What is Power Apps?

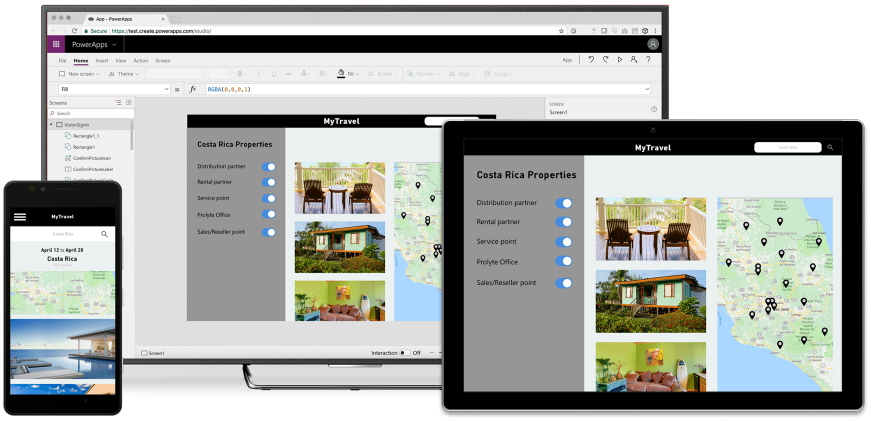
Power Apps is a suite of apps, services, and connectors, as well as a data platform, that provides a rapid development environment to build custom apps for your business needs. With Power Apps, you can quickly build custom business apps that connect to your data stored either in the underlying data platform (Microsoft Dataverse) or in many online and on-premises data sources (such as SharePoint, Microsoft 365, Dynamics 365, SQL Server, and so on).



Apps built with Power Apps provide rich business logic and workflow capabilities to transform your manual business operations into digital, automated processes. What's more, apps built with Power Apps have a responsive design and can run seamlessly in browser and on mobile devices (phone or tablet). Power Apps "democratizes" the business-app-building experience by enabling users to create feature-rich, custom business apps without writing code.

Power Apps also provides an extensible platform that lets pro developers programmatically interact with data and metadata, apply business logic, create custom connectors, and integrate with external data.

Power Apps and Microsoft Copilot let you describe the app you want and AI designs it. Make edits, add automation, and write code—all with Copilot in Power Apps.

For more information:

- Try Power Apps for free
- Watch videos on the Power Apps channel on YouTube

Power Apps for app makers and creators

> **Note**

Try the new Power Apps experience—an AI-native solution designed to simplify app creation. Effortlessly automate workflows, connect data sources, and speed up development, all without needing advanced coding skills. For more information, see Overview of the New Power Apps experience (preview).

With Power Apps, you can create two types of apps: **canvas** and **model-driven**. For more information, see Overview of creating apps in Power Apps.

To create an app, start with make.powerapps.com.

- **Plans** in Power Apps is a copilot-first development tool that lets you quickly create comprehensive business solutions. Describe your business use case in natural language and add relevant images, like business process flows or screenshots of legacy apps. For more information, see Overview of plans.
- **Power Apps Studio** is the app designer you use to build canvas apps. The app designer makes creating apps feel more like building a slide deck in Microsoft PowerPoint. For more information, see Generate an app from data.
- **App designer** for model-driven apps lets you define the sitemap and add components to build a model-driven app. For more information, see Design model-driven apps using app designer.

Ready to convert your ideas into an app? Start here: Planning a Power Apps project.

Power Apps for app users

Run apps that you created, or that someone else created and shared with you, in a browser or on mobile devices (phone or tablet). For more information, see:

- Find and run apps
- Run apps on Power Apps mobile

Power Apps for admins

Power Apps administrators can use the **Power Platform admin center** (admin.powerplatform.microsoft.com) to create and manage environments, view Dataverse analytics, and get real-time, self-help recommendations and support for Power Apps and Power Automate. For more information, see Administer Power Platform.

Power Apps for developers

Developers are app makers who write code to extend business app creation and customization. Use code to create data and metadata, apply server-side logic with Azure functions, plug-ins, and workflow extensions, apply client-side logic with JavaScript, integrate with external data by using virtual tables and webhooks, build custom connectors, and embed apps into your website experiences to create integrated solutions. For more information, see:

- Dataverse developer
- Model-driven apps developer
- Canvas apps developer

Power Apps and Dynamics 365

Dynamics 365 apps (such as Dynamics 365 Sales, Dynamics 365 Customer Service, and Dynamics 365 Marketing) also use the underlying Dataverse platform that Power Apps uses to store and secure data. This feature enables you to build apps by using Power Apps and Dataverse directly against your core business data already used within Dynamics 365, without the need for integration. For more information, see Dynamics 365 and Dataverse.

Try Power Apps for free

You can build Power Apps for free. Sign in to Power Apps. For more information, see Sign in to Power Apps for the first time. Initially, you have access to the default environment. You can build in your own developer environment with Dataverse by signing up for the Power Apps Developer Plan. For more information, see About the Power Apps Developer Plan.

You need a license to play the apps you make with Power Apps. You can play Power Apps for free by signing up for a 30-day trial.

Request a Power Apps license

If you're a Power Apps user and want to run apps, request a Power Apps license while running the app. For more information, see Request a Power Apps license.

Purchase Power Apps

To purchase Power Apps, go to Purchase Power Apps for detailed information.

Power Apps US Government plans

Power Apps US Government offers several plans designed for US government organizations to address the unique and evolving requirements of the United States public sector. The Power Apps GCC environment complies with federal requirements for cloud services, including FedRAMP High, DoD DISA IL2, and requirements for criminal justice systems (CJI data types). For more information, see Power Apps US Government.

Last updated on 11/18/2025

Explore Power Apps for free for 30 days

Get instant access to all Power Apps capabilities with a free 30-day trial. Whether you're new to Power Apps or want to explore premium features, this trial unlocks everything you need to build powerful business applications.

If you don't have a license for Power Apps, the trial plan gives temporary access to these activities:

- Extend the capabilities of Office 365 (SharePoint Online, Teams, Excel, and more)
- Create and run canvas apps that connect to Microsoft Dataverse and over 200 other data sources, including premium connectors and on-premises data.
- Create and run model-driven apps
- Automate workflows with Power Automate
- Create and manage environments and Dataverse databases

If you have a Power Apps license or a license through Office 365, you already have access to some of these features. However, the trial license temporarily expands your access to include all features in the previous list. Learn what capabilities each type of license offers on the pricing page.

> **Note**
>
> - If you're an administrator, see Purchase Power Apps for your organization or Power Apps in your organization Q&A.
> - Starting January 2020, self-service purchase, subscription, and license management capabilities for Power Platform products (Power BI, Power Apps, and Power Automate) are available for commercial cloud customers in the United States. For more information, including steps to enable or disable self-service purchasing in your organization, see the Self-service purchase FAQ.

Need an account?

If you don't have a work or school account, create a free account with Microsoft Entra and become a low-code developer with Power Apps. To keep building apps after the trial period, opt in to the free Power Apps Developer Plan.

Ready to get started?

1. **Start your free trial now →** - Go to PowerApps.com and select **Start free**.

2. Enter your email. If your email isn't a work or school account, you're prompted to create a free Microsoft Entra account by using this sign-up experience.

If you want to evaluate Power Apps integrations with Microsoft 365, sign up for an Office 365 trial account.

> **Note**
>
> If you don't have an organization account or aren't part of a tenant or organization account, you can establish a developer's account through the Microsoft Developer Program.

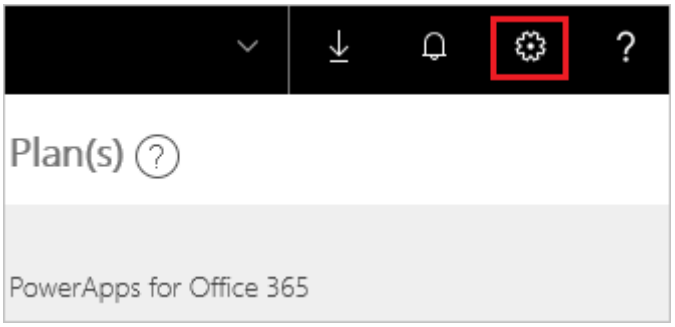
Identify your current license

Compare license options: Learn what capabilities each type of license offers on the pricing page to choose the best plan for your needs.

1. Sign in to Power Apps using your work or school credentials.

   > **Important**
   >
   > You can't sign in by using a personal email address, such as one that ends in outlook.com, hotmail.com, or gmail.com. For more information, see What email address can I use? later in this article.

2. Select the gear icon in the upper-right corner, and then select **Plan(s)**.



Upgrade an existing license

To start a free 30-day trial of Power Apps per user plan from an existing license, sign in to Power Apps. Then, try any feature that requires a premium Power Apps license. For example, select the gear icon near the upper-right corner, select **Admin center**, and select **New**

environment near the upper-right corner. Follow the prompts to complete the sign-up process.

Get a license from scratch

Whether or not you have a license for Power Apps, start a free 30-day trial per user plan by following these steps:

1. Open the Power Apps site, and then select **Try free**.

   If you're using a phone, select the menu in the top-right corner, and then select **Try free**.

2. In the middle of the screen, select **Pricing**, and then select **Start free trial**.

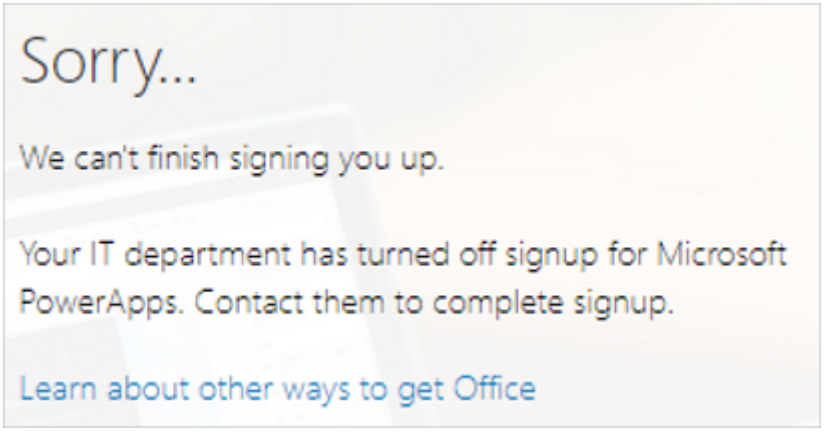
3. In the dialog box, enter your work or school email address, and then select **Submit**.

   > **Important**
   >
   > For more information, see What email address can I use? later in this article.

4. If a dialog box indicates that Power Apps recognizes your organizational credentials, follow the prompts to finish signing in.

   
   Otherwise, follow the prompts to check your email, verify your email address, provide more information if necessary, and then select **Start**.

   You see the following message if your admin disables free trials.



> **Note**
>
> For more information, including the steps to enable or disable trial licenses in your organization, see Block trial licenses commands.

FAQ

What email address can I use?

You can use a work or school email address, backed by Microsoft Entra ID, to sign up for a trial license. If you use a different kind of address, you might experience one of the symptoms in this table.

Expand table

Symptom / error message	Cause and workaround

Personal email addresses (for example, `@gmail.com` email address)
 	
You receive a message like the following during signup:
 	
`You entered a personal email address: Please enter your work email address so we can securely store your company's data.`
 	
or
 	
`That looks like a personal email address. Enter your work address so we can connect you with others in your`
	Power Apps doesn't support email addresses provided by consumer email services or telecommunications providers.
	
	To complete signup, try again using an email address assigned by your work or school.

Symptom / error message	Cause and workaround
`company. And don’t worry. We won’t share your address with anyone.`	

.gov or .mil addresses
 	
You receive a message like the following during signup:
 	
`Power Apps unavailable: Power Apps is not available for users with .gov or .mil email addresses at this time. Use another work email address or check back later.`
 	
or
 	
`We can't finish signing you up. It looks like Microsoft Power Apps isn't currently available for your work or school.`
	Power Apps doesn't support .gov or .mil addresses at this time.

Email address is not an Office 365 ID You receive a message like the following during signup: `We can't find you at contoso.com. Do you use a different ID at work or school? Try signing in with that, and if it doesn't work, contact your IT department.`	Your organization signs in to Office 365 and other Microsoft services with IDs other than email addresses. For example, your email address might be Nancy.Smith@contoso.com, but your ID is nancys@contoso.com. To complete signup, use the ID that your organization has assigned to you for signing in to Office 365 or other Microsoft services. If you don't know what this is, contact your IT administrator.

Does the cloud environment I use Power Apps in allow the use of trial licenses?

Power Apps trial licenses are available only in the Azure commercial cloud. They aren't available in Azure Government or Microsoft Azure China clouds.

What happens when my trial expires?

You're prompted to request an extension of the trial or purchase a plan 30 days after the trial starts. You can extend the trial two more times (30 days each)—with a maximum trial period of 90 days. You can find details about all plans on the pricing page.

If you don't extend the trial or purchase a plan but you still have another kind of license, you can use all the features of Power Apps that your other license provides. Any data in Dataverse remains unchanged, and any app or flow that uses Dataverse continues to run if your license supports them. If you try to use premium Power Apps features but your existing license doesn't support them (for example, modify a schema or entities in Dataverse), you are prompted to purchase a plan.

Request a Power Apps license for yourself

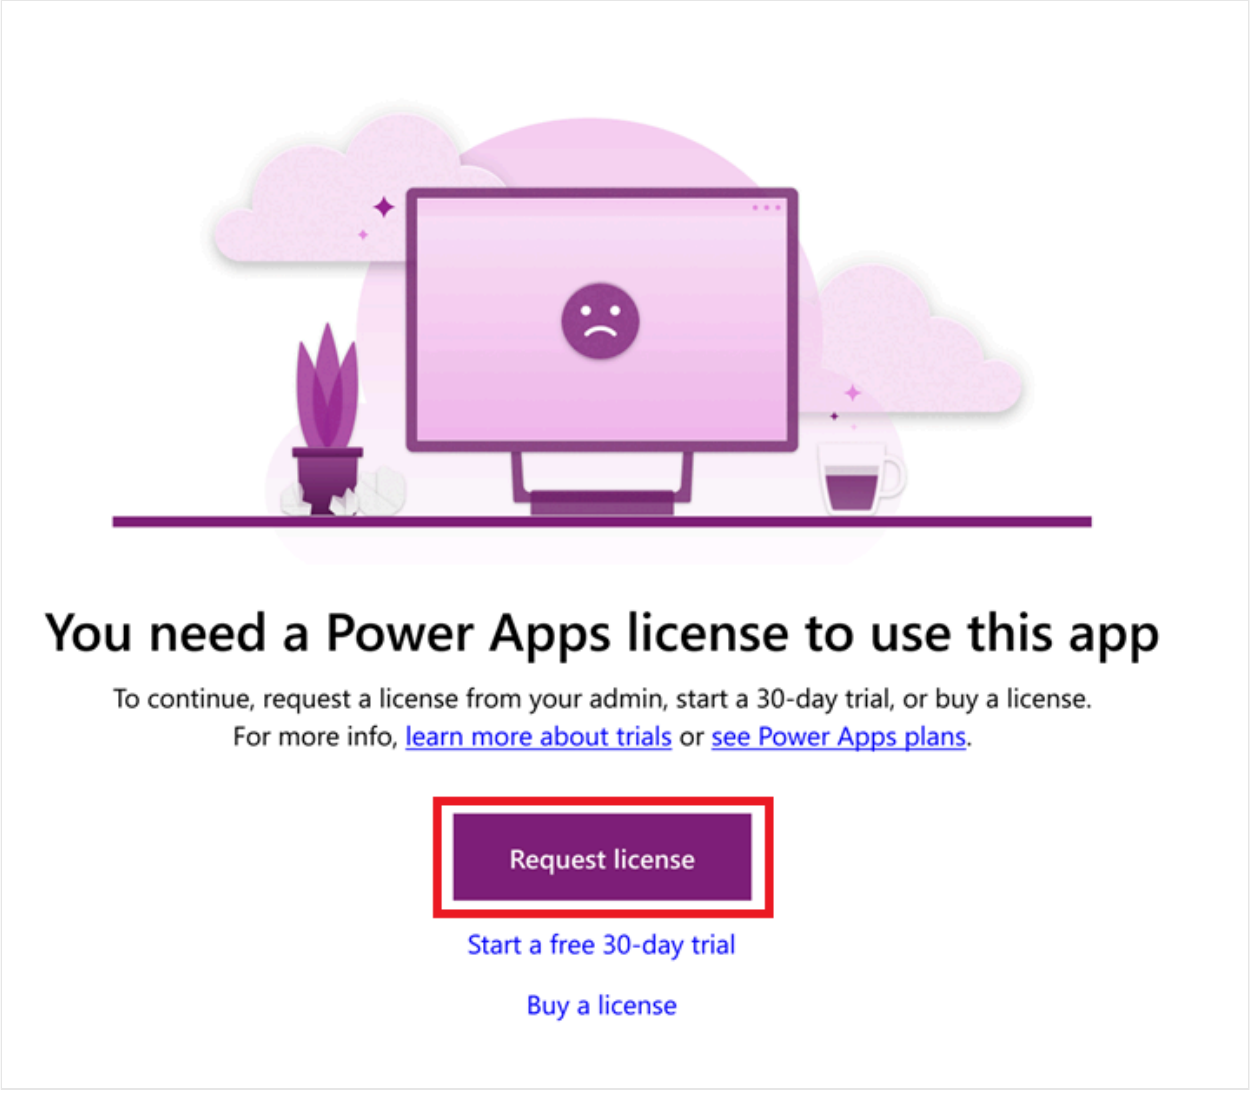
Article • 05/08/2023

You can request a Power Apps license from your admin directly using Power Apps.

Request a license

If you don't have a license and are trying to open apps made with Power Apps, you'll see the options in the following image. Select **Request license** to submit a license request to your admin.

> **Note**
>
> The options in the following image may differ depending on whether you've exhausted any Power Apps trials.



Request a license through a trial

If you're already in an active Power Apps trial, you can request a license by selecting **Request license** near the top of the page.

Wait for a response from your admin

After you request a license, you'll see a banner at the top of the page that confirms that your request was sent, and that it might take a few days for your admin to respond to the request.

If you're using a Power Apps trial, you can continue to use the trial while you wait for your request to be approved.

After your admin has reviewed your request, you'll receive an email notification indicating whether the request was approved.

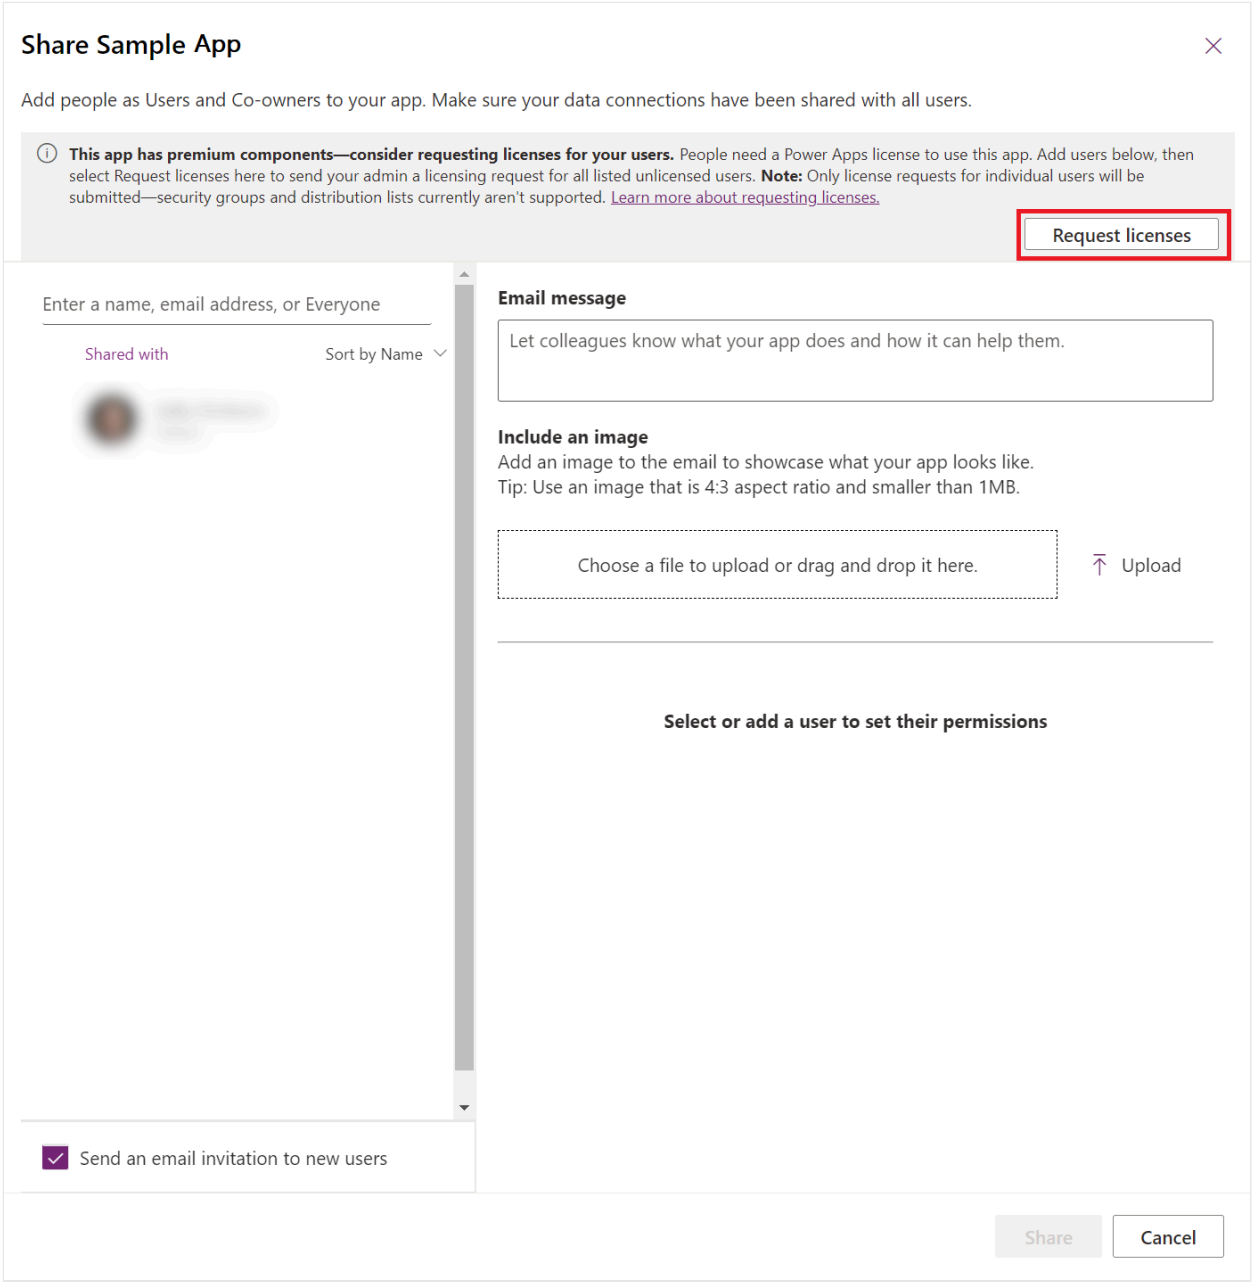
Request Power Apps licenses for your app users

Article • 06/30/2023

As a Power Apps maker, you can create an app that requires a license for use. For example, if you create an app with premium components or connectors, users must have an appropriate Power Apps license to use it.

When you share a canvas app or model-driven app that contains premium components, select **Request licenses**. The request is submitted to your admin for approval. You can't request licenses for security groups or distribution lists.



After your admin has reviewed your request, you'll receive an email notification indicating whether the request was approved or denied.

Overview of creating apps in Power Apps

Power Apps is a high-productivity development platform for business apps. It has these major components:

- Plans
- Copilot
- Canvas apps
- Model-driven apps
- Microsoft Dataverse

Let's learn more about each of these components.

> **Note**
>
> Try the new Power Apps experience—an AI-native solution designed to simplify app creation. Effortlessly automate workflows, connect data sources, and speed up development, all without needing advanced coding skills. For more information, see Overview of the New Power Apps experience (preview)

Plans

Plans in Power Apps is a copilot-first development tool that helps you rapidly build end-to-end business solutions. Simply describe your business scenario in natural language and include relevant visuals, such as process flows or screenshots of existing systems. Plans then generates a complete Power Platform solution tailored to your requirements, including Microsoft Dataverse tables, canvas apps, model-driven apps, Power Pages sites, Power Automate flows, and Copilot Studio agents.

Create apps using Copilot

Copilot in Power Apps lets you to quickly create apps by simply describing your business requirements in natural language. Copilot automatically generates both the app and its data model—no coding needed. Users can interact with your app using everyday language, making the experience intuitive and engaging. For more information, see Copilot and AI features in Power Apps

Canvas apps

Canvas apps start with your user experience. You craft a highly tailored interface with the power of a blank canvas and connect it to your choice of more than 200 data sources. You can build canvas apps for web, mobile, and tablet applications.

Canvas apps give you the flexibility to arrange the user experience and interface the way you want it. Let your creativity and business sense guide how you want your apps to look and feel.

You can start to build your app from Microsoft tools where your data lives, such as:

- From a SharePoint list
- From a Power BI dashboard

Creating a canvas app is easy. With Power Apps, you can find or create your app in several ways:

- From a Dataverse source
- From data in a SharePoint List
- From Excel data
- From a blank canvas
- Via AppSource

In addition to creating apps in Power Apps, you can also create apps directly within Microsoft Teams by using Power Apps. For more information, see Create apps in Microsoft Teams by using Power Apps.

Model-driven apps

Model-driven apps start with your data model. You build up from the shape of your core business data and processes in the Dataverse to model forms, views, and other components. Model-driven apps automatically generate a great UI that's responsive across devices.

When you create a model-driven app, you can use all the power of the Dataverse to rapidly configure your forms, business rules, and process flows. You create a model-driven app from the Power Apps site.

As part of the custom page public preview, you can add the new page type based on canvas into a new or existing model-driven app. This addition brings the power and flexibility of a canvas experience within the model-driven app. Custom pages allow

- Full control over page layout
- Out of box controls and custom components
- Power Apps connectors
- Low-code authoring

Getting started with model-driven apps is simple. You can begin with these topics:

- Create an app
- Create and design forms
- Create or edit views
- Create or edit a system chart
- Create or edit dashboards
- Add security
- Add business logic
- Converging model and canvas using custom page (preview)

Dataverse

Dataverse is the data platform that comes with Power Apps and allows you to store and model business data. It's the platform on which Dynamics 365 apps (such as Dynamics 365 Sales, Customer Service, Field Service, Marketing, and Project Service Automation) are built. If you're a Dynamics 365 customer, your data is already in Dataverse.

Dataverse allows you to securely store and manage data within a set of standard and custom tables. You can add columns to those tables when you need them.

Start working with Dataverse by reading these topics:

- Create a custom table
- Manage columns
- Create custom choices
- Create a business rule

Planning a Power Apps app or project

It's easy to begin building your first app. Simply sign in to Power Apps. For more information, see Sign in to Power Apps for the first time. If you're interested in exploring even more functionality, such as creating environments, we have a 30-day trial or Developer Plan.

If you're new to Power Apps and want to learn about how to convert your ideas into a fully working solution, start with Planning a Power Apps project.

Last updated on 11/18/2025

Sign in to Power Apps

Sign in to Power Apps at https://make.powerapps.com to create, edit, or play an app.

This article shows you how to access Power Apps for the first time, choose the right environment, and navigate different authentication options including Azure B2B and Microsoft Account sign-in.

To create canvas apps, you need the environment maker predefined security role.

If you don't have a work or school account, you can sign up for a trial account. For information, see Explore Power Apps for free for 30 days.

What you'll learn:

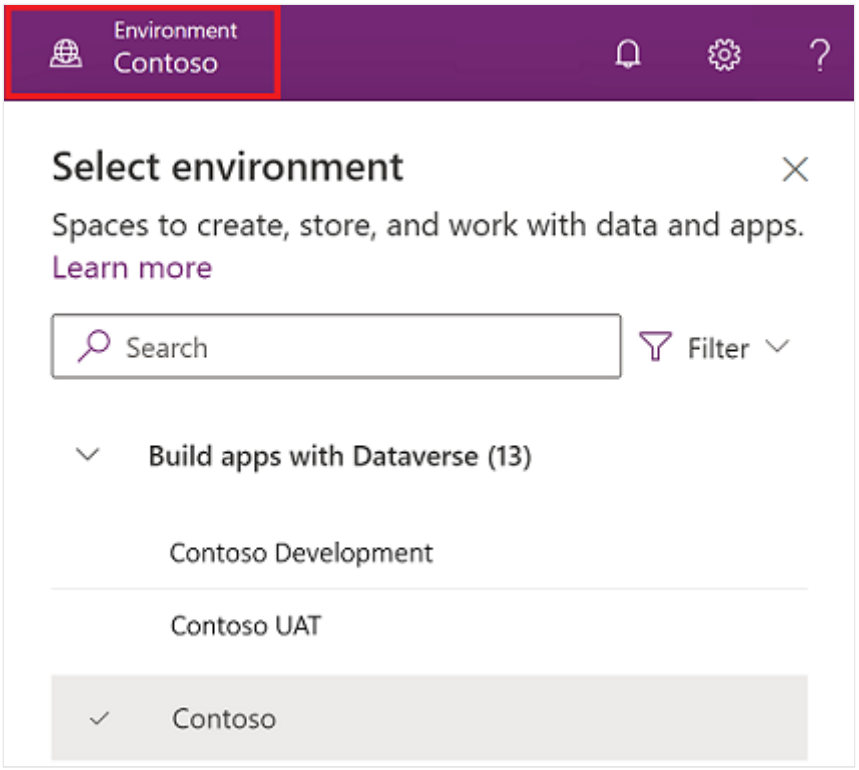
- How to choose the right environment for your work
- Different sign-in options including Azure B2B and Microsoft Account
- How to access environments and create your first app

For more information about the Power Apps home page, see Get started with Power Apps.

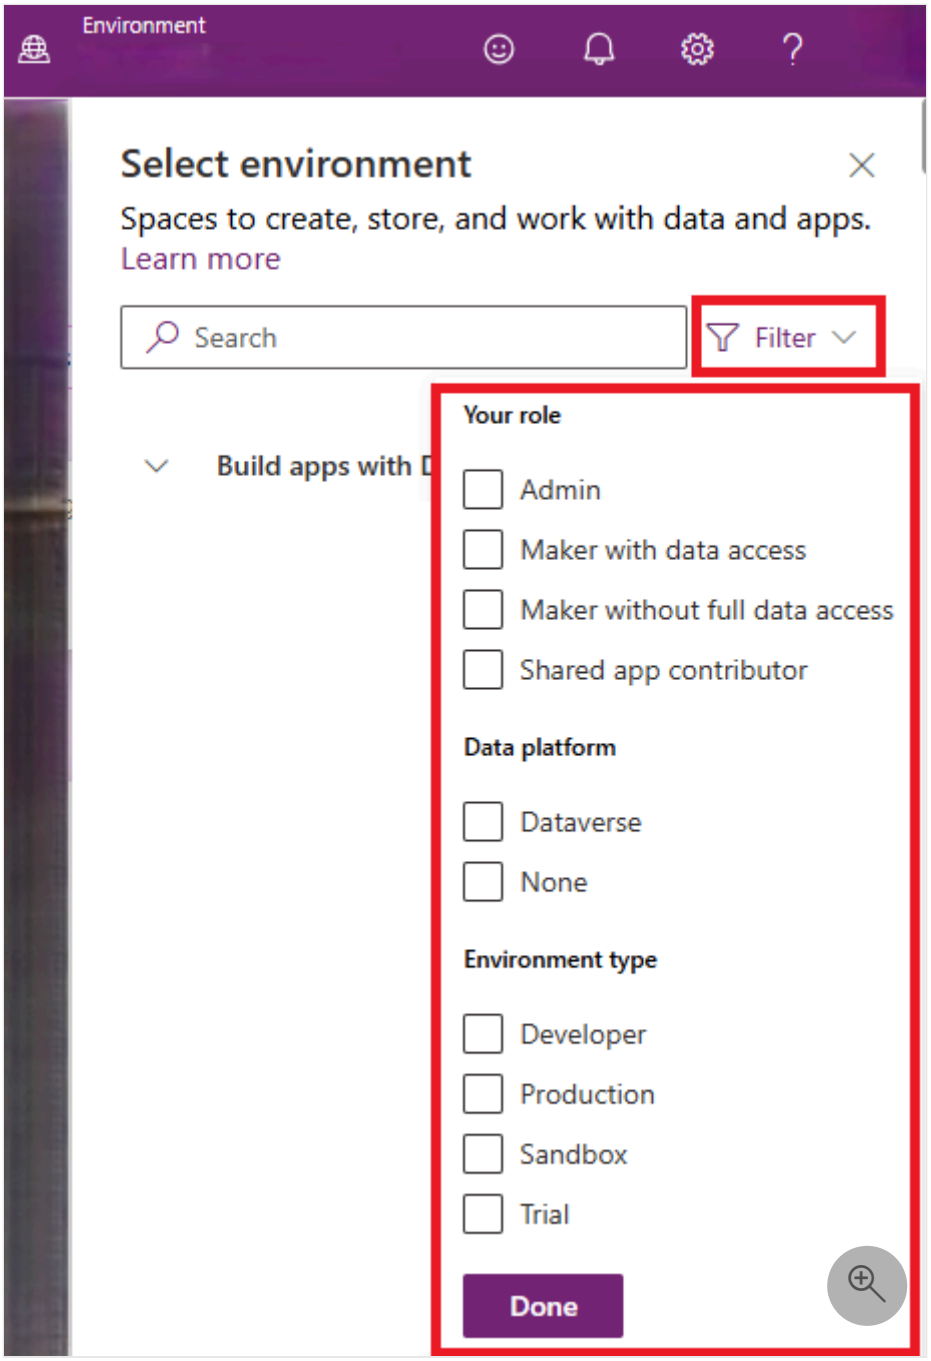
Choose an environment

When you create an app, a flow, a data connection, or a table in Microsoft Dataverse, most work in Power Apps happens in a specific environment. Environments set boundaries between types of work. For example, an organization can use separate environments for different departments. Many organizations use environments to separate apps in development from those ready for use. You might have access to multiple environments or just one. If you have the right permissions, you can create your own environment.

To check which environment you're in, find the environment switcher near the right side of the header.



With the environment selector, environments are grouped into two types: **Build apps with Dataverse** and **Other environments**. Select **Filter** to filter the list of environments by your role, data platform (Dataverse or none), and environment type, like production or sandbox.



Environments where you have system administrator or system customizer security role membership appear under **Build apps with Dataverse**. The **Other environments** list shows environments where you have only environment maker or editing privileges to at least one canvas app in the environment.

> **Tip**
>
> Hover over an environment in the list to see its details.

Filter environments by role

Expand table

Filter role	Power Platform role or description
Admin	System administrator Environment admin
Maker with data access	System administrator System customizer
Maker without full data access	Environment maker (with or without Dataverse)
Shared app contributor	User without a maker-level security role assigned but with edit permission to at least one canvas app in the environment

Important

- To see the environment list in the environment switcher in Power Apps, you need the Environment Maker, System Customizer, or System Administrator security role in the environment. For information about predefined security roles, see Predefined security roles in the Microsoft Power Platform admin guide.
- Make sure you're in the right environment before you create an app, a flow, or a similar component. You can't easily move components from one environment to another.

Note

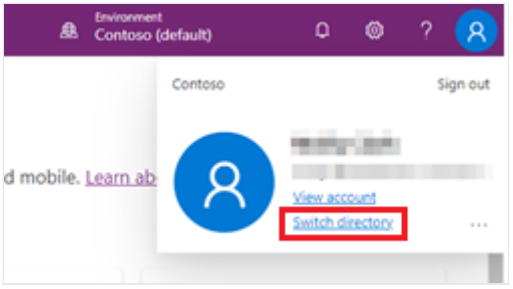
- Every member in an organization can use the default environment. Like any environment, users can see apps where they have enough privileges to use an app.
- All users with the Environment Maker security role in an environment can see all model-driven apps in that environment, including the default environment. For more information, see Model-driven app privileges to view and access apps.
- When you create an app in one environment, you can't see it from another environment. People who want to run your app need access to the environment where you created it.

For more information about environments, see Environments overview.

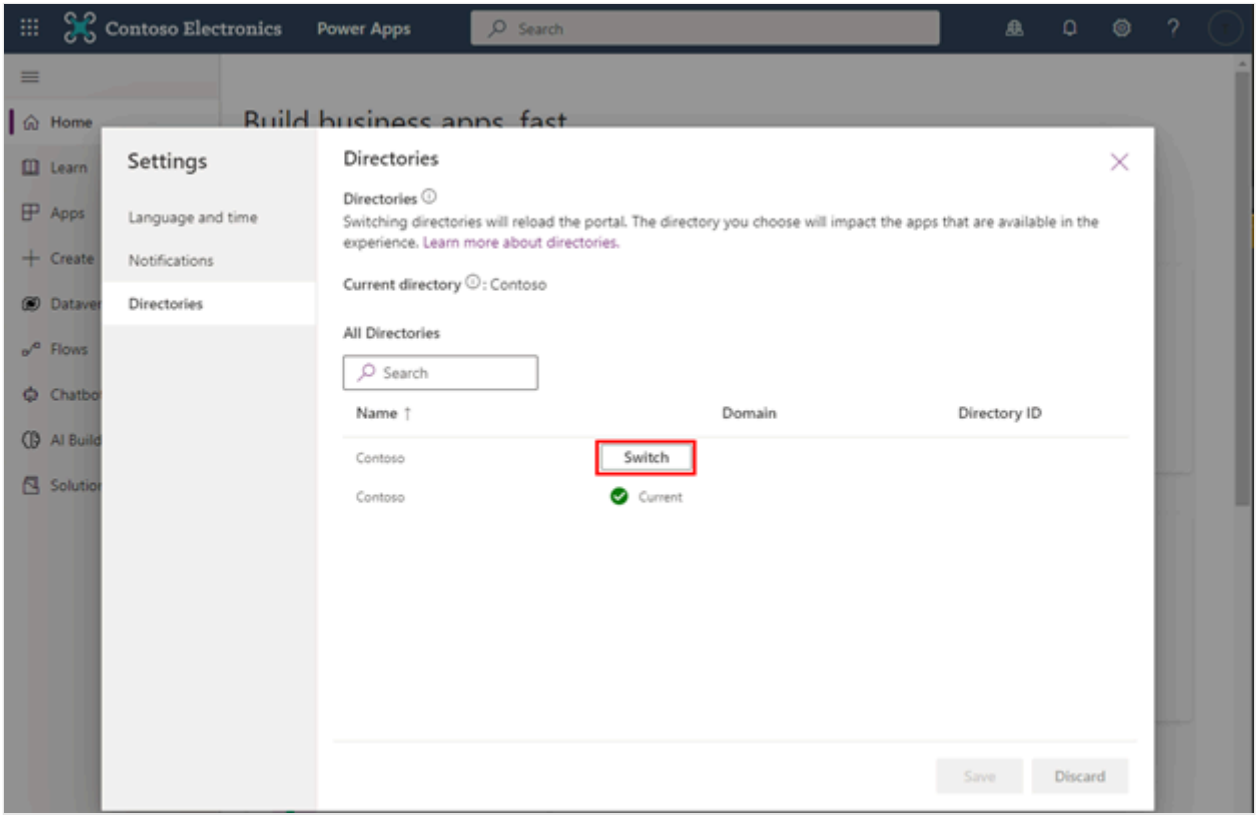
Sign in by using Azure B2B collaboration

> **Note**
>
> - A **resource tenant** is the Microsoft Entra tenant where an app is expected to exist, and where the user is expected to create and edit the app. For Azure B2B makers, this tenant is different from the tenant their account resides.
> - A **home tenant** is where the user's account resides and authenticates against.
> - To create and edit apps in a resource tenant, an admin must follow these steps to give Azure B2B users the prerequisite privileges to build apps.

When a user signs into Power Apps, they sign into their **home tenant** - the Microsoft Entra tenant where their credentials are provisioned. After signing in, the user can change the directory they intend to build apps in by selecting the **Switch directory** link as shown here:



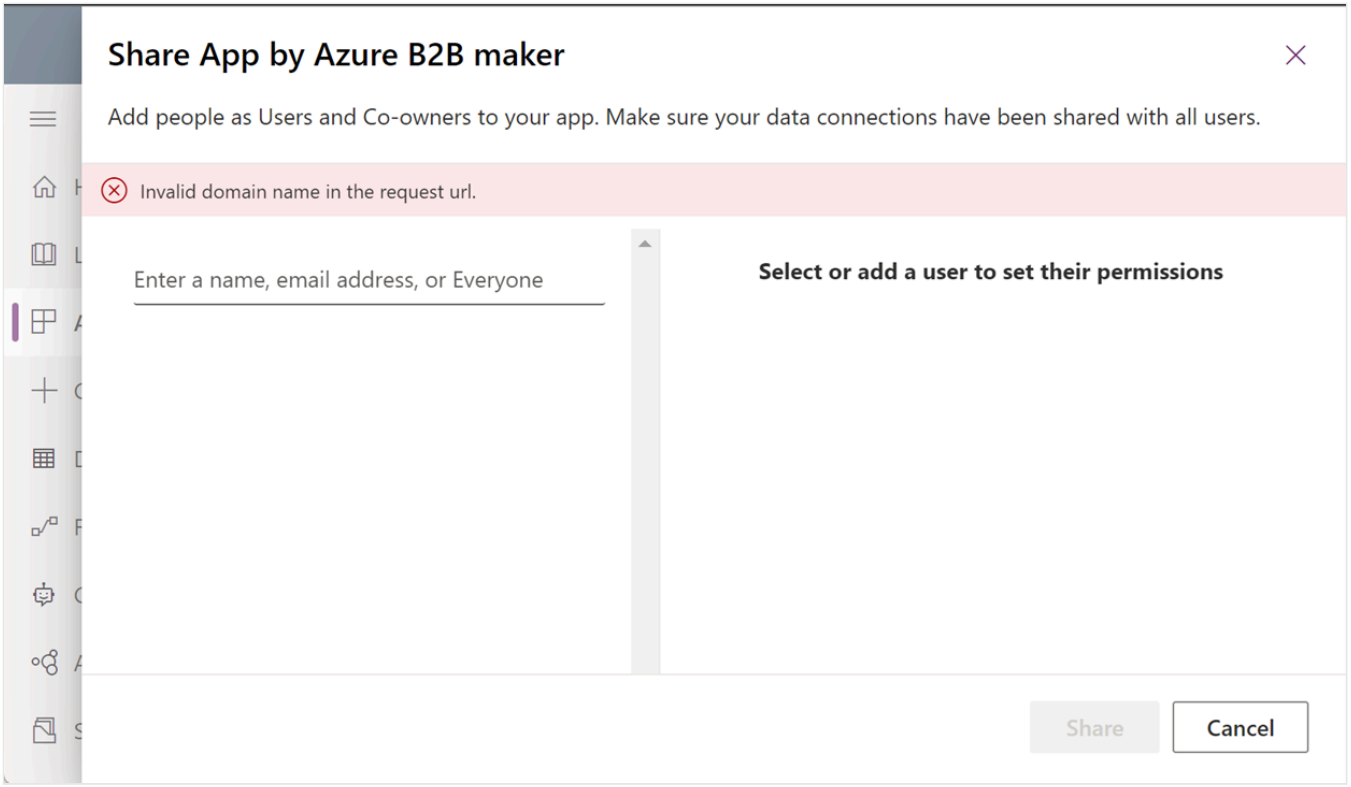
The switch directory link opens Power Apps settings with a **Directories** tab that lists all the Microsoft Entra tenants where the user is a member or an Azure B2B guest. Selecting **Switch** signs out of the current tenant and then signs into the selected tenant in Power Apps.



Frequently asked questions

As an Azure B2B maker, why can't I share apps?

The Power Apps sharing experience requires users to have permissions in the tenant when the Azure Microsoft Entra ID external collaboration settings lets guest user access to "(most inclusive)". Azure B2B makers without enough privileges see the following error dialog when sharing.



Can I work in Power Apps in both my home tenant and a resource tenant?

- Yes, but only in separate browser sessions. For example, Microsoft Edge can be open in its standard mode, and you can start a separate session in a new **InPrivate** window.
- If you open multiple tabs in the same browser session, you can only access resources in the most recently signed-in tenant.

Can I sign in to Power Apps, in a resource tenant with GDAP?

No, https://make.powerapps.com doesn't recognize Granular delegated admin privileges (GDAP), but the Power Platform admin center does.

Sign in by using Microsoft Account (preview)

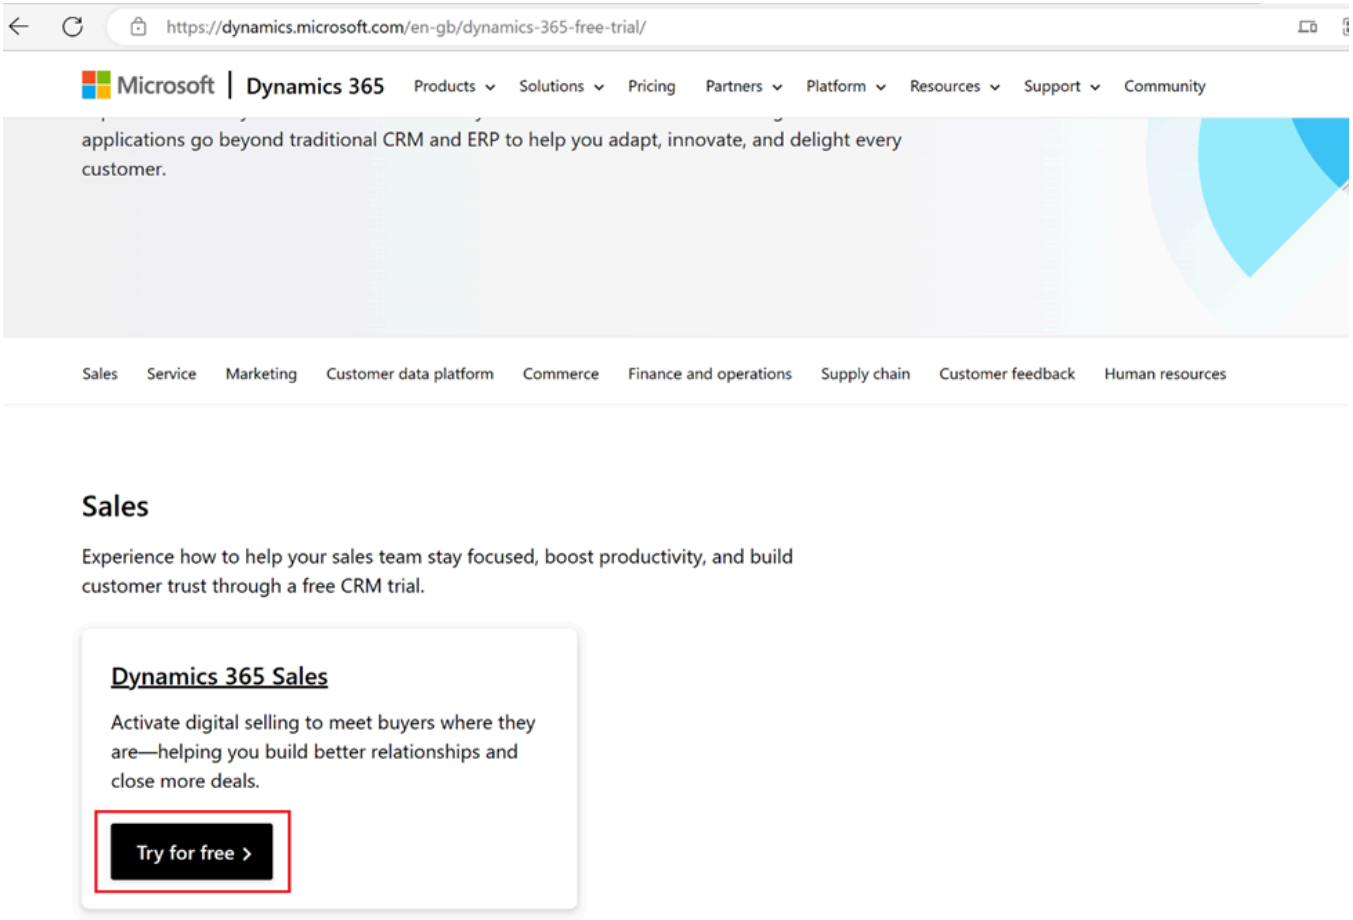
Anyone can build Power Apps, even if they don't have a work or school account. Sign up for a Dynamics 365 Sales trial by using a Microsoft Account and then use that account to sign in to Power Apps.

During the 30-day trial period, you can make and play with as many apps as you like. You can also build apps with Dataverse or other premium connectors. However, if you plan to run these apps beyond the trial period or share them with others, you need to create a (free) Microsoft Entra account.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Where can I get a license with Power Apps use rights for my Microsoft Account?

The Dynamics 365 Sales free trial includes Power Apps use rights, along with other Dynamics and Power Platform use rights. You can sign up here: Dynamics 365 free trial.



> **Note**
>
> Not all Power Apps free licenses support Microsoft Account sign-up. The list of free licenses that allow free sign-up is expected to grow over time.

How do I create model-driven apps and use Dataverse?

Select or create an environment with Dataverse. You can create Developer environments with Dataverse for free.

1. Sign in to Power Apps.
2. Select the environment picker.
3. In the **Need your own environment?** prompt, select **Try it now** to create an environment with Dataverse.

How do I access Power Platform admin center?

Power Platform admin center (https://admin.powerplatform.microsoft.com) doesn't support Microsoft Account sign-in. However, your Microsoft Account is associated with a Microsoft Entra tenant and you can provision a Microsoft Entra based identity to use in the Power Platform admin center.

1. Follow the steps under **How do I create a Microsoft Entra identity with the same administrative privileges as my Microsoft Account?**
2. Using the newly created Microsoft Entra identity, sign in to https://admin.powerplatform.microsoft.com.

How do I create a Microsoft Entra identity with the same administrative privileges as my Microsoft Account?

1. Sign in to https://portal.azure.com.
2. Search for **Microsoft Entra ID**.
3. Add a new user.
4. Associate or add an Azure subscription to your Microsoft Entra tenant. For administrative purposes, assign the same admin role as your Microsoft Account has in Microsoft Entra ID, such as Power Platform or Dynamics 365 admin.

The free license assigned to my Microsoft Account expired, how can I access Power Apps?

If your Microsoft Account is associated with a Microsoft Entra tenant, you can sign in to Power Apps and edit your apps. However, without an active license you can't play the apps.

Today, Microsoft accounts are bound to limited trial periods. You can't sign up for the same free license twice with the same account. Also, Microsoft accounts can't purchase Power Apps plans.

You might proceed with building and running apps by creating a Microsoft Entra identity in the same Microsoft Entra tenant your Microsoft Account is associated with and sign up for a Power Apps Developer plan by using that identity. With your Microsoft Account, you need to share your apps with your Microsoft Entra identity to proceed with editing and playing them.

To create a Microsoft Entra identity with administrative rights, follow the steps under "How do I create a Microsoft Entra identity with the same administrative privileges as my Microsoft Account?".

Can I use my Microsoft Account with the Power Platform PowerShell cmdlets?

No. In the meantime, follow the steps described in the previous questions. Add a new Microsoft Entra identity to the Microsoft Entra tenant associated with your Microsoft Account to use the Power Platform PowerShell cmdlets.

Can I share my apps with other users?

Yes, but you need to add users to the Microsoft Entra tenant associated with your Microsoft Account, assign a license to these users, and then share your app with these users. As an admin, you can assign free licenses to users but these licenses expire.

1. To create a Microsoft Entra identity with administrative rights, follow the steps under **How do I create a Microsoft Entra identity with the same administrative privileges as my Microsoft Account?**.
2. Add each user you want to share an app with to Microsoft Entra ID.
   a. Sign in to https://portal.azure.com.
   b. Search for **Microsoft Entra ID**.
   c. Add a new user or Add a guest user. You can add users that have either a Microsoft Account or Microsoft Entra identity.
3. With your Microsoft Entra admin identity, either purchase Power Apps plans. As an admin, you receive 25 Power Apps per user trials. All of these trials expire.
4. With your Microsoft Entra admin identity, assign licenses to the users you added to your Microsoft Entra tenant.
5. Sign in to Power Apps to proceed with sharing your apps to users.

Can I run my apps in Power Apps mobile?

Yes. You must launch an app from an app link. Without launching an app directly, Power Apps mobile doesn't support Microsoft Account sign in out of the context of launching an app.

You can get the app link for an app by going to Power Apps > **Apps** > (select an app) > **Details** > See the **Web link** property.

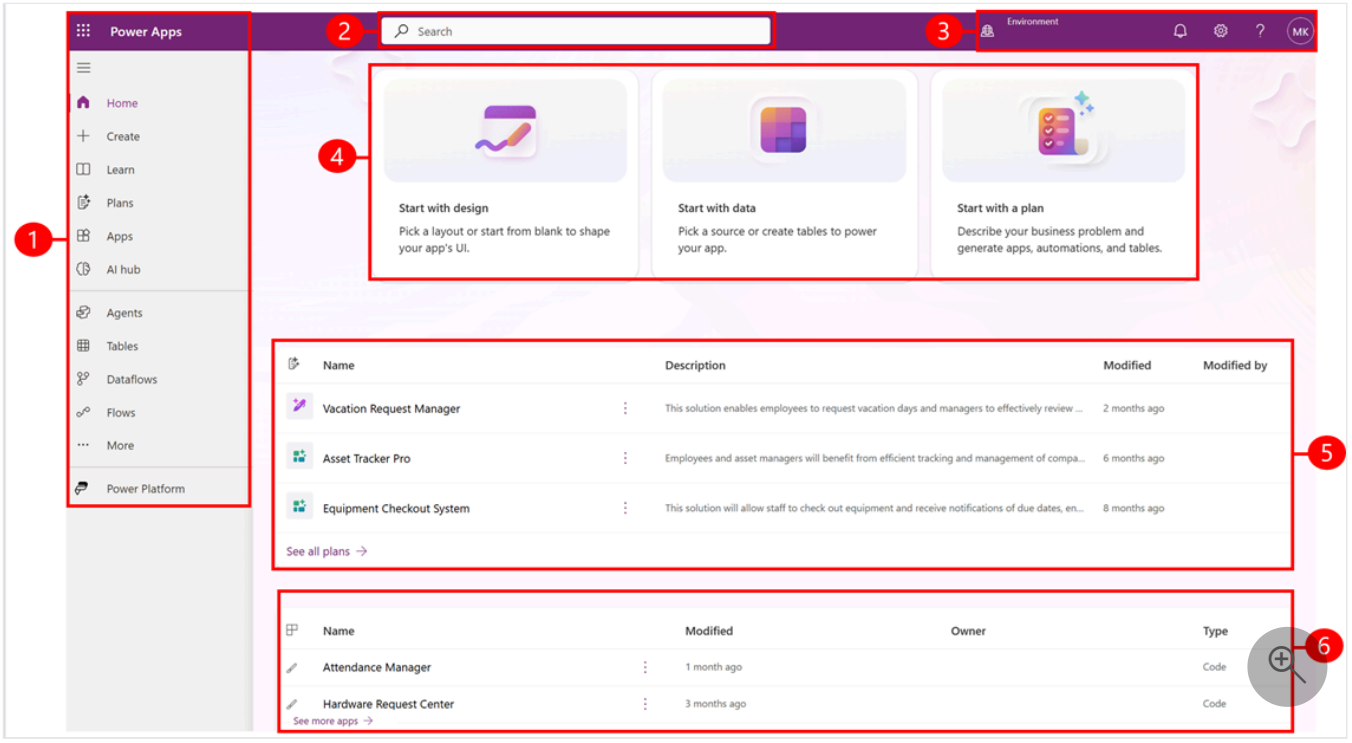
Get started with Power Apps

Summarize this article for me

Get started with Power Apps to build your first app quickly and efficiently. The Power Apps home page is your starting point for creating apps, managing existing ones, and accessing powerful features that streamline your workflow.

What you'll accomplish: By the end of this article, you'll learn how to navigate the interface, create your first app, and access Copilot AI features to accelerate development.

Select the appropriate tab in the following section to learn more.



Legend:

1. Left navigation pane
2. Search
3. Environment information and settings
4. Build apps
5. View and edit plans
6. View and edit apps

> **Note**
>
> Try the new Power Apps experience—an AI-native solution designed to simplify app creation. Effortlessly automate workflows, connect data sources, and speed up

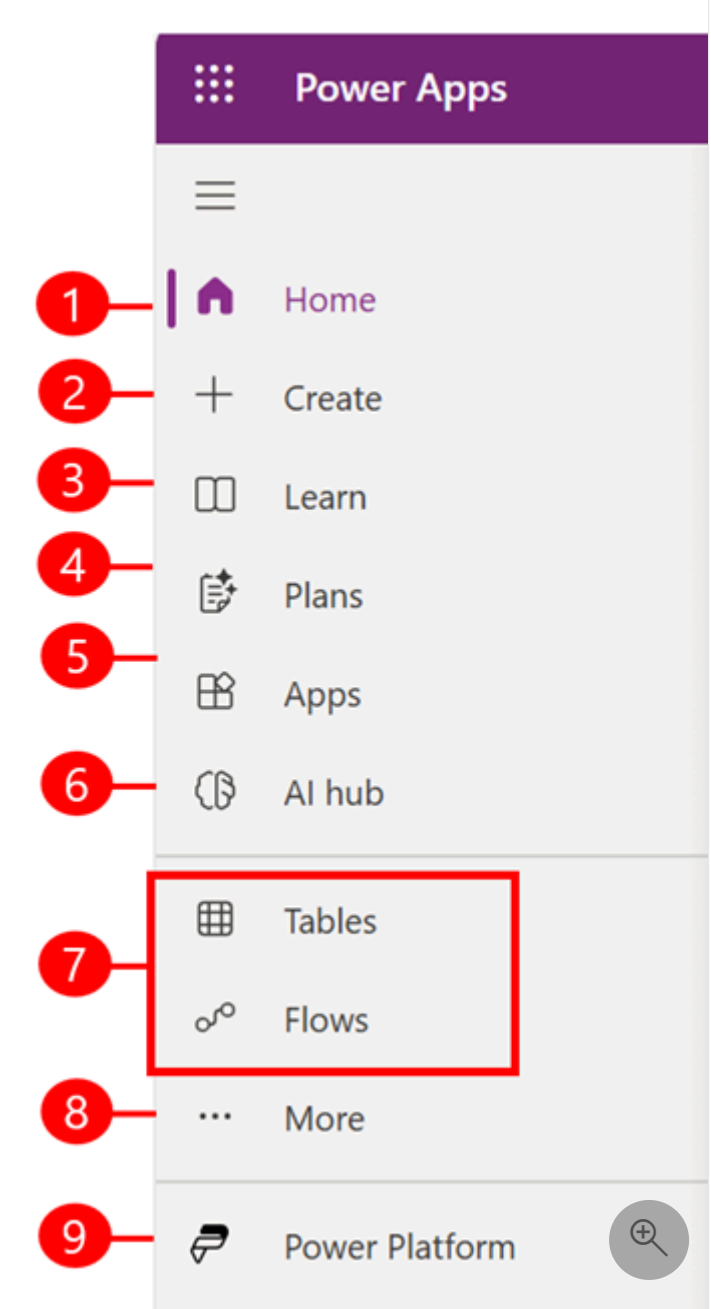
development, all without needing advanced coding skills. For more information, see Overview of the New Power Apps experience (preview).

Quick start options

- **New to Power Apps?** Start with our 5-minute canvas app tutorial
- **Have existing data?** Create an app from SharePoint or Excel
- **Need help choosing?** Review which app type is right for you

1 – Left navigation pane

Your main control center. When you sign in to the Power Apps home page, the left navigation pane gives you quick access to everything you need. Here's what each option does:



Legend:

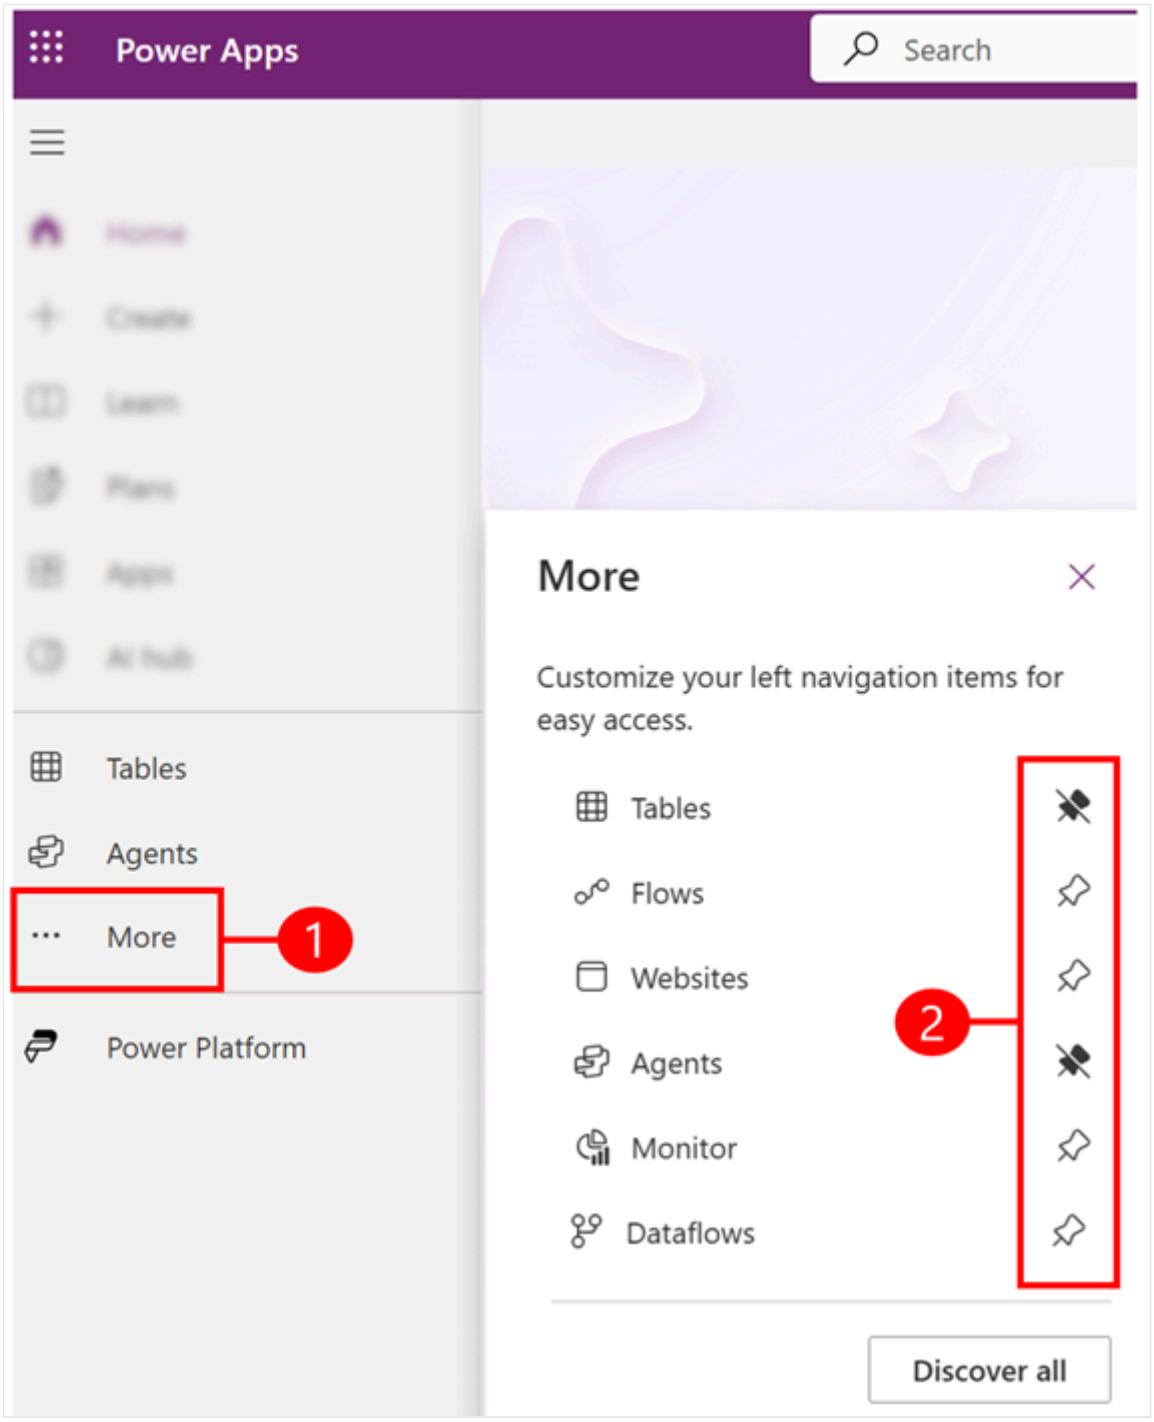
1. **Home**: Takes you to the Power Apps home page.
2. **Create**: Create apps such as canvas apps, model-driven apps, chatbots, and AI models.
3. **Learn**: The learn hub lets you explore documents, training material, get help from the Power Apps community, and other resources that help you to create and build Power Apps.
4. **Plans**: View and edit your plans. For more information, see Overview of Plan designer.
5. **Apps**: If you created an app or someone else created one and shared it with you, you can play or edit it. You can also filter the list of apps based on criteria such as whether you opened it recently.
6. **AI hub**: Create and use AI models that optimize your business processes. For more information, see Overview of AI Builder.
7. **Your most used pages such as Tables, Connections, Flows**: When you first sign in, the top three pages that you use most are pinned to the left navigation pane. Use the **More** option to unpin any of these pages and pin something else.
8. **More**: Pin your most used items to the left navigation such as tables, flows, and more.
9. **Power Platform**: Explore other Power Platform products or service.

Pin and unpin

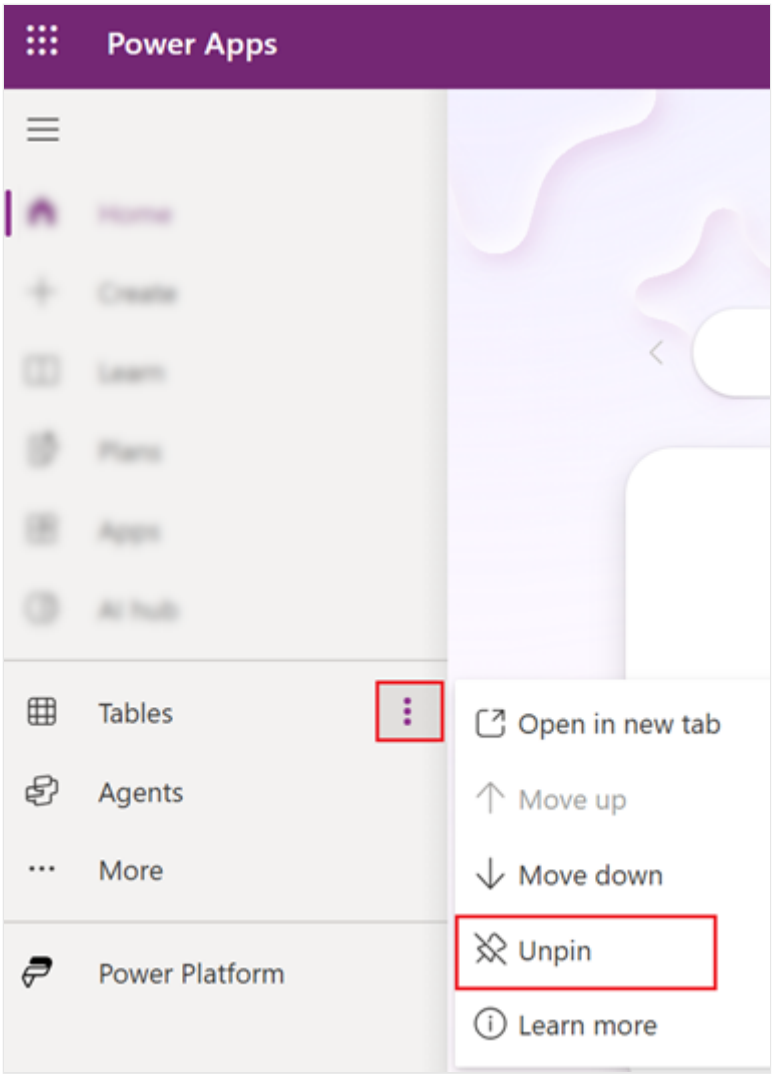
Pin your most used pages in the navigation pane so you can quickly access features that you use frequently. Links to other pages are available through the **More** link. When you pin an item, it appears in the middle section above **More**.

When you sign in, the system automatically pins your most and recently used pages on the left navigation pane. However, you can pin and unpin pages and customize it to your preference.

To pin or unpin a page from the left navigation pane, select **More**, and then select the  pin or  unpin button.



You can also unpin an item by selecting the more button and then select **Unpin**.



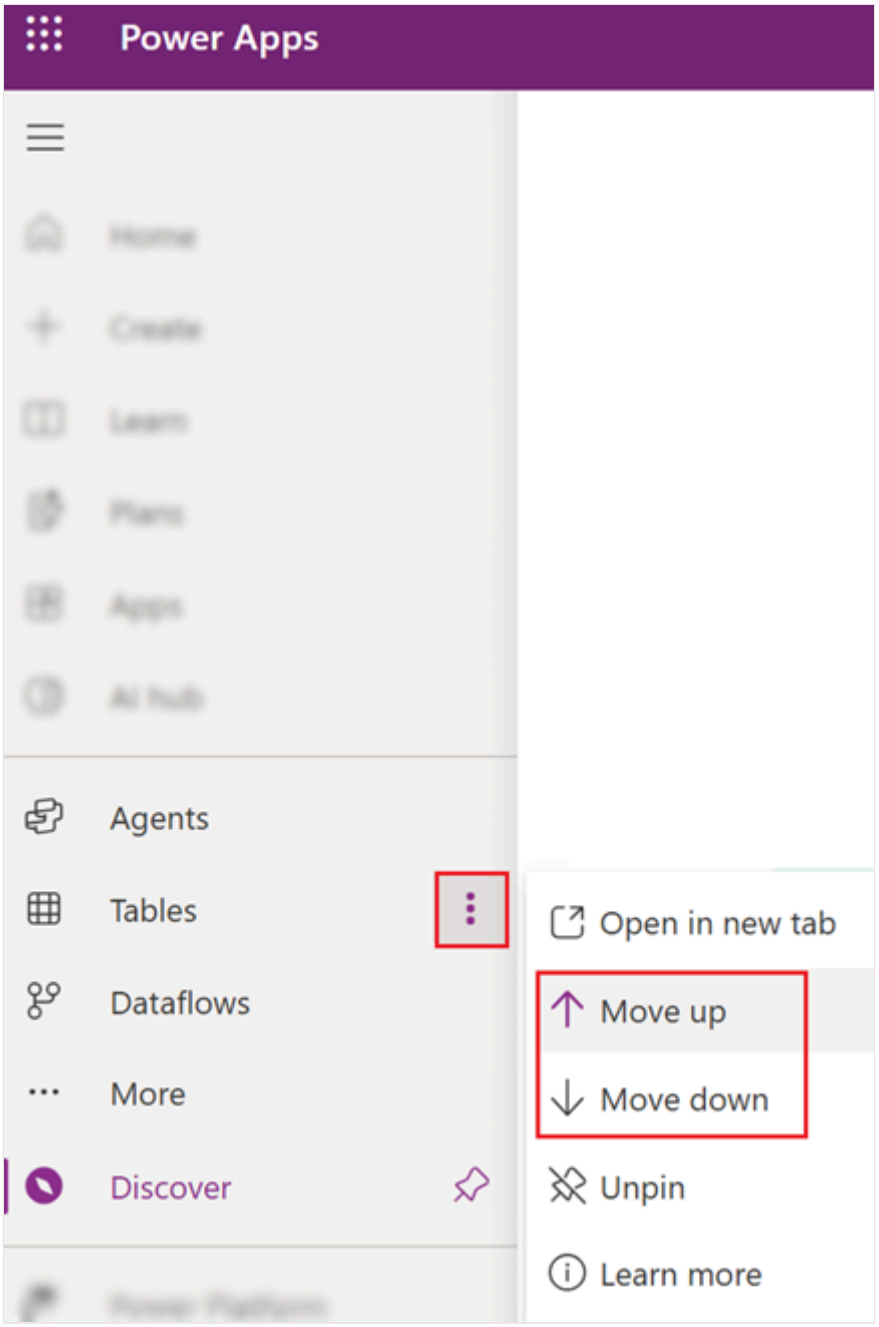
Discover all

To see all your Power Apps, from the left navigation pane, select **More** > **Discover all**. To keep it pinned, select the pin button.

Move up or move down

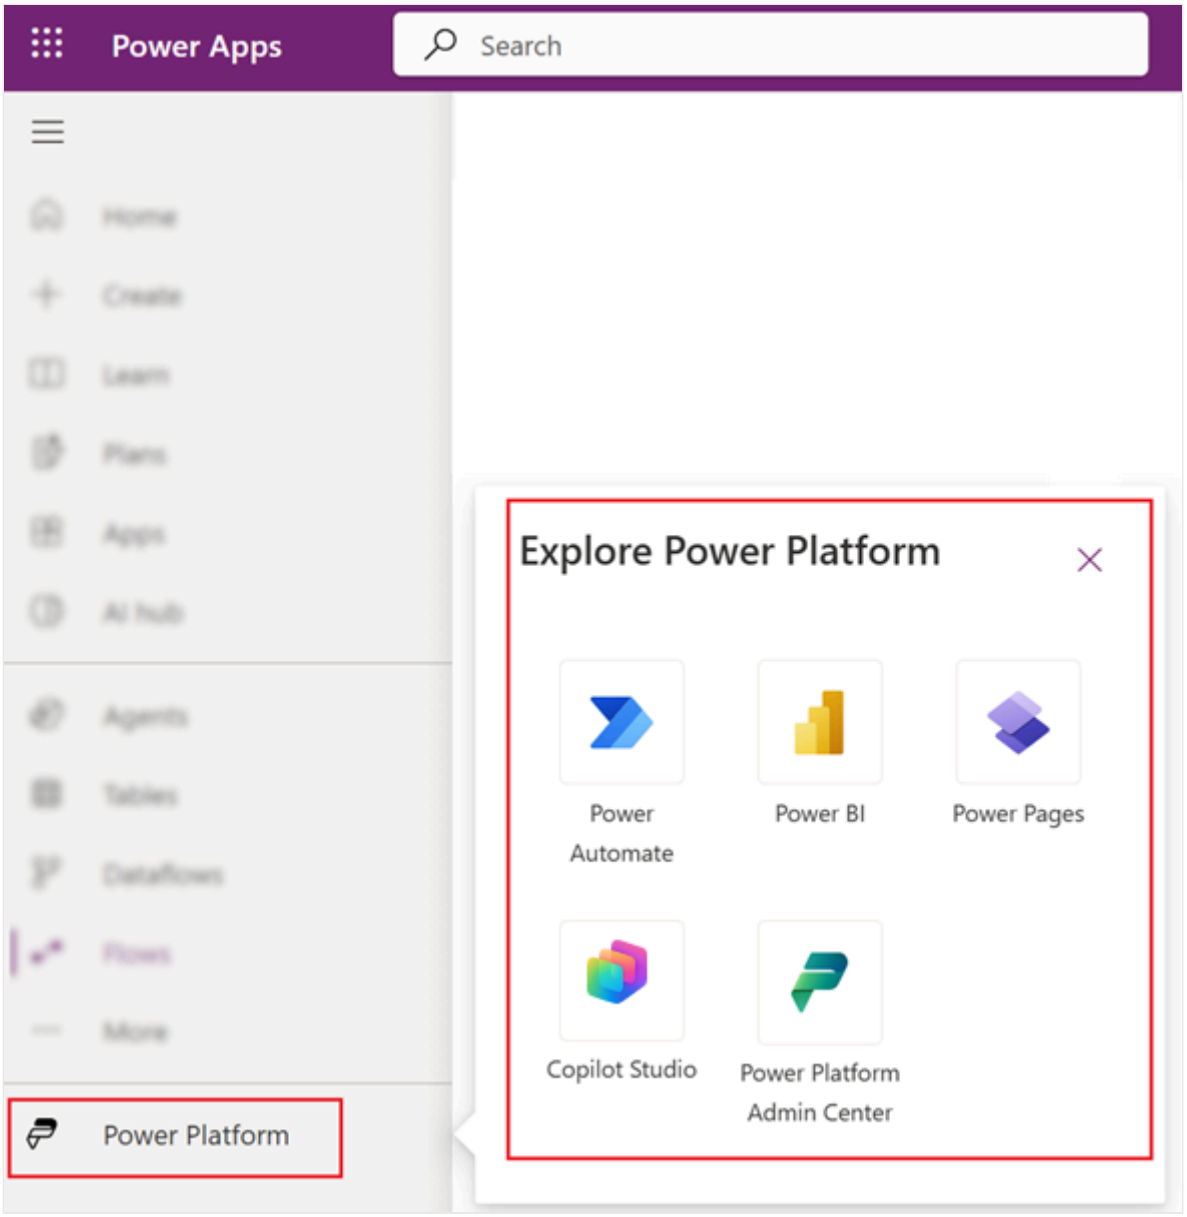
When you have a few pages pinned in the navigation pane, you can start moving them up or down.

To move a page up or down, select the more button next to the page that you want to move, and then select **Move up** or **Move down**.



Power Platform

From the left navigation pane, select **Power Platform** to access Power Platform services such as Power Platform Admin Center, Power BI, and Power Automate.



2 – Search

Find anything fast. The search bar helps you:

- Locate your apps by typing any part of the name
- Discover new app templates
- Access help documentation

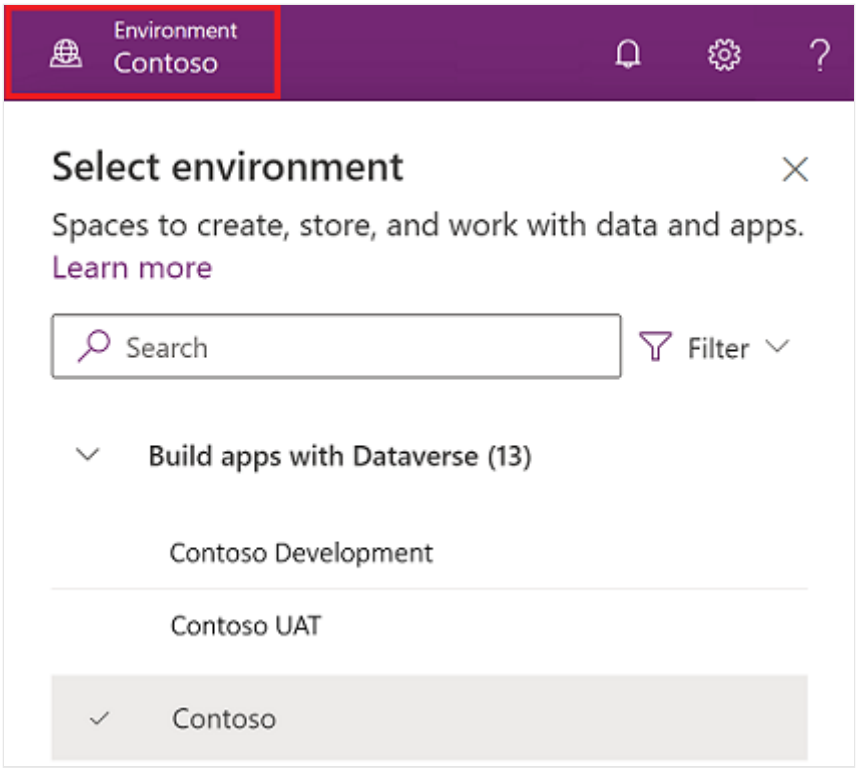
Quick tip: Start typing in the search bar, and then select the banner icon next to your app to open or edit it.

3 – Environment information and settings

View your environment information and settings.

Choose an environment

For best results, start by ensuring that the home page is set to the right environment. For more information, see Choose an environment.



Manage environments by using Power Platform admin center.

Notifications

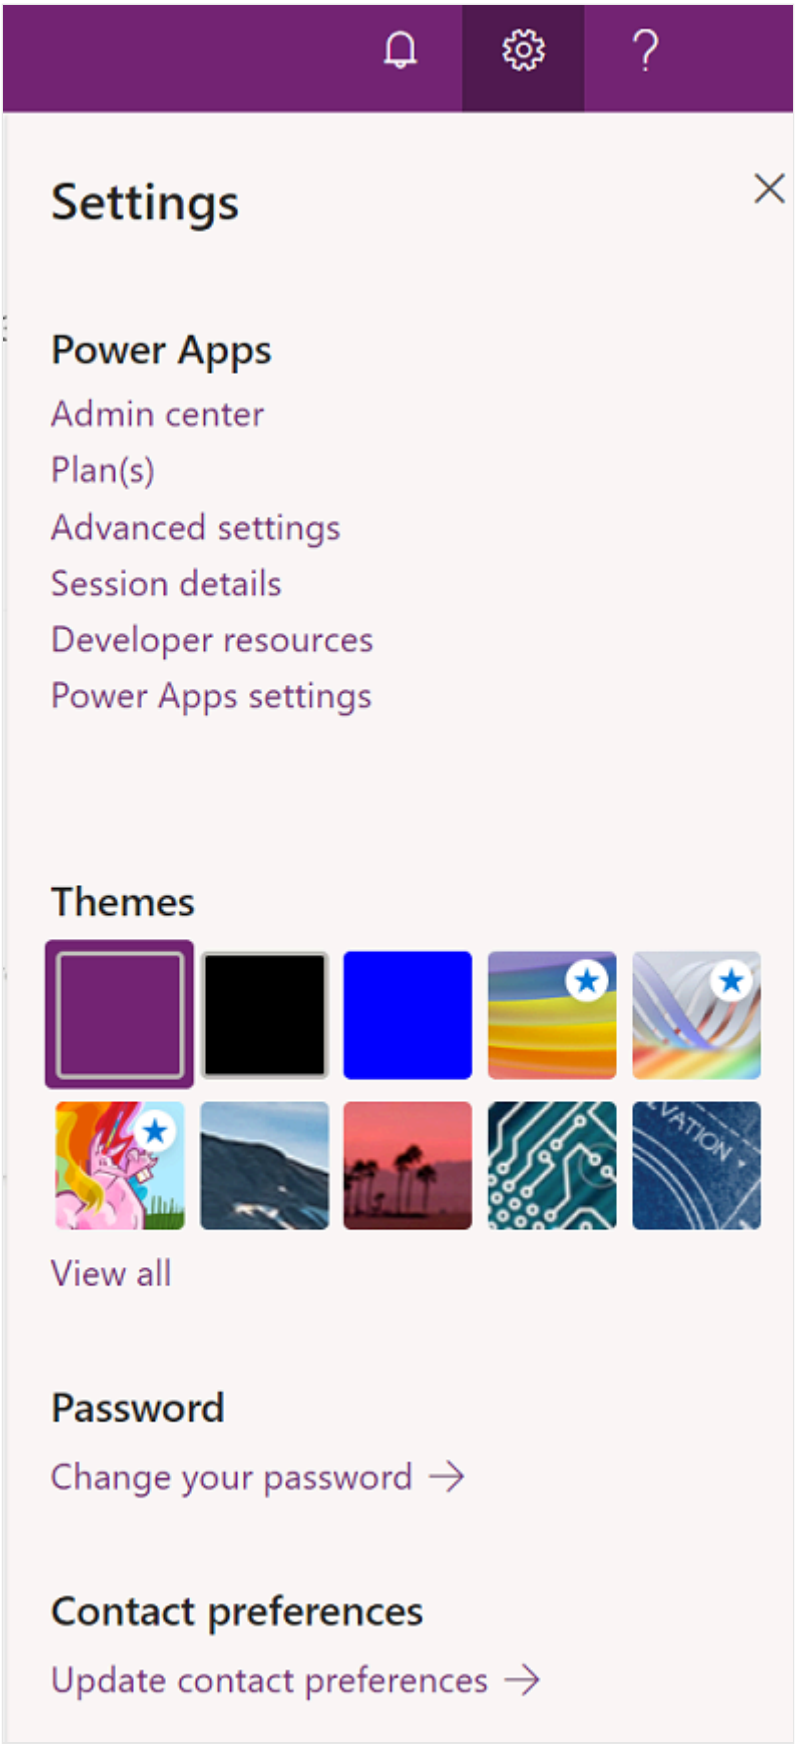
Select the bell icon to see notifications. The notification center stores notifications until you dismiss them or when they expire.

Settings

Select the gear icon to perform tasks such as connecting to data sources, identify your Power Apps licenses, and open the page where you can perform administrative tasks.

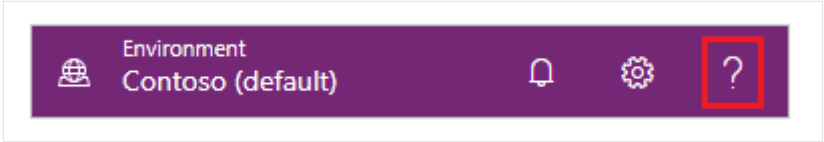
- **Admin center**: Opens another window and goes to the Power Platform admin center.
- **Plans(s)**: View your licenses. For more information, see Licensing overview.
- **Advanced settings**: Manage your admin settings. For more information, see Manage Microsoft Dataverse settings.
- **Session details**: View your Power Apps session details such as session ID, tenant ID, environment ID, and more.

- **Developer resources**: Access developer resources.
- **Power Apps settings**: View or update your language and time settings, notifications, or access directories.
- **Themes**: From the list of themes, select a theme for your organization.
- **Password**: Change your password.
- **Contact preferences**: Update your contact information.



Help

In the header, select the question mark icon to find more information about Power Apps.



You find links to documentation, Power Apps training on Microsoft Learn, the Power Apps Community where you can share information with users in other organizations, and the Power Apps blog where the newest features are announced.

4 – Build apps

Ready to build your first app? Choose the option that best fits your needs:

- **Start with a design →**: Pick a layout or start with blank canvas app and design your app.
- **Start with data →**: Create a new table in Dataverse, or connect to an existing datasource, such as Dataverse, SharePoint, Excel, SQL, or upload a file.
- **Start with a plan →**: Use plans to describe your business problem and generate apps, tables, and more.

You can also create app using the **Create** menu on the left navigation pane. Review the following articles, to learn more about creating apps:

- Create a blank canvas app from scratch.
- Create a canvas app using Microsoft Dataverse
- create a canvas app based on Excel data.
- Create a canvas app with data from a list

> ⓘ Note
>
> If you're trying to create an app by using Dataverse but the option is unavailable, review the permissions table in this article.

Permissions for Dataverse

Can't create a Dataverse app? This table shows what happens based on your permissions and helps you understand your next steps.

Expand table

Maker has access to a developer environment	Maker has permission to create a developer environment	Maker has access to another Dataverse environment with required permissions	Action
Yes	n/a	n/a	Switch to the developer environment that appears first in the alphabetical list
No	Yes	n/a	Create a developer environment
No	No	Yes	Switch to another environment using the environment picker
No	No	No	Contact your admin

5 - View and edit plans

Select a plan to view and edit a plan. You can also, use the **Plans** menu in the left navigation pane to access your plans.

6 – View and edit apps

Manage your apps effectively:

- **Access your apps:** Use the **Apps** menu in the left navigation pane to find apps you own or apps shared with you
- **Find apps quickly:** Filter and sort apps to locate what you need
- **Take action:** Hover over any app name to **Edit**, **Play**, or access **Commands** for sharing, viewing details, and settings

Ready to customize? Learn advanced app editing techniques →

Copilot in Power Apps overview

Copilot in Power Apps lets you quickly build apps using natural language. Describe your business needs, and the service generates an app and data model for you—no coding required. People interact with your app by asking questions or giving commands in everyday language, making the experience more intuitive and engaging. This article gives an overview of Copilot in Power Apps, including prerequisites, availability, and how to manage Copilot features in your environment. Learn about Copilot and generative AI features in Microsoft Power Apps.

Prerequisites

Each Copilot feature can have different requirements. Check the documentation for each feature to learn what you need.

> **Important**
>
> - This capability is powered by **Azure OpenAI Service**.
> - Some Copilot features are in preview.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to **supplemental terms of use**, and are available before an official release so customers can get early access and provide feedback.

Availability

- This capability might not be available in your region yet. Learn more in Explore Copilot features by geography and languages.
- This capability might be subject to usage limits or capacity throttling.
- Understand the capabilities and limitations of AI-powered and Copilot features in Power Apps. Learn more in FAQ about using AI responsibly in Power Apps.

Enable or disable Copilot features

Generally available Copilot features are on by default and can't be turned off except by Microsoft Support. To turn them off, a tenant admin needs to contact Support.

Turn off Copilot preview features in Power Apps

Copilot preview features are on by default, but your admin can turn them off for an environment or a tenant.

Turn off Copilot preview features for an environment

1. Sign in to the Power Platform admin center.
2. In the navigation pane, select **Environments**, and then select an environment.
3. On the command bar, select **Settings** > **Features**.
4. Set the **Copilot** toggle to **Off**.

Turn off Copilot preview features for your tenant

1. Sign in to the Power Platform admin center.
2. In the navigation pane, select **Settings** to open the **Tenant settings** page.
3. Select **Copilot in Power Apps (preview)**, and then set the toggle to **Off**.
4. Select **Save**.

> **Note**
>
> Turning off Copilot for your tenant turns off Copilot for makers only. It doesn't turn off the Copilot control for canvas apps or Copilot for model-driven apps.

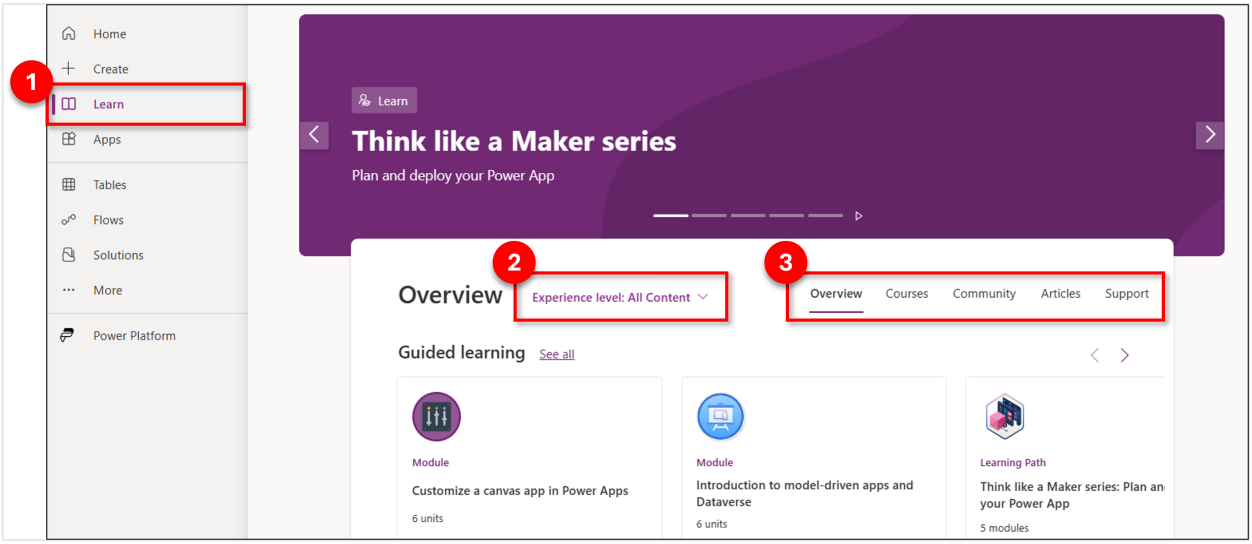
Use the Learn hub

Article • 09/27/2023

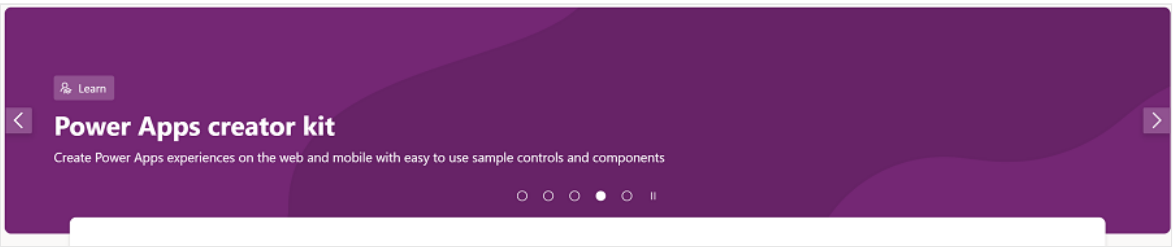
The Learn hub gives you easy access to resources that help you as you're learning to build Power Apps, include training material, product documentation, announcements and event notices, and help from the Power Apps community.

1. To access the Learn hub, go to the Power Apps home page and select **Learn** in the left navigation pane.
2. Use **Experience level** to select the content level that best suits your needs.
3. Select a tab to access the information that you're looking for.



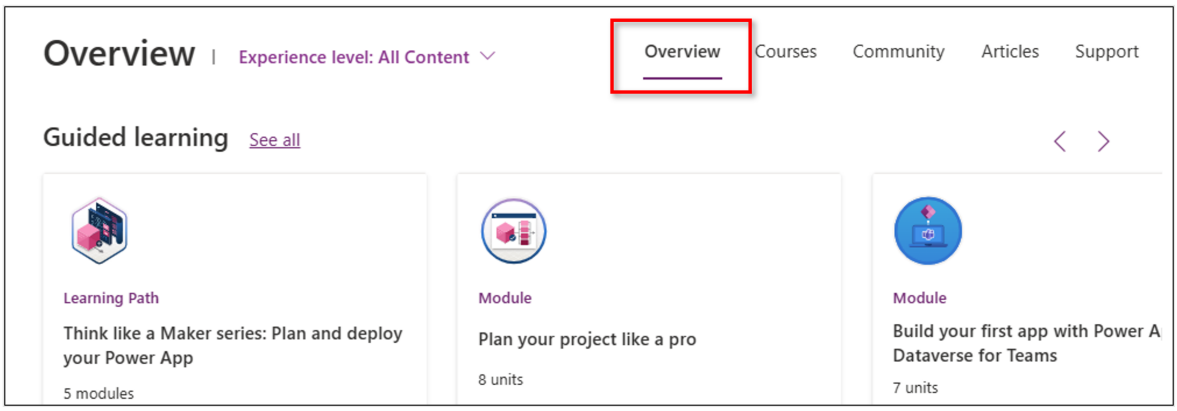
The Learn hub includes the following sections:

- The banner at the top showcases the latest announcements, trending posts, and information about upcoming Microsoft events.



- The **Experience Level** menu provides learning content based on the experience level that you select. For instance, if you are a developer seeking information about extensibility points in Power Apps, choose **Advanced** to find relevant help resources.

- The **Overview** tab lists featured training paths and modules, posts from the community, help articles, and training videos on YouTube.



- The **Courses** tab provides guided training such as training paths, modules, and training events.
- The **Articles** tab lists relevant posts in public blogs.
- The **Community** tab provides access to content from the Power Apps community, including user groups, networking events, the LinkedIn Power Apps community, and more.
- The **Support** tab is where you can find help articles, report a problem, and submit an idea.

From your org (preview)

In Managed Environments, admins can provide customized welcome content to help makers get started with Power Apps. Learn about customizing maker welcome content (preview). If your organization has created custom welcome content, you see it when you sign in to Power Apps as a maker.

You can select **Don't show this again here** if you prefer not to see the custom content when you sign in.

To get back to it later, open the Learn hub and select **From your org**.

What's new in Power Apps?

Article • 08/14/2024

This topic provides resources for you to learn about the new features that have been recently released, features that will be releasing over the next few months, and known limitations and resolutions.

Weekly releases

For information about the new features, fixes, and improvements released in the past few weeks, see Released versions for Microsoft Power Apps.

To learn more about how to browse information in the weekly release notes, read this blog post.

> **Note**
>
> Releases are rolled out over several days. New or updated functionality might not appear immediately.

Release plan

For information about new features being released over the next few months that you can use for planning, see Release Planner.

Monthly releases for model-driven apps

Power Platform admins can define the release cadence for features in model-driven apps.

Expand table

Channel	Frequency	Notes
Semi-annual	Twice per year	Rollout follows weekly releases starting in early April and early October. Default release cadence within Power Apps and Dynamics 365.
Monthly	Once per month	Rollout follows the weekly release schedule starting with the first weekly release for the month.

For more information about release channel options and monthly channel, go to Release channel overview.

Known limitations

For information about known limitations, see Common issues and resolutions.

Get your developer environment (preview)

Article • 04/18/2023

[This topic is pre-release documentation and is subject to change.]

By default, Microsoft Power Platform app makers can create up to three developer type environments. Developer environments are special environments intended only for use by the owner. Use these environments to build, test, and perform application lifecycle management (ALM) with Power Apps, Power Automate, and Microsoft Dataverse.

> **ⓘ Important**
>
> This is a preview feature.

Developer type environments allow you to:

- Create apps and flows without writing code, with full-featured Power Apps and Power Automate development tools. Easily share and collaborate on these solutions with others.
- Use a fully managed, scalable data platform with Dataverse, including support for common business application actions. Use out-of-the-box common tables or build your own data schema.
- Export the solutions you create in your developer environment and then import them into other Power Platform environments so users can test and use them.

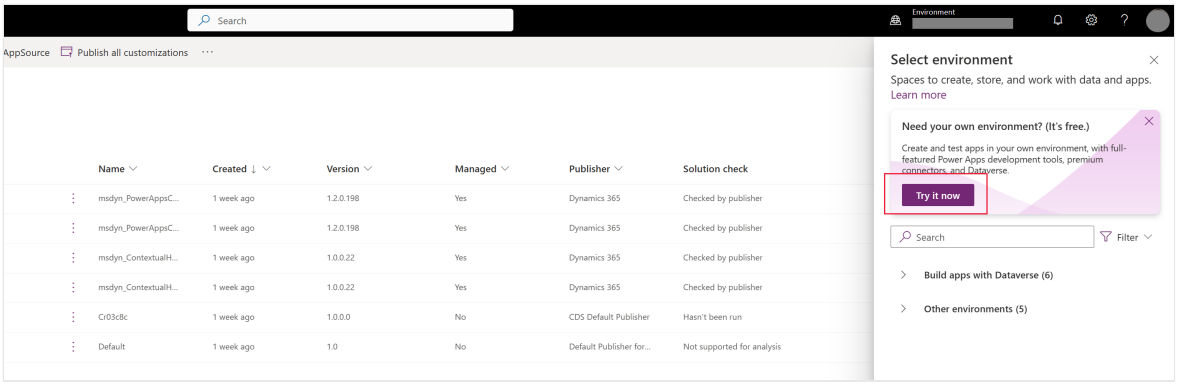
Prerequisites

To create a developer environment, you need an active Power Platform plan that includes Dataverse. More information: Licensing overview for Microsoft Power Platform

Create your own developer type environment

1. Sign in to Power Apps.

2. Select the environment picker > **Try it now**.



3. Follow the instructions on your screen to create your environment.

Create your own environment when you sign up for the Power Apps Developer Plan

The Power Apps Developer Plan gives you up to three free development type environments to build and test with Power Apps, Power Automate, and Microsoft Dataverse. The developer environments maintained under this plan will be available as long as you actively use the Power Apps Developer Plan.

More information: Create a developer environment with the Power Apps Developer Plan

Environments overview

Power Apps preview program

Article • 05/15/2024

Microsoft Power Apps updates the platform and its capabilities every few days or weeks. The Power Apps preview program is a way to get early access to features and updates before they become available in other regions (where customer production apps are deployed).

With the Power Apps preview program, you can:

- **Try out, learn, and dogfood upcoming features**: Many features are rolled out first in the preview for a few days to get feedback. By participating in the preview program, you can learn about new features sooner and provide feedback. Also, you can quickly take advantage of new features as soon as they reach regions where their production apps are created.
- **Enable business continuity by ensuring current apps continue to work** with the upcoming updates (vNext) of Power Apps.

What in Power Apps is available for preview?

To access the preview features, you need to be in a preview environment or using a preview URL. We have preview features for the following areas across Power Apps.

Canvas apps

For preview, experimental, and retired features in canvas apps, use Power Apps Studio to turn the features On or Off while editing your app.

For early access to upcoming changes in canvas apps, use the following environments:

- Preview environments - Upcoming changes are typically rolled out to preview environments 1-2 weeks before they're available to all other regions.
- Sandbox environments - To access preview version of Power Apps on sandbox environments, use make.preview.powerapps.com.

Model-driven apps and app management

You can create, manage, and share apps using Power Apps (make.powerapps.com). To use the preview features, we recommend that you are in a preview or sandbox environment and not in a production environment. Then, go to the preview version of Power Apps (make.preview.powerapps.com).

How to get early access to the upcoming updates?

> **Note**
>
> **Preview (United States)** has been replaced with the **Early release cycle** option. Following the instructions below, you can create preview, or *early release cycle* environments in the United States region and other regions that may be closer to your location.

For Power Platform, all the apps, flows, and related resources are stored in an environment. Early access to all preview features is available when an admin creates an environment that supports the **Get new features early** option. A subset of the regions currently have this capability and the environment must be created in one of those regions. For more information, see Early release cycle environments.

All the apps and other resources created in this environment are on the vNext version of the platform.

How to learn about the latest updates?

You can get aware of the new features, which are available for preview at What's new in Power Apps. The features that are only available in the preview have a 'Preview' tag.

Key scenarios to test with the preview program

1. **Validate your production apps with the upcoming Power Apps updates (vNext)**

   You might like to verify your production apps, to be working fine with the next upcoming updates on Power Apps. You can copy the apps from a production environment to an environment in First Release and play the apps to test out the scenarios. Note, all the other necessary resources like CustomAPI, Power Automate, etc., need to be moved along with it. This should just create another copy of these apps and required resources. You can start testing out the newer updates not just for playing an app, but also while editing and managing the apps.

2. **Trying out the new features available in preview**

   We launch many new features initially in the **Preview (United States)** region. You can try out the new features before they become available in the rest of the

regions (which might impact your production environment).

How to provide feedback to the product team?

You can provide feedback on the Power Apps forum and/or contact support.

What are the known issues and limitations?

1. **Clients not available in preview**

   There are certain features, and services available in preview:

   Expand table

Create an app	Playing an app	Others	Available in preview?
Web studio	Web player	Flow, Connectors and Gateways	Yes
Desktop version of studio	Power Apps mobile for iOS, Android, and Windows		No

2. **Using apps created in preview environments in production environments**

   Power Apps doesn't support opening apps saved in preview only versions of Power Apps in production environments. Most versions of Power Apps eventually move from preview into production, but how and when this happens is influenced by many factors so it shouldn't be relied on. We recommend you use production environments to create or edit any app intended for use in a production environment.

System requirements, limits, and configuration values for Power Apps

This article contains information on supported device platforms, web browser requirements, limits, and configuration values for Power Apps.

Supported platforms for running apps by using the Power Apps mobile app

> **Note**
>
> - To ensure an optimal user experience, test your app on the specific devices you plan to use for production deployment.
> - Performance testing and results can vary between device types such as mobile, desktop, and laptops. Factors include processing power, memory capacity, network connectivity, app complexity, and other apps running in parallel on a device. Make sure the test results meet your business requirements before you roll out the solutions in production.

Expand table

Platform	Version
iOS	The latest version of iOS is always the recommended version to run Power Apps mobile. The previous version is the minimum required.
Android	The latest version of Android is always the recommended version to run Power Apps mobile. The previous three versions are the minimum required to run Power Apps mobile.
Windows	Windows 10 version 17763.0 or later to run Power Apps for Windows.

> **Note**
>
> New major versions of iOS and Android release each year. When a new version releases, if you're using the oldest previously supported version, you have 60 days to update your device to at least the new minimum supported version to continue to run Power Apps mobile.

Supported browsers for running Power Apps

Expand table

Browser	Supported versions	App type
Google Chrome	Latest three major releases	Model-driven apps, canvas apps, app and component designers[1].
Microsoft Edge	Latest three major releases	Model-driven apps, canvas apps, app and component designers[1].
Mozilla Firefox	Latest three major releases	Model-driven apps and canvas apps.
Apple Safari	13 and later	Model-driven apps and canvas apps.

[1]App and component designers include Power Apps studio, model-driven app designer, and model-driven custom page designer.

Supported operating systems for browsers running Power Apps

Expand table

Operating system	Supported versions	App type
Windows	Windows 10 or later	Model-driven apps, canvas apps, app and component designers[1].
macOS	10.13 or later	Model-driven apps, canvas apps, app and component designers[1].
iOS	iOS 13 or later	Model-driven apps[2] and canvas apps.
Android	10 or later	Model-driven apps[2] and canvas apps.

[1]App and component designers include Power Apps studio, model-driven app designer, and model-driven custom page designer.

[2]Using the web browser on a phone to run a model-driven app isn't supported; use the Power Apps mobile app.

For classic web application system requirements, see Web application requirements.

> **Note**
>
> Canvas apps running on Windows platform must use the legacy Microsoft Dataverse connector. A warning is displayed for apps that still use the legacy connector, but using it for Windows platform is supported.

Request limits

These limits apply to each single outgoing request:

Expand table

Name	Limit
Timeout	180 seconds
Retry attempts	4

> **Note**
>
> The retry value might vary. For certain error conditions, retrying isn't necessary.

IP addresses

Requests from Power Apps use IP addresses that depend on the region of the environment that the app is in. Microsoft doesn't publish fully qualified domain names for Power Apps scenarios.

Calls made from an API connected through an app (for example, the SQL API or the SharePoint API) come from these IP addresses.

Required services

This list identifies all services to which Power Apps communicates and their usages. Your network must **not** block these services.

Expand table

>
> **US Government**: Power Apps US Government service URLs, Power Automate US Government service URLs
>
> **China**: Power Platform and Dynamics 365 apps - operated by 21Vianet in China.

Deprecated endpoints

This section lists endpoints that Microsoft no longer supports. Instead, use the new endpoints listed in the table. Update any bookmarks that use the deprecated endpoint to the new endpoint.

Expand table

Deprecated endpoint	New endpoint
web.powerapps.com/apps/{yourAppGuid}	apps.powerapps.com/play/{yourAppGuid}
web.powerapps.com/apps/{yourAppGuid}/open	apps.powerapps.com/play/{yourAppGuid}

Embedding limits for Power Apps

Canvas app embedding

Power Apps doesn't support the nested embedding of canvas apps in native desktop, mobile, or other non-browser clients.

The following table shows some of the examples where embedding a canvas app is and isn't supported:

Expand table

Power Apps embedding scenario	Supported clients	Unsupported clients
A canvas app embedded in a SharePoint page.	Web, for example, Sharepoint.com	• Teams desktop • Teams mobile
A canvas app embedded in a SharePoint page that is added as a tab in a Microsoft Teams channel.	Web, for example. • Sharepoint.com • Teams.microsoft.com	• Teams desktop • Teams mobile
A canvas app used as a custom form in the SharePoint page.	Web, for example, Sharepoint.com	• Teams desktop • Teams mobile
A canvas app used as a custom form in the SharePoint page that is added to a Teams team.	Web, for example. • Sharepoint.com • Teams.microsoft.com	• Teams desktop • Teams mobile • SharePoint mobile
A Power BI report that is added to Teams, or a SharePoint site.	Web, for example, Teams.microsoft.com	• Teams desktop • Teams mobile • SharePoint mobile
A canvas app is embedded in a third party client.	Third party websites in a browser	Third party native applications
A canvas app in Unified Service Desk	None	Unified Service Desk Desktop app
A canvas app embedded in Power BI	Web, for example, app.powerbi.com	Power BI Desktop Client

Model-driven app embedding

Power Apps doesn't support embedding a model-driven app or page within an IFrame in another application.

Proxies

Power Apps doesn't support running with a proxy enabled. This limitation can cause unpredictable behavior. If you encounter problems, disable the proxy and then try again.

- Some proxies, such as Zscaler and Blue Coat, remove headers from Power Apps requests. Power Apps relies on these headers, like CORS or authentication headers, to load the app.

- Some proxies, such as Microsoft Defender for Cloud Apps and McAfee, might intercept and change the URL of an app or embedded app. For example, if there's a Dynamics 365 app that runs under domain **org.crm.dynamics.com** or a canvas app that runs under domain **apps.powerapps.com**, the platform doesn't support a proxy that changes these domains to a custom domain such as **mycustomdomain.com**. This limitation can cause unpredictable behavior when the platform tries to retrieve tokens that are necessary to run the app.

Local network access and permission problems

In 2025, many browsers introduced additional security controls to prevent cross-origin attacks and unauthorized access to private network resources. These changes went into effect for Edge with their December 4, 2025 release.

Some proxies are configured by default to host resources in a way that appears to the end-user's browser as a local network resource. This configuration now results in those requests being blocked. This behavior might appear to end-users as unexpected permission prompts, silent failures, or generic messages such as "This app stopped working. Try refreshing your browser".

> **Note**
>
> Microsoft Support can't resolve these networking problems. Enterprise admins might be able to mitigate this problem by updating browser policies such as LocalNetworkAccessAllowedForUrls for Microsoft Edge and Google Chrome or by updating proxy configurations according to their vendor's guidelines.

Data types size limits

For canvas app data type limits, you can find information about size limits on text, hyperlinks, images, and media in Data types in Power Apps.

For Microsoft Dataverse data type size limits, you can find information on column types, such as text and image columns, in Types of columns.

Power Apps per app plan

For more information, see Power Apps per app plan in the Power Platform admin guide.

How do I find and run apps?

Article • 10/23/2024

No need to manually work on a task to get your work done. With Power Apps, you can create and use a canvas app or model-driven app to get your work done quickly. Once you create an app, you can share the app with your organization.

Canvas apps give you much control over the user experience of the app. An app maker can use templates to create a canvas app, or they can configure the app any way they like. A canvas app, like its name, is a blank canvas, so you can create an app to fit the needs of users in your organization.

Because canvas apps can essentially be anything, there isn't much help documentation on how to use an app once it's created. If you need help with using a canvas app, contact your app maker or Power Apps admin.

Model-driven apps use the Unified Interface that provides a responsive and accessible design. You can run the app on a web browser or on popular mobile devices. The app has multiple components including dashboards, forms, views, charts, and business processes that together help make the app easy to use.

This section provides information about how to find and run canvas and model-driven apps from various places. It also provides information on how to navigate and work within a model-driven app: Use model-driven apps.

What's required to run apps?

Ensure that you're using a supported web browser and operating system. For more information, see System requirements, limits, and configuration values for Power Apps

Additionally, you need a Power Apps license to run an app. If you don't have a license, you can request one by following instructions here: Request a Power Apps license

Run an app in a web browser

Article • 06/05/2024

When you create an app, or someone shares an app with you, you can run that app on the Power Apps mobile app or in a web browser. In this topic, you'll learn how to run a canvas or model-driven app in a web browser from the Microsoft 365 apps page.

For full functionality and optimized experience on a tablet device, we strongly recommend that you use the Power Apps mobile app. If you don't have the Power Apps mobile app installed, you can still use the web browser on your tablet, as long as your device has sufficiently high screen resolution. For more information: Required privileges and supported devices.

> **Note**
>
> Using the web browser on your phone to run your model-driven apps isn't supported; you must use the **Power Apps mobile app**.

To follow this quickstart, you need:

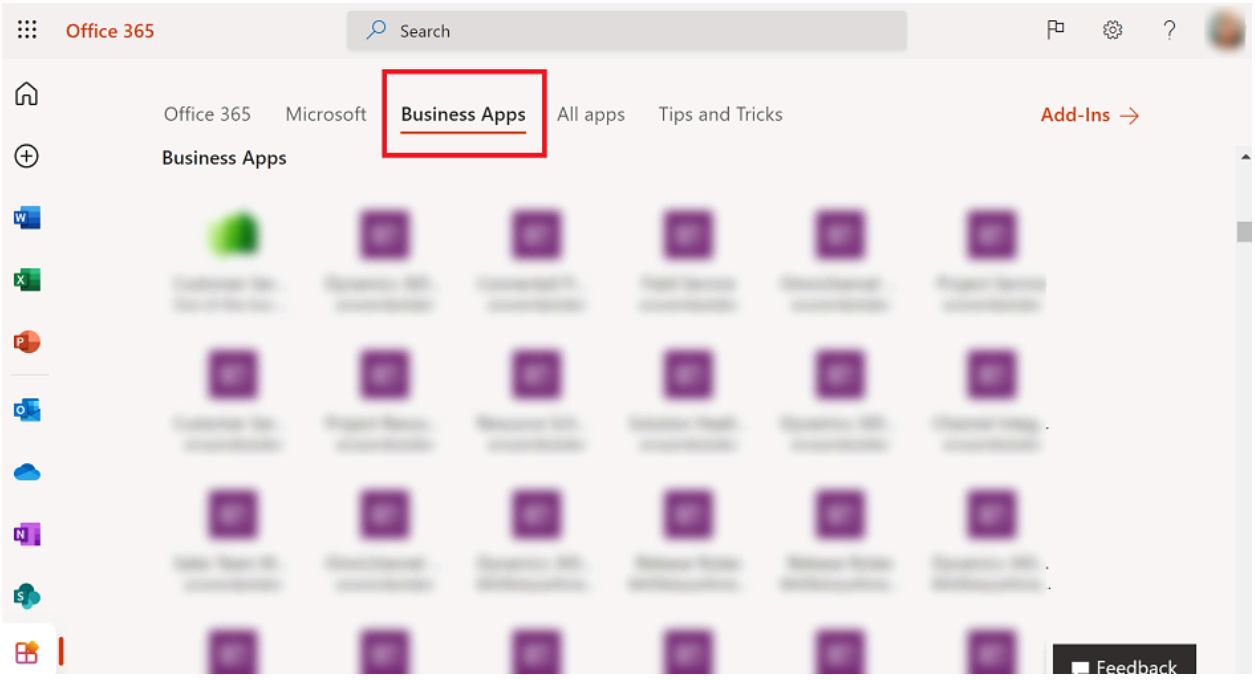
- A Power Apps license. This is available with a Power Apps plan, such as the Power Apps per user plan, or Power Apps trial, or any of the Microsoft Office 365 or Dynamics 365 plans that include Power Apps.
- Access to an app that you built or that someone else built and shared with you.
- Access to a supported web browser and operating system. For more information: System requirements, limits, and configuration values for Power Apps

Sign in to Microsoft 365 apps page

Sign in to the Microsoft 365 apps page.

Find an app on the Home page

The Home page may show several types of business apps.



The list of Office apps is a limited, curated list based on the following criteria:

- Apps that you launched in the last week.
- Apps that you created.
- Apps your admin marked as **Featured** in your tenant.
- First-party, model-driven apps such as Dynamics 365 Sales, Dynamics 365 Customer Service, and Dynamics 365 Field Service that you can access and are hosted in production or default environments.

> **Note**
>
> Marking an app as **Featured** is the only way to guarantee inclusion in the list.

Known limitations

- When a new app is shared with users, the app needs to meet the criteria listed above. It can take up to 24 hours for the app to appear in the list of **Office** apps.
- Some model-driven apps aren't recording the last launched time. Until this issue is resolved, we recommend using featured apps. Featured apps only appear to users who have access to the apps. Featured apps don't appear to all users.
- It's possible that users will be able to see model-driven apps that they used to be able to access, but can no longer. There's also a chance that users won't be able to see model-driven apps that they have access to.
- It can take up to a week for users to start seeing the new URL after an org URL update.

- In the case of model-driven apps, changes made only to the icon may not be reflected. Until this issue is resolved, changing another property, like description, causes the icon to be updated.

What if I can't find an app?

Apps that haven't been used in the last week won't appear in the list of **Office** apps. If you can't find an app, then you need to use the web link to open the app directly in your browser.

1. To find the web link for an app, sign in to Power Platform admin center or Power Apps.
2. Find the app that you're looking for.
3. Across the app name, select (...) **More Commands** > **Details**.
4. From the **Details** tab copy the **Web link**.
5. Paste the web link in a browser window to launch the app.

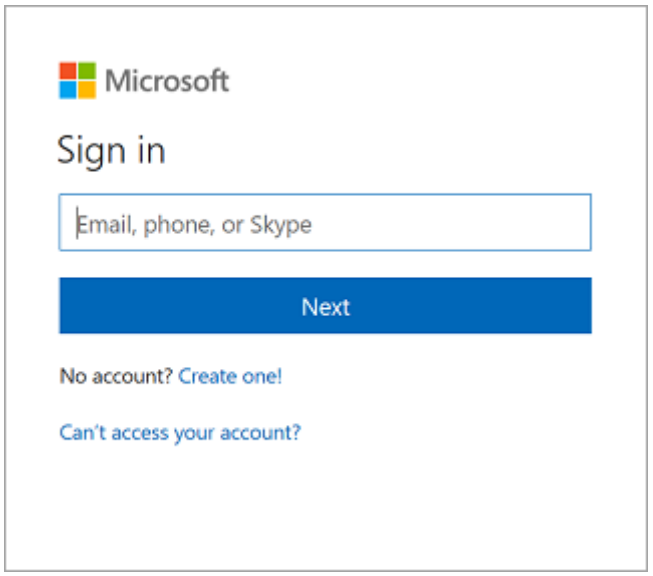
The Microsoft 365 apps page has a different URL per cloud.

Expand table

#	Cloud	Microsoft 365 app discovery URL
1	Commercial	https://www.office.com/apps
2	Government Community Cloud (GCC)	https://www.office.com/apps
3	Government Community Cloud (GCC High)	https://www.office365.us/apps
4	Department of Defense	https://www.ohome.apps.mil/apps
5	Office 365 operated by 21Vianet	There isn't a corresponding https://www.office.com/apps experience for this cloud. However, the Microsoft 365 app launcher experience throughout Microsoft 365 experiences includes Power Apps and Dynamics apps such as new word document in https://portal.partner.microsoftonline.cn/NewSpoDocument?docType=Word

Run an app from a URL

You can save an app's URL as a bookmark in your browser and run it by selecting the bookmark, or you can send a URL as a link through email. If someone else created an app and shared it with you in an email, you can run the app by selecting the link in the email. When running an app using a URL, you may be prompted to sign in using your Azure Active Directory credentials.

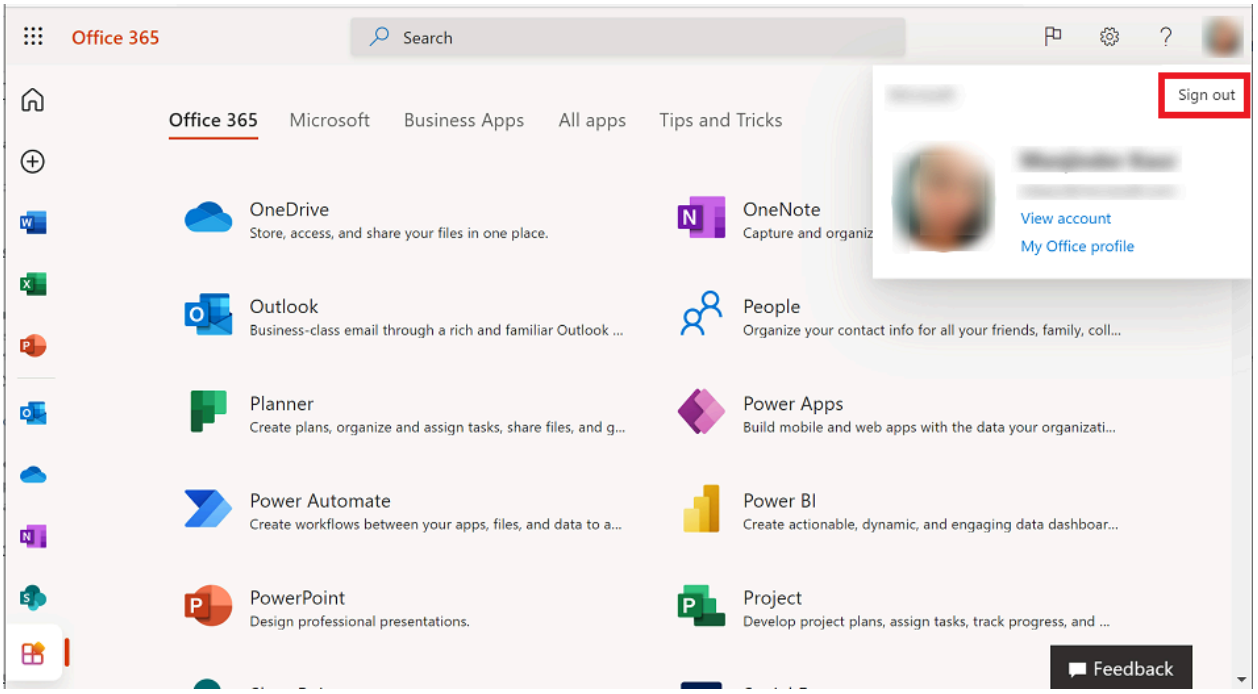


Connect to data

If an app requires a connection to a data source or permission to use the device's capabilities (such as the camera or location services), you must give consent before you can use the app. Typically, you're prompted only the first time.

Sign out

To sign out of the Microsoft 365 apps page, select your profile image and then select **Sign out**.



Next steps

In this topic, you learned how to run a canvas or model-driven app in a web browser. To learn how to:

- run a model-driven apps or canvas apps on a mobile device, see Run model-driven apps and canvas apps on Power Apps mobile
- use a model-driven app, see Use model-driven apps
- mark an app as featured, see Set-AdminPowerAppsFeatured

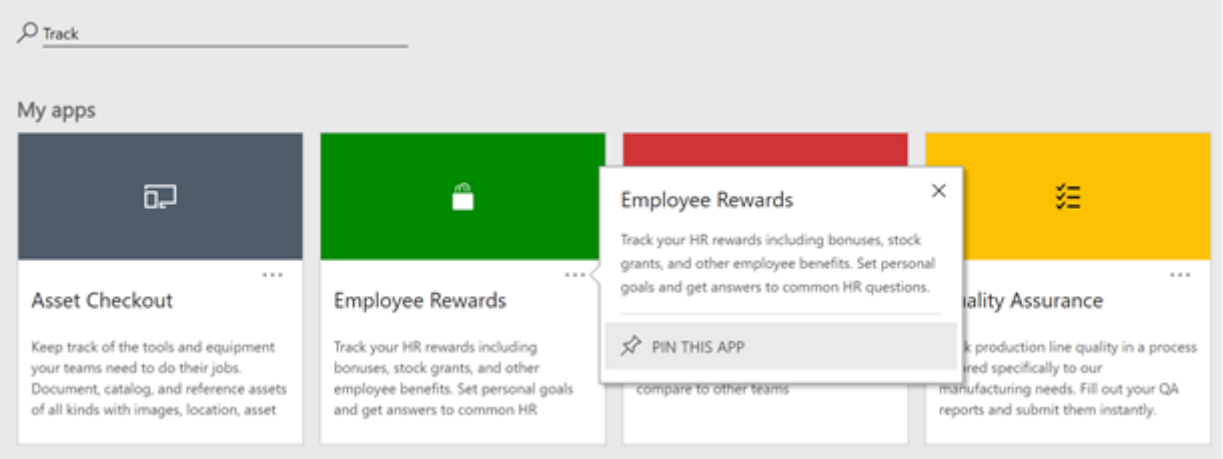
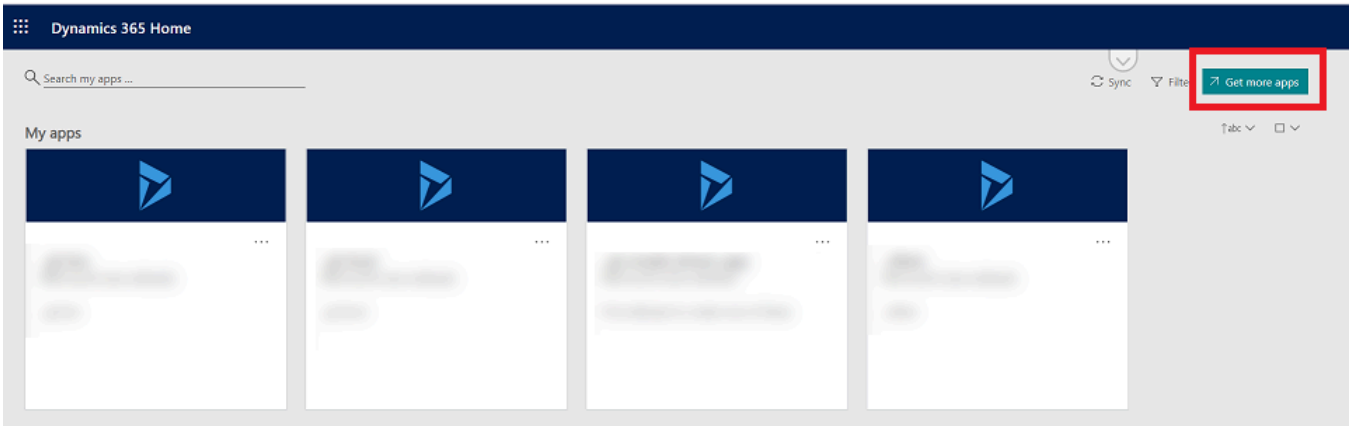
Discover apps via Marketplace

The apps you build and publish with Power Apps are discovered and used in Dynamics 365 on the web. It displays all of your apps--the apps that you've chosen to use (that is, by launching from a share email or opening from Marketplace) or that an admin has provisioned for you. This includes all of your apps from Power Apps, and Dynamics 365 applications from Microsoft. You can search for apps, filter by environment, and pin the apps you use most frequently to the top of the page.



Find apps via the Marketplace organization gallery

Microsoft Marketplace is now embedded in the Microsoft 365 apps (https://www.office.com/apps) home page and throughout the common navigation. It now includes a private gallery of apps available to you within your company. Select **Get more apps** from the home page or task pane, and navigate to the **My Organization** tab to see apps that are available to you.



Apps built with Power Apps and shared with a security group or the entire company with **User** permission appear here, instead of cluttering your home page by default. When you get an app from Marketplace, it will then appear on the home page and be easily accessible throughout the experience.

Use Microsoft 365 Copilot in canvas apps (preview)

Microsoft 365 Copilot for apps is a next-generation AI assistant that helps you gain insights into the data in your apps through conversations in natural language. Microsoft 365 Copilot boosts your productivity through AI-powered insights and navigation assistance.

> **Important**
>
> - This feature is in preview.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use. They're available before an official release so that customers can get early access and provide feedback.
> - This feature is in the process of rolling out and might not be available in your region yet.

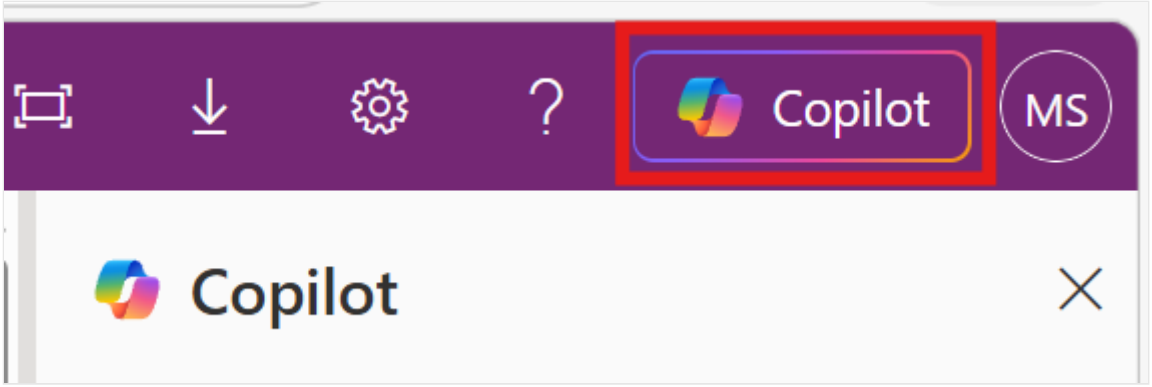
Prerequisites

An administrator must enable Microsoft 365 Copilot in your application before it becomes visible in your app. For more information, see Add Microsoft 365 Copilot for app users.

> **Note**
>
> - To use the Microsoft 365 Copilot feature in your app, you must have a Microsoft 365 Copilot license.
> - You must have access to an early release cycle environment to use this feature.

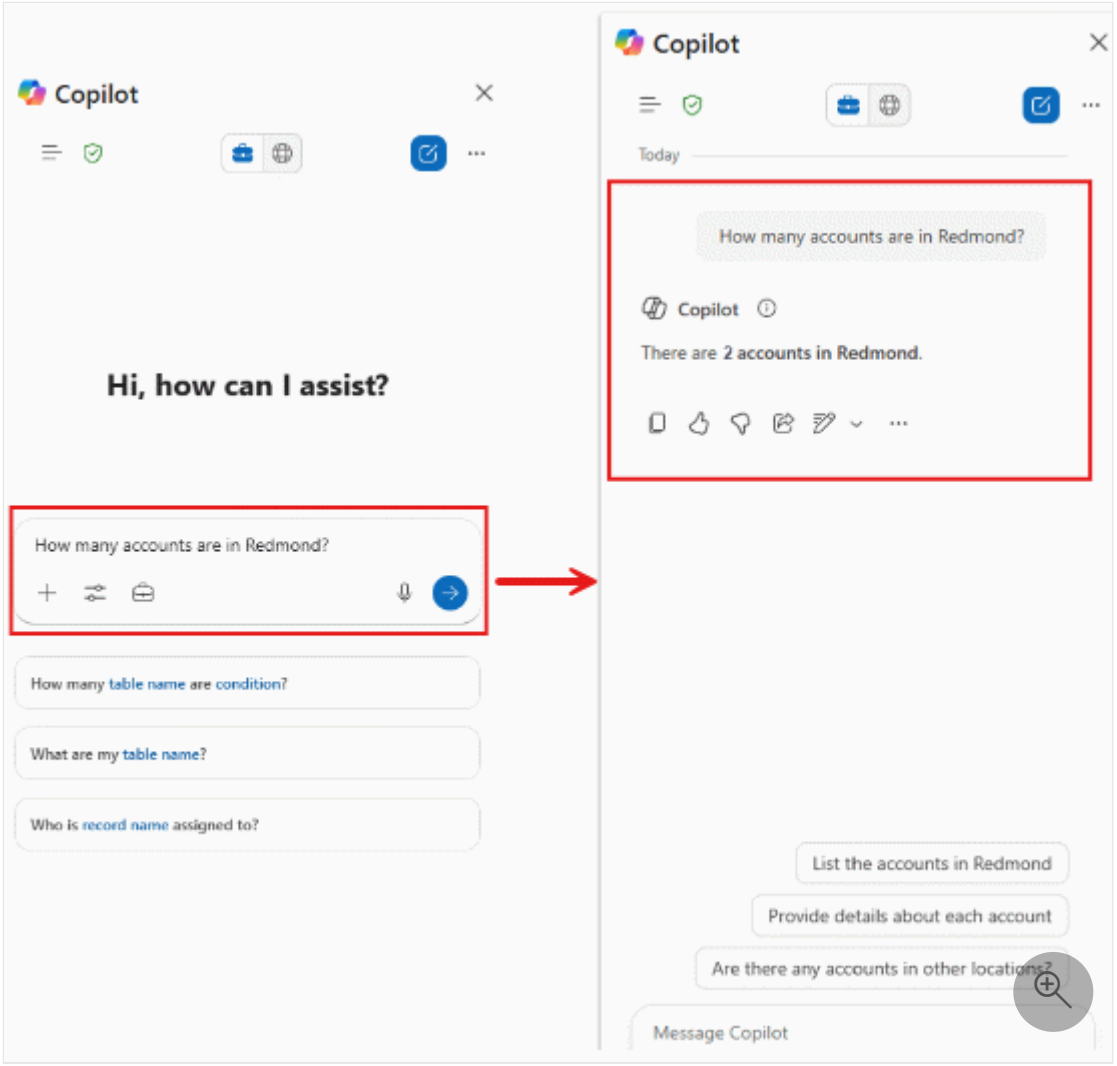
Copilot pane

After Microsoft 365 Copilot is enabled, access it through the Copilot button near the upper-right corner of the page.



Use Microsoft 365 Copilot to ask questions

Microsoft 365 Copilot in apps answers questions about the Dataverse tables or SharePoint list data in the app.



Share your feedback

Help us improve Copilot responses by using the feedback controls on each response. Provide feedback for every response:

- If a response is high quality and helpful, select the thumbs up button.
- If a response is incorrect, incomplete, or not helpful, select the thumbs down button.

When you provide feedback, share as much information as possible. For example, include what you expected to see, what was missing or incorrect, and any relevant context. The more detail you share, the better we can understand your feedback and continuously improve responses.

Copilot

Today

Show me all the accounts in Redmond.

Copilot

Here are **all the accounts in Redmond** that I found in your app. There are **3 accounts total** that have their city set to *Redmond*:

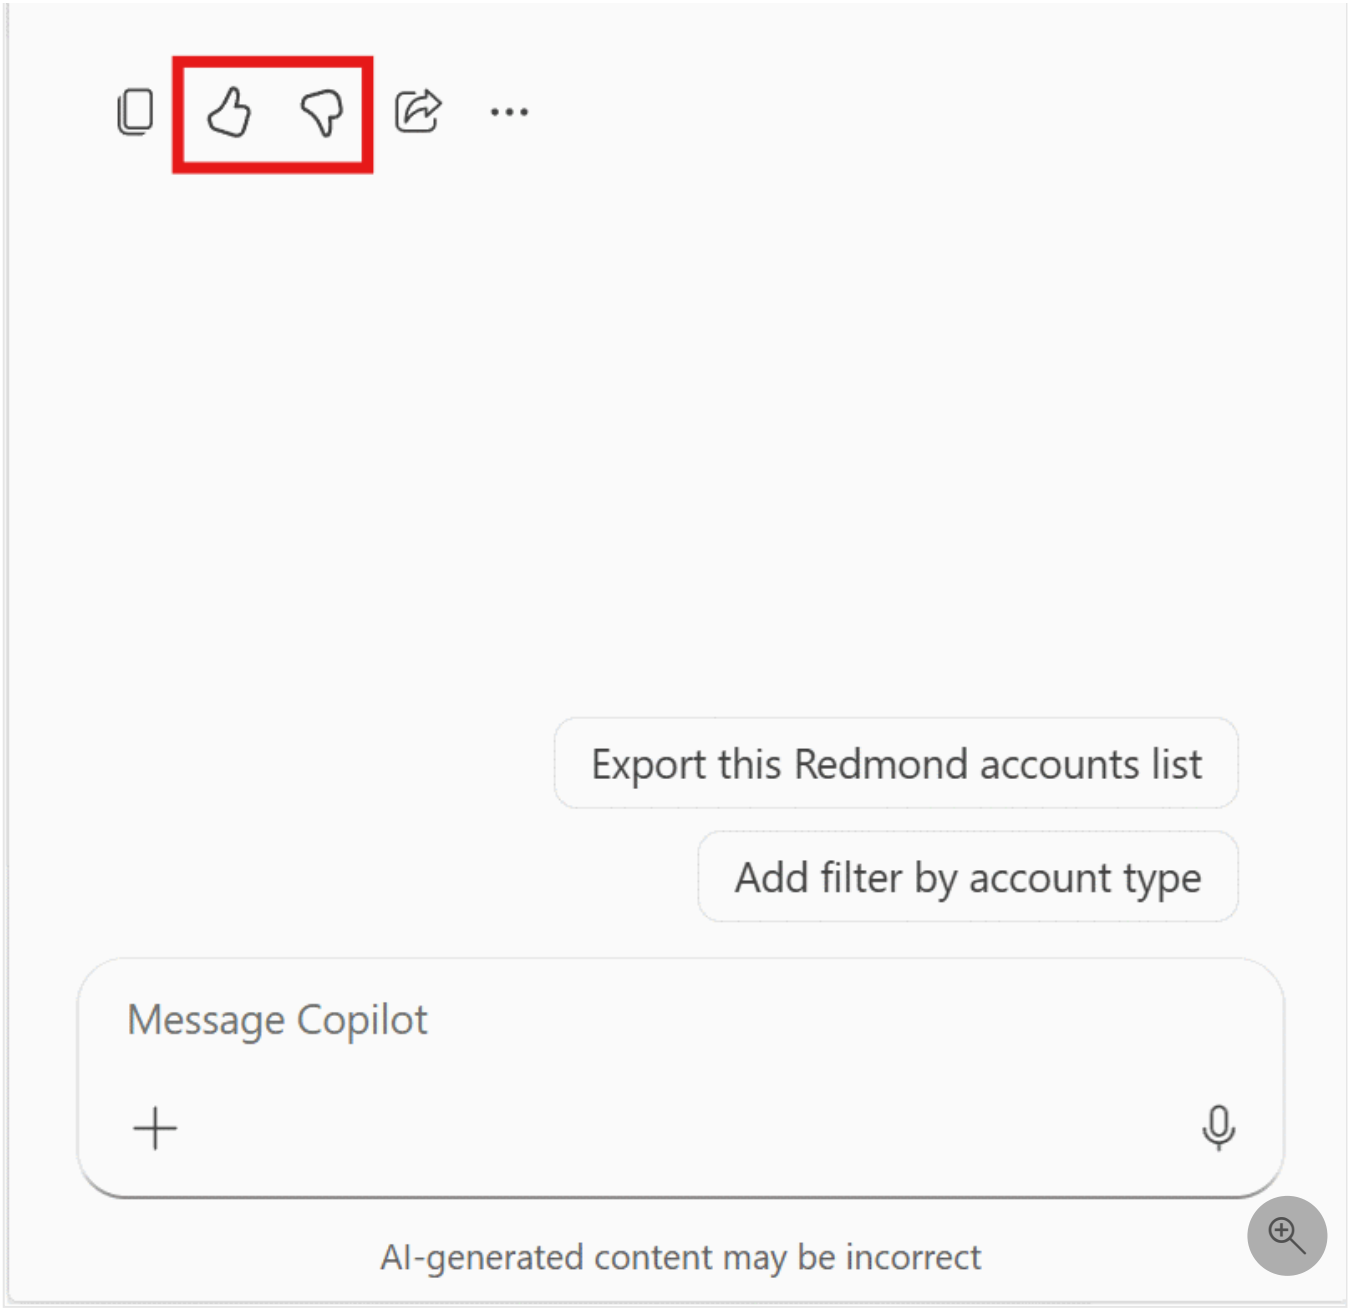
Accounts in Redmond

Account Name	City
City Power & Light (sample)	Redmond
Contoso Pharmaceuticals (sample)	Redmond
A. Datum Corporation (sample)	Redmond

If you'd like, I can:

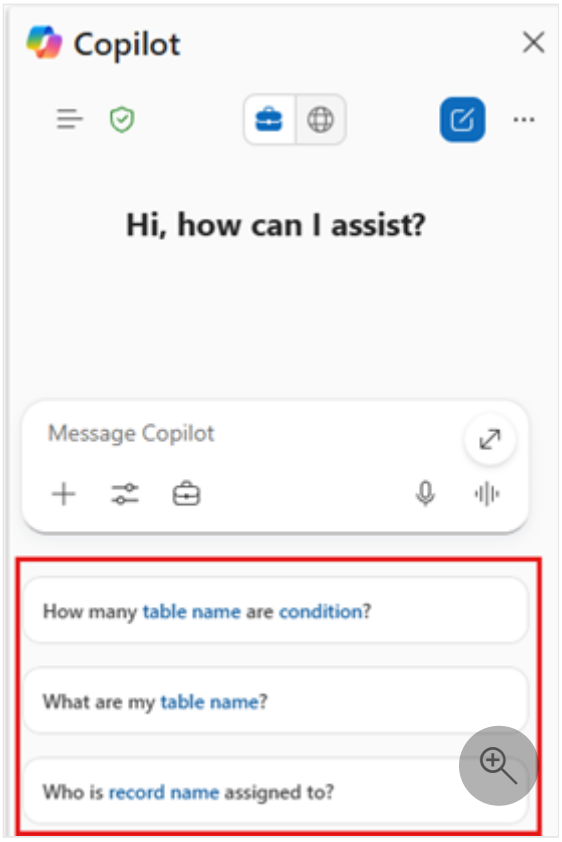
- Open any of these accounts
- Export this list
- Add additional filters (state, owner, account type, etc.)
- Turn this into a saved view for quick access

Just let me know how you want to use this.



Microsoft 365 Copilot suggested questions

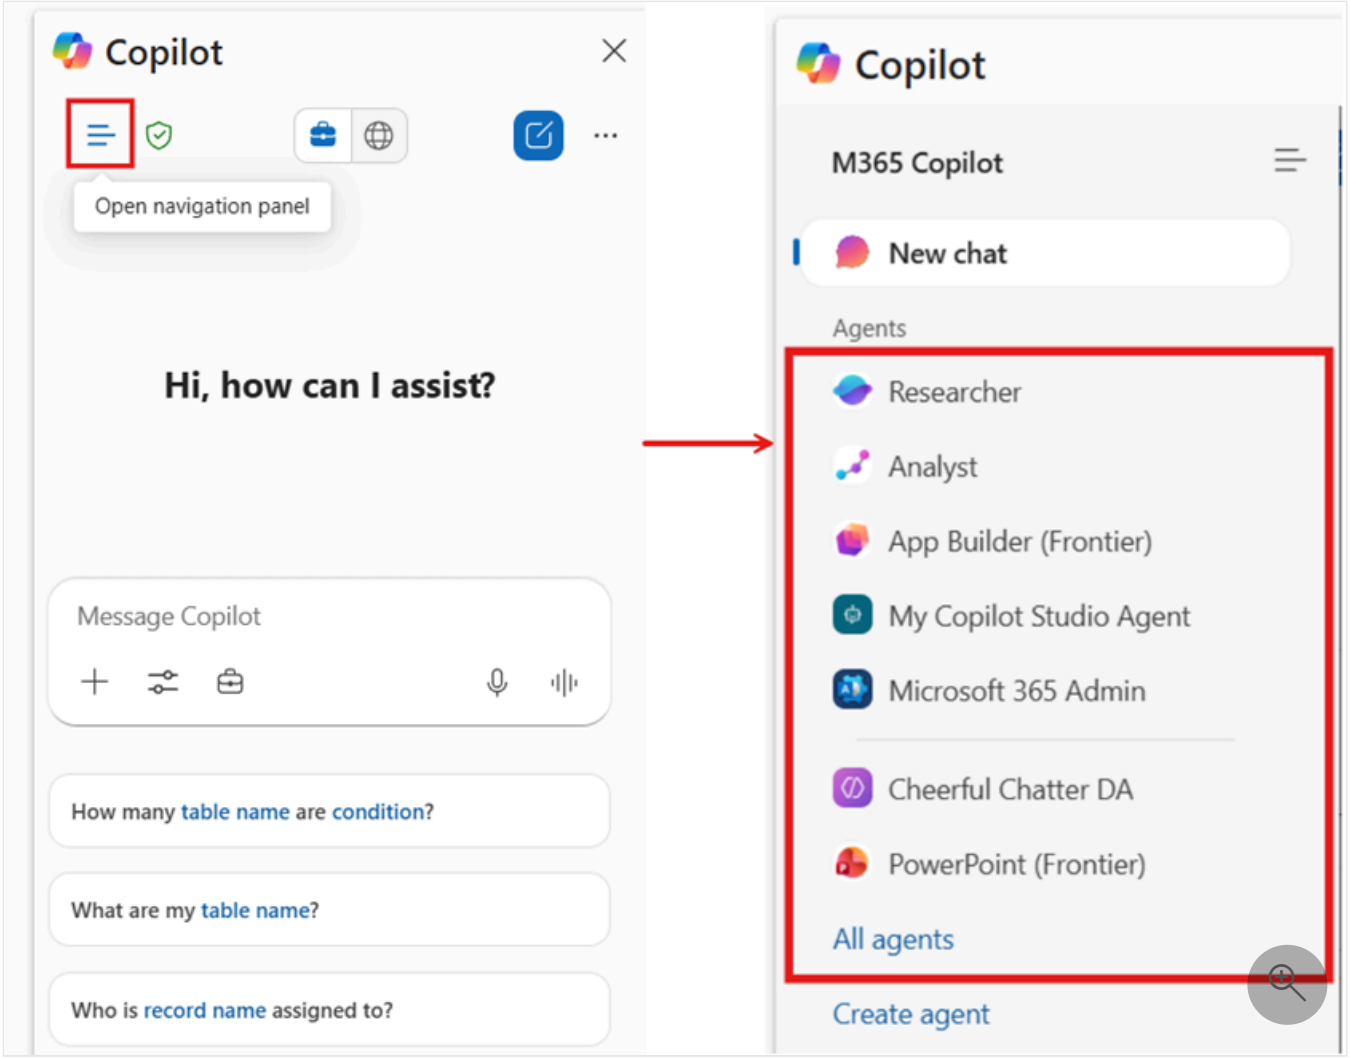
To help you get started, Microsoft 365 Copilot suggests questions to ask. Many suggested questions have placeholders you replace with appropriate text.



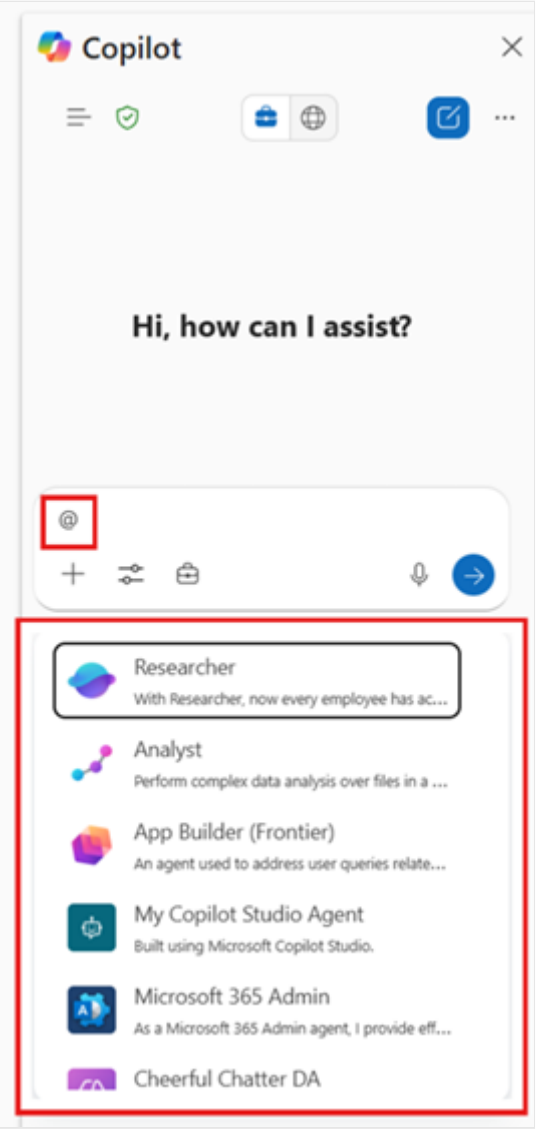
Use agents in Microsoft 365 Copilot

> **ⓘ Important**
>
> When you explicitly select an agent in Microsoft 365 Copilot in apps, the agent no longer answers questions about the Dataverse table or SharePoint list data in the app unless you explicitly configure your agent to do so. However, the agent uses information from the chat history. To get the side chat to answer questions about the Dataverse table or SharePoint list data in the app again, you need to remove the explicit agent selection.

Microsoft 365 Copilot in apps lets you use any agent available in Microsoft 365 Copilot right from the side pane. Once an agent is available within Microsoft 365 Copilot, you can interact with your agent by either choosing it from the navigation panel or @ mentioning it.



One of the benefits of @ mentioning an agent is that you can add or remove it from an ongoing conversation, which lets you have several agents collaborating in one conversation. When you select an agent from the navigation panel, you have a direct conversation only with the agent you selected.



Limitations

- M365 Copilot in canvas apps supports apps that use either SharePoint or Dataverse as a data source but not both within the same app.
- During the initial preview phase, for SharePoint, only applications containing a single SharePoint list will return answers to questions.
- If your canvas app connects to a SharePoint list through an environment variable, Microsoft 365 Copilot responses will not reference data from that SharePoint list.
- Microsoft 365 Copilot for canvas apps allows users to view data by using read-only operations. This capability means that users can only view data that matches their queries and can't make any changes. To make changes, customization with an agent is required.
- Microsoft 365 Copilot for canvas apps isn't available in the Power Apps mobile app.
- As this feature is being gradually deployed, certain settings in the Power Platform Admin Center might not be accessible yet, depending on the geographic location of your tenant.

Use model-driven apps in Power Apps

06/30/2025

A model-driven app has multiple components including dashboards, forms, views, charts, and business processes that make the app easy to use. Model-driven apps can also include AI features that let users to supervise and interact with agents around business processes more efficiently and productively.

This section explains how to navigate in a model-driven app, work with rows, import and export data, and automate processes by using Power Automate.

> **Important**
>
> Because canvas apps provide a lot of control over the user experience and can essentially be anything, there isn't much help documentation on how to *use a canvas app*. If you need help using a canvas app, contact your app maker or Power Apps admin.

Modern, refreshed look for model-driven apps

Model-driven apps have updated styling including fonts, colors, borders, and shadows that align with the latest Microsoft Fluent design system. The updated look makes model-driven apps easier to use so that users can accomplish their goals quickly and efficiently. The Fluent design system provides consistency, quality, and Microsoft-wide platform coherence. It also provides a solid foundation for extensibility and allows support for dark mode in the future.

> **Important**
>
> With the **2026 Wave 1** release, all users must use the **New Look**. Makers can't switch a model-driven app back to the classic look. This requirement doesn't include the **Header and navigation refresh (preview)**.
>
> The **New look** toggle was removed for users with the **2025 Wave 1** release.

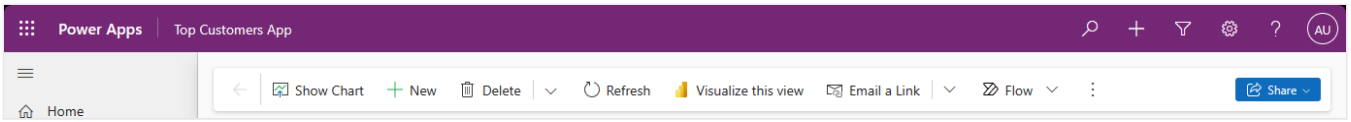
What's included in the modern, refreshed look

Here's what you can expect in the modern, refreshed experience:

- Updated styling in form, view, and dashboard pages, which includes the use of drop shadows and brighter background colors to create an elevated or *floating* appearance. The floating appearance helps to visually separate sections and focuses attention on primary content.
- New Fluent-based controls in forms, business process flows, and dialogs. Dialogs now resize height automatically based on the content.
- A new Power Apps grid in place of the read-only grid in view and standard, dashboard pages.
- A new mechanism for customizing the app header colors to match your personal or organizational branding. To learn more, see Use modern themes.

Command bar

The *floating* command bar aligns with the Microsoft 365 experience, with consistent spacing, rounded corners, and elevation. Notice how the command bar is in a separate section at the top of the page in the following example.

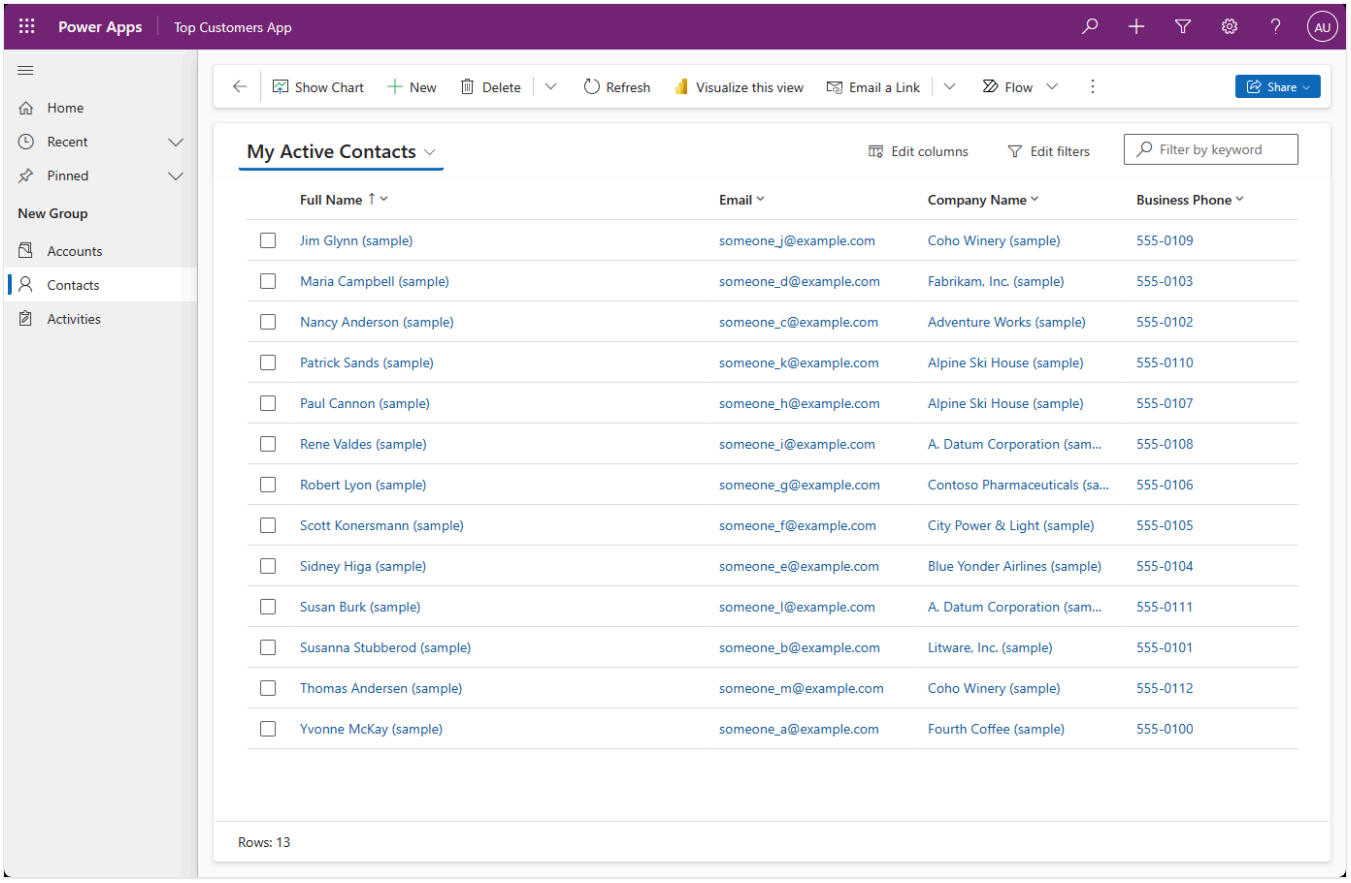


View pages

View pages use the new command bar and updated grid areas that take advantage of the elevation changes to help draw the user's attention.

The most significant change on view pages is the switch from the read-only grid to the Power Apps grid control, which features infinite scrolling for a modern, data browsing experience. This grid also appears in subgrids and associated grids in main forms and dashboards. The Power Apps grid control also supports inline editing by using the **Enable filtering** property. Makers can manually configure their editable grids to use the Power Apps grid control.

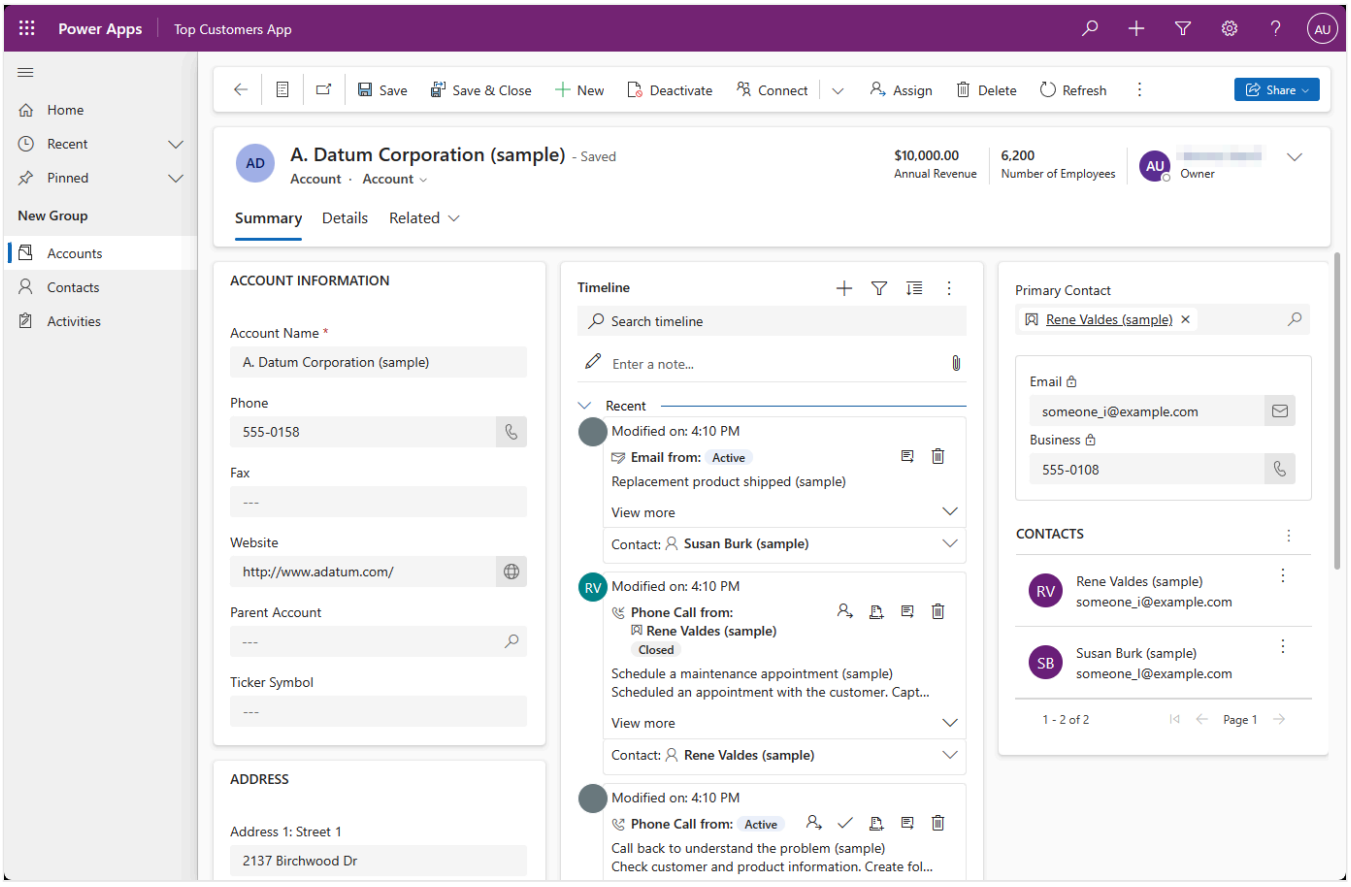
The following example shows a view page with the modern, refreshed look.



Form pages

Form pages use the new command bar with refreshed headers, tabs, sections, and business process flows. Quick views, card forms, headers, sitemaps, and timeline controls also feature updated styling.

The following example shows a form page with the modern, refreshed look.

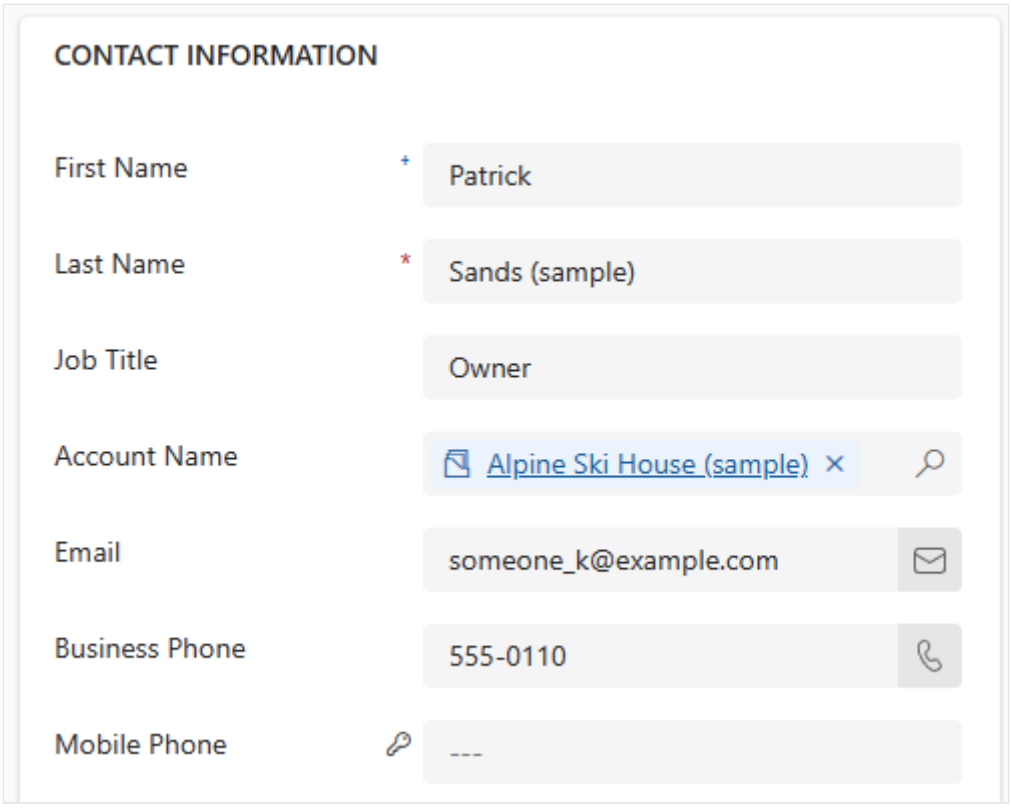


Field controls

Field controls such as text input, action input, lookup, and check box controls are built and designed by using Fluent components. Future updates will modernize more field controls by using Fluent design.

Field sections, which are containers for the fields on a form, have a more streamlined design. Icons are now on the right side of field labels. Some redundant icons were removed for a cleaner layout. Input and error message styling is also refreshed based on Fluent design.

The following example shows a set of fields with the modern, refreshed look.



Dashboard page

The system dashboard page, with independent subgrids and charts, uses the new command bar and has styling similar to the sections in form and view pages. When you turn on the modern experience, or when you use the monthly channel, the system dashboard grids use the new Power Apps grid control. The new grid isn't turned on by default.

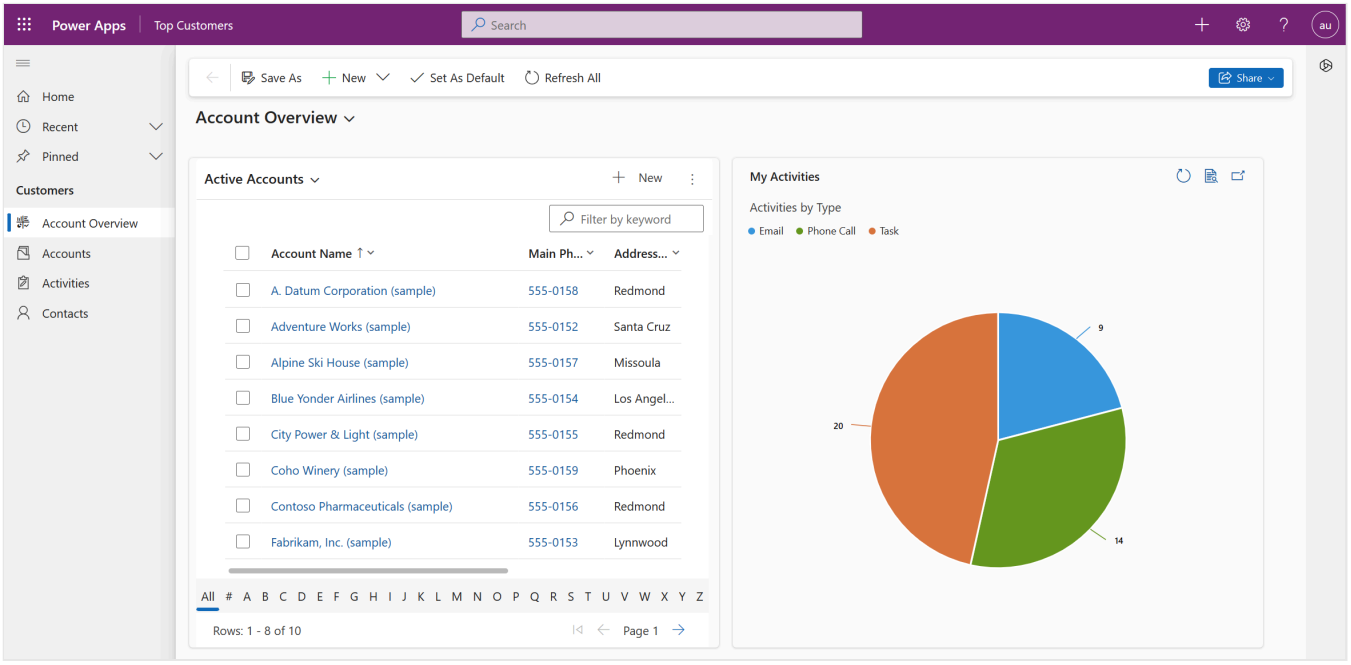


Chart controls

The chart controls on view pages and dashboards are updated to a new color palette for the modern, refreshed look.

If you customize the chart colors, the new look overrides your custom colors. To keep your custom colors, add the **CustomColorOverride** property in the chart .xml file.

XML

```
<Chart CustomColorOverride="true">
```

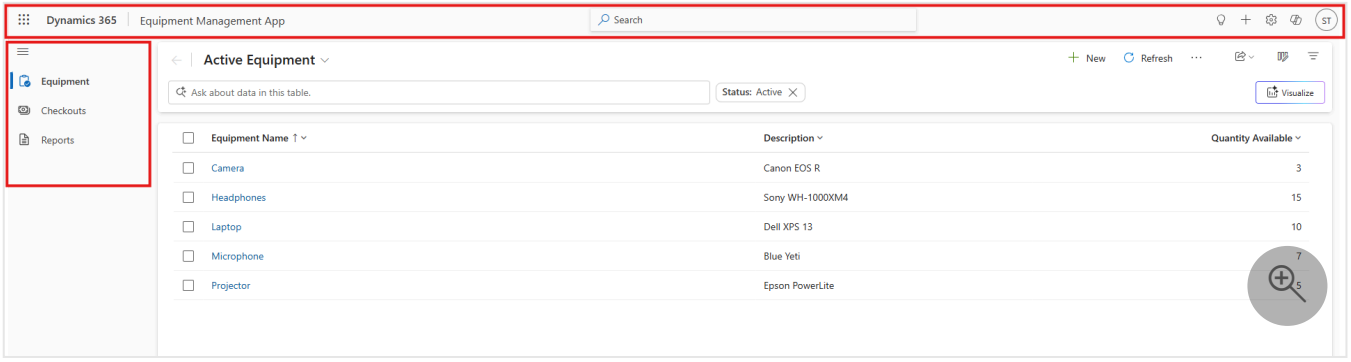
Header and navigation refresh (preview)

[This topic is pre-release documentation and is subject to change.]

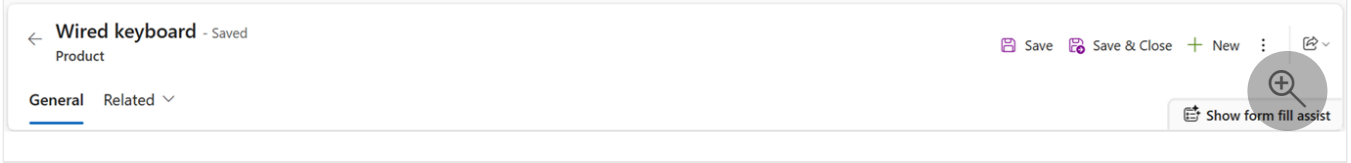
> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

The refreshed header and navigation make apps easier to use with a modern app header, streamlined sitemap, and condensed page headers with compact commands. This experience enhances productivity by reducing time spent navigating pages, finding commands, and learning layouts.

Here's how the new app header and the streamlined sitemap look:

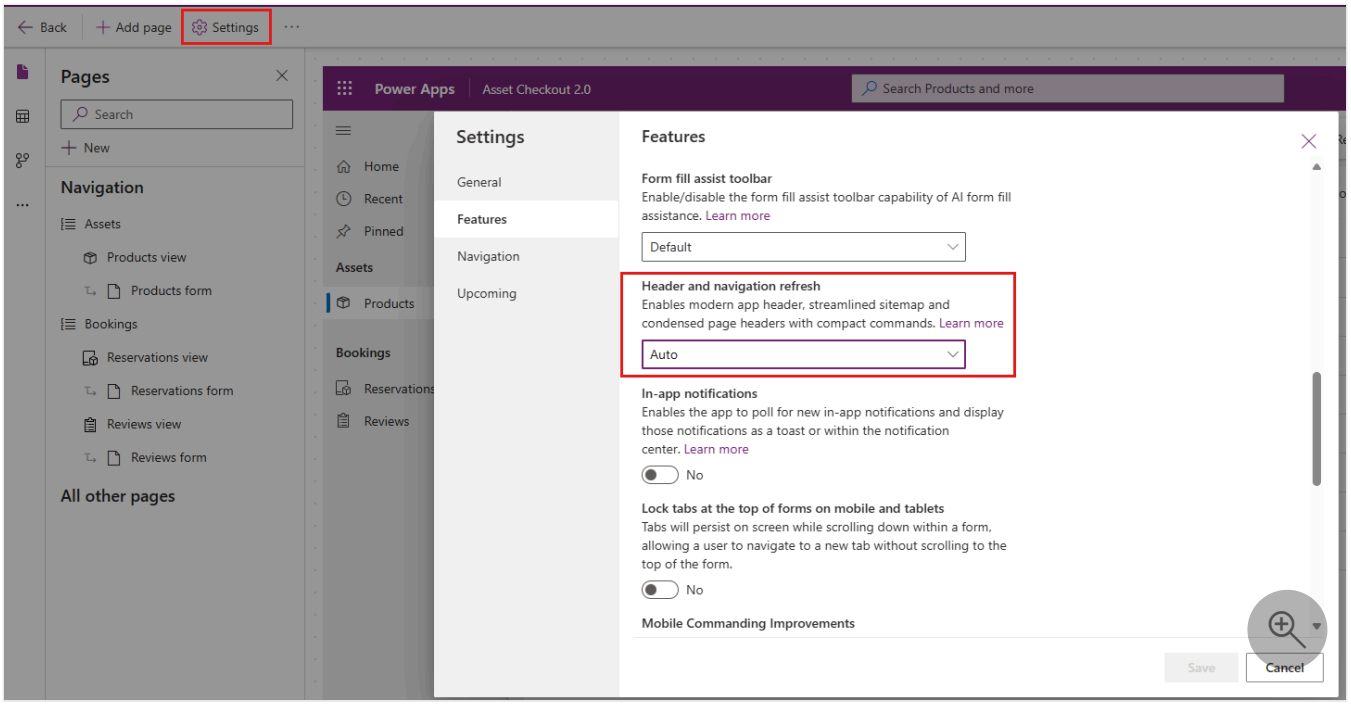


Here's how the new form header looks with more focus on row details:



This update automatically applies to all apps generated by the Plan designer. For other existing apps, you can opt in by following these steps:

1. In the app designer, select **Settings** on the command bar.
2. Select **Features**, and then enable **Header and navigation refresh**.



Learn more in FAQ for header and navigation refresh (preview).

Known limitations

The modern, refreshed look for model-driven apps has some limitations:

Modern, refreshed look outside of browser

The mobile app and mail app don't support the modern, refreshed look. They aren't part of the preview or general availability.

Switching themes or enabling dark mode

Switching themes or enabling dark mode isn't supported at this time.

Honoring classic theming

With the modern, refreshed look, Power Apps is no longer honoring classic theme customizations. You can, however, override the colors for the app header to match your organization branding with the modern, refreshed look. Learn more in Change the color of the

app header. Other theme customization options for the modern, refreshed look aren't available yet.

Custom icons

Only SVG icons are supported. If you use other formats such as PNG, the navigation doesn't display them and a default icon appears instead.

Frequently asked questions (FAQs)

1. Can I use the modern, refreshed look in the Power Apps component framework or in custom code components?

The modern theme in use is passed to Power Apps component framework components, so you can style your components with modern theming.

2. Can I use the modern, refreshed look in custom pages?

You can use modern controls with custom pages and the modern, refreshed look. Currently, custom pages don't use the modern theme.

3. Can I change the color of the app header?

You can change the color of the app header to match your organization while using the modern, refreshed look. To learn more, see Use modern themes. Other theme customization options for the modern, refreshed look aren't available yet.

4. FAQ for header and navigation refresh (preview)

Can I turn on Header and navigation refresh without turning on the New look?

No, you need to turn on New look in addition to turning on Header and navigation refresh to see the refreshed header and navigation experience in the app.

How do I enable the Header and navigation refresh for existing apps?

The feature is available as an opt-in capability for existing apps. You can enable it through the app setting.

Why don't I see the Help icon in the global command bar in the app header?

Help link to documentation is available in the **Settings** pane.

Where is the side pane rail next to the Copilot chat pane?

The side pane switcher becomes available only when there are two or more side panes in the app. When Copilot chat is the only side pane, the switcher is hidden.

Why does the sitemap of an app generated by the Plan designer look different from existing apps' sitemap?

Apps generated by the Plan designer will have a streamlined sitemap. Home, Recent, Pinned and sitemap groups are turned off by default for a simplified flat list of navigation options in the sitemap.

Revert to the classic look

> **Note**
>
> With the **2026 Wave 1** release, the **New Look** is mandatory for all users. Makers will no longer be able to switch a model-driven app to the classic look.

While end users have not been able to switch themselves back to the classic look since the **2025 Wave 1** release, admins can still turn off the new look for all users by updating the **New look for model driven apps** app setting.

1. Open https://make.powerapps.com/.
2. Under **Solutions**, open an existing solution with one or more model-driven apps.
3. Select **Add Existing** > **More** > **Setting**.
4. Search for **New look**.
5. Select **New look for model driven apps**.
6. Select **Add** to add it to the solution.
7. Select **New look for model driven apps** from the solution explorer.
8. Update **Setting Environment Value** to **No**.
9. Add the **apps to the solution** for which you want to turn off new look.
10. Update the **value of the apps** to **No**.
11. Select **Save**.
12. Publish all customizations.

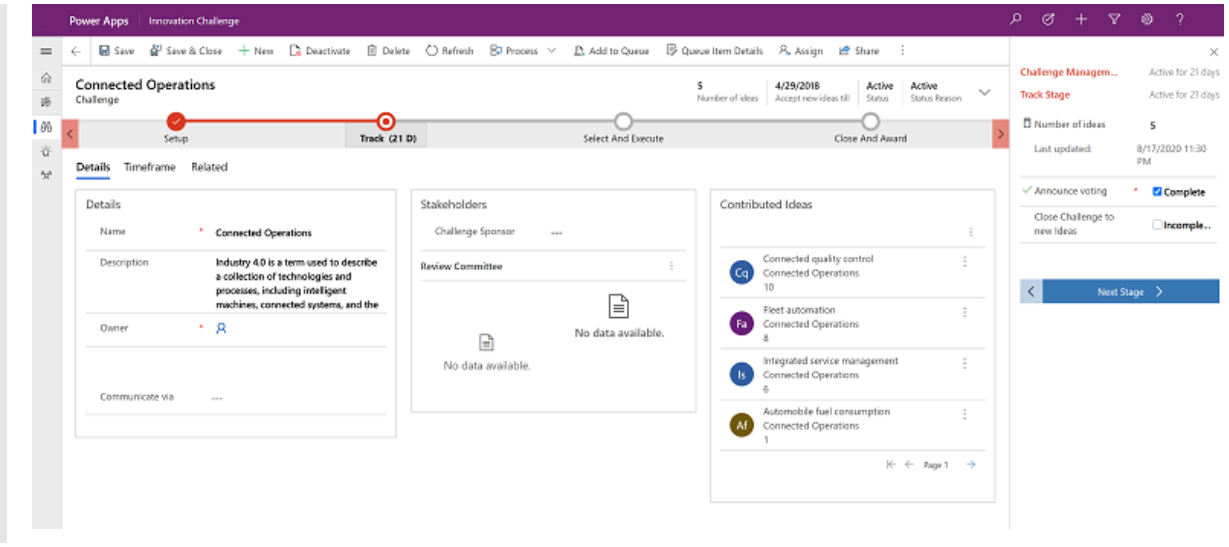
To learn more about this and other app settings, see Manage model-driven app settings in the app designer.

Last updated on 03/24/2026

Enhanced user experience with Unified Interface for model-driven apps

Article • 06/27/2023

Unified Interface for model-driven apps provides a consistent and accessible user experience across devices—whether on a desktop, laptop, tablet, or phone. The apps scale by reflowing the components on the screen. The responsive design adapts to your environment based on screen size, so the more available space that you have, the more information can be displayed.



For an overview of Unified Interface in model-driven apps, watch this video: Introduction to Unified Interface

Reflow

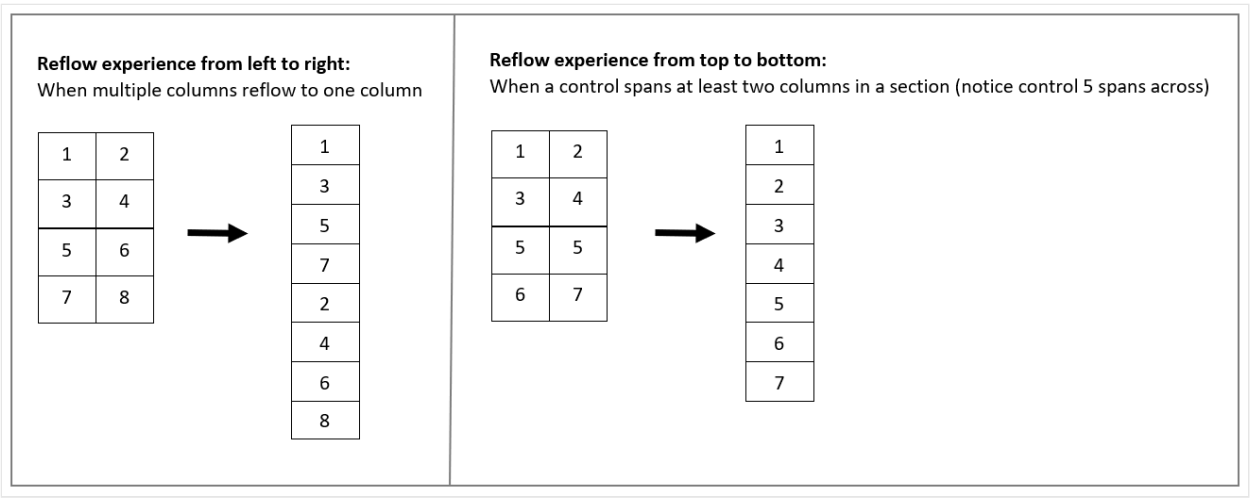
Unified Interface is designed for a modern reflow experience.

For forms, there are pixel breakpoints that cause information on a form to move on the screen based on the space available for the form to display in. This happens when the display space available to the form decreases. For example, if you resize the window that your app is in and decrease the width of the window it will decrease the space available for the form to display in. When the width decreases past certain breakpoints, information that would be hidden will move below where it used to be so that it is either visible or you can vertically scroll down to see it.

When columns in a form section reflows from multiple columns to one column, it reflows from top to bottom. When a control spans at least two columns in a section,

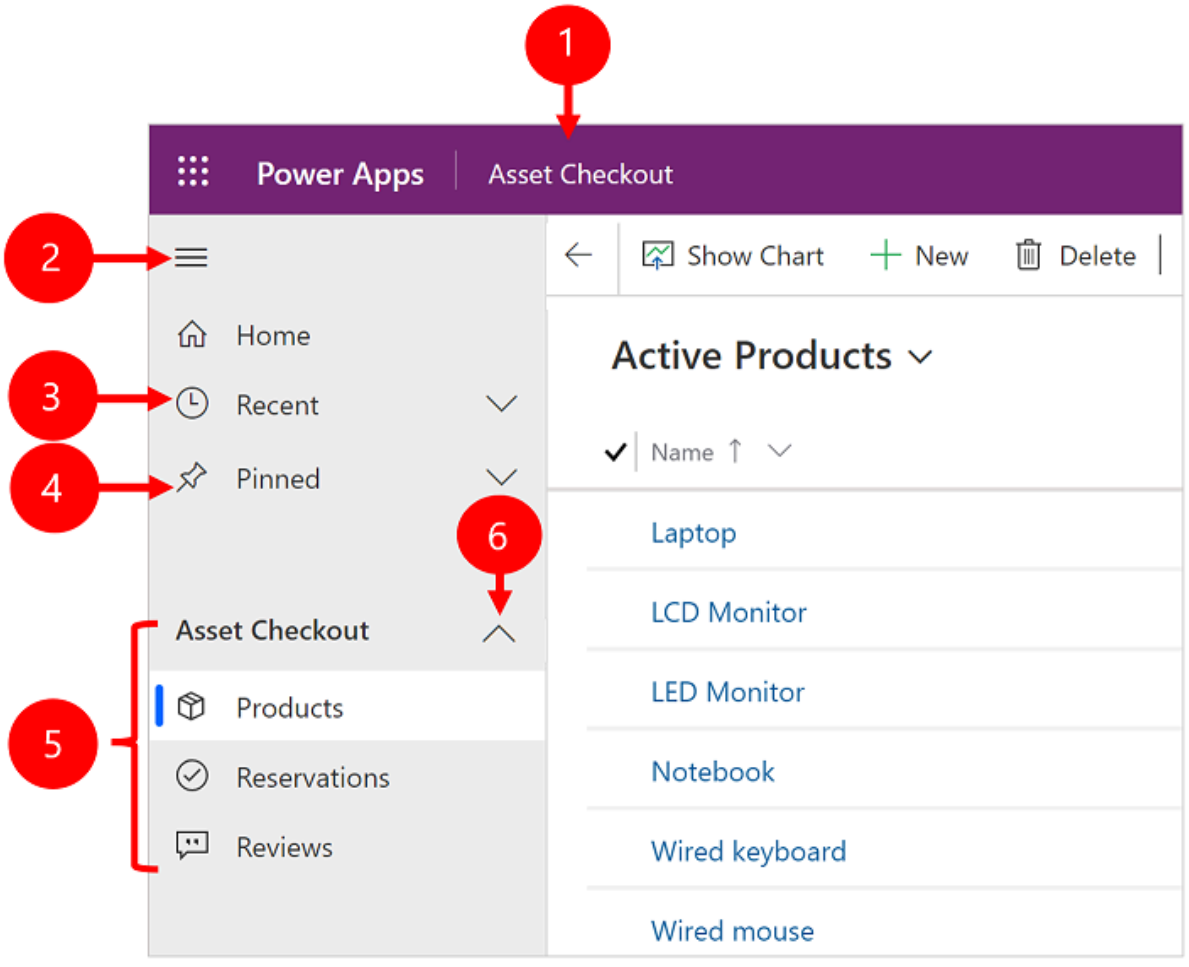
then it reflows from left to right (in left-to-right languages). The difference in behavior is so that tab navigation order is kept after reflow.

In example below, each number corresponds to a control.



Navigation

The menu options let you swiftly navigate the different apps in the system. They provide quick access to recently viewed rows and pinned favorites.



Legend

1. **Click to change app**: Select the current app name to change a differ app.
2. **Collapse/expand button**: Select this to collapse the navigator to allow more room for the main part of the page. If the navigator is already collapsed, select this button to expand it again.
3. **Recent rows**: Expand this entry to view a list of rows you were recently using. Select a row here to open it. Select the push-pin icon next to a row listed here to add it to your favorites (pinned rows).
4. **Favorite rows**: Expand this entry to view and open your favorite (pinned) rows. Use the **Recent rows** list to add rows here. Select the remove-pin icon next to a row listed here to remove it from this list.
5. **Page navigation**: This area lists each entity and dashboard page available for the current work area. Select any entry here to open the named dashboard or list view for that entity.

For more information, see Basic navigation in a model-driven app.

Dashboards and charts

You can access all the system and user dashboards from within your Unified Interface apps. The interactive dashboards are now available for all row types with richer interactive dashboard capabilities. For more information, see Track your progress with dashboards and charts.

Timeline control

The timeline view helps you collaborate with your team by tracking customer communication in a row on a single page in an easy-to-read view. You can see everything from posts and voice attachments, to emails and notes. It provides a quick way to see the entire communication thread. For more information, see Add an appointment, email, phone call, notes or task activity to the timeline.

Business process

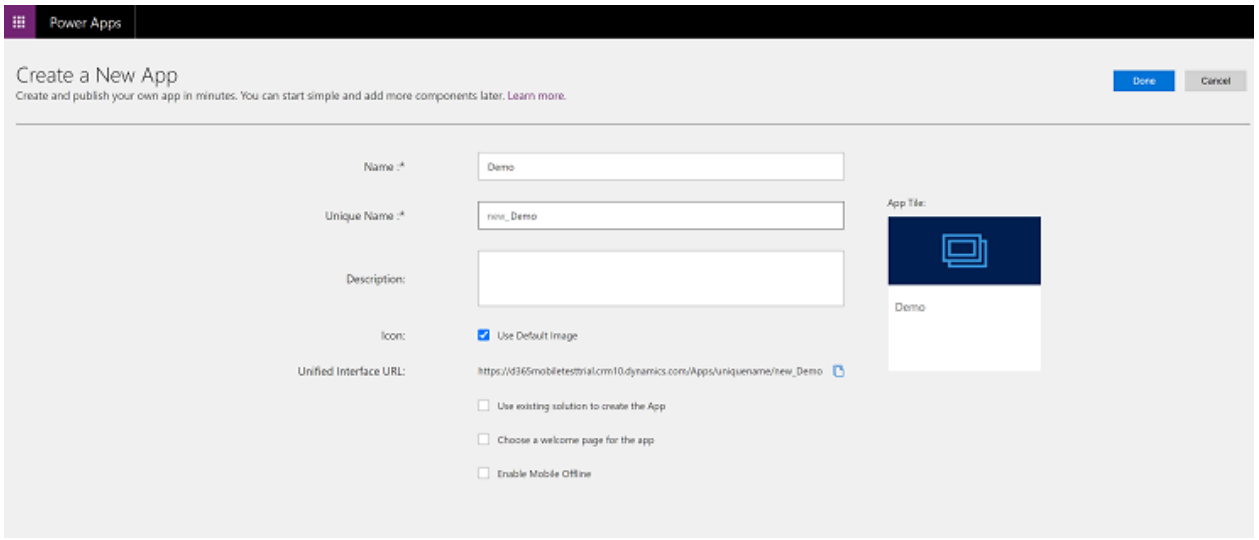
The business process flow has been improved by the docking mechanism. You can dock the business process stage on your screen to help you stay focused on the task at hand in your business process flow. This is especially useful when the stage of the process has complex steps to complete. For more information, see Work with business processes.

Accessibility

The improved accessibility experience lets you use screen readers to translate on-screen information into audible sound and print to a Braille reader so that more people can use the app. For more information, see Use a screen reader.

Create a Unified Interface app

If you have requirements to create your own experience on Unified Interface, you can create a model-driven app using the app designer. See Overview of building model-driven apps.



Feedback

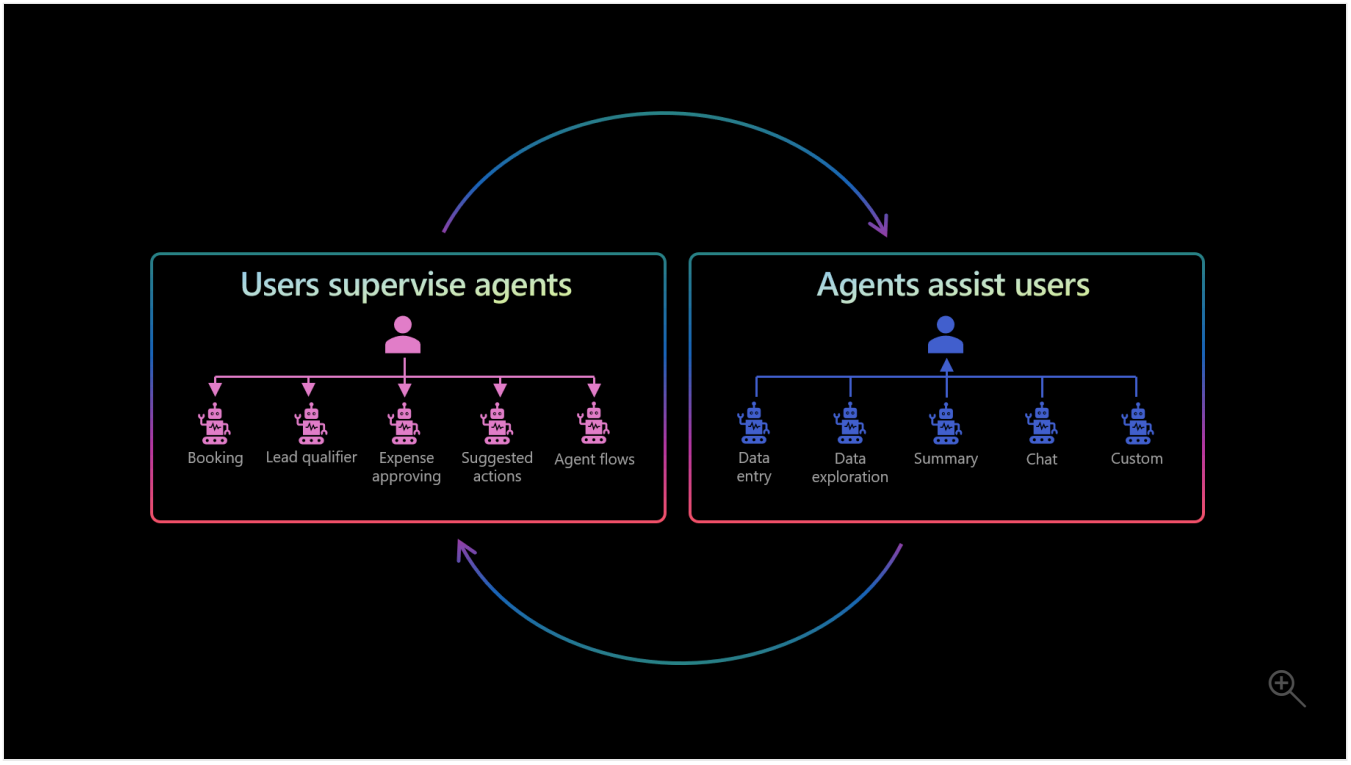
Provide product feedback

AI features overview

AI features in apps combine model-driven apps with intelligent automation and assistance. Business users can supervise their team of AI agents doing work on their behalf, spot-checking accuracy, intervening when they get blocked, and handle exceptions. Users get inline assistance from agents, fill out forms faster, explore data more easily, and understand what changed at a glance. AI in apps lets users supervise and interact with agents around business processes for more efficiency and productivity.



Prerequisites

Copilot needs to be enabled for your tenant and environment, and apps need to have the new look turned on. AI features also have their own enablement settings.

Agent supervision

Agent feed helps business users manage and work with agents directly in their apps. It makes apps a central hub for human-agent collaboration by showing a complete activity feed of what agents have done on their behalf, wherever they are in the app.

- Add agents to be supervised in app
- Supervise agents in app

AI in apps

Built-in skills help you enter, explore, and summarize data faster and better.

Data entry

- Get assistance filling forms
- Smart paste into forms
- Draft richer text

Data exploration

- Explore data in a view
- Generate data visuals for a view

Summary

- Create custom row summaries
- See row summaries in a form and view

Copilot in apps

- Microsoft 365 Copilot in model-driven apps
- Customize Microsoft 365 Copilot in model-driven apps
- Chat with Copilot
- Customize Copilot chat

Custom AI experiences

- Use APIs to create custom AI-powered experiences
- Add an agent response control

Last updated on 04/15/2026

Use Microsoft 365 Copilot in model-driven apps

Microsoft 365 Copilot for apps is a next-generation AI assistant that helps you gain insights into the data in your apps through conversations in natural language. Microsoft 365 Copilot boosts your productivity through AI-powered insights and navigation assistance.

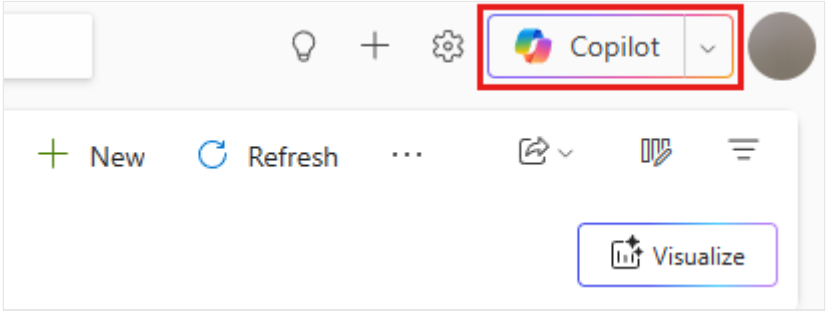
Prerequisites

An administrator must enable Microsoft 365 Copilot in your application before it becomes visible in your app. For more information, see Add Microsoft 365 Copilot for app users.

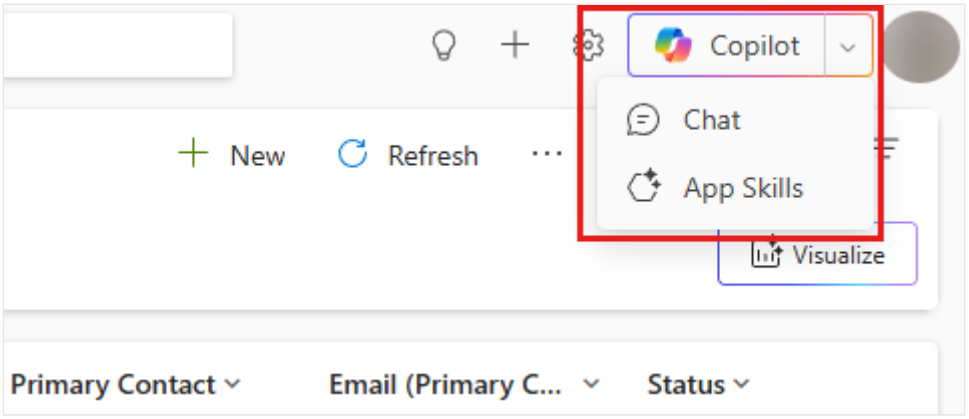
> **Note**
>
> To use the Microsoft 365 Copilot feature in your app, you must have both a Power Apps premium license and a Microsoft 365 Copilot license.

Copilot pane

After Microsoft 365 Copilot is enabled, access it through the Copilot button near the upper-right corner of the page.



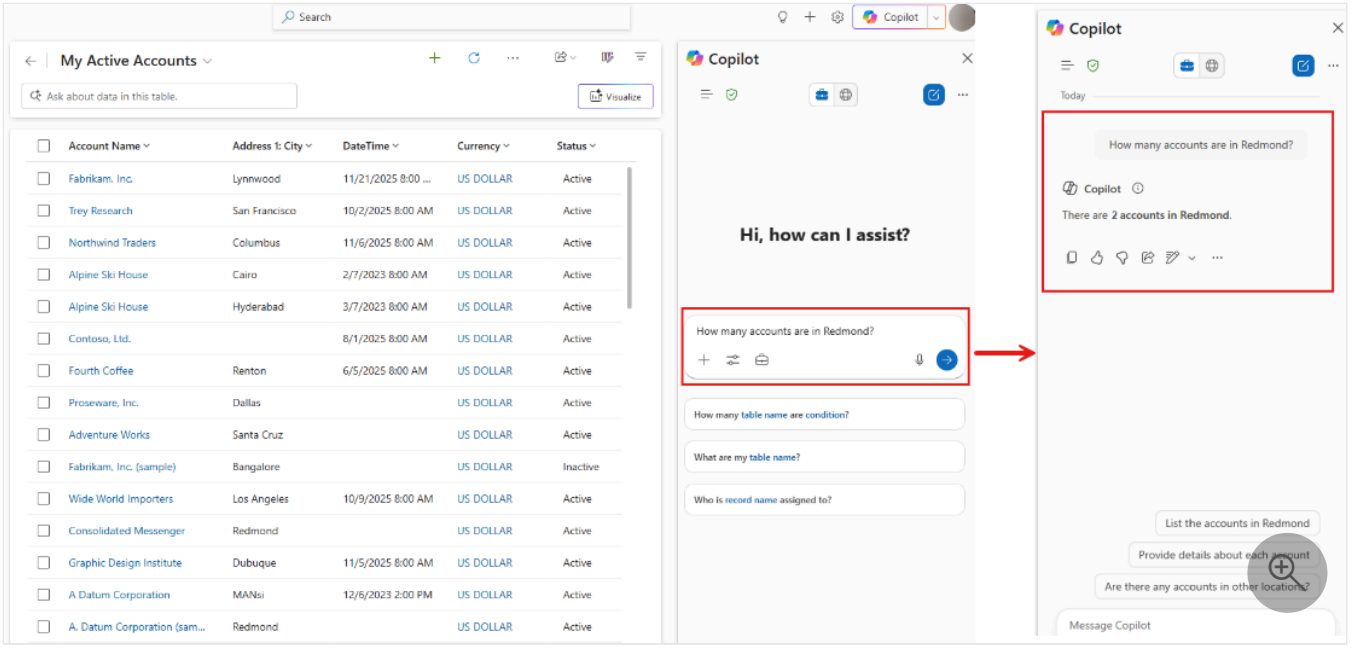
If both Microsoft 365 Copilot and Copilot chat in apps are enabled, you can access and try each option. The **Chat** option opens Microsoft 365 Copilot, and the **App Skills** option opens Copilot chat in apps. These terms align with Microsoft 365 apps for consistency.



Expand or collapse the Microsoft 365 Copilot pane as needed.

Use Microsoft 365 Copilot to ask questions

Microsoft 365 Copilot in apps answers questions about the Dataverse table data in the app.



Share your feedback

Help us improve Copilot responses by using the feedback controls on each response. Provide feedback for every response:

- If a response is high quality and helpful, select the thumbs up button.
- If a response is incorrect, incomplete, or not helpful, select the thumbs down button.

When you provide feedback, share as much information as possible. For example, include what you expected to see, what was missing or incorrect, and any relevant context. The more detail you share, the better we can understand your feedback and continuously improve responses.

Copilot

Today

Show me all the accounts in Redmond.

Copilot

Here are **all the accounts in Redmond** that I found in your app. There are **3 accounts total** that have their city set to *Redmond*:

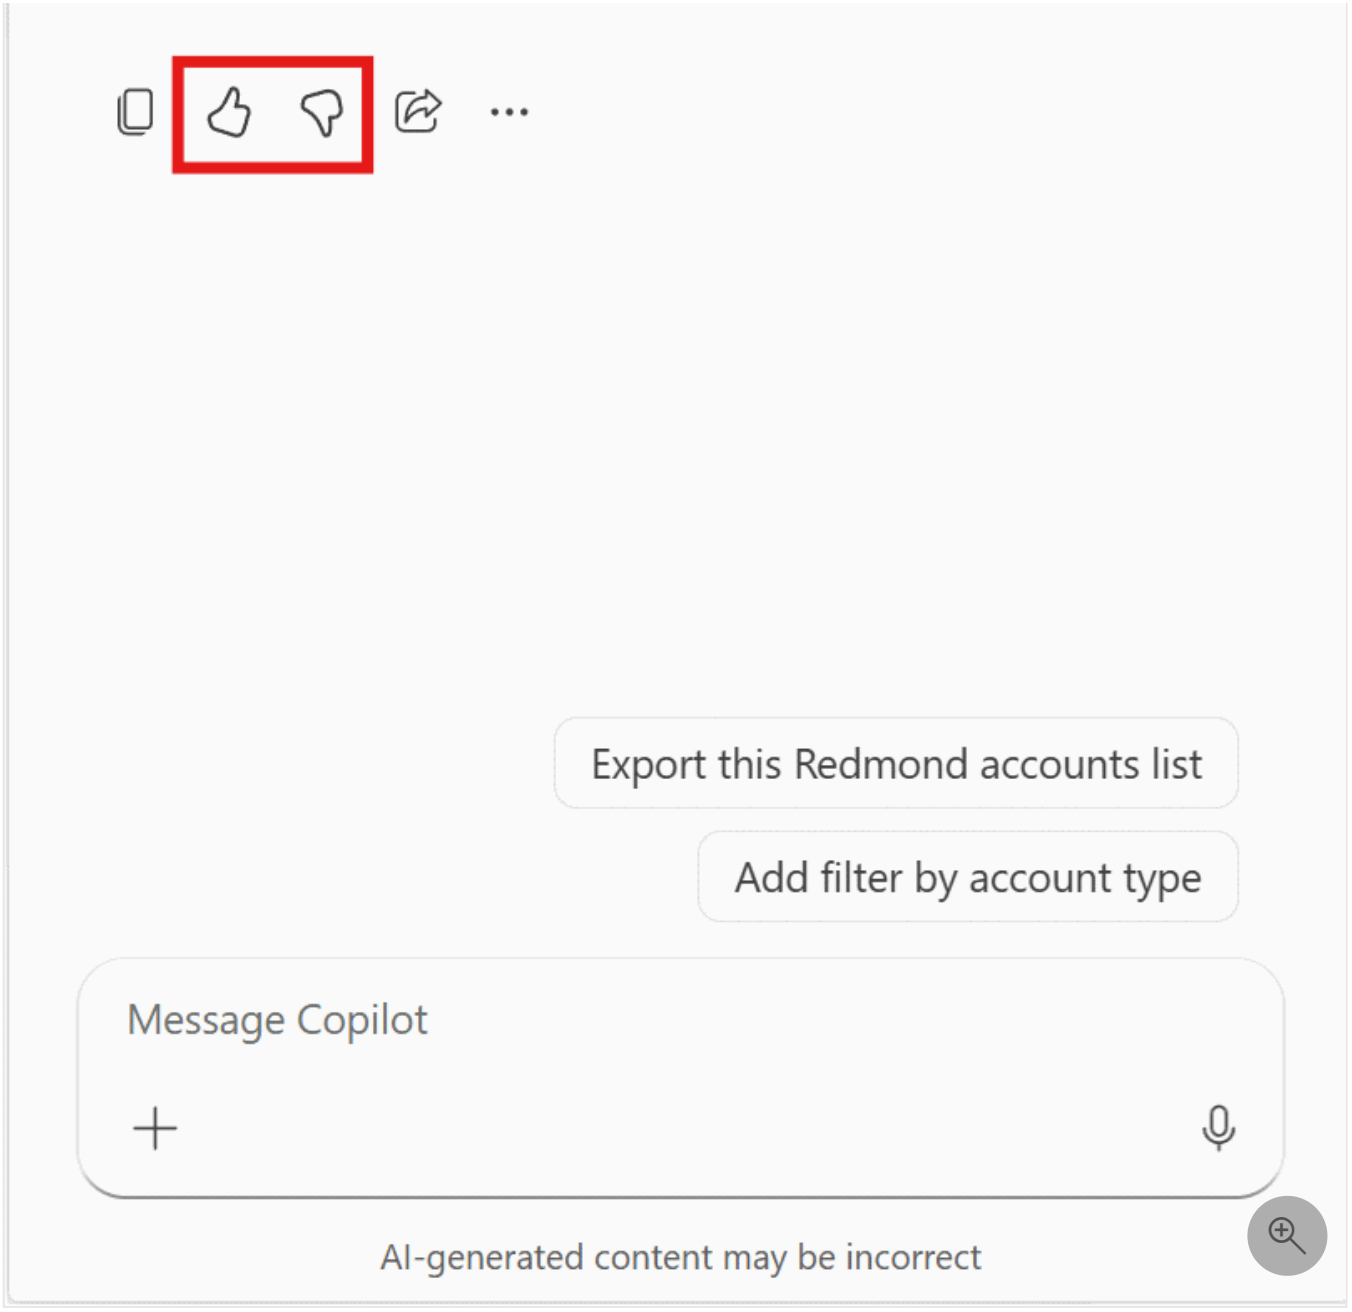
Accounts in Redmond

Account Name	City
City Power & Light (sample)	Redmond
Contoso Pharmaceuticals (sample)	Redmond
A. Datum Corporation (sample)	Redmond

If you'd like, I can:

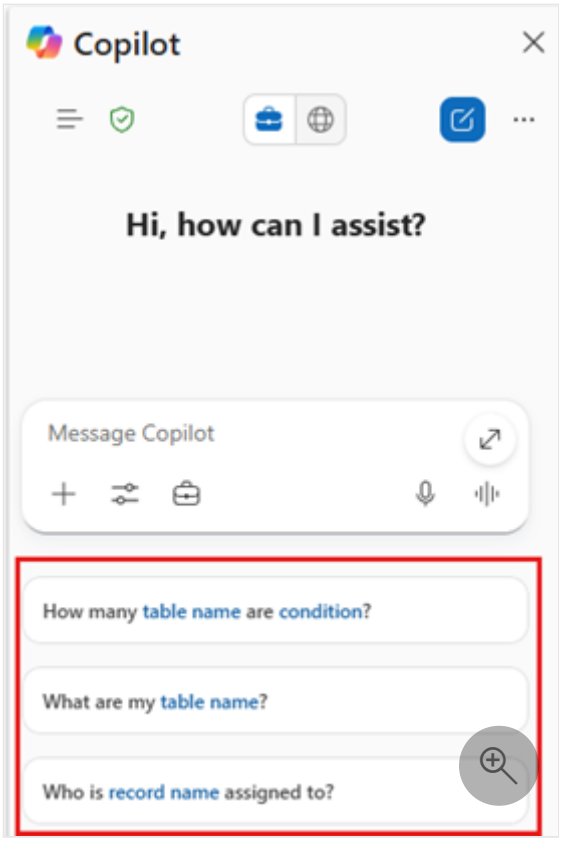
- Open any of these accounts
- Export this list
- Add additional filters (state, owner, account type, etc.)
- Turn this into a saved view for quick access

Just let me know how you want to use this.



Microsoft 365 Copilot suggested questions

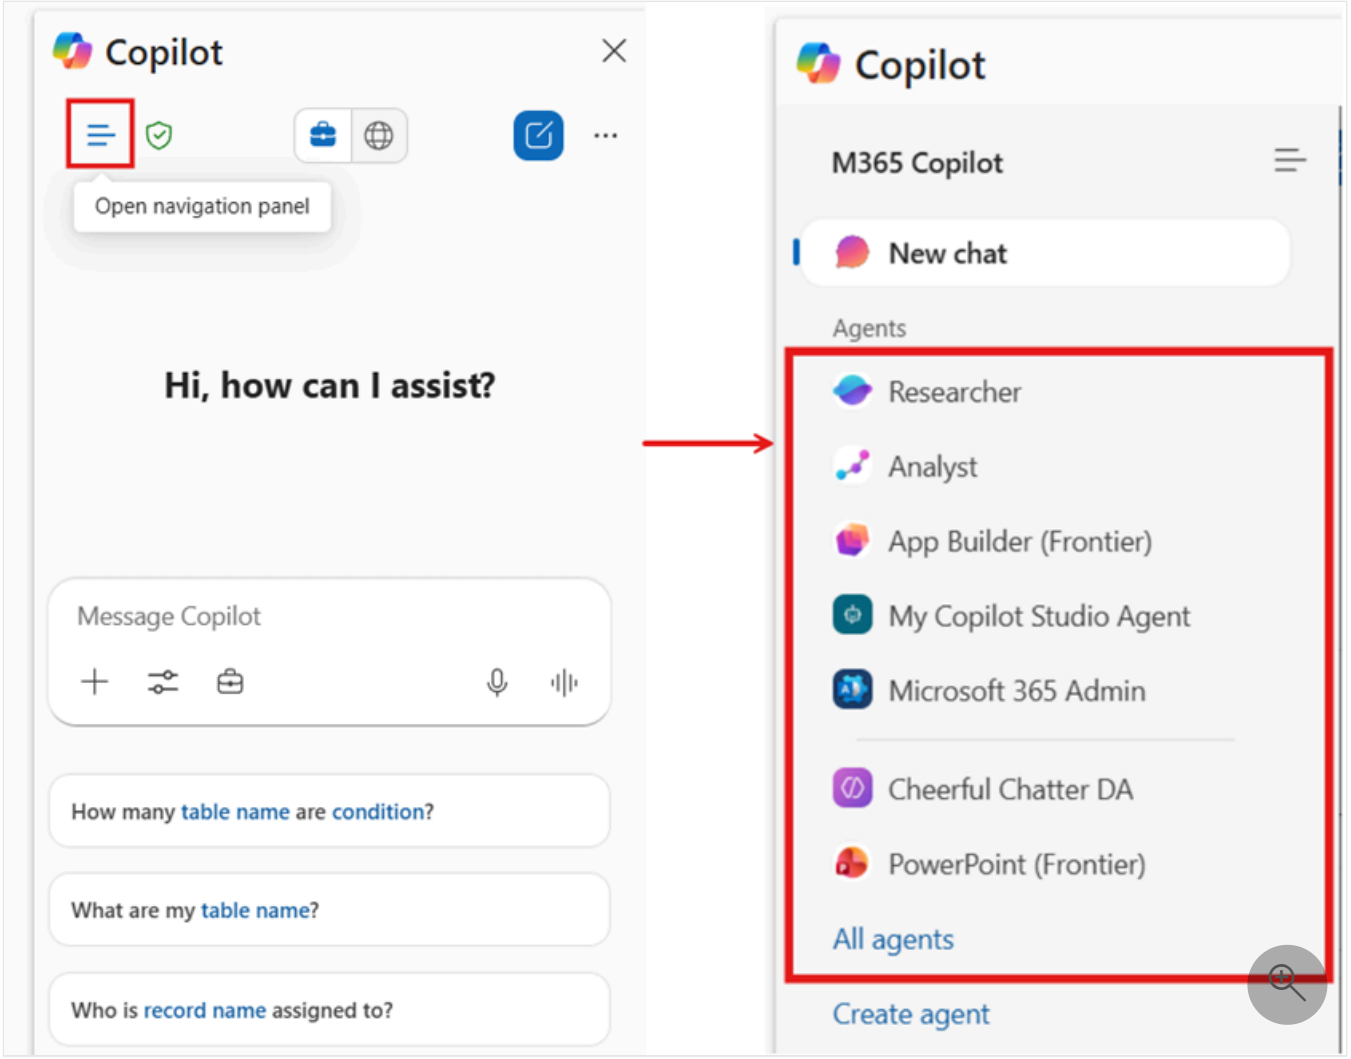
To help you get started, Microsoft 365 Copilot suggests questions to ask. Many suggested questions have placeholders you replace with appropriate text.



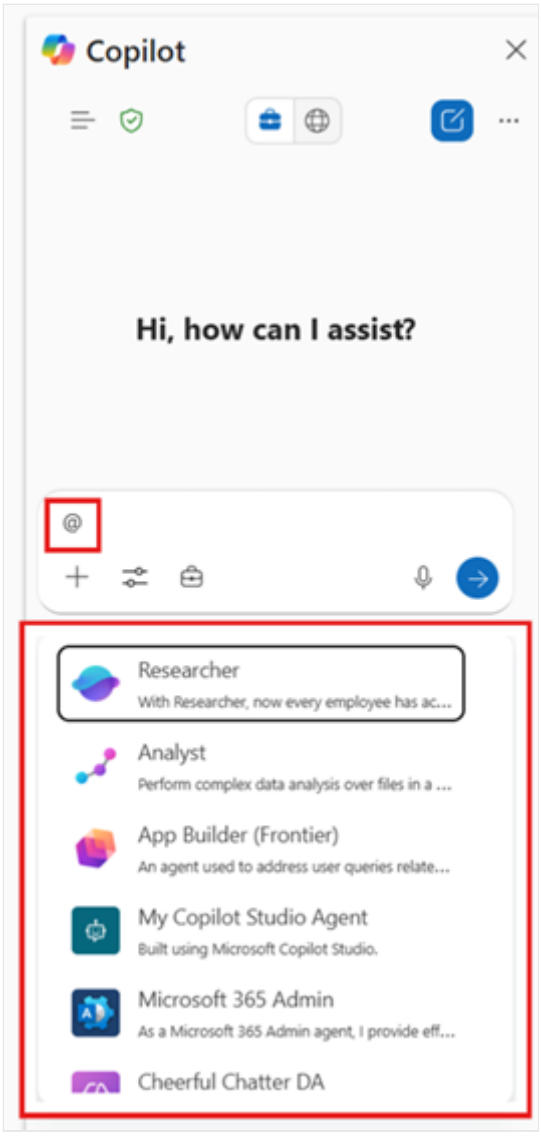
Use agents in Microsoft 365 Copilot

> **Important**
>
> When you explicitly select an agent in Microsoft 365 Copilot in apps, the agent no longer answers questions about the Dataverse table data in the app unless you explicitly configure your agent to do so. However, the agent uses information from the chat history. To get the side chat to answer questions about the Dataverse table data in the app again, you need to remove the explicit agent selection.

Microsoft 365 Copilot in apps lets you use any agent available in Microsoft 365 Copilot right from the side pane. Once an agent is available within Microsoft 365 Copilot, you can interact with your agent by either choosing it from the navigation panel or @ mentioning it.



One of the benefits of @ mentioning an agent is that you can add or remove it from an ongoing conversation, which lets you have several agents collaborating in one conversation. When you select an agent from the navigation panel, you have a direct conversation only with the agent you selected.



Limitations

- Microsoft 365 Copilot for model-driven apps allows users to view data by using read-only operations. This capability means that users can only view data that matches their queries and can't make any changes. To make changes, customization with an agent is required.
- Microsoft 365 Copilot for model-driven apps isn't available in the Power Apps mobile app.
- As this feature is being gradually deployed, certain settings in the Power Platform Admin Center might not be accessible yet, depending on the geographic location of your tenant.

Related information

- Add Microsoft 365 Copilot to model-driven apps

Supervise agents in model-driven apps with agent feed (preview)

[This article is prerelease documentation and is subject to change.]

> **Important**
>
> Starting May 01, 2026, agent feed will support those agents only that use the Power Apps MCP server to create tasks. Make sure that your agents are properly onboarded to the Power Apps MCP server by this date to continue using the agent feed. If your agents don't use the Power Apps MCP server, the agent feed won't appear in your model-driven app.

Agent feed enables human-agent collaboration in apps by surfacing agent-generated, actionable tasks that users can review, validate, and complete. By using agent feed, apps act as a collaboration surface where users supervise and interact with agent work through a unified, task-based feed.

Prerequisite

The agent feed shows when at least one agent uses the Power Apps MCP server and is supervised in the app. Learn how to Add agents to an app.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is being gradually rolled out across regions and might not be available yet in your region.
> - This feature is only available in English language and replaces older Microsoft Copilot Studio activity-based agent feed version.

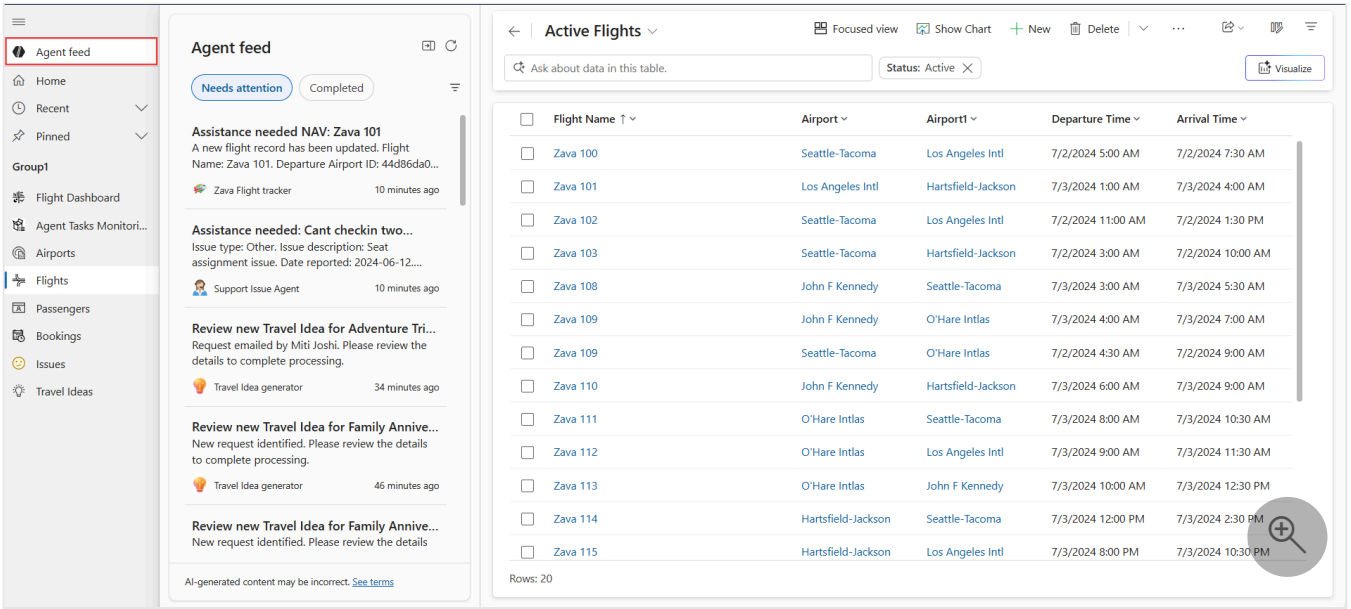
> **Note**
>
> Currently, all users who have access to the Agent Task table can see agent feed items in apps. To prevent unintended exposure, don't configure agents to log tasks targeted at specific users.

Use agent feed to supervise agents

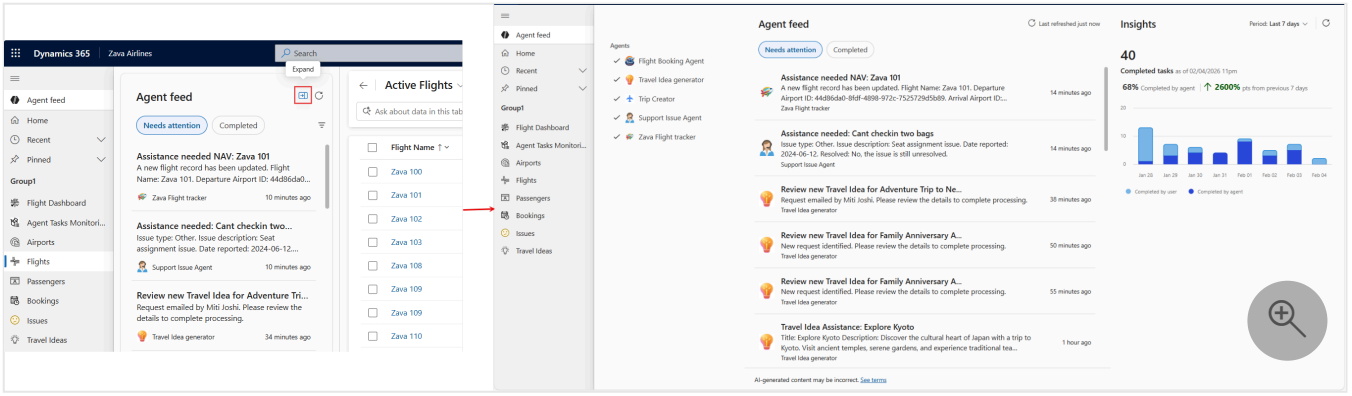
The enhanced agent feed is powered by the autonomous agents using Power Apps MCP server. Power Apps MCP server tools enable following two core human-agent collaboration patterns:

1. Autonomous Dataverse record creation and updates with human-in-the-loop approval and review.
2. Agent requests for human assistance and logging tasks for human review. In agent-enabled apps, user focus shifts from doing the work to supervising and prioritizing agent-driven work. Agents help with automations and organize work, ensuring business experts remain involved in decision-making and critical actions.

To allow users to view an agent's activity in the app, the agent must connect to Power Apps MCP server. The agent feed appears at the top of the site map in an app.

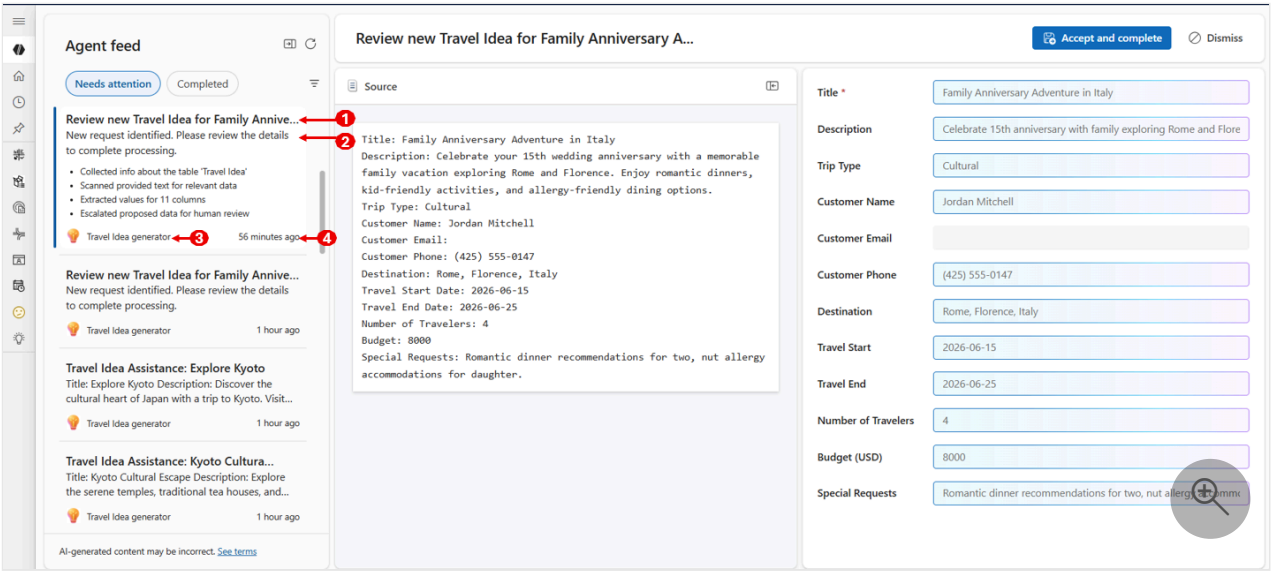


You can view the feed in the side pane or expand it to full screen.



The feed shows a list of agent tasks. Each item can include:

- Title of the task
- Description of the tasks with optional steps
- The agent's name and icon
- A timestamp of when the task was logged

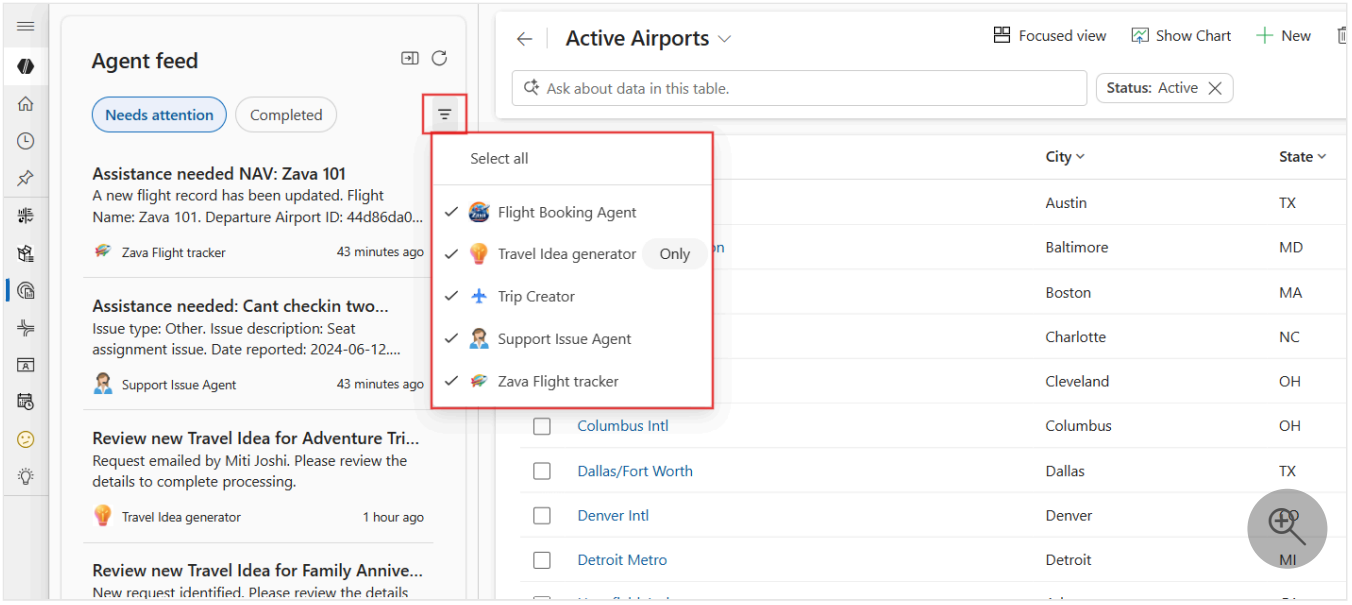


Activity is grouped into two sections:

- **Needs Attention**: Shows tasks that are waiting for your input or need your attention. These tasks are logged by using the `request_assistance` or `invoke_data_entry` MCP tools.
- **Completed**: Displays all other agent feed tasks, including tasks the user completed and tasks the agent completed that are logged for review by using the `request_review` MCP tool.

By default, each section loads 20 agent tasks and lazy loading is enabled as you scroll. The sections are sorted chronologically by the last modification date of each action.

You can filter the feed by agents.

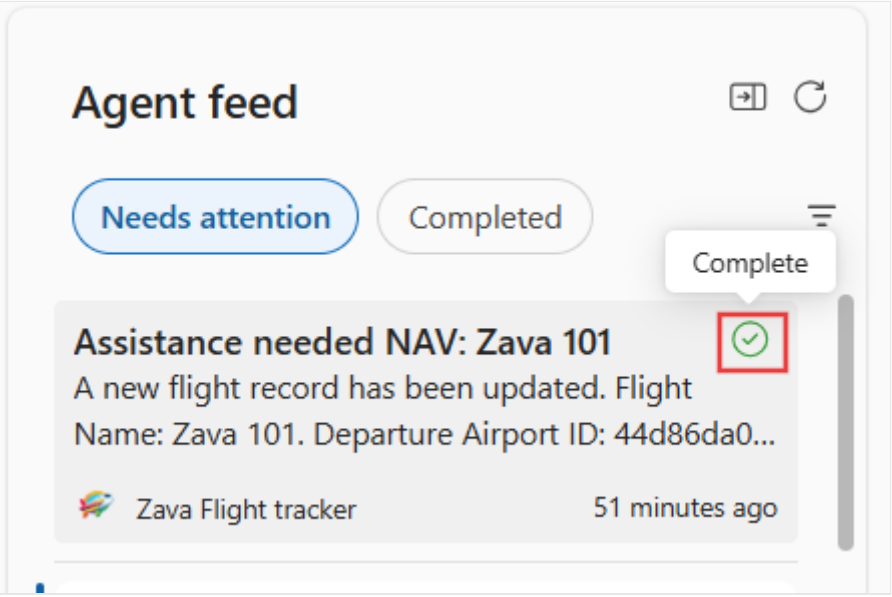


View the agent feed in a side pane to support multitasking or expand it to full screen for focused review.

Take action on agent activity

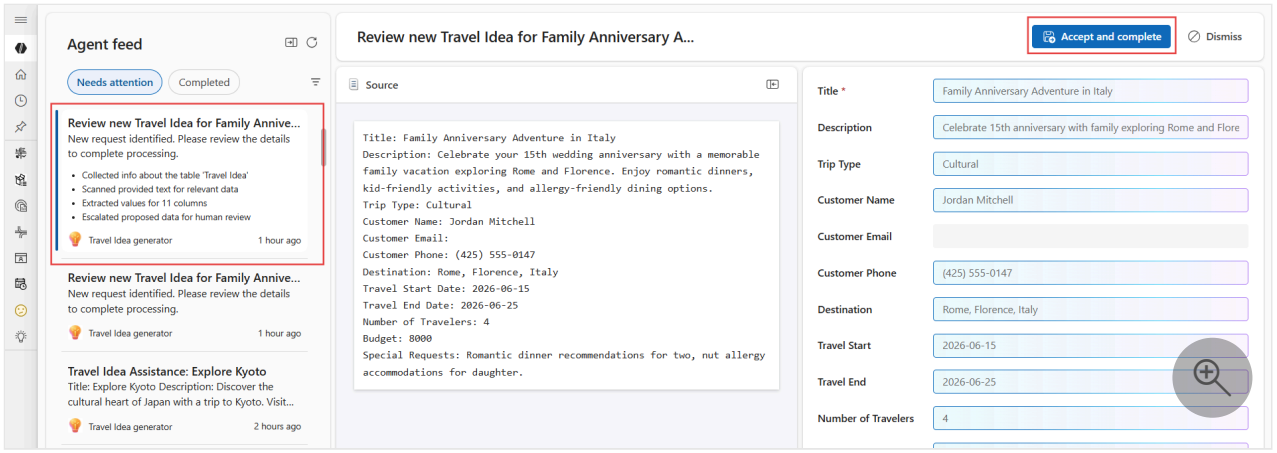
Take these actions on tasks under the **needs attention** tab in agent feed:

- **Complete**: Move a task from the **needs attention** section to **Completed** after completing the task the agent couldn't finish. This action is available for the agent tasks logged by using the **request_assistance** mcp tool.

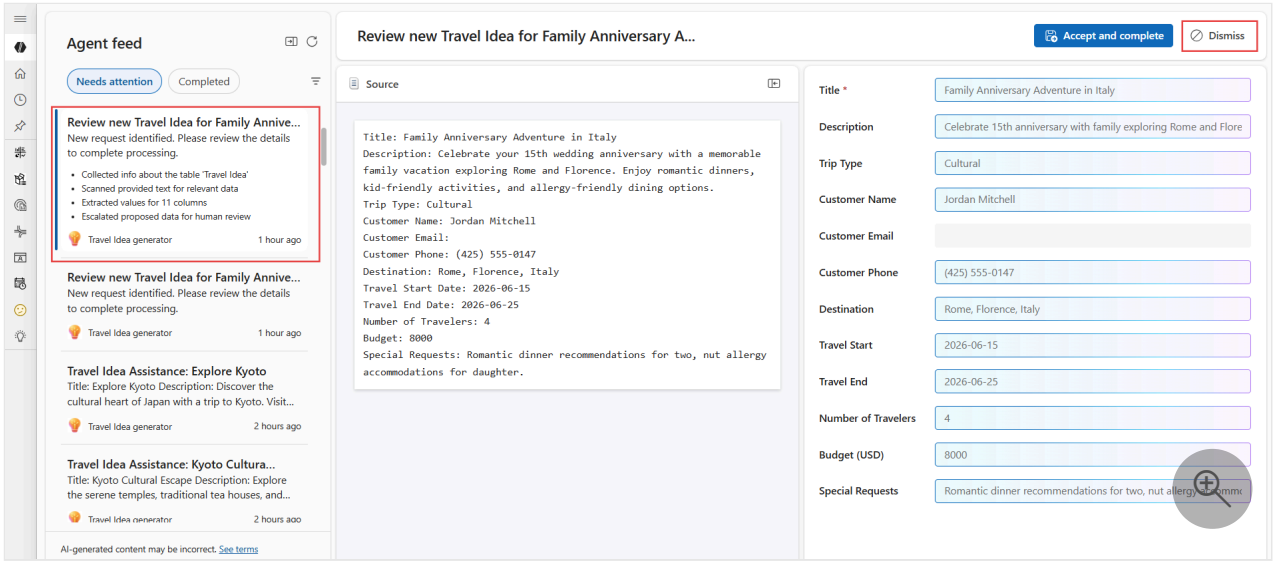


- **Accept and complete**: Move a data entry task from the **Needs attention** section to **Completed** after reviewing and accepting the data entry suggestions from

invoke_data_entry mcp tool. The **Accept and complete** button is available inside the agent pane associated with the agent feed task.

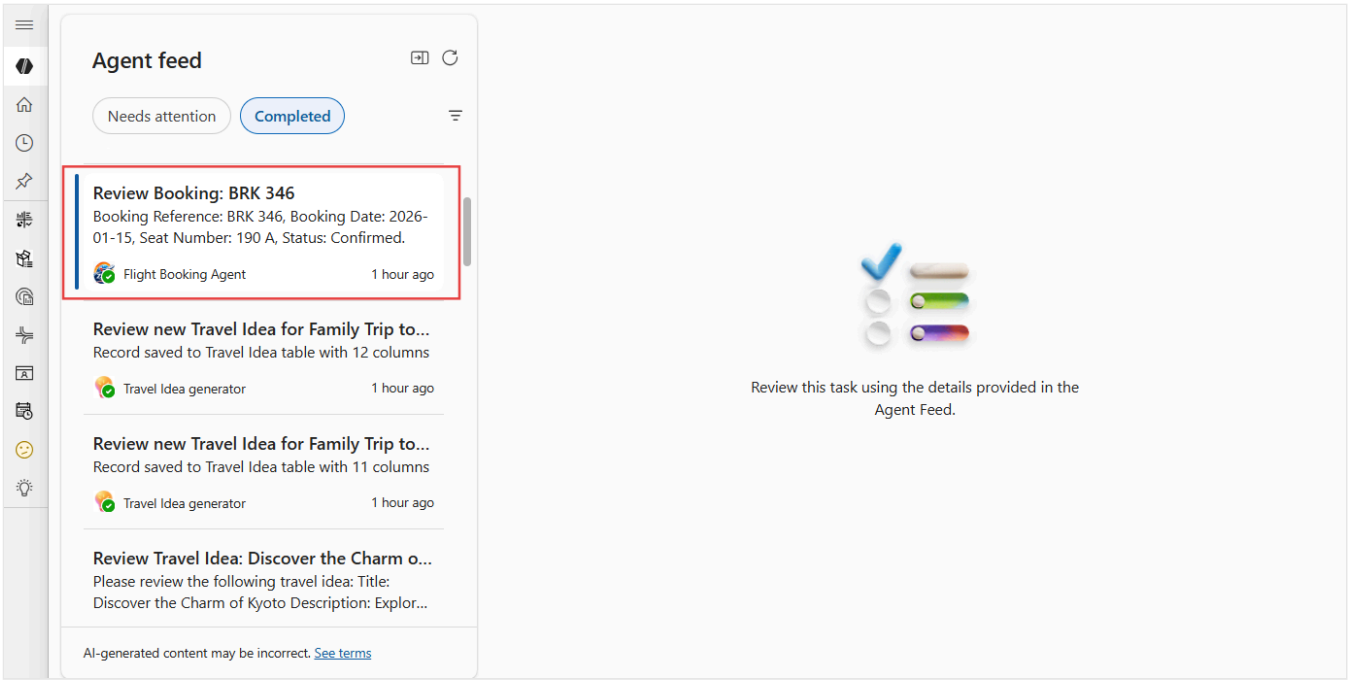


- **Dismiss**: Remove a data entry task logged via **invoke_data_entry** mcp tool from the **Needs attention** section if it's no longer relevant. The **Dismiss** button is available inside the agent pane associated with the agent feed task.



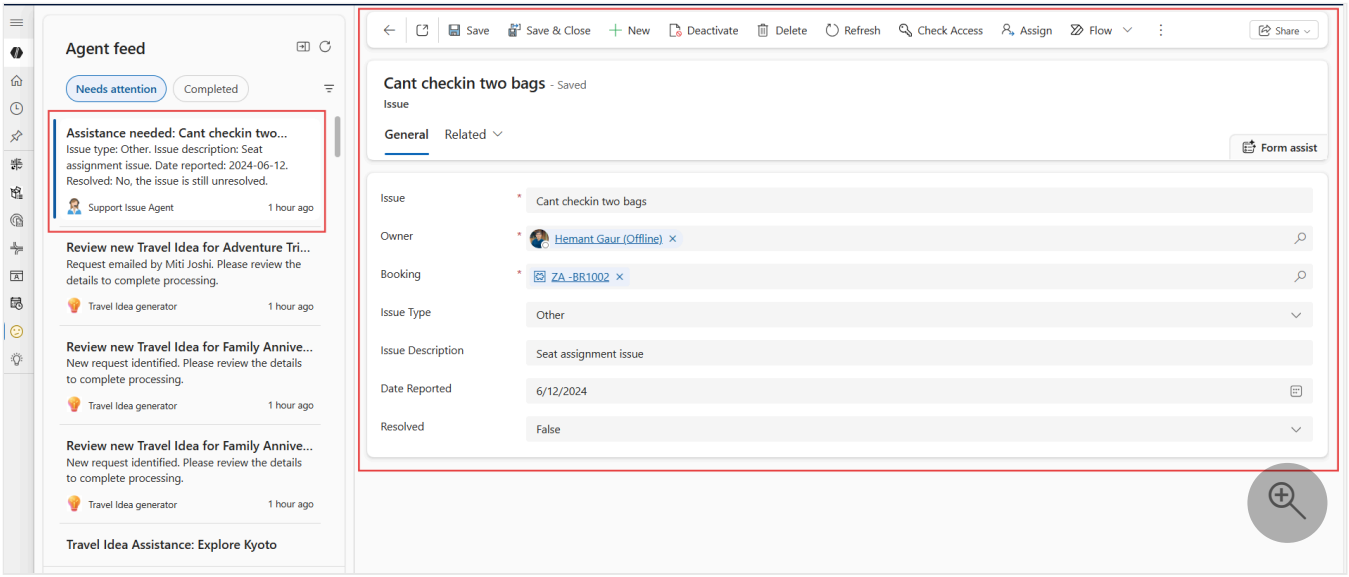
> **Note**
>
> You can perform all actions either from the main screen in the feed or from the details page of a specific action.

- **Request_review tasks**: Tasks logged via request_review mcp tool don't have any actions for the users. They're informational tasks completed autonomously by agent and can be found in completed agent feed tab.



Navigation from agent feed item

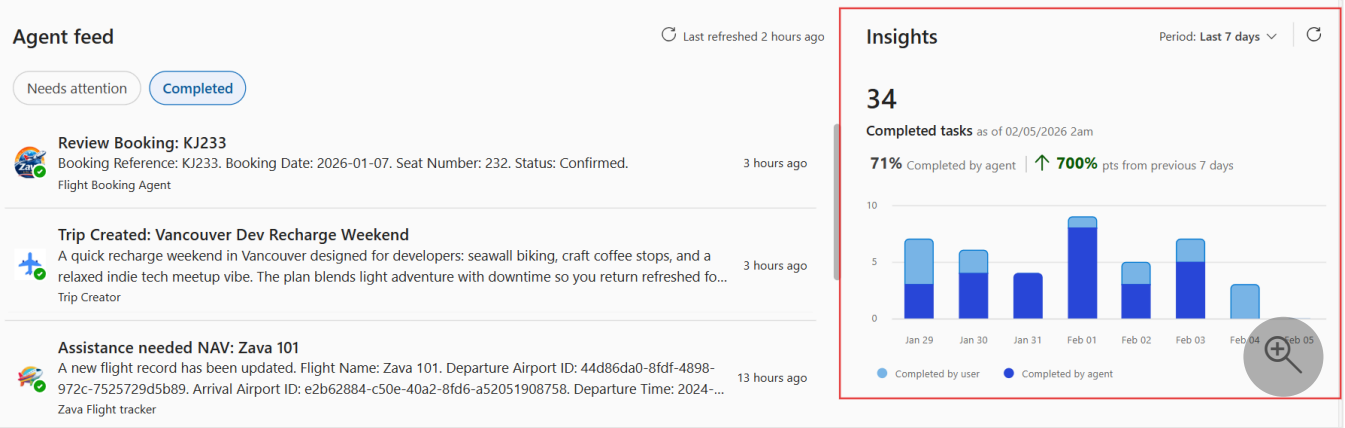
Agent feed tasks generated through the request_assistance or request_review MCP tools can reference a Dataverse record as a related navigation link in the agent description. This reference allows users to easily open and review associated data when interacting with the feed item.



Insights panel

The default insights panel complements the agent feed by giving users a clear, aggregated view of how their agents and users collaborate over time. While the agent feed surfaces individual tasks and actions in the moment, the Insights chart provides a historical, high-level representation of those interactions. This representation helps organizations understand the

true patterns of human–agent collaboration, whether users step in to provide missing context, guide agents through a complex workflow, complete tasks directly, or monitor agent activity. By visualizing these trends over time, organizations gain transparency into how their agentic workflows actually operate in practice, strengthening trust, identifying friction points, and revealing opportunities to improve system reliability and user experience.



The insights chart presents aggregated activity across the last 7, 14, or 30 days. It gives customers a time-based snapshot of collaboration between agents and users. Activity is categorized into two groups:

- Tasks completed by agents
- Tasks completed by users These at-a-glance aggregations offer a concise understanding of collaboration volume and balance over time. They help teams quickly assess how work is distributed across human and agent participants.

Add agents to an app

Customize Copilot Chat

Last updated on 04/07/2026

Use AI form fill assistance feature in model-driven apps

Form fill assistance suggests AI-generated content for fields, making it easier and faster to enter data in forms. The suggestions are entirely optional and aren't saved until the user explicitly reviews and accepts them.

Prerequisites

- Form fill assistance is available for all apps on the web where the modern, refreshed look is turned on.
- Requires at least one of the AI form fill assistance environment feature settings enabled.
- The **Allow form fill assistance** column property is enabled for the column where form fill assistance occurs. For more information, see Create and edit columns in Dataverse using Power Apps.

Limitations

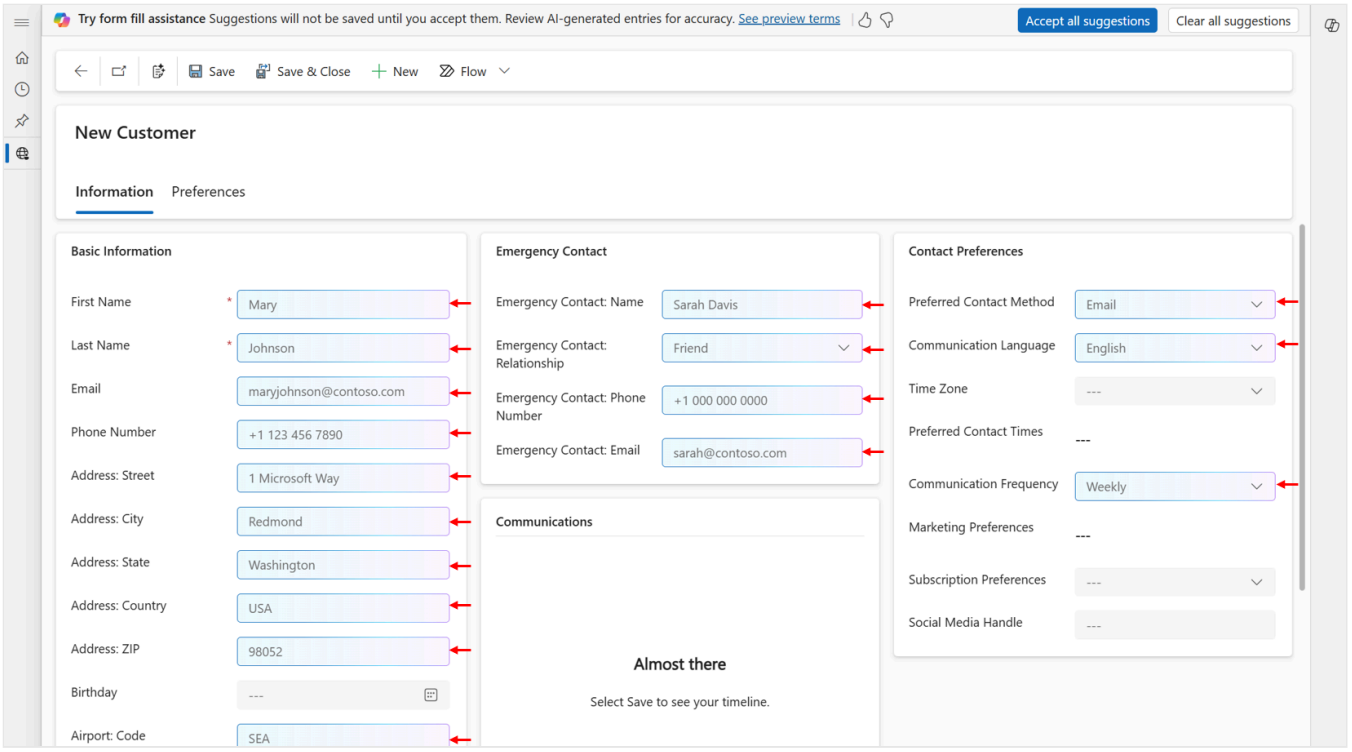
- Inside apps, suggestions are provided for fields only in main forms and quick create forms. In Microsoft 365 Copilot chat, suggestions are provided for fields based on main forms only.
- The currently supported field types inside apps are text, numeric, choice, and date. The currently supported field types inside Microsoft 365 Copilot chat are text, numeric, choice, date, and lookup.
- Fields that have column security aren't currently supported.

Use form fill assistance in apps

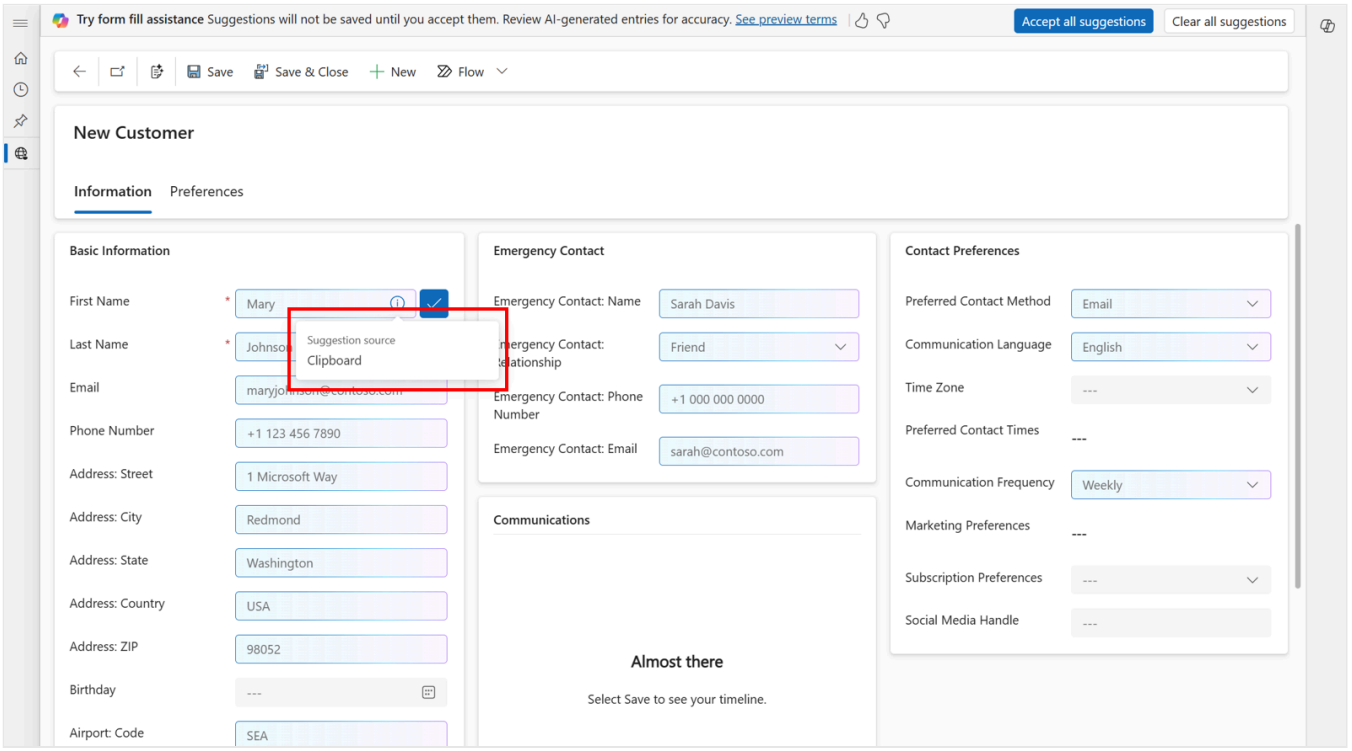
Form fill assistance in apps (Power Apps and Dynamics 365) provides suggestions for blank form fields in three ways:

1. Based on the user's usage of the app, what information is already available in the form, and their frequently used data.
2. Based on the copied text the user provides through the **Smart paste** capability.
3. Based on the file contents the user provides through the **Files** capability.

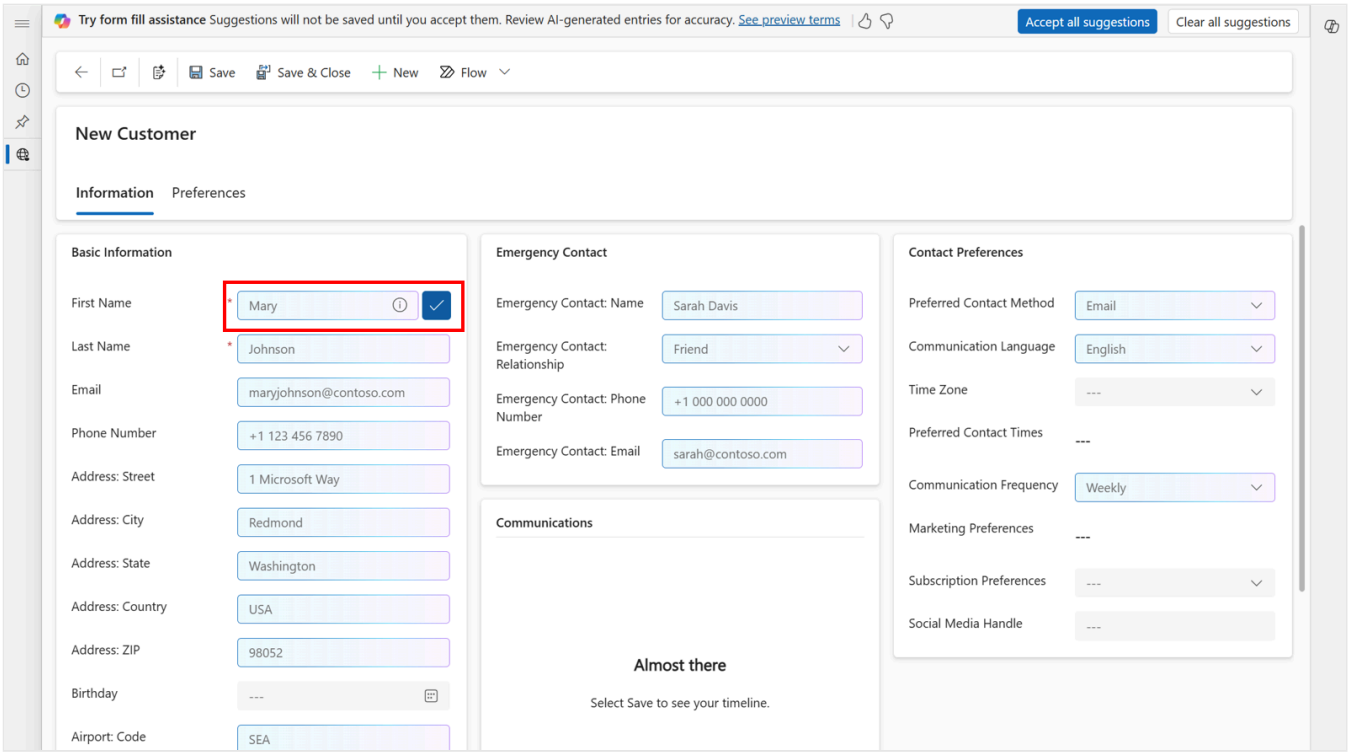
The feature generates suggestions only for the open tab. It presents suggestions inline in the form.



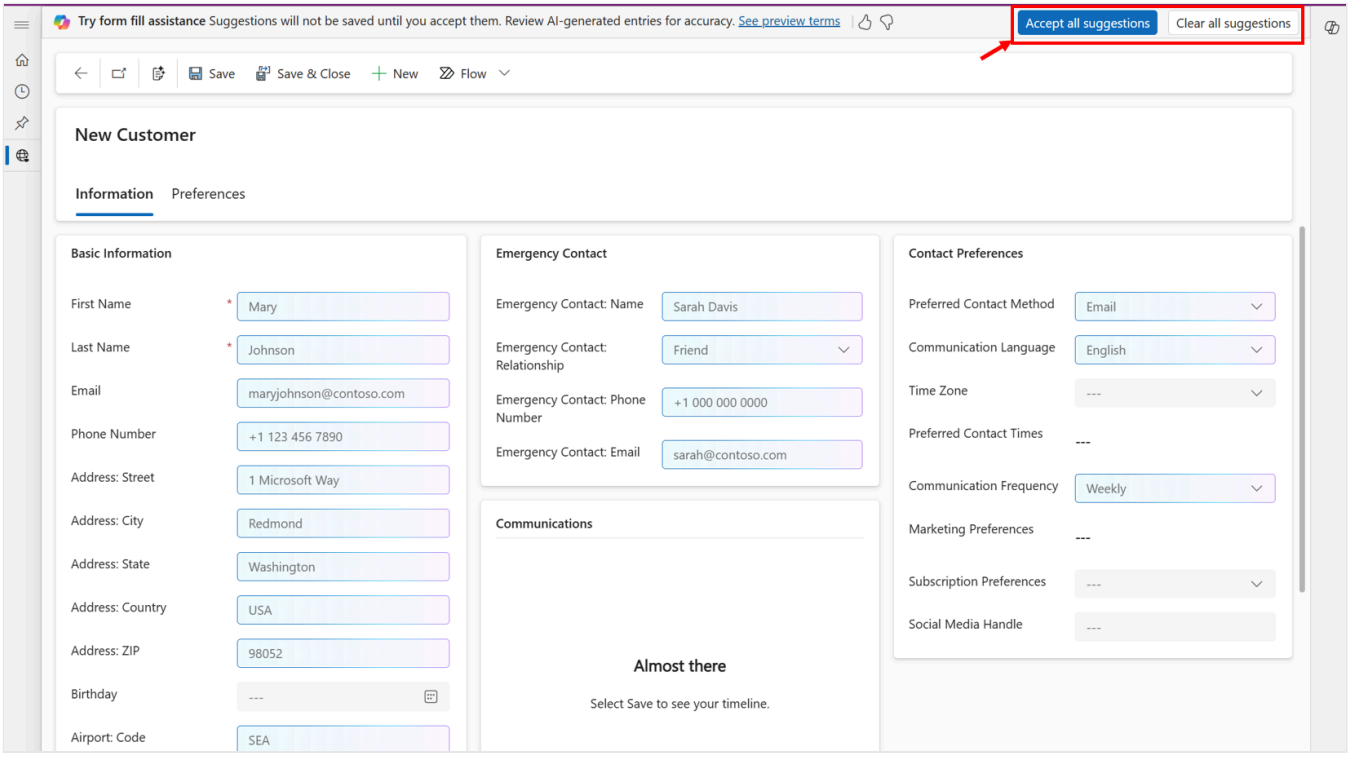
Suggestions are entirely optional and aren't saved in the app until you accept them. To learn more about a suggestion, hover over the field, and specifically hover over the information icon. This icon is a citation, and identifies the source of a specific suggestion, such as "Records you have updated recently" or "Clipboard".



To accept a specific suggestion, hover over the field, and then select **Accept**. Alternatively, select the field, and then press the **Enter** key.



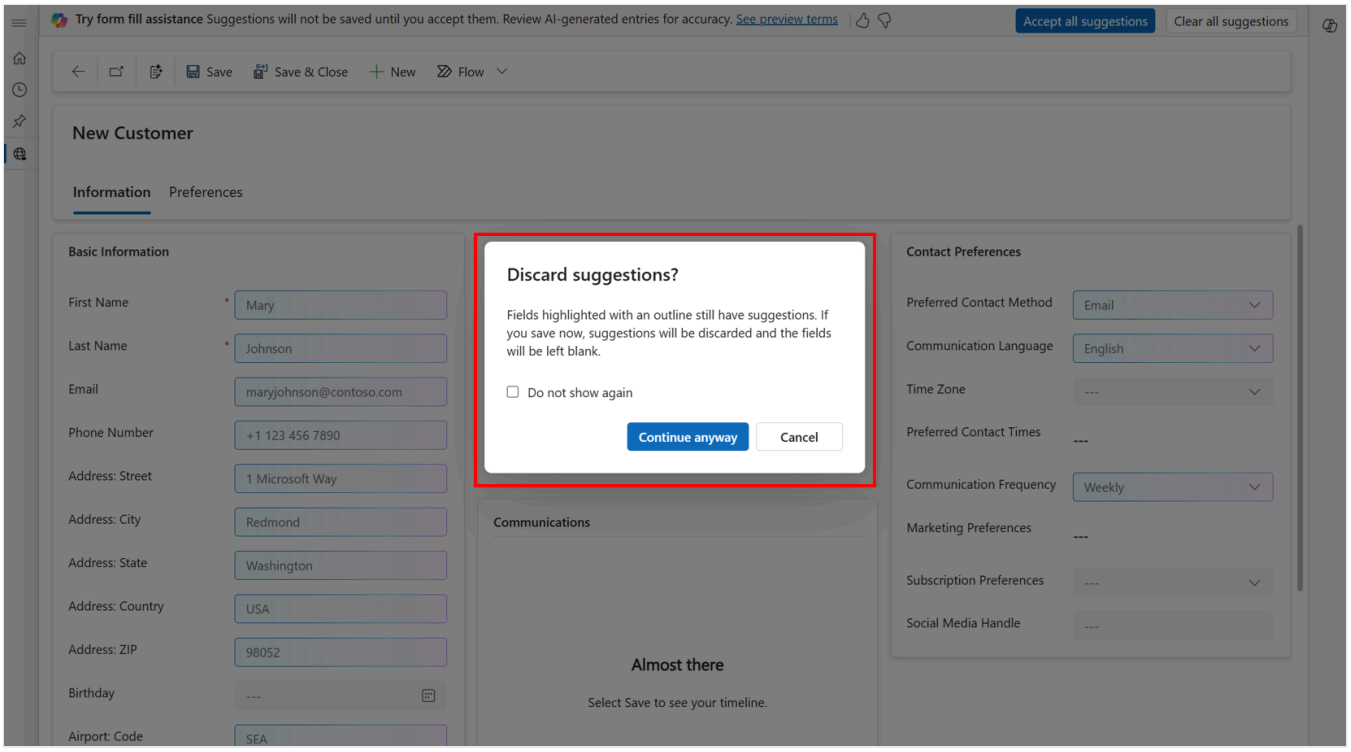
To accept all suggestions on the open tab of the form, select **Accept all suggestions** on the notification bar. To clear all suggestions on the open tab of the form, select **Clear all suggestions**.



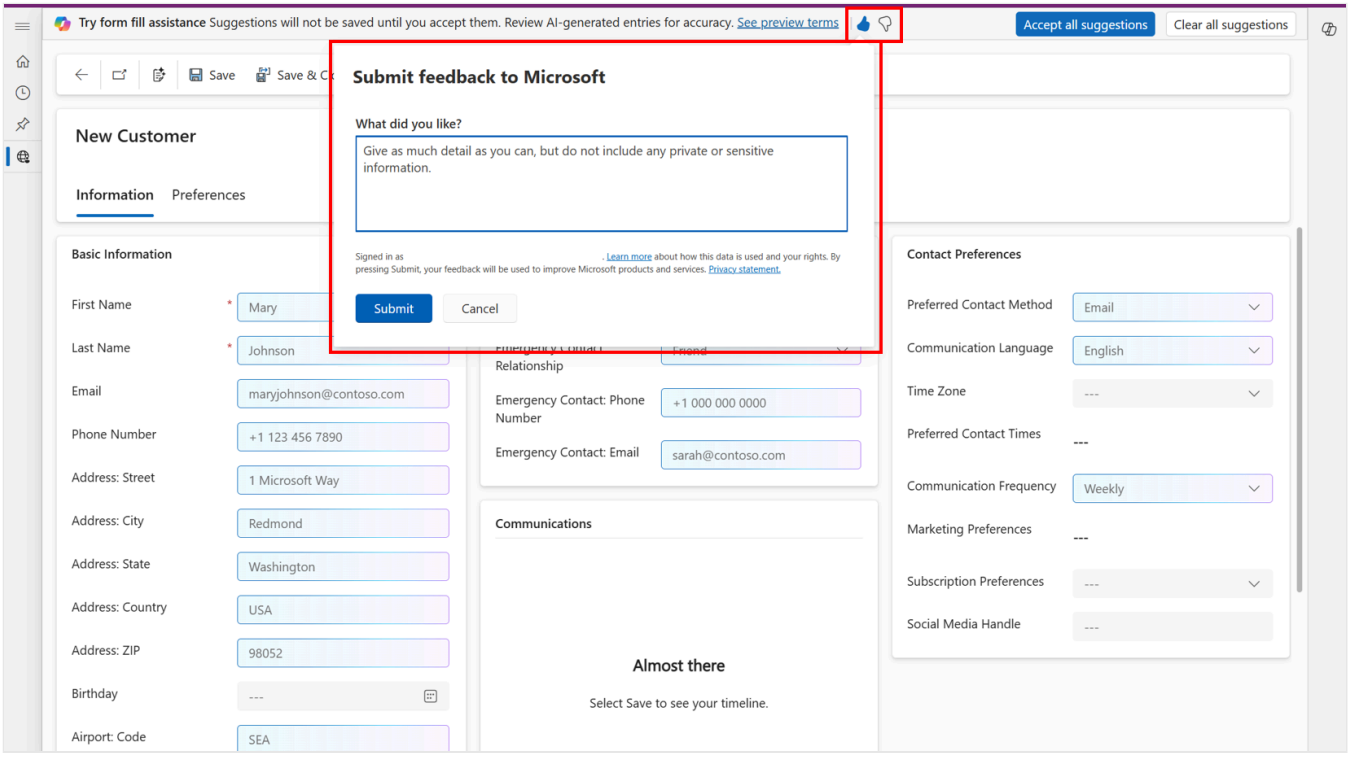
To replace a suggestion with a different value, select the field and start typing to overwrite the suggestion. Alternatively, select the field, press **Backspace** or **Delete**, and then start typing.

If you have unsaved suggestions in a form and try to navigate away, you get a prompt asking if you want to discard those suggestions. The suggestions are saved only when you accept them.

You can continue navigating away or stay on the form to review your pending suggestions. You can also select **Do not show again** to avoid being prompted in the future.



To provide feedback about the feature, select the thumbs up or down button on the notification bar, and optionally provide detailed comments to help improve the feature.



> **Important**
>
> - This feature is generally available in Dynamics 365 apps.

- This feature is in production ready preview in Power Apps.
  - Preview features are available before an official release so that customers can get early access and provide feedback.
- Due to high demand, this feature might be unavailable intermittently. If the feature is unavailable, try again later.

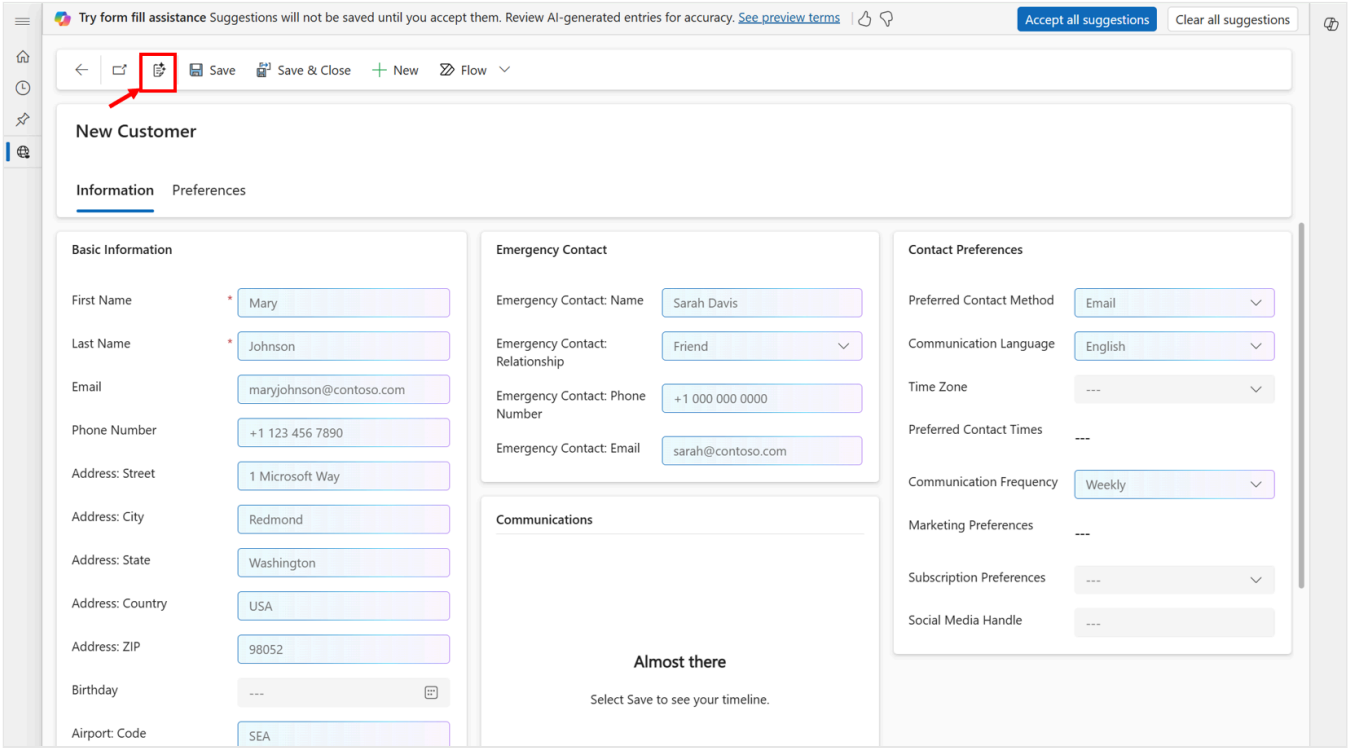
Use smart paste

Smart paste is a capability that analyzes the form and the text or image you copy to your clipboard. It suggests what text could fill specific fields and provides suggestions inline in the form. To use smart paste (preview):

1. Copy the text or image you want to use to fill in the form.
2. Select the **smart paste** icon in the command bar. Alternatively, make sure you don't select any specific fields in the form, and then use the regular paste keyboard shortcut (Ctrl+V or Cmd+V).

To use the smart paste (preview) capability, your admin must enable it. For more information, see Manage feature settings.

You can continue to paste directly, without smart paste (preview), into a specific field by selecting that field first and then pasting.

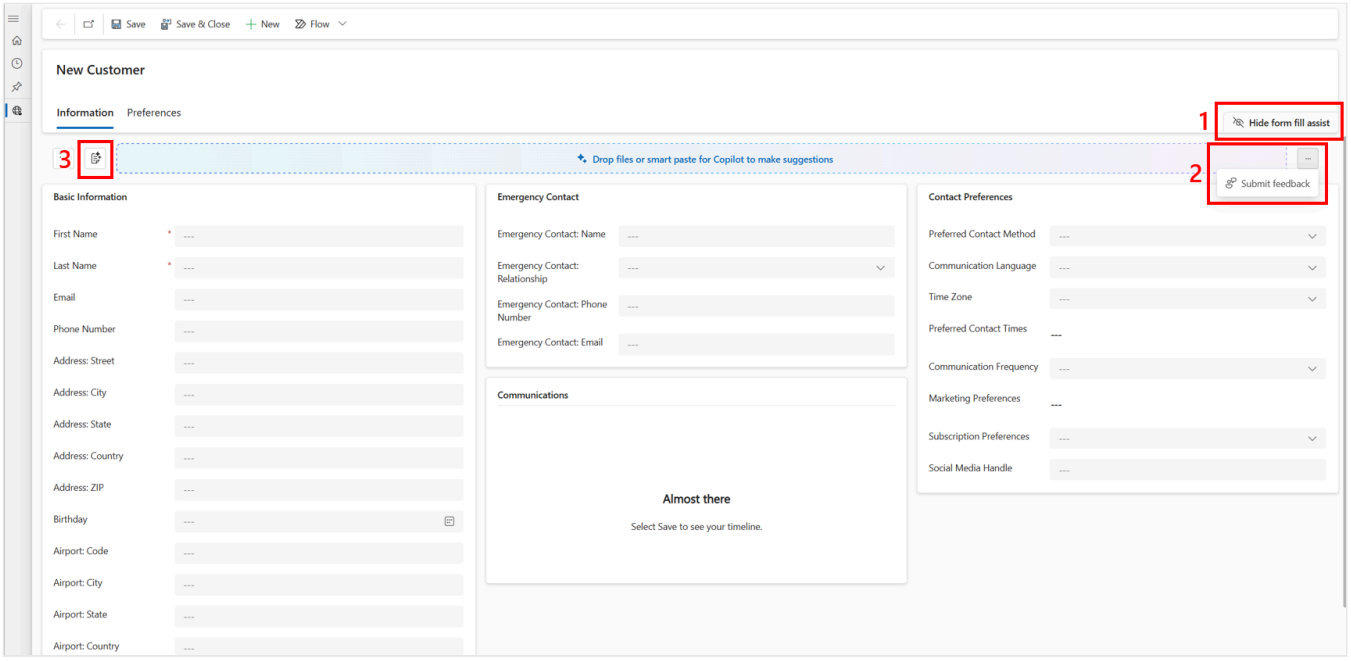


Use toolbar and files

Files is a capability that can reason over the form and the file you provide to suggest what text could fill specific fields. It provides suggestions inline in the form. Supported file types are .txt, .docx, .csv, .pdf, .png, .jpg, .jpeg, and .bmp. Files classified with sensitivity labels aren't supported.

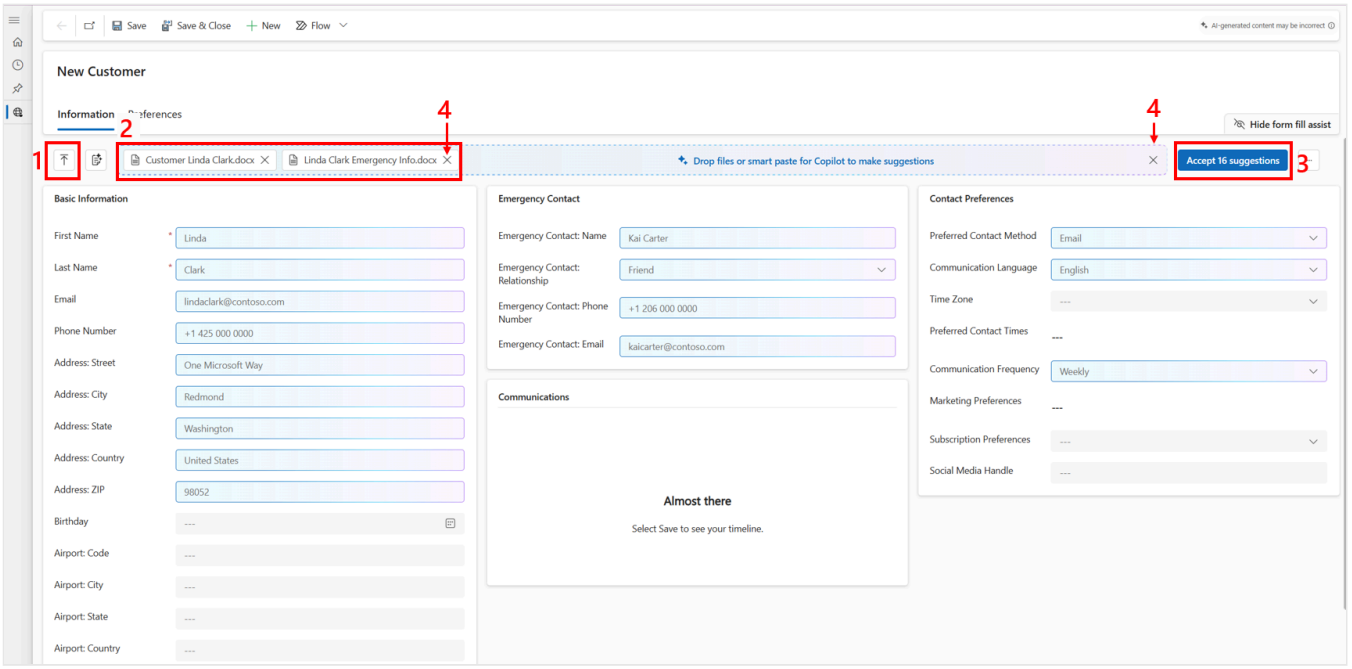
The form fill assist toolbar

1. Show or hide the form fill assist toolbar by using the show/hide button.
2. To provide feedback, select the more actions button (...) and give a compliment, report a problem, or make a suggestion.
3. The smart paste button is now located to the left of the toolbar.



To use files:

1. Use the file selector button to select the file you want to use to fill in the form. Alternatively, drag and drop the file in the toolbar.
2. Hover over the file's source tag to identify which fields are suggested based on the file's contents.
3. To accept all suggestions from the sources listed in the toolbar, select the accept all button located to the right of the toolbar. This button identifies the number of open suggestions in the form that it accepts.
4. To clear suggestions from the file, select the clear button in the tag. If the toolbar lists multiple sources, clear all suggestions by using the clear all button in the toolbar.



Licensing requirements

The form fill assistance requires specific user licenses based on the product. If the user doesn't have the license, the feature is hidden. This license enforcement will gradually rollout following the feature's general availability.

- **Power Apps model-driven app**: The user must have a Power Apps premium license. For details, see the Power Platform License Guide.
- **Dynamics 365 model-driven app**: The user must have a Dynamics 365 enterprise or premium license as outlined in Dynamics 365 License Guide.

Usage might be subject to service limits or throttling. Microsoft reserves the right to update the limits.

Admin control

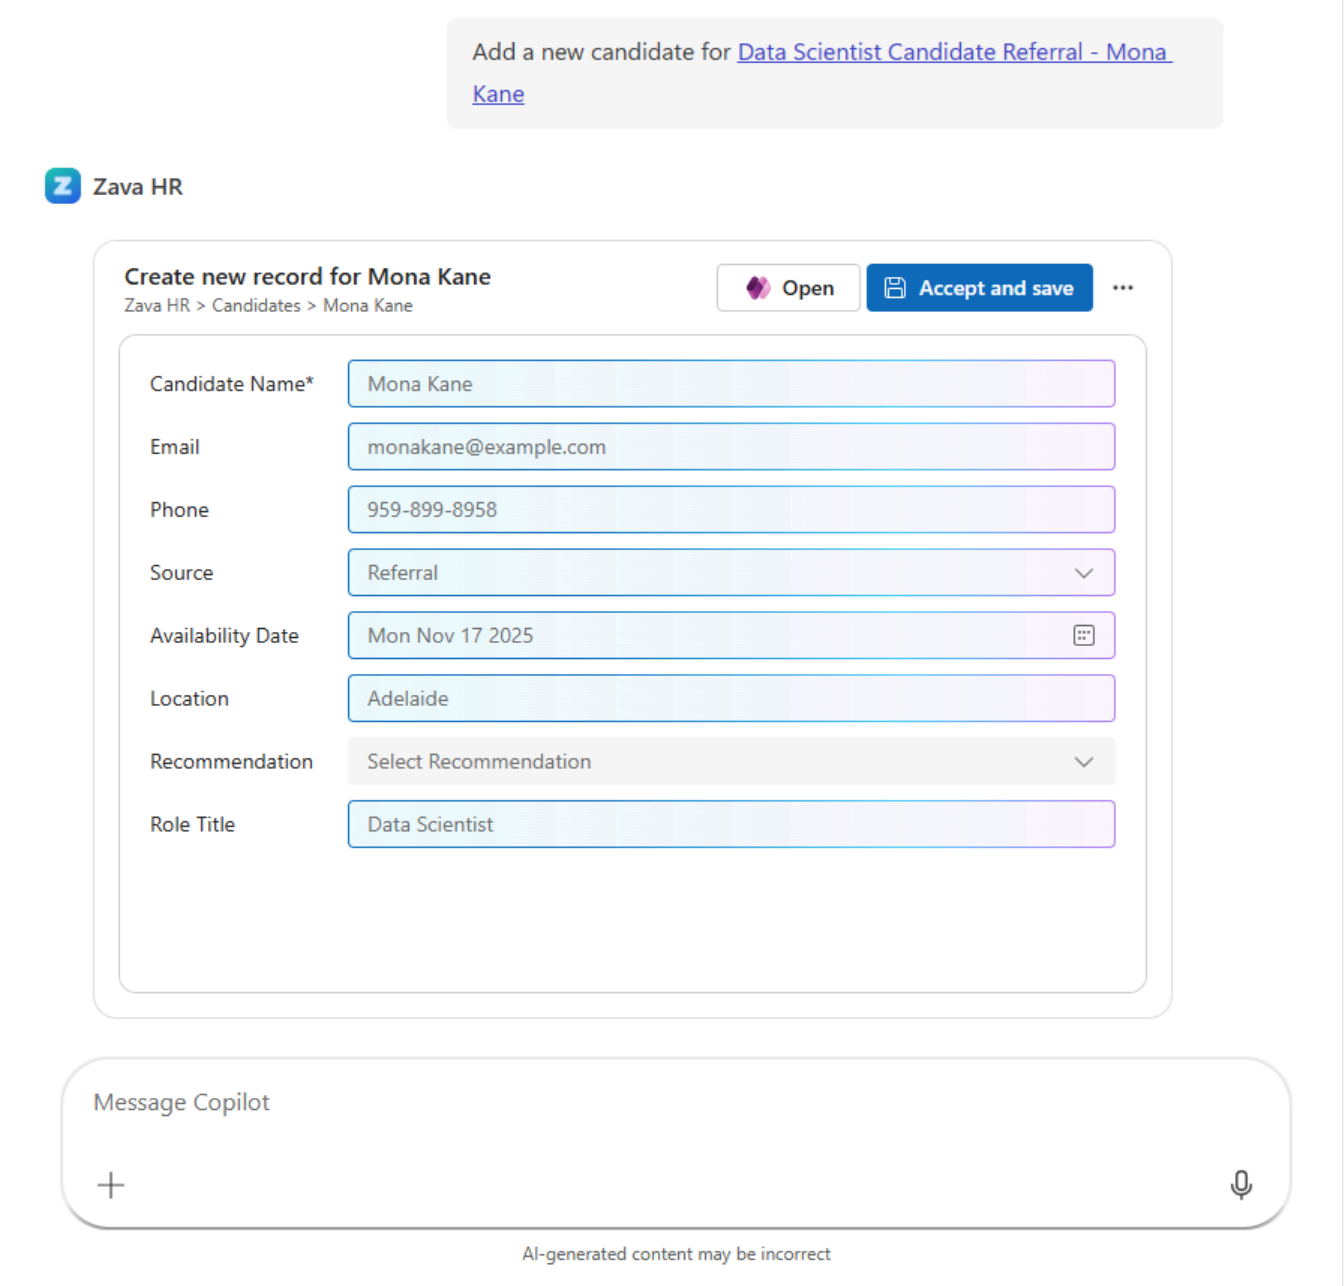
The primary admin control for form fill assistance is moving to the Power Platform admin center under **Copilot** > **Settings** > **Power Apps** > **Data entry**. Learn more in Copilot hub. This is gradually rolling out over the next coming weeks.

Smart paste (`FormPredictSmartPasteEnabled`) or **form fill assist toolbar** (`FormFileUploadEnabled`) app settings previously available in Power Platform admin center **Environment** > **Settings** > **Product** > **Features** page is moving and you can configure this setting at the app level either by using Manage model-driven app settings in the app designer or Updating a setting definition.

Use form fill assistance with agents in Microsoft 365 Copilot (preview)

[This section is prerelease documentation and is subject to change.]

With Microsoft 365 Copilot, you have ability to bring app-based experiences to agents. The app experience can leverage the form fill assistance right in the chat.



> **ⓘ Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are

available before an official release so that customers can get early access and provide feedback.
- This feature is being gradually rolled out across regions and might not be available yet in your region.

> **Note**
>
> To use this capability, you need to set up an apps agent in Microsoft 365 Copilot.

When you interact with agents in Copilot, agents can surface forms from apps directly in the conversation. Form fill assistance helps populate these forms by suggesting values based on relevant context, such as existing data you have access to from emails, chats, or any document.

The suggestions appear inline in the chat-based form and you can review or edit them before submission. All suggestions are optional and aren't saved until you explicitly accept and save the input.

After submission, the data is saved to the connected app and is available, just as if you complete the form directly in the app.

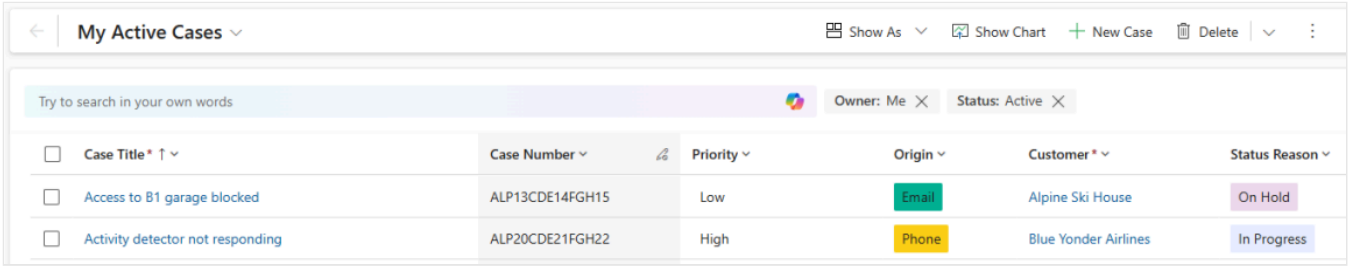
Find data in a view with AI

Users can quickly find, filter, and sort their data by using natural language, so they don't need to use complicated advanced filters. If your administrator turns on **Natural Language Grid and View Search**, you see the natural language search box.

Natural language search in apps

Use smart grid natural language search to ask data-related questions in natural language. For example, request “cases with high priority with overdue follow-up by date” to filter your view and display only those relevant cases.



Licensing requirements

Natural language grid and view search requires specific user licenses based on the product. If the user doesn't have the license, the feature is hidden. This license enforcement will gradually rollout following the feature's general availability.

- **Power Apps model-driven app**: The user must have a Power Apps premium license. For details, see the Power Platform License Guide.
- **Dynamics 365 model-driven app**: The user must have a Dynamics 365 enterprise or premium license as outlined in Dynamics 365 License Guide.

Usage might be subject to service limits or throttling. Microsoft reserves the right to update the limits.

Admin control

The primary admin control for **Natural Language Grid and View Search** is moving to the Power Platform admin center under **Copilot** > **Settings** > **Power Apps** > **Data exploration**. Learn more in Copilot hub. This is gradually rolling out over the next coming weeks.

Natural language grid and view search app setting (`NLGridSearchSetting`) previously available in Power Platform admin center **Environment** > **Settings** > **Product** > **Features** page is moving and you can configure this setting at the app level either by using Manage model-driven app settings in the app designer or Updating a setting definition.

Explore data with agents in Microsoft 365 Copilot (preview)

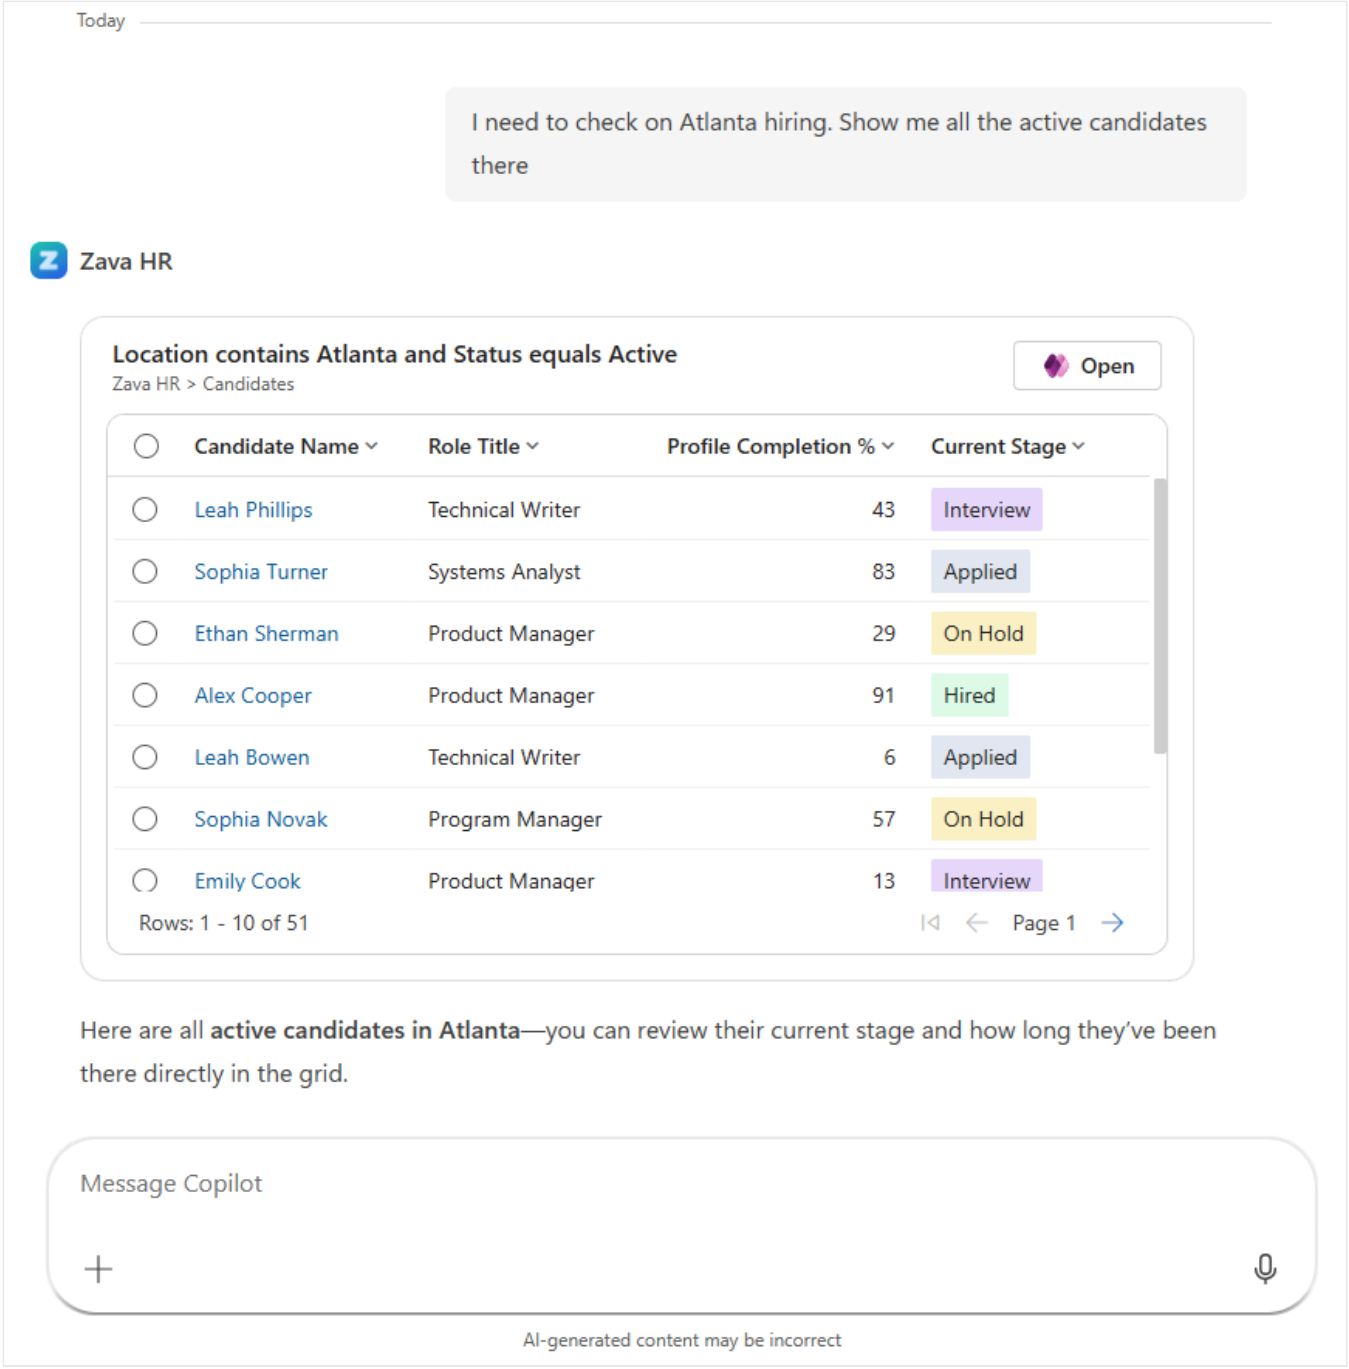
[This section is prerelease documentation and is subject to change.]

With Microsoft 365 Copilot you have the ability to bring app-based experiences to agents, the app experience can also use the AI assisted search in the grid view.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is being gradually rolled out across regions and might not be available yet in your region.

> **Note**
>
> To use this capability, you need to set up an apps agent in Microsoft 365 Copilot.

When users interact with agents in M365 Copilot, the agents can search and retrieve data from apps view directly within the conversation. By using natural language, users can find, filter, and review app data without switching to the app experience. Natural language search interprets the user's request and applies the appropriate filters, sorting, and text search against the underlying view data. The agent returns the results in Copilot chat, presented in a structured, tabular format that reflects the view data. Users can continue to work with the returned results in the conversation, iterating with natural language to refine the output until it reflects the exact results they're looking for.



Supported features

- Filtering of records
- Sorting
- Text search

Known limitations

These capabilities aren't supported:

- Query aggregation
- Query grouping

- Adding columns

Considerations

- After you run a query, check the generated filter tags to make sure that the filter conditions were correctly interpreted from your natural language query. If any part of your query is missing from the filter tags, the results aren't filtered by that condition.
- If search doesn't give the desired results, consider modifying your query by:
  - Referring to data columns by the names shown in the grid header.
  - Separating multiple conditions with commas or periods.
- In model-driven app for grids, if your search string has two words or fewer, the search does a text search. To do a natural language search, use more than two words. To do a text search with more than two words, put the search term in single or double quotes. This behavior doesn't apply to Copilot chat.

Last updated on 04/21/2026

Visualize data in a view with AI

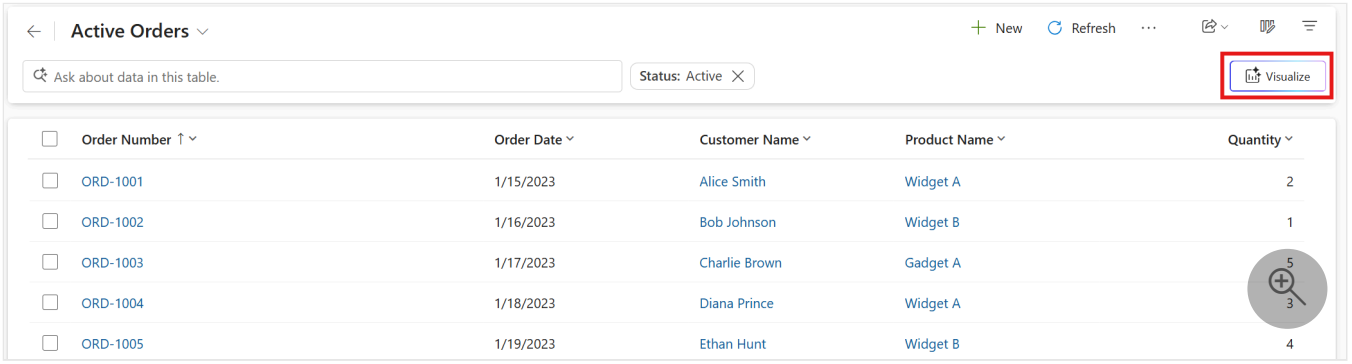
Chart visualization helps you visualize the data in the view as a chart. This visualization makes it easy to understand trends, patterns, and relationships in your data. The visualization is interactive, based on the visible columns in the view, and you can personalize it to support further data exploration.

Prerequisites

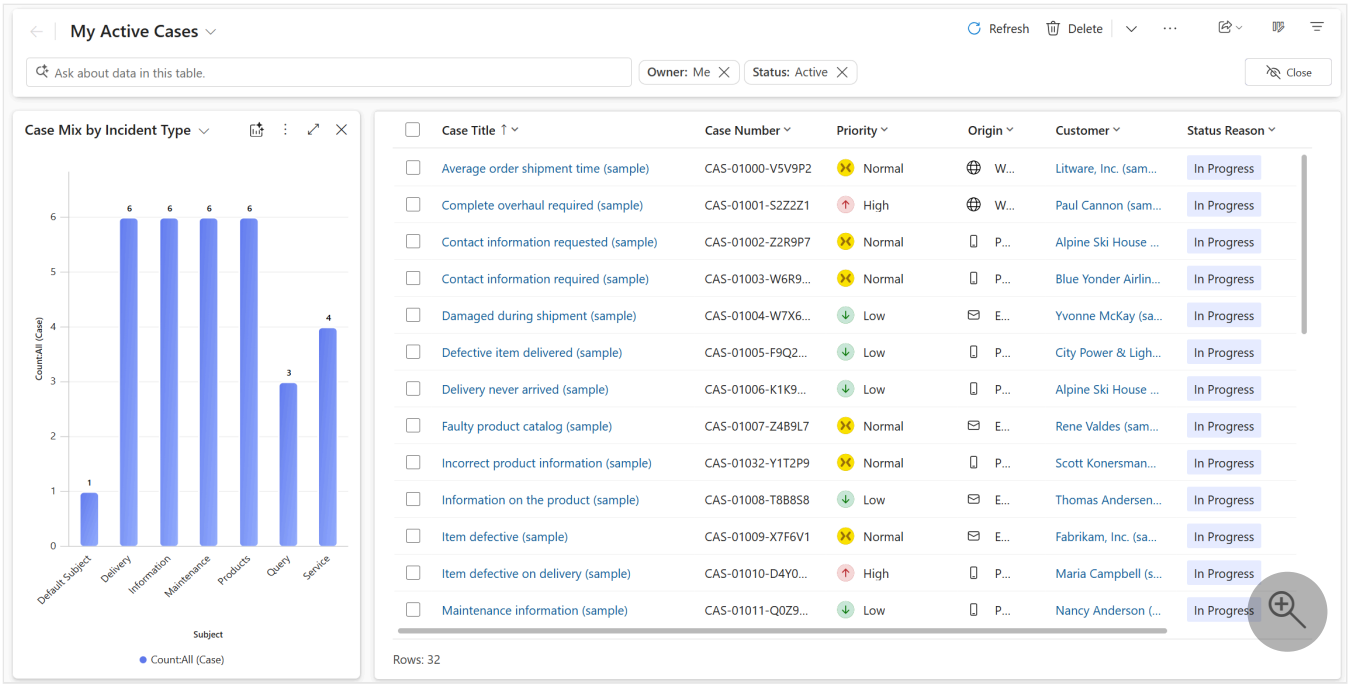
- All apps on the web support chart visualization when the modern, refreshed look is turned on.
- See License requirements and Admin control for additional settings.

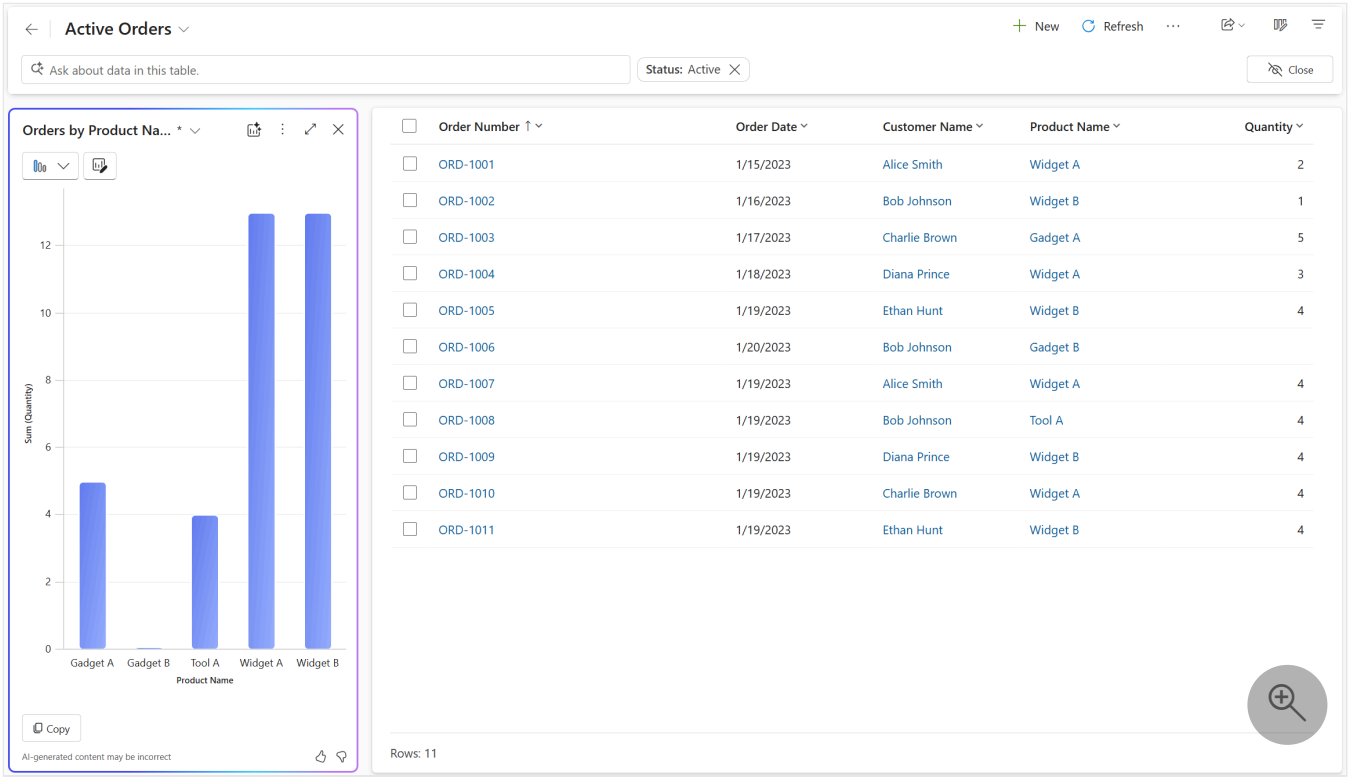
Visualize data in a view

When you navigate to a grid page, you can see the **Visualize** option on top of the page.

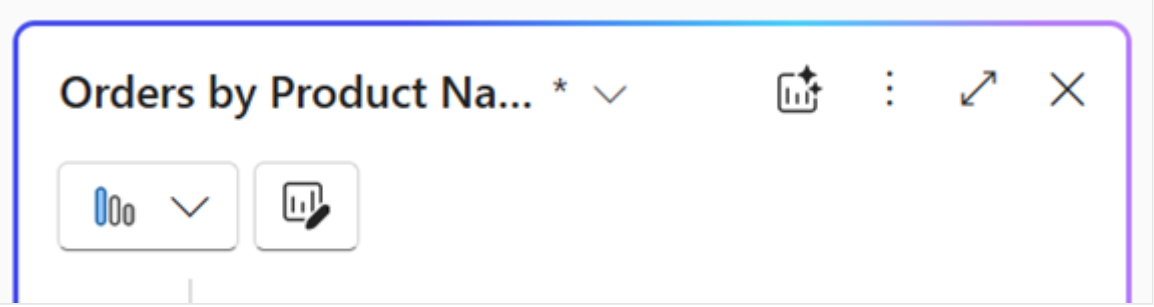


When you select **Visualize**, the chart pane opens next to the grid, complementing the table of rows. If the table has system or personal charts, the default chart for the table appears. If the table doesn't have charts, AI generates a visualization for the view based on the visible columns and filters. The visualization is a chart that aggregates the data in the view.





If chart visualization generates a visualization for the view, you can edit the chart by changing the chart type, the columns that are visualized, or both. If you add or remove columns from the view, chart visualization regenerates the chart based on the updated set of columns for the visualization. If you add or remove filters, chart visualization refreshes the chart without changing the visualization. The asterisk (*) next to the chart name shows that the chart isn't saved yet.



Select the three dots in the upper-right corner of the chart pane, and then select **Save As** to save the chart.

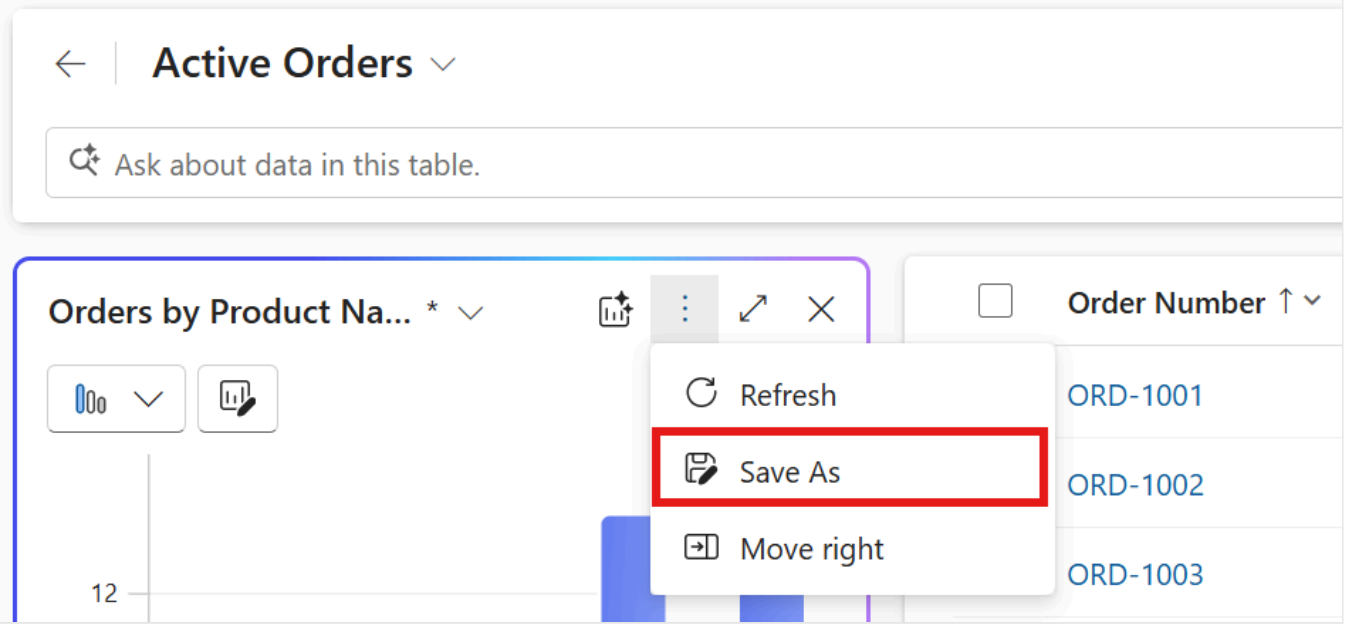


Chart visualization automatically populates the chart name and description, but you can edit them to suit your needs. Select **Save** to save the chart. You access the saved chart by using the chart switcher in the chart pane. The **Visualize** icon next to the chart name indicates that it's an AI-generated chart, helping you distinguish it from other charts.

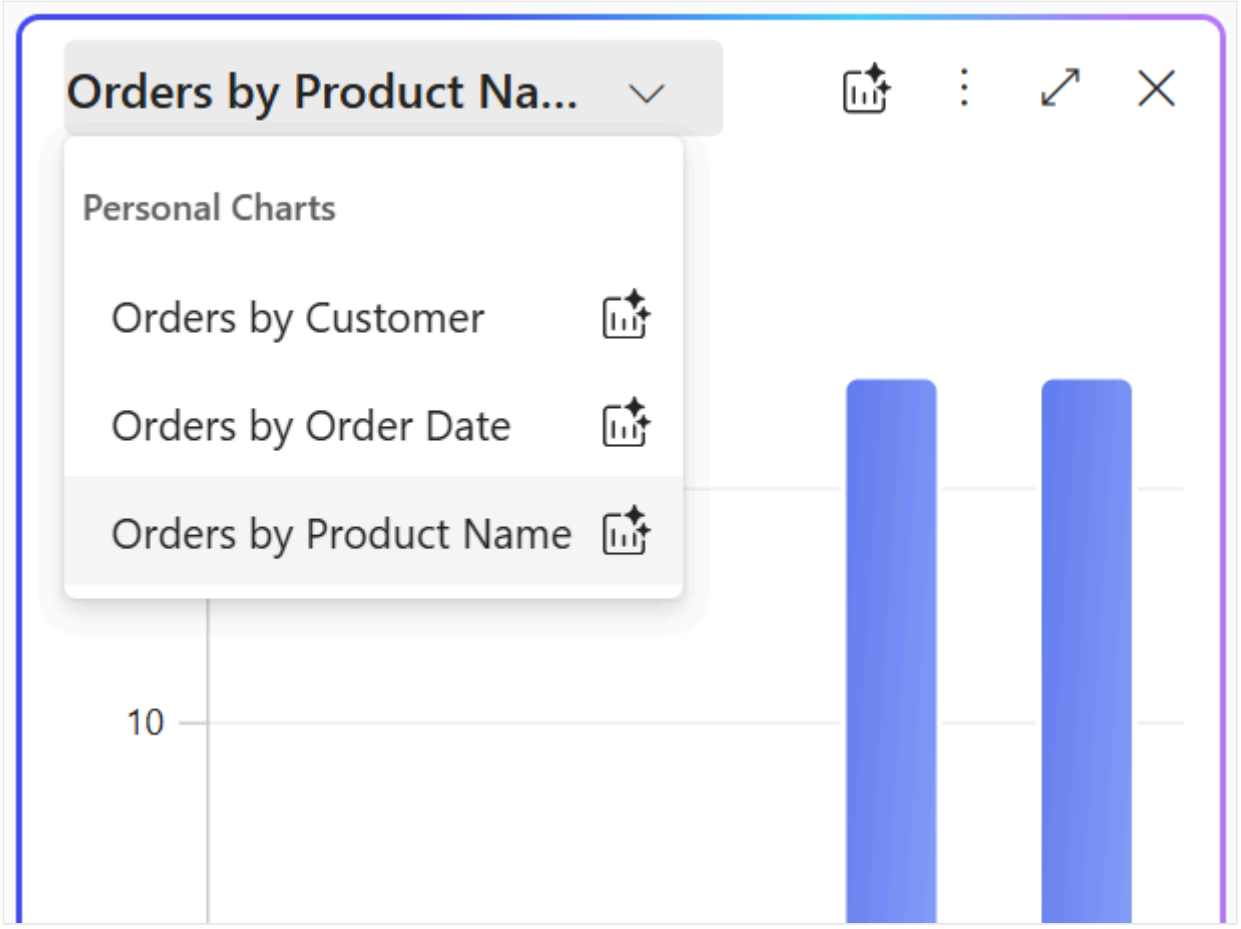
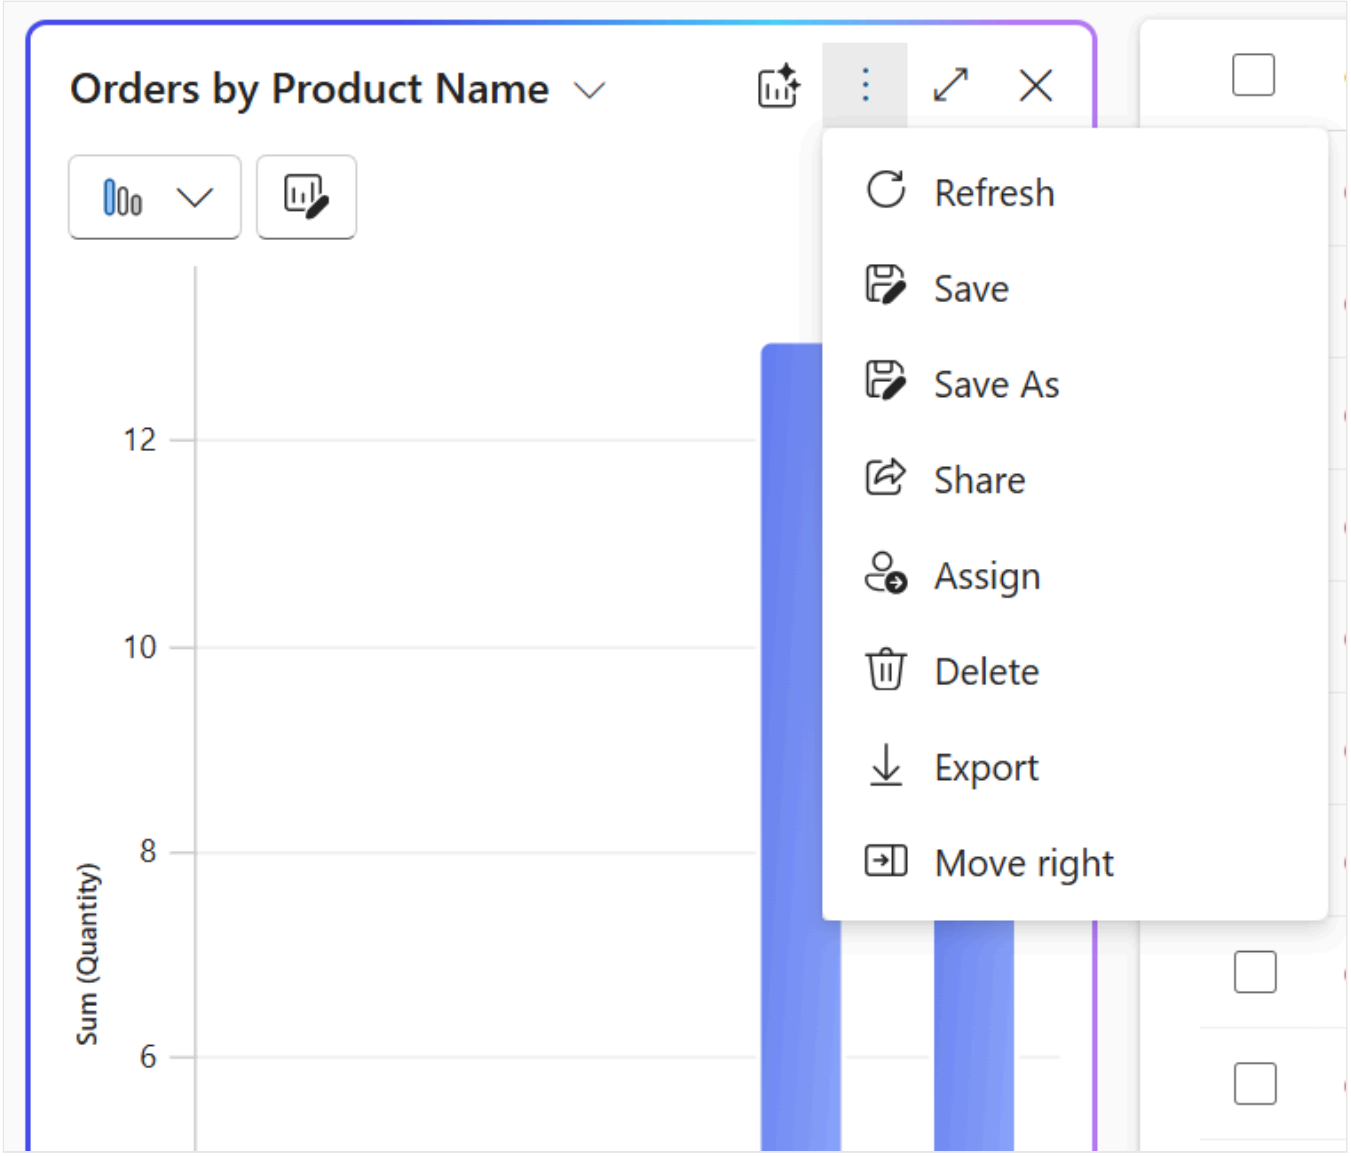


To manage a personal chart, select the chart in the chart switcher, and then select the three dots in the upper-right corner of the chart pane. Select an option to delete, assign, or share the chart with others in your organization.



Hover over the charts to examine data points or select chart elements to drill into the data. The grid filters rows automatically to match the selected area of the chart. Selecting the same area of the chart again toggles the selection and removes the filter.

> **Note**
>
> Charts created by using the legacy chart designer use the same styling as AI-generated charts. To learn how to turn off the styling update for charts created by using the legacy chart designer, see Manage feature settings.

Visualize data in a view with natural language

Use natural language prompts in the search bar on the grid page to visualize data in the view. Here are example prompts to help you understand the types of requests supported.

- *Visualize data as a bar chart.*

- *Customers by location. Use the prompt [table name] by [column] generically depending on the table you're visualizing.*
- *Trend of orders created during this fiscal year.*
- *Visualize average revenue per month as a column chart.*
- *Visualize high-priority cases as a chart.*
- *Visualize data as a bubble chart.*

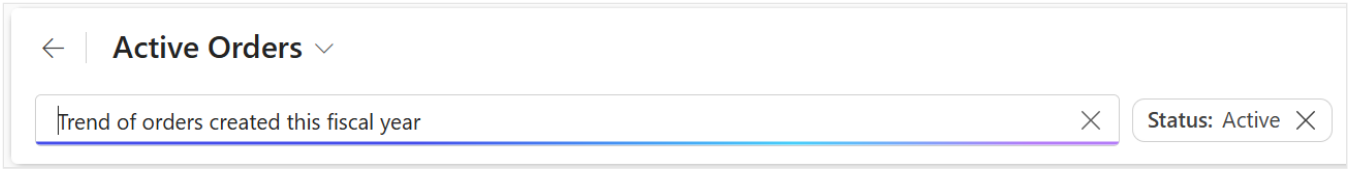


Chart pane

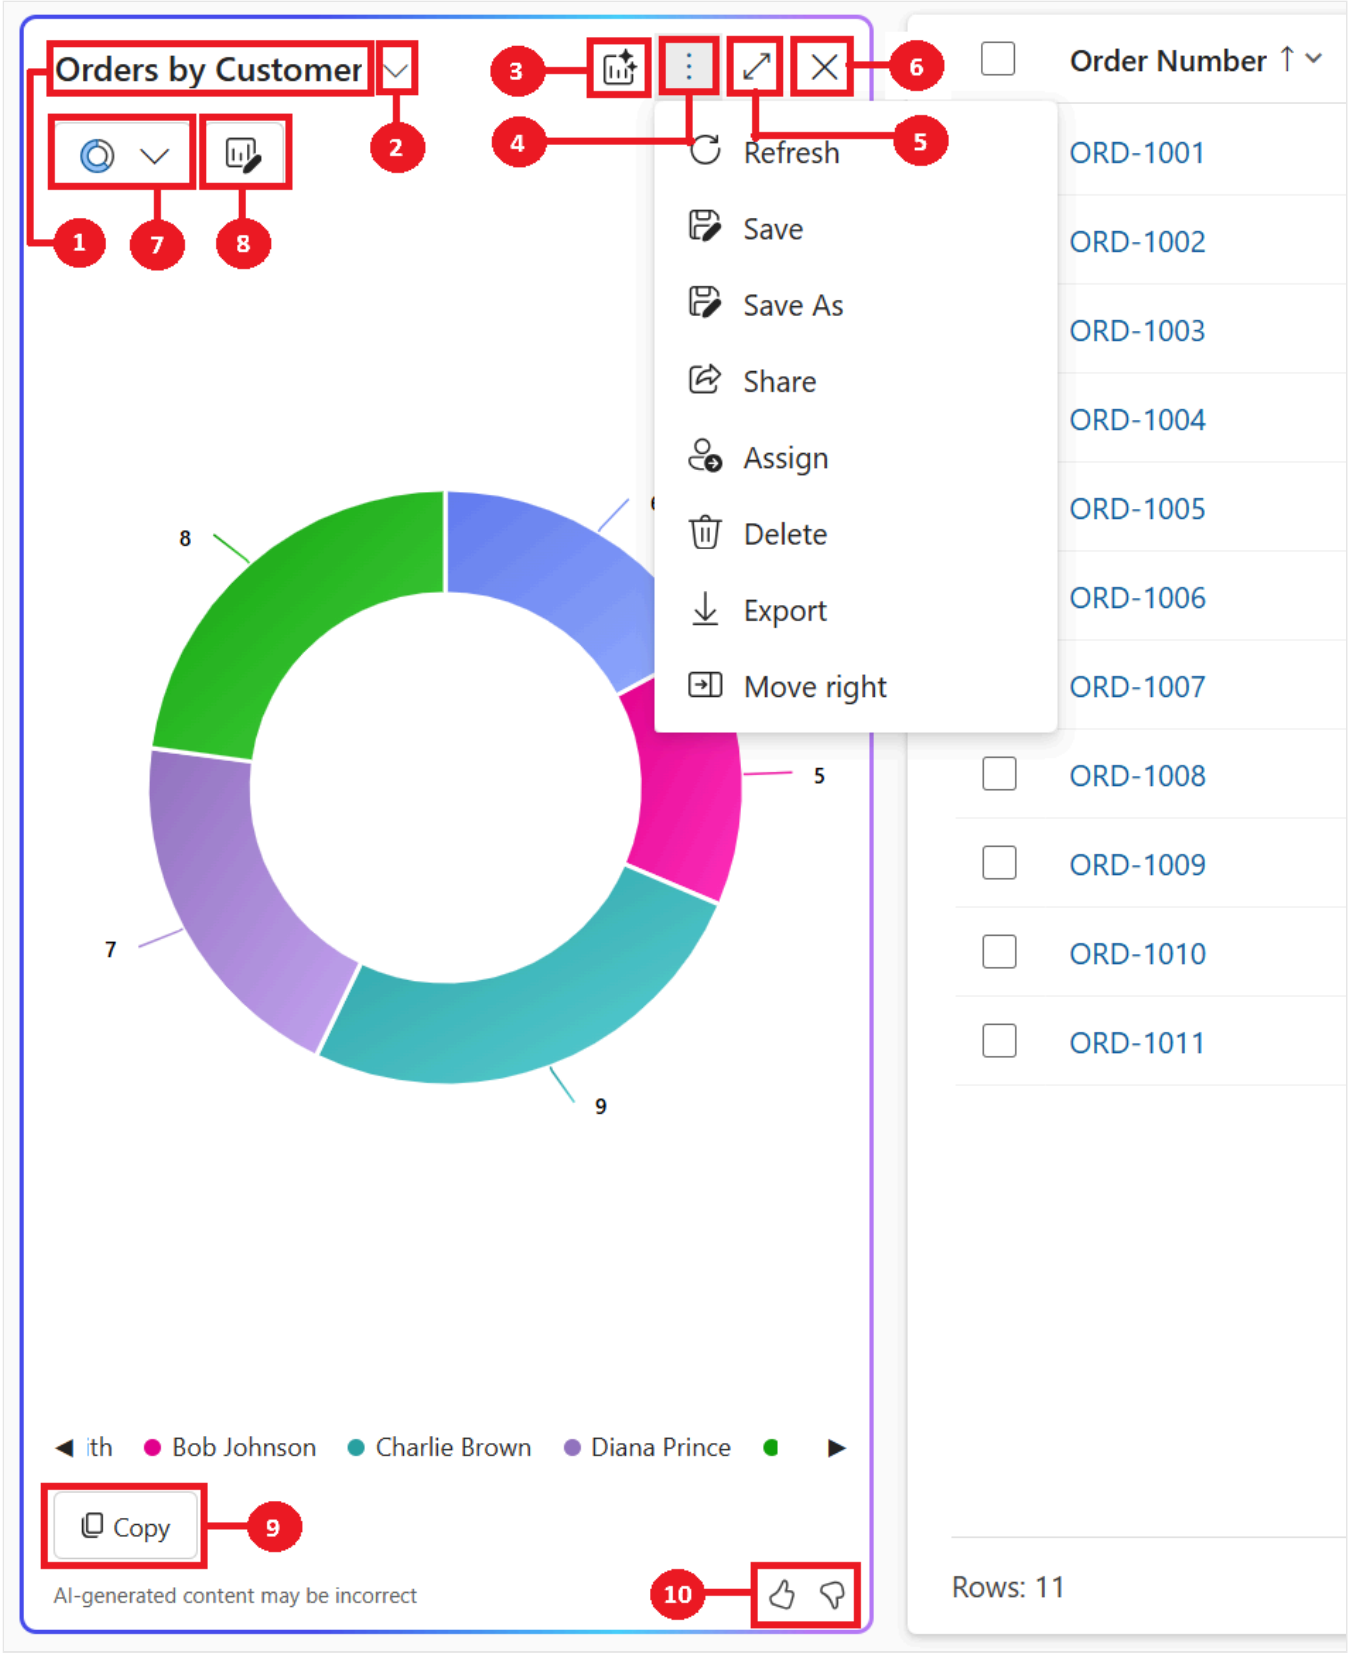

1. **Chart title**: AI-generated title for the chart based on the data and columns visualized.
2. **Chart switcher**: Select and manage saved charts. Use it to switch between different charts, including AI-generated and personal charts, for the current view.
3. **Create new chart with AI**: AI-generated chart for the visualization of this view.
4. **Commands to manage saved chart**: The **Commands to manage saved chart** appear as three dots in the top-right corner of the chart pane. They provide options to perform actions on saved charts.

5. **Expand**: Select **Expand** to expand the chart to full screen for a better view of the chart area.
6. **Close**: Select **Close** to close the chart pane.
7. **Chart selector**: List of 11 supported chart types – Pie, Donut, Bar, Column, Clustered Bar, Stacked Bar, Clustered Column, Stacked Column, Line, Histogram, and Bubble chart.
8. **Edit chart columns**: Customize the chart by selecting which columns from the view are visualized.
9. **Copy**: Select **Copy** to copy the chart as a PNG file to the clipboard.
10. **Feedback**: Select **Thumbs up** or **Thumbs Down** to provide feedback about the feature.

To provide feedback about the feature, select the thumbs up or down button on the chart pane, and provide detailed comments to help improve the feature.

Licensing requirements

The visualize data in a view requires specific user licenses based on the product. If the user doesn't have the license, the feature is hidden. This license enforcement will gradually rollout following the feature's general availability.

- **Power Apps model-driven app**: The user must have a Power Apps premium license. For details, see the Power Platform License Guide.
- **Dynamics 365 model-driven app**: The user must have a Dynamics 365 enterprise or premium license as outlined in Dynamics 365 License Guide.

Usage might be subject to service limits or throttling. Microsoft reserves the right to update the limits.

Admin control

The primary admin control for visualize data in a view is moving to the Power Platform admin center under **Copilot** > **Settings** > **Power Apps** > **Data exploration** > **Chart Visualization**. Learn more in Copilot hub. This is gradually rolling out over the next coming weeks.

Allow AI to generate charts to visualize the data in a view app setting (`NLChartDataVisualizationSetting`) previously available in Power Platform admin center **Environment** > **Settings** > **Product** > **Features** page is moving and you can configure this setting at the app level either by using Manage model-driven app settings in the app designer or Updating a setting definition.

Responsible AI FAQ about Copilot visualizations on a view

Last updated on 04/21/2026

Use row summaries in model-driven apps

The **Row summary** feature in apps provides users with a concise, AI-generated overview of key details about a record. Summaries help users quickly understand essential information without manually scanning fields, related records, or activity timelines. You see summaries as a paragraph or bullet points, so they're easy to read.

Summaries can be accessed in two ways:

- From the **Insights** bar at the top of main forms.
- From view pages by selecting the inline **Summary** action in the grid, which opens the summary for a record in a modal popup.

The feature enhances user efficiency by delivering context-rich insights directly within the form. Users can interact with summaries to copy content, regenerate updated information, and provide feedback on their relevance, improving both usability and accuracy.

Prerequisite

Each of the following settings must be turned on to see the row summaries for apps.

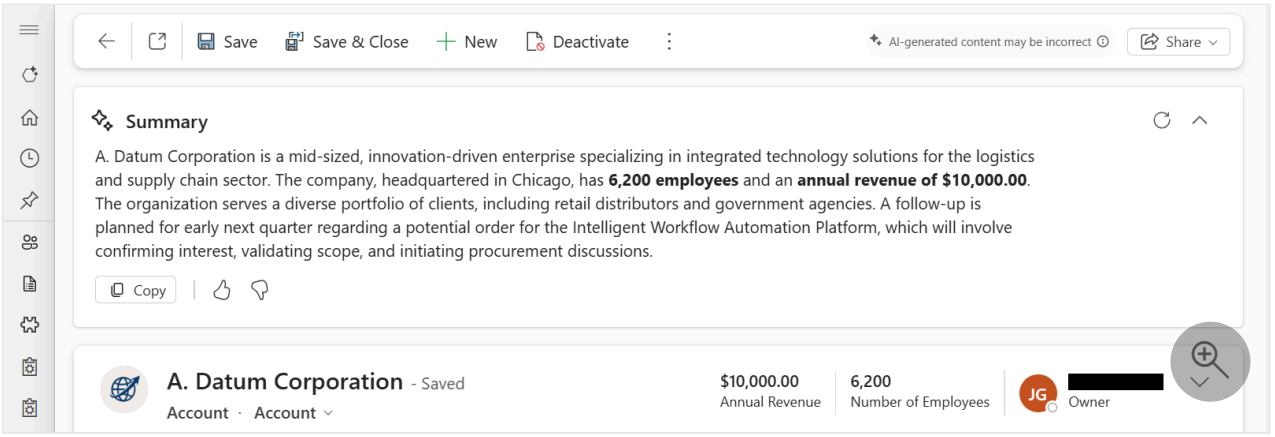
- The AI insight cards toggle is turned on for the Power Platform environment.

Feature details

Accessing record summaries

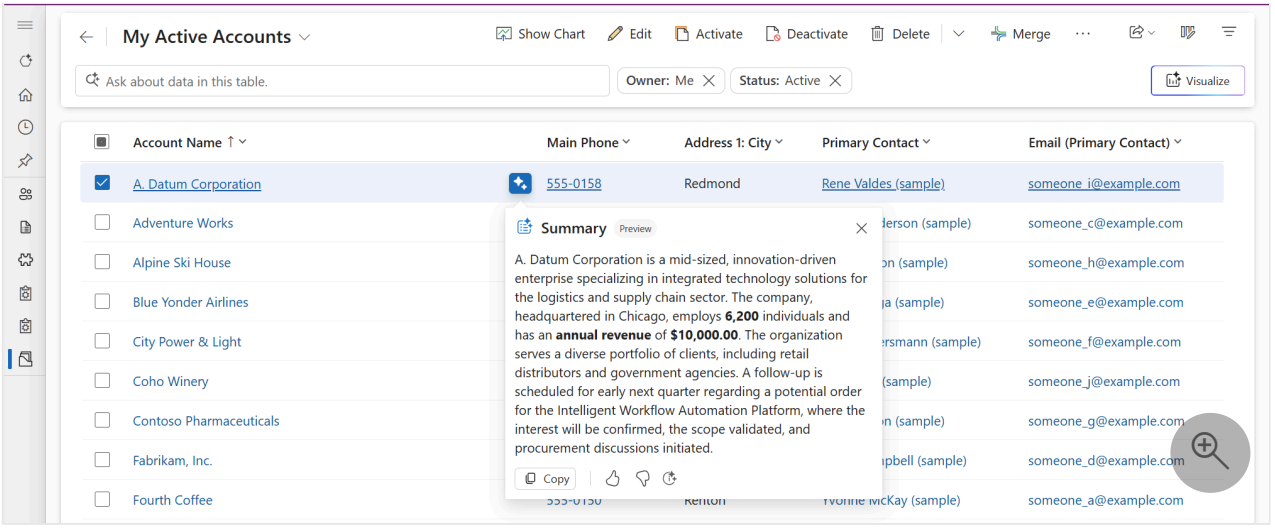
View the record summary from a form or view when a table is configured to display summaries.

- **Forms**: When viewing a record in a main form, the summary appears in the insights bar at the top of the main form.



> **Note**
>
> You see the record summary after you save a new record. If you haven't saved the record, the summary area stays hidden.

- **Views**: When browsing records in a view, select the inline Summary action next to a record to open the summary in a modal popup.

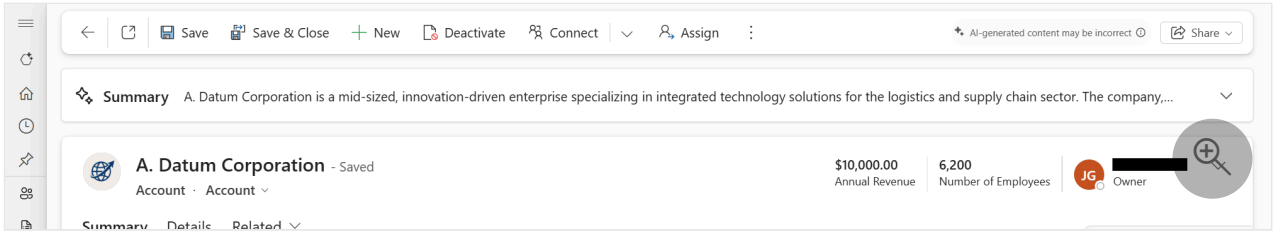


Interacting with summaries

Here are some actions you can take with summaries:

- **Copy**: Select to copy the summary content directly to your clipboard for easy sharing or documentation. The summary copies in markdown format, so when you paste it into other applications, the formatting might not appear exactly as it appears in the app.
- **Feedback**: Use the thumbs up or thumbs down icons to rate the summary's usefulness. Your feedback helps improve future summaries so they better meet your expectations and needs.

- **Refresh** (forms only): Select the **Refresh** button to regenerate the summary so it reflects the latest updates to the record.
- **Expand/Collapse** (forms only): In forms, the insights bar is collapsed by default and shows a one-line peek of the summary. Expand the insights bar to see more details.



Licensing requirements

The row summary feature requires specific user licenses based on the product. If the user doesn't have the license, the feature is hidden. This license enforcement will gradually rollout following the feature's general availability.

- **Power Apps model-driven app**: The user must have a Power Apps premium license. For details, see the Power Platform License Guide.
- **Dynamics 365 model-driven app**: The user must have a Dynamics 365 enterprise or premium license as outlined in Dynamics 365 License Guide.

Usage might be subject to service limits or throttling. Microsoft reserves the right to update the limits.

Admin control

The primary admin control for row summary is moving to the Power Platform admin center under **Copilot** > **Settings** > **Power Apps** > **Summary** > **Row summaries**. Learn more about the Copilot hub here.

The **AI insight cards** app setting (EnableFormInsights) for main forms, previously available in Power Platform admin center **Settings** > **Product** > **Features** is being moved and you can configure this setting at the app level either by using the Model App Designer Setting or Solution Explorer App Settings.

Configuring summaries for tables

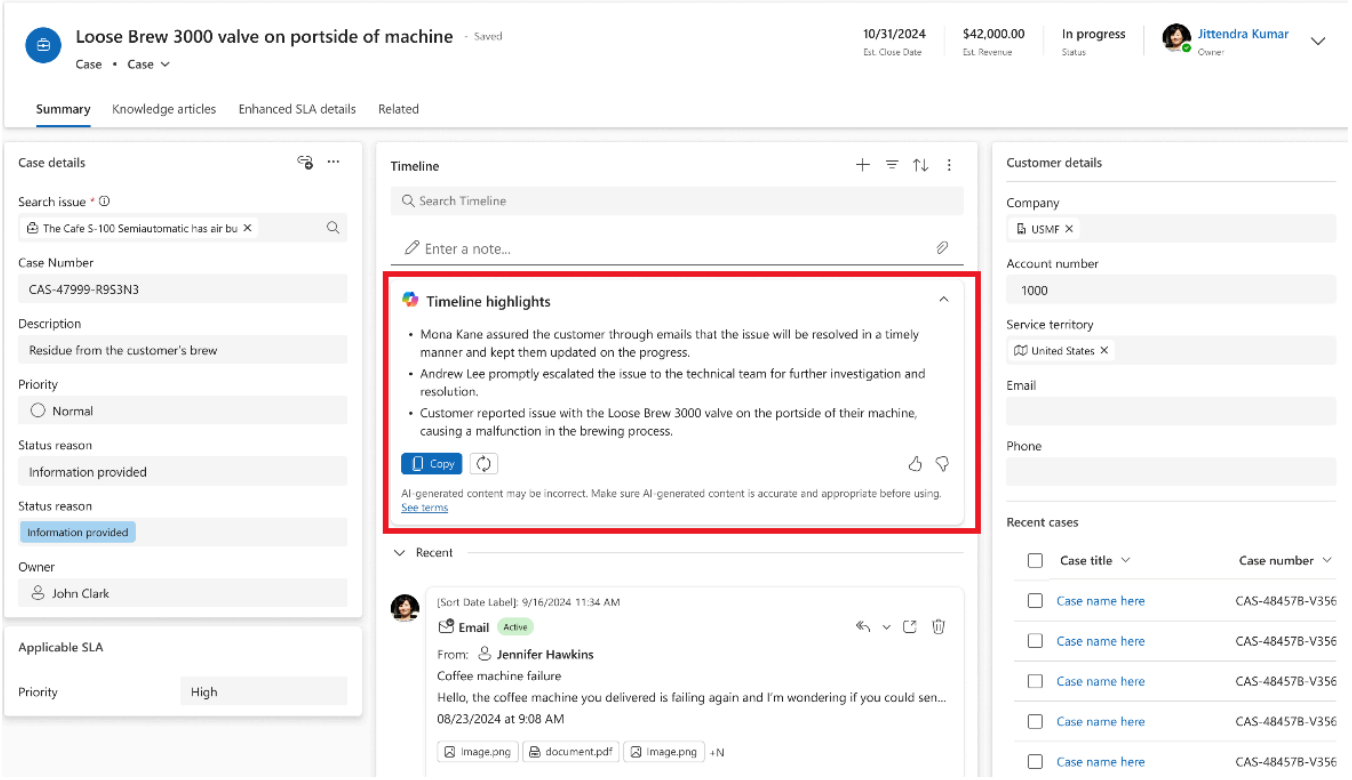
Last updated on 04/21/2026

Use AI-generated timeline highlights

If timeline highlights are enabled on your app, Copilot creates an AI-generated, bulleted list that populates at the top of the timeline. You can use timeline highlights to quickly get caught up on a record's status.

The highlights include a record's main activities, such as details about who you or the previous user interacted with, the reported issue, and actions taken to try to resolve the issue.

You can copy the timeline highlights by selecting **Copy**.



> **Important**
>
> This feature is only available with Power Platform environments with Dataverse that have the **Enable Dynamics 365 apps** setting enabled.

Last updated on 02/04/2026

Use Copilot case summary in model-driven apps

07/08/2025

Copilot case summaries help users quickly understand the context of a case and resolve customer issues more efficiently. The case summary includes key information such as the case title, customer, subject, product, priority, case type, and description.

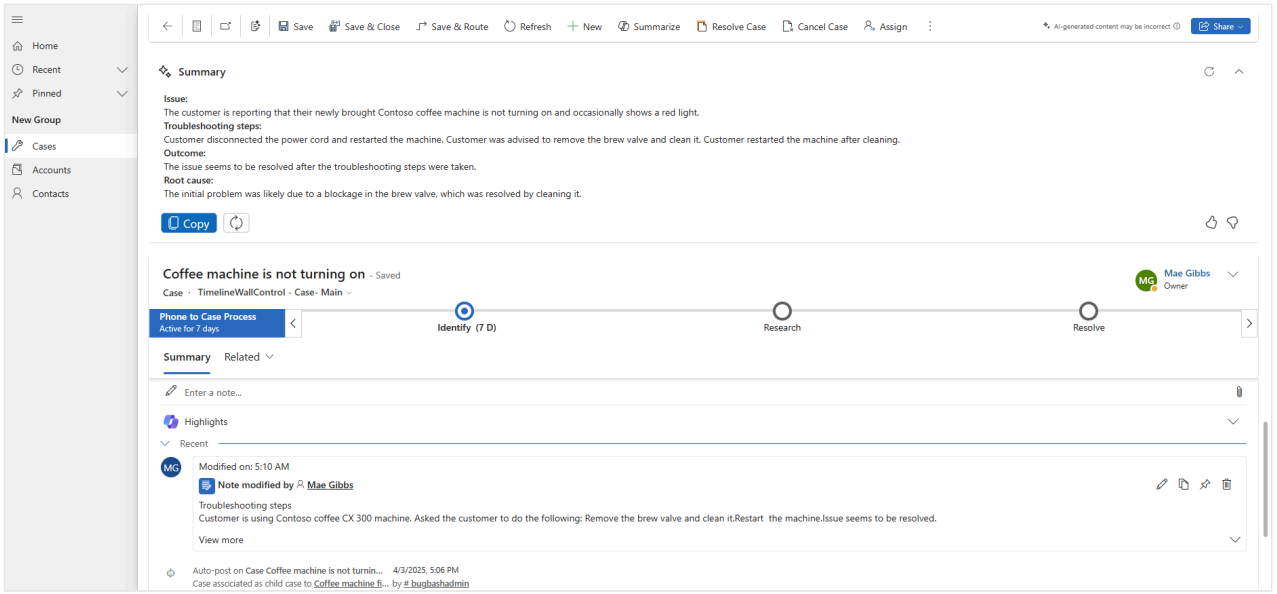
View case summary card

Copilot case summary is enabled by default for all model-driven apps that use the **incident** table. When you open a case record, the case summary card appears. When you open the case or custom record in a new session the summary card is expanded by default until you collapse it for the first time. The card then remains in collapsed state

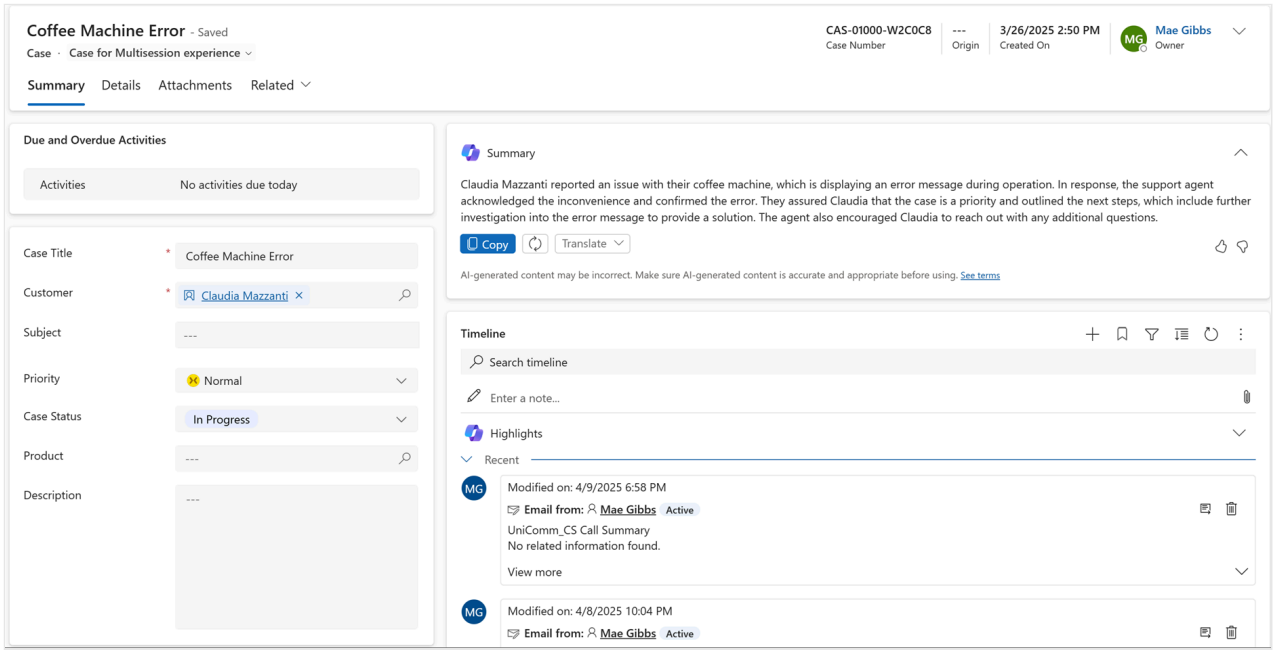
Based on the case form configured, users see the summary either on the top of the case form or within the form.

> ⓘ **Note**
>
> Users won't see case summary cards on case forms
>
> - By default, if their organization has opted out of the automatic enablement of Copilot feature.
> - If case summary is disabled in the experience profile.

- Users can see the case form displayed on the top of all case forms except **Case for Interactive experience**, **Enhanced full case form**, **Case**, and **Case for Multisession experience** forms. Users can copy the summary, refresh it, regenerate the summary, and provide feedback.



- Users can see the case form displayed within the case form for **Case for Interactive experience**, **Enhanced full case form**, **Case**, and **Case for Multisession experience** forms. Users can copy the summary, translate the summary into multiple languages, refresh it, regenerate the summary, and provide feedback.



- If custom record summary is enabled, users see the custom record displayed on top of the form by default.

Supervise agents in model-driven apps with agent feed (preview)

[This article is prerelease documentation and is subject to change.]

> **Important**
>
> Starting May 01, 2026, agent feed will support those agents only that use the Power Apps MCP server to create tasks. Make sure that your agents are properly onboarded to the Power Apps MCP server by this date to continue using the agent feed. If your agents don't use the Power Apps MCP server, the agent feed won't appear in your model-driven app.

Agent feed enables human-agent collaboration in apps by surfacing agent-generated, actionable tasks that users can review, validate, and complete. By using agent feed, apps act as a collaboration surface where users supervise and interact with agent work through a unified, task-based feed.

Prerequisite

The agent feed shows when at least one agent uses the Power Apps MCP server and is supervised in the app. Learn how to Add agents to an app.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is being gradually rolled out across regions and might not be available yet in your region.
> - This feature is only available in English language and replaces older Microsoft Copilot Studio activity-based agent feed version.

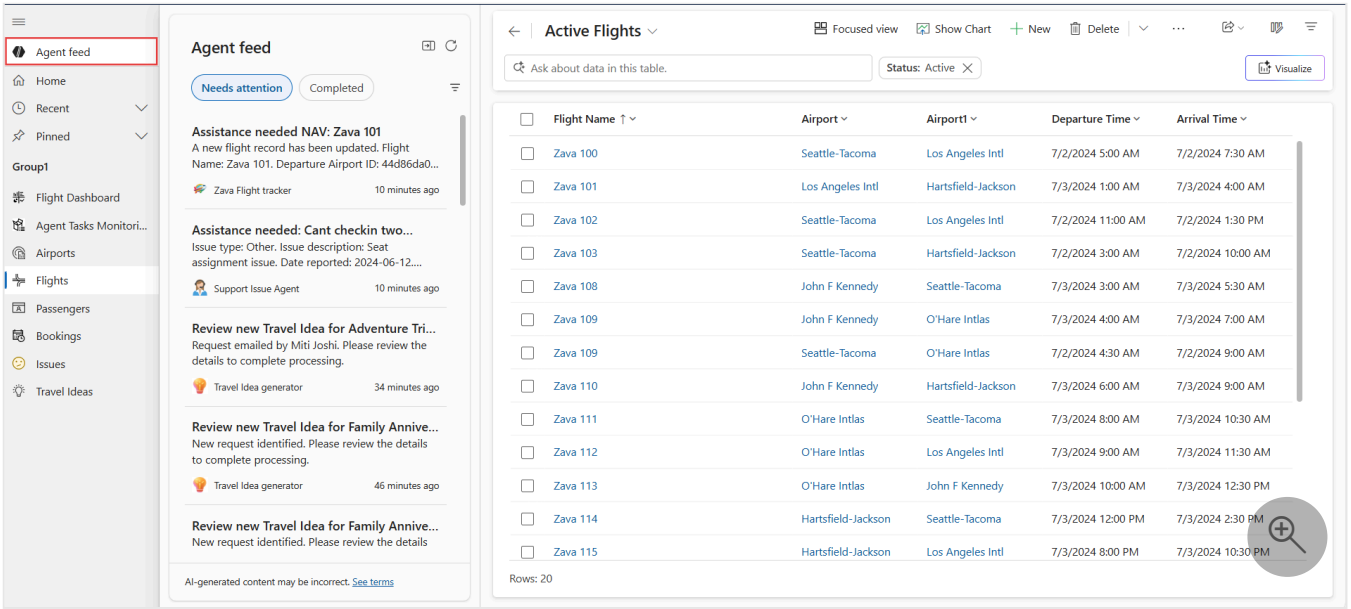
> **Note**
>
> Currently, all users who have access to the Agent Task table can see agent feed items in apps. To prevent unintended exposure, don't configure agents to log tasks targeted at specific users.

Use agent feed to supervise agents

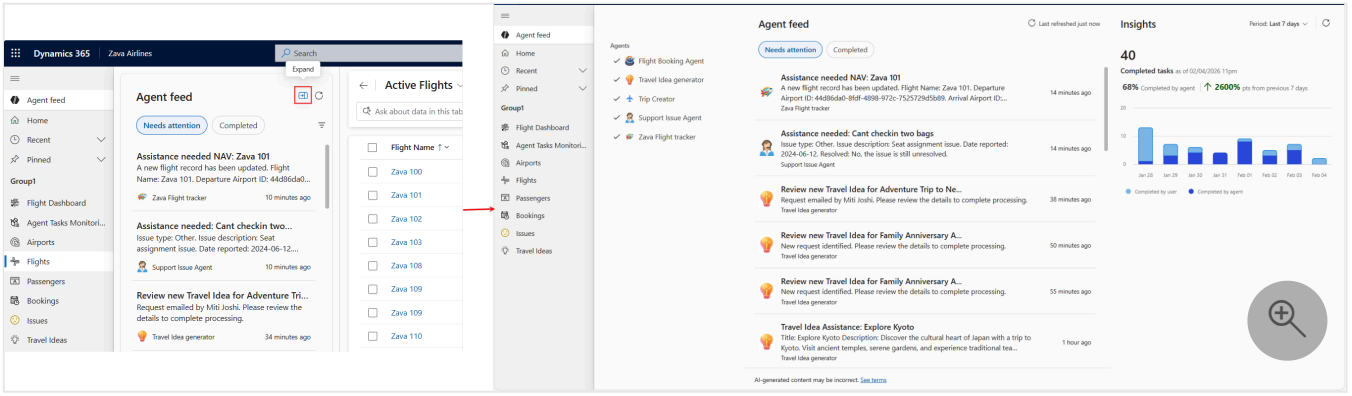
The enhanced agent feed is powered by the autonomous agents using Power Apps MCP server. Power Apps MCP server tools enable following two core human-agent collaboration patterns:

1. Autonomous Dataverse record creation and updates with human-in-the-loop approval and review.
2. Agent requests for human assistance and logging tasks for human review. In agent-enabled apps, user focus shifts from doing the work to supervising and prioritizing agent-driven work. Agents help with automations and organize work, ensuring business experts remain involved in decision-making and critical actions.

To allow users to view an agent's activity in the app, the agent must connect to Power Apps MCP server. The agent feed appears at the top of the site map in an app.

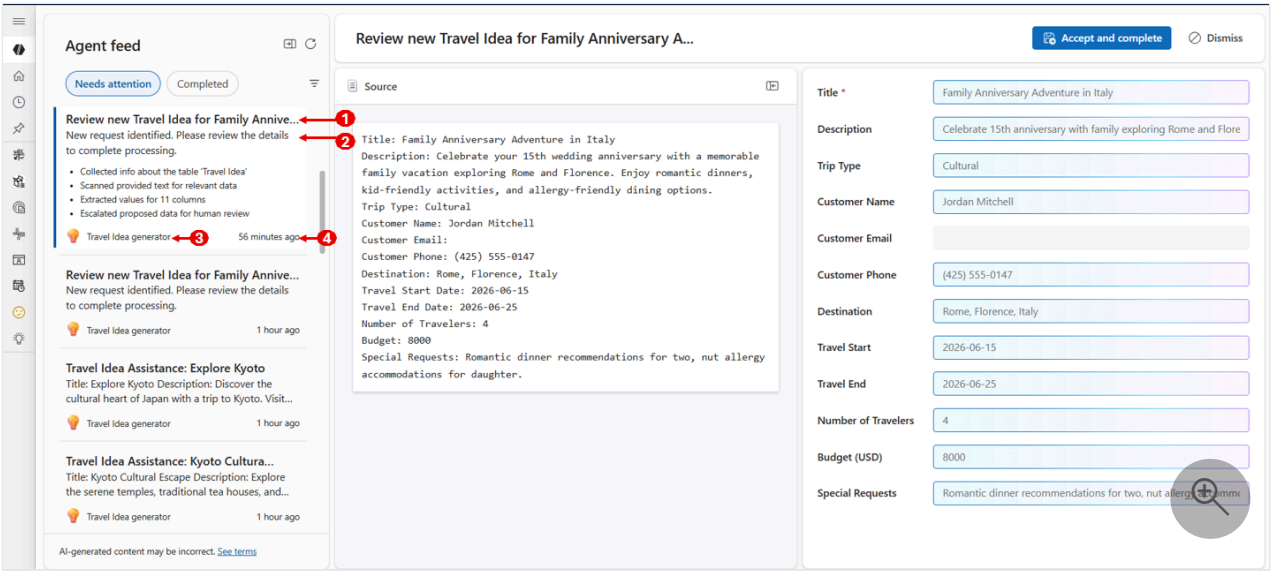


You can view the feed in the side pane or expand it to full screen.



The feed shows a list of agent tasks. Each item can include:

- Title of the task
- Description of the tasks with optional steps
- The agent's name and icon
- A timestamp of when the task was logged

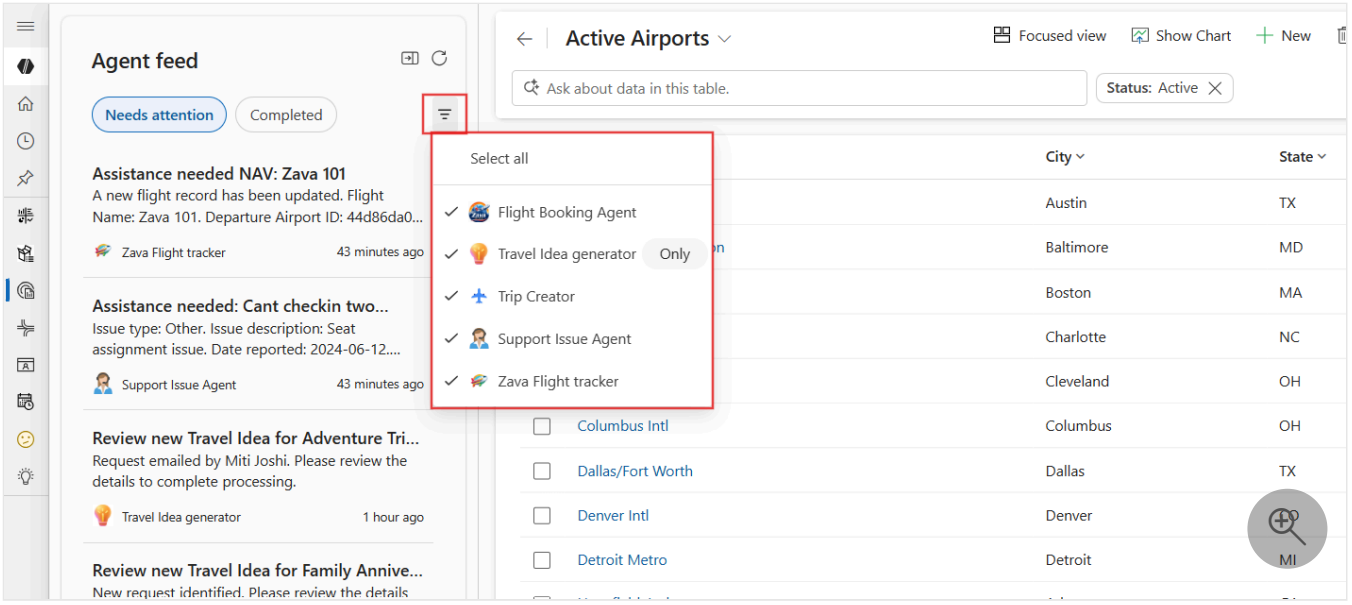


Activity is grouped into two sections:

- **Needs Attention**: Shows tasks that are waiting for your input or need your attention. These tasks are logged by using the `request_assistance` or `invoke_data_entry` MCP tools.
- **Completed**: Displays all other agent feed tasks, including tasks the user completed and tasks the agent completed that are logged for review by using the `request_review` MCP tool.

By default, each section loads 20 agent tasks and lazy loading is enabled as you scroll. The sections are sorted chronologically by the last modification date of each action.

You can filter the feed by agents.

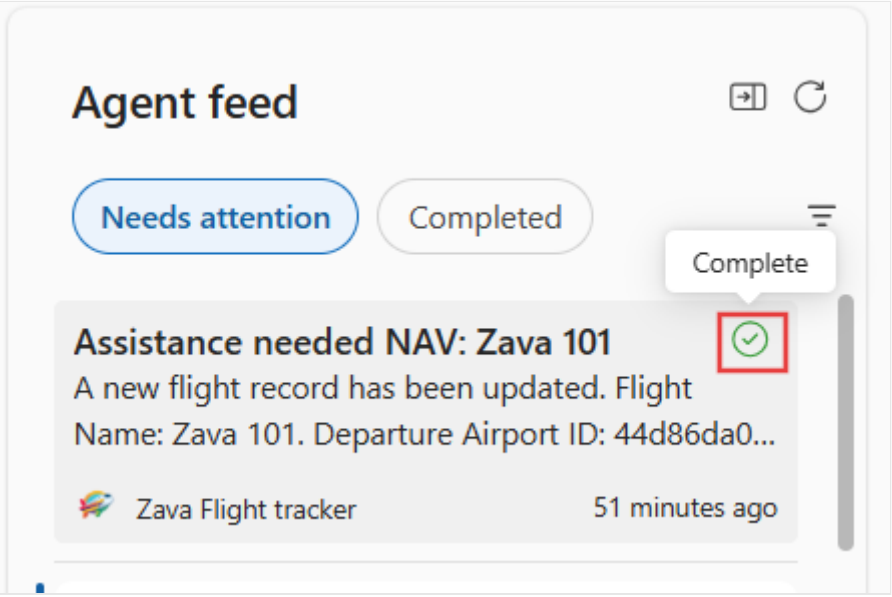


View the agent feed in a side pane to support multitasking or expand it to full screen for focused review.

Take action on agent activity

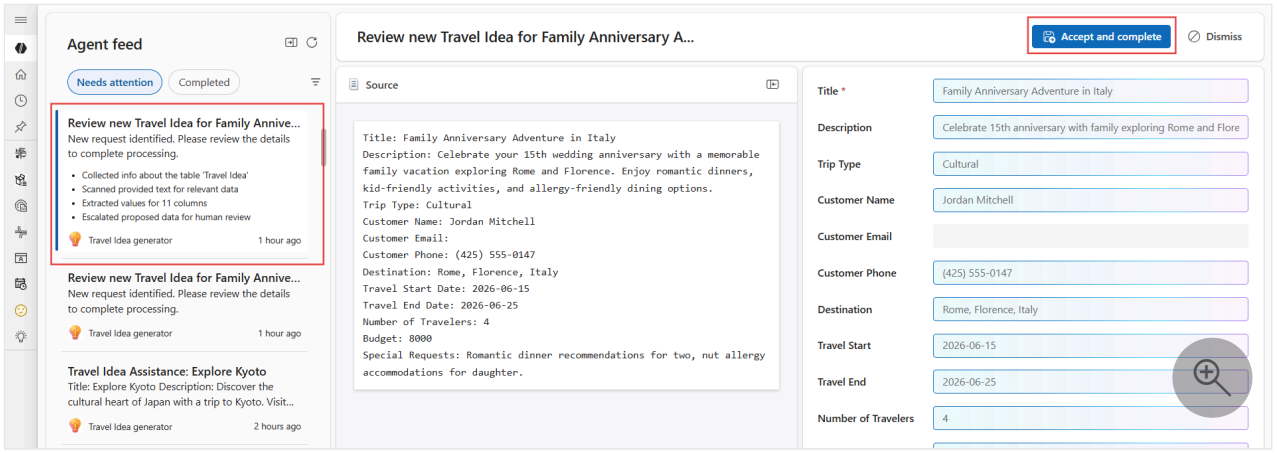
Take these actions on tasks under the **needs attention** tab in agent feed:

- **Complete**: Move a task from the **needs attention** section to **Completed** after completing the task the agent couldn't finish. This action is available for the agent tasks logged by using the **request_assistance** mcp tool.

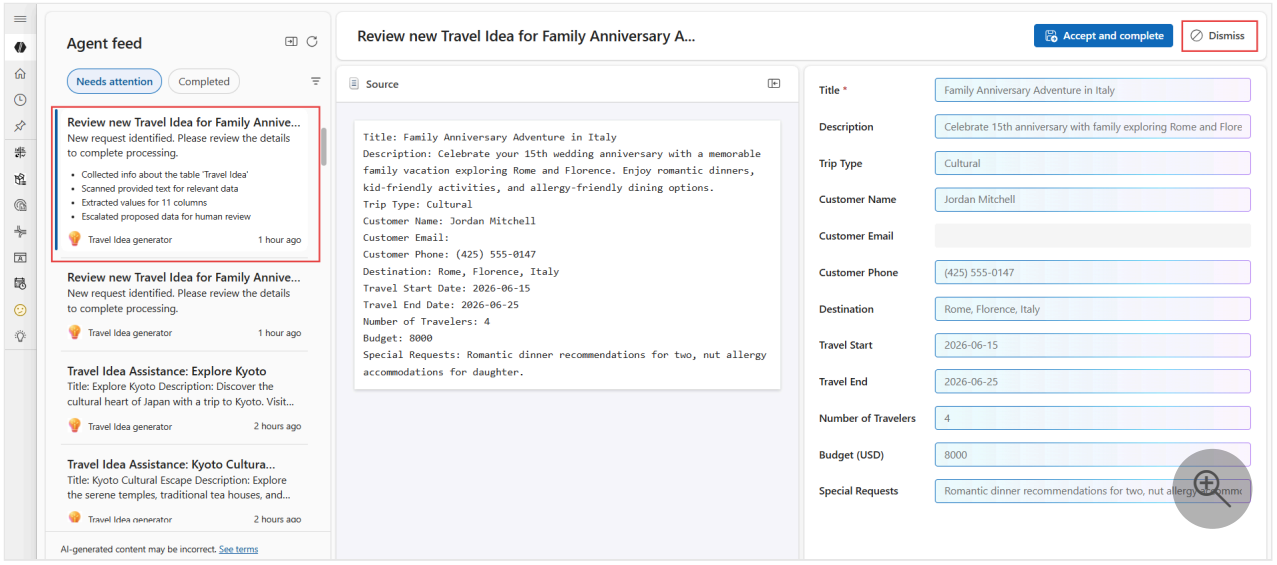


- **Accept and complete**: Move a data entry task from the **Needs attention** section to **Completed** after reviewing and accepting the data entry suggestions from

invoke_data_entry mcp tool. The **Accept and complete** button is available inside the agent pane associated with the agent feed task.

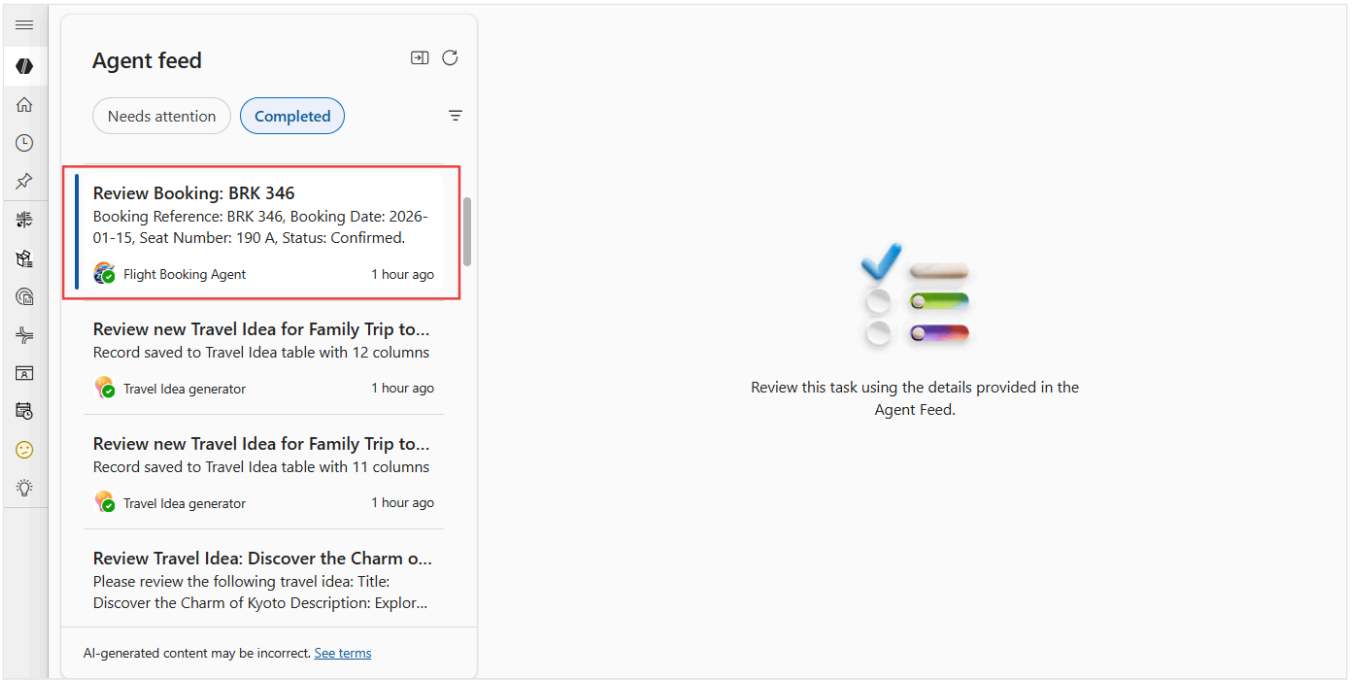


- **Dismiss**: Remove a data entry task logged via **invoke_data_entry** mcp tool from the **Needs attention** section if it's no longer relevant. The **Dismiss** button is available inside the agent pane associated with the agent feed task.



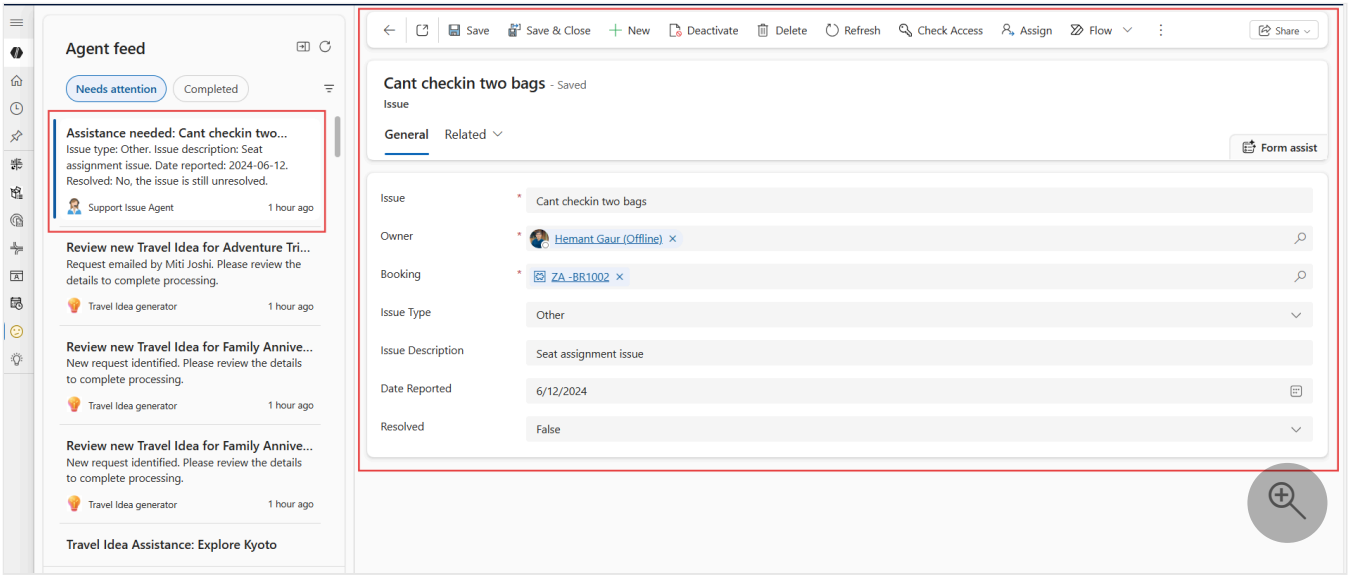
> **Note**
>
> You can perform all actions either from the main screen in the feed or from the details page of a specific action.

- **Request_review tasks**: Tasks logged via request_review mcp tool don't have any actions for the users. They're informational tasks completed autonomously by agent and can be found in completed agent feed tab.



Navigation from agent feed item

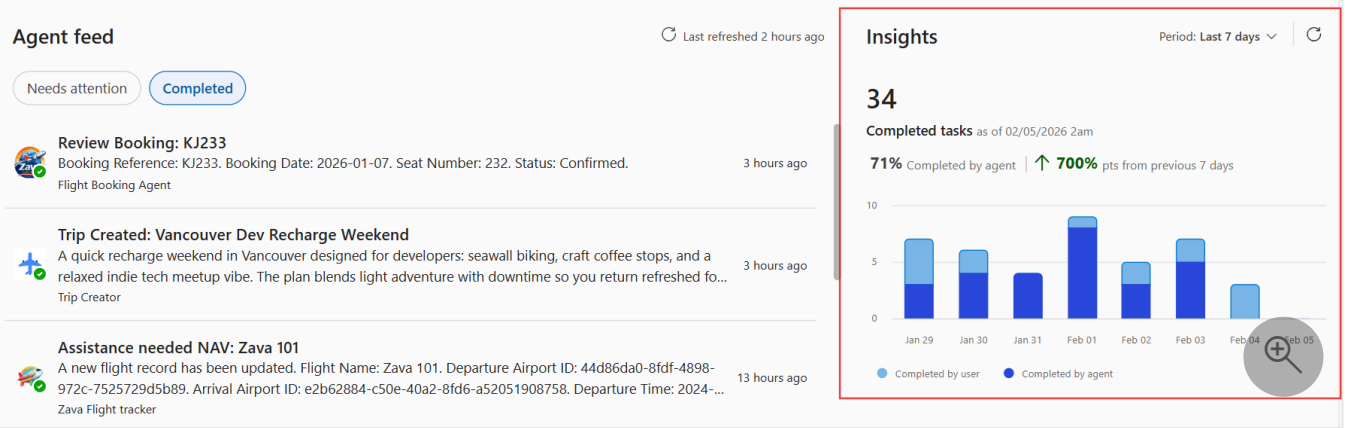
Agent feed tasks generated through the request_assistance or request_review MCP tools can reference a Dataverse record as a related navigation link in the agent description. This reference allows users to easily open and review associated data when interacting with the feed item.



Insights panel

The default insights panel complements the agent feed by giving users a clear, aggregated view of how their agents and users collaborate over time. While the agent feed surfaces individual tasks and actions in the moment, the Insights chart provides a historical, high-level representation of those interactions. This representation helps organizations understand the

true patterns of human–agent collaboration, whether users step in to provide missing context, guide agents through a complex workflow, complete tasks directly, or monitor agent activity. By visualizing these trends over time, organizations gain transparency into how their agentic workflows actually operate in practice, strengthening trust, identifying friction points, and revealing opportunities to improve system reliability and user experience.



The insights chart presents aggregated activity across the last 7, 14, or 30 days. It gives customers a time-based snapshot of collaboration between agents and users. Activity is categorized into two groups:

- Tasks completed by agents
- Tasks completed by users These at-a-glance aggregations offer a concise understanding of collaboration volume and balance over time. They help teams quickly assess how work is distributed across human and agent participants.

Customize Copilot Chat

Last updated on 04/07/2026

Use Copilot chat in model-driven apps

Copilot chat for model-driven apps in Power Apps is a next-generation AI assistant that helps you gain insights into the data in your apps through conversations in natural language. Copilot chat helps you boost your productivity through AI-powered insights and navigation assistance.

> **Important**
>
> - This feature is generally available in Dynamics 365 apps, but remains a preview feature in Power Apps.
> - Preview features aren't meant for production use and might have restricted functionality These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

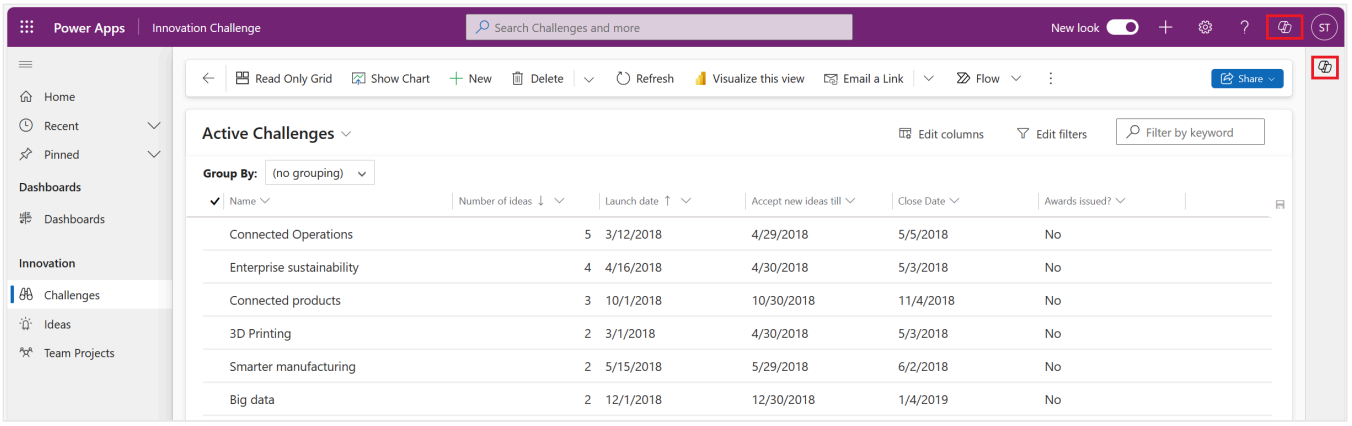
> **Note**
>
> Copilot chat in Power Apps is a preview feature that will be deprecated for model-driven apps in environments not enabled for Dynamics 365 apps, starting January 2026. We recommend switching to Microsoft 365 Copilot chat. During the transition period, makers can enable either one or both chat experiences. For more information, see Deprecation of Copilot chat in model-driven apps

Prerequisites

An administrator must enable Copilot chat in your application before it becomes visible in your app. More information: Add Copilot for app users in model-driven apps.

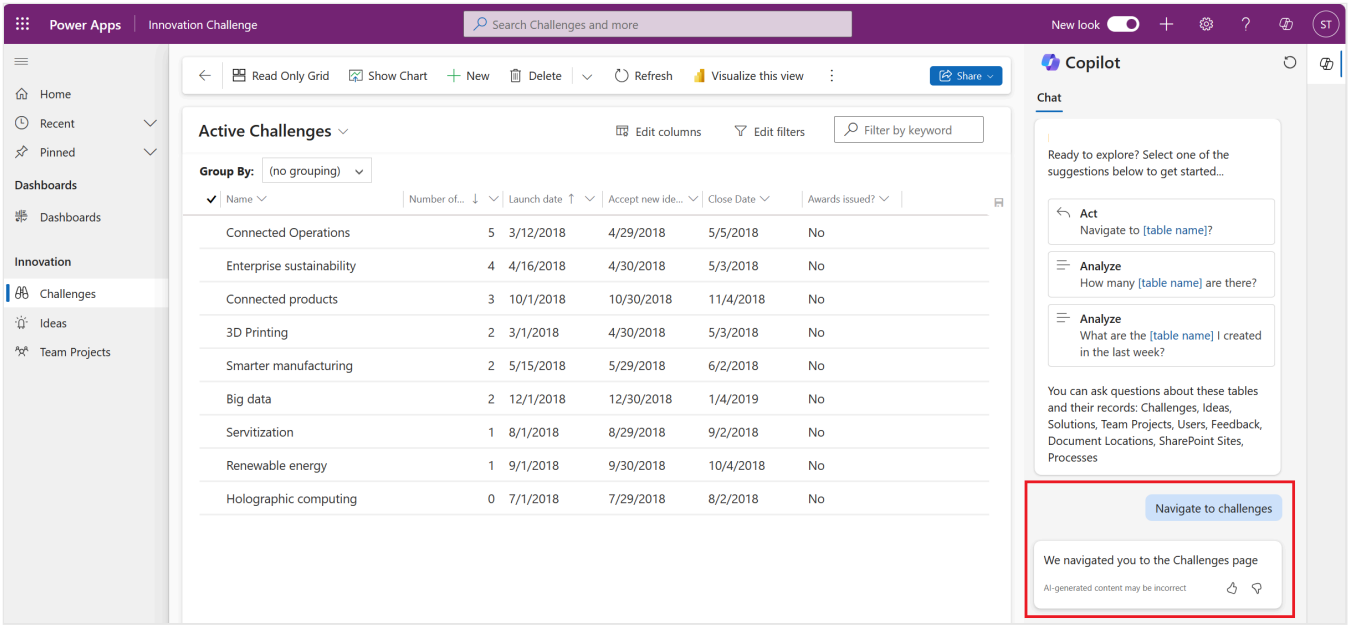
Copilot pane

After Copilot chat is enabled, you can access it through the Copilot icon near the upper-right corner of the page or through the Copilot icon at the right side of the command bar. You can expand or collapse the Copilot pane as you want. By default, the pane is expanded after Copilot chat is enabled.



Use Copilot to ask questions

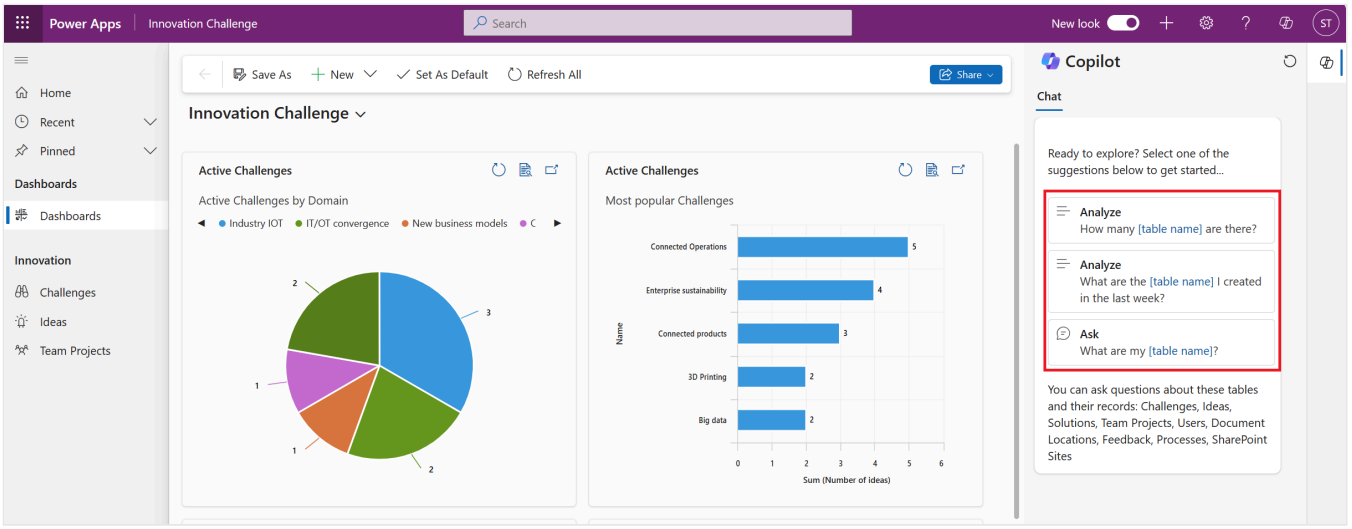
Copilot chat in model-driven apps can answer questions about the Dataverse table data in the app. It can also help you navigate the app. For example, if you enter **Navigate to challenges**, Copilot automatically opens the relevant page in the app.



Copilot chat suggested questions

To help you get started, Copilot chat can suggest questions for you to ask. You can edit and personalize these questions (also known as prompts) based on your app and the type of insight that you need from Copilot.

To view more suggested questions, select **View prompts** in the Copilot pane. Many of the suggested questions have placeholders that you must replace with appropriate text to complete the question.

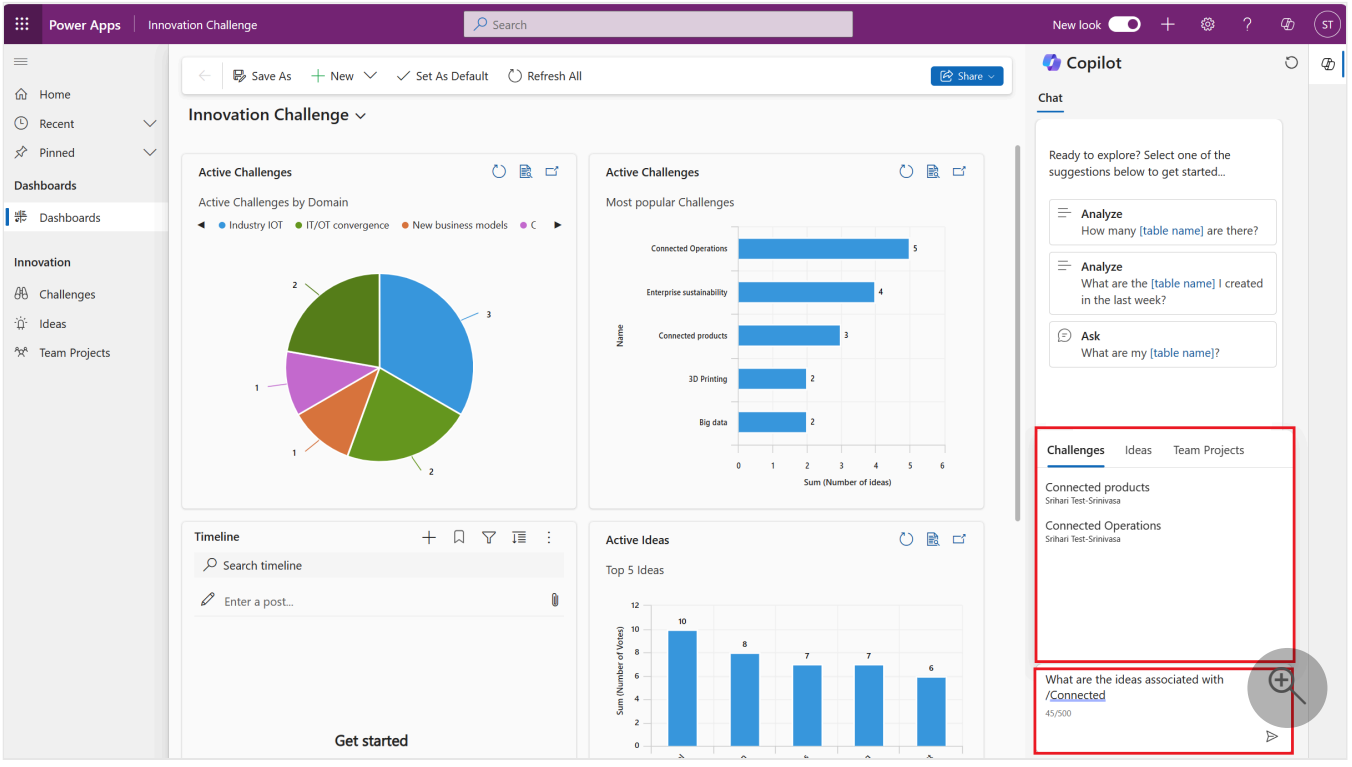


Use the record picker

When you ask a question, you can use the record picker to select the object of your question. The record picker helps Copilot chat understand the context of your question and provide a more accurate response.

Enter a slash (/) to open the record picker, and then enter the name of the record. Select the record that you want, and complete the question to make it meaningful. Finally, submit the question to Copilot to view the response.

For example, you ask Copilot "What are the details for Contoso?" Many accounts might have "Contoso" in their name, such as Contoso, Inc., Contoso Co., and Contoso NW. What you really want are the details for Contoso, Inc. The record picker helps Copilot scope the question to the right record for a more relevant and accurate response.



The record picker is available in Dynamics 365 Sales and Power Apps model-driven apps.

> **Note**
>
> - By using the record picker, you increase the likelihood that Copilot chat can understand your question and therefore respond with an accurate answer.
> - The record picker requires that Dataverse search is enabled and configured for the type-ahead search capability.

Provide feedback

Unless your admin turned off the feedback feature, every Copilot response includes a **Like** button ("thumbs up" icon) and a **Dislike** button ("thumbs down" icon). For each response, you can select one of these icons to provide feedback that helps us improve Copilot chat. Select the "thumbs up" or "thumbs down" icon as appropriate. Optionally, provide feedback in your own words about what you liked or didn't like about the response. When you're done, select **Submit**.

Basic navigation in a model-driven app

Article • 01/16/2025

This introduction explains how to find and open an app, and how to work with its common user interface elements including lists, forms, and business processes.

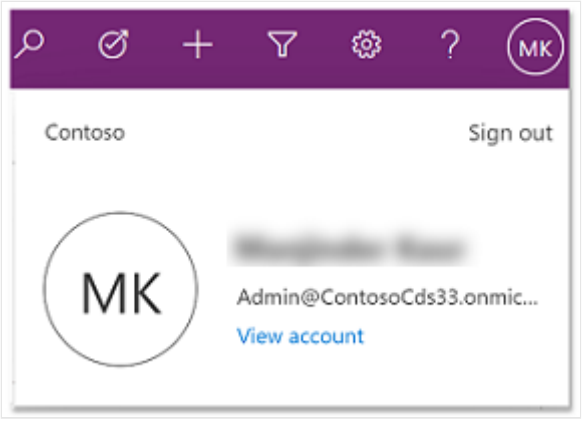
Navigating among apps, areas, and tables

A model-driven app is built out of applications (apps), areas, and tables.

- *Apps* provide a collection of functionalities for accomplishing a specific class of activity, such as managing your accounts and contacts. Use the app-selector menu to navigate between the apps that are available to your organization.
- A *work area* is a subdivision of an app, dedicated to a specific feature. Each work area provides a targeted collection of tables for working in that area. In some cases, the same table appears in more than one area (or even more than one app). The Contact and Account tables, for example, appear in various apps and work areas. Use the work-area menu to navigate between work areas for your current app.
- *Tables* represent a specific type of data, such as contacts or accounts. Tables use a structured data format, which defines the collection of columns available to the table. Each table consists of a collection of individual rows. For example, for the Contact table, each row describes a single person, and each row includes a collection of columns such as first name, last name, and email address. Tables normally present two views: a list view, which is typically a table listing available rows; and a form view, which shows all available data and settings for a single row. Use the side navigator to move between tables in your current work area.

User info and sign out

Select the user menu to view your account information or sign out. Go to your account page by selecting the **View account** hyperlink.

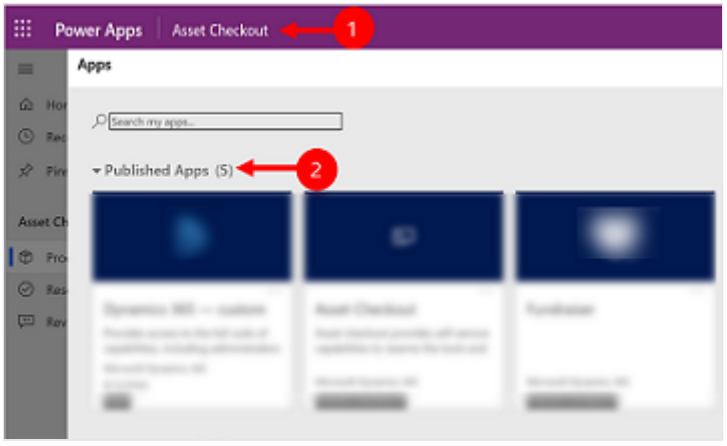


Move between apps

Use the app-selector menu to switch between apps.

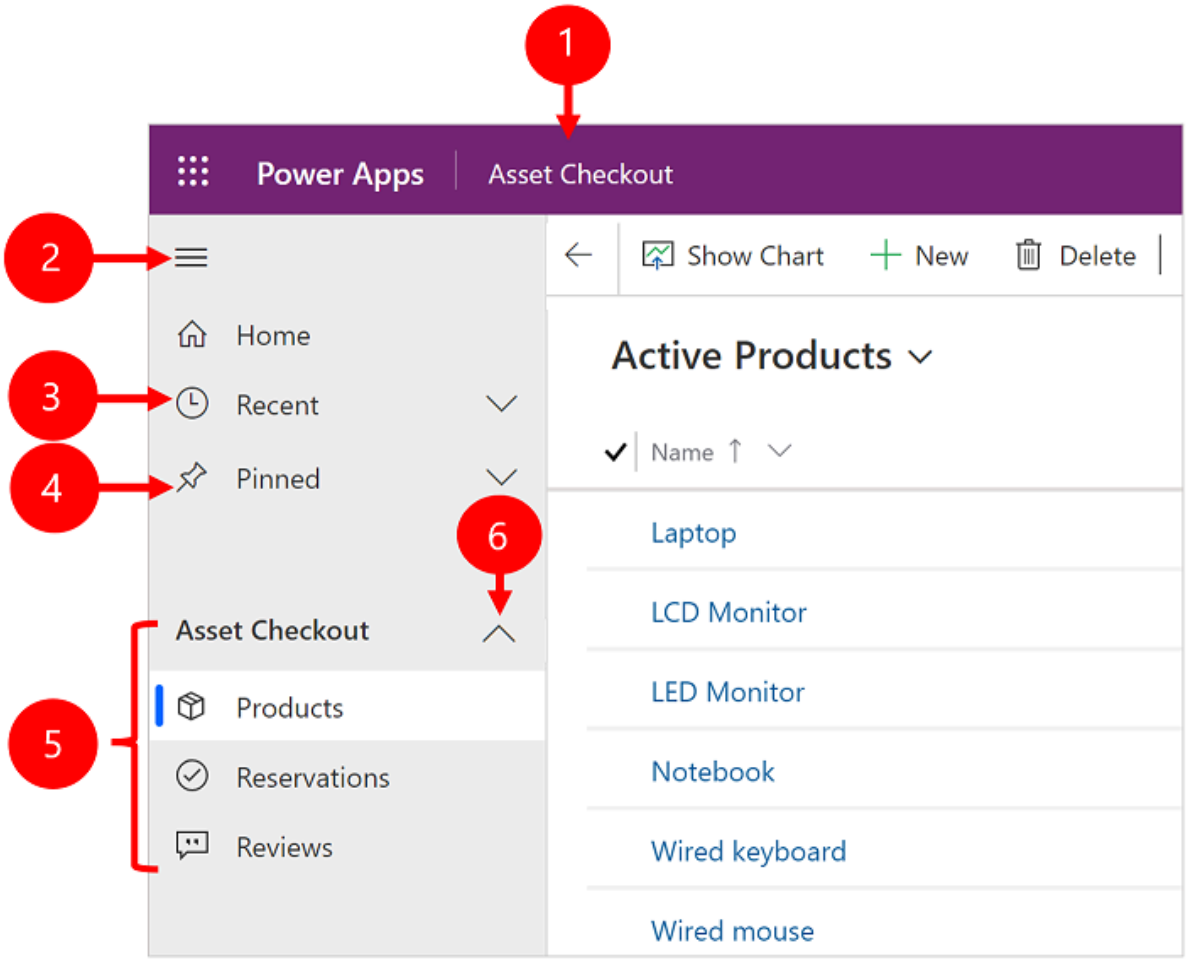
1. Select the current app name.

2. On the Apps page, select an app. You'll only see apps for your organization.



Move between pages and rows

It's easy to get around and get back to your favorite or most-used rows. The following illustration shows the primary navigation elements.



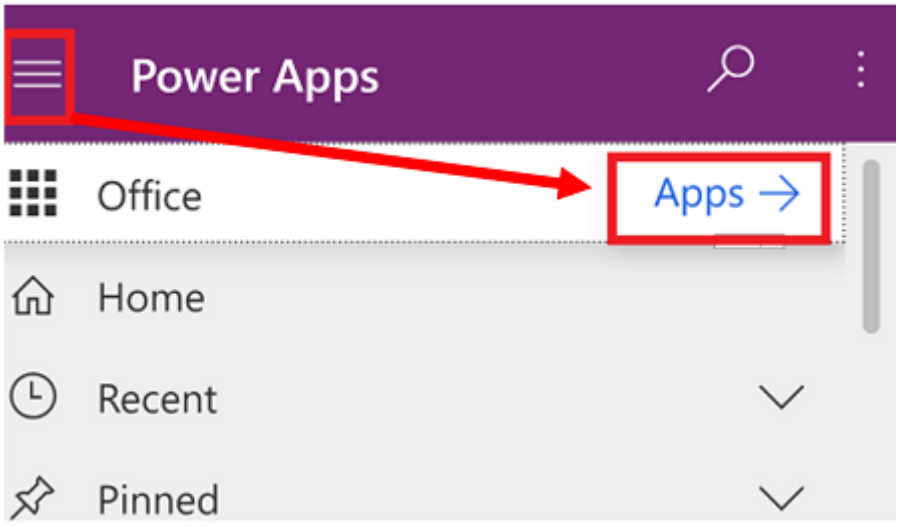
Legend

1. **Click to change app**: Select the current app name to change to a different app.
2. **Collapse/expand site map**: Select this to collapse the navigator to allow more room for the main part of the page. If the navigator is already collapsed, select this button to expand it again.
3. **Recent**: Expand this entry to view a list of rows you were recently using. Select a row here to open it. Select the push-pin icon next to a row listed here to add it to your pinned rows. This is limited to displaying the last 10 rows of pages most recently loaded across apps for the user within this organization.
4. **Pinned**: Expand this entry to view and open your favorite pinned rows. Use the **Recent** list to add rows here. Select the remove-pin icon next to a row listed here to remove it from this list. The number of pinned rows displayed is limited to 25, but no more than 15 rows from a single table are displayed.
5. **Page navigation**: This area lists each table and dashboard page available for the current work area. Select any entry here to open the named dashboard or list view for that table.

> **Note**
>
> When a user sets a dashboard as default (via the **Set as default** action in the command bar), all page navigation to dashboards will take the user to the default dashboard, which may be a different dashboard than the named dashboard the user selected.

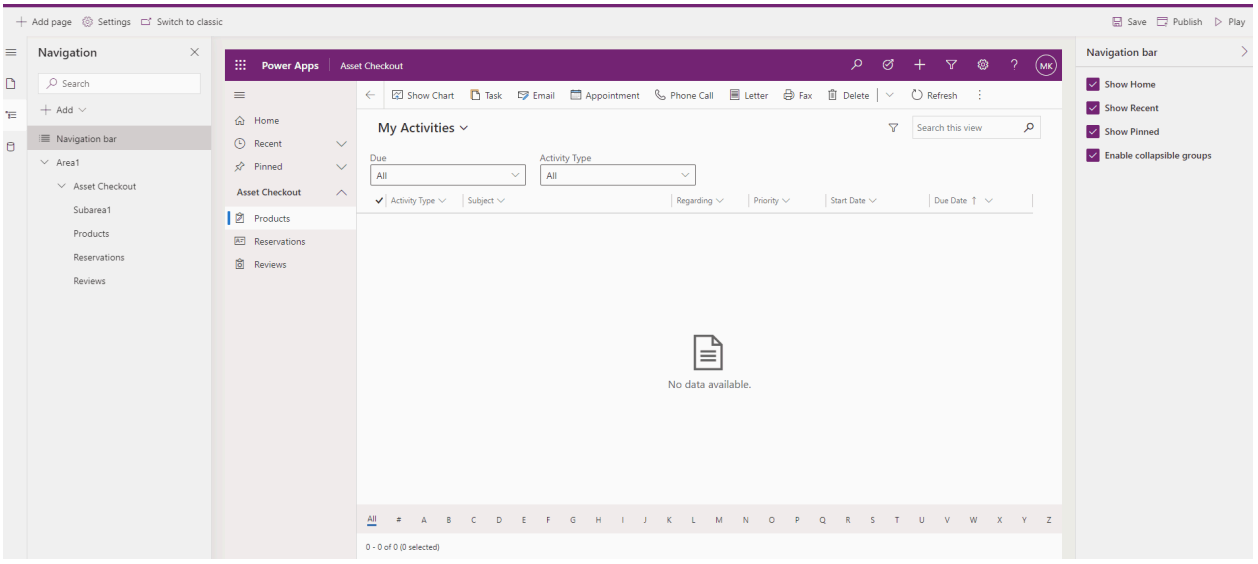
6. **Collapsible groups**: Your app maker can enable collapsible groups. For information on how to customize the navigation bar, see Overview of the model-driven app designer.

If your screen is zoomed in too much or is narrow, then you won't see your current app name which lets you change apps. To access the change app button, select **Site map** > **Apps**.



Hide or show the Home, Pinned, Recent, and collapsible groups

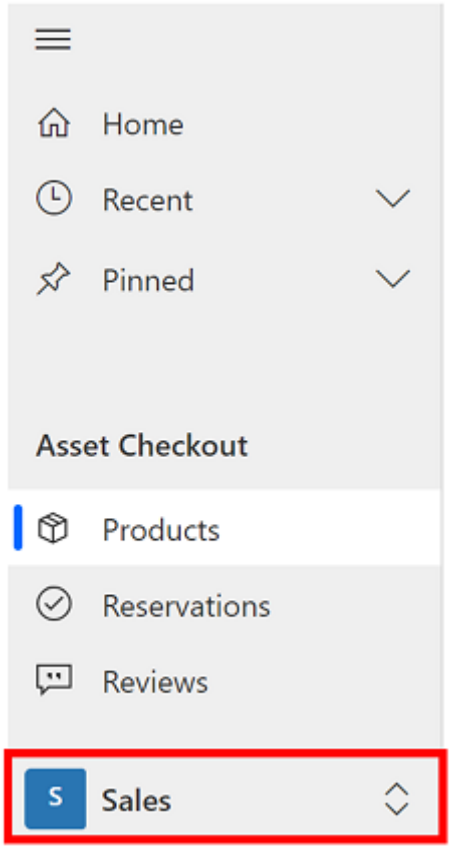
Your site map might look different if it's been customized. Your app maker can customize the navigation bar to show or hide the **Home**, **Recent**, **Pinned** buttons in the site map. An app maker can also make groups collapsible. For information on how to customize the navigation bar, see Overview of the model-driven app designer.



Area switcher

In the left-hand navigation pane, the area switcher appears at the bottom left only when a single model-driven app has more than one area in the sitemap definition.

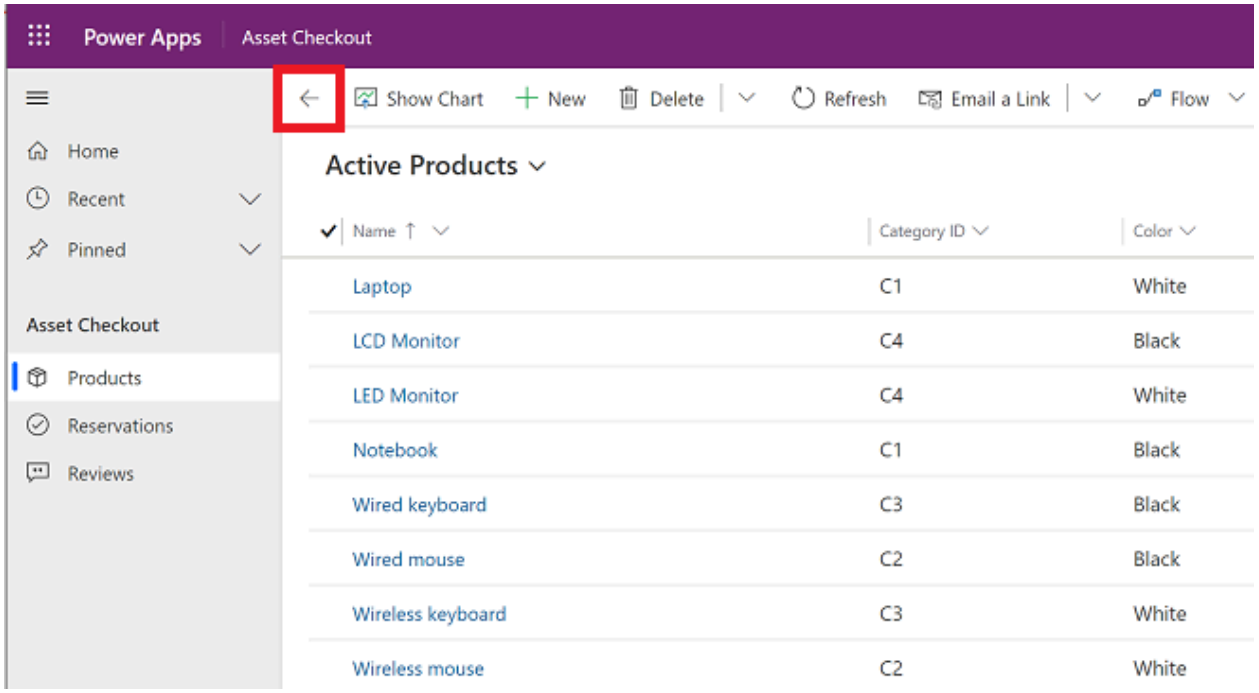
Open this menu to move to another work area. The current work area is named here.



Go back

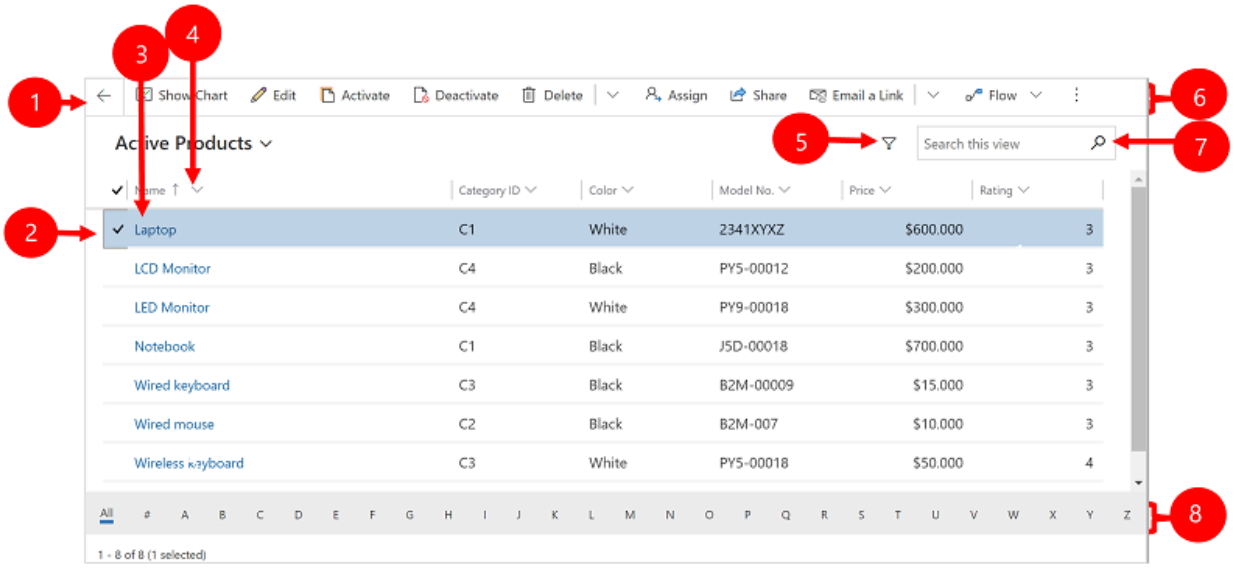
Use the back button for form, view, and dashboard pages on the command bar to go back to the previous page.

To go back to the previous page, select the **Go back** button.



Working with list views

Usually, when you first open a table, you'll see the list view, which shows a list of rows belonging to that table, formatted as a table. For example, if you open the **Products** table, you'll see a list of accounts.



Legend:

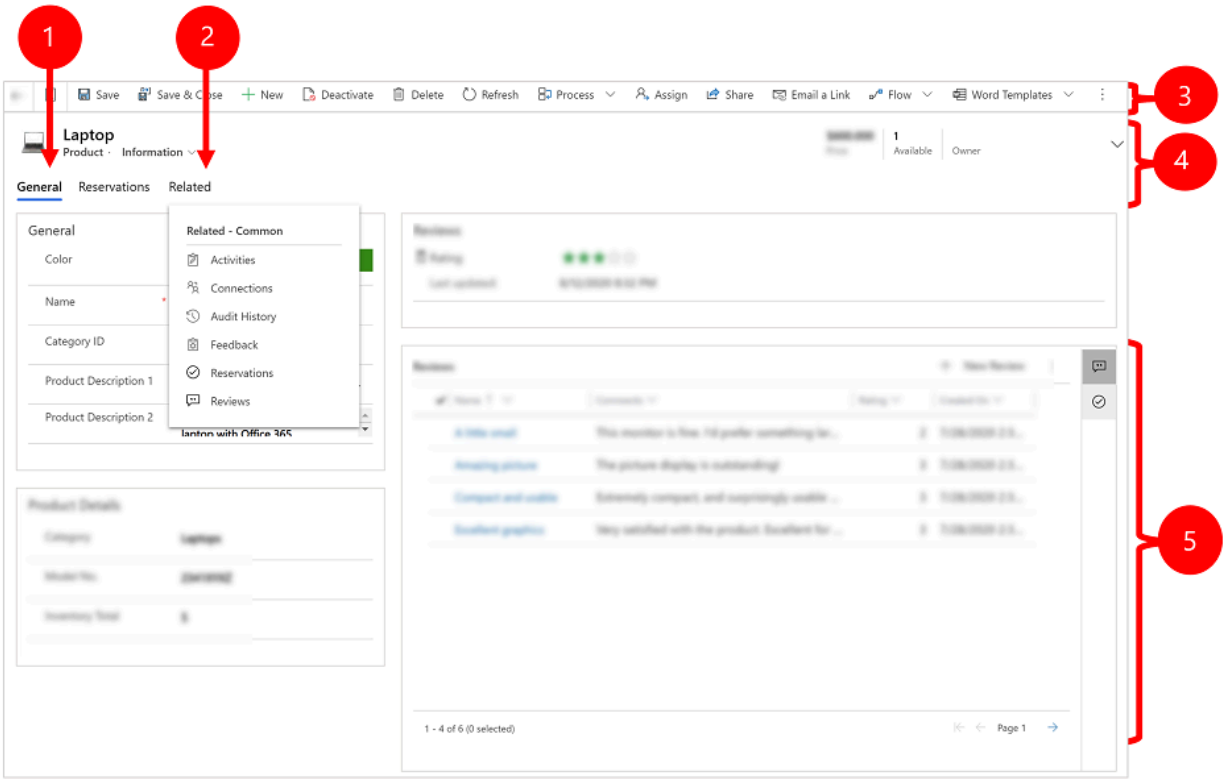
1. **Go back**: Select to go back to the previous page.
2. **Select rows**: Select one or more rows by placing a check mark in this column. Depending on where you're working, you might be able to apply a single operation to all the selected rows at once by using buttons in the command bar.

Note, when you use the **Email a link** command on the command bar you can only select up to 10 rows to send via email.

3. **Open a row**: Select any row in the list to open its row view, which shows all the details about the row. Usually you select from the **Name** column to open a row from the current table. Some tables provide links to rows from related tables in other columns (such as a related contact).
4. **Sort or filter the list**: Select to sort the list by values in that column or filter the list by values in that column. An arrow in the column heading indicates which column is being sorted and in which direction.
5. **Open advanced filtering panel**: See which filters are applied to the current view and add or modify view filters.
6. **Command bar**: Use the commands in the command bar to operate on rows in the list and do related actions. Some commands (such as **Delete**) require that you first select one or more target rows by placing a check mark in the leftmost column, while others operate on the entire list. You can export the list to an Excel workbook (possibly based on a template), open charts and dashboards, and more, depending on the type of rows you're working with.
7. **Search the view**: Enter text in the search column above the list to show only those rows in the current view that contain your text.
8. **Jump bar and paging**: Select a letter to show only those rows whose names start with that letter. If the list contains more rows than can be shown on one page, use the paging arrows at the bottom of the list to move forward and backward through the pages.

Working with row views

Row views show all the details about a single row and sometimes also provide special features for working with it. Usually you'll open a row view by selecting a row that appears in a list view, but you can also open a row view by following a link from a related row.



Legend:

1. **Tabs**: Most row views are divided into tabs. Each tab provides a collection of related columns from the row. When tabs are available, they're listed below the row name. Select any tab name to go to that tab. The current tab is shown underlined.
2. **Related**: Nearly all types of rows show a **Related** tab after you've saved them at least once. This tab is actually a drop-down list that you can use to find other types of rows that use or reference the displayed row. When you choose a table name from the **Related** drop-down list, a new tab named for that table opens, showing a list of all related rows of that type. The **Related** tab remains available, and you can still use it to find other types of rows that reference the current one.
3. **Command bar**: Use the commands in the command bar to operate on the current row or perform a task related to the row. The available commands vary based on the row type, but you can typically use the command bar to save your changes, delete the row, refresh the page, email a link to the row, reassign the row owner, or export the row by using a Word template.
4. **Heading bar**: Some row views display a few especially important columns in the heading bar, opposite the row name. These are typically columns that are fundamental to working with rows of the current type (such as a row name or row owner).
5. **View and edit all column values**: In the main body of the row view, you'll find all of the columns related to the current tab, form view, and row type. Columns marked with a red asterisk are required, and you can't save the row without their having valid values. Columns marked with a blue plus sign are especially important or

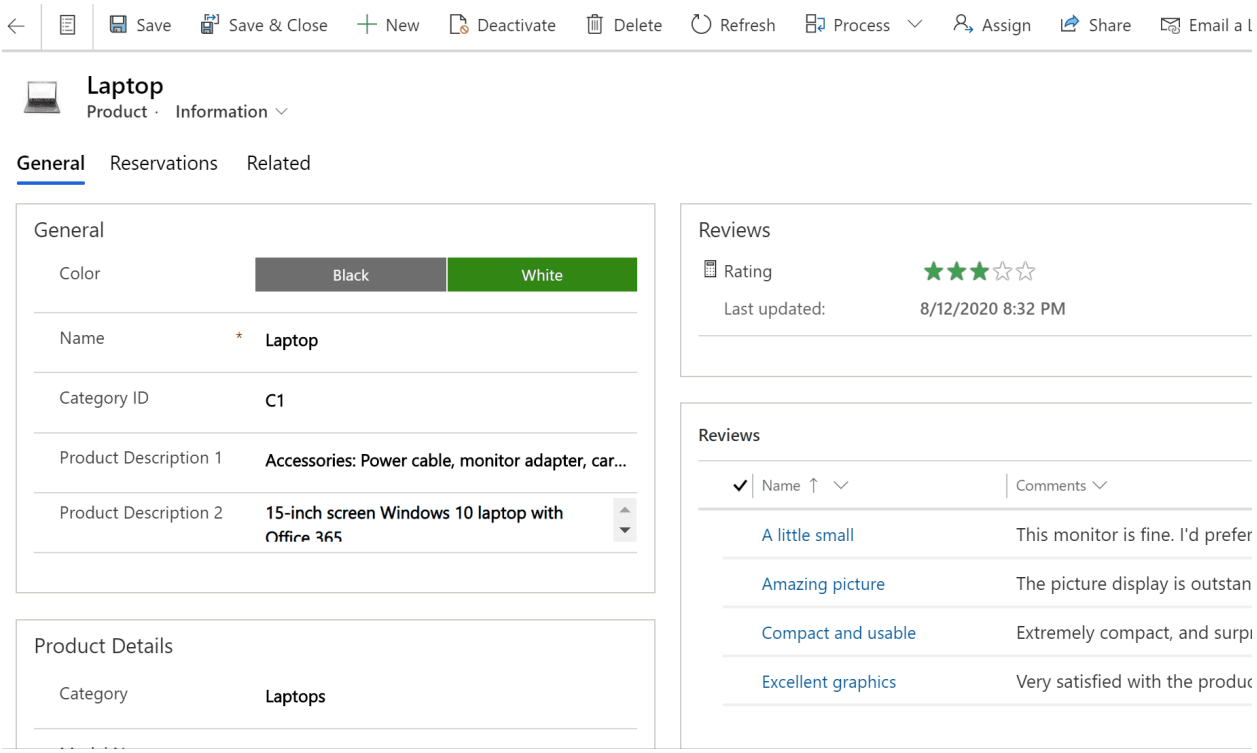
recommended, but aren't strictly required. Columns showing a lock icon are read only and can't be edited.

Row set navigation

Navigate through multiple rows by using preset views and queries. The row-focused navigation improves productivity by allowing users to jump from row to row in the list and easily navigate back without losing their working list.

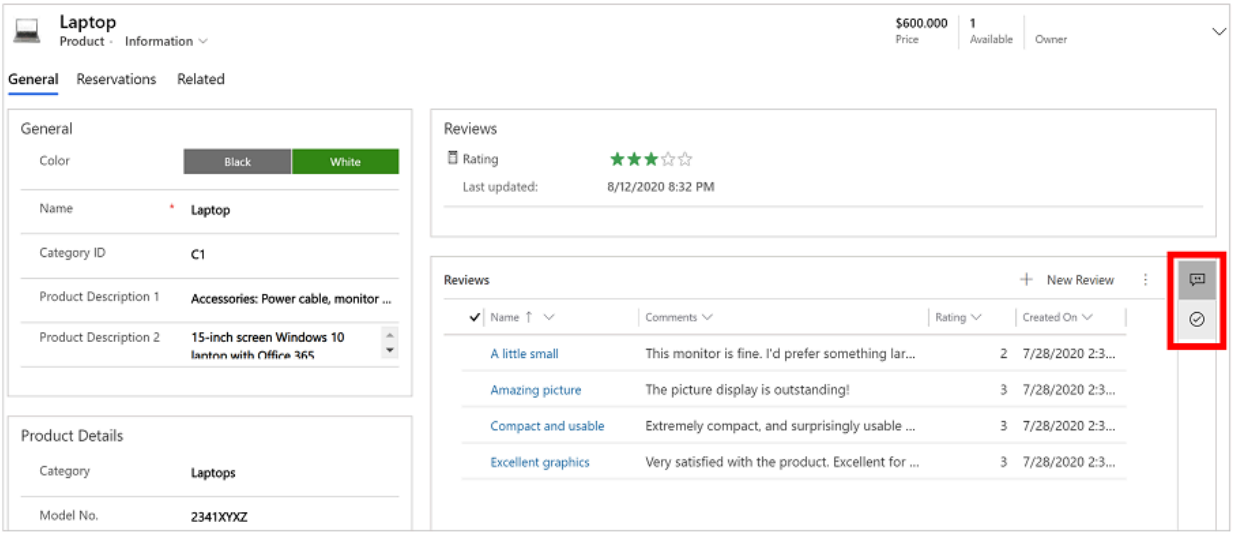
The number of rows that you see in the row set navigation pane is based on the number of rows that your system administrator has defined for the subgrid.

1. To use row set navigation, open a page with a list of rows.
2. Open a row and then select **Open Row Set** and then select a row from the list.



Reference panel

The reference panel is a great way to get work done without moving away from the screen you're on. You can look up other related items—such as reviews or reservations for a product—within the context of the row you're viewing, without having to navigate to other screens.

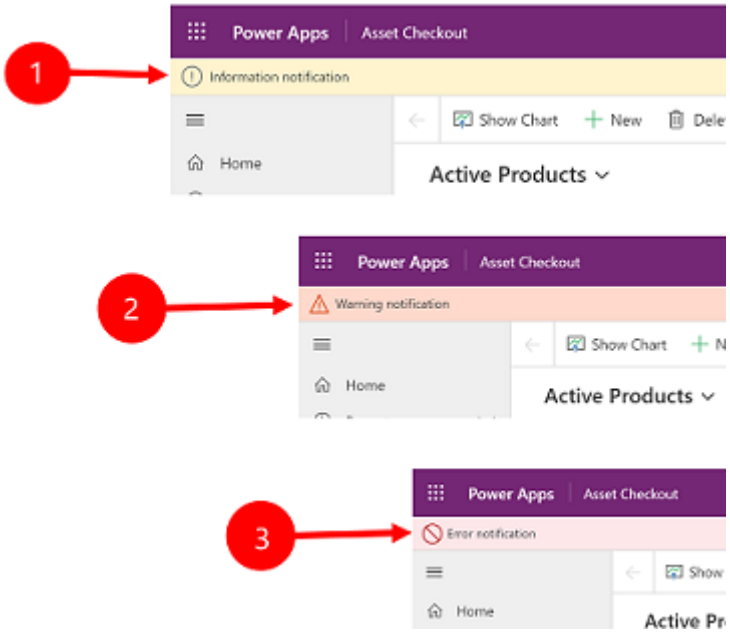


Watch the How to use the Reference panel in the Customer Service Hub video to learn more about the reference panel.

App message bar

The app message bar shows three types of notifications: informational, warning, and error.

When you select the error notification, it will take you to the column on the form where the error occurred.



Legend:

1. **Information notifications** ⓘ: The notification is informational.
2. **Warning notifications** ⚠: The notification is a warning.
3. **Error notifications** ⛔: The notification is an error.

Multiple notifications

If there's only one notification, you'll see a single line. If there are multiple notifications, you'll see chevron button. Select the chevron to view each message.

In-app notifications in model-driven apps

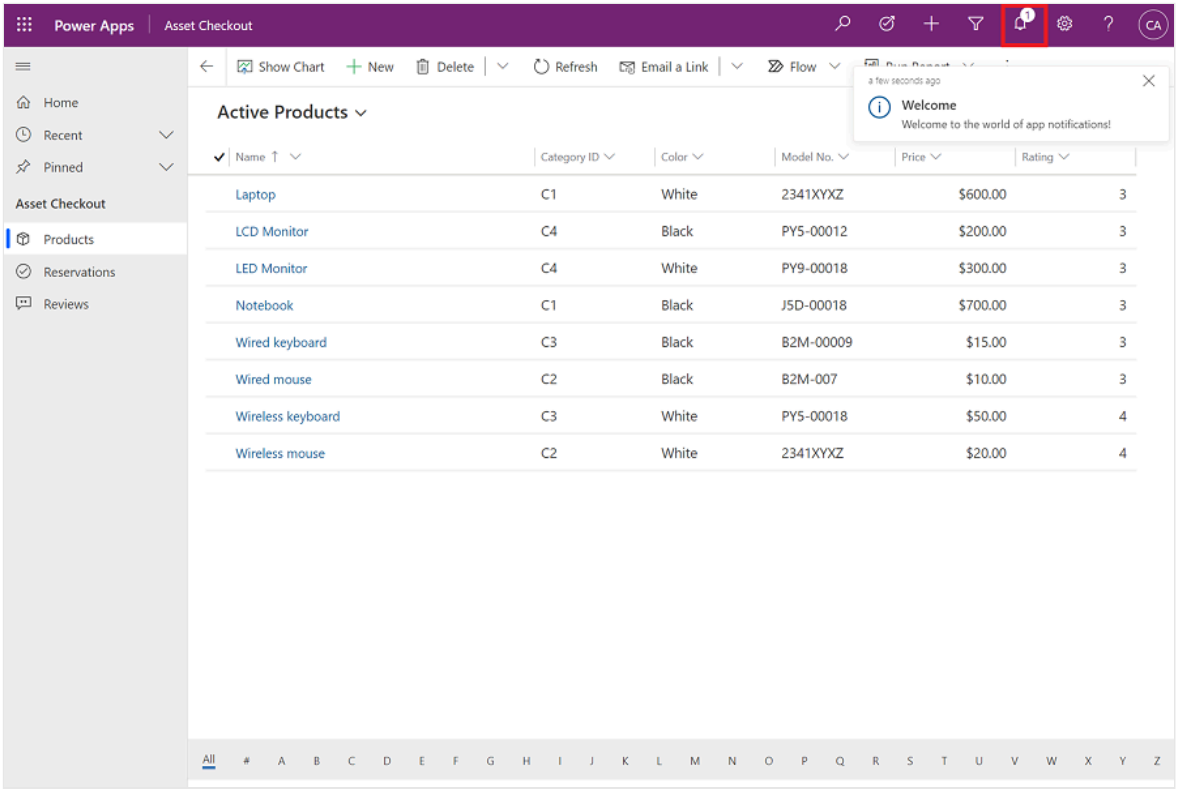
Article • 12/13/2022

In-app notifications allow you to receive notifications in the notification center of your model-driven app. Notifications are stored in the notification center until you dismiss them or when they expire. By default, notifications expire in 14 days but your system administrator can modify the expiration date.

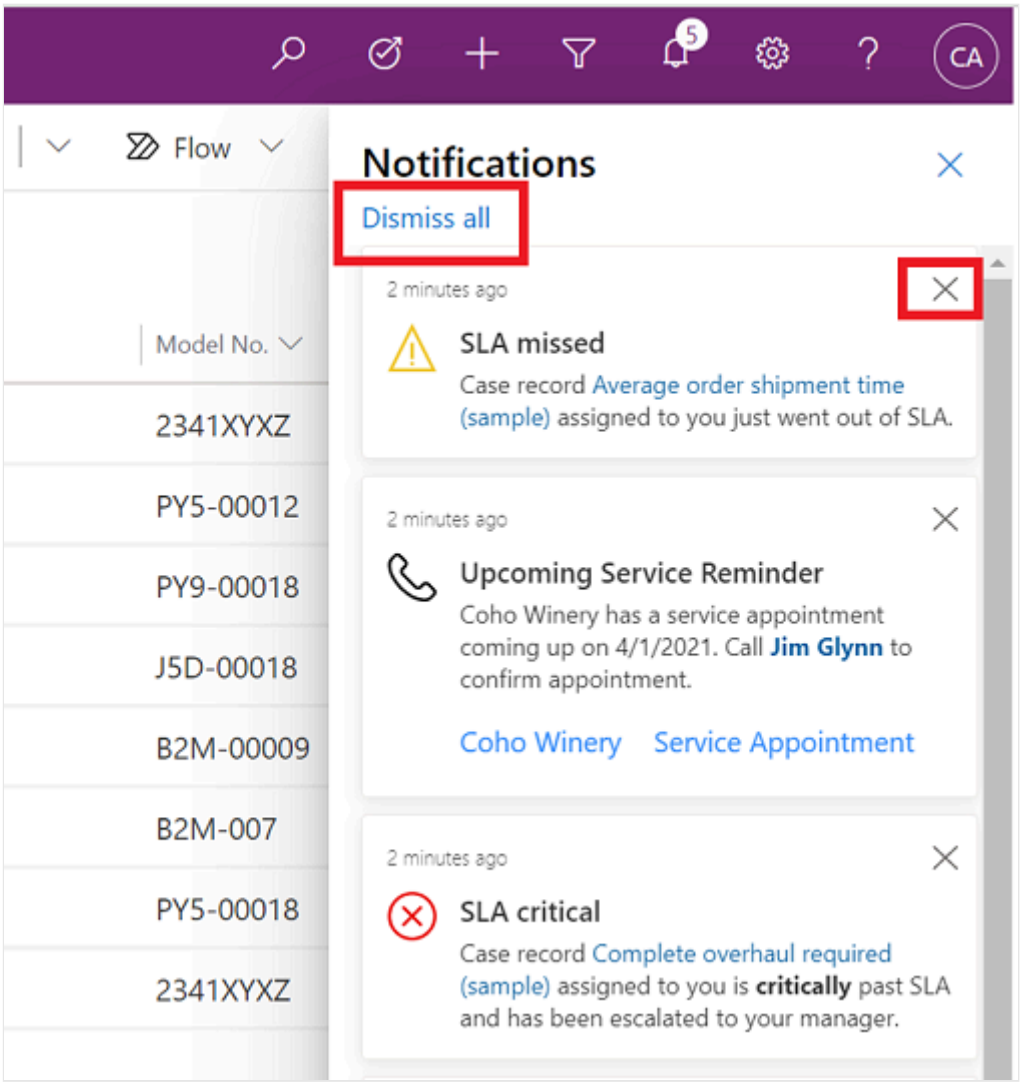
You only see notifications when you're using an app. That's when the system runs a check and displays any new notification. Notifications are at the organization level so you'll see notifications in the app you're using for all apps in your environment.

Notification center

- The notification bell icon shows the count of new notifications. When you open the notification center the count is cleared. To access your notifications, select the bell icon on the nav bar.

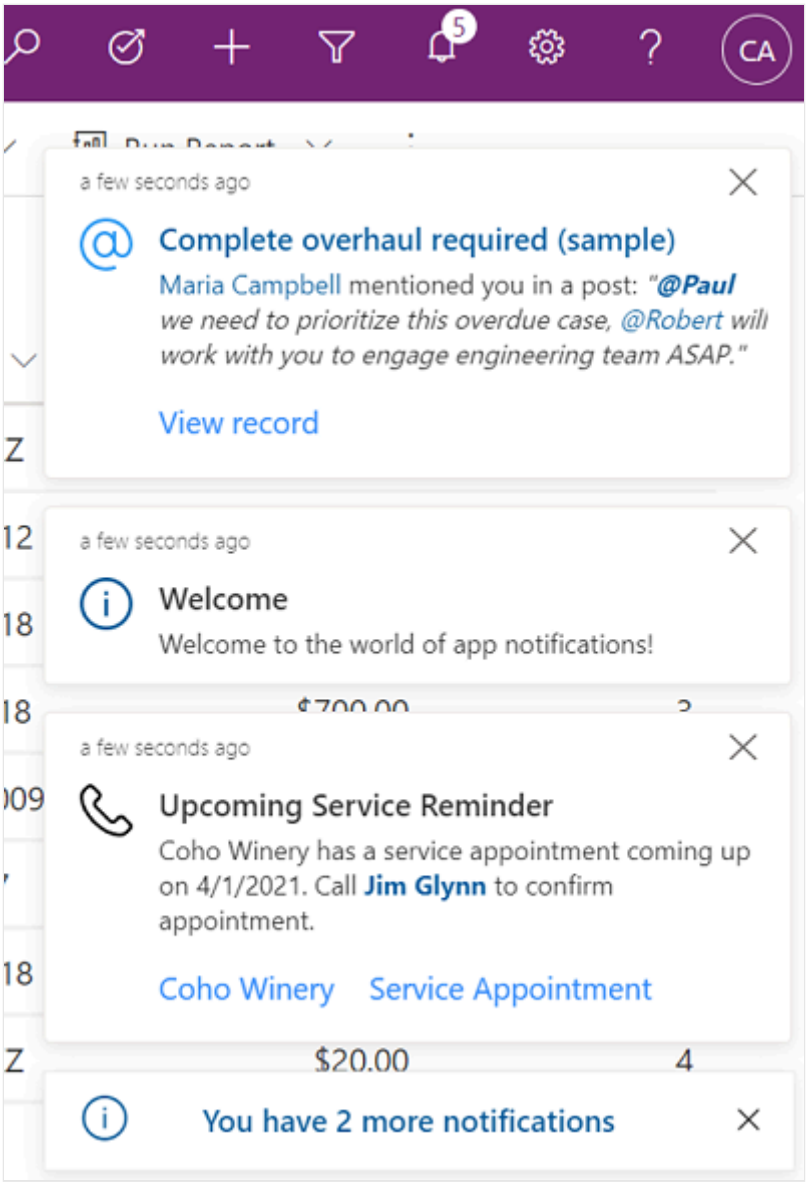


- To dismiss and delete a notification, select the close **X** button on a notification. Or, select **Dismiss all** to dismiss and delete all notifications.



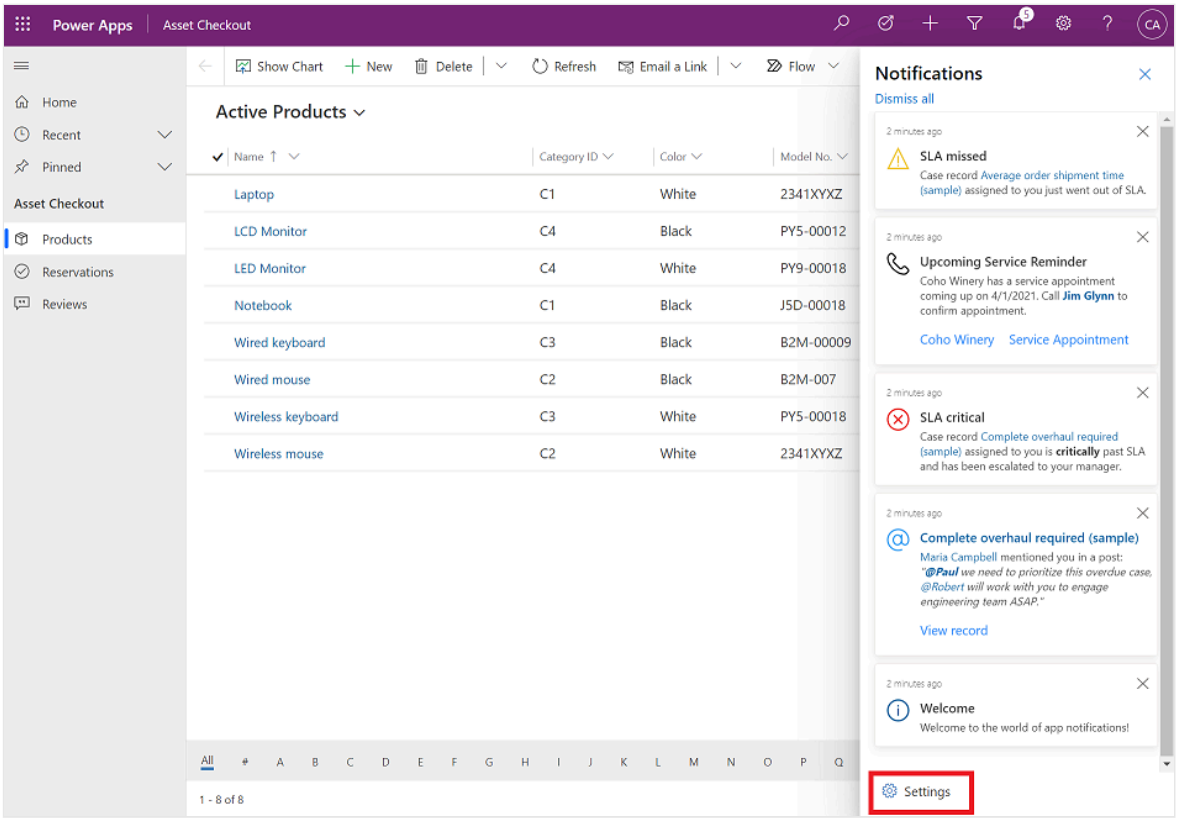
Toast notifications

Toast notifications appear temporarily to the right side of your app. When multiple notifications appear, they are stacked. When there's more than three toast notifications at the same time, you'll get a toast letting you know that there's more notifications. You can use the F2 shortcut key to access the notification toasts.



Your system administrator can enable or disable toast notifications. If toasts are enabled, you can turn them off at a user level. Regardless of the toast being shown, all notifications can be accessed from notification center.

1. To enable or disable toast notifications in the notification center, select **Settings**



2. To enable or disable toast notifications, do one of the following:

   - **To enable toast notifications**: Move the toggle to **On** and then enter how many seconds the toast will show.
   - **To disable toast notifications**: Move the toggle to **Off**.

3. When you're done, select **Save**.

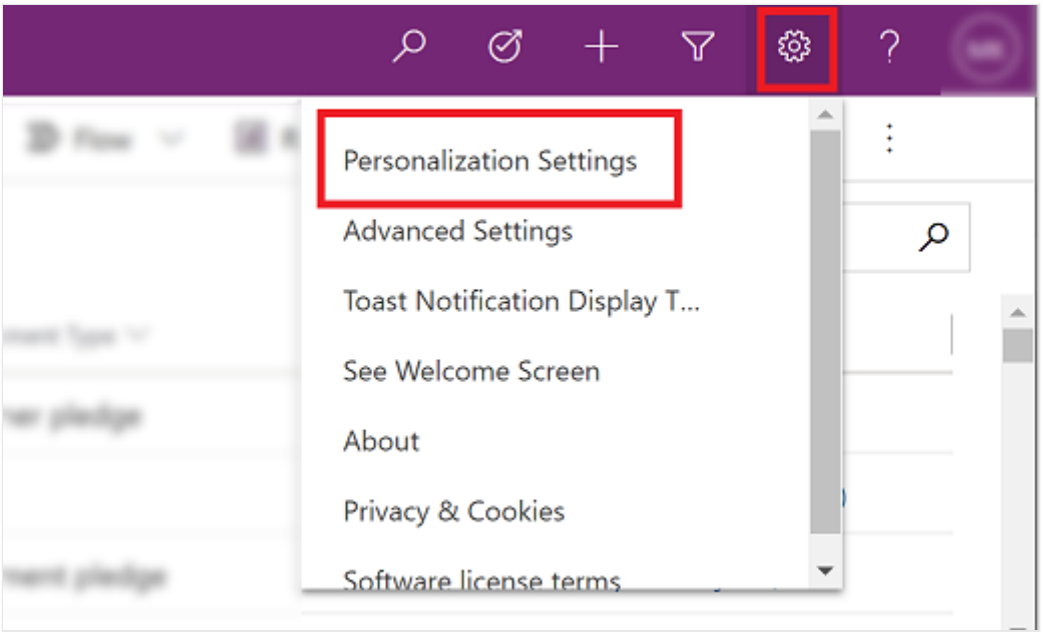
View your user information

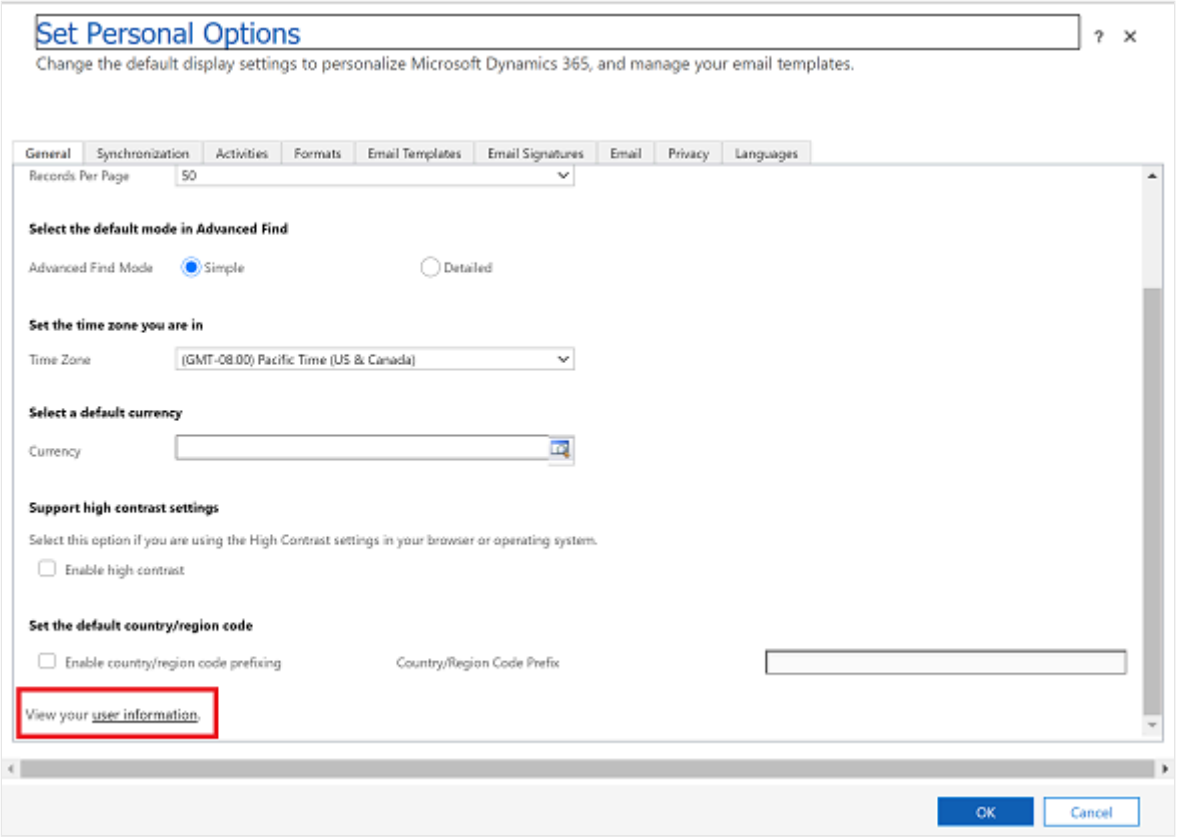
Article • 10/22/2024

The user information page displays useful information about you and your organization. On the page you can view your contact information, your security role, and information about your organization. Depending on your security role, you might be able to make changes to your user profile.

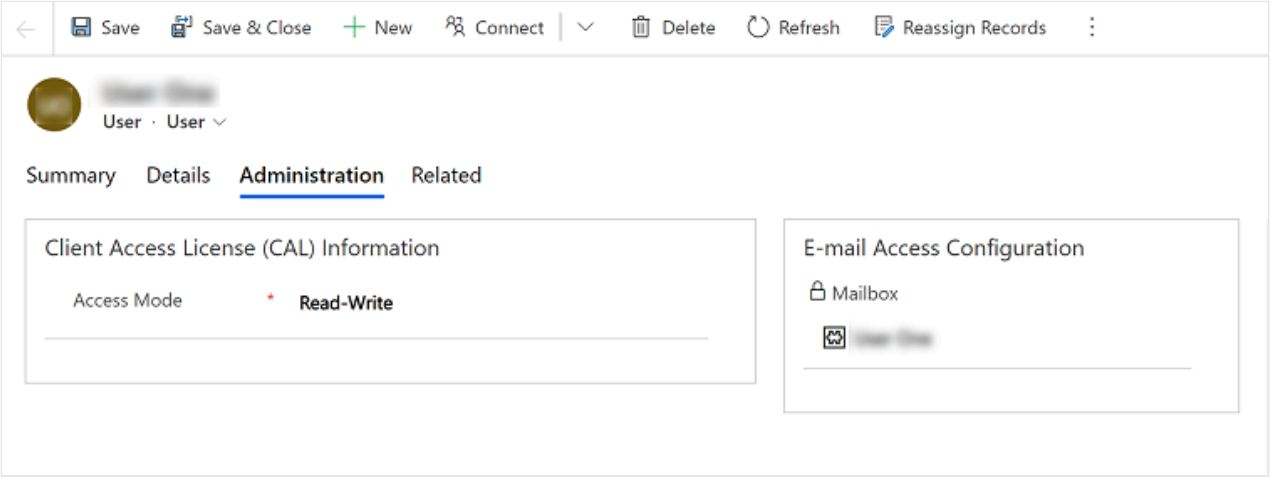
1. Open an app and in the upper-right corner of the screen, select **Settings** > **Personalization Settings**.



2. On the **General** tab, scroll down to the bottom and select the **user information** link.



3. On the user information page, select the different tabs, such as **Summary**, **Details**, or **Administration** to see details about your profile.



Set personal options

Article • 11/27/2023

Change your display settings in an app to suit your preferences. For example, you can choose the page that you want to see as soon as you sign in to the app. You can also personalize many other options such as language, currency, and time zone.

> **Note**
>
> You may need to refresh your app twice for some changed settings to take effect.

To set personal options

1. In the upper-right corner of the screen, select **Settings** > **Personalization Settings**.
2. Fill in the information, as required.
3. When you're done, select **OK**.

General tab options

Expand table

Options	Description
Select your home page and settings for Get Started panes	
Default Pane	Select the default home pane (page) that you want to see when you sign in. By default, the **Default based on user role** option is selected, which shows the default pane based on the app you are using. This option does not apply when you sign in using the Power Apps mobile app.
Default Tab	Select the default tab that you want to see for the selected default pane. For example, select the **Accounts** tab for the **Service** pane.
Set the number of rows shown per page in any list of rows	

Options	Description
Rows Per Page	Select the maximum number of rows you want to see in a list on a page. You can set a value from 25 to 250. A smaller number of rows per page is recommended, as it will help maximize grid performance. Selecting a larger number of rows per page can negatively impact grid performance.
Select the default mode in Advanced Find	
Advanced Find Mode	By default, every time you open the **Advanced Find Mode** dialog box, the query details are hidden. To see the query details every time, select **Detailed**.
Select the default search experience	
Default Search Experience	Select your default search experience. For more information, see Compare search options
Set the time zone you are in	
Time Zone	Select the time zone that you want to display for your region.
Select a default currency	
Currency	Choose the default currency value to use in financial transactions. Select the **Lookup** button to search for a currency.
Support high-contrast settings	
Enable high contrast	Select this check box to enable high-contrast levels in your app display. **Tip:** Set this option if you are using high contrast settings in your browser or operating system.
Set the default country/region code	
Enable country/region code prefixing	Select this check box to enable the default calling code for your region.
Country/Region Code Prefix	Enter the value of your region's calling code in the text box. For example, enter **+1** for the United States.
View your user information	Select this link to view details about you. These details are displayed to your entire organization and include your contact information and security role. For more information, View your user profile.

Synchronization tab options

Expand table

Options	Description
Synchronize Dynamics 365 items with Outlook or Exchange	
filters	Choose the rows to synchronize between Dynamics 365 and Dynamics 365 for Outlook or Exchange (using server-side synchronization).
synchronized columns	View the columns that are synchronized between Dynamics 365 and Dynamics 365 for Outlook so you can see where the data is coming from.
Manage your offline filters and take your information offline in Dynamics 365 for Outlook	
offline filters	Choose a subset of Dynamics 365 data that you want to work with when you go offline with Dynamics 365 for Outlook.

Activities tab options

Expand table

Options	Description
Default view	
Default Calendar	Select the default view for your calendar.
Start your default work hours	Select your default start and end time for your work hours.

Formats tab options

Expand table

Options	Description
Current Formats	

Options	Description
Customize	Choose this option to add a new region and formats.
Format preview	Shows the current region and its formats for **Number**, **Currency**, **Time**, and **Date**.

Email Templates tab options

Expand table

Options	Description
Create and modify personal email templates	
New	Create an email template with custom values (such as a date or signature), so you don't have to enter the same information, repeatedly, when you send an email. On the command bar, select **New** and enter values for the template.

Email Signatures tab options

Expand table

Options	Description
Create and modify personal email signatures	
New	Create an email signature to save time and be consistent in your responses. The owner of an email signature can be a user or a team. On the command bar, select **New** and enter values for the signature.

Email tab options

Expand table

Options	Description
Select if other users can send emails for you	
Allow other users to send email on your behalf.	Select this option to allow other users of Dynamics 365 to send email on your behalf. **Caution**: If you select this option, other users can send email on your behalf with or without your consent. Your email name will appear as the sender.
Select the email messages to track in Dynamics 365	
Track	Select the email messages that you want to automatically track in Dynamics 365. **Options:** - All Email messages - Email messages in response to Dynamics 365 email - Email messages from Dynamics 365 Leads, Contacts and Accounts - Email messages from Dynamics 365 rows that are email enabled
Configure Folder Tracking Rules	Set up folders to automatically track incoming email.
Automatically create rows in Dynamics 365	
Create	Select this option to allow Dynamics 365 to create leads or contacts automatically from the information in tracked email messages.
Show emails as conversation on Timeline	Select this to list emails in a conversation thread, the way many email applications work when viewing emails in a conversation.
View your Mailbox	Select this link to see your mailbox details.

Privacy tab options

> **Note**
>
> This tab isn't available if your system administrator has selected the privacy preference for the entire organization in System Settings. Talk to your administrator.

Expand table

Options	Description
Select your error notification preference	
Options: - Ask me for permission to send an error report to Microsoft. - Automatically send report to Microsoft without asking me for permission. - Never send an error report to Microsoft about Dynamics 365.	Specify what you want Dynamics 365 to do when an error occurs. Based on your selection, the error reports are shared with and used by Microsoft for product improvements. We recommend that you send the error reports to Microsoft so that Microsoft can use the information for product improvements.

Languages tab options

Expand table

Options	Description
Select the language you prefer to see Dynamics 365 displayed in	
Base Language	Shows the base language. The base language is set during the Dynamics 365 installation process. You can't edit this option.
User Interface Language	Select the language that you want to see for labels and dialog boxes in the Dynamics 365 user interface.
Help Language	Select the language for Help. To add an additional language other than the base language, your admin must install the required language packs and enable them. Talk to your administrator.

Use a screen reader

Article • 02/15/2022

Screen readers make model-driven apps accessible to people who have low or no vision or might need extra support for a temporary scenario, such as eye fatigue. Commonly used screen readers such as Narrator, JAWS, and NVDA are supported.

- Learn more about working with Microsoft Narrator
- Learn more about working with JAWS
- Learn more about working with NVDA

Basic tasks using a screen reader

Open an app

1. On the navigation bar, use the **Tab** key to move to the app drop-down control and press **Enter** to open the site map.
2. Press the **Tab** key until you hear the name of the application you want to open—for example, "Sales." Press **Enter** to open the app.

Use scan mode in Narrator

You can use scan mode to quickly navigate apps using the arrow keys and common keyboard shortcuts. Quickly jump to headings, links, landmarks, form columns, controls, and tables in this mode. Turn scan mode on and off by pressing **Caps lock+Spacebar**. More information: Using scan mode

Find your way around the app

Navigation bar

When you open an app, a vertical bar with subarea icons is displayed on the left. You can either use the **Tab** key to move through these icons until you hear the name of the subarea you want, such as "Accounts," or you can use the site map control. For example, press the **Tab** key until you hear "Accounts" and then press **Enter** to open the Accounts view.

Grids

Screen readers navigate grids more reliably and consistently, and announce row and column headings, as well as the position within the grid. When you first open a grid, the default tab stop is the view selector.

Whenever you enter a cell within the grid from outside of the grid, Narrator announces the name of the table, the row and column counts, and the position of your cursor within the table.

If your cursor is within the table header, quickly navigate between headers by using the **Tab** key or **Shift+Tab**. Narrator will announce the name of each header as you enter the header cell. It also announces the type of cell (for example, "column header"), the location of the column (for example, "column 1 of 6"), and whether the column is sorted or selected. If you press **Enter** in a table header, it will sort the table by that column. Narrator announces the sort order, and you can press **Enter** again to change the order.

When you move out of the last column in the table, the cursor moves to the second row of the grid, and from this point, you must use the Up and Down arrow keys to navigate between the non-header cells. If you instead press the **Tab** key again, your cursor will move to the next interactive element, typically the table filter list. When moving between non-header row cells, Narrator announces the column name, the location of the column, and text within the cell.

Forms

Multiple navigation modes are available for navigating a form using Narrator, with the most common modes being landmarks, headings, and form columns. To change the navigation mode, press **Caps lock+Up arrow**. Hold the Caps lock key down while pressing the Up arrow key to cycle through the modes until you hear the mode you want to use. Then use Caps lock + the Left/Right arrow keys to navigate through the various items. For example, if you want to go to the Last Name column in the Contact Information section of a contact, do the following:

1. Press and hold the **Caps lock** key and press the **Up arrow** key until you hear "Landmarks."
2. Press and hold the **Caps lock** key and press the **Right arrow** key until you hear "Contact information."
3. Change the mode by pressing and holding the **Caps lock** key and pressing the **Up arrow** key until you hear "Form Columns."
4. Navigate to the Last Name column by using Caps lock + the Left/Right arrow keys until you hear "Last Name." Narrator also announces the control type, value, state,

and any special instructions for the column.

You can also use the Tab key to quickly navigate to interactive elements on the form. Some form columns have an icon that will perform the default action when you press Ctrl+Enter. For example, an email form column might have an envelope icon that opens an email editor.

Dashboards/charts

You can navigate through the dashboard charts using the Tab key and Caps lock + arrow keys. Press the **Tab** key to quickly go to the interactive elements and use Caps lock + an arrow key for navigation of non-interactive elements, such as headings, landmarks, and items.

> **Note**
>
> You must have the latest Windows 10 Update installed to have all of the accessibility features available for charts.

Interactive dashboard streams

You can use the **Tab** key or **Shift+Tab** keys to move between interactive dashboard streams, such as found in the Accounts dashboard, or just change the navigation mode until you hear “Headings” and then use the **Tab** key to quickly move between dashboard streams.

To navigate through each element of a dashboard stream, use the Up/Down arrow keys. Narrator will read the type of control and the title of the control.

Business process flows

You can navigate a business process flow, such as the one found at the top of the Lead form, by pressing the **Tab** key to move forward, and **Shift+Tab** to move backward between the tables. Use the **Enter** key on the **Move to the Left** or **Move to the Right** buttons to display additional tables in the process flow. Narrator reads the table type, stage, status, title, element number out of total elements, and whether it is currently selected.

Dialog boxes

When a dialog box opens, Narrator announces the title. For dialog boxes with input columns, the **Close** button has the default focus, allowing you to close the dialog box by pressing **Enter**. For dialog boxes that require user action, the focus is on the primary action button, such as **Delete** or **OK**.

You can navigate through the controls by using the **Tab** key. The cursor will loop through each element in the dialog box, and you can press **Esc** to close it.

Use keyboard shortcuts in Power Apps

Article • 04/12/2023

Keyboard shortcuts give you an alternate way to do common tasks instead of using your mouse or tapping with your finger. They help in seamless navigation of the interface. The following keyboard shortcuts apply across apps.

> **Note**
>
> The keyboard shortcuts described here refer to the United States keyboard layout. Keys on other keyboard layouts might not correspond exactly to the keys on a US keyboard.

Global shortcuts

Expand table

Type	Shortcut key	Description
General	F2	Activates the flyouts including toast notifcations.
Landmark	Ctrl+F6	Navigates you through the landmarks of a page in clockwise order. Remembers the last selected item in each landmark and will navigate to that last item.
Landmark	Ctrl+F6+Shift	Navigates you through the landmarks of a page in counter clockwise order. Remembers the last selected item in each landmark and will navigate to that last item.
General	Ctrl+[or Ctrl+Shift+[	Set the focus on first focusable element of the main page

Form shortcuts

Expand table

Task	Unified Interface
Complete the command for the active option or button	Enter
Cancel a command, or close a selected list or dialog box	Esc

Task	Unified Interface
Save	Ctrl+S
Save and Close	N/A
Cancel edits and close (Close)	Esc
Delete the row (when forms are in edit mode)	N/A
Save and then open a new form (Save and New) (when forms are in edit mode)	N/A
Open the lookup menu with the most recently used items in alphabetical order	Down arrow
Open a lookup drop-down list	Enter
Close a lookup drop-down list	Esc
Open a row found in lookup with forms in edit mode	Enter
View more information when focus is on a lookup row item with a chevron	Right arrow (→) key
Close the more information when focus is on a lookup item with a chevron	Left (←) arrow key
Add an article to an email	N/A
Apply an email template (when editing an email message)	N/A

Form navigation shortcuts

Expand table

Task	Unified Interface
Move to the next option, option group, or column	Tab
Move to the previous option, option group, or column	Shift+Tab
Move between options in an open list, or between options in a group of options	Arrow keys
Go to the Command Bar	N/A
Go to the landmark section of a page	Ctrl+HOME

Email

The following table outlines a list of accessibility shortcuts available when using email. You can access this list while composing email by pressing **Alt+0**.

Expand table

Type	Shortcut key	Description
General	Alt+F11	Toggle full-screen view.
Tab navigation	Alt+Ctrl+0	Go to the editor toolbar.
Tab navigation	Alt+1	Go to the rich-text editor.
Tab navigation	Alt+2	Go to the HTML editor.
Tab navigation	Alt+3	Go to the preview view.
General editor commands	Alt+F10	Navigate to the editor toolbar. Move to the next and previous toolbar group with Tab and Shift+Tab. Move to the next and previous toolbar button with Right Arrow or Left Arrow. Press Space or Enter to activate the toolbar button.
General editor commands	Alt+-	Expand/collapse the toolbar.
General editor commands	See description.	Editor dialog: Inside a dialog, press Tab to navigate to the next dialog element, press Shift+Tab to move to the previous dialog element, press Enter to submit the dialog, press ESC to cancel the dialog. When a dialog has multiple tabs, the tab list can be reached either with Alt+F10 or with Tab, following the dialog tabbing order. With a tab list focused, move to the next and previous tab with Right and Left Arrow, respectively.
General editor commands	See description.	Editor list box: Inside a list box, move to next list item with Tab or Down Arrow. Move to previous list item with Shift+Tab or Up Arrow. Press Space or Enter to select the list option. Press ESC to close the list box.
Base commands	Ctrl+Z	Undo command.

Type	Shortcut key	Description
Base commands	Shift+Ctrl+Z	Redo command.
Base commands	Ctrl+B	Bold command.
Base commands	Ctrl+I	Italic command.
Base commands	Ctrl+U	Underline command.
Base commands	Alt+0	Accessibility help.
Base commands	Esc	Cancel operation.

Editable grids (views)

If your administrator has enabled editable grids (views), you can edit data directly in a grid (view). The following table lists the keyboard shortcuts:

Expand table

Task	Unified Interface
When the focus is on a column header, sort by column	Spacebar to drop down list and then down arrow to select an action, followed by Enter
When the focus is on a column header, open filter dialog	Spacebar to drop down list and then down arrow to select the **Filter by** option, followed by Enter
When the focus is on the cells, move to the next column	Right arrow (→) key
When the focus is on the cells, move to the previous column	Left arrow (←) key
When the focus is on the column header, move to the next column header	Tab
When the focus is on the column header, move to the previous column header	Shift+Tab

Task	Unified Interface
Move to the cell above	Up arrow (↑) key
Move to the cell below	Down arrow (↓) key **Or** Enter, when cell is not in edit mode
Go to edit mode for Text, Number, and Simple columns when the focus is on a column	Type the value directly to overwrite the existing value **Or** Spacebar to continue modifying the existing value **Or** F2 to select the existing value
Go to edit mode for Date and Time columns	Type the value directly **Or** F4 or Alt+↓ to display the date/time picker
Go to edit mode for drop-down (Lookup, Option Set) columns	Spacebar to open the list
Go to edit mode for Two Options columns	Spacebar to switch between the two options **Or** F4 **Or** Alt+↓ to open the list
Move between entries in an open drop-down list	Up/Down (↑/↓) Arrow keys
Select an option in an open drop-down list	Enter
Close an open drop-down list	Esc
Cancel your edits	Esc
Navigate to and open the lookup row	Enter when the focus is on (→) icon
Move to the next page (if any)	Page down key
Move to the previous page (if any)	Page up key
Move to the column header when the focus is in the grid	Shift+Tab
Move to the Save button when the focus is on the column header (if any unsaved data)	Tab
Move to the Refresh button when the focus is on the column header	Tab

Interactive dashboard shortcuts

Interactive dashboards enable new functionality, such as filtering, sorting, and quick actions.

Expand table

Task	Unified Interface
Activate a dashboard element (simulate left-click)	Enter **Or** Spacebar
Move to the next element	Tab
Move to the previous element	Shift+Tab
Move to the next item within a dashboard element	Down (↓) arrow key
Move to the previous item within a dashboard element	Up (↑) arrow key
Close a menu	Escape
Select a check box or radio button	Spacebar
Modify the date range filter	Ctrl+Alt+D
Show the visual filter pane	Ctrl+Alt+V
Move to the global command bar	Ctrl+Alt+A

Global filter shortcuts

Expand table

Task	Unified Interface
Open a menu	Enter **Or** Spacebar **Or** Down (↓) arrow key
Activate a button	Enter **Or** Spacebar
Move to the next element	Tab
Move to the previous element	Shift+Tab
Open a tree view control	Right (→) arrow key
Close a tree view control	Left (←) arrow key
Move to the next tree view node	Up (↑) arrow key
Move to the previous tree view node	Down (↓) arrow key
Move to the first tree view node	Home
Move to the last tree view node	End
Perform the default action for the tree view node	Enter

Task	Unified Interface
Remove a filter	Delete

Dashboard stream control shortcuts

Expand table

Task	Unified Interface
Move to the first command on the active dashboard stream's command bar	Ctrl+Alt+Q
Move to the next element	Tab
Move to the previous element	Shift+Tab
Activate a button	Enter **Or** Spacebar
Activate the **Sort by column** button and open flyout	Enter **Or** Spacebar **Or** Down (↓) arrow key
Move to the next item	Down (↓) arrow key
Move to the previous item	Up (↑) arrow key
Move to the first item	Home
Move to the last item	End
Move to the next stream	Ctrl+F6
Move to the previous stream	Ctrl+Shift+F6
Close a menu	Escape
Change the state of a check box	Spacebar

Chart shortcuts

Expand table

Task	Unified Interface
Move to the first element in a chart	Tab

Task	Unified Interface
Move to the next data point	Right (→) arrow key **OR** Down (↓) arrow key
Move to the previous data point	Left (←) arrow key **OR** Up (↑) arrow key
Move to the **See More** button in a Tag chart	Tab
Move back from the **See More** button to the tags in a Tag chart	Shift+Tab
Filter the dashboard when the focus is on a data point in an interactive dashboard	Enter **Or** Spacebar

Date-Time control shortcuts

Expand table

Task	Unified Interface
Open the date picker flyout	Enter **Or** Spacebar **Or** Down (↓) arrow key
Activate the option and close the flyout	Enter **Or** Spacebar
Move to the next item	Down (↓) arrow key
Move to the previous item	Up (↑) arrow key
Move to the first item	Home
Move to the last item	End
Close the date picker flyout	Escape
Move to the next element	Tab
Move to the previous element	Shift+Tab
Select the calendar	Enter **Or** Spacebar
Activate a button	Enter **Or** Spacebar

Search results shortcuts

Expand table

Task	Unified Interface
Move to the next search result	Up (↑) arrow key
Move to the previous search result	Down (↓) arrow key
Move to the list of available views	Right (→) arrow key
Move from the list of available views to search results	Left (←) arrow key
Navigate between buttons	Tab

Navigating submenus

If you use a screen reader, follow these steps to access any of the submenus that are displayed when you hover the mouse over a navigation link.

1. Navigate between the menu options using standard link navigation.
2. Activate the link by selecting Enter or the space key as you usually would. A list of submenus will be displayed.
3. To access these submenu options, use the assistive technology (AT) shortcut key to navigate to the next button. For example, if you use the NVDA screen reader, you would use the “b” shortcut key (NVDA+b). To navigate through all the options, select the key repeatedly.

> **ⓘ Important**
>
> Several areas in the user interface (UI) have auto-collapse built in for menus. This includes the Navigation Bar and Form Navigation. Both expand when selected, but after 30 seconds of inactivity, the items collapse.

Navigating through stages of a process

If you’re in a row—for example, a lead—this section shows you the keyboard shortcuts to navigate through the different stages in the sales process to qualify the lead, and how to make selections in those stages. For example, if you want to move easily from the Qualify stage through to the Close stage, try these keyboard actions:

- After you select a stage, get to the columns by selecting the Down (↓) arrow.
- If a stage is collapsed, select Enter to expand it.

> **Note**
>
> The process name is an icon at the bottom of the page, not the top.

- **Keyboard shortcuts in Windows**: If you are using the Windows operating system, select the following link and choose the version number from the drop-down list. You can view all the shortcuts that are applicable to a Windows environment. See Windows keyboard shortcuts.
- **Keyboard shortcuts in Mac**: If you are using a Mac operating system, select the following link to view all the shortcuts that are applicable to a Mac environment. See Mac keyboard shortcuts.

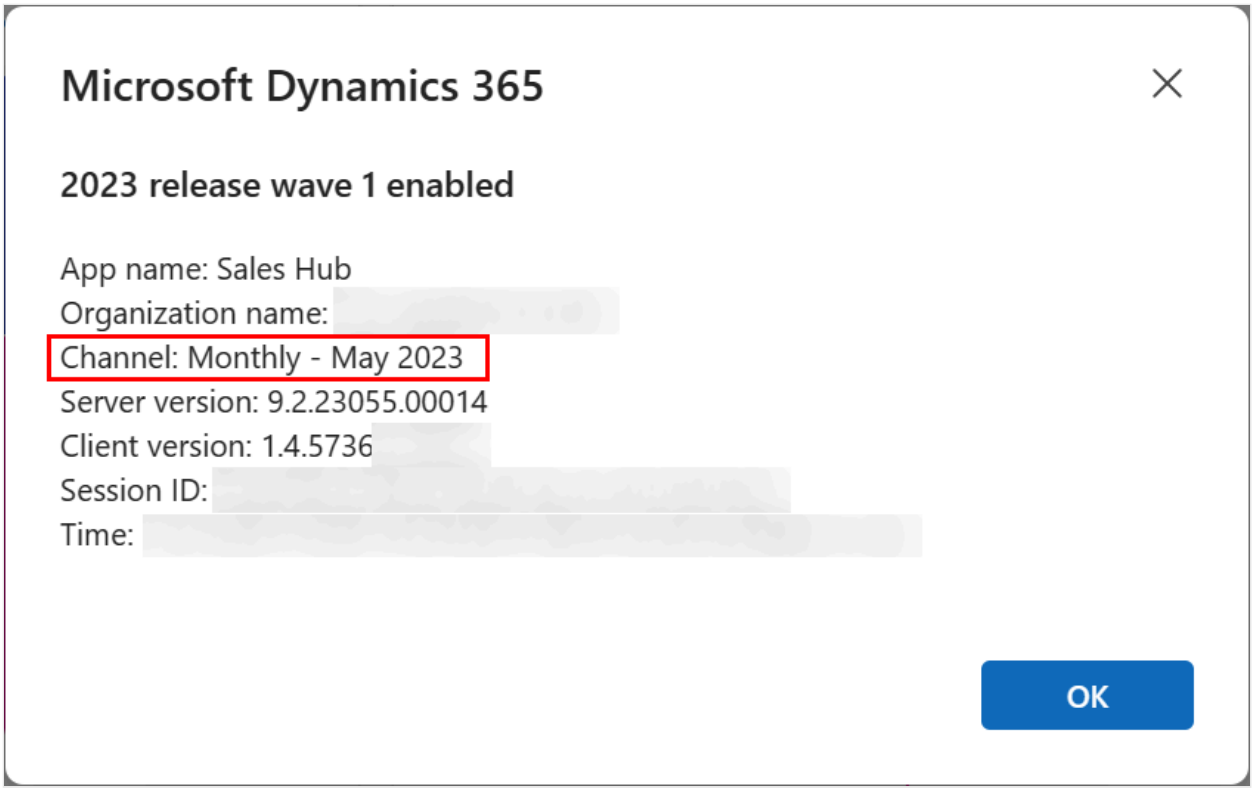
About dialog for model-driven apps

Article • 11/07/2023

This article explains the various parts of the **About** dialog for model-driven apps.



- The **Channel** attribute indicates the feature set being used. This attribute can be set by environment, app, user, or URL parameter so that a suffix indicates the release name of the current session. More information: Changing release channels
- The **semi-annual channel** is the current, twice-a-year release wave that is updated in April and October. The release for the semi-annual channel is shown at the top of the dialog like **2023 release wave 1 enabled**.
- The **monthly channel** is the new, release cadence that happens once per month. The release for the monthly channel is shown after **Channel: Monthly** as a month and year. For example, in the screenshot provided, the monthly channel is May 2023.

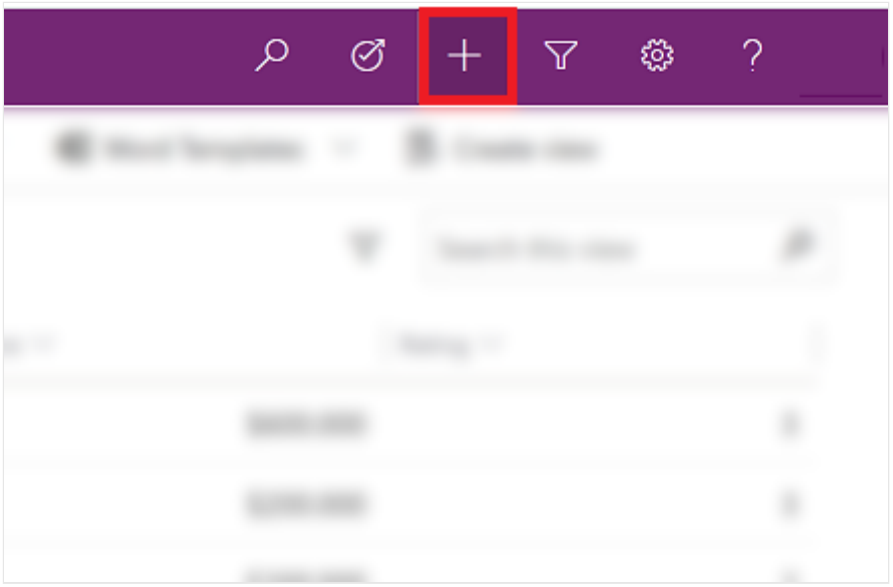
Create a new row

Article • 01/31/2024

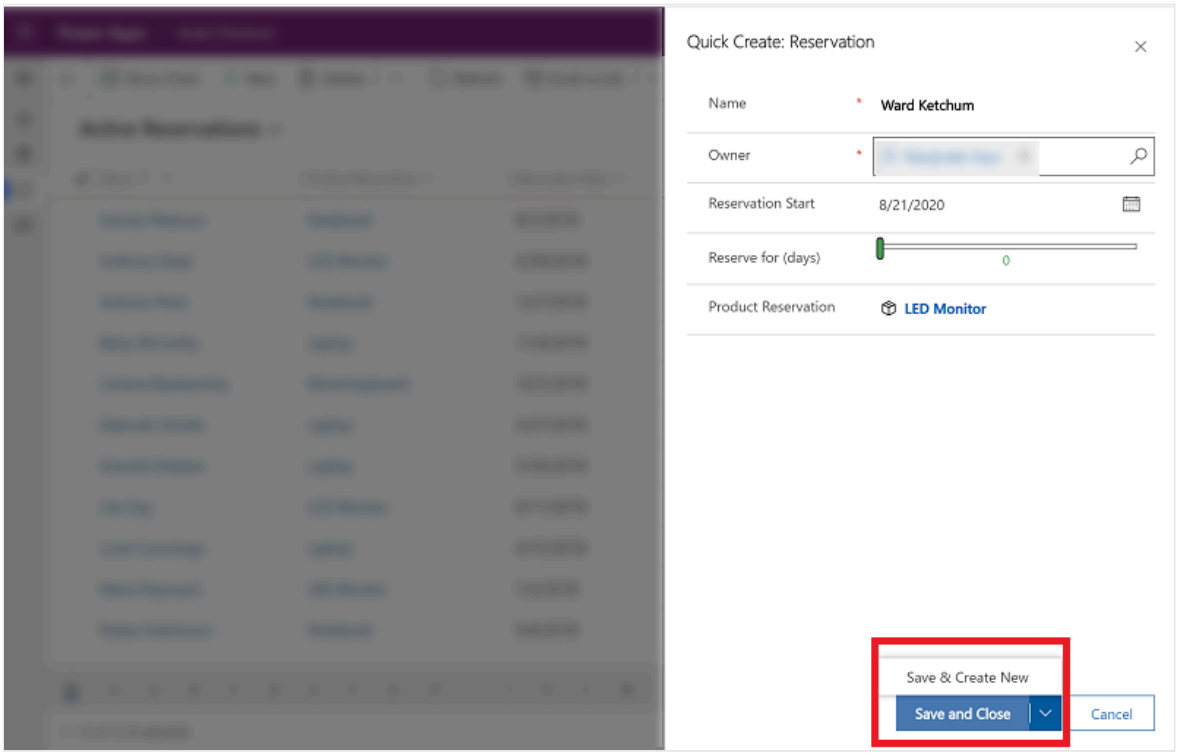
The **New** command or **Quick create** makes it fast and easy to enter almost any type of information into the system. The command is on the navigation bar, so it's available whenever you need to enter new information into the system. You can also save a row and create a new one directly from the **Quick create** form.

> **Note**
>
> The **Quick create** option is only available for rows that are enabled by your admin.

1. On the navigation bar, select the **plus sign** , and then select the item you want.



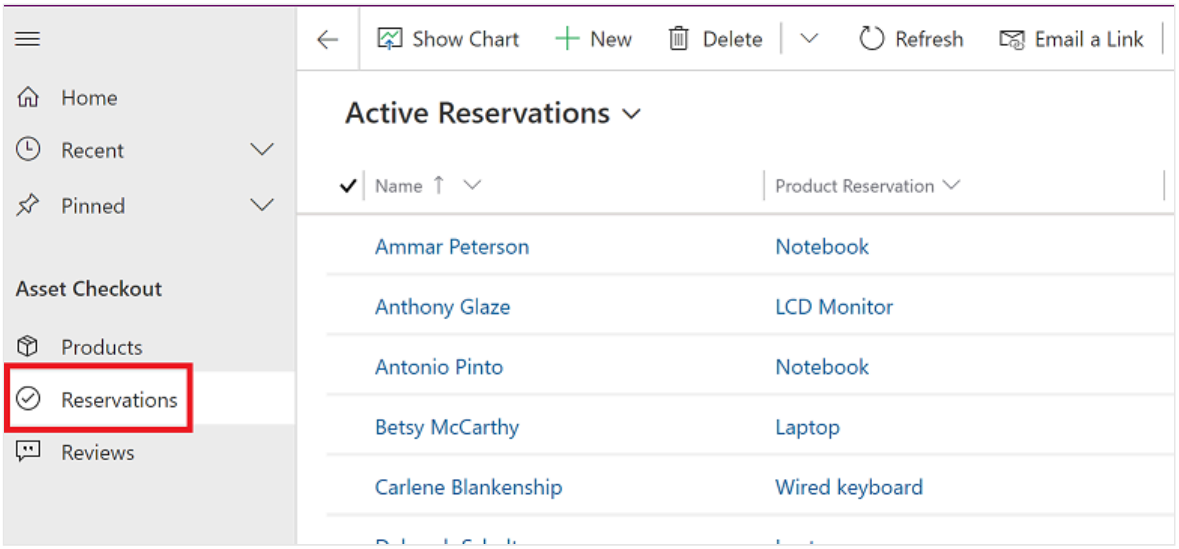
2. Fill in the columns, and then select **Save and Close**. Or, to save and create another row, select the down arrow and then select **Save & Create New**.



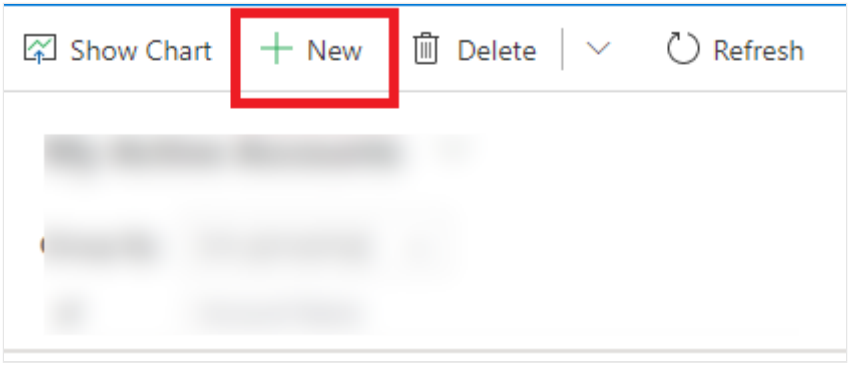
> **Note**
>
> An asterisk * next to the column on the screen means the column is required. If you select **Save and Close** before entering required columns an error message will be displayed or if you have entered information and select **Cancel** a warning will be displayed.
>
> A plus sign + next to the column on the screen means your organization recommends that you fill in the column.
>
> A lock sign next to the column on the screen means this field is read-only and cannot be edited.

Create a new row using the New button

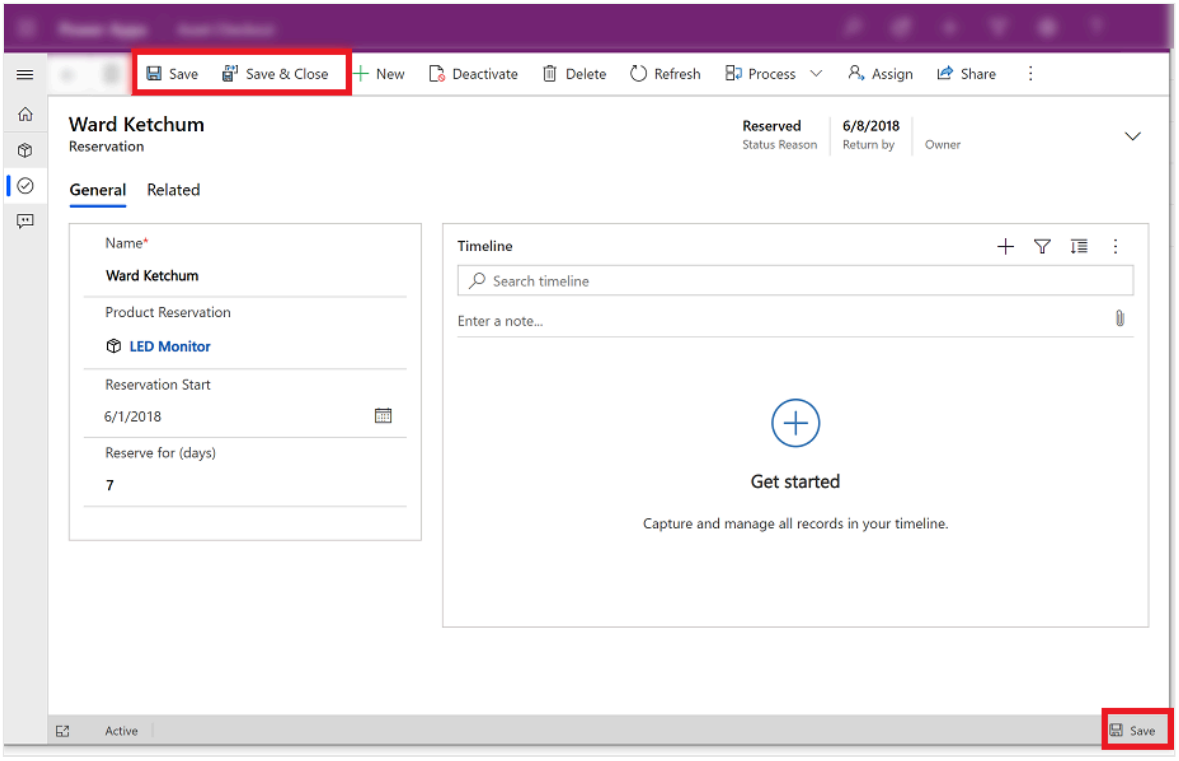
1. From the left navigation pane, select a table type.



2. On the command bar, select **+New**.



3. Fill in the columns and then on the command bar, select **Save** or **Save & Close**. The **Save** option is still available on the bottom right corner.



> **Note**

If you have unsaved changes and try to go to another row, a **Unsaved changes** dialog box will pop-up. If you select **Save and continue**, it will attempt to save your information and open the page you wanted to go to. If you choose to save and continue and there is an error on a column, the dialog will close and you will remain on the page to fix the error before you can navigate away.

Edit multiple rows (Bulk edit)

Article • 02/15/2022

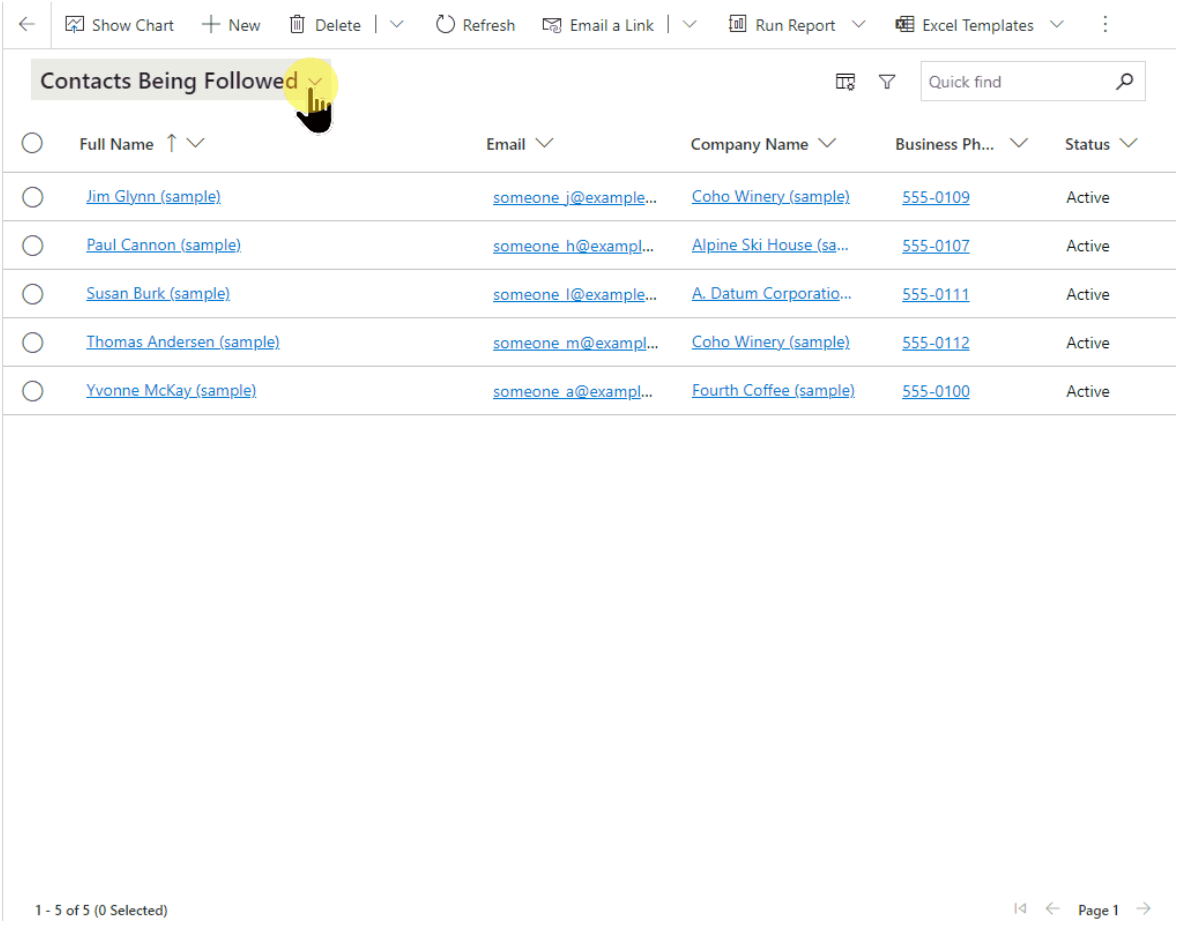
[This topic is pre-release documentation and is subject to change.]

You can edit multiple rows in model-driven apps and quickly update several columns of data across multiple rows in a single action. This is useful in scenarios when you need to update the same column for multiple rows.

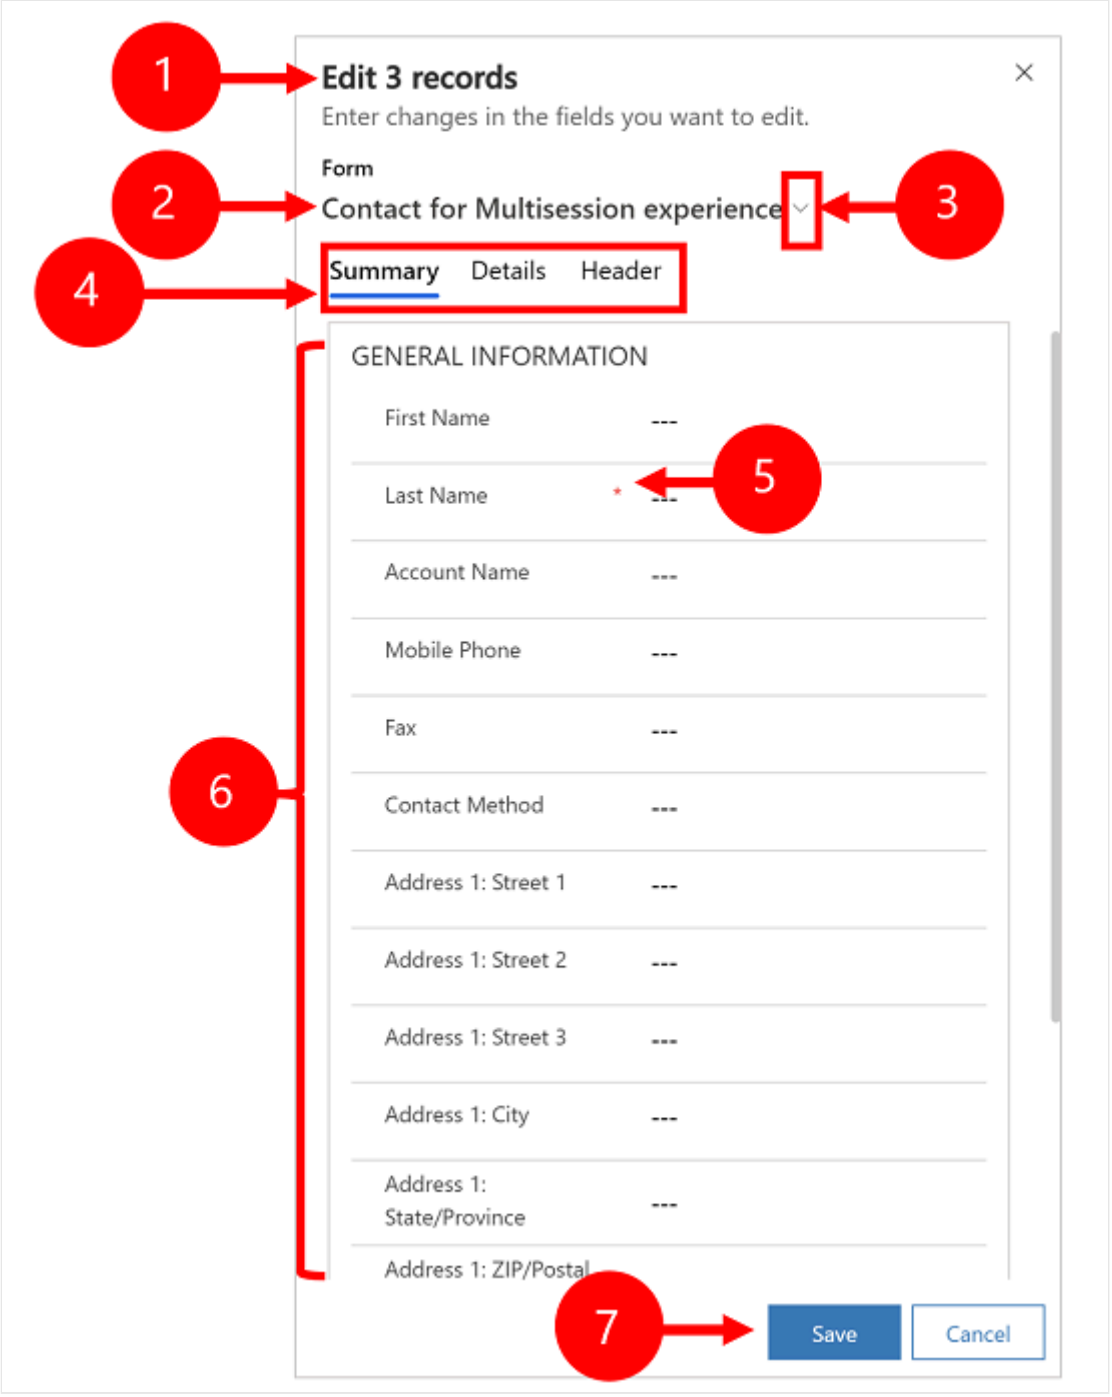
> **Note**
>
> Your administrator must grant you the Bulk Edit miscellaneous privilege to edit multiple rows.

Columns such as timeline wall, quick view forms, reference panel, and etc. aren't available when you're editing multiple rows.

1. To edit multiple rows, go to view page with the list of rows and select two or more rows.
2. On the command bar, select **Edit**.



The **Edit (number of rows) records** dialog opens with your last used form for the table.



Legend

1. Shows the number of rows that you're editing.
2. Shows the form title.
3. Select the chevron icon to switch from the default form to another form.
4. Select a tab to edit the columns on the form. The header column is always listed on the last tab.
5. If you changed the data for a required column, it needs to contain data otherwise you won't be able to save your changes.
6. Shows the form details that can be edited.
7. Save or cancel your changes. Saved changes are saved for all selected rows.

> **Note**
>
> You can't edit multiple rows with Power Apps mobile.

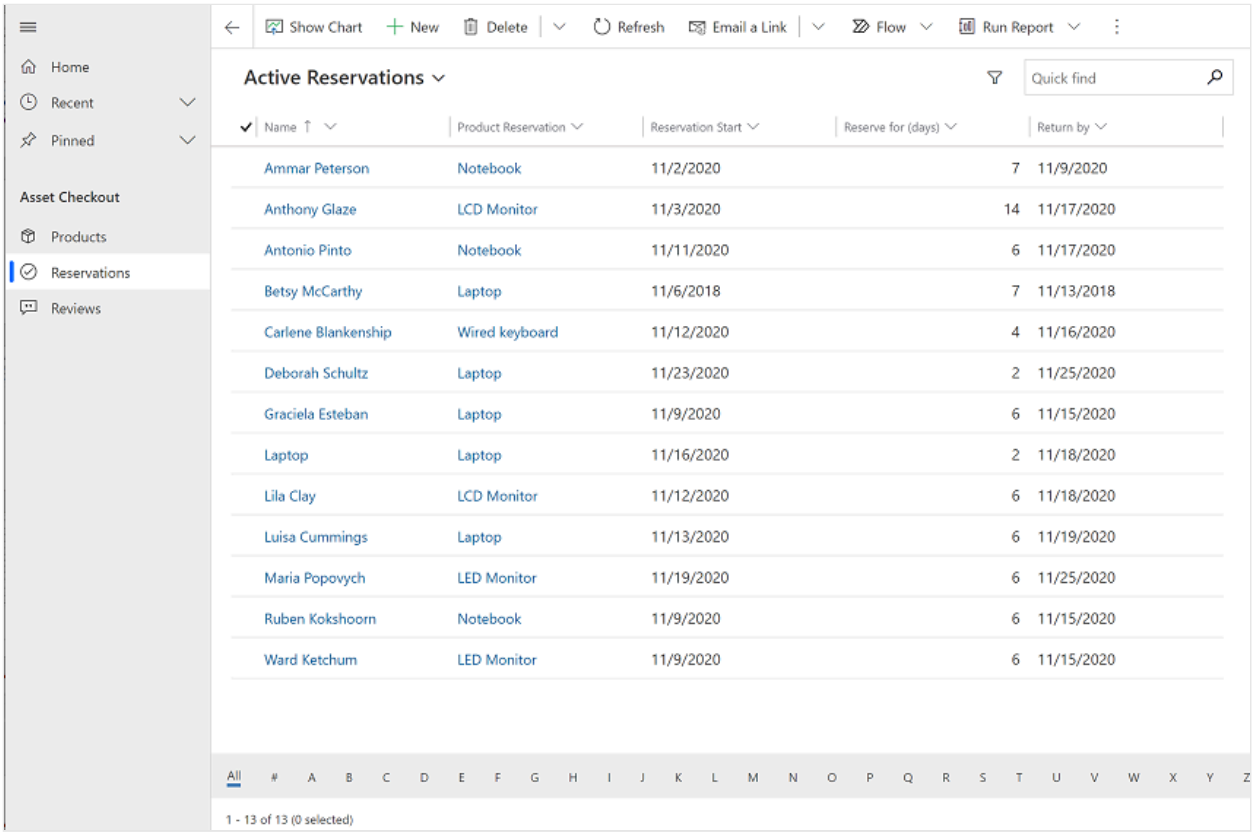
Work with rows in the calendar view

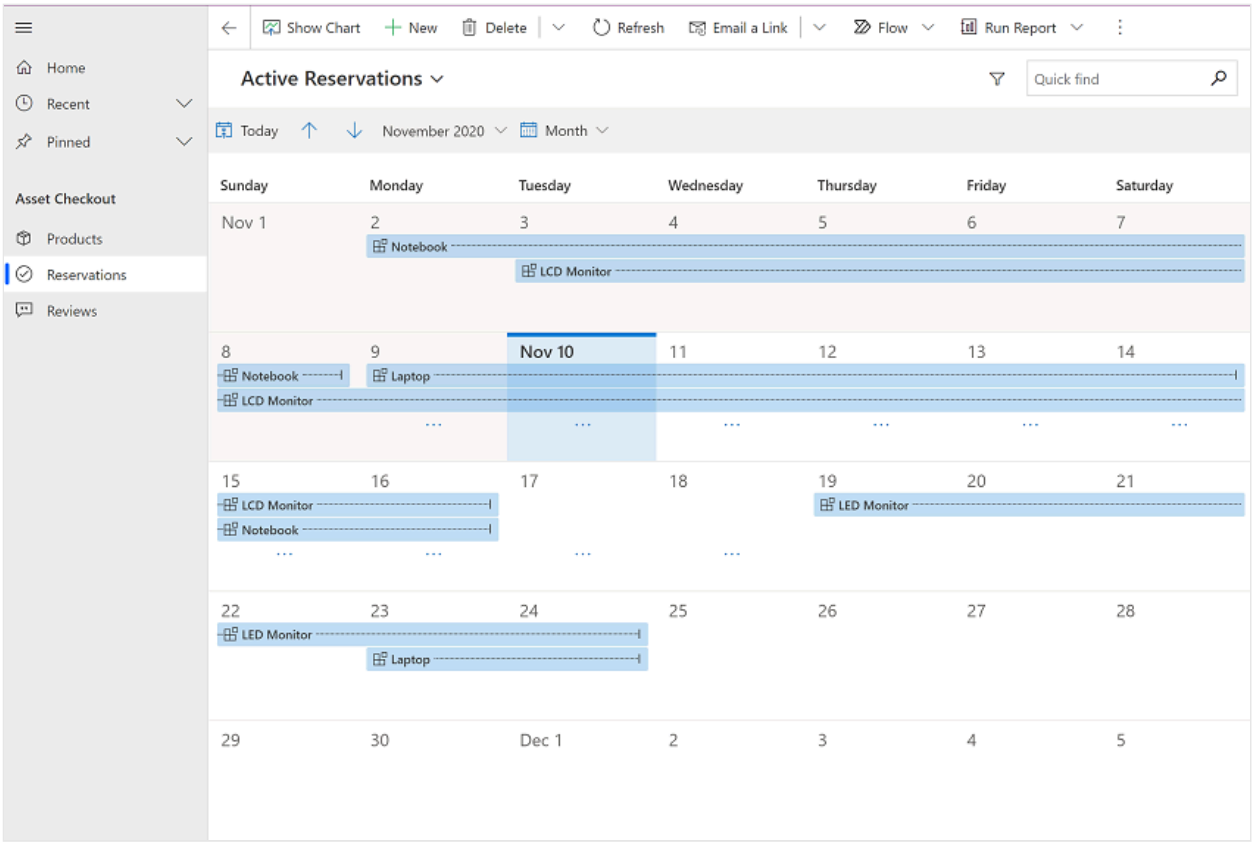
Article • 01/24/2024

The calendar view displays scheduled activities and their associated details. You can view, create, and delete your activities in a day, week, or month view. For the new calendar view to be visible, the **Calendar** control must be added to a table view by a system customizer or a system administrator. For more information, see Add the calendar control to tables. The **Calendar** control can be added to any table.

By default, rows are displayed in a read-only grid.



When the **Calendar** control is added to a table, the default view is changed to the calendar view. Rows associated with the table are displayed in an interactive calendar.

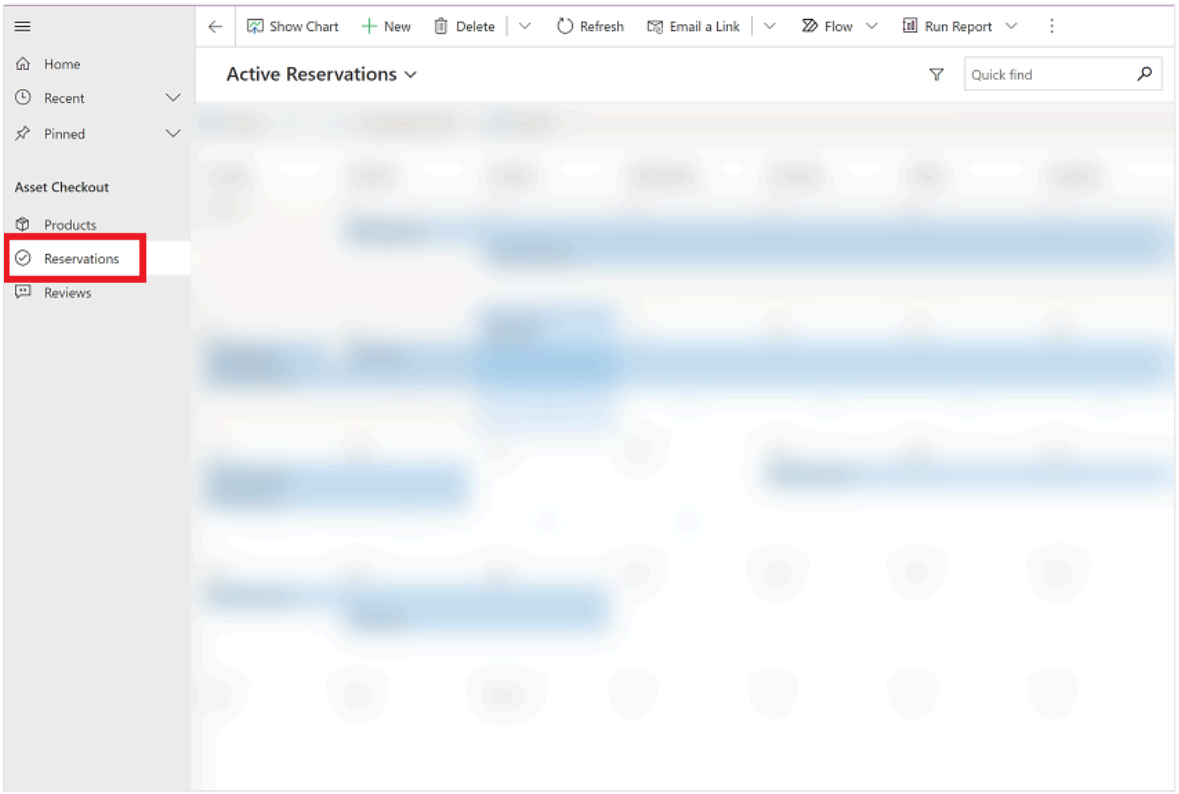


> **Note**
>
> The **Calendar** control is not supported in mobile offline. For more information about mobile offline, see Work offline on your mobile device.

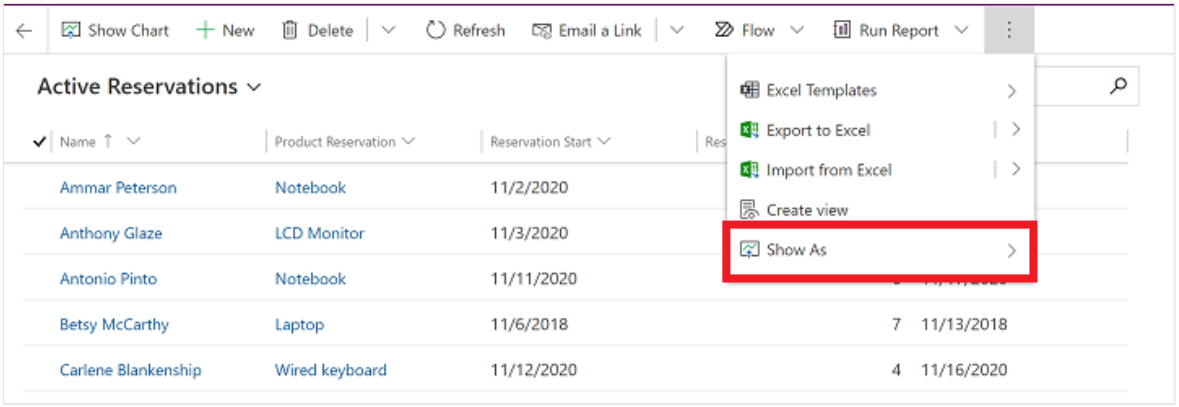
Switch between calendar view and grid view

When the calendar view is turned on, it's the default view for the table. However, you can still switch between the grid view or the calendar view.

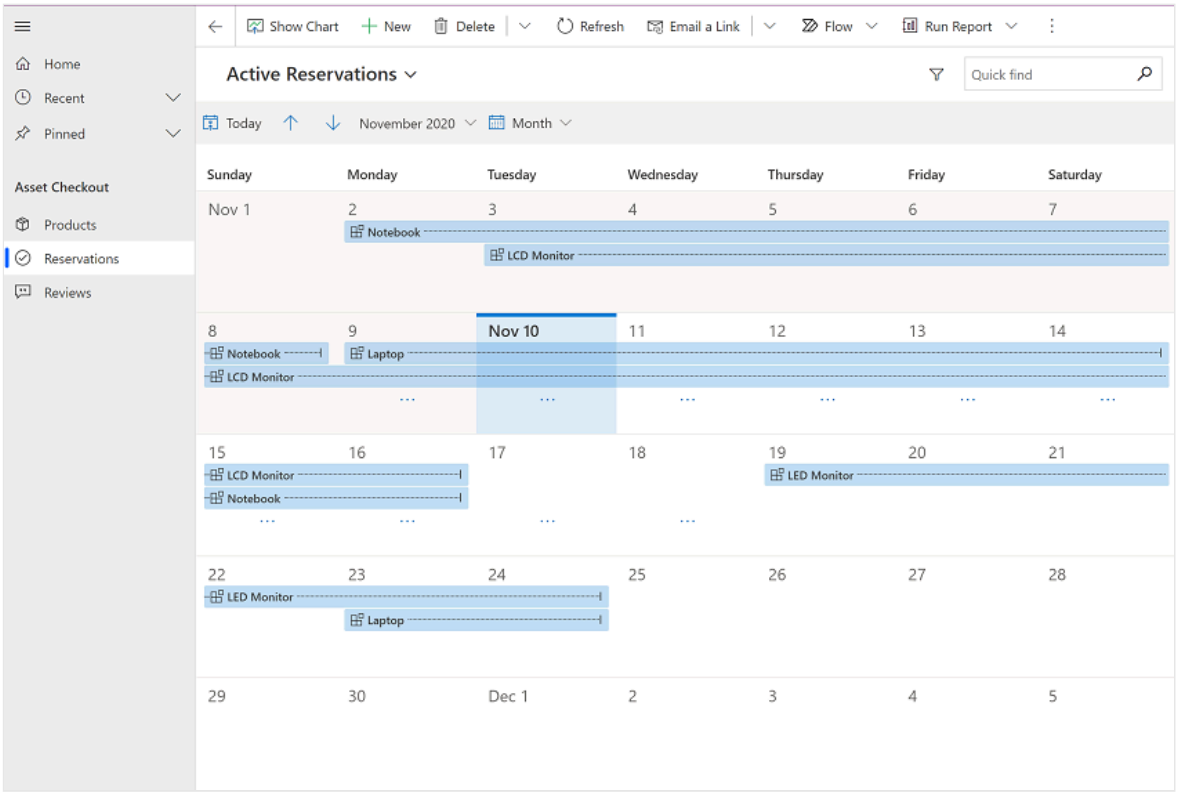
1. To switch between views, on the left navigation pane, select the table that has the calendar view turned on.



2. On the command bar, select the **More commands** icon, and then select **Show As** and choose either **Calendar** or **Read Only Grid**.



When you select the **Calendar** view, activities are displayed in a calendar view.

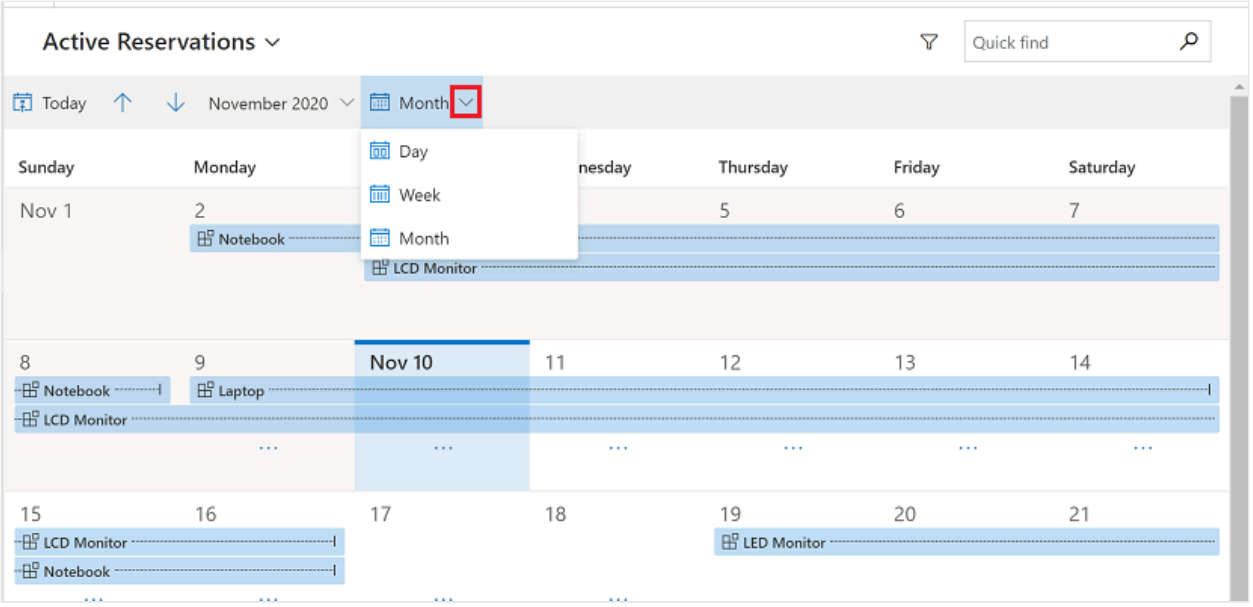


View the calendar by Day, Week, or Month

You can choose from these calendar views:

- **Day**: View the current day.
- **Week**: View the week from Sunday through Saturday, by default. You can change the first day of the week in system settings.
  To view the week numbers, ask your admin to enable displaying the week numbers in the calendar view for your environment. Follow the steps in Customize regional options and select **Show week numbers on Calendar views**.
- **Month**: View the entire month.

To change the calendar format, on the calendar select the drop-down menu and then select **Day**, **Week**, or **Month**.

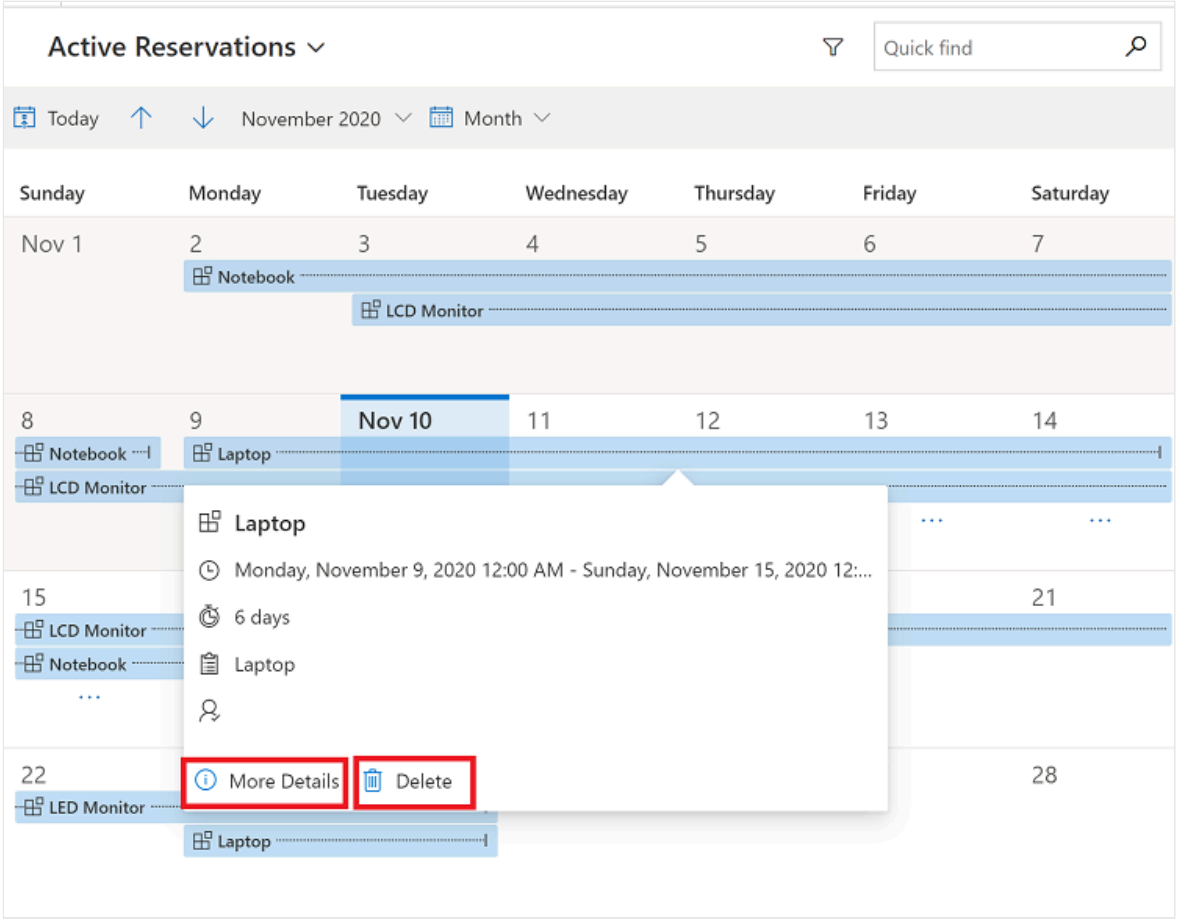


If you want to set a calendar view as the default view, use personalization settings. For more information, see Set personal options.

View details of a calendar item and take action

You can view a summary of a row by selecting it in the calendar. A pop-up window opens and displays the summary information.

- To view complete details about the row, select **More Details** in the pop-up window.
- To delete the row, select **Delete** in the pop-up window.



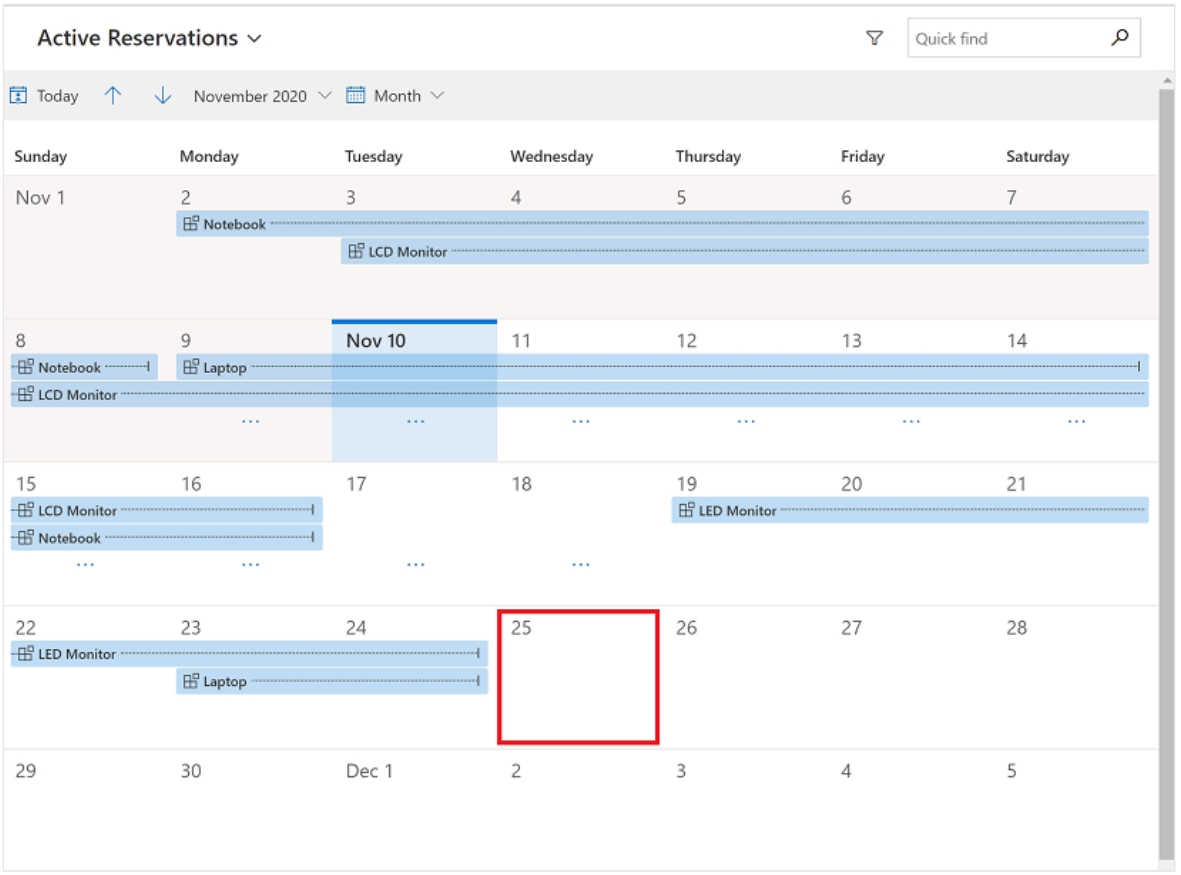
> **Note**
>
> This view is not customizable. If you would like to customize this view, add your suggestion here.

Create a new row from the calendar

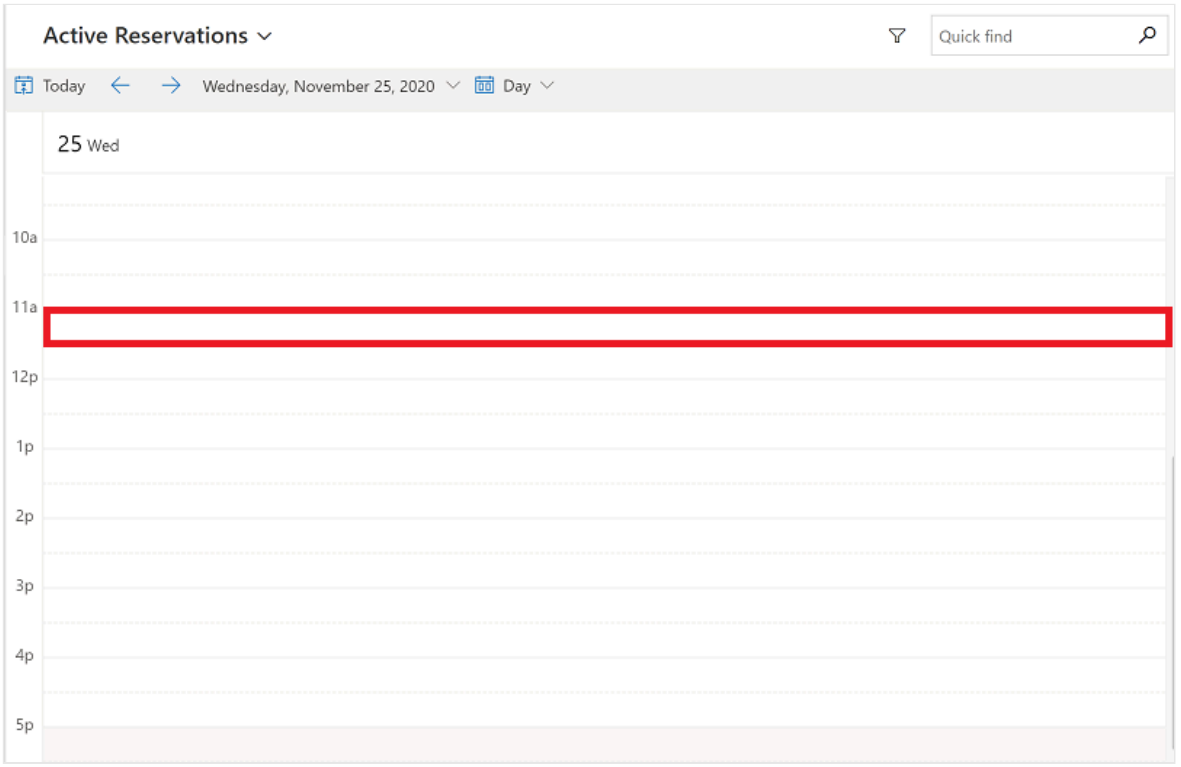
The calendar view allows you to easily create a new row.

1. Depending on your calendar view, create a new row:

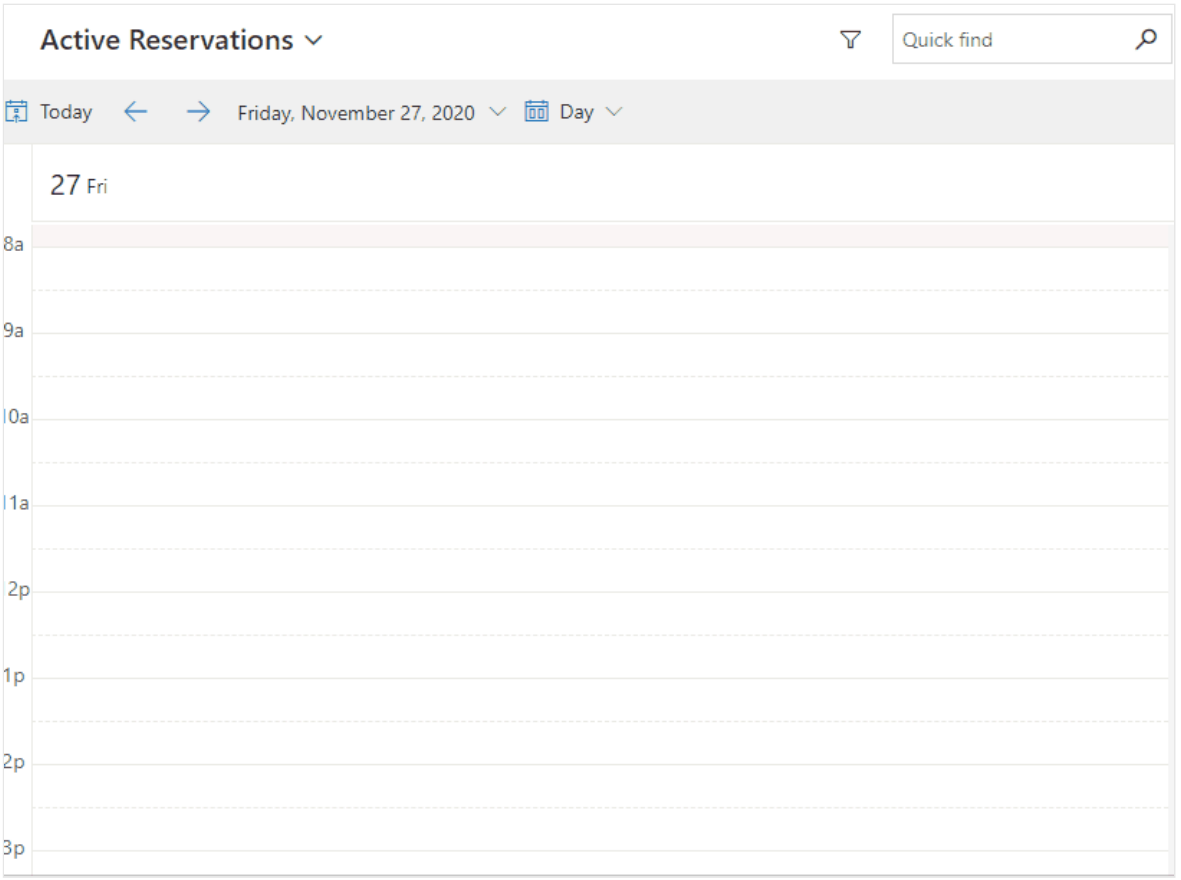
    - On the **Month** view, double-click a date tile, in which you want to create a new row.



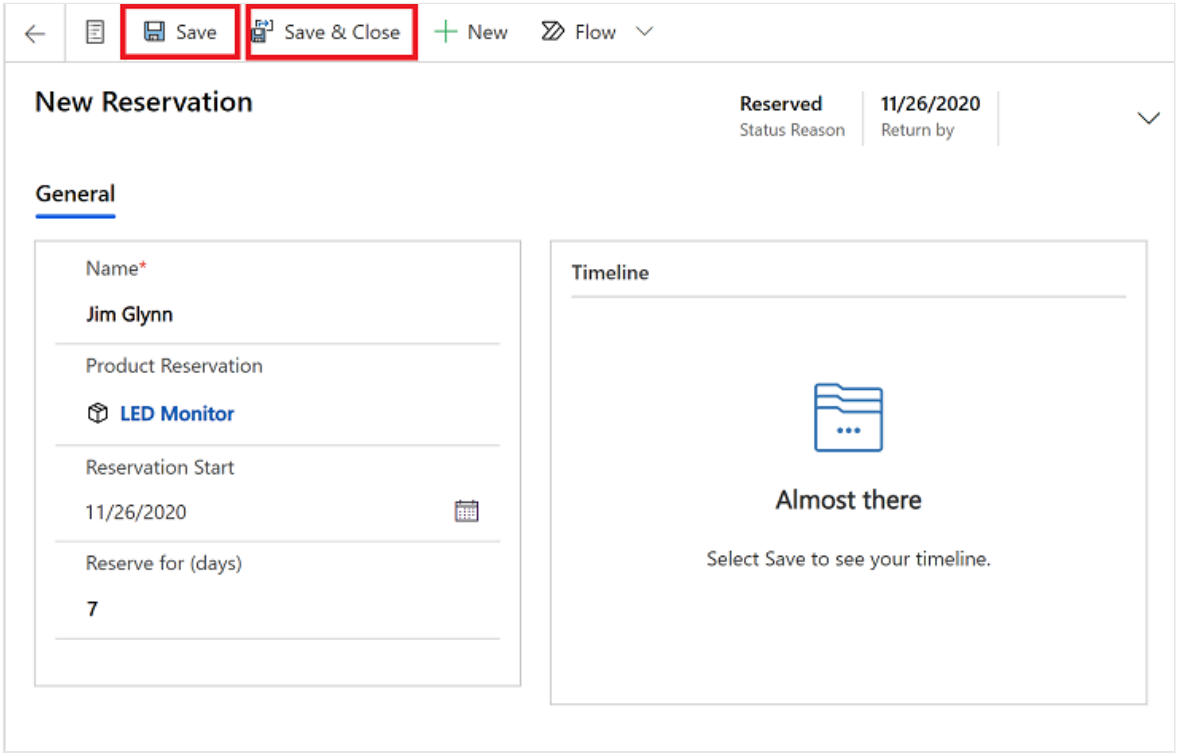
- On the **Day** or **Week** view, select a date and time in which you want to create a row.



- You can also create a new row by selecting and dragging across time slots in **Day** or **Week** view.



2. A new form opens. In this example, a **New Reservation** form is opened. Enter the details, and then select **Save** or **Save & Close**.



> **Note**
>
> - If your form has start and end times columns, they are filled-in automatically as per the selected date tile or time slots. By default, the

duration is set to 30 minutes.

- When you add the new calendar control on a table other than Activity, the corresponding table row is created when you create a row from the calendar.

Search through rows

You can use the search box to search for data in the view you're in. For example, when you enter the keyword **laptop**, it refreshes the calendar view to show only the rows where the title begins with **laptop**. For more information, see Explore data in a view on a grid page.

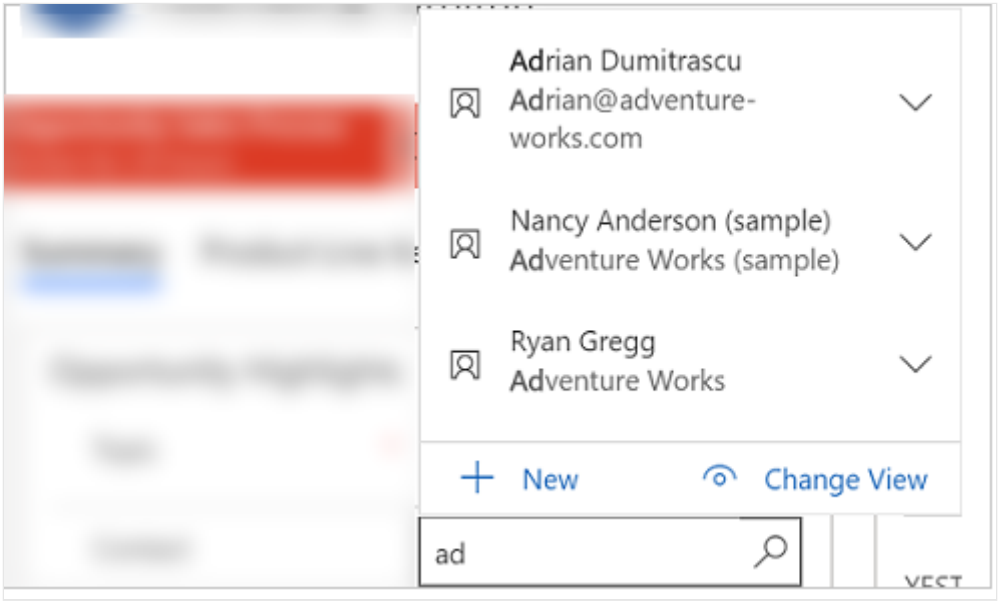
Use the lookup column on a row

Article • 04/10/2023

Lookup helps you to choose rows from a related table. When you select a related table and enter search criteria, such as a name or email address, lookup automatically begins to resolve the partial text and displays any matching rows. If no rows are displayed after you have typed the full text of your search criteria, a message is displayed specifying that there are no rows.

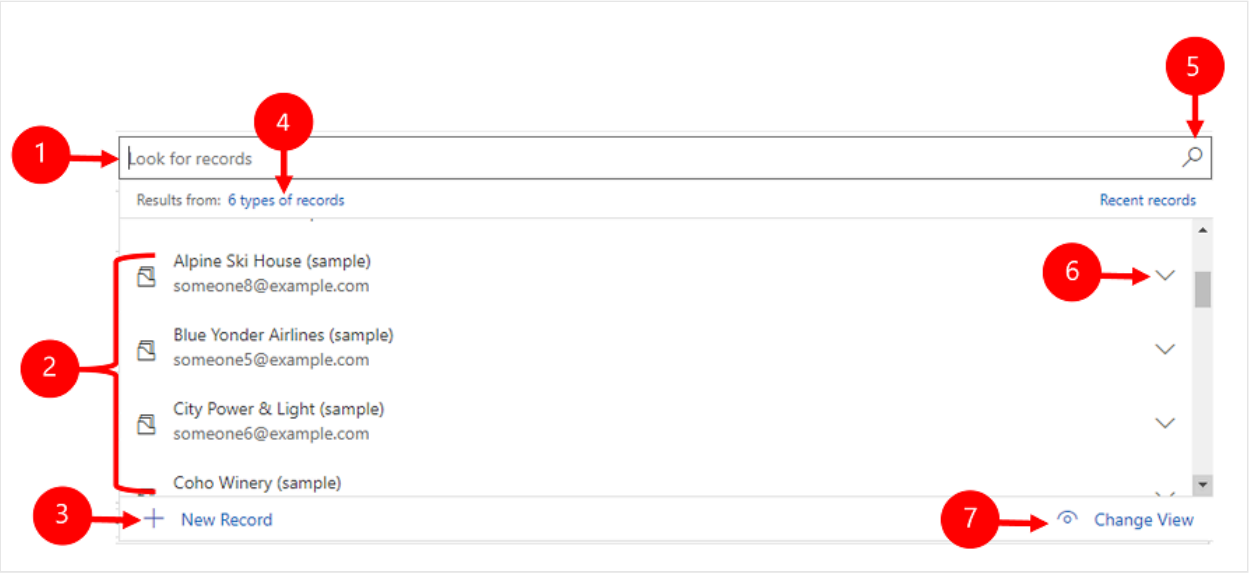
For example, you might search for the name **Adrian Dumitrascu**. When you type **ad**, possible matching rows are automatically populated and displayed.



> **Note**
>
> - An administrator can define the criteria that lookup uses for resolving partial search text.
> - To enable search on multiple columns, see Configure searchable fields.

Also, you can create a new row by selecting the **New** button. You must have sufficient permissions to view the **New** button and create a row. When you select the lookup column, the five most recently used rows are displayed along with five favorite rows. Which rows are displayed depends on your view history and the favorites you've pinned.

For example, if there's only three rows in your history, then the lookup will display those three rows, along with seven of your favorite rows. If you haven't pinned any rows to favorites, then the most recently viewed rows will be displayed.



Legend

1. **Look for records**: Select the textbox and type your search criteria to look for rows.
2. **Recent**: Rows that were recently searched.
3. **New Record**: Create a new row.
4. **Types of records**: Select to filter by a table type such as Contact table or Account table. The number in front of **type of records** represents how many table are available to filter from.
5. **Browse in a lookup column**: To browse a lookup, select the lookup icon (magnifying glass). A full list of items will be shown in the dropdown.
6. **Expand item**: Use the Right and Left arrow keys on your keyboard to expand collapse each item. For more information on keyboard shortcuts, see Use keyboard shortcuts in Power Apps.
7. **Change View**: Select to switch to another view. For more information on views, see Explore data in a view on a grid page.

Types of lookups

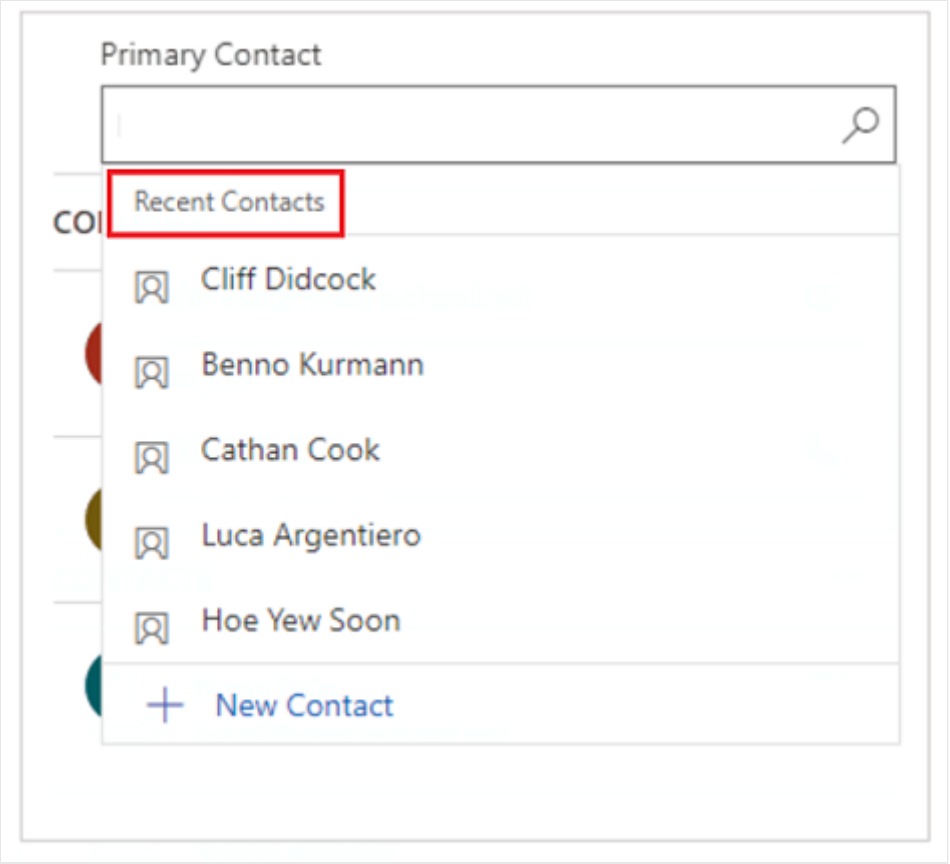
Lookups are classified into the following:

- **Simple lookup:** Select a single row from a single table.
- **PartyList-type lookup:** Use to select multiple rows from multiple tables in a lookup. Use partylist-type columns to select multiple rows. This allows you to add each row by performing a new search, multiple times. Every time you select a row, you will be able to perform a new search for another row. Note, you can't customize the system and disable views for PartyList-type look.
- **Regarding-type lookup:** Use to select a single row from multiple tables in a lookup. Activities must be enabled for a table to use the Regarding lookup. For

more information: Enable activities for a table

Search in a lookup column

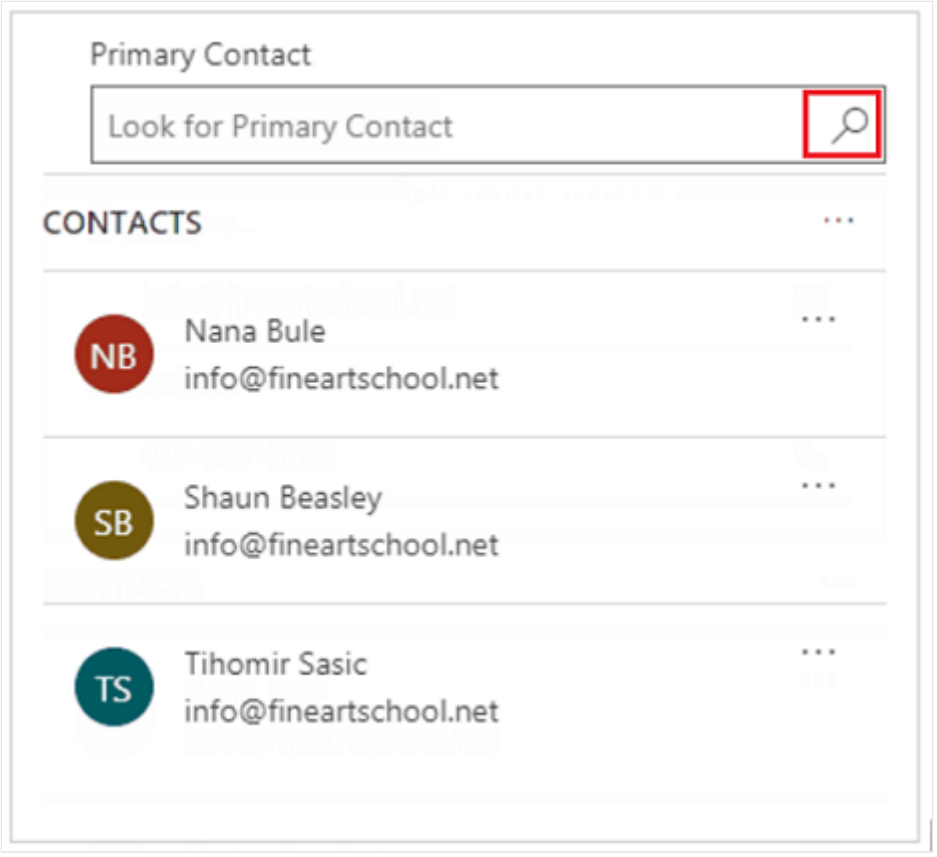
To search a lookup, select the textbox and type your search criteria. If recent rows are enabled for your lookup, your recent rows will be displayed when you select the textbox.



> **Note**
>
> The default search result for lookup search is, **begins with**. This means results include rows that begin with a specific word. For example, if you want to search for **Alpine Ski House**, type **alp** in the search box; if you type **ski**, the row will not show up in the search result.
>
> For a wildcard search use asterisks: For example, type *ski or *ski*.

Browse in a lookup column

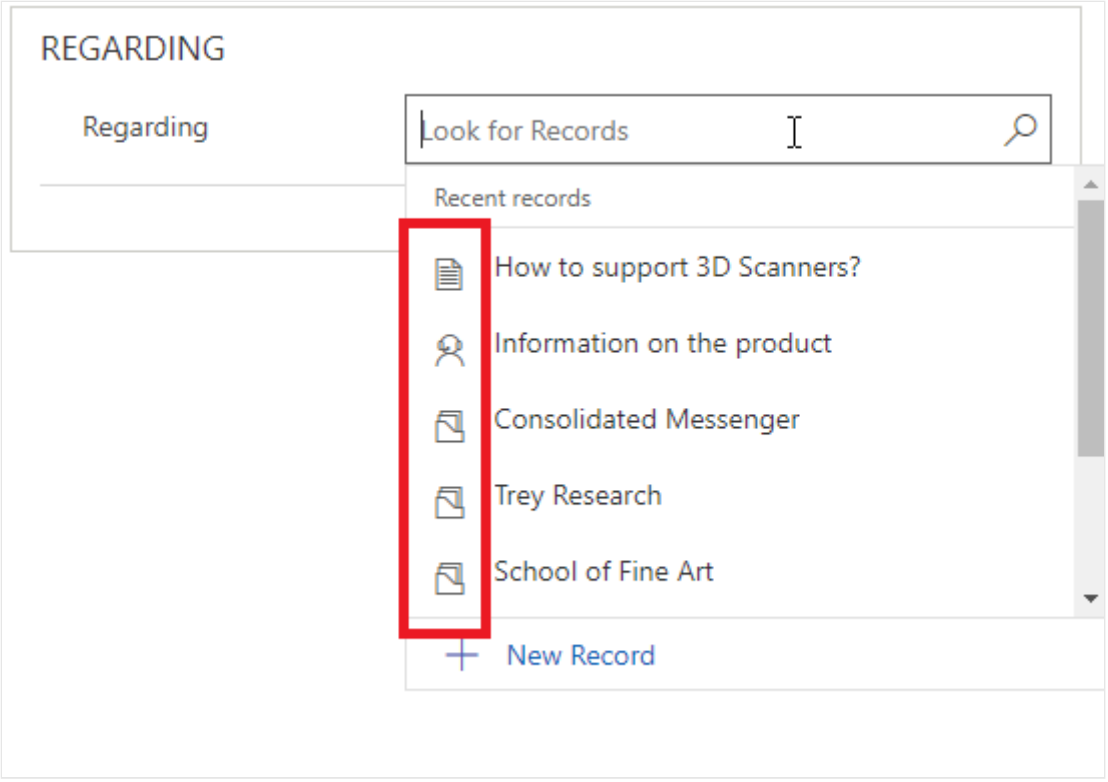
To browse a lookup, select the lookup icon (magnifying glass). A full list of items will be shown in the dropdown.



Most recently used row type images

The most recently used list of rows shows an image to help distinguish between row types.

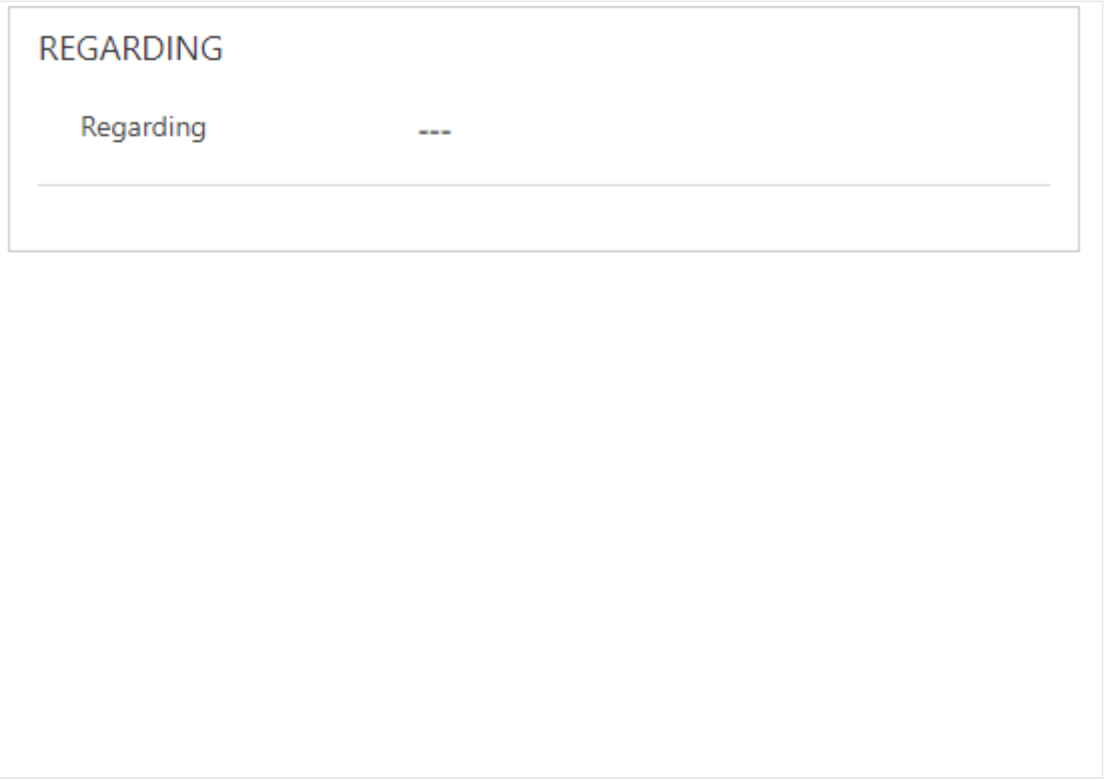
> **Note**
>
> Recent rows are not filtered by search term, selected view or related rows.



Row type selection list

When results span multiple row types, you can see how many types of rows there are and select them from the list. The **Lookup Row** option is not available in Unified Interface. Instead, use the following to search:

- To look for rows, enter text in the search box.
- To search by table type select **types of rows**.
- Select **Change View** to select a view.



Create a new row if you don’t find an existing row

If you do not find a row, select **New** in the lookup area to create a new row. When the row is created it will show up in the lookup.

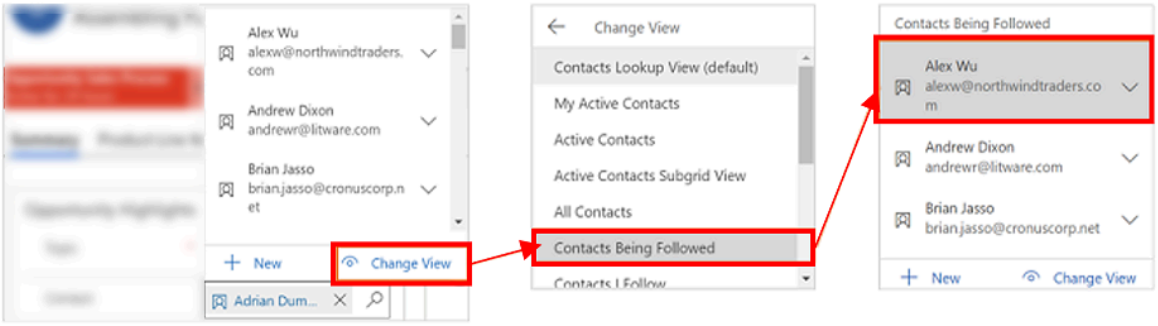
Replace the selected lookup item

You can replace an existing row while using simple and regarding-type lookups. Search for a row and then select the row to replace it with a new row.

Change a view in a lookup column

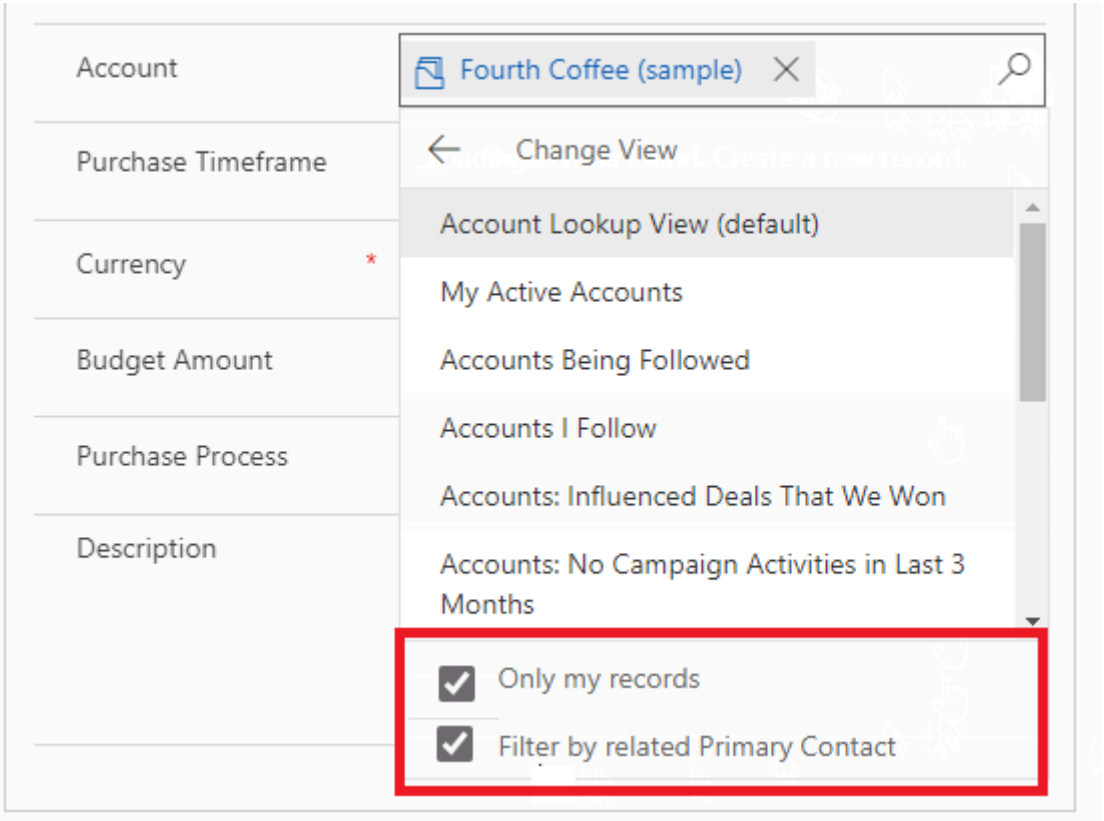
Selecting **Change View** lets you determine:

- How you want to view rows such as **Contacts Being Followed**, **Contacts Lookup View**, or **Active Contacts**.
- What you want to view in the rows, such as name, email, or telephone number. For example, if you want to view only the contacts that you follow, select **Change View** > **Contacts being followed**. Only the contacts that you are following will be displayed, as illustrated here.



Filter by, Only my rows or Filter by related primary contact

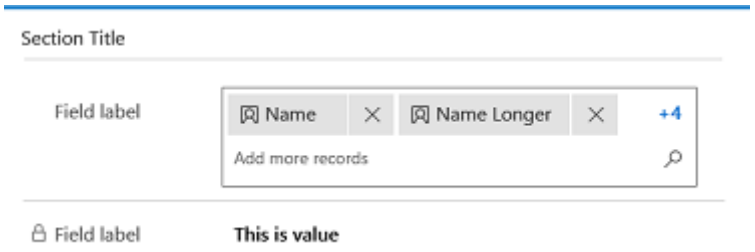
To apply extra filters, in the **Change View** menu, select **Only my rows** or **Filter by related Primary Contact**.



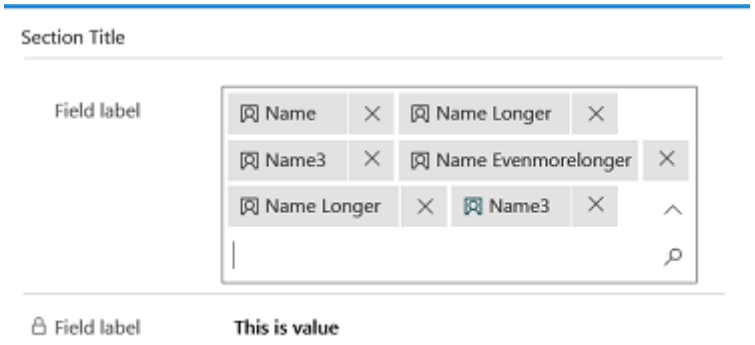
Choose from multiple rows

When lookup has more rows in a column than can fit in the available display area, the display area is collapsed—that is, the rows that do fit the display area are shown next to the number of rows that are not shown. To view all rows, select the number. The following images show the difference between collapsed and non-collapsed columns.

Collapsed:



Non-collapsed:



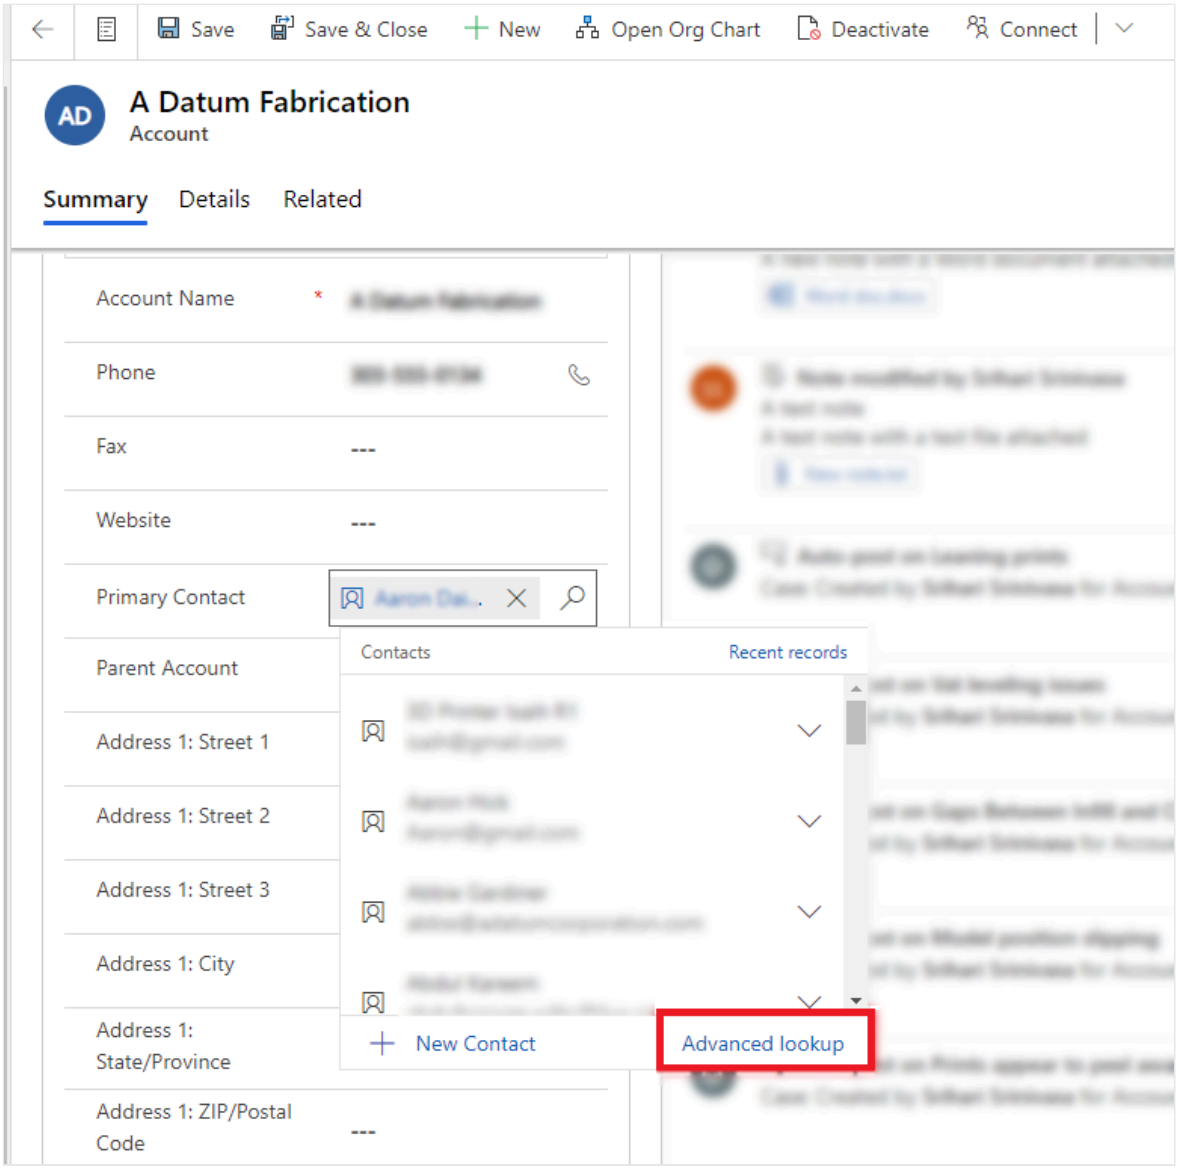
Advanced lookup

The **Advanced lookup** feature is available for early access in 2021 release wave 2. To use **Advanced lookup** your administrator needs to enable early access. For more information, see Manage behavior settings.

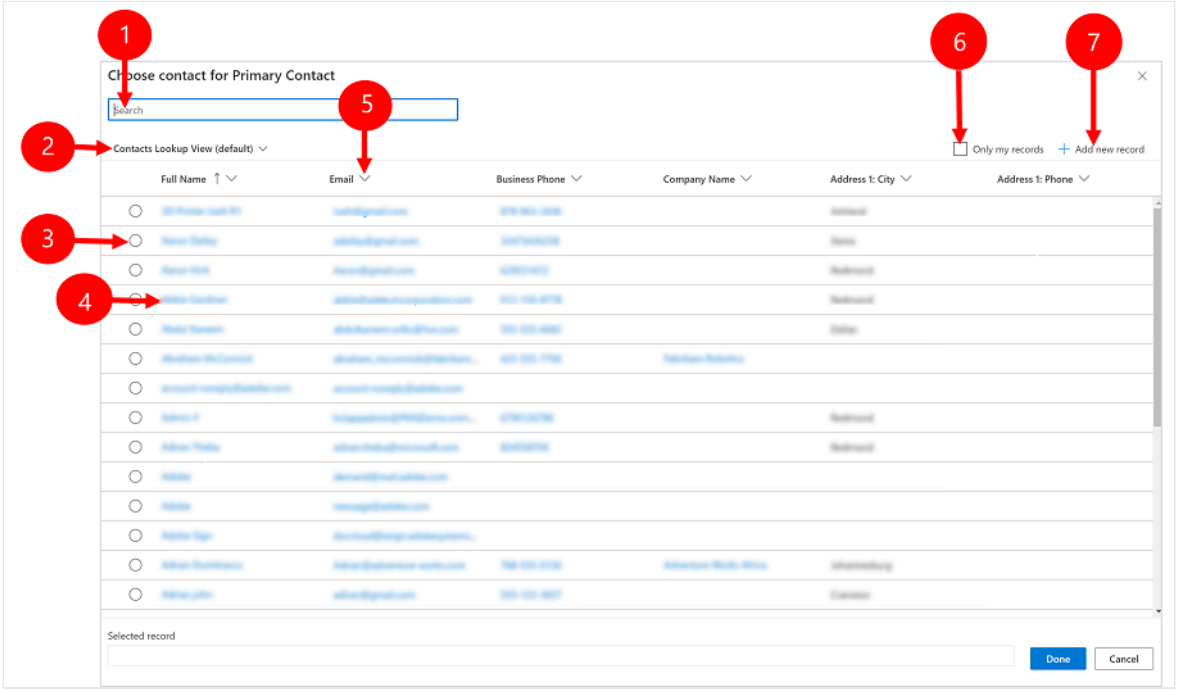
Once enabled **Advanced lookup** is available on any lookup column that's on a quick create form, edit form, or dialog box. With **Advanced lookup** you can easily sort rows and switch between tables or views in a lookup column.

Advanced lookup supports customizations on lookup control through Client APIs such as *addCustomView*, *addCustomFilter*, *addPreSearch* and *removePreSearch*.

1. To use **Advanced lookup**, select the lookup icon (magnifying glass) on any lookup column and then select **Advanced lookup**.



2. The **Advanced lookup** gird opens with a list of rows.



Legend

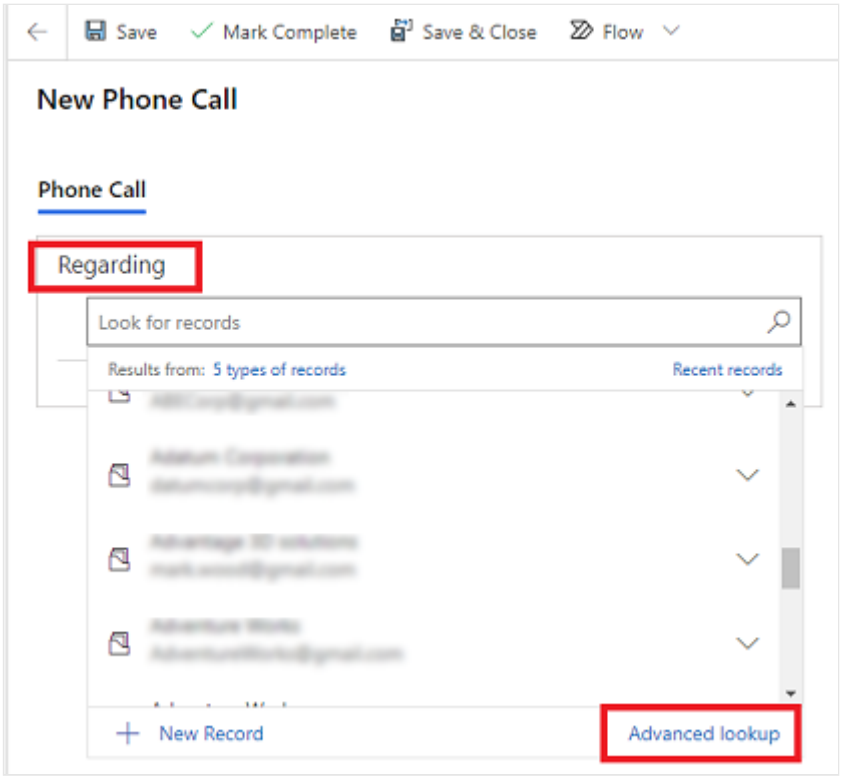
1. **Search**: Enter search text to find the row that you're looking for. When you changes views the search text is retained.
2. **Change views**: Select to change views.
3. **Select row**: Select the radio button to choose a row for the lookup and then select **Done**. The selected row will appear at the bottom under **Selected record**.
4. **Open row**: Select to open the row and make edits and then save your changes. Any saved changes are reflected in the advanced lookup grid.
5. **Sort**: Select the arrow at the top of any column to sort in ascending or descending order.
6. **Only my records**: Select to only show rows that you own.
7. **Add new record**: Opens the quick create form where you can add a new row for the table. When you save the new row, the advanced lookup grid will refresh and show the newly added row.

> ⚠ **Warning**
>
> Advanced lookup isn't available with offline scenarios. The **Advanced lookup** button is replaced by a **Change view** button when the user is offline.

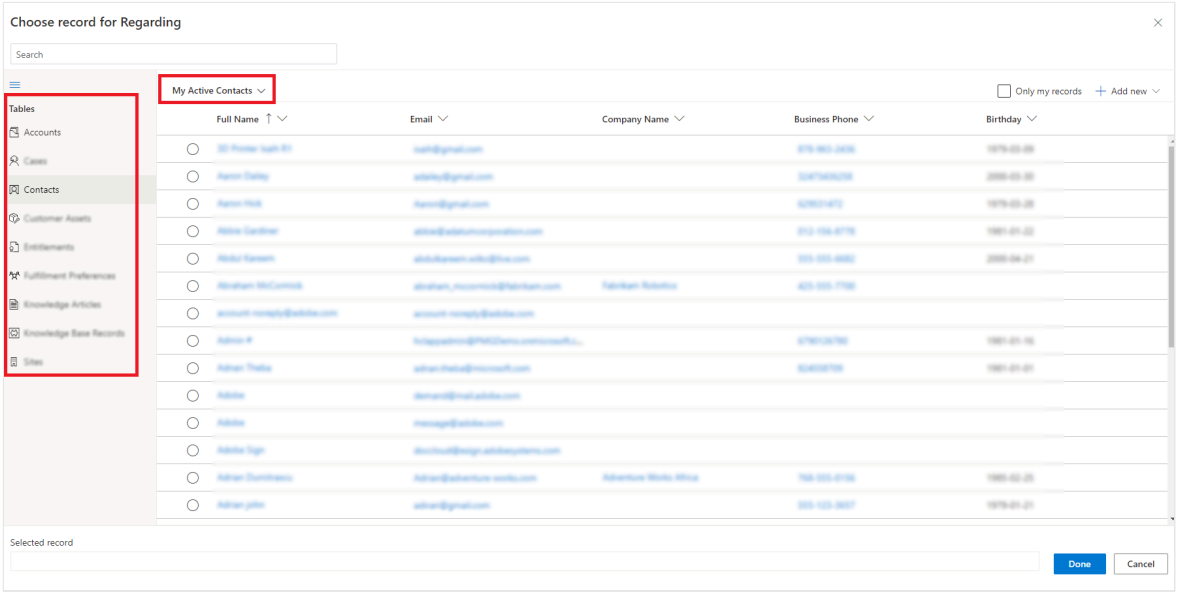
Regarding advanced lookup

In a **Regarding** lookup, you can switch between tables and their views

1. In a **Regarding** lookup column, select the lookup icon (magnifying glass) then select **Advanced lookup**.



2. On the advanced lookup grid, select a table from the list to see rows for the selected table. You can also select the current view to change views.

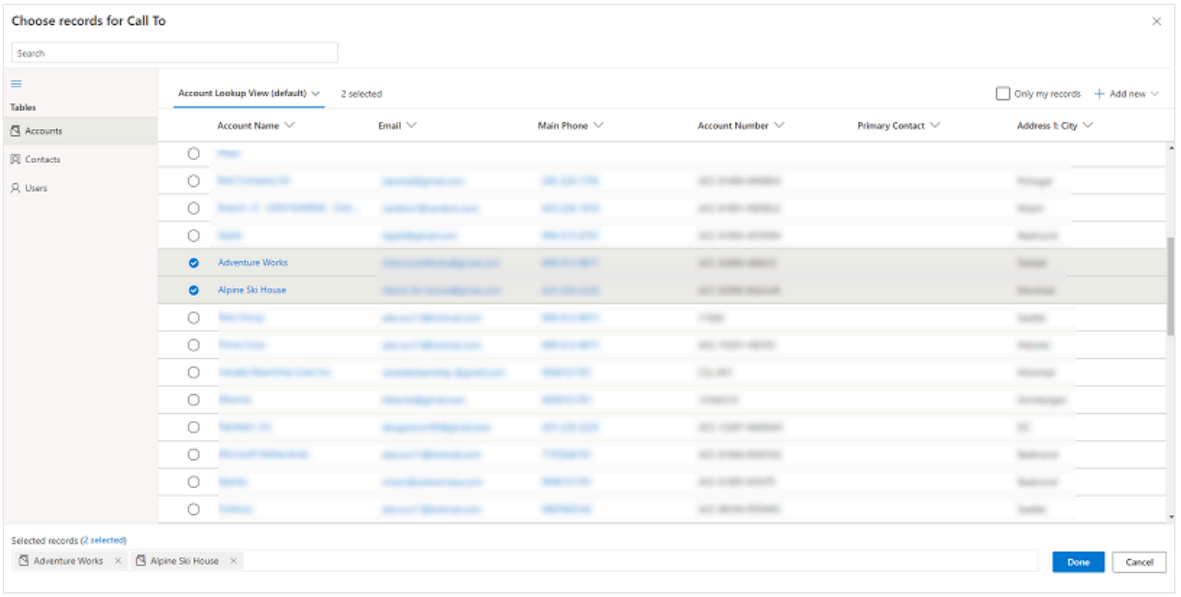


Party list advanced lookup

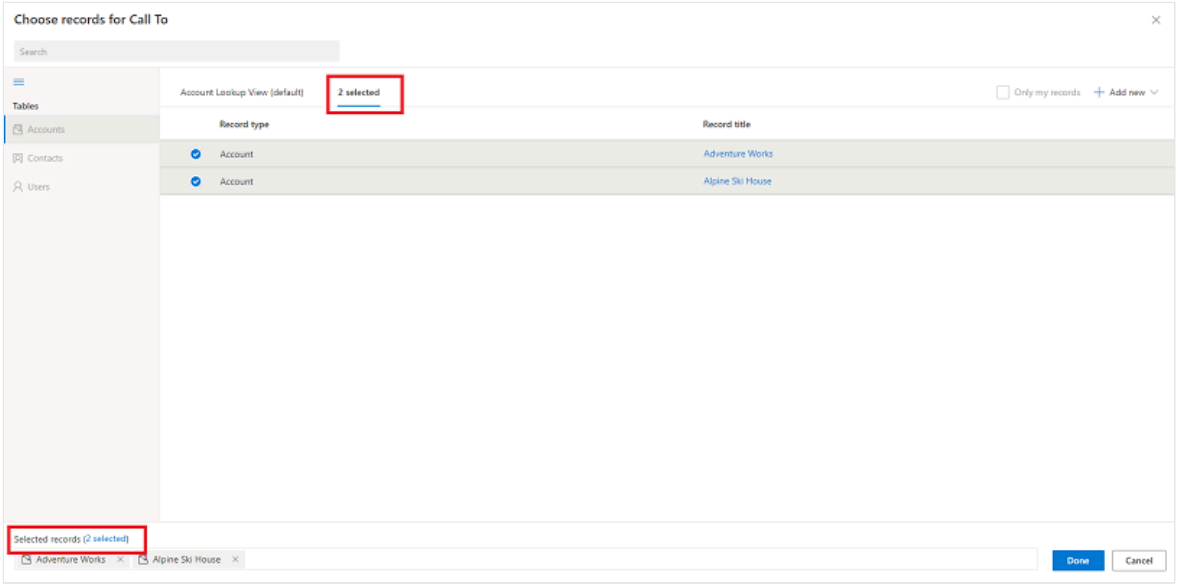
For lookup columns that is a party list, you can select multiple rows from different tables such as the **Call To** field on a phone call activity.

1. Go to a lookup column with party list and select the lookup icon (magnifying glass) then select **Advanced lookup**.

2. On the advanced lookup grid, select from multiple rows from different tables.



3. Select the **(number of rows) selected** tab or the link at the bottom to review and edit your choices and then select **Done**.



4. The selected rows appear in the lookup.

View the profile card for a contact or user

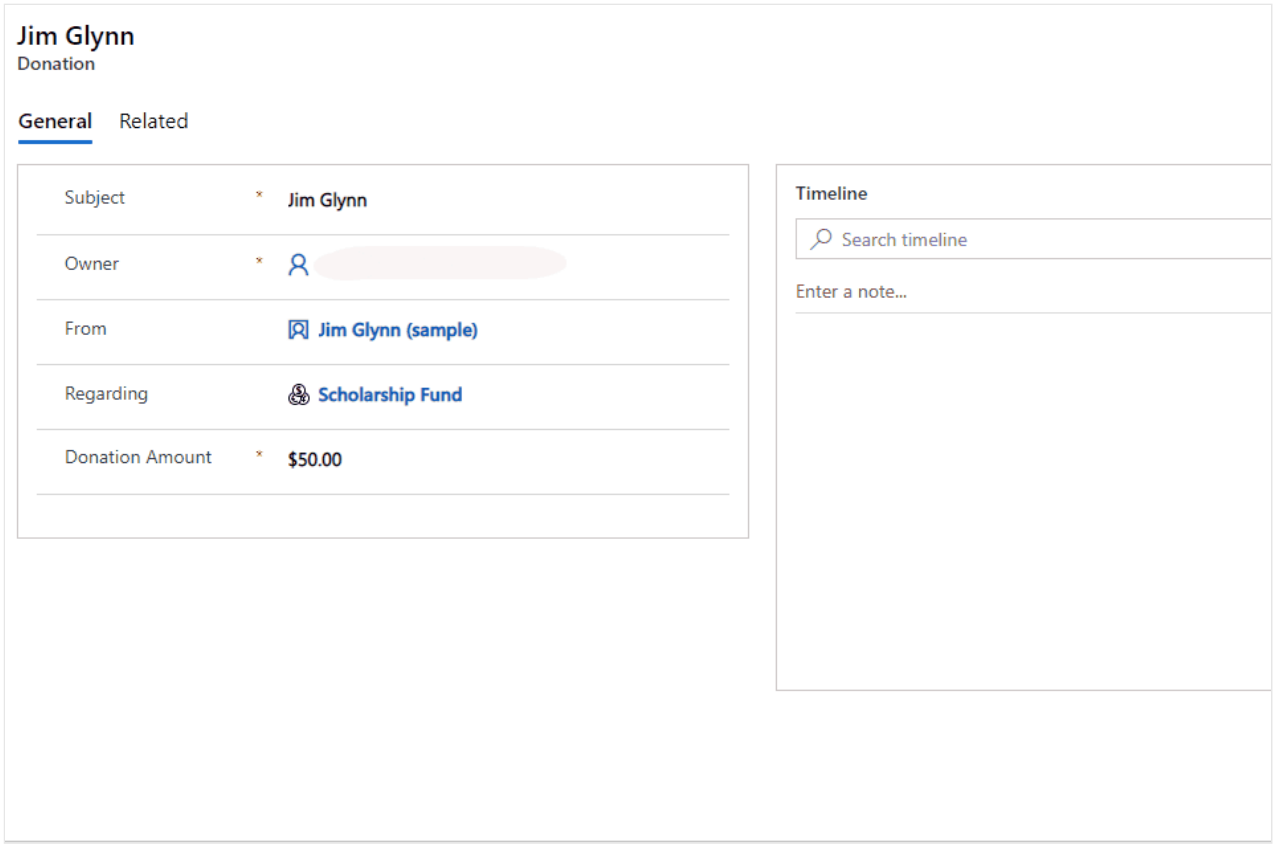
When you select someone's name or picture in Outlook or other Office apps, you can find information related to them on their profile card. The profile card is also sometimes referred to as contact card or people card. In model-driven Power Apps, profile cards can be seen on contact and user rows. You can only view them when they are in a lookup.

For more information about profile cards, see Profile cards in Office 365.

> **Note**
>
> - Profile cards are available on contacts and users in any Unified Interface app. For information, see **Enable viewing profile cards (for admins)**.
> - The profile card in Microsoft Dataverse is not displayed if multi-factor authentication is turned on for Office Delve service in Azure Active Directory.
> - Profile cards are not available when the signed-in user is a Microsoft Entra ID guest user.

View a contact's profile

1. Open a row and go to a lookup column that has a contact or owner name.
2. Hover over the name to view the profile card.



FAQs

Where can I see profile cards in Dynamics 365?

Profile cards can be seen on contact and user rows. You can only view them when they are in a lookup.

Where is information shown in the profile card coming from?

The information shown on the contact profile card is fetched from Dataverse (and not Microsoft Exchange).

The information shown on the user profile card is fetched from Office 365 (Azure Active Directory). For more information, see Profile cards in Office 365 (admin section) .

How can I customize the columns shown on the profile card?

Currently, the list of columns displayed on the profile card is not open for customization.

Why is the Start chat option on the profile card disabled (greyed out)?

The **Start chat** and the **Send Email** options on the profile card will open your default instant message and email apps. The **Start chat** option is enabled if the person you are trying to contact is in the same Azure Active Directory environment as you or is a federated contact.

Why isn't the profile card opening for a user?

If profile cards are not appearing when hovering over any user's name, the signed-in user might be a Microsoft Entra ID guest user. Profile cards aren't supported for signed-in guest users.

Last updated on 04/02/2026

Assign or share a row

Article • 09/26/2022

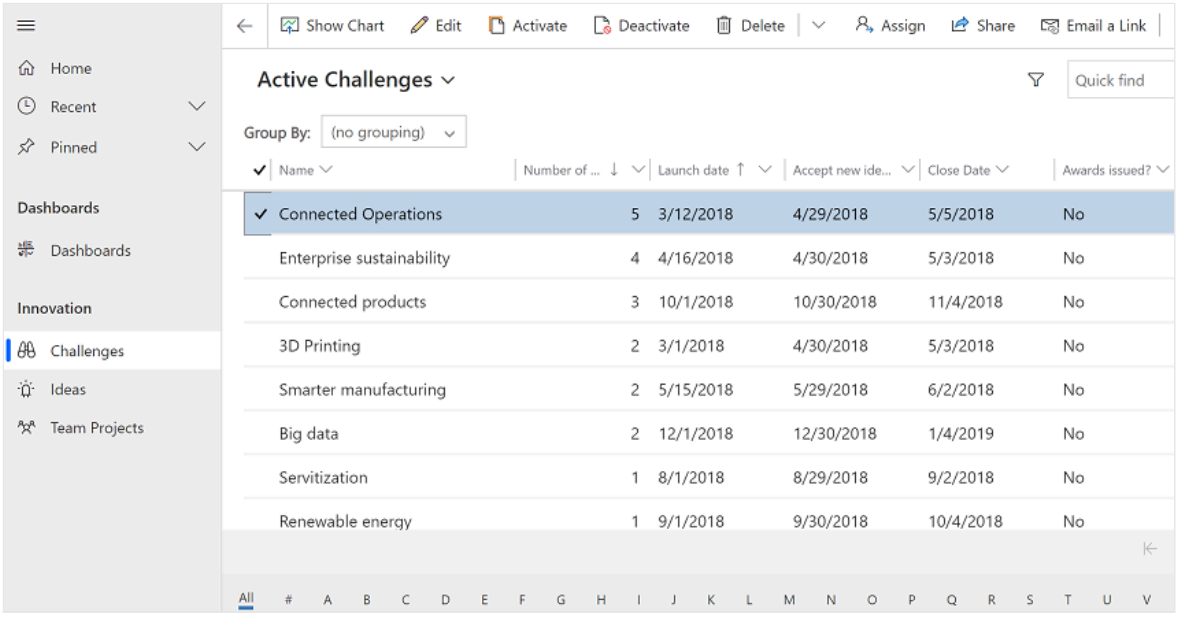
When you create a row, you are the owner of the row. If you would like another person in your organization to take ownership of the row, then you can assign the row to that person. You can assign a row to a user or team. You can also assign a row to yourself that another user owns but you need to have system administrator privilege to do this.

If you want to keep ownership of the row but let someone else work on it with you, then use the **Share** option to share the row. For more information, see Share a row.

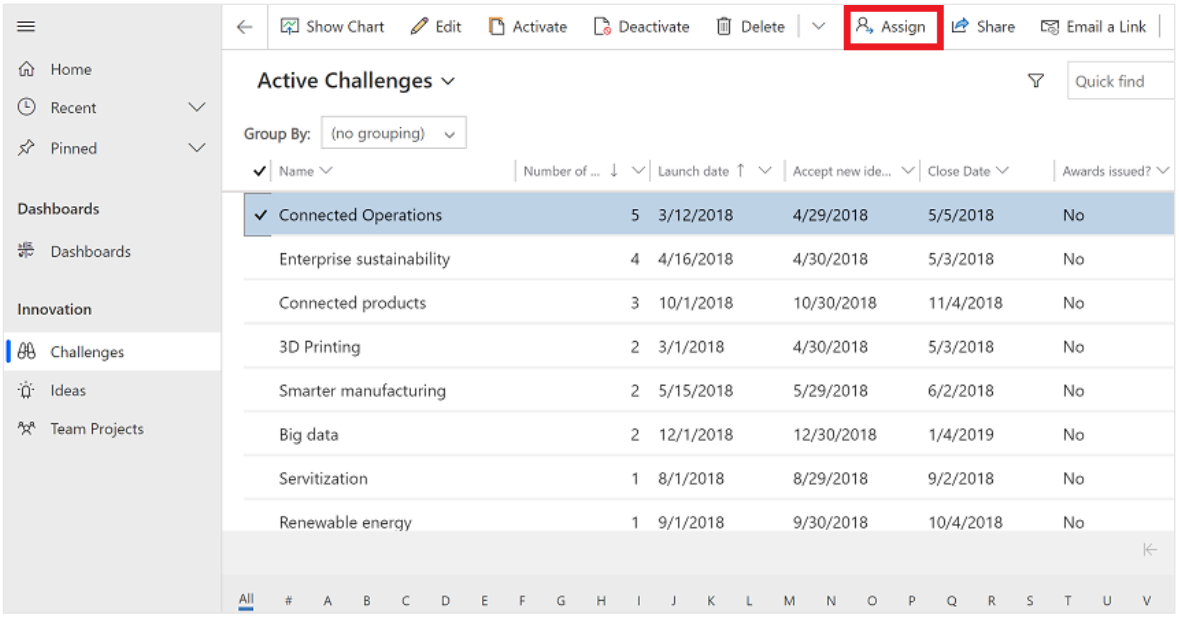
For more information on how privileges and access works, see How access to a row is determined.

Assign a row to a user or team

1. From a list of rows, select the row that you want to assign to someone else. You can select multiple rows.



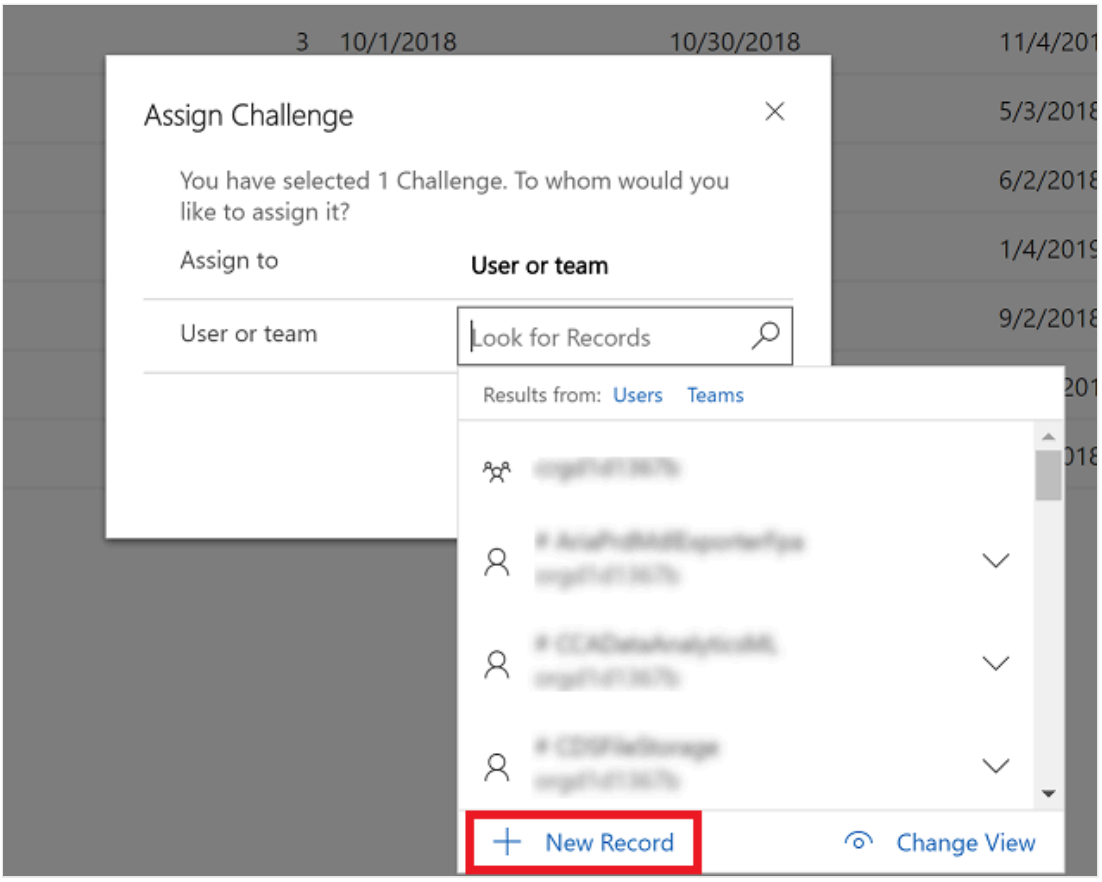
2. On the command bar, select **Assign**.



3. In the assign dialog box, select the **Assign to** column, and choose one of the following options:

   - Select **Me** to assign the row to yourself and them select **Assign**. Remember only a system administrator can assign a row that belongs to someone else to themself.

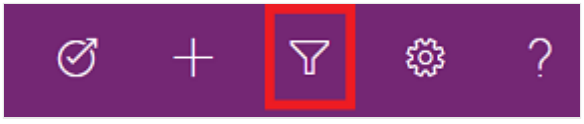
   - Select **User or Team** and then enter the name of the user or team or use the lookup to find them. Or, select **New Row** to create a new user or team row. When you're done select **Assign**.



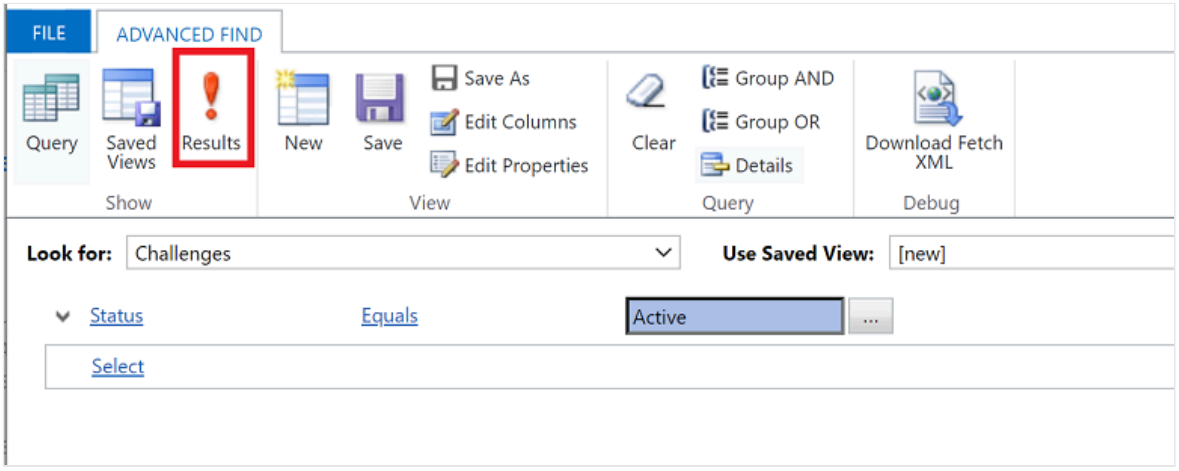
Use advanced find to reassign rows

Use advanced find to search for rows and then reassign them to someone else. For more information on advanced find, see Create, edit, or save an Advanced Find search.

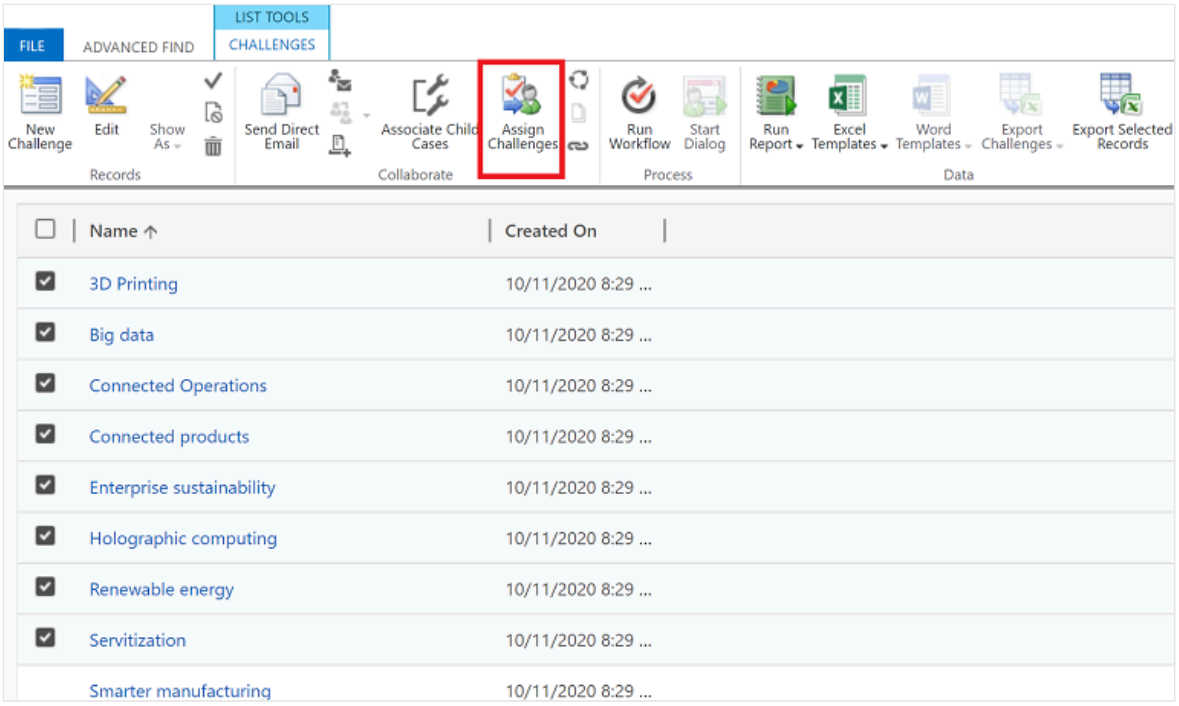
1. On the command bar, select **Advanced Find**.



2. Use the advanced find search to find rows that you want to assign to someone else. For example, to look for active row types that are **Challenges**, in **Look for:** enter **Challenges** and status equals **Active**. Then select **Results** to run the query.



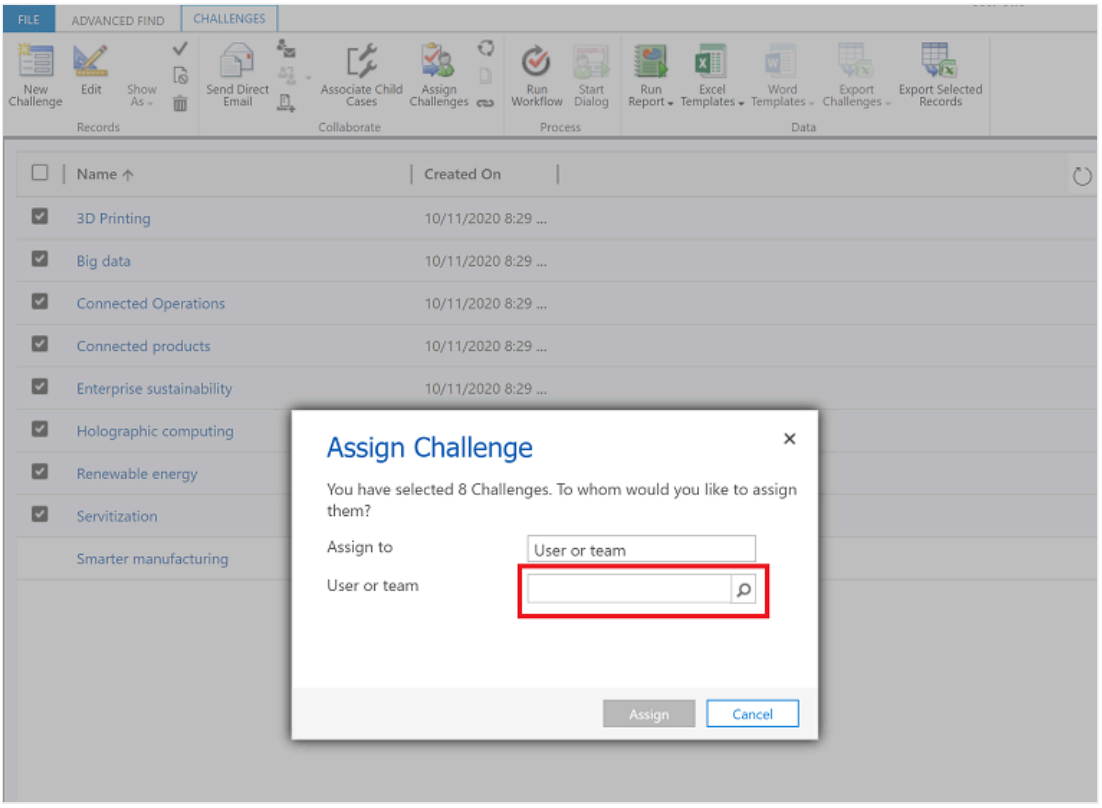
3. Select the rows that you want to assign and then select **Assign (page name)**



4. In the assign dialog box, select the **Assign to** column and choose one of the following options:

   - Select **Me** to assign the row to yourself and then select **Assign**. Remember only a system administrator can assign a row that belongs to someone else to themself.

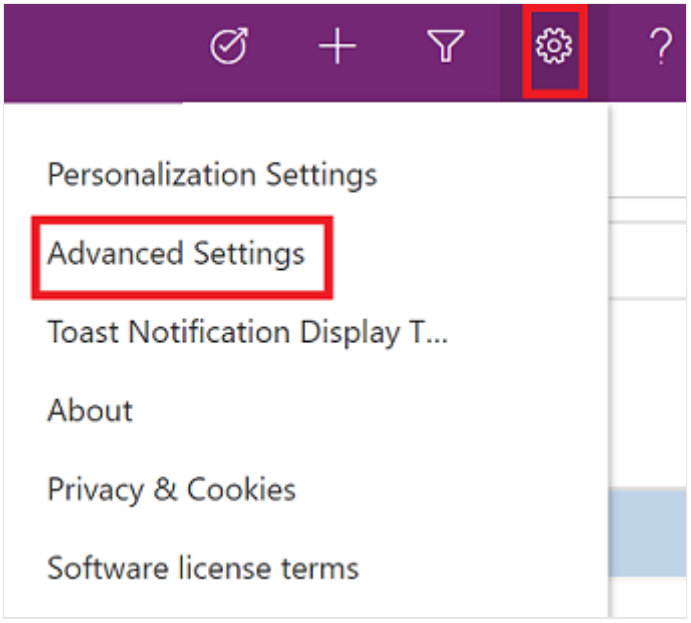
   - Select **User or Team** and then enter the name of the user or team or use the lookup to find them. Or, select **New Row** to create a new user or team row. When you're done select **Assign**.



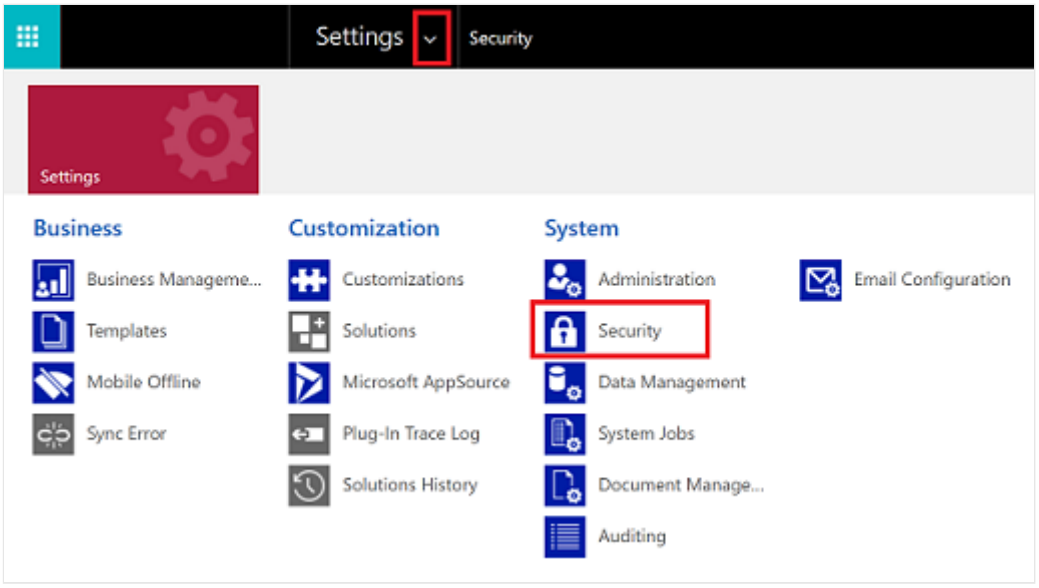
Reassign all rows (for admins)

When you have a user that leaves your organization or ownership needs to change from one user to another the rows can be reassigned by an administrator.

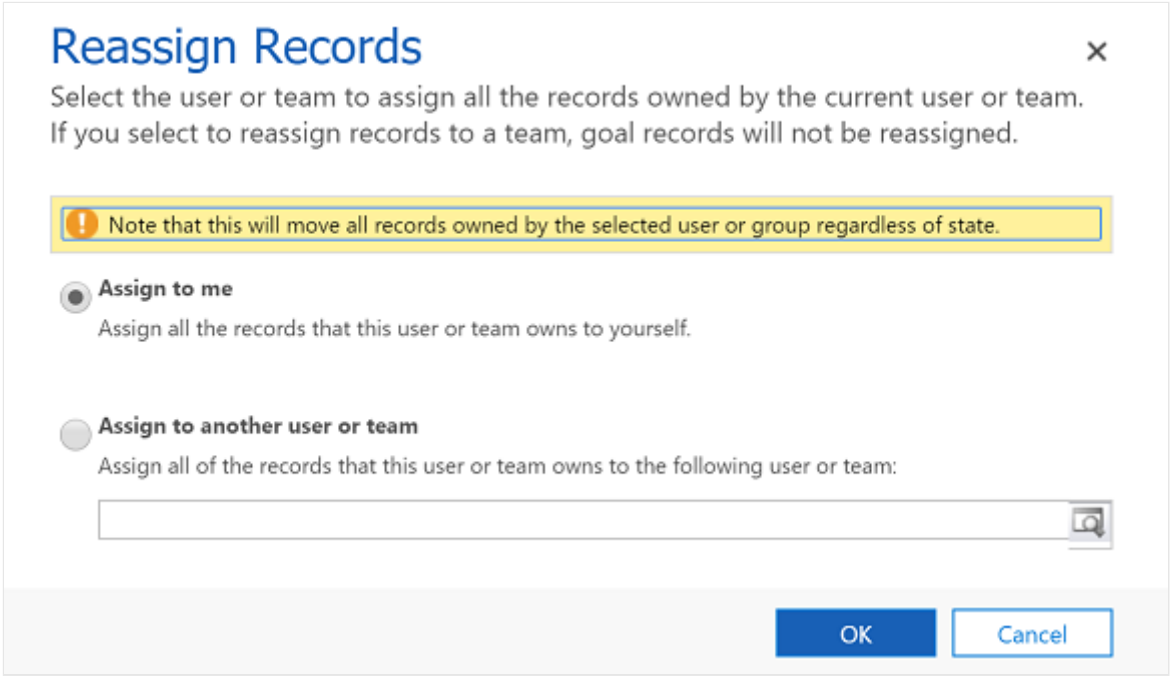
1. Go to **Settings** > **Advanced Settings**.



2. From the top menu navigate from **Settings** > **Security**.



3. Under **Security** select **Users**.
4. From the list of users, select a user name to open the user's profile.
5. On the command bar, select **REASSIGN ROWS**.
6. On the **Reassign Rows** dialog box choose how to want to reassign all the rows and then select **OK**.



> ⓘ Note
>
> - The **Reassign Rows** option will reassign all rows regardless of their status. Inactive and active rows will be reassigned to the other user or team. This will also deactivate all activated processes including business rules and workflows

when the row is reassigned to another user or team. The new owner must activate the processes that was deactivated when the row is reassigned.

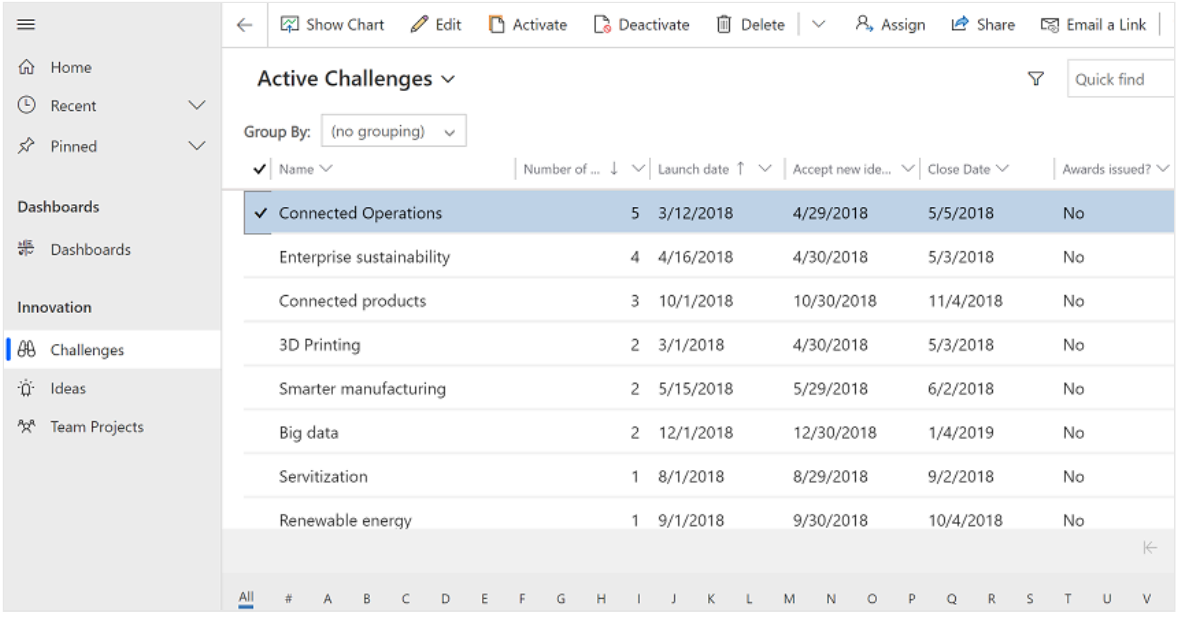
- When there is a large amount rows to reassign, the system may take a while to process.
- If there is an issue during the reassignment process such as the user that the rows are being reassigned to doesn't have the required privileges then the **Reassign Rows** process will stop. The rows that are processed before the issue will be updated and saved. For the rows that were not saved, you will need to reassign the rows again using the **Reassign Rows** option.

Share a row with someone else

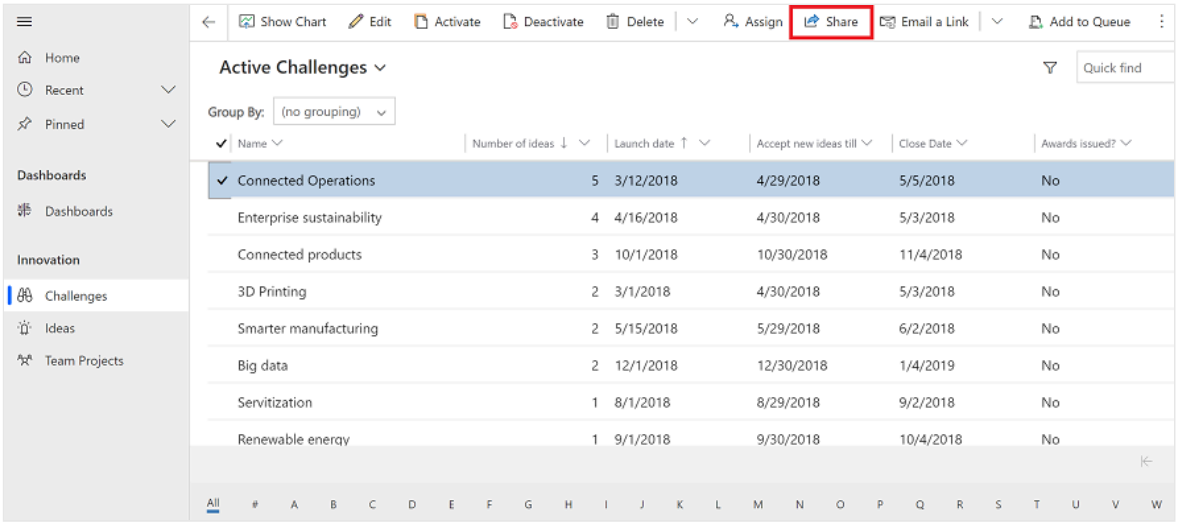
If you want to keep ownership of a row but let someone else work on the row with you then use the share option.

> **Note**
>
> For users on early access the sharing feature has been updated for 2021 release wave 2. For more information, see Share a row with someone else.

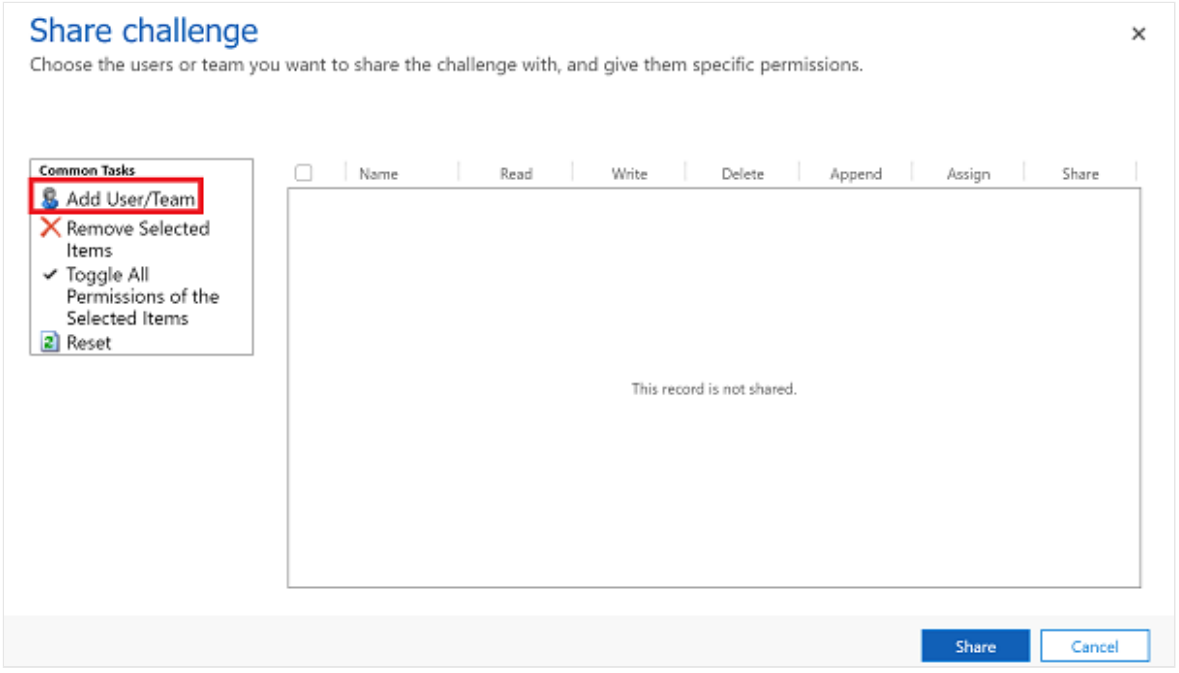
1. From a list of rows, select the row that you want to share with someone else. You can select multiple rows.



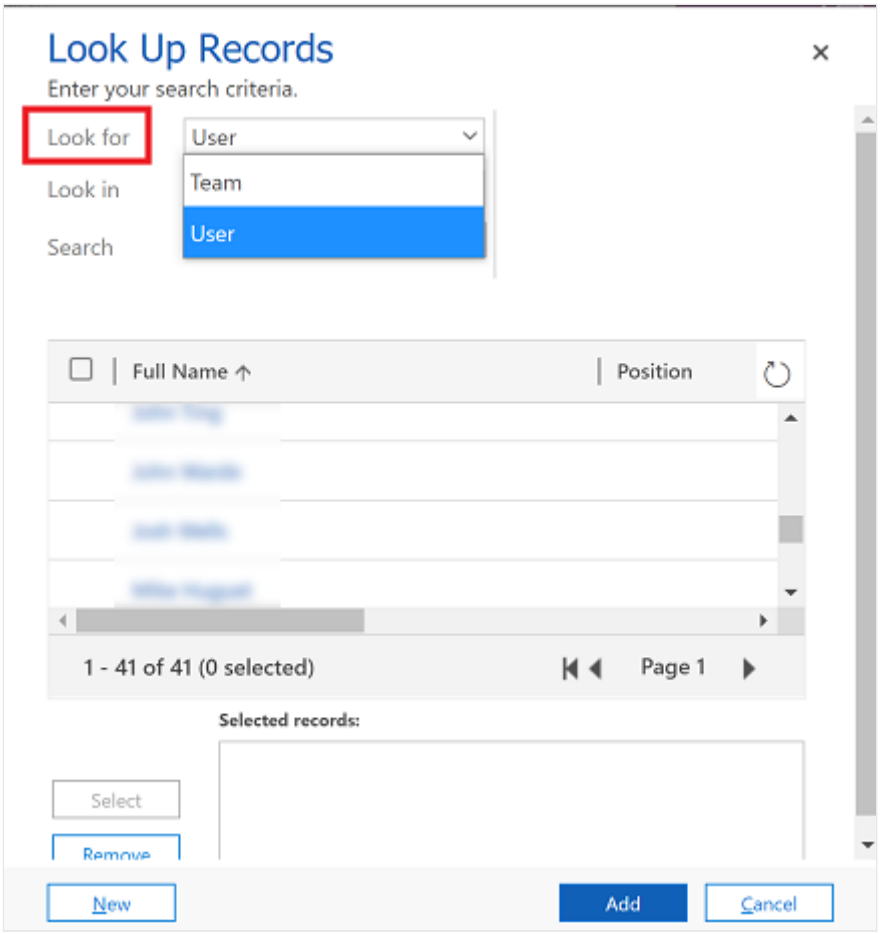
2. On the command bar, select **Share**.



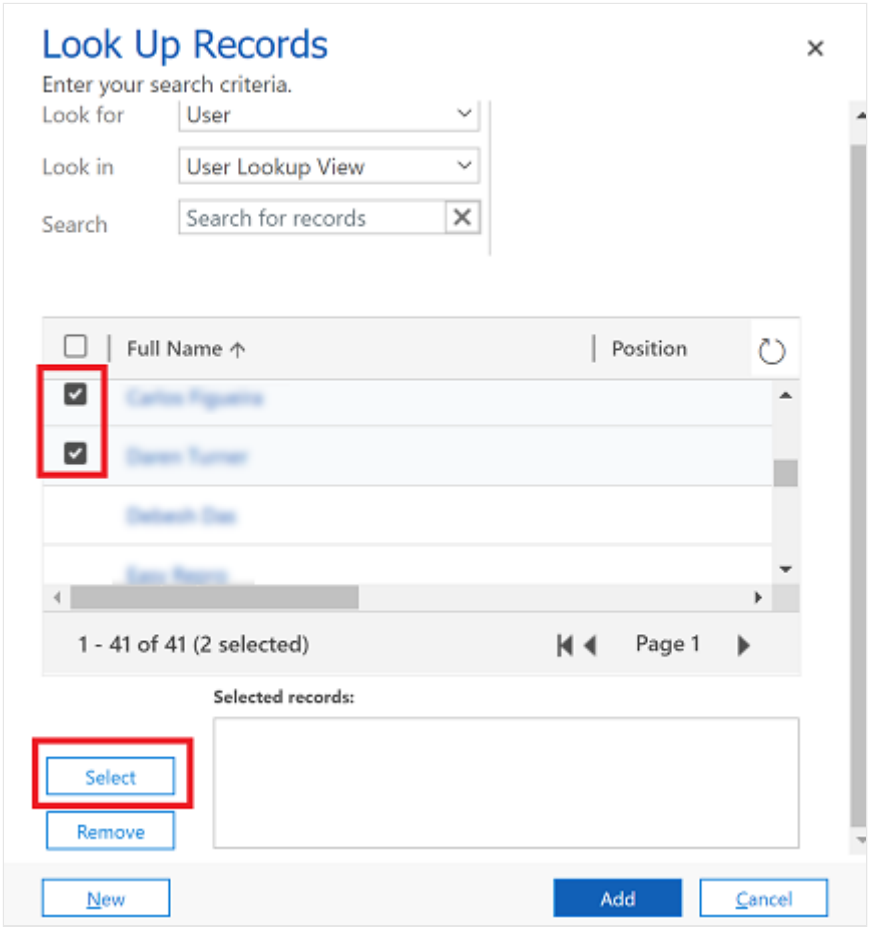
3. On the share dialog box, select **Add User/Team**.



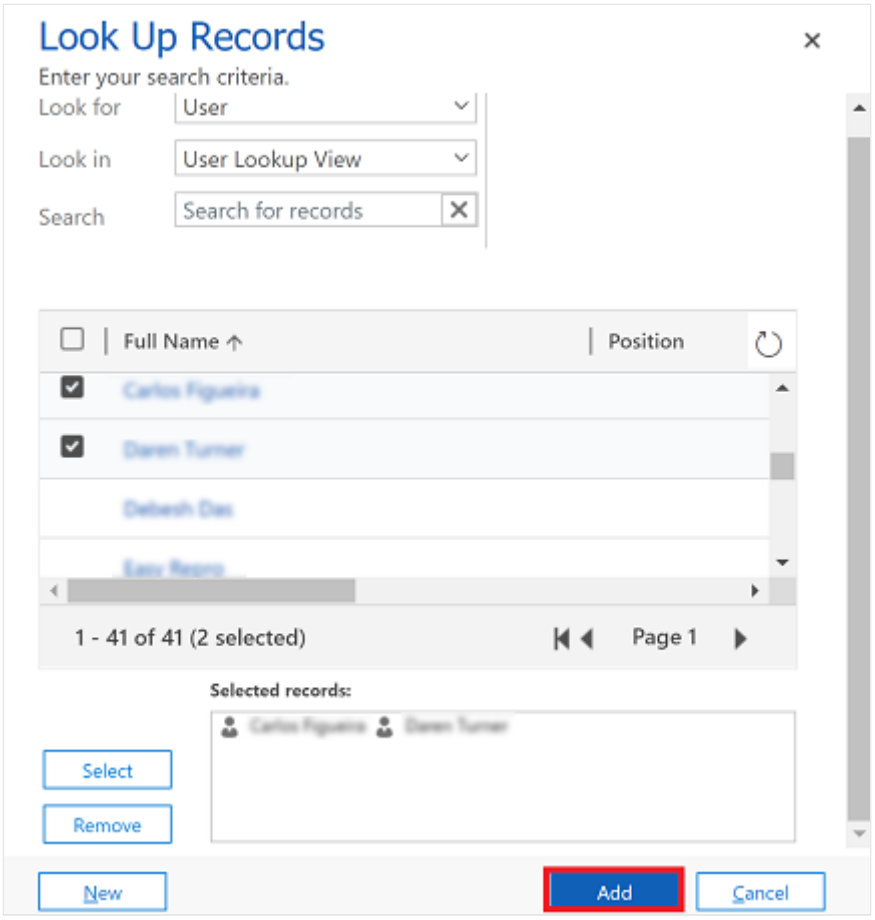
4. On the **Look up Rows** dialog box, select the **Look for** menu and choose **User** or **Team**.



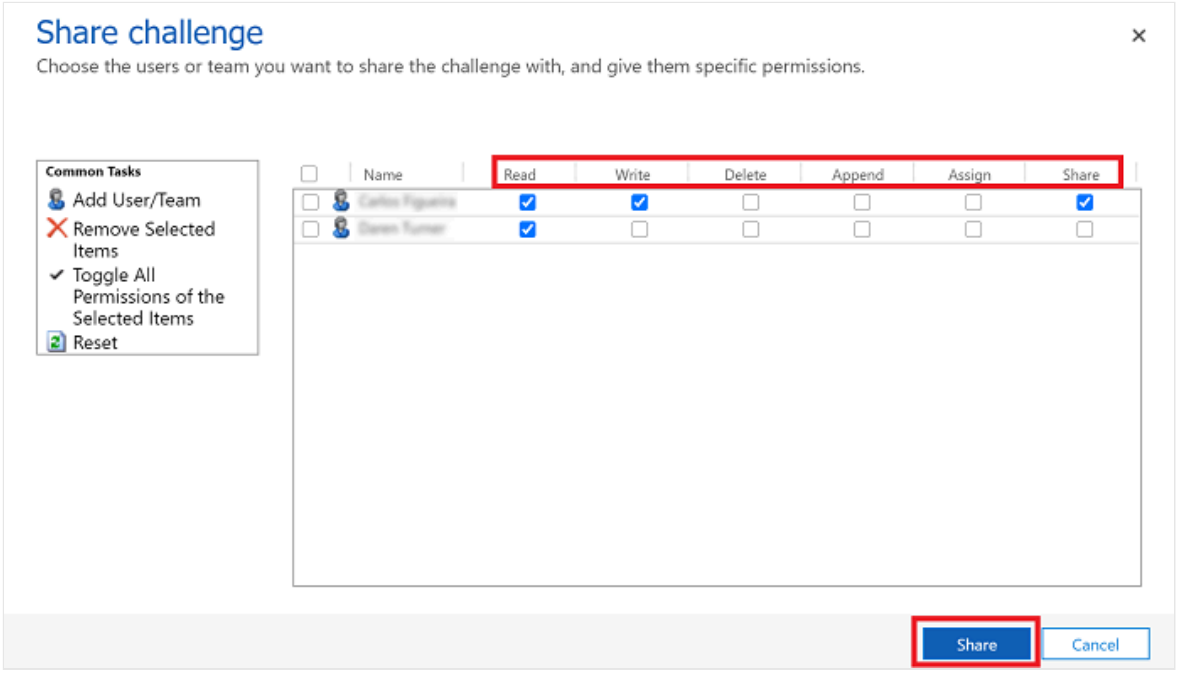
5. Use the lookup to find the user or team and select the name and then choose **Select**.



6. Select **Add**.



7. On the share dialog box, select the type of permissions the user or team has for the row. When you're done, select **Share**



Remove someone from a shared row

When you are the assigned owner of a row, you can remove another user the row is shared with.

1. From a list of rows that you own, select the row that you want to remove someone from the shared row.
2. On the command bar, select **Share**.
3. On the share dialog box, select the user or team who you want to remove sharing from.
4. Select the **Remove Selected items**.
5. Select the **Share** button.

Share rows with a user or team

Article • 02/15/2022

Keep ownership of a row and use the share feature to share the row with another user or team.

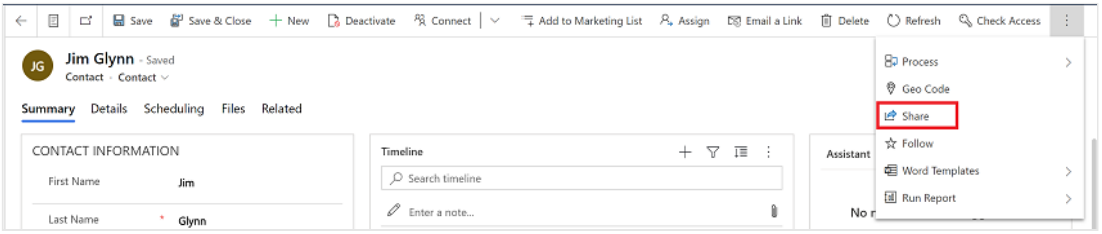
> **Note**
>
> - This feature isn't supported on Power Apps mobile or when you're using the app in offline mode with no internet connection.
> - Any user that you share a row with needs to have basic level access that is granted by a system administrator. If you cannot select permissions such as read or write then contact your system administrator and check if the user or team has the required access.

Share rows

1. Share a row from a view page or when you open a row.

   - **Share from the view page**: Select one or more rows on a view page and then select **Share** on the command bar.

   - **Open a row and share**: Open a row and then select **Share** on the command bar. If you don't see the share option, then select the **More commands** ellipsis and then select **Share**.



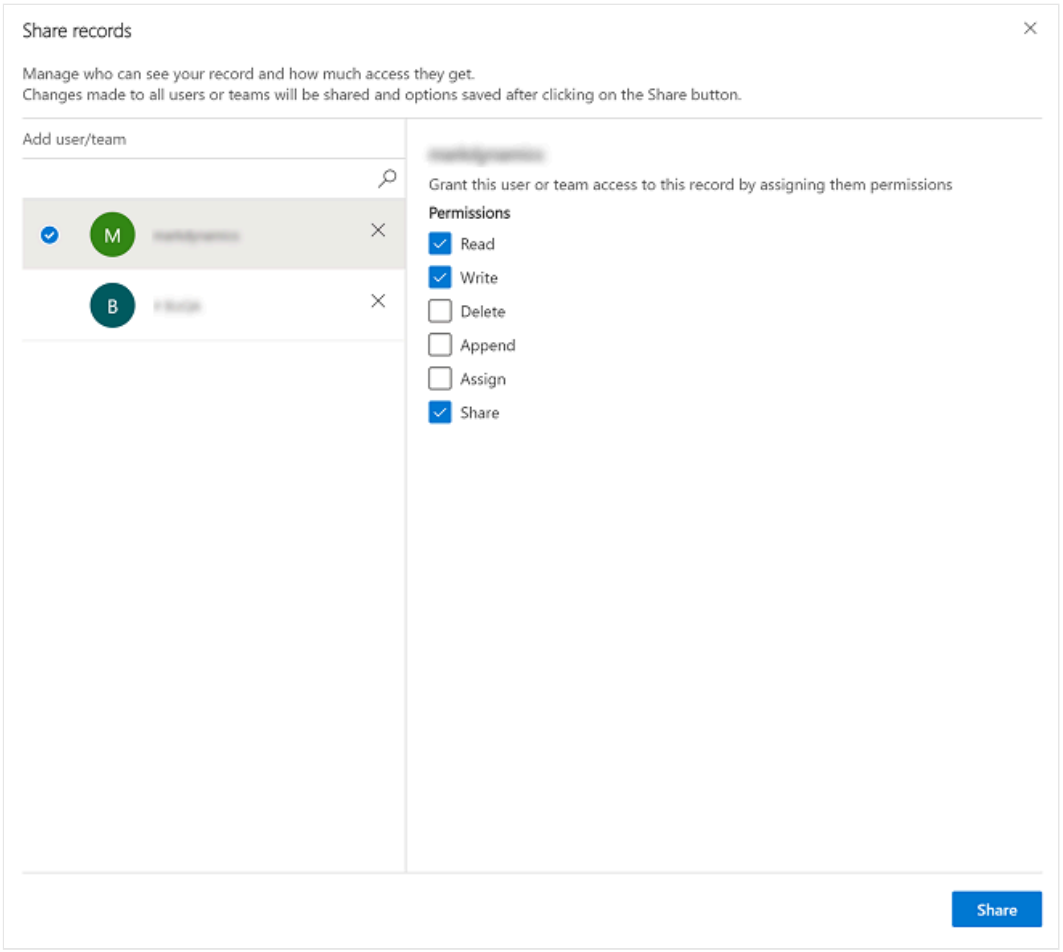
2. On the share dialog box, do one of the following:

   - **First time sharing a row**

     a. Select the lookup column under **Add user/team**. Enter the name of the user or team in the lookup column. The lookup will start displaying users or teams based on what you typed, or you can select the lookup icon (magnifying glass) and an alphabetical list of names appears that you can select to assign access. You can also search for a user that previously had share rights to manage or change access privileges.

     b. Select a user or team one at a time, and then grant them the appropriate permissions to the row.

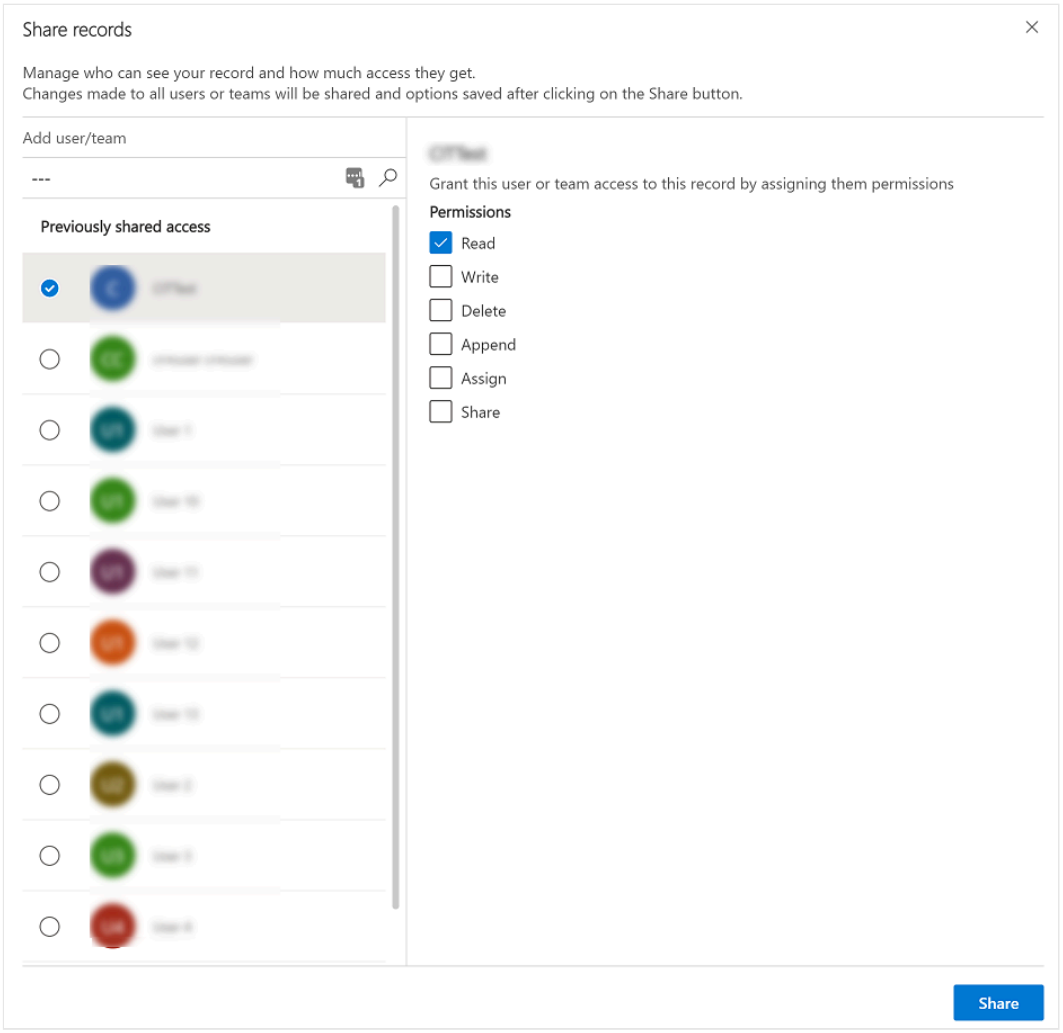
        If check boxes are disabled it means a user or team does not have basic privileges to the row. For more information on user access, see Check your user access to a row.



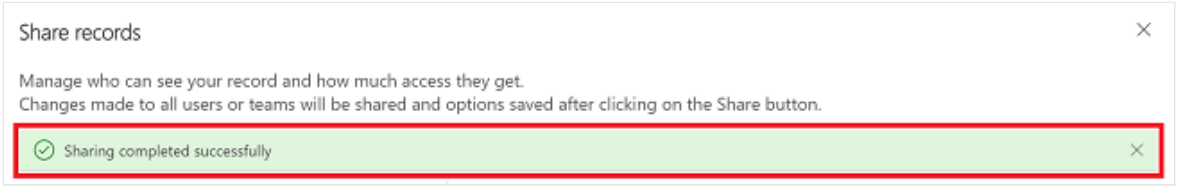
- **Previously shared access to a row**

  a. Under **Previously shared access** select a user or team one at a time and then grant them the appropriate permissions to the row.

  If check boxes are disabled it means a user or team does not have basic privileges to the row. For more information on user access, see Check your user access to a row.



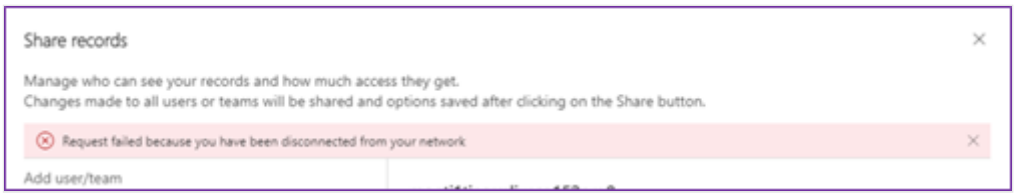
3. Select **Share** to save your changes.



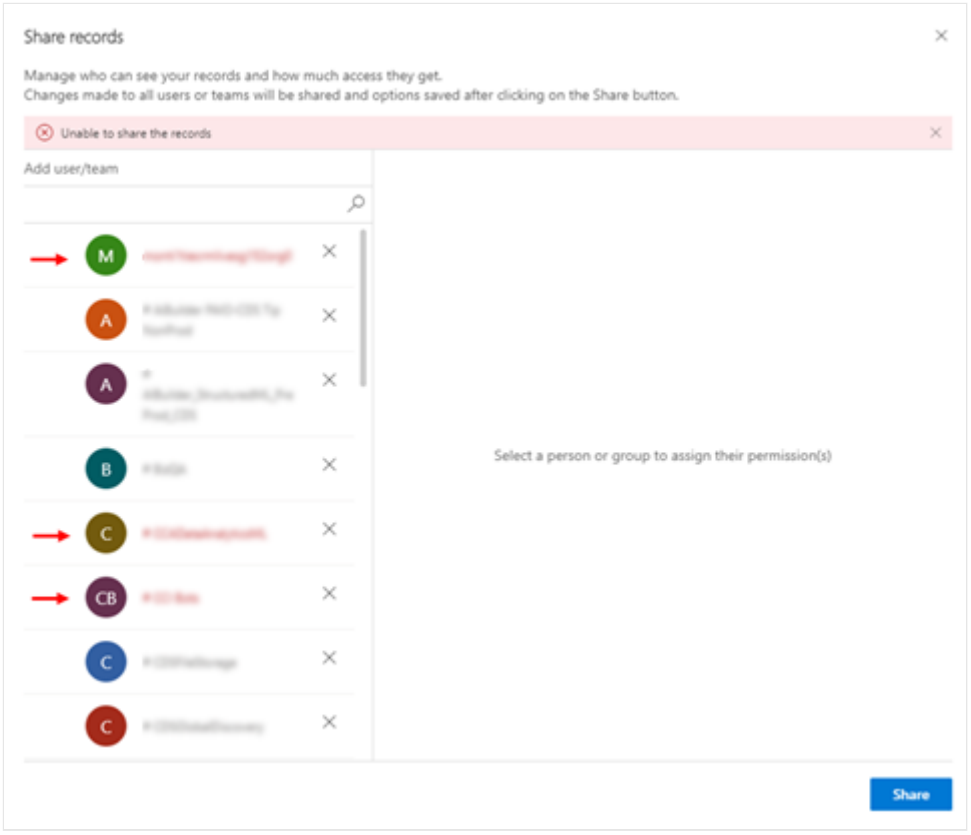
> **Note**
>
> If you add additional users or teams after saving share access and the check box is disabled but has a value, this means that your administrator has changed the basic privileges for the user, and they no longer have basic access rights, however, the share permissions is retained and isn't reset when the administrator changes the base privileges. Contact your system administrator to update a user's access if you want to change or update the disabled options for sharing a row.

Issues and errors

1. If you're disconnected from the internet when sharing a row, then you won't be able to set or update options for users or teams. Sharing won't be available.



2. If you get a generic error while sharing, this means that one or more of the rows can't be shared. The users will be hi-lighted in red. Select **Share** in the dialog to attempt another share with those users or close the dialog and retry. This usually happens if you are sharing lots of rows at once.



3. You may see an error when the system is unable to retrieve the users to assign share rights or sharing fails due to access related issues.

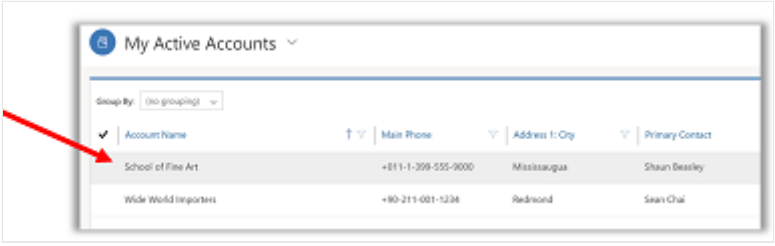
Share rows using Access Team

Article • 08/09/2023

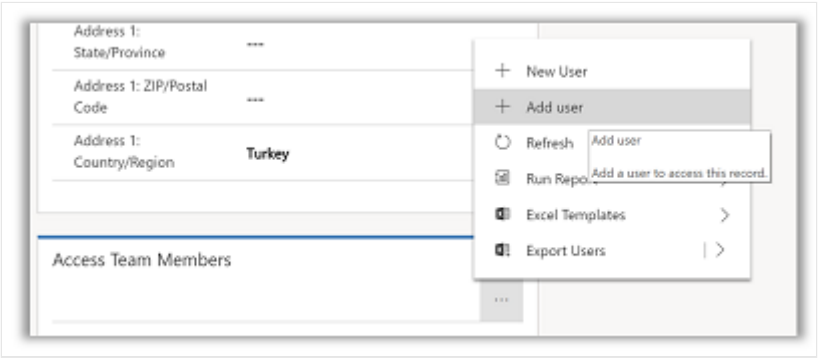
Access Team grant access to rows via sharing rows. Access Team members have privileges defined by their individual security roles and by roles from the teams they are members of.

> **Note**
>
> Before you can share rows using Access Team, your admin will need to set-up an Access Team template. For more information, see About team templates.

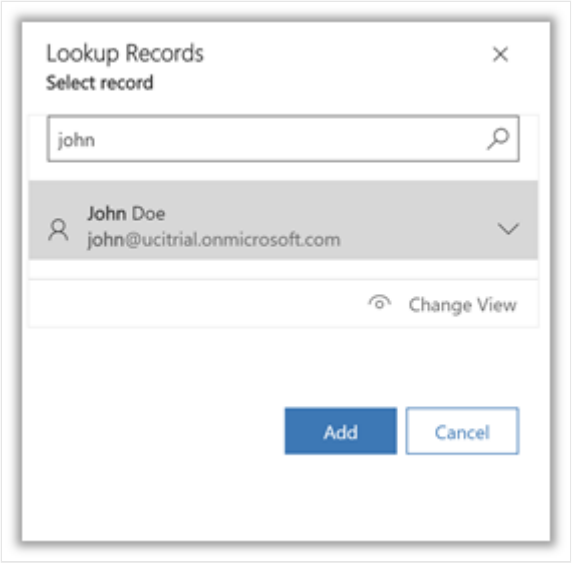
1. To give a user permission to access a row, from the site map, select the row type. For example, **Accounts**.
2. From the list of rows, open the row that you want to provide another user access to.



3. In the **Access Team Members** section, select **More Commands** (...) > **Add User**.



4. In the search box, type in the user name to find the user and then select **Add**.



Remove a user from Access Teams

You can easily remove a user's access to a row just as easily as you added them.

1. Open the row that you want to remove the user from.
2. Under **Access Team Members** subgrid, select **Remove user**.

Check user access to a row

To perform an action on a row, a user needs to have the required privilege assigned through a security role or the user must be a member of a team that has a security role with assigned privileges.

To perform actions on a row, the system checks your privileges and if the privilege check passes, then the system performs an access check. The access check verifies that you have the required rights to perform actions on a row such as read, write, create, delete, append, append to, share, and assign.

You can have access rights to perform an action on a row through ownership, role access, shared access, or hierarchy access.

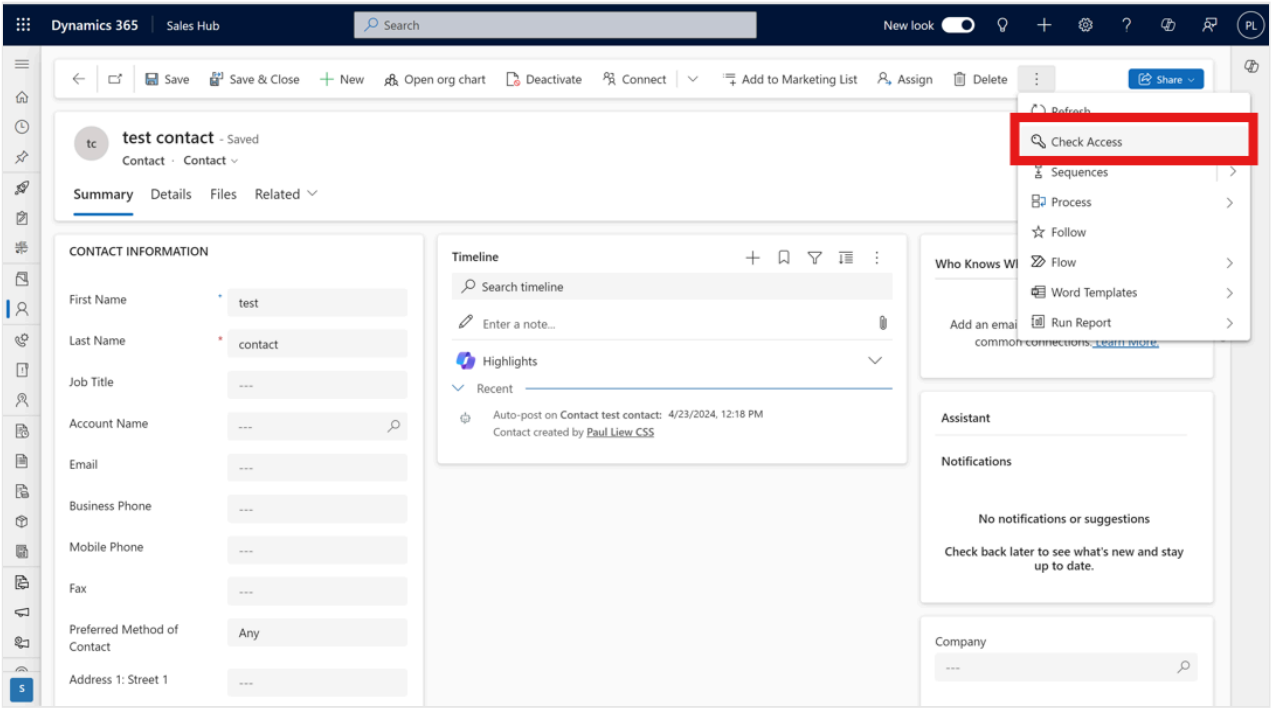
Expand table

Access type	Description
Ownership	User owns the row or belongs to a team that owns the row.
Role access	User has access to perform an action on a row because of their security role.
Shared access	The row is shared with a user, team, or organization by a user that has appropriate share rights.
Hierarchy access	Hierarchy access only takes place if hierarchy security management is turned on for the organization and the table. The user also needs to be a manager.

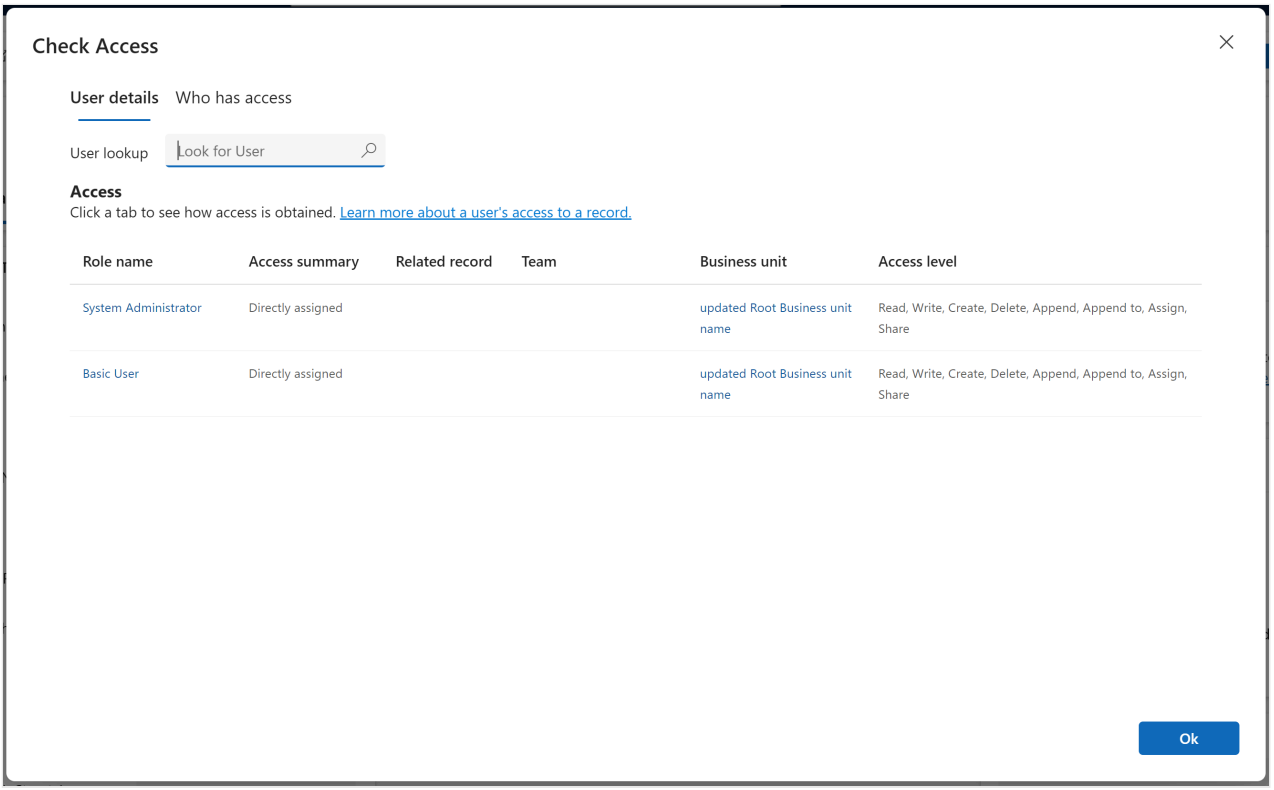
For more information on how privileges and access checks work, go to How access to a row is determined.

Check your access to a row

1. Select a row.
2. Select **Check Access** on the command bar.



3. The **Check Access** window displays your access information.



Contact your administrator if you don't have the required access. Only an administrator can edit your security role and privileges. To find your administrator, go to Find your administrator or support person.

Check another user's access to a row

If you're an administrator, you can check the access another user has to a row.

1. Select a row.
2. Select **Check Access** on the command bar.
3. In the **User Lookup** field, select or enter a user name to search for the user.
4. The **Check Access** window displays the user's access information.

Check all users who have access to a row

The admin, owner of the record, or users who have access to a row can share the row with other users for collaboration.

To see who has access to a row and their respective access level, complete the following steps.

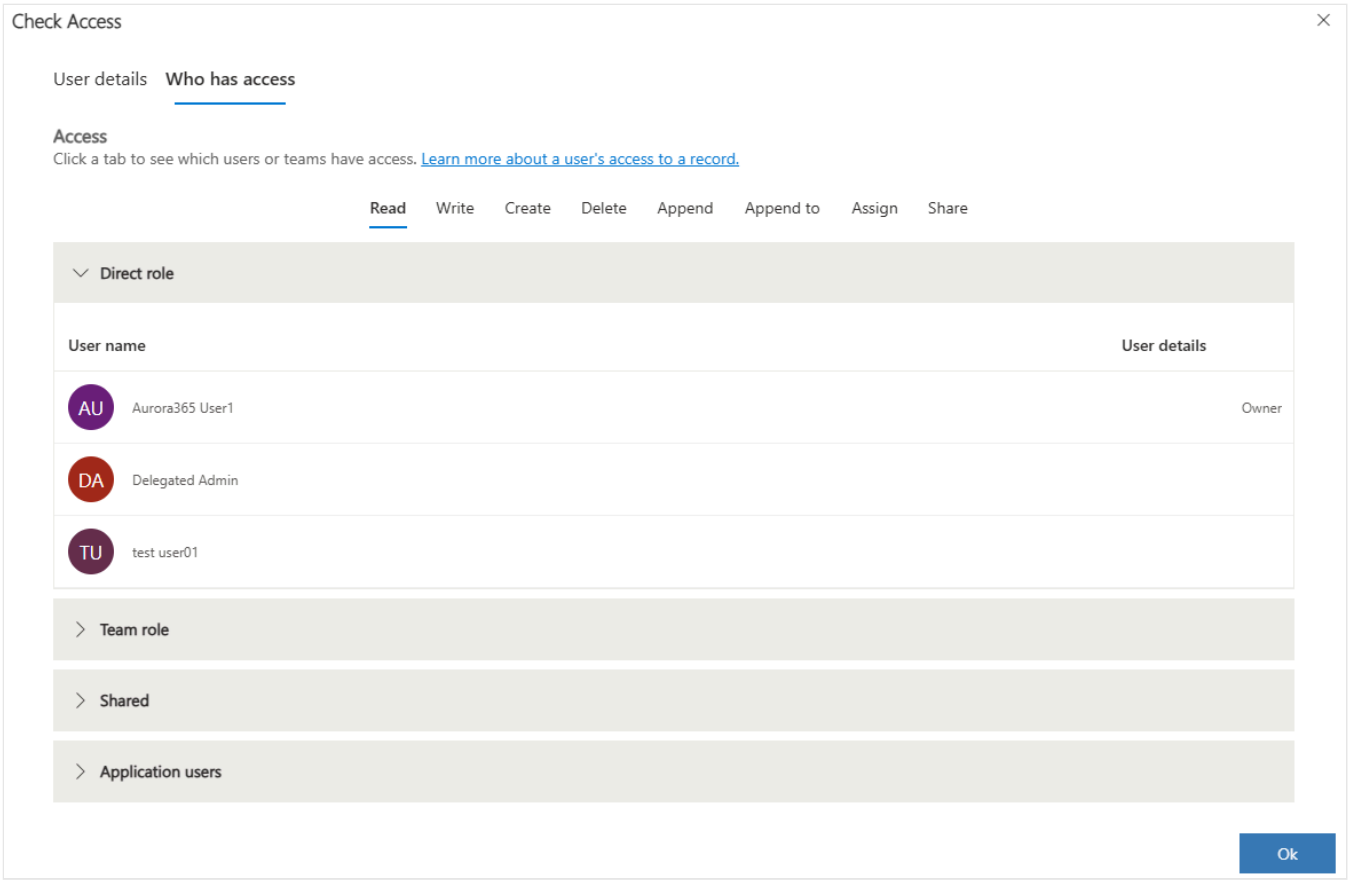
> ⓘ **Note**
>
> There are two database settings for each environment that enable the **Who has access** feature. System adminstrators can Install the OrganizationSettingsEditor tool and set the following options to true:
>
> - **IsAccessCheckerAllUsersEnabled**: This allows the admin to see who has access to the row.
> - **IsAccessCheckerNonAdminAllUsersEnabled**: This allows the admin, owner of the record, and users who have access to the row to see who has access.

1. Select a row.
2. Select **Check Access** on the command bar.
3. In the **Check Access** window, select **Who has access**.

   > ⓘ **Note**
   >
   > The manager list from heirarchy and position security is not shown under **Who has access** as this list can be long.
   >
   > If you select a user who doesn't have access to the record, the page returns with a blank screen.

Check who has access results

The user's record privileges are displayed. You can tab to each of these privileges to see who has this privilege on the record.



A user can have access to a record through one or more of these categories.

- **Direct role** - The record access is granted to a security role that is assigned to the user. Learn more at Role access.
- **Team role** - The record access is granted to a security role that is assigned to the team, and the user is a member of the team. Learn more at Role access.
- **Shared** - The record access is shared with the user or team who the user is a member of. Learn more at Shared access.
- **Application users** - Dataverse's application users who have access to the record because they're assigned to a security role that has privilege to the record.

Add a connection role to link rows to each other

Article • 08/09/2023

Connections enable you to easily associate users, contacts, quotes, sales orders, and many other table rows with each other. The rows in the association can be assigned particular roles that help define the purpose of the relationship.

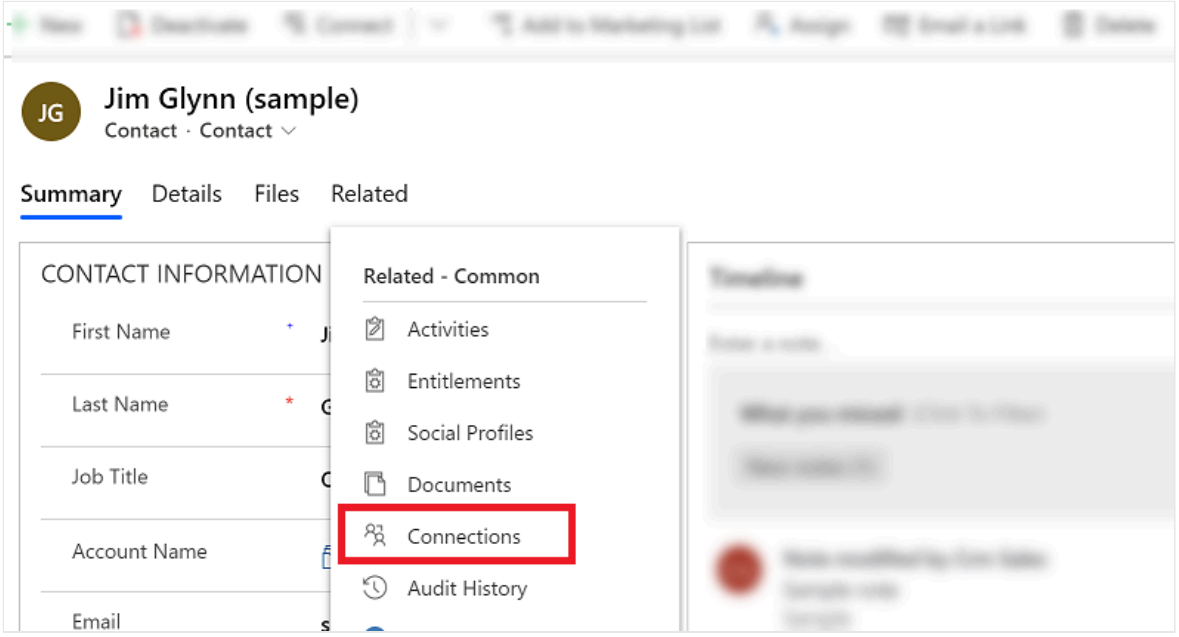
It's a quick way to create multiple connections and roles for a particular row. For example, a contact may have many relationships with other contacts, accounts, or contracts. In each relationship, a contact may play a different role.

Connection roles are directly associated to a connection. To use a connection role, you must first add a connection to your row.

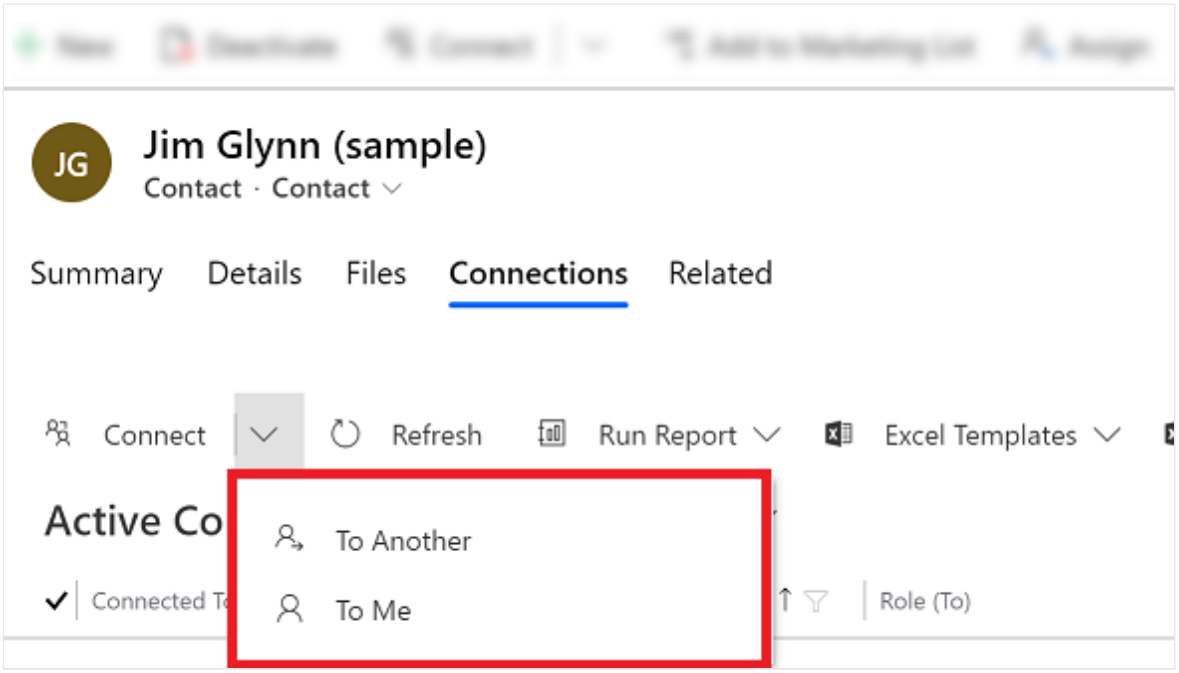
Before you can add connection roles, it needs to be enabled by your admin. For more information see, Configure connection roles.

1. To add or manage connections, select the row you want to manage like an opportunity.

2. Select the **Related** tab and then select **Connection**. This opens the connection grid with the list of connections for the row.

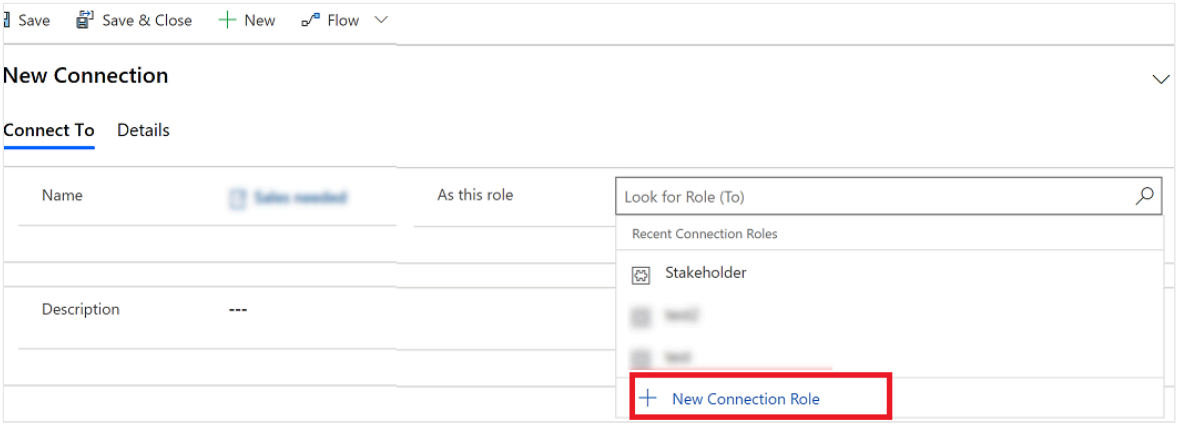


3. Select **Connect** and then choose **To Another** or **To Me**.



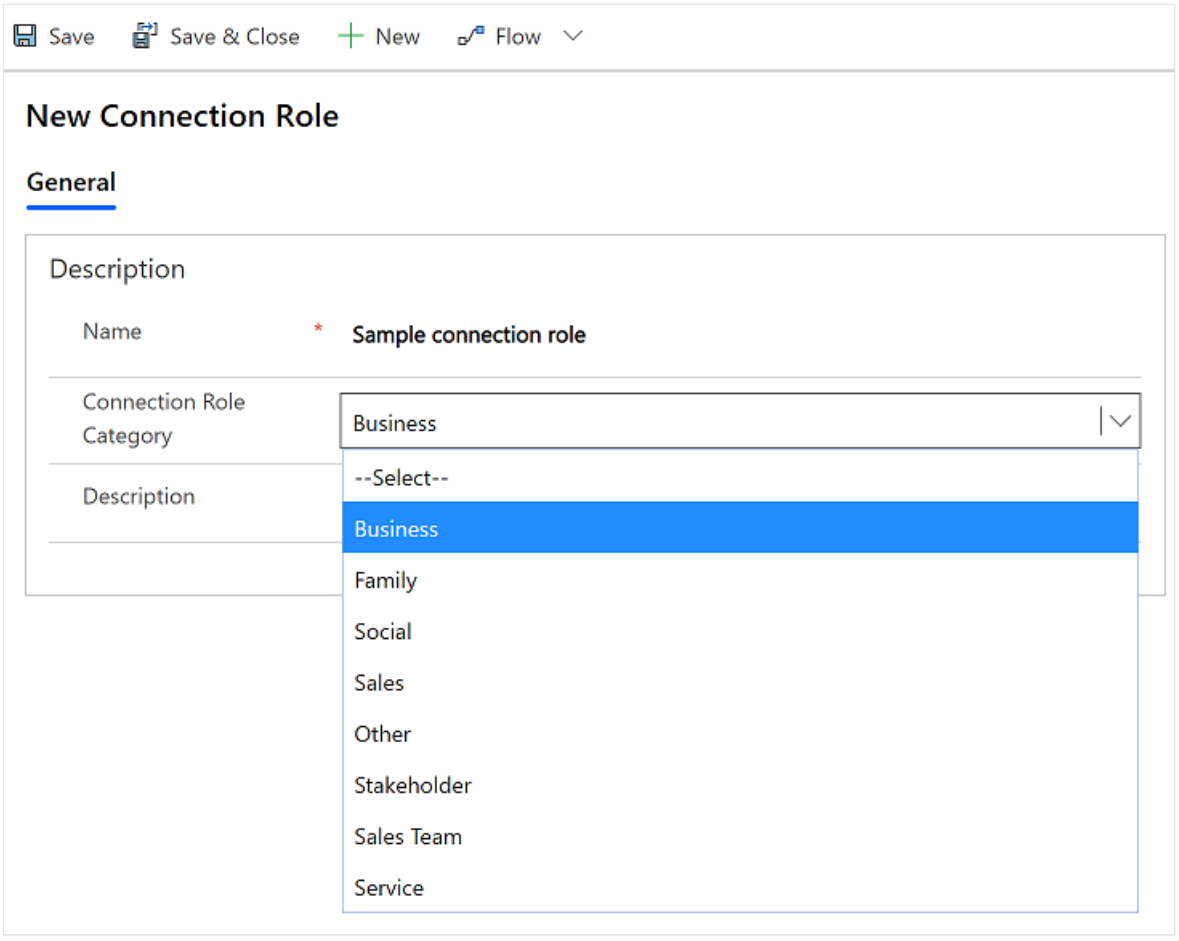
4. On the **Name** column, enter or find the name of the row for the connection.

5. On the **As this Role** column, select the lookup icon and then choose **New Connection Role**. Or, use the search to find an existing role that you want to associate to the connection and then select **Save**.



> **Note**
>
> If you have entered information before creating a new connection role, a warning dialog will be displayed asking if you would like to cancel and continue working on the connection or to go ahead and leave the current row you are working on.

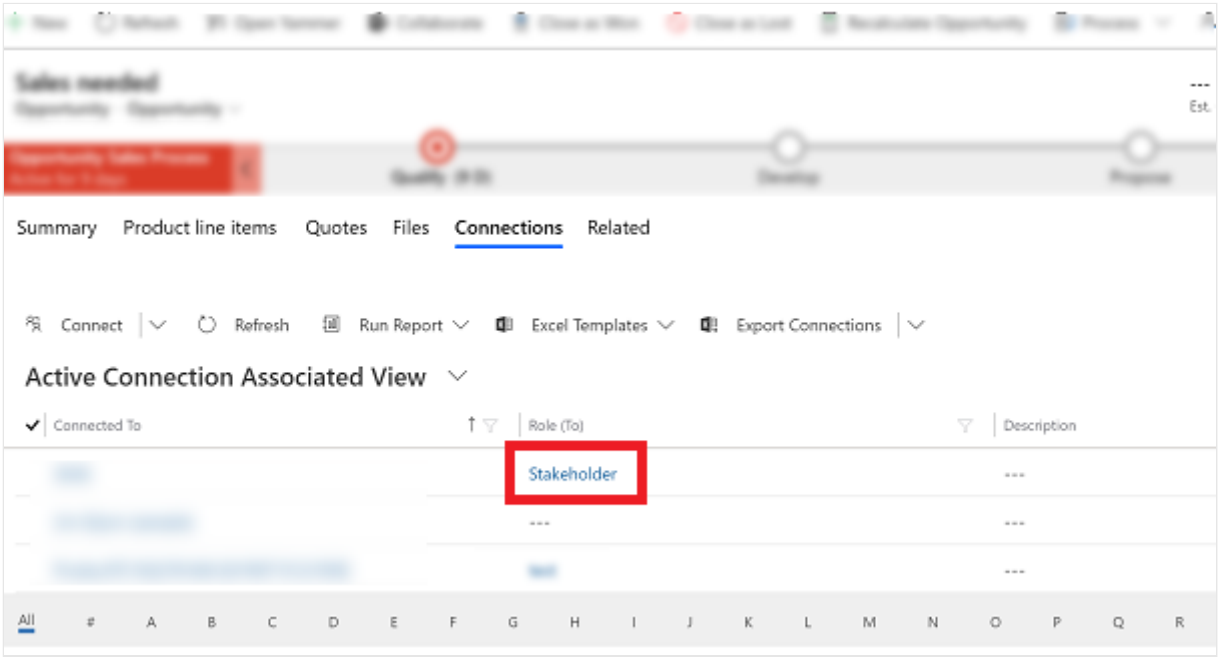
6. To create a new connection role, on the **New Connection Role** screen enter a name and then choose a **Connection Role Category**.



7. When you are done, select **Save & Close**.

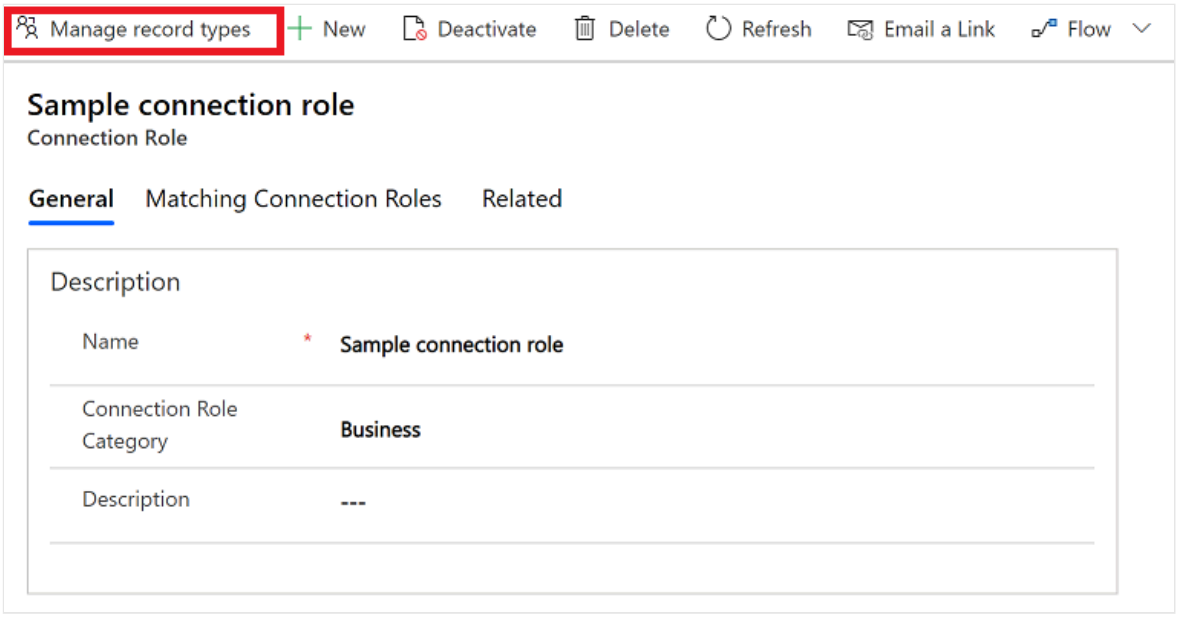
Manage Connection Roles

To manage a connection role, select the connection role from a connection table. This opens the connection role table row. You can edit the name, select a connection role category, and add a description.



You can also manage the connection role types that you want to associate with the connection role.

1. Open the connection role and then select **Manage Row Type** on the command.



2. This opens a list of connection role types that you can add or remove for this connection role.

Deactivate or activate an account or contact

Article • 12/10/2024

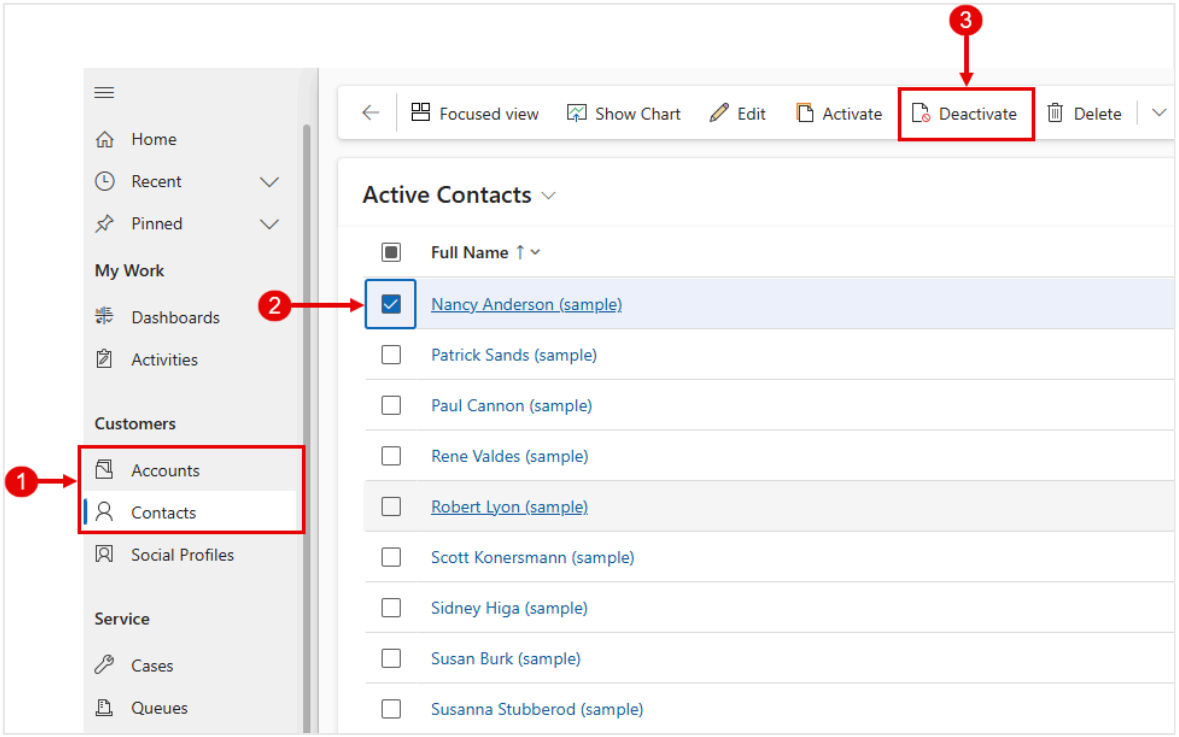
In a model-driven app, you can deactivate an account or contact rather than deleting it. This ensures the integrity of the audit trail associated with that row.

A deactivated account or contact becomes inactive, which means it cannot be edited or used in establishing new relationships with other rows. However, all relationships created with the deactivated item are still available.

If later you need to reactivate a deactivated account, it's easy to do so.

Deactivate an account or contact

1. From the menu on the left, go to **Accounts** or **Contacts**.
2. Select the active account or contact that you want to deactivate, on the command bar select **Deactivate**, and then confirm the deactivation.



Activate an account or contact

1. From the menu on the left, go to **Accounts** or **Contacts**.

2. Go to the **System Views** list.

3. Select **Inactive Accounts** or **Inactive Contacts**.

4. Select the inactive accounts or contacts you want to activate.

5. Select **Activate**, and then confirm the activation.

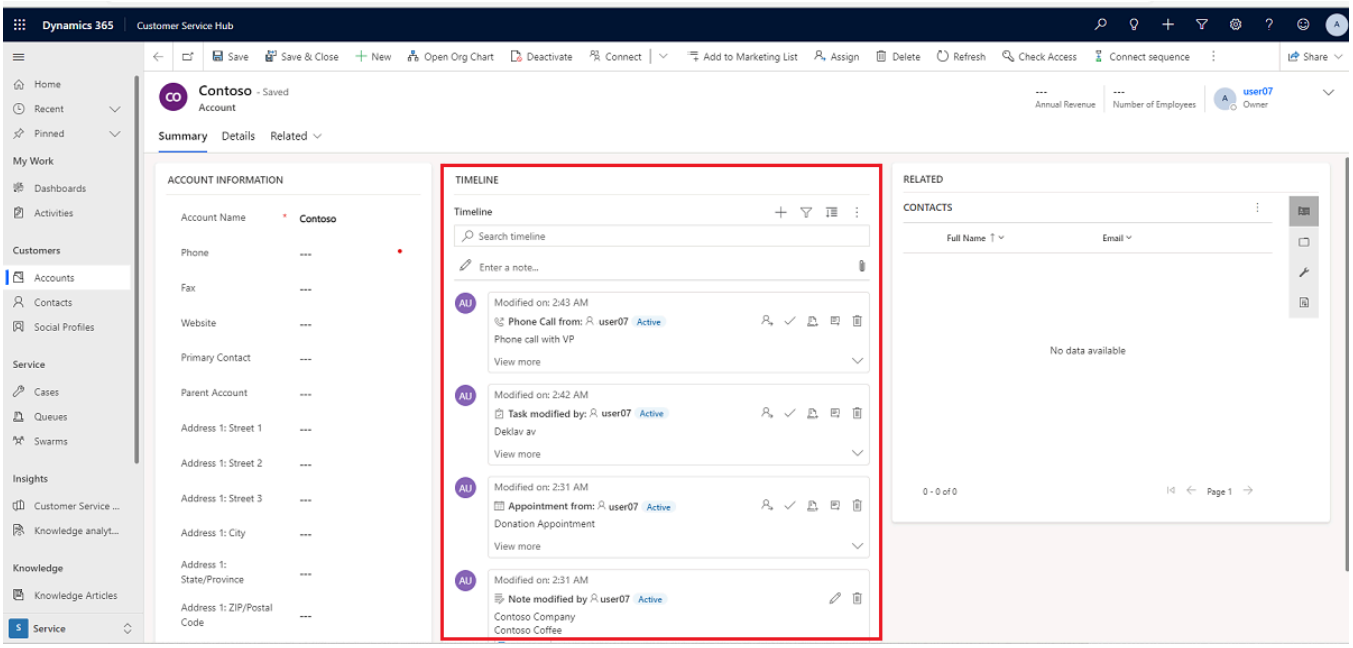
Use timeline

Article • 05/29/2025

Timeline is a modernized and optimized control that helps provide you with at-a-glance understandability when working with your customers. You can use the timeline to view information that is connected to a row in a table and occurs over time in a single stream. Some information that can be logged into the timeline includes notes and posts, in addition to displaying activities such as emails, appointments, phone calls, and tasks.

Timeline allows you to:

- Access the command bar to perform common actions quickly
- Filter and view important notes, posts, and activities using multiple filter options, and keep the filtered settings across activities
- Quickly view and manage email conversation threads with ease
- Keep detailed customer records by attaching important files and images to posts



Timeline functionality

The timeline section on the table form is intended to centralize access to information and streamline effort to accomplish actions. The following section is an overview of how the timeline functionality works in each section on the table form.

When enabled by your system administrator, you can use the icons that are displayed on the top-right navigation in the timeline for quick access to do the following actions:

- Create a timeline row
- Work with Filters

- Work with row
- Explore more commands
- Search row
- Add attachments

The timeline dashboard displays only the entities that are configured for the signed-in user. So, what you see on the timeline may differ from what another user sees. The signed-in user sees any rows they followed if those rows are configured to display on the dashboard. For example, if only email and appointments are configured to display, then the signed-in user only sees email that relates to them, which can be email they sent, email sent to them, and email they follow. The same would be true for appointments in this scenario. For more information on setting up timeline, see Set up the timeline control.

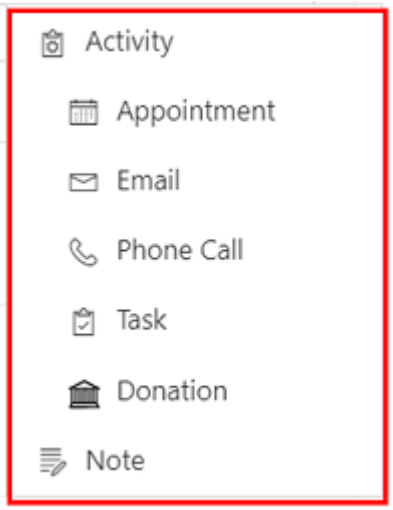
> **Note**
>
> The Notes feature isn't available from the timeline.

Create a timeline row

When enabled by your system administrator, you can use the **Create a timeline record** feature to quickly create appointments, tasks, send emails, and make notes and posts and associate them with other rows.

1. Select **Create a timeline record** icon.

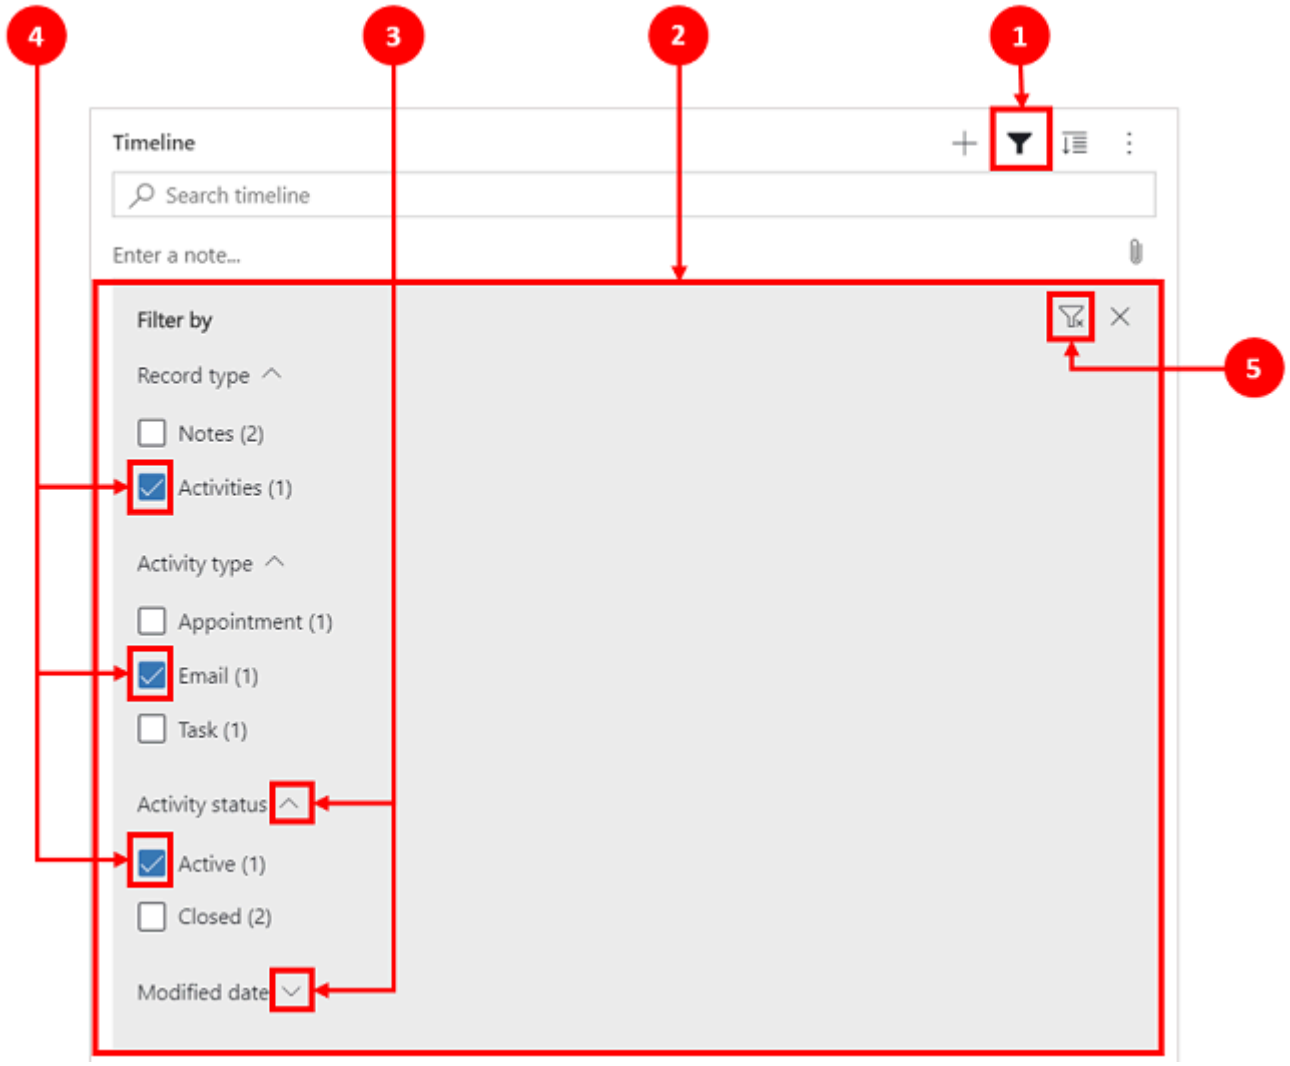
2. Select the type of row you want to create from the display options available.



For information on timeline row configuration, Set up the timeline control.

Work with filters

When enabled by your system administrator, the timeline **Filter** further streamlines your productivity by allowing you to customize your experience and view data that's relevant to you.



Legend:

1. The timeline **Filter** icon is located in the top-right navigation on the timeline.
2. The filter pane displays when the filter icon is selected.
3. Use the carats to expand or minimize selections.
4. When enabled by your system administrator, row and activity types are displayed in the filter pane. Row and activity types can be filtered by selecting the corresponding box next to the item.
5. The icon removes and clears all filter selections from the filter pane.

Filter rows on timeline

Filters are valuable for sorting data. You can easily filter through rows and activity types using multiple options to quickly see what matters to you. The filter is available for the activities, notes, posts, and custom entities that are present in timeline.

Filter icon display

- When the **Filter** icon displays as a transparent , it means the filter pane is empty and nothing has been applied.
- When the **Filter** icon displays as dark , it means filters are applied.

Filter options

The following category and subcategory options are available on the filer menu:

Expand table

Category	Subcategory
Row type	• Notes • Posts • Activities
Activity type	• Appointment • Campaign Activity • Campaign Response • Email • Fax • Case Resolution • Letter • Opportunity Close • Order Close • Phone Call • Quote Close • Recurring Appointment • Social Activity • Task • Project Service Approval • Booking Alert • Conversation • Session • Customer Voice survey invite • Customer Voice survey response • Custom activities (as configured by your system administrator)
Activity status	• Active • Overdue

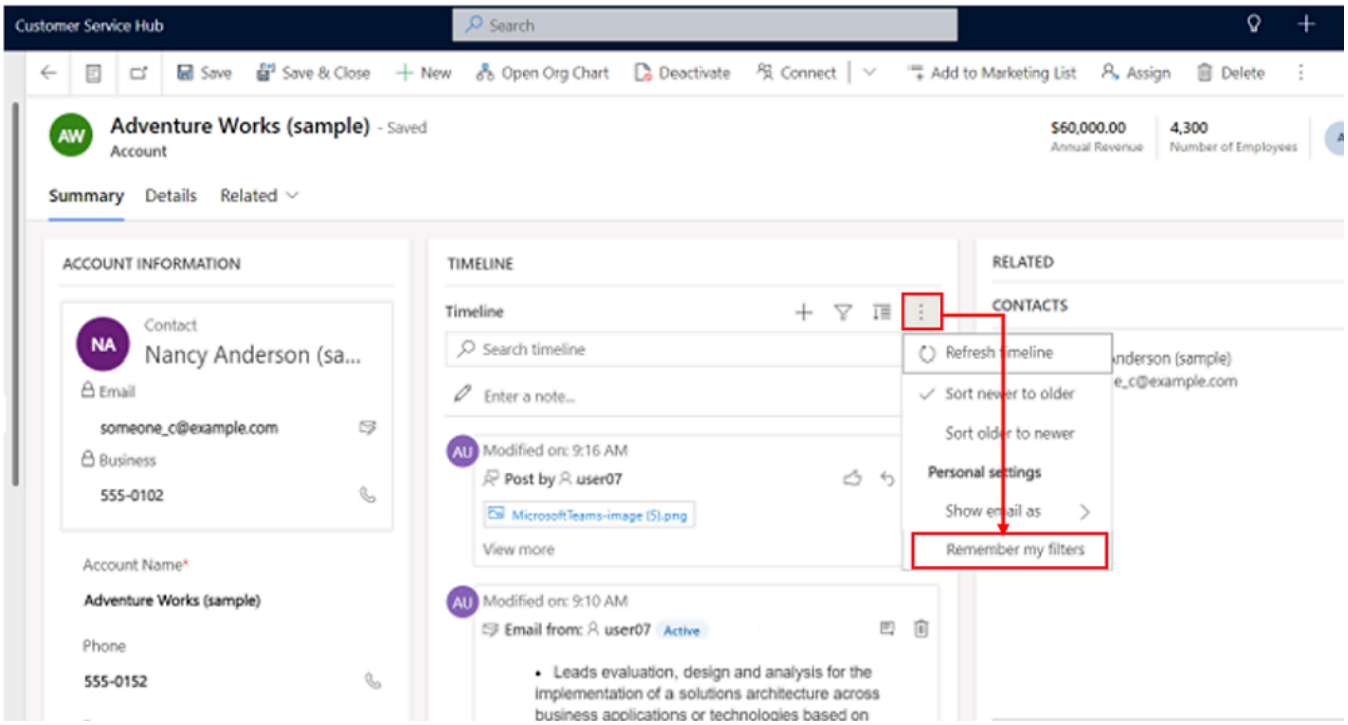
Category	Subcategory
	• Closed
Activity due date (active)	• Next 30 days • Next seven days • Next 24 hours • Last 24 hours • Last seven days • Last 30 days
Posts by	• Auto post • Users
Modified date	• Last 24 hours • Last seven days • Last 30 days

Save filter settings

You can choose to save your filter settings so that you don't have to set them again each time you work with activities in the timeline.

To save your filter settings, after configuring the filters you want, select the ellipses, and then select **Remember my filters**.

> ⓘ **Note**
>
> If you have a system administrator or basic user role, Remember my filters works by default. If you don't have either of these roles, you must have Create/Read/Write privileges to be added to the msdyn_customcontrolextendedsettings table for the setting to work.

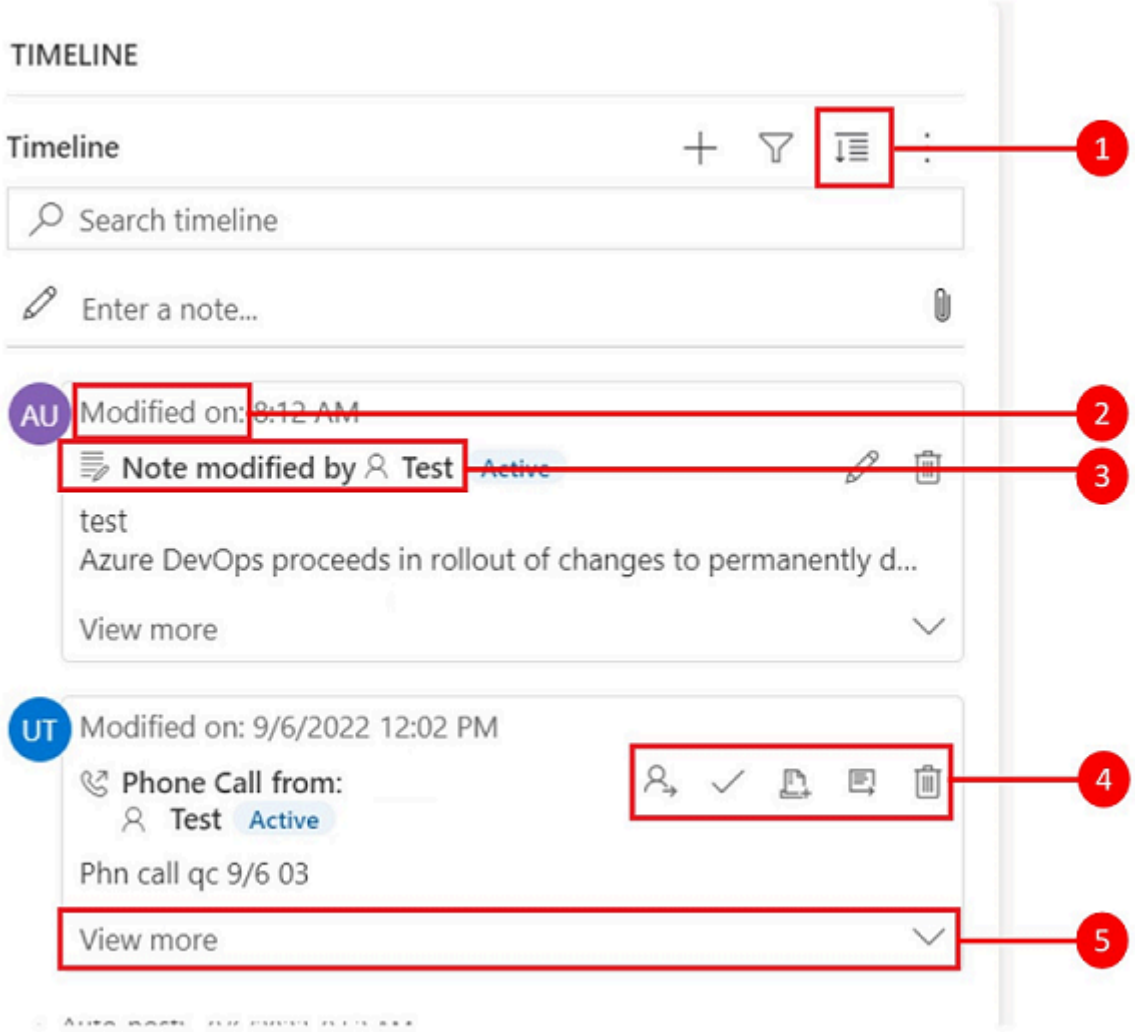


Work with rows

When working with rows, you can view key information at a glance or expand rows to view more details. When you hover over a row, actions display that you can use.

Expand all rows

When enabled by your system administrator, you can view timeline rows quickly in a collapsed format or expand a row to see more details for ease of use.

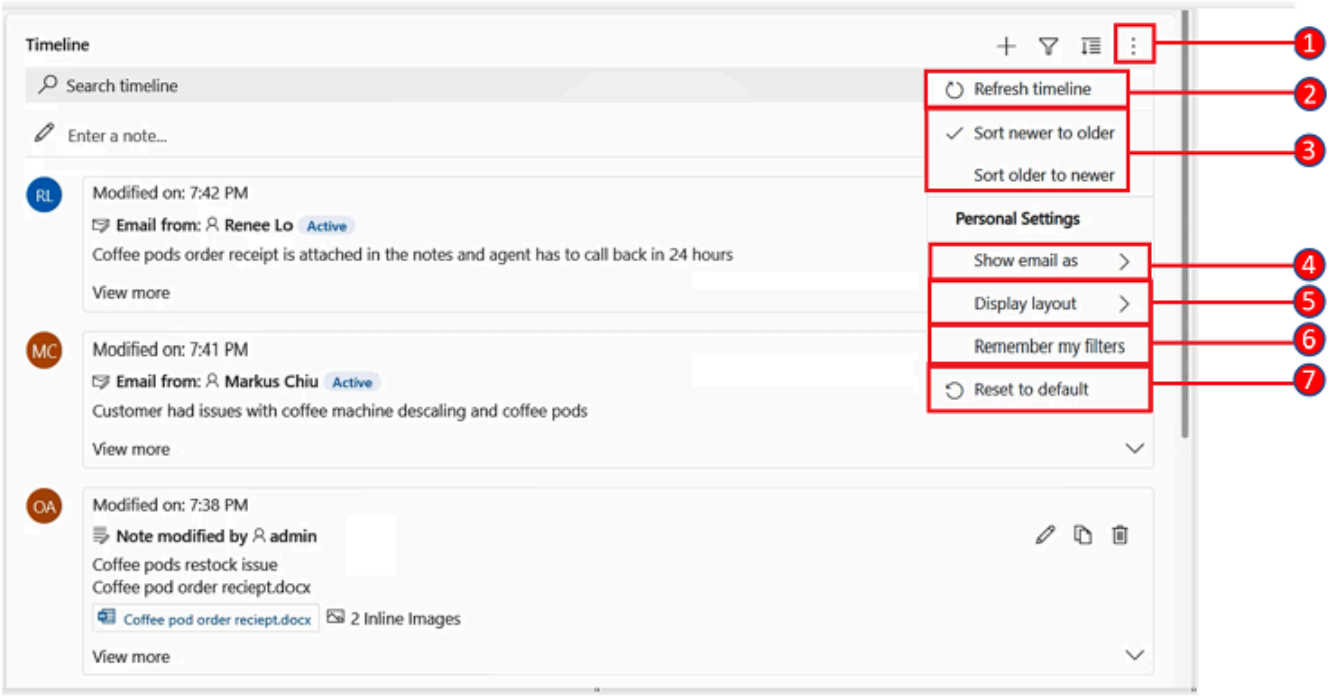


Legend

1. The **Expand all records** icon is used to expand all rows listed on the timeline.
2. The **Modified on** timestamp displays the time the record was last updated.
3. Each row has a list of commands relevant to their row type that displays in the top right corner for ease of use.
4. Row backgrounds change to grey when you hover over it, and it becomes transparent again when you move the mouse away.
5. The carats in the bottom-right corner of each row allow you to expand (^) or minimize (v) the display views.

More commands

The **More commands** option contains refresh, sort, and email functionalities.



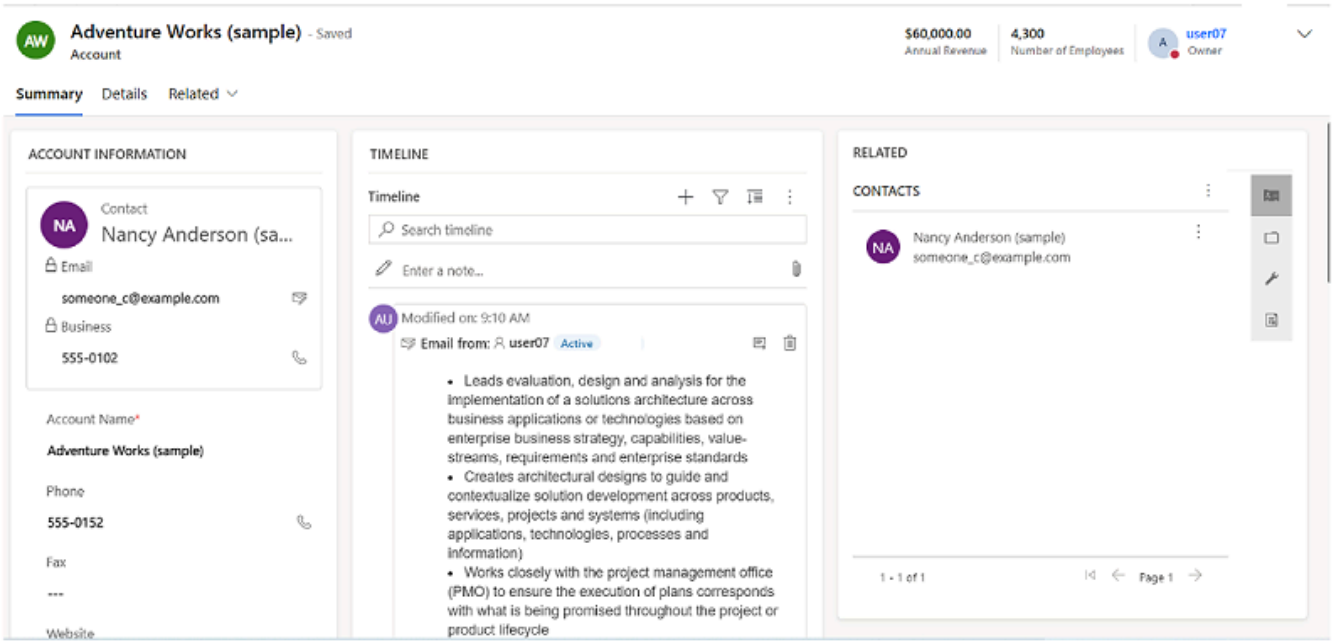
Legend

1. The **More commands** icon, when expanded, provides more functionality options.
2. The **Refresh timeline** command updates row details in the timeline.
3. The **Sort newer to older** or **Sort older to newer** command is used to sort rows.
4. The **Show email as** command is used to enable or disable threaded email views.
5. The **Display layout** command allows you to choose from two different views: **Roomy** or **Cozy**. **Roomy** (set by default) shows you more information, such as profile details, and adds space between the rows. **Cozy** hides some of the details, such as icons, and compacts the space between rows.
6. The **Remember my filters** command allows your filters to persist when you close the record so that they continue to be applied across sessions.
7. The **Reset to default** command reverts all of the command settings you changed back to the default settings.

View email inline in timeline

If preferred, you can view email messages inline on the timeline rather than open them as separate pages.

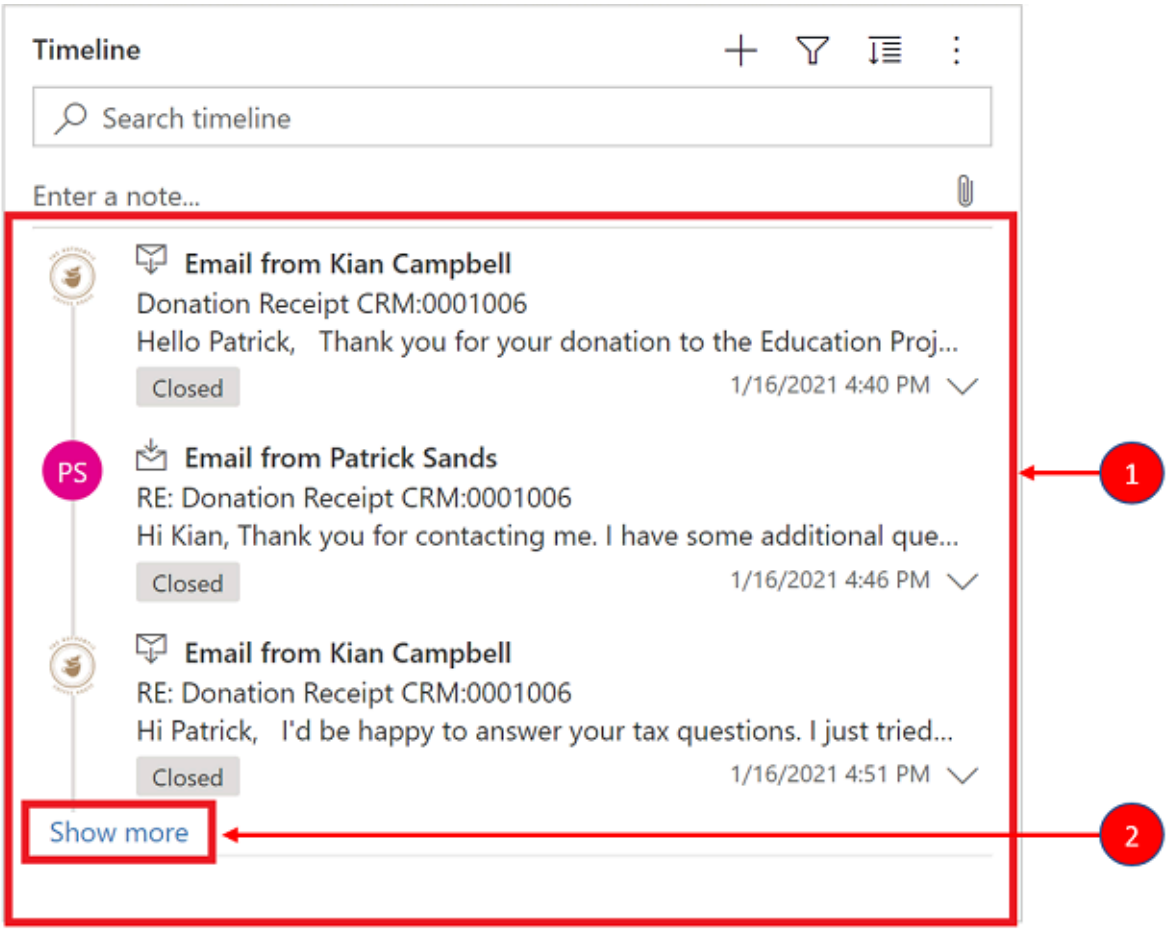
To view an email directly in the timeline, on the row, select **View more**. The email is displayed on the same form. When you're finished viewing the email, you can collapse the screen and return to the previous view of the form.



Threaded email views in timeline

Use the threaded email view option to save valuable space when you have emails with multiple replies. This view consolidates email threads when collapsed.

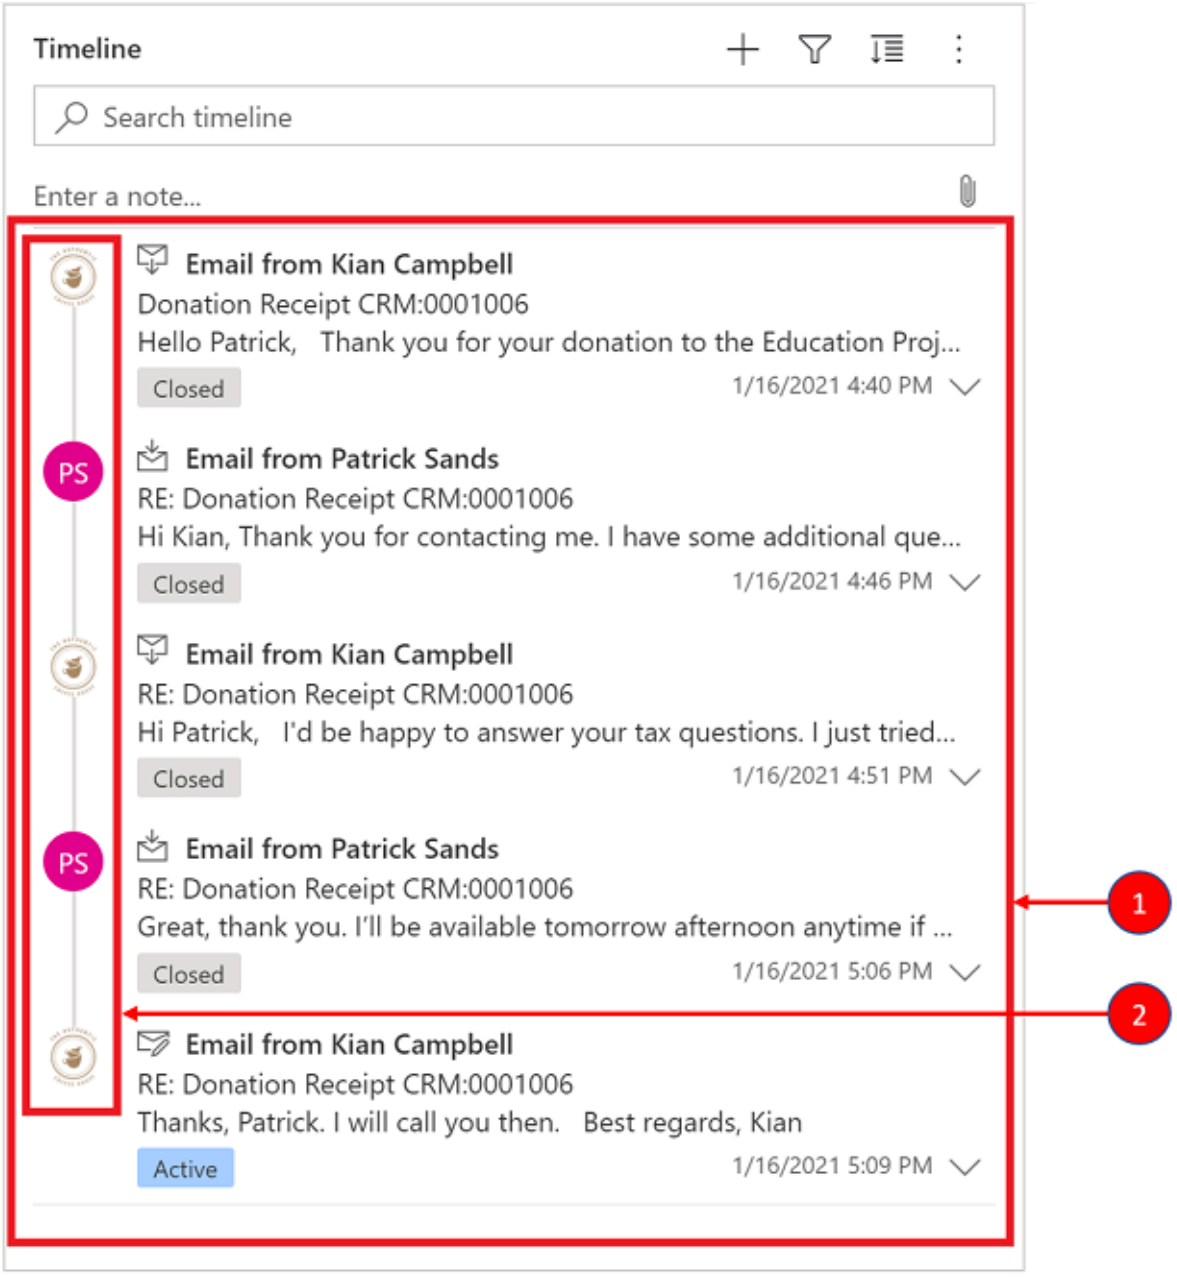
Collapsed threaded email view



Legend

1. When enabled using the **Always show email as conversations** option under **More commands** ⋮, emails with multiple responses are grouped together into threaded emails.
2. The **Show more** link appears in the bottom-left corner of the last visible email in the thread to view the complete string of email responses.

Expanded threaded email view



Legend

1. When expanded, the most recent 10 email responses in the thread display. To display more, select **Show more** to expand the view again.
2. Emails in the same thread are displayed as being linked together.

Enable threaded email views in timeline

Enabling the threaded email view is done via the timeline configuration in Power Apps. Threaded email views must be done in this setting for the specific table, in the specific form, for each specific timeline.

Threaded email views can be enabled in timeline via two options:

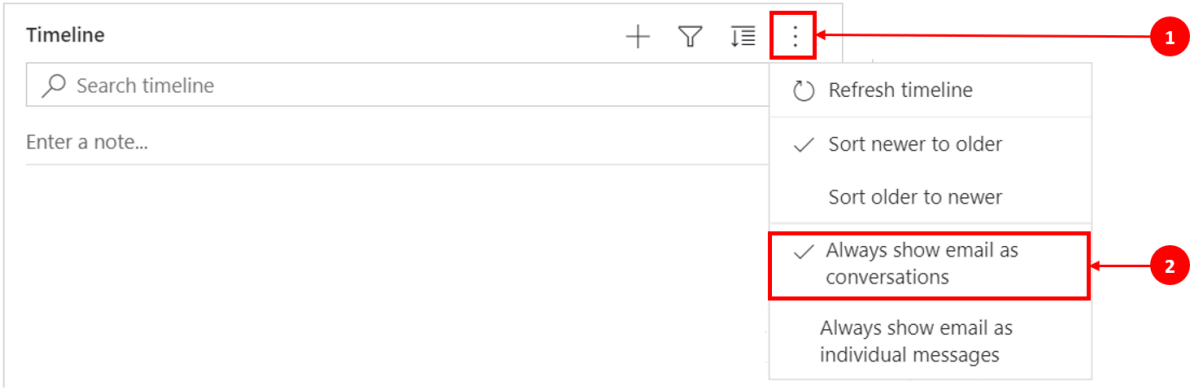
Option 1:

You can enable the threaded email view using the **More Commands** ⋮ feature, located on the right-hand side of the timeline.

Enable threaded email through the More Commands option

Steps:

1. Use the **More commands** ⋮ icon on timeline that displays a flyout menu.
2. Select **Always show email as conversations** to thread and group all emails in that specific timeline.



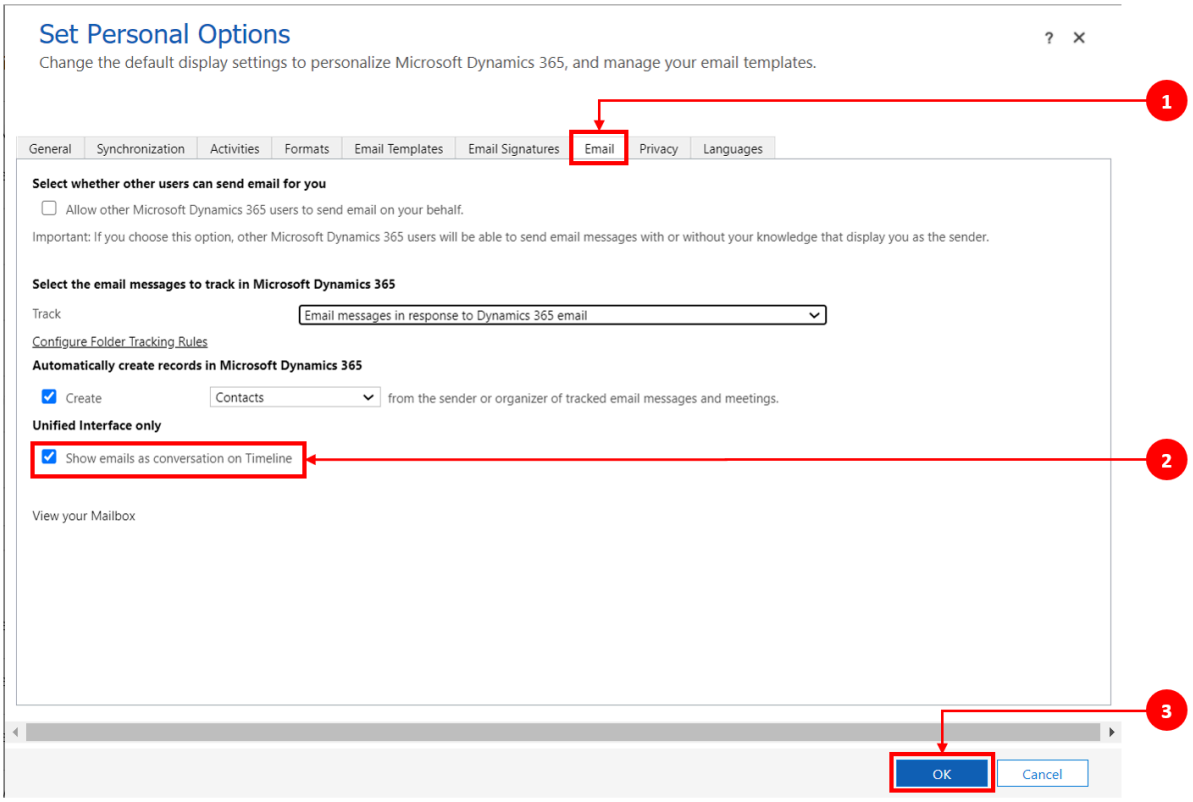
Option 2:

Enable threaded email through Personal Options setting

To enable threaded email via this option, go to the command bar and select **Settings**, then **Personalization Settings**. The **Set Personal Options** dialog box is displayed so you can use the following steps to enable the threaded email view on timeline.

Steps:

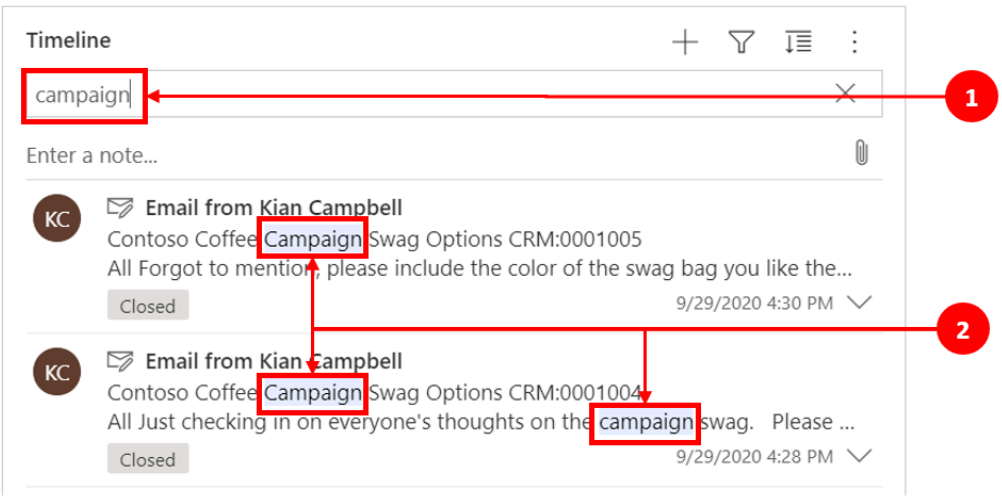
1. Select the **Email** tab.
2. Select the **Show emails as conversation on Timeline** check box.
3. Select **OK**.



> **Note**
>
> The **emails as conversation** view is based on the user's preference. Personal settings are tied to the user, not the form, which means when you enable the threaded email view, the setting is applied to all of your timeline views.

Search rows on timeline

When enabled by your system administrator, you can easily search for rows in the timeline. When you search for a phrase in the timeline, it searches in the title, subject of the row, body, or description fields of the row and displays the row for you.



Legend

1. The **Search** bar allows you to quickly find rows using keywords or phrases that the search feature retrieves and displays below the search bar.
2. Keywords that are used are highlighted.

Work with notes and posts

Notes allow you to record richly formatted information and images for reference, summary, or investigation. You can easily add a mention to another user or a reference to a timeline row. The mention capability is available in timeline only when rich text notes and rich text posts are enabled.

When you type the @ symbol, the results you see are matches with the first name, last name, or email address of system users starting with your search string. When you mouse over the profile image, you can view the user's detailed profile card and online presence status. More information: View the profile card for a contact or user.

When you type the # symbol, the results you see are matches with the account and contact name table rows starting with your search string.

Add a note or post to a row on timeline

When enabled by your system administrator, you can either add a note or a post to a row on timeline. Each note and post has a maximum size limit of 100,000 characters.

You can also enter a note and add it to a row, but you can only add one attachment per note. You can only add an attachment if notes are enabled.

Note display view

When enabled by your system administrator, the **Note** field is displayed under the **Search** feature on timeline.

Post display view

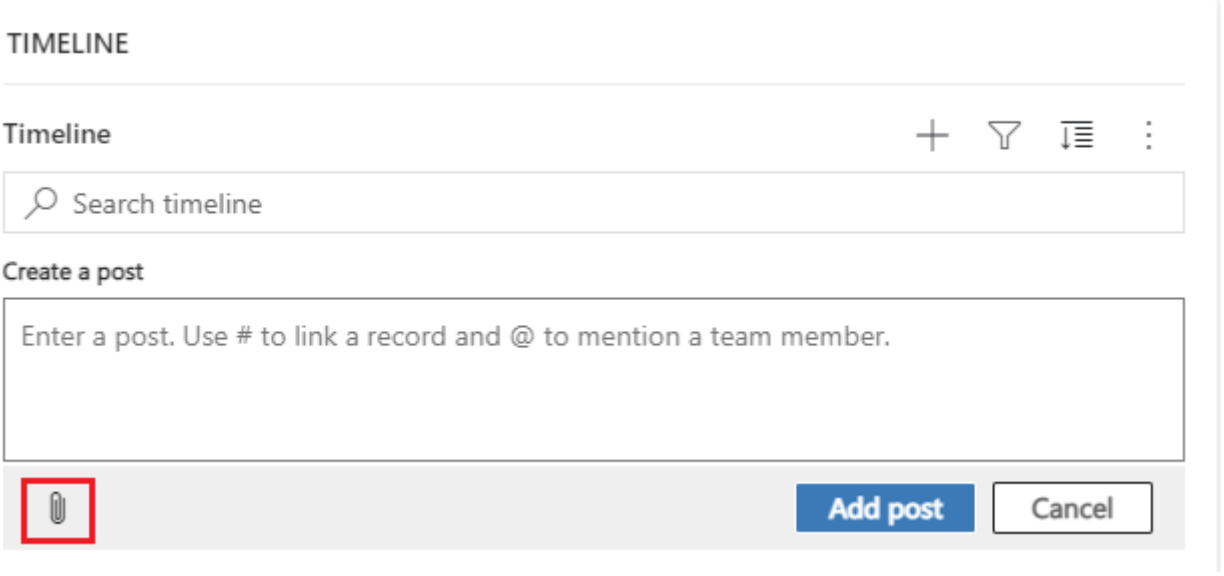
When enabled by your system administrator, the **Post** field is also displayed under the **Search** feature on timeline.

Add an attachment to a post

You can add an attachment to a post, such an image or a document. The supported file formats are as follows: .JPG, .PNG, and .PDF.

To add an attachment to a post:

1. In the **Create a post** section in the timeline, select the **Attach** icon in the lower-left corner.

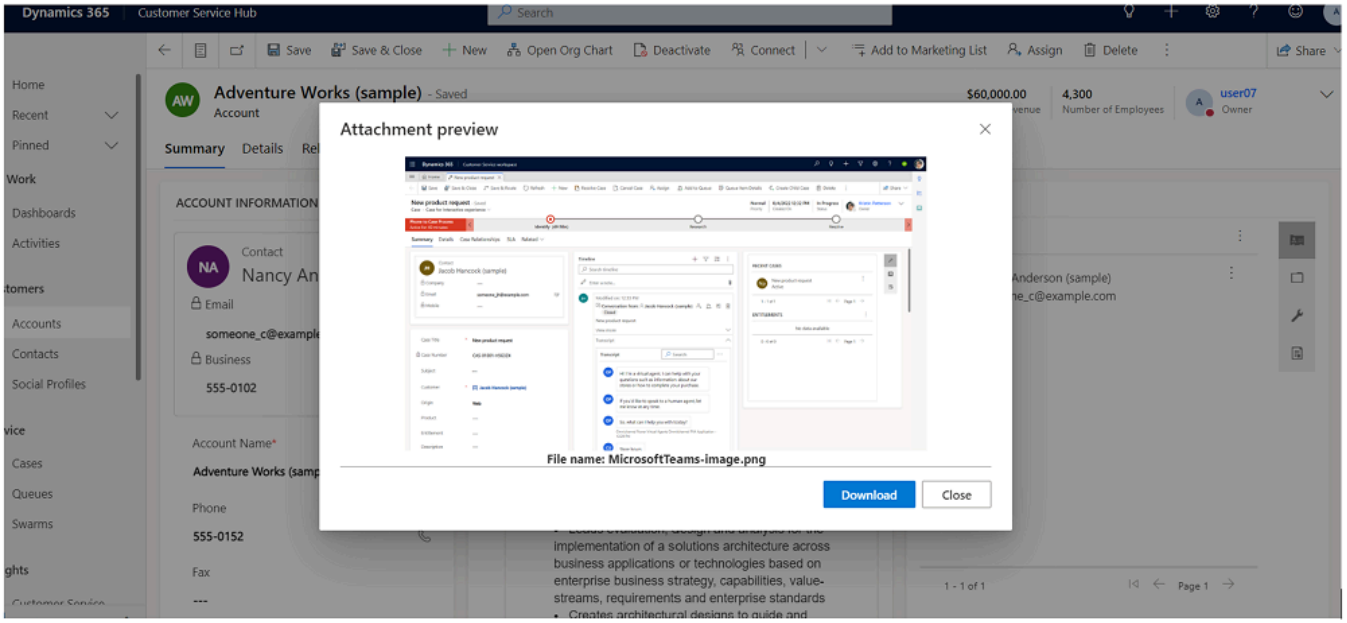


2. Browse to the file you want to attach to the post, and then select it.

3. Finish the edits you want to make to your post, and then in the timeline, select **Add post**.

Preview an attachment in the timeline

You can view previews of attachments in the timeline if they're in the supported file format (.JPG, .PNG., or .PDF). Any attachment that's viewable inline on the timeline can be downloaded, whether or not a preview is available.



To preview an attachment in the timeline, do either of the following steps:

In edit mode:

1. Right-click the attachment, and then select **Preview**. The **Attachment preview** dialog opens with the attachment displayed. You can view and download the attachment from the dialog.
2. When you're finished viewing the attachment, select **Close** to return to the note or post.

OR

In read mode:

1. Select the attachment. The **Attachment preview** dialog opens with the attachment displayed. You can view and download the attachment from the dialog.
2. When you're finished viewing or downloading the attachment, select **Close** to return to the note or post.

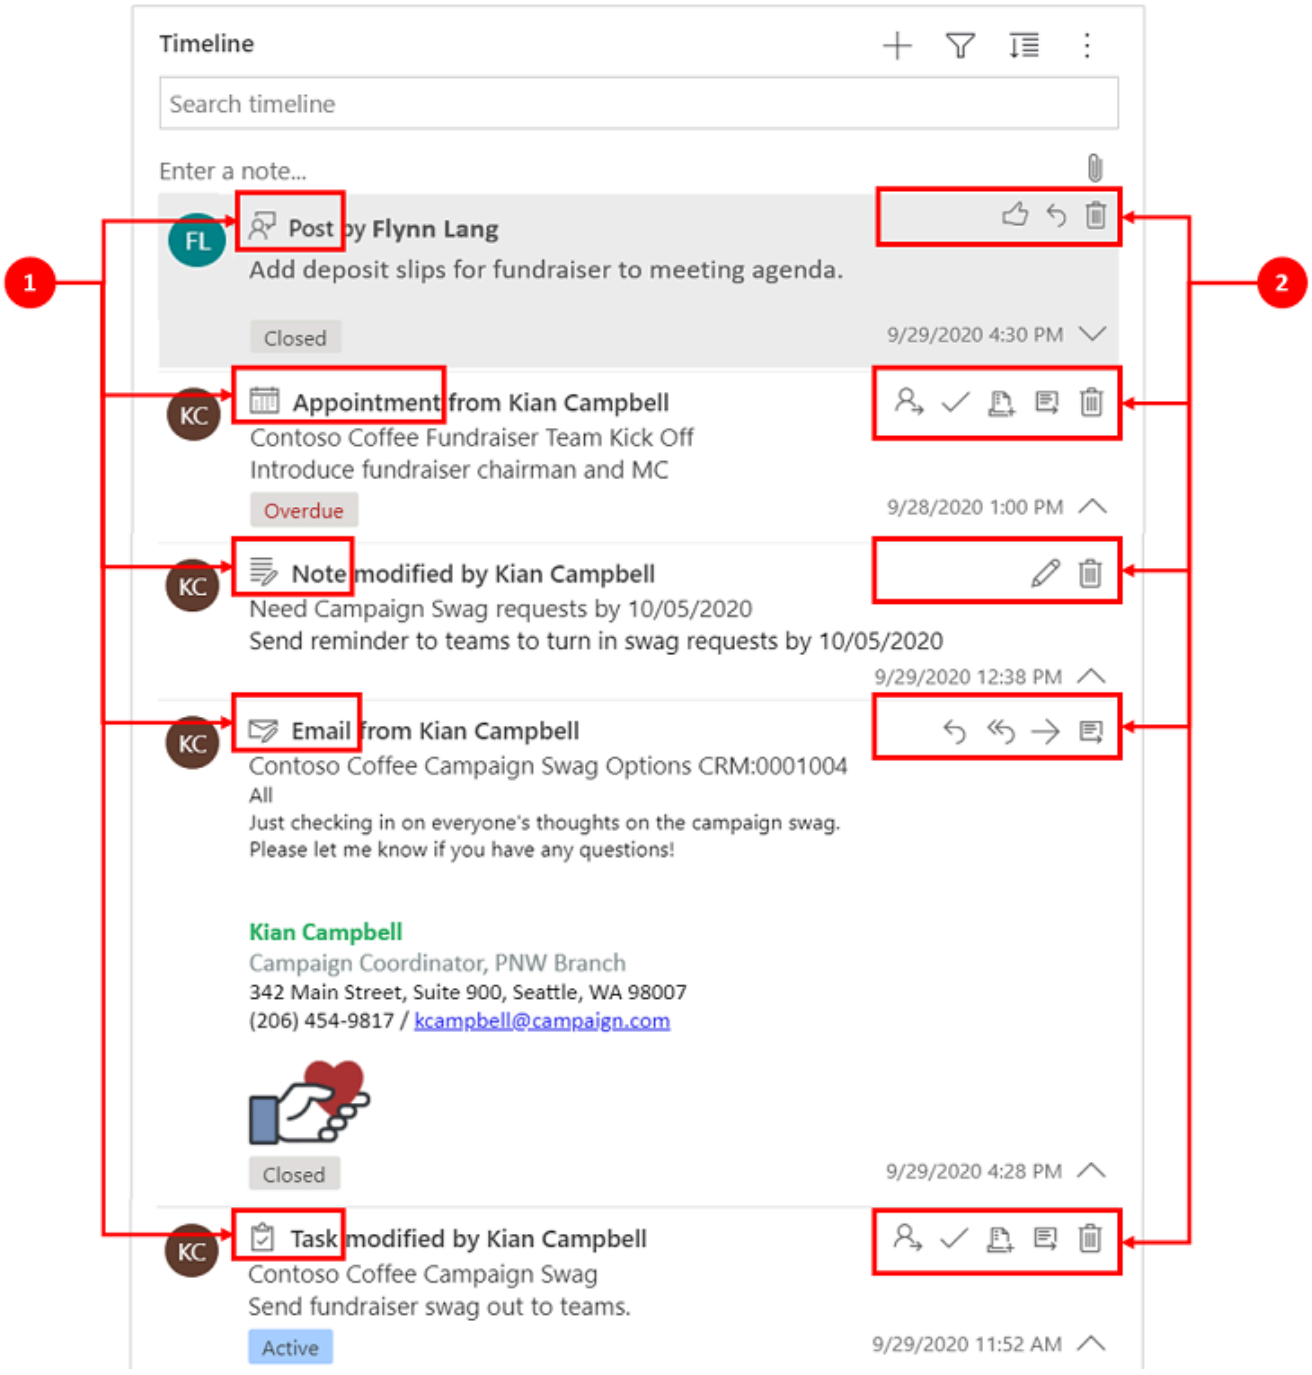
> ⓘ **Note**
>
> The use of the **Attachment preview** dialog to view the file can be skipped in the browser by using **Ctrl + Left click (of mouse)**. By doing so, the attachment is directly downloaded without previewing it.

Access the command bar to perform actions

When you hover your cursor on or expand an activity, post, or note, the command bar appears in the top-right corner of the row with the specific options that support that activity, such as

assigning it to others, adding it to a queue, converting it to a case, liking or replying to a post, editing a note, or deleting an activity. However, not all rows can perform the same actions.

Command actions by row



Legend

1. Only the actions associated with that row are displayed in the top-right command bar displayed in the row.
2. Each row displays a different set of associated actions. Not all actions work on all rows.

The following table is an overview of the command bar icons and the actions they support:

Expand table

Icon	Name	Description
	Assign	Lets you assign a task.
	Close Activity	Lets you close the activity row.
	Add to Queue	Lets you add a task to a queue.
	Open Row	Lets you open a row.
	Delete	Lets you delete the row.
	Reply	Lets you reply to an email. **Note**: This command is only available for Email.
	Reply All	Lets you reply to all for an email. **Note**: This command is only available on Email.
	Forward	Lets you forward an email. **Note**: This command is only available on Email.
	Like this post	Lets you like a post. **Note**: This command is only available on Posts.
	Edit this note	Lets you edit a note. **Note**: This command is only available on Notes.

The following table is an overview of the default command bars for frequently used activities, notes, and posts:

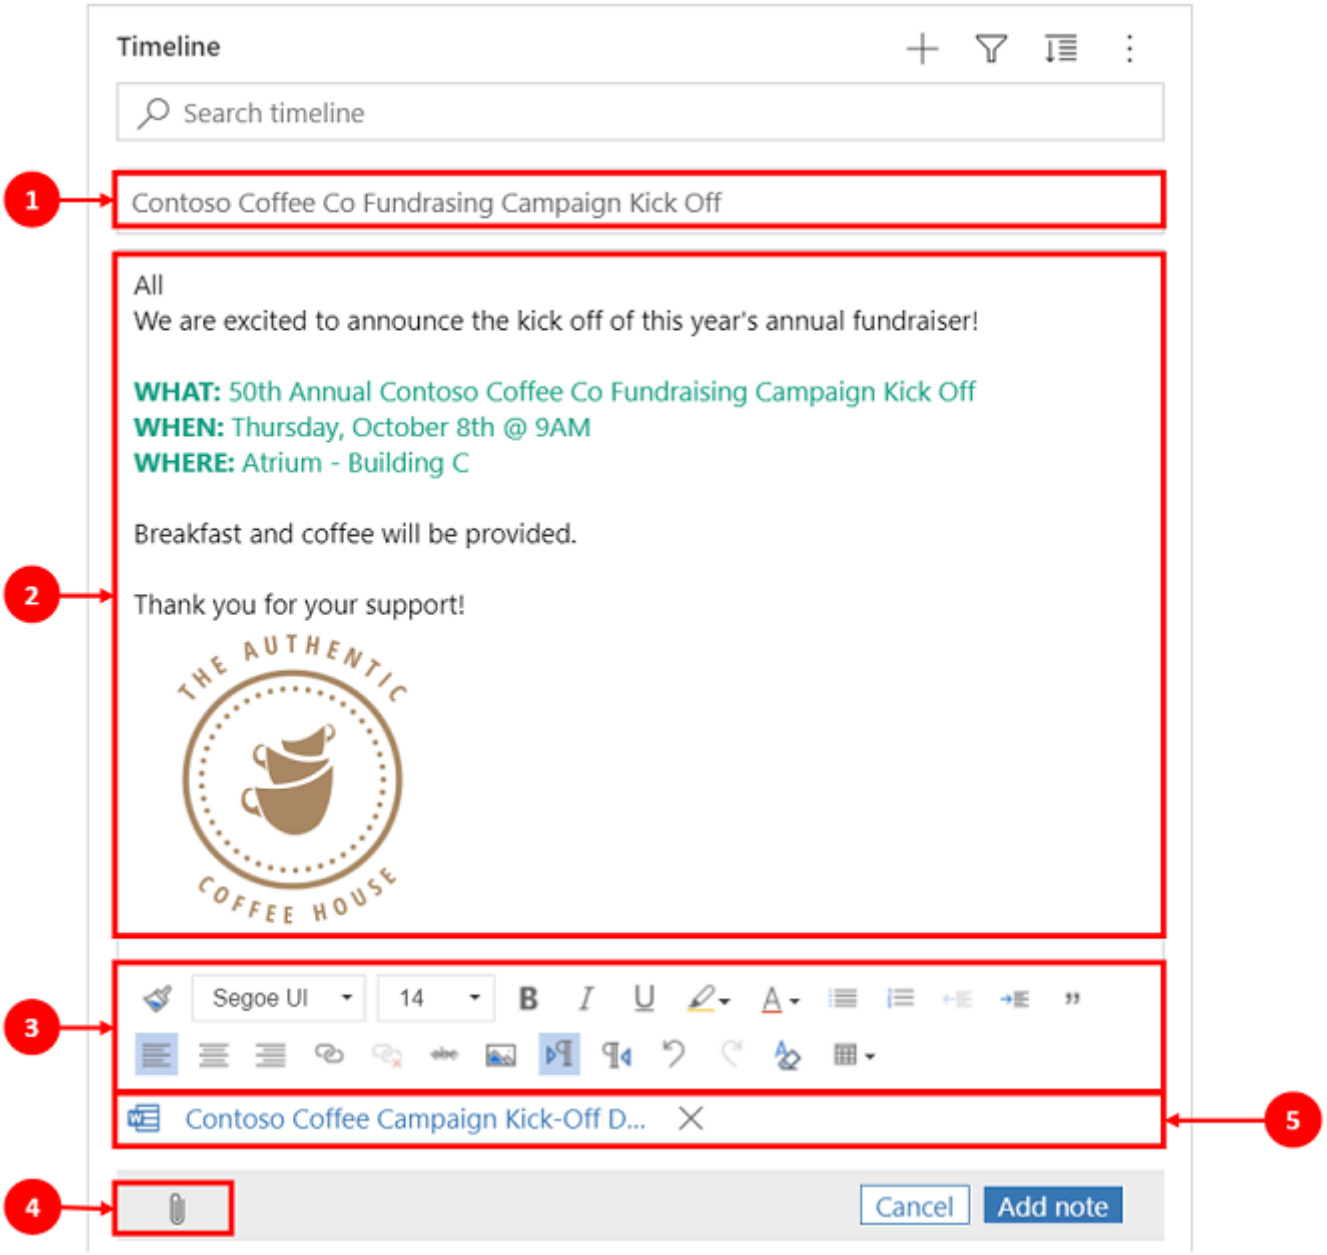
Expand table

Activity	Command bar icons	Notes
Email (draft)	Open Row, Delete	
Email	Reply, Reply All, Forward, Open Row	
Appointment	Assign, Close Activity, Add to Queue, Open Row, Delete	

Activity	Command bar icons	Notes
Appointment (closed)	Assign, Add to Queue, Open Row, Delete	
Task	Assign, Close Activity, Add to Queue, Open Row, Delete	
Task (closed)	Assign, Add to Queue, Open Row, Delete	
Phone Call	Assign, Add to Queue, Open Row, Delete	
Note	Edit, Delete	
Post (user)	Like, Reply, Delete	Only the author of the post has the ability to delete it. The author always has the ability to delete regardless of user privilege.
Autopost	Like, Reply, Delete	

Work with notes

The **Note** message box has a rich text editor that enables you to use rich text and create well-formatted content.



Legend

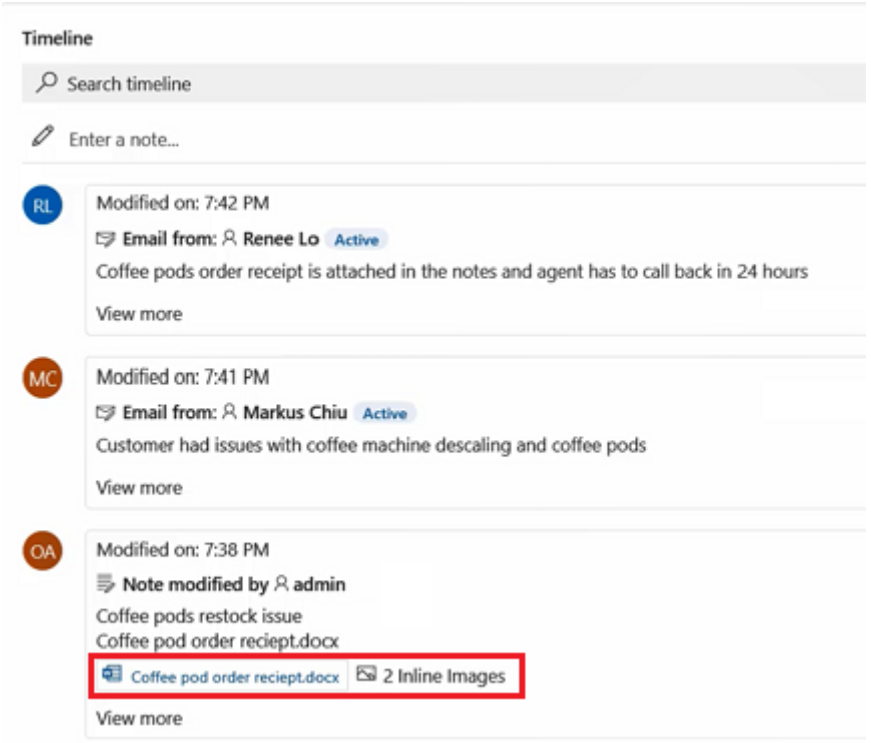
1. Note title field for adding headings and subjects.
2. Notes have a rich text editor so you can format and structure your messages.
3. The rich text editing tool expands to a full menu for quick access to formatting features.
4. The paperclip is used to attach files to your note.
5. Attached files are displayed at the bottom of the note.

> **Note**
>
> - Only **Notes** have rich text capability, and they're only available in the timeline.
> - You can only format the message body of a note; not the title.
> - The rich text editor is available only for Unified Interface.

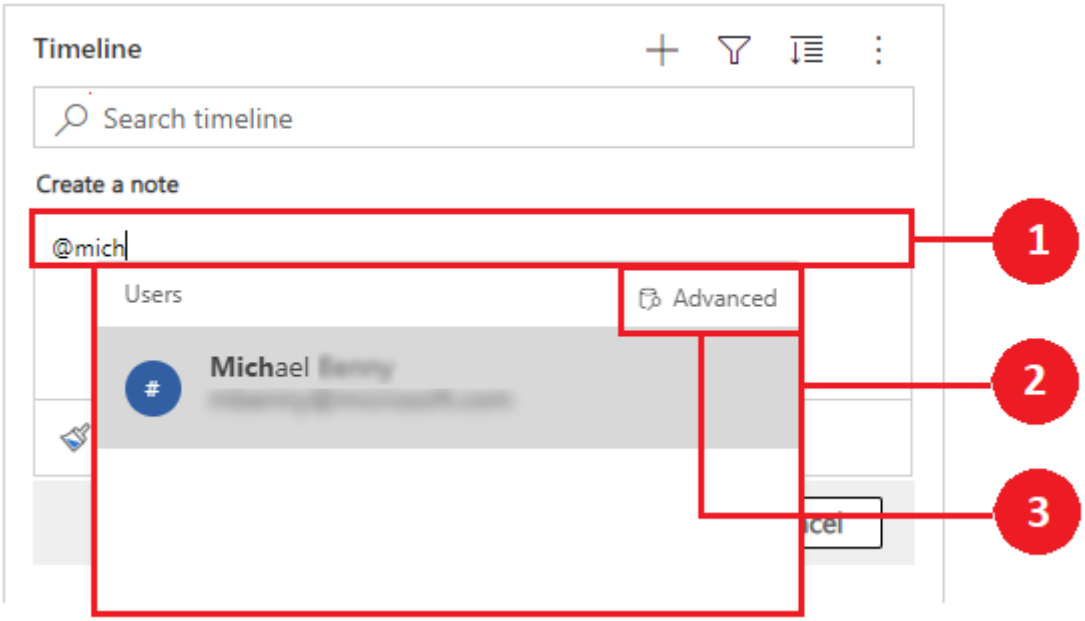
- If you create a rich text editor note in Unified Interface and then view the note in the web client, it displays in HTML syntax.

View whether a note has attachments and inline files in the timeline

If you attach a file to a note or include an inline image in the note, the timeline shows that the note has an attachment or inline files. If you attach a file or include multiple files inline, the note shows the number of files using the first two file names and a number to represent the remaining count of and the file type.



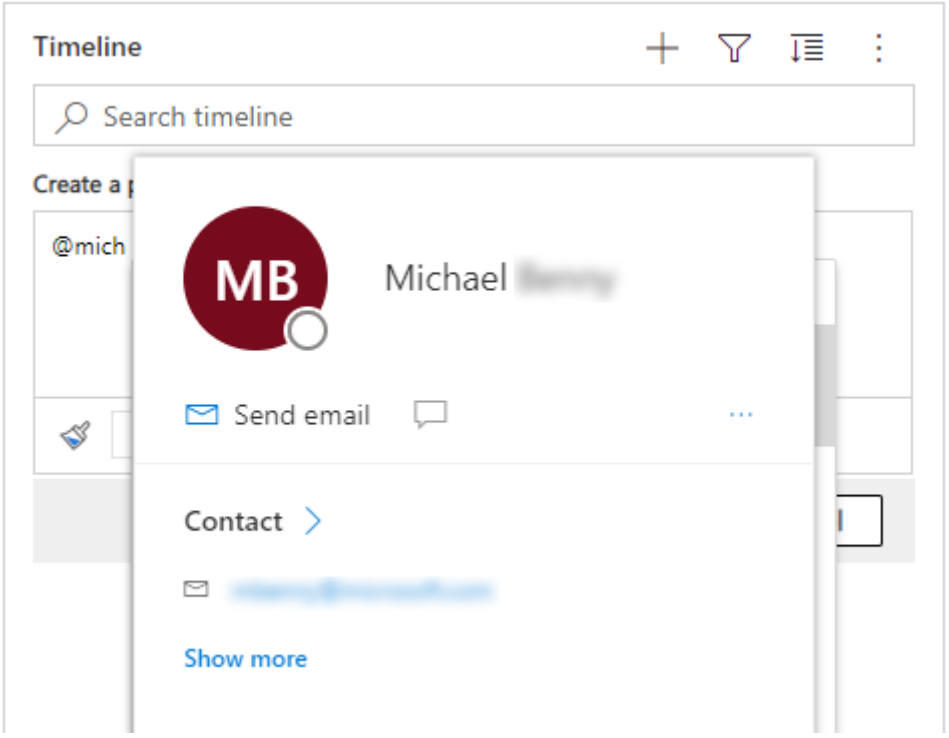
Add a mention or reference a team member in a note



Legend

1. Typing the @ sign in the **Note** field displays a flyout menu with a list of users that have been recently used.
2. If the user row isn't displayed, typing the name after the @ sign refreshes the rows in the flyout menu using the **Quick Find** search engine that's operating in the background.
3. Switch views using **Advanced** to display the **Lookup Records** pane. In the **Lookup Records** pane, you can switch between the **Recent records** and **All records** view to search rows.

When you mouse over the profile image, you can view the user's detailed profile card and online presence status.



> **Note**
>
> You can mention only a system user in a note. For example, a team member within your organization.

Add an attachment to a note in timeline

When enabled by your system administrator, you can add an attachment, such as a file, to a note in timeline to share with users. Any attachment that is viewable inline on the timeline can be downloaded, whether or not a preview is available.

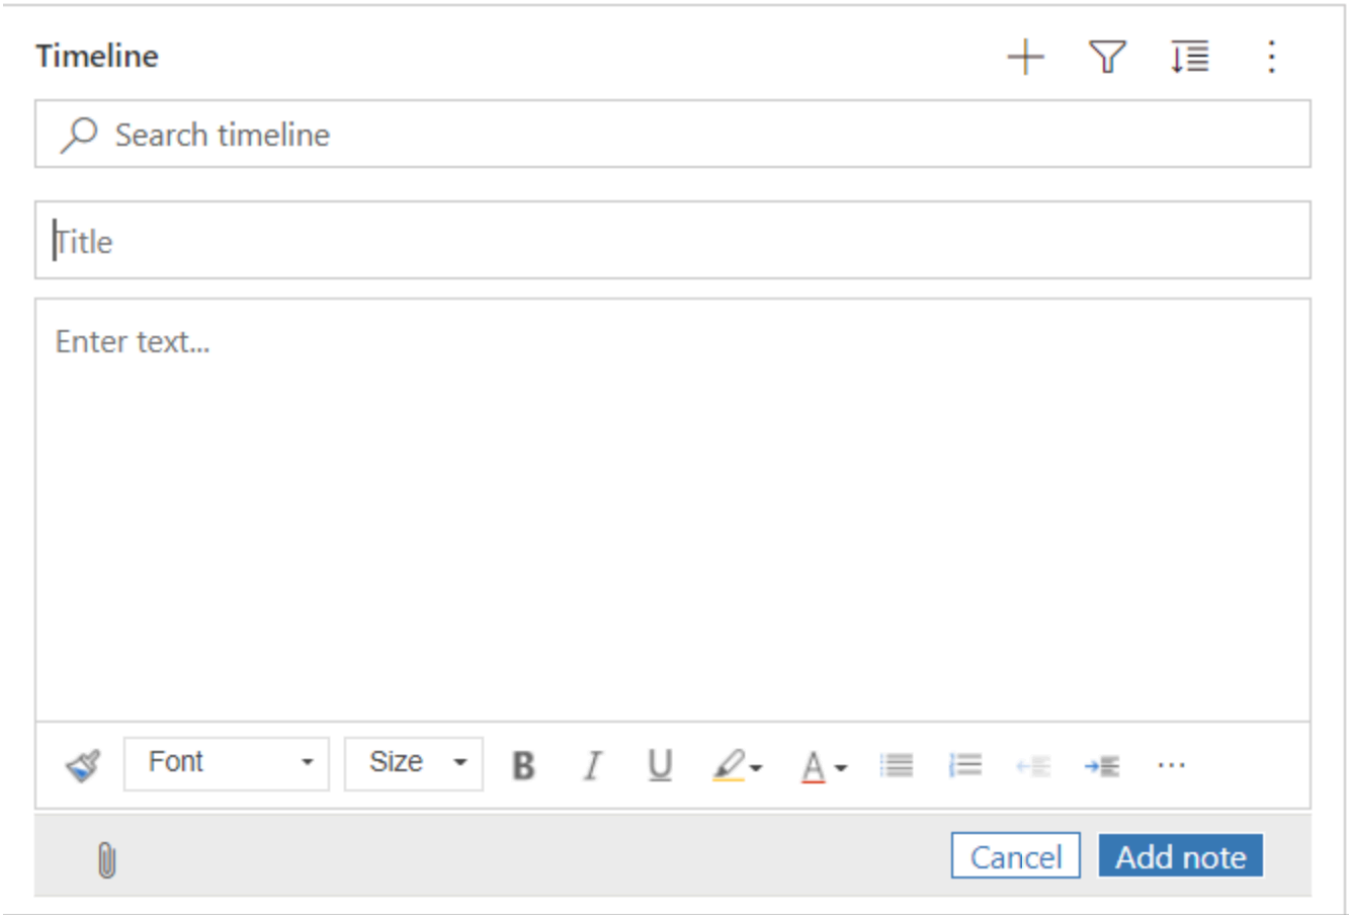
> **Note**
>
> - The list of allowed attachments is configured by your system administrator.
> - On iOS and Android you can only select and attach a picture or video.

Select the paperclip icon to attach a file to a note.

Edit Note

When you attach a file to your note, the **Edit note** screen displays, and attachments show at the bottom of the **Edit note** screen.

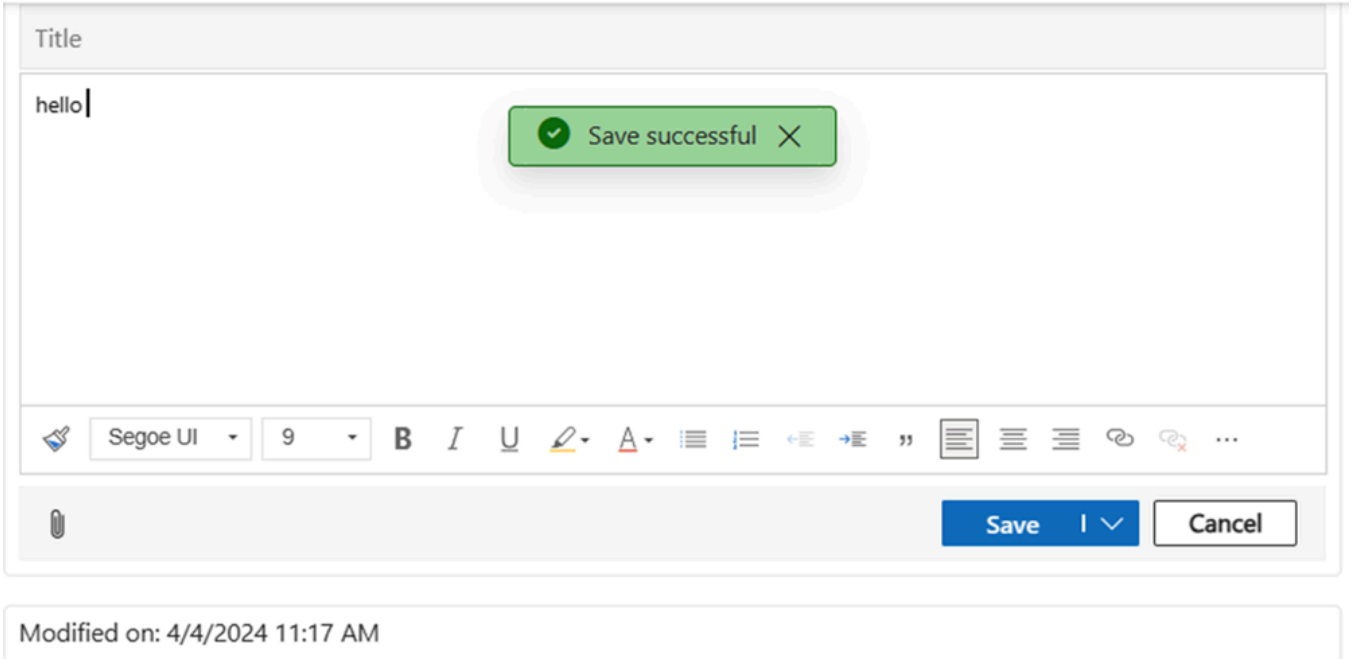
> **Important**
>
> You can only add one file attachment per note.



Quickly save notes

The Quick save feature allows you to save your notes faster by selecting **Ctrl**+**S** on your keyboard at any point when you're typing a note. When you use Quick save, you don't have to navigate to **Save** or **Save and Close** on the command bar.

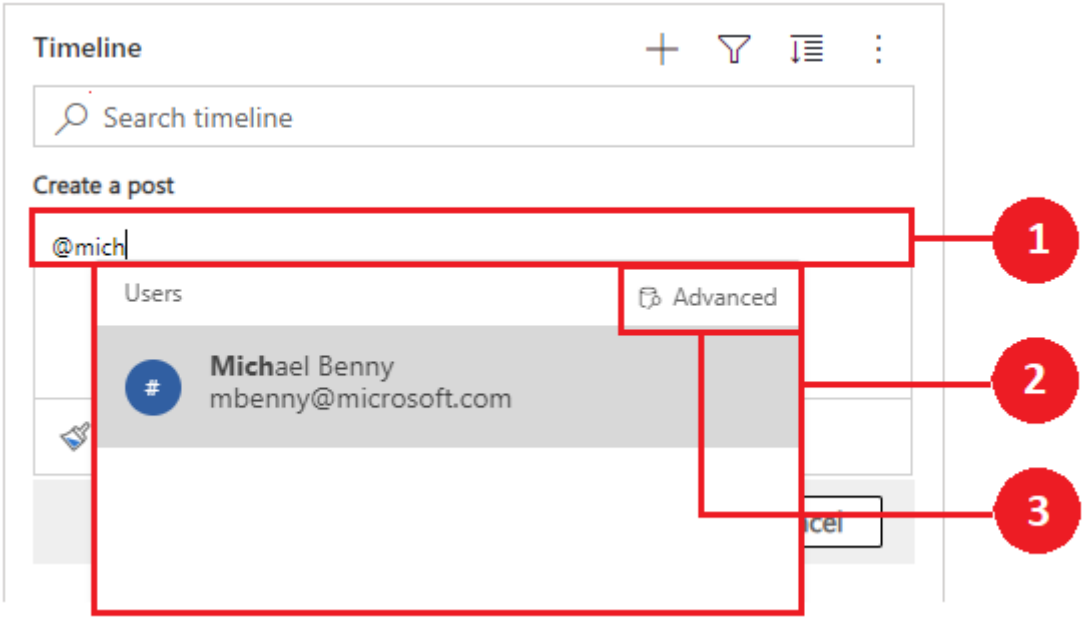
When you use **Ctrl**+**S**, a **Save successful** confirmation message is displayed in the note to let you know your note saved on the timeline.



Work with posts

When enabled by your system administrator, you can either add a post to a row or mention to another user or timeline.

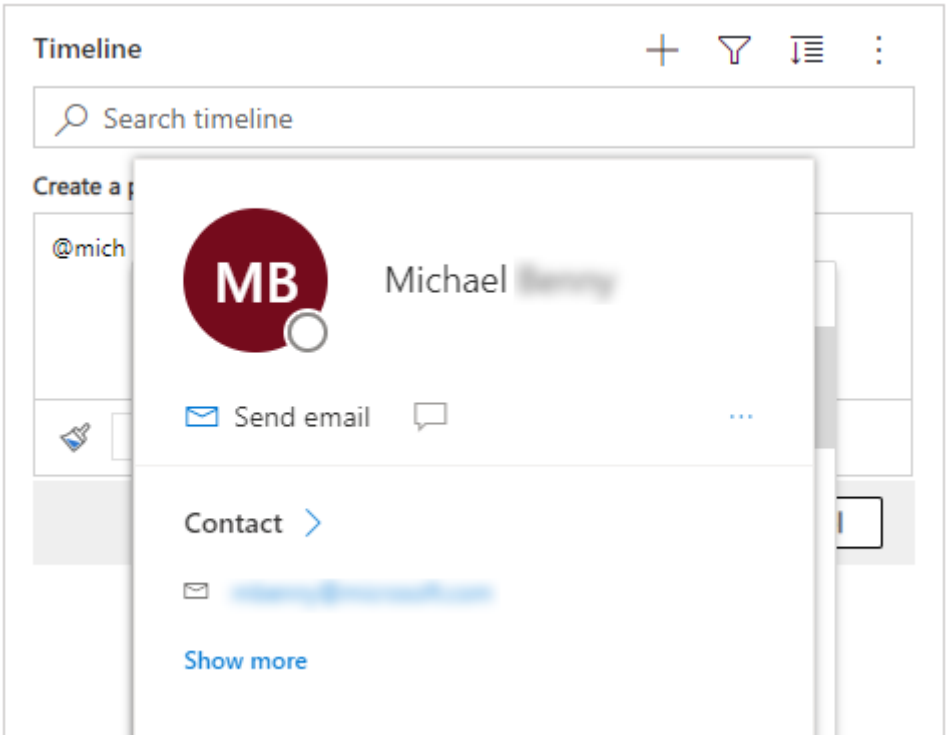
Add a mention or reference a team member in a post



Legend

1. Typing the @ sign in the **Post** field displays a flyout menu with a list of users that have been recently used.
2. If the user row isn't displayed, typing the name after the @ sign refreshes the rows in the flyout menu using the **Quick Find** search engine that's operating in the background.
3. Switch views using **Advanced** to display the **Lookup Records** pane. In the **Lookup Records** pane, you can switch between the **Recent records** and **All records** view to search rows.

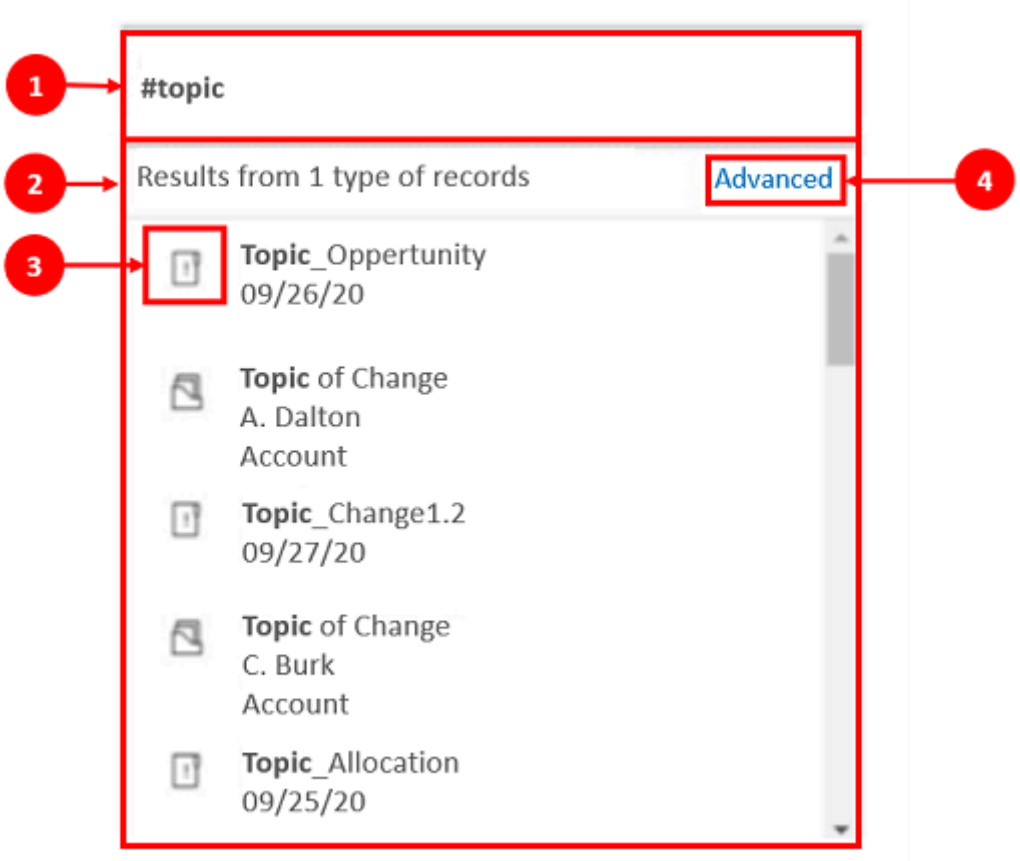
When you mouse over the profile image, you can view the user's detailed profile card and online presence status.



> **Note**
>
> You can mention only a system user, i.e. a team member within your organization, in a post.

Add references in a post in timeline rows

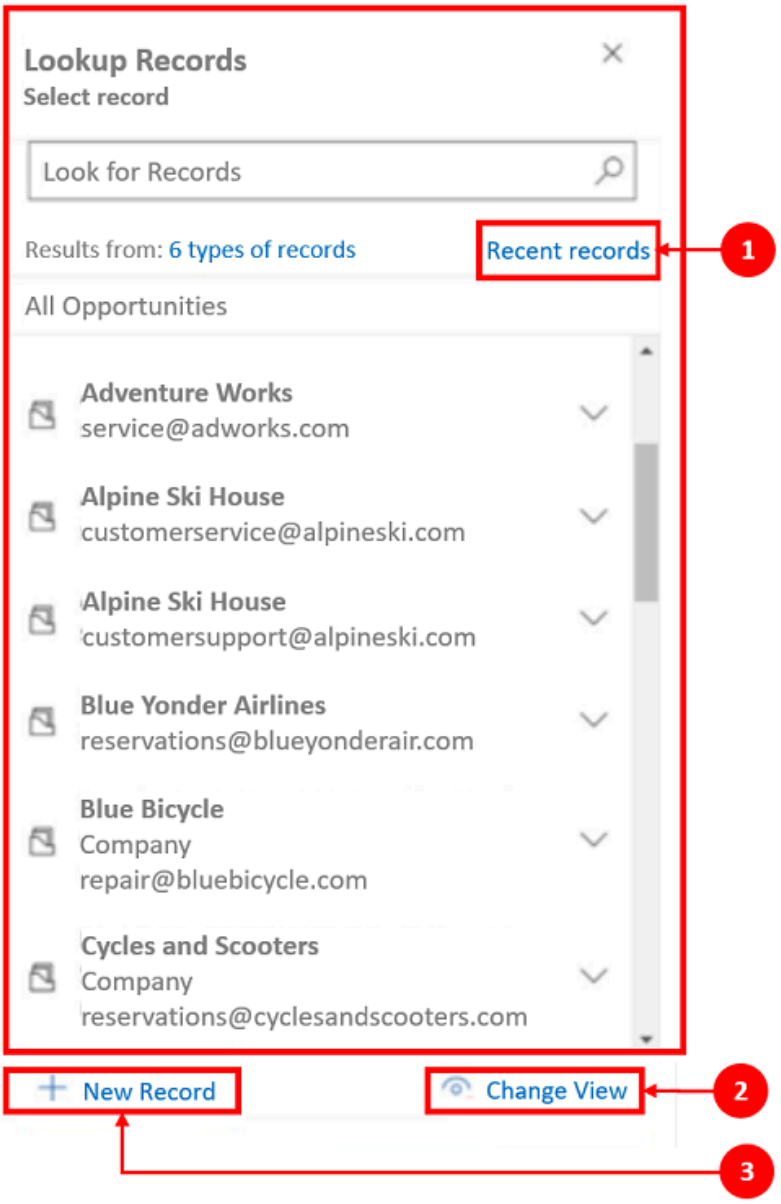
To add a reference such as links in a post to a timeline row, select the + icon, select **Post**, and then complete these steps:



Legend

1. Links can be added to a row by typing # which displays a flyout menu with a list of rows recently accessed. Type a keyword after the # tag and the display refreshes in the flyout menu via the **Quick Find** search engine that's operating in the background.
2. Rows displayed can be of any row type, such as accounts, contacts, or leads.
3. The icons beside the row names in the flyout menu indicate the row types, which help you determine which row to select.
4. **Advanced** provides more options when a row can't be located by allowing the user to switch to a different view or create a new row.

Look up rows in posts in timeline



Legend

1. The **Lookup Records** pane provides users with options to switch between the **Recent records** and **All records** view to find a row.
2. **Change View** to see rows from a different view.
3. **New Record** allows you to create a new row if you can't find the row you need.

For more information on notes and post functionality and configuration, see: Set up the timeline control

Use the rich text editor toolbar

The rich text editor toolbar provides features and functionality that allows you to work with rich text format in notes.

Formatting options

The following table describes the different formatting features and functionality options that are available in the rich text editor that you can use in notes.

> **Note**
>
> You can access your browser's context menu by selecting **Ctrl + right-click**. This setting is useful if you need to use your browser's built-in spellchecker. Otherwise, you can right-click to provide contextual formatting for any element you are using.

Expand table

Icon	Name	Shortcut key	Description
	Format Painter	Ctrl+Shift+C, Ctrl+Shift+V	Apply the look of a particular section to another section.
	Font	Ctrl+Shift+F	Select a font of your choice. The default font is Segoe UI. **Note**: When you select any formatted content, the font name for that content displays. If your selection contains multiple fonts, the topmost font name of your selection is displayed.
	Font size	Ctrl+Shift+P	Change the size of your text. The default size is 9 pt. **Note**: When you select any formatted content, the font size for that content displays. If your selection contains multiple font sizes, the topmost font name of your selection is displayed.
	Bold	Ctrl+B	Make your text bold.
	Italic	Ctrl+I	Italicize your text.
	Underline	Ctrl+U	Underline your text.
	Text Highlight Color		Make your text stand out by highlighting it in a bright color.
	Font Color		Change the color of your text.
	Bullets		Create a bulleted list.
	Numbering		Create a numbered list.
	Decrease Indent		Move your paragraph closer to the margin.

Icon	Name	Shortcut key	Description
	Increase Indent		Move your paragraph farther away from the margin.
	Block Quote		Apply a block-level quotation format in your content.
	Align Left	Ctrl+L	Align your content with the left margin. (Commonly used for body text to make it easier to read.)
	Align Center	Ctrl+E	Center your content on the page. (Commonly used for a formal appearance.)
	Align Right	Ctrl+R	Align content to the right on the page. (Commonly used for a formal appearance.)
	Link		Create a link in your document for quick access to web pages and files. Pasted or typed URL text is converted into a link. For example, "http://myexample.com" becomes "http://myexample.com ". In the **Link** dialog box, choose the type of link you'd like to insert. The **Link Info** tab allows you to choose the link type and set the link protocol and URL. The **Target** tab is only available for the URL link type. It specifies the location where the link opens after you select it.
	Unlink		Delete a link in your email or document. When you place the cursor on a link, the **Unlink** button on the toolbar becomes active. Select the button to remove the link and make it plain text.
	Superscript		Type small letters just above the line of text.
	Subscript		Type small letters just below the line of text.
	Strikethrough		Cross out text by drawing a line through it.
	Insert Image		You can insert an image by directly copying and pasting it inline in the editor, dragging and dropping it from your desktop or local folder directly into the editor, or by typing a URL. The following formats are supported: .PNG, .JPG., or .GIF. To insert an image inline in your article: 1. Drag and drop the image or copy and paste it directly into the article.

Icon	Name	Shortcut key	Description
			2. Drag any corner of the image to resize it. To insert an image using a URL or navigating to the local image: 1. Choose Insert Image. 2. In the **Image** property dialog, choose from the following options: • Select **Browse** to navigate to the image on your computer. • Or specify the web address of the image, and properties to define how the image appears in the email or article. **Note:** ◦ If the image is located on the external server, use the full absolute path. ◦ If the image is located on a local server, you can use a relative path. ◦ If you want the image to be linked to a target, add a URL for the image. ◦ You can also specify if you want the targeted page to open in a new window, topmost window, same window, or parent window.
	Left to Right		Change the text to left-to-right for content such as a paragraph, header, table, or list. Commonly used for bi-directional language content. This setting is the default setting.
	Right to Left		Change the text to right-to-left for content such as a paragraph, header, table, or list. Commonly used for bi-directional language content. The default setting is left-to-right.
	Undo Typing		Undo changes you made to the content.
	Redo Typing		Redo changes you made to the content.
	Clear All Formatting		Remove all formatting from a selection of text, leaving only the normal, unformatted text.
	Add a Table		Add a table to your content. After adding a table, you can do any of the following: • Resize table columns by clicking and dragging your mouse to resize to the columns to the desired width.

Icon	Name	Shortcut key	Description
			• Select one or several cells within a table and apply specific formatting, add links to the selection, or cut, copy, or paste entire rows or columns. • Right-click to access the properties. This setting supports features such as cell type, width and height, word wrapping, alignment, merging, and splitting cells horizontally and vertically, inserting or deleting rows and columns, row and column span, and cell and border color.
•••	Expand Toolbar		Appears when the toolbar is collapsed. Select to expand the toolbar and make all options visible.
	Copy to Clipboard		Copies entire text in a note to the clipboard so that you can paste the contents in another location.

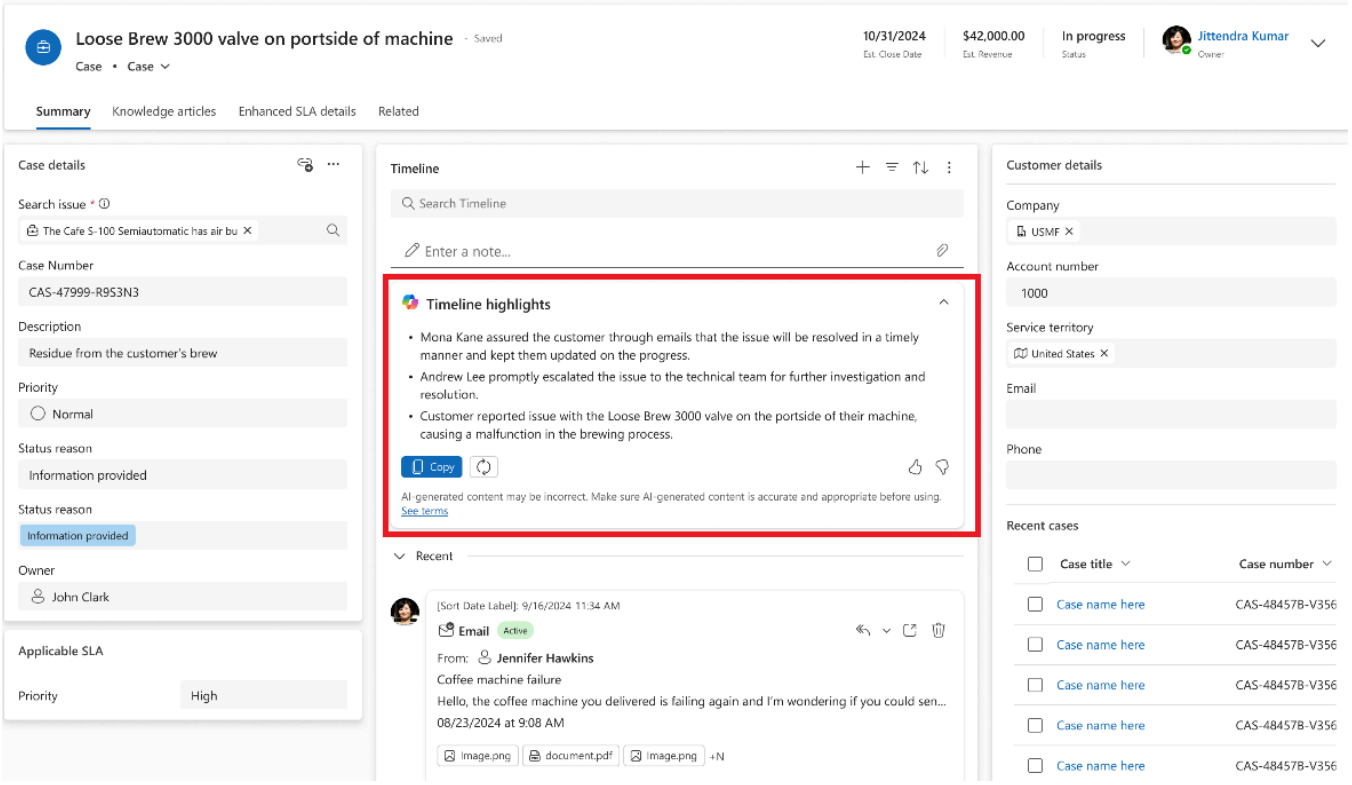
The rich text editor is enabled by default. Your system administrator can enable or disable the editor for you.

Use timeline highlights powered by generative AI

If timeline highlights are enabled on your app, Copilot creates an AI-generated, bulleted list that populates at the top of the timeline. You can use timeline highlights to quickly get caught up on a record's status.

The highlights include a record's main activities, such as details about who you or the previous user interacted with, the reported issue, and actions taken to try to resolve the issue.

You can copy the timeline highlights by selecting **Copy**.

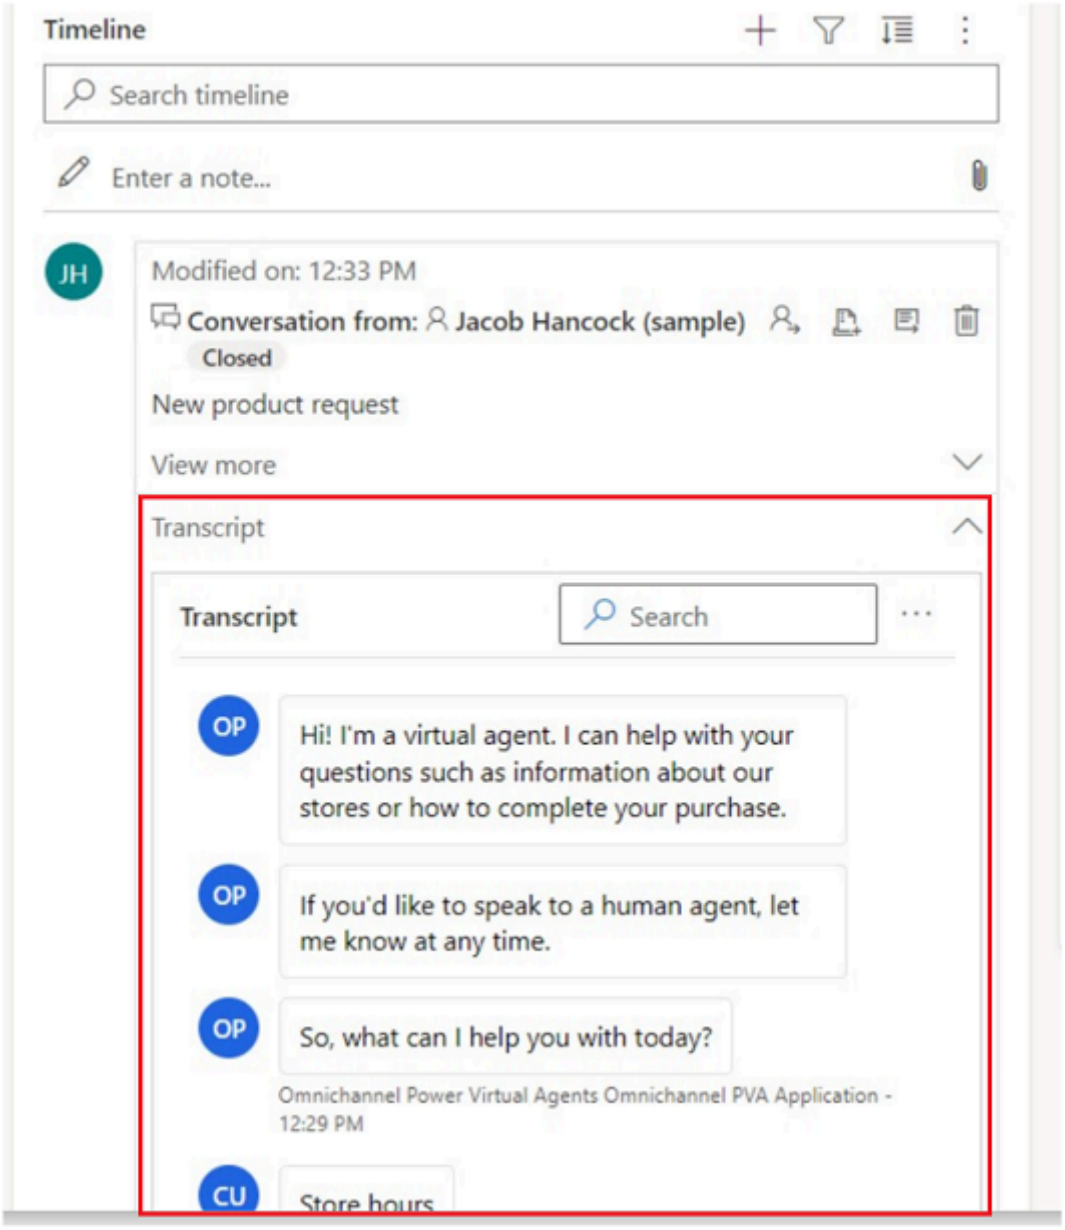


> **Important**
>
> This feature is only available with Power Platform environments with Dataverse that have the **Enable Dynamics 365 apps** setting enabled.

View a conversation transcript

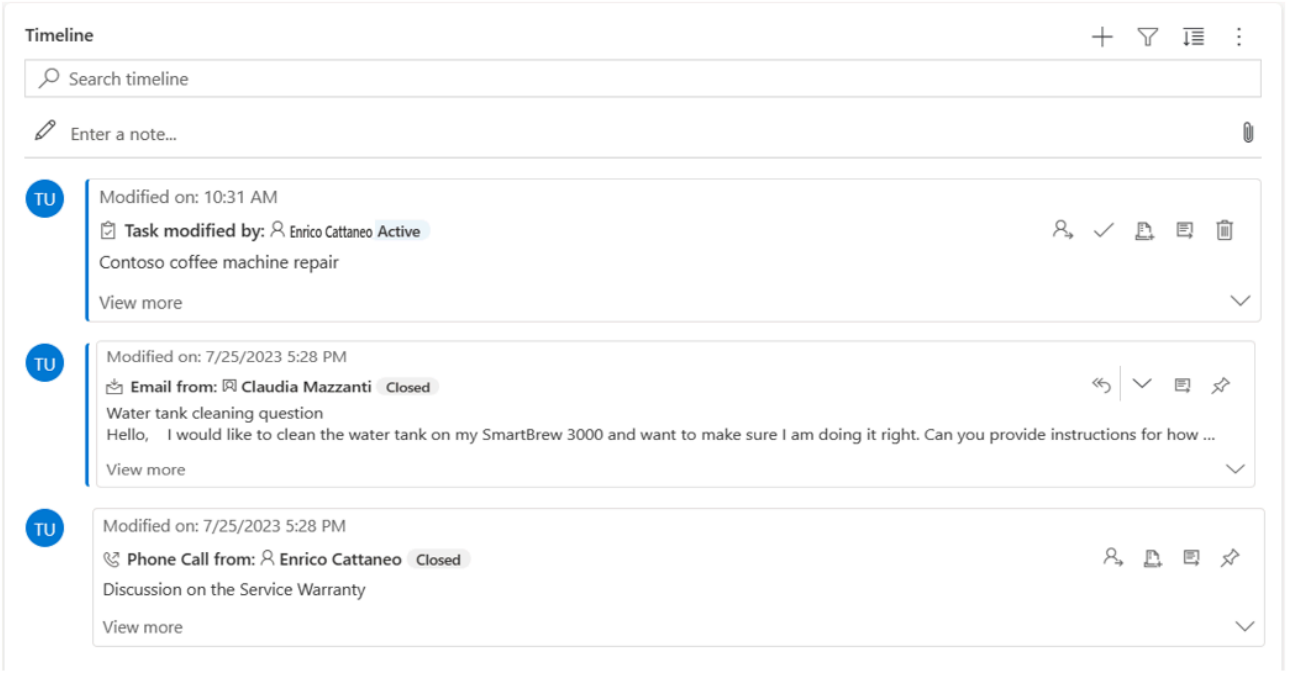
In the timeline, you can view the transcripts of completed chats you had in conversation channels. To view these transcripts, you must have prvReadmsdyn_transcript permission. More information: Roles and permissions

To view a conversation transcript, select the **View more** link in the row for which you want to view the transcript. The row expands and the entire transcript is displayed inline.



View what you missed in timeline

When you access the timeline after being away, activities that you missed display at the top of the timeline, denoted with a blue vertical line next to them. You can quickly open the activities or scroll past them.



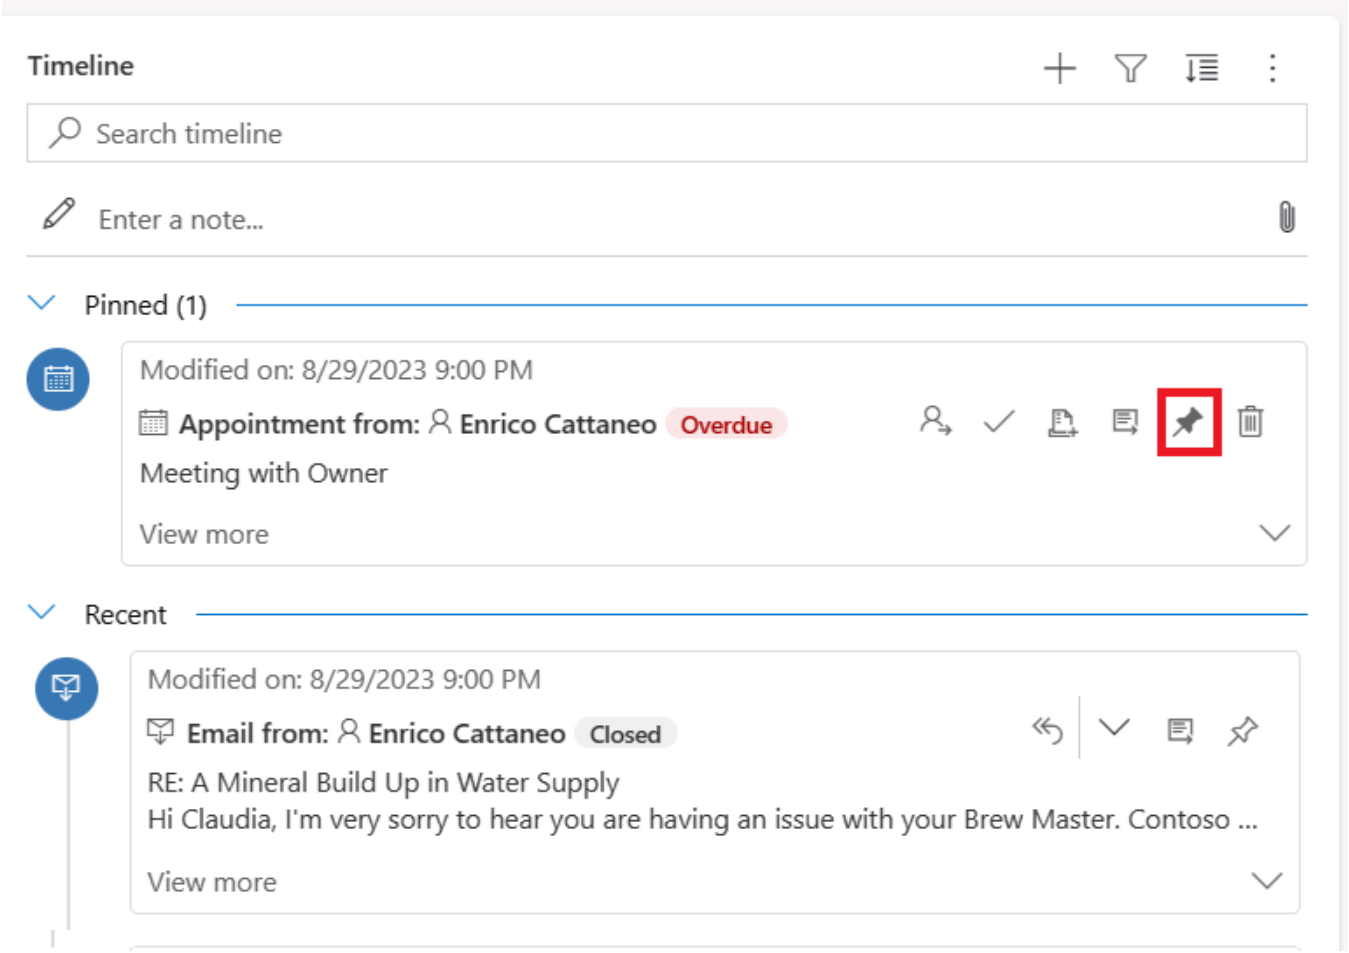
Pin or unpin records in timeline

If your administrator has enabled the pin setting and you have write/delete access, you can quickly access records, such as activities, by keeping them at the top of the timeline. Pinning a record eliminates the need to scroll through every record to find the one you need.

> **Note**
>
> If you have a system administrator or basic user role, the pin and unpin settings work by default. If you don't have either of these roles, you must have Create/Read/Write privileges to be added to the msdyn_customcontrolextendedsettings table for these settings to work.

By default, you can pin notes. The activities that you can pin depend on how your administrator has set up the feature. More information: Let users pin and unpin activities to the top of timeline.

Pin a record by selecting the pin icon next to it. This setting moves it to the top of the timeline in the **Pinned** section, where it can be quickly accessed. The Pinned section also lists the number of records that are pinned. You can pin a maximum of 15 records. Records that are pinned will stay at the top of the timeline for a year unless you unpin them.



To unpin a record, select the pin icon next to it. Unpinning it moves it out of the **Pinned** section and back to where it originally appeared in the list of records in the timeline.

Bookmarks

Bookmarks are a quick way for the user to set, and switch between, different sets of filters. Bookmarks are enabled by default. If necessary, you can disable them from the Advanced section.

> **Note**
>
> Bookmarks feature replaces **Remember my filters** button. Use the steps in the following section to set up your user filters.

Create a bookmark

1. Open the filter pane, and select the filters that will be associated with the new bookmark. You may have no filters selected.

2. Select the bookmark icon in timeline's action bar.

3. Select **Add bookmark**.
4. Enter a bookmark name. Optionally, set it as a default bookmark.
5. Select **Save**.

Selecting the bookmark icon again will now display a flyout of your created bookmarks. You can apply a bookmark by selecting it from this list, or edit it using the **More options** button on the right side of the bookmark.

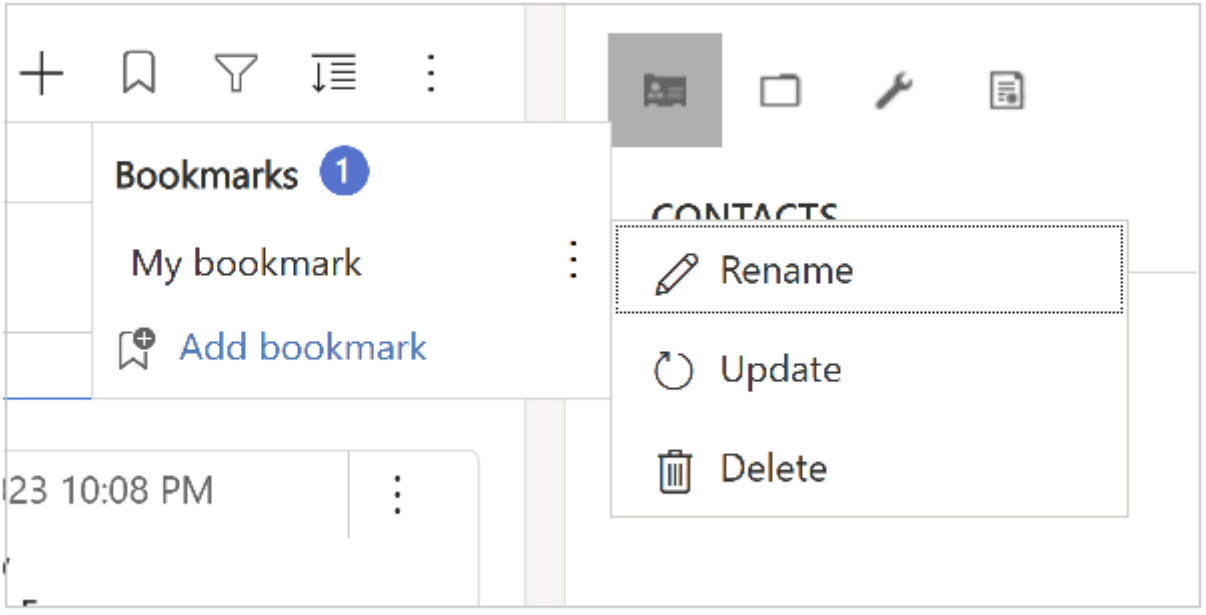
If a bookmark is selected, its filters are applied to the timeline, and is indicated by a filled bookmark icon in the action bar. Hover over the icon to see the name of the bookmark, or select the icon. The selected bookmark has a grey background color.

> **Note**
>
> You can have a maximum of 15 bookmarks.

Edit a bookmark

Any bookmark can be renamed, updated, or deleted from the **More options** menu.

> **Note**
>
> Selecting **Delete** directly deletes the bookmark.



Updating a bookmark will change its filters to the currently selected filters.

You may also set this bookmark as a default for the current form or all forms.

Set a default bookmark

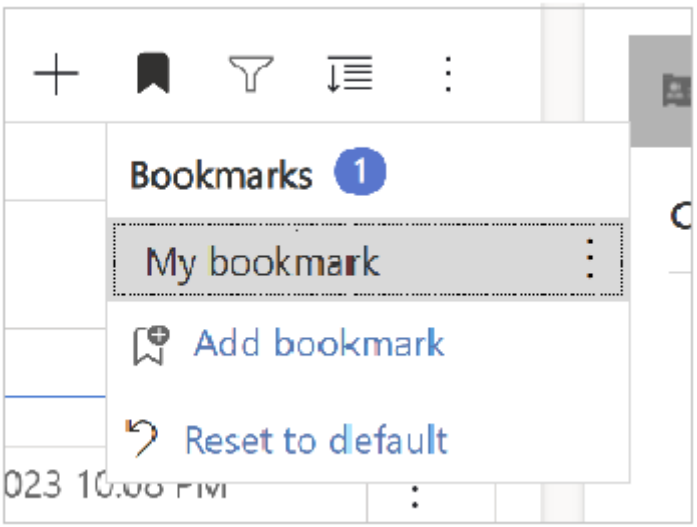
When creating or updating a bookmark, you may select the **Set as default bookmark** checkbox, with the option to apply this change for the current form or globally.

A default bookmark has a star icon ☆ next to its name, and is selected automatically when the timeline loads, overriding any admin filters set for timeline.

> **Note**
>
> You may set a bookmark as a form default for multiple forms; however, it can't be both a form default and a global default. A form-default bookmark will override a global one.

Reset to the default view

If a nondefault bookmark is selected, or if other filters are applied, a reset to default button appears in the bookmark flyout. This applies the **default bookmark** to timeline, if one exists, otherwise **clearing all filters**.



Bookmark filters can't be applied

If a bookmark's filters can't be applied (for example, a bookmark that filters for notes while timeline has notes disabled), then an exclamation mark icon is displayed next to its name.

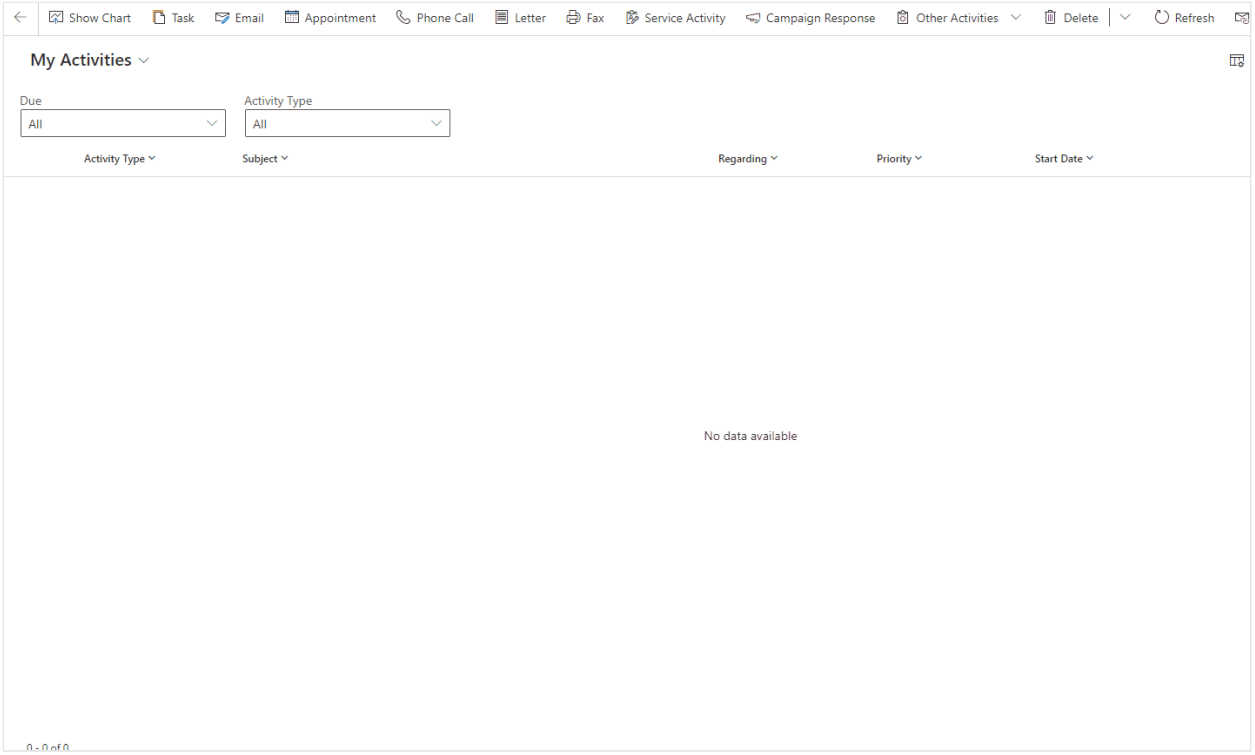
FAQs about Activities and the Timeline Wall

Create and join a Teams meeting from an appointment

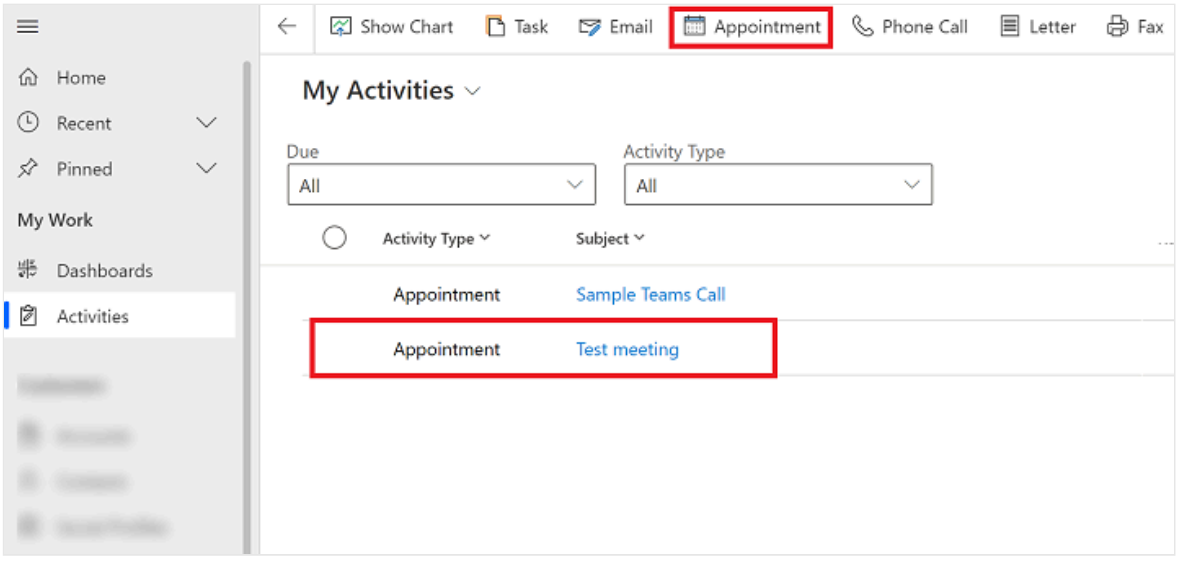
Article • 10/25/2022

Now you can create and join a Teams meeting from an appointment in your model-driven app.



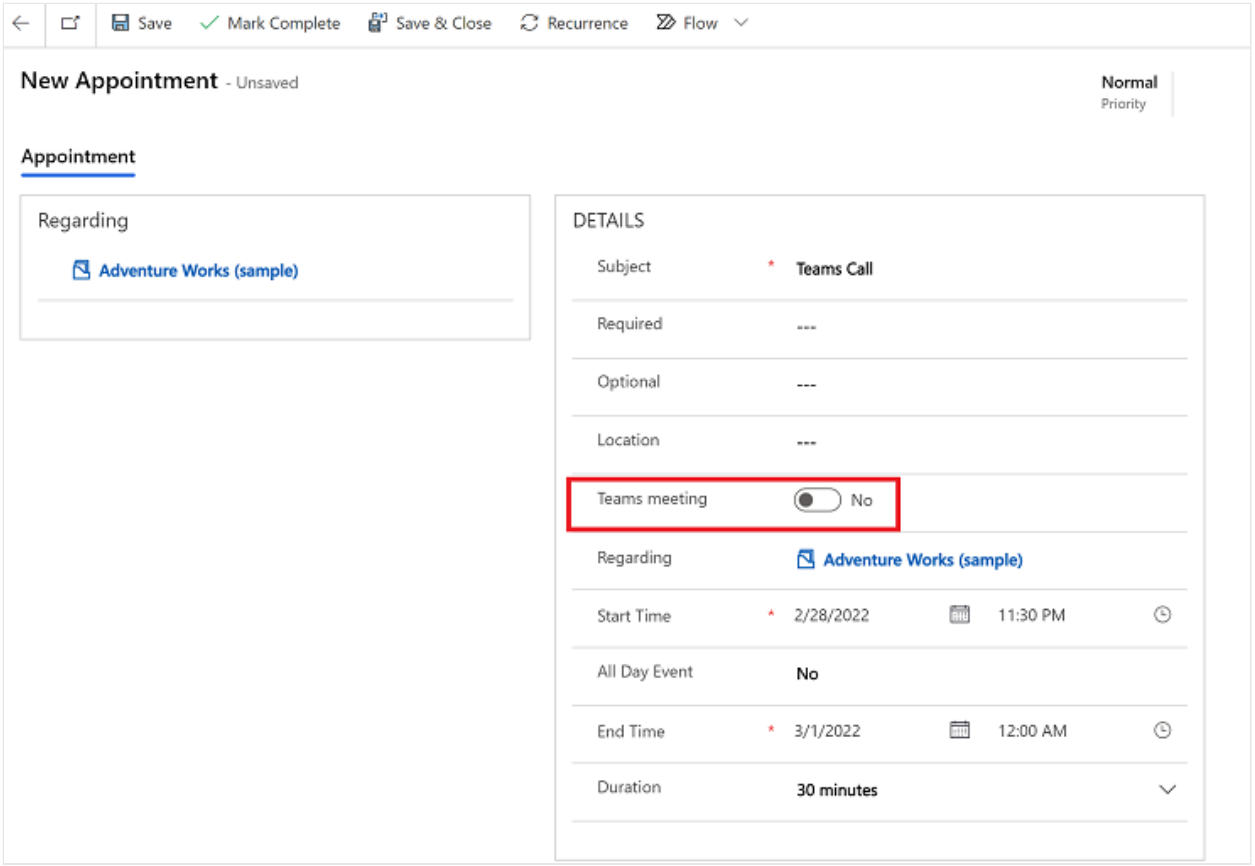
Add a Teams meeting to an appointment

1. From the left navigation pane, select **Activities**.
2. From the list of activities, select an existing appointment or select **Appointment** on the command bar to create a new one.



3. Enter the required information and in the **Details** section, set the **Teams meeting** toggle to, **Yes**.

> **Important**
>
> For the join link to be created successfully, the user enabling the meeting for Teams needs to be the meeting organizer. The organizer field is not exposed by default on the appointment form but the value defaults to the user who creates the meeting.



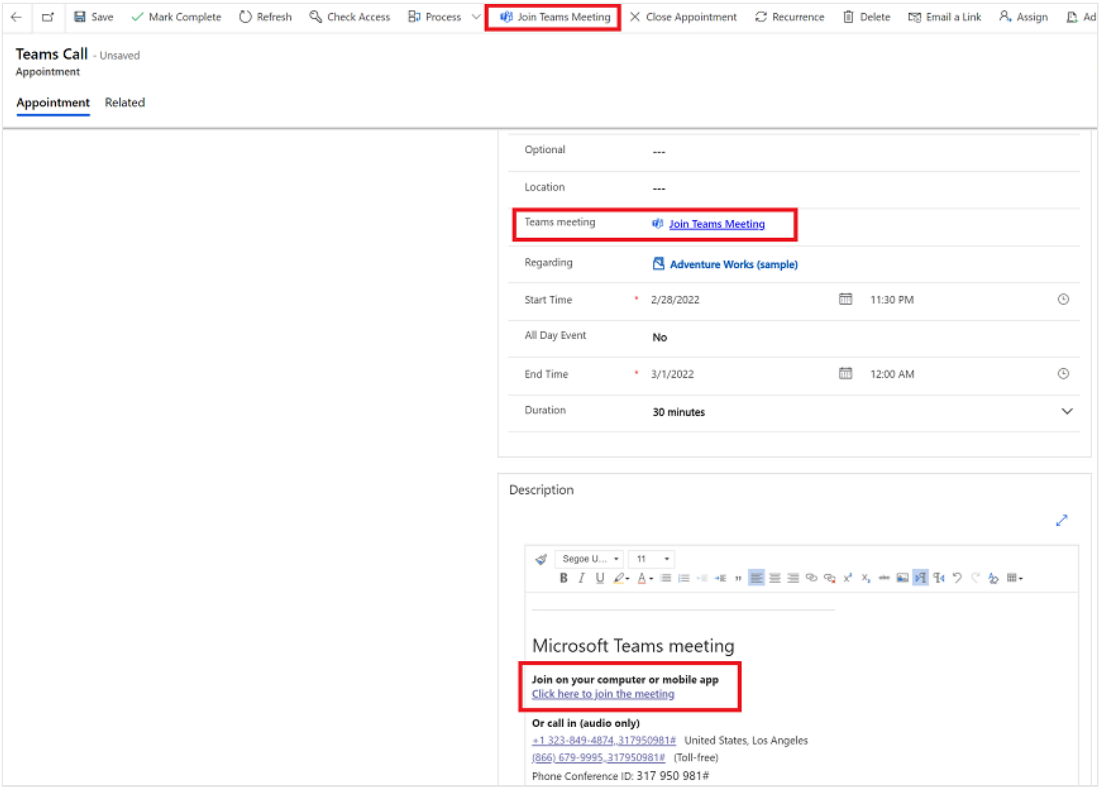
4. When you're done, select **Save**.

> **Note**

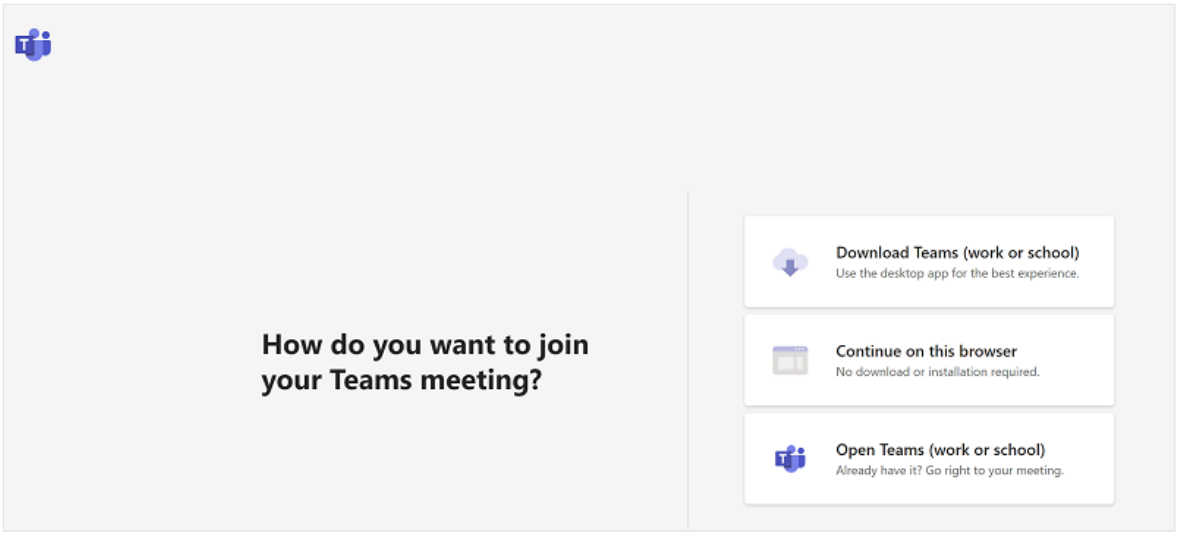
It may take a couple of minutes for the meeting to sync with Outlook and for the meeting link to appear in the appoitnment.

Join a Teams meeting from an appointment

1. Open an appointment activity.
2. Choose one of the following ways to join the meeting:
    - On the command bar select, **Join Teams Meeting**.
    - From the **Details** section, select the **Join Teams Meeting** link.
    - Scroll down the **Description** section of the appointment and select, **Click here to join the meeting**.



3. Follow the instructions on your screen and choose how you want to join the Teams meeting.



> **Note**
>
> For the meeting to synchronize from Dynamics 365 to the user's calendar in Microsoft Outlook and Teams, the user needs to be configured for appointment, contact, and task synchronization.

Known issues about activities

Summarize this article for me

Learn about known issues that may occur with activities in model-driven apps.

- On appointment grids, all-day appointments may show incorrect values for **Start Time** and **End Time**. This issue is limited to the grid control showing appointment records, as forms and calendar control show correct **Start Time** and **End Time** for all-day appointments.

  To fix this issue, use the calendar control as the default control to view appointments.

- The process that checks for conflicts for the people and resources on an appointment is triggered only when a valid Dynamics 365 solution is installed on the environment, as this requires a few scheduling-related tables to be a part of the environment. Appointments created in an environment without a relevant Dynamics 365 solution installed have an **Open** status, rather than the **Scheduled** status. For more information on the scheduling tables and the license required, see Restricted tables for create, update, and delete operations.

- When you use the calendar control view for appointments and navigate through time periods (like moving from Day to Week view or using the navigation arrows), selecting **Edit filters** and then **Apply** can result in duplicate Start Time and End Time filter conditions. This duplication causes appointments not to display in the view. To resolve this issue, select **Edit filters**, manually remove one set of the duplicated Start Time and End Time filters, and then select **Apply**. Alternatively, work in the grid view instead of the calendar view.

- Error message `Unable to find one-to-many relationship, entity: [entity name], referencing entity: activityparty`

  This transient error appears when saving records with relationships to activity parties. The root cause of the issue is that schema information about the relationship is not loaded when you save the record. The work around is to try to save the record again because the schema information will be loaded eventually. If this error occurs due to custom scripts on the page, the script developer should catch the error and retry after a short delay.

Understand the email experience

Article • 02/15/2022

Having the ability to communicate effectively with customers can lead to increased sales and customer satisfaction. The email capability in customer engagement apps empowers users with the ability to respond and provide timely customer interaction effortlessly through quick email access with enhanced features and functionality. You can compose, reply, and review email, as well as quickly attach and send images that add value and support to customer communication using streamlined functionality. You can also ensure interactions between you and your customers are consistent and professional by using email templates with rich text and images.

You can work in either the **navigate-to** email or the **contextual** email experience. The difference between the navigate-to vs. contextual email experience is where the email displays on your screen. Both experiences use the same **Enhanced Email** form, which is enabled by default out-of-the-box (OOTB).

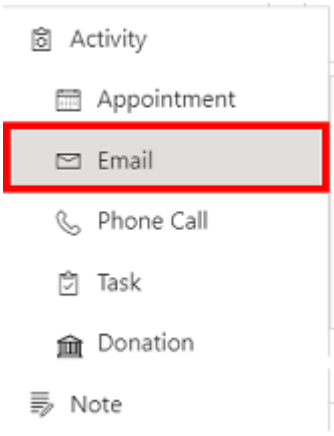
> **Important**
>
> - **Contextual** email is also referred to as enhanced email. Please be aware that there isn't any special functionality associated with the contextual email experience, other than it is a pop-up experience.

- **Navigate-to email experience**: Always displays in a new screen.
- **Contextual email experience**: Can only be initiated from the timeline, displays email in a pop-up screen, and allows you to:
  - Move to different pages without losing email content.
  - Minimize the email window to return to the records you were working on.
  - Simultaneously view, compose, and reply to five emails in pop-up windows when enabled.

The following highlights the difference between the "navigate-to" and contextual email experience in the timeline based on how your system administrator has configured your email:

1. Select **Create a timeline record**.

2. Select **Email**.



Depending on the experience you are using, your email will display as follows:

Expand table

Navigate-to email experience	-	Contextual email experience
		The "navigate-to" email will display in a new screen.		The contextual email will display in a pop-up window on your current screen.

ⓘ Important

- The pop-up window only opens when the height and width of your screen size is at least 400 x 650 pixels or greater. If lower, "navigate-to" email will be the default experience.
- The contextual email experience is available only for timeline.

ⓘ Note

- If you use customized forms in email, you will still be able to see and use them. The **Enhanced Email** form showcases various email capabilities

and functionality.

For more information, see View, compose and respond to email.

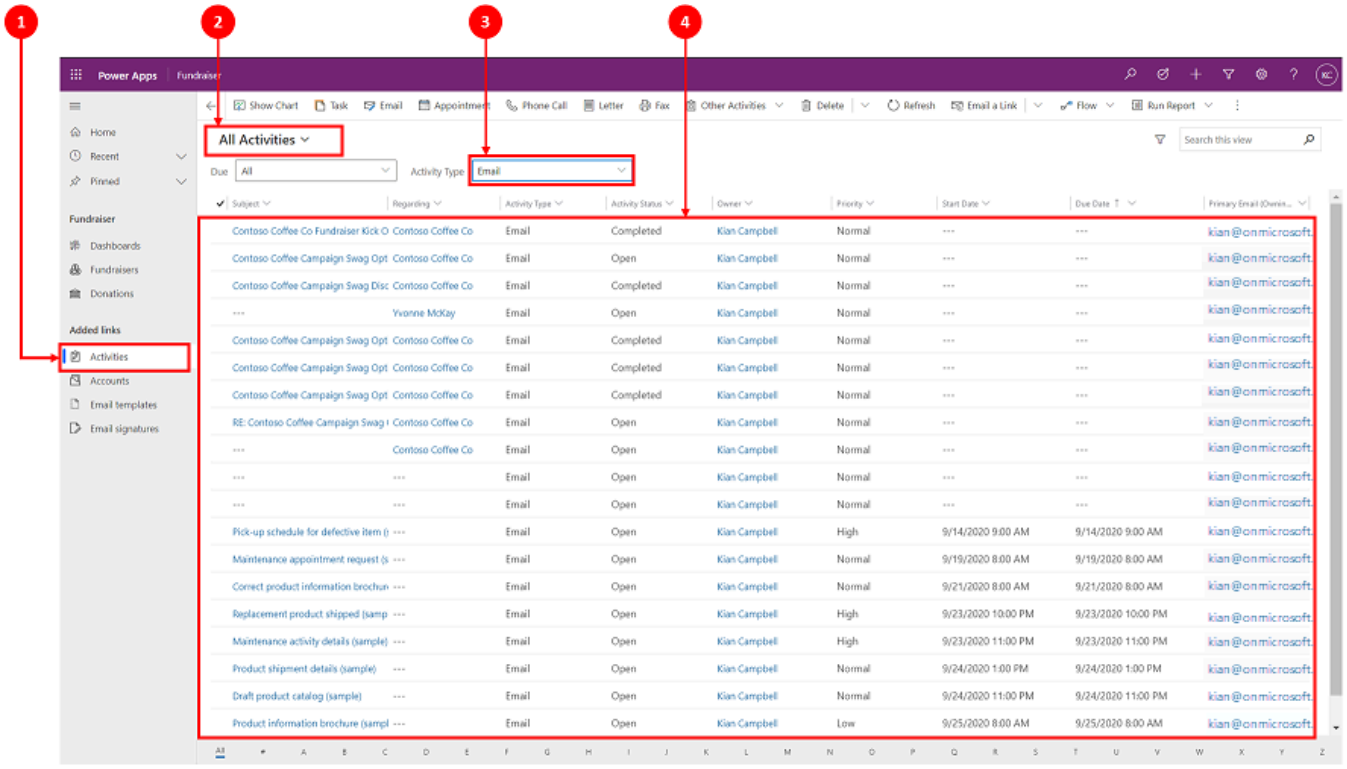
View, compose and respond to email

Users can view, create, and send email faster with streamlined access that helps users compose, reply, and send emails using rich text editing and drag-and-drop attachment features and functionalities to embed images in emails.

Access and view emails



Legend

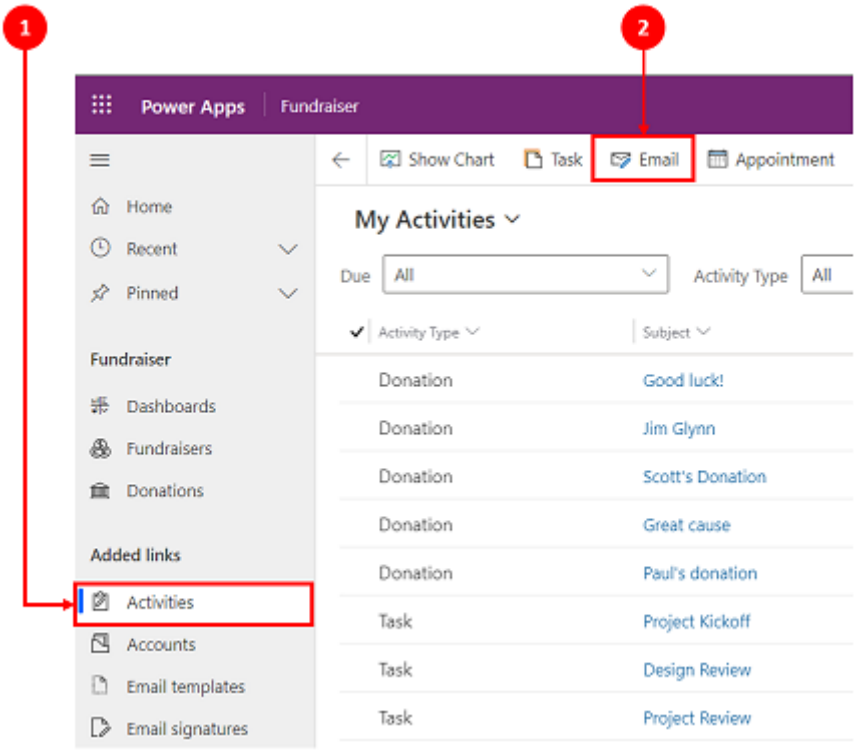
1. Select **Activities**
2. Select **All Activities**
3. Under **Activity Type** select **Email**. The email list appears in the screen.

Compose an email

Email capabilities, like rich-text editing and drag-and-drop or copy-and-paste images enriches customer interactions when composing email.

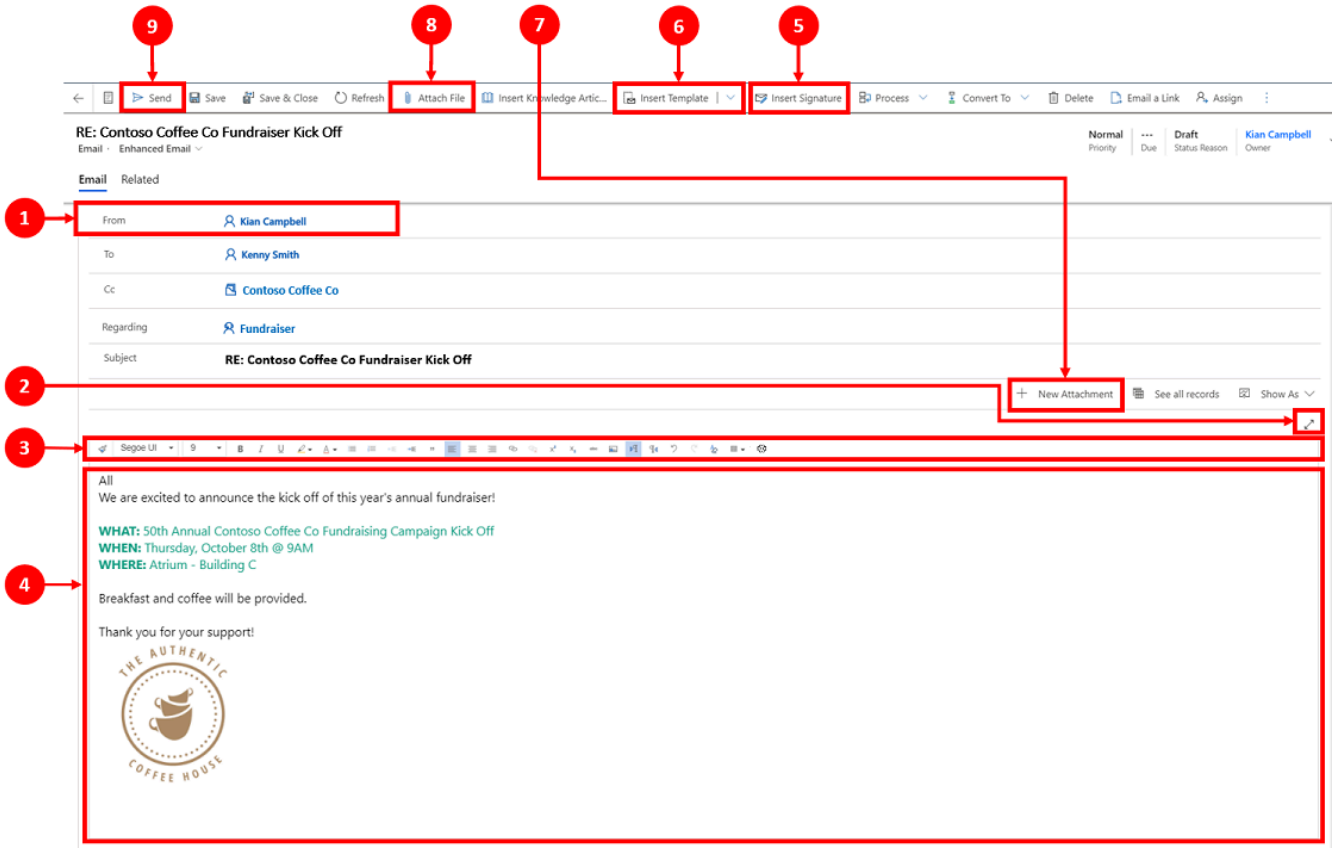
When enabled by your system administrator, you can access email from the top navigation bar.

Compose an email



1. Select **Activities**
2. On the command bar, select **Email**. An email then opens in a new window where you can begin composing.

Anatomy of an email form



Legend

1. **From**. The name displayed in the **From** field is automatically populated based on the user who is currently signed in.
2. **Expand**. The **Expand** icon allows you to compose your email in a full-screen view and minimize when done.
3. **Rich text editor**. This tool bar helps you format emails. The editor is displayed as a single line that can be expanded to view the full list of editing features by default. For more information, see Use the rich text editor toolbar in email and Accessibility shortcuts for email. **User Personalization**. The icon allows you to set the default font and font size for your emails. Once set, the **Font** and **Font Size** display these values by default.
4. **Body**. The body is where you compose and/or reply to an email.
5. **Insert Signature**. Use this command to personalize your message.
6. **Insert Template**. This function is used to apply an email template.
   For more information, see Insert an email template.

   > **Note**
   >
   > The **To** box must contain a recipient to select a template.

7. **New Attachment**. This command is used to add a file to your email.
8. **Attach File**. This command uses the 'plus' icon functionality to add attachments.

   > **Note**
   >
   > After you save your email, you can use Attach file and New Attachments interchangeably.

9. **Send**. Select this icon to **Send** your email.

   > **Important**
   >
   > - The **From** and **To** fields are automatically populated based on the user and the account and contact of the original record.

View email sentiment (preview)

[This article is prerelease documentation and is subject to change.]

When you get an incoming email from a customer, the customer sentiment card is displayed on the email form.

When enabled by your system administrator, the customer sentiment card displays the following features:

- **Current sentiment**: The customer's current sentiment. A sentiment intensity indicator in the corresponding colors is also displayed.
- **Sentiment timeline**: A visual representation that shows how the customer sentiment in the emails received changes across a period.
  The timeline displays indicators for up to six customer emails, including the current email. Customer service representatives can select historical sentiment and then select **View email**. The system shows the relevant email for that period and sentiment in a new tab.
- The **Inbox** view also displays the sentiment with the sentiment intensity indicator.

> ⓘ **Note**
>
> For emails received before the feature is enabled, the system doesn't display the sentiment.

> ⓘ **Important**
>
> - This is a production-ready preview feature.
> - Production-ready previews are subject to supplemental terms of use.

Reply to an email

The way you can reply to an email depends on where you are in your app.

When enabled by your system administrator, the email option displays in the top navigation bar and in the activities command bar.

> ⓘ **Note**
>
> The best performance is achieved when the HTML content size is 1 MB or less. When your HTML content size exceeds 1 MB, you might notice slower response times for loading and editing content. By default, image content is referenced from the content HTML but isn't

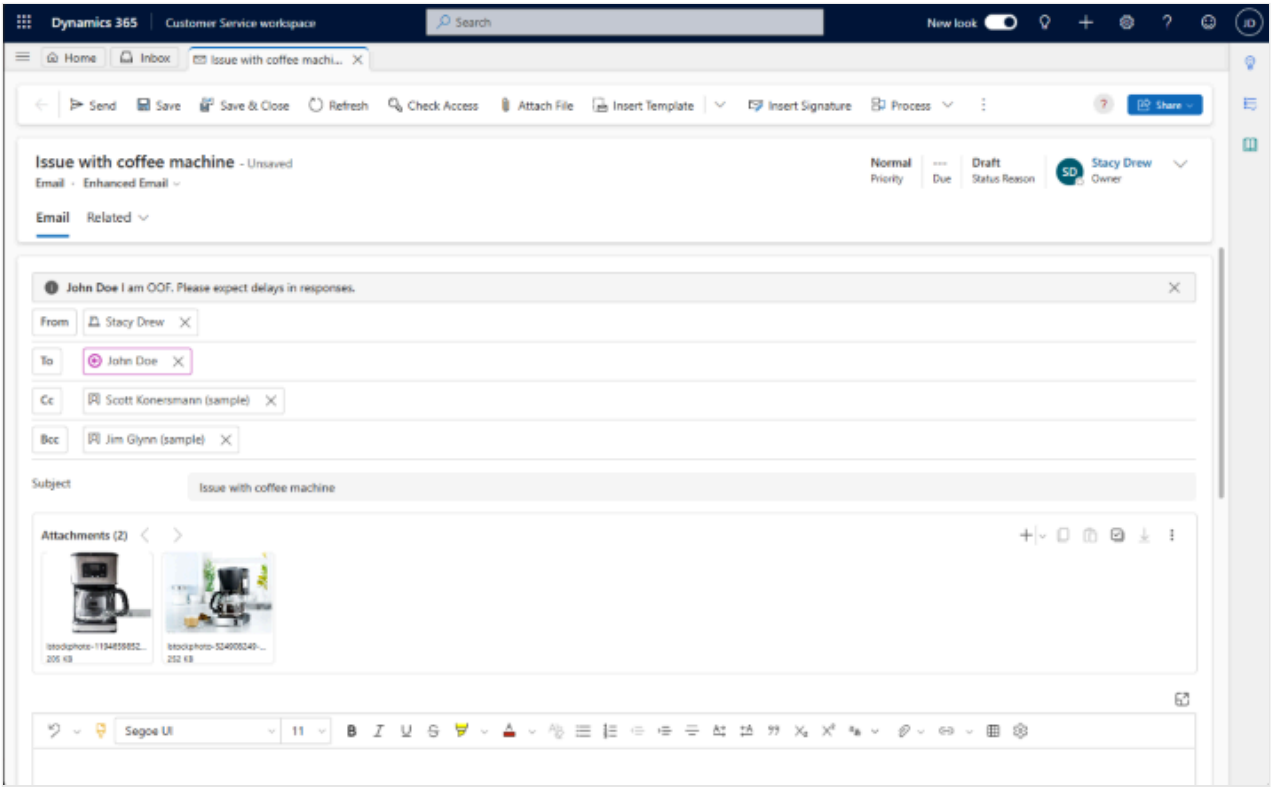
stored as part of the HTML content, so in the default configuration, images don't negatively impact performance.

Enhanced recipient handling

Users can perform the following actions only if the administrator added the **Email Recipient control** component to an email form:

- Drag and drop recipient names across **To**, **CC**, and **BCC** fields.
- View the recipient's email address along with their names.
- View the recipients' presence status and out-of-office messages.
- Resolve an unresolved email address faster. In the email editor, if there's an unresolved email address, the application displays a banner message and the **Review** option to map the email. Select the button to view and map an unresolved email address to an existing record.

  > **Note**
  >
  > You can't resolve an unresolved email address for a read-only email.



Access email

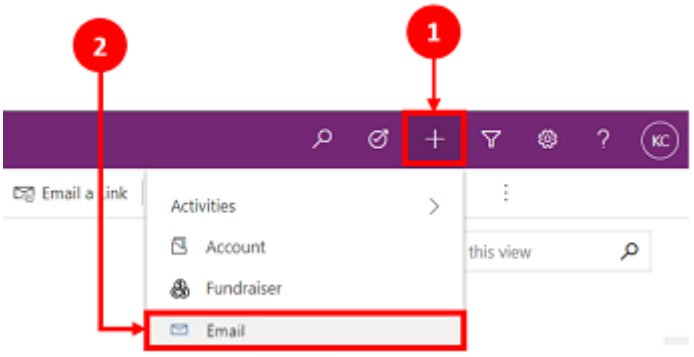
When you access email, there are a couple of options you can use.

- **Option 1:**

  - Select **Email** on the command bar.

> ⓘ **Note**
>
> Email option will only appear in the drop-down list and the command bar when enabled by your system administrator.

- **Option 2:**



1. From the navigation bar, select the plus icon.
2. Select **Email** from the drop-down menu.

Set the default font and font size

You can set the default font and font size for your email text. Perform the following steps:

- In the email editor, in the Rich text editor tool bar, select .
- In **User Personalization** specify the **Font** and **Font Size**.
- Select **Ok**. The application defaults the values specified in the Font and Font Size fields of the rich text editor toolbar.

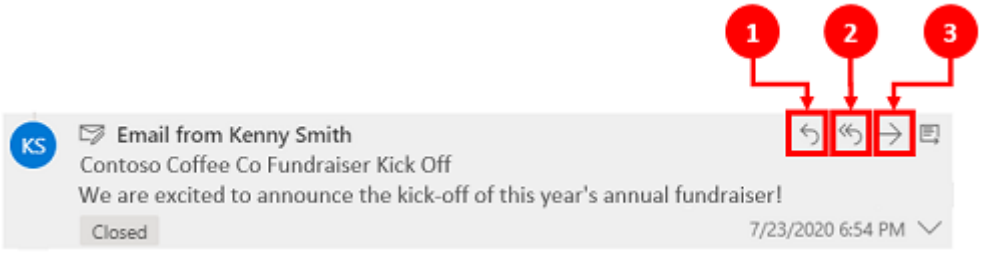
If your administrator set a default font and font size, the application displays the set values in the Font and Font Size fields of the rich text editor toolbar.

Reply to email in timeline

When you reply to an email in the timeline, the command bar in the top-right corner provides you with reply options. When you select an option, your email automatically is set and opens in

that state ready for you to begin your message.

You can use the following command options when working with emails in the timeline.



1. **Reply**. Use this command to reply directly the sender of the email you received.
2. **Reply All**. Use this command to reply to everyone on an email you received.
3. **Forward**. Use this command to forward the email to someone else.

Download email

Select **Download** to download emails as an .eml file.

Last updated on 02/04/2026

Attach a file to email

Article • 02/01/2024

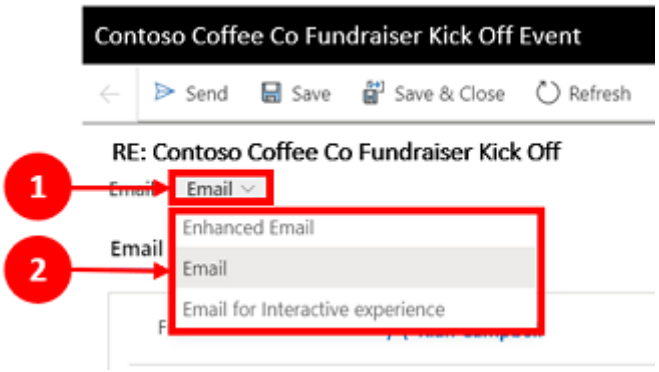
The option to attach files to an email is a useful feature when you need to share additional information. Use the **Attach file** button on the command menu or the **New Attachments** button in the email body to attach files to the email.

> **Important**
>
> - The default file size limit for an email file attachment is 5 MB. The size limitations on email file attachments can be increased by your system administrators.
> - You can't attach files to sent email messages after they have been attempted for delivery through server-side synchronization.

Work with attachments

You can attach an unlimited number of files to an email; however, there are file size limitations that are managed by your system administrator.

Enhanced email is the default email form, however you can switch forms by doing the following:



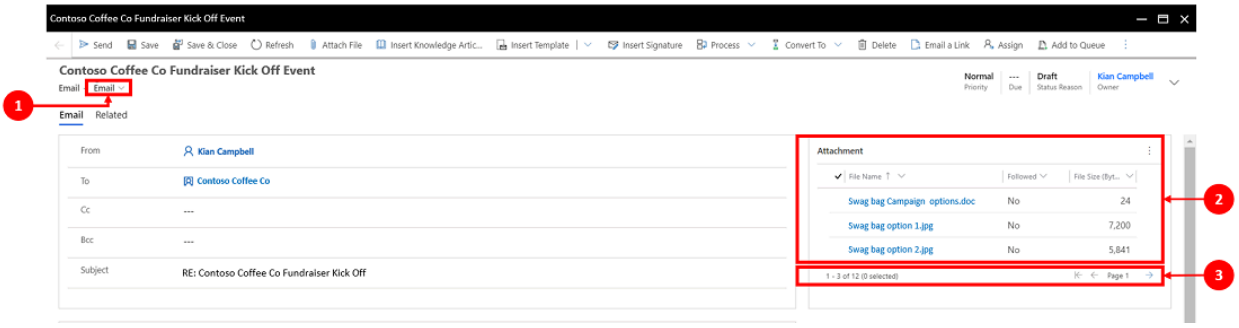
1. Under the email subject name, select on the caret (v) next to **Email**
2. A dropdown appears with a list of email form options you can choose from.

File attachments display differently, depending on the email form you're working in. You can switch email forms without losing information.

If you specify "attach" or "attachments" in the subject or the body of the email and you select **Send** without attaching a file, the application displays a warning message reminding you to attach a file.

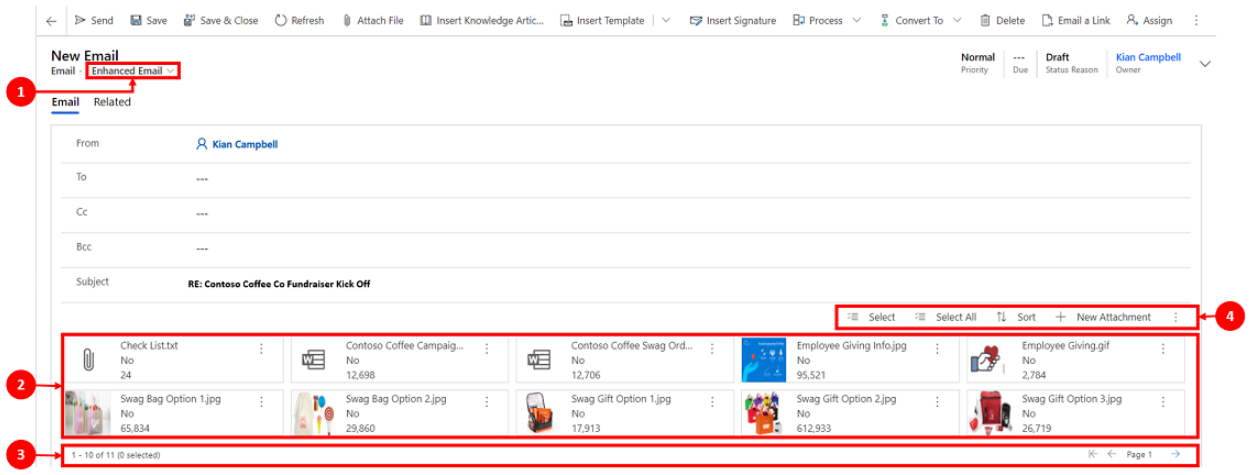
> **ⓘ Important**
>
> - The warning message reminding you to attach a file is an early access feature.
> - Early access features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Email form file attachment



1. **Email**. This display confirms which email form you're working in.
2. **Attachment**. This section displays a list of file attachments in a vertical view and only displays the first three attachments.
3. **File count**. This displays when you have more files than what can be viewed and allows you to see the total number of attached files on the left side under the last attachment with the option to page over to see more files.

Enhanced email form file attachment



1. **Enhanced Email**. This display confirms you're working in the **Enhanced email** form.
2. **Attached files**. This section displays all your email attachments in a tile view above your message horizontally. The defaulted setting for the maximum number of files that can display is five attachments before displaying the page forward functionality.
3. **File count**. This displays when you have files that occupy more than two rows and allows you to see the total number of attached files on the left side under the last attachment with the option to page over to see more files.
4. **Attachment Commands**. This allows you to use the select, select all, sort, delete, and download functionality when working with your file attachments.

Work with the attachment command bar

When you've attached one or more files to a message, you can manage them using the file attachment commands.

Select commands

Select commands allow you to select individual files or multiple files at once.

Legend

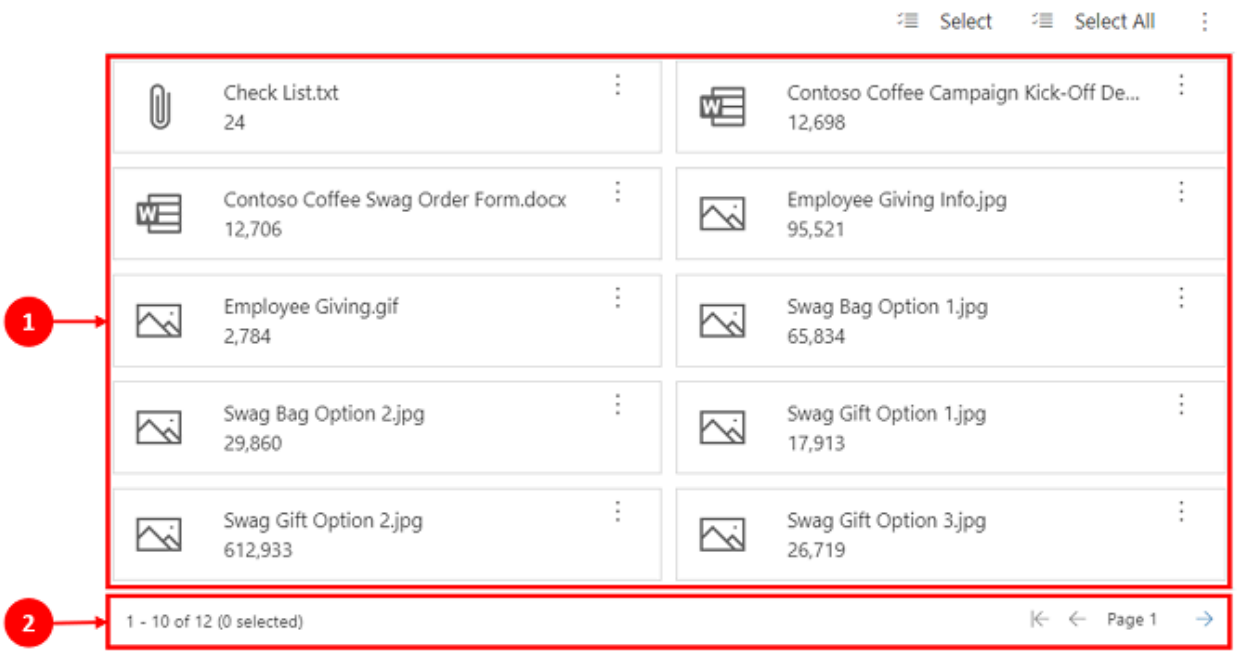
1. **Select All**. This command is located on the right, above your attached files and allows you to select all file attachments at once.

   > **Note**
   >
   > **Select All** only selects files that are visible. If you have multiple pages of file attachments, you will need to go to that page and select those files independently.

2. **Tile Color Transparency**. The background color of selected file attachments changes to light grey to identify which files have been selected.

3. **Check box** You can also verify which files have been selected by viewing whether the checkbox in the top-right corner of the file attachment is selected.

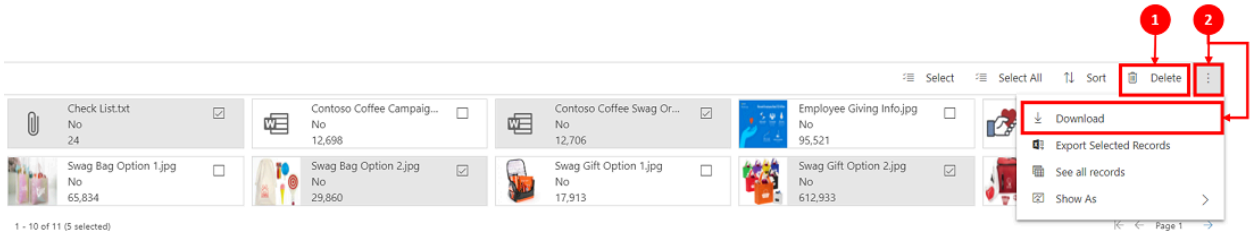
Formatting of file attachments in email can be realigned based on the device being used and format it's being worked in.



1. **Format Display** Regardless of format display, file attachments will only display the number of files that are enabled by your system administrator.
2. **Page view**. The page view displays the total number of email attachments and always is displayed under the file attachments.

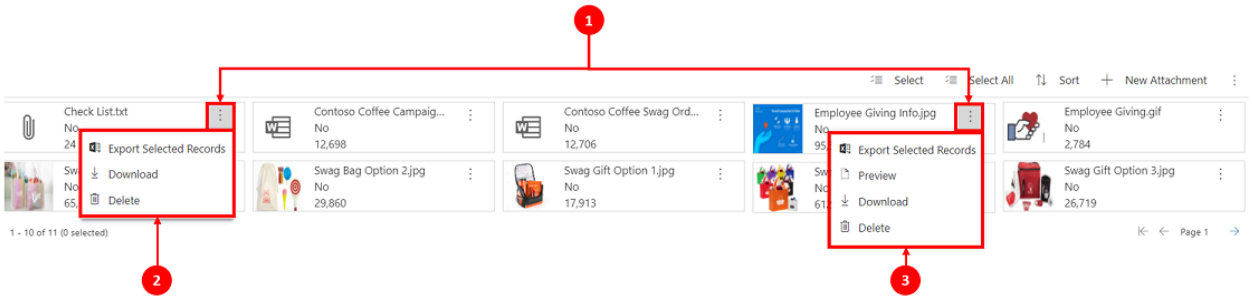
Delete and download commands

These are two of the most important commands when working with images.



1. **Delete**. This command works with the **Select** commands. You must first select a file before you can delete it. A confirmation request appears, requiring you to confirm you want to delete the file(s) you've selected.
2. **Download**. This command also works with the **Select** commands and your browser download settings, allowing you to download an individual file or multiple files at once.

Preview image attachments



1. **More options**. This command provides a list of actions for that file type.
2. **Non-preview image**. Only non-preview image types allow you to either **export selected records**, **download**, or **delete** the attached file.
3. **Preview image types**. Allow you to **export selected record**, **preview**, **download**, or **delete** the attached file. When you select the **preview** option, a pop-up window appears, displaying the image with the image name listed below.

Supported email file attachments

The following is a list of file image types that are supported:

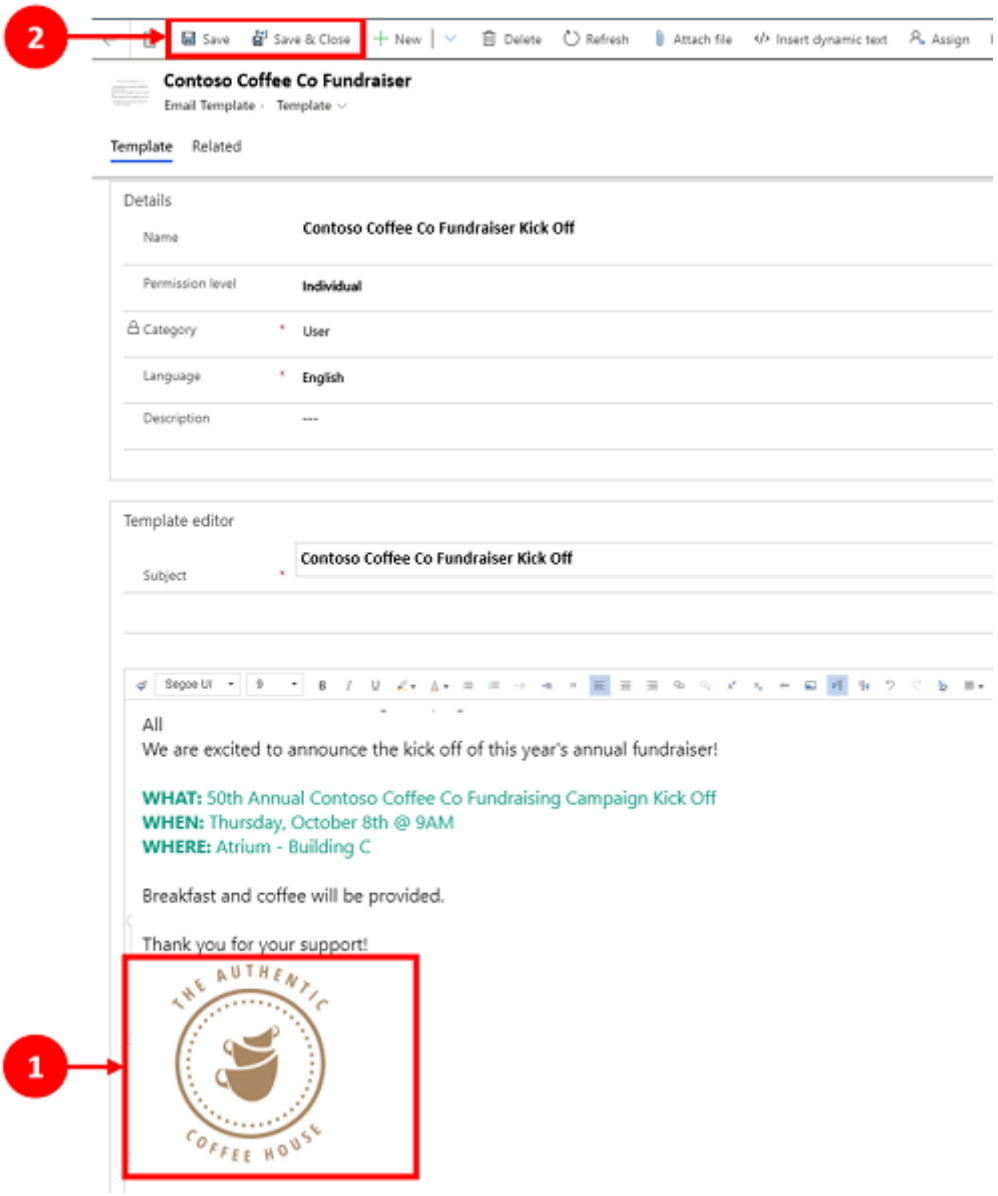
Expand table

image type	supports preview	supported inline (in editor)
BMP.bmp	Yes	Yes
GIF.gif	Yes	Yes
ICO.ico	Yes	Yes
JPG.jpg	Yes	Yes
PNG.png	Yes	Yes
SVG.svg	Yes	Yes
PDF.pdf	Yes (preview not supported on IE)	No

View and insert images in email

The use of visual aids helps users convey a tremendous amount of information with just a glance. Having the ability to view and insert inline images in email using the drag-and-drop or copy-and-paste functionality is a powerful tool for users. Additionally, you can browse to a file or reference an online URL using the image toolbar button.

You can drag-and-drop or copy-and-paste images into the email.



1. **Email images** You can adjust the image size.

2. **Save**. When you complete your edits, select **Save** or **Save & Close**.

> **Note**
>
> There's a 1 MB file size limitation when adding an inline image to an email for email templates. (For new or replied emails, there isn't a limit to the email size (it becomes part of the total email size).

Use the rich text editor toolbar in email

Article • 10/03/2022

The rich text editor toolbar provides features and functionality that allows you to work with rich text formats in emails to better communicate with your customers.

Formatting options

The following table describes the different formatting features and functionality options available in the rich text editor that you can use in the email form.

> **Note**
>
> You can access your browser's context menu by pressing **Ctrl** + right-click. This is useful if you need to use your browser's built-in spell checker. Otherwise, you can use the right-click to provide contextual formatting for any element you might be using.

Expand table

Icon	Name	Shortcut key	Description
	Format Painter	Ctrl+Shift+C, Ctrl+Shift+V	Apply the look of a particular section to another section.
	Font	Ctrl+Shift+F	Select your desired font. The default font is Segoe UI. **Note**: When you select any formatted content, the font name for that content displays. If your selection contains multiple fonts, the topmost font name of your selection is displayed.
	Font size	Ctrl+Shift+P	Change the size of your text. The default size is 9. **Note**: When you select any formatted content, the font size for that content displays. If your selection contains multiple font sizes, the topmost font name of your selection is displayed.
	Bold	Ctrl+B	Make your text bold.
	Italic	Ctrl+I	Italicize your text.

Icon	Name	Shortcut key	Description
	Underline	Ctrl+U	Underline your text.
	Text Highlight Color		Make your text stand out by highlighting it in a bright color.
	Font Color		Change the color of your text.
	Bullets		Create a bulleted list.
	Numbering		Create a numbered list.
	Decrease Indent		Move your paragraph closer to the margin.
	Increase Indent		Move your paragraph farther away from the margin.
	Block Quote		Apply a block-level quotation format in your content.
	Align Left	Ctrl+L	Align your content with the left margin. (Commonly used for body text to make it easier to read.)
	Align Center	Ctrl+E	Center your content on the page. (Commonly used for a formal appearance.)
	Align Right	Ctrl+R	Center your content on the page. (Commonly used for a formal appearance.)
	Link		Create a link in your document for quick access to web pages and files. Pasted or typed URL text is converted into a link. For example, "http://myexample.com" will become "http://myexample.com ". In the **Link** dialog box, choose the type of link you'd like to insert. The **Link Info** tab allows you to choose the link type as well as set the link protocol and URL. The **Target** tab is only available for the URL link type. It specifies the location where the link will open after you select it.
	Unlink		Delete a link in your email or document. When you place the cursor on a link, the **Unlink**

Icon	Name	Shortcut key	Description
			button on the toolbar becomes active. Select the button to remove the link and make it plain text.
	Superscript		Type very small letters just above the line of text.
	Subscript		Type very small letters just below the line of text.
	Strikethrough		Cross out text by drawing a line through it.
	Insert Image		You can insert an image by directly copying and pasting it inline in the editor, dragging and dropping it from your desktop or local folder directly into the editor, or by typing a URL. The following formats are supported: .PNG, .JPG., or .GIF. To insert an image inline in your article: 1. Drag and drop the image or copy and paste it directly into the article. 2. Drag any corner of the image to resize it. To insert an image using a URL or navigating to the local image: 1. Choose Insert Image. 2. In the **Image** property dialog, choose from the following options: • Select **Browse** to navigate to the image on your computer. • Or specify the web address of the image, and properties to define how the image will appear in the email or article. **Note:** ◦ If the image is located on the external server, use the full absolute path. ◦ If the image is located on a local server, you can use a relative path. ◦ If you want the image to be linked to a target, add a URL for the image. ◦ You can also specify if you want the targeted page to open in a new window, topmost window, same window, or parent window.
	Left to Right		Change the text to left-to-right for content such as a paragraph, header, table, or list. Commonly used for bi-directional language content. This is the default setting.

Icon	Name	Shortcut key	Description
	Right to Left		Change the text to right-to-left for content such as a paragraph, header, table, or list. Commonly used for bi-directional language content. The default setting is left-to-right.
	Undo Typing		Undo changes you made to the content.
	Redo Typing		Redo changes you made to the content.
	Clear All Formatting		Remove all formatting from a selection of text, leaving only the normal, unformatted text.
	Add a Table		Add a table to your content. After adding a table, you can do any of the following: • Resize table columns by clicking and dragging your mouse to resize to the columns to the desired width. • Select one or several cells within a table and apply specific formatting, add links to the selection, or cut, copy, or paste entire rows or columns. • Right-click to access the properties. This supports features such as cell type, width and height, word wrapping, alignment, merging and splitting cells horizontally and vertically, inserting or deleting rows and columns, row and column span, and cell and border color.
	User personalization		Select the default Font Name and Font Size. After they're added, the **Font** and **Font Size** reflect these values as default font and font size.
	Expand Toolbar		Displays when the toolbar is collapsed and not all options appear. Click to expand the toolbar and make all options visible.

> **Note**
>
> You can access your browser's context menu by pressing **Ctrl** + right-click. This is useful if you need to use your browser's built-in spell checker. Otherwise, you can

use the right-click to provide contextual formatting for any element you might be using.

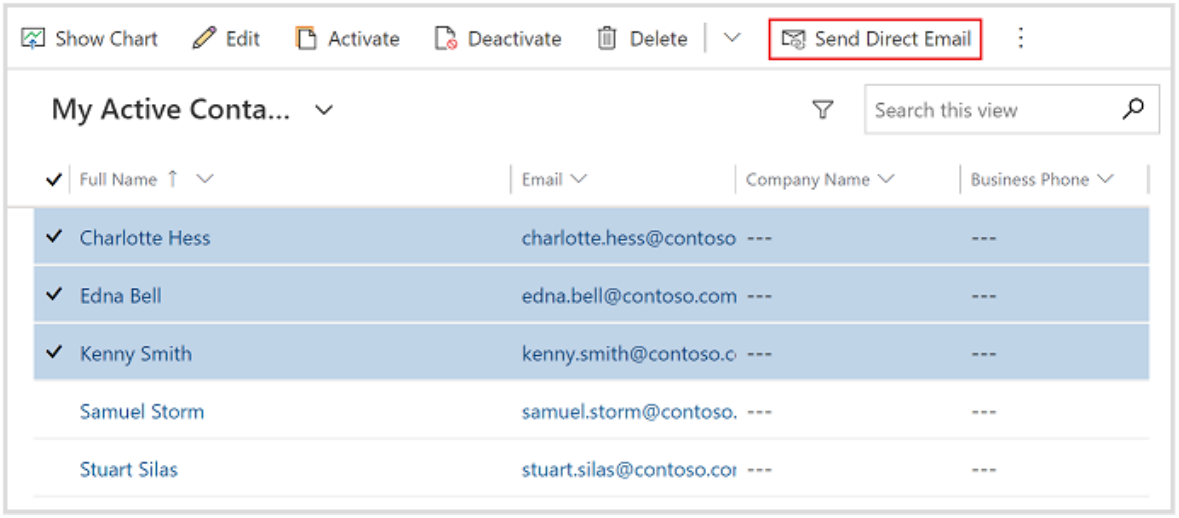
Send email to multiple recipients

Article • 02/15/2022

You can send an email to multiple recipients by using email templates. This is known as *direct* or *bulk* emailing. By default, the direct email feature is disabled. An administrator must enable the direct email feature by selecting **Yes** for **Enable Send Direct Email Action in Unified Interface for Send Email enabled tables** on the **Email** tab in the **System Settings** dialog box. More information: System Settings Email tab

To send email to multiple recipients

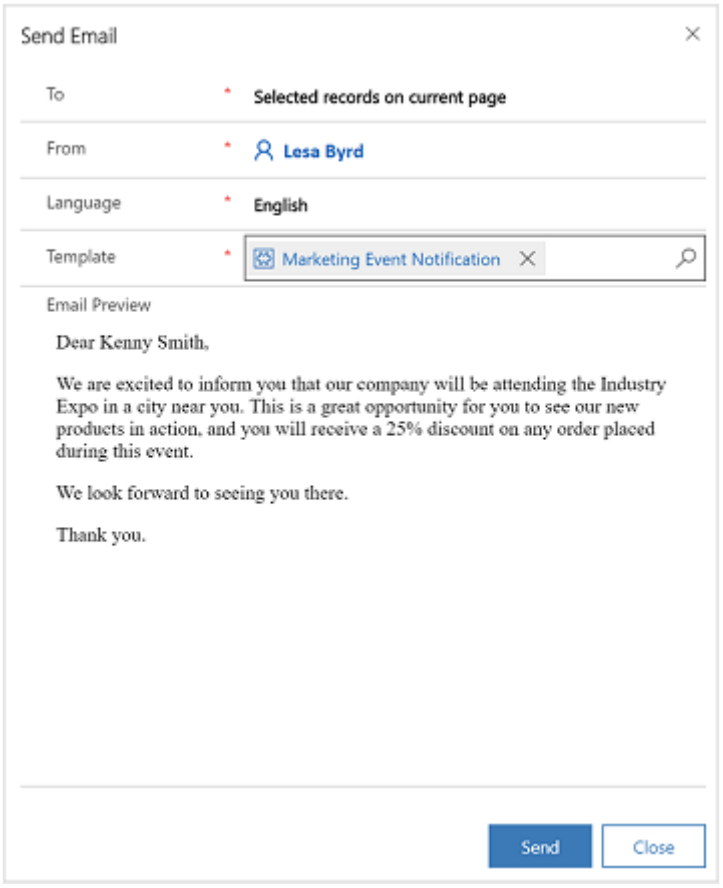
1. In the site map for the model-driven app, select a table to which you want to send email. For example, **Contacts**.
2. In the list of rows, select the contacts you want to send an email to.
3. On the command bar, select **Send Direct Email**.



4. In the **Send Email** pane, select an email template from the **Template** list.

> **Note**
>
> - If you have multiple rows that span multiple pages, you can select one of following options from the **To** list:
>   - **All rows on current page**: Sends the email to all rows displayed on the current page.
>   - **All rows on all pages**: Sends the email to all the stored rows.
> - If a few rows don't have an email address or they have an invalid email address, those rows will be skipped from sending the email.

5. Select **Send**.

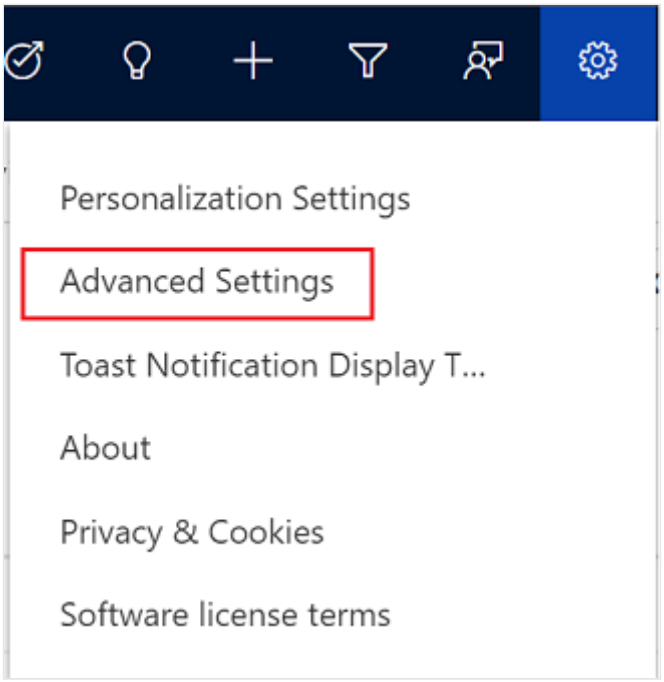


Check the status of bulk email action

You can check the status of bulk email action on the **System Jobs** page. You can see whether the bulk email job has failed or succeeded. If a job has failed, you can open the failed job to see its details.

To check the bulk email status

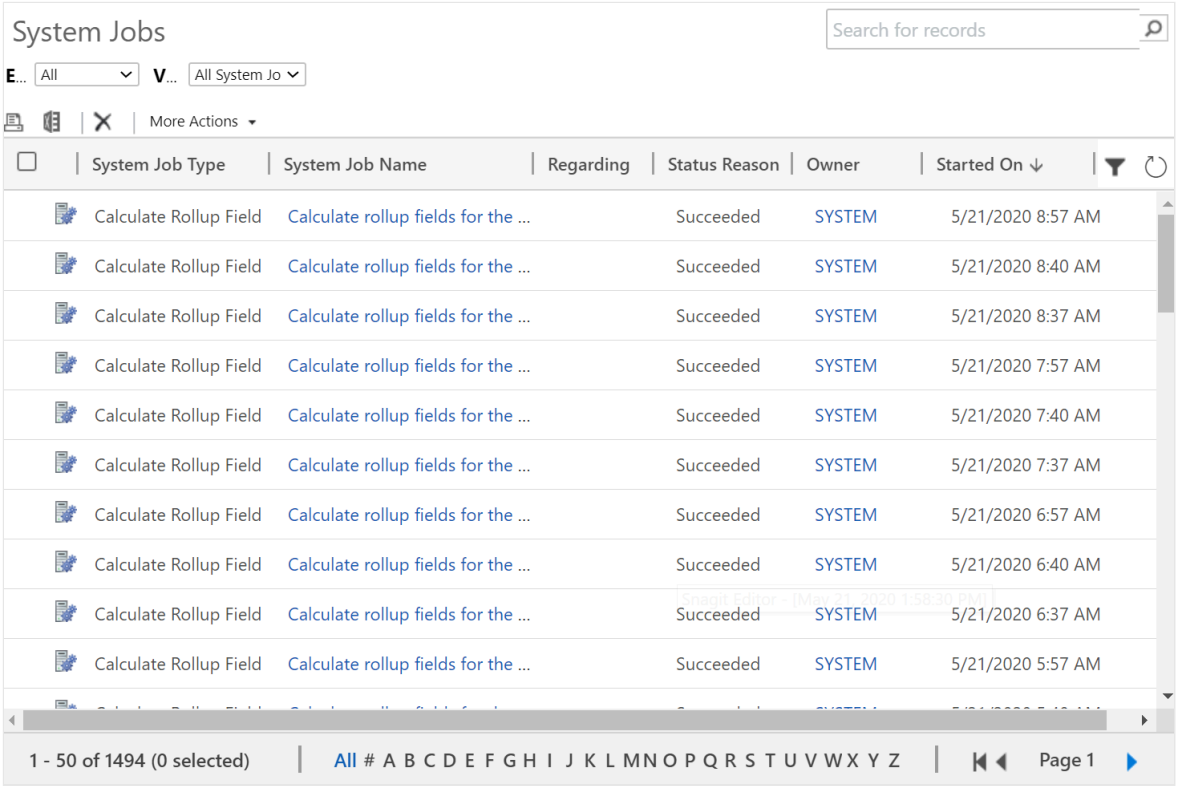
1. In your app, select the **Settings** icon, and then select **Advanced Settings**.



The **Business Management** page opens in a new browser tab.

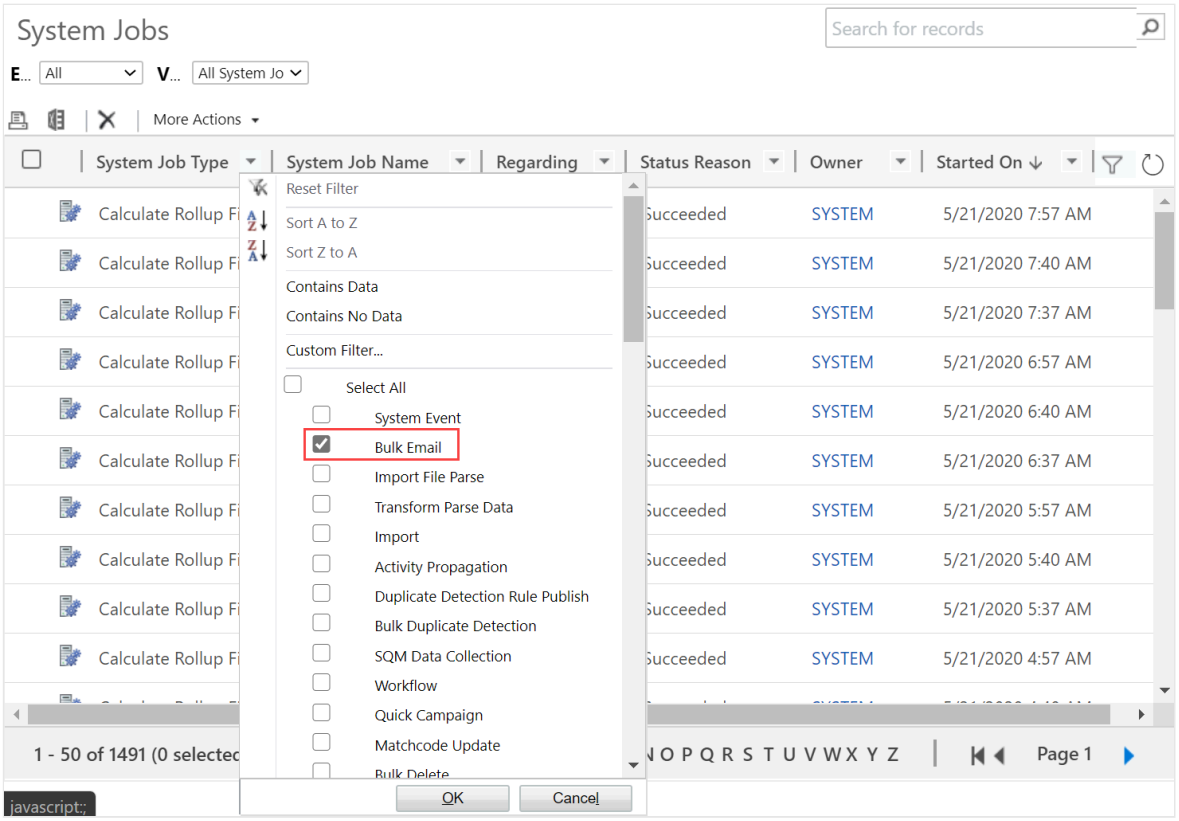
2. On the navigation bar, select **Settings**, and then under **System**, select **System Jobs**.

   A list of system jobs is displayed.

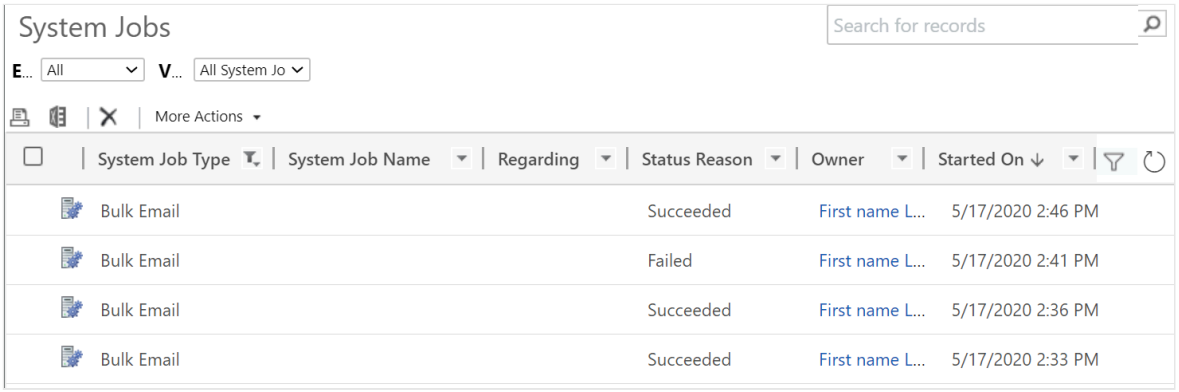


3. In the grid header, select **Filter** .

4. In the **System Job Type** column header, select the down arrow, select **Bulk Email**, and then select **OK**.



Bulk email jobs are displayed with their corresponding status.



5. Double-click the failed job to see its details.

Resolve an unresolved email recipient

Article • 02/15/2022

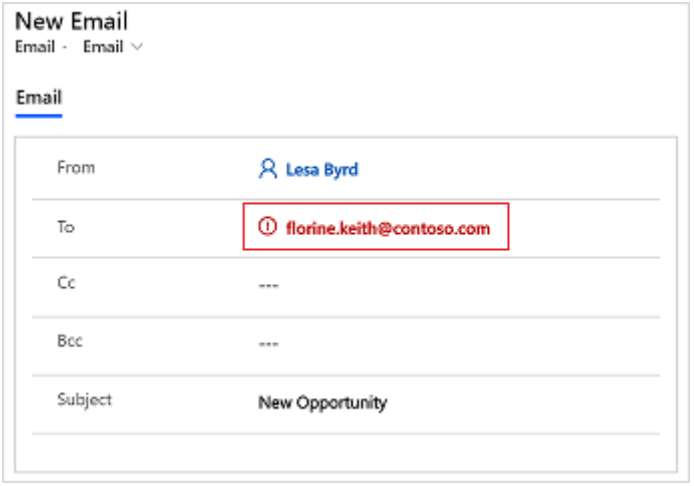
An *unresolved email recipient* is one whose email address isn't associated with any table rows in Microsoft Dataverse. By default, you can't send an email to an unresolved email recipient. If you enter an unresolved email recipient address, the email address is deleted as soon as you move the focus out of the **To**, **Cc**, or **Bcc** column. An administrator must enable the unresolved email recipient feature by selecting **Yes** for **Allow messages with unresolved email recipients to be sent** on the **Email** tab in the **System Settings** dialog box. More information: System Settings Email tab

After the feature is enabled, you can add an unresolved email recipient in the **To**, **Cc**, or **Bcc** column. The entered email address is shown in red. You can then select the email address and associate it with a table row in Dataverse without navigating away from the email form.

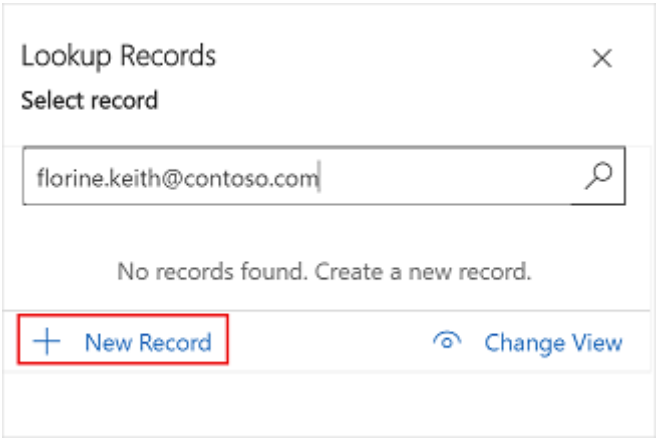
If you receive an email that has email addresses that aren't associated with a table row, the email addresses are shown in red. You can then individually select the email addresses and associate them with a table row. You can then send emails to the newly added email addresses.

To resolve an unresolved email recipient

1. Open the email editor and select the unresolved email recipient.

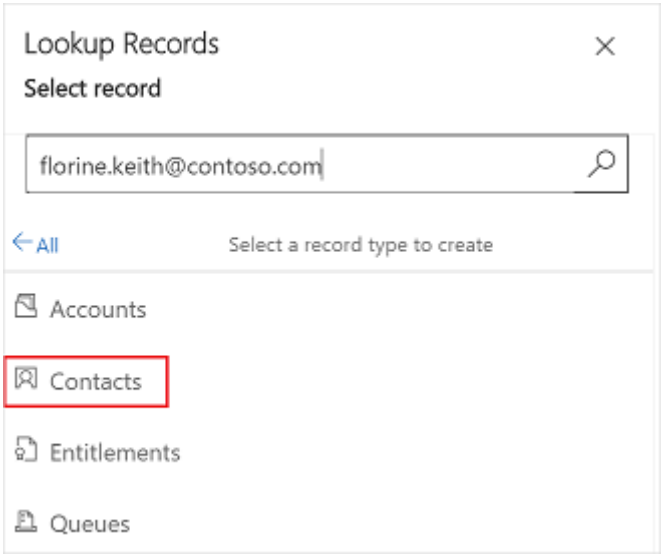


2. In the **Lookup Rows** pane, select **New Row**.

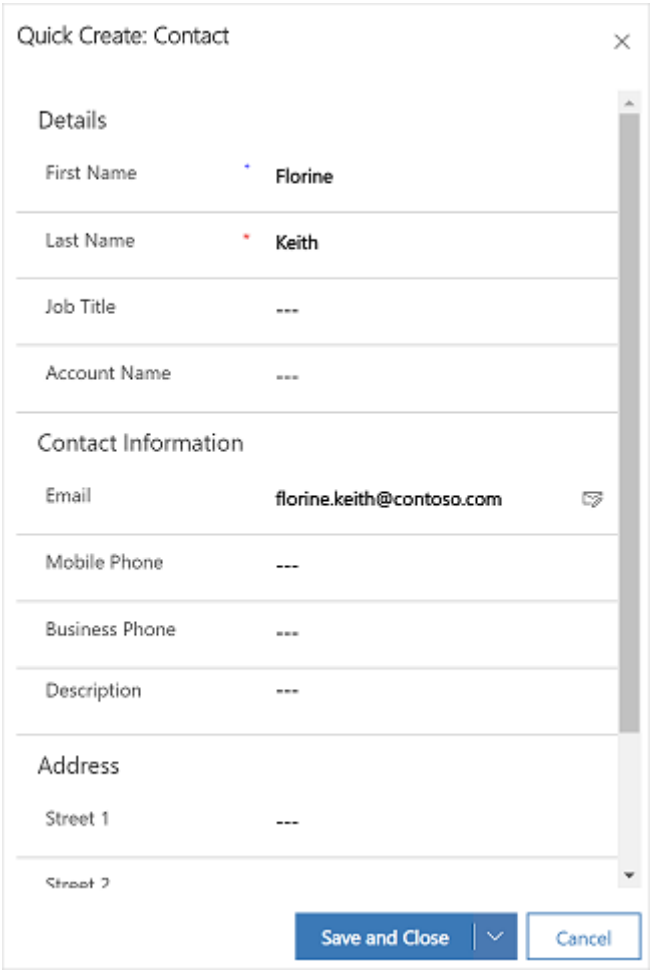


> **Note**
>
> If rows are displayed in search results, you can resolve the email to one of the existing rows.

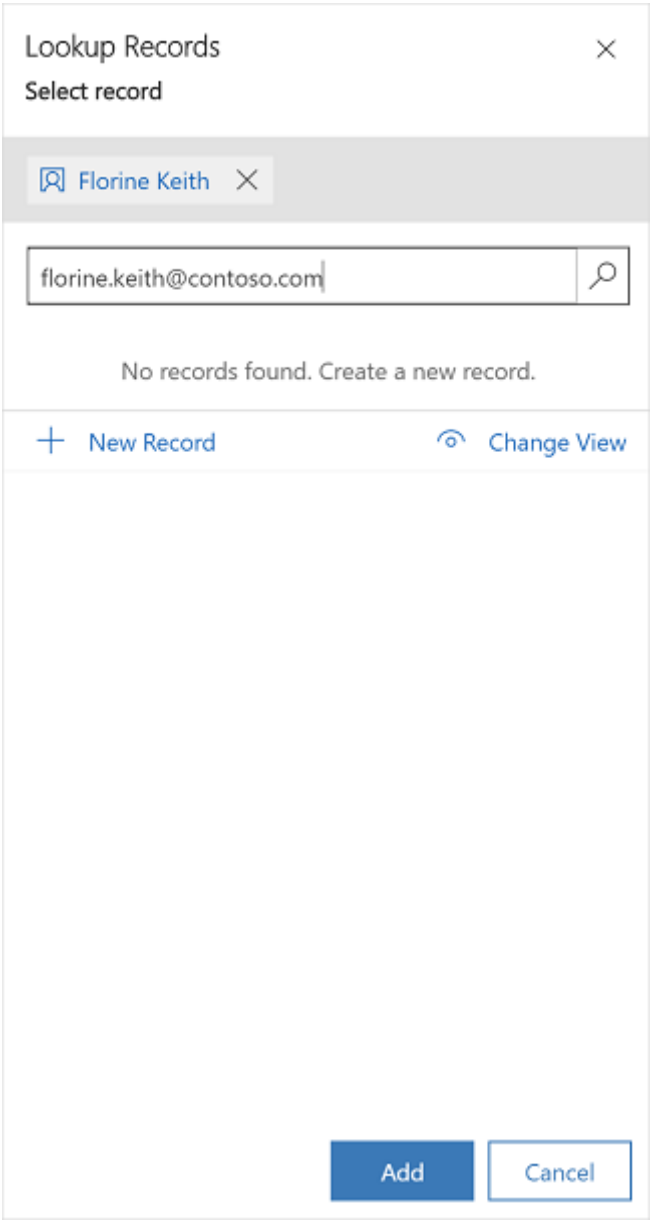
3. Select the row type to create. For example, **Contacts**.



4. In the **Quick Create: Contact** pane, enter the required details, and select **Save and Close**.



5. The contact is created and selected in the **Lookup Rows** pane. Select **Add**.



6. The unresolved email recipient is resolved and shown in the **To** column in the email editor.

Email FAQs and known issues

Article • 02/15/2022

Find answers to common questions regarding the email experience features and functionality, configurations, and other key concepts.

Email content is lost after entering text in the body of the message

Issue: Recent content added to the email may get lost if you enter text in the body of an email and immediately select **Save**, **Save and Close**, or **Send**.

Resolution: To avoid this issue, wait a few seconds before you select **Save**, **Save and Close**, or **Send** after you enter text in the body of the email.

The From column is read only or lookup isn't working

Issue: The **From** column in an email form is read-only or you can't look up rows and filter results by **User** or **Queue**.

Resolution: This happens when customization specifically have been applied on this column by your system administrator. To fix the issue, open a browser window and run the following two commands replacing the **environment URL** with the URL of your environment.

- (replace with your environment URL)/api/data/v9.1/RemoveActiveCustomizations(SolutionComponentName='AttributeLookupValue',ComponentId=(25E9AF0C-2341-DB11-898A-0007E9E17EBD))
- (replace with your environment URL)/api/data/v9.1/RemoveActiveCustomizations(SolutionComponentName='AttributeLookupValue',ComponentId=(26E9AF0C-2341-DB11-898A-0007E9E17EBD))

To find the URL, in the address bar the first part of the URL that starts with **https://** and ends with **.com** is your environment URL. For more information on how to find the environment URL, see Get the environment UR.

I've enabled an email form but it doesn't display.

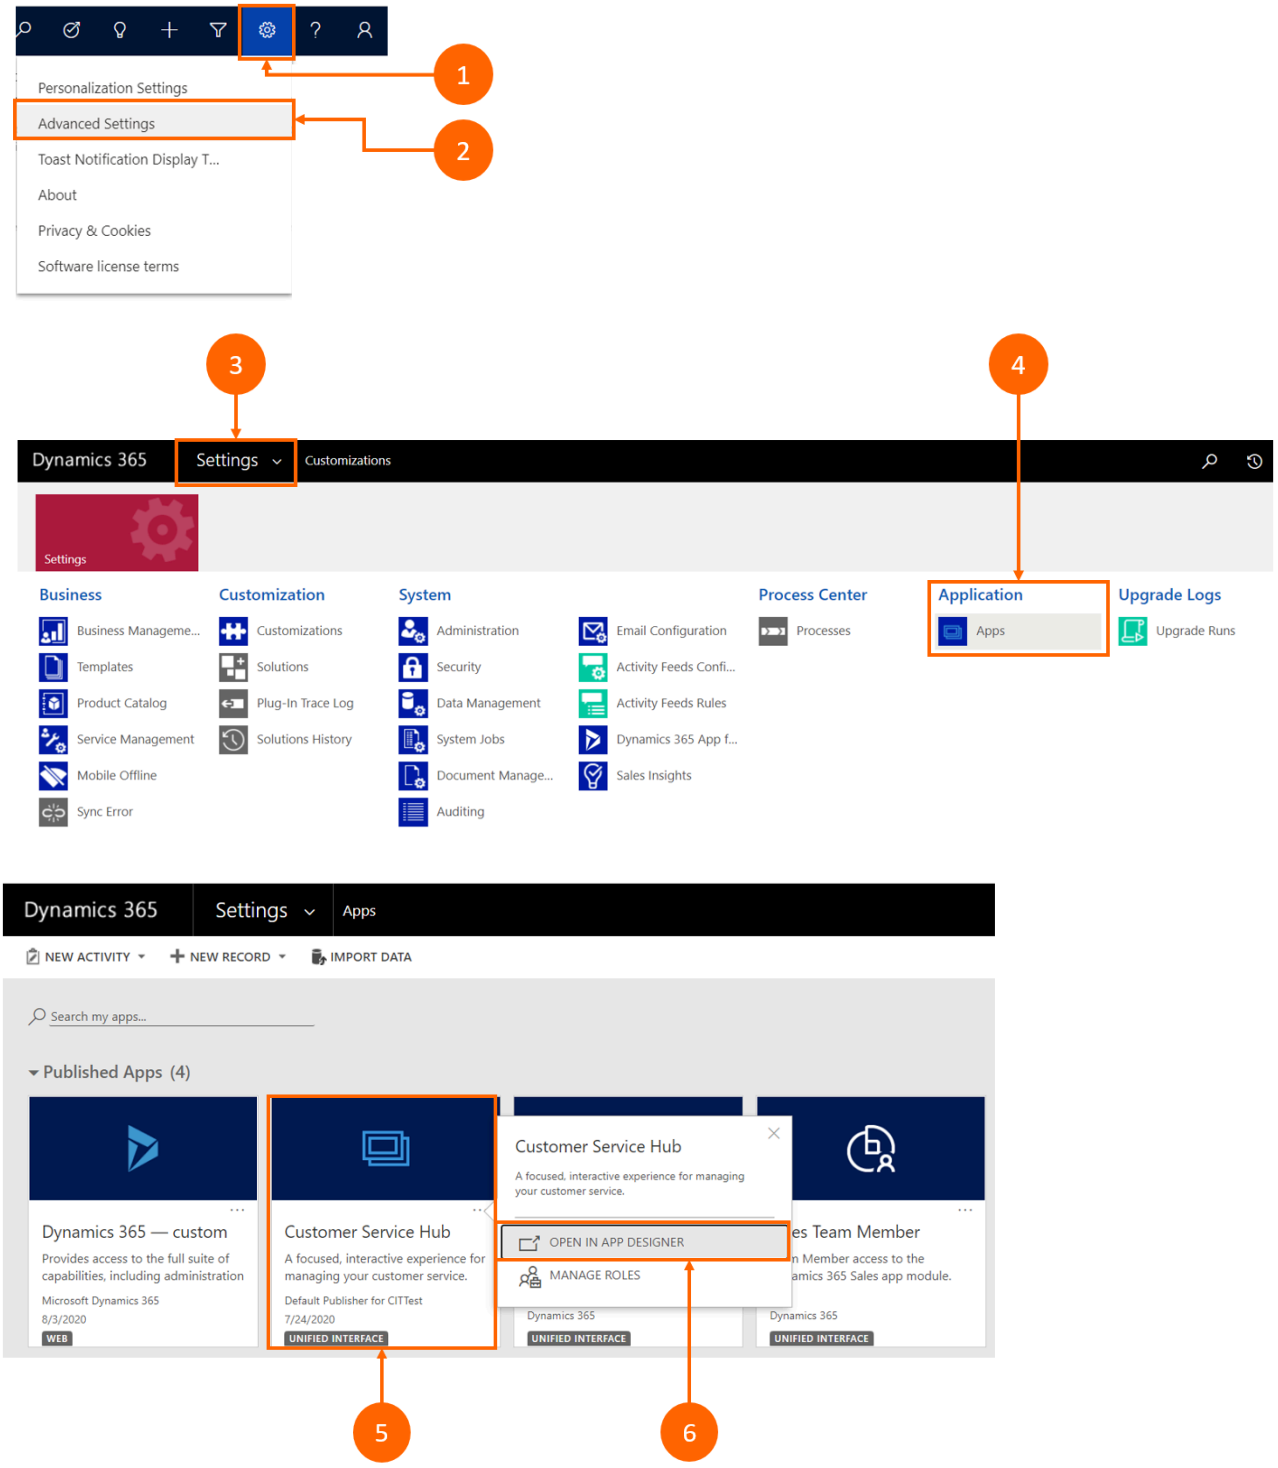
If you've enabled an email form but it is doesn't display, you'll need to enable it in the **App Designer** by doing the following:

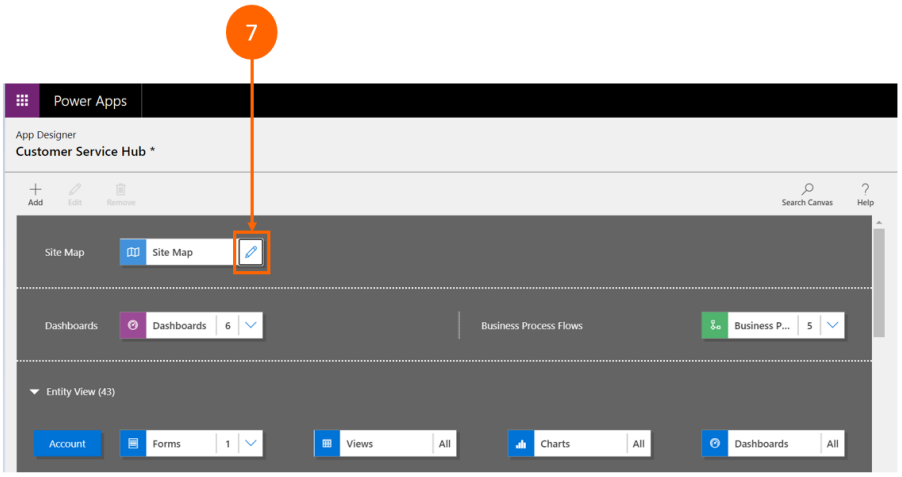
1. Go to **Settings** > **Advanced Settings**.
2. Select **Settings**.
3. In **Application** settings, select **Apps*.
4. Select ⋮ **More Options** on **Customer Service Hub**.
5. On the **App Designer** drop-down menu, select **Open**.
6. On the site map, select the edit feature.
7. Under the **Email** form selector, select the drop-down menu to display the **Email** forms you have enabled.

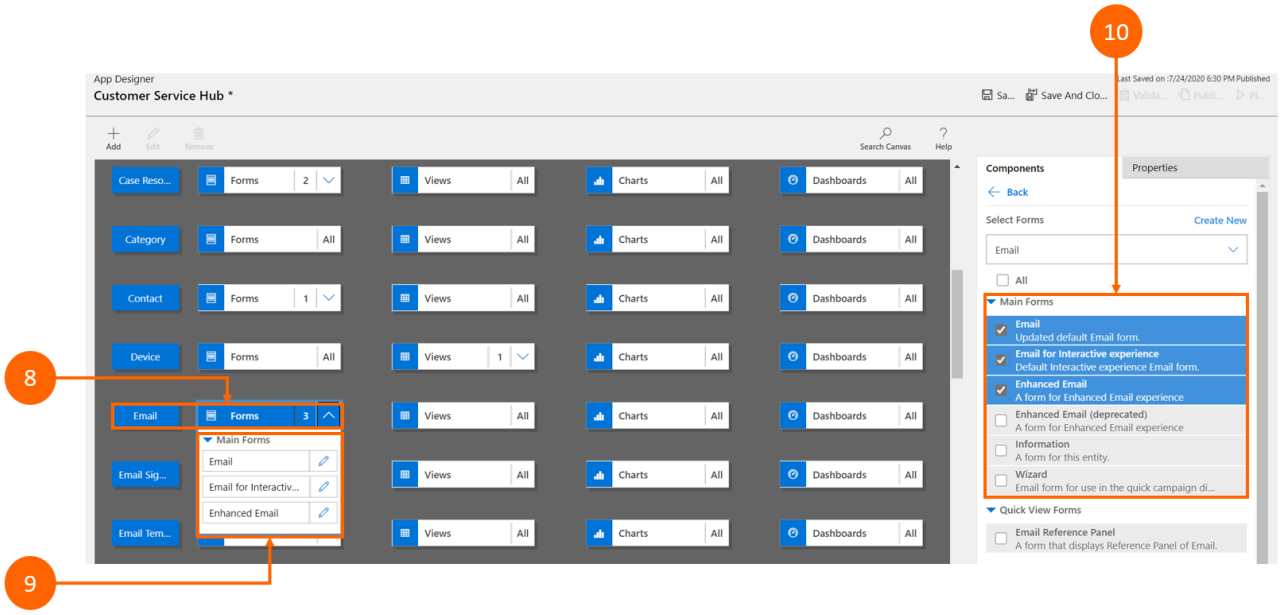
If the form isn't displayed in the list, it hasn't been enabled.

8. To enable a form, go to **Main Forms** and select the form.

> **Note**
>
> You can't change the display order under **Main Form**. You must go back to the **Form Order** to change the display order.







9. Add the email template and signature link to the site navigation by going to the site map and doing the following:

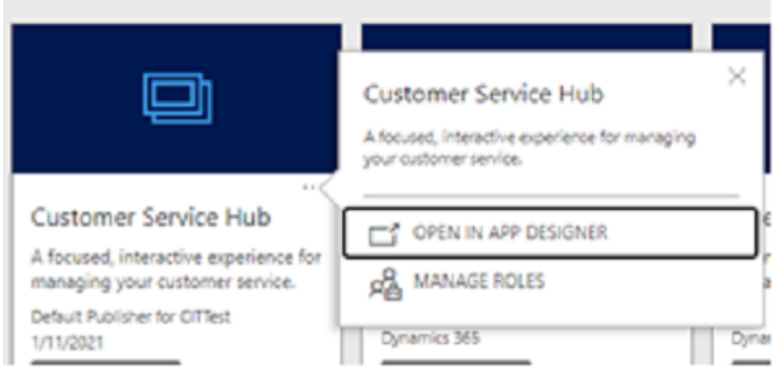
   a. Go to **Settings** > **Advanced Settings**.

   b. Select **Settings**.

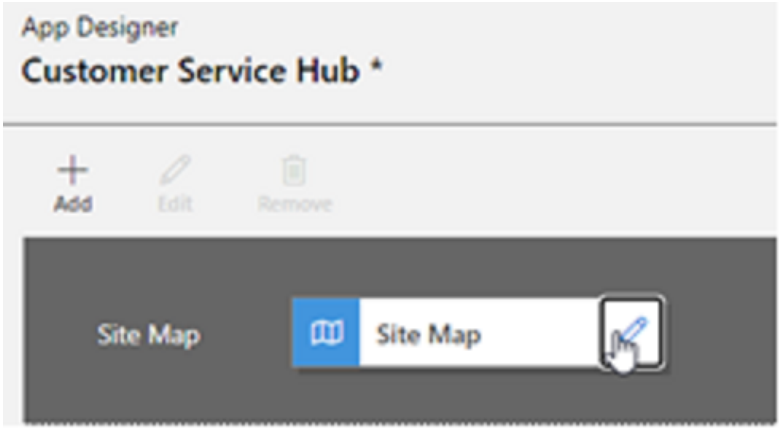
   c. In **Application settings**, select **App*.

   d. Select **More Options** on the **Customer Service Hub** tile.

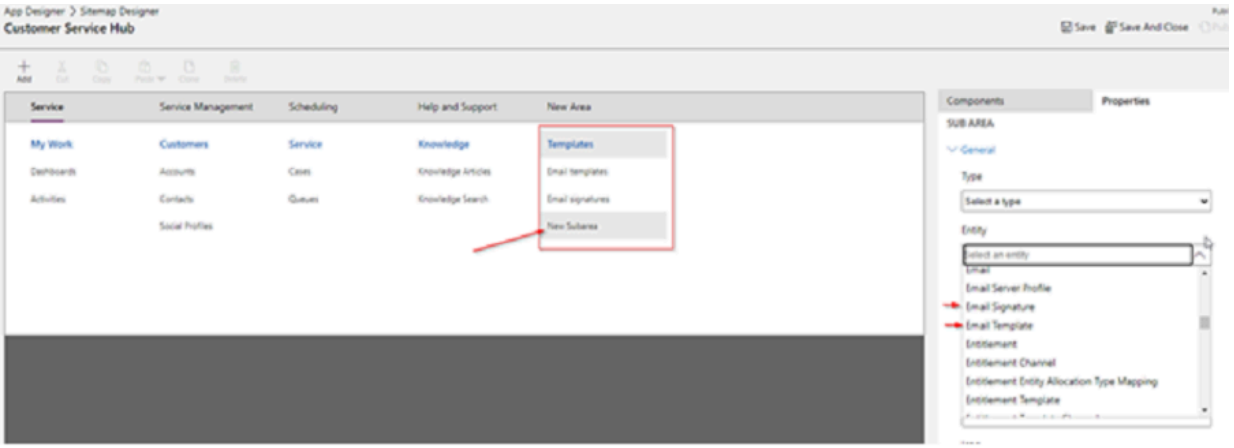
   e. Select **OPEN IN APP DESIGNER**.



f. Select the pencil icon to edit.



g. When the site map opens, create a new group for templates by selecting **New subarea**.



h. Select **email templates** or **email signature**.

i. Add a title. (This is the name that will show instead of **New subarea** when saved.)

j. Save and publish. A link is added to the site map.

Create email templates

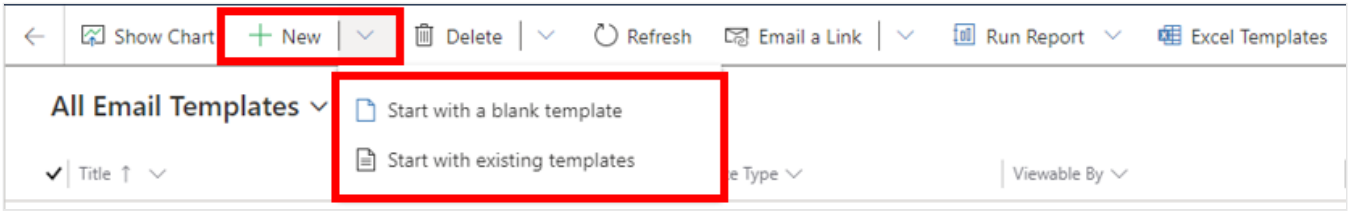
06/03/2025

> **Important**
>
> - As of May 23, 2025, the following functionalities will no longer be available:
>   - The enhanced email template and legacy rich text editor.
>   - The drag and drop functionality of the enhanced email template editor.
> - The modern rich text editor supports HTML formatting. Any existing templates created using the enhanced email template editor will now open in the modern rich text editor. If you any see any formatting issues, we recommend that you update or recreate the template using the modern rich text editor.

Email templates are a fast and easy way to send consistent, professional, preformatted email messages to your customers.

You can create email templates by using one of the following options:

- **Start with a blank template**: Create a template from scratch.
- **Start with an existing template** : Create a template by choosing an existing template.



Prerequisites

When you need to create an email template based on a table, make sure that you have the necessary permissions on the related tables, such as the Account table for the email template based on a case.

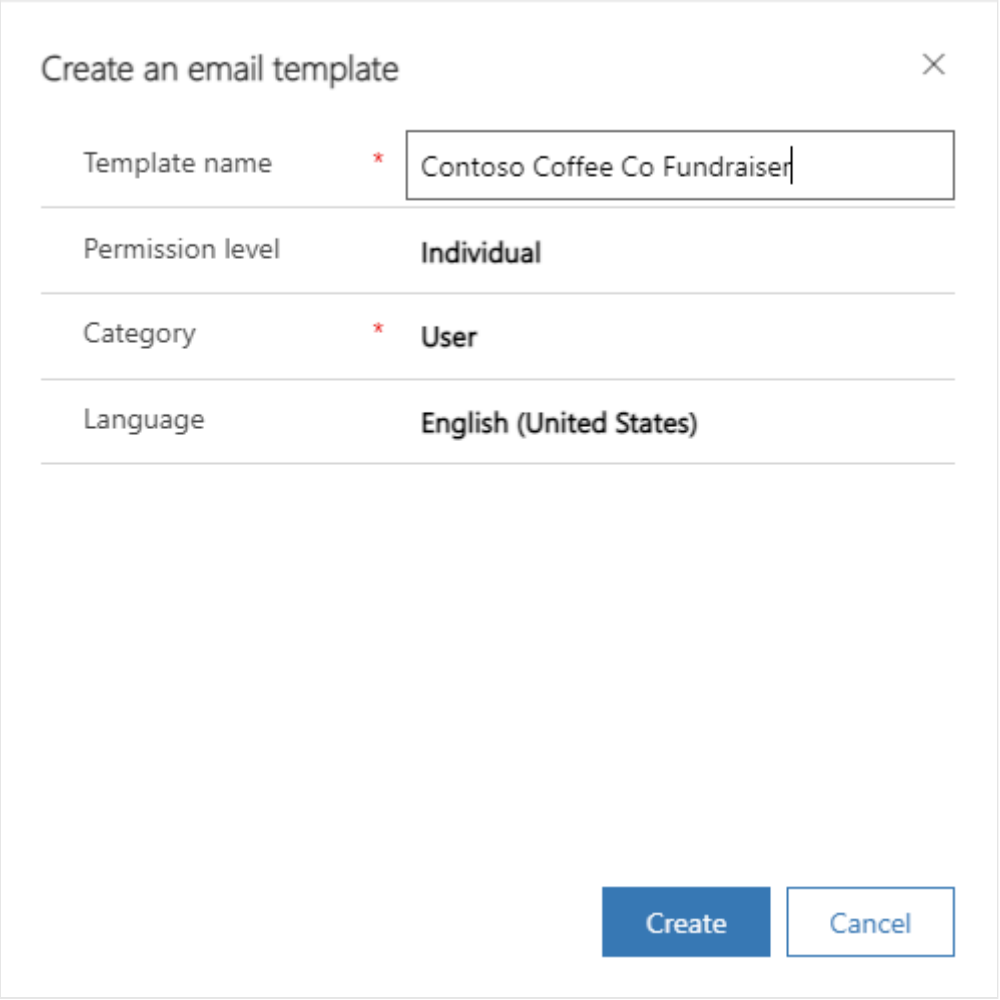
Start with a blank template

When you start with a blank template, nothing is provided for you. You must add everything you want customers to see.

1. On the **Email Templates** command bar, select **New**, and then select **Start with a blank template**.

2. Enter the following details:

   - **Template name**: Give your email template a detailed name to help you identify it later.
   - **Permission level**: Select from **Organization** or **Individual**. More information: Permission level for email templates
   - **Category**: The default value is **User**. Categories determine which dynamic text fields are available for use in your template.
   - **Language**: Display installed language packs. **Language** also helps to categorize your templates.
   - **Create**: Opens one of two editors where you can build your template.



3. Select **Create**. The template editor is displayed.

Permission level for email templates

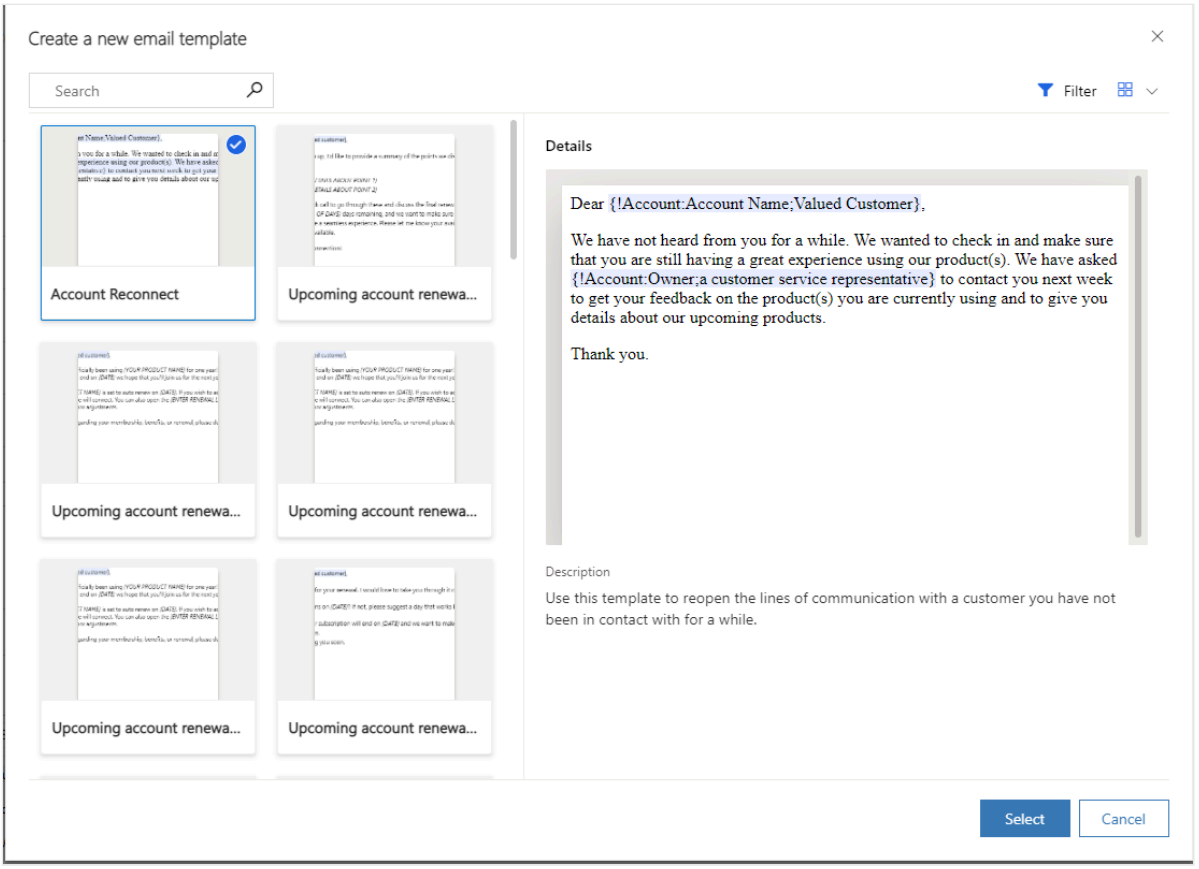
Selecting **Organization** permission level for email templates allows you to create templates that everyone in the organization can use. **Individual** permission level is for personal use.

> **Note**
>
> For **Individual** permission templates, these templates do not show up on the list of email templates unless your are the owner of the templates or the owner has shared the template with you.
>
> For **Organization** permission templates, these templates show up for all users in the organization.

Start with existing templates

Start with an existing template to create an email template faster and with less effort. The template is pre-populated with data. All you need to do is customize it for your needs.

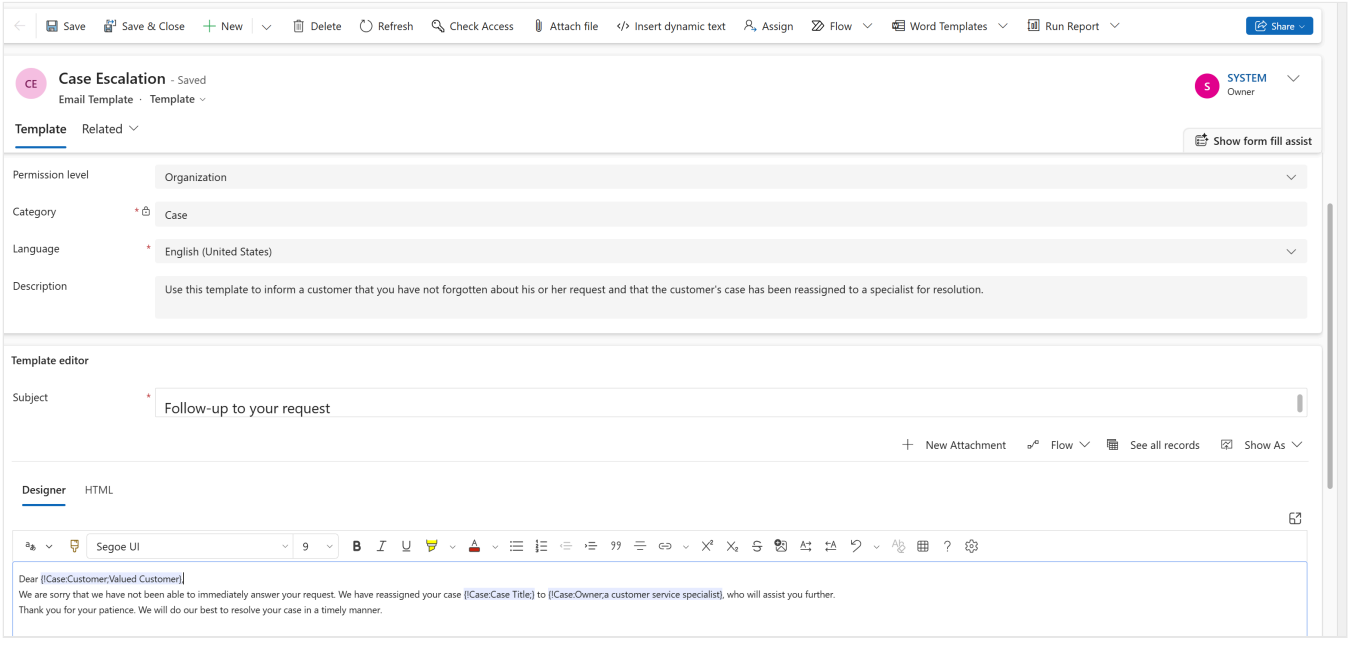
1. On the **Email Templates** command bar, select **New**, and then select **Start with existing templates**.
2. Enter the following details:
    - **Search**: Search for the name of a template to start from. Search doesn't support regular expressions.
    - **Browse** out-of-the-box templates, global and entity-specific, listed in alphabetical order. Global templates are shown as the type User. If you've created custom email templates, they're also listed.
    - **Details**. Preview the templates so that you can pick the one that best meets your needs. You can modify it as needed later.



3. The template editor page is displayed.

Email template editor

You can use the email template editor to to create a new email template or edit an existing template.



- **Designer** tab: Use this tab to draft and apply standard formatting to your email template. You can also add dynamic text, images, and attachments. You can add Copilot prompts to

your email template for a consistent experience. Learn more in Add Copilot prompts to email template.

> **Note**
>
> Across all the model-driven apps, the email template editor supports upto 1048576 characters.

- **HTML** tab: Use this tab to view and edit the HTML code of your email template. You can add HTML code to customize your templates with elements such as layouts, images, and buttons.
- **Template** tab: Specify or change the template details and the email subject.
- **Attachments** tab: Add attachments to your template if needed.

Personalize emails with dynamic text

Article • 03/05/2025

Generic greetings like "Dear customer" make customers less likely to engage with your emails. Personalize your outreach instead with dynamic text in your email templates.

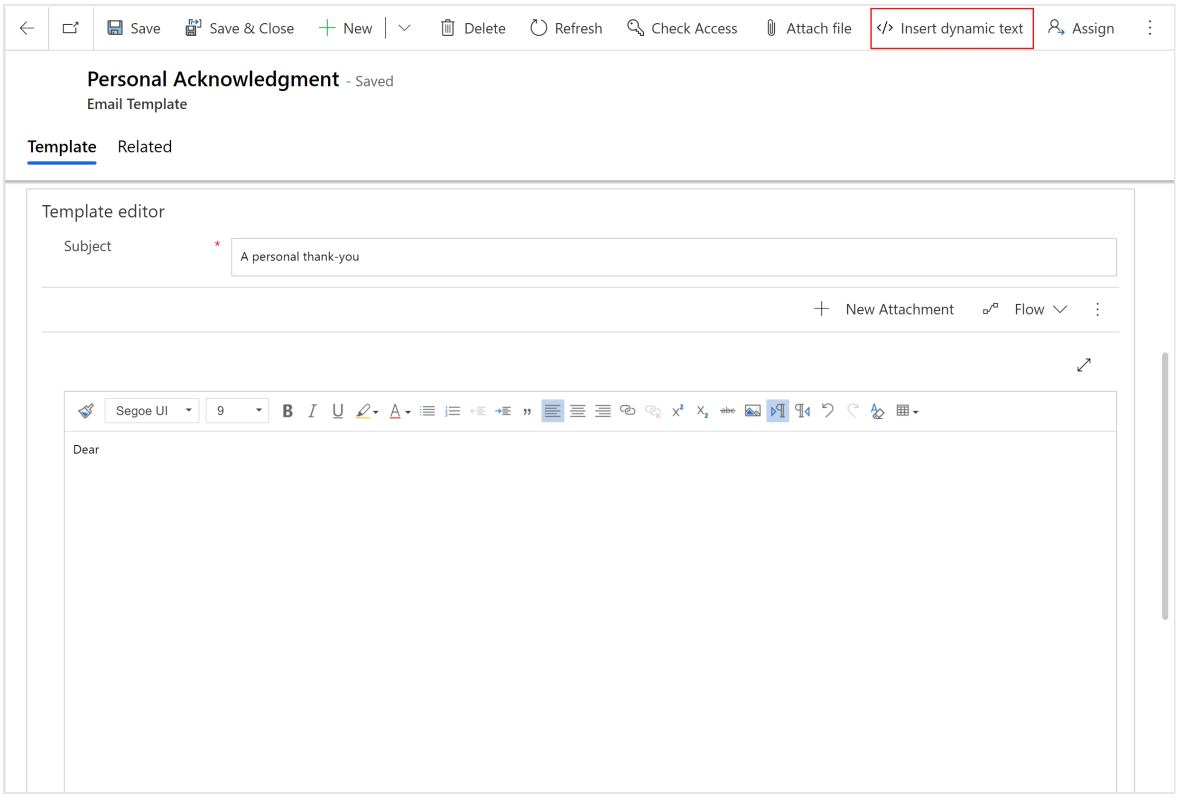
Dynamic text replaces a placeholder entity with the value of the entity when you send the email. For example, your email template might contain "Dear `{!User:First Name;}`" but your customer sees "Dear Sal".

Insert dynamic text

You can insert dynamic text in existing email templates or templates that you create.

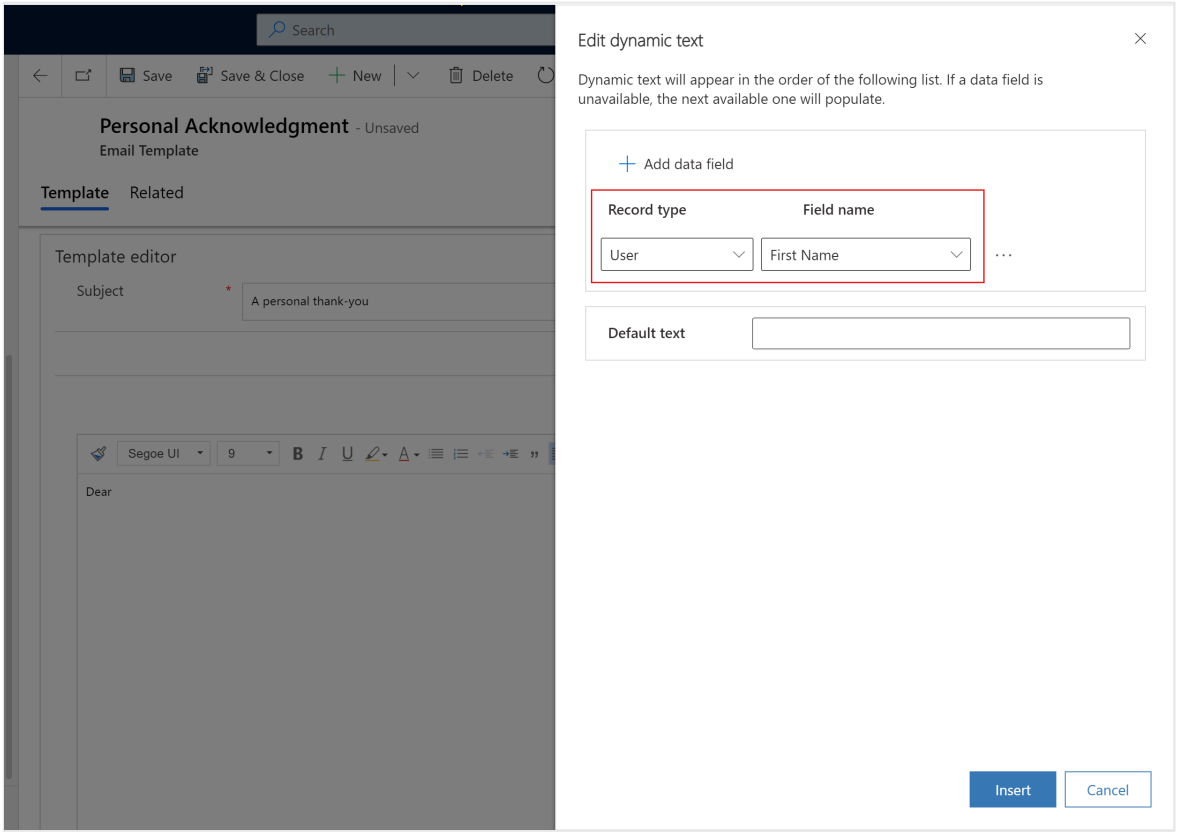
> **Note**
>
> Dynamic text in a hyperlink or an anchor tag isn't supported.

1. Select **Email Template** to edit an existing template or create a new email template.
2. On the template editor, place your cursor where you want the personalized content to appear.
3. Select **Insert dynamic text**.



4. Select the **Record type** and **Field name**.

   The category that you specified when you created the email template determines the record types you can choose. The record type you choose determines the fields you can select.



Insert custom fields

You can insert fields from custom entities by typing them directly in your email template.

Use the following syntax:

Expand table

Field Type	Syntax
• Single line of text • Currency • Multiple lines of text • Decimal number • Floating number	`{!EntityLogicalName:FieldLogicalName;}`

Field Type	Syntax
• Lookup • Multi-select option set • Option set	`{!EntityLogicalName:FieldLogicalName/@name;}`
Date	`{!EntityLogicalName:FieldLogicalName/@date;}`
Time	`{!EntityLogicalName:FieldLogicalName/@time;}`

For example, let's say you want to insert a custom field, *Customer ID*, linked to the record type *User*. Type the following placeholder in your template: `{{!User:CustomerId;}}`.

If you want to insert a custom field, *ModifiedOn*, linked to the record type *User*. Type the following placeholder in your template: `{{!User:ModifiedOn/@date;}}`.

Insert an email template

Article • 04/14/2025

If you previously created an email template, you can easily use it as the basis for your email by inserting it into the email.

You can access the email template you created from the command bar by selecting **Insert Template**.

Insert an email template overview

After you select **Insert Template**, a window appears displaying a list of existing **Email templates** that are available to use.

> **Note**
>
> There is an intermediary window that might appear if:
>
> - You don't have either a Recipient or Regarding field for your email.
>
> >
>
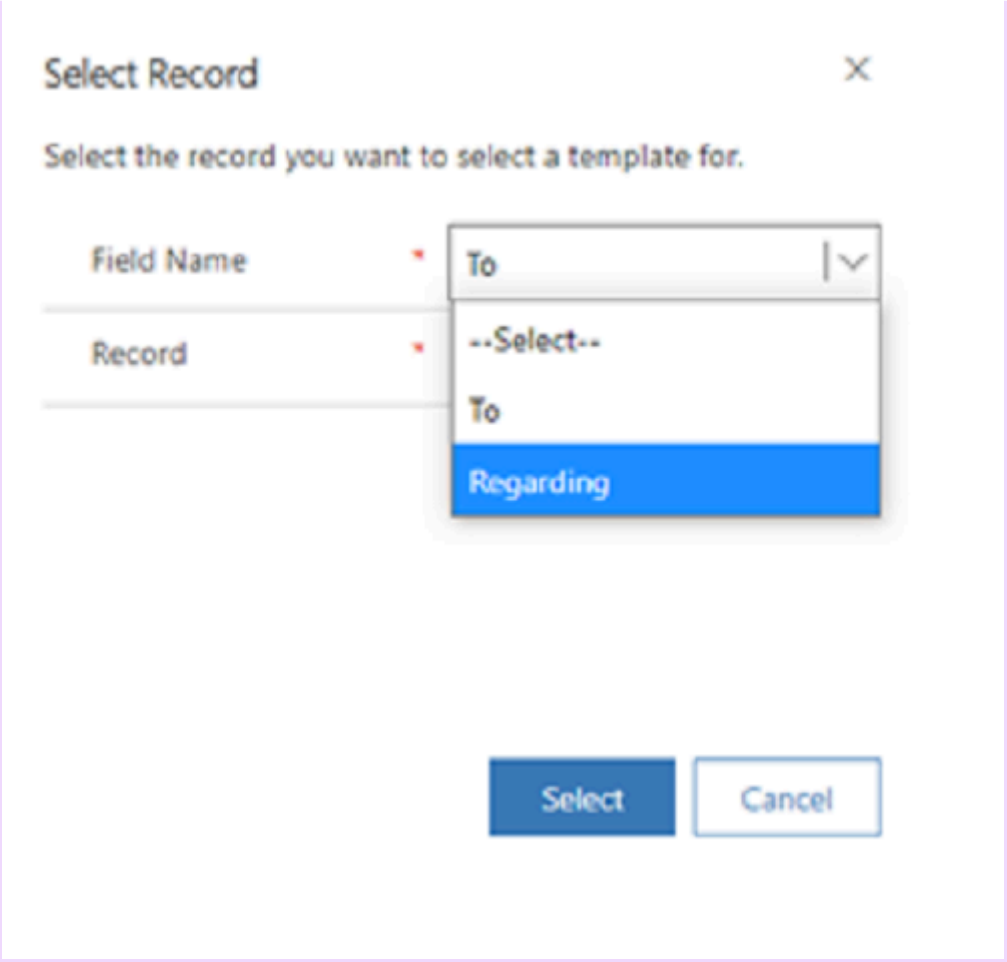
> - You have both a Recipient and Regarding field. You must select one.



This window doesn't appear if your administrator has set **Skip Select Record dialog** in **Advanced Settings** to **Yes**. The selection of one of these fields determines which template types are shown to a user in the template selection window:

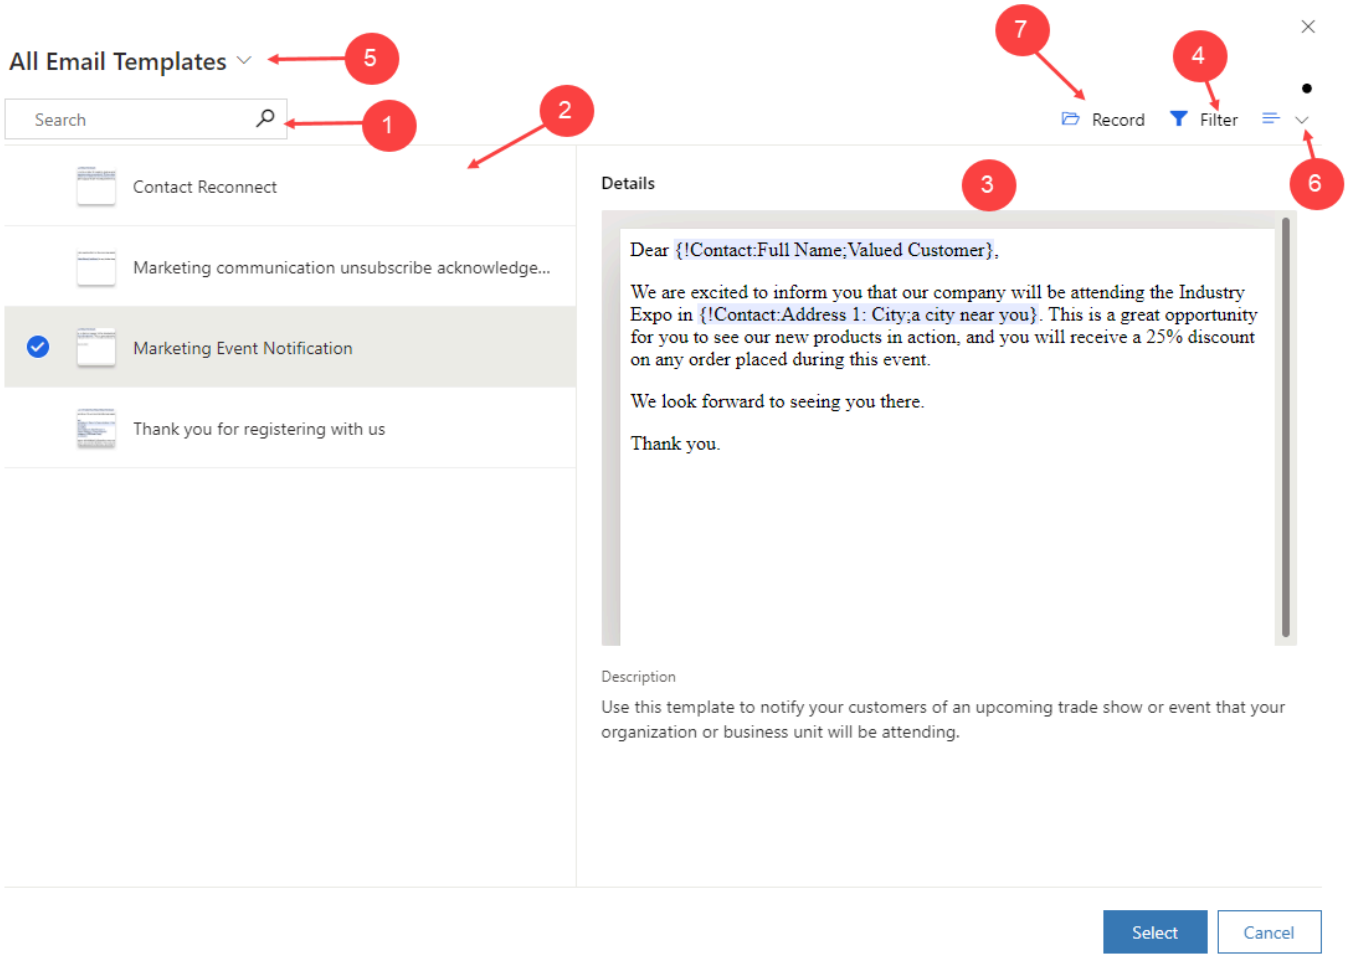
- Recipient (TO): user (global) and contact templates are displayed.
- Regarding: user (global) and templates for the regarding entity are shown.

Enhanced email template selection dialog

The application displays the enhanced email template selection window only if your admin has configured the enhanced insert template dialog option. You can perform the following actions in the enhanced email template selection window:

- Switch between email template views.
- Switch among list, tile, and grid views.
- Search for templates based on their title, subject, description, or content of the template.
- By default, you can filter templates based on standard and custom attributes, and language, if your Administrator has enabled **Language** in the **Template Gallery Filter Form**. See: Add the language filter in the email template selection view
- Additionally, if your administrator has set **Enable Email Template views** in **Advanced Settings** to **Yes**, you can filter templates based on the email template view filters.

- Zoom in to view templates on a full screen. The application provides an option to navigate between templates.



Legend

1. **Search**. Use search to find a template. You can search for templates based on name, subject, description, or content. Search doesn't support regular expressions.
2. **All templates**. Choose and browse from the templates displayed based on TO or Regarding, the filters applied, or a combination of both. You can change the view to display the templates in a grid, list, or tile view. Hover over the template tile to see the zoom option. Select the tile to open the template on a full screen.
3. **Preview**. When you select an email template, a preview of the template is displayed here. The preview shows you the content so you can pick the template that best meets your needs. After inserting an email template, you can modify the content as needed in the email editor.
4. **Filter**. You can filter templates based on standard or custom attributes.
5. **View**. Use the view to switch between email template views. Copilot can recommend the relevant email template for your email. The **Copilot recommended templates** view displays five relevant email templates with prompts that Copilot recommends.
6. Use the dropdown list to switch between grid, tile, or list views. Based on your admin's settings, the application displays a specific view. More information: Customize the email.

7. **Record**. Specify the **Field Name** and **Record**. The template types shown to a user is based on what you've selected for these fields.

    - Recipient (TO): user (global) and contact templates are displayed.
    - Regarding: User (global) and templates for the regarding entity are shown. By default, **Field Name** is set to **Regarding**.

> ⓘ Note
>
> - Bookable Resource Booking isn't supported.
> - You can see the **Record** tab and switch between email template views only if your administrator has enabled the **Enable Email Template views** and **Skip Select Record dialog**. More information: Customize the enhanced email template selection view
> - The enhanced email template selection view might vary based on the customizations your administrator has configured on the **Template Gallery Filter Form**, **Email Template Sorted View**, and **Template Gallery Properties Form**.
> - If you try to insert an email template on a device with a smaller screen size, you'll only see an option to search and select a template only.

Customize your email template selector filters

With the enhanced email template selector dialog, you can switch between multiple email template views. The filters set for the email template views are available on the template selector, and lets you to view only the relevant email templates. You can modify the filters set for the view, but you can't save the modified filter conditions.

For example, you have a custom view, Agent email template view, with filters set to display only the templates that have "case" in the title.

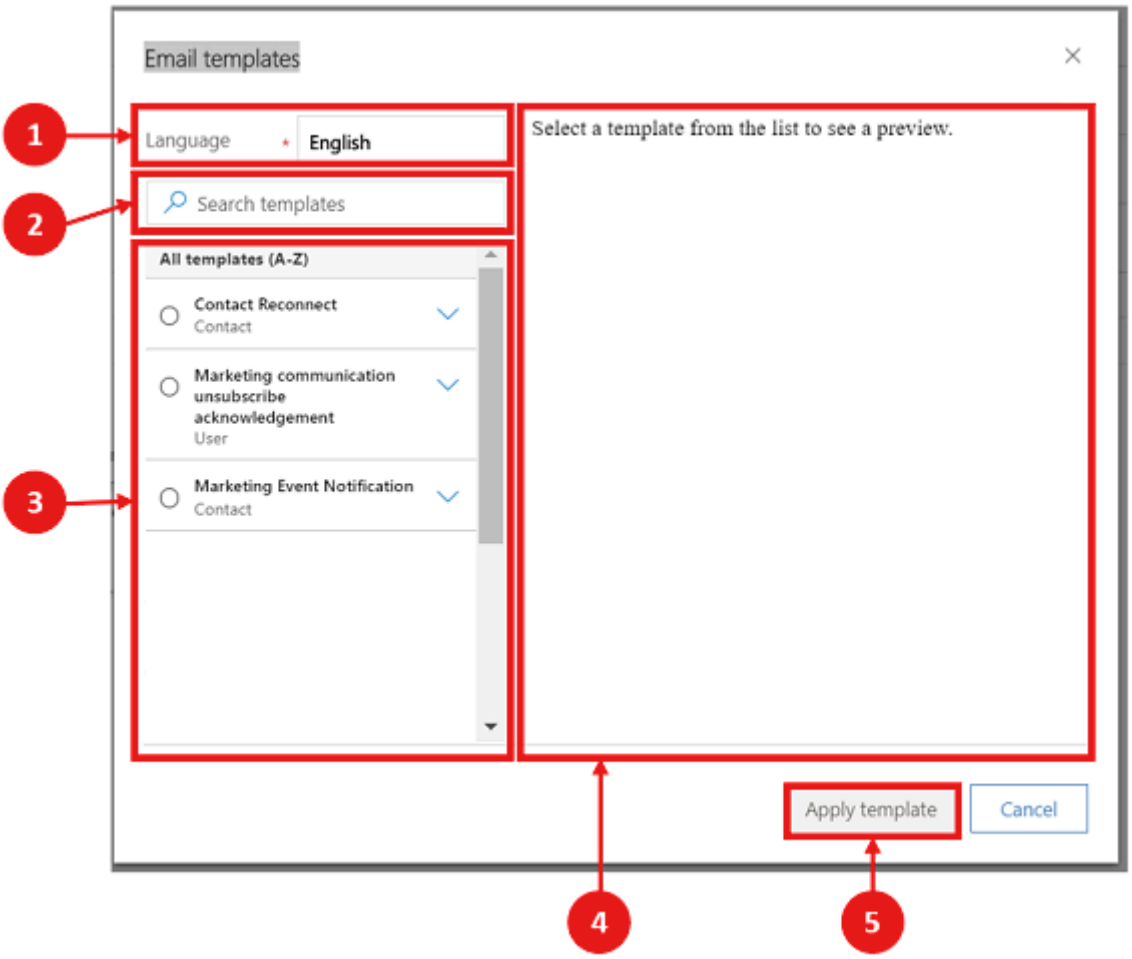
When you access the enhanced email template selector and choose Agent email template view, the application displays only the templates with "case" in the title.

> ⓘ Note
>
> The email templates that are displayed are filtered based on the specified email template view filters and record.

Email template selection dialog

You can perform the following actions on the email template selection window:

- Select a language.
- Search for templates by title.
- Modify the content for a selected template.



Legend

1. **Language**. Templates are loaded according to the selected language.
2. **Search**. Use search to find a template. Search doesn't support regular expressions and only works when using the name of that specific template.
3. **All templates**. All existing templates that have been created are displayed in this window, which you can browse and choose from.
4. **Preview**. When you select an email template, a preview of the template is displayed here. The preview shows you the content so you can pick the template that best meets your needs. After inserting an email template, you can modify the content as needed.
5. **Apply template** to insert the content to your email.

> ⓘ **Note**

If you try to insert an email template on a device with a smaller screen size, you'll only see an option to search and select a template.

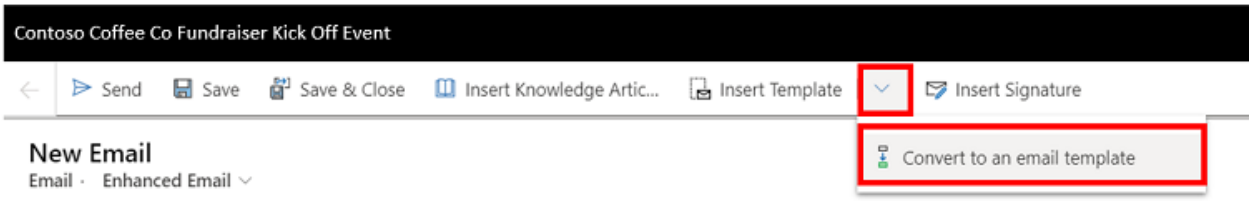
Convert an email to a template

Article • 02/17/2025

When you've composed an email that you'd like to reuse with other customers, you can convert it to an email template and save it for future use.

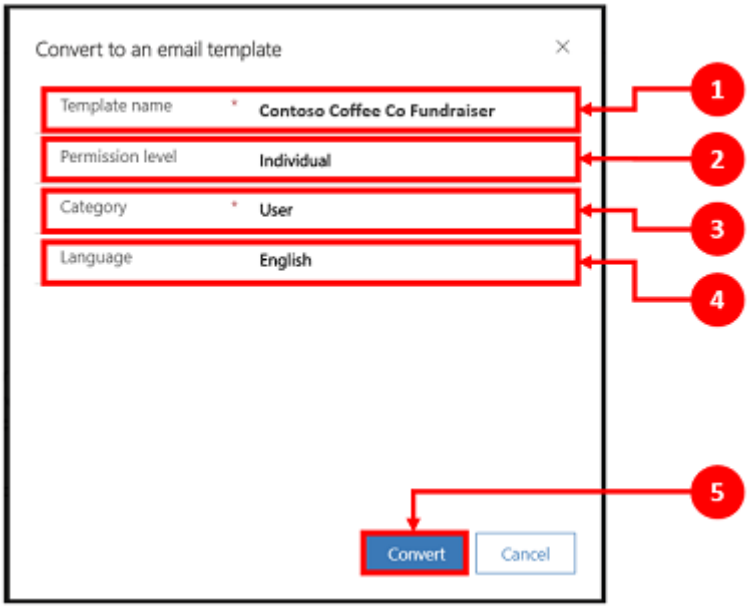
Convert an email into a template



To save an email you've composed and formatted an email message as a template, select the downward-facing caret (v) next to **Insert Template**, and then select **Convert to an email template** from the drop-down list.

Convert an email to a template overview

The following window will display with a list you can customize.



Legend

1. **Template name**. Assign your email template a detailed name you want to save for future use.
2. **Permission level**. Select from **Organization** or **Individual**. More information: Permission level for email templates

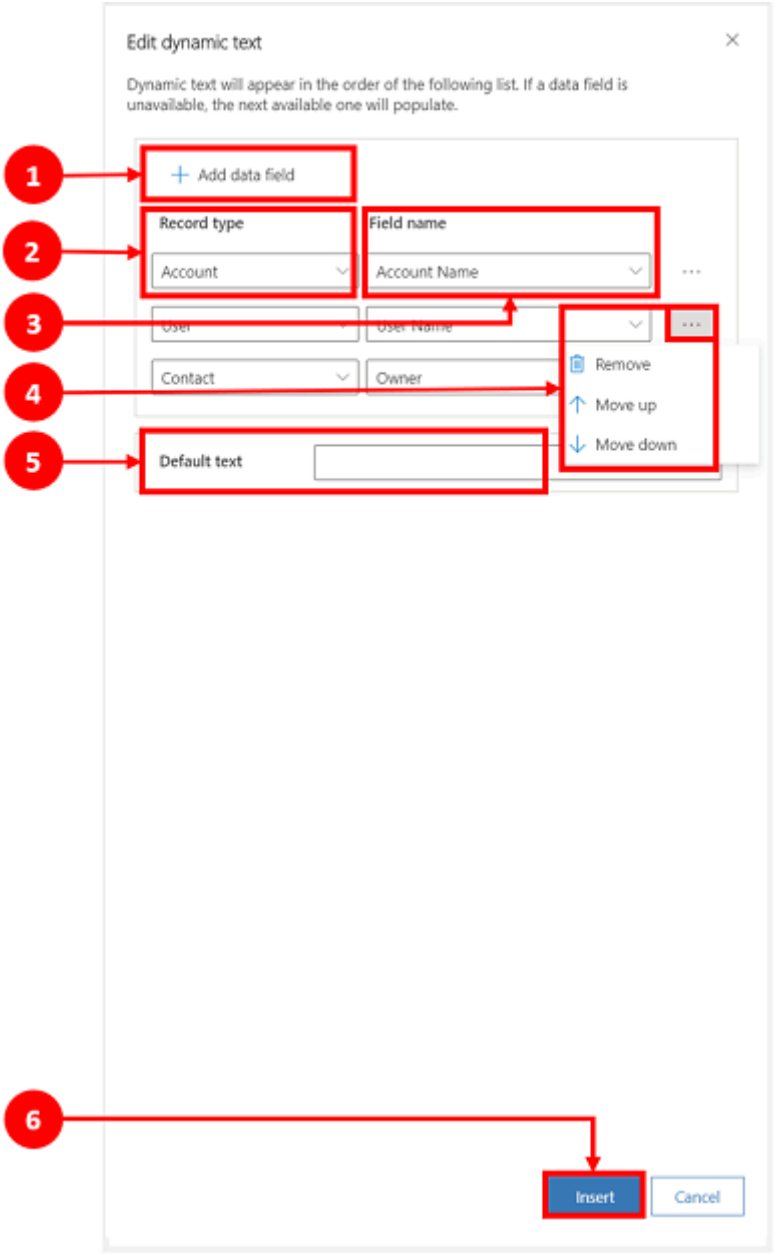
3. **Category**. The default for this field is set to **User**.
4. **Language**. You can display your installed language packs in this field. **Language** also helps to categorize your templates.
5. **Convert**. Once an email is formatted, you can convert it to an email template.

View an email template

To view a complete list of all the email templates you've created:

1. Go to the **Templates** section on the left-hand pane.
2. Select **Email templates** A list of **All Email Templates** is displayed, which you can edit and update.

Insert dynamic text in an email template form



Legend

1. **Add data fields**. When you add data fields, the template adds **Record type** and **Field name** fields below. You can add as many data fields you want.
2. **Record type**. You can then customize the record types. Default is set to account.
3. **Field name**. You can customize the field names. Default is set to account name.
4. **More Commands**. The **More commands** ⋮ icon allows you to edit the order of the record types using the **Move Up** or **Move down** functionality to align records in a customized order.
5. **Default text**. Allows you to select the style of text for the subject and body of your email template. If no text is selected, it will display using the default text.
6. **Insert**. When done this command inserts and saves your form.

> **Note**
>
> If you click in an area on the form that does not support dynamic text, it displays **Unable to insert**.

For more information on creating email templates and configurations, see Create templates for email.

Create a signature for emails

Article • 04/10/2023

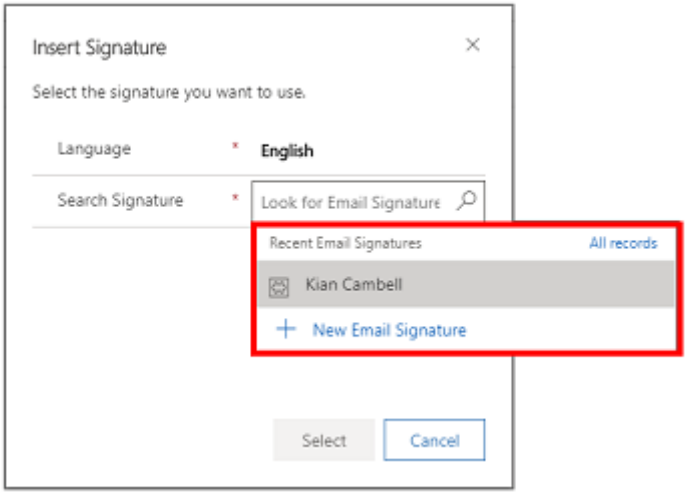
Email signatures are an important and valuable tool for users. Email signatures are like electronic business cards you include when you send an email, and can promote professional branding for your company.

Add text to an email signature

Adding an email signature is easy and can be done at any point while you are composing an email. You can either add an email signature with static or dynamic text. Dynamic placeholders are used to define dynamic text. The placeholders are replaced with the corresponding values of the email's sender, specified in the **From** field.

Add an email signature

- On the command bar, select **Insert Signature**.
- From the drop-down list, select an existing signature or select **New Email Signature**.



Based on the email's sender specified in the **From** field, one of the following actions occur:

- If the sender is a user, the dynamic placeholders defined in the email signature template are replaced with the values corresponding to the user.
- If the sender is set to a queue and the queue's owner is a user, the dynamic placeholders defined in the email signature template are replaced with the values corresponding to the queue's owner.
- If the sender is set to a queue and the queue's owner is a team, the dynamic placeholders are replaced with the values corresponding to the team's

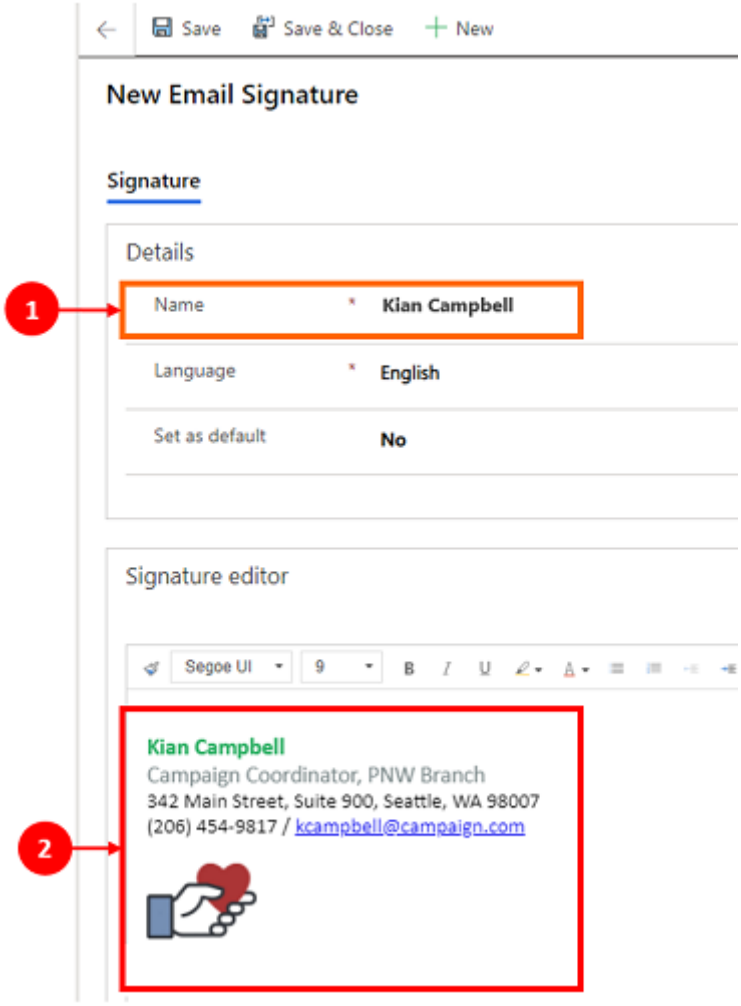
administrator.

Create an email signature

You can quickly create an email signature at any point while you are composing an email.

Create a new email signature

You can add a new email signature by:



1. **Details** in this section, enter the name of the email signature.
2. **Signature editor**. This allows you to create your email signature and **Save** when finished.

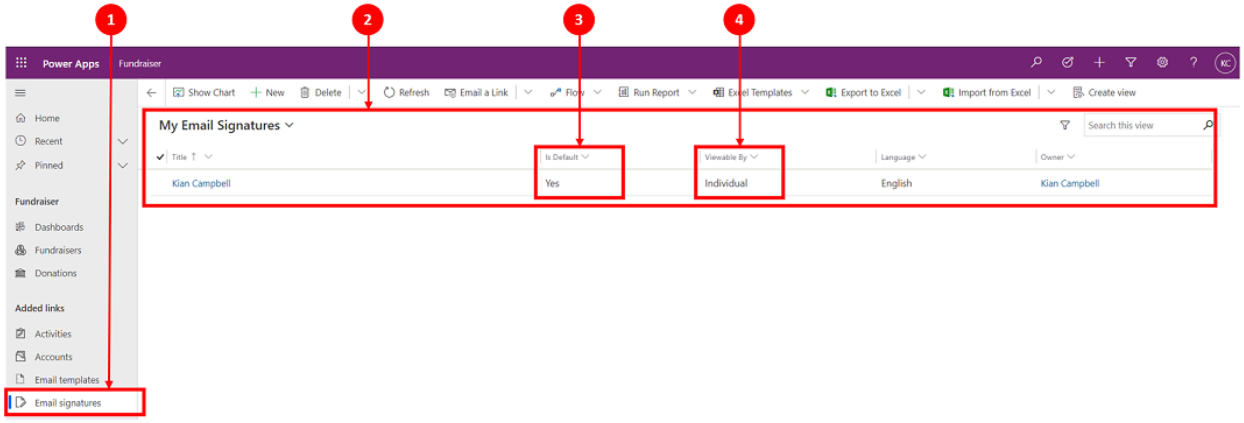
> ⓘ **Note**
>
> - You can include inline images, such as a business logo, in email signatures, as long as they are under 1 MB in size. However, the inline

image might not render properly if you open the email in the Outlook Desktop app.

- You can add only those fields as dynamic placeholders that are linked to the **Record type** user.
- Signatures can also be created and used for queues.

Manage email signature lists

You can view and manage email signatures you have created to make edits, change default, and who can view your signatures.

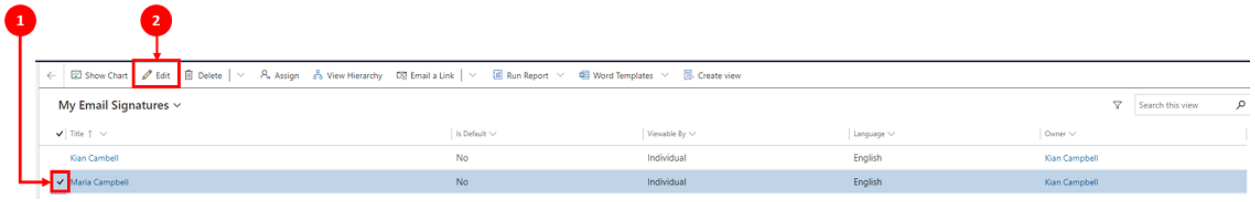


Legend

1. Under **Templates** select **Email signatures**.
2. **My Email Signatures** list displays, showing all your email signatures you can edit and update.
3. You can select a default signature for email. Only one signature per user can be set as **Is Default**.
4. Email signatures can only be **Viewable By** the individual user.

Change the default email signature setting

While you can create multiple email signatures depending on your needs, only one can be set as your default email.



To change your default email signature setting:

1. Select the email signature you want to set as default. This will change the command bar to display **Edit**.
2. Select **Edit**. A new page opens, where you can update the email default setting. While you are on this page, you can also delete one or multiple email signatures just by selecting them.

Configure the enhanced insert email template selection dialog

Article • 04/10/2023

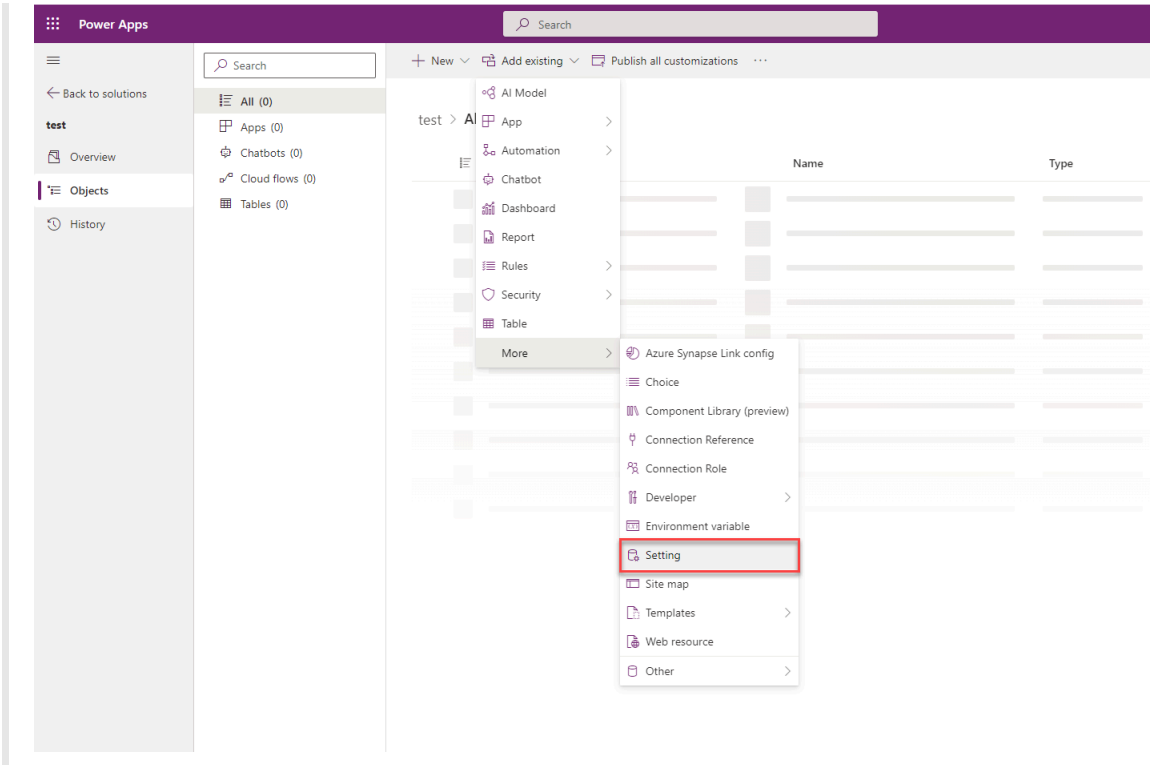
Turn on the enhanced email template selection experience for apps across your organization. If you need to, you can turn off the enhanced email template selection dialog for a specific app. And then, the users of the app see the default email template editor page.

Enable the enhanced email selection dialog

1. In Power Apps, select the environment the environment that contains your solution.
2. Select **Solutions**, and then select the solution in which you want to turn on the enhanced template editing experience.

   > **Note**
   >
   > Don't select the default solution to configure the template.

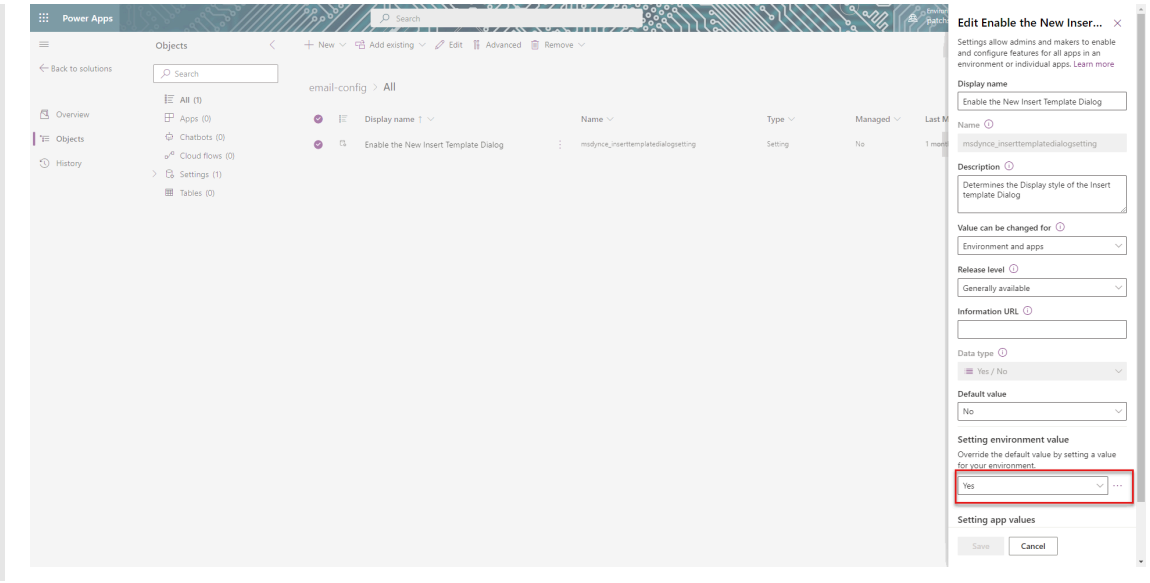
3. Select **Add Existing** > **More** > **Setting**.



4. On the **Add existing Setting Definition** pane, select the **Enable the New Insert Template Dialog** option and then select **Next**.

5. Select **Add** on the **Selected Setting Definition**. The **Enable the New Insert Template Dialog** option is added to your solution. Select **Edit**.

6. Set the **Setting environment value** option to **Yes** on the **Edit Enable the New Insert Template Dialog** pane.



7. Select **Publish All Customizations**.

Disable the enhanced email selection dialog for an app

For an app to display the default email template selection dialog, you must disable the enhanced email template selection option. To disable the option for a specific app, you must add the app to the Solution in which you've added the email template selection option. Perform the following steps:

1. Go to **Power Apps** instance.
2. Select **Solutions**.
3. On the **Solutions** page, select the Solution in which you've added the email template selection option.
4. Go to **Add Existing** > **App** > **Model-driven app**> **Add existing model-driven apps** pane. Select the app for which you want to disable the enhanced insert email template selection dialog. The app is added to the solution.
5. Select the **Enable the New Insert Template Dialog** option in the solution.
6. On the **Edit Enable the New Insert Template Dialog**, in the **Setting app value** section, the selected app is displayed.

7. Select **New app value** for the app, and select **No** for the specified app.
8. Select **Save** and **Publish All Customizations**.

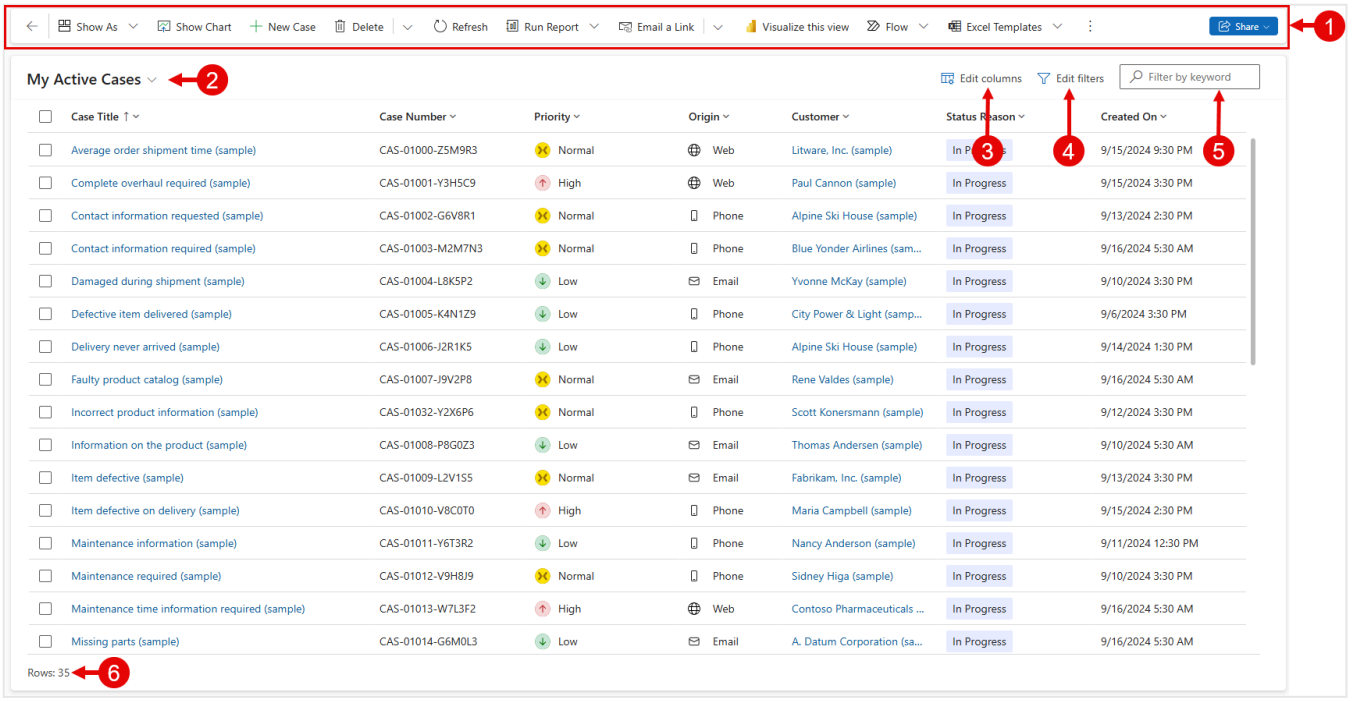
Explore data on a grid page

06/30/2025

In model-driven apps, the default control that's used to show data in tabular form is the read-only grid. When a subarea contains a table, the subarea's default layout in the app sitemap is called the grid page.



Legend:

1. **Command bar**: The commands available for the page
2. **View selector**: Select to change views
3. **Edit columns**: Select to add, remove, or reorder columns
4. **Edit filters**: Select to filter the view with advanced queries
5. **Filter by keyword** or **Quick find**: Show only the rows in the current view that match your search criteria
6. **Row counter**: Shows total number of rows

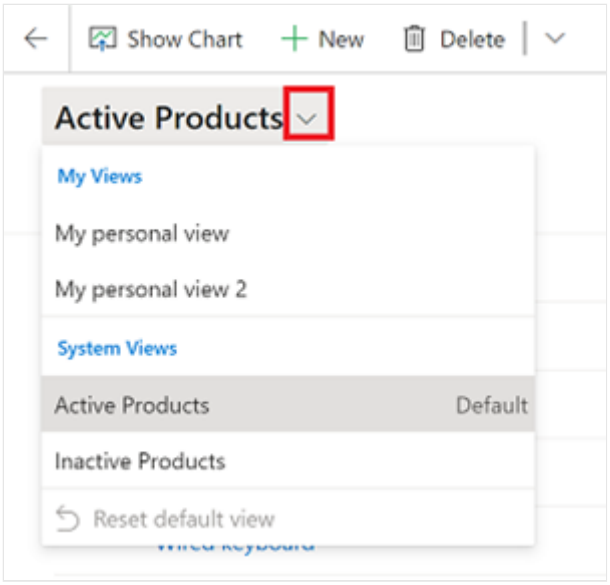
Command bar

The command bar provides quick access to various commands and actions within an application.

View selector

The view selector lists the views that are available for the table. By default, the list is divided into two groups:

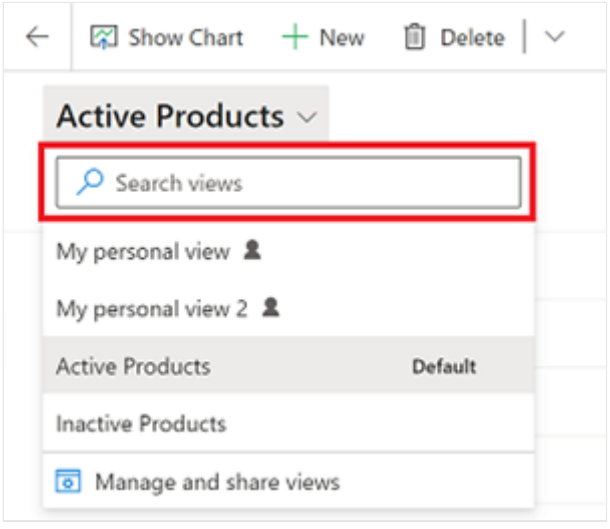
- **My Views**: Personal views that you created
- **System Views**: Views that your administrator created and shared with you



Personal views are listed before system views by default. Both lists are sorted alphabetically. You can change the order the views are listed in.

> **Note**
>
> If your administrator has turned on the modern advanced find experience, the list of views isn't divided. To easily tell which kind of view you're looking at, personal views have a user icon. You can also hover over the information icon to see the view type.

To quickly find a view in a long list, use the search box at the top of the view selector.



Every table in your app has a default view that's set by your administrator. The **Default** label in the view selector identifies which view is the default for the table.

Column editor

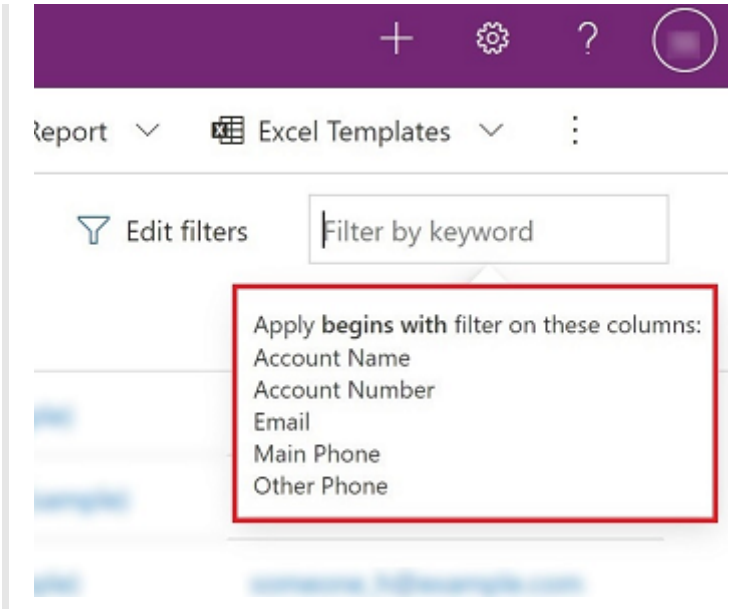
Use the column editor to add, remove, or reorder columns.

Filter editor

Use the filter editor to see or modify the query that selected the records in the view.

Grid search

Grid search enables you to filter the current view based on a keyword. When you choose the search box, an information tooltip appears to indicate the list of columns on which a begins-with match is applied.



The search box can offer two different experiences, depending on how your administrator has configured search.

> **Note**
>
> If your app is configured to be offline by default, the search box will utilize **Quick find** regardless of the grid search configuration in place.

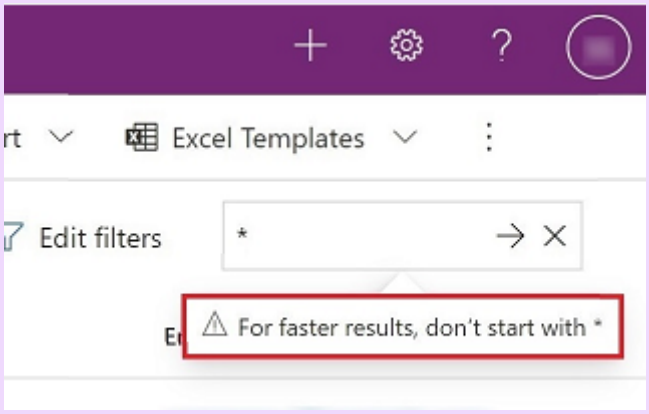
Filter by keyword

Filter by keyword is the default experience. When you enter text in the **Filter by keyword** box, the system filters the current view. It displays the results in the same columns that are used in the current view.

Quick find

If your administrator has turned on quick find, then the search box shows **Quick find**. When you enter text in the **Quick find** box, the system filters the table's quick find view. It displays the results in the columns of the quick find view rather than the current view.

> **Note**
>
> Grid search keywords that begin with an asterisk (*) will display a warning informing you that the search might be slower. If your administrator has turned on the Prevent slow keyword filter for quick find terms on view pages setting, then you cannot perform a search on keywords that begin with an asterisk (*).



Find and visualize data

Find data with AI and visualize data with AI using the natural language text input box.

Row counter

Row counter displays the total number of rows and indicates infinite scrolling on the page. This is the default view available.

Record counter

Record counter shows the position of the current page of records within the total number of records in the view. This is typically shown as a record counter, such as "Records 21-40 of 100".

To view the record counter, your administrator must enable the settings.

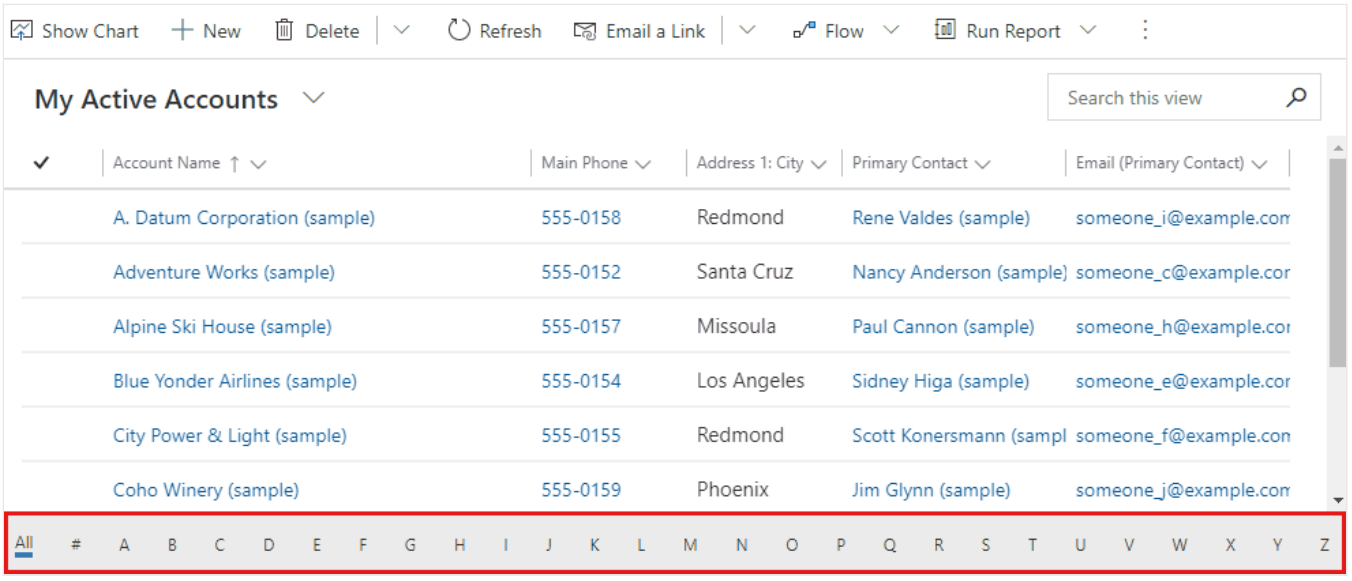
Page navigation

Page navigation allows you to move forward or backward by page in the set of records shown in the view and see the position of each page within the total dataset. To view the page navigation, your administrator must enable the settings.

Jump bar

The jump bar is a quick way to filter out records based on letters of the alphabet. To see only records that start with the letter *S*, for instance, select **S** in the jump bar.

The jump bar acts on the first sorted column. If the sort order hasn't changed, the jump bar uses the primary column. To view the jump bar, your administrator must enable the settings.



Column header actions

Dropdown column headers provide various options to let you modify the data shown in the grid.

Sorting

You can modify the order of records in the grid using the sorting actions in the dropdown column headers. By default, selecting to sort by a column replaces any existing sorting criteria on the grid.

> **Note**
>
> Multi-column sorting can be accomplished by holding the **Shift** key when you select a sort on a different column. This adds the sort condition to the existing sorting criteria on the grid, instead of replacing the sorting criteria.

Filtering

To focus on records that meet particular criteria, you can filter a view by one or more columns. The type of data in the column determines the available filter options.

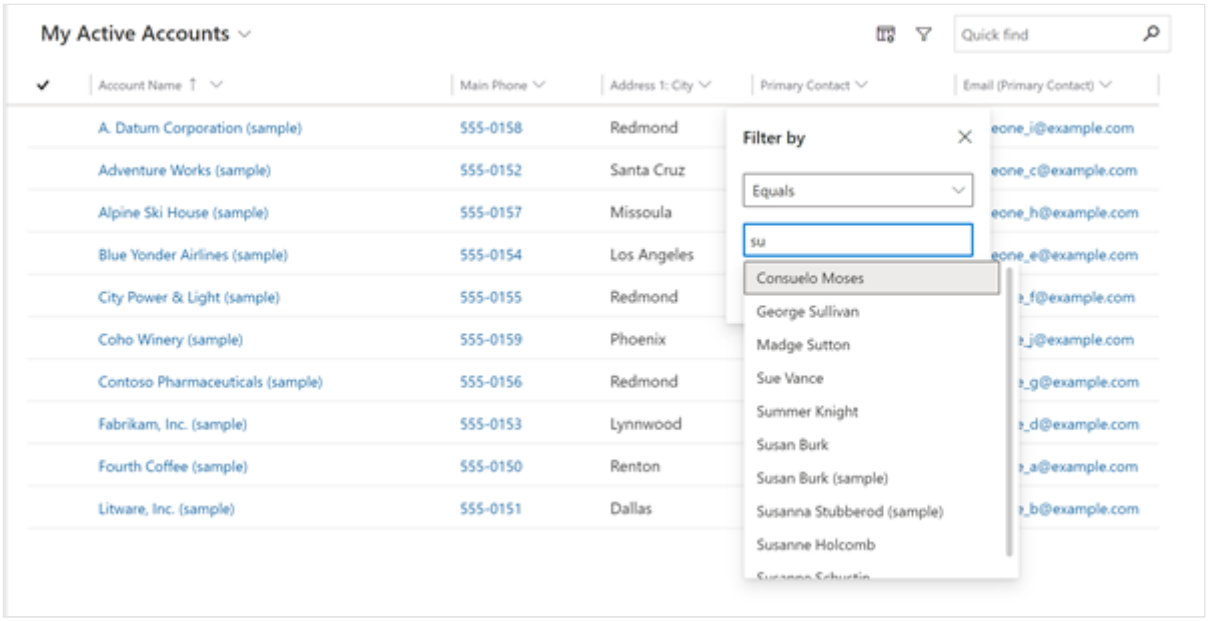
> **Important**
>
> In Unified Interface, grids don't pre-populate column filters based on the current view definition.

> **Note**
>
> Filtering isn't supported on virtual entities. The grid filter's look-up list is limited to 100 results.

Filtering on a lookup column

When you filter data on a lookup column, you can select from a list of values, rather than typing. For example, to filter a view by **Primary Contact**, you can select a name from the list that appears when you select the filter text box.

If you start typing, the filter suggests matching results to help you complete the search. The results include all rows that aren't otherwise filtered out.

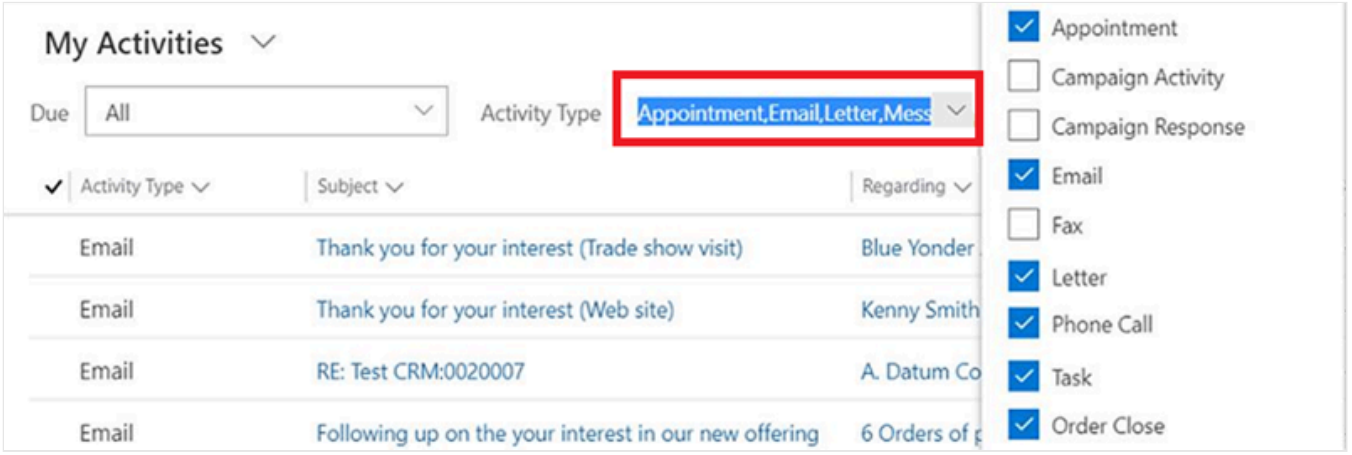


Filtering on a date column

When you filter on a date column, you can select from many different ways to specify a date or a time frame. For example, you can search **On or after** an exact date, **Next fiscal year**, or **Last week**.

Filtering activities

Use the activity type filter to show only the activities you're interested in, such as appointments or email.



Grouping

When configured, the dropdown column headers surface a **Group by** option. This allows you to group the data in the grid by values in the selected group.

- Grouping is available for most kinds of columns. This notably doesn't include lookup columns.

- When grouping on date fields, you need to choose a timeframe to on which to group. This includes day, week, month, quarter, and year.
- You can only group by one column at a time; selecting **Group by** on a different column replaces any existing grouping criteria.
- You can remove the grouping by selecting **Ungroup** from the same dropdown column header to remove the grouping.

> ⓘ **Note**
>
> Grouping criteria isn't saved to a view. Grouping is not supported on nested grids or when paging on the grid is allowed.

Aggregation

When configured, the dropdown column headers surface a **Totals** option in numeric columns. This allows you to surface an aggregate calculation in the grid footer for the data in this column. You can choose between showing a sum, the maximum value, the minimum value, or the average value. If the data in the grid has been grouped, the aggregate is calculated and displayed for each group.

> ⓘ **Note**
>
> Aggregations aren't saved to a view.

Show as

While the default read-only grid is initially used to show data, if multiple dataset controls are configured for the table view, you can switch between these controls using the **Show as** menu in the command bar, which is typically found under the **More commands** action. Once you've switched to a different display of the data, that control is remembered for future sessions on that device.

Create and manage personal views on a grid page

Article • 03/08/2024

In model-driven apps, views define the data that's displayed in tabular form on a grid page. System views are views that are created by your administrator and shared with you. You typically can't modify them. However, you can create and manage personal views. Personal views are available to you only unless you share them.

A view consists of the following elements:

- The columns to display
- Default sorting options
- Filters to show rows that match specific criteria, if needed

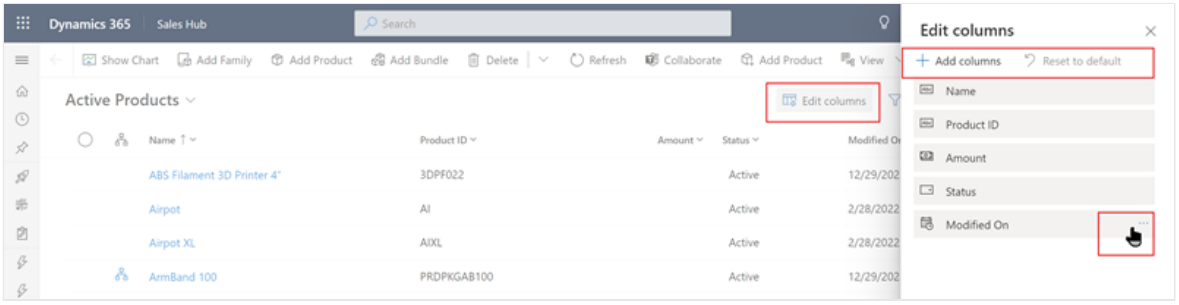
> **Important**
>
> To ensure proper functionality of all views, it's recommended to create all views with the View designer in the maker portal or the Edit filters panel in the view page. Custom views imported from solutions can include invalid fetchXML and might not be supported.

For more information, see Understand model-driven app views.

Select columns in the column editor

1. Select **Edit columns** to remove, reorder, or add columns to get a clearer view of your data.

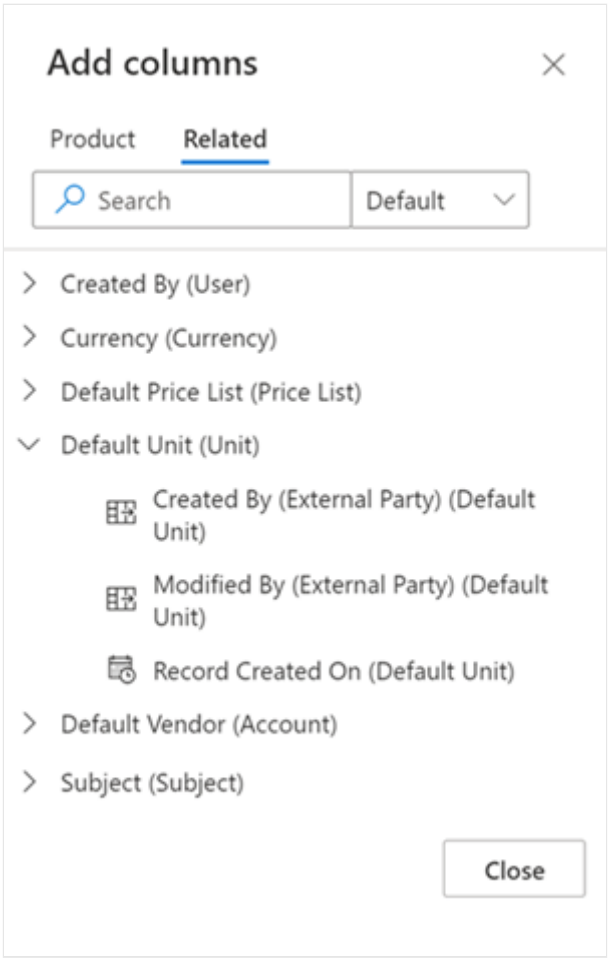
2. Select **Apply** to see your changes on the grid page.



The following actions are available in the column editor:

- To remove a column, hover over the column name, select **...**, and then select **Remove**.
- To change the order of the columns, select **...**, and then select **Move up** or **Move down**. Or, drag the column to the desired position in the list.
- To add columns to the view, select **Add columns**, and then do one or more of the following:
  - Select a column from the default set of system columns in the table.
  - Select **Default**, then select **All** or **Custom**, and then select from the set of columns in the table.
  - Type a column name in the **Search** box to find a specific column, and then select it.

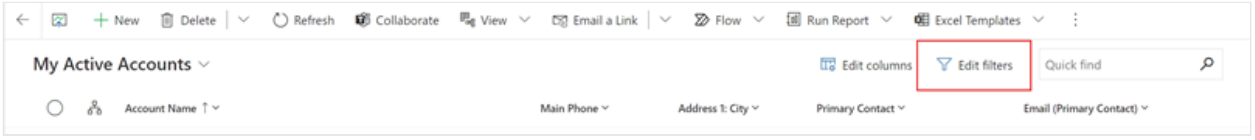
  - To add columns from other tables, select the **Related** tab. Expand the table that contains the column you want to add, and then select the column. When you're done adding columns, select **Close**.



To undo changes to the view's columns at any time, select **Reset to default**.

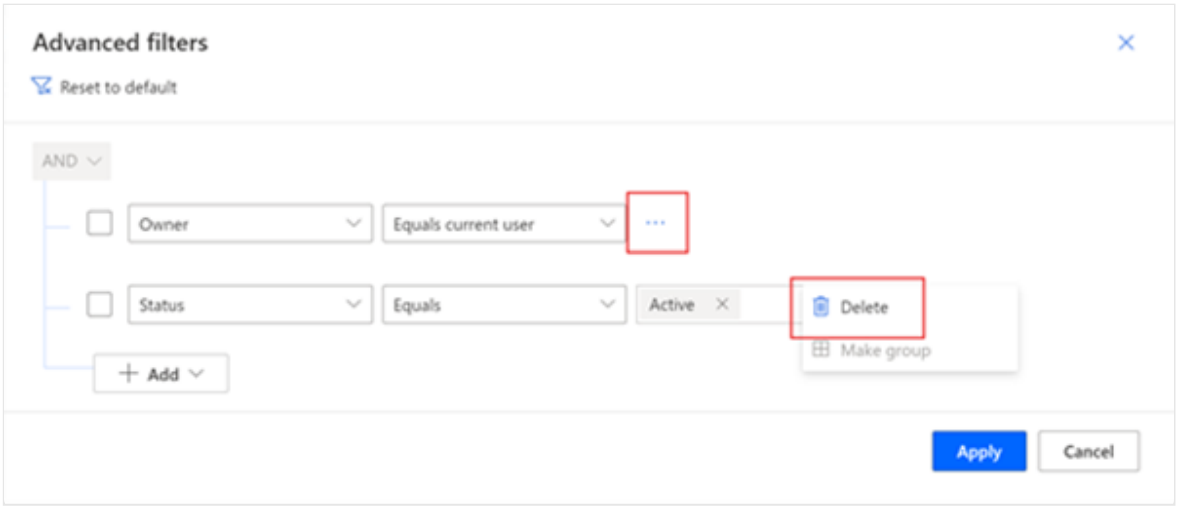
Select filter conditions in the filter editor

Use the filter editor to view or change the query that underlies the data in the current view.



Edit or delete a condition

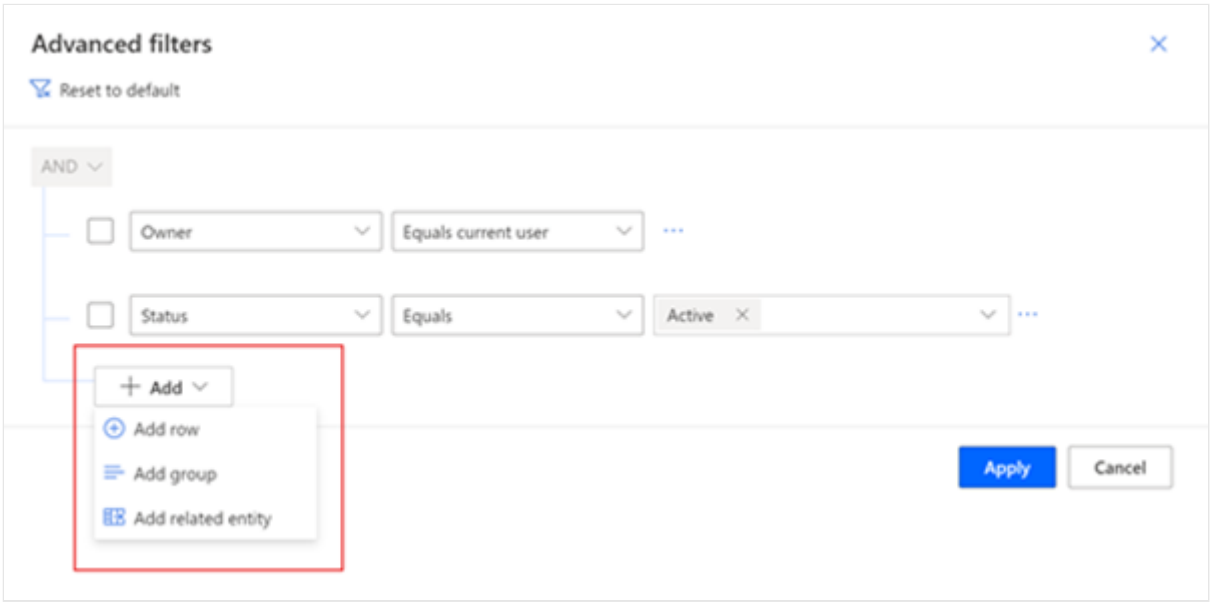
- To change a condition, select the column, operator, or value and edit as needed.
- To remove a condition, select More commands (...) next to the row, and then select **Delete**.



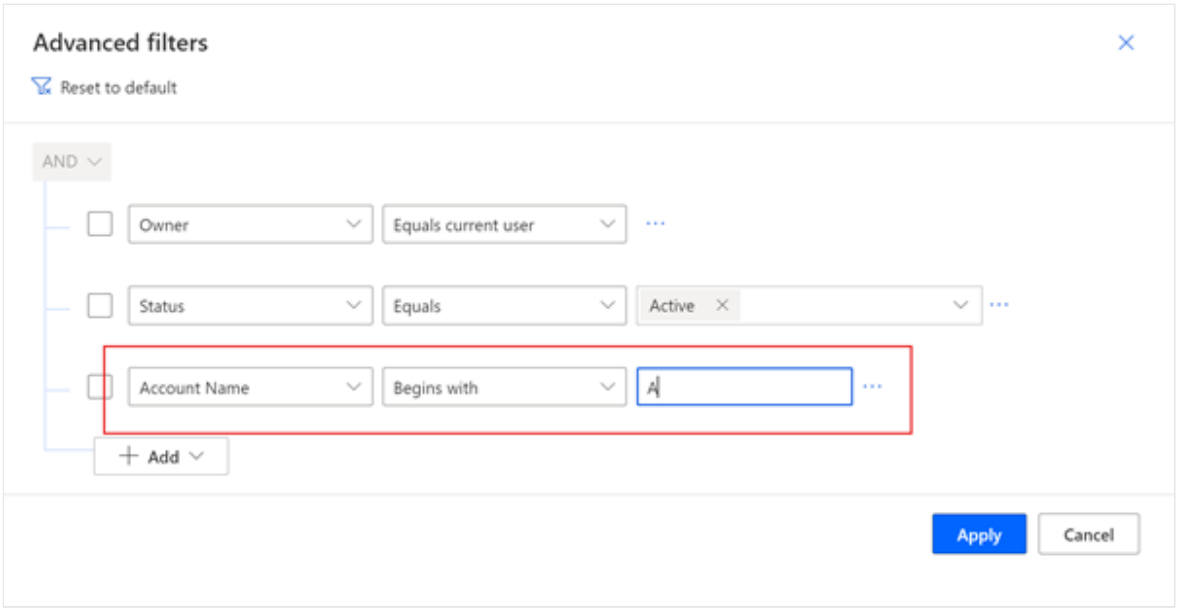
Add conditions

1. To add one or more conditions, select **Add**.
2. When you're finished editing the view filters, select **Apply** to see your changes on the grid page.

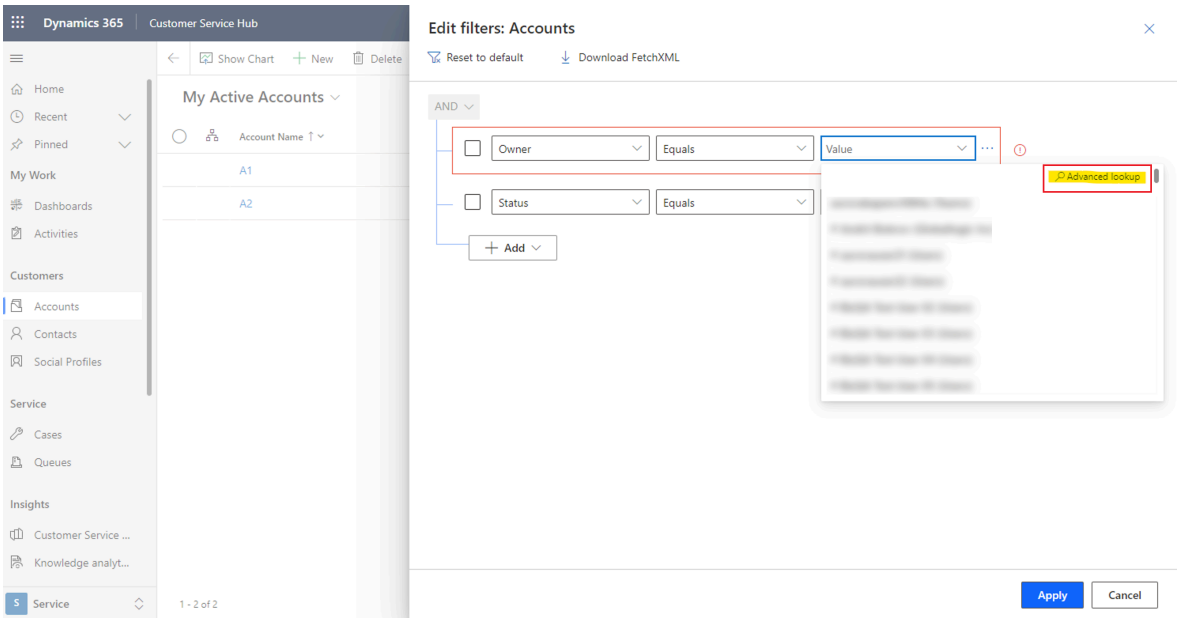
The following options are available when you add conditions in the filter editor:

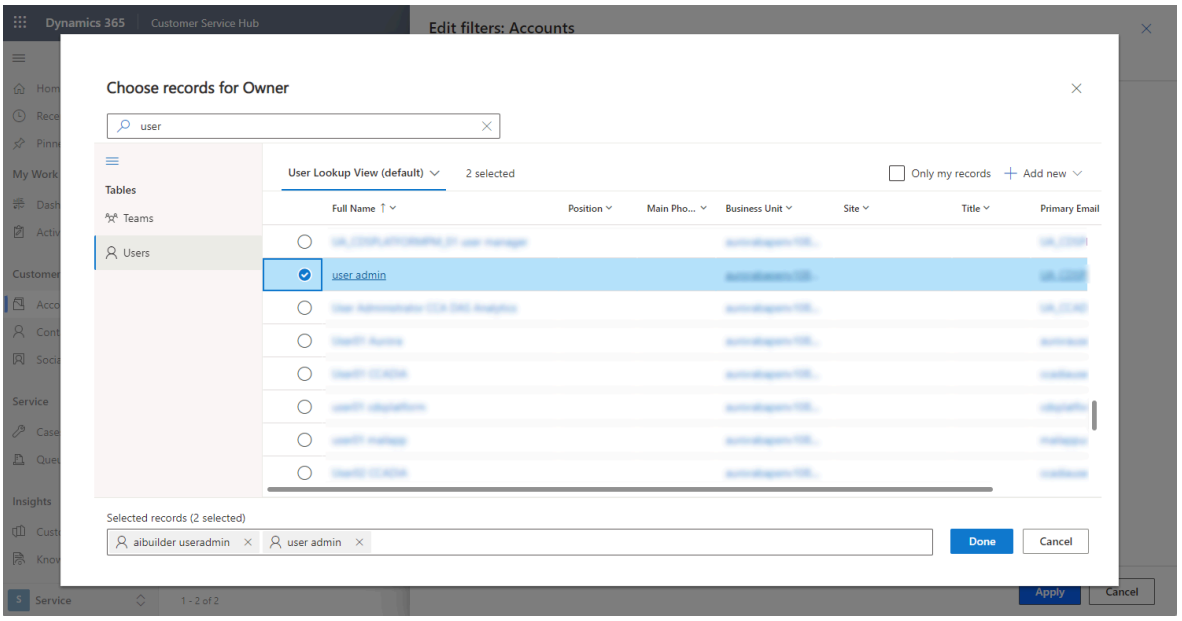


- To add a condition, select **Add row**, and then select a column, an operator, and a value.

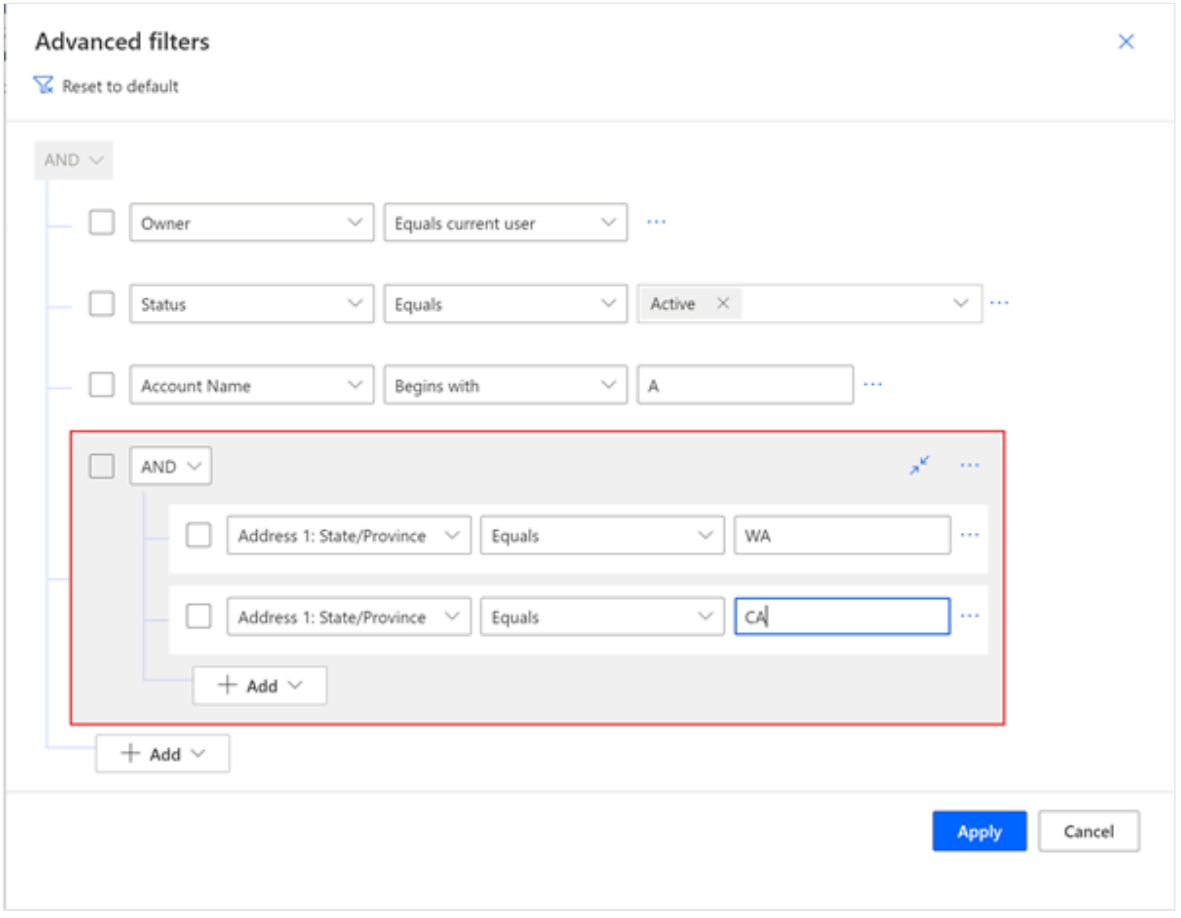


If you're adding a condition to a column with lookups, you can look up the record in the **Value** field. In the lookup drop-down menu, you can choose **Advanced lookup** to see more fields and search for records within a specific view.



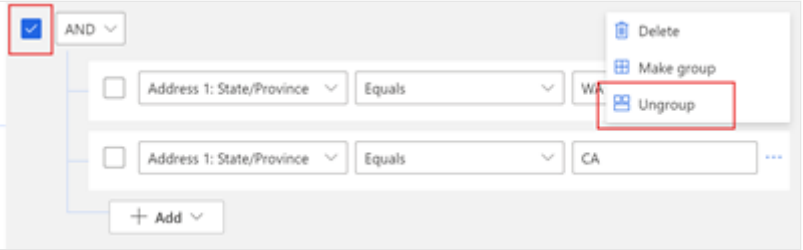


- To add a group of conditions, select **Add group**. You can create multiple subconditions and group them using AND and OR operators to create an expression.

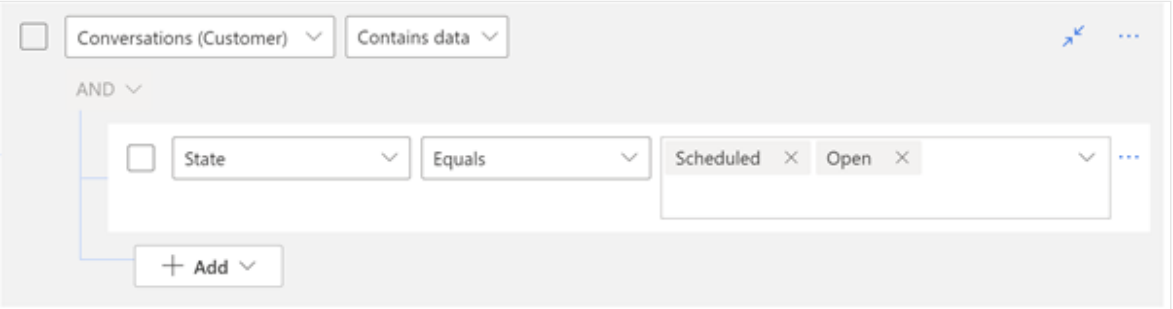


- To add a single condition to a group, select the condition checkbox, then select **...**, and then select **Make group**.

- To separate a group of conditions, select the group's checkbox, then select **...**, and then select **Ungroup**.



- To add a condition based on a column in a related table, select **Add related entity**, and then select a table. **Contains data** is the only conditional operator that can be used with a related table in a view filter. Then, select a column in the related table, an operator, and a value.



To undo changes to the view filter at any time, select **Reset to default**.

> **Tip**
>
> If you have the security privilege **Enable Download Fetch XML**, found under Miscellaneous Privileges section of the **Customization** tab within the security role definition page, you can download the FetchXML expression for a view. Contact your administrator if you need this capability.

Sort the data

Select a column heading, and then select how the view should sort data in the column. You can sort on one column at a time.

Sorting options depend on the type of data. Alphanumeric columns can be sorted in A to Z (ascending) or Z to A (descending) order. Date columns can be sorted in older to newer (ascending) or newer to older (descending) order. An arrow to the right of the column name indicates the view is sorted on that column. The direction the arrow is pointing indicates whether the column is sorted in ascending or descending order.

Edit column width

If your administrator has turned on modern advanced find, you can drag the vertical column separator bar to change the **minimum** width of a column. When you change the width of a column, as asterisk appears beside the view name to indicate that you edited the view and haven't saved it. See Save your edits to as a new view to learn more about different options to save a view.

> **Tip**
>
> Since the column width edits change the **minimum** width of the column, you might see column widths getting adjusted after the view is saved, to fill the available horizontal screen space.

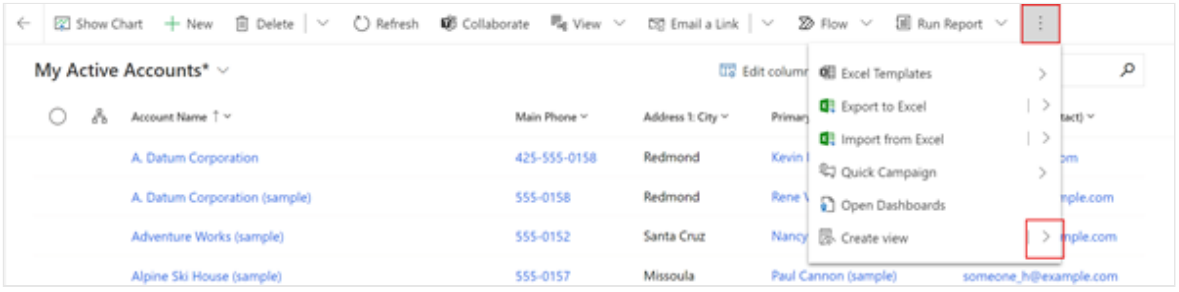
Save your view

An asterisk beside the view name indicates you edited the view and haven't saved it. If you switch to another view or leave the page, the view will revert to its original definition. To keep your changes and add the new view to the list of views available to you, be sure to save it.

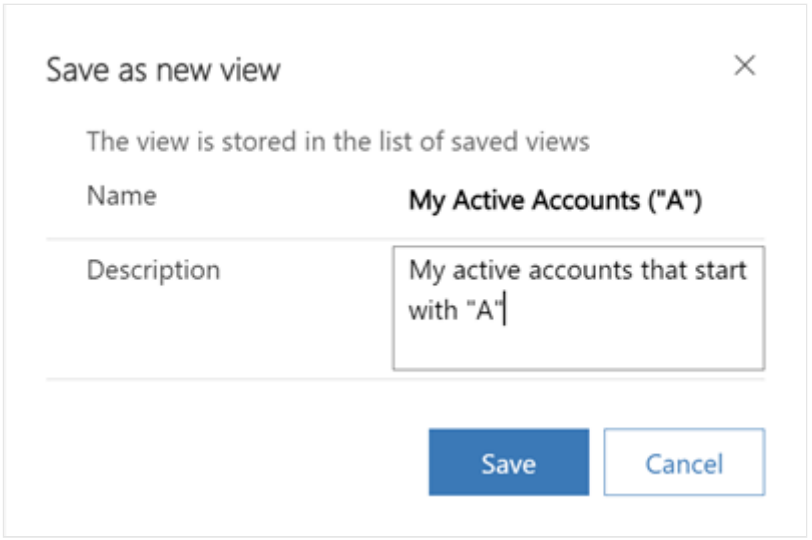
Save your edits as a new view

To keep the original view, save your edited version as a new view with a different name. If you made changes to a view you don't have *Write* permission to, whether it's a system view or a personal view, then you can only save it as a new view.

1. On the command bar, select **More commands** (⋮) > **Create view** > **Save as new view**.



2. Enter a new name for the view, and a description if you like, and then select **Save**.

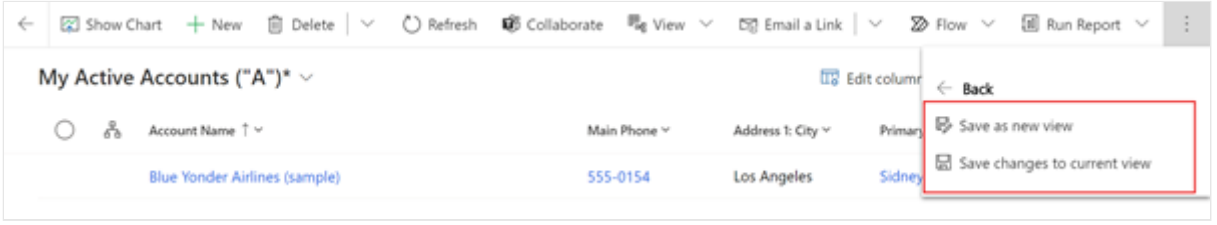


> **Note**
>
> If you want to keep the original view, be sure to give your edited view a different name. If you don't, your changes will overwrite the existing view without confirmation, even though you selected to save it as a new view.

Change the definition of an existing view

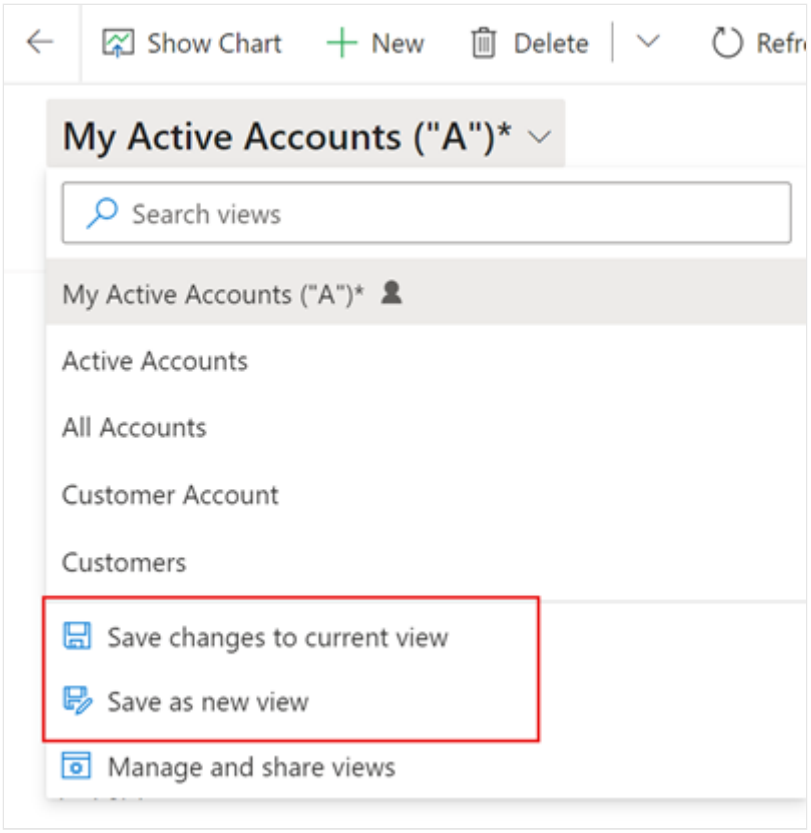
If you don't want to keep the original view, you can replace it with your edited version. You'll need *Write* permission to the view to overwrite the original definition with your changes.

On the command bar, select **More commands** (⋮) > **Create view** > **Save changes to current view**.



Save changes to views in modern advanced find

If your administrator has turned on modern advanced find, you can create and manage views directly from the view selector.



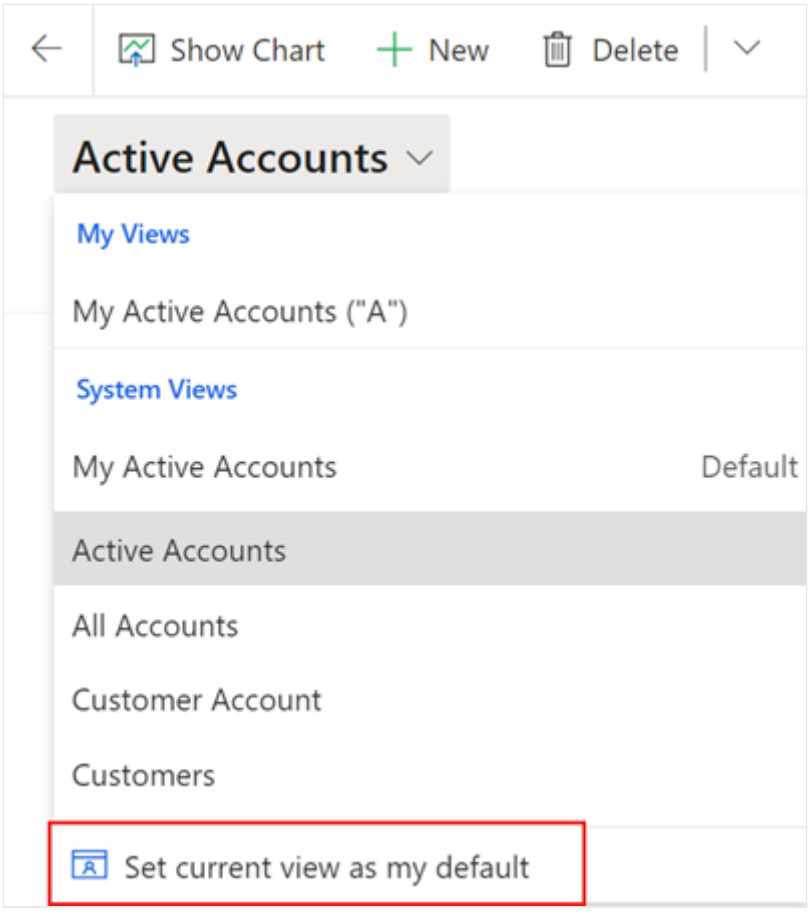
Change the default view

The default view for a table is indicated by the **Default** label in the view selector. Your administrator sets a default view for each table in your app. However, you can set a different view as your personal default.

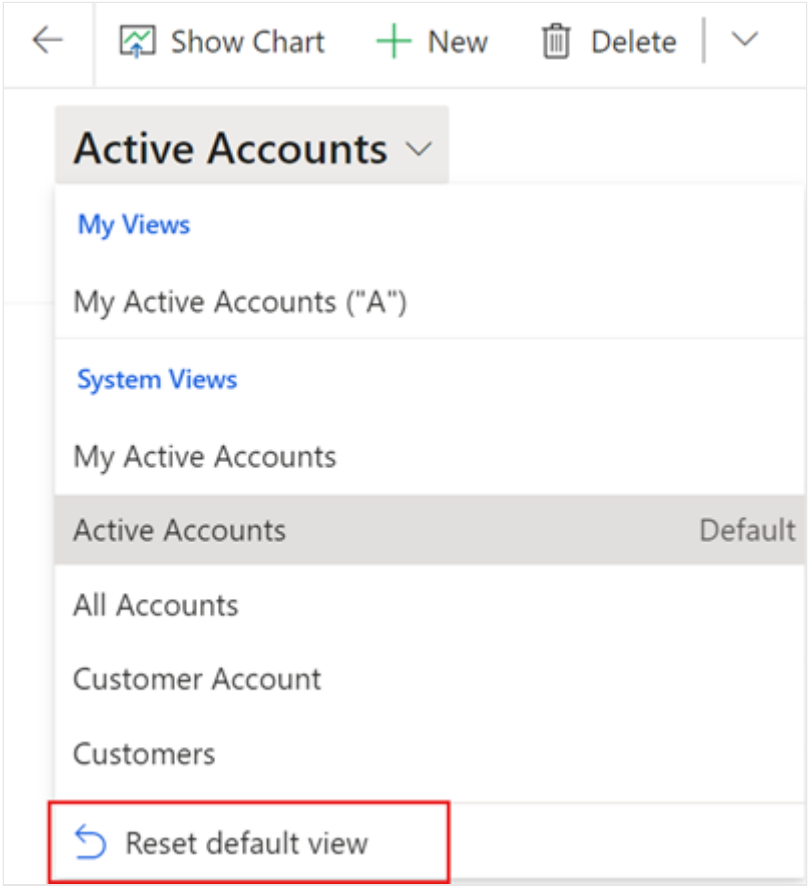
In the following example, the administrator set the view *My Active Accounts* as the default for the Accounts table. To change your default view to *Active Accounts*:

1. In the view selector, select **Active Accounts** to apply the view to the grid page.

2. Open the view selector again and select **Set current view as my default**.



To change your personal default view back to the view that was set by your administrator, select **Reset default view** in the view selector.

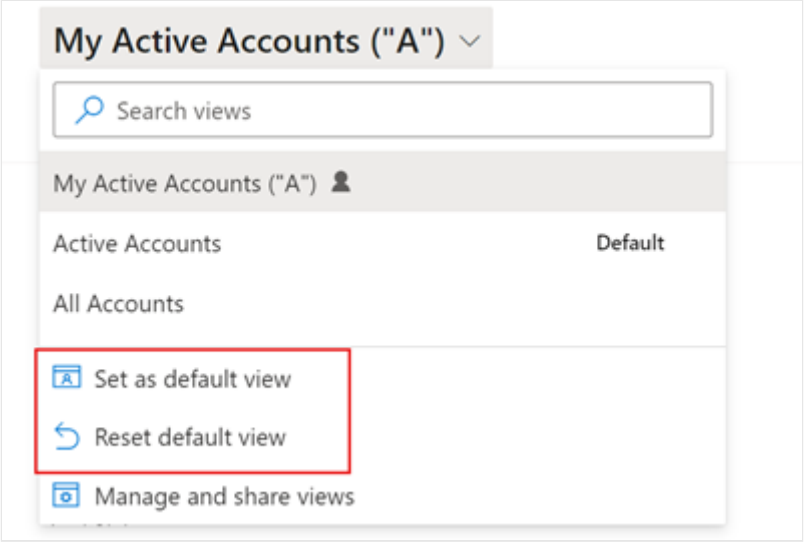


Note

If you don't see **Reset default view**, it means the current default view for the table is the one set by the administrator.

Change the default view in modern advanced find

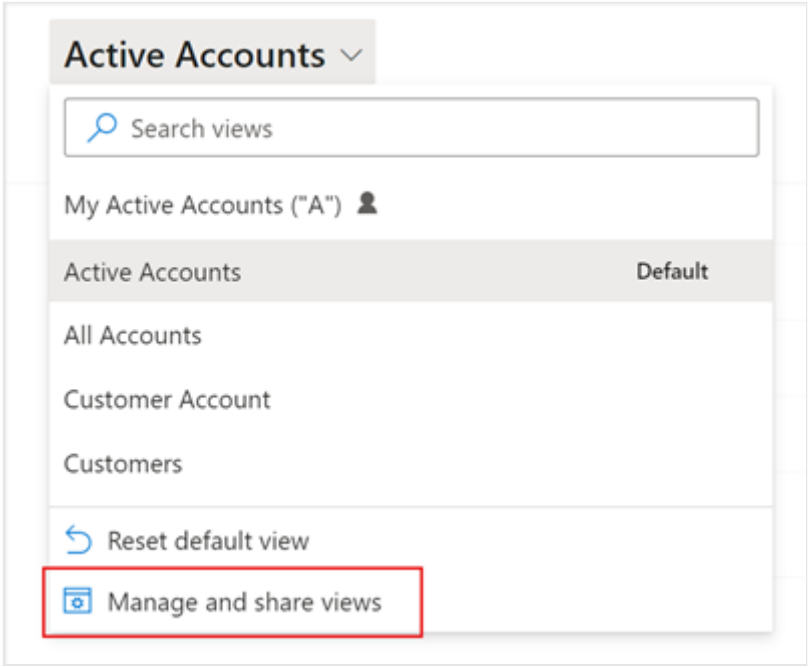
If your administrator has turned on modern advanced find, you can change and reset the default view directly from the view selector.



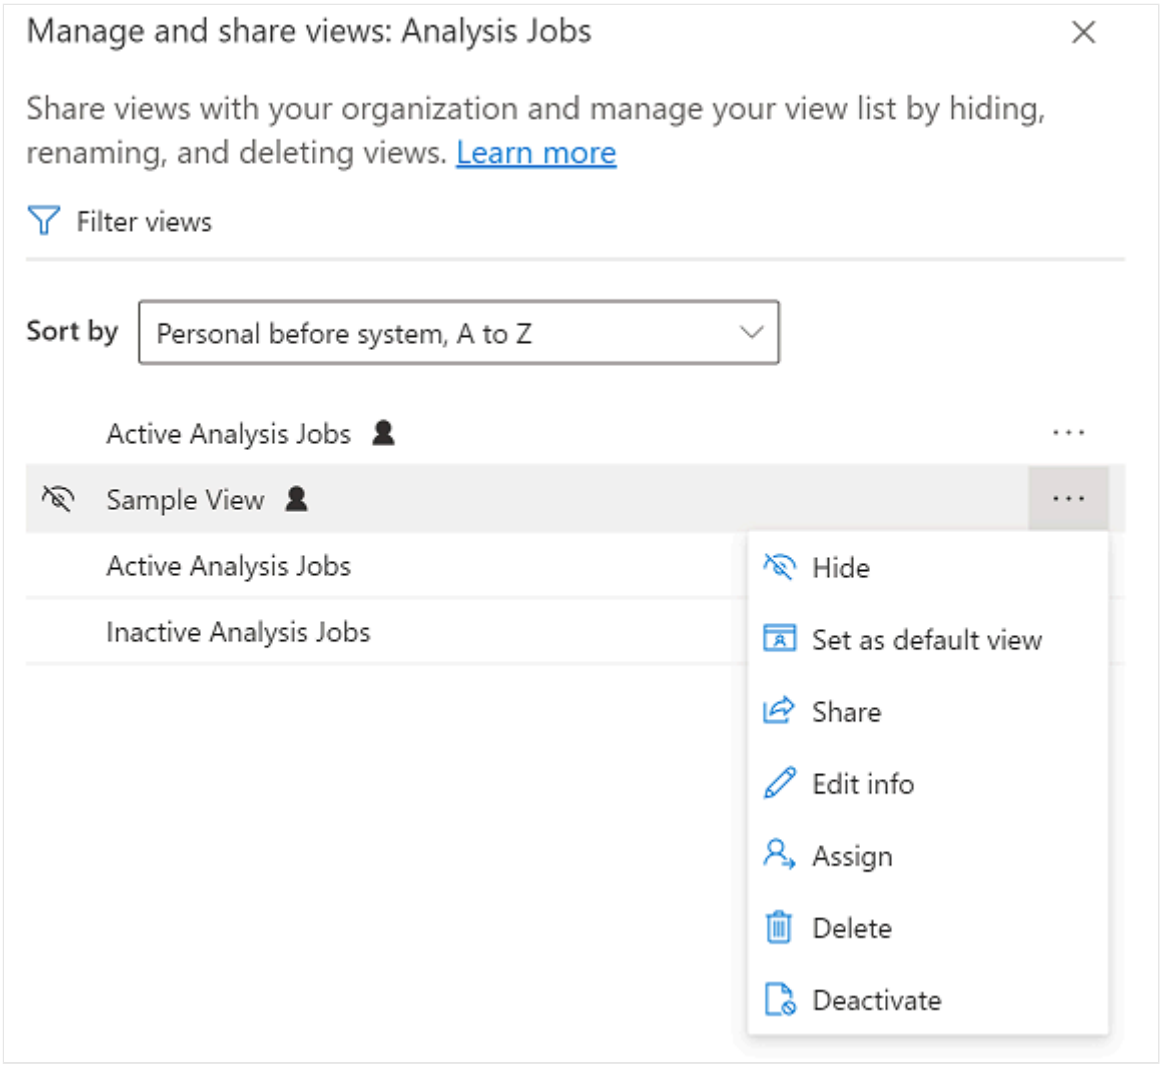
Manage and share personal views

If your administrator has turned on modern advanced find, you can share, hide, rename, and delete views.

1. In the view selector, select **Manage and share views**.



2. Select View commands (...) and then choose your option.

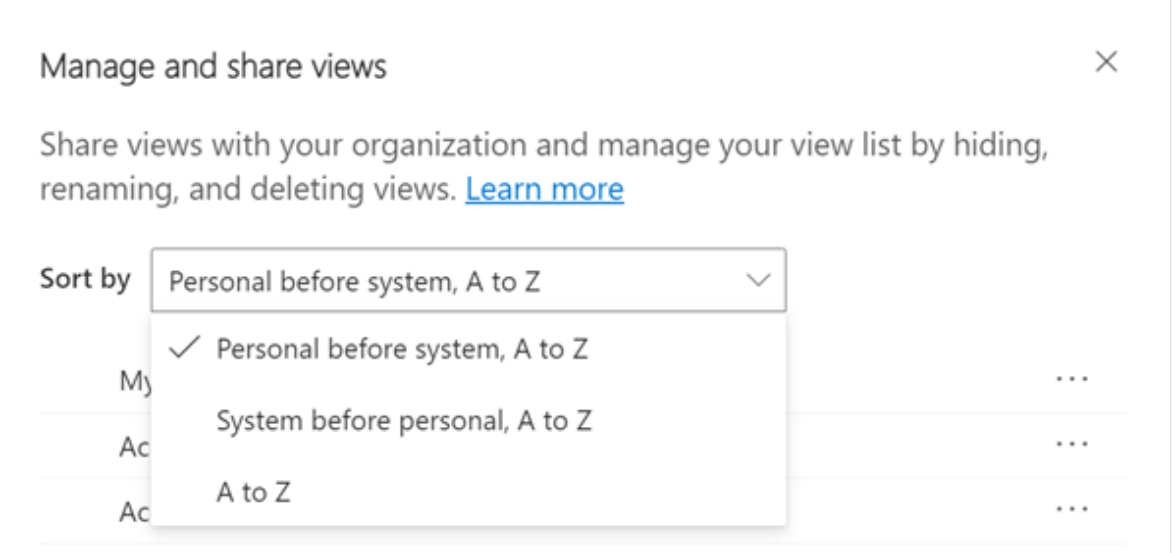


Change the order of views in the view selector

By default, the view selector lists views in two groups, personal views and system views, each ordered alphabetically. You can change the sort order within groups, or remove the grouping entirely and order the entire list alphabetically.

1. In the view selector, select **Manage and share views**.

2. Change the view selector sort order, and then select **Apply**.



The following sorting options are available:

- **Personal before system, A to Z**: This is the default. Both groups are ordered alphabetically. Personal views appear above system views.
- **System before personal, A to Z**: Both groups are ordered alphabetically. System views appear above personal views.
- **A to Z**: The grouping is removed. All views (system and personal) are presented in alphabetical order.

> **Note**
>
> If your administrator has turned on the modern advanced find experience, the list of views isn't divided. To easily tell which kind of view you're looking at, personal views have a user icon. You can also hover over the information icon to see the view type.

Hide views

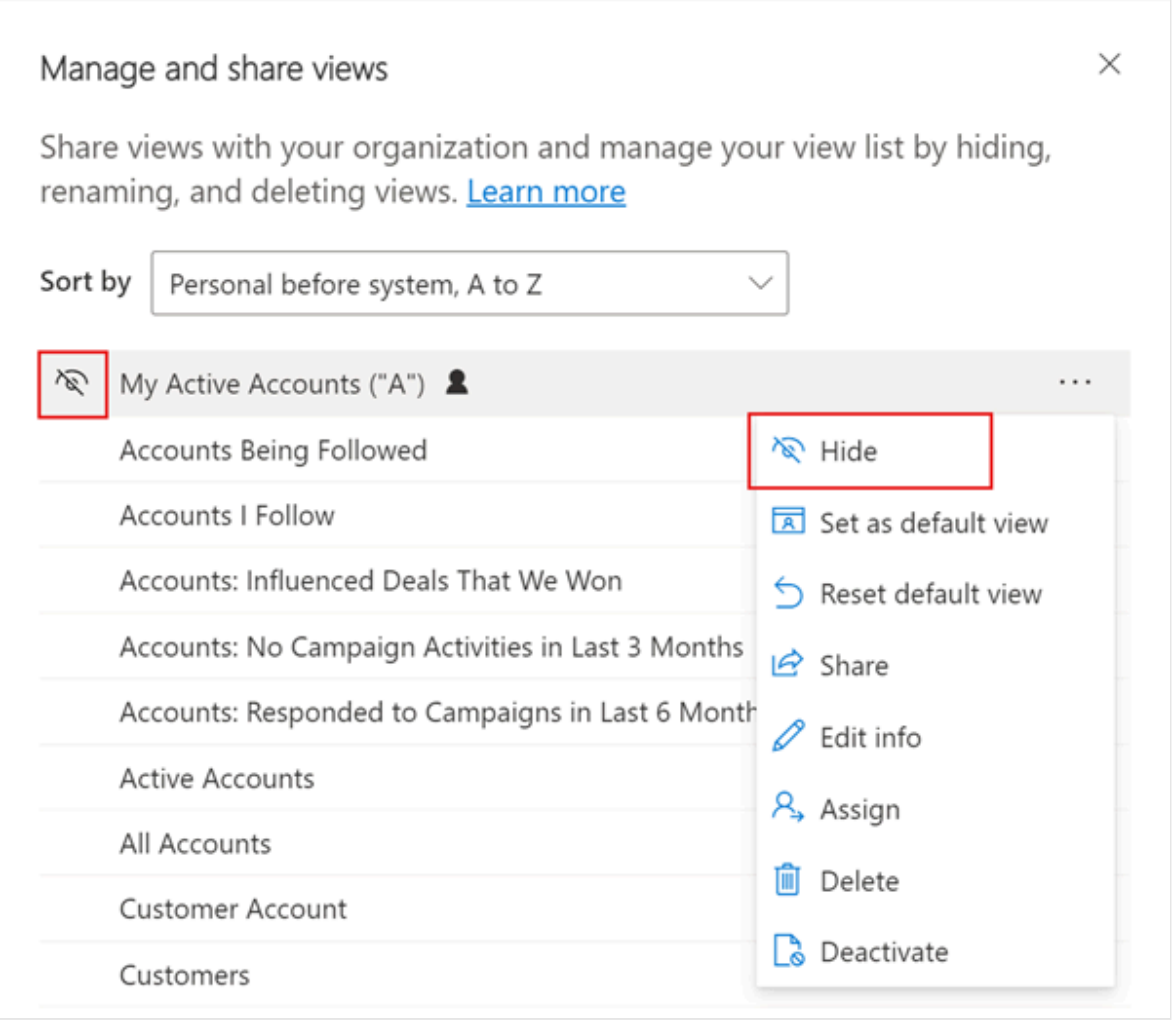
You can hide views in the view selector to personalize the list and reduce clutter. You should keep some things in mind:

- When you hide a view, it's hidden from that table's views in all model-driven apps on all devices.
- If the view is shared with you and other team members, hiding it only hides the view for you. It's not hidden for everyone else who has access to the view.
- You can hide your personal views by default. You can hide system views only if the administrator has allowed it.

- You can't hide a table's default view. If you want to hide the default view, set another view as the default first.
- You can't set a hidden view as the default view for a table.

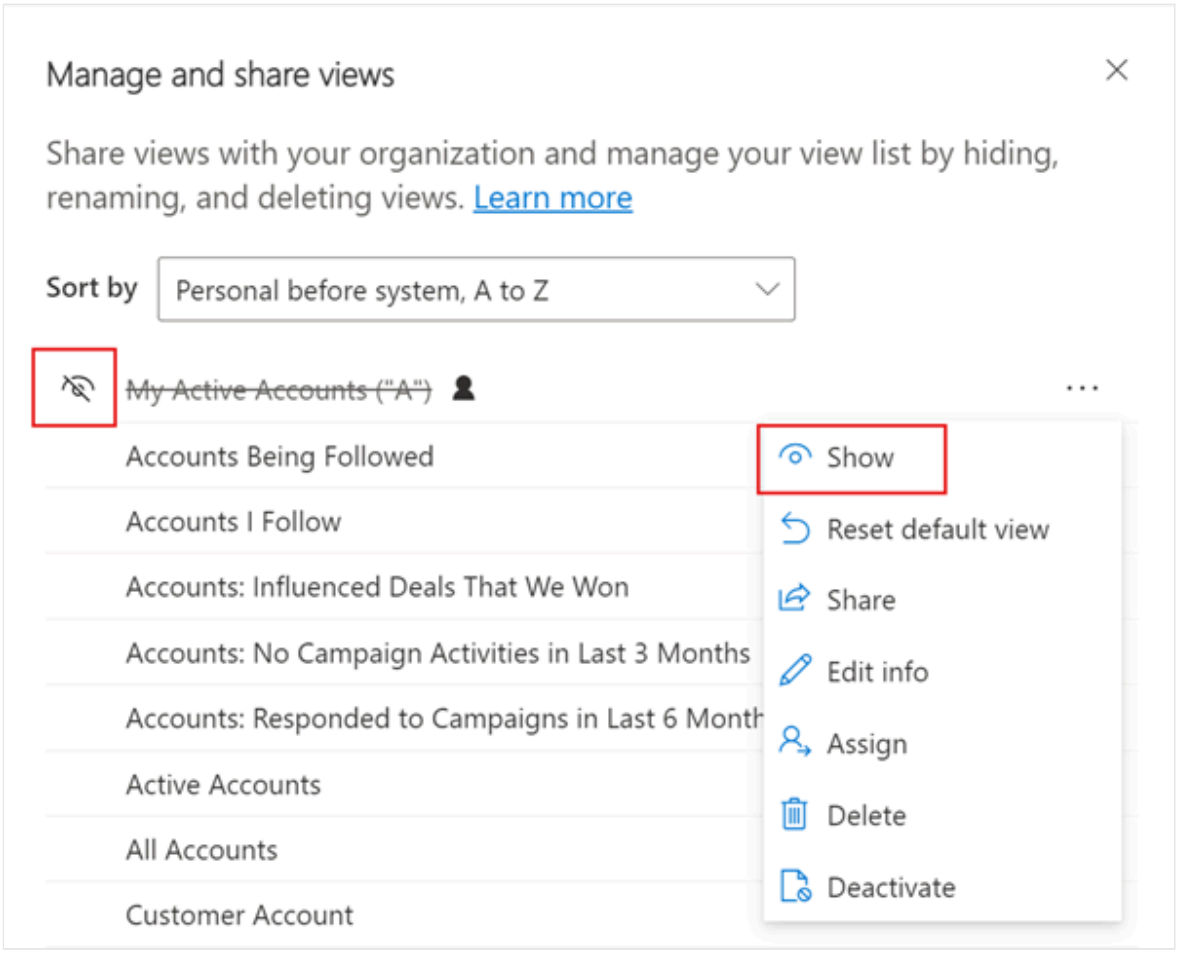
To hide a view:

1. In the view selector, select **Manage and share views**.
2. Hover over the view and select **Hide**. Or, select **View commands** (...) to the right of the view, and then select **Hide**.
3. Select **Apply**.



To restore a hidden view:

1. In the view selector, select **Manage and share views**.
2. Hover over the view and select **Show**. Or, select **View commands** (...) to the right of the view, and then select **Show**.
3. Select **Apply**.



Other view management tasks

- **Set as default**: Makes a view the default view for that table across all model-driven apps in the environment. This option doesn't appear on a hidden view or on a view that's already the default.
- **Reset default**: Changes the default view of a table back to what the administrator set, across all model-driven apps in the environment.
- **Share**: Shares the view with other members of your organization. This option appears only on personal views that you have *Share* permission to. For more information, see Share rows with a user or team.
- **Edit info**: Change the view name and description. This option appears only on personal views that you have *Write* permission to.
- **Assign**: Assigns ownership of the view to another user or team in your organization. This option appears only on personal views that you own.
- **Delete**: Deletes the view. If you delete a personal view, the view is deleted for everyone who has access to it. This option appears only on personal views you have *Delete* permission to.
- **Deactivate/Activate**: Deactivates or activates the view. If you deactivate or activate a personal view, the view becomes inactive or active for everyone who has access to it. This option appears only on personal views you have *Write* permission to.

- **Download Fetch XML**: Download the FetchXML expression for the view. This capability is enabled by an administrator with the security privilege **Enable Download Fetch XML**, found under Miscellaneous Privileges section of the **Customization** tab within the security role definition page.

FAQs and known issues about grids and views

Article • 10/14/2022

[This topic is pre-release documentation and is subject to change.]

How many levels of related table columns can I add to a view using the column editor?

You can add one level of related table columns using the column editor (**Edit columns**) on a grid page.

How many levels of related table columns can I add to nested conditions in a view using the filter editor?

You can add up to 10 levels of related table conditions using the filter editor (**Edit filters**) on a grid page.

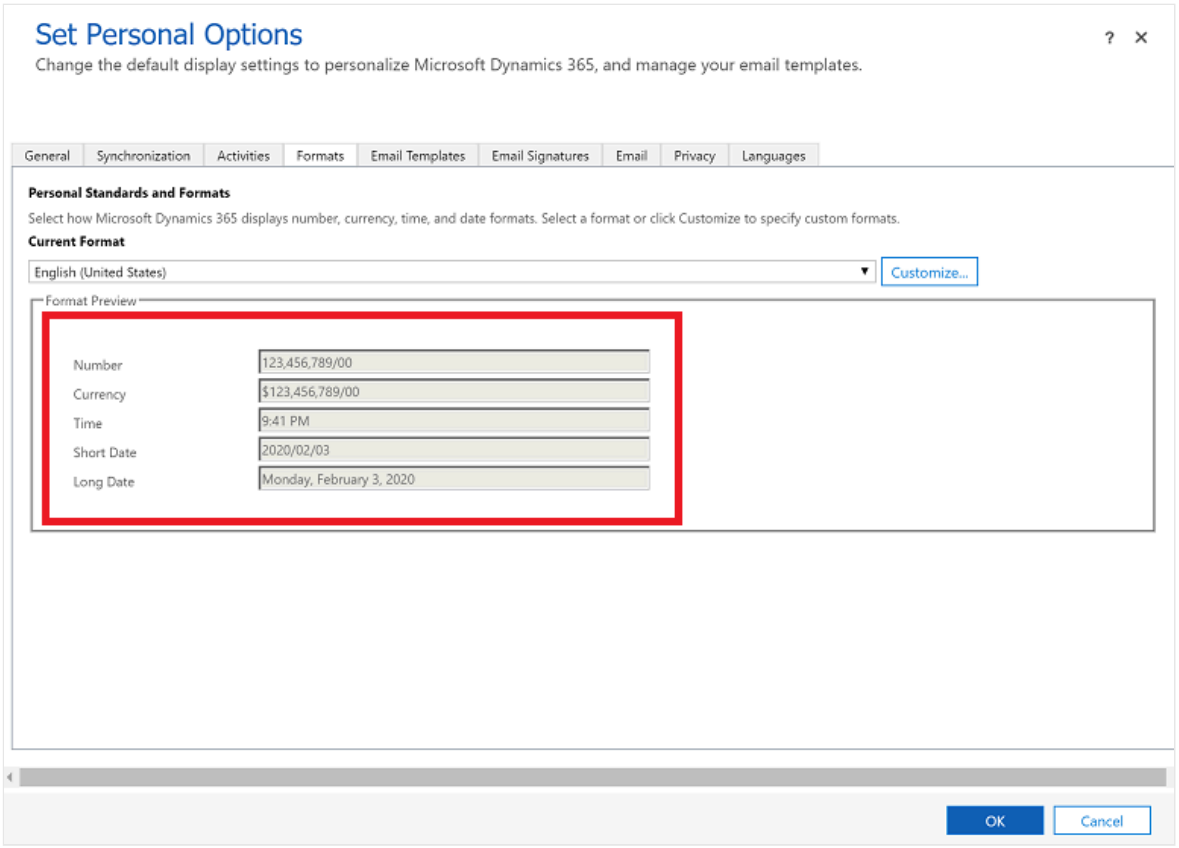
Known issues

- If you change the default display format for number, currency, time, or date and then filter data on a grid, the filter won't show your selected display format. The filters are still displayed in the system default format. In some cases, filtering might not work at all.

  To fix the issue, set the display format for number, currency, time, and date back to the default setting.

  1. In the upper-right corner, select the gear icon  , and then select **Personalization Settings**.

  2. On the **Formats** tab, change the number, currency, time, and date value back to the default setting.



We're working to correct this issue. Check here for updates.

- The advanced filter option on the Queues table doesn't work and displays this error message: *We are unable to display the filter conditions for this view.*
- Public views that include **Contains data** or **Does not contain data** filters don't appear in the list of saved views in legacy advanced find.
- When you open the **Edit filters** panel on certain Activity tables, you will see a condition filtering tables that are not valid for Unified Client. These conditions may not be a part of the FetchXML of the view.
- When you choose the **Search for rows in a table using advanced filters** option or the **Advanced find** button when working in a **Dynamics 365 - Custom** app with a modern, advanced find experience enabled, you might see a loading spinner appear indefinitely.

View and manage records in focused view

09/15/2025

Focused view allows you to view and manage account, contact, lead, opportunity, and other records and their associated activities on one page. This view makes it easier for you to stay focused on your tasks and reduces the need to navigate between multiple screens. It also allows you to better organize and prioritize your tasks, thus saving time and effort.

Focused view is now available for all entities, including custom entities. However, your administrator must enable it for you to access it. More information: Enable focused view and set it as the default view.

> **Note**
>
> - Focused view is similar to the sales accelerator workspace view. **Learn how to prioritize your sales pipeline through work lists**.
> - To view the latest updates and features of focused view, you must opt in for early access updates. Contact your administrator to enable early access updates for you. More information: **Opt in to early access updates**.

Open the focused view

Focused view is a centralized place to view all your open records that have activities that are due or pending, without having to navigate through multiple screens. By default, the lead entity grid opens in focused view. However, an administrator must enable and set other entities such as Account, Contact, Opportunity, and custom as default. More information: Enable focused view and set it as the default view.

From the sitemap, select an entity such as lead, account, contact, or opportunity. The entity grid opens in the focused view.

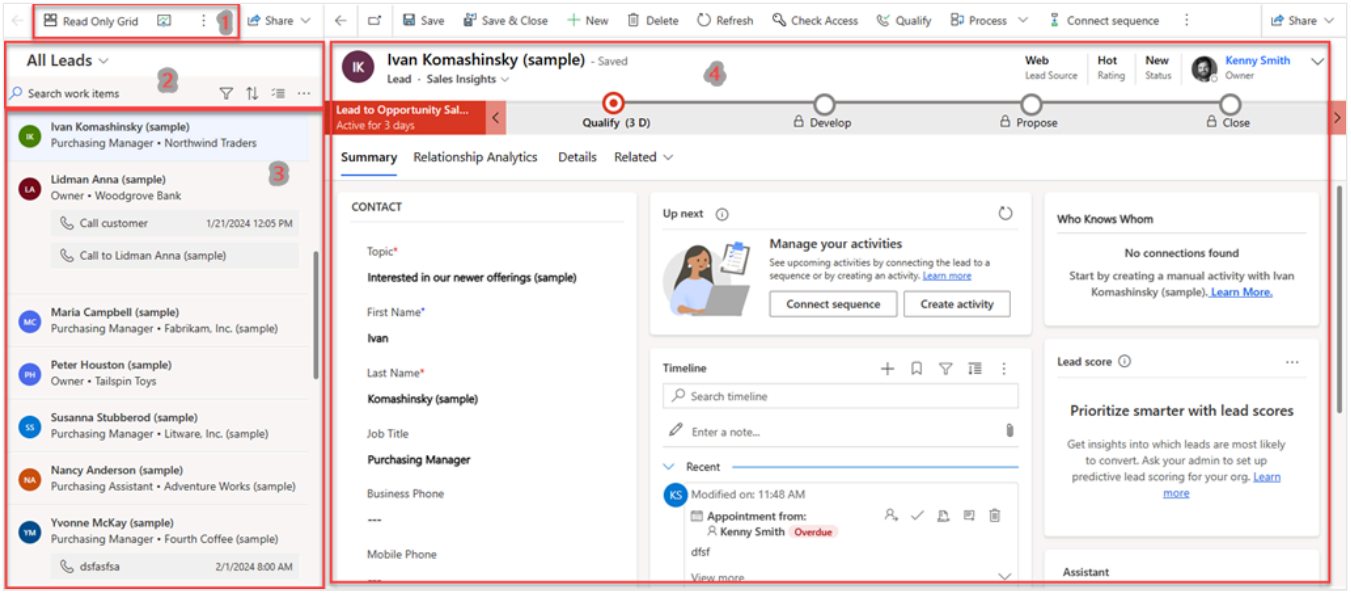
If you open an entity grid in the focused or list view and then close it within the same view, the application will remember to open the grid in the same view when you access it the next time. For example, if you open the Account entity grid in the focused view and then close it, the next time you open the Account entity grid, it will open in the focused view.

> **Note**

Focused view is now available for the **Activities** entity. However, you must opt in for early access features.

Understand the focused view

The following image is an example of focused view for the Lead entity:



Focused view is categorized into the following sections.

1. **Switch view and command bar**:

   - **Switching a View**: This action allows you to change from the focused view to the list view. To do this, select the **Read Only Grid** option. The **Read Only Grid** option is only available if you have one control for the entity. If you have multiple controls, the **Show As** option is displayed instead. Select **Show As** and then choose an option to change to the required view.
     If you have opted in for early access updates, the **Show As** option is displayed as first option on the command bar.
   - **Command bar**: This feature contains actions that help you perform bulk actions on multiple records. To use it, select **More options**. You can then choose the records that you want to work with and perform the required actions.

2. **Work list actions**:

   - **Search, filter, and sort**: These options are displayed at the top of the work list item view. You can search, filter, and sort the records that you want to view in the list to quickly identify only the records that you want to work with. You can also switch between focused view and list view. The attributes available in the view are displayed as filters and sort. These attributes include fields added through

workspace customizations in the sales accelerator, and any new fields added to the work list card through card customization.

> ⓘ **Note**
> - The following attributes types are not supported in filter and sort—Uniqueidentifier, related entities, and advanced filter that are created through workspace customizations.
> - Filters aren't supported on mobile devices.

For lead and opportunity entities, filters might display deprecated attribute options. To remove these filters, go to work list card customization and remove the **Predictive scoring** field.

If you want to add more filters to the view, you can create an advanced filter.

- **Advanced filter**: Create an advanced filter option using the expression builder to refine the content displayed in the work list. You can have only one advanced filter defined for an entity in focused view. Select **Edit filters** to open the expression builder. In the expression builder, create the conditions as required and then select **Apply**. When the advanced filter is applied, the filter icon is filled with a blue color, and the advanced filter tag is displayed under the filter options.

- **Select multiple records**: To perform bulk actions on multiple records, select the **Select multiple records** option. You can choose the records that you want to work with and then perform the required actions. On the command bar, select **More options** to perform the bulk actions.

- **Refresh and Settings**: Select **More options** to perform list refresh and configure the work list card through settings.
  - **Refresh**: Select **Refresh** to refresh the list of records.
  - **Customize work list card**: Select **Settings** to customize the work list card. More information: Customize the work list card

3. **Records list**: All records for the selected entity, including records with no associated activities, are displayed in a card format. You can perform and complete the activities, whether manual or automated, on these cards from the current date and from previous dates. Each card displays information such as the name of the record, the primary contact name, and the next best action.

   - **Next best actions**: These include the top two activities with the latest due date. To complete the next best action, hover over the action and then select the action icon.

- **No action items**: When no action items are available for the record, the record displays information such as the name and contact details.
- **Predictive scoring**: When predictive scoring is enabled in your organization, the list also displays the score for that lead or opportunity at the upper-right corner of the card. Learn more about prioritizing leads through scores and prioritizing opportunities through scores.

4. **Record details**: Select a record from the work list to view its details on the same page. When you select an entity record in the detail view page, the selected entity record is displayed inline on the same page, keeping the work list visible. For example, selecting a contact record within an opportunity record keeps the work list visible while displaying the contact details.
   However, when you perform certain actions such as creating a new record, composing an email, or opening an organization chart, the view opens in full page and hides the work list. Select the **Back** button to return to the actual work list record with the work list visible.
   When records are updated in the view, work list gets auto-refreshed if the entity on the work list matches the entity form of the record. After the refresh, if the current form record exists in the work list, the same record will remain selected else, the first record in the work list is selected.

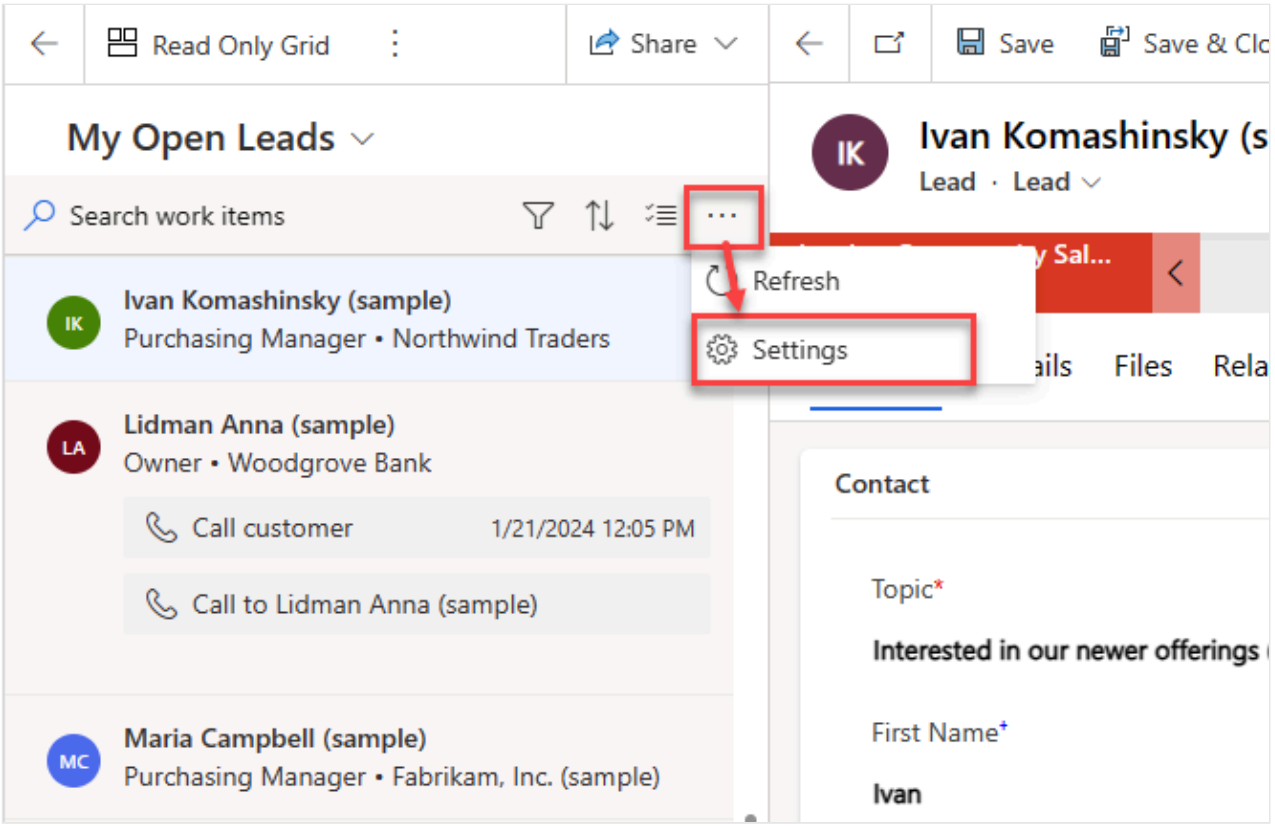
Customize the work list card

You can customize the work list card to display the information that you want to see. When sales accelerator is enabled, the customizations you make here are also reflected in the sales accelerator work list items. More information: Customize the appearance of work items in sales accelerator

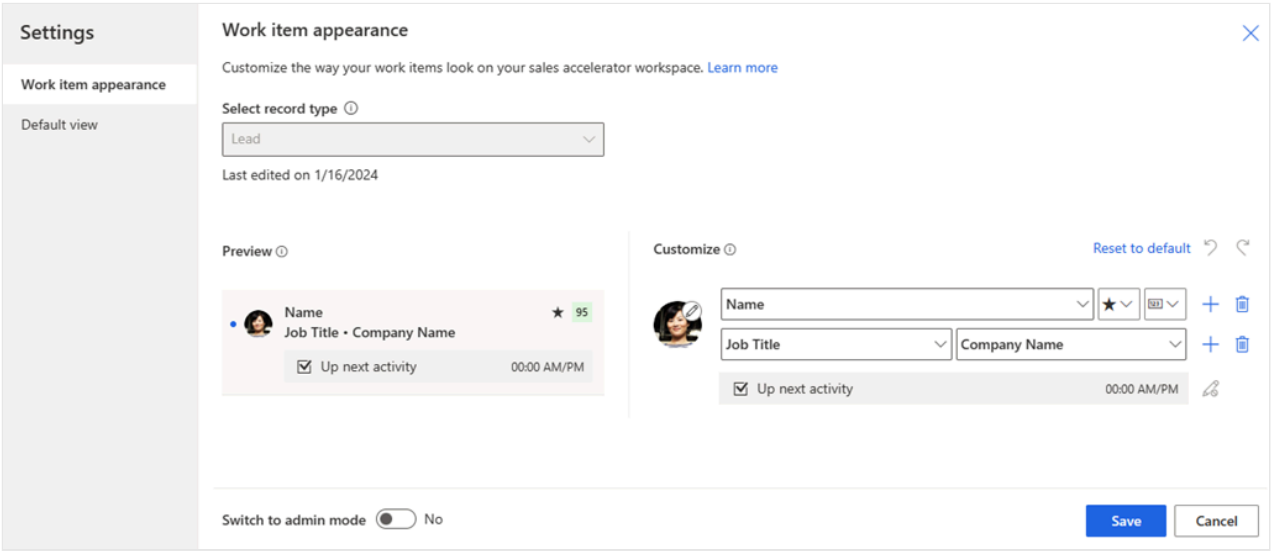
The customization that you make to the work list card is specific to the entity type. For example, if you customize the work list card for the Lead entity, the customization is applied only to the Lead entity. The customization isn't applied to the Account, Contact, Opportunity, or other entities. These customizations also affect the sales accelerator workspace view.

> **Note**
>
> You need to have read permissions for the **Work list user setting** entity to see the **Settings** icon and customize the work list card. Contact your administrator to provide the required permissions.

1. In the focused view page, on the work list pane, select **More options** and then select **Settings**.



2. In the **Settings** dialog box, select **Work item appearance**.



The following are the considerations to keep in mind when customizing the work list card in focused view:

- The **Switch to admin mode** and **Lock customization** options are available only for administrators.
- If the customization is disabled, contact your administrator to turn off the customization lock.
- When admin mode is turned on, you can customize work items for all users within your organization. When turned off, you can customize work items only for yourself. If admin mode is turned off, contact your administrator to turn it on. More information: Lock or unlock customization for other user roles

- You can't customize the action items in the work list card. Also, in preview mode, the **More options** icon isn't visible to select action items that are configured in the sales accelerator workspace view.

3. Under the **Customize** section, use the following options to customize:

   - To change the icon that appears on a work item, select the pencil icon, and then choose one of the following options:
     - **Record image**: A photo of the contact, if one is available.
     - **Record initials**: The contact's first and last initials.
     - **Record type**: The icon associated with the record type.
     - **Activity type**: The icon associated with the current activity on the record.

   - To change the content of work items, select the fields or attributes to display:
     - To change an existing attribute, select a different one in its place from the list.
     - To add an attribute in the same row, hover over an existing attribute and select **More options** > **Add a field**. You can show up to three fields in a row.
     - To add an icon in the same row, hover over an existing attribute and select **More options** > **Add an icon**. You can show up to three icons in a row.
     - To add a row, select the add icon (+). You can show up to four rows of information in a work item.
     - To delete a field or an icon, hover over it and select **More options** > **Remove**.

     > ⓘ Note
     >
     > Currently, the **Follow indicator** option doesn't work in focused view.

   - To remove all customizations and restore work items to their original appearance, select **Reset to default**.

   The **Preview** section displays a preview of the work list card based on the customizations that you make.

4. Select **Save**.

Auto-refresh records

Records in the work list can be refreshed automatically when they are updated. However, an administrator must enable this feature and configure the time interval for the records to refresh. For more information on how to configure this feature, see Automatically refresh records.

Increase the number of records displayed in focused view

You can configure the number of records that are displayed per page in the focused view. By default, 50 records are displayed, but you can increase this number up to a maximum of 250. To do so, go to your personalization settings, and under the **General** tab configure the **Set the number of rows shown per page in any list of rows** option to increase the number of records displayed per page in focused view. More information: Set personal options

Visualize data in a view with Power BI service

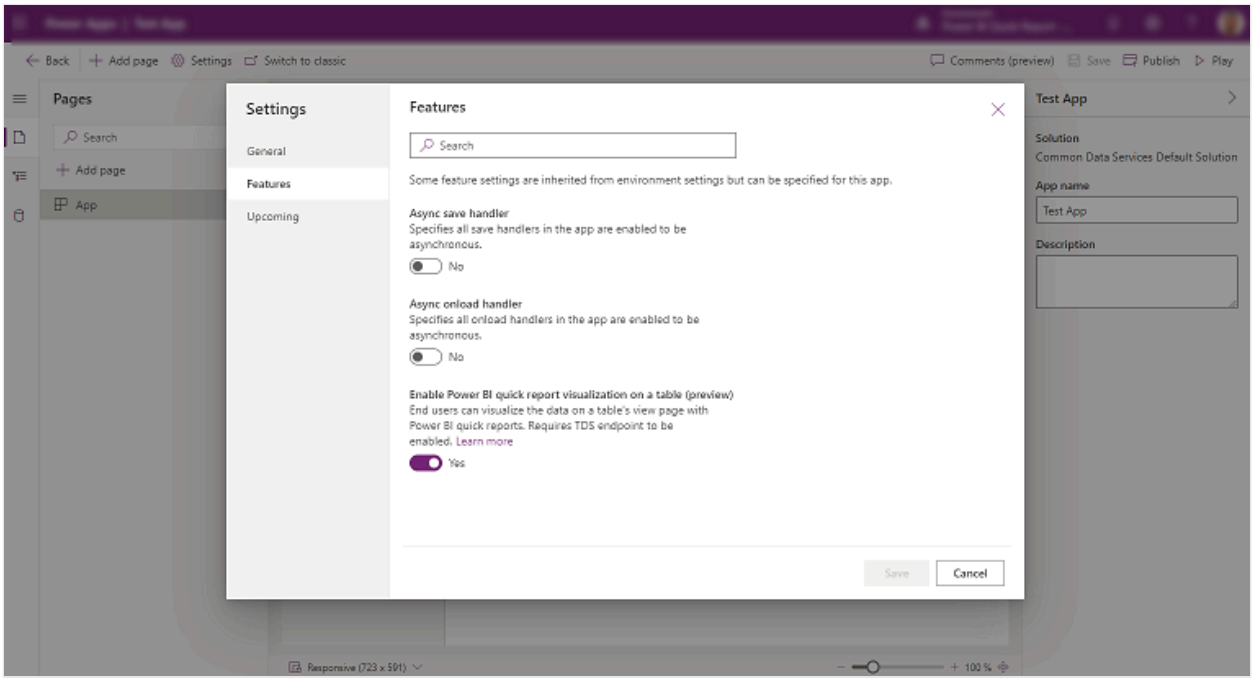
Article • 03/10/2025

Create reports in the Power BI service using the data that's in a view of your model-driven app. Power BI automatically generates the visuals for you, so you can start exploring the data with just a few clicks.

If you're new to Power BI reports and need more information, see Reports in Power BI.

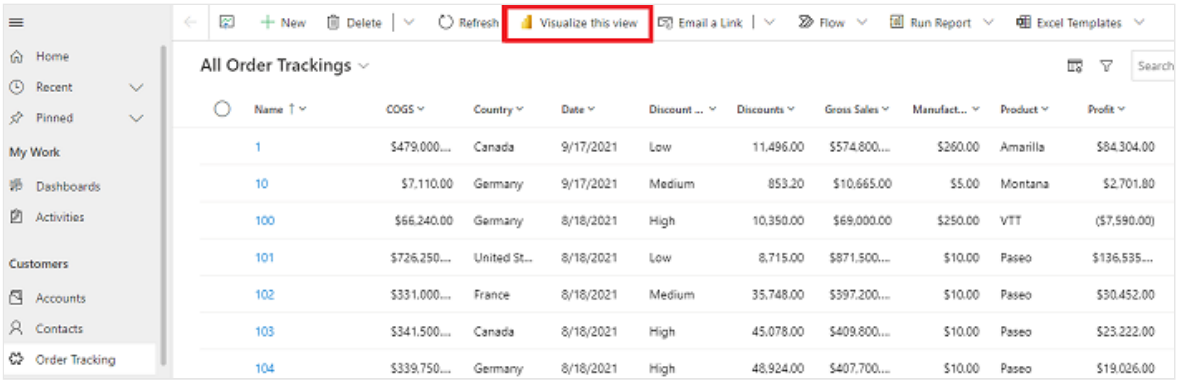
If you're using Power BI Desktop, you can also create a report using data from Dataverse in Power BI Desktop.

> **Note**
>
> Your administrator needs to turn on the **Enable Power BI quick report visualization on a table** feature setting, to use the capabilities that are covered in this topic. For more information, see Manage feature settings.

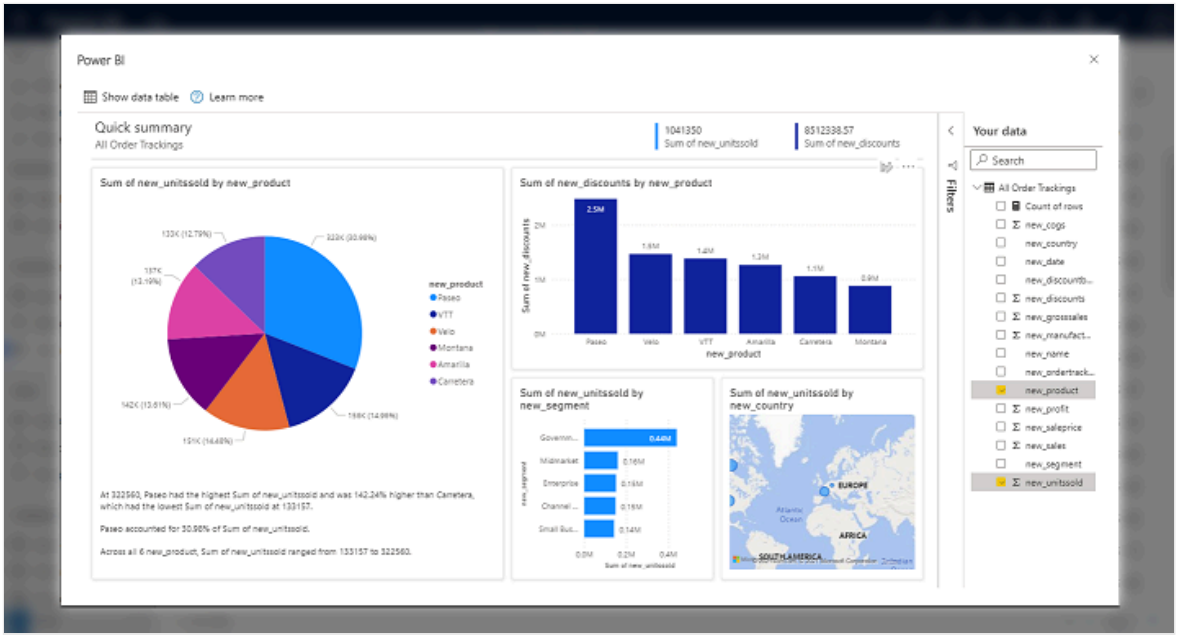


Visualize in Power BI

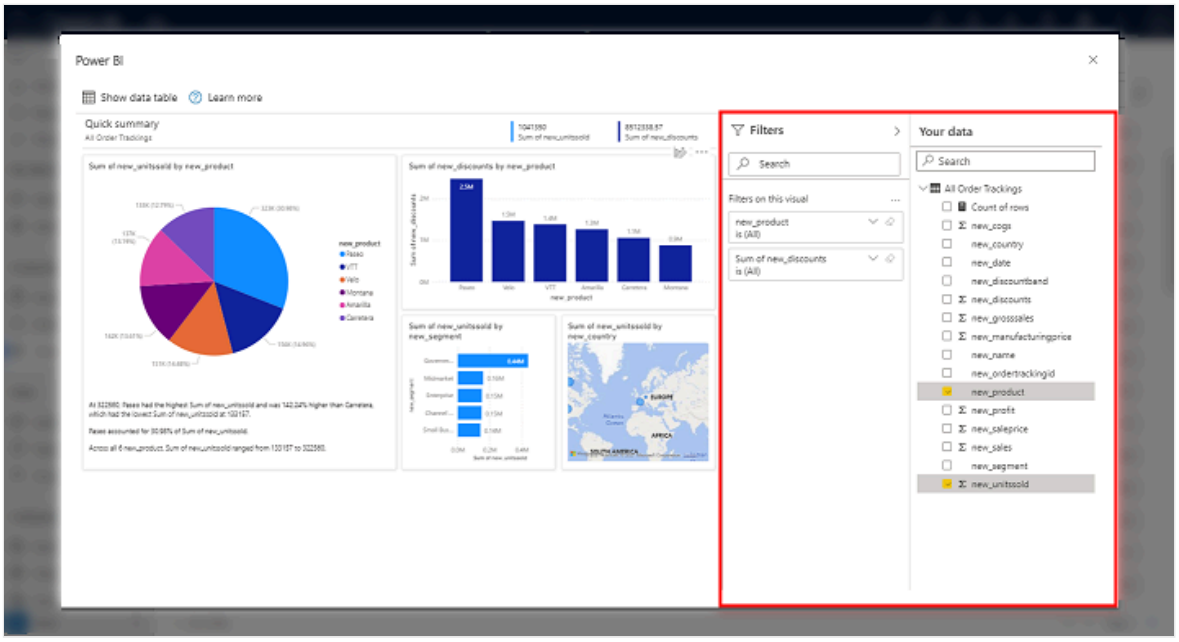
1. In your model-driven app, select a table and then on the command bar, select **Visualize this view**.



2. Power BI-generates visuals of the data in your view, based on the view definition. That is, the filters acting on the view are automatically applied to the Power BI visualization. A subset of columns that are part of the view are used to auto-generate the Power BI visuals.



The full set of view columns are available in the Power BI report to be used to change the data you see in the report.



For more information on how you can interact with this visualization, see Visualize your data quickly from Power Apps and Dynamics 365 apps (preview).

Licensing considerations

Anyone can use the **Visualize this view** feature to explore the data in a view, but to use the full edit experience, publish reports, access reports that others have published, or delete reports, you need a Power BI Pro license. If you don't currently have a Pro license, you can buy a Power BI Pro license or start a free trial.

Known issues and limitations

- The first time you visualize the data in a view, creating the dataset and report can take some time. We're working to improve this performance experience.
- This feature isn't supported for the **Activities** table due to a limitation in generating charts.
- This feature isn't supported for guest users in a tenant.
- If you're building your app for mobile, Power BI dashboards aren't a recommended choice to visualize data. Power BI dashboards are suited for larger screens, and the small screens and form factor of mobile devices can cause usability issues with scroll bars, filters, and more.

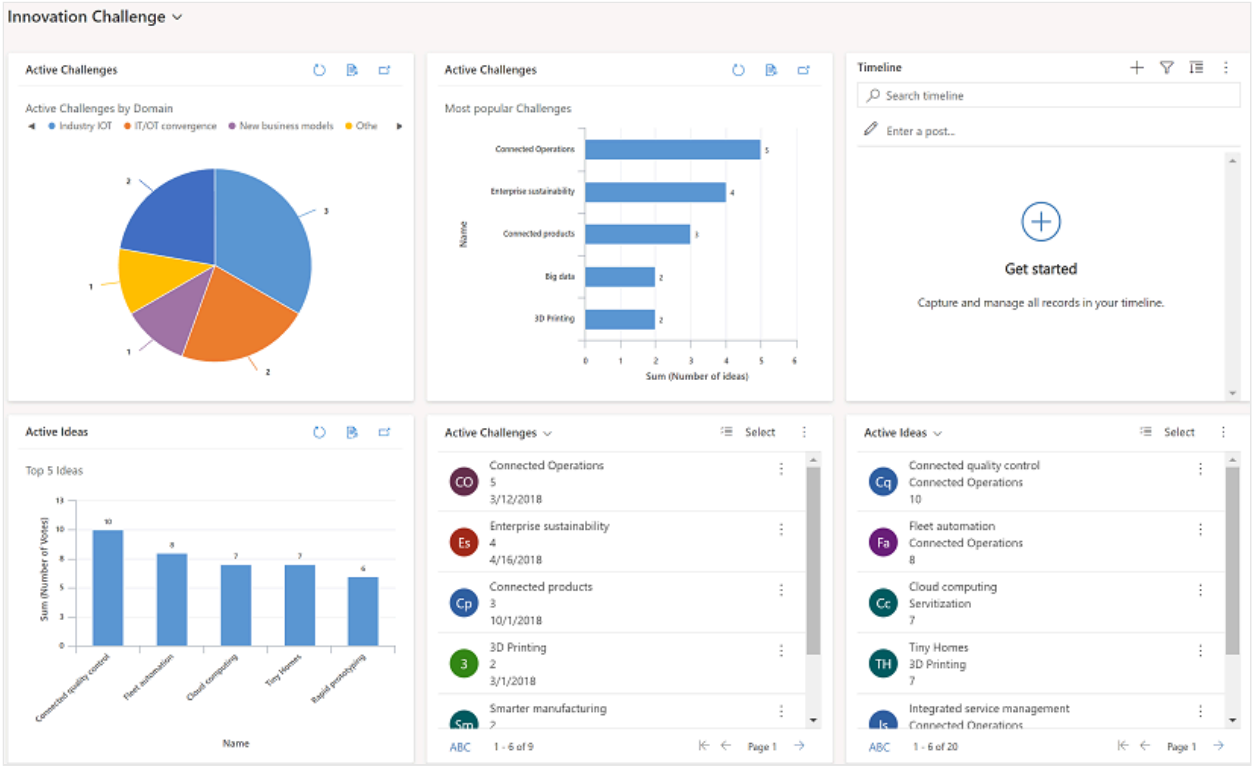
Track your progress with dashboards and charts

Article • 01/16/2025

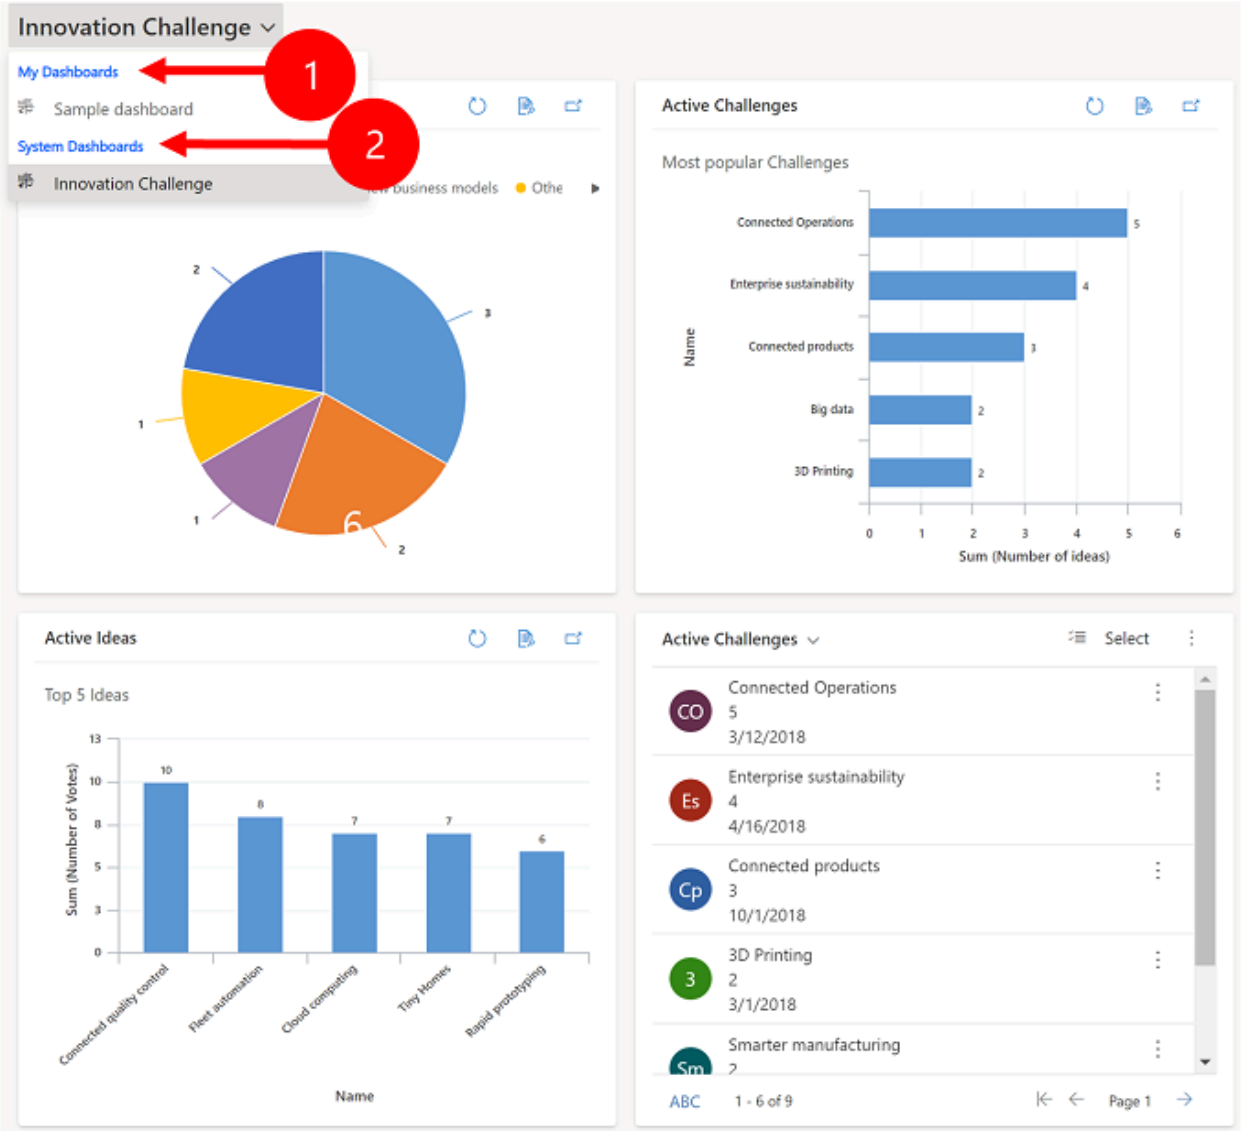
A dashboard is made up of a collection of easy-to-read charts and graphs that provide visual representation of filtered app data. The interactive charts and graphs on a dashboard display important data that gives you a 360-degree view of your business and helps you to understand key performance indicators (KPI).

Dashboards are available for all row types. Charts are available on the Dashboard page, Grid page, Associated Home page, and Edit Form page.



View dashboards

There are two types of dashboards, **System Dashboards** and **My Dashboards**.



Legend:

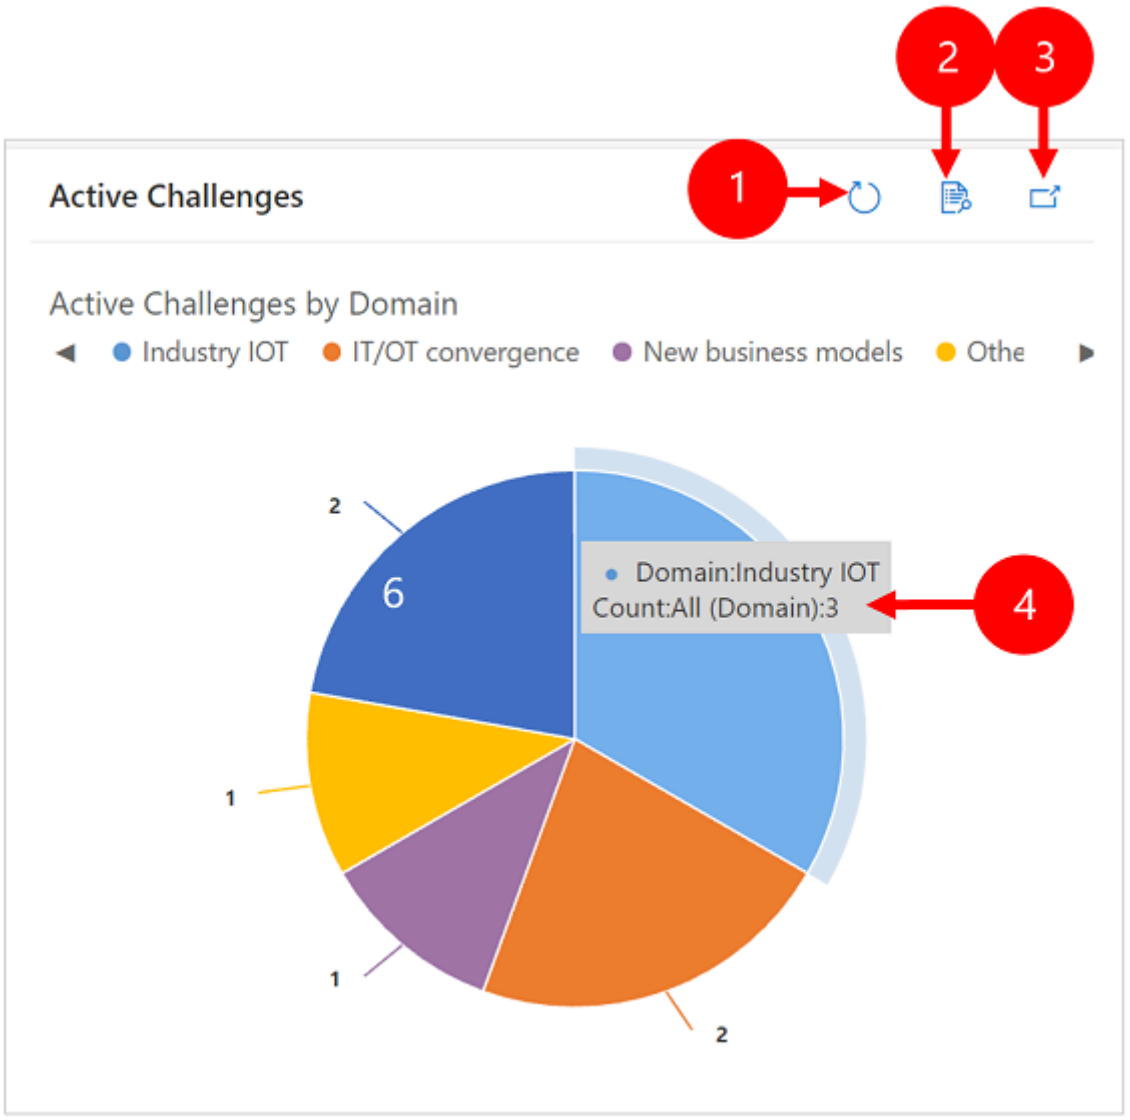
1. **My Dashboards**: Personal dashboards that can only be seen by the user who creates them. The user can also share their personal dashboard with other users if the user has sharing privileges for their security role.

2. **System Dashboards**: Created by your administrator. By default, these dashboards are visible to all users.

> ⓘ Note
>
> - When a personal dashboard is shared, the owner of the personal dashboard needs to explicitly share any contained, personal charts or personal views because they have separate permissions.
> - When a user sets a dashboard as default (via the **Set as default** action in the command bar), all page navigation to dashboards will take the user to the

default dashboard, which may be a different dashboard than the named dashboard the user selected.

Expand, refresh, and view rows

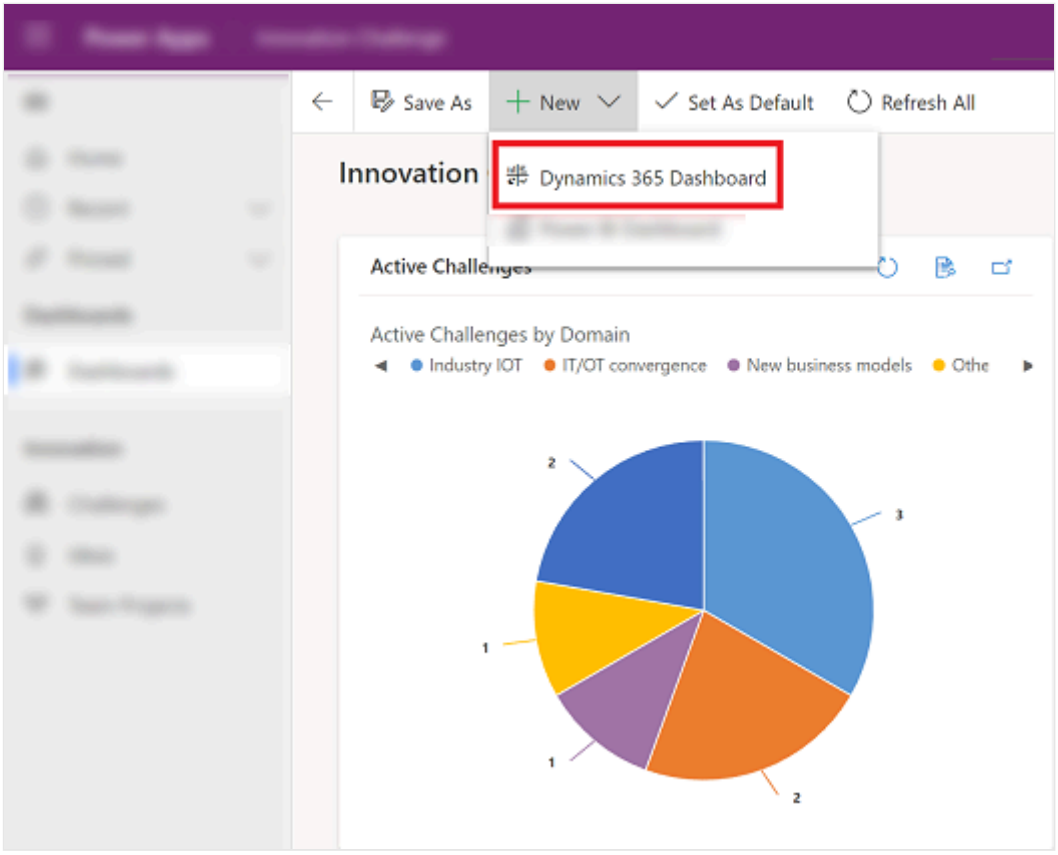


Legend:

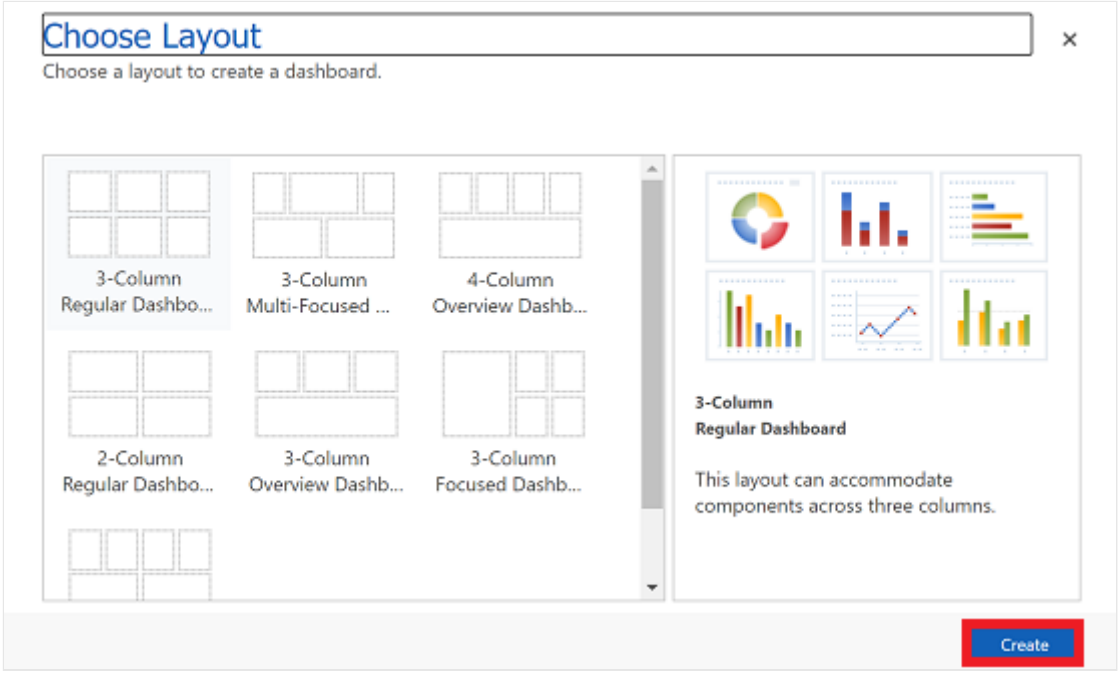
1. **Refresh**: Refreshes the rows in the chart.
2. **View Records**: See the chart and the underlying rows together. This opens the chart for the corresponding rows.
3. **Expand Chart**: Shows the chart in full screen mode. The chart is still interactive in expanded mode.
4. **Tool tips**: Hover your mouse over the chart to see a tooltip that provides quick information about that area of the chart.

Create a dashboard with charts

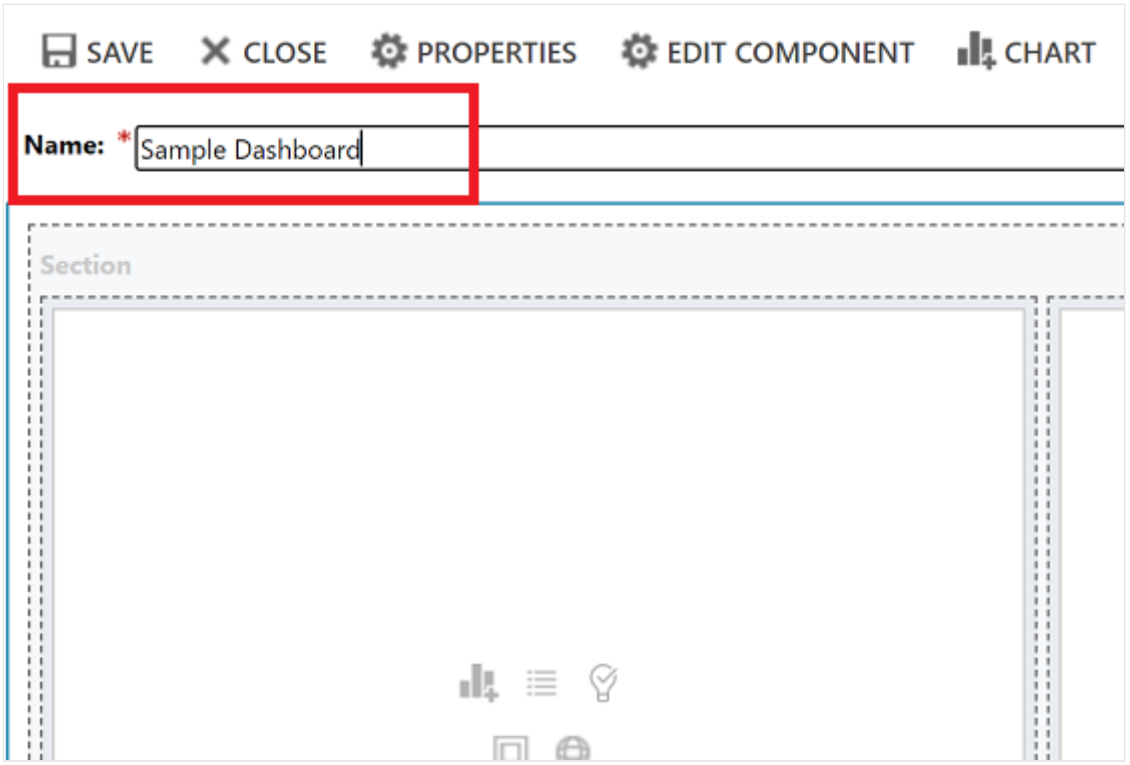
1. Go to **Dashboards** and then on the command bar select **New** > **Dynamics 365 Dashboard**.



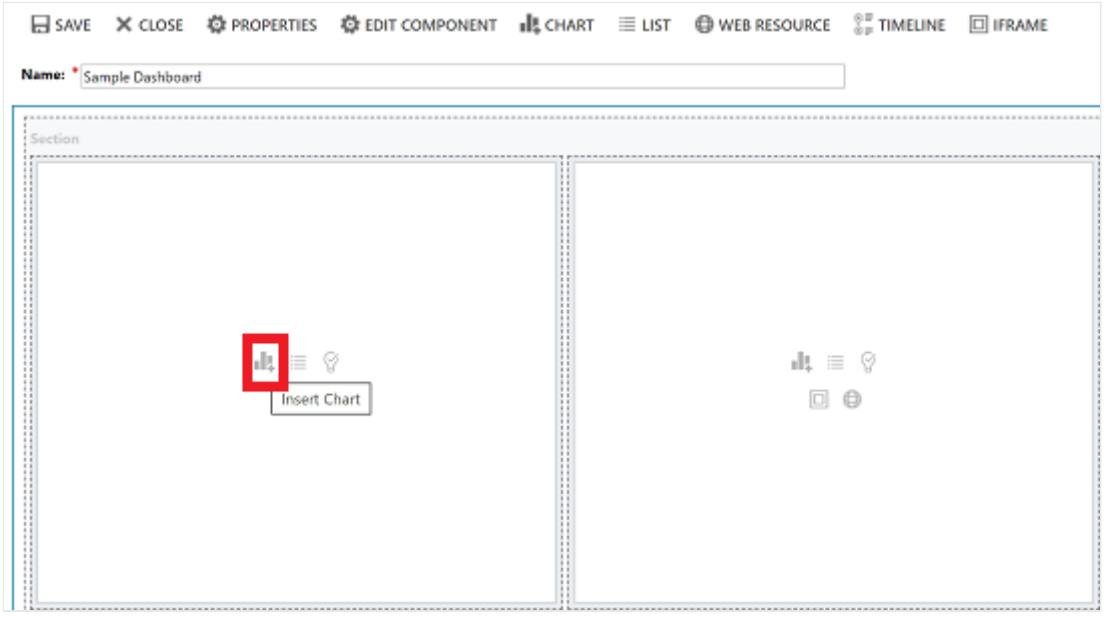
2. Choose a layout and then select **Create**. This is how your dashboard displays the charts, graphics, and numbers.



3. Type a name for the dashboard.



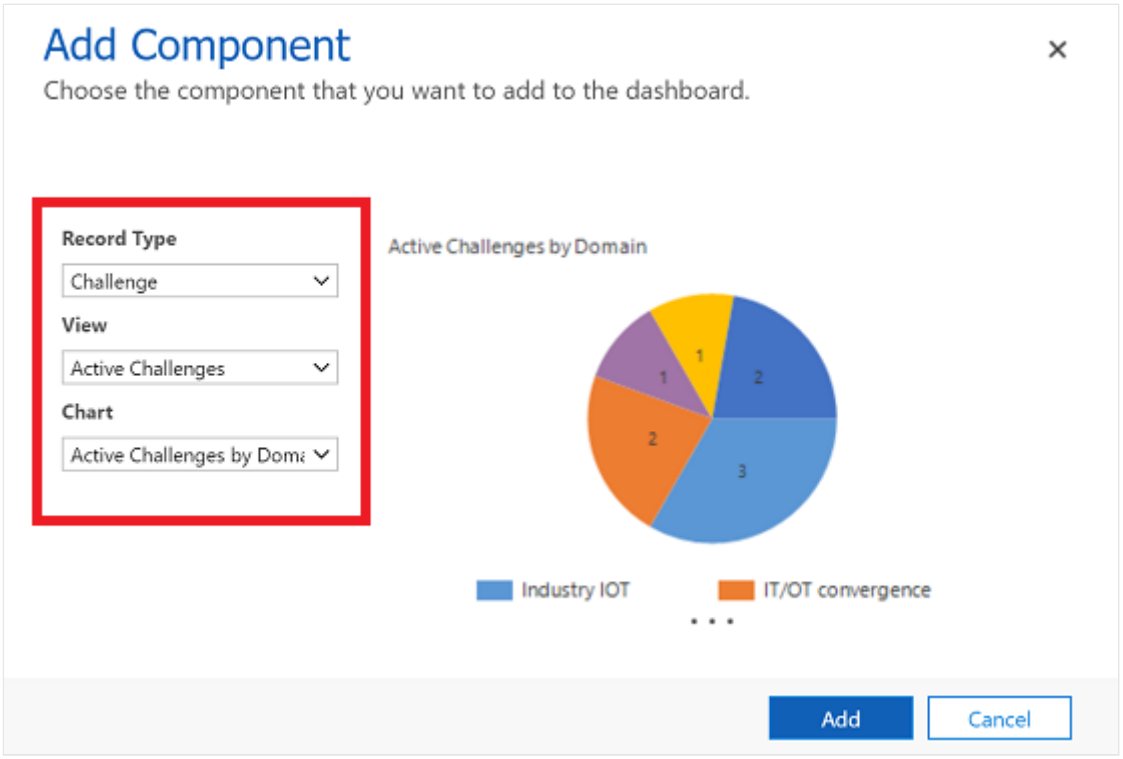
4. Add what you want to each area of your dashboard. For example, let's add a chart.



5. On the **Add Component** dialog box, select your options.

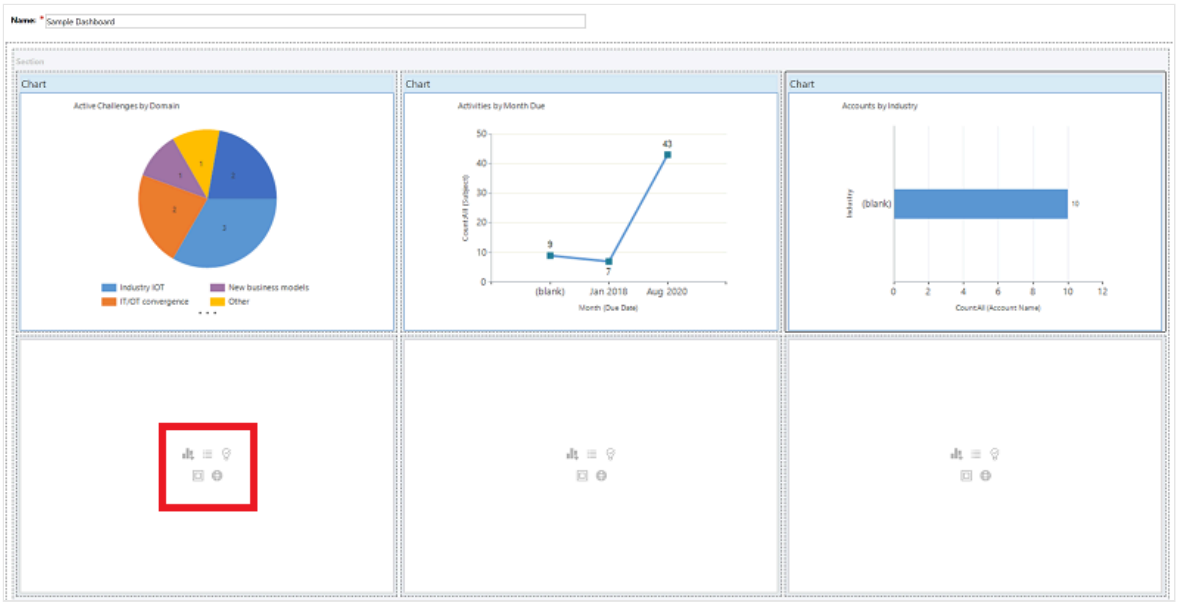
Expand table

	Options
Row Type	Select a row.
View	Select a view for the row.
Chart	Select the type of chart that you want use.



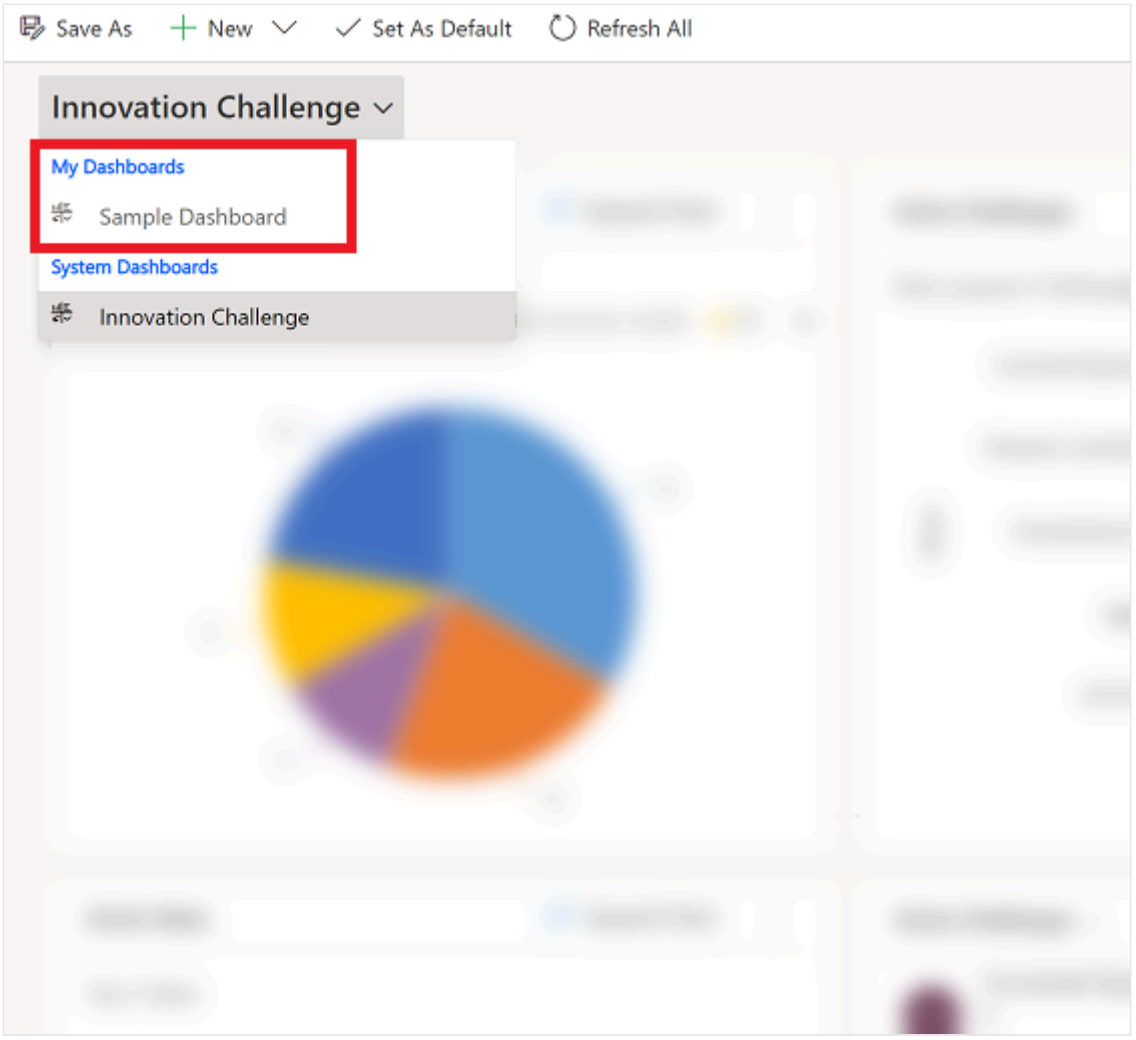
6. When you're done adding each component, select **Add**.

7. Continue adding components to the dashboard. You can add up to six components.



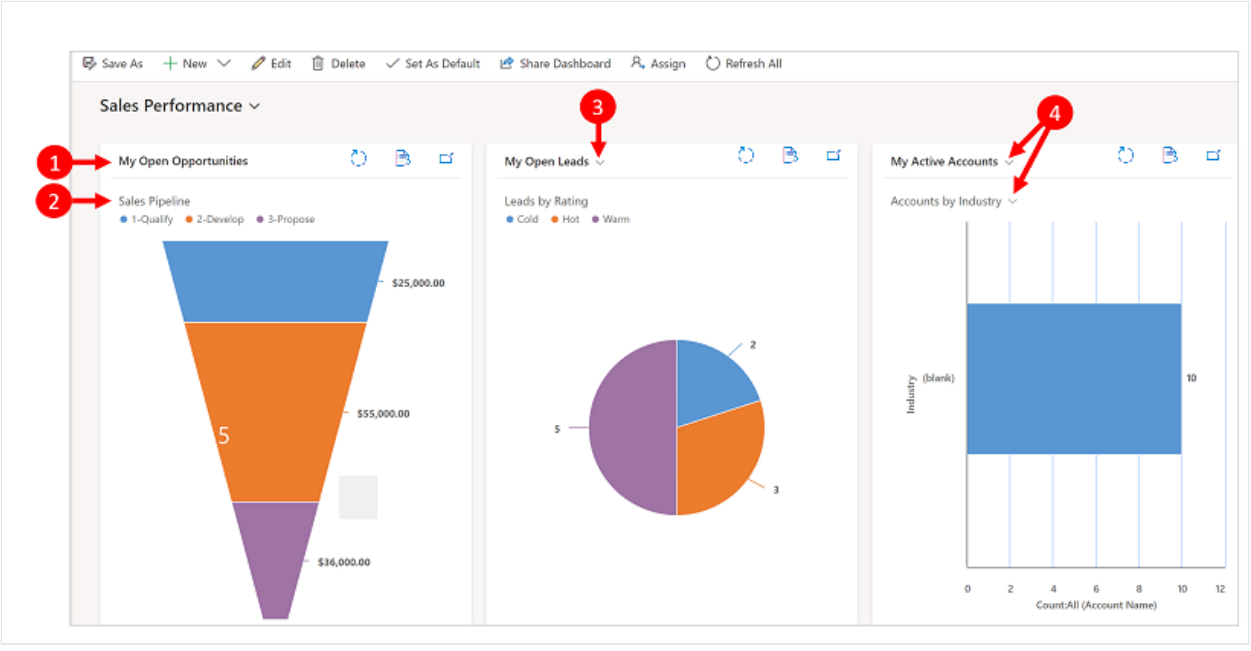
8. When you're done, on the command bar select **Save**.

9. The dashboard that you created will appear in the drop-down menu under **My Dashboards**.



Edit the properties of a chart

When you add a chart on a dashboard, you can edit the chart properties and modify the chart view and display options. The following screenshot shows how a chart will display based on the chart properties that you selected.

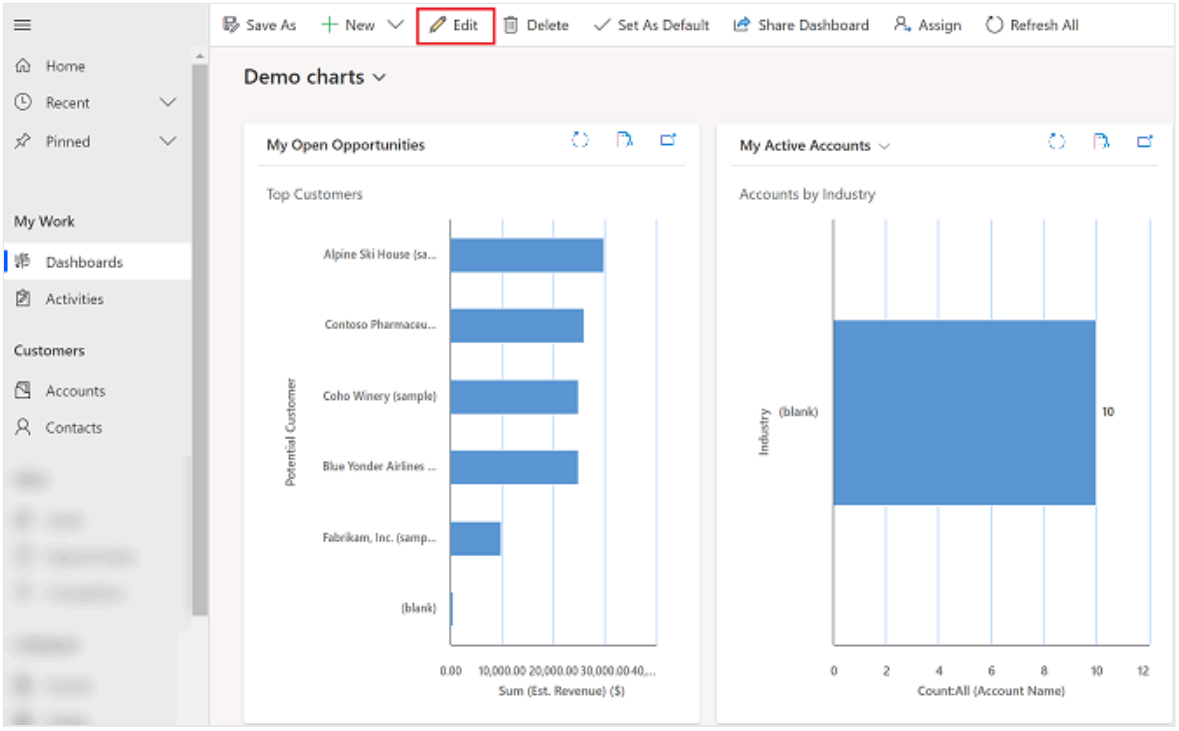


Legend:

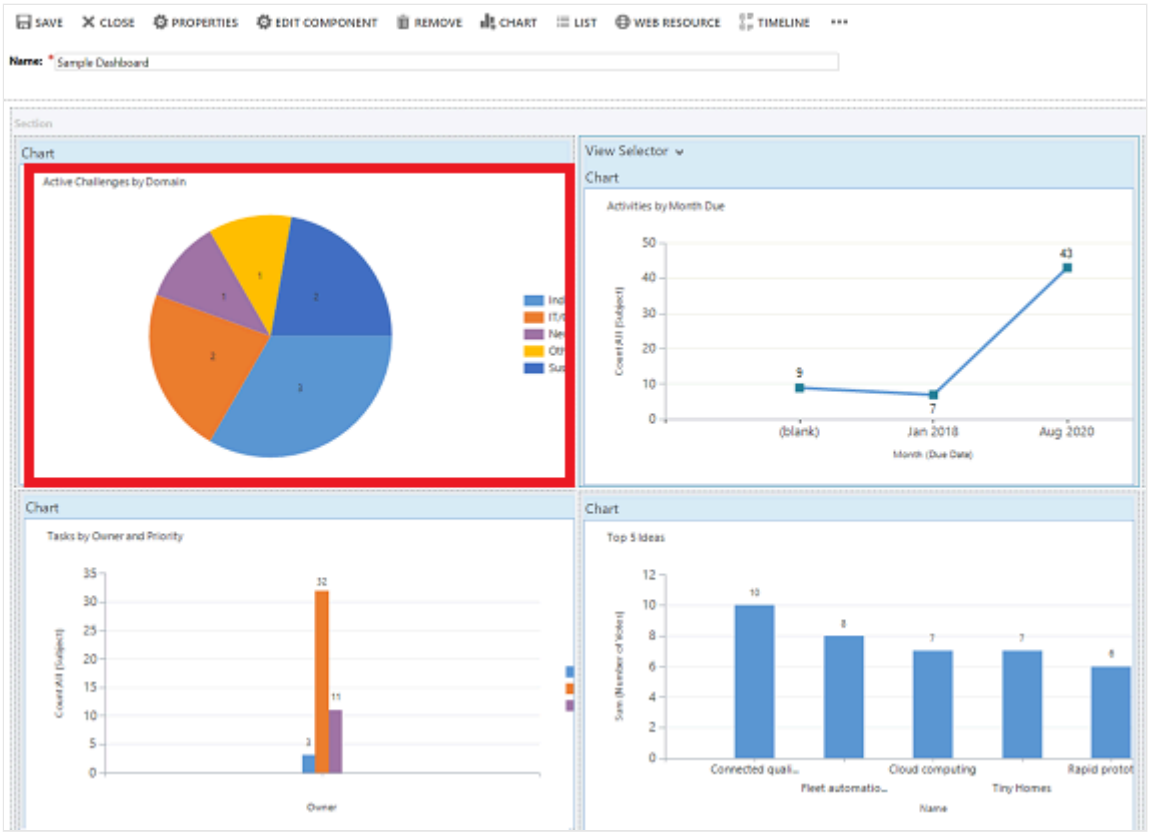
1. View title with **View Selector** turned off. You can't toggle between different views. You only see the title.
2. Chart title with **Display Chart Selection** turned off. You can't toggle between different charts for the table. You only see the title.
3. Only **View Selector** is turned on. You can toggle to a different view and the chart will render based on the underlying data for the selected view.
4. Both **View Selector** and **Display Chart Selection** is turned on. You can toggle to a different view and chart for the table.

To edit the chart properties, you need to edit the dashboard that the chart is in. If you're in the process of adding a new chart on a dashboard, then you're already in edit mode and can skip to step 2.

1. Go to the dashboard that the chart is in and on the command bar, select **Edit**.

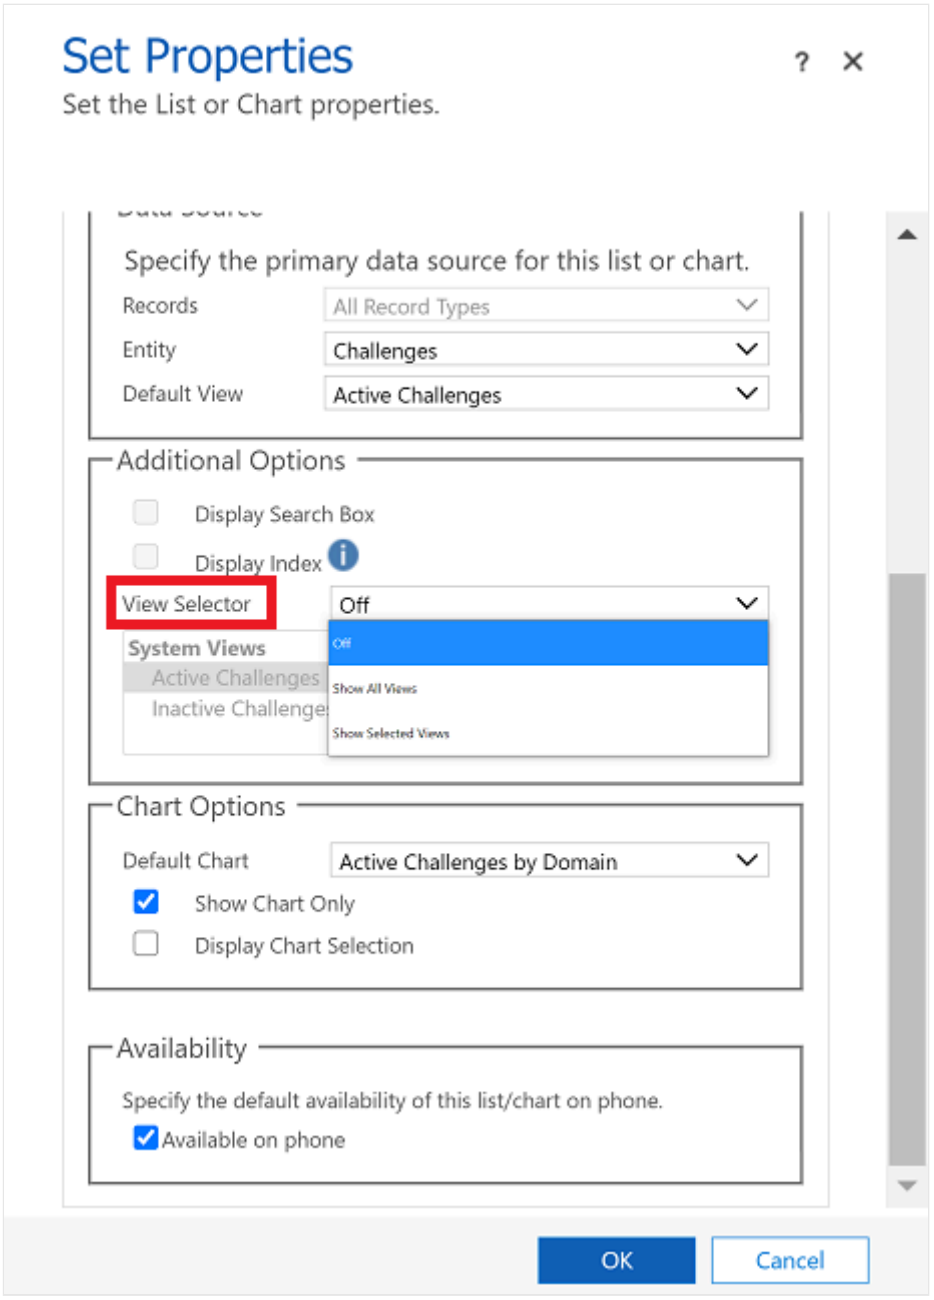


2. Double-select the chart that you want to edit.

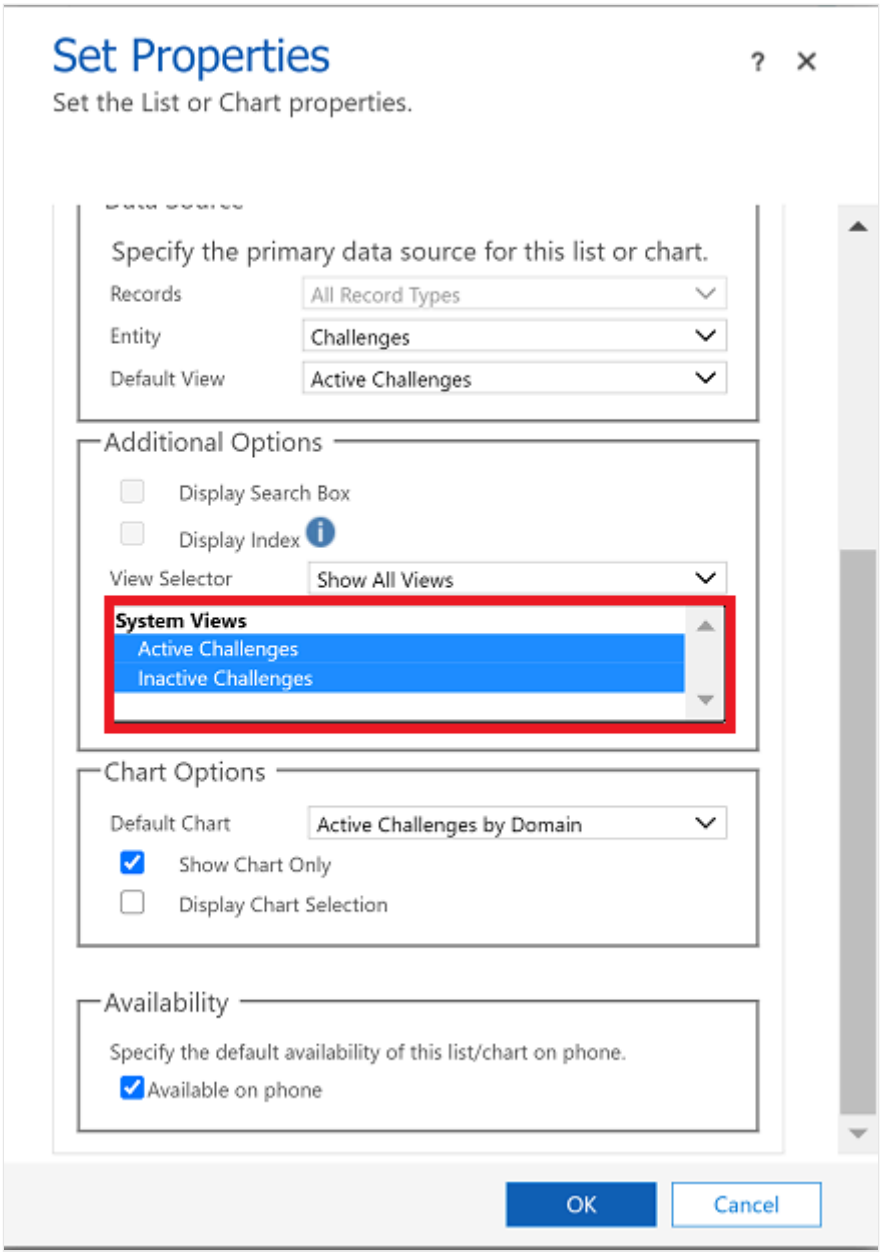


3. On the **Set Properties** dialog box, select a **View Selector** option.

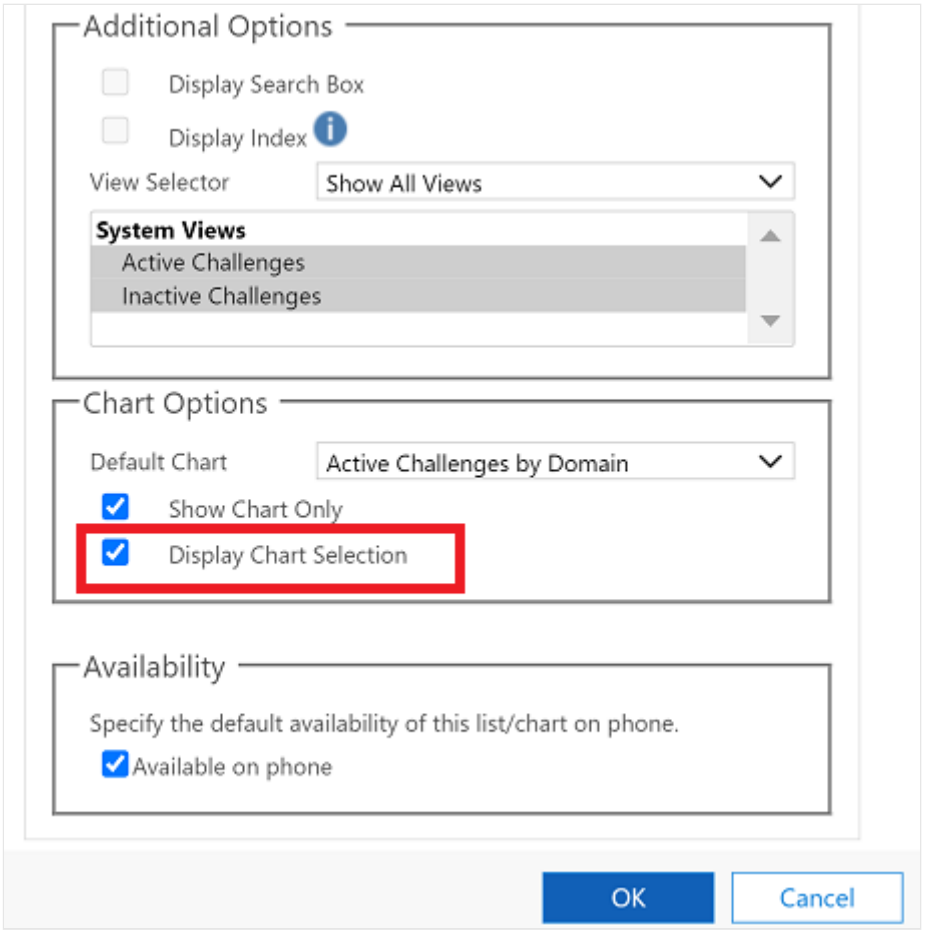
   - **Off**: Don't show view selector, show the view title only.
   - **Show All Views**: Show the view selector on chart and display all views in the view selector.
   - **Show Selected Views**: Show the view selector on chart and display only the selected views in the view selector.



4. Once **View Selector** is turned on, you can select different views to see how the chart renders with different data associated with the view.



5. Select the **Display Chart Selection** check box to show the chart selector. When chart selector is enabled, you can toggle to a different chart for the table and see different visualizations of the data. If the box is unchecked, then you only see the chart title.



6. When you're done, select **OK**.

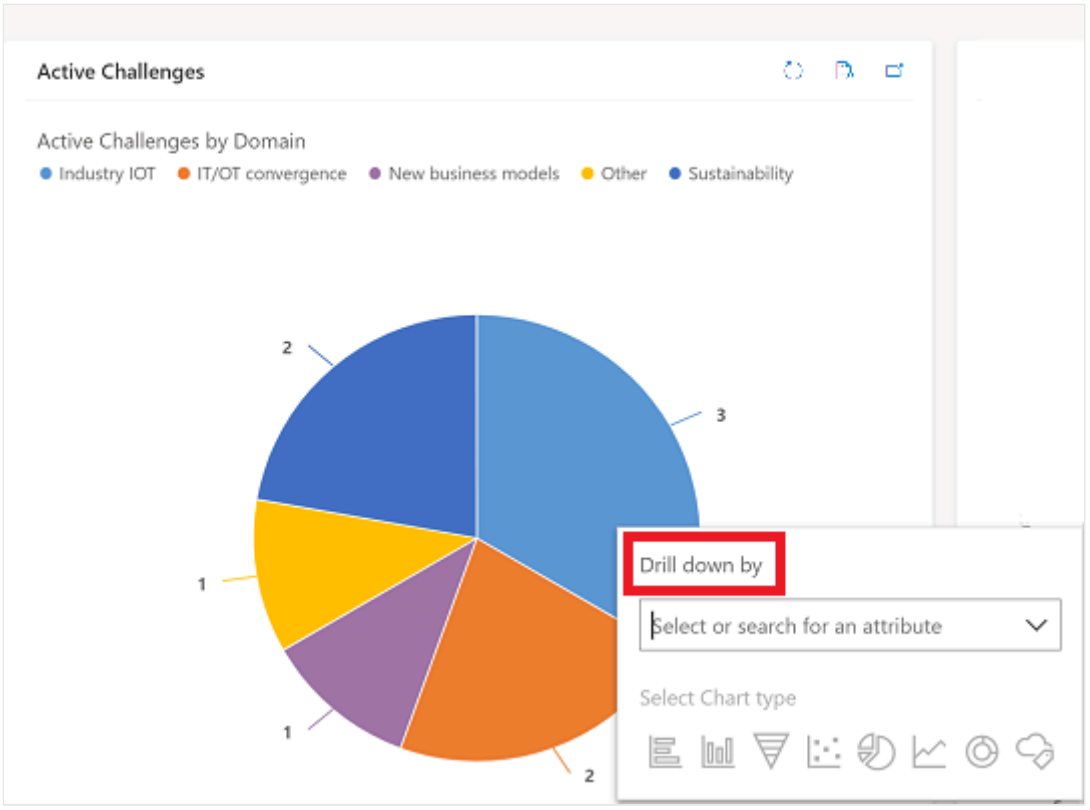
Drill-down in a chart

You can drill down into a segment on a chart and filter the data for that segment. For example, you can drill down on one segment of a chart and change the chart type as you drill down.

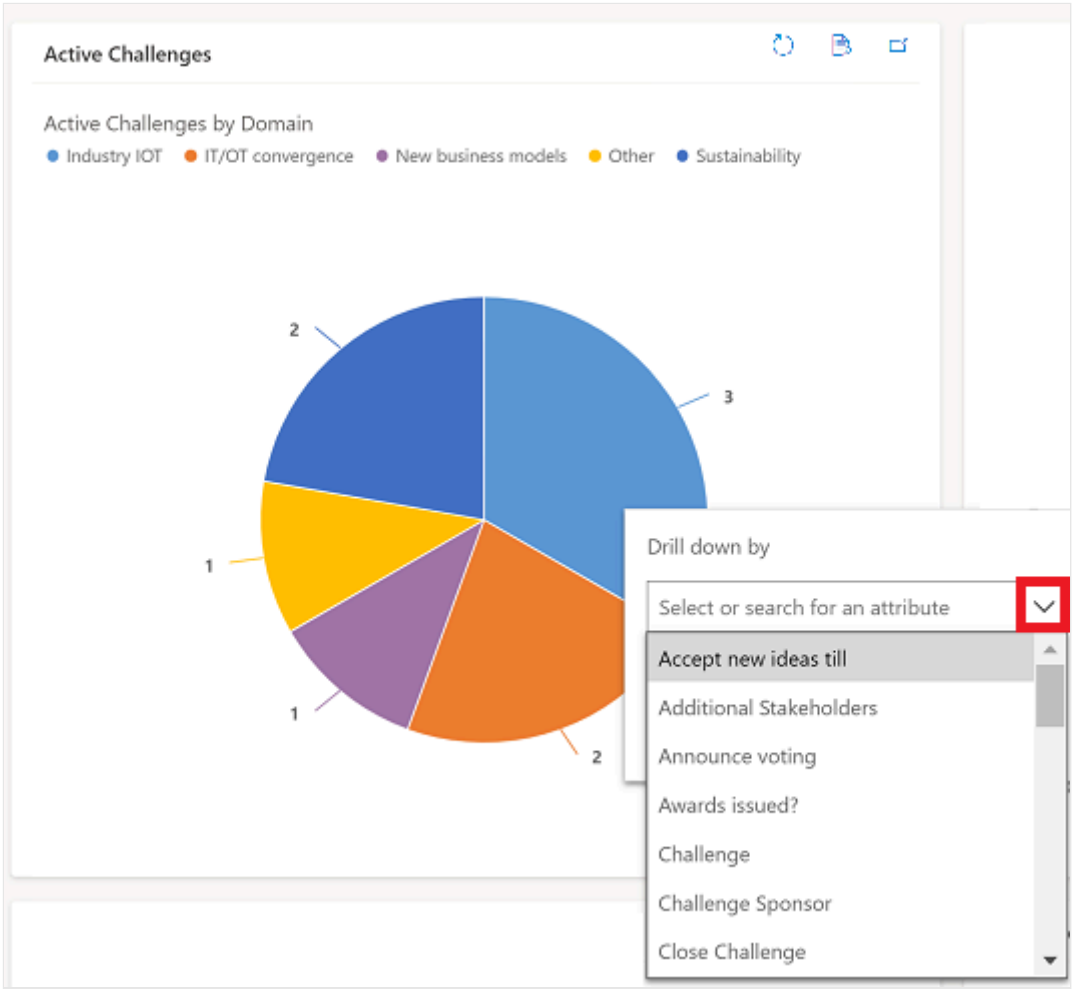
The chart drill-down feature is only available on the browser. It isn't available on the mobile app for phones or tablets.

In the following example, let's further drill-down into the chart.

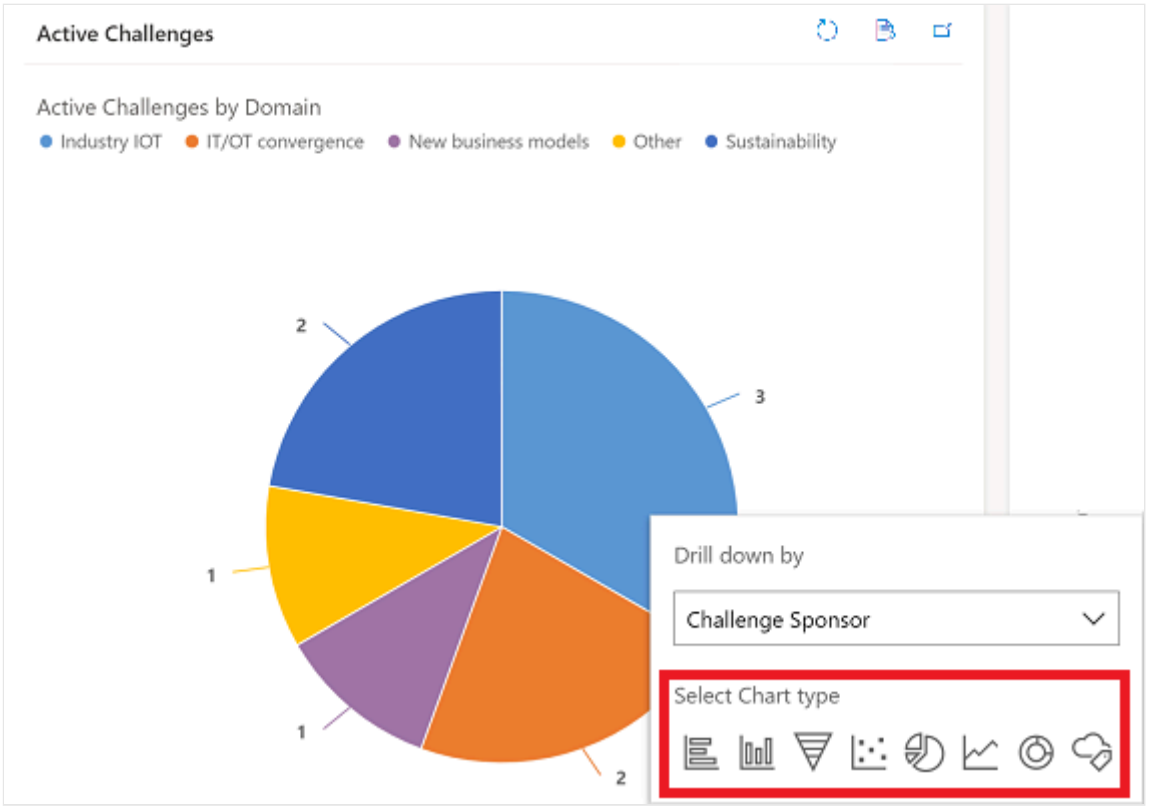
1. Select a data point on the chart to open the **Drill down by** dialog box.



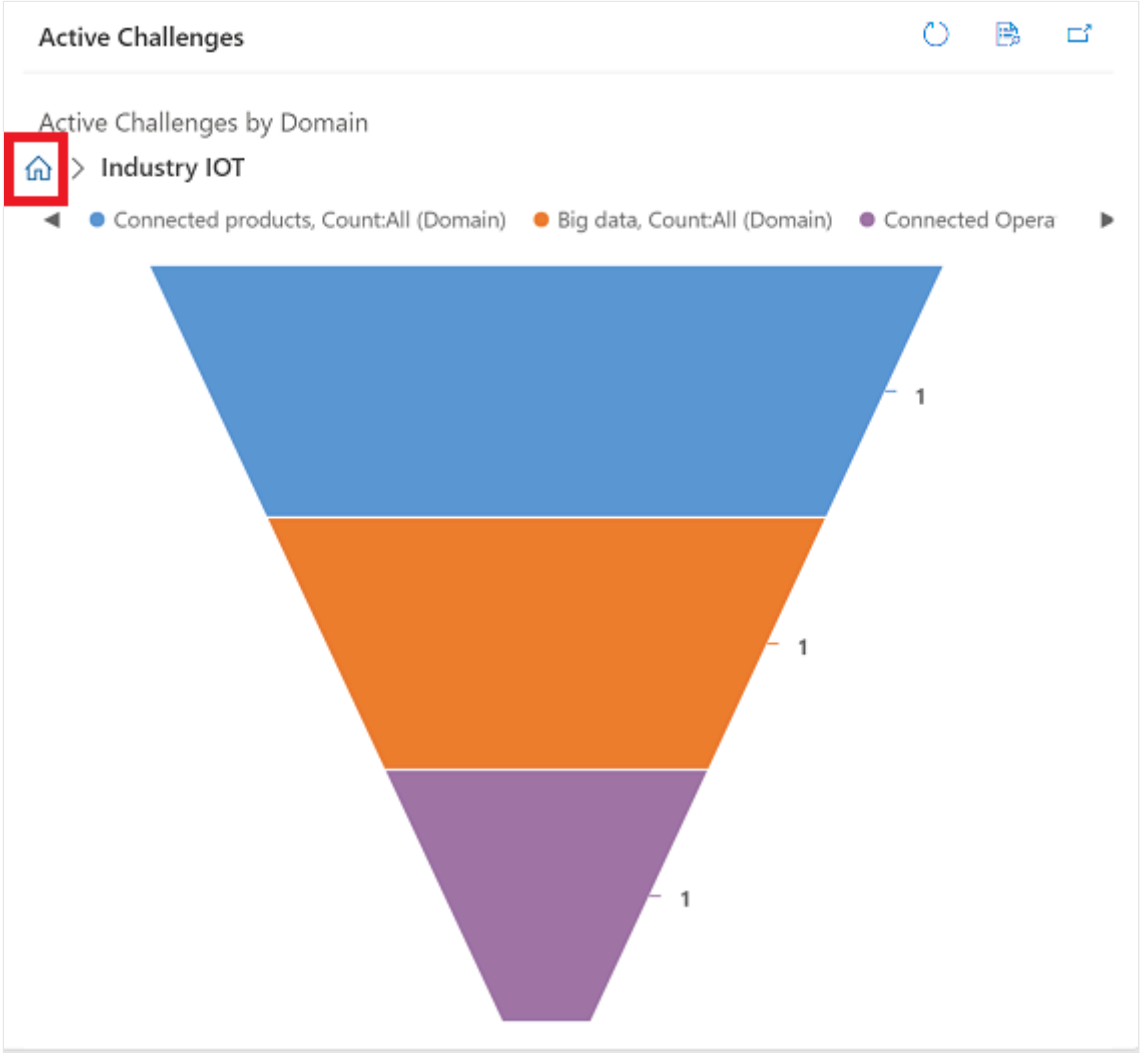
2. Select the drop-down menu and choose how you want to group the data.



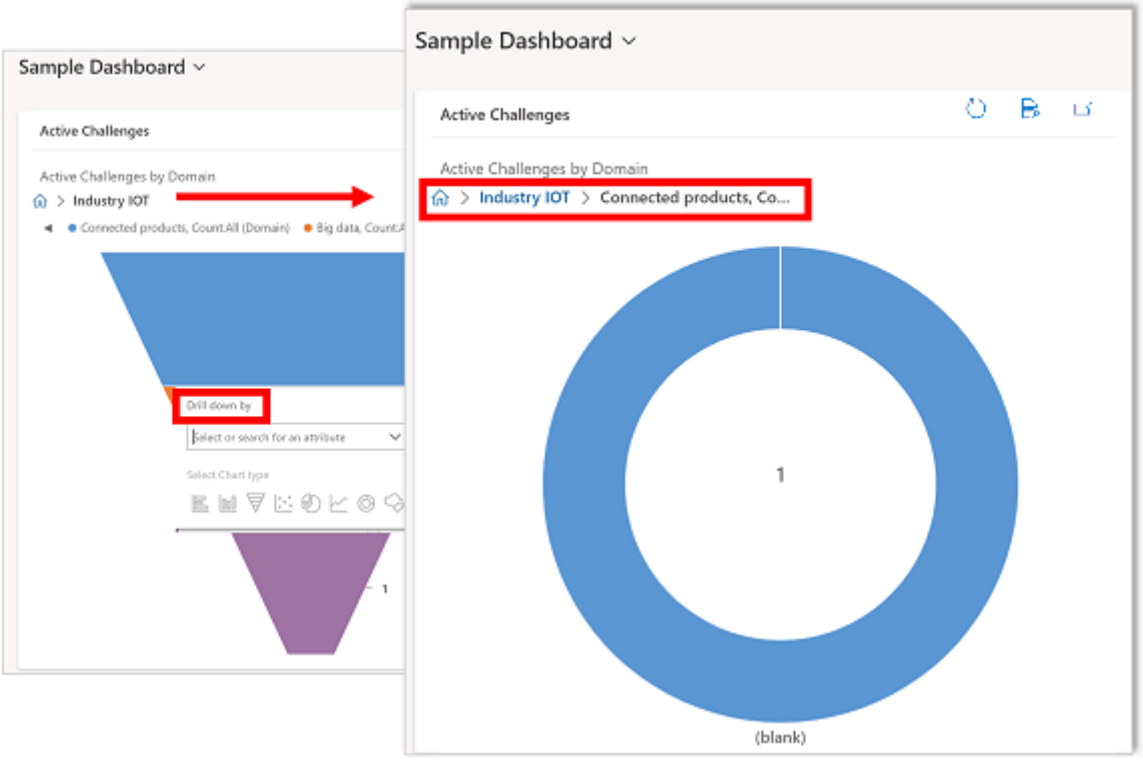
3. Select the type of chart that you want to see the drill-down data in.



4. The chart with the drilled-down data will show. The breadcrumbs at the top show the filter criteria of the drill-down data. You can select the breadcrumbs to go back home or to the previous screen.



You can continue drilling further into the chart data. As you drill down deeper, the breadcrumbs will expand and you can go back to the previous screen or select the Home button to go back to the Home screen.



Known issues

- In the chart designer, adding an order on certain calculated columns isn't supported and will cause an error. The calculated columns causing this are using other calculated columns, a related table column, or a local column on the table.
- Chart displays zero values when there's no data. With Unified Interface for model-driven apps you can still select a chart with zero value and drill down in to the data. More information: Chart displays zero values when there's no data
- By design, charts in rollup column can't be displayed because rollup columns contain an aggregate value computed over the rows related to a specified row.
- Chart drill-down functionality isn't available on charts in a subgrid or an associated grid.
- When you add a list control to a dashboard and switch the control to the **Power Apps Read-Only grid** control, you'll see a blank tile on the dashboard because the **Power Apps Read-Only grid** control isn't supported on dashboards. We recommend that you use **Power Apps grid** control.

View charts on a page or in a row

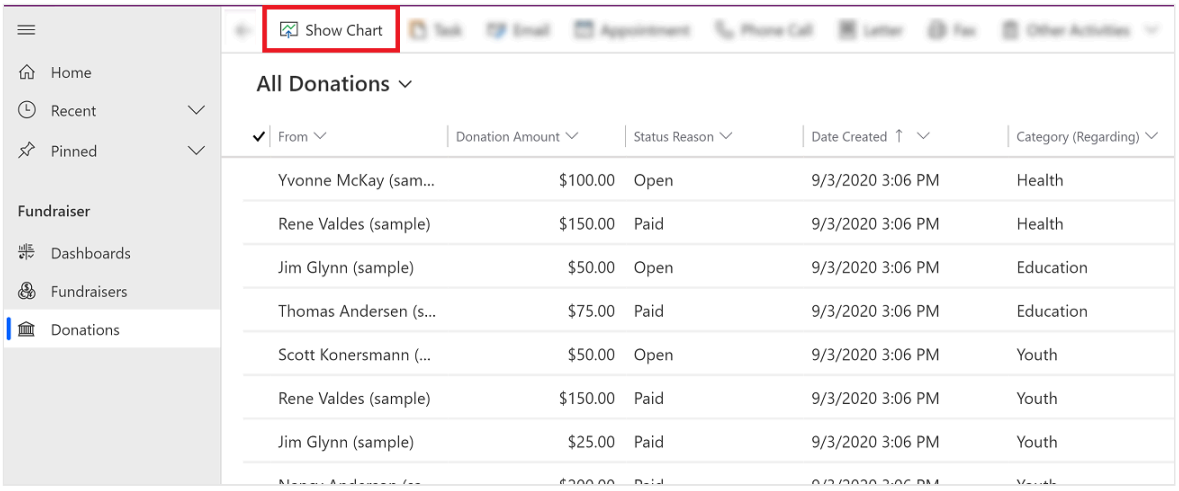
Article • 10/14/2022

You can view charts on a page that has a list of rows. You can also open a row and view a chart in the row.

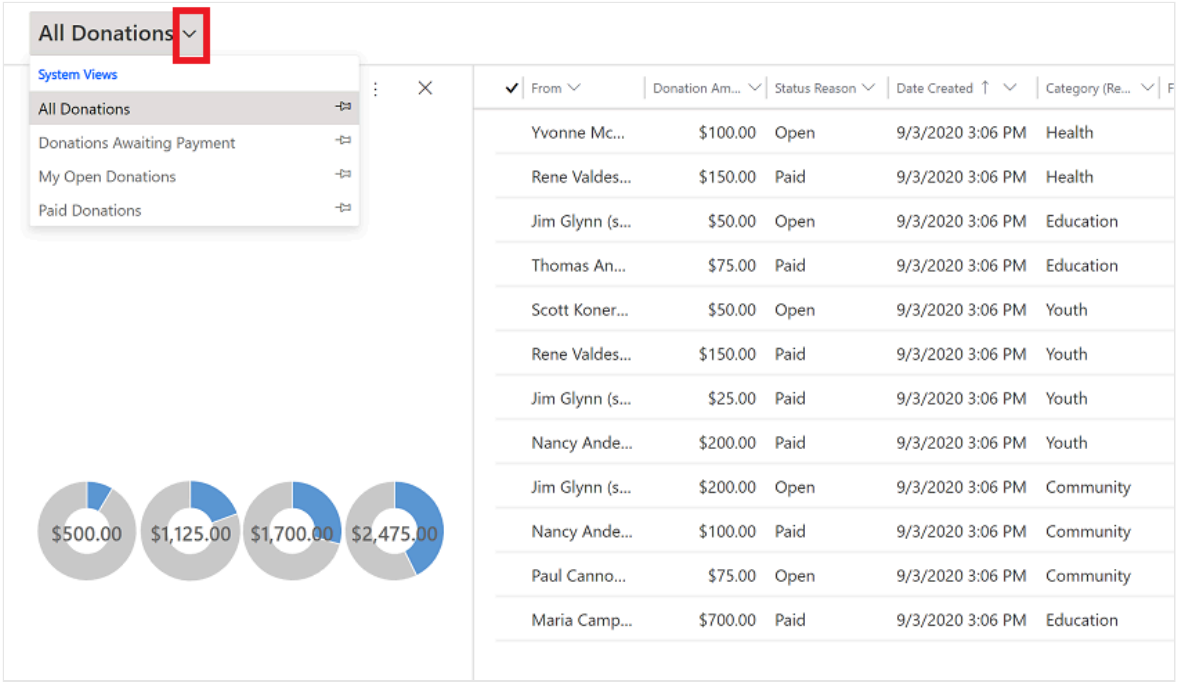
Only an administrator can add charts to a row. For information, go to Add a chart to a form.

View charts on a page

1. On the left navigation pane, select a page.
2. On the command bar, select **Show Chart**.

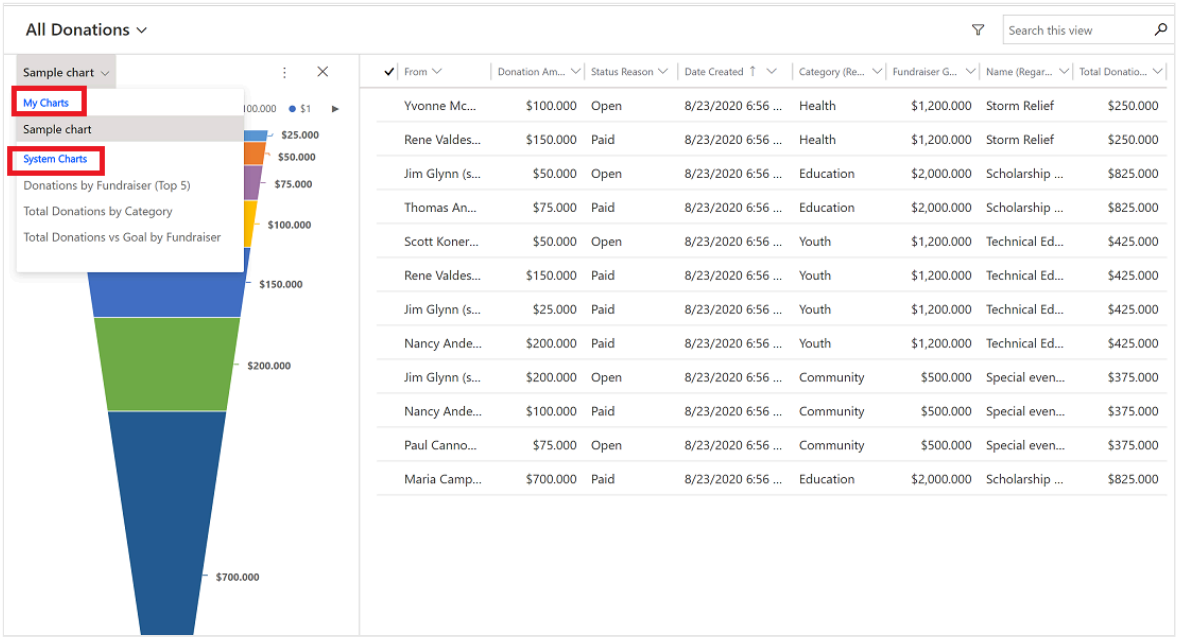


3. Select the drop-down menu to choose a view.



4. Select the chart view drop-down menu to choose between a system or personal view.

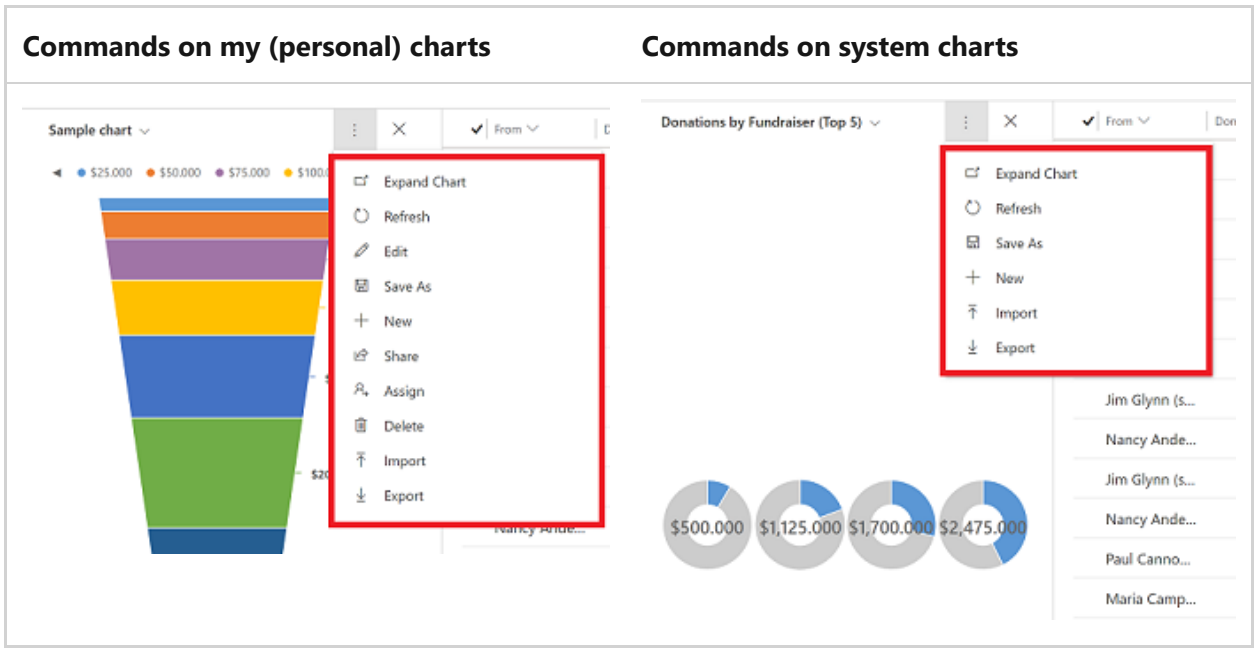
    - **My Charts**: Personal charts that can only be seen by the user who created the chart. The user can also share their personal chart with other users if the user has sharing privileges for their security role.
    - **System Charts**: Created by your administrator. By default, these charts are visible to all users.



Commands on a chart view

Use the **More Commands** button ⋮ to access commands such as create a new chart, import, export, and more. The chart commands options are different for system charts and personal charts.

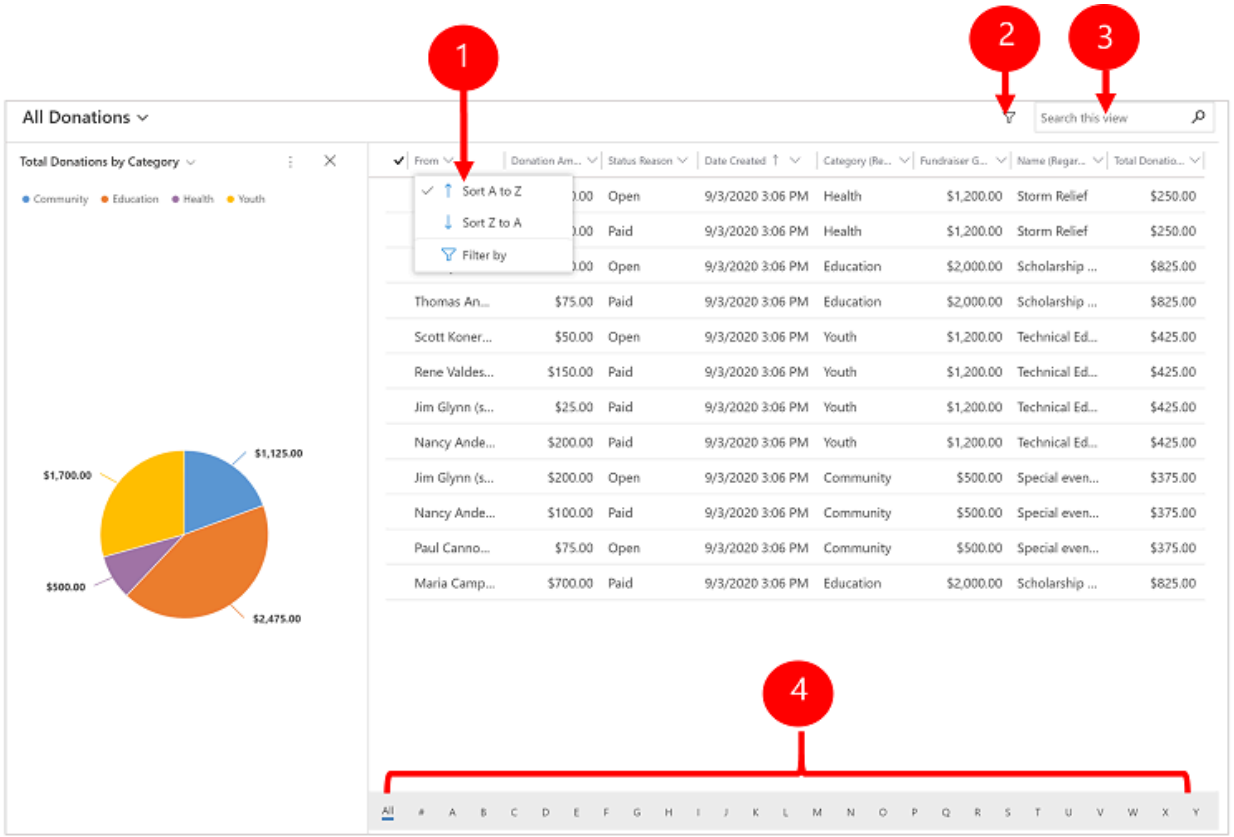
Expand table



Grid filter on charts

Grid home page provides multiple filter options for a user to filter the grid data such as quick find, advanced find, grid column filter, and jump bar. For more information, go to How to use grid filters.

When a chart is shown together with grid, the grid filter option that you select will filter both chart and grid.

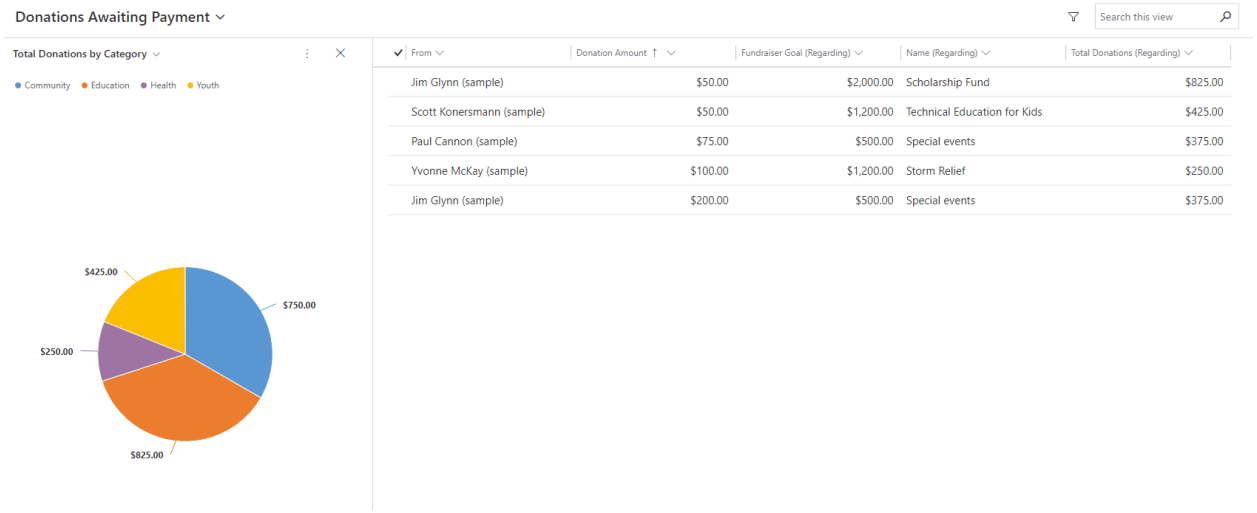


Legend:

1. **Sort**: Sorts rows. Use **Filter by** to filter both grid and chart data based on the filter criteria.
2. **Open advanced filtering panel**: See which filters were applied to the current view. For more information, go to Create and manage personal views on a grid page.
3. **Search this view**: Search for data in the view you're in.
4. **Jump bar**: The page jump bar uses the first sorted column. If no change has been made to the sort order, the jump bar uses the primary column.

Drill-down in the chart data

You can drill down into a segment on a chart and filter the data for that segment. When a chart is shown together with grid, the drill-down option that you select will filter both chart and grid as shown in this illustration.



> **Note**
>
> Chart drill-down functionality is not available on charts in a subgrid or an associated grid.

For more information on how to use the drill-down feature, go to Drill-down in a chart.

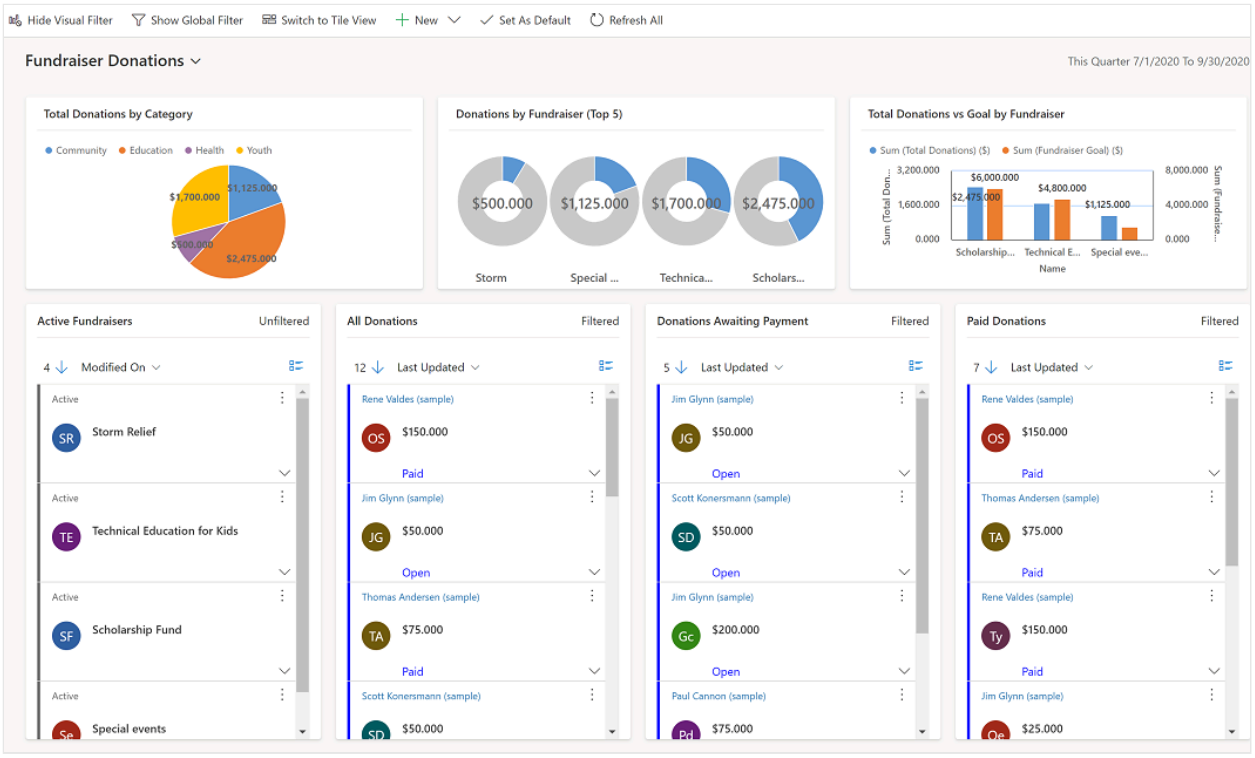
Use interactive dashboards to filter data

Article • 02/15/2022

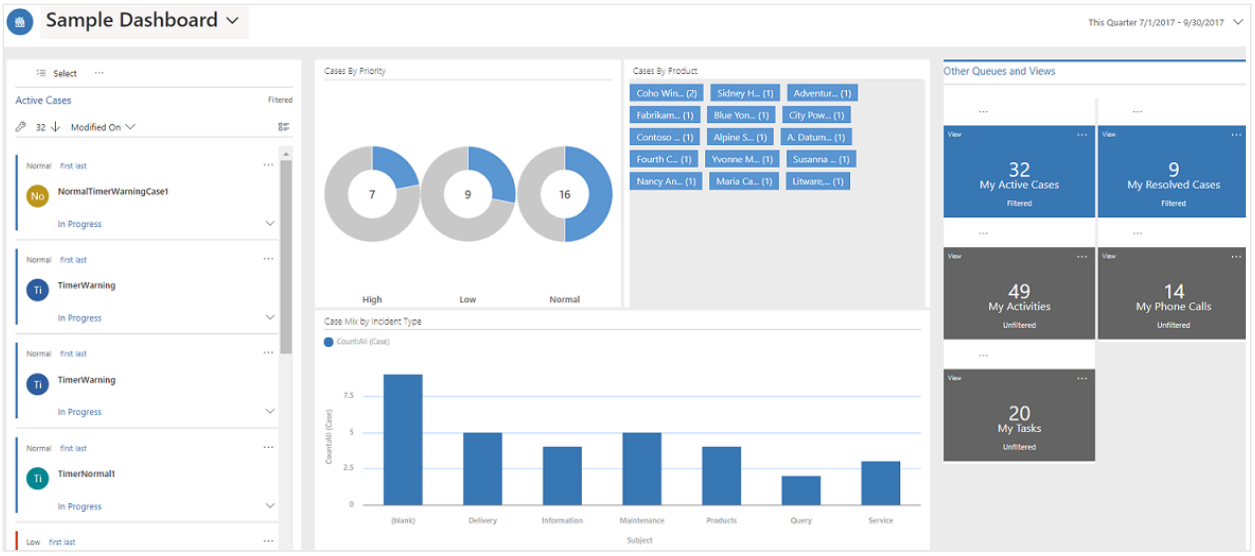
Use interactive dashboards to filter and view your app data. Charts on an interactive dashboard serve as a simple filtering source. You can select different data points on a chart to filter data based on the filter criteria.

Interactive dashboards are system dashboards that only an admin can create. To learn more about how to create and configure interactive dashboards, go to Create and configure model-driven app interactive experience dashboards.

Interactive dashboards come in two forms: multi-stream and single-stream. In addition, multi-stream dashboards can be home page or table-specific dashboards. The multi-stream dashboards display data in real time over multiple data streams.



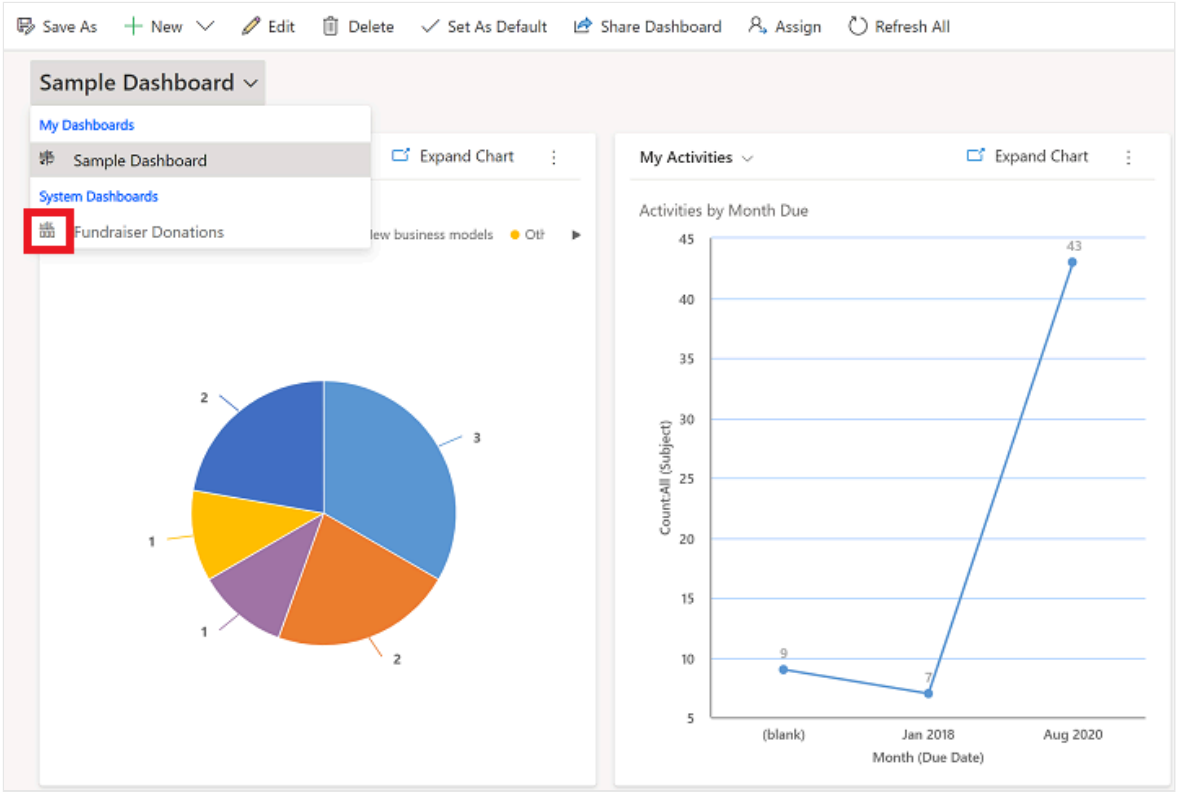
The single-stream dashboards display real-time data over one stream based on a table view. Visual filters are already applied. The tiles are positioned on the right side of the dashboards and are always shown.



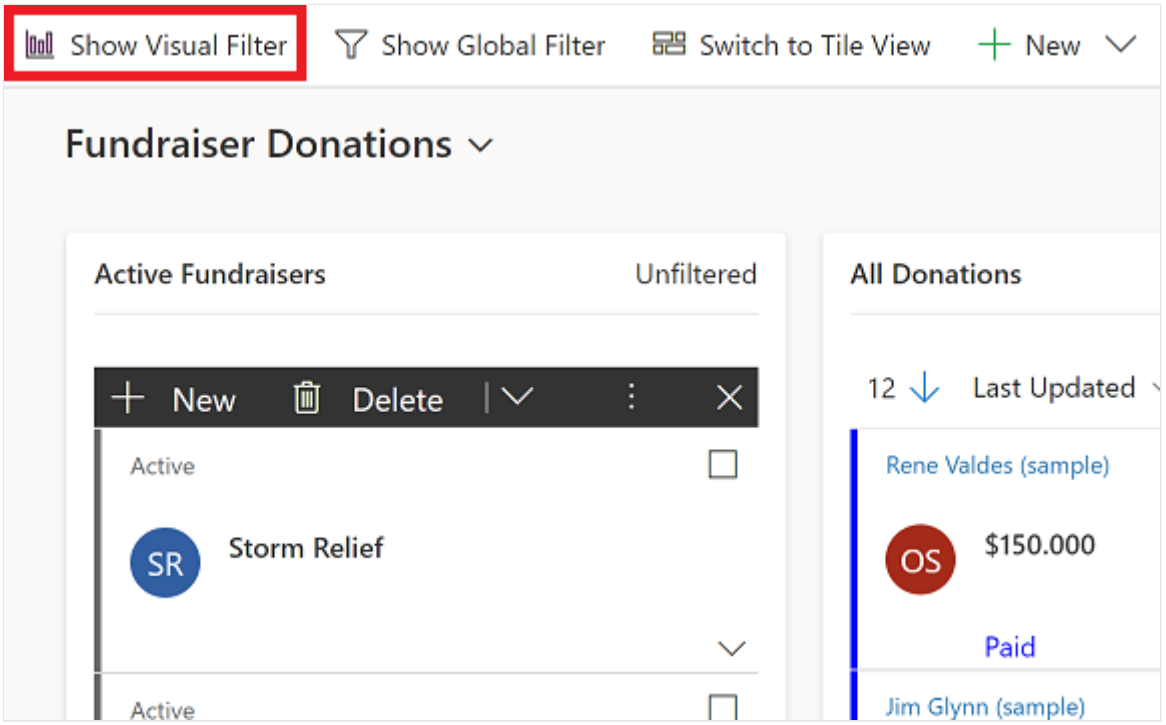
Use visual filters

Use the visual filter option to drill down into the data on the charts. This displays information that interests you most.

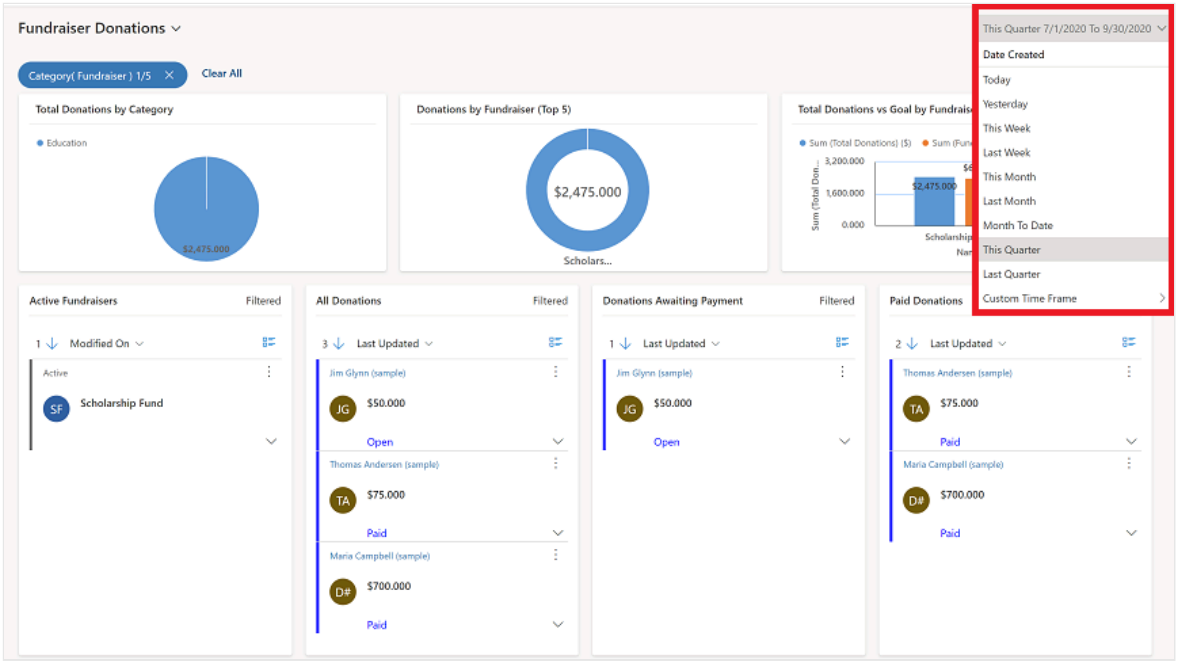
1. To view an interactive dashboard, go to the list of dashboards and find the one that has the interactive icon  next to the dashboard name.



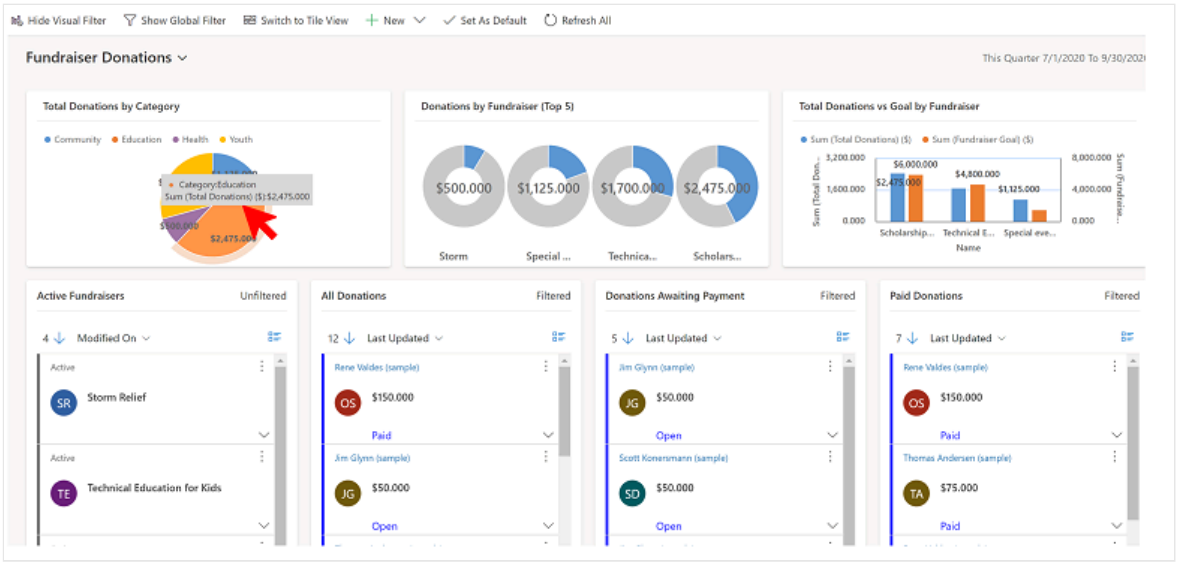
2. On the command bar, select **Show Visual Filter**.



3. Select a drill-down option.



4. Select an area on one of the charts or graphs to apply a filter.



5. To clear the filter, select **X** next to the filter or to clear all filters, select **Clear All**.

Add or edit Power BI visualizations on your dashboard

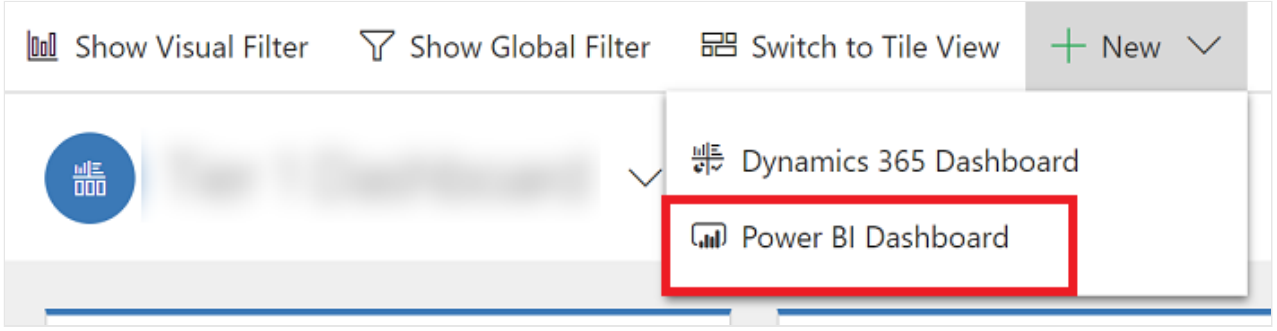
Create rich, interactive reports and real-time visualizations with Power BI dashboards and tiles that you add to your personal dashboards.

> **Note**
>
> To add Power BI visualizations to personal dashboards in your model-driven app, you must:
>
> - Enable Power BI visualizations for your organization in **Advanced Settings** > **System** > **Administration** > **Reports** > **Embed Power BI visuals**.
> - Have a Power BI account and have access to at least one Power BI dashboard.
> - Enable third-party cookies in your browser, otherwise authentication to Power BI will fail.

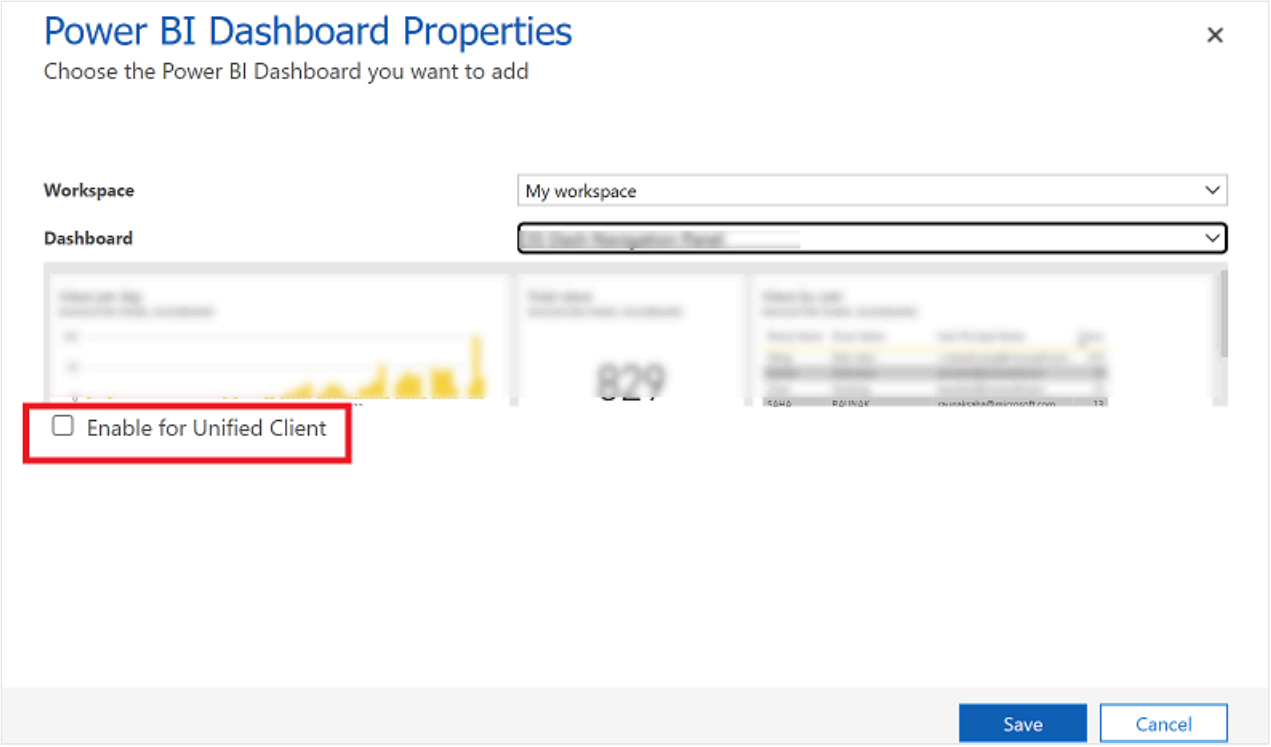
Create a personal Power BI dashboard

Follow these steps to add a Power BI dashboard to your model-driven app. If you are connecting to the Power BI service, you need an account and to have selected your Microsoft Dataverse instance as a data source. For more information about registering and connecting data sources, see Microsoft Power BI.

1. Open your app and go to **Dashboards**.
2. Select **New** and then select **Power BI Dashboard**.



3. In the **Power BI Dashboard Properties** dialog select the workspace and then select the Power BI dashboard that you want to embed in your dashboard. Select **Enable for Unified Client** if you want to make the dashboard available for Dynamics 365 for tablets and Dynamics 365 for phones.

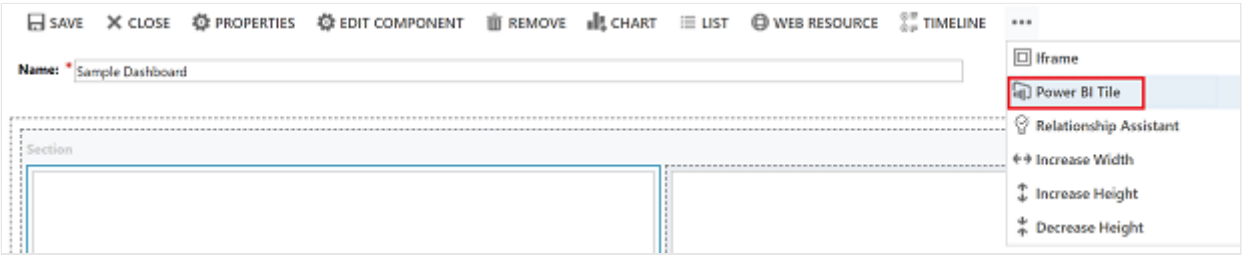


4. Select **Save** to save your dashboard.

Embed Power BI tiles on your personal dashboard

Follow these steps to add one or more Power BI tiles to your personal dashboard. If you are connecting to the Power BI service, you need an account and to have selected your Dataverse instance as a data source. For more information about registering and connecting data sources, see Microsoft Power BI.

1. Open your app and go to **Dashboards**.
2. Select an existing personal dashboard or select **New** to create one.
3. On the dashboard, select an area where you want the tile to appear, and then select **Power BI Tile** on the toolbar.



4. In the **Power BI Tile** dialog, select the workspace and then select the Power BI tile that you want to display on your dashboard. Select **Enable for mobile** if you want to make the tile available for Dynamics 365 for tablets and Dynamics 365 for phones.

Select another area of the dashboard and repeat this step to add another Power BI tile, or other component, such as a chart or list, to your dashboard.

5. Select **Save** to save your dashboard.

> **Note**
>
> If a user clicks on the title of an embedded Power BI dashboard, a modal popup will be triggered, showing the dashboard along with **Refresh** and **Open in Power BI** actions.

Share a personal dashboard that contains Power BI visualizations

To share your personal dashboard that contains Power BI visualizations you must configure sharing in both Dataverse and Power BI, and the user or group must have the same credentials and appropriate level of access in both services. To share your personal dashboard in your app go to, **Dashboards**. In the list of dashboards, select the personal dashboard you want, and then select **SHARE DASHBOARD**. For more information about sharing a dashboard in Power BI, see Power BI: Share a dashboard with colleagues and others.

Privacy notice

By enabling the embedding of Power BI tiles and dashboards, when a user embeds a Power BI tile or dashboard, that user's Microsoft Entra ID authorization token for Microsoft Dataverse is used to authenticate with the Power BI service with an implicit grant, providing a seamless "single-sign on" experience for the end user.

An administrator can disable embedding of Power BI tiles and dashboards at any time to stop use of the Dynamics 365 authorization token for authenticating with Power BI service. Any existing tiles or dashboards will stop rendering for the end user.

The Azure component or service that is involved with embedding of Power BI tiles is detailed in the following section.

Note: For more information about additional Azure service offerings, see the Microsoft Azure Trust Center.

Microsoft Entra ID

This service provides the authentication token exchanged with Power BI service for API and UI authentication.

Collaborate with others in model-driven apps

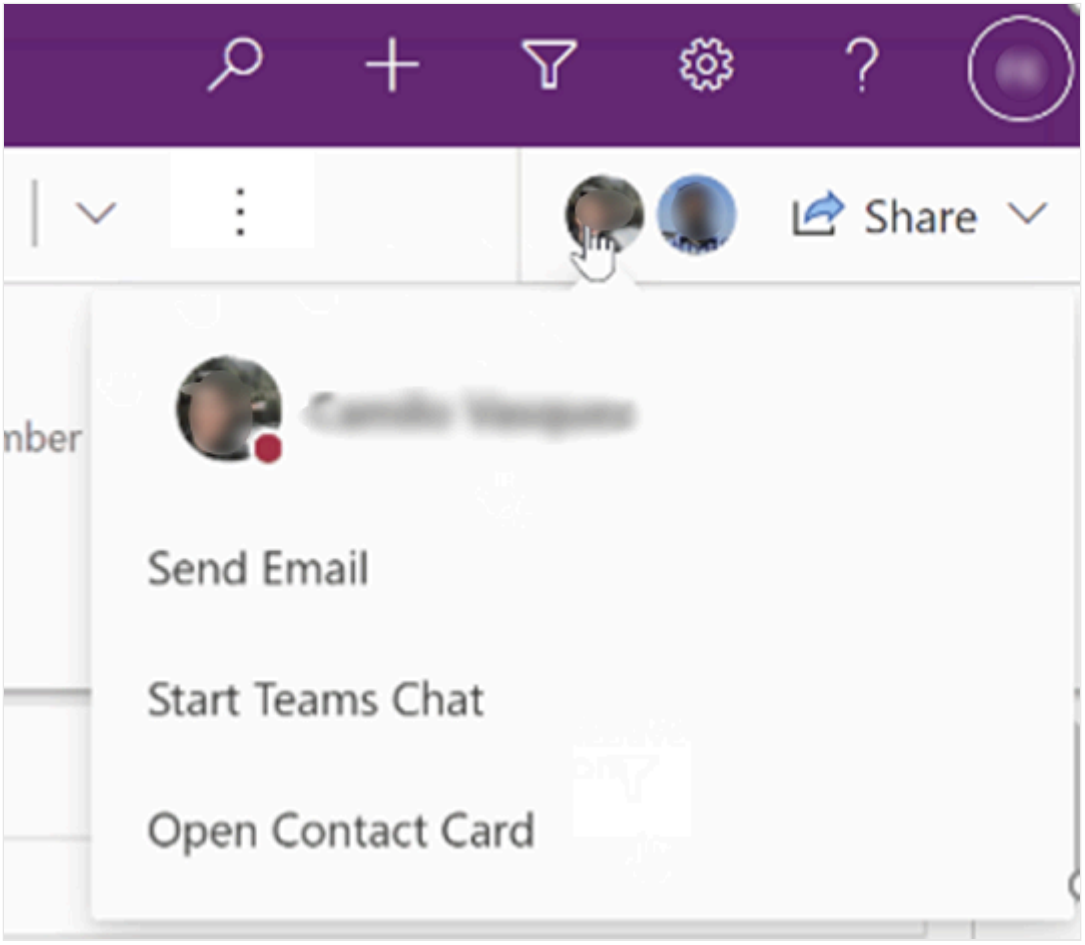
Article • 10/10/2023

Collaborate with colleagues and share links in model-driven Power Apps the same way do you as in Microsoft Office.

Multiplayer apps

When you're working on a record, you can also see other users who are working on the same record.

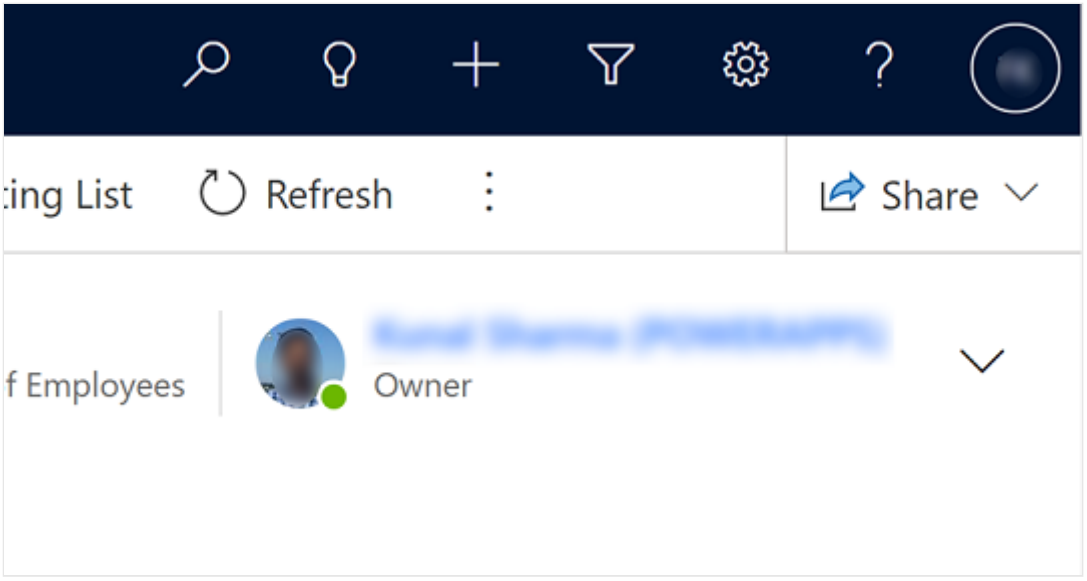
You can also select a user's picture to see their online status, send them an email, or start a Teams chat.



This feature uses the Azure Fluid Relay service, which must be available in your region. For more information, see Azure Fluid Relay service availability. Because this feature uses the Azure Fluid Relay service, users must be able to access fluidrelay.azure.com.

View a user's status and picture

App users, such as the record owner, as well as the users appearing in grids and lookups are displayed with their picture and online status. This feature is now available on all model-driven apps and cannot be disabled.



> **Note**
>
> This feature will be extended to user lookups and grid user columns.

Share

You can now easily share records with your colleagues using the new **Share** button. Select **Copy link** or **Email link** in order to send a record link to your colleagues.

> **Note**
>
> If you have the share privilege on a record and you email a record link to a colleague, the colleague will automatically get read access to the record.

Use OneDrive for Business

Article • 02/15/2022

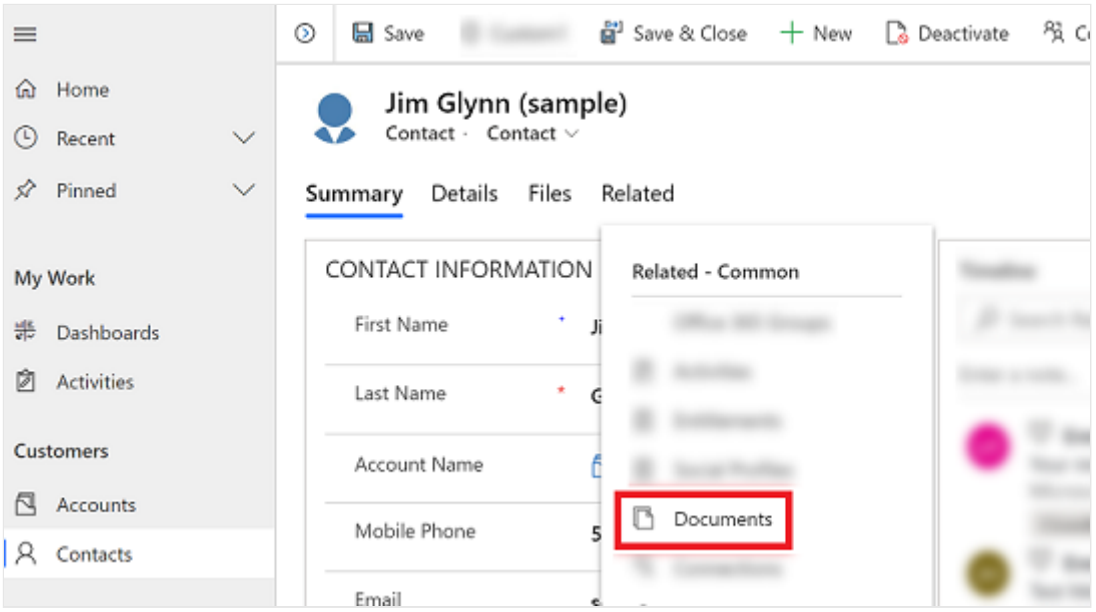
Create and manage private documents from within Microsoft Dataverse apps by using OneDrive for Business. More information: What is OneDrive for Business?

Before you can use OneDrive for Business, it must be enabled by your system administrator. More information:

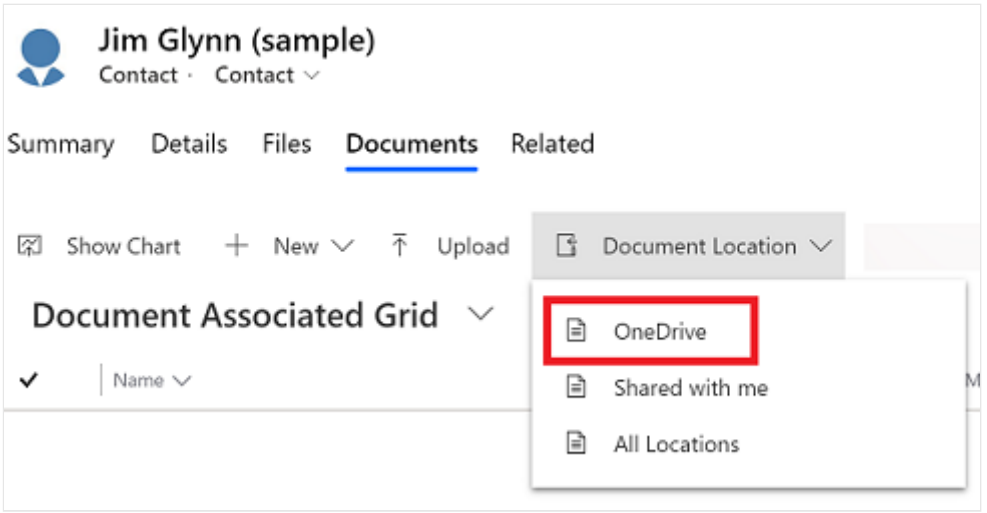
- Find your administrator or support person
- Enable OneDrive for Business

The first time you view your documents

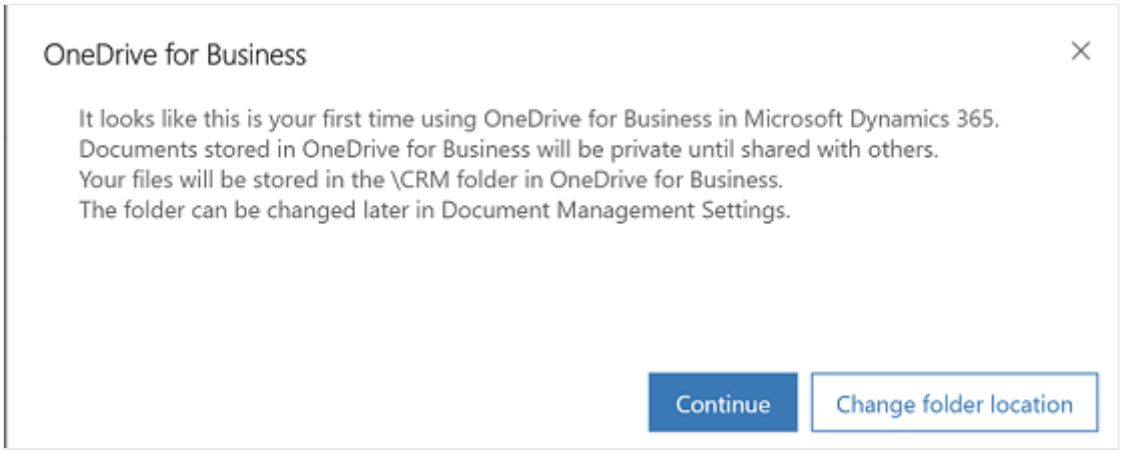
1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.
2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location** > **OneDrive**.



4. After OneDrive for Business is enabled, you'll see the following dialog box when you go to the **Documents** tab to view documents in Dataverse and upload a file to OneDrive, or when you attempt to create a new document or folder.

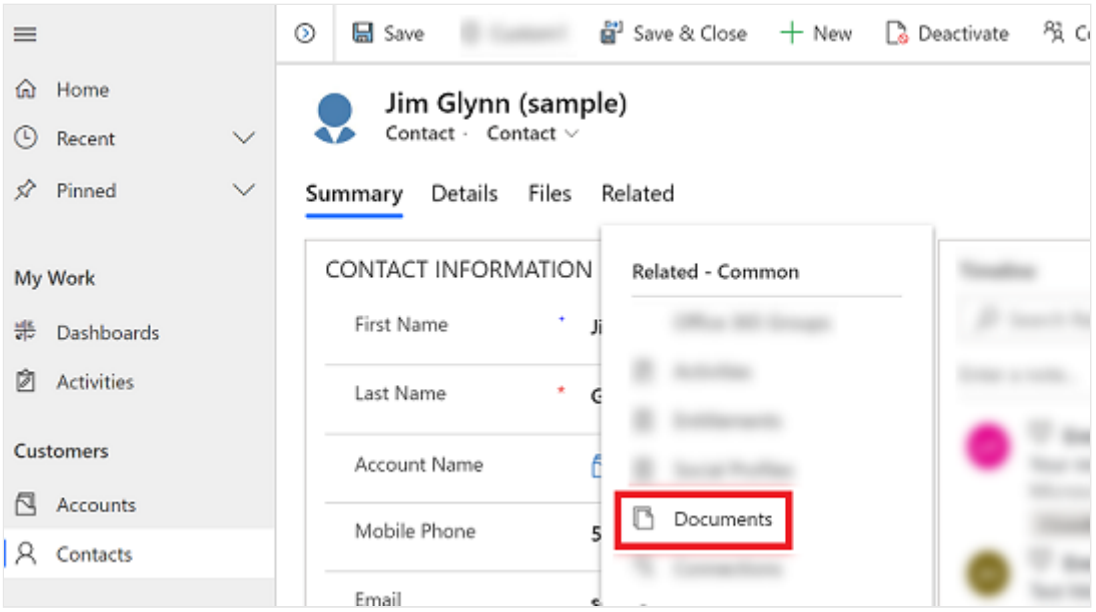


5. Select **Change folder location** to pick a new location to store OneDrive documents, or select **Continue** to accept the default folder location.

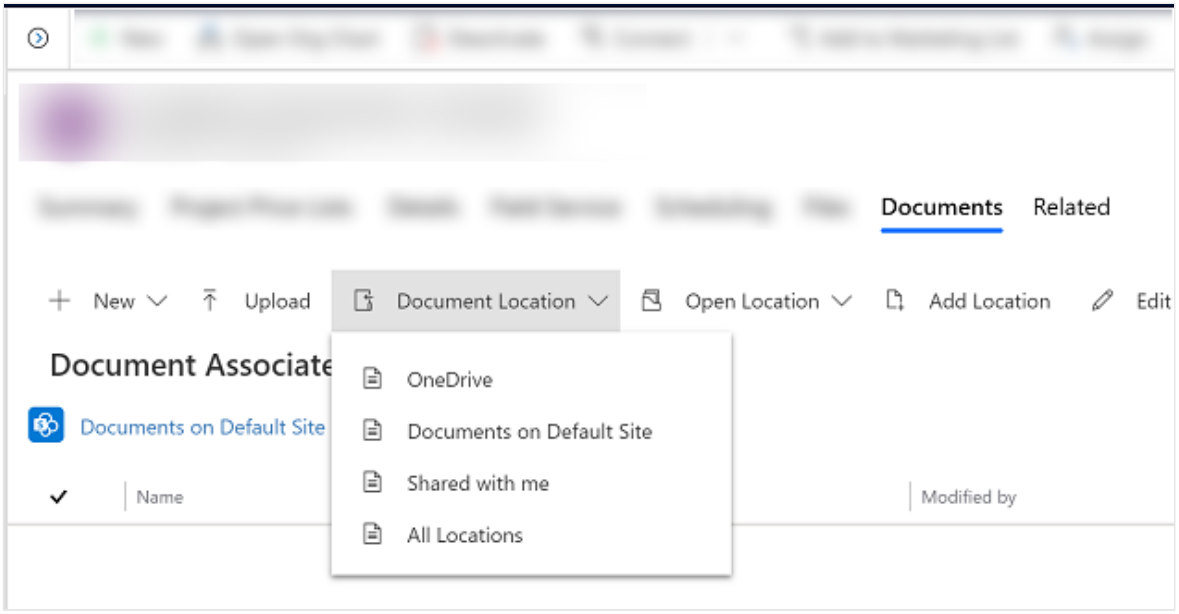
View existing OneDrive documents

1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.

2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location** to filter the document list.



4. Select a location as described in the following table.

Expand table

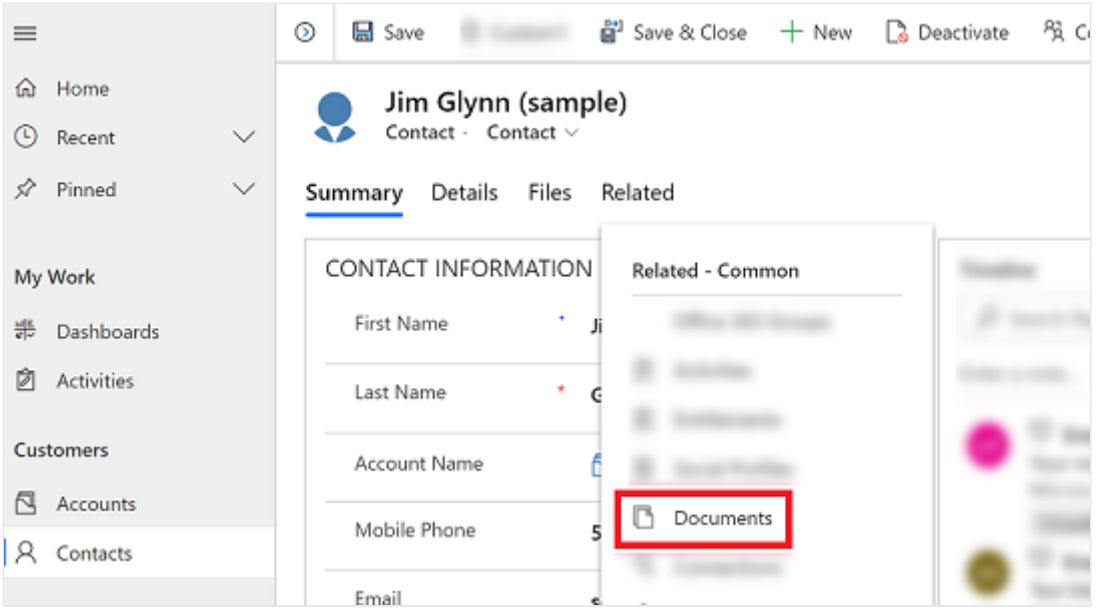
Document Location	Description
OneDrive	Documents stored in OneDrive for Business
Documents on Default Site	Documents stored in your default SharePoint site
Shared with me	Documents that others shared with you that are associated with this row
All Locations	All document locations associated with this row

5. After you select a location, you'll see the documents saved in that location.

Create a new document and save it to OneDrive

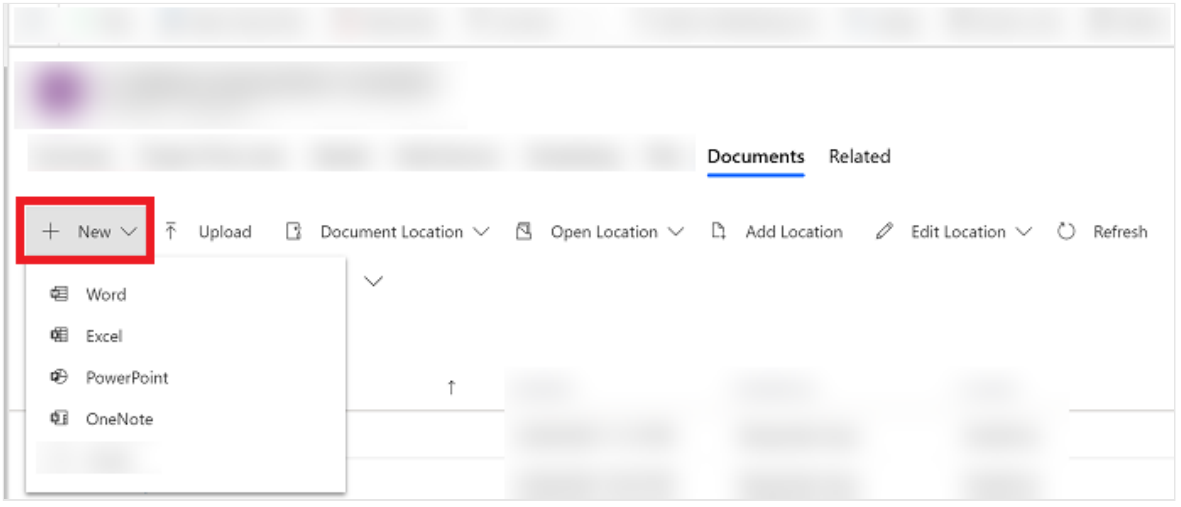
1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.

2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location**, and change the location to **OneDrive**.

4. Select **New**, and then choose a document type such as PowerPoint or Word.



5. Enter a document name, and then select **Save**.

Things to consider

Be aware of the following regarding OneDrive for Business in Dataverse:

- OneDrive storage folders are created in the user's current Dataverse language. If the language changes, new folders will be created in the new language. Old folders will remain in the previous language.
- There might be a delay between when the documents are shared in OneDrive and when they're available to other users.

Take notes by using OneNote

Article • 02/15/2022

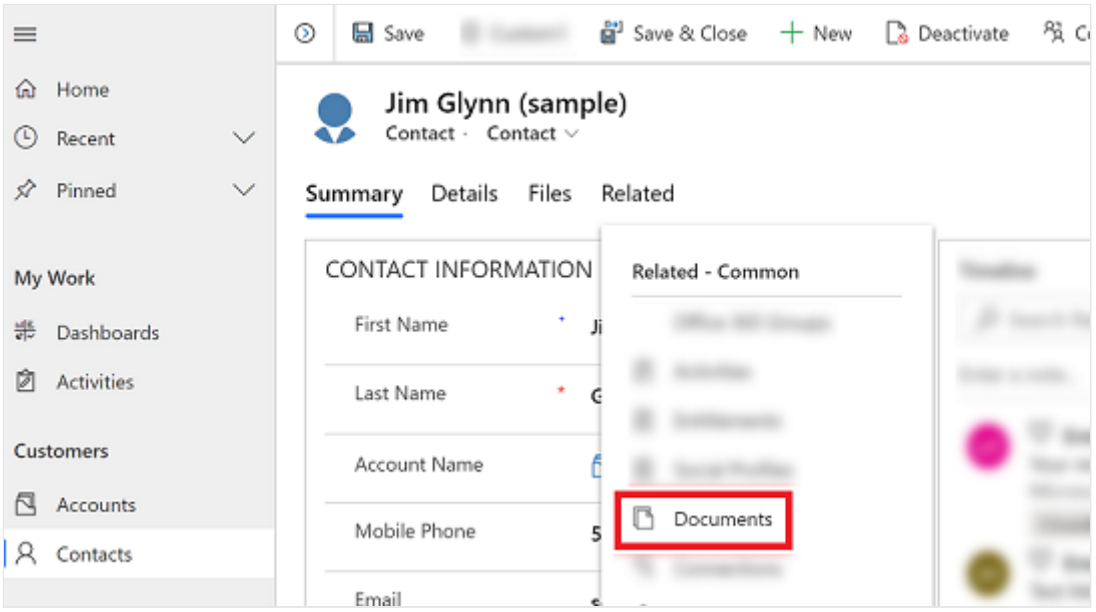
Use OneNote to take or review notes, ideas, plans, and research from the **Document Associated Grid** view of a row in Microsoft Dataverse.

Before you can use OneNote, it must be enabled by your system administrator. More information:

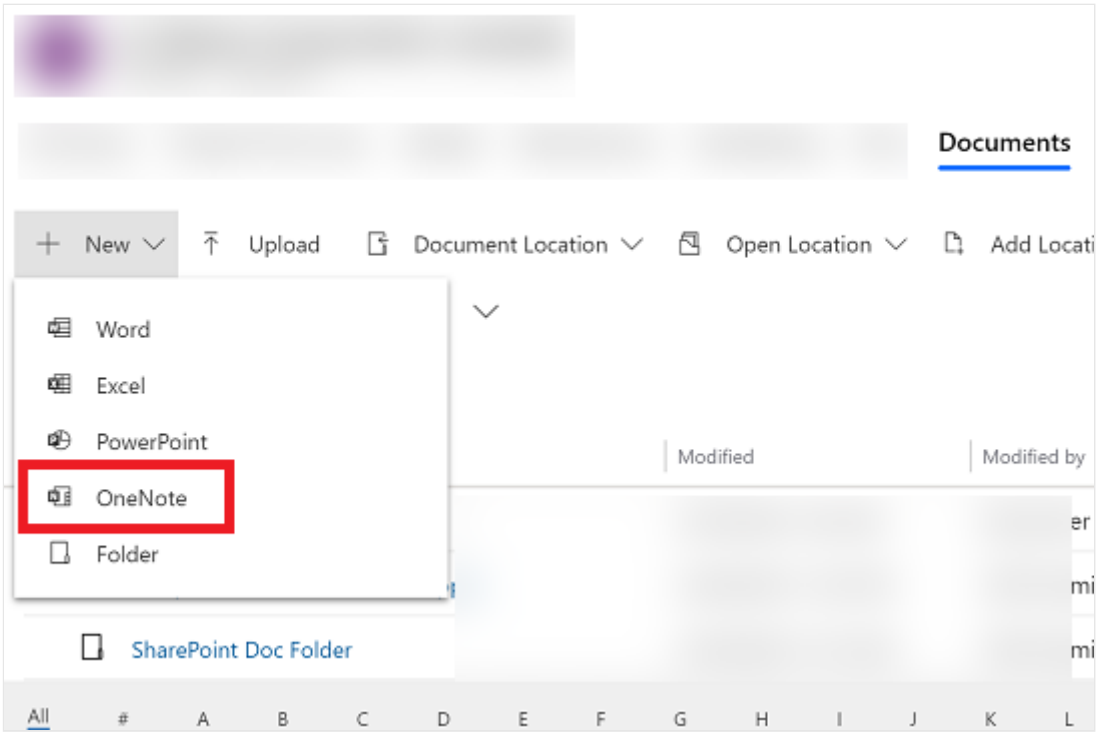
- Find your administrator or support person
- Set up OneNote integration

Start a new OneNote notebook

1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.
2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location**, and select the location where you want to save the notebook. For more information, see View existing OneDrive documents.
4. Select **New**, and then select **OneNote**.

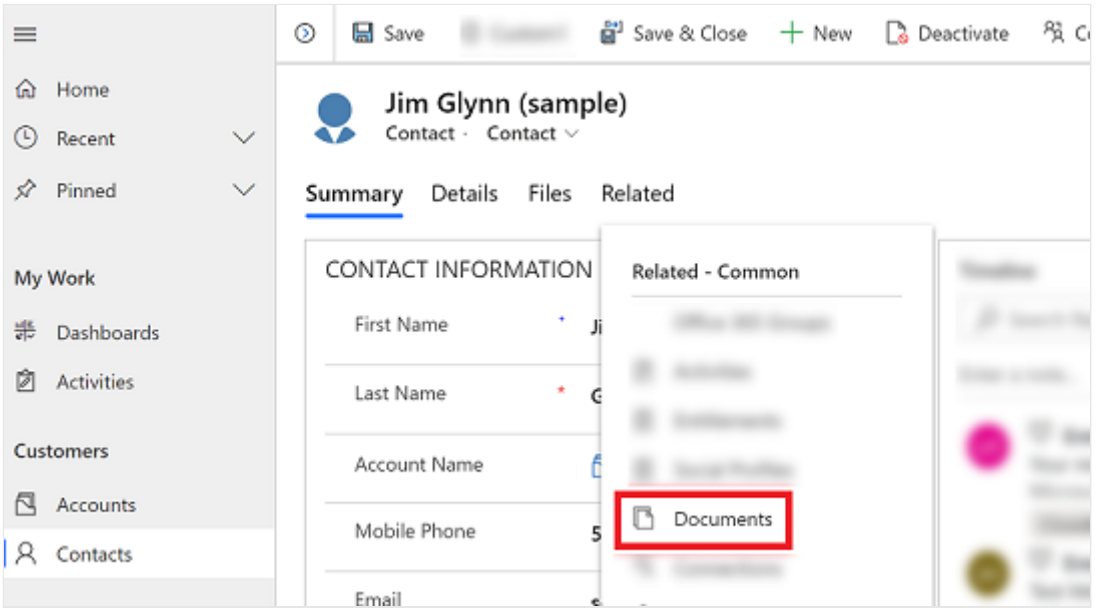


5. Enter a name for the notebook, and then select **Save**. A new notebook is created and opened.

Open an existing OneNote notebook

1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.

2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location**, and select the location of your notebook. For example, choose **OneDrive** if your notebook is stored on OneDrive. More information: View existing OneDrive documents

4. Select your notebook to start adding notes.

Collaborate using SharePoint

07/15/2025

With Microsoft Dataverse, you can store your documents on SharePoint and manage them from within your app. The documents that you create in your app are stored on SharePoint, and are automatically synced to your desktop and mobile devices.

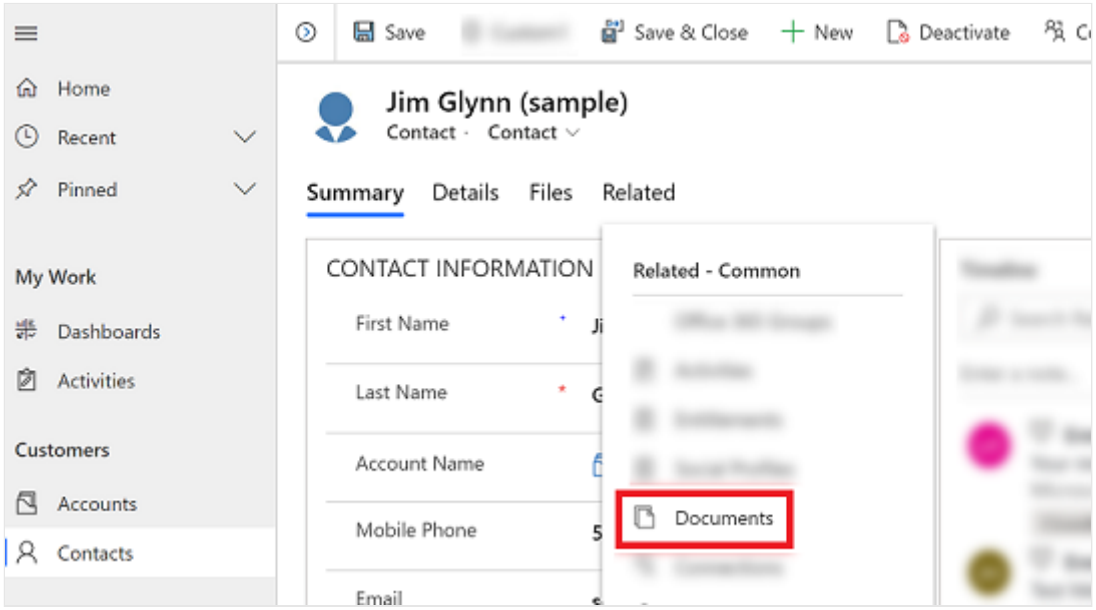
Before you can use SharePoint to store documents, it must be enabled by your system administrator. More information:

- Find your administrator or support person
- Manage your documents using SharePoint

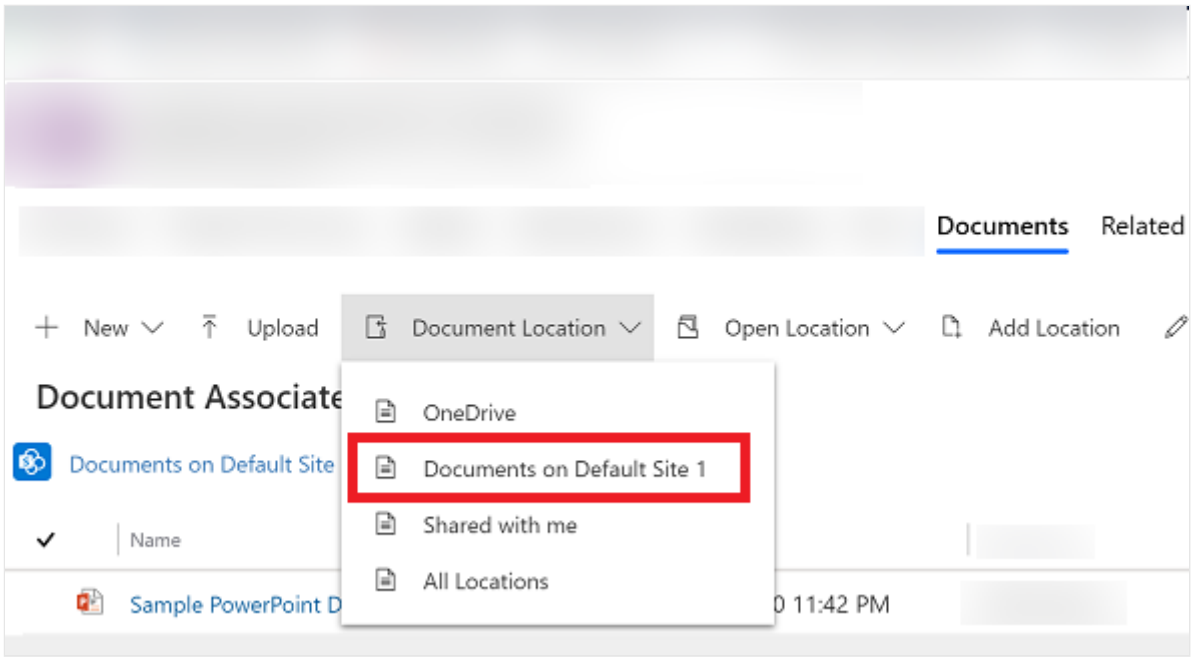
> **Important**
>
> - When you delete a SharePoint managed document using a Power Apps or Dynamics 365 customer engagement app, the app permanently deletes the document from both the app and the SharePoint site.
> - When you merge records, the app doesn't merge SharePoint document libraries. The app deactivates the subordinate record, but its SharePoint folder and documents remain accessible unless you delete them manually.

Where do you access the documents from?

1. For row types that support document management, open the row, select the **Related** tab, and then select **Documents**.



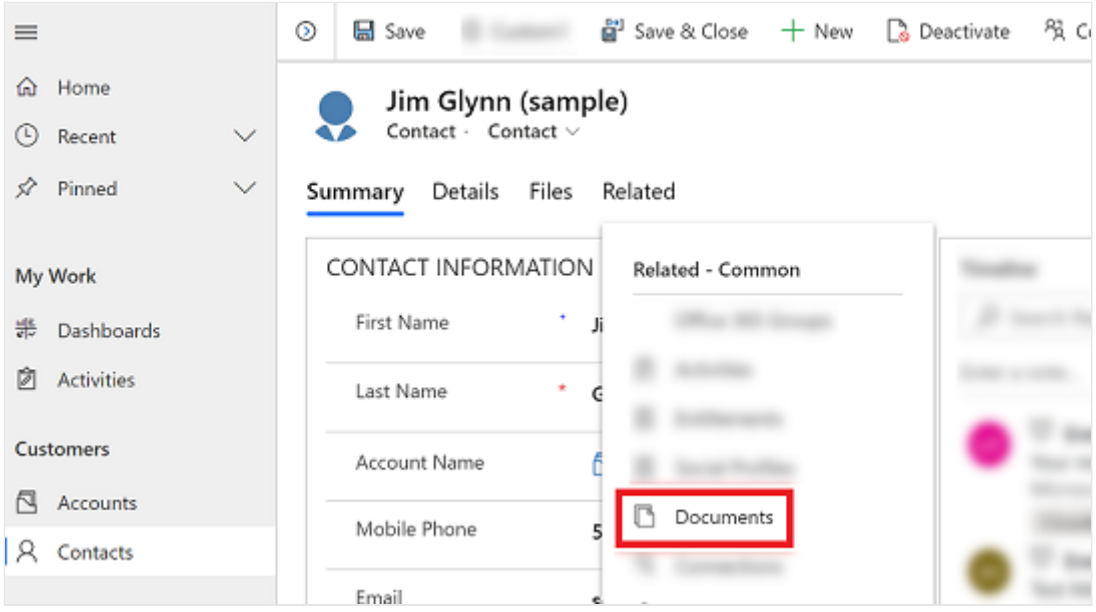
2. Select **Document Location** > **Documents on Default Site 1**. When SharePoint is enabled, the location is set to **Documents on Default Site 1** by default.



Create a new document and save it to SharePoint

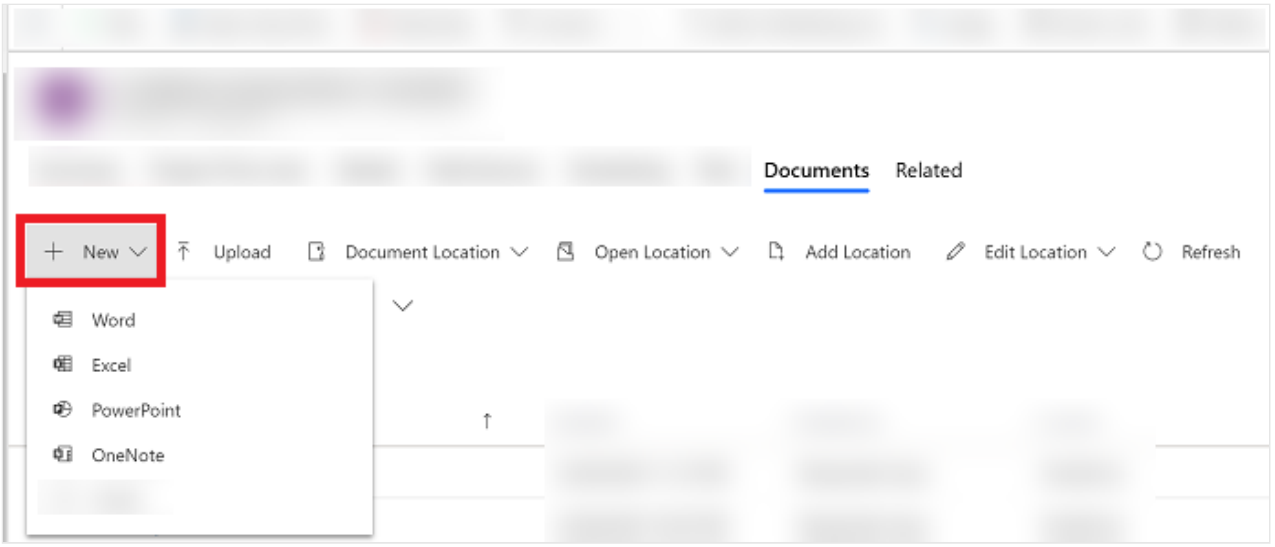
1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.

2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location**, and change the location to **Documents on Default Site 1**.

4. Select **New**, and then choose a document type such as Word, Excel, or PowerPoint.

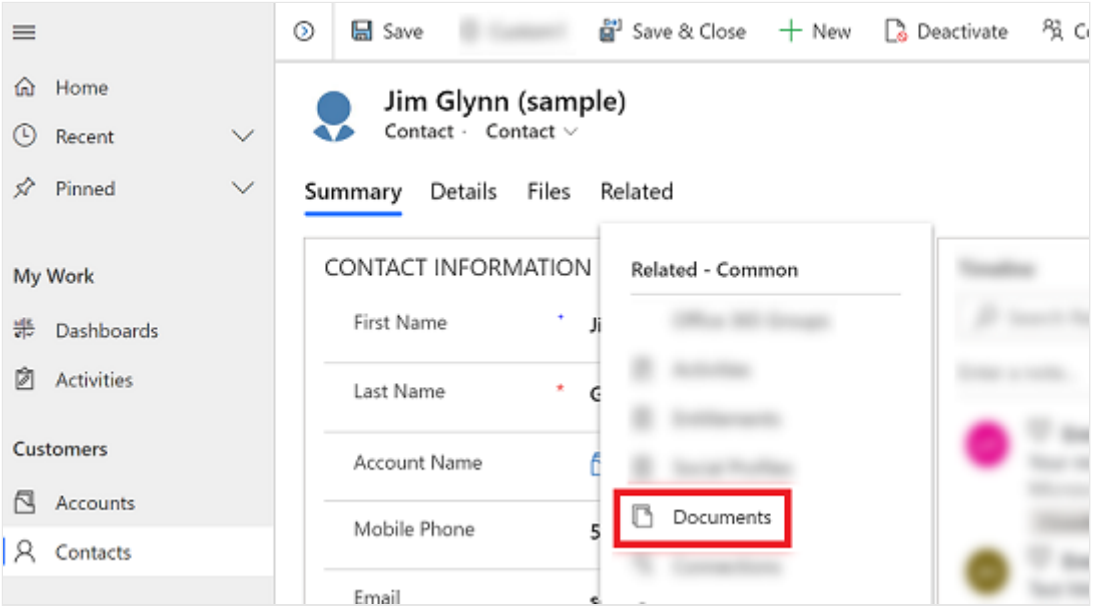


5. Enter a document name, and then select **Save**.

Create a new folder in the default SharePoint site location

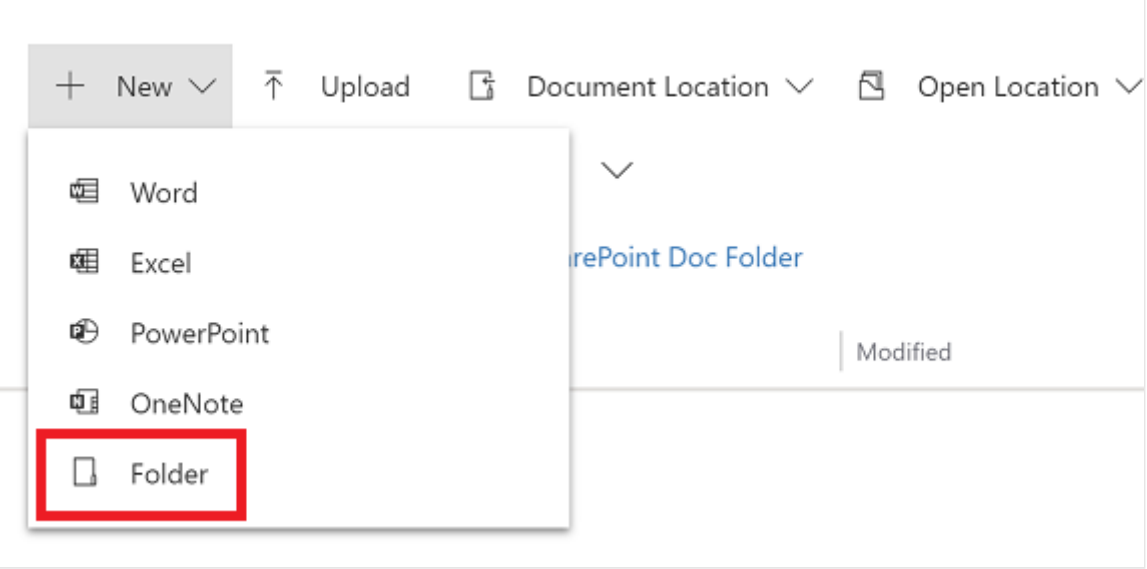
1. Open a row and go to the **Document Associated Grid** view. For example, open a contact row.

2. On the open row, select the **Related** tab, and then select **Documents**.



3. Select **Document Location**, and change the location to **Documents on Default Site 1**.

4. Select **New**, and then choose **Folder**.

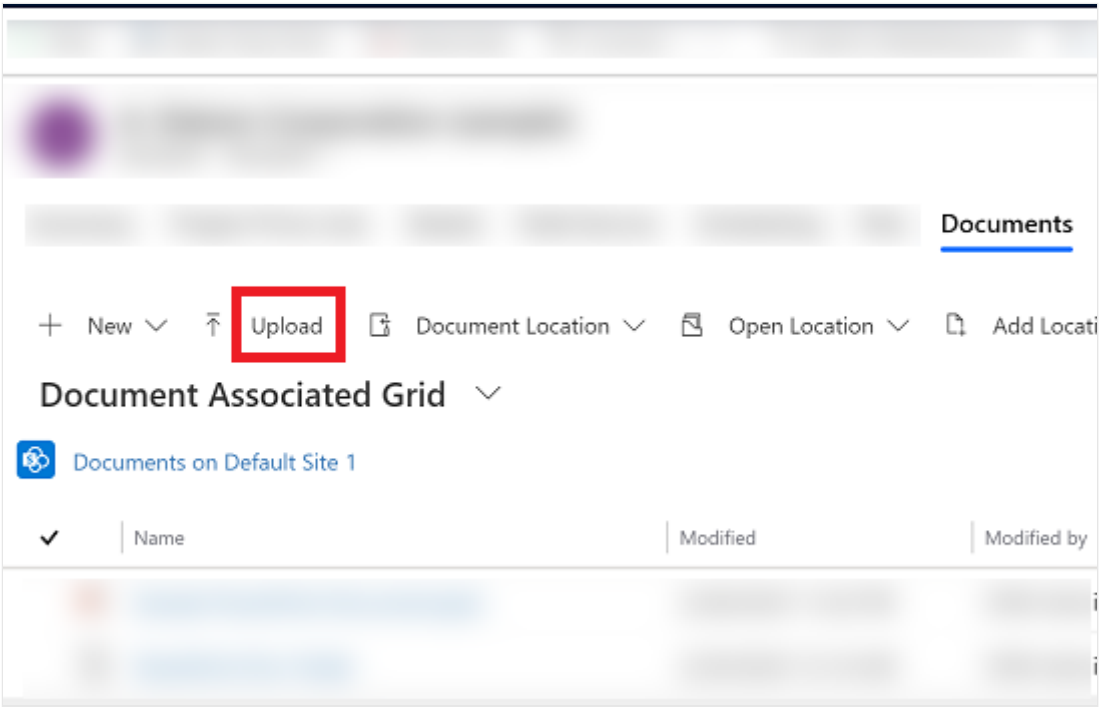


5. Enter a folder name, and then select **Save**.

Upload an existing document to SharePoint from your app

1. Go to the row you want to create the document for, select the **Related** tab, and then select **Documents**.

2. Select **Upload**.



3. Choose the file you want to upload. You can choose only one file at a time.

   The document is created in the current document location you're in.

> **Note**
>
> You can upload a file of up to 50 MB. If your internet connection is slow, you might get an error while uploading large files.

4. If files with the same name exist in SharePoint, select whether you want to overwrite the files.

5. Select **OK**.

Manage SharePoint locations

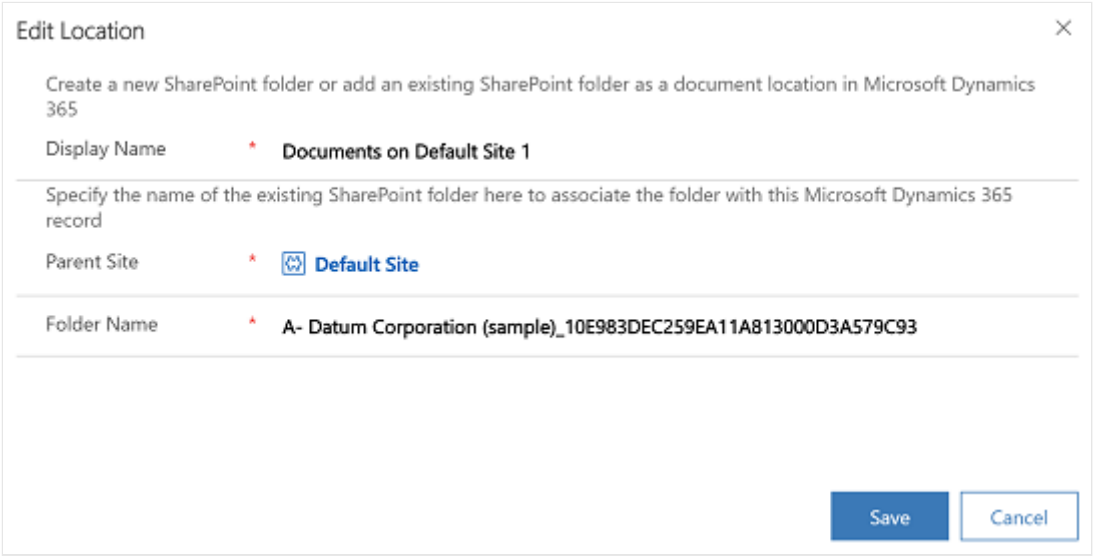
You can create new or edit existing SharePoint locations from your app in Dataverse.

Edit a location

1. Open a row, select the **Related** tab, and then select **Documents**.

2. Select **Edit Location**, and then select a SharePoint site location.

   The **Edit Location** dialog box appears.



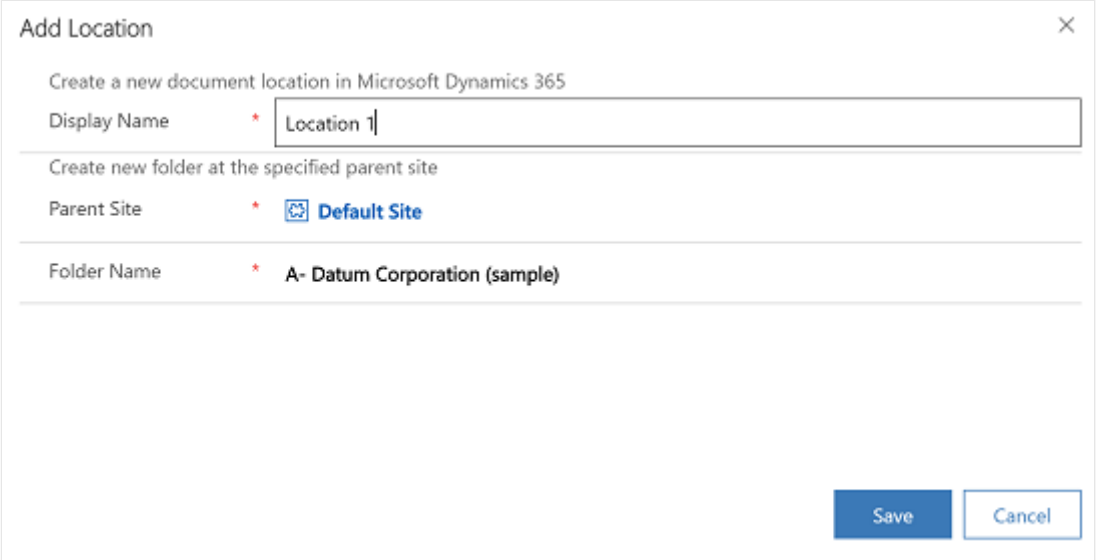
3. The display name, parent site, and folder name are automatically populated. Enter details about the new location, and then select **Save**.

Add a new location

1. Open a row, select the **Related** tab, and then select **Documents**.

2. Select **Add Location**.

The **Add Location** dialog box appears.



3. The display name, parent site, and folder name are automatically populated. Change the details if necessary, and then select **Save**.

Files tab FAQ

Why was the location to access documents moved?

- We moved the command to make documents easier to find with fewer clicks.

Has the Documents tab gone away?

- No, it hasn't gone away. Users can still access the documents associated with the row in question the old way, simply by selecting the **Related** menu and then the **Documents** link.

With the change, will subfolders in SharePoint still be created automatically?

- Yes. The behavior is similar to that of the **Documents** link under the **Related** menu. When a user selects the **Files** tab for the first time, the corresponding SharePoint subfolder is created by the system.

Is there a way to add the Files tab to other tables, or remove it?

- Yes. To add or remove the **Files** tab, follow the steps in this article: Add the SharePoint documents tab to the main form for a table

Use @mention to collaborate with your team using Notes

Article • 03/21/2025

Collaborate effortlessly by mentioning your coworkers in Notes on the timeline.

The administrator must enable the **@mention people when in rich text editor to add and notify user settings** in Power Platform admin center and enable in-app notifications for the app for this capability to be available.

> **ⓘ Important**
>
> Users must have the Read privilege for the **msdyn_postconfig** entity, as well as the Share privilege for the entity for which they use @mentions (for example, account, contact, case, and so forth).

@mention a user in Notes

1. Open a row and go to the activity timeline on the page.
2. Add a note by selecting *Enter a note*.
3. In the **Description** field, enter @ and the first few letters of the person's first name to see a list of options.
4. Select the name you want.

   If the user doesn't already have permission to view the row and you have the Share privilege for the row, you're asked to provide basic read permission for the row you're adding a note on.

Notifications

1. The notification bell icon indicates a new notification when you're @mentioned in a note.
2. Open the notification center and select the notification to navigate to the record on which you were mentioned.

Compare search options in Microsoft Dataverse

Article • 04/05/2025

There are three ways to search rows in Dataverse:

- Dataverse search
- Quick Find (single-table or multi-table)
- Advanced Find

> **Note**
>
> Multi-table Quick Find is also called Categorized Search. For a given query, the search results from the following three options might be different due to the search cope and search behavior.

The following table provides a brief comparison of the three options.

Expand table

Functionality	Dataverse search	Quick Find	Advanced Find
Enabled by default	"On" state for all new production environments. "Default" state for all other environments. Learn more about how Dataverse search works.	Yes, for the table grid. No, for multiple-table quick find (categorized search). An administrator must first disable Dataverse search before multiple-table grid find can be enabled.	Yes
Single-table search scope	Not available in a table grid. You can filter the search results by a table on the results page.	Available in a table grid.	Available in a table grid.
Multi-table search scope	There's no maximum limit on the number of tables you can search.	Searches up to 10 tables, grouped by a table.	Multi-table search not available.

Functionality	Dataverse search	Quick Find	Advanced Find
Search behavior	Finds matches to any word in the search term in any column in the table.	Finds matches to all words in the search term in one column in a table; however, the words can be matched in any order in the column.	Query builder where you can define search criteria for the selected row type. Can also be used to prepare data for export to Office Excel so that you analyze, summarize, or aggregate data, or create PivotTables to view your data from different perspectives.
Searchable columns	Text columns like Single Line of Text, Multiple Lines of Text, Lookups, and Option Sets. Doesn't support searching in columns of Numeric or Date data type.	All searchable columns.	All searchable columns.
Search results	Returns the search results in order of their relevance, in a single list.	For single-table, returns the search results in a table grid. For multi-table, returns the search results grouped by categories, such as accounts, contacts, or leads.	Returns search results of the selected row type with the columns you have specified, in the sort order you have configured.
Wildcards (*)	Trailing wildcard supported for word completion.	Leading wildcard supported. Trailing wildcard added by default.	Leading wildcard supported.

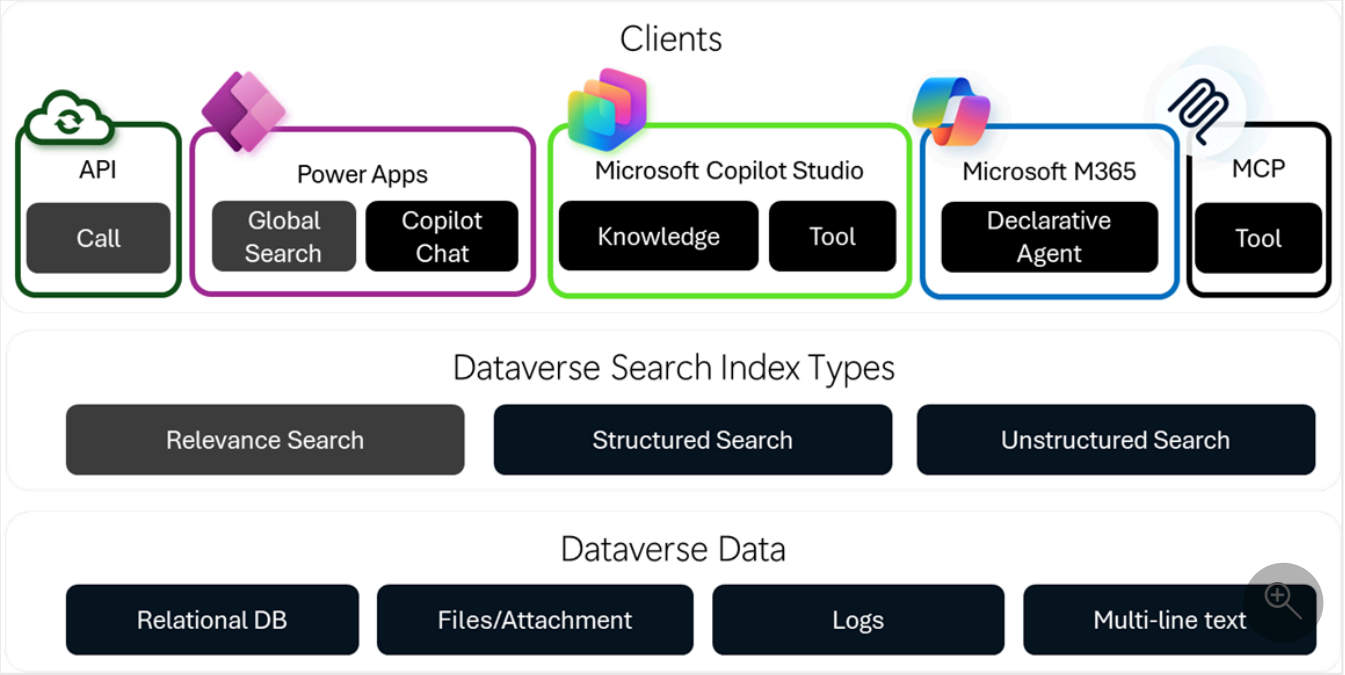
What is Dataverse search?

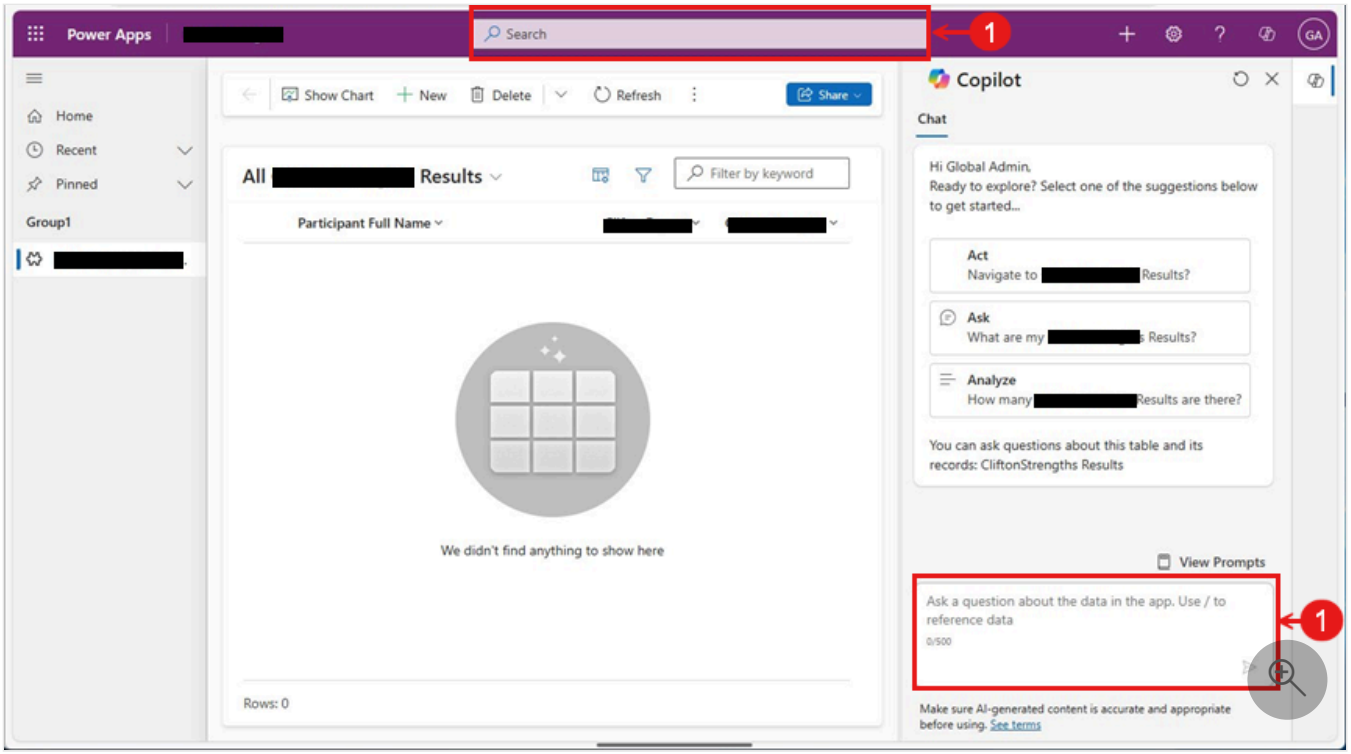
Dataverse search is the foundation that enables Copilot and in-app search experiences to understand and process business data. It turns raw information into actionable intelligence.

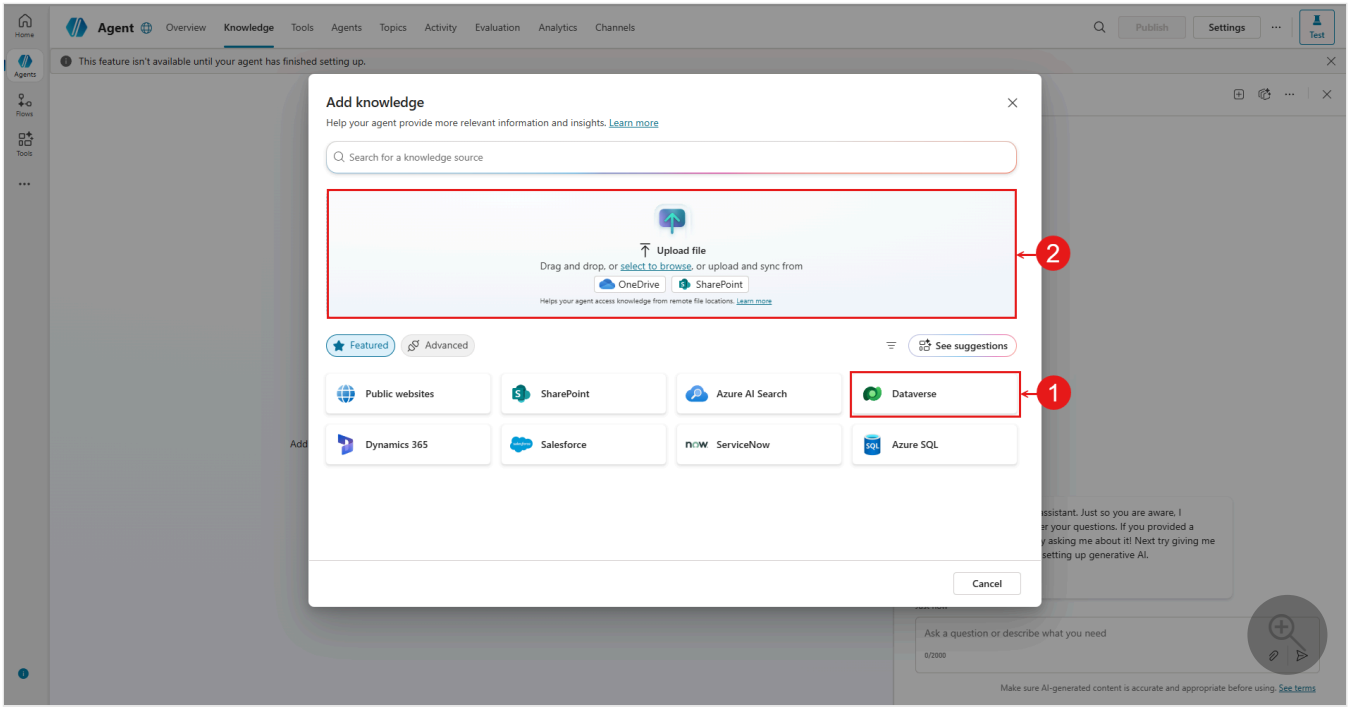


Dataverse search powers global search experiences, API calls, and agents built with Copilot Studio, including those running on Microsoft 365 Copilot and MCP tools. Beyond helping users of model-driven apps quickly, find what they need, Dataverse search enables rich search and AI-driven experiences across products that use Dataverse as a data source.

What type of data does Dataverse search index?

Dataverse search includes structured data (tables) and unstructured data (files).





Legend:

1. **Structured data**: Supports multiple experiences, including global search, Copilot for model-driven apps, and Copilot Studio agents that use Dataverse knowledge from tables.
2. **Unstructured data**: Supports experiences like Copilot Studio agents that use Dataverse knowledge from files.

Dataverse search includes three index types:

- **Relevance search**: Powers global search and SearchQuery API.
- **Structured index**: Enables Copilot and generative AI experiences.
- **Unstructured index**: Enables Copilot and generative AI experiences.

The structured and unstructured indexes enable Copilot and generative AI experiences in scenarios such as agents built with Copilot Studio, Copilot in Dynamics 365, declarative agents, app Copilot, Copilot chat, and Dataverse MCP.

What's the value of indexed data?

Dataverse search uses indexed Dataverse data to help systems perform more efficient searches. Indexed Dataverse data is enterprise content that's organized in a specific structure, like a data catalog. When an agent or system uses the indexed data structure, search performance increases based on a specific input.

Experiences enabled by Dataverse search

Dataverse search lets you use multiple features in Power Platform, including Copilot indexes. Here are the experiences:

Microsoft Copilot Studio Agents

- Add files as a knowledge source
- Add Dataverse as a knowledge source
- Add SharePoint as a knowledge source
- Add OneDrive as a knowledge source
- Agent Copilot

Dynamics 365 Copilots

- Sales Copilot
- Customer Service Copilot
- Contact Center Copilot
- Field Service Copilot

Power Apps: Model-driven apps

- Copilot for app users in model-driven apps
- Dataverse search

Experiences across the Power Platform

- In Power Apps or Power Automate
- In Microsoft Copilot Studio
- Power Apps or Power Automate—custom AI prompts

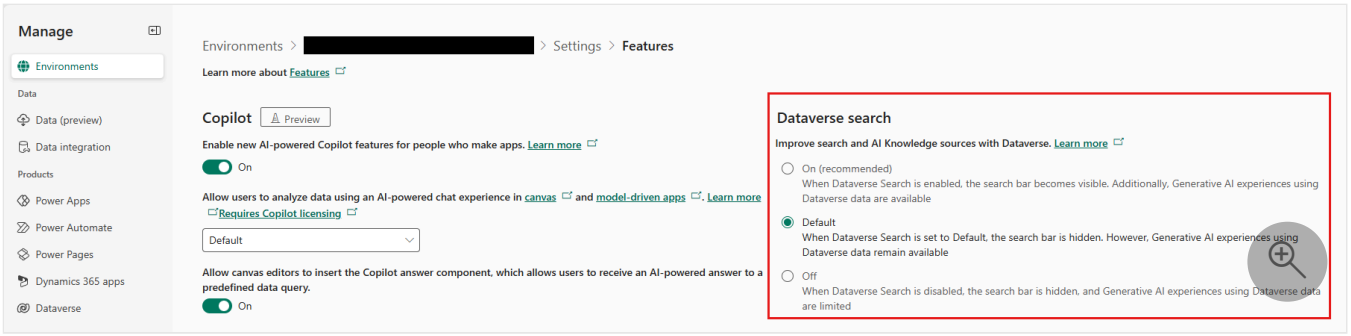
Benefits of Dataverse search

1. **Integration with AI and Copilot experiences:** By using natural language, you can have a conversation with your data and identify themes, patterns, and insights. This feature uses AI technology to interpret natural language, such as misspellings, common abbreviations, and synonyms, to deliver quality results.
2. **Unified search:** Dataverse search lets you quickly find content in model-driven apps and other products that use Dataverse as a data source. It provides a better user experience than quick find, where all words in the search term must be found in one column.
3. **Efficient relevance-based results:** Intelligent ranking algorithms return the most relevant records first, with performance that's superior to categorized search. This feature reduces time spent searching and increases accuracy.
4. **Smart fuzzy search:** Dataverse search handles variations in spelling and terminology, so it doesn't depend on exact keyword matches.
5. **Security and compliance:** Dataverse search respects Dataverse security roles and permissions. Users can only see search results for records that they have access to.
6. **Scalability and performance:** Dataverse search is optimized for large datasets and supports multiple data types, such as Choice and Lookup.
7. **Search across documents in Microsoft Dataverse:** Dataverse search includes search results for text in documents that are stored in Dataverse, such as PDF, Microsoft Office documents, HTML, XML, ZIP, EML, plain text, and JSON file formats. It also searches text in notes and attachments.

> **Note**
>
> Global search supports up to 2 MB of file search.

Dataverse search implications

Dataverse search is an opt-out feature. The feature is **On** for all new production environments and set to **Default** for all other environment types. Find this setting in Power Platform admin center by going to **Manage** > **Environment** > **Settings** > **Product** > **Features** > **Dataverse Search**.



In Power Platform admin center, admins can use the Dataverse Search setting to manage search. The selected Dataverse search state affects how to use Dataverse data across the enabled experiences for the entire organization. The following tables show how each Dataverse search setting affects global search experiences (including SearchQuery API) and Generative AI experiences, and how admins can use this setting to manage it.

What Dataverse search setting means for global search

When you set Dataverse search to **On**, the **Global Search** box appears at the top of every page in your model-driven app. This search box is the default global search experience for all model-driven apps. Learn more in Search for records by using Dataverse search.

Expand table

Dataverse search set to On	Dataverse search set to Default	Dataverse Search set to Off
Search bar is visible. (Quick Find isn't visible or accessible)	Search bar isn't visible. (Quick Find is an alternative)	Search bar isn't visible. (Quick Find is an alternative.)
Dataverse search is used for all production environments	Dataverse search isn't available for Global search in any environment	Dataverse search isn't available for Global search in any environment
Dataverse data is automatically indexed. Data is searchable for global search	Dataverse data isn't indexed. Data isn't searchable for global search	Dataverse data isn't indexed. Data isn't searchable for global search

What Dataverse search means for generative AI enabled experiences

Some generative AI experiences use Dataverse search data, such as Copilot chat in model-driven applications. You can access Copilot chat through the Copilot icon in the right navigation bar in a model-driven app. You can open or minimize the Copilot chat pane as needed.

- **Power Apps**: Copilot chat for model-driven apps in Power Apps is a next-generation AI assistant that helps app users get insights about the data in their apps through conversation in natural language.
- **Copilot Studio**: Integrating Dataverse tables as your knowledge source allows you to ground your agent in the data contained in your tables. This integration can also happen by using unstructured data as knowledge or Dataverse tools.

> **Note**
>
> An enabled generative AI feature's availability isn't managed by Dataverse search itself and is enabled through its own feature setting.

Expand table

Dataverse search set to On	**Dataverse search set to Default**	**Dataverse search set to Off**
All production environments use Dataverse search	Sandbox, Trial, Developer, Dataverse for Teams environments use Dataverse search for generative AI experiences	No environment uses Dataverse search
Dataverse data is automatically indexed and becomes searchable	Dataverse data (tables and files) is indexed when triggered and becomes searchable	Dataverse data isn't indexed nor searchable

What actions can makers or admins take to manage Dataverse search efficiently?

Depending on the experience that uses Dataverse search and its usage, consumption size can increase. The following recommendations help you optimize storage consumption for efficient and value-added output, from granular and less impactful actions (data level) to broader and more impactful actions (environment level).

> **Note**
>
> While one action helps optimize the amount of indexed data within a specific feature, other enabled features might trigger index provisioning. For more impactful approaches, go through all the steps, in order of recommendation, or consider turning off features in the Power Platform admin center.

Data level

To manage the search index at the data level, review each table and each column to confirm that search is needed. If not, take the following actions:

Global Search: Break down tables into multiple columns

Why this helps?

Indexed data includes structures like inverted indexes, metadata, and pointers to enable fast search and retrieval. These components add overhead beyond the raw data and can significantly increase storage requirements compared to the original dataset.

How to implement?

- Ensure the data is consistently formatted across records to increase repetitiveness of words and reduce the number of indexes.
- By breaking down the data across multiple columns, you can be more specific about which data to search over.

Global Search: Only select columns that need to be searchable

Why this helps?

Dataverse search has default selected columns. By default, certain columns like Primary Name and ID are indexed for all tables. These columns are part of the 50 fields indexed by default and don't count toward the limit for every table. Enable columns for Dataverse search only if a Quick Find view is set as the default view for the table. For more information, see Managing Dataverse search.

How to unselect tables that aren't used so that they're not indexed or searchable

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**.
3. Choose the solution you want to modify, and then select **Edit** in the command bar.
4. On the **Objects** page, in the navigation pane, select **Overview**.
5. In the Dataverse search pane, select **Manage search index**.
6. Review the tables that are indexed.
7. Unselect the tables, and then select **Save**.

How to unselect columns that aren't used so that they're not indexed or searchable

1. Sign in to Power Apps.
2. On the left navigation pane, select **Tables**.
3. On the **Tables** page, select the table you want to edit.
4. In the **Data experiences** pane, select **Views**.
5. From the list of views, select the Quick Find view type. For example, select **Quick Find Active Accounts**.
6. Edit **View columns**.
7. Go to the columns you want to remove, and select **Remove** in the dropdown menu.
8. Select **Save and Publish** to publish the changes to the view.

Copilot Studio: Ensure specific Dataverse tables or files are added to Copilot Studio agent's knowledge

Why this helps?

When you add a Dataverse tool or knowledge, such as Dataverse MCP, Dataverse table, or file to a Copilot Studio agent, the process automatically indexes all the underlying Dataverse data for efficient, semantically relevant searches. Reducing knowledge and tools to only the necessary content helps indexing processing and storage consumption and increases search quality.

How to remove unnecessary content or imagery, or tables from files

- **File Upload, OneDrive, and SharePoint upload**: Remove files that aren't needed for search from the agent's knowledge base. You might want to consider removing pages, sheets, or any accessory data point from the files themselves.
- **OneDrive and SharePoint upload**: Select only the files or folders you need instead of selecting nested folders.

How to remove Dataverse tables or files from Copilot studio agent’s knowledge

In the **Overview** or **Knowledge** tabs on a Copilot Studio agent, go to the **Knowledge** section and select the dot menu for each of the Dataverse-enabled knowledge sources, and then select **Delete**. Use the same instructions for the following knowledge sources:

- Dataverse Tables
- Files you upload

- OneDrive files
- SharePoint files (from upload)

> **Note**
>
> The same process applies to Dataverse MCP tools, but you complete it in the Tools section (instead of the Knowledge section).

App or agent level

To manage the search index at the app or agent level, review the purpose and usage of each application and agent to confirm search is needed. If not, take the following actions:

Copilot for Power Apps: Specify which applications you'd like Copilot to be enabled for

Why this helps?

Copilot in model-driven apps uses AI to interpret natural language queries and generates suggestions or actions based on the app's underlying Dataverse data. In some situations, applications don't require enhanced search through Copilot, so managing Copilot at an app level can help control consumption.

How to turn off Copilot feature for each model-driven application

1. In the app designer, open the model-driven app for editing.
2. Select **Settings** from the command bar.
3. On the **Settings** screen, select **Upcoming**.
4. Select the **Copilot control** setting, and set it to **Off**.
5. Select **Save and Publish** to apply your changes.

Copilot for Dynamics 365 Apps: Specify which applications you'd like Copilot to be enabled for

Why this helps?

Just like model-driven applications in Power Apps, Copilot in model-driven apps uses AI to interpret natural language queries and generate suggestions or actions based on the app's

underlying Dataverse data. In some situations, applications don't require that level of enhanced search through Copilot. Managing Copilot at an app level can help with consumption control.

How to turn off Copilot feature for each Dynamics 365 application

1. In the Sales Hub app, change the area by using the option in the lower-left corner of the page.
2. Select **App Settings** to open sales setting.
3. Select **Copilot** > **Edit settings** > **Advanced settings**, which opens a new Copilot in Dynamics 365 Sales page.
4. Select **Individual apps**.
5. Select desired app and turn the setting to **Off**.

How to turn off Copilot feature for all Dynamics 365 application

1. In the Sales Hub app, change the area by using the option in the lower-left corner of the page.
2. Select **App Settings** to open sales setting.
3. Select **Copilot** > **Edit settings** > **Advanced settings**, which opens a new Copilot in Dynamics 365 Sales page.
4. Select **All Apps** and turn the setting to **Off**.

The other way to turn off Copilot feature for all apps is as follows:

1. In the Sales Hub app, change the area by using the option in the lower-left corner of the page.
2. Select **App Settings** to open sales settings.
3. Select **Copilot** > **Edit settings**.
4. Select **Off** from the Copilot dropdown, which opens a dialog box.
5. Select **Continue**, and then save your changes.

Environment level

To manage the search index at the environment level, admins can review the purpose and usage of each application and agent, as well as global search to confirm that search is needed. If not, admins can take the following actions:

Global search is disabled while Copilot experiences are enabled

Why this helps?

When Dataverse search is set to **Default**, the global search experience isn't enabled on the navigation of the model-driven apps or Dynamics 365. This setting means that users can't query global search, and data marked as "searchable" for the exclusive purpose of global search isn't indexed. However, Dataverse data might still be indexed for other experiences, such as Copilot in model-driven applications or Copilot Studio agents.

How to change Dataverse search to Default value

1. In Power Platform admin center, go to **Manage** > **Environments**.
2. Select the environment, and then select **Settings**.
3. Select **Product** > **Features**.
4. Change **Dataverse search** to **Default**.
5. Select **Save**.

> **Note**
>
> For organizations that want to search in these applications and don't need relevance-based search, they can enable Quick Find.

Copilot for Power Apps and Dynamics 365 apps is disabled while global search is anabled

Why this helps?

Copilot in Power Apps uses Dataverse indexed data to quickly retrieve and interpret relevant records when responding to natural language queries within the model-driven app. The semantic indexes enable efficient search across tables and relationships, allowing Copilot to provide accurate suggestions and automate actions based on the underlying data context. For organizations that don't want Copilot to be used with their model-driven applications, admins can turn off the feature at an environment level.

How to turn off the Copilot setting in Power Platform admin center

1. In Power Platform admin center, go to **Manage** > **Environments**.
2. Select the environment, and then select **Settings**.
3. Select **Product** > **Features**.
4. Turn the toggle and the set the dropdown to **Off**:

Dataverse search isn't needed for the environment

Why this helps?

At any time, you can manually set Dataverse to **Off**. If you set Dataverse search to "Off" for the environment, all users of features, apps, or agents of the environment can't use the search capability in the Power Apps navigation bar or any generative AI experience that relies on Dataverse, like uploaded files or using OneDrive or SharePoint files (via upload) in Microsoft Copilot Studio agents, among other experiences.

How to turn off Dataverse search for the environment

1. In Power Platform admin center, go to **Manage** > **Environments**.
2. Select the environment, and then select **Settings**.
3. Select **Product** > **Features**.
4. Change **Dataverse search** to **Off**. This change opens a dialog box. Acknowledge the impact of turning off Dataverse search, write the name of the environment, and select **Turn Off**:
5. Select **Save**.

> **Note**
>
> - Turning off Dataverse search deprovisions and removes the index within a period of 12 hours. If you turn on Dataverse search after it's been off for 12 hours, it provisions a fresh index that needs to go through a full sync. Syncing might take up to an hour or more for average size organizations, and a couple of days for large organizations. Be sure to consider these implications when you turn off Dataverse search temporarily. Configure Dataverse search for your environment
> - Index removal (or provisioning) can take multiple days to be completed, depending on the amount of Dataverse search consumption. For example, an organization with 10 GB of indexed data might take one day to clean up all indexes, while an organization with 500 GB might take multiple days to see it reflected in Dataverse search reporting. Give a few days or a week before submitting a support ticket, to ensure a complete removal of Dataverse search indexed data.

What happens when you turn off Dataverse search?

Expand table

Feature	Maker experience	End user experience
Microsoft Copilot Studio Agent – Add Knowledge	You can't upload files or select Dataverse tables. The agent doesn't provide results that rely on this indexed data until Dataverse search is enabled for the environment. Ask the environment's admin to enable Dataverse search.	The agent doesn't provide results that rely on this indexed data until Dataverse search is enabled for the environment. The agent uses the fallback answer by default.
Microsoft Copilot Studio Agent – Using Copilot Chat	The agent doesn't provide results that rely on this indexed data until Dataverse search is enabled for the environment. Ask your environment admin to enable Dataverse search.	The agent doesn't provide results that rely on this indexed data until Dataverse search is enabled for the environment. By default, the agent uses a fallback answer.
Model Driven Applications – Dataverse search	The search bar isn't visible in model-driven apps.	The search bar isn't visible in model-driven apps.

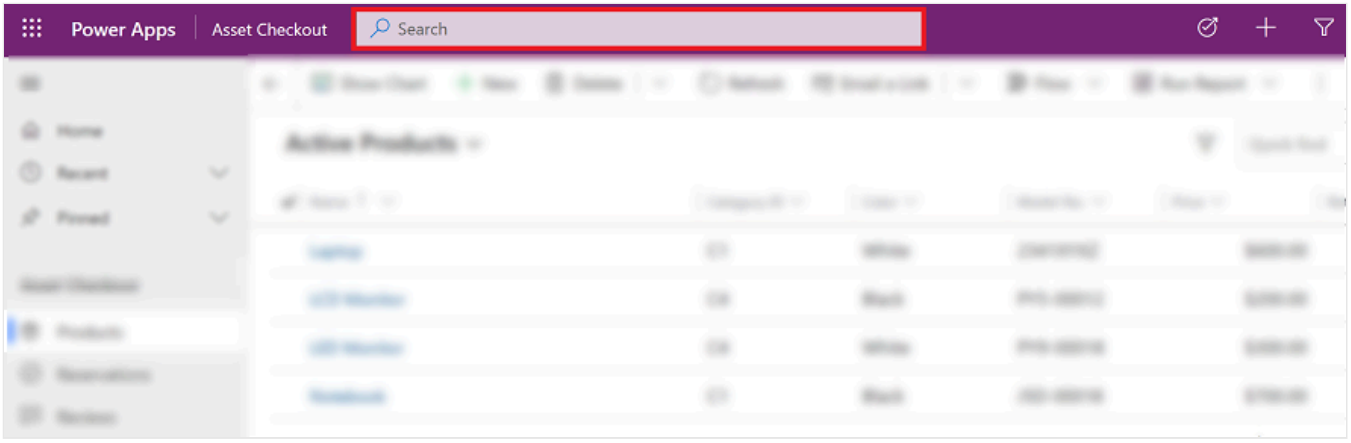
Search for records by using Dataverse search

06/26/2025

When Dataverse search is "**On**", the search box appears at the top of every page in your app and is the default global search experience for all model-driven apps. Dataverse search also lets you use certain generative AI experiences. You can't switch to quick find search, also known as categorized search. Start a new search to quickly find the information you need.

Turn on Dataverse search to give users a better search experience in model-driven apps. Environment admins can manage their environments by selecting **Off** to opt out of this feature.

[!Note] If Dataverse search is set to "**Default**", the search box isn't visible for searching content. Generative AI experiences are still available.

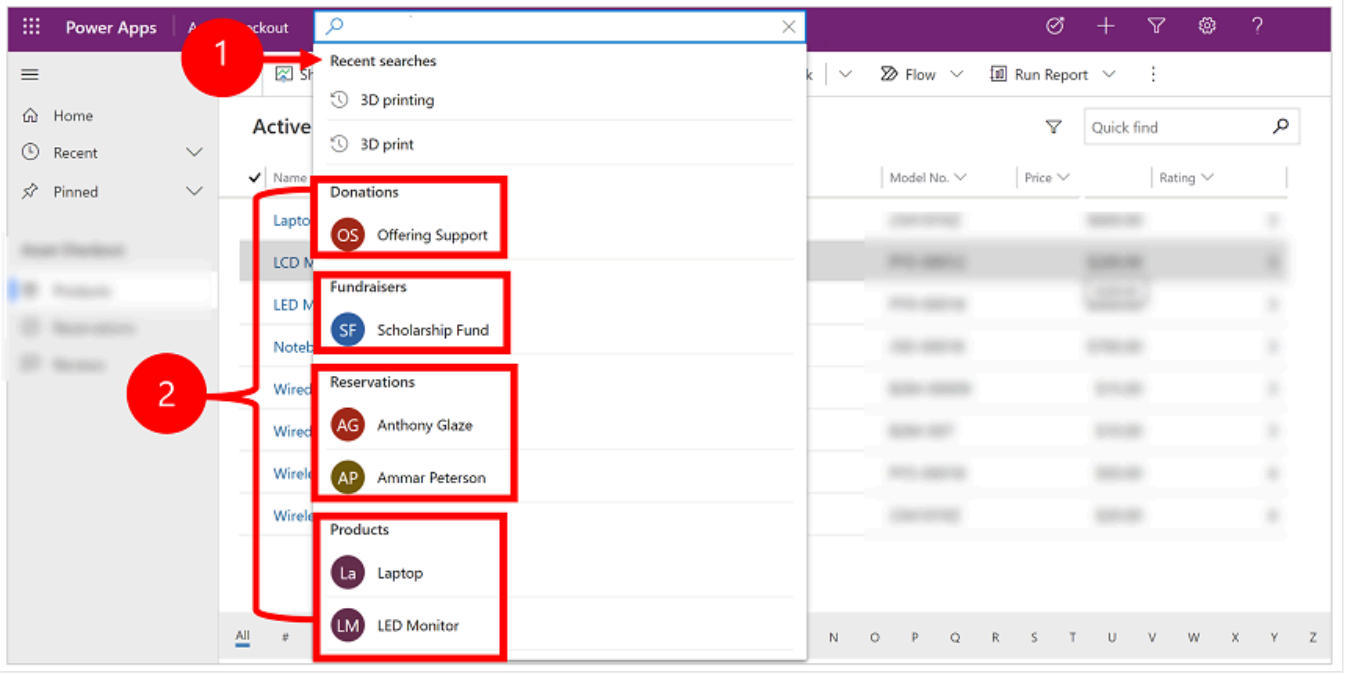


See recent rows and searches

See your recent searches and recently accessed rows when you select the search box. Before you start typing in the search box, you'll see information pop-up that helps you complete your search.

Up to three recent search terms appear at the top, based on the last three search queries that you viewed the results for. These recent search terms are personalized and based on your device and browser.

The recent search terms are followed by up to seven of the rows you recently accessed. If you frequently access a few rows, you can quickly get to them from here. Recently accessed rows are independent of tables that have been indexed for Dataverse search, because no search has been performed yet. The rows are also grouped by table type, which lets you quickly scan the list.



Legend

1. **Recent searches**: Shows your recent searches.
2. **Recently accessed rows**: Shows rows that you recently accessed, grouped by table type.

Inline suggestions

> **Note**
>
> If you're using custom analyzers for searching records, the records don't show in the inline suggestions.

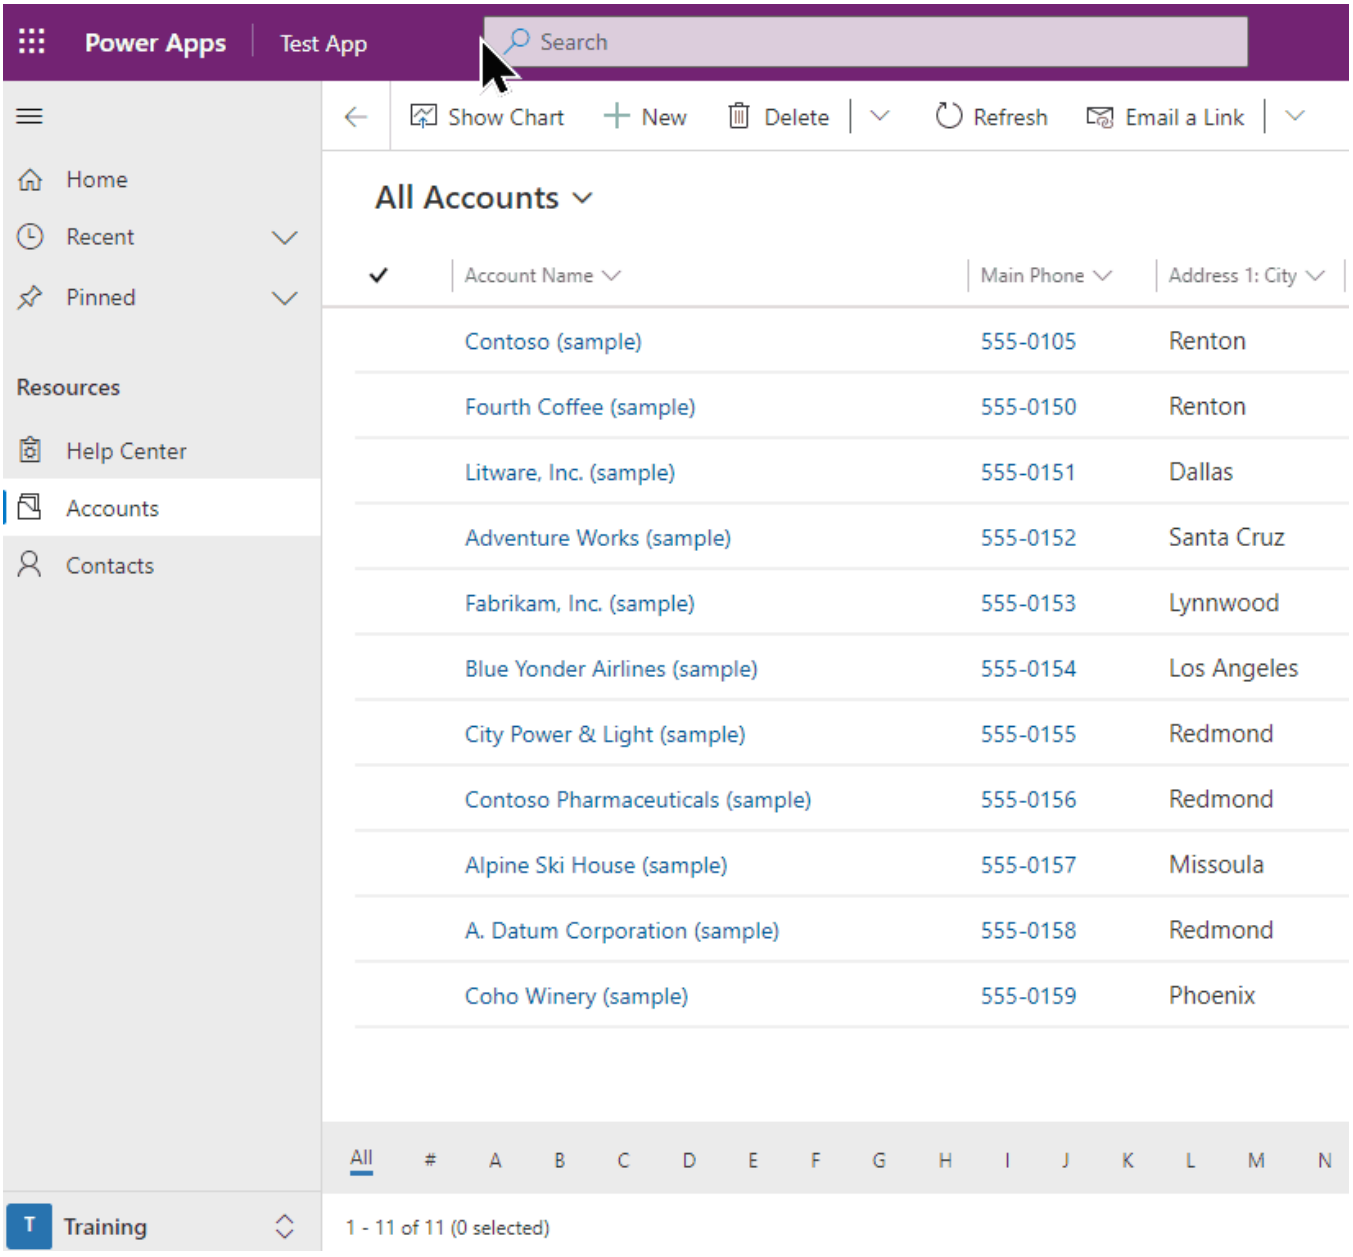
As you start entering text, you'll see suggested results that help minimize keystrokes and simplify page navigation. Suggested results are based on a search performed on all searchable columns of a table, which is enabled for Dataverse search and included in your model-driven app. For more information, see Add or edit model-driven app components in the Power Apps app designer.

Suggestions are shown when three or more characters are entered in the search box, and are based on two types of matching:

- **Word completion**: Rows where the primary field contains a word that begins with the search term. For example, entering **work** will show the account **AdventureWorks** and the contact **John Worker**, among other results.
- **Fuzzy search**: Terms that are misspelled by one character are matched. For example, entering **winry** will show the account **Coho Winery**, among other results.

Suggested rows display a secondary field alongside the primary field to help differentiate rows with the same primary field value. The secondary field is selected based on the table's quick find view:

- If the search text appears in a field within the quick find view, that field is used as the secondary field.
- If no match is found, the first non-primary field in the quick find view that contains data for the row is displayed instead.



With suggestions, you can access your information quickly by using minimal keystrokes even when the search term is misspelled by a character. Text that's highlighted in bold in the suggestions shows the term that was matched.

Search results page

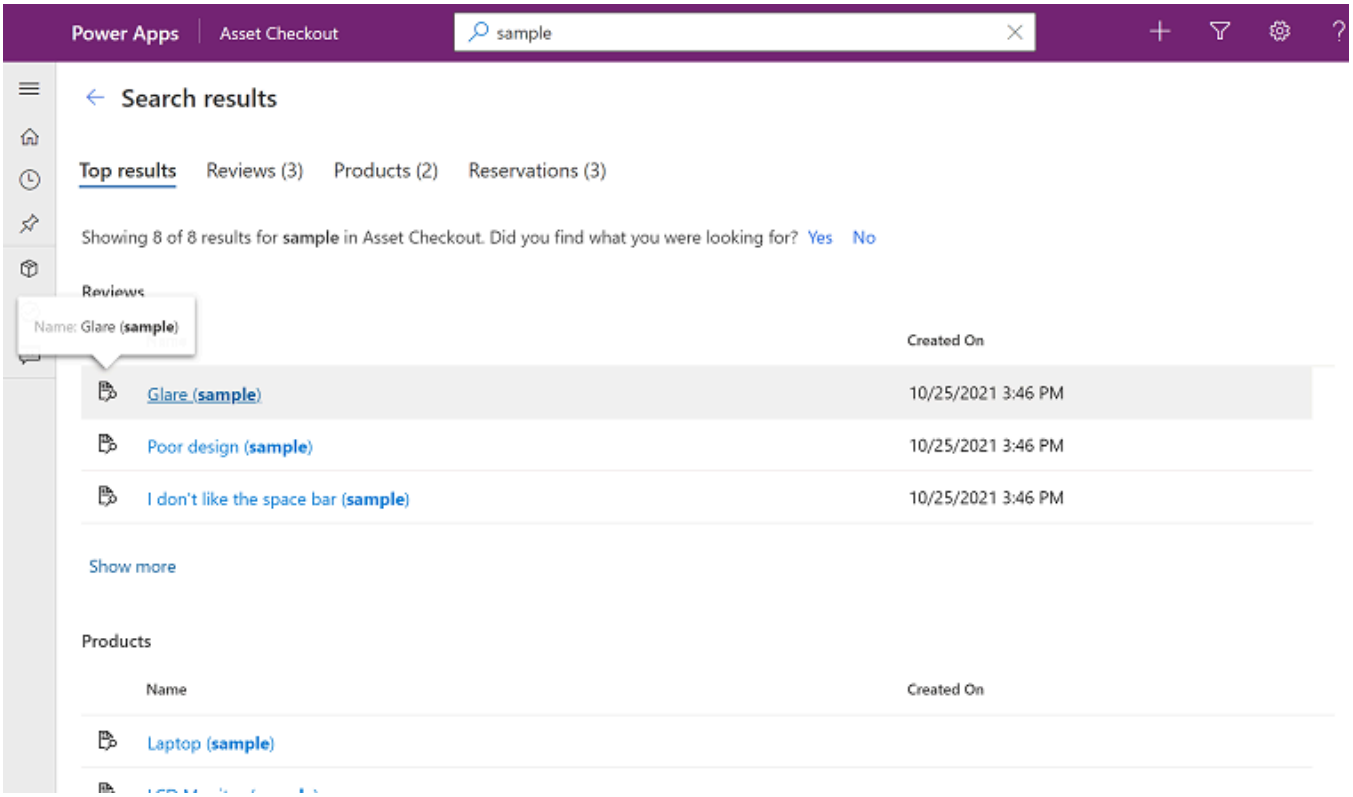
View the full results for a search by pressing **Enter** on your keyboard or selecting **Show more results**. Dataverse search will append "*" to the search if two or less characters are entered.

Search results are ranked based on relevance and grouped by tables. The list of tables that include rows that match the search term are displayed horizontally as tabs along the top of the screen.

When a search query contains multiple words, it's automatically split into individual search terms. Additionally, our fuzzy search feature expands results by including related words such as synonyms, acronyms, and abbreviations. For example, searching for "Robert Clark" might return results for "Bob Clark" due to fuzzy matching and "John Clark" because one of the search terms matches. To ensure an exact match, enclose the entire query in double quotes (for example, "Robert Clark").

To understand why a row appears in your search results, hover over the icon at the beginning of each row to see the text that matched your search.

> **Note**
>
> Rows returned in the search grid can't be sorted.



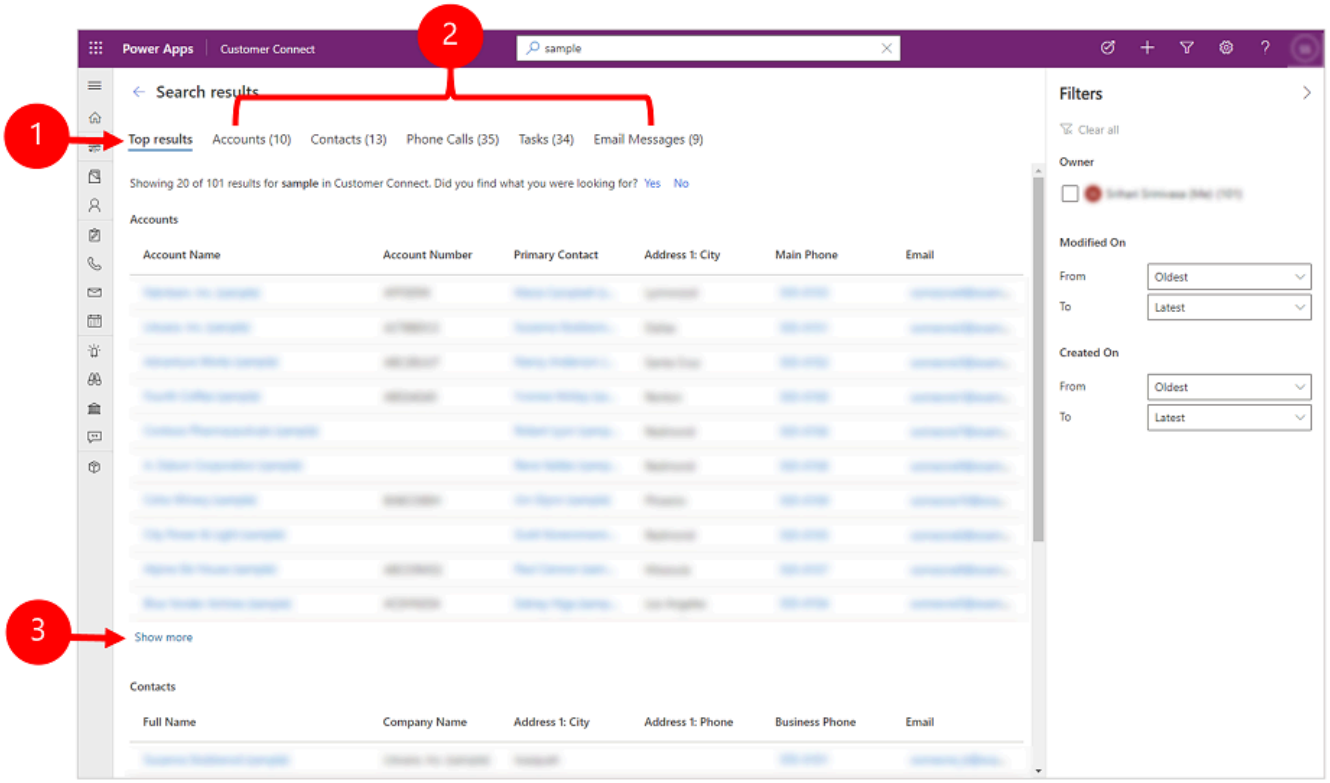
Top results tab

The **Top results** tab displays the top 20 results for the search term, with results grouped by table type. Each group shows results for a table in a grid that has up to six columns. The

columns are the first six columns of the table's **View columns** quick find view.

> **Note**
>
> - The primary column of a table is always used as the first column in the results on the **Top results** tab.
> - For notes and attachment tables, two additional columns show information about the related row for that note or attachment.
> - Party list columns on activity tables—such as **To**, **CC**, and attendees—can't be searched on or shown, and will be blank.

In the following image, the top search results from three tables are displayed.



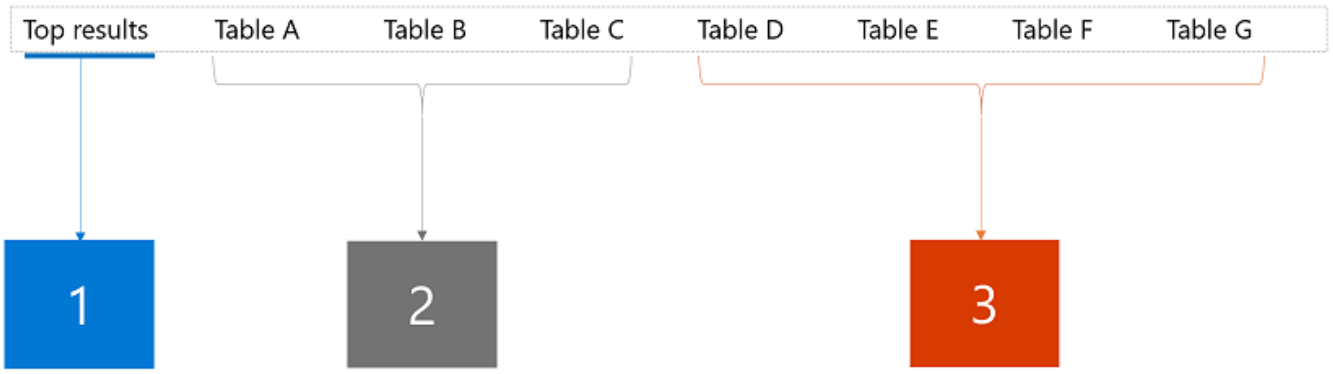
Legend:

1. **Top results**: This tab shows the top 20 results for your search term.
2. **Rows grouped by table type**: To narrow your search results to a specific table, select the table-specific tab.
3. **Show more**: When you select **Show more** at the bottom of a group, you switch to the table-specific tab.

Table-specific tabs

Tabs for the specific tables that contain search results are displayed horizontally. The exact order of the tables from left to right (in a left-to-right environment) is based on the relevance of the results. You can collapse the filter panel or hover over the list of tabs to scroll horizontally.

The tables that include the rows in the top 20 results are shown in the first three tabs from left to right, from most to least relevant. The tables that include the results outside of the top 20 are displayed in descending order.



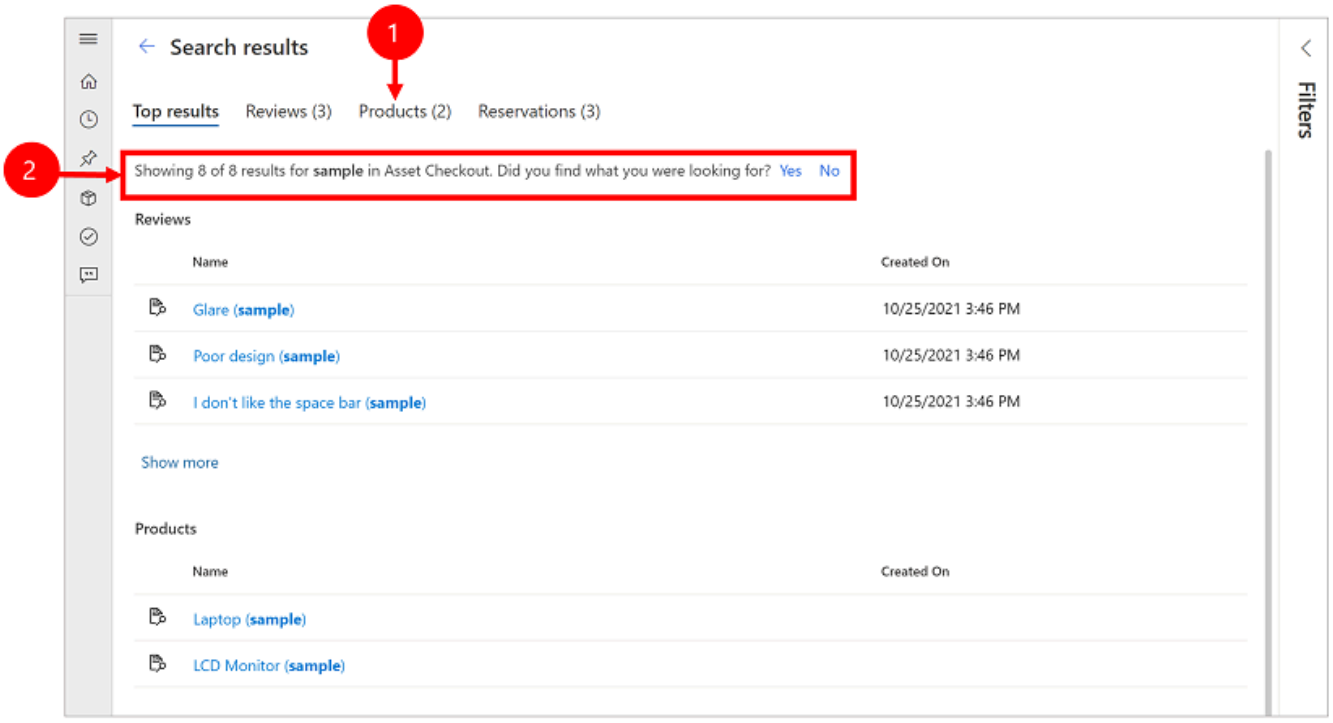
Legend:

1 Shows the top 20 results from three different tables.

2 Shows the three tables that are part of the top results, ordered by relevance.

3 Shows the rest of the matched table types, ordered by the number of records that match the search.

Select a tab to drill down into a specific table and view more information about the rows in the results.



Legend:

1. Shows the number of results for this specific table.
2. Shows the columns that were searched for the table.

Each table-specific tab displays more information than the **Top results** tab along two different dimensions:

- If the quick find view for the table has more than six **View Column**, then all columns are displayed on the table-specific tab, compared to the maximum of six columns shown on the **Top results** tab.
- All matching rows for the table are accessible in the table-specific tab as an infinitely scrollable list.

Filter results by using facets

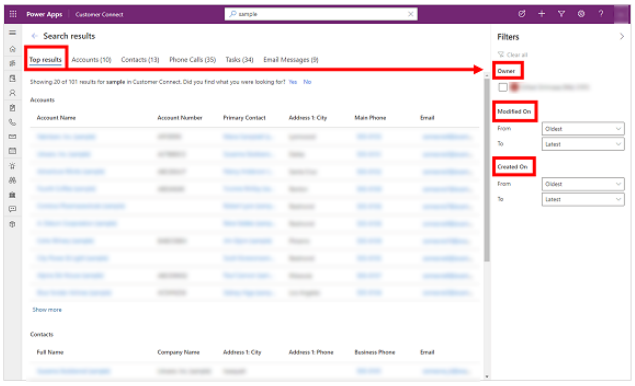
On the search results page, you can use facets and filters to refine and explore your search results. Facets are available on the **Filter** panel, which you can expand or collapse.

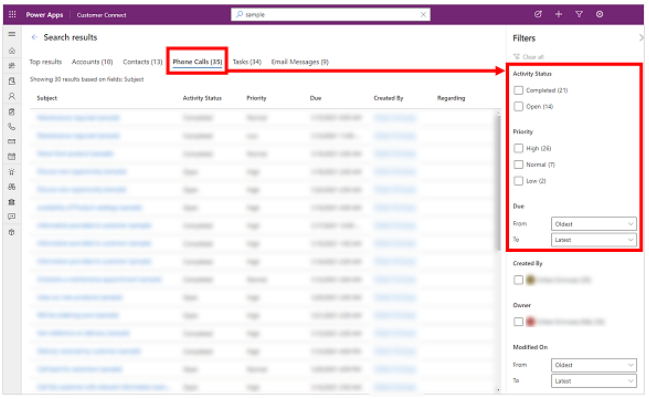
The **Top results** tab shows search results across different row types, such as a contact versus a phone call. Thus, the **Top results** tab only shows the three global facets that apply to all row types:

- Owner
- Modified On
- Created On

On a table-specific tab, facets that apply to that table type are displayed above the three global facets.

Expand table

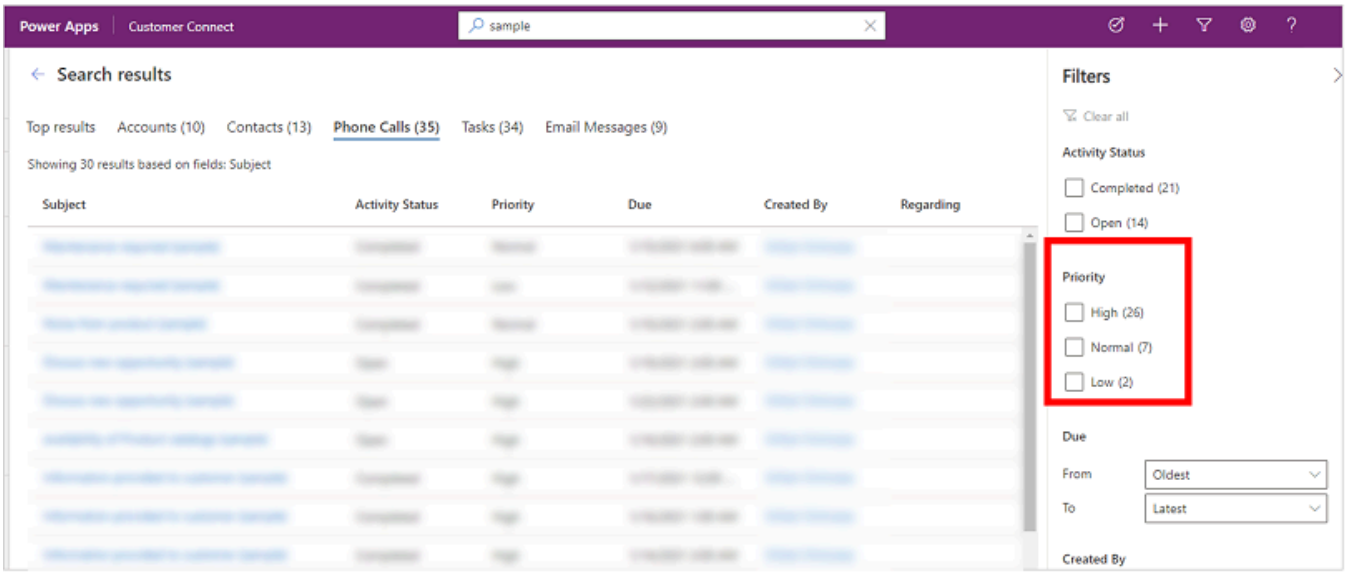
The Top results tab shows only global facets	Other tabs show facets that are specific to that table type
	




You can personalize facets for a table by using the **Set Personal Options** dialog box. More information: Configure facets and filters

Text-based facets with discrete values

All **Lookup** and **Choice** data types are text-based facets. For example, the text-based facet **Priority** consists of a list of column values (choices) and their corresponding counts.

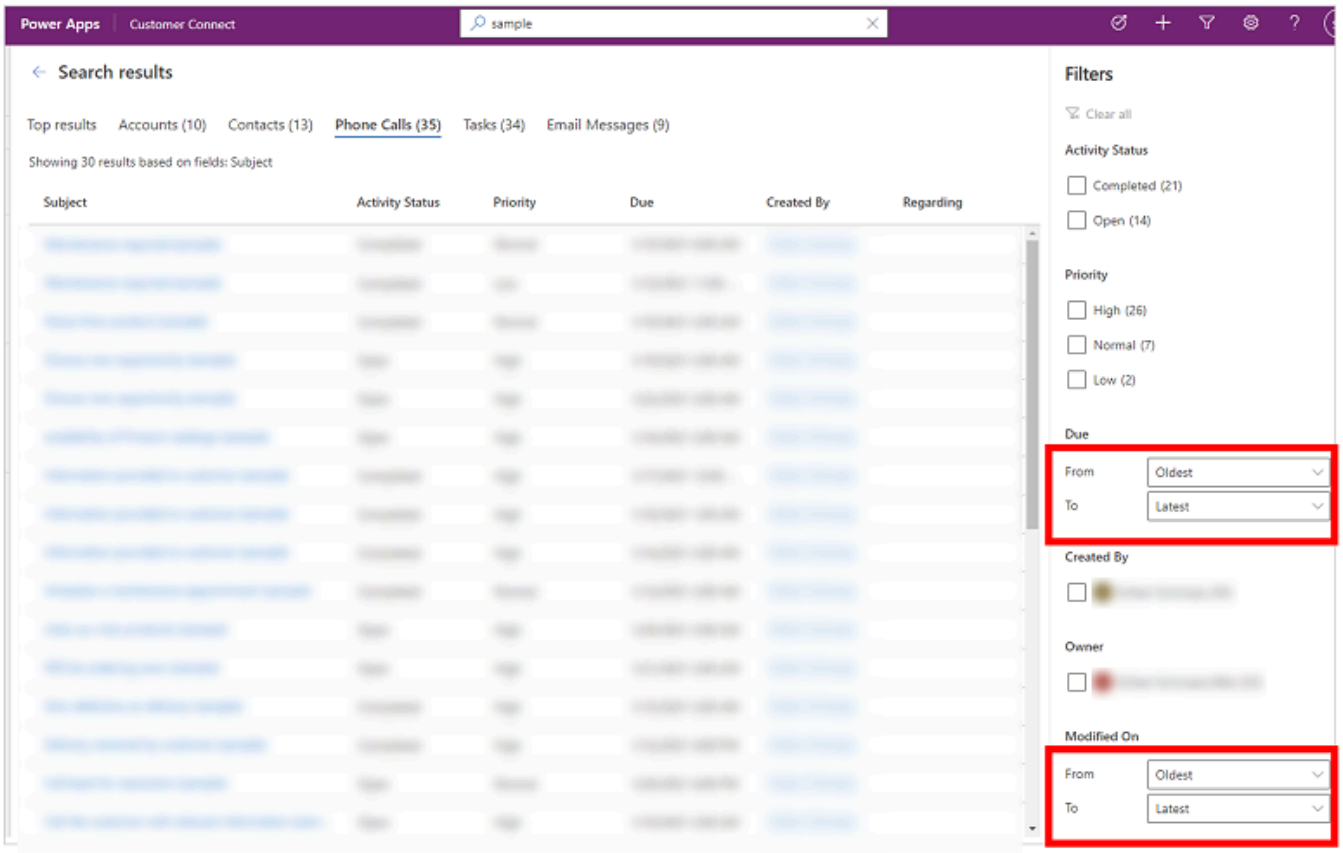


Filters in these facets are sorted in descending order by count. By default, the top four-facet values are displayed. When there are more than four-facet values, you can select **Show more** to expand the list and see up to 15 results.

When you select a facet value, you filter search results to show only rows where the column includes the value that you selected.

Date and time facets

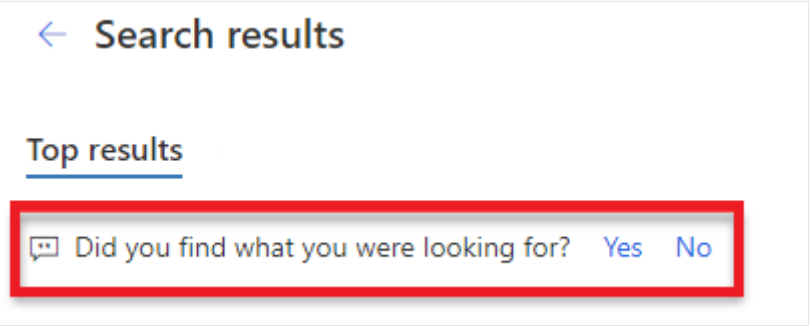
The date and time facets let you filter and see search results for a specific period. Use the **From** and **To** drop-down lists to specify a time period.



Feedback link

On the search results page, the answer to **Did you find what you were looking for?** is collected in our product telemetry as a binary feedback. Search parameters—like the query text that you entered in the search box—isn't collected, irrespective of your response to the question. We only use **Yes** or **No** response statistics to help us understand the usefulness of the search experience.

Currently there's no option to disable the feedback question prompt.



Understand search results

Dataverse search has a powerful set of capabilities to help you put Microsoft Dataverse at your fingertips. Here are some pointers to help you understand what results you can expect in different scenarios.

> **Note**
>
> - Dataverse search is text-based, and can search only on columns of type **Single line of text**, **Multiple lines of text**, **Choice**, or **Lookup**. Columns of type **Numeric** and **Date** aren't searched on.
> - Dataverse search enables you to search for rows that are shared with you and rows that you own. Hierarchical security models aren't supported. This means that even if you see a row in Dataverse because you have access to it through hierarchical security, you won't see that row matched by Dataverse search unless you own it or it was shared with you.
> - Dataverse search supports column level security. This means that a user with access to a restricted column can search for the column and will see it in the search results. A user that doesn't have permission to the restricted column won't be able to search or see results for the column.

> **Tip**
>
> The order of tables in the **Top results** tab and in the horizontal list of tabs is based on the ranking and relevance of search results for that search term. You can make results from a particular table appear at the top by including the table name in the search term. For example, searching for **account fabrikam** would, in most cases, rank result records that have the term **fabrikam** of type **account** higher than result records that have the term **fabrikam** of type other than **account**.

- **Boosted search results**
  Use important attributes as keywords to "boost" your search for information. Entering a table type to boost search results is an easy way to indicate which results you prefer. For example, searching for **Susan Adatum** indicates that you're looking for a contact **Susan** related to the account **Adatum**.

- **Natural language understanding**
  Search has a better understanding of terms that are used to indicated intent. Some examples include:
  - Searching for **open phone calls** will show phone call activity records that have the status **open**.
  - Searching for **contact missing email** will show contacts who have an empty email address field, rather than treating **missing** as a keyword.

- **Spelling correction**
  Search forgives common spelling mistakes. For example, when you search for **william conatc**, search results will include the contact record with the name **William**, even though the word **contact** was misspelled.

- **Synonyms, acronyms, and abbreviations**
  With support for common abbreviations and synonyms, you can search for your information the way you remember it, not necessarily the way it's stored. Some examples include:
  - Common name variations like **Bob/Robert** are matched with either search term.
  - A search term that uses an abbreviation like **active accts** will be interpreted semantically as "active accounts."

- **The power of common knowledge**
  Search can understand popular locations, date, time, holidays, and numbers. For example, a search for **account in WA** will generate results for accounts located in Washington state.

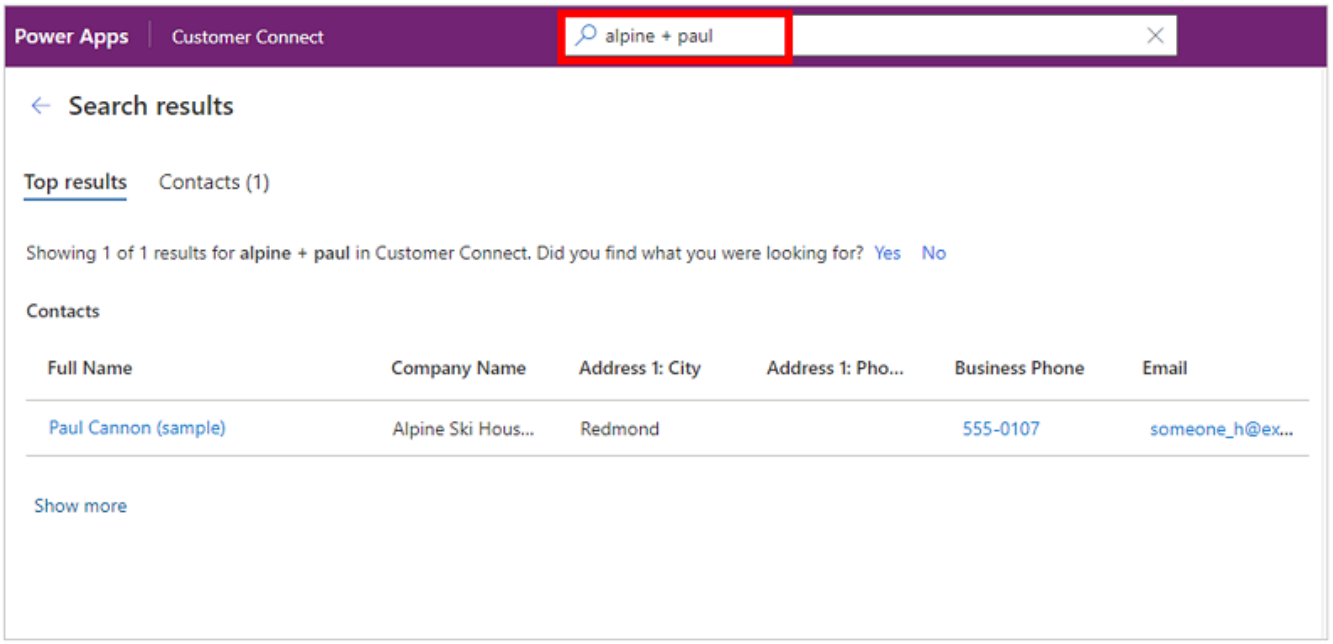
> ⓘ **Note**
>
> - All the preceding capabilities are part of intelligent search, which is only available for public cloud environments that have English as the base language.
> - To get these results, the preceding examples assume that specific fields for each table were indexed.

Working with operators

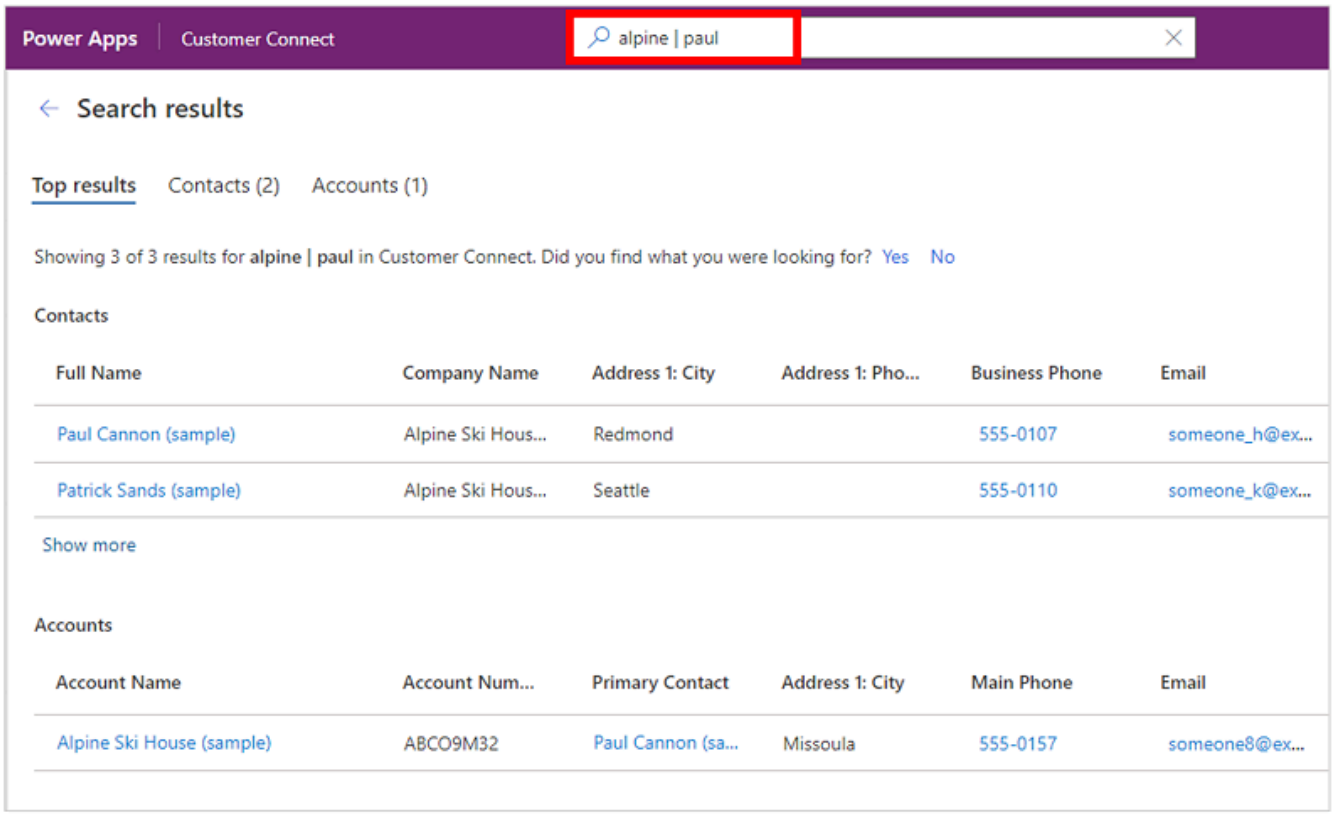
Operators help you craft precise search queries that can tailor your results according to specific conditions. This section describes some of the supported operators.

Boolean operators

Search on a combination of terms using the + operator, which performs an **AND** search and shows results containing all the individual terms separated by +. For example, **alpine + paul** returns the contact record **Paul Cannon** related to the account record **Alpine Ski House**.

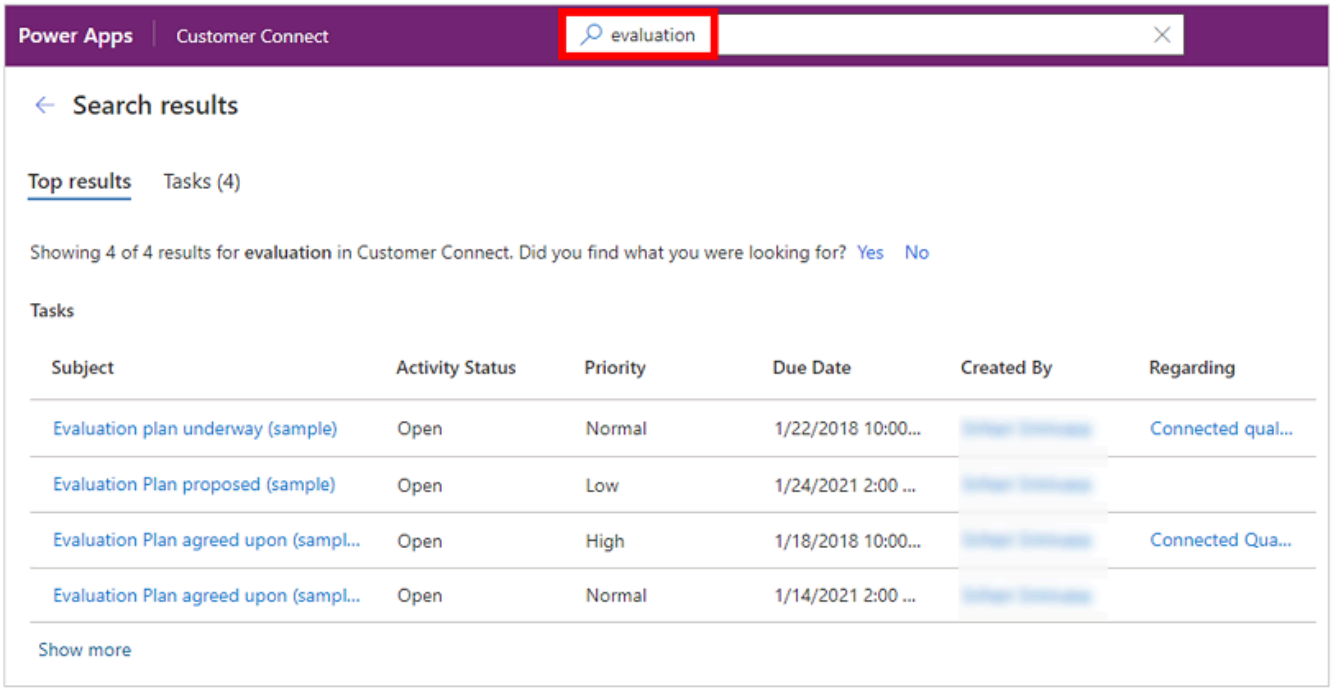


Similarly, the **OR** operator can be indicated by separating terms with a vertical bar (|). For example, searching for **alpine | paul** returns records with reference to either term.

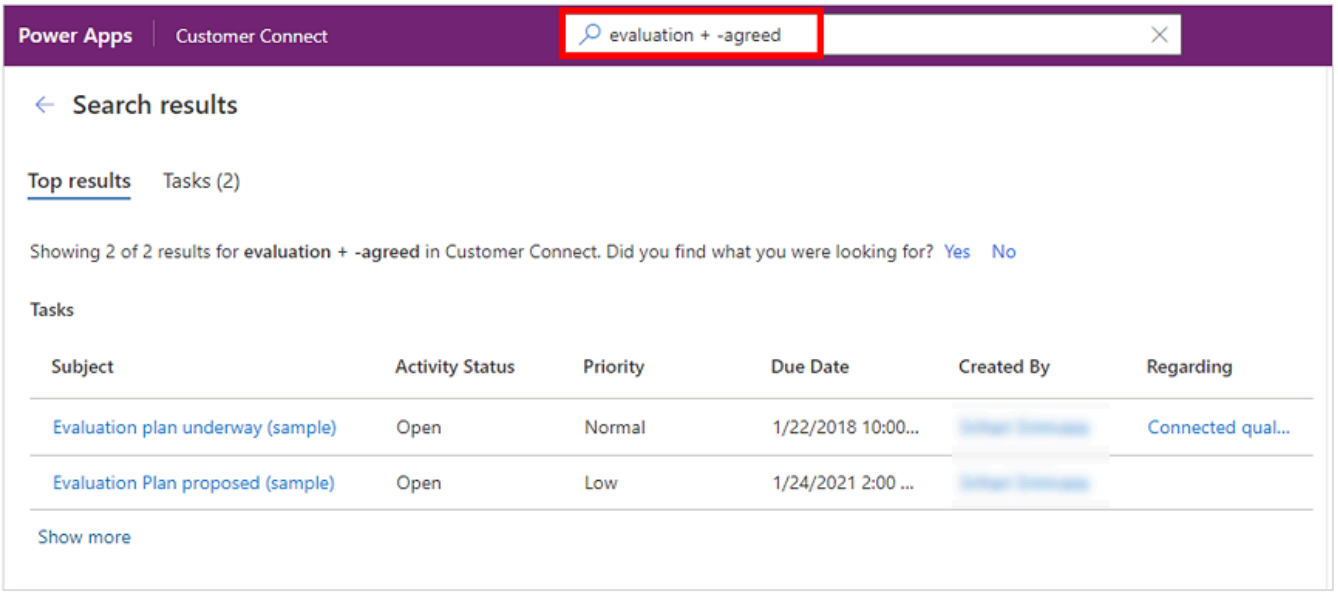


Use the **NOT** operator with a hyphen (-) before a keyword to indicate that it should be excluded from results.

For example, when you search for **evaluation**, all rows matching the term **evaluation** will appear in results.

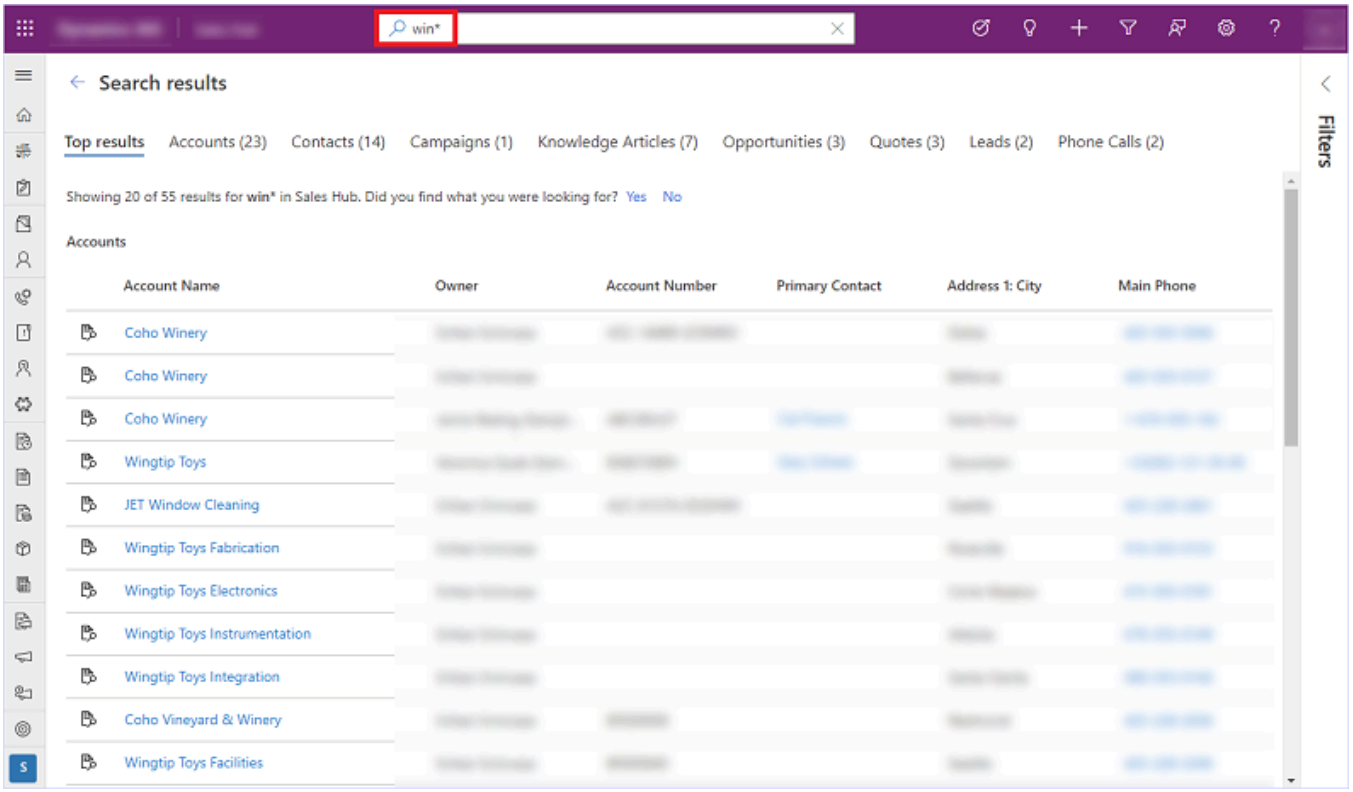


However, searching for **evaluation + -agreed** will match all rows that contain the term **evaluation** but not the term **agreed**.



Wildcards

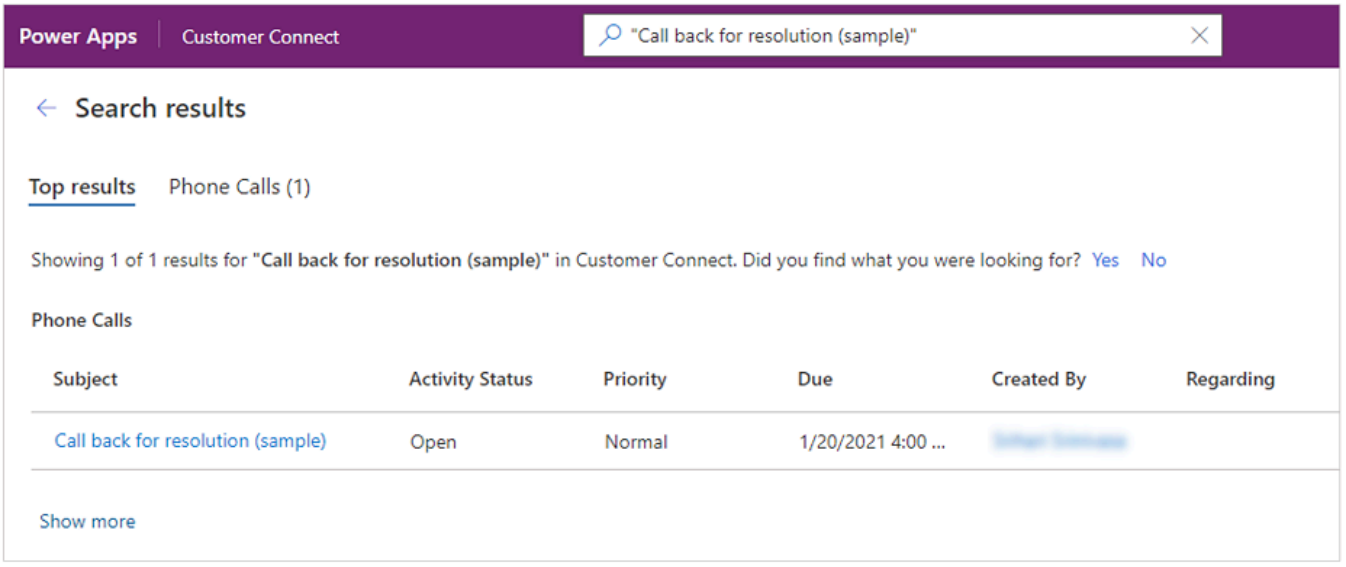
Use wildcards for operators such as **begins-with** and **ends-with**. Using an asterisk (*) at the beginning or end of a keyword makes the asterisk a placeholder for zero or more characters. For example, searching on ***win** will show results for all records associated with a keyword that ends with **win**.



Exact matches

Use double quotation marks around a keyword to perform an exact match. Search ignores common used words such as **the**, **an**, and **a**. To improve matching, use double quotation marks

and force an exact match for your search. For example, searching on **"Call back for resolution (sample)"** will match the exact keywords.



Quick actions

The Dataverse search experience brings some of the most frequently used actions closer to search results, to help you complete your task without having to navigate to the record page in model-driven apps.

Quick actions are a small set of commands specific to a table. You can see quick actions when you're interacting with search in model-driven apps running on a web browser. Some of the commonly used tables are configured to show a set of commands to help you complete your task without losing context.

Expand table

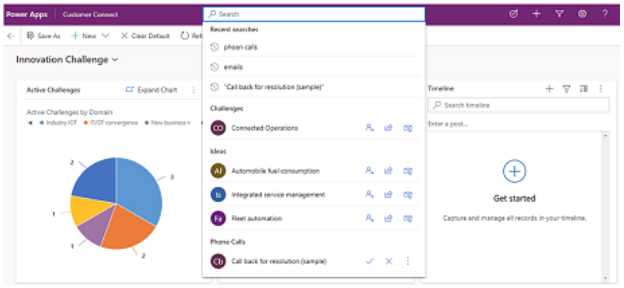
Table	Quick actions
Account	Assign, Share, Email a link
Contact	Assign, Share, Email a link
Appointment	Mark complete, Cancel, Set Regarding, Assign, Email a link
Task	Mark complete, Cancel, Set Regarding, Assign, Email a link
Phone Call	Mark complete, Cancel, Set Regarding, Assign, Email a link
Email	Cancel, Set Regarding, Email a link

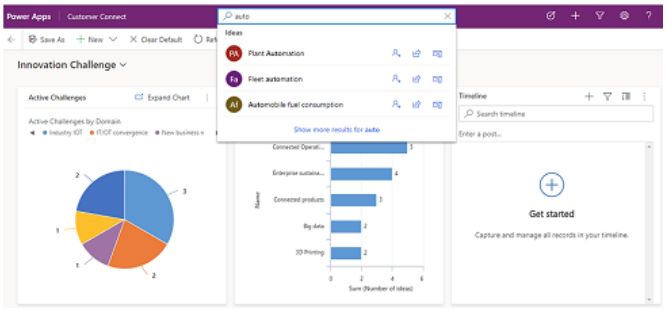
For more information on how to configure quick actions, see Configure Dataverse search to improve search results and performance.

Quick actions and suggested results

As you interact with search, you'll find quick actions next to the most recently accessed records and the suggested results that appear as you type.

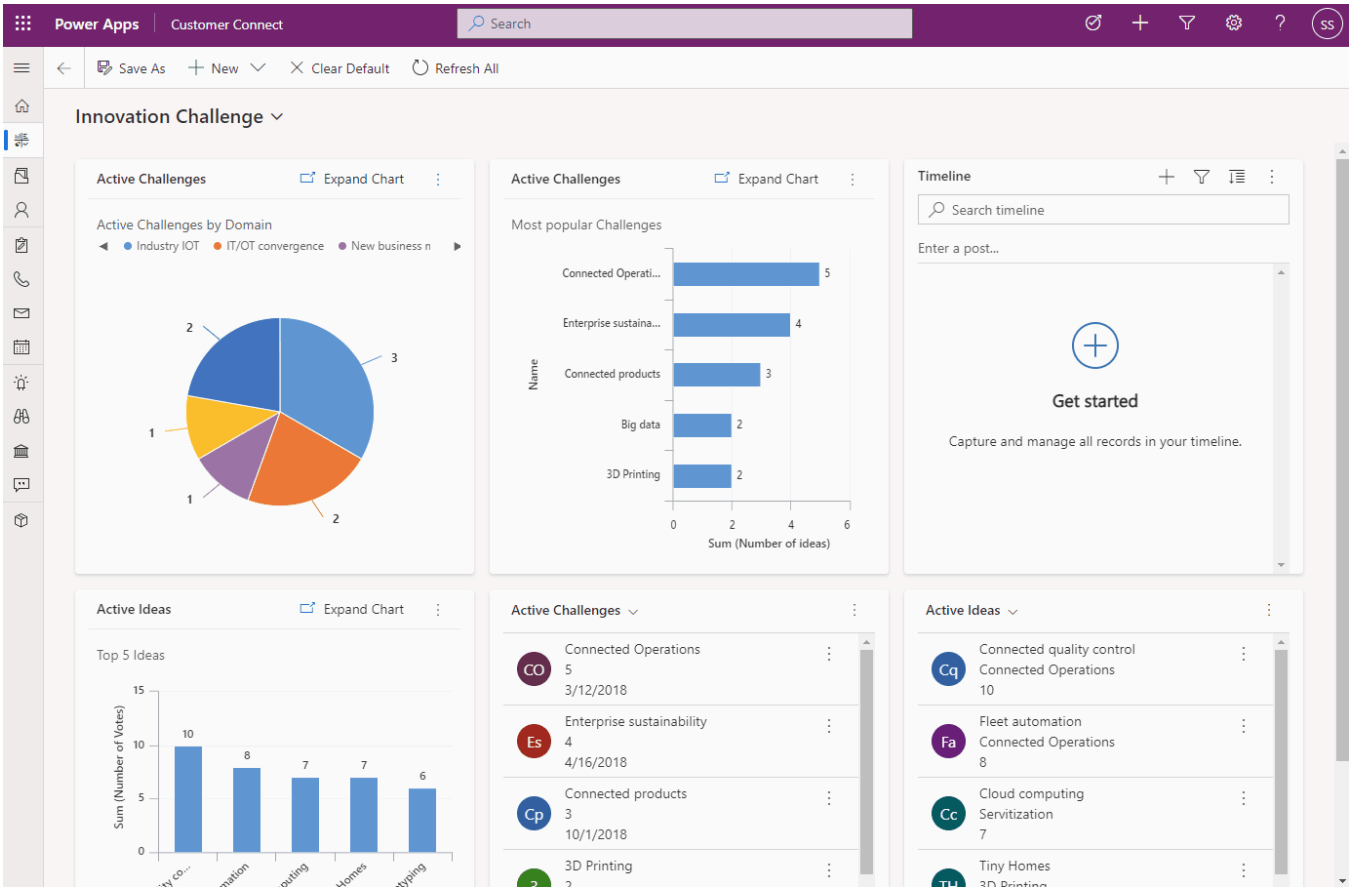
Expand table

Quick actions for recently accessed rows	Quick actions for suggested results as you type
	


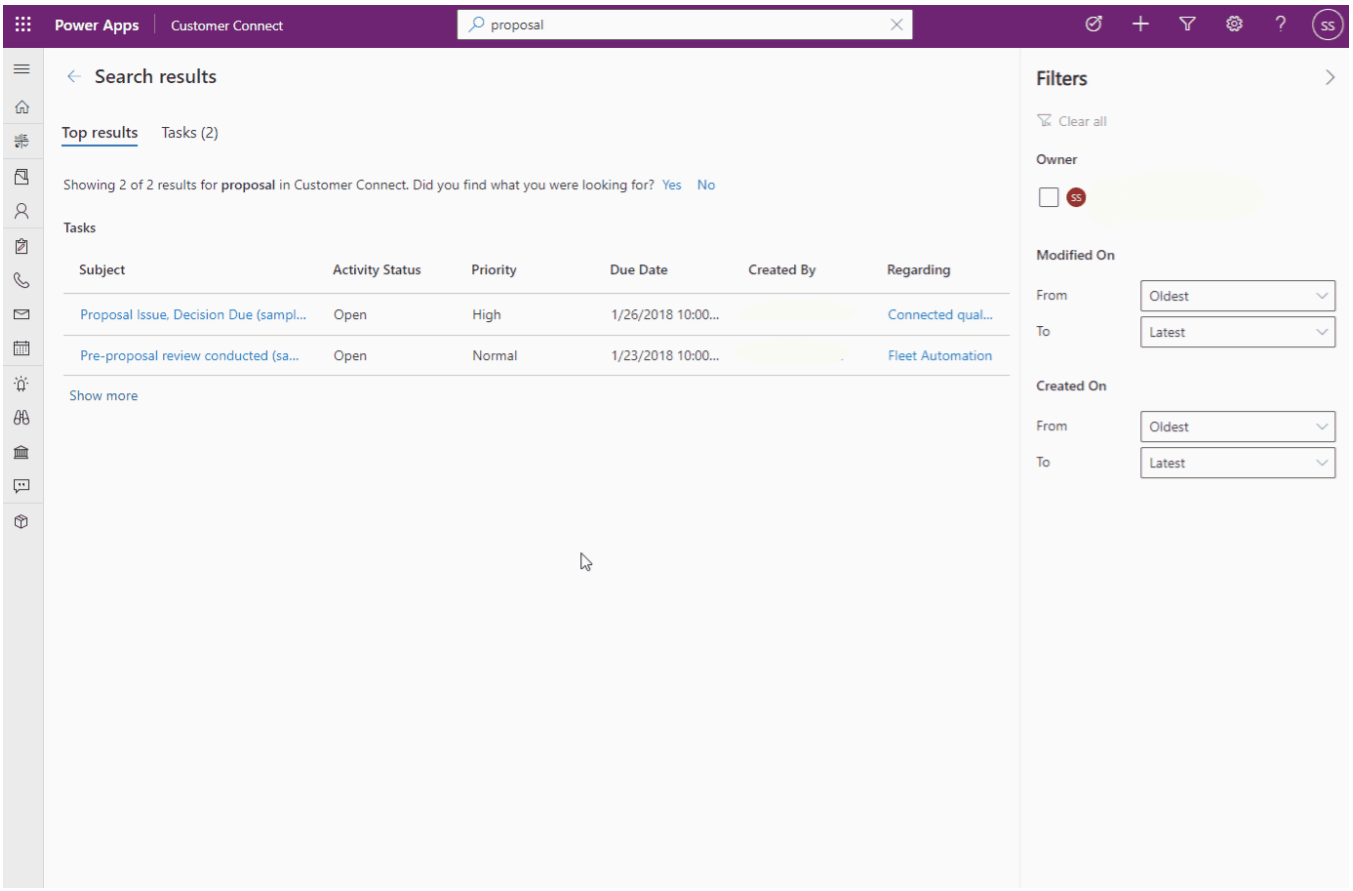


Quick actions in results pages

As you type, quick actions will appear for suggested results.



On the results page, hover over the results to see quick actions available for the row.



Use keyboard shortcuts

The following keyboard shortcuts apply to grids. For more information, see:

- Navigation
- Editing
- Selection

Frequently asked questions about Dataverse search

Configure facets and filters

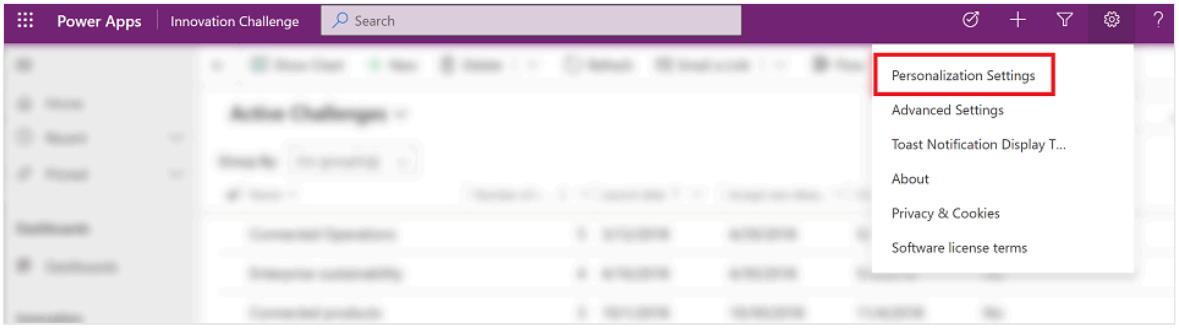
Article • 02/15/2022

With Microsoft Dataverse, you can refine your search results by using facets and filters. Facets and filters let you drill into and explore the results of your current search without having to repeatedly refine your search terms.

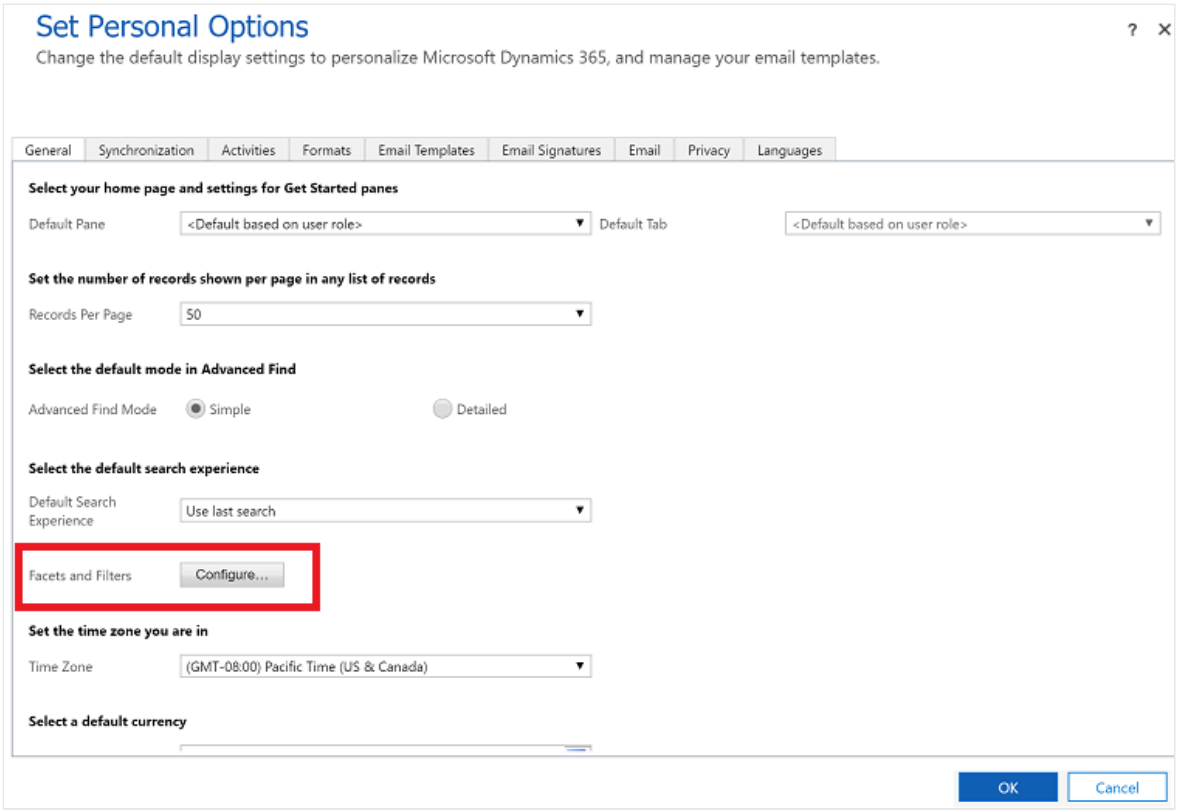
In the **Set Personal Options** dialog box, you can personalize the facets for a table.

> **Note**
>
> Your admin can use the quick find view to define which fields appear as default facets when you use Dataverse search. The first four view columns that include data types other than **Single line of text** or **Multiple lines of text** are displayed as default facets in the result. You can override this setting in your personalization settings. At any time, you can select up to four fields as facets.

1. In the upper-right corner, select **Settings**, and then select **Personalization Settings**.



2. On the **General** tab, in the **Select the default search experience** section, for **Facets and Filters**, select **Configure**.



3. In the **Configure Facets and Filters** dialog box, specify the facets you'd like to see for a table:

    - In the **Select Table** drop-down list, select the table you want to configure facets for. This drop-down list contains only the tables that are enabled for Dataverse search.

    - For the selected table, select up to four facet columns. By default, the first four "facet-able" columns in the quick find view for the selected table are selected in the list. At any time, you can only have four columns selected as facets.

You can update multiple tables at a time. When you select **OK**, the changes for all tables that you've configured are saved. To revert to the default behavior for a table that you previously configured, select **Default**.

> ⓘ **Note**
>
> If a system customizer deletes a column or makes it no longer searchable, and you've saved a facet for that column, it will no longer show up as a facet. You'll only see the columns that exist in the default solution and have been configured as searchable by your system customizer.

Frequently asked questions about Dataverse search

What is Dataverse search?

Dataverse search is the foundation that enables Copilot and in-app search experiences to understand and process business data. It helps organizations turn raw information into meaningful insights. For more information about Dataverse search and its enabled experiences, see What is Dataverse search.

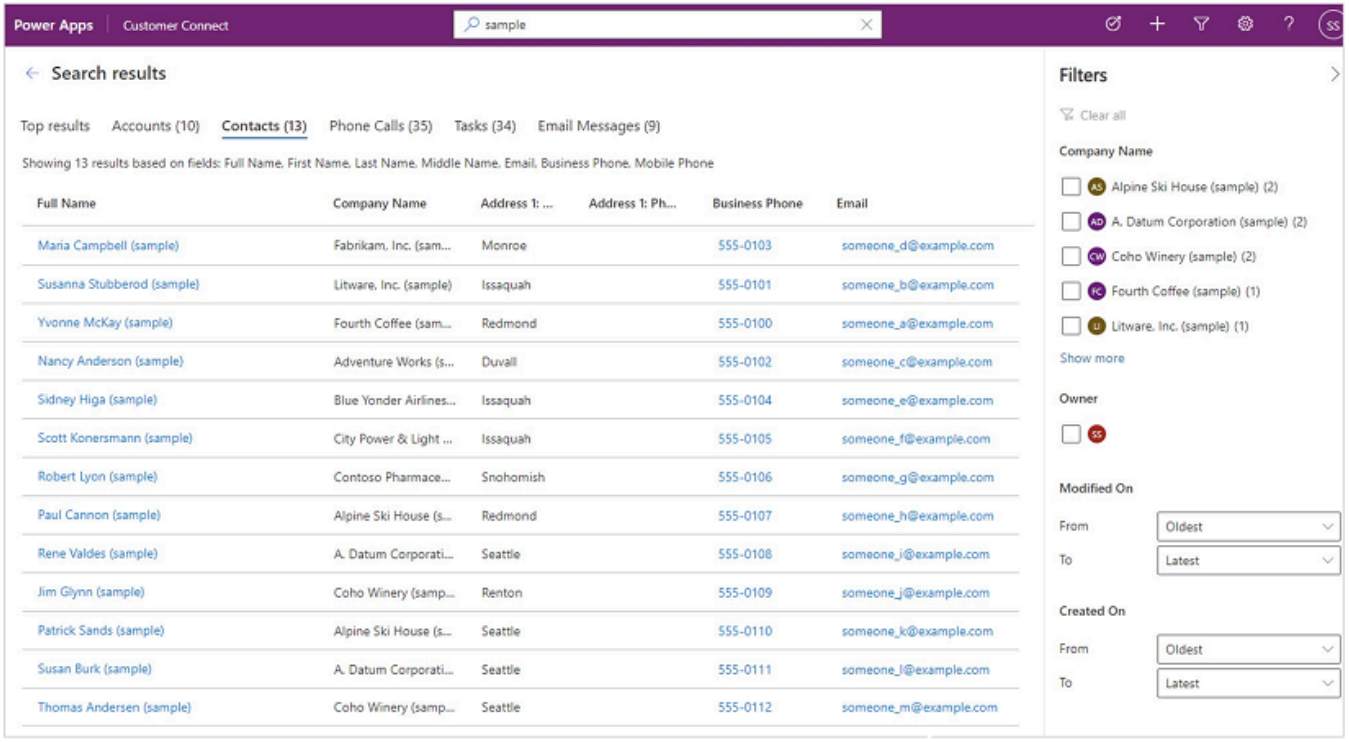
What is the difference between "On" and "Default" state for Dataverse search?

The state you select for Dataverse search affects the ability to use Dataverse data across the enabled experiences for your organization. For a better understanding of what each Dataverse search state means, see:

- What Dataverse search setting means for global search
- What Dataverse search means for generative AI enabled experiences

What is the scope of content searched by Dataverse search using Global Search?

Any file or Dataverse knowledge added to Agents or model-driven apps defines the scope of content that's searched.



What are the column types that Dataverse search can search by using Global Search?

The **Find Columns** on a **Quick Find View** define the searchable fields in the Dataverse search index. Text fields such as Single Line of Text and Multiple Lines of Text, Lookups, and Option Sets are searchable. **Find Columns** of all other data types such as Integer and Double are ignored. For more information, see Select searchable fields and filters for each table.

Why don't I see Global Search results from a table that I enabled for Dataverse search?

If a table isn't part of the model-driven app, it isn't included in search results. Use the Power Apps app designer to verify that the table is included in that app's components. Make sure that the table has a default Quick Find View created and defined. A default Quick Find View is created with a table, but if you remove it, you need to select the Quick Find View you want and set as the default for your table. For more information, see Add or edit model-driven app components.

Can I configure quick actions to show or hide certain commands?

Yes, you can configure quick actions by using version 9.2.21034.00126 or later. Quick actions are a subset of a table's grid-level command set. You can configure them by using ribbon rules. For more information on how to configure quick actions, see Configure Dataverse search to improve search results and performance.

Why are results that appear in suggestions sometimes not seen on the results page?

Suggestions are quick results based on a search performed on the primary column of a table. This feature is enabled for Dataverse search in model-driven apps. Learn more in Inline suggestions.

When you go to the results page, the search terms are treated as the complete search query. The search performs many more types of matching to display a more comprehensive set of results.

Can I configure the order of tables appearing in the Global Search results page?

The order of tables in the **Top results** tab and in the horizontal list of tabs is based on the ranking and relevance of search results for that search term. You can make results from a particular table appear at the top by including the table name in the search term. For example, searching for **account fabrikam** usually ranks result records that have the term **fabrikam** of type **account** higher than result records that have the term **fabrikam** of a type other than **account**.

Can I see search results from SharePoint files and documents through Global Search?

Currently, Dataverse search searches your data in Microsoft Dataverse only. It doesn't search SharePoint files and documents, including the names of the files and the content in the files. It also doesn't search objects of **File** data type in Dataverse.

Why am I unable to view information for party list fields like To, From, and CC in full results?

Party list fields are special fields. Dataverse search doesn't support them, and it doesn't include them in the search results page.

Why don't returns support HTML formatting for memo data types?

Dataverse search doesn't return HTML formatting for memo types to optimize the UI experience.

Why aren't columns enabled for Dataverse search after adding them to a quick find view, to use them in Global Search?

Columns are enabled for Dataverse search only if a quick find view is set as the default view. For more information on how to set a default view, see Specify a default view for a table.

Why doesn't search on the OwnerID attribute work when I enable search on it?

The search and suggest operations don't have access to data from the Owner column. For more information, see Types of columns.

Why doesn't search on the RegardingObjectId attribute work when I enable search on it?

Search doesn't support polymorphic lookup attributes. The RegardingObjectId attribute in activity tables like email and task is a polymorphic lookup attribute.

How is the Dataverse search API throttled?

When you use the Dataverse search API, throttling limits restrict you to one request per second for each user. Additionally, each organization can make up to 150 requests per minute.

What attribute types does Dataverse search indexing support?

- BigInt
- Boolean
- Customer

- DateTime
- Decimal
- Double
- EntityName
- Integer
- Lookup
- Memo
- Money
- Owner
- Picklist
- State
- Status
- String
- Uniqueidentifier
- Virtual (only for MultiSelectPicklistType and FileType)

What attribute types are eligible for facet list fields?

- Lookup
- DateTime
- Money
- Picklist
- Integer
- Customer
- Decimal
- MultiSelectPicklist
- State
- Status

How can I use the Dataverse search API?

See Developer's guide: Search for Dataverse records using the API.

Does Dataverse search support US Government clouds?

Dataverse search strives to maintain functional parity between our commercially available services and those available through our US Government clouds. It's available in US

Government Community Cloud (GCC), US GCC High, and Department of Defense (DoD).

How is Dataverse search reported?

In addition to the database and file storage, Dataverse search includes the indexes that power different experiences. These indexes support search and generative AI across structured or tabular, and unstructured data stored in Dataverse, including files. Dataverse search storage appears at the environment level in the `DataverseSearch` table, previously called `RelevanceSearch`.

Learn more in Dataverse capacity-based storage.

What actions can admins take to manage Dataverse search?

Depending on the experience that uses Dataverse search and its usage, the consumption size might increase. To learn more about managing Dataverse search, see What is Dataverse search.

What happens if I turn off Dataverse search?

If you set Dataverse search to **Off** for the environment, you can't use the search capability in the Power Apps navigation bar or any generative AI experience that relies on Dataverse. This limitation includes experiences like uploaded files or using OneDrive or SharePoint files (via upload) in Microsoft Copilot Studio agents, among other experiences. For details about these limitations, see What is Dataverse search.

Use quick find search

Article • 10/22/2024

Quickly search across multiple tables at the same time and find the information that you're looking for. When you enter a search term the system finds matches to all words in the search term in one column within a table. The words can be matched in any order in the column.

With categorized search, you can search for rows that begin with a specific word or use a wildcard character.

- **Begins with**: Results include rows that begin with a specific word. For example, if you want to search for "Alpine Ski House," type **alp** in the search box; if you type **ski**, the row won't show up.
- **Wildcard**: For example, *ski or *ski*.

> **Note**
>
> Using a wildcard at the beginning of your quick find (single or multiple-table) search query might result in slower performance.

Single table quick find

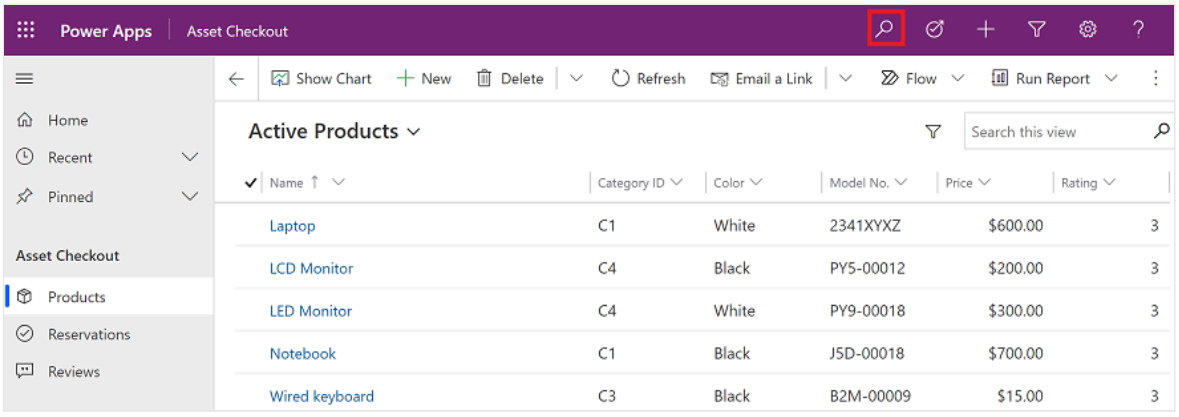
Single table quick find is also called *grid search*. For more information, see Grid search.

Multiple-table quick find (categorized search)

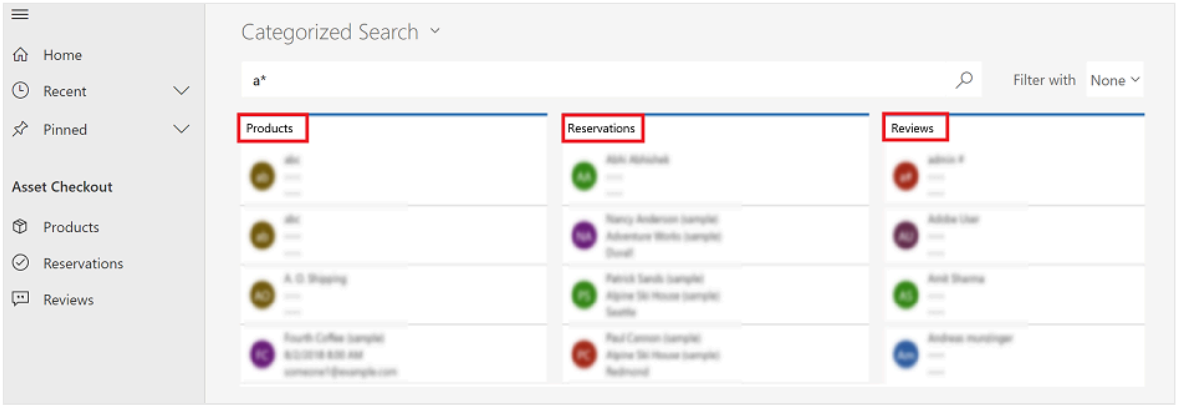
Multiple-table quick find searches up to 10 tables and returns the search results grouped by table.

You can view a maximum of 80 rows per table with multiple-table quick find. You might need to refine your query, if the row that you're looking for is outside the maximum range.

1. To start a categorized search, on the command bar, select **Search**.



2. Type your search words in the search box, and then select **Search**. The search results are grouped by table such as Products, Reservations, and Reviews.



3. Select a table from the **Filter with** list to filter results by table type. To search across all tables, select **None**.

Advanced find in model-driven apps

Article • 01/16/2024

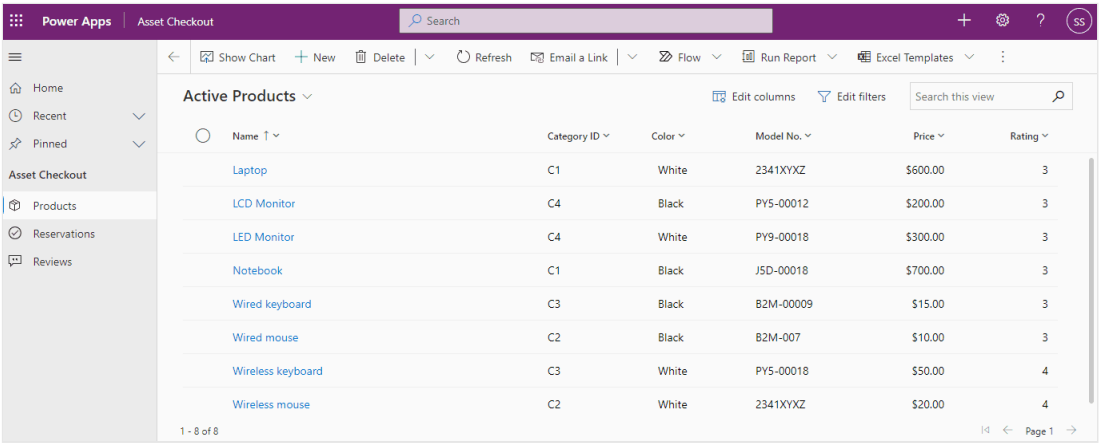
The topic covers the various different ways to use the advanced find experience.

Search for rows and create personal views with modern advanced find

When your administrator enables the modern advanced find experience, it lets you search for rows and create personal views in your app. Depending on how search is setup for your app, the search experience might look a little different. Your administrator can turn on Dataverse search or disable it.

1. To start a search, choose one of the following:

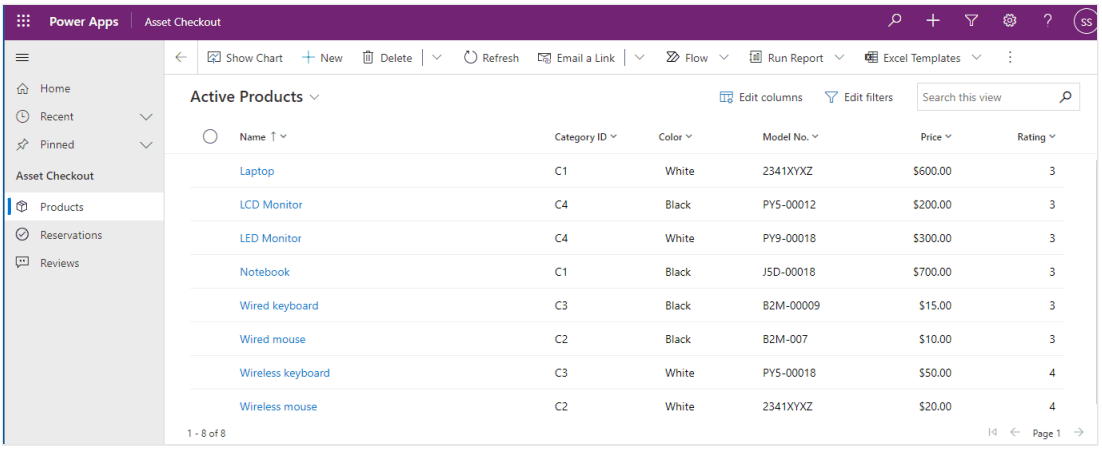
   - **Dataverse search enabled**: If your administrator has enabled Dataverse search, you will see a search bar at the top. Select the search box and then select **Search for rows in a table using advanced filters** to see the list of tables to choose from.



> **Tip**
>
> **Search for rows in a table using advanced filters** option appears at the bottom of the search drop-down menu, only when you have not entered a search term. Once you start typing, you will see results for the search term, with an option to see more search results.

   - **Dataverse search disabled**: If your administrator has not enabled Dataverse search, then you will see the **Search** button and the **Advanced Find** button

on the command bar. Select the **Advanced Find** button, to see the list of tables to choose from.



2. Select a table and choose **Continue** to access the table. The tables in the filter must meet the following requirements:

   - Part of the model-driven app
   - Enabled for Unified Interface
   - Valid for advanced find

3. You will be navigated to the table's grid page, with the default view for the table selected and the rows displayed in a read-only grid. The **Edit filters** panel will be opened, so you can filter the data on that table. For more information, see create and manage personal views for that table.

For more information on creating and managing system views, see Create and edit public or system views.

Create, edit, or save a view using legacy advanced find

If your administrator has not enabled the modern advanced find experience, you can find the rows you want by using the legacy Advanced Find search option. You can also use Advanced Find to prepare data for export to Office Excel so that you analyze, summarize, or aggregate data, or create PivotTables to view your data from different perspectives.

> **Note**

To use the modern advanced find in model-driven apps, see Create and manage personal views on a grid page .

1. On the command bar, select **Advanced Find** button  .
2. Specify what to search for.
    a. In the **Look for** list, select a row type.
    b. Choose **Select** to define search criteria: column (for example, Account Name or City), the query relational operator (part of an expression such as "is equal to" or "contains" that defines how a specified column should be compared with a value.), and the values to locate (for example, "Seattle" or "Email").

    You can select columns from the current row type, or from related rows. For example, an account might have many related contact rows.

    At the bottom of the **Select** list, the **Related** section shows related row types. For example, most row types have a related Notes row type. To select columns from a related row type, select column and a new **Select** link appears.
3. Specify the columns to include in the search results.
    a. Select **Edit Columns**, and then select **Add Columns**.
    b. Select the row type that includes the columns you want to add.
    c. Select the columns you want to add, and then select **OK**.
4. Specify the sort order.
    a. Select **Edit Columns**.
    b. Select **Configure Sorting**.
    c. Specify the column to sort on, specify the sort order, and then select **OK**.
    d. Select **OK**.
5. Select **Results**.

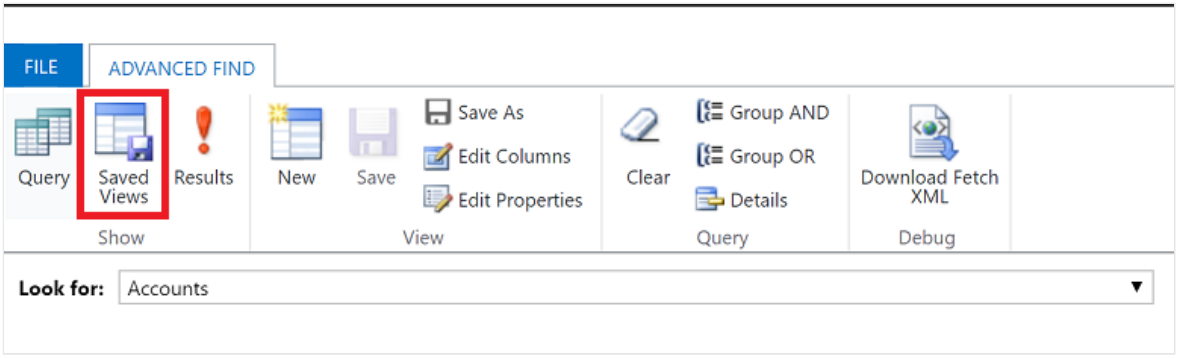
To save the results, select **Save As** and name the personalized view.

Share a personal view

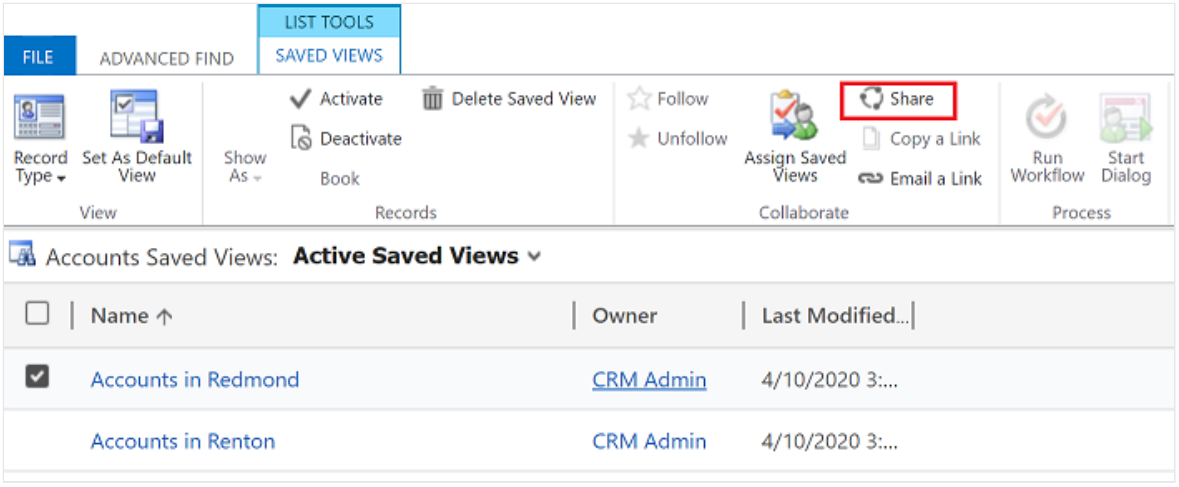
Before you can share a personal view, it must be saved.

1. On the command bar, select the **Advanced Find** button.

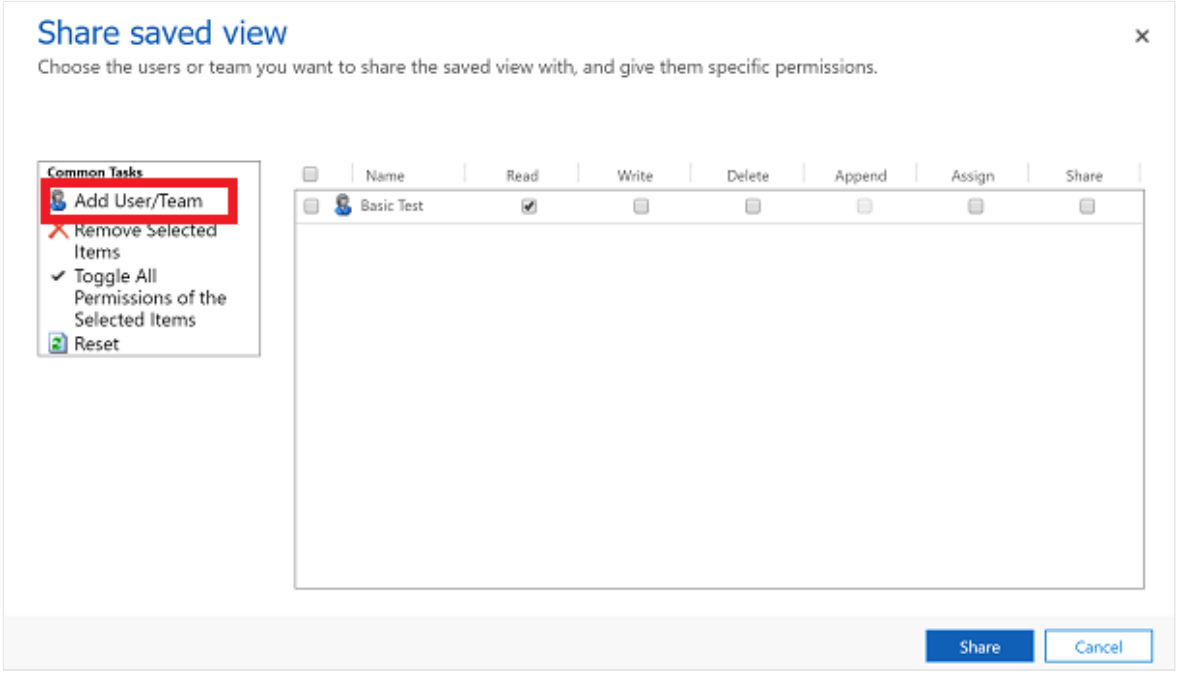
2. On the Advanced Find tab, select **Saved Views**.



3. From the list of saved views, select a view and then select **Share**.

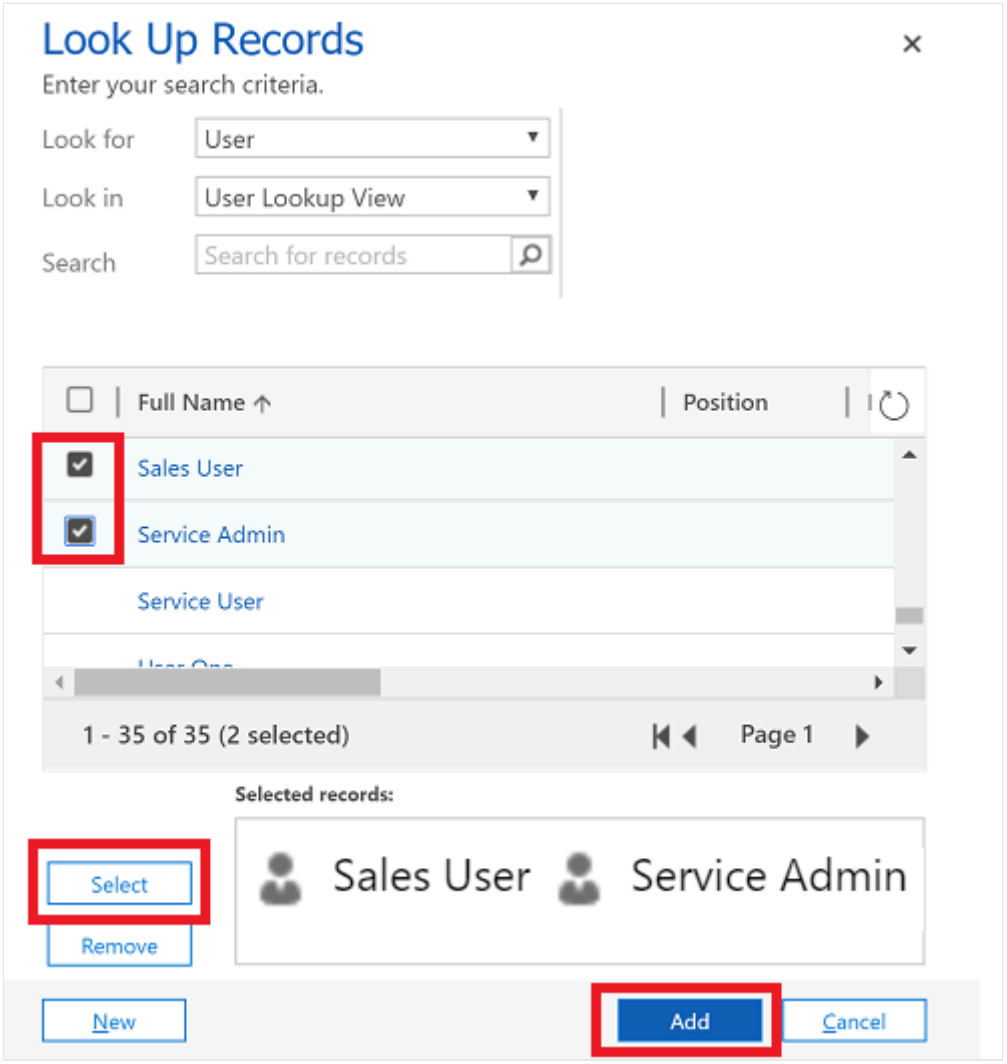


4. In the **Share saved view** screen, select **Add User/Team**.

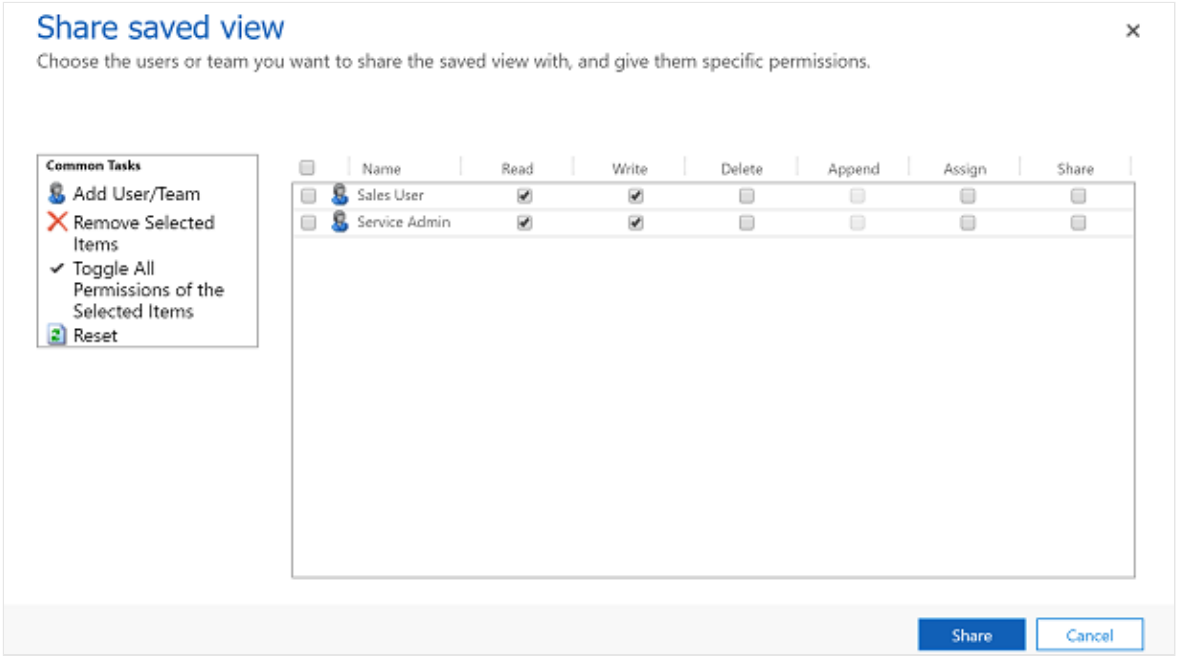


5. Use the look up to find the users or team that you want to share the view with.

6. When you find the user or team, select their name and then choose **Select** and then **Add**.

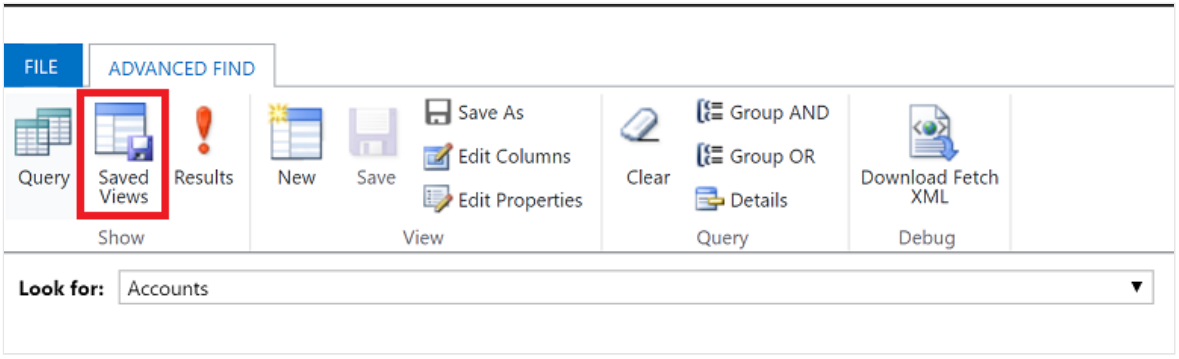


7. Select each user's permission and then select **Share**.



Delete a personal view

1. On the command bar, select the **Advanced Find** button.
2. On the Advanced Find tab, select **Saved Views**.



3. From the list of saved views, select the view that you want to delete and then select **Delete Saved View**.

How to import data

10/22/2025

Import data stored somewhere else into your model-driven app using the import feature in Power Apps.

Every table requires columns that must exist in your input file. You should download an Excel template, add your data, and then import the file to your app. The template saves time and effort. Don't add or modify columns in the template to avoid issues during the import.

Before you import a file, make sure the column headings match the column names in your app. During the import process, the system tries to map the column names from your input file to the column names in the app. If they don't match, then you have to manually map the fields or you might run into issues during the import process.

If you're an advanced user and know the required columns for a given Dataverse table, define your own Excel, CSV, or XML source file and then follow the steps in this article on how to import data to your app. These file formats are supported:

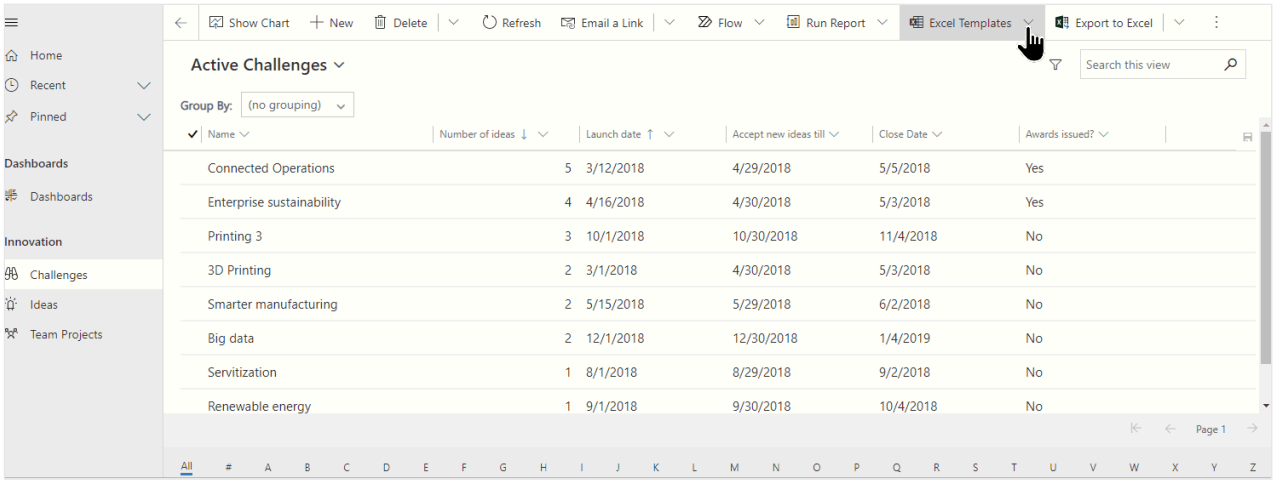
- Excel workbook (.xlsx)
- Comma-separated values (.csv)
- XML Spreadsheet 2003 (.xml)

The maximum file size allowed for .zip files is 32 MB. For the other file formats, the maximum file size allowed is 8 MB.

Download an Excel template

To avoid mapping issues, you should use an Excel template that you can download from your app. Once the template is downloaded, add your data and then import the file back to your app. Remember don't add or modify columns in the template to avoid issues during the import process.

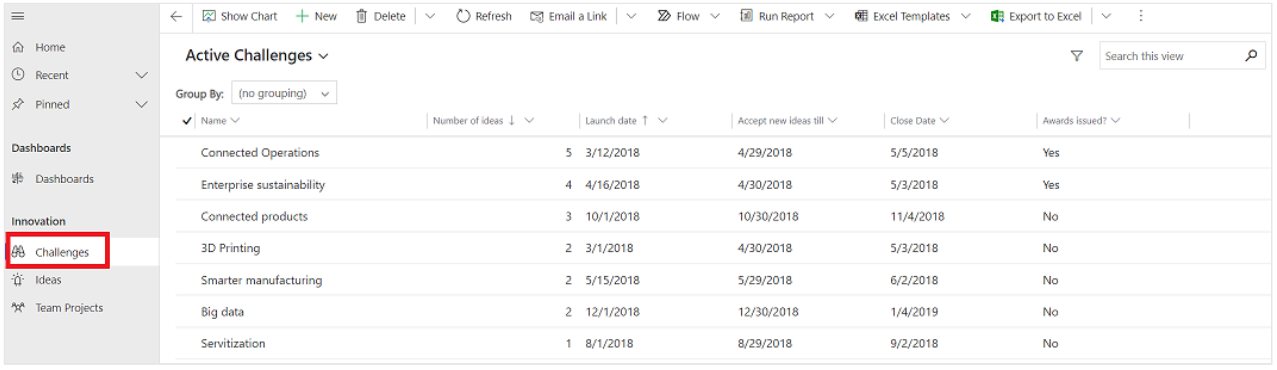
1. Open your app and from the left nav select a table.
2. On the command bar, select **Excel Templates** > **Download Template**.
3. Select the table type and view to download or select **Edit Columns** and choose the rows to include in the template.
4. Select **Download**.



Import your data

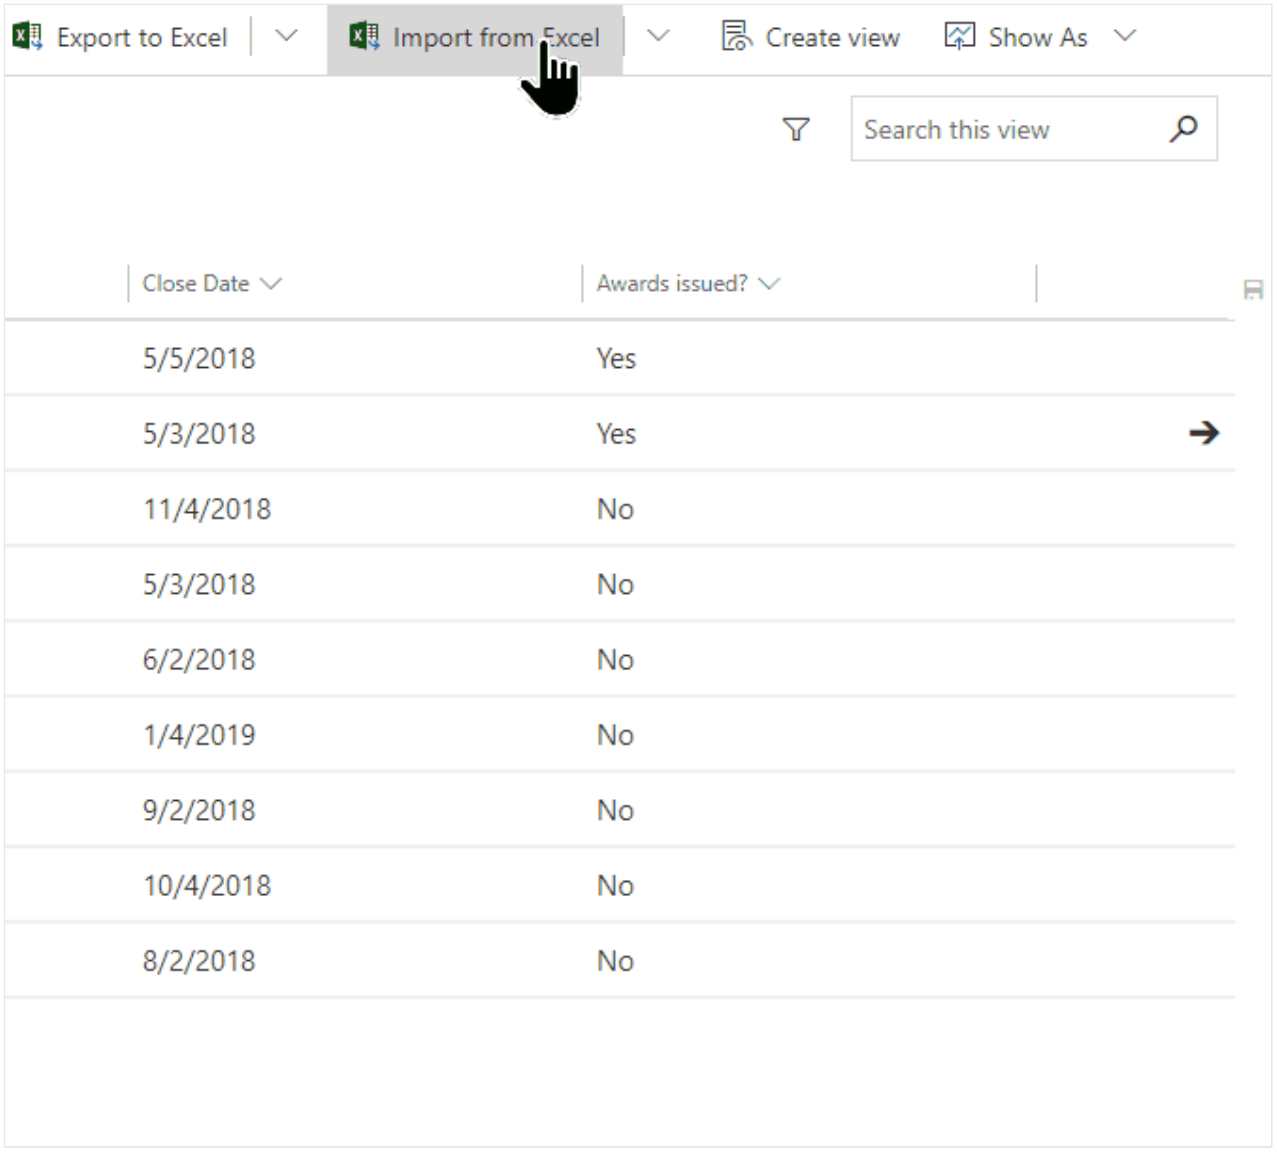
Use the template that you downloaded in the previous step (modified with your data) and import the file to your app.

1. Open an app and from the left nav select a table.



2. On the command bar, select the file type to import from:

   - **Import from Excel**: Select **Import from Excel** if you're using an Excel template.
   - **Import from CSV**
   - **Import from XML**



3. Select **Choose File** and browse to the folder where the file is saved. Select the file, select **Open**, and then select **Next**.

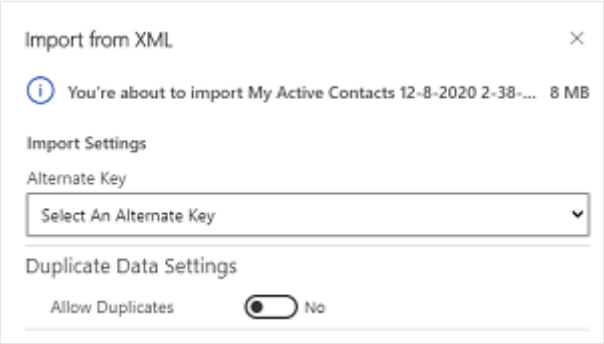
   > **Tip**
   >
   > You can only import one file at a time. To bring in more files, run the wizard again.

4. Select whether to **Allow Duplicates** or not. More information, see Set up duplicate detection rules to keep your data clean.

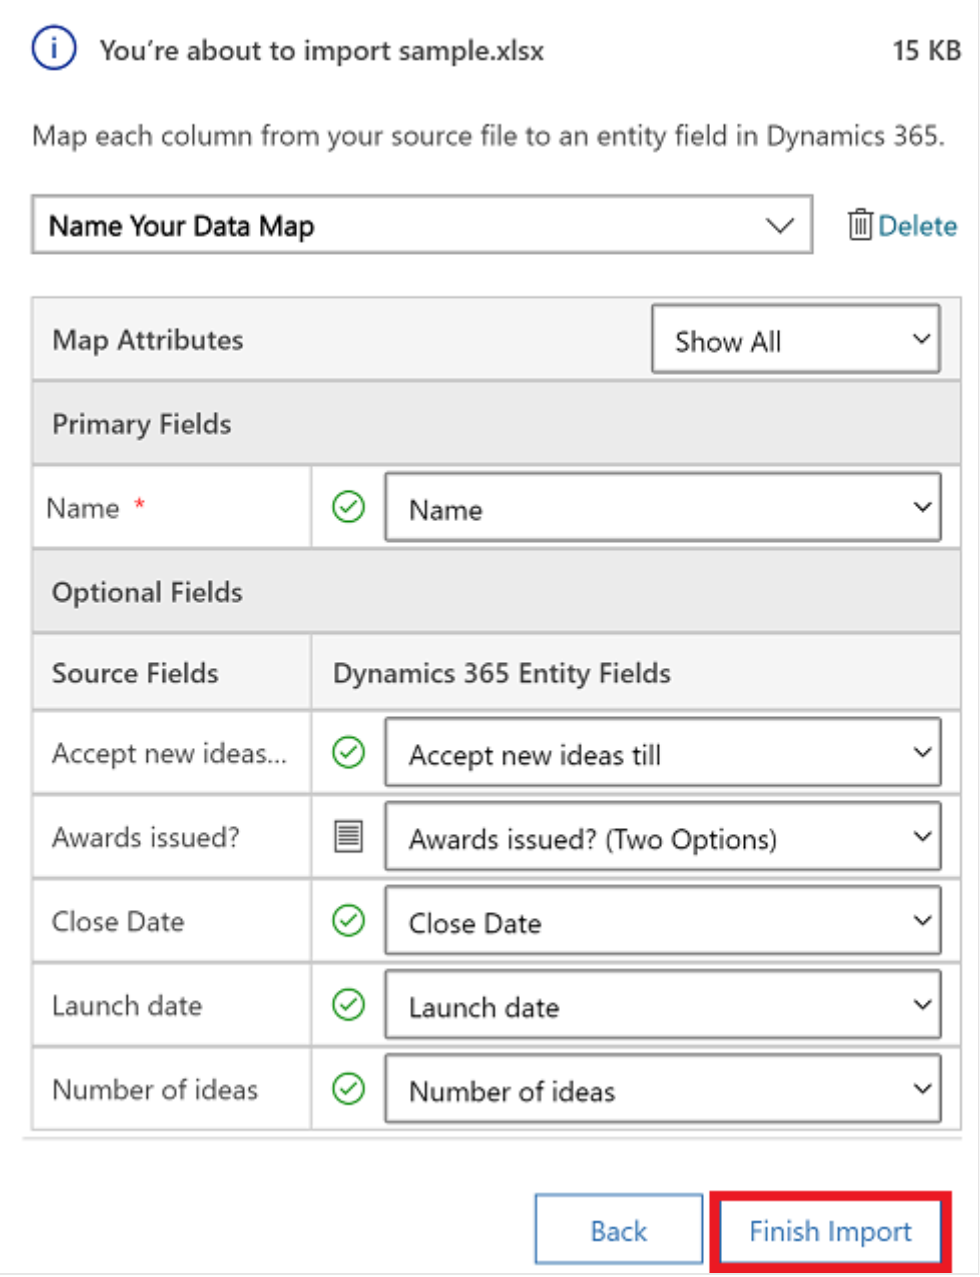
5. For CSV and XML files (skip this step if you're importing an Excel file):

   - For a CSV file: Select the drop-down list and select the data delimiter and field delimiter that's used for the CSV file.

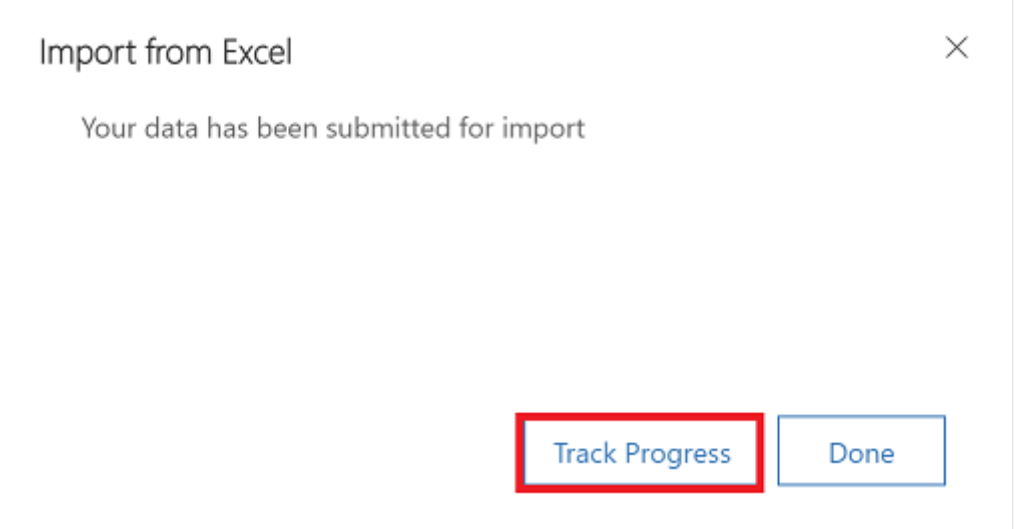
   - For CSV or XML file: If you have an alternate key defined, select it from the alternate Key drop-down list. The alternate key is used to uniquely identify and update rows during import. More information: Define alternate keys to reference rows.



6. Select Review Mapping and verify the columns (fields) are mapped correctly. If everything looks good, select **Finish Import**.

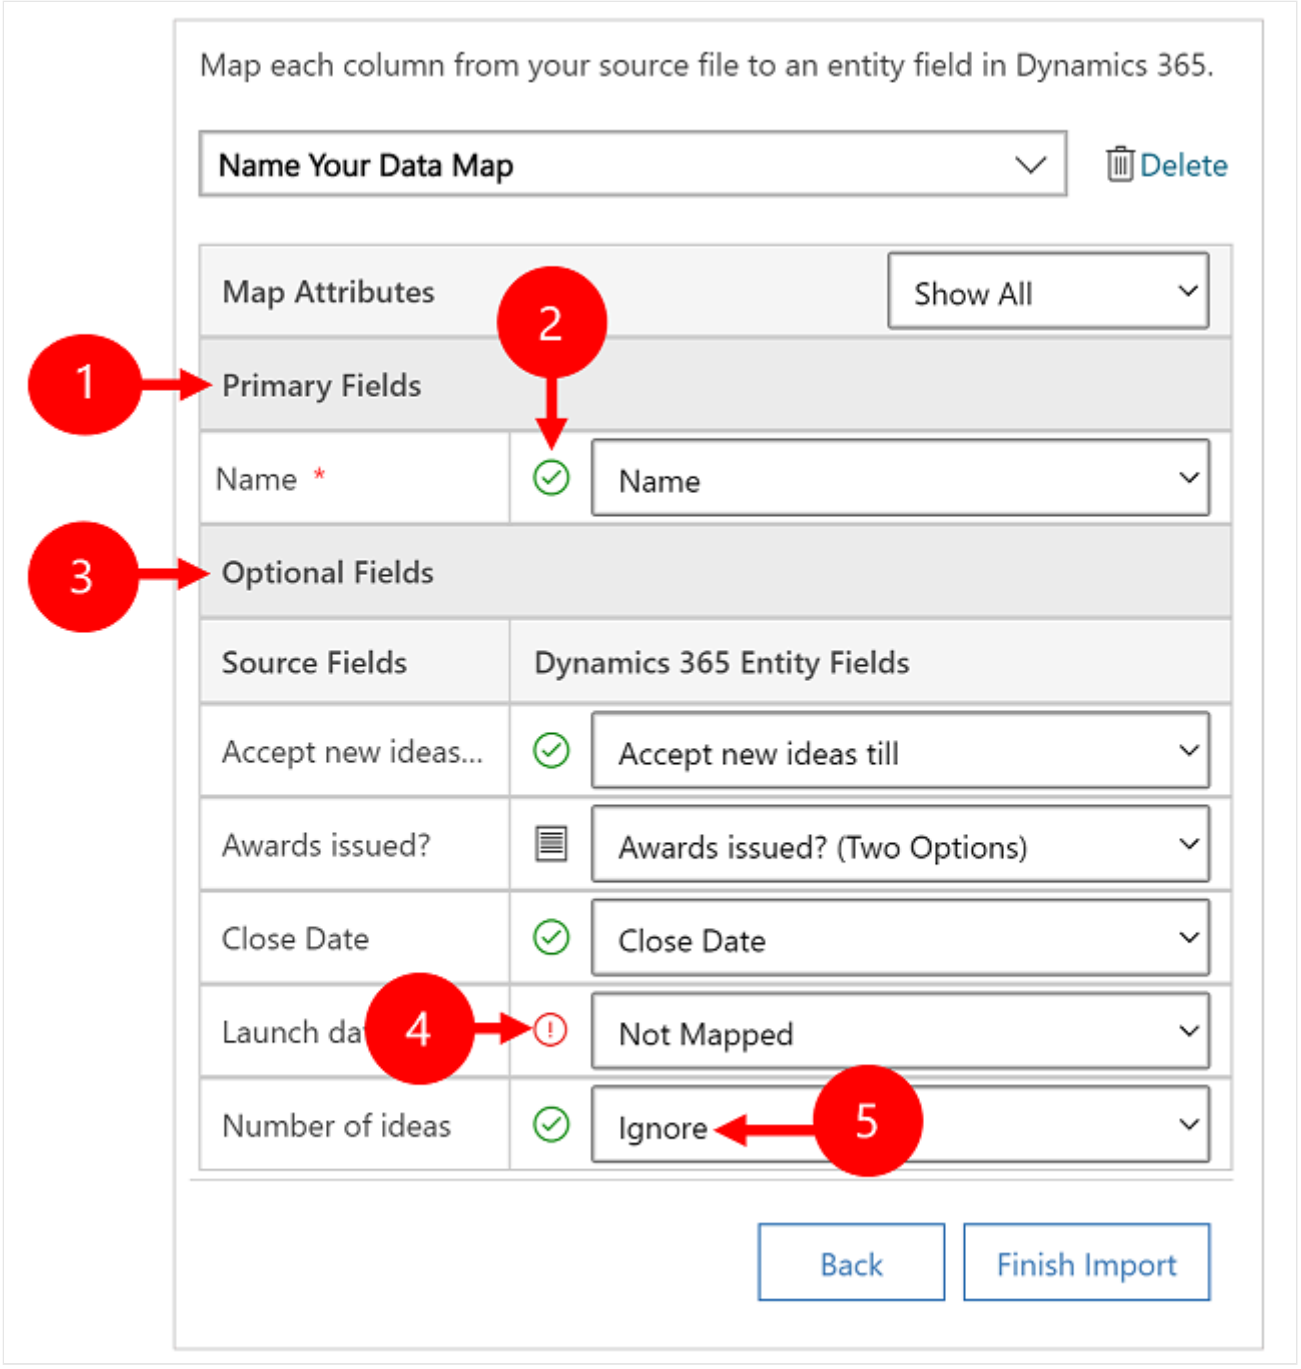


7. Select **Track Progress** to see the progress of the import.



Review mapping

When you import a file, it's important to review the column headings and verify that they match the columns (fields) in your app.



Legend:

1. **Primary Fields**: Shows all the required columns for the table that must be mapped for the data to be imported successfully. If the column headings of your source file match the column display names, these columns are automatically mapped.

2. **Mapped columns**: Correctly mapped columns are shown with a green check mark.

3. **Optional Fields**: These are optional column headings in your source file. If the column headings match the column display names, the columns are automatically selected in the corresponding drop-down lists.

4. **Unmatched columns**: If the column headings don't match, the unmapped columns are shown with a red exclamation point. To map the column correctly, select a column to map

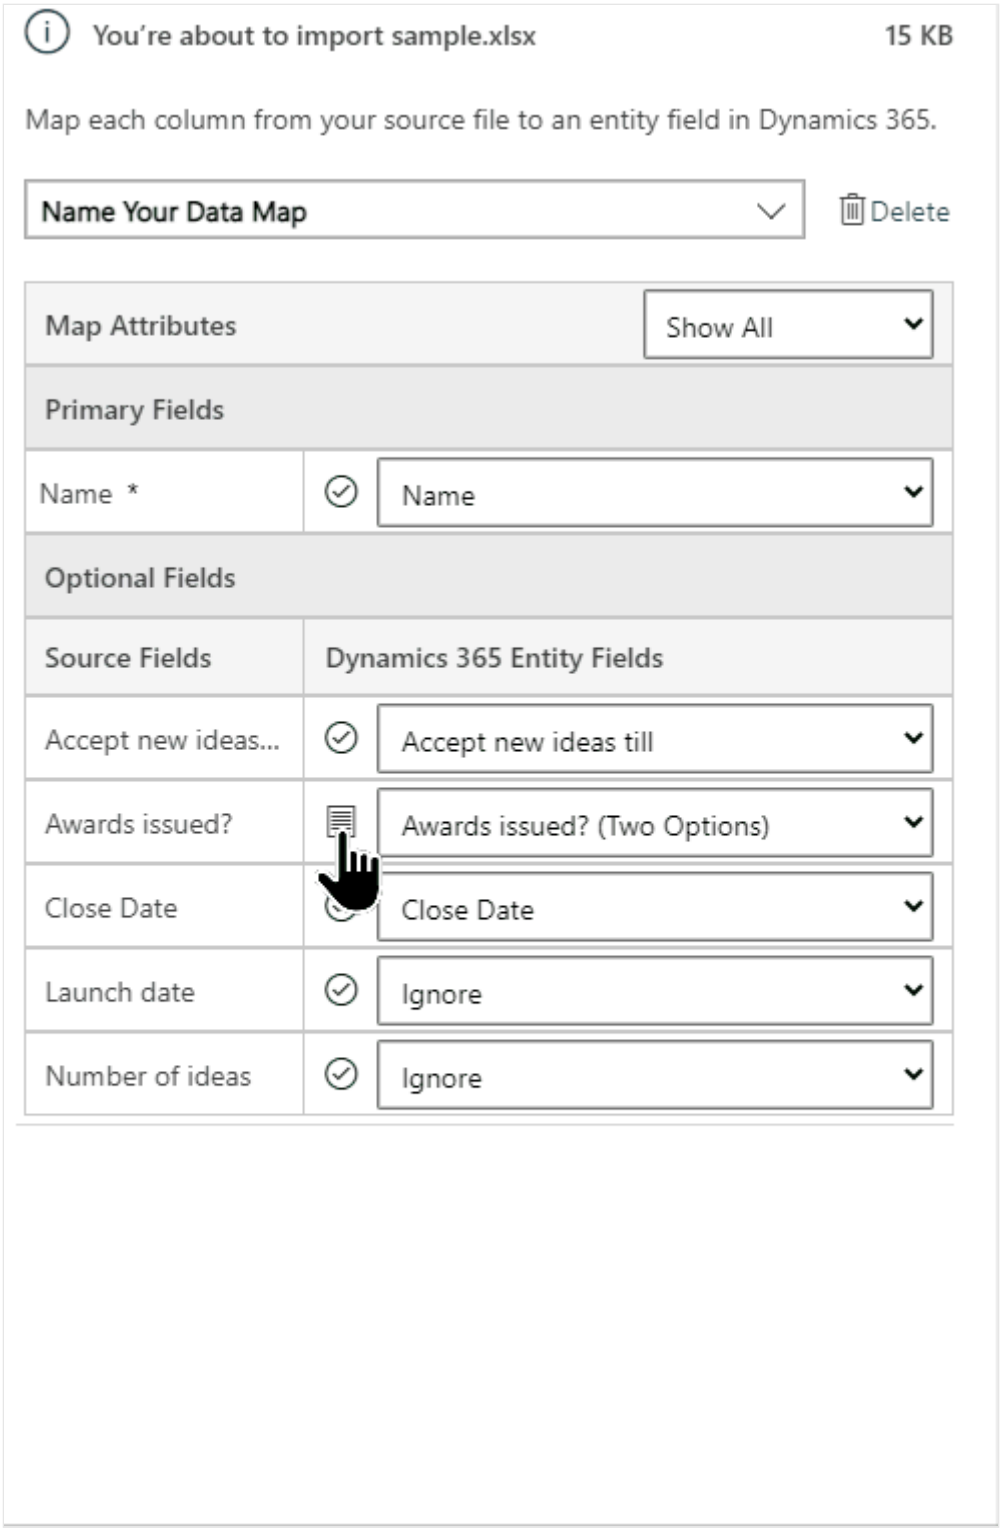
to the unmapped column heading of your file.

5. **Ignore** (For **Optional Fields** only): Choose **Ignore** from the drop-down list. Data from ignored columns aren't imported into your app.

Option set

If any column in your source file includes a fixed set of values, you must map the column to a column of type **Option Set**. A column of this type has values such as **Yes** and **No** or **Low** and **High**.

To do this, select the button next to the option set column, select the values, and then select **OK**.



The option values drop-down list combines the values available in the incoming file with those already in your app. For example:

- **Values in import file**: Low, High
- **Values already in your app**: Cold, Warm, Hot
- **Resulting target values**: Cold, Warm, Hot, Low, High

After import, the import wizard will add all mapped values in your app, but will drop unmapped values from the import file that aren't yet in your app. For example, you could map the "Low" source value to the "Cold" target value, but map the "High" source value to the (new) "High" target value. Based on these mappings, the import wizard creates "High" as a target

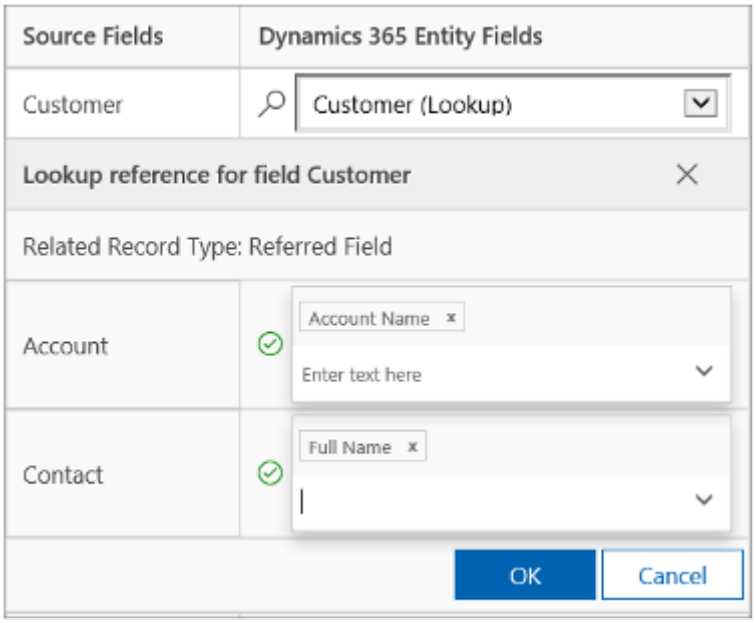
value in your app. It doesn't create "Low" as a target value in your app because you didn't map any source to this target value.

> **Note**
>
> You can map a column in your source file to a "Two Options" or "Multiselect Option Set" column. When mapping to a "Multiselect Option Set," if your source file includes values not available in your app, new values may be created in Dataverse if the import mapping is set to **NotMapped**. If the mapping is set to **Ignore**, the record can be successfully imported. And, for "Multi-Select Option Set" fields, the values are not imported, and no new values are created in the target environment.

Map lookup columns

If some data in your source file references other existing rows in your app, you must map the column in the source file to a lookup column in your app.

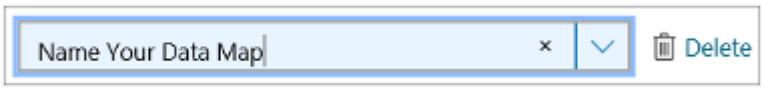
For example, you might want to import a file named Leads.csv, which contains customer rows. The **Customer** column in Leads.csv contains the associated account or contact data. To map this, select the **Lookup Reference** button next to the lookup column. The **Lookup Reference** section opens and lists the tables related to the current table.



For each table, select the columns to search during import to retain the relationships between the rows, and then select **OK**.

Save mapping settings

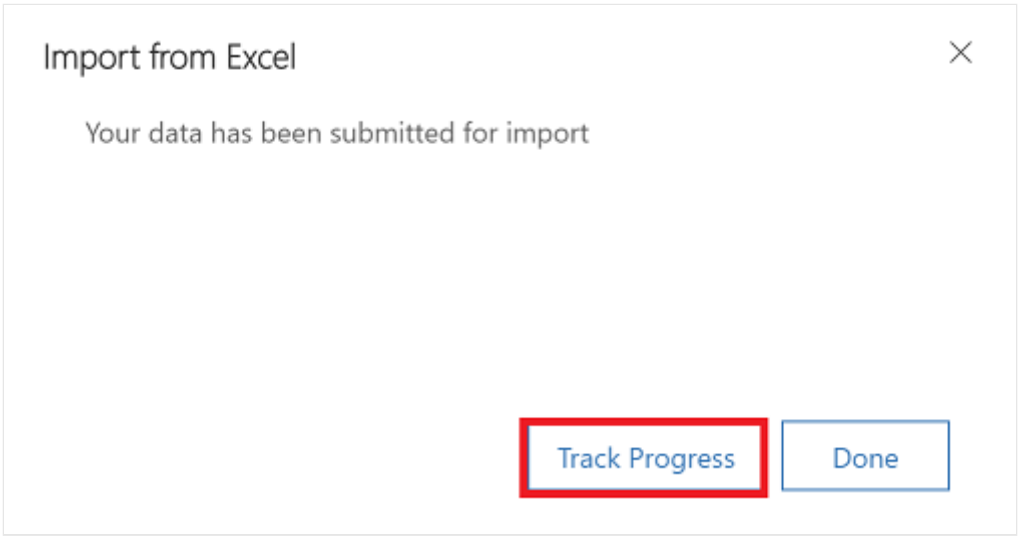
To save the mapping settings for next time, enter a name in the **Name your data map** box. This way, the next time you import a similar set of data, you'll be able to use the same mapping.



Open the import log

After you initiate an import, you can monitor the status of the import job and view results in the import log.

In the last step of the import wizard, select **Track Progress** to view the progress of the import job.



If you missed this step, append the following code to your app URL: `&newWindow=true&pagetype=entitylist&etn=importfile&viewid=a2927069-e4dc-4e8f-8fb1-d2f6c40c427e&viewType=1039`.

For example, if your app URL is `https://org12345.crm.dynamics.com/main.aspx?appid=00001111-aaaa-2222-bbbb-3333cccc4444`, then the URL to view the import log is `https://org12345.crm.dynamics.com/main.aspx?appid=00001111-aaaa-2222-bbbb-3333cccc4444&newWindow=true&pagetype=entitylist&etn=importfile&viewid=a2927069-e4dc-4e8f-8fb1-d2f6c40c427e&viewType=1039`.

View the status of an import, and correct errors

After the import is complete, you can view the records that were successfully imported, failed to import, or were partially imported.

1. Open the import log.

Delete imported records

You can delete the import file and imported records if you want to reimport the data or you don't need the data for some reason.

1. Open the import log.
2. Select the import file that you want to delete, followed by one of the following actions:
    - **Delete import source file**. This option deletes the import log file and its details.
    - **Delete imported records**. This option deletes all records that were imported from the selected file.
    - **Delete All**. This option deletes the import file along with the records that were imported from the import file.

Limitations

- Excel Import isn't supported with Virtual tables or Elastic tables
- Excel import updates fields from the primary table but ignores fields from related tables.
- Excel import jobs run in parallel only when the file size is under 1 MB. Files larger than 1 MB are processed sequentially to avoid resource exhaustion.

> **Note**
>
> To enable parallel processing, keep each file under 1 MB. For `.zip` files, the decompressed size must also be under 1 MB. Note that files with special characters may have a calculated size that exceeds 1 MB even if the original file appears smaller.

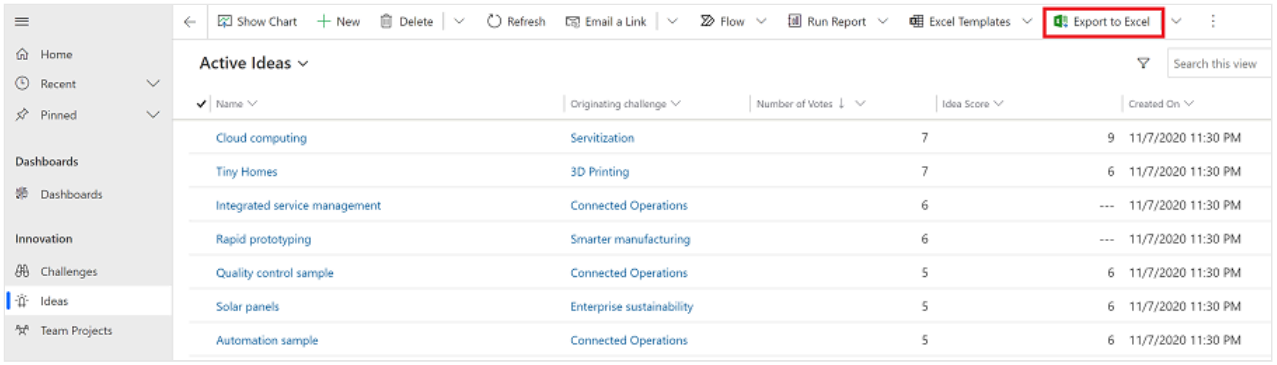
Download a template for data import

Export data to Excel

08/05/2025

Export data from your model-driven app to Excel. The allowed data export size depends on the number of rows, columns, lookup fields, and lookup relationship types. The export query might time out depending on the combination of these factors.

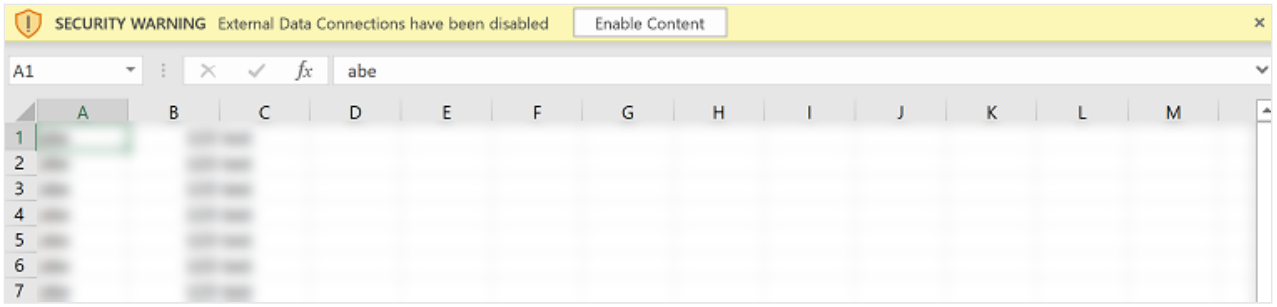
1. From the left nav, select a table that you want to export data from.
2. On the command bar, select **Export to Excel**.



3. When the download is complete, navigate to the location of the downloaded file.

> **Note**
>
> When you download a worksheet, it should automatically save to your computer. However, if it doesn't then make sure that you save it before you open and edit it. Otherwise, you might get this error message: **Excel cannot open or save any more documents because there is not enough available memory or disk space.**
>
> Follow these steps to fix the issue:
>
> a. Open Excel and go to **File** > **Options** > **Trust Center Settings Center Settings** > **Protected View**.
>
> b. In **Protected View**, clear all three items.
>
> c. Select **OK** > **OK**.
>
> We still strongly recommend that you save and then open the data file rather than disabling protected view, which might put your computer at risk.

4. Open the saved Excel file.
5. If you see the security warning **External Data Connections have been disabled**, select **Enable Content**.



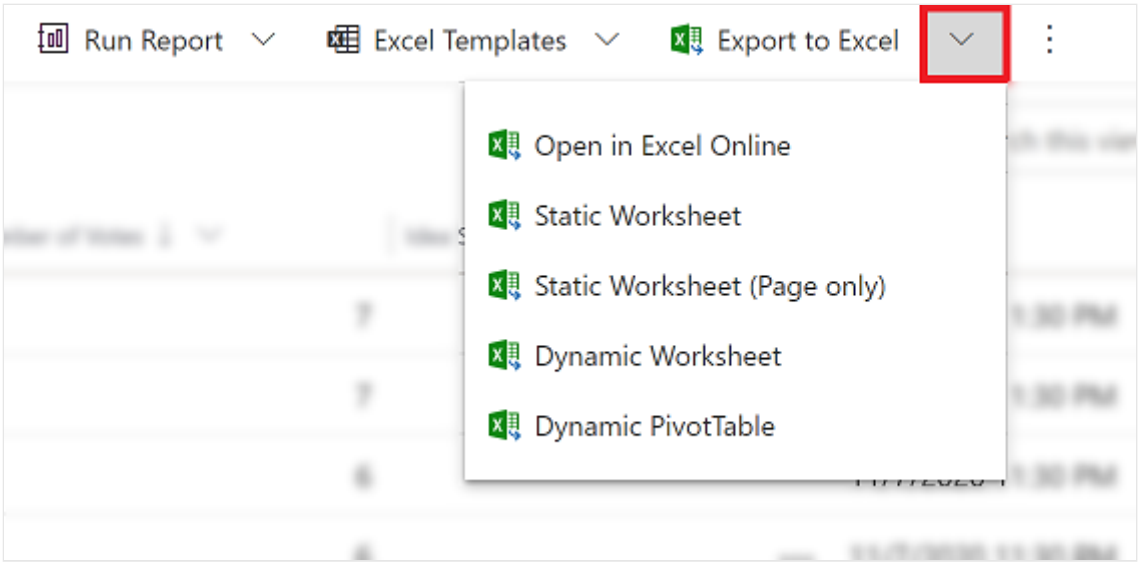
The data is exported in the same format that you see in your app. Text remains as text, numbers remain as numbers, and dates remain as dates. However, when you export data from your app to Excel, some cell formats might change. The following table summarizes how you see the data in apps and how the cell format changes when you export the data to Excel.

Expand table

Data format in model-driven apps	Cell format in Excel
Text, Ticker Symbol, Phone, Options set, and Look Up	Shows as Text and option set becomes drop-down list
Email, URL	Shows as General
Number	Shows as Number without group separator
Currency	Shows as Number and doesn't include dollar sign ($)
Date only, Date and Time	Shows as Date only
Calculated and Roll-up columns	Editable in Excel but can’t be imported back to Power Apps
Secured columns	Editable in Excel but can’t be imported back to Power Apps

Export options

There are other export options such as Excel Online, Static Worksheet, Dynamics Worksheet, or Dynamics PivotTable.



The following table summarizes the different options. Pick the one that works best for you.

Expand table

Task	Learn more
Do an *ad-hoc* or *what if* analysis without modifying app data. Or, quick bulk edits to multiple rows.	Open app data in Excel Online
Get a snapshot of the data at the current date and time or if you want to share the data with others.	Export to an Excel static worksheet
Get the most up-to-date information and be able to refresh it in Excel and match what you see in your app at any time.	Export to an Excel dynamic worksheet
View your app data in a pivot table.	Export to an Excel PivotTable

Known issues

Exporting to Excel doesn't support virtual tables.

- If Export to Excel times out, try these options:
  - Export smaller batches by adjusting the filter criteria.
  - Reduce lookup fields that increase query complexity when retrieving data from related tables.
  - Reduce the number of columns.

- You can export your app data to Excel (.xlsx format), use the file as a template to add more data, and import it back into your app. If you add or modify columns in the Excel file and import it back into your app, the import fails because the added or modified columns don’t map to tables in your app. When you import an Excel file into your app,

make sure that columns and tables are mapped correctly to avoid import failures. For more information on mapping, see Review mapping.

- If you're using Excel 2010, you might get this error message when you export data from the Accounts area: `The file is corrupt and cannot be opened.`
  The error message occurs due to a setting in Excel. To fix the issue:

  1. Open Excel 2010 and go to **File** > **Options** > **Trust Center** > **Trust Center settings**.
  2. Select **Protected view** and then clear the check boxes for the first two options.
  3. Select **OK** and then close the **Options** dialog box.

Troubleshoot export to excel

Open your app data in Excel Online

Article • 10/23/2024

Open your app data in Excel Online and make quick edits or do an ad-hoc analysis. You can make changes to your app data in Excel Online and then save the updated information back to your app.

This feature requires that you have an Office 365 subscription or a subscription to an online service such as SharePoint Online or Exchange Online and a Microsoft account.

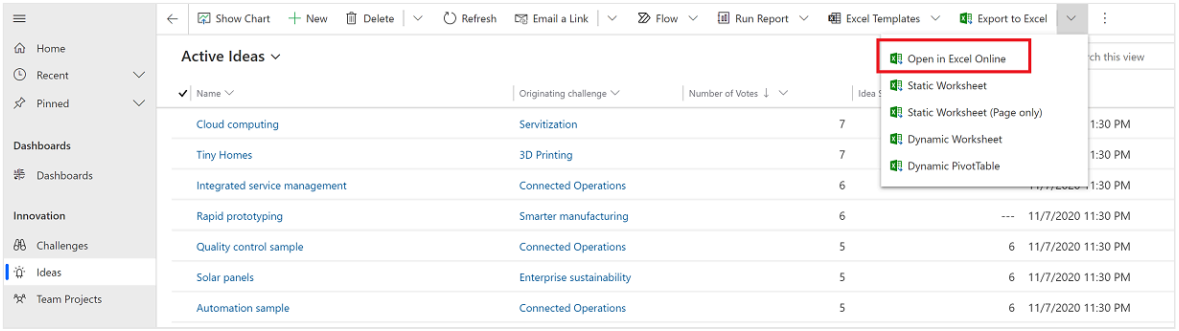
A few things to note:

- The data for an *ad-hoc* analysis with Excel Online is stored temporarily. Any additions, such as charts, graphs, calculations, columns, and colors won't be saved back to the app from the ad-hoc analysis in Excel Online. Keep the existing format of the Excel cells to prevent problems when you save the file. The file import might fail if you make numerous changes.
- Updated data in an app isn't immediately reflected in Excel Online if the same view was opened in the last two minutes in Excel Online. After that time frame, any updated data should show in Excel Online.
- The option to open data in Excel Online isn't available for all tables. If you don't see the option for a table, then it's not available for that table.

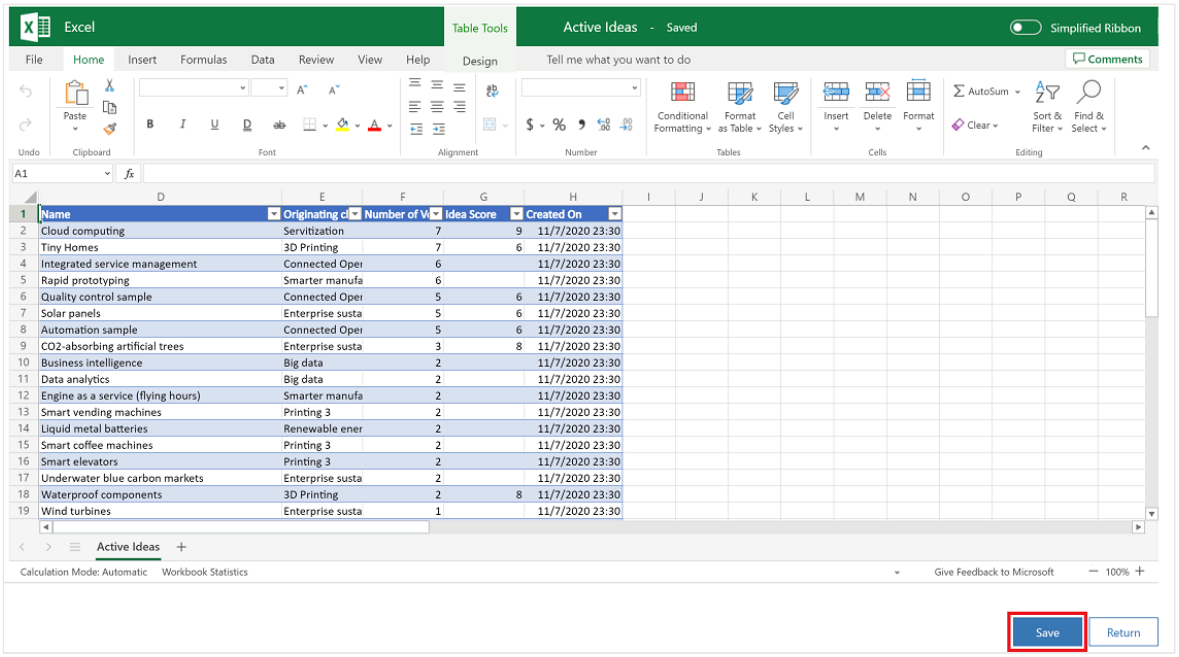
Export to Excel Online

1. On the left nav, select a table.

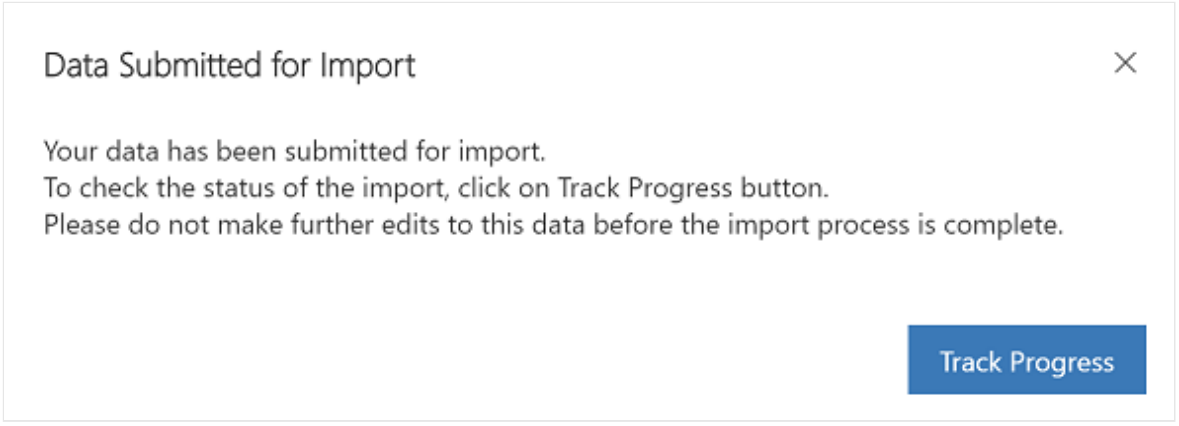
2. On the command bar, select the **Export to Excel** menu and then select **Open in Excel Online**.



3. Make your edits in the Excel Online file and when you're done select **Save**.



4. Your changes are submitted for import. To track the progress of the import, select **Track Progress**.



> **Note**
>
> By design, you can't do a File > **Save As** in Excel Online. If you do, you'll get a **Can't Save Workbook** error message.

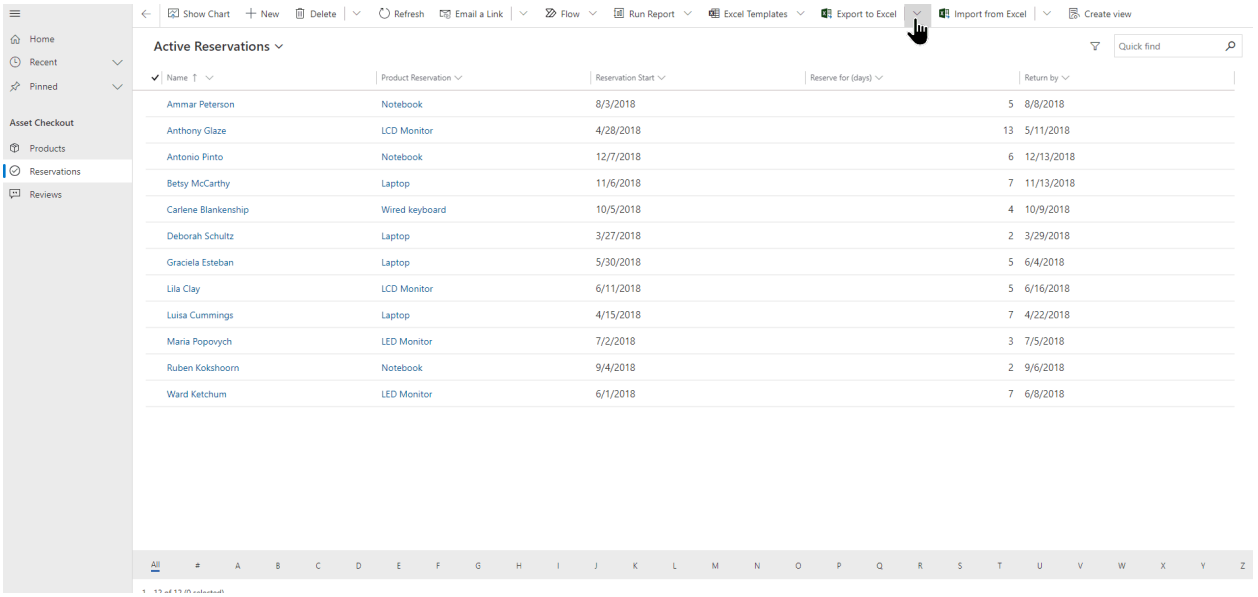
Export data to an Excel dynamic worksheet

Article • 10/22/2024

Export your app data to an Excel dynamic worksheet to get the most up-to-date information from your app. When you export your data to an Excel dynamic worksheet and then make changes to your data in the app, you can use the refresh feature in Excel to get the latest information from the app.

In the example below, we downloaded an Excel dynamic worksheet then went back to the app and changed the **Reserve for days** column from **5** days to **10**. Then opened the Excel worksheet and refreshed the data to get the latest information from the app.



A few things to note:

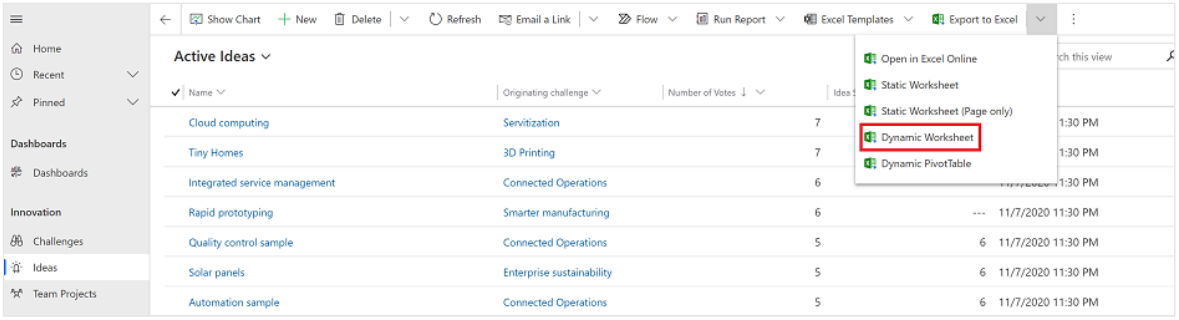
- You can export up to 100,000 rows at a time. You can't export data to a dynamic worksheet in Excel for all tables. If you don't see the option for a table, then it's not available for that table.
- You can email a dynamic Excel file or store it as a shared file if the recipients are in the same domain as you. When recipients open the dynamic file, they only see the data that they have permission to view.
- Some system views can be exported only to a static Excel worksheet.
- Currency values are exported to Excel as numbers. To format the data as currency after you have completed the export, see Format numbers as currency.
- The date and time values that you see in the app show up only as Date when you export the file to Excel, but the cell actually shows both the date and time.
- If you're an app maker, you can use the Microsoft Power Apps Excel Add-in to download your app data and make edit in Excel and then save the data back to

your app. For more information, see Open table data in Excel.

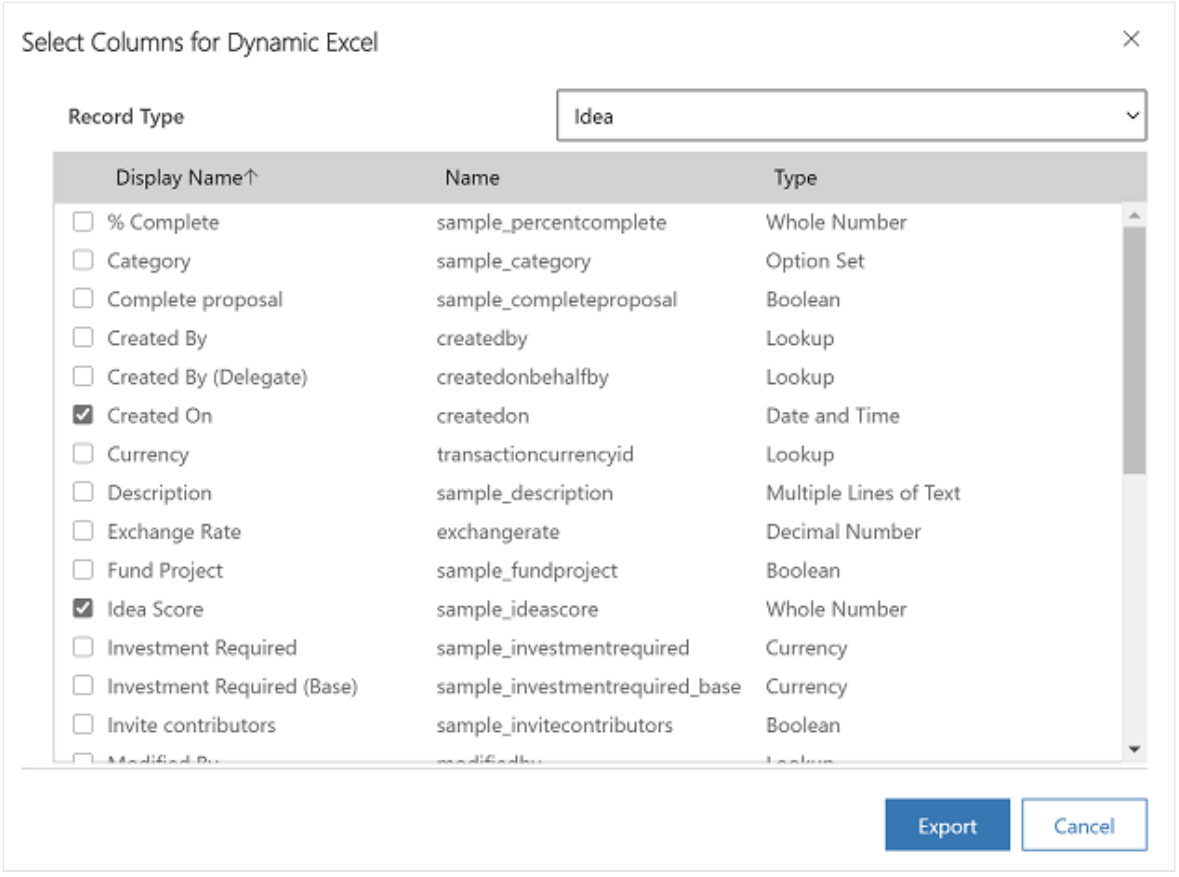
Export a dynamic worksheet

1. On the left nav, select a table.

2. On the command bar, select the **Export to Excel** menu and then select **Dynamic Worksheet**.



3. Select the columns to export and then select **Export**.



4. When the download is complete, navigate to the location of the downloaded file.

> **Note**

When you download a worksheet it should automatically save to your computer. However, if it doesn't then make sure that you save it before you open and edit it. Otherwise, you might get this error message: **Excel cannot open or save any more documents because there is not enough available memory or disk space.**

To fix the issue:

a. Open Excel and go to **File** > **Options** > **Trust Center Settings Center Settings** > **Protected View**.

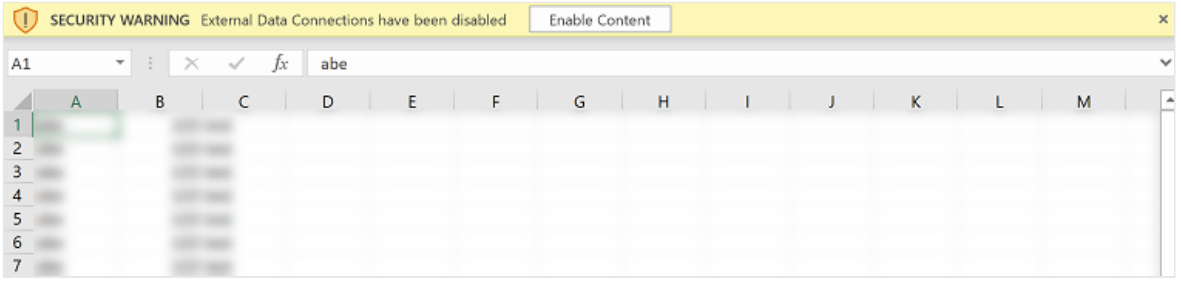
b. In **Protected View**, clear all three items.

c. Select **OK** > **OK**.

We still strongly recommend that you save and then open the data file rather than disabling protected view, which might put your computer at risk.

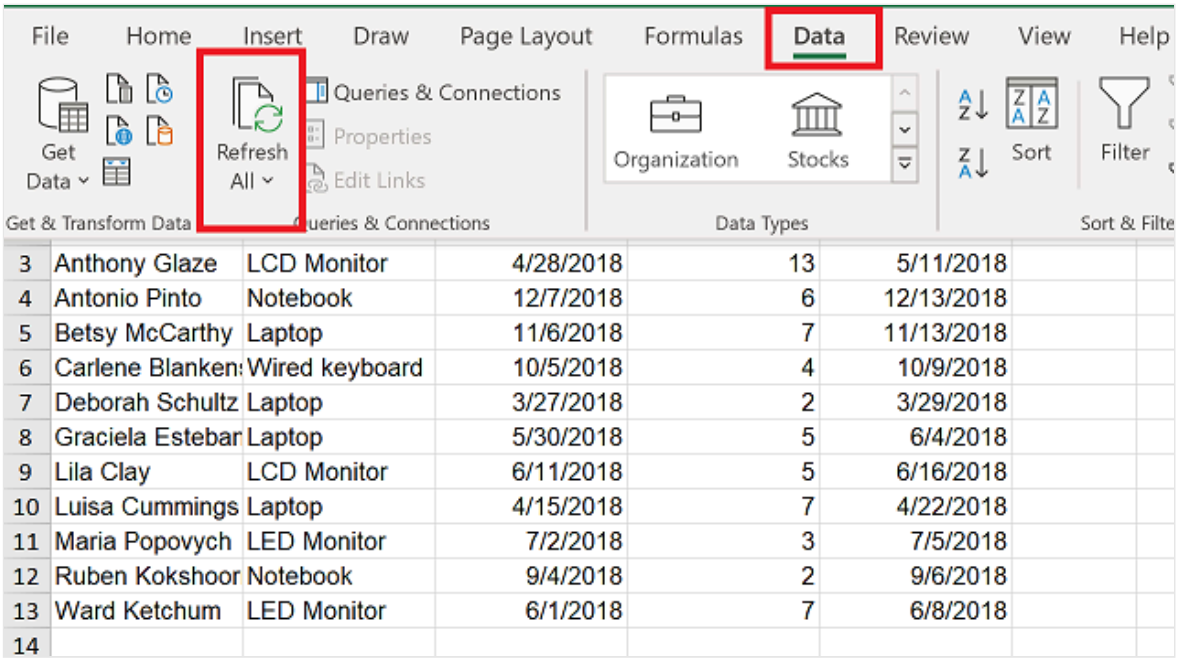
5. Open the saved Excel file.

6. If you see the security warning **External Data Connections have been disabled**, select **Enable Content**.



7. Go back to your app and update your app data.

8. To see your updates in the Excel dynamics worksheet, in Excel go to **Data** > **Refresh All**. If this doesn't work, see Refresh All doesn't work.



3	Anthony Glaze	LCD Monitor	4/28/2018	13	5/11/2018	
4	Antonio Pinto	Notebook	12/7/2018	6	12/13/2018	
5	Betsy McCarthy	Laptop	11/6/2018	7	11/13/2018

Export to an Excel static worksheet

Article • 02/15/2022

When you want to present information about the data in your app to an individual who doesn't have access to the app, or you have data that doesn't change often, consider exporting the app data to an Excel static worksheet.

There are two types of static worksheets that you can export.

- **Static worksheet**: Exports all the pages in the current view.
- **Static worksheet (Page only)**: Exports the data from the current page only.

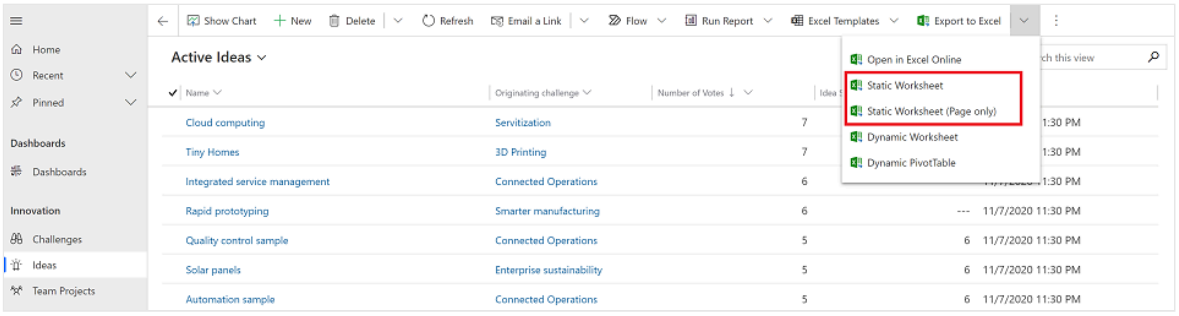
A few things to note:

- You may have the option to export data to an Excel static worksheet in all row types. However, in some cases the format might be old, or the data might not be filtered by what you see in the app.
- You can export up to 100,000 rows at a time. By default, a model-driven app lists up to 50 rows per page.
- Once imported, you can email the static worksheet to anyone or store it in a shared file. Anyone who opens the file will see all the data in the file.
- You can't change the columns for a system view. You must either customize the view, which requires the System Administrator or System Customizer security role, or use Advanced Find to create your own view based on the current view.
- Currency values are exported to Excel as numbers. After you have completed the export, see Format numbers as currency.
- The date and time values that you see in the app show up only as Date when you export the file to Excel, but the cell actually shows both the date and time.

Export a static worksheet

1. To export data, on the left nav, select a table.

2. On the command bar select the **Export to Excel**, and then choose **Static worksheet** or **Static worksheet (Page only)**.

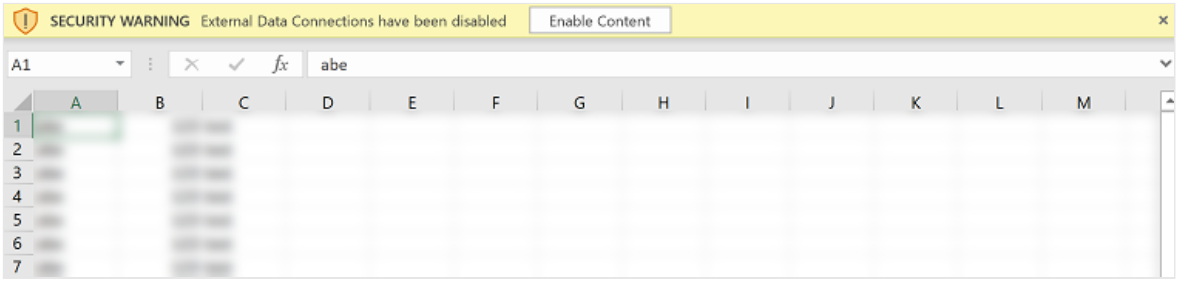


3. when the download is complete, navigate to the location of the downloaded file.

> **Note**
>
> When you download a worksheet it should automatically save to your computer. However, if it doesn't then make sure that you save it before you open and edit it. Otherwise, you might get this error message: **Excel cannot open or save any more documents because there is not enough available memory or disk space.**
>
> To fix the issue:
>
> a. Open Excel and go to **File** > **Options** > **Trust Center Settings Center Settings** > **Protected View**.
>
> b. In **Protected View**, clear all three items.
>
> c. Select **OK** > **OK**.
>
> We still strongly recommend that you save and then open the data file rather than disabling protected view, which might put your computer at risk.

4. Open the saved Excel file.

5. If you see the security warning **External Data Connections have been disabled**, select **Enable Content**.



By default, an exported worksheet includes the columns that are displayed in the list, using the same column order, sorting, and column widths.

Export to an Excel PivotTable

Article • 10/26/2022

You can export app data to an Office Excel PivotTable to see patterns and trends in data. An Excel PivotTable is a great way to summarize, analyze, explore, and present your app data. You can export up to 100,000 rows at a time.

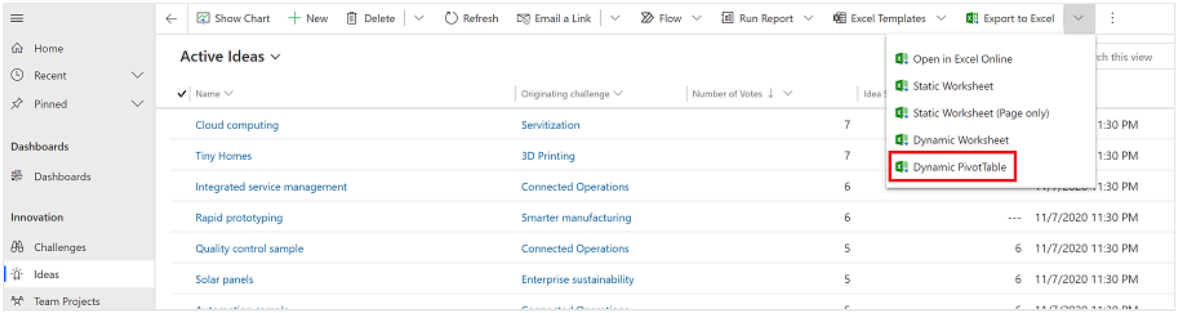
A few things to note:

- The option to export data to an Excel PivotTable isn't available in all row types. If you don't see the option, it's not available for that row.
- Currency values are exported to Excel as numbers. After you complete the export, see the Excel Help topic "Display numbers as currency" to format the data as currency.
- The date and time values that you see in the app show up only as Date when you export the file to Excel, but the cell actually shows both the date and time.

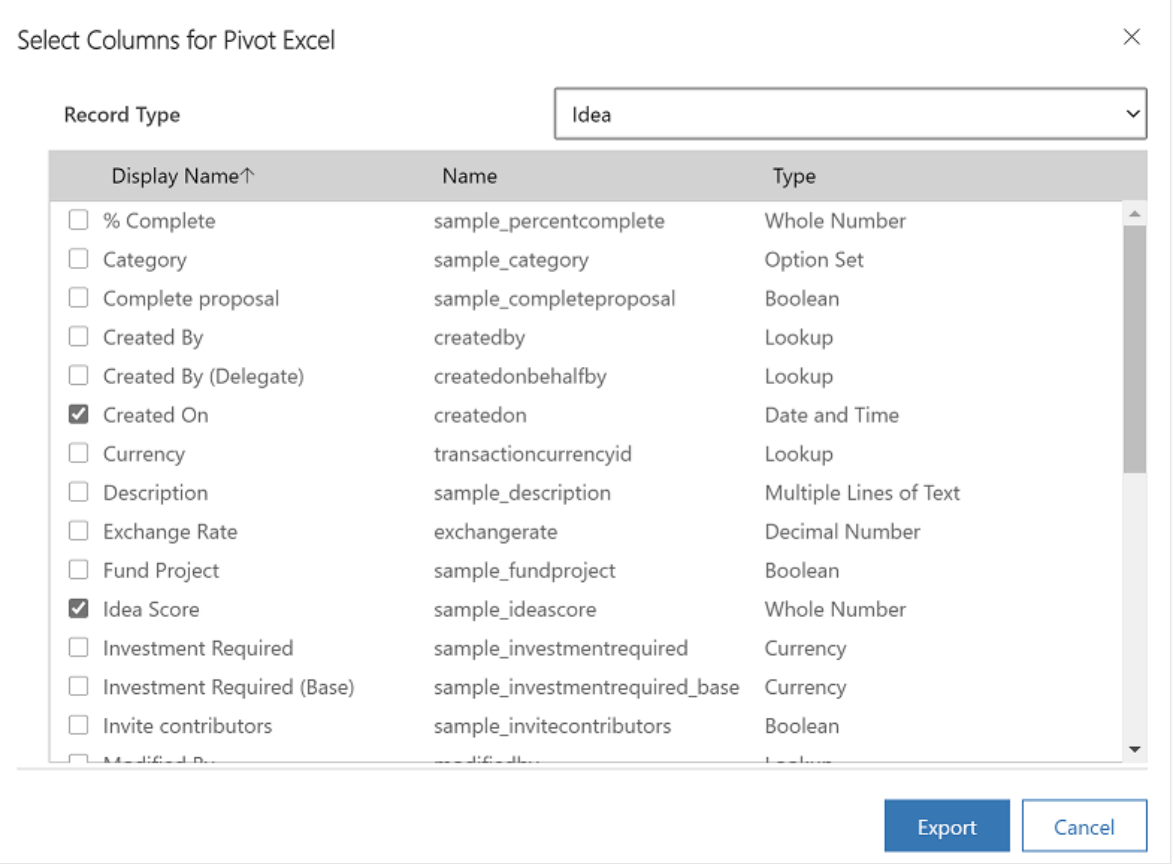
Export data to a PivotTable

1. On the left nav, select a table.

2. On the command bar select the **Export to Excel** menu, and then select **Dynamic PivotTable**.



3. In the **Select Columns for Pivot Excel** dialog box, select the column settings and then select **Export**.



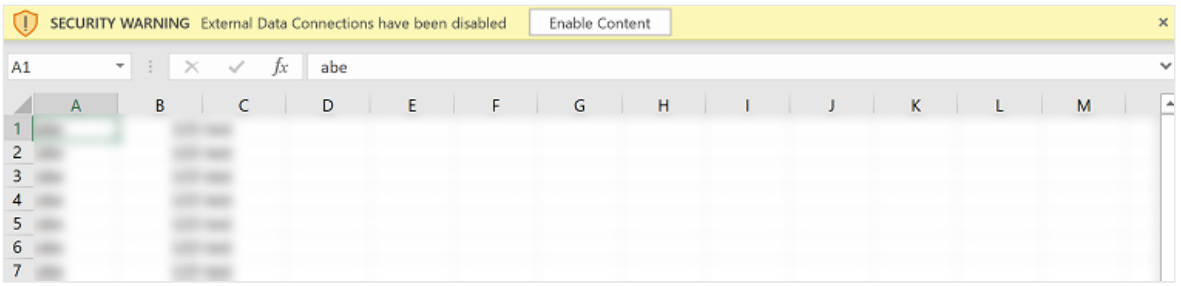
By default, the **PivotTable Column List** includes only columns that are displayed in the **Select Columns for Pivot Excel** list.

4. When the download is complete, navigate to the location of the downloaded file.

> **Note**
>
> When you download a worksheet it should automatically save to your computer. However, if it doesn't then make sure that you save it before you open and edit it. Otherwise, you might get this error message: **Excel cannot open or save any more documents because there is not enough available memory or disk space.**
>
> To fix the issue:
>
> a. Open Excel and go to **File** > **Options** > **Trust Center Settings Center Settings** > **Protected View**.
>
> b. In **Protected View**, clear all three items.
>
> c. Select **OK** > **OK**.
>
> We still strongly recommend that you save and then open the data file rather than disabling protected view, which might put your computer at risk.

5. Open the saved Excel file.

6. If you see the security warning **External Data Connections have been disabled**, select **Enable Content**.



> **Note**
>
> If don't see any data and you get an error, see Refresh all doesn't work.

7. To add a PivotTable, on the **Insert** tab, select **PivotTable**.

> **Note**
>
> You must complete this step to insert the PivotTable. The PivotTable is not created automatically.

8. Drag the columns from the PivotTable Column List to the PivotTable. For more information, see Overview of PivotTables and PivotCharts.

Merge duplicate rows

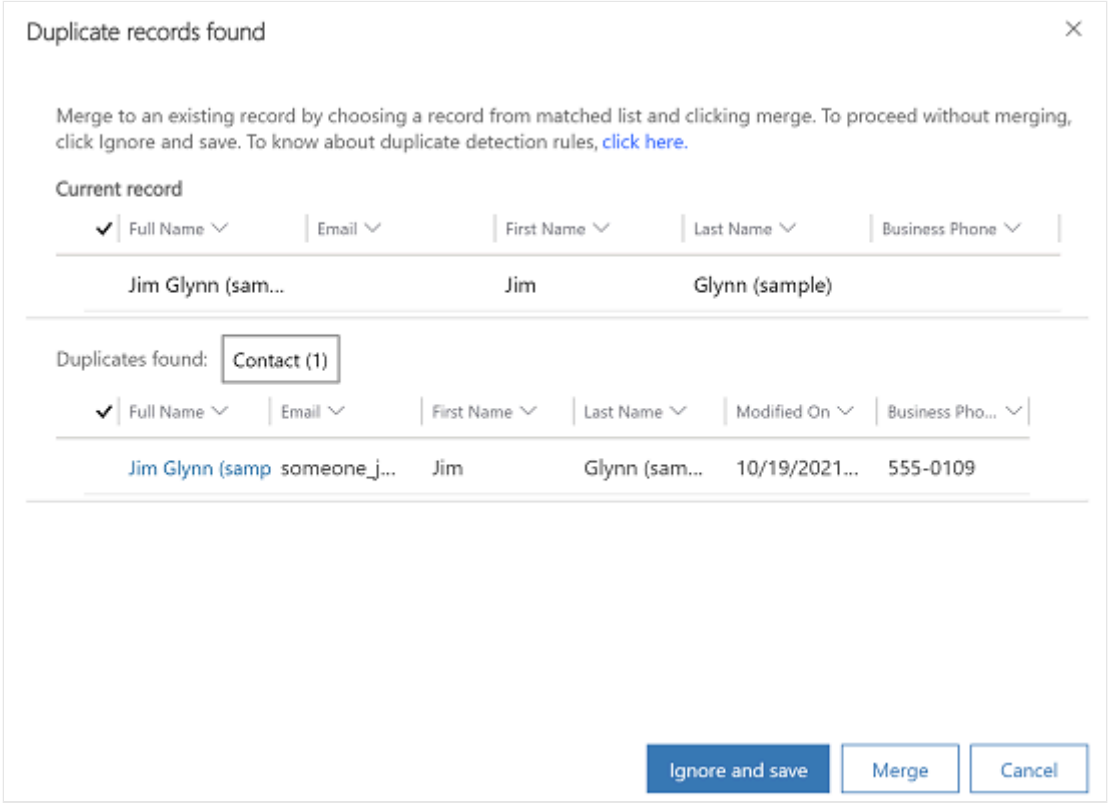
07/22/2025

Duplicate rows can creep into your data when you or others enter data manually or import data in bulk. Microsoft Dataverse helps you address potential duplicates by providing duplicate detection for active rows, such as accounts and contacts. When you merge a row, any related or child rows are also merged. Your administrator may also set up duplicate detection rules for other situations.

There are a few situations when duplicates might be found:

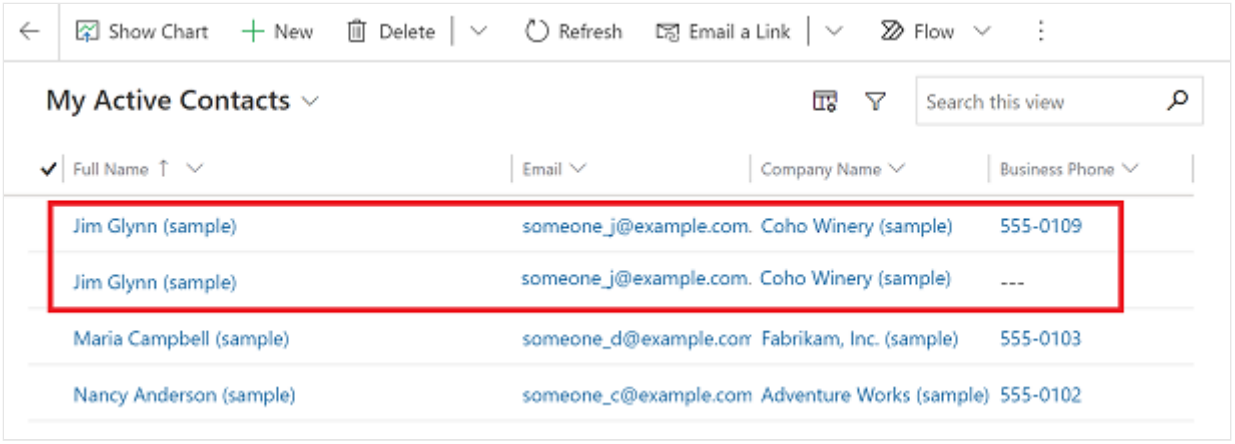
- When a row is created or updated.
- When you're using Dynamics 365 for Outlook and you go from offline to online.
- When you import data using the Import Data wizard.
- Duplicates aren't detected when you merge rows, save an activity as completed, or change the status of a row. For example, when activating or reactivating a row.

For example, let's say you enter a contact row, Jim Glynn, along with a mobile phone number. The duplicate detection rule discovers that you already have a similar row, and displays this dialog box.



You're not sure if this is a different person that has the same name as an existing contact, so you select **Ignore And Save**.

Next, you go to the **My Active Contacts** list and see that now you have two rows with the same name. After reviewing the rows, you determine that they're duplicates that need to be merged.



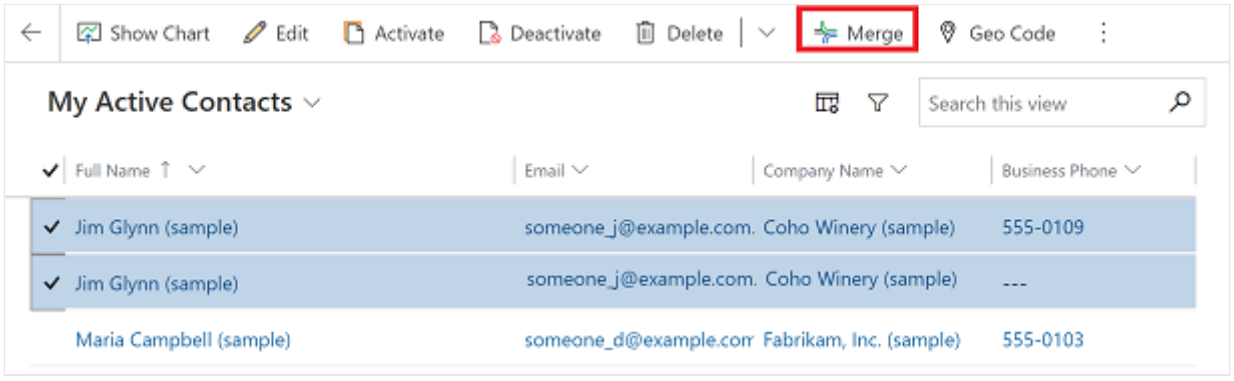
Dataverse includes duplicate detection rules for accounts and contacts. These rules are automatically turned on, so you don't have to do anything to set up duplicate detection for these row types.

> **Note**
>
> If available on your system, you may also be able to check for duplicates of other row types, in addition to contacts and accounts. Check with your system administrator. Find your administrator or support person

> **Note**
>
> To modify the columns that are visible for the current record in the duplicate detection dialog, administrators can modify the **Advanced Find View** for that entity.

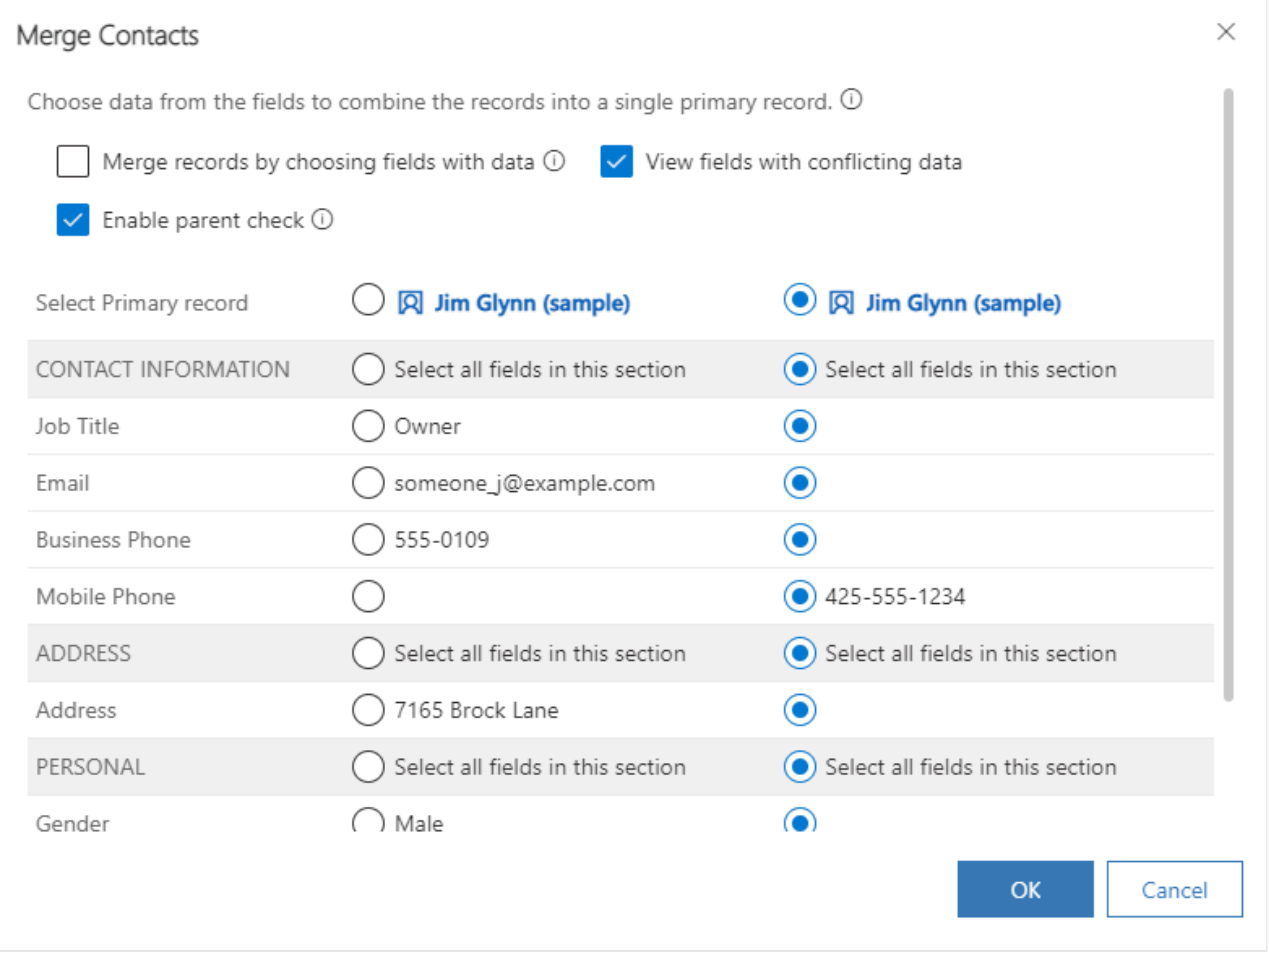
How to merge duplicate rows

1. Select the duplicate rows from the view page in your model-driven app, and then select **Merge** in the command bar at the top of the page.



2. In the **Merge Contacts** dialog box, select the primary row (the one you want to keep) and then select any columns in the new row that you want to merge into the primary row. Data in these columns may override the existing data in the primary row. Select **OK**.

> **Note**
>
> If you run into issues during the merge process, uncheck **Enable parent check**. If files are deleted during the merge process, you can skip the parent check. This allows your merge to continue even if someone deletes a row from the set while the job is running in the background. For more information, see Asynchronous processing of cascading transactions.



Limitations

- You can merge rows only from Account, Contact, and Lead tables. Other out-of-box Dataverse tables and custom tables aren't supported.
- You can only merge two records at a time.
- File and image columns can't be previewed. They show as base64 text. Go to the original records to view the file or image.

- If a column or control for the column matches any of the following conditions, it doesn't appear in the merge dialog:
  - The column or containing section is hidden by default in column or section properties. Hidden columns and sections can be forced to appear using Client API functions, but they still aren't be eligible for merging.
  - The column's `ValidForUpdate` property is `False`.
  - The column is **Choice** or **Choices** type and it has either a parent choice or child choice column.
  - The column is `parentaccountid` on the Account table.
  - The column is `parentcustomerid` on the Contact table.
  - The column is **Owner** type (example: `ownerid`).
  - The control for the column does not have a class property.
  - The control for the column is **Quick Form Collection Control** or **Reference Panel Quick Form Collection Control**.
- Merging records with a SharePoint documents library merges only the records, not the documents libraries. Learn more in Collaborate using SharePoint.

Work with reports

Article • 02/27/2024

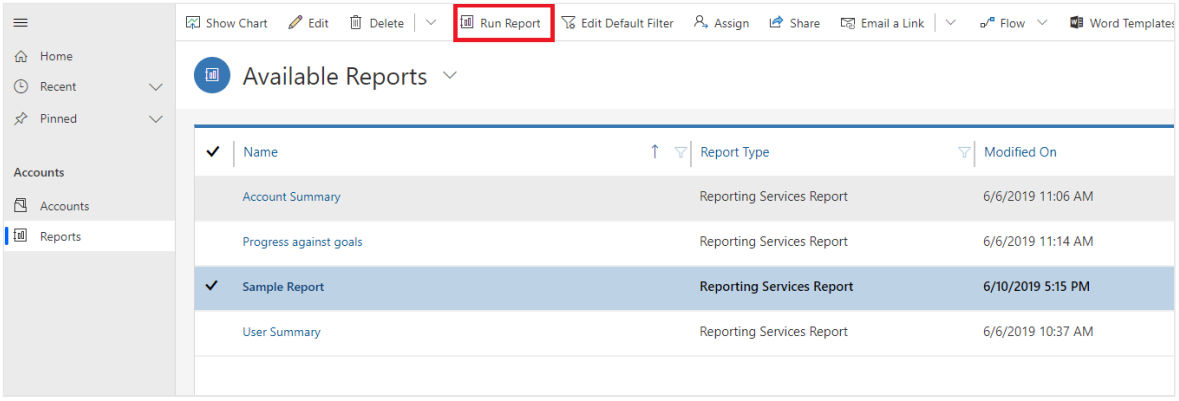
Reports help you monitor your progress towards your business goals by helping you see how you're doing. You can also track trends - which can give you an advantage over your competitors.

The reporting features need to be enabled for your model-driven app for you to see the reports area on the left navigation pane. For more information, see Add reporting features to your model-driven app.

Run a report

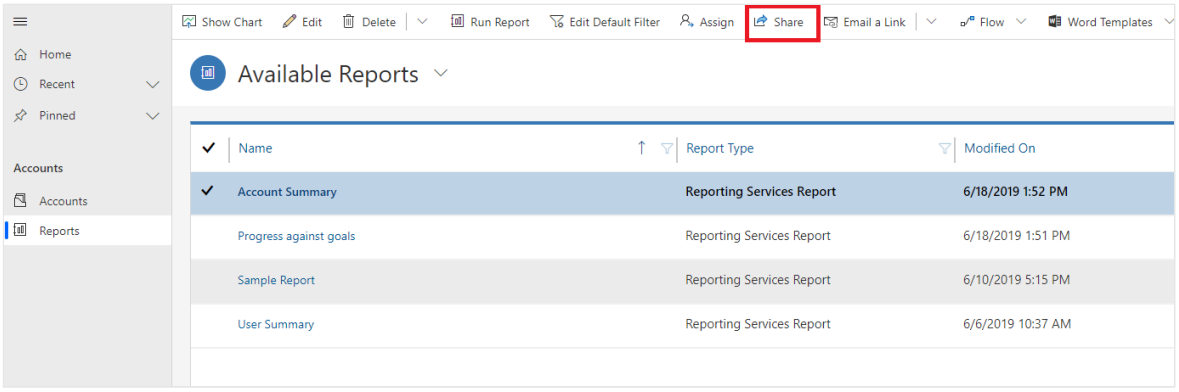
1. From the left navigation pane, select the reports area.
2. Choose the report you want > **Run Report**.

> **Note**
>
> In **Report Viewer** dialog box, you can leave the search criteria as is, or change it as needed.



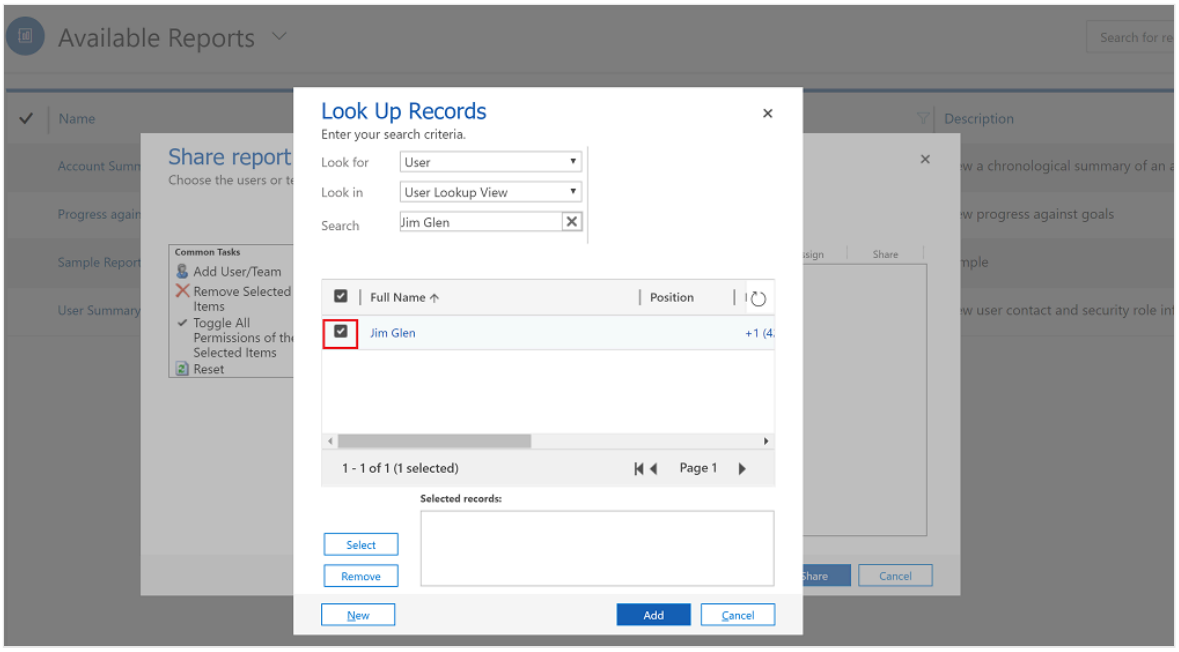
Share a report with other users or teams

1. From the left navigation pane, select the reports area.
2. In the list of reports, select the report you want to share.
3. On the command bar, select **Share**.

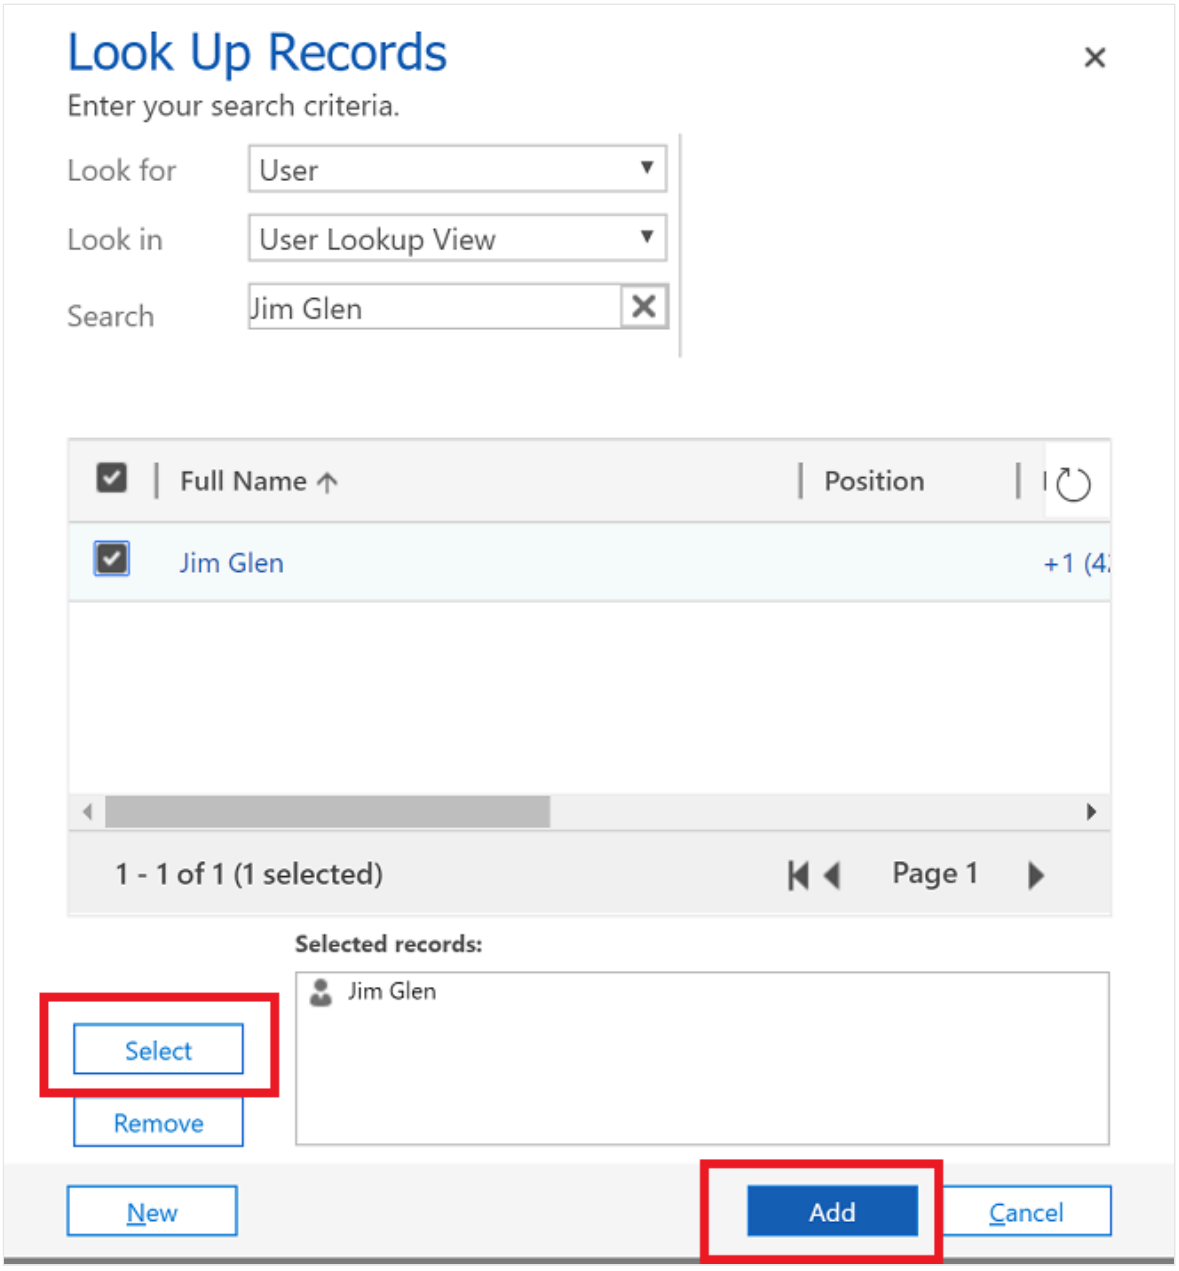


4. On the **Share Report** dialog box, select **Add User/Team**.

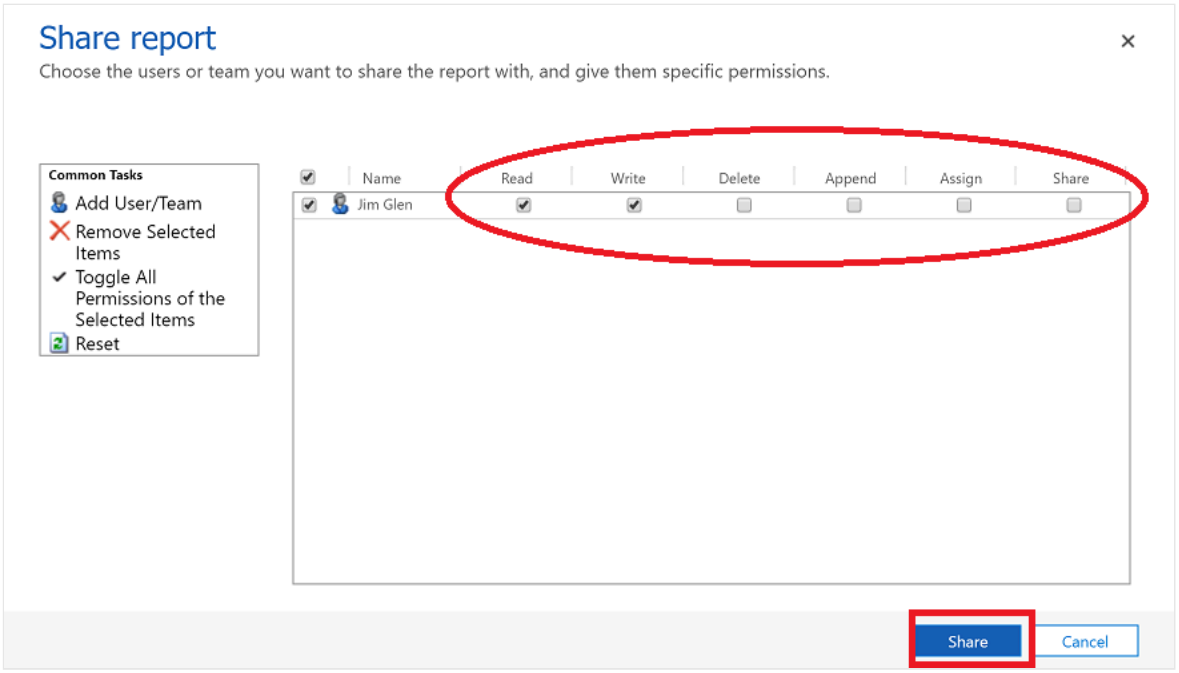
5. In the **Look Up Rows** dialog box, find the users or team row that you want to share the report with, and select the check box next to the row.



6. Choose **Select** to add the user or team row to the **Selected rows** box and then select **Add**.



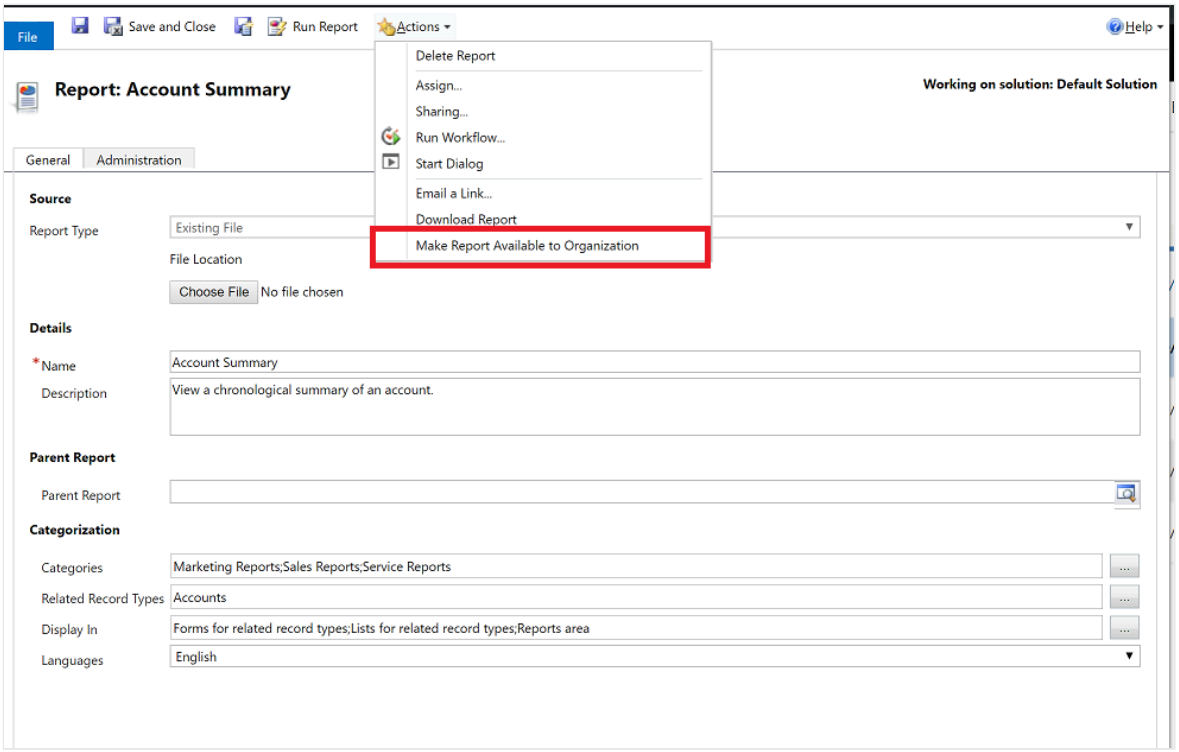
7. In the **Share Report** dialog box, select the type of share access that you want. The available permissions are: Read, Write, Delete, Append, Assign, or Share. This will add the user or team row to the **Selected rows** box.



Share a report with your organization (for admins)

If the report would be useful for all users, make it available to the organization.

1. From the left navigation pane, select the reports area.
2. In the list of reports, select the report you want to share.
3. On the command bar, select **Edit**.
4. On the **Actions** menu, select **Make Report Available to Organization**.



Download a report

1. From the left navigation pane, select the reports area.
2. In the list of reports, select the report you want to share.
3. On the command bar, select **Edit**.
4. On the **Actions** menu, select **Download Report**.
   The RDL file contains the fetchXML that the report is based on.
5. Open the report once the download is complete.

Known issue

Reports rely on a hybrid experience called out in Enable hybrid experience which are not supported in mobile or Teams.

Create a report using the Report Wizard

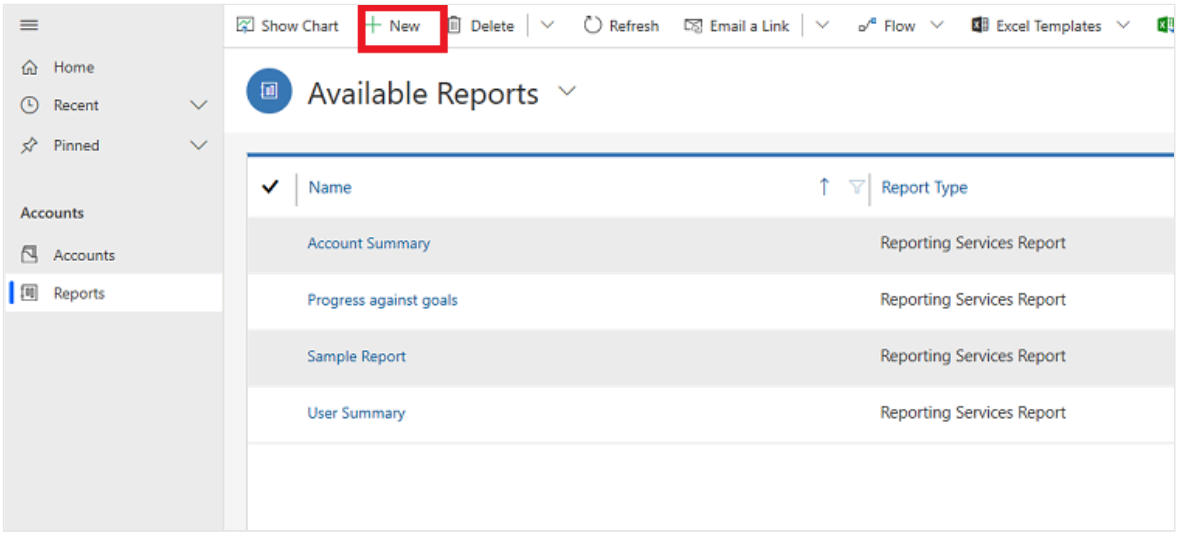
Article • 11/17/2023

Use the Report Wizard to create reports with charts and tables that allow you to easily analyze your data.

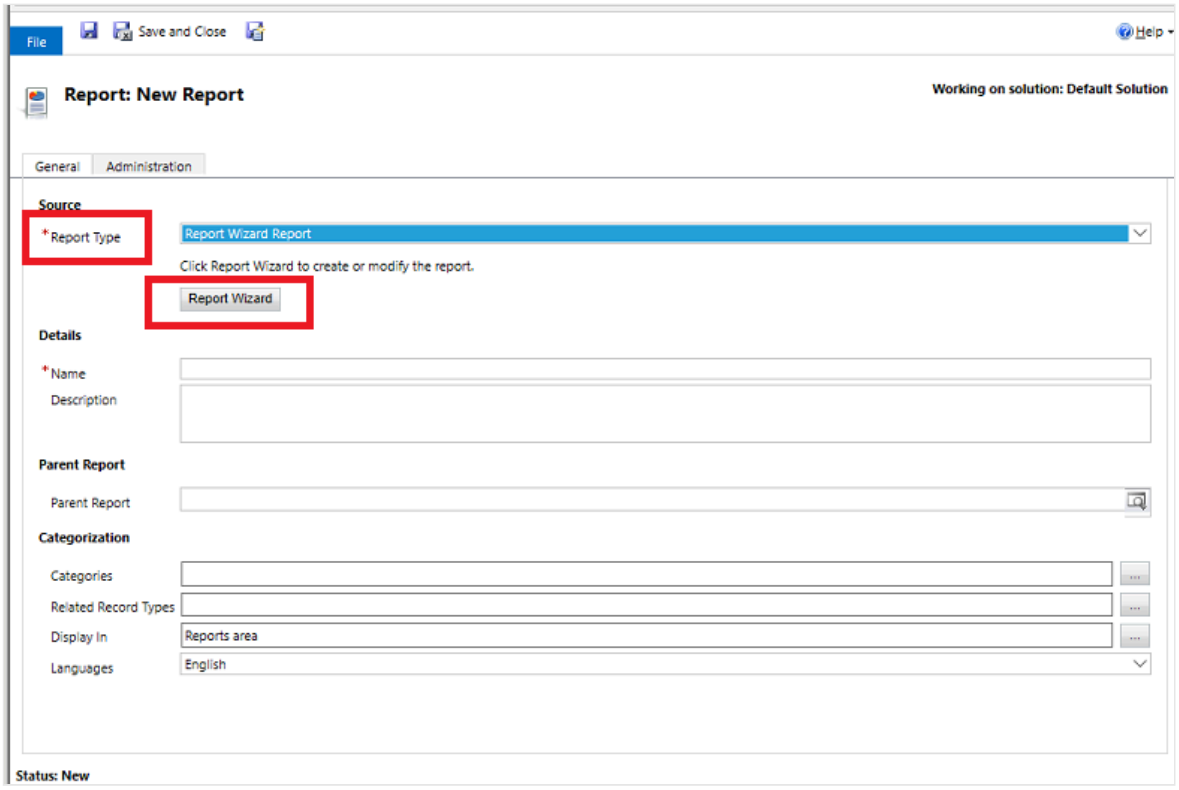
All reports that are created using the Report Wizard are Fetch-based reports. All reports generated with the Report Wizard print in landscape mode.

Create a new report

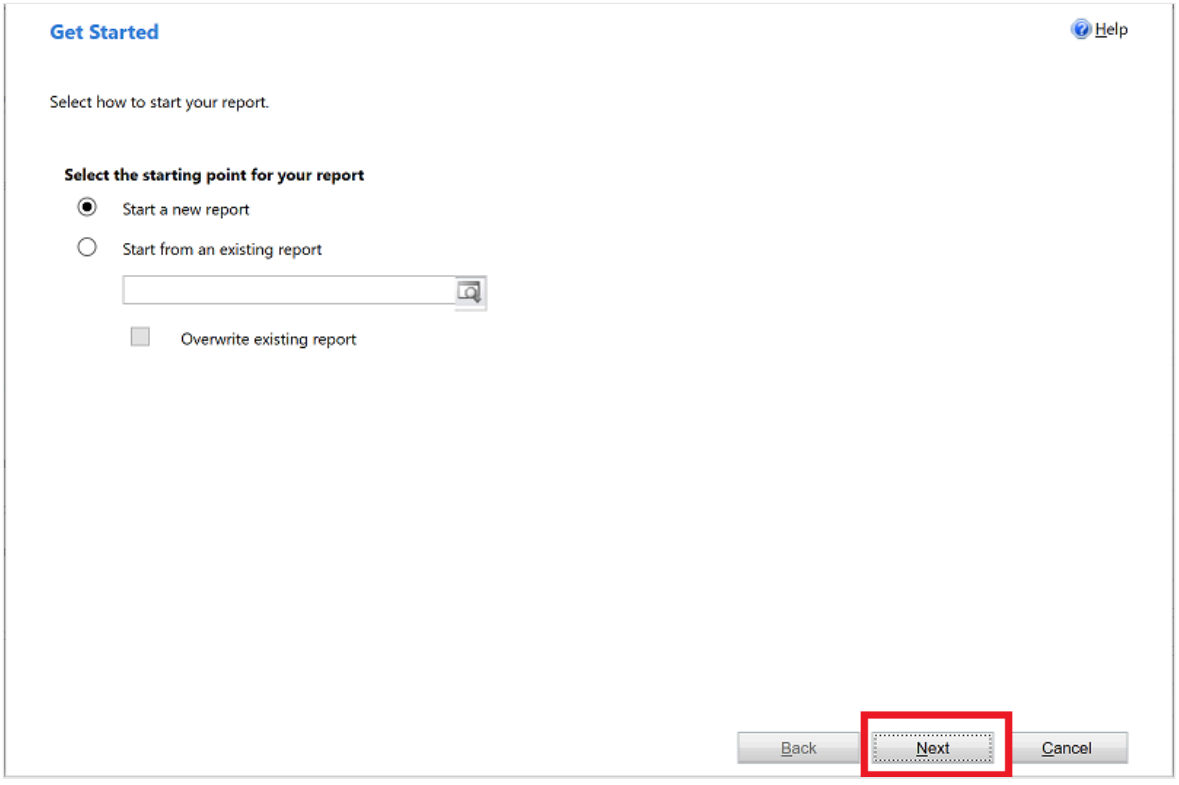
1. From the left navigation pane, select the reports area.
2. On the command bar, select **New**.



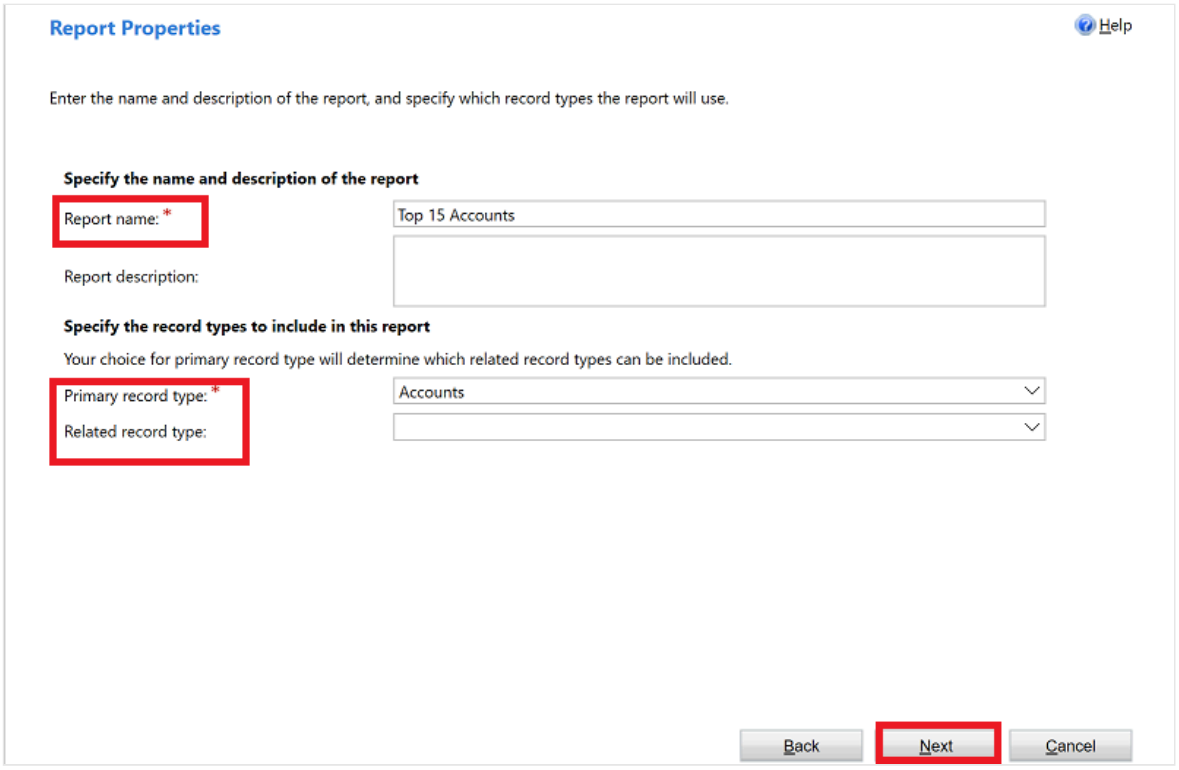
3. A **Report:New Report** screen appears. For **Report Type** leave the default selection to, **Report Wizard Report** and select the **Report Wizard** button.



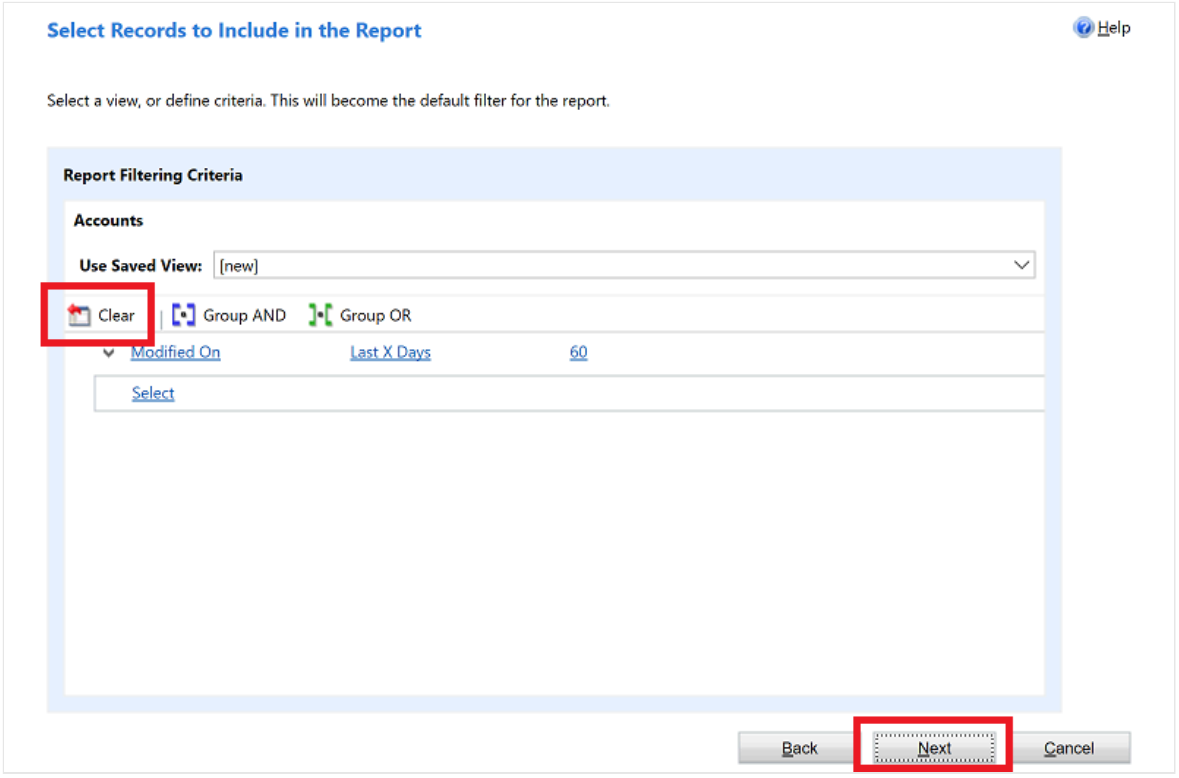
4. In the next screen, leave the default selections and then select **Next**.



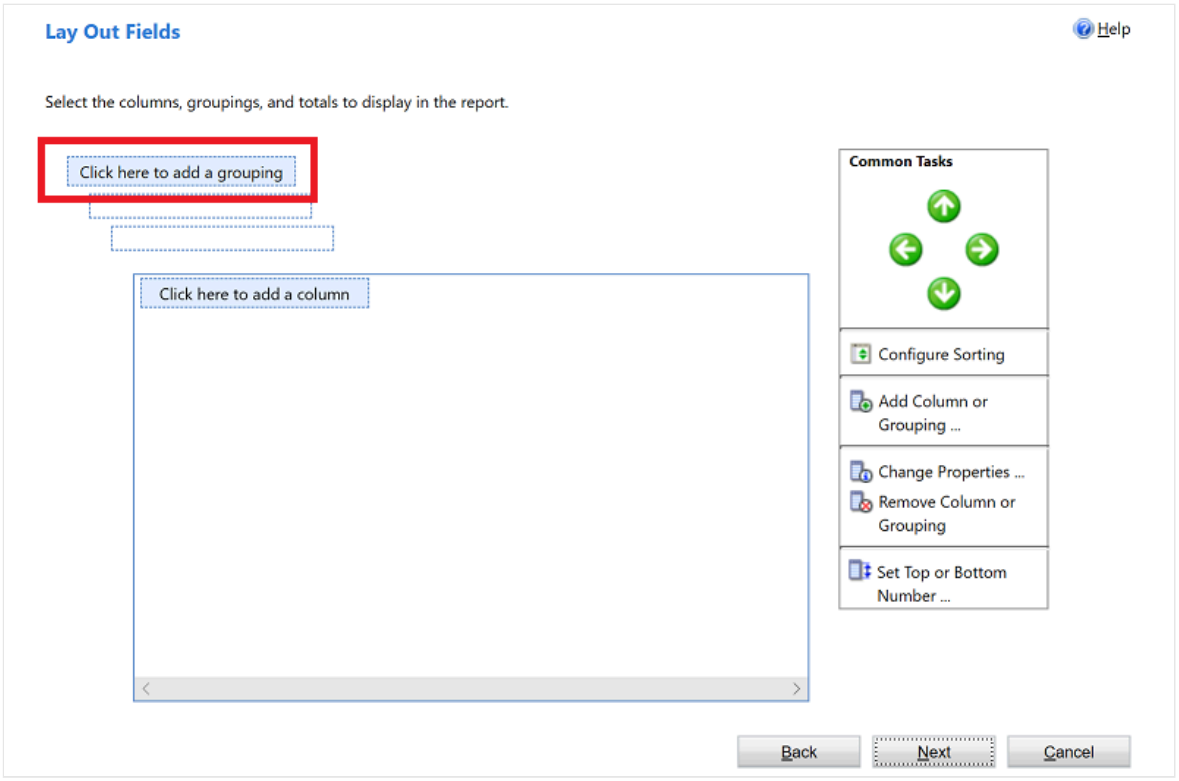
5. On the **Report Properties** screen, enter a name for the report and then choose the row to include in the report and then select **Next**.



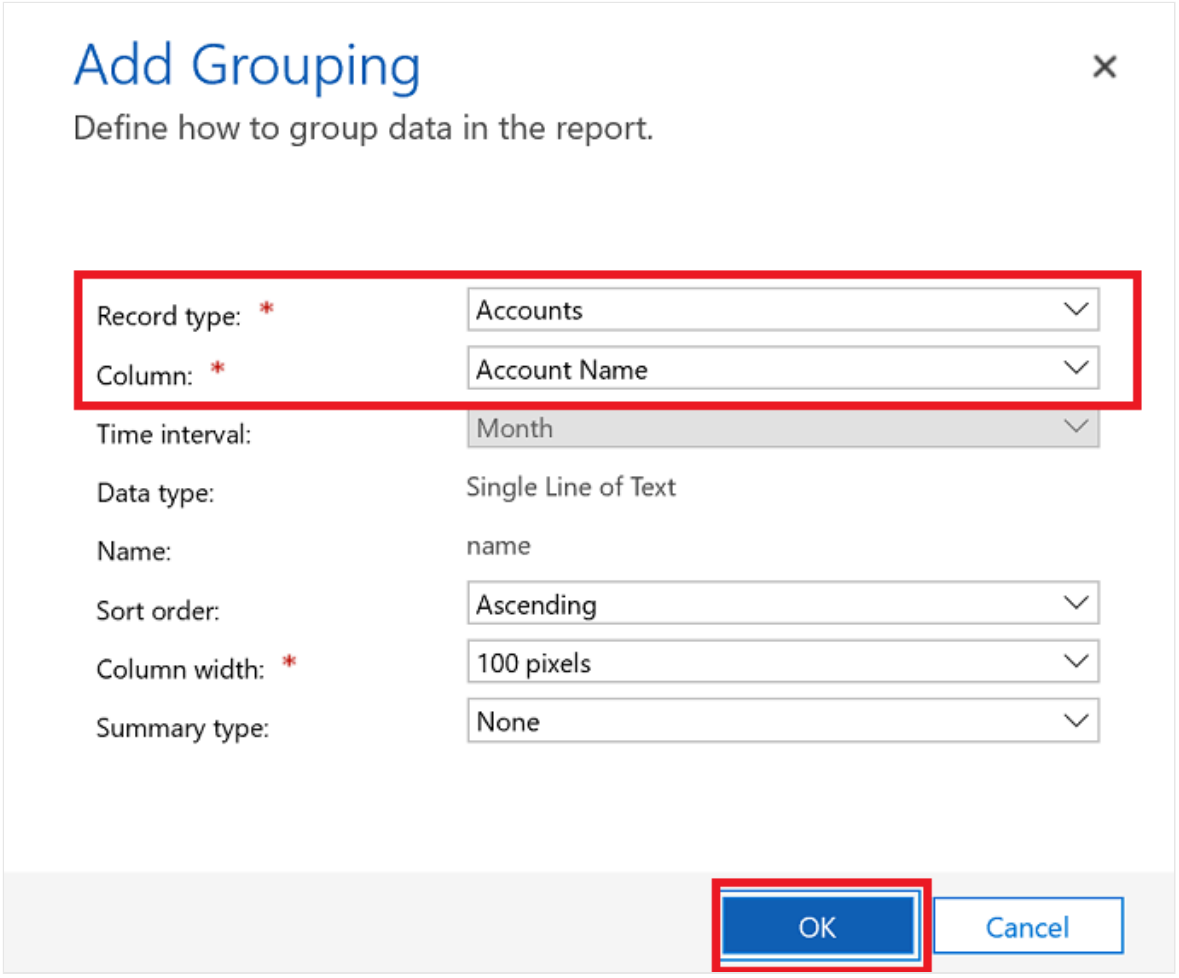
6. On the **Select Rows to Include in the Report** screen, choose the filters to determine which rows are included in your report. For example, if you only want to see results for rows modified in the last 60 days, you can set that filter in this screen. If you don't want the data filtered, select **Clear**.



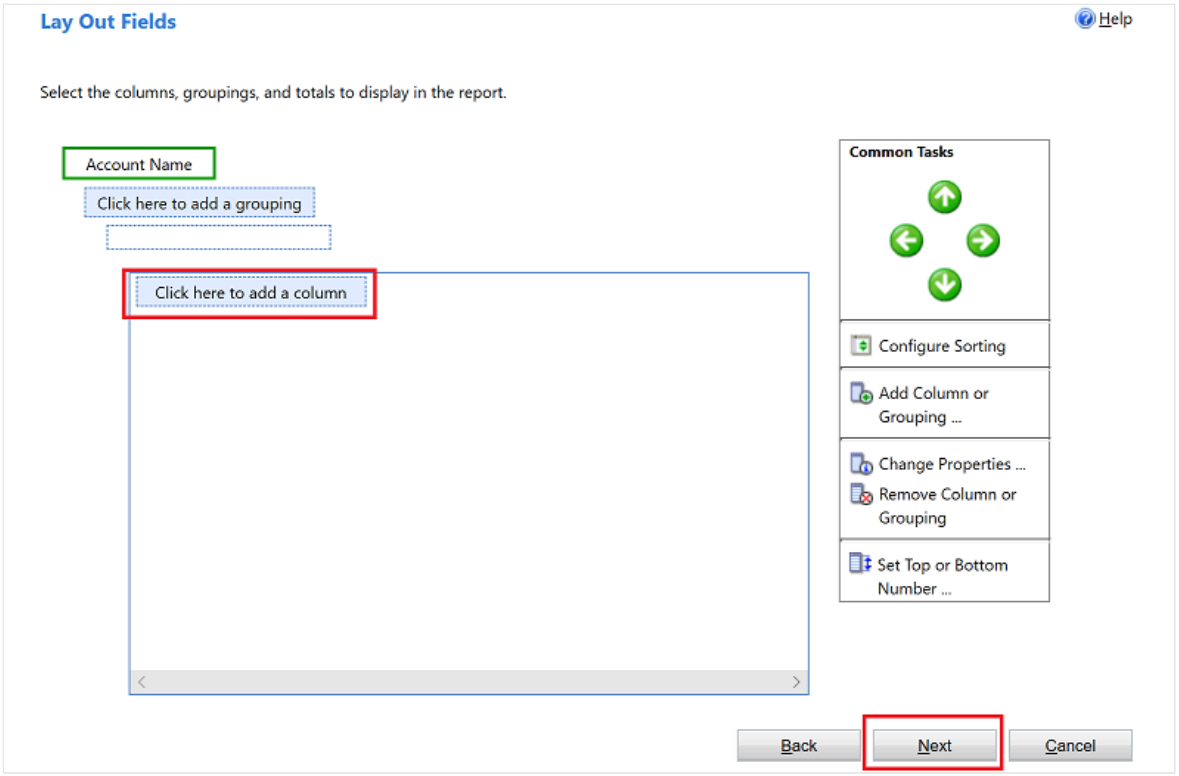
7. On the **Lay out Columns** screen, choose the layout of your report. Select **Click here to add a grouping** and choose how you want your data grouped.



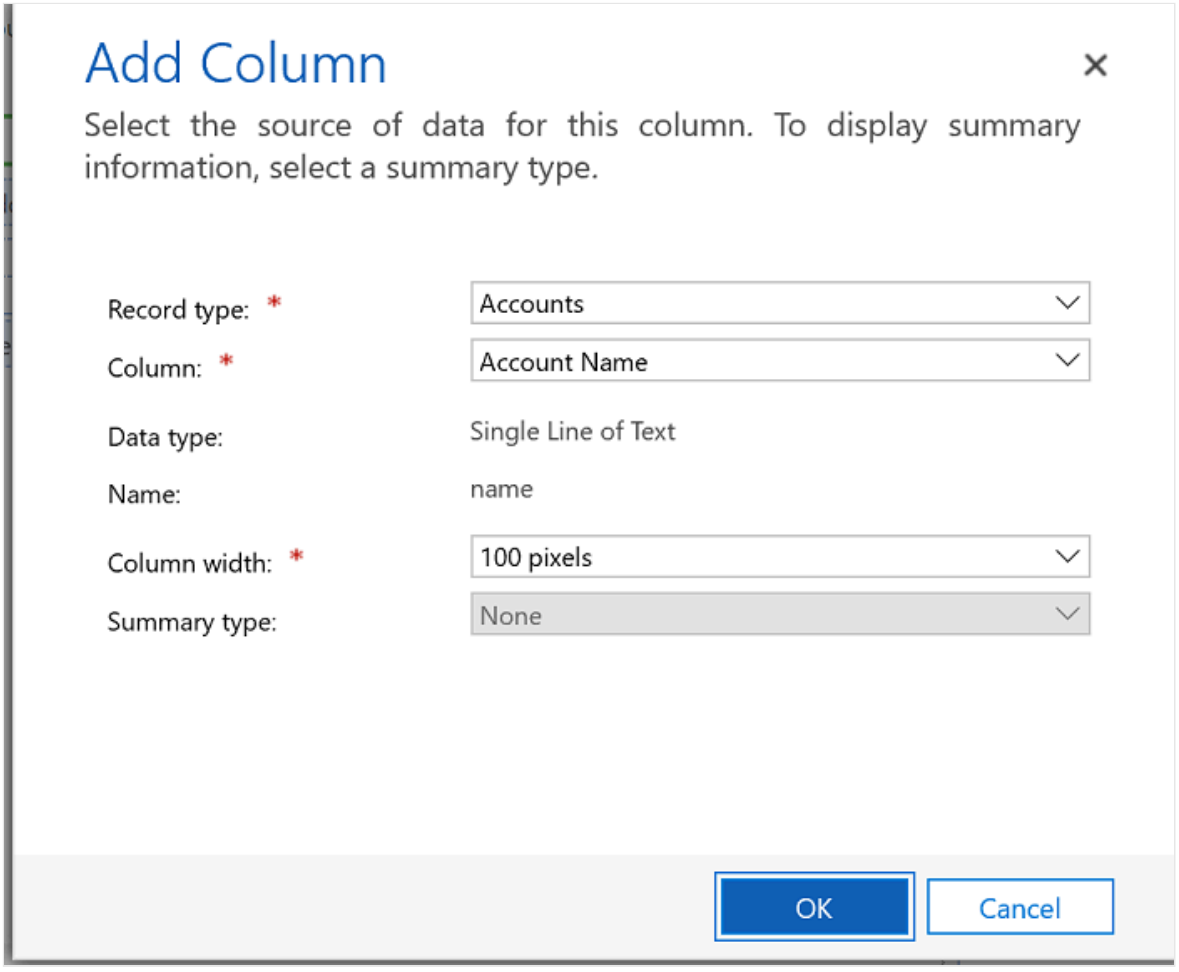
8. Select the **Row type** and the **Column** for the data you want to have grouped in the report. When you are done with your selections, select **OK**.



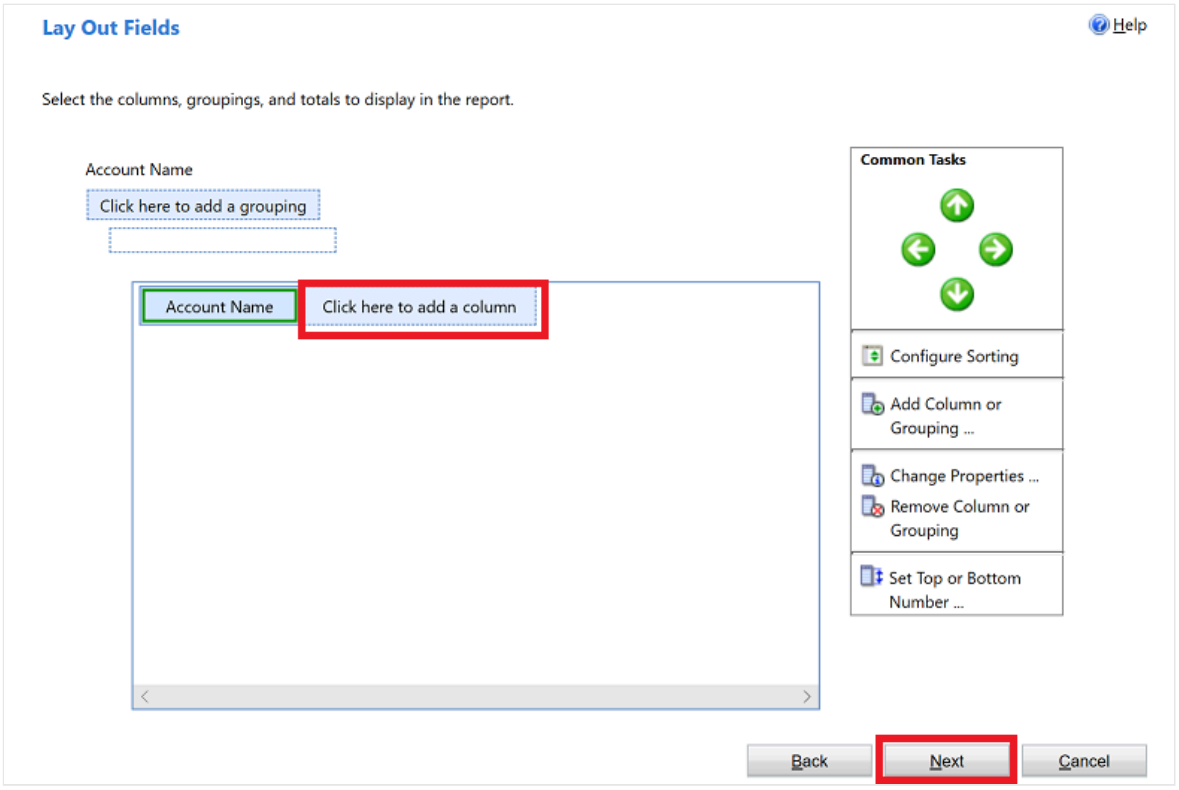
9. Select **Click here to add a column** to columns of data related to the row type you chose in the previous step.



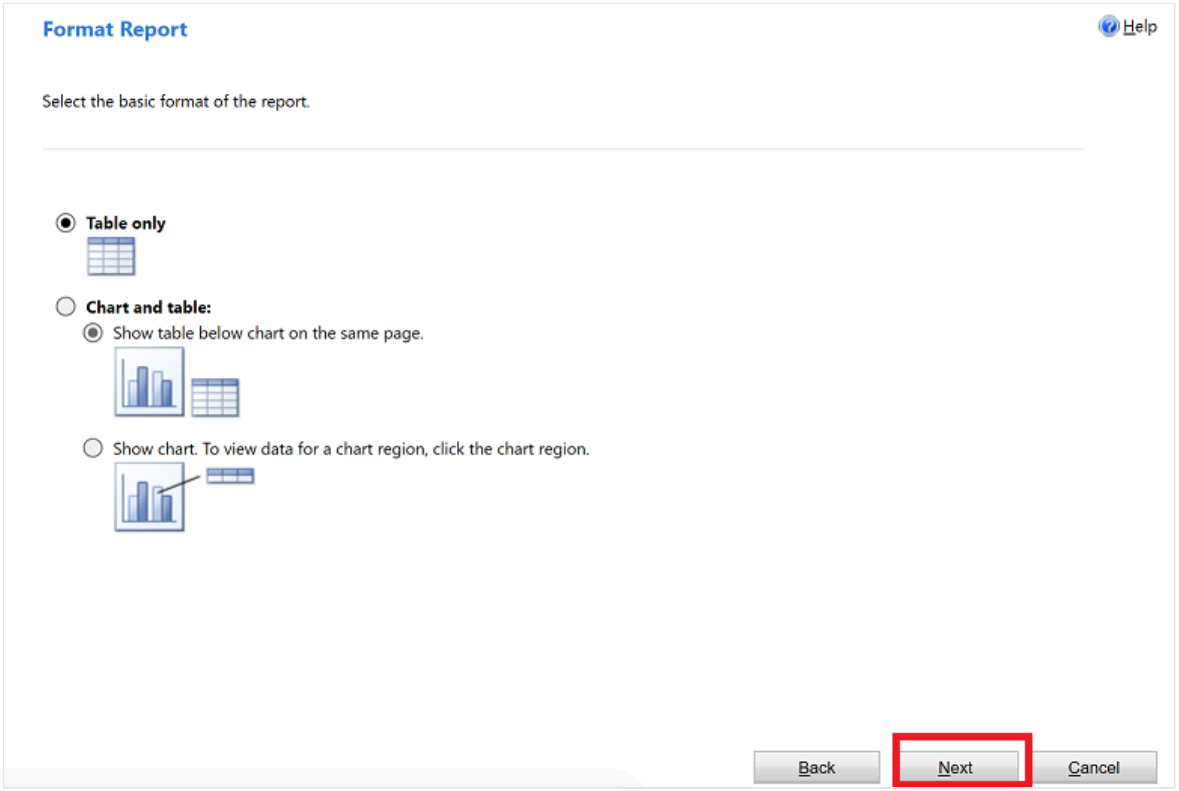
10. On the **Add Column** screen choose the data you want to have displayed for the column and then select **OK**.



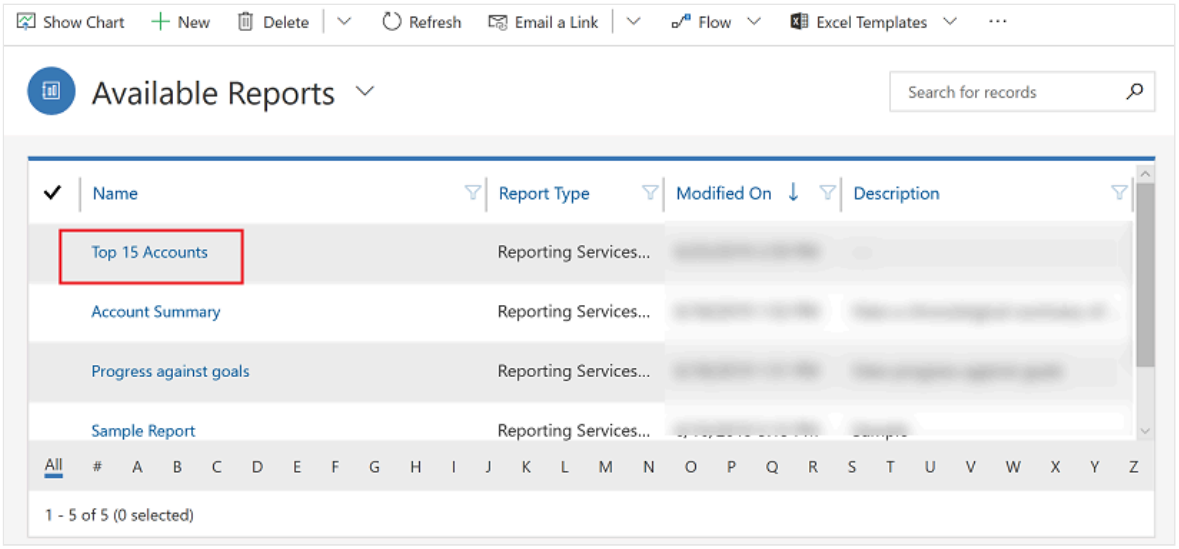
11. Repeat the previous step for any more columns that you want to add. When you are done, on the **Lay Out Columns** screen, select **Next**.



12. On the **Format Report** screen, choose how to format your report and then select **Next**.



13. Review the summary of your report and select **Next** and then select **Finish**. You can now see this report in the list of report in the system.



> **Note**
>
> The reports that are querying notes, may display in HTML-formatted text instead of plain text. This is because the rich-text editor is enabled by default. To workaround this issue, do one of the following:
>
> - Disable the rich-text editor. For more information, see Rich text editor control in Power Apps. When you disable the rich-text editor, new notes that are created will not then have the HTML tags. The existing notes that were created when the rich-text editor was enabled will still show in HTML-formatted text.
> - Update the report definition to support formatted text. For more information, see Importing HTML into a Report.
>
> Note that multi-select picklist fields are not fully supported in the Report Wizard. Multi-select picklist fields can't be added as a grouping or a column to the report.

Add a report from outside Power Apps

Article • 09/08/2022

If you've created a custom report outside of the system, you can easily add it to Power Apps.

For information about how to create a custom report, see Reporting and Analytics Guide.

1. From the left navigation pane, select the reports area.
2. On the command bar, select **New**.

   Add a file created in another application

   a. In the **Source** section, in the **Report Type** box, select **Existing File**.

   b. In the **File Location** box, enter the path and file name of the file to add, or choose **Browse** to locate the file.

      You can upload many other file types such as an Excel file but for this to run like a SQL Server Reporting Services report or Report Wizard created report, the file needs to be an .RDL file. For more information, see Report writing environment using SQL Server Data Tools.

      > ⓘ Note

> The maximum size of the report file is determined by the **Maximum file size for attachments** setting in the Email settings environment setting. However, a report definition file (.RDL) can't be more than 4 MB in size, even if the maximum file size for attachments setting is larger than 4 MB.

-OR

Add a link to a webpage

a. In the **Source** section, in the **Report Type** box, select **Link to Webpage**.

b. In the **Webpage URL** box, enter the URL of the webpage.

3. Specify the properties for the report.

   a. In the **Details** section, specify a meaningful name and description for the report.

   b. The **Parent Report** text box displays the parent report of the current report, if one exists.

   c. **Categories**. Choose the **Select or change the values for this column** button, and then specify the categories to include in this report.

   d. **Related Row Types**. To have the report appear in the Reports list on a page for specific row types, choose the **Select or change the values for this column** button, and then select row types.

   e. **Display In**. To specify where reports should be visible, choose the **Select or change the values for this column** button, and then select one or more of the options.

      If no values are selected, the report won't be visible to end users.

4. Choose **Save** or **Save and Close**.

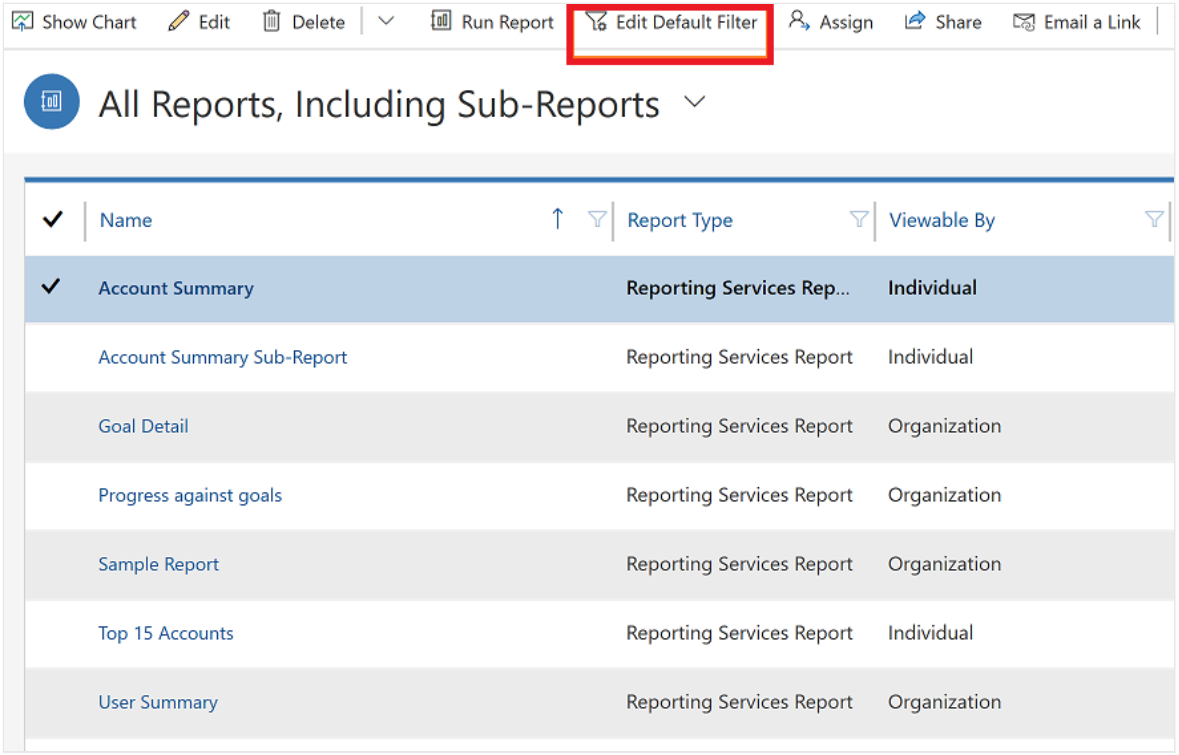
Edit the default filter of a report

Article • 12/06/2022

When a report is a SQL Server Reporting Services report, is enabled for prefiltering, and has a default filter, you can change the default filter to display the data you expect to see in the report. This filter is used each time any user runs the report.

1. From the left navigation pane, select the reports area
2. Choose a report and on the command bar, select **Edit Default Filter**.



3. Modify the filter criteria.

   The criteria are grouped by row types that you can use in the filter, such as **Accounts** or **Contacts**.

To edit an existing row

a. Select the query relational operator and select an operator, or Select the underlined value and enter a new value.

b. Select the query relational operator, and select an operator.

To add a criteria row:

a. Select **Select**, and specify the column to filter on.

b. Select the query relational operator, and select an operator.

c. Select **Enter Value**, and enter a value to filter on. For some values, you can select the **Select or change the values for this column** button  to open the **Select Values** dialog box and select the value you want.

To group criteria

You must select two or more rows for the same row type. However, rows with column values from different row types, such as **Account** and **Contact** row types, cannot be grouped.

a. For each row you want to group, in detailed mode, select the **Options menu** button for that row, and then choose **Select Row**.

b. On the Filter toolbar, select **Group AND** or **Group OR**.

c. To remove a row from a group, select the **Options menu** button for that row, and then select **Delete**.

d. To select a group, select the **Options menu** button for that group, and then select **Select Group**.

e. To add a criteria clause to a group, select the **Options menu** button for that group, select **Add Clause**, and then select the column, query relational operator, and value.

f. To unselect a group that has been previously selected, select the **Options menu** button for that group, and then select **Deselect Group**.

g. To ungroup a group, select the **Options menu** button for that group, and then select **Ungroup**.

h. To change a **Group AND** group to a **Group OR** group, or a **Group OR** group to a **Group AND** group, select the **Options menu** button for that group, and then select **Change to OR** or **Change to AND**.

Tip

- To clear all criteria and start over, on the Filter toolbar, select **Clear**, and then select **Confirm**.
- To delete a row, select the **Options menu** button for that row, and then select **Delete**.

4. When you are done, select **Save Default Filter**.

Troubleshoot problems with data not displaying in a report

Article • 02/15/2022

There are several possible reasons why data that you expect to be in a report does not appear:

- **Insufficient security permissions**. If you don't have permission in Microsoft Dataverse to view a row, it will not appear in the report.
- **Data is not entered.** The person entering data may have left columns empty.
- **Data does not match the criteria for the report.** Many reports include a default filter that displays only active rows, or you may have selected criteria that don't have any matching row. Try changing the report filter. For more information, see Edit the default filter of a report
- **You may be viewing a cached copy of the report.** By default, data in Dataverse reports is pulled from the database each time you run a report. However, your system administrator may have changed a report to run from the cache. If data you entered recently is not included in the report, you may have an older version of the report from the cache. To refresh the report, on the Report toolbar, select the **Refresh** button.
- **You may not have permission to read rows in a sub-report.** If you do not have permission to read row types that are included in a sub-report, you will get an error message saying that the sub-report could not be displayed.
- **Your Microsoft Internet Explorer privacy settings may block required cookies.** For chart reports, if instead of seeing the chart, you see a red letter X, your privacy settings may be blocking a cookie that is required for the chart control. To fix this problem, in your browser, enable cookies for the server that is running Reporting Services.

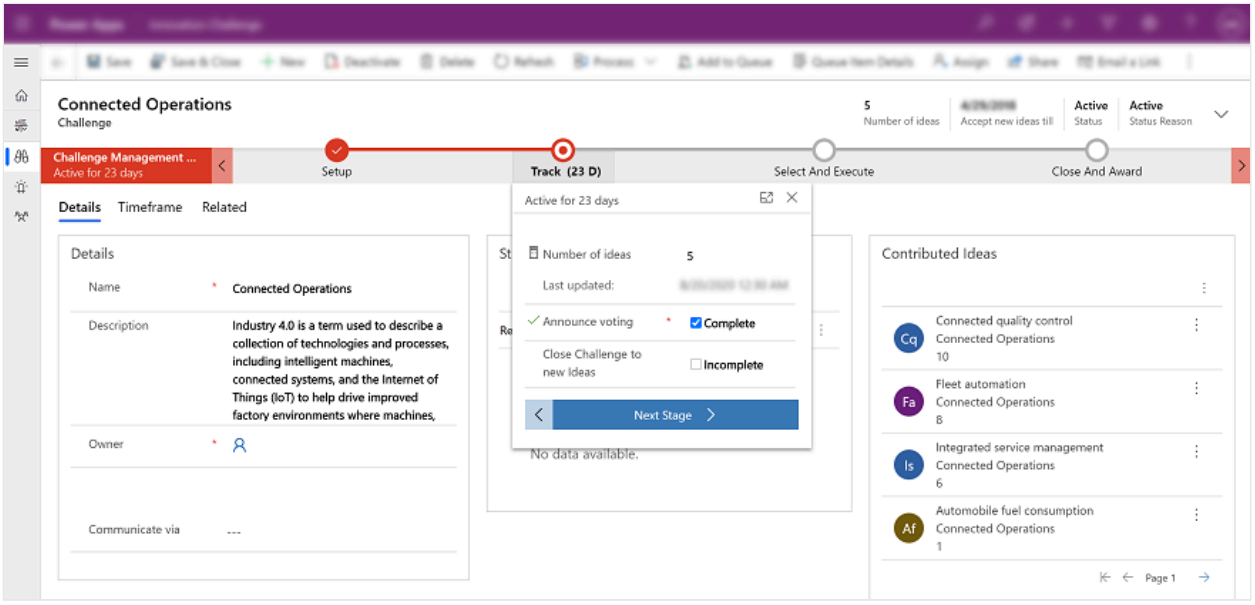
Work with business processes

Article • 10/23/2024

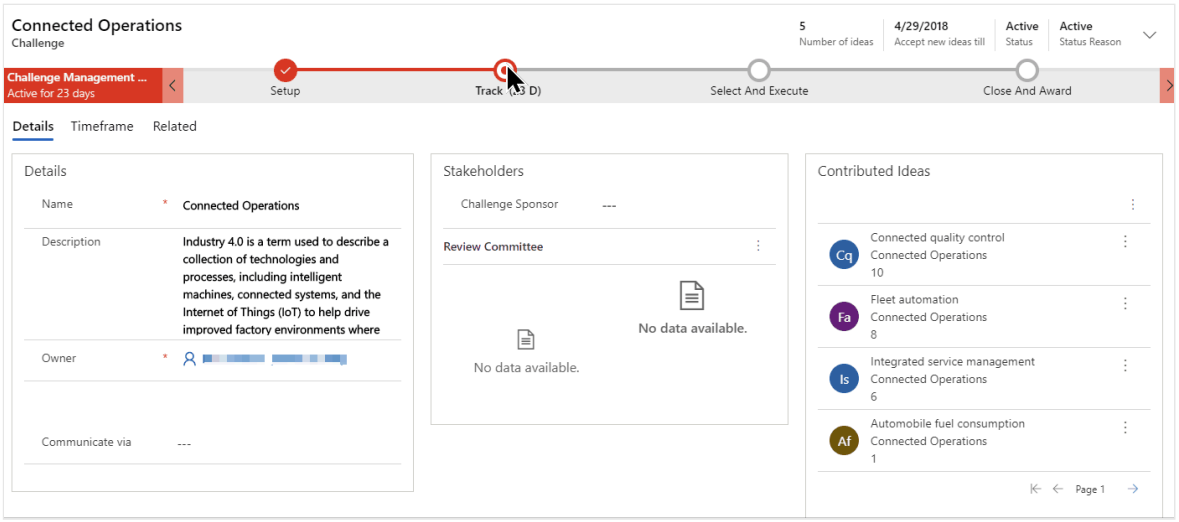
Business processes help everyone follow best practices, even for situations that don't occur often. Where available, business processes provide a step-by-step timeline for the stages of a process at the top of the relevant row. You open the menu for the active stage, enter each column of required and business-critical data, and then select the next stage when you're ready to work with it. Some business processes can be completed in the time it takes to make a single phone call, while others might take several weeks.

As you work on a new customer row, the business process flow helps you see each step that you need to take to create the new row and fill out the required information according to your organizations business process.



The process bar can also be docked to the right side of the screen for easy reference as you work with a customer row.

- On the process bar, select a stage, and then select **Pin the stage flyout** .



What if your business processes look different from these examples?

The system comes with business processes for common tasks. However, most organizations customize these processes to match the way they do things. Or, you might have added processes to the system that have been customized for your industry or business goals. In other words, what you see here may not exactly match the process bars you see on your system. But regardless, the process bars work the same for everyone. You enter data in the columns, and then move the customer to the next stage.

For more information on to how to apply custom business logic with business rules and flows, see Apply custom business logic with business rules and flows in model-driven app.

Use Power Automate to automate processes

Article • 02/15/2022

Power Automate lets you create automated processes between your favorite apps and services. From within your app, you can run a flow on one or more rows.

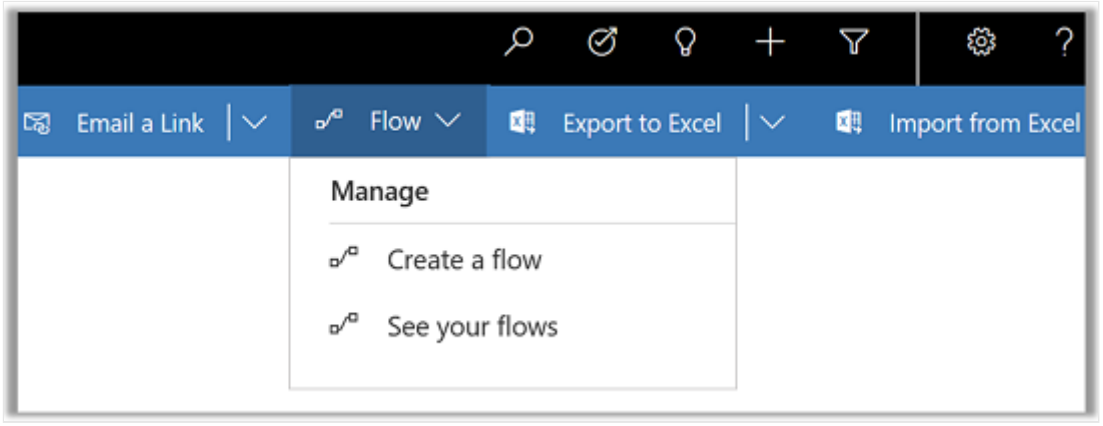
Also, you can open Power Automate from your app to view, edit, or create new flows. More information: Get started with Power Automate

Manage your flows

Connect with Power Automate from your app to manage your flows.

> **Note**
>
> To manage and run Power Automate from your app, Power Automate must be enabled in System Settings for you organization. More information: Flows in your organization

1. On the command bar, select **Flow**.



2. The following options appear:

   - Select **Create a flow** to open a new browser tab and direct you to the Power Automate site. On the Power Automate page, select **Continue** to use an existing template or **X** to close, choose, or create a different one.
   - Select **See your flows** to open a new browser tab and direct you to the Power Automate site where any flows in the Flow environment are displayed.

- Select **Login to flow** to connect with Power Automate and display available flows for you to run. This only appears if you aren't currently signed in to Power Automate.

For information about creating a flow, see Get started with Power Automate

Find it with unified search

Article • 09/26/2024

Unified search helps you quickly discover apps in Power Apps, flows in Power Automate, templates, and external web content. From a single entry point, you can find:

Expand table

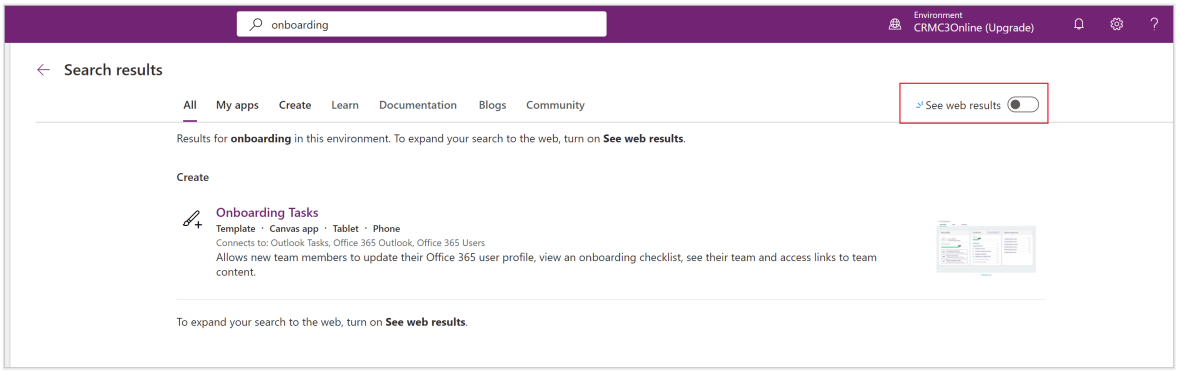
Item	Content type
(Power Apps) Apps that have been built and published	Environment
(Power Automate) Flows that have been built and published	Environment
Templates	Environment
Documentation and learn content	External web
Community content	External web
Blog posts	External web

> **Note**
>
> To open the Power Automate documentation, go to the Power Automate Overview.

Use search

By default, search displays items only from your environment, which are apps, flows, and templates.

1. To display suggestions, type in the **Search** box.
    - For Power Apps, suggestions include apps and templates.
    - For Power Automate, suggestions include flows and templates.
2. To go directly to that item, select any suggestion.
3. (Optional) To expand your search to external web content, select **See web results**.



> **⚠ Warning**
>
> Don't send personal data or confidential/proprietary information as part of your search when you choose this option.

To prevent users from using the **See web results** option to perform external web content searches for an environment, go to Manage search providers.

Manage search providers

The Microsoft.PowerApps.Administration.PowerShell module includes the cmdlets that members of either the Power Platform administrator or Dynamics 365 administrator security groups can use to modify the search providers. More information: Get started using the Power Apps admin module.

By default, all search providers are enabled, except for the docs search provider `PowerPlatform.Search.disableDocsSearch`. The following search providers can be enabled or disabled.

Expand table

Search provider namespace	Default	Description
`PowerPlatform.Search.disableDocsSearch`	True	Setting the provider namespace to True disables search for the provider. When this provider is disabled, users in the environment will see a message that Microsoft Learn and Documentation search categories have been turned off by the administrator in the search results page. When the provider is enabled, users' keywords might be sent outside their

Search provider namespace	Default	Description
		company, region, or cloud. Make sure keywords don't contain sensitive or confidential information.
`PowerPlatform.Search.disableCommunitySearch`	False	Setting the provider namespace to True disables search for the provider. When this provider is disabled, users in the environment will see a message that Community and Blog search categories have been turned off by the administrator in the search results page.

To return the current settings including which search providers are enabled or disabled, run this cmdlet: `Get-TenantSettings`

Disable a search provider

Members of the Power Platform admin role can disable or enable a search provider by specifying the search provider namespace when running the Set-TenantSettings cmdlet.

For example, to disable the Microsoft Learn and Documentation search provider, run this cmdlet:

PowerShell

```
$requestBody = @{PowerPlatform.Search.disableDocsSearch = $true}
Set-TenantSettings -RequestBody $requestBody
```

To enable the Microsoft Learn and Documentation search provider, run this cmdlet:

PowerShell

```
$requestBody = @{PowerPlatform.Search.disableDocsSearch = $false}
Set-TenantSettings -RequestBody $requestBody
```

Alternatively, run:

PowerShell

```
$settings = Get-TenantSettings
$settings.PowerPlatform.Search.disableDocsSearch = $false
Set-TenantSettings -RequestBody $settings
```

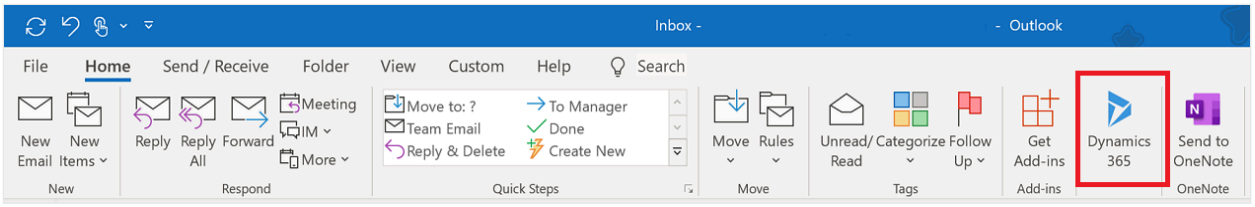
Use Dynamics 365 App for Outlook

Article • 02/15/2022

Use Dynamics 365 App for Outlook to manage your app data while using Outlook on the desktop, web, or mobile. You can view information about an email or appointment or link it to a row in your app.

When Dynamics 365 App for Outlook is installed, in the Outlook ribbon select **Dynamics 365** to open the **Dynamics 365** pane next to a selected Outlook email message, or when you're composing an email message or setting up a meeting or appointment.



What Dynamics 365 App for Outlook offers?

With Dynamics 365 App for Outlook, you can:

- Track your emails and appointments in Outlook and associate them to the right record in your app.
- Synchronize contacts and related information so that Exchange and your app are always up to date.
- View information about Dataverse contacts and accounts while you're working in Outlook. You can view this information in the context of an email message, meeting, or appointment. For example, view phone numbers, company name, last and next activities, and recent rows.

For information on using Dynamics 365 App for Outlook, see Basic navigation in App for Outlook.

Overview of the new Power Apps vibe experience (preview)

[This article is prerelease documentation and is subject to change.]

The new Power Apps vibe experience is an AI-native platform that builds solutions to business problems, including requirements, data, and full apps with generated code. You can automate workflows, integrate data sources seamlessly, and accelerate app development without extensive coding knowledge.

Why choose Power Apps vibe?

The vibe experience transforms how you build business applications by combining three key capabilities in a single, integrated workspace:

- **Rapid prototyping**: Go from idea to working app in minutes, not weeks. Simply describe your business needs in natural language, and AI generates a complete solution including data models, business logic, and user interface.
- **Unified development**: Instead of switching between separate tools for planning, data modeling, and app building, work with everything in one place. Make changes to your plan, data, or app, and see updates automatically reflected across all components.
- **AI-powered assistance**: Get intelligent suggestions, code generation, and guided problem-solving throughout the development process. The AI understands your business context and helps you make better architectural decisions.

Ideal for: Business analysts, citizen developers, and professional developers who want to build line-of-business applications quickly without getting bogged down in technical implementation details.

Common use cases: Employee onboarding apps, inventory management systems, project tracking tools, customer feedback applications, and departmental workflow solutions.

Watch this video to see the vibe experience in action. The video demonstrates how to create a complete business application from a simple text description:

https://learn-video.azurefd.net/vod/player?id=085271a3-bec6-4740-89df-044f984466d2&locale=en-us&embedUrl=%2Fpower-apps%2Fvibe%2Foverview

After watching the video, explore the detailed walkthrough in Create apps, data, and plans together to understand the full development process.

> **Important**
>
> - This feature is in preview.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Prerequisites

- A tenant admin must enable Copilot for the tenant. To enable Copilot, admins should:

  1. Sign in to the Power Platform admin center.
  2. In the navigation pane, go to **Settings** to open the **Tenant settings** page.
  3. Set the toggle for **Copilot in Power Apps (preview)** to **On**.
  4. Select **Save** to apply the changes.

- **Optional but recommended**: For higher quality apps, enable **Anthropic models** by going to Power Platform Admin Center > **Environments** > **[Name of Environment]** > **Settings** > **Features** > **Enable External Models**.

  For more information, see Tenant settings.

- This capability isn't available in a default environment.

- This capability is currently available only in the US, Australia, Asia, and India regions, and only in English. For more information, see Explore Copilot features by geography and languages.

Troubleshooting connectivity issues

If you're experiencing connection errors or can't access environments:

- **Verify environment region**: Ensure you have access to an environment located in the US, Australia, Asia, or India region. You can check your environment region in the Power Platform admin center:

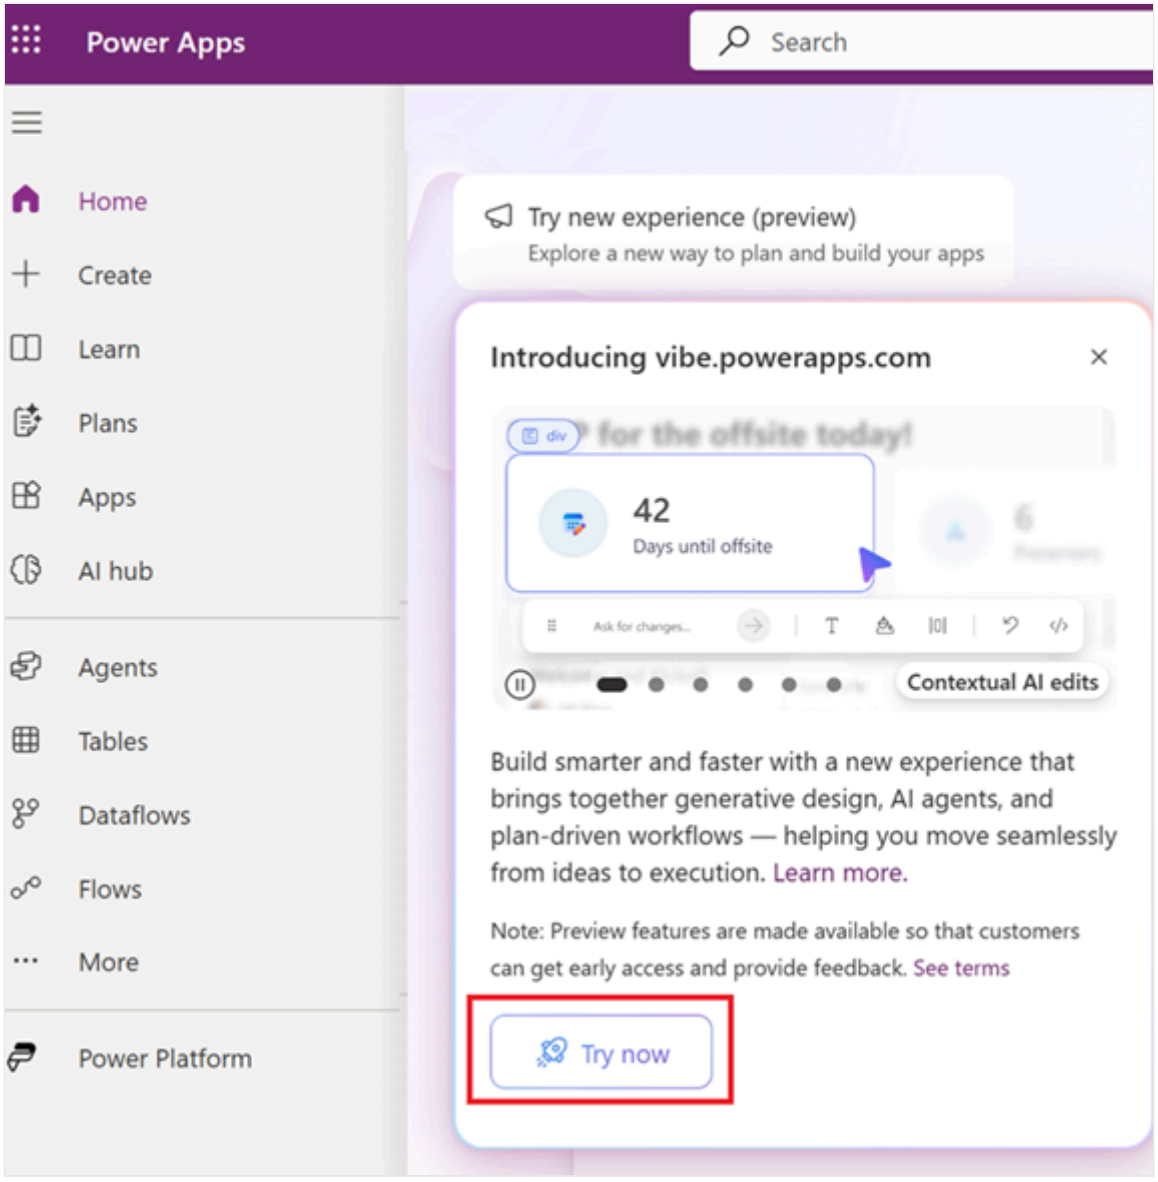
1. Sign in to the Power Platform admin center.
2. In the navigation pane, select **Manage** > **Environments**.
3. Locate the **Region** column to see where your environments are hosted.

For additional support with connectivity issues, contact Power Platform support.

Access Power Apps vibe

You can access the new vibe experience in one of two ways:

- Go to https://vibe.powerapps.com and sign in to start using the new experience.
- Alternatively, sign in to Power Apps. At the top, select **Try new experience (Preview)** to enable it.

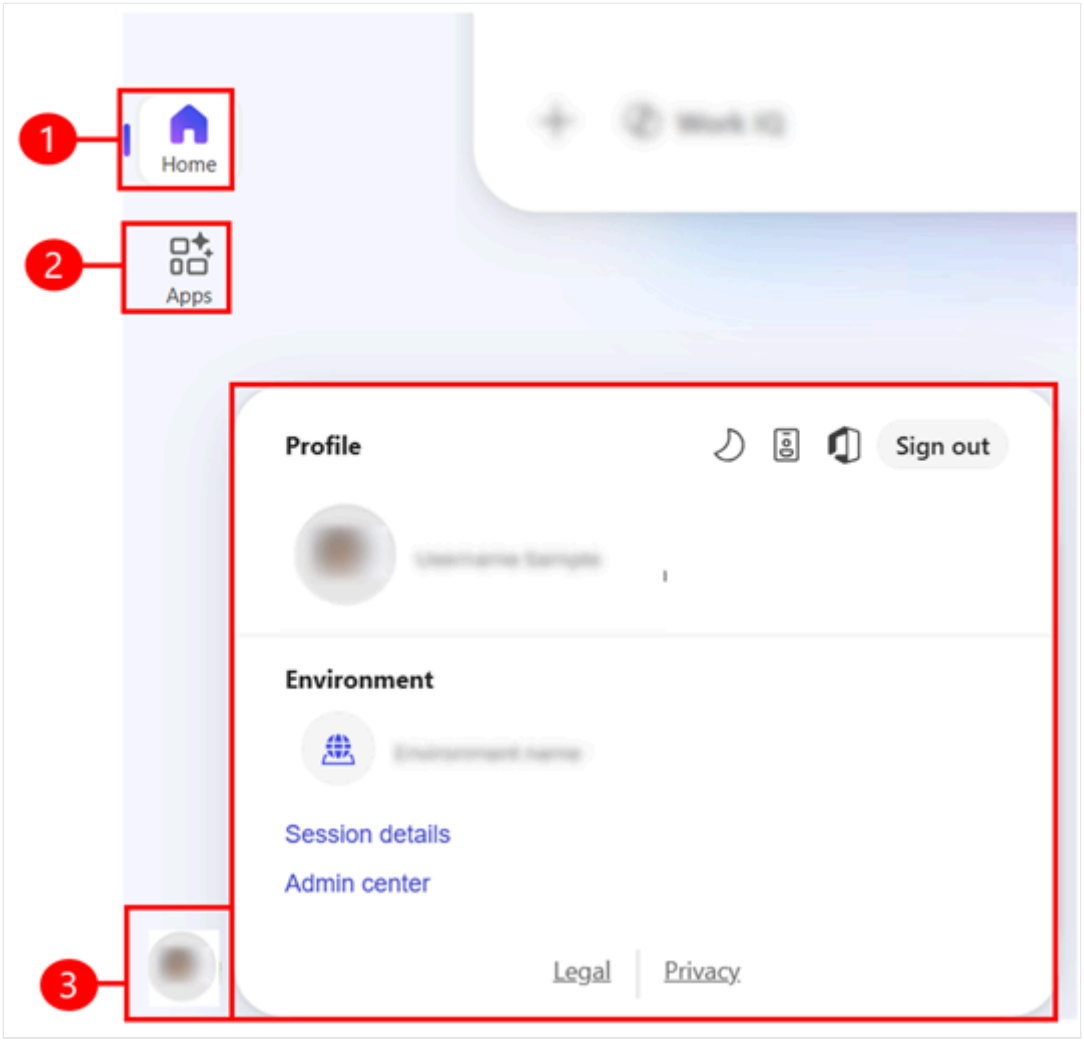


> **Note**

If you access the new experience through Power Apps, you need to enable it each time you sign in.

Navigation

The left navigation shows the following items:

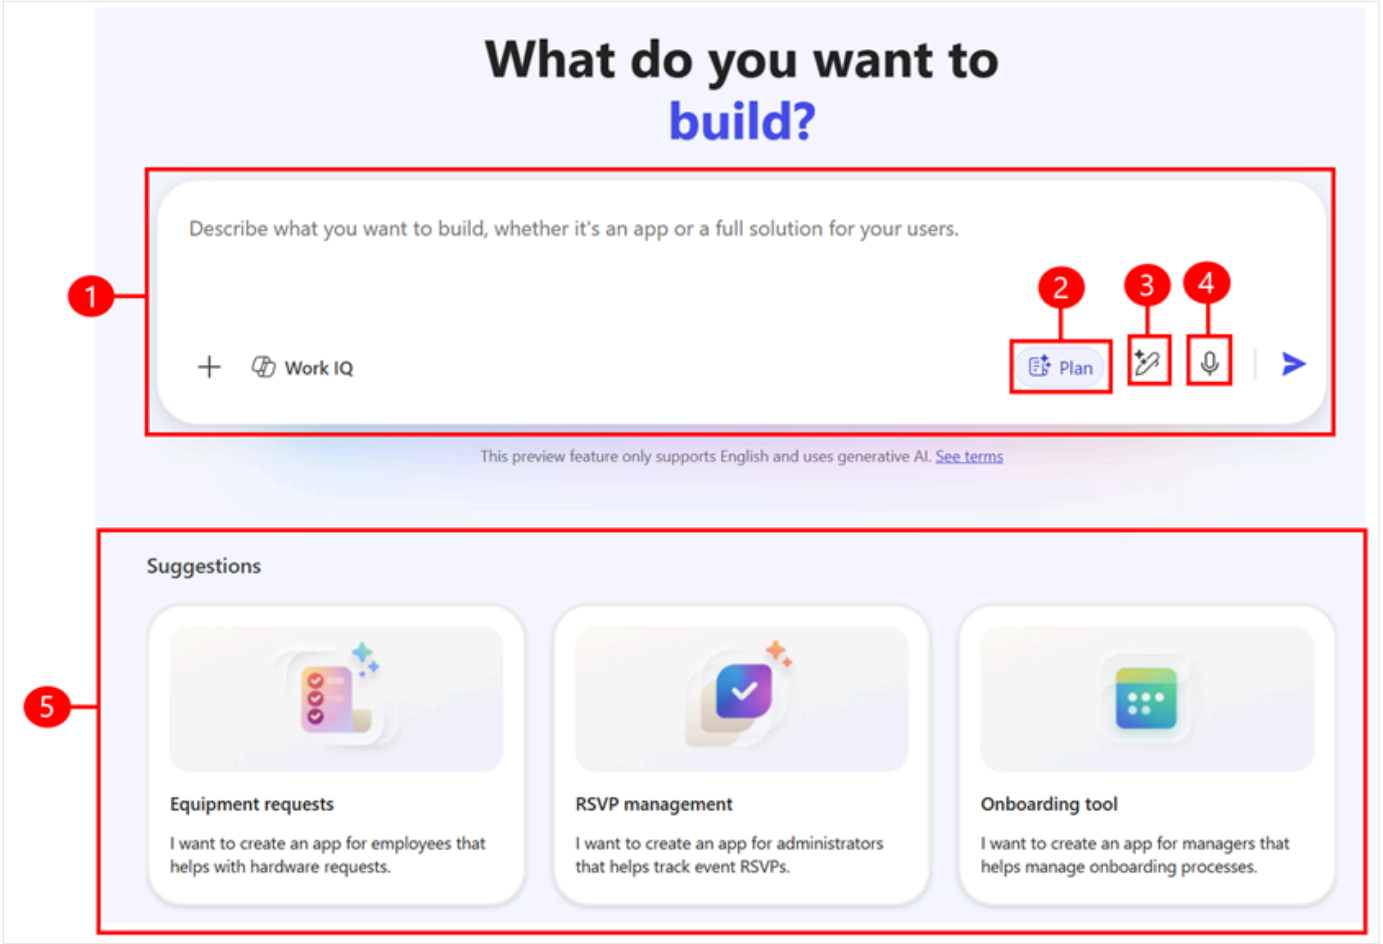


Legend:

1. **Home**: Returns you to the main landing page.
2. **Apps**: Open, play, or edit apps you created or that others shared with you.
3. **Profile**: Access the environment picker, session details, notifications, and settings.

Enter your prompt to build apps

Describe your idea using natural language.



Legend:

1. **Enter prompt**: Type a description of what you want to build.
2. **Plan**: Use this mode to review and discuss a plan with agenta before making changes.
3. **Enhance prompt** (Optional): Add more detail to your prompt before generating your app.
4. **Start dictation**: Start speech to text and speak into a microphone to convert your voice into text.
5. **Suggestions**: Want to experiment? Select one of the suggestions to explore the new app-building experience.

Create apps, data, and plans together using vibe (preview)

[This article is prerelease documentation and is subject to change.]

The new vibe experience in Power Apps combines plans, data models, and apps in a single design surface. This integrated approach minimizes distractions and keeps you focused on building solutions efficiently.

Key capabilities

- **Design everything together**: Build apps, plans, and data models together in a single, cohesive process.
- **Build faster with AI**: Quickly move from ideas to working prototypes with conversational chat.
- **Instant app creation**: Generate modern web apps directly from your requirements and data with one click.

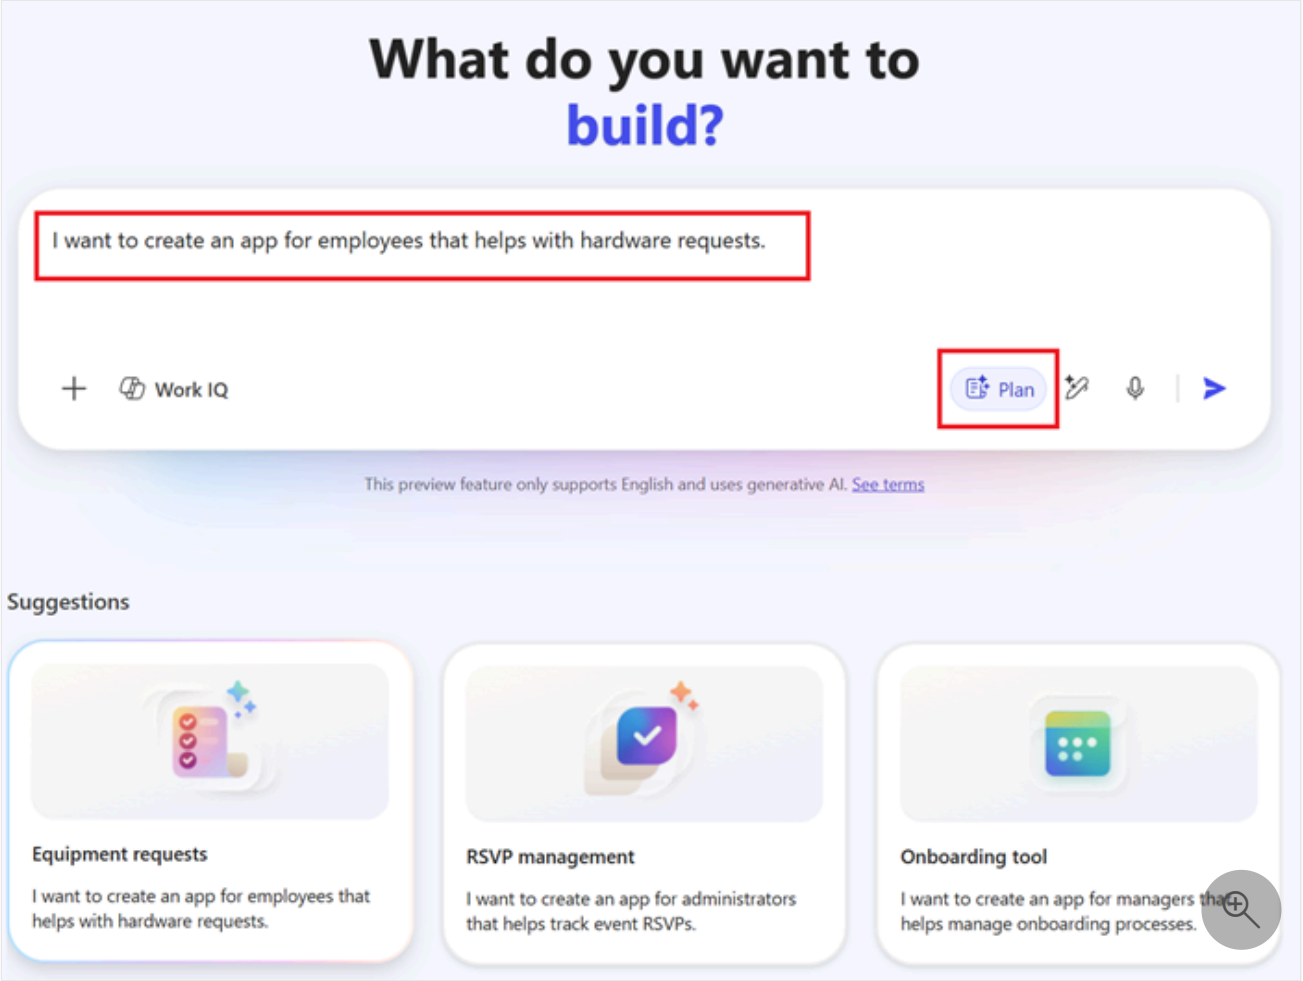
> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Create an app

1. Sign in to https://vibe.powerapps.com.
2. Enter your prompt in the text box. **Plan** mode is the default mode, which means it starts with a plan that includes potential clarifying questions before building the app. You can also select **Start dictation** and use your voice to turn speech into text.

   > **Tip**

To skip planning and start creating apps, select **Plan** again to turn it off.



3. In **Plan** mode, the agent shows you a proposed plan to review before generating the app. It might also ask follow-up questions to clarify your requirements.

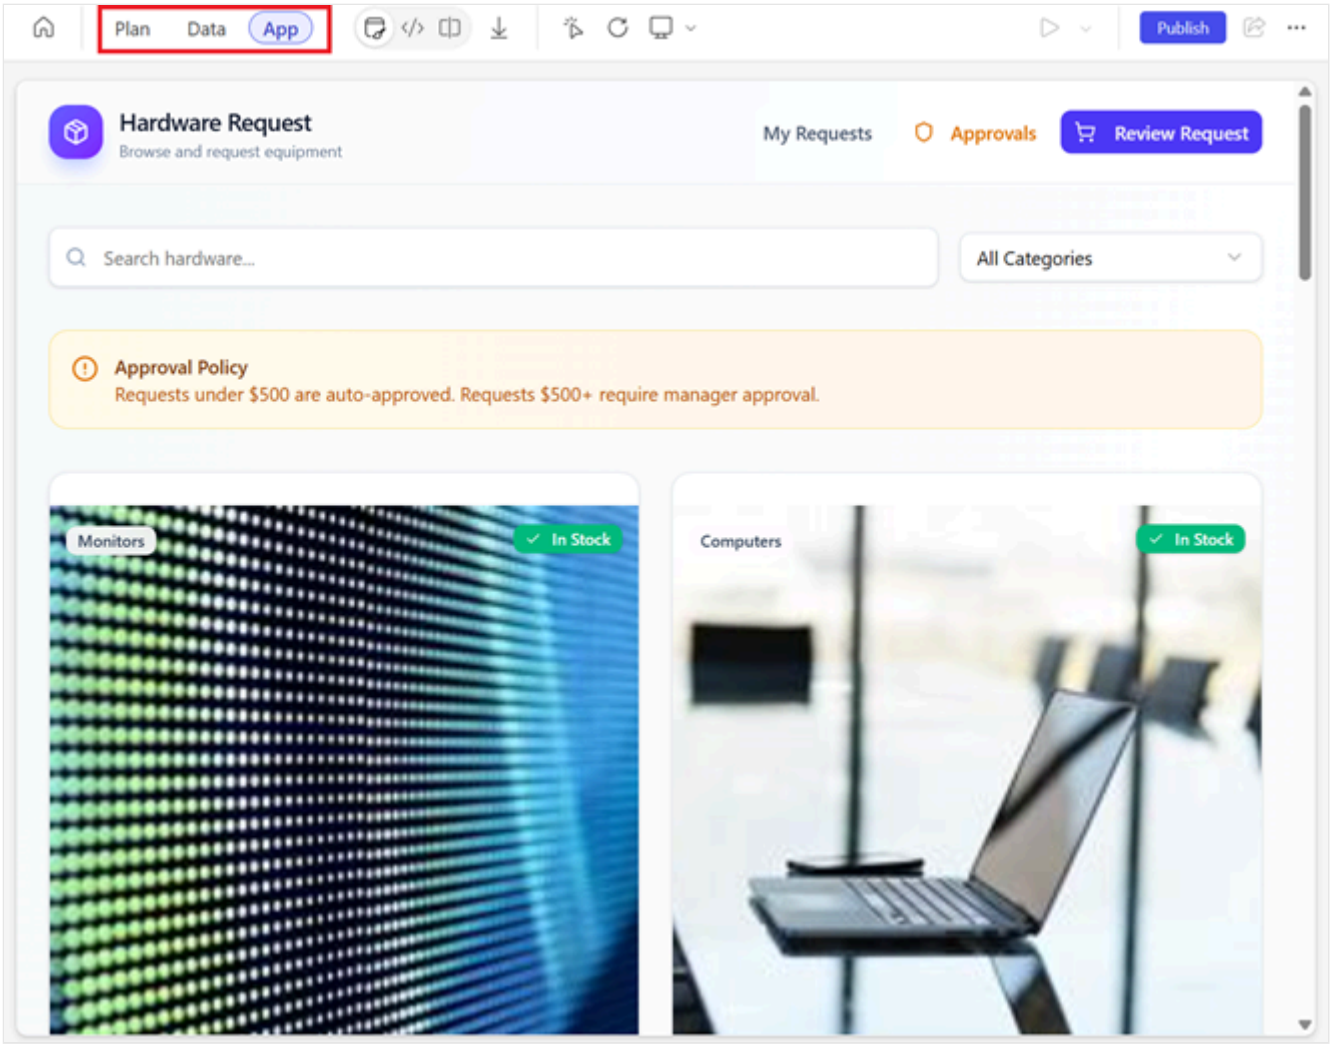
4. When the plan looks good, select **Accept this plan and create app** > **Submit** to start generating your app.

5. The agent starts working and loads assets. When it's finished, you have a generated app, data model (if applicable), and a plan (if applicable). You can then make any necessary edits.

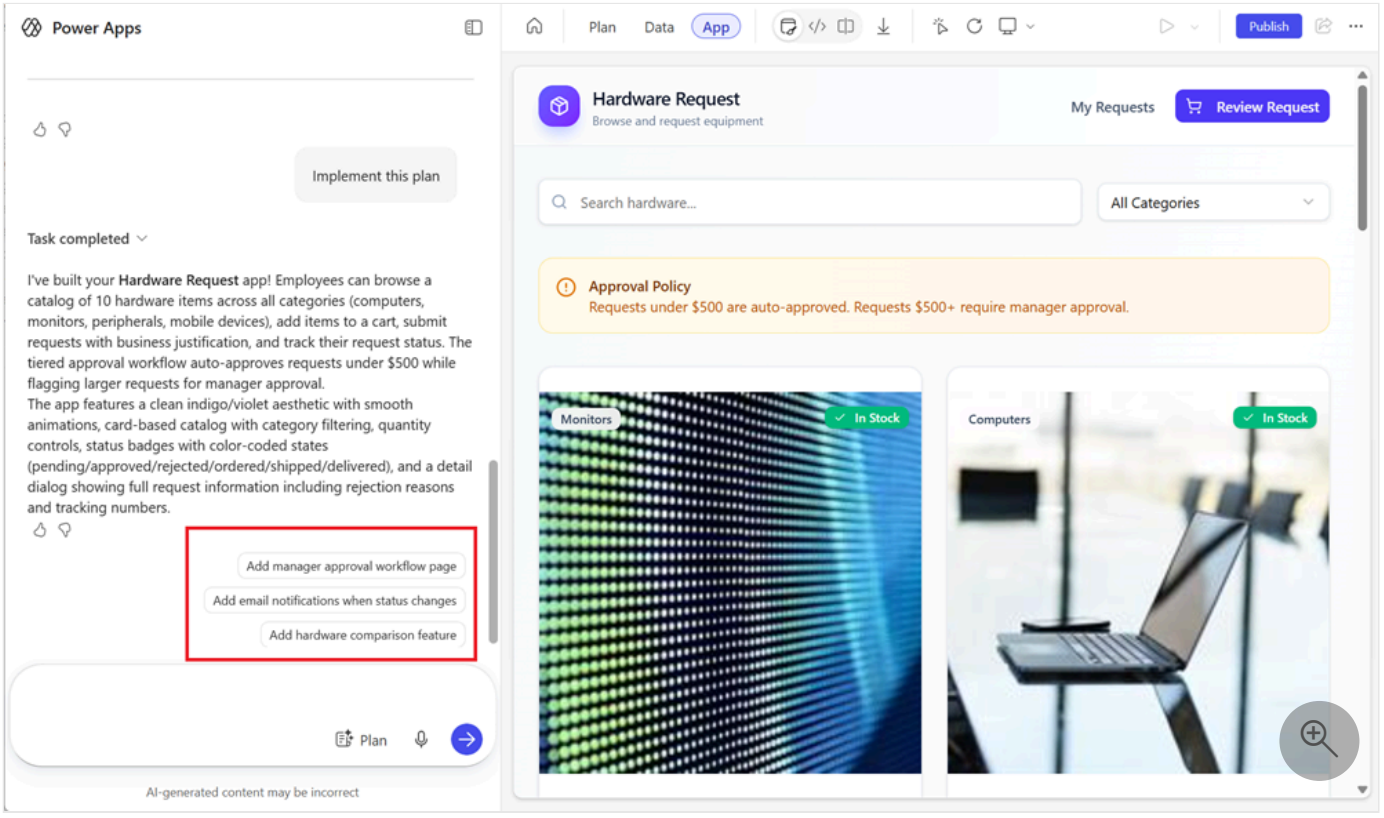
6. The first save stores the app, tables, and plan together in your selected solution, while your data remains in draft tables (in memory). If you don't see a **Save** button in the top right of the screen, your app is autosaved automatically.

Review and refine your generated app and data model

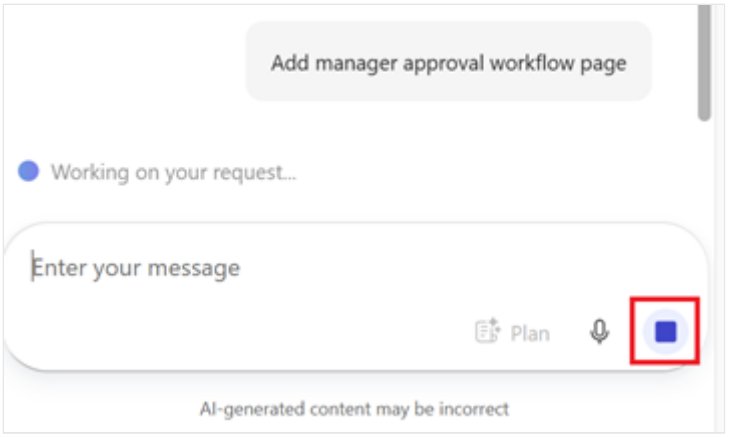
The new workspace uses a unified chat experience that keeps context as you switch between **Plan**, **Data**, and **App**. It speeds up development by letting you preview the app visually, inspect the code, and make changes without leaving the workspace.



A list of next actions appears above the chat area to suggest relevant next steps.

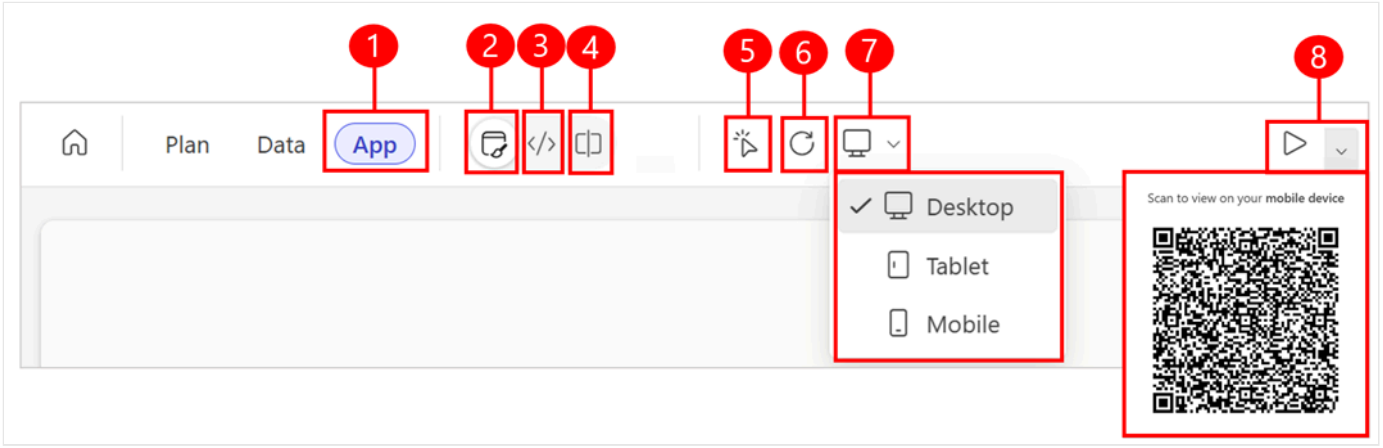


If you submit a request and then decide to cancel it, select the stop button.



Focus area

Each focus area displays its specific tools above the work surface. For instance, when you select the **App** focus area, you see these options:



Legend:

1. **App**: When selected, this focus area displays menu options specific to the app.
2. **Preview**: View a live preview of the app.
3. **Code**: Access and review the app's code.
4. **Split**: See both the code and the app preview side by side.
5. **Toggle inline edits**: Select any area in the app and edit its text directly.
6. **Refresh preview**: Reload the app preview to see the latest changes.
7. **Select preview screen size**: Choose **Desktop**, **Tablet**, or **Mobile** to see how your app renders across screen sizes and orientations.
8. **Play**: Run the app to test behavior and interactions. Use the drop-down to show a QR code, then scan it to open the app on your mobile device in a browser.

Edit the generated app

When generation finishes, the visual preview appears in focus on the work surface.

You can interact with the app directly, using the navigation items and buttons to see how they function and respond.

To inspect the code, switch to **Code** view or **Split** view. Expand the **src** folder to see subfolders and files, and select any file to view the generated code.

When you modify the app, plan, or data, the agent analyzes your changes to see if updates are needed elsewhere in the solution. If so, the agent automatically applies updates and summarizes them in the chat.

Edit the app using chat

Use the chat input on the work surface to ask questions or request changes to the generated app. For example: "What does this button do?" or "Change theme to blue."

- **Plan mode**: To discuss potential changes with the agent before applying them, select **Plan** in the chat box. The agent proposes a plan for your review. Once you accept it, the agent executes the plan and makes the necessary edits. When the edits are complete, **Plan** mode turns off automatically.
- **Questions**: If you ask a question, the agent provides an explanatory response.
- **Change requests**: If you request a change, the agent evaluates the request, outlines an implementation plan, and then applies it.
- **Unsupported changes**: If the agent can't implement the change directly, you receive step-by-step guidance or instructions for retrying the request.

Edit the app using inline actions

Use inline actions to edit the style of your app.

1. Select the option to toggle inline edits.
2. Select the item you want to edit. The element is outlined and labeled with the corresponding code object so you know exactly what you're editing.

   Depending on the element type, a properties pane or inline controls appear for typography, styling, or layout. Adjust values like font, color, or spacing directly in the pane.

   > **Tip**

If multiple elements share the same style, a single change applies across the group. For example, changing a button color inside a card updates all buttons in that card group.

Inline edits update the associated code directly without involving the AI agent.

You can also open inline chat on a selected element and request a change like **Make this button primary blue**. The element's context is passed automatically, so you don't need to describe it in the prompt.

3. When you're done, review the result in the visual preview. If needed, switch to **Code** view or **Split** view to inspect the generated files.

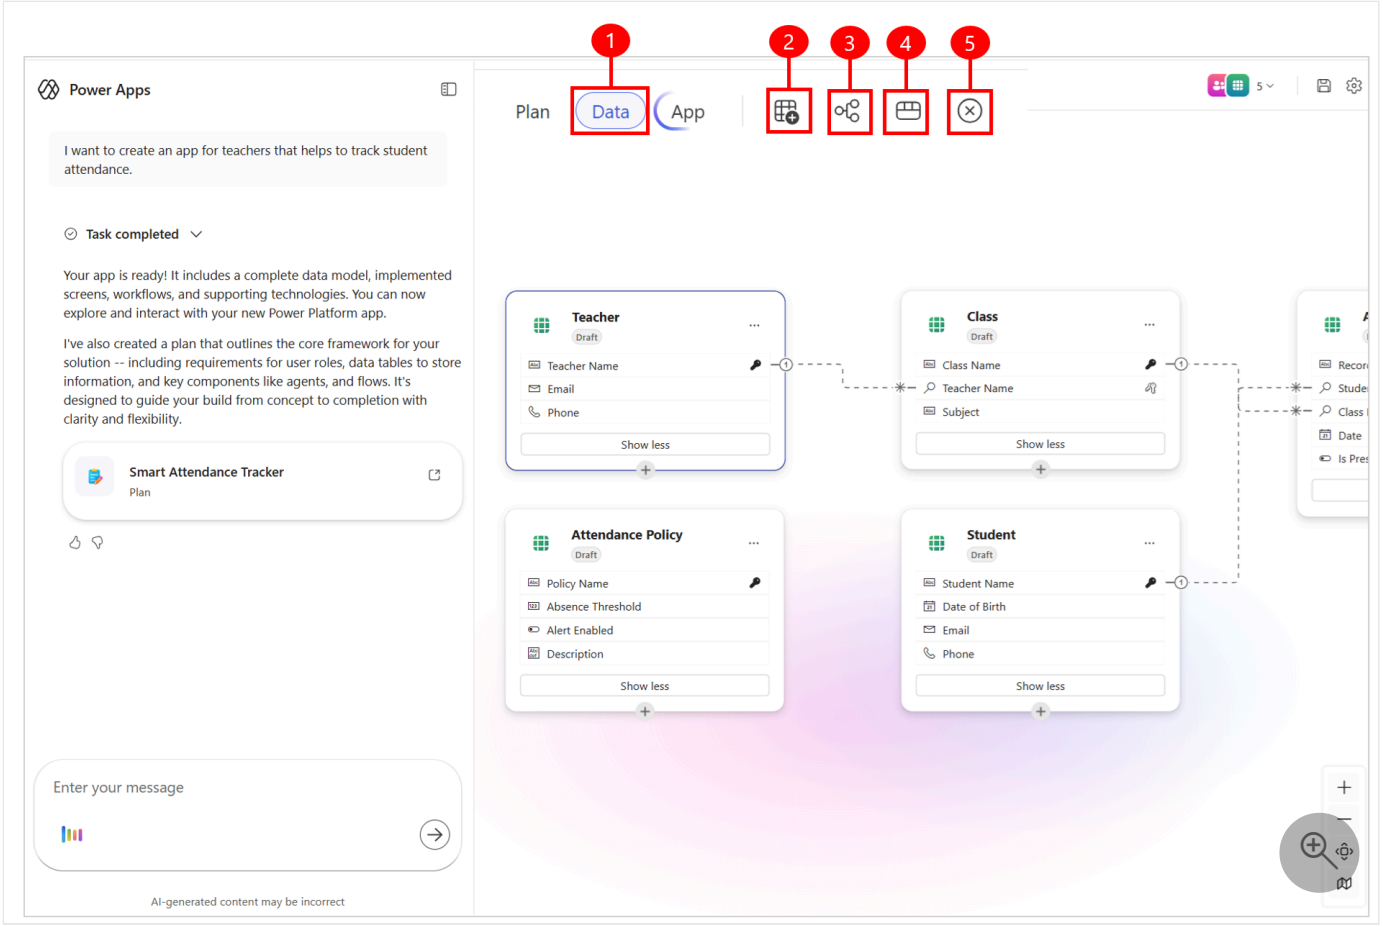
Keyboard shortcuts for inline actions

Use keyboard shortcuts to open and close inline edit actions while editing your app.

- **Hold and release Alt** to toggle the inline edit gesture.
- **Press Esc** to dismiss the inline edit gesture.

Edit the generated data model

Select **Data** to review and refine your data model. The data view displays all proposed tables, their relationships, and sample data to help you understand the schema and how the generated app uses the data. The tables exist in memory only and aren't published to a data source until you explicitly publish them. You can modify them until they meet your business needs. For more information, see Create and edit tables using Power Apps.



Legend

1. **Data**: Edit the data model directly in this view.
2. **Add table**: Add a draft or existing table.
3. **Create relationships**: Creates a table relationship between two tables.
4. **Data view**: View the data workspace experience where you create tables, configure table relationships, and can view a diagram of your data.
5. **Remove**: Deletes the table and all associated table rows.

Edit data using chat

Use the chat to ask questions or request changes to the proposed fields, tables, and relationships.

You can also ask for more sample data to enrich your dataset for the app. The agent analyzes your requests and makes the necessary updates.

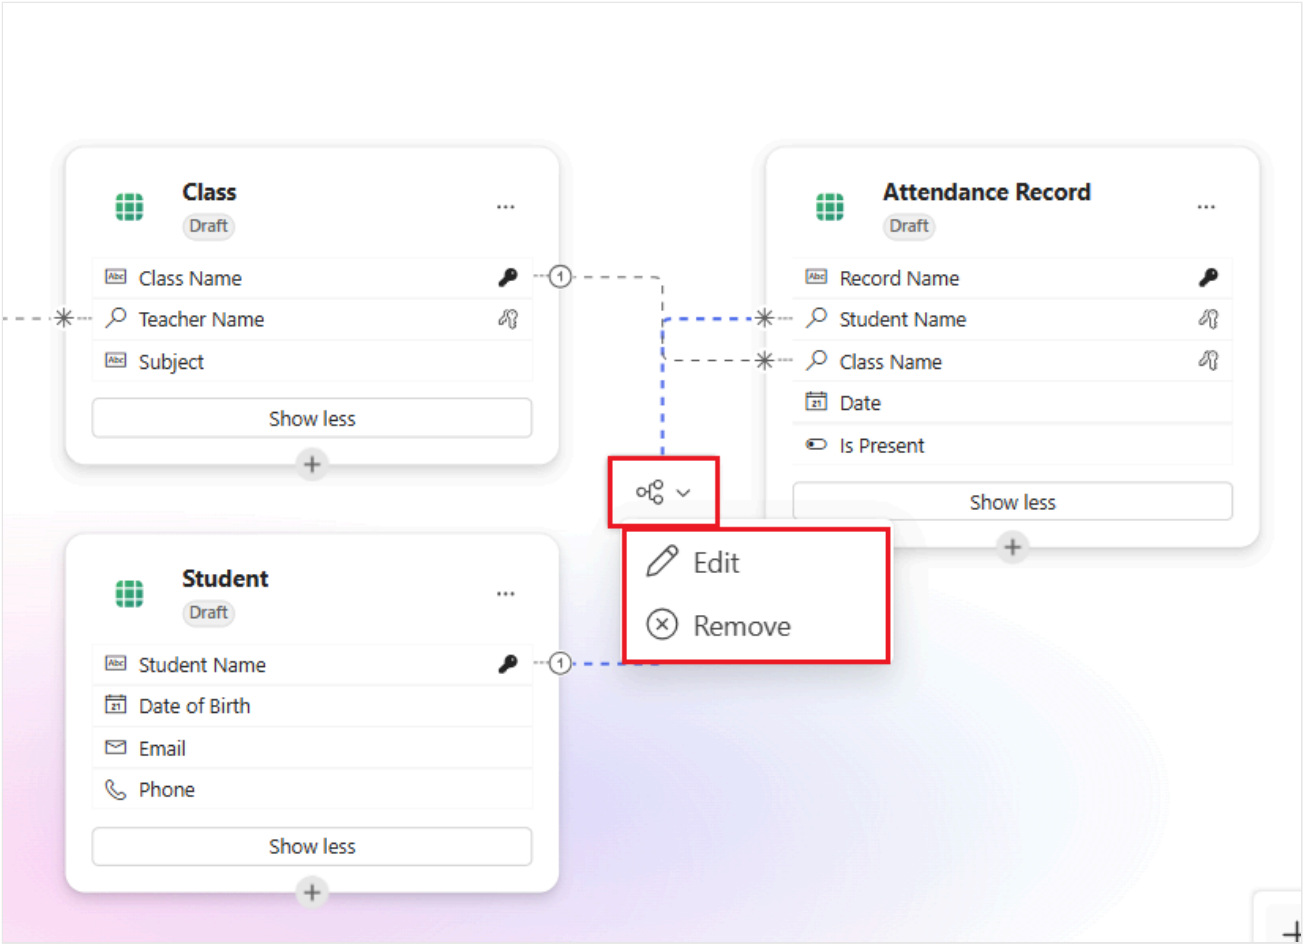
Some actions might not be supported through agent chat. For more information, see the limitations section in the article.

Edit data using inline actions

Add new or existing tables, or make targeted changes to relationships, tables, and sample data directly within the data workspace.

1. To edit data, select the relationship line or the ellipsis (...) next to the table you want to modify.

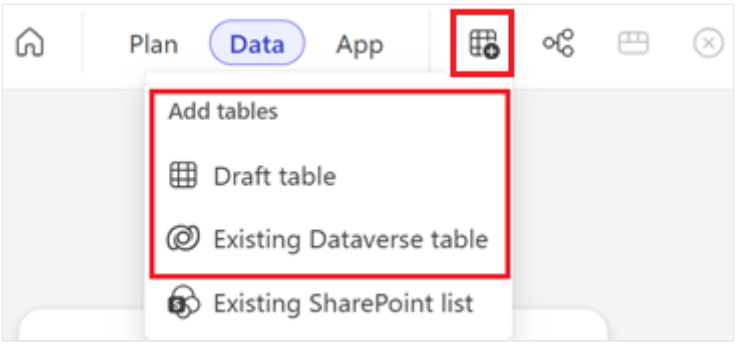
2. Select **Remove** to remove relationships or tables from the data model, or make specific edits as needed.



Add a data table

1. Select **Add table** in the command bar to include a new or existing table in your data model.

2. Choose **Draft table** to create a new in-memory table from scratch, or select **Existing Dataverse table** to add data you already have.



> **Note**
>
> You can also add SharePoint data. For more information, Add a SharePoint list in Power Apps vibe.

Add and edit relationship

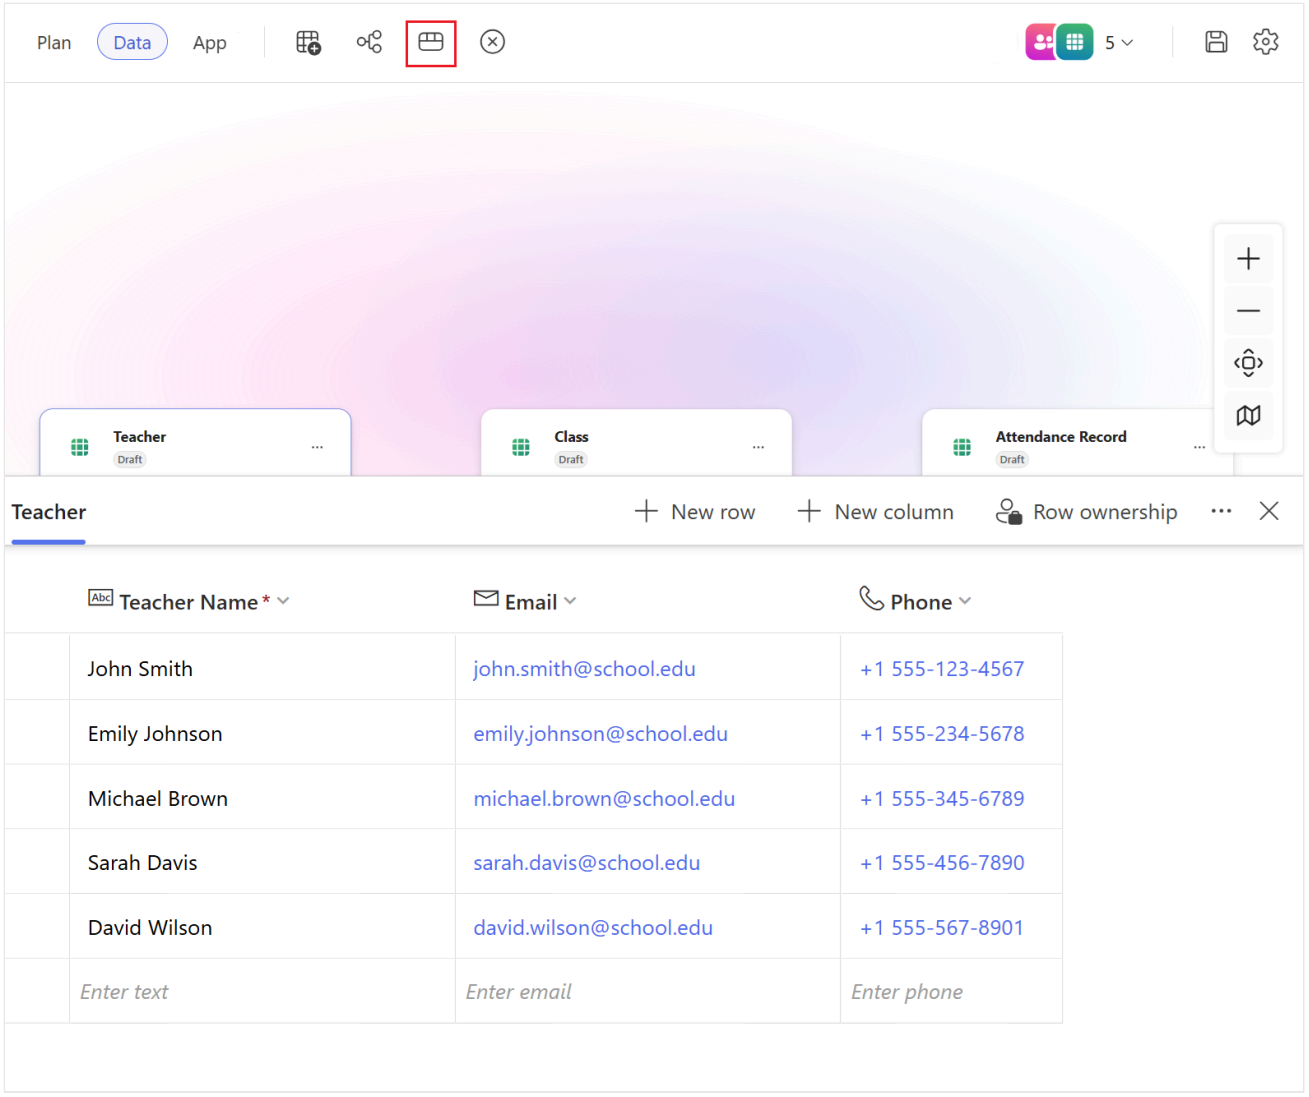
1. Select **Add relationship** in the command bar to add a new relationship between two tables.
2. To edit a relationship, select the relationship line between two tables and select **Edit** from the dropdown menu. Change the relationship type or add a lookup column. You can also perform advanced edits like changing the logical names used in the relationship.
3. Some relationship configurations currently aren't supported. For more information, see Known limitations.

Remove a data table

1. Select the table you want to remove.
2. Select **Remove** in the command bar.
    - If you remove a draft table, you delete it along with all its rows.
    - If you remove an existing Dataverse table, the table and its data remain in the original source; you only remove the reference from your solution.

View and edit data in a table

1. Select **View data** from the command bar.

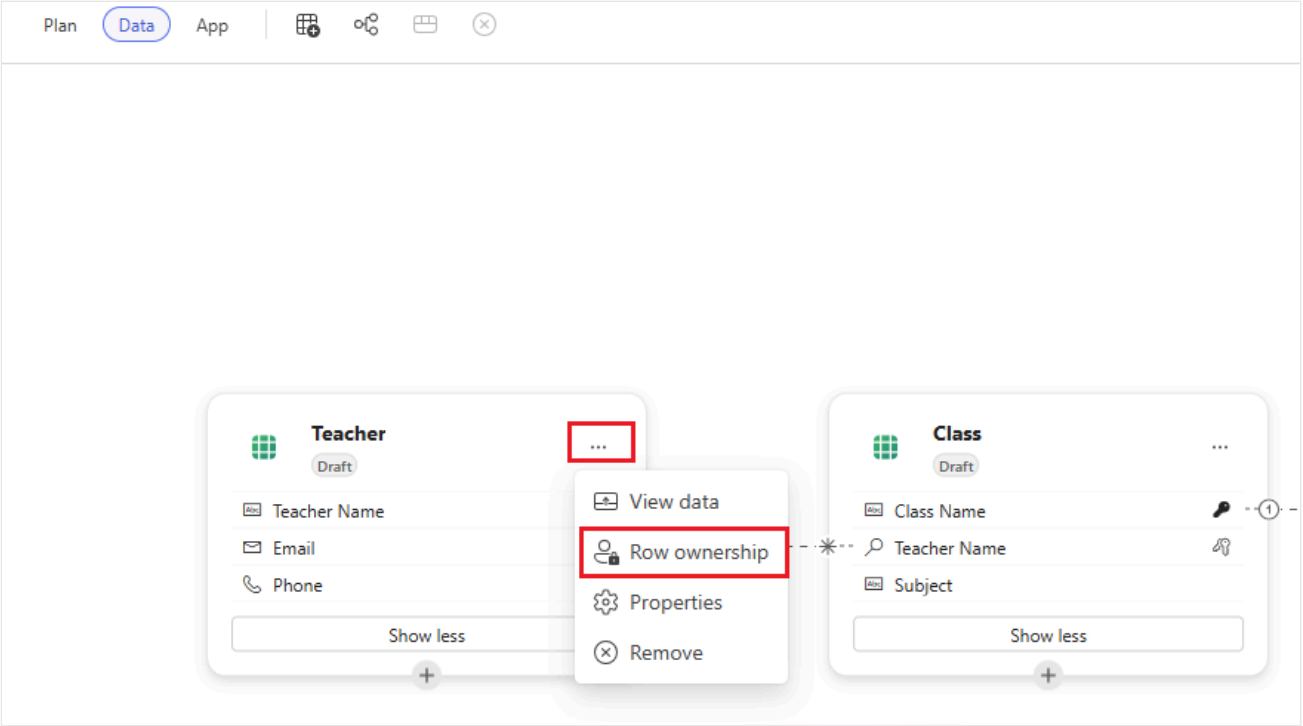


2. In this view, you can add, remove, or modify columns and rows as needed.

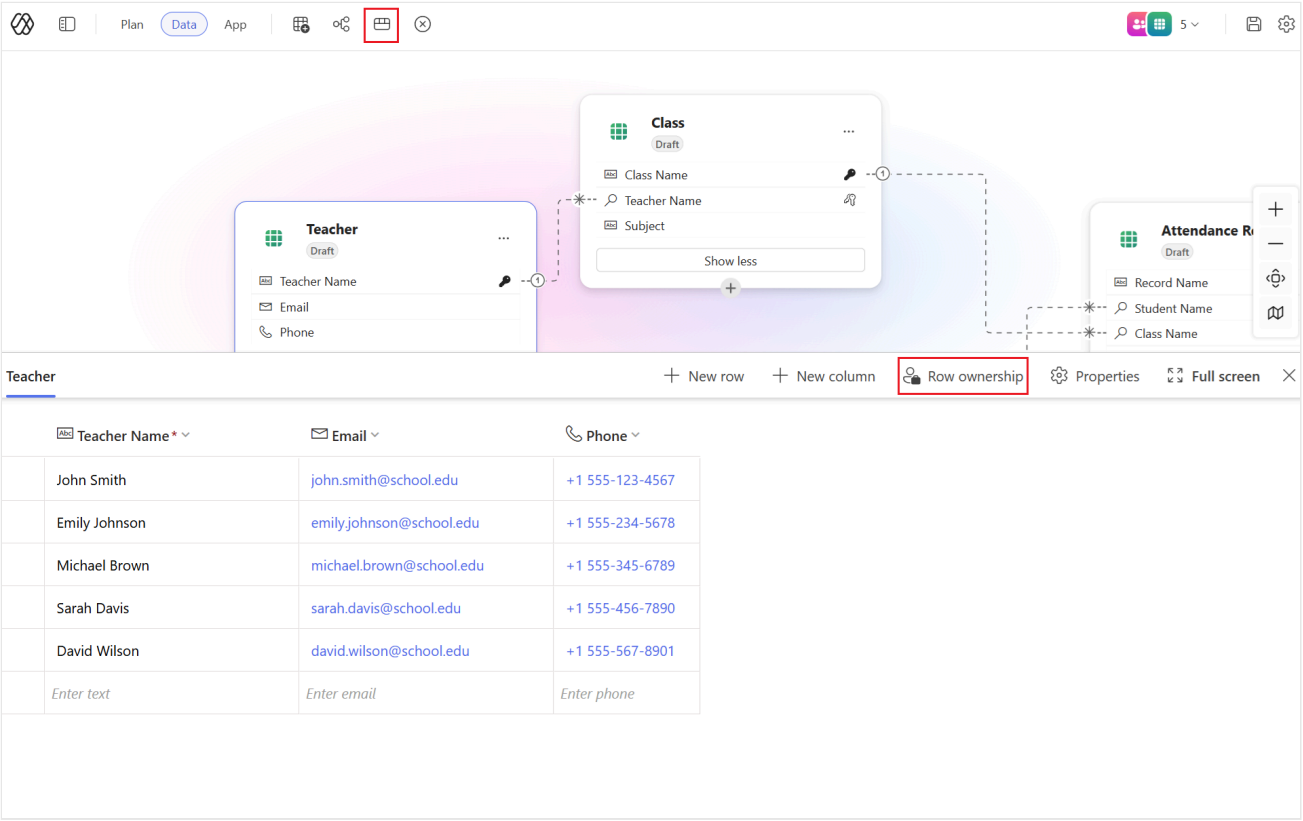
Row ownership

To change the ownership type to **User**, **Team**, or **Organization**, use one of the following methods:

1. Select **View options**, and then select **Row ownership**.

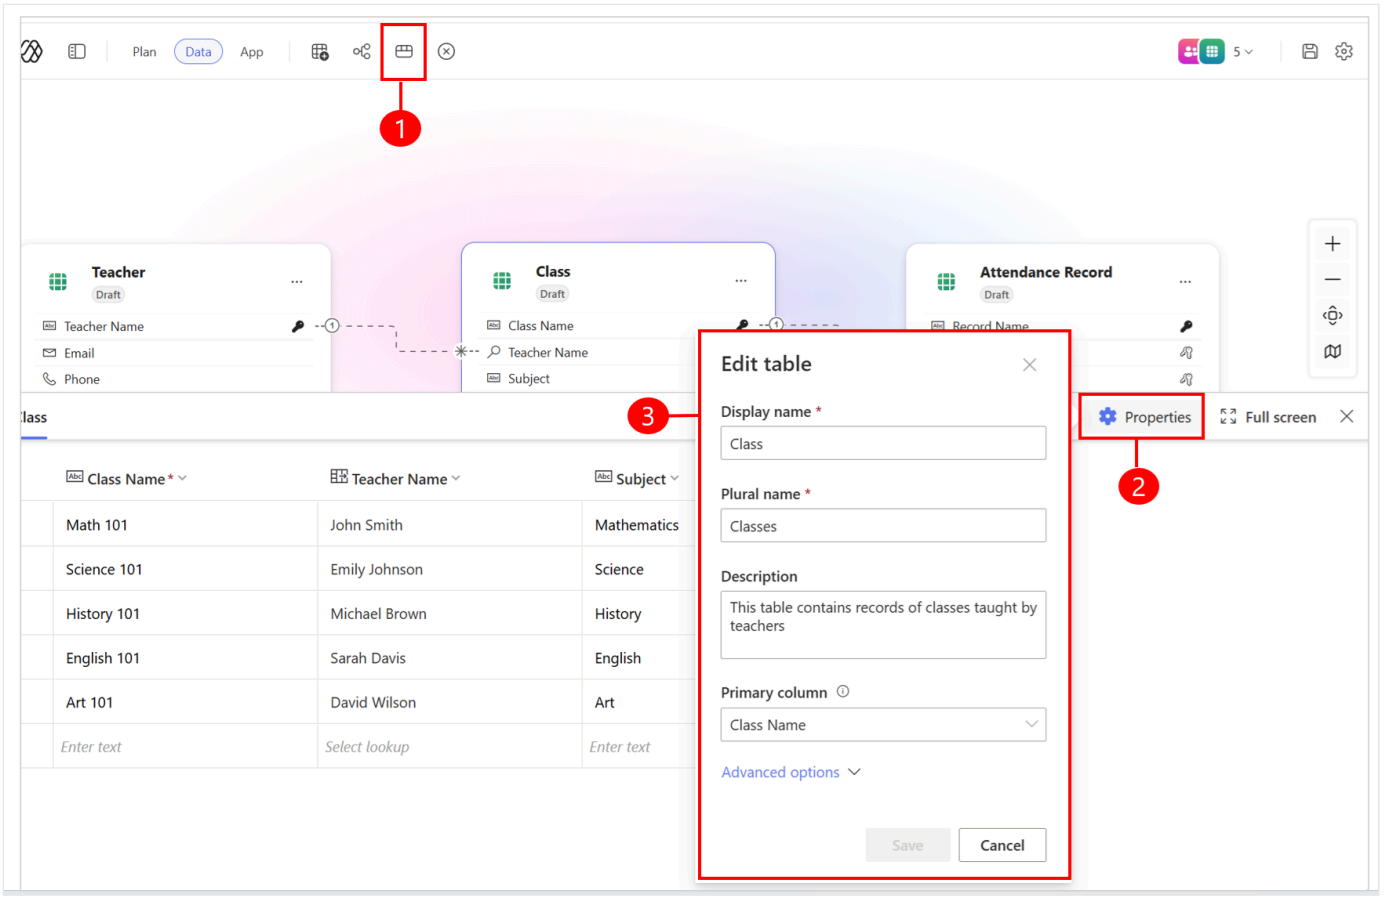


2. Select **View data** on the command bar, select a row, and then select **Row ownership**.



Edit the data table properties

1. Select the table you want to edit. Then, select **View data** in the command bar.
2. Select **Properties** to update the table's display name, plural name, description, and other details.



Application lifecycle management (ALM) capabilities

The following ALM features are supported:

- **Save**: For new apps created after April 9, 2026, AutoSave is turned on by default. You don't need to manually select save. For apps created before this date, manual saving is still required. To save your progress, select **Save** in the command bar at any time. This action saves all edits to every solution object in your preferred solution.

- **Publish data**: To publish draft tables, select **Publish draft tables** from the data card's context menu when you're ready to make a table available for production. You can choose Dataverse as the target data source. Once published, any apps using these draft tables automatically update to use the published versions.

- **Publishing app**: When you're ready to release your app for production, select **Publish** in the app's command bar. If your app uses any draft tables, you're prompted to publish those tables as well.

- **Share the app**: To share your app with others, select **Share** and add the accounts of users you want to grant access to. You can also share with Microsoft Entra ID security-enabled groups. Distribution lists and nonsecurity Microsoft 365 Groups aren't supported.

> **Note**
>
> Group sharing only works in production environments. Developer environments don't support group-level permissions.

Choose a data source and publish

1. When you're ready to publish, select **Publish**.
2. Your Dataverse tables are published in the same environment.

Known limitations

The new Power Apps experience has the following limitations:

- You can't access or edit apps created in the new authoring experience outside of the new authoring experience.
- If you export an app and edit it outside the new authoring experience (for example, in VS Code), redeploying via PAC CLI creates a new app, and it disconnects from the original plan.
- Currently, you can only have one app per plan; multiple apps within a single plan aren't supported.
- You can't open preexisting plans in the new experience.
- Canvas and model-driven apps aren't supported; you can't recommend, open, or edit these app types in the new authoring experience.
- Existing tables aren't automatically recommended during data model proposal; you can manually add existing tables to your plan.
- Editing existing Dataverse tables via chat isn't currently supported; you can make changes to these tables through the data editor manually.
- Direct code edits in **Code** view or **Split** view aren't supported; you can't modify code directly in these views.

Share your feedback

- **Feedback on generated content**: Use the thumbs up or thumbs down icons in the chat pane to rate the generated content. For more details, select **Tell us why** to provide specific feedback.

- **Feedback on the overall experience**: Select **Give feedback** in the command bar to share your thoughts about the overall experience. Choose a feedback category and enter your comments in the provided field.

Add a SharePoint list in Power Apps vibe (preview)

[This article is prerelease documentation and is subject to change.]

Connect your SharePoint lists directly to Power Apps vibe and start building apps with your existing data in minutes. No migration required.

Build a functional app using your SharePoint list data while keeping your current workflows intact. This approach is ideal for scenarios where you want to:

- Use existing SharePoint lists.
- Build apps quickly without data migration.
- Maintain your current SharePoint-based workflows.

> **Important**
>
> SharePoint lists are currently read-only in Power Apps vibe. To modify list items, you need to make changes directly in SharePoint.

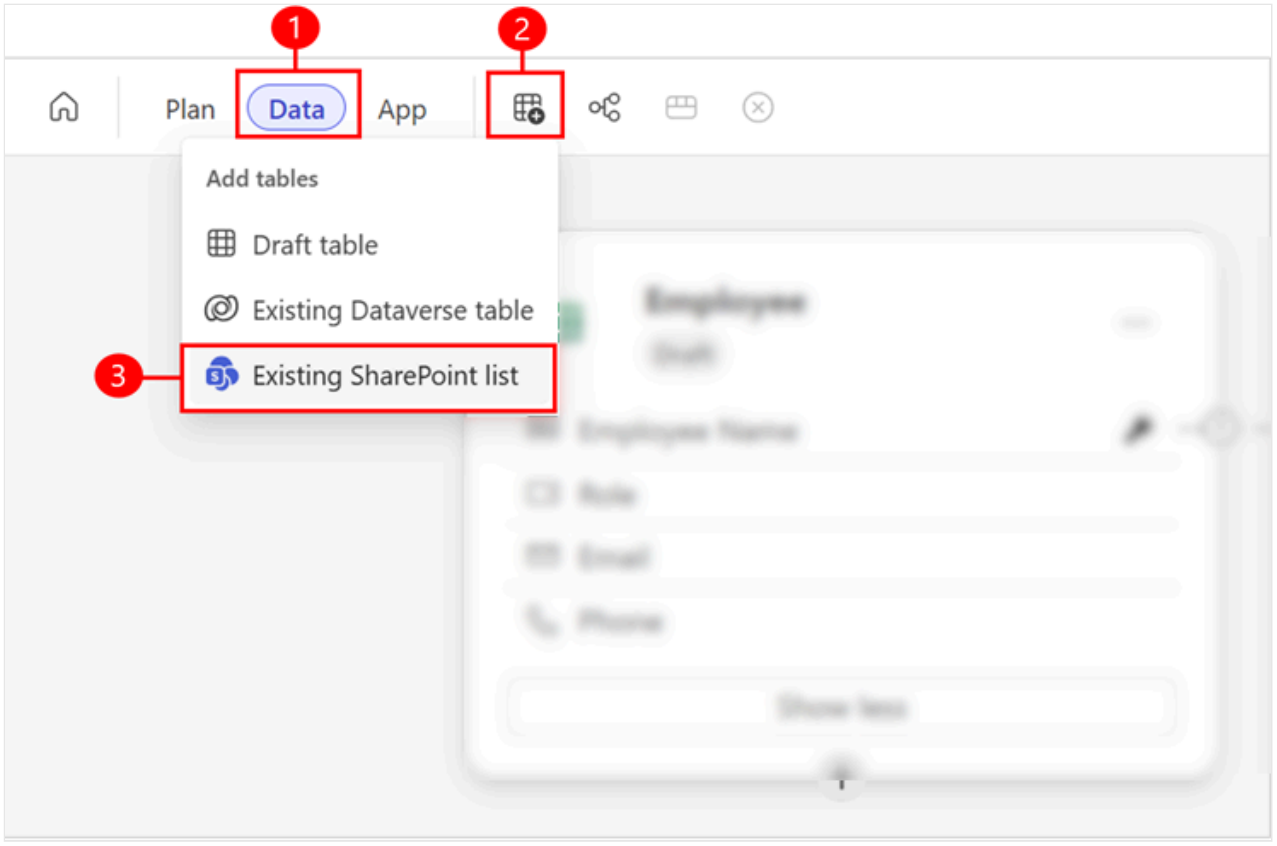
Prerequisites

You need access to the SharePoint site that contains the list you want to use.

Add an existing SharePoint list

Select an existing SharePoint list to use with your app. Vibe doesn't suggest or automatically identify available lists.

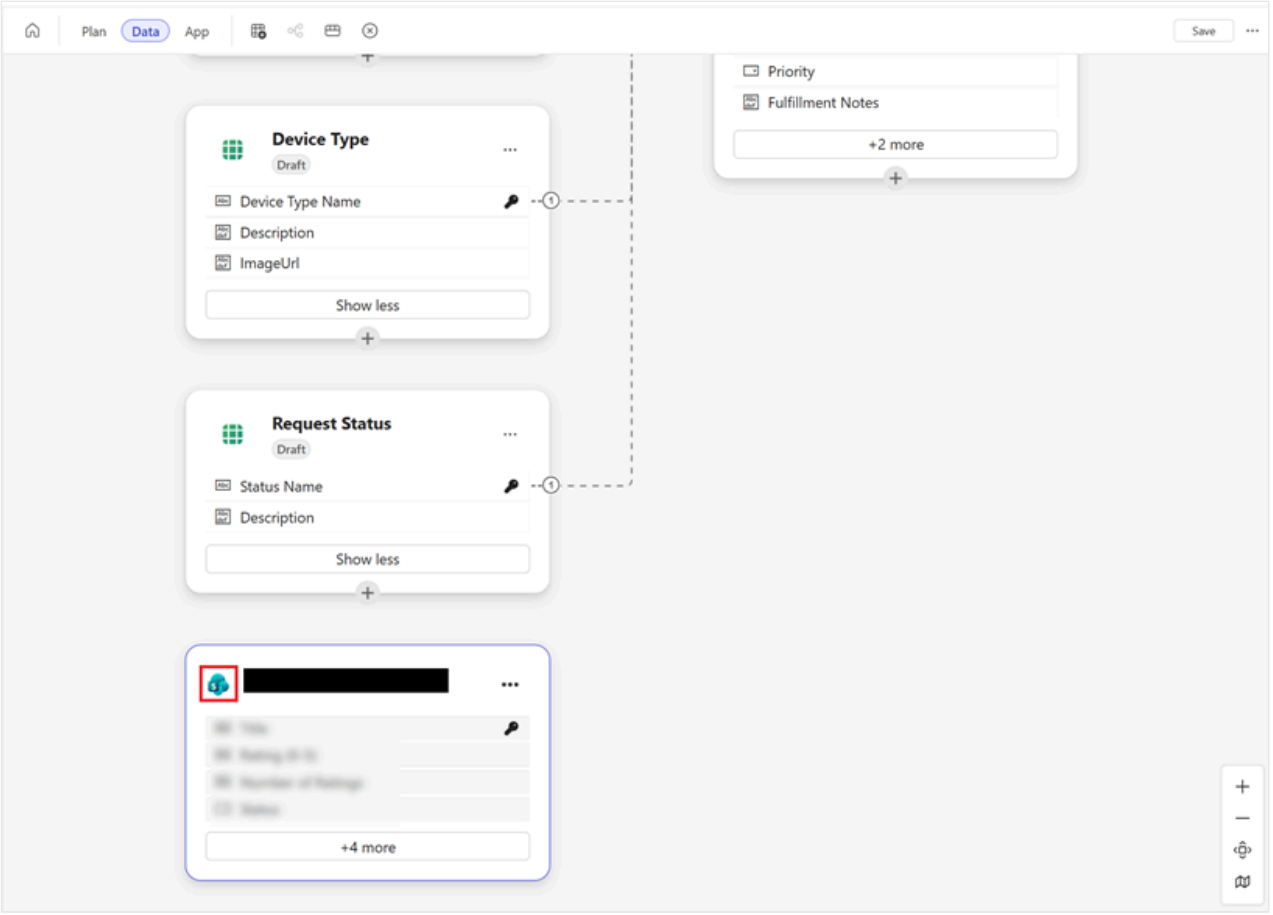
1. Sign in to https://vibe.powerapps.com.
2. Open an app for editing, and then select **Data** > **Add table** > **Existing SharePoint list**.



3. Enter the SharePoint site URL, and then select **Connect**. Alternatively, select a site from **Recent sites**.

4. Under **Select a list**, choose the list you want to add, and then select **Connect**.

5. Vibe connects directly to your SharePoint list. After the list is added, it appears in the data workspace with a SharePoint icon and its columns.



Limitations

- **Location**,**ManagedMetadata**, **Calculated**, **ExternalData**, and **TaskOutcome** columns aren't currently supported and are converted to text columns.

Released versions - new Power Apps experience (preview)

This capability is in preview with the following limitations:

- Copilot must be enabled in the tenant and environment.
- This capability isn't available in a default environment.
- This capability is available only in the US region and in English only.

Latest version availability

Expand table

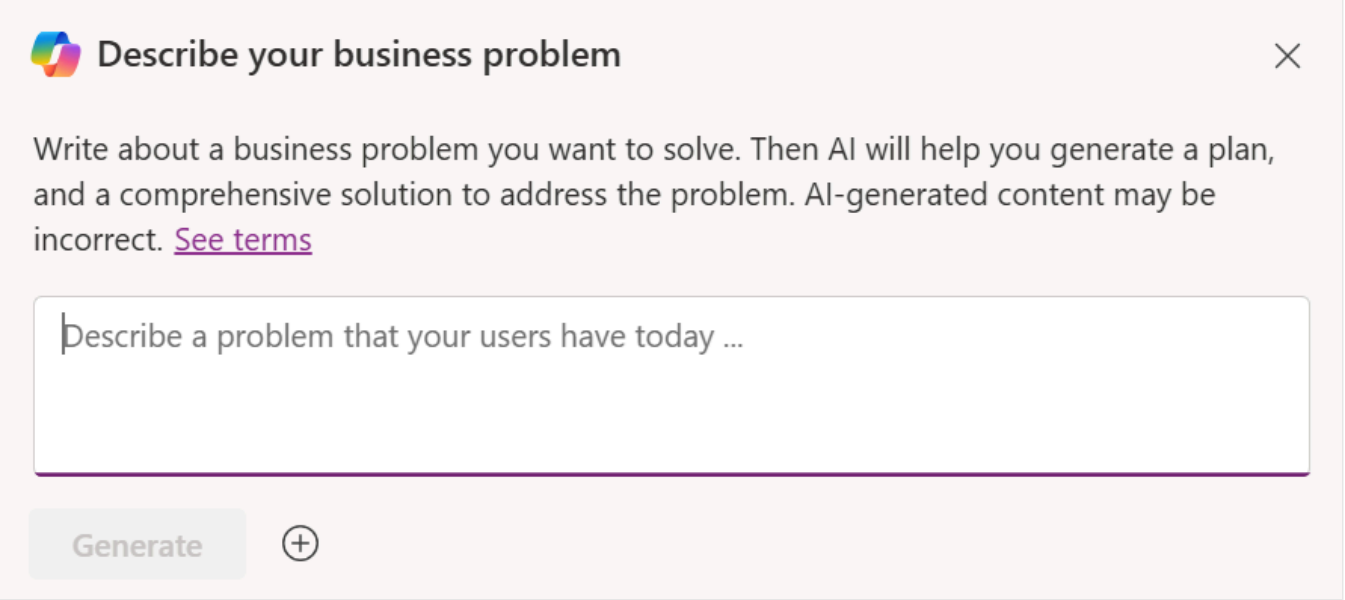
Month	Released version
December 2025	251218
January 2026	260130
February 2026	260227
March 2026	260331
April 2026	260430

Last updated on 04/30/2026

Overview of plans

Summarize this article for me

Plans in Power Apps is a copilot-first development tool that lets you quickly create comprehensive business solutions. Describe your business use case in natural language and add relevant images, like business process flows or screenshots of legacy apps. Plans generates a complete Power Platform solution tailored to your needs. It includes Microsoft Dataverse tables, canvas apps, model-driven apps, Power Pages sites, Power Automate flows, and Copilot Studio agents.



Prerequisites

> **Important**
>
> For Government Community Cloud users, plans is supported only in the Government Community Cloud (GCC). For more information, see Plans in Sovereign Clouds

To use plans in Power Apps, follow these steps:

1. Environment requirements

1. **Dataverse database required:** Make sure your environment includes a Microsoft Dataverse database.
2. **Copilot features enabled:** Plans is generally available and enabled by default. It can't be turned off except through Microsoft Support. A tenant administrator must contact Support to request that it be turned off.
3. **Environment must be in an eligible locale**

2. What if you don’t meet the prerequisites?

1. **Developer Environment Option**: If your current environment doesn’t meet the requirements but you can use developer environments, you're automatically routed to your own developer environment. There, you have permission to create Dataverse tables. Learn more in Create a developer environment.
2. **No Developer Environment Available:** If you can’t use or create a developer environment, you won’t be able to create plans in your current environment. In this case, switch to an environment where you have permission to create tables and start building your plan there.

3. Who can access plans?

The following security roles can see the entry point for plans on the Power Apps home page:

- System admin
- System customizer
- Environment maker: Are redirected to their own developer environment when they save tables.
- For custom security roles: You need the following privileges for each operation in plans:

Expand table

Operation in plans	Table	Privilege
Create a plan	Plan	Read
	Publisher	Read
	Entity	Read
	Attribute	Read
	Solution	Read
	Relationship	Read
	Entity	Create
Save tables in plan	Entity	Read
	User settings	Read
	Async operations	Read
	Entity	Append to

Operation in plans	Table	Privilege
	Entity	Create
Share a plan	Plan	Share

Availability

Plans is generally available and enabled by default. Check if the feature is available in your region. Learn more in Explore Copilot features by geography and languages.

Create a plan

Last updated on 02/24/2026

Create a plan

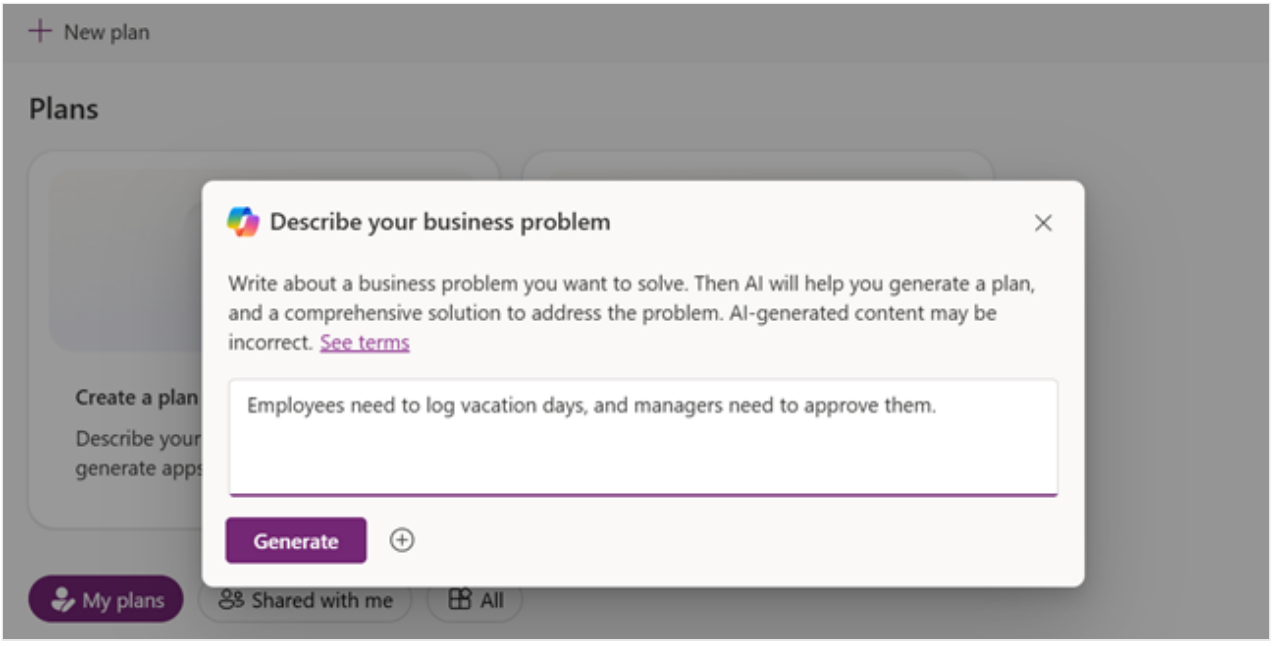
Summarize this article for me

Use plans to create user roles, data tables, and apps that address your business needs.

This article uses a sample scenario to show how plans works by building a solution for managing paid time off (PTO) requests for employees and managers.

1. Sign in to Power Apps.
2. On the Home screen, select **Start with a plan**
3. Select **Create a plan**
4. Enter your prompt in the text box, like the example. Add context such as process diagrams, data models, or screenshots of legacy apps. When you're done, select **Generate**.

Copilot prompt
`Employees need to log vacation days, and managers need to approve them.`



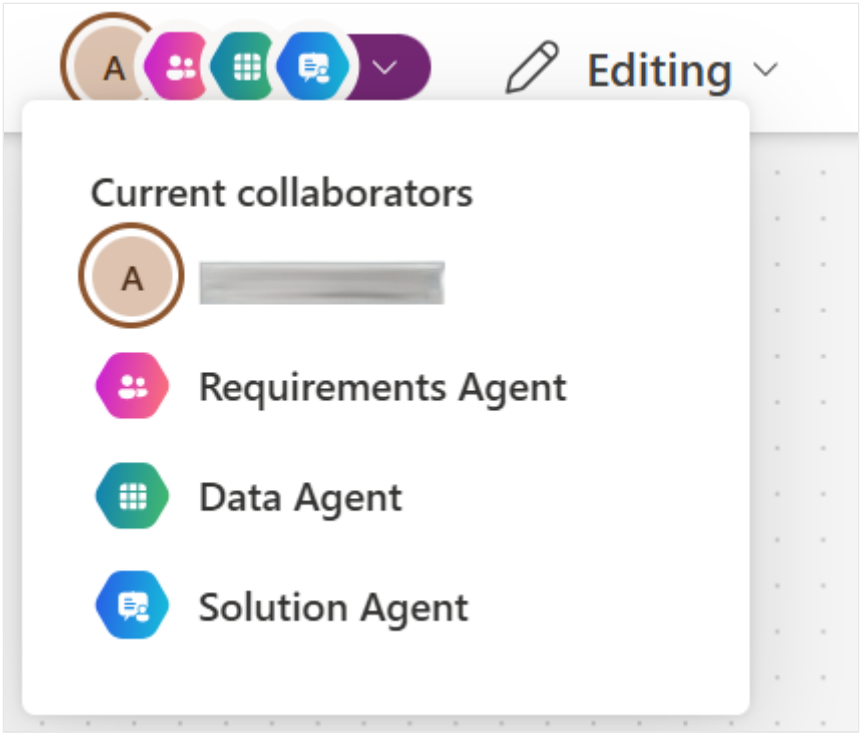
Copilot opens the plan and analyzes your business scenario based on the description.

Plan agents and copresence

When working within a plan, you can view the presence status of all collaborators, including plan agents. Plan agents are AI assistants that review your business problem and assist in generating a tailored plan to address your needs.

- The **Requirement Agent** examines the business problem and uses AI to generate user requirements. This step is first step in the plan.
- The **Data Agent** suggests a set of tables for storing business information, complete with recommended columns, data types, and relationships.
- The **Solution Agent** evaluates the needs, processes, and data to create a solution that includes technologies such as apps, flows, and AI agents to address your business problem.

As the plan builds, review and edit the outputs generated by the agents.



Copresence

Plans lets multiple authors use the same plan at the same time. The first author who enters the plan gets editing rights, and any author who joins later can only view the plan in read-only mode. You see other authors in the command bar, along with the agents in the plan. If you have read-only permissions, you can get editing rights after the author with editing permission exits the plan or after a period of inactivity. Plans supports up to 100 authors for copresence, but only one author can edit at a time. Multi-author coauthoring isn't supported.

> ⓘ **Important**
>
> Multiple users can't edit the plan at the same time.

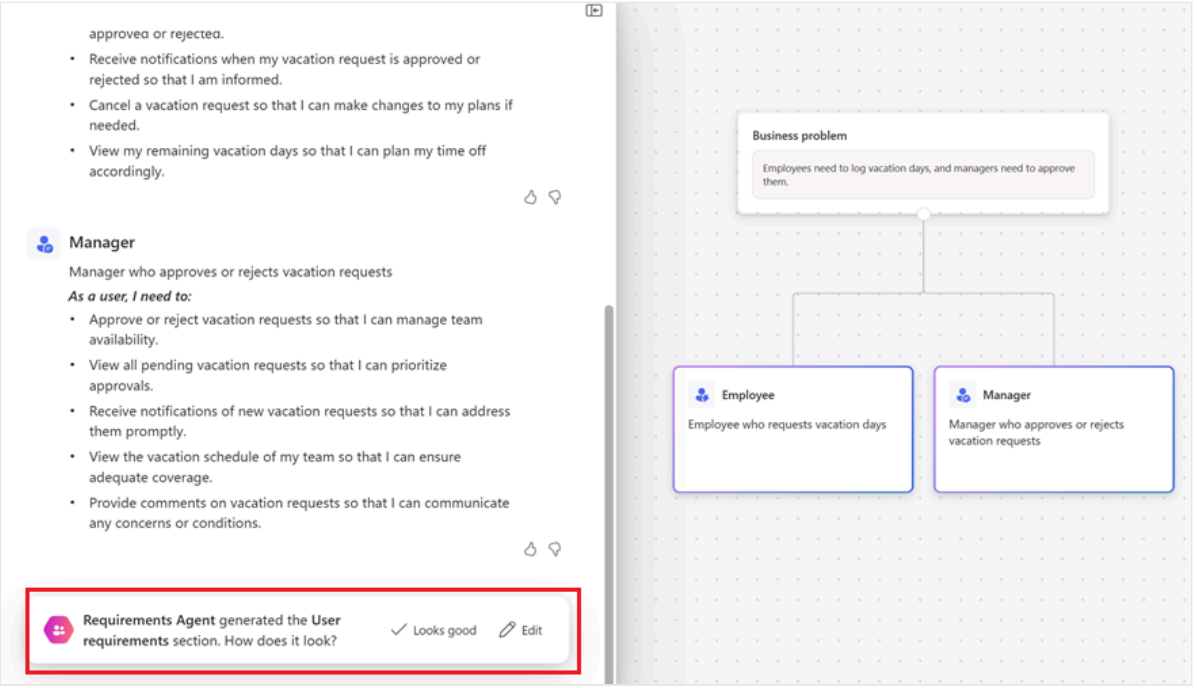
Generate user requirements

When a plan starts, the **Requirements Agent** identifies user needs based on your description.

In this scenario, two user roles are generated: the employee and the manager. Each user role includes a description and user needs. The user roles and needs appear in a bullet list and on the right side is a visual diagram.

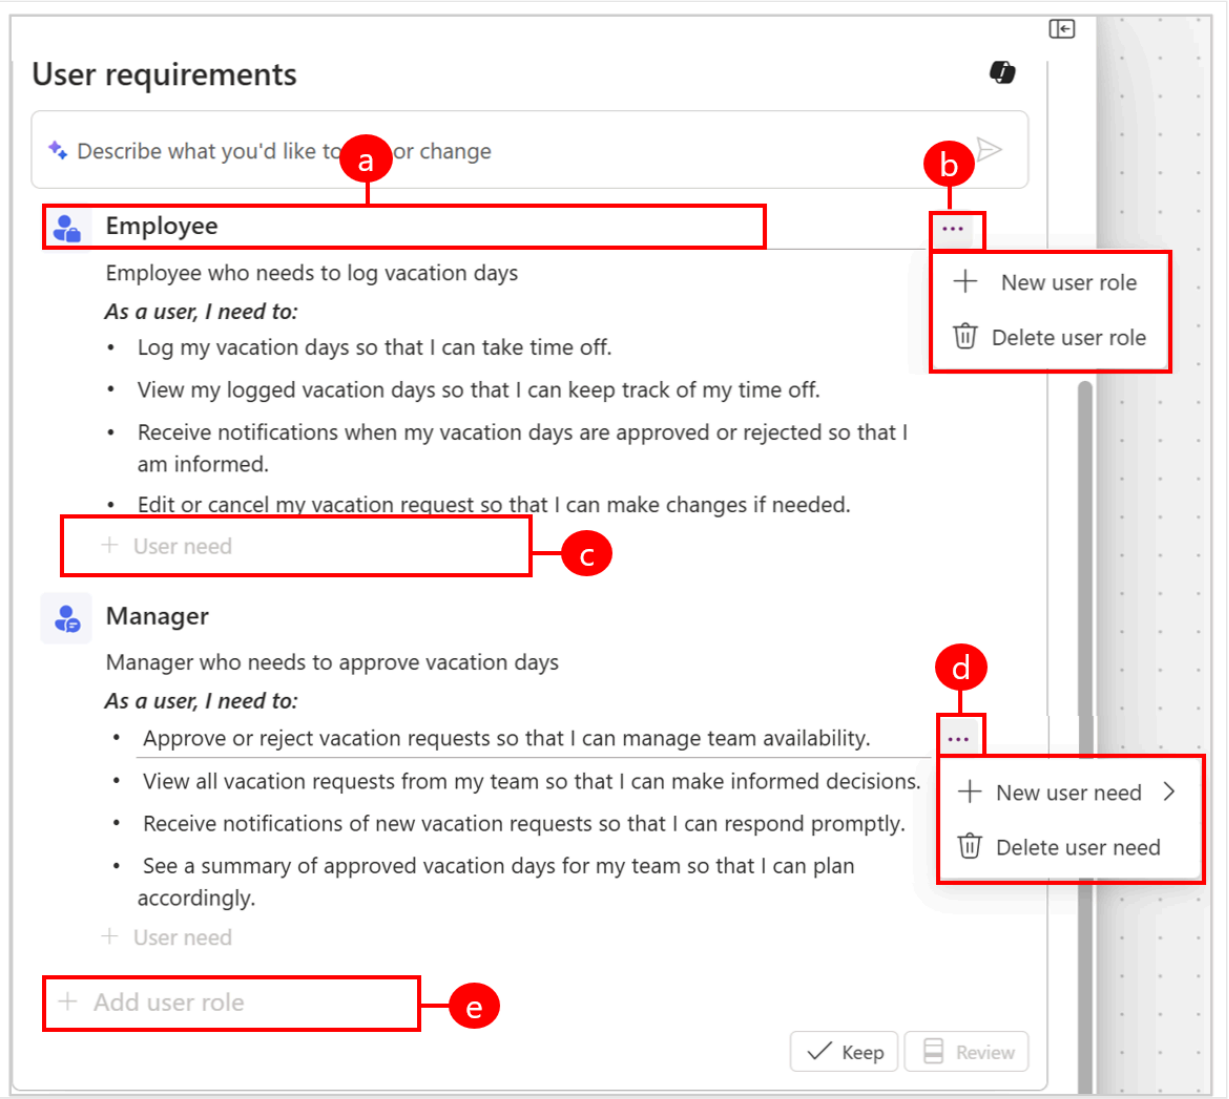
1. Review the user roles and needs. Then, choose one of the following options:

    - Select **Looks good** to move to the next step and generate a data model.
    - Select **Edit** to make edits inline or add new user roles or needs.



Making edits

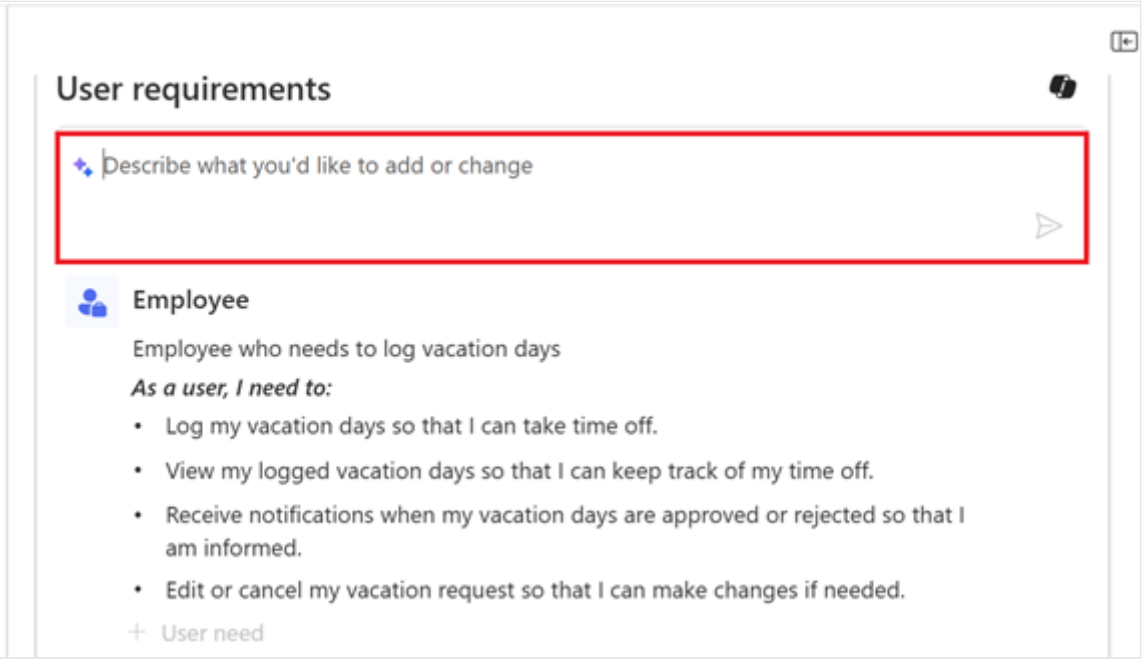
a. Inline editing provides these options:



Legend:

a. Select and modify a user role. b. Add a new user role or delete the selected user role.
c. Add a new user need.
d. Add a new user need either at top of selected user need or after it, or delete the selected user need.
e. Add a new user role.

b. Alternatively, use **Copilot** to provide feedback on the generated user needs.

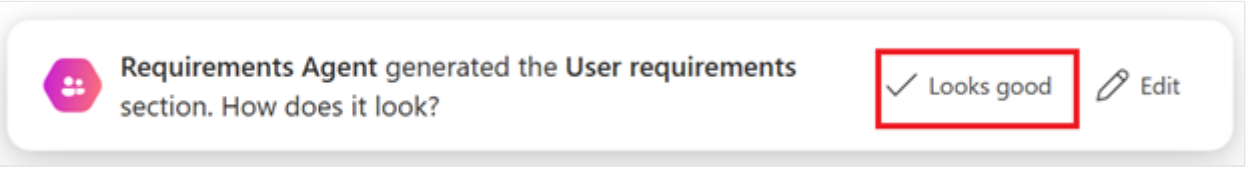


To make changes, provide a brief description of what you want to modify. Here are examples of what to ask Copilot to do:

- Add a user role for HR admin to monitor PTO across teams to manage payroll.
- Add a user need for employees to view PTO blackout dates.
- Remove the user need for managers for viewing vacation history of team members.

Select **Keep** or **Review** to finalize your edits.

2. When you're done, select **Looks good** to proceed to the next step and generate data tables.

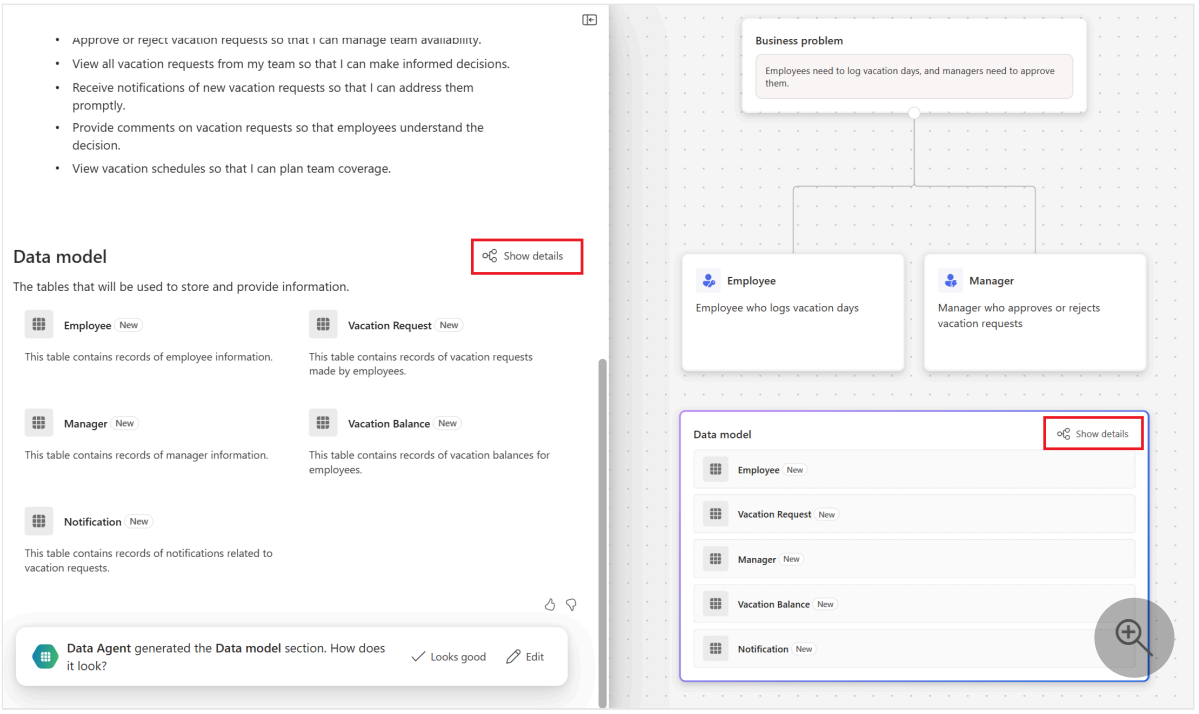


Generate data model

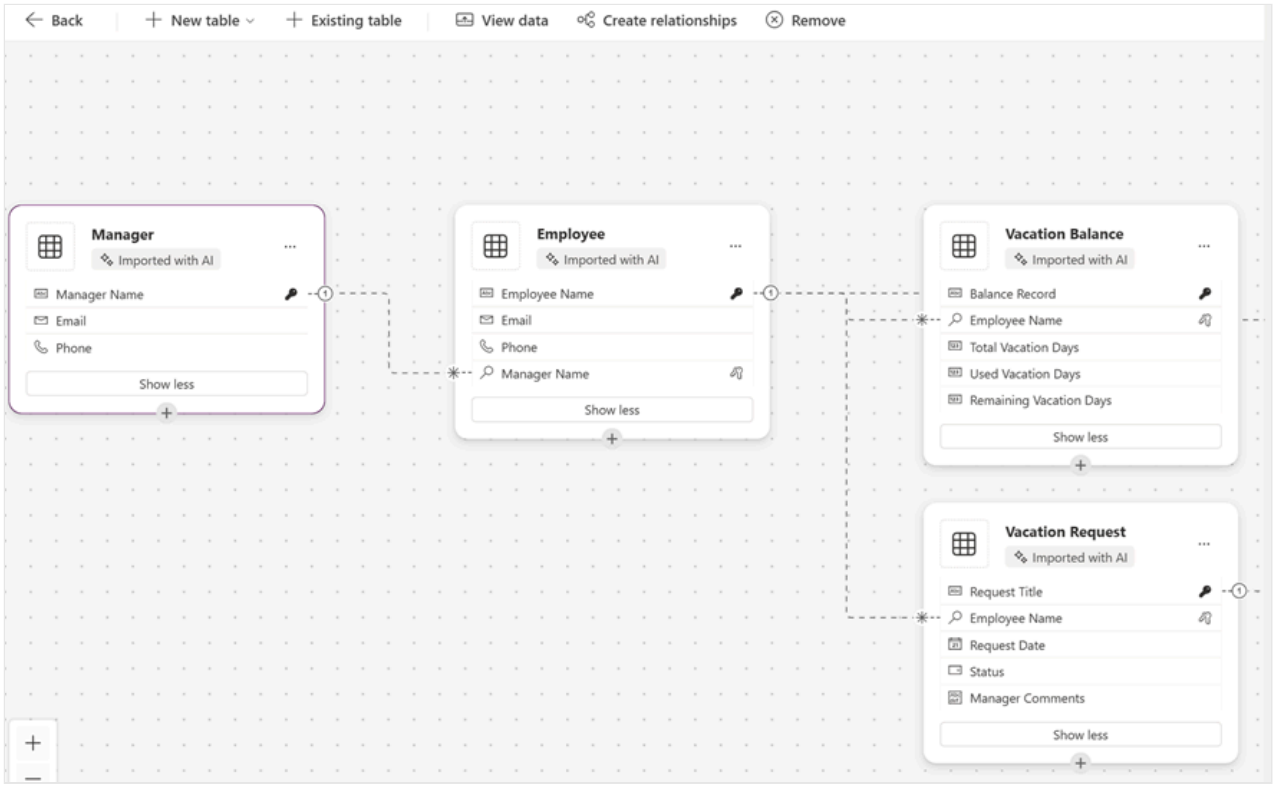
Next, the **Data Agent** suggests tables to store your business data.

1. Suggested data tables appear in the **Data model** section of the plan.

   - Select **Edit** and use Copilot to describe what you want to change or add.
   - Select **Show details** to view the data in a diagram, and edit it.



2. If you select, **Show details** it opens the data workspace. Use the data workspace to create tables, set up relationships, and view a data diagram. For more information, see Create and edit tables using Power Apps.

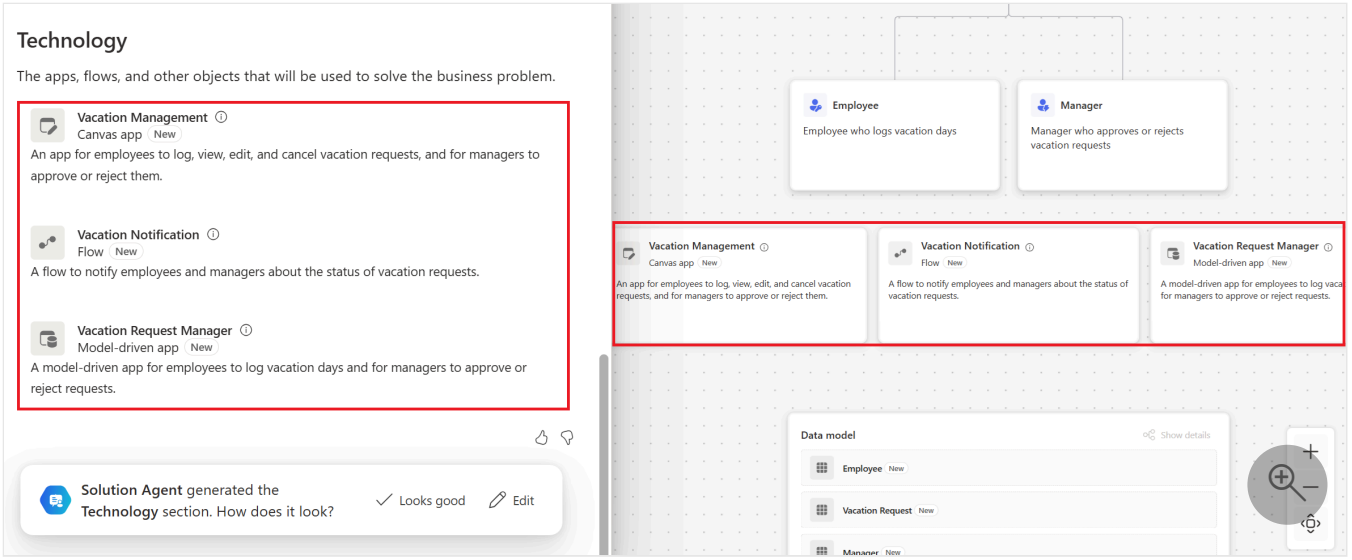


3. When you're done, select **Back**.

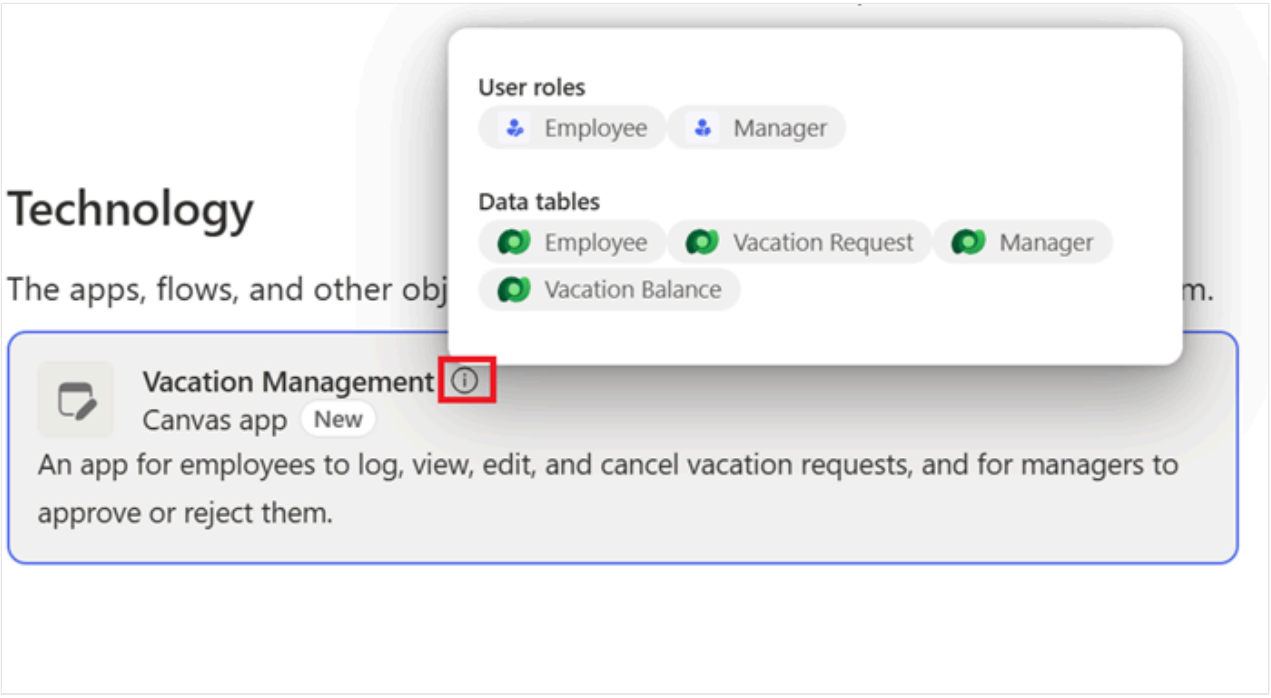
4. When you're ready to generate the technology proposal, select **Looks good** to continue.

Generate technology proposal

The **Solution Agent** analyzes the plan and proposes technologies tailored to solve your business problem. In this scenario, a canvas app, a model-driven app, and a Power Automate flow are created.



1. To view details of the proposed technologies, hover over the **information icon**. The pop-up info card shows the user roles being met and the data tables being used by the proposed technology.



2. Select **Looks good** to accept the proposed technologies, or select **Edit** to use Copilot and describe what you want to change.

Proposed technologies

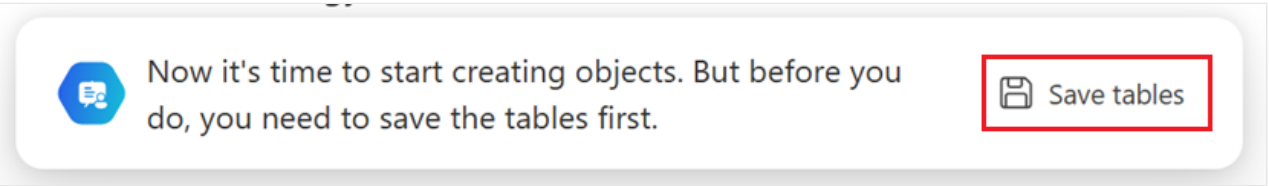
Plans suggests technologies from the following list:

- Apps like canvas apps or model-driven apps
- Power Pages websites
- Power Automate flows
- Power BI Report
- Copilot Studio Agents

Save tables

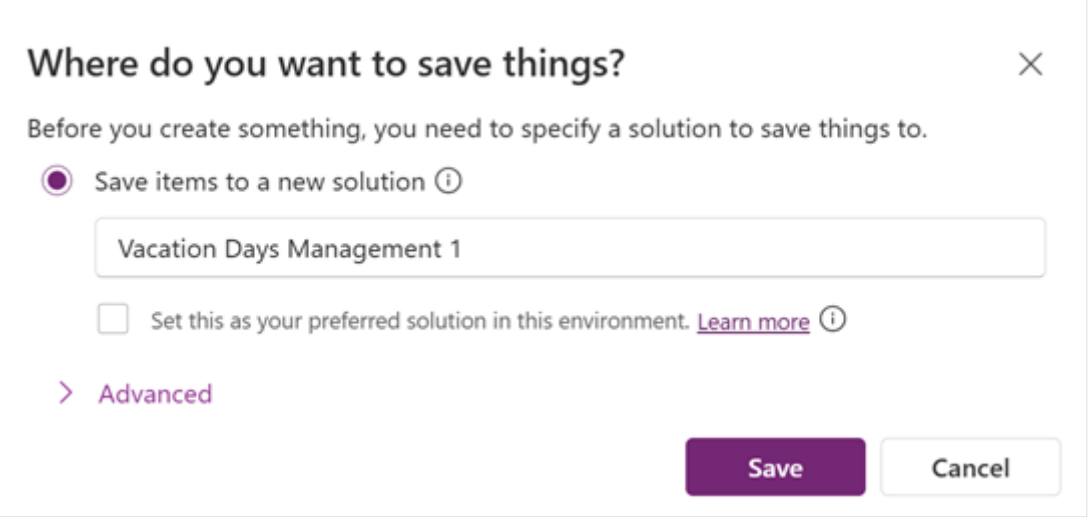
To create objects such as apps, flows, sites, and agents, you need to save your plan and tables.

1. Select **Save tables**.



2. Enter a solution name.

3. Choose a publisher or select an existing solution to contain the items generated from the plan, and then select **Save**.



The plan is stored in a solution. This action enables the **Objects** view in the plan, so you can switch between the plan and the solution view without leaving the plan. Learn more about solutions in Solution view.

> **Note**
>
> - The solution name must only contain letters, numbers, and underscores. For more information, see Create a solution.

- Anyone with the required plan privileges can access your plan.

You're now ready to build your solutions.

Your tables have been saved. To create and customize an object, just hover over it and select **Create**.

Share a plan

Share your plan with other makers to collaborate by assigning read or edit access.

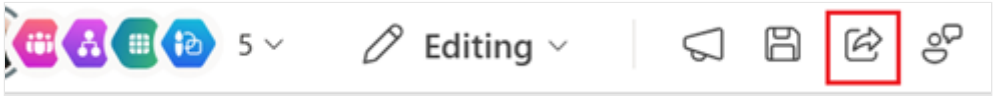
Plan collaborators need sufficient privileges to open and work with a shared plan. If your admin enabled plan level security roles in Power Platform Admin Center, makers with the System Admin security role can directly give collaborators plan-level privileges when sharing the plan.

For example, User 1 doesn't have enough privileges to see or edit plans. When the maker shares a plan with User 1, a custom security role is automatically created and assigned, which then gives them the needed plan privileges. The auto-generated security role appears in Power Platform Admin Center with the naming convention **Plan + Plan name + Role name + Plan ID**. To change assigned security roles, unshare and reshare the plan to assign the right security role under **Manage Access**.

If plan level security roles isn't enabled in Power Platform Admin Center, makers need to manually give collaborators the needed privileges so they can access the plan.

Follow these steps to share your plan:

1. Open your plan and then select **Share** in the top right corner.



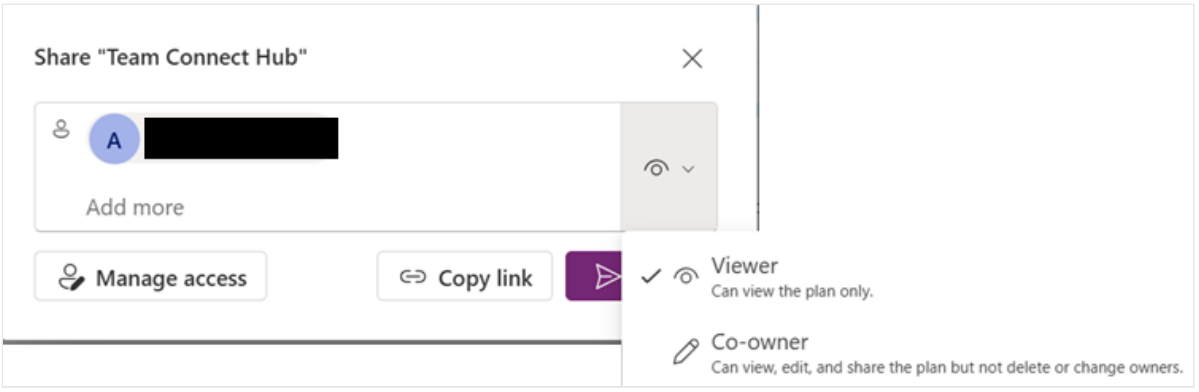
2. Select **Share**.

3. In the **Share** dialog box, type the names or alias of the user or security groups.

4. Select the down arrow to choose permissions for the plan. Options include:

    - **Viewer**: Can only view the plan.

- **Co-Owner**: Can use, edit, and share the plan but not delete or change owners.



5. Select **Manage access** to see access details, including current users and co-owners. You can also edit user access and assign security roles here.

6. When you're done, select **Share**.

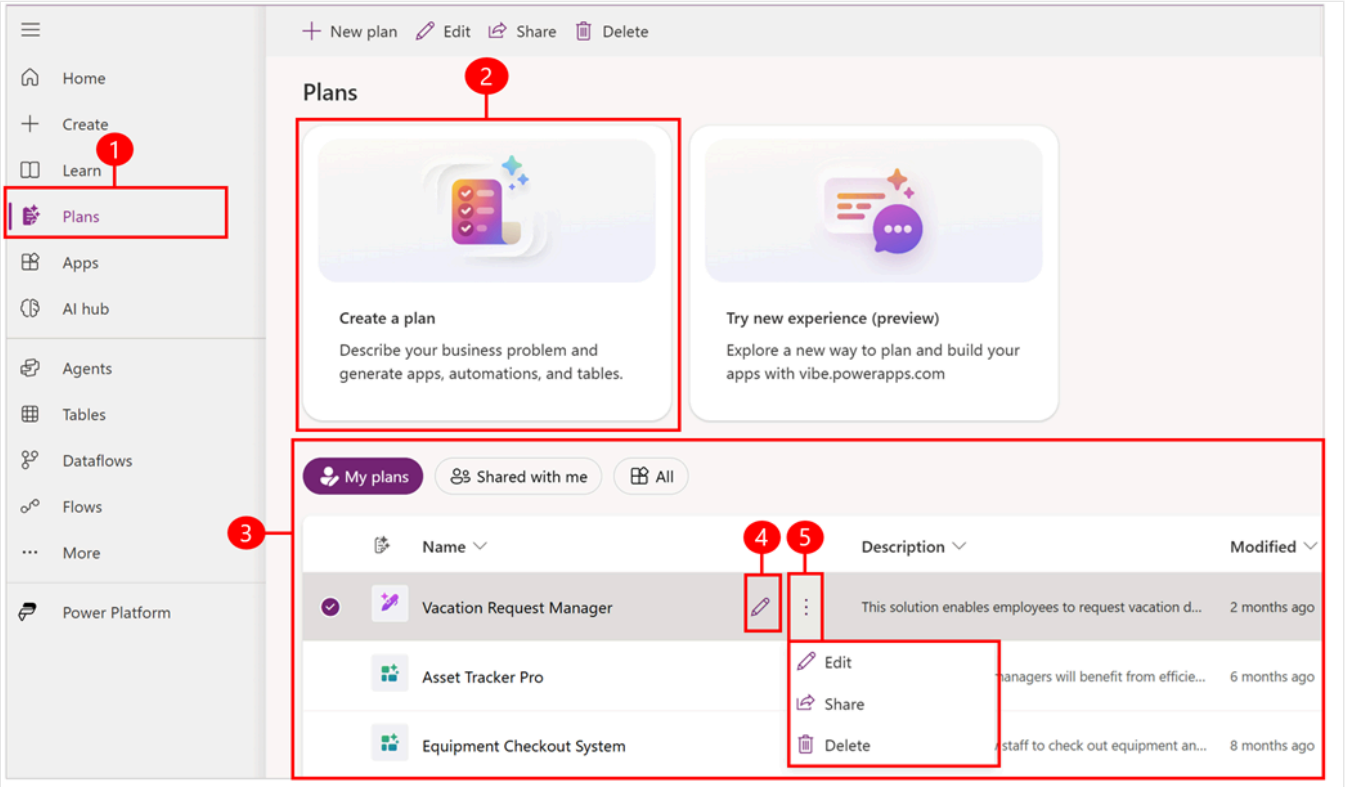
Export a plan to a PDF

The export to PDF feature lets you share plans with stakeholders. It includes all content from the document side of the plan, but not the diagram side. Use this feature to share user requirements, data models, and proposed data tables with leaders who don't have access to Power Apps.

- To export a plan to PDF open a plan and then select **Share** > **Export as a PDF** in the top right corner.

View and edit plans

Use the **Plans** menu in the left navigation pane to access and edit your plans.



Legend:

1. **Plans**: Access your plans.
2. **Create a plan**: Create a new plan.
3. **Your plans**: View your plans.
4. **Edit**: Edit the selected plan.
5. **Edit, share, or Delete**: Edit, share, or delete the selected plan.

Next steps

Build a solution from a plan

Last updated on 02/18/2026

Generate process diagrams

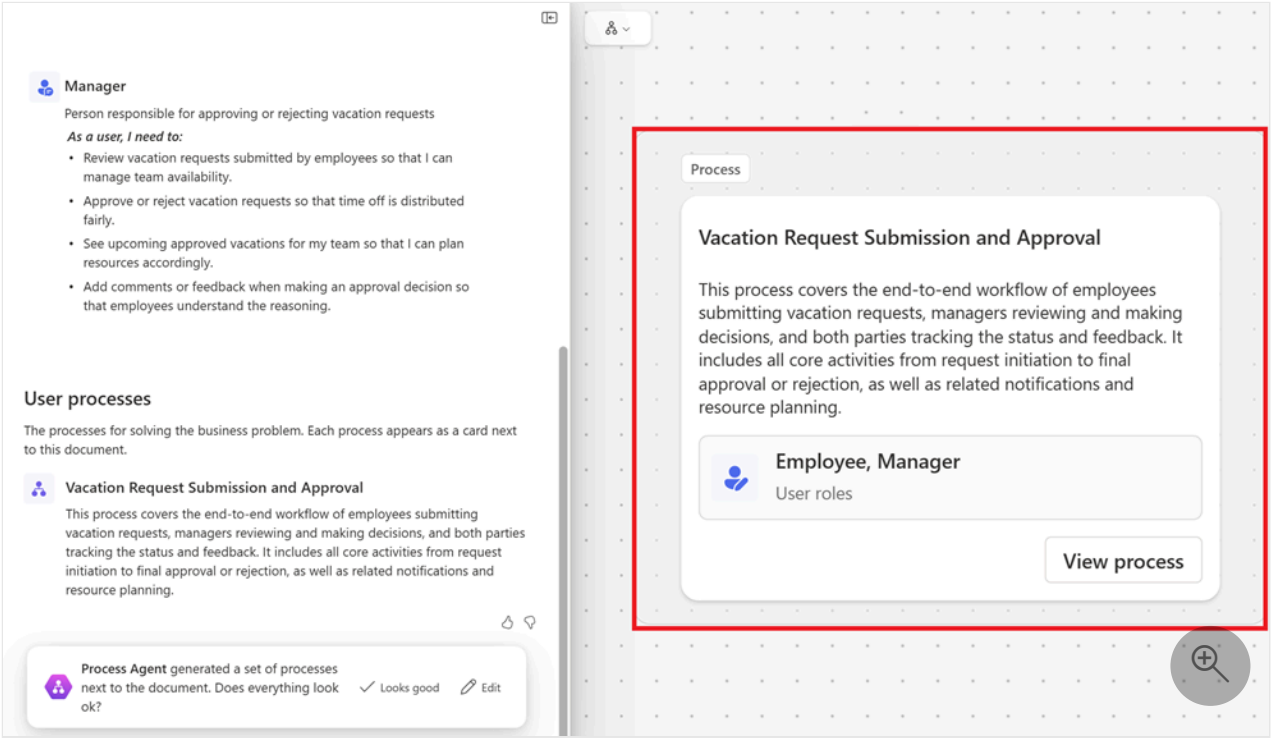
Transform complex workflows into clear, visual process diagrams with plans in Power Apps. Whether you're managing multi-step approvals or mapping customer journeys, these AI-generated diagrams help your team communicate better and work more efficiently on complex projects.

Optionally, include images of existing process diagrams as additional resources during the creation experience to enhance clarity. But if you add predefined processes, Copilot might just replicate what you provide, which can limit creativity and cause duplication or misinterpretation.

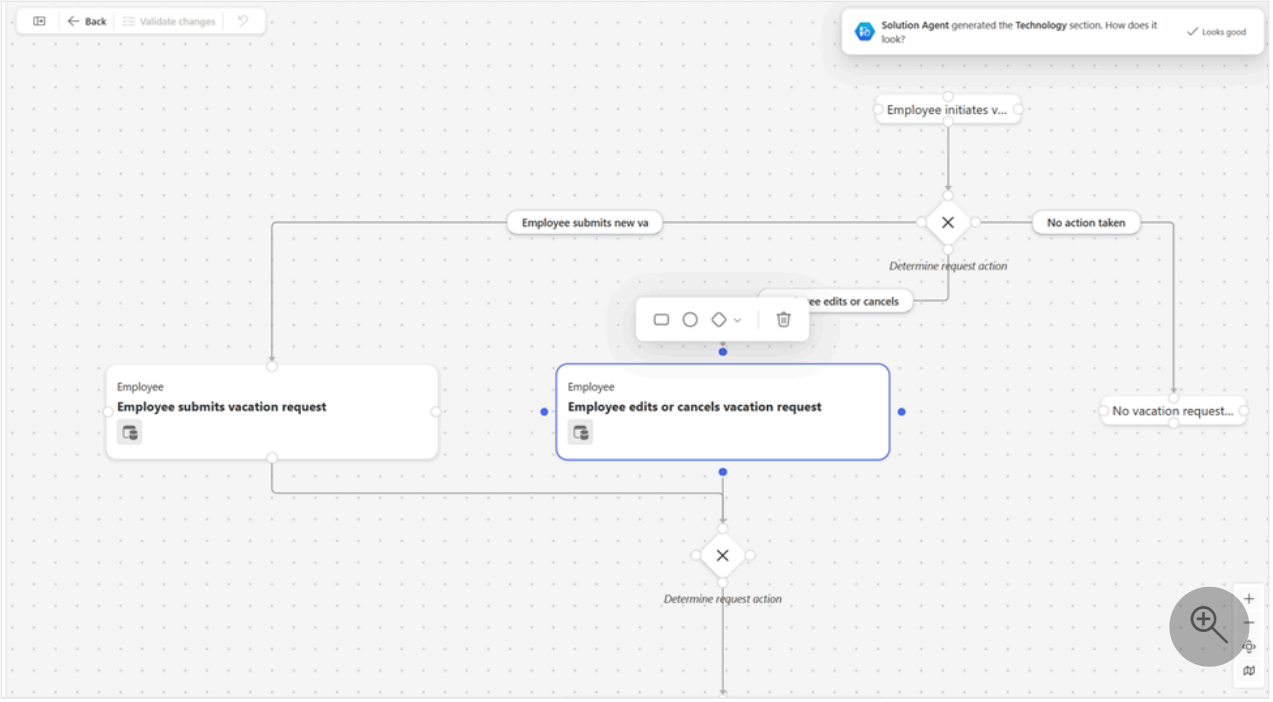
The process diagram appears on the right as you create a plan. The diagram generates after you create user requirements. If you prefer to see a plan overview instead, you can toggle off the process diagram.

Processes use a two level hierarchy.

- **Process stages**: An overview of the processes needed to address the business problem and user stories.



- **Process maps**: Select **View process** on a process tile to see detailed steps, events, and decision points for developing a process. Each activity shows the user role responsible for the action.



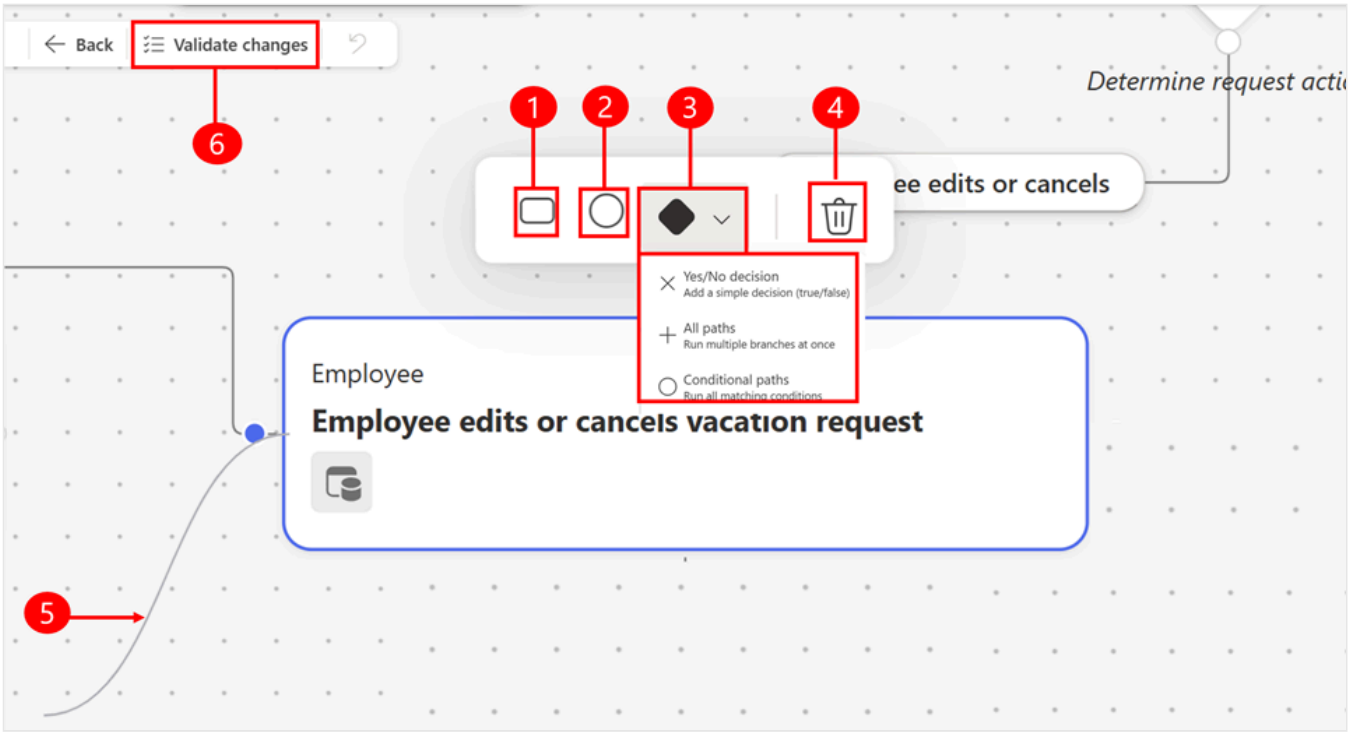
Understand a process

Process diagrams use three main types of nodes to represent different workflow elements:

1. **Events** control the flow of your proces:
    - **Start**: Triggers the beginning of your workflow
    - **Intermediate**: Marks a checkpoint during the process
    - **End**: Indicates successful completion
2. **Gateways** handle decision-making:
    - **Exclusive**: Creates a single path based on conditions (if/then logic)
3. **Activities** represent actionable work:
    - **Task**: Specific actions performed by users or systems

Edit a process

The process is an AI-first experience and might not always produce the results you expect. Use natural language to describe the changes you want, or manually edit the process. The AI then reassesses your changes and the overall process to generate a new process map.



Legend:

1. **Add step**: Add a new step.
2. **Add event**: Add a new event.
3. **Add decision**: Add a yes/no decision, run multiple branches at once, or run all matching conditions.
4. **Delete**: Delete a node. Remove connecting lines by selecting the backspace key.
5. **Connect nodes**: Add connecting edges between nodes by selecting a node anchor and dragging it to another node.
6. **Validate changes**: Confirm your changes. Changes aren't finalized or saved with the plan until you validate them. The process experience in plans is an AI-first experience, even when you make manual edits. When you validate changes, the AI reviews and merges them with the existing process. As a best practice, batch three to five manual changes at a time, then validate them. If you want to make more than five changes, try the natural language update first to save time and improve the accuracy of the AI-generated content.

Known limitations

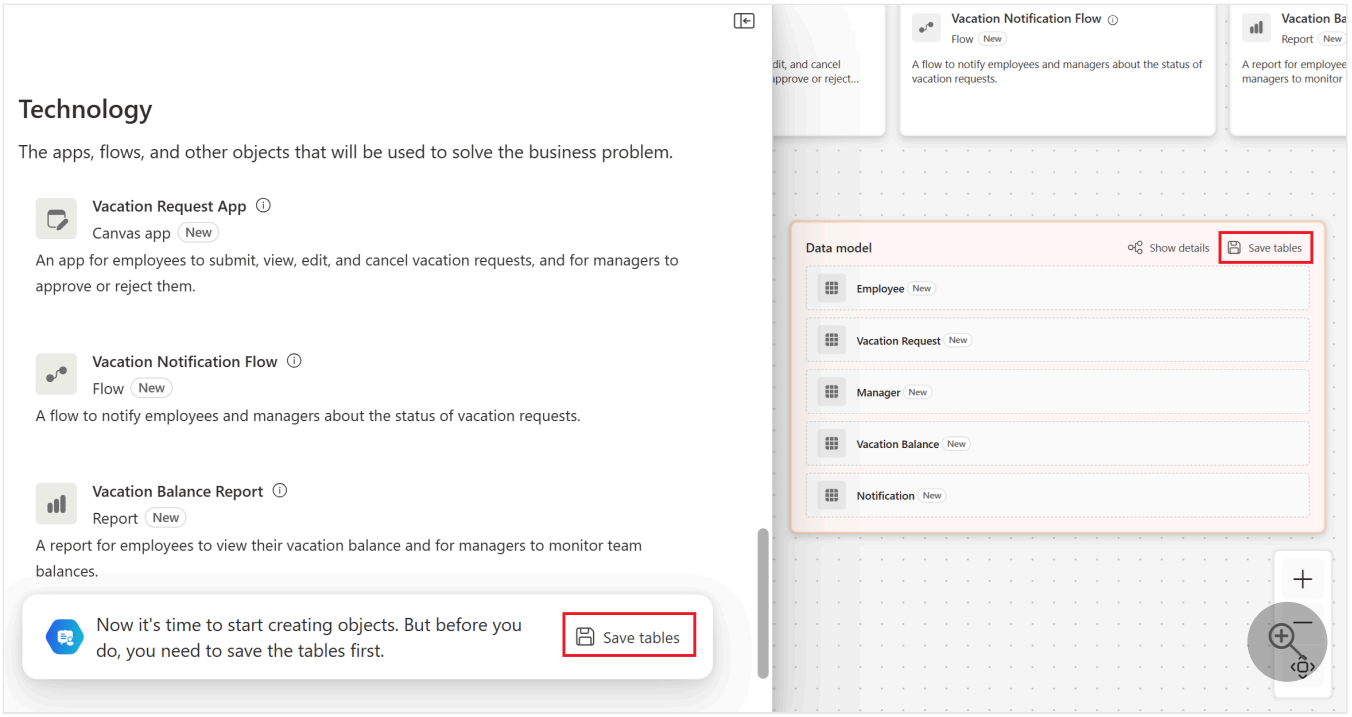
- You can't add events manually.
- The process doesn't directly affect technology proposals.
- You can validate only one set of changes at a time.
- You can't change node types. You can only delete and re-add them.

Last updated on 01/14/2026

Build a solution from a plan

Build a solution based on the objects plan's suggests for your business problem.

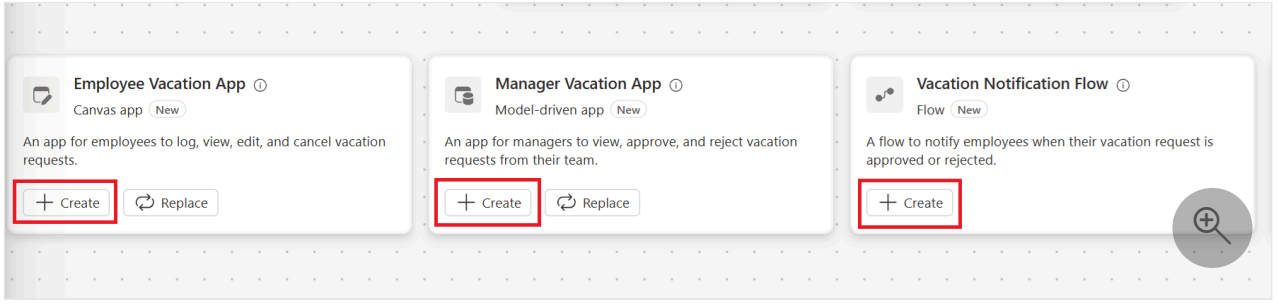
To follow this article, create and save a plan. Learn more in Create a plan.



After you save a plan in a solution, create apps like canvas apps, model-driven apps, Power Automate flows, and Copilot Studio agents based on the solution proposal from a plan.

Create objects

1. Select **Create**.

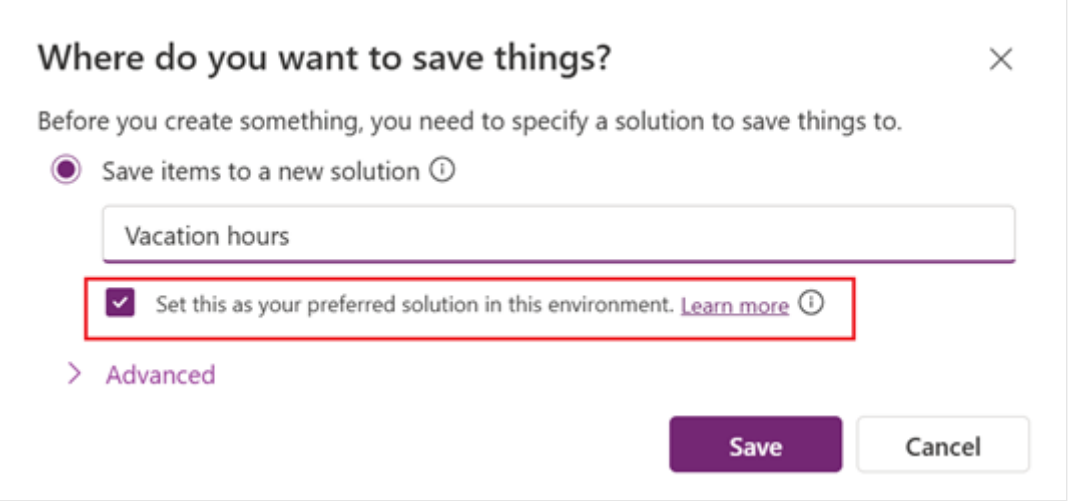


2. When you select **Create** on one of these tiles, these objects are created:

   - **Canvas app**: Opens Power Apps Studio with a data-connected app that starts for you. The app has responsive screens to view and edit data for each recommended

table, and a welcome screen to navigate the app. Learn more about customizing screens in Add and navigate screens. Before you use the app, save and publish it.

- **Model-driven app**: Opens the modern app designer with data tables already added. Before you use the app, save and publish it.
- **Power Pages site**: Opens Power Pages design studio with the initial setup, including layout design, domain configuration, and pages tailored to your goals. Use the studio to develop your website. Learn more in Overview of designing and building sites. To create a Power Pages site, you need the System administrator role in the environment and permissions to register an app in Microsoft Entra.
  - Save and publish the site before you use it. Save the site to the same solution as the plan for healthy application lifecycle management (ALM).
  - When you save a plan in a new solution, make sure to select the **Set this as your preferred solution in this environment** option to save the subsequent items created in this solution by default.



- **Power Automate cloud flow**: Opens the Power Automate using natural language to flow experience with a prefilled prompt based on the business problem, user story, flow description, and data sources. To use the flow, save and publish it.

> **Note**
>
> If you're using the preview experience to create flows, use a preview environment for consistent results. Learn more in Early release cycle environments.

- **Copilot Studio agents**: Opens Microsoft Copilot Studio, where you finish creating your agent and then publish it. An agent is an AI-powered assistant that simplifies

workflows, boosts productivity, and automates repetitive tasks. Plans includes agents as part of its recommended technologies. The plan prefills the agent with the following information:

- **Name**: Name of the agent.
- **Description**: Purpose of the agent.
- **Instructions**: Set of actions for the agent to take.
- **Knowledge**: All tables created by the plan are added to the agent as knowledge sources.

Review the instructions and update the agent as needed for your scenario. For example, add a trigger or an action to the agent. Test the agent to make sure it works as expected before you publish it.

Learn more about Microsoft Copilot Studio.

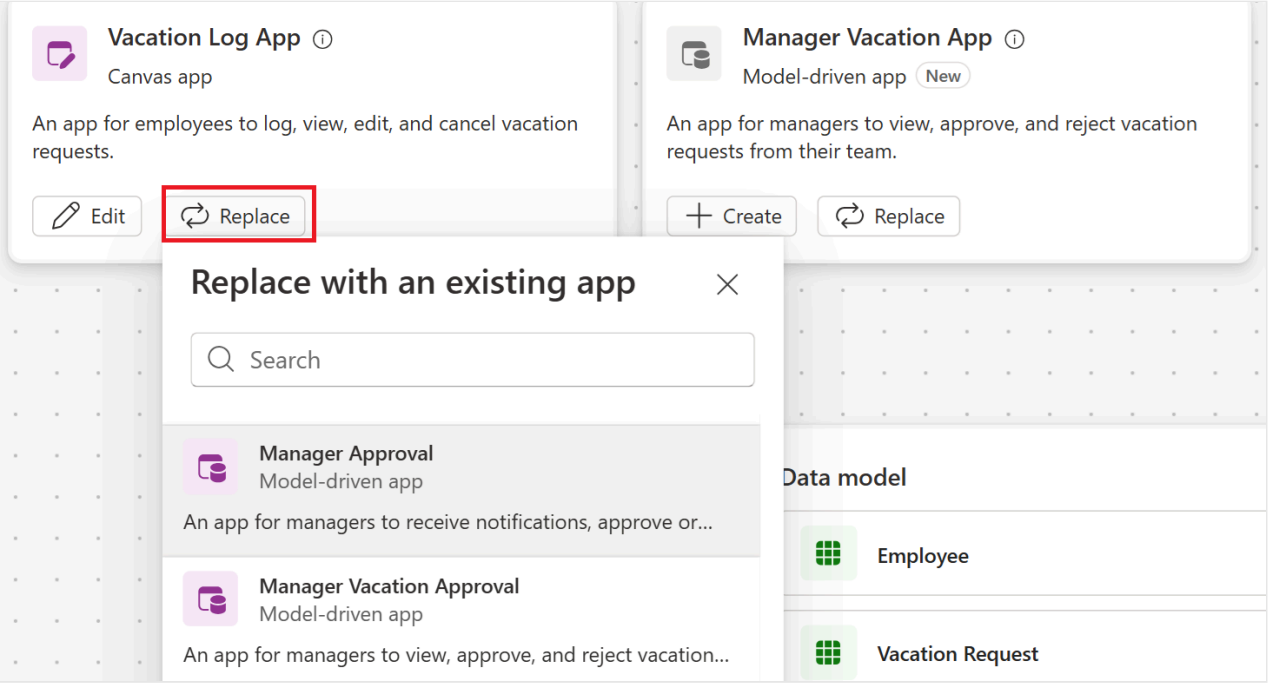
- Agent flows overview
- Add actions to custom agents
- Test your agent
- Key concepts – Publish and deploy your agent
- Key concepts - Analytics

- **Power BI dashboards**: Plans can recommend Power BI dashboards, but connecting a Power BI report with plan context is not currently supported.

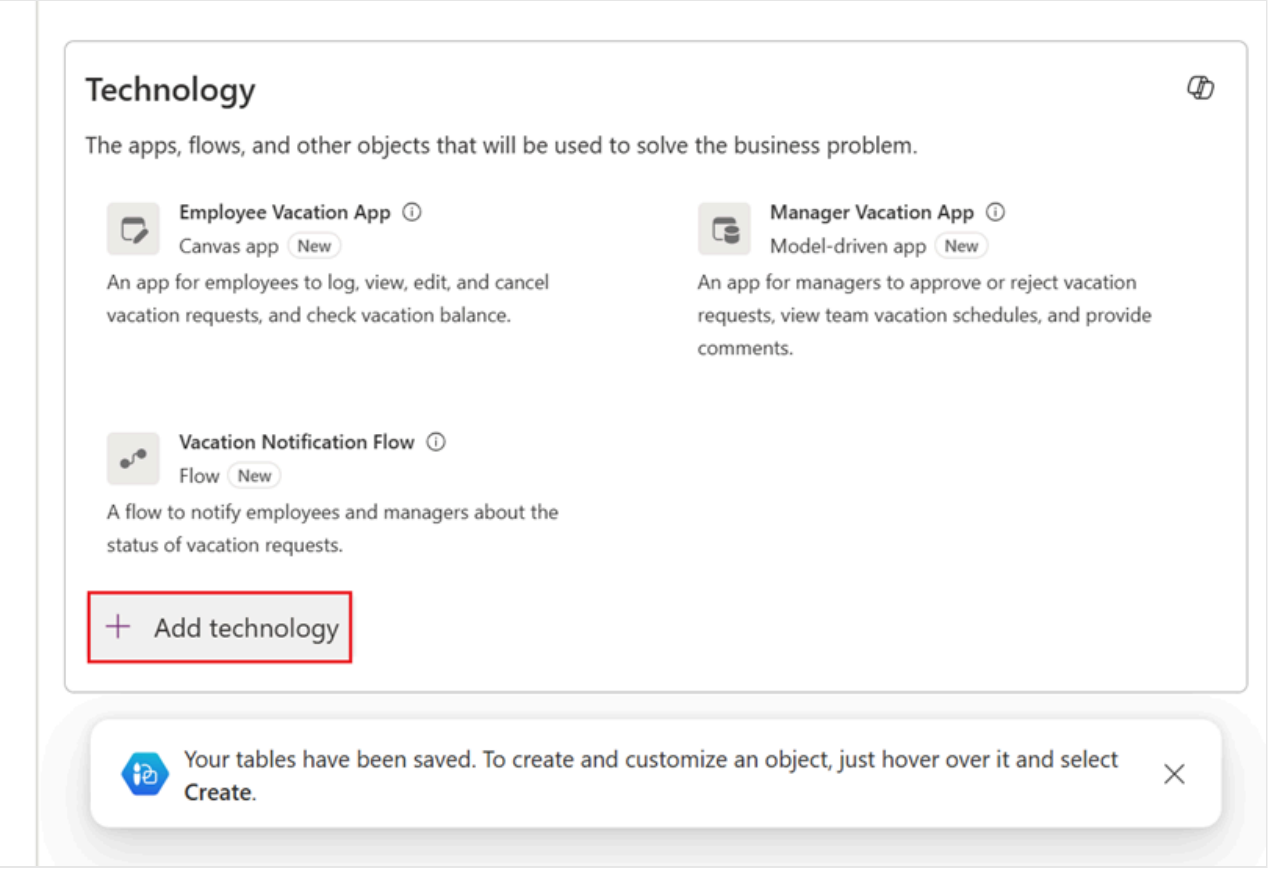
Use existing apps

When apps are proposes apps, replace a proposed app with an existing app or add an existing app to the plan. This approach helps if you already developed apps and want to use them in a new business solution. It saves time, reduces redundancy, and keeps your solutions consistent.

- To replace an app proposed in the plan, select **Replace** on the app tile you want to replace, and then select an app.



- To add an existing app that isn't related to the proposed scenarios, select **Add technology**, and then select an app.



Existing apps you add to the plan aren't included in a new solution. Use the solution view to see all solutions related to the plan.

Next steps

Manage your solution

Last updated on 12/10/2025

Manage your solution

10/02/2025

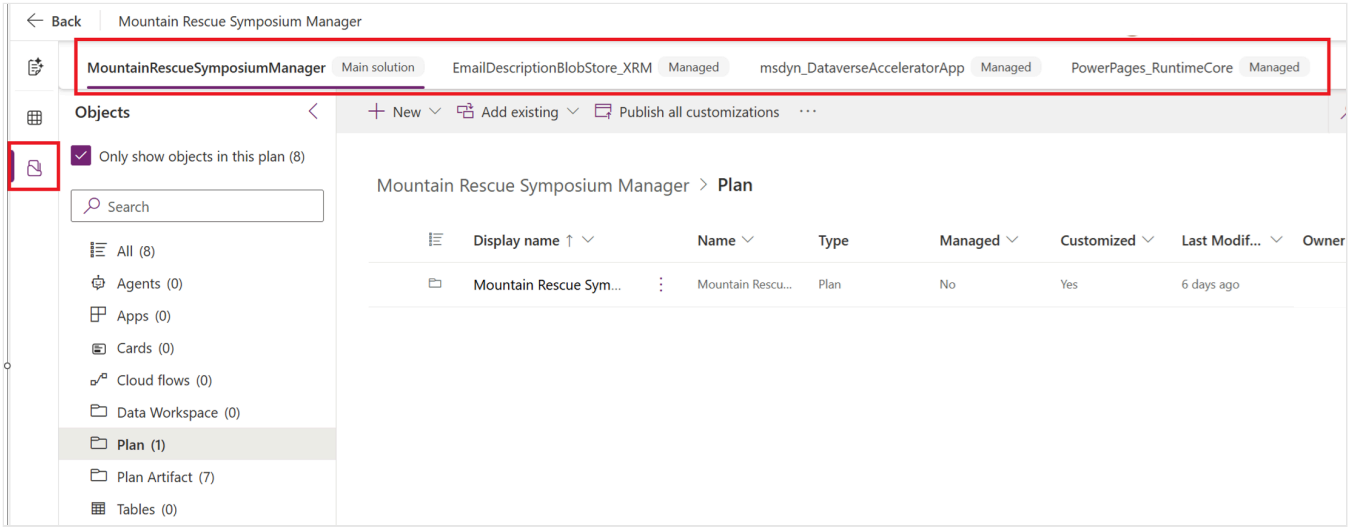
Business solutions built with plans promote healthy application lifecycle management (ALM) practices by using Power Platform resources. Use advanced ALM capabilities to deploy artifacts to target environments through managed solutions by packaging all components of a plan into a single solution artifact.

When you create a plan, the plan is stored in the main solution, which enables the **Objects** view in plans. Makers can switch between the plan and the solution view without leaving the plan.

A plan might be associated with multiple solutions. For example, adding an existing Microsoft Dataverse table to the plan's data model links the solutions associated with the Dataverse table to the plan.

The solutions associated with the plan display as tabs across the top when you select the **Objects** view. Select a tab to view objects in the solution. If there are more than five solutions, an overflow menu shows the remaining solutions. All solution objects are displayed, not just the ones included in the plan.

Learn more about solutions in Solution view.

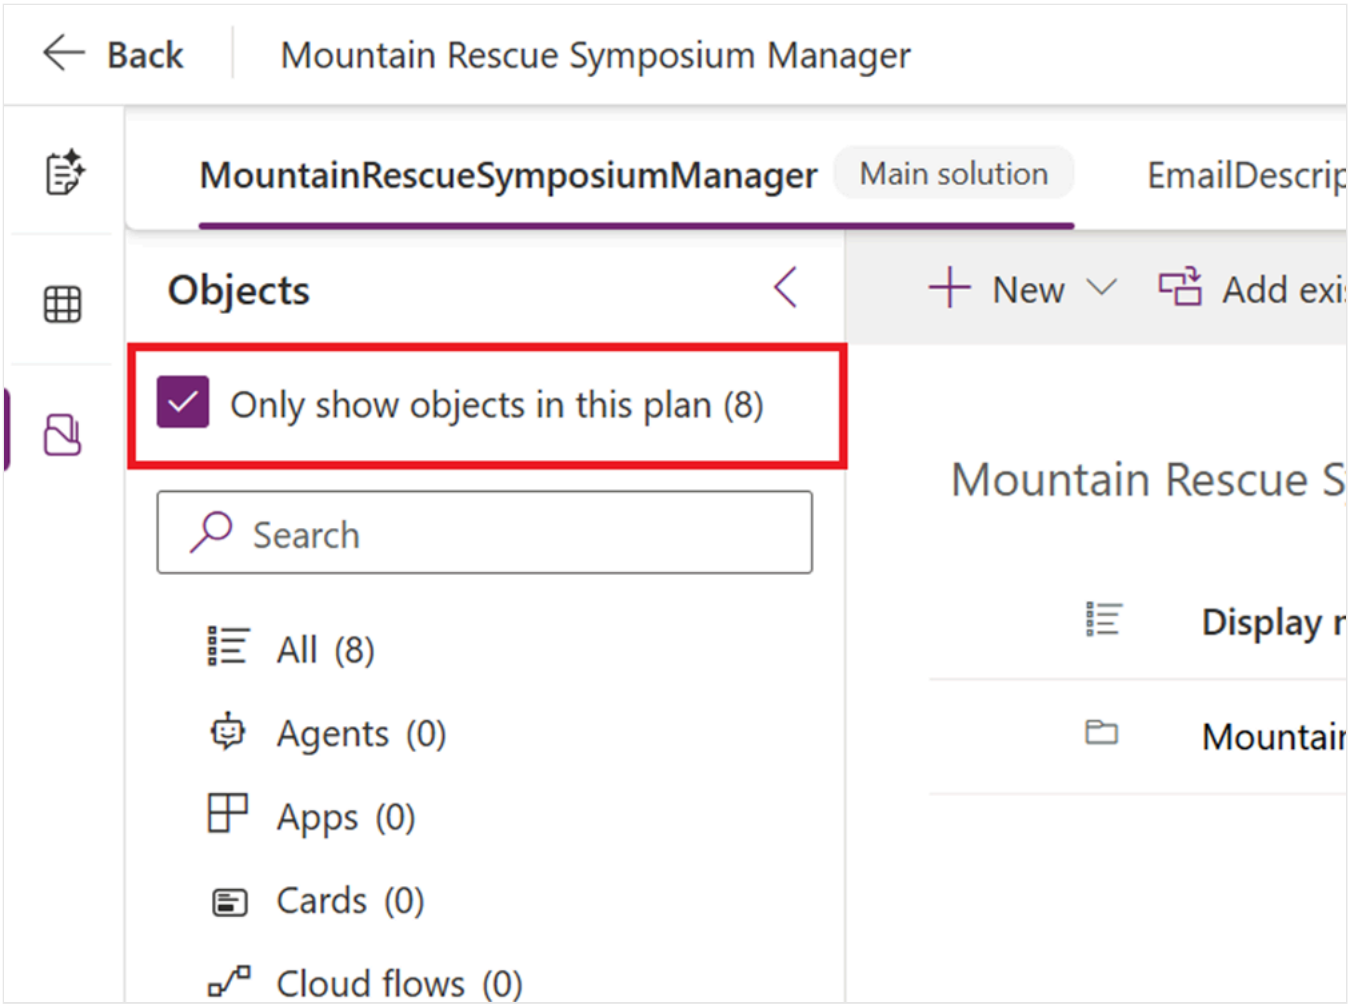


Show objects in this plan

Each plan has a main solution, but other solutions are associated with the plan when you add existing tables or apps from them. These associated solutions might include many objects beyond the ones you add to the plan.

To track which objects from the associated solutions are tied to the plan, select **Only show objects in this plan**. This option lets you view components explicitly designated as part of the

plan.



When you clear **Only show objects in this plan**, the complete contents of these solutions are shown. It helps you understand the broader context, overall composition, and potential dependencies.

Known issues

- When the **Only show objects in this plan** filter is on, some object categories with zero items still appear in the left tree view.
- Some existing canvas apps added to the plan might not filter properly with the **Only show objects in this plan** filter. This issue sometimes affects canvas apps that aren't connected to Dataverse.
- Intermittent caching issues occur. If associated solutions don't show up in the **Objects** view, resave the plan and refresh the **Objects** view to fix the issue.

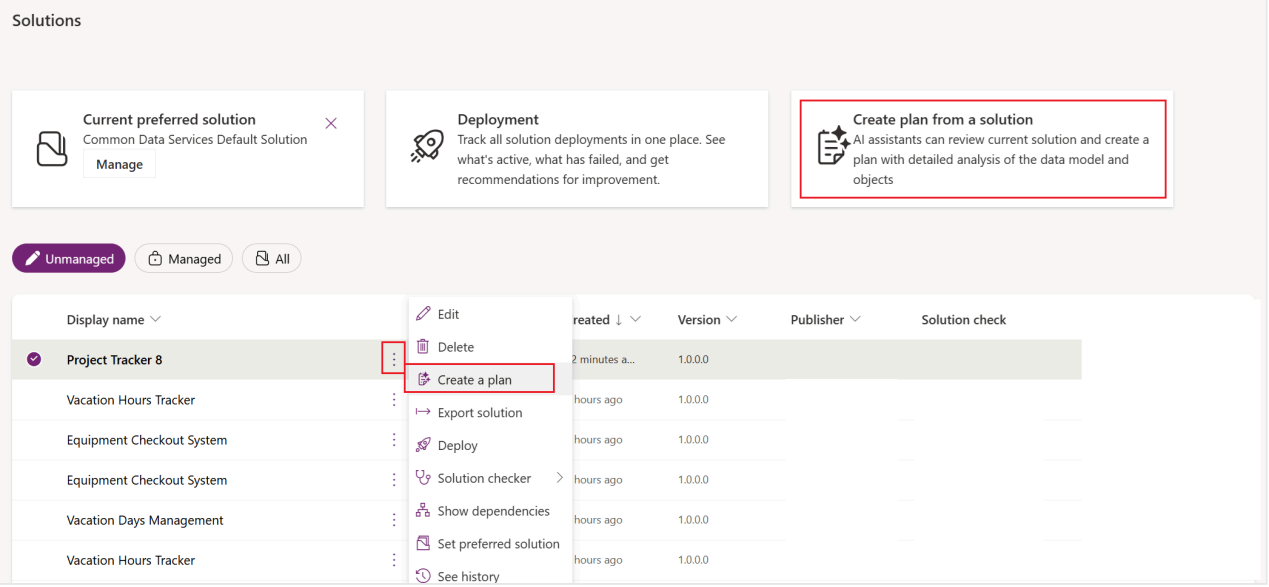
Related information

- Create a plan
- Create a plan from a solution

Create a plan from a solution

Learn how to create a plan for your existing solution. Plans generates a detailed document that describes your solution. The plan covers the business problem, user requirements like user roles and stories, the data model, and technologies like apps, flows, and sites. This feature saves time when you're trying to understand a solution's content and helps makers improve an existing solution.

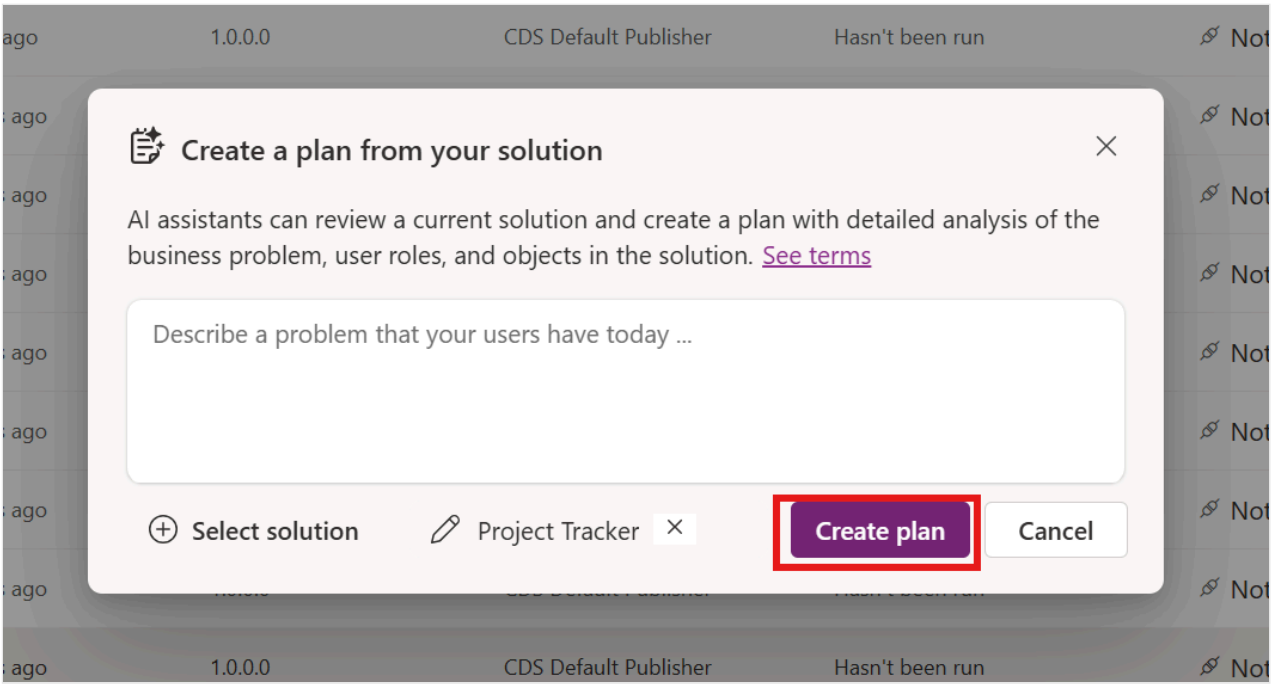
1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**.
3. Select **Create plan from a solution**. Or, from the list of solutions, select a solution, and then select **Commands** > **Create a plan**.



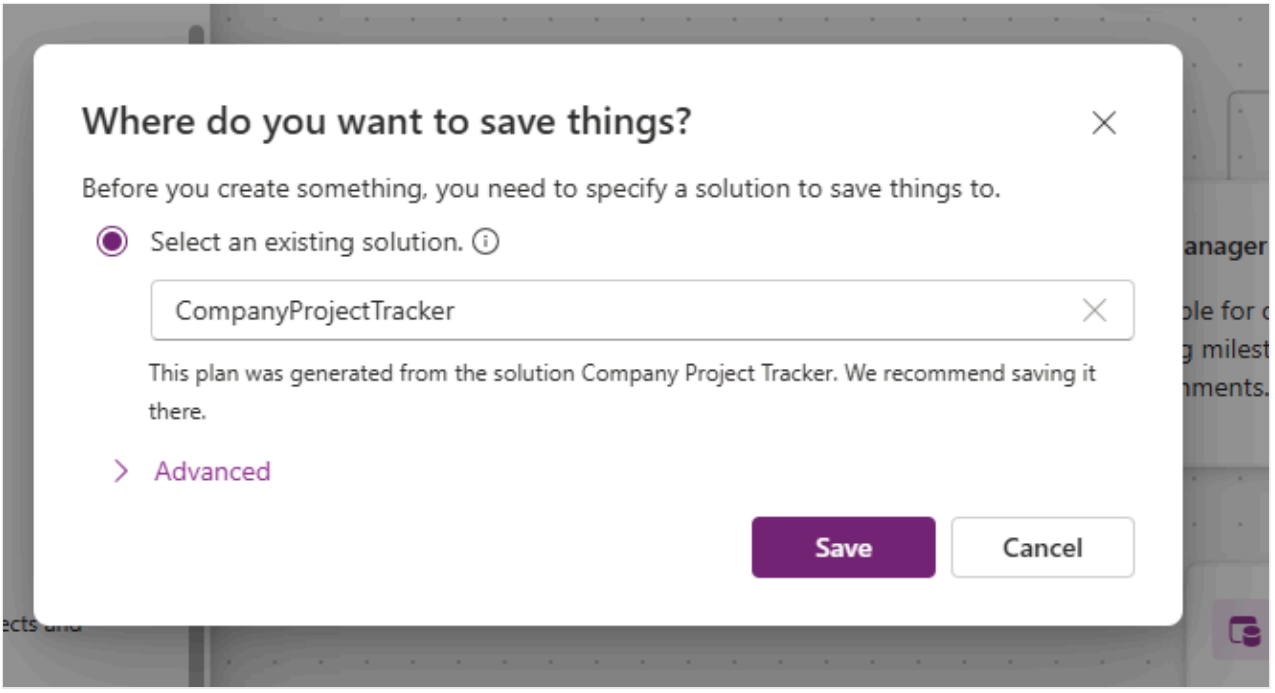
4. Select **Select solution** and then choose a solution.

> **Note**
>
> The solution must have at least one app and one associated table.

5. Select **Create plan**.



6. When the plan is created, save it. For an unmanaged solution, the plan is saved in the same solution. For a managed solution, the plan is saved in a new unmanaged solution by default.



Known limitations

- A solution needs at least one app and one associated table to create a plan.
- It's not recommended to create a plan from a default solution.

What are canvas apps?

Canvas apps are custom business applications you can create in Microsoft Power Apps without writing code. Think of a canvas as a blank design surface where you can drag and drop components to build exactly the user interface you need. Whether you're creating a simple data entry form or a complex business workflow, canvas apps give you the flexibility to design solutions that work the way your business works.

With canvas apps, you can:

- Connect to data from hundreds of sources, including Microsoft 365, Dataverse, SharePoint, and other data sources
- Create responsive designs that work seamlessly across browsers and mobile devices
- Use AI-powered Copilot to build apps through natural language conversations
- Share your apps securely within your organization
- Embed apps directly in SharePoint, Power BI, and Microsoft Teams

This overview helps you understand how to get started building canvas apps and guide you through the key concepts for creating effective business solutions.

Build an app

The following articles provide guidance on building apps:

- Create a plan
- Create a blank canvas app from scratch
- Build apps through conversation with Copilot
- Create a canvas app using Microsoft Dataverse
- Create a canvas app with data from a list
- Create a canvas app based on Excel data

For more information on where makers can create apps, see Get started with Power Apps.

After you generate an app automatically, customize its default appearance and behavior based on your users' workflows. For example, change which types of data appear, how they're sorted, or whether users specify a number by typing it or adjusting a slider. Add and customize screens, galleries, forms, and other controls.

After you generate and customize an app automatically, create an app from scratch based on Dataverse, Excel, or another data source. By working from the ground up, you get flexibility in app design, flow, and controls, and you can use a larger variety of data sources.

If you're new to Power Apps and want to turn your ideas into a working solution, start with Planning a Power Apps project.

Connect to data

Canvas apps can connect to a wide variety of data sources. Choose the data source that best fits your scenario:

- **Microsoft Dataverse** – Use Dataverse as your primary data store for business applications with built-in security, logic, and data management.
- **SharePoint** – Build apps on top of SharePoint lists to extend your existing collaboration workflows.
- **Excel** – Create apps based on Excel workbooks stored in cloud storage like OneDrive or SharePoint.
- **SQL Server and Azure SQL** – Connect directly to SQL databases for enterprise data scenarios.
- **Other connectors** – Browse hundreds of available connectors for services like Dynamics 365, Salesforce, and more.

For guidance on linking Power Apps data to Microsoft Fabric, see Configure your environment and link to Microsoft Fabric.

Share and run an app

When you finish the app and save it to the cloud, share it with others in your organization. Specify which users or groups can run the app, and whether they can also customize and share it with more people in the organization.

Run your own apps, and any apps shared with you, on Windows, in a web browser, or on an iOS or Android device.

Licensing and trials

To get started with Power Apps, you need the right license for your scenario:

- **Free trial** – If you don't have a license for Power Apps, you can sign up for a free trial. Trial licenses provide access to most Power Apps features for a limited time.
- **Trial extension** – If your trial is expiring, contact your admin or visit the Power Platform admin center to explore extension options.
- **Developer environment** – If you don't have an organization account, establish a developer's account through the Microsoft Developer Program.
- **Licensing overview** – For detailed plan comparisons, see the Power Apps pricing page.

Troubleshoot common issues

If you encounter issues while building or running canvas apps, the following resources can help:

- **Known issues for canvas apps** – Solutions for common errors and known limitations.
- **Performance optimization** – Tips for improving app load times and responsiveness, including slow site performance.
- **Formula reference** – Complete reference for Power Fx formulas and functions used in canvas apps.
- **Coding guidelines** – Best practices for maintaining clean, performant canvas app code.
- **Dataverse troubleshooting** – Resolve issues with Dataverse connections, including mailbox configuration and solution imports.

If your issue isn't resolved through documentation, you can create a support request through the Power Platform admin center.

Learn more

- Want to turn your ideas into an app? Start with Planning a Power Apps project.
- Explore step-by-step, conceptual, and reference articles in the navigation pane on the left.
- Check out the webinars and video gallery to learn how to use Power Apps features and functions.

Share your experience

- Read and post in the Power Apps Community, where anyone who uses Power Apps can post a question for others to answer. Before you post a question, search the community to see if your question is already answered.
- Submit an idea to improve Power Apps in the Power Apps Ideas Forum.

- If you're a Power Apps admin for your organization, open a support ticket in the Power Platform admin center.

Keyboard shortcuts for canvas apps

> **Note**
>
> Shortcuts can vary based on keyboard layout.

File

Expand table

Shortcut	Action
Ctrl+Shift+S (or Alt+P)	Save the app with a different name
Ctrl+S	Save the app with the same name or for the first time
Ctrl+Shift+P	Save the app and activate the publish dialog
F12	Download the app file (.msapp)

Ribbon

Expand table

Shortcut	Action
Enter	Run the selected command
Tab	Move between commands on the selected tab, then to the next tab
Alt+I	Select the **Insert** tab

Editing

Expand table

Shortcut	Action
Ctrl+A	Select all
Ctrl+X	Cut
Ctrl+C	Copy

Shortcut	Action
Ctrl+V	Paste
Ctrl+Z	Undo
Ctrl+Y	Redo
Ctrl+=, Ctrl+Shift+=, or Ctrl+Mouse wheel up	Zoom in
Ctrl+-, Ctrl+Shift+-, or Ctrl+Mouse wheel down	Zoom out
Ctrl+0	Fit canvas to page
`Enter` or `Shift` + `Enter`	Select a suggestion in a formula without adding a new line (Enhanced formula bar shortcuts is turned off)
`Enter`	Select a suggestion in a formula and create a new line (Enhanced formula bar shortcuts must be turned on)
`Shift` + `Enter`	Create a new line in a formula without keeping the suggestion (Enhanced formula bar shortcuts must be turned on)

> **Important**
>
> To use keyboard shortcuts for the formula bar, turn on **Enhanced formula bar shortcuts**. In Power Apps, go to Settings, and then select **Power App settings**. On the **Editing** tab, turn on **Enhanced formula bar shortcuts**.

Preview

Expand table

Shortcut	Action
F5	Open Preview mode
Esc	Close Preview mode, a dialog box, or a flyout pane

Canvas

Expand table

Shortcut	Action
`Tab`	Select the next control
`Shift` + `F11`	Set focus to the inline action bar
Hold down `Ctrl` while selecting or hold down `Shift` while selecting	Select multiple objects at once
`Right arrow`	Move the selected control to the right
`Left arrow`	Move the selected control to the left
`Up arrow`	Move the selected control up
`Down arrow`	Move the selected control down

Tree view

> **Note**
>
> These shortcuts work when the **Tree view** pane has focus.

Expand table

Shortcut	Action
F2	Rename a control
Esc	Cancel renaming a control
Ctrl+G	Group or ungroup controls
Ctrl+]	Bring a control forward
Ctrl+[	Send a control backward
Ctrl+Shift+]	Bring to front
Ctrl+Shift+[	Send to back

Resize

Expand table

Shortcut	Action
Shift+Left arrow	Decrease width
Ctrl+Shift+Left arrow	Decrease width slightly
Shift+Down arrow	Decrease height
Ctrl+Shift+Down arrow	Decrease height slightly
Shift+Right arrow	Increase width
Ctrl+Shift+Right arrow	Increase width slightly
Shift+Up arrow	Increase height
Ctrl+Shift+Up arrow	Increase height slightly

Text format

Expand table

Shortcut	Action
Ctrl+B	Cycle through levels of bold
Ctrl+I	Turn italics on or off
Ctrl+U	Add or remove underline

Alternate behavior

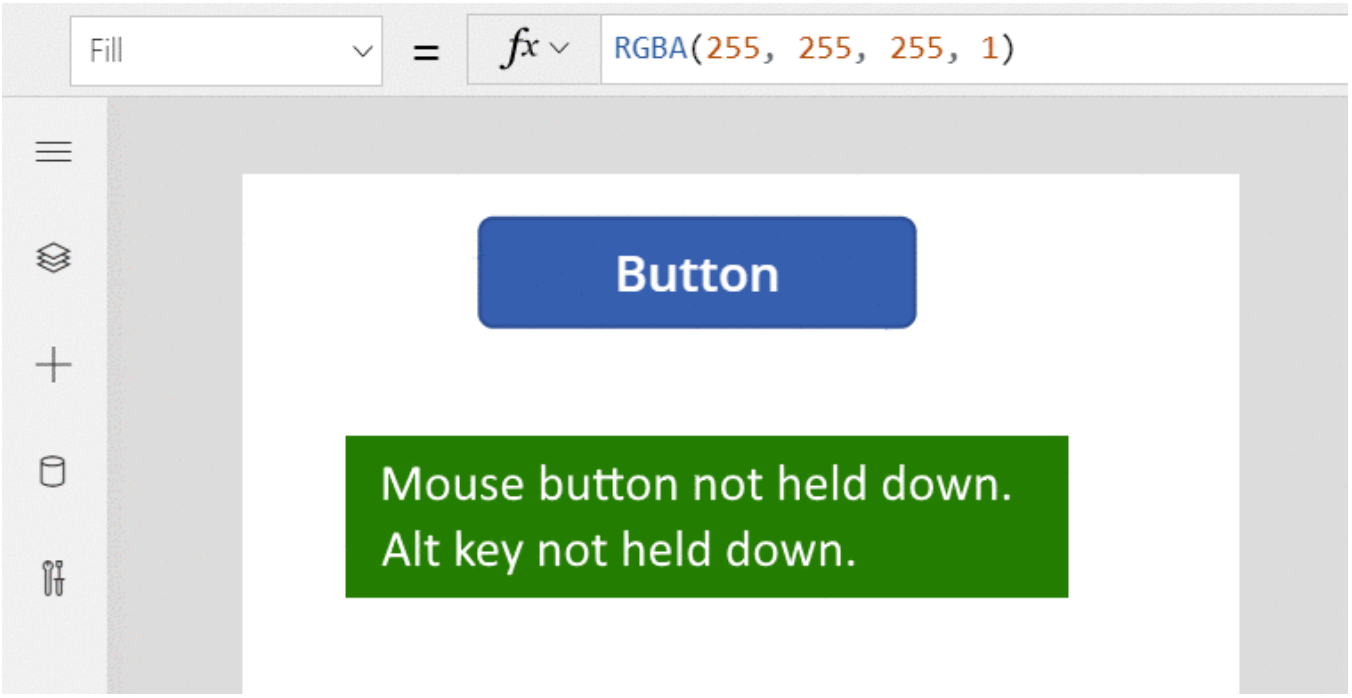
Expand table

Shortcut	Action
Alt or Ctrl+Shift	1. Before selecting a control, hide design elements so that you can interact with the controls as the app's user would. 2. After initiating a resize or reposition of a control, holding down these keys overrides any snap points.

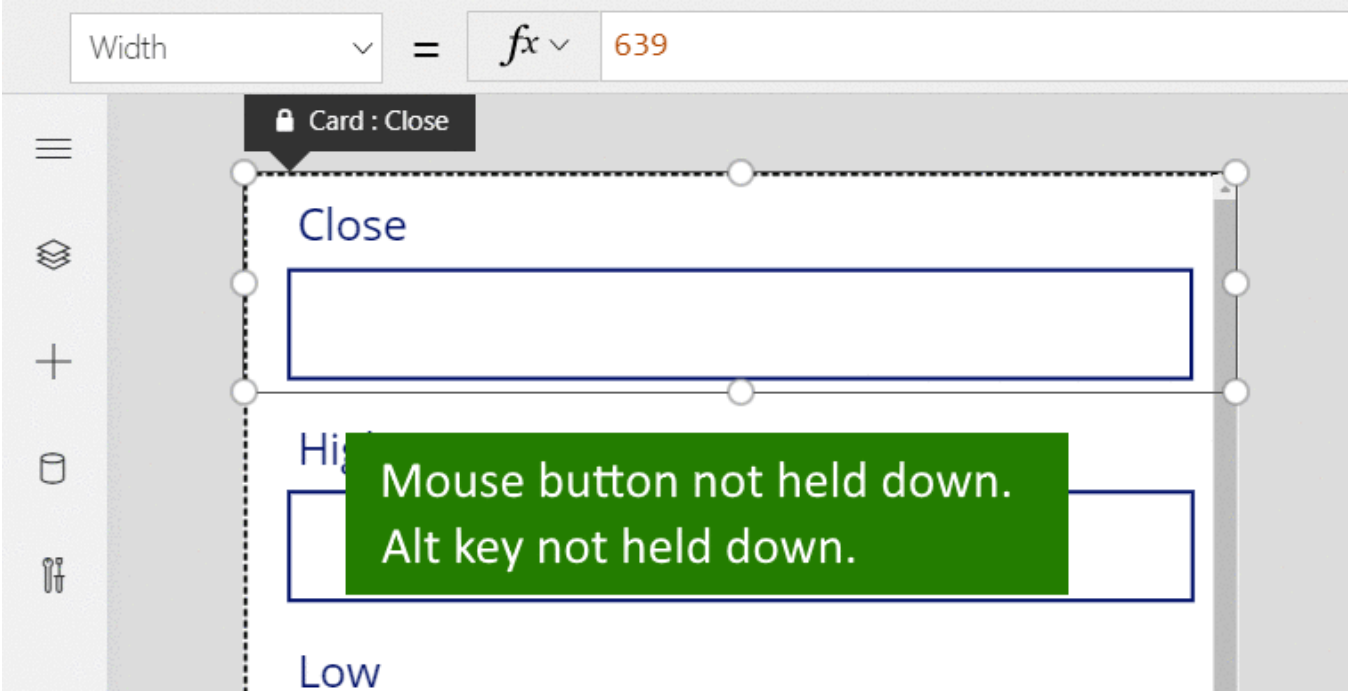
Like an Excel spreadsheet, canvas apps are live and running even when you're editing them. You don't need to switch to preview mode to test your app, so editing and testing are much faster. But this feature creates a challenge: How do you select a button control to resize it instead of selecting it to run the app logic?

When you're in design mode, selecting an object lets you edit it. You can move, resize, change properties, and configure the object. To override this default behavior, hold down the Alt or Ctrl+Shift keys *before* you select the object. This action treats the selection as if a user of the app selected it.

In the following animation, a button control is first selected for editing. Adorners appear around the control, and the formula bar shows the **OnSelect** property, ready to edit. After you release the button, hold down the Alt key and select the button control again. This time, the **OnSelect** property runs, and the notification appears, just like when a user selects the button in a running app.



You can also use the Alt key *after* you select a control to override snap points when moving or resizing. The next animation shows how to resize a data card in an **Edit form** control. At first, resizing is limited to specific snap points. Later, *without releasing the mouse button*, hold down the Alt key. This action overrides the snap points, so you can set any width with the mouse.



Other

Expand table

Shortcut	Action
F1	Open documentation
Ctrl+F6	Go to the next landmark. It navigates clockwise through the landmarks of a page (for example, headers, navigation bars, main content). Adding the Shift key (Ctrl+Shift+F6) moves through them in counterclockwise order.
Ctrl+Shift+F6	Go to the previous landmark. It navigates in counterclockwise order through the landmarks of a page (for example, headers, navigation bars, main content).
Shift+F10	Open a shortcut menu, for example, in **Tree view**

Create a blank canvas app from scratch

Summarize this article for me

Power Apps canvas apps give you the flexibility to design custom business apps tailored to your specific needs. When you create a blank canvas app, you start with an empty design surface that you can customize with controls, data connections, and business logic.

Prerequisites

Ensure you have the Environment Maker security role, either directly or through a Microsoft Dataverse team that is part of the **AAD Security Group** category. Custom security roles aren't currently supported for Canvas App maker scenarios.

Create a blank canvas app

1. Sign in to Power Apps.
2. In the left navigation pane, select **Create** > **Start from blank**.
3. Choose an app size (format) such as responsive, tablet, or phone.

When you create the app, it opens in Power Apps Studio where you can start building and customizing it.

Next steps

Configure the app's functionality and, depending on your business scenario, add the necessary connections and data sources.

- Add a connection
- Add and configure controls
- Save and publish an app

Last updated on 02/24/2026

Create and edit canvas apps with AI code generation tools (preview)

[This article is prerelease documentation and is subject to change.]

This article describes how to use AI code generation tools, such as GitHub Copilot CLI and Claude Code, to create and edit canvas apps in Power Apps. By using this approach, you can integrate advanced code generation capabilities directly into your development workflow. You can create new canvas apps or iterate on existing ones by using natural language instructions.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Using AI code generation tools with canvas apps provides an alternative development approach that complements the UI-based experience in Power Apps (make.powerapps.com).

What you can do with code generation tools

- *Create new canvas apps* by using plain-language requirements.
- *Update existing canvas apps* by requesting changes or enhancements through your AI tool.
- *Work locally* by using your preferred IDE and development tools, syncing with live coauthoring sessions.

How it works

1. You describe what you want to build in natural language, for example, "Create a canvas app for tracking expense reports with an approval workflow."
2. The AI code generation tool uses installed canvas app skills to discover available controls, connectors, and data sources. It asks clarifying questions about your requirements.
3. The tool generates `.pa.yaml` files that define your app screens, controls, and Power Fx formulas.
4. The tool validates the generated code by using the canvas app authoring MCP server and fixes any errors.

5. Your canvas app syncs with Power Apps Studio through the coauthoring session.

Prerequisites

Before you start, make sure you have the required software and permissions described in this section.

Software requirements

Expand table

Component	Minimum version	More information
.NET SDK	10.0 or later	Download .NET SDK
GitHub Copilot CLI, Claude Code, or other code generation tool	Latest	GitHub Copilot CLI or Claude Code

Additional requirements

- A Power Platform environment with a canvas app.
- Power Apps Studio open with **coauthoring enabled** for your canvas app.
  - To enable coauthoring, open your app in Power Apps Studio, go to **Settings** > **Updates**, and turn on **Coauthoring**.

Install the canvas apps plugin

To install the canvas apps MCP plugin, run the following commands in either Copilot CLI, or Claude Code:

1. Add the Power Platform Skills marketplace plugin:

```shell
/plugin marketplace add microsoft/power-platform-skills
```

2. Install the canvas apps plugin:

```shell
/plugin install canvas-apps@power-platform-skills
```

After you install the plugin, you need to configure the canvas app authoring MCP server before you can create or edit apps. You can configure the server by either of the following options:

- Run the `/configure-canvas-mcp` command to set up the MCP server connection.
- Describe what you want to build - the tool detects that the MCP server needs to be configured and guides you through setup.

Configure the canvas app authoring MCP server

The canvas apps plugin uses an MCP (Model Context Protocol) server to communicate with Power Apps. Before creating or editing apps, you need to configure this server connection:

1. Open your canvas app in Power Apps Studio and ensure **coauthoring** is enabled.
2. Copy the Power Apps Studio URL from your browser.
3. Run `/configure-canvas-mcp` in your AI tool, or ask the tool to configure the MCP server.
4. Provide the Designer URL when prompted. The tool extracts your environment ID, app ID, and cluster information automatically.

By using the MCP server, your AI tool can list and describe available controls, discover APIs and data sources, validate app YAML, and sync app state from live coauthoring sessions.

The canvas-apps plugin repository includes control documentation, design guidance, technical reference, and workflow instructions necessary to create code adhering to canvas app requirements. Refer to the repository for information on accessing and using these resources with your preferred tool.

Skills overview

The canvas apps plugin provides these skills for working with canvas apps.

Expand table

Skill	Command	Description
Generate canvas app	`/generate-canvas-app`	Create a new canvas app from a natural language description
Edit canvas app	`/edit-canvas-app`	Edit an existing canvas app from a natural language description
Configure Canvas MCP	`/configure-canvas-mcp`	Register the canvas app authoring MCP server with your AI tool

These skills enable you to describe what you want to build and have the AI tool generate complete `.pa.yaml` files for your canvas app, validate them against the Canvas Authoring server, and sync changes with your live Power Apps Studio session.

Create a new canvas app

Follow this workflow when building a new app from scratch.

1. Start a conversation with your AI tool. Describe what you want to create, including the layout and what data you want to include (which Dataverse tables, or connectors to use). Be as specific as you want - the more vague you are with the request, the more details the agent tries to fill in itself. You can also attach or provide an image or other materials to help guide the visuals, theming, and layout. For example:

    - "Create a canvas app for tracking inventory with a searchable list and detail view"
    - "Build a canvas app for employee onboarding with a multi-step form"
    - "Make a canvas app dashboard showing sales metrics with charts and KPIs"
    - "Create a canvas app for field inspections with photo capture"

2. Answer clarifying questions. The AI tool discovers available controls and data sources using the MCP server and asks questions to understand your requirements. Be specific about business needs and data requirements and mention any specific UI components or layout preferences.

3. Review code and validate. The AI tool generates `.pa.yaml` files for each screen and validates them using the canvas app authoring MCP server. The tool fixes any validation errors automatically. Your changes sync with the live coauthoring session in Power Apps Studio.

4. Test and iterate. Open your canvas app in Power Apps Studio to preview and test. If you need to make changes, return to your AI tool and describe the updates using natural language.

Edit an existing canvas app

Use this workflow to update an app that already exists in your coauthoring session.

1. Sync the existing app. In your AI code generation tool, ask to edit your canvas app. The tool syncs the current app state from the coauthoring session, pulling all existing screens and controls into local `.pa.yaml` files. For example, "I want to edit my expense tracking canvas app."

2. Describe your updates. Tell the AI tool what changes you want to make. For example:

    - "Add a filter to show only pending expenses"
    - "Change the home screen layout to use a card-based grid"
    - "Add a new screen for viewing expense history with charts"
    - "Update the form to include a dropdown for expense categories"

3. Review, validate, test, and iterate. The AI tool generates updated `.pa.yaml` files based on your requested changes and validates them with the Canvas Authoring server. Follow the same review and test process described in the "Create a new canvas app" section. Continue iterating with natural language instructions until the app meets your requirements.

Troubleshooting

App doesn't reflect changes

If your changes don't appear in Power Apps Studio:

1. Verify the connection to the canvas app authoring MCP server by asking the tool to list available controls.
2. Ensure coauthoring is enabled in your Power Apps Studio session (**Settings** > **Updates** > **Coauthoring**).
3. Check that the MCP server is configured with the correct environment ID and app ID by running `/configure-canvas-mcp` again.

MCP server connection problems

If the canvas app authoring MCP server isn't responding:

1. Verify that the .NET 10 SDK is installed by running `dotnet --version` in your terminal.
2. Ensure your Power Apps Studio session is still active and coauthoring is enabled.
3. Re-run `/configure-canvas-mcp` with a fresh Designer URL.

Revert to a working version

If recent changes break your app or make problems worse, ask the AI tool to roll back to a previous working version:

"The recent changes broke the app. Please revert to the last working version."

The AI tool then:

1. Syncs the current state from the coauthoring session
2. Identifies the changes that you made
3. Restores the previous working code
4. Validates and resyncs the stable version

Best practices

- Start simple. Begin with a basic version of your app and iterate to add complexity.
- Test frequently. Preview your app in Power Apps Studio after each significant change.
- Be specific. Provide detailed requirements to get better initial results.
- Use existing patterns. Reference similar apps or UI patterns when describing your requirements.
- Validate generated code. Always review the generated `.pa.yaml` files to ensure they meet your organization standards and compliance requirements.
- Bold design choices. Don't settle for generic layouts - describe the visual style and aesthetic direction you want.

> **Important**
>
> While AI code generation tools make a best-effort attempt to generate complete, production-ready code with accessibility and security best practices, you're ultimately responsible for validating the code. Ensure the generated code meets your organization standards, policies, and compliance requirements.

Build apps through conversation with Copilot

Create apps without writing code or designing screens. By using Copilot in Power Apps, you use natural language to describe what you want your app to do, and AI does the rest.

Copilot is a feature in Power Apps that helps you build apps with AI assistance. From the Power Apps home screen, select **Start with data**, and then select **Create new data** to open the table editor with Copilot. Enter the type of information you want to collect, track, or show in your app, and Copilot generates one or more Microsoft Dataverse tables that you use to build your canvas app.

Prerequisites

- Check the prerequisites and region availability in Copilot in Power Apps overview (preview).
- Depending on where your environment is hosted, you might need to enable data movement across regions. For more information, see Copilots and generative AI features that are available when you enable data movement across regions. You need access to a Microsoft Dataverse database in your environment to use this feature. For more information, see Add a Microsoft Dataverse database.
- Check if this feature is available in your region. For more information, see Explore Copilot features by geography and languages.
- Assign the system customizer security role in the environment.

Create an app by using Copilot

Let's create an app to track housekeeping tasks for a hotel so you can see how Copilot works.

1. Sign in to Power Apps.
2. On the home screen, select **Start with data**.
3. Select **Create new data**.

   The **Create new tables** workspace opens with a blank table and the Copilot panel on the right side.

4. In the Copilot panel text box, enter your prompt, like the example prompt in the following section.

   Copilot prompt

   ```
   Create tables to track hotel housekeeping tasks including room numbers, task types, staff assignments, and task status
   ```

5. Select **Submit** or press **Enter**.

Copilot creates one or more Dataverse tables with data that includes typical hotel housekeeping tasks.

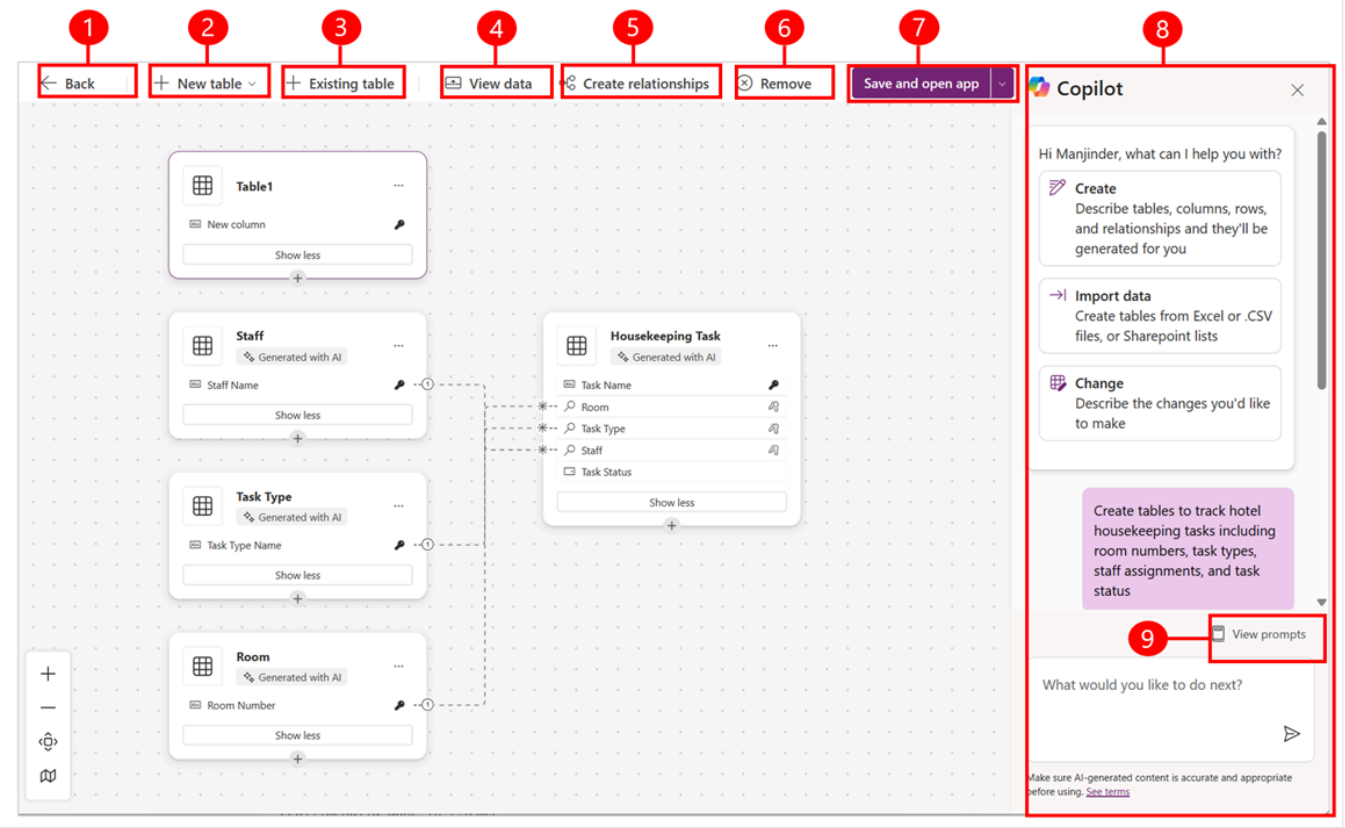
> **Important**
>
> If you don't have the right permissions or access to Dataverse in the environment you're working in, an alert asks you to create the app in your own environment. Make sure you can create the table and app in your environment to continue. If you don't have a personal developer environment, a new one is created for you automatically. For more information, see Get your developer environment (preview).

Review the table

Copilot generates tables and relationships based on your description. Review them and make any changes you need before you create your app.

Review the tables for your app

Copilot shows you the tables and relationships it generates based on your description in the **Create new tables** workspace.



The workspace includes the following options:

Expand table

Option	Description
1. **Back**	Return to the previous screen.
2. **New table**	Add a new table to your workspace.
3. **Existing table**	Add an existing Dataverse table.
4. **View data**	View the data in your tables.
5. **Create relationships**	Create relationships between tables.
6. **Remove**	Remove a table from the workspace.
7. **Save and open app**	Creates draft tables and relationships, then opens your app for editing.
8. **Copilot panel**	Ask Copilot to create tables, import data, or make changes using natural language.
9. **View prompts**	See examples of what you can ask Copilot to do.

Use Copilot to make changes

To change something, enter a brief description of the change in the Copilot panel. Copilot makes the change for you.

The Copilot panel provides three options to help you get started:

- **Create**: Describe tables, columns, rows, and relationships and they'll be generated for you.
- **Import data**: Create tables from Excel or .CSV files, or SharePoint lists.
- **Change**: Describe the changes you'd like to make.

For example, ask Copilot to add columns to track cleaning start and end time.

1. In the Copilot text box, enter **Add columns to track start and end time**.

   Copilot adds two new columns called **Start Time** and **End Time**.

2. Continue editing the table as needed. For example, add room status, change room types, or set a priority level for each room.

3. When you're ready to create your app, select **Save and exit**.

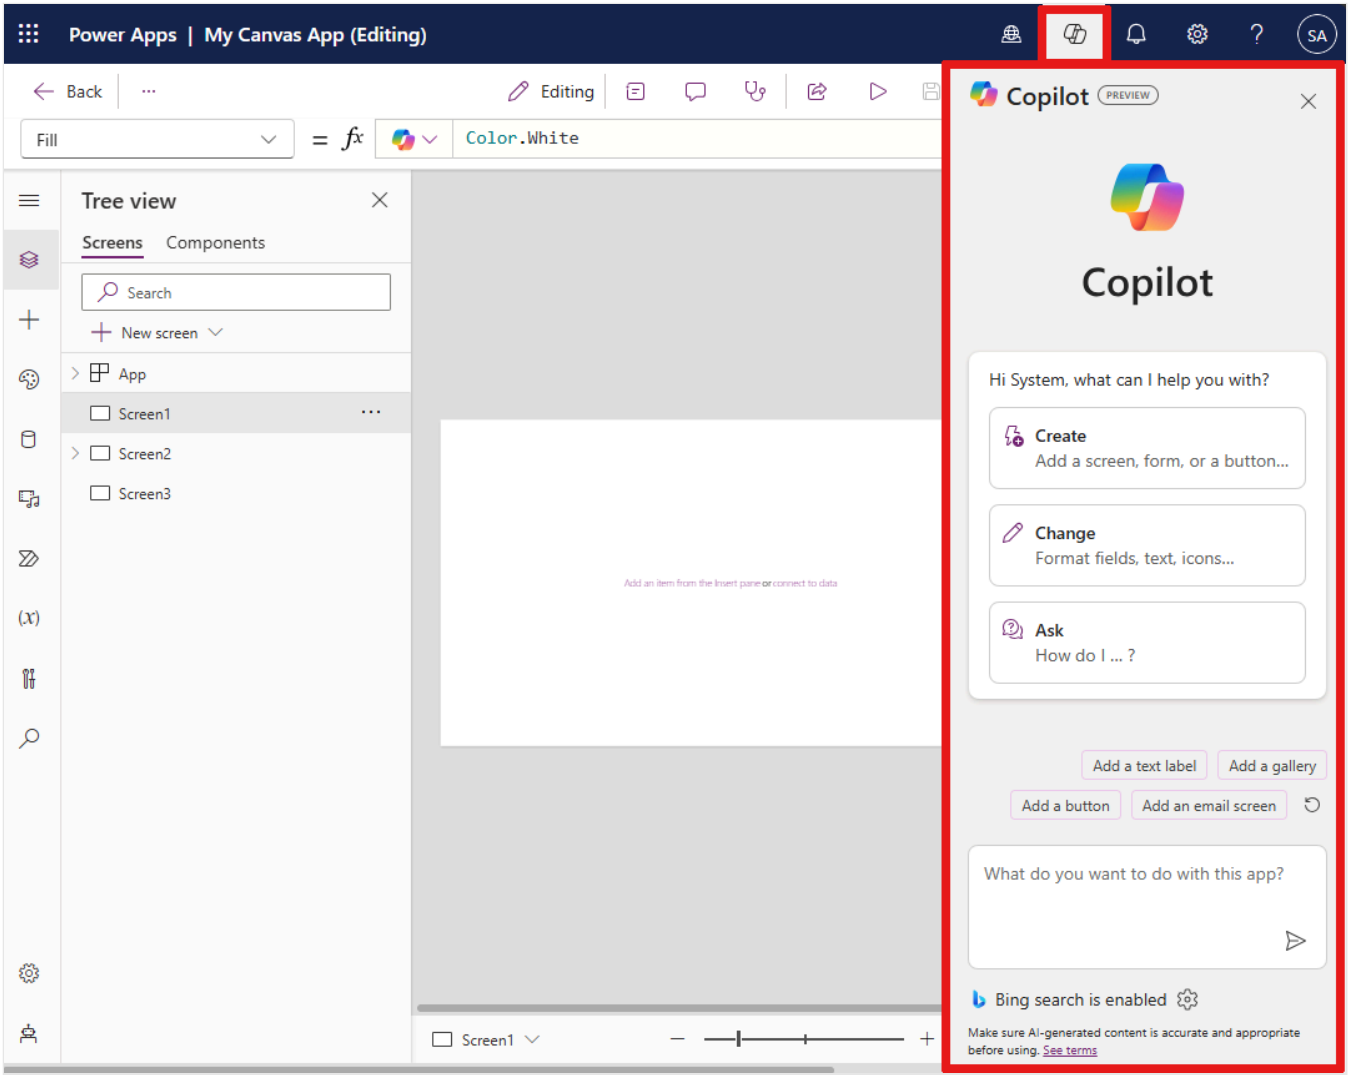
Edit your app with Copilot in Power Apps Studio (preview)

[This article is prerelease documentation and is subject to change.]

> **Important**
>
> Starting January 6, 2026, this feature will be removed. To continue creating apps with Copilot, use Plans.

Edit your apps without writing code or designing screens. With Copilot in Power Apps, you can use natural language to describe the changes you want to make, and AI does the rest.

Copilot is a feature in Power Apps that helps you edit your apps with AI assistance. You can access Copilot from Power Apps Studio when you edit a canvas app. Tell Copilot what kind of changes you want to make in the Copilot conversation pane, such as adding a screen, configuring navigation, styling a control, or editing multiple controls at a time.



> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

> **Note**
>
> This capability:
>
> - Is powered by Azure OpenAI Service
> - Might be subject to usage limits or capacity throttling

Prerequisites

Ensure you meet the prerequisites and region availability in Copilot in Power Apps overview (preview).

Supported languages

The following table lists the languages that Copilot understands.

You can track future language availability in the Copilot product report.

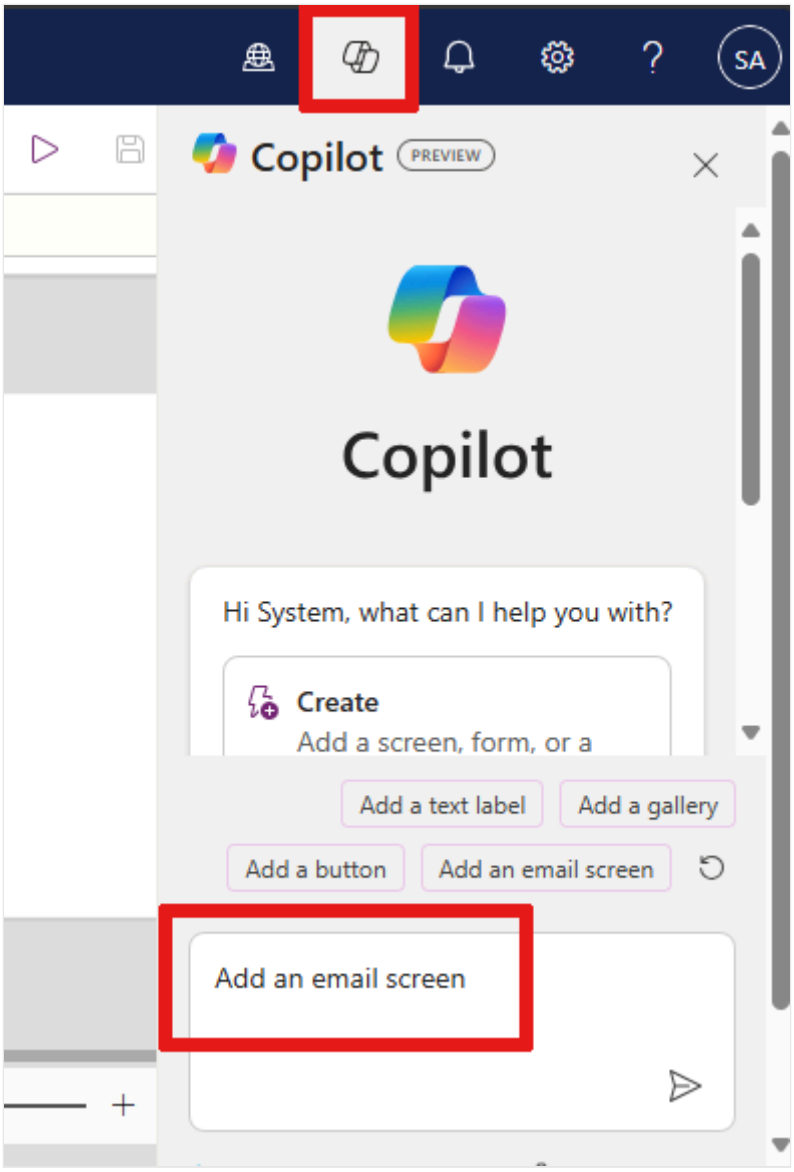
Expand table

Name	Language Code
English	en-US
Chinese (simplified)	zh-Hans
Czech	cs-CZ
Danish	da-DK
Dutch	nl-NL
Finnish	fi-FI

Name	Language Code
French	fr-FR
German	de-DE
Greek	el-GR
Italian	it-IT
Japanese	ja-JP
Korean	ko-KR
Norwegian (Bokmål)	nb-NO
Polish	pl-PL
Portuguese	pt-BR
Russian	ru-RU
Spanish (Traditional Sort)	es-ES
Swedish	sv-SE
Thai	th-TH
Turkish	tr-TR

Use Copilot to edit your app

1. Sign in to Power Apps and open a canvas app for editing.
2. In Power Apps Studio, in the upper-right corner of the page, select **Copilot**.
3. In the Copilot text box, describe a change you want to make, such as *Add an email screen*.



What you can do with Copilot in Power Apps

Copilot in Power Apps allows you to perform the following tasks:

- Add a new screen using a template. Learn more in Add a screen.
- Modify the properties of some controls, including:
  - Screen
  - Horizontal and vertical containers
  - Gallery
  - Edit form
  - Button
  - Text label
  - Text input

Sample commands you can try

When you open the Copilot pane, you can select from three preset prompts that demonstrate Copilot's capabilities: **Create**, **Change**, and **Ask**. You can also try entering the following commands in the Copilot text box.

> ⓘ **Note**
>
> Some Copilot requests are built into preview features, which only work when **Try the new data experience** toggle is turned on from your Power Apps home page. Learn more in Build apps with Copilot in Power Apps (preview).

Scenario: Add a new screen using a template

- Add a new screen
- Add a new email screen
- Add a new screen with header, body, and footer

Scenario: Add/edit/style a control

- Add a new button
- Change the selected button to have width 100
- Add a new icon
- Add a new text label
- Add a submit button and a cancel button to the form

Scenario: Bulk editing

- Change all buttons to gray
- Change all labels in the selected container to red

Scenario: Working with containers

- Add a button to the selected container

Scenario: Templatized formulas

- When the user selects `Button1`, show `Screen2`

Scenario: Modern theming

- Change my app to deep forest green

Use field suggestions by Copilot

Copilot is an AI feature in Microsoft Power Apps that helps you select the best fields to display when you link a data source to a control in a canvas app. Instead of using the default fields that Power Apps selects, you can view up to 10 suggestions from Copilot. The field suggestions are based on the data schema and the context of the app. You can review the suggestions and make adjustments as needed, saving time and improving the quality of the app.

Prerequisites

Ensure you meet the prerequisites and region availability in Copilot in Power Apps overview (preview).

Use field suggestions

Field suggestions by Copilot work when you bind a data source to one of the following controls:

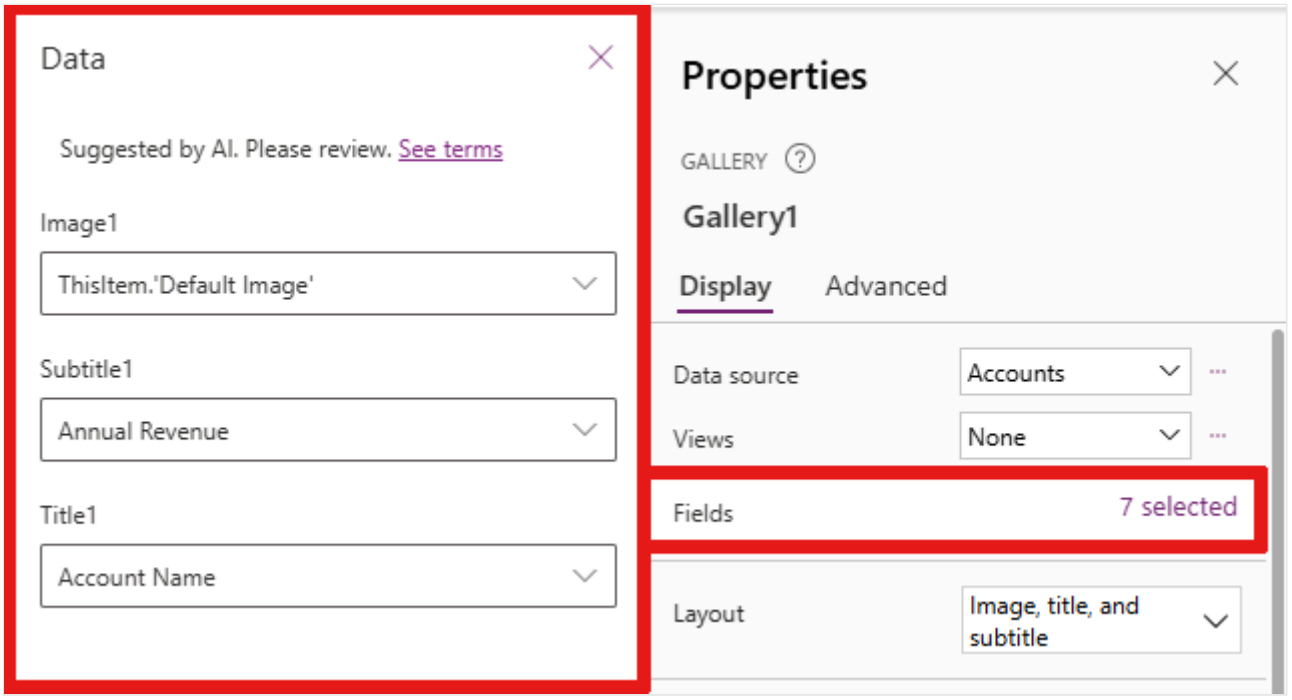
- Gallery
- Form (modern)
- Table (modern)
- Edit form (classic)
- Display form (classic)
- Data table (classic)

You can bind these controls to one of the following data sources:

- Dataverse
- SQL Server
- SharePoint list

When you select a data source for a control, Copilot analyzes the data schema and recommends up to 10 fields that are relevant and meaningful for your app. If you have more than 10 required fields, Copilot combines the AI suggestions with the required fields so that you don't get an error when you submit a form.

You can view the suggestions in the **Fields** pane and preview how they look in your app. You can also adjust the order, remove fields, and add more fields from the data source.



When you're done, apply the changes and view the results in your app.

Create a canvas app using Microsoft Dataverse

Summarize this article for me

Microsoft Dataverse provides a secure, cloud-based platform for storing and managing business data. With Power Apps, you can create canvas apps that connect directly to Dataverse to display, edit, and manage your organization's data without complex data connections.

This article shows you how to build canvas apps using Dataverse tables. You'll learn three different approaches: generating apps from existing data, creating new tables and apps together, and building custom apps from scratch. Whether you're working with standard tables or custom organizational data, these methods help you create functional business apps quickly.

Prerequisites

- Switch to an environment where a database is created with sample data. If you have an appropriate license, you can create an environment to meet this need.
- Ensure you have the Environment Maker security role, either directly or through a Dataverse team that is part of the **AAD Security Group** category. Custom security roles aren't currently supported for Canvas App maker scenarios.

Create an app

1. Sign in to Power Apps.
2. From the home screen, choose one of the following options based on how you want to create your app using Dataverse:

Expand table

Create options using Dataverse	Benefits	Navigation
A single-page gallery app	Use your existing business data in Dataverse and create a lightweight responsive app.	Select **Start with data** > **Dataverse**. Select a table and select **Create app**.
Create new data and build an app	Set up structured tables in Dataverse to organize data and build secure, scalable apps.	Select **Start with data** > **Create new data**. Use the table designer or Copilot to create tables, then select **Save and exit**.

Create options using Dataverse	Benefits	Navigation
Blank app that uses data from Dataverse	Use your existing business data in Dataverse to tailor your app with flexibility, free from the limitations of predesigned templates.	In the left navigation pane, select **Create** > **Start with blank canvas** > **Phone size**.

> **Note**
>
> The Power Apps home screen now surfaces a **vibe.powerapps.com** prompt, introducing a new experience that brings together generative design, AI agents, and plan-driven workflows. You can try this experience to go from idea to a working app faster.

3. The app is created and Power Apps Studio opens, where you continue building the app.

Start with data using Dataverse

The **Start with data** experience lets you quickly connect to an existing Dataverse table and generate a canvas app. You can also create new tables directly from this experience.

Connect to an existing Dataverse table

1. Sign in to Power Apps.
2. From the home screen, select **Start with data**.
3. On the **Create an app** page, select **Dataverse**.
4. Select an existing Dataverse table and select **Create app**.

Power Apps Studio opens with a gallery app connected to your selected table.

Create new data

If you don't have an existing table, you can create one directly from the **Start with data** experience.

1. From the home screen, select **Start with data**.
2. Select **Create new data**.

3. In the **Create new tables** designer, you can:

    - Add a new table by selecting **+ New table**.
    - Add an existing table by selecting **+ Existing table**.
    - Use **Copilot** to describe your tables, columns, rows, and relationships, and it generates them for you.
    - Import data from Excel or .CSV files, or SharePoint lists by selecting **Import data** in the Copilot pane.

4. When you finish defining your tables, select **Save and exit** to generate the app.

Add a Dataverse table in a blank app

To help you understand how to create an app with data from Dataverse, start by creating a blank app and then adding data from Dataverse.

1. Sign in to Power Apps.

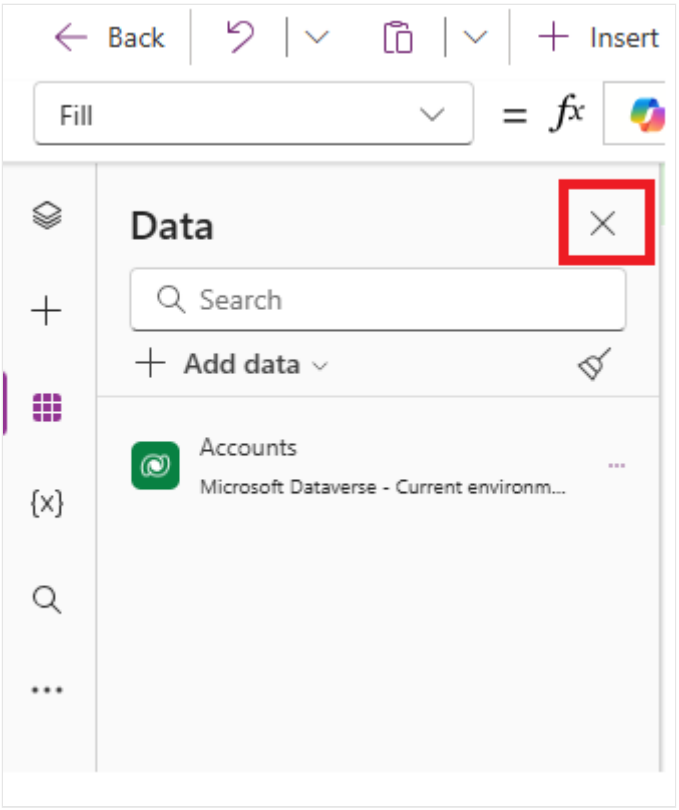
2. In the left navigation pane, select **Create** > **Start with blank canvas** > **Phone size**.

3. When Power Apps Studio opens, go to the app authoring menu and select **Data**.

    > **Note**
    >
    > If this is your first time connecting to Dataverse, you're prompted to create a connection. Select **Create** to establish the connection.

4. Select **Add data**, enter **Accounts** in the search box, and select it.

5. Close the **Data** pane by selecting the close icon in the upper right corner.



Add a list screen

1. On the command bar, select **New screen** > **List**.

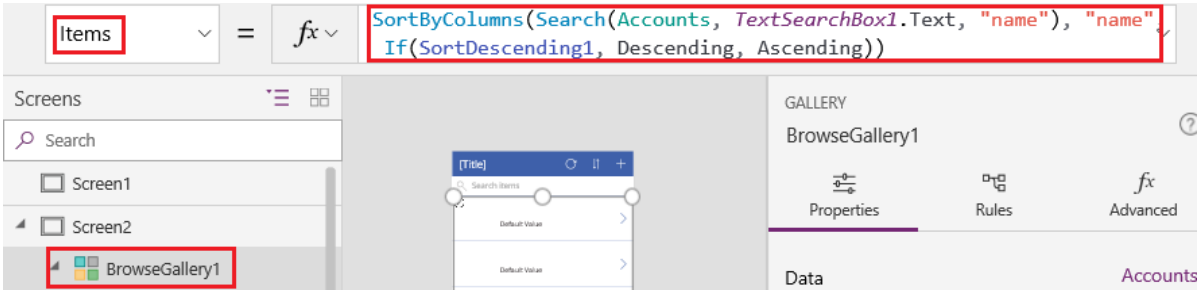
2. In the left navigation bar, select **BrowseGallery1**, and then set the value of the **Items** property to this formula:

   ```
   SortByColumns(Search(Accounts, TextSearchBox1.Text, "name"), "name",
   If(SortDescending1, SortOrder.Descending, SortOrder.Ascending))
   ```

   This formula specifies that:

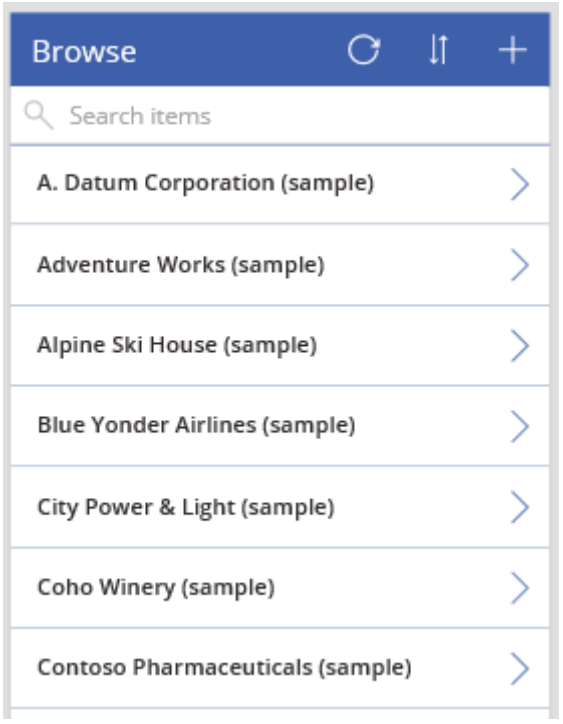
   - The gallery shows data from the **Accounts** table.
   - The data is sorted in ascending order until a user selects the sort button to toggle the sort order.
   - If a user types or pastes one or more characters into the search bar (**TextSearchBox1**), the list shows only those accounts for which the **name** field contains the characters that the user specified.

     You can use these and many other functions to specify how your app appears and behaves.



3. In the gallery's **Properties** pane, set the **Layout** to **Title**.

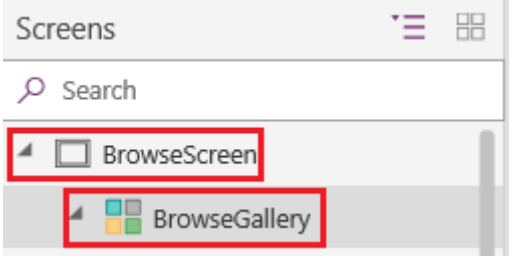
4. Edit the **Title** text property and rename it to **Browse**. For more information, see Customize a gallery.



5. In the left app authoring pane, hover over **Screen1**, select the ellipsis icon (...), and then select **Delete**.

6. In the left app authoring pane, hover over **Screen2**, select the ellipsis icon (...), and then select **Rename**.

7. Type or paste **BrowseScreen**, and then rename the gallery in that screen as **BrowseGallery**.



Add a form screen

1. Repeat the first step of the previous procedure, but add a **Form** screen instead of a **List** screen.

2. Set the form's **DataSource** property to **Accounts** and its **Item** property to **BrowseGallery.Selected** as the **Advanced** tab of the right-hand pane shows.

3. On the **Properties** tab of the right-hand pane, select **Edit Fields** to open the **Fields** pane.

4. Select **Add field**, and then select the checkboxes for these fields:

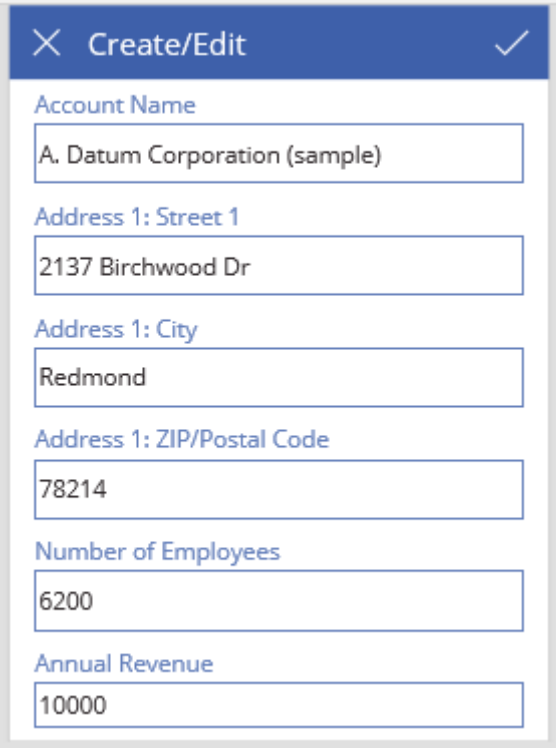
   - **Account Name**
   - **Address 1: Street 1**
   - **Address 1: City**
   - **Address 1: ZIP/Postal code**
   - **Number of Employees**
   - **Annual Revenue**

   > **Note**
   >
   > Outside of this scenario, you can create a custom field by selecting **New field**, providing the required information, and then selecting **Done**. For more information, see Create a column.
   >
   > 
   >

5. Select **Add**.

6. Set the title bar's **Text** property to show **Create/Edit**.

   The screen reflects your changes.



7. Rename this screen **FormScreen**.

Configure icons

1. On the **BrowseScreen**, set the **OnSelect** property of the circular icon near the top of the screen to this formula:

   ```
   Refresh(Accounts)
   ```

2. Set the **OnSelect** property of the plus icon to this formula:

   ```
   NewForm(EditForm1); Navigate(FormScreen, ScreenTransition.None)
   ```

3. Set the **OnSelect** property of the first arrow pointing to the right to this formula:

   ```
   EditForm(EditForm1); Navigate(FormScreen, ScreenTransition.None)
   ```

4. On the **FormScreen**, set the **OnSelect** property of the cancel icon to this formula:

```
ResetForm(EditForm1);Navigate(BrowseScreen, ScreenTransition.None)
```

5. Set the **OnSelect** property of the checkmark icon to this formula:

```
SubmitForm(EditForm1); Navigate(BrowseScreen, ScreenTransition.None)
```

6. On the **Insert** tab, select **Icons**, and then select the **Trash** icon.

7. Set the **Trash** icon's **Color** property to **White** and its **OnSelect** property to this formula:

```
Remove(Accounts, BrowseGallery.Selected); Navigate(BrowseScreen,
ScreenTransition.None)
```

Test the app

1. On the actions menu, select **Preview the app**. For more information, see Preview an app.

2. Toggle the list between ascending and descending sort orders, and filter the list by one or more characters in the account name.

3. Add an account, edit the account that you added, start to update the account, but cancel your changes, and then delete the account.

Integrate SharePoint Online into Power Apps overview

This article guides you through creating a list from SharePoint or Microsoft Lists, integrating that list into Power Apps, and customizing the list in your app.

When you add data to an app, you can choose a SharePoint list or Microsoft Lists as a source. Alternatively, you can create an app based on a SharePoint list through the **integrate** menu in Microsoft Lists. Once your list is in your app, you can filter it and customize the list.

> **Note**
>
> When you create or view a list in SharePoint, you're automatically redirected to Microsoft Lists. You can always find the list in both Microsoft Lists and SharePoint. Learn more in What is a list in Microsoft 365?

Prerequisites

- A subscription to Microsoft 365 and Microsoft Power Platform.
- A basic familiarity with SharePoint Online and Power Apps:
  - Get started with SharePoint
  - What is Power Apps?

Create a list

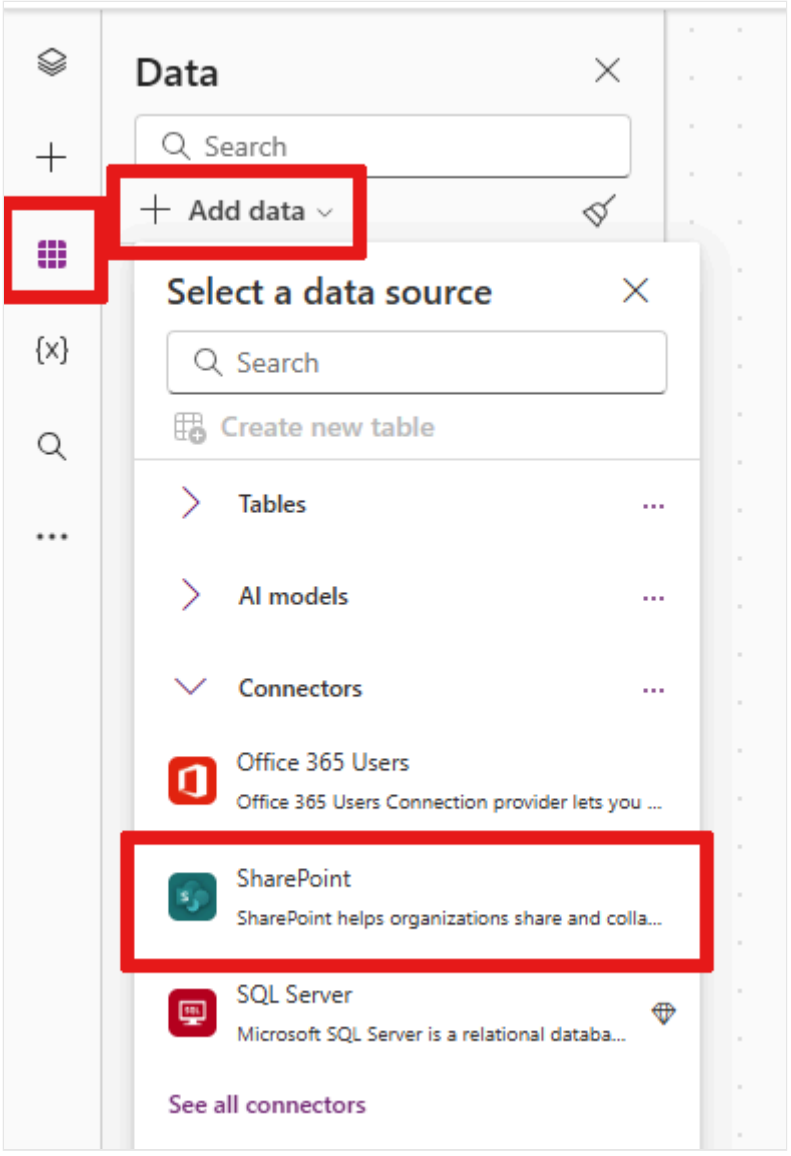
You can create a new SharePoint list through the Microsoft Lists app in Create a list.

Integrate a list

Once you have a list, you can integrate it into Power Apps or create an app based on a SharePoint list or Microsoft Lists.

Connect with a list in Power Apps

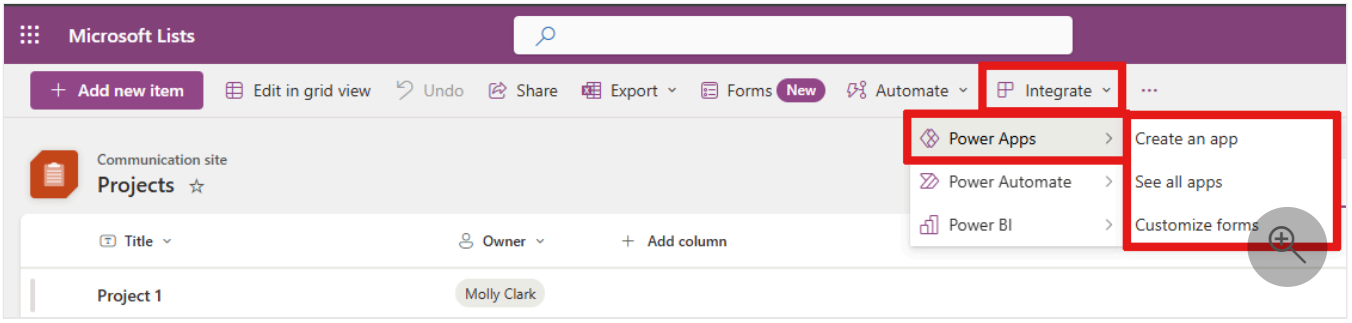
One way to work with a list in your app is to connect to SharePoint through the **Data** menu of an app to import a list. The list serves as a data source in Power Apps.



Learn more in Connect to SharePoint from a canvas app.

Create an app based on a list

When you view a SharePoint list, you automatically go to Microsoft Lists where you can integrate a list with Power Apps:



Learn more in Create a canvas app with data from Microsoft Lists.

Customize a list or form

When you import a list into Power Apps as a data source, you can use it to display a form on a screen. You can customize the appearance of your list in your app, including the formatting and behavior for the list.

Customization includes how the list displays the:

- Addition or removal of fields
- Control type and data type for the fields
- Layout orientation and number of columns
- Formatting like alignment, color, and borders
- Interactive features such as **OnFailure** or **OnSuccess**

Learn how to customize a list in Customize a form for a SharePoint list.

Learn more about form properties in Understand SharePoint forms integration.

Filter a list in Power Apps

You can apply formulas to interface elements of your app, such as filters. For a list, add a filter formula to a vertical gallery in your app screen by adding the formula to the formula bar of an *Items* property.

Learn more in Filter, Search, and LookUp functions.

Example of a search and filter function

Put this example formula on a gallery for the *Items* property. The formula searches for the status in a column and filters for the *Active* status. The list then only shows the list items with an *Active* status.

powerfx

```
SortByColumns(Filter('Issue Tracking', 'Issue Status'.Value = "Active",
StartsWith(Title, TextSearchBox1.Text)), "Title", If(SortDescending1, Descending,
Ascending))
```

The formula contains the following functions:

- SortByColumns sorts a table based on one or more columns.
- Filter finds the records in a table according to a formula that you specify.
- StartsWith tests whether one text string begins with another text string.
- If returns a value depending on whether a condition is true or false.

Learn more in Formula reference - canvas apps.

Linking lists with a lookup column

You can link two lists where one list uses one of its columns as a *lookup* column. A lookup column is the point where the list connects to another list.

Learn more in How to link lists from Microsoft Lists using a lookup column in Power Apps.

If you want your lookup column to be a dropdown list with options, use the Choices function. The choices function returns a table of the possible values for a lookup column.

For example, you can add a choices function to a dropdown control in your canvas app by adding this formula to your *Items* property of the control. You include your list name and the name of the lookup column in the formula.

PowerApps Formula

```
Choices([@'Your list name'].Lookup_x0020_column)
```

Create a canvas app with data from a list

Summarize this article for me

Transform your Microsoft Lists or SharePoint data into a powerful mobile and web app in minutes—no coding required. This article shows you how to create a fully functional canvas app that connects directly to your existing lists, giving you and your team an intuitive way to view, edit, and manage data on any device.

You can also connect to on-premises SharePoint lists through a data gateway.

You can create an app by using a list in SharePoint or Lists in two ways:

- Sign in to Power Apps and then create an app by connecting to a list in SharePoint from Power Apps.
- Create an app directly from a list in SharePoint or Lists.

When you create the app, Power Apps Studio opens and shows an app with three screens:

- **Browse screen**: Scroll through all items in the list.
- **Details screen**: Show all information about a single item in the list.
- **Edit screen**: Create an item or update information about an existing item.

Watch this video to learn how to create a canvas app from a list.

https://learn-video.azurefd.net/vod/player?id=de3b0fbc-f5b6-4958-855e-109f9c3692ac&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fapp-from-sharepoint

> **Note**
>
> When you create or view a list in SharePoint, you're automatically redirected to Microsoft Lists. The list is always available in both Microsoft Lists and SharePoint. Learn more in What is a list in Microsoft 365?

Prerequisites

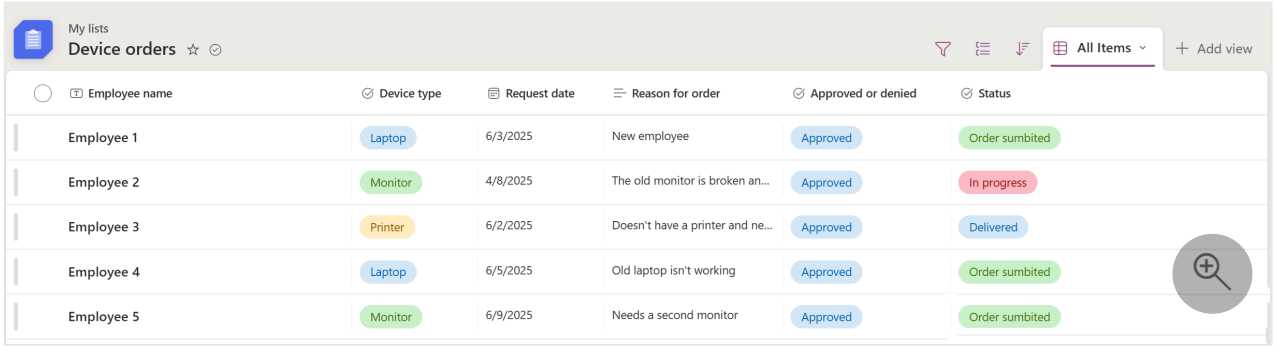
Use SharePoint and Power Apps with a subscription to Microsoft 365 and Microsoft Power Platform.

Create a list

Before you create an app from a list, create a list.

For this example, create a list to track device orders for your company. Include the following columns with sample data:

1. Employee name
2. Device type
3. Request date
4. Reason for the order
5. Approved or denied
6. Status



Use a list in SharePoint or Lists to create an app

Now, use the list that you created to build an app from the list.

1. Sign in to Power Apps.
2. From the home screen, select **Start with data**.
3. On the **Create an app** page, select **SharePoint**.
4. Enter the SharePoint URL, and then select **Connect**. Or, select a recent site.
5. Select a list or select the sample list you created earlier, and then select **Create app**.

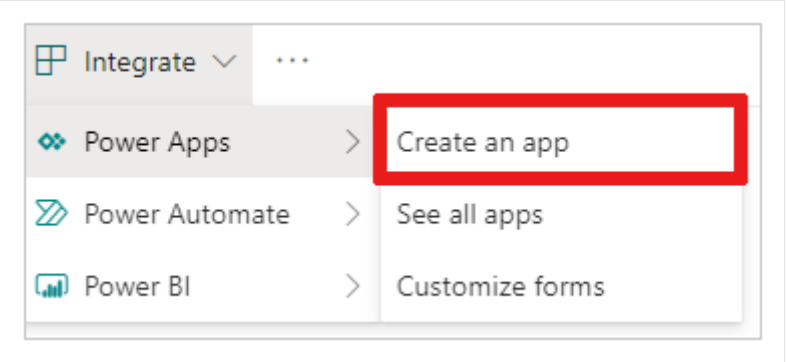
   The app opens in Power Apps Studio, where you design, build, and manage the app. For more information, see Understand Power Apps Studio.
6. Select the **Preview the app** icon to see how the app works.
7. Save and publish your app.

When you add or edit information in the app, the information in SharePoint or Lists also updates.

Create an app directly from a list in SharePoint or Lists

Before you create the app, make sure you create a list.

1. Sign in to SharePoint: `https://yourorganizationname.sharepoint.com`
2. Open a list in either SharePoint or Lists. If you open the list from SharePoint, you're taken to Lists to view the list.
3. Select **Integrate** > **Power Apps** > **Create an app**.



4. Select the **Preview the app** icon to see how the app works.
5. Save and publish your app.

   When you add or edit information in the app, the information in SharePoint or Lists also updates.

Manage your app

After you create an app, you can play, save, share, and publish it.

Learn more about these app actions in the Power Apps Studio interface.

Link lists using a lookup column in Power Apps

Article • 03/07/2025

This tutorial shows you how to connect two lists with a lookup column in a canvas app in Power Apps.

SharePoint provides two types of lookup columns:

- **Lookup**: Links to another list. For example, an **Orders** list might have a lookup column that links to customers in a **Customer** list.
- **Choice**: Selecting a column displays a menu of items you can choose.

> **Note**
>
> When you create or view a list in SharePoint, you're automatically redirected to Microsoft Lists. The list can always be found in both Microsoft Lists and SharePoint. Learn more in What is a list in Microsoft 365?

Prerequisites

- A SharePoint license or a Microsoft 365 license
- A SharePoint site

  To create a SharePoint site, see Guided walkthrough: Creating an organization site.

Why use a lookup column?

Data in an enterprise is large and complex. Data in one list often relates to data in another list. Lookup columns are the primary way such business data comes together.

For example, you might have an **Orders** list which has a lookup column that links to a **Customers** list, to show which customer placed the order. The lookup column in the **Orders** list lets you get other data from the **Customers** list as well.

You might also use a lookup column to connect the **Orders** list to a **Product** list, and bring in information you need about the product ordered, such as product pictures, specifications, or manufacturer details.

What are choice columns used for?

Choice columns are used for short lists. Instead of creating a separate list, you include the list values in a small menu. This menu appears when you select a **Choice** column, and then you can select one of the values from the menu.

Examples include data like Customer Status Code, Product Availability, State Codes—any fixed, relatively short list.

The choice data can stay as a separate list, if you use a **Lookup** column to link them. However, a **Choice** column implementation is easier and quicker than a **Lookup** column implementation.

Learn more in Integrate SharePoint Online into Power Apps overview.

Create the lists

In this tutorial, you link two lists together, **Assets** and **RepairShop**. The **Assets** list is used to track hardware equipment in a team. Since hardware breaks from time to time, we use the **RepairShop** list to track the local shops which can fix it.

The lookup column used in this example

The **RepairShop** list uses the *ContactEmail* column to identify the shop. This list is defined first so that each row in the **Assets** list points to something.

The **Assets** list has two lookup columns:

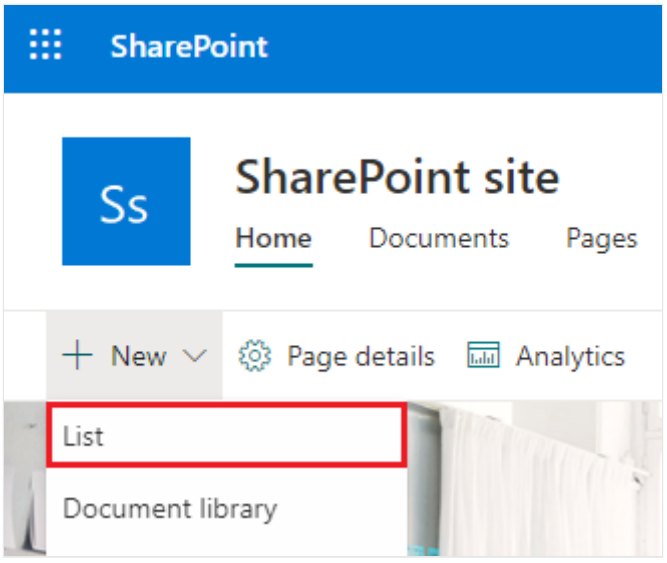
- *RepairShop*, of type **Lookup**, uses email addresses to point to entries in the **RepairShop** list.
- *AssetType*, of type **Choice**, lists the asset types for hardware.

You can define more columns, depending on the information you need to track.

Define the RepairShop list and add data

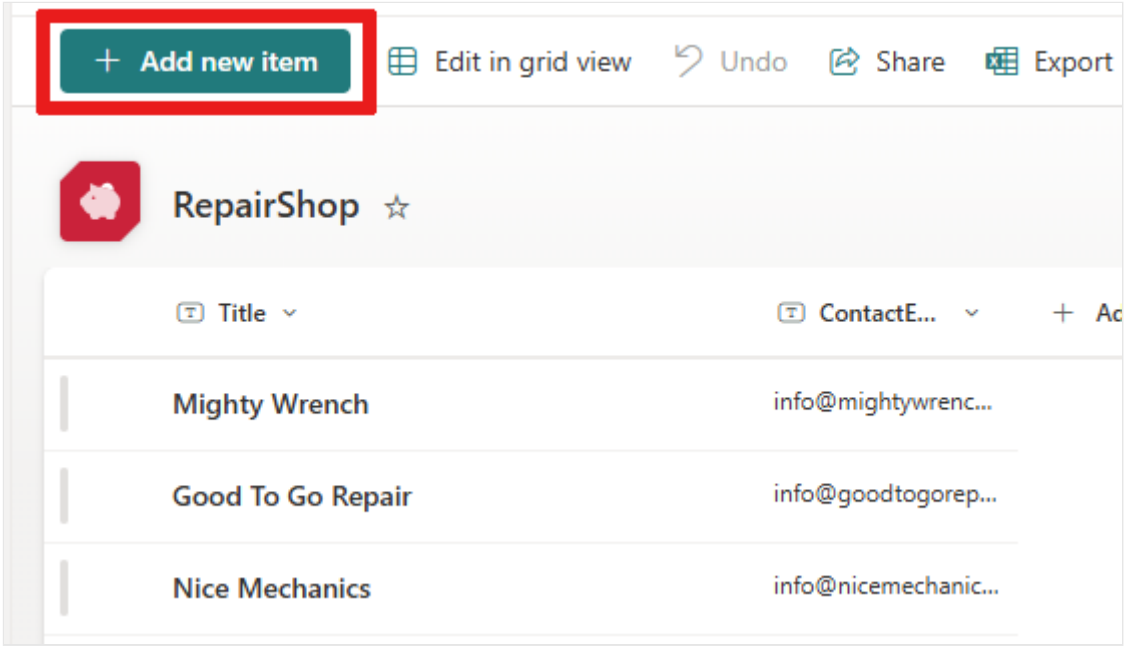
Create this list first, so when you add data to the **Assets** list, **RepairShop** entries are available from the *Assets.RepairShop* lookup column.

1. On any SharePoint site, create a new **RepairShop** list from a **Blank list** template.



2. Select **Add a column** of type **Text** and name it *ContactEmail*, then choose **Save**.

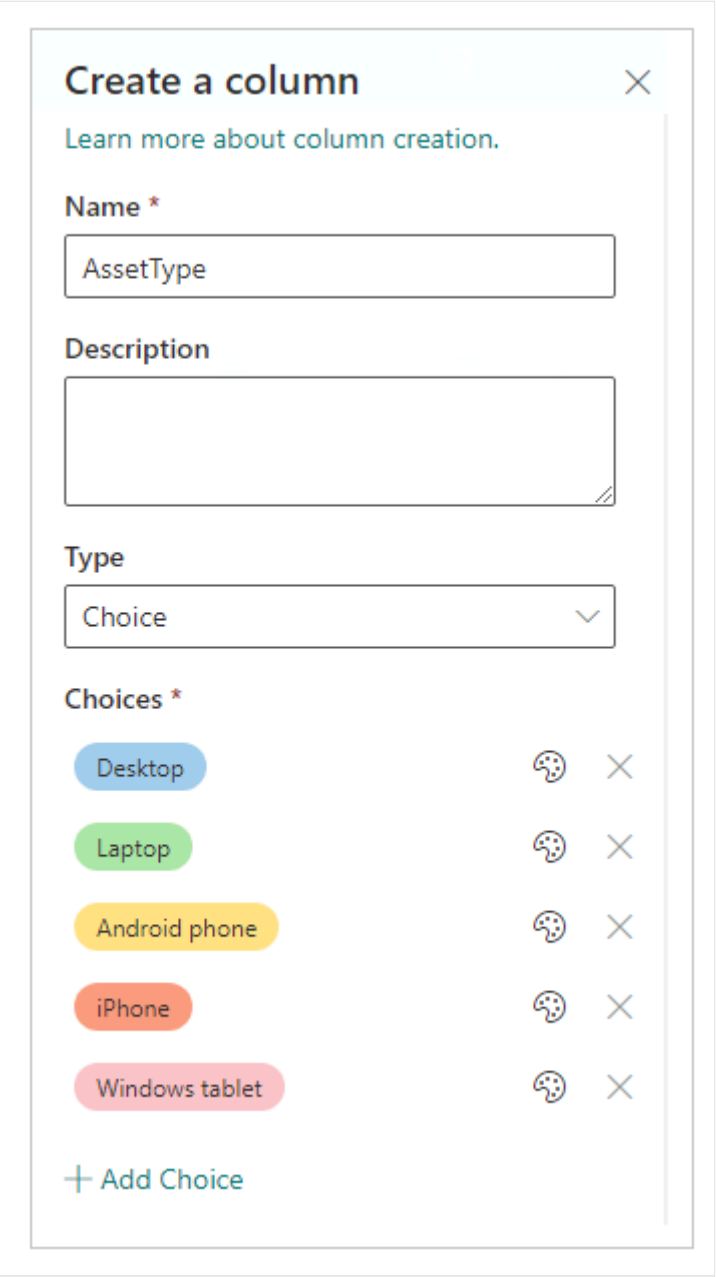
3. Select **+ Add new item** to enter at least three rows with different *ContactEmail* sample values. When an asset needs to be repaired, you choose one of these repair shops.



Define the Assets list

1. On the same SharePoint site, create a new **Assets** list from a **Blank list** template.

2. Select **+ Add column** and choose the **Choice** column type. Select **Next** and name it *AssetType*. Fill in the *Choice* values under the **Choices** section with sample assets such as *Desktop*, *Laptop*, *Android phone*, *iPhone*, and *Windows tablet*.



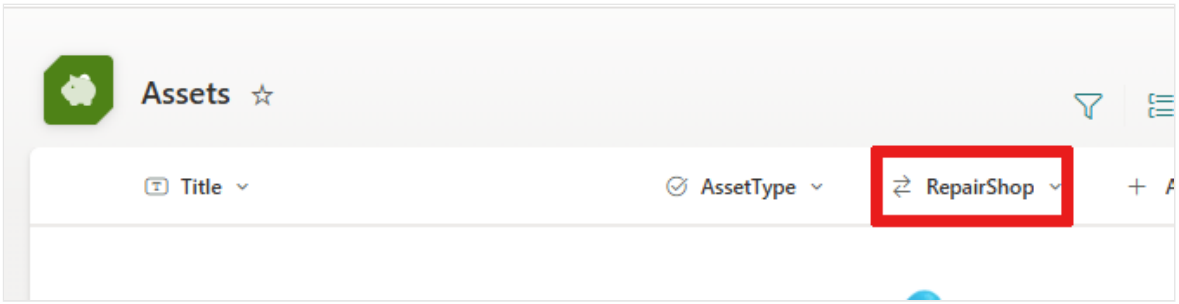
3. Select **Save**.

4. Select + **Add column** and choose the **Lookup** column type, then select **Next**.

5. In the **Create a column** pane, add RepairShop to the **Name** field. Go to **Select a list as a source** and choose **RepairShop**. Go to **Select a column from the list above** and choose **ContactEmail**.

6. Select **Save**.

   You see the column *RepairShop* has a two-arrows icon that indicates it's a lookup type column.



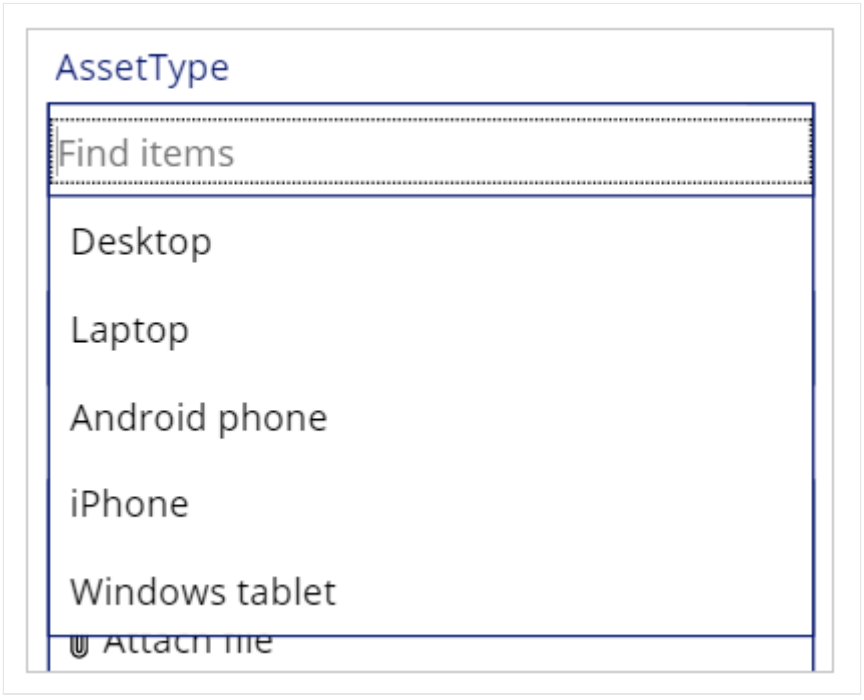
Create an app from the Assets list

Create a canvas app from the Assets list created earlier.

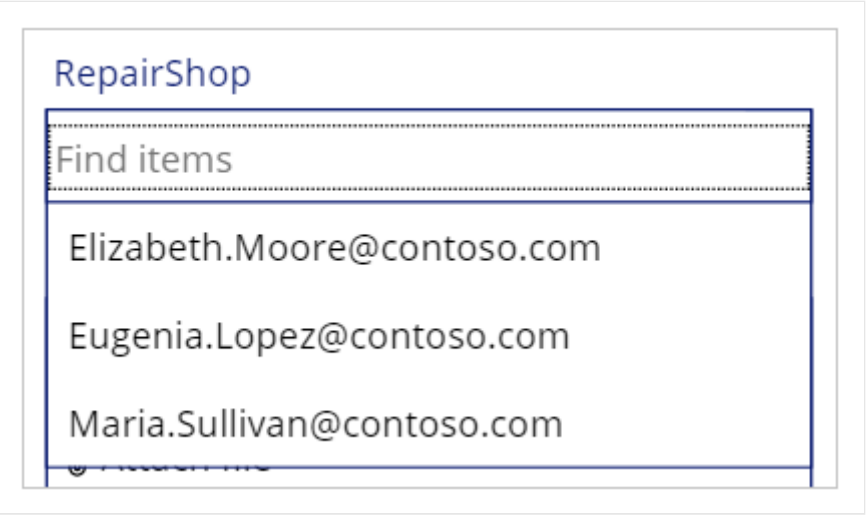
Add data to the Assets list

Let's preview the app and add items to your **Assets** list.

1. Press F5 or select Preview (▷).
2. Select the + symbol in the upper right corner of your app to add an entry.
3. Enter a **Title** for this asset, for example *Micah's Laptop*.
4. Select the **AssetType** dropdown arrow. The values displayed are values you entered when you created this column. Choose one of the entries.



5. Select the **RepairShop** dropdown arrow. Choose one of the entries.



6. Select the check mark to save the new entry.

7. (Optional) Add more items to the list.

8. Press `Esc` to return to the default workspace.

9. Save and publish the app.

Understand SharePoint forms integration

You can customize a form for a SharePoint list when you integrate a list into Power Apps. In this article, you learn how these forms work and how you can customize them.

When you customize a form for a list, you see the default generated form works for all operations, like creating, showing, or editing an item. This functionality uses generated formulas and the **SharePointIntegration** control.

> **Note**
>
> When you create or view a list in SharePoint, you're automatically redirected to Microsoft Lists. You can always find the list in both Microsoft Lists and SharePoint. For more information, see What is a list in Microsoft 365?

Understand the default generated form

The default generated form consists of the following controls and their corresponding defaults. Formulas are autogenerated within the defaults.

- **FormScreen1**: This screen contains the form.
- **SharePointForm1**: This form can create, show, or edit a list item.
  - **Data Source**: The list for which the form is customized. For example, a SharePoint list acts as a data source.
  - **Item**: A selected item from a list. This item is set to `First()` item in the list for your convenience, when working in Power Apps Studio.

```
Power Fx
If( IsBlank(SharePointIntegration.Selected) ||
IsEmpty(SharePointIntegration.Selected),
    First('*YourListName*'),
SharePointIntegration.Selected )
```

> **Tip**
>
> This formula pattern uses `... SharePointDatasourceName.Selected` and works for the **Item** property of a form. See the Common issues with the

SharePointIntegration object for a formula pattern to set the value of a SharePoint record.

- **OnSuccess**: Once the item is created or saved successfully, the form resets and SharePoint hides the form.

```
Power Fx
ResetForm(SharePointForm1); RequestHide()
```

- **SharePointIntegration**: Communicates user actions between SharePoint and Power Apps.

Expand table

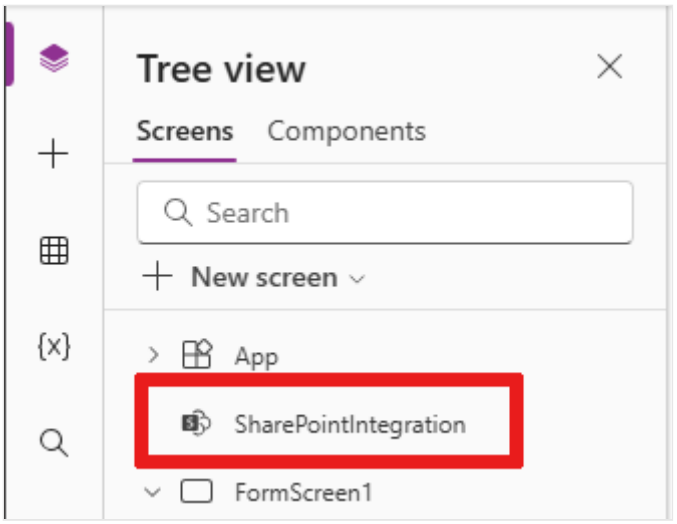
Property	Description	Example
Data Source	The list for which the form is customized.	*YourListName*
OnNew	Sets **SharePointForm1** in new mode.	*NewForm(SharePointForm1)*
OnView	Sets **SharePointForm1** in view mode.	*ViewForm(SharePointForm1)*
OnEdit	Sets **SharePointForm1** in edit mode.	*EditForm(SharePointForm1)*
OnSave	Submits the changes to **SharePointForm1**. The **SharePointForm1.OnSuccess** formula executes when you successfully submit a form.	*SubmitForm(SharePointForm1)*
OnCancel	Resets the changes to **SharePointForm1**. SharePoint always hides the form when a user selects **Cancel** in SharePoint.	*ResetForm(SharePointForm1)*

These defaults ensure that the form works when running within SharePoint. The defaults change the Power Apps form mode as the user interacts with it in SharePoint, and they ensure that the changes are submitted to SharePoint.

> **Note**
>
> While you can manually copy a form from one environment to another, there's currently no automated method in Power Apps to copy a form from one environment to another.

Understand the SharePointIntegration control

The **SharePointIntegration** control communicates user actions between SharePoint and Power Apps.



> **Note**
>
> You can access properties for the **SharePointIntegration** control only when the form runs in SharePoint, not when you're customizing the form in Power Apps Studio. These properties might not be available in **OnStart** or **OnVisible**.

The **SharePointIntegration** control has these properties:

Expand table

Property	Effect or description
Selected	The selected item from the list.
OnNew	Activates when a user selects the **New** button or opens the **Create item** form in SharePoint.
OnView	Activates when a user selects an item or opens the **Item detail** form in SharePoint.
OnEdit	Activates when a user selects the **Edit all** button or opens the **Edit item** form in SharePoint.
OnSave	Activates when a user selects the **Save** button in SharePoint.
OnCancel	Activates when a user selects the **Cancel** button in SharePoint.
SelectedListItemID	Item ID for the selected item in a list.
Data Source	The list that contains the record that the form shows, edits, or creates. If you change this property, the **Selected** and **SelectedItemID** properties might stop working.

Customize the default form

You can change the formulas to further customize the forms.

Consider these tactics when you customize forms:

- Use the **OnSave** formula of the `SharePointIntegration` control to customize the effect of a user selecting **Save** in SharePoint. If you have multiple forms, make sure to submit the changes only for the form currently being used.

  > **Tip**
  >
  > Set different values for a variable in the **OnNew**, **OnView**, and **OnEdit** formulas. You can use this variable in the **OnSave** formula to determine which form is being used.

- Include **RequestHide()** in the **OnSuccess** formula of all your forms. Without this function, SharePoint doesn't know when to hide the form. Avoid running important code *after* calling **RequestHide()**. Code should run while the form is still visible and able to run logic.

- You can't control the hiding of a form when a user selects **Cancel** in SharePoint. Always reset your forms in the **OnCancel** formula of the `SharePointIntegration` control.

- Properties for the `SharePointIntegration` control might not be available in **OnStart** or **OnVisible**. These events execute only once while the list is loaded. You can use **OnNew**, **OnView**, or **OnEdit** to run logic before the form is shown to the user.

Common issues with the SharePointIntegration object

- When you set the value of `SharepointIntegration.Selected` to a collection on the **OnView** property, it doesn't show the latest value. To fix this problem, use `SharepointIntegration.SelectedListItemID`, and then do a lookup on the table to get the selectedRecord.

  For example, for **OnView** property:

  - Instead of:

    Power Fx

    ```
    Set( selectedItem,
    SharePointIntegration.Selected );
    ```

- Use:

```
Power Fx
Set( selectedLookupItem,
LookUp( YourSharepointIntegrationObject,
ID=SharePointIntegration.SelectedListItemID ) );
```

- Collection variables aren't reset when you close the Power Apps form. The state persists for the entire session. If you need to reset the variables, clear them in the **OnView** property of the `SharePointIntegration` object.
- Don't use imperative functions such as **Launch()** in the `SharePointIntegration` properties (such as **OnNew** and **OnView**). This use can cause unexpected behavior since the `SharePointIntegration` lifecycle events (such as selections changing) can trigger in the background even when the form isn't visible.
-

Understand user access to customized forms

You can't manually share a SharePoint form customized with Power Apps. Instead, any user who has at least **Read** or **Restricted View** access to the linked SharePoint list inherits access to the form. Users who have only been given permissions to specific items in the list don't have access to the customized form.

Integrate SharePoint Online into Power Apps overview

This article guides you through creating a list from SharePoint or Microsoft Lists, integrating that list into Power Apps, and customizing the list in your app.

When you add data to an app, you can choose a SharePoint list or Microsoft Lists as a source. Alternatively, you can create an app based on a SharePoint list through the **integrate** menu in Microsoft Lists. Once your list is in your app, you can filter it and customize the list.

> **Note**
>
> When you create or view a list in SharePoint, you're automatically redirected to Microsoft Lists. You can always find the list in both Microsoft Lists and SharePoint. Learn more in What is a list in Microsoft 365?

Prerequisites

- A subscription to Microsoft 365 and Microsoft Power Platform.
- A basic familiarity with SharePoint Online and Power Apps:
  - Get started with SharePoint
  - What is Power Apps?

Create a list

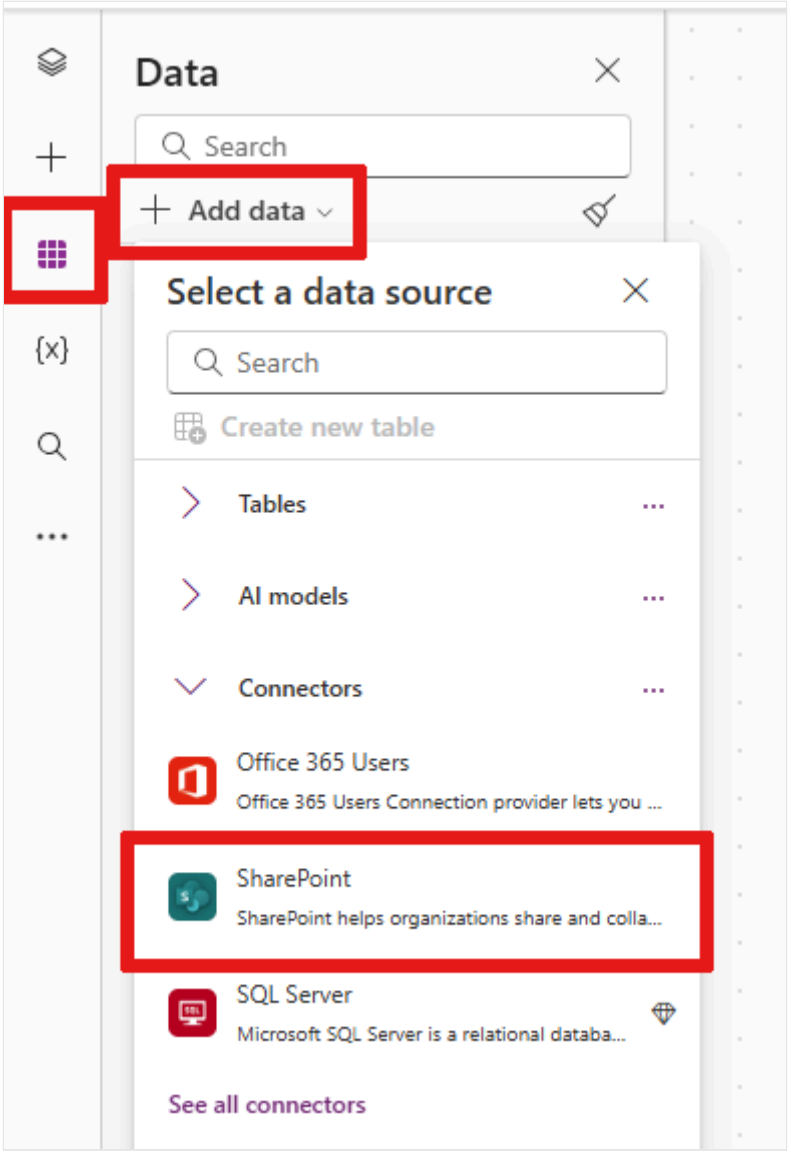
You can create a new SharePoint list through the Microsoft Lists app in Create a list.

Integrate a list

Once you have a list, you can integrate it into Power Apps or create an app based on a SharePoint list or Microsoft Lists.

Connect with a list in Power Apps

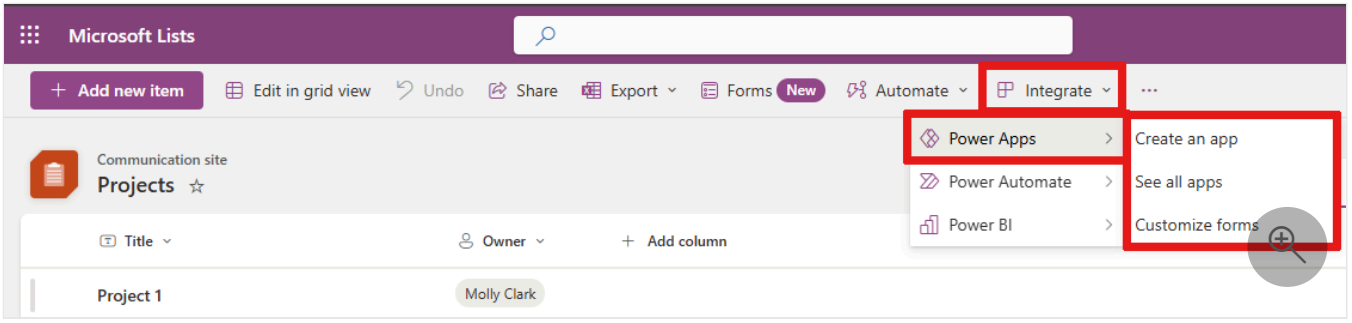
One way to work with a list in your app is to connect to SharePoint through the **Data** menu of an app to import a list. The list serves as a data source in Power Apps.



Learn more in Connect to SharePoint from a canvas app.

Create an app based on a list

When you view a SharePoint list, you automatically go to Microsoft Lists where you can integrate a list with Power Apps:



Learn more in Create a canvas app with data from Microsoft Lists.

Customize a list or form

When you import a list into Power Apps as a data source, you can use it to display a form on a screen. You can customize the appearance of your list in your app, including the formatting and behavior for the list.

Customization includes how the list displays the:

- Addition or removal of fields
- Control type and data type for the fields
- Layout orientation and number of columns
- Formatting like alignment, color, and borders
- Interactive features such as **OnFailure** or **OnSuccess**

Learn how to customize a list in Customize a form for a SharePoint list.

Learn more about form properties in Understand SharePoint forms integration.

Filter a list in Power Apps

You can apply formulas to interface elements of your app, such as filters. For a list, add a filter formula to a vertical gallery in your app screen by adding the formula to the formula bar of an *Items* property.

Learn more in Filter, Search, and LookUp functions.

Example of a search and filter function

Put this example formula on a gallery for the *Items* property. The formula searches for the status in a column and filters for the *Active* status. The list then only shows the list items with an *Active* status.

powerfx

```
SortByColumns(Filter('Issue Tracking', 'Issue Status'.Value = "Active",
StartsWith(Title, TextSearchBox1.Text)), "Title", If(SortDescending1, Descending,
Ascending))
```

The formula contains the following functions:

- SortByColumns sorts a table based on one or more columns.
- Filter finds the records in a table according to a formula that you specify.
- StartsWith tests whether one text string begins with another text string.
- If returns a value depending on whether a condition is true or false.

Learn more in Formula reference - canvas apps.

Linking lists with a lookup column

You can link two lists where one list uses one of its columns as a *lookup* column. A lookup column is the point where the list connects to another list.

Learn more in How to link lists from Microsoft Lists using a lookup column in Power Apps.

If you want your lookup column to be a dropdown list with options, use the Choices function. The choices function returns a table of the possible values for a lookup column.

For example, you can add a choices function to a dropdown control in your canvas app by adding this formula to your *Items* property of the control. You include your list name and the name of the lookup column in the formula.

PowerApps Formula

```
Choices([@'Your list name'].Lookup_x0020_column)
```

Create a canvas app based on Excel data

Summarize this article for me

This article shows you how to create a canvas app using Excel data as your data source. Whether you have existing Excel spreadsheets with business data or want to leverage Excel's familiar structure, Power Apps provides flexible options to transform your data into powerful applications.

You'll learn three different approaches to work with Excel data:

Upload Excel files to create Dataverse tables for enhanced data management and security Connect to external Excel files stored in cloud services for quick app creation Start with a blank canvas app and add Excel data for complete customization control Before you begin, ensure your Excel data is properly formatted. This preparation step helps Power Apps read and interact with your data more effectively. For more information, see Formatted as a table in Excel.

To create an app by using Excel data, select one of the following options in Power Apps.

Expand table

Create options by using Excel	Benefits	Navigation
Upload an Excel or .CSV file to Power Apps	Uploaded Excel data generates a Dataverse table. With Dataverse's standard and custom tables, you can securely store your data in the cloud. These tables enable you to define your organization's data in a way that is tailored to your business needs, making it easier to use within your apps.	Select **Start with Data** > **Upload file**.
Connect to an external Excel file and use it to create a canvas app. Your data stays where it is.	Using the Excel connector in Power Apps provides a straightforward and fast method to create and deploy apps with data stored in Excel. It's especially advantageous for makers that already use Excel and want to enhance its functionality with minimal effort. Makers benefit from cloud access, easy data manipulation, rapid prototyping, and no need for a complex database setup.	Select **Start with Data** > **Excel Online (Business)**.
Create a blank canvas app and then add Excel data	You have complete flexibility, control, and customization. It allows you to design an app that meets your exact specifications without being limited by predesigned templates, providing greater creative freedom and adaptability to suit your unique needs.	On the left navigation pane, select **Create** > **Create from blank**. Then select the app size.

Upload an Excel or CSV file to Power Apps

When you upload your Excel data to Power Apps, it doesn't just stay as an Excel file. Instead, Power Apps converts it into a Dataverse table. This conversion makes it easier to integrate and manage your data within Power Apps, and you get more powerful features compared to using Excel alone. For more information, see Why use Dataverse?

1. Sign in to Power Apps.
2. On the home screen, select **Start with data**.
3. On the **Create an app** page, select **Upload file**.
4. Select **Select from device** and go to the location where your Excel file is saved. Select the file to upload it.

   > **Note**
   >
   > The maximum file size limit is 5 GB.

5. When Power Apps creates the table, select a column name or the table name to edit the properties to suit your needs. If you change column data types and there are values in cells that don't match the selected data type, Power Apps removes those values when it generates the table. For more information, see Create and edit tables using Power Apps.
6. Select **Row ownership** and choose how you want to manage row ownership.
7. When you're done, select **Save and open app**. Power Apps uploads the first 20 rows of data so you can start reviewing the data in your app. The system uploads the remaining data in the background.

Known issues

- The current data upload process doesn't take into account the environment data format setting.

Connect to an external Excel file from Power Apps

Store the Excel file in a cloud storage service like Dropbox, Google Drive, OneDrive, or OneDrive for Business because Power Apps can only connect to Excel files that are stored in the cloud.

Power Apps has an Excel connector that you can use to access your Excel data. The Excel Online (Business) connector offers flexibility by accessing a wide variety of cloud-based file storage services.

1. Sign in to Power Apps.
2. On the home screen, select **Start with data**.
3. On the **Create an app**, select **Excel Online (Business)**.
4. Only one connection appears at a time. To select a different connection, select the **...** button to switch connections or add a new connection.
5. Enter the file location and select the table.
6. When you're done, select **Create app**.

For more information about how to share Excel data, see Sharing Excel tables.

Create a blank canvas app and add Excel data

Create a blank app and then use Excel data that's formatted as a table as the source of the app's information.

Follow the example below to create an app with two screens where users can view (browse) the data from an Excel file on one screen, and on another screen, they can interact with (add, modify, or remove) that data. The data interaction features, such as creating, updating, and deleting records, are built into the second screen of the app.

Prerequisites

1. Copy this data and paste it into an Excel file.

Expand table

StartDay	StartTime	Volunteer	Backup
Saturday	10am-noon	Vasquez	Kumashiro
Saturday	noon-2pm	Ice	Singhal
Saturday	2pm-4pm	Myk	Mueller
Sunday	10am-noon	Li	Adams
Sunday	noon-2pm	Singh	Morgan

StartDay	StartTime	Volunteer	Backup
Sunday	2pm-4pm	Batye	Nguyen

2. Format the table in Excel and name it **Schedule** so that Power Apps can parse the information.

3. Save the file as **eventsignup.xlsx**, close it, and then upload it to a cloud-storage account such as OneDrive.

> **Important**
>
> You can use your own Excel file and review this example for general concepts only. However, the data in the Excel file must be formatted as a table.

Create a blank app and connect to data

1. Sign in to Power Apps.

2. On the left navigation pane, select **Create** > **Start from blank**.

3. Select the **Phone size** layout.

   The app opens in Power Apps Studio where you can add data and start building the app.

4. In the middle of the screen, select **Connect to data**.

5. In the **Data** pane, select **Add data**. Select the connection for your cloud-storage account if it appears. Otherwise, follow these steps to add a connection such as OneDrive:
   a. In the search box, enter **OneDrive** and select it.
   b. Select **Add a connection**.
   c. On the connection pane, select **Connect**.
   d. If prompted, provide your credentials for that account.

6. Under **Choose an Excel file**, find and then select the **eventsignup.xlsx** that you saved earlier.

7. Under **Choose a table**, select the check box for **Schedule**, and then select **Connect**.

8. In the upper-right corner of the **Data** pane, close it by selecting the close icon (**X**).

Create the view screen

1. On the command bar, select **New screen** > **List**.

A screen is added with several default controls, such as a search box and a **Gallery** control. The gallery covers the entire screen under the search box.

2. At the top of the new screen, select the **[Title]** label control and rename it to **View records**.

3. In the **Tree view**, select **BrowseGallery1**.

4. In the gallery's **Properties** pane, set the **Layout** to **Title, subtitle, and body**.

5. In the formula bar, replace **CustomGallerySample** with **Schedule**, and replace both instances of **SampleText** with **Volunteer**.

6. On the right edge of the formula bar, select the **Expand formula bar** down arrow, and then select **Format text**.

   The formula matches this example:

   powerfx

   ```
   SortByColumns(
       Search(
           Schedule,
           TextSearchBox1.Text,
           "Volunteer"
       ),
       "Volunteer",
       If(
           SortDescending1,
           SortOrder.Descending,
           SortOrder.Ascending
       )
   )
   ```

7. In the **Properties** pane, select **Edit** next to the **Fields** label.

8. In the **Title2** box, select **Volunteer**, in the **Subtitle2** box, select **StartDay**, and in the **Body1** box, select **StartTime**.

9. In the upper-right corner of the **Data** pane, close it by selecting the close icon (X).

   Users can sort and filter the gallery by volunteer name based on the **SortByColumns** and **Search** functions in that formula.

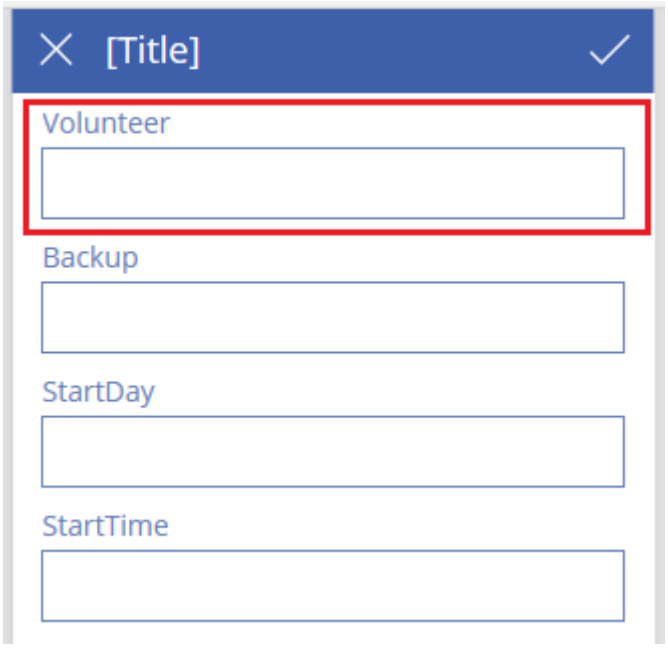
   - If a user types at least one letter in the search box, the gallery shows only those records for which the **Volunteer** field contains the text that the user typed.

- If a user selects the sort button (between the refresh button and the plus button in the title bar), the gallery shows the records in ascending or descending order (depending on how many times the user selects the button) based on the **Volunteer** field.

For more information about these and other functions, see the formula reference.

Create the change screen

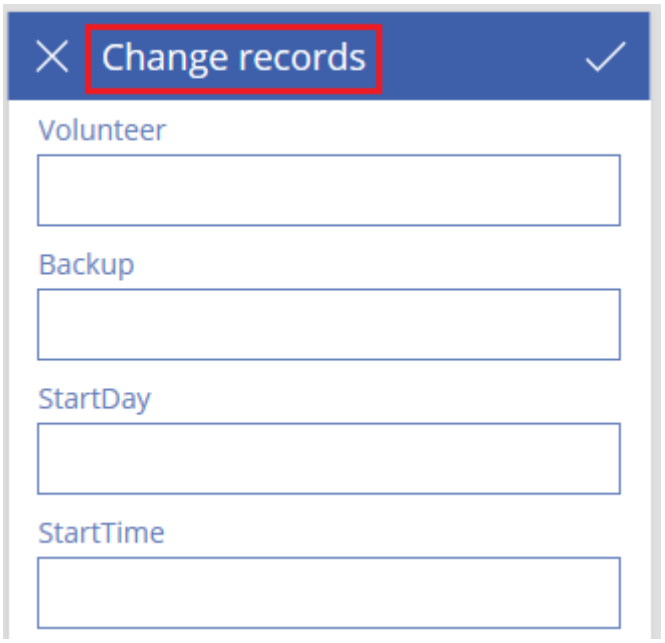
1. On the command bar, select **New screen** > **Form**.
2. In the **Tree view**, select **EditForm1**.
3. On the **Properties** pane, select the down arrow next to **Data source**, and then select **Schedule** in the list that appears.
4. Under the data source that you specified, select **Edit fields**.
5. In the **Fields** pane, select **Add field**, select the check box for each field, and then select **Add**.
6. Select the arrow next to the name of each field to collapse it, and then drag the **Volunteer** field up so that it appears at the top of the list of fields.



7. In the upper-right corner of the **Fields** pane, close it by selecting the close icon (X).
8. Set the **Item** property of the form to this expression in the formula bar:

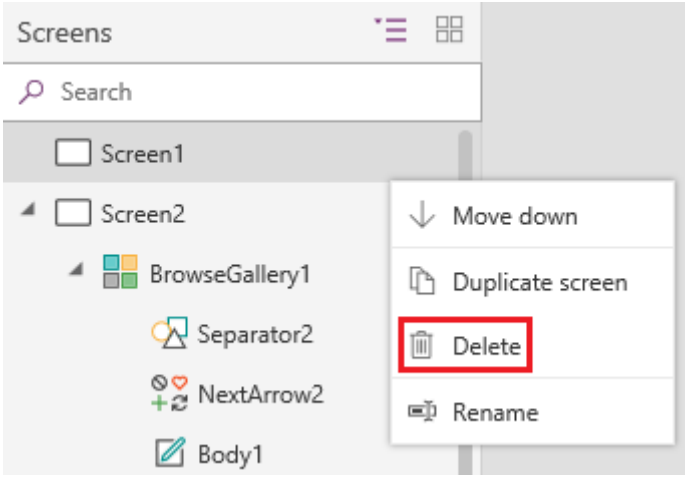
```
BrowseGallery1.Selected
```

9. At the top of the screen, select the **Label** control, and then replace **[Title]** with **Change records**.



Delete and rename screens

1. In the **Tree view**, select the ellipsis (...) for **Screen1**, and then select **Delete**.



2. Select the ellipsis (...) for **Screen2**, select **Rename**, and then type or paste **ViewScreen**.

3. Select the ellipsis (...) for **Screen3**, select **Rename**, and then type or paste **ChangeScreen**.

Configure icons on the view screen

1. Near the top of the **ViewScreen**, select the circular arrow icon.

2. Set the **OnSelect** property for that icon to this formula:

```
Refresh(Schedule)
```

When the user selects this icon, the data from **Schedule** refreshes from the Excel file.

For more information about this and other functions, see formula reference.

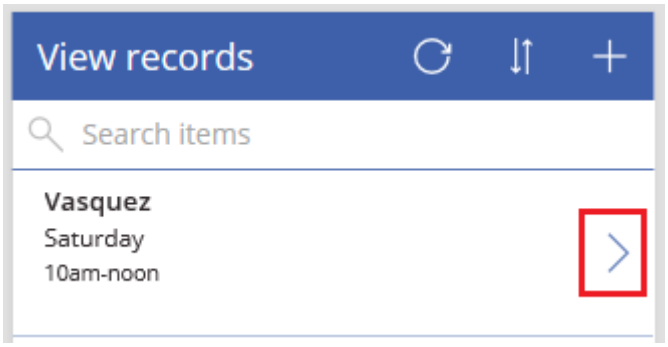
3. In the upper-right corner of the **ViewScreen**, select the plus icon.

4. Set the **OnSelect** property for that icon to this formula:

```
NewForm(EditForm1);Navigate(ChangeScreen,ScreenTransition.None)
```

When the user selects this icon, **ChangeScreen** appears with each field empty, so the user can create a record more easily.

5. Select the right-pointing arrow for the first record in the gallery.



6. Set the **OnSelect** property for the arrow to this formula:

```
EditForm(EditForm1); Navigate(ChangeScreen, ScreenTransition.None)
```

When the user selects this icon, **ChangeScreen** appears with each field showing the data for the selected record, so the user can edit or delete the record more easily.

Configure icons on the change screen

1. On **ChangeScreen**, select the "X" icon in the upper left corner.

2. Set the **OnSelect** property for that icon to this formula:

```
ResetForm(EditForm1);Navigate(ViewScreen, ScreenTransition.None)
```

When the user selects this icon, the app discards any changes made in this screen and opens the view screen.

3. In the upper-right corner, select the checkmark icon.

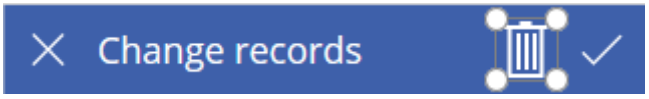
4. Set the **OnSelect** property for the checkmark to this formula:

```
SubmitForm(EditForm1); Navigate(ViewScreen, ScreenTransition.None)
```

When the user selects this icon, the app saves any changes made in this screen and opens the view screen.

5. On the **Insert** tab, select **Icons**, and then select the **Trash** icon.

6. Set the new icon's **Color** property to **White** and move the new icon so it appears next to the checkmark icon.



7. Set the **Visible** property for the trash icon to this formula:

```
EditForm1.Mode = FormMode.Edit
```

This icon appears only when the form is in **Edit** mode, not in **New** mode.

8. Set the **OnSelect** property for the trash icon to this formula:

```
Remove(Schedule, BrowseGallery1.Selected); Navigate(ViewScreen,
ScreenTransition.None)
```

When the user selects this icon, the app deletes the selected record from the data source and opens the view screen.

Test the app

1. Select the **ViewScreen**, and then preview the app by pressing `F5` or select **Preview**.

2. Type or paste one or more letters in the search box to filter the list based on the volunteer's name.

3. Select the sort icon one or more times to show the data in ascending or descending order based on the volunteer's name.
4. Add a record.
5. Update the record that you added, and then save the changes.
6. Update the record that you added, and then cancel the changes.
7. Delete the record that you added.
8. Close Preview mode by pressing Esc or selecting the close icon in the upper-right corner.

Next steps

- Press Ctrl+S to save your app in the cloud so you can run it from other devices.
- Share the app so other people can run it.

Last updated on 02/24/2026

Create a canvas app from a template

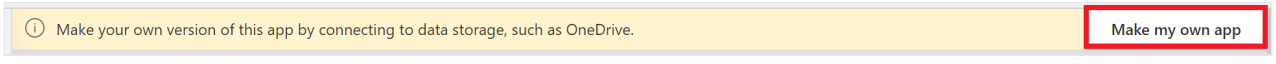
Creating a canvas app by using templates in Power Apps is a streamlined and efficient way to develop applications tailored to your needs. By using templates, you can quickly create a mobile app with three screens or choose from various templates designed for real-world scenarios with fictitious data. These templates come with prebuilt layouts, controls, and sample data, so you can focus on customizing the app to meet your specific requirements.

Create a three-screen mobile app

1. Sign in to Power Apps.
2. From the home screen, select the **Start with an app template** tile.
3. If your data is stored in Dataverse, select **From Dataverse**. Or choose from one of the external data sources:
    - **From SharePoint**
    - **From Excel**
    - **From SQL**
4. Select the data that appears in your app. When ready, select **Create app**.
5. The app opens in Power Apps Studio, where you can customize it.
6. Preview the app by pressing F5 or selecting the play button near the upper-right corner.
7. When ready, save and publish the app.

Use other templates to create an app

1. Sign in to Power Apps.
2. On the home screen, select the **Start from template** tile.
3. Select a template from the list of **other app templates**.
4. Update the **App name**, and then select **Next**.
5. Select **Make my own app** to connect the app to data storage, such as OneDrive.



6. After you select or connect to storage from the available choices, select **Done**.

The app opens in Power Apps Studio where you can customize it.

1. Preview the app by pressing F5 or selecting the play button near the upper-right corner.

When you're ready, save and publish the app.

Overview of connectors for canvas apps

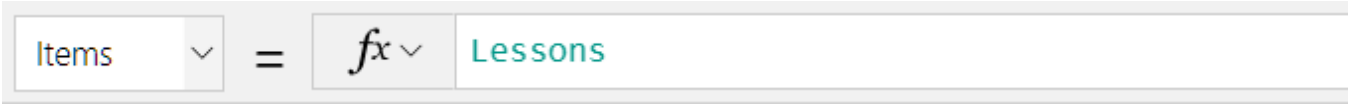
Data is at the core of most apps, including apps you build in Power Apps. You store data in a *data source*, and you bring that data into your app by creating a *connection*. The connection uses a specific *connector* to talk to the data source. Power Apps has connectors for many popular services and on-premises data sources, including SharePoint, SQL Server, Office 365, Salesforce, and Twitter. To get started adding data to a canvas app, see Add a data connection in Power Apps.

A connector might provide **tables** of data or **actions**. Some connectors provide only tables, some provide only actions, and some provide both. Also your connector might be either a standard or custom connector.

> **Note**
>
> Keep the number of connectors in a canvas app to a maximum of 10, and connection references to no more than 20. Going beyond these limits can lead to longer loading times for users when launching the app and can cause problems when saving the app.

Tables

If your connector provides tables, add your data source, and then select the table in the data source that you want to manage. Power Apps retrieves table data into your app and updates data in your data source automatically. For example, add a data source that has a table named **Lessons**, and then set the **Items** property of a control, such as a gallery or a form, to this value in the formula bar:



Specify the data that your app retrieves by customizing the **Items** property of the control that shows your data. Continuing the previous example, sort or filter the data in the **Lessons** table by using that name as an argument for the **Search** and **SortByColumn** functions. In this graphic, the formula set for the **Items** property specifies that the data is sorted and filtered based on the text in **TextSearchBox1**.

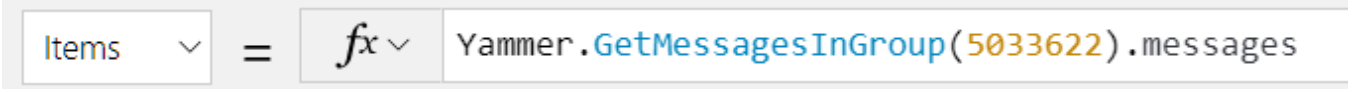
For more information about customizing your formula with tables, see these articles:

Understand data sources in Power Apps
Generate an app from Excel data
Create an app from scratch
Understand tables and records in Power Apps

> **Note**
>
> To connect to data in an Excel workbook, host it in a cloud storage service like OneDrive. For more information, see Connect to cloud-storage from Power Apps.

Actions

If your connector provides actions, select your data source as you did before. Instead of selecting a table as the next step, manually connect a control to an action by editing the **Items** property of the control that shows your data. The formula you set for the **Items** property specifies the action that retrieves data. For example, the app doesn't retrieve any data if you connect to Yammer and then set the **Items** property to the name of the data source. To populate a control with data, specify an action such as **GetMessagesInGroup(5033622).messages**.



To handle custom data updates for action connectors, build a formula that includes the **Patch** function. In the formula, identify the action and the fields that bind to the action.

> **Note**
>
> For action-based connectors, galleries and other controls don't automatically page in more data like they do for tabular connectors. For example, if you bind a tabular data source to a gallery, it retrieves the first set or page of records (for example, 100 records), and then it pages in more data as the control requests it. For an action-based connector, it retrieves a "page" of data, but if the data requested exceeds the page size, the control doesn't automatically get the next page.

For more information about how to customize your formula for custom updates, see these articles:

Patch
Collect
Update

Dynamic schema is a common type of result for action based connectors. Dynamic schema refers to the possibility that the same action might return a table with different columns depending on how it's called. Conditions that might cause the columns in the table to differ include input parameters, the user or role executing the action, and the group in which the user is working, among others. For example, SQL Server stored procedures might return different columns if run with different inputs, or an Azure DevOps instance might use custom fields that aren't available by default.

> **Note**
>
> The connector documentation shows dynamic schema results with this message **"The outputs of this operation are dynamic."** as the return value.

For more information about how to work with dynamic schema in Power Apps, see Working with Dynamic values for an overview and Connect to Azure DevOps from Power Apps for a detailed example.

Popular connectors

This table links to more information about popular connectors. For a complete list, see All connectors.

Expand table

Microsoft Dataverse	Cloud storage **
Dynamics AX	Excel
Microsoft Translator	Office 365 Outlook
Office 365 Users	Oracle
Power BI	SharePoint
SQL Server	Twitter

** Applies to Azure Blob, Box, Dropbox, Google Drive, and OneDrive.

Standard and custom connectors

Power Apps provides *standard* connectors for many commonly used data sources. If Power Apps has a standard connector for the type of data source you want to use, use that connector. To connect to other types of data sources, like a service you built, see Register and use custom connectors.

All standard connectors

Standard connectors don't require special licensing. For more information, see Power Apps plans.

Ask questions about a specific connector in the Power Apps forums, and suggest connectors you want to add or other improvements in Power Apps Ideas.

Security and types of authentication

As you author your app and create a connection to a data source, you might see that your choice of connector offers different ways to authenticate. For instance, the SQL Server connector allows you to use Microsoft Entra Integrated, SQL Server Authentication, and Windows Authentication. Each type of authentication has different levels of security. Understand what information and rights you share with users who use your application. The primary example in this article is SQL Server. However, the principles apply to all types of connections.

> **Note**
>
> - For detailed information about security considerations when using a relational database server, such as Microsoft SQL Server or Oracle, as the data source for an app, see Use Microsoft SQL Server securely with Power Apps.
> - Power Apps doesn't support **External member** identities. For more information, see Properties of a Microsoft Entra B2B collaboration user.
> - Gateway selection isn't supported for custom connectors that use the anonymous authentication type.

Microsoft Entra ID

This authentication is a secure type of connection. For example, SharePoint uses this type of authentication. SQL Server also allows for this type of authentication. When you connect, the Microsoft Entra service identifies you separately to SharePoint on your behalf. You don't have to supply a username or password. As an author, you can create and work with the data source

by using your credentials. When you publish your application, your application user signs in by using their credentials. If the data is appropriately secured on a back-end, your users can only see what they're authorized to see based on their credentials. This type of security allows you to change rights for specific application users on the back-end data source after the application is published. For instance you can grant access, deny access, or refine what a user or set of users can see all on the back-end data source.

Open-standard authorization (OAuth)

This type of connection is also secure. For example, Twitter uses this type of authentication. When you connect, **you must supply your user name and password.** As an author, you can create and work with the data source by using your credentials. When you publish your application and your application user signs in, they must also supply their credentials. Therefore this type of connection is secure as your users must use their own credentials to access the data source service.

Shared connections and secure implicit connections

In a shared connection, the Power Apps author provides the user name and password for the connection when creating the data source in the application. The connection authentication to the data source is then **implicitly shared** with end users. Once the application is published, the connection is also published and available to your users.

Before January 2024, your end users could take the connection that you shared with them and create separate new applications. Your users can't see the user name or password, but the connection is available to them. However, **after January 2024, all newly created shared connections are secured.** To secure existing apps, republish them. The connection is no longer shared with end users. The published Power App talks to a connection proxy. The connection proxy only talks to the specific Power App for which it's linked. The connection proxy limits the actions that are sent to the connections to the ones in the Power App **{Get, Put/Patch, Delete}** for a given data source. If you have an app using the connections published before January 2024, republish your application and unshare any connections with end users that shouldn't have them.

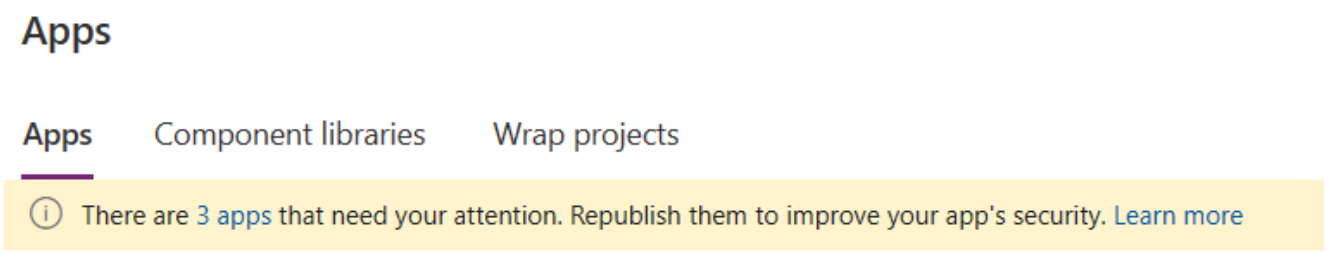
In SQL Server, an example of this type of connection is **SQL Server Authentication**. Many other database data sources provide a similar capability. When you publish your application, your users don't need to supply a unique user name and password.

> ⓘ **Note**

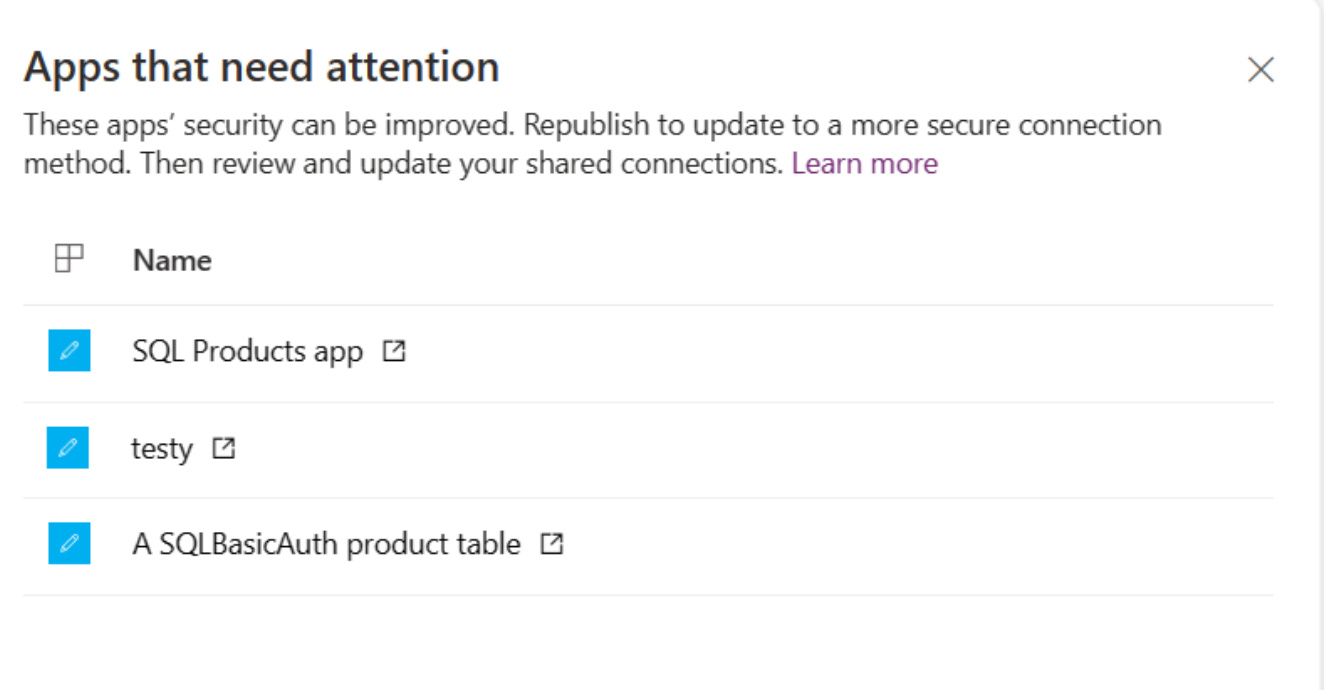
Your end-users might encounter the error message **You do not have correct permissions to use this connection** in the consent dialog. Two situations might cause this error. First, the application might have a shared implicit connection that **isn't** a secure implicit connection. Sharing the connection with the end user resolves this issue but isn't recommended because all shared connections should be secure implicit connections. The author should convert all connections in the application to be secure implicit connections to resolve this issue. Second, the connection might already be a secure implicit connection. Republishing might resolve this issue. If it doesn't, then a product bug should be filed.

Notification to update your apps (secure implicit connections)

If you have applications that might be upgraded to use this feature, you see a message on the **Apps** page. It indicates the number of apps that need your attention.



Select the link and it opens a side panel that lists all of the apps that need attention.



Select the **open** icon to the right of the app name to open and republish it. Continue with the following directions.

Enable secure implicit connections for an existing app

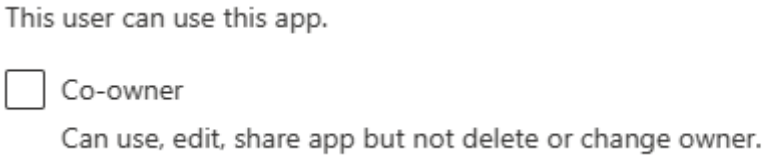
Open an existing app open for editing with implicitly shared connections already published:

1. On the command bar, select **Settings** and search for "**Secure**".
2. Update the feature switch appropriately to enable secure implicit connections.
3. Save and publish the app.

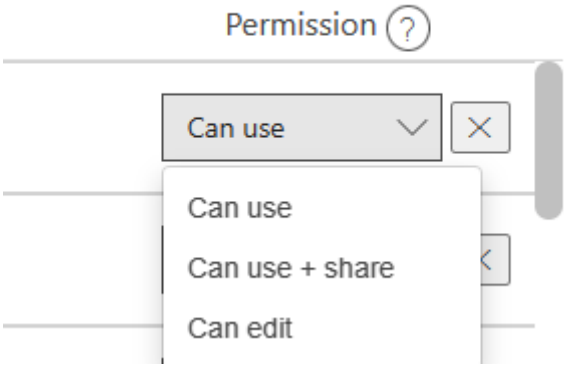
Unsharing

Once you publish the app, follow these steps to verify that sharing works correctly:

- Check if connections are shared with co-owners. If you don't want an end-user to get a connection, then uncheck the **Co-owner** checkbox.



- To verify the feature works correctly, share the app with a different user who isn't an owner. Once you share the app, check the **Connections** list in the **Dataverse** tab in Power Apps for that user. Verify that the user doesn't have a connection available.
- Open the **Sharing** panel to change the end-user's right to the connection. Choose the **X** to remove the user's access to the connection.



Use apps with a new secure implicit connection

When you republish and share your app, end-users don't have access to the connection but work with the hidden proxy connection. Users can't create a new app based on your original connection.

Limitations

1. All types of implicitly shared connections work, such as action and tabular.
2. Server and database names are hidden in network traces but visible in the consent dialog. Column names aren't hidden.
3. For tabular connectors, the feature only limits CRUD actions such as Get, Post, Put, or Delete. If you have permissions to **Put**, then you have access to **Post**.
4. Action based connectors limit based on the specific API being used in the application.
5. Warnings are still enabled in sharing. The warning around implicitly shared connections still warns while in preview. However, your connection with this feature is secure – despite the warning.
6. Publishing to an entire tenant, as opposed to specific groups or individuals isn't supported.
7. There's a known issue when importing an implicitly shared secure connection via a connection reference. The security isn't set properly in the target environment.
8. There's a known issue importing a solution using a service principal, causing import failure. A workaround is to share the connection with the service principal.

Windows Authentication

This type of connection isn't secure because it doesn't rely on end-user authentication. Use Windows authentication when you need to connect to a data source that is **on-premises**. An example of this type of connection is to an on-premises server that has a SQL Server. The connection must go through a gateway. Since it goes through a gateway, the connector has access to all of the data on that data source. As a result, any information that you can access with the Windows credentials you supply is available to the connector. When you publish the application, you also publish the connection and make it available to your users. This behavior means that your end users can create applications by using this same connection and access the data on that machine. Connections to the data source are also **Implicitly Shared** with users that the app is shared with. This type of connection might be valid when your data source only lives on an on-premises server and the data on that source is freely shareable.

Data sources in solutions

Solutions help with application lifecycle management and offer other ways to manage the lifecycle of **data sources**. If a canvas app is in a solution, you can create connection references and environment variables to store information about the data sources. This setup makes it easy to change or reconnect data sources when you move solutions to different environments.

Rename data sources in apps

Learn how to rename data sources in an app, and understand the difference between tabular and action-based data sources. For more information, see Rename Power Apps action-based data sources.

Connection consent dialog

When users open an app that uses connectors for the first time, they see a connection consent dialog for the following purposes.

1. To inform users about the data sources accessed by the app.
2. To outline the actions a connector might or might not perform in an app. For example, for apps using the **Office 365 Users** connector:

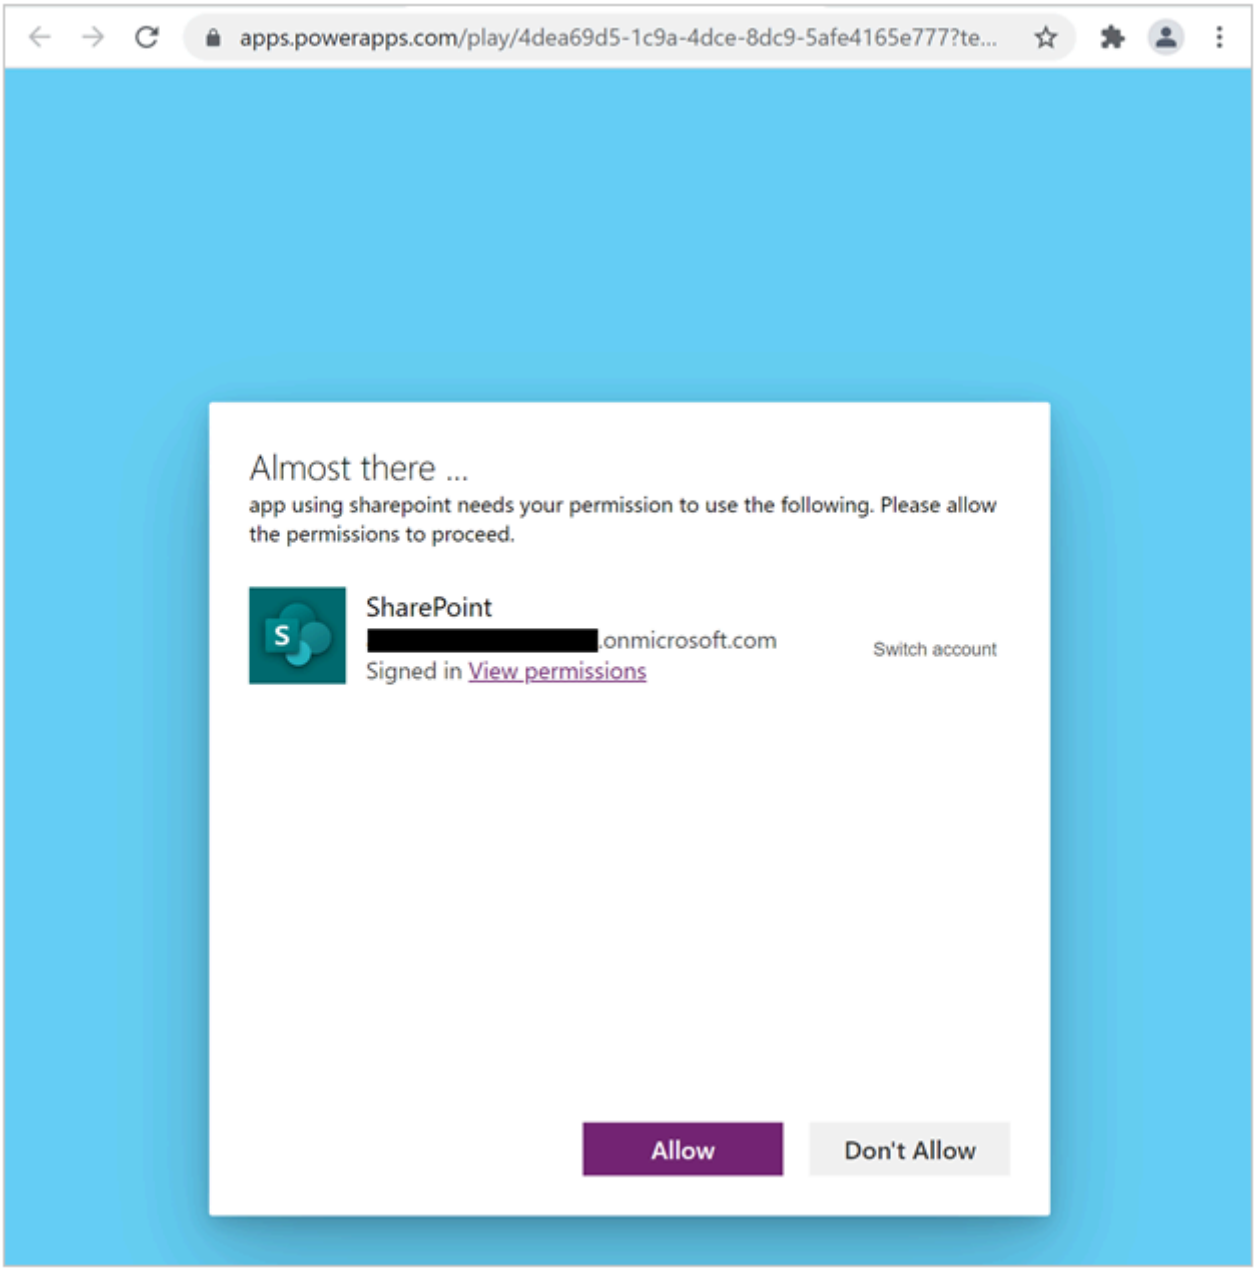
- This app is able to:
  - Read your full user profile
  - Read the full profile of all users
- The app can't:
  - Modify or delete any user-profile information

1. To capture end-user consent to connect to the data sources that the app uses.
2. To facilitate manual end-user authentication, when needed.

For some connections, Power Platform can automatically authenticate a user to access a data source. However, if the automatic sign-in fails, this dialog prompts users to fix a connection by manually signing in. Power Platform can only attempt automatic sign-in for a connection when a data source preauthorizes Microsoft's Azure API connections service principal, granting it permission to perform single sign-on for a user when a connection is created. For more information on single sign-on, see What is single sign-on (SSO)?

For model-driven apps that use custom pages, when there are multiple custom pages in an app, the consent dialog asks for data permissions for all of the connectors in all the custom pages even if users don't open them.

The following image is an example of the connection consent dialog for an app connecting to a SharePoint site.



For select connectors, admins can suppress this dialog and consent on behalf of end users to connect to a data source. The following table explains which types of connectors the consent dialog might be suppressed for an app.

> **Note**
>
> If an admin suppresses the consent dialog but the platform can't perform single sign-on for an end-user, the dialog is presented to the user when they launch the app.

Expand table

Connector type	Consent dialog suppressible?	Reference
Microsoft connectors that support single sign-on (such as SharePoint, Office 365 users)	Yes	Power Apps admin cmdlet
Connector accessing a non-Microsoft, partner service, such as Salesforce	No	Not applicable
Custom connectors using OAuth with Microsoft Entra ID as the identity provider. These custom connectors are built by organizations, and are only accessible by the users within the organization (for example, built by Contoso for only Contoso users)	Yes	Manage Connections

Microsoft Power Platform can only suppress the consent dialog for connections to data sources where all the following conditions are true:

1. The data source doesn't require an explicit consent UI.
2. The data source preauthorizes Microsoft's Azure API connections service principal to enable single sign-on.
3. An admin configures an app to suppress the consent for the preceding connections.

Microsoft's Azure API connections service principal preauthorization exists for Microsoft's first-party data sources. Custom applications registered in a Microsoft Entra tenant that are used by custom connectors might configure this preauthorization. An admin manages consent suppression on a per-app basis (as opposed to connector basis), so suppression is managed at the most granular app experience level. This level of granularity prevents consent suppression for an organization's "approved apps" from inadvertently suppressing consent for apps that aren't approved or reviewed.

Working with dynamic values

06/21/2025

When you use actions in Power Apps, you can encounter dynamic return values or input values for some actions. Previously, Power Apps ignored dynamic input fields, and they weren't visible in Power Fx expressions. Now, you work directly with these fields. Previously, when a return type was dynamic, Power Apps returned a Boolean value. Now, it returns a dynamic value instead.

> **Note**
>
> If your Power Fx expressions rely on a Boolean return value from these functions, rewrite the formula and explicitly cast the dynamic value to a Boolean. Certain functions, like 'IfError,' don't fully support dynamic values yet. If your expression uses one of these functions, see the note at the end of this article for workarounds.

Passing in dynamic values as parameters

Certain actions necessitate using a dynamic value as a parameter. If you have a Power Fx record, convert it to a dynamic value to pass it to the action.

In the following example, the merge action on a Dataverse **Account** table requires several dynamic arguments. To prepare, define three variables to hold the TargetObject, SubordinateObject, and UpdateContextObject. Start by assigning the text string **Microsoft.Dynamics.CRM.account** to a variable, which you reuse throughout the example.

Power Fx

```
Set (OdataType, “Microsoft.Dynamics.CRM.account”);
```

Then assign TargetObject a Power Fx record with the properties name, accountid, and @odata.type. Similarly, assign Power Fx records to the Subordinate and UpdateContext objects.

Power Fx

```
Set (TargetObject, {name: "Test 2", accountid: "145dc2ba-85a2-ed11-aado-
0022482d76a5", '@odata.type': OdataType});
Set (SubordinateObject, {name: FirstRecord.’Account name’, accountid:
FirstRecord.Account, ‘@odata.type’ : OdataType });
Set (UpdateContextObject, {telephone1: FirstRecord.’Main Phone’, address1_city:
FirstRecord.’Address 1 : City’, ‘@odata.type’ : OdataType });
```

Next, create three more variables to store the dynamic records after the conversion: TargetDynamicValue, SubordinateDynamicValue, and UpdateContextDynamicValue. To convert, use the ParseJSON(JSON()) function on the original variables. This action transforms the Power Fx records into dynamic values.

Power Fx

```
Set (TargetDynamicValue, ParseJSON(JSON(TargetObject)));
Set (SubordinateDynamicValue, ParseJSON(JSON(SubordinateObject)));
Set (UpdateContextDynamicValue, ParseJSON(JSON(UpdateContextObject)));
```

Finally, call the merge action and pass in the necessary parameters for both dynamic and specific types:

Power Fx

```
Environment.Merge({Target: TargetDynamicValue, Subordinate:
SubordinateDynamicValue, UpdateContent: UpdateContextDynamicValue,
PerformParentingChecks: false  });
```

Using dynamic values returned via an action

If an **Action** based connector returns an object, you can access its properties directly, even if they don't have a type. But if you want to use a property for something specific in Power Apps, like labeling, cast it first.

In this example, the `httpRequest` function returns a dynamic value that's already cast as a Boolean.

Power Fx

```
Set (response, Office365Groups.HttpRequest("/v1.0/me", "GET", ""));
```

One of the properties in the response is displayName. It can be accessed, and cast, with a Power Fx expression like the following:

Power Fx

```
Text(response.displayName)
```

Cast to the object **Text** to use it in a Power Apps label control.

Working with Dynamic fields

Action responses now capture dynamic output, and you can use the method described above to access these properties. You can also work with dynamic input fields.

Consider the `GetMessageDetails` action in Microsoft Teams, which has a dynamic input `body` parameter. Previously, you couldn't view or specify this parameter. With the recent update, set a variable called `body` with the appropriate Power Fx record structure.

Power Fx

```
Set ( body, ParseJSON(JSON( {recipient: { groupID: “7f733b36-7c7f-4f4c-9699-
0a7b7a2b3897”, channelID: “19: 085d522328fb4a439220641006f7f25@thread.tacv2”}})));
```

Then, we can call the GetMessageDetails action and assign the response to the teamsResponse variable.

Power Fx

```
Set (teamsResponse, MicrosoftTeams.GetMessageDetails ( 1661365068558, “channel”,
body ));
```

Converting formulas that return dynamic values that previously returned Boolean

Power Fx takes a limited number of dynamic values so explicit conversion may be necessary for your formula. In particular, if your formula depends on a Boolean response then you need to convert. If you need to simply know if an error exists, you can use the IsError function:

Power Fx

```
If(
  IsError(Office365Outlook.CalendarDeleteItemV2("Calendar", 1)),
  Notify("An Outlook appointment could not be found or could not be deleted")
)
```

To access error information that is exclusively available through IfError, you must transform the dynamic value into a specific type using a conversion function such as Boolean, Text, or Value. These functions will produce an error if they are given one. The following example, illustrates this:

Power Fx

```
With({result: Office365Outlook.CalendarDeleteItemV2("Calendar", 1)},
If( IsError(result),
  IfError(
    Boolean(result),  // any conversion function would do, such as Text, Value, …
    Notify("An Outlook appointment could not be found or could not be deleted: " &
FirstError.Message)
) ) )
```

Manage expired tokens

Article • 04/03/2025

This article explains how tokens are managed to ensure apps continue to function smoothly when credentials change.

API Hub handles connections differently for Power Apps, Logic App, and Power Automate. When you change your credentials, Power Apps automatically reauthenticates using a new token, while Logic Apps and Power Automate might run into issues because they use stored tokens that can become stale.

Manage tokens in Power Apps

When a connection is invoked from Power Apps, API Hub uses the OBO (on-behalf-of) token sent in the 'invoke' request from Power Apps. API Hub exchanges the OBO token for a token to the target service. The OBO token is generated and validated during each Power Apps session before invoking the connector.

For example, if a user **changes their password**, all tokens are revoked. When Power Apps directly invokes the connection, it uses the new token in the 'invoke' request to proceed. The request to the connector succeeds without the user having to reauthenticate the connection.

Manage tokens in Logic Apps and Power Automate

When a connection is invoked from Logic Apps or Power Automate, API Hub uses the stored token in the connection to exchange it for a token to the target service.

For example, **changing passwords or enforcing an MFA policy** revokes all tokens. A Logic Apps or Power Automate SSO (single sign-on) connection call fails during token exchange because the tokens aren't marked as broken, and the token stored in the connection is stale.

Refresh tokens in Power Apps, Logic Apps, and Power Automate

Power Apps automatically renews or reauthenticates any connection that is broken. However, connections aren't marked as broken when tokens are revoked. They're

marked as broken when the token exchange on API Hub fails.

Therefore, Logic Apps and Power Automate must first attempt to run the connector with expired tokens. This action causes the connection to be marked as broken. Once Power Apps encounters a broken connection, it refreshes its local cache of connections, and the connection is repaired.

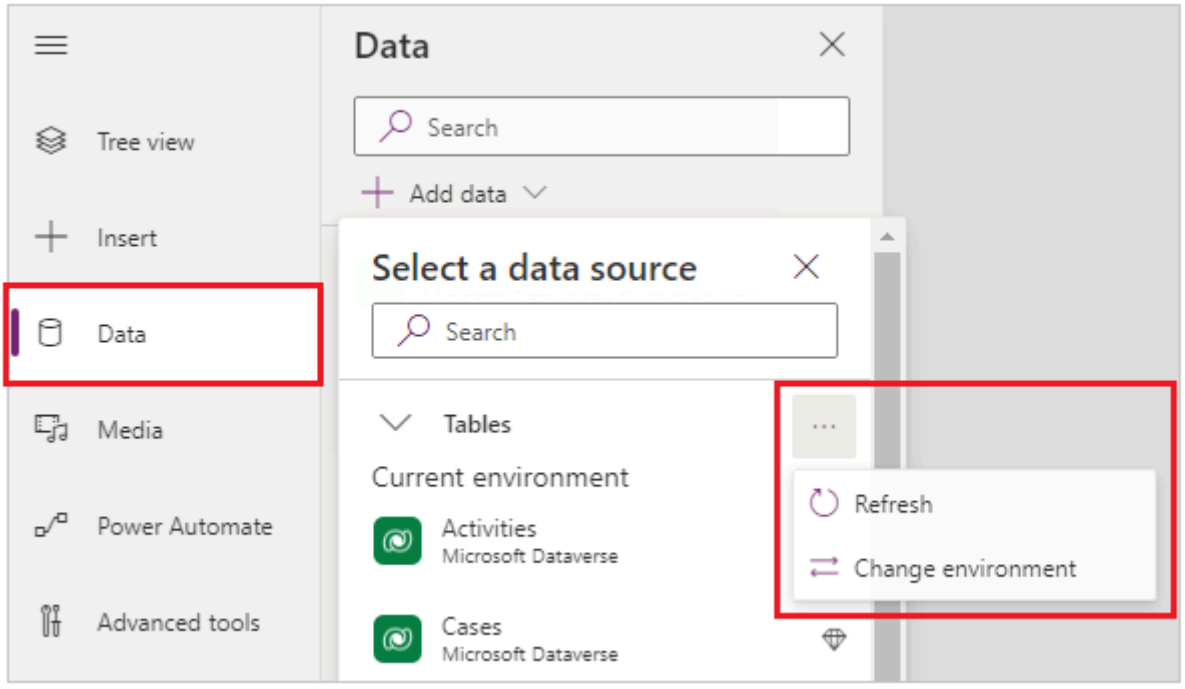
Connect to Microsoft Dataverse

06/21/2025

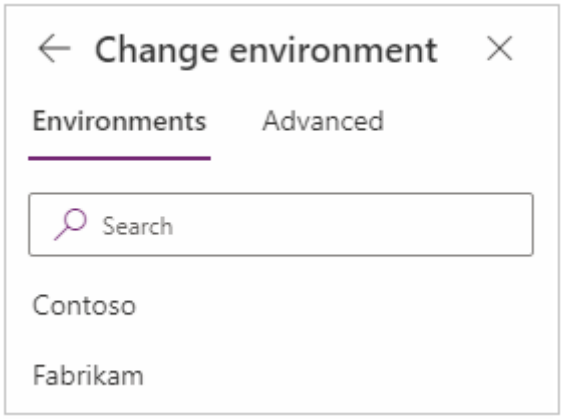
Securely store your business data in Dataverse and build rich apps in Power Apps so users can manage that data. You can also integrate that data into solutions that include Power Automate, Power BI, and data from Dynamics 365.

By default, the app connects to the current environment for Dataverse tables. If your app moves to another environment, the connector connects to data in the new environment. This behavior works well for an app that uses a single environment or follows an application lifecycle management (ALM) process for moving from development, to test, and then to production.

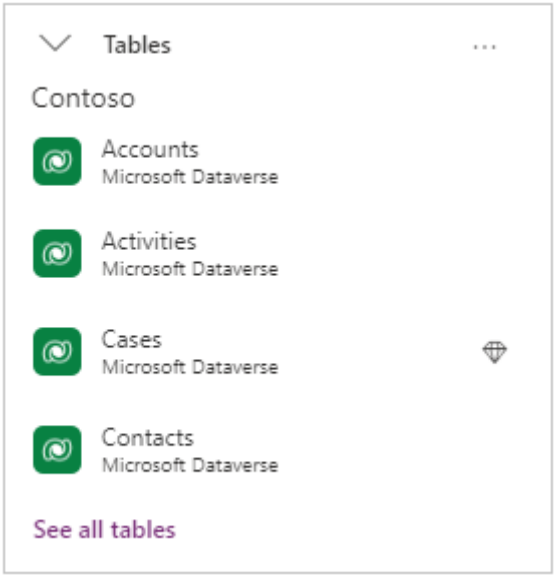
When you add data from Dataverse, change the environment, and then select one or more tables. By default, the app connects to data in the current environment.



If you select **Change environment**, specify a different environment to pull data from instead of, or in addition to, the current environment.



The name of the selected environment appears under the tables list.



Visibility and access

When you select **Change environment**, you see a list of environments. Even if you see an environment in the list, the security roles in the environment control what you can do there. For example, if you don't have read privileges, you can't see the tables and records in the environment.

> **Note**
>
> Connections listed in the app details pane outside of the app designer show connections that need user consent. Because native Dataverse connections used in the app don't need additional consent, a native connection isn't in that list.

Power Apps data type mappings

The Microsoft Dataverse connector is more robust than the Dynamics 365 connector and is approaching feature parity. The following table lists the data types in Power Apps and how they map to data types in Dataverse.

Expand table

Power Apps	Microsoft Dataverse
Choice	Choice, Yes/No
DateTime	Date Time, Date and Time, Date Only
Image	Image
Number	Floating Point Number, Currency, Decimal Number, Duration, Language, TimeZone, Whole Number
Text	Email, Multiline Text, Phone, Text, Text Area, Ticker Symbol, URL
Guid	Unique Identifier

Power Apps delegable functions and operations for Dataverse

These Power Apps operations, for a given data type, can be delegated to Dataverse for processing instead of processing locally within Power Apps.

Expand table

Item	Number [1]	Text [2]	Choice	DateTime [3]	Guid
<, <=, >, >=	Yes	Yes	No	Yes	-
=, <>	Yes	Yes	Yes	Yes	Yes
And/Or/Not	Yes	Yes	Yes	Yes	Yes
CountRows [4] [5], CountIf [6]	Yes	Yes	Yes	Yes	Yes
Filter	Yes	Yes	Yes	Yes	Yes
First [7]	Yes	Yes	Yes	Yes	Yes
In (membership) [8]	Yes	Yes	Yes	Yes	Yes
In (substring)	-	Yes	-	-	-

Item	Number [1]	Text [2]	Choice	DateTime [3]	Guid
IsBlank [9]	Yes	Yes	No	Yes	Yes
Lookup	Yes	Yes	Yes	Yes	Yes
Search	No	Yes	No	No	-
Sort	Yes	Yes	Yes	Yes	-
SortByColumns	Yes	Yes	Yes	Yes	-
StartsWith	-	Yes	-	-	-
Sum, Min, Max, Avg [6]	Yes	-	-	No	-
UpdateIf/RemoveIf [10]	Yes	-	-	No	-

Notes

1. Numeric with arithmetic expressions (for example, `Filter(table, field + 10 > 100)`) aren't delegable. Language and TimeZone aren't delegable. Casting a column to a number isn't supported. If a value appears as a number in Power Apps but the backend data source isn't a simple number, such as currency, then it isn't delegated.
2. Doesn't support Trim[Ends] or Len. Supports other functions like Left, Mid, Right, Upper, Lower, Replace, and Substitute. Also, casting such as Text(column) isn't supported for delegation.
3. DateTime is delegable except for DateTime functions Now() and Today().
4. CountRows on Dataverse uses a cached value. For non-cached values where the record count is under 50,000 records, use `CountIf(table, True)`.
5. For CountRows, ensure that users have appropriate permissions to get totals for the table.
6. All aggregate functions are limited to a collection of 50,000 rows. If needed, use the Filter function to select 50,000 rows. Aggregate functions aren't supported on views.
7. The FirstN function isn't supported.
8. The `In` operator is subject to the 15-table query limit of Dataverse.
9. Supports comparisons. For example, `Filter(TableName, MyCol = Blank())`.
10. UpdateIf and RemoveIf work locally but simulate delegation to a limit of 500 or 2,000 records. They successively bring down records beyond the nondelegation 500 or 2,000 record limit. Records that meet the If condition are collected. Generally, a maximum of 500 or 2,000 records are collected separately and then changed per execution. However, more records can be updated if the existing local data cache is large because the function can access more records for evaluation.

Call Dataverse actions directly in Power Fx

As part of the Power Fx language, you can now directly invoke a Dataverse action within a formula. Both unbound and bound actions are supported. Add a Power Fx `Environment` language object to your app to use Dataverse actions.

You can work with dynamic fields for both inputs and outputs. For inputs, many Dataverse actions require a dynamic value as an argument. Pass these arguments by using ParseJSON to convert a Power Fx record into a dynamic value. For outputs, if an action returns dynamic values, just use dot notation to access object properties. Cast specific values for use in Power Apps, such as in a label.

Before this feature, you often used Power Automate to call Dataverse directly. Calling Dataverse from Power Fx gives you significant performance benefits and is easier to use, so use this approach for direct transactional reads and updates. If your app uses Power Automate to call Dataverse actions, you see a banner suggesting you use this direct action approach instead.

Working with dynamic fields isn't limited to Dataverse. This feature works with all types of connectors and provides basic ad hoc dynamic schema support.

> ⓘ **Note**
>
> 1. DV actions aren't fully supported in Power Fx commanding (for any action call with parameters).
> 2. Direct references to an entity or entity collections aren't supported.
> 3. For parameters of object type that are nested two or more levels deep, Power Apps treats the second-level attributes as required.

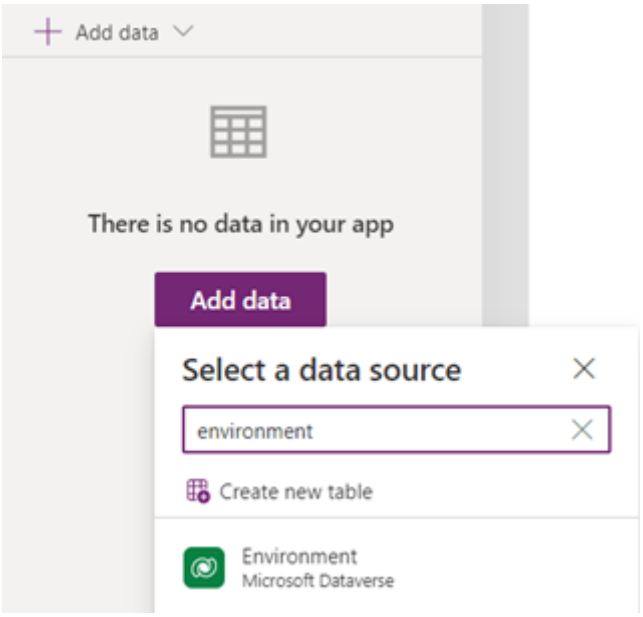
Enable access to Microsoft Dataverse actions

For new apps, this feature is automatically enabled. For apps you created earlier, enable access to Dataverse actions.

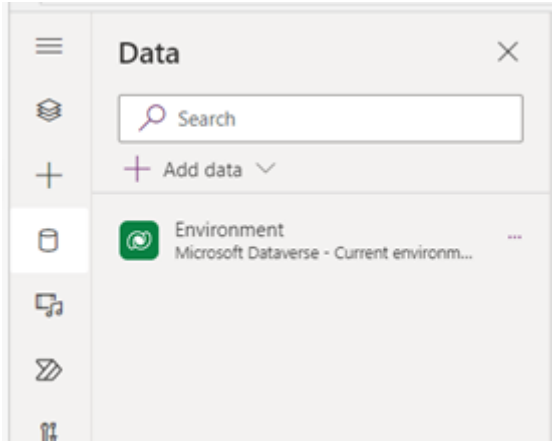
For older apps, open your canvas app for editing. Go to **Settings** > **Upcoming features** > **Retired**, and enable Dataverse actions.

Add the Power Fx Environment language object to your app

To use Dataverse actions in your Power Fx formulas, select **Add data**, search for **Environment**, and add it to your app.

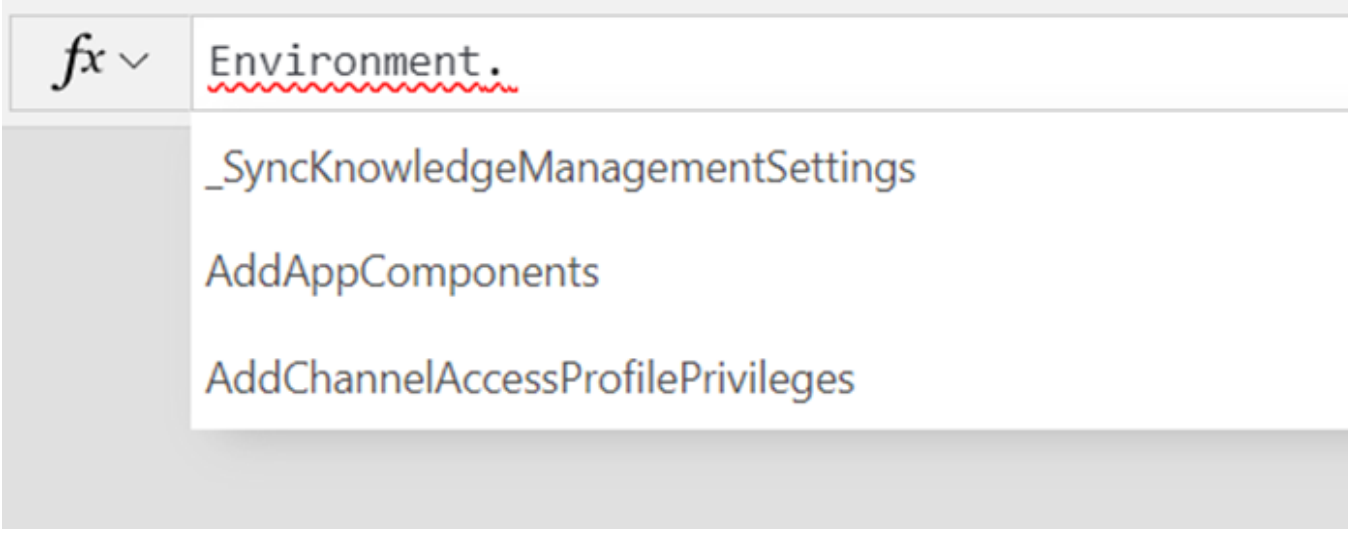


This step adds the Power Fx `Environment` language object to your app.

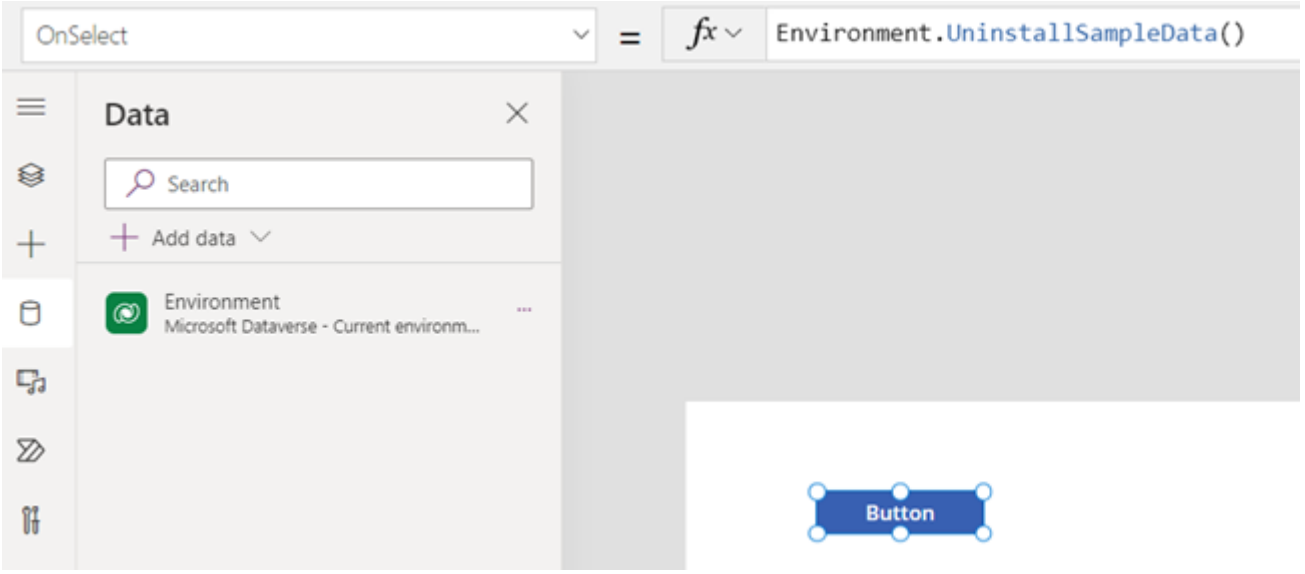


Access Dataverse actions

After you add the Power Fx `Environment` object to your app, access Dataverse actions by adding `Environment` to your formula and then using dot notation for the actions.



Unbound Dataverse actions are at the same level as tables and need the parent scope of the **Environment** language object. All actions in your environment are available—both system and custom. Both bound and unbound actions are available. The two-level call limit is removed.



For more details on how to use Dataverse actions in your formulas, see Working with dynamic values.

Pass entity type arguments for bound and unbound actions

To pass entity type arguments for Dataverse actions, set the entity type argument value to a variable. Make sure to fill in any missing values, such as ***activityId**. This step is important for entities that don't have defined types in the swagger.

Power Fx

```
Set(MyArgVar, {
  name: First(systemUser).name,
```

```
    Id: First(systemUser).Id
    ... })
```

Rename, refresh, and use actions in other environments

To rename an Environment, select the ellipses and then select "Rename". If you add a new Dataverse action in Dataverse and want Power Apps to see it, select "Refresh". To use an action in a different environment, change the environment, then search for 'Environment', select it, and add it to your app.

Microsoft Dataverse and the improve data source experience

Article • 01/24/2024

Overview

In May 2021, many features that were previously optional are now the default behavior for all new apps. This article provides guidance to users who developed an app before the introduction of new features, on how to upgrade their app to leverage the latest functionalities.

Native Dataverse

If you created a canvas app with either the Dataverse or the Dynamics 365 connector before November 2019, then you might not have the benefits of using the current native connection experience for the Dataverse.

If you created your app prior to November 2019 and you aren't using a native Dataverse connection, then in Settings in the Upcoming features tab, in the 'Retired' tab you'll find the **Improve data source experience and Microsoft Dataverse views** option along with the **Relational data, choices, and other new features for Microsoft Dataverse**.

How do I upgrade?

Upgrade your app by inspecting the settings of the features and then by following the directions below:

Relational data, option sets and other new features for Microsoft Dataverse is Off

Check *Retired* section under *Upcoming features*. If set to *Off*, continue with the following instructions as a first step in the conversion.

If you don't see **Relational data, option sets and other new features for Microsoft Dataverse** in *General settings*, or if it's already *On*, skip the following steps and continue to the next section.

- **Step 1**: Turn **Use display names** feature **On**:

1. Turn **Use display names** feature *On*.
2. Wait for the health monitor to finish analyzing your app.
3. Save, close, and reopen your app.
4. Resolve all formula errors.
5. Save, close, and reopen your app.

Possible errors and suggestions:

It's possible that some of the newly shown display names may conflict with the display names for other tables, fields, or controls. For example, you may have a control and a field with the same name. You can change the name of the control with a unique value to fix.

For any field and table display name conflict, you may see a formula that expects a table but resolves to a locally scoped field name.

Use the square bracket with an @ symbol to indicate a global scope so it resolves to the table; for example, **[@tableName]**.

- **Step 2**: Turn **Relational data, option sets and other new features for Microsoft Dataverse** and **Use GUID data types instead of strings** features **On**:

  1. Turn **Relational data, option sets and other new features for Microsoft Dataverse** feature *On*.
  2. Turn **Use GUID data types instead of strings** feature *On*.
  3. Wait for the health monitor to finish analyzing your app.
  4. Resolve all formula errors.
  5. Save, close, and reopen your app.

  Possible errors and suggestions:

  It's possible to have errors at this stage if you're using a choice field or hard-coded GUID text values.

  - *Choice values*: If you're using choice field with a text identifier for the choice value, use the dot notation instead to reference the choice value. For example, change `Patch(Accounts, OptionSet1 = "12345")` to `Patch(Accounts, OptionSet.Item1)` where `Item1` corresponds to the `12345` value.
    More information: Detailed Examples.
  - *GUIDs*: If you're using a static GUID string such as `015e45e1044e49f388115be07f2ee116`, convert it to a function that returns a GUID object; for example `GUID("015e45e1044e49f388115be07f2ee116")`.

- *Lookups*: If you're using Lookup functions to get first-level lookup values such as `Lookup(Contacts, 'contactID' = ThisItem.ContactID")`, consider using `ThisItem.PrimaryContacts` (where PrimaryContacts is the name of the table) instead.

Improve data source experience and Microsoft Dataverse views is Off

Use the following instruction to turn **Improve data source experience and Microsoft Dataverse views** feature *On*:

1. Remove your existing Dataverse data source connections.
2. Turn *On* the **Improve data source experience and Microsoft Dataverse views** feature.
3. Add the Dataverse connection using the new data source selection experience.
4. Save your application.

> ⓘ **Note**
>
> If your application is extremely large, adding your data source connections back may take a while. Don't close the application during this process.

Converting canvas apps with the Dynamics 365 connector

To convert your app that uses the Dynamics 365 connector, you need to remove and add the connections to your data sources. Use the steps below to convert your connections to your data sources.

1. Ensure the **Improve data source experience and Microsoft Dataverse views** feature is turned *On*.
2. Remove your existing Dynamics 365 data source connections.
3. Add the connections to your data sources to the Dataverse using the new data source selection experience.

   > ⓘ **Note**

- If you have connections to other environments (other than current), select the *Table* category and then the *More* (...) option to change the environment. You can then select a table from a different environment to add to your application. Cross-tenant connections don't work with the improved native connector. You'll need to use data integration to access data cross-tenant.
- You need to meet one of the following requirements to be able to see an environment that you want to add the connection to:
  - You're the **Owner** of the app, or the app is shared with you as a **Co-owner**.
  - You're a member of at least one of these security roles: **Environment Admin**, **Environment Maker**, or **System Administrator**. For more information about the security roles in an environment, go to Configure user security to resources in an environment.

4. Save your application.

Possible errors and suggestions:

It's possible to have errors as you convert if: you aren't using Display Names, if you're using GUID strings, or if you're using a choice.

- If control name conflicts, change the name of the control to be different and unique.
- For field and table display name conflicts, you might see a formula that is expecting a table but is resolving to a more locally scoped field name. Use the square bracket with an @ symbol to indicate a global scope so it resolves to the table; for example, **[@tableName]**.
- *Choice values*: If you're using a choice field with a text identifier for the choice value, use the dot notation instead to reference the choice value. For example, change `Patch(Accounts, OptionSet1 = "12345")` to `Patch(Accounts, OptionSet.Item1)` where `Item1` corresponds to the `12345` value.
  More information: Detailed Examples.
- *GUIDs*: If you're using a static GUID string such as `015e45e1044e49f388115be07f2ee116`, convert it to a function that returns a GUID object; for example `GUID("015e45e1044e49f388115be07f2ee116")`.
- *Lookups*: If you're using Lookup functions to get first-level lookup values such as `Lookup(Contacts, 'contactID' = ThisItem.ContactID")`, consider using

`ThisItem.PrimaryContacts` (where PrimaryContacts is the name of the table) instead.
- For any Polymorphic references, refer to the Detailed Examples section below.

Detailed Examples

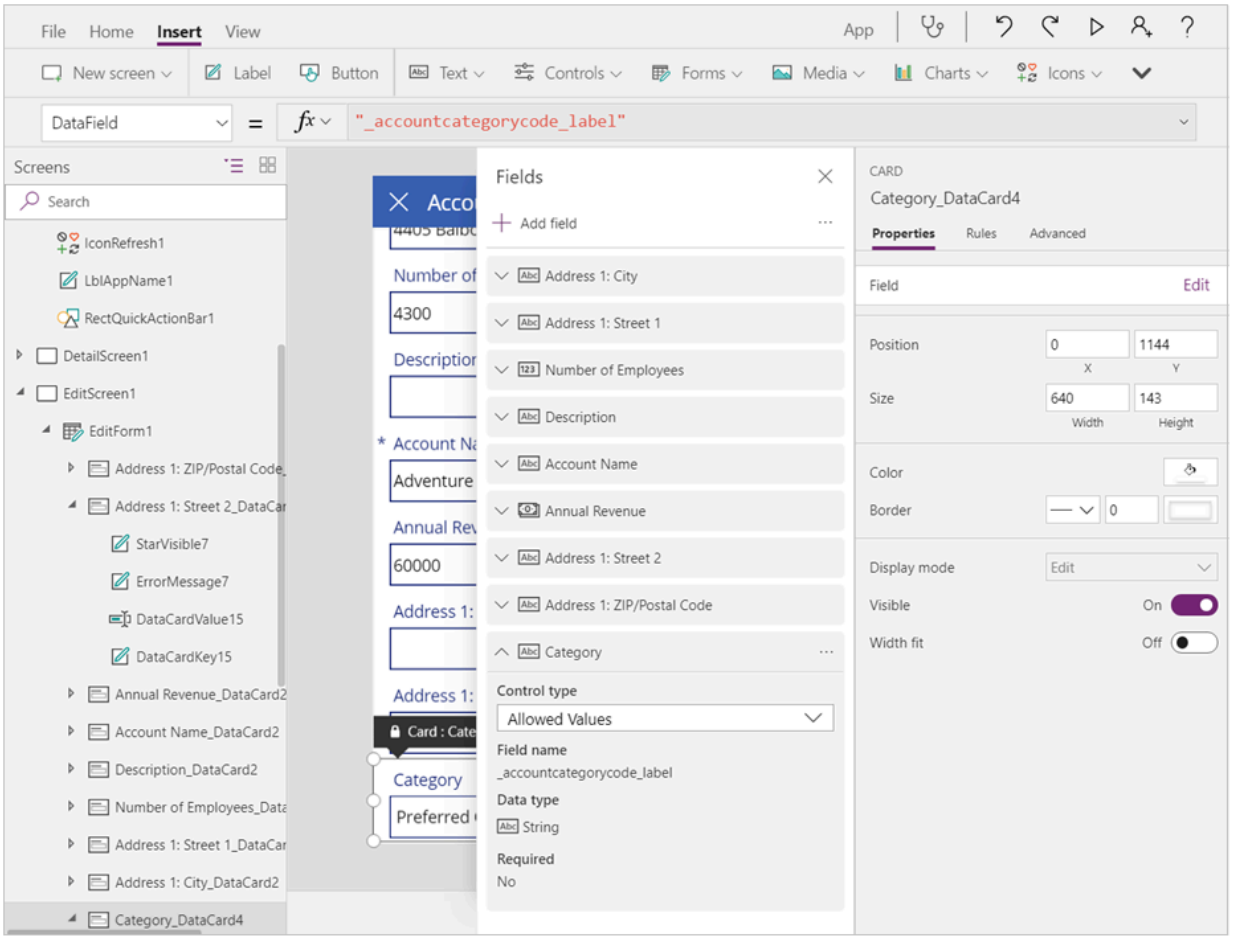
Converting your app to use the new **Option sets** and **Two options** data types with supporting controls can be challenging while upgrading an app to use the new *Improve data source experience and Microsoft Dataverse views* feature.

Choices

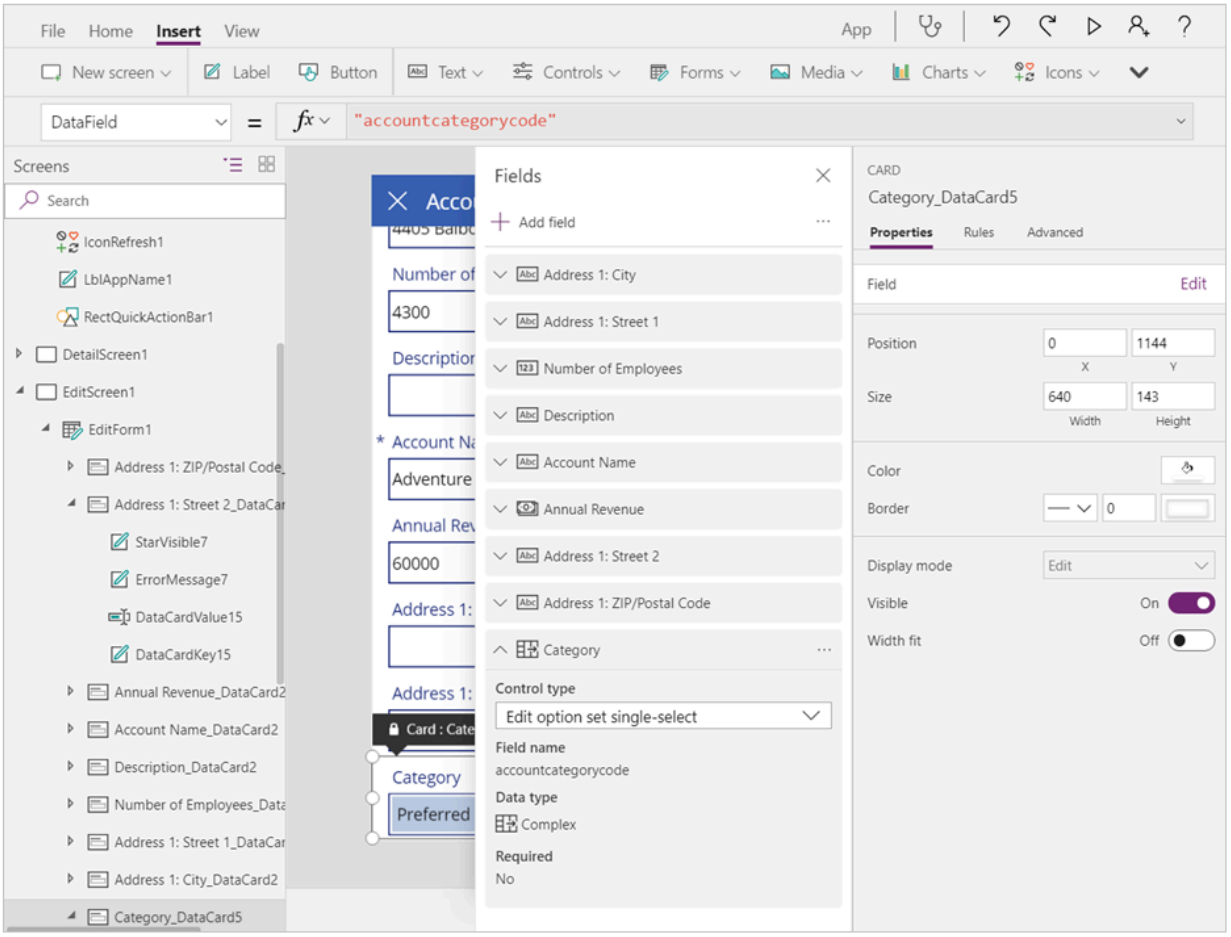
Separate `_myfield` and `_myfield_label` fields were used for choice earlier. Now, there's a single `myfield` that can be used both for locale-independent comparisons and to obtain the locale-specific label.

Removing and adding choice Data cards

We recommend that youremove existing data cards and add them back to work with your choice. For example, if you're working with the Account table and the Category choice, you see that the *DataField* property of the data card was set to `_accountcategorycode_label`. In the field list you can see that the data card has a type of *String*:



With the new *Improved data source experience and Microsoft Dataverse views* feature, you no longer see `_accountcategorycode_label`. It's replaced by `accountcategorycode`. Your card is now be marked as **custom** and you'll see errors. Remove the old data card and add the *Choice* back. The new data card is *Choice* aware.



Editing the Choice Filter expressions to use new syntax

Previously, if you wanted to use a Choice value in a Filter expression you would need to use the *Value* field. For example:

Power Fx

```
Filter(Account,'Category Value' = "1")
```

You'll need to edit this formula. Choice text identifer is no longer used for the value. This expression should be updated to:

Power Fx

```
Filter(Account, Category= ‘Category (Accounts)’.’Preferred Customer’)
```

'Category(Accounts)' is the name of enum used in the Category field of the Accounts table. This is a local choice. You can read more about local and global choices here: Global choices.

Editing choices patch statements to use new syntax

Following is an example of earlier Patch statement for choice:

```
Power Fx

Patch( Accounts, First(Accounts), { ‘Category Value’: 1 } ) )
```

You'll need to update your statements to follow this form:

```
Power Fx

Patch( Accounts, First(Accounts), { Category: ‘Category
(Accounts)’.’Preferred Customer’ } )
```

Choice disambiguation

If the display name of an choice **field** and the name of the choice are the same, you'll need to disambiguate the formula. To continue using the Accounts Category Code example, the @ implies to use the choice, not the field.

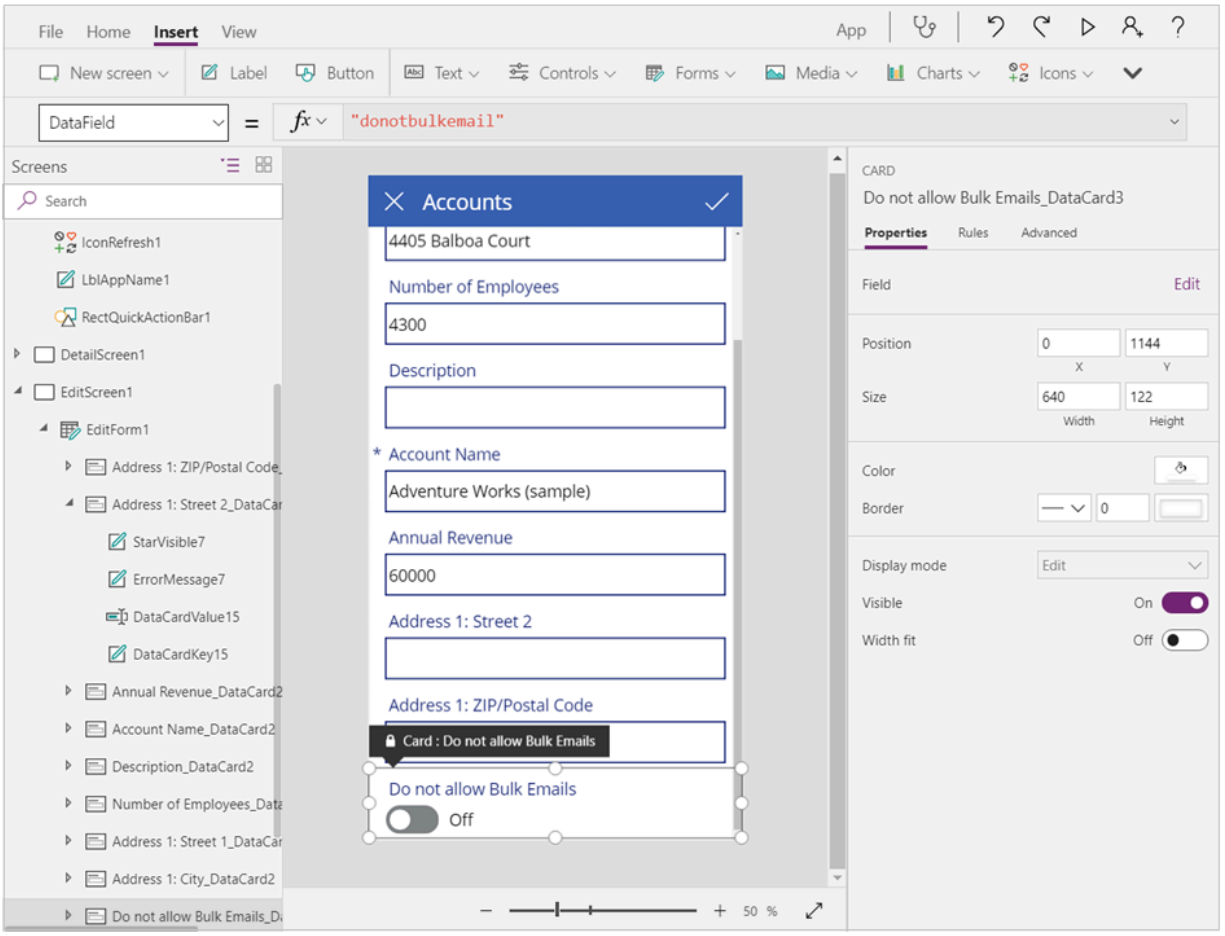
```
Power Fx

Filter(Accounts, 'Category Code' = [@’Category Code’].'Preferred Customer')
```

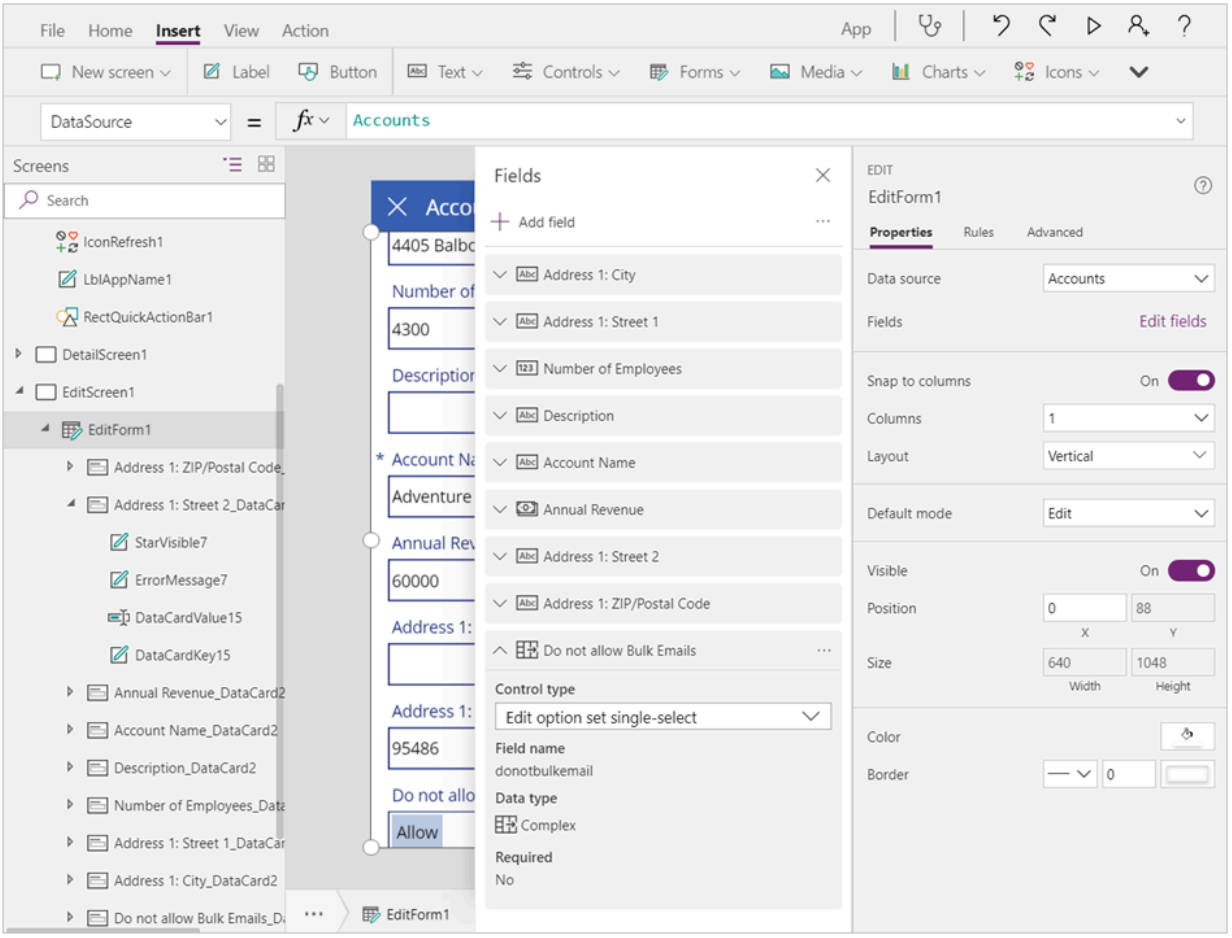
Two Options

Removing and adding Yes/No Data cards

Remove existing data cards and add them back to work with your Yes/No. The data types were earlier recognized as simple boolean - such as true/on and false/off with no labels:



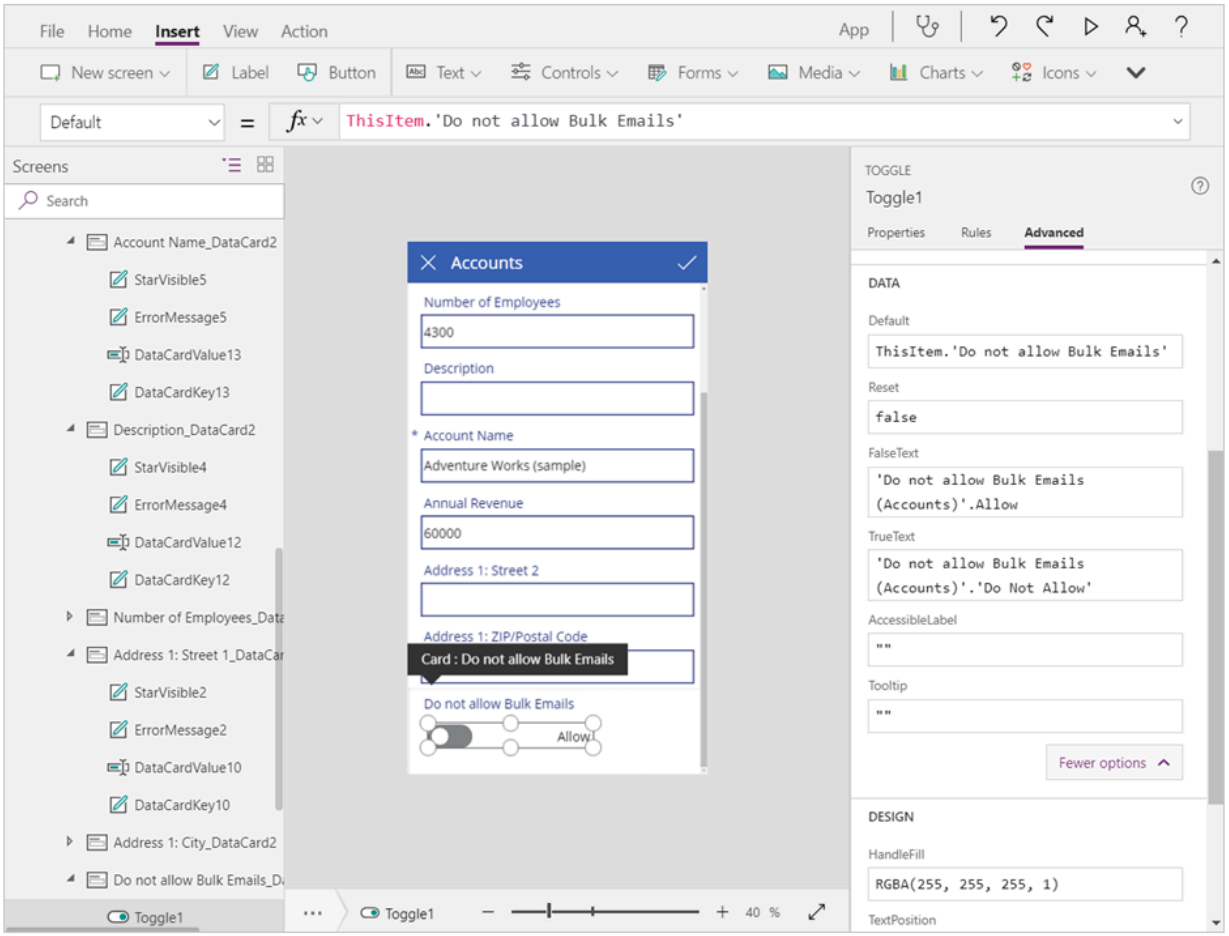
With the new *Improved data source experience and Microsoft Dataverse views* feature, your card will now be marked as **custom** and you'll see errors. Remove the old data card and add the choice back. You'll see an edit control with two options by default after you add.



If you prefer the toggle switch for your boolean field, you can unlock the data card and replace the control in the data card with a toggle instead. You'll also need to set these properties on the Toggle.

Power Fx

```
Toggle1.Default = ThisItem.’Do not allow Bulk Emails’
Toggle1.TrueText = ‘Do not allow Bulk Emails (Accounts)’.’Do Not Allow’
Toggle1.FalseText = ‘Do not allow Bulk Emails (Accounts)’.Allow
DataCard.Value = If( Toggle1.Value,
    ‘Do not allow Bulk Emails (Accounts)’.’Do Not Allow’,
    ‘Do not allow Bulk Emails (Accounts)’.Allow )
```



Refining Two Option Patch statements

Using the Patch function with Two option should work 'as is'. It supports direct use of true and false, similar to Boolean. The only difference is being if you had put the value in a Label control earlier that showed true and false, it will now show the Two option labels instead.

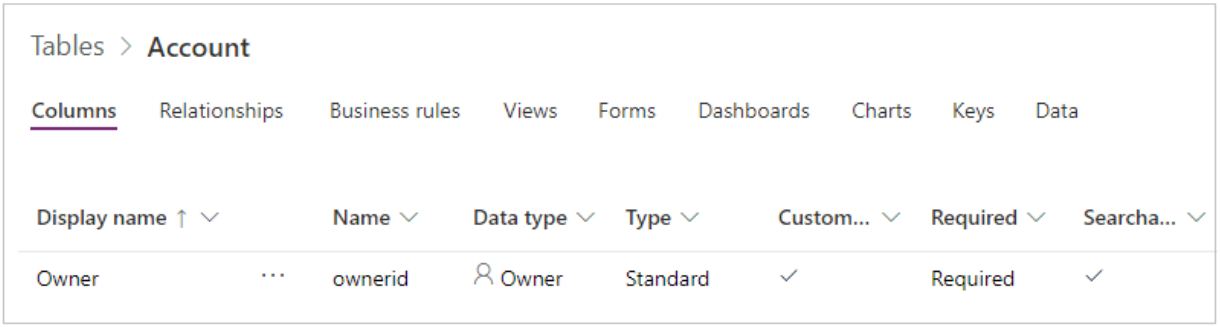
Polymorphic lookups

Following guidelines help to upgrade your application if it referenced polymorphic fields. Polymorphic lookups, from the same field, support references to a restricted set of multiple tables. Similar to references in other languages, a record reference is a pointer to a specific record in a specific table. A record reference carries the table information allowing it to point to a record in several other tables, which differs from a normal lookup that can only point to records in one table.

Access, Set, and Filter on the Owner field of a record

For instance, the Owner field in a table can refer to a record in the Users table or the Teams table. The same lookup field in different records could refer to records in

different tables.



Polymorphic with Filter and Patch

Record references can be used just like a full record:

```
Power Fx
```

```
Filter( Accounts, Owner = First( Teams ) )
Patch( Accounts, First( Accounts ), { Owner: First( Users ) })
```

Polymorphic with a Gallery displaying Owner name

Since a reference can point to different tables, you must be specific. You can't use **ThisItem.Owner.Name**, as the name field in the **Team** table is **Team Name**, and the name field in the **User** table is **Full Name**. Power Apps doesn't know which type of lookup you're referring to, until you run the app.

To fix this issue:

1. Add the data sources for the entity types that Owner could be; in current example, Users and Teams).
2. Use more functions to make your intent clear.

There are two new functions you can make use of:

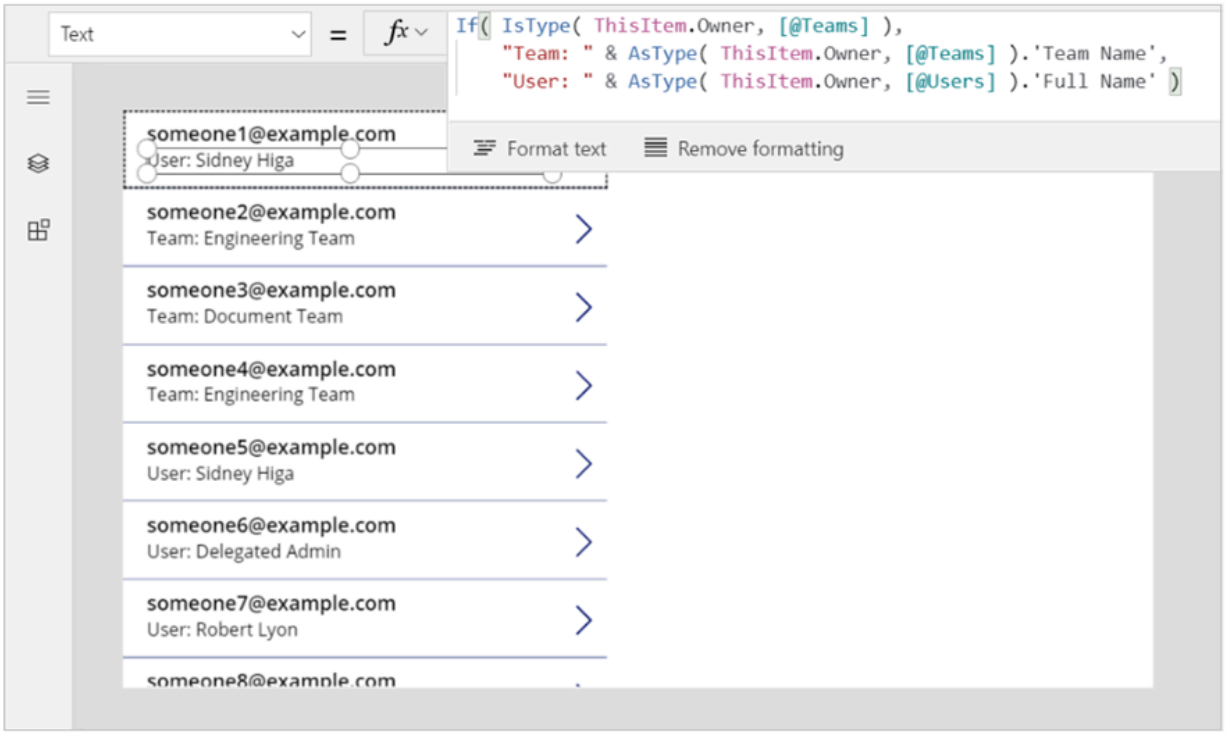
- IsType – Checks if a record reference is of a particular table type.
- AsType – Casts a record reference to a particular table type.

With these functions, you can write a formula that displays the name of the Owner taken from two differently named fields, based on the table type of the Owner:

```
Power Fx
```

```
If( IsType( ThisItem.Owner,  [@Teams]),
    AsType( ThisItem.Owner, [@Teams]).'Team Name',
```

```
    AsType( ThisItem.Owner, [@Users]).'Full Name' )
```



Global disambiguation operator for `[@Teams]` and `[@Users]` is used to ensure that you reference the global table type. Though in this case it's not necessary, it's a recommended to always be clear. One-to-many relationships often conflict in the gallery's record scope, and this practice avoids that confusion.

Access and set the Company Name field (a Customer data type) of the Contacts table

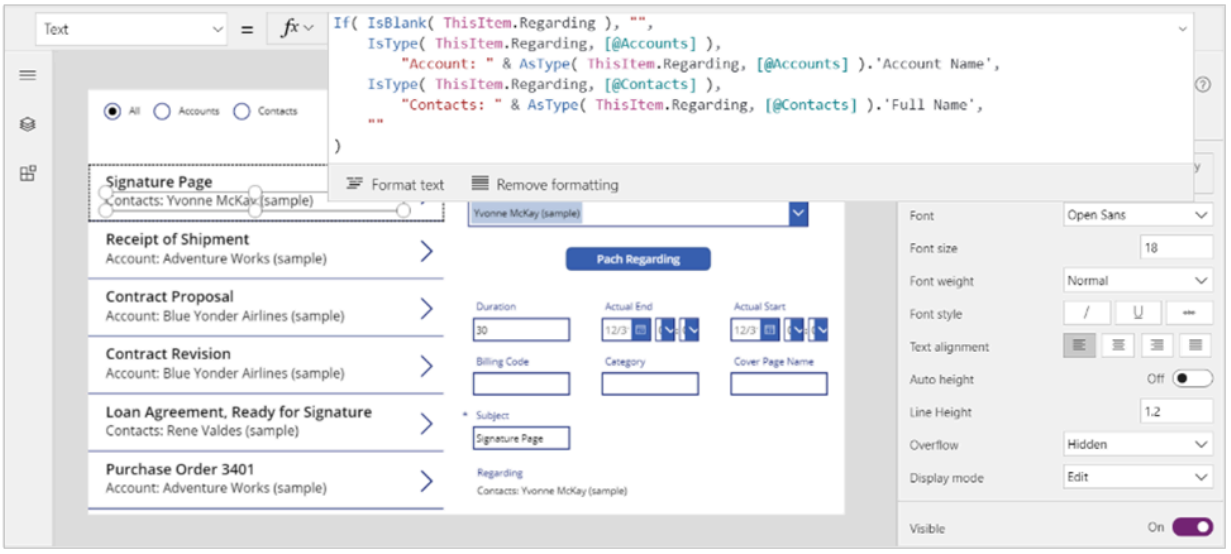
Customer lookup field is another polymorphic lookup that's similar to Owner. You can only have one Owner field per table. But a table can include zero, one, or more Customer lookup fields. The Contacts system table includes the Company Name field, which is a Customer lookup field. Read show the fields of a customer for more details.

Access and set the Regarding field of activity tables such as Faxes, Phone Calls, Email Messages

Polymorphic lookups aren't limited to Accounts and Contacts. The list of tables is extensible with custom tables. For example, the Faxes table has a polymorphic Regarding lookup field, which can refer to Accounts, Contacts, and other tables. If you have a gallery with data source set to Faxes, you can use the following formula to display the name associated with the Regarding lookup field.

```
Power Fx
```

```
If( IsBlank( ThisItem.Regarding ), "",
   IsType( ThisItem.Regarding, [@Accounts] ),
       "Account: " & AsType( ThisItem.Regarding, [@Accounts] ).'Account
Name',
   IsType( ThisItem.Regarding, [@Contacts] ),
       "Contacts: " & AsType( ThisItem.Regarding, [@Contacts] ).'Full Name',
   "" )
```



Read Regarding lookup fields and Regarding relationships for more details.

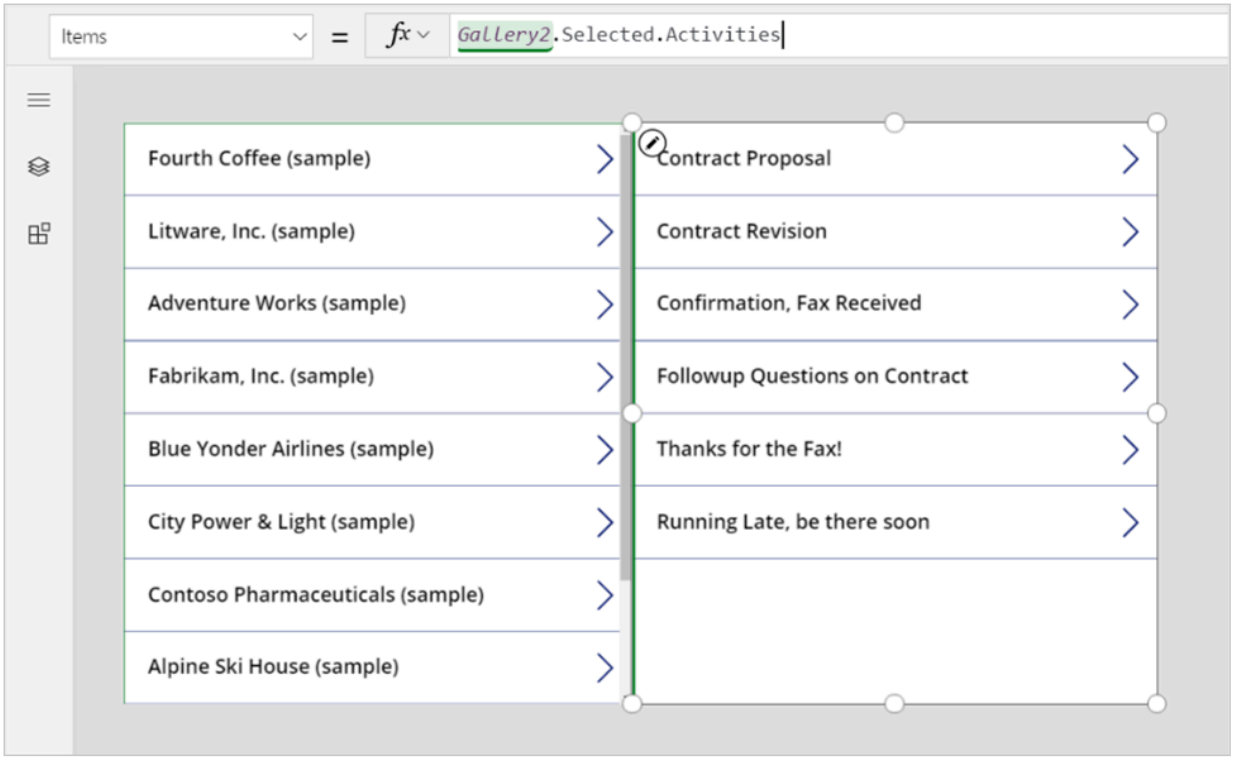
Access the list of all Activities for a record

In Dataverse, tables such as Faxes, Tasks, Emails, Notes, Phone Calls, Letters, and Chats are designated as activities. You can also create your own custom activity tables.

You can show activities of a specific type (such as Faxes or Taxes), or all activities associated with a table such as account. Add the Activities table and other individual tables whose data you plan to display in the canvas app.

Each time you add a record to (for example the Tasks table), a record in the Activity table with the fields common across all activity tables is created. Read activity table for more details.

The following example shows that as you select an Account, all the Activities associated with that account will be displayed:

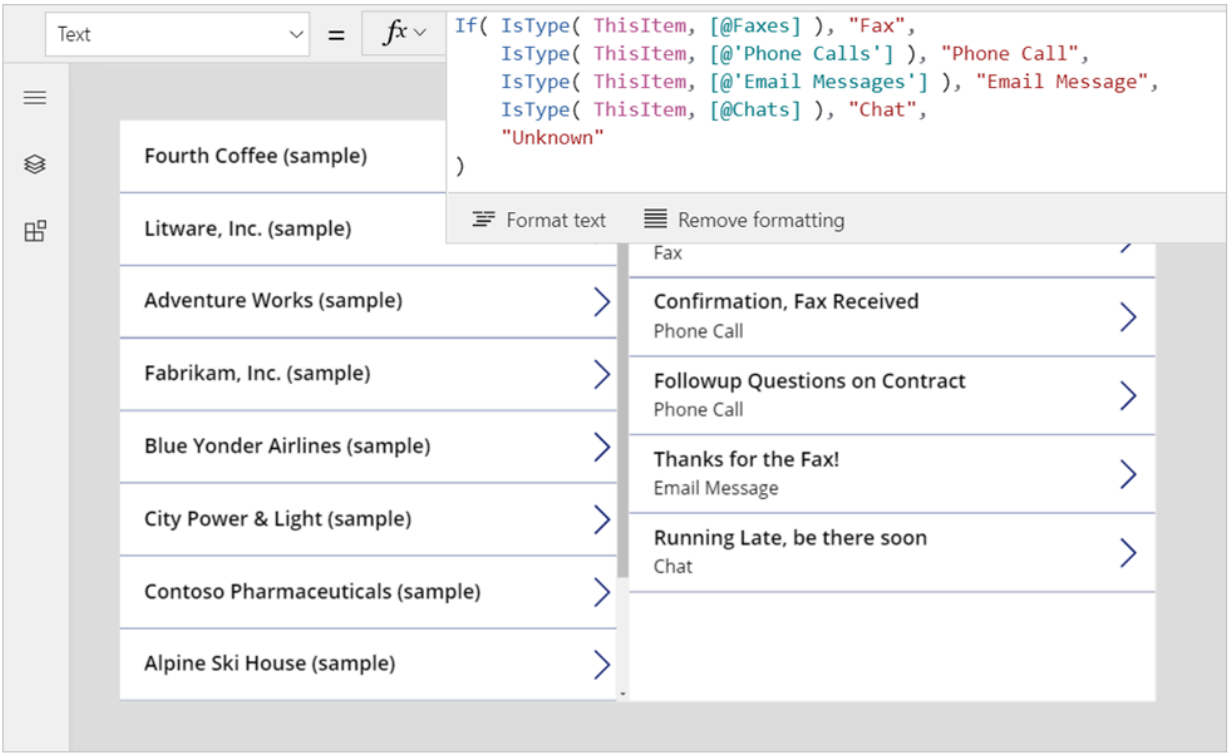


The records are being displayed from the Activity table. But you can still use the IsType function to identify which kind of activity they are. Again, before you use IsType with a table type, you must add the necessary data source.

By using this formula, you can show the record type in a label control within the gallery:

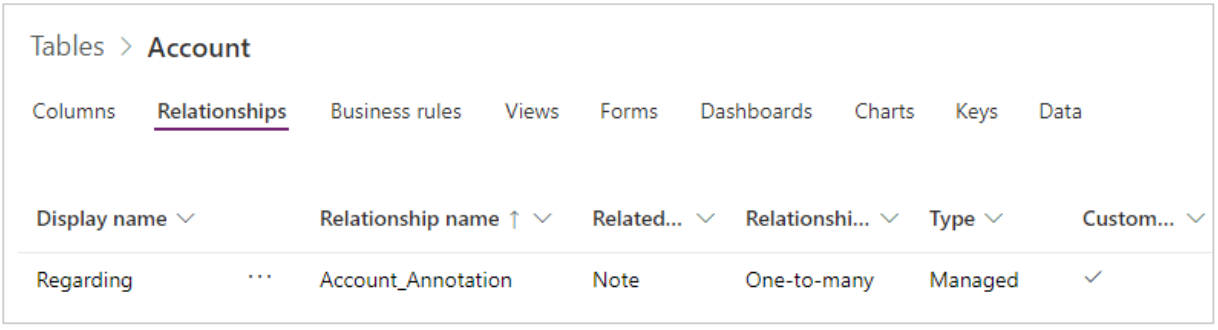
Power Fx

```
If( IsType( ThisItem, [@Faxes] ), "Fax",
   IsType( ThisItem, [@'Phone Calls'] ), "Phone Call",
   IsType( ThisItem, [@'Email Messages'] ), "Email Message",
   IsType( ThisItem, [@Chats] ), "Chat",
   "Unknown")
```



Access the list of Notes for a record

When you create a table, you can enable attachments. If you select the check box for enabling attachments, you create a Regarding relationship with the Notes table, as this graphic shows for the Accounts table:



Filtering

You can't read or filter based on the Regarding field. However, the reverse Notes one-to-many relationship is available. To list all the Notes associated to an Account table, you can use the following formula:

Power Fx

```
First( Accounts ).Notes
```

Patch

You can't set the Notes field on a table by using Patch. To add a record to a table's Notes table, you can use the Relate function. Create the note first, as in this example:

Power Fx

```
Relate( ThisItem.Notes, Patch( Notes, Defaults( Notes ), { Title: "A new
note", isdocument:'Is Document (Notes)'.No } ) )
```

Connect to cloud-storage from Power Apps

Article • 12/16/2022

Power Apps offers several cloud-storage connections. Using any of these connections, you can store an Excel file and use the information in it throughout your app. These connections include:

Box	Dropbox	Google Drive	OneDrive	OneDrive for Business
				

> **Note**
>
> To learn about using Azure Blob Storage with Power Apps, go to **Connect to Azure Blob Storage from Power Apps**.

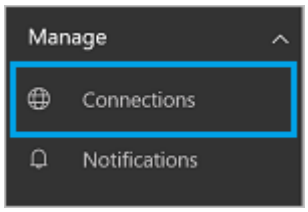
Prerequisites

- Access to Power Apps
- Add the connection
- Create an app from a template, from data, or from scratch
- An Excel file with the data formatted as a table:

    1. Open the Excel file, and then select any cell in the data that you want to use.
    2. On the **Insert** tab, select **Table**.
    3. In the **Save as Table** dialog box, select the **My table has headers** checkbox, and then select **OK**.
    4. Save your changes.

Connect to the cloud storage connection

1. At powerapps.com, expand **Manage**, and select **Connections**:



2. Select **New connection**, and select your cloud storage connection. For example, select **OneDrive**.

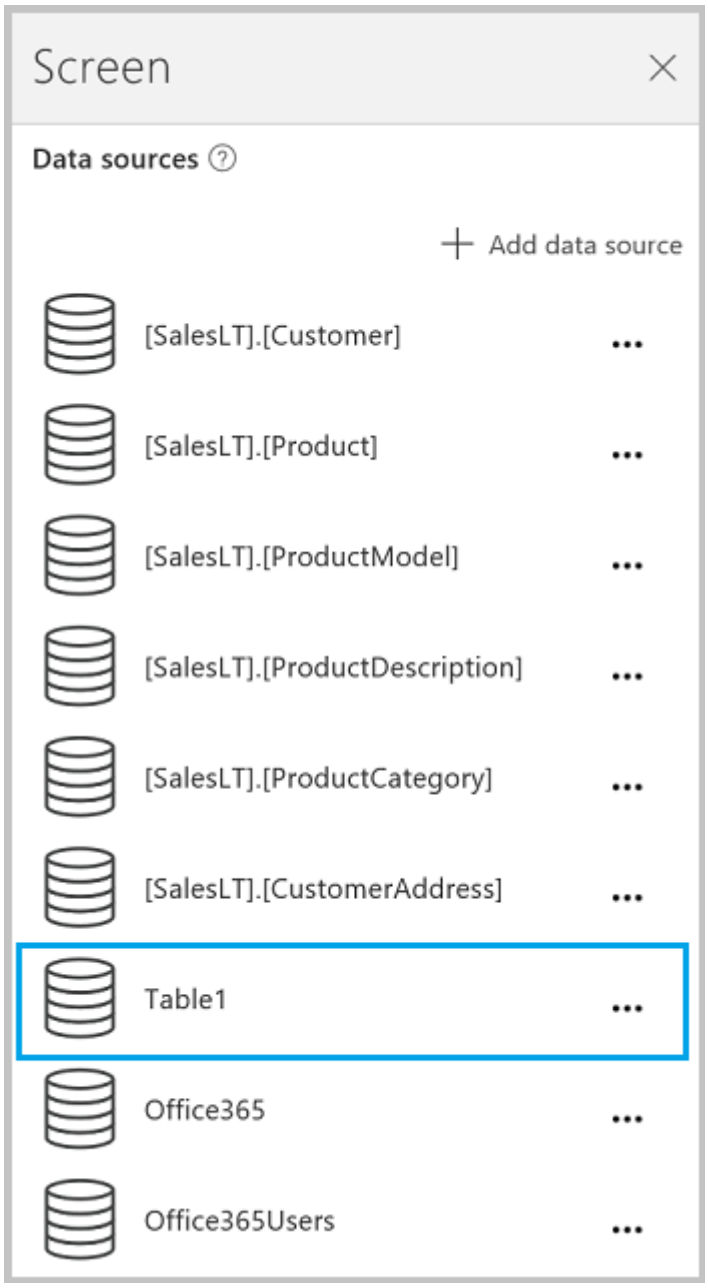
3. You are prompted for the user name and password of your cloud storage account. Enter them, and then select **Sign in**:

   Once you are signed in, this connection is ready to be used within your apps.

4. In your app, click or tap **Data sources** on the **View** tab of the ribbon. In the right-hand pane, click or tap **Add a data source**, click or tap your cloud-storage connection, and then choose the Excel table.

5. Select **Connect**.

   The table is listed as a data source:



> **Note**
>
> Remember, the Excel data must be formatted as a table.

Using the Excel data in your app

1. On the **Insert** tab, select **Gallery**, and then select a **With text** gallery control.

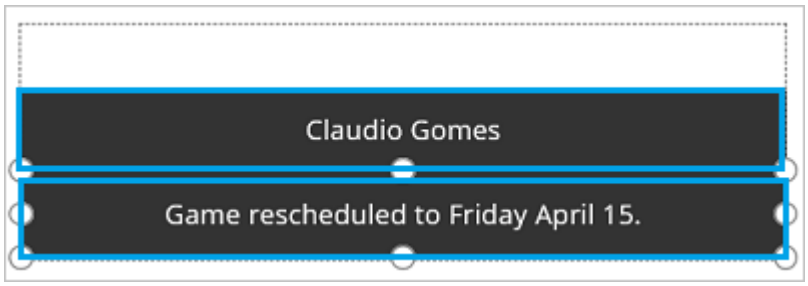
2. Set the **Items** property of the gallery to your Excel table. For example, if your Excel table is named **Table1**, then set it to Table1:

The gallery is automatically updated with information from your Excel table.

3. In the gallery, select the second or third **Label** control. By default, you see the **Text** property of the second and third labels is automatically set to `ThisItem.something`. You can set these labels to any column in your table.

   In the following example, the second label is set to `ThisItem.Name` and the third label is set to `ThisItem.Notes`:

   Sample output:



> **Note**
>
> The first box is actually an image control. If you don't have an image in your Excel table, then you can delete the image control, and add a label in its place. **Add and configure controls** is a good resource.

Understand tables and records provides more details and some examples.

Sharing your app

You can share your app, your resources such as connectors, and your data with others in your organization.

If you're sharing a folder in Dropbox, the shared folder must be attached to the user's Dropbox account.

There are certain limitations with connectors involving Excel files.

Known limitations

- If **Data type unsupported** or **Not formatted as a table** appears when you try to use an Excel connection in your app, format the data as a table.
- If your Excel data includes a calculated column, you can't use it to build an app, and you can’t add that data to an existing app.
- Power Apps mobile app for Windows platform doesn't support **Dropbox** connector. A pop-up dialog will show the following message in this situation:
  `Upgrade browser to use Dropbox`
  When this happens, consider using web player on Windows platform.

Sharing Excel tables

To share data in an Excel file:

- In OneDrive for Business, share the file itself.
- In OneDrive, share the folder that contains the file, and specify file paths, not URLs, for any media.
- In Dropbox or Google Drive, share either the file or the folder.

Connect to Azure Blob Storage from Power Apps

Article • 12/16/2022

Power Apps can connect to Azure Blob Storage. You can upload files such as Word, Excel, or multimedia images, audio or video using the Azure Blob Storage connector for Power Apps.

When you design a canvas app that connects to Azure Blob Storage, the app uses the blob storage account name and key to connect. After you share the app with others, users can use the connection configured inside the app to upload files to Azure Blob Storage without the need to share blob storage name and keys with the app users.

In this article, you'll learn how to create a sample canvas app that connects to Azure Blob Storage, and add controls to the app that allow you to upload different types of files to the connected blob storage.

> ⓘ **Note**
>
> To learn more about other types of cloud storage options with Power Apps (such as OneDrive, OneDrive for Business, Google Drive, Dropbox, or Box), go to **Connect to cloud storage from Power Apps**.

Prerequisites

Before you begin, create and configure a BlockBlobStorage account. You can also use legacy BlobStorage account, though not recommended. More information: Types of storage accounts in Azure Blob Storage

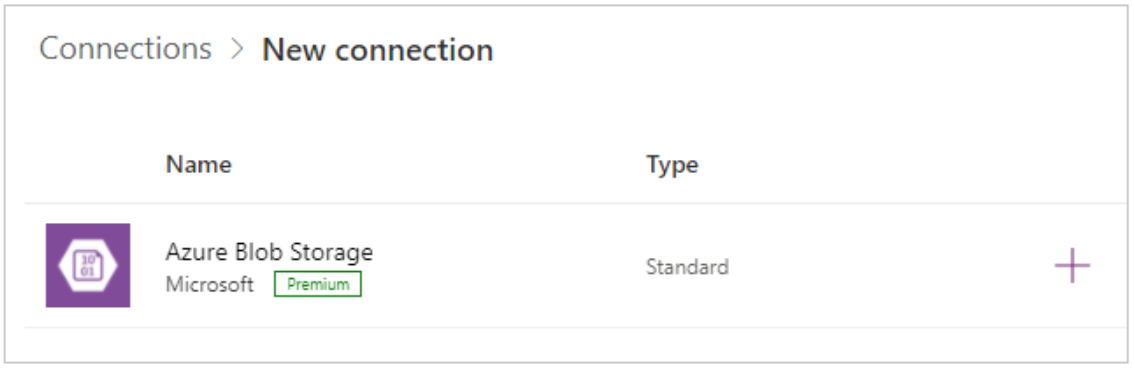
Create Azure Blob Storage connection

Power Apps requires a connection to Azure Blob Storage to be created for the app to connect to the storage.

To create the Azure Blob Storage connection:

1. Sign in to Power Apps.
2. On the left-pane, expand **Data**.

3. Select **Connections**.
4. Select **New connection**.
5. Select **Azure Blob Storage**.



6. Copy and paste the account name, and access key.

   For more information about how to copy account name and access key, go to View account access keys in Azure.

7. Select **Create**.

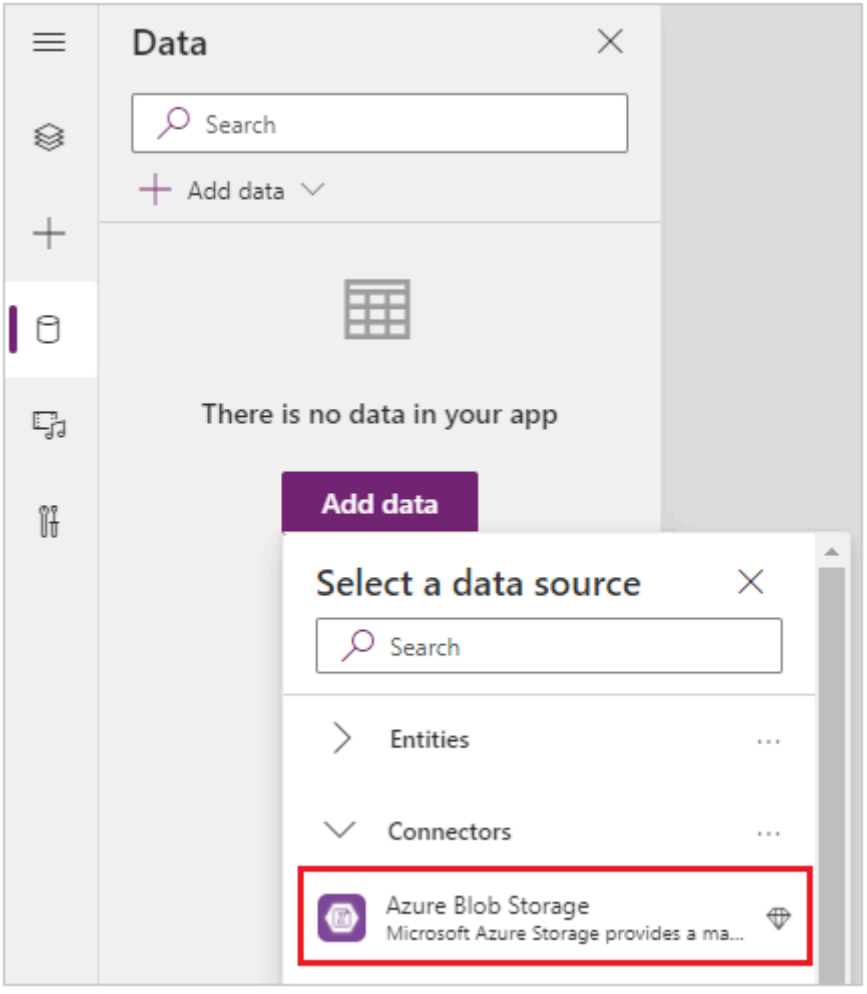
Your connection to the Azure Blob Storage is now configured and ready to use with canvas apps.

Create canvas app with Azure Blob Storage connection

Now that you have the connection with Azure Blob Storage created, let's create a canvas app that connects to this storage.

> **Note**
>
> In this section, you'll create a sample app with sample controls, functionality and layout design. Depending on your business requirement, you can create the app with a different structure, or customize differently.

1. Create a blank canvas app with the name "Sample app for Azure Blob Storage" and **Phone** layout.
2. Inside Power Apps Studio, on the left-pane, select .
3. Select **Add data**.
4. From the list of connectors, select **Azure Blob Storage**.

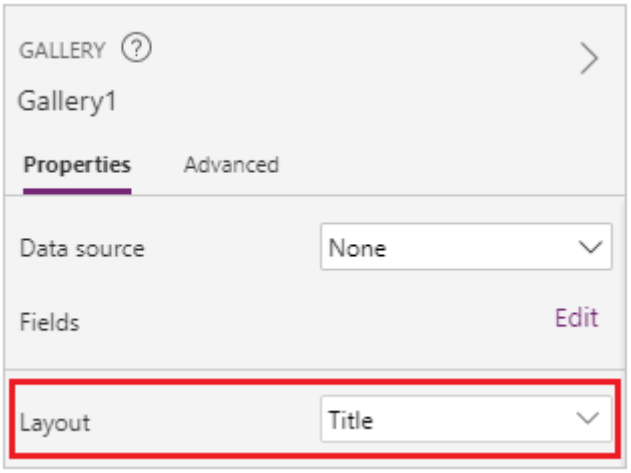


View containers and files

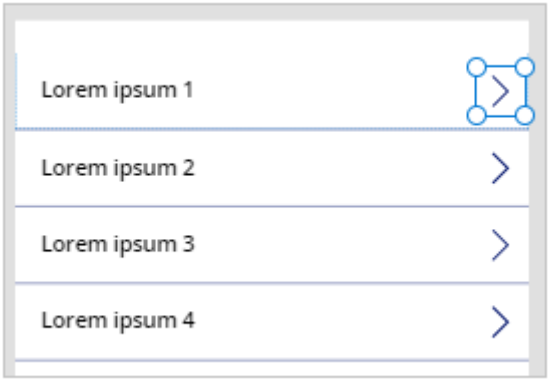
Now that you have the app connected to Azure Blob Storage, let's add galleries to see containers and files within the containers from the connected storage.

1. Select **Insert** -> **Gallery** -> **Blank vertical**.

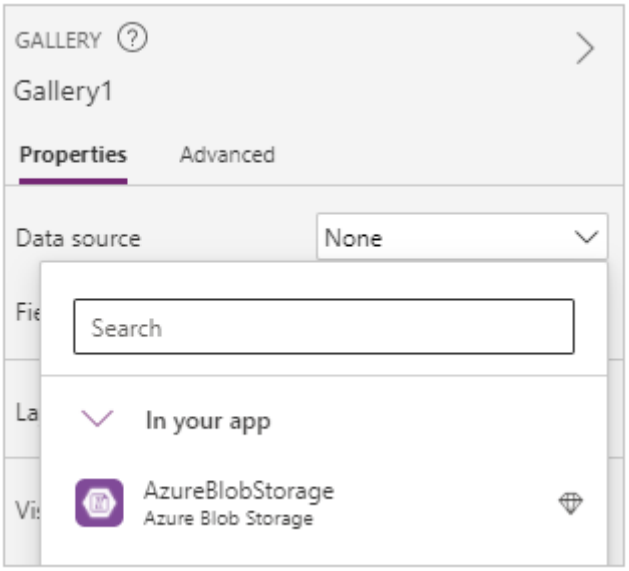
2. From the right-side of the screen, on the property pane, select the layout drop-down and choose **Title**.



3. Select first > inside the gallery, and delete it.

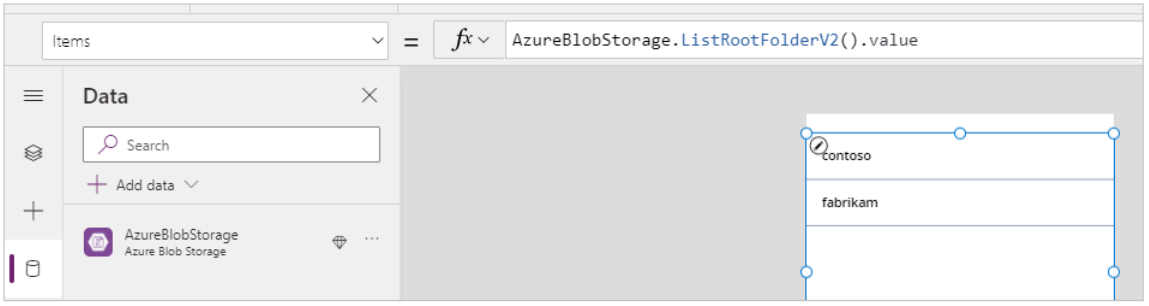


4. From the right-side of the screen, on the property pane, select the drop-down for data source, and choose **Azure Blob Storage**.



5. Set the **Items** property of the gallery to:

```
AzureBlobStorage.ListRootFolderV2().value
```



This operation lists blobs in the Azure Blob Storage root folder. More information: List blobs in root folder

6. Select **Insert** -> **Gallery** -> **Blank vertical** to add another blank vertical gallery.

7. Move the gallery below the gallery you added earlier that shows the list of containers.

8. From the right-side of the screen, on the property pane, select the layout drop-down and choose **Title, subtitle, and body**.

9. Select first > inside the gallery, and delete it.

10. From the right-side of the screen, on the property pane, select the drop-down for data source, and choose **Azure Blob Storage**.

11. Set the **Items** property of the gallery to:

Power Fx

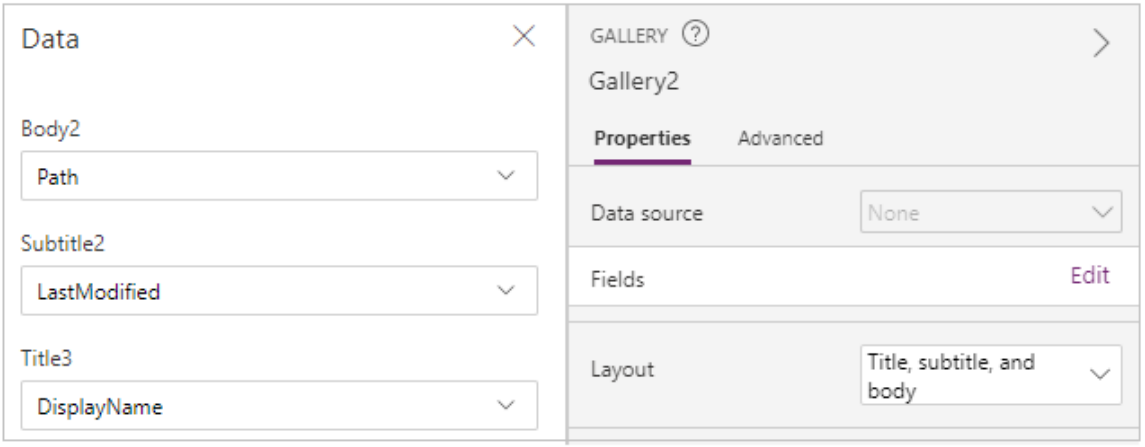
```
AzureBlobStorage.ListFolderV2(Gallery1.Selected.Id).value
```

This operation lists blobs in a container. More information: List blobs

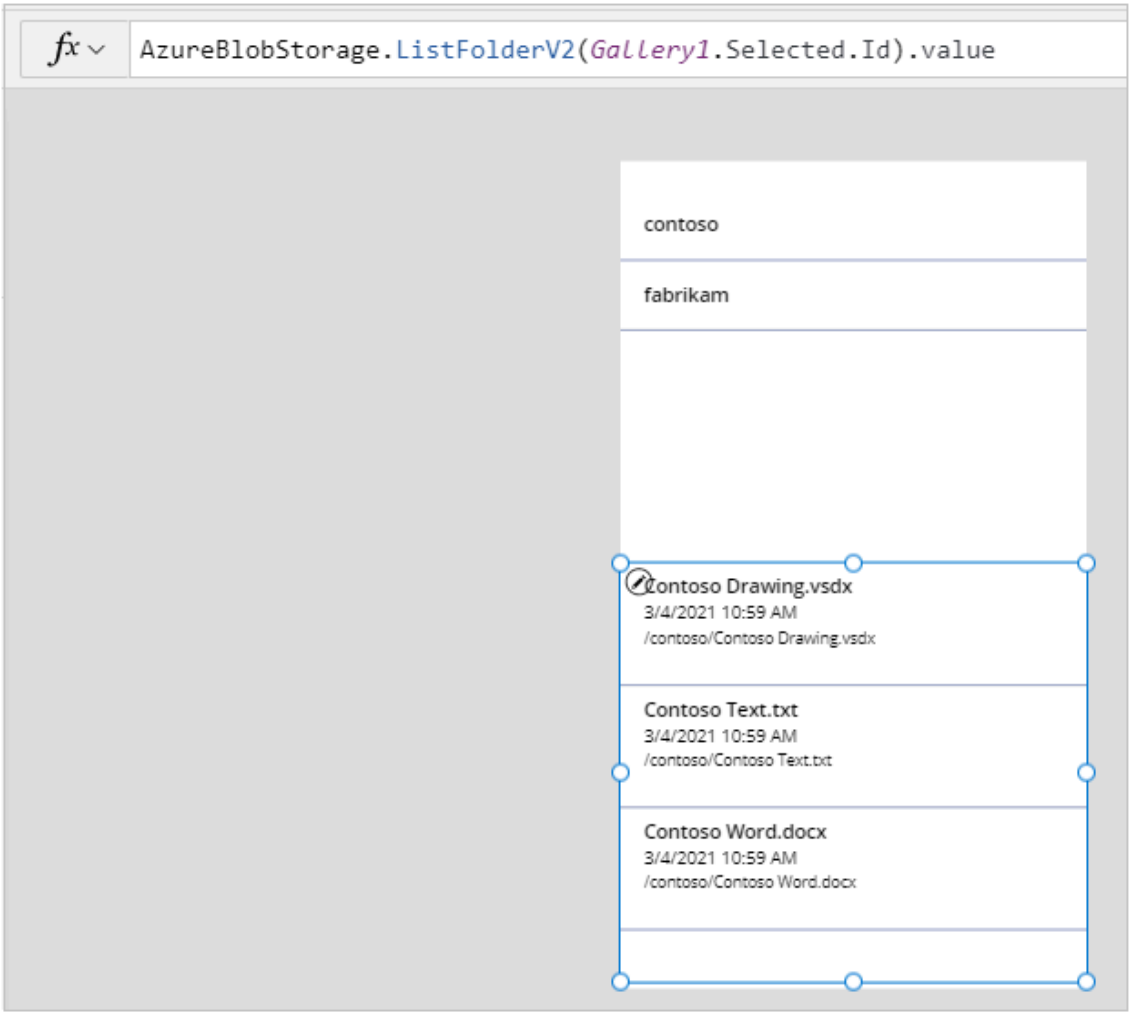
> **Note**
>
> *Gallery1* in this formula is the reference to the gallery added earlier that lists all containers in the storage account. Update the formula with the gallery name if different.

12. From the right-side of the screen, on the property pane, select **Edit** for **Fields**.

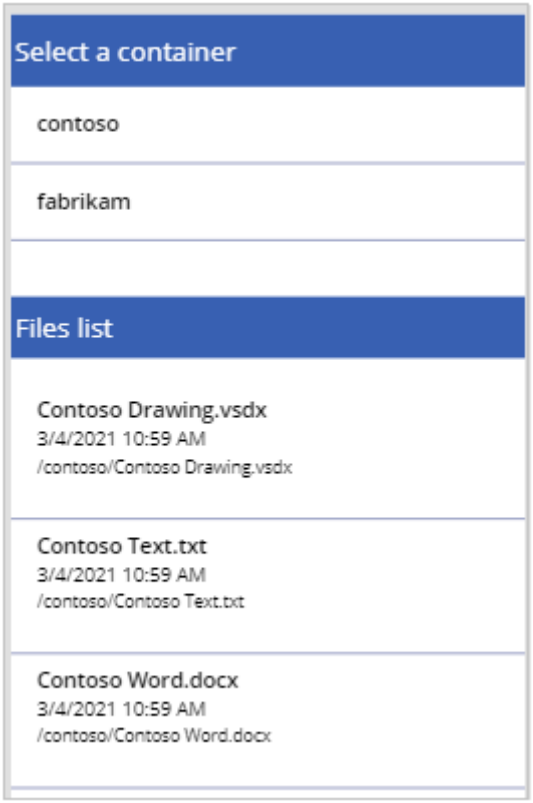
13. Change the selected fields for the gallery title as **DisplayName**, subtitle as **LastModified**, and body as **Path**.



The gallery now shows the list of files from the container selected using the gallery on the top.



14. Select **Insert** -> **Text label**.
15. Place the label on top of the app screen.
16. Set the label's **Text** property as "Select a container".
17. Use the properties pane on the right-side of the screen and choose the label text color, size, and label text background color of your choice.
18. Select **Insert** -> **Text label**.
19. Place the label above the gallery with the list of files.
20. Set the label's **Text** property as "Files list".



Upload files to Azure Blob Storage

With the app design so far, you're able to select a container and then list the files from the container.

Let's configure the app with controls and logic to allow upload of files to the connected Azure Blob Storage.

1. Select **Insert** -> **Media** -> **Add picture** to add the ability to select files to upload.
2. Resize the **Add picture** control and place it on the bottom-left of the app screen.
3. Set the **Text** property of the control to "Select a file to upload".
4. Select **Insert** -> **Button**.
5. Place the button on bottom-right side of the app screen.
6. Set the **Text** property of the button to "Upload".
7. Select **Insert** -> **Text input**.
8. Place the text input control above the **Upload** button.
9. Set the **Default** property of the button to "Enter File Name".
10. Set the **OnSelect** property of the button to:

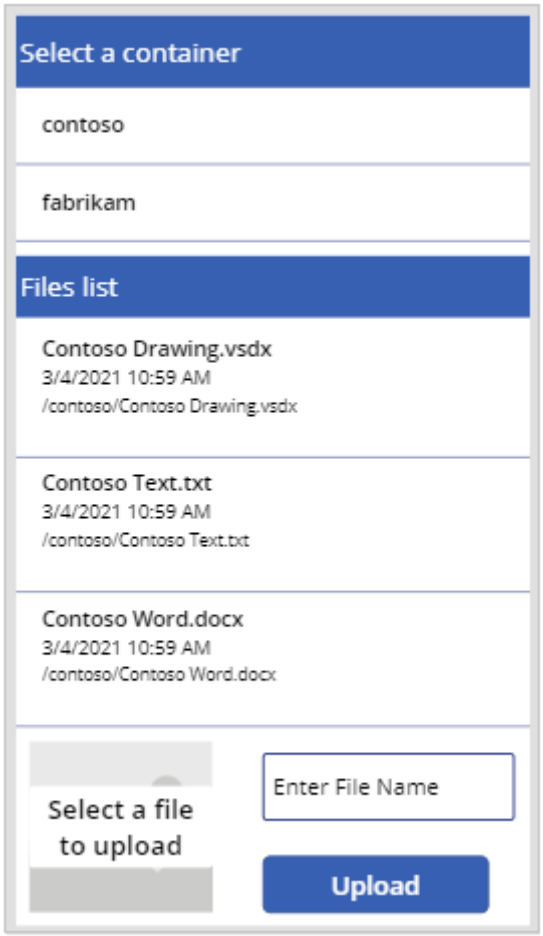
Power Fx

```
AzureBlobStorage.CreateFile(Gallery1.Selected.Name,TextInput1.Text,
UploadedImage1.Image)
```

This operation uploads a blob to Azure Blob Storage. More information: Create blob

> **Note**
>
> *Gallery1* in this formula is the reference to the gallery added earlier that lists all containers in the storage account. The file will be uploaded to the selected container in gallery 1. *TextInput1* and *uploadImage1* reference the text input and upload image controls. Update the formula with the control names if different.

The app controls look like this in the sample app now.



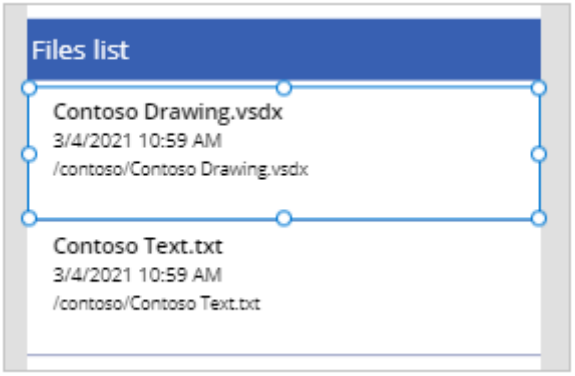
> **Tip**

Ensure you select **All files** when using the upload option to ensure all file types are visible in the file explorer dialog box.

Download files from Azure Blob Storage

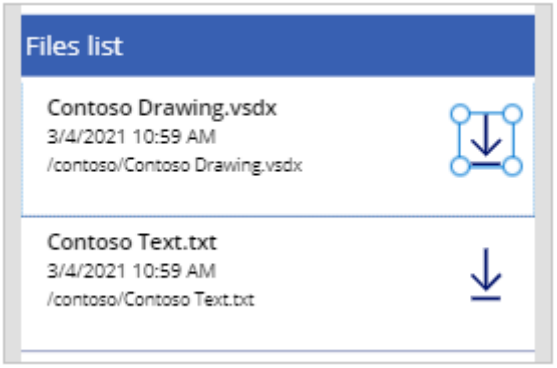
So far you've added the ability to view containers, files from the selected container, and the option to upload files to the storage. Now, let's understand how to work with the download capability with the connected storage.

1. Select the first row in the gallery with the list of files from a container.



2. Select **Insert** -> **Icons** -> **Download**. This adds the download icon for all rows in the gallery.

3. Move the first download icon towards the right side inside the gallery on the app screen. This also moves the rest of the icons for the next rows in the gallery.



4. Set the **OnSelect** property of the download icon to:

```
Power Fx

Launch(AzureBlobStorage.CreateShareLinkByPath(ThisItem.Path).WebUrl)
```

This operation creates a SAS link for a blob using the path. More information: Create SAS URI by path

> **Important**
>
> SAS URI created using **CreateShareLinkByPath** has a default expiry of 24 hours. If you have a business requirement to expire the URI in a shorter or different time, consider updates to this formula. For example, the below sample expires the URI in 1 hour using Now() and DateAdd() functions.

Power Fx

```
Launch(AzureBlobStorage.CreateShareLinkByPath(ThisItem.Path,
{ExpiryTime:DateAdd( Now(),1)}).WebUrl)
```

> **Tip**
>
> For more information about configuring Azure Blob Storage for public anonymous access, and different public access levels, go to Configure anonymous public read access for containers and blobs.

The app now has the ability to allow you to download the files.

Test, save, publish and share the app

Play the app to test, and verify the app works as expected. After the testing, ensure you save and publish the app before you close Power Apps Studio. And then, you can share the app with others within your organization, or guests outside your organization.

Optional customizations

In this section, you'll learn about optional and additional customizations that you can consider for your app.

Media type

You can use **Media type**, or **Path** fields for the gallery to optionally display the image content in the respective controls. For example, PDF viewer for PDF files, Image for images, or Audio/video for audio/video files.

For example, to filter the files with the file extension type of **.pdf**, use the following sample formula.

```
Power Fx
```

```
If(".pdf" in Gallery2.Selected.Path,
AzureBlobStorage.GetFileContent(Gallery2.Selected.Id))
```

Similarly, you can use different file extension types, or media types to additionally customize added controls.

Refresh galleries connected to Azure Blob Storage

The Azure Blob Storage connection doesn't refresh data inside the galleries automatically when the data is updated. If you have more than one container, you can select the other container and then, select the previously selected container back to refresh the connected gallery to display the changes.

Another method that can be considered is to use a collection for the first gallery, and then, use the function ClearCollect to refresh the collection.

For example, the following formulas allow you to update the collection for the top containers list in the first gallery, and update the second gallery when the upload button is selected, or when the screen appears (OnVisible screen property).

1. Set the **Items** property of the first gallery for the list of containers to "TopLevelList".
2. Append to the upload button **OnSelect** property:

   ```
   Power Fx
   ```

   ```
   ClearCollect(TopLevelList, AzureBlobStorage.ListRootFolderV2().value)
   ```

3. Add to the screen **OnVisible** property:

   ```
   Power Fx
   ```

   ```
   ClearCollect(TopLevelList, AzureBlobStorage.ListRootFolderV2().value)
   ```

Limitations

You can't use Microsoft Excel as the data source when the file is stored in Azure Blob Storage. To use Excel as the data source, use the other cloud storage connectors (such

as OneDrive, OneDrive for Business, Google Drive, Dropbox, or Box). More information: Connect to cloud storage from Power Apps

Connect to Azure DevOps from Power Apps

06/21/2025

The Power Apps connector for Azure DevOps lets you work with your Azure DevOps instance. View Azure DevOps queries, select work items by type, and view or edit details—all from inside a canvas app connected to Azure DevOps.

> **Tip**
>
> For a complete list of all actions, see **Azure DevOps connector actions**.

This article guides you through building a canvas app that connects to Azure DevOps to get a list of queries and interact with work items in your project.

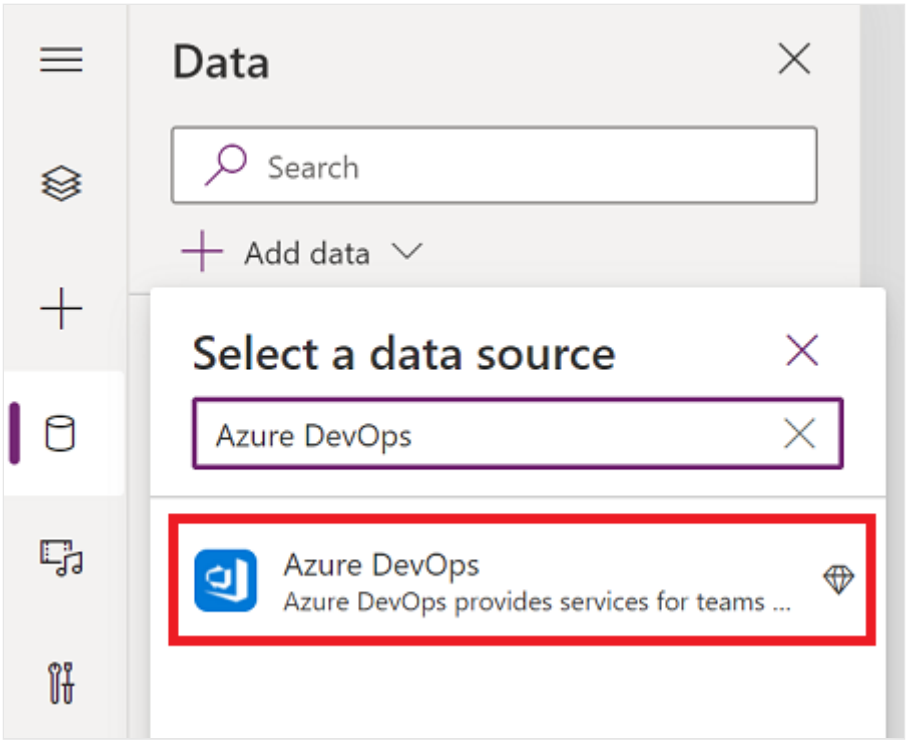
Prerequisites

You need the following:

- A Power Apps license. If you don't have one, use a 30-day trial, or sign up for a developer plan for non-production use.
- If you're new to Power Apps, learn the basics by generating an app, then customize the app's controls, gallery, forms, and cards.
- A blank canvas app to connect to Azure DevOps.
- To create the app in this article, you need an Azure DevOps instance with an organization, a project, and a shared query that has a few sample work items available for editing.
- The Azure DevOps instance must let **Third-party application access via OAuth**. For more information, see Manage access policies for Azure DevOps.

Step 1 - Add Azure DevOps data source

To connect to Azure DevOps, edit the blank canvas app, and add the **Azure DevOps** data source.



If you don't have an Azure DevOps connection, select **Connect**, follow the prompts to enter your details, and allow the app to connect.

Step 2 - List shared queries

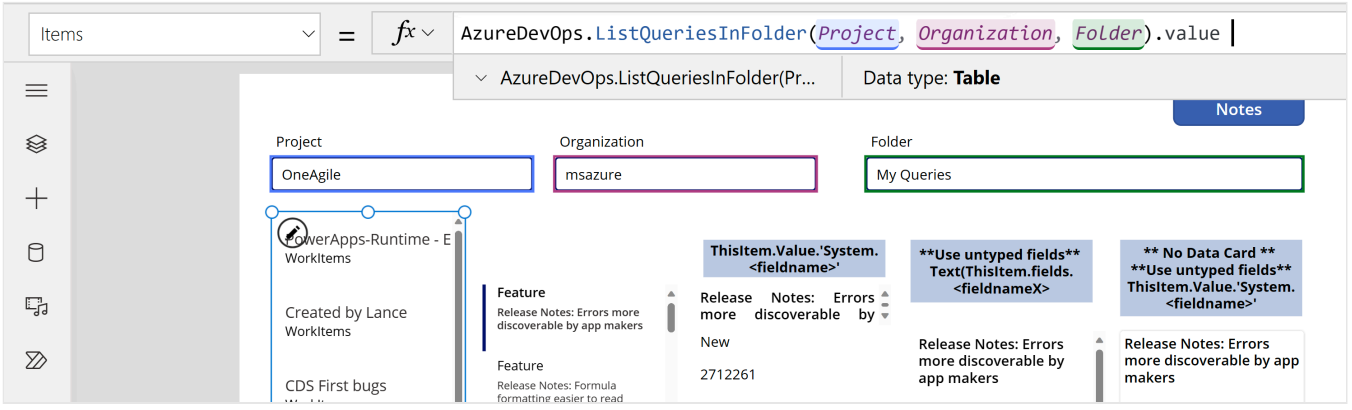
In this section, you use the ListQueriesInFolder action for the Azure DevOps connector to list the available queries.

1. In the left pane, select **Insert** > **Layout** > **Blank vertical gallery**.

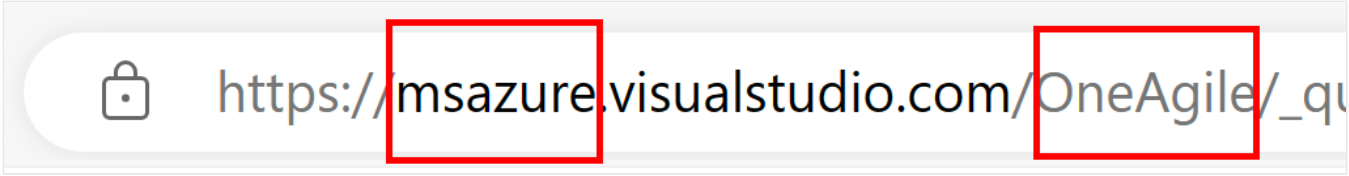
2. Enter the following formula for the **Items** property of the gallery. Replace the example parameter values with your own values.

```
Power Fx

AzureDevOps.ListQueriesInFolder("Project", "Organization", "Folder").value
```



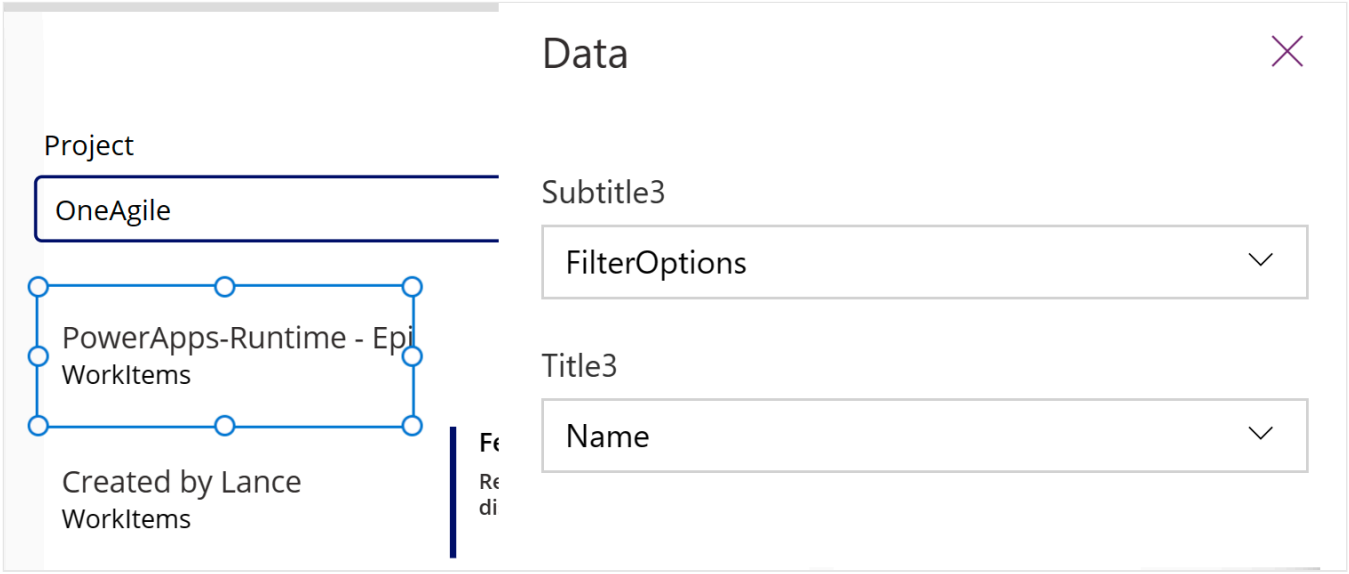
The example uses the variables "Project", "Organization", and "Folder". The actual values are in the text boxes below the formula bar (highlighted). You find your Project and Organization values in the URL used to connect to Azure DevOps. The Folder is usually "Shared Queries" or "My Queries".



If you get the following error in the above formula, enable third-party app access using OAuth in your Azure DevOps organization, and try again.

"AzureDevOps.ListQueriesInFolder failed:{"status":401,"message":"TF400813:The user 'GUID' isn't authorized to access this resource."}"

1. Set the **Layout** for the gallery to **Title and subtitle**.
2. Choose the fields appropriate for Azure DevOps as **Name** and **FolderOptions** for the title and subtitles.



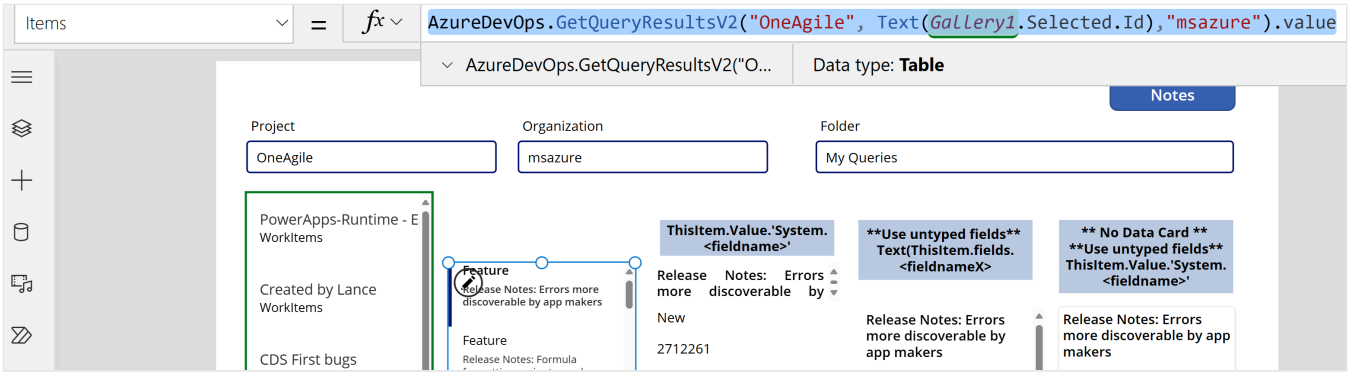
Step 3 - List work items

Use the GetQueryResultsV2 action for the Azure DevOps connector to list all work items for the selected query. This action binds the gallery to the data source.

1. Insert another blank vertical gallery and place it next to the existing gallery.
2. Enter the following formula for the **Items** property of the gallery. Replace the example parameter values with your project and organization names.

Power Fx

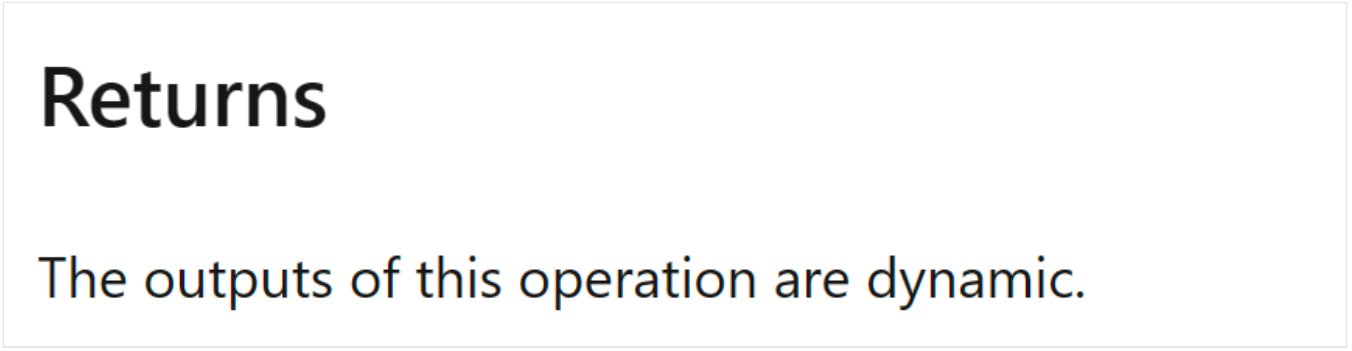
```
AzureDevOps.GetQueryResultsV2("Project", Text(Gallery1.Selected.Id),
"Organization").value
```



This formula uses the GetQueryResultsV2 action with the project name, query ID, and organization name. The query ID in this example (`Gallery2.Selected.Id`) refers to the query selected from the list of queries available through the gallery added earlier. Replace the gallery name as needed.

Add dynamic return values to your gallery

The result of **GetQueryResultsV2** is dynamic, so the values are dynamic as well.



But you can access some of the values. Azure DevOps returns a basic set of values for all typed items. Select the data card in the gallery and insert two text labels. Set the text property of the labels as follows:

Power Fx

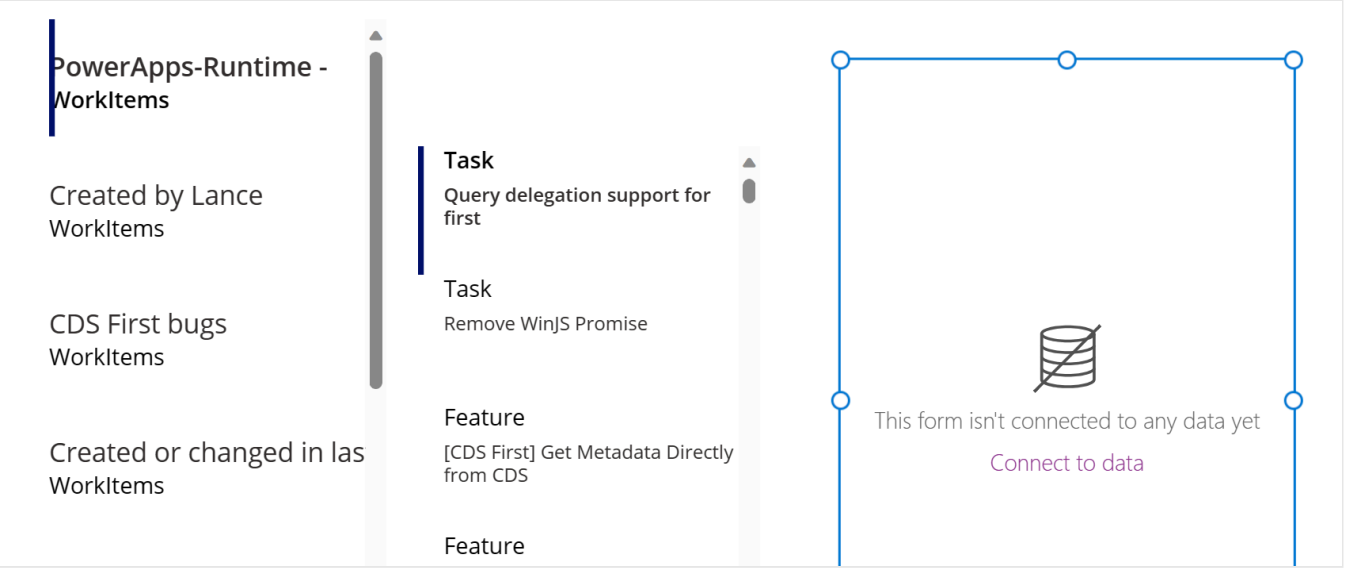
```
ThisItem.Value.'System.WorkItemType'
ThisItem.Value.'System.Title'
```

Step 4 - Display work items

The app shows a list of all queries and the list of work items for the selected query. Now, add an edit form to display data.

1. Move both galleries to the left side of the screen to make room for the edit form.

2. Add **Edit form** to the screen and move it to the right side of the galleries.

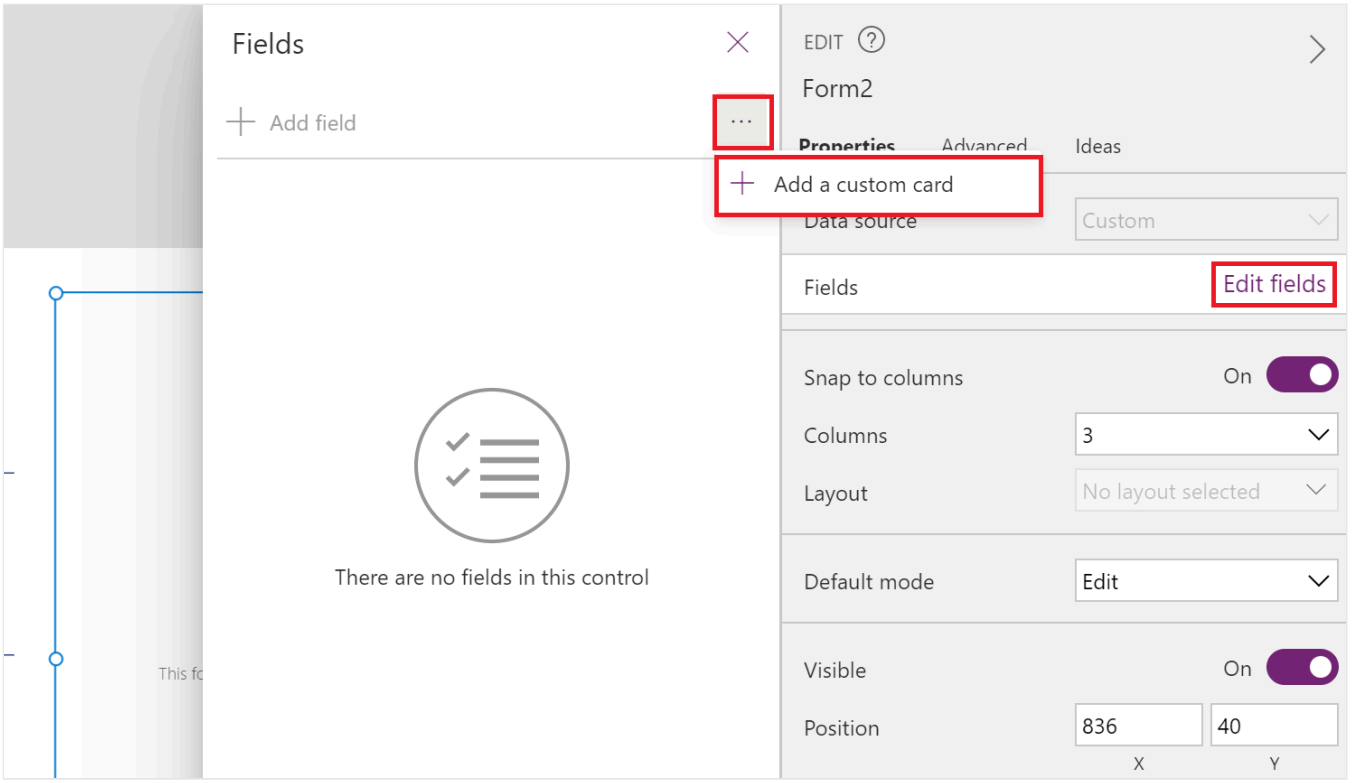


1. Set the **DataSource** property of the edit form to `AzureDevOps.GetQueryResultsV2("Project", Text(Gallery1.Selected.Id),"Organization").value`. Replace "Project" and "Organization" with your project and organization names.

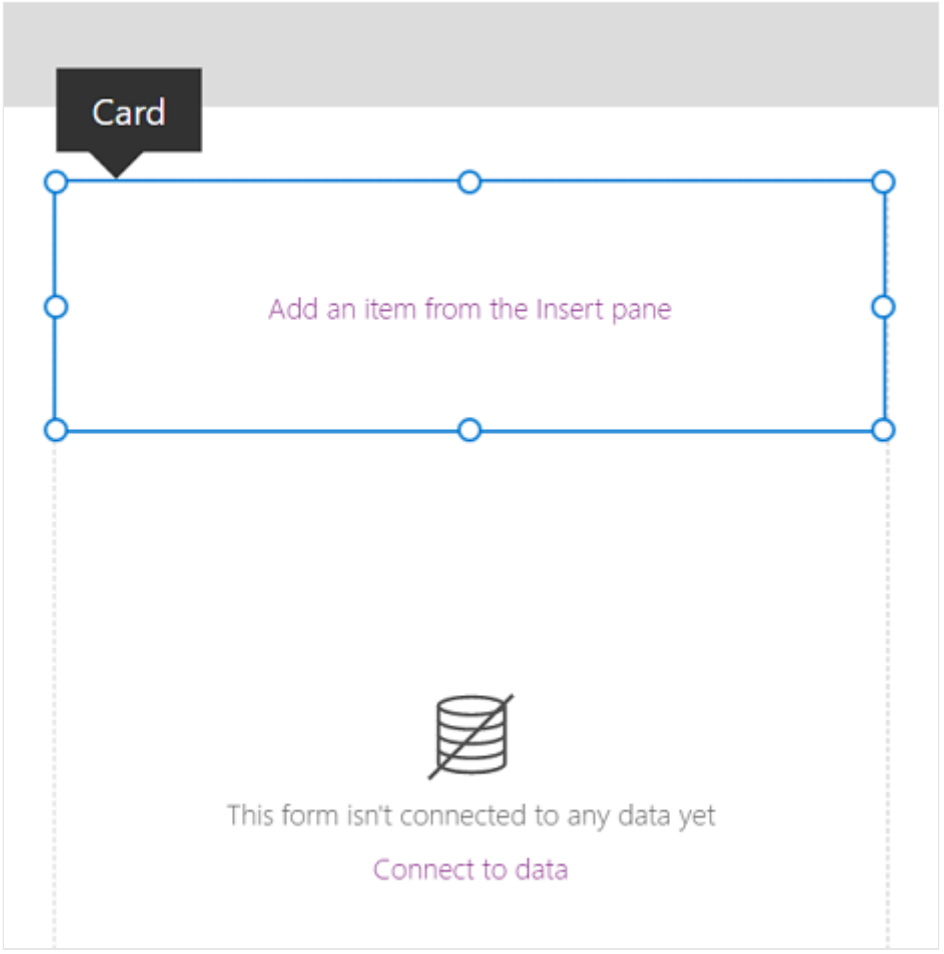
2. Set the **Item** property of the edit form to `Gallery2.Selected`.

This formula sets the **Item** property for the edit form to the work item that is selected.

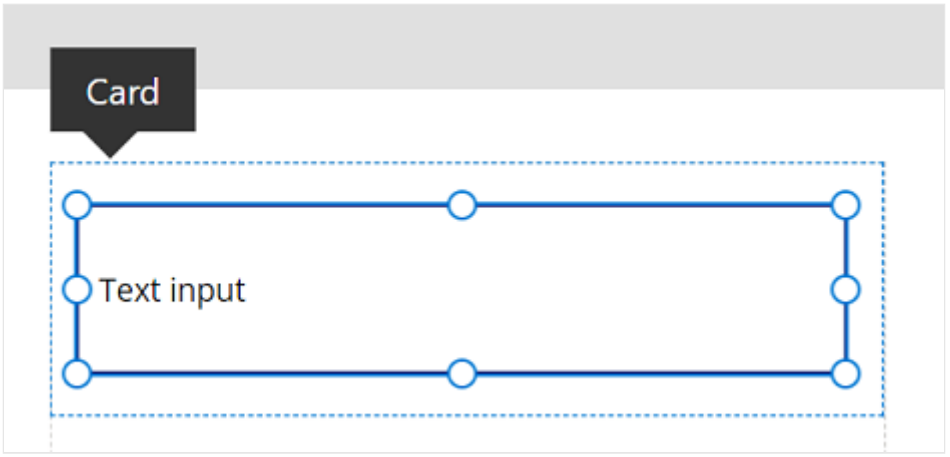
1. Select **...** (ellipsis) > **Add a custom card**.



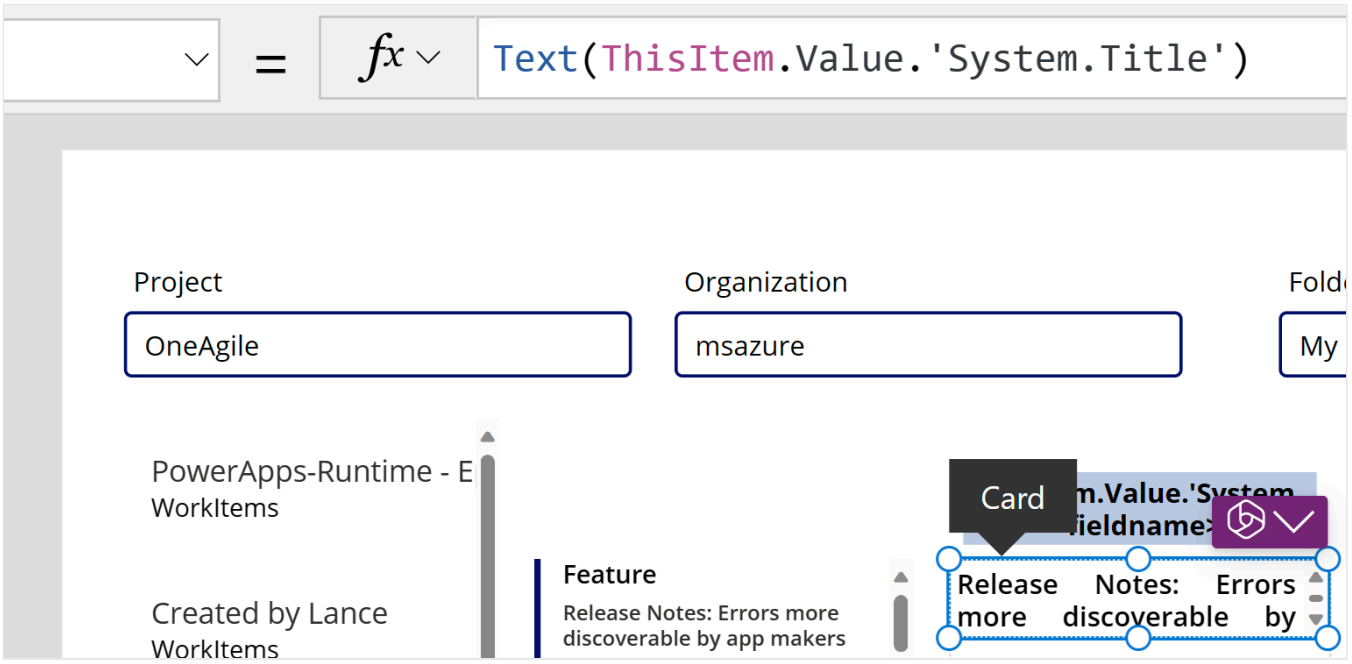
1. Move the data card to the top of the edit form.



1. Increase the size of the text input control.



1. Set the **Default** property of the text input control to `Text(ThisItem.Value.'System.Title')`. The Text function returns the value as text.



This formula sets the default text inside the text input control to the **Title** field from the selected Azure DevOps work item.

> **Tip**
>
> If your Azure DevOps project uses the **Description** field with HTML or rich text, use the Rich text editor input control instead of the Text input or label controls. The **Rich text editor** control helps display the description as rich text instead of HTML code.

1. Repeat the previous steps to add another custom card, with a text input control inside with the **Default** property set to `Text(ThisItem.Value.'System.State')`.

This formula sets the default text inside the text input control to the **State** field from the selected Azure DevOps work item.

1. Rearrange the data cards inside the edit form to create space for the save icon.

Add dynamic return values to your forms

So far, you use the Edit form, which simplifies data access by providing a common DataSource and Item property for all data cards in the form. To access dynamic values, set **both** the data source and the item properties as follows (replace Organization and Project with your values):

```
Power Fx

AzureDevOps.GetWorkItemDetails(Gallery2.Selected.Value.'System.Id',Organization,
Project, Gallery2.Selected.Value.'System.WorkItemType')
```

When you pass the text property "WorkItemType", such as "Feature", you can switch between items like Features and Work Items. Because the set of fields for these items differs, the return type from this call is dynamic.

Access specific values using the common method Text(ThisItem.Value.'System.Id'). Alternatively, access them through the more general dynamic response using Text(ThisItem.fields.System_Id). These dynamic value names aren't typically documented. To find the correct names for these fields, including non-standard fields, open the monitor tool and examine the data response for the GetWorkItemDetails call. See the image below for guidance.

If you aren't using an Edit form but are using a container, retrieve these values with a formula like the one below, which gets information from a custom team field.

```
Power Fx

Text(AzureDevOps.GetWorkItemDetails(Gallery2.Selected.Value.'System.Id',Organizati
on, Project,
Gallery2.Selected.Value.'System.WorkItemType').fields.One_custom_CustomField1)
```

GetWorkItemDetails

Details Formula Request Response

```
"propertyName": "Item",
"nodeId": 11,
"formulaData": {…
},
"data": {
  },
  "response": {
    "duration": 362.8,
    "body": {
      "id": 1770396,
      "rev": 34,
      "url": "https://dev.azure.com/msazure/_apis/wit/workItems/1770396",
      "fields": {
        "System_Id": 1770396,
        "System_AreaId": 197452,
        "System_AreaPath": "OneAgile\\PowerApps\\Runtime",
        "System_TeamProject": "OneAgile",
        "System_NodeName": "Runtime",
        "System_AreaLevel1": "OneAgile",
        "System_AreaLevel2": "PowerApps",
        "System_AreaLevel3": "Runtime",
        "System_Rev": 34,
        "System_AuthorizedDate": "2020-05-15T16:36:14.233Z",
        "System_RevisedDate": "9999-01-01T00:00:00Z",
        "System_IterationId": 232968,
        "System_IterationPath": "OneAgile\\PowerApps\\MakerX\\2020\\20.8",
        "System_IterationLevel1": "OneAgile",
        "System_IterationLevel2": "PowerApps",
```

Updating values in Azure DevOps

To update a value in Azure DevOps, use the `UpdateWorkItem` function in the `OnSelect` property of a button.

Power Fx

```
AzureDevOps.UpdateWorkItem(
    Gallery2.Selected.Value.'System.Id',
    Organization,
    {
        description: "This is a new description",
        dynamicFields: ParseJSON(JSON({'Custom Field 1': "This is new custom text"
}))
    }
)
```

The formula adds new sample text, but you can also use a Power Fx expression.

Make sure the formula uses lowercase for built-in field names. For example, when you refer to the Description field, use `description: "This is a new description"` instead of `Description: "This is a new description"`. Incorrect casing can result in the error "400 Required parameter missing for requested operation: 'UpdateWorkItem'". For custom or dynamic values, use the display name as shown in the UI, such as 'Custom Field 1'. This naming convention is specific to Azure DevOps and might differ from other services.

Next steps

Run the app. Select a query from the list of queries. Then, choose a work item you want to update the title or description of. Make a change, and then select the save button. The app saves your changes to the Azure DevOps work item. Switch to another query, and then switch back to see the changes in the app.

You can also customize the app further or create an app with more data cards on forms. Use a display form instead of an edit form to show data in different data cards. When you use a display form, use the Text label control to show text. When you use rich text or HTML format (like the **Description** field in Azure DevOps), use the HTML text control. For more information about customizing the app, see controls, gallery, forms, and cards.

Connect to Dynamics 365 from Power Apps

Article • 12/16/2022

If you want to connect to Dynamics 365 Business Central, Dynamics 365 Customer Insights, or Dynamics 365 Finance and Operations apps, choose the relevant connector.

> **ⓘ Important**
>
> The Dynamics 365 connector is deprecated. For more information, see **Dynamics 365 connector deprecation announcement**.
>
> - Use the **Microsoft Dataverse connector** when connecting to the Microsoft Dataverse used for Microsoft Dynamics 365 Sales, Microsoft Dynamics 365 Customer Service, Microsoft Dynamics 365 Field Service, Microsoft Dynamics 365 Marketing, and Microsoft Dynamics 365 Project Service Automation.
> - To convert your app that uses the deprecated Dynamics 365 connector, go to **Converting canvas apps with the Dynamics 365 connector**.

Connect to Dynamics AX from Power Apps

Article • 12/16/2022

Use this connection to easily build apps that read, update, and delete data from these versions of Dynamics AX:

• Dynamics AX Update1 + hotfix-KB article

• Dynamics AX Update 2 and later

For information about how to create an app, see Generate an app automatically or Create an app from scratch. These topics are written for Excel, but the same principles apply to Dynamics AX.

For information about how to add data from Dynamics AX to an existing app, see Add a data connection.

See the list of available connections, and learn how to manage connections in Power Apps.

Next steps

- Learn how to show data from a data source.
- Learn how to view details and create or update records.

Create a canvas app based on Excel data

Summarize this article for me

This article shows you how to create a canvas app using Excel data as your data source. Whether you have existing Excel spreadsheets with business data or want to leverage Excel's familiar structure, Power Apps provides flexible options to transform your data into powerful applications.

You'll learn three different approaches to work with Excel data:

Upload Excel files to create Dataverse tables for enhanced data management and security Connect to external Excel files stored in cloud services for quick app creation Start with a blank canvas app and add Excel data for complete customization control Before you begin, ensure your Excel data is properly formatted. This preparation step helps Power Apps read and interact with your data more effectively. For more information, see Formatted as a table in Excel.

To create an app by using Excel data, select one of the following options in Power Apps.

Expand table

Create options by using Excel	Benefits	Navigation
Upload an Excel or .CSV file to Power Apps	Uploaded Excel data generates a Dataverse table. With Dataverse's standard and custom tables, you can securely store your data in the cloud. These tables enable you to define your organization's data in a way that is tailored to your business needs, making it easier to use within your apps.	Select **Start with Data** > **Upload file**.
Connect to an external Excel file and use it to create a canvas app. Your data stays where it is.	Using the Excel connector in Power Apps provides a straightforward and fast method to create and deploy apps with data stored in Excel. It's especially advantageous for makers that already use Excel and want to enhance its functionality with minimal effort. Makers benefit from cloud access, easy data manipulation, rapid prototyping, and no need for a complex database setup.	Select **Start with Data** > **Excel Online (Business)**.
Create a blank canvas app and then add Excel data	You have complete flexibility, control, and customization. It allows you to design an app that meets your exact specifications without being limited by predesigned templates, providing greater creative freedom and adaptability to suit your unique needs.	On the left navigation pane, select **Create** > **Create from blank**. Then select the app size.

Upload an Excel or CSV file to Power Apps

When you upload your Excel data to Power Apps, it doesn't just stay as an Excel file. Instead, Power Apps converts it into a Dataverse table. This conversion makes it easier to integrate and manage your data within Power Apps, and you get more powerful features compared to using Excel alone. For more information, see Why use Dataverse?

1. Sign in to Power Apps.
2. On the home screen, select **Start with data**.
3. On the **Create an app** page, select **Upload file**.
4. Select **Select from device** and go to the location where your Excel file is saved. Select the file to upload it.

   > **Note**
   >
   > The maximum file size limit is 5 GB.

5. When Power Apps creates the table, select a column name or the table name to edit the properties to suit your needs. If you change column data types and there are values in cells that don't match the selected data type, Power Apps removes those values when it generates the table. For more information, see Create and edit tables using Power Apps.
6. Select **Row ownership** and choose how you want to manage row ownership.
7. When you're done, select **Save and open app**. Power Apps uploads the first 20 rows of data so you can start reviewing the data in your app. The system uploads the remaining data in the background.

Known issues

- The current data upload process doesn't take into account the environment data format setting.

Connect to an external Excel file from Power Apps

Store the Excel file in a cloud storage service like Dropbox, Google Drive, OneDrive, or OneDrive for Business because Power Apps can only connect to Excel files that are stored in the cloud.

Power Apps has an Excel connector that you can use to access your Excel data. The Excel Online (Business) connector offers flexibility by accessing a wide variety of cloud-based file storage services.

1. Sign in to Power Apps.
2. On the home screen, select **Start with data**.
3. On the **Create an app**, select **Excel Online (Business)**.
4. Only one connection appears at a time. To select a different connection, select the **...** button to switch connections or add a new connection.
5. Enter the file location and select the table.
6. When you're done, select **Create app**.

For more information about how to share Excel data, see Sharing Excel tables.

Create a blank canvas app and add Excel data

Create a blank app and then use Excel data that's formatted as a table as the source of the app's information.

Follow the example below to create an app with two screens where users can view (browse) the data from an Excel file on one screen, and on another screen, they can interact with (add, modify, or remove) that data. The data interaction features, such as creating, updating, and deleting records, are built into the second screen of the app.

Prerequisites

1. Copy this data and paste it into an Excel file.

Expand table

StartDay	StartTime	Volunteer	Backup
Saturday	10am-noon	Vasquez	Kumashiro
Saturday	noon-2pm	Ice	Singhal
Saturday	2pm-4pm	Myk	Mueller
Sunday	10am-noon	Li	Adams
Sunday	noon-2pm	Singh	Morgan

StartDay	StartTime	Volunteer	Backup
Sunday	2pm-4pm	Batye	Nguyen

2. Format the table in Excel and name it **Schedule** so that Power Apps can parse the information.

3. Save the file as **eventsignup.xlsx**, close it, and then upload it to a cloud-storage account such as OneDrive.

> **Important**
>
> You can use your own Excel file and review this example for general concepts only. However, the data in the Excel file must be formatted as a table.

Create a blank app and connect to data

1. Sign in to Power Apps.

2. On the left navigation pane, select **Create** > **Start from blank**.

3. Select the **Phone size** layout.

   The app opens in Power Apps Studio where you can add data and start building the app.

4. In the middle of the screen, select **Connect to data**.

5. In the **Data** pane, select **Add data**. Select the connection for your cloud-storage account if it appears. Otherwise, follow these steps to add a connection such as OneDrive:
   a. In the search box, enter **OneDrive** and select it.
   b. Select **Add a connection**.
   c. On the connection pane, select **Connect**.
   d. If prompted, provide your credentials for that account.

6. Under **Choose an Excel file**, find and then select the **eventsignup.xlsx** that you saved earlier.

7. Under **Choose a table**, select the check box for **Schedule**, and then select **Connect**.

8. In the upper-right corner of the **Data** pane, close it by selecting the close icon (**X**).

Create the view screen

1. On the command bar, select **New screen** > **List**.

A screen is added with several default controls, such as a search box and a **Gallery** control. The gallery covers the entire screen under the search box.

2. At the top of the new screen, select the **[Title]** label control and rename it to **View records**.

3. In the **Tree view**, select **BrowseGallery1**.

4. In the gallery's **Properties** pane, set the **Layout** to **Title, subtitle, and body**.

5. In the formula bar, replace **CustomGallerySample** with **Schedule**, and replace both instances of **SampleText** with **Volunteer**.

6. On the right edge of the formula bar, select the **Expand formula bar** down arrow, and then select **Format text**.

   The formula matches this example:

   powerfx

   ```
   SortByColumns(
       Search(
           Schedule,
           TextSearchBox1.Text,
           "Volunteer"
       ),
       "Volunteer",
       If(
           SortDescending1,
           SortOrder.Descending,
           SortOrder.Ascending
       )
   )
   ```

7. In the **Properties** pane, select **Edit** next to the **Fields** label.

8. In the **Title2** box, select **Volunteer**, in the **Subtitle2** box, select **StartDay**, and in the **Body1** box, select **StartTime**.

9. In the upper-right corner of the **Data** pane, close it by selecting the close icon (X).

   Users can sort and filter the gallery by volunteer name based on the **SortByColumns** and **Search** functions in that formula.

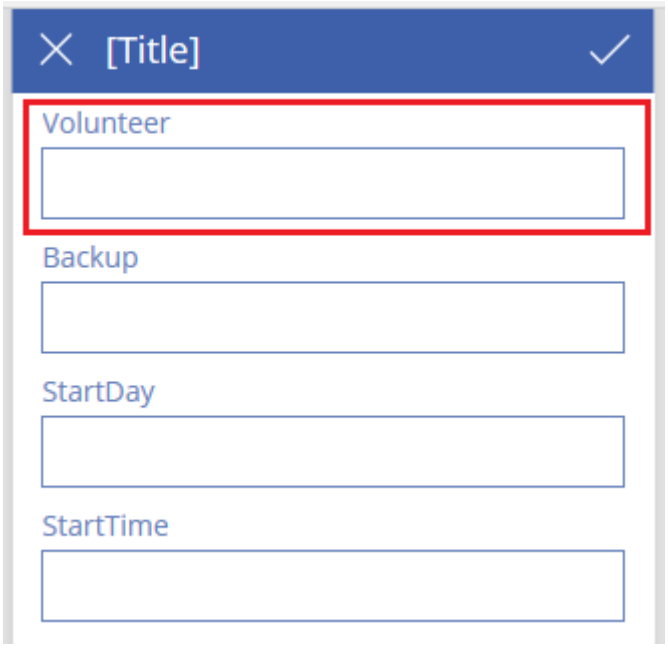
   - If a user types at least one letter in the search box, the gallery shows only those records for which the **Volunteer** field contains the text that the user typed.

- If a user selects the sort button (between the refresh button and the plus button in the title bar), the gallery shows the records in ascending or descending order (depending on how many times the user selects the button) based on the **Volunteer** field.

For more information about these and other functions, see the formula reference.

Create the change screen

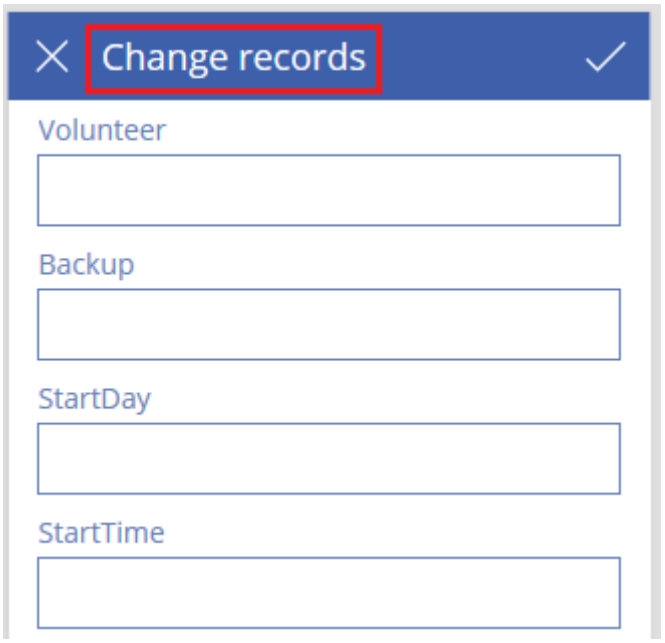
1. On the command bar, select **New screen** > **Form**.
2. In the **Tree view**, select **EditForm1**.
3. On the **Properties** pane, select the down arrow next to **Data source**, and then select **Schedule** in the list that appears.
4. Under the data source that you specified, select **Edit fields**.
5. In the **Fields** pane, select **Add field**, select the check box for each field, and then select **Add**.
6. Select the arrow next to the name of each field to collapse it, and then drag the **Volunteer** field up so that it appears at the top of the list of fields.



7. In the upper-right corner of the **Fields** pane, close it by selecting the close icon (X).
8. Set the **Item** property of the form to this expression in the formula bar:

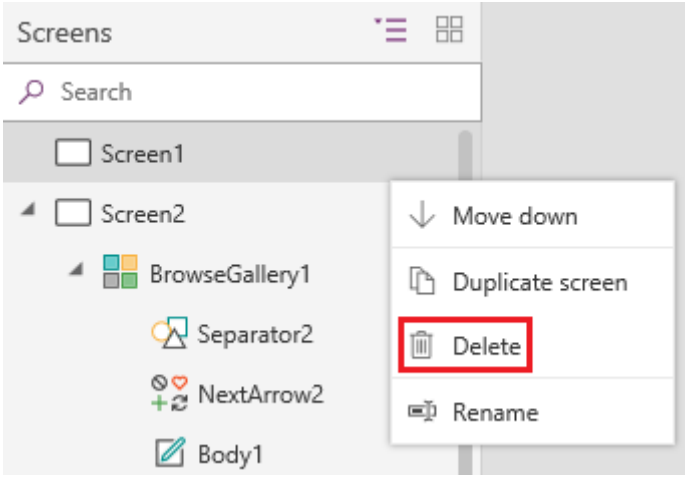
```
BrowseGallery1.Selected
```

9. At the top of the screen, select the **Label** control, and then replace **[Title]** with **Change records**.



Delete and rename screens

1. In the **Tree view**, select the ellipsis (...) for **Screen1**, and then select **Delete**.



2. Select the ellipsis (...) for **Screen2**, select **Rename**, and then type or paste **ViewScreen**.

3. Select the ellipsis (...) for **Screen3**, select **Rename**, and then type or paste **ChangeScreen**.

Configure icons on the view screen

1. Near the top of the **ViewScreen**, select the circular arrow icon.

2. Set the **OnSelect** property for that icon to this formula:

```
Refresh(Schedule)
```

When the user selects this icon, the data from **Schedule** refreshes from the Excel file.

For more information about this and other functions, see formula reference.

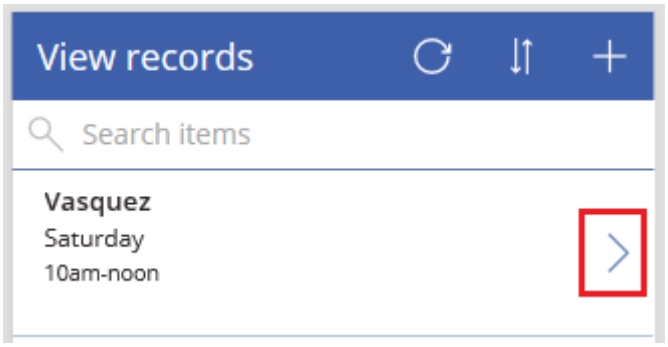
3. In the upper-right corner of the **ViewScreen**, select the plus icon.

4. Set the **OnSelect** property for that icon to this formula:

```
NewForm(EditForm1);Navigate(ChangeScreen,ScreenTransition.None)
```

When the user selects this icon, **ChangeScreen** appears with each field empty, so the user can create a record more easily.

5. Select the right-pointing arrow for the first record in the gallery.



6. Set the **OnSelect** property for the arrow to this formula:

```
EditForm(EditForm1); Navigate(ChangeScreen, ScreenTransition.None)
```

When the user selects this icon, **ChangeScreen** appears with each field showing the data for the selected record, so the user can edit or delete the record more easily.

Configure icons on the change screen

1. On **ChangeScreen**, select the "X" icon in the upper left corner.

2. Set the **OnSelect** property for that icon to this formula:

```
ResetForm(EditForm1);Navigate(ViewScreen, ScreenTransition.None)
```

When the user selects this icon, the app discards any changes made in this screen and opens the view screen.

3. In the upper-right corner, select the checkmark icon.

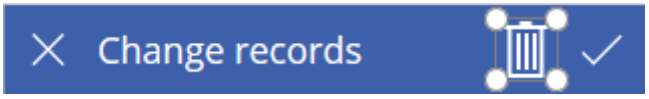
4. Set the **OnSelect** property for the checkmark to this formula:

```
SubmitForm(EditForm1); Navigate(ViewScreen, ScreenTransition.None)
```

When the user selects this icon, the app saves any changes made in this screen and opens the view screen.

5. On the **Insert** tab, select **Icons**, and then select the **Trash** icon.

6. Set the new icon's **Color** property to **White** and move the new icon so it appears next to the checkmark icon.



7. Set the **Visible** property for the trash icon to this formula:

```
EditForm1.Mode = FormMode.Edit
```

This icon appears only when the form is in **Edit** mode, not in **New** mode.

8. Set the **OnSelect** property for the trash icon to this formula:

```
Remove(Schedule, BrowseGallery1.Selected); Navigate(ViewScreen,
ScreenTransition.None)
```

When the user selects this icon, the app deletes the selected record from the data source and opens the view screen.

Test the app

1. Select the **ViewScreen**, and then preview the app by pressing `F5` or select **Preview**.

2. Type or paste one or more letters in the search box to filter the list based on the volunteer's name.

3. Select the sort icon one or more times to show the data in ascending or descending order based on the volunteer's name.
4. Add a record.
5. Update the record that you added, and then save the changes.
6. Update the record that you added, and then cancel the changes.
7. Delete the record that you added.
8. Close Preview mode by pressing Esc or selecting the close icon in the upper-right corner.

Next steps

- Press Ctrl+S to save your app in the cloud so you can run it from other devices.
- Share the app so other people can run it.

Connect to Microsoft Translator from Power Apps

Article • 12/16/2022

Add the Microsoft Translator connector to display translated text in a **Label** control in your app. For example, you can create an input text box that asks the user to enter some text to translate. In another label, you can display the translated text.

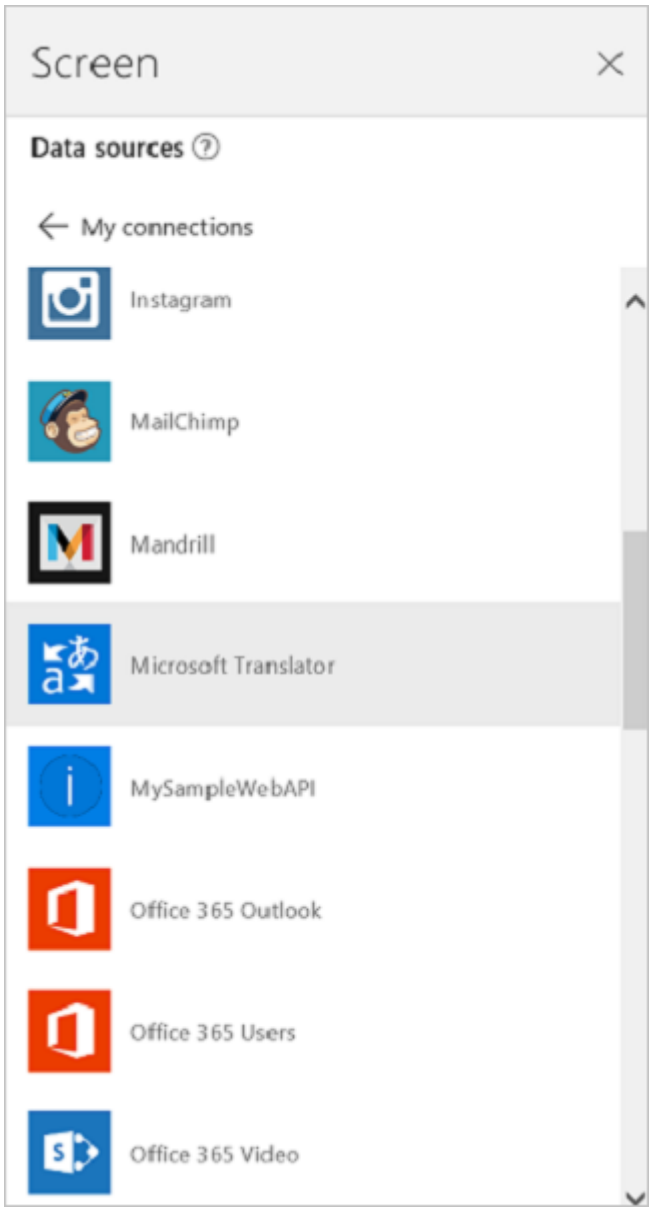
This topic shows you how to create the Microsoft Translator connection, use the Microsoft Translator connection in an app, and lists the available functions.

Prerequisites

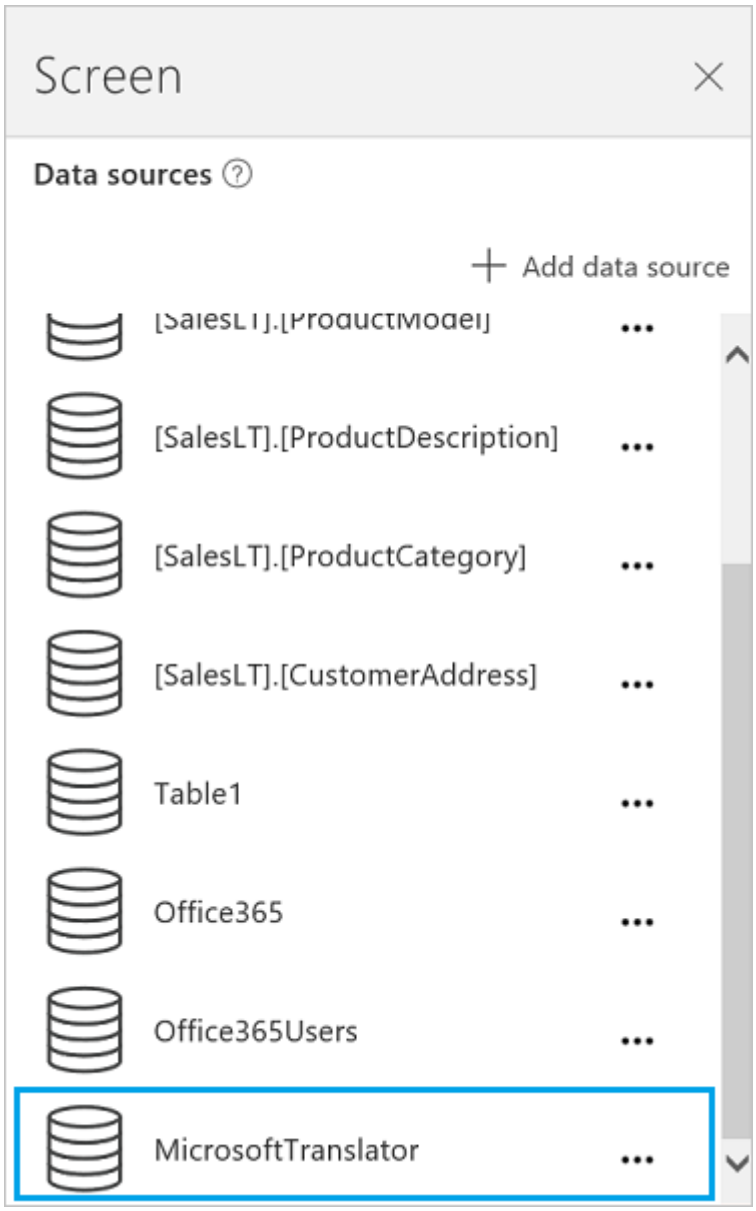
- Access to Power Apps
- Add the connection
- Create an app from a template, from data, or from scratch

Connect to Microsoft Translator

1. Create a blank canvas app.
2. In the left-hand pane, select **Data** tab, and then select **Add data source**.
3. Select **New connection**, and then select **Microsoft Translator**:



4. Select **Connect**. Your connection appears under **Data sources**:



Use the Microsoft Translator connection in your app

Translate text

1. From the **Tree View** on the left-side of the screen, select **Insert**, and then choose the **Text input** control. Rename the text input control to **Source**.

2. Add a **Drop down** list (**Insert** menu > **Controls**), rename it to **TargetLang**, and move it below **Source**.

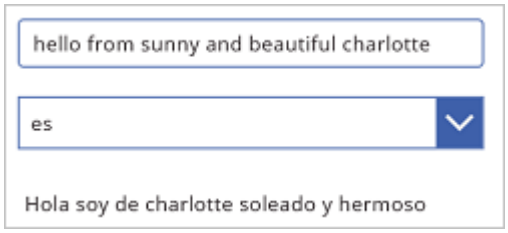
3. Set the Items property of **TargetLang** to the following formula:

```
MicrosoftTranslator.Languages()
```

4. Add a label, move it below **TargetLang**, and set its **Text** property to the following formula:

   ```
   MicrosoftTranslator.Translate(Source.Text, TargetLang.Selected.Value)
   ```

5. Type some text into **Source**, and select a language in **TargetLang**. The label shows the text that you entered in the language you chose:



Speak translated text

If you haven't already, follow the steps in the previous section to translate some text. These next steps use the same controls.

1. Set the **Items** property of the **TargetLang** drop-down list to the following formula:

   ```
   MicrosoftTranslator.SpeechLanguages()
   ```

2. Rename the second label (not the **Source** box) to **Target**.

3. Add an **Audio** control (**Insert** menu > **Media**), and set its **Media** property to the following formula:

   ```
   MicrosoftTranslator.TextToSpeech(Target.Text, TargetLang.Selected.Value)
   ```

4. Press F5, or select the Preview button (). Type some text into **Source**, select a language in **TargetLang**, and then select the play button in the audio control.

   The app plays an audio version of the text that you entered in the language you chose.

5. Press Esc to return to the default workspace.

Detect the source language

These next steps use the same **Source** text input and **Target** text controls. You can create new controls if you prefer, just update the names in the formula.

1. Select the **Target** text control, and set the **Text** property to the following formula:

`MicrosoftTranslator.Detect(Source.Text).Name`

2. Type some text into **Source**.

   The label shows you the language of the text that you typed. For example, the label shows **French** if you type **bonjour**, or **Italian** if you type **ciao**.

View the available functions

This connection includes the following functions:

Function Name	Description
Languages	Retrieves all languages that Microsoft Translator supports
Translate	Translates text to a specified language using Microsoft Translator
Detect	Detects source language of given text
SpeechLanguages	Retrieves the languages available for speech synthesis
TextToSpeech	Converts a given text into speech as an audio stream in wave format

Languages

Get languages: Retrieves all languages that Microsoft Translator supports

Input properties

None.

Output properties

Property Name	Data Type	Required	Description
Code	string	No	
Name	string	No	

Translate

Translate text: Translates text to a specified language using Microsoft Translator

Input properties

Name	Data Type	Required	Description
query	string	yes	Text to translate
languageTo	string	yes	Target language code (example: 'fr')
languageFrom	string	no	Source language (if not provided, Microsoft Translator will try to auto-detect) (example: en)
category	string	no	Translation category (default: 'general')

Output properties

None.

Detect

Detect language: Detects source language of given text

Input properties

Name	Data Type	Required	Description
query	string	yes	Text whose language will be identified

Output properties

Property Name	Data Type	Required	Description
Code	string	No	
Name	string	No	

SpeechLanguages

Get speech languages: Retrieves the languages available for speech synthesis

Input properties

None.

Output properties

Property Name	Data Type	Required	Description
Code	string	No	
Name	string	No	

TextToSpeech

Text to speech: Converts a given text into speech as an audio stream in wave format

Input properties

Name	Data Type	Required	Description
query	string	yes	Text to convert
language	string	yes	Language code to generate speech (example: 'en-us')

Output properties

None.

Connect to Office 365 Outlook from Power Apps

Article • 12/16/2022

If you connect to Office 365 Outlook, you can show, send, delete, and reply to email messages, in addition to other tasks.

You can add controls to perform these functions in your app. For example, you can add **Text input** controls to ask for the recipient, the subject, and the body of the email, and add a **Button** control to send the email.

This article shows you how to add Office 365 Outlook as a connection, add Office 365 Outlook as a data source to your app, and use this data in different controls.

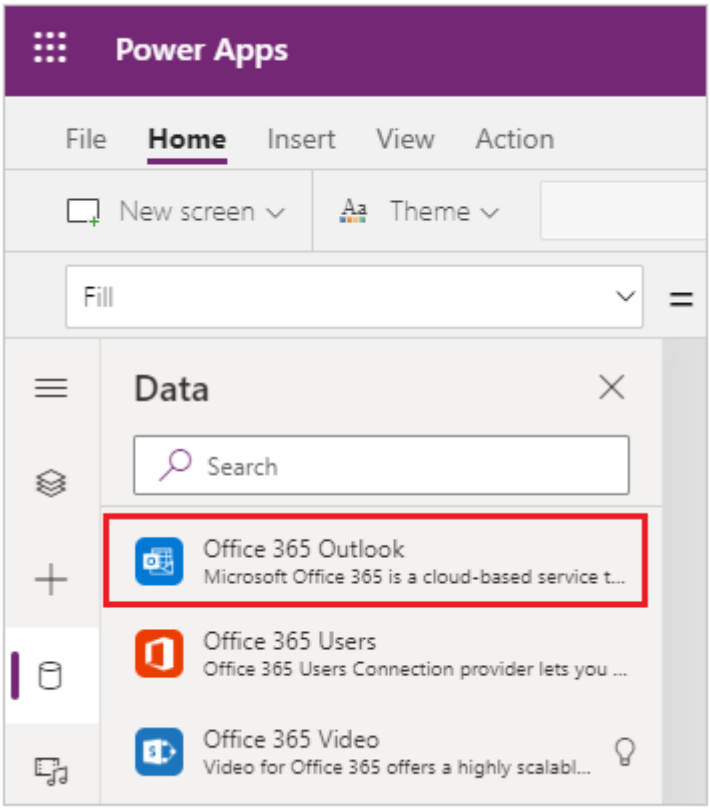
> **Important**
>
> As of this writing, the calendar operation doesn't support recurring events.

Prerequisites

- Access to Power Apps
- Add the connection
- Create an app from a template, from data, or from scratch

Connect to Office 365 Outlook

1. Add a data connection and select **Office 365 Outlook**:



2. Select **Connect**, and if prompted to sign in, enter your work account.

The Office 365 Outlook connection has been created and added to your app. Now, it's ready to be used.

Show messages

1. On the **Insert** menu, select **Gallery**, and then select a **Blank vertical** control.

2. Set its Items property to the following formula:

   ```
   Office365Outlook.GetEmails({fetchOnlyUnread:false})
   ```

   After changing the settings, change **Layout** to **Title, Subtitle, Body**.

   The gallery control is automatically populated with some of your emails.

3. In the gallery, set the **Text** property of the first label to `ThisItem.From`. Set the second label to `ThisItem.Subject`. Set the third label to `ThisItem.BodyPreview`. You can also resize the labels.

   The gallery control is automatically populated with the new properties.

4. This function has several optional parameters available. Set the gallery's **Items** property to one of the following formulas:

`Office365Outlook.GetEmails({fetchOnlyUnread:false})`

`Office365Outlook.GetEmails({fetchOnlyUnread:false, top:2})`

`Office365Outlook.GetEmails({folderPath:"Sent Items", fetchOnlyUnread:false, top:2})`

`Office365Outlook.GetEmails({folderPath:"Sent Items", fetchOnlyUnread:false, top:2, searchQuery:"powerapps"})`

`Office365Outlook.GetEmails({folderPath:"Deleted Items", fetchOnlyUnread:false, top:2, skip:3})`

Send a message

1. On the **Insert** menu, select **Text**, and then select **Text input**.

2. Repeat the previous step 2 more times so that you have three boxes, and then arrange them in a column:

3. Rename the controls to:

   - **inputTo**
   - **inputSubject**
   - **inputBody**

4. On the **Insert** menu, select **Controls**, and then select **Button**. Set its **OnSelect** property to the following formula:

   `Office365Outlook.SendEmail(inputTo.Text, inputSubject.Text, inputBody.Text)`

5. Move the button so that it appears under all the other controls, and set its **Text** property to "**Send email**".

6. Press F5, or select the Preview button (▷). Type in a valid email address in **inputTo**, and type whatever you want in the other two **Text input** controls.

7. Select **Send email** to send the message. Press Esc to return to the default workspace.

Send a message with an attachment

You can, for example, create an app in which the user takes pictures by using the device's camera and then sends them as attachments. Users can also attach many other kinds of files to an email app.

To add an attachment to a message, follow the steps in the previous section, but add a parameter to specify an attachment (when you set the **OnSelect** property of the button). This parameter is structured as a table in which you specify up to three properties for each attachment:

- Name
- ContentBytes
- @odata.type

> ⓘ **Note**
>
> You can specify the @odata.type property for only one attachment, and you can set it to an empty string.

In this example, a photo will be sent as **file1.jpg**:

```
Office365Outlook.SendEmail(inputTo.Text, inputSubject.Text, inputBody.Text, {Attachments:Table({Name:"file1.jpg", ContentBytes:Camera1.Photo, '@odata.type':""})})
```

In this example, an audio file will be sent in addition to the photo:

```
Office365Outlook.SendEmail(inputTo.Text, inputSubject.Text, inputBody.Text, {Attachments:Table({Name:"file1.jpg", ContentBytes:Camera1.Photo, '@odata.type':""}, {Name:"AudioFile", ContentBytes:microphone1.audio })})
```

Delete a message

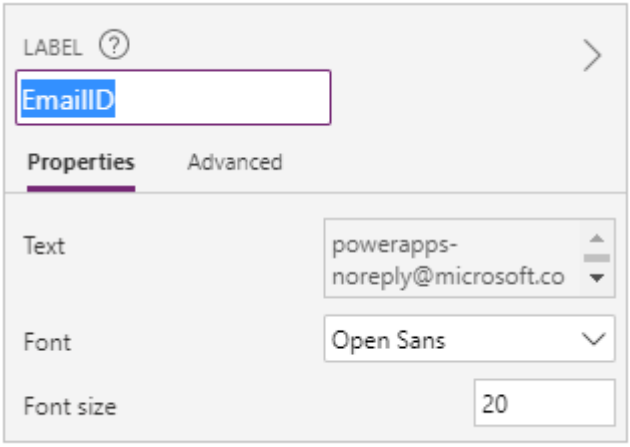
1. On the **Insert** menu, select **Gallery**, and then select a **Text gallery** control.
2. Set its **Items** property to the following formula:

   ```
   Office365Outlook.GetEmails({fetchOnlyUnread:false})
   ```

The gallery control is automatically populated with some of your emails.

3. In the gallery, set the **Text** property of the first label to `ThisItem.Id`. Set the second label to `ThisItem.Subject`. Set the third label to `ThisItem.Body`.

4. Select the first label in the gallery, and rename it to **EmailID**:



5. Select the third label in the gallery, and add a **Button** (**Insert** menu). Set the button's **OnSelect** property to the following formula:

   ```
   Office365Outlook.DeleteEmail(EmailID.Text)
   ```

6. Press F5, or select the Preview button (▷). Select one of the emails in your gallery, and select the button.

   > **Note**
   >
   > This deletes the selected email from your inbox. So, choose wisely.

7. Press Esc to return to the default workspace.

Mark a message as read

This section uses the same controls as Delete a message.

1. Set the button's **OnSelect** property to the following formula:

   ```
   Office365Outlook.MarkAsRead(EmailID.Text)
   ```

2. Press F5, or select the Preview button (▷). Select one of the unread emails, and then select the button.

3. Press Esc to return to the default workspace.

Connect to Office 365 Users connection from Power Apps

Article • 12/16/2022

Office 365 Users lets you access user profiles in your organization using your Office 365 account. You can perform various actions such as get your profile, a user's profile, a user's manager or direct reports.

You can display this information in a label on your app. You can display one function, multiple functions, or even combine different functions. For example, you can create an expression that combines the User Name and Phone Number, and then display this information in your app.

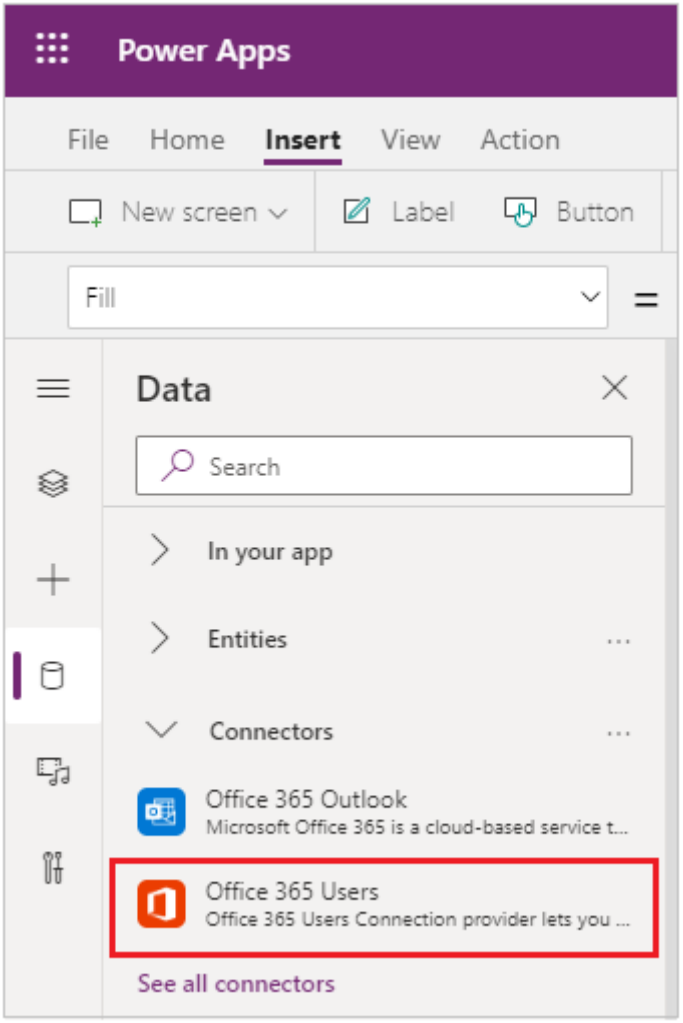
This article shows you how to add Office 365 Users as a connection, add Office 365 Users as a data source to your app, and use table data in a gallery control.

Prerequisites

- Access to Power Apps
- Add the connection
- Create an app from a template, from data, or from scratch

Add a connection

1. Add a data connection and select **Office 365 Users**:



2. Select **Connect**, and if prompted to sign in, enter your work account.

The Office 365 Users connection has been created and added to your app. Now, it's ready to be used.

Use the connection in your app

Show information about the current user

1. On the **Insert** menu, select **Label**

2. In the function bar, set its **Text** property to any of the following formulas:

```
Office365Users.MyProfile().City
Office365Users.MyProfile().CompanyName
Office365Users.MyProfile().Country
Office365Users.MyProfile().Department
Office365Users.MyProfile().DisplayName
Office365Users.MyProfile().GivenName
```

`Office365Users.MyProfile().Id`

`Office365Users.MyProfile().JobTitle`

`Office365Users.MyProfile().Mail`

`Office365Users.MyProfile().MailNickname`

`Office365Users.MyProfile().mobilePhone`

`Office365Users.MyProfile().OfficeLocation`

`Office365Users.MyProfile().PostalCode`

`Office365Users.MyProfile().Surname`

`Office365Users.MyProfile().TelephoneNumber`

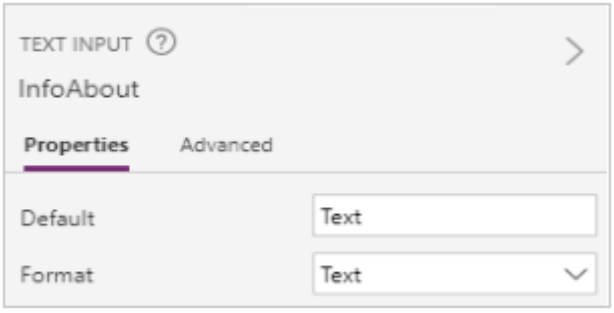
`Office365Users.MyProfile().UserPrincipalName`

`Office365Users.MyProfile().AccountEnabled`

The label shows the information that you entered about the current user.

Show information about another user

1. On the **Insert** menu, select **Text**, and then select **Text input**. Rename it **InfoAbout**:



2. In **InfoAbout**, type or paste an email address of a user in your organization. For example, type in *yourName@yourCompany.com*.

3. Add a **Label** (**Insert** menu), and set its **Text** property to any of the following formulas:

   - To show information about another user:

     `Office365Users.UserProfile(InfoAbout.Text).City`

     `Office365Users.UserProfile(InfoAbout.Text).CompanyName`

     `Office365Users.UserProfile(InfoAbout.Text).Country`

     `Office365Users.UserProfile(InfoAbout.Text).Department`

     `Office365Users.UserProfile(InfoAbout.Text).DisplayName`

     `Office365Users.UserProfile(InfoAbout.Text).GivenName`

     `Office365Users.UserProfile(InfoAbout.Text).Id`

`Office365Users.UserProfile(InfoAbout.Text).JobTitle`

`Office365Users.UserProfile(InfoAbout.Text).Mail`

`Office365Users.UserProfile(InfoAbout.Text).MailNickname`

`Office365Users.UserProfile(InfoAbout.Text).mobilePhone`

`Office365Users.UserProfile(InfoAbout.Text).OfficeLocation`

`Office365Users.UserProfile(InfoAbout.Text).PostalCode`

`Office365Users.UserProfile(InfoAbout.Text).Surname`

`Office365Users.UserProfile(InfoAbout.Text).TelephoneNumber`

`Office365Users.UserProfile(InfoAbout.Text).UserPrincipalName`

`Office365Users.UserProfile(InfoAbout.Text).AccountEnabled`

`Office365Users.UserProfile(InfoAbout.Text).BusinessPhones`

- To show information about another user's manager:

`Office365Users.Manager(InfoAbout.Text).City`

`Office365Users.Manager(InfoAbout.Text).CompanyName`

`Office365Users.Manager(InfoAbout.Text).Country`

`Office365Users.Manager(InfoAbout.Text).Department`

`Office365Users.Manager(InfoAbout.Text).DisplayName`

`Office365Users.Manager(InfoAbout.Text).GivenName`

`Office365Users.Manager(InfoAbout.Text).Id`

`Office365Users.Manager(InfoAbout.Text).JobTitle`

`Office365Users.Manager(InfoAbout.Text).Mail`

`Office365Users.Manager(InfoAbout.Text).MailNickname`

`Office365Users.Manager(InfoAbout.Text).mobilePhone`

`Office365Users.Manager(InfoAbout.Text).OfficeLocation`

`Office365Users.Manager(InfoAbout.Text).PostalCode`

`Office365Users.Manager(InfoAbout.Text).Surname`

`Office365Users.Manager(InfoAbout.Text).TelephoneNumber`

`Office365Users.Manager(InfoAbout.Text).UserPrincipalName`

`Office365Users.Manager(InfoAbout.Text).AccountEnabled`

`Office365Users.Manager(InfoAbout.Text).BusinessPhones`

The label shows the information that you entered about the user you specified or that user's manager.

> ⓘ **Note**

If you're developing an app based on a table in the Microsoft Dataverse, you can specify a user based on ID instead of email address.

For example, you can create an app automatically, add a screen that contains a **Label** control, and set the control's **Text** property to this formula: **Office365Users.UserProfile(BrowseGallery1.Selected.CreatedByUser).DisplayName**

If you create a contact and select that contact in the browse screen of the app, the **Label** control will show your display name.

Show the direct reports of another user

1. Add a **Text input** control (**Insert** menu > **Text**), and rename it **InfoAbout**.
2. In **InfoAbout**, enter the email address of a user in your organization. For example, enter *yourManagersName@yourCompany.com*
3. Add a **With text** gallery (**Insert** menu > **Gallery**), and set its **Items** property to the following formula:

   ```
   Office365Users.DirectReports(InfoAbout.Text)
   ```

   The gallery shows information about the direct reports of the user you entered.

   With the gallery selected, the right-hand pane shows options for that gallery.
4. In the second list, select **JobTitle**. In the third list, select **DisplayName**. The gallery is updated to show these values.

> ⓘ **Note**
>
> The first box is actually an image control. If you don't have an image, you can delete the image control, and add a label in its place. Add and configure controls is a good resource.

Search for users

1. Add a **Text input** control (**Insert** menu > **Text input**).
2. Select **Insert** > **Vertical gallery**.
3. Change layout of the vertical gallery to **Title, subtitle, and body**.

4. Select the arrow icon from first row inside the gallery, and delete it.

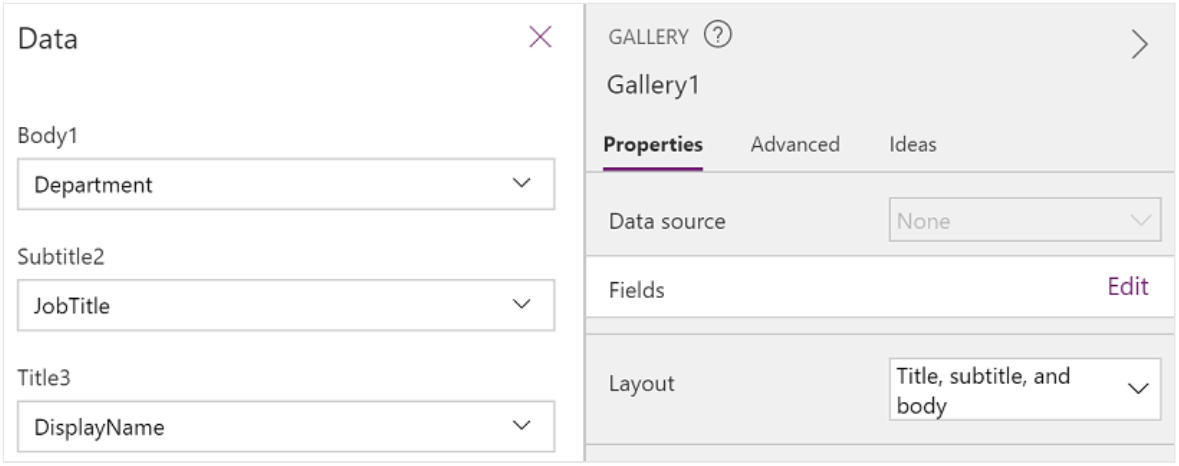
5. Update the vertical gallery formula to the following.

```
Power Fx

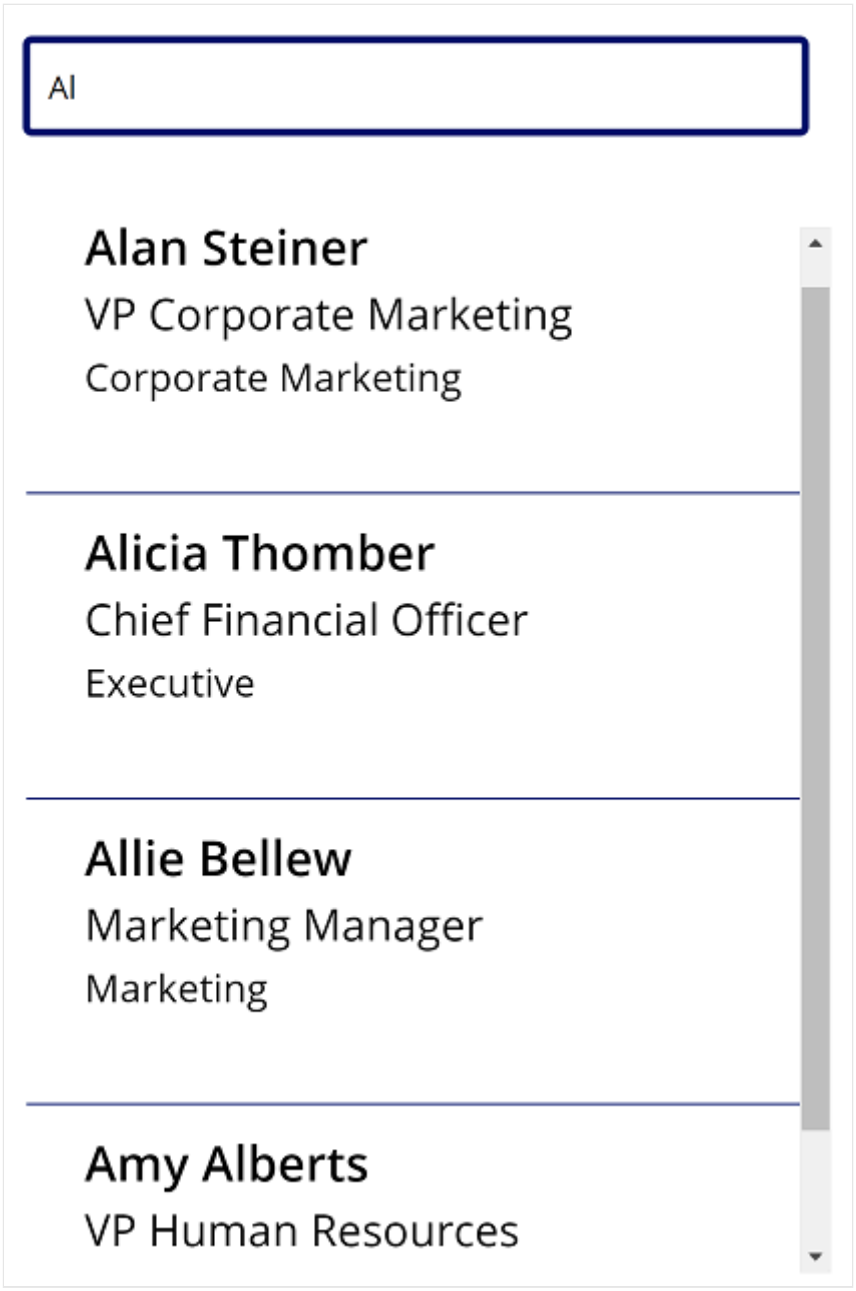
Office365Users.SearchUserV2({searchTerm:TextInput1.Text,top:5}).value
```

   In the formula above, the search term references text entered in the text input control ("TextInput1" in this example); and the search results are limited to top 5.

6. Update vertical gallery fields to show **DisplayName** in gallery title, **JobTitle** in subtitle, and **Department** in body.



7. Play the app, and enter text inside the text input box. As you enter text, the results change based on the input string changes.



View the available functions

This connection includes the following functions:

Expand table

Function Name	Description
DirectReports	Returns the direct reports for the specified user.
Manager	Retrieves user profile for the manager of the specified user.
MyProfile	Retrieves the profile for the current user.
SearchUser	Retrieves search results of user profiles.

Function Name	Description
UserProfile	Retrieves a specific user profile.

MyProfile

Get my profile: Retrieves the profile for the current user.

Input properties

None.

Output properties

Expand table

Property Name	Type	Description
City	string	City of user.
CompanyName	string	Company of user.
Country	string	Country of user.
Department	string	Department of user.
DisplayName	string	Display name of user.
GivenName	string	Given name of user.
Id	string	User id.
JobTitle	string	Job title of user.
Mail	string	Email id of user.
MailNickname	string	Nickname of user.
mobilePhone	string	Mobile phone of user.
OfficeLocation	string	Office location of user.
PostalCode	string	Postal code of user.
Surname	string	Surname of user.
TelephoneNumber	string	Telephone number of user.

Property Name	Type	Description
UserPrincipalName	string	User Principal Name.
AccountEnabled	boolean	Account enabled flag.
BusinessPhones	string	Phone numbers of user's company.

UserProfile

Get user profile: Retrieves a specific user profile.

Input properties

Expand table

Name	Data Type	Required	Description
Id	string	yes	User principal name or email id.

Output properties

Expand table

Property Name	Type	Description
City	string	City of user.
CompanyName	string	Company of user.
Country	string	Country of user.
Department	string	Department of user.
DisplayName	string	Display name of user.
GivenName	string	Given name of user.
Id	string	User id.
JobTitle	string	Job title of user.
Mail	string	Email id of user.
MailNickname	string	Nickname of user.
Surname	string	Surname of user.

Property Name	Type	Description
TelephoneNumber	string	Telephone number of user.
UserPrincipalName	string	User Principal Name.
AccountEnabled	boolean	Account enabled flag.
BusinessPhones	string	Phone numbers of user's company.

Manager

Get manager: Retrieves user profile for the manager of the specified user.

Input properties

Connect to an Oracle database from Power Apps

09/04/2025

List tables, and create, read, update, and delete table rows in an Oracle database after you create a connection and build an app in Power Apps. The Oracle Database connection supports full delegation of filtering, sorting, and other functions but not triggers or stored procedures.

Prerequisites

- Oracle 9 and later
- Oracle Data Access Client (ODAC) software 11.2 or later
- Installation of an on-premises data gateway
- Installation of the Oracle client SDK

Install an on-premises data gateway

To install a gateway, follow the steps in this tutorial.

An on-premises data gateway acts as a bridge, providing quick and secure data transfer between on-premises data (data that isn't in the cloud) and the Power BI, Power Automate, Logic Apps, and Power Apps services. You can use the same gateway with multiple services and multiple data sources. For more information, see Understand gateways.

Install Oracle client

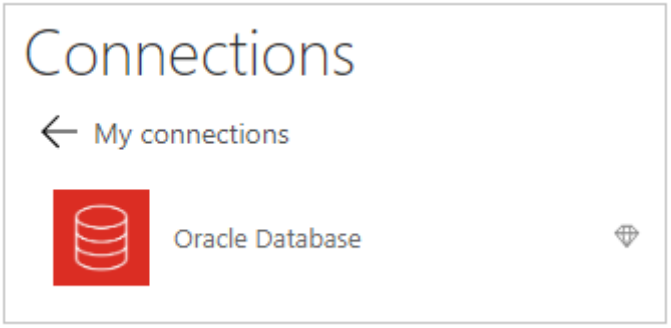
On the same computer as the on-premises data gateway, install ODAC 11.2 or later. For example, you can install 64-bit ODAC 12c Release 4 (12.1.0.2.4) for Windows x64 or choose a version that you prefer. You must choose a windows installer version since xcopy version does not work with on-premises data gateway. Otherwise, an error will appear if you try to create or use the connection, as the list of known issues describes.

Create an app from a table in an Oracle database

1. Go to Power Apps.
2. Select **Create** from the left-pane.
3. Under **Start from**, select **More data sources**.

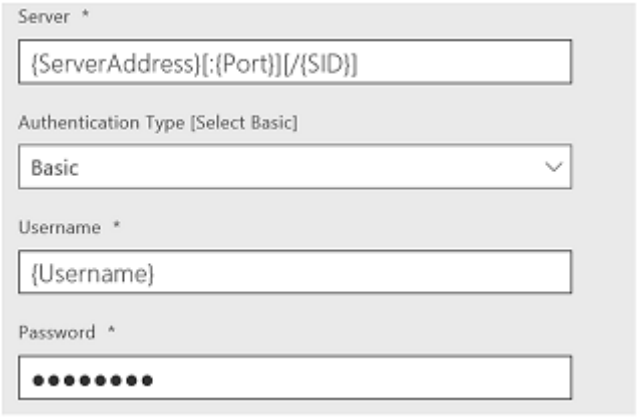
4. Select **New connection**.

5. In the list of connections, select **Oracle Database**.



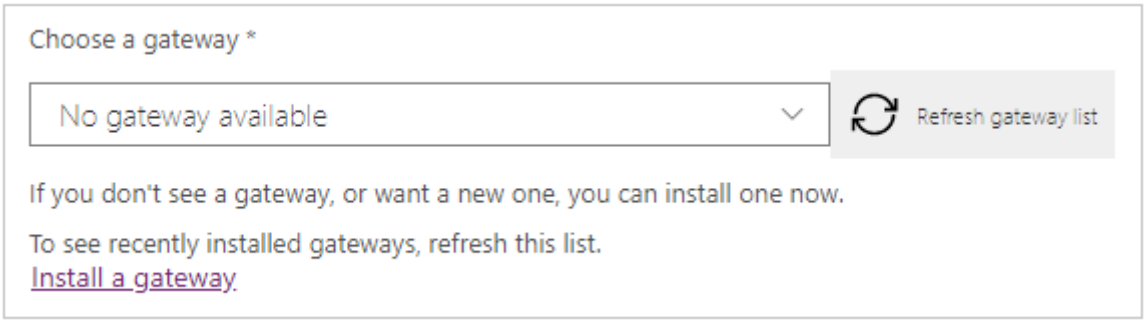
6. Specify the name of an Oracle server, a username, and a password.

   Specify a server in this format if an SID is required:
   `ServerName/SID`



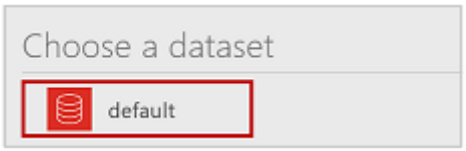
7. Select the gateway that you want to use, or install one.

   If your gateway doesn't appear after you install it, select **Refresh gateway list**.

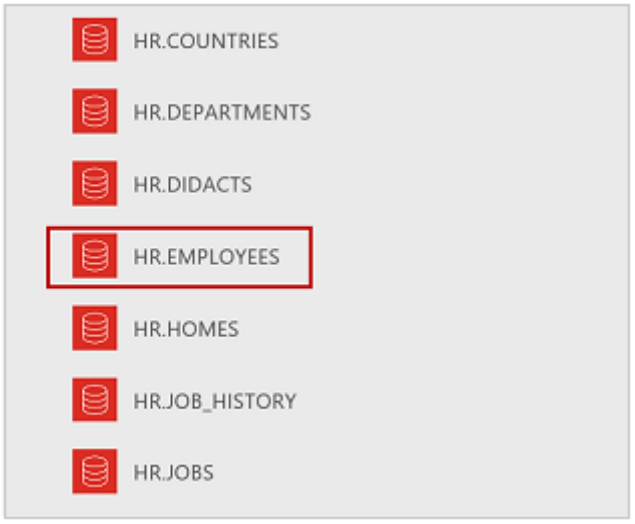


8. Select **Create** to create the connection.

9. Select **default** dataset.



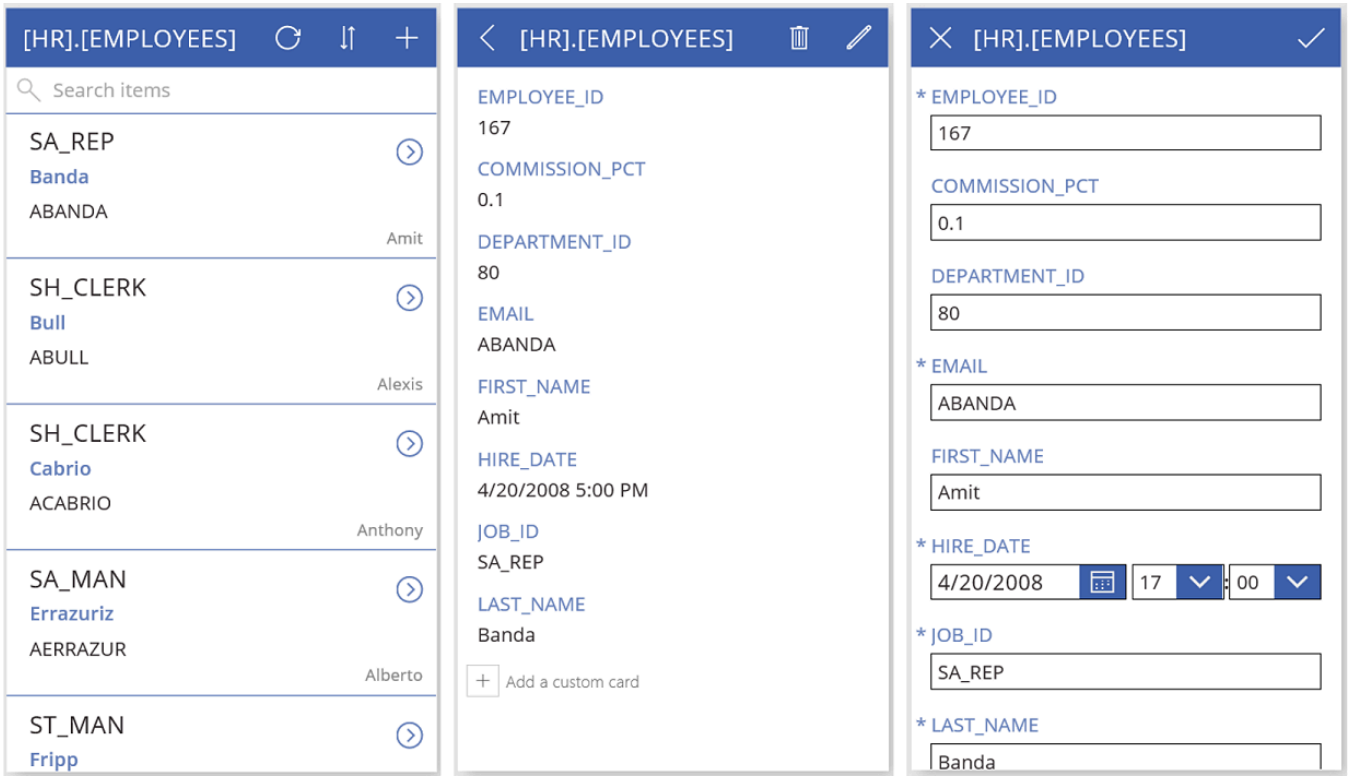
10. In the list of tables, select the table that you want to use.



11. Select **Connect** to create the app.

Power Apps creates an app that has three screens and shows data from the table that you selected:

- **BrowseScreen1**, which lists all entries in the table.
- **DetailScreen1**, which provides more info about a single entry.
- **EditScreen1**, in which users can update an entry or create an entry.



Next steps

- To save the app that you've generated, press Ctrl-S.
- To customize **BrowseScreen1** (which appears by default), see Customize a layout.
- To customize **DetailsScreen1** or **EditScreen1**, see Customize a form.

Known issues, tips, and troubleshooting

1. Can't reach the Gateway.

   This error appears if the on-premises data gateway can't connect to the cloud. To check the status of your gateway, sign in to powerapps.microsoft.com, select **Gateways**, and then select the gateway that you want to use.

   Make sure that your gateway is running and can connect to the Internet. Avoid installing the gateway on a computer that may be turned off or asleep. Also try restarting the on-premises data gateway service (PBIEgwService).

2. System.Data.OracleClient requires Oracle client software version 8.1.7 or greater.

   This error appears if the Oracle client SDK isn't installed on the same computer as the on-premises data gateway. To resolve this issue, install the official provider.

3. Table '[Tablename]' doesn't define any key columns.

This error appears if you're connecting to a table that doesn't have a primary key, which the Oracle Database connection requires.

4. Stored procedures, tables with composite keys, and nested object types in tables aren't directly supported in Power Apps. However, stored procedures using Power Automate are supported.

5. Schema name dependency across environments.

   When connecting Power Apps to Oracle on-premises data sources, the schema prefix is treated as part of the table name. This means that the schema name must be exactly the same in every environment such as development, preproduction, and production. If you use different Oracle usernames or schemas in each environment, your app may not be able to find the tables during deployment—even if you update the connection references correctly. This will result in an **Entity Not Found** error.

   This limitation is by design: Power Apps does not currently support dynamic schema name substitution using environment variables. To prevent deployment failures, you should use the same Oracle schema name in all environments. Alternatively, you can consider solutions like Power Automate flows or Dataverse virtual entities, which provide more flexibility for managing environment-specific configurations.

Connect to Power BI from Power Apps

Article • 12/16/2022

Power BI is a suite of business analytics tools to analyze data and share insights. Monitor your business and get answers quickly with rich dashboards available on every device. In your app, you can check the status of the data alerts that you have set up in the Power BI service. For more information on data alerts in Power BI, head to the documentation page.

This topic shows you how to use the Power BI connection in an app, and lists the available functions.

> ⓘ **Note**
>
> The Power BI connection is not **delegable**.

Prerequisites

- Sign up
- Add the Power BI connection
- Create an app from a template, from data, or from scratch

Use the Power BI connection in your app

List the alerts that you've set up in the Power BI service

1. On the **Insert** menu, select **Gallery**, and add any of the **Text galleries**.
2. To show the current user's alerts, set the Items property of the gallery to the following formula:

   ```
   PowerBI.GetAlerts()
   ```

The gallery will update with the list of alerts. For each alert, you will receive the alert name, the ID number of the alert, and the ID of the group workspace in which the alert

was configured. You will need the alert ID to get further information about the alert.

View the status of an alert

To view the status of the alert, call the CheckAlertStatus function with the alert ID obtained from the step above.

The alert ID can be passed in either as a literal string (e.g. "1234") or as a reference to a gallery section populated using the GetAlerts() call (e.g. Gallery1.Selected.alertId)

To proceed, add a label, and then set its Text property to one of these formulas:

- `PowerBI.CheckAlertStatus( /* alert ID that you received from GetAlert */ ).alertTitle`
- `PowerBI.CheckAlertStatus( /* alert ID that you received from GetAlert */ ).currentTileValue`
- `PowerBI.CheckAlertStatus( /* alert ID that you received from GetAlert */ ).alertThreshold`
- `PowerBI.CheckAlertStatus( /* alert ID that you received from GetAlert */ ).isAlertTriggered`

The label will update with the current status of the alert.

View the available functions

This connection includes the following functions:

Function Name	Description
GetAlerts	List the alerts that you have set up in the Power BI service
CheckAlertStatus	Check the status of a particular alert

GetAlerts

List the alerts that you have set up in the Power BI service.

Input properties

None.

Output properties

Property Name	Data Type	Required	Description
value	array	No	An array of the data alerts that you have set up in the Power BI service. Each element in the array will include: • alertTitle: the title of the alert • alertId: the ID of the alert • groupId: the ID of the group that the alert was created in

CheckAlertStatus

Check the status of an alert.

> ⓘ Note
>
> Requests to this endpoint will be throttled on a per-alert basis if called too frequently.

Input properties

Property Name	Data Type	Required	Description
alertId	integer	Yes	The ID of the alert, as returned by GetAlerts

Output properties

Property Name	Data Type	Required	Description
tileValue	number	No	The value of the tile when the alert was triggered
tileUrl	string	No	URL for the tile that has the alert
alertTitle	string	No	Name of the alert
isAlertTriggered	boolean	No	Whether the alert is currently triggered
alertThreshold	number	No	The threshold at which the alarm is triggered

Connect to SharePoint from a canvas app

Article • 03/14/2025

There are different ways to connect to SharePoint in a canvas app:

- Connect to a SharePoint site to generate an app automatically from a list.
- Create a SharePoint connection before you add data to a new or existing app.

> **Note**
>
> When you create or view a list in SharePoint, you're automatically redirected to Microsoft Lists. The list can always be found in both Microsoft Lists and SharePoint. Learn more in What is a list in Microsoft 365?.

Connect SharePoint to an app by creating an app

If you have a SharePoint site with a SharePoint list, you can create an app in Power Apps through the list menu in Microsoft Lists.

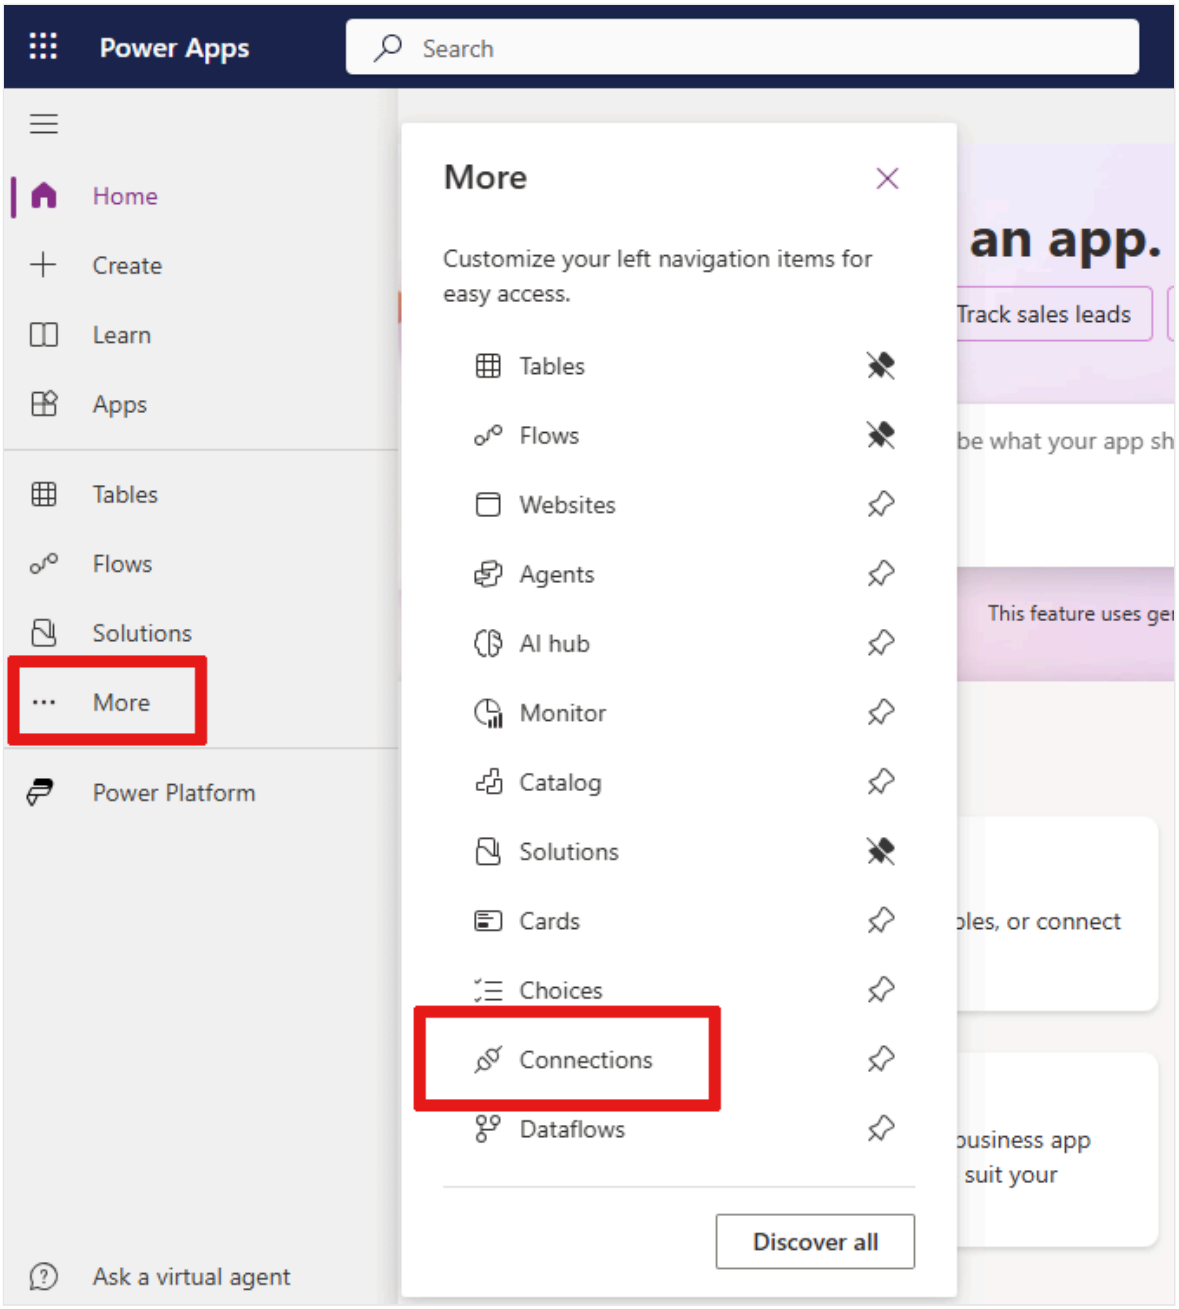
The **Integrate** > **Power Apps** > **Create an app** menu in Microsoft Lists takes you to Power Apps and builds an app using your list as a data source.

Learn more in Create a canvas app with data from Microsoft Lists.

Create a SharePoint connection

If you build a new app or have an existing app, you can connect to SharePoint through the **Data** menu in Power Apps.

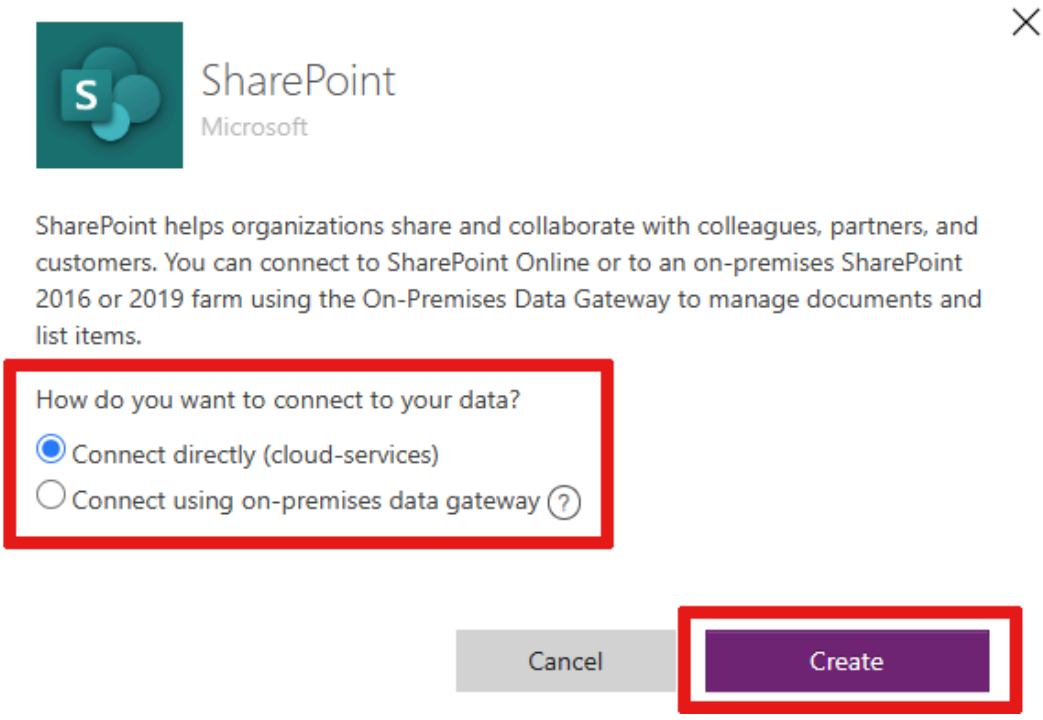
1. Sign in to Power Apps.
2. Select **More** > **Connections** in the left navigation bar.



3. Select + **New connection** and choose **SharePoint**. A popup appears.

4. Choose either the cloud-services or on-premises option:

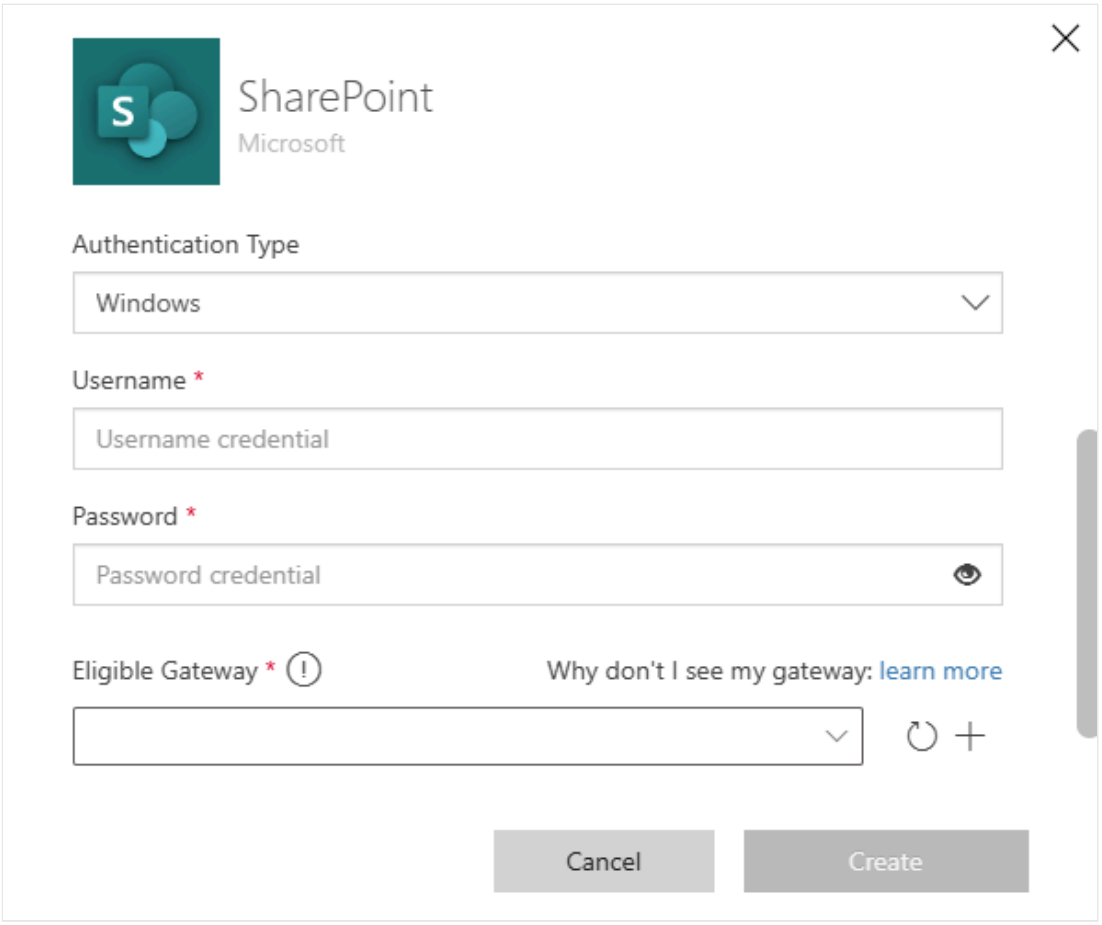
    - To connect to SharePoint Online, select **Connect directly (cloud services)** and then **Create**. Provide credentials (if prompted).



The connection is created, and you can add data to an existing app or build an app from scratch.

- To connect to an on-premises site, select **Connect using on-premises data gateway**.

  Choose **Windows** as the authentication type and add your credentials. If your credentials include a domain name, specify it as `domain\alias`.



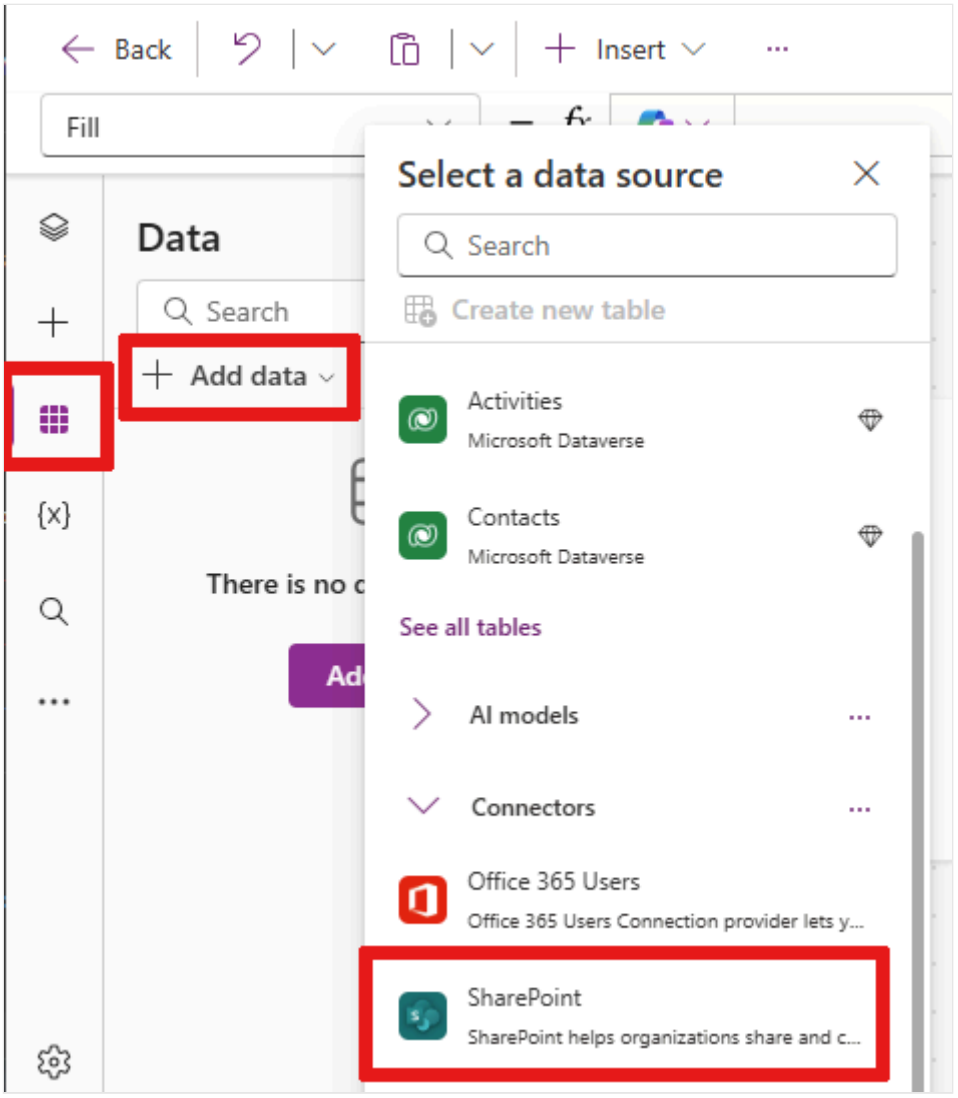
Under **Choose a gateway**, select the gateway that you want to use, and then select **Create**.

> **Note**
>
> If you don't have an on-premises data gateway installed, install one, and then select the refresh icon for a list of gateways.

The connection is created. You can add data to an existing app or build an app from scratch.

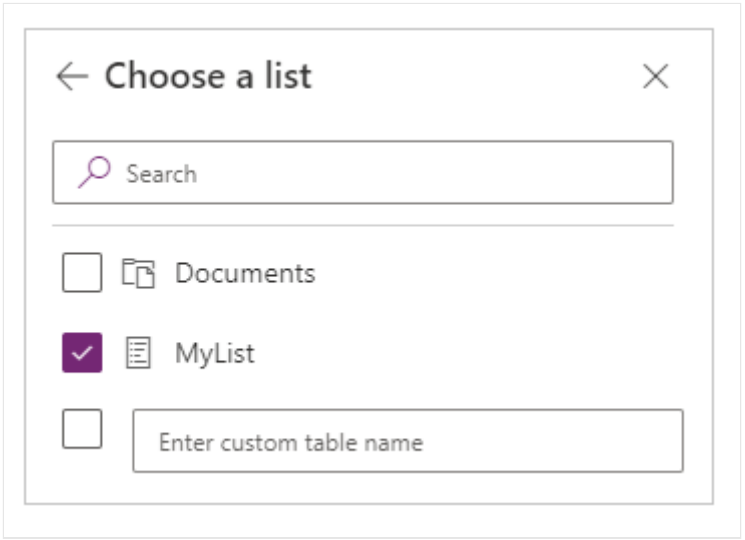
Add data to an existing app

1. In Power Apps Studio, open the app that you want to update, select **Data** on the left-pane.
2. Select **Add data** > **Connectors** > **SharePoint**.



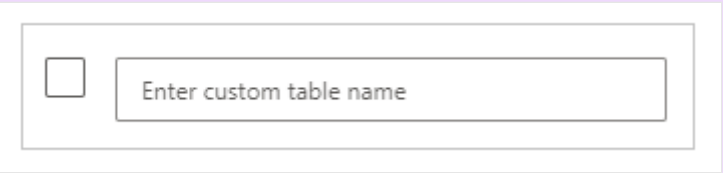
3. A side panel opens. Under **Connect to a SharePoint site**, select an entry in the **Recent sites** list (or add your own URL), and then select **Connect**.

4. Under **Choose a list**, select the check box for one or more lists, then select **Connect**:



> ⓘ Note

Power Apps supports lists, not template-based lists. If you don't see your list, type the list name in **Enter custom table name** box.



You see a confirmation banner that your data source was added to your app.

Power Apps data type mappings

Expand table

Power Apps	SharePoint
`Boolean`	Yes/No (checkbox)
`DateTime`	Date and Time
`Image`	Hyperlink or Picture, Image
`Complex`	Choice, Lookup, Person, Group, Task Outcome, External Data, Managed Metadata
`Number`	Number, Currency, ID
`Text`	Single line of text, Multiple lines of text, Calculated

> **Note**
>
> SharePoint types that map to Power Apps as complex often have subfields that map to basic types such as text and number.

Power Apps delegable functions and operations for SharePoint

The following Power Apps operations, for a given data type, may be delegated to SharePoint for processing (rather than processing locally within Power Apps).

Expand table

Operation/Function [1]	Number	Text	Boolean	DateTime	Complex [2]
`<, <=,<>, >, >=`	Yes [3]	No	No	Yes	Yes
`=`	Yes	Yes	Yes	Yes	Yes
`Filter`	Yes	Yes	Yes	Yes	Yes
`IsBlank`	-	No [4]	-	-	No
`Lookup`	Yes	Yes	Yes	Yes	Yes
`Sort`	Yes	Yes	Yes	Yes	No
`SortByColumns`	Yes	Yes	Yes	Yes	No
`StartsWith`	-	Yes	-	-	Yes
`UpdateIf/RemoveIf` [5]	Yes	No	-	-	No

Notes

1. Expressions that are joined with **And** or **Or** are delegable to SharePoint. **Not** won't delegate. SharePoint system fields don't generally delegate. These fields include:

- Identifier
- IsFolder
- Thumbnail
- Link
- Name
- FilenameWithExtension
- Path
- FullPath
- ModerationStatus
- ModerationComment
- ContentType
- IsCheckedOut
- VersionNumber
- TriggerWindowStartToken
- TriggerWindowEndToken

2. SharePoint supports delegation of complex types by deferring the decision for delegation to the subfield involved. Check the type of the subfield being used on the complex type and then check this table for delegation capabilities. Only Email and DisplayName are delegable in the Person data type.

3. SharePoint ID fields are shown as a number field in Power Apps. However, the underlying type is actually Text. SharePoint only supports the equal ('=') operation for delegation on an ID field. Relational operations such as `<, <=,<>, >, >=` won't work on a SharePoint ID field.
4. A formula such as Filter(..., IsBlank(CustomerId)) won't delegate to SharePoint. However, that formula is semantically close to Filter(..., CustomerId = Blank()), will delegate to SharePoint. These formulas aren't equivalent because the second formula won't treat the empty string ("") as empty. However, the second formula might work for your purposes. On SharePoint, this approach works for the 'equals' operator ("=") but not the operator for 'not equals' ("<>").
5. UpdateIf and RemoveIf work locally but simulate delegation to a limit of 500/2000 records. They successively bring down records beyond the non-delegation 500/2000 record limit. Records that meet the If condition are collected. Generally, a maximum of 500/2000 records are collected separately and then changed per execution. However, more records may be updated if the existing local data cache is large as the function may have access to more records for evaluation.

Connect to SQL Server from Power Apps overview

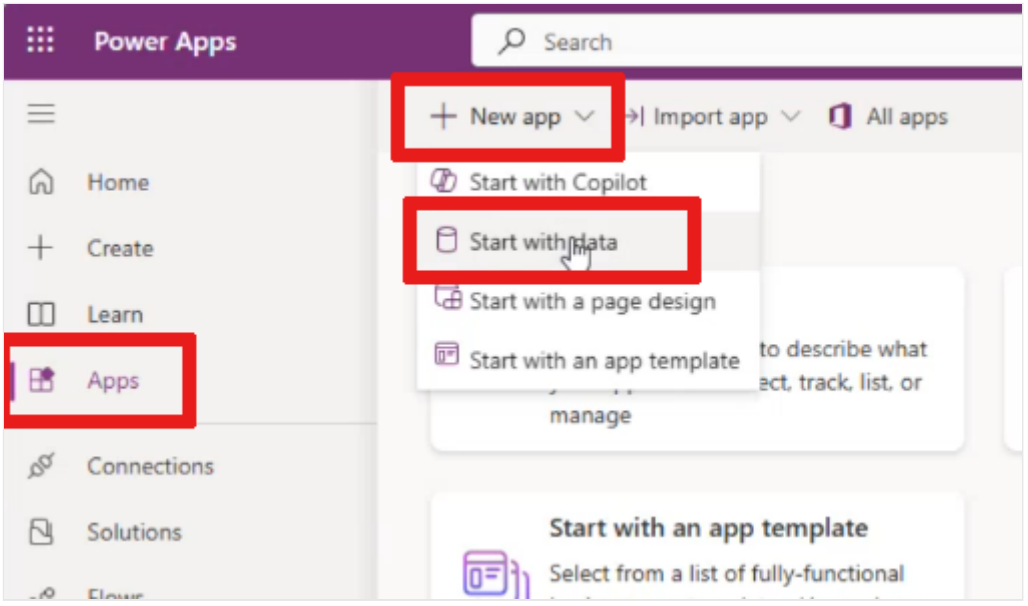
Article • 03/14/2025

There are different ways to connect to data in SQL Server in your app, using Power Fx formulas. You can access data directly or use a view or stored procedures to create, update, or delete data in your app.

Prerequisites

To access data directly, you can create a *Start with data* app for your SQL Server data. This method lets you get a basic, working app that you can modify with views and stored procedures.

1. Sign in to Power Apps and go to the **Apps** page.
2. Select **New app** > **Start with data**.



3. From the **Start with data** page, choose **Connect external data**.
4. Under **Choose a data set to start** select **From SQL**.

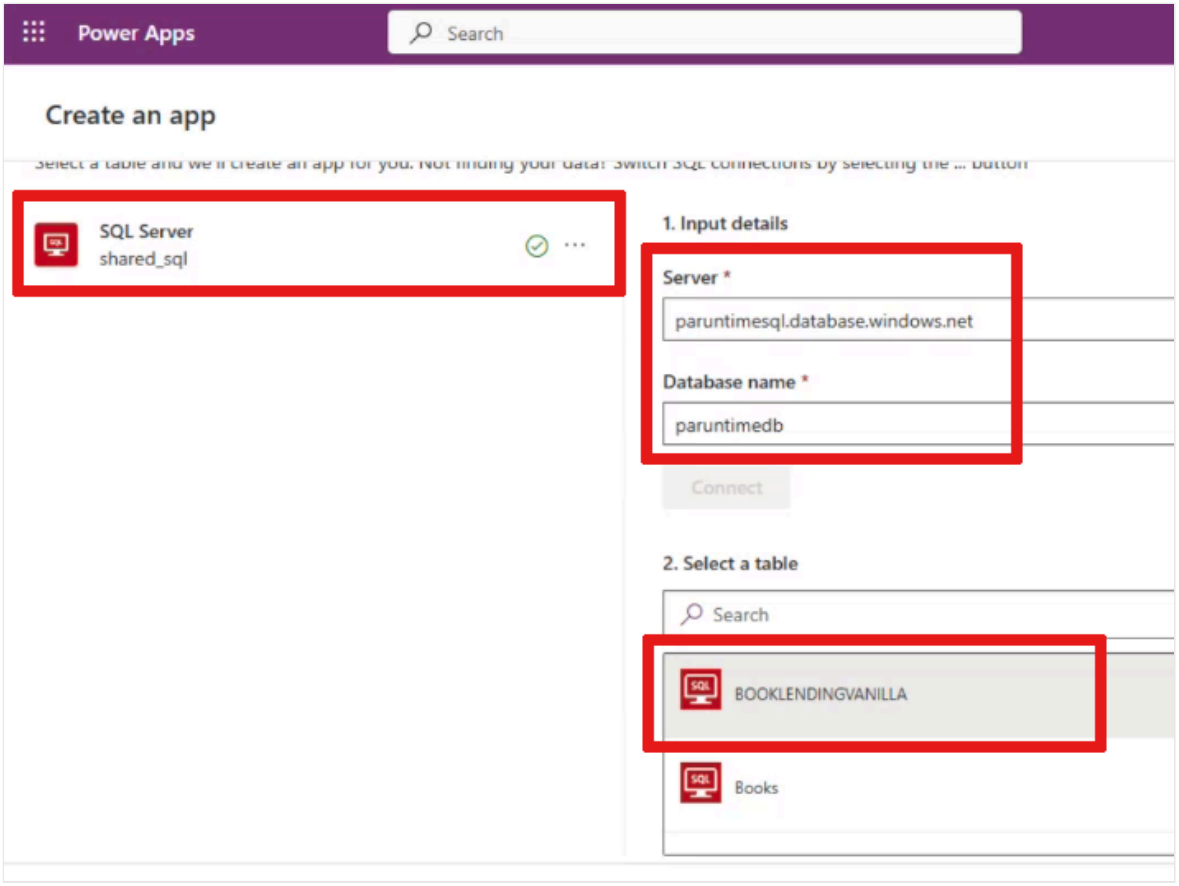
   If you have an existing SQL Server connection, it loads.

> **Note**

If you don't already have a SQL Server connection, you're prompted to create one.

5. Select your SQL connection.

6. Enter your **Server** name and **Database name**, then choose **Connect**. Choose a table from the list of tables that appear.



> **Note**
>
> Only one connection is shown at a time. To use a different connection, select the ... overflow menu on your SQL connection, then find a new one or create a new SQL connection.

7. Select **Create app**.

Access data

Once your app is connected to SQL Server, you can access data: Access data in SQL Server.

View results

To view the results of your SQL queries, see: View results in SQL Server.

Power Apps data type mappings

Expand table

SQL Server	Power Apps
`bigint`, `decimal`, `int`, `money`, `numeric`, `smallint`, `smallmoney`, `tinyint`, `float`, `real`	Number
`char`, `nchar`, `varchar`, `nvarchar`, `text`, `ntext`	Text
`bit`	Boolean
`date`, `datetime`, `datetime2`, `smalldatetime`, `datetimeoffset`, `time`	DateTime
`uniqueidentifier`	Guid

> **Note**
>
> If a SQL Server data type doesn't appear in the previous table, that data type isn't supported. Unsupported data types include the following examples: `binary()`, `varbinary()`, `image`, `cursor`, `rowversion`, `hierarchyid`, `sql_variant xml`, Spatial Geometry Types, Spatial Geography Types, and table. Also, 'tinyint' and 'smallint' are not supported as primary keys.

Power Apps functions and operations delegable to SQL Server

Power Apps can delegate Power Fx query operations (for example, Filter) to the back-end data source for processing. Delegation allows the back-end data service (for example, SQL Server) to do the filtering work so that only a few records must be transferred to your device.

This table shows which operations are delegable to SQL Server by data type. Expressions joined with `And`, `Or`, and `Not` are delegable.

Expand table

Operation or function	Number	Text	Boolean	DateTime	Guid
`*, +, -, /`	Yes	-	-	No	-
`<`, `<=`, `>`, `>=`	Yes	No	No	Yes	-
`=`, `<>`	Yes	Yes	Yes	Yes	Yes
`Average`	Yes	-	-	-	-
`EndsWith`	-	Yes [1]	-	-	-
`Filter`	Yes	Yes	Yes	Yes [2]	Yes
`In` (substring)	-	Yes [3]	-	-	-
`IsBlank` [4]	No	No	No	No	No
`Len` (length)	-	Yes [5]	-	-	-
`Lookup`	Yes	Yes	Yes	Yes	Yes
`Max`	Yes	-	-	No	-
`Min`	Yes	-	-	No	-
`Search`	No	Yes	No	No	-
`Sort`	Yes	Yes	Yes	Yes	-
`SortByColumns`	Yes	Yes	Yes	Yes	-
`StartsWith`	-	Yes [6]	-	-	-
`Sum`	Yes	-	-	-	-
`UpdateIf, RemoveIf` [7]	Yes	Yes	Yes	Yes	Yes

Notes

1. Supported for `(EndsWith(\<column>, "string value"))` but not for `(EndsWith("string value", \<column>))`. If a char(10) column has a value of "hello", `EndsWith(\<column>, "llo")` returns false, by design. A char(10) column has 10 characters.

2. Direct date filters don't work for SQL Server with an on premise Data Gateway. However, you can create a calculated column that works. For example, you can

create:
`ALTER TABLE myTable ADD DateAsInt AS (YEAR([date]) * 10000 + MONTH([date]) * 100 + DAY([date]))`
And then filter on the calculated number column.

3. Supported for `("string value" in \<column>)`, but not for `(\<column> in "string value")`.

4. An expression such as `Filter('[dbo].[MyOrders]', !IsBlank(CustomerId))` won't delegate to the server. However, you can use an expression such as `Filter('[dbo].[MyOrders]', CustomerId <> Blank())`, which does delegate to the server and is semantically close. The difference is that the second expression won't treat the empty string ("") as empty. Although the expressions aren't equivalent, the latter might work for your purposes. You can't use this method for the Guid data type.

5. Power Apps delegates the `Len` function, but the behavior might not work as you expect. In SQL Server, a char(10) column with value "hello" always has a length of 10. However, Power Apps treats that string as having a length of 5, which may cause discrepancies and confusion. Don't use `char`/`nchar` on SQL server, but use `varchar`/`nvarchar` instead.

6. Supported for `(StartsWith(\<column>, "string value"))`, but not for `(StartsWith("string value", \<column>))`

7. UpdateIf and RemoveIf work locally but simulate delegation to a limit of 500/2000 records. They successively bring down records beyond the non-delegation 500/2000 record limit. Records that meet the If condition are collected. Generally, a maximum of 500/2000 records are collected separately and then changed per execution. However, more records may be updated if the existing local data cache is large as the function may have access to more records for evaluation.

Use Microsoft SQL Server securely with Power Apps

Article • 05/21/2025

There are different ways to connect and authenticate to SQL Server with Power Apps. This article outlines concepts that can be helpful in making a choice about how to connect to SQL Server with a security approach that matches requirements for your app.

> **Important**
>
> The secure implicit connections feature was released in January 2024. Microsoft strongly encourages all apps currently using implicit connections to convert to secure implicit connections and to revoke connections shared with end users.

Difference between explicit, implicit, and secure implicit connections

A connection to SQL Server is created whenever you create an app using Power Apps connecting to SQL Server. When such apps are published and shared with others, both the app and the connection are deployed to those users. In other words, the app and the connection—both are visible to users the apps is shared with.

The authentication method used for such connections can be **explicit** or **implicit**. We can also say such connection is shared explicitly or implicitly.

- An **explicitly shared connection** means that the end user of the application must authenticate to SQL Server with their own explicit credentials. Usually this authentication happens behind the scenes as part of Microsoft Entra or Windows authentication handshake. The user doesn't even notice when the authentication takes place.
- An **implicitly shared connection** means that the user implicitly uses the credentials of the account that the app maker used to connect and authenticate to the data source during while creating the app. The end user's credentials are **not** used to authenticate. Each time the end user runs the app, they're using the credentials the author created the app with.
- A **secure implicitly shared connection** refers to a scenario where the end user of the app implicitly uses the credentials of the account that the app maker used to connect and authenticate to the data source while creating the app. This means that the end user's own credentials are not used to authenticate. Instead, when the user runs the app, they are using the credentials that the author of the app created it with. It is important to note

that the end user is not provided with direct access to the connection, and the app only allows access to a limited set of actions and tables.

The following four connection authentication types can be used with SQL Server for Power Apps:

Expand table

Authentication Type	Power Apps connection method
Microsoft Entra Integrated	Explicit
SQL Server Authentication	Implicit / Secure Implicit
Windows Authentication	Implicit / Secure Implicit
Windows Authentication (nonshared)	Explicit

Implicit connection sharing risks

All new applications automatically use the new secure implicit connections. However, with apps that use the older 'implicit connections', both the app and its connections are deployed to end users, it means that **end users can author new applications based on those connections**.

When an author uses secure implicit connections, it means that no connection is shared and no end user receives the connection object. This eliminates the risk of an end-user author reusing a connection to create a new app. Instead, the app works with a proxy connection that is aware of the app and only communicates with that specific app. The proxy connection allows limited actions (create, read, update, delete) and access to specific tables in the app that are defined when the app is published. Therefore, only authorized actions and access are granted to the end user.

The older style simple implicit connection actually distributes a connection object to the end user. For example, if you create an app that filters out the data you don't want users to see. But, the filtered out data is present in the database. But you're relying on the filter you configured to ensure the end users won't see certain data.

Again, with older style simple implicit connections, after you deploy the app, end users can use the connection deployed with your app in any new apps they create. In the new apps, users can see the data you filtered out in your application. It's important to use the new secure implicit connections.

> ⓘ **Important**

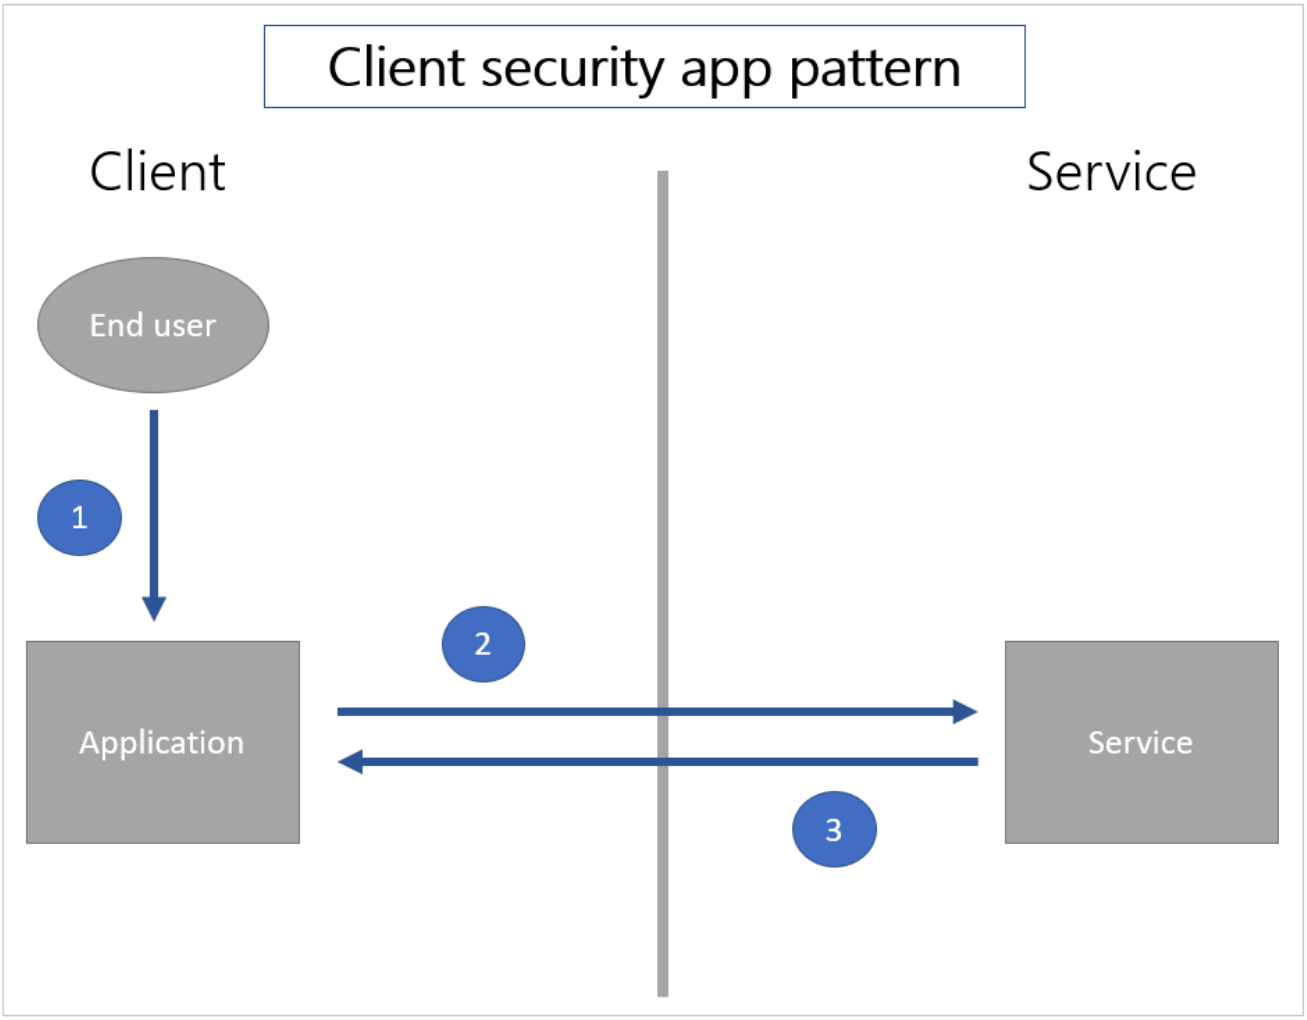
Once an older implicitly shared connection is deployed to end users, the restrictions you may have put in the app you shared (such as filters or read-only access) are no longer valid for new apps end users create. The end users will have whatever rights the authentication allows as part of implicitly shared connection. Therefore, when you convert an app to use secure implicit connections, you must **also** revoke the connections you shared with your app. Admins can get a report of apps with implicitly shared connections with the COE toolkit.

Client and server security

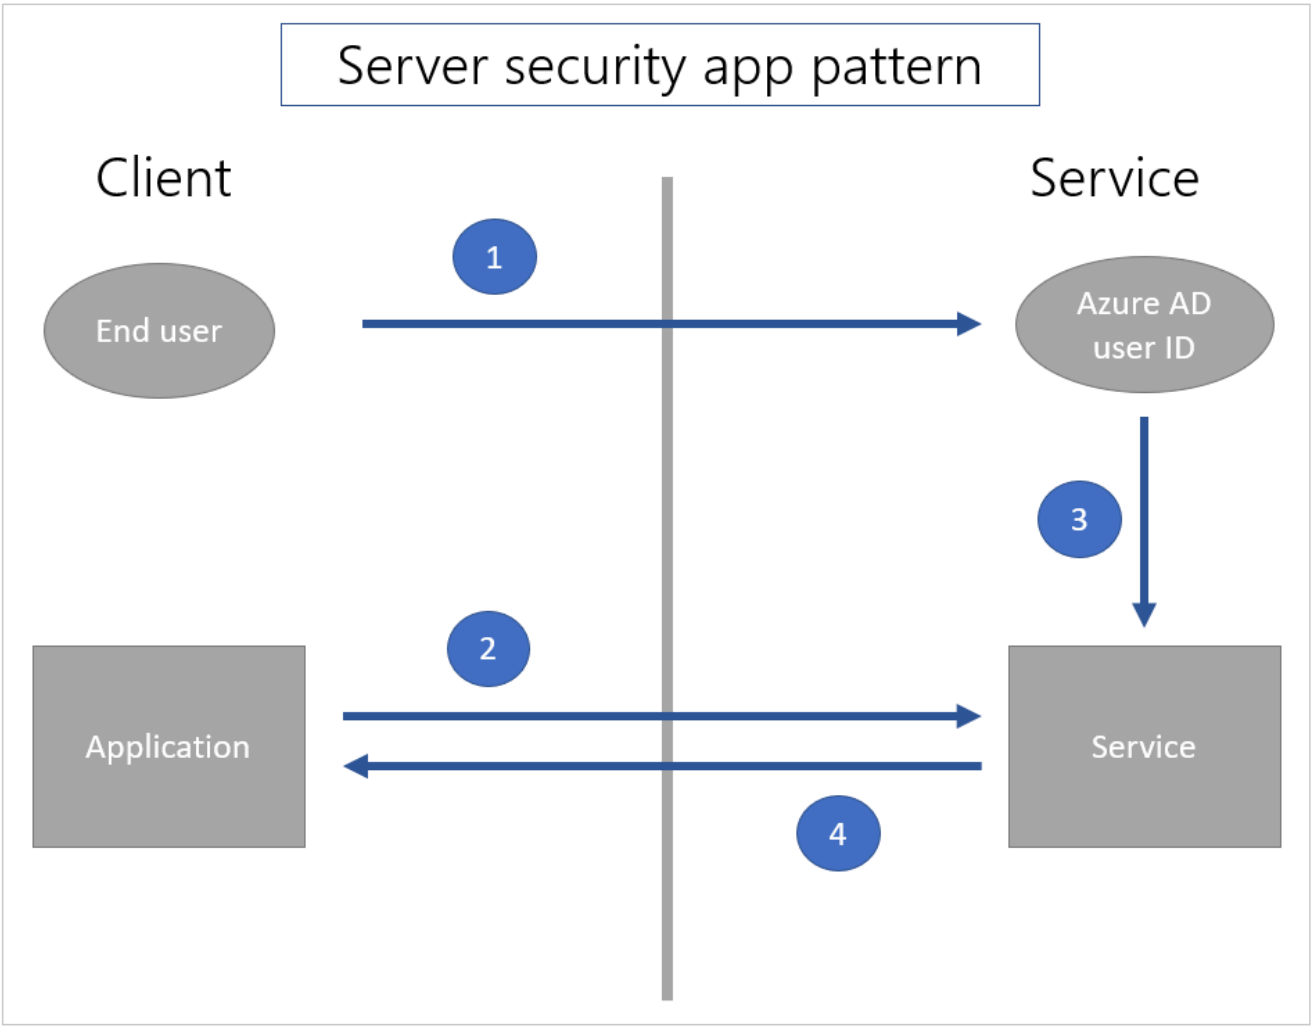
You can't rely on the security of data through filtering or other client-side operations to be secure. Applications that require secure filtering of data must ensure that both the user identification and filtering happens on the server.

Use services such as Microsoft Entra ID instead of relying on the filters designed within the apps when it comes to user identity and security. This configuration ensures server-side filters work as expected.

The following illustrations explain how the security patterns within the apps differ between client-side and server-side security models.



In a client security app pattern, [1] the user only authenticates to the application on the client side. Then [2] the application requests information of the service, and [3] the service returns the information solely based on the data request.



In a server-side security pattern, [1] the user first authenticates to the service so the user is known to the service. Then, [2] when a call is made from the application, the service [3] uses the known identity of the current user to filter the data appropriately and [4] returns the data.

The implicit departmental sharing scenarios described above is combination of these two patterns. The user must log in to the Power Apps service using Microsoft Entra credentials. This behavior is the server security app pattern. The user is known using the Microsoft Entra identity on the service. Hence, the app is restricted to the set of users to which Power Apps has formally shared the application.

However, the implicit shared connection to SQL Server is the client security app pattern. SQL Server only knows that a specific user name and password is used. Any client-side filtering, for instance, can be bypassed with a new application using the same user name and password.

To securely filter data on the server side, use built-in security features in SQL Server such as row level security for rows, and the deny permissions to specific objects (such as columns) to specific users. This approach uses the Microsoft Entra user identity to filter the data on the server.

Some existing corporate services have used an approach where the user identity is captured in a business data layer much in the same way that Microsoft Dataverse does. In this case, the

business layer may or may not use SQL Server's row level security and deny features directly. If it doesn't, it's often the case that the security is enabled using stored procedures or views.

The business layer (on the server side) uses a known user Microsoft Entra identity to invoke a stored procedure as a SQL Server principal and filter the data. However, Power Apps doesn't currently connect to stored procedures. A business layer may also invoke a view that uses the Microsoft Entra identity as a SQL Server principal. In this case, use Power Apps to connect to the views so that the data is filtered on the server-side. Exposing only views to users may need Power Automate flows for updates.

Access data in SQL Server

06/21/2025

Add a data source

Direct access:

If you select the *Start with data* option when you create an app, the **Items** property of your gallery uses a Power Fx formula with a data source name that points directly to your database table.

For example, if you have a `BOOKLENDING` table, you see this formula:

Power Fx

```
Search([@'[dbo].[BOOKLENDING]'], SearchInput1.Text, author,
author,book_name,category)
```

Views and stored procedures:

A common professional data access pattern is to use views and then stored procedures for create, update, and delete instead of allowing direct access. If you want to use views or stored procedures, change the example formula. Similarly, the form for the record doesn't use the built-in direct approach of the `SubmitForm()` formula.

Triggers:

One database pattern is to use triggers on tables. If a table has a trigger, you can't use the direct pattern `Submit()` for create, update, and delete. `Submit()` conflicts with SQL trigger handling and the built-in Power Apps behavior, which use the same output parameter.

You can directly access the table for queries, but to handle `Create`, `Update`, or `Delete`, call a stored procedure.

> ⓘ **Note**
>
> The SQL Server connector, like all connectors that work with relational data, assumes that tables have a primary key. A primary key is critical for finding specific records to update. If a SQL Server table doesn't have a primary key, the data is read-only. If you have access and edit rights to the SQL Server table, consider adding an auto-generated key.

Use a view

A *view* is a saved query that shows as a single table of data.

Views appear in the list of tables you can select when you add a data source. Views only support queries—not updates. To update data, use a stored procedure.

If you create a table with the `Start with data` option, you get screens and formulas that show records in a gallery and form. You see formulas and functionality for creating, editing, and deleting records. But if you use a view, you only see a display screen for the gallery and form.

You might want autogenerated screens from `Start with data` for views.

To use this autogenerated option:

1. Choose `Start with data` with a *basic table*.
2. Delete and replace the table data source.

Example:

For example, if you have a `BOOKLENDINGVIEW` table and add it as a data source for Power Apps, the formula can be as simple as:

```
Power Fx

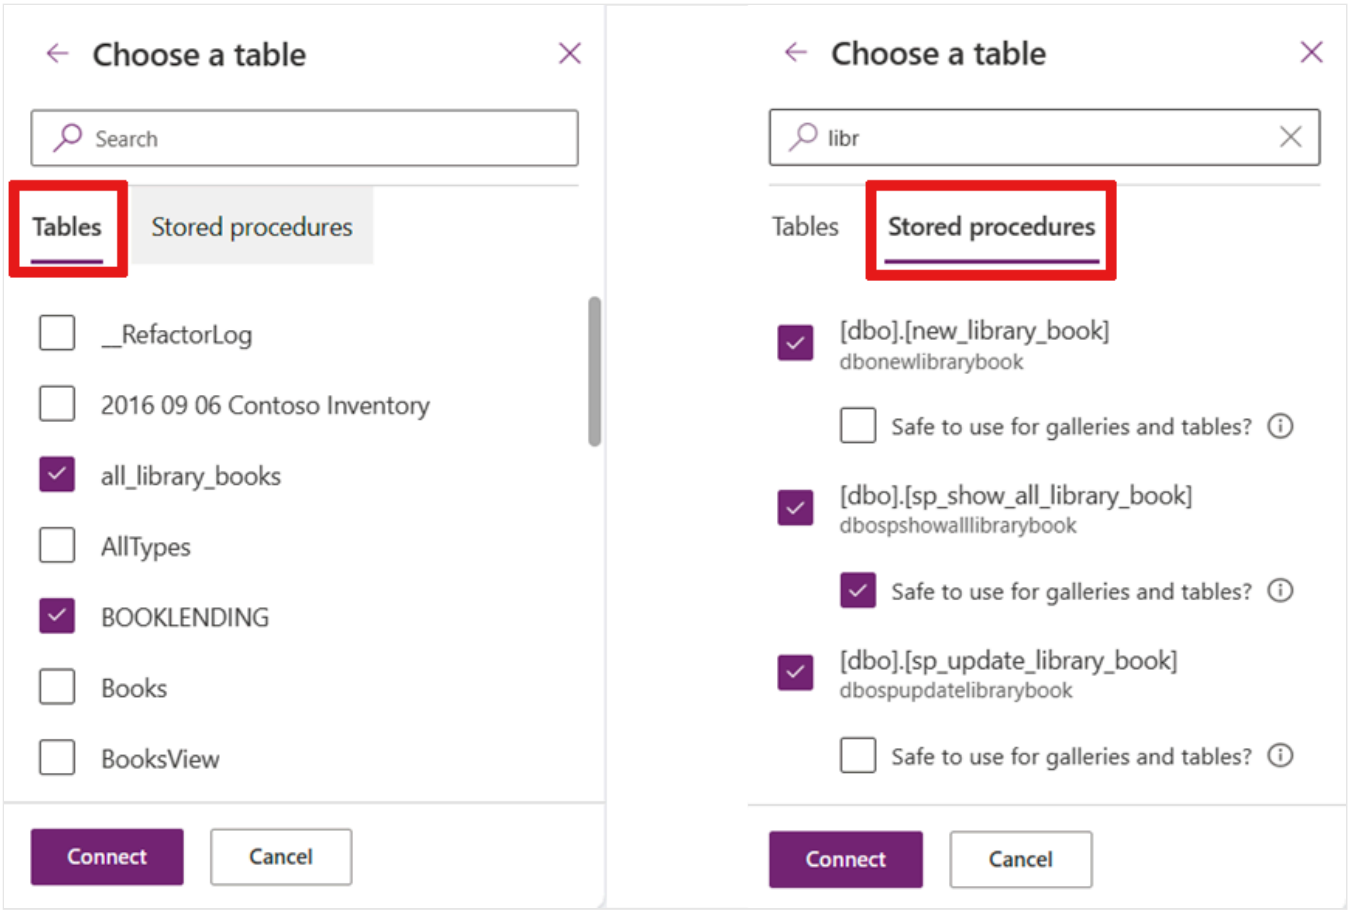
BOOKLENDINGVIEW
```

You can also replace other create, update, and delete formulas with a view data source and calls to stored procedures.

Use stored procedures

When you add a SQL Server connection to your app, you can add stored procedures and call them directly in Power Fx.

> **Note**
>
> This feature also works with secure, implicit connections.



After you select a stored procedure, a child node appears, and you can designate the stored procedure as **Safe to use for galleries and tables**.

A stored procedure is *safe* if it doesn't perform any action that might be unwanted in certain scenarios. For example, if a stored procedure collects all accounts from a given city and then sends them an email, you might not always want emails sent every time the stored procedure is called. In that case, don't mark the stored procedure as safe.

Check a stored procedure as safe only if:

1. There are **no side effects** to calling this procedure on demand.

   You can call the procedure multiple times or whenever Power Apps refreshes the control. When you use it with an **Items** property of a gallery or table, Power Apps calls the stored procedure whenever the system determines a refresh is needed. You can't control when the stored procedure is called.

2. The stored procedure returns a modest amount of data.

   Action calls, like stored procedures, don't have a limit on the number of rows retrieved. They aren't automatically paged in 100-record increments like tabular data sources such as tables or views.

   If the stored procedure returns too much data (many thousands of records), your app might slow down or crash. For performance reasons, bring in fewer than 2,000 records.

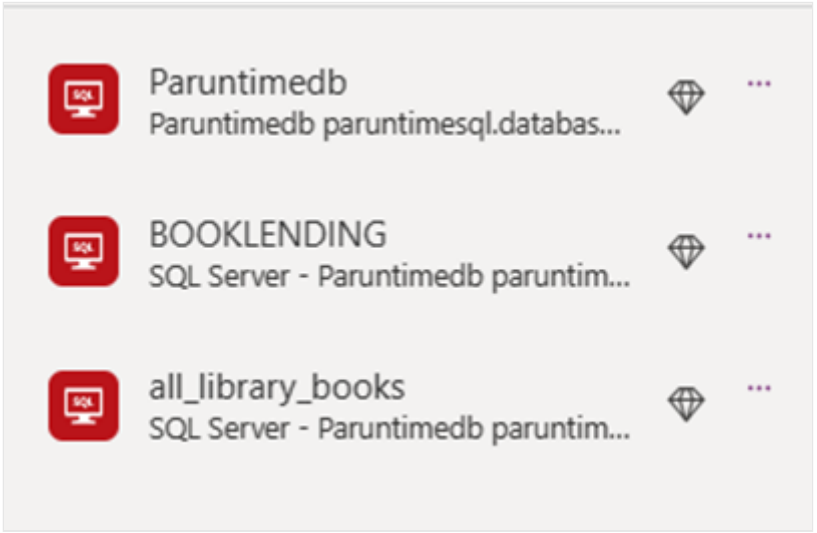
If you check a stored procedure as safe, you can assign it as an **Items** property in galleries or tables in your app.

> **Important**
>
> The schema of the return values of the stored procedure should be *static*, so the values don't change from call to call. For example, if a stored procedure returns two tables, it *always* returns two tables. You can work with either specific or dynamic results.
>
> The structure of the results also needs to be static. For example, if the schema of the results is *dynamic*, then results are dynamic and you must provide a specific type to use them in Power Apps. For more information, see dynamic results.

SQL namespace prepended to stored procedure name

The SQL Server namespace name, where you store the procedure, is added to the start of the stored procedure name. For example, all stored procedures in the '**DBO**' SQL Server namespace have '**dbo**' at the start of the name.

For example, when you add a stored procedure, you might see more than one data source in your project.



Calling a stored procedure

To use a stored procedure in Power Apps, add the connector name before the stored procedure name, such as `Paruntimedb.dbonewlibrarybook`.

> **Note**

When Power Apps brings in the stored procedure, it combines the namespace and procedure name so that `dbo.newlibrarybook` becomes `dbonewlibrarybook`.

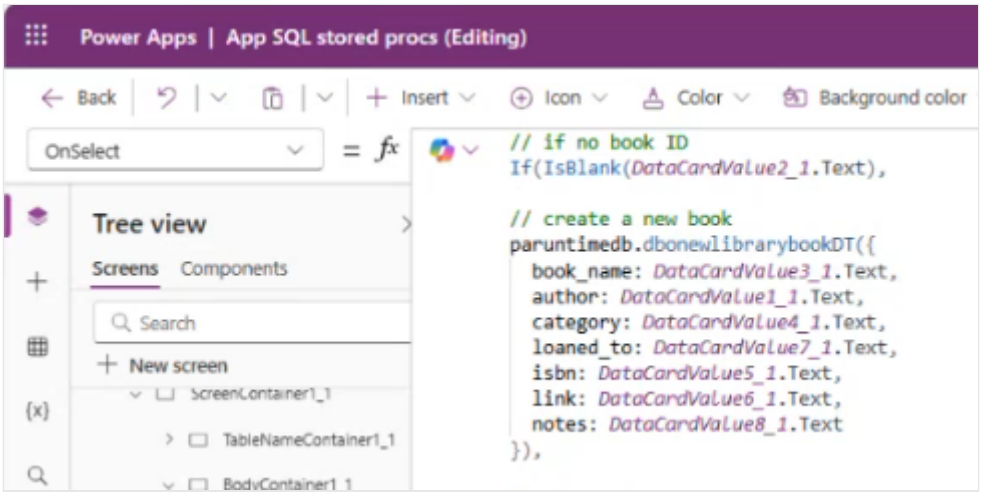
Arguments are passed as a Power Apps record with named value pairs:

```
Power Fx

<datasourceName>.<StoredprocedureName>({<paramName1: value, paramName2: value, ...
>})
```

> **Tip**
>
> Convert values if needed as you pass them into your stored procedure, since you're reading from a text value in Power Apps. For example, if you're updating an integer in SQL, convert the text in the field using `Value()`.

Here's an example of what stored procedures could look like when assigning them to an `OnSelect` property.



Variables and all stored procedures

Access a stored procedure for the **Items** property of a gallery after you declare it safe for the UI. Reference the data source name and the name of the stored procedure followed by `ResultSets`. Access multiple results by referencing the set of tables returned, such as Table 1, Table 2, and so on.

For example, a stored procedure from the table `Paruntimedb` with the name `dbo.spo_show_all_library_books()` looks like this:

```
Power Fx
```

```
Paruntimedb.dbospshowalllibrarybooks().ResultSets.Table1
```

This query populates the gallery with records. However, stored procedures are *action* behaviors on the tabular model. `Refresh()` only works with tabular data sources and doesn't work with stored procedures. Refresh the gallery when a record is created, updated, or deleted.

> **Note**
>
> When you use a `Submit()` on a form for a tabular data source, it effectively calls `Refresh()` under the hood and updates the gallery.

Use a variable to populate and refresh the gallery

Use a variable in the `OnVisible` property for the screen, and set the stored procedure to the variable.

Power Fx

```
Set(SP_Books, Paruntimedb.dbospshowalllibrarybooks().ResultSets.Table1);
```

You can then set the `Items` property of the gallery to the variable name.

Power Fx

```
SP_Books
```

After you create, update, or delete a record with a call to the stored procedure, set the variable again to refresh the gallery.

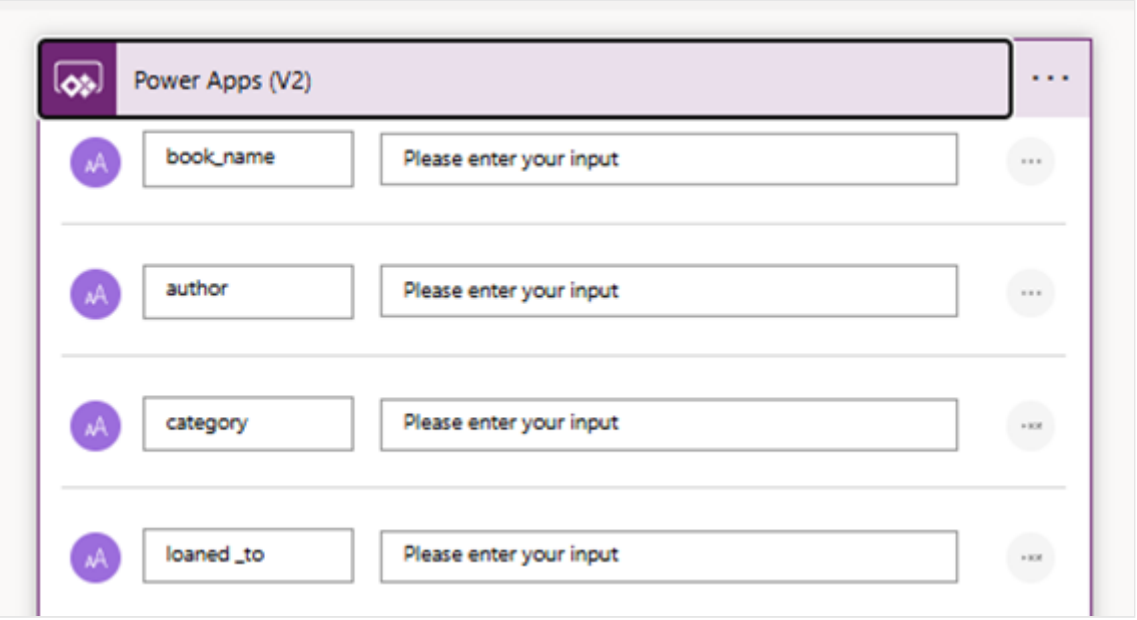
Power Fx

```
Paruntimedb.dbonewlibrarybook({
  book_name: DataCardValue3_2.Text,
  author: DataCardValue1_2.Text,
    ...
});
Set(SP_Books, Paruntimedb.dbospshowalllibrarybooks().ResultSets.Table1);
```

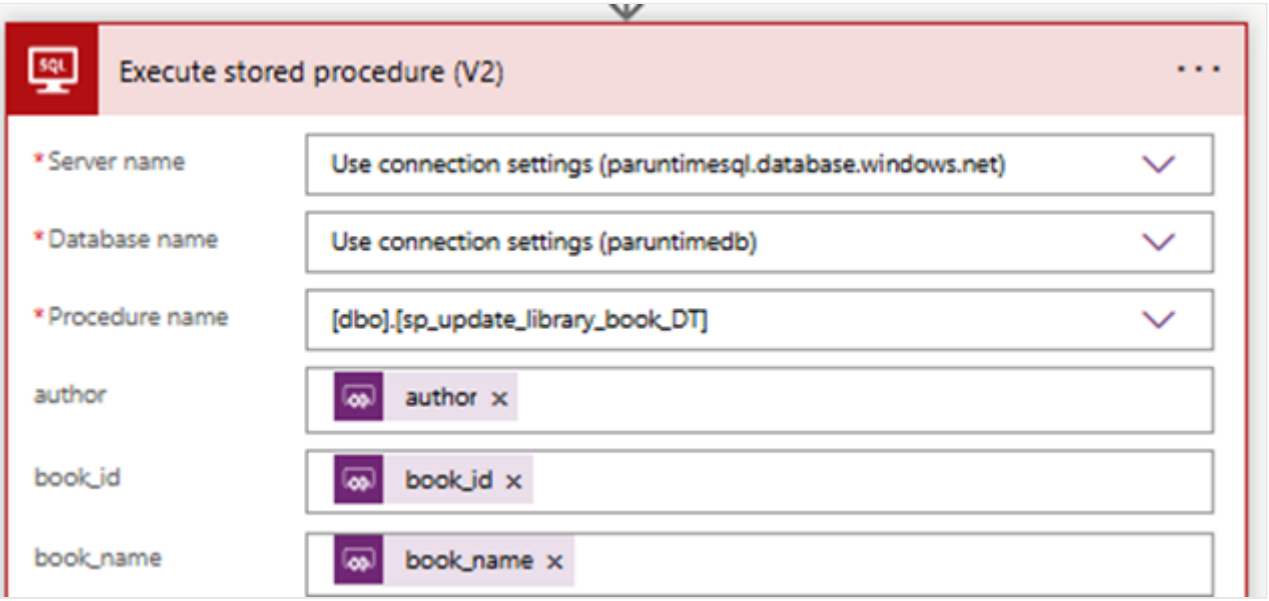
Use Power Automate to call stored procedures

Power Automate handles asynchronous actions best. Call stored procedures as part of a series of calls in a business process.

To call Power Automate and then call stored procedures, create input variables as part of your flow.



Then pass your input variables into the call of your stored procedure.



Add this Power Automate flow to your app and call it. Pass optional arguments as a record "{ ... }". The following example includes all optional arguments.

```
Addanewbook.Run(
{
text:   If(IsBlank(DataCardValue3_6.Text), "", DataCardValue3_6.Text),  // book_name
text_1: If(IsBlank(DataCardValue1_6.Text), "", DataCardValue1_6.Text),  // author
text_2: If(IsBlank(DataCardValue4_6.Text), "", DataCardValue4_6.Text),  // category
text_3: If(IsBlank(DataCardValue7_6.Text), "", DataCardValue7_6.Text),  // loaned_to
```

View results in SQL Server

06/21/2025

If you use a direct table access pattern or a view, the query result binds to the control or table. Power Fx automatically lets your app page data into the gallery or table. However, stored procedures can return a query result, a return code, or values from `Out` parameters.

To use these different result types in your app, follow these patterns.

Formulas for different controls

Here are typical formulas for views and stored procedures:

Expand table

Control	Property	Formula	Description
Gallery or Table	Items	`DataSource`	You can further refine the table or view data source with a Filter and a StartsWith. The other generated query clauses are appended to the existing query.
Form	DataSource	`DataSource`	The table or view data source.
Submit button on a form	OnSelect	`DataSource.dboSPName({ args}); Refresh ('DataSource')`	The first `DataSource` in this formula is the stored procedure data source, which holds your stored procedure. The `DataSource` in the refresh formula is the view data source.
Delete button on a form	OnSelect	`SP DataSource.dboSPName({ args}); Refresh ('View DataSource')`	The first `DataSource` in this formula is the stored procedure data source, which holds your stored procedure. The `DataSource` in the refresh formula is the view data source.

Return code

Use this return code to get the result of a return statement.

Power Fx

```
<datasourceName>.<StoredprocedureName>({<paramName1: value, paramName2: value, ... >}).ReturnCode
```

Output parameters

Use the parameter name as it appears in the JSON payload.

```
Power Fx

<datasourceName>.<StoredprocedureName>({<paramName1: value, paramName2: value, ...
>}).OutputParameters.<parameterName>
```

Result Sets

You can use other tables by their name, like `Table1`, `Table2`, or `Table3`.

```
Power Fx

<datasourceName>.<StoredprocedureName>({<paramName1: value, paramName2: value, ...
>}).ResultSets.Table1
```

Dynamic results

Some complicated stored procedures return dynamic results. This result is common for stored procedures that use temporary tables. Power Apps can't easily determine the results ahead of time. So, the return is marked as *dynamic* and you can't access these results directly. First, provide a type.

You can access the data with the following data access example pattern.

Data access example

1. Pull the results into a variable named `MyDynamicValue`.
2. Pull `Table1` from that variable and put it into a variable named `table1`.

   > **Tip**
   >
   > This step isn't strictly necessary. It's useful, though, to put all the results in a variable and then pull out the parts you need later.

3. Iterate through `table1` and extract the JSON elements as named value pairs.
4. Match the names with those returned in the JSON payload.

5. To validate, open Power Apps monitor and look at the body section of the data node for a record.

Power Fx

```
Set(
    <MyDynamicValue>, // pull results into variable
    <datasourceName>.<StoredprocedureName>(
      { <paramName1>: "someString" }
    ).ResultSets
);
Set(
    table1, // put Table1 into table1
    <MyDynamicValue>.Table1
);
Set(
    TypedTable,
    ForAll(
        table1, // extract JSON from table1
        {
            BookID: Value(ThisRecord.BookID),
            BookName: Text(ThisRecord.BookName)
        }
    )
);
```

Connect to Twitter from Power Apps

Article • 12/16/2022

Twitter lets you post tweets and get tweets, timeline, friends, and followers from your Twitter account.

You can display this information in a label on your app. For example, you can add an input text box, ask the user to enter in some Tweet text, and then add a button that "posts" the tweet. You can use similar methods to get a tweet or search for a tweet, and then display the text in a label or gallery control in your app.

This topic shows you how to create the Twitter connection, use the Twitter connection in an app, and lists the available functions.

Prerequisites

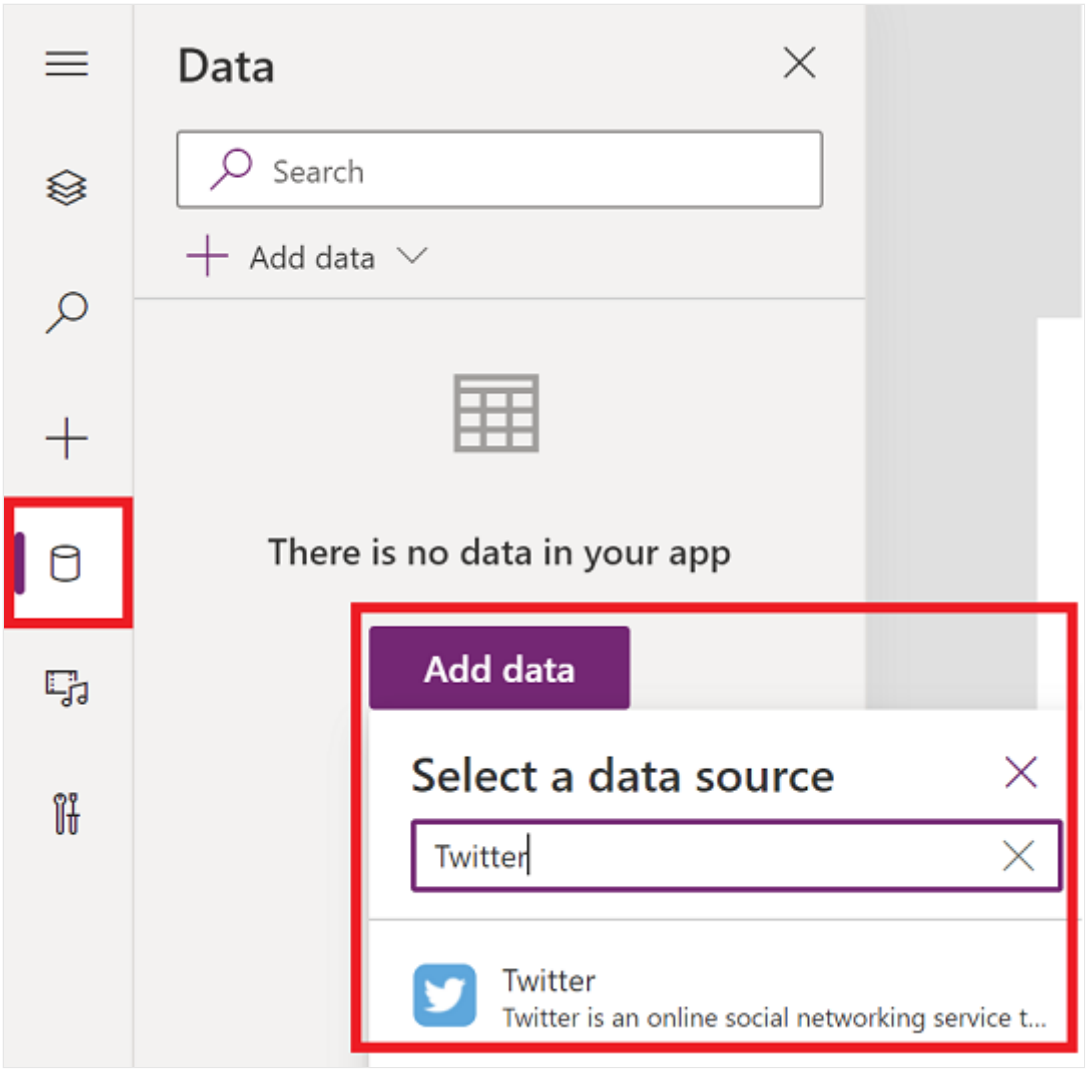
- Access to Power Apps
- Add the connection
- Create an app from a template, from data, or from scratch

Connect to Twitter

1. Start by creating a blank canvas app.

2. In the left-hand pane, select **Data** > **Add data**.

3. Select **New connection**, and then select **Twitter**:

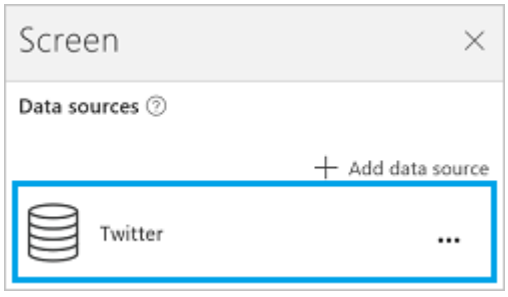


4. Select from the default shared application, or choose to bring your own application (along with Consumer Key/Consumer Secret).

5. Select **Connect**.

6. Choose , enter your Twitter sign in credentials, and then select **Authorize app**.

7. Select **Add Data Source**. Your connection appears under **Data sources**:



The Twitter connection has been created, and added to your app. Now, it's ready to be used.

Use the Twitter connection in your app

Show a timeline

1. On the **Insert** menu, select **Gallery**, and add any of the **With text** galleries.

2. Let's show some timelines:

   - To show the current user's timeline, set the **Items** property of the gallery to the following formulas:

     `Twitter.HomeTimeline().TweetText`

     `Twitter.HomeTimeline({maxResults:3}).TweetText`

   - To show another user's timeline, set the **Items** property of the gallery to the following formula:

     `Twitter.UserTimeline( *TwitterHandle* ).TweetText`

     Enter a Twitter handle in double quotation marks or an equivalent value. For example, enter `"satyanadella"` or `"powerapps"` directly in the formula expression.

   - Add a text input control named **Tweep**, and set its Default property to `Tweep.Text`. In the Tweep text box, type in a Twitter handle such as `satyanadella` (without quotation marks and without the @ symbol).

     In the gallery control, set the Items property to the following formula:

     `Twitter.UserTimeline(Tweep.Text, {maxResults:5}).TweetText`

     The gallery control automatically shows the tweets of the Twitter handler you type in.

     > **Tip**
     >
     > Some of these formulas use the **maxResults** argument to show the *x* number of most recent tweets in a timeline.

3. Set the gallery's **Items** property to `Twitter.HomeTimeline()`.

   With the gallery selected, the right-hand pane shows options for that gallery.

4. Select **TweetText** in the first list, select **TweetedBy** in the second list, and select **CreatedAt** in the third list.

   The gallery now shows the values of the properties you chose.

Show followers

1. Using a **With text** gallery, let's show some followers:

    - To show the current user's followers, set the **Items** property of the gallery to the following formula:

      `Twitter.MyFollowers()`

      `Twitter.MyFollowers({maxResults:3})`

    - To show another user's followers, set the **Items** property of the gallery to the following formula:

      `Twitter.Followers( *TwitterHandle* )`

      Enter a Twitter handle in double quotation marks or an equivalent value. For example, enter `"satyanadella"` or `"powerapps"` directly in the formula expression.

    - Add a text input control named **Tweep**, and set its Default property to `Tweep.Text`. In the Tweep text box, type in a Twitter handle such as `satyanadella` (without quotation marks and without the @ symbol).

      In the gallery control, set the Items property to the following formula:

      `Twitter.Followers(Tweep.Text, {maxResults:5})`

      The gallery control automatically shows who is following the Twitter handle you type in.

      > **Tip**
      >
      > Some of these formulas use the **maxResults** argument to show the *x* number of most recent tweets in a timeline.

2. Set the gallery's **Items** property to `Twitter.MyFollowers()`.

   With the gallery selected, the right-hand pane shows options for that gallery.

3. Select **UserName** in the second list, and select **FullName** in the third list.

   The gallery now shows the values of the properties you chose.

Show followed users

1. Using a **With text** gallery, let's show some followed users:

    - To show which users the current user is following, set the **Items** property of the gallery to the following formula:

      `Twitter.MyFollowing()`

      `Twitter.MyFollowing({maxResults:3})`

    - To show which users another user is following, set the **Items** property of the gallery to the following formula:

      `Twitter.Following( *TwitterHandle* )`

      Enter a Twitter handle in double quotation marks or an equivalent value. For example, enter `"satyanadella"` or `"powerapps"` directly in the formula expression.

    - Add a text input control named **Tweep**, and set its Default property to `Tweep.Text`. In the Tweep text box, type in a Twitter handle such as `satyanadella` (without quotation marks and without the @ symbol).

      In the gallery control, set the Items property to the following formula:

      `Twitter.Following(Tweep.Text, {maxResults:5})`

      The gallery control automatically shows the other handles you are following.

      With the gallery selected, the right-hand pane shows options for that gallery.

2. Select **Description** in the **Body1** list, **UserName** in the **Heading1** list, and **FullName** in the **Subtitle1** list.

    The gallery now shows the values of the properties you chose.

Show information about a user

Add a label, and then set its **Text** property to one of these formulas:

- `twitter.User( *TwitterHandle* ).Description`
- `twitter.User( *TwitterHandle* ).FullName`
- `twitter.User( *TwitterHandle* ).Location`
- `twitter.User( *TwitterHandle* ).UserName`
- `twitter.User( *TwitterHandle* ).FollowersCount`
- `twitter.User( *TwitterHandle* ).FriendsCount`

- `twitter.User( *TwitterHandle* ).Id`
- `twitter.User( *TwitterHandle* ).StatusesCount`

Enter a Twitter handle in double quotation marks or an equivalent value. For example, enter `"satyanadella"` or `"powerapps"` directly in the formula expression.

Or, you can use an input text control to type in a Twitter handle, just as we have throughout this topic.

Search tweets

1. Using a **With text** gallery, set its **Items** property to the following formula:

   `Twitter.SearchTweet( *SearchTerm* ).TweetText`

   Enter a *SearchTerm* in double quotation marks or by referring to an equivalent value. For example, enter `"PowerApps"` or `"microsoft"` directly in the formula.

   Or, you can use an **Input text** control to specify a search term, just as we have throughout this topic.

   > **Tip**
   >
   > Show the first five results by using maxResults:

   `Twitter.SearchTweet(SearchTerm.Text, {maxResults:5}).TweetText`

2. Set the gallery's **Items** property to `Twitter.SearchTweet(SearchTerm.Text, {maxResults:5})`.

   With the gallery selected, the right-hand pane shows options for that gallery.

3. Select **TweetText** in the first list, **TweetedBy** in the second list, and **CreatedAt** in the third list.

   The gallery now shows the values of the properties you chose.

Send a tweet

1. Add a text input control, and then rename it **MyTweet**.
2. Add a button, and then set its **OnSelect** property to the following formula:
   `Twitter.Tweet("",{tweetText: MyTweet.Text})`
   Example: `Twitter.Tweet("",{tweetText:"Sample tweet!"})`

3. Press F5, or select the Preview button (). Type some text into **MyTweet**, and then select the button to tweet the text that you entered.
4. Press Esc to return to the default workspace.

View the available functions

This connection includes the following functions:

Function Name	Description
UserTimeline	Retrieves a collection of the most recent tweets posted by the specified user
HomeTimeline	Retrieves the most recent tweets and re-tweets posted me and my followers
SearchTweet	Retrieves a collection of relevant tweets matching a specified query
Followers	Retrieves users following the specified user
MyFollowers	Retrieves users who are following me
Following	Retrieves users who the specified user is following
MyFollowing	Retrieves users that I am following
User	Retrieves details about the specified user (example: user name, description, followers count, etc.)
Tweet	Tweet
OnNewTweet	Triggers a workflow when a new tweet is posted which matches your search query

UserTimeline

Get user timeline: Retrieves a collection of the most recent tweets posted by the specified user

Input properties

Name	Data Type	Required	Description
userName	string	yes	Twitter handle
maxResults	integer	no	Maximum number of tweets to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description
TweetText	string	Yes	
TweetId	string	No	
CreatedAt	string	No	
RetweetCount	integer	Yes	
TweetedBy	string	Yes	
MediaUrls	array	No	

HomeTimeline

Get home timeline: Retrieves the most recent tweets and re-tweets posted me and my followers

Input properties

Name	Data Type	Required	Description
maxResults	integer	no	Maximum number of tweets to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description
TweetText	string	Yes	
TweetId	string	No	
CreatedAt	string	No	
RetweetCount	integer	Yes	
TweetedBy	string	Yes	
MediaUrls	array	No	

SearchTweet

Search tweet: Retrieves a collection of relevant tweets matching a specified query

Input properties

Name	Data Type	Required	Description
searchQuery	string	yes	Query text (you may use any Twitter supported query operators: https://www.twitter.com/search)
maxResults	integer	no	Maximum number of tweets to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description
TweetText	string	Yes	
TweetId	string	No	
CreatedAt	string	No	
RetweetCount	integer	Yes	
TweetedBy	string	Yes	
MediaUrls	array	No	

Followers

Get followers: Retrieves users following the specified user

Input properties

Name	Data Type	Required	Description
userName	string	yes	Twitter handle of the user
maxResults	integer	no	Maximum number of users to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description
FullName	string	Yes	
Location	string	Yes	

Property Name	Data Type	Required	Description
Id	integer	No	
UserName	string	Yes	
FollowersCount	integer	No	
Description	string	Yes	
StatusesCount	integer	No	
FriendsCount	integer	No	

MyFollowers

Get my followers: Retrieves users who are following me

Input properties

Name	Data Type	Required	Description
maxResults	integer	no	Maximum number of users to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description
FullName	string	Yes	
Location	string	Yes	
Id	integer	No	
UserName	string	Yes	
FollowersCount	integer	No	
Description	string	Yes	
StatusesCount	integer	No	
FriendsCount	integer	No	

Following

Get following: Retrieves users who the specified user is following

Input properties

Name	Data Type	Required	Description
userName	string	yes	Twitter handle of the user
maxResults	integer	no	Maximum number of users to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description
FullName	string	Yes	
Location	string	Yes	
Id	integer	No	
UserName	string	Yes	
FollowersCount	integer	No	
Description	string	Yes	
StatusesCount	integer	No	
FriendsCount	integer	No	

MyFollowing

Get my following: Retrieves users that I am following

Input properties

Name	Data Type	Required	Description
maxResults	integer	no	Maximum number of users to retrieve, e.g. {maxResults:5}

Output properties

Property Name	Data Type	Required	Description

Property Name	Data Type	Required	Description
FullName	string	Yes	
Location	string	Yes	
Id	integer	No	
UserName	string	Yes	
FollowersCount	integer	No	
Description	string	Yes	
StatusesCount	integer	No	
FriendsCount	integer	No	

User

Get user: Retrieves details about the specified user (example: user name, description, followers count, etc.)

Input properties

Name	Data Type	Required	Description
userName	string	yes	Twitter handle of the user

Output properties

Property Name	Data Type	Required	Description
FullName	string	Yes	
Location	string	Yes	
Id	integer	No	
UserName	string	Yes	
FollowersCount	integer	No	
Description	string	Yes	
StatusesCount	integer	No	

Property Name	Data Type	Required	Description
FriendsCount	integer	No	

Tweet

Post a new tweet: Tweet

Input properties

Name	Data Type	Required	Description
tweetText	string	no	Text to be posted e.g. {tweetText:"hello"}
body	string	no	Media to be posted

Output properties

Property Name	Data Type	Required	Description
TweetId	string	Yes	

OnNewTweet

When a new tweet appears: Triggers a workflow when a new tweet is posted which matches your search query

Input properties

Name	Data Type	Required	Description
searchQuery	string	yes	Query text (you may use any Twitter supported query operators: https://www.twitter.com/search)

Output properties

Property Name	Data Type	Required	Description
value	array	No

Add data connections to canvas apps

Article • 10/04/2023

In Power Apps, add a data connection to an existing canvas app or to an app that you're building from scratch. Your app can connect to SharePoint, Microsoft Dataverse, Salesforce, OneDrive, or many other data sources.

Your next step after this article is to display and manage data from that data source in your app, as in these examples:

- Connect to OneDrive, and manage data in an Excel workbook in your app.
- Connect to Twilio, and send an SMS message from your app.
- Connect to Dataverse, and update a table from your app.
- Connect to SQL Server, and update a table from your app.

Prerequisites

Sign up for Power Apps, and then sign in by providing the same credentials that you used to sign up.

Add data source

1. Create a blank canvas app.
2. From the app authoring menu in Power Apps Studio, select **Data** > **Add data**.
3. Expand **Connectors**, and if the list of connections includes the one that you want, select it to add it to the app. Otherwise, skip to the next step. To connect to a table in Microsoft Dataverse instead, choose a table from the list of tables.
4. To create a new connection, search for or select a connector such as SharePoint.
5. Select **Add a connection** to both create the connection and add it to your app.

   Some connectors, such as **Office 365 Outlook**, require no additional steps, and you can show data from them immediately. Other connectors prompt you to provide credentials, specify a particular set of data, or perform other steps. For example, SharePoint and SQL Server require additional information before you can use them. With Dataverse, you can change the environment before you select a table.

Identify or change a data source

If you're updating an app, you might need to identify or change the source of data that appears in a gallery, a form, or another control. For example, you might need to identify a data source as you update an app that someone else created or that you created long ago.

1. Select the control, such as a gallery, for which you want to identify or change the data source.

   The name of the data source appears on the **Properties** tab of the right-hand pane.

2. To show more information about the data source or to change it, select the down arrow next to its name.

   More information about the current data source appears, and you can select or create another source.

Next steps

- To show and update data in a source such as Excel, SharePoint, Dataverse, or SQL Server, add a gallery, and add a form.
- For data in other sources, use connector-specific functions such as those for Office 365 Outlook, Twitter, and Microsoft Translator.

Manage connections in canvas apps

08/27/2025

In powerapps.com, create a connection to one or more data sources, delete a connection, or update its credentials.

Your canvas app's data connection can connect to SharePoint, SQL Server, Office 365, OneDrive for Business, Salesforce, Excel, and many other data sources.

Your next step after this article is to display and manage data from the data source in your app, as in these examples:

- Connect to OneDrive for Business, and manage data in an Excel workbook in your app.
- Update a list on a SharePoint site.
- Connect to SQL Server, and update a table from your app.
- Send email in Office 365.
- Send a tweet.
- Connect to Twilio, and send an SMS message from your app.

Prerequisites

1. Sign up for Power Apps.
2. Sign in to make.powerapps.com using the same credentials that you used to sign up.

Background on data connections

Most canvas apps use external information called **Data Sources** that is stored in cloud services. A common example is a table in an Excel file stored in OneDrive for Business. Apps are able to access these data sources by using **Connections**.

The most common type of data source is the table, which you can use to retrieve and store information. You can use connections to data sources to read and write data in Microsoft Excel workbooks, Microsoft Lists, SQL tables, and many other formats, which can be stored in cloud services like OneDrive for Business, DropBox, and SQL Server.

There are other kinds of data sources that aren't tables, such as email, calendars, twitter, and notifications.

Using the **Gallery**, **Display form**, and **Edit form** controls, it's easy to create an app that reads and writes data from a data source. To get started, read the article Understand data forms.

In addition to creating and managing connections in powerapps.com, you also create connections when you do these tasks:

- Automatically generate an app from data, such as a list created using Microsoft Lists.
- Update an existing app, or create one from scratch as add a connection describes.
- Open an app that another user created and shared with you.

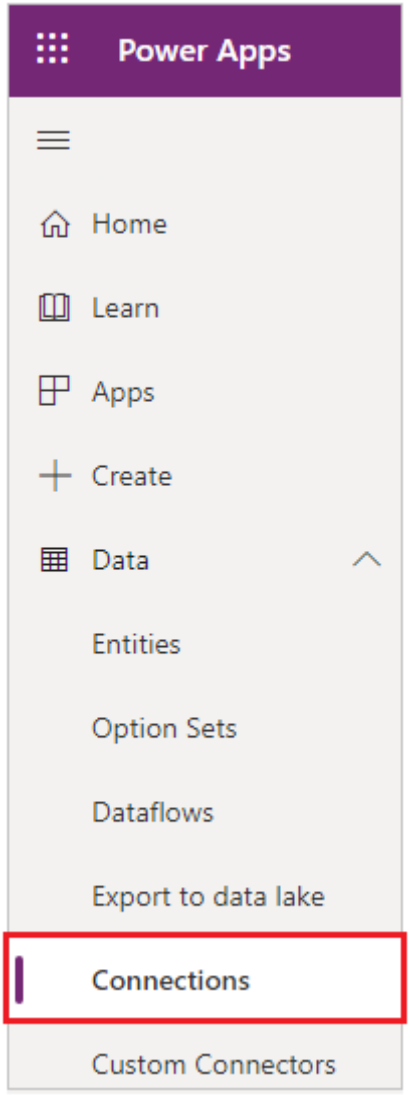
How data connections are used when running the app

When a canvas app runs, Power Apps attempts to locate and reuse an existing connection. If no suitable connection is found, a new one is created for the user based on the connection information stored in the app. This newly created connection may differ from the one originally used during app authoring. This behavior may differ from how other products in the Power Platform handle connections.

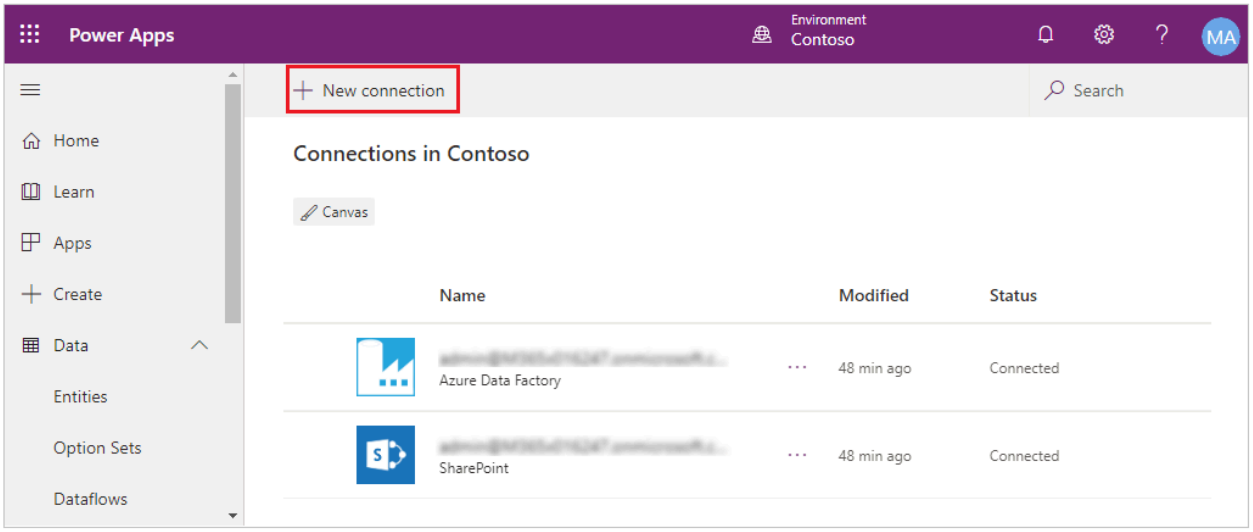
> **Note**
>
> If you want to use Power Apps Studio instead, open the **File** menu, and then click or tap **Connections**, powerapps.com opens so that you can create and manage connections there.

Create a new connection

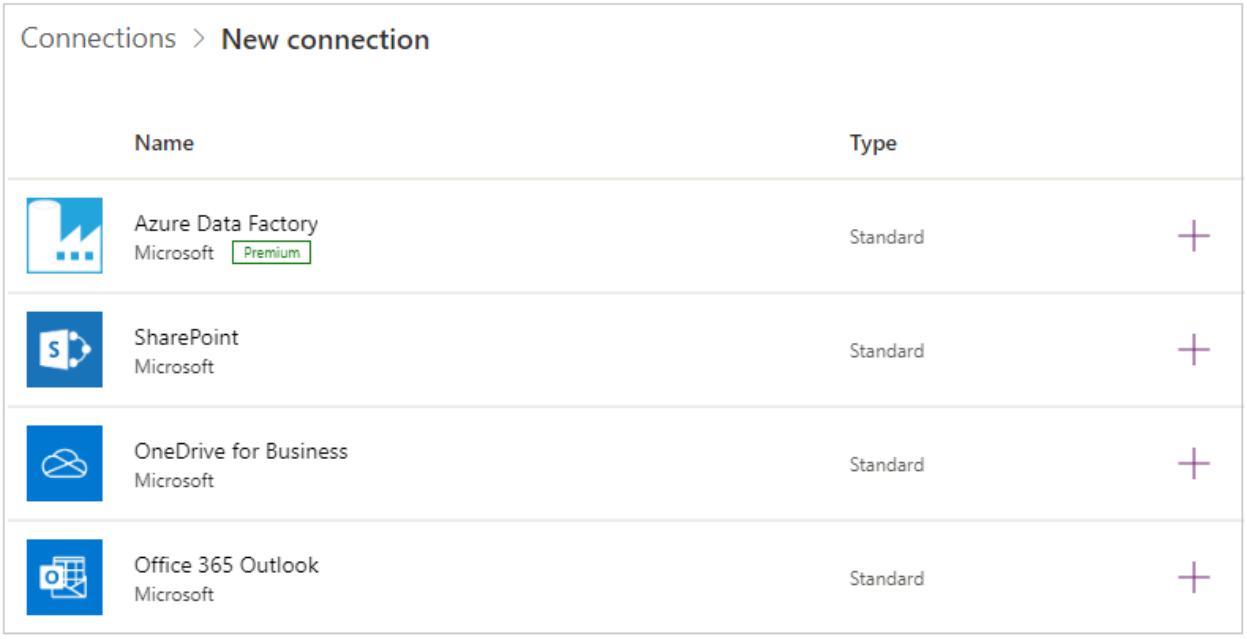
1. If you haven't already done so, log in to make.powerapps.com.
2. In the left navigation, expand **Data** and select **Connections**.



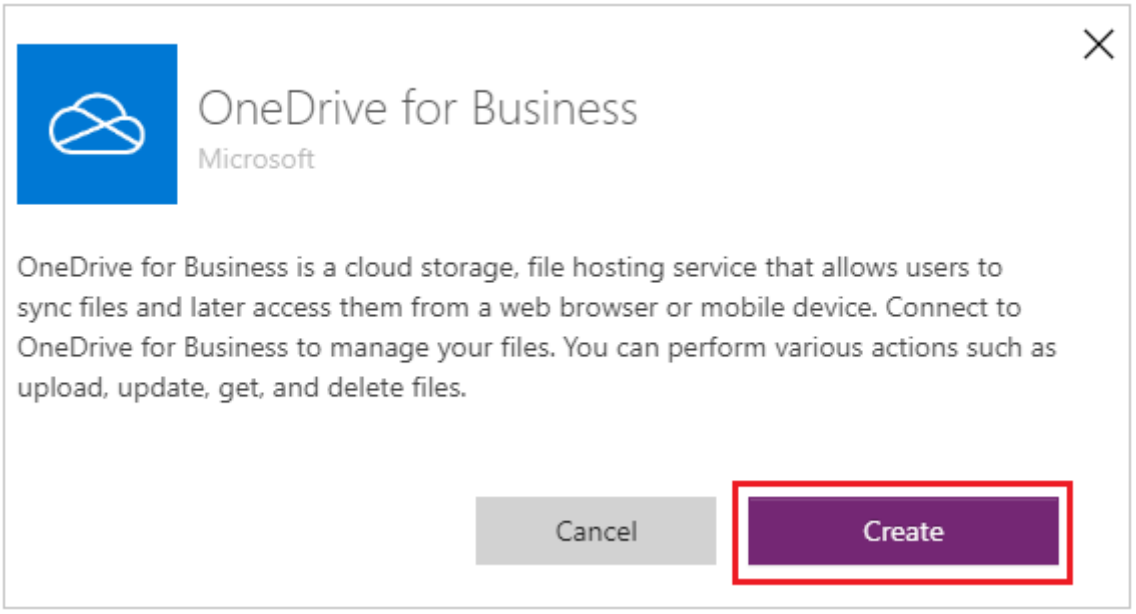
3. Select **New connection**.



4. Select a connector in the list that appears, and then follow the prompts.



5. Select the **Create** button.



6. Follow the prompts. Some connectors prompt you to provide credentials, specify a particular set of data, or perform other steps. Others such as **Microsoft Translator**, don't.

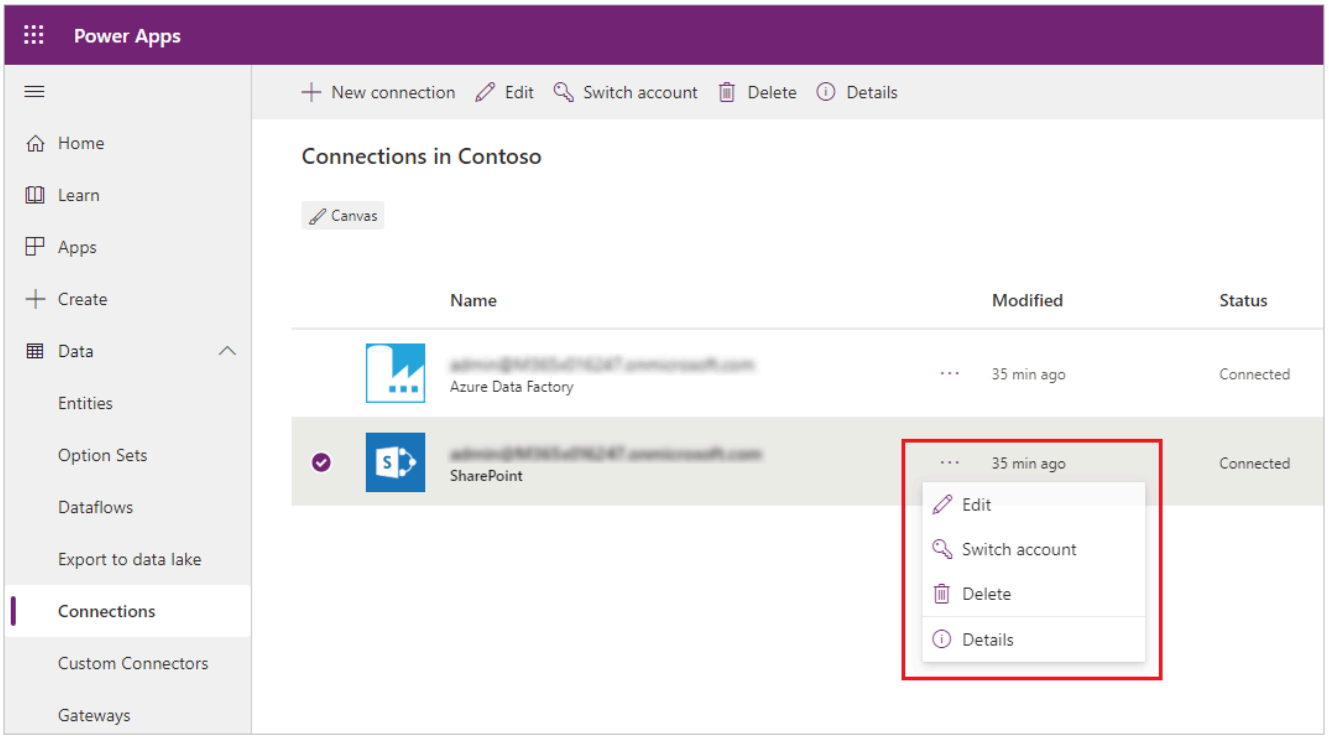
   For example, these connectors require additional information before you can use them.

   - SharePoint
   - SQL Server

The new connector appears under **Connections**, and you can add it to an app.

Update or delete a connection

In the list of connections, find the connection that you want to update or delete, and then select the ellipsis (...) on the right of the connection.



- To update the credentials for a connection, select the key icon, and then provide credentials for that connection.
- To delete the connection, select delete.
- Select the information icon to see the connection details.

Consent dialog fine-grained permissions

The consent dialog presents **fine-grained** permissions to end users. Instead of asking the user to give permissions to all actions a connector can perform, the consent dialog lists the specific permissions that the app uses. The operations that an app uses are captured and stored in the app metadata when app is saved. For example, if an app is published with the specific Read action, then it will initially just request permission for the Read action. If then the author subsequently adds **Create**, **Update**, and **Delete** record actions then the consent dialog will be presented to the user again for the aggregated permissions of **Read**, **Create**, **Update**, and **Delete**. If the author subsequently removes the **Delete** records action, then the consent dialog isn't presented again. The permissions continue with the maximum set of actions that have ever been used in the app at any point. If you wish to publish an app that only shows reduced permissions, the app must be republished under a different name.

The exception to this rule is for actions used in a Power Automate Flow that is embedded in a Power App. In this case **all** the actions are always shown for the actions used by a Power Automate flow.

Manage the consent dialog appearance for custom connectors using Microsoft Entra ID OAuth

By default, when end-users launch canvas apps they're presented a connection consent dialog before they're able to access the app experience for the first time. It's possible for admins to suppress this consent dialog for select connectors:

- Microsoft First Party connectors (like SharePoint, Office 365 Users) and
- Custom connectors using either Microsoft Entra ID OAuth or NoAuth (No Authentication)

Suppress consent dialog for apps that use custom connectors using Microsoft Entra ID OAuth

To suppress consent dialog for apps created using Power Apps that connect through custom connectors using Microsoft Entra ID OAuth/NoAuth, follow the below steps.

Step 1. Provision Microsoft's Azure API connections service principal in your Microsoft Entra tenant

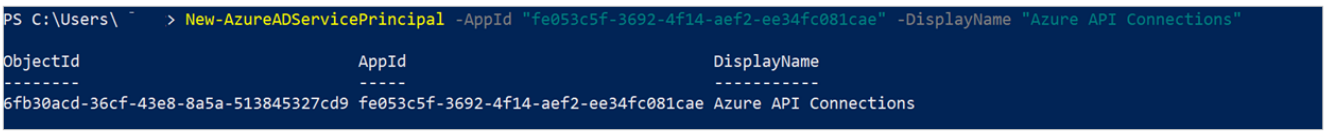
Microsoft's Azure API connectors service is used by all Power Apps using connectors. Provisioning this service in your tenant is a prerequisite for your custom applications, and custom connectors to pre-authorize this service to exercise single-sign-on capabilities with your custom applications and allow Power Apps to suppress the consent dialog.

A tenant admin must run the following PowerShell commands:

Powershell

```
Connect-MgGraph -Scope Application.ReadWrite.All -TenantId <target tenant id>
New-MgServicePrincipal -AppId "fe053c5f-3692-4f14-aef2-ee34fc081cae" -DisplayName
"Azure API Connections"
```

Example successful output:

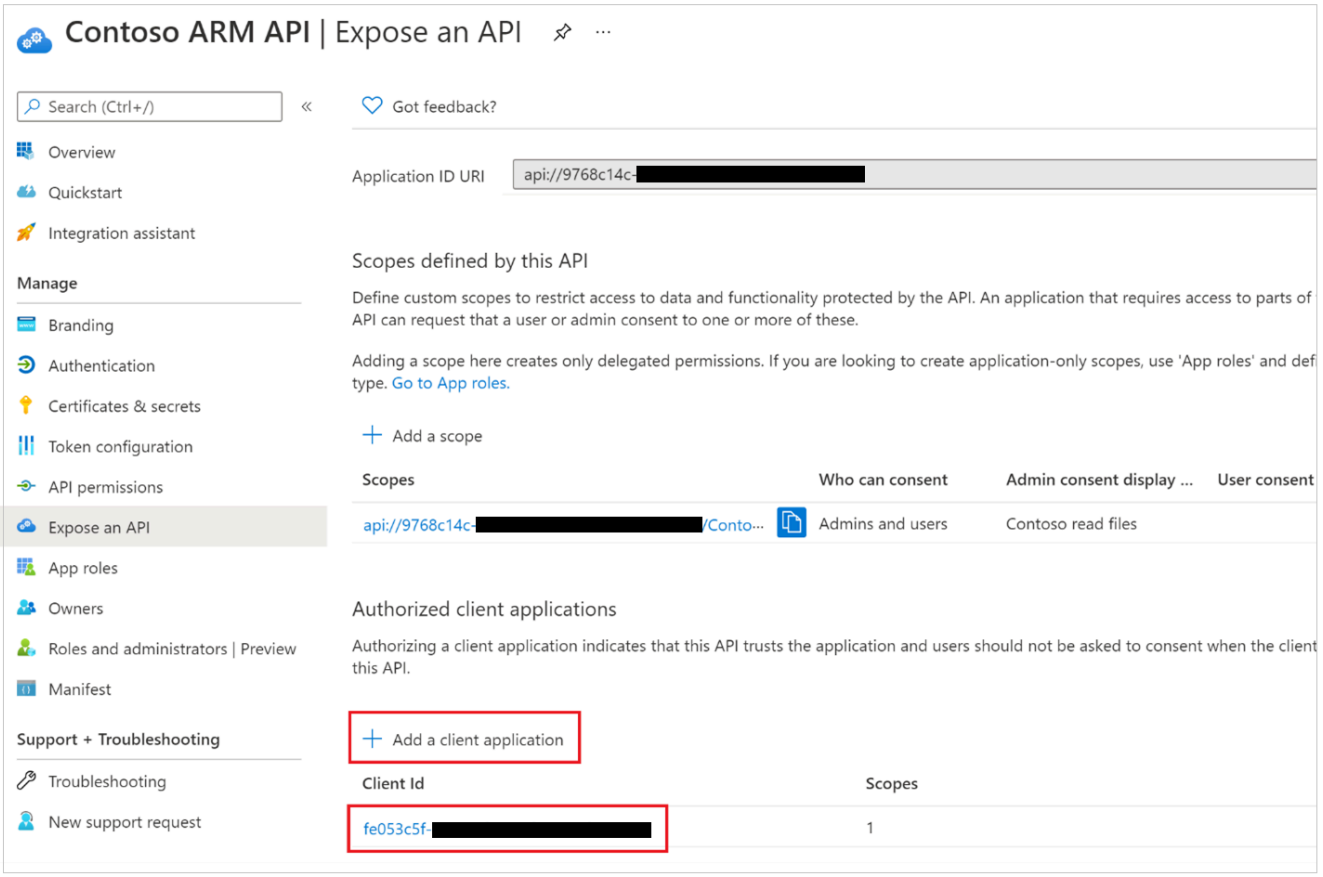


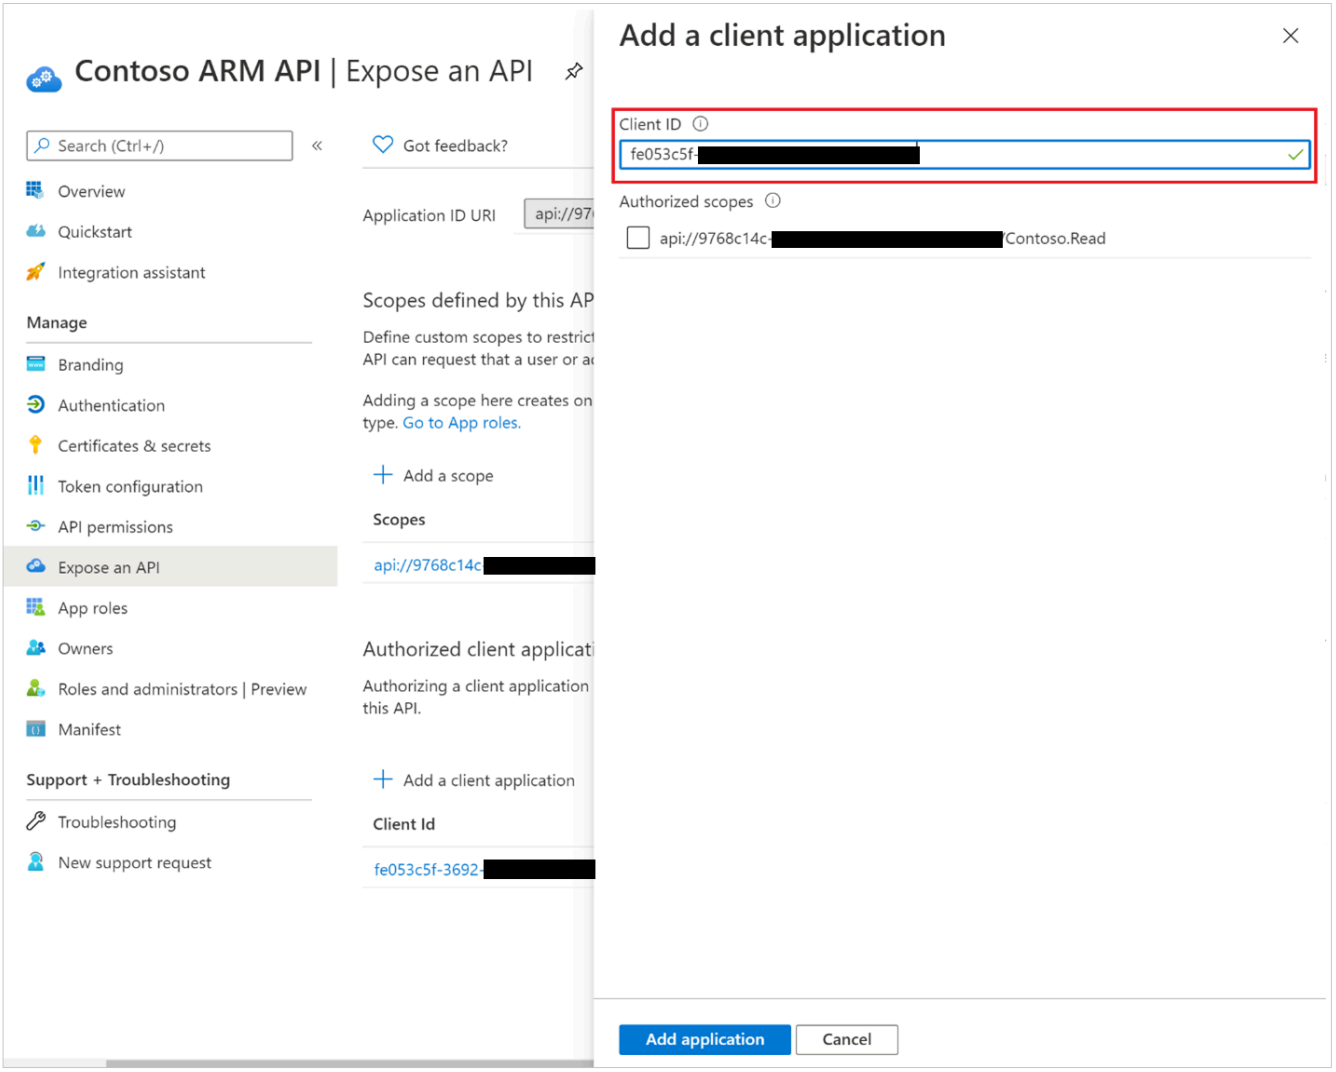
Step 2. Pre-authorize Microsoft's Azure API connections service principal in your Microsoft Entra app

For each custom connector where consent is expected to be suppressed, authorize "Microsoft's Azure API Connections" service principal to one of the scopes defined in your app.

The owner of the Microsoft Entra custom application used by a custom connector must add the app ID "fe053c5f-3692-4f14-aef2-ee34fc081cae" to one of the application scopes. Any scope can be created and used for single-sign-on to succeed.

To set the scope using Azure portal, go to Azure portal > Microsoft Entra ID > App Registrations > Select the relevant app > Expose an API > Add a client application > Add the app ID "fe053c5f-3692-4f14-aef2-ee34fc081cae" to one of the application scopes.





Step 3. Grant admin consent the client third-party Microsoft Entra app

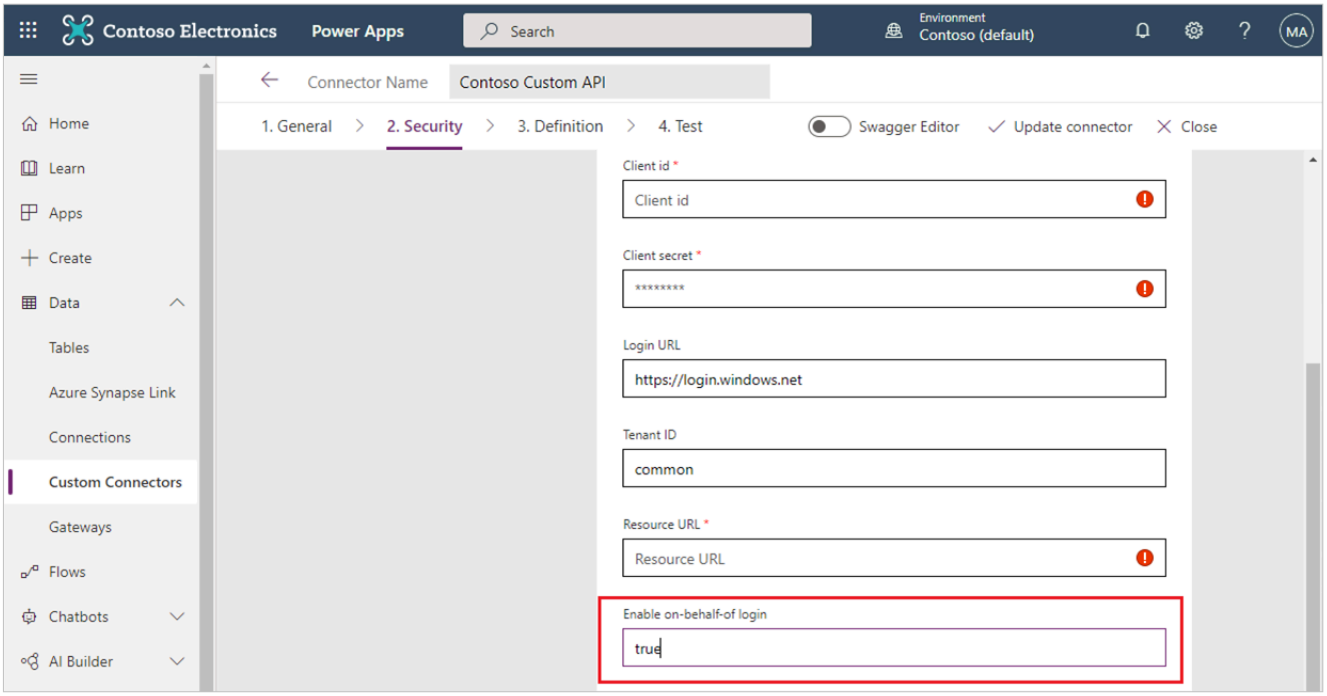
For each custom connector using OAuth/NoAuth where consent is expected to be suppressed, an admin must use Microsoft Entra's grant tenant-wide admin consent to an application.

> **Note**
>
> Admins have granular control on which custom applications, and the corresponding custom connector consent may be suppressed.

Step 4. Update custom connector in Power Platform to attempt single-sign-on

For each custom connector using OAuth/NoAuth where consent is expected to be suppressed, a user with edit permissions on the custom connector must change the "Enable on-behalf-of login" value to "true".

The owner of the custom connector must choose to edit the connector, go to the **Security** section, and change the value in **Enable on-behalf-of login** from "false" to "true".



Step 5. Admin configures consent bypass for the app

In addition to the admin consent granted on a custom application in Microsoft Entra ID, which is used by a custom connector, an admin must also configure an app to bypass consent. For each app where consent is expected to be bypassed an admin must run the following command:

Powershell

```
Set-AdminPowerAppApisToBypassConsent -AppName <Power Apps app id>
```

Remove consent suppression for apps that use custom connectors using Microsoft Entra ID OAuth/NoAuth

To remove consent suppression for a custom connector, an admin must perform at least one of the following actions:

1. Remove the tenant-wide admin consent grant to the application in Azure: Microsoft Entra's grant tenant-wide admin consent to an application.
2. Use the following Power Apps admin cmdlet to disable Power Apps' attempt to suppress the consent dialog. Clear-AdminPowerAppApisToBypassConsent

Rename Power Apps action-based data sources

Article • 12/16/2022

A change in the display name of a connector in Power Apps may cause errors in formulas used by the app. This problem takes extra efforts to update existing formulas with manual intervention, and name changes.

With the ability to rename action-based data sources, you can save the extra efforts required to fix the formulas affected by the connector name change.

Action-based and tabular data sources

Before you start using this feature, it's important to understand the difference between action-based and tabular data sources.

Action-based data sources use the data source, or the service name in the formula. Tabular data sources use the name of the table instead.

For example, Azure DevOps is action-based connector, while Excel is tabular data source.

For example, when you reference an Azure DevOps instance, the formula uses Azure DevOps as the data source name

When using Excel, the data source name in formula uses the table name (instead of the connector, or the service name):

How are data source names generated?

Data source names are generated from the display name of the connection they're based on. The first instance of a data source name in an app is typically the exact name

of the connection. For instance, if you use “AzureDevOps” data source, the name of the connection will be “AzureDevOps”. And, if you add another “AzureDevOps” data source to the same application, the second data source will be named “AzureDevOps_1”.

Renamed connectors

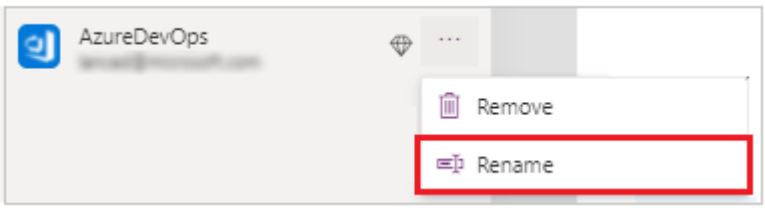
Occasionally, a connector goes through a change in the display name. For example, from “OldConnector” to “NewConnector”.

Existing apps will continue to work even though your data source names say “OldConnector”. This behavior is because your data sources still point (under the covers) to the correct connector type.

However, if you drop your existing data source in the app, and add it again, the new data source will be named “NewConnector”. Your formulas will still reference “OldConnector” though, causing formula errors wherever this data source name exists.

Fixing broken formula references to data source names

Using the new “Rename” feature, you can rename your action-based connectors and fix up your formulas automatically.



To fix this kind of problem, rename the data source from the new display name back to the old display name.

For example, rename the data source display name from “New Connector” back to “Old Connector”. Once you rename, all your formula references will reconnect and work as before. Your application will now work correctly. You can save the app changes and publish the new version.

Optional – use new data source name (Recommended)

After your data source name and formulas are in sync, you can also rename your data source again to bring it in line with the new connector name.

For example, you can rename your data source to be “NewConnector”. This rename updates all formula references to use the new name. We recommended this approach because if you ever have to drop your data source again, then readding the data source will be based on the newer connector display name. This step will help you avoid future issues.

This approach works because the data source display name, and the formula referenced data sources are in sync. In other words, exactly same display name. Renaming data sources in the formulas can’t happen before you rename your data source back because the data source display name, and the formula referenced data sources aren’t the same.

Limitations

This rename capability is limited to action-based connectors. It doesn’t work for tabular data sources. Tabular data sources use the name of the tables they’re pointing to (as opposed to the general name of the service hosting them).

Query limitations: Delegation and query limits

Power Apps works best with a back-end data source when a Power Fx query fully translates into an equivalent query that runs on the data source. Power Apps sends a query the data source understands, the data source runs the query, and Power Apps gets the results. For example, the data source filters the data and only returns the rows that meet the filter criteria. When this process happens, Power Apps **delegates** the query to the data source.

But Power Fx queries can't always translate into equivalent queries on every data source. For example, Dataverse supports more query features than Excel. Dataverse supports the 'in' (membership) query operator, but Excel doesn't. A query is **nondelegable** if it uses a feature the data source doesn't support. If any part of a query expression is nondelegable, Power Apps doesn't delegate any part of the query.

When a query is nondelegable, Power Apps gets the first 500 records from the data source and then runs the actions in the query. You can increase this limit to 2,000 records. Changing the limit **Power Apps limits the result size to 500 records to keep your app performing well.** Larger result sets can cause performance problems for your app and Power Apps.

But this limitation can be a problem because the query might return incorrect results if the data source has more than 500 or 2,000 records. For example, if your data source has 10 million records and your query needs to work on the last part of the data, like family names that start with 'Z', and your query uses a nondelegable operator like distinct, you only get the first 500 or 2,000 records. So, you get incorrect results.

Create your Power Fx queries by using the delegable tables for your data source. Only use query functions that can be delegated. It's the only way to keep your app performing well and to make sure users get all the information they need.

Pay attention to delegation warnings that show where delegation isn't possible. If you work with small data sets (fewer than 500 records), you can use any data source and formula because the app processes data locally if the formula isn't delegated.

> ⓘ **Note**
>
> Delegation warnings help you manage your app so it returns correct results. If the data in your data source exceeds 500 records and a function isn't delegated, Power Fx marks the formula with a blue underline.

Delegable data sources

Delegation works only with certain tabular data sources. If a data source supports delegation, its connector documentation explains that support. These popular tabular data sources support delegation:

- Power Apps delegable functions and operations for Microsoft Dataverse
- Power Apps delegable functions and operations for SharePoint
- Power Apps delegable functions and operations for SQL Server
- Power Apps delegable functions and operations for Salesforce

Imported Excel workbooks (by using the **Add static data to your app** data source), collections, and tables stored in context variables don't need delegation. This data is already in memory, so you use the full Power Apps language.

Delegable functions

Use only formulas that can be delegated. This article lists formula elements that can be delegated. Every data source is different, and not all data sources support all these elements. Check for delegation warnings in your formula.

Filter functions

You can delegate **Filter**, **Search**, **First**, and **LookUp**.

Within the **Filter** and **LookUp** functions, use these functions with columns of the table to select the appropriate records:

- **And** (including **&&**), **Or** (including **||**), **Not** (including **!**)
- **In** > [!NOTE]

  > In is only delegated for columns on the base data source. For example, if the data source is the **Accounts** table, `Filter(Accounts, Name in ["name1", "name2"])` delegates to the data source for evaluation. But `Filter(Accounts, PrimaryContact.Fullname in ["name1", "name2"])` isn't delegated because the **Full name** column is on a different table (**PrimaryContact**) than **Accounts**. The expression is evaluated locally.

- =, <>, >=, <=, >, <
- +, -
- TrimEnds

- **IsBlank**
- **StartsWith**, **EndsWith**
- Constant values that are the same across all records, like control properties, and global and context variables.

You can also use parts of your formula that evaluate to a constant value for all records. For example, **Left(Language(), 2)**, **Date(2019, 3, 31)**, and **Today()** don't depend on any columns of the record, so they return the same value for all records. These values are sent to the data source as a constant and don't block delegation.

The previous list doesn't include these notable items:

- **If**
- *, /, **Mod**
- Column casting operations: **Text**, **Value**
- **Concatenate** (including **&**)
- **ExactIn**
- String manipulation functions: **Lower**, **Upper**, **Left**, **Mid**, **Len**, ...
- Signals: **Location**, **Acceleration**, **Compass**, ...
- Volatiles: **Rand**, ...
- Collections

Delegation and collections

When you use `With`, `UpdateContext`, or `Set`, these functions create collections internally. Collections are a static in-memory list of records and can't participate in delegation. You don't see a delegation warning.

Query limitations

Lookup and expand levels

Power Apps lets you use up to two lookup levels. A Power Fx query expression can include a maximum of two lookup functions to maintain performance. When a query expression includes a lookup, Power Apps first queries the base table, then runs a second query to expand the first table with the lookup information. One additional level beyond this is supported as the maximum. For offline scenarios, only one level of lookup expand is supported.

You can expand or join up to 20 entities in a single query. If you need to join more than 20 tables in one query, try creating a view on the data server if possible.

Expression evaluation - property of entity must be on left side 'LHS' of equality operator

Put the property of an entity to be compared on the left hand side (LHS) of an equation. For example, in the following expression, the entity property **'Business unit ID'.Name** is on the LHS, and the expression works:

Power Fx

```
Filter(
        Budgets,
        'Business unit ID'.Name = LookUp(
            Users,
            'Primary Email' = User().Email,
            'Business Unit'
        ).Name,
        DataCardValue37.Selected.'Date Range String'='Date Range String'
    )
```

However, this expression doesn't work:

Power Fx

```
 Filter(
        Budgets,
        LookUp(
            Users,
            'Primary Email' = User().Email,
            'Business Unit'
        ).Name = 'Business unit ID'.Name,
        'Date Range String'=DataCardValue37.Selected.'Date Range String'
    )
```

Sorting functions

Sort and SortByColumns can be delegated.

In **Sort**, the formula can only be the name of a single column and doesn't include other operators or functions.

Aggregate functions

Some aggregate functions can be delegated based on back-end support. Functions like Sum, Average, Min, and Max can be delegated. Counting functions, like CountRows and Count, can also be delegated. However, RemoveIf and UpdateIf have delegation restrictions. Only a

limited number of data sources support delegation for these functions. For more information, see the Delegation list.

Nondelegable functions

All other functions can't delegate. Notable functions include:

- **FirstN**, **Last**, **LastN**
- **Choices**
- **Concat**
- **Collect**, **ClearCollect**
- **GroupBy**, **Ungroup**

Nondelegable limits

Formulas that can't be delegated are processed locally. Local processing lets you use the full Power Apps formula language. But there's a tradeoff: all the data comes to the device first, which can mean getting a large amount of data over the network. This process can take time and make your app seem slow or unresponsive.

To avoid this problem, Power Apps limits the amount of data that can be processed locally to 500 records by default. This limit lets you use small data sets completely and work with large data sets by seeing partial results.

Be careful when using this feature because it can confuse users. For example, if you use the **Filter** function with a selection formula that can't be delegated over a data source with a million records, only the first 500 records are scanned. If the record you want is record 501 or 500,001, **Filter** doesn't find or return it.

Aggregate functions can also be confusing. For example, if you use **Average** over a column in that same million-record data source, **Average** can't be delegated because the expression isn't delegated (see the earlier note). Only the first 500 records are averaged. If you're not careful, a user might think a partial answer is the complete answer.

Changing the limit

The default number of records is 500, but you can change this number for your app:

1. Select **Settings**.
2. Under **General**, change the **Data row limit** setting from 1 to 2,000.

In some cases, 2,000, 1,000, or 1,500 records is enough for your scenario. You can increase this number to fit your needs, but as you do, your app's performance can degrade, especially for wide tables with many columns. It's still best to delegate as much as possible.

To make sure your app scales to large data sets, set this value to 1. Anything that can't be delegated returns a single record, which is easy to detect when testing your app. This helps you avoid surprises when moving a proof-of-concept app to production.

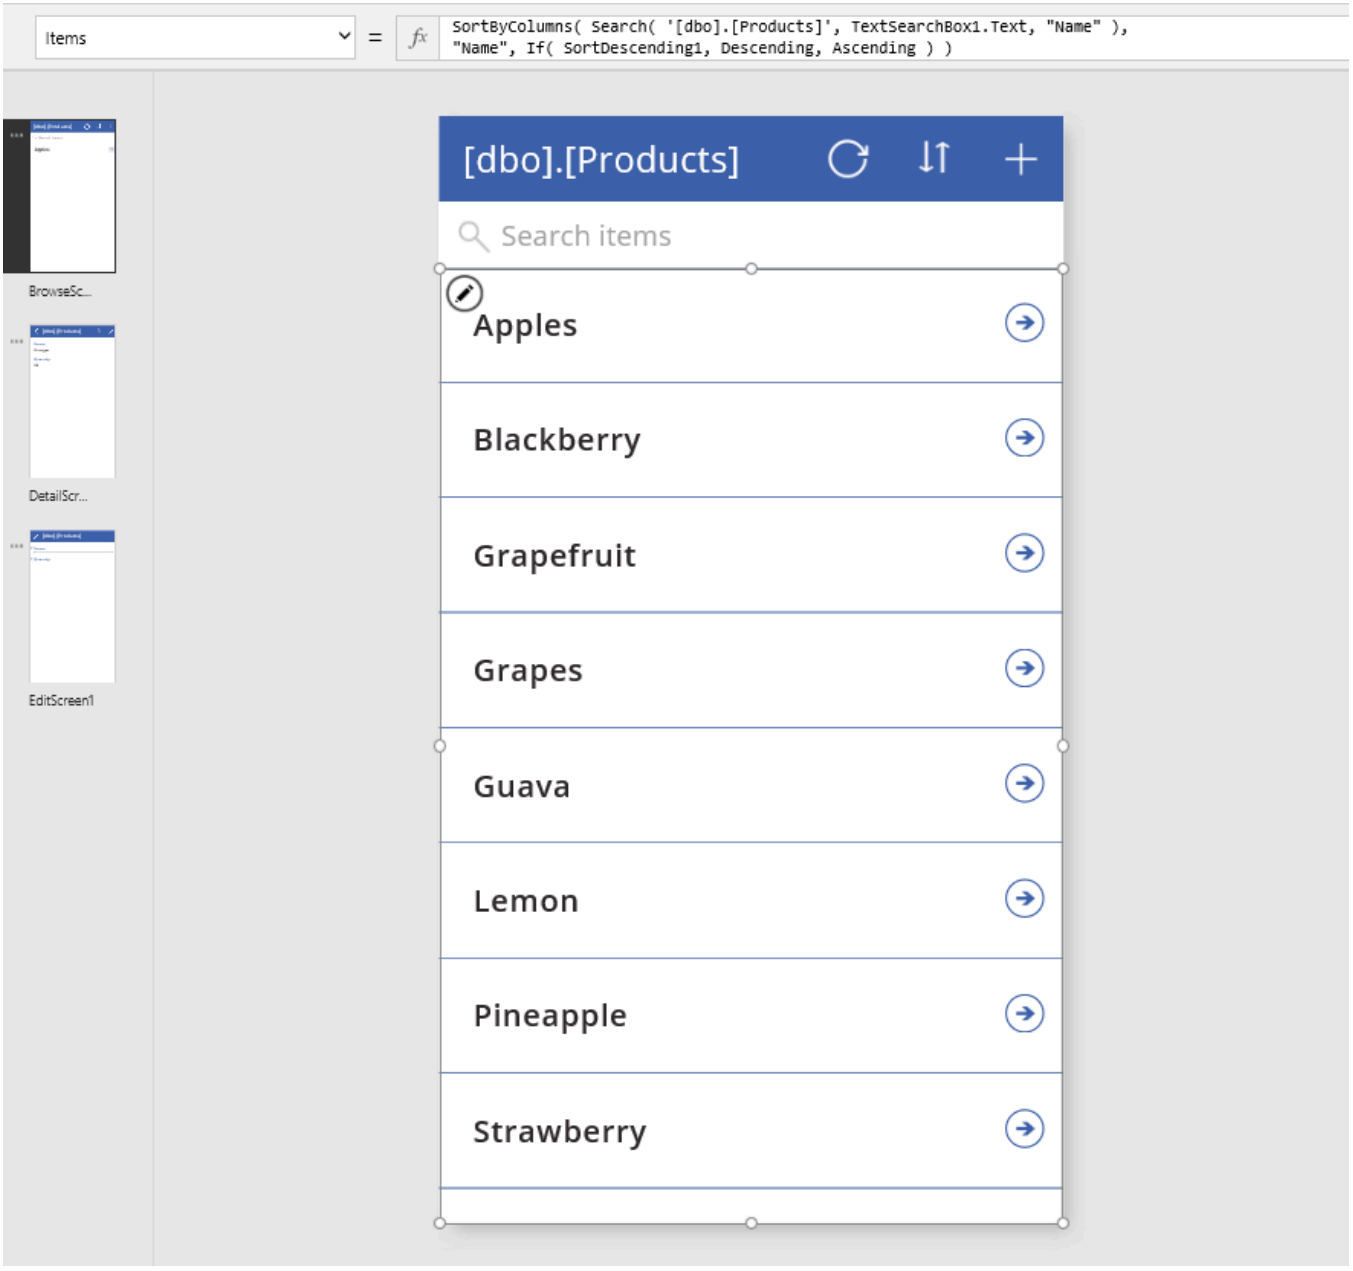
Delegation warnings

Power Apps shows a warning (yellow triangle) when you create a formula that can't be delegated. It's easier to know what is and isn't delegated.

Delegation warnings appear only on formulas that use delegable data sources. If you don't see a warning but think your formula isn't delegated, check your data source type against the list of delegable data sources earlier in this article.

Examples

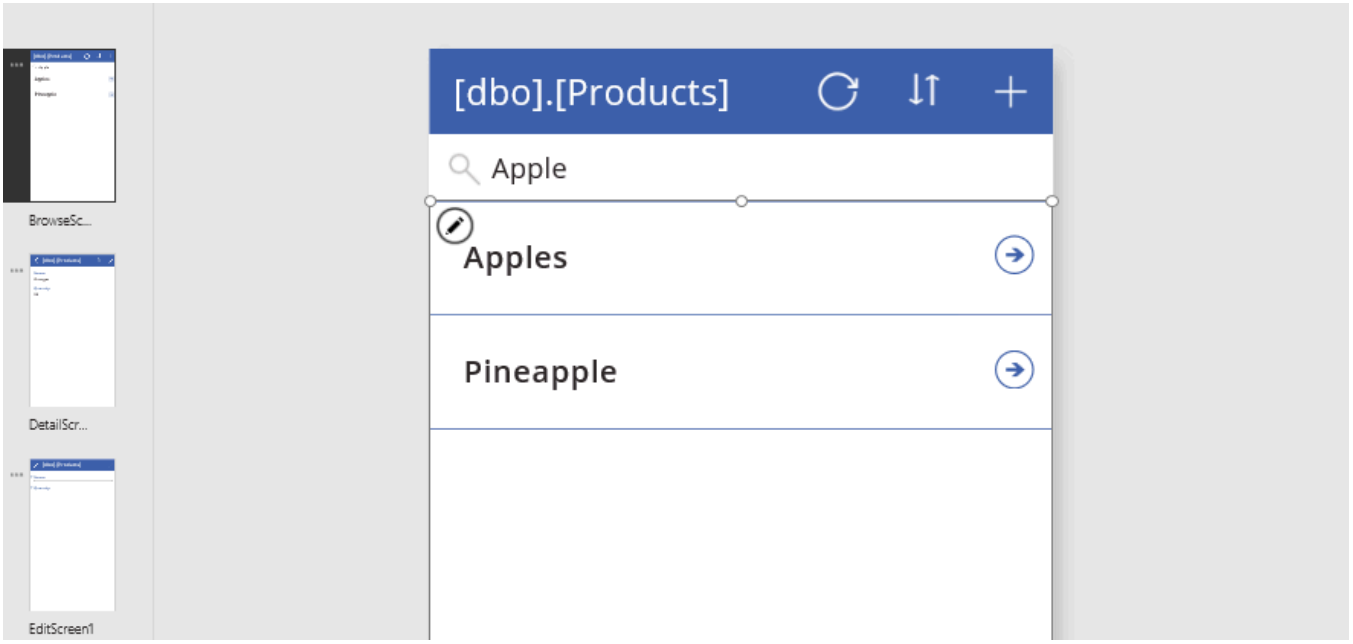
In this example, you automatically generate a three-screen app based on a SQL Server table named **[dbo].[Fruit]**. To learn how to generate the app, apply similar principles from the article about Dataverse to SQL Server.



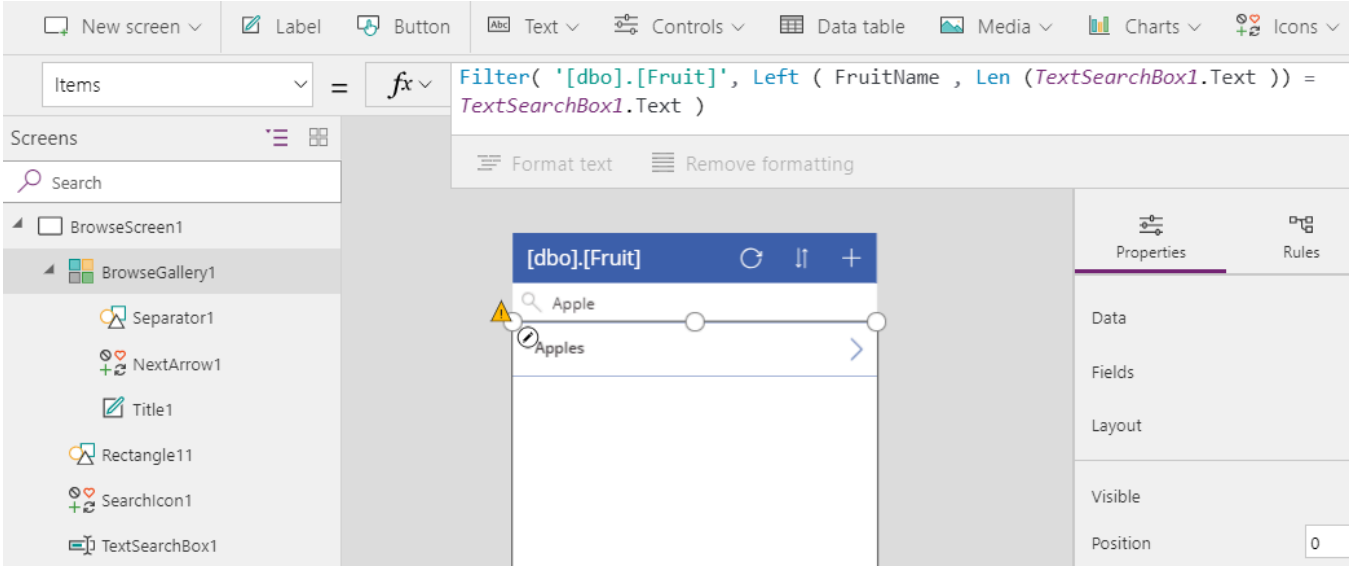
The gallery's **Items** property uses a formula with the **SortByColumns** and **Search** functions, both of which can be delegated.

In the search box, enter "**Apple**".

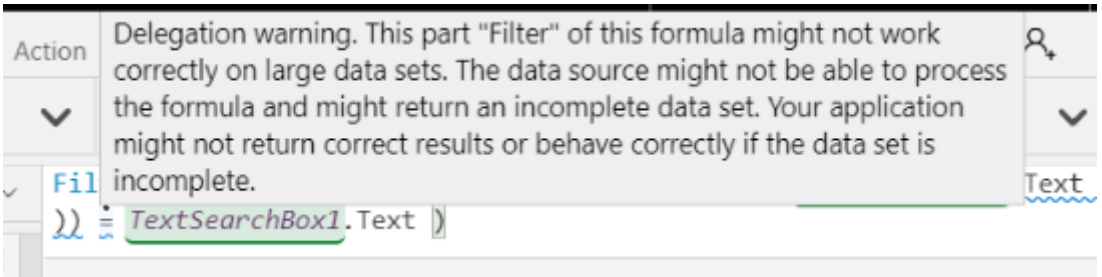
Marching dots briefly appear near the top of the screen as the app communicates with SQL Server to process the search request. All records that match the search criteria appear, even if the data source has millions of records.



The search results include "**Apples**" and "**Pineapple**" because the **Search** function looks everywhere in a text column. To find only records that contain the search term at the start of the fruit's name, use another delegable function, **Filter**, with a more specific search term. For simplicity, remove the **SortByColumns** call.



The new results include "**Apples**" but not "**Pineapple**". A yellow triangle appears next to the gallery and in the screen thumbnail if the left navigation bar shows thumbnails. A blue, wavy line appears under part of the formula. Each of these elements indicates a warning. When you hover over the yellow triangle next to the gallery, this message appears:



SQL Server is a delegable data source, and **Filter** is a delegable function. However, **Mid** and **Len** can't be delegated to any data source.

But it works, doesn't it? Kind of. That's why this is a warning and not a red, wavy squiggle.

- If the table has fewer than 500 records, the formula works perfectly. All records are brought to the device, and **Filter** is applied locally.
- If the table has more than 500 records, the formula doesn't return record 501 or higher, even if it matches the criteria.

Manage an on-premises data gateway in Power Apps

Article • 12/16/2022

Install an on-premises data gateway to transfer data quickly and securely between a canvas app that's built in Power Apps and a data source that isn't in the cloud, such as an on-premises SQL Server database or an on-premises SharePoint site. View all gateways for which you have administrative permissions, and manage permissions and connections for those gateways.

You can connect to on-premises data over the connectors that use data gateway.

Prerequisites

- The user name and password that you used to sign up for Power Apps.
- Administrative permissions on a gateway. (You have these permissions by default for each gateway that you install, and an administrator of another gateway can grant you these permissions for that gateway.)
- A license that supports accessing on-premises data using an on-premises gateway. For more information, see the pricing page.

Install a gateway

To install a gateway, follow the steps in Install an on-premises data gateway. Install the gateway in standard mode because the *on-premises data gateway (personal mode)* is available only for Power BI.

View and manage gateway permissions

1. In the left navigation bar of powerapps.com, click or tap **Gateways**, and then click or tap a gateway.

2. Add a user to a gateway by clicking or tapping **Users**, specifying a user or group, and then specifying a permission level:

    - **Can use**: Users who can create connections on the gateway to use for apps and flows, but cannot share the gateway. Use this permission for users who will run apps but not share them.

- **Can use + share**: Users who can create a connection on the gateway to use for apps and flows, and automatically share the gateway when sharing an app. Use this permission for users who need to share apps with other users or with the organization.
- **Admin**: Administrators who have full control of the gateway, including adding users, setting permissions, creating connections to all available data sources, and deleting the gateway.

For **Can use** and **Can use + share** permission levels, select the data sources that the user can connect to over the gateway.

> ⓘ Note
>
> **Can use** and **Can use + share** does not apply to custom connectors. Only gateway **Admins** can create connections for custom connectors.

View and manage gateway connections

1. In the left navigation bar of powerapps.com, click or tap **Gateways**, and then click or tap a gateway.
2. Click or tap **Connections**, and then click or tap a connection to view its details, edit the settings, or delete it.
3. To share a connection, click or tap **Share**, and then add or remove users.

   > ⓘ Note
   >
   > You can share only some types of connections, such as SQL Server. For more information, see Share app resources.

For more information about how to manage a connection, see Manage your connections.

Troubleshooting and Advanced Configuration

For more information about troubleshooting issues with gateways, see Troubleshoot the on-premises data gateway. For more information about configuration, see Use the on-premises data gateway app.

Next steps

- Install the on-premises data gateway.
- Create an app that connects to an on-premises data source, such as SQL Server or SharePoint.
- Share an app that connects to an on-premises data source.

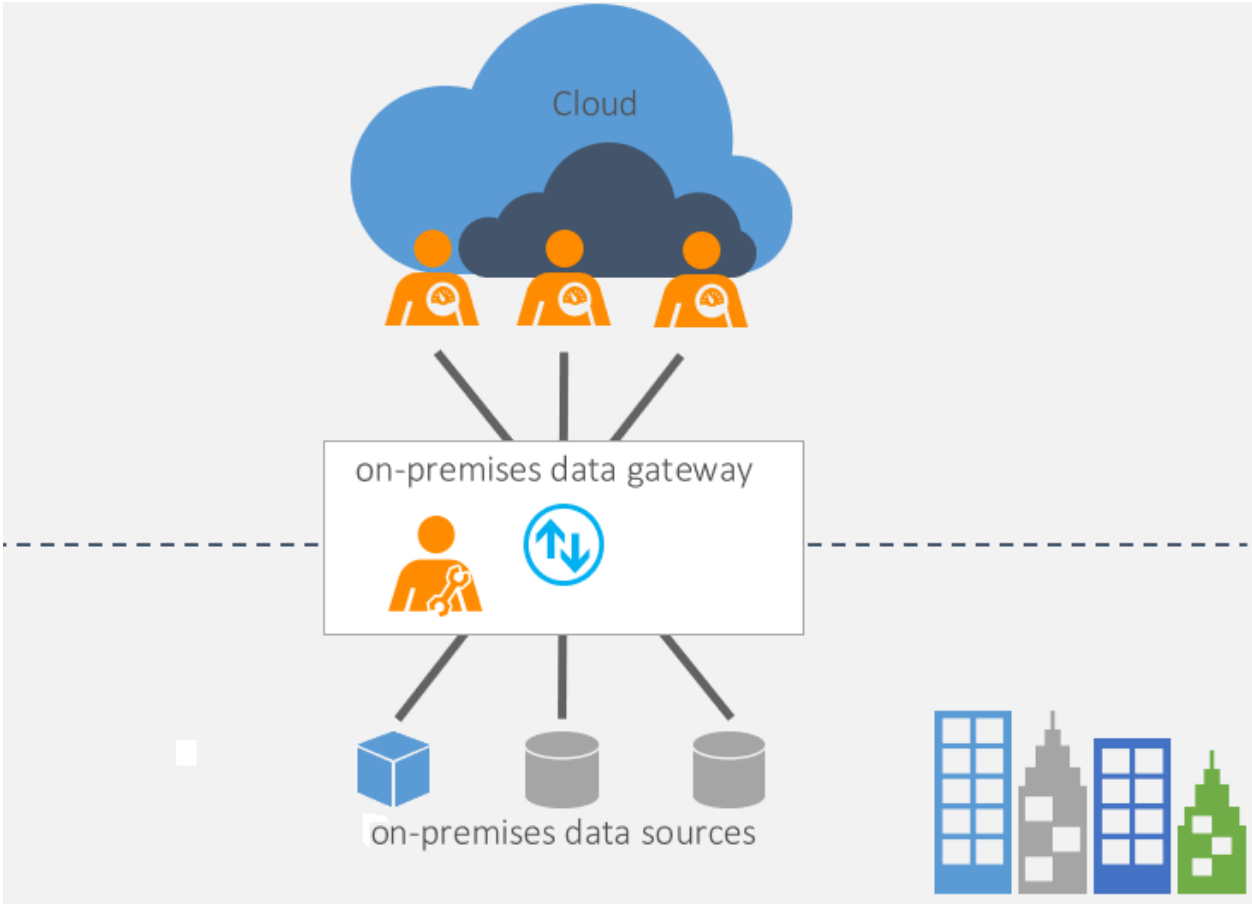
What is an on-premises data gateway?

Article • 03/01/2024

The on-premises data gateway acts as a bridge to provide quick and secure data transfer between on-premises data (data that isn't in the cloud) and several Microsoft cloud services. These cloud services include Power BI, Power Apps, Power Automate, Azure Analysis Services, and Azure Logic Apps. By using a gateway, organizations can keep databases and other data sources on their on-premises networks, yet securely use that on-premises data in cloud services.

How the gateway works



For more information on how the gateway works, see On-premises data gateway architecture.

Types of gateways

There are two different types of gateways, each for a different scenario:

- **On-premises data gateway** allows multiple users to connect to multiple on-premises data sources. You can use an on-premises data gateway with all

supported services, with a single gateway installation. This gateway is well-suited to complex scenarios with multiple people accessing multiple data sources.

- **On-premises data gateway (personal mode)** allows one user to connect to sources, and can't be shared with others. An on-premises data gateway (personal mode) can be used only with Power BI. This gateway is well-suited to scenarios where you're the only person who creates reports, and you don't need to share any data sources with others.

Use a gateway

There are four main steps for using a gateway.

1. Download and install the gateway on a local computer.
2. Configure the gateway based on your firewall and other network requirements.
3. Add gateway admins who can also manage and administer other network requirements.
4. Troubleshoot the gateway in case of errors.

End user accessing via a gateway

An end user will use the credentials for the gateway that the Power Apps author used to create the gateway. End users will see a connection in the consent dialog but it will be with the credentials provided by the Power Apps author.

Next steps

- Install the on-premises data gateway

Understand data sources for canvas apps

Article • 03/07/2025

In Power Apps, most canvas apps use external information stored in cloud services called **Data Sources**. A common example is a table in an Excel file stored in OneDrive. Apps access these data sources by using **Connections**.

This article discusses the different kinds of data sources and how to work with table data sources.

It's easy to create an app that does basic reading and writing to a data source. But sometimes you want more control over how data flows in and out of your app. This article describes how the **Patch**, **DataSourceInfo**, **Validate**, and **Errors** functions provide more control.

Kinds of data sources

Data sources can be connected to a cloud service, or they can be local to an app.

Connected data sources

The most common data sources are **tables**, which you can use to retrieve and store information. You can use **connections** to data sources to read and write data in Microsoft Excel workbooks, lists created using Microsoft Lists, SharePoint libraries, SQL tables, and many other formats, which can be stored in cloud services such as OneDrive, DropBox, and SQL Server.

Data sources other than tables include email, calendars, Twitter, and notifications, but this article doesn't discuss these other kinds of data sources.

Local data sources

With **Gallery**, **Display form**, and **Edit form** controls, you can create an app that reads and writes data from a data source. To get started, see Understand data forms.

When you ask Power Apps to create an app from data, these controls are used. Behind the scenes, the app uses an internal table to store and manipulate the data that comes from the data source.

A special type of data source is the Collection, which is local to the app and not backed by a connection to a service in the cloud. Therefore, the information can't be shared across devices for the same user or between users. Collections can be loaded and saved locally.

Kinds of tables

Tables that are internal to an app are fixed values, just as a number or a string is a value. Internal tables aren't stored anywhere, but exist in your app's memory. You can't directly modify the structure and data of a table. What you can do instead is to create a new table through a formula: you use that formula to make a modified copy of the original table.

External tables are stored in a data source for later retrieval and sharing. Power Apps provides "connections" to read and write stored data. Within a connection, you can access multiple tables of information. You can select which tables to use in your app, and each becomes a separate *data source*.

To learn more, see Working with tables about internal tables, but also external tables residing in a cloud service.

Working with tables

You can use table data sources the same way that you use an internal Power Apps table. Just like an internal table, each data source has records, columns, and properties that you can use in formulas. In addition:

- The data source has the same column names and data types as the underlying table in the connection.

  > ⓘ **Note**
  >
  > For SharePoint and Excel data sources that contain column names with spaces, Power Apps replaces the spaces with **"_x0020_"**. For example, **"Column Name"** in SharePoint or Excel appears as **"Column_x0020_Name"** in Power Apps when displayed in the data layout or used in a formula.

- The data source is loaded from the service automatically when the app is loaded. You can force the data to refresh by using the **Refresh** function.

- As users run an app, they can create, modify, and delete records and push those changes back to the underlying table in the service.
  - Records can be created with the **Patch** and **Collect** functions.
  - Records can be modified with the **Patch**, **Update**, and **UpdateIf** functions.
  - Records can be removed with the **Remove** and **RemoveIf** functions.
  - Errors when working with a data source are available through the **Errors** function.

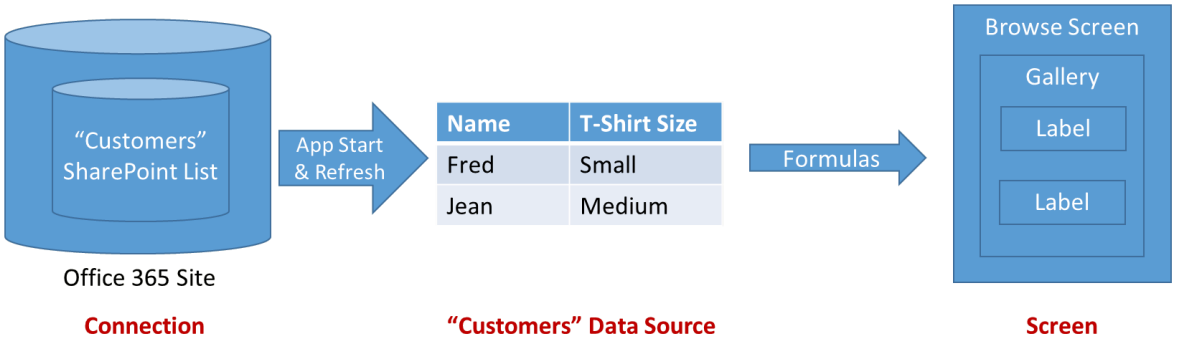
- The **DataSourceInfo**, **Defaults**, and **Validate** functions provide information about the data source that you can use to optimize the user experience.

Creating data sources

Power Apps can't be used to create a connected data source, or modify its structure; the data source must already exist in a service somewhere. For example, to create a table in an Excel workbook stored on OneDrive, you first use Excel Online on OneDrive to create a workbook. Next you create a connection to it from your app.

However, collection data sources *can* be created and modified inside an app, but are only temporary.

Display one or more records



This diagram shows the flow of information when an app reads the information in a data source:

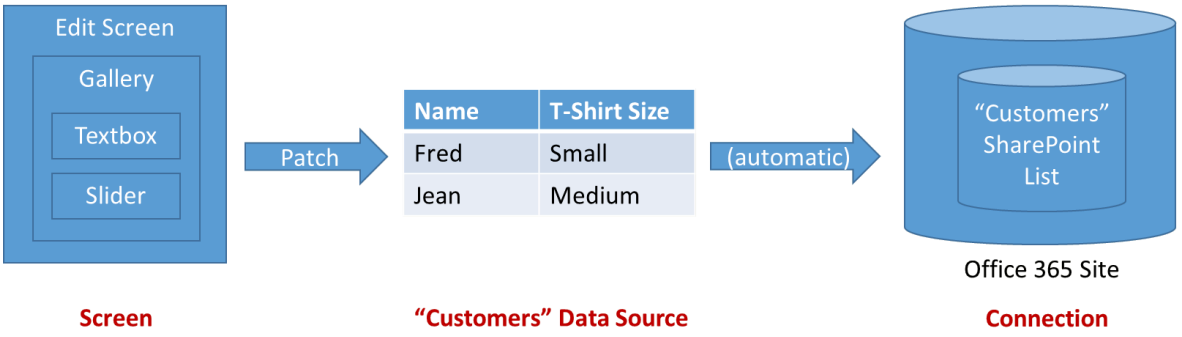
- The information is stored and shared through a storage service (in this case, Microsoft Lists or SharePoint Online).
- A connection makes this information available to the app. The connection takes care of authentication of the user to access the information.
- When the app is started or the **Refresh** function is pressed, information is drawn from the connection into a data source in the app for local use.

- Formulas are used to read the information and expose it in controls that the user can see. You can display the records of a data source by using a gallery on a screen and wiring the **Items** property to the data source: **Gallery.Items** = **DataSource**. You wire controls within the gallery, to the gallery, using the controls' **Default** property.
- The data source is also a table. So you can use **Filter**, **Sort**, **AddColumns**, and other functions to refine and augment the data source before using it as a whole. You can also use the **Lookup**, **First**, **Last**, and other functions to work with individual records.

Modify a record

The arrows in the previous diagram are one way. Changes to a data source aren't pushed back through the same formulas in which the data was retrieved. Instead, new formulas are used. Often a different screen is used for editing a record than for browsing records, especially on a mobile device.

To modify an existing record of a data source, the record must have originally come from the data source. The record might display in a gallery, a context variable, and any number of formulas, but its origin should be traceable back to the data source. Extra information travels with the record that uniquely identifies it, ensuring that you modify the correct record.



This diagram shows the flow of information to update a data source:

- An **Edit form** control provides a container for input cards, which are made up of user input controls such as a text-input control or a slider. The **DataSource** and **Item** properties are used to identify the record to edit.
- Each input card has a **Default** property, which is set to the field of the form's **ThisItem** record. The controls within the input card take their input values from **Default**. Normally, you don't need to modify this default.
- Each input card exposes an **Update** property. This property maps the user's input to a specific field of the record for writing back to the data source. Normally, you don't need to modify this property.

- A button or an image control on the screen enables the user to save changes to the record. The **OnSelect** formula of the control calls the **SubmitForm** function to do this work. **SubmitForm** reads all the **Update** properties of the cards and writes back to the data source.
- Sometimes there are issues. A network connection might be down, or a validation check is made by the service that the app didn't know about. The **Error** and **ErrorKind** properties of the form control makes this information available, so you can display it to the user.

For more fine grained control over the process, you can also use the **Patch** and **Errors** function. The **Edit form** control exposes an **Updates** property so that you can read the values of the fields within the form. You can also use this property to call a custom connector on a connection, completely bypassing the **Patch** and **SubmitForm** functions.

Validation

Before you make a change to a record, the app should do what it can to make sure the change is acceptable. There are two reasons for checking:

- *Immediate feedback to the user*. The best time to fix a problem is right when it happens, when it's fresh in the user's mind. Literally with each touch or keystroke, red text can appear that identifies an issue with their entry.
- *Less network traffic and less user latency*. More issues detected in the app mean fewer conversations over the network to detect and resolve issues. Each conversation takes time during which the user must wait before they can move on.

Power Apps offers two tools for validation:

- The data source can provide information about what is and isn't valid. For example, numbers can have minimum and maximum values, and one or more entries can be required. You can access this information with the **DataSourceInfo** function.
- The **Validate** function uses this same information to check the value of a single column or of an entire record.

Error handling

Now that you validated your record, update that record with **Patch**.

But, there might still be a problem. The network is down, validation of the service failed, or the user doesn't have the right permissions, just to name a few of the possible errors your app might encounter. Your app needs to respond appropriately to error situations, providing feedback to the user and a means for them to make it right.

When errors occur with a data source, your app automatically records the error information and makes it available through the **Errors** function. Errors are associated with the records that had the problems. If the problem is something the user can fix, such as a validation problem, they can resubmit the record, and the errors are cleared.

If an error occurs when a record is created with **Patch** or **Collect**, there's no record to associate any errors with. In this case, *blank* is returned by **Patch** and can be used as the record argument to **Errors**. Creation errors are cleared with the next operation.

The **Errors** function returns a table of error information. This information can include the column information, if the error can be attributed to a particular column. Use column-level error messages in label controls that are close to where the column is located on the edit screen. Use record-level error messages where the **Column** in the error table is *blank*, in a location close to the **Save** button for the entire record.

Working with large data sources

When you create reports from large data sources (perhaps millions of records), you want to minimize network traffic. Let's say you want to report on all **Customers** having a **StatusCode** of *Platinum* in New York City. Your **Customers** table contains millions of records.

You don't want to bring those millions of customers into your app, and then choose the ones you want. The choice should happen inside the cloud service where your table is stored, where you send the chosen records over the network.

Many, but not all, functions that you can use to choose records can be *delegated*, which means that they're run inside the cloud service. Learn more in Delegation.

Collections

Collections are a special type of data source. They're local to the app and not backed by a connection to a service in the cloud. Therefore, the information can't be shared across devices for the same user or between users.

Collections operate like any other data source, with a few exceptions:

- Collections can be created dynamically with the **Collect** function. They don't need to be established ahead of time, as connection-based data sources do.
- The columns of a collection can be modified at any time using the **Collect** function.
- Collections allow duplicate records. More than one copy of the same record can exist in a collection. Functions such as **Remove** operate on the first match they

find, unless the **All** argument is supplied.

- You can use the **SaveData** and **LoadData** functions to save and reload a copy of the collection. The information is stored in a private location that other users, apps, or devices can't access.
- You can use the **Export** and **Import** controls to save and reload a copy of the collection to a file that the user can interact with.

For more information on working with a collection as a data source, see create and update a collection.

Collections are commonly used to hold global state for the app. See working with variables for the options available for managing state.

Understand tables and records in canvas apps

In Power Apps, you can create a canvas app that accesses information in Microsoft Excel, SharePoint, SQL Server, and several other sources that store data in records and tables. To work most effectively with this kind of data, review the concepts that underlie these structures.

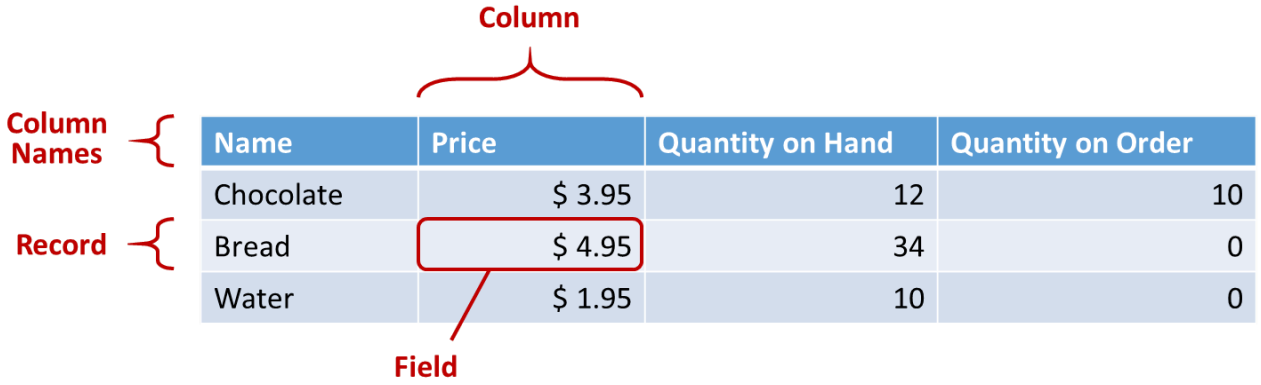
- A record contains one or more categories of information about a person, a place, or a thing. For example, a record might contain the name, the email address, and the phone number of a single customer. Other tools refer to a record as a "row" or an "item."
- A table holds one or more records that contain the same categories of information. For example, a table might contain the names, the email addresses, and the phone numbers of 50 customers.

In your app, use formulas to create, update, and manipulate records and tables. You probably read and write data to an external data source, which is an extended table. In addition, you might create one or more internal tables, which are called collections.

You can build a variety of formulas that take the name of a table as an argument, just as a formula in Excel takes one or more cell references as arguments. Some formulas in Power Apps return a table that reflects the other arguments that you specify. For example, you might create a formula:

- to update a record in a table by specifying that table as one of multiple arguments for the **Patch** function
- to add, remove, and rename columns in a table by specifying that table as an argument for the **AddColumns**, **DropColumns**, or **RenameColumns** function. None of those functions modifies the original table. Instead, the function returns another table based on the other arguments that you specify.

Elements of a table



Records

Each record contains at least one category of information for a person, a place, or a thing. The example above shows a record for each product (**Chocolate**, **Bread**, and **Water**) and a column for each category of information (**Price**, **Quantity on Hand**, and **Quantity on Order**).

In a formula, you can refer to a record by itself, outside of a table's context, by using curly braces. For example, this record **{ Name: "Strawberries", Price: 7.99 }** isn't associated with a table. Field names, such as **Name** and **Price** in that example, aren't enclosed in double quotation marks.

Fields

A field is an individual piece of information in a record. You can visualize this sort of field as a value in a column for a particular record.

Just as with a control, you refer to a field of a record by using the **.** operator on the record. For example, **First(Products).Name** returns the **Name** field for the first record in the **Products** table.

A field can contain another record or table, as the example for the **GroupBy** function shows. You can nest as many levels of records and tables as you want.

Columns

A column refers to the same field for one or more records in a table. In the preceding example, each product has a price field, and all products share the same column for that price. The preceding table has four columns, shown horizontally across the top:

- **Name**
- **Price**
- **Quantity on Hand**
- **Quantity on Order**

The column's name reflects the fields in that column.

All values within a column are of the same data type. In the preceding example, the "Quantity on Hand" column always contains a number and can't contain a string, such as "12 units," for one record. The value of any field can also be *blank*.

You might have referred to columns as "fields" in other tools.

> ⓘ **Note**

For data sources such as SharePoint, Excel, or Power BI tiles that contain column names with spaces, Power Apps replaces the spaces with "_x0020_". For example, "**Column Name**" in SharePoint, Excel, or Power BI tile appears as "**Column_x0020_Name**" in Power Apps when displayed in the data layout or used in a formula.

Table

A table comprises one or more records, each with multiple fields that have consistent names across the records.

You use the table name to refer to any table stored in a data source or a collection. You can also pass the table name to functions that take tables as arguments. A function or formula can also return tables.

As shown in the following example, you can express a table in a formula by using the **Table** function with a set of records, which you express in curly braces:

```
Table( { Value: "Strawberry" }, { Value: "Vanilla" } )
```

You can also define a single-column table by using square brackets. The following expression is an equivalent way to write the preceding expression:

```
[ "Strawberry", "Vanilla" ]
```

Table formulas

In Excel and Power Apps, you use formulas to manipulate numbers and strings of text in similar ways:

- In Excel, type a value, such as **42**, in cell **A1**, and then type a formula, such as **A1+2**, in another cell to show the value of **44**.
- In Power Apps, set the **Default** property of **Slider1** to **42**, and set the **Text** property of a label to **Slider1.Value + 2** to show the value of **44**.

In both cases, the calculated value changes automatically if you change the values of the arguments (for example, the number in cell **A1** or the value of **Slider1**).

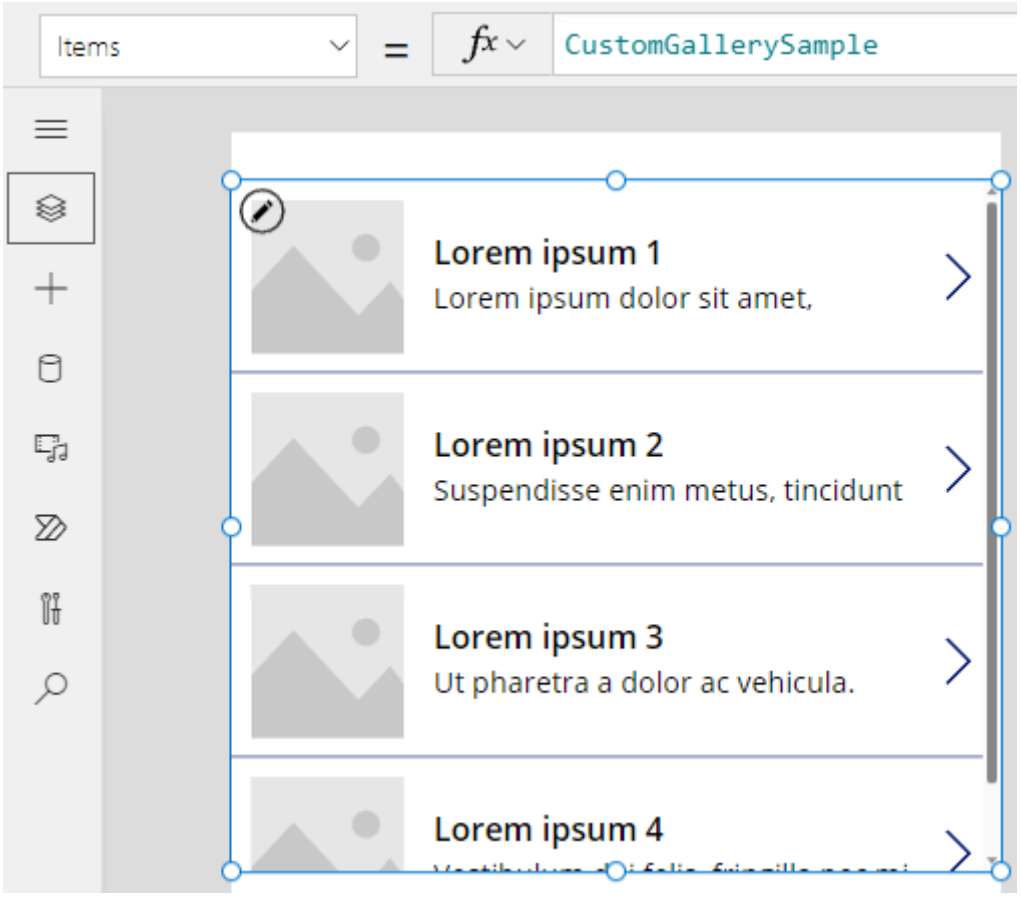
Similarly, you can use formulas to access and manipulate data in tables and records. You can use names of tables as arguments in some formulas, such as **Min(Catalog, Price)** to show the lowest value in the **Price** column of the **Catalog** table. Other formulas provide whole tables as return values, such as **RenameColumns(Catalog, "Price", "Cost")**, which returns all the records from the **Catalog** table but changes the name of the **Price** column to **Cost**.

Just as with numbers, formulas that involve tables and records automatically recalculate as the underlying table or record changes. If the cost of a product in the **Catalog** table is lowered to a value that is less than the previous minimum, the return value of the Min formula automatically changes to match it.

Let's walk through some simple examples.

1. Create a blank app for a phone, and add a vertical Gallery control that contains other controls.

   By default, the screen shows placeholder text from a table named **CustomGallerySample**. The Items property of the screen's Gallery control is automatically set to that table.



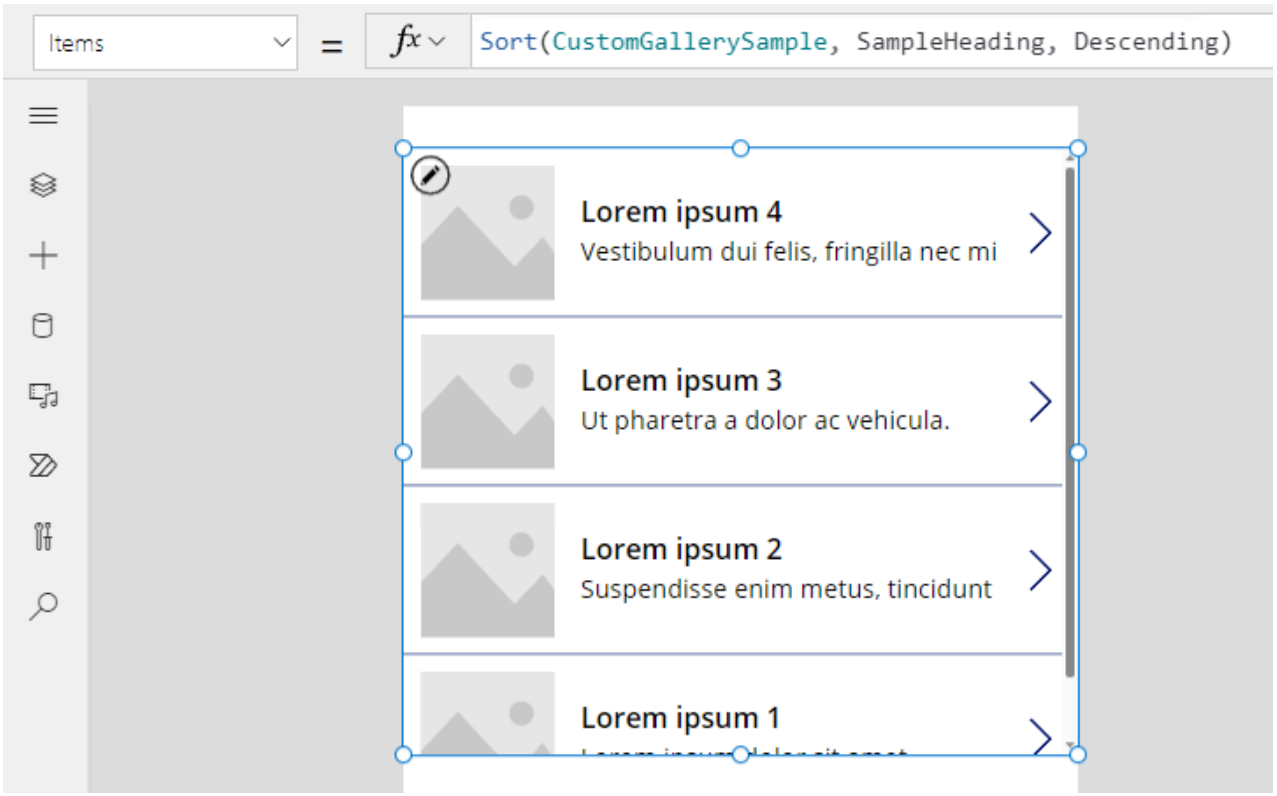
> ⓘ **Note**
>
> Some controls are rearranged and enlarged for illustration purposes.

2. Instead of setting the Items property to the name of a table, set it to a formula that includes the name of the table as an argument, as in this example:

   ```
   Sort(CustomGallerySample, SampleHeading, SortOrder.Descending)
   ```

   This formula incorporates the Sort function, which takes the name of a table as its first argument and the name of a column in that table as its second argument. The function

also supports an optional third argument, which stipulates that you want to sort the data in descending order.



3. Set the **Items** property to a formula that takes the formula from the previous step as an argument and returns a table, as in this example:

```
FirstN(Sort(CustomGallerySample, SampleHeading, SortOrder.Descending), 2)
```

In this formula, you use the **FirstN** function to show a particular number of records in a table. You use the **Sort** function as the first argument to **FirstN** and a number (in this case, **2**) as the second argument, which specifies how many records to show.

The entire formula returns a table that contains the first two records of the **CustomGallerySample** table, sorted by the **SampleHeading** column in descending order.

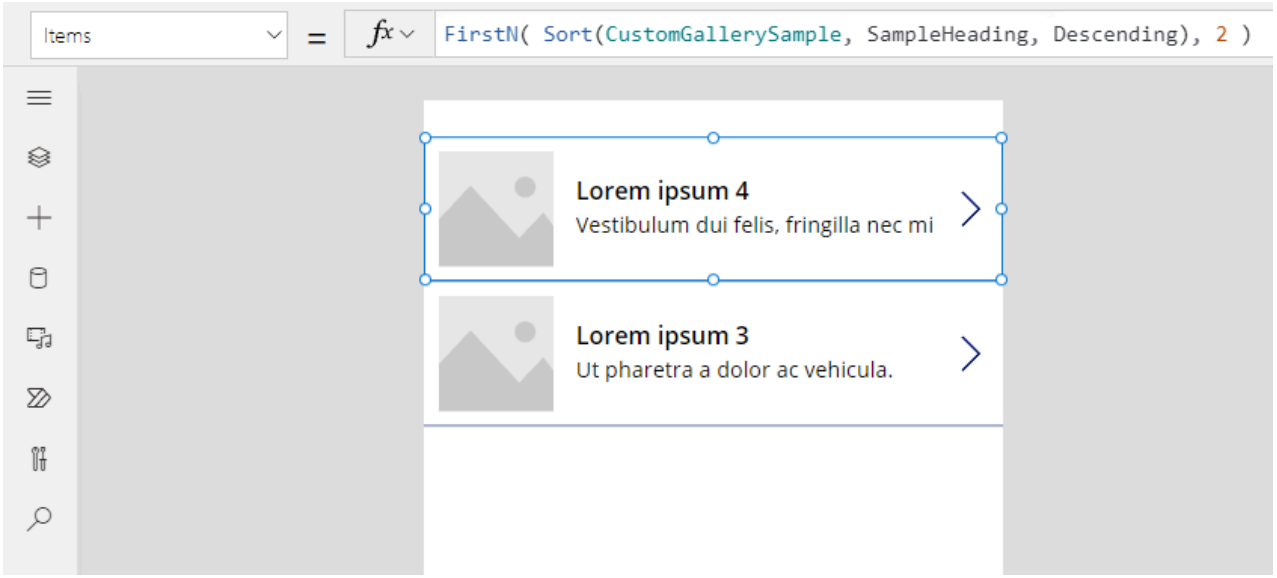


Table functions and control properties

Consider the **Lower** function. If the variable **welcome** contains the text string **"Hello, World"**, the formula **Lower(welcome)** returns **"hello, world"**. This function doesn't change the value in that variable. **Lower** is a pure function because it only processes input and produces output. It has no side effects. All functions in Excel and most functions in Power Apps are pure functions, which means the workbook or the app recalculates automatically.

Power Apps offers a set of functions that operate on tables in the same manner. These functions take tables as input and filter, sort, transform, reduce, and summarize entire tables of data. In fact, **Lower** and many other functions that typically take a single value can also take a single-column table as input.

- **Sort**, **Filter** - Sort and filter records.
- **FirstN**, **LastN** - Return the first N or last N records of the table.
- **Abs**, **Sqrt**, **Round**, **RoundUp**, **RoundDown** - Perform arithmetic operations on each record of a single-column table, resulting in a single-column table of results.
- **Left**, **Mid**, **Right**, **Replace**, **Substitute**, **Trim**, **Lower**, **Upper**, **Proper** - Perform string manipulations on each record of a single-column table, resulting in a single-column table of strings.
- **Len** - For a column of strings, returns a single-column table that contains the length of each string.
- **Concatenate** - Concatenates multiple columns of strings, resulting in a single-column table of strings.
- **AddColumns**, **DropColumns**, **RenameColumns**, **ShowColumns** - Perform column manipulation of the table, resulting in a new table with different columns.
- **Distinct** - Removes duplicate records.
- **Shuffle** - Shuffles records into a random order.
- **HashTags** - Searches for hashtags in a string.
- **Errors** - Provides error information when you work with a data source.

Many of these functions take a single-column table as their input. If an entire table has only one column, you can specify it by name. If a table has multiple columns, you can specify one of those columns by using *Table.Column* syntax. For example, **Products.Name** returns the single-column table of only **Name** values from the **Products** table.

You can completely reshape a table however you want by using the **AddColumns**, **RenameColumns**, **ShowColumns**, or **DropColumns** function. Again, these functions change only their output, not their source.

Properties of controls can also be tables:

- **Items** - Applies to galleries, list boxes, and combo boxes. This property defines the table that the gallery or the list shows.
- **SelectedItems** - Applies to list boxes and combo boxes. This property defines the table of items that the user selected if **SelectMultiple** is enabled.

Behavioral formulas

Some functions are specifically designed to modify data and have side effects. Because these functions aren't pure, you must build them carefully. They can't participate in automatically recalculating values in the app. You can use these functions only within behavioral formulas.

- **Collect**, **Clear**, **ClearCollect** - Creates collections, clears them, and adds data to them.
- **Patch** - Modifies one or more fields in a record.
- **Update**, **UpdateIf** - Updates records that match one or more criteria that you specify.
- **Remove**, **RemoveIf** - Deletes records that match one or more criteria that you specify.

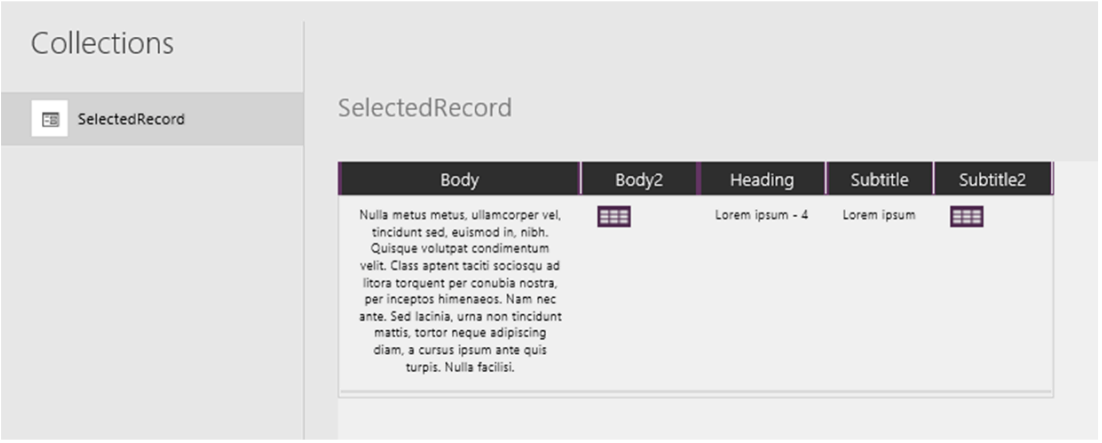
Record formulas

You can also build a formula that calculates data for an individual record, takes an individual record as an argument, and provides an individual record as a return value. Returning to the gallery example, use the **Gallery1.Selected** property to display information from whatever record the user selects in that gallery.

1. Add a **Button**, and set its **OnSelect** property to this formula:
   Collect(SelectedRecord, Gallery1.Selected)

2. Select the button while holding down the Alt key.

3. In the **File** menu, select **Collections.**



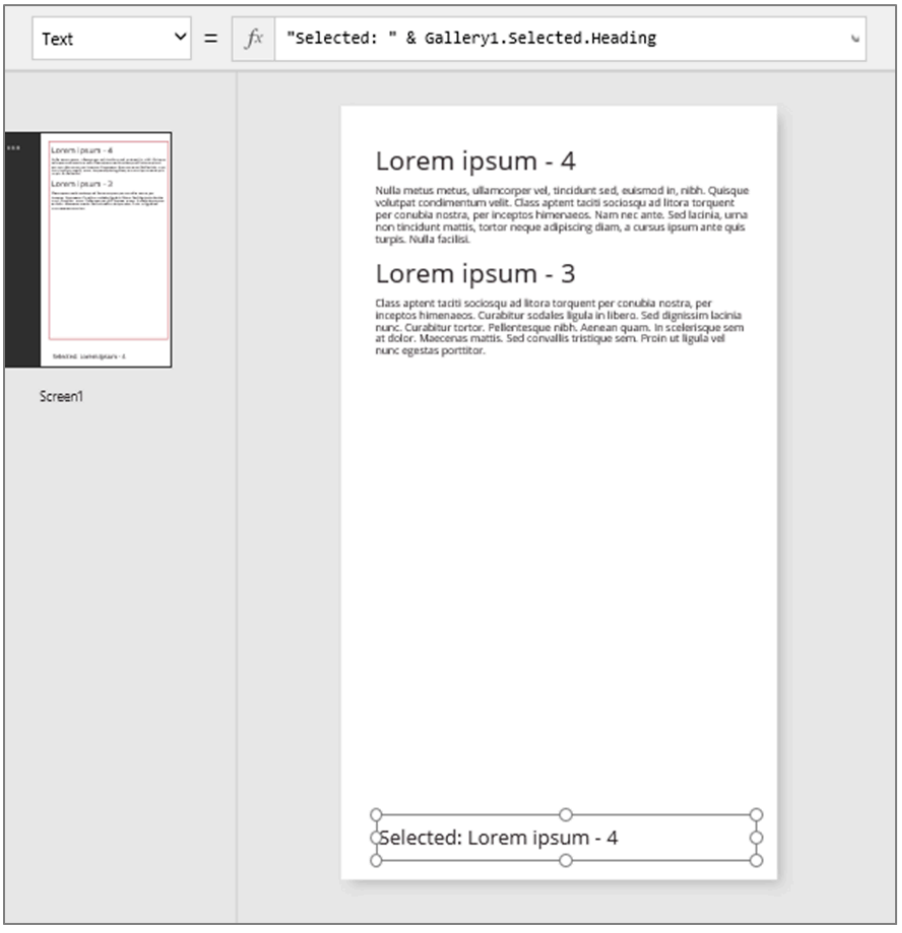
This formula returns a record that includes not only the data from the record that's currently selected in the gallery but also each control in that gallery. For example, the record contains

both a **SampleText** column, which matches the **SampleText** column in the original table, and a **Subtitle1** column, which represents the label that shows the data from that column. Select the table icon in the **Subtitle1** column to drill into that data.

> **Note**
>
> The **Subtitle1** column might be named **Subtitle2** or similar if you add elements other than those that this topic specifies.

Now that you have the selected record, you can extract individual fields from it by using the **.** operator.

1. Add a **Label** control, and then move it under the gallery and the button.
2. Set the label's **Text** property to this expression:
   "Selected: " & Gallery1.Selected.SampleHeading



You took the **Selected** property, which is a record, and extracted the **SampleHeading** property from it.

You can also use a record as a general-purpose container for related named values.

- If you build a formula around the **UpdateContext** and **Navigate** functions, use a record to gather the context variables that you want to update.
- Use the **Updates** property on an **Edit form** control to gather the changes that the user makes in a form.
- Use the **Patch** function to update a data source but also to merge records.

In these cases, the record was never a part of a table.

Record functions and control properties

Functions that return records:

- **FirstN**, **LastN** - Returns the first or last record or records of the table.
- **Lookup** - Returns the first record from a table that matches one or more criteria.
- **Patch** - Updates a data source or merges records.
- **Defaults** - Returns the default values for a data source.

Properties that return records:

- **Selected** - Applies to galleries and list boxes. Returns the currently selected record.
- **Updates** - Applies to galleries. Pulls together all the changes that a user makes in a data-entry form.
- **Update** - Applies to input controls such as text-input controls and sliders. Sets up individual properties for the gallery to pull together.

Record scope

Some functions work by evaluating a formula across all the records of a table, one record at a time. You use the formula's result in different ways for each function:

- **AddColumns** - Use the formula to get the value for the new field you add.
- **Average**, **Max**, **Min**, **Sum**, **StdevP**, **VarP** - Use the formula to get the value you want to aggregate.
- **Filter**, **Lookup** - Use the formula to decide if the record should be part of the output.
- **Concat** - Use the formula to decide which strings to join together.
- **Distinct** - Use the formula to return a value that helps find duplicate records.
- **ForAll** - Use the formula to return any value, possibly with side effects.
- **Sort** - Use the formula to get the value to sort the records by.
- **With** - Use the formula to return any value, possibly with side effects.

Inside these formulas, you can reference the fields of the record you're working on. Each of these functions creates a "record scope" where the formula runs. The fields of the record show

up as top-level identifiers. You can also reference control properties and other values from throughout your app.

For example, consider a table of **Products**:

Product	Quantity Requested	Quantity Available
Widget	6	3
Gadget	10	20
Gizmo	4	11
Apparatus	7	6

To create this example table in your app, insert a button, set its **OnSelect** property to this formula, and then select the button (click it while you hold down the Alt key in Power Apps Studio):

Power Fx

```
Set( Products,
    Table(
        { Product: "Widget",    'Quantity Requested': 6,  'Quantity Available': 3 },
        { Product: "Gadget",    'Quantity Requested': 10, 'Quantity Available': 20
},
        { Product: "Gizmo",     'Quantity Requested': 4,  'Quantity Available': 11
},
        { Product: "Apparatus", 'Quantity Requested': 7,  'Quantity Available': 6 }
    )
)
```

To check if any of these products have more requested than is available, use this formula:

```
Filter( Products, 'Quantity Requested' > 'Quantity Available' )
```

The first argument to **Filter** is the table of records to work on. The second argument is a formula. **Filter** makes a record scope for evaluating this formula. The fields of each record are available, like **Product**, **Quantity Requested**, and **Quantity Available**. The result of the comparison decides if each record should be part of the function's result:

Product	Quantity Requested	Quantity Available
Widget	6	3
Apparatus	7	6

You can add to this example by calculating how much of each product to order:

Power Fx

```
AddColumns(
    Filter( Products, 'Quantity Requested' > 'Quantity Available' ),
    "Quantity To Order", 'Quantity Requested' - 'Quantity Available'
)
```

Here, you add a calculated column to the result. **AddColumns** uses its own record scope to calculate the difference between what you requested and what is available.

Product	Quantity Requested	Quantity Available	Quantity To Order
Widget	6	3	3
Apparatus	7	6	1

Finally, you can reduce the result table to just the columns that you want:

Power Fx

```
ShowColumns(
    AddColumns(
        Filter( Products, 'Quantity Requested' > 'Quantity Available' ),
        "Quantity To Order", 'Quantity Requested' - 'Quantity Available'
    ),
    "Product",
    "Quantity To Order"
)
```

Product	Quantity To Order
Widget	3
Apparatus	1

In the preceding example, you used double quotes (") in some places and single quotes (') in other places. You need single quotes when you reference the value of an object, such as a field or table, and the name of the object contains a space. Use double quotes when you're not referencing the value of an object but instead talking about it. Use double quotes especially in situations where the object doesn't yet exist, as in the case of **AddColumns**.

Disambiguation

Field names you add with the record scope override the same names from elsewhere in the app. When this happens, you can still access values from outside the record scope by using the @ disambiguation operator:

- To access values from nested record scopes, use the @ operator with the name of the table you're operating upon, using this pattern:
  Table[@*FieldName*]

- To access global values, such as data sources, collections, and context variables, use the pattern **[@***ObjectName***]** (without a table designation).

If the table you're operating upon is an expression, such as **Filter(** *Table***, ...)**, you can't use the disambiguation operator. Only the innermost record scope can access fields from this table expression, by not using the disambiguation operator.

For example, imagine having a collection **X**:

Value
1
2

You create this collection by using **ClearCollect(X, [1, 2])**.

And another collection **Y**:

Value
"A"
"B"

You create this collection by using **ClearCollect(Y, ["A", "B"])**.

In addition, define a context variable named **Value** with this formula: **UpdateContext({Value: "!"})**

Let's put it all together. In this context, the following formula:

Power Fx

```
Ungroup(
    ForAll( X,
        ForAll( Y,
            Y[@Value] & Text( X[@Value] ) & [@Value]
        )
    ),
    "Value"
)
```

produces this table:

Value
"A1!"
"A2!"
"B1!"
"B2!"

What's going on here? The outermost **ForAll** function defines a record scope for **X**, allowing access to the **Value** field of each record as it processes. You can access it by simply using the word **Value** or by using **X[@Value]**.

The innermost **ForAll** function defines another record scope for **Y**. Since this table also has a **Value** field defined, using **Value** here refers to the field in **Y**'s record and no longer the one from **X**. To access **X**'s **Value** field, you must use the longer version with the disambiguation operator.

Since **Y** is the innermost record scope, accessing fields of this table doesn't require disambiguation, so you can use this formula with the same result:

Power Fx

```
Ungroup(
    ForAll( X,
        ForAll( Y,
            Value & Text( X[@Value] ) & [@Value]
        )
    ),
    "Value"
)
```

All the **ForAll** record scopes override the global scope. The **Value** context variable you defined isn't available by name without the disambiguation operator. To access this value, use **[@Value]**.

Ungroup flattens the result because nested **ForAll** functions result in a nested result table.

Single-column tables

To operate on a single column from a table, use the **ShowColumns** function as in this example:

Power Fx

```
ShowColumns( Products, "Product" )
```

This formula produces this single-column table:

Product
Widget
Gadget
Gizmo
Apparatus

For a shorter alternative, specify *Table.Column*, which extracts the single-column table of just *Column* from *Table*. For example, this formula produces exactly the same result as using **ShowColumns**.

Power Fx

```
Products.Product
```

Inline records

Express records by using curly braces that contain named field values. For example, you can express the first record in the table at the start of this topic by using this formula:

```
{ Name: "Chocolate", Price: 3.95, 'Quantity on Hand': 12, 'Quantity on Order': 10 }
```

You can also embed formulas within other formulas, as this example shows:

```
{ Name: First(Products).Name, Price: First(Products).Price * 1.095 }
```

You can nest records by nesting curly braces, as this example shows:

```
{ 'Quantity': { 'OnHand': ThisItem.QuantOnHand, 'OnOrder': ThisItem.QuantOnOrder } }
```

Enclose each column name that contains a special character, such as a space or a colon, in single quotes. To use a single quote within a column name, double it.

Note that the value in the **Price** column doesn't include a currency symbol, such as a dollar sign. That formatting is applied when the value is displayed.

Inline tables

Create a table by using the Table function and a set of records. You can express the table at the start of this topic by using this formula:

Power Fx

```
Table(
    { Name: "Chocolate", Price: 3.95, 'Quantity on Hand': 12, 'Quantity on Order':
10 },
    { Name: "Bread", Price: 4.95, 'Quantity on Hand': 34, 'Quantity on Order': 0 },
    { Name: "Water", Price: 4.95, 'Quantity on Hand': 10, 'Quantity on Order': 0 }
)
```

You can also nest tables:

Power Fx

```
Table(
    { Name: "Chocolate",
      'Quantity History': Table( { Quarter: "Q1", OnHand: 10, OnOrder: 10 },
                                 { Quarter: "Q2", OnHand: 18, OnOrder: 0 } )
    }
)
```

Inline value tables

Create single-column tables by specifying values in square brackets. The resulting table has a single column, named **Value**.

For example, `[ 1, 2, 3, 4 ]` is equivalent to `Table( { Value: 1 }, { Value: 2 }, { Value: 3 }, { Value: 4 } )` and returns this table:

Value
1
2
3
4

Understand record references and polymorphic lookups in canvas apps

Article • 12/16/2022

When you wrote a research paper in school, you probably provided a list of your references at the end. You didn't include a copy of the actual background material you used but rather a web link, book title and author, or other information so that someone could track down the original source. You mixed different kinds of sources in a single list, newspaper articles next to audio recordings, each with their own specific details for a proper citation. For example, Wikipedia articles often include a long list of references.

In canvas apps, you often work with copies of records downloaded from data sources. You use the **LookUp** and **Filter** functions and the **Gallery** control's **Selected** property to identify the specific record that you want. All the records from **Filter** or **Selected** will be of the same table type, so you can use fields with a simple *.Field* notation. These copies often include reference information so you can use the **Patch** function to update the original source.

Canvas apps also support *record references*. Much like a research-paper reference, a record reference refers to a record without including a complete copy of it. Such a reference can refer to a record in any table. Also like research-paper references, you can mix records from different tables in a single column.

Many operations on record references are identical to working with records. You can compare record references to each other and to full records. You can set a record reference's value with the **Patch** function just as you would a lookup with a full record.

There is one important usage difference: you can't directly access the fields of a record reference without first establishing to which table it refers. This is because canvas apps require that all types be known when you write formulas. Because you don't know the type of a record reference until the app is running, you can't use the simple *.Field* notation directly. You must first dynamically determine the table type with the **IsType** function and then use *.Field* notation on the result of the **AsType** function.

Table type refers to the schema of each record in a table. Each table has a unique set of fields with different names and data types. Each record of the table inherits that structure; two records have the same table type if they come from the same table.

> **Note**

You can choose from many different connectors to connect to different types of data sources for canvas apps. However, when working with canvas apps inside Power Apps Studio, **columns** in Microsoft Dataverse are referred to as **fields** similar to all other data sources. **Column** is only used when referring to a column inside Dataverse. More information: Dataverse terminology updates

Polymorphic lookups

Microsoft Dataverse supports relationships between records. Each record in the **Accounts** table has a **Primary Contact** lookup column to a record in the **Contacts** table. The lookup can only refer to a record in **Contacts** and can't refer to a record in, say, the **Teams** table. That last detail is important because you always know what columns will be available for the lookup.

Dataverse also supports polymorphic lookups, which can refer to a record from any table in a set. For example, the **Owner** column can refer to a record in the **Users** table or the **Teams** table. The same lookup column in different records could refer to records in different tables. In this case, you don't always know what columns will be available.

Canvas record references were designed for working with polymorphic lookups in Dataverse. You can also use record references outside of this context, which is how the two concepts differ.

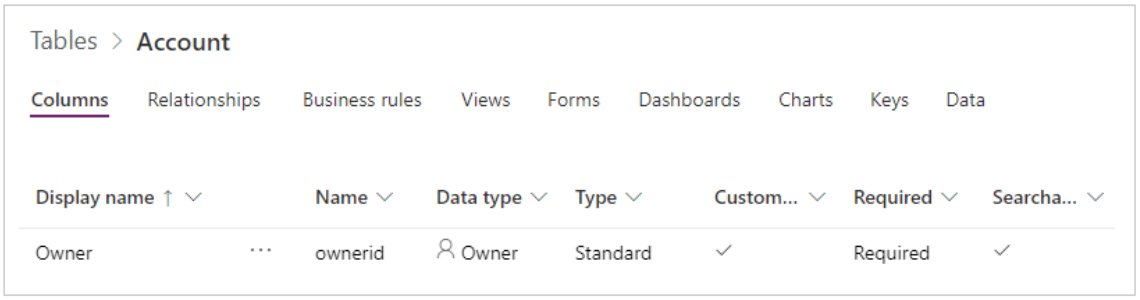
In the next section, you'll start to explore these concepts by working with the **Owner** lookup.

Show the columns of a record owner

Every table in Dataverse includes an **Owner** column. This column can't be removed, you can't add another, and it always requires a value.

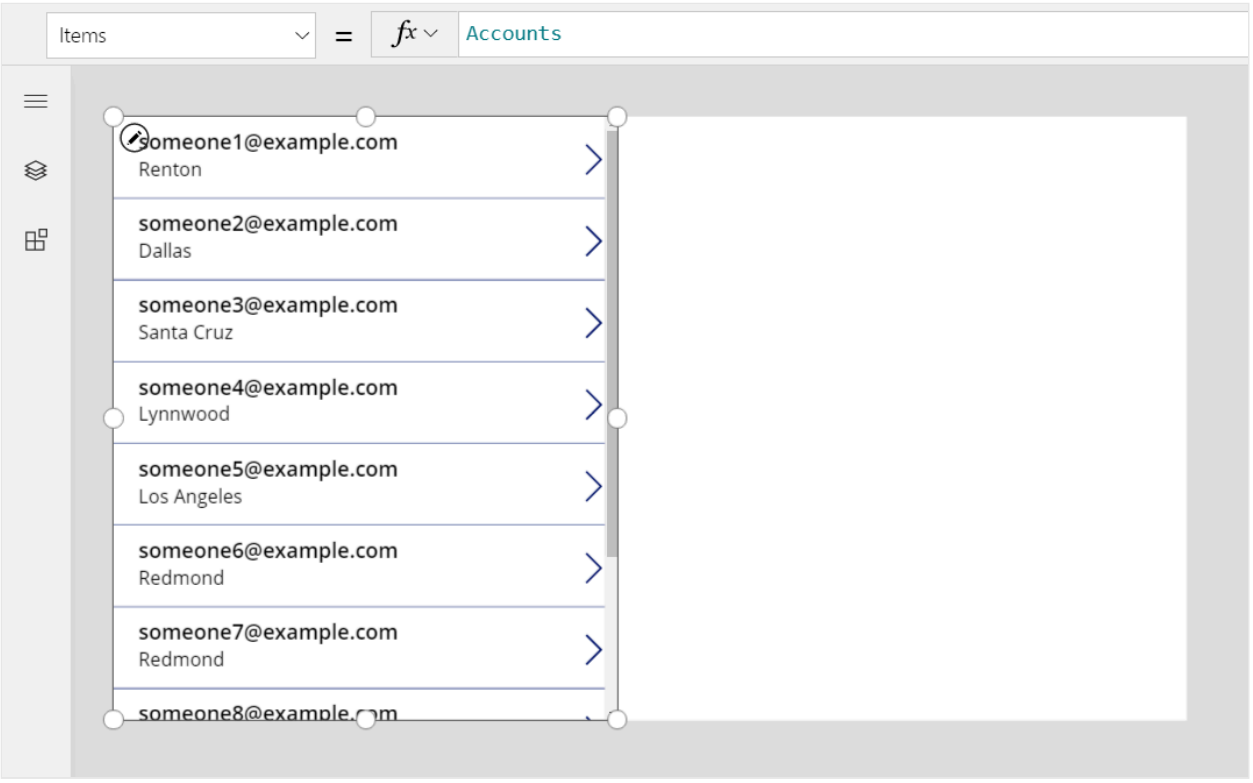
To show that column in the **Account** table:

1. Sign in to Power Apps.
2. In the left pane bar, select **Data** > **Tables**.
3. In the list of tables, select **Account**.
4. In the upper-right corner, open the filter list (which is set to **Default** by default), and then select **All**.
5. Scroll down until the **Owner** column appears.



This lookup column can refer to a record from either the **Teams** table or the **Users** table. Not every record in these tables has permission to be an **Owner**; check the supported roles if you run into a problem.

This graphic shows a simple gallery of **Accounts**, where the **Accounts** table has been added to the app as a data source:

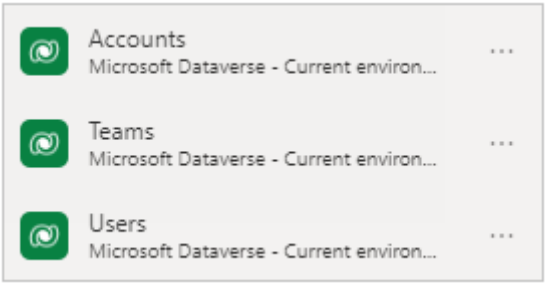


> **Important**
>
> Throughout this topic, the graphics show some names and other values that aren't part of the sample data that ships with Dataverse. The steps accurately demonstrate how to configure controls for a particular result, but your experience will vary based on the data for your organization.

To show the owner of each account in the gallery, you might be tempted to use the formula **ThisItem.Owner.Name**. However, the name field in the **Team** table is **Team Name**, and the name field in the **User** table is **Full Name**. The app can't know which type

of lookup you're working with until you run the app, and it can vary between records in the **Accounts** table.

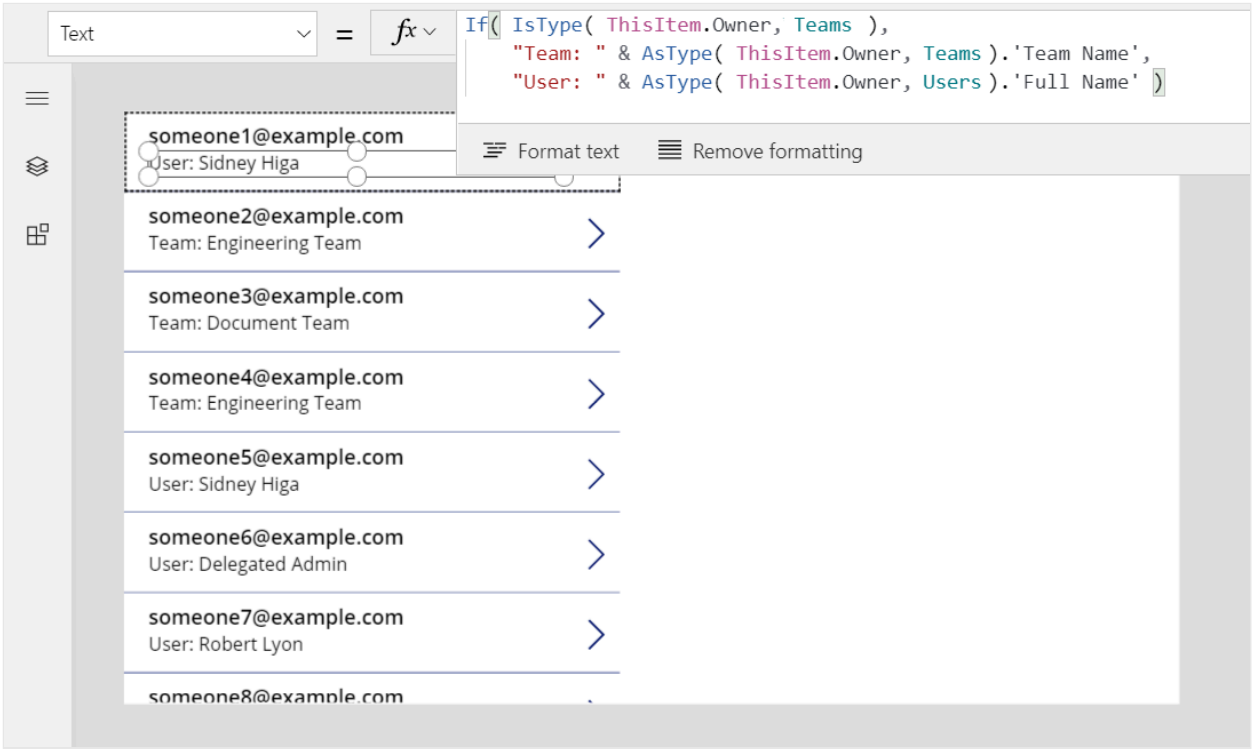
You need a formula that can adapt to this variance. You also need to add the data sources for the table types that **Owner** could be (in this case, **Users** and **Teams**). Add these three data sources to your app:



With these data sources in place, use this formula to display the name of either a user or a team:

Power Fx

```
If( IsType( ThisItem.Owner, Teams ),
    "Team: " & AsType( ThisItem.Owner, Teams ).'Team Name',
    "User: " & AsType( ThisItem.Owner, Users ).'Full Name' )
```

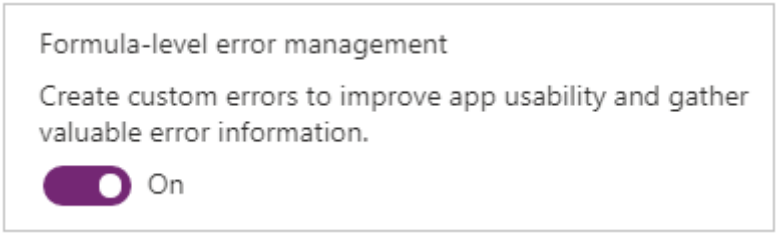


In this formula, the **IsType** function tests the **Owner** field against the **Teams** table. If it's of that table type, the **AsType** function casts it to a **Team** record. At this point, you can access all the fields of the **Teams** table, including **Team Name**, by using the *.Field*

notation. If **IsType** determines that the **Owner** isn't a record in the **Teams** table, that field must be a record in the **Users** table because the **Owner** field is required (can't be *blank*).

To use any fields of a record reference, you must first use the **AsType** function to cast it to a specific table type. You can't access fields directly from the **Owner** field because the system doesn't know what table type you want to use.

The **AsType** function returns an error if the **Owner** field doesn't match the table type being requested, so you can use the **IfError** function to simplify this formula. First, turn on the experimental feature **Formula-level error management**:



Then replace the previous formula with this one:

Power Fx

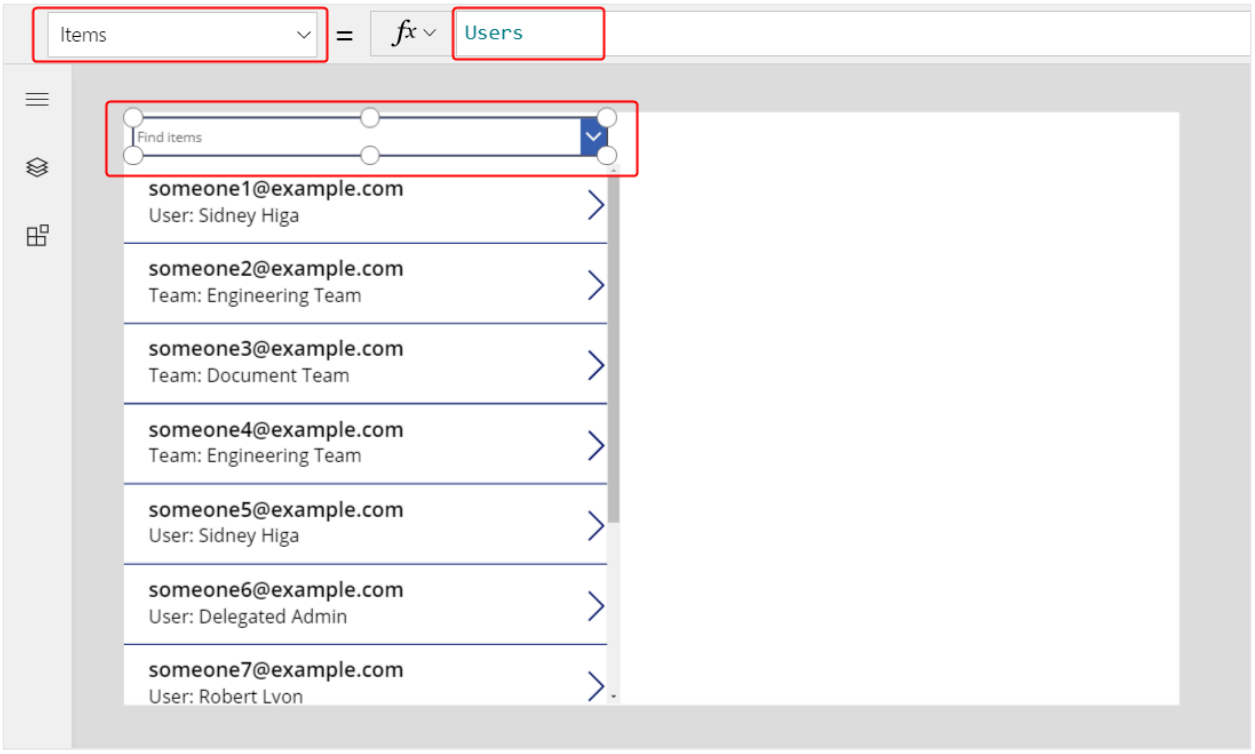
```
IfError(
    "Team: " & AsType( ThisItem.Owner, Teams ).'Team Name',
    "User: " & AsType( ThisItem.Owner, Users ).'Full Name' )
```

Filter based on an owner

Congratulations—you've finished the hardest aspect of working with a record reference. Other use cases are more straightforward because they don't access fields of the record. As a case in point, take filtering, which you'll explore in this section.

Add a **Combo box** control above the gallery, and set these properties of the new control:

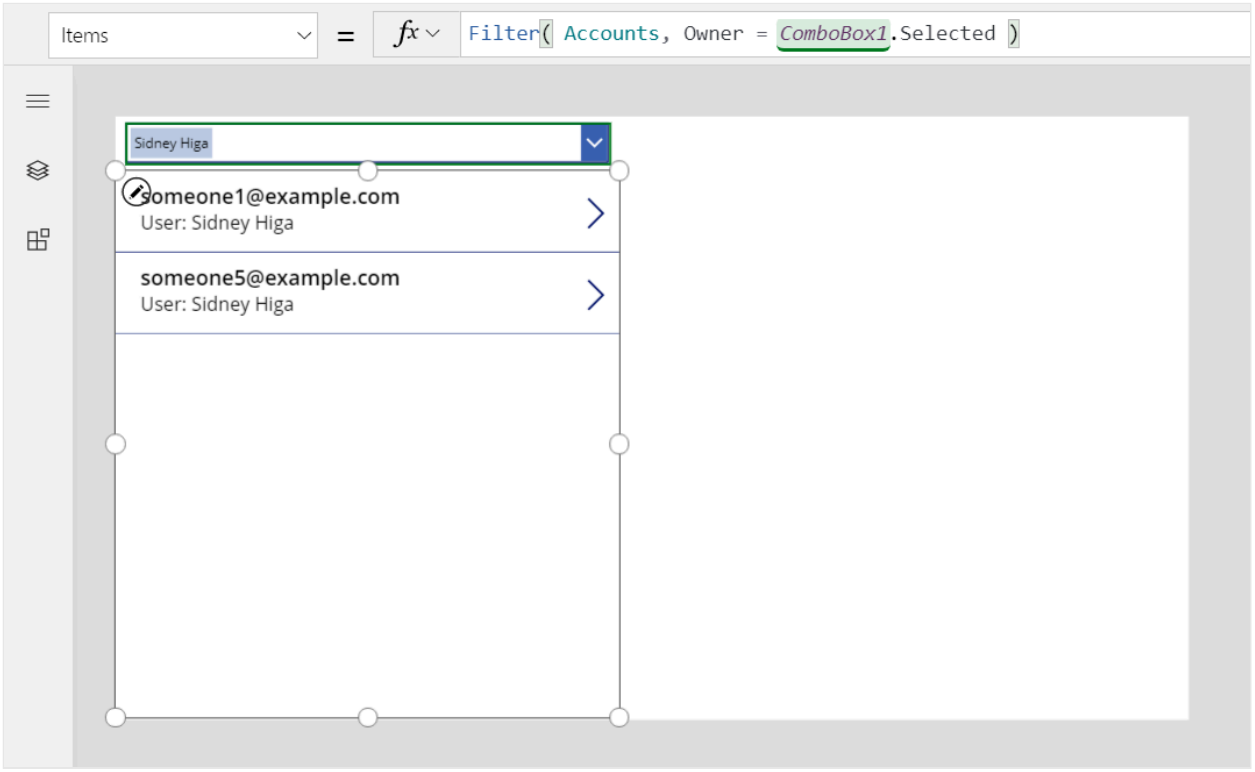
- **Items**: `Users`
- **SelectMultiple**: `false`



To filter the gallery by a specific user selected from this combo box, set the gallery's **Items** property to this formula:

Power Fx

```
Filter( Accounts, Owner = ComboBox1.Selected )
```



Important

The instructions in this topic are accurate if you follow the steps exactly. However, any formula that refers to a control by its name fails if the control has a different name. If you delete and add a control of the same type, the number at the end of the control's name changes. For any formula that shows an error, confirm that it contains the correct names of all controls.

You don't need to use **IsType** or **AsType** because you're comparing record references to other record references or to full records. The app knows the table type of **ComboBox1.Selected** because it's derived from the **Users** table. Accounts for which the owner is a team won't match the filter criterion.

You can get a little fancier by supporting filtering by either a user or a team.

1. Make some space near the top of the screen by resizing the gallery and moving the combo box, insert a **Radio** control above the gallery, and then set these properties for the new control:

   - **Items**: `[ "All", "Users", "Teams" ]`
   - **Layout**: `Layout.Horizontal`

2. For the **Combo box** control, set this property (if the combo box disappears, select **Users** in the radio control):

   - **Visible**: `Radio1.Selected.Value = "Users"`

3. Copy and paste the **Combo box** control, move the copy directly over the original, and then set these properties for the copy:

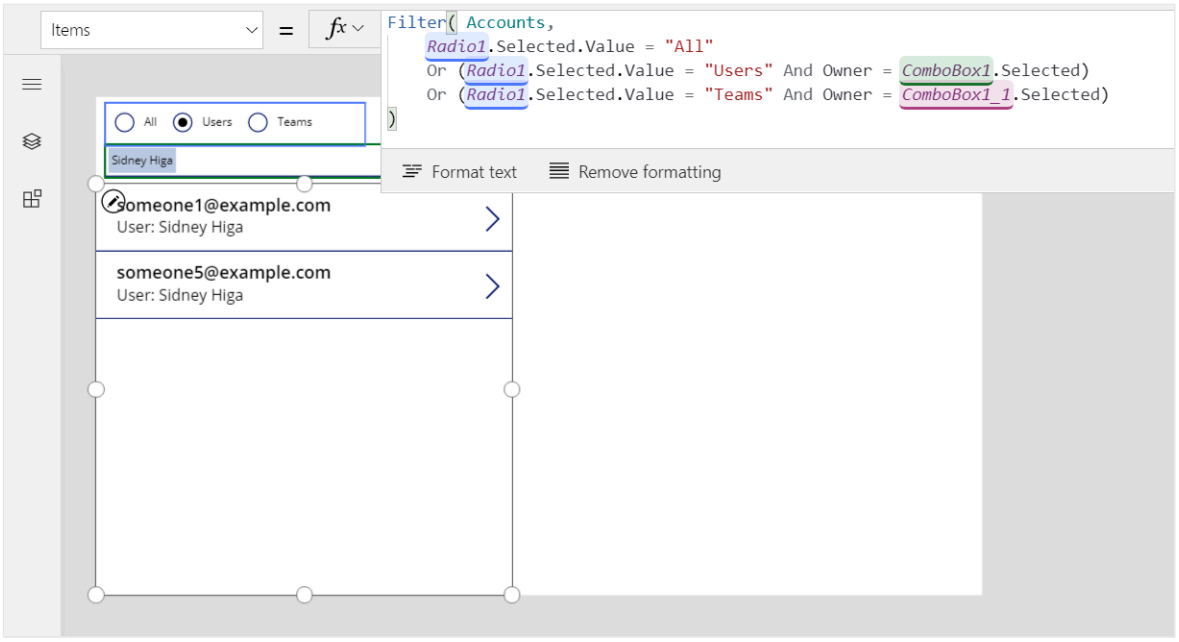
   - **Items**: `Teams`
   - **Visible**: `Radio1.Selected.Value = "Teams"`

   The app will display only one combo box at a time, depending on the state of the radio control. Because they're directly above one another, they'll appear to be the same control that changes its contents.

4. Finally, set the **Items** property of the **Gallery** control to this formula:

   Power Fx

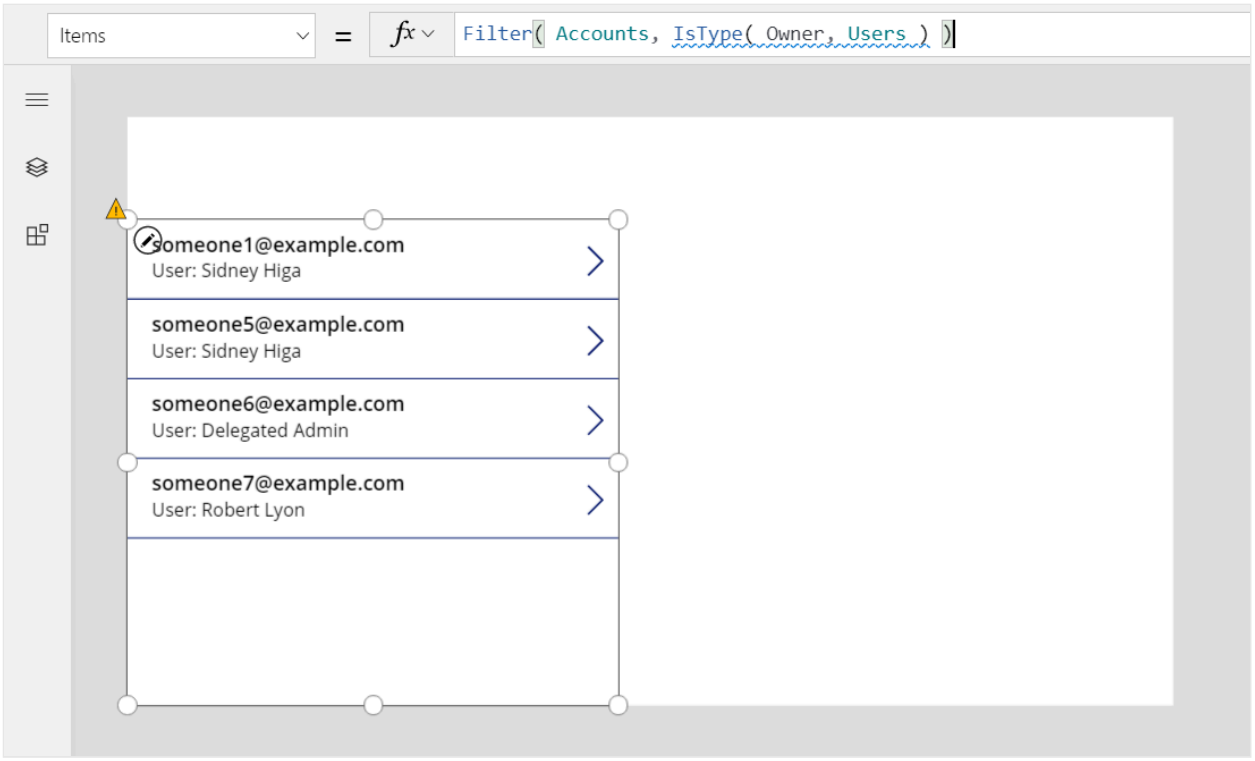
   ```
   Filter( Accounts,
       Radio1.Selected.Value = "All"
       Or (Radio1.Selected.Value = "Users" And Owner = ComboBox1.Selected)
       Or (Radio1.Selected.Value = "Teams" And Owner =
   ComboBox1_1.Selected)
   )
   ```



With these changes, you can show all records or filter them based on either a user or a team:

The formula is fully delegable. The portion that's comparing the radio-button values is a constant across all records and is evaluated before the rest of the filter is sent to Dataverse.

If you want to filter on the type of the owner, you can use the **IsType** function, but it's not yet delegable.



Update the owner by using Patch

You can update the **Owner** field in the same manner as any other lookup. To set the currently selected account's owner to the first team:

Power Fx

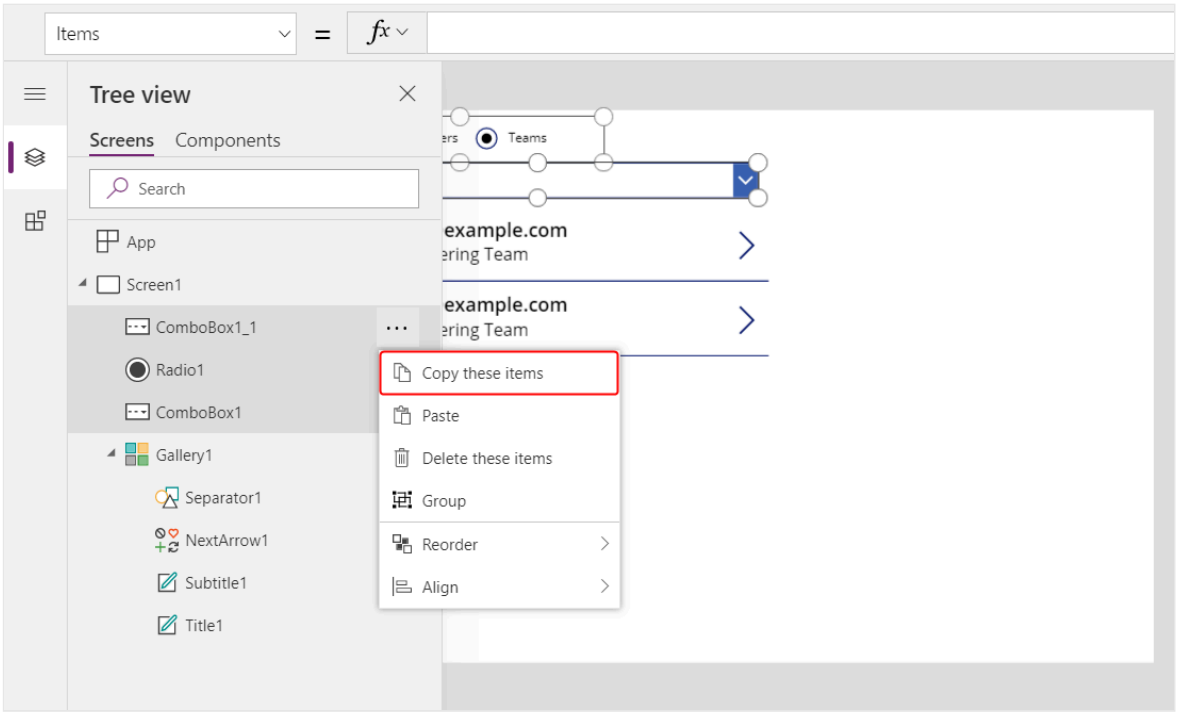
```
Patch( Accounts, Gallery1.Selected, { Owner: First( Teams ) } )
```

This approach doesn't differ from a normal lookup because the app knows the type of **First(Teams)**. If you want the first user instead, replace that portion with **First(Users)**. The **Patch** function knows that the **Owner** field can be set to either of these two table types.

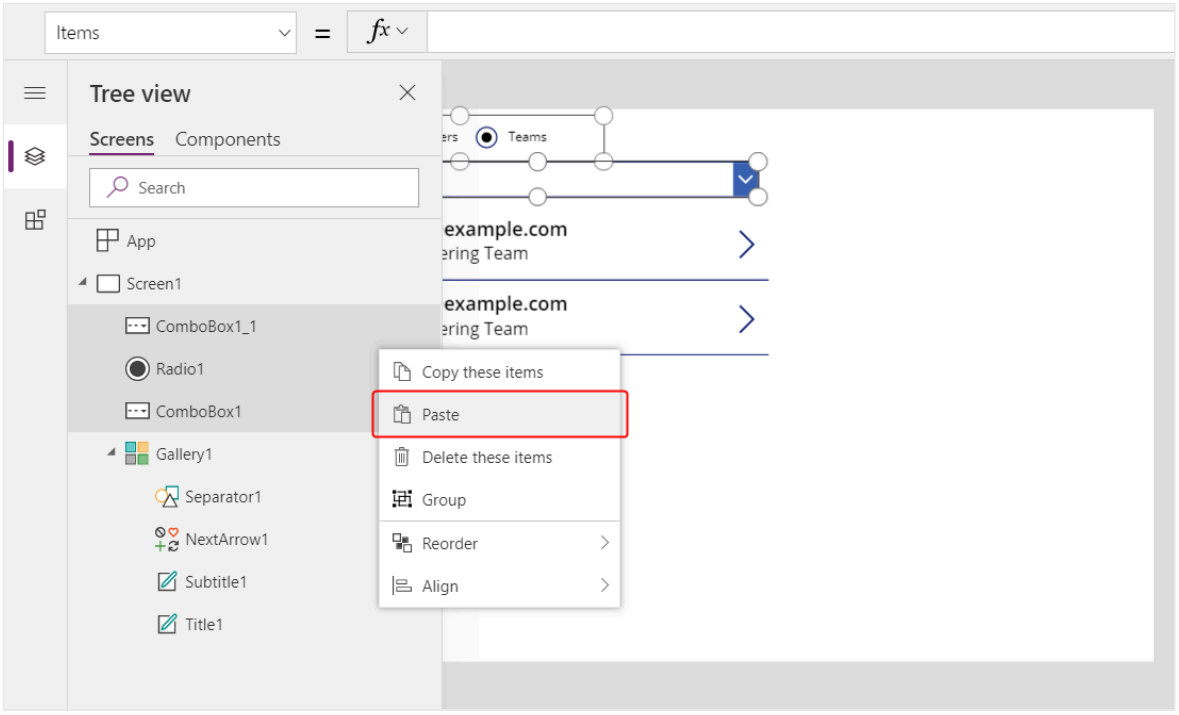
To add this capability to the app:

1. In the **Tree view** pane, select the **Radio** control and the two **Combo box** controls at the same time.

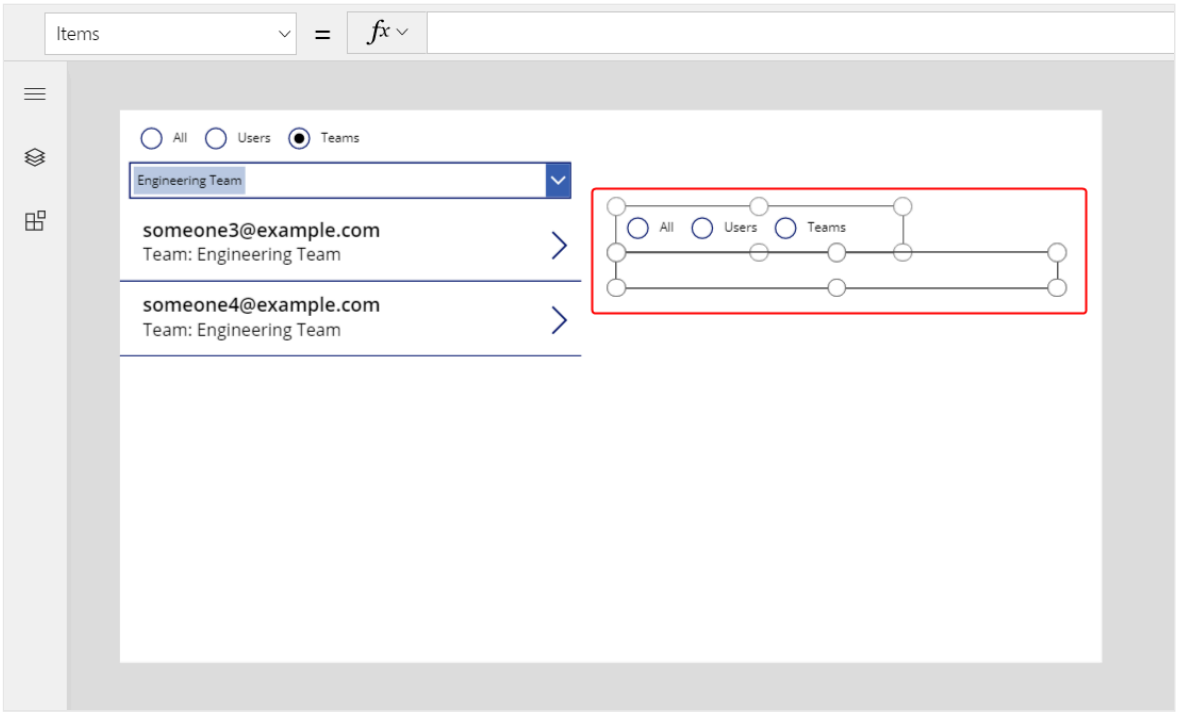
2. On the ellipsis menu, select **Copy these items**.



3. On the same menu, select **Paste**.

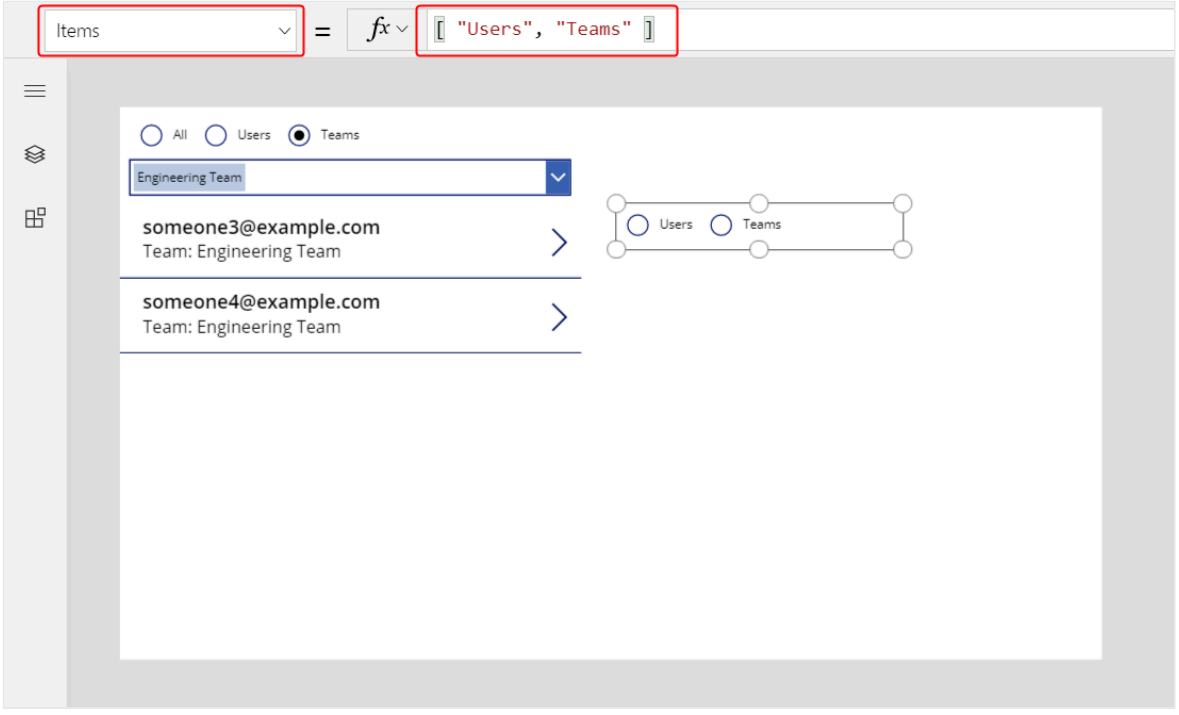


4. Move the copied controls to the right of the gallery.



5. Select the copied **Radio** control, and then change these properties:

   - Items: `[ "Users", "Teams" ]`
   - Default: `If( IsType( Gallery1.Selected.Owner, Users ), "Users", "Teams" )`

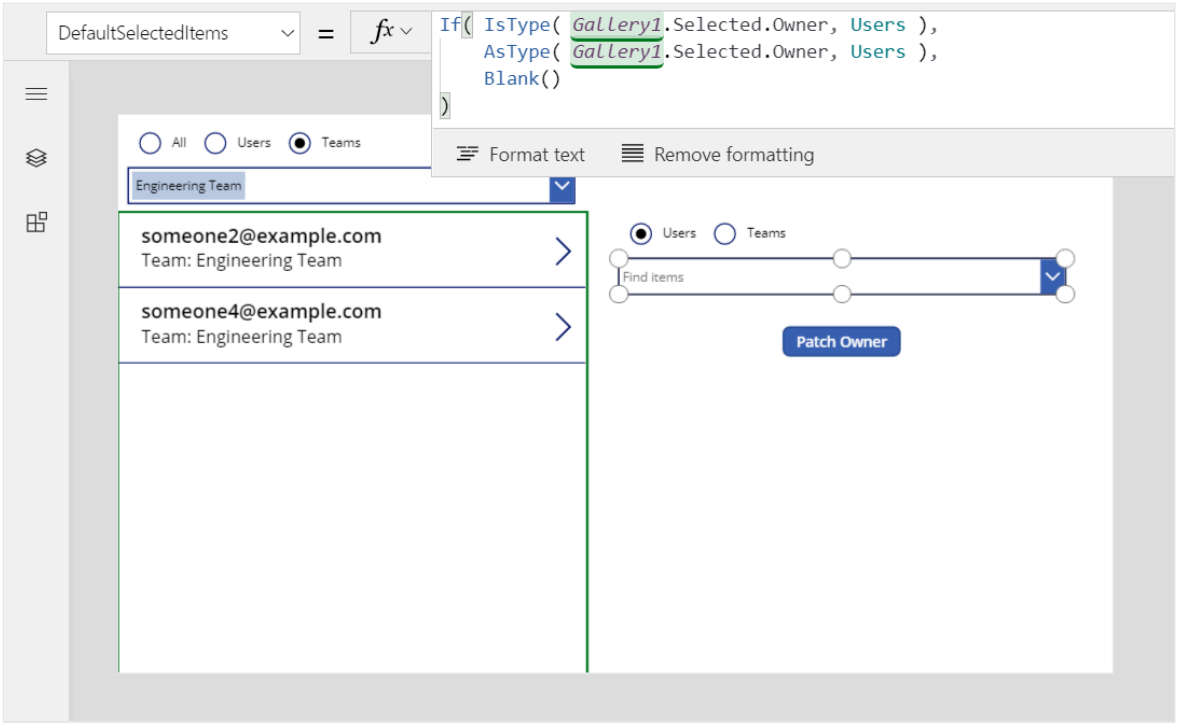


6. In the **Radio** control, select **Users** so that the **Combo box** control that lists users is visible.

7. Select the visible **Combo box** control, and then set the **DefaultSelectedItems** property to this formula:

```
Power Fx
```

```
If( IsType( Gallery1.Selected.Owner, Users ),
    AsType( Gallery1.Selected.Owner, Users ),
    Blank()
)
```



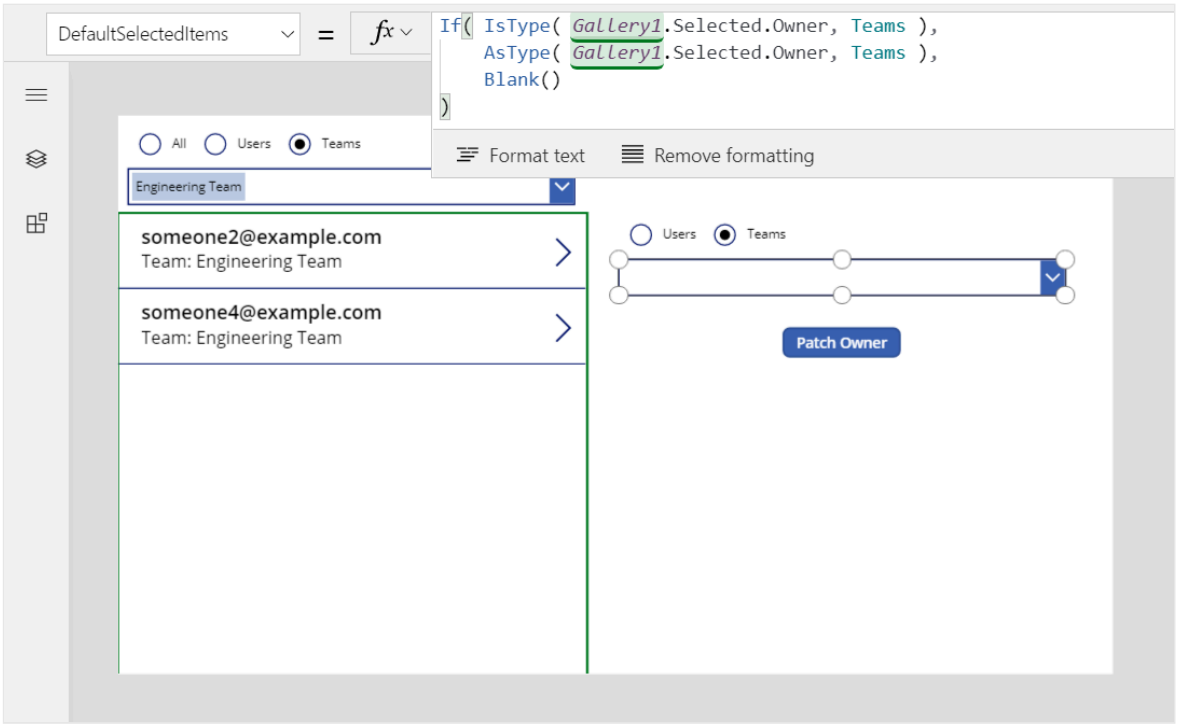
8. In the **Radio** control, select **Teams** so that the **Combo box** control that lists teams is visible.

9. Select the **Radio** control to take selection away from the now-invisible **Combo box** control for users.

10. Select the visible **Combo box** control for teams, and then set its **DefaultSelectedItems** property to this formula:

Power Fx

```
If( IsType( Gallery1.Selected.Owner, Teams ),
    AsType( Gallery1.Selected.Owner, Teams ),
    Blank()
)
```

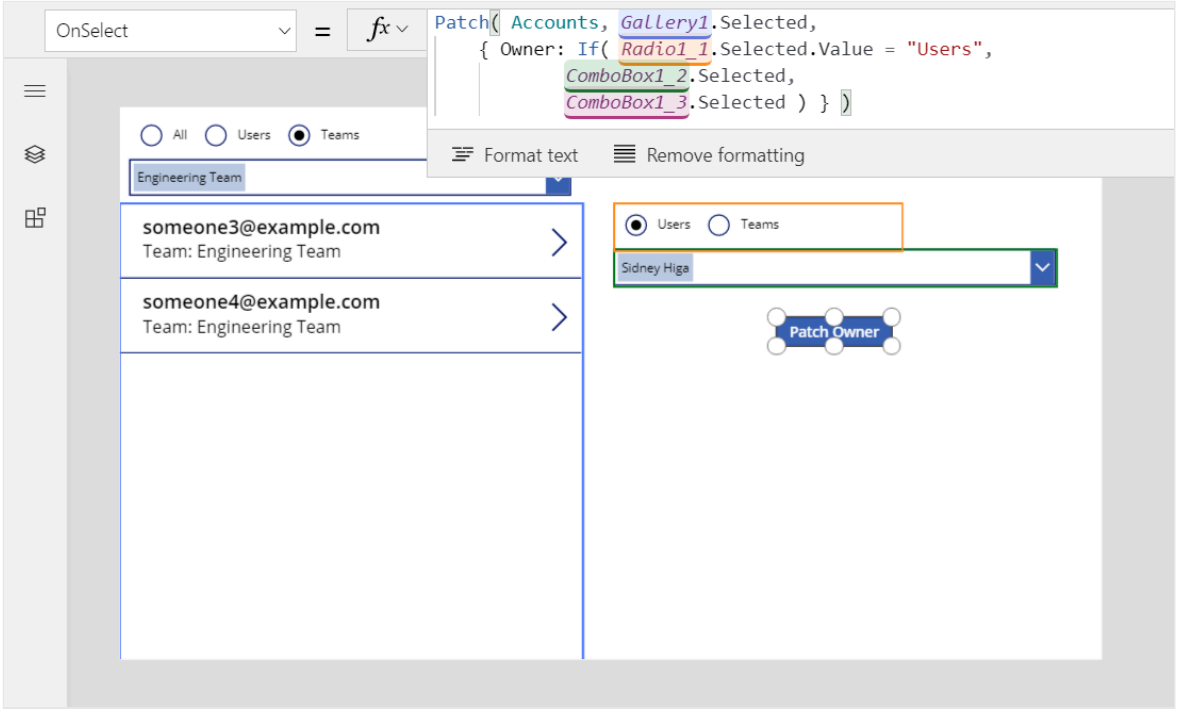


11. Insert a **Button** control, move it under the **Combo box** control, and then set the button's **Text** property to `"Patch Owner"`.

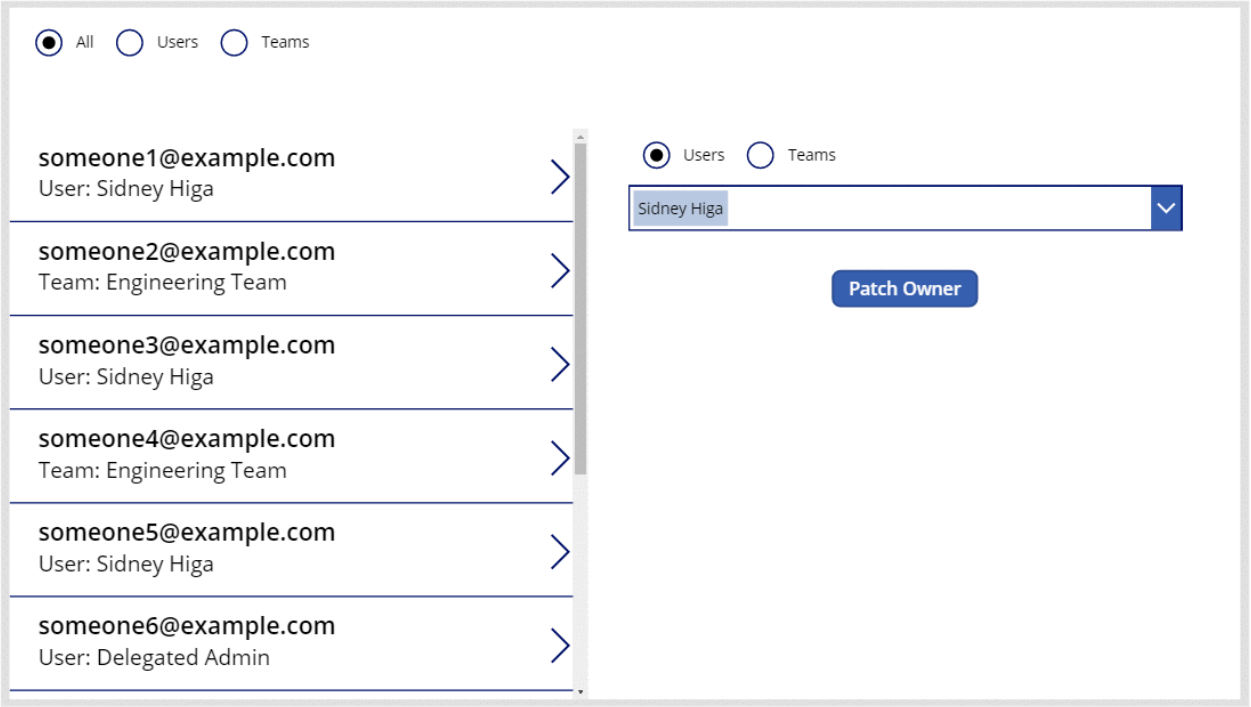
12. Set the **OnSelect** property of the button to this formula:

```
Power Fx

Patch( Accounts, Gallery1.Selected,
    { Owner: If( Radio1_1.Selected.Value = "Users",
                 ComboBox1_2.Selected,
                 ComboBox1_3.Selected ) } )
```



The copied **Radio** and **Combo box** controls show the owner for the currently selected account in the gallery. With the same controls, you can set the owner of the account to any team or user by selecting the button:

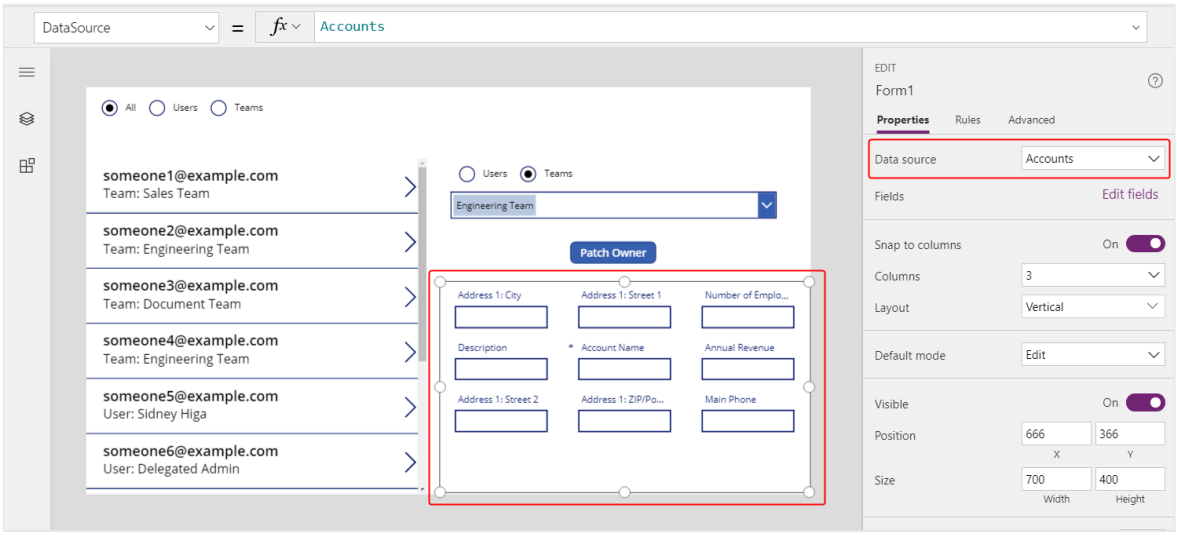


Show the owner by using a form

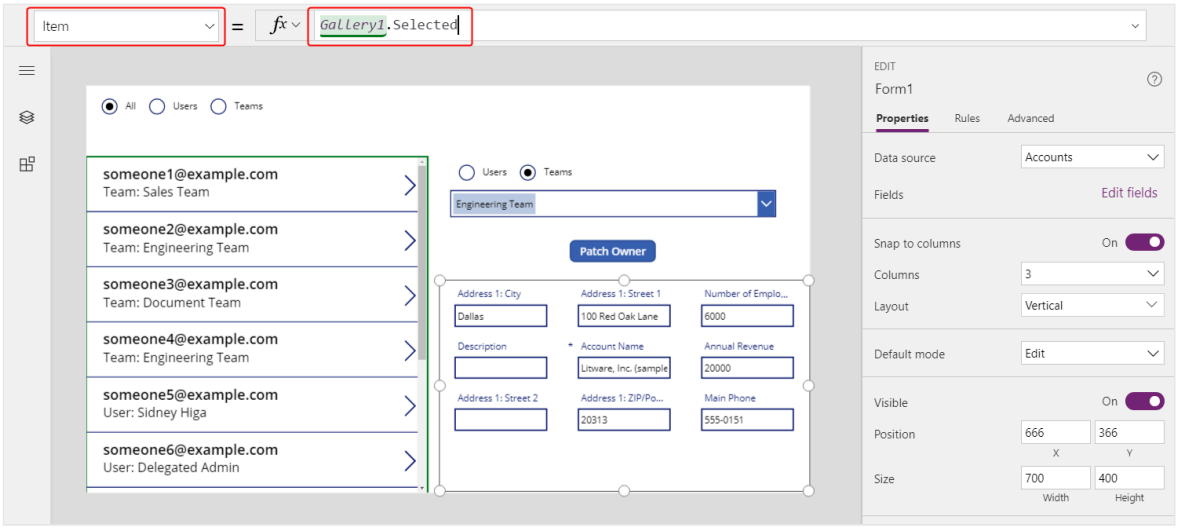
You can show an **Owner** field inside a form by adding a custom card. As of this writing, you can't change the value of the field with a form control.

1. Insert an **Edit form** control, and then resize and move it to the lower-right corner.

2. On the **Properties** tab near the right side of the screen, open the **Data source** list, and then select **Accounts**.

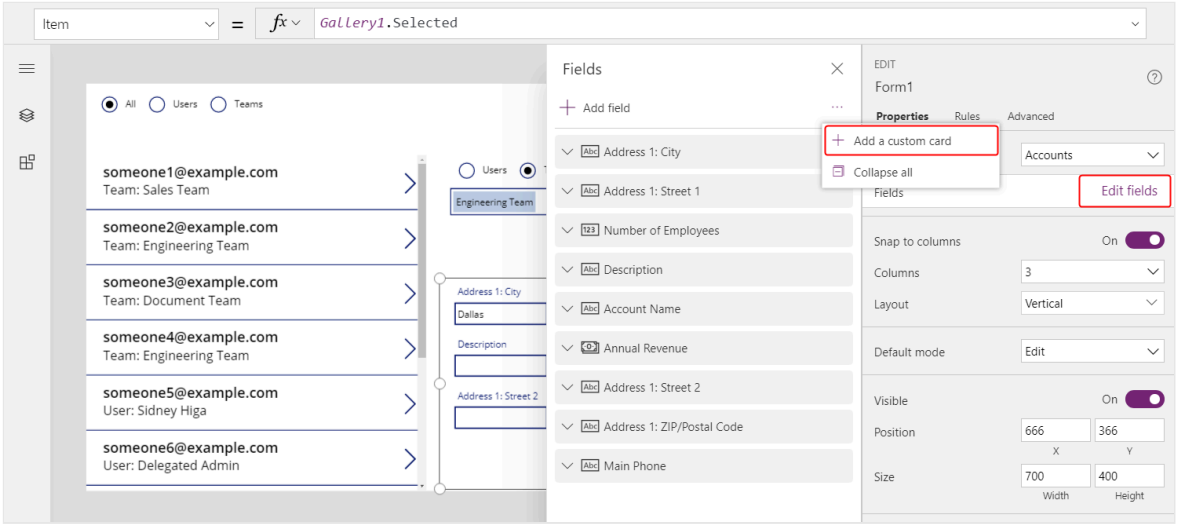


3. Set the form's **Item** property to `Gallery1.Selected`.



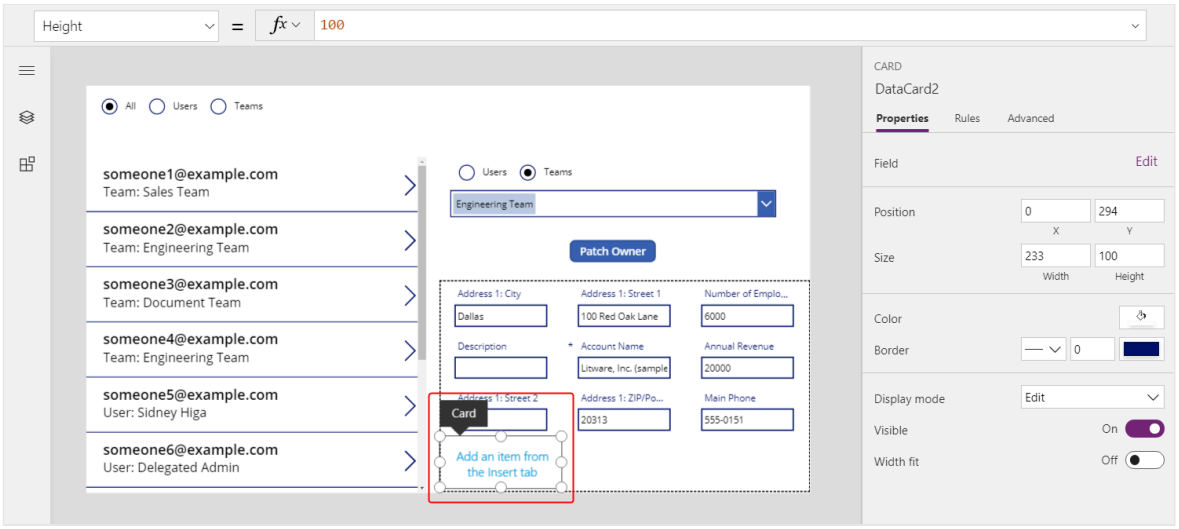
4. On the **Properties** tab near the right side of the screen, select **Edit fields**.

5. In the **Fields** pane, select the ellipsis, and then select **Add a custom card**.



The new card appears at the bottom of the form control.

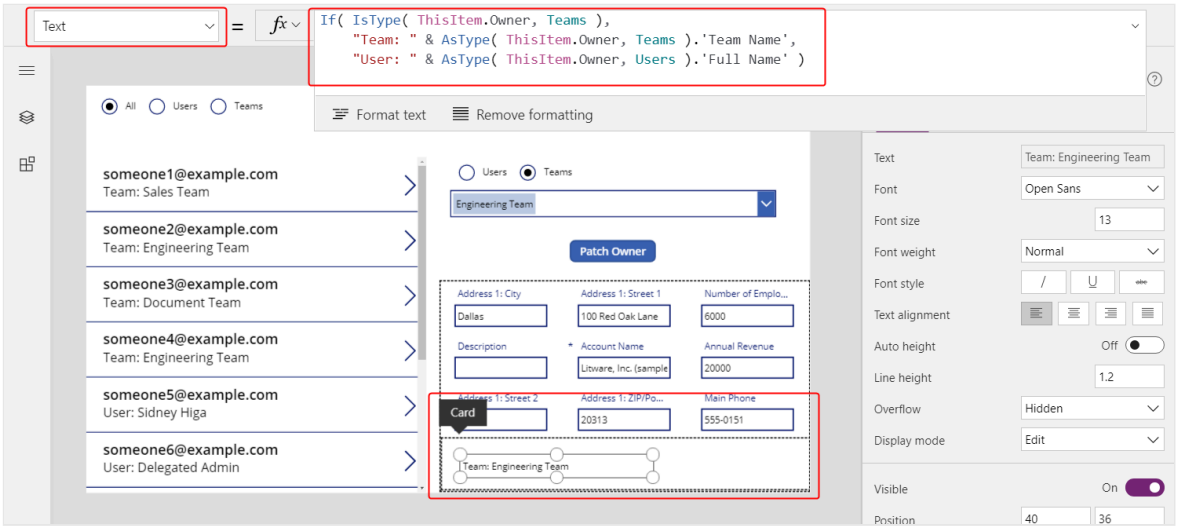
6. Resize the card as needed to show all the text.



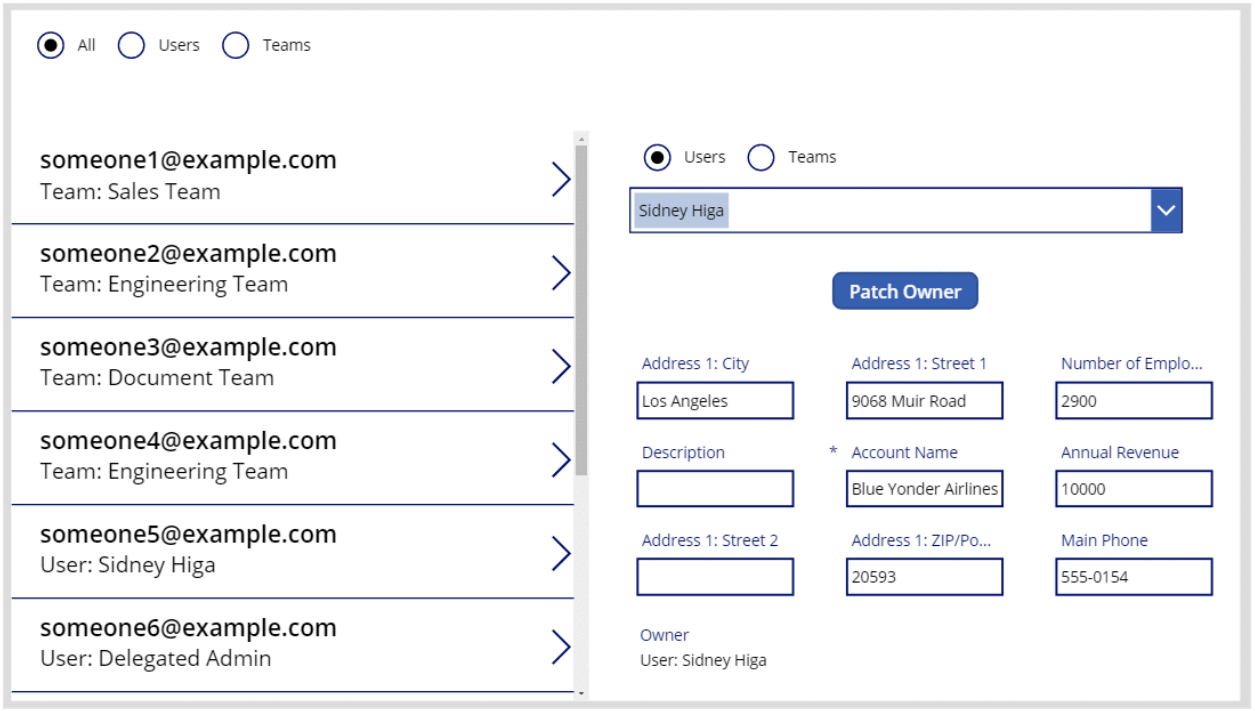
7. Insert a **Label** control into the custom card, and then set the label's **Text** property to the formula that you used in the gallery:

```
Power Fx

If( IsType( ThisItem.Owner, Teams ),
    "Team: " & AsType( ThisItem.Owner, Teams ).'Team Name',
    "User: " & AsType( ThisItem.Owner, Users ).'Full Name' )
```



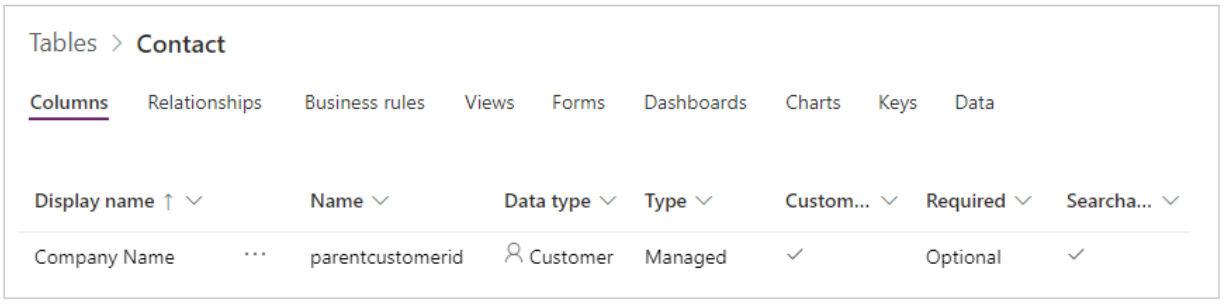
For each selection in the gallery, more fields of the account, including the record's owner, appear in the form. If you change the owner by using the **Patch** button, the form control also shows that change.



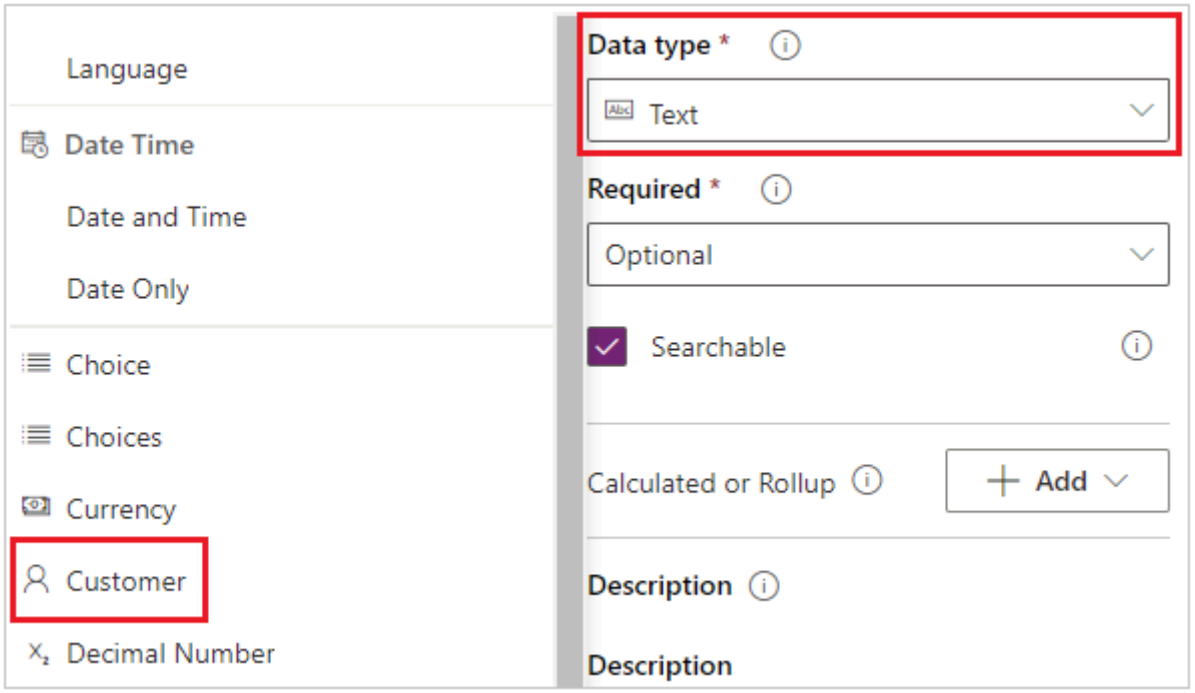
Show the columns of a customer

In Dataverse, the **Customer** lookup column is another polymorphic lookup that's very similar to **Owner**.

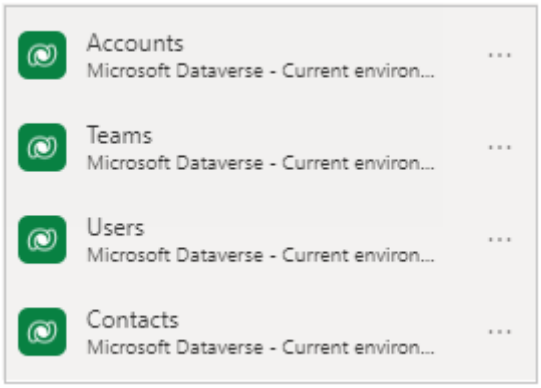
Owner is limited to one per table, but tables can include zero, one, or more **Customer** lookup column. The **Contacts** system table includes the **Company Name** column, which is a **Customer** lookup column.



You can add more **Customer** lookup columns to a table by selecting the **Customer** data type for a new column.



A **Customer** lookup field can refer to a record from either the **Accounts** table or the **Contacts** table. You'll use the **IsType** and **AsType** functions with these tables, so now is a good time to add them as data sources (you can leave **Teams** and **Users** in place).



The treatment of the **Customer** and **Owner** fields is so similar that you can literally copy the app (**File** > **Save as**, and then specify a different name) and make these simple replacements:

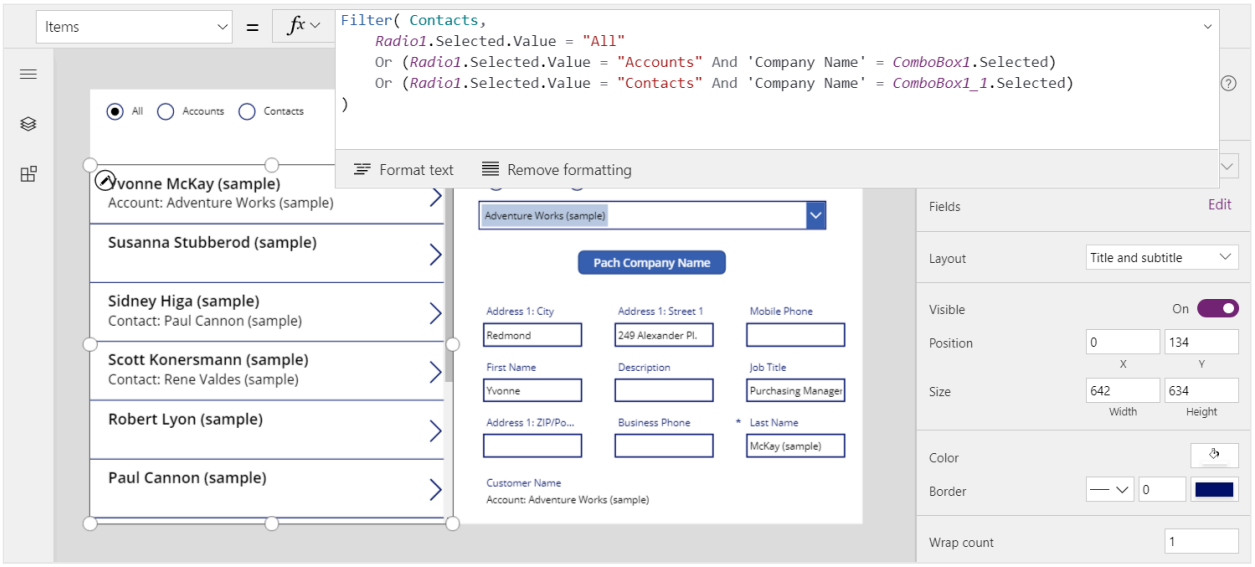
Expand table

Location	Owner **sample**	Customer **sample**
Throughout	**Owner**	**'Customer Name'**
Throughout	**Users**	**Accounts**
Throughout	**Teams**	**Contacts**
Gallery's **Items** property	**Accounts**	**Contacts**
Form's **Items** property	**Accounts**	**Contacts**
The first argument of **Patch** in the button's **OnSelect** property	**Accounts**	**Contacts**
Filter radio's **Items** property	**["All", "Users", "Teams"]**	**["All", "Accounts", "Contacts"]**
Patch radio's **Items** property	**["Users", "Teams"]**	**["Accounts", "Contacts"]**
Combo box's **Visible** property	**"Users"** and **"Teams"**	**"Accounts"** and **"Contacts"**

For example, the new gallery should have this **Items** property:

Power Fx

```
Filter( Contacts,
    Radio1.Selected.Value = "All"
    Or (Radio1.Selected.Value = "Accounts" And 'Company Name' =
ComboBox1.Selected)
    Or (Radio1.Selected.Value = "Contacts" And 'Company Name' =
ComboBox1_1.Selected)
)
```



Two important differences between **Customer** and **Owner** require an update to the formulas inside the gallery and the form:

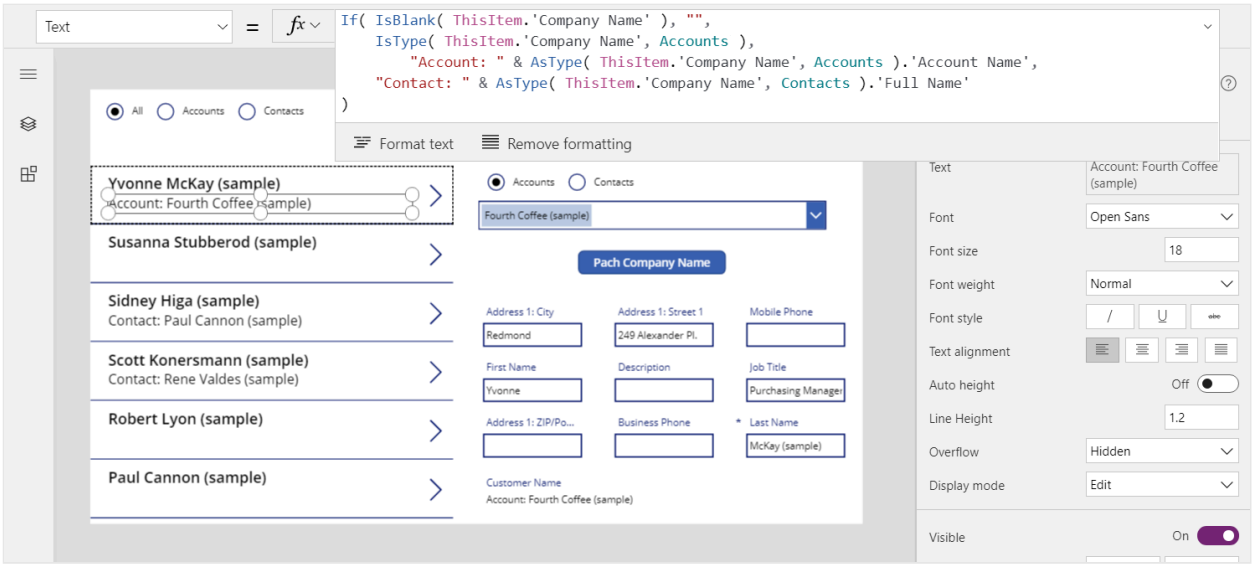
1. One-to-many relationships between **Accounts** and **Contacts** take precedence when you refer to these table types by name. Instead of **Accounts**, use **[@Accounts]**; instead of **Contacts**, use **[@Contacts]**. By using the global disambiguation operator, you ensure that you're referring to the table type in **IsType** and **AsType**. This problem exists only in the record context of the gallery and form controls.

2. The **Owner** field must have a value, but **Customer** fields can be *blank*. To show the correct result without a type name, test for this case with the **IsBlank** function, and show an empty text string instead.

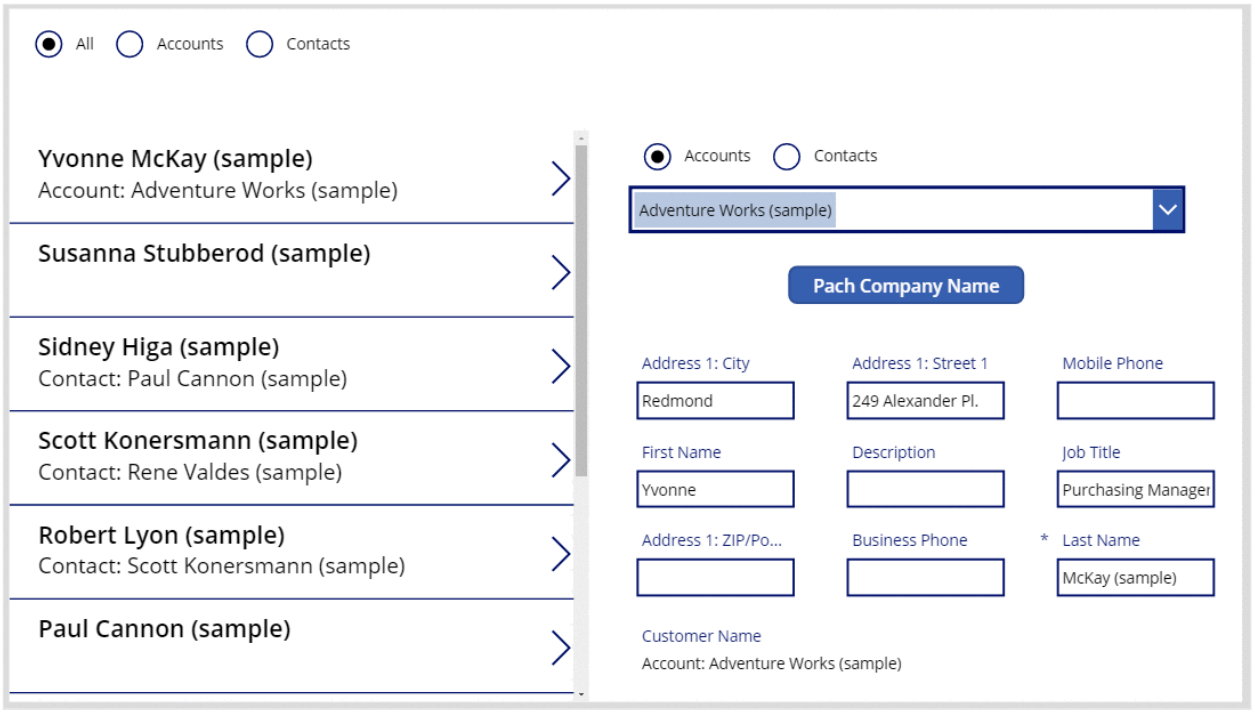
Both of these changes are in the same formula, which appears in the custom card in the form, as well as in the **Text** property of the gallery's label control:

Power Fx

```
If( IsBlank( ThisItem.'Company Name' ), "",
    IsType( ThisItem.'Company Name', Accounts ),
        "Account: " & AsType( ThisItem.'Company Name', Accounts ).'Account
Name',
    "Contact: " & AsType( ThisItem.'Company Name', Contacts ).'Full Name'
)
```



With these changes, you can view and change the **Company Name** field in the **Contacts** table.



Understand Regarding lookup columns

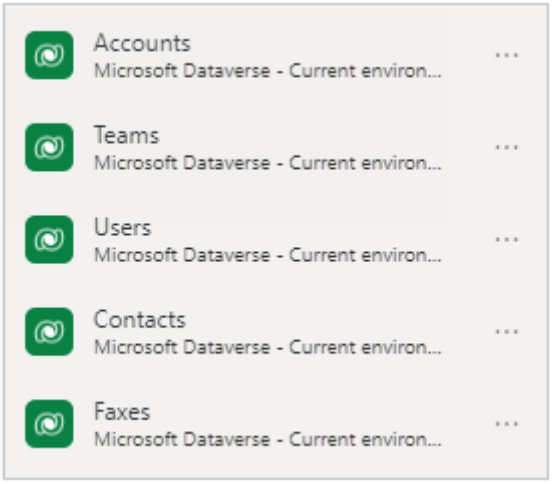
The **Regarding** lookup column differs a little from those that you've already worked with in this topic. You'll start by applying the patterns that this topic described earlier, and then you'll learn other tricks.

You can start simply with the **Faxes** table. This table has a polymorphic **Regarding** lookup column, which can refer to **Accounts**, **Contacts**, and other tables. You can take the app for **Customers** and modify it for **Faxes**.

Expand table

Location	Customer **sample**	Faxes **sample**
Throughout	**'Customer Name'**	**Regarding**
Gallery's **Items** property	**Contacts**	**Faxes**
Form's **Items** property	**Contacts**	**Faxes**
The first argument of **Patch** in the button's **OnSelect** property	**Contacts**	**Faxes**

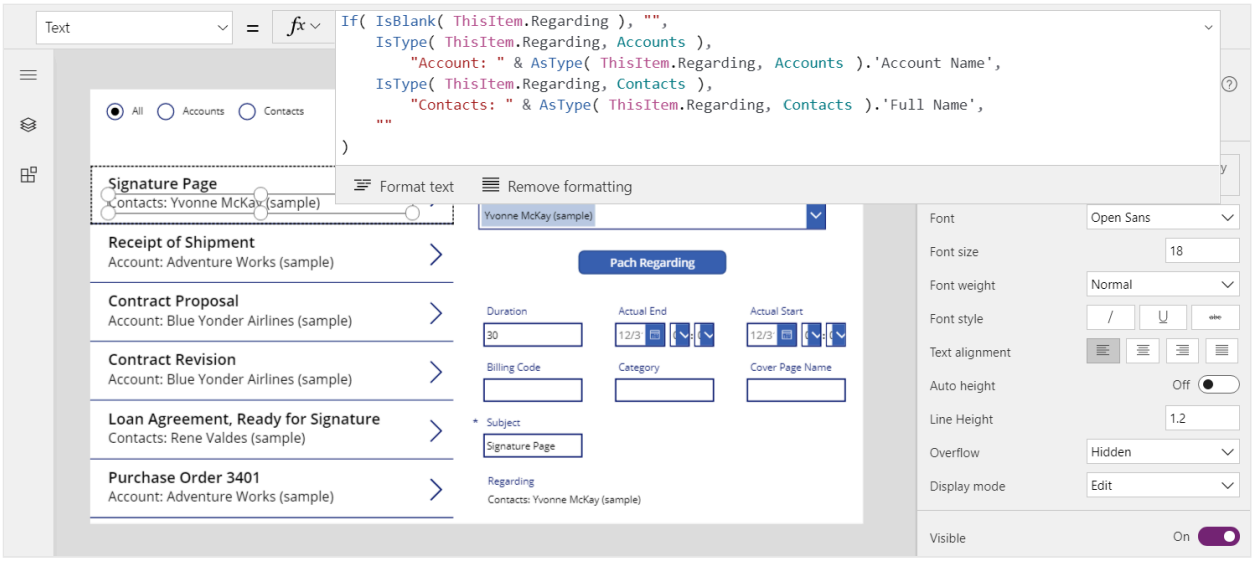
Again, you'll need to add a data source: this time for **Faxes**. On the **View** tab, select **Data sources**:



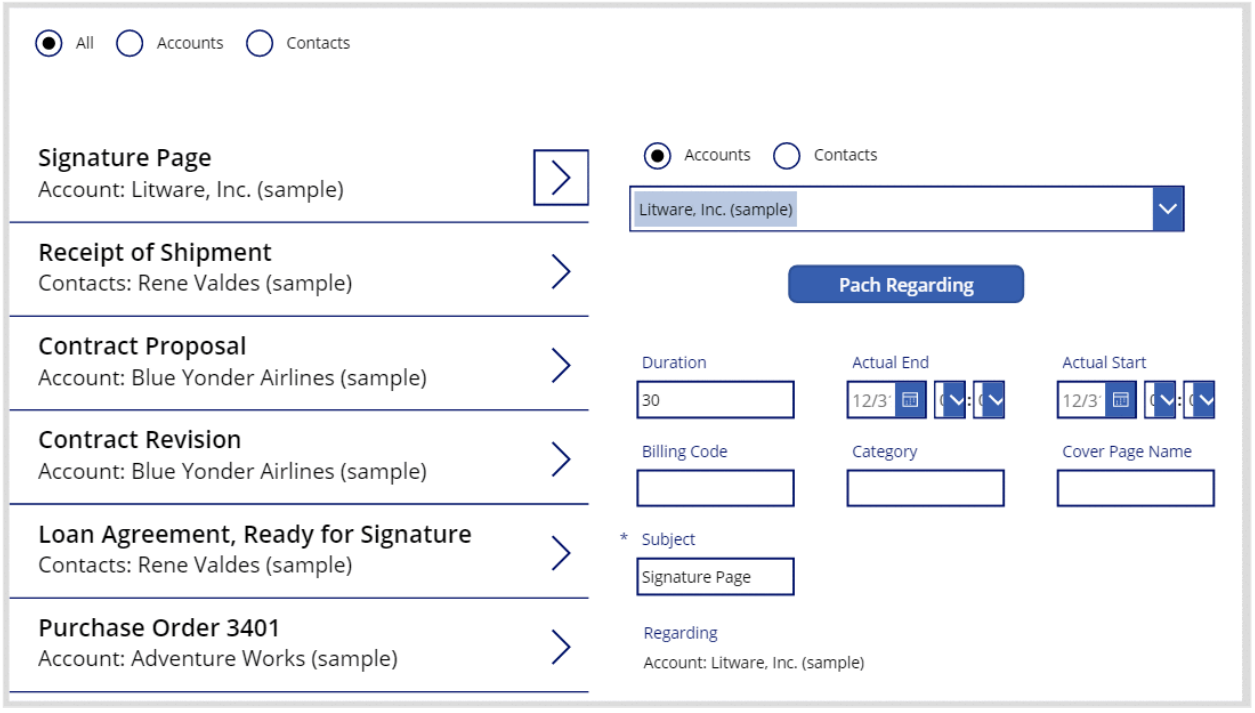
An important difference for **Regarding** is that it isn't limited to **Accounts** and **Contacts**. In fact, the list of tables is extensible with custom tables. Most of the app can accommodate this point without modification, but you must update the formula for the label in the gallery and the form:

Power Fx

```
If( IsBlank( ThisItem.Regarding ), "",
    IsType( ThisItem.Regarding, Accounts ),
        "Account: " & AsType( ThisItem.Regarding, Accounts ).'Account Name',
    IsType( ThisItem.Regarding, Contacts ),
        "Contacts: " & AsType( ThisItem.Regarding, Contacts ).'Full Name',
    ""
)
```



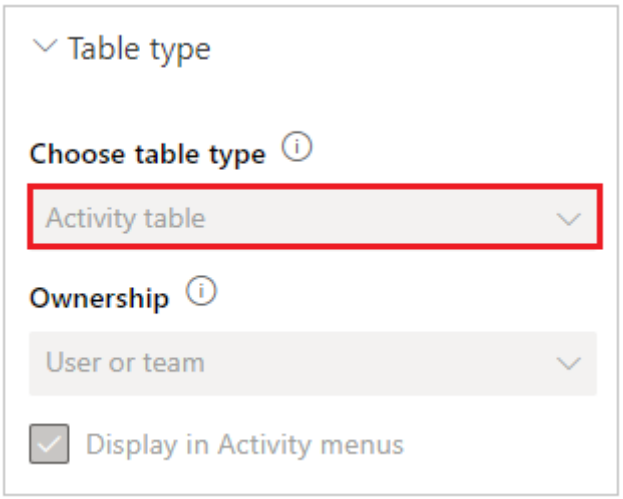
After you make these changes, you work with the **Regarding** lookup just as you did the **Owner** and **Customer** lookups.



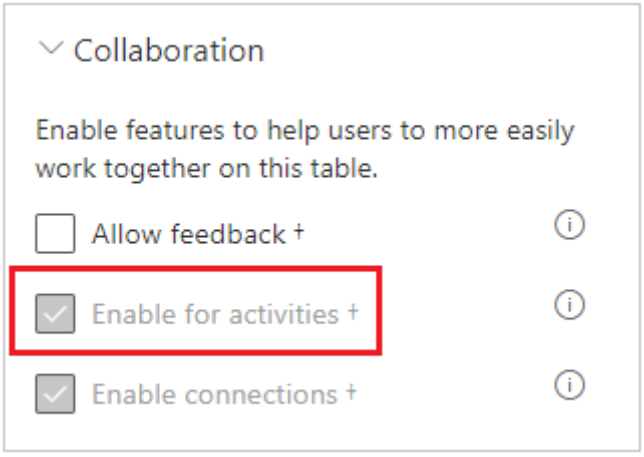
Understand Regarding relationships

Regarding differs from **Owner** and **Customer** because the former involves a many-to-one relationship. By definition, a reverse, one-to-many relationship allows you to write **First(Accounts).Faxes**.

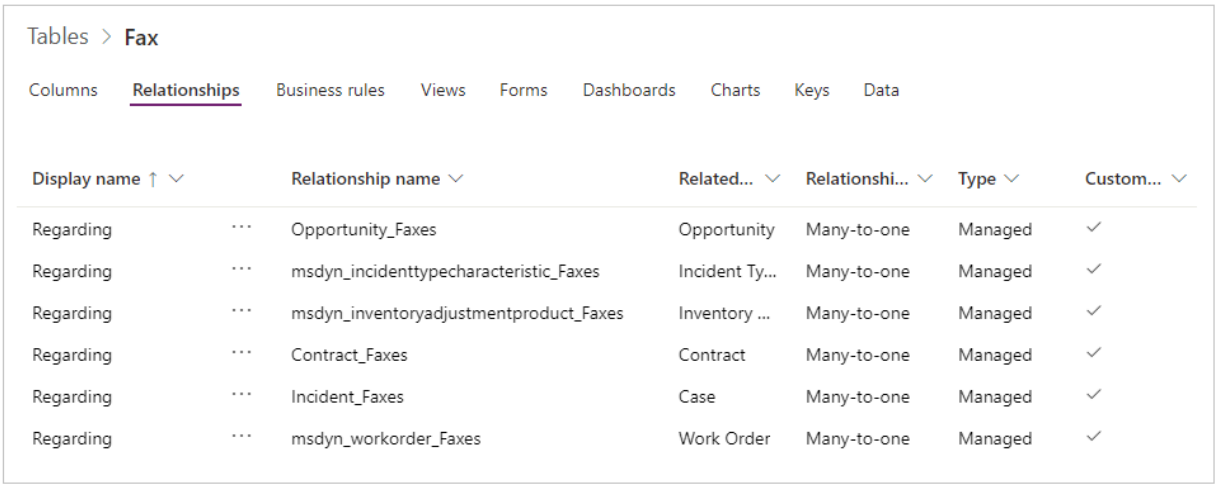
Let's back up and look at the table definitions. In Dataverse, tables such as **Faxes**, **Tasks**, **Emails**, **Notes**, **Phone Calls**, **Letters**, and **Chats** are designated as *activities*. You can also create your own custom activity tables. When you view or create an activity table, its settings appear under **More settings**.



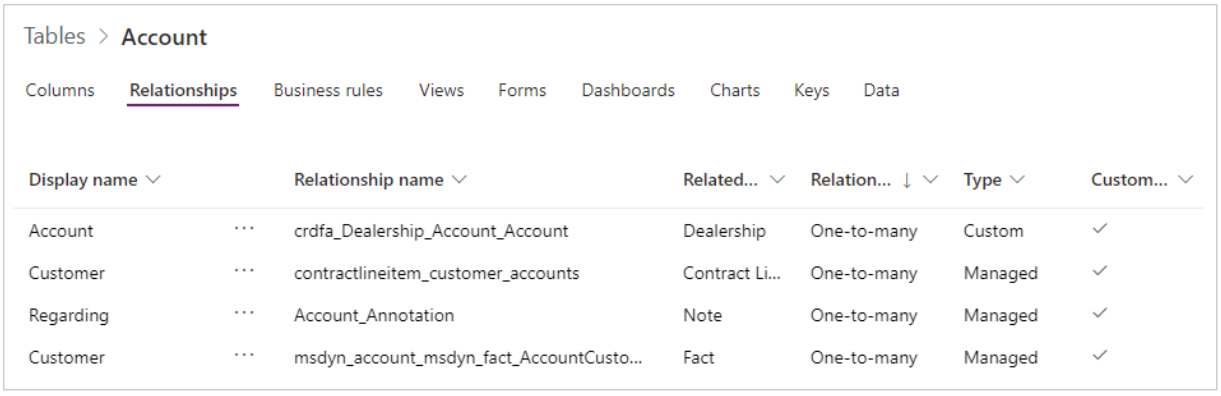
Other tables can be related to an activity table if they're enabled as an *activity task* in the table's settings. **Accounts**, **Contacts**, and many other standard tables are so designated (again, under **More settings**).



All activity tables and activity-task tables have an implied relationship. If you change the filter to **All** at the top of the screen, select the **Faxes** table, and then select the **Relationships** tab, all tables that can be a target of a **Regarding** lookup appear.



If you show the relationships for the **Accounts** table, all the tables that can be a source of a **Regarding** lookup field appear.

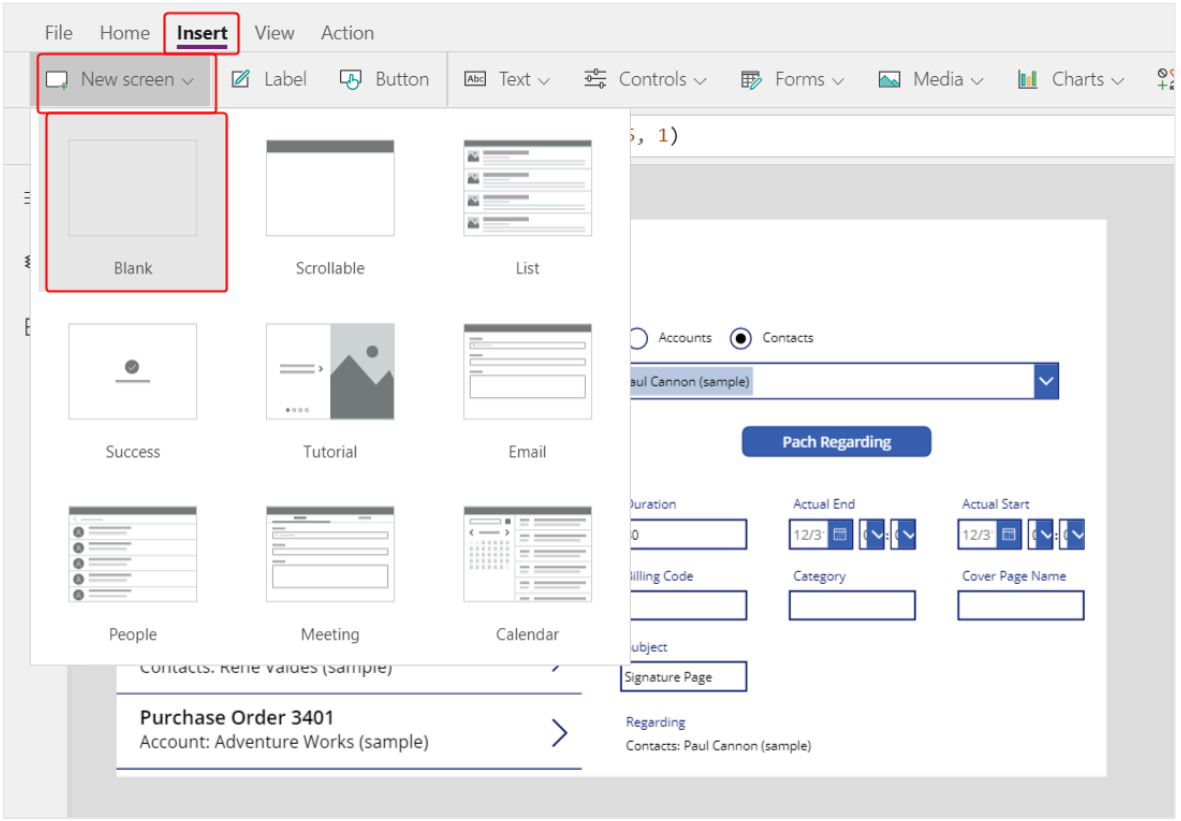


What does it all mean?

- When you write formulas, you must consider that the list of activity tables isn't fixed, and you can create your own. The formula must appropriately handle an activity table that you didn't expect.
- Activity tasks and activities have a one-to-many relationship. You can easily ask for all faxes that relate to an account.

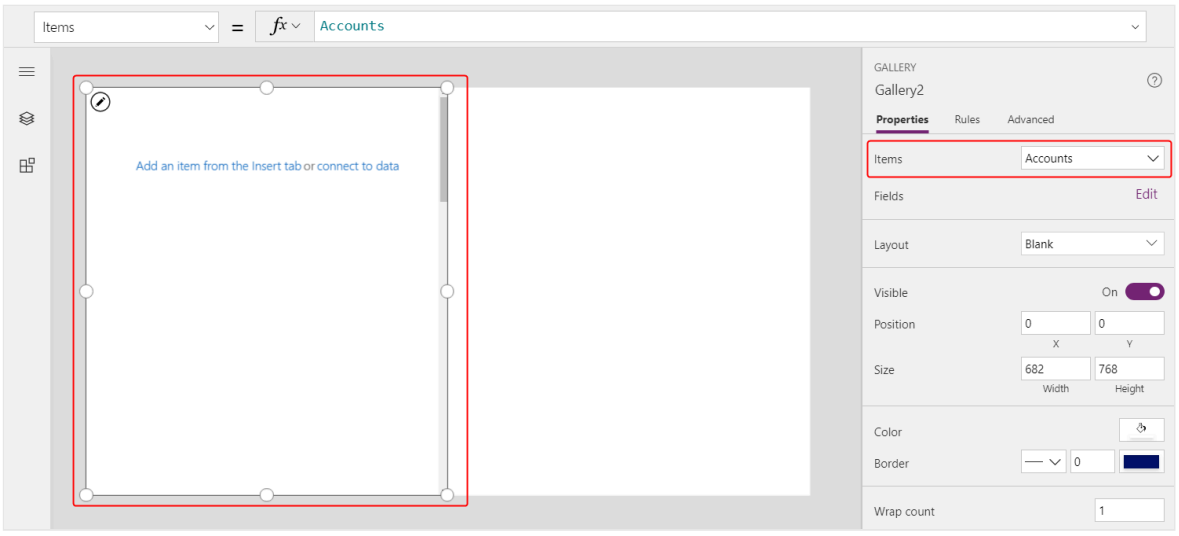
To explore this concept in the app:

1. Add another screen.

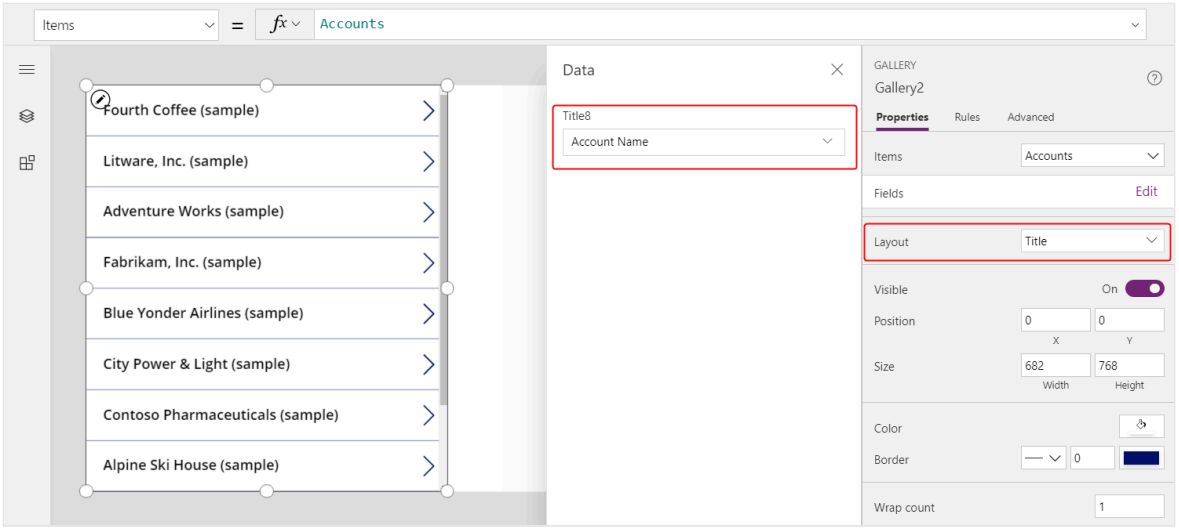


2. Insert a gallery control, resize it, and then move it to the left side of the screen.

3. On the **Properties** tab near the right side of the screen, set the gallery's **Items** to **Accounts**.



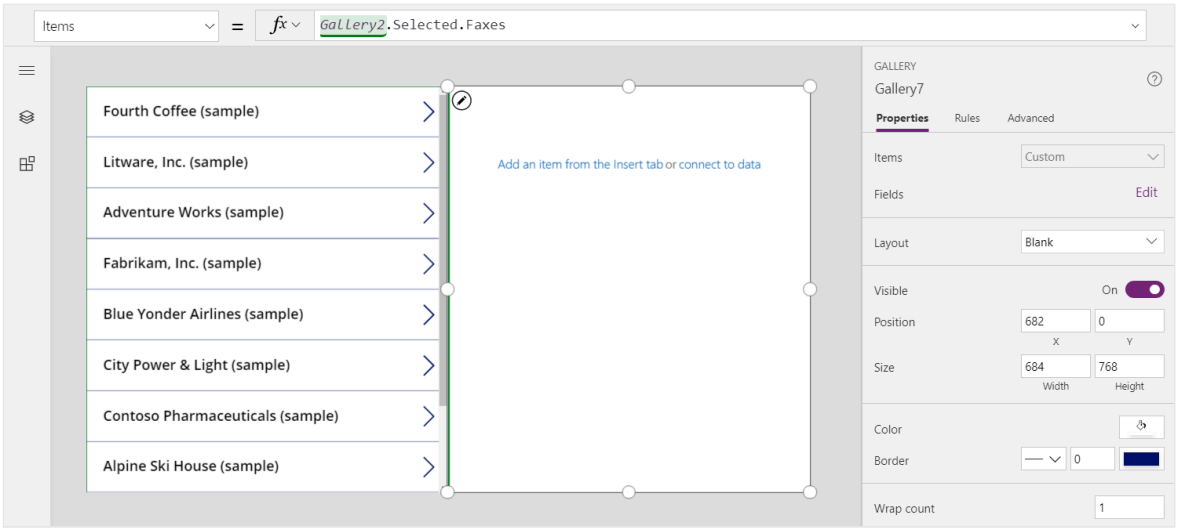
4. Set the gallery's layout to **Title**, and then set the title field to **Account Name**.



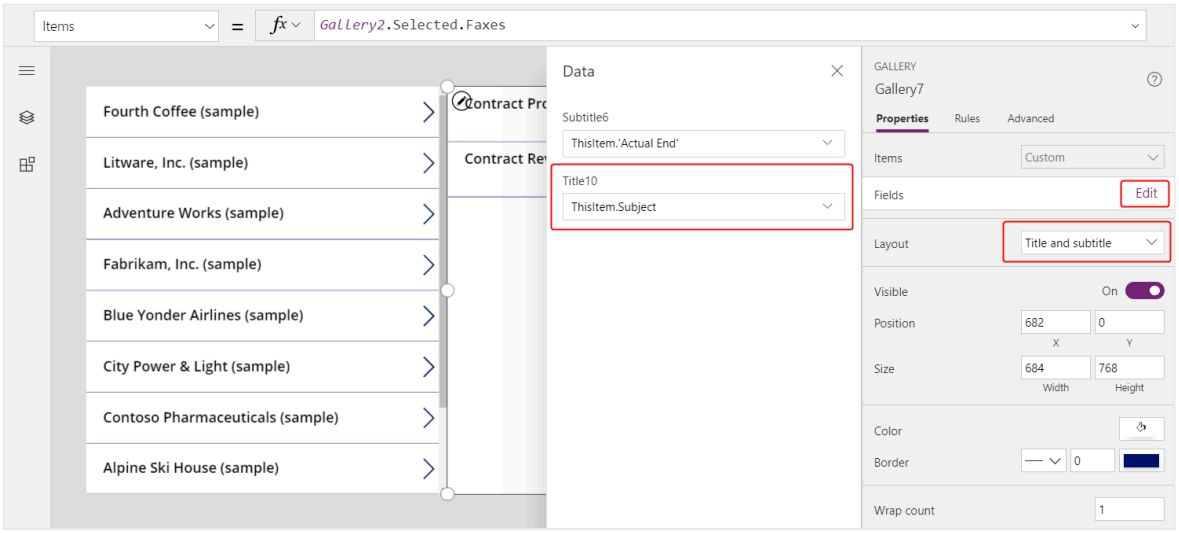
5. Add a second gallery, resize it, and then move it to the right side of the screen.

6. Set the new gallery's **Items** property to `Gallery2.Selected.Faxes`.

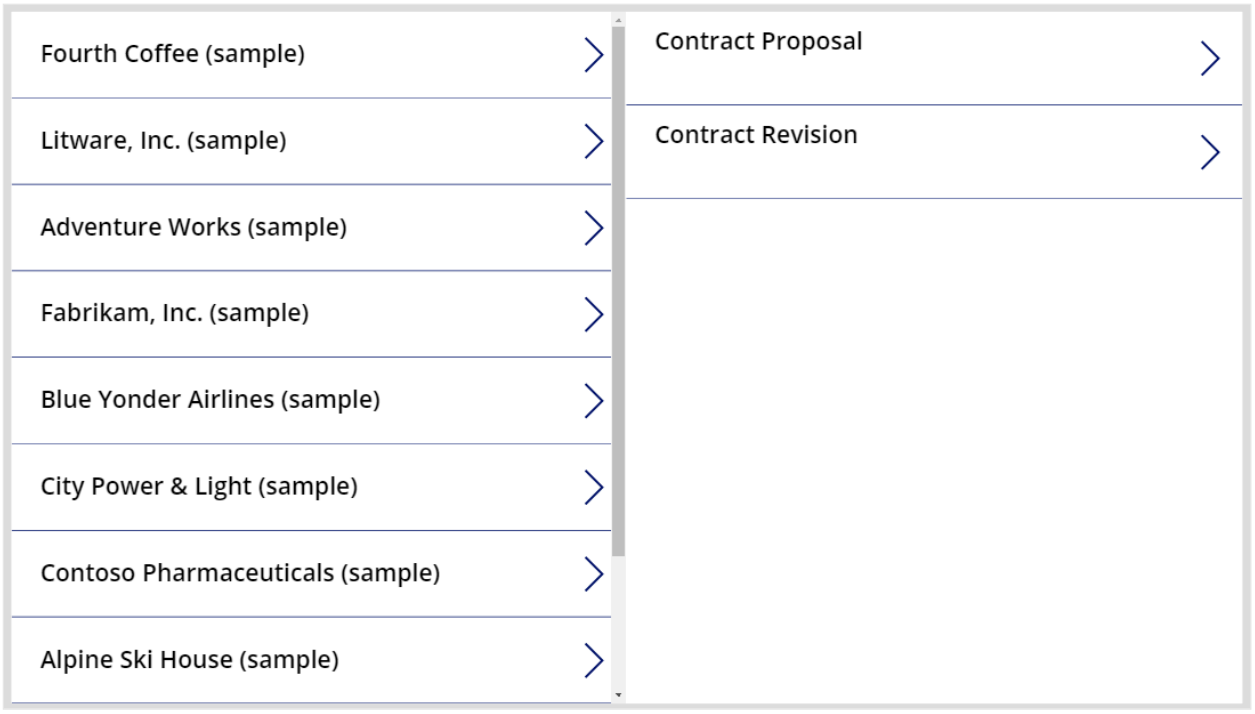
   This step returns the filtered list of faxes for a given account.



7. Set the gallery's layout to **Title and subtitle**, and then set the title field to show the **Subject** field (which might be lowercase **subject**).



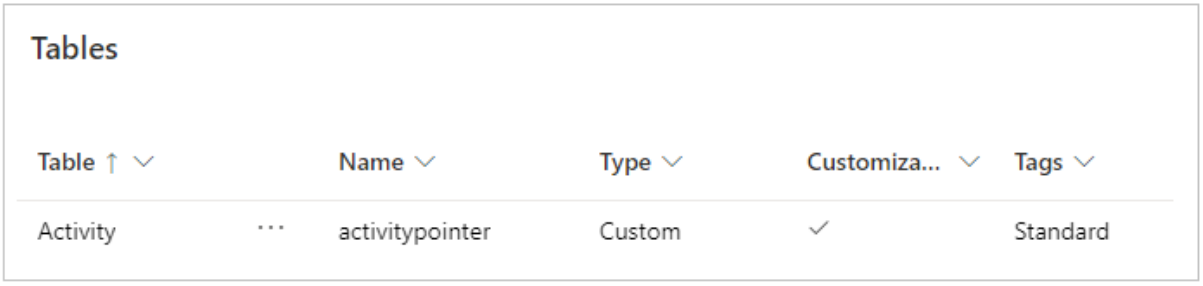
As you select an item in the list of accounts, the list of faxes shows faxes for only that account.



Activity table

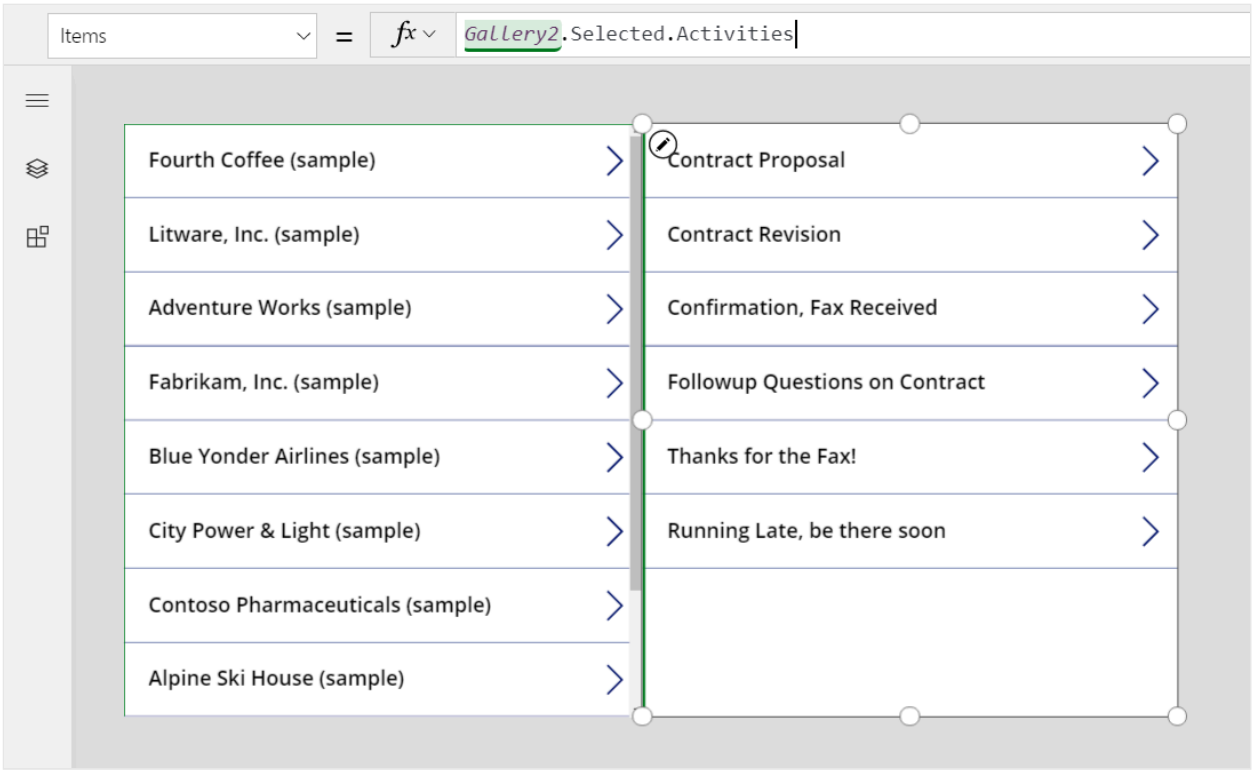
As the previous section describes, you can show all the faxes for an account. However, you can also show all the activities for an account, including faxes, email messages, phone calls, and other interactions.

For the latter scenario, you use the **Activity** table. You can show this table by turning on **All** in the upper-right corner to remove the filter from the list of tables.

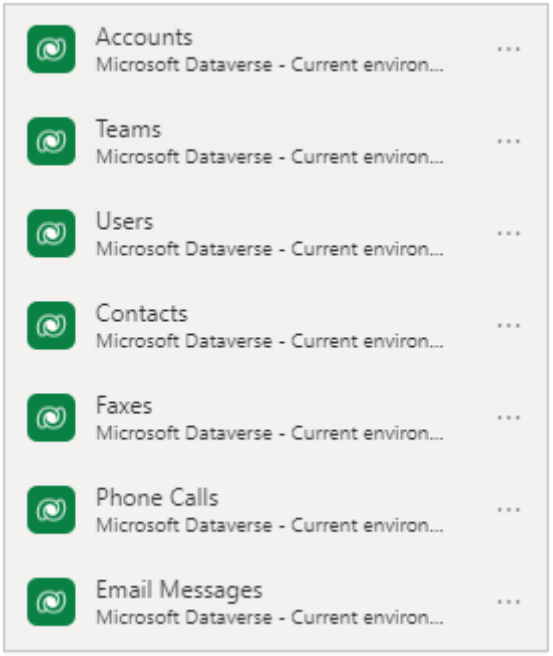


The **Activity** table is special. Whenever you add a record to the **Faxes** table, the system also creates a record in the **Activity** table with the columns that are common across all activity tables. Of those columns, **Subject** is one of the most interesting.

You can show all activities by changing only one line in the previous example. Replace `Gallery2.Selected.Faxes` with `Gallery2.Selected.Activities`.



Records are coming from the **Activity** table, but you can nevertheless use the **IsType** function to identify which kind of activity they are. Again, before you use **IsType** with a table type, you must add the data source.

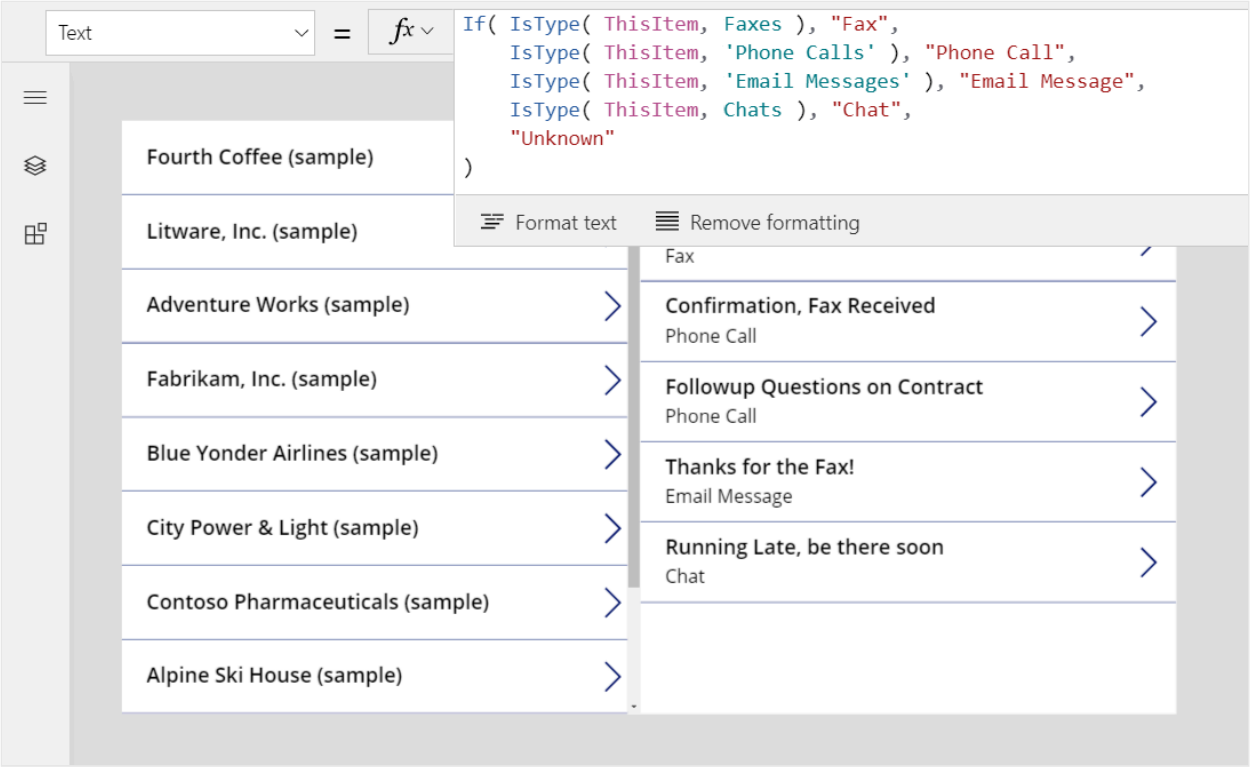


By using this formula, you can show the record type in a label control within the gallery:

Power Fx

```
If( IsType( ThisItem, Faxes] ), "Fax",
    IsType( ThisItem, 'Phone Calls' ), "Phone Call",
    IsType( ThisItem, 'Email Messages' ), "Email Message",
    IsType( ThisItem, Chats ), "Chat",
```

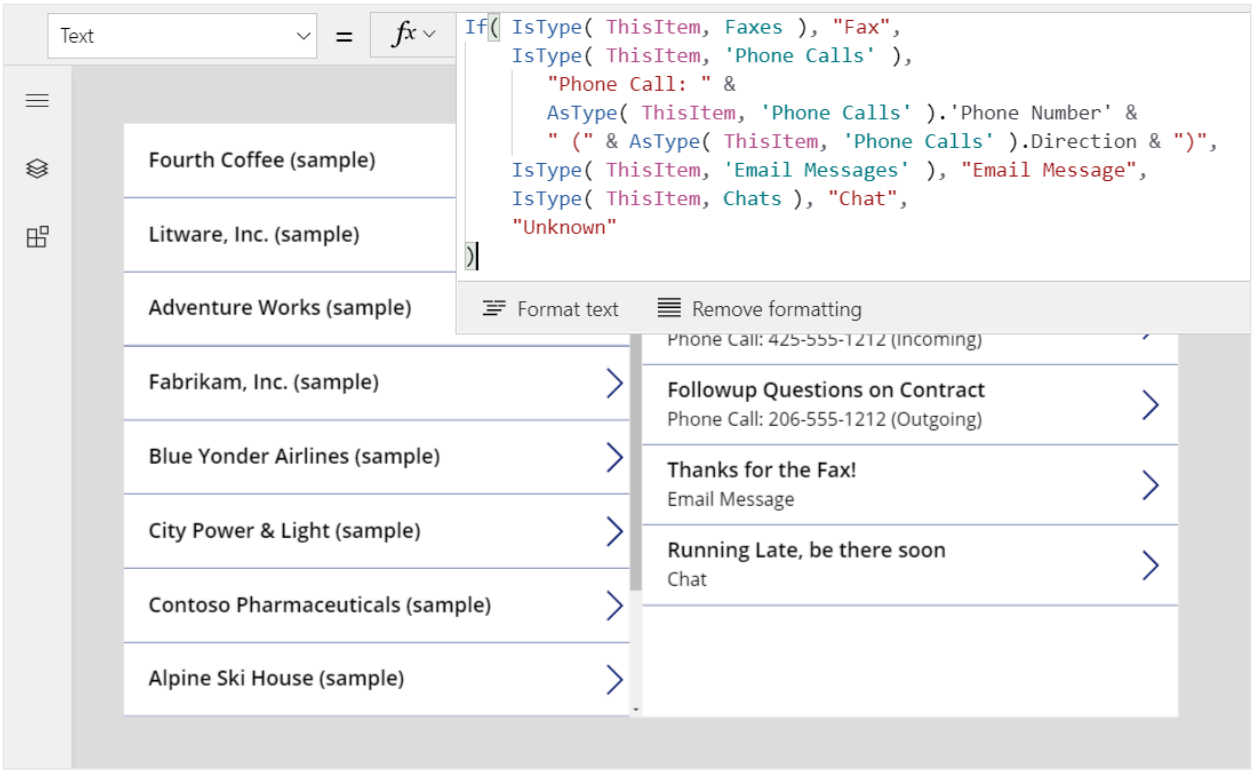
```
    "Unknown"
)
```



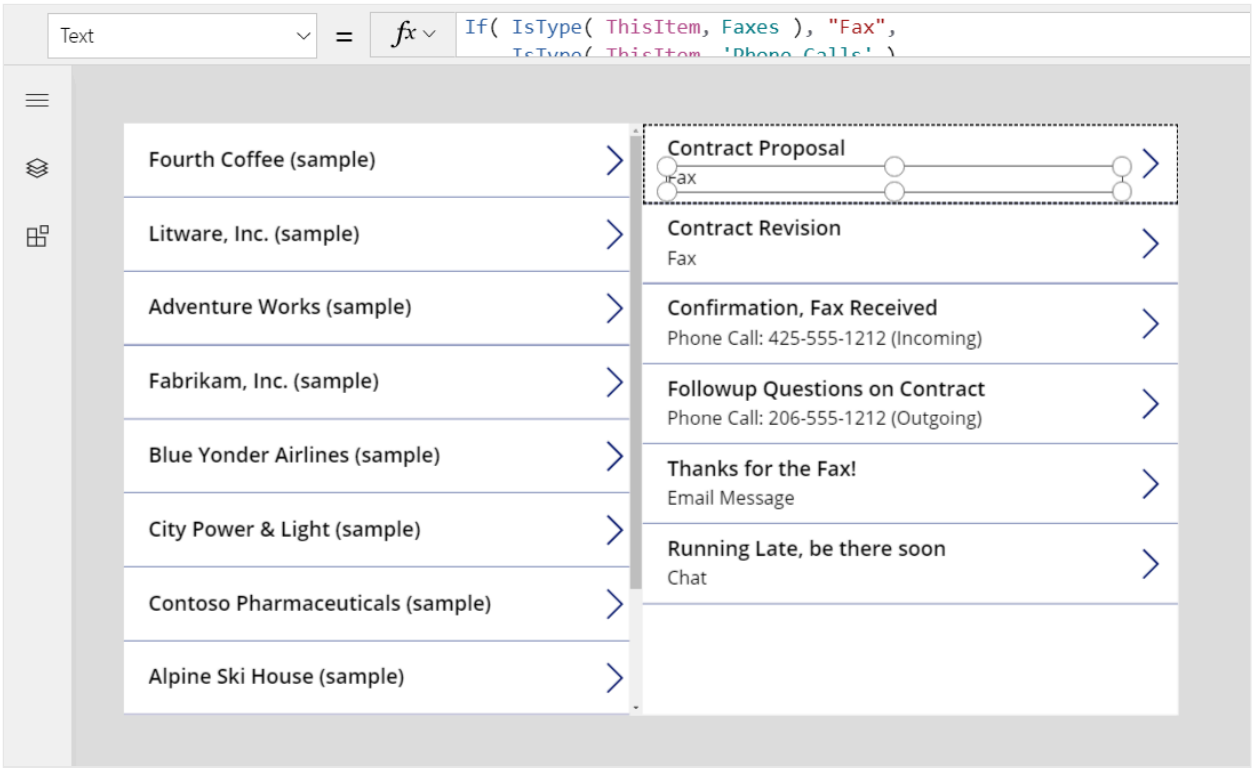
You can also use **AsType** to access the fields of the specific type. For example, this formula determines the type of each activity and, for phone calls, shows the phone number and call direction from the **Phone Numbers** table:

Power Fx

```
If( IsType( ThisItem, Faxes ), "Fax",
    IsType( ThisItem, 'Phone Calls' ),
       "Phone Call: " &
       AsType( ThisItem, 'Phone Calls' ).'Phone Number' &
       " (" & AsType( ThisItem, 'Phone Calls' ).Direction & ")",
    IsType( ThisItem, 'Email Messages' ), "Email Message",
    IsType( ThisItem, Chats ), "Chat",
    "Unknown"
)
```



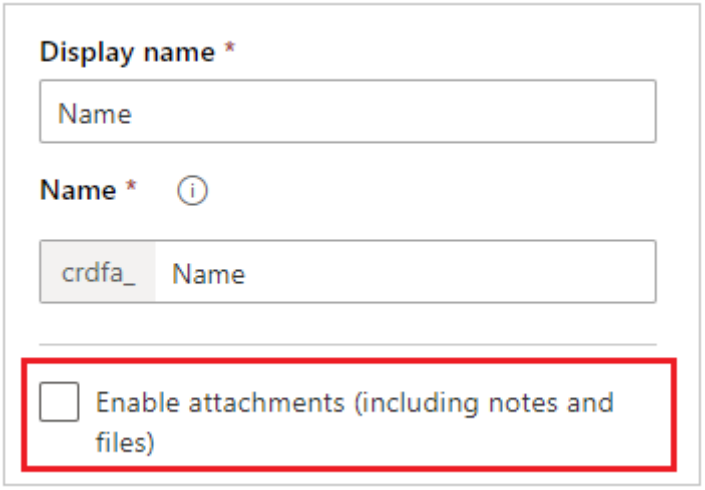
As a result, the app shows a complete list of activities. The **Subject** field appears for all types of activities, whether the formula takes them into account or not. For types of activities that you know about, you can show their type names and type-specific information about each activity.



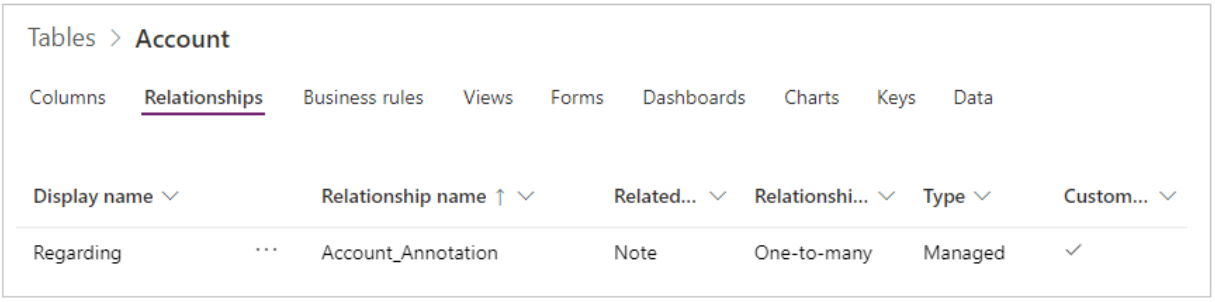
Notes table

So far, all of the **Regarding** examples have been based on activities, but the **Notes** table represents another case.

When you create a table, you can enable attachments.



If you select the check box for enabling attachments, you'll create a **Regarding** relationship with the **Notes** table, as this graphic shows for the **Accounts** table:



Other than this difference, you use the **Regarding** lookup in the same manner in which you use activities. Tables that are enabled for attachments have a one-to-many relationship to **Notes**, as in this example:

```
First( Accounts ).Notes
```

> **Note**
>
> As of this writing, the **Regarding** lookup isn't available for the **Notes** table. You can't read or filter based on the **Regarding** column, and you can't set the column by using **Patch**.
>
> However, the reverse **Notes** one-to-many relationship is available, so you can filter a list of notes for a record that's enabled for attachments. You can also use the Relate function to add a note to a record's **Notes** table, but the note must be created first, as in this example:

```
Relate( ThisItem.Notes, Patch( Notes, Defaults( Notes ), { Title: "A new note" } ) )
```

Activity parties

As of this writing, canvas apps don't support activity parties.

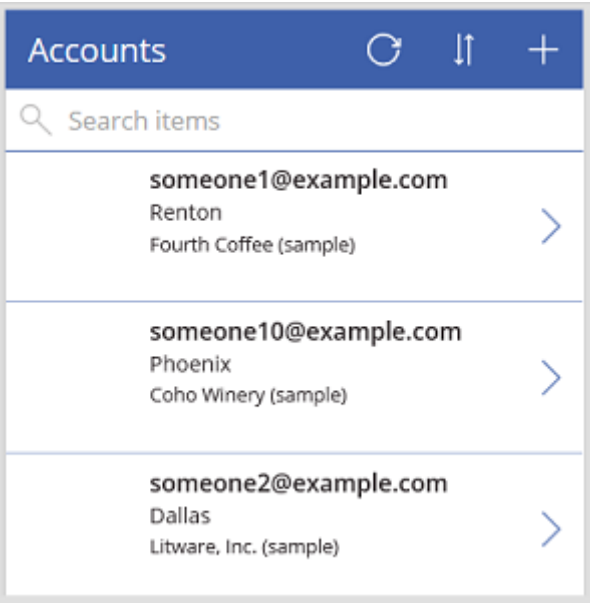
Tutorial: Customize a gallery in Power Apps

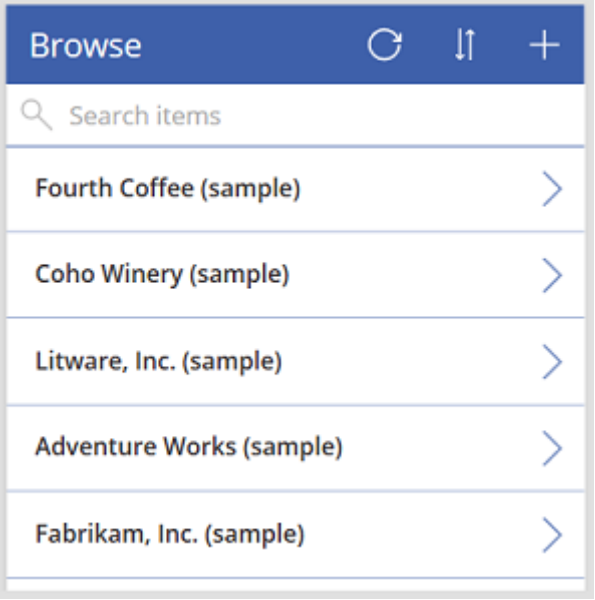
Article • 03/03/2023

In this tutorial, you'll customize a list of records, called a gallery, and make other changes in an app that was generated automatically in Microsoft Power Apps. Users can manage data in the app even if you don't make these changes, but the app will be easier to use if you customize it for your organization's needs.

For example, the gallery for this tutorial matches this graphic by default. The email address is featured more prominently than other types of data, and users can sort and filter the gallery based on text in that address:



However, your users might be more interested in the account name more than the email address, so you'll reconfigure the gallery to highlight, sort, and filter based on the key data for your organization. In addition, you'll change the title of the default screen to differentiate it from the other screens in the app.



You'll also add a scroll bar so that users who don't have touch screens or mouse wheels can browse the entire gallery.

- ✓ Change the layout of the gallery
- ✓ Change the type of data that appears in the gallery
- ✓ Change the columns by which users can sort and search the data
- ✓ Change the screen title
- ✓ Show a scroll bar

This tutorial starts with an app that was generated from a specific data source. However, the same concepts apply to any app that you generate in Power Apps, whether from a list created using Microsoft Lists, a SharePoint library, an Excel table, or some other data source.

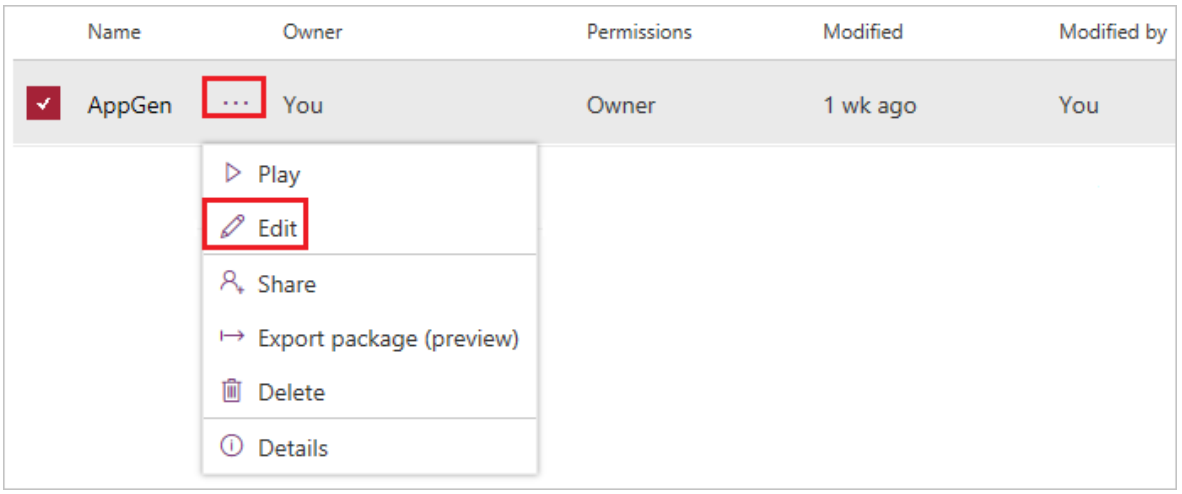
If you're not signed up for Power Apps, sign up for free before you start.

Prerequisites

Generate an app from the **Accounts** table of Microsoft Dataverse.

Open the generated app

1. Sign in to Power Apps, and then select **Apps** near the left edge.
2. Find the app that you generated, select the ellipsis icon (...) for it, and then select **Edit**.

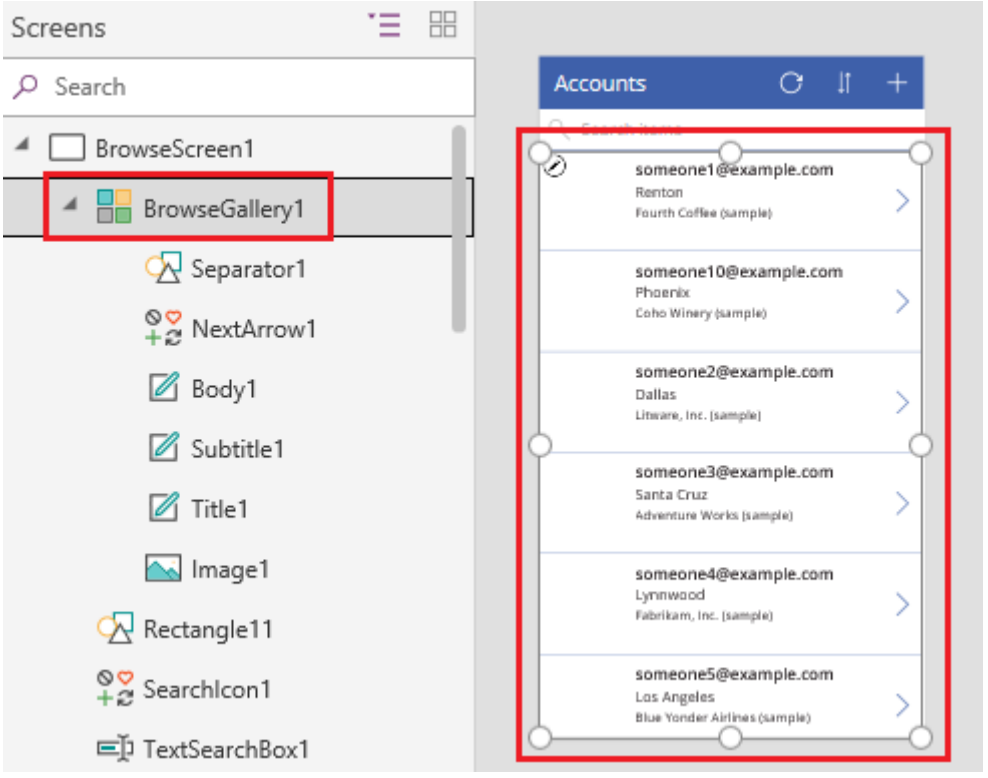


3. If the **Welcome to Power Apps Studio** dialog box appears, select **Skip**.

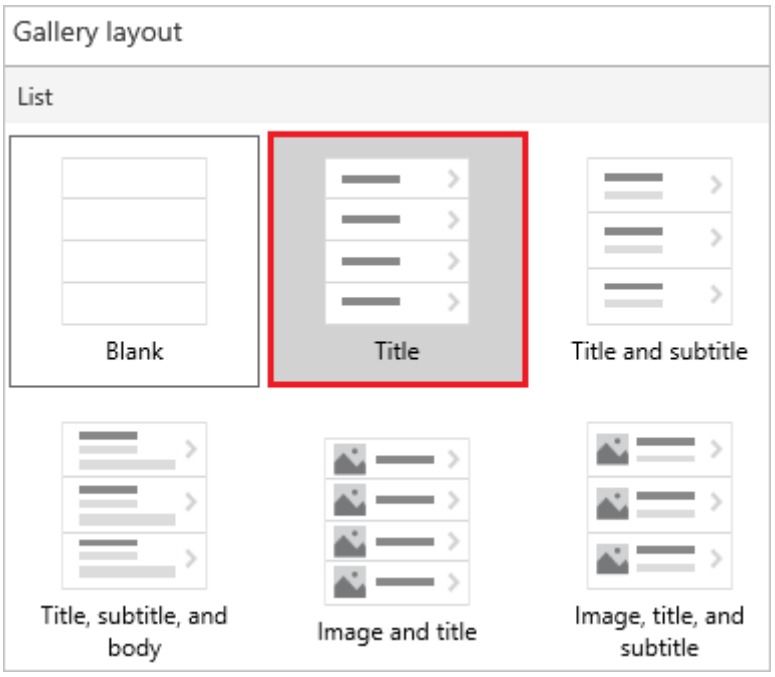
Change the layout

1. In the left navigation pane, select **BrowseGallery1**.

   When the gallery is selected, a selection box with handles surrounds it.



2. On the **Properties** tab of the right-hand pane, open the list of options under **Layout**, and then select the option that shows only a title.



3. Next to **Fields**, select **Edit**, and then select the down arrow for the title box.

   The name of this control will end in a numeral, such as **Title1**, but the numeral might differ based on other actions you might have taken.

4. In the list of options, select **Account name**, and then close the **Data** pane.

   The gallery shows the name of each account.

Change sort and search columns

1. Select the gallery as the previous section describes.

2. Near the upper-left corner, confirm that the property list shows **Items**.

   The value of this property appears in the formula bar. You set this property to specify not only the data source for the gallery but also the columns by which users can sort and search the data.

3. Copy this formula, and then paste it in the formula bar.

```
SortByColumns(Search(Accounts, TextSearchBox1.Text, "name"), "name",
If(SortDescending1, Descending, Ascending))
```

   By using this formula, you ensure that:

   - If a user types one or more characters in the search bar, the gallery shows only those account names that contain the text that the user typed.
   - If a user selects the sort icon, the gallery is sorted alphabetically by account name in either ascending or descending order, depending on how many times the user selects the icon.

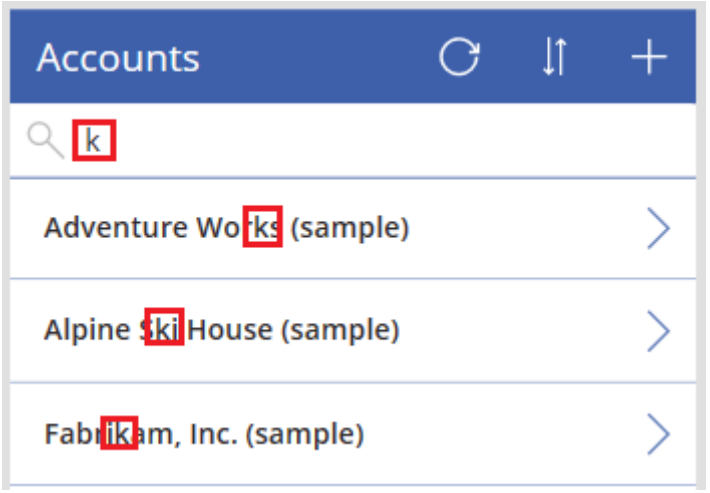
   For more information about these and other functions, see the formula reference.

Test sorting and searching

1. Open Preview mode by pressing F5 (or by selecting the play button near the upper-right corner).

2. Near the upper-right corner of the browse screen, select the sort icon one or more times to change the alphabetical sort order between ascending and descending.

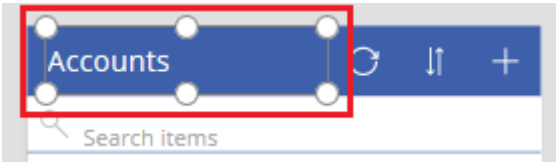
3. In the search box, type **k** to show only those account names that contain the letter that you typed.



4. Remove all text from the search bar, and then close Preview mode by pressing Esc (or by selecting the close icon near the upper-right corner).

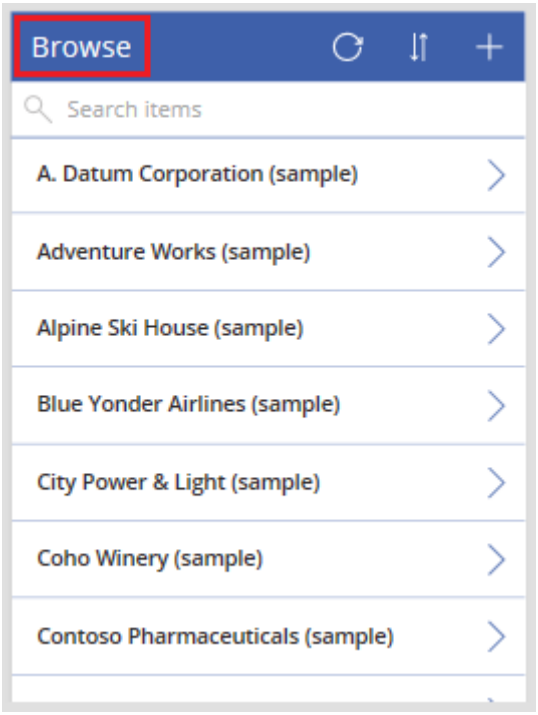
Change the screen title

1. Select the title of the screen by clicking or tapping it.



2. Ensure that the property list shows **Text** and then, in the formula bar, replace **Accounts** with **Browse** (retaining the double quotation marks).

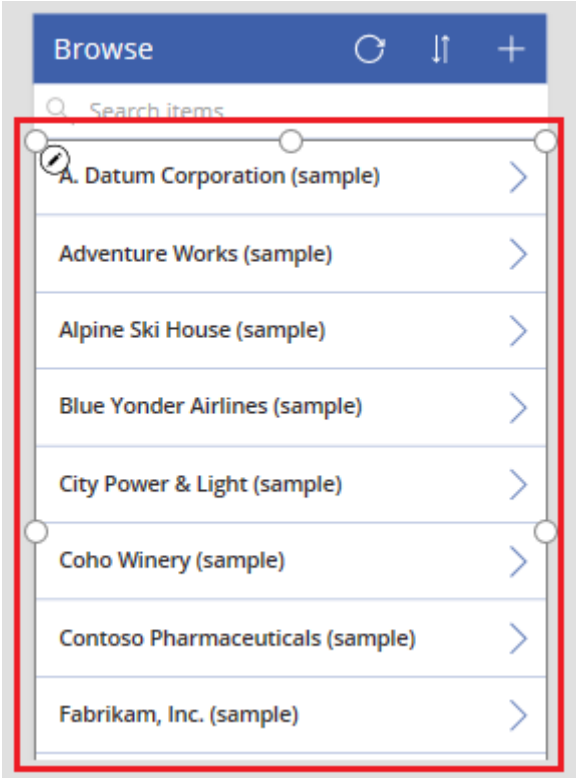
The screen reflects your change.



Show a scrollbar

If your users might have neither touch screens nor mouse wheels, configure the gallery to show a scrollbar when the user hovers over it with the mouse. That way, users can show all accounts even if the screen can't show them all at once.

1. Select the gallery as the first procedure describes.



2. Set the gallery's **Show scrollbar** property to **true**.

Next steps

In this tutorial, you've customized the gallery and made other changes to the default screen for browsing records in a generated app. You can also customize the default screens for displaying details and creating or updating accounts. As the browse screen contains a gallery, the other two screens in the app contain forms. You can change, for example, which types of data the forms show and in which order.

Customize forms in canvas apps

Article • 03/03/2023

In a canvas app, customize a **Display form** control and an **Edit form** control so that they show the data that matters most and in the most intuitive order to help users easily understand and update the data.

Each form comprises one or more cards, each of which shows data from a particular column in the data source. By following the steps in this topic, you can specify which cards appear in a form and move cards up and down within a form.

If you're unfamiliar with canvas-pps, see What are canvas apps?.

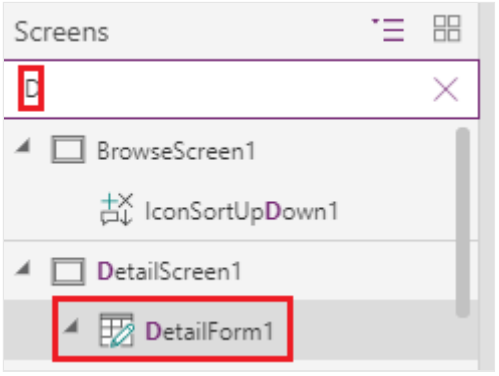
Prerequisites

Generate an app from the Microsoft Dataverse, and then customize the gallery in that app.

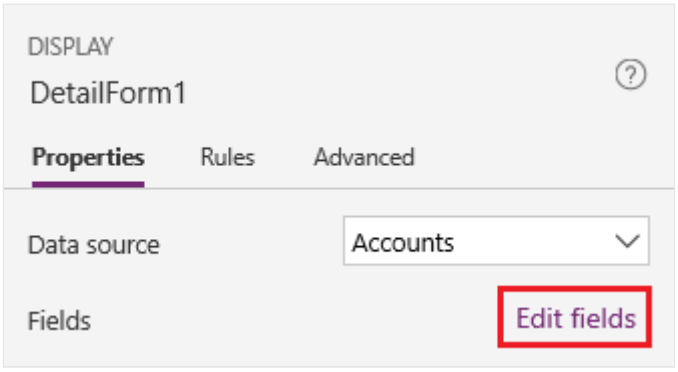
Show and hide cards

1. Sign in to Power Apps, and then open the app that you generated and customized.

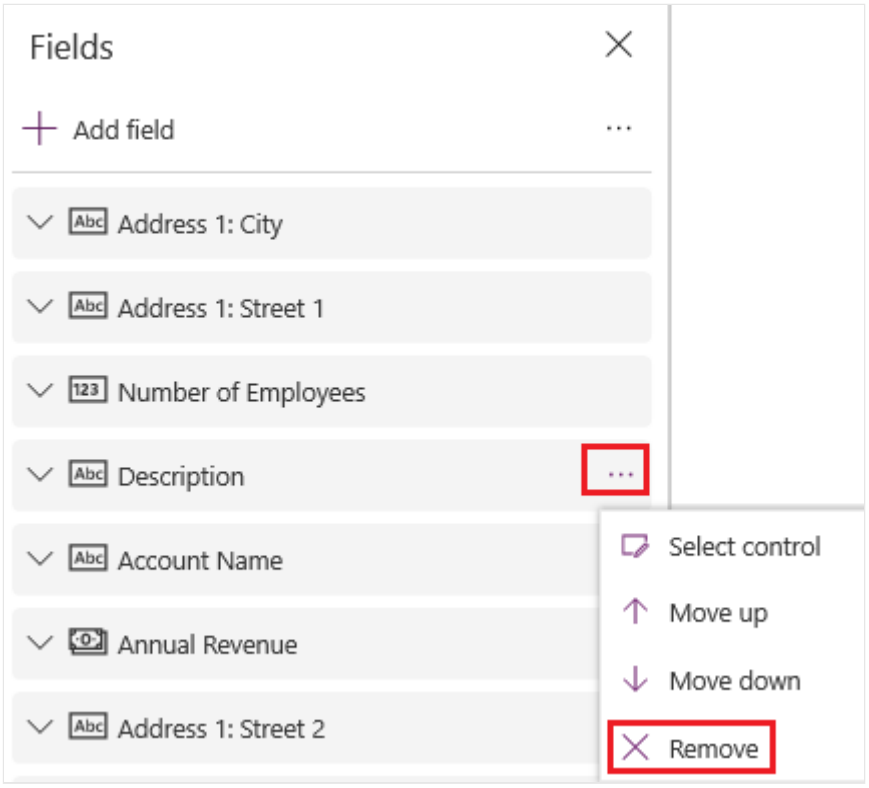
2. In the left navigation bar, type or paste **D** in the search bar to filter the list of elements, and then select **DetailForm1**.



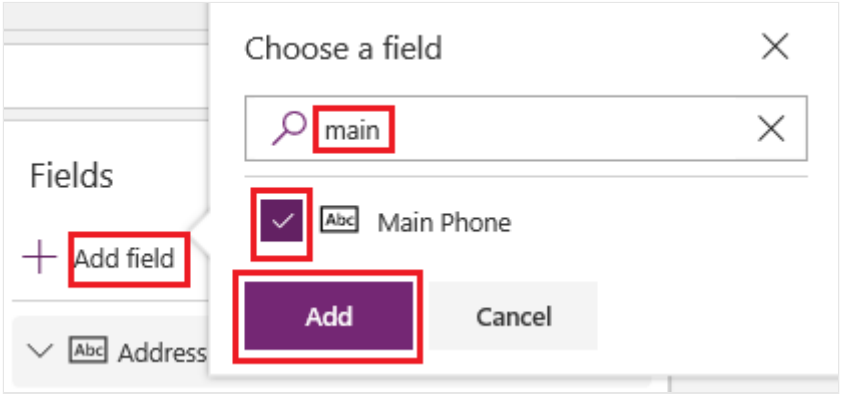
3. On the **Properties** tab of the right-hand pane, select **Edit fields** to open the **Fields** pane.



4. Hide a field, such as **Description**, by hovering over it, selecting the ellipsis (...) that appears, and then selecting **Remove**.



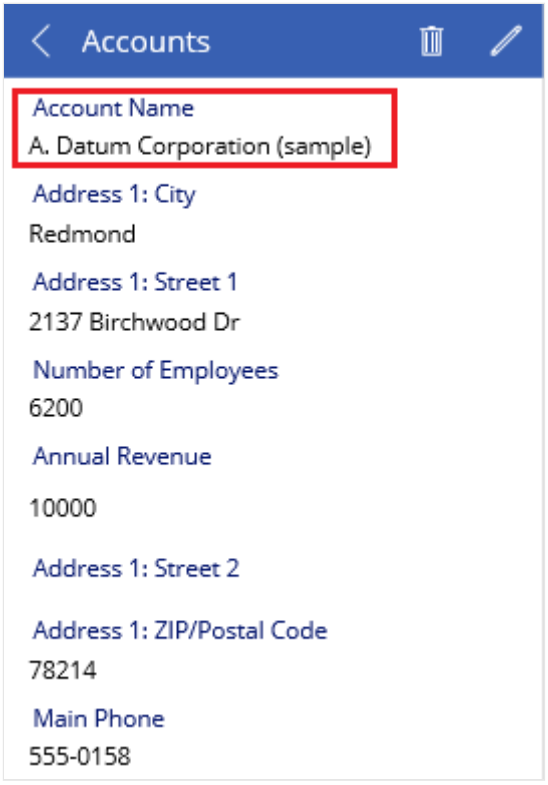
5. Show a field by selecting **Add field**, typing or pasting the first few letters of the field's name in the search box, selecting the field's check box, and then selecting **Add**.



Reorder the cards

1. In the **Fields** pane, drag the **Account Name** field to the top of the list of fields.

   The cards in **DetailForm1** reflect the change.



2. (optional) Reorder the other cards into this sequence:

   - Account Name
   - Number of Employees
   - Annual Revenue
   - Main Phone
   - Address 1: Street 1
   - Address 1: Street 2
   - Address 1: City
   - Address 1: ZIP/Postal Code

3. In the left navigation bar, type or paste **Ed** in the search bar, and then select **EditForm1** to select it.

4. Repeat the steps in the previous procedure and this one so that the fields in **EditForm1** match those in **DetailForm1**.

Run the app

1. In the left navigation bar, type or paste **Br** in the search bar, and then select **BrowseScreen1** to select it.

2. Open Preview mode by pressing F5 (or by selecting the **Preview** icon near the upper-right corner).

3. In the upper-right corner, select the plus icon to add a record in **EditScreen1**.

4. Add whatever data you want, and then select the checkmark icon in the upper-right corner to save your changes and return to **BrowseScreen1**.

5. Select the arrow for the item that you just created to show details about that item in **DetailScreen1**.

6. In the upper-right corner, select the edit icon to update the record in **EditScreen1**.

7. Change the information in one or more fields, and then select the check mark in the upper-right corner to save your changes and return to **DetailScreen1**.

8. Near the upper-right corner, select the trash-can icon to delete the record that you just updated and to return to **BrowseScreen1**.

9. Close Preview mode by pressing Esc (or by selecting the close icon near the upper-left corner).

Next steps

- Save and publish your app.

- Customize a card in your app.

Customize a card in a canvas app

Article • 03/03/2023

Perform basic customization (without unlocking a card) by, for example, changing its control. Perform advanced customization by unlocking the card and, for example, adding a control that isn't available for that card by default.

For an overview, see Understand data cards.

Prerequisites

- Learn how to add and configure controls.
- You can review this topic for general concepts only, or you can follow it step by step if you first complete the procedures in these topics:

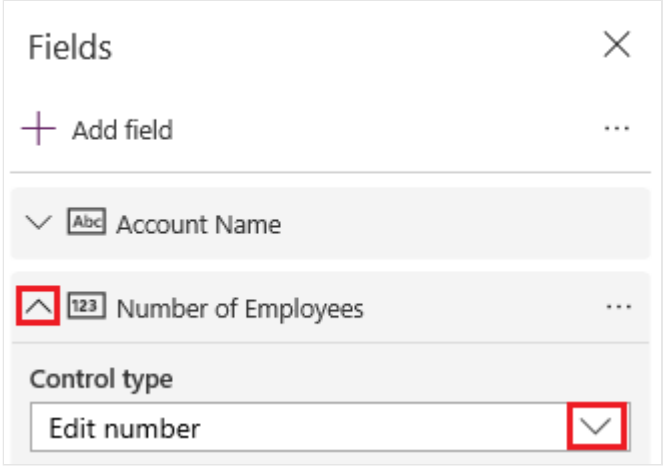
    1. Generate an app.
    2. Customize its gallery.
    3. Customize its forms.

Customize a locked card

In this procedure, you'll replace a **Text-input** control with a **Slider** control without unlocking the card.

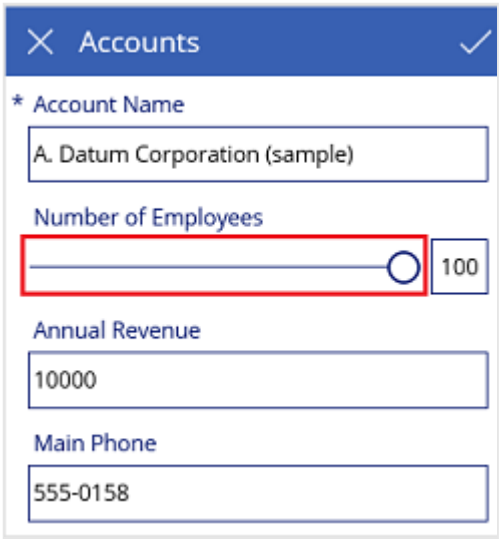
1. In the app that you generated and customized, select **EditForm1** in the left navigation bar, and then select **Edit fields** on the **Properties** tab of the right-hand pane.

2. In the list of fields, select the down arrow for **Number of Employees**, and then open the list under **Control type**.



3. Select **Edit Slider**.

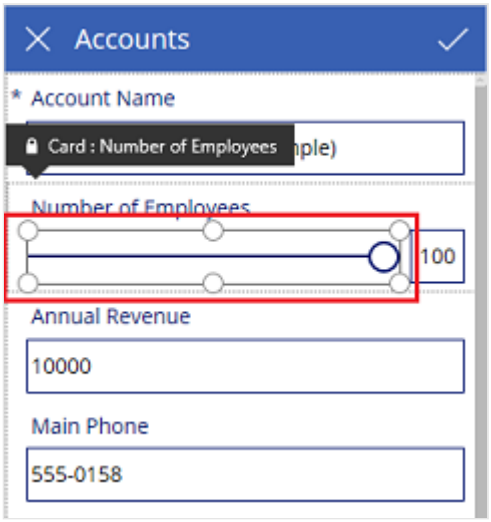
   The screen reflects your change.



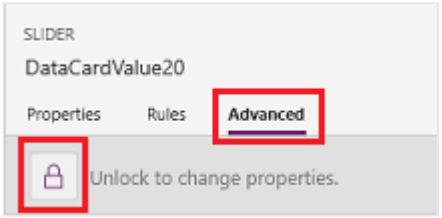
Unlock and customize a card

In this procedure, you'll unlock a card and update the **Max** property of the **Slider** control that you just added.

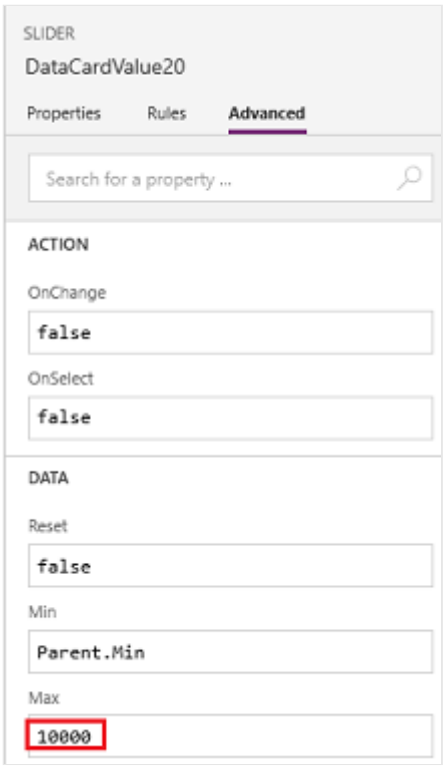
1. In **EditForm1**, select the **Slider** control in the **Number of Employees** card.



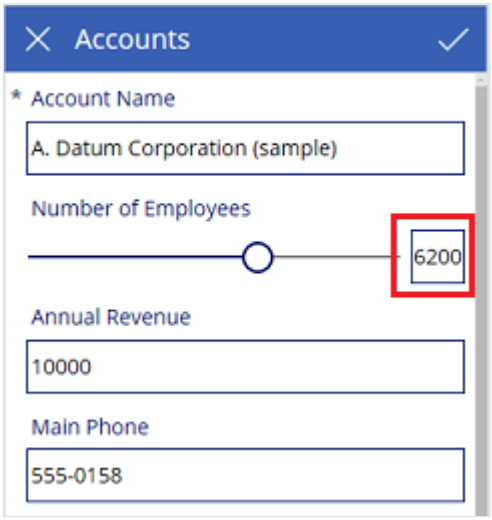
2. On the **Advanced** tab of the right-hand pane, select the lock icon to unlock the card.



3. Set the **Max** property of the **Slider** control to 10,000.



The **Slider** control shows a more accurate value.



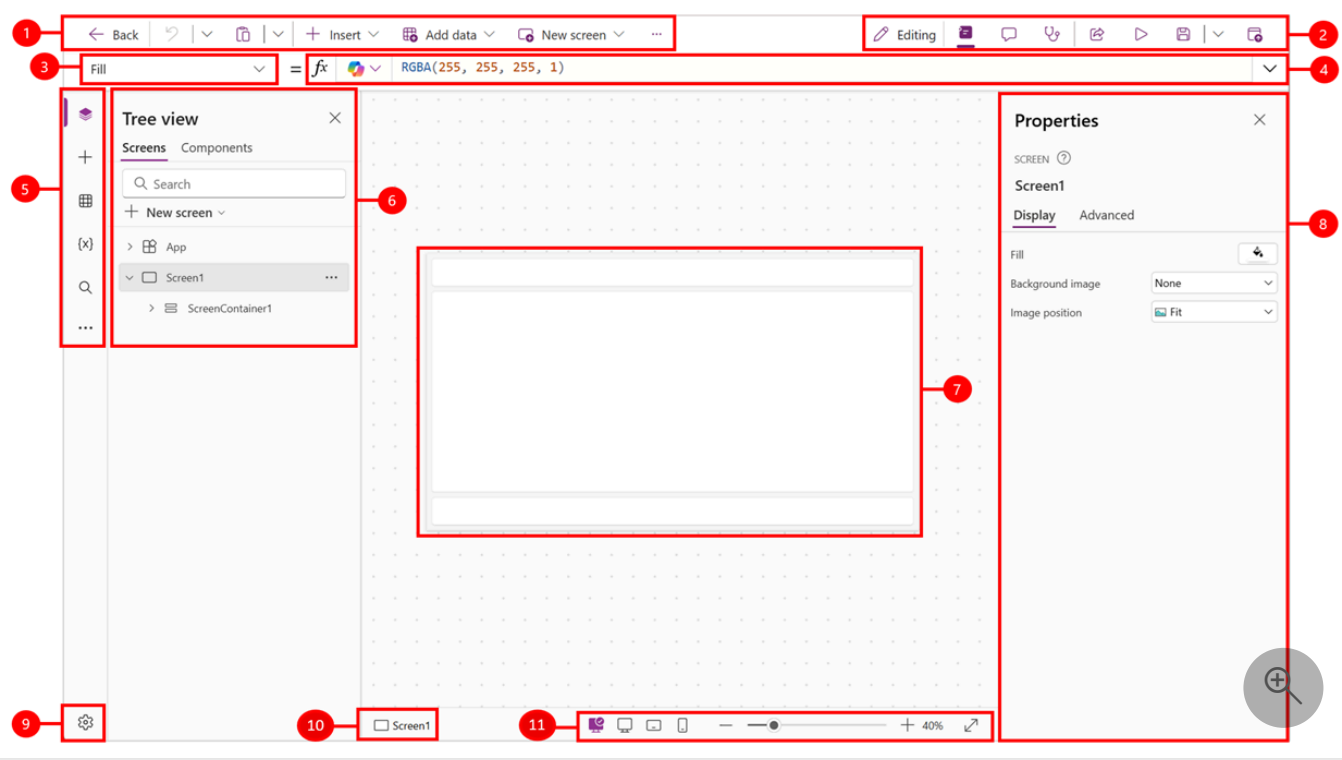
Next steps

Now that you have a basic understanding of how to generate an app and customize a gallery, a form, and a card, you can build your own app from scratch.

Understand Power Apps Studio

Power Apps Studio is the integrated development environment where you design, build, and manage canvas apps. Learn about its key components including the command bar, formula bar, canvas, and authoring tools to create effective business applications.

Overview of Power Apps Studio



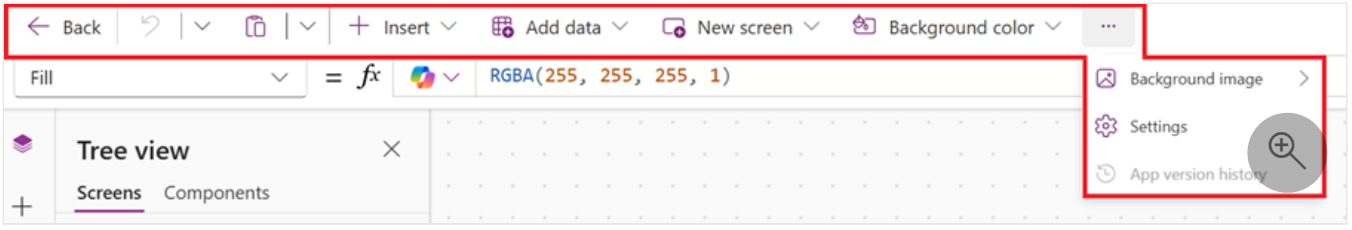
1. Power Apps Studio modern command bar: Dynamic command bar that shows a different set of commands based on the control selected.
2. App actions: Options to view properties, add comments, run the app checker, share, preview, save, or publish the app.
3. Properties list: List of properties for the selected object, such as *fill* or *height*.
4. Formula bar: Compose or edit a formula for the selected property with one or more functions.
5. App authoring menu: Selection pane to switch between data sources and allows you to insert options.
6. App authoring options: This pane reveals the corresponding authoring feature when a feature is selected from the app authoring menu.
7. Canvas/screen: Primary canvas for composing the app structure.

8. Properties pane: Properties list for the selected object in Tree view.
9. Settings: Configure your app in settings.
10. Screen selector: Switch between different screens in your app. Tree view selections display here.
11. Change canvas screen size: Change the display size of the canvas as you author your app.

Let's understand each option in Power Apps Studio in detail.

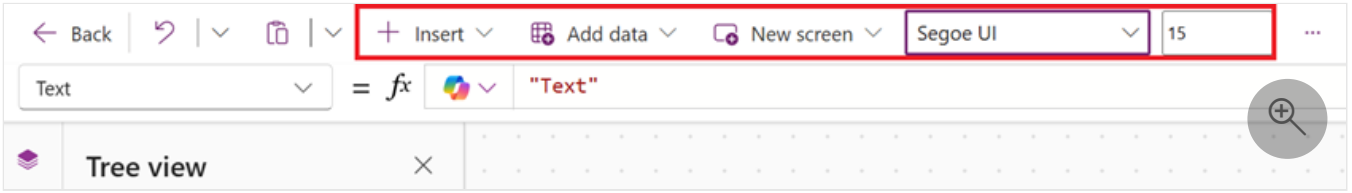
1 – Power Apps Studio modern command bar

The command bar provides Power Apps Studio options. These options are relevant to the current session and app-related settings.



Modern command bar

The modern command bar displays the relevant set of commands depending on the control that you select. For example, if you select an item to *insert* like a text label, you see the modern command bar change to accommodate your selection. The bar now has font type, size, color, and other text label controls.



The command bar changes when you select one of the following controls or objects:

1. App object
2. Screen
3. Button
4. Shape
5. Icon
6. Blank form
7. Form with data
8. Blank gallery

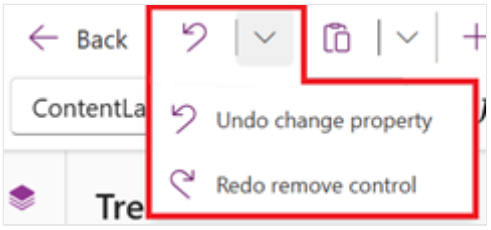
9. Gallery with data
10. Label
11. Text input
12. Date picker

When you select more than one type of control, the command bar shows the common commands between the selected controls.

Back

Takes you back to the build hub, closing the current Power Apps Studio session.

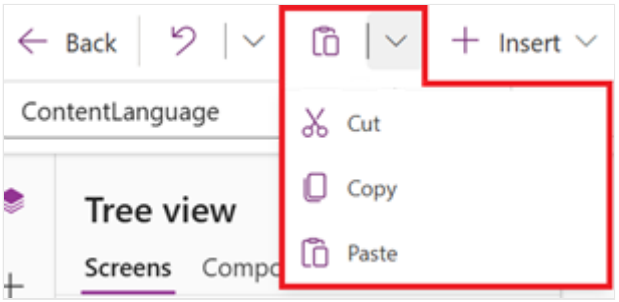
Undo and redo



- **Undo**: Undo the last action.
- **Redo**: Repeat the last action.

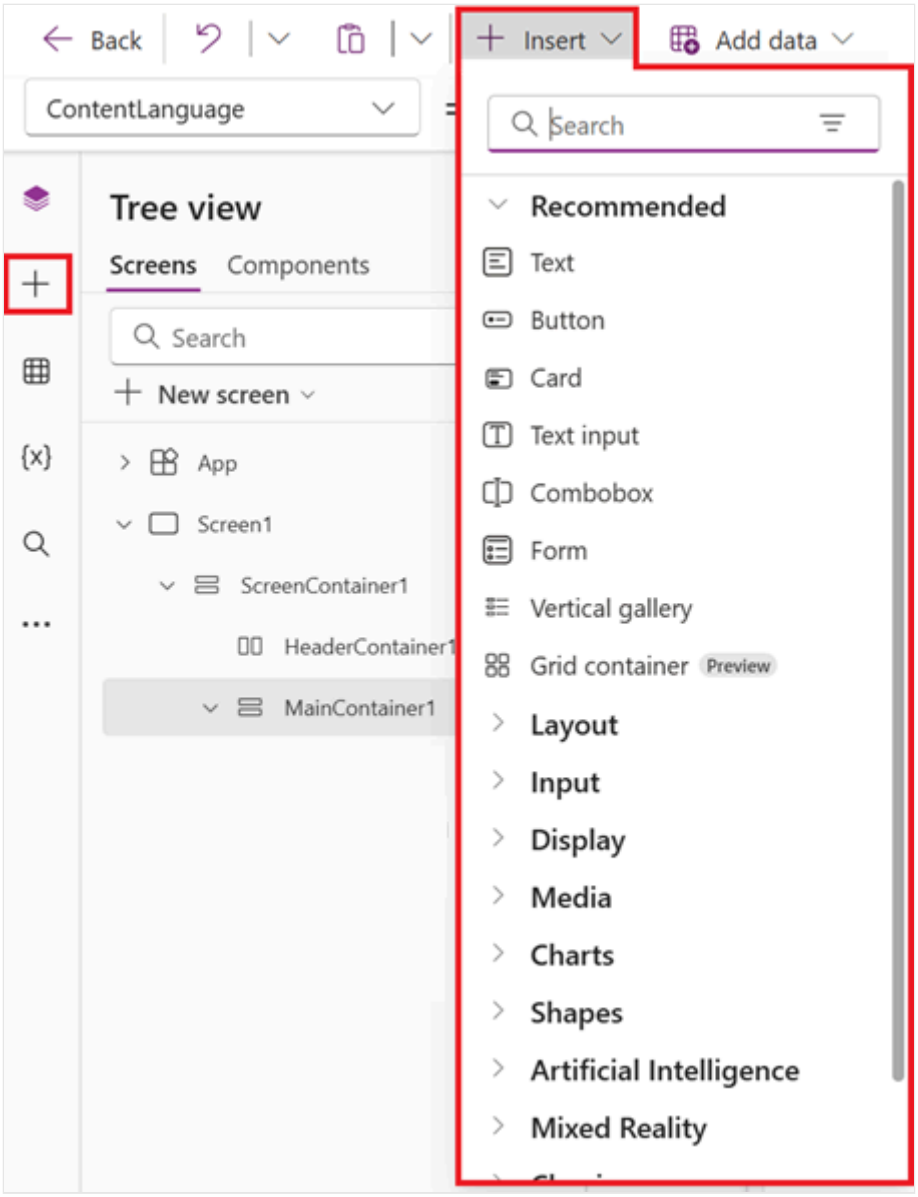
> **Note**
>
> You can't undo or redo data operations, such as insert or delete a data source.

Cut, copy, and paste



- **Cut**: Cut the selection, and store it in the clipboard.
- **Copy**: Copy the selection, and store it in the clipboard.
- **Paste**: Paste the last cut or copied selection from the clipboard.

Insert



You can access the **Insert** menu from the command bar and from the app authoring menu.

Insert shows all the popular objects or controls that you can add on the selected screen in your canvas app. You can also expand other choices or use the components option to insert controls from a component library.

To insert controls on the canvas, drag the control to the canvas or select the control.

Popular controls to insert

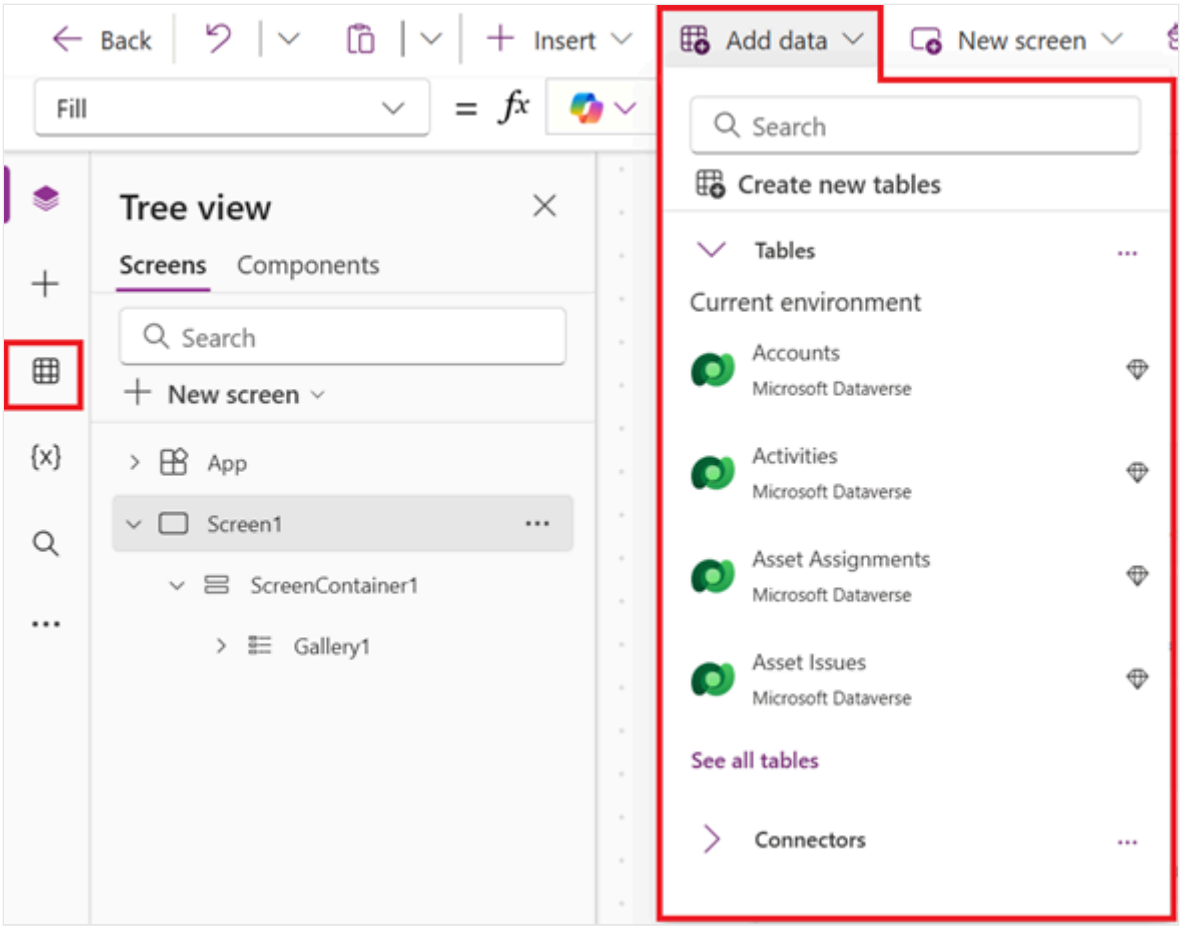
Expand table

Name	Description
Form	Display, edit, or create a record in a data source.
Input > *Button*	A control that the user can select to interact with the app.

Name	Description
Input > Date picker	A control that the user can select to specify a date.
Input > Text input	A text box that allows user input.
Shapes > Rectangle	A rectangular shape to configure the canvas appearance.
Text	A box that displays data such as text, numbers, dates, or currency.
Vertical gallery	A control that you can add other controls to and display a set of data. For example, list items made up of an image, title, and description is contained within a vertical gallery. 
For more information about the controls you can insert, including their properties and definitions, see Controls and properties in canvas apps.

Add data

Add, refresh, or remove data sources from your canvas app. You can add one or more connections by using data sources.



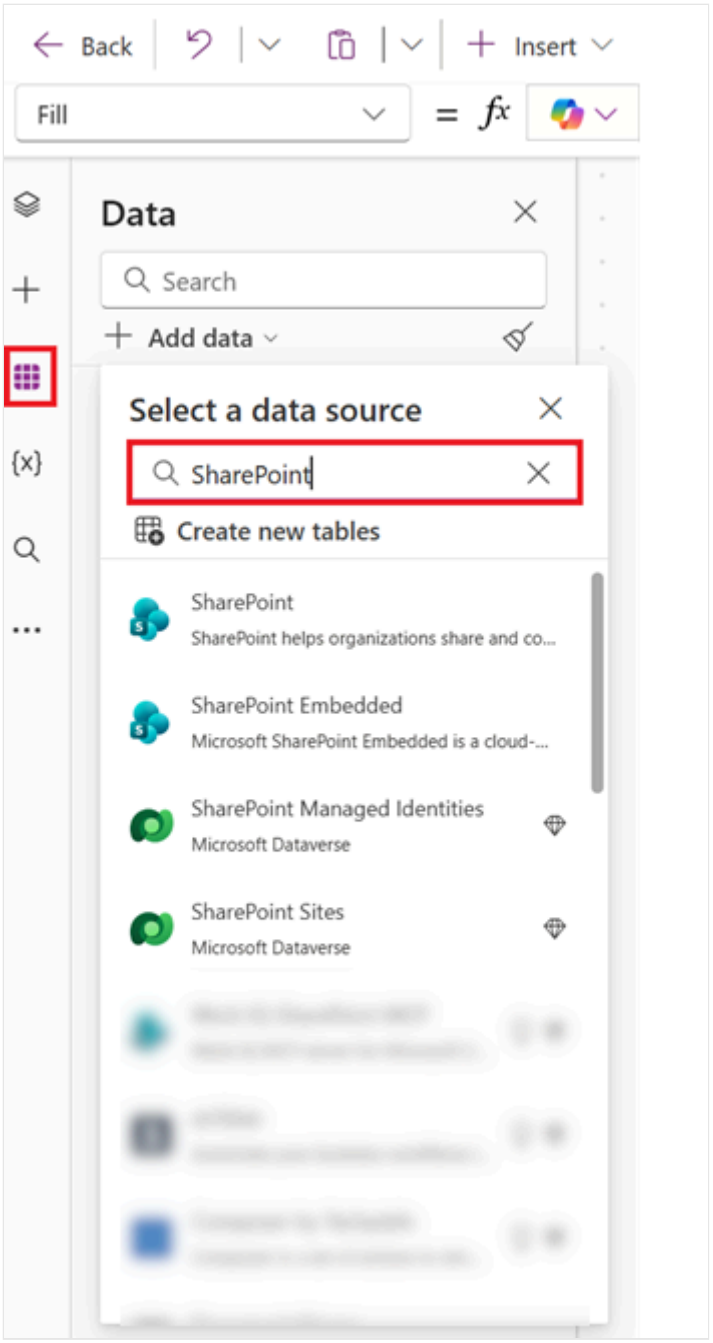
From the **Add data** menu, you can:

- Select any other existing tables from the current environment.
- Search for and select a connector, such as **SharePoint** or **SQL Server**.

Connectors

In addition to data stored within tables, many connectors are available to interact with data in popular software as a service (SaaS), services, and systems.

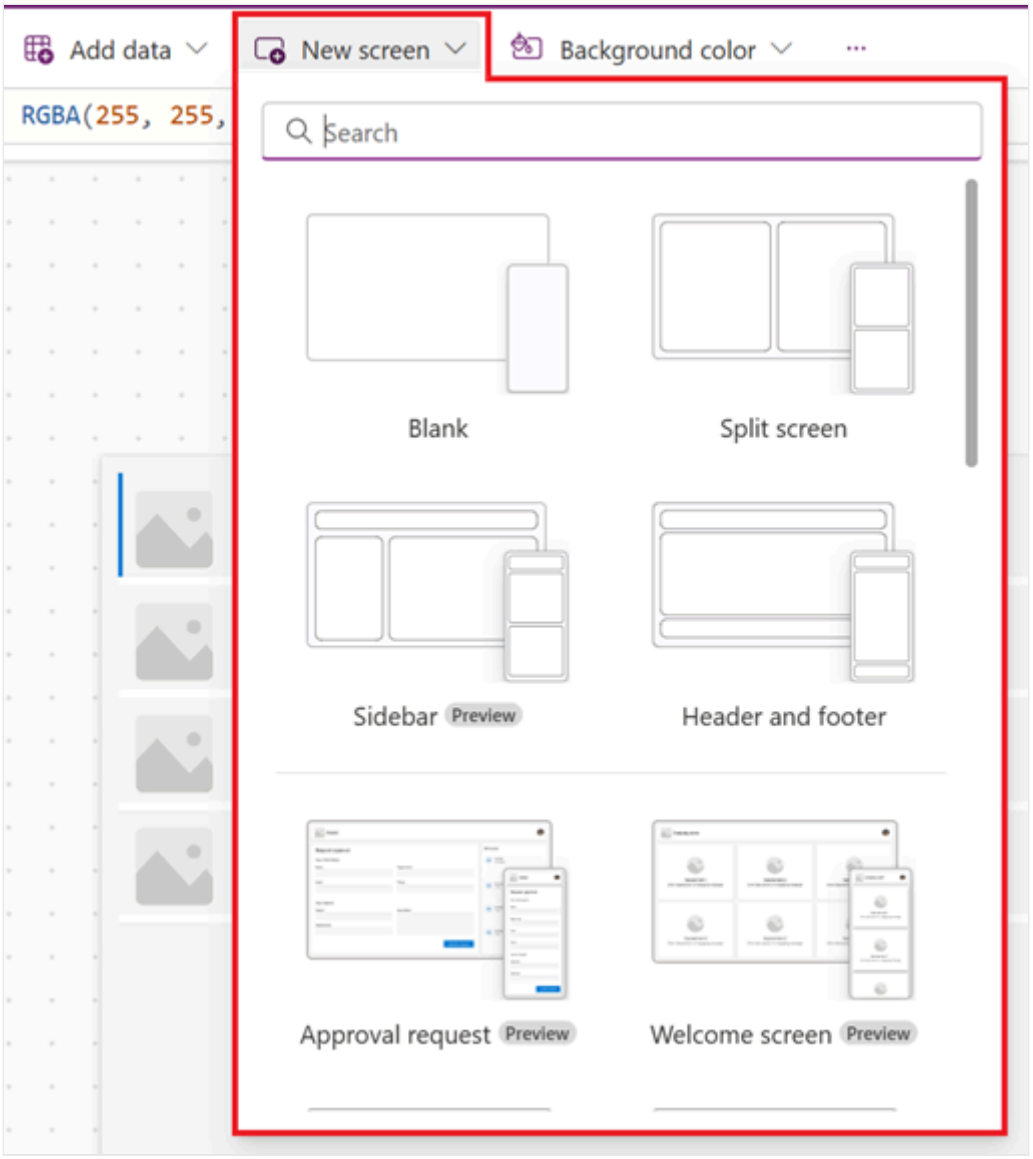
To choose other connectors such as SharePoint, OneDrive, or SQL Server, enter text in the data source search box or select from the list of connectors.



For more information, see List of all Power Apps connectors.

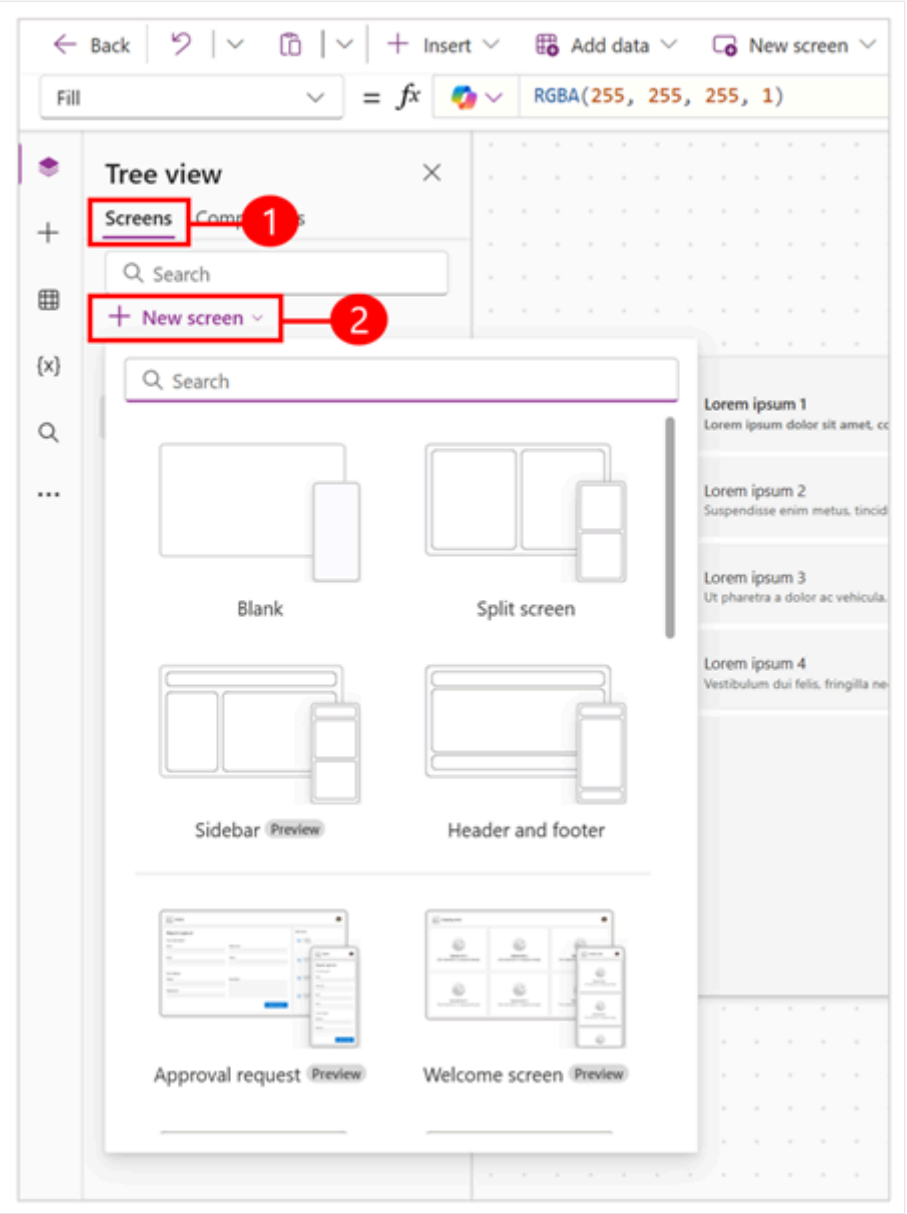
New screen layouts

Add a new screen to your app from the **New screen** option in the command bar.



You can also add a new screen from the tree view.

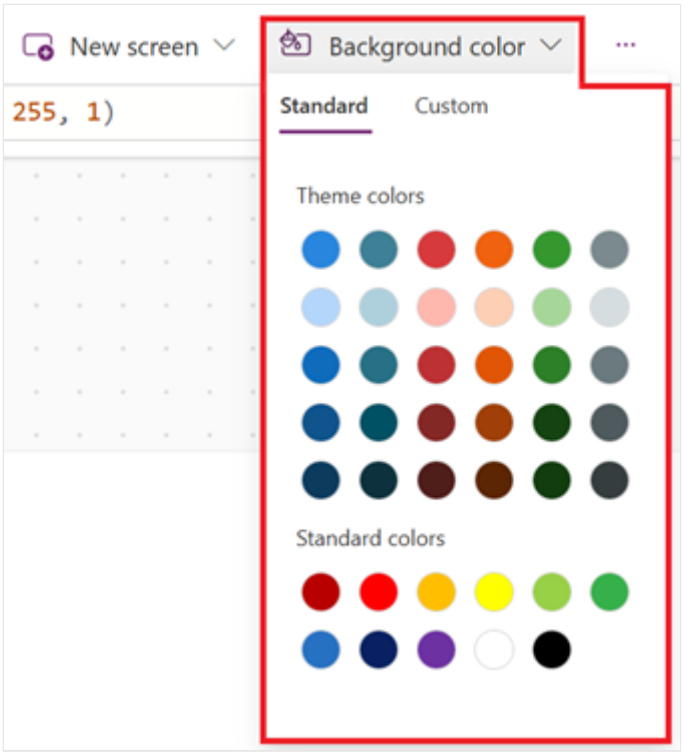
1. From the **Screens** tab, select **+ New screen**.



2. Select from the list of available screen layouts such as **Sidebar**, new layouts in preview such as **Header and form**, or templates like **Email**.

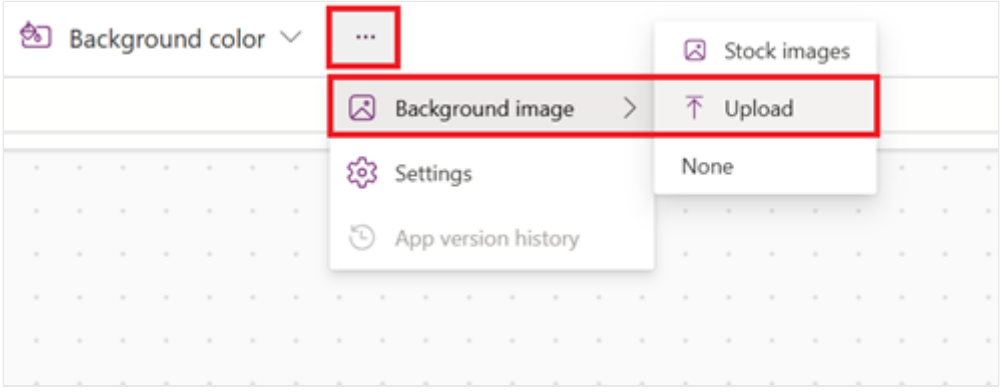
Background color

Select a background color for a screen. You can select from the list of standard colors or select the **Custom** tab and choose your own color.



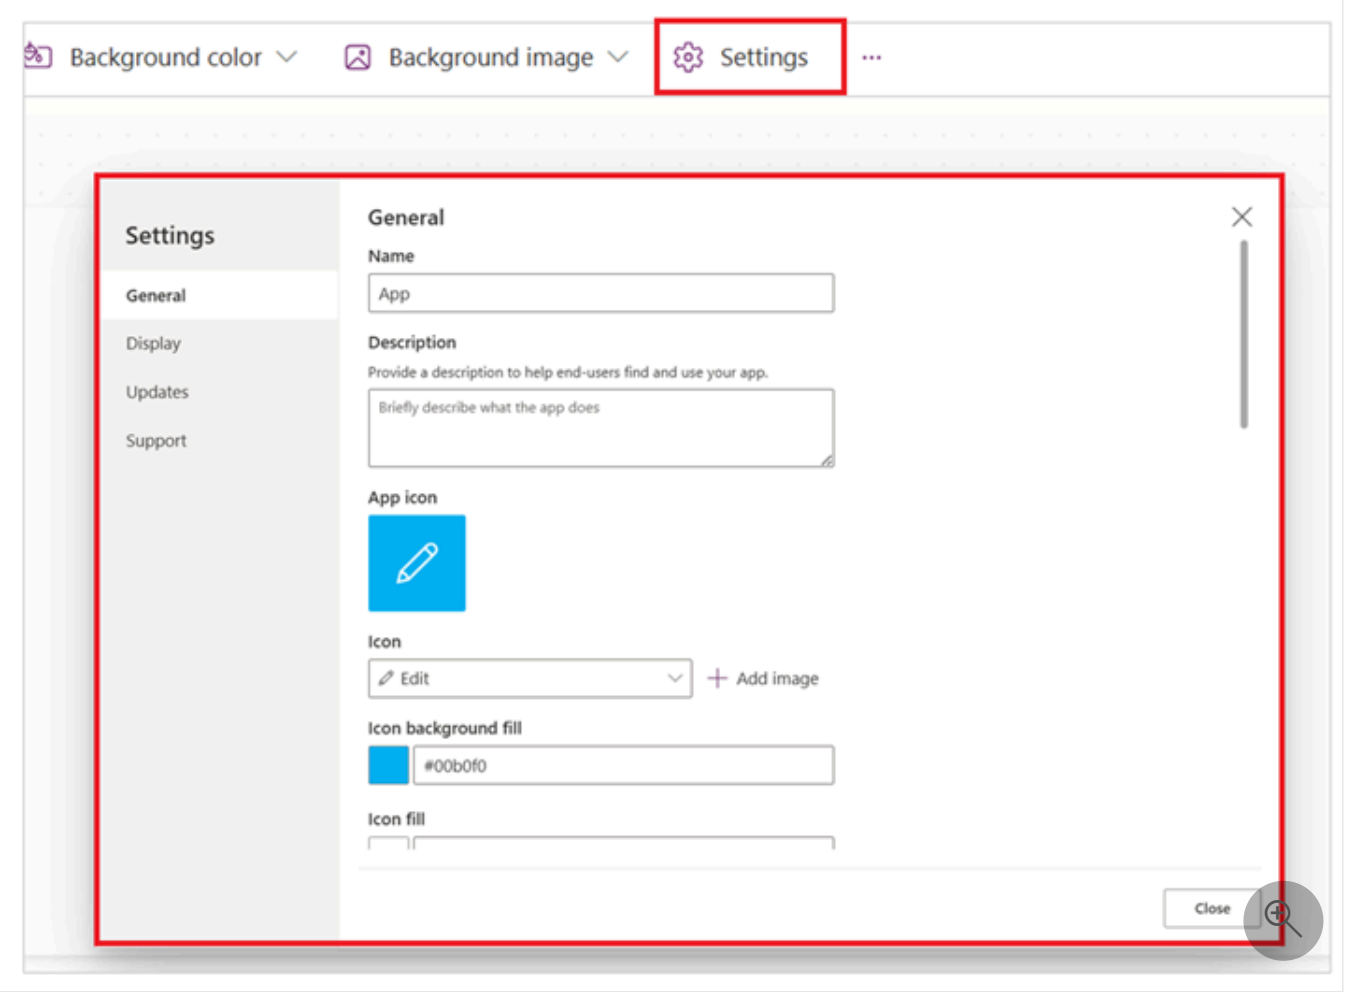
Background image

Select **Upload** to upload images to set as the background image.



Settings

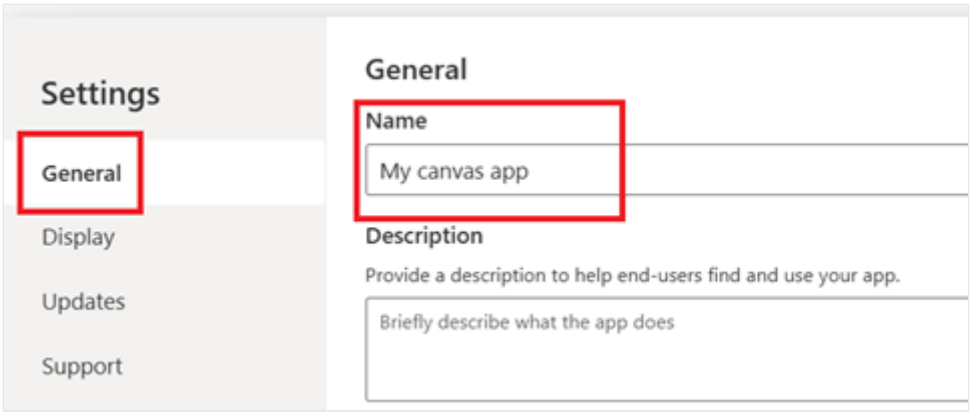
Configure the app's settings from the General, Display, Updates, or Support tab.



General

- Edit the app **Name** and **Description**.
- Add or update the **App icon**. Add a custom icon by selecting **+ Add image**.
- Select an **Icon background fill** or **Icon fill** color.
- Toggle **Auto save** to save every two minutes automatically.
- Configure offline use.
- Set your **Data row limit**.
- Include debug information when you publish.
- Enable autocreation of environment variables.
- Enable the `App.OnStart` property.

To edit the app **Name**, go to the **General** tab in **Settings**.



Display

- Select the **Orientation** and screen **Size**.
- **Scale to fit**: Scales the app to fit available space.
- **Lock aspect ratio**: Locks the height and width ratio.
- **Lock orientation**: Maintains app orientation when device rotates.
- **Show mobile device notifications area**: Displays notifications at the top of the screen.

For more information, see Change screen size and orientation.

Updates

Configure advanced settings for the app that include features under preview, experimental, or retired features.

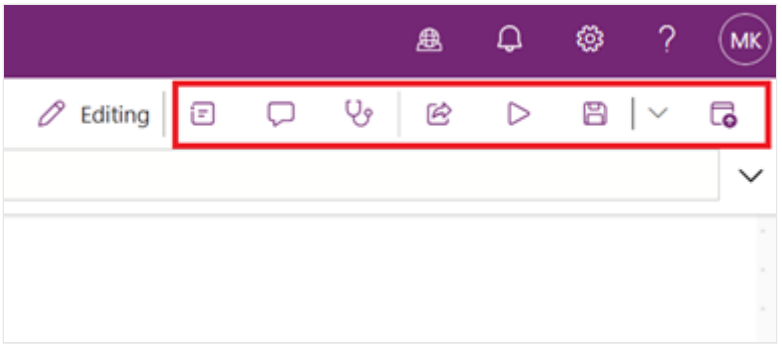
For more information, see Understand experimental, preview, and retired features in Power Apps.

Support

Access current Power Apps Studio information such as environment, authoring version, session ID, and session details. This information is useful for Microsoft Support sessions.

2 – App actions

To perform app-specific actions, use the options such as **Properties**, **Comments**, **App checker**, **Share**, **Preview the app**, **Save**, and **Publish**.



Share

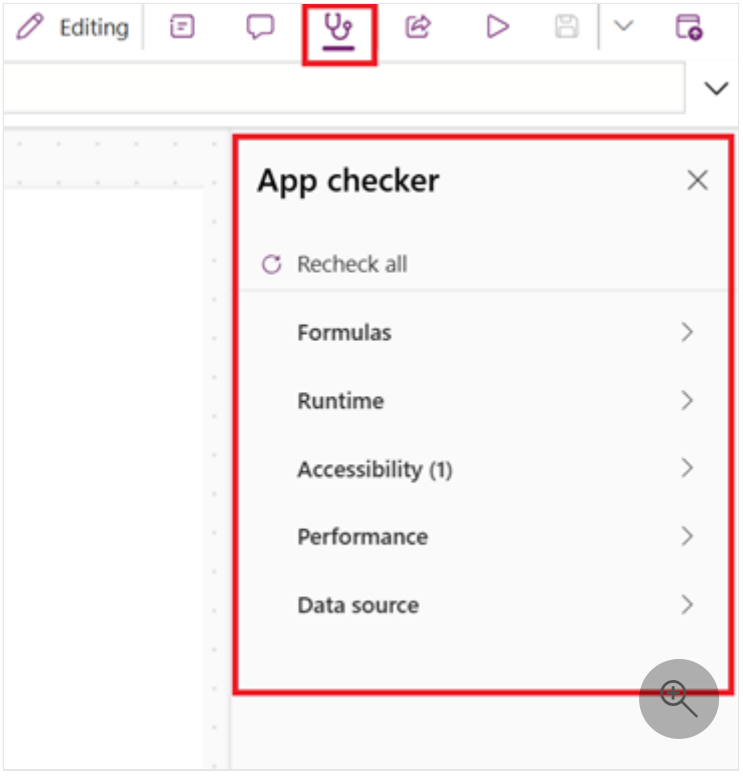
When you select the **Share** app action, a new window opens where you can share the app. You can share with other users or add them as co-owners of your app. For more information, see Share an app.

> **Tip**
>
> You must save the app before you can share it.

App checker

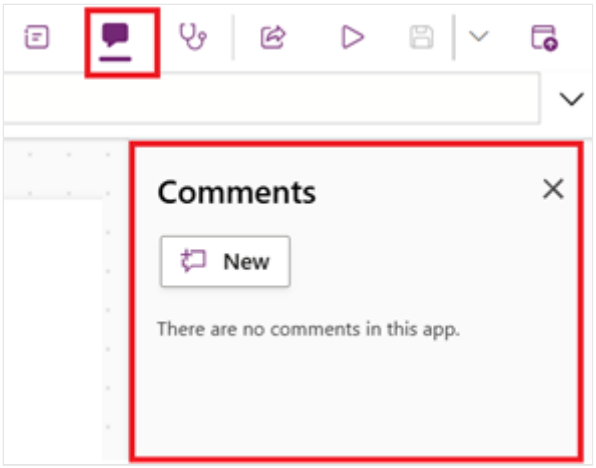
Select **App checker** to run a check.

For more information, see PowerApps checker now includes App checker results for canvas apps in solutions.



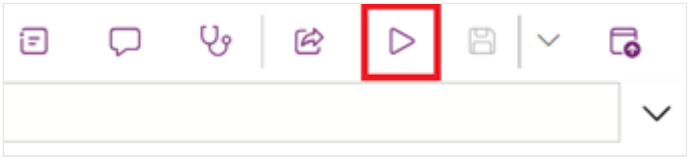
Comments

Comments are notes associated with items in your app. Use comments to help your team review the app and provide feedback, or provide additional information on implementation details in your app.



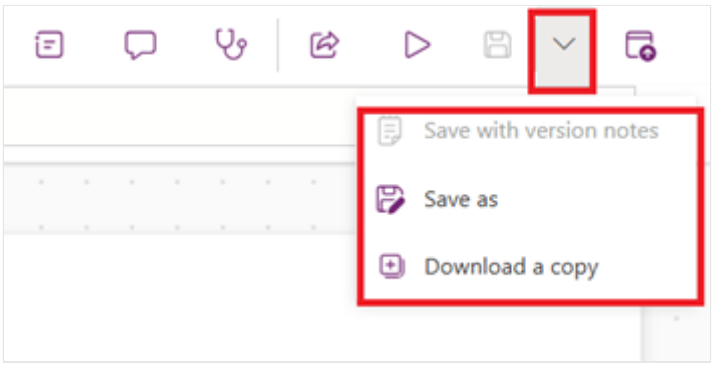
Preview

Select **Preview the app** to go into preview mode. Here you can view and interact with the current version of the app.



Save

You can save your app in different ways, such as **Save**, **Save with version notes**, **Save as**, or **Download a copy**. The save options dropdown is located next to the **Save** app action.



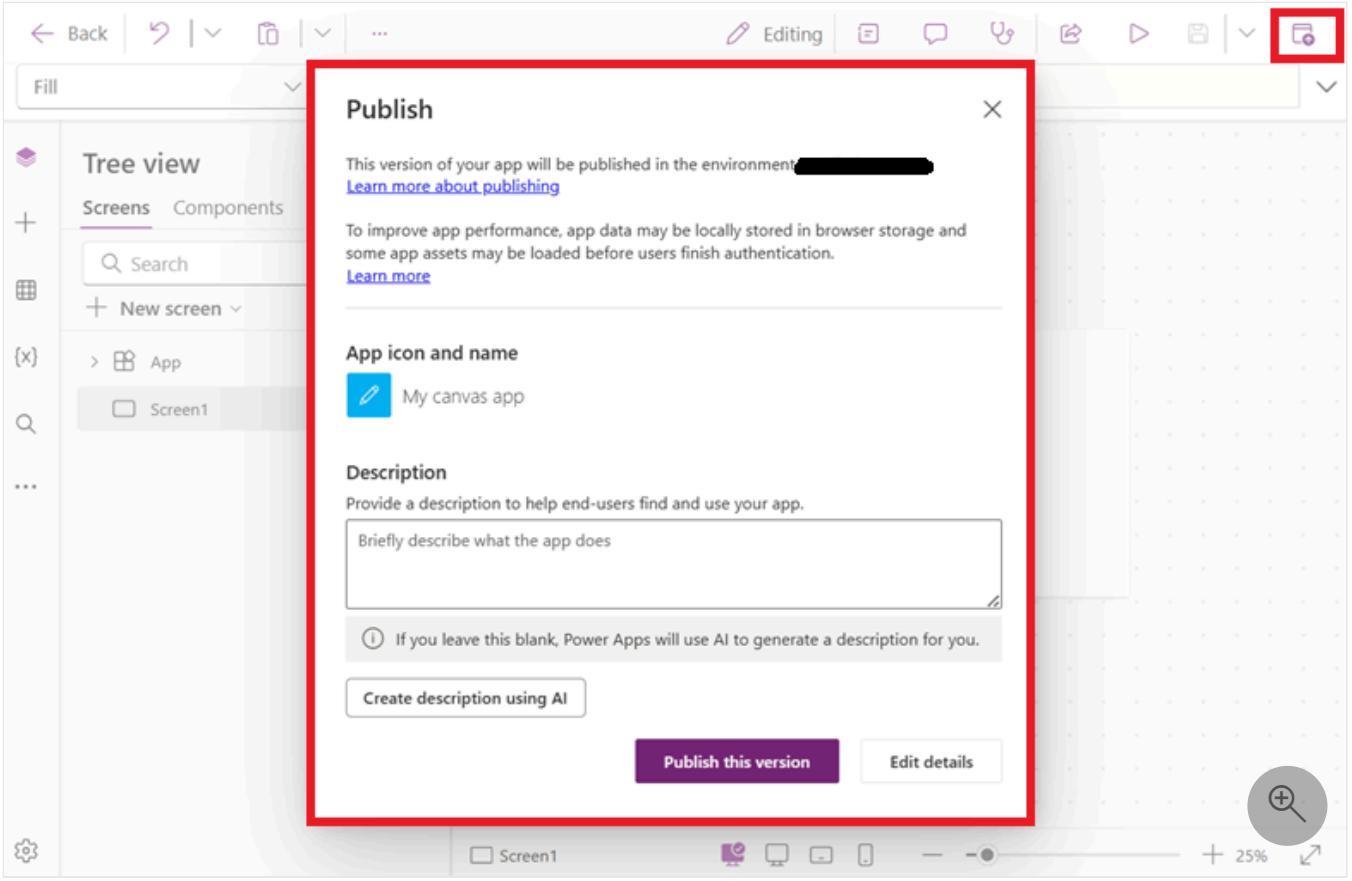
Save options include:

- **Save**: Saves recent and unsaved changes you made to the app. Each time you save changes, a new version is created.

- **Save with version notes**: Save and add notes about your updates.
- **Save as**: Duplicate the app by saving it with a different name.
- **Download a copy**: Download a local copy of the app.

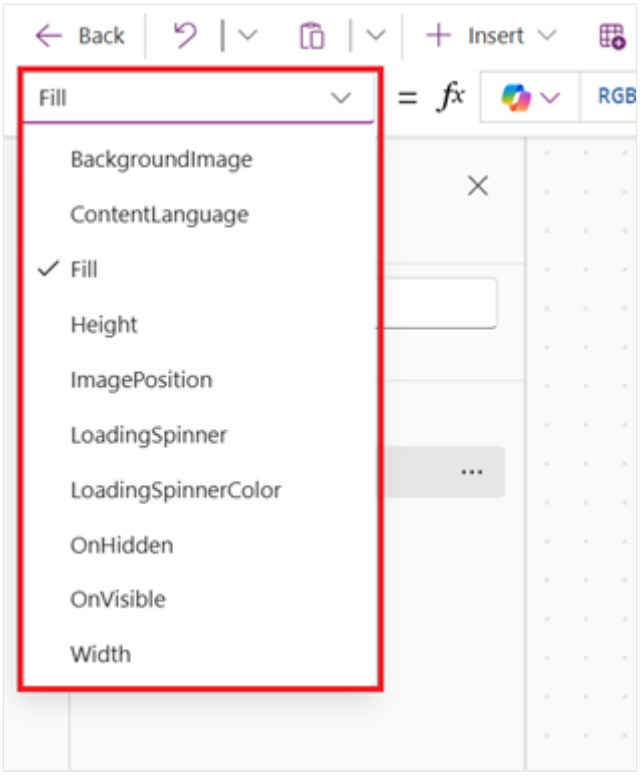
Publish

Select **Publish** to publish the app's current version. For more information, see Save and publish canvas apps.



3 – Properties list

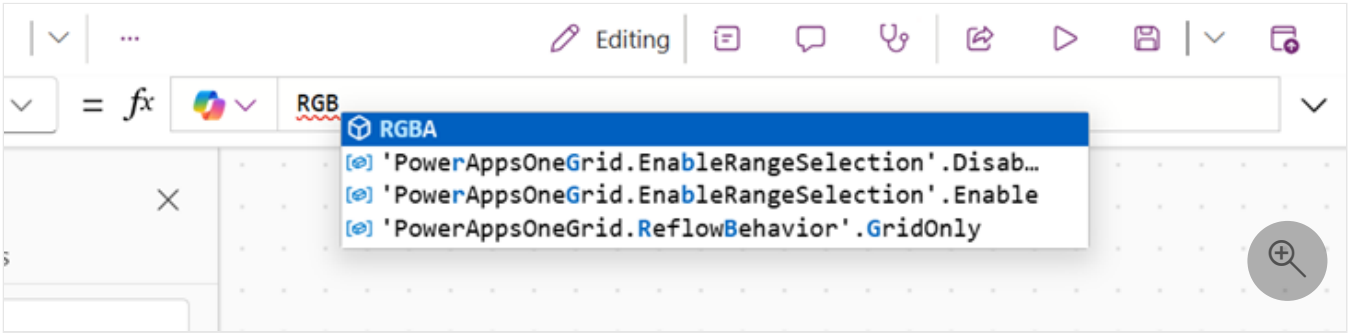
When you select an object in your canvas, you can choose one of the object's properties from its properties list. For a complete list of all possible properties, see All properties.



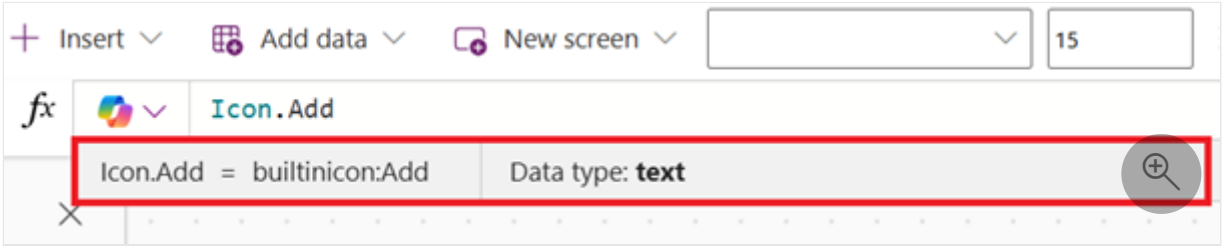
4 – Formula bar

The formula bar lets you add, edit, or remove functions of a property from your selected object. For example, select the app screen to update the background color by using the RGBA function.

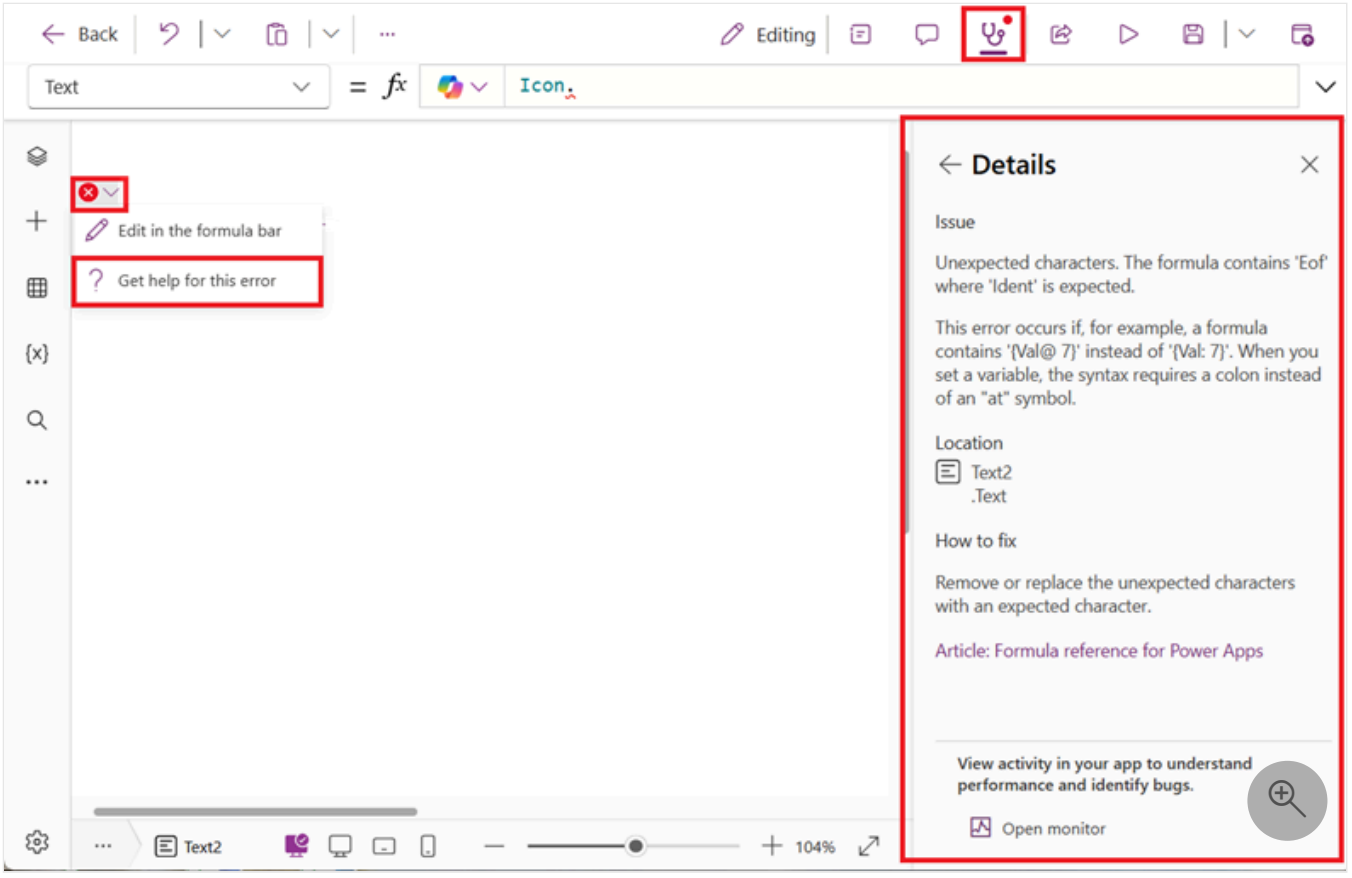
The formula bar is IntelliSense-enabled. When you start entering text that matches one or more functions, the formula bar shows a list of functions.



When you select a function, the formula bar shows inline function help and highlights help text relevant to the cursor position.



If a formula returns an error, you can view the error details in **App checker** or directly from the app view in the canvas.

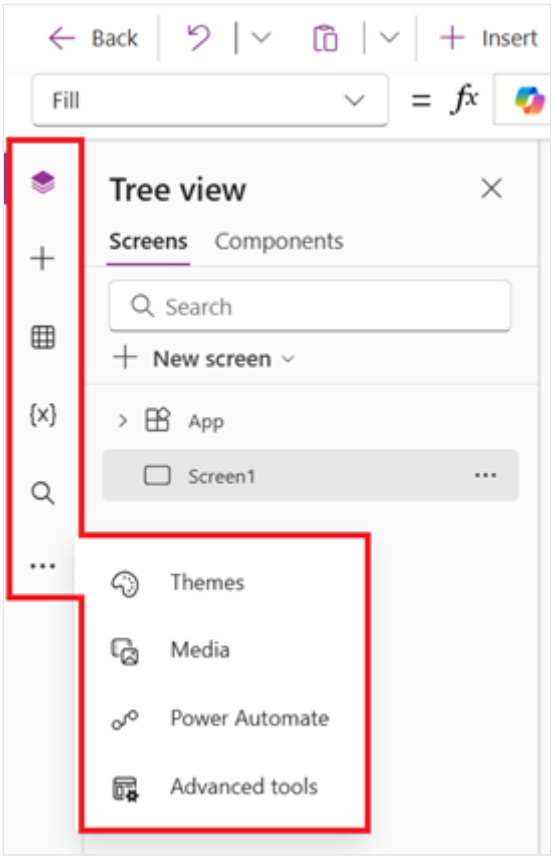


Similarly, you find help when working with complex functions, nested functions, or when correcting a formula syntax.

For a complete list of all canvas app functions, see Formula reference - Power Apps.

5 – App authoring menu

Switch between various authoring options while working with the app.



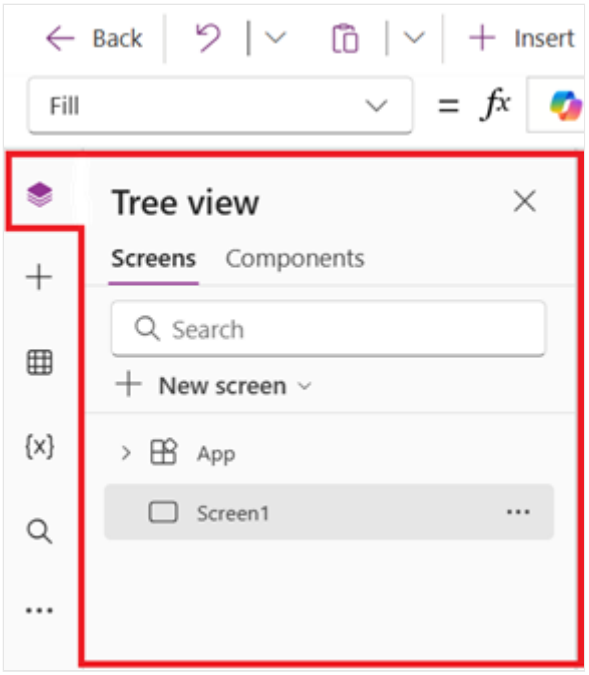
- **Tree view**: Shows a tree view of all screens and controls in the current app.
- Insert: Add different controls to the screen.
- **Data**: Add data and other connectors, such as tables that connect to your app.
- **Variables**: Work with variables and collections while editing your app.
- **Search**: Select to search for media, formulas, text, and more in your app.
- **Themes**: Choose a colored theme for the Power Apps UI.
- **Media**: Insert or remove media from the app.
- **Power Automate**: Add a flow by using the Power Automate pane.
- **Advanced tools**: Access the Monitor and Test tools to debug and test your app.

The options for working with canvas apps change depending on your selection from the authoring menu. For example, when you select the **Tree view** menu option, you see a **Tree view** pane appear.

6 – App authoring options

Tree view

Select the tree view to show the screens available in the app.



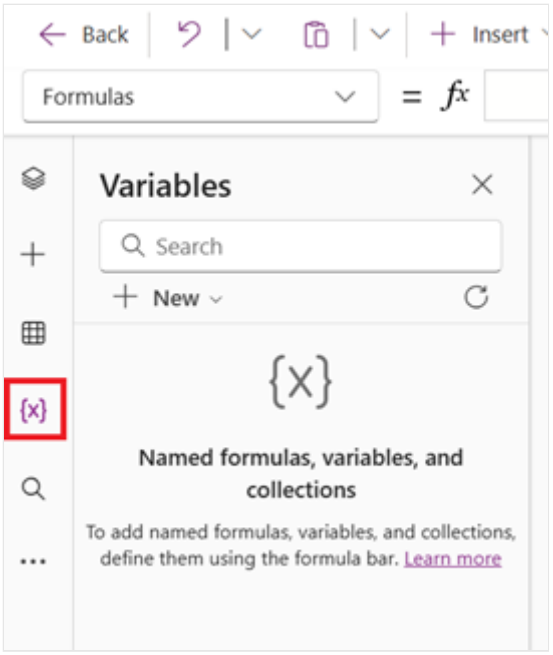
> **Tip**
>
> Select **App** in the tree view to work with app-specific controls. You can change app behavior, such as adding a formula for the *OnStart* event of the app.

Switch to the **Components** tab of **Tree view** to work with component library features. You can add new components or reuse ones from the published component libraries. For more information, see Component library.

For more information on adding components by selecting **+ New component**, see the Insert section.

Variables

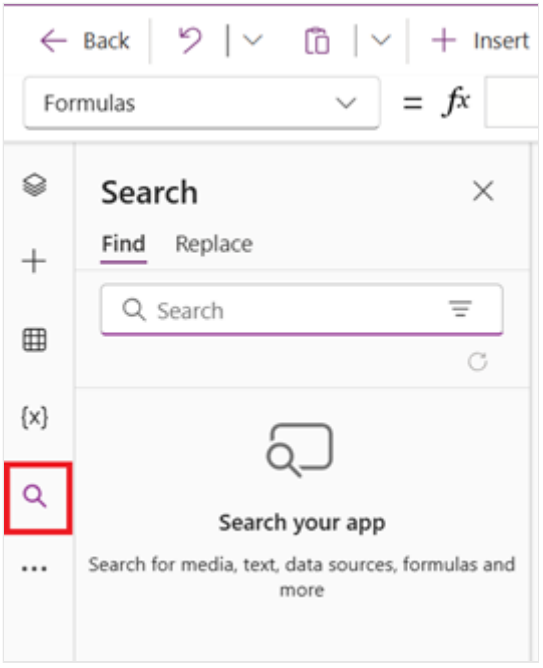
You can save data such as resulting values from a data set into temporary storage by using variables. This section lists variables used by the current app. For more information, see Variables in canvas apps.



A collection is a group of items that are similar, such as products in a product list. For more information, see Collections in canvas apps.

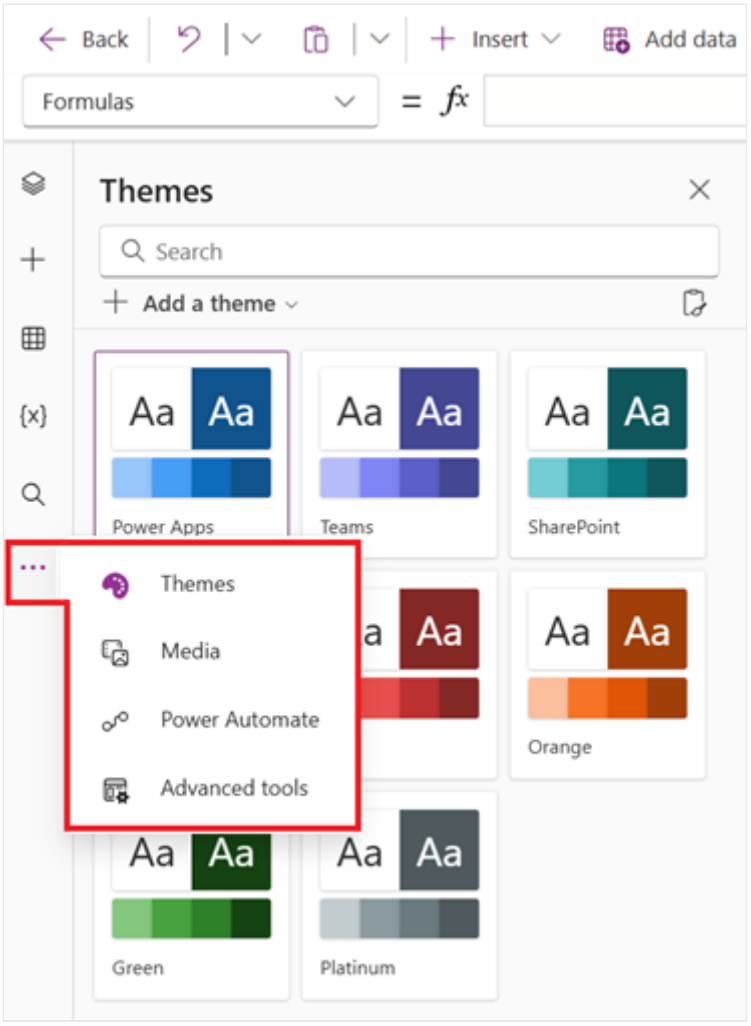
Search

You can find components in your app or find and replace them.



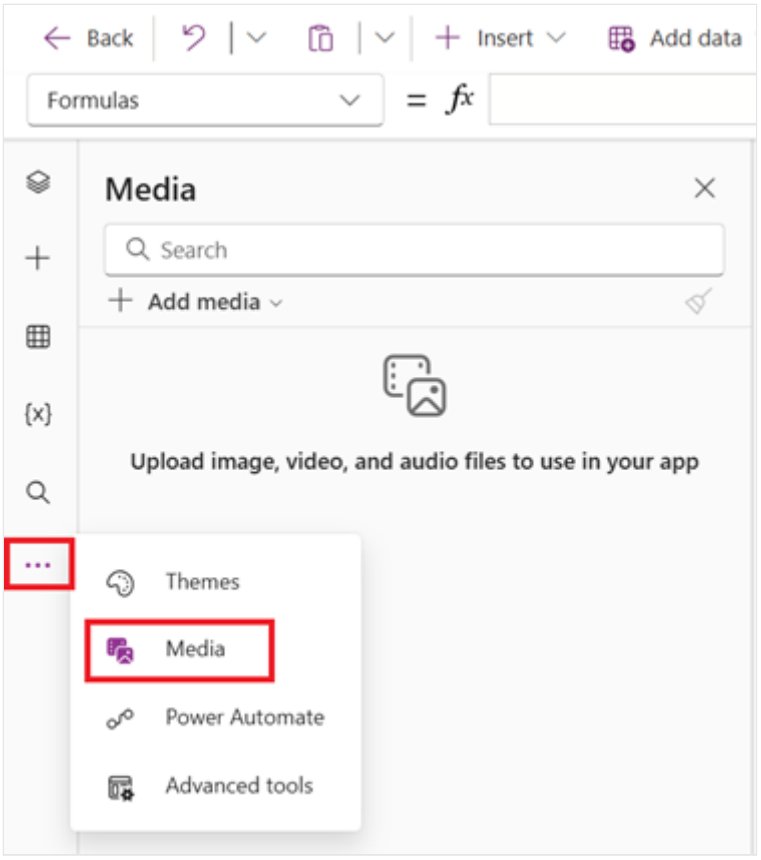
Themes

You can choose a premade colored theme or custom-make your own colored theme by selecting + **Add a theme**.



Media

Select **Media** to add images, video, or audio files to your app. Adding media directly to your app uploads the files to the app and uses the app storage.



Tip

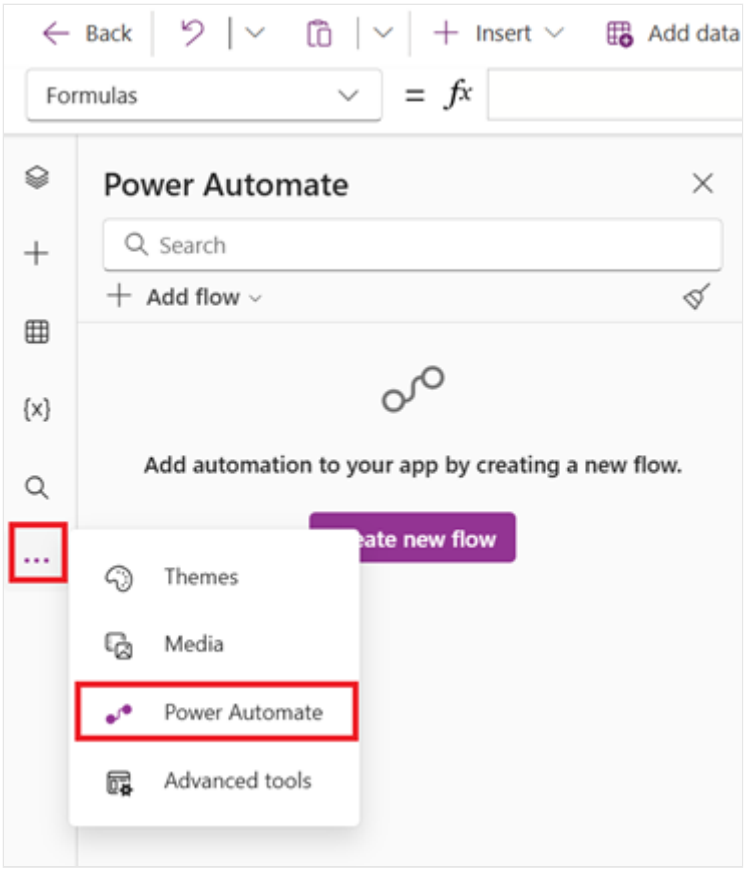
- Each file uploaded to the app as media must be 64 MB or smaller.
- The size of all media files uploaded to an app can't exceed 200 MB.

If you want to reference more media, consider using audio and video controls with URLs, media from Azure Media Services.

For more information, see Using multimedia files in Power Apps.

Power Automate

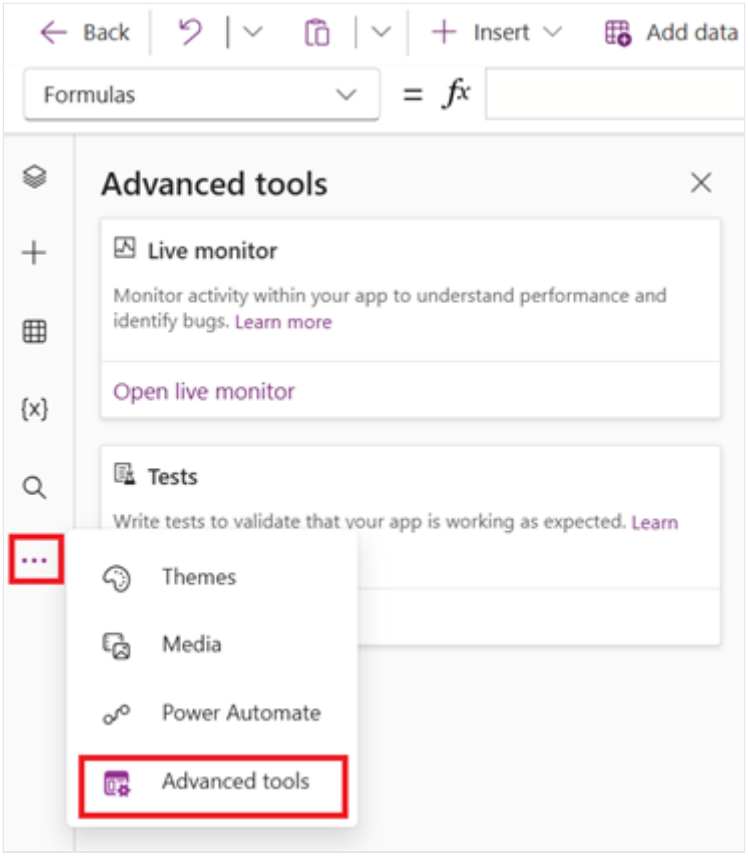
Create a new flow with Power Automate, or select a flow you added previously.



For more information, see Use Power Automate pane.

Advanced tools

Advanced tools include **Monitor** and **Tests**, where you can track and test your app.



7 – Canvas/screen

The canvas shows the currently selected screen in the **Tree view** from the authoring menu.

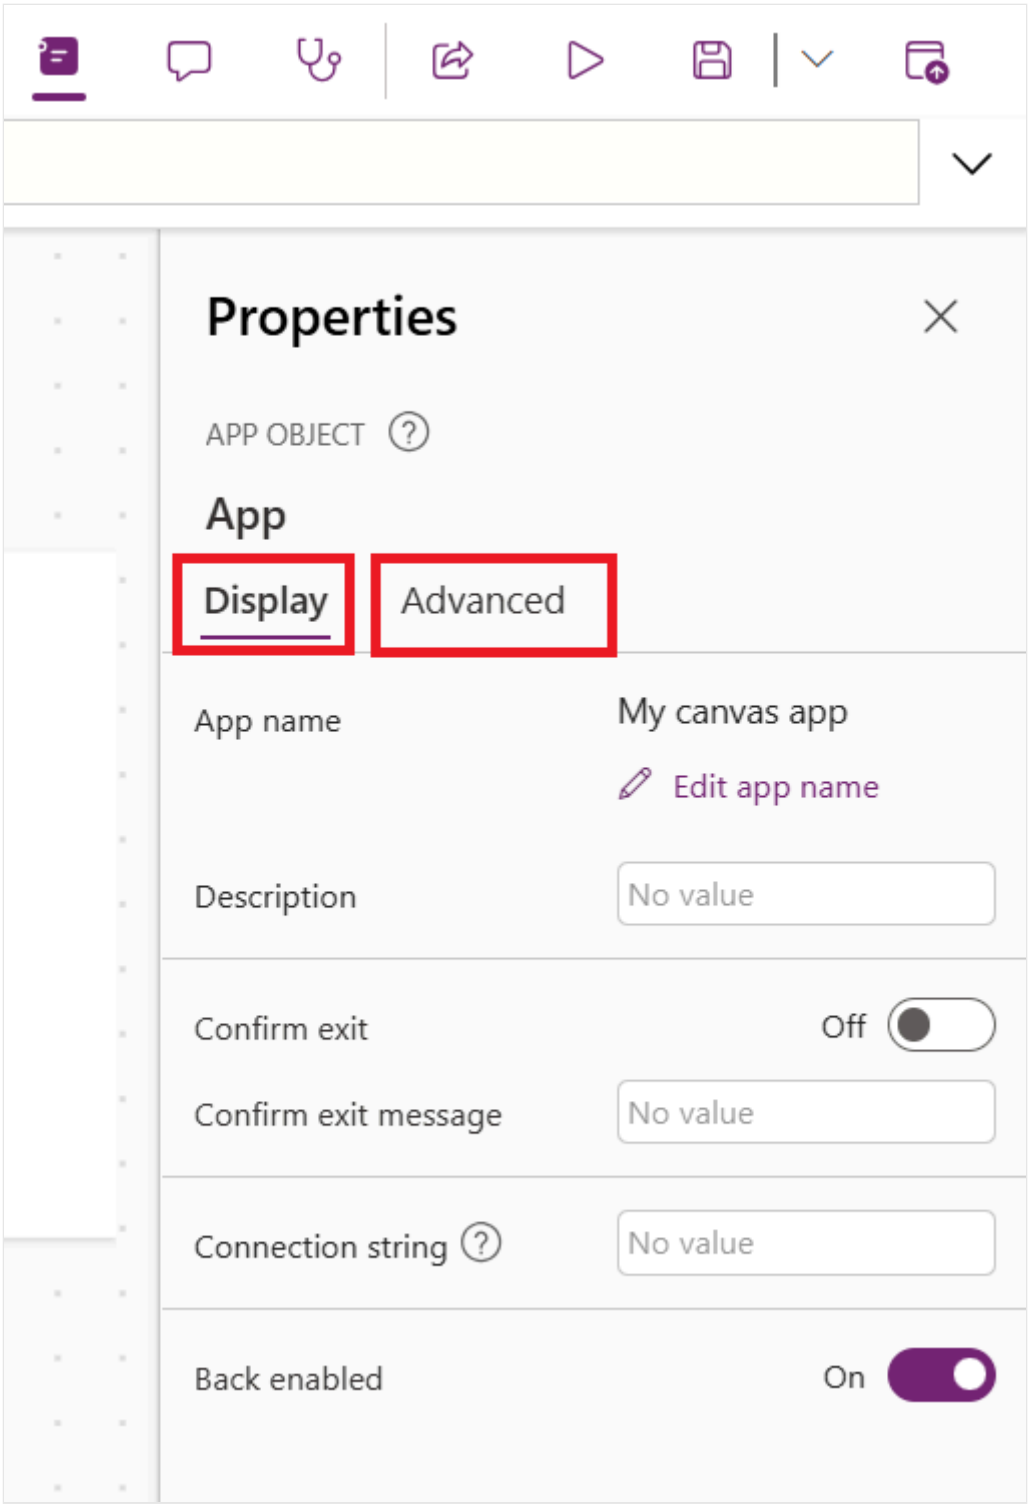
When you edit a canvas app, you can Use inline actions in Power Apps Studio so you don't have to leave your current view. Inline actions make the development process more efficient.

8 – Properties pane

The properties pane shows properties and options for the currently selected object on the canvas.

- The **Display** tab shows generic options such as the name, description, exit or exit message, and more.
- The **Advanced** tab shows options for customization with key value pairs in areas of action, data, and design in your app.

  > **Tip**
  >
  > The advanced properties might be locked for editing, such as when working with data cards. Select **Unlock to change properties** in such situations.



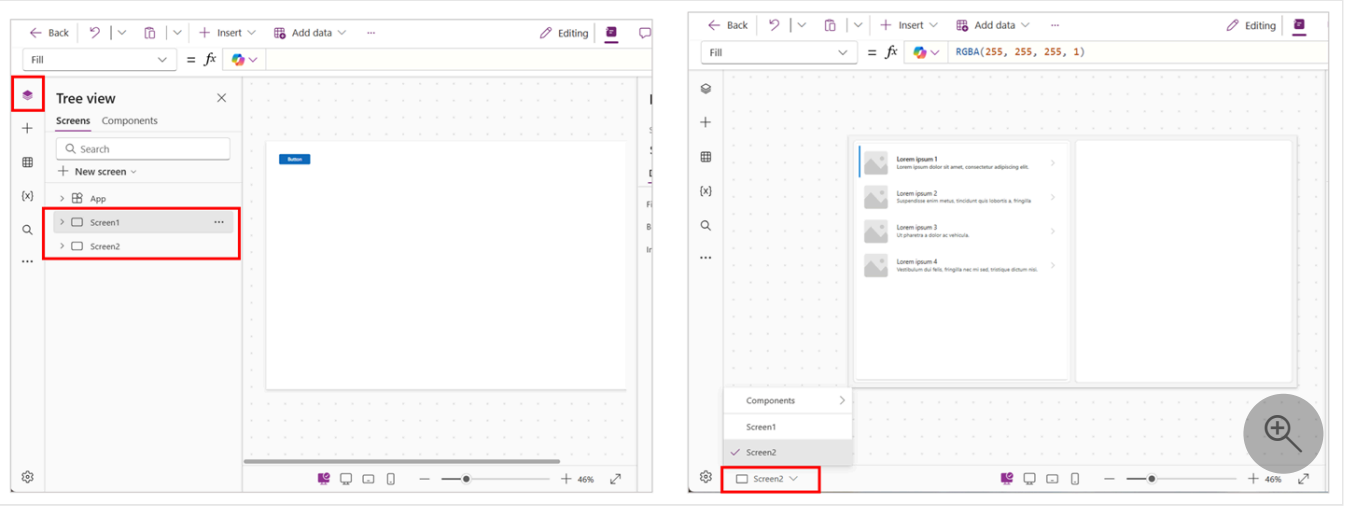
9 – Settings

Access Settings at the bottom of the app authoring menu or from the command bar as previously described.

10 – Screen selector

Use the screen selector to switch between screens when your canvas app has multiple screens. You can also select a screen from the authoring menu by selecting the tree view. If the current

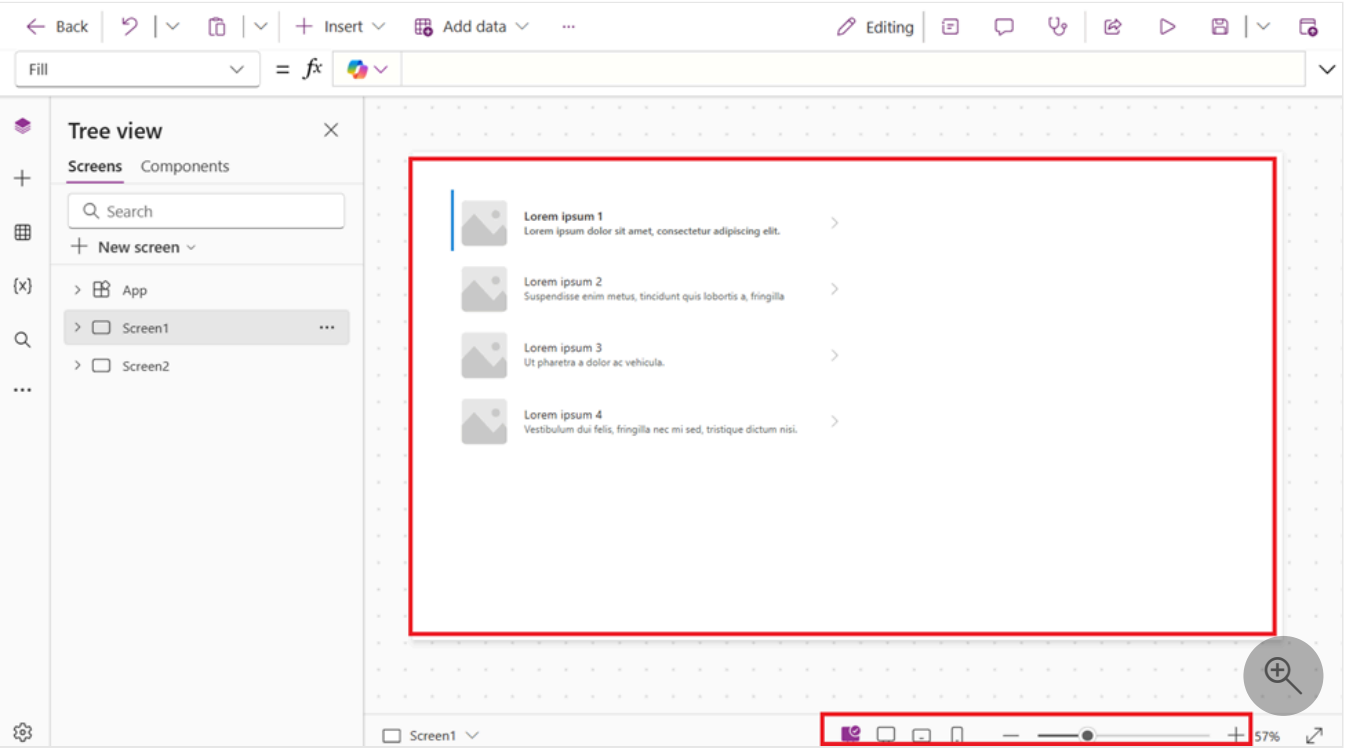
selection is inside a container, or inside an individual cell in a gallery, the selector shows the breadcrumbs for the parent elements at each level.



11 – Change canvas screen size

You can zoom in or out while authoring the canvas app. Select **Ctrl**+**0** (zero) to *fit to window*, which fits the canvas to the current authoring window size.

The following image shows what the canvas looks like when *fit to window*. You can also use the controls to zoom further in or out to view your canvas.



> **Note**
>
> The zoom percentage or screen size you use when authoring a canvas app doesn't affect the aspect ratio you configure for the app. When you preview your app or play a

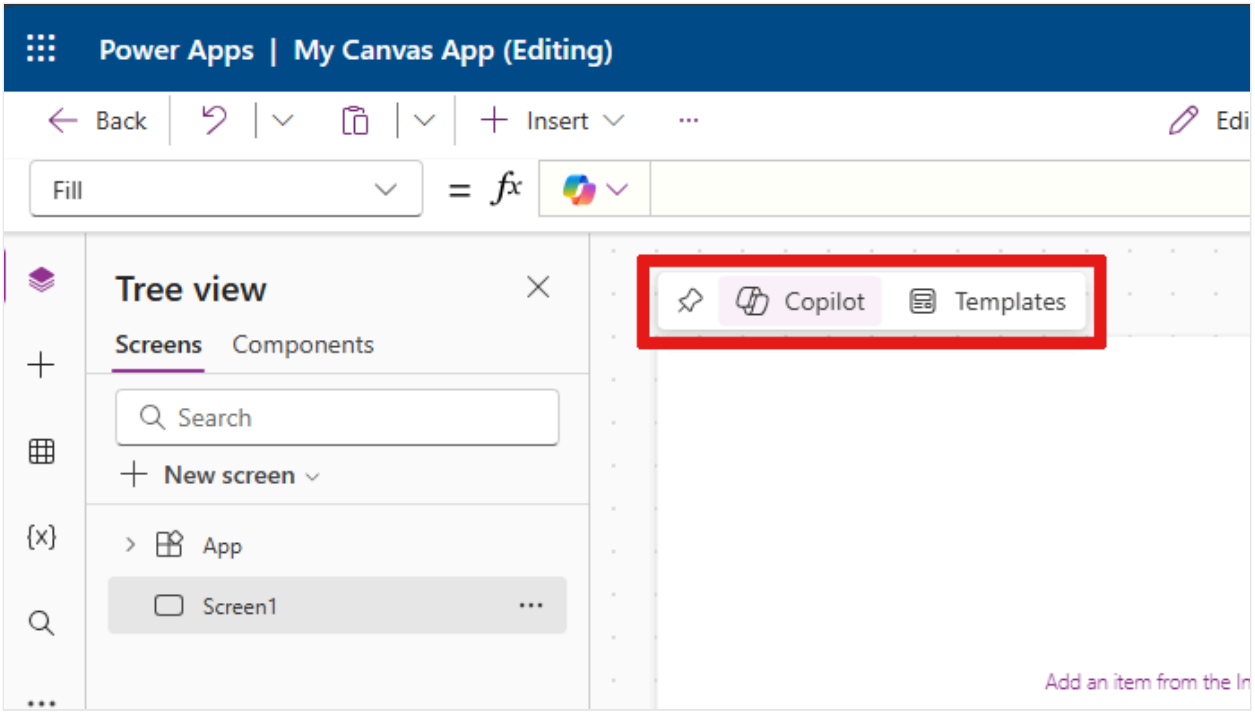
published app, your screen size is temporary.

Last updated on 03/25/2026

Use inline actions in Power Apps Studio

Article • 10/29/2024

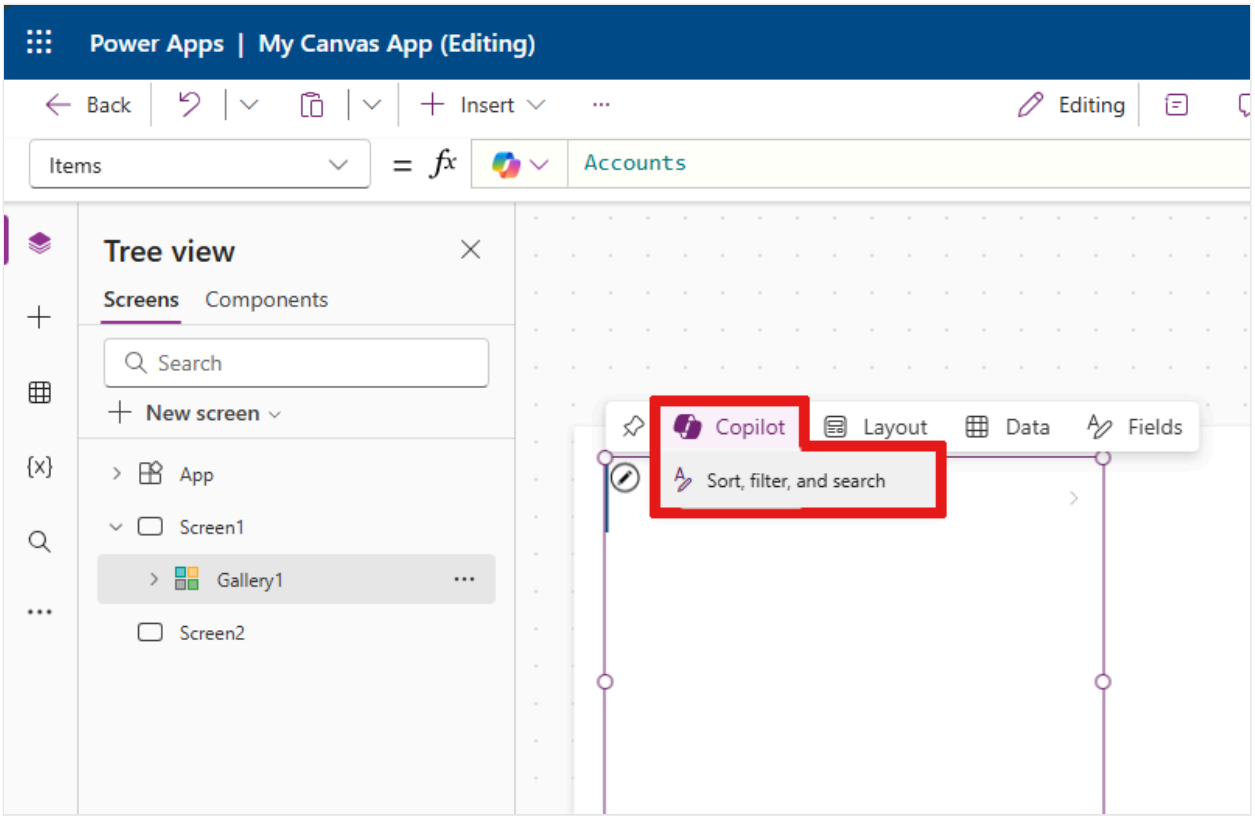
Inline actions are hidden menus that appear when you hover over screen layouts such as a blank screen and gallery or form controls. For example, if you hover over the canvas of a blank screen of your app, you see the **Copilot** and **Templates** inline actions appear.



Use inline actions to update layouts, work with data, collaborate with your colleagues, and use Copilot directly on the canvas for specific controls. This means you can build and modify your app without navigating away from your current view in Power Apps Studio. Inline actions provide a more streamlined and efficient way to work.

Use Copilot inline

Use Copilot inline to help you write Power Fx formulas. Use Copilot to apply conditional formatting, sort and filter your data, and more with the help of Power Apps Ideas. The Copilot button appears where applicable, offering suggestions for supported controls such as **Gallery**, **Data table**, **Text input**, **Drop down**, **Combo box**, and **Text label**. For more information, see Power Apps Ideas.



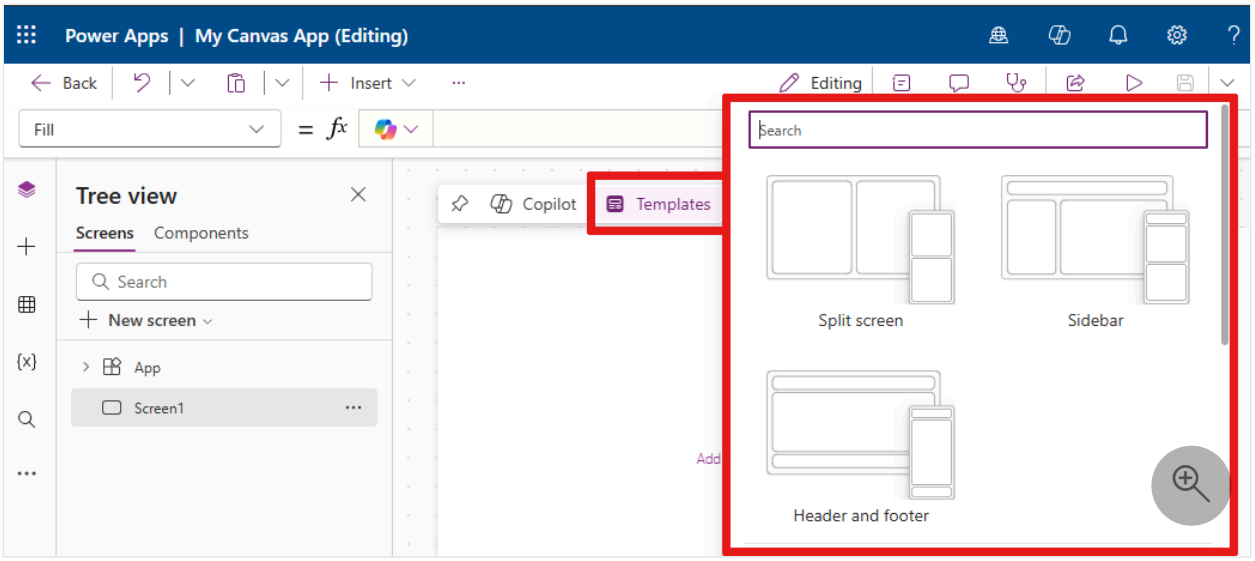
Choose a layout

Inline actions can help you with layout options to create the look you want.

Blank screens

You can use inline actions to apply a layout to blank screens. For example, if you add a new blank screen to your app and hover over the canvas, you can select the inline action **Templates** and then select one of more than one dozen layouts.

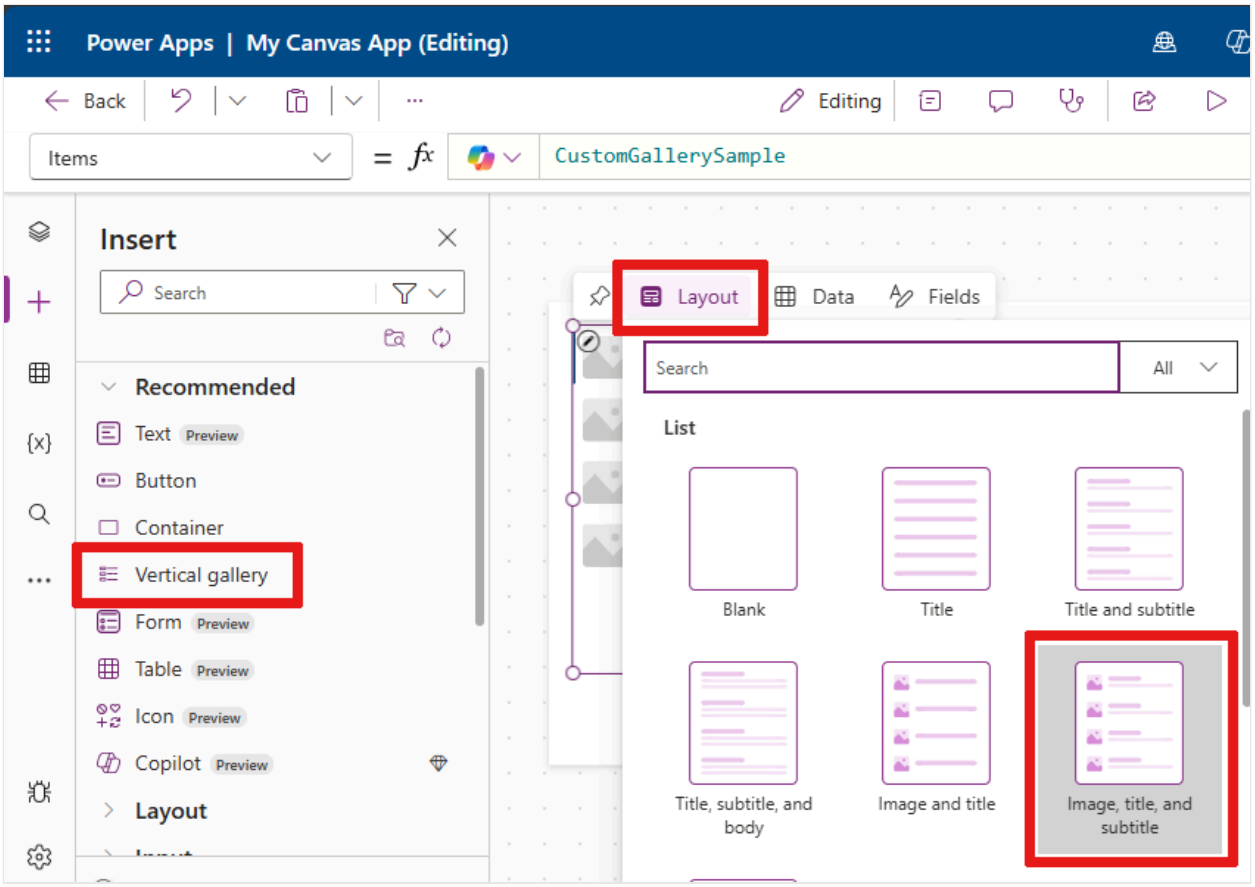
> **Note**
>
> Once you add content to a screen, the **Templates** button is no longer available unless you remove the content.



Gallery control (classic) layouts

You can insert a gallery control, hover over the control, and then use the **Layout** inline action to change the layout for that control. Different layout options appear when you add a **Vertical gallery** or **Horizontal gallery**.

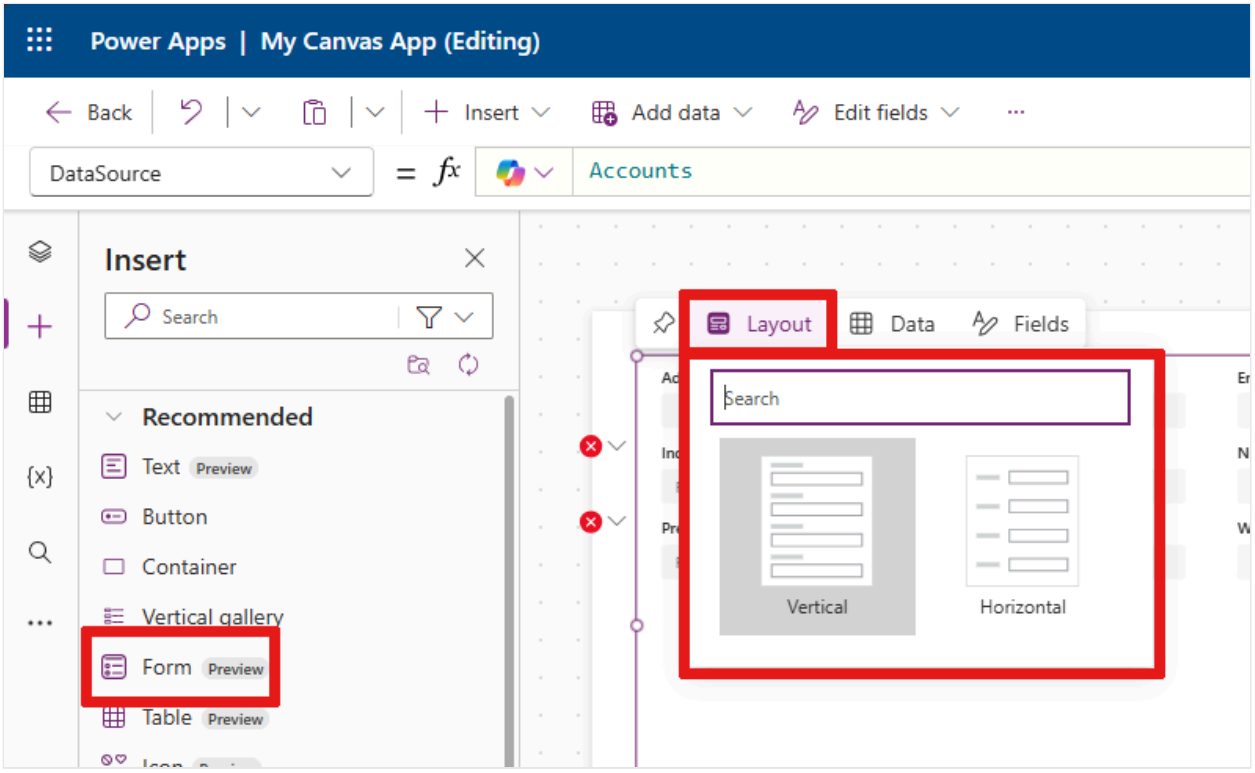
> **Note**
>
> When you change or remove controls after applying a layout, your customizations are removed.



Form control (modern or classic) layouts

When you add a modern or classic **Form** control, you're prompted to add a data source. Once the control is linked to data and added to your screen, you can see the **Layout** inline action appear when hovering over the control.

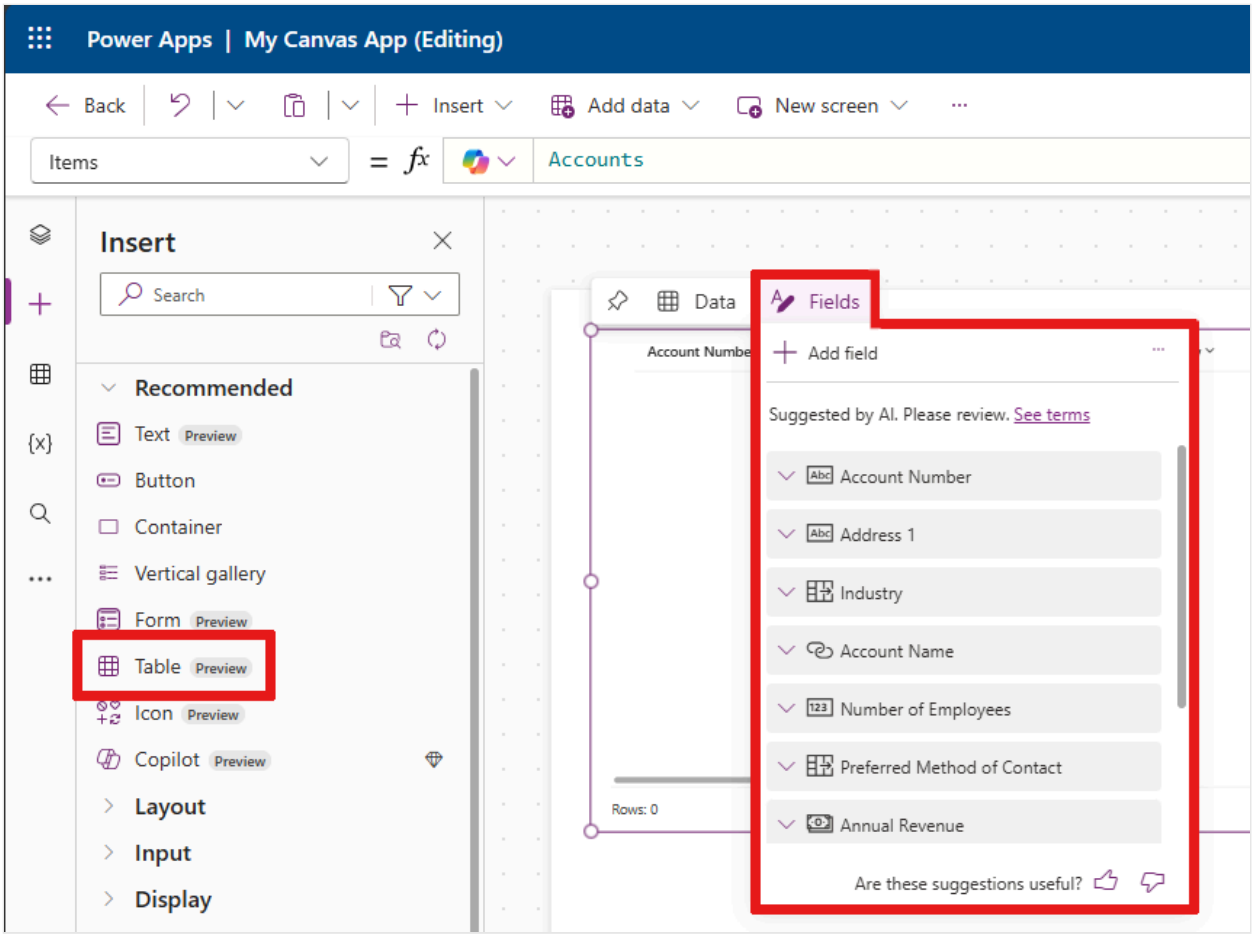
You can then use the **Layout** option to select whether the labels and inputs are arranged vertically or horizontally.



- Select the **Vertical** layout to place the label above the corresponding input control. For example, you might want a title displayed with a description below the title.
- Select the **Horizontal** layout to place the label to the left of the input control. For example, you might want an image on the left side of your list item and a name on the right side of your list item.

Add Data and Fields

When you link any control with data, you see the **Fields** inline action fill with fields from the data. For example, linking a **Table** control with data populates the **Fields** inline action with fields directly from the data such as **Account Number**, **Address 1**, and **Account Name**. You can choose which fields you want to display or add a new field.

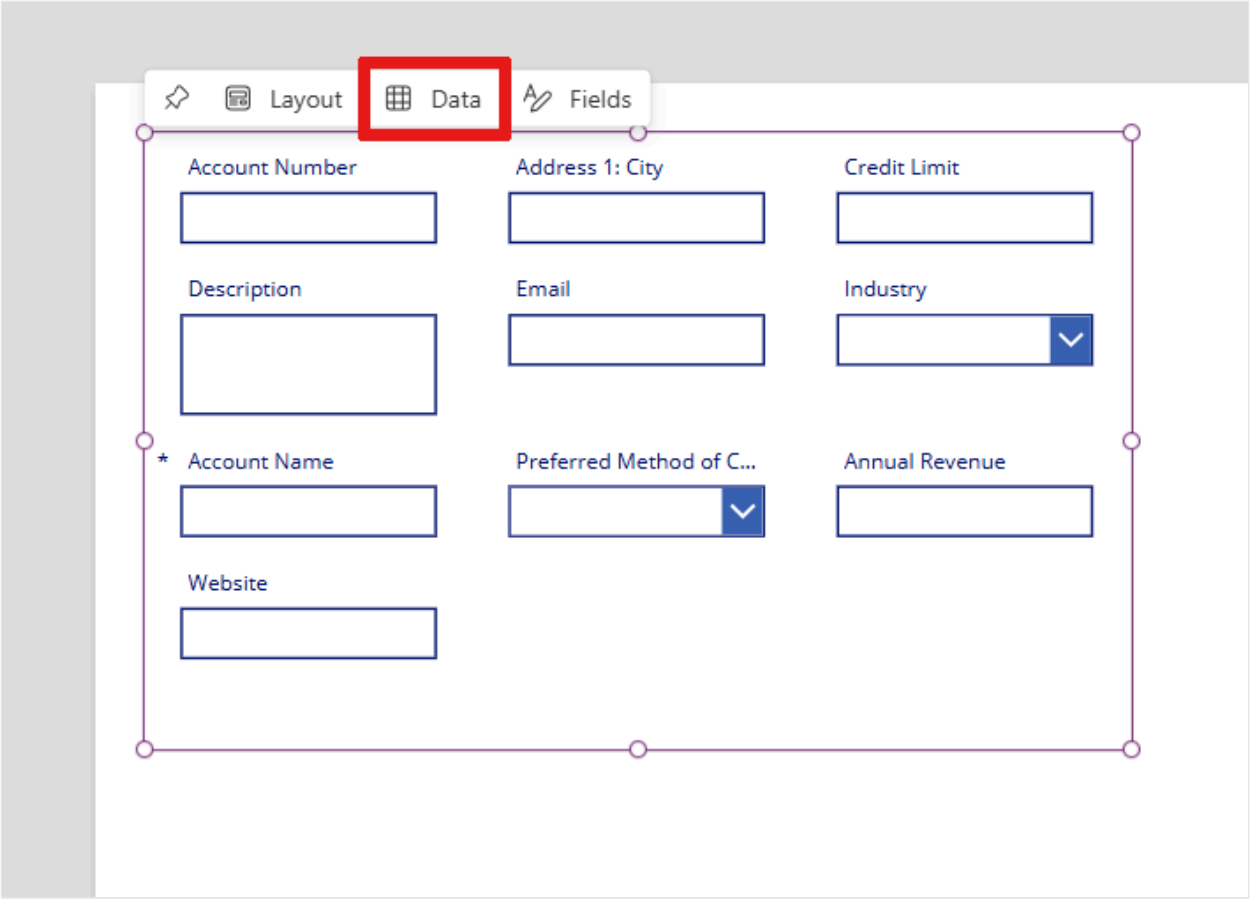


Gallery, Table, and Form

When you add a **Gallery**, **Table**, or **Form** control, you're prompted to add a data source through the **Select a data source** popup. Once you add a data source, the control displays the data. Use the **Fields** inline action to select which fields are shown on the control from the selected data source.

- In a **Table** control, you can drag and drop the fields to change the order that they appear in the table.
- In a **Form** control, if you choose a new data source, you're prompted to replace the data card. When you confirm your selection, it removes any customizations and generates a new form with fields corresponding to the new data source.

This form control has the **Accounts** data set as a data source. If you change that source by selecting the **Data** inline action, all customized fields are removed or replaced with fields from the new data.



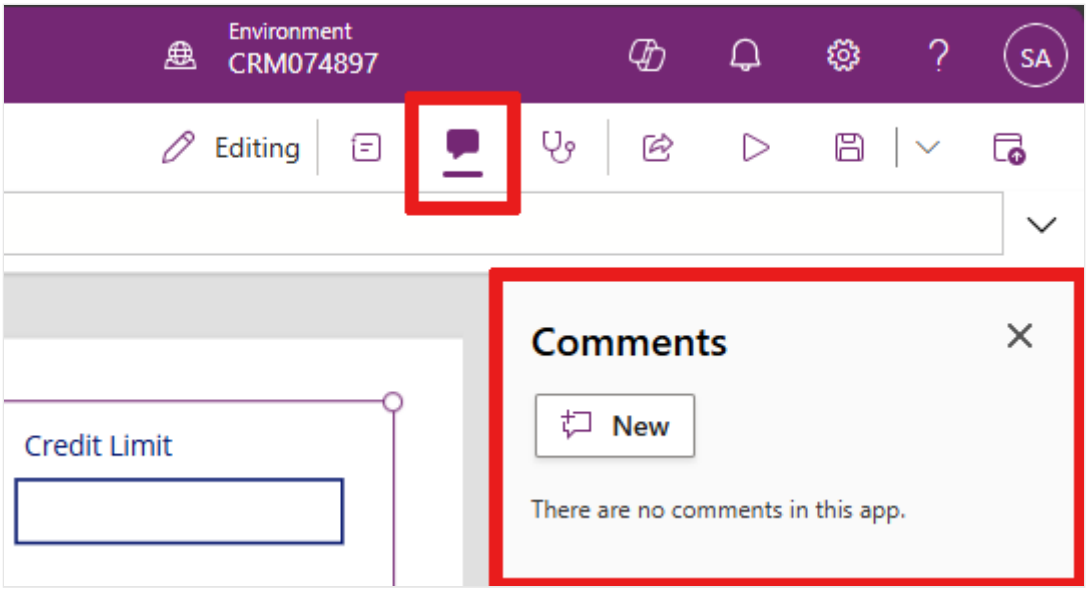
Tip

You can always access the **Data** and **Fields** inline actions to modify data used in the **Form**, **Gallery**, or **Table** control. These inline actions are available when hovering, whether or not you've selected a data source already.

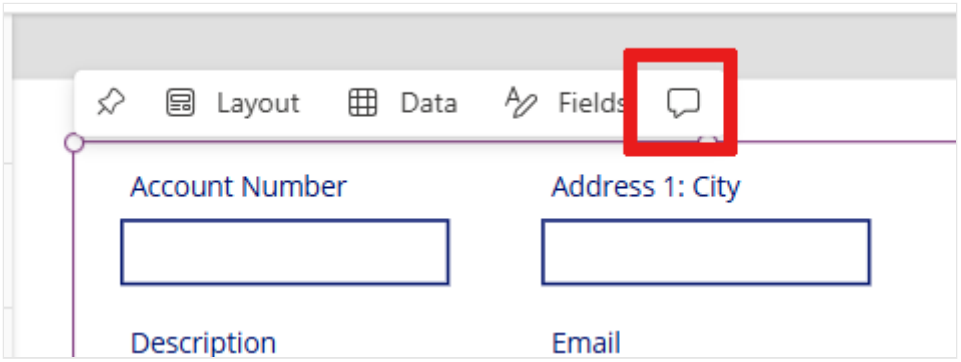
Add comments

Comments allow you to tag peers in your app to ask questions, leave instructions, and propose next steps. You can add and read comments on a screen and any control from inline actions.

To add a comment, select the **Comments** icon in the command bar to show the **Comments** pane. Select the **New** button to start writing a comment.



Once the comment is posted, you see a comment icon in the inline action menu, when you hover over a control.



If you remove all comments from a control, the comment icon in the inline action menu is removed too.

Feedback

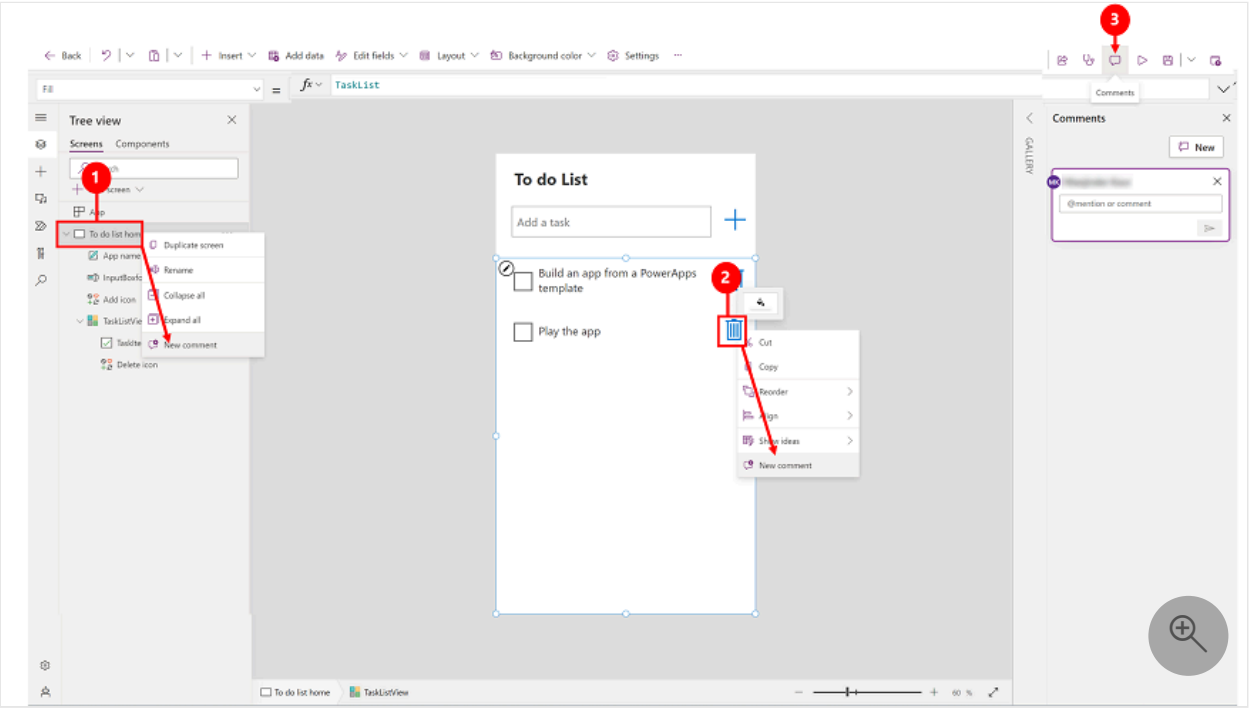
Provide product feedback

Add comments when you're building a canvas app

Article • 03/07/2025

Easily add comments when you're building a canvas app in Power Apps Studio. Use comments to help your team review the app and provide feedback, or provide additional information on implementation details in your app. To allow other makers to add comments, make sure to share the app with them.

You can add comments to different components or pages.



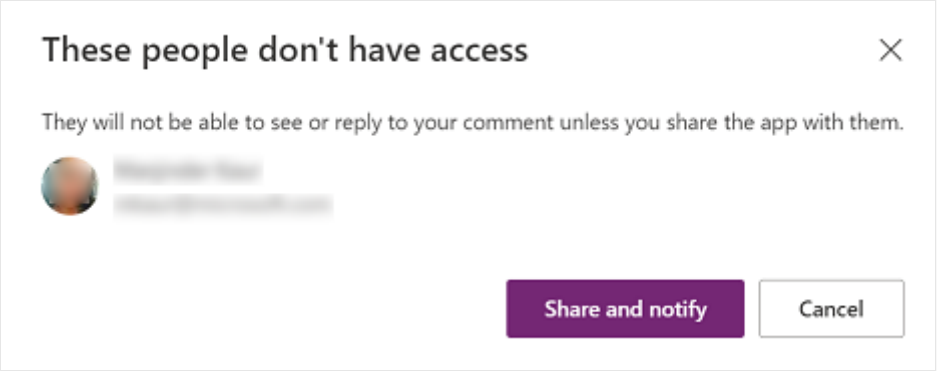
Legend

1. **Tree view**: Select a screen from the tree view and right-click to add a **New comment**.
2. **Component**: In the canvas area, right-click on a component to add a **New comment**.
3. **App actions**: Select **Comments** > **New** and then add your comments.

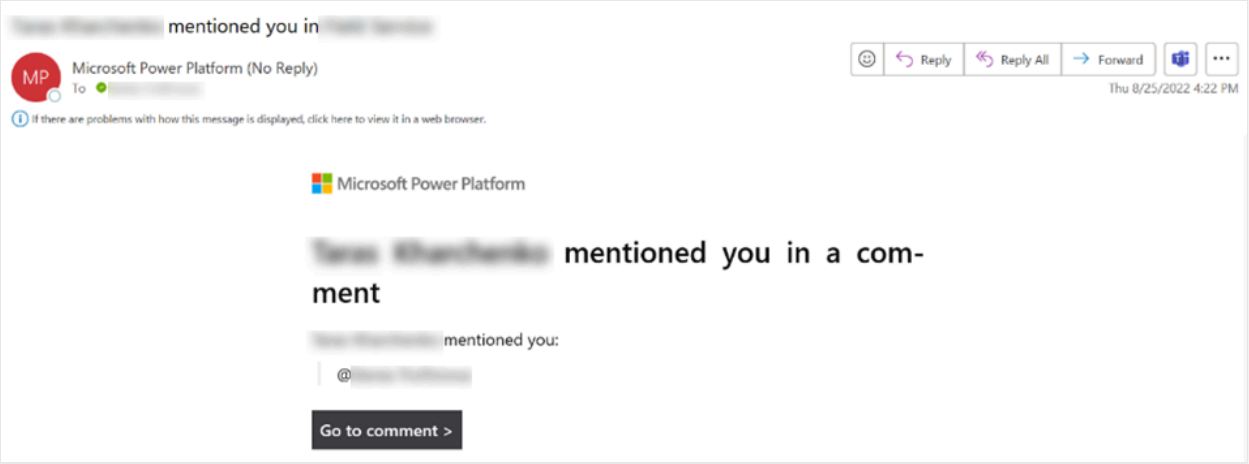
Use @mention in comments to tag someone for feedback

Connect with other makers in your organization as you collaborate on creating your app. You can tag people in the comments by using @+ their name.

If you tag a maker that doesn't have access to your app, then you're prompted to share the app with them.



When someone tags you in a comment, you receive an email that lets you know which app you're tagged in and the person who tagged you. It also includes the comment text and a direct link to that comment.



Edit or delete a comment

You can edit your comments or remove existing comments from appearing in the app.

In the **Comments** pane, next to a comment, select **...**, and then select **Edit comment** or **Delete comment**.

Resolve a comment

Comments are commonly questions, feedback, or ideas that are important context to live alongside your app. But they might not be active discussions anymore. You can resolve a comment or reopen a resolved comment thread to better track the active comments.

1. In the **Comments** pane, next to a comment, select **...**, and then select **Resolve comment**.

2. The comment thread appears as **Resolved**.

3. Select one to remove the comment:

 **Reopen a thread**.

 **Delete a thread**.

Limitations

1. The numbers of users who can access an app in edit mode is limited. If you have an app open and tag someone, the user receives an email notification. The user must wait for you to exit the app in order to see the comment and resolve it.
2. Comments aren't supported when you're working on an app using Git.
3. @mention isn't supported for SharePoint custom Power Apps. Learn more in Customize a form for a SharePoint list.

Understand coauthoring and copresence in canvas apps

Summarize this article for me

Collaborate on canvas apps in Power Apps Studio by using copresence and coauthoring. These features let you work with other makers in real time, improving productivity and teamwork.

https://learn-video.azurefd.net/vod/player?id=719b89e6-32ce-498b-9597-600d91019ec4&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fcopresence-power-apps-studio

What you'll learn:

- How to see who's working on your app and work together effectively
- When to use copresence vs. coauthoring for your collaboration needs
- Step-by-step instructions to enable and use these features

Key differences:

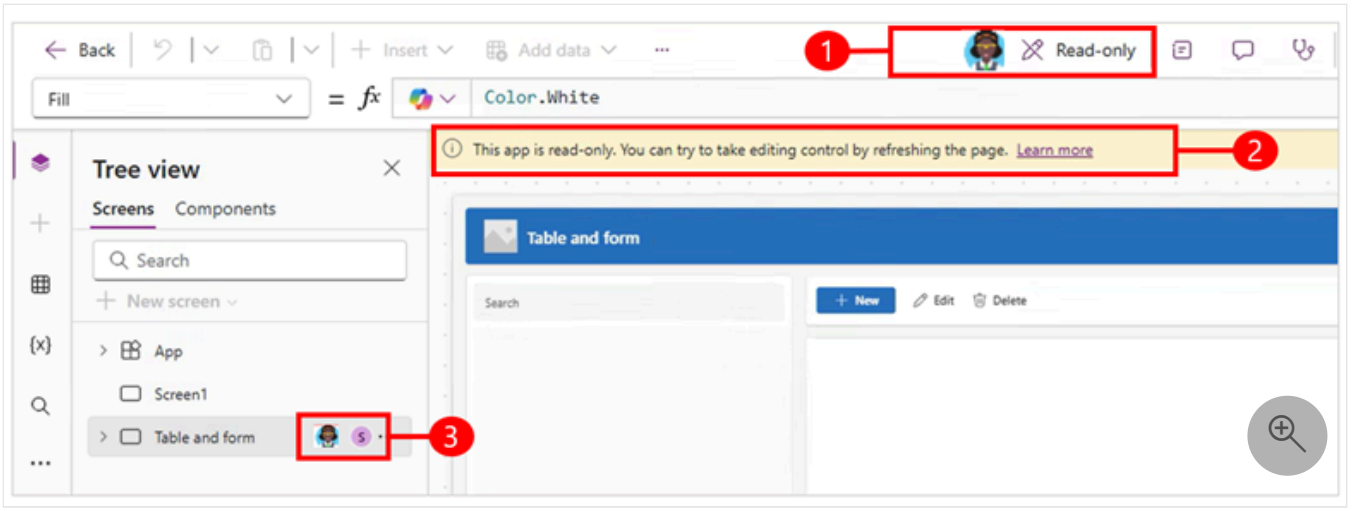
- **Copresence** shows who else is working on the same app, but only one person can edit the app at a time. The first person who opens the app gets editing control.
- **Coauthoring** lets multiple people edit the app at the same time and see each other's changes in real time.

Use copresence to see who's working on the same app

When you open an app for editing in Power Apps Studio, indicators might show that other people are also working on the app. These indicators are part of the copresence feature.

The first person who opens the app gets editing control. If another person opens the app, a notification lets them know that someone else is editing the app, and they're viewing it in read-only mode. In read-only mode, you can't add new screens, edit control properties, or use the command bar. You can save a copy of the app.

The command bar shows the names and icons of other makers who are editing or viewing the app. The left navigation pane shows the app's structure and highlights which part of the app someone else is editing. You also get a notification to refresh the app when someone saves changes to the app.



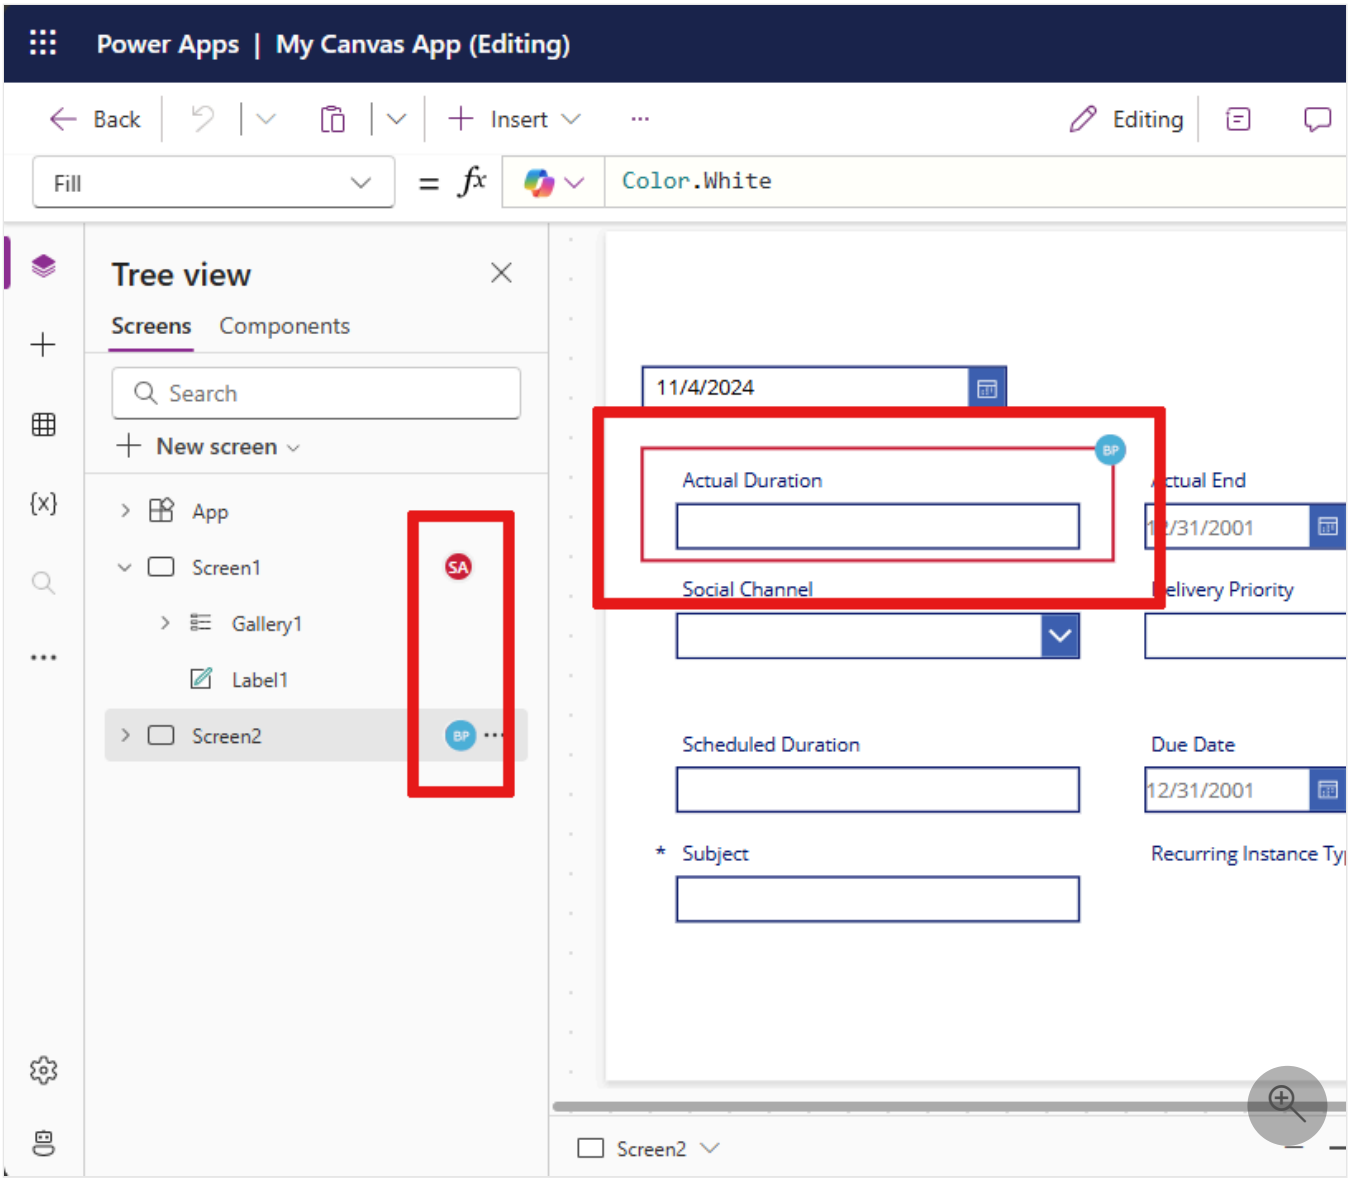
Legend:

1. The command bar shows the names and icons of other makers who are editing or viewing the app.
2. A **Read-only** warning appears if someone already has editing control elsewhere. You can select **Override** to become the main author and regain editing rights.
3. In **Tree view**, you see the app's structure and other people's profile pictures on the part of the app someone else is editing.

> **Tip**
>
> If you're inactive for two hours while editing an app, Power Apps asks if you want to keep editing or switch to read-only mode. If you don't respond, the system puts you in read-only mode so other makers can become the editor.
>
> If autosave is on, your changes are automatically saved. If autosave isn't on, Power Apps notifies you that you're no longer editing and lets you save a copy of your changes.

Use coauthoring to edit the same app together

Coauthoring lets multiple makers edit a canvas app at the same time. When you use coauthoring, you can see where other makers are working on the app and view their changes in real time.



When multiple editors work on the app, their avatars appear.

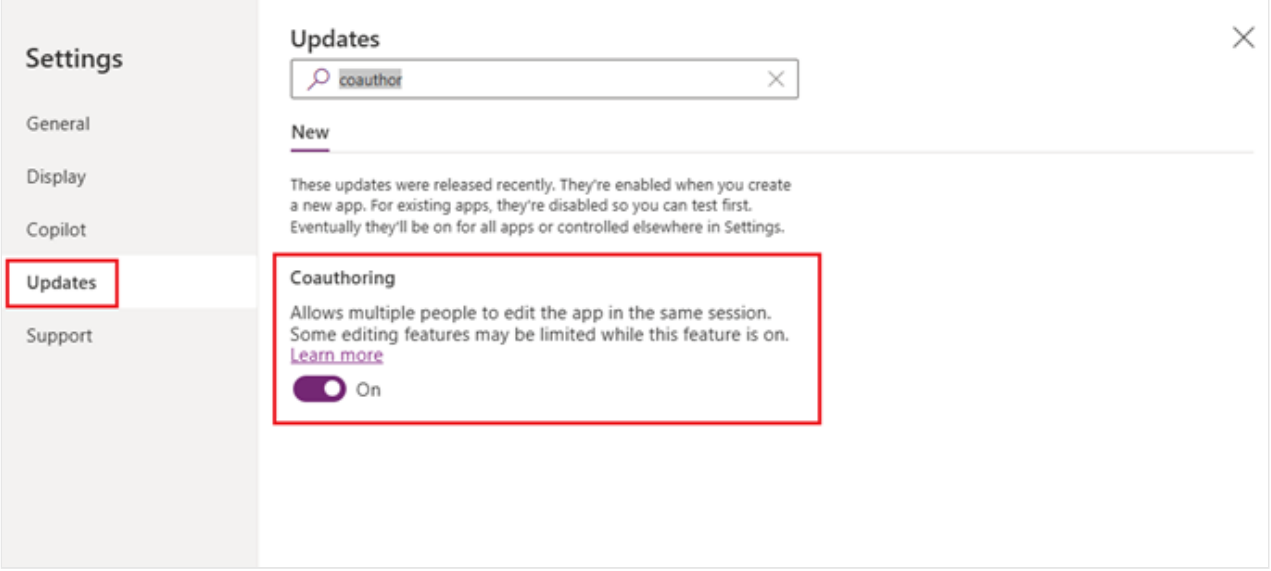
- The left navigation pane shows the app's structure in **Tree view** and shows which part of the app someone else is editing. For example, you might edit **Screen 1**, while someone else edits **Screen 2**.
- The area that another maker edits is highlighted and shows their initials. For example, someone else might edit a part of a form, which is highlighted for the first user.

> **Important**
>
> Multiple makers can select and edit a control at the same time. Be careful not to overwrite each other's changes.

Turn on coauthoring

To use coauthoring, turn it on for each app. When you turn on coauthoring, it overrides the copresence feature.

1. Open your app for editing in Power Apps Studio.
2. Go to **Settings** > **Updates** > **New**.
3. In the search box, type **coauthor**.
4. Turn on the **Coauthoring** toggle.



Limitations of coauthoring

- When more than one maker edits an app, the following actions aren't available:
  - Search
  - Save as
  - Open another or new app
  - Undo and redo
  - Switch authoring versions
- The maximum number of coauthors is 10, either in one session or across a total of 10 tabs, depending on which limit you reach first. Any other coauthors or tabs beyond 10 are in copresence and can't edit the app or view real-time updates.
- The app language is locked to the locale of the first maker who opens the app for editing. Opening the same app in a different locale can lead to errors in formulas.
- Cut isn't available.
- Coauthoring is turned off in the Monitor tool.
- You can encounter a problem with the following actions:

- Renaming a control
- Adding AI Builder components
- Adding geospatial controls
- Running a flow that another coauthor added, without refreshing the app first

Add and configure controls in canvas apps

Article • 10/29/2024

Add a variety of UI elements to your canvas app, and configure aspects of their appearance and behavior directly, from the toolbar, in the **Properties** tab, or in the formula bar. These UI elements are called controls, and the aspects that you configure are called properties.

Prerequisites

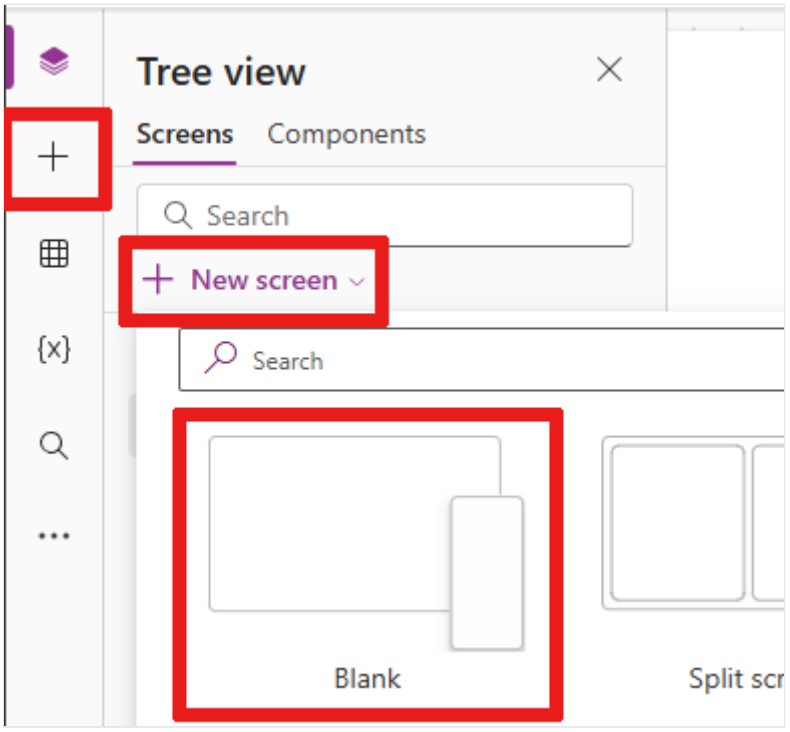
1. If you don't already have a Power Apps license, sign up, and then sign in.
2. Create a blank canvas app.

   You can always take the tour later by selecting the question-mark icon near the upper-right corner of your screen and then selecting **Take the intro tour**.

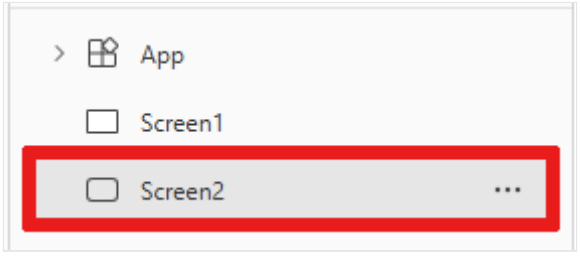
Add and select a control

Let's add a new screen and a button control. However, you can add any type of control.

1. Select **Insert** from the authoring menu, then select **New screen**.
2. Choose **Blank** to add a blank screen to your app. (Screens are a type of control that can contain other types of controls.)

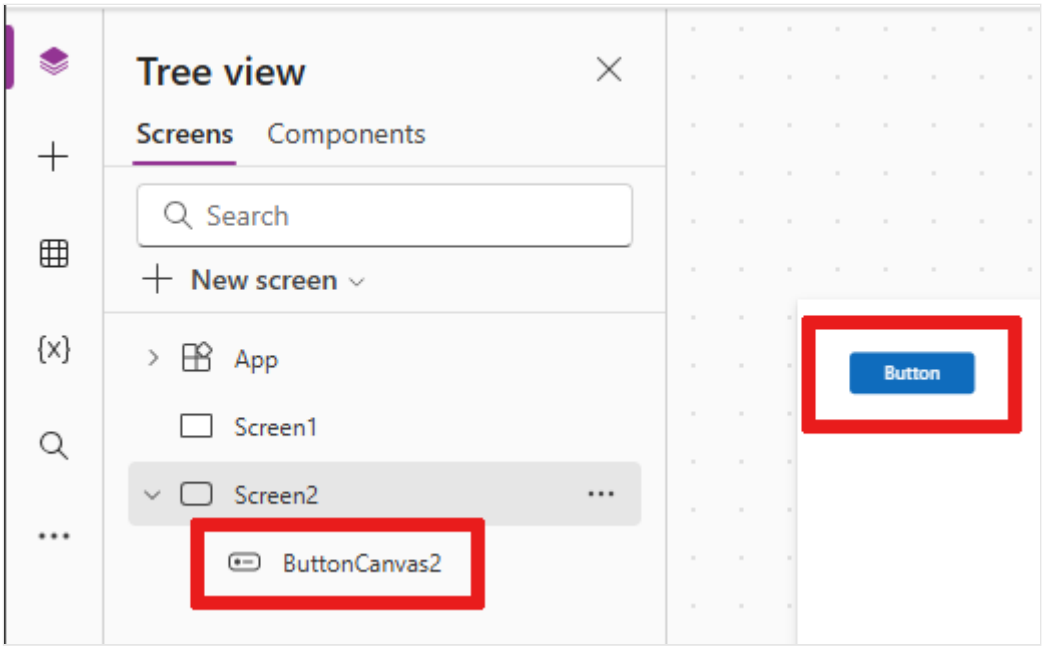


The new screen is named **Screen2** and appears in the **Tree view**. This pane shows a hierarchical list of controls in your app so that you can easily find and select each control.



3. With **Screen2** selected, select **Insert** again.

4. Select the **Button** control. The new control appears under **Screen2** in the hierarchical list of **Tree view**.



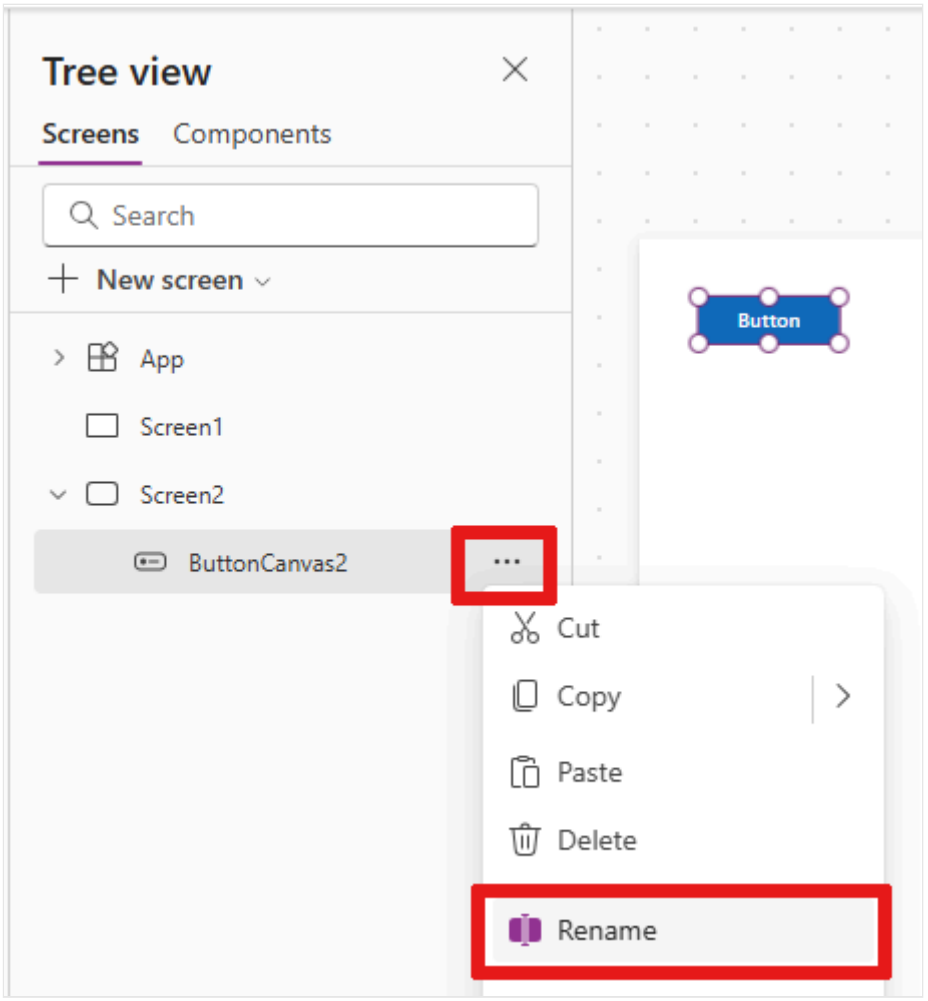
In the screen, a box with six handles surrounds the button by default. These handles surround any control selected and are used to size the control.

5. Select the screen (outside the button) and the box handles disappear. To select the control again, select it directly on the canvas or from the **Tree view** list.

> **Important**
>
> You must always select a control before you can configure it.

Rename a control

1. In the list of controls, hover over the control that you want to rename to reveal the overflow menu (ellipsis).
2. Select the ellipses.
3. Select **Rename**. Add a unique, memorable name to make building your app easier.



Delete a control

You can delete a control either through control in the **Tree view** list or directly from the canvas.

Delete a control from Tree view

1. In the list of controls, hover over the control that you want to delete to reveal the overflow menu (ellipsis).
2. Select the ellipses.
3. Select **Delete**.

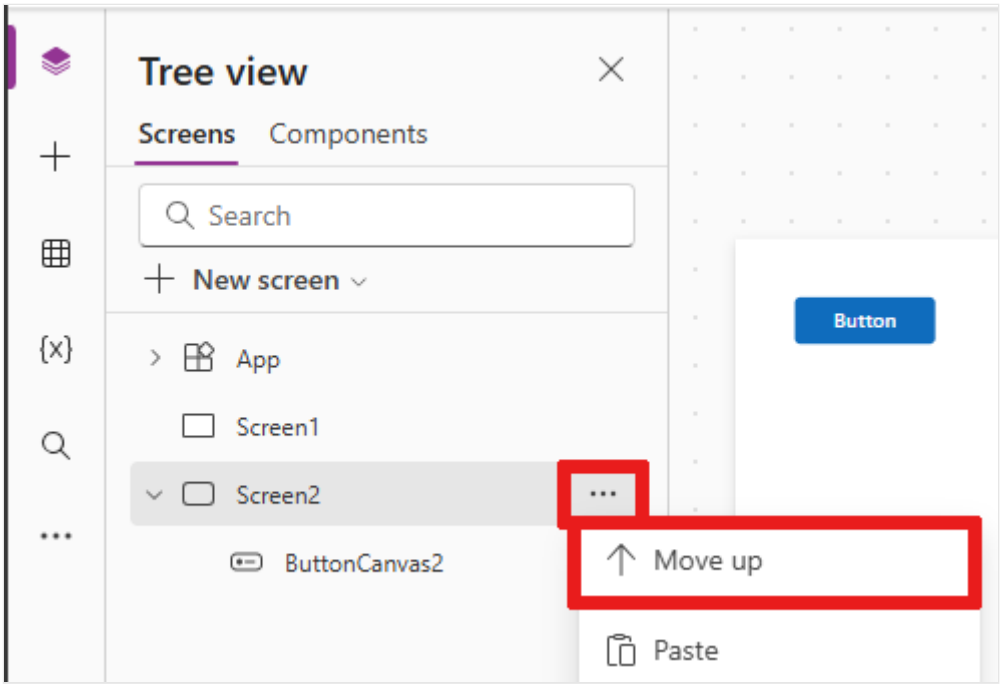
Delete a control from the canvas

Select the control on the canvas, then press the `Delete` key.

Reorder screens

1. In **Tree view**, hover over a screen that you want to move up or down to reveal the overflow menu (ellipses).

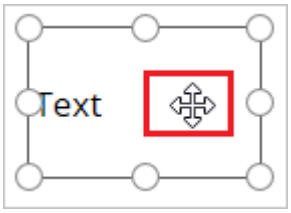
2. Select the ellipsis, then choose **Move up** or **Move down**. If you don't see a **Move down** option, your screen is at the lowest point in the list already.



> [!NOTE]
> When the app is opened, the screen at the top of the list of controls usually appears first. However, you can specify a different screen by setting the OnStart property to a formula that includes the Navigate function.

Move and resize a control

To move a control, select it, hover over its center so that the four-headed arrow appears, and then drag the control to a different location.



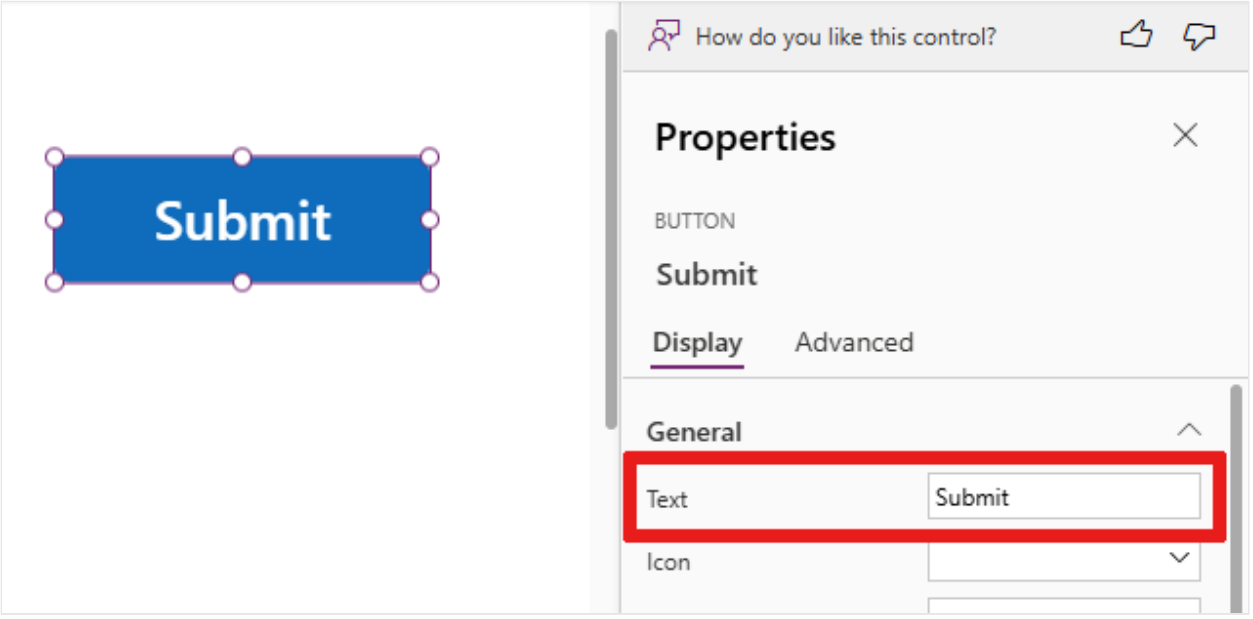
To resize a control, select it, hover over any handle in the selection box so that the two-headed arrow appears, and then drag the handle.

> **Note**
>
> As this topic describes later, you can also move and resize a control by modifying any combination of its X, Y, Height, and Width properties in the formula bar.

Configure a control in the Properties pane

By using the **Properties** pane, specific to the control you select, you can specify a wide variety of options.

For example, if you select a button control, you can replace the value of the text displayed through the control's **Properties** pane.



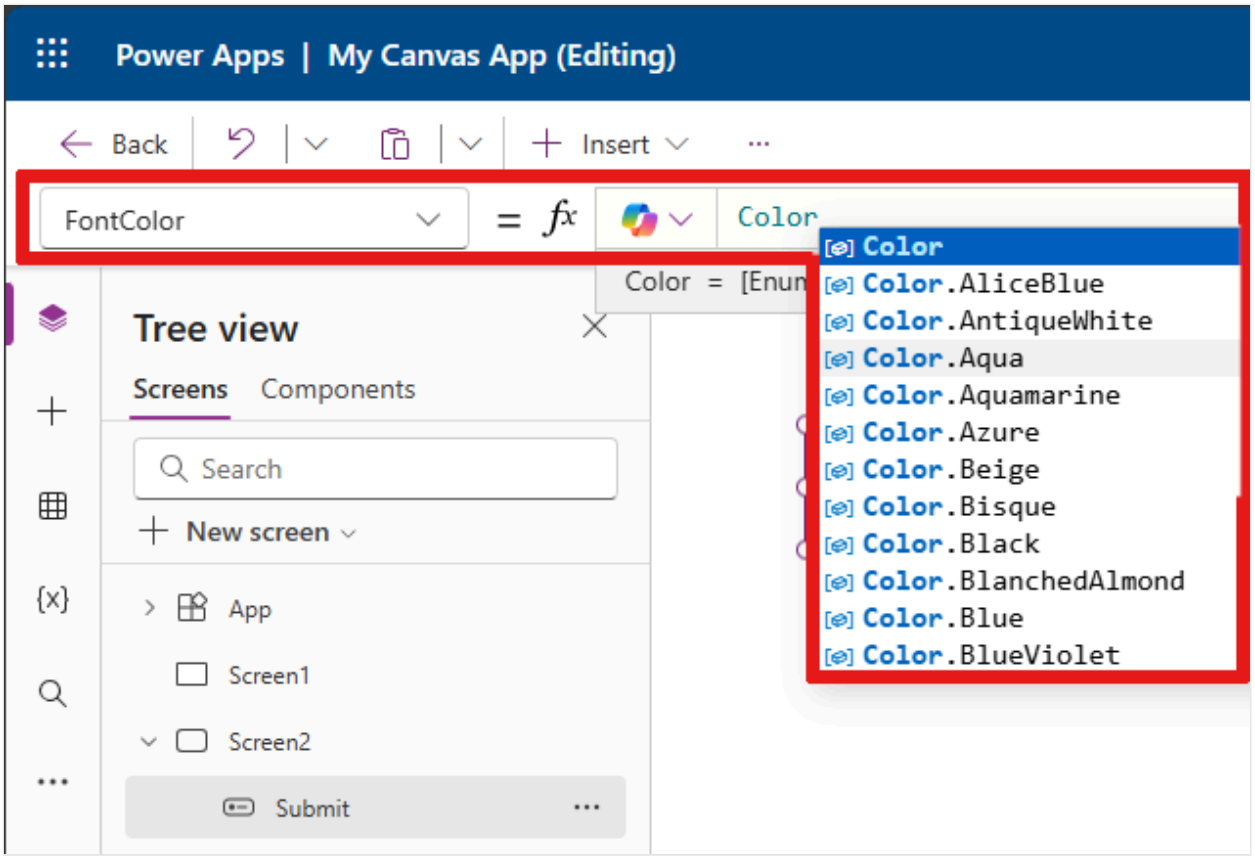
> **Note**
>
> You can alternatively change display text by modifying its Text property in the formula bar.

Configure a control in the formula bar

You can configure a control by selecting a property in the property list and then specifying a value in the formula bar. Autocomplete can be helpful in the formula bar to see values you can use for a control.

Change the font color of a control

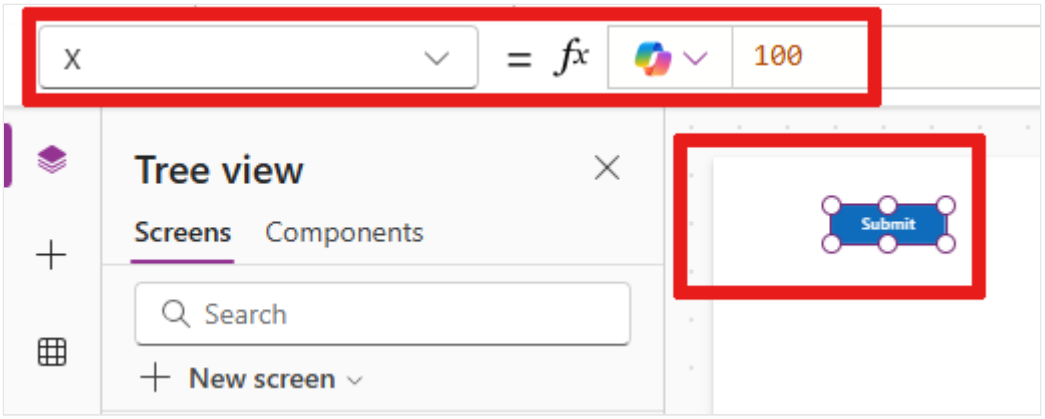
For example, if you want to change the font color for your control's text. You see many color options.



Change the position on the canvas of a control

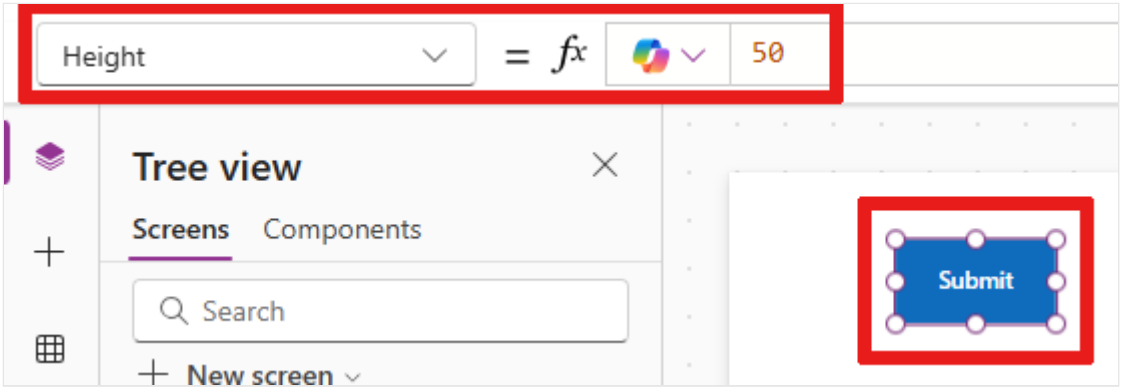
You can set the X and Y coordinates for the position of the control using the formula bar. Setting coordinates in the formula bar gives you greater precision of control placement.

For example, if you select **X** or **Y** in the properties list and specify a number in the formula bar, you see the control move to that coordinate. In this case, the button moves to position 100 on the X axis, assuming the far left side of the canvas is the zero point.



Change the control's size

You can resize a control by selecting **Height** or **Width** in the properties list and then specifying a different number in the formula bar.

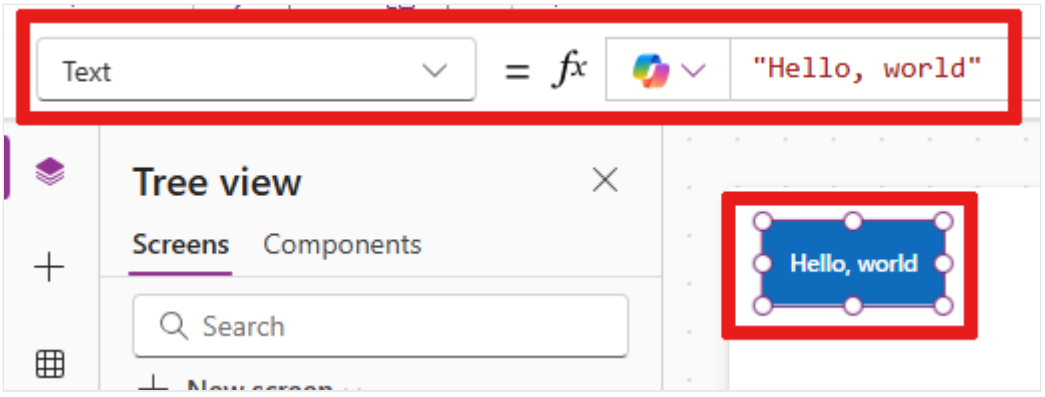


Change the control's display text

You can change a control's display text by selecting **Text** in the properties list and then specifying any combination of a literal string, an expression, or a formula in the formula bar.

Literal string

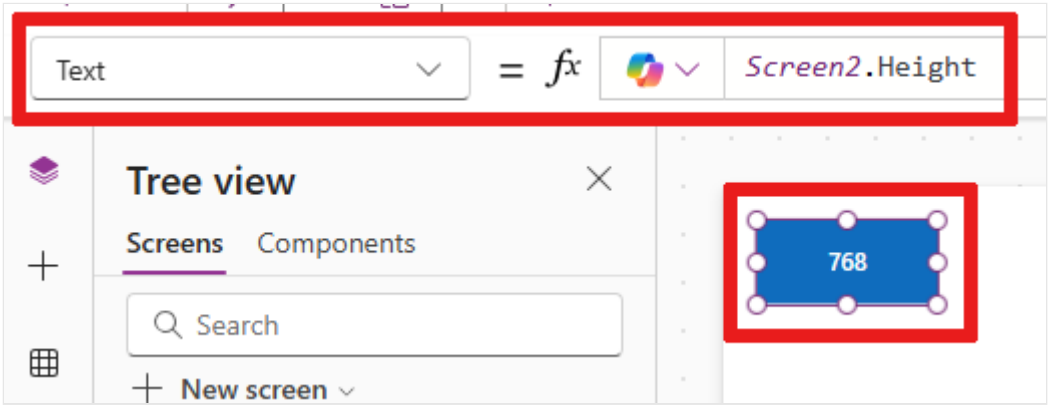
A literal string is surrounded by quotation marks and appears exactly as you type it. **"Hello, world"** is a literal string.



> **Note**
>
> When you add text that is longer than the width of your control, the control doesn't change its width to accomodate the text. You must manually change the control's size to fit the text.

Expression

An expression is often based on a property of another control. **Screen2.Height** is an expression that shows the height of **Screen2** where the display text is shown for a button control.

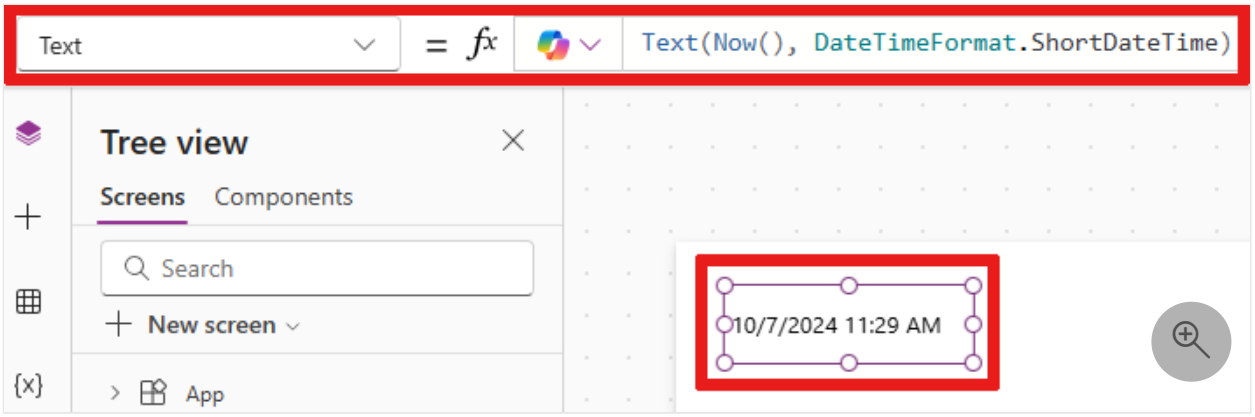


Using an expression, for example, you can set a background image or icon as the fill for your button.

Formula

A formula includes one or more functions. The **Now** function returns the current date and time in your local time zone, and the **Text** function formats values such as dates, times, and currency.

For example, you can display the date and time in a **Label**:



Formulas are usually much more complex than this example so that they can update data, sort it, filter it, and perform other operations. For more information, see the formula reference.

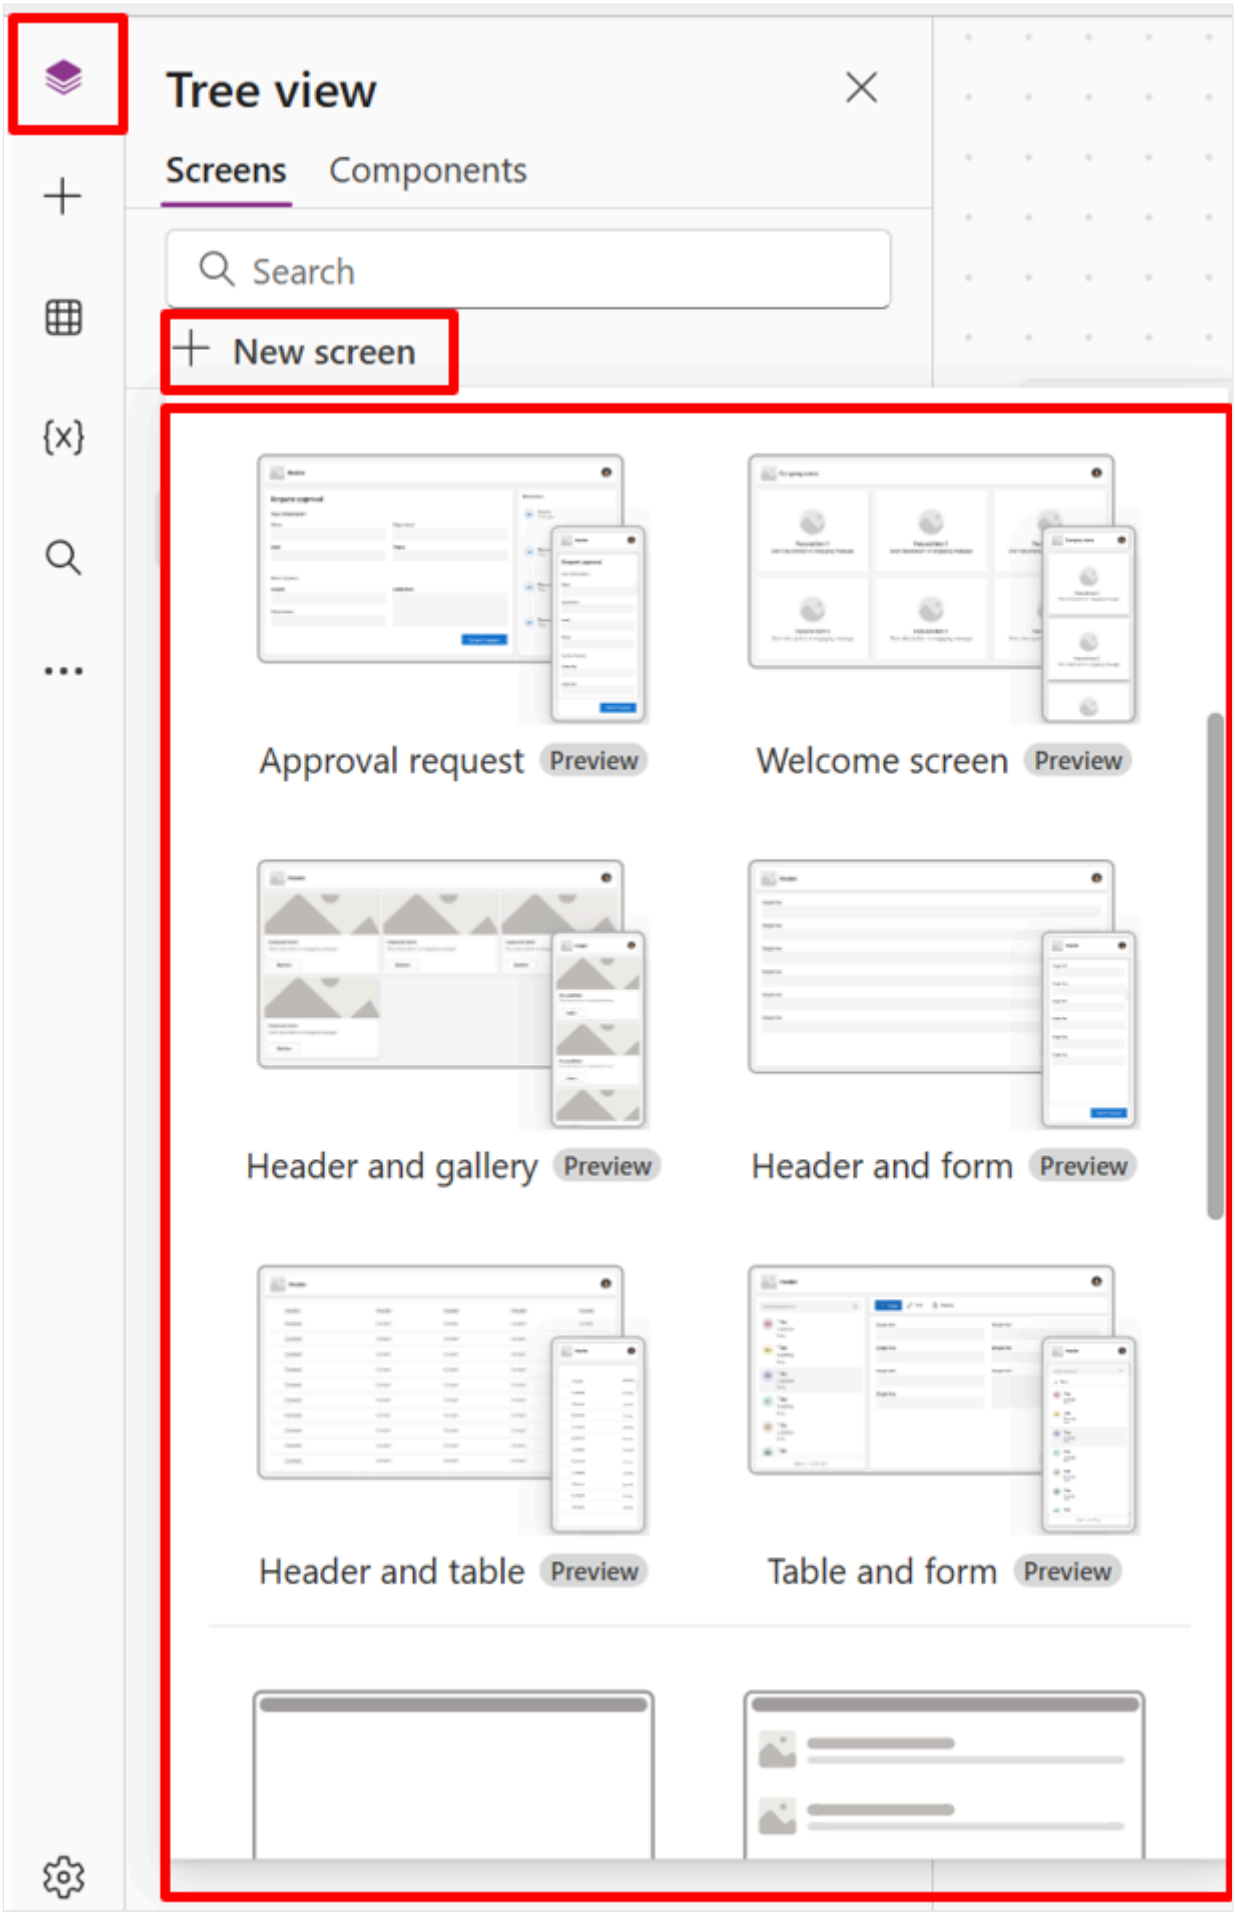
Provide product feedback

Add and navigate screens in canvas apps

Create modern, responsive apps by adding prebuilt screens for common app scenarios. The screens feature responsive containers and modern controls that adapt to different screen sizes. You can also add custom screens with different layouts and controls.

The following new prebuilt screens are available:

- Approval request
- Welcome screen
- Header and gallery
- Header and form
- Header and table



Add a new screen

1. Sign in to Power Apps.
2. Create a canvas app or open one for editing.
3. On the command bar, select **New screen**, and then select a screen layout.
4. Preview the app to determine how it looks on different devices. For more information, see Preview an app.

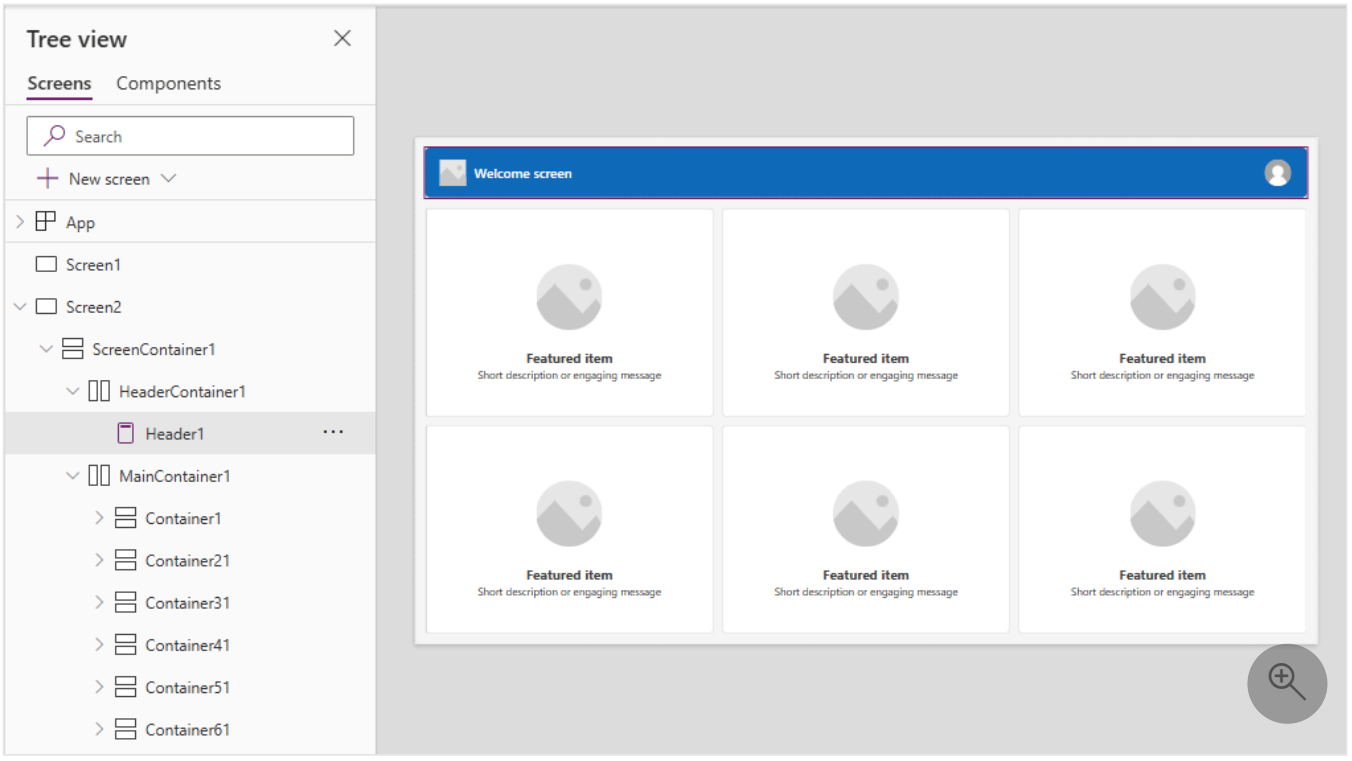
> **Tip**
>
> To make the app adapt to the size of the device display it's running on, turn off the **Scale to fit** option.

Welcome screen

The **Welcome screen** works well as the first screen of an app. You can customize each tile with an image, a title, and a description. Add or remove tiles in the main container to change the number of tiles. Use the tiles to guide users to other parts of the app.

The **Welcome screen** template includes the following controls:

- Screen container
  - Header container
    - Header
  - Main container
    - Container
      - Image container
        - Image
      - Title container
        - Feature item button
        - Description text

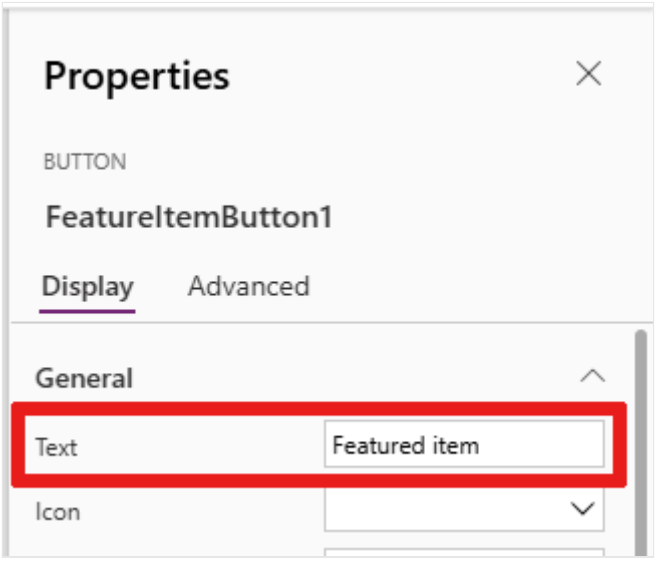


Add and customize the Welcome screen

1. Select **New screen** > **Welcome screen**.

2. To change the image of a tile, select it and then select **Edit**.

3. Select the **Feature Item** button control and add your own text in the Properties pane.



4. Select the **Short description or engaging message** text and add your own.

5. Add and remove tiles if needed.

    - To add tiles in the tree view, copy and paste a **Container** item.

    - To remove a tile in the tree view, right-click a **Container**, and then select **Delete**.

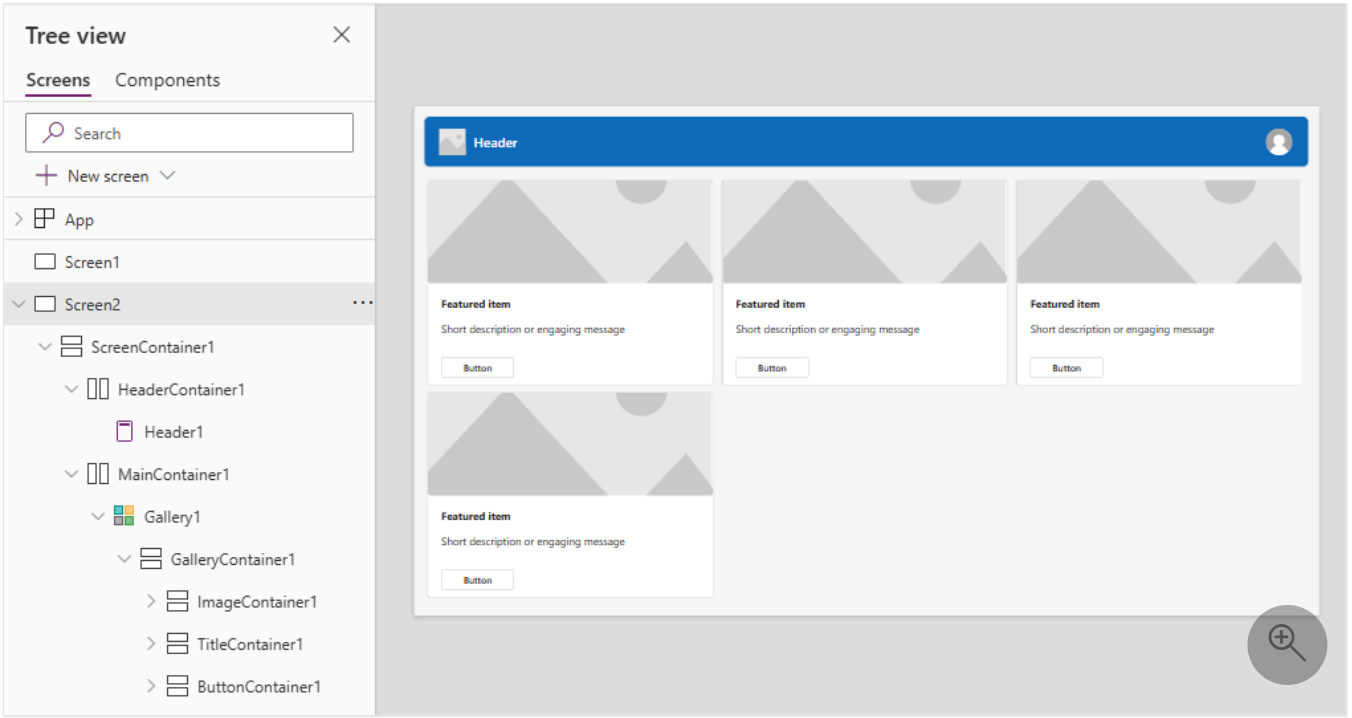
Header and gallery screen

Use the **Header and gallery** screen to show a range of product or service information, like a product catalog. When you connect a gallery control to a data source, a catalog is automatically created with little customization required.

The gallery control in the **Header and gallery** screen is a classic control. When the modern gallery control is released, the **Header and gallery** screen uses it. For more information, see Overview of modern controls and themes in canvas apps.

The **Header and gallery** screen has the following template for controls:

- Screen container
  - Header container
    - Header
  - Main container
    - Gallery
      - Gallery container
        - Image container
          - Image
        - Title container
          - Title text
          - Description text
        - Button container
          - Button



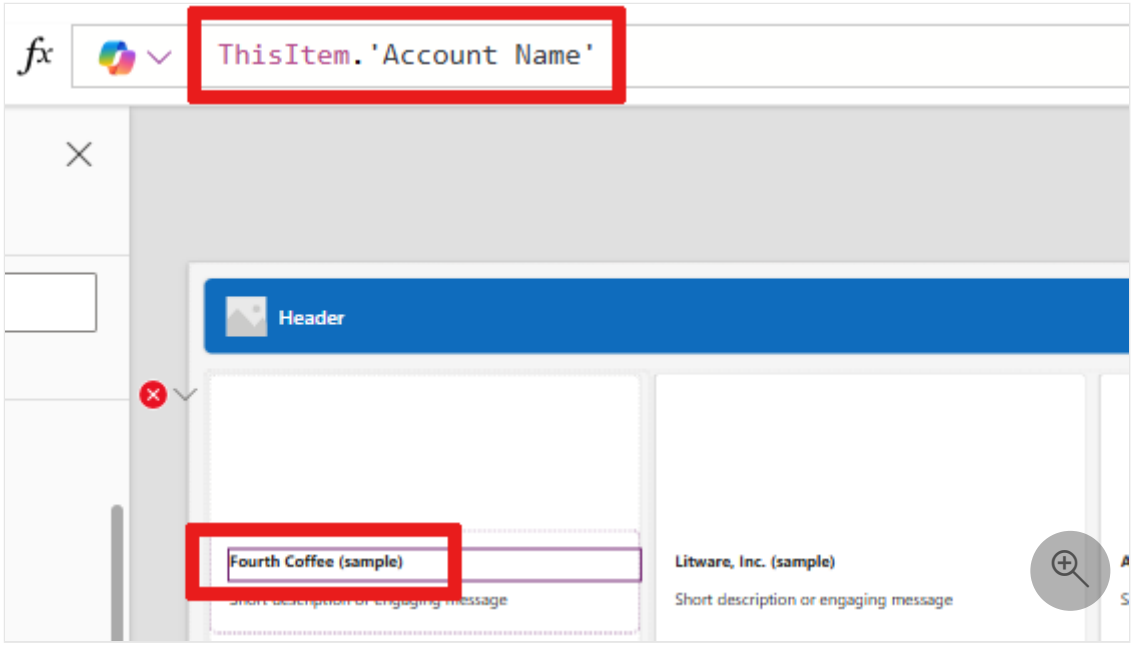
Add and customize the header and gallery screen

1. Select **New Screen** > **Header and gallery**.

2. In the tree view, select **Gallery** and connect it to a data source such as Dataverse.

3. Select specific controls inside the gallery, such as the image, title text, and text description. In the control's properties, use the *ThisItem* syntax to set the desired image, title text, and description.

   For example, to add the **Account name** to the title text control, find it by typing `ThisItem` in the formula bar to see a list of available items to add from your data set.



Approval request screen

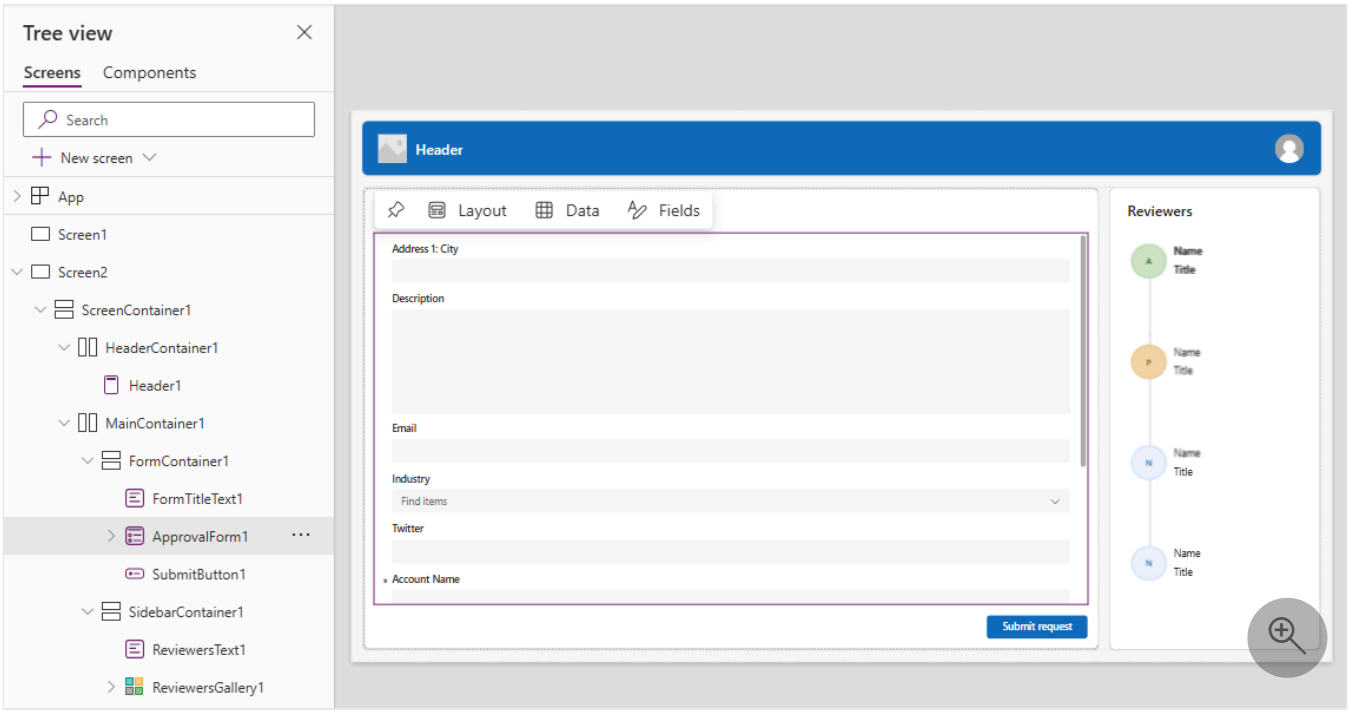
The **Approval request** screen has a header, a form with a submit button, and a gallery with predefined stages. The **Approval request** screen is useful for scenarios where actions are triggered by form submissions, such as submitting an approval request or displaying a workflow process for a business.

> **Tip**
>
> When you add an approval request screen, connect it to a data source. The data source determines the field names in the request form.

The **Approval request** screen has the following template for controls:

- Screen container

- Header container
  - Header
- Main container
  - Form container
    - Form title text
    - Approval form
    - Submit button
  - Sidebar container
    - Reviewers text
    - Reviewers gallery



Add and customize the Approval request screen

1. Select **New Screen** > **Approval request**.

2. In the tree view on **ApprovalForm**, connect to a data source such as Dataverse.

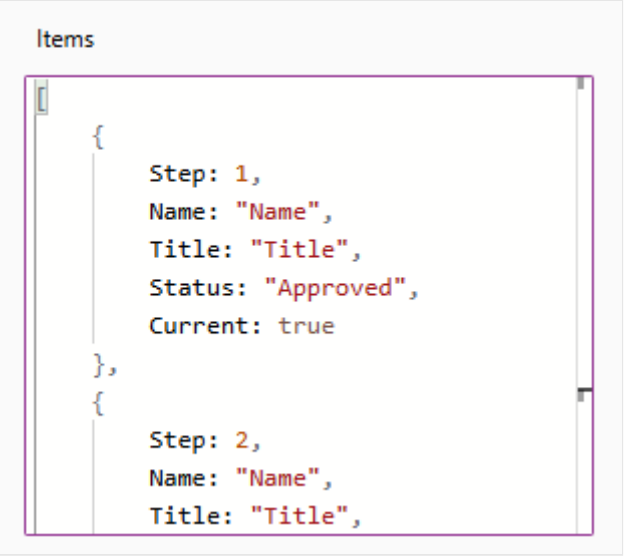
3. Choose a data source.

4. To view the details of the approval stages, select **ReviewersGallery** under the **SidebarContainer** node in the tree view. Then, in the properties pane, select the **Advanced** tab and go to **Items**.

   The approval stages have the following details:

   - **Name**: Name of the stage or approver
   - **Title**: Subtitle of the stage or approver
   - **Status**: Stage status

- **Current**: Whether this stage is the current stage of the approval request



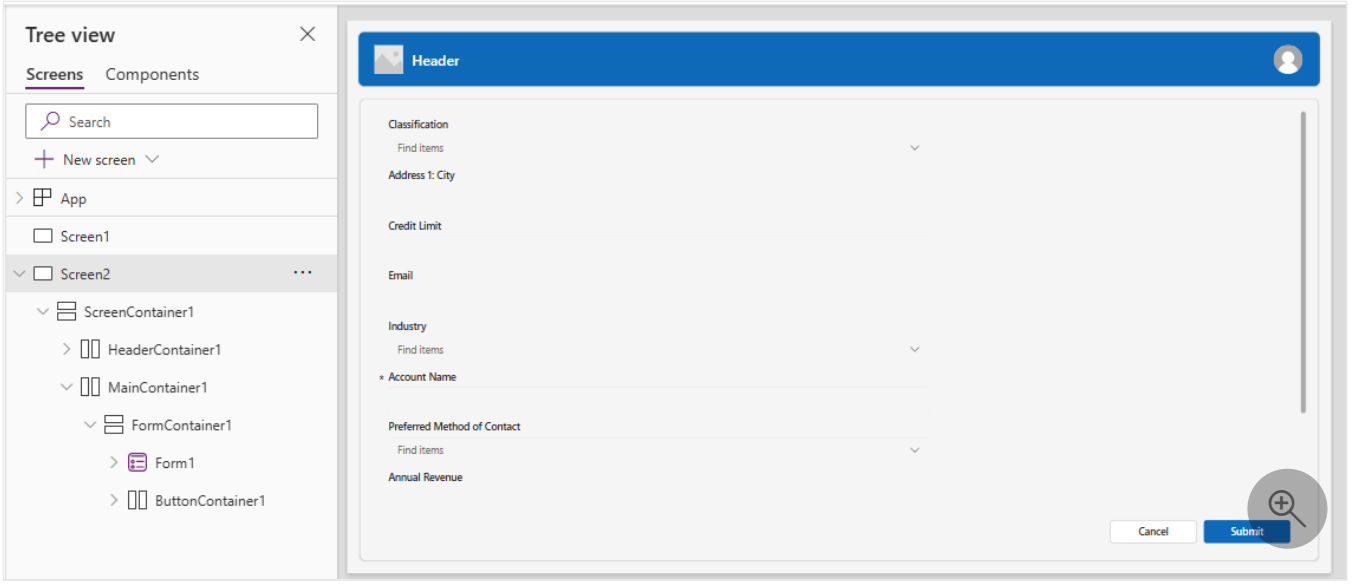
To notify the approver, add a Power Automate approval workflow in the button. For more information, see Create and test an approval workflow with Power Automate.

Header and form

The **Header and form** screen has a header, a form, and two buttons to submit the form or cancel form submission. This screen is great for using a full-screen form.

The **Header and form** screen has the following template for controls:

- Screen container
  - Header container
    - Header
  - Main container
    - Form container
      - Form
    - Button container
      - Cancel button
      - Submit button



Add and customize the Header and form screen

1. Select **New Screen** > **Header and form**.
2. In the tree view, you see **Form** selected and a prompt appears for you to connect the form to a data source.
3. Choose a data source.
4. Optionally, to ensure the best screen responsiveness, select each data card on the form and set its **Width Fit** property to **On** in the **Display** tab of the **Properties** pane.

Header and table

The **Header and table** screen has two controls: a header control and a table control. This template is great for showing a detailed data table on a screen.

The **Header and table** screen has the following controls:

- Header container
  - Header
- Main container
  - Table

Add and customize the Header and table screen

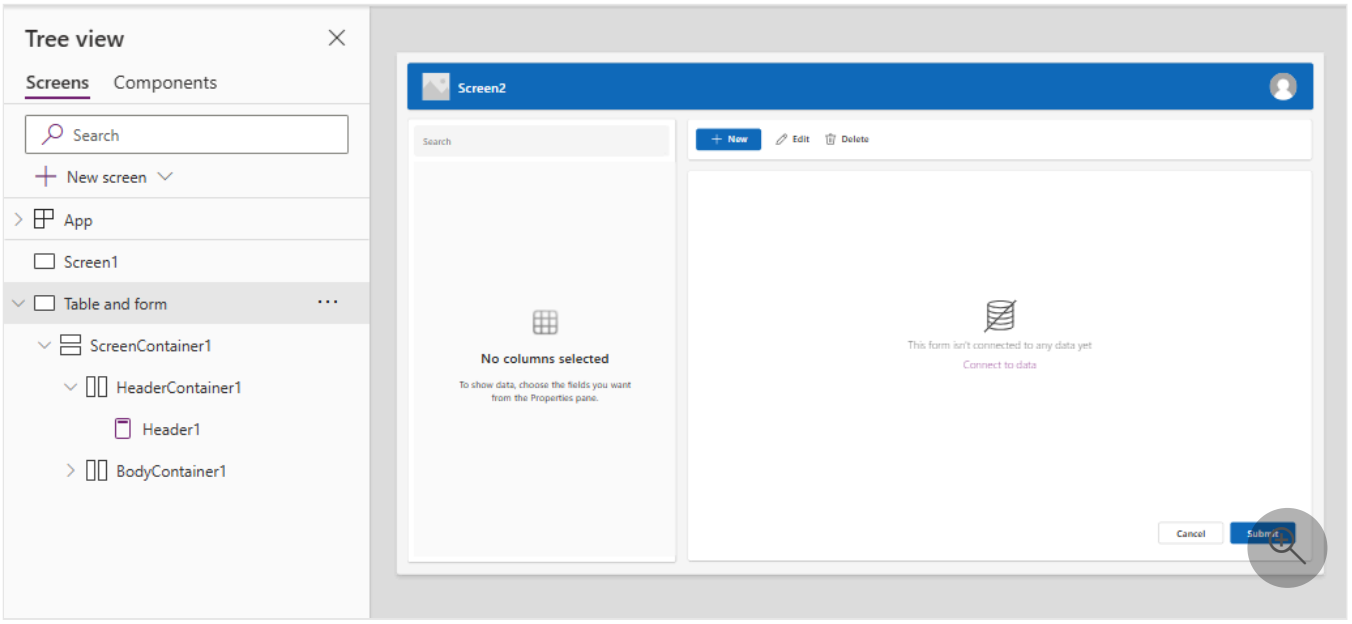
1. Select **New Screen** > **Header and table**.
2. In the tree view, select **Table** and connect it to a data source.

Table and form

The Table and form screen contains two main controls: the modern table control and the modern form control. This template has built-in Power Fx formulas to make data connection and customization easy. This template is ideal for selecting and editing a record by using a form.

The Table and form screen contains the following controls:

- Screen container
  - Header container
    - Header control
  - Body container
    - Text input (Search)
    - Table control
    - Form control
    - Button
      - New
      - Edit
      - Delete
      - Submit
      - Cancel



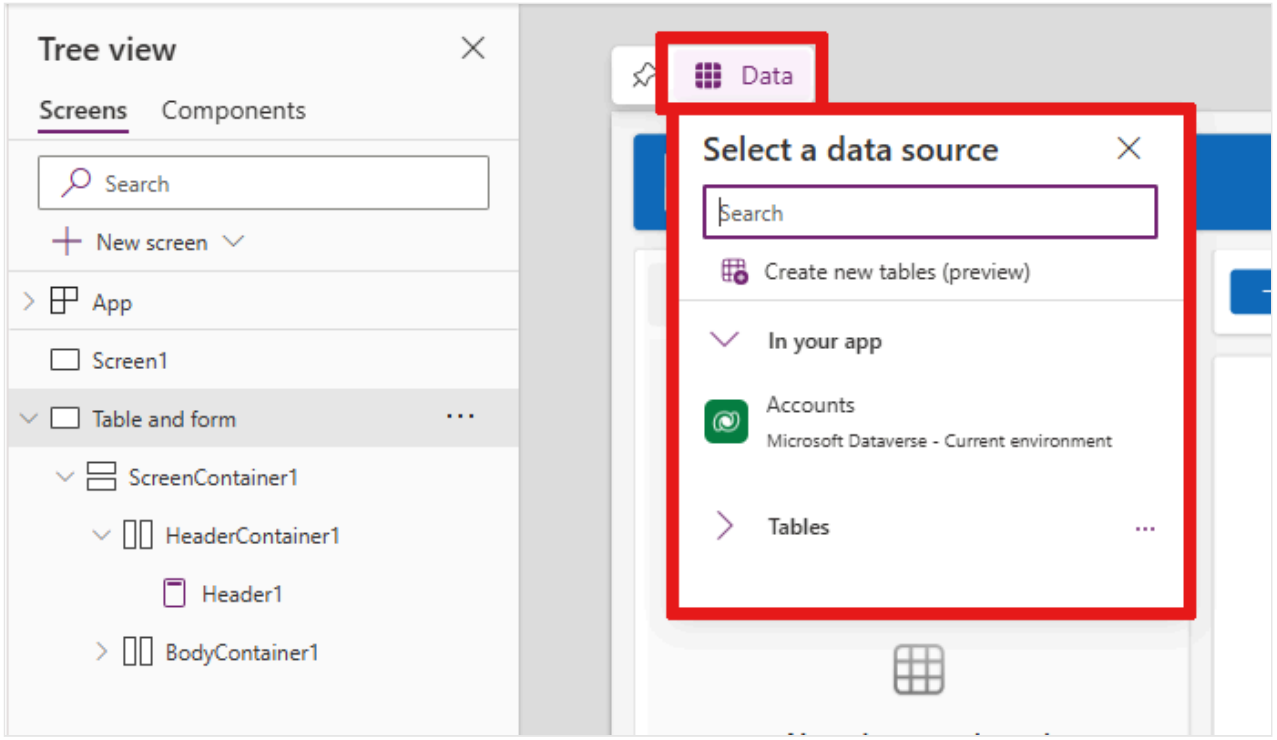
Add and customize Table and form screen

In Power Apps Studio:

1. Select **New Screen** > **Table and form**.

2. Select **Data** in the inline action bar.

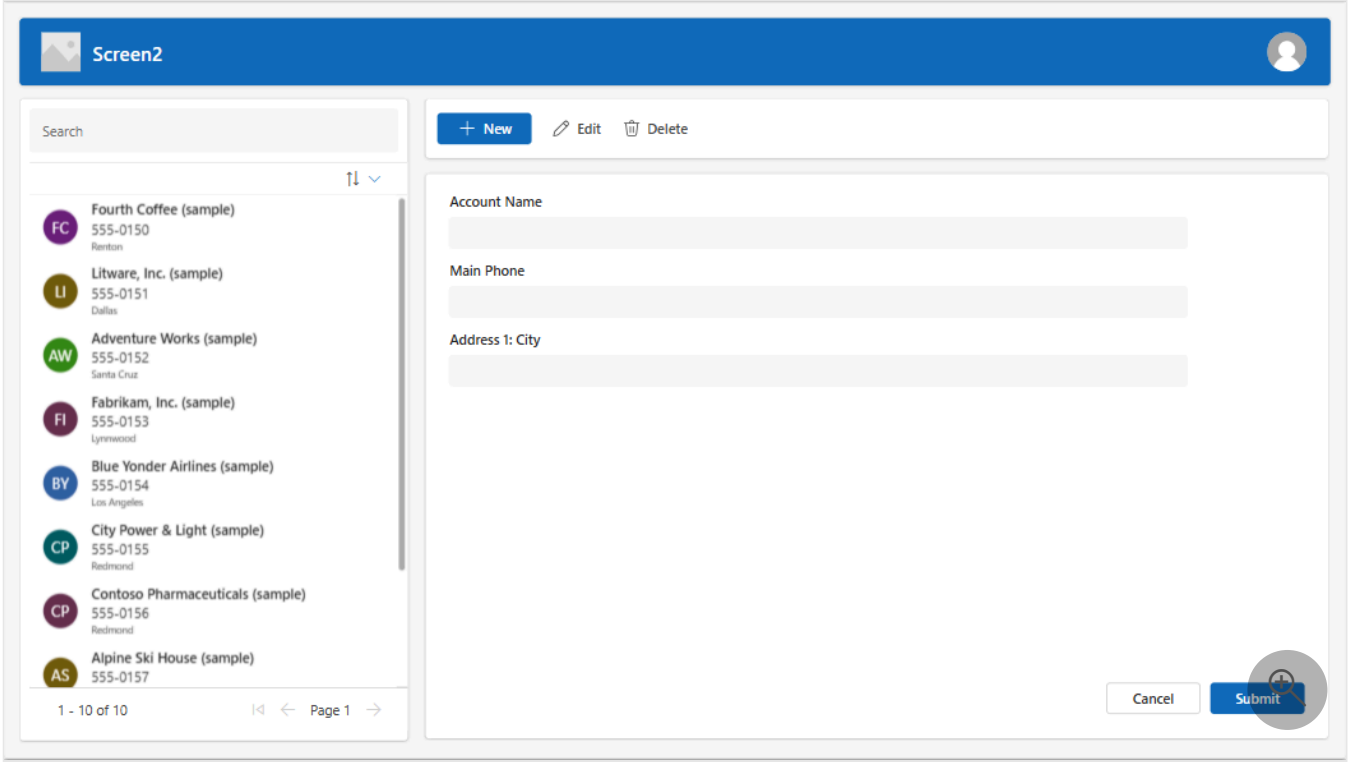
3. Select the data source you want.



When you connect, the table and form controls both connect to the data source.

You can select a record in the table control, and the form shows the details of the selected record.

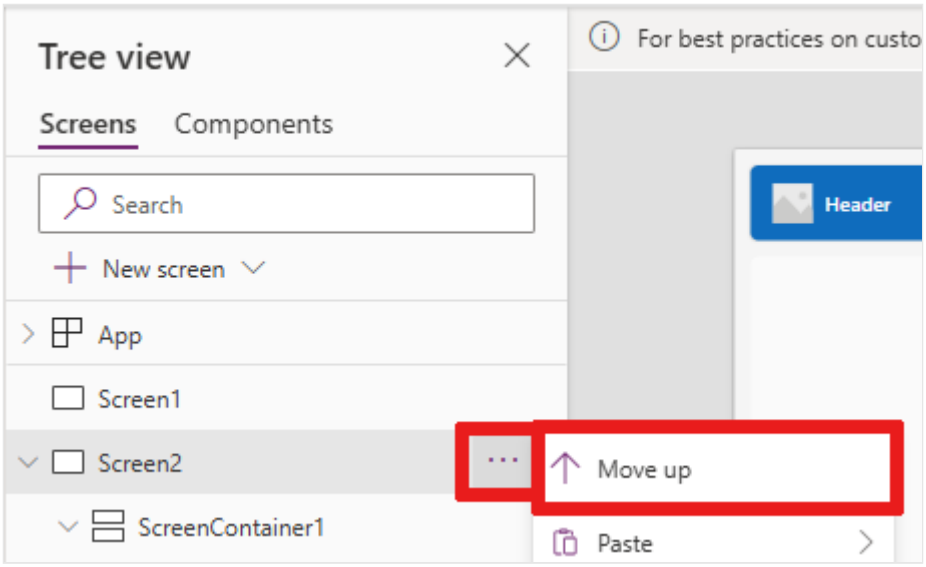
All buttons in this template have prebuilt Power Fx, so you don't need to customize them. When you connect the screen to the selected data source, the screen becomes fully functional.



Reorder screens

When your app has more than one screen, you can change their order in the tree view.

Select the overflow menu of a screen that you want to reorder, and then select **Move up** or **Move down**.



Use the StartScreen property to set the screen that displays first.

Add navigation

When your app has more than one screen, add navigation so your users can move between them.

1. Select the screen. Select **Insert**. In the search box, type **Next arrow** and then select it.

2. Move the arrow to where you want it to appear on the screen.

3. Select the arrow. Set the OnSelect property to the **Navigate** function. For example, use **Navigate(*Target*, Fade)**.

   Replace *Target* with the name of the screen where you want to navigate.

   
   In this example, when a user selects the arrow, the target screen fades in.

4. On the *Target* screen, add a **Back arrow** icon the same way. Set its OnSelect property, for example, `Navigate(Target, ScreenTransition.Fade)`.

   Replace *Target* with the name of the screen where you want to return.

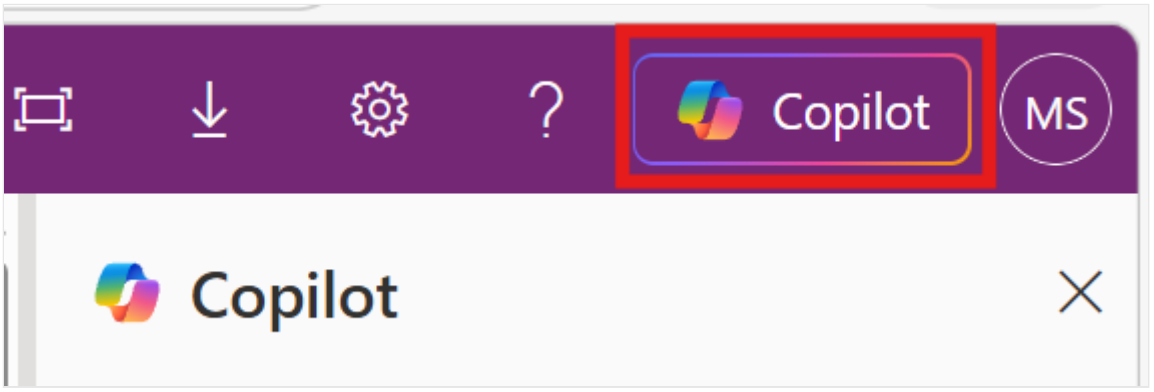
Add Microsoft 365 Copilot for app users in canvas apps (preview)

[This article is prerelease documentation and is subject to change.]

Microsoft 365 Copilot makes it easier for users to work with canvas apps by offering AI-powered insights through natural language conversations. By using this feature, users can quickly find information, navigate apps more easily, and get help to boost their productivity. App makers can enable Microsoft 365 Copilot to give users access to conversational AI that understands app data and provides helpful, contextual answers. Users can ask questions about their Microsoft Dataverse table or SharePoint list data in plain language and receive immediate, relevant responses.

This article shows you how to enable and configure Microsoft 365 Copilot for your canvas apps, both at the environment level and for individual apps.

When enabled, users can open Microsoft 365 Copilot in their canvas app by selecting **Copilot** on the upper-right corner. For more information, see Use Microsoft 365 Copilot in canvas apps.



Important

- This feature is in preview.
- Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use. They're available before an official release so that customers can get early access and provide feedback.
- This feature is in the process of rolling out and might not be available in your region yet.

Prerequisites

To use Microsoft 365 Copilot in canvas apps, make sure the following prerequisites are met:

- You must have access to an early release cycle environment to use this feature.
- Your tenant must be set to allow **Dataverse data available in Microsoft 365 Copilot**. For more information, see Enable Microsoft 365 admin center Copilot Dataverse settings.
- Dataverse Search must be set to **Default** or **On** for the environment. For more information, see Understand what this means for generative AI experiences.
- To use the Microsoft 365 Copilot feature in your app, users must have a Microsoft 365 Copilot license.

> **Note**
>
> - Microsoft 365 Copilot for canvas apps with Dataverse relies on Dataverse Search indexes. Enabling this feature might increase your environment's Dataverse capacity consumption. For more information, see What actions can makers or admins take to manage Dataverse Search efficiently.
> - Sufficient Dataverse database capacity must be available to support indexing, semantic search, and Copilot operations. For more information, see Capacity page details.

Enable Microsoft 365 Copilot for your environment

To manage Microsoft 365 Copilot for canvas apps, start by learning how to manage Microsoft 365 Copilot.

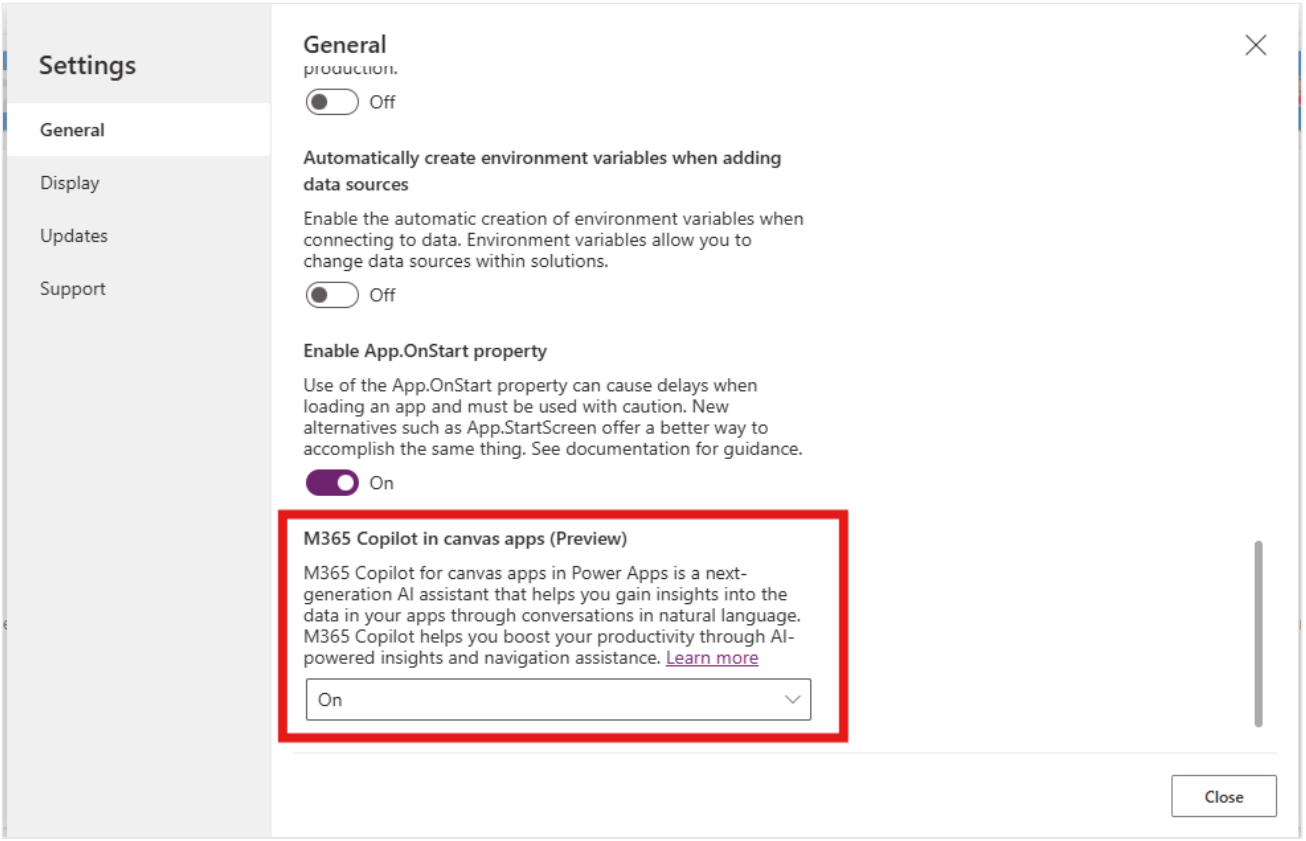
Power Platform administrators can set up and configure the Microsoft 365 Copilot feature for users in their environment.

1. Sign in to the Power Platform admin center.
2. In the navigation pane, go to **Copilot** > **Settings**. Under **Power Apps**, expand **Chat Agent** and choose **M365 Copilot**.
3. Select an environment group or an environment name, and then select **Edit Setting**.
4. Select **On** and then select **Save** to enable Microsoft 365 Copilot for your canvas apps in the selected environment group or environment.

Enable Microsoft 365 Copilot in a canvas app

Makers can enable or disable Microsoft 365 Copilot for a specific canvas app.

1. Sign in to Power Apps.
2. Open a canvas app for editing.
3. Select **Settings** in the command bar.
4. On the left, select **General**.
5. To enable Microsoft 365 Copilot, set **M365 Copilot in canvas apps (Preview)** to **On**. To disable it, set the option to **Off**.



6. Select **Save** and then publish the app for the changes to take effect.

Microsoft 365 Copilot vs. Copilot chat

Microsoft 365 Copilot is replacing Copilot chat in canvas apps.

Known limitations

- Agents you author can't yet use in-app user context to optimize their responses.

- M365 Copilot in canvas apps supports apps that use either SharePoint or Dataverse as a data source but not both within the same app.
- During the initial preview phase, for SharePoint, only applications containing a single SharePoint list will return answers to questions.
- If your canvas app connects to a SharePoint list through an environment variable, Microsoft 365 Copilot won't reference data from that SharePoint list.
- Microsoft 365 Copilot for canvas apps allows users to view data by using read-only operations. This capability means that users can only view data that matches their queries and can't make any changes. To make changes, customization with an agent is required.
- Microsoft 365 Copilot for canvas apps isn't available in the Power Apps mobile app.
- As this feature is being gradually deployed, certain settings in the Power Platform Admin Center might not be accessible yet, depending on the geographic location of your tenant.

Related information

- Customize Microsoft 365 Copilot with an agent
- Use Microsoft 365 Copilot in canvas apps

Last updated on 04/22/2026

Customize Microsoft 365 Copilot with an agent

Microsoft 365 Copilot in Power Apps enables users to interact with custom agents that extend Copilot's capabilities beyond standard functionality. By customizing agents, you can create tailored experiences that address your organization's specific business processes and data requirements. For more information, see Use agents in Microsoft 365 Copilot

This article describes the different types of agents you can build and integrate with Microsoft 365 Copilot in Power Apps. You'll learn about the capabilities and use cases for each agent type, helping you choose the right approach for your customization needs.

You can customize agents in several ways to fit your organization's needs.

Expand table

Agent Type	Description	Common use cases
Declarative Agent	Configured using low-code tools and templates, allowing quick setup for common scenarios within Microsoft 365 Copilot.	Automating routine tasks, answering FAQs, and providing guided workflows.
Custom Engine Agent	Developed with custom logic and integrations, offering advanced capabilities tailored to specific business needs.	Complex business processes, custom data integrations, and specialized automation.
Copilot Studio Agent	Built and managed in Microsoft Copilot Studio, enabling integration with Teams and Microsoft 365 for conversational experiences.	Interactive chatbots, team collaboration, and personalized support within Microsoft 365 apps.

Use the following information to find the best solution for your organization:

- Microsoft 365 Copilot Agents Overview documentation provides guidance on how to choose what type of agent to build.
- Create agents as Declarative Agents for Microsoft 365 Copilot or as Custom engine agents for Microsoft 365.
- Use Microsoft Copilot Studio to connect and configure an agent for Teams and Microsoft 365, making it available in Microsoft 365 Copilot.
- Review guidance on how to Choose between Microsoft 365 Copilot and Copilot Studio to build your agent.

Limitation

- Agents you author can't yet use in-app user context to optimize their responses.

Add a Copilot control to a canvas app (preview)

Summarize this article for me

[This article is prerelease documentation and is subject to change.]

The Copilot control is an AI assistant that you can add to your canvas apps. By using Copilot, app users can get insights about the data in your app through natural language conversations with an AI-powered copilot. Makers can add the control to any canvas app and choose which data provide answers.

> **Important**
>
> Starting February 2, 2026, you can't add the Copilot control to new canvas apps. Existing apps with this control will remain functional for a limited time but will eventually no longer be supported. Microsoft 365 Copilot Chat in canvas apps is the new the recommended solution for natural language interactions in canvas apps. To ensure a smooth transition and prevent any disruption, we recommend that you migrate to Microsoft 365 Copilot chat as soon as it becomes available in your environment.

> **Note**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is powered by Azure OpenAI Service.

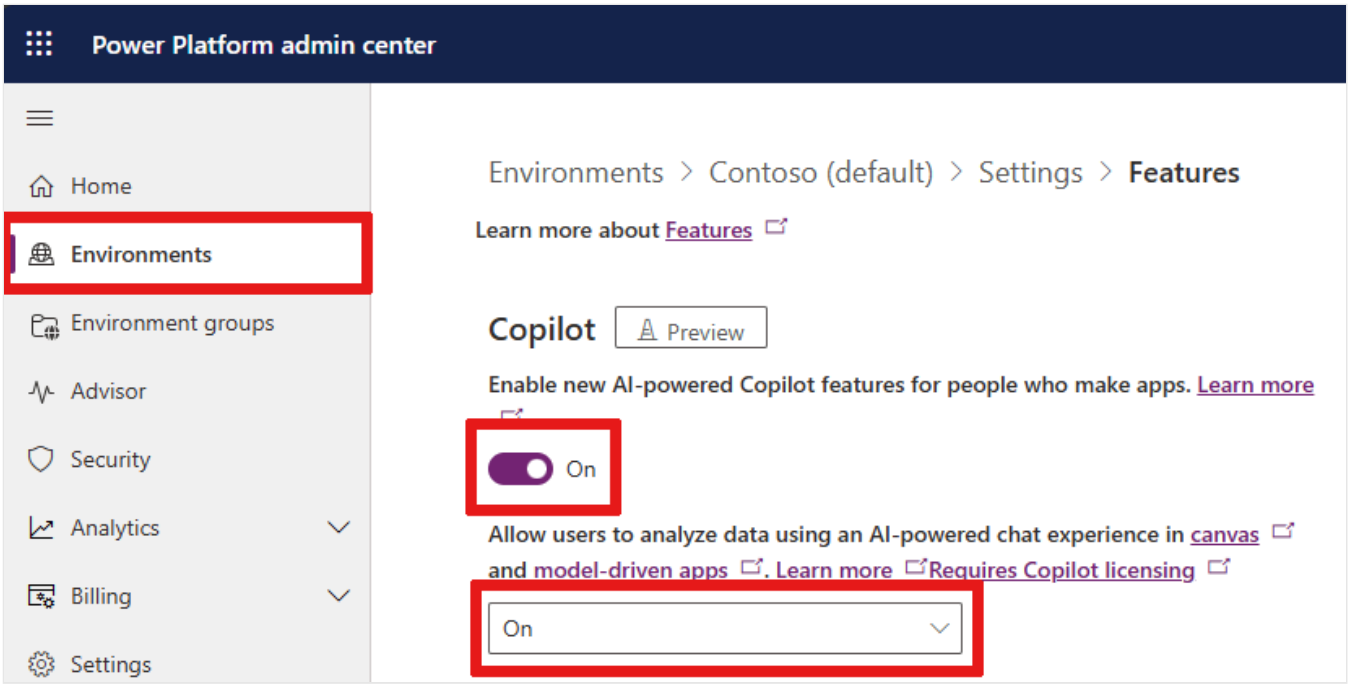
Prerequisites

Ensure you meet the prerequisites and region availability in Copilot in Power Apps overview (preview).

Copilot doesn't work in environments that use a customer-managed key or Customer Lockbox.

Set up Copilot for your environment

To let app users use the Copilot chat experience in a canvas app, a Power Platform admin needs to enable **Allow users to analyze data using an AI-powered chat experience in canvas and model-driven apps** in the Power Platform admin center. Learn more in Manage feature settings.



Set up Copilot for your canvas app

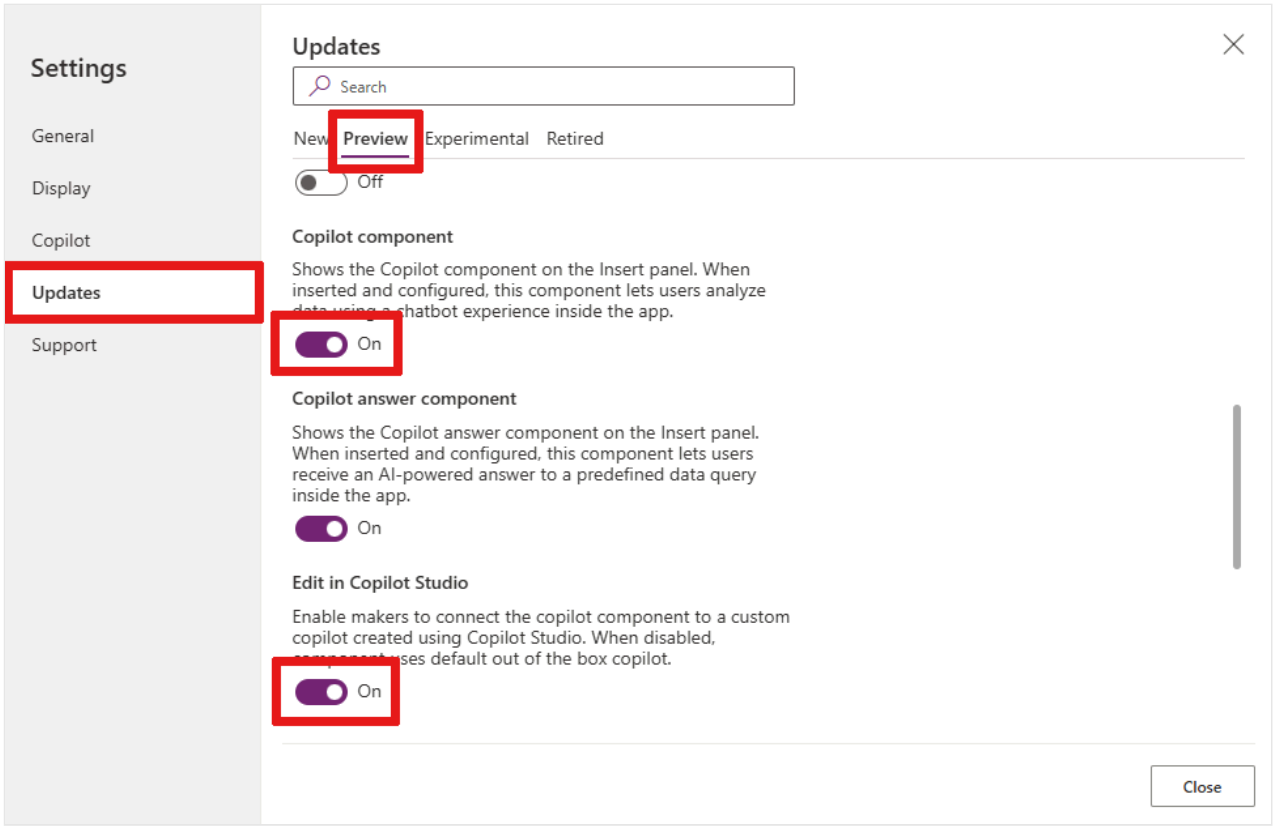
To add a Copilot control to your canvas app, turn on **Copilot component** and **Edit in Copilot Studio** in the app settings in Power Apps.

Copilot component: Turns on the Copilot feature in your canvas app so you can add the Copilot control and connect it to a copilot.

Edit in Copilot Studio: Lets you customize the copilot using Copilot Studio. If you turn off this option, only the default copilot is available.

1. Open your canvas app for editing in Power Apps Studio. On the command bar, select **Settings** > **Updates**.

2. On the **Preview** tab, turn on the **Copilot component** and **Edit in Copilot Studio** settings.

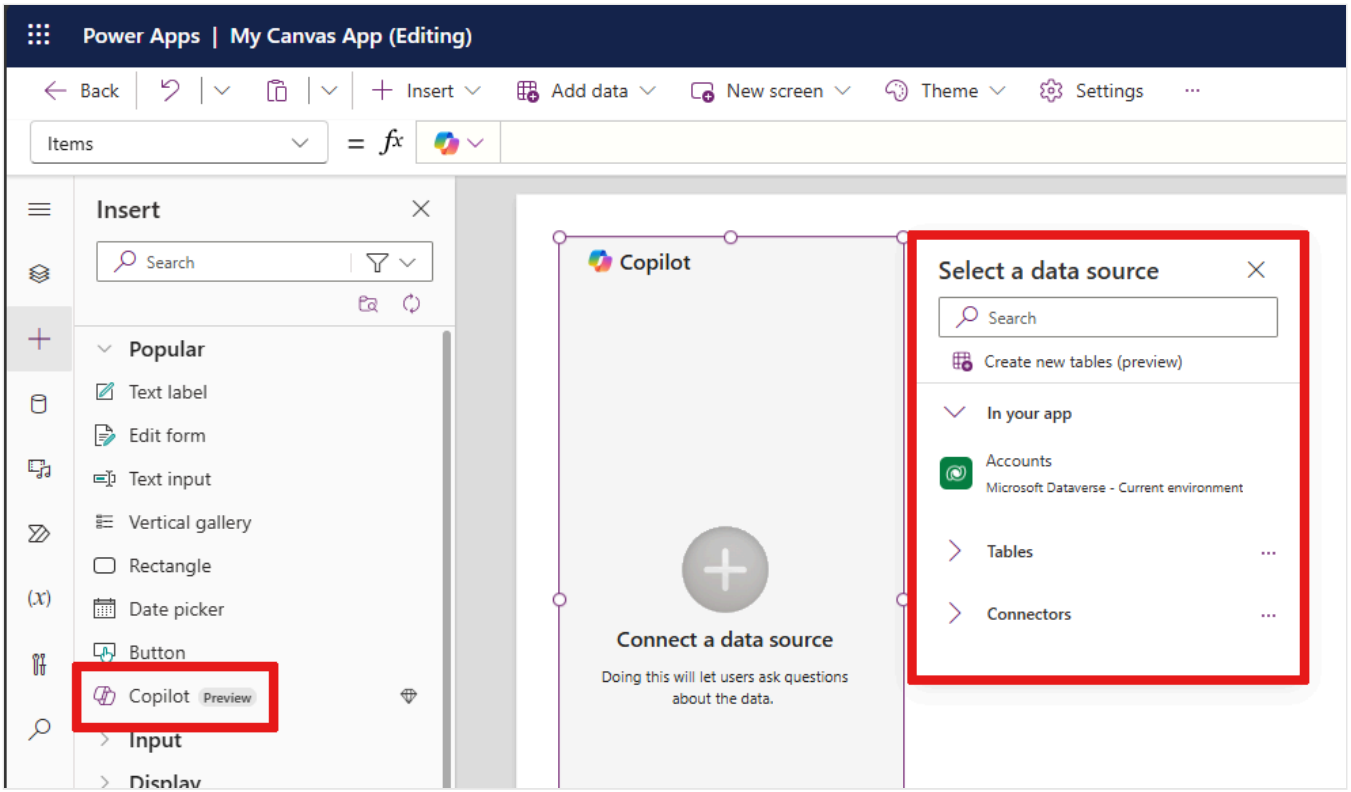


Add the Copilot control to your canvas app

With your canvas app open for editing, and all settings configured:

1. In the app authoring menu, select **Insert**, and then select **Copilot (preview)**.

2. When prompted to add a data source to Copilot, select a Dataverse table as the data source.



> **Note**
>
> The Copilot control only supports Dataverse tables for the data source.

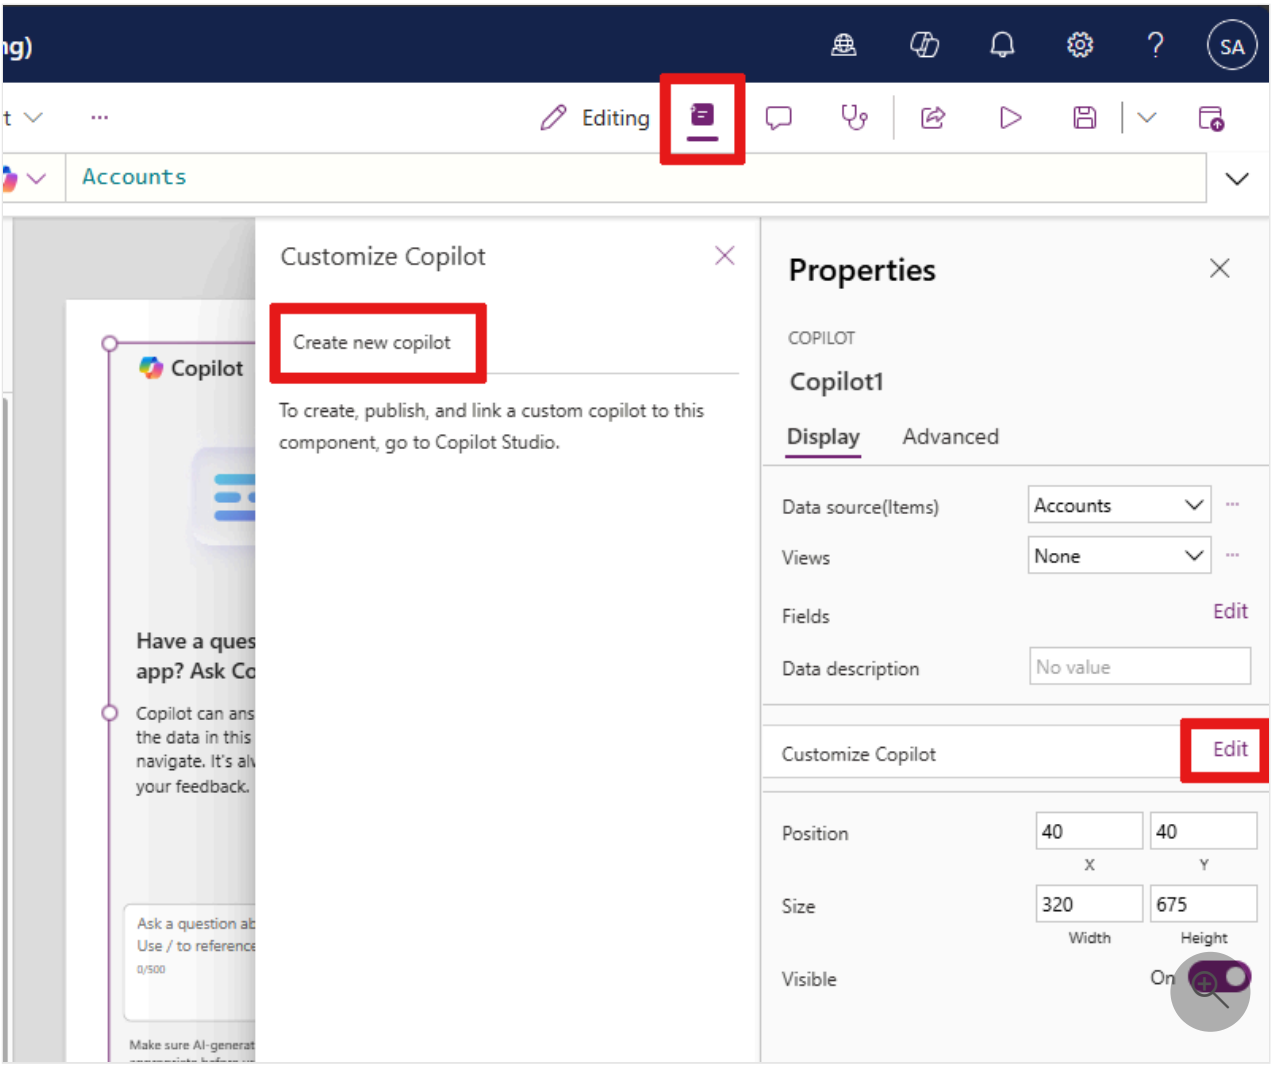
Customize the copilot by using Copilot Studio

Copilot Studio is an app that you use to create and edit copilots for your apps. Define your copilot's articles, actions, and other features. For example, make your copilot respond to specific questions about your app's data or perform actions like opening a screen or sending an email.

Customize your newly connected copilot in Power Apps through the properties menu.

1. Select the Copilot control on your canvas. Select **Edit** next to the **Customize copilot** field in **Properties**.

2. If you don't have a copilot, select **Create new copilot** in the **Customize Copilot** pane. The Copilot control in Power Apps Studio doesn't support enabling an existing Copilot from Copilot Studio.



Copilot Studio opens in a new tab. Any changes you make in Copilot Studio appear in your connected copilot in your canvas app.

Learn more in Quickstart: Create and deploy a copilot.

Collect feedback from app users

Makers and app users provide feedback on copilot responses by selecting the **Like** (thumbs up) or **Dislike** (thumbs down) button for each response. Enter detailed feedback in the text box, and then select **Submit**.

Feedback goes to Microsoft to help improve the Copilot control.

Disallow feedback from app users

If you don't want your app users to provide feedback to Microsoft, turn off the feedback option.

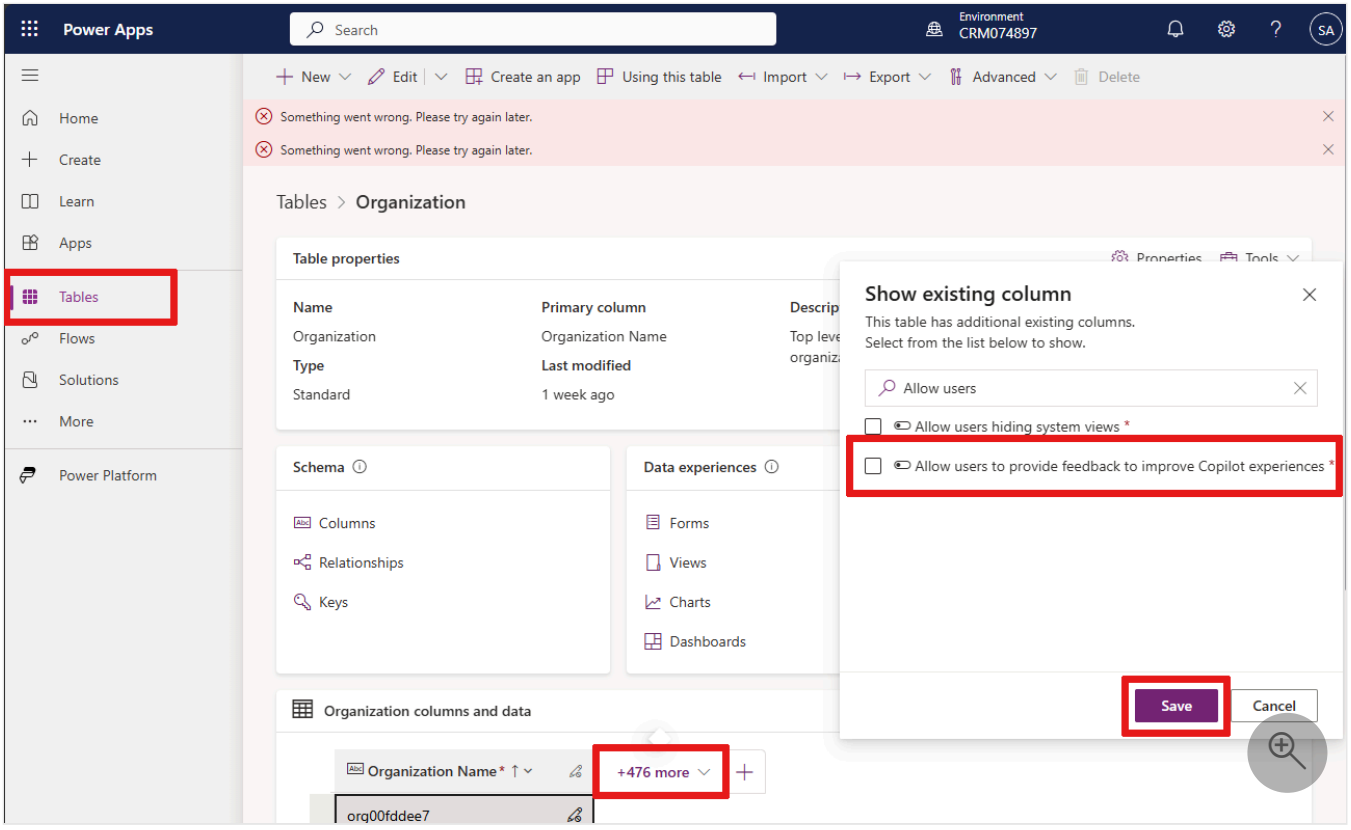
1. Sign in to Power Apps, and select **Tables** from the left navigation pane.

2. Select the **Organization** table from the list.

3. In the **Organization columns and data** section, select the column headers list. The **Show existing column** popup appears.

4. Search for **Allow users to provide feedback for App Copilot**, and make sure the check box is unchecked.

5. Select **Save**.



Related information

- Build apps through conversation (preview)
- Use your prompt in Power Automate

Add a custom Copilot to a canvas app (preview)

Summarize this article for me

[This article is prerelease documentation and is subject to change.]

You can integrate a custom Copilot created in Microsoft Copilot Studio and enable it for your canvas app. This lets users interact with Copilot to ask questions about the data in your app. With just a few simple steps, you can embed a custom Copilot across all your canvas app screens without changing the app's design.

> **Important**
>
> Starting February 2, 2026, adding a custom Copilot to new canvas apps will be discontinued. Existing apps using this feature will remain functional for a limited time but will eventually no longer be supported. Microsoft 365 Copilot Chat in canvas apps is the new the recommended solution for natural language interactions in canvas apps. To ensure a smooth transition and prevent any disruption, we recommend that you migrate to Microsoft 365 Copilot chat as soon as it becomes available in your environment.

> **Note**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - App Copilot for canvas apps is currently rolling out and might not yet be available in your region. App Copilot may be available on Power Apps mobile for mobile devices before it becomes available on the web browser during rollout.

Availability

- This capability might not be available in your region yet. Learn more in Explore Copilot features by geography and languages.
- During the rollout, this capability might be accessible on the Power Apps mobile app before it becomes available on web browsers.

- To use copilots in Power Apps, you must enable data movement across regions for generative AI features. This is crucial if your organization and environment are located in different regions. For more information, see Enable copilots and generative AI features.

Prerequisites

Before using this feature, make sure the following prerequisites are met:

- Create a custom Copilot in Copilot Studio and publish it in the same environment as your canvas app.
- Configure the custom Copilot with user authentication in Microsoft Entra ID.
- Give makers and users access to the Copilot within the environment.

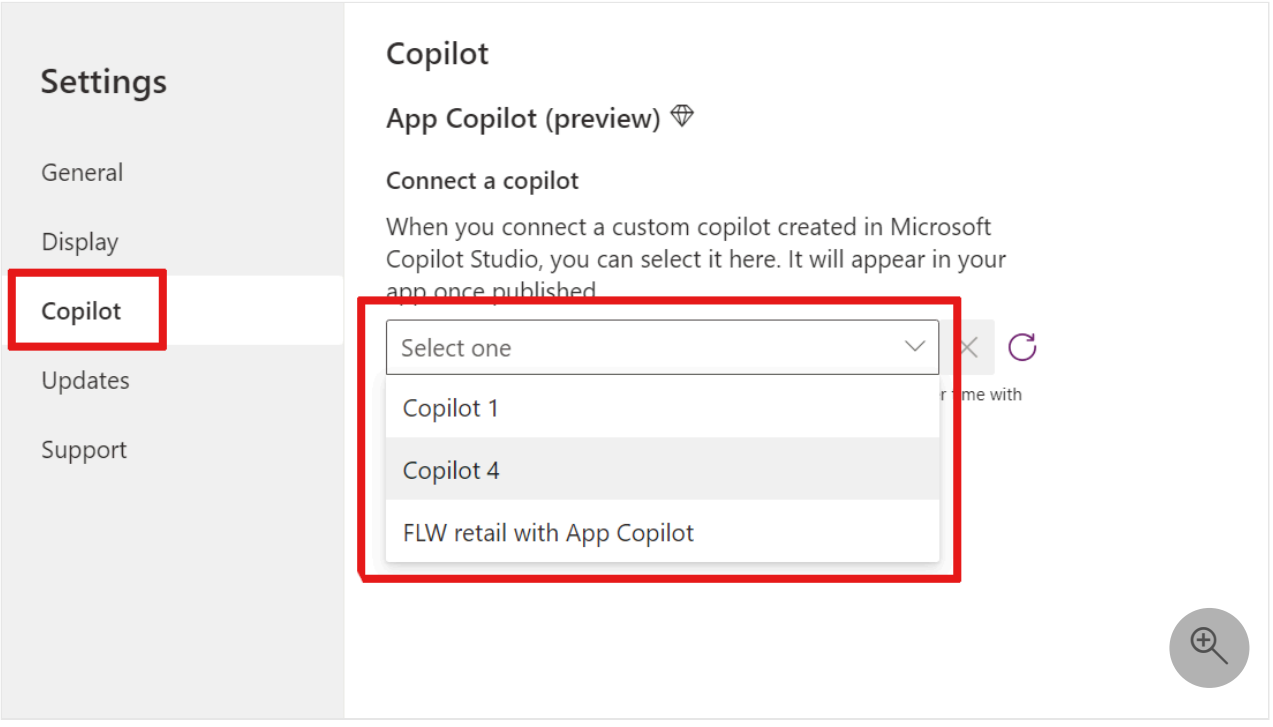
Connect Copilot to your app

Open your canvas app for editing in Power Apps Studio:

1. In the command bar, go to **Settings** > **Updates** > **Preview** tab, and set the toggle for **App Copilot** to **On**.

   You see a **Copilot** tab appear in **Settings**.

2. Select the **Copilot** tab. In the drop-down list under **Connect a copilot**, select a custom copilot published and shared in the same environment as your canvas app.



3. Once you select a Copilot, close the settings dialog box and publish the app. Once the app is published, users are able to use Copilot within it.

Copilot isn't visible when previewing an app in Power Apps Studio. To see Copilot in action, save and publish your app, and then open it using the Power Apps mobile app or a web browser.

> **Tip**
>
> Removing the custom Copilot from the app will disable its functionality.

Use Copilot in your app

- Open your canvas app in a web browser. On the command bar, select **Copilot**.

- In the Power Apps mobile app on iOS or Android devices, select the floating button to access Copilot. You can reposition the button or dismiss it. To use Copilot again after dismissing it, close and reopen the app.

Difference between this feature and the Copilot control

This feature lets you add a custom Copilot created in Microsoft Copilot Studio to a canvas app. It doesn't require any changes to the app's layout. It's available both on the web and natively on mobile devices, and it can connect to existing custom Copilots created in Copilot Studio.

When you add a Copilot control to a canvas app, makers need to update the app's layout to accommodate the control, which is only available on the web. This control supports asking questions about your data or connecting to a new custom copilot from Copilot Studio.

Create and edit tables using the table designer

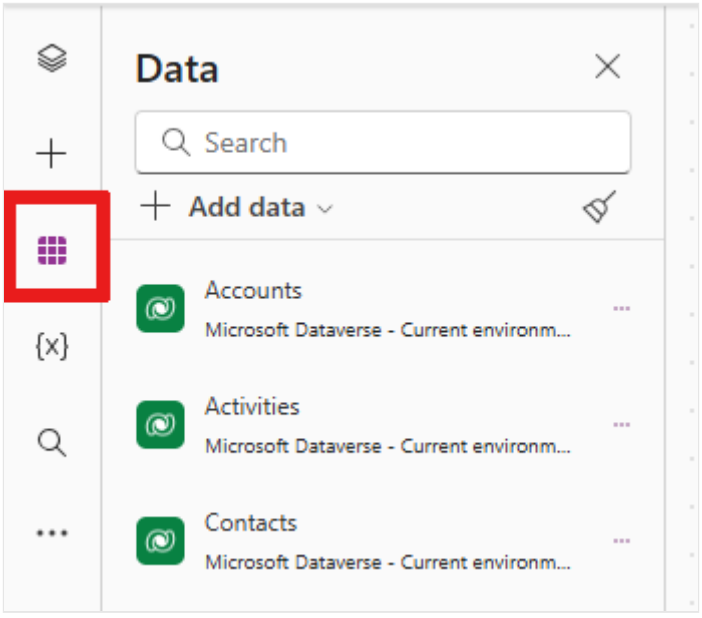
Article • 10/29/2024

Create and edit Dataverse tables in canvas apps using the table designer inside Power Apps Studio. You can also work with the data that's in the table without leaving the app that you're working on.

Create a table

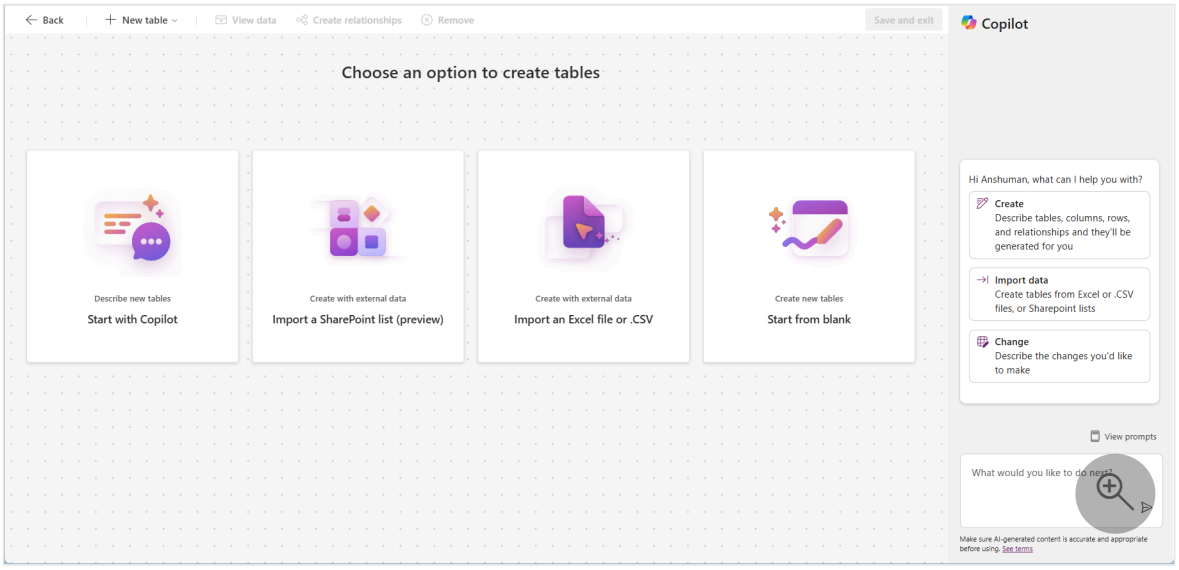
1. Create a new or open an existing app in Power Apps Studio.

2. In the app authoring menu, select **Data**.



3. On the **Data** pane, select **Add Data** > **Create new table**.

> ⓘ Note
>
> If the **Create new table** button is disabled then review Required permissions and limitations.



4. You see **Choose an option to create tables**. For example, you can choose to **Start from blank** or **Start with Copilot** to create a new table.

5. A new table is created for you in the canvas. Enter a name for the table directly where you see the table name.

   You can also expand the **Properties** pane found in the table's overflow menu (the ellipses) to edit the table properties, such as the plural name for the table. For example, a table name can be Ticket, and the plural table name can be Tickets.

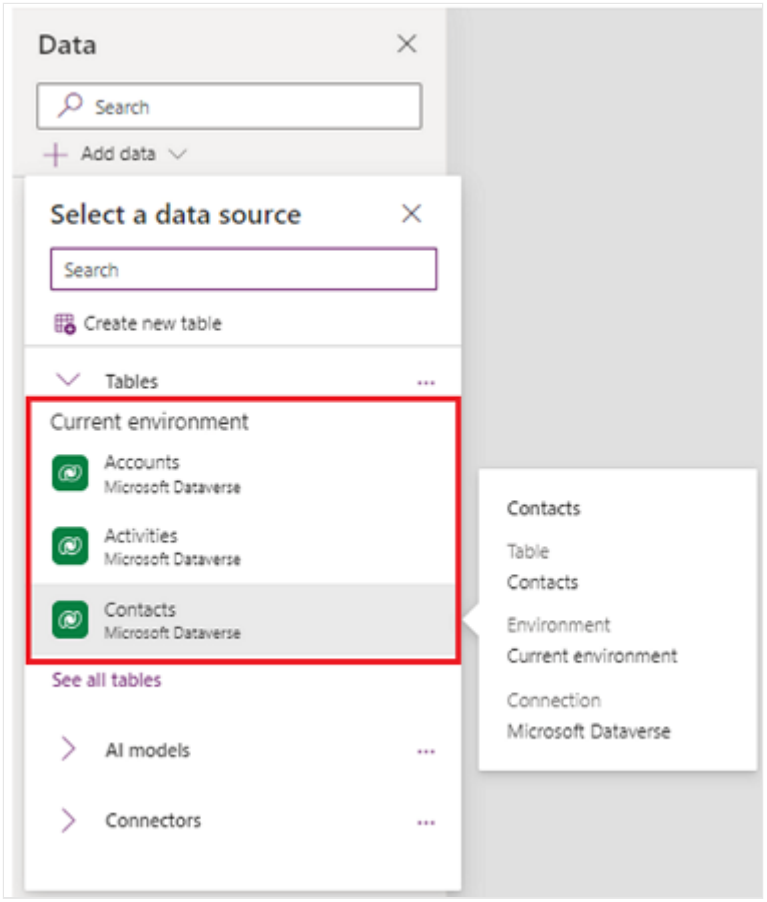
   Can you also add columns or sample data to the table.

6. When you're done editing, select **Save** and exit.

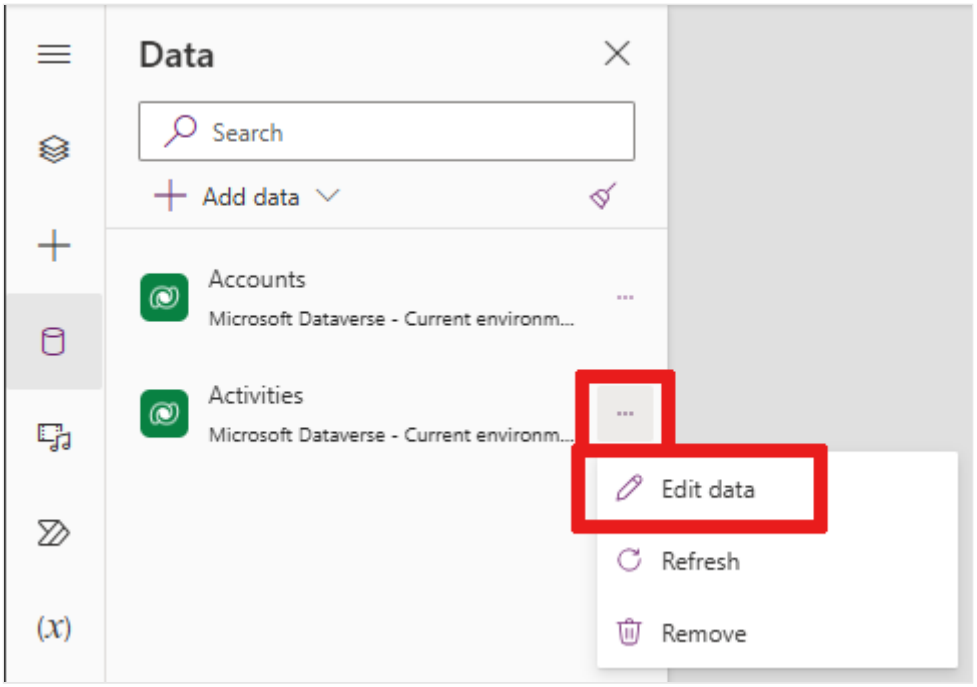
Edit an existing table

Once a Dataverse table is created, you can start editing the table. You can also add existing Dataverse tables to your app and edit those tables using the table designer.

1. From the app authoring menu, select **Data**.
2. On the **Data** pane, select **Add data**.
3. In the **Select a data source** dialog box, from the list of Dataverse tables, select a table to add to your app.



4. On the newly added table select, **More actions** > **Edit data**.



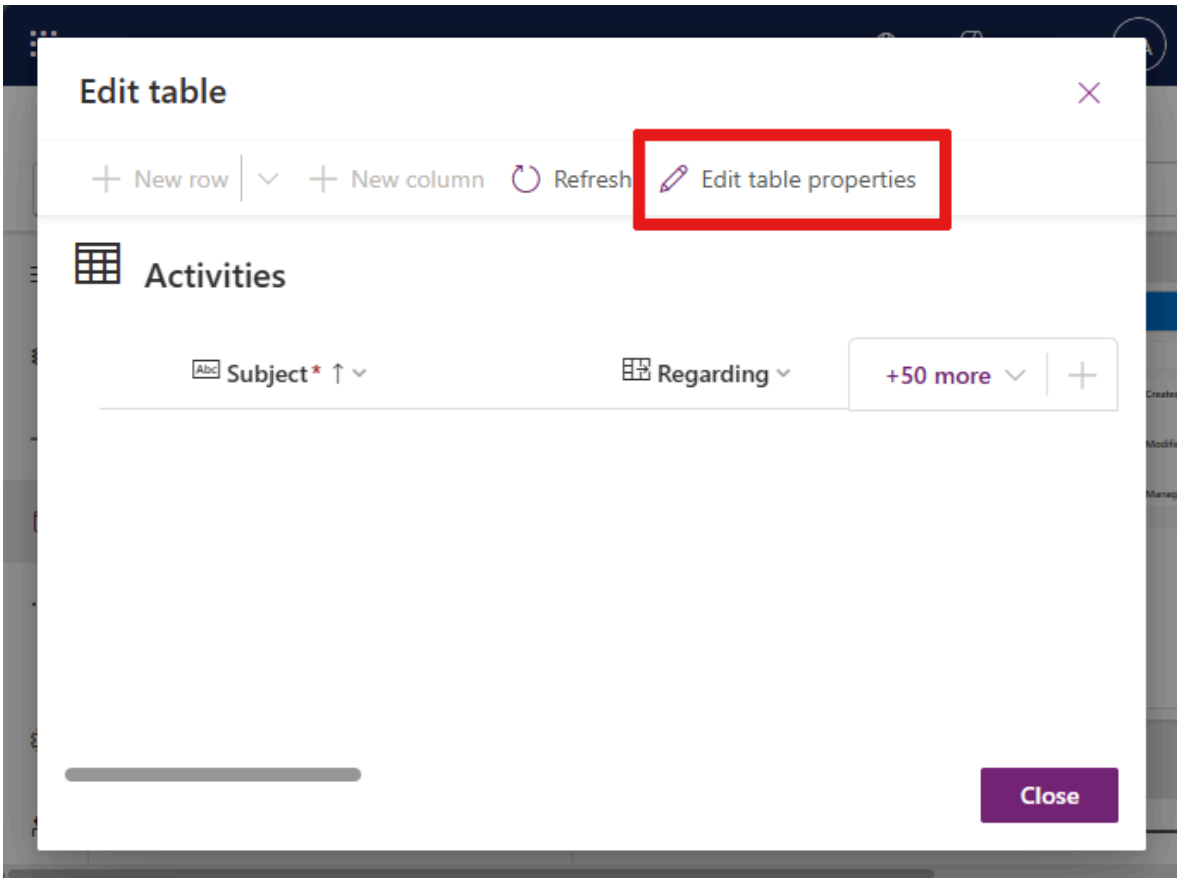
5. The selected table is ready for editing in the table designer.

> **Note**
>
> Some system tables might not be available for editing, or some editing actions may be disabled.

Edit the table properties

After selecting **Edit data**, you see the **Edit table** designer.

1. Select **Edit table properties**.



You can edit the following table properties.

Expand table

Property	Description
Display name	The singular name for the table shown in the app. The display name can be changed later.
Plural display name	The plural name for the table shown in the app. The plural display name can be changed later.
Description	Provide a meaningful description of the purpose of the table.

Select **Enable Attachments** to append notes and files to records for this table.

Select the **Primary column** tab if you want to change its **Display Name** or **Description**. The primary column is used by lookup fields when establishing relationships with other tables.

Advanced options

Select **Advanced options** to see the optional properties you can set. Otherwise some are already set for you.

Expand table

Property	Description
Schema name	By default, the schema name is automatically created for you based on the display name, but you can change it. The schema name can't contain spaces and includes the customization prefix for the Dataverse solution publisher. You can't change the schema name after the table is saved.
Logical name	A unique identifier for the entity. This name can't be changed once the entity is created.
Type	Select the type of table. Use standard for most tables. Activity tables are special tables that can only be owned by a user or team, but can't be owned by an organization. Virtual tables require the table be populated with data from an external source.
Record ownership	Switch the table type to Activity table, so you can create tables that can manage tasks. The type of **Ownership** defines who can perform operations on a record.
Color	You can select your table color using words or hex codes.
Primary row image	You can choose whether to display an image for the table. This image is displayed in Power Apps in some design areas. Notice that the image doesn't appear in apps using the table. To display images in apps, use the image column. Learn more in Image columns.
Apply duplicate detection rules	If duplicate detection is enabled for your organization, enabling allows you to create duplicate detection rules for this table.
Track changes	Enables data synchronization in a performant way by detecting what data changed since the data was initially extracted or last synchronized.
Provide custom help	When selected, set a **Help URL** to control what page users see when they select the help button in the application. Use help to provide guidance specific to your company processes for the table.
Audit changes to its data	When auditing is enabled for your organization, table records can change to be captured over time. When you enable auditing for a table, auditing is also enabled on all its fields. You can select or clear fields that you want to enable auditing on.
Leverage quick create form if available	After you create and publish a Quick Create Form for this table, people can create a new record using the Create button in the navigation pane. Learn more in Create and design model-driven app forms. If enabled for a custom activity table, the custom activity is visible in the group of activity entities when people use the **Create** button in the navigation pane. However, because activities don't support quick create forms, the main form is used when the custom table icon is selected.

Property	Description
Enable long term retention	Table can be included in the configuration of data retention, which moves certain records to long term storage.
Creating a new activity	Associate activities to records for this table.
Doing a mail merge	App users can use this table with mail merge.
Setting up SharePoint document management	After other tasks are performed to enable document management for your organization, enabling this feature allows for this table to participate in integration with SharePoint.
Can have connections	Use the connections feature to show how records for this table have connections to records of other tables that also have connections enabled.
Can have a contact email	Send emails using an email address stored in one of the fields for this table. If a **Single Line of Text** column with format set to email doesn't already exist for this table, a new one is created when you enable sending email.
Have an access team	Create team templates for this table.
Can be linked to feedback	Let app users write feedback for any table record, or rate table records within a defined rating range. Learn more in Configure a table for feedback/ratings.
Appear in search results	Enable so that table records can be included in search results when using an app.
Can be taken offline	Makes data in this table available while the Power Apps application isn't connected to a network.
Can be added to a queue	Use the table with queues. Queues improve routing and sharing of work by making records for this table available in a central place that everyone can access.

Add and edit columns

You can create and edit columns in the table editor.

Learn more in How to create and edit columns.

Editing other table properties

For more advanced table editing scenarios, using the table hub is required. Some examples of these kinds of edits are table relationships, keys, and deleting the table.

Learn more in Create and edit tables using Power Apps.

Add and edit data

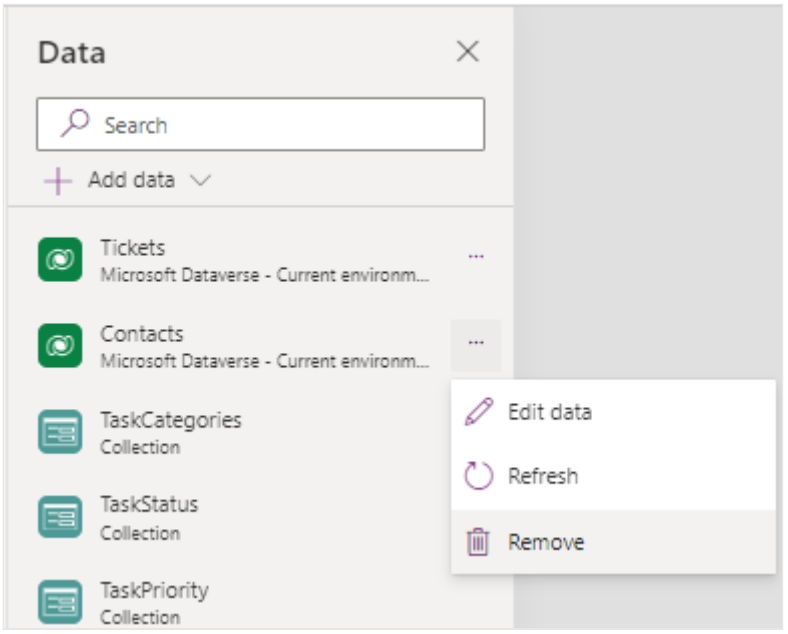
The table designer for canvas apps allows you to add new rows to a Dataverse table or edit rows inside Power Apps Studio using the table designer. You can start typing directly into the grid or select, **New row**.

Learn more in Create your first table.

Remove a table

To remove a table from your app, select **More options** to the right of the table name then select, **Remove**.

> **Note**
>
> When you remove a table, the table is removed and not deleted.



Required permissions and limitations

- To create a table in Dataverse, the environment must have a Dataverse database provisioned. You must have system customizer or system administrator

permissions for the environment where you'd like to build a table. If these conditions aren't met, the **Create New Table** button is disabled.

- You can only create and edit tables in the current Dataverse environment. If you changed your Dataverse environment using the environment picker, then the **Create new table** and **Edit table** options is disabled.

Show a list of items in canvas apps

05/31/2025

Show a list of items from any data source by adding a **Gallery** control to your canvas app. This topic uses Excel as the data source. Filter the list by configuring the **Gallery** control to show only those items that match the filter criterion in a **Text input** control.

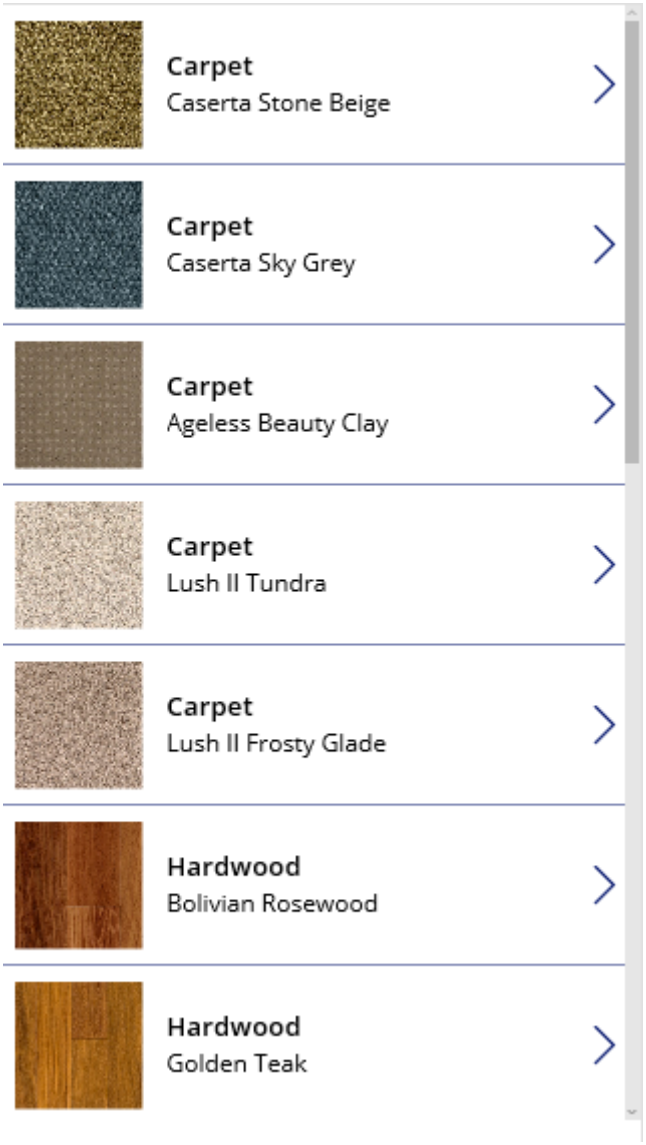
Prerequisites

- Learn how to add and configure a control in Power Apps.
- Set up the sample data:
    1. Download this Excel file, which contains sample data for this tutorial.
    2. Upload the Excel file to a cloud-storage account, such as OneDrive for Business.
- Open a blank app:
    1. Create a blank canvas app.
    2. Add a connection to the **FlooringEstimates** table in the Excel file.

Add a gallery to a blank screen

1. On the **Insert** tab, select **Gallery**, and then select **Vertical**.

2. On the **Properties** tab of the right-hand pane, open the **Items** list, and then select **Flooring Estimates**.



3. (optional) In the **Layout** list, select a different option.

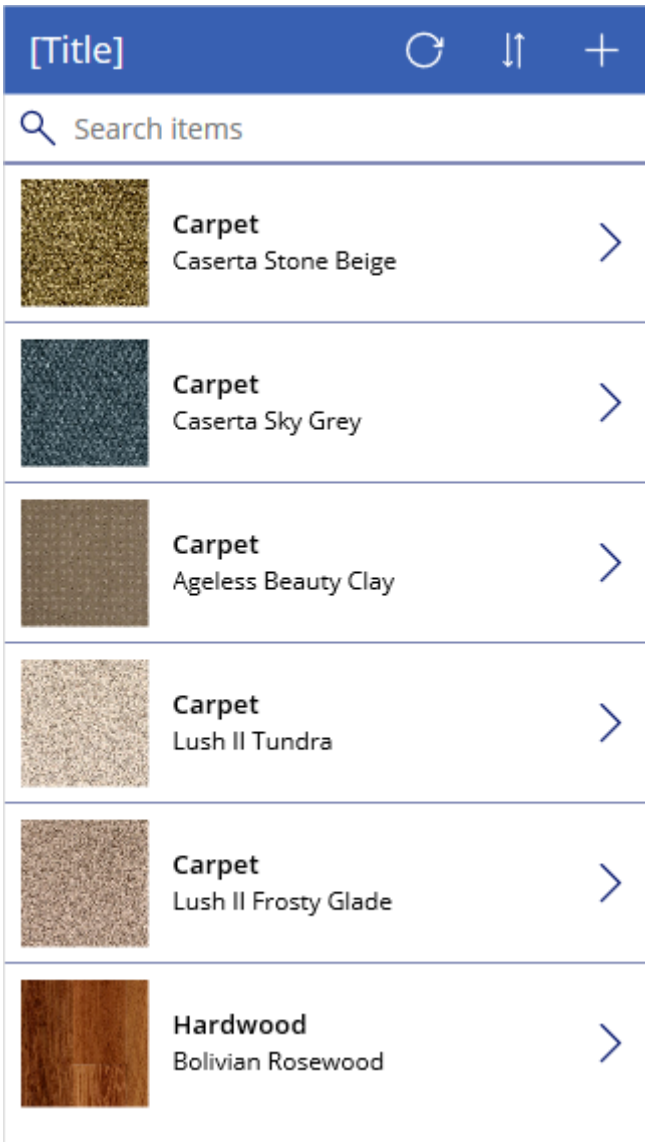
Add a gallery in a screen

1. On the **Home** tab, select **New screen** > **List screen**.

   A screen that contains a **Gallery** control and other controls, such as a search bar, appears.

2. Set the gallery's **Items** property to `FlooringEstimates`.

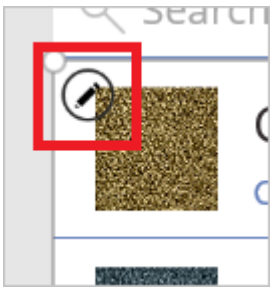
   The **Gallery** control shows the sample data.



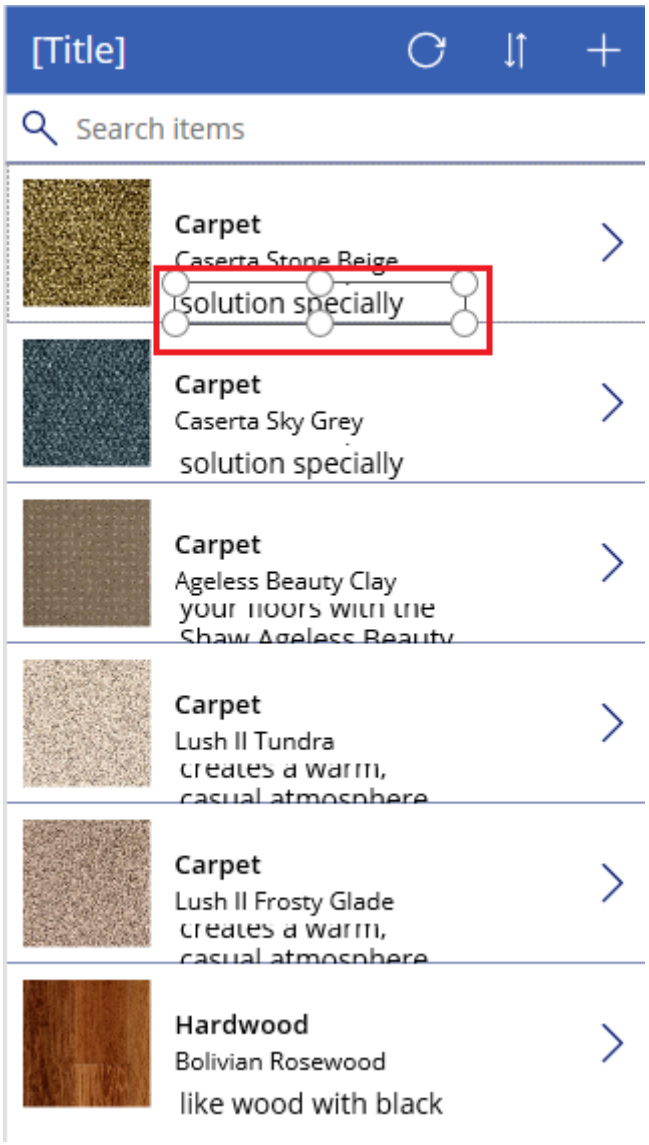
Add a control to the Gallery control

Before you do any other customization, ensure that the layout for your **Gallery** control most closely matches what you want. From there, you can further modify the **Gallery** template, which determines how all data in the **Gallery** control appears.

1. Select the template by clicking or tapping near the bottom of the **Gallery** control and then selecting the pencil icon in its upper-left corner.

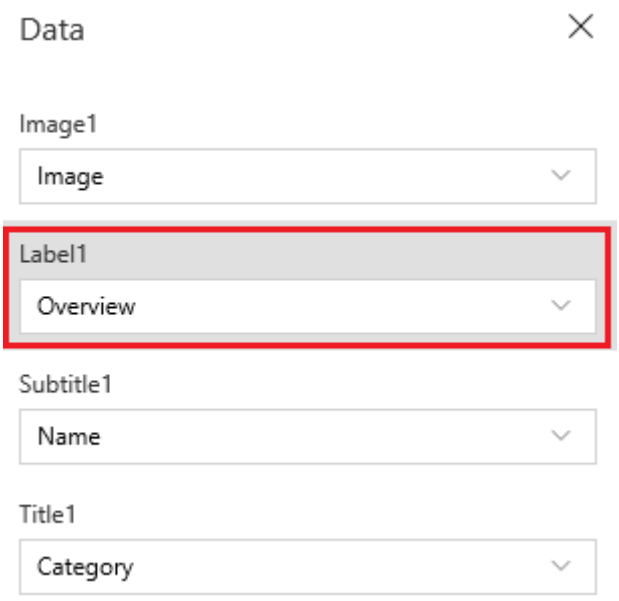


2. With the template still selected, add a **Label** control, and then move and resize it so that it doesn't overlap with other controls in the template.



3. Select the gallery, and then select **Edit** next to **Fields** on the **Properties** tab of the right-hand pane.

4. Select the label that you added earlier in this procedure, and then open the highlighted list in the **Data** pane.

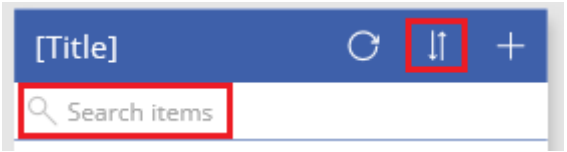


5. In that list, click or tap **Price**.

   The **Gallery** control shows the new values.

Filter and sort a gallery

The **Items** property of a **Gallery** control determines which items it shows. In this procedure, you configure that property so that it also determines which records appear based on filter criteria and in what order.



1. Set the **Items** property of the **Gallery** control to this formula:

```
Power Fx
```

```
Sort(
    Filter(
       FlooringEstimates,
       IsBlank(TextSearchBox1.Text) or TextSearchBox1.Text in Text(Name)
    ),
    Name,
    If(
        SortDescending1,
        SortOrder.Descending,
        SortOrder.Ascending
    )
)
```

For more information about the functions in this formula, see the formula reference.

2. Double-click the search box, and then type part or all of a product name in it.

   Only those items that meet the filter criterion appear.

3. While pressing the Alt key, select the sort icon one or more times to switch the sort order.

   The records toggle between ascending and descending alphabetical order based on the product name.

Highlight the selected item

Set the **Gallery** control's **TemplateFill** property to a formula that's similar to this example, but you can specify different colors if you want:

If(ThisItem.IsSelected, LightCyan, White)

Change the default selection

Set the **Gallery** control's **Default** property to the record that you want to select by default. For example, you can specify the fifth item in the **FlooringEstimates** data source:

Index(FlooringEstimates, 5)

In this example, you specify the first item in the **Hardwood** category of the **FlooringEstimates** data source:

LookUp(FlooringEstimates, Category = "Hardwood")

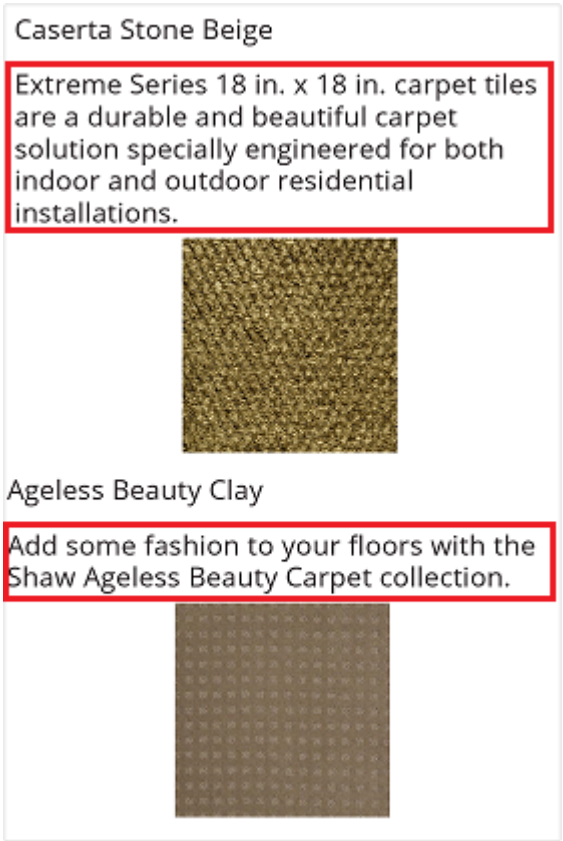
Show items of different heights in canvas apps gallery

Article • 01/19/2023

If different items in your data set contain different amounts of data in the same field, you can completely show items that contain more data without adding empty space after items that contain less data. Add and configure a **Flexible height** gallery control so that you can:

- Configure **Label** controls to expand or shrink based on their contents.
- Position each control so that it automatically appears just under the control above it.

In this tutorial, you show data about flooring products in a **Flexible height** gallery control. The image of each product appears 5 pixels below the overview, whether the overview contains five lines of text or two lines.



Suggested reading

If you've never added controls to a gallery, follow the steps in Show a list of items before you proceed in this topic.

Add data to a blank app

1. Download this Excel file, which contains names, overviews, and links to images of flooring products.

	A	B	C	D	E
1	Name	Category	Price	Image [image]	Overview
2	Lush II Frosty Glade	Carpet	$3.79	https://az787822.vo.msecr	Made with 100% premium nylon fiber, this textured carpet creates a warm, casual atmosphere that invites you to relax and thoroughly enjoy your home.
3	Ageless Beauty Clay	Carpet	$1.98	https://az787822.vo.msecr	Add some fashion to your floors with the Shaw Ageless Beauty Carpet collection.

2. Upload the Excel file to a cloud-storage account such as OneDrive, Dropbox, or Google Drive.

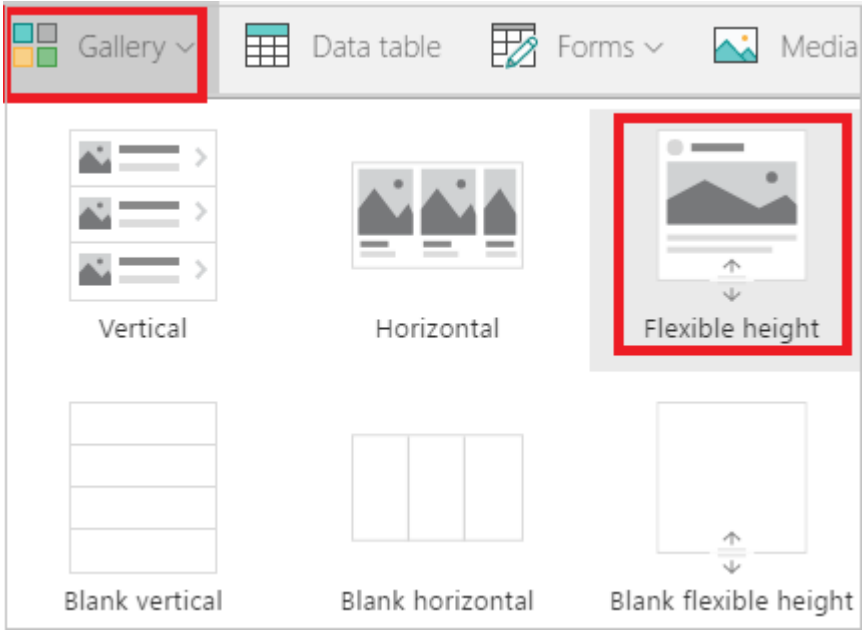
3. Create a blank app with **Phone** layout.

4. Add a connection to the **FlooringEstimates** table in the Excel file.

   For more information, see Add a connection.

Add data to a gallery

1. On the **Insert** tab, click or tap **Gallery**, and then click or tap **Flexible height**.



2. Resize the gallery to take up the entire screen.

3. Set the gallery's **Items** property to **FlooringEstimates**.

Show the product names

1. In the upper-left corner of the gallery, click or tap the pencil icon to select the gallery template.

2. With the gallery template selected, add a **Label** control to it.

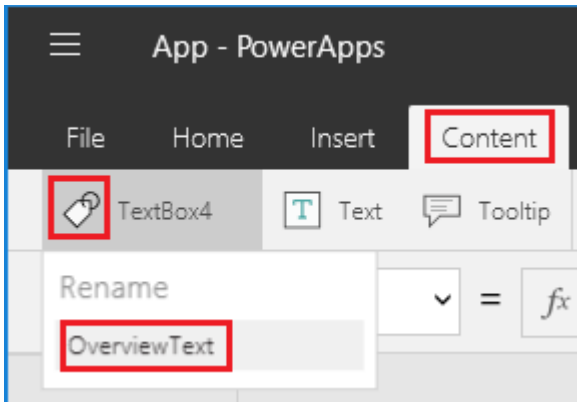
3. Set the **Text** property of the **Label** control to this expression: **ThisItem.Name**

Show the product overviews

1. With the gallery template selected, add another **Label** control, and move it below the first **Label** control.

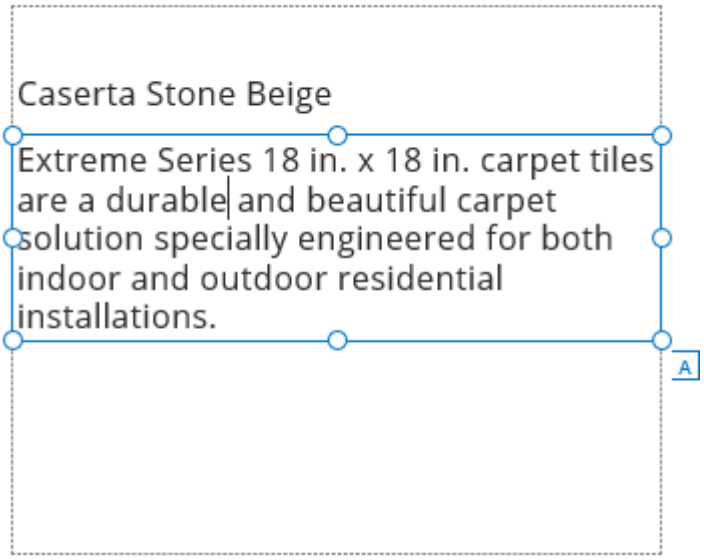
2. Set the **Text** property of the second **Label** control to this expression: **ThisItem.Overview**

3. With the second **Label** control selected, click or tap the name-tag icon on the **Content** tab, and rename the control to **OverviewText**.



4. Set the **AutoHeight** property of the **OverviewText** box to **true**.

   This step ensures that the box will grow or shrink to fit its contents.



Show the product images

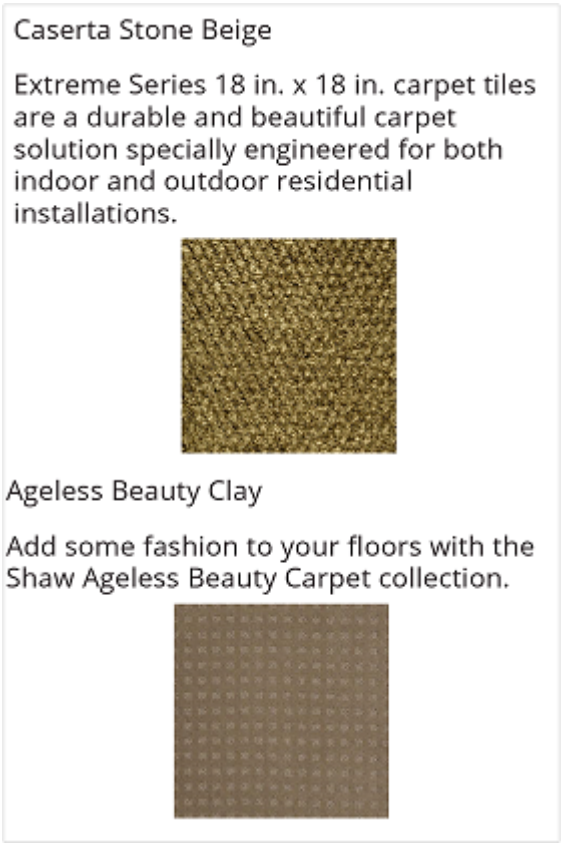
1. Resize the template so that it's twice as tall as it was.

   You can add controls to the template more easily as you build the app, and this change won't affect how the app looks when it runs.

2. With the gallery template selected, add an **Image** control, and move it below the **OverviewText** box.

3. Ensure that the **Image** property of the **Image** control is set to this expression: **ThisItem.Image**

4. Set the **Y** property of the **Image** control based on the position and the size of the **OverviewText** box, as in this expression:
   OverviewText.Y + OverviewText.Height + 5



Apply the same concept if you want to add more controls: set each control's **Y** property based on the **Y** and **Height** properties of the control above it.

Best practices and recommendations

Article • 04/11/2024

The Gallery is the only control that can create other controls. It has its own scope. These advanced features can lead to unexpected behavior if the **Gallery** isn't configured correctly. This article covers best practices and recommendations when you're working with **Galleries**.

Don't change gallery items from within the gallery

It's easy to create unstable behavior if `OnChange` or `OnSelect` of child controls modifies the **Items** of the parent gallery. For example, a **Text input** in a gallery can have its `OnChange` property set to:

Power Fx

```
Patch(GalleryData, ThisItem, {Name: TextInput.Text})
```

This is usually fine. Most controls will only trigger `OnChange` when users change their value directly. However, these controls can cause issues because they also trigger OnChange when the system changes their value:

- Combo box
- Date picker
- Slider
- Toggle

For example, when `ComboBox.DefaultSelectedItems` changes, it triggers `OnChange`. Consider a **Combo box** in a **Gallery** with `DefaultSelectedItems` set to `First(ThisItem.A)` and its `OnChange` property set to:

Power Fx

```
UpdateIf(GalleryData, Name = ThisItem.Name, {
    A: Table({
        B: First(Self.SelectedItems).B
    })
})
```

This expression updates a record in the gallery's data source that matches the current item's name. The change is to replace the `A` column of the record with a new table.

This causes an infinite loop. When the user changes the value of the **Combo box**, `OnChange` is triggered, which updates `GalleryData`, which changes `DefaultSelectedItems` (because `First(ThisItem.A)` refers to a new table), which triggers `OnChange` again, and so on.

To avoid infinite loops, you can use modern controls or other controls that don't trigger `OnChange` when their data changes.

Slow performance from patching items

Even if you avoid unwanted loops, patching or updating **Gallery** items can be slow if the **Gallery** has many items. The **Gallery** doesn't just update the rows associated with the changed records. In some cases, it reloads all items. This is because of the loosely structured nature of data sources. It can be difficult for the **Gallery** to know whether just a single record changed or the entire data source changed.

Gallery.Selected can change unexpectedly

The **Selected** property of the **Gallery** is a moving target. It can change without user interaction when:

- **Gallery.Default** changes
- **Gallery.Items** changes
- Refreshing or updating data sources

This might not be desirable for your scenario. If you want a stable copy of the item that is selected by the user, consider storing it in a variable. For example, set the **OnSelect** property of the **Gallery** to a global variable `CurrentItem`:

Power Fx

```
Set(CurrentItem, Self.Selected)
```

You can then use `CurrentItem` in other parts of the app to refer to the most recent item selected by the user rather than by the system.

Don't use Gallery.Selected in a child control's event

The **Selected** property of the **Gallery** changes when a user selects an item. However, this event isn't related to events of child controls. Referring to `Gallery.Selected` in a child control's events can lead to unexpected results.

For example, when a user selects a **Checkbox** in a **Gallery**, the following events occur:

- `Checkbox.OnSelect`
- `Checkbox.OnCheck`
- `Gallery.Selected` changes to the newly clicked row

The order of these events isn't fixed. This is a problem if `Checkbox.OnSelect` is set to:

```
Power Fx

Notify(Gallery.Selected.Name)
```

`Gallery.Selected` might still be referring to the previously selected row when `Checkbox.OnSelect` is executed.

To avoid timing issues, don't use `Gallery.Selected` in events. If you must, use `Gallery.OnSelect` to respond to changes to `Gallery.Selected`.

Ensure that the Gallery knows the schema of its items

Setting `Gallery.Items` to a variable or output of a Canvas component can give unexpected results, depending on when the variable is set or changed.

Galleries need to know the schema of its **Items** when the app loads. A schema, also known as shape, is the name and type of columns in a data source. Consider this table:

```
Power Fx

[{A: "abc", B: 123}, {A: "def", B: 456}]
```

Its schema consists of a text column `A` and a number column `B`.

Most of the time, the **Gallery** can guess the schema of its **Items** from the data source and expressions used in the app. But if the **Items** property is set to the output of a **Canvas component** or **Import** control, the **Gallery** can't determine its schema. The output table from these controls might not be available when the app loads and the schema might even change. The **Gallery** won't render any items when it doesn't know its schema.

The same issue might happen when **Items** is set to a variable that's not initialized when the app loads.

As a workaround, you can hint the expected schema to the Gallery with a variable. Set **App.OnStart** to:

```
Power Fx

If(false, Set(GalleryData, [{A: "abc", B: 123}]), Set(GalleryData, []))
```

This lets the system know the schema of the `GalleryData` table. Then, you can use `GalleryData` as the **Items** property of the **Gallery**. Change it to the actual data source when needed.

Don't assume AllItems contains all items of its dataset

The **AllItems** property are the items that are loaded into view in a gallery. It's not all items in **Items**. **AllItems** can change when the user scrolls the gallery to load more items. Typically, this property is used to get values of child controls when the user is interacting with them. Hence, **AllItems** is guaranteed to have loaded that item and it's safe to refer to it. Don't refer to an item in **AllItems** if you're not sure whether the user has seen it.

Similarly, **AllItemsCount** is the number of items that are loaded into view in the gallery. It's not the total number of records in **Items**. To get the total records in **Items**, use `CountRows(<expression used for Items property>)`.

Show, edit, or add a record in a canvas app

Article • 01/19/2023

In a canvas app, add and configure a **Display** form control to show all fields in a record. You can also add and configure an **Edit** form control to edit any field in a record, add a record, and save your changes back to a data source.

Prerequisites

- Learn how to add and configure a control in Power Apps.
- Download this Excel file, which contains sample data for this tutorial.
- Upload the Excel file to a cloud-storage account, such as OneDrive for Business.
- Create or open an app for phones, add a connection to the **FlooringEstimates** table in the Excel file.

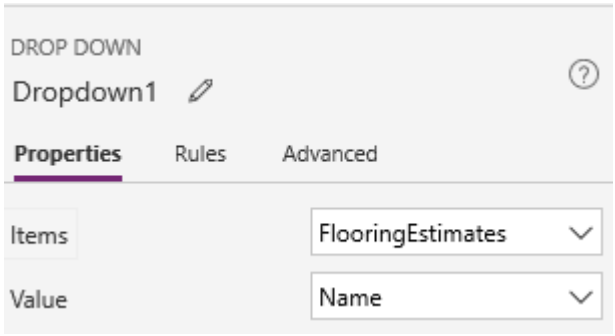
  You can add a form to a tablet app, but it won't match this article because the form will have three columns by default.
- If you open an existing app, add a screen to it.

Add a form, and show data

1. On a blank screen, add a **Drop down** control, and name it **ChooseProduct**.

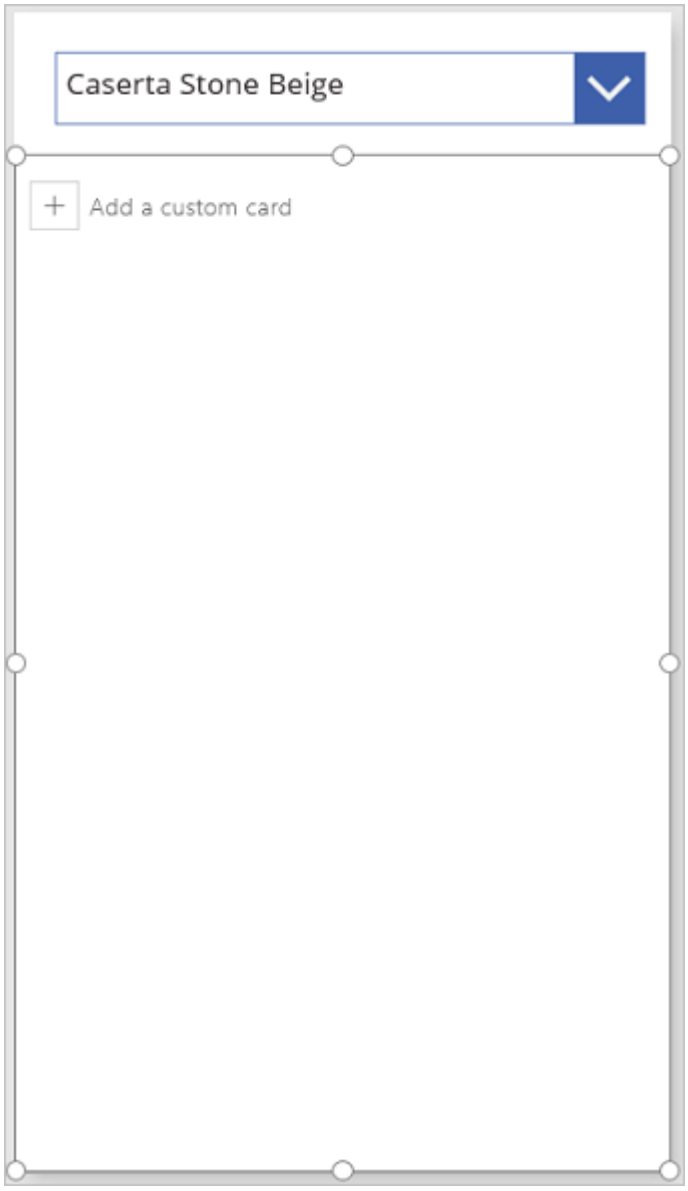
   > **Note**
   >
   > If you're not sure how to add a control, rename it, or set a property, see **Add and configure controls**.

2. On the **Properties** tab of the right-hand pane, set **Items** to `FlooringEstimates` and **Value** to `Name`.



The list shows names of flooring products from the data source.

3. Add an **Edit** form control, move it below **ChooseProduct**, and then resize the form to cover most of the screen.



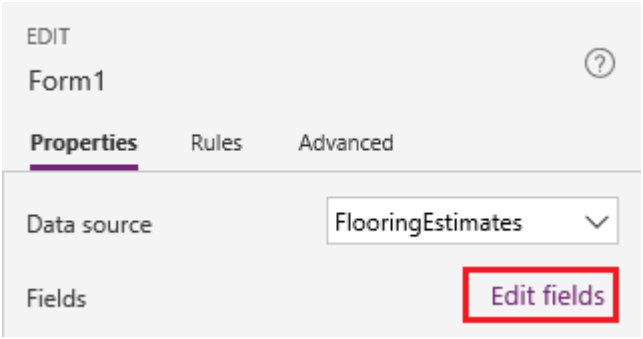
> **Note**
>
> This topic describes the **Edit** form control, but similar principles apply to the **Display** form control.

4. Set the form's DataSource property to **FlooringEstimates** and its Item property to this formula:

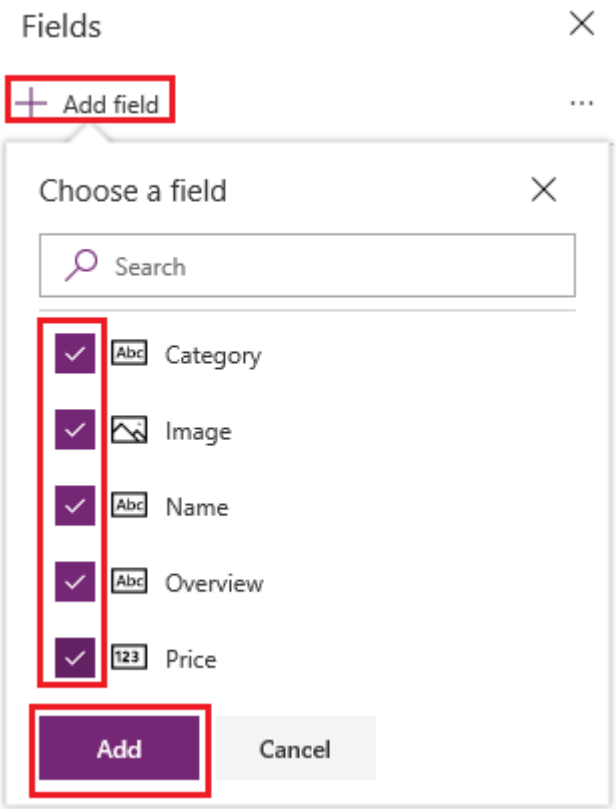
   ```
   ChooseProduct.Selected
   ```

   This formula specifies that, after you finish configuring the form, it will show the record that the user selects in **ChooseProduct**.

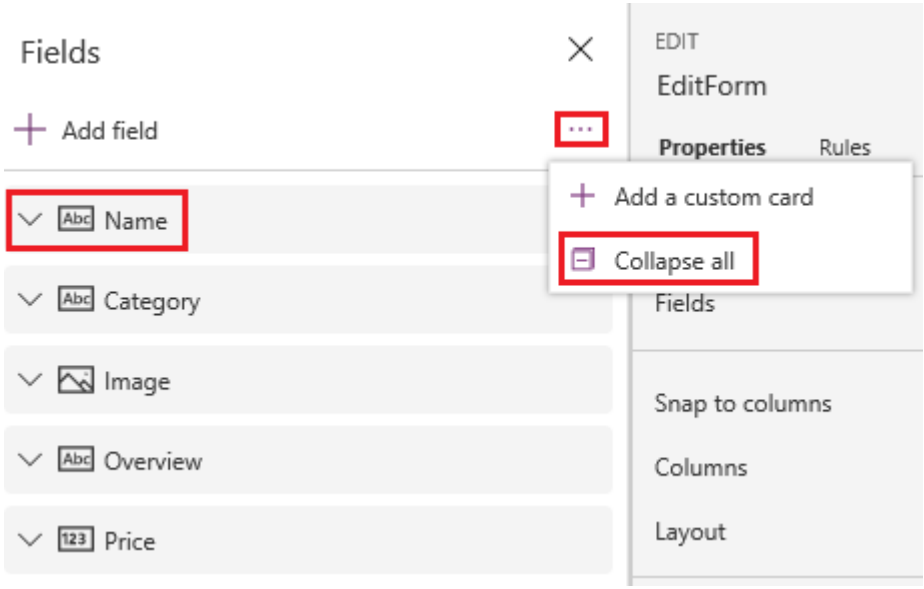
5. On the **Properties** tab of the right-hand pane, select **Edit fields**.



6. In the **Fields** pane, select **Add field**, select the check box for each field, and then select **Add**.



7. Select the ellipsis (...) next to **Add field**, select **Collapse all**, and then drag **Name** to the top of the list.



The **Edit** form control reflects your change.

Set the card type for a field

1. In the **Fields** pane, expand the **Price** field by selecting its down arrow.

2. Open the **Control type** list, and then select **Edit slider**.

   In the form, the **Price** field shows a **Slider** control instead of a **Text input** control.

3. (optional) Follow the same process to change the control for the **Overview** field to an **Edit multi-line text** control.

(Edit form only) Save changes

1. Rename the form **EditForm**.

2. Add a **Button** control, and set its **OnSelect** property to this formula:

   ```
   SubmitForm(EditForm)
   ```

3. Press F5 to open Preview, change the name of a product, and then select the button that you created.

   The **SubmitForm** function saves your changes to the data source.

4. (optional) Close Preview by pressing Esc (or by selecting the close icon in the upper-right corner).

Next steps

Learn more about working with forms and formulas.

Understand canvas-app forms

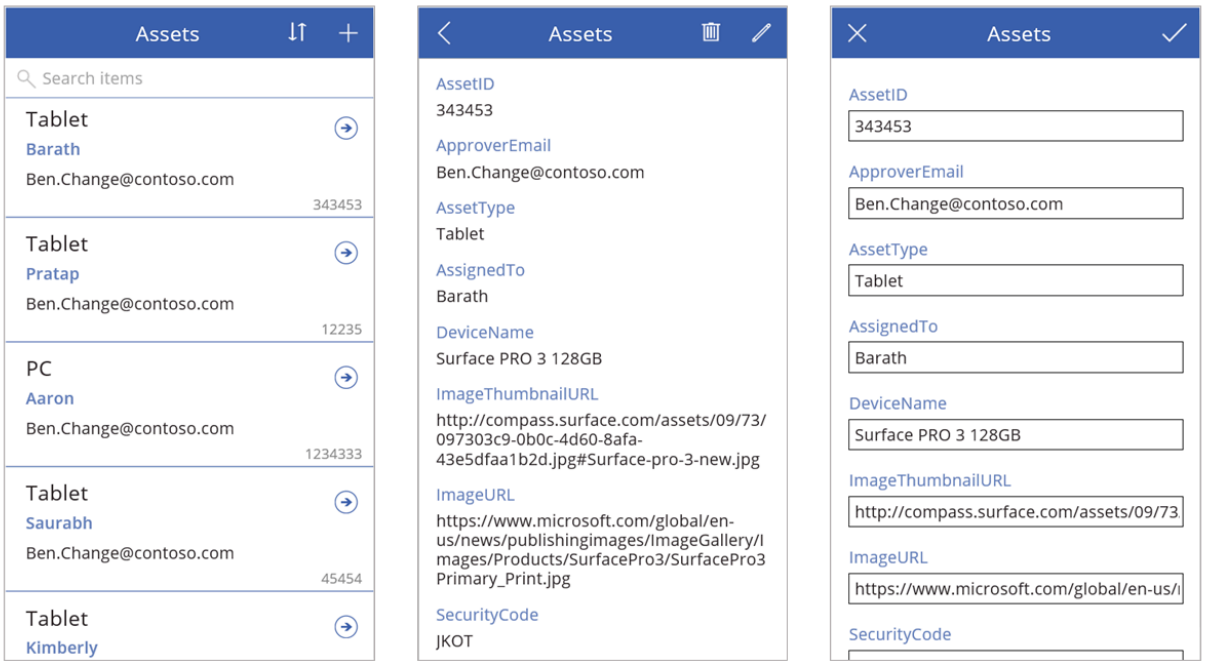
Article • 12/16/2022

Add three types of controls to a canvas app so that the user can browse for a record, display details about that record, and edit or create a record:

Expand table

Activity	Control	Description
Browse for a record	Gallery control	Filter, sort, search, and scroll through records in a data source, and select a specific record. Display only a few fields from each record to show several records at a time, even on a small screen.
Show details of a record	Display form control	For a single record, display many or all fields in that record.
Edit or create a record	Edit form control	Update one or more fields in a single record (or create a record starting with default values), and save those changes back to the underlying data source.

Put each control on a different screen to make them easier to distinguish:



Browse screen
Primary control: Gallery

Details screen
Primary control: Display form

Edit and Create screen
Primary control: Edit form

As this topic describes, combine these controls with formulas to create the overall user experience.

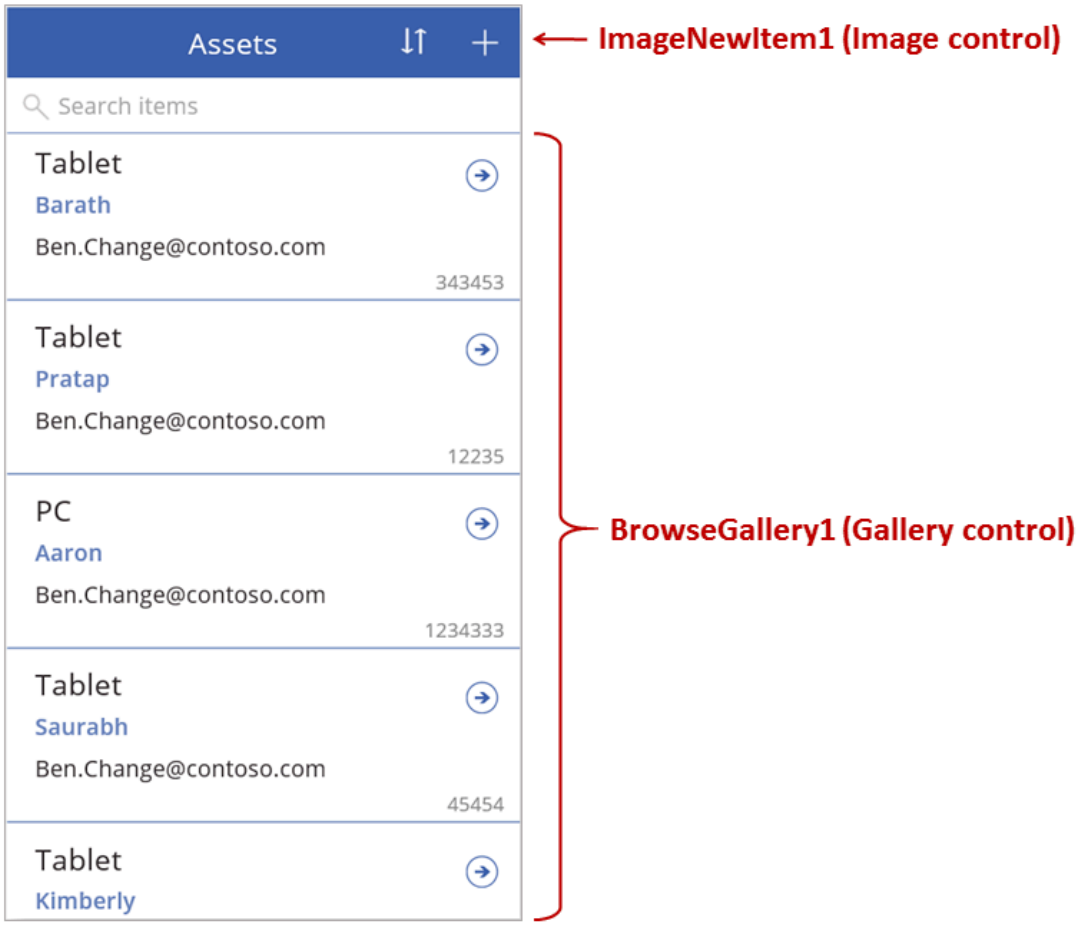
Prerequisites

- Sign up for Power Apps, and then sign in by providing the same credentials that you used to sign up.
- Learn how to configure a control in Power Apps.

Explore a generated app

Power Apps can automatically generate an app based on a data source that you specify. Each app contains three screens with the controls described earlier and formulas that connect them. Run these apps "out of the box," customize them for your specific goals, or examine how they work so that you can learn useful concepts that apply to your own apps. In the following sections, inspect the screens, controls, and formulas that drive a generated app.

Browse screen



This screen features these key formulas:

Expand table

Control	Supported behavior	Formula
BrowseGallery1	Display records from the **Assets** data source.	The **Items** property of the gallery is set to a formula that's based on the **Assets** data source.
ImageNewItem1	Display the **Edit and Create** screen with each field set to a default value, so that the user can easily create a record.	The **OnSelect** property of the image is set to this formula: **NewForm(EditForm1); Navigate(EditScreen1, None)**
NextArrow1 (in the gallery)	Display the **Details** screen to view many or all fields of the currently selected record.	The **OnSelect** property of the arrow is set to this formula: **Navigate(DetailScreen1, None)**

The primary control on this screen, **BrowseGallery1**, covers most of the area of the screen. The user can scroll through the gallery to find a specific record to display more fields or to update.

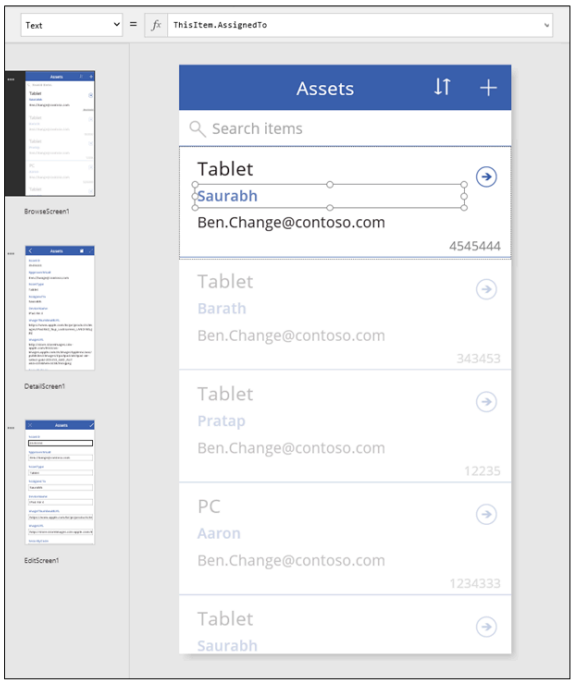
Set the **Items** property of a gallery to show records from a data source in it. For example, set that property to **Assets** to show records from a data source of that name.

> **Note**
>
> In a generated app, **Items** is set to a significantly more complicated formula by default so that the user can sort and search for records. You'll learn how to build that formula later in this topic; the simpler version is enough for now.

Instead of finding a record to display or edit, the user can create a record by selecting the "+" symbol above the gallery. Create this effect by adding an **Image** control, showing a "+" symbol in it, and setting its **OnSelect** property to this formula: **NewForm(EditForm1); Navigate(EditScreen1, None)**

This formula opens the **Edit and Create** screen, which features an **Edit form** control named **EditForm1**. The formula also switches that form into **New** mode, in which the form shows default values from the data source so that the user can easily create a record from scratch.

To examine any control that appears in **BrowseGallery1**, select that control in the first section of that gallery, which serves as a template for all other sections. For example, select the middle **Label** control on the left edge:



Text control selected, used to display a field of the record

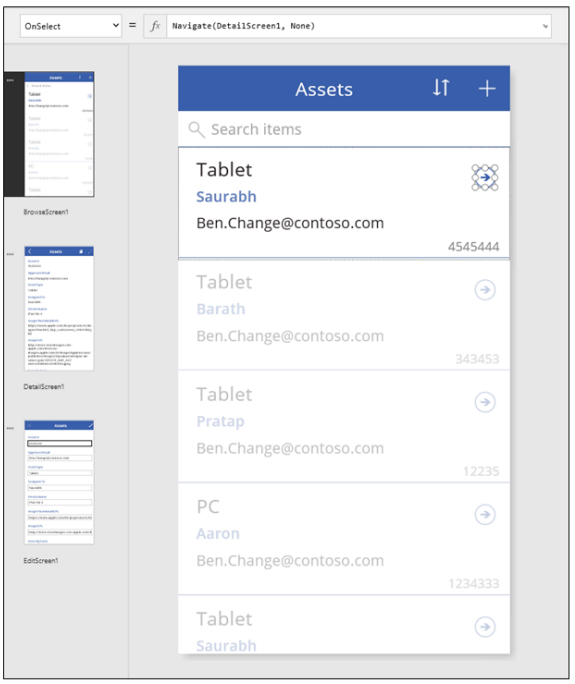


Image control selected, used to change screens

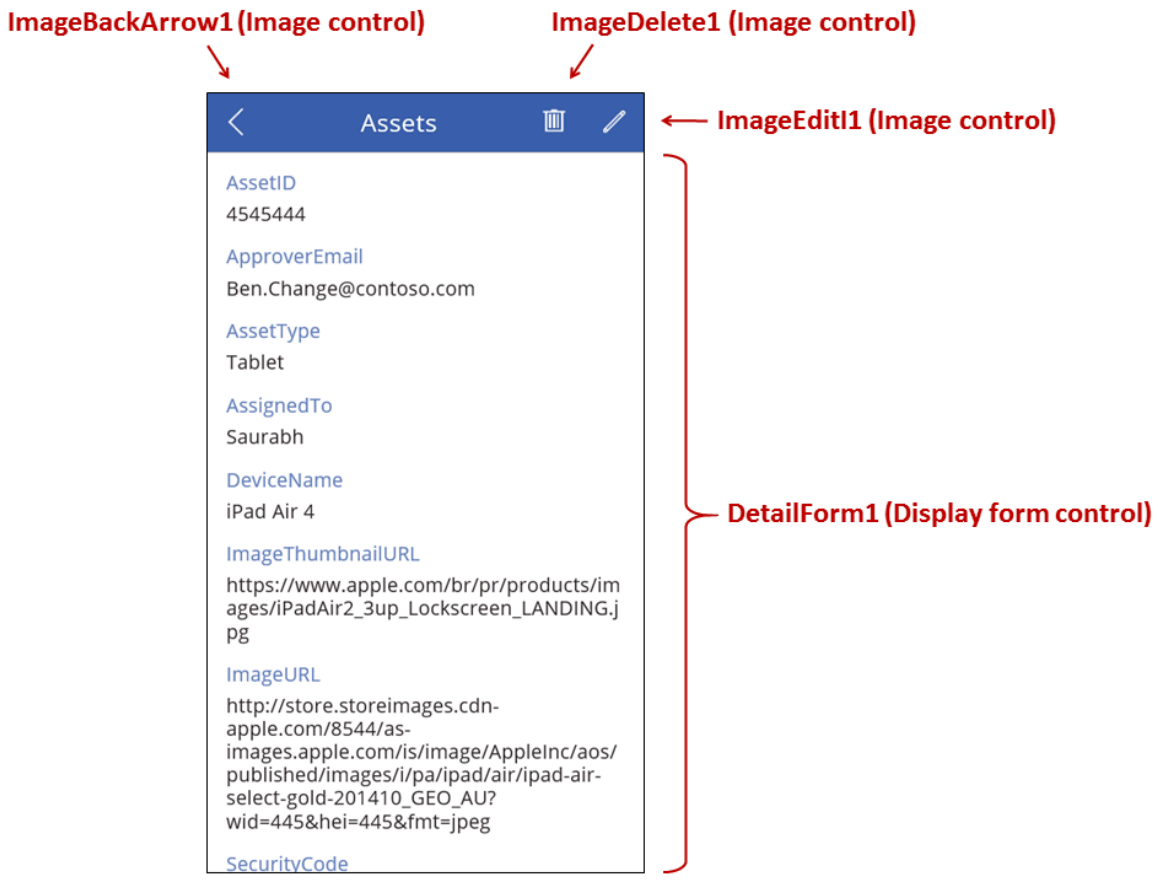
In this example, the control's **Text** property is set to **ThisItem.AssignedTo**, which is a field in the **Assets** data source. The **Text** property of the other three **Label** controls in the gallery are set to similar formulas, and each control shows a different field in the data source.

Select the **Shape** control (the arrow), and confirm that its **OnSelect** property is set to this formula:
Navigate(DetailScreen1, None)

If the user finds a record in **BrowseGallery1**, the user can select the arrow for that record to show more information about it in **DetailScreen1**. By selecting an arrow, the user changes the value of the **Selected** property of **BrowseGallery1**. In this app, that property determines which record appears in not only **DetailScreen1** but also, if the user decides to update the record, the **Edit and Create** screen.

Detail screen



This screen features these key formulas:

Expand table

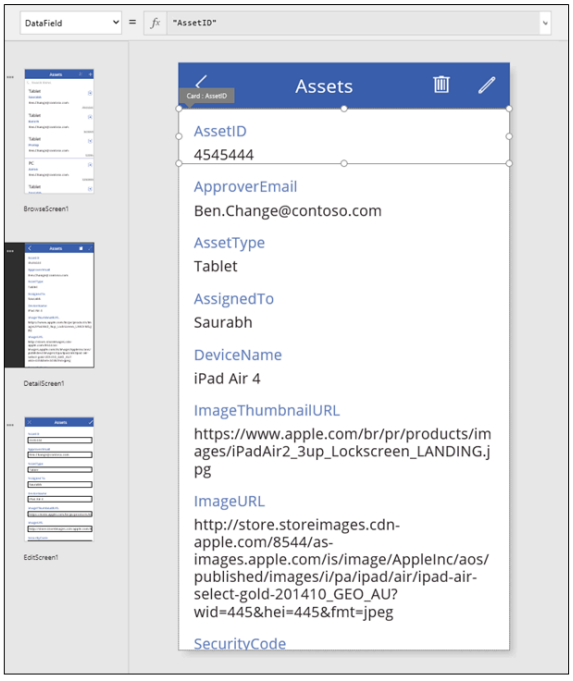
Control	Supported behavior	Formula
DetailForm1	Displays a record in the **Assets** data source	Set the DataSource property to **Assets**.
DetailForm1	Determines which record to display. In a generated app, displays the record that the user selected in the gallery.	Set the Item property of this control to this value: **BrowseGallery1.Selected**
Card controls	In a Display form control, displays a single field in a record.	Set the DataField property to the name of a field, enclosed in double quotation marks (for example, **"Name"**).
ImageBackArrow1	When the user selects this control, opens **BrowseScreen1**.	Set the OnSelect property to this formula: **Back()**
ImageDelete1	When the user selects this control, deletes a record.	Set the OnSelect property to this formula: **Remove(Assets, BrowseGallery1.Selected)**

Control	Supported behavior	Formula
ImageEdit1	When the user selects this control, opens the **Edit and Create** screen to the current record.	Set the OnSelect property to this formula: **Navigate(EditScreen1, None)**

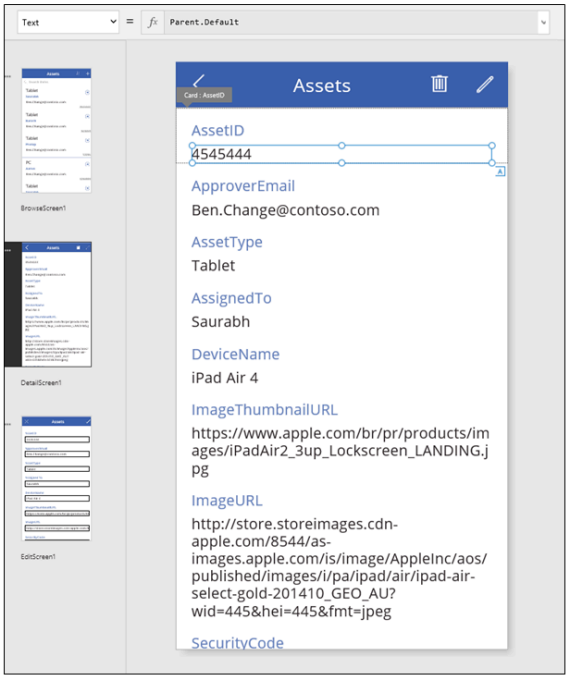
At the top of the screen, three images sit outside of **DetailForm1** and act as buttons, orchestrating between the three screens of the app.

DetailForm1 dominates this screen and displays the record that the user selected in the gallery (because the form's Item property is set to **BrowseGallery1.Selected**). The DataSource property of the form also provides metadata about the data source, such as a user-friendly display name for each field.

DetailForm1 contains several Card controls. You can select either the Card control itself or the control that it contains to discover additional information.



Card selected, used to display a field of the record

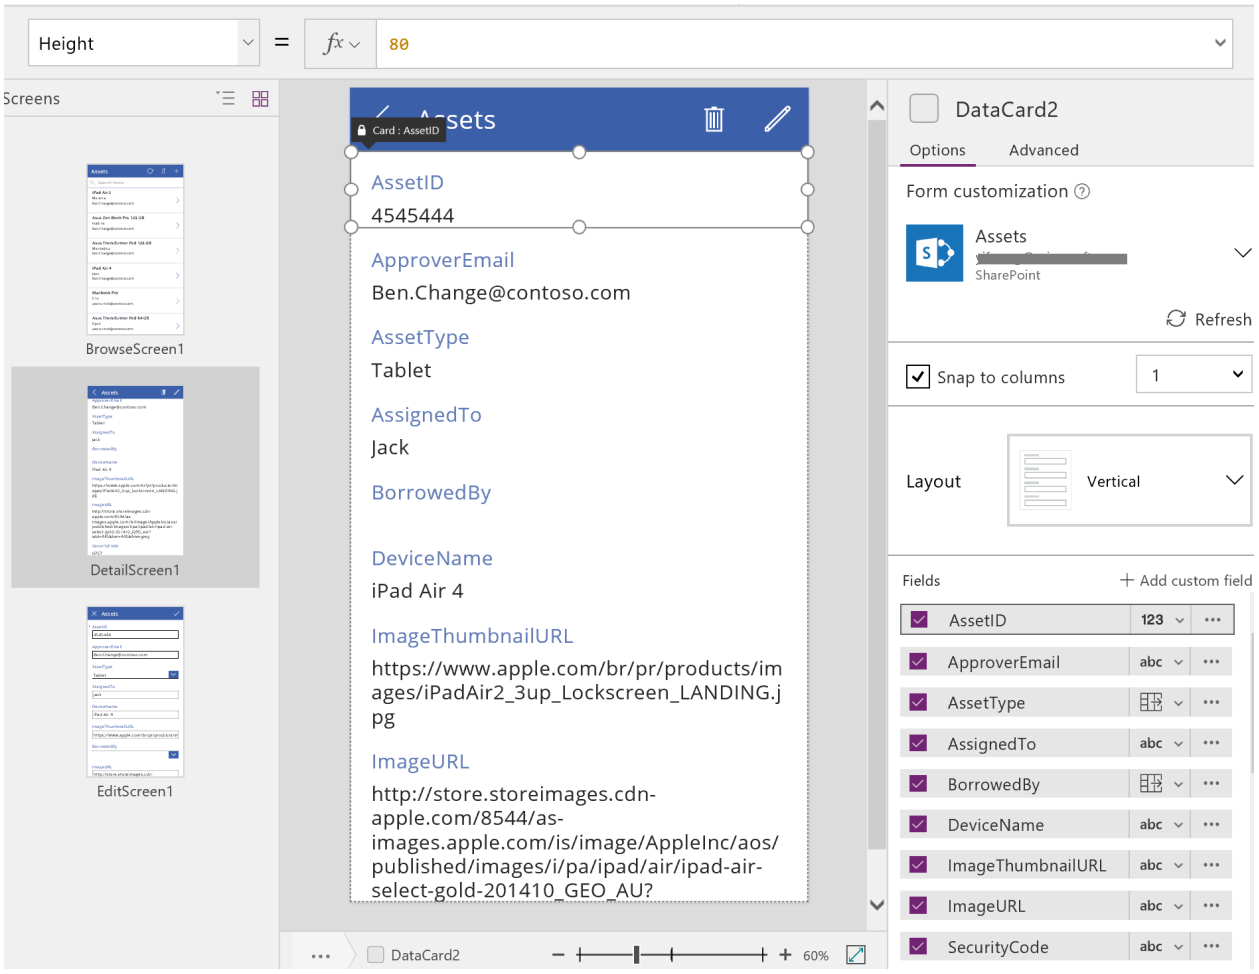


Text control selected, showing the field's value

The DataField property of a Card control determines which field the card displays. In this case, that property is set to **AssetID**. The card contains a Label control for which the Text property is set to **Parent.Default**. This control shows the **Default** value for the card, which is set through the DataField property.

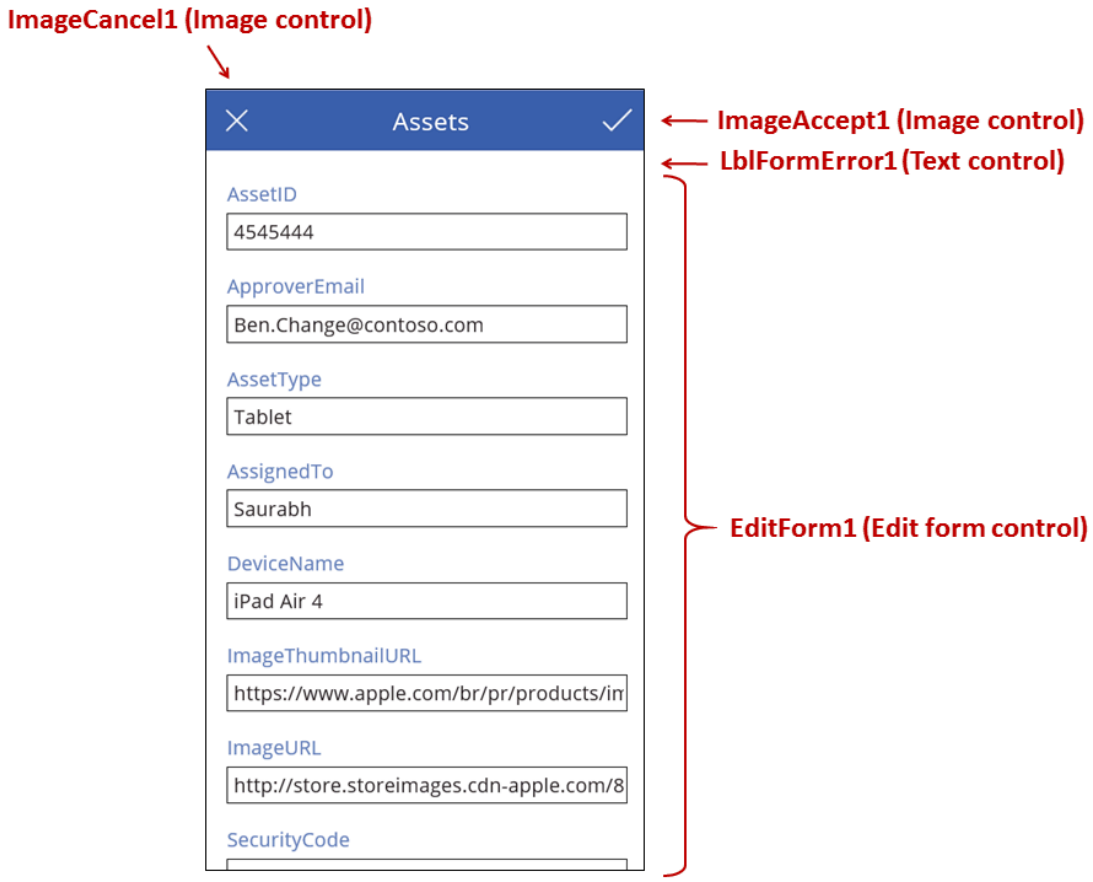
In a generated app, Card controls are locked by default. When a card is locked, you can't modify some properties, such as DataField, and the formula bar is unavailable for those properties. This restriction helps ensure that your customizations don't break the basic

functionality of the generated app. However, you can change some properties of a card and its controls in the right-hand pane:



In the right-hand pane, you can select which fields to display and in which kind of control each field displays.

Edit/Create screen



This screen features these key formulas:

Expand table

Control	Supported behavior	Formula
EditForm1	Displays a record in the **Assets** data source.	Set the DataSource property to **Assets**.
EditForm1	Determines which record to display. In a generated app, displays the record that the user selected in **BrowseScreen1**.	Set the Item property to this value: **BrowseGallery1.Selected**
Card controls	In a Edit form control, provides controls so that the user can edit one or more fields in a record.	Set the DataField property to the name of a field, enclosed in double quotation marks (for example, **"Name"**).
ImageCancel1	When the user selects this control, discards any changes in progress, and opens the **Details** screen.	Set the OnSelect property to this formula: **ResetForm(EditForm1); Back()**
ImageAccept1	When the user selects this control, submits changes to the data source.	Set the OnSelect property to this formula: **SubmitForm(EditForm1)**

Control	Supported behavior	Formula
EditForm1	If changes are accepted, returns to the previous screen.	Set the **OnSuccess** property to this formula: **Back()**
EditForm1	If changes aren't accepted, remain on the current screen so that the user can fix any issues and try to submit again.	Leave the **OnFailure** property blank.
LblFormError1	If changes aren't accepted, shows an error message.	Set the **Text** property to this value: **EditForm1.Error**

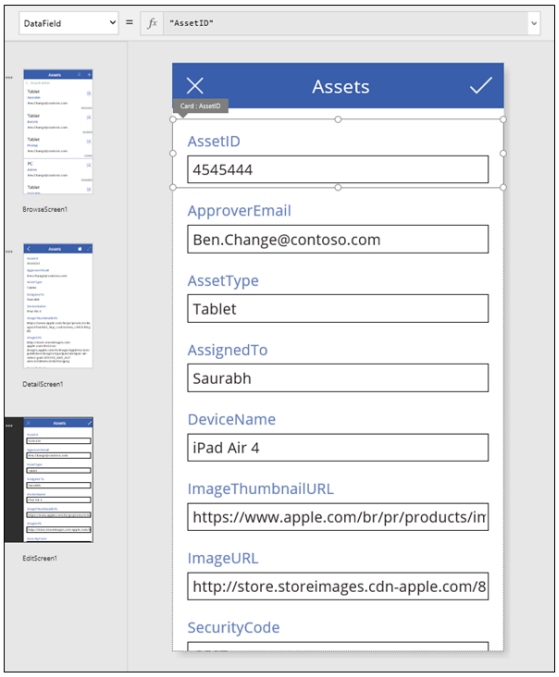
As in the **Details** screen, a form control, named **EditForm1**, dominates the **Edit and Create** screen. In addition, the **Item** property of **EditForm1** is set to **BrowseGallery1.Selected**, so the form displays the record that the user selected in **BrowseScreen1**. While the **Details** screen shows each field as read-only, the user can update the value of one or more fields by using the controls in **EditForm1**. It also uses the **DataSource** property to access metadata about this data source, such as the user-friendly display name for each field and the location where changes should be saved.

If the user selects the "X" icon to cancel an update, the **ResetForm** function discards any unsaved changes, and the **Back** function opens the **Details** screen. Both the **Details** screen and the **Edit and Create** screen show the same record until the user selects a different one on **BrowseScreen1**. The fields in that record remain set to the values that were most recently saved, not any changes that the user made and then abandoned.

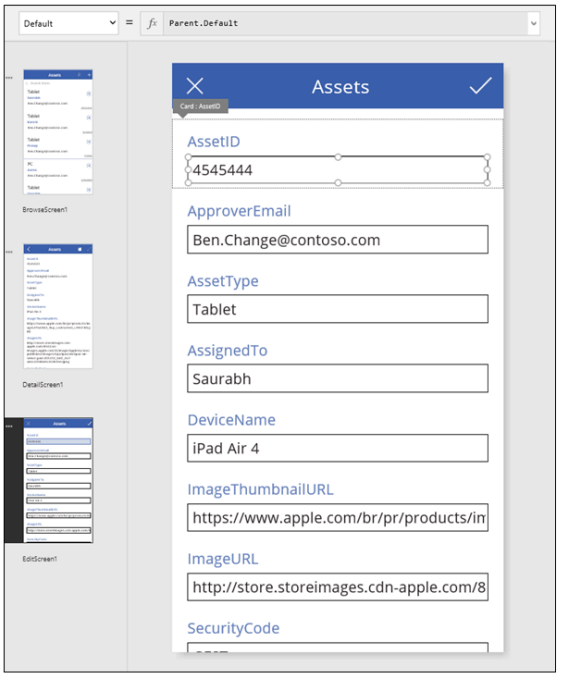
If the user changes one or more values in the form and then selects the "checkmark" icon, the **SubmitForm** function sends the user's changes to the data source.

- If the changes are successfully saved, the form's **OnSuccess** formula runs, and the **Back()** function opens the detail screen to show the updated record.
- If the changes aren't successfully saved, the form's **OnFailure** formula runs, but it doesn't change anything because it's *blank*. The **Edit and Create** screen remains open so that the user can either cancel the changes or fix the error. **LblFormError1** shows a user-friendly error message, to which the form's **Error** property is set.

As with a **Display form** control, an **Edit form** control contains **Card** controls, which contain other controls that show different fields in a record:



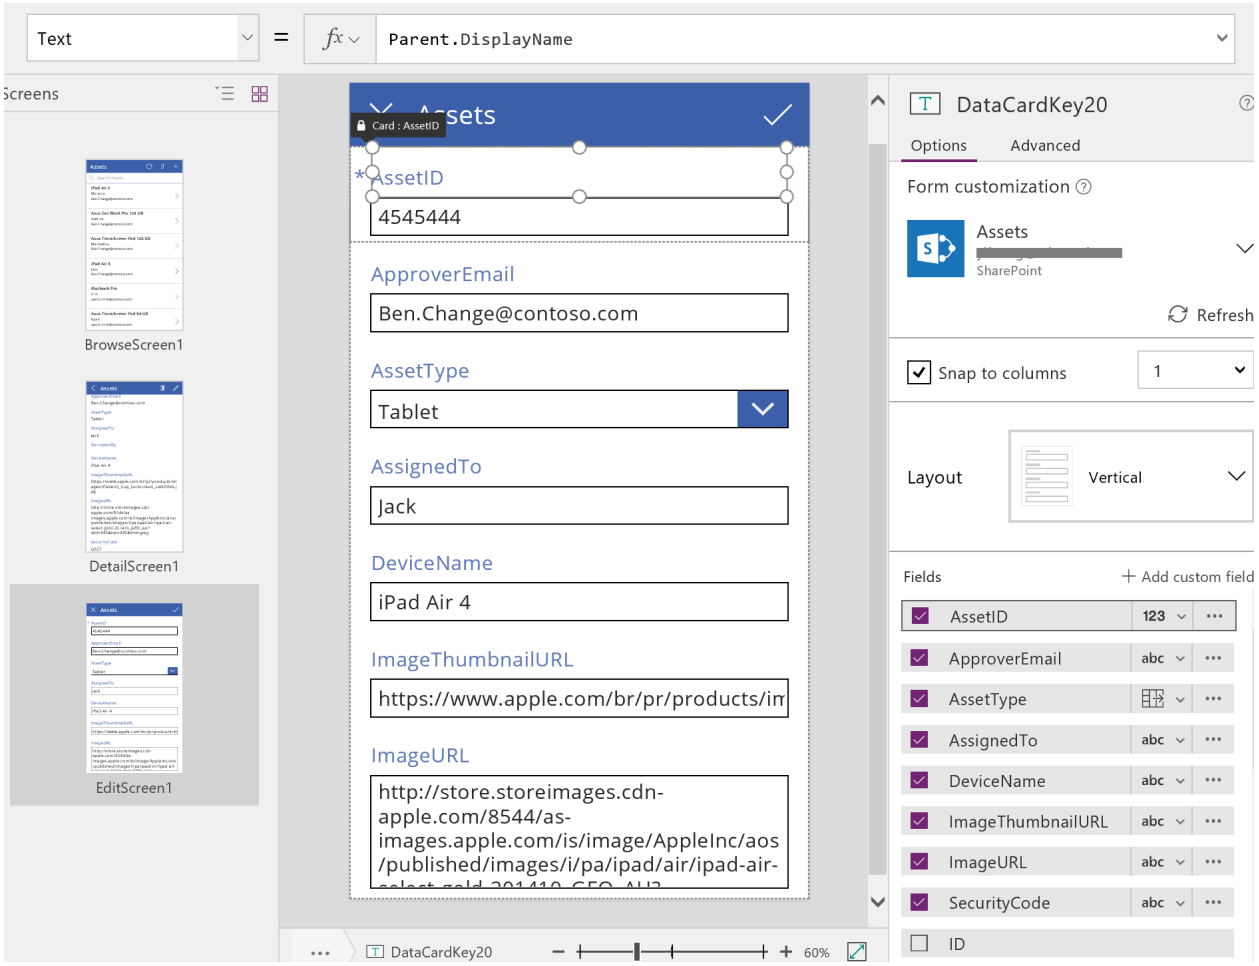
Card selected, used to edit a field of the record



Text input control selected, for editing the field's value

In the previous image, the selected card shows the **AssetID** field and contains a **Text input** control so that the user can edit the value of that field. (In contrast, the detail screen shows the same field in a **Label** control, which is read-only.) The **Text input** control has a **Default** property, which is set to **Parent.Default**. If the user were creating a record instead of editing one, that control would show an initial value that the user can change for the new record.

In the right-hand pane, you can show or hide each card, rearrange them, or configure them to show fields in different types of controls.



Build an app from scratch

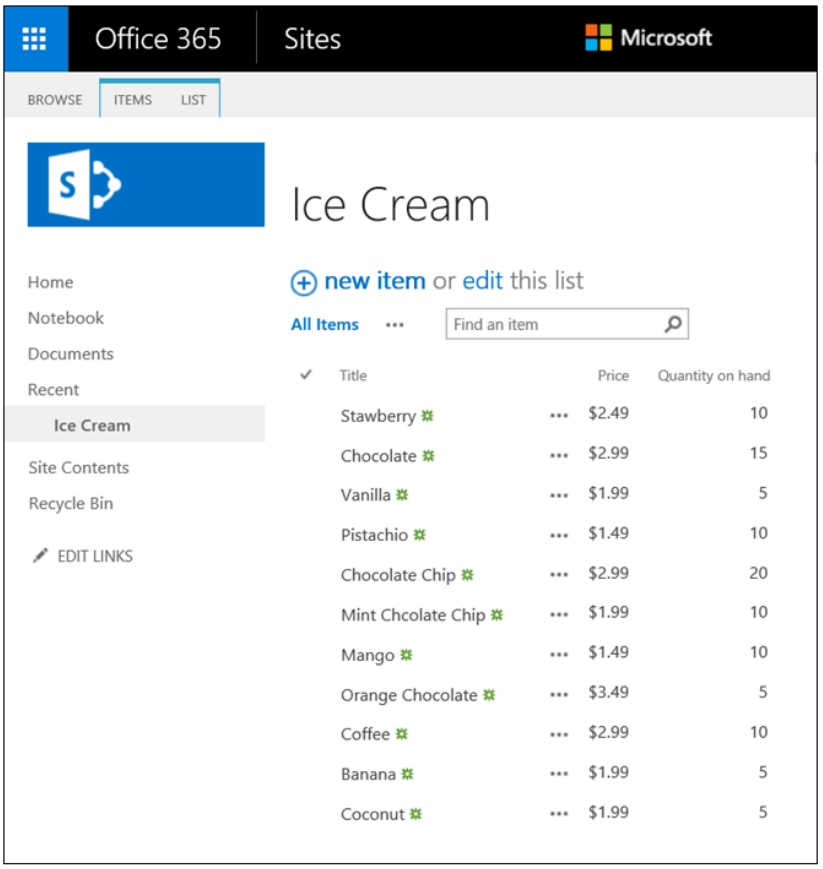
By understanding how Power Apps generates an app, you can build one yourself that uses the same building blocks and formulas discussed earlier in this topic.

Identify test data

To get the most from this topic, start with a data source with which you can experiment. It should contain test data that you can read and update without concern.

> **Note**
>
> If you use a list created using Microsoft Lists, a SharePoint library, or an Excel table that contains column names with spaces as your data source, Power Apps will replace the spaces with "_x0020_". For example, "**Column Name**" in SharePoint or Excel will appear as "**Column_x0020_Name**" in Power Apps when displayed in the data layout or used in a formula.

To follow the rest of this topic exactly, create a list named "Ice Cream" that contains this data:



- Create an app from blank, for phones, and connect it to your data source.

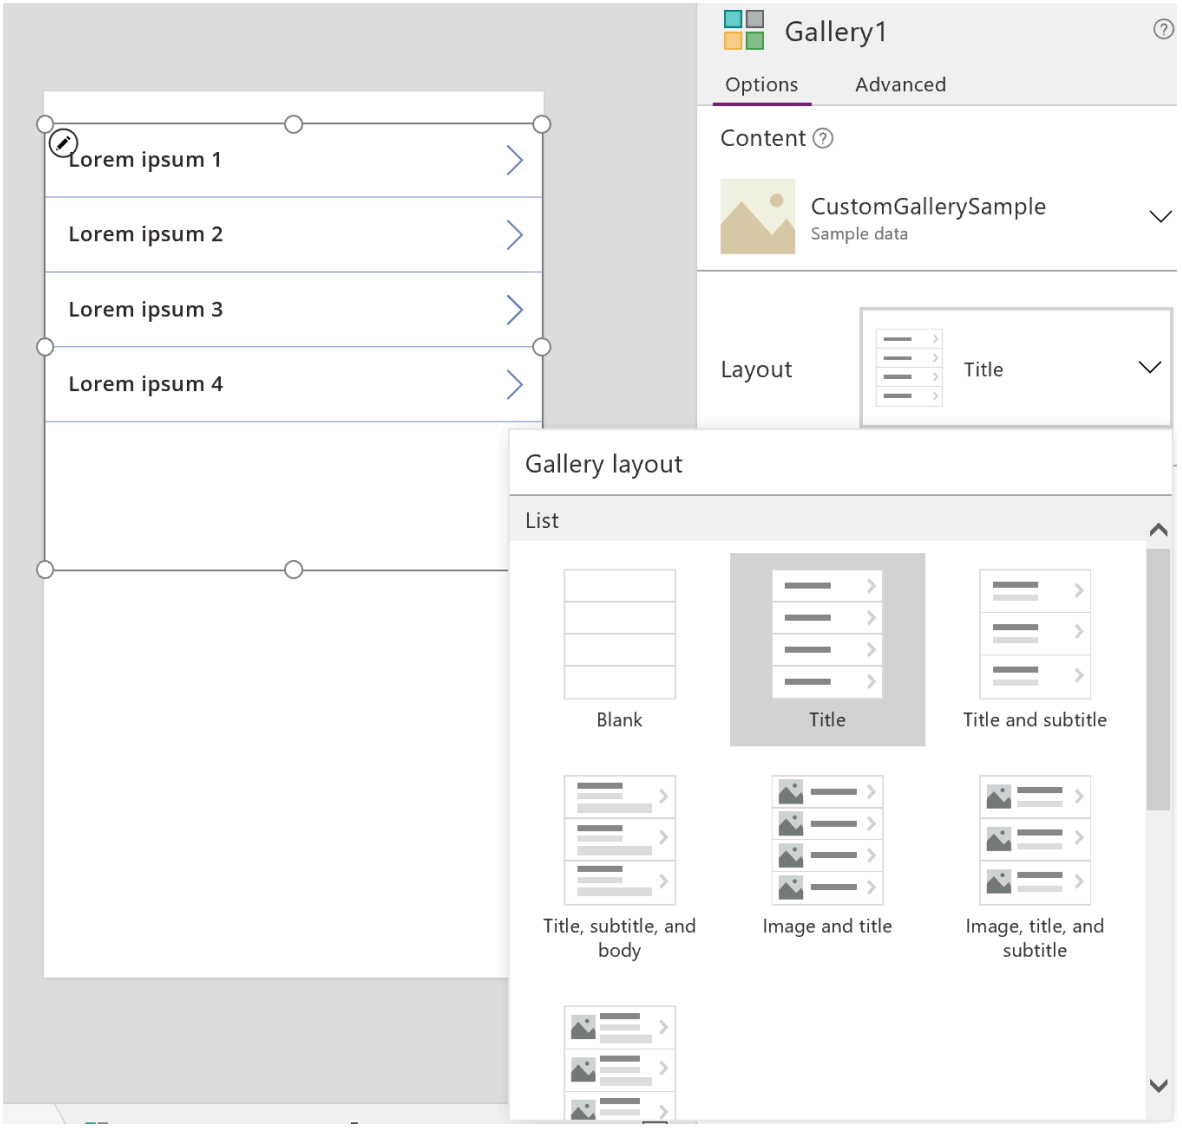
  > **Note**
  >
  > Tablet apps are very similar, but you may want a different screen layout to make the most of the extra screen space.

  The examples in the rest of the topic are based on a data source named **Ice Cream**.

Browse records

Get a quick piece of information from a record by finding it in a gallery on a browse screen.

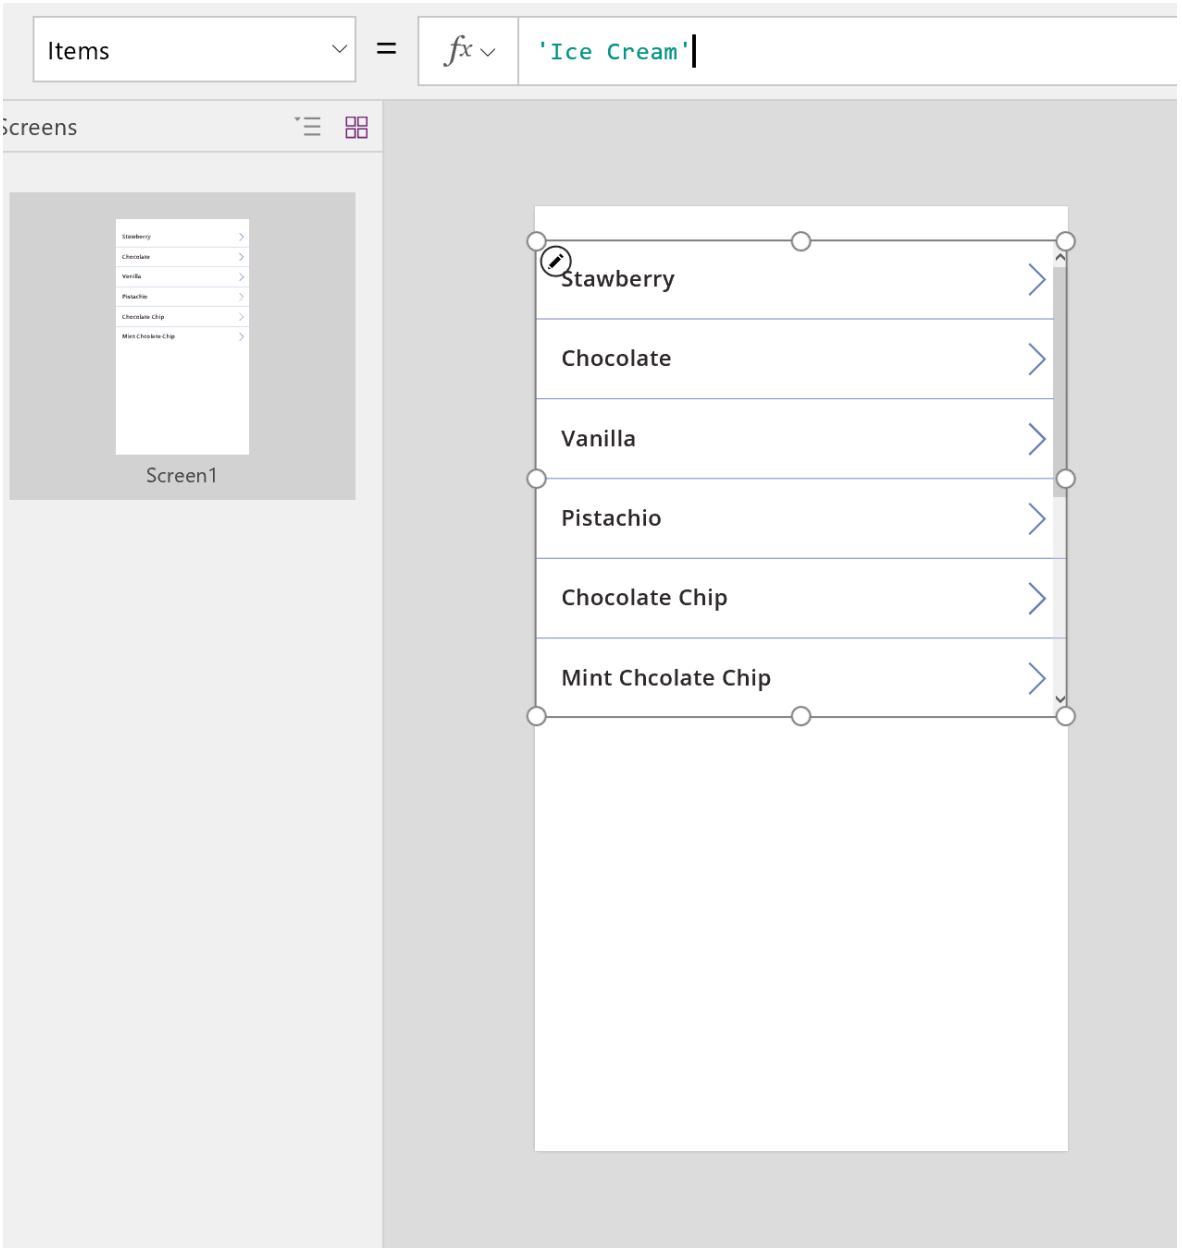
1. Add a **Vertical** gallery, and change the layout to **Title** only.



2. Set the gallery's **Items** property to **Ice Cream**.

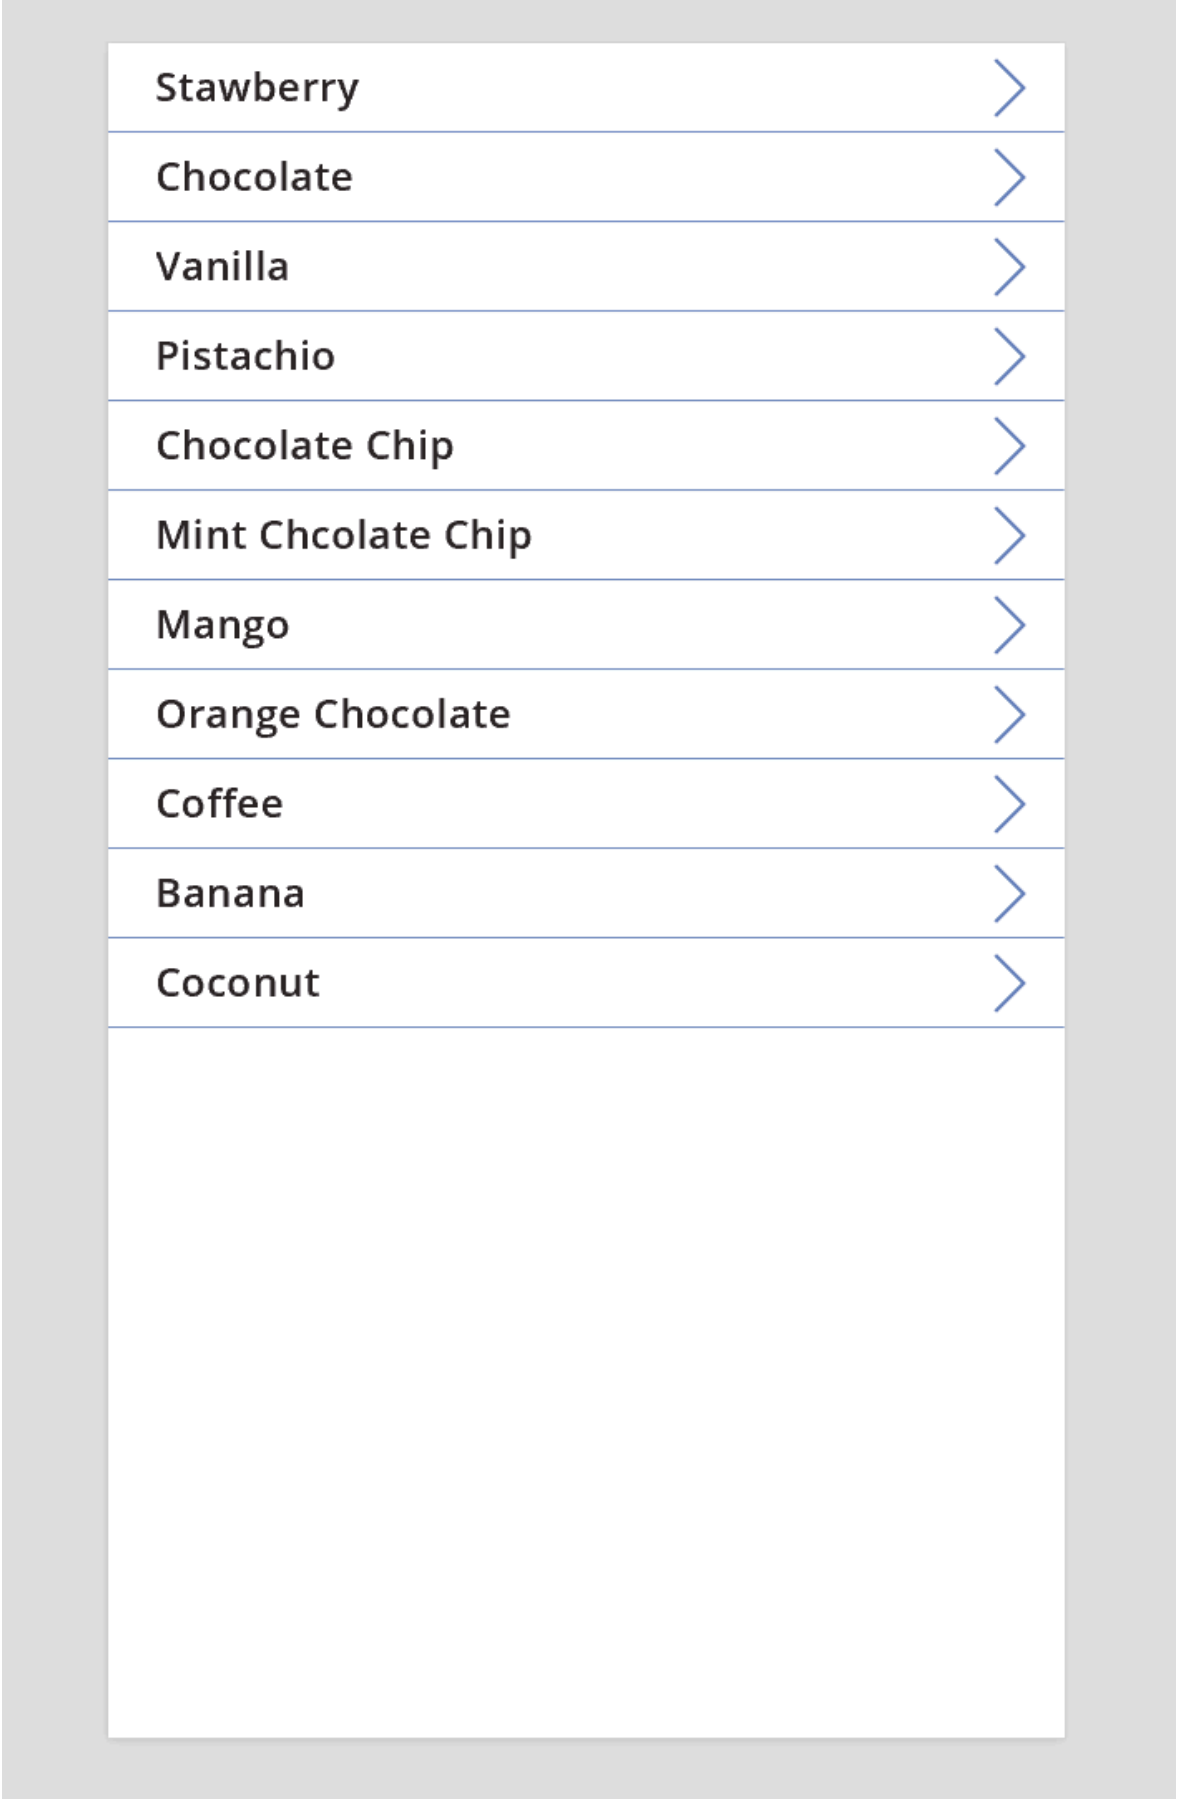
3. Set the **Text** property of the first label in the gallery to **ThisItem.Title** if it's set to something else.

   The label now shows the value in the **Title** field for each record.



4. Resize the gallery to fill the screen, and set its **TemplateSize** property to **60**.

   The screen resembles this example, which shows all records in the data source:



View details

If the gallery doesn't show the information that you want, select the arrow for a record to open the details screen. A Display form control on that screen shows more, possibly

all, fields for the record that you selected.

The **Display form** control uses two properties to display the record:

- **DataSource** property. The name of the data source that holds the record. This property populates the right-hand panel with fields and determines the display name and data type (string, number, date, etc.) of each field.
- **Item** property. The record to display. This property is often connected to the **Selected** property of the **Gallery** control so that the user can select a record in the **Gallery** control and then drill into that record.

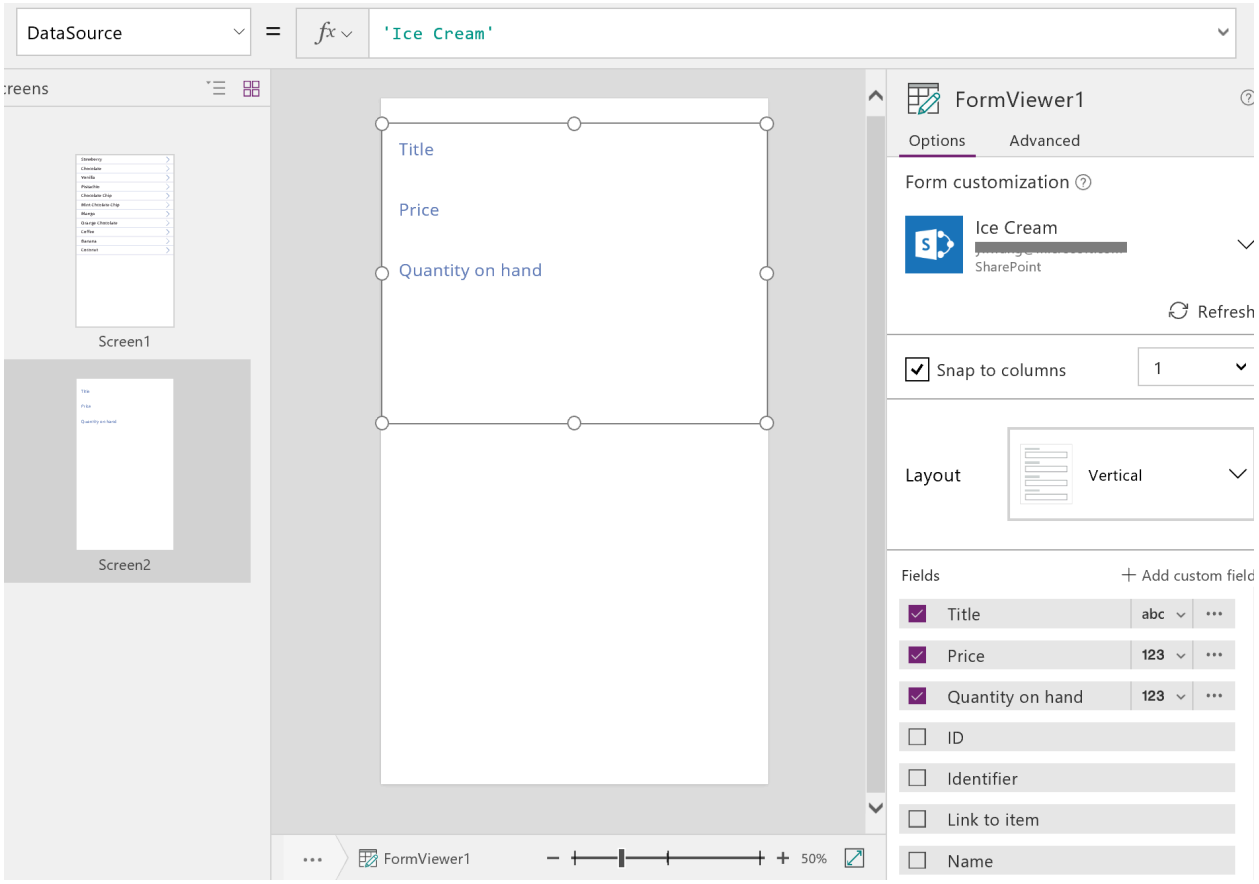
When the **DataSource** property is set, you can add and remove fields through the right-hand pane and change how they're displayed.

On this screen, users can't intentionally or accidentally change any values of the record. The **Display form** control is a read-only control, so it won't modify a record.

To add a **Display form** control:

1. Add a screen, and then add a **Display form** control to it
2. Set the **DataSource** property of the form control to '**Ice Cream**'.

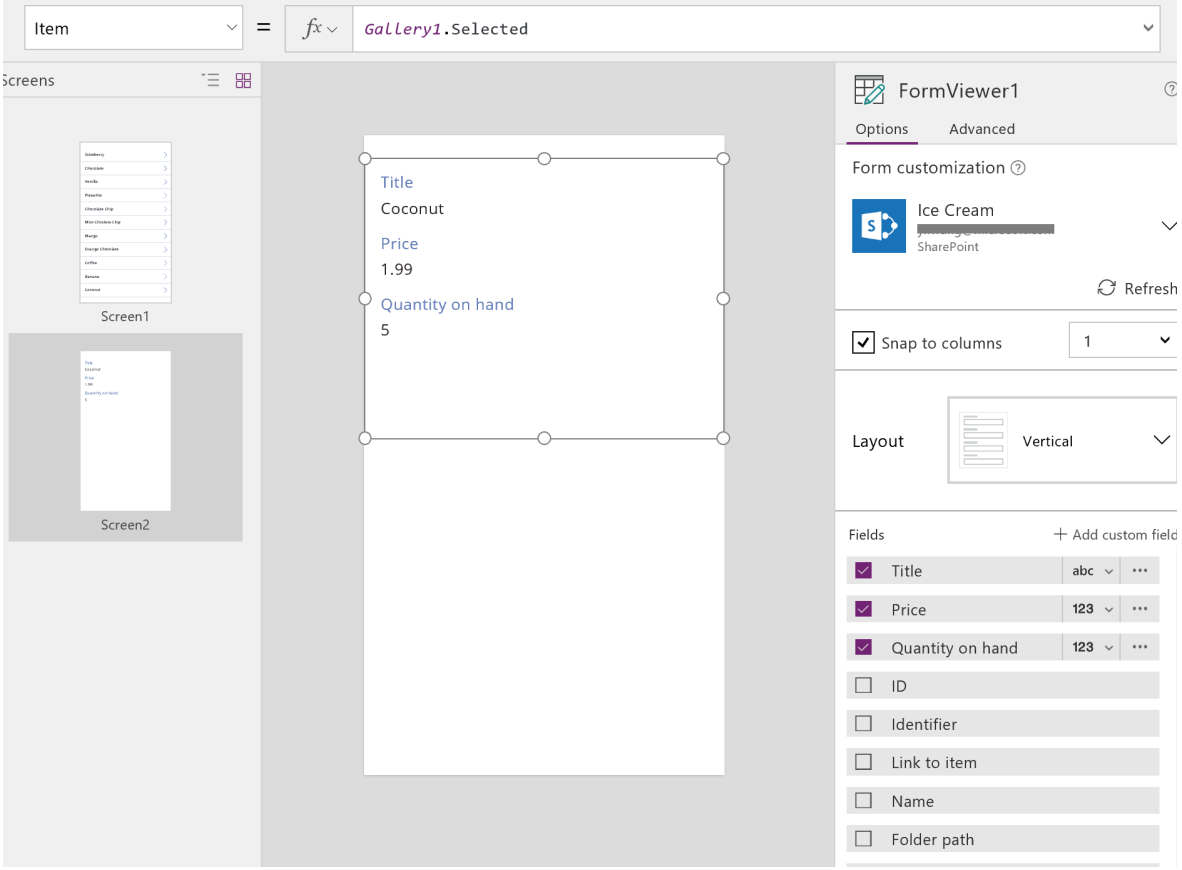
In the right-hand pane, you can select the fields to display on your screen and which type of card to display for each field. As you make changes in the right-hand pane, the **DataField** property on each **Card** control is set to the field that the user will interact with. Your screen should resemble this example:



Finally, we need to connect the **Display form** control to the **Gallery** control so that we can look at details for a specific record. As soon as we complete setting the **Item** property, the first record from the gallery will appear in our form.

- Set the **Item** property of the **Display form** control to **Gallery1.Selected**.

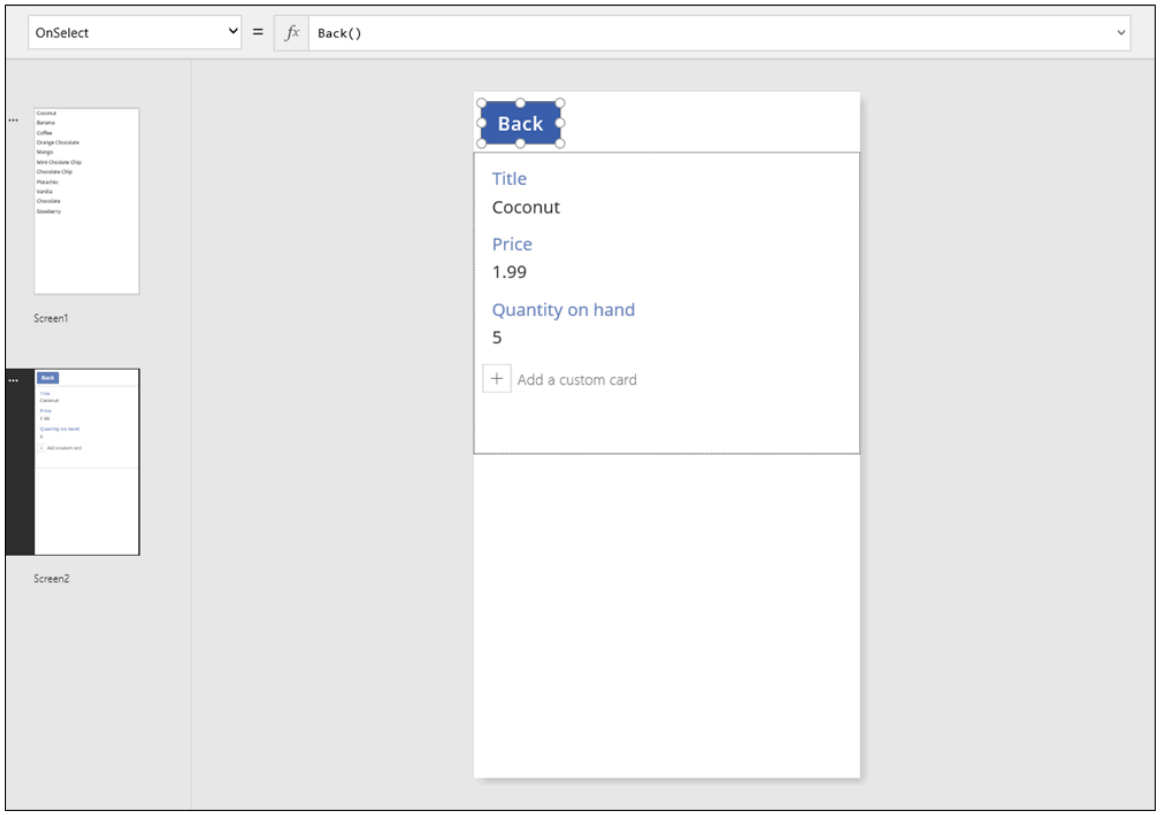
  The details for the selected item appear in the form.



Great! We now turn to navigation: how a user opens the details screen from the gallery screen and opens the gallery screen from the details screen.

- Add a **Button** control to the screen, set its **Text** property to show **Back**, and set its **OnSelect** property to **Back()**.

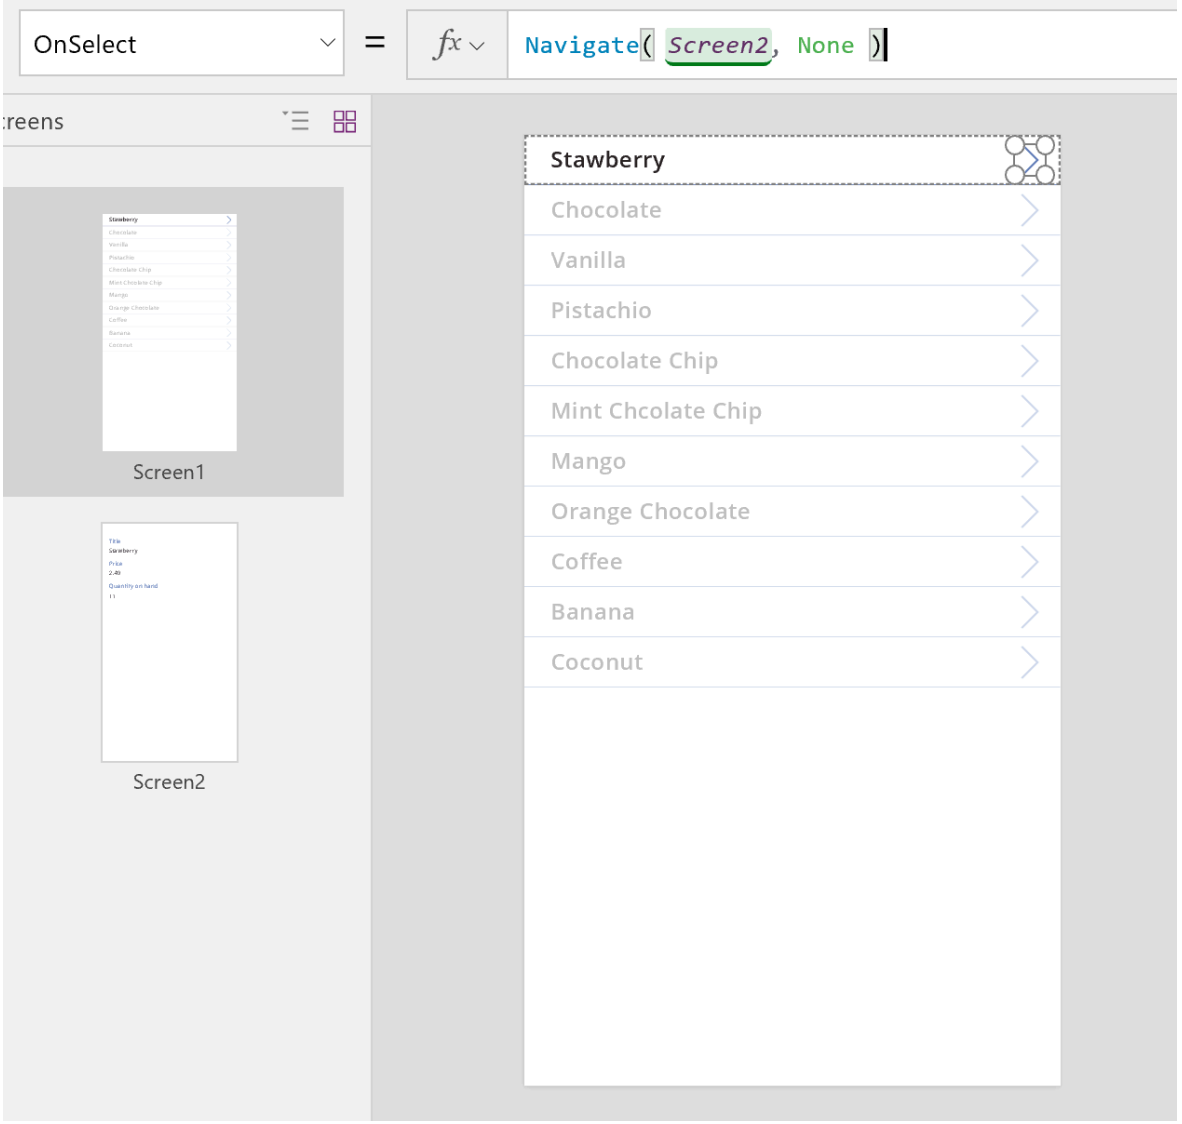
  This formula returns the user back to the gallery when they finish viewing details.



Now, let's return to the **Gallery** control and add some navigation to our detail screen.

1. Switch to the first screen, which is hosting our **Gallery** control, and select the arrow in the first item in the gallery.

2. Set the **OnSelect** property of the shape to this formula:
   Navigate(Screen2, None)



3. Press F5, and then select an arrow in the gallery to show the details for an item.

4. Select the **Back** button to return to the gallery of products, and then press Esc.

Editing details

Finally, our last core activity is changing the contents of a record, which users accomplish in an **Edit form** control.

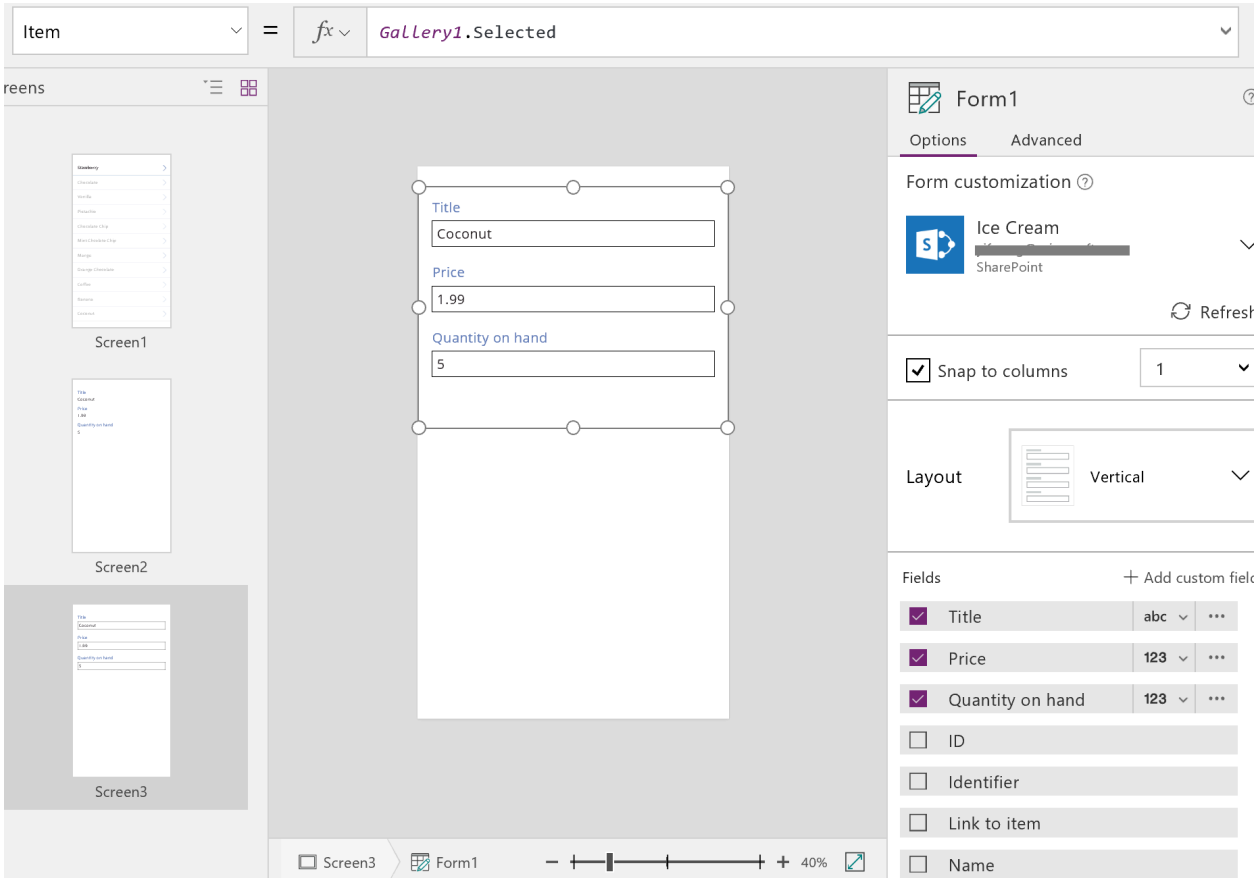
The **Edit form** control uses two properties to display and edit the record:

- **DataSource** property. The name of the data source that holds the record. Just as with the **Display form** control, this property populates the right-hand panel with fields and determines the display name and data type (string, number, date, etc.) for each field. This property also determines whether each field's value is valid before submitting it to the underlying data source.
- **Item** property. The record to edit, which is often connected to the **Selected** property of the **Gallery** control. That way, you can select a record in the **Gallery** control, show it in the details screen, and edit it in the **Edit and Create** screen.

To add an **Edit form** control:

1. Add a screen, add an **Edit form** control, and then set the form's **DataSource** property to '**Ice Cream**'.
2. Set the **Item** property to **Gallery1.Selected**.

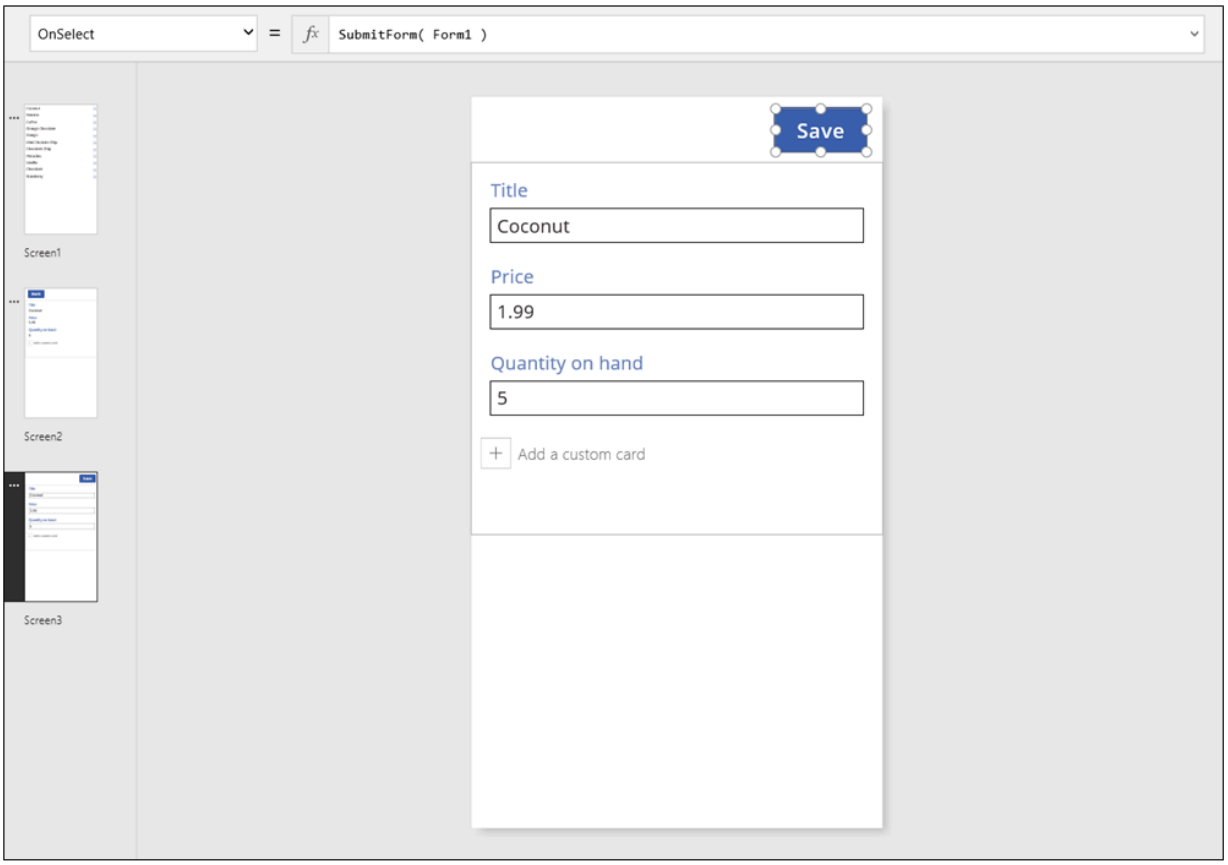
You can now select the fields to display on your screen. You can also select which type of card to display for each field. As you make changes in the right-hand pane, the **DataField** property on each **Card** control is set to the field your user will interact with. Your screen should resemble this example:



These two properties are the same as the properties on the **Display form** control. And with these alone, we can display the details of a record.

The **Edit form** control goes further by offering the **SubmitForm** function to write back changes to the data source. You use this with a button or image control to save a user's changes.

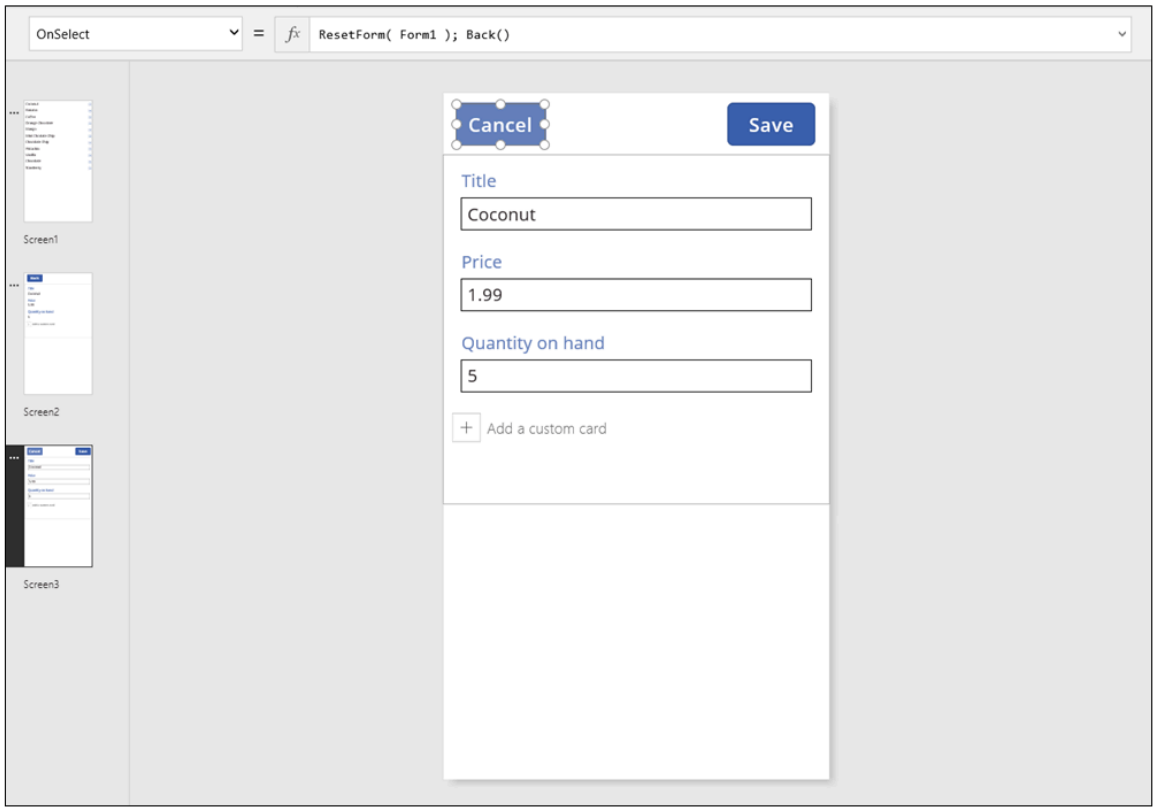
- Add a **Button** control, set its **Text** property to show **Save**, and set its **OnSelect** property to this formula:
  SubmitForm(Form1)



To add navigation to and from this screen:

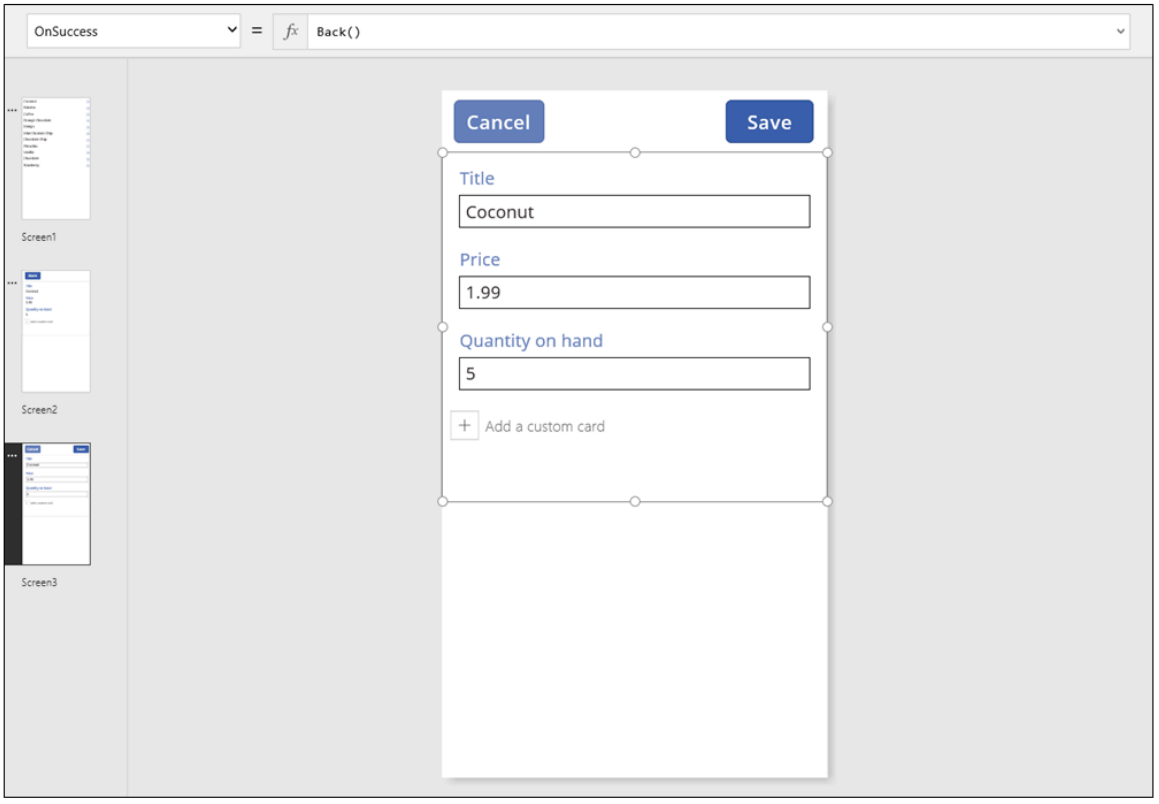
1. Add another **Button** control, set its **Text** property to show **Cancel**, and set its **OnSelect** property to this formula:
   ResetForm(Form1); Back()

   This formula discards any unsaved edits and opens the previous screen.



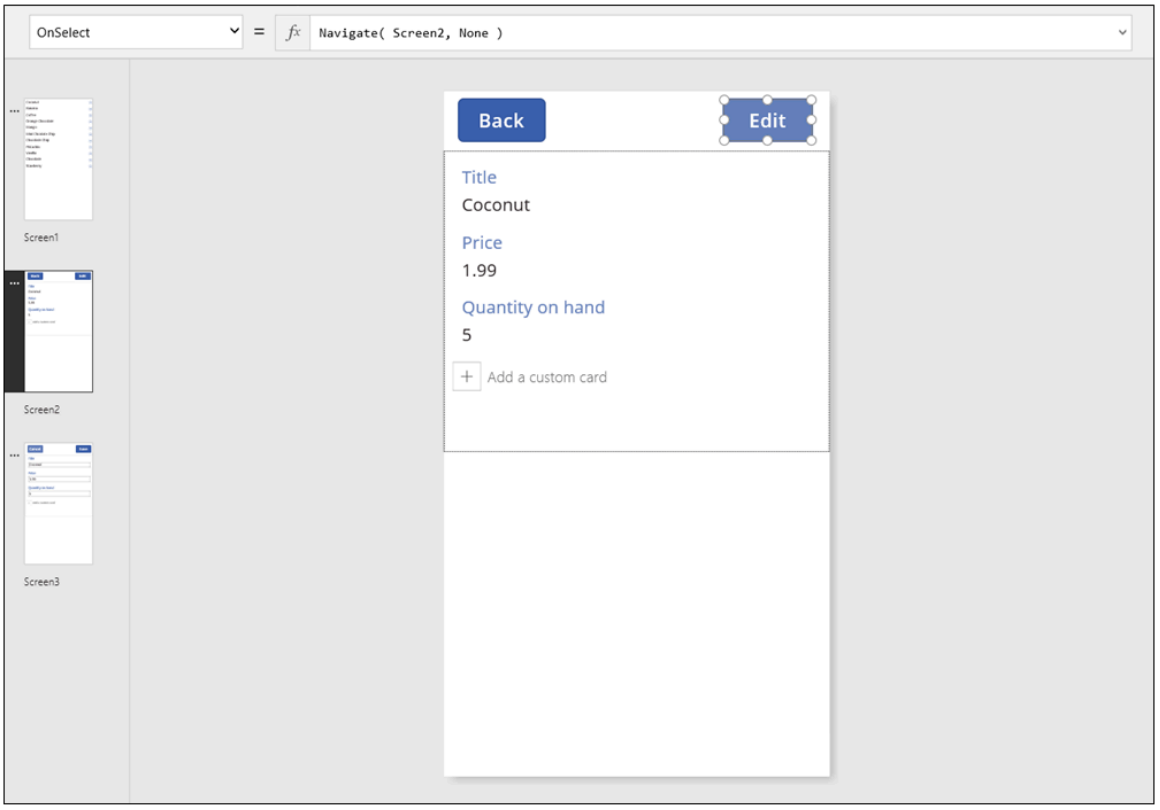
2. Set the **OnSuccess** property of the form to **Back()**.

   When updates are successfully saved, the previous screen (in this case, the details screen) opens automatically.

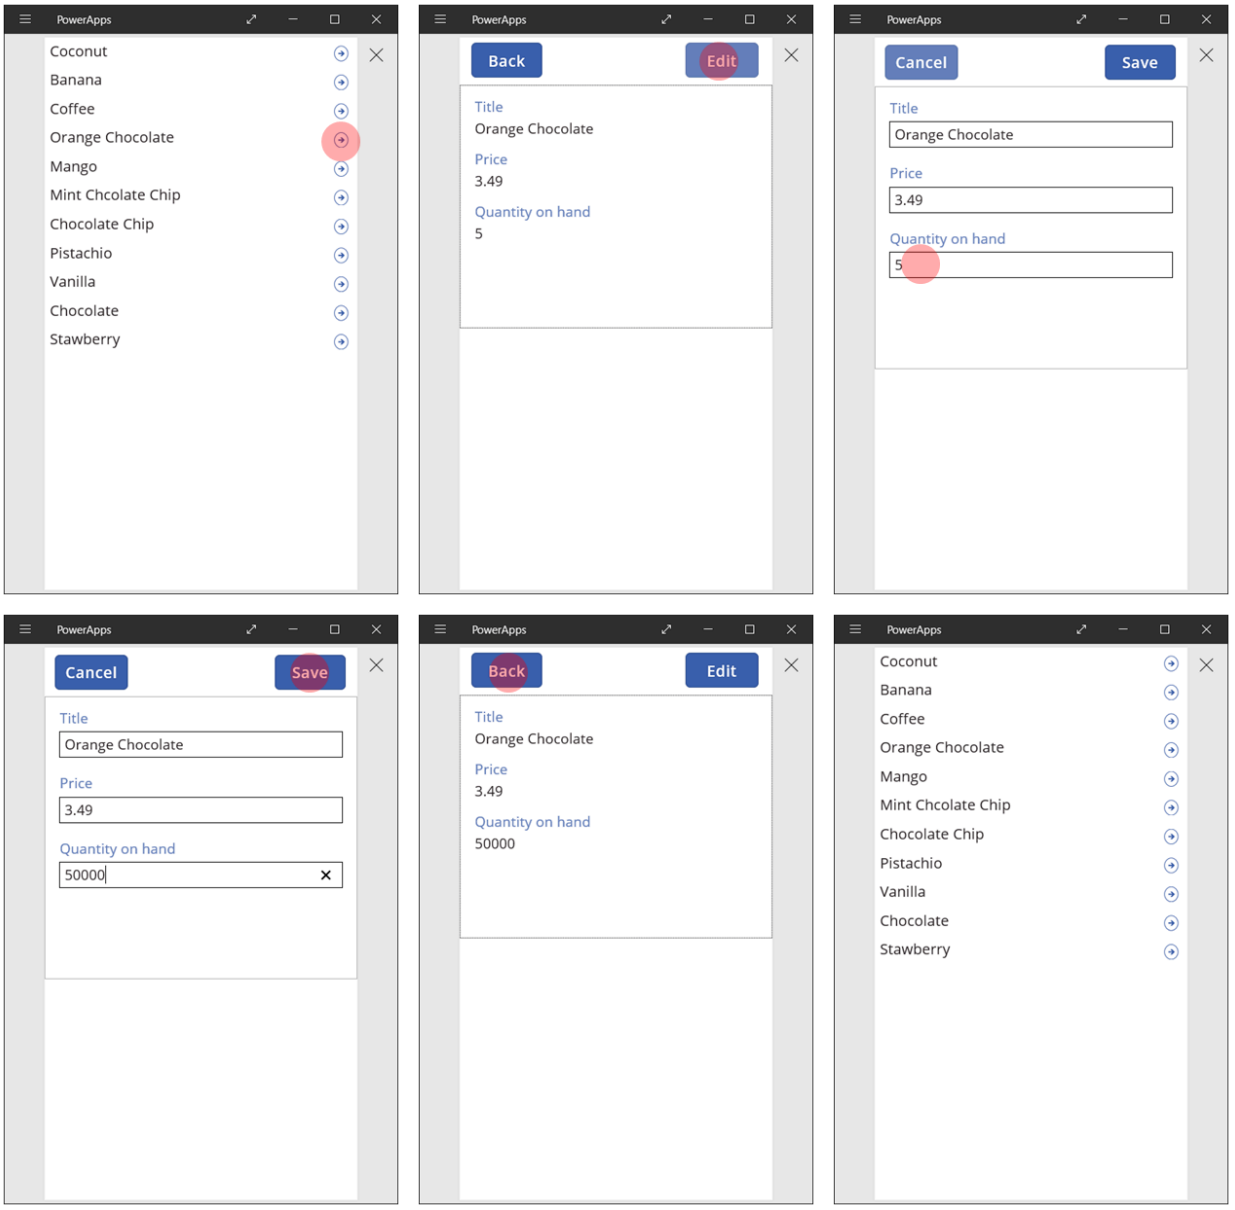


3. On the **Display** screen, add a button, set its **Text** property to show **Edit**, and set its **OnSelect** property to this formula:

Navigate(Screen3, None)



You've built a basic app with three screens for viewing and entering data. To try it out, show the gallery screen, and then press F5 (or select the forward arrow "Preview" button near the upper-left corner of the screen). The pink dot indicates where the user clicks or taps the screen at each step.



Create a record

The user interacts with the same **Edit** form to both update and create records. When the user wants to create a record, the NewForm function switches the form to **New** mode.

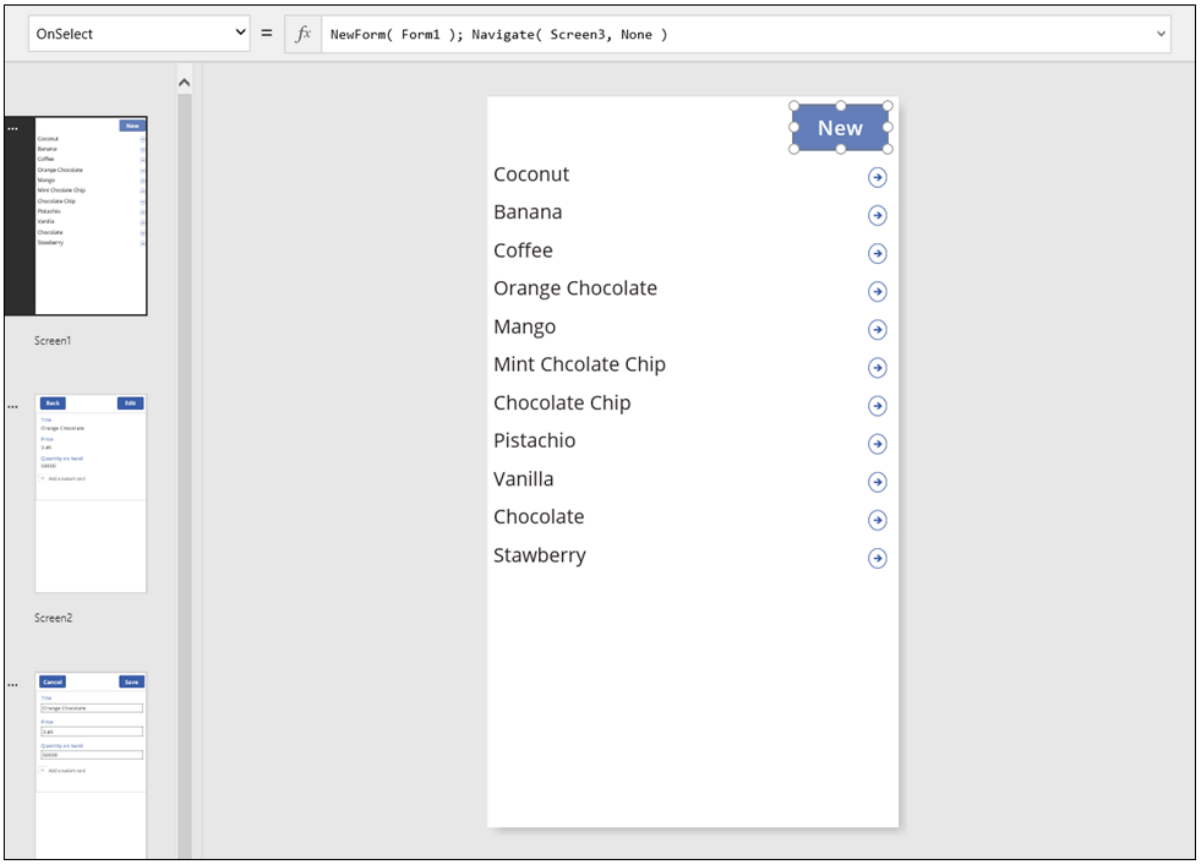
When the form is in **New** mode, the value of each field is set to the defaults of the data source. The record that's provided to the form's Item property is ignored.

When the user is ready to save the new record, SubmitForm runs. After the form is successfully submitted, the form is switched back to **EditMode**.

On the first screen, you'll add a **New** button:

1. On the screen with the gallery, add a Button control.
2. Set the button's Text property to **New** and its OnSelect property to this formula:
   NewForm(Form1); Navigate(Screen3, None)

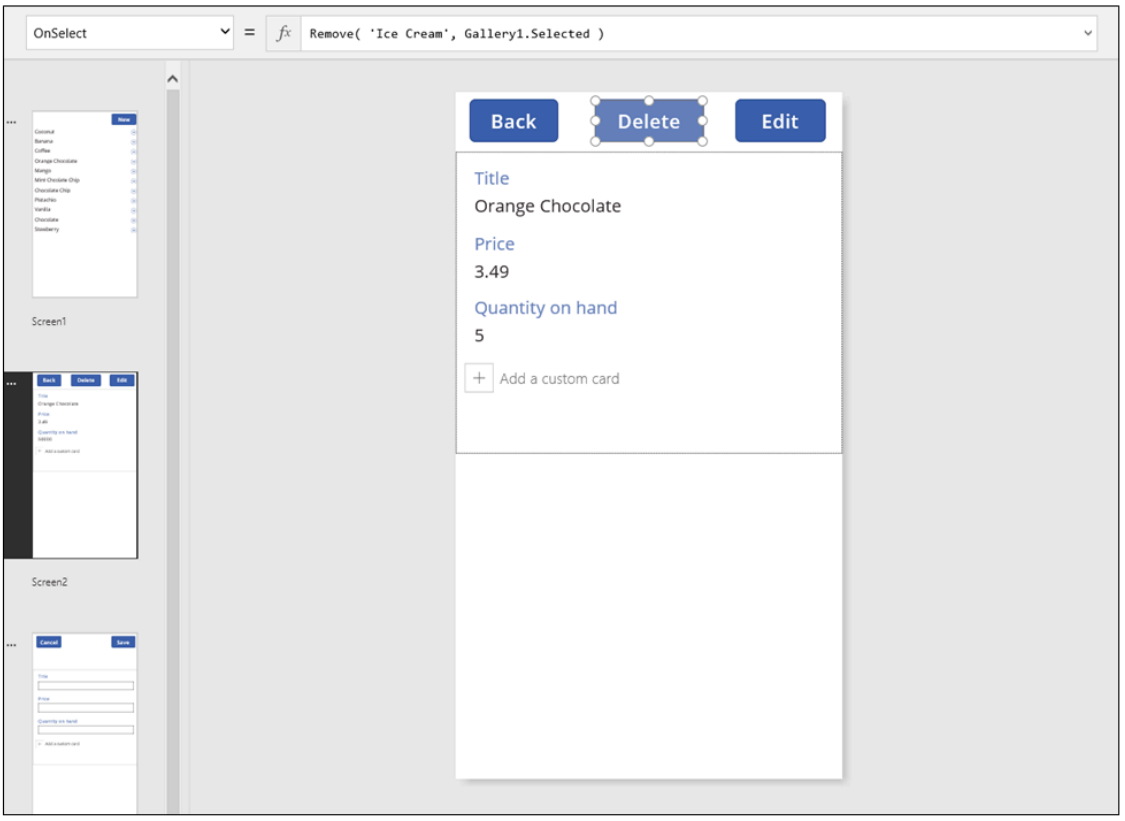
This formula switches the Edit form control on **Screen3** to **New** mode and opens that screen so that the user can fill it in.



When the Edit and Create screen opens, the form is empty, ready for the user to add an item. When the user selects the **Save** button, the SubmitForm function ensures that a record is created instead of being updated. If the user selects the **Cancel** button, the ResetForm function switches the form back to **Edit** mode, and the Back function opens the screen for browsing the gallery.

Delete a record

1. On the **Display** screen, add a button, and set its Text property to show **Delete**..
2. Set the button's OnSelect property to this formula:
   Remove('Ice Cream', Gallery1.Selected); Back()



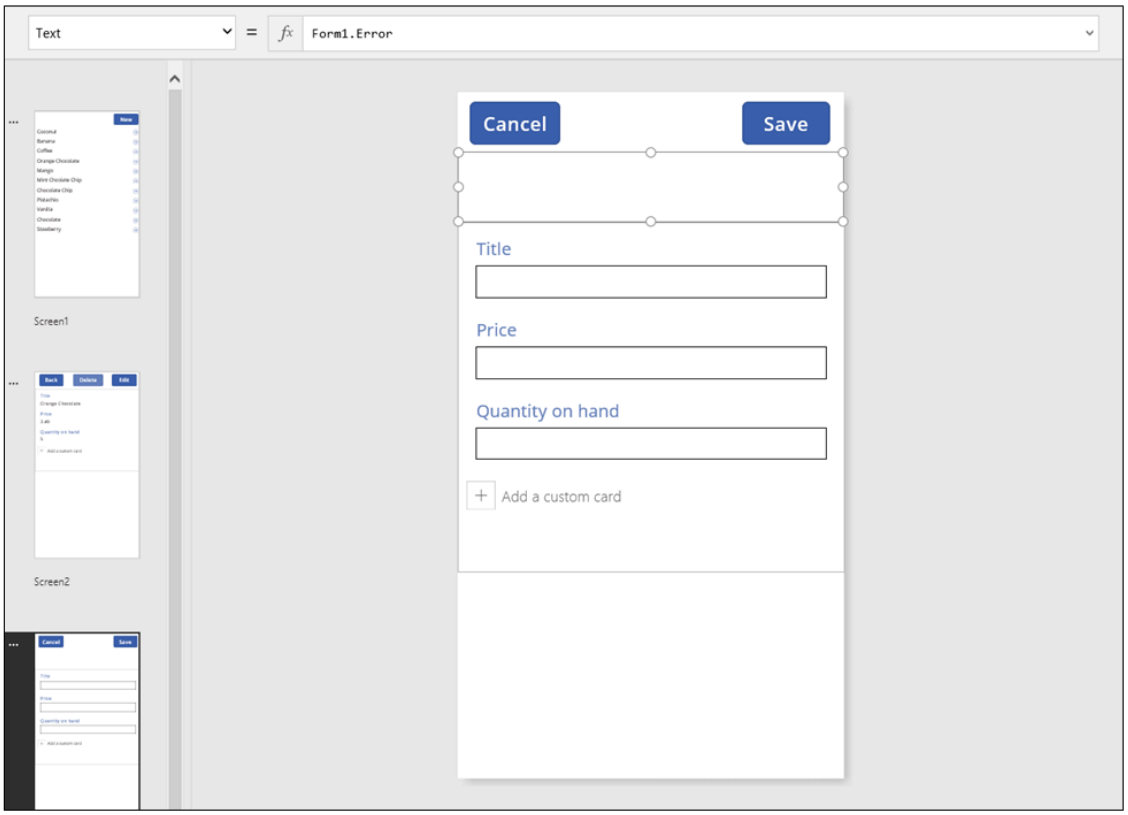
Handling errors

In this app, an error occurs when the value of a field is not valid, a required field is blank, you're disconnected from the network, or any number of other problems pop up.

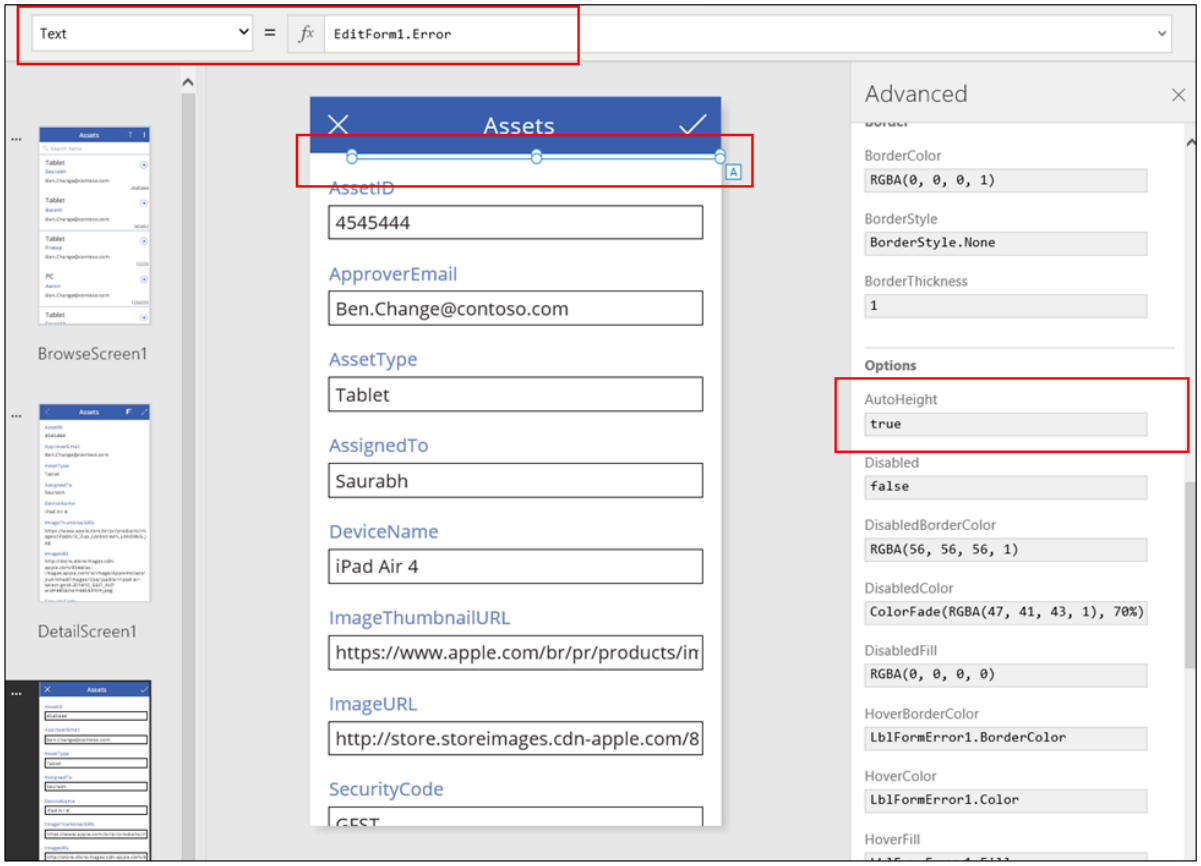
If **SubmitForm** fails for any reason, the **Error** property of the **Edit form** control contains an error message to show the user. With this information, the user should be able to correct the issue and resubmit the change, or they can cancel the update.

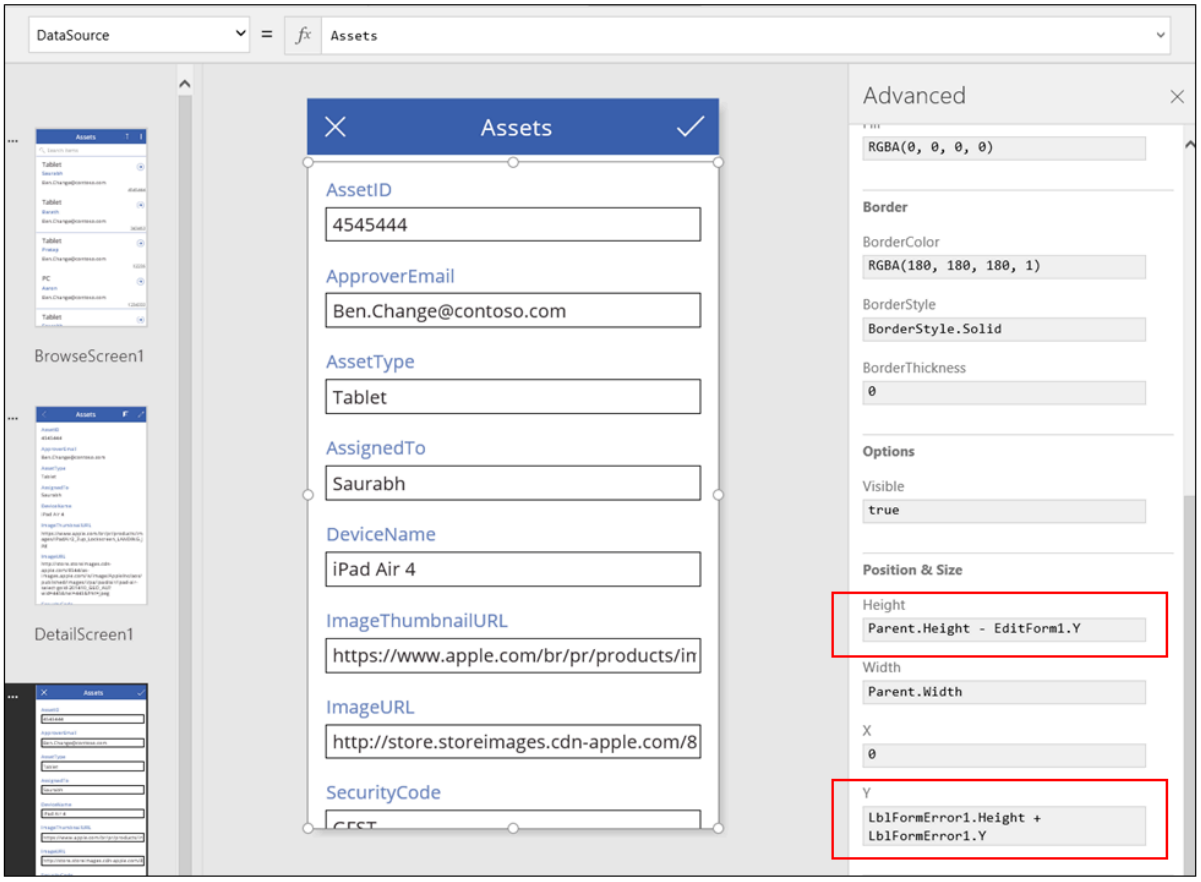
1. On the Edit and Create screen, add a **Label** control, and move it just below the **Save** button. Any error will be easy to see after the user selects this control to save changes.

2. Set the **Text** property of the **Label** control to show **Form1.Error**.



In an app that Power Apps generates from data, the **AutoHeight** property on this control is set to *true* so that no space is consumed if no error occurs. The **Height** and **Y** properties of the **Edit form** control are also adjusted dynamically to account for this control growing when an error occurs. For more details, generate an app from existing data, and inspect these properties. The text-box control for errors is very short when no error has occurred, you may need to open the **Advanced** view (available on the **View** tab) to select this control.



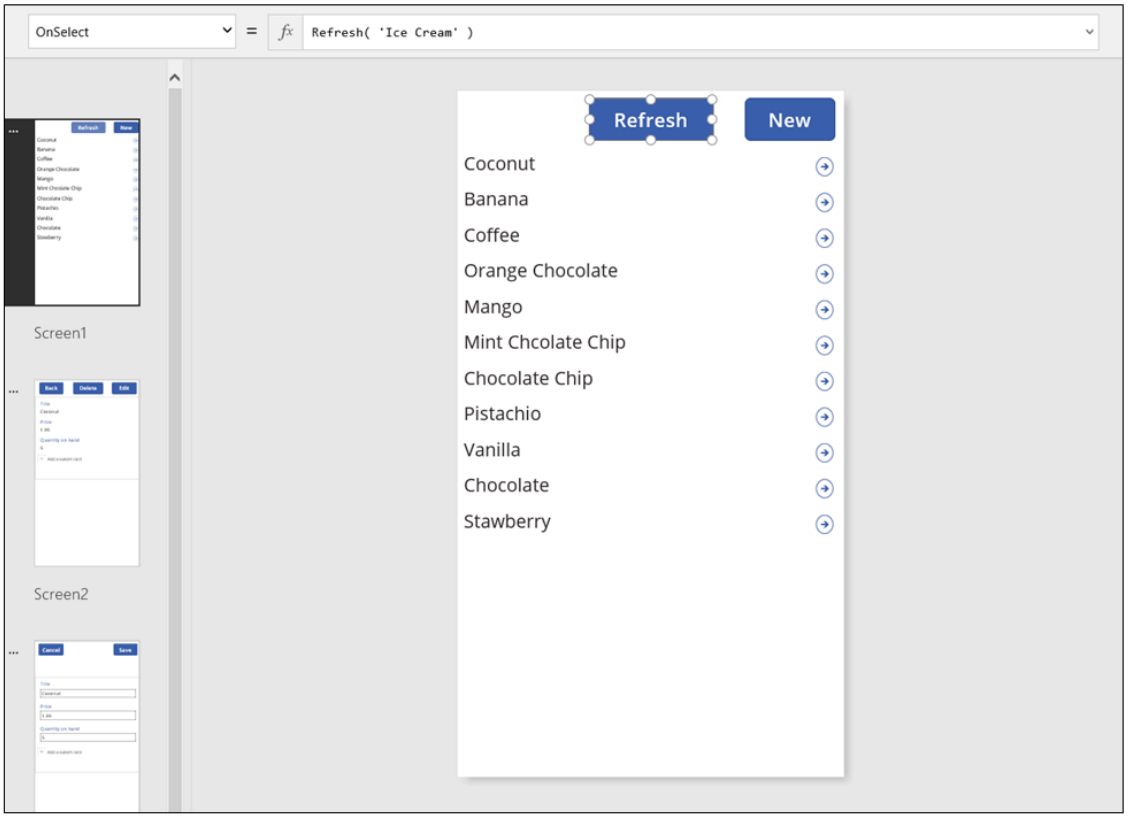


Refresh data

The data source is refreshed whenever the user opens the app, but the user might want to refresh the records in the gallery without closing the app. Add a **Refresh** button so that the user can select it to manually refresh the data:

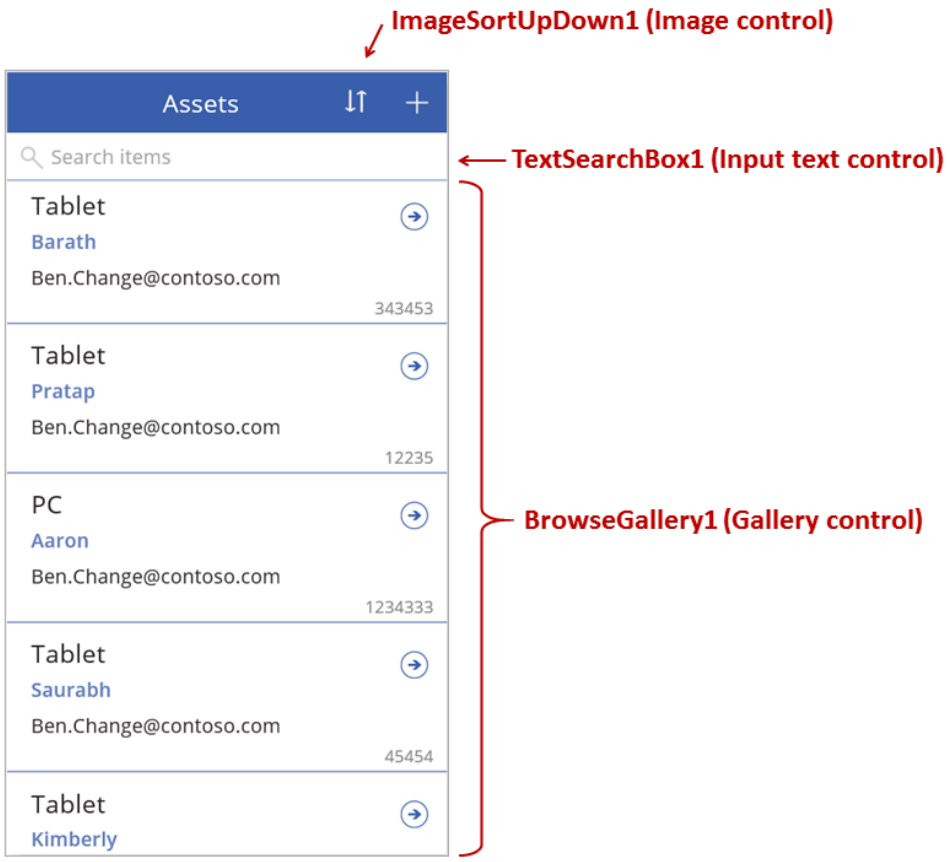
1. On the screen with the **Gallery** control, add a **Button** control and set its **Text** property to show **Refresh**.

2. Set the **OnSelect** property of this control to this formula:
   Refresh('Ice Cream')



Search and sort the gallery

In the app that Power Apps generated from data, we neglected to discuss two controls at the top of the Browse screen. By using these controls, the user can search for one or more records, sort the list of records in ascending or descending order, or both.



When the user selects the sort button, the sort order of the gallery reverses. To create this behavior, we use a *context variable* to track the direction in which the gallery is sorted. When the user selects the button, the variable is updated, and the direction reverses. The OnSelect property of the sort button is set to this formula:
UpdateContext({SortDescending1: !SortDescending1})

The UpdateContext function creates the **SortDescending1** context variable if it doesn't already exist. The function will read the value of the variable and set it to the logical opposite by using the **!** operator. If the value is *true*, it becomes *false*. If the value is *false*, it becomes *true*.

The formula for the Items property of the Gallery control uses this context variable, along with the text in the **TextSearchBox1** control:

Power Fx

```
Sort(
    If( IsBlank(TextSearchBox1.Text),
        Assets,
        Filter( Assets, TextSearchBox1.Text in Text(ApproverEmail) )
    ),
    ApproverEmail,
    If(SortDescending1, Descending, Ascending)
)
```

Let's break this down:

- On the outside, we have the **Sort** function, which takes three arguments: a table, a field on which to sort, and the direction in which to sort.
  - The sort direction is taken from the context variable that toggles when the user selects the **ImageSortUpDown1** control. The *true/false* value is translated to the constants **Descending** and **Ascending**.
  - The field to sort on is fixed to **ApproverEmail**. If you change the fields that appear in the gallery, you'll need to change this argument too.

- On the inside, we have the **Filter** function, which takes a table as an argument and an expression to evaluate for each record.
  - The table is the raw **Assets** data source, which is the starting point before filtering or sorting.
  - The expression searches for an instance of the string in **TextSearchBox1** within the **ApproverEmail** field. Again, if you change the fields that appear in the gallery, you'll also need to update this argument.
  - If **TextSearchBox1** is empty, the user wants to show all records, and the **Filter** function is bypassed.

This is but one example; you can craft your own formula for the **Items** property, depending on the needs of your app, by composing **Filter**, **Sort**, and other functions and operators together.

Screen design

So far, we haven't discussed other ways to distribute controls across screens. That's because you have many options, and the best selection depends on your specific app's needs.

Because real estate on phone screens is so limited, you probably want to browse, display, and edit/create on different screens. In this topic, the **Navigate** and **Back** functions open each screen.

On a tablet, you can browse, display, and edit/create on two or even one screen. For the latter, no **Navigate** or **Back** function would be required.

If the user is working on the same screen, you need to be careful that the user can't change the selection in the **Gallery** and potentially lose edits in the **Edit form** control. To keep the user from selecting a different record when changes to another record haven't been saved yet, set the **Disabled** property of the gallery to this formula:
EditForm.Unsaved

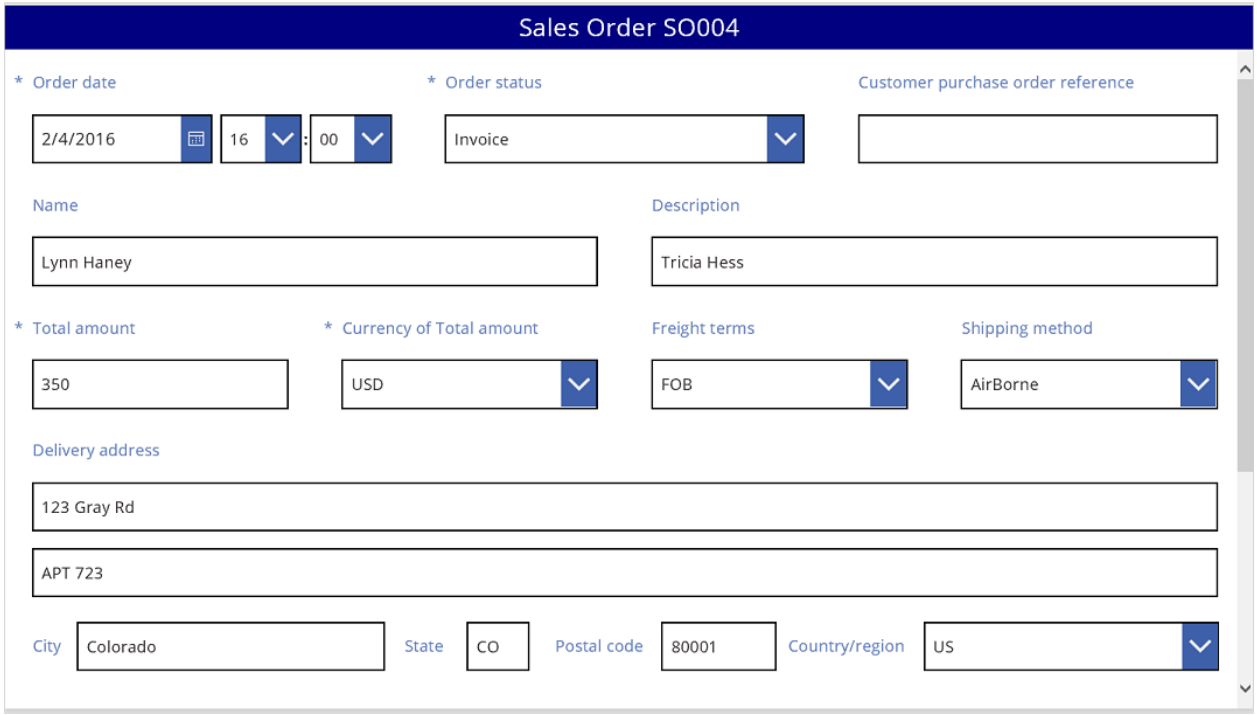
Understand data-form layout for canvas apps

Article • 12/16/2022

Easily create an attractive and efficient form when you build a canvas app in Power Apps. For example, consider this basic form for recording sales orders:



In this tutorial, we'll walk through the steps to create this form. We'll also look at some advanced topics, such as dynamic sizing of fields to fill available space.

Before you start

If you're new to Power Apps (or have only generated apps automatically), you'll want to build an app from scratch before you dive into this article. By building an app from scratch, you'll become familiar with required concepts, such as adding data sources and controls, that are mentioned but not explained in this article.

This article is written as though you have a data source that's named **Sales order** and that contains the fields in the previous graphic. If you have a Power Apps per user, per app, or trial license and system administrator or system customizer permissions, you can create a table in Microsoft Dataverse and add similar fields.

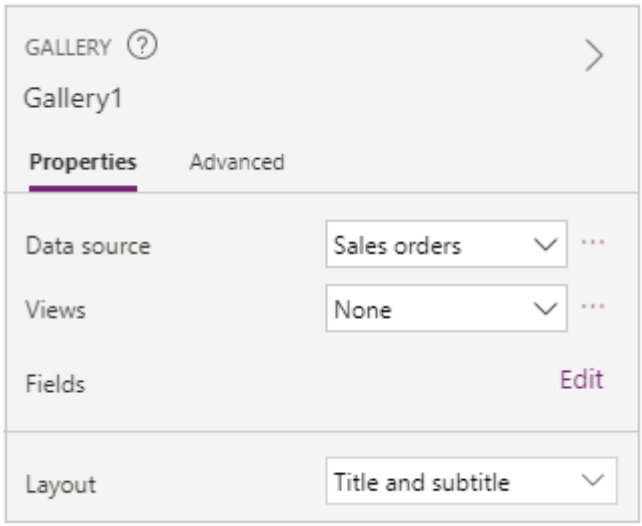
Add a gallery

1. Create a tablet app from scratch, and add your data source.

   Everything discussed in this article also applies to phone layouts, but phone apps often have only one vertical column.

2. Add a vertical **Gallery** control, and set its **Items** property to '**Sales order**'.

   (optional) To match the examples in this tutorial, change the gallery's **Layout** to show only **Title and subtitle**.



3. In the gallery, click or tap **SO004**.

   This record will appear in the form that you build by following steps later in this article.

Add a title bar

1. Add a blank screen where you'll put the form.

   Outside of this tutorial, you can put the **Gallery** and **Edit form** controls on the same screen, but you'll have more room to work with if you put them on separate

screens.

2. At the top of the new screen, add a **Label** control, and set its **Text** property to this expression:
   "Sales Order " & Gallery1.Selected.SalesOrderId

   The label shows the sales-order number of the record that you selected in the gallery.

3. (optional) Format the label as follows:

   a. Set its **Align** property to **Center**.

   b. Set its **Size** property to **20**.

   c. Set its **Fill** property to **Navy**.

   d. Set its **Color** property to **White**.

   e. Set its **Width** property to **Parent.Width**.

   f. Set its **X** and **Y** properties to **0**.

Add a form

1. Add an **Edit form** control, and then move and resize it to fill the screen under the label.

   In the next step, you'll connect the form control to the **Sales order** data source by using the right-hand pane, not the formula bar. If you use the formula bar, the form won't show any fields by default. You can always show any fields that you want by selecting one or more check boxes in the right-hand pane.

2. In the right-hand pane, click or tap the down arrow next to **No data source selected**, and then click or tap **Sales order**.

   A default set of fields from the **Sales order** data source will appear in a simple, three-column layout. However, many are blank, and they may take a few moments to settle into their final positions.

3. Set the form's **Item** property to **Gallery1.Selected**.

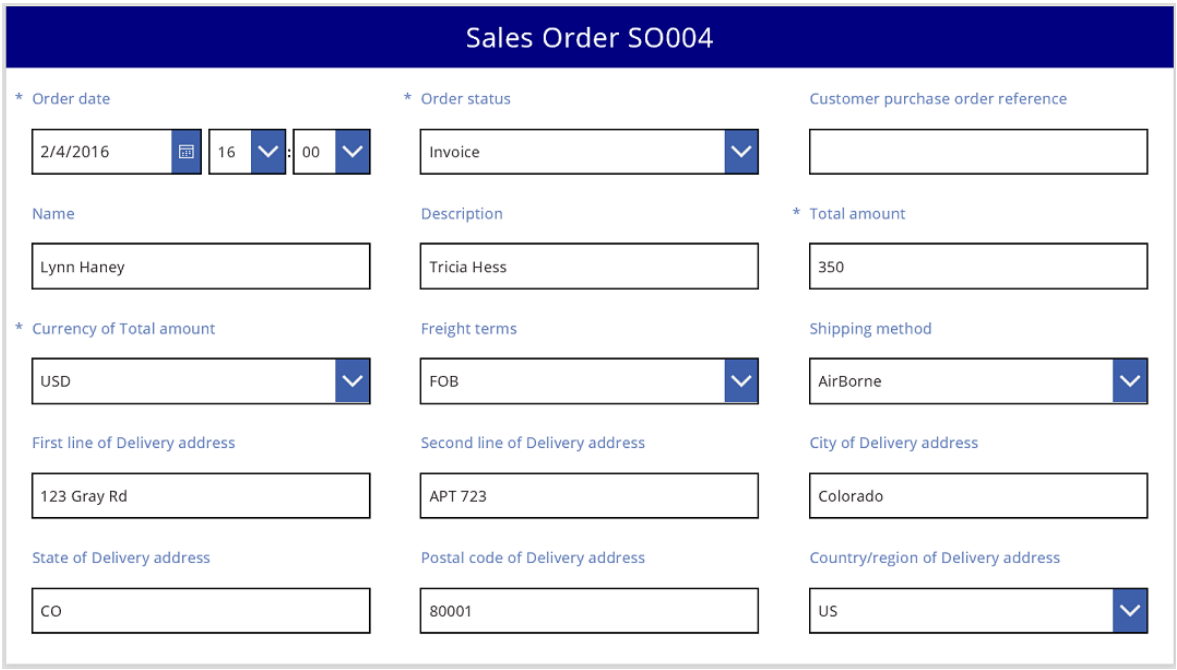
The form shows the record that you selected in the gallery, but the default set of fields might not match what you want in your final product.

4. In the right-hand pane, hide each of these fields by clearing its checkbox:

   - **Sales order ID**
   - **Account**
   - **Sales person**
   - **Account contact**

5. Move the **Order status** field by dragging it to the left and then dropping it on the other side of the **Customer purchase order reference** field.

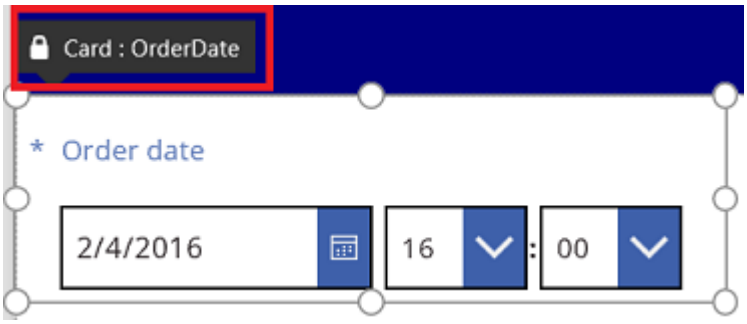
   Your screen should resemble this example:



Select a data card

Each field displayed has a corresponding data card on the form. This card includes a set of controls for the field title, an input box, a star (which appears if the field is required), and a validation error message.

You can also select cards directly on the form. When a card is selected, a black caption appears above it.

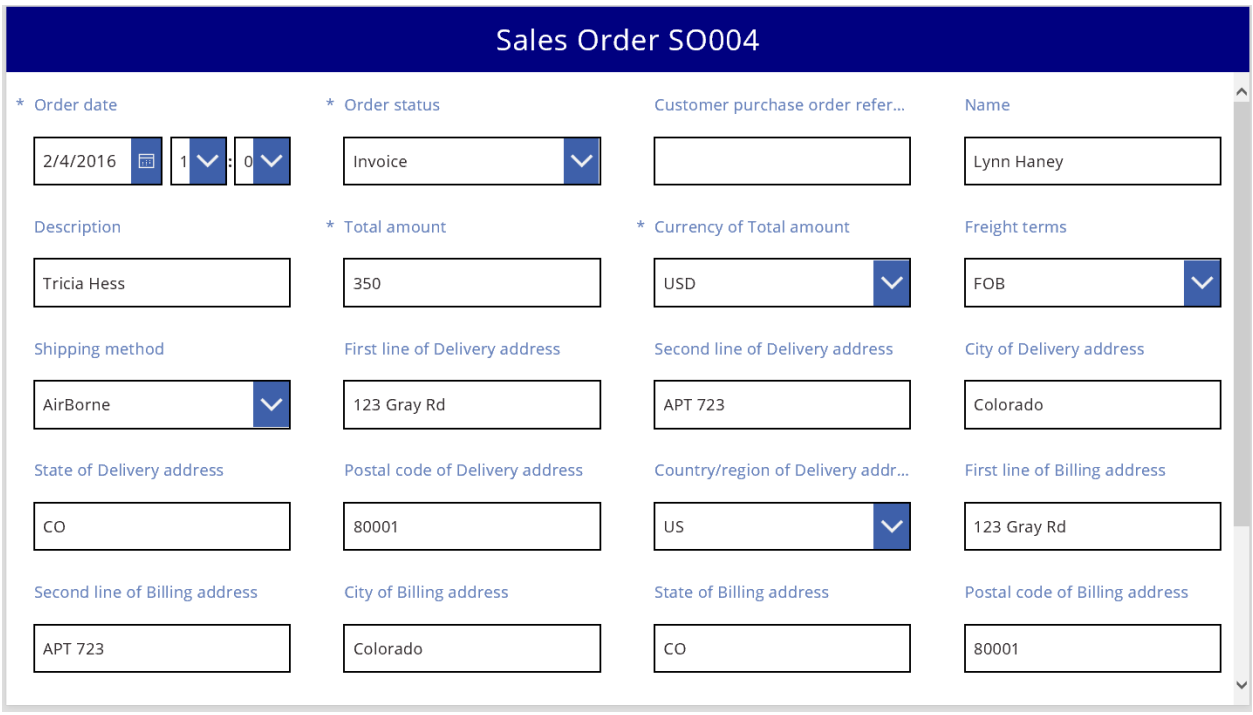


> **Note**
>
> To delete a card (not just hide it), select it, and then press Delete.

Arrange cards in columns

By default, forms in tablet apps have three columns, and in phone apps have one. You can specify not only how many columns a form has but also whether all cards should fit within column borders.

In this graphic, the number of columns in the form was changed from three to four with the **Snap to columns** check box selected. The cards in the form were arranged automatically to fit the new layout.



Resize cards across multiple columns

Depending on the data in each card, you might want some cards to fit in a single column and other cards to span multiple columns. If a card contains more data than you

want to show in a single column, you can widen the card by selecting it and then dragging the grab handle on the left or right border of its selection box. As you drag the handle, the card will "snap" to column boundaries.

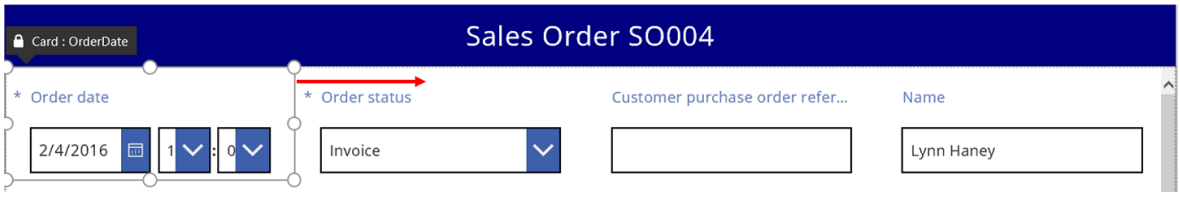
To make your design more flexible but keep some structure, you can increase the number of columns to 12. With that change, you can easily configure each card to span the entire form, half of the form, one-third, one-quarter, one-sixth, and so forth. Let's see this in action.

1. In the right-hand pane, set the number of columns in the form to **12**.

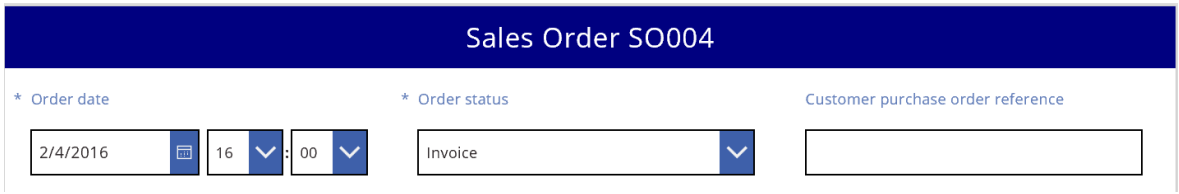
   The form doesn't visibly change, but you have more snap points as you drag the left or right grab handle.

2. Increase the width of the **Order date** card by dragging the grab handle on the right one snap point to the right.

   The card spans four of the form's 12 columns (or 1/3 of the form), instead of only three of the form's 12 columns (or 1/4 of the form). Whenever you increase a card's width by one snap point, the card spans an additional 1/12 of the form.



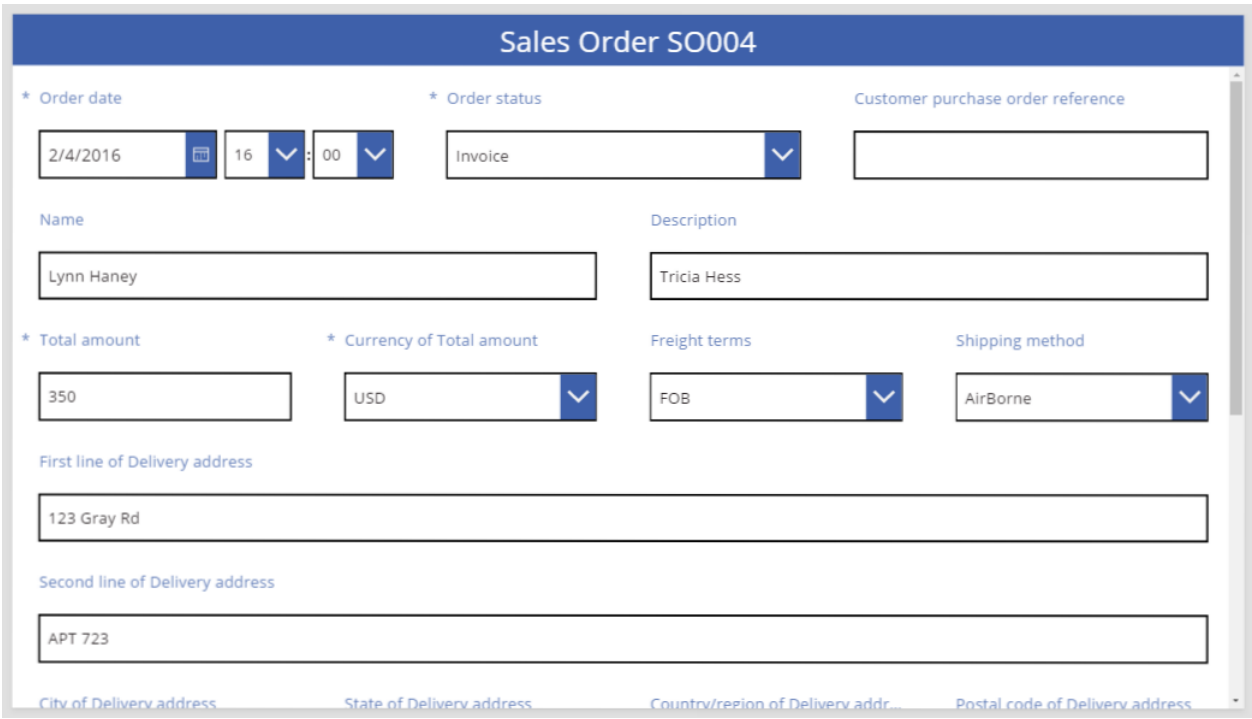
3. Repeat the previous step with the **Order status** and **Customer purchase order reference** cards.



4. Resize the **Name** and **Description** cards to take up six columns (or 1/2) of the form.

5. Make the first two lines of the delivery address stretch entirely across the form:

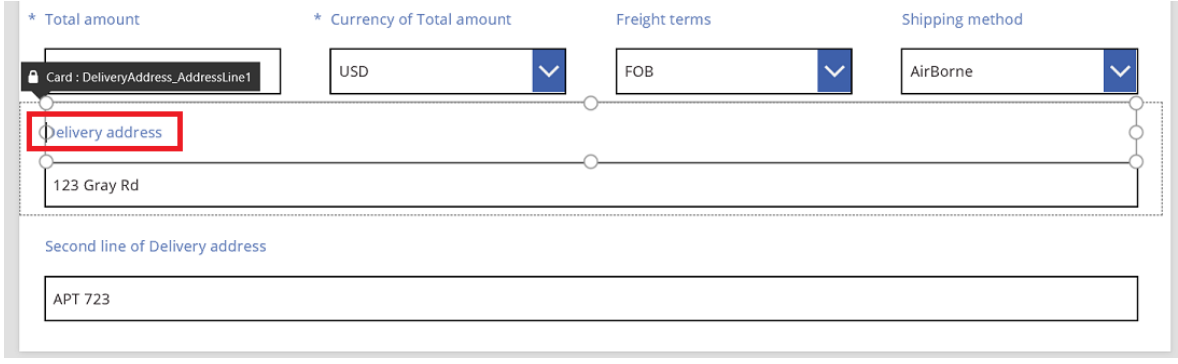
All done. We have our desired form, mixing rows with different numbers of columns:



Manipulate controls in a card

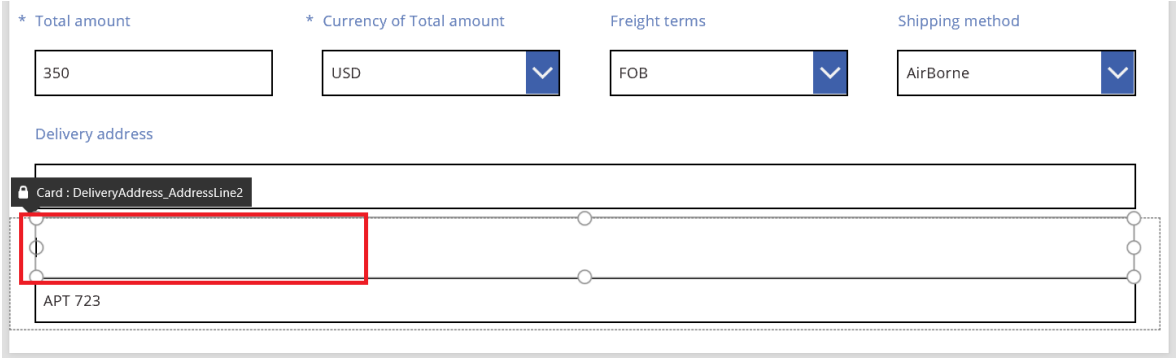
The delivery address includes several pieces of information that we want to visually group together for the user. Each field will remain in its own data card, but we can manipulate the controls within the card to make them fit better together.

1. Select the **First line of Delivery address** card, select the label within that card, and then delete the first three words from the text.



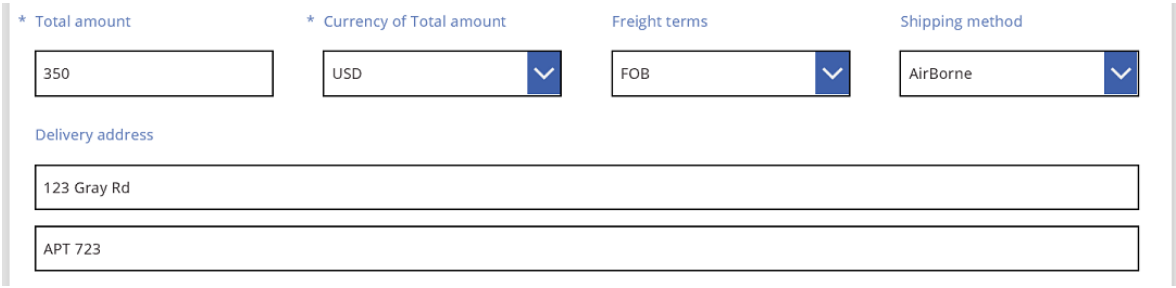
2. Select the **Second line of Delivery address** card, select the label within that card, and then delete all of the text in it.

   It may be tempting to remove the label control and, in many cases, that will work fine. But formulas might depend on that control being present. The safer approach is to remove the text or to set the **Visible** property of the control to **false**.



3. In the same card, move the text input box over the label to reduce the space between the first and second lines of the address.

   The height of the card shrinks when its contents take up less space.



Now let's turn our attention to the third line of the address. Similar to what we just did, let's shorten the text of each label for these cards and arrange the Text input box to be to the right of each label. Here are the steps for the **State** card:

Step	Description	Result
1	Select the **State** card so that grab handles appear around it.	
2	Select the label within this card so that grab handles appear around it.	
Step	Description	Result
3	Place the cursor to the right of the text, and then delete the portion that we don't need.	4	Using the grab handles on the sides, size the label control to fit the new text size.	5	Select the text input control within this card.	6	Using the grab handles on the sides, size the text input control to the size that you want.	7	Drag up the text input box and to the right of the label control, and then drop the text input box.	Our modifications to the **State** card are now complete.		

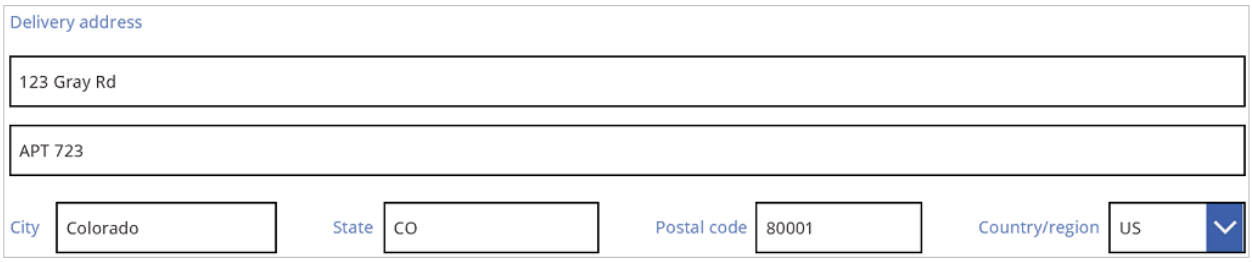
The result for the complete third address line:



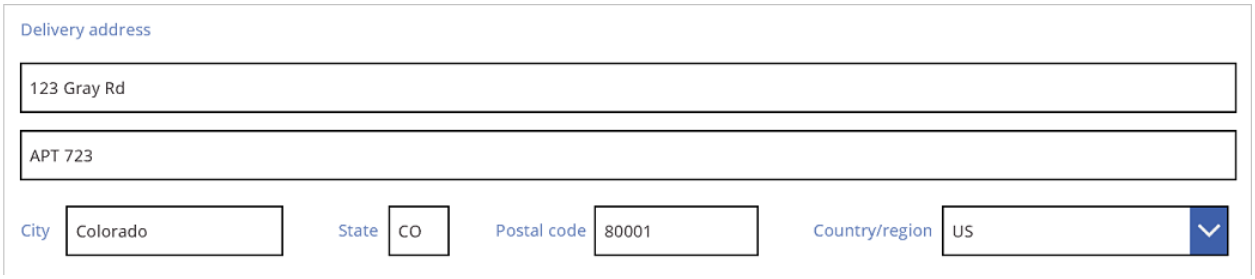
Many of the cards start out with dynamic formulas for their properties. For example, the Text input control that we resized and moved above had a **Width** property based on the width of its parent. When you move or resize a control, these dynamic formulas are replaced with static values. If you want, you can restore the dynamic formulas by using the formula bar.

Turning off Snap to columns

Sometimes you'll want finer control than the standard 12 columns can provide. For these cases, you can turn off **Snap to columns** and then position cards manually. The form will continue snapping to 12 columns, but you can also hold down the Alt or Ctrl+Shift keys after starting a resize or reposition to override the snap points. For more information, see alternate behavior keyboard shortcuts.

In our example, the four components that make up the third line of the address all have exactly the same width. But this may not be the best layout, as city names are longer than state abbreviations, and the Text input box for countries/regions is short because of the length of its label. To optimize this space, turn off **Snap to columns** in the right-hand pane and then hold down the Alt or Ctrl+Shift keys after starting to size and position these cards.

After careful positioning, the result has appropriate sizes for each field and even spacing horizontally between fields:



In summary, what are the differences when **Snap to columns** is on versus off?

Behavior	**Snap to columns On**	**Snap to columns Off**
Resize snaps to	Number of columns you select: 1, 2, 3, 4, 6, or 12	12 columns
Resize snap can be overridden	No	Yes, with Alt or Ctrl+Shift keys after starting the resize
Cards automatically relayout between rows (more on this later)	Yes	No

Set width and height

As with everything in Power Apps, the form's layout is governed by properties on the card controls. As already described, you can change the values of these properties by dragging controls to different locations or dragging grab handles to resize controls. But you'll discover situations in which you'll want to understand and manipulate these properties more precisely, especially when making your forms dynamic with formulas.

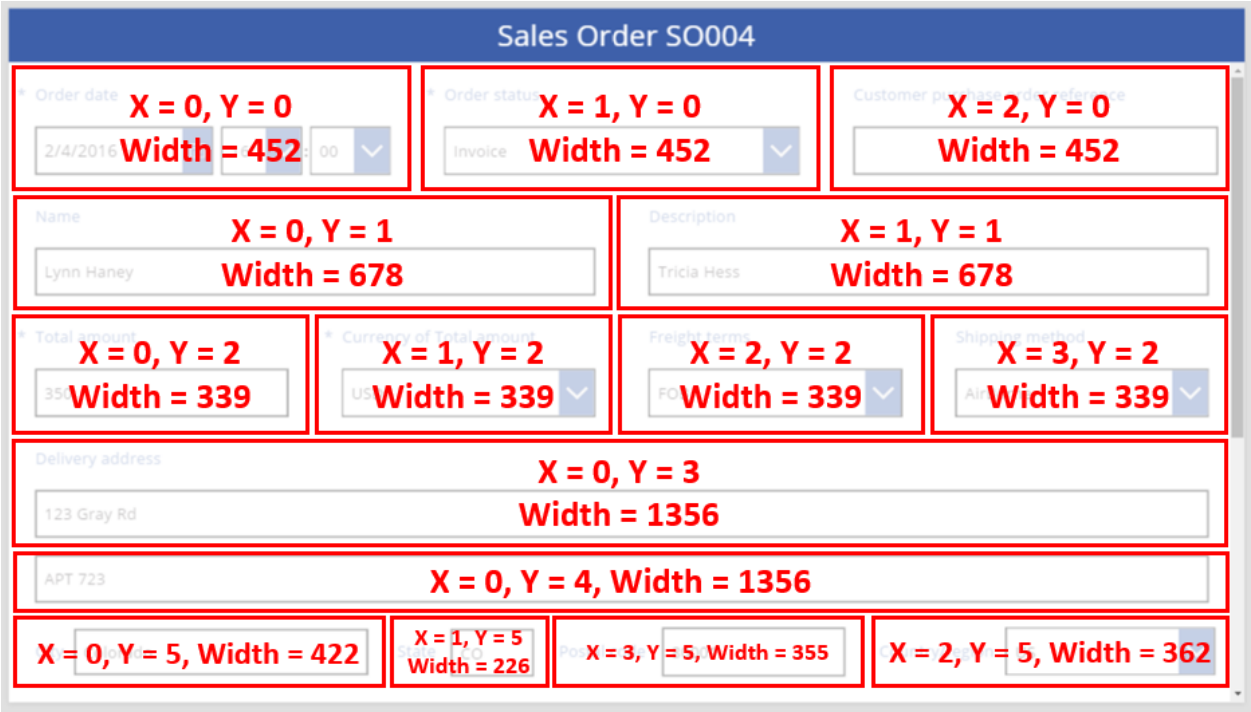
Basic Layout: X, Y, and Width

The **X** and **Y** properties control the position of cards. When we work with controls on the raw canvas, these properties provide an absolute position. In a form, these properties have a different meaning:

- **X**: Order within a row.
- **Y**: Row number.

Similar to controls on the canvas, the **Width** property specifies the minimum width of the card (more on the minimum aspect in a moment).

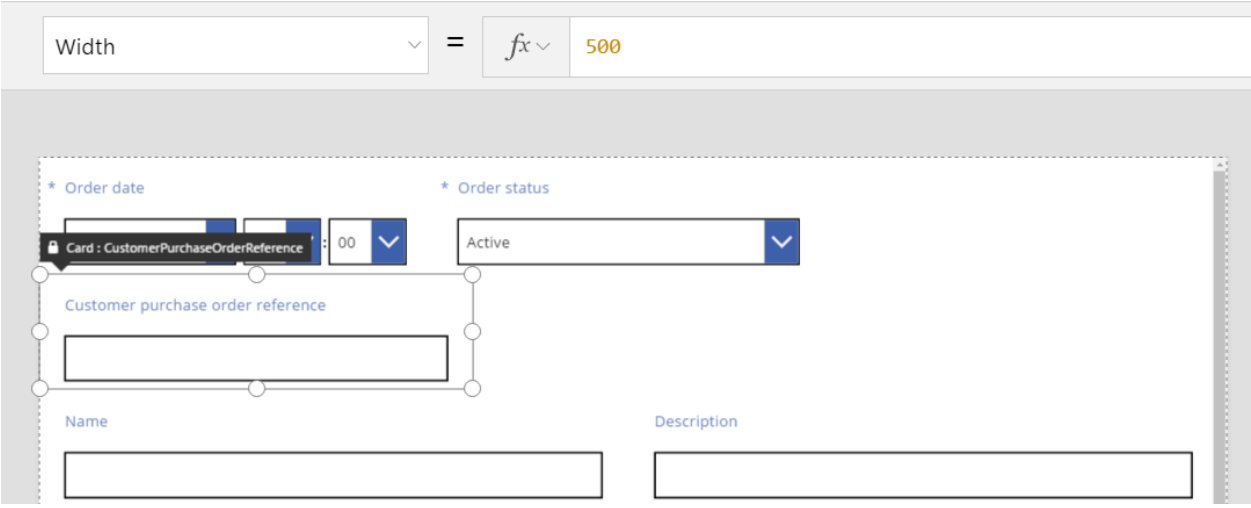
Let's take a look at the **X**, **Y**, and **Width** properties of the cards in our form:



Overflowing rows

What happens if the cards on a row are too wide to fit on that row? Normally you don't need to worry about this possibility. With **Snap to columns** on, these three properties will automatically be adjusted so that everything fits nicely within rows without overflowing.

But with **Snap to columns** turned off or a formula-based **Width** on one or more of your cards, overflowing a row can happen. In this case, the cards will automatically wrap so that, effectively, another row is created. For example, let's manually change the **Width** property of our **Customer purchase order reference** card (first row, third item) to **500**:



The three cards on the top row no longer fit horizontally, and another row has been created to wrap the overflow. The **Y** coordinate for all these cards is still the same at 0, and the **Name** and **Description** cards still have a **Y** of 1. Cards that have different **Y** values aren't merged across rows.

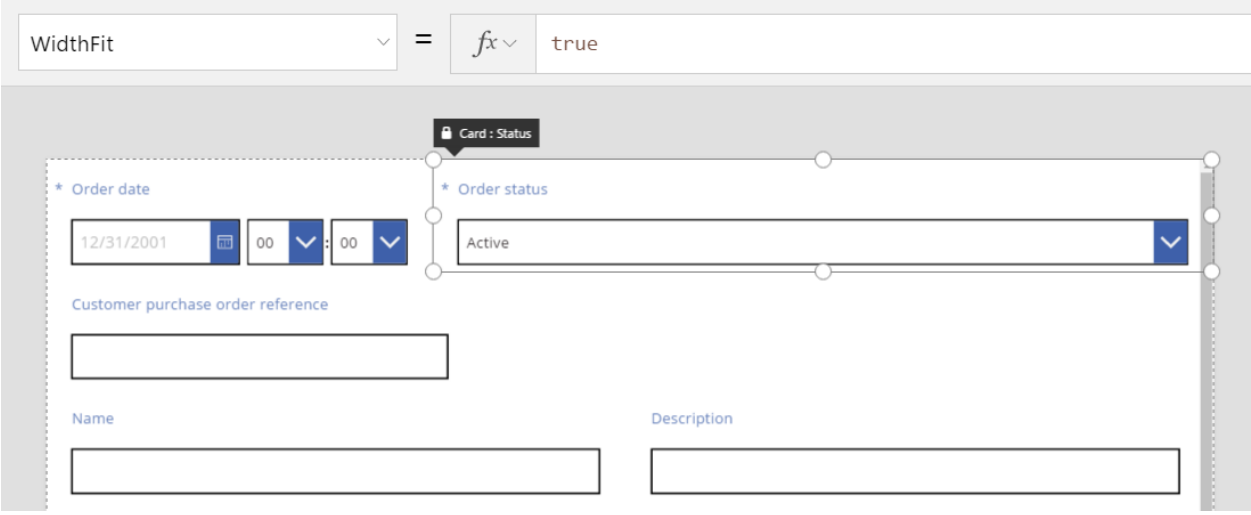
You can use this behavior to create a fully dynamic layout, where cards are placed based on a Z-order, filling across as much as possible before moving to the next row. To achieve this effect, give all the cards the same **Y** value, and use **X** for the order of the cards.

Filling spaces: WidthFit

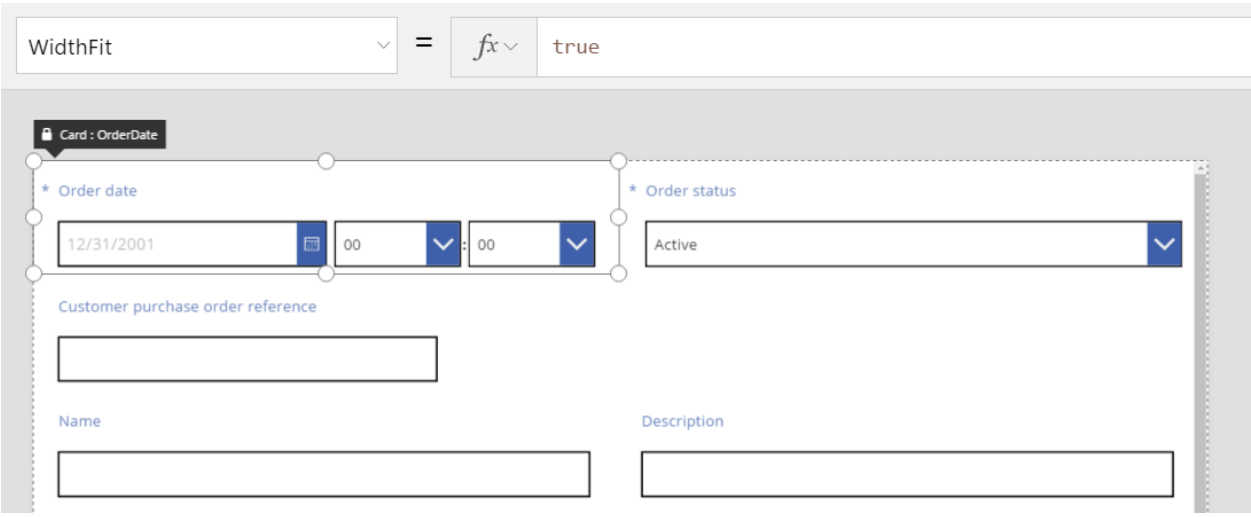
The overflow in the last example created a space after the **Order status** card, which was the second card in the first row. We could manually adjust the **Width** properties of the two remaining cards to fill this space, but this approach is tedious.

As an alternative, use the **WidthFit** property. If this property is set to **true** for one or more cards in a row, any remaining space on the row will be evenly divided between them. This behavior is why we said earlier that the **Width** property of a card is a *minimum*, and what is seen can be wider. This property will never cause a card to shrink, only expand.

If we set **WidthFit** to **true** on the **Order status** card, it fills the available space, while the first card remains unchanged:



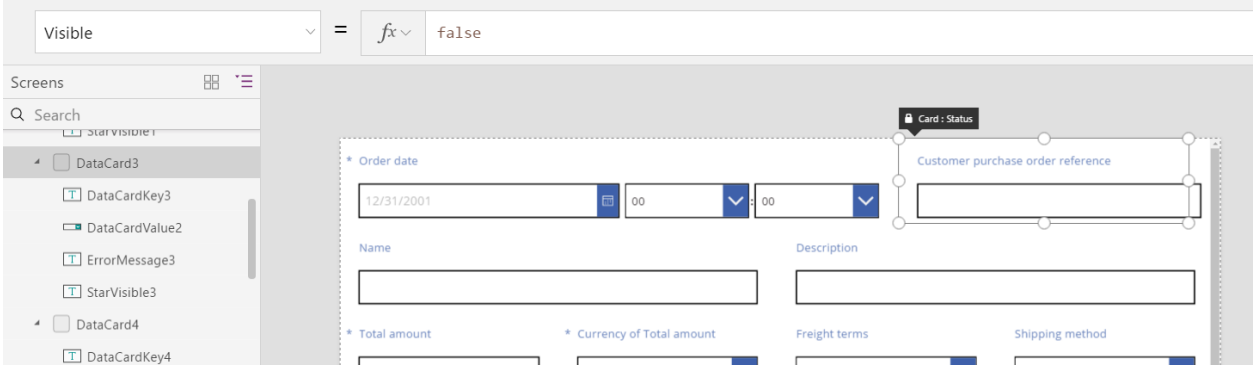
If we also set **WidthFit** to **true** on the **Order date** card, both cards will evenly split the available space:



Grab handles on these cards take into account the extra width provided by **WidthFit**, not the minimum width provided by the **Width** property. It can be confusing to manipulate the **Width** property while **WidthFit** is turned on; you may want to turn it off, make changes to **Width**, and then turn it back on.

When might **WidthFit** be useful? If you have a field that is used only in certain situations, you can set its **Visible** property to **false**, and the other cards on the row will automatically fill the space around it. You might want to use a formula that shows a field only when another field has a particular value.

Here, we'll set the **Visible** property of the **Order status** field to a static **false**:



With the second card effectively removed, the third card can now return to the same row as the first card. The first card still has **WidthFit** set to **true**, so it alone expands to fill the available space.

Because **Order status** is invisible, you can't select it as easily on the canvas. However, you can select any control, visible or not, in the hierarchical list of controls on the left side of the screen.

Height

The **Height** property governs the height of each card. Cards have the equivalent of **WidthFit** for **Height**, and it's always set to **true**. Imagine that a **HeightFit** property exists, but don't look for it in the product because such a property isn't yet exposed.

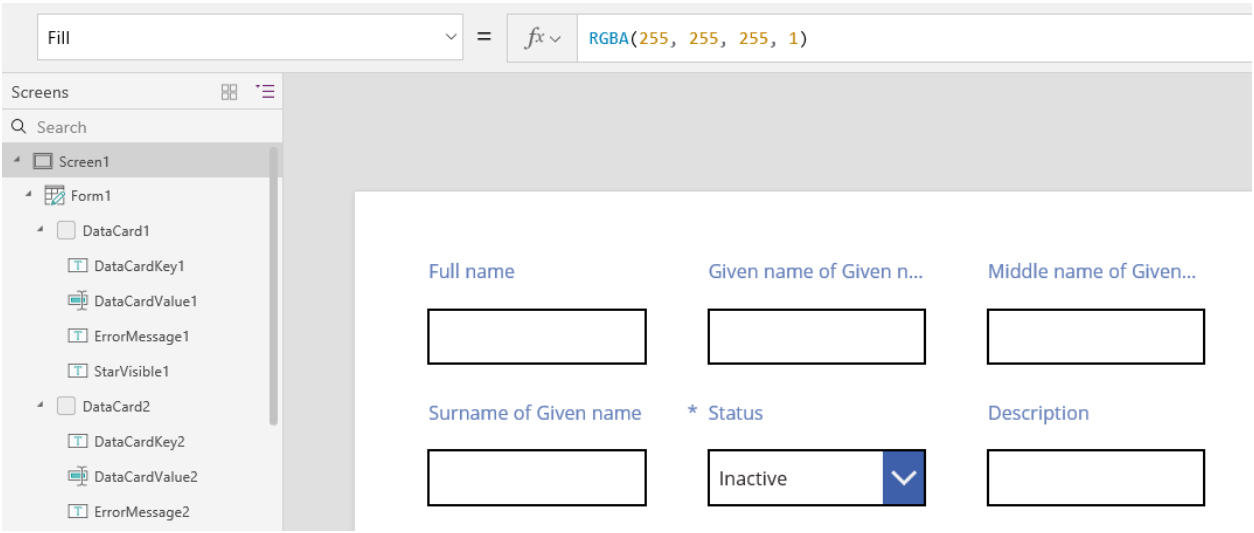
You can't turn off this behavior, so changing the heights of cards can be challenging. All cards within a row appear to be the same height as the tallest card. You might look at a row like this:

Which card is making the row tall? In the previous graphic, the **Total amount** card is selected and appears tall, but its **Height** property is set to **80** (same as the height of the first row). To reduce the height of a row, you must reduce the **Height** of the tallest card in that row, and you can't identify the tallest card without reviewing the **Height** property of each card.

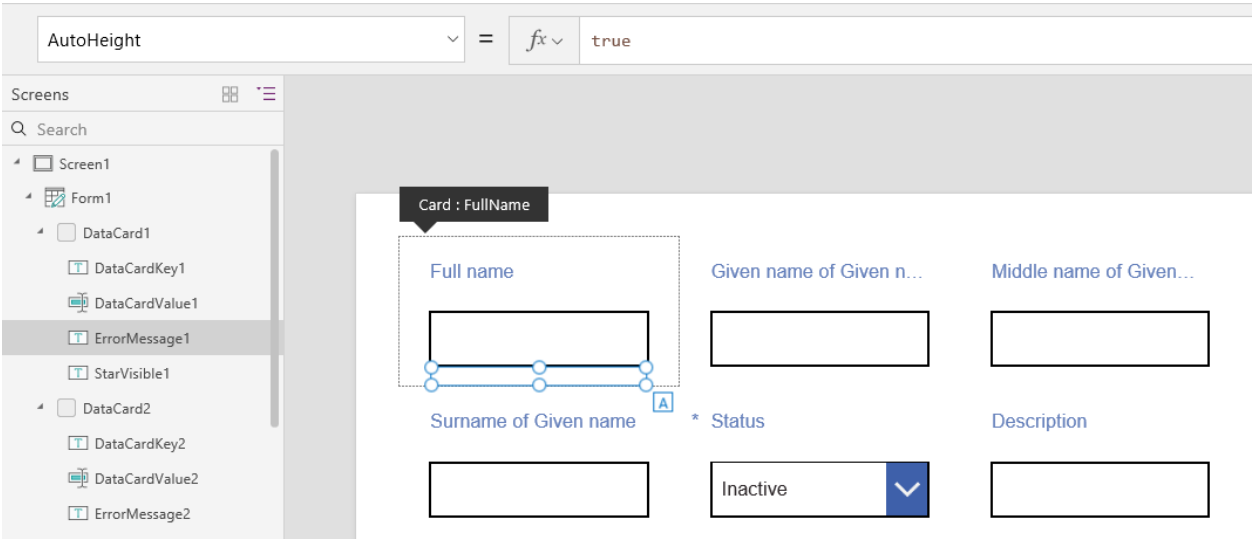
AutoHeight

A card might also be taller than you expect if it contains a control for which the **AutoHeight** property is set to **true**. For example, many cards contain a label that displays an error message if the field's value causes a validation problem.

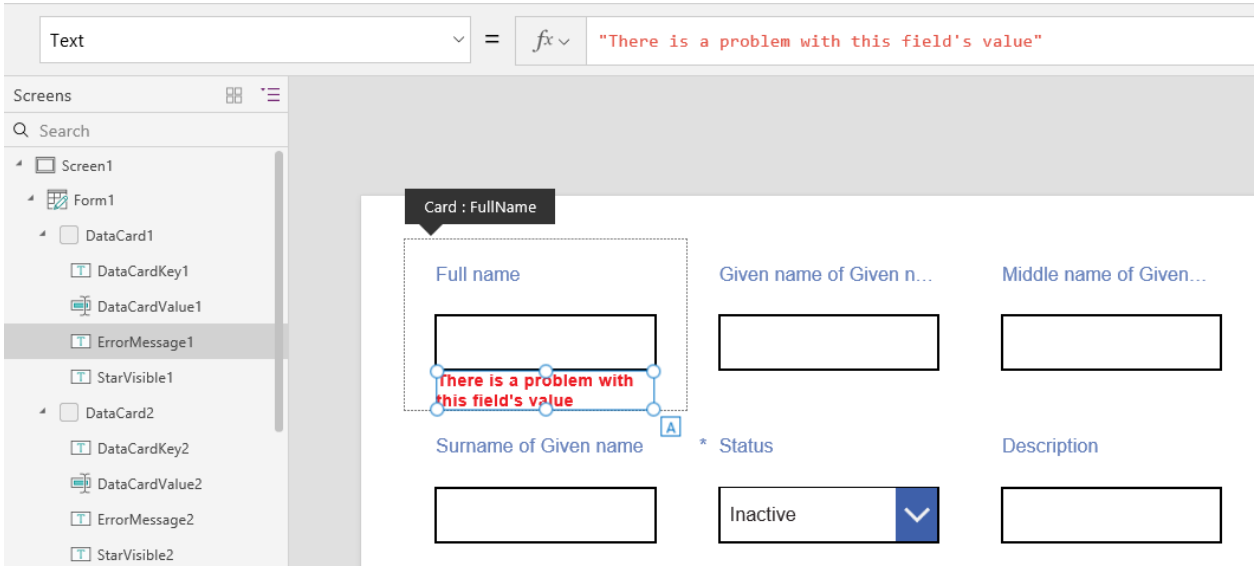
Without any text to display (no error), the label collapses to zero height. If you didn't know any better, you wouldn't know it was there, and that's as it should be:



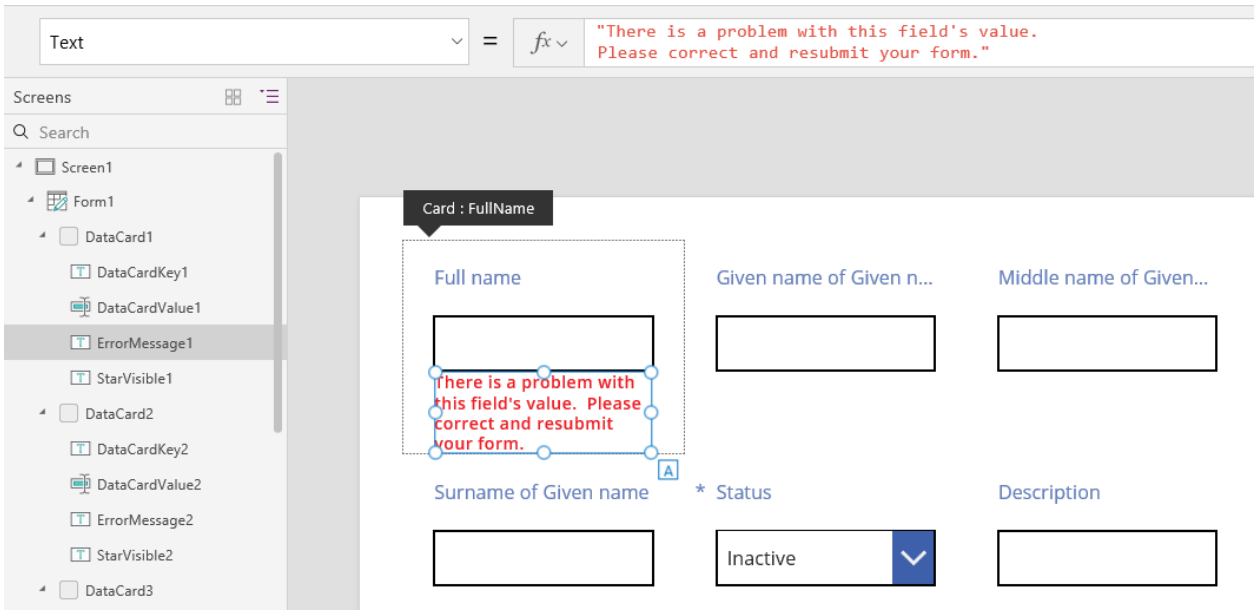
On the left side of the screen, the list of controls shows **ErrorMessage1**, which is our label control. As you update an app, you can select this control to give it some height and show grab handles with which you can position and size the control. The "A" in a blue box indicates that the control has **AutoHeight** set to **true**:



The **Text** property of this control is set to **Parent.Error**, which is used to obtain dynamic error information based on validation rules. For illustration purposes, let's statically set the **Text** property of this control, which will increase its height (and, by extension, the height of the card) to accommodate the length of the text:



Let's make the error message a little longer, and again the control and the card grow to accommodate. The row overall grows in height, keeping vertical alignment between the cards:

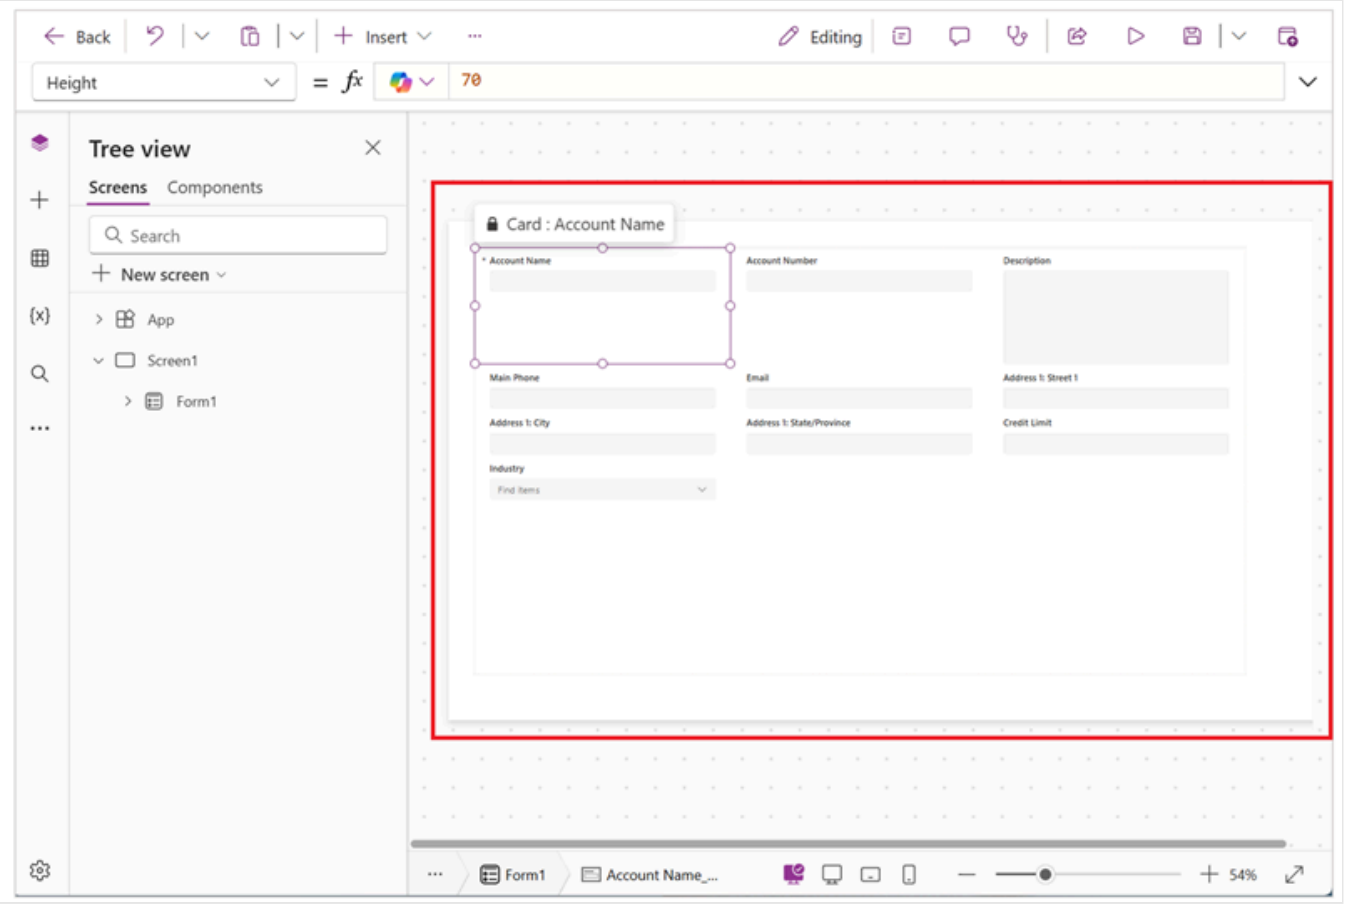


Understand data cards in canvas apps

This article explains what a data card is, how to change the control users enter data into, when to unlock a card, and how the form saves changes back to Dataverse.

Data cards are the building blocks of Power Apps forms. Each data card displays and collects a value for a single field such as Name, Job Title, or Phone Number.

The following screenshot shows a form with a data card for **Account name** selected.



A **Display form** shows one record. **Edit forms** let users update an existing record or create a new one. In either type of form, each data card is connected to exactly one field (one column) in your data source—often a Dataverse table.

A data card is a container that includes the field label, required validation behavior, and the control that users interact with. A data card contains the following:

- **Required indicator (asterisk or star)**: Shows that the field must have a value.
- **Title**: The label shown to users for the field.
- **Data card value**: The input control (for example, a text box or dropdown) where users enter or edit the value

- **Error message**: Displays validation errors, usually after the form is submitted.

Prerequisites

If you're new to forms, start by reading add-form.md and working-with-forms.md.

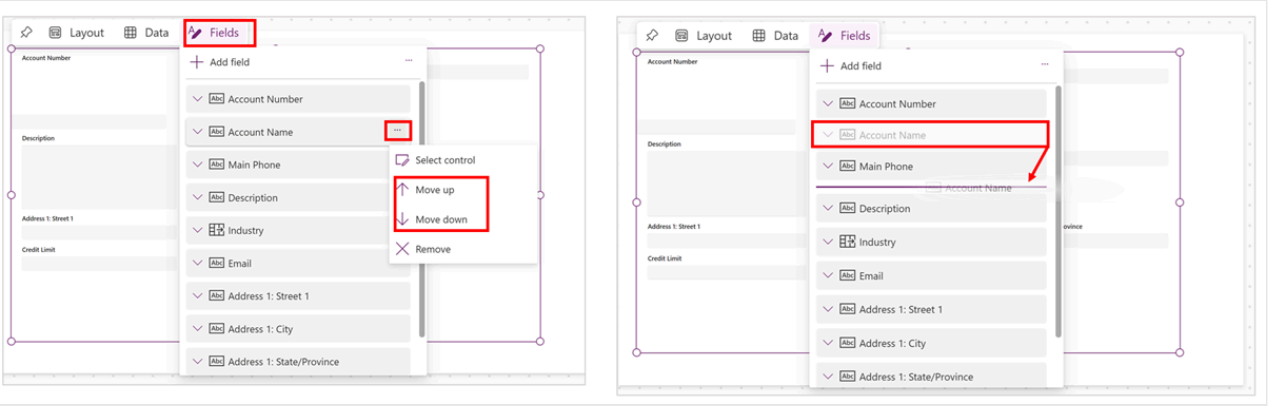
Customize a card

A data card contains the controls that users see - usually a label such as the title, an input control like text input or dropdown, and an error message label. To customize how a field looks, select the control *inside* the card for example, the text input and adjust its size, position, or properties.

Reorder fields on a form

Power Apps offers predefined cards for strings, numbers, and other data types. You edit the form and rearrange fields letting you change the layout without unlocking any cards.

1. Open your app for editing in Power Apps Studio.
2. Select the form then select **Fields**.
3. Select **More actions** and then selet **Move up** or **Move down**. You can also select and then drag fields into the order you want.



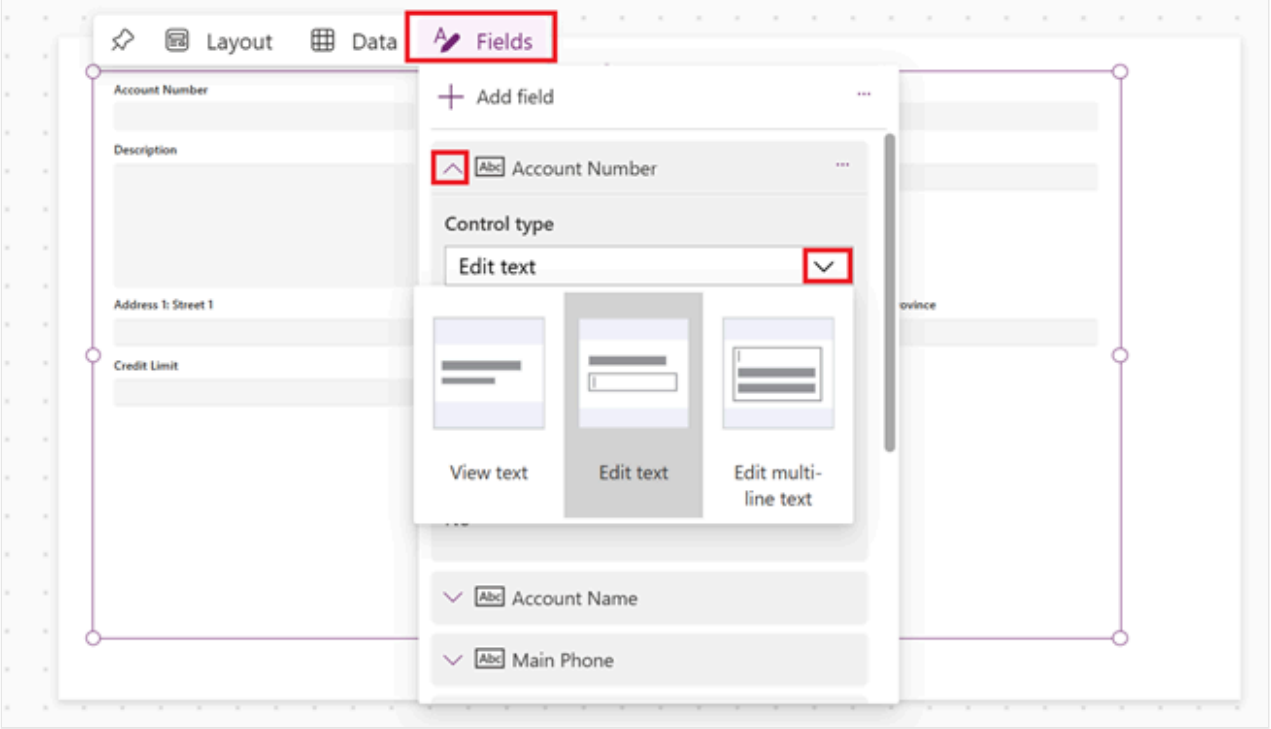
Change a card's control type

You can easly change a card's control type. For exmaple you might want to change a single-line text card to a multiline text card so users have more space to enter information.

1. Open your app for editing in Power Apps Studio.
2. Select the form then select **Fields**.

3. Select **Expand field details** which is the down arrow next to the field that you want to edit.

4. Select the dropdown for **Control type** and then select a different control type. For example, switch from **Edit text** to **Edit multi-line text**.



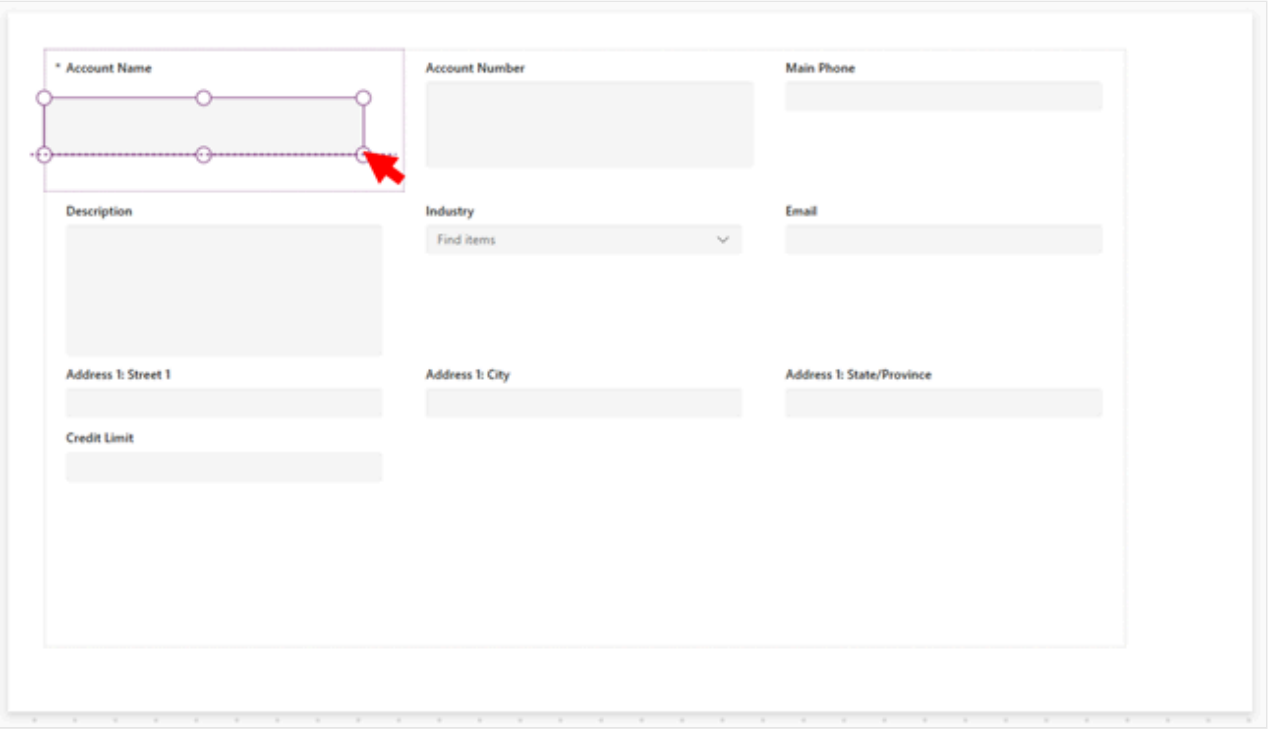
Resize a card

You can move and resize controls in a locked card.

You editing the controls inside a card without changing what field the card connects to.

1. In the form, select the data card that you want to resize such as **Account Name**.

2. Drag to move the text input within the card, and use the handles to resize it. This improves spacing and readability without unlocking the card.

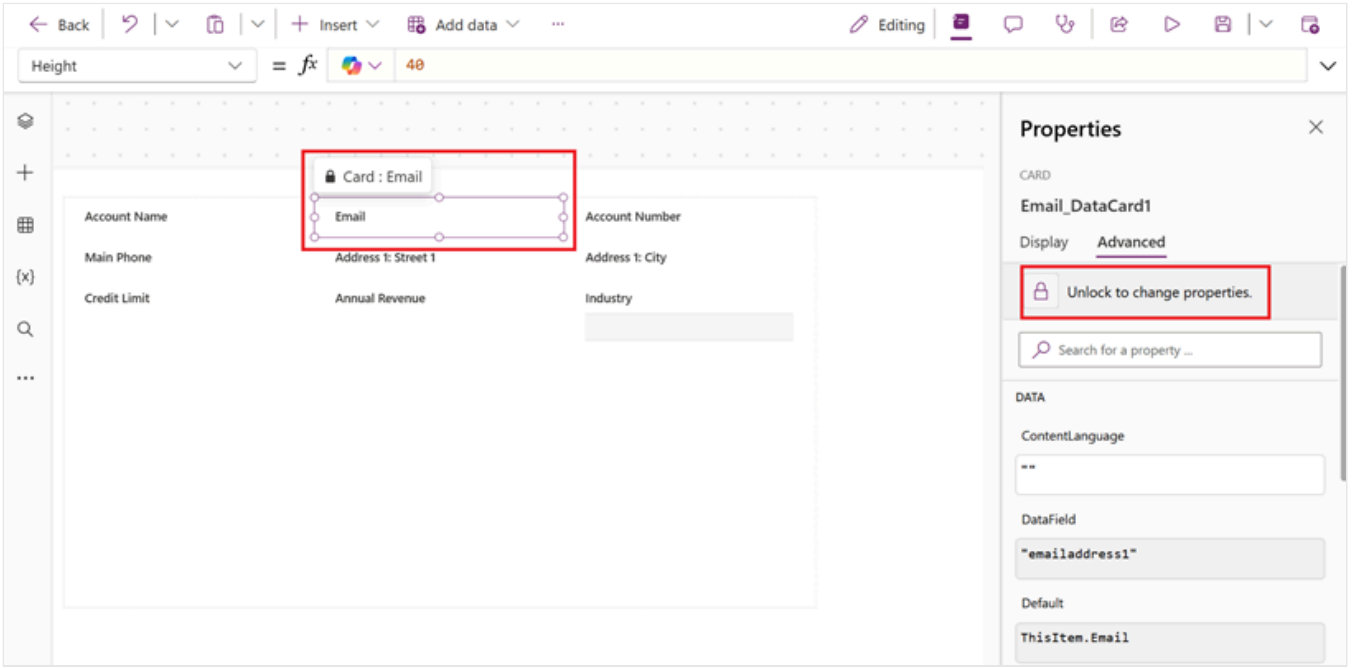


Unlock a card

To make changes like deleting a control or adding a new control requires unlocking the card.

When you add a field to a form, Power Apps creates a data card for you and sets up the basic formulas that connect the card to the data source. By default, Power Apps locks these cards so you don't accidentally break that connection. If you need more control, such as a custom layout, extra controls, or different formulas, you can unlock the card.

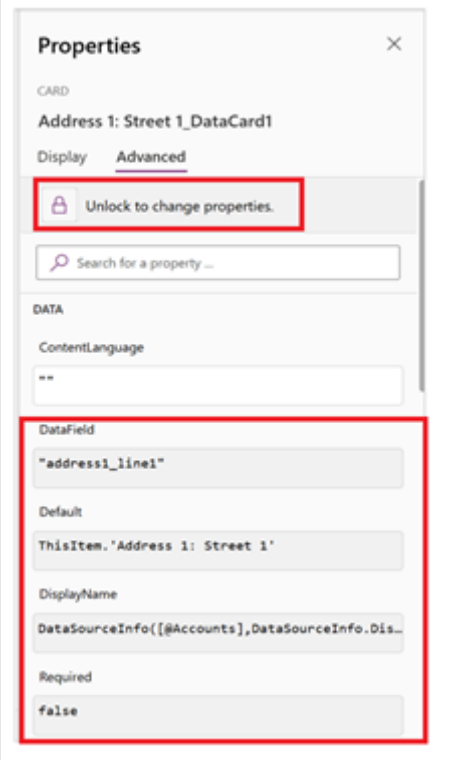
The following screenshot shows a form with a data card that is locked.

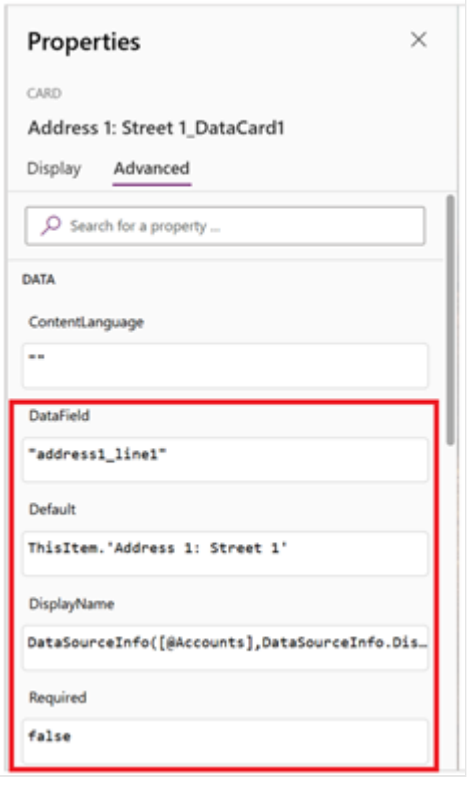


The key setting is DataField. It tells Power Apps which field (column) this card is responsible for. When the form submits, Power Apps uses the card's **DataField** value to know what field to update.

1. To unlock a card, select the card
2. In the **Properties** pane, select the **Advanced**.
3. Select lock icon or select **Unlock to change properties** to unlock properties such as **DataField**, **DisplayName**, or **Required**.
4. After you unlock the card, edit the generated formulas and add or remove controls inside the card.

Expand table

Locked properties	Unlocked properties
	




You now take control over this card and can modify it further to fit your needs. But you lose the ability to change the card from one representation to another (for example, single-line text to multi-line text) as you did before. You transformed the predefined card into a "custom card" that you now control.

> **Important**

You can't relock a card after you unlock it. To get a card back to a locked state, remove it, and reinsert it in the right-hand pane.

Interact with a form

After you unlock a card, you can control how values move between the form and the controls inside the card.

A helpful way to think about an Edit form is: **data flows in** to show the current record (defaults), and **data flows out** when you submit the form updates. The card sits in the middle - its properties tell the form which field it represents and what value should be saved.

DataField property

The card's **DataField** property is the "this card edits this field" setting. It helps Power Apps decide what to validate, what value is required, and what field should be updated when you submit the form.

Information flowing in

When a form shows a record, it exposes that record as **ThisItem**. Think of **ThisItem** as the current row you're editing. It contains every field for that record.

In Dataverse-backed forms, the card's **DataField** typically matches the field's logical name. The card's **Default** formula commonly references the current record, for example, **ThisItem.FieldName**, and the input control inside the card usually reads that value through **Parent.Default**. This pattern keeps the input control independent of the data source and lets the card encapsulate how the field value flows in.

Most cards set their **Default** property to the current record's value, like **ThisItem.FieldName**. You can optionally transform that value, for example, format text before it shows in the input.

Inside the card, the input control usually uses **Parent.Default** so it always shows whatever value the card provides. This approach keeps the card "self-contained". If you later change the card's default formula, you don't have to rewrite formulas inside the card.

By default, the data source's metadata sets the **DefaultValue** and **controls/control-card.md** properties based on the **controls/control-card.md** property. You can override these formulas with your own logic by using the **functions/function-datasourceinfo.md** function to integrate the data source's metadata.

Information flowing out

When the user selects **Save**, this typically call **SubmitForm**. The form gathers values from each data card and writes them back to the data source. It uses each card's **DataField** to know *which* field to update.

To save changes from an **Edit form**, trigger **SubmitForm(FormName)** (for example, from a **Save** button). If you want to clear the inputs after a successful submit, follow with **ResetForm(FormName)**. To create a new record instead of editing an existing one, set the form's **DefaultMode** property to **FormMode.New** before the user starts entering data.

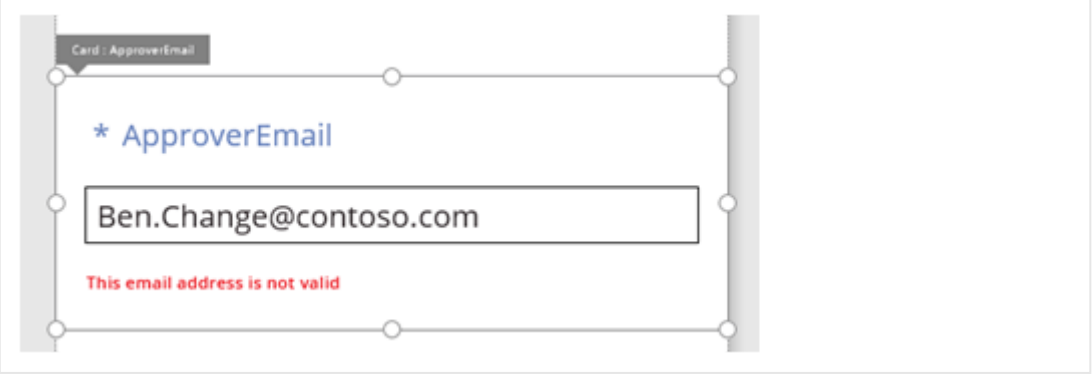
The form also reads each card's **Update** property - this is the value that gets saved for that field. If you need to clean up a value before saving, such as removing extra spaces, converting text to a number, or reversing a formatting change you made in **Default**, **Update** is usually the right place to do it.

Valid is basically "is this field okay to submit?" Power Apps uses the data source rules and the card's **Required** setting to decide this. If the value isn't valid, the card's **Error** property contains a message that you can show to the user, often through the **Error Message** label in the card.

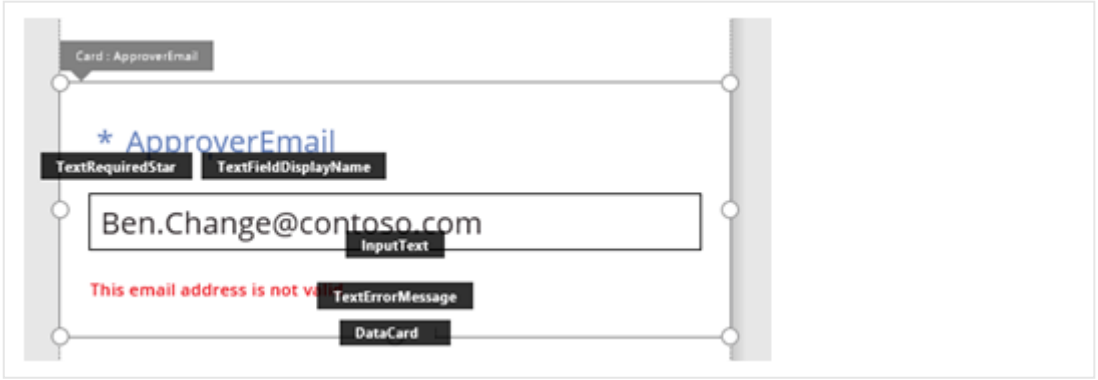
If a card's **DataField** is blank, the card isn't tied to any field - it's just a container you can use for layout. In that case, its **Update** and **Valid** values don't affect what gets saved when you submit the form.

Dissecting an example

Take a closer look at what's inside a typical data-entry card. The following screenshots spread the controls out so you can see each piece clearly.



In the next image, the controls inside the card are labeled so you can match what you see on the canvas to what's in the tree view.



Here are the main controls you usually see inside a card:

Expand table

Name	Type	What it does
TextRequiredStar	**Label** control	Shows a star or asterisk when the field is required.
TextFieldDisplayName	**Label** control	Shows the friendly field name the user sees. This name often differs from the internal schema name.
InputText	Text input control	Shows the current value and lets the user type a new one.
TextErrorMessage	**Label** control	Shows a message if the value can't be submitted, such as missing required data.

These controls usually don't connect to Dataverse directly. Instead, they read simple values from the **parent card** by using **Parent**, and the card handles the connection to the data source. The following formulas are common examples.

Expand table

Control property	Formula	Beginner explanation
TextRequiredStar.Visible	**Parent.Required**	Only show the star when the field is required.

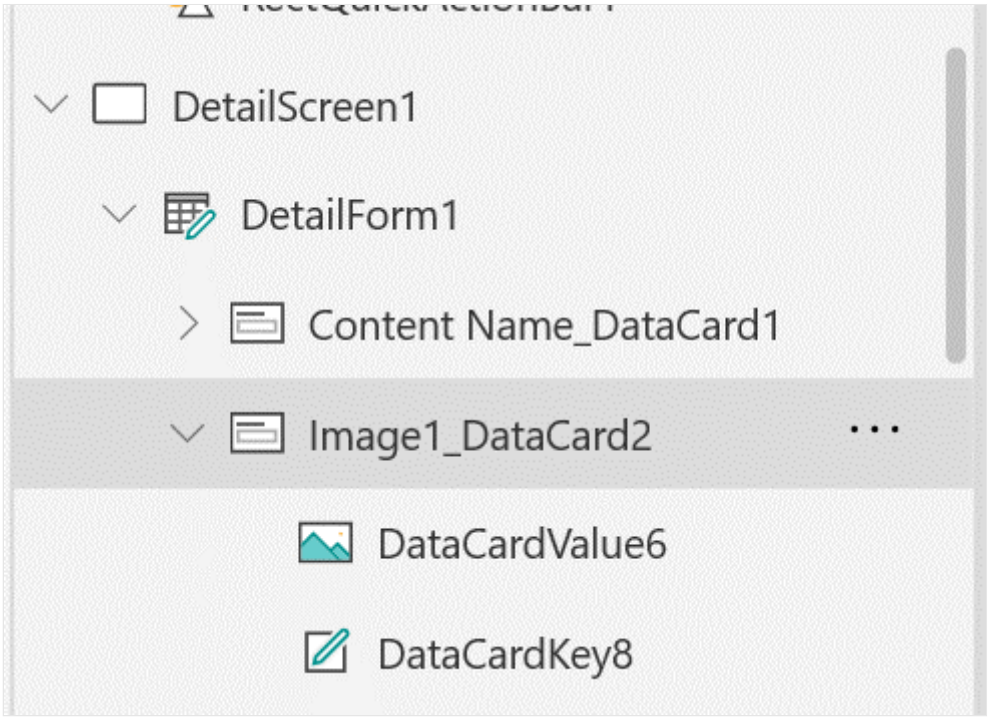
Display a full-sized image on a canvas app form

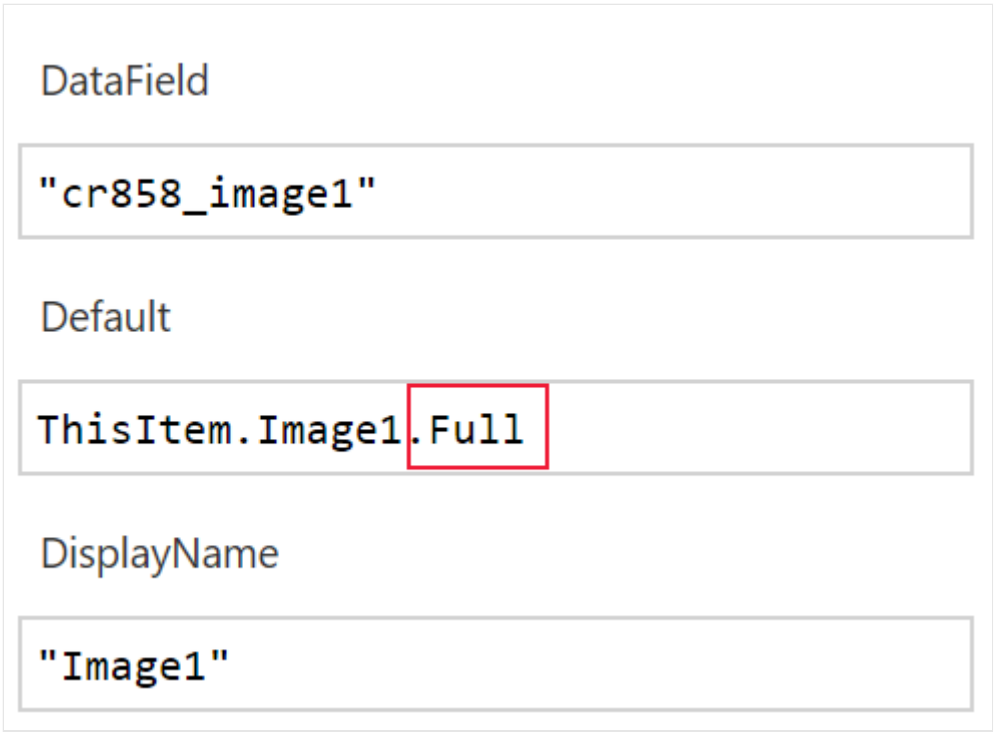
Article • 12/16/2022

By default, when an app user adds an image to display to a form in a canvas app, the image displayed is the thumbnail image. To display a full image for a canvas app, follow these steps:

1. Open the canvas app in PowerApps Studio.
2. Select **Insert**, and then select **Image**.
3. Select the image data card.



4. Under the **Advanced** tab set the **Data** field to the table that contains the image you want to display.
5. Add **.Full** after the value for the image **Default** setting.



6. Select **Save**.

Add a list box, a drop-down list, a combo box, or radio buttons to a canvas app

Article • 12/16/2022

Show a single column of data (for example, from a multi-column table) in a canvas app so that users can select one or more items in a list.

- Add a list box to allow users to select more than one option.
- Add a drop-down list or combo box to take up less space on a screen.
- Add a set of radio buttons for a particular design effect.

This topic focuses on lists boxes and radio buttons, but the same principles apply to drop-down lists.

Prerequisites

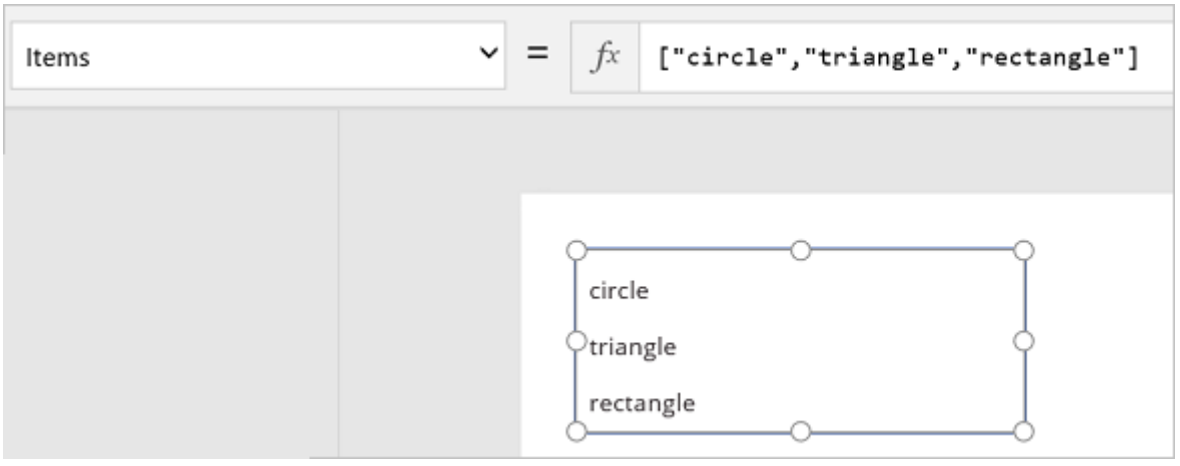
1. Create a blank canvas app.
2. Learn how to add and configure controls.

Create a simple list

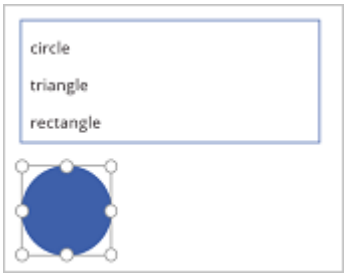
1. Add a **List box** control named **MyListBox**, and set its **Items** property to this expression:

   ```
   ["circle","triangle","rectangle"]
   ```

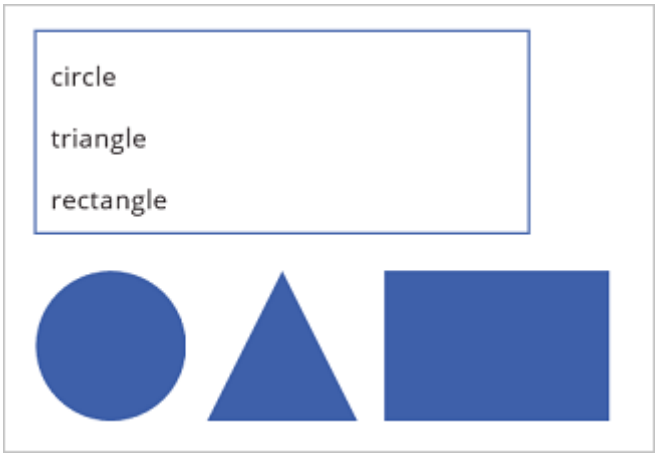
   Your designer looks similar to the following:

2. On the **Insert** tab, select **Icons**, select the circle, and move it under **MyListBox**:



3. Add a triangle and a rectangle, and then arrange the shapes in a row under **MyListBox**:



4. Set the **Visible** property of the following shapes to the following functions:

Expand table

Shape	Set Visible function to
circle	`If("circle" in MyListBox.SelectedItems.Value, true)`
triangle	`If("triangle" in MyListBox.SelectedItems.Value, true)`
rectangle	`If("rectangle" in MyListBox.SelectedItems.Value, true)`

5. While holding down the Alt key, select one or more shapes in **MyListBox**.

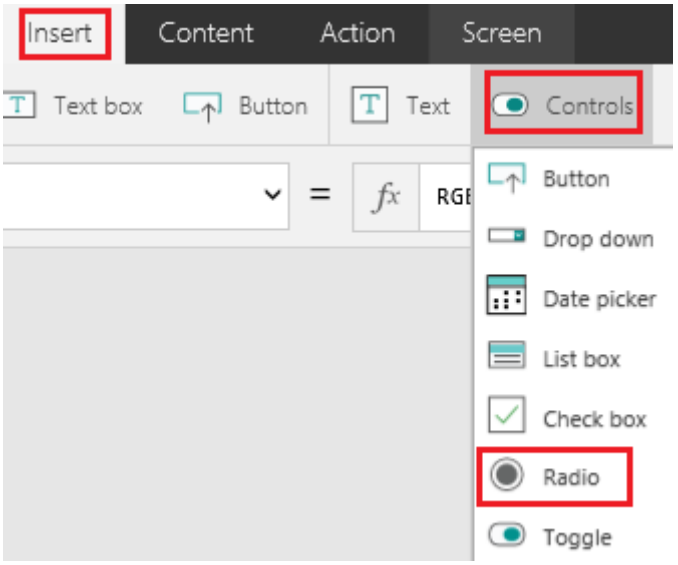
   Only the shape or shapes that you select appear.

In these steps, you used an expression to create a list of items. You can apply this to other elements within your business. For example, you can use a **Drop down** control to display product images, product descriptions, and so on.

Add radio buttons

1. On the **Home** tab, select **New Screen**, and then select **Blank**.

2. On the **Insert** tab, select **Controls**, and then select **Radio**.



3. Rename the **Radio** control to **Choices**, and set its **Items** property to this formula: `["red","green","blue"]`

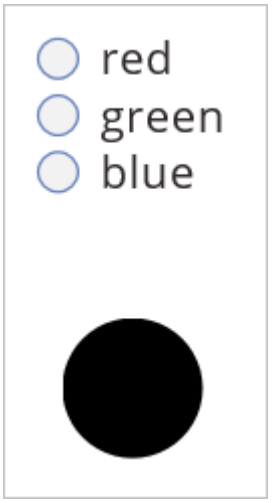
If needed, resize the control to show all the options.

4. On the **Insert** tab, select **Icons**, and then select the circle.

5. Set the **Fill** property of the circle to the following function:
`If(Choices.Selected.Value = "red", Red, Choices.Selected.Value = "green", Green, Choices.Selected.Value = "blue", Blue)`

In this formula, the circle changes its color depending on which radio button you choose.

6. Move the circle under the **Radio** control, as in this example:



7. While holding down the Alt key, select a different radio button to change the color of the circle.

Add an item to an existing list

1. Add a **Button** control and name it "btnReset".

   Don't know how to add, name, and configure a control?

2. Set **OnSelect** property on **btnReset** to this formula:

   ```
   Power Fx
   ClearCollect(MyItems, {value: "circle"},{value: "triangle"},{value: "rectangle"})
   ```

3. Set the **Text** property on **btnReset** to `"Reset"`.

4. Add a **List box** control named **lbItems**, and set its **Items** property to `MyItems`.

5. While holding down the **Alt** key, press the **Reset** button.

   > **Note**
   >
   > The list box should populate with the items from the "MyItems" collection.

6. Arrange the list box and button so they're lined up vertically.

7. Add a **Text Input** control, and name it "txtAdd".

8. Set **Text** property of **txtAdd** to `""`.

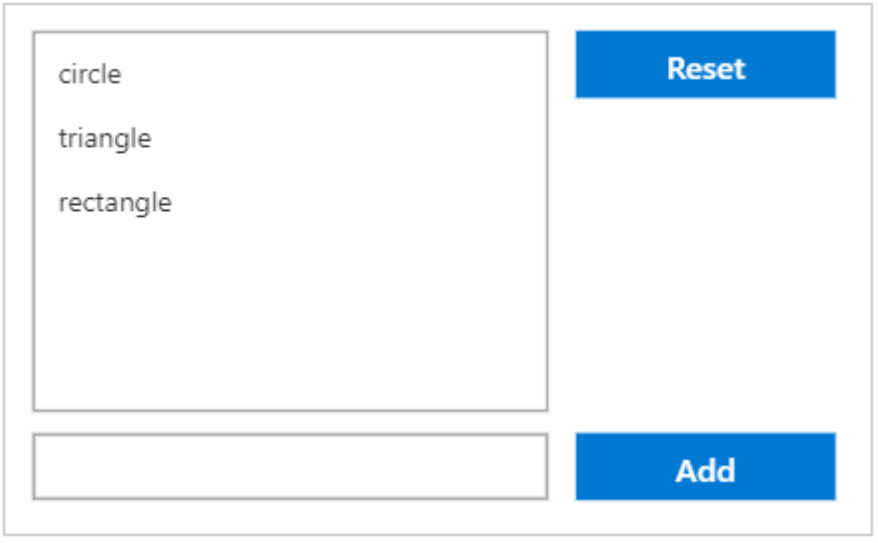
9. Add a **Button** control, and name it "btnAdd".
10. Set the **Text** property of **btnAdd** to `"Add"`.
11. Set **OnSelect** property of **btnAdd** to the following formula:

```
Power Fx

Collect(MyItems,{value: txtAdd.Text}); Reset(txtAdd)
```

> **Note**
>
> - The collect function will add the text from the text input as an item in the collection.
> - The reset function will reset the text input back to it's default state.

12. Arrange **txtAdd** and **btnAdd** so they're lined up vertically underneath **lblItems** and **btnReset**.



13. Preview the app by pressing **F5**.
14. Add a text value to **txtAdd** text input control.
15. Press the Add button.

> **Note**
>
> The list box should populate with the items from the MyItems collection.

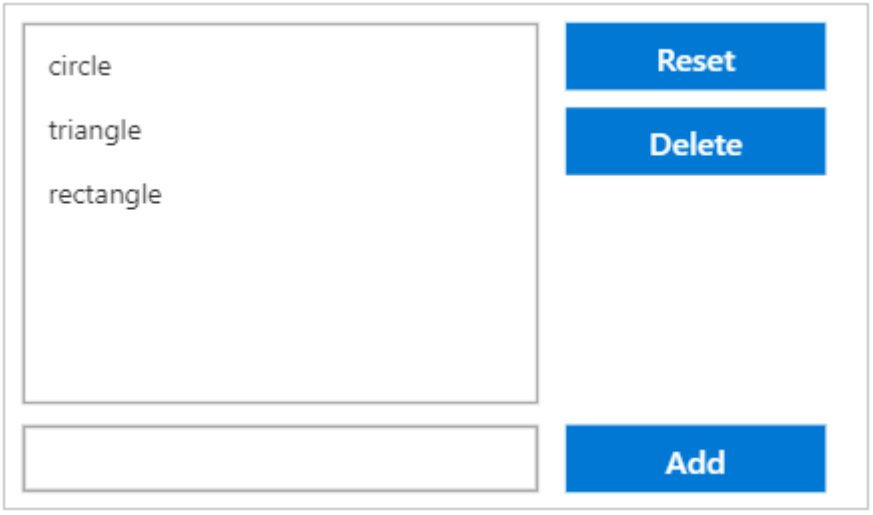
(Optional) Remove an item from an existing list

1. Add a **Button** control, and name it "btnDelete".
2. Set the **Text** property of **btnDelete** to `"Delete"`.
3. Set **OnSelect** property of **btnDelete** to the following formula:

```
Power Fx

Remove(MyItems, lbItems.Selected)
```

4. Arrange **btnDelete** so it's lined up vertically underneath **btnReset**



5. Preview the app by pressing **F5**.
6. Press the Reset button to reset the list box.
7. Press an item in the list box to select it.
8. Press the Delete button to delete item.

Create dependent drop-down lists in a canvas app

Article • 12/16/2022

When you create dependent (or cascading) drop-down lists, users select an option in a list to filter options in another list. Many organizations create dependent lists to help users fill out forms more efficiently. For example, users might select a country or region to filter a list of cities, or users might select a category to show only the codes in that category.

As a best practice, create a data source for the values in the "parent" and "child" lists (for example, countries/regions and cities) that's separate from the data source that users update by using the app. If you take this approach, you can use the same parent and child data in more than one app, and you can update that data without republishing the app or apps that use them. You can accomplish the same outcome by using a collection or static data, but it isn't recommended for enterprise scenarios.

For the scenario in this topic, store employees submit issues to an **Incidents** list through a form. Employees specify not only the location of the store at which the incident occurred but also the department within that location. Not all locations have the same departments, so a **Locations** list ensures that employees can't specify a department for a location that doesn't have that department.

> **Note**
>
> This article uses a list created using Microsoft Lists as the data source. However, all tabular data sources work the same way. Within **Dataverse for Teams**, you'll need to enable **classic controls** to get the classic drop-down to work for this scenario.

Create data sources

A **Locations** list shows the departments at each location.

Location	Department
Eganville	Bakery
Eganville	Deli
Eganville	Produce

Location	Department
Renfrew	Bakery
Renfrew	Deli
Renfrew	Produce
Renfrew	Pharmacy
Renfrew	Floral
Pembroke	Bakery
Pembroke	Deli
Pembroke	Produce
Pembroke	Floral

An **Incidents** list shows contact information and information about each incident. Create the Date column as a **Date** column, but create the other columns as **Single line of text** columns to simplify configuration and avoid delegation warnings in Microsoft Power Apps.

First Name	Last Name	Phone Number	Location	Department	Description	Date
Tonya	Cortez	(206) 555 - 1022	Eganville	Produce	I had a problem with...	2/12/2019
Moses	Laflamme	(425) 555 - 1044	Renfrew	Floral	I experienced an issue...	2/13/2019

By default, lists include a **Title** column that you can't rename or remove, and it must contain data before you can save an item in the list. To configure the column so that it doesn't require data:

1. Near the upper-right corner, select the gear icon, and then select **List settings**.
2. On the **Settings** page, select **Title** in the list of columns.
3. Under **Require that this column contains information**, select **No**.

After that change, you can ignore the **Title** column, or you can remove it from the default view if at least one other column appears.

Open the form

1. Open the **Incidents** list, and then select **Integrate** -> **Power Apps** -> **Customize forms**.

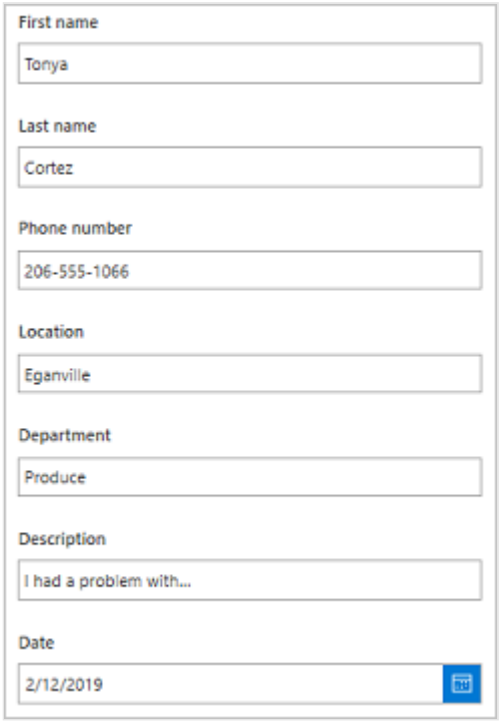
   A browser tab opens with the default form in Power Apps Studio.

2. (optional) In the **Fields** pane, hover over the **Title** field, select the ellipsis (...) that appears, and then select **Remove**.

   If you've closed the **Fields** pane, you can open it again by selecting **SharePointForm1** in the left navigation bar and then selecting **Edit fields** on the **Properties** tab of the right-hand pane.

3. (optional) Repeat the previous step to remove the **Attachments** field from the form.

   The form appears with just the fields that you added.



Replace the controls

1. In the **Fields** pane, select the arrow next to **Location**.

   If you've closed the **Fields** pane, you can open it again by selecting **SharePointForm1** in the left navigation bar and then selecting **Edit fields** on the **Properties** tab of the right-hand pane.

2. Open the **Control type** list, and then select **Allowed Values**.

   The input mechanism changes to a **Drop down** control.

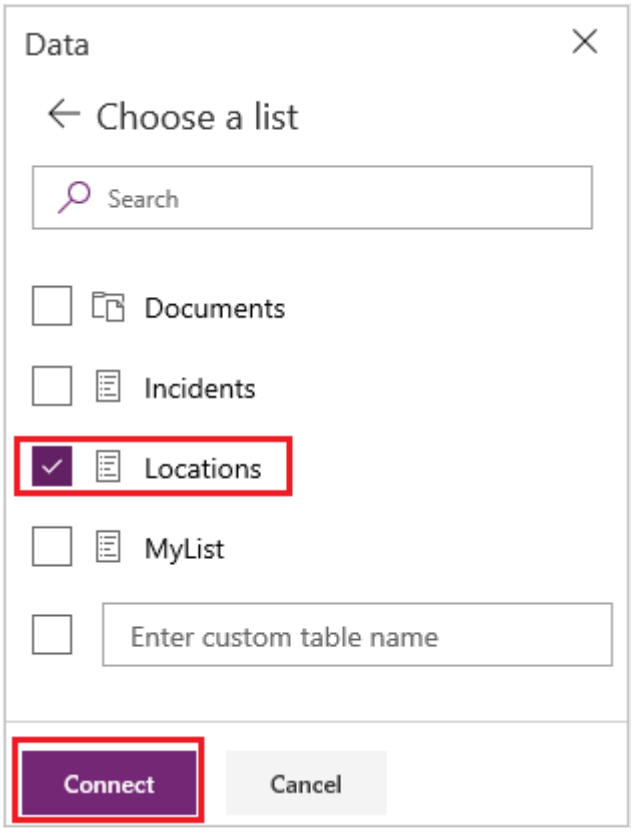
3. Repeat these steps for the **Department** card.

Add the Locations list

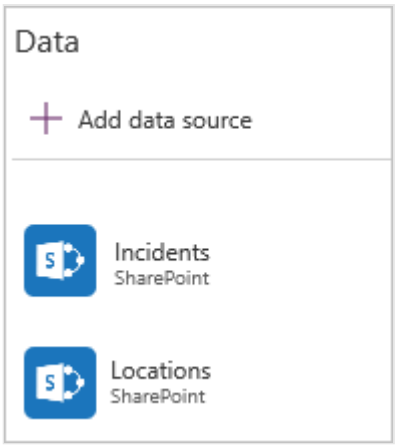
1. Select **View** > **Data Sources** > **Add data source**.

2. Select or create a SharePoint connection, and then specify the site that contains the **Locations** list.

3. Select the check box for that list, and then select **Connect**.



The list of connections shows the **Incidents** list, on which the form is based, and the **Locations** list, which will identify locations and departments in the form.



Unlock the cards

1. Select the **Location** card, select the **Advanced** tab in the right-hand pane, and then select **Unlock to change properties**.

2. Repeat the previous step for the **Department** card.

Rename the controls

If you rename your controls, you can identify them more easily, and the examples are easier to follow. To discover other best practices, review the Coding Standards and

Guidelines whitepaper.

1. In the **Location** card, select the **Drop down** control.
2. Near the top of the right-hand pane, rename the selected control by typing or pasting **ddLocation**.

3. Repeat the previous two steps in the **Department** card to rename the **Drop down** control to **ddDepartment**.

Configure the locations

1. Set the **Items** property of **ddlocation** to this formula:

```
Distinct(Locations, Location)
```

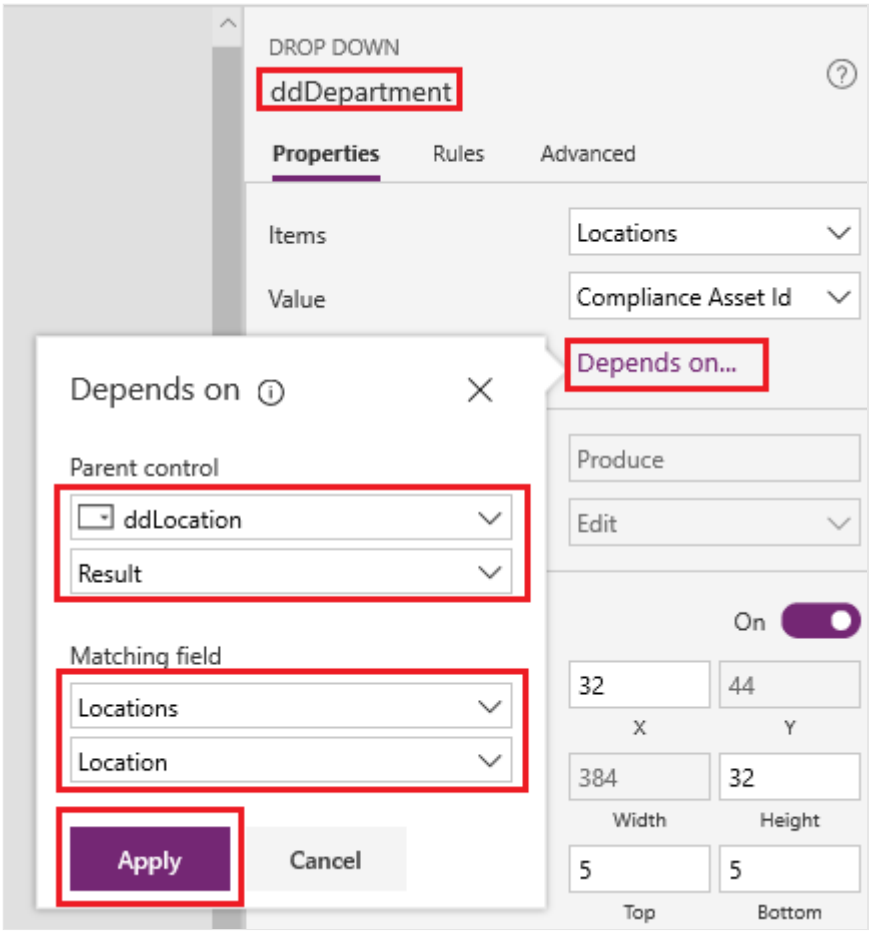
2. (optional) While holding down the Alt key, open **ddLocation**, and confirm that the list shows the three locations.

Configure the departments

1. Select **ddDepartment**, and then, on the **Properties** tab of the right-hand pane, select **Depends on.**
2. Under **Parent control**, ensure that **ddLocation** appears in the upper list and **Result** appears in the lower list.

> **Note**
>
> If you don't want to match on a string but on the actual ID of the row of data, select **ID** Instead of **Result**.

3. Under **Matching field**, select **Locations** in the upper list, select **Location** in the lower list, and then select **Apply**.



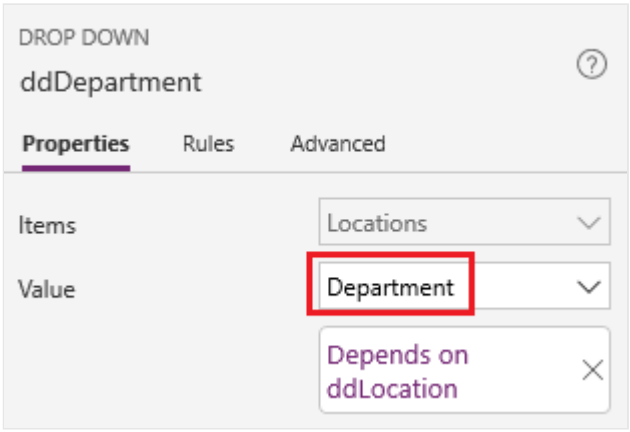
The **Items** property of **ddDepartment** is set to this formula:

```
Filter(Locations, Location = ddLocation.Selected.Result)
```

This formula filters the items in **ddDepartment** based on what the user selects in **ddLocation**. Such a configuration ensures that the "child" list of departments reflects the data for its "parent" location, as the **Locations** list in SharePoint specifies.

4. On the **Properties** tab of the right-hand pane, open the list next to **Value**, and then select **Department**.

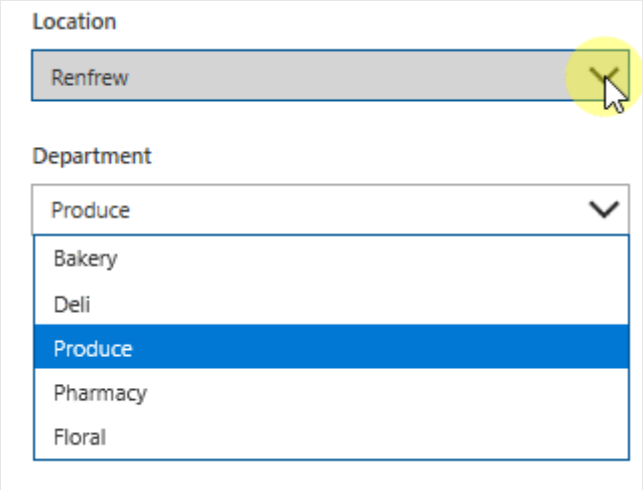
   This step sets the display text to the options from the **Department** column of the **Locations** list in SharePoint.



Test the form

While holding down the Alt key, open the list of locations, select one, open the list of departments, and then select one.

The lists of locations and departments reflects the information in the **Locations** list in SharePoint.



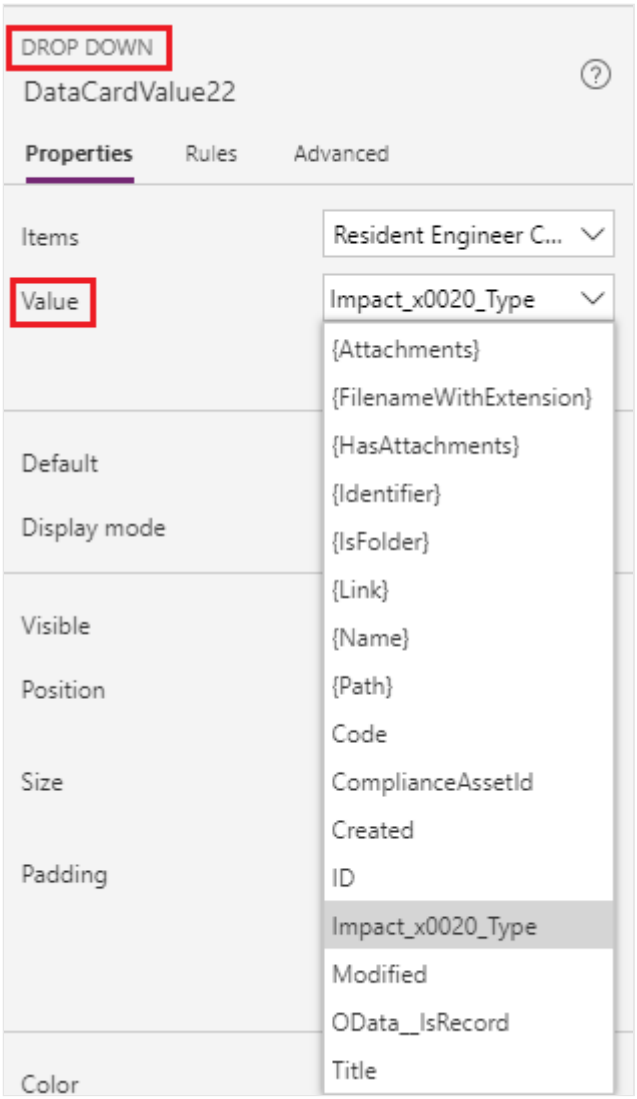
Save and open the form (optional)

1. Open the **File** menu, and then select **Save** > **Publish to SharePoint** > **Publish to SharePoint**.
2. In the upper-left corner, select the back arrow, and then select **Back to SharePoint**.
3. In the command bar, select **New** to open your customized form.

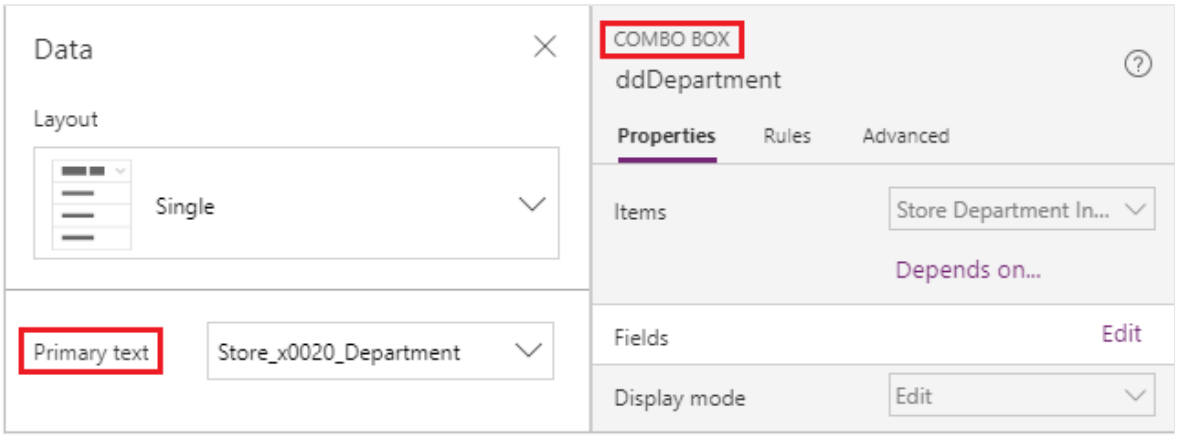
FAQ

I can’t see any data: the sources are all blank or have the wrong data. Confirm whether you're displaying the correct field for your control in either of these ways:

- Select a drop-down list, and then select the **Value** property in the **Properties** tab of the right-hand pane.



- Select a combo box, and then ensure that the primary text is the field that you want to display.



My child drop-down list contains duplicate items. This symptom is likely due to using a **LookUp** column in SharePoint or a **Choices** function in Power Apps. To remove the duplication, wrap a **Distinct** function around the properly returning data. More information: Distinct function.

Known limitations

This configuration is available on **Drop down** controls, as well as **Combo box** and **List box** controls that allow one selection at a time. You can't use the **Depends On** configuration for any of those controls if they allow multiple selections. This approach isn't recommended for working with choices in Microsoft Dataverse.

The **Depends On** configuration doesn't support static data or collections. To configure dependent drop-down lists with these sources, edit the expression directly in the formula bar. In addition, Power Apps doesn't support using two choice fields in SharePoint without any matching table of data, and you can't define **Matching field** within this UI.

Show data in a line, pie, or bar chart in canvas apps

Article • 05/21/2025

Use line charts, pie charts, and bar charts to display your data in a canvas app. When you work with charts, the data that you import should be structured based on these criteria:

- Each series should be in the first row.
- Labels should be in the leftmost column.

For example, your data should look similar to the following:

Expand table

Product	Revenue2012	Revenue2013	Revenue2014
Europa	21000	26000	28000
Ganymede	15000	17000	21000
Callisto	14000	19000	23000

You can create and use these charts within Power Apps. Let's get started.

Prerequisites

- Sign up for Power Apps, and then sign in using the same credentials that you used to sign up.
- Create an app from a template, from data, or from scratch.
- Learn how to configure a control in Power Apps.
- Create your own sample data using the example above and save it in Excel. Follow the steps in this topic to import it directly into your app.

Import the sample data

In these steps, we import the sample data into a collection, named **ProductRevenue**.

1. On the command bar select, **Insert** > **Media** > **Import**.

2. Set the control's **OnSelect** property to the following function:

```
Collect(ProductRevenue, Import1.Data)
```

3. On the app actions menu, select **Preview the app** and then select the **Import Data** button.

4. In the **Open** dialog box, select your Excel file, select **Open**, and then press Esc.

5. On the app authoring menu select, **Variables** > **Collections**.

   The ProductRevenue collection should be listed with the chart data you imported.

   > **Note**
   >
   > The import control is used to import Excel-like data and create the collection. The import control imports data when you are creating your app, and previewing your app. Currently, the import control does not import data when you publish your app.

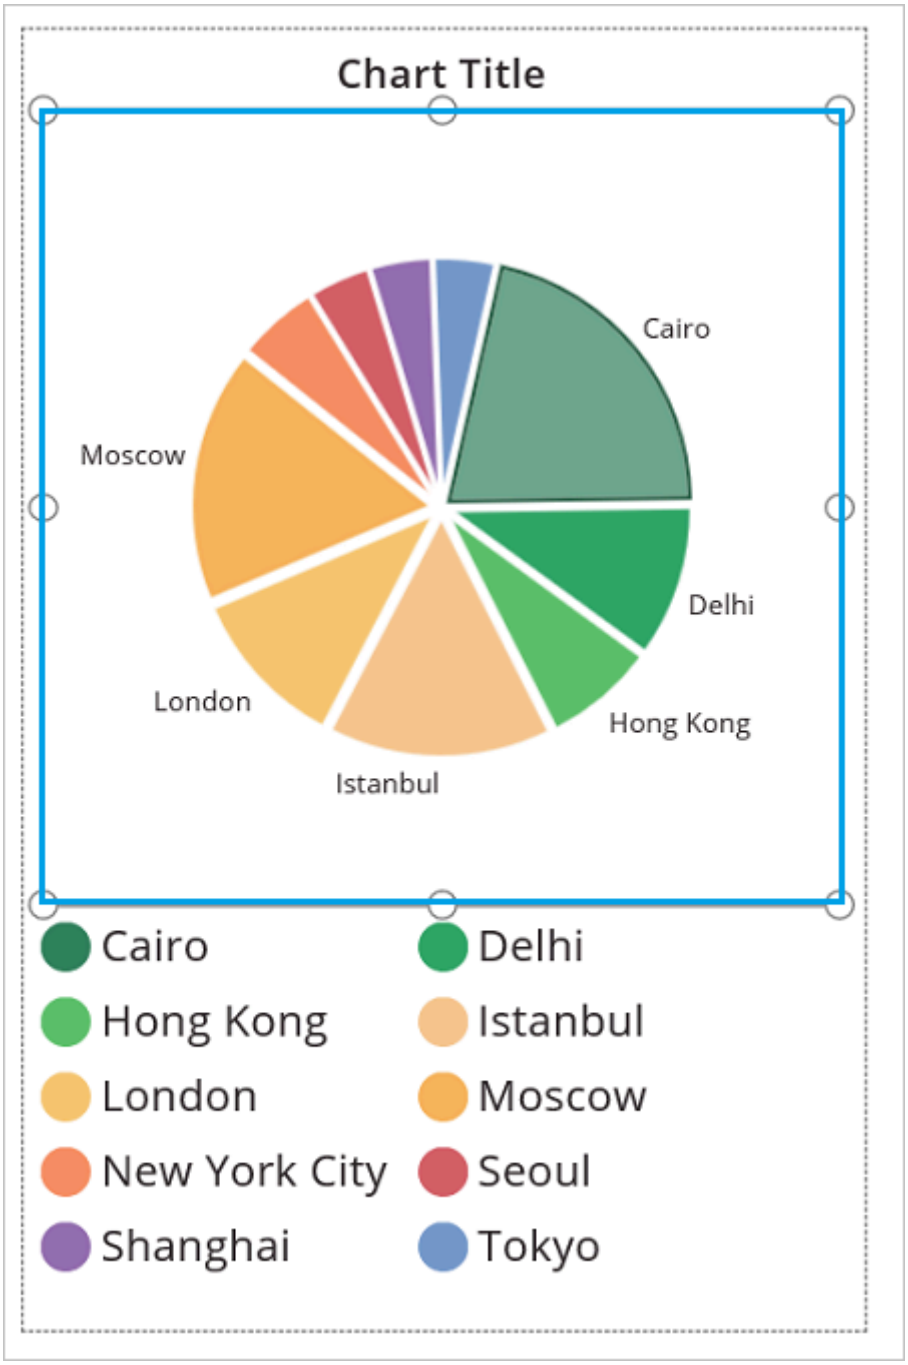
6. Press Esc to return to the default workspace.

Add a pie chart

1. On the command bar selelct, **Insert** > **Charts** > **Pie Chart**.

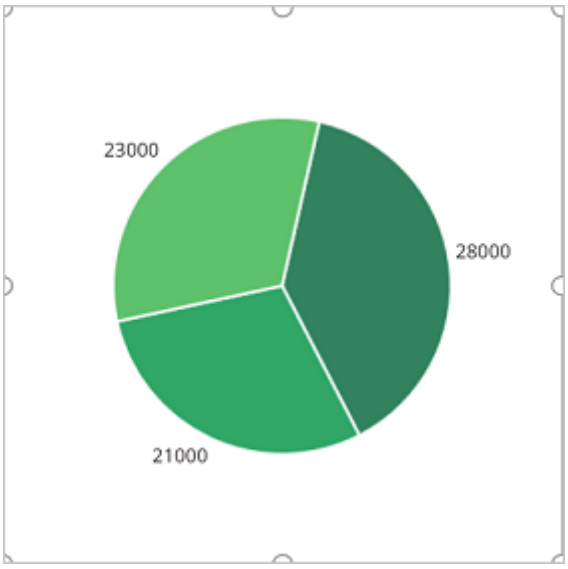
2. Move the pie chart under the **Import data** button.

3. In the pie-chart control, select the middle of the pie chart:



4. Set the **Items** property of the pie chart to this expression: `ProductRevenue.Revenue2014`

The pie chart shows the revenue data from 2014.



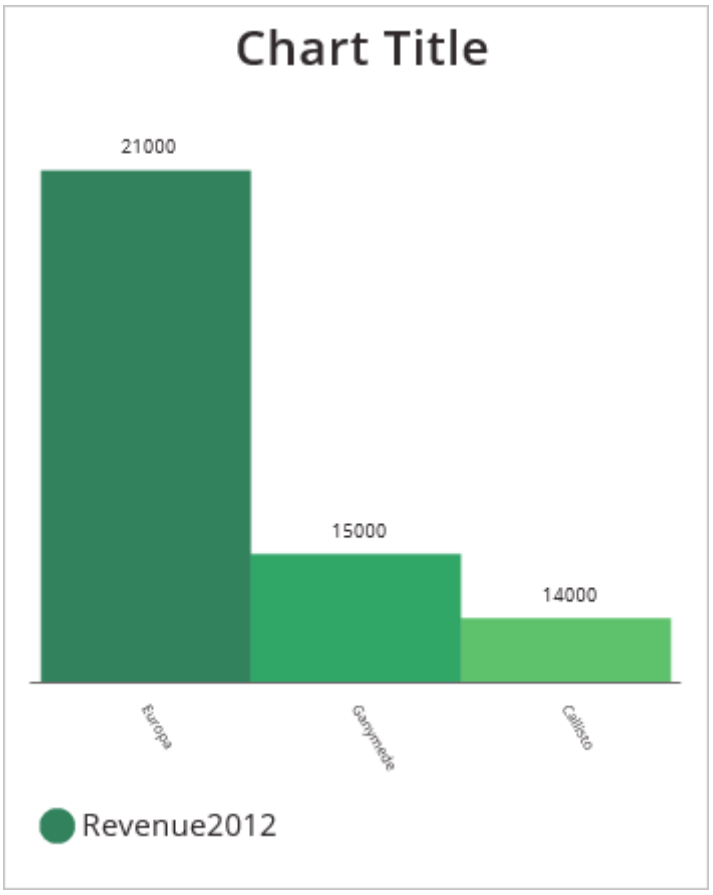
Add a bar chart to display your data

Now, let's use this ProductRevenue collection in a bar chart:

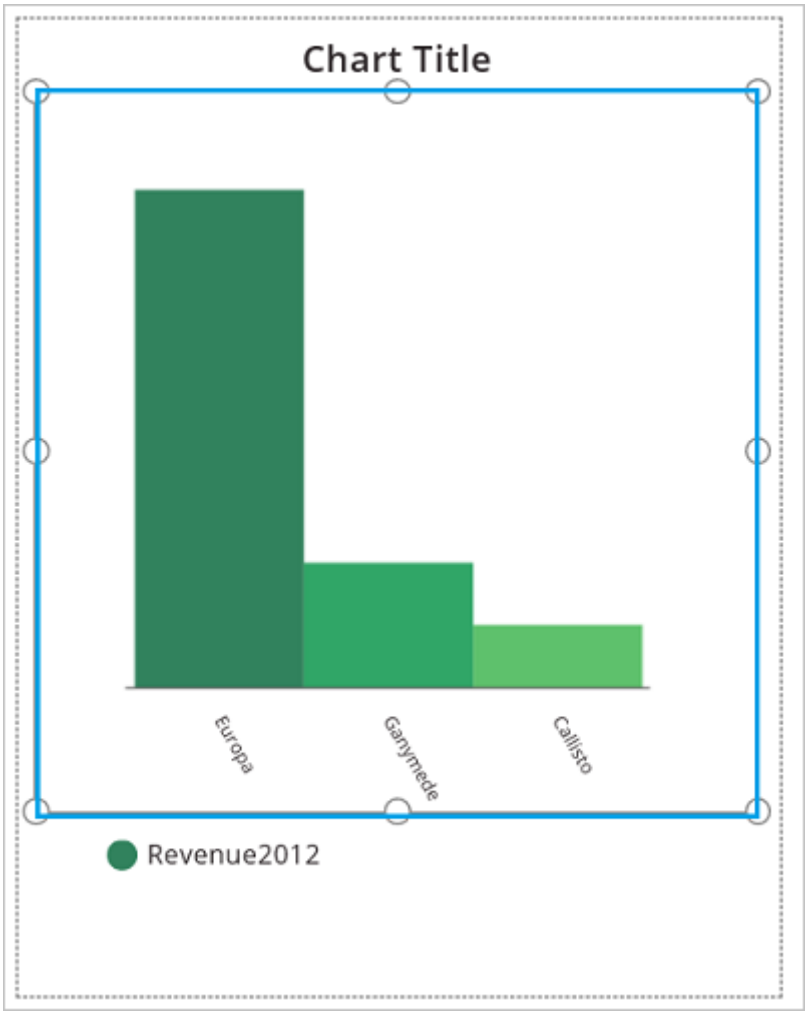
1. On the command bar, select **New screen** > **Blank**.
2. On the command bar, select **Insert** > **Tree view** > **Column Chart**.
3. Select the middle of the column chart. Set the **Items** property of the column chart to `ProductRevenue`:

   The column chart shows the revenue data from 2012:

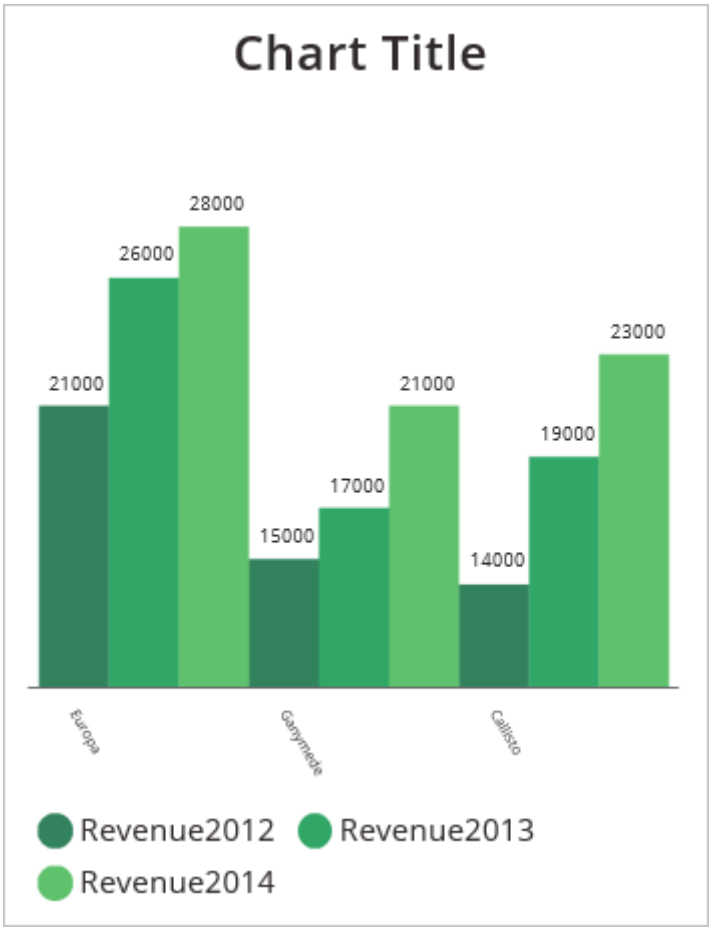


4. In the column chart, select the center square:



5. On the **Chart** tab, select **Number of Series**, and then enter **3** in the formula bar:

The column chart shows revenue data for each product over three years:



Using multimedia files in canvas apps

Summarize this article for me

You can add images, audio, and video files to a canvas app. Add video from streaming services such as Microsoft Clipchamp, Azure Media Services, or third-party streaming services, such as YouTube. Or use input controls such as **Pen Input** to collect signatures.

This article walks you through working with multimedia, streaming, and input control scenarios. The data source used in this article is an Excel file in OneDrive for Business.

Prerequisites

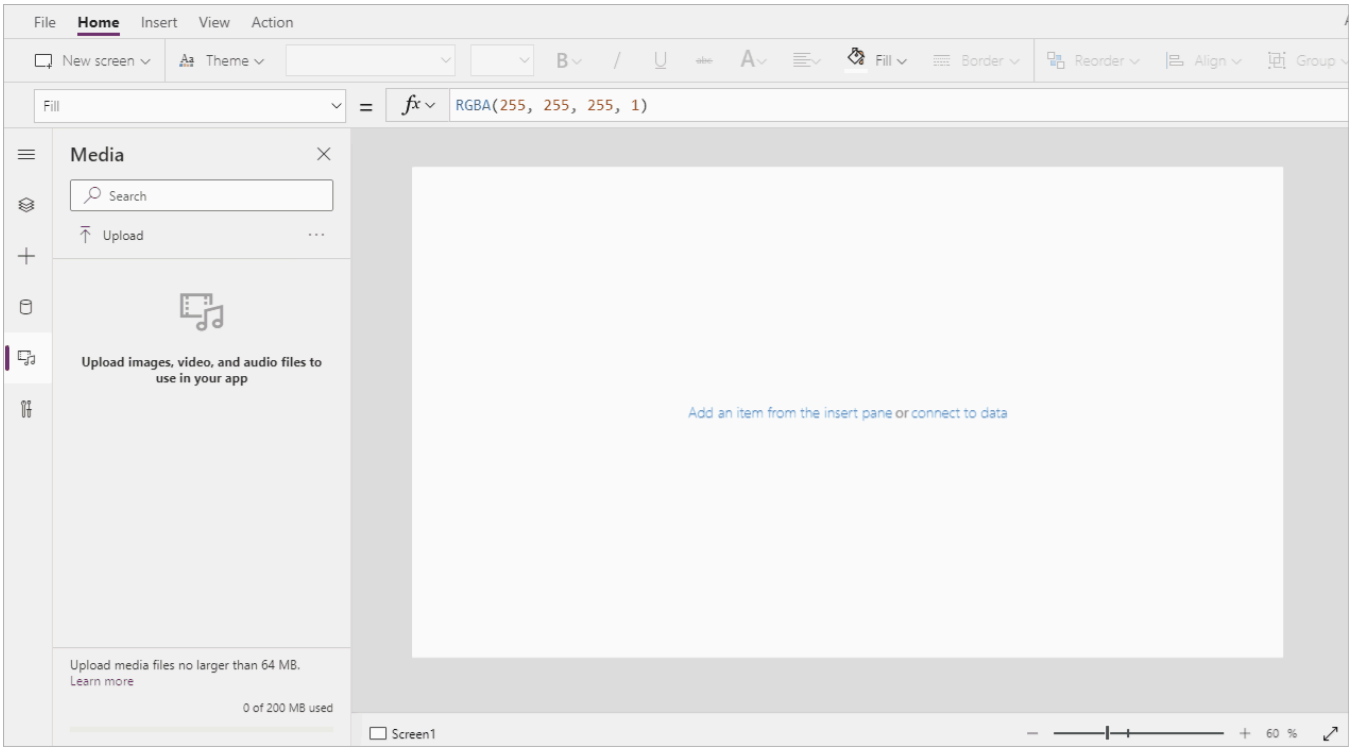
Sign up for Power Apps, and then sign in by using the same credentials that you used to sign up.

Watch this video to learn how to use multimedia files in canvas apps:

https://learn-video.azurefd.net/vod/player?id=d8fdba22-a9cf-4ce4-a77d-7c7be89666bc&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fadd-images-pictures-audio-video

Add media from a file or the cloud

You can choose the kind of media file to add (for example, images, video, or audio). You can add images by using the media pane or by using the images control.

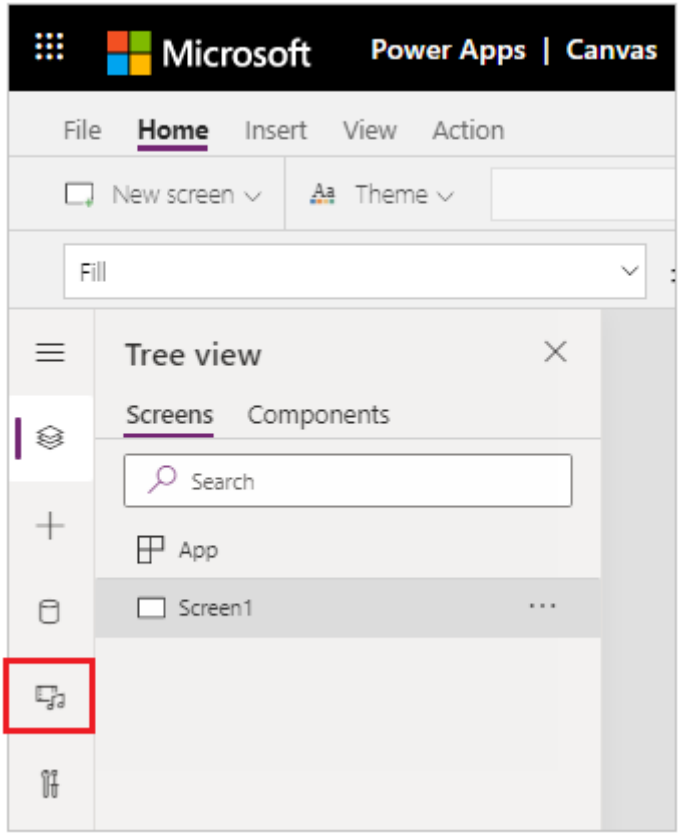


> **Note**
>
> When adding media files by URL,
>
> - Use HTTPS to ensure compatibility with modern browsers.
> - Ensure the URL is accessible anonymously without any authentication. Try to enter the URL in private browsing mode to verify that it's accessible without signing in.

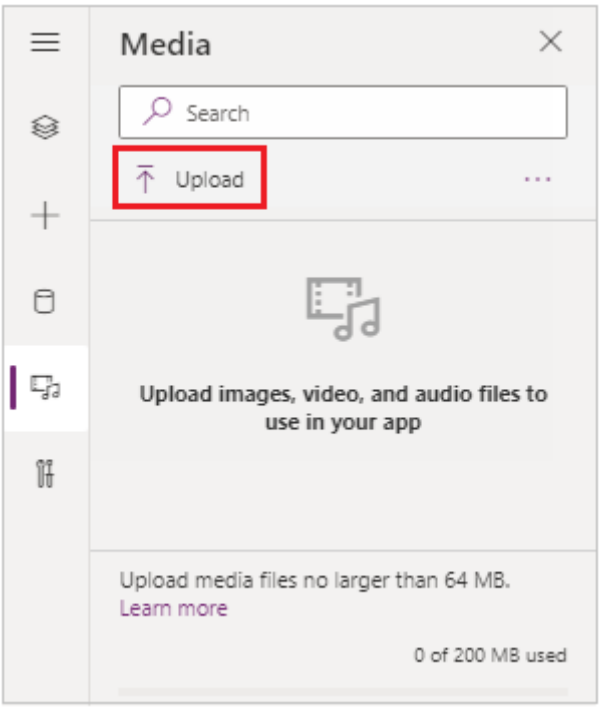
Add images, audio, or video by using the media pane

To add or remove media files in your app by using the **Media** pane:

1. Select **Media** from the left pane.

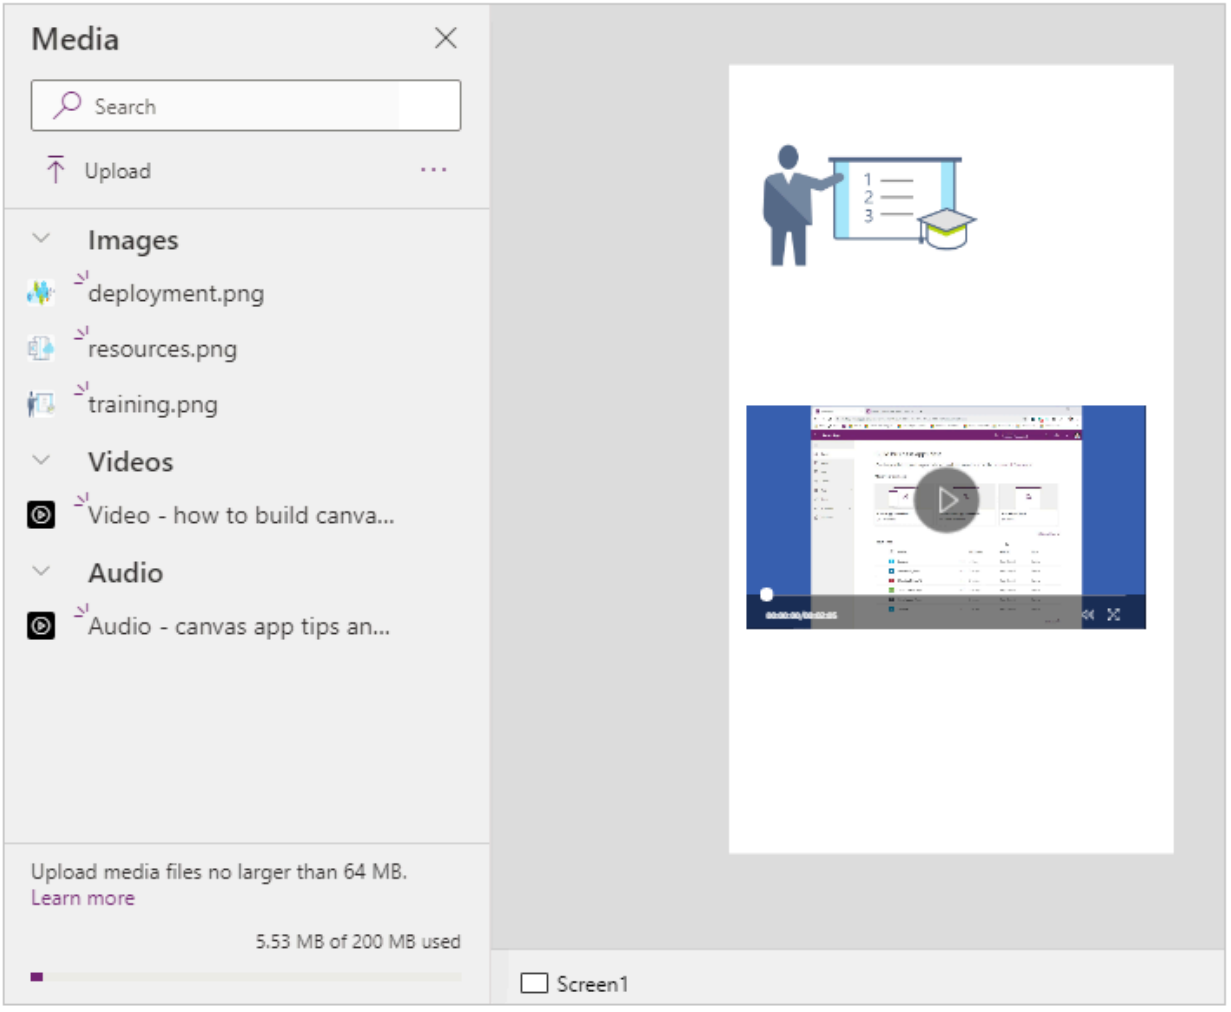


2. Select **Upload** from the media panel.



3. Select the files that you want to add, and then select **Open**.

4. Select the file from the media pane to insert into the screen.



5. Save and publish your app.

6. Share app with others.

Add images, audio, or video by using the controls

To add images, audio, or video by using the Image, Audio or Video controls:

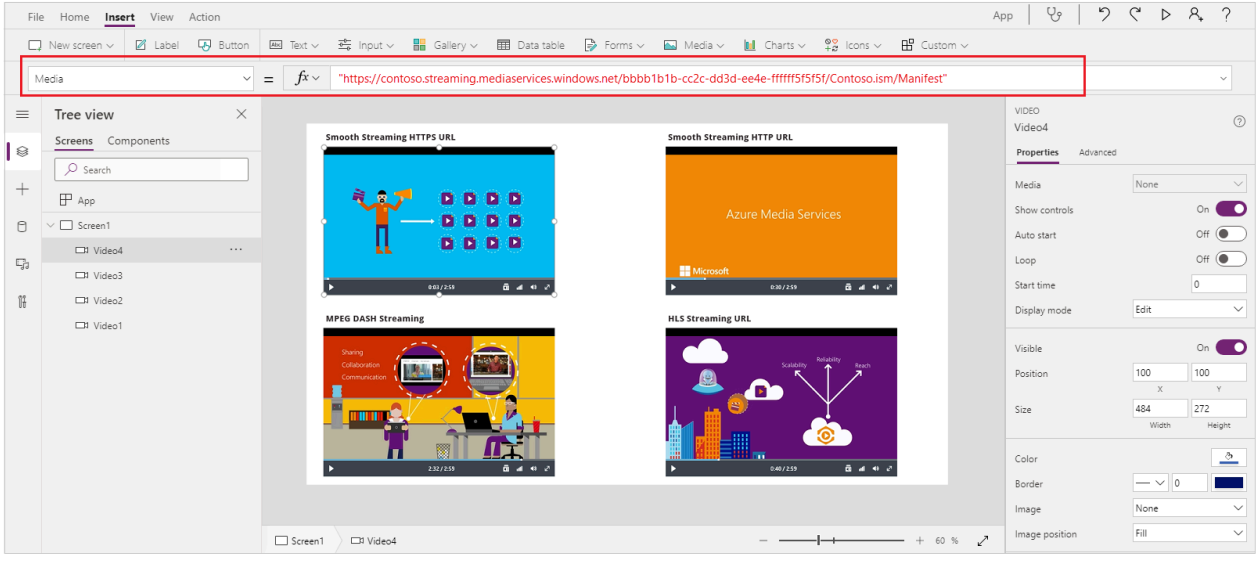
1. Select **Insert** from the top menu.
2. Select the **Media** drop-down.
3. Choose from **Image**, **Audio**, or **Video** controls.

For the **Image** control, update the *Image* property with the image file name, without extension. For the **Audio** or **Video** control, update the *Media* property with the file name, or the URL such as YouTube video URL in double quotation marks.

Add media from Azure Media Services

1. From your Azure Media Services account, upload and publish your video asset from **AMS** > **Settings** > **Assets**.
2. After the video is published, copy its URL.
3. From Power Apps, add the **Video** control from **Insert** > **Media**.
4. Set the **Media** property to the URL that you copied.

   As this graphic shows, you can choose any streaming URL that Azure Media Services supports:



5. Save and publish your app.

6. Share app with others.

Add Microsoft Clipchamp media

For information about how to add a Microsoft Clipchamp video control, see Microsoft Clipchamp video control example.

Add images from the cloud to your app

In this scenario, you save images in a cloud storage account, OneDrive for Business. You use an Excel table to contain the path to the images, and you display the images in a gallery control in your app. In this scenario, you use your own image files stored in OneDrive for Business. You create an Excel table that contains the file paths to those images, and then display the images in a gallery control in your app.

> **Note**
>
> The path to these images in the Excel file must use forward slashes. When Power Apps saves image paths in an Excel table, the path uses backslashes. If you use image paths from such a table, change the paths in the Excel table to use forward slashes instead of backslashes. Otherwise, the images won't display.

1. In OneDrive for Business, create a folder named Assets_images, and upload a few .jpg or .png files to that folder.

2. (Optional) If you used a different folder name, rename the folder to Assets_images.

3. In an Excel spreadsheet, create a one-column table named Images, and then add one row per image. In each row, paste the file path (direct link) to an image in your Assets_images folder.

Images
https://contoso.sharepoint.com/personal/contoso_com/Assets_images/Jacket_10_LightBrown.jpeg
https://contoso.sharepoint.com/personal/contoso_com/Assets_images/Jacket_5_Lilac.jpeg
https://contoso.sharepoint.com/personal/contoso_com/Assets_images/Jacket_7_DARKBLUE.jpeg
https://contoso.sharepoint.com/personal/contoso_com/Assets_images/Jacket_7_DarkGreen.jpeg
https://contoso.sharepoint.com/personal/contoso_com/Assets_images/Jacket_8_PaleMarigold.jpeg

   Tip: To copy the file path from **OneDrive for Business**, select an image file, and then select **Path** (*Copy direct link*) from the details pane on the right side of the screen.

4. Name the table **Jackets**, and name the Excel file **Assets.xlsx**.

5. In your app, add the **Jackets** table as a data source.

6. Optionally, update your app orientation to Landscape.

7. Select **Insert** > **Gallery**, and then select **Horizontal**.

8. Optionally, select the text field and then the heading field under the first image, and delete them to keep only images on the screen.

   If you see a formula error, press **Ctrl+Z** to undo the delete. Then, delete the *Subtitle* field and the *Title* field.

9. Set the gallery's **Items** property of the gallery to `Jackets`.

10. Select the first image in the gallery, and set its **Image** property to `ThisItem.Images`:

    The gallery is automatically updated with the images:

When you set the **Items** property, a column named **PowerAppsId** is automatically added to the Excel table.

11. Save and publish your app.

12. Share app with others.

Upload pen drawings to the cloud

In this scenario, you learn how to upload pen drawings to your data source, OneDrive for Business, and examine how the drawings are stored there.

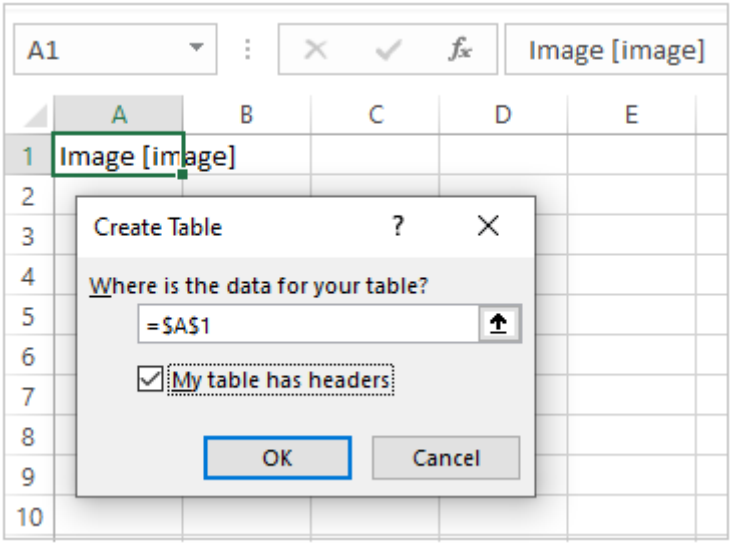
1. In Excel, add **Image [image]** to cell A1.

2. Create a table by using the following steps:

   a. Select cell A1.

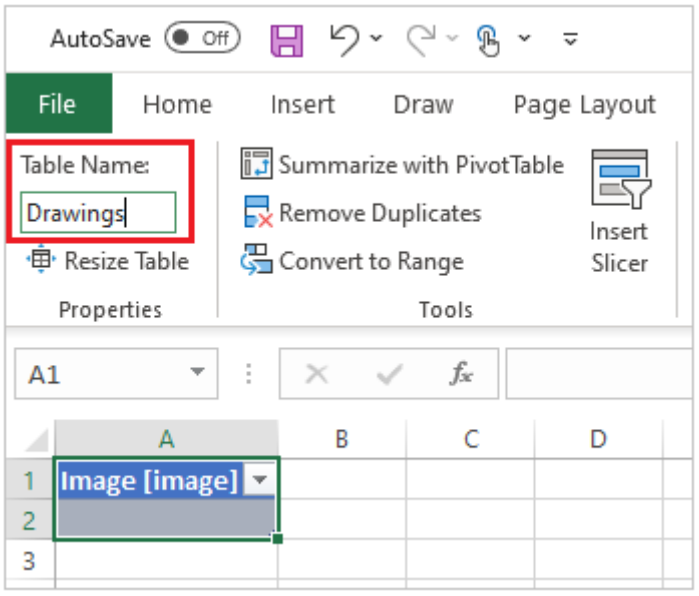
   b. On the **Insert** ribbon, select **Table**.

   c. In the dialog box, select **My table has headers**, and then select **OK**.



Your Excel file is now in a table format. For more information about table formatting in Excel, see Format the data as a table.

d. Name the table **Drawings**:



3. Save the Excel file to OneDrive for Business as **SavePen.xlsx**.

4. In Power Apps, create a blank app with Tablet layout.

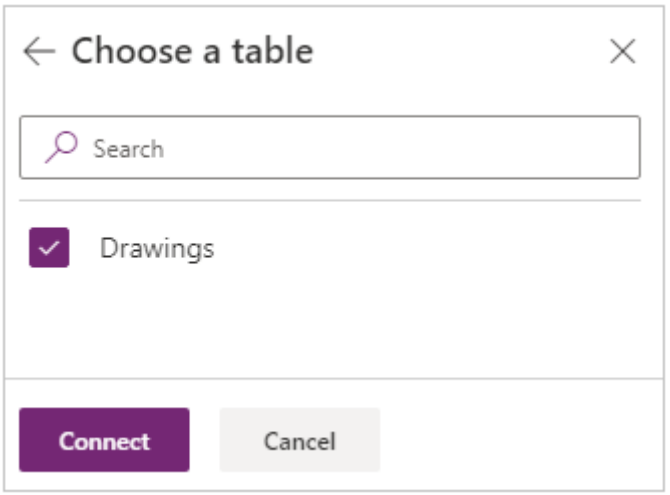
5. In your app, add the OneDrive for Business account as a data source:

   a. Select **View** menu, and then select **Data sources**.

   b. Select **Add data source**, and then select **OneDrive for Business**.

   c. Select **SavePen.xlsx**.

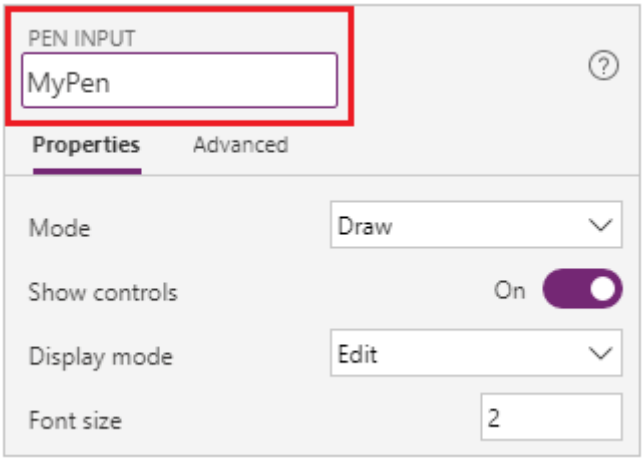
   d. Select the **Drawings** table, and then select **Connect**.



Now, the Drawings table is listed as a data source.

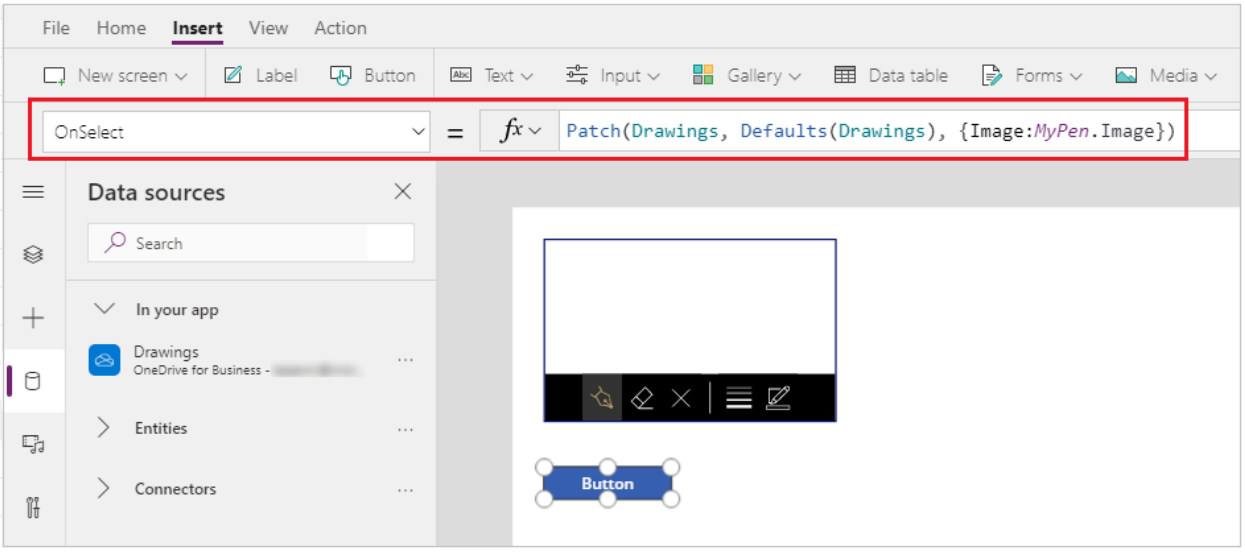
6. Select **Insert** > **Input**, and then select **Pen Input**.

7. Rename the new control **MyPen**:



8. On the **Insert** tab, add a **Button** control, and set its **OnSelect** property to this formula:

   Patch(Drawings, Defaults(Drawings), {Image:MyPen.Image})



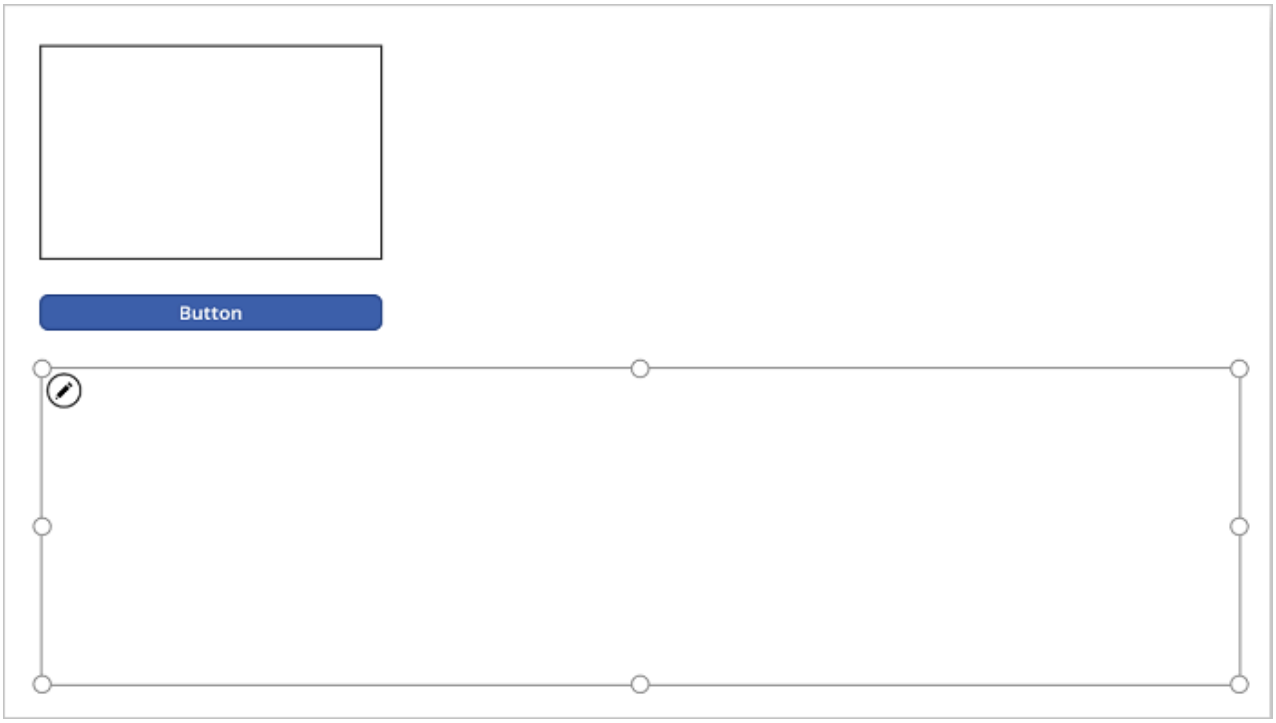
9. Add a **Horizontal** gallery control (**Insert** tab > **Gallery**).

10. Optionally, select the text field and then the heading field under the first image, and delete them to keep only images on the screen.

    If you see a formula error, press **Ctrl+Z** to undo the delete. Then, delete the *Subtitle* field and the *Title* field.

11. Set the gallery **Items** property to `Drawings`. The **Image** property of the gallery control is automatically set to `ThisItem.Image`.

    Arrange the controls so that your screen resembles the following image:



12. Press F5, or select Preview ( ).

13. Draw something in MyPen, and then select the button.

    The first image in the gallery control displays what you drew.

14. Add something else to your drawing, and select the button.

    The second image in the gallery control displays what you drew.

15. Close the preview window by pressing Esc.

    In your cloud storage account, a **SavePen_images** folder is automatically created. This folder contains your saved images with IDs for their file names. To show the folder, you might need to refresh the browser window by, for example, pressing F5.

    > **Note**
    >
    > The folder name might be different if your Excel file name is different. For example, if your file name is Pen.xlsx, the folder name is Pen_images.

    In **SavePen.xlsx**, the **Image** column specifies the path to the new images.

16. Save and publish your app.

17. Share app with others.

Remove unused media

To clean up your app or reduce its size, remove all unused media files by selecting **Media** > **Remove unused media**.

Known limitations

- To enable better performance while loading an app, the following size restrictions apply:
  - The total size of all media files uploaded to an app can't exceed 200 MB.
  - The maximum size of an individual media file in an app can't exceed 64 MB.
- Supported media file types: `.jpg, .jpeg, .gif, .png, .bmp, .tif, .tiff, .svg, .wav, .mp3, .mp4`.
- When connecting your app to cloud-based storage, Cloud-storage known limitations apply.

Use Copilot answer control for canvas apps (preview)

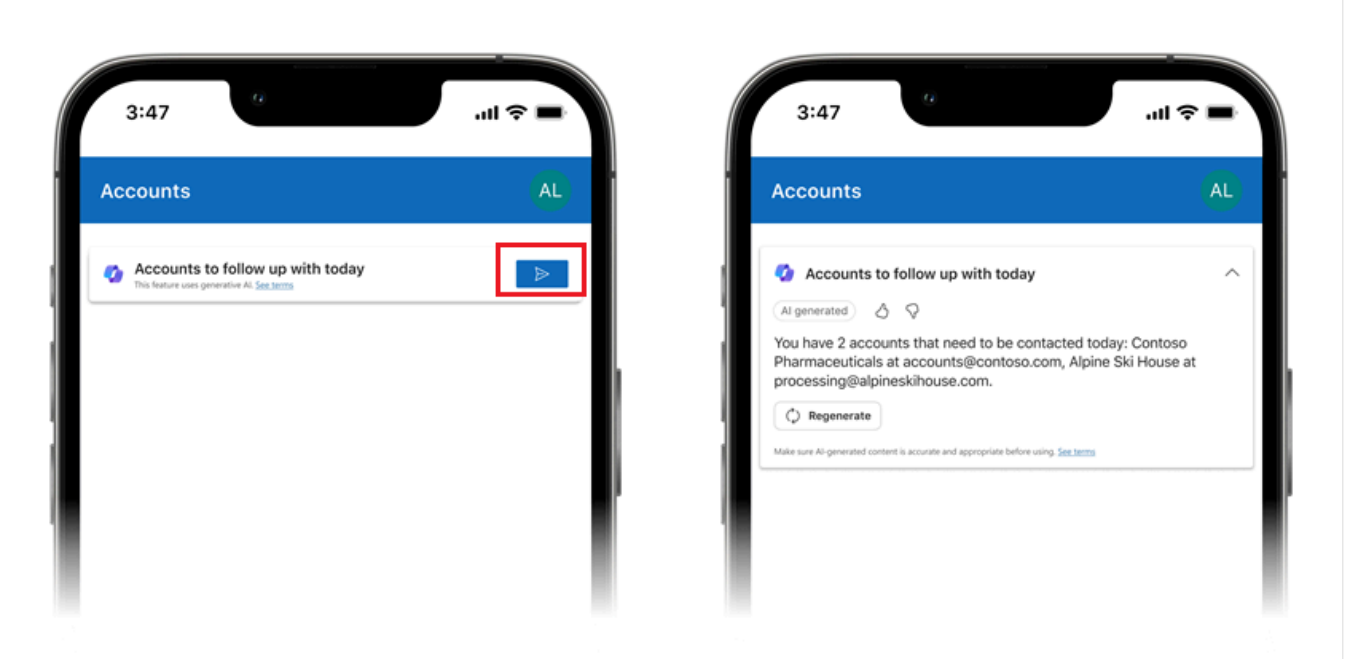
Summarize this article for me

[This article is prerelease documentation and is subject to change.]

Makers can use the Copilot answer control to set predefined questions that end users can use to get AI-generated information with a single click. The control is powered by Microsoft Copilot and is designed for mobile users to provide them with immediate answers to frequently asked questions.

> **Important**
>
> Starting February 2, 2026, this feature will be removed. Existing apps with this control will remain functional for a limited time but will eventually no longer be supported. Microsoft 365 Copilot Chat in canvas apps is the new the recommended solution for natural language interactions in canvas apps. To ensure a smooth transition and prevent any disruption, we recommend that you migrate to Microsoft 365 Copilot chat as soon as it becomes available in your environment.

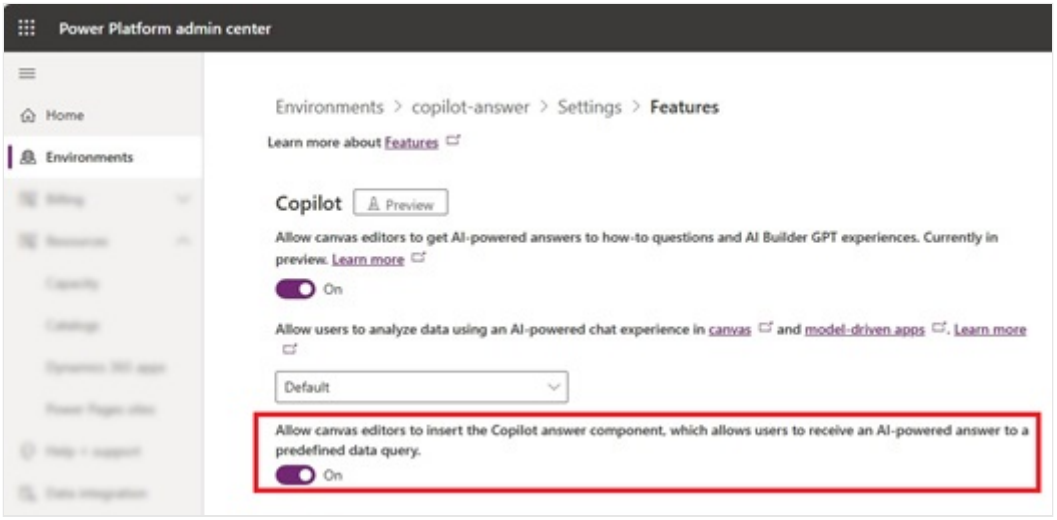
> **Note**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.



Enable Copilot answer control for your environment

To use the Copilot answer control in a canvas app, an admin must first turn on the feature, **Allow canvas editors to insert the Copilot answer component, which allows users to receive an AI-powered answer to a predefined data query** in their environment.

This setting can be found in the Power Platform admin center by going to **Environments** > [select an environment] > **Settings** > **Product** > **Features**. For more information, see Manage feature settings.

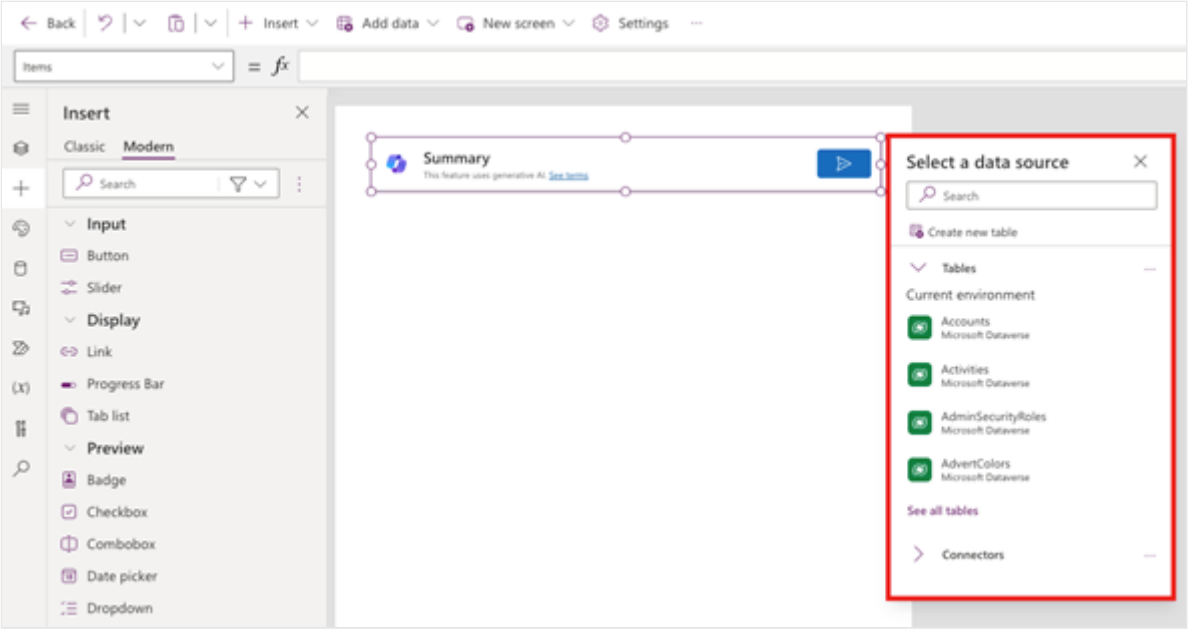


Add Copilot answer control

With your canvas app open for editing in Power Apps Studio:

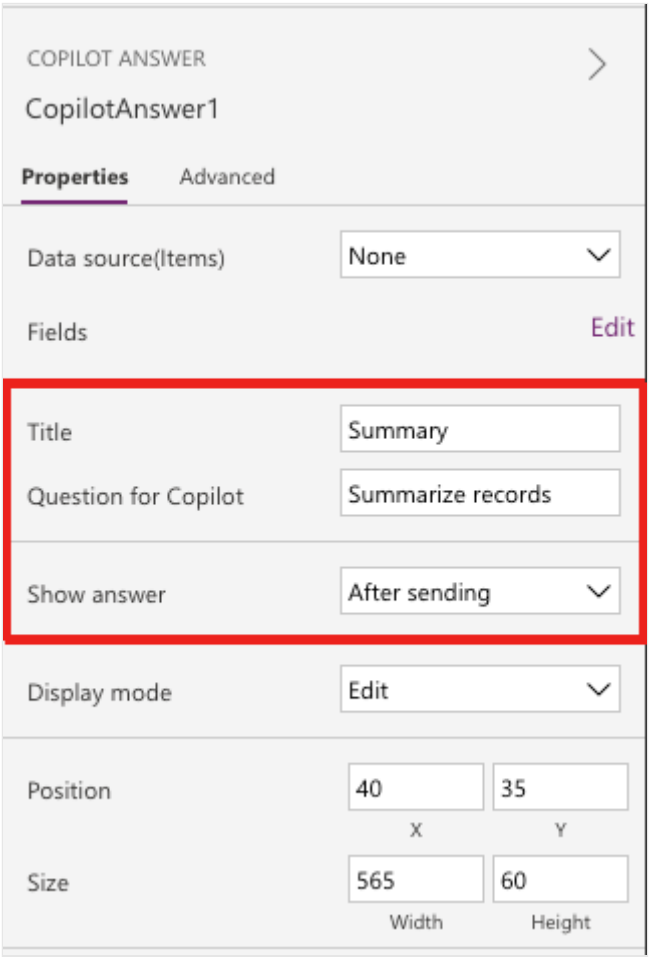
1. On the command bar, select **Insert** and then select **Copilot answer (preview)**

2. When the **Copilot answer (preview)** control is added to the canvas app, select a data source from the pane. Copilot only supports Dataverse tables.



3. On the control properties pane, select the **Properties** tab.

4. In the properties, enter the **Title**, **Questions for Copilot**, and **Show answer** for the question. You can also edit other control properties as needed.



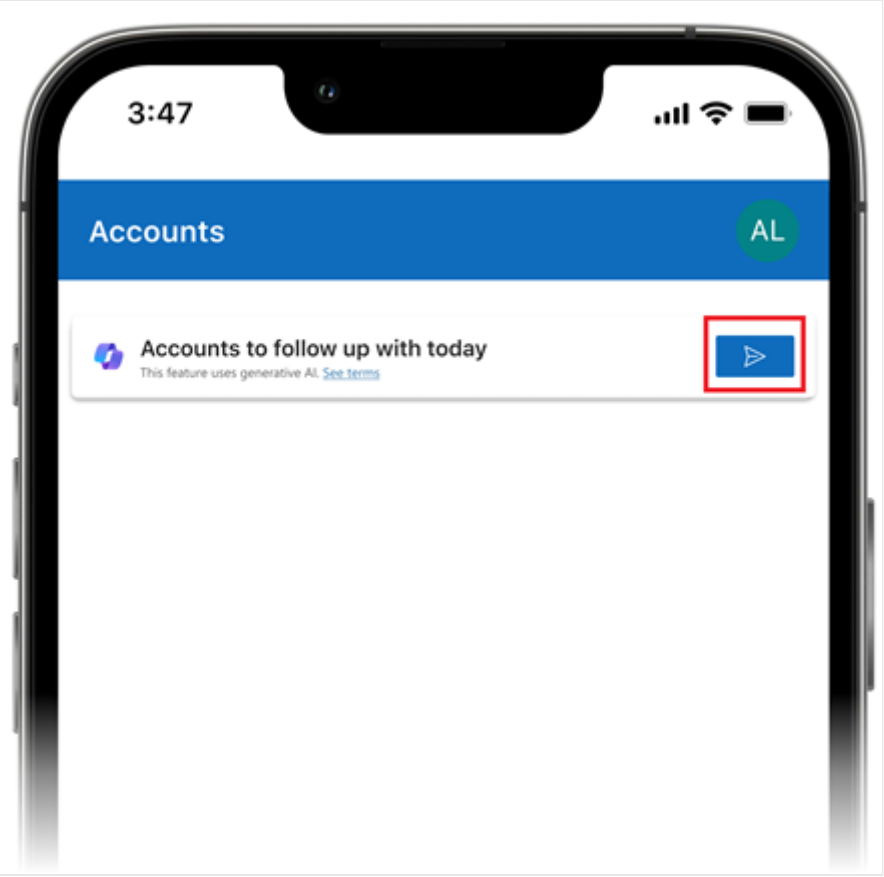
5. When you're done, save and publish your app.

Use Copilot answer control

End users can regenerate responses and provide feedback on the quality of responses.

Follow these steps to see answers generated by the Copilot answer control:

1. Open a canvas app on Power Apps mobile and navigate to the Copilot answer control in your app.
2. On the Copilot answer control select, **Send**.



Last updated on 02/24/2026

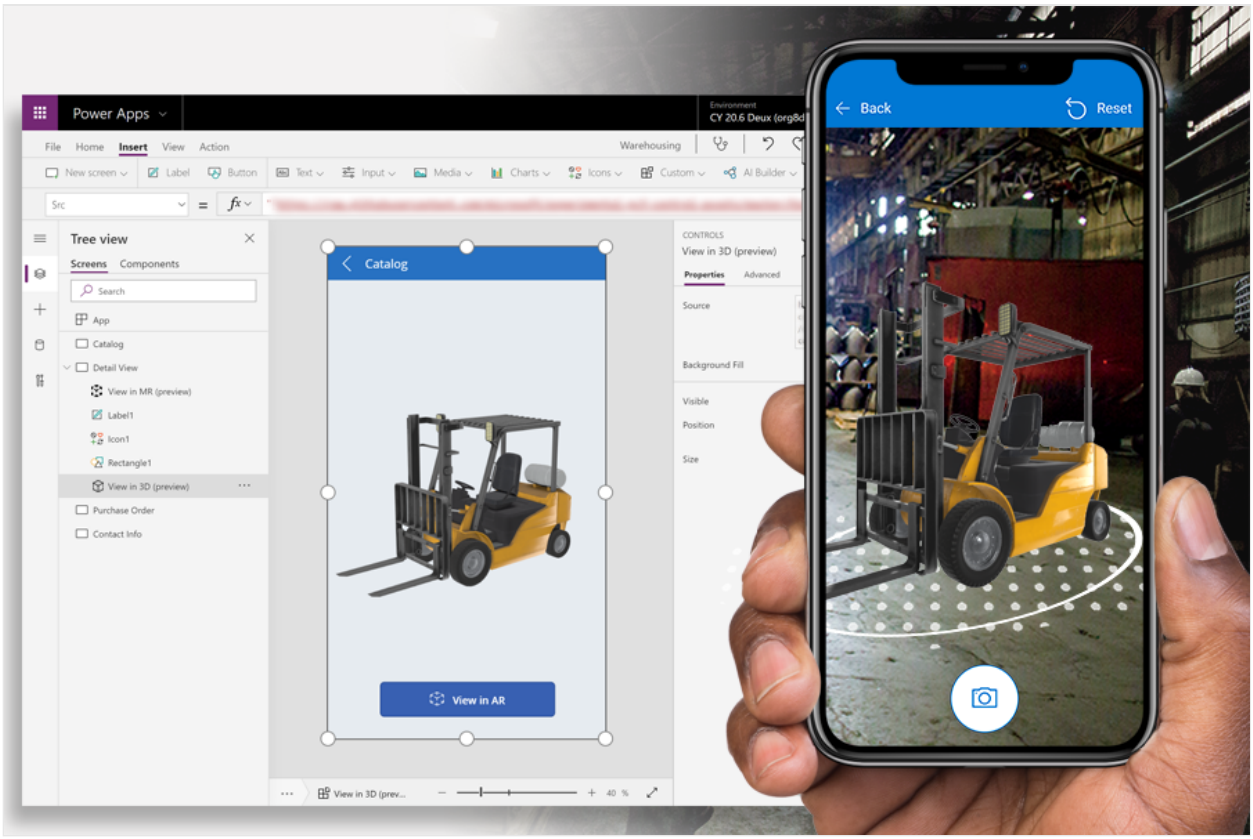
Add mixed reality controls to your canvas app

Article • 09/20/2022

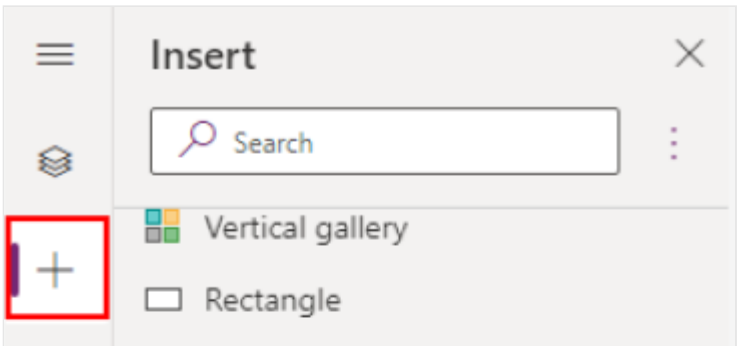
Add mixed reality (MR) controls to your canvas apps to interact with the real world in 3D.

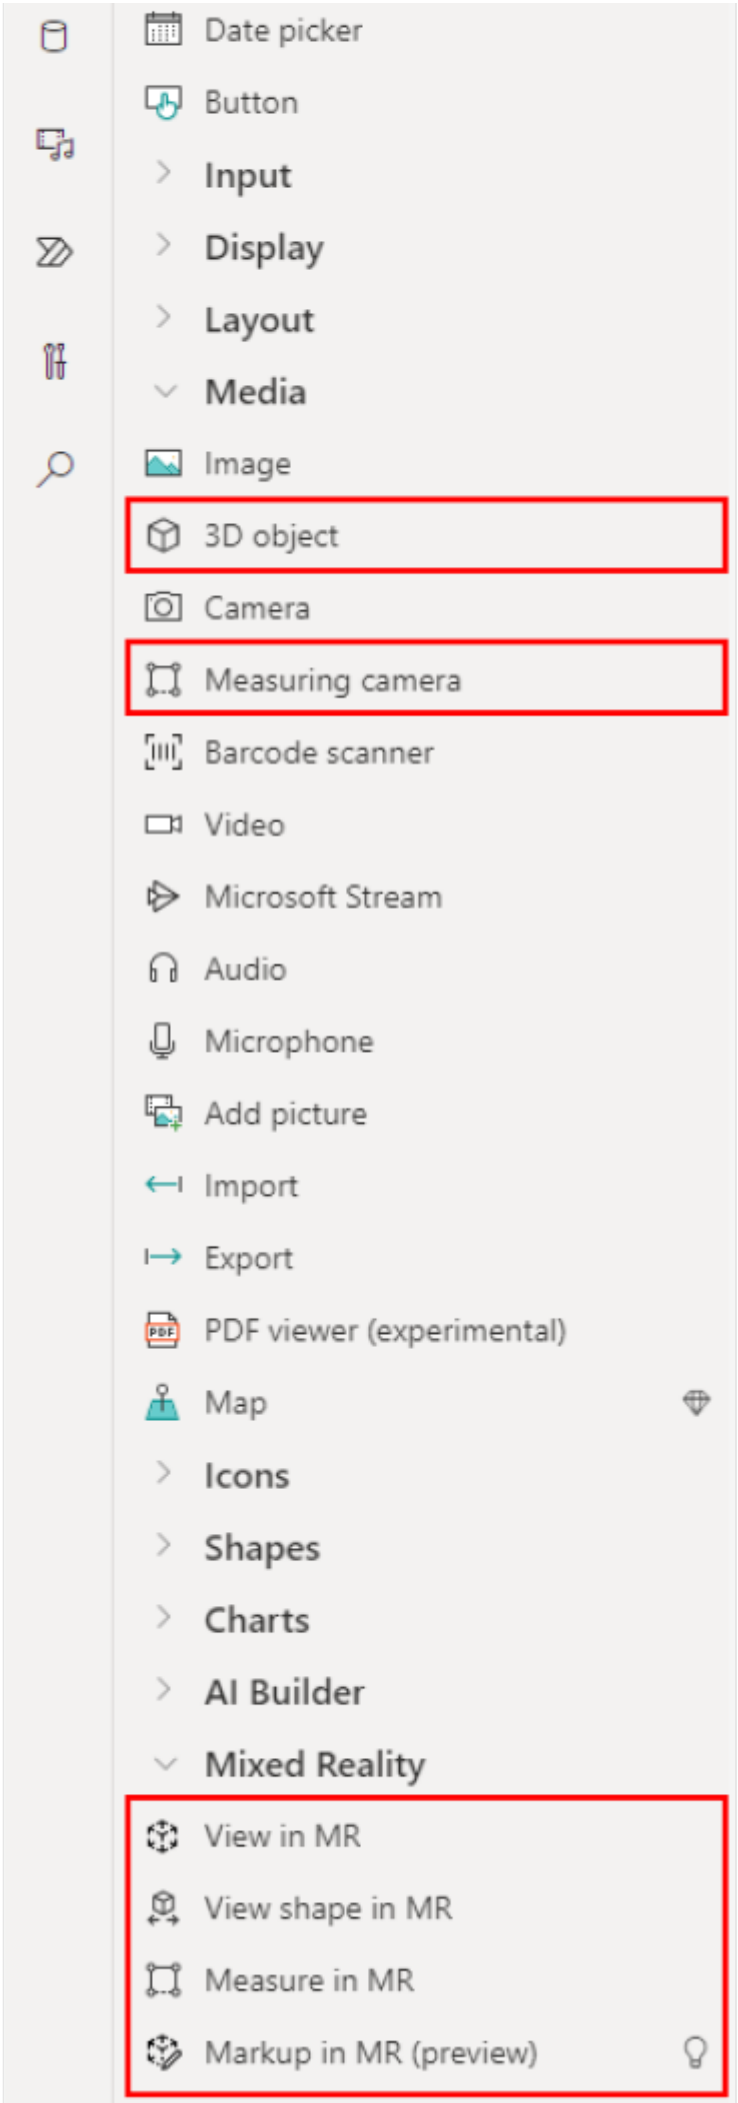
You can use MR controls to:

- View and manipulate 3D content with 3D object
- Overlay 3D content and 2D images on the camera feed with View in mixed reality
- Measure distance, area, and volume with Measure in mixed reality
- Identify spaces and locations by painting 3D lines and arrows with Markup in mixed reality



You'll find the controls on the **Insert** pane, under **Media** and **Mixed Reality**:





Date picker
Button
Input
Display
Layout
Media
Image
3D object
Camera
Measuring camera
Barcode scanner
Video
Microsoft Stream
Audio
Microphone
Add picture
Import
Export
PDF viewer (experimental)
Map
Icons
Shapes
Charts
AI Builder
Mixed Reality
View in MR
View shape in MR
Measure in MR
Markup in MR (preview)

> **Tip**
>
> The MR controls in Power Apps use Babylon and Babylon React Native. Mixed reality content that works in the **Babylon sandbox** should work in Power Apps through this shared MR platform. If your content works in Babylon but not in Power Apps, ask a question in the **Power Apps community forum**.
>
> **Read more about our integration with Babylon**.

Prerequisites

The device you use to create an app with MR controls, such as your PC, doesn't need to be MR-capable. Mobile devices that run the app must have specific hardware and software to use MR controls.

Android devices

Android devices need to have Google Play Services for AR (known more commonly as ARCore) installed. ARCore should be installed automatically on MR-capable devices. If necessary, download Google Play Services for AR from the Google Play Store.

For more information about ARCore and devices that support it, see the list of supported devices on the Google ARCore support site.

The experience is a little different for devices in China, which don't ship with the Google Play Store. ARCore must be downloaded from specific app stores in China.

iOS (Apple) devices

iPhones and iPads with specific hardware can run MR apps using the ARKit framework. For more information about MR and iOS devices that support it, see the list of supported devices on the Apple augmented reality website. (Scroll to the bottom of the page to see the list.)

Mixed reality controls

Start adding the controls to your apps:

- View 3D content with the **3D object** control.

- View images and 3D content in the real world with the **View in mixed reality** control.
- Measure distance, area, and volume with the **Measure in mixed reality** control.
- Create and view 3D shapes with the **View shape in mixed reality** control.
- Paint 3D lines or draw 3D arrows to specify an area or asset in your environment with the **Markup in MR** control.

See also

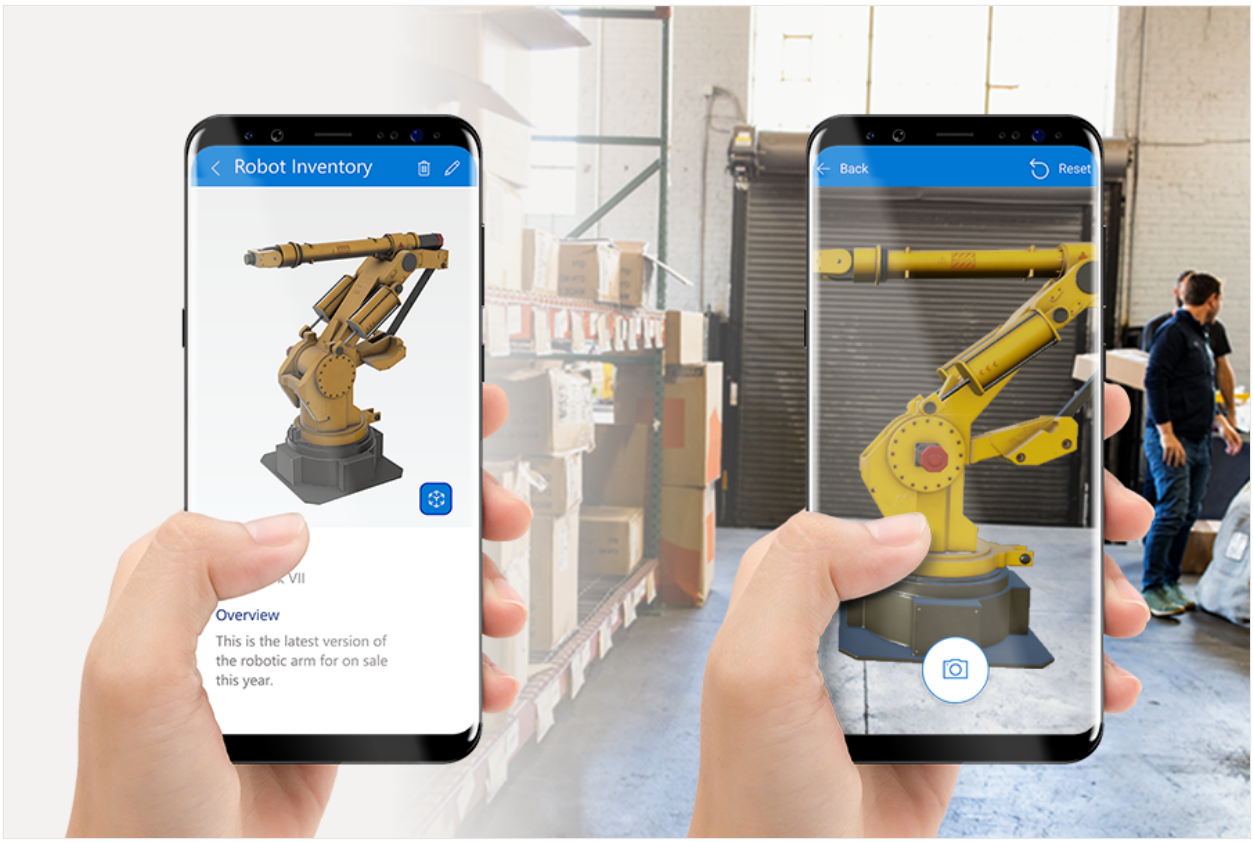
Improve sales conversation by placing products directly in your customer's space with Mixed Reality

View 3D content in Power Apps

Article • 05/09/2022

Easily add interactive 3D content to your canvas apps. You can select from a gallery of 3D content then rotate and zoom into the model with simple gestures.



Important

Your 3D content must be in the .glb, .obj, or .stl file formats. You can **convert your existing 3D models into the .glb file format** from a variety of 3D formats.

Tip

The mixed reality (MR) controls in Power Apps use Babylon and Babylon React Native. Mixed reality content that works in the **Babylon sandbox** should work in Power Apps through this shared MR platform. If your content works in Babylon but not in Power Apps, ask a question in the **Power Apps Community Forum**. (Tag it with "mixed reality.")

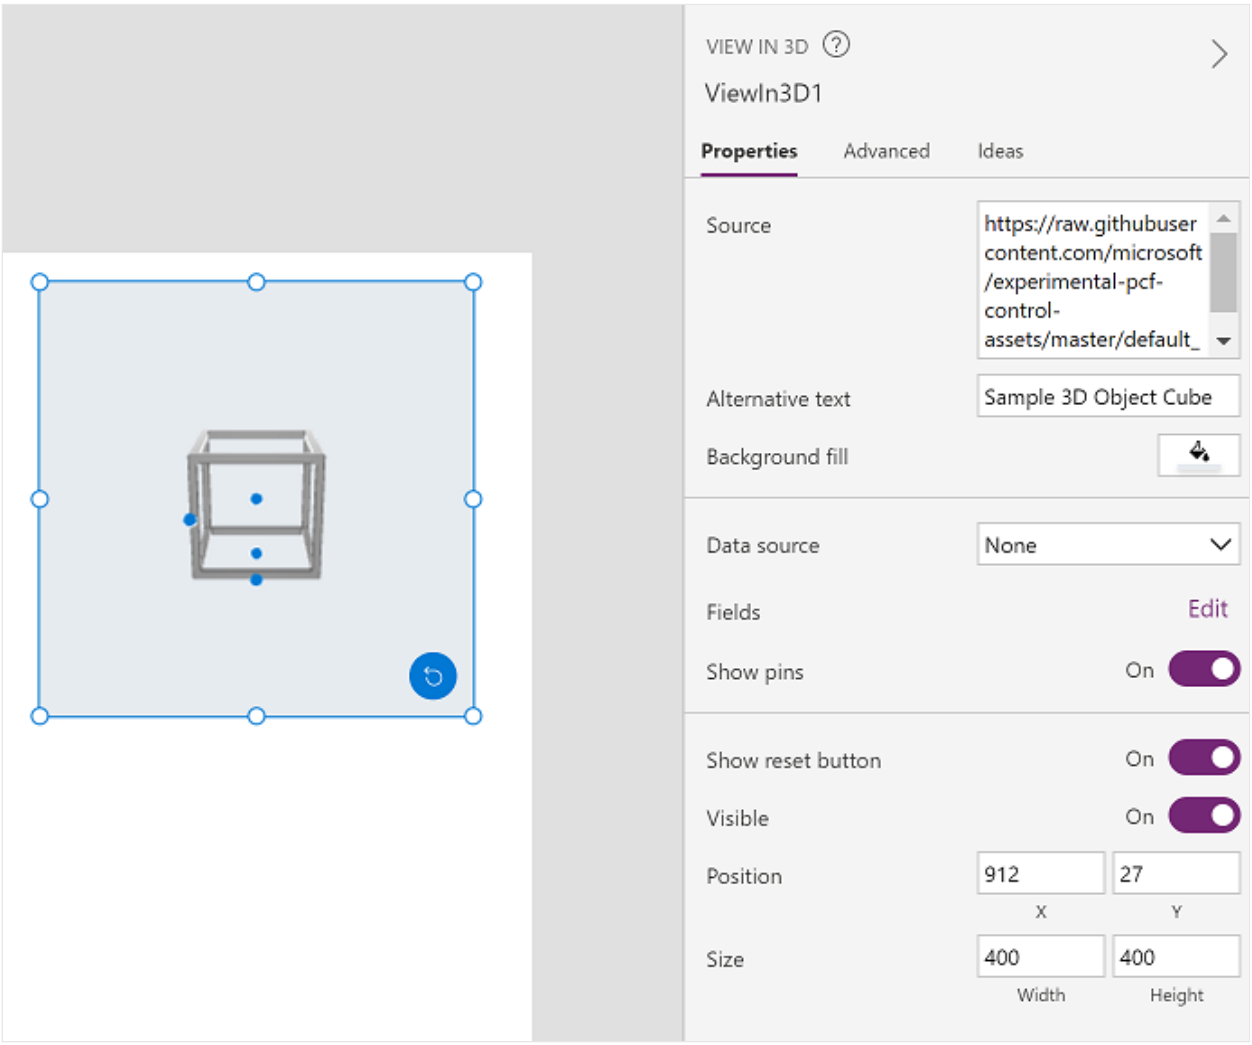
Add 3D object control to an app screen

With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab and expand **Media**.
2. Select **3D object** to place the control in the app screen, or drag the control to the screen to position it more precisely.

Key properties

Change the 3D content control's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



Property	Description	Type	Location
Source	Identifies the object file to display. The **3D object** control supports loading models from various sources. See Loading external 3D models for details.	Not applicable	Properties; Advanced: **Source**
Alternative text	Specifies the text to be displayed if the model can't load or if the user hovers over the model.	String	Properties; Advanced: **AltText**

Property	Description	Type	Location
Background fill	Sets the control's background color.	Color picker	Properties; Advanced: **BackgroundFill** (accepts RGBA or HTML hexadecimal color codes)
Pins(Items)	Shows pins on the model at specific coordinates, provided in a data source (**Items**). If *None*, no pins are shown.	Data table	Properties; Advanced: **Items**
Show pins	Shows the pins described in **Items**.	Boolean	Properties; Advanced: **ShowPins**
MaxPins	Specifies the maximum number of pins that can be shown on the model.	Integer	Advanced
PinsX	Specifies the location of pins on the X axis in 3D coordinate space.	Floating point number	Advanced
PinsY	Specifies the location of pins on the Y axis in 3D coordinate space.	Floating point number	Advanced
PinsZ	Specifies the location of pins on the Z axis in 3D coordinate space.	Floating point number	Advanced
Show reset button	Shows or hides a button that resets the model to its initial state.	Boolean	Properties; Advanced; **ShowReset**
OnModelLoad	Contains behavior formula that runs when a model is loaded.	Event	Advanced
OnChange	Contains behavior formula that runs when any property of the control is changed.	Event	Advanced
OnSelect	Contains behavior formula that runs when the user selects a pin or the control.	Event	Advanced

Additional properties

Property	Description	Type	Location

Property	Description	Type	Location
ContentLanguage	Determines the display language of the control, if it's different from the language used in the app.	String	Advanced
DisplayMode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Dropdown list	Advanced
Position	Places the upper-left corner of the control at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the control using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
TabIndex	Specifies the order the control is selected if the user navigates the app using the Tab key.	Integer	Advanced
Tooltip	Determines the text to display when the user hovers over a pin.	String	Advanced
Visible	Shows or hides the control.	Boolean	Properties; Advanced: **Visible**

Performance considerations

We recommend that you use one 3D control on a screen for the best user experience. Multiple instances of the **3D object** control on one screen will try to load their 3D models at the same time, which can severely degrade the performance of your app.

Other mixed reality controls

- View 3D content and images in the real world with the **View in mixed reality** control.
- Measure distance, area, and volume with the **Measure in mixed reality** control.
- Create and view predefined 3D shapes with the **View shape in mixed reality** control.
- Paint 3D lines or draw 3D arrows to specify an area or asset in your environment with the **Markup in MR** control.

Create an app with 3D and mixed reality controls

Load 3D models in canvas apps

Article • 02/25/2023

Load a 3D model in your canvas apps from a variety of sources. You can get models from attachments or media content, a direct URL, or a Base64-encoded URI (uniform resource identifier).

Make sure your 3D models are optimized for use with Power Apps to minimize load times.

Loading 3D models from common connectors

Loading 3D models from attachments or media content depends on how a data connector is supported. To check if a data connector will work the mixed reality controls, add a label control to the canvas app and set the **Text** property to the data source. If the label text starts with `appres://`,then that data connector should work with the **3D object control**.

> **Tip**
>
> You can rename a .glb file extension to .jpg and directly upload it to the app through the Media tab.

Load 3D models from Microsoft Lists

First, create a list in SharePoint and add an entry for each 3D model that you want to have in your app.

1. Create a list using Microsoft Lists.
2. Select the **+ Add column** column heading and then select **Show/hide columns**.
3. Select **Attachments** and then select **Apply**.
4. Add an entry to the list. In the entry form, select **Add attachments** and select your 3D model file.
5. Repeat for each model you want to include in your app.

Then, add a gallery to your app, set its source to the list, add a **3D object** control, and set its source to the gallery.

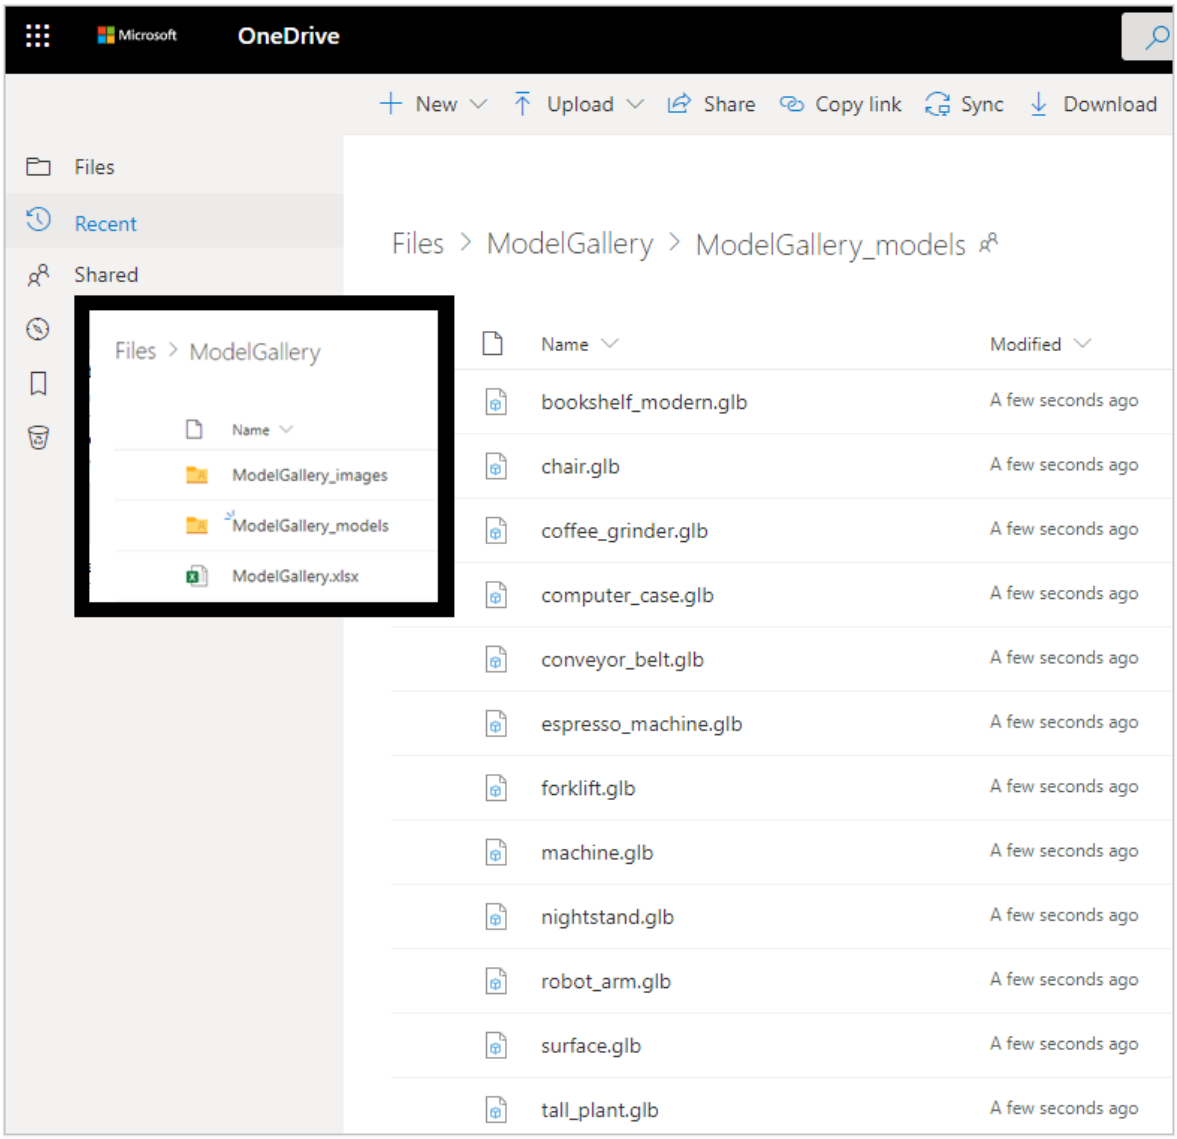
1. Add a gallery in Power Apps Studio.
2. Set the gallery data source to the list.

3. Add the **3D object** control.
4. In the **Advanced** properties tab, set **Source** to **First(Gallery1.Selected.Attachments).Value**.

Load 3D models from an Excel workbook

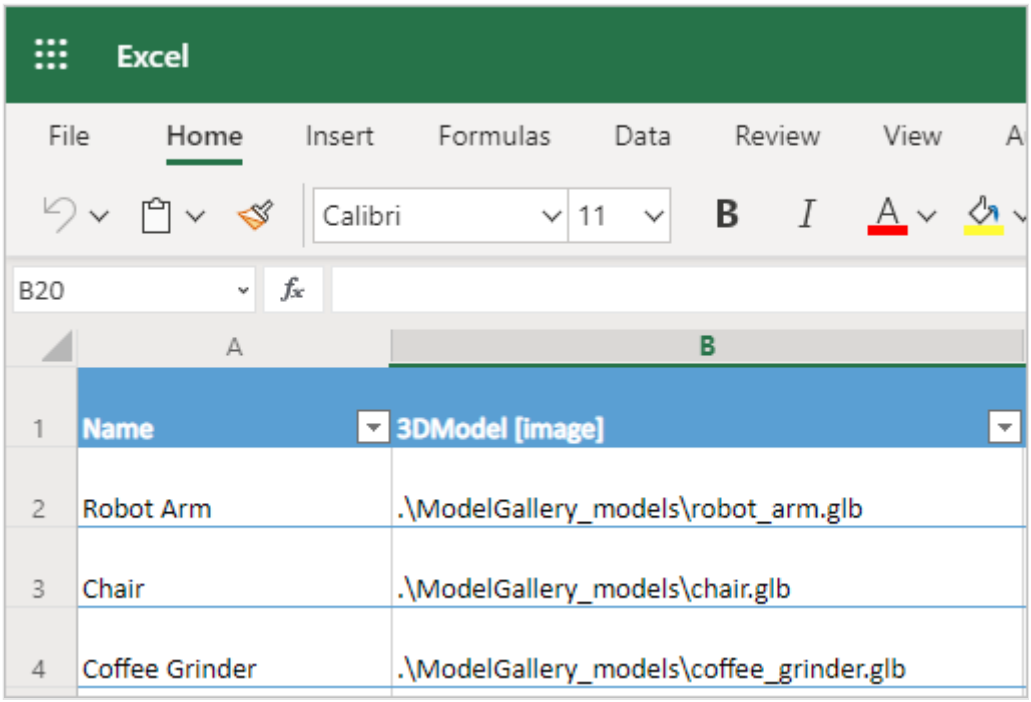
First, create an Excel workbook in OneDrive in the same folder that contains your model files. Add a table with rows for each model that you want to have in your app.

1. Create an Excel workbook and save it in the OneDrive folder that contains your model files.



2. In the workbook, create a table with columns named **3DModel [image]** and **Name**.

3. Add a row for each model you want to show in the app gallery. Enter a label for the model in the **Name** column and the relative file path to the model file in the **3DModel [image]** column.



4. Close the workbook.

Then, add a gallery to your app, set its source to the Excel workbook, add a **3D object** control, and set its source to the gallery.

1. Add a gallery in Power Apps Studio.
2. Use the OneDrive connector to set the gallery data source to the Excel workbook.
3. Add the **3D object** control.
4. In the **Advanced** properties tab, set **Source** to **Gallery1.Selected.'3DModel'**.

Load 3D models from a URL

The **Source** property of the **3D object** control can be the URL of a 3D model file.

The 3D model file must be on a server that doesn't have restrictive cross-origin resource sharing (CORS) settings. The hosting server must permit cross-origin requests from *powerapps.com*. You can use Dropbox or GitHub to host your files and get a CORS-compliant URL.

Host your 3D model files in Dropbox

1. Upload a 3D model file to Dropbox and select **Share**.
2. Generate a public download link. For example, *https://www.dropbox.com/s/rANdoMGeneR4tedLink/my-file.glb?dl=0*.
3. Modify the URL like this: replace **www** with **dl**, and remove **?dl=0** at the end.

You now have a direct-access URL (in our example, *https://dl.dropbox.com/s/rANdoMGeneR4tedLink/my-file.glb*), that you can use as the source of your 3D control.

Host your 3D model files in GitHub

1. Make sure the 3D model file is stored in a public repo.
2. Get the URL of the file. For example, *https://github.com/microsoft/experimental-pcf-control-assets/blob/master/robot_arm.glb*.
3. Modify the URL like this: remove **/blob/**, and replace **https://github.com** with **https://raw.githubusercontent.com**.

You now have a CORS-compliant URL (in our example, *https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/robot_arm.glb*), that you can use as the source of your 3D control.

Load Base64-encoded 3D models

The **Source** property of the **3D object** control can be a Base64-encoded 3D model data URI that is in the format *data:base64,<Base64-encoded content>*.

> **Important**
>
> Your app may take longer to load if you use Base64-encoded models.

You can create a Base64-encoded URI of your model using Microsoft Power Automate or Microsoft Dataverse.

Create a Base64-encoded 3D model with Microsoft Power Automate

Power Automate can convert 3D model files stored in a SharePoint document library to Base64 using the **dataUri(base64(*file content*))** expression.

In the following example, a document library named *3DModelBase64Library* and a list named *3DModelBase64* exist in the same SharePoint site. The list must include a column of type **multiple-line text**.

1. In the document library, create a flow based on the **When a new file is added in SharePoint, complete a custom action** template.

2. Set **Library Name** to *3DModelBase64Library* (the name of the document library in this example).

3. Add a step, **Get file content from SharePoint**.

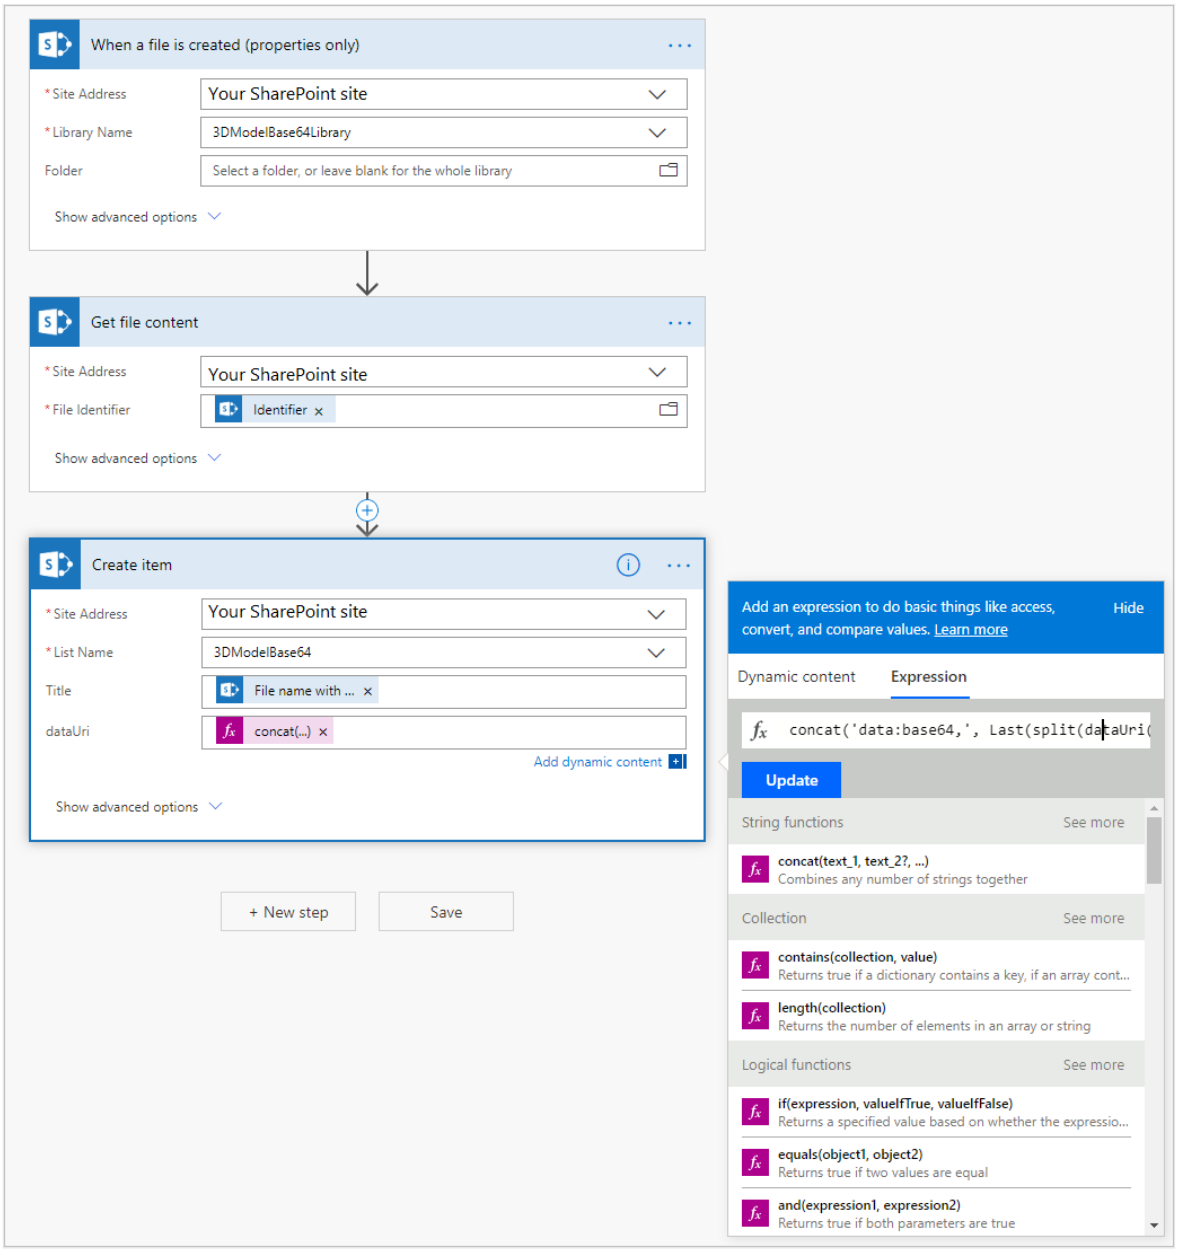
4. Set **File Identifier** to **Identifier**.

5. Add a step, **Create item from SharePoint**.

6. Set **List Name** to *3DModelBase64* (the name of the list in this example) and **Title** to **File Name with extension**.

7. Set **dataUri** to the following expression:

```
concat('data:model/gltf-binary; base64,',
Last(split(dataUri(base64(body('Get_file_content'))), ',')))
```



The flow runs when a file is added to the document library, converting the file to a Base64-encoded data URI.

In Power Apps Studio, connect the **3D object** control to the list using the SharePoint data connector. Set the control's **Source** property to the Base64-encoded data URI.

Create a Base64-encoded 3D model with Microsoft Dataverse

The Note (Annotation) table in Microsoft Dataverse converts any file attached in the **Document** field to Base64.

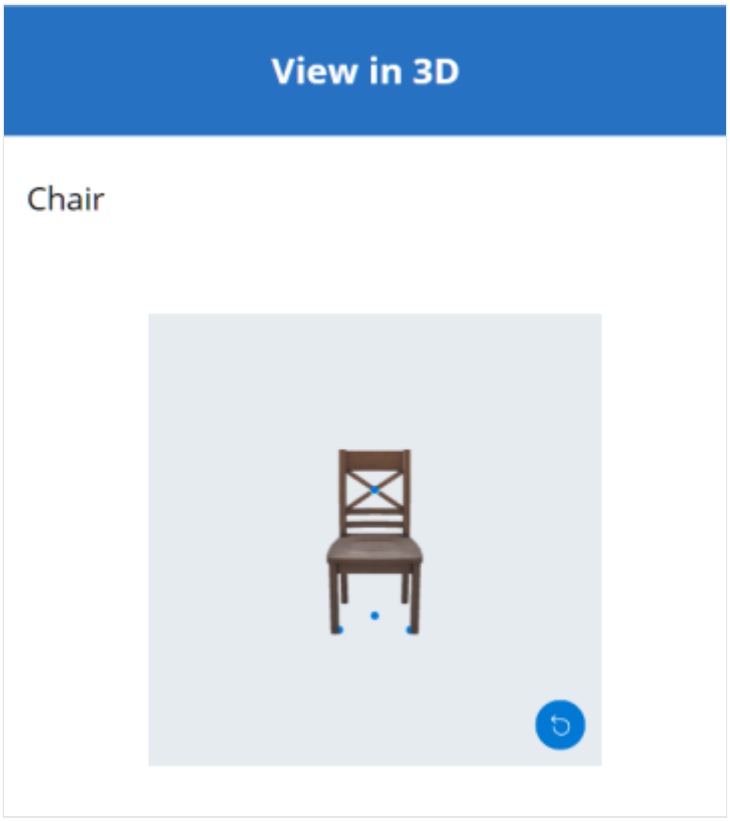
Known constraints when loading 3D models from URLs in canvas apps

- The security architecture of Power Apps requires HTTPS links, not HTTP.
- The server that hosts the model files must not require authentication and must be CORS-compliant.

Add pins to 3D models in Power Apps

Article • 07/15/2022

Add pins (shown as circular markers) to 3D models in your canvas apps. Users can add their own pins and view information about pins they select.



Add predefined pins to a 3D model from an Excel workbook

The easiest way to add pins to a 3D model is to load them from an Excel workbook.

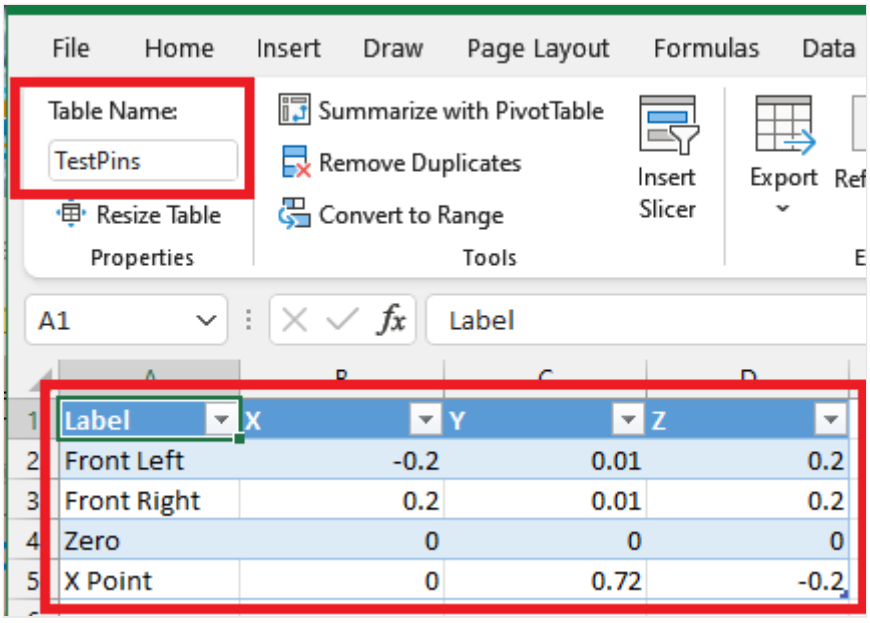
The data source for the pins must be a named table in Excel. The table must have four columns. Each column corresponds to a property of the **3D object** control. Each row is plotted as a pin on the model. The rows determine the placement of the pins in a three-dimensional coordinate system.

> **Important**
>
> The mixed-reality (MR) controls in Power Apps use a left-handed coordinate system.

Expand table

Column	Corresponds to
Label	ItemsLabels
X	PinsX
Y	PinsY
Z	PinsZ

Here's an example of a table named "TestPins" that contains coordinates to place four pins on a 3D model:



To try this example, start by creating a table in Excel.

1. Copy the following sample data and paste it in cell A1 of a new Excel worksheet.

Expand table

Label	X Pins	Y Pins	Z Pins
Front Left	-0.2	0.01	0.2
Front Right	0.2	0.01	0.2
Zero	0	0	0
X Point	0	0.72	-0.2

2. Select one of the pasted cells. On the **Home** tab, select **Format as Table**, choose a style, and then select **OK**.

3. On the **Table Design** tab under **Table Name**, enter a name such as *TestPins*.

4. Save the workbook and close it.

Next, add the table as a data source to display pins on a 3D model.

1. In Power Apps Studio, insert a 3D model or select an existing model.
2. Set the **3D object** control's **Source** property to *https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/chair.glb* (or any other model file of your choosing).

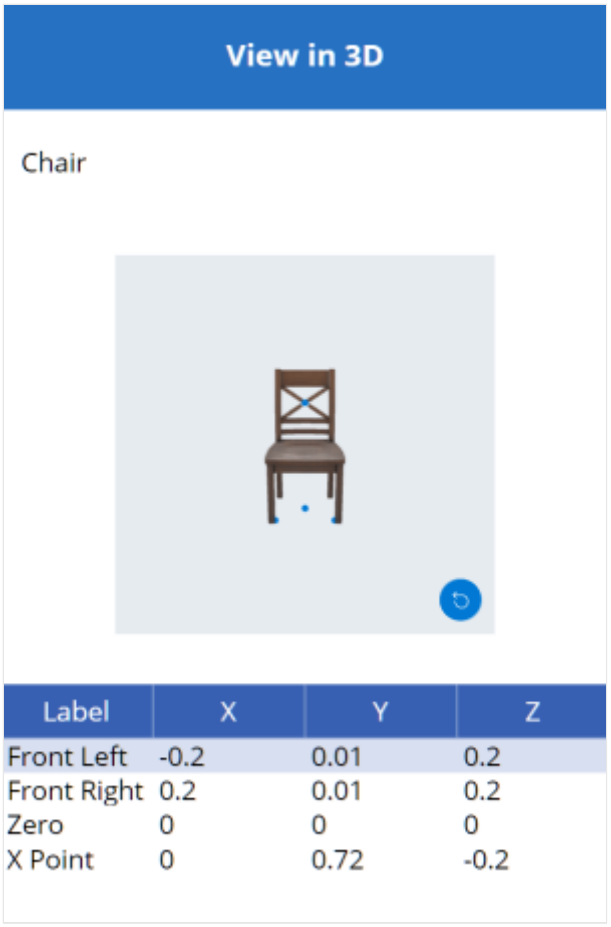
> **Note**
>
> The first instance of the **3D object** control is named *3DObject1* by default and that's the name we'll use in the following examples. Additional instances of the control would be referred to as *ViewIn3D2*, *ViewIn3D3*, and so on.

1. On the model's **Properties** tab, select the **Pins(Items)** dropdown list.
2. Type *excel* in the search box, and then select **Import from Excel**.
3. Locate the Excel workbook you saved earlier and open it.
4. Select the name you gave the table in Excel and then select **Connect**.
5. On the **Advanced** tab, find **PinsX**, **PinsY**, and **PinsZ** and enter the name of the corresponding column in the table. (In this example, enter *Label* in **ItemsLabels**, *X* in **PinsX**, and so on.) Enclose the column name in quotation marks.

Pins appear on the model at the locations described by the coordinates.

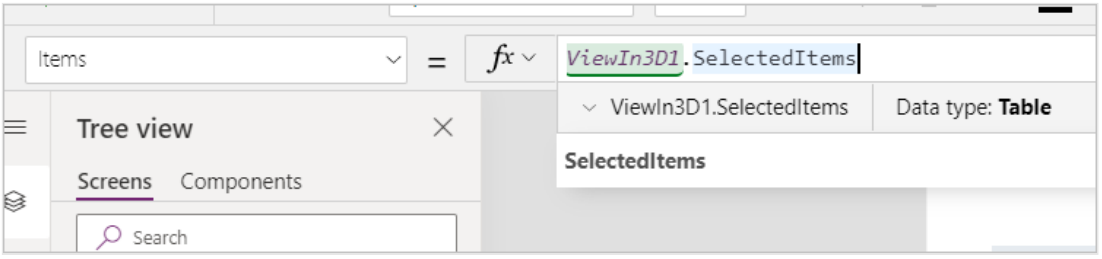
Show the label and coordinates of pins on a 3D model

Use a data table to display the label and coordinates of selected pins in a canvas app.



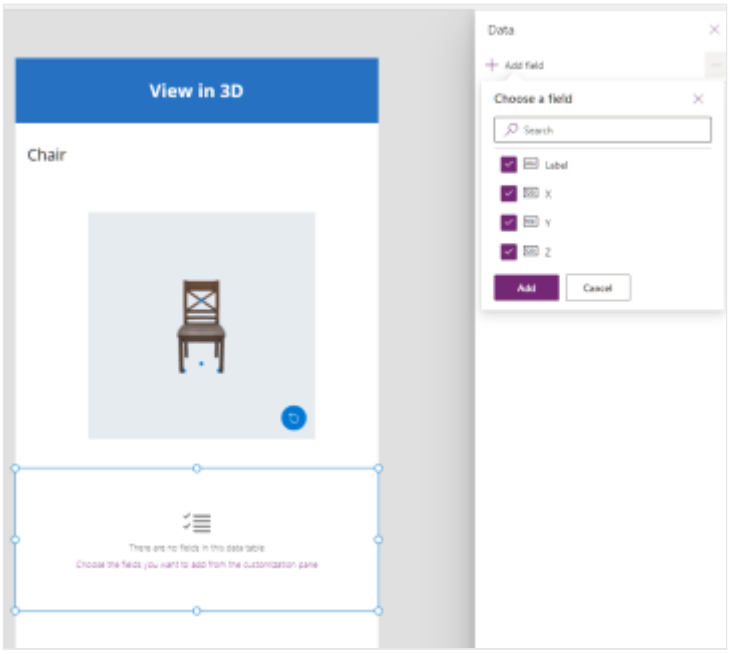
With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab and expand **Layout**.
2. Select **Data table** to place a table in the app screen, or drag the control to the screen to position it more precisely.
3. Choose to show information about all pins or only the selected pin. With the data table selected:
   - **Show all pins:** In the **Properties** pane, select the **Pins(Items)** dropdown list and select the Excel table you connected to earlier.
   - **Show the selected pin only:** In the Power Apps Studio expression editor, enter *3DObject1.SelectedItems*.



4. On the **Properties** pane, select **Edit fields**, and then select **Add field**.

5. Select the columns to show, and then select **Add**.



Show the label of a selected pin on a 3D model

Use a text box to display just the label of the selected pin in a canvas app.

With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab.
2. Select **Text label** to place a text box in the app screen, or drag the control to the screen to position it more precisely.
3. In the expression editor, enter *3DObject1.Selected.Label*.

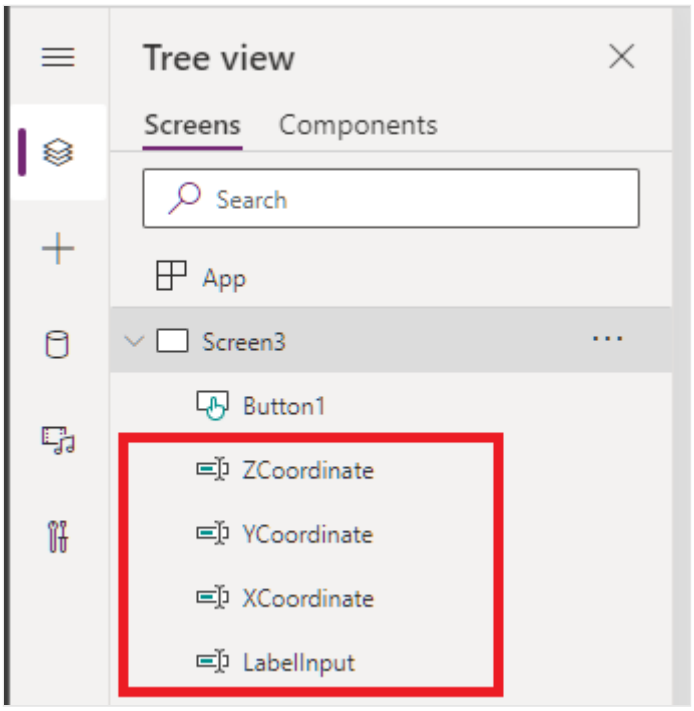
Create a collection to let users add their own pins to a 3D model

If you want to allow users to place pins on a 3D model, use a collection.

With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab.
2. Select **Text input** to place a text entry box in the app screen.
3. Copy the text box and paste it three times to create four text input controls.
4. Set the **Default** property for each control to *X*, *Y*, *Z*, and *Label*, respectively.
5. Open the **Tree view** tab.

6. Rename each control, as appropriate, to *XCoordinate*, *YCoordinate*, *ZCoordinate*, and *LabelInput*.



Next, add a button to append the user's data to the pin collection.

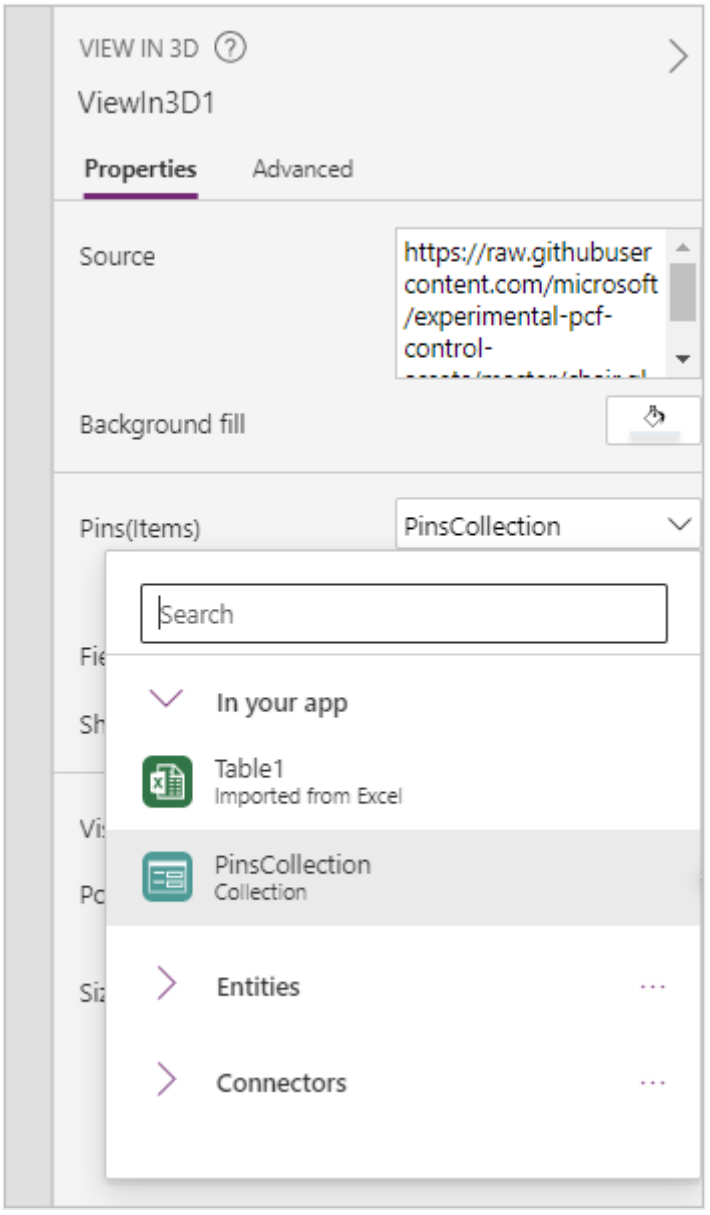
1. Open the **Insert** tab.
2. Select **Button** to place a button in the app screen.
3. Set the button's **Text** property to *Add pin*.
4. Enter the following code in the button's **OnSelect** property, exactly as shown:

```
Power Fx

Collect(
PinsCollection,
  {
    X: XCoordinate.Text,
    Y: YCoordinate.Text,
    Z: ZCoordinate.Text,
    Label: LabelInput.Text
  }
)
```

Now you'll change the data source of the pins from the Excel table to the new collection.

1. Select the 3D model.
2. On the **Properties** tab, select the **Pins(Items)** dropdown list, and then select **PinsCollection**.



3. On the **Advanced** tab, find **PinsX**, **PinsY**, and **PinsZ** and set them to *X*, *Y*, and *Z*, respectively.

When the user enters coordinates and a label and selects **Add pin**, a labeled pin is placed on the model at the entered coordinates.

Show information about pins as they're added to a 3D model

Finally, combine the previous examples by displaying information about the pins as the user adds them.

With your app open for editing in Power Apps Studio :

1. Add a data table to the screen.

2. On the **Properties** tab, select the **Pins(Items)** dropdown list and select **PinsCollection**.
3. Select **Edit fields**, and then select **Add field**.
4. Select the columns to show in the table, and then select **Add**.

Other mixed reality controls

- View 3D content in mixed reality with the **View in MR** control.
- Measure distance, area, and volume with the **Measuring Camera** control.
- Create and view predefined 3D shapes with the **View shape in MR** control.
- Paint 3D lines or draw 3D arrows to specify an area or asset in your environment with the **Markup in MR** control.

Feedback

Was this page helpful? Yes No

Provide product feedback

View predefined 3D shapes in mixed reality

Article • 06/17/2022

Use the **View shape in MR** control in a canvas app to see whether a digital cube of a given size fits in a real-world space. (To compare a 3D model of an object instead, use the View in MR control.)

The **View shape in MR** control adds a button to your app. When a user selects the button, the app overlays a cube on the device camera feed. The cube's dimensions are set as a property on the control when you author the app in Microsoft Power Apps Studio. Users may not change the size of the cube while they use the app.

Tip

The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

Tip

The MR controls in Power Apps use Babylon and Babylon React Native. Mixed reality content that works in the **Babylon sandbox** should work in Power Apps

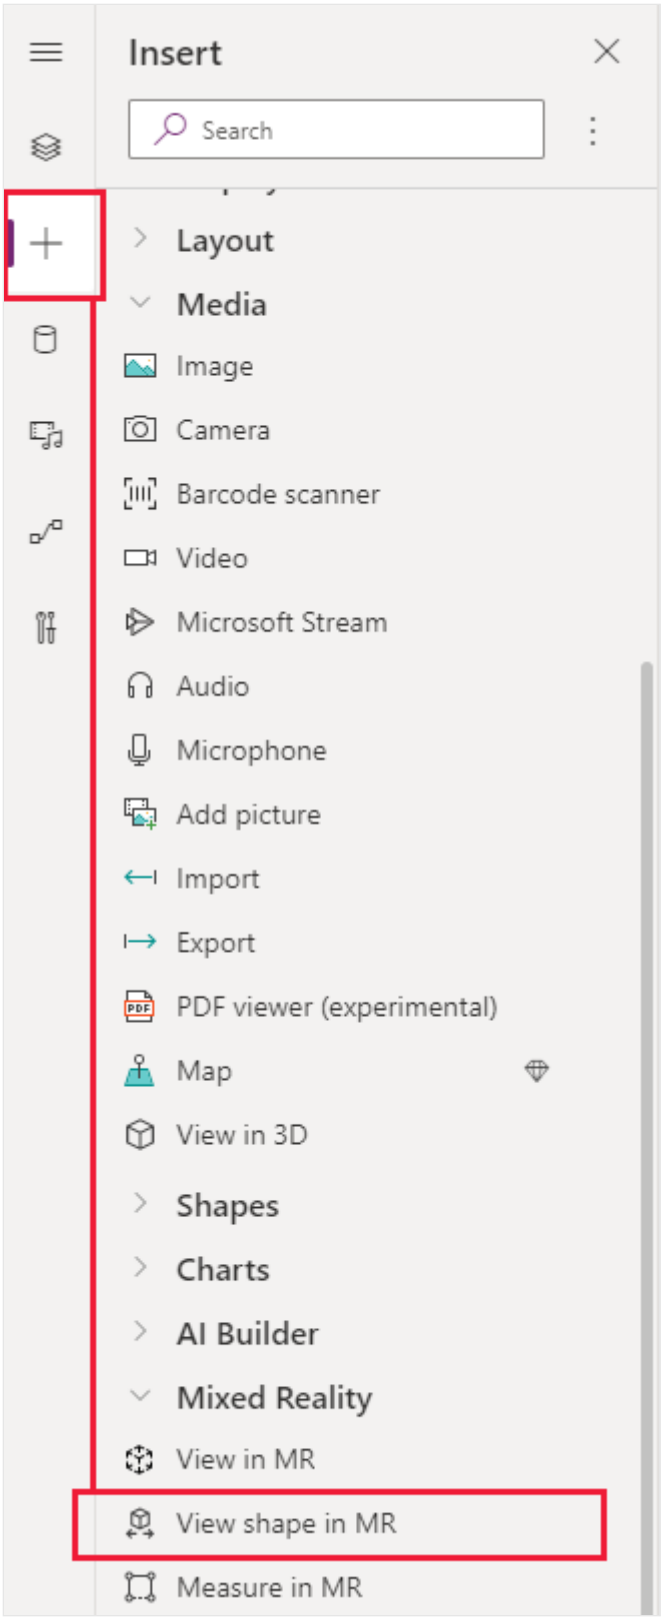
through this shared MR platform. If your content works in Babylon but not in Power Apps, ask a question in the **Power Apps Community Forum**. (Tag it with "mixed reality.")

Add a View shape in MR button to an app screen

With your app open for editing in Power Apps Studio:

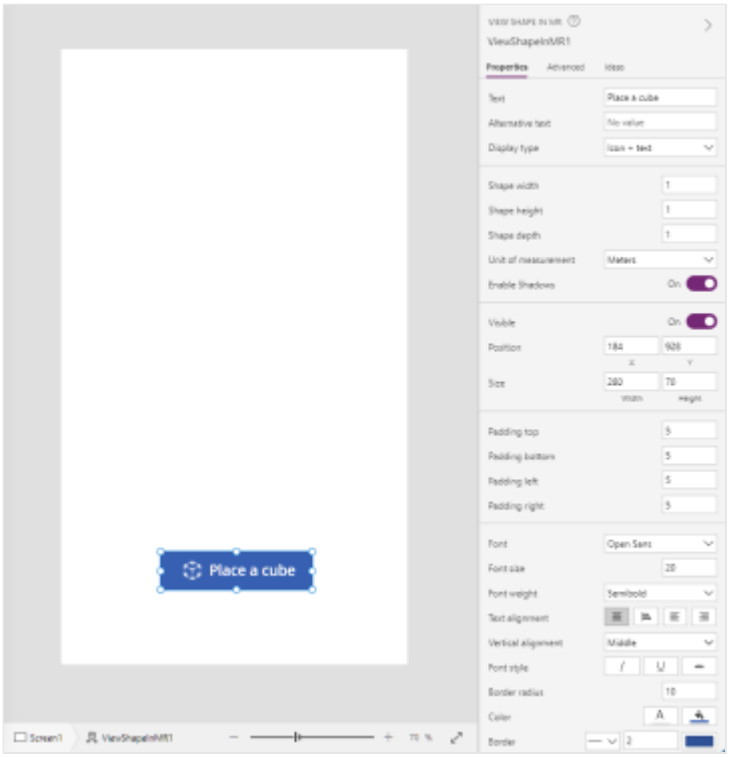
1. Open the **Insert** tab and expand **Mixed Reality**.
2. Select **View shape in MR** to place the control in the app screen, or drag the control to the screen to position it more precisely.

The control is a button that's labeled with an icon of a cube and the text *Place a cube*. Change the label and hide the icon if you like in the **Text** and **Display type** properties.



Properties

Change the **View shape in MR** button's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



Property	Description	Type	Location
Text	Sets the button label text.	String	Properties; Advanced: **Text**
Alternative text	Specifies the text to be displayed if the model can't load or if the user hovers over the model.	String	Properties; Advanced: **AltText**
Display type	Determines whether the button label shows an icon of a cube, text, or both.	Drop-down selection	Properties; Advanced: **DisplayType**
Shape width	Sets the width of the cube.	Integer	Properties; Advanced: **ShapeWidth**
Shape height	Sets the height of the cube.	Integer	Properties; Advanced: **ShapeHeight**
Shape depth	Sets the depth of the cube.	Integer	Properties; Advanced: **ShapeDepth**
Unit of measurement	Sets the measurement unit used for the cube's width, height, and depth.	Drop-down selection	Properties; Advanced: **Units**
Enable Shadows	Determines whether shadows are used to enhance the 3D effect when the cube is shown.	Boolean	Properties; Advanced: **EnableShadows**

Property	Description	Type	Location
Enable Marker Detection	Determines whether marker detection will be used to to determine model position and rotation. See Use marker detection with mixed reality controls	Boolean	Properties; Advanced: **EnableMarkerDetection**
Visible	Shows or hides the button.	Boolean	Properties; Advanced: **Visible**
Position	Places the upper-left corner of the button at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the button using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Padding top	Sets the distance between the button label text and the top of the button.	Floating point number	Properties; Advanced: **PaddingTop**
Padding bottom	Sets the distance between the button label text and the bottom of the button.	Floating point number	Properties; Advanced: **PaddingBottom**
Padding left	Sets the distance between the button label text and the left edge of the button.	Floating point number	Properties; Advanced: **PaddingLeft**
Padding right	Sets the distance between the button label text and the right edge of the button.	Floating point number	Properties; Advanced: **PaddingRight**
Font	Sets the name of the family of fonts used for the button label text.	Dropdown list	Properties; Advanced: **Font**
Font size	Sets the size of the button label text.	Floating point number	Properties; Advanced: **FontSize**
Font weight	Sets the weight of the button label text, either *Bold*, *Lighter*, *Normal*, or *Semibold*.	Dropdown list	Properties; Advanced: **FontWeight**
Text alignment	Sets the horizontal alignment of the label text in the button, either *Center*, *Justify*, *Left*, or *Right*.	Not applicable	Properties; Advanced: **TextAlignment**

Property	Description	Type	Location
Vertical alignment	Sets the vertical alignment of the label text in the button, either *Bottom*, *Middle*, or *Top*.	Dropdown list	Properties; Advanced: VerticalAlign
Font style	Sets the style of the button label text, either *Italic*, *Underline*, *Strikethrough*, or none.	Not applicable	Properties; Advanced: **Italic**, **Underline**, **Strikethrough**
Border radius	Determines the corner radius of the button border.	Floating point number	Properties; Advanced: **BorderRadius**
Color	Sets the colors of the button label text and the button background.	Not applicable	Properties; Advanced: **FillColor**, **TextColor**
Border	Determines the style, width, and color of the button border.	Not applicable	Properties; Advanced: BorderStyle, BorderThickness, BorderFillColor
Disabled	Turns off the button but leaves it visible.	Boolean	Properties; Advanced: **Disabled**
Disabled color	Sets the colors of the button label text, the button background, and the button border if DisplayMode is **Disabled**.	Not applicable	Properties; Advanced: **DisabledContentColor**, **DisabledFillColor**, **DisabledBorderColor**
Pressed color	Sets the colors of the button label text, the button background, and the button border when the user selects the button.	Not applicable	Properties; Advanced: **PressedContentColor**, **PressedFillColor**, **PressedBorderColor**
Hover color	Sets the colors of the button label text, the button background, and the button border when the user hovers the mouse pointer over it.	Not applicable	Properties; Advanced: **HoverContentColor**, **HoverFillColor**, **HoverBorderColor**
OnMixedRealitySelect	Behavior that is triggered when user selects the button to launch into the mixed reality experience.	Defined action	Advanced

Property	Description	Type	Location
OnChange	Behavior that is triggered when any property on the button is changed. This is a common property across multiple controls.	Defined action	Advanced
Tooltip	Determines the text to display when the user hovers over the button.	String	Advanced
ContentLanguage	Determines the display language of the button label, if it's different from the language used in the app.	String	Advanced
DisplayMode	Determines whether the button allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Enum	Advanced
TabIndex	Specifies the order the button is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **TabIndex**

Output properties

Your app can make use of more properties when a user interacts with the **View shape in MR** control. These are known as output properties. You can use these properties in other controls or to customize the app experience.

Property	Description	Type
Photos	Collects the photos captured during the mixed reality session. You can upload the mixed-reality photos to OneDrive and show them in a gallery.	Not applicable

Other mixed reality controls

- View 3D content with the **3D object** control.
- View images and 3D content in the real world with the **View in mixed reality** control.
- Measure distance, area, and volume with the **Measure in mixed reality** control.
- Paint 3D lines or draw 3D arrows to specify an area or asset in your environment with the **Markup in MR** control.

View 3D content or images in mixed reality

Article • 07/15/2022

Use the **View in MR** control to place a 3D model of an object or an image in a real-world space. For instance, preview a painting on a wall before you hang it, or see whether a 3D virtual bookcase will fit where you intend it to go.

What if you don't have a 3D model of the object? Load an image of the object and set its dimensions to the object's size. The control applies the image as the face of a virtual cube of the desired size. Place this stand-in for the 3D model in your space.

The **View in MR** control adds a button to your app. When a user selects the button, the app overlays a selected 3D model (in .glb, .stl, or .obj file formats) or image (in .jpg or .png file formats) on the device camera feed.

You can also take photos using the **View in MR** control and upload them to OneDrive.

> **Important**
>
> Your 3D content must be in the .glb, .stl, or .obj file formats. You can convert your existing 3D models into the .glb file format from a variety of 3D formats. 3D content compressed with Draco compression Draco is not supported.

> **Tip**
>
> - Make sure your 3D models are optimized for use with Power Apps to minimize load times.
> - The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

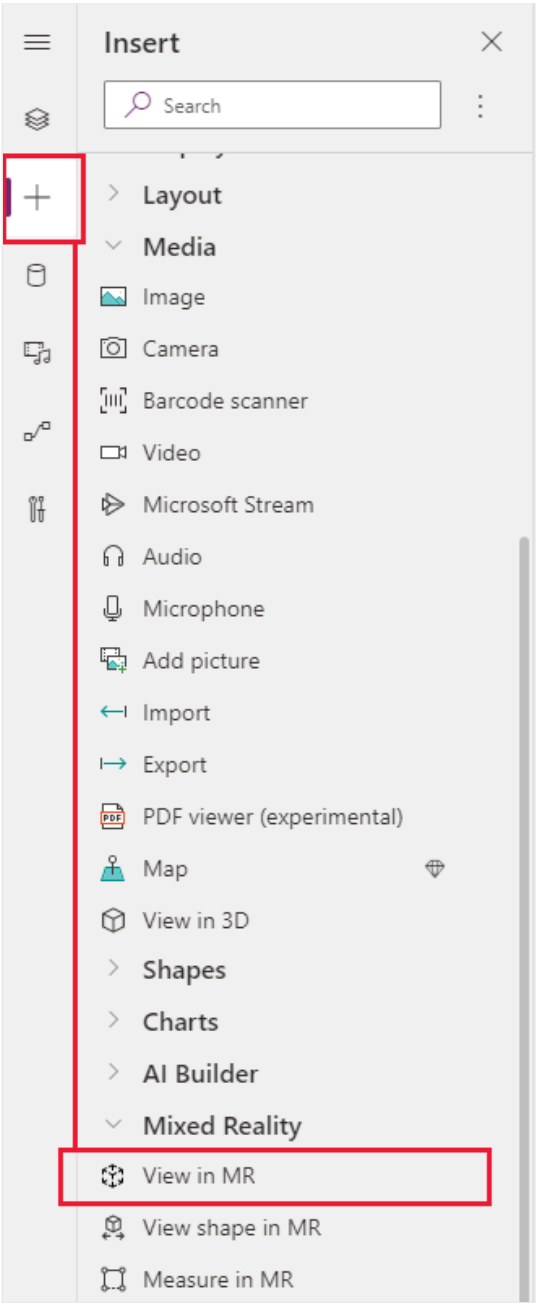
- The MR controls in Power Apps use Babylon and Babylon React Native. Mixed reality content that works in the Babylon sandbox should work in Power Apps through this shared MR platform. If your content works in Babylon but not in Power Apps, ask a question in the Power Apps Community Forum. (Tag it with "mixed reality.")

Add a View in MR button to an app screen

With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab and expand **Mixed Reality**.
2. Select **View in MR** to place the control in the app screen, or drag the control to the screen to position it more precisely.

The control is a button that's labeled with an icon of a cube and the text *View in MR*. Change the label and hide the icon if you like in the **Text** and **Display type** properties.



View different models in a single session

The View in MR control displays one media file by default. To view different media files selected through a media gallery during the MR experience, use the control's *Items* advanced property. This property creates a table that lists media files the user can choose from in the mixed reality experience.

When you use the *Items* property, you need to set a value for the following additional advanced properties to map the columns of your table:

Expand table

Property	Description
ItemsSource (required)	Specifies which column in *Items* identifies the 3D model or image to show in the mixed reality view. See Connect 3D models to Power Apps to learn more about bringing models into Power Apps.
ItemsLabel	Specifies which column in *Items* contains the label to show in the media gallery. The *Alternative text* property is used for items that don't have a label specified.
ItemsThumbnail	Specifies which column in *Items* identifies the thumbnail to show in the media gallery. A default thumbnail is provided for items that don't have one specified.
ItemsObjectWidth, ItemsObjectHeight, ItemsObjectDepth	Specifies an explicit size for each media item in the table. *Object width*, *Object height*, and *Object depth* are used for items that don't have a specific size.

To test it, let's create a media gallery that shows three different plants in a room setting. Our *Items* table looks like this:

Expand table

label	source	thumbnail
Birds of Paradise	https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/bird_of_paradise_blue.glb	https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/bird_of_paradise_blue.png
Fiddle Leaf Fig	https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/flf_orange.glb	https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/flf_orange.png
Small Palm Tree	https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/palm_green.glb	https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/palm_green.png

With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab and expand **Mixed Reality**.
2. Select **View in MR** to place the control in the app screen, or drag the control to the screen to position it more precisely.
3. On the **Advanced** properties tab, select the *Items* property and type or paste the following code:

```
Power Fx

Table(
{
label: "Birds of Paradise",
source: "https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/bird_of_paradise_blue.glb",
thumbnail: "https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/bird_of_paradise_blue.png"
},
{
label: "Fiddle Leaf Fig",
source: "https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
```

```
assets/master/flf_orange.glb",
thumbnail: "https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/flf_orange.png"
},
{
label: "Small Palm Tree",
source: "https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/palm_green.glb",
thumbnail: "https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/palm_green.png"
}
)
```

4. Set the *ItemsLabel* property to `"label"`.

5. Set the *ItemsSource* property to `"source"`.

6. Set the *ItemsThumbnail* property to `"thumbnail"`.

> **Note**
>
> The *Items* property is set to your data source which can be a collection, from a connector, or a hardcoded table like in this example. The *ItemsSource*, *ItemsLabel*, and *ItemsThumbnail* properties are set to the column names of that data source within quotation marks.

7. Save and publish the app, then open it on your mobile device to try it out.

How objects are scaled if you resize them

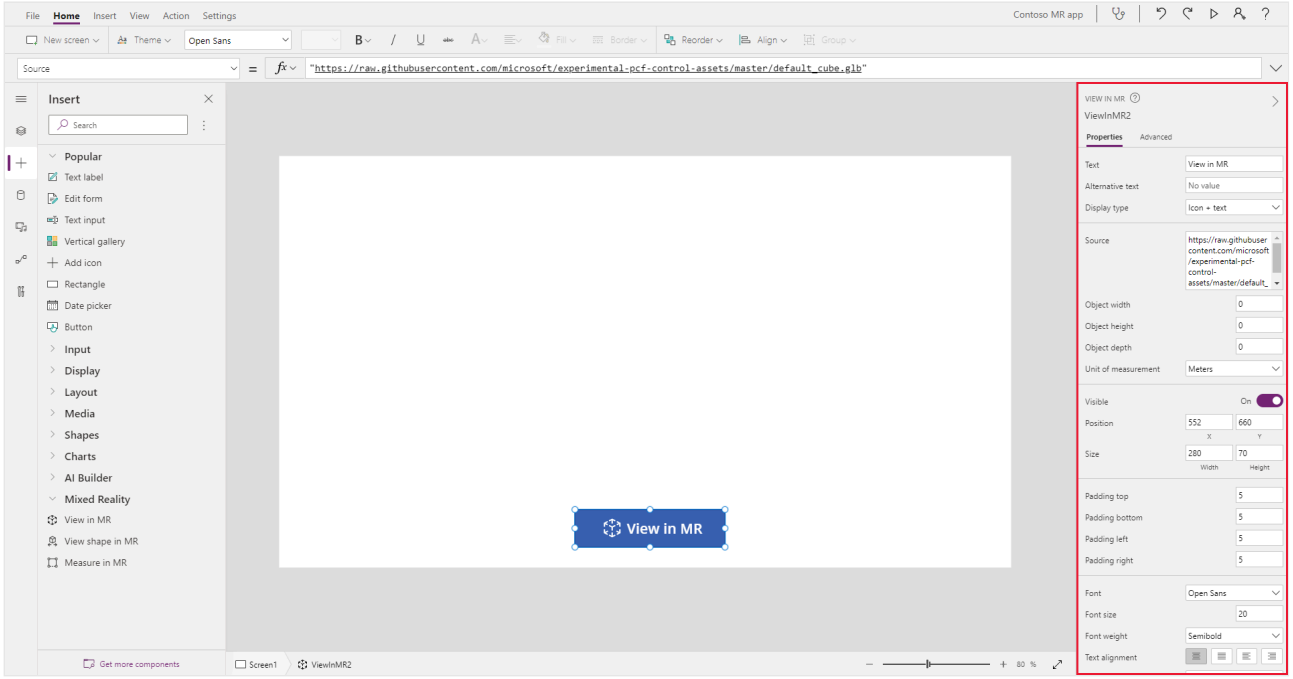
If you don't specify dimensions when you place a model, the **View in MR** control follows the dimensions given in the object file. You can resize the model by entering a value other than 0 in one or more of the control's width, height, and depth properties (**Object width**, **Object height**, and **Object depth**). How the model is scaled depends on how many dimensions you change.

- If all dimensions are *0* (the default), the model's size is left as it's set in the object file.
- If one dimension is set, the model is scaled equally based on the changed dimension, similar to setting "keep aspect ratio" when you resize an image.
- If two dimensions are set, the model scales to the two given dimensions and an average of the first two. For example, say you have a model that is 12 m high, 6 m wide, and 3 m deep. You set the **View in MR** control's properties as follows: **Object height**: **24**, **Object width**: **9**, **Object depth**: **0** (unchanged). The height increases by a factor of 2, and the width increases by a factor of 1.5. The increase in height and width is averaged to find the factor by which the depth should be increased: 2 + 1.5 = 3.5 / 2 = 1.75. The final dimensions of the model are **Object height** 24, **Object width** 9, and **Object depth** 5.25 (3 x 1.75).
- If all three dimensions are set, the model's size is changed to what you specified.

> **Note**
>
> If the measurements don't adhere to the original aspect ratio, the model could be squashed or distorted when it's viewed in MR.

Properties

Change the **View in MR** button's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



Expand table

Property	Description	Type	Location
Text	Sets the button label text.	String	Properties; Advanced: **Text**

Property	Description	Type	Location
Alternative text	Specifies the text to be displayed if the model can't load or if the user hovers over the model.	String	Properties; Advanced: **AltText**
Display type	Determines whether the button label shows an icon of a cube, text, or both.	Drop-down selection	Properties; Advanced: **DisplayType**
Source	Identifies the data source (.glb, .stl, or .obj file) to display.	Not applicable	Properties; Advanced: **Source**
Sources List (Items)	Data source (table) that lists multiple media files to view in a single mixed reality session.	Table	Properties; Advanced: **Items**
Object width	Sets the width of the model.	Integer	Properties; Advanced: **ObjectWidth**
Object height	Sets the height of the model.	Integer	Properties; Advanced: **ObjectHeight**
Object depth	Sets the depth of the model.	Integer	Properties; Advanced: **ObjectDepth**
Unit of measurement	Sets the measurement unit used for the model's width, height, and depth.	List	Properties; Advanced: **Units**
Enable shadows	Determines whether shadows are used to enhance the 3D effect when the model is shown.	Boolean	Properties; Advanced: **EnableShadows**
Enable marker detection	Determines whether marker detection will be used to determine model position and rotation. See Use marker detection with mixed reality controls	Boolean	Properties; Advanced: **EnableMarkerDetection**
Visible	Shows or hides the button.	Boolean	Properties; Advanced: **Visible**
Position	Places the upper-left corner of the button at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the button using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Padding top	Sets the distance between the button label text and the top of the button.	Floating point number	Properties; Advanced: **PaddingTop**
Padding bottom	Sets the distance between the button label text and the bottom of the button.	Floating point number	Properties; Advanced: **PaddingBottom**
Padding left	Sets the distance between the button label text and the left edge of the button.	Floating point number	Properties; Advanced: **PaddingLeft**
Padding right	Sets the distance between the button label text and the right edge of the button.	Floating point number	Properties; Advanced: **PaddingRight**

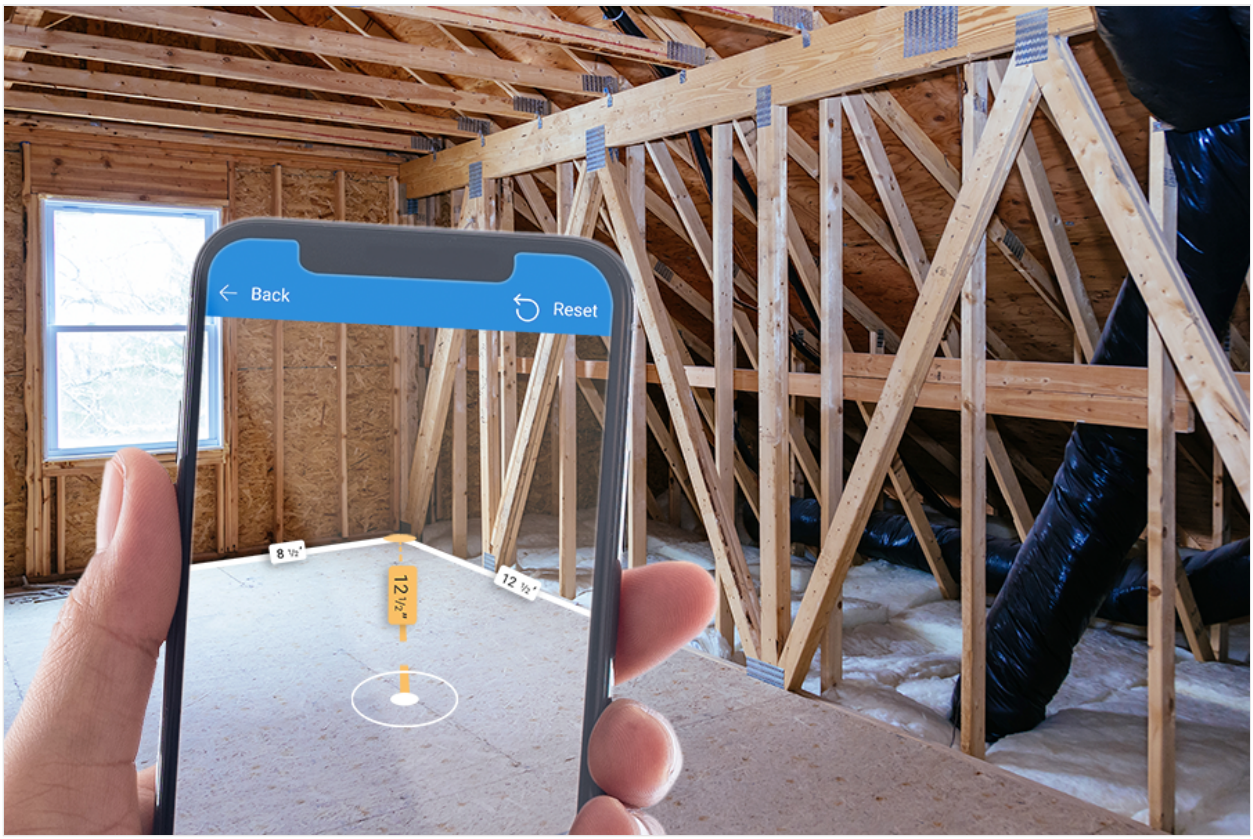
Take measurements in mixed reality

Article • 05/09/2022

Use the **Measuring camera** control in a canvas app to measure distance, area, and volume in the real world. You can also create two- and three-dimensional freeform shapes and see how they fit in a real-world space.

The **Measuring camera** control adds a button to your app. When a user selects the button, the app shows a live feed from the device camera. On-screen instructions direct the user to establish tracking by slowly panning the device from right to left across the surface to be measured. The user identifies a starting point and adds segments as needed until the measurement is complete. Dimensions of the measured space are overlaid on the camera feed.

The user can submit the measurements for capture in the control's **Measurements** output properties. The user can also take screenshots while a space is measured. The screenshots are captured in the control's **Photos** output property.



Tip

The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

Add a Measuring camera button to an app screen

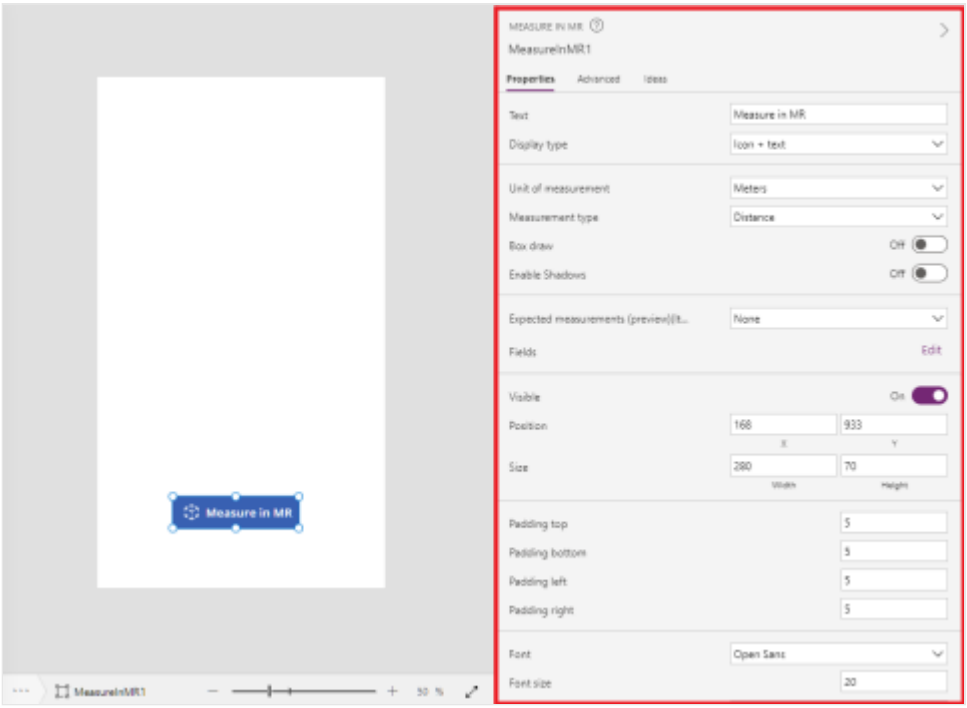
With your app open for editing in Power Apps Studio :

1. Open the **Insert** tab and expand **Media**.
2. Select **Measuring camera** to place the control in the app screen, or drag the control to the screen to position it more precisely.

The control is a button that's labeled with an icon of a cube and the text *Measure*. Change the label and hide the icon if you like in the **Text** and **Display type** properties.

Properties

Change the **Measuring camera** button's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



Property	Description	Type	Location
Text	Sets the button label text.	String	Properties; Advanced: **Text**
Display type	Determines whether the button label shows an icon of a cube, text, or both.	Dropdown list	Properties; Advanced: **DisplayType**
Unit of measurement	Sets the unit used for the dimensions.	Dropdown list	Properties; Advanced: **Units**

Property	Description	Type	Location
Measurement type	Determines the kind of measurement the user can make, either *Distance*, *Area*, or *Volume* (area plus height or depth).	Dropdown list	Properties; Advanced: **MeasurementType**
Box draw	Locks captured measurements to rectangular shapes.	Boolean	Properties; Advanced: **BoxDraw**
Enable Shadows	Determines whether shadows are used to enhance the 3D effect when a shape is drawn.	Boolean	Properties; Advanced: **EnableShadows**
Expected measurements (Items)	Identifies a data source (**Items**) in the form of a table in an Excel workbook from which to get the measurements the user should capture.	Not applicable	Properties; Advanced: **Items**
Visible	Shows or hides the button.	Boolean	Properties; Advanced: **Visible**
Position	Places the upper-left corner of the button at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the button using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Padding top	Sets the distance between the button label text and the top of the button.	Floating point number	Properties; Advanced: **PaddingTop**
Padding bottom	Sets the distance between the button label text and the bottom of the button.	Floating point number	Properties; Advanced: **PaddingBottom**
Padding left	Sets the distance between the button label text and the left edge of the button.	Floating point number	Properties; Advanced: **PaddingLeft**

Property	Description	Type	Location
Padding right	Sets the distance between the button label text and the right edge of the button.	Floating point number	Properties; Advanced: **PaddingRight**
Font	Sets the name of the family of fonts used for the button label text.	Dropdown list	Properties; Advanced: **Font**
Font size	Sets the size of the button label text.	Floating point number	Properties; Advanced: **FontSize**
Font weight	Sets the weight of the button label text, either *Bold*, *Lighter*, *Normal*, or *Semibold*.	Dropdown list	Properties; Advanced: **FontWeight**
Text alignment	Sets the horizontal alignment of the label text in the button, either *Center*, *Justify*, *Left*, or *Right*.	Not applicable	Properties; Advanced: **TextAlignment**
Vertical alignment	Sets the vertical alignment of the label text in the button, either *Bottom*, *Middle*, or *Top*.	Dropdown list	Properties; Advanced: **VerticalAlign**
Font style	Sets the style of the button label text, either *Italic*, *Underline*, *Strikethrough*, or none.	Not applicable	Properties; Advanced: **Italic**, **Underline**, **Strikethrough**
Border radius	Determines the corner radius of the button border.	Floating point number	Properties; Advanced: **BorderRadius**
Color	Sets the colors of the button label text and the button background.	Not applicable	Properties; Advanced: **FillColor**, **TextColor**
Border	Determines the style, width, and color of the button border.	Not applicable	Properties; Advanced: **BorderStyle**, **BorderThickness**, **BorderFillColor**
Disabled	Turns off the button but leaves it visible.	Boolean	Properties; Advanced: **Disabled**
Disabled color	Sets the colors of the button label text, the button background, and the button border if **DisplayMode** is **Disabled**.	Not applicable	Properties; Advanced: **DisabledContentColor**, **DisabledFillColor**, **DisabledBorderColor**

Property	Description	Type	Location
Pressed color	Sets the colors of the button label text, the button background, and the button border when the user selects the button.	Not applicable	Properties; Advanced: **PressedContentColor**, **PressedFillColor**, **PressedBorderColor**
Hover color	Sets the colors of the button label text, the button background, and the button border when the user hovers the mouse pointer over it.	Not applicable	Properties; Advanced: **HoverContentColor**, **HoverFillColor**, **HoverBorderColor**
OnMixedRealitySelect	Contains code that runs when the user exits the measurement screen with new results.	Event	Advanced
OnChange	Contains code that runs when a button property is changed.	Event	Advanced
OnSelect	Contains code that runs when the user selects the button.	Event	Advanced
ItemsLabels	Identifies the column in **Items** that contains the labels for the measurements users should capture.	ColumnName	Advanced
ItemsMeasurementType	(Optional) Identifies the column in **Items** that contains a string (*Distance*, *Area*, *Volume*, or *Freeform*) that specifies the type of measurement users should capture.	ColumnName	Advanced; see **MeasurementType**
ItemsBoxDraw	(Optional) Identifies the column in **Items** that contains a string (*True* or *False*) that locks measurements to rectangular shapes.	ColumnName	Advanced; see **BoxDraw**
Tooltip	Determines the text to display when the user hovers over a visual.	String	Advanced

Property	Description	Type	Location
ContentLanguage	Determines the display language of the control, if it's different from the language used in the app.	String	Advanced
DisplayMode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Enum	Advanced
TabIndex	Specifies the order the control is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **Tab index**

Output properties

Your app can make use of more properties when a user interacts with the **View in MR** control. These are known as output properties. You can use these properties in other controls or to customize the app experience.

Property	Description
Photos	Captures, in a collection, information about photos the user takes while a space is measured. Use the collection to upload mixed-reality photos to OneDrive and show them in a gallery.
Measurements	Captures, in a table, the measured distances, volumes, and areas.
Segments	Captures, in a table, information about segments in a measured object.

The Measurements table has the following columns:

- **Label:** A string that identifies the measurement
- **Id:** A number that uniquely identifies the measurement
- **Units:** A string that identifies the unit of the measurement
- **Height:** A number that represents the height of the measured volume (0 if a 2D area was measured)
- **Length:** A number that represents the total length of the measured perimeter or path
- **BoundingWidth:** A number that represents the minimum width that bounds the shape

- **BoundingDepth:** A number that represents the minimum depth that bounds the shape
- **Area:** A number that represents the estimated area of the measured shape in units squared
- **Volume:** A number that represents the estimated volume of the measured shape in units cubed

The Segments table has the following columns:

- **Length:** A number that represents the total distance of a segment in the specified units
- **DirectionX:** A number that represents the X direction of the segment in world (3D) space
- **DirectionY:** A number that represents the Y direction of the segment in world(3D) space (typically 0)
- **DirectionZ:** A number that represents the Z direction of the segment in world (3D) space

Learn more about how to use output properties of the **Measuring camera** control in your apps: Validate measurements in mixed reality using a spatial test filter

Other mixed reality controls

- View 3D content with the **3D object** control.
- View images and 3D content in the real world with the **View in mixed reality** control.
- Create and view predefined 3D shapes with the **View shape in mixed reality** control
- Paint 3D lines or draw 3D arrows to specify an area or asset in your environment with the **Markup in MR** control.

Create an app using the Measuring Camera control

Test whether an object will fit in a space using mixed reality

Article • 12/16/2022

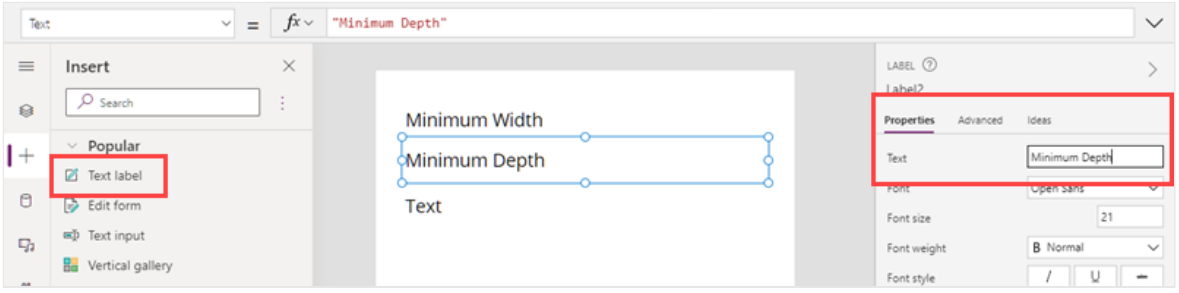
You can use the Measuring Camera control to determine whether an object of a known size will fit in a particular space. In this article, we'll create a canvas app to do just that.

> **Tip**
>
> The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

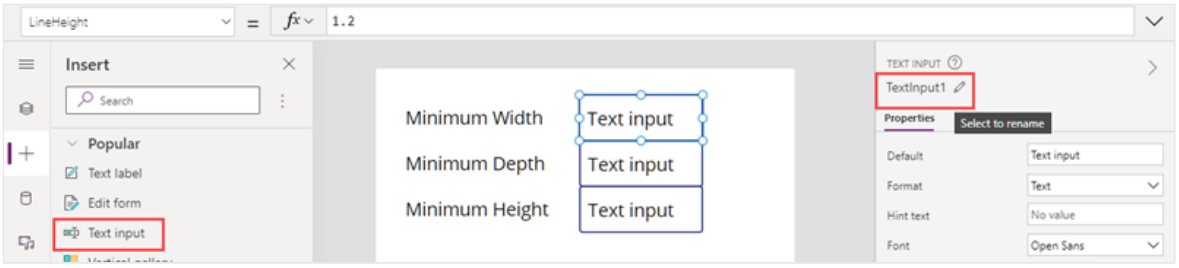
Add minimum dimensions input fields to a canvas app

First, we'll create a blank canvas app. Then we'll add a way for the user to enter the minimum dimensions to test against (that is, the smallest space that will hold the object we want to fit).

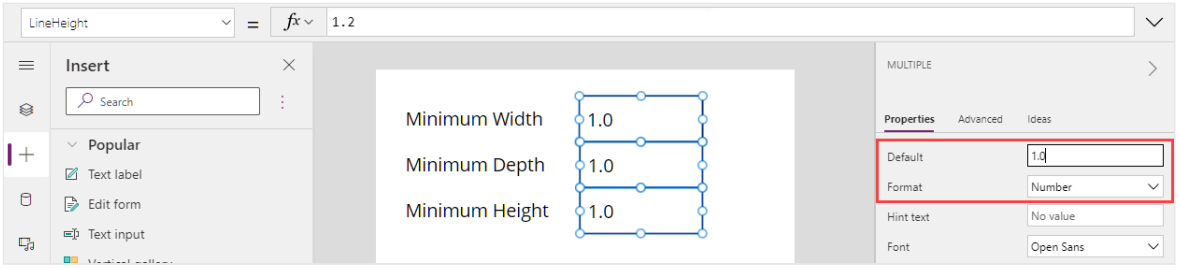
1. Create a blank canvas app.
2. Select the **Insert** tab. Insert and place three **Text label** controls on the screen.
3. Change the **Text** property of the labels to **Minimum Width**, **Minimum Depth**, and **Minimum Height**, respectively.



4. Select the **Insert** tab. Insert three **Text Input** controls, and place them to the right of the three labels.
5. Rename the text input controls to **minWidth**, **minDepth**, and **minHeight**, respectively.



6. Select all three text input controls. Change the group's **Format** property to **Number** and set the **Default** property to **1.0**.



Add and bind the Measuring camera control

Next, we'll add the **Measuring camera** control to allow the user to measure a three-dimensional space. We'll bind the measurements to a data table for later use.

1. Select the **Insert** tab, and expand **Media**.

2. Select **Measuring camera** to place the control in the app screen. Drag the control near the bottom of the screen.

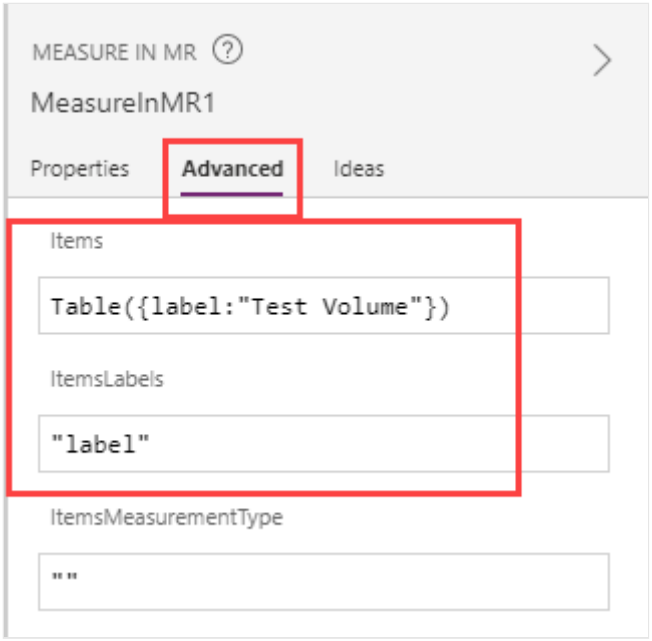
3. Change the control's properties as follows:

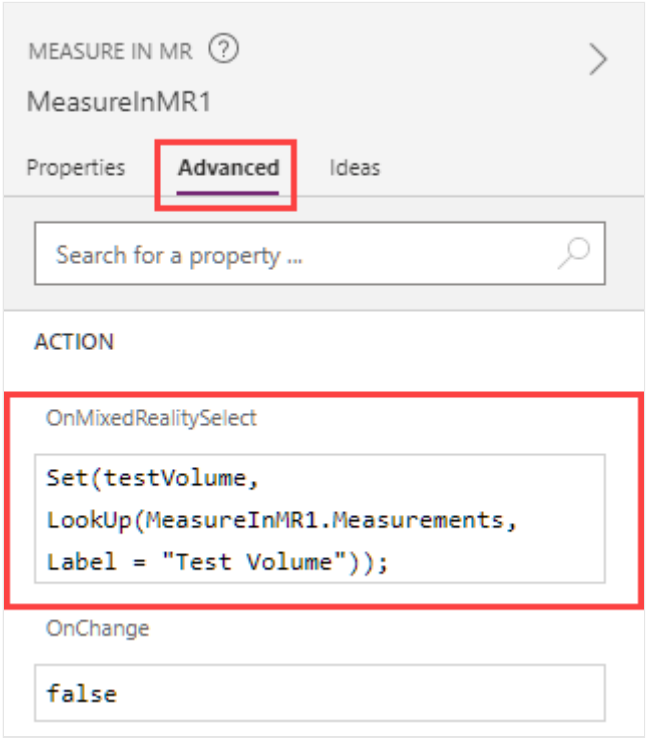
Expand table

Property name	Value	Where
Unit of measurement	Feet or Meters	Select on the **Properties** tab
Measurement type	Volume	Select on the **Properties** tab
Box draw	On	Select on the **Properties** tab
Items	**Table({label:"Test Volume"})**	Enter on the **Advanced** tab
ItemsLabels	**"label"**	Enter on the **Advanced** tab

Property name	Value	Where
OnMixedRealitySelect	**Set(testVolume, LookUp(MeasureInMR1.Measurements, Label = "Test Volume"));**	Enter on the **Advanced** tab

The **Items**, **ItemsLabels**, and **OnMixedRealitySelect** properties of the **Measuring camera** control should look like the following examples when you're done:





The formula in **Items** captures the dimensions of the measured space in a data table named "Test Volume." The formula in **OnMixedRealitySelect** sets a variable named "testVolume" to the values captured in the "Test Volume" table.

Display the results

Finally, we'll add text labels to display the measurements that were taken and the result of the test (that is, whether the object will fit in the measured space).

1. Select the **Insert** tab. Insert and place four **Text label** controls on the screen.

2. Change the **Text** property of the label controls as follows. (Hint: Copy each formula and paste it in the formula bar or on the **Advanced** properties tab, whichever you prefer.)

    - First label:

```
Power Fx
```

```
    If(IsBlankOrError(testVolume), "No Measurement captured",
        If(testVolume.Height >= Value(minHeight.Text) &&
        ((testVolume.BoundingWidth >= Value(minWidth.Text) &&
testVolume.BoundingDepth >= Value(minDepth.Text)) ||
        (testVolume.BoundingWidth >= Value(minDepth.Text) &&
testVolume.BoundingDepth >= Value(minWidth.Text))),
        "Fit Test Succeeded", "Fit Test Failed"))
```

      This formula sets the label text according to whether the test succeeded or failed, based on the minimum dimensions required to hold the object we want to fit. If the test didn't run, either because no measurements were captured or an error occurred, the label text reflects that.

    - Second label:

```
Power Fx
```

```
    Concatenate("Bounding Width: ",
Text(testVolume.BoundingWidth))
```

This formula sets the label text to "Bounding Width:" followed by the width dimension of the measured space.

- Third label:

```
Power Fx

    Concatenate("Bounding Depth: ",
Text(testVolume.BoundingDepth))
```

This formula sets the label text to "Bounding Depth: " followed by the depth dimension of the measured space.

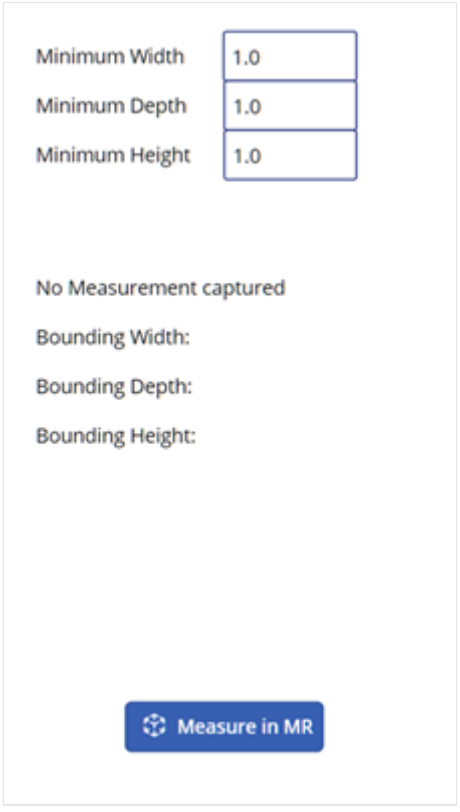
- Fourth label:

```
Power Fx

    Concatenate("Bounding Height: ", Text(testVolume.Height))
```

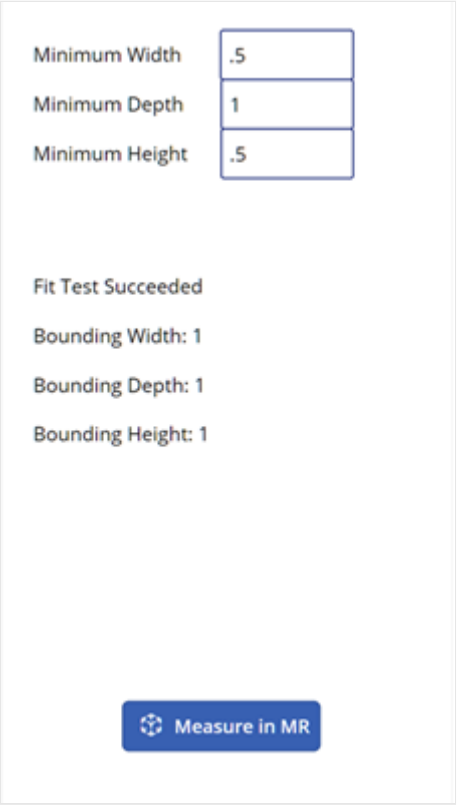
This formula sets the label text to "Bounding Height: " followed by the height dimension of the measured space.

The app screen should now look like this:



Test the app

Select the preview button to run the app in preview mode. Select **Measuring camera** to populate the labels with data. To verify that the label bindings are working, enter new values in the text input fields.



The values for **Bounding Width** and **Bounding Depth** can be swapped when you perform the test.

Save and publish your app. Open it on a mixed-reality–enabled device to test whether an object with the specified dimensions will fit within the bounds of any measurement captured.

Filtering a data source

The app we created tests a single set of dimensions that are specified by the user when the app runs. However, you can extend it to test against any data source by applying the formula as a **Filter** predicate.

For example, let's say that our app contains a reference to a Dataverse table named **Products** that includes three columns: **Width**, **Depth**, and **Height** (corresponding to each product's dimensions). To filter the collection to show only the measurements that would fit in a measured volume, we can apply the following formula.

```
Power Fx
```

```
    If(IsBlankOrError(testVolume), Products,
    Filter(Products, testVolume.Height >= Height &&
        ((testVolume.BoundingWidth >= Width && testVolume.BoundingDepth >=
Depth) ||
        (testVolume.BoundingWidth >= Depth && testVolume.BoundingDepth >=
Width))))
```

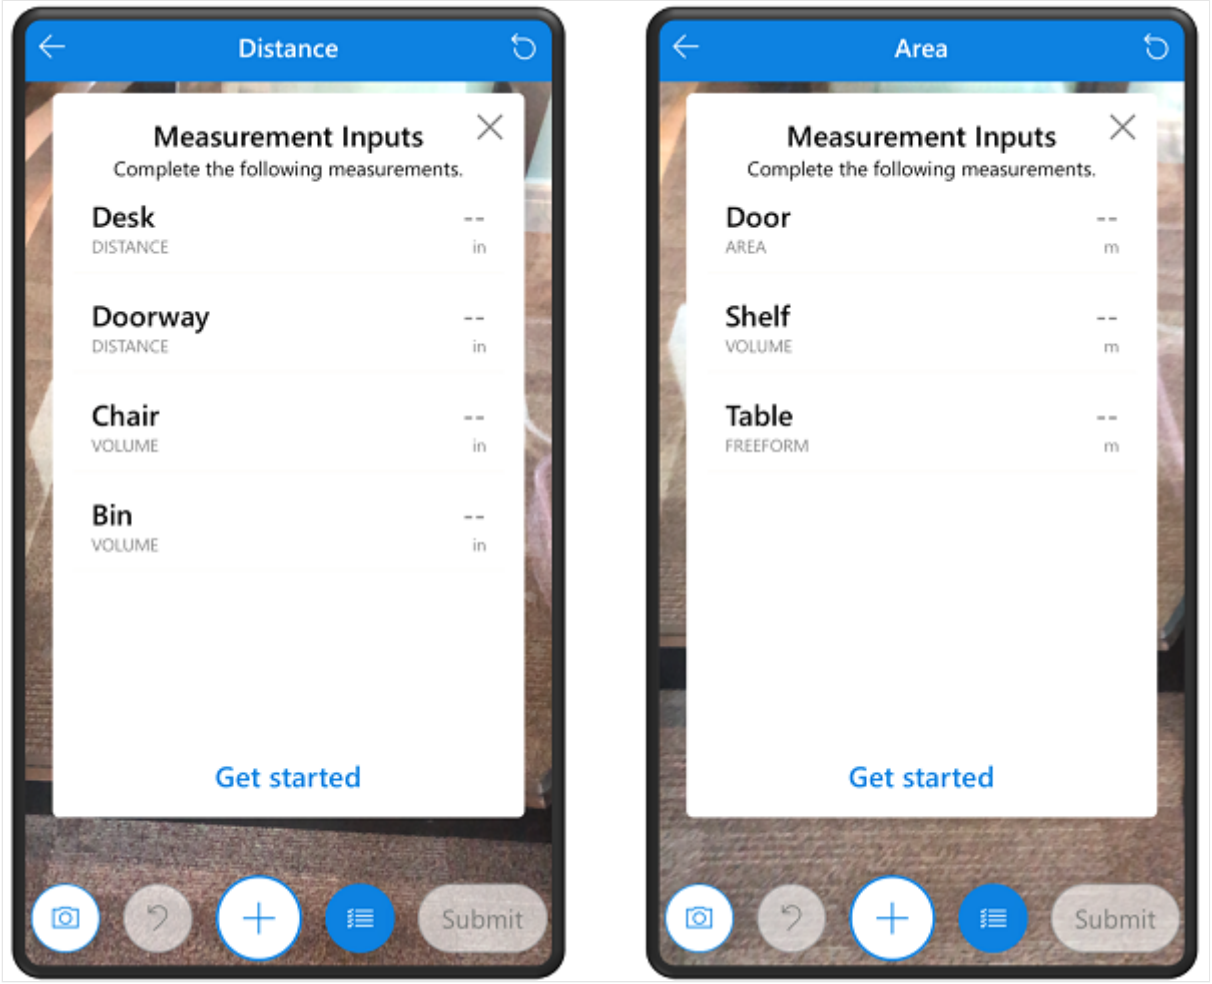
Use the Measure in MR control to take measurements

Article • 07/15/2022

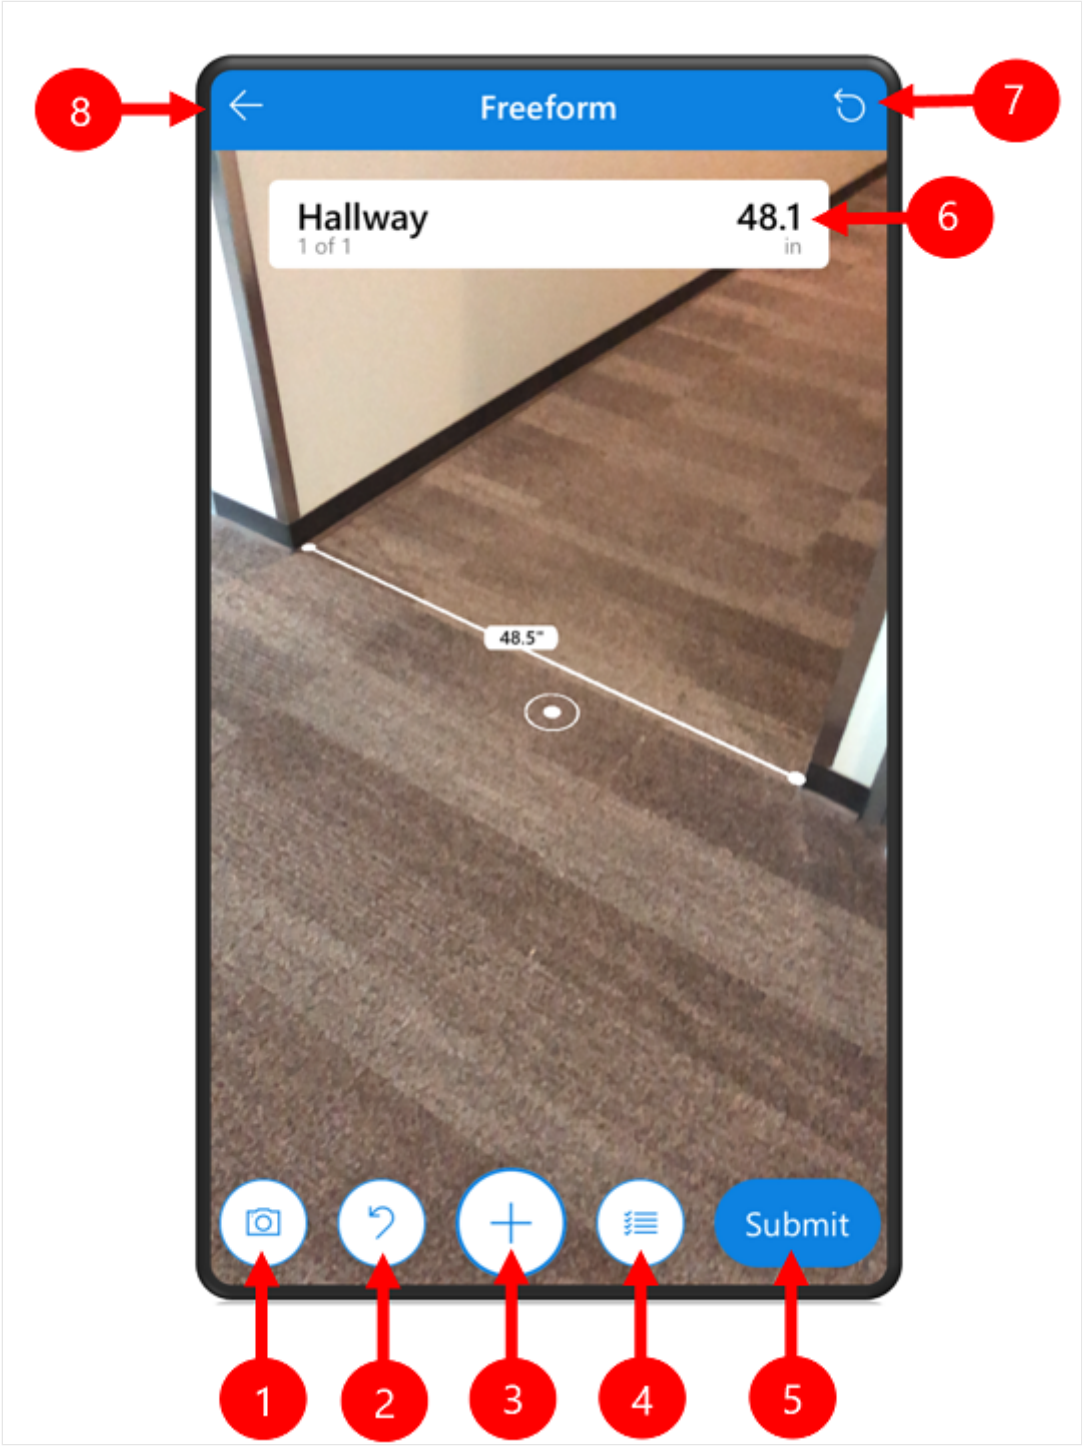
Measure the distance, area, and volume of your physical space using your device camera.

To use the measurement feature, your app maker needs to enable the Measure in MR control for your canvas app. Depending on how your app maker has configured the app, the type of measurements can vary as shown in the example below.



Basic navigation

It's easy to get around and take measurements of your space. The following illustration shows the primary navigation elements.



Legend

1. **Camera**: Take a picture of your current view. The picture can be used by your canvas app but isn't viewable when you're in a mixed reality experience.
2. **Undo**: Rewinds the last measurement action taken and returns to the state before the last add, reset, or delete.
3. **Add**: Select to start a new measurement or add a new measurement point. When you're done measuring the button changes to a checkmark button that you select to complete your measurement.
4. **Overview**: Opens a list with details of the items you have measured.
5. **Submit**: When you're done taking your measurement(s), use the Submit button to close the mixed reality experience and send the measurement(s) to your canvas

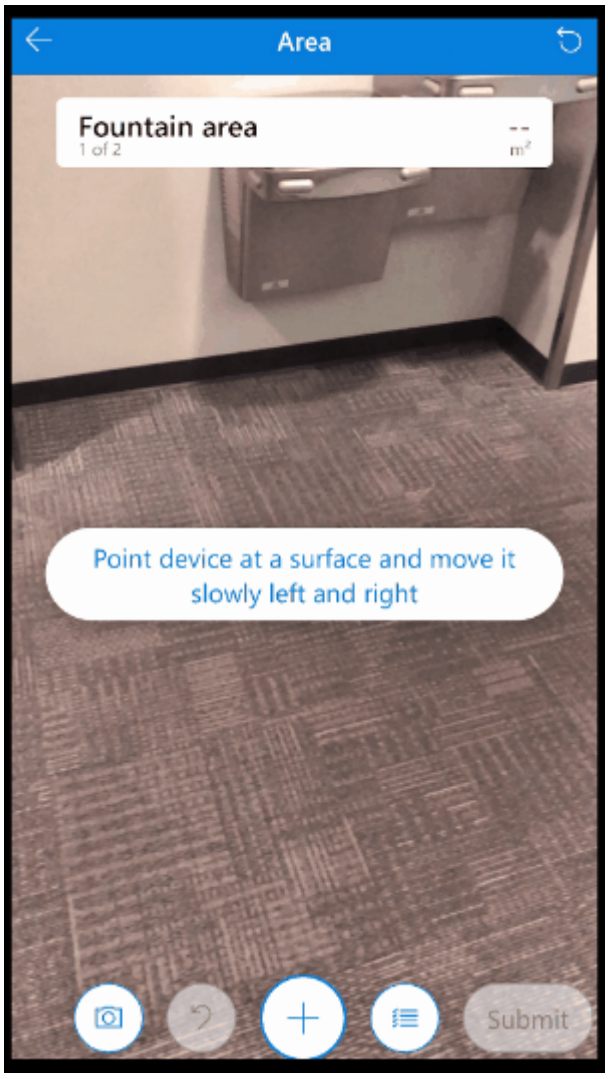
app. The button is grayed out if there are no measurements or when you're in the process of taking measurements.

6. **Overview**: Opens a list with details of the items you have measured.
7. **Reset**: Clear all your measurements at once.
8. **Exit**: Leave the mixed reality experience and return to your canvas app.

Take a measurement

1. Open your canvas app and select the **Measure in MR** button.

2. Follow the instructions on the screen by moving your device until it vibrates, and white dots appear. The white dot with a circle is the starting point of your measurement.

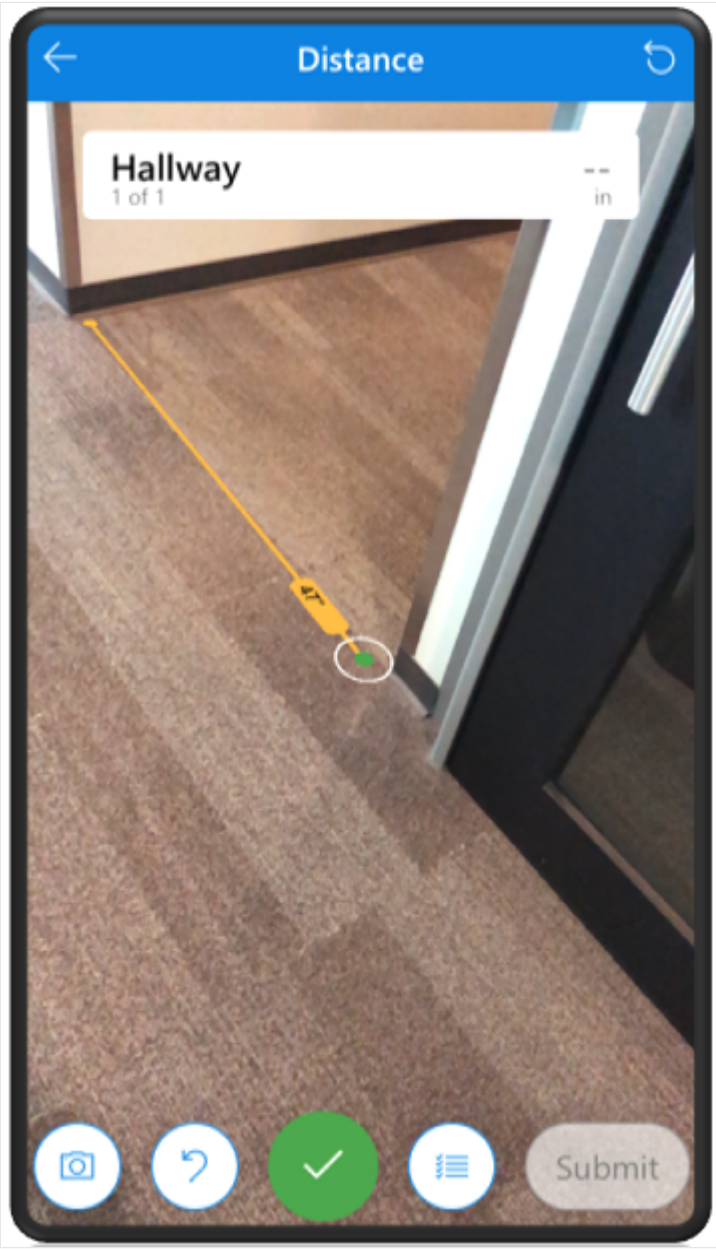


3. Select  to start a new measurement. Then follow these steps depending on the type of measurement you're taking:

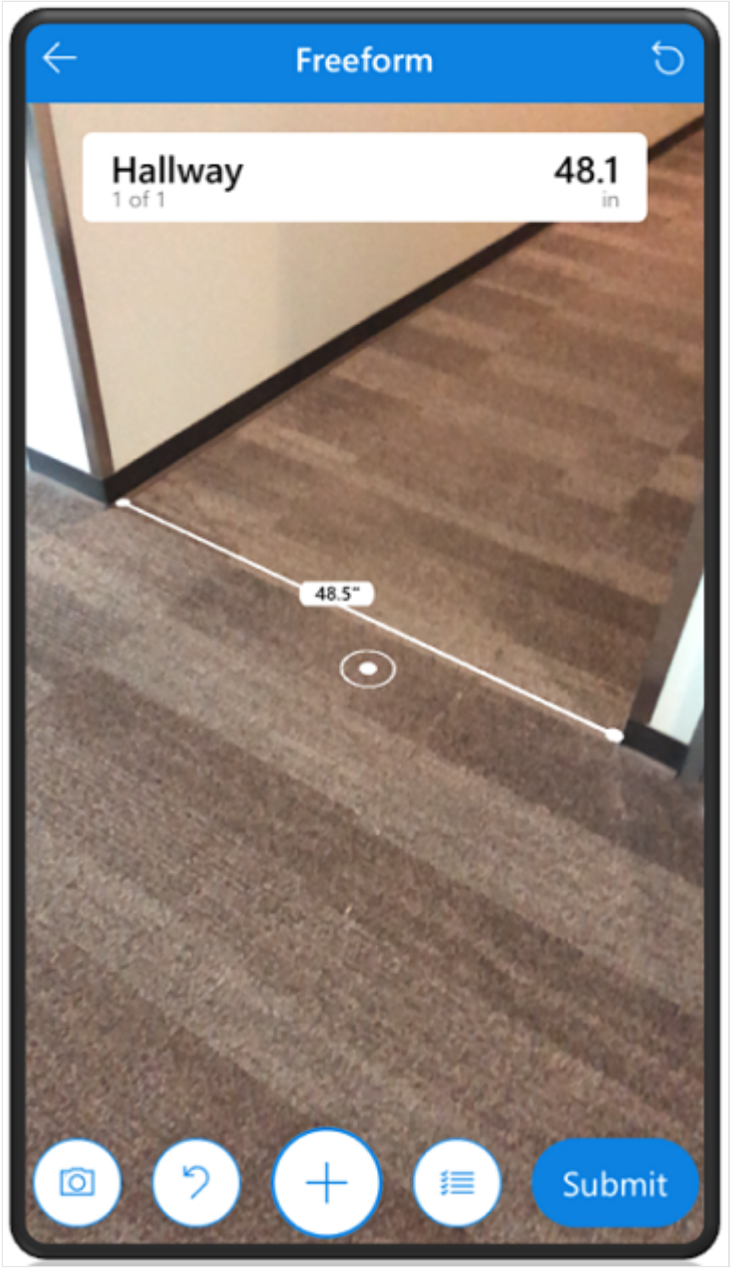
   - **Distance**

a. Select and then slowly move the dot to where you want the measurement to end.

b. Select the checkmark button to finish the measurement.

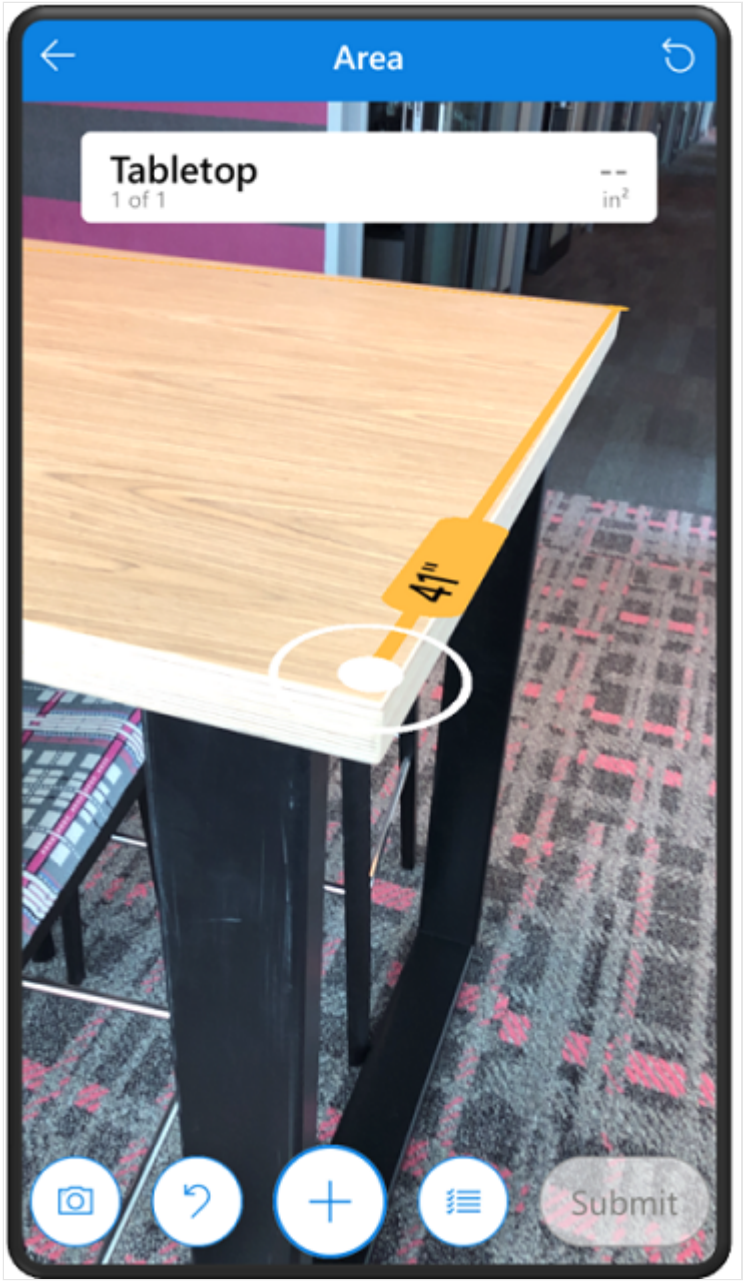


c. Continue taking measurements, or select **Submit** to save your final measurements and return to your canvas app.

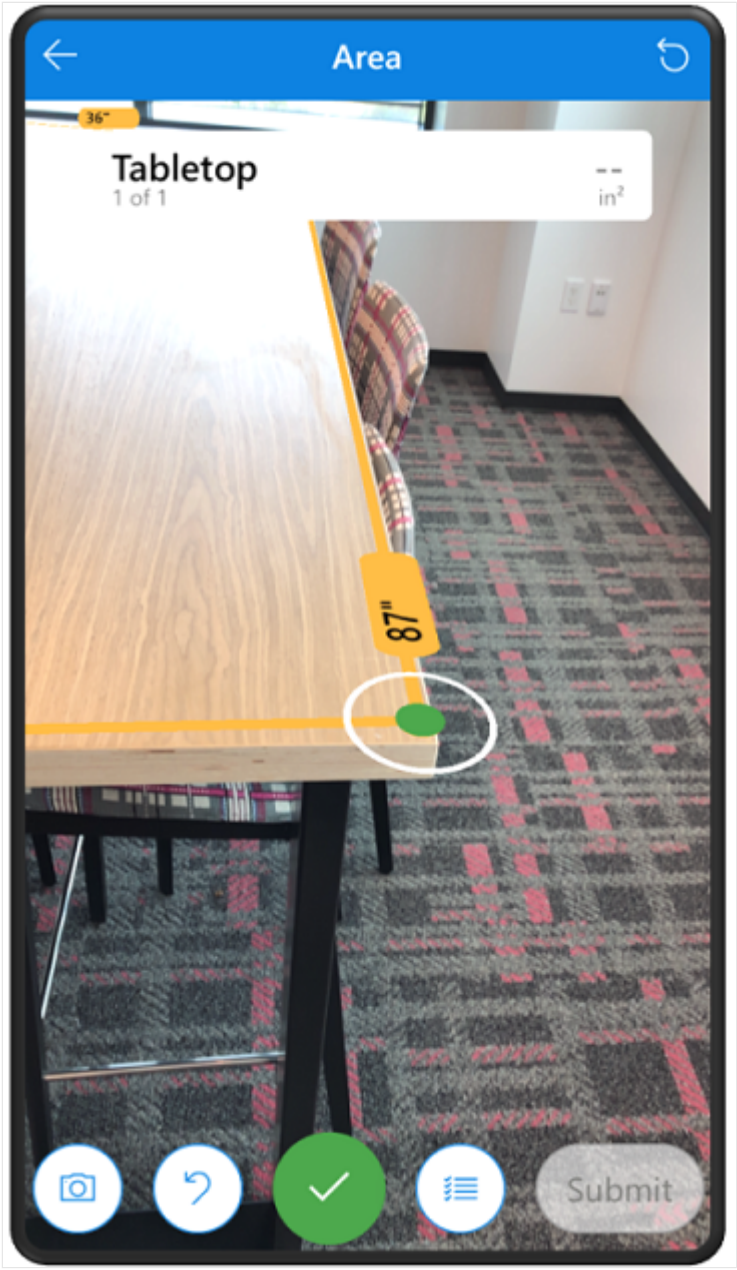


- **Area**

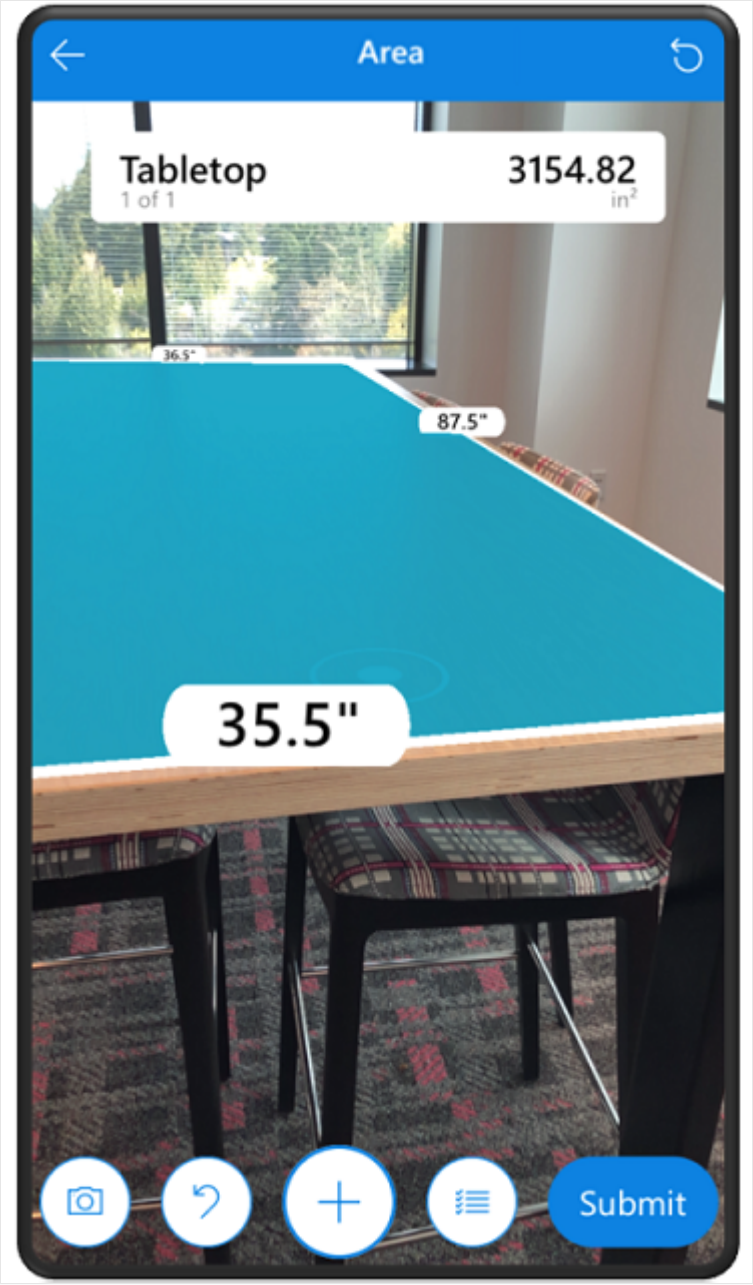
  a. Select  to add points and outline the area that you want to measure.



b. Connect the last dot to the first dot to complete the measurement. When you're done, select the checkmark button.

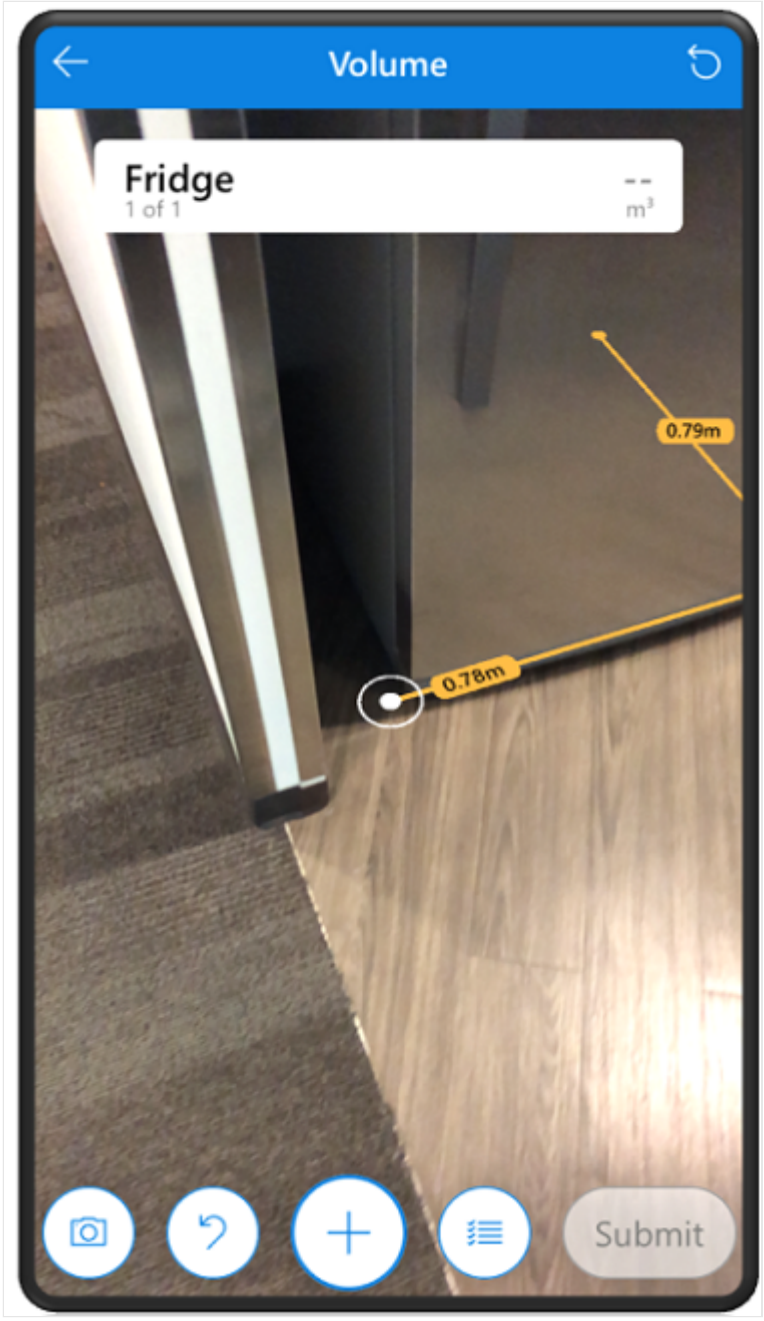


c. Continue taking measurements, or select **Submit** to save your final measurements and return to your canvas app.



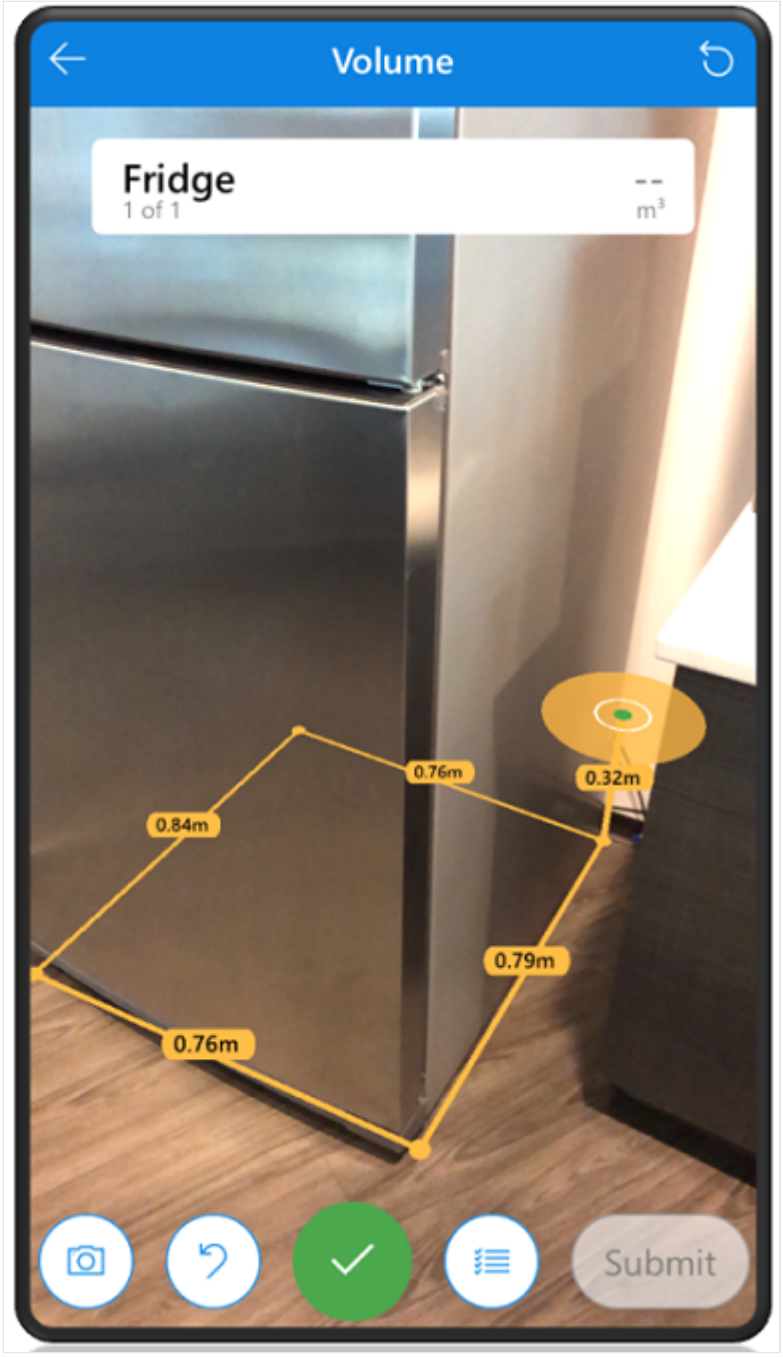
- **Volume**

  a. Select  to add points and outline the base of the volume that you want to measure.



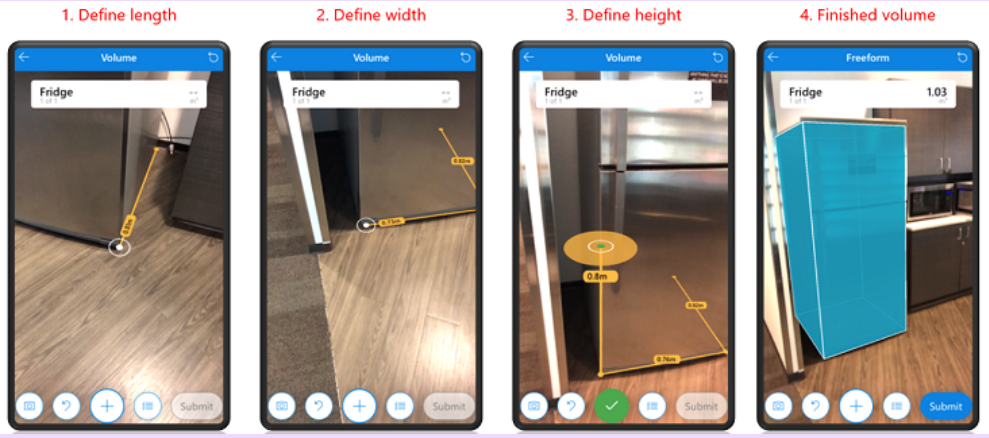
b. Connect the last dot to the first dot to complete the measurement.

c. Move your device upwards and select the desired height and then select the checkmark button.



d. Continue taking measurements, or select **Submit** to save your final measurements and return to your canvas app.

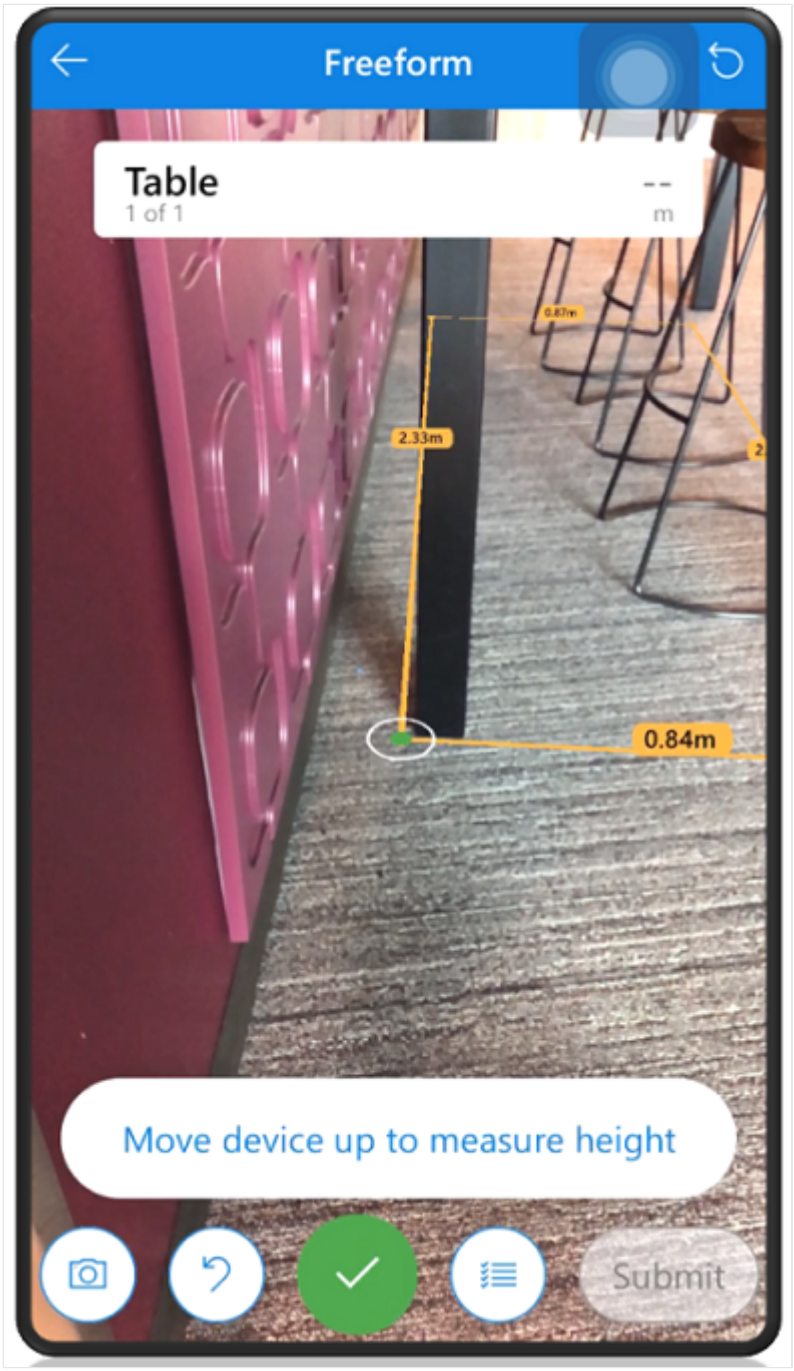
> **Note**
>
> If your app has **Box Draw** enabled then you can only measure volume by a rectangular prism. To take this measurement select four points; three to draw the base and one for the height.



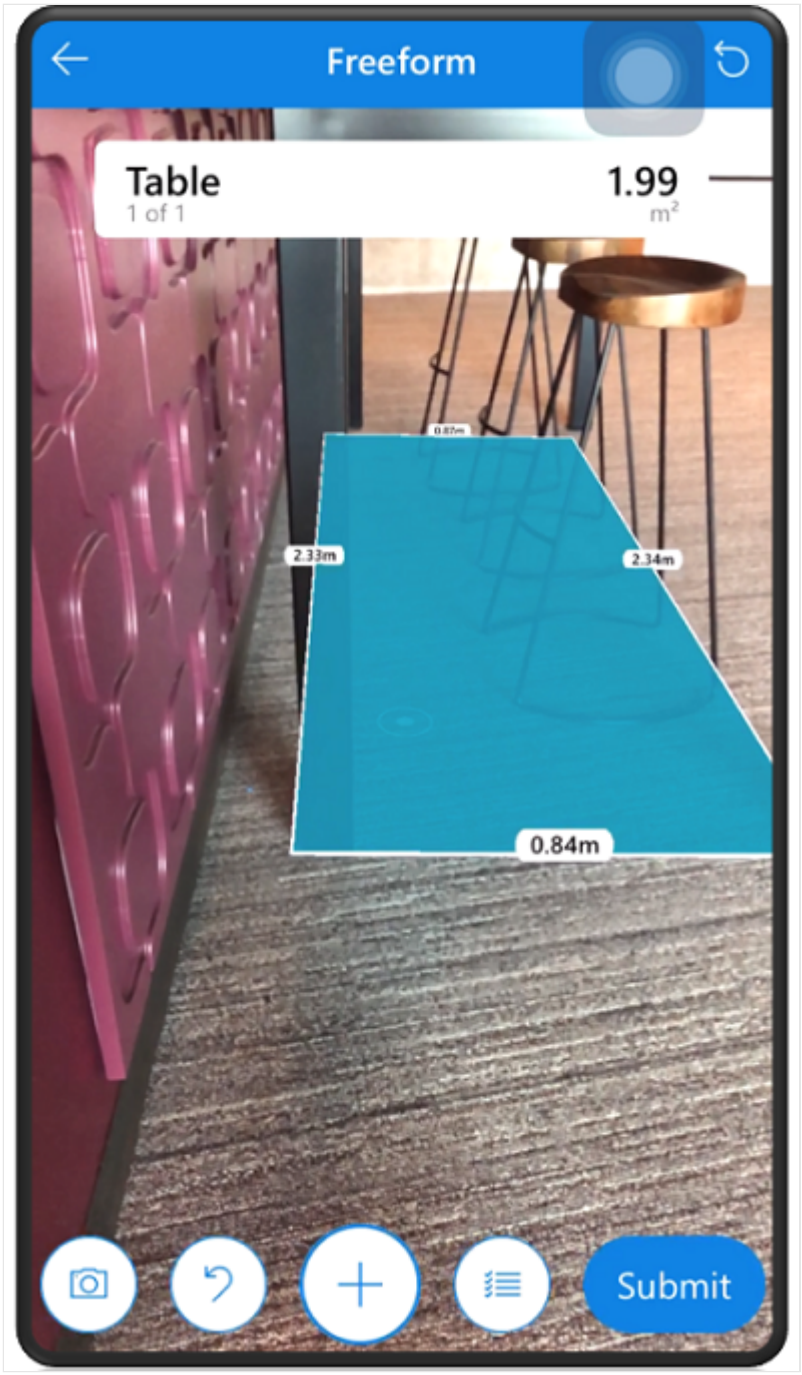
- **Freeform**

  a. Select  to measure distance, multi-segment, area, and volume all together.

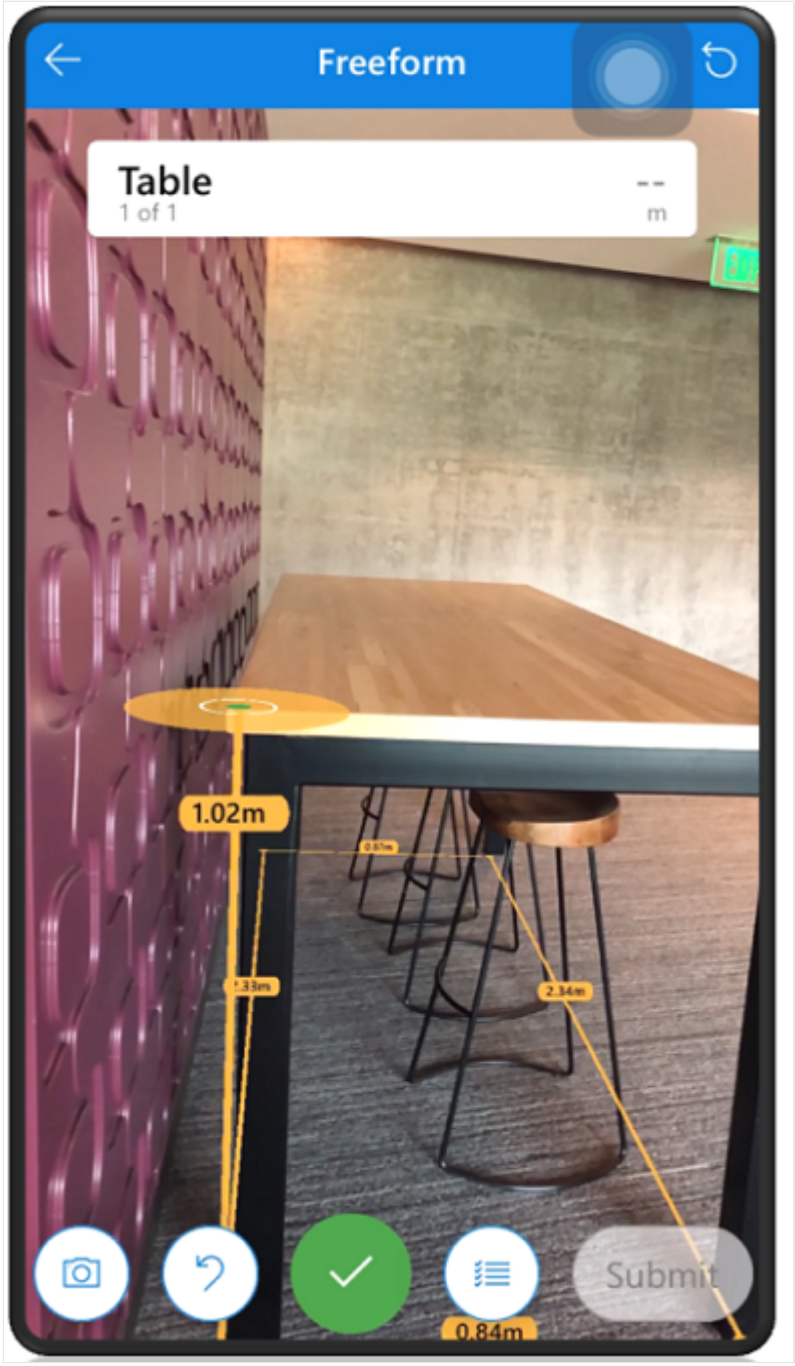
  b. Connect the last dot to the first dot to complete the measurement.



c. Keep the dot at the last point and tap the green checkmark to finish your current measurement. Continue taking other measurements, or if you are done, select **Submit** to return to your canvas app.



The same rectangle can be part of a volume measurement. Instead of selecting the last point you added, rotate your phone upwards to select a height and then tap the green checkmark. Continue taking other measurements, or if you are done, select **Submit** to return to your canvas app.

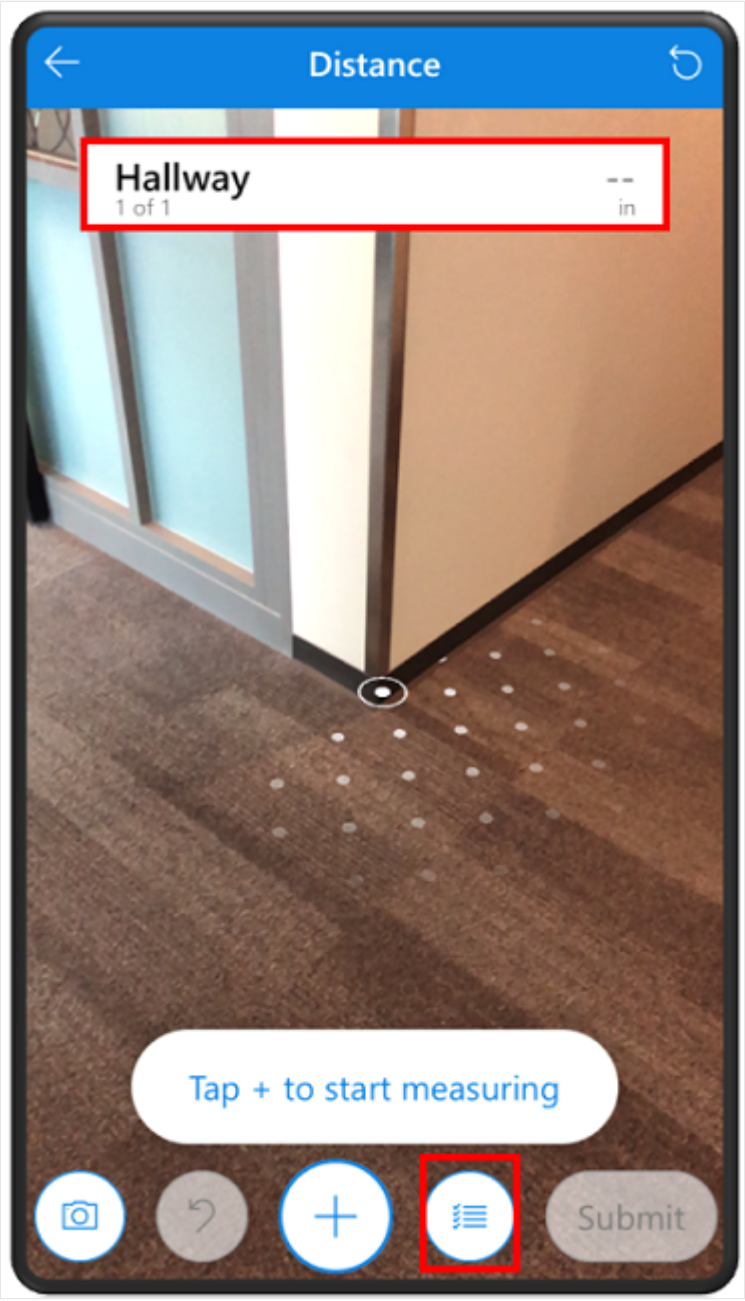


> ⓘ **Note**
>
> If your app has **Box Draw** enabled, then in freeform you can only measure in a rectangular area and volume.

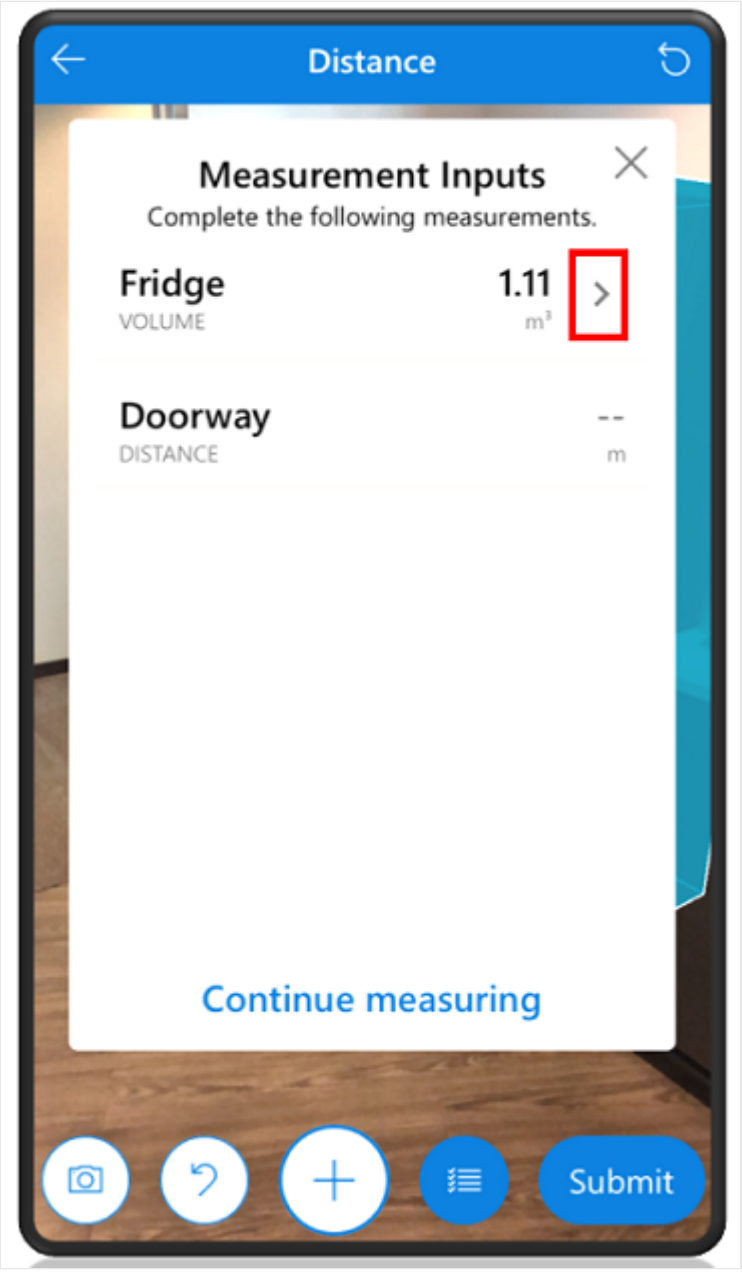
track of your measurements

When you take measurements, you can always go back and review your measurements.

1. At the top select the measurement overview or select the overview button.

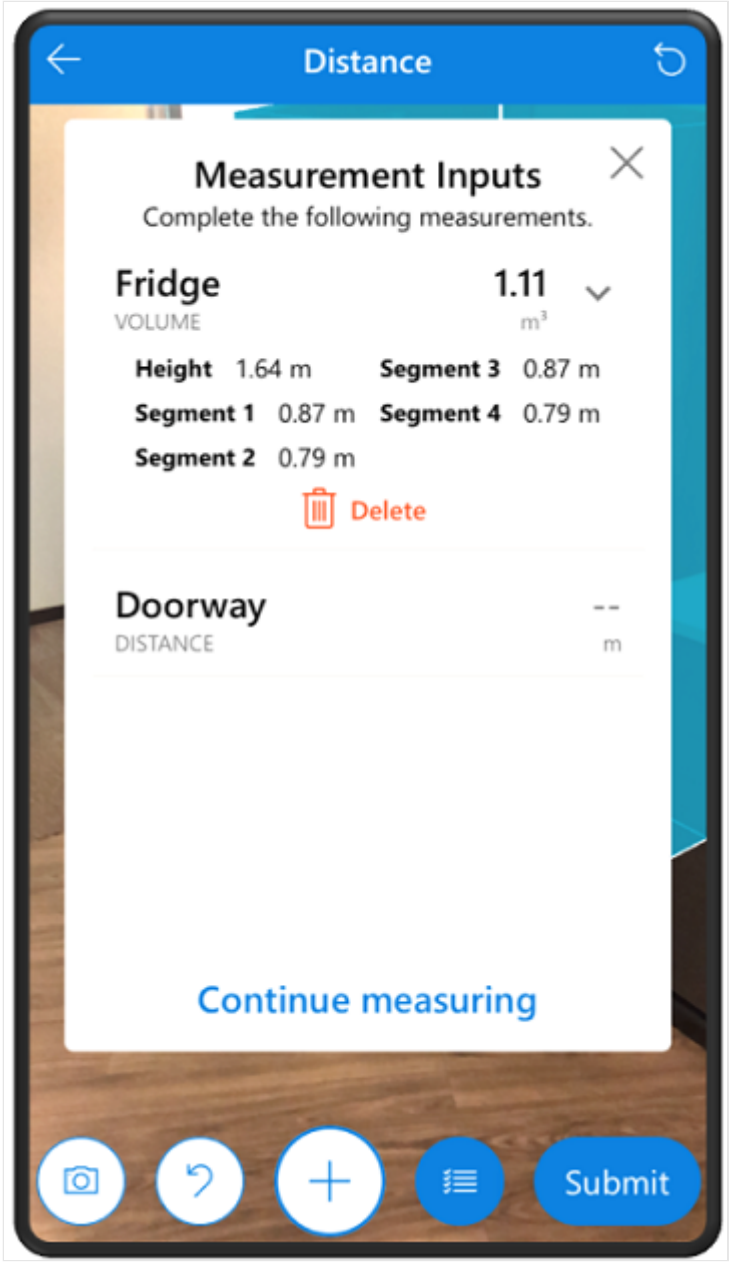


2. If your app maker has given you specific measurements to take, you can see their types here, beneath their label. Select the arrow next to measurement to view more details.



3. On the **Measurement Inputs** screen, you can do the following:

- Select an incompleted measurement to measure it immediately.
- Select the delete button to clear or remove a measurement.
- Select the close button or overview button to continue measuring where you left off.



Distance
Measurement Inputs
Complete the following measurements.

Take and upload mixed-reality photos

Article • 08/05/2022

In this article, we'll create an app that can take photos of a mixed-reality session and upload them to a folder on OneDrive. We'll use the **View in MR** control in this example, but the **View shape in MR** and **Measuring camera** controls would work as well.

We'll cover the following tasks:

- Adding a **3D object** control to view and manipulate a sample 3D object
- Connecting the **3D object** control to a **View in MR** control to view the 3D object in the real world
- Adding a gallery control to view photos taken with the **View in MR** control
- Uploading the photos to OneDrive with a Microsoft Power Automate flow
- Uploading photos captured in mixed-reality to Dataverse

Prerequisites

- Create a blank canvas app.
- Create a folder called **MRPhotos** on OneDrive. You'll use this folder to store your uploaded photos.

> **Tip**
>
> The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

Add a button to take a photo of a 3D object in mixed reality

This example has three parts. First, we'll add a button that lets users take a photo of a 3D object in a mixed reality experience.

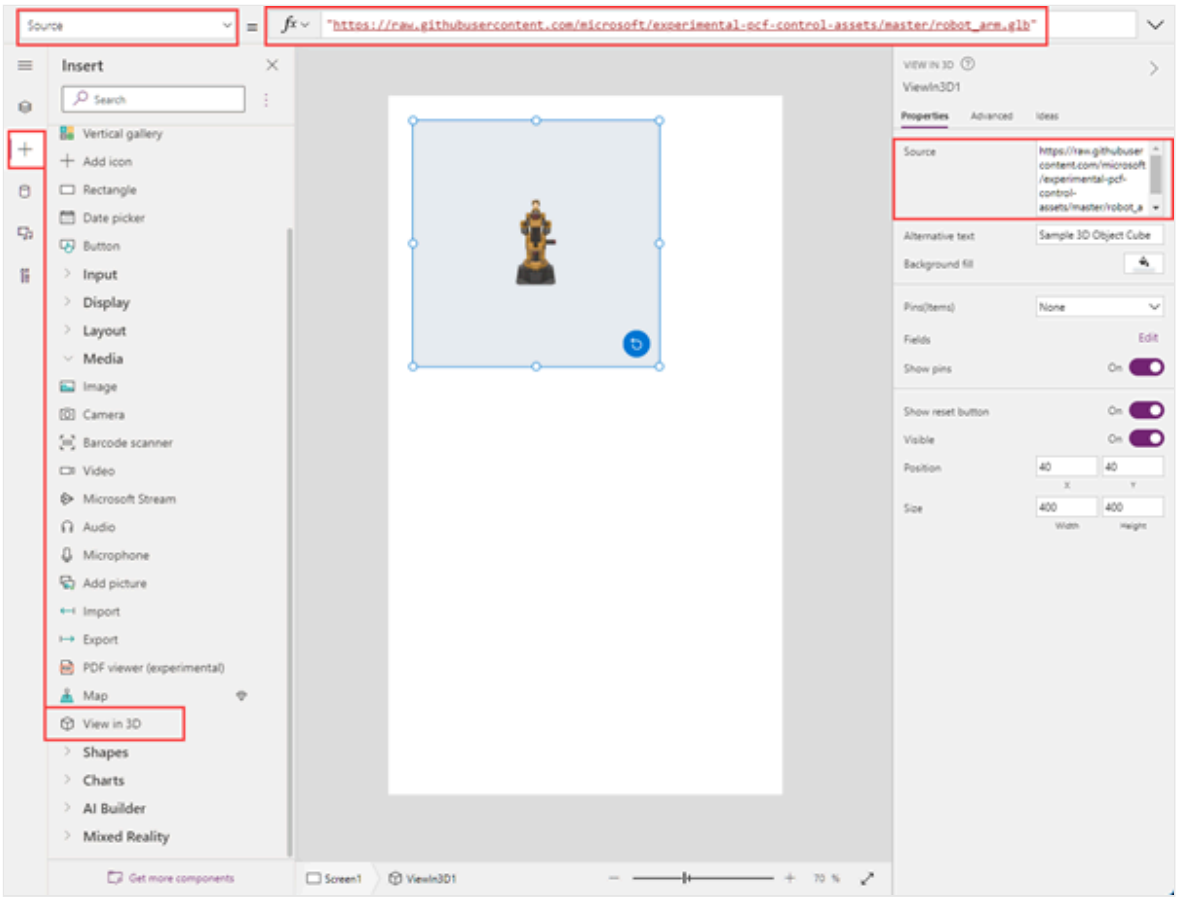
Insert a 3D object control

With your app open for editing in Power Apps Studio:

1. Open the **Insert** tab and expand **Media**.

2. Select **3D object** to place a 3D object on the app screen. Drag the control to the screen to position it more precisely.

   The control comes with a transparent cube shape. If you like, change the control's **Source** property to load a different 3D model. In this example, we'll use the URL *https://raw.githubusercontent.com/microsoft/experimental-pcf-control-assets/master/robot_arm.glb*.

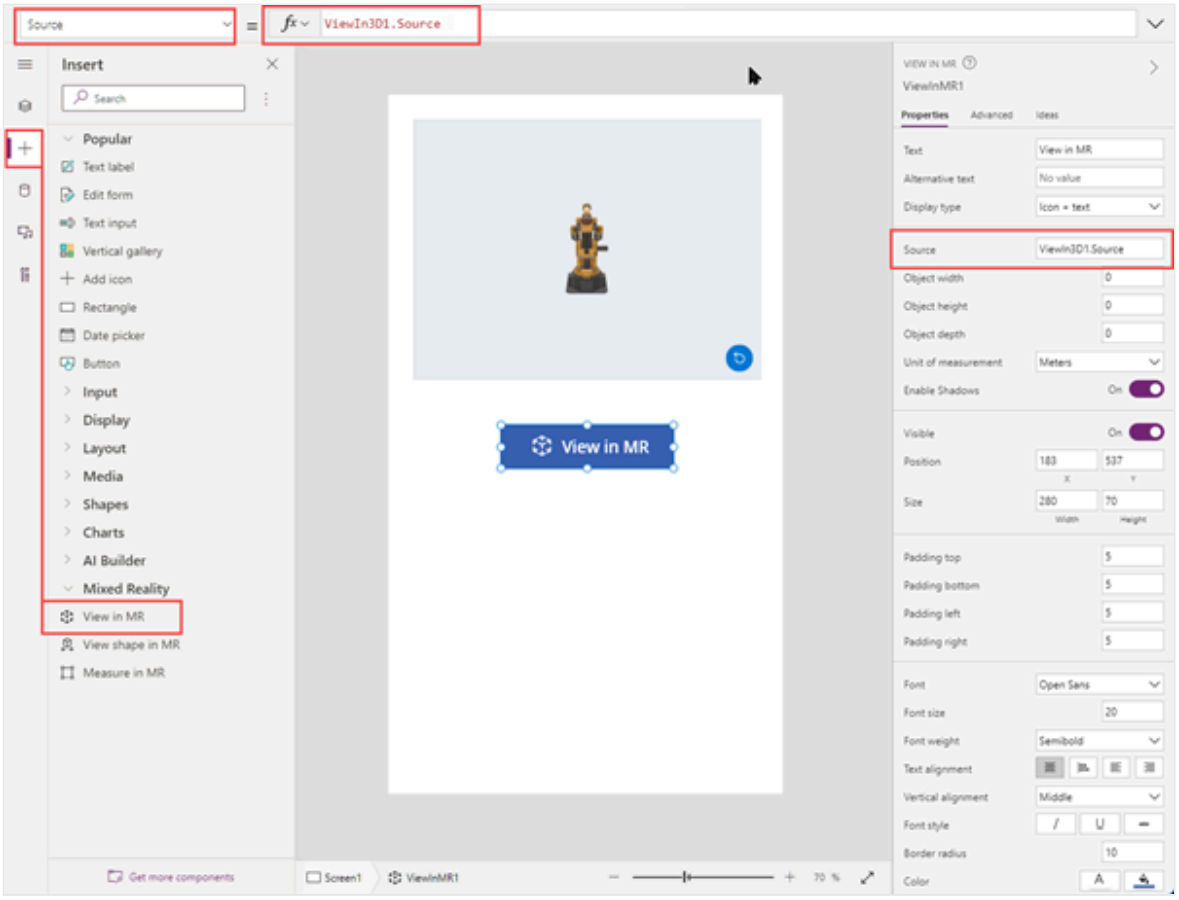


Insert and connect a View in MR control

1. Open the **Insert** tab and expand **Mixed Reality**.

2. Select **View in MR** to place the control on the app screen, or drag the control to the screen to position it more precisely.

3. Change the control's **Source** property to **3DObject1.Source**. (*3DObject1* is the name of the **3D object** control we added earlier.) This expression directs the **View in MR** control to overlay the 3D model on the device camera feed.



4. Save and publish the app and run it on your mobile device.

5. Select **View in MR** to view the 3D object in mixed reality. Select the camera icon to take a photo of the MR view.

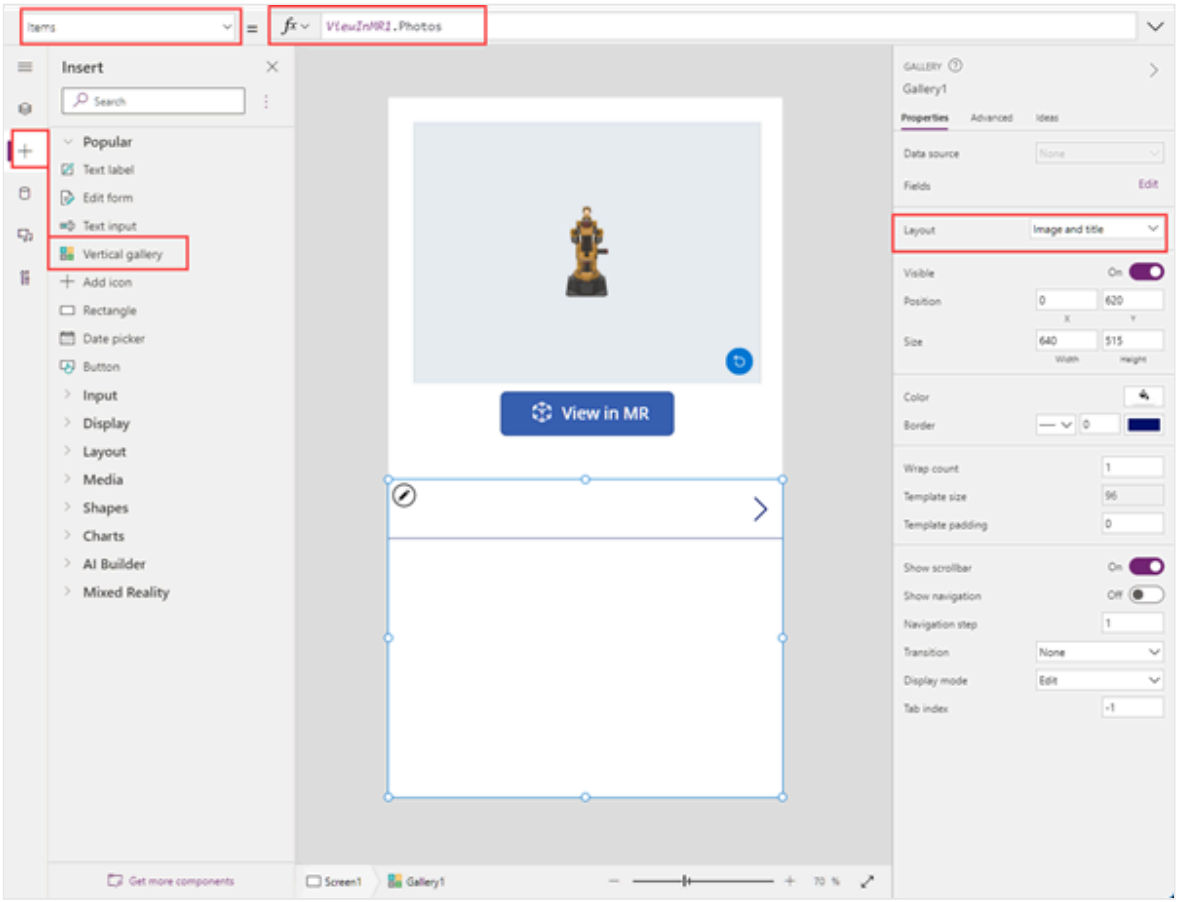
Insert a gallery control to view photos taken in the app

Next, we'll add a gallery so users can view the photos they've taken.

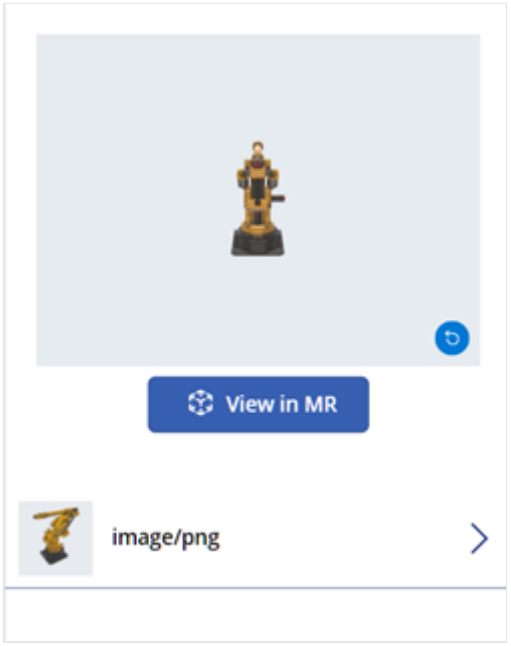
1. Edit your app again. Open the **Insert** tab and place a **Vertical gallery** control on the screen.

2. Change the control's **Items** property to **ViewInMR1.Photos**. (*ViewInMR1* is the name of the **View in MR** control we added earlier.)

3. Optionally, change the gallery's **Layout** property to **Image and title**.



4. Preview the app and select **View in MR** to generate a sample photo. The gallery populates with a sample picture.



> **Note**
>
> If users exit the MR view to see the gallery, then enter the MR view again and take more photos, the new photos will replace the ones they took earlier.

Add a larger overlay to the thumbnail images in the gallery

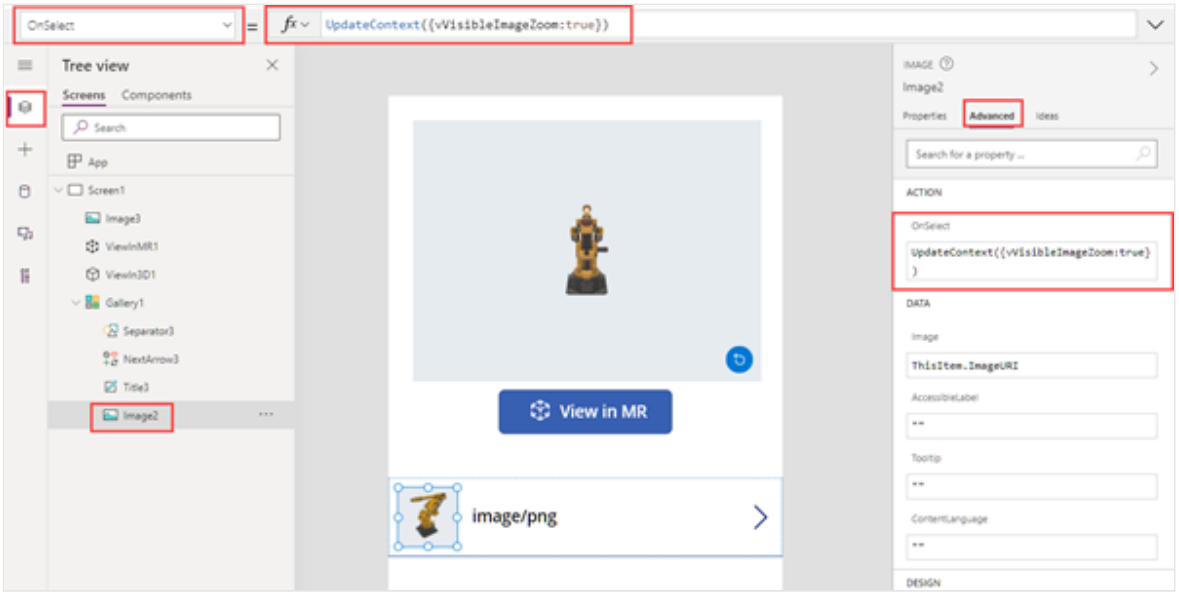
To make the photos in the gallery easier to see, you can add a full-size overlay that appears when the user selects a thumbnail image.

1. Edit your app again. Open the **Insert** tab and expand **Media**.

2. Select **Image** to place an image control on the screen. Move and size it according to how you want the larger photo to appear when a thumbnail image is selected.

3. Change the image control's properties as follows: | Property | Value | | - | - | | **OnSelect** | **UpdateContext({vVisibleImageZoom:false})** | | **Image** | **Gallery1.Selected.Image2** (assuming the gallery control is *Gallery1* and the first thumbnail image is *Image2*) | **Visible** | **vVisibleImageZoom**

4. Select the first thumbnail image in the gallery control. Change its **OnSelect** property to **UpdateContext({vVisibleImageZoom:true})**.



5. Save and publish the app and run it on your mobile device.

6. Select **View in MR**, and then select the camera icon to take a photo. Select the back arrow at the top of the screen to exit the MR view.

7. Select the thumbnail in the gallery to show a larger version of the photo. Select the image to hide it.

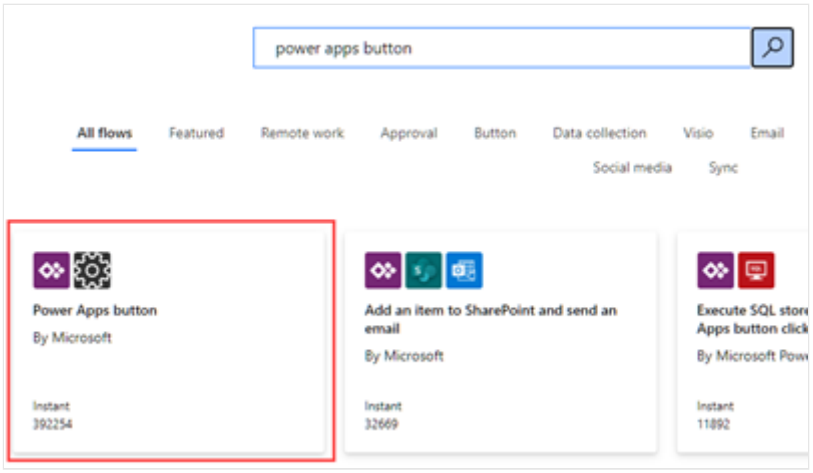
Upload photos to OneDrive with a Power Automate flow

Last, we'll create a workflow using the Power Automate pane. The workflow uploads photos from the app to a folder named **MRPhotos** on OneDrive.

Create a flow in Power Automate

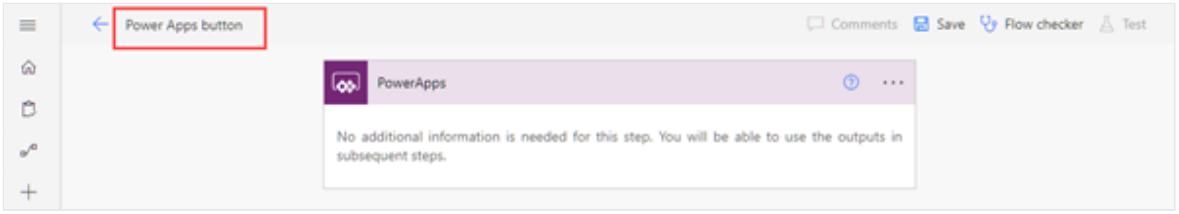
1. Edit your app. On the app authoring menu, select **Power Automate** > **Create new flow**.

2. Search for and select the Power Apps button template.

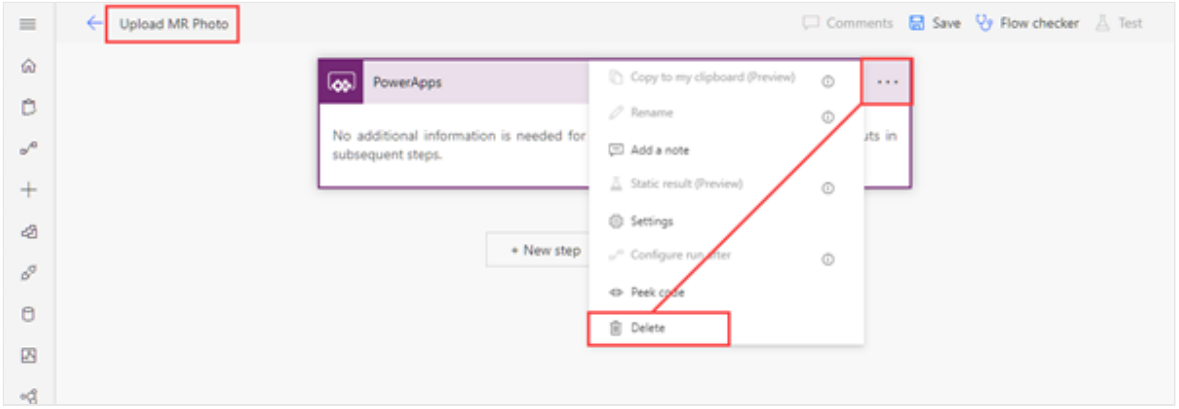


3. In the **Create your flow** window, select **Edit in advanced mode**.

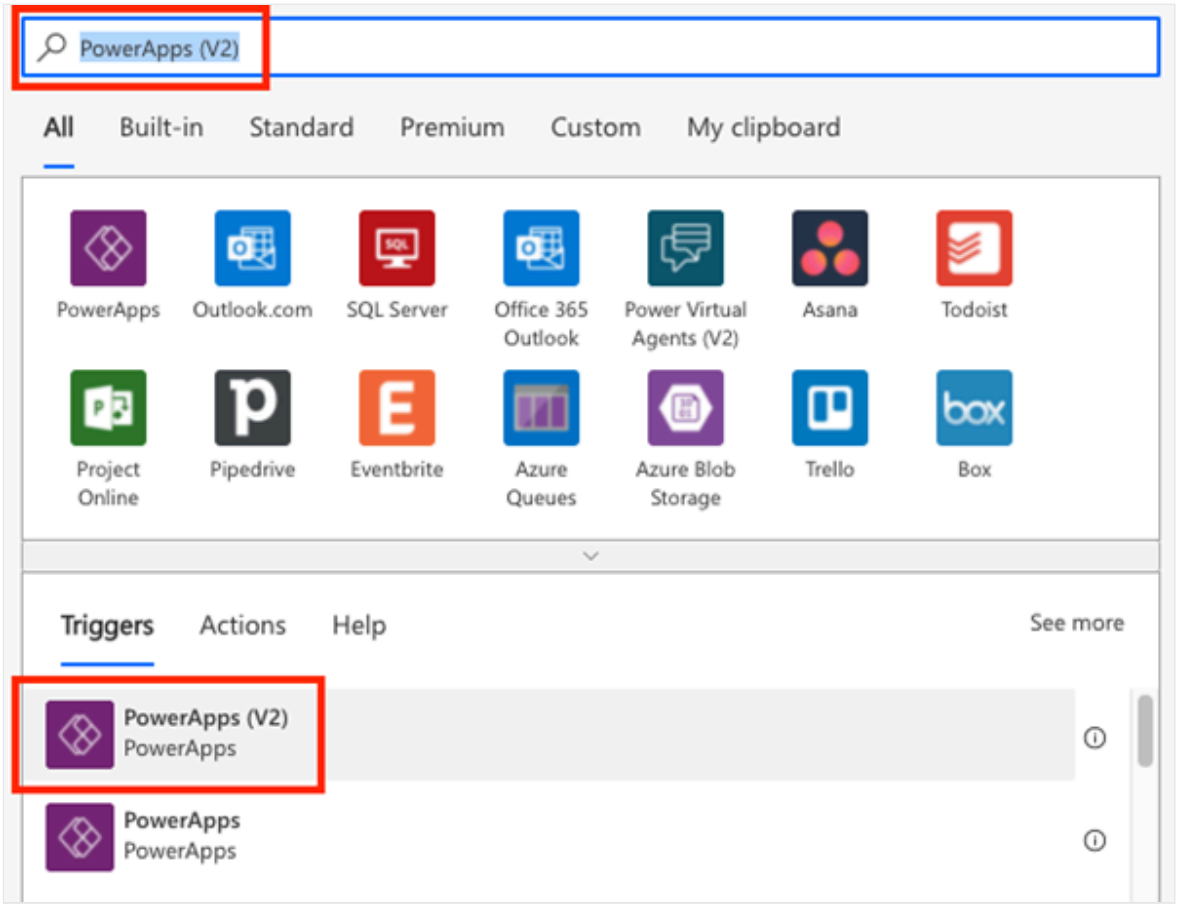
4. Select **Power Apps button** at the top of the window and enter a new name for your flow. In this example, we'll name the flow *Upload MR Photo*.



5. Select Power Apps button at the top of the window and enter a new name for your flow. In this example, we'll name the flow Upload MR Photo.

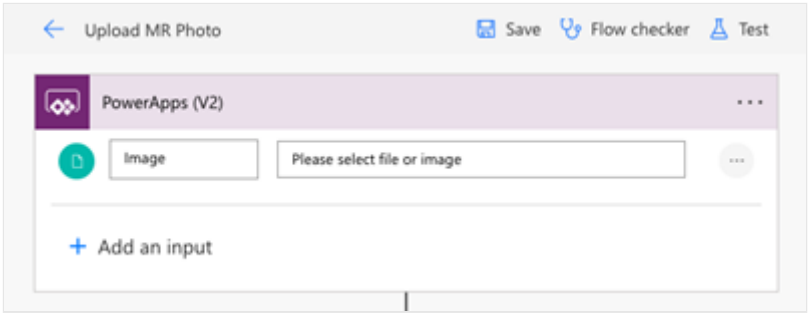


6. Search for **PowerApps (V2)** and select the PowerApps (V2) trigger.

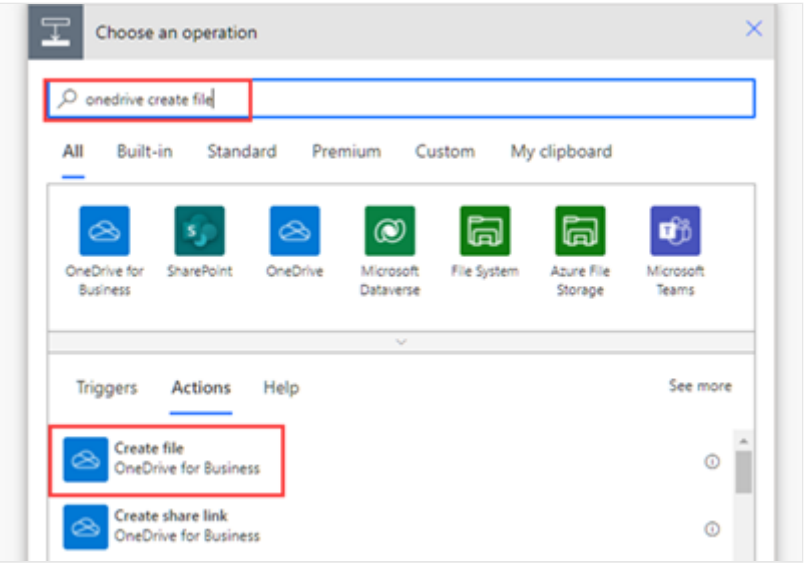


7. Select **Add an input**, and then select **File**.

8. Change the label *File Content* to **Image**.



9. Select **New step**. Search for **OneDrive Create file** and select the **Create file** action.



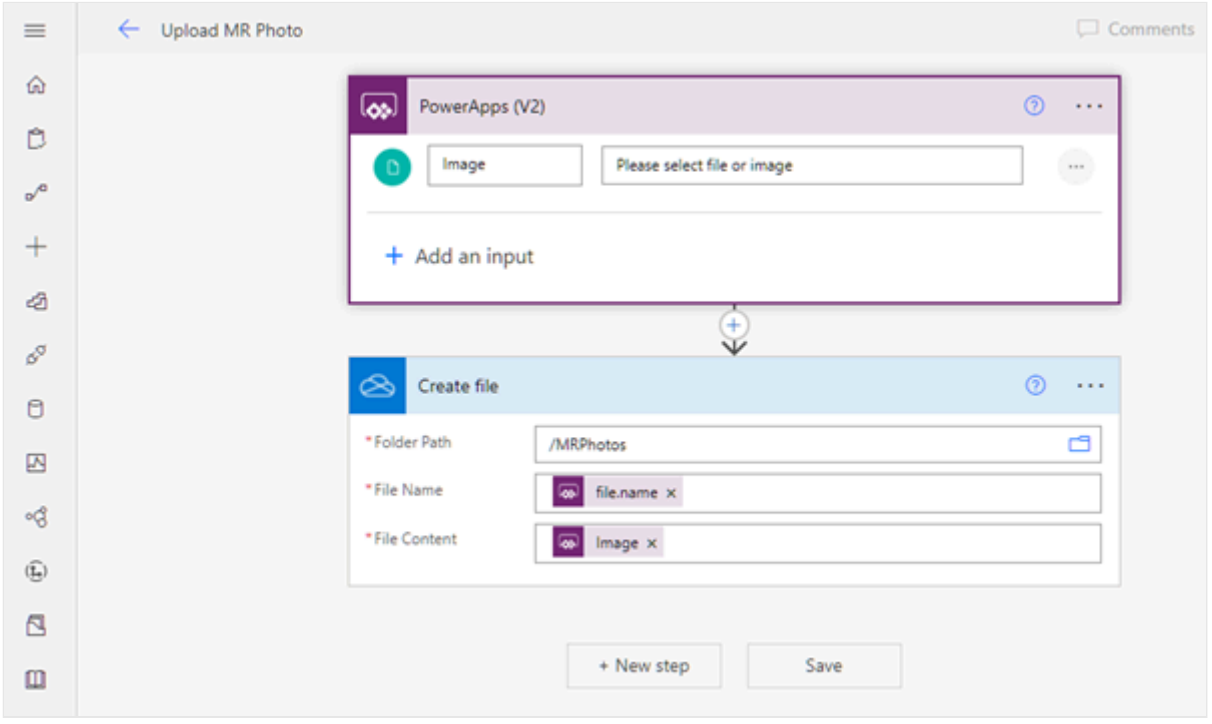
10. In **Folder Path**, select the folder icon and navigate to the **MRPhotos** folder you created earlier.

11. In **File Name**, enter **@{triggerBody()?['file']?['name']}** (Your text changes to "file.name.")

12. In **File Content**, enter **@{triggerBody()['file']['contentBytes']}** (Your text changes to "Image.")

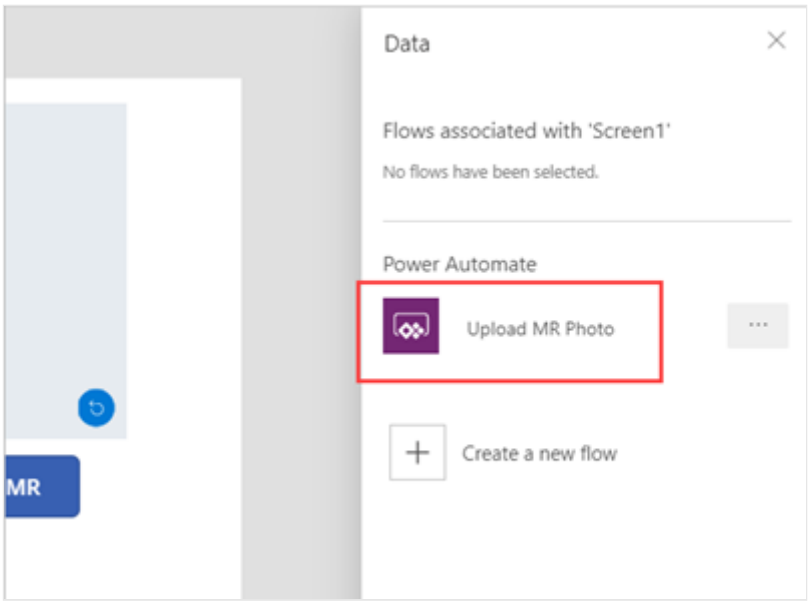
13. Save your flow.

The complete flow should look like this:



Connect the workflow to a button in your app

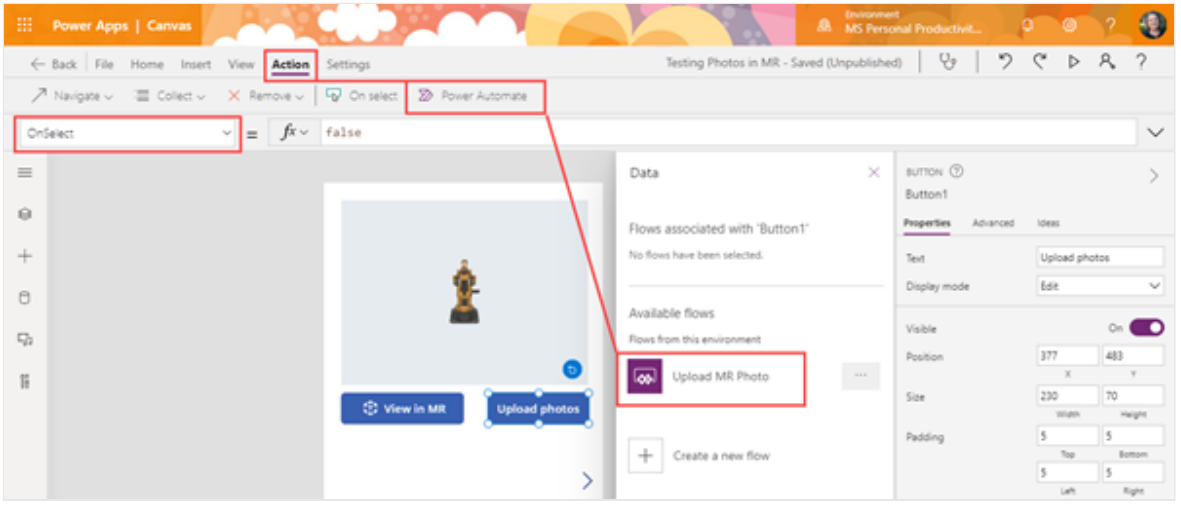
1. Return to your app in Power Apps Studio. Your flow is now listed under **Available flows**.



2. Open the **Insert** tab and select **Button**. Place the button control on the screen and resize it as needed.

3. Change the button control's **Text** property to **Upload photos**.

4. In the formula bar at the top of the Power Apps window, select the **OnSelect** property. Select **Action** > **Power Automate** > **Upload MR Photo**.



The button control's **OnSelect** property changes to **UploadMRPhoto.Run(**.

5. To upload the last photo taken, paste the following code after the opening parenthesis: **{file:{name:GUID() & ".png", contentBytes:Last(ViewInMR1.Photos).ImageURI}})**

If you placed the button control inside the gallery, paste the following code instead: **{file: {name:GUID() & ".png", contentBytes:ThisItem.ImageURI}})**

To make the button upload all the photos taken, delete **UploadMRPhoto.Run(** and paste the following code: **ForAll(ViewInMR1.Photos, UploadMRPhoto.Run({file: {name:GUID() & ".png", contentBytes:ImageURI}}))**

6. Preview the app and select **View in MR**, and then select **Upload photos**. Check the **MRPhotos** folder on OneDrive and confirm that the sample photo has been uploaded.

Add offline capability to your app

You can use your app even when you have limited or no network connectivity using the **SaveData** and **LoadData** functions.

Upload photos captured in mixed-reality to Dataverse

You can add photos to Dataverse tables through an Image data type column. Image columns in Dataverse have two required fields - Full and Value - which can be set to the ImageURI output of the MR controls.

For example, if you wanted to upload the first photo captured by the Markup in MR control to a Dataverse column called Image:

Power Fx

```
    Image: {Full: First(MarkupInMR.Photos).ImageURI, Value:
First(MarkupInMR.Photos).ImageURI}
```

Load 3D models from CGTrader into mixed reality controls (preview)

Article • 07/15/2022

[This article is pre-release documentation and is subject to change.]

> **Important**
>
> This is a preview feature.
>
> Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Want to build apps with mixed-reality 3D content without having to create your own 3D models? Use the CGTrader connector to import 3D content from CGTrader into your canvas apps. CGTrader offers a library of thousands of free and premium 3D models. Browse and load models inside your app, and then use them with the 3D object and View in MR controls.

The connector provides a no-code replacement for working with the CGTrader API. Using *actions*, apps send requests to the CGTrader API and fetch model data. For more information, see the Connectors overview.

Prerequisites

Request an API key (OAuth client ID and client secret) at https://www.cgtrader.com/developers. Be sure to store your API key in a secure location.

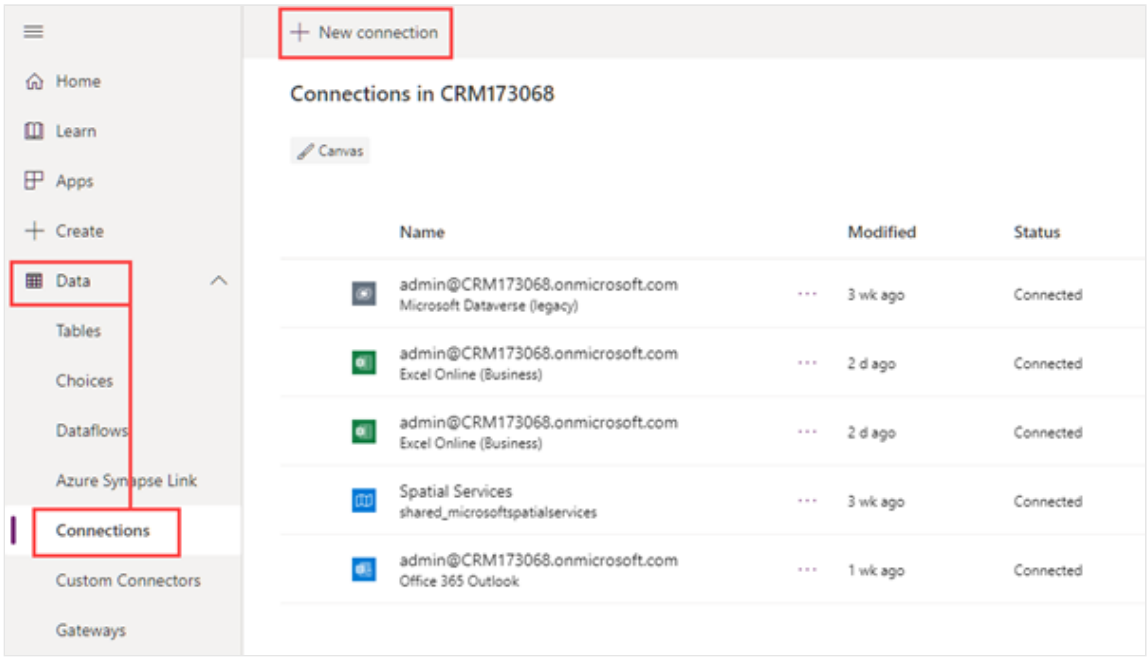
Create a CGTrader connection

You'll need to create a CGTrader connection in Power Apps after you receive your API key. In this example, we'll create a connection on the Power Apps home page. You can also create a connection when you're editing an app in Power Apps Studio.

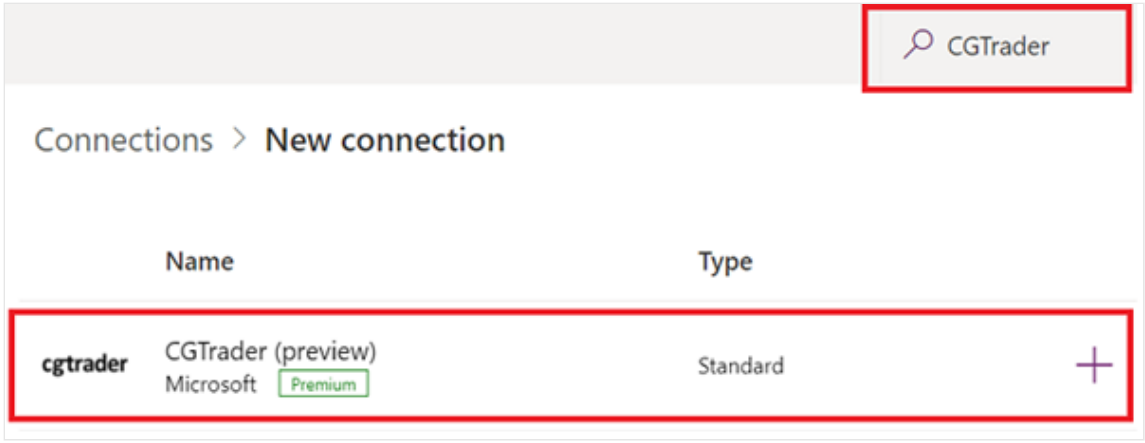
> **Tip**
>
> A connection is an instance of a connector. You can create multiple connections with different configurations.

1. Sign in to Power Apps.

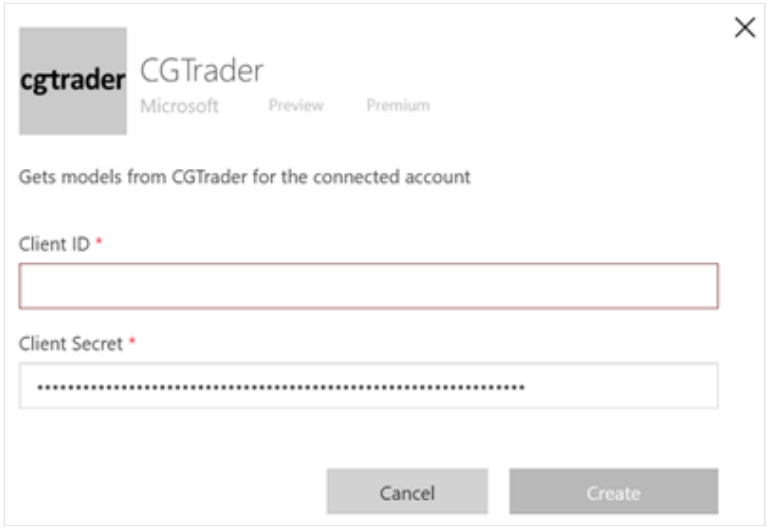
2. In the navigation bar, select **Data** > **Connections** > **New connection**.



3. Search for and select **CGTrader (preview)**.



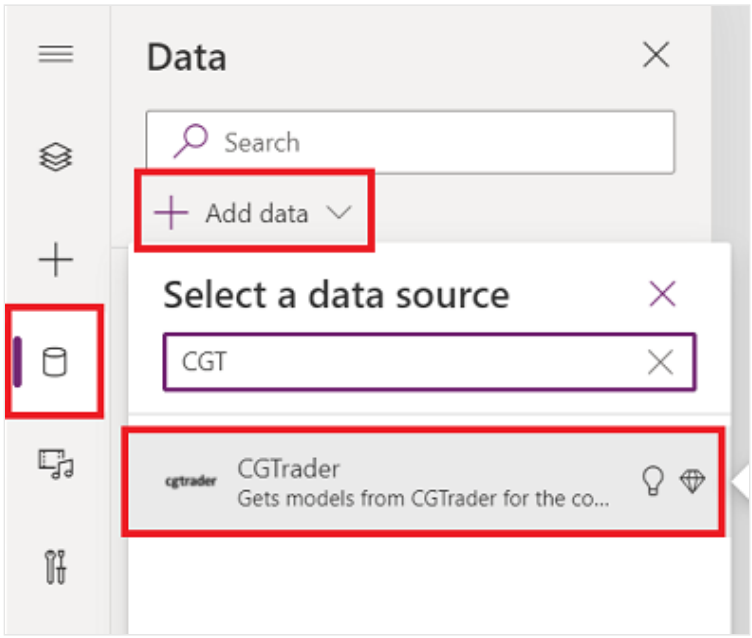
4. Enter the **Client ID** and **Client Secret** you received from CGTrader.



A CGTrader connection is now listed on the **Connections** page.

Add a CGTrader connection to your canvas app

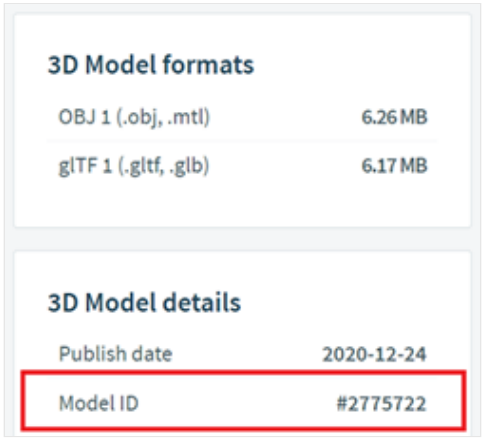
1. Edit or create a canvas app.
2. In the navigation bar, select **Data** > **Add data**. Search for and select **CGTrader**.



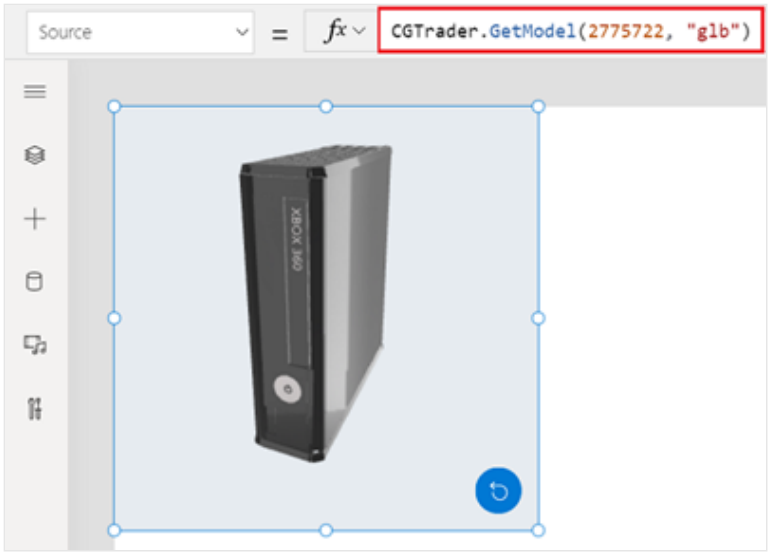
3. Select the connection you created earlier.

Load CGTrader models directly into 3D object or View in MR controls

1. Find and select a model on the CGTrader website.
2. Note the supported file types and Model ID.



3. In Power Apps Studio, add a **3D object** or **View in MR** control to the app screen.
4. Set the control's **Source** property to **CGTrader.GetModel(*model_id*, "*file_type*")**, where *model_id* is the ID of the model you selected, and *file_type* is one of the supported file types.



Connector actions

The following table lists the most common CGTrader connector actions and examples. For a list of all connector actions, their parameters, and return types, see the CGTrader connector reference.

Expand table

Action	Description	Example
GetModel	Downloads a 3D object with the given Model ID and file type.	CGTrader.GetModel(*model_id*, "*file_type*")
GetModelInfo	Gets information about a 3D object with the given Model ID.	CGTrader.GetModelInfo(*model_id*)
SearchModels	Searches for models from CGTrader based on the given filters. Consider binding this action to	CGTrader.SearchModels({keywords:"*keywords*",extensions:"*file_types*"}).Models

Action	Description	Example
	the items in a gallery.	
GetCategories	Gets available category names and Model IDs.	**CGTrader.GetCategories()**

Use the Markup in MR control in Power Apps (preview)

Article • 07/15/2022

[This article is pre-release documentation and is subject to change.]

> **Important**
>
> This is a preview feature.
>
> Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Add the **Markup in MR** control in your app to allow users to add markups to visually specify an area or a particular asset in their environment. Users can instantly place mixed reality markups such as arrows, add drawings, and then take photos of the marked-up object.

The **Markup in MR** control creates a **Markup in MR** button in your mixed reality app. When a user selects the **Markup in MR** button, it shows a live camera feed of the device. A user can identify points of interest to begin inking or adding arrows directly on the object.

Ink and arrows will scale appropriately depending on the distance from the objects. When you exit the **Markup in MR** screen screenshots are captured in the control's **Photos** output property.

> **Tip**
>
> The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

> **Tip**
>
> The MR controls in Power Apps use Babylon and Babylon React Native. Mixed reality content that works in the **Babylon sandbox** should work in Power Apps through this shared MR platform. If your content works in Babylon but not in Power

Apps, ask a question in the **Power Apps Community Forum**. (Tag it with "mixed reality.")

Use Markup in MR

When a user selects the **Markup in MR** button, they will be prompted to move their phone side-to-side for better object or area detection. Once an object or area is detected the user can start using the markup toolbar.

Add an arrow

To position an arrow:

- Make sure the arrow is selected in the markup toolbar.
- Move your device around to position the dot on the object or area you want. to highlight
- Select to place the ghost arrow on your device screen.
- To rotate the arrow, select and drag the arrow in a circular motion (360 degrees).

Inking

To determine where you start drawing:

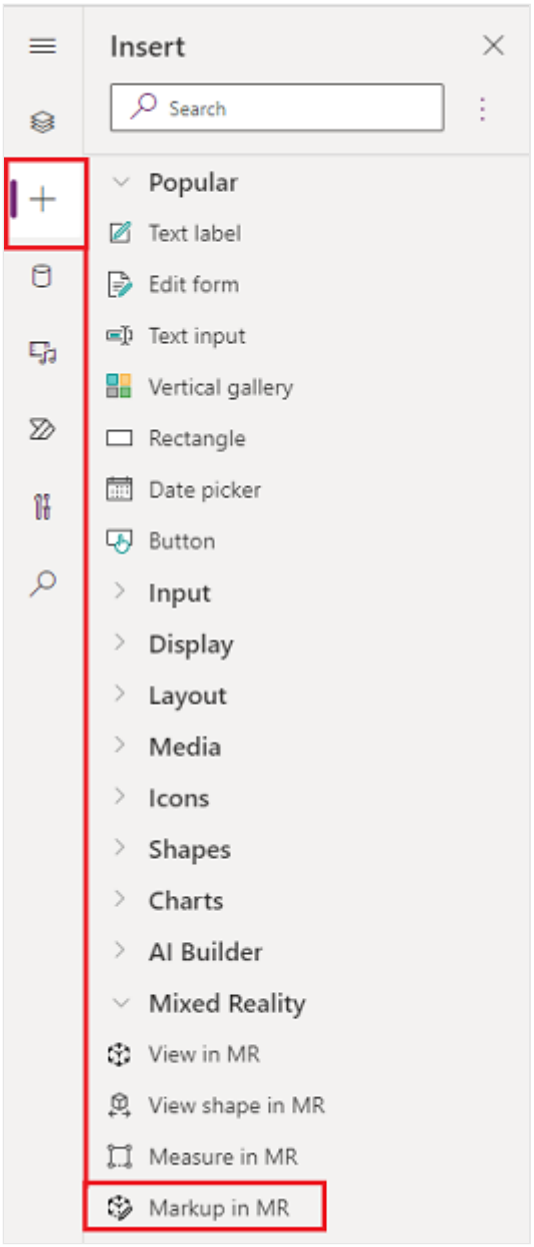
- Make sure the ink pen is selected in the markup toolbar.
- Select and drag on the screen to start drawing.

Add the Markup in MR control

Insert the control into your app as you normally would for any other button control.

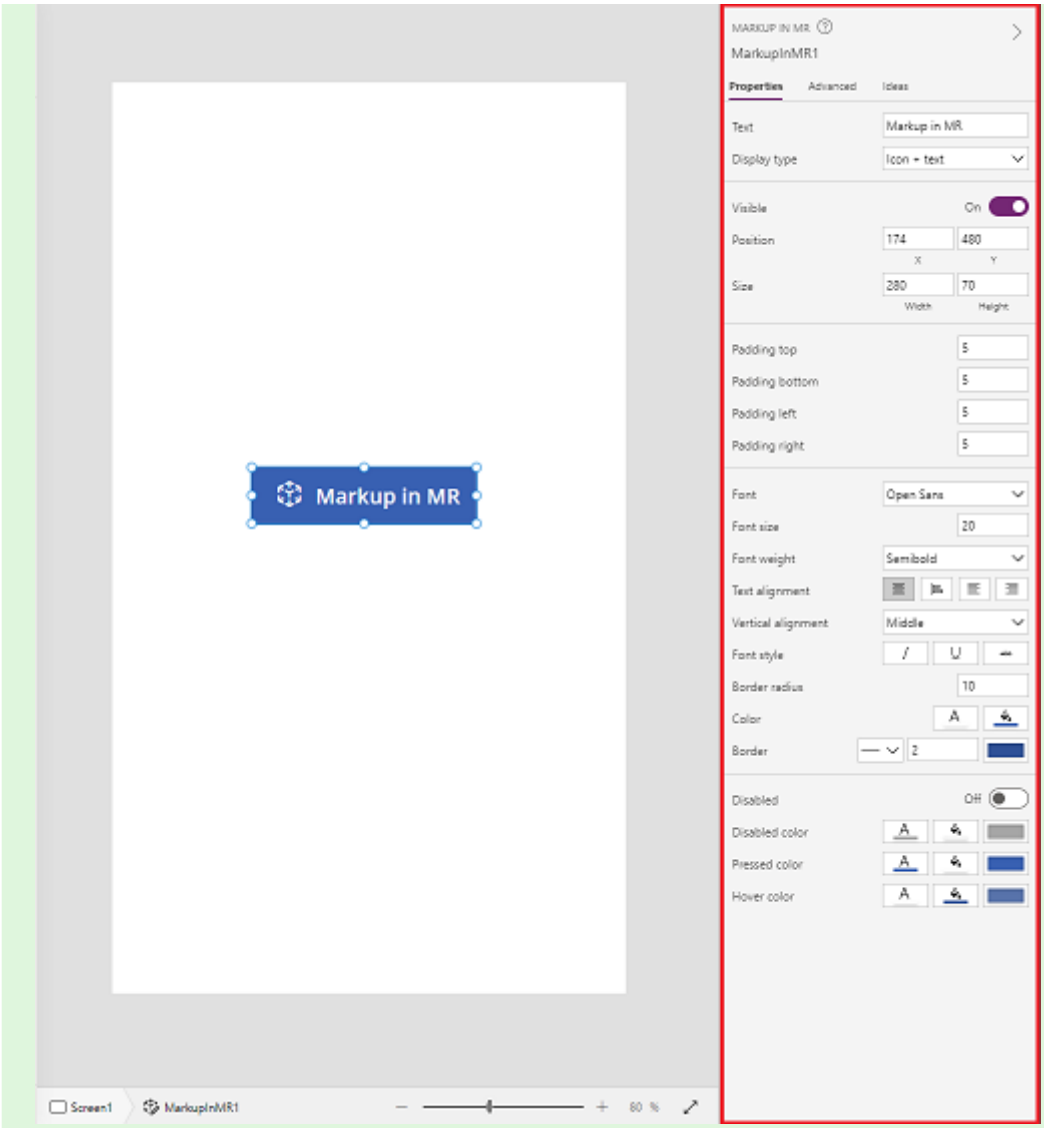
With an app open for editing in Power Apps Studio:

1. Open the **Insert** tab.
2. Expand **Mixed reality**.
3. Select the control **Markup in MR** to place it in the center of the app screen or drag and drop it to position it anywhere on the screen.



You can modify the control with several properties.

> **Tip**
>
> Some properties are only available under **More options** in the **Advanced** tab on the **Markup in MR** pane.



Property	Description	Type	Location
Photos	The photos captured during the mixed reality session. Note: You can upload the mixed-reality photos to OneDrive and show them in a gallery.	Not Applicable	Not Applicable (Output property only)
OnMixedRealitySelect	Behavior that is triggered when exiting the MR experience with new results.	Defined Action	Advanced
OnChange	Behavior that is triggered when any property on the button is changed.	Defined Action	Advanced

Additional properties

Property	Description
BorderColor	The color of a control's border.

Property	Description
BorderStyle	Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.
BorderThickness	The thickness of a control's border.
Color	The color of text in a control.
DisplayMode	Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).
DisabledBorderColor	The color of a control's border if the control's DisplayMode property is set to **Disabled**.
DisabledColor	The color of text in a control if its DisplayMode property is set to **Disabled**.
DisabledFill	The background color of a control if its DisplayMode property is set to **Disabled**.
FillColor	The background color of a control.
Font	The name of the family of fonts in which text appears.
FontStyle	The style of the text in the control: **None**, **Strikethrough**, **Underline**, or **Italic**.
FontSize	The font size of the text that appears on a control.
FontWeight	The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**
Height	The distance between a control's top and bottom edges.
HoverBorderColor	The color of a control's border when the user keeps the mouse pointer on that control.
HoverColor	The color of the text in a control when the user keeps the mouse pointer on it.
HoverFill	The background color of a control when the user keeps the mouse pointer on it.
PaddingBottom	The distance between text in a control and the bottom edge of that control.
PaddingLeft	The distance between text in a control and the left edge of that control.
PaddingRight	The distance between text in a control and the right edge of that control.
PaddingTop	The distance between text in a control and the top edge of that control.
PressedBorderColor	The color of a control's border when the user taps or clicks that control.

Property	Description
PressedColor	The color of text in a control when the user taps or clicks that control.
PressedFill	The background color of a control when the user taps or clicks that control.
TabIndex	Keyboard navigation order.
TextAlignment	The alignment of the text: **Center**, **Left**, **Right**, or **Justify**
Tooltip	Explanatory text that appears when the user hovers over a control.
VerticalAlign	The location of text on a control in relation to the vertical center of that control: **Middle**, **Top**, or **Bottom**
Visible	Whether a control appears or is hidden.
Width	The distance between a control's left and right edges.
X	The distance between the left edge of a control and the left edge of its parent container (or the screen if there's no parent container).
Y	The distance between the top edge of a control and the top edge of the parent container (or the screen if there's no parent container).

Output properties

Property	Description	Type
Photos	Collects the photos captured during the mixed reality session. You can upload the mixed-reality photos to OneDrive and show them in a gallery.	Not applicable

Other Mixed Reality controls

- View 3D content with the View in 3D control.
- View images and 3D content in the real world with the View in mixed reality control.
- Create and view predefined 3D shapes with the View shape in mixed reality control.
- Measure distance, area, and volume with the Measure in mixed reality control.

Use marker detection with mixed-reality controls (preview)

Article • 07/15/2022

[This article is pre-release documentation and is subject to change.]

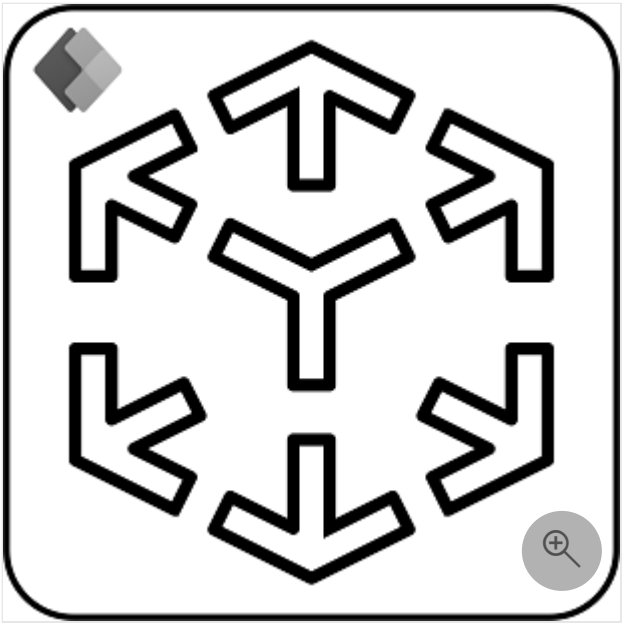
> **Important**
>
> This is a preview feature.
>
> Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Use physical markers to improve the precision and persistence of media that's placed using the View in MR and View shape in MR controls. This topic covers how to enable marker detection and how to add markers to your space.

Prerequisites

In addition to the standard device compatibility requirements outlined in add mixed reality controls to your canvas app, marker detection requires physical markers to be present in your space.

To create a marker, print out the image below or display the image on a monitor or tablet. For best results, the marker should be printed in portrait orientation on standard A4 or 8.5" x 11" letter paper. Ensure that the marker is fully visible and not cut off on either the top or bottom. The marker should be approximately 20 x 20 cm for optimal tracking speed and accuracy.

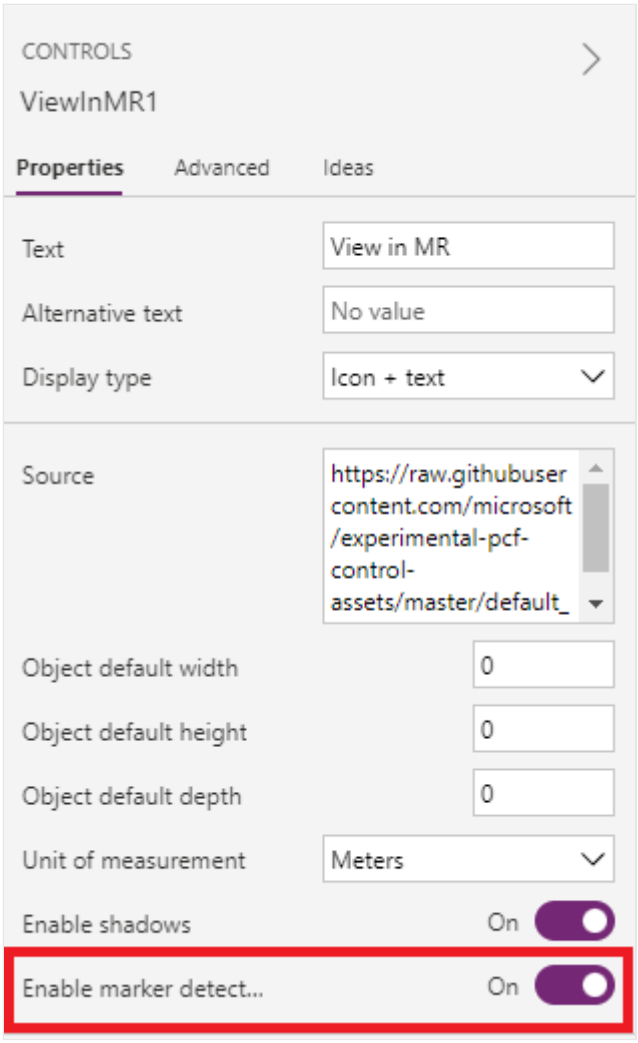


Enable marker detection

Enable marker detection for the **View in MR** and **View shape in MR** controls.

With an app open for editing in Power Apps Studio:

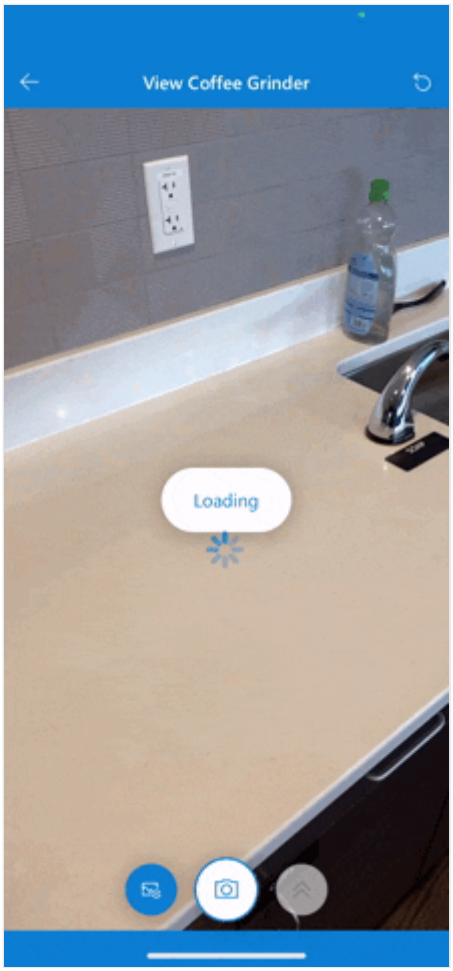
1. Open the **Insert** tab.
2. Expand **Mixed reality**.
3. Select the **View shape in MR** or **Markup in MR** control.
4. On the **Properties** tab, set the **Enable marker detection** property to **On** in the properties panel or the formula bar.



Use marker detection on device

When you enter the mixed-reality experience, you'll be prompted to point your device at a physical marker in your space. To quickly acquire tracking, make sure the marker is fully in frame and about 2-5 feet from the device.

Once the marker is detected, the loaded media will be automatically aligned and placed directly on top of the marker. You can manipulate the media's position or rotate it by using the on-screen gestures or by physically moving the marker.



If no marker is present or detection is taking too long, you can turn off the marker detection by selecting the highlighted marker detection button.

Add geospatial controls to your canvas apps

Article • 12/16/2022

Add interactive maps with dynamic routing and address lookup to your canvas apps using geospatial controls.

Use the following prebuilt controls for geospatial applications:

- Interactive map
- Address input

The map control runs with limited features available by default. You can enable additional map control features and support for the address input control by turning on full support in the Power Platform admin center. Refer to the table at the bottom of the page for more details on data usage in limited and full support.

Prerequisites for full support

Before you can use geospatial features in your apps, your Power Platform administrator has a couple of tasks to complete:

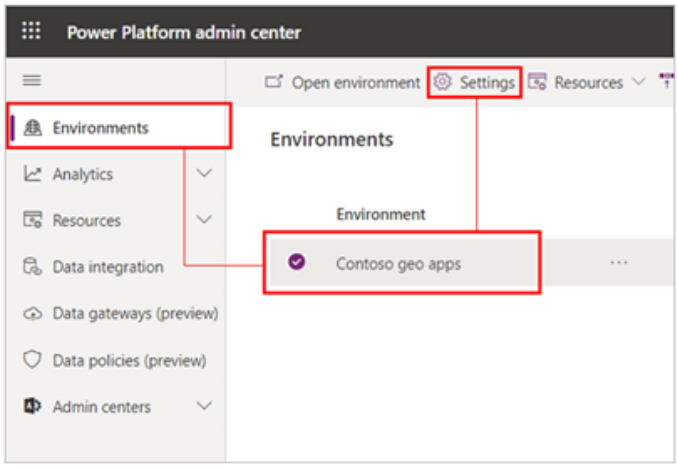
1. Enable geospatial features in the Power Platform admin center for the environment you intend to use. The geospatial features require their own terms of service, which your admin must review and agree to.
2. Make sure the geospatial controls aren't blocked by the environment's data loss prevention policies.

> ⓘ **Important**
>
> Geospatial controls are not available in **Power Apps US Government**.

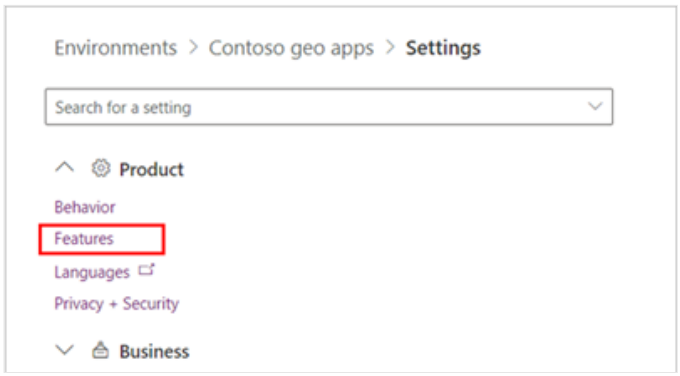
Enable geospatial features for the environment

If you don't have administrative access to the Power Platform admin center, ask your admin to enable geospatial features for you. You can similarly follow these steps to disable geospatial features.

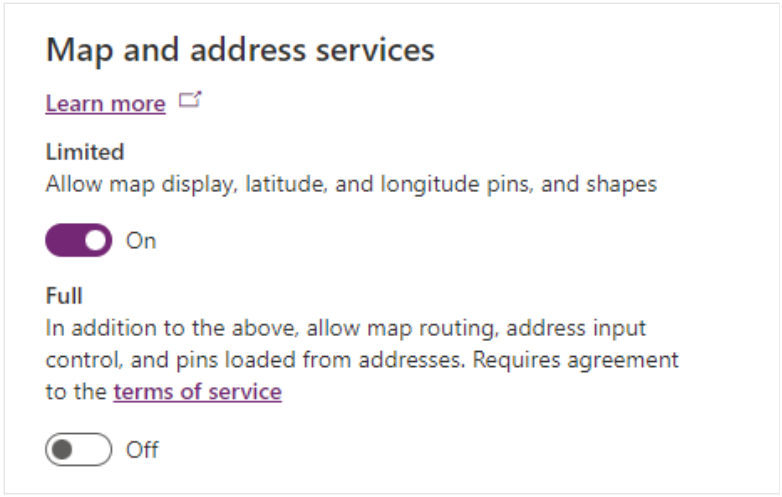
1. Open the Power Platform admin center.
2. On the **Environments** tab, select the environment you want to use for your apps, and then select **Settings**.



3. Expand **Product**, and then select **Features**.



4. Under **Map and address services**, turn on the **Full** toggle. You can use the toggles in this section to similarly turn on and off limited support as well.



5. Read the terms of service. Select **I agree to the terms of service**, and then select **Enable**.

> **Important**
>
> The terms of service must be agreed to before you can use all geospatial features in your apps.
>
> Mapping capabilities are provided by a third party. Microsoft shares address and location queries, but not customer or user names, with the provider. Requests are sent securely over HTTPS or aren't exposed to the public Internet.

6. Select **Save**.

Review the environment's data loss prevention policies

Geospatial controls use the Spatial Services connector to fetch map tiles and to look up and geocode addresses. Your Power Platform admin must make sure data loss prevention policies that apply to that connector don't conflict with the policies that affect the controls. Learn more about data loss prevention policies for Power Platform.

Privacy and security considerations

- Power Apps doesn't link search queries to any user or tenant when shared with TomTom, and the shared search queries can't be used to identify individuals or tenants.
- Azure Maps doesn't store the request information sent by you. For more information about Azure Maps compliance, see Azure global compliance
- Requests sent between TomTom and Azure Maps are not exposed over the public Internet.
- Requests sent between apps you create with the geospatial controls and Azure Maps are sent over HTTPS.
- The following table describes the user data that Power Apps sends to Azure Maps, Bing Maps, and TomTom on full support:

Expand table

Control	Feature	Data	Purpose	Sent to Azure Maps	Sent to Bing Maps	Sent to TomTom	User identifiers or tracking data sent	Enabled in Full Support	Enabled in Limited Support

Address Input	Address Search	Current device location	To bias address search results around the device location.	No	Yes	Yes	No	Yes	No

Next steps

Add the controls to your apps:

- Visualize and interpret location data with the **Interactive map** control.
- See dynamic address suggestions as you type with the **Address input** control.

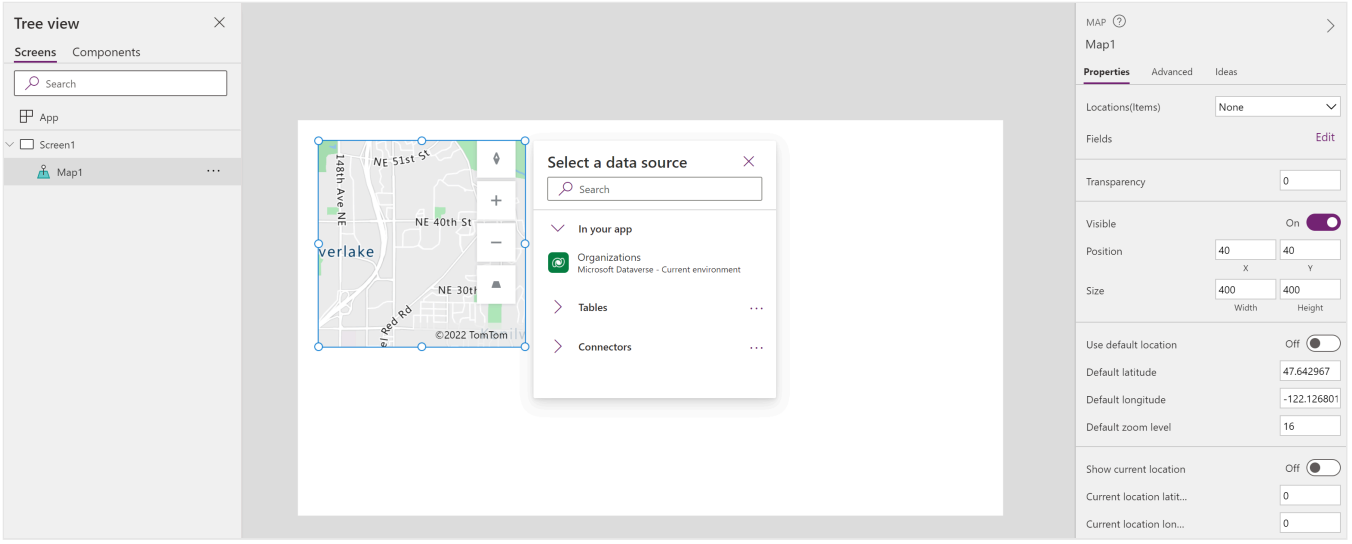
Create an app that uses the address input and map controls

Interactive map control

Article • 03/15/2023

Easily add an interactive map to your canvas apps. Plot markers from a data source containing addresses or latitude and longitude pairs. As you zoom out, the markers will optionally cluster to condense groups of data. On mobile devices and web experiences, a map can show the user's current position and calculate a route to the user's destination. Maps can be switched between road and satellite views.



Interactive map features

- Use a data source to insert pins
- Display information about map pins
- Show routes between waypoints
- Draw and insert shapes

Prerequisites

You'll need to satisfy a few prerequisites before you can use maps in your canvas apps. Refer to the privacy and security table for more details on how different map features use data.

Add a map to an app screen

With your app open for editing in Power Apps Studio :

1. Select the **Insert** tab and expand **Media**.
2. Select **Map** to place a map in the app screen, or drag the control to the screen to position it more precisely.

Adding pins, routes, and shapes

Pins, routes, and shapes are data set properties that need to both identify a data source, which is a table from a collection or connector, and the relevant columns. The data source is set in the Items property (Items for pins, RouteWaypoints_Items for routes, Shape_Items for shapes) and the relevant columns are set in the related properties (e.g. ItemLatitudes, ItemLongitudes, etc for pins). The Properties section contains additional information about these data sets and their related properties.

For example, if you had a table collection named **Locations** with **Name**, **Longitude**, and **Latitude** columns:

Expand table

Name	Longitude	Latitude
Fourth Coffee (sample)	-98.29277	26.2774
Litware, Inc. (sample)	-96.85572	32.55253
Adventure Works (sample)	-96.99952	32.72058

To display these as labeled pins on the map:

1. Set the **Items** property to Locations
2. Set the **ItemLabels** property to "Name"
3. Set the **ItemLongitude** property to "Longitude"
4. Set the **ItemLatitude** property to "Latitude"

> **Important**
>
> The relevant column names need to be in quotation marks in the related properties. The data source should not have quotation marks.

You can see how to do display pins from an Excel sheet or build an app that uses the address input control to populate pins on the map control as additional examples.

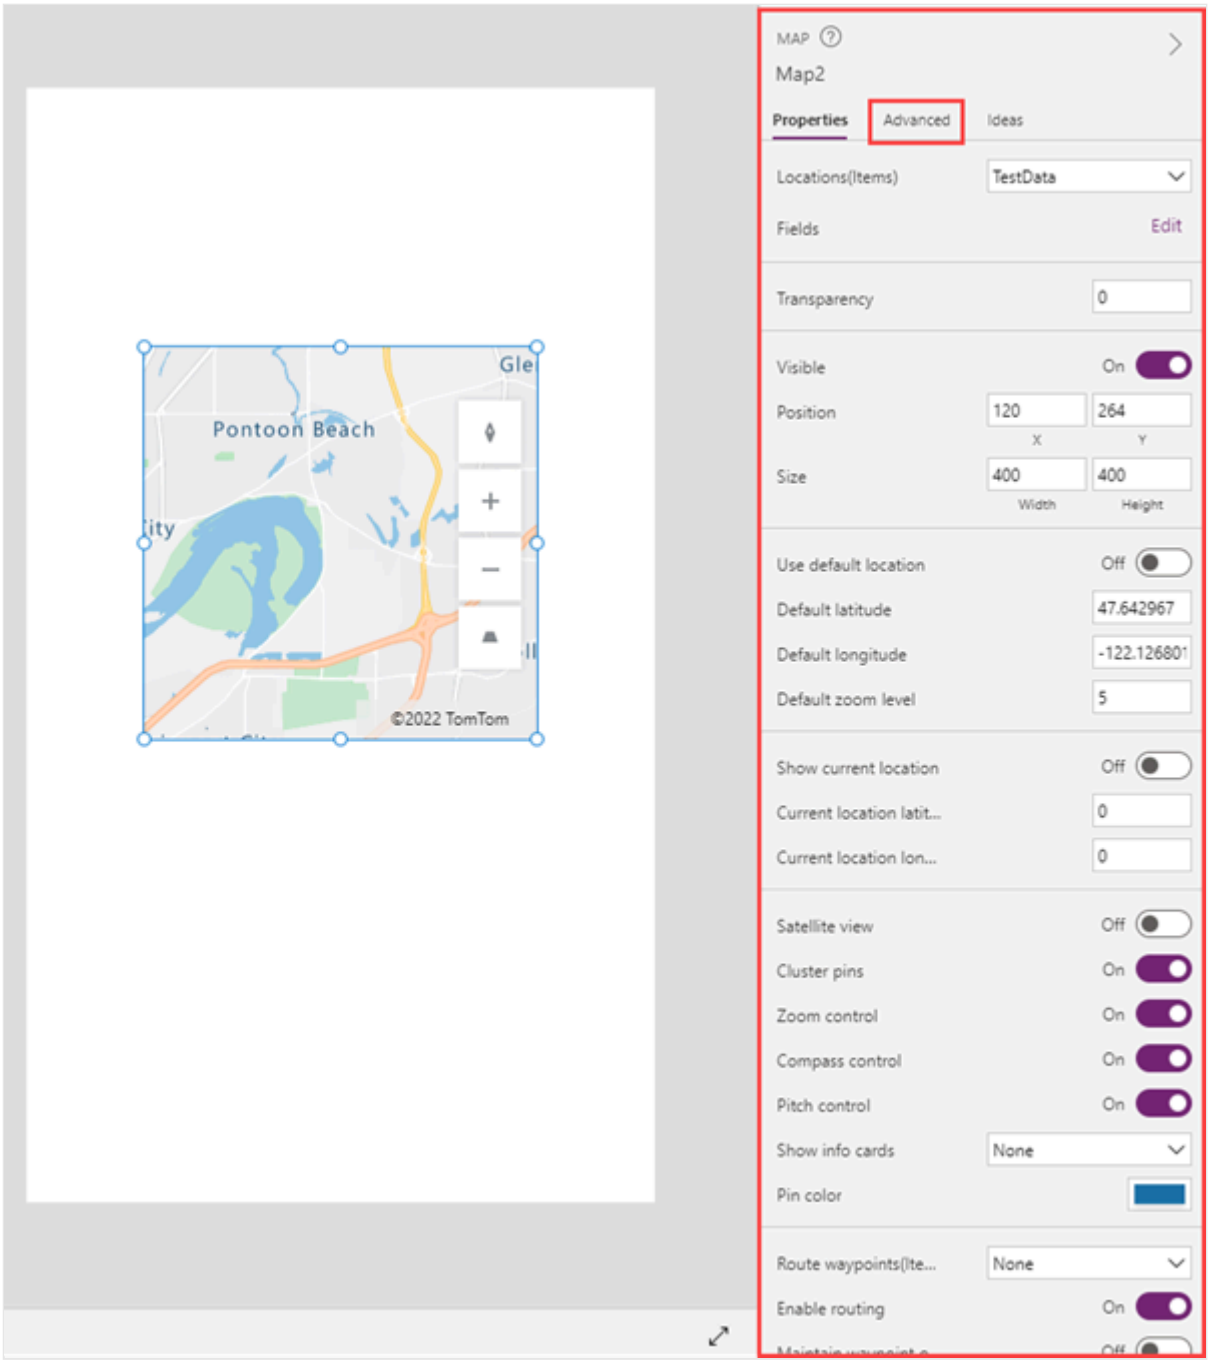
> **Note**
>
> - Each map control can display up to 5000 pins from latitude or longitude and 50 pins from addresses. The pin limit is lower for addresses as the map needs to geocode

these addresses into latitude or longitude to display them. We recommend not using addresses where possible. You can save geocoded addresses back to your data source.

- When both latitude or longitude and an address is given for a single pin, the map control will prioritize using the latitude or longitude to avoid geocoding the address.
- The maximum number of shapes that can be drawn in a map control is limited to 500.

Properties

Change a map's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



The map control has six different types of properties:

1. Styling properties
2. Behavioral properties
3. Pin properties
4. Route properties
5. Shape properties
6. Output properties

Styling properties

Expand table

Property	Description	Type	Tab
Satellite view	Displays the map in satellite view. Leave this property off to display the map in road view.	Boolean	Properties; Advanced: **SatelliteView**
Map style	Sets the map style. Options: Road, Night, Road shaded relief, Satellite, Satellite road labels, High contrast light, High contrast dark, Grayscale light, Grayscale dark.	Enum	Properties
Transparency	Determines the map's transparency, from 0 (opaque) to 100 (transparent).	Integer	Properties; Advanced: **Transparency**
Visible	Shows or hides the map.	Boolean	Properties; Advanced: **Visible**
Position	Places the upper-left corner of the map at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the map using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Border radius	Determines the corner radius of the map border.	Floating point number	Properties; Advanced: **BorderRadius**
Border	Determines the style, width, and color of the map border.	Not applicable	Properties; Advanced: **BorderStyle**, **BorderThickness**, **BorderColor**
DisplayMode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Enum	Advanced

Behavioral properties

Expand table

Property	Description	Type	Tab
Show info cards	Shows information about a mapped location when the user selects it (*On click*) or points to it (*On hover*). If *None*, no information is shown.	Enum	Properties; Advanced: **InfoCards**
Use default location	Initializes the map at a default location.	Boolean	Properties; Advanced: **DefaultLocation**

Property	Description	Type	Tab
Default latitude	Sets the latitude coordinate the map shows if **Use default location** is enabled.	Floating point number	Properties; Advanced: **DefaultLatitude**
Default longitude	Sets the longitude coordinate the map shows if **Use default location** is enabled.	Floating point number	Properties; Advanced: **DefaultLongitude**
Default zoom level	Sets the zoom level if **Use default location** is enabled, from 0 to 22.	Integer	Properties; Advanced: **DefaultZoomLevel**
Show current location	Displays the user's current location.	Boolean	Properties; Advanced: **CurrentLocation**
Current location latitude	Sets the latitude coordinate of the current location pin that the map shows if **Show current location** is enabled. To place the pin at the user's current location, set this property to Location.Latitude.	Floating point number	Properties; Advanced: **CurrentLocationLatitude**
Current location longitude	Sets the longitude coordinate of the current location pin that the map shows if **Show current location** is enabled. To place the pin at the user's current location, set this property to Location.Longitude.	Floating point number	Properties; Advanced: **CurrentLocationLongitude**
Zoom control	Shows the zoom control.	Boolean	Properties; Advanced: **Zoom**
Compass control	Shows the compass control.	Boolean	Properties; Advanced: **Compass**
Pitch control	Shows the pitch (tilt) control.	Boolean	Properties; Advanced: **Pitch**
TabIndex	Specifies the order the map is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **Tab index**
Tooltip	Determines the text to display when the user hovers over a visual.	String	Advanced
ContentLanguage	Determines the display language of the map, if it's different from the language used in the app.	String	Advanced
OnLoad	Contains code that runs when the map is loaded.	Event	Advanced

Property	Description	Type	Tab
OnMapClick	Contains code that runs when the user selects the map. The latitude and longitude of the clicked point is in the **ClickedLocation** output property.	Event	Advanced
OnChange	Contains code that runs when any aspect of the map is changed.	Event	Advanced
OnSelect	Contains code that runs when the user selects something on the map.	Event	Advanced

Pin properties

Expand table

Property	Description	Type	Tab
Locations(Items)	Identifies a data source (**Items**) in the form of a table from which to get locations to show on the map. The table lists sets of longitudes and latitudes, or physical addresses, to display as pins. Using latitude or longitude is recommended as addresses need to be geocoded and so have a more restrictive pin limit. The table can be a collection or from a data source like Excel Online. Each row must have an entry for label, longitude, and latitude, or a physical address, and optionally the pin color and icon.	Not applicable	Properties; Advanced: **Items**
ItemsLabels	Identifies the column in **Items** that contains the labels for the pins.	ColumnName	Advanced
ItemsLatitudes	Identifies the column in **Items** that contains the latitude position of the pins.	ColumnName	Advanced
ItemsLongitudes	Identifies the column in **Items** that contains the longitude position of the pins.	ColumnName	Advanced
ItemsAddresses	Identifies the column in **Items** that contains addresses that represent the location of the pins. There is a limit to how many pins can be displayed from addresses. We recommend geocoding your addresses to latitude, longitude pairs and using those to display pins when possible.	ColumnName	Advanced
ItemsColors	Identifies the column in **Items** that contains the colors of the pins.	ColumnName	Advanced

Property	Description	Type	Tab
ItemsIcons	Identifies the column in **Items** that contains the icons of the pins.	ColumnName	Advanced
Cluster pins	Groups nearby map pins instead of displaying them individually.	Boolean	Properties; Advanced: **Clustering**
Pin color	Determines the default color of pins shown on the map. This color is overridden by the **ItemsColors** property if set	Color picker	Properties; Advanced: **PinColor**
OnItemsChange	Contains code that runs when pins on the map are changed.	Event	Advanced

Route properties

Expand table

Property	Description	Type	Tab
Enable routing	Determines whether the user can request directions to a specified location.	Boolean	Properties; Advanced: **UseRouting**
Route waypoints(Items)	Shows route waypoints, as provided in a data source (**RouteWaypoints_Items**) in the form of a table. The table can be a collection or from a data source like Excel Online. If *None*, no waypoints are shown.	Enum	Properties; Advanced: **RouteWaypoints_Items**
RouteWaypointsLabels	Identifies the column in **RouteWaypoints_Items** that contains the labels for the waypoints.	ColumnName	Advanced
RouteWaypointsLatitudes	Identifies the column in **RouteWaypoints_Items** that contains the latitude position of the waypoints.	ColumnName	Advanced
RouteWaypointsLongitudes	Identifies the column in **RouteWaypoints_Items** that contains the longitude position of the waypoints.	ColumnName	Advanced

Property	Description	Type	Tab
RouteWaypointsAddresses	Identifies the column in **RouteWaypoints_Items** that contains addresses that represent the location of waypoints.	ColumnName	Advanced
Maintain waypoint order	Determines whether a calculated route maintains waypoints in the order provided.	Boolean	Properties; Advanced: **RouteMaintainOrder**
Optimize route	Determines whether a calculated route is optimized for distance, time, or isn't optimized.	Enum	Properties; Advanced: **RouteOptimization**
Route travel mode	Determines whether a route is calculated for a car or a truck, which may require avoiding bridges with certain height or weight restrictions.	Enum	Properties; Advanced: **RouteTravelMode**
OnRouteDirectionChange	Contains code that runs when the app detects the user has changed direction while on a computed route.	Event	Advanced

Shape properties

Expand table

Property	Description	Type	Tab
Show shapes	Shows the shapes in **Shapes_Items**.	Boolean	Properties; Advanced: **ShowShapes**
Shapes_Items	Identifies a data source (**Shapes_Items**) in the form of a table from which to get shapes to show on the map. The table can be a collection or from a data source like Excel Online. Each row must have an entry for the shape (GeoJSON object) and (optionally) a label and color.	TableName	Advanced

Property	Description	Type	Tab
ShapeGeoJSONObjects	Identifies the column in **Shapes_Items** with strings that represent the GeoJSON objects of the shapes, in shape collection or single shape GeoJSON format.	ColumnName	Advanced
ShapeLabels	Identifies the column in **Shapes_Items** that contains the labels for the shapes.	ColumnName	Advanced
ShapeColors	Identifies the column in **Shapes_Items** that contains the colors of the shapes.	ColumnName	Advanced
Show shape labels	Shows the shape labels, if provided.	Boolean	Properties; Advanced: **ShowShapeLabels**
Enable shape drawing	Shows drawing tools on the map.	Boolean	Properties; Advanced: **ShapeDrawing**
Enable shape deleting and label editing	Determines whether the user can delete shapes and edit their labels.	Boolean	Properties; Advanced: **ShapeEditingDeleting**
OnShapeCreated	Contains code that runs when the user adds a shape to the map.	Event	Advanced
OnShapeSelected	Contains code that runs when the user selects a shape on the map.	Event	Advanced
OnShapeEdited	Contains code that runs when the user modifies a shape on the map.	Event	Advanced
OnShapeDeleted	Contains code that runs when the user deletes a shape on the map.	Event	Advanced

Output properties

Other properties become available when a user interacts with a map. You can use these *output properties* in other controls or to customize the app experience.

Expand table

Property	Description	Type
CenterLocation	Captures the map's center point.	Not Applicable

Property	Description	Type
ClickedLocation	Captures the last location the user selected, either *.Latitude* or *.Longitude*.	Record
Selected	Captures the selected pin.	Record
SelectedItems	Captures the selected pin or pins in the selected cluster.	Table
GeocodedItems	Captures the geocoded locations of the pins.	Table
RouteWaypoints_Selected	Corresponds to the record of the selected shape in **RouteWaypoints_Items**.	Record
RouteWaypoints_SelectedItems	Corresponds to the records of the selected overlapping shapes in **RouteWaypoints_Items**.	Table
Shapes_Selected	Corresponds to the record of the selected shape in **Shapes_Items**.	Record
Shapes_SelectedItems	Corresponds to the records of the selected overlapping shapes in **Shapes_Items**.	Table
SelectedShape	Captures the *.Perimeter* and *.Area* of the selected shape.	Record
DeletedShape	Captures the *.Perimeter* and *.Area* of the last deleted shape.	Record
GeoJSON	Captures the list of shapes in Feature Collection GeoJSON format.	String

Other geospatial controls

To see dynamic address suggestions as you type, use the **Address input** control.

Known limitations

- Requires internet connection

Create an app with address input and map controls

Use a data source to insert pins

Article • 03/15/2023

You can load a table that contains existing data into the map control. The control will then plot each row in your table as a map pin.

Prerequisites

1. Create a Canvas app and make sure it meets the Geospatial prerequisites.
2. In your app, insert a map.

Add pin data from an Excel workbook

Your data source needs to contain a named table with the following columns that should then be mapped to the associated property in the control's **Advanced** pane.

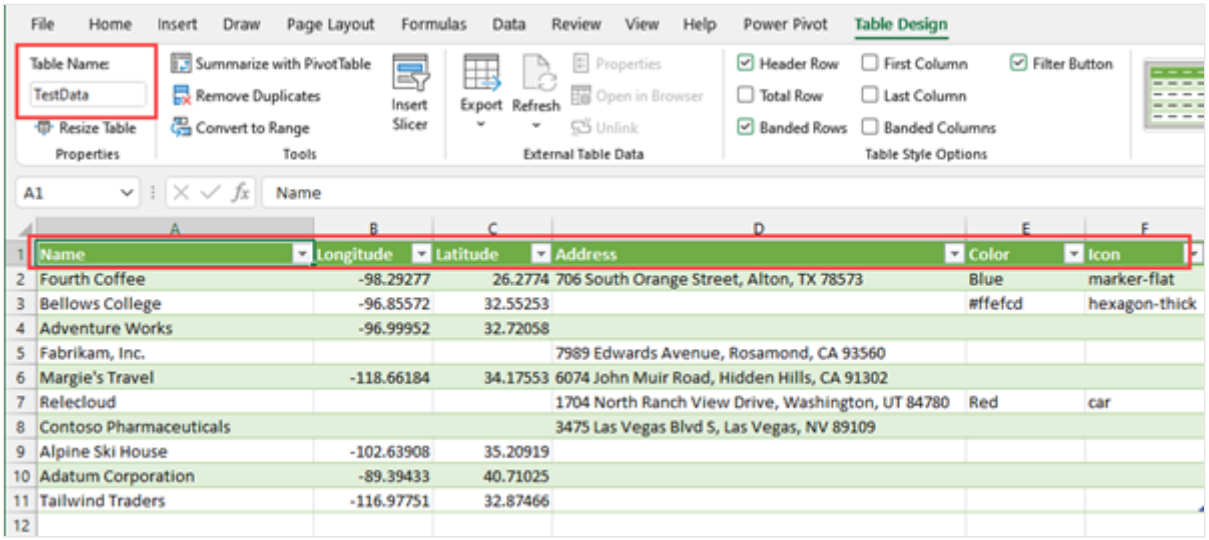
Expand table

Column description	Maps to property	Required
Label for the pin	ItemsLabels	Required
Longitude of the pin	ItemsLongitudes	Required
Latitude of the pin	ItemsLatitudes	Required
Color of the pin	ItemsColors	Optional
Icon for the pin	ItemsIcons	Optional

The color field accepts any CSS string, as defined in Color enumeration and ColorFade, ColorValue, and RGBA functions in Power Apps.

You can use the icons described in the List of image templates topic as your icon.

The following Excel table shows the required columns:



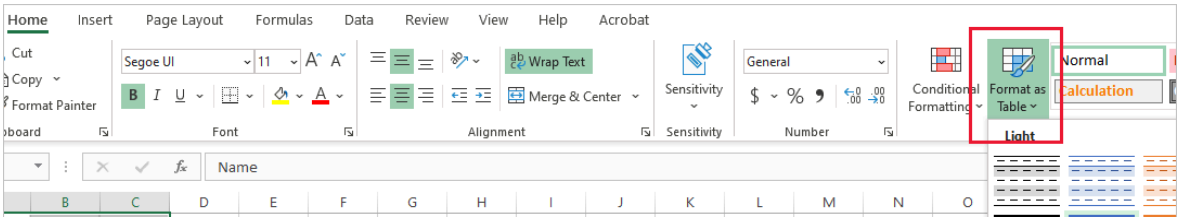
You can copy the following sample data to test this functionality:

Expand table

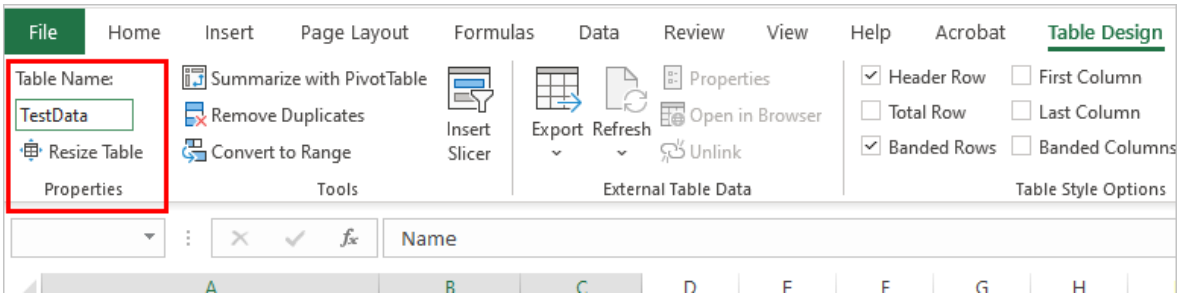
Name	Longitude	Latitude	Color	Icon
Fourth Coffee (sample)	-98.29277	26.2774	Blue	marker-flat
Litware, Inc. (sample)	-96.85572	32.55253	#ffefcd	hexagon-thick
Adventure Works (sample)	-96.99952	32.72058		car
Fabrikam, Inc. (sample)	-118.30746	34.86543		
Blue Yonder Airlines (sample)	-118.66184	34.17553		
City Power & Light (sample)	-113.46184	37.15363		
Contoso Pharmaceuticals (sample)	-80.26711	40.19918		
Alpine Ski House (sample)	-102.63908	35.20919		
A Datum Corporation (sample)	-89.39433	40.71025		
Coho Winery (sample)	-116.97751	32.87466		

1. Copy and paste the table into a new data source. In this example, we are using an Excel workbook.

2. Select one of the cells, and then on the Home tab in the ribbon, select **Format as Table** and choose any style, and then **OK**.



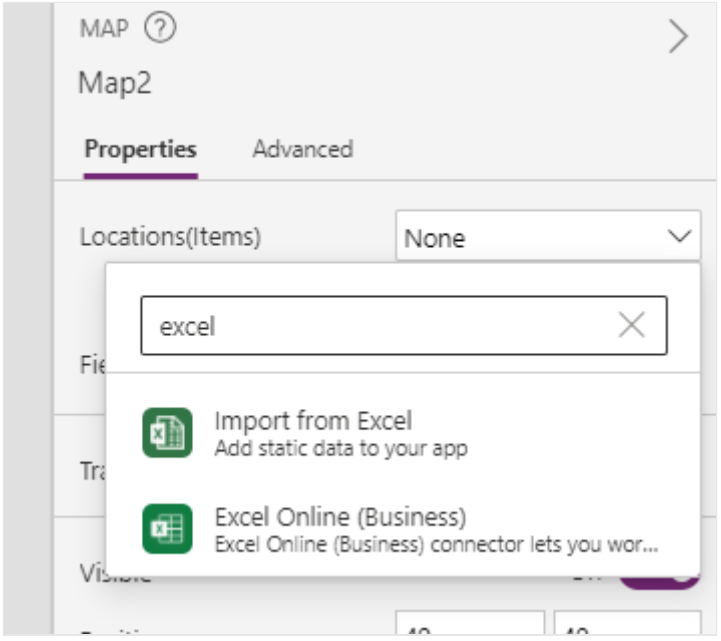
3. Select the table, and then go to the **Table Design** tab on the ribbon. Enter a name for the table under **Table Name:**, for example *TestData*.



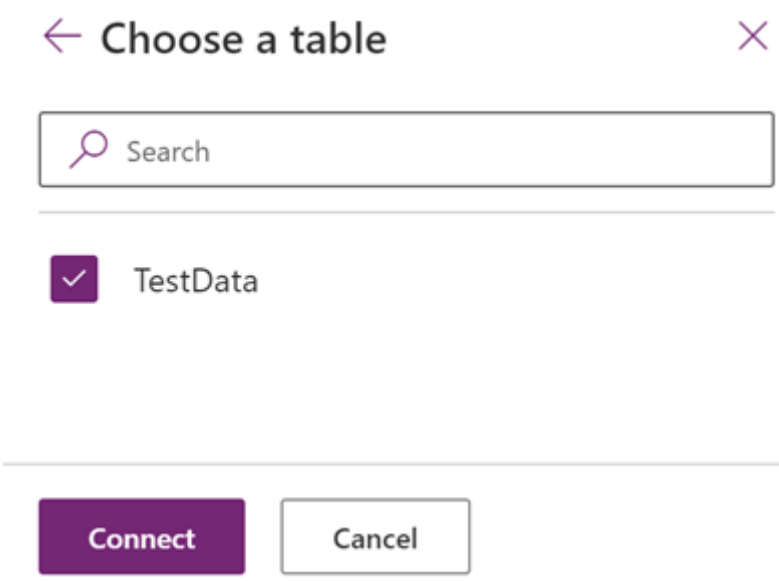
4. Save the workbook.

5. Open or create a new app in Power Apps, and insert the map control.

6. On the **Properties** pane, select the **Locations(Items)** field and then search for *excel* and select **Import from Excel**.



7. Locate the Excel workbook and then select **Open**. Select the table that contains the information, **TestData**, and then **Connect**.

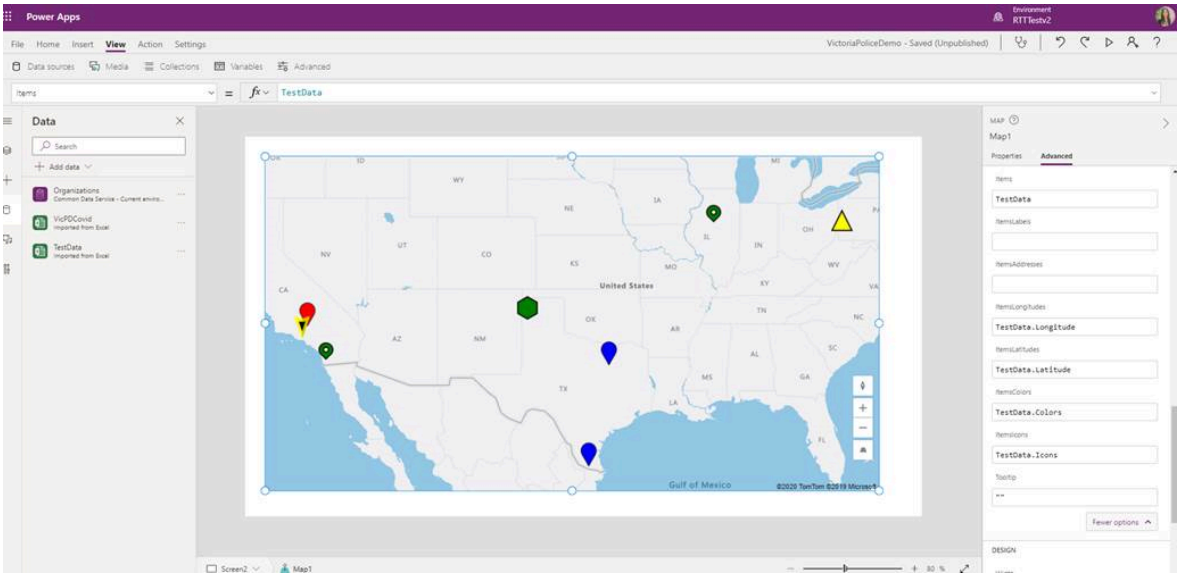


8. On the **Properties** pane, go to the **Advanced** tab, and select **More options**.

9. Set the following properties:

   - **ItemsLabels** as "*Name*"
   - **ItemsLatitudes** as "*Latitude*"
   - **ItemsLongitudes** as "*Longitude*"
   - (Optional) **ItemsColors** as "*Colors*"
   - (Optional) **ItemsIcons** as "*Icons*"

10. The map control will now show each row in the table as a pin, labeled with its *Name* as defined in the Excel table, and using the provided icons and colors. If an icon or color isn't provided, then the control will use the default icon and color.



> ⓘ **Note**

Each map control can display up to 5000 pins from latitude or longitude and 50 pins from addresses. The pin limit is lower for addresses as the map needs to geocode these addresses into latitude or longitude to display them. We recommend not using addresses where possible. You can save geocoded addresses back to your data source.

When both latitude or longitude and an address is given for a single pin, the map control will prioritize using the latitude or longitude to avoid geocoding the address.

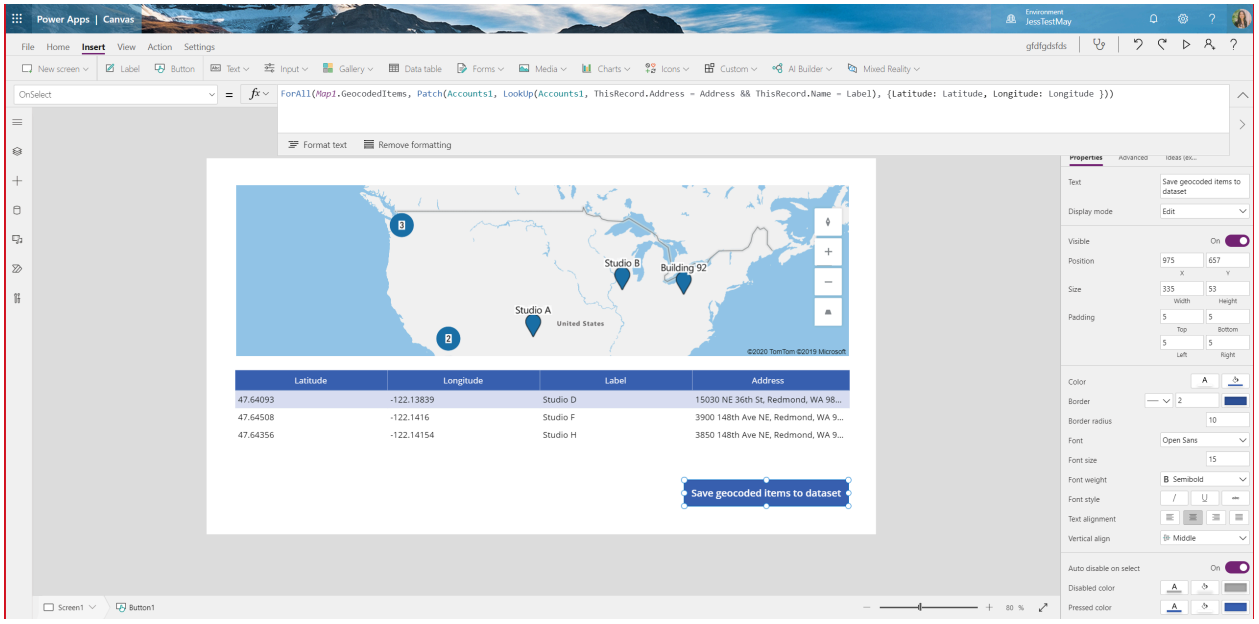
Save geocoded addresses from map control to data source

To avoid geocoding the same set of addresses every time the map control is launched, you can save the geocoded addresses back to the original data source, such that when the map relaunches, it will use the latitude and longitude instead of geocoding the addresses again.

To do so, add a button to save the geocoded address back to the original data source with the following formula:

Power Fx

```
 ForAll(Map1.GeocodedItems, Patch(Accounts1, LookUp(Accounts1,
ThisRecord.Address = Address && ThisRecord.Name = Label), {Latitude:
Latitude, Longitude: Longitude }))
```



Other interactive map features

- Add info cards to pins
- Show routes between waypoints
- Draw and insert shapes onto maps

Other geospatial controls

To see dynamic address suggestions as you type, use the **Address input** control.

Add informational cards to pins on a map

Article • 12/16/2022

Easily add cards to maps in your canvas apps to show details about pinned locations. When a user selects a pin, a card pops up with information from the data source you bound to the map control. Any column in the data source (for example, an Excel table) can be shown as a field on the card.

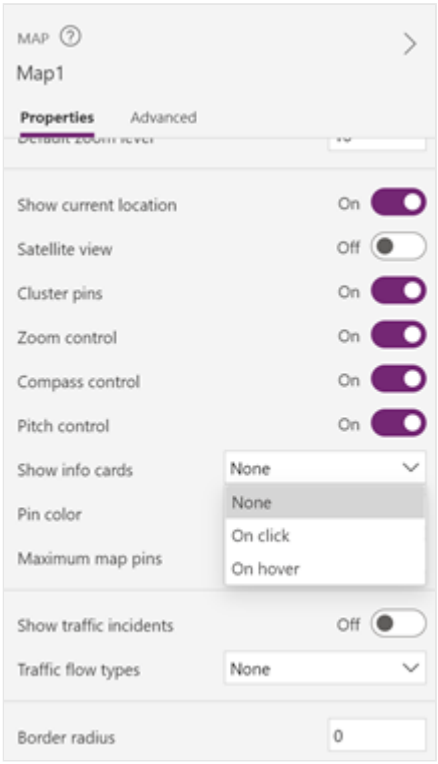
Prerequisites

1. Create a canvas app and make sure it meets the geospatial prerequisites.
2. Insert a map.

Add info cards to pins

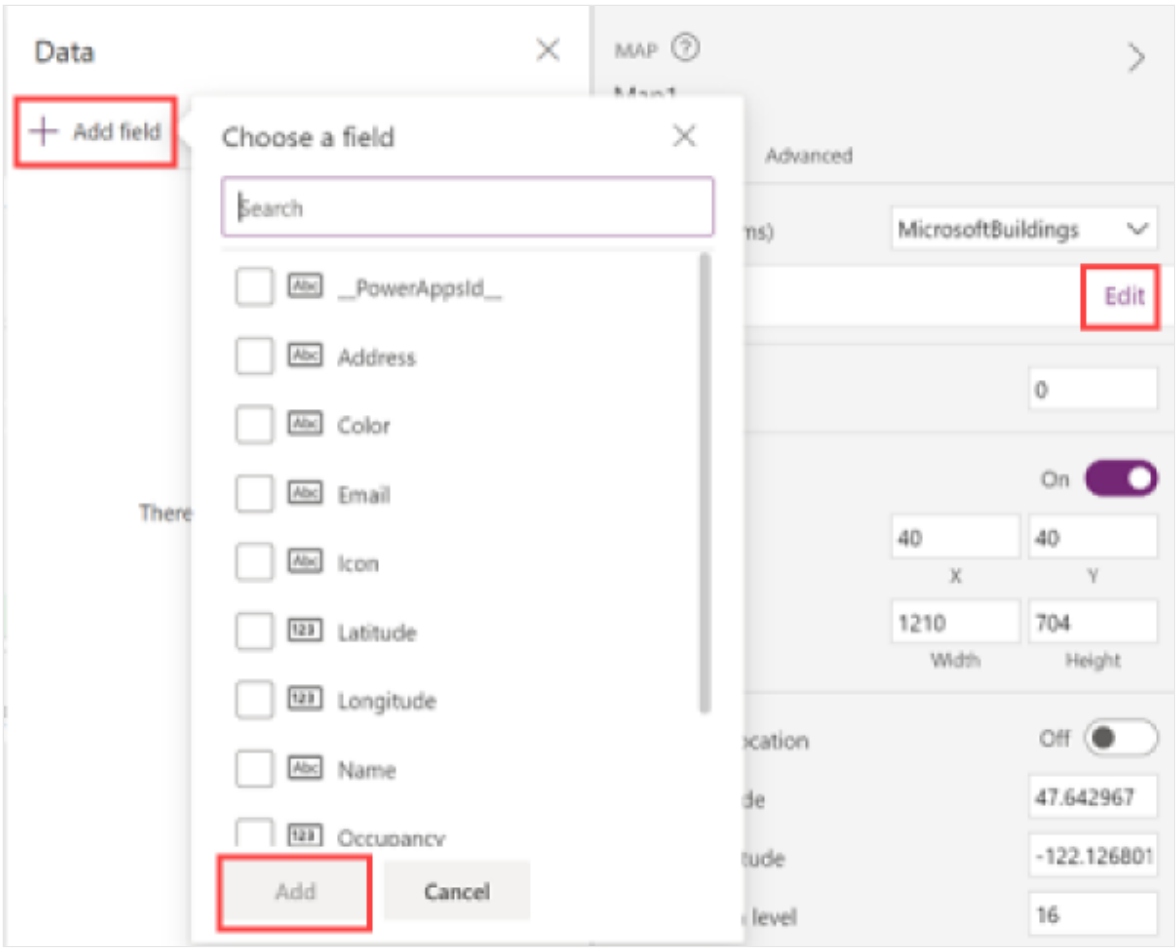
1. Bind the map to a data source.

2. In the map control's **Properties** pane, select **Show info cards**. Select **On click** to show the info card when the user selects a pin, or **On hover** if it should appear when the user hovers over the pin.



3. In the **Properties** pane, next to **Fields**, select **Edit**.

4. Select **Add field**, and then select the fields from the data source that you want to show in the card. Select **Add**.



When the user selects a pin, an info card shows the fields you selected.

Other interactive map features

- Use data from Excel to insert pins
- Show routes between waypoints
- Draw and insert shapes onto maps

Other geospatial controls

To see dynamic address suggestions as you type, use the **Address input** control.

Draw and insert shapes on a map (preview)

Article • 12/16/2022

[This topic is pre-release documentation and is subject to change.]

Add a drawing panel to your maps to let users draw and label shapes on them. You can also insert and label predefined shapes to highlight specific regions or areas of interest.

Important

- This is a preview feature.
- Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

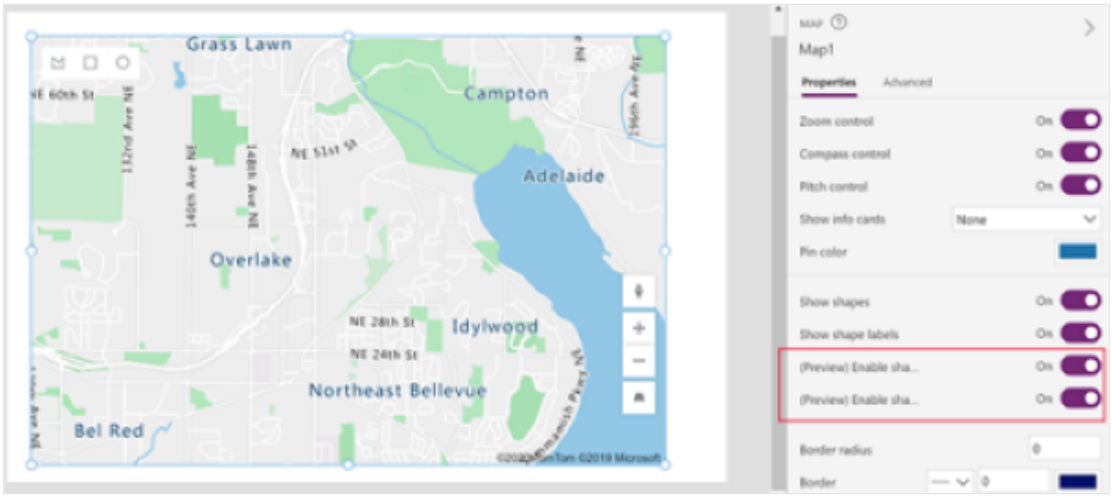
Prerequisites

1. Create a canvas app and make sure it meets the geospatial prerequisites.
2. Insert a map.

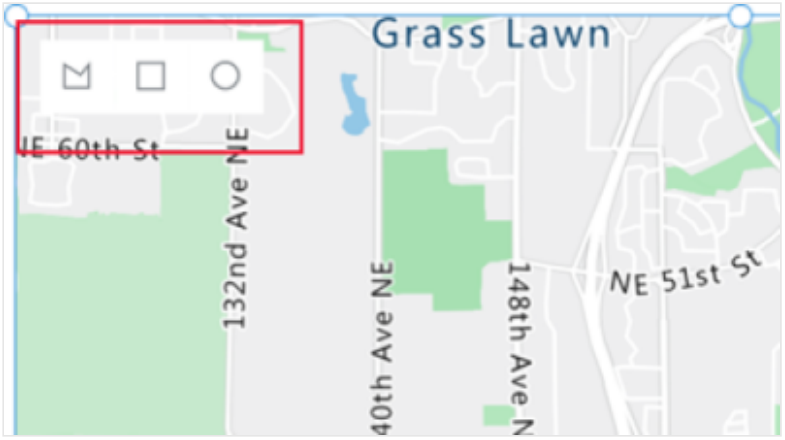
Draw and label shapes on an interactive map

1. In the map control's **Properties** pane, turn on the following properties:

    - **(Preview) Enable Shape Drawing**
    - **(Preview) Enable Shape Deleting and Label Editing**



A drawing panel appears in the upper-left corner of the map control.



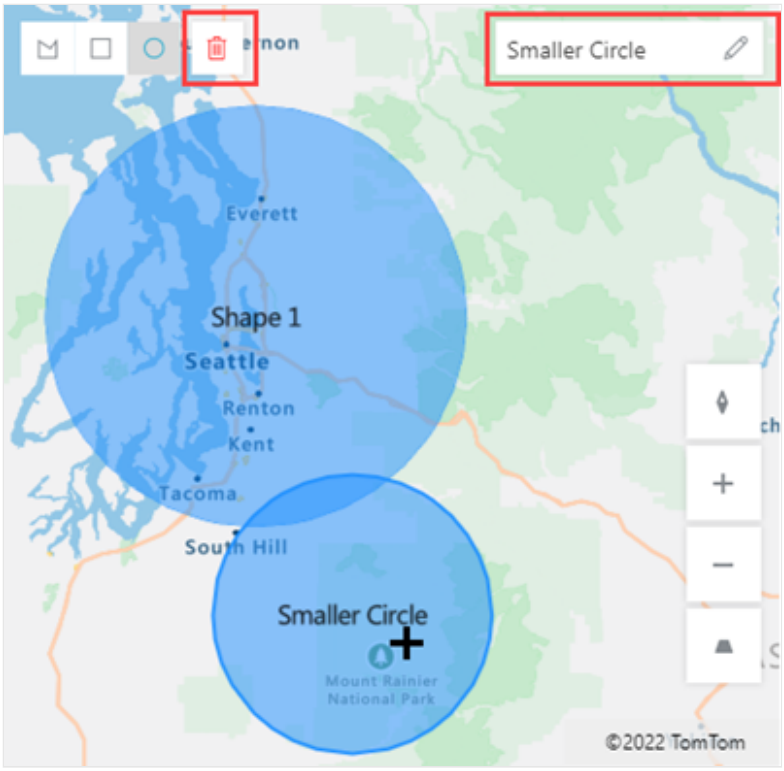
The panel features three tools:

- A polygon drawing tool for drawing freeform shapes
- A square drawing tool for drawing squares and rectangles
- A circle drawing tool for drawing circles and ovals

2. Select a tool and draw a shape on the map. To finish and close a freeform shape, double-click the final point.

Drawn shapes are automatically labeled. To change a label, select the shape, and then enter a new name in the box in the upper-right corner of the map.

To delete a shape, select it, and then select the trashcan.

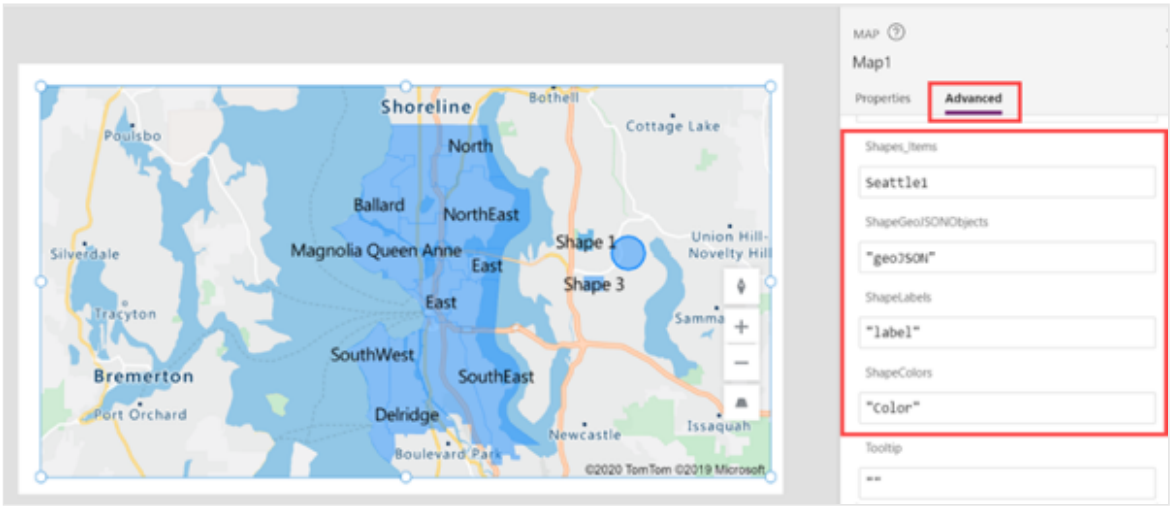


Import GeoJSON shapes into a map

If you already have shapes defined in GeoJSON format, you can import them into your map. For example, you might have a shape that defines a specific area that you want to highlight.

The GeoJSON string for each shape in your data source needs to be in the correct format, in a single cell.

To import shapes, first connect your data source to the map control. Then, assign the control's properties to the appropriate columns in the data source, as in the following example:

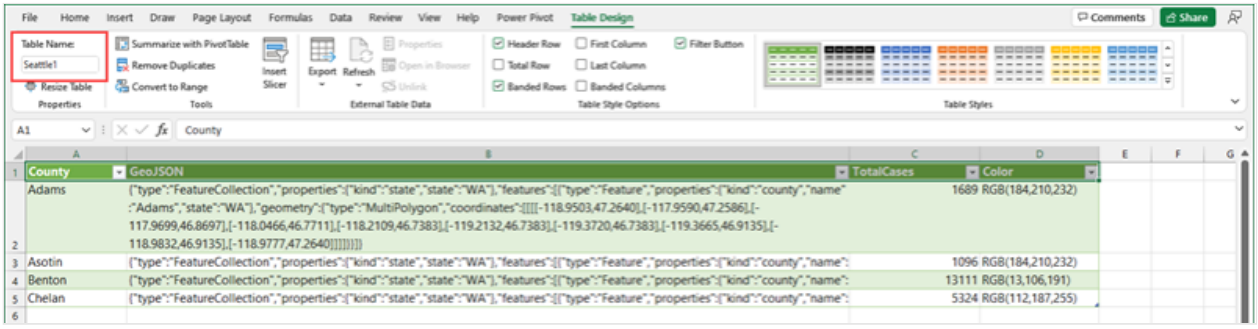


Your data source must be a named table with at least three columns. Each column corresponds to an advanced property of the map control.

Column description	Corresponds to	Required
The shape's GeoJSON coordinates in the correct format	ShapeGeoJSONObjects	Required
Shape label	ShapeLabels	Optional
Shape color	ShapeColors	Optional

> **Tip**
>
> Specify the color using a **name, CSS color definition, or RGBA value**. If the color isn't provided, then the shape will use the app's defaults.

The data source must be named. If you're using an Excel workbook as the data source, use the name of the table that contains the data. In this example, we'll import shapes from an Excel table named *Seattle1*.



1. Copy the following sample data into a blank workbook, format it as a table, and name the table *Seattle1*. Then, connect the workbook to your map as a data source. For detailed instructions using a similar example, see Use a data source to place pins on a map.

County	GeoJSON	TotalCases	Color

County	GeoJSON	TotalCases	Color
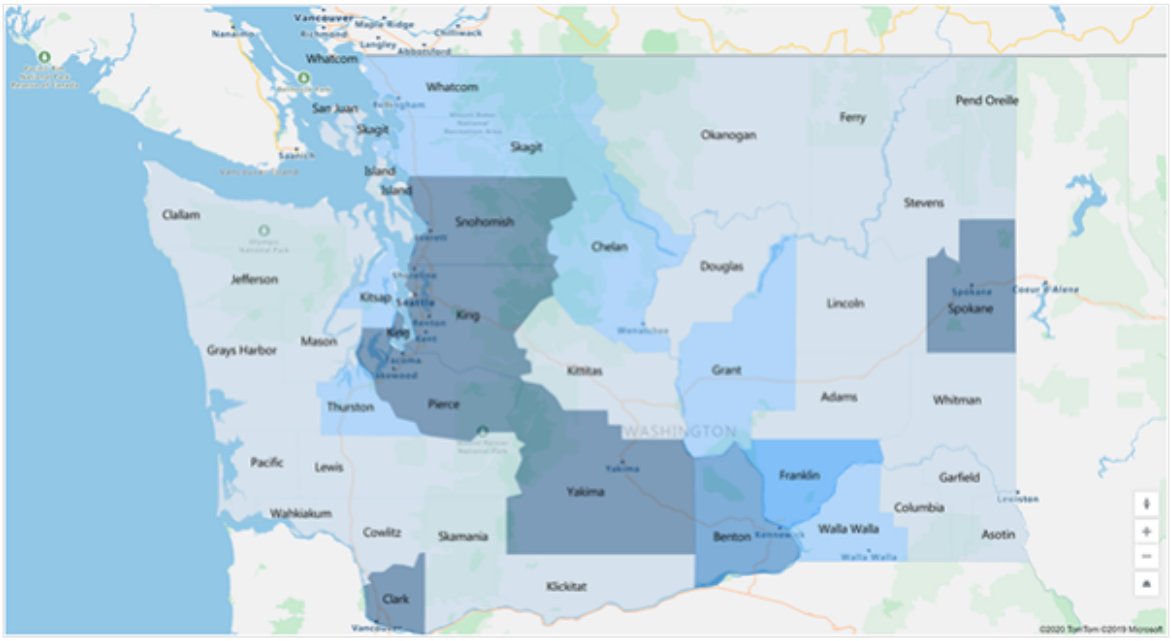
Chelan	{"type":"FeatureCollection","properties": {"kind":"state","state":"WA"},"features": [{"type":"Feature","properties": {"kind":"county","name":"Chelan","state":"WA"},"geometry": {"type":"MultiPolygon","coordinates":[[[[-120.7029,48.5292], [-120.6536,48.5347],[-120.6262,48.4964], [-120.6646,48.4471],[-120.6481,48.3978], [-120.5605,48.3704],[-120.5879,48.3211], [-120.5112,48.3101],[-120.3524,48.2170], [-120.3633,48.1568],[-120.3250,48.1294], [-120.1443,48.0637],[-120.1443,48.0363], [-120.0895,48.0199],[-120.0512,47.9596], [-119.8704,47.9596],[-119.9964,47.7789], [-120.2100,47.7515],[-120.1990,47.6803], [-120.2374,47.5872],[-120.3031,47.5215], [-120.3195,47.4557],[-120.2921,47.4010], [-120.0895,47.3407],[-120.0950,47.2640], [-120.3907,47.2586],[-120.5276,47.3352], [-120.5605,47.3079],[-120.8015,47.4229], [-120.9165,47.4284],[-121.1137,47.5981], [-121.1301,47.6748],[-121.0644,47.7132], [-121.1192,47.7789],[-121.0699,47.8282], [-121.1520,47.8446],[-121.1739,47.8884], [-121.1630,47.9541],[-121.1192,47.9980], [-121.1520,48.0418],[-121.0151,48.0746], [-120.9439,48.1130],[-120.9548,48.1513], [-120.9056,48.1623],[-121.0041,48.2937], [-121.0699,48.3156],[-121.0425,48.3485], [-121.0644,48.3923],[-121.0370,48.4306], [-121.0480,48.4854],[-120.8563,48.5511], [-120.7851,48.5073]]]]}}]}	5324	RGB(112,187,255)

2. Bind the following advanced properties of the map control to the appropriate columns in the data source:

Property	Column
ShapeGeoJSONObjects	GeoJSON
ShapeLabels	County
ShapeColors	Color

Your map should look something like this:

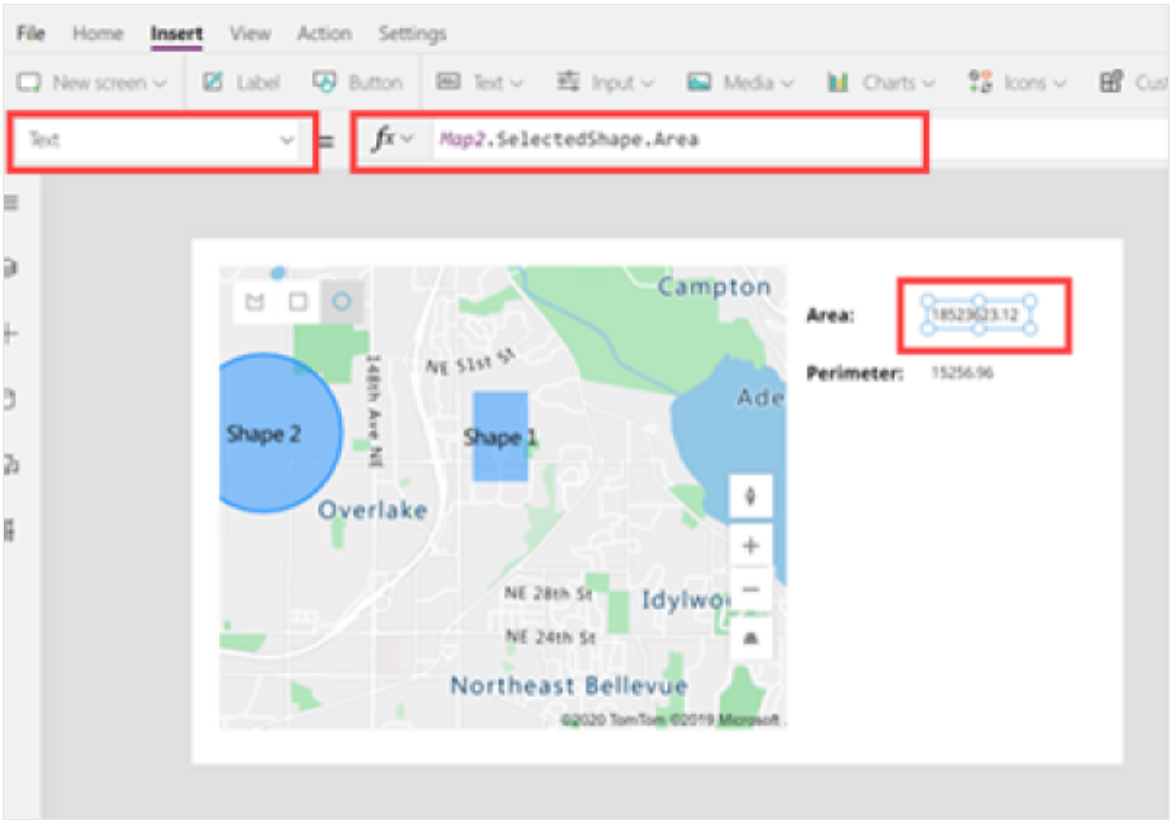


Display the perimeter and area of drawn or inserted shapes (preview)

Your apps can show the perimeter (in feet) and area (in square feet) of a selected shape on a map.

1. In your app, open the **Insert** tab and expand **Display**.
2. Select **Text label** to insert a label on the app screen. Move and resize it as you like.
3. Change the **Text** property of the label control to *[Map].SelectedShape.Area* or *[Map].SelectedShape.Perimeter* to display the selected shape's area or perimeter. (Hint: Enter the given value in the formula bar or on the **Properties** tab, whichever you prefer.)

In the following example, we used four text labels to display both the area and perimeter of the selected shape:



Other interactive map features

- Use data from Excel to insert pins
- Add info cards to pins
- Show routes between waypoints

Other geospatial controls

To see dynamic address suggestions as you type, use the **Address input** control.

Calculate routes between waypoint pins on a map (preview)

Article • 07/15/2022

[This topic is pre-release documentation and is subject to change.]

The map control in a canvas app can add waypoint pins using data imported from a table in an Excel workbook. The control can calculate routes between waypoints, reorder waypoints, and recalculate a route to improve travel time or distance.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

You'll need a data source that contains a named table with the following columns. Each column corresponds to an advanced property of the map control. Each row is pinned as a waypoint on the map.

Column name	Corresponds to	Required
Name (or Label)	RouteWaypointsLabels	Optional
Longitude	RouteWaypointsLongitudes	Optional (required if Address isn't given)
Latitude	RouteWaypointsLatitudes	Optional (required if Address isn't given)
Address	RouteWaypointsAddresses	Optional (required if Longitude and Latitude aren't given)

> **Note**
>
> All properties are technically optional. However, at least one of an address or a latitude/longitude pair must be provided for the waypoint location to be plotted.

Import waypoint pins from an Excel table

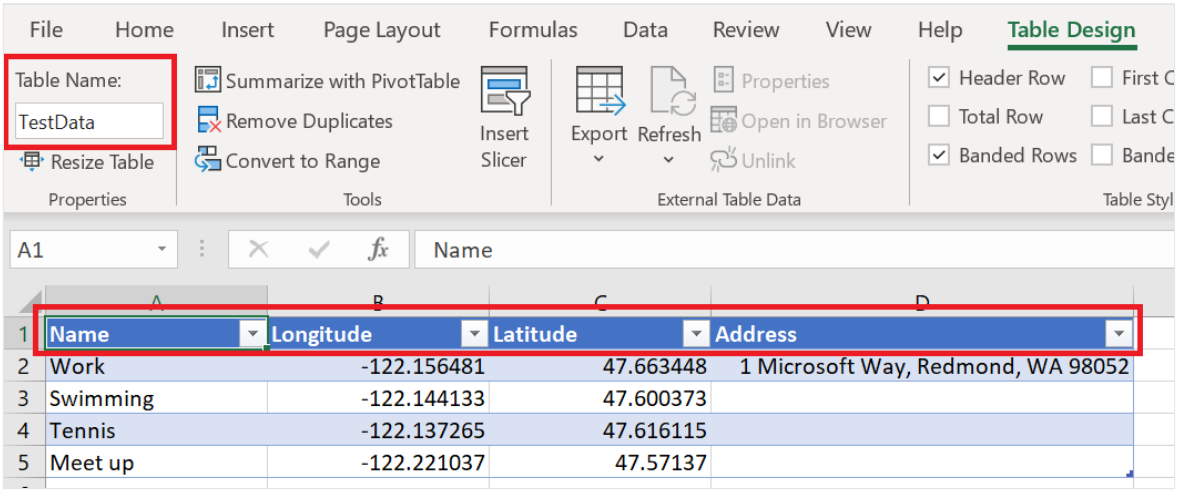
In this example, we'll import waypoint data from an Excel table named *TestData*.

Create a data source

1. Create a table in Excel with the following data. Name the table **TestData**.

Name	Longitude	Latitude	Address
Work	-122.156481	47.663448	1 Microsoft Way, Redmond, WA 98052
Meet up	-122.221037	47.57137	
Swimming	-122.144133	47.600373	
Tennis	-122.137265	47.616115	

   Your table should look something like this:



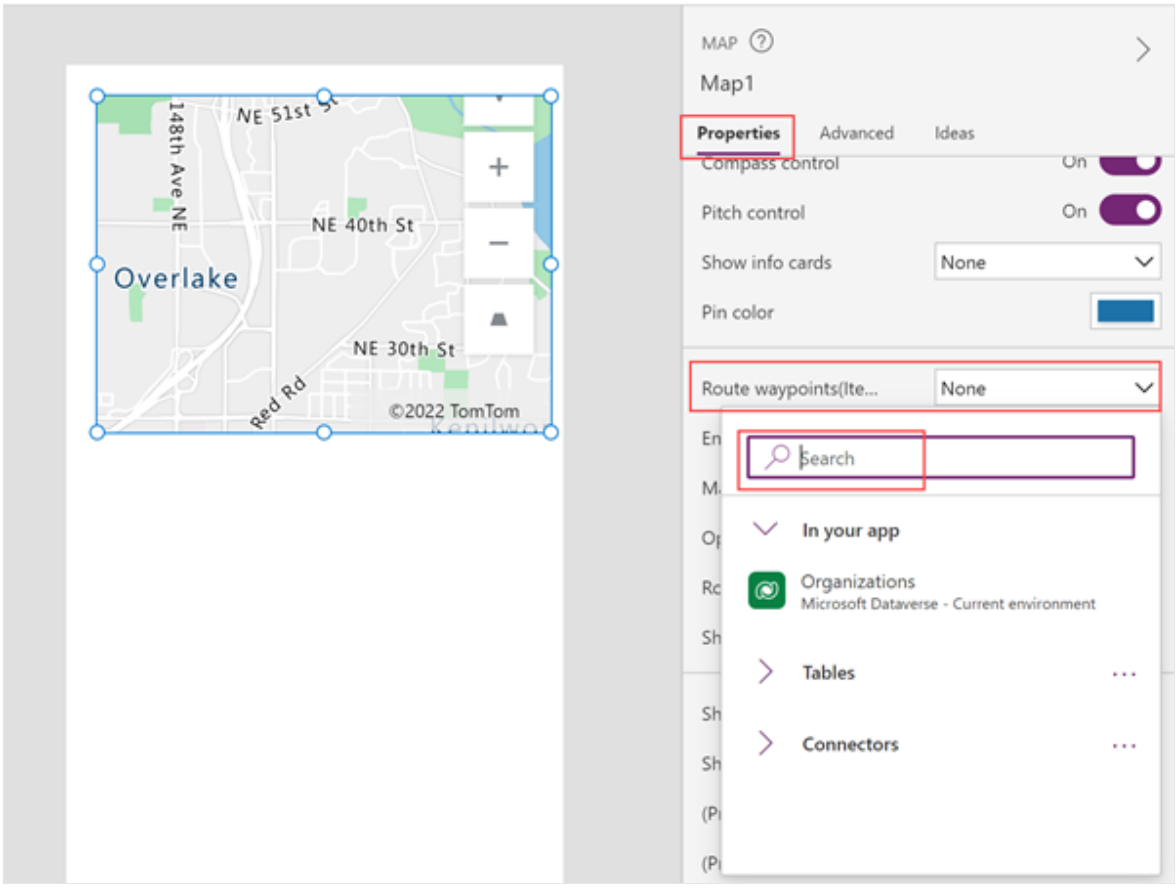
2. Save the workbook to your OneDrive for Business and close the file.

Bind the data source to a map control

1. Create a canvas app. Make sure it meets the geospatial prerequisites.

2. Insert a map control.

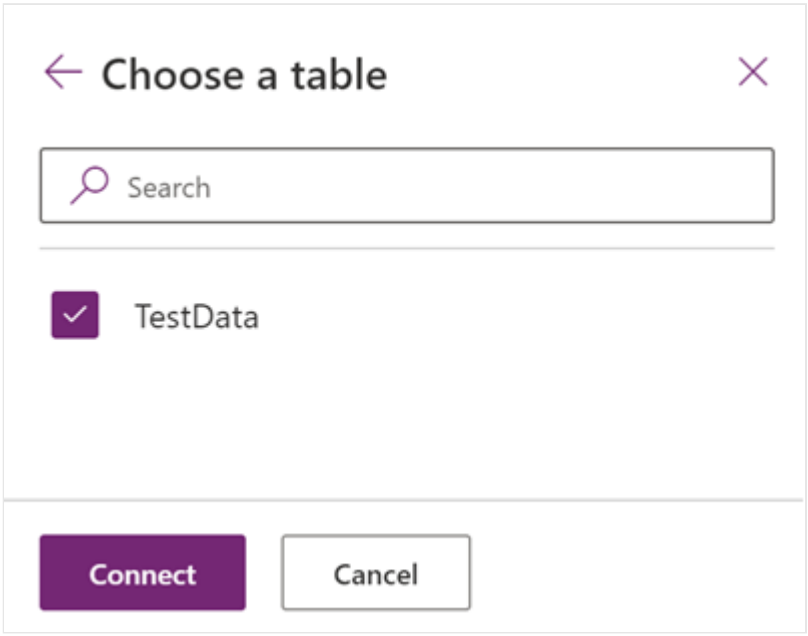
3. On the control's **Properties** tab, select the **Route waypoints(Items)** box and type *excel*.



4. Select **Import from Excel**.

5. Navigate to your OneDrive for Business and select the Excel workbook you saved earlier.

6. Select the table **TestData**, and then select **Connect**.

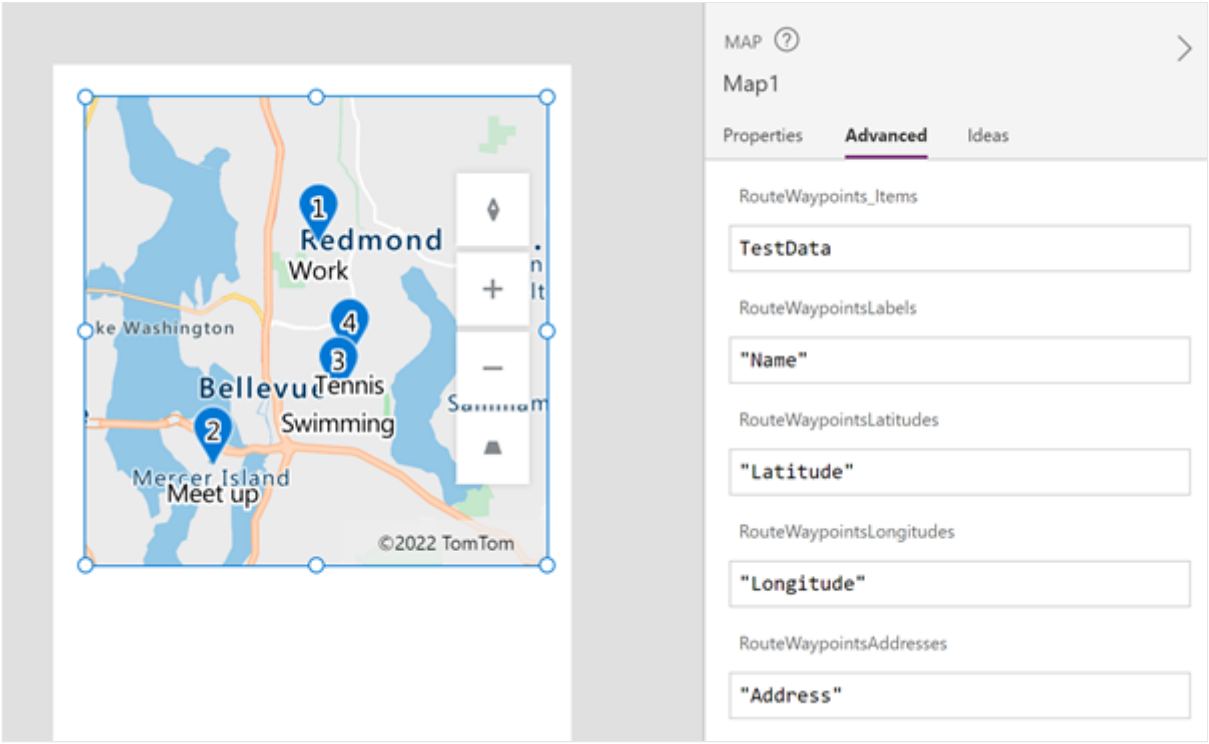


7. On the **Advanced** tab, find **RouteWaypointsLabels**, **RouteWaypointsLatitudes**, **RouteWaypointsLongitudes**, and **RouteWaypointsAddresses** and enter the name of the corresponding column in the table. (In this example, enter *Name* in

RouteWaypointsLabels, *Latitude* in **RouteWaypointsLatitudes**, and so on.) Enclose the column name in quotation marks.

> **Note**
>
> Address is interchangeable with Latitude and Longitude. If Latitude and Longitude are provided, then Address isn't used. If Address is provided, then Latitude and Longitude aren't needed. There is a limit to the number of waypoints that can be displayed when using address, so use Latitude and Longitude when possible.

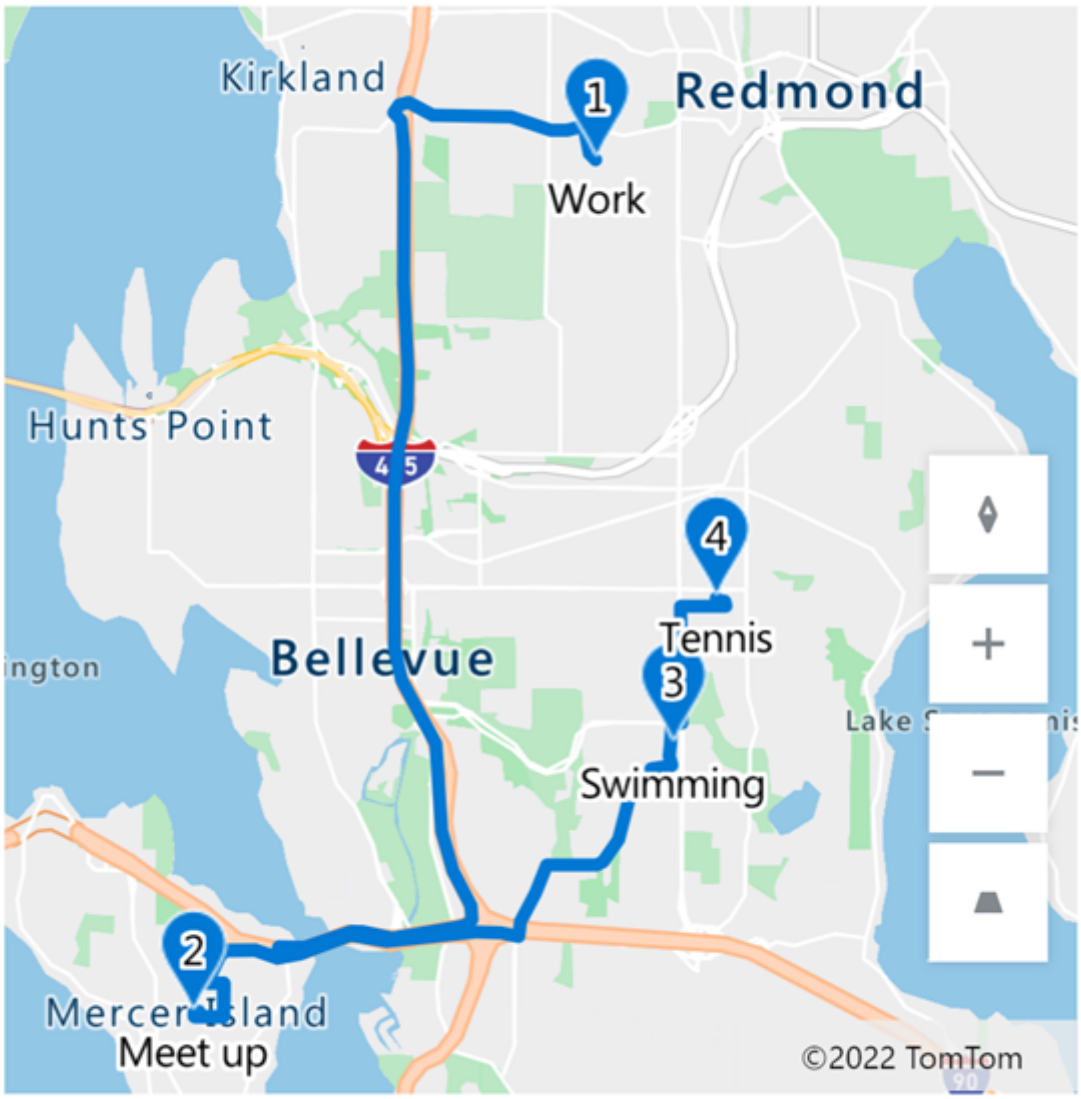
Pins appear on the map at the locations described by the coordinates or addresses in the table. If the table included labels, the pins are labeled. The pins are numbered in the order the waypoint locations appear in the table.



Calculate routes between the waypoints

With the map control selected, open the **Properties** tab and turn on **Enable routing**.

The control calculates routes between the pinned waypoints.



> **Note**
>
> By default, the map control reorders the middle waypoints to decrease travel time or travel distance. The first and last waypoints are considered the origin and destination and can't be reordered. To keep the waypoints in the order given in the data source, turn on the control's **Maintain waypoint order** property.

Properties

Change how a route is calculated using properties.

Property	Description	Type	Tab

Property	Description	Type	Tab
Enable routing	Calculates routes between waypoints.	Boolean	Properties; Advanced: **UseRouting**
Maintain waypoint order	Determines whether a calculated route maintains waypoints in the order provided in the data source.	Boolean	Properties; Advanced: **RouteMaintainOrder**
Optimize route	Determines whether a calculated route is optimized for distance, time, or isn't optimized.	Dropdown list	Properties; Advanced: **RouteOptimization**
Route travel mode	Determines whether a route is calculated for a car or a truck, which may require avoiding bridges with certain height or weight restrictions.	Dropdown list	Properties; Advanced: **RouteTravelMode**
Show route pins	Determines whether pins are shown over the route waypoints.	Boolean	Properties; Advanced: **ShowRoutePins**

Output Properties

Some properties become available only when a calculated route changes. These *output properties* are placed in the **RouteDirection** object. The **OnRouteDirectionChange** event is a recommended way to use the output in other controls or to customize the app experience.

Property	Description	Type	Tab
OnRouteDirectionChange	Contains code that runs when the route is changed.	Event	Advanced

Property	Description	Type	Tab
RouteDirection	Describes the routing outputs: • LengthInMeters: The length in meters of the entire route • TravelTimeInSeconds: The expected travel time in seconds of the entire route • RouteGeoJSON: A string that describes the route in GeoJSON format • RouteLegs: A table that describes each leg of the route: ◦ Index: A number that represents the leg's order in the route ◦ LengthInMeters: The length of the leg in meters ◦ TravelTimeInSeconds: The expected travel time of the leg in seconds ◦ StartLabel: The label of the leg's starting point ◦ StartLatitude: The latitude of the leg's starting point ◦ StartLongitude: The longitude of the leg's starting point ◦ StartAddress: The address of the leg's starting point ◦ EndLabel: The label of the leg's ending point ◦ EndLatitude: The latitude of the leg's ending point ◦ EndLongitude: The longitude of the leg's ending point ◦ EndAddress: The address of the leg's ending point • OrderedWaypoints: A table that describes each waypoint after the waypoints are ordered: ◦ Index: A number that represents the waypoint's order in the route ◦ Label: The label of the waypoint ◦ Latitude: The latitude of the waypoint ◦ Longitude: The longitude of the waypoint ◦ Address: The address of the waypoint	Object	Not applicable (output property only)

Interactive map control

Use the address input control to easily enter addresses

Article • 07/15/2022

Entering addresses can be frustrating and error-prone, particularly in mobile apps. Use the address input control to make address entry easier. The control uses fuzzy logic to suggest potential matches as you type. Select the one you want to quickly and easily enter an accurate address.

The control returns the address as structured data. Your app can extract information such as city, street, municipality, and even latitude and longitude coordinates. The data is in a format that's friendly to many locales and international address formats.

Prerequisites

Before you can use the control in your apps, you'll need to enable geospatial features for the environment. Make sure you also review the prerequisites for using geospatial controls. Refer to the privacy and security table for more details on the address input control's data usage.

Add an address input control to your app

With your app open for editing in Power Apps Studio :

1. Open the **Insert** tab and expand **Input**.
2. Select **Address input** to place an address input box in the app screen, or drag the control to the screen to position it more precisely. You must enter at least three characters including one number for the address input control.

Set a default search radius

By default, the control will search around the user's location. You can refine the default search area to help narrow the initial results.

1. On the address input control's **Properties** tab, turn on the **Search within radius** property.
2. Enter a longitude, latitude, and radius in meters.

The control will start searching at the given latitude and longitude, out to the distance specified.

Use the map control with the address input control

You can add a button to your app to save entered addresses as a data collection. Then you can retrieve the addresses and display them in the map control.

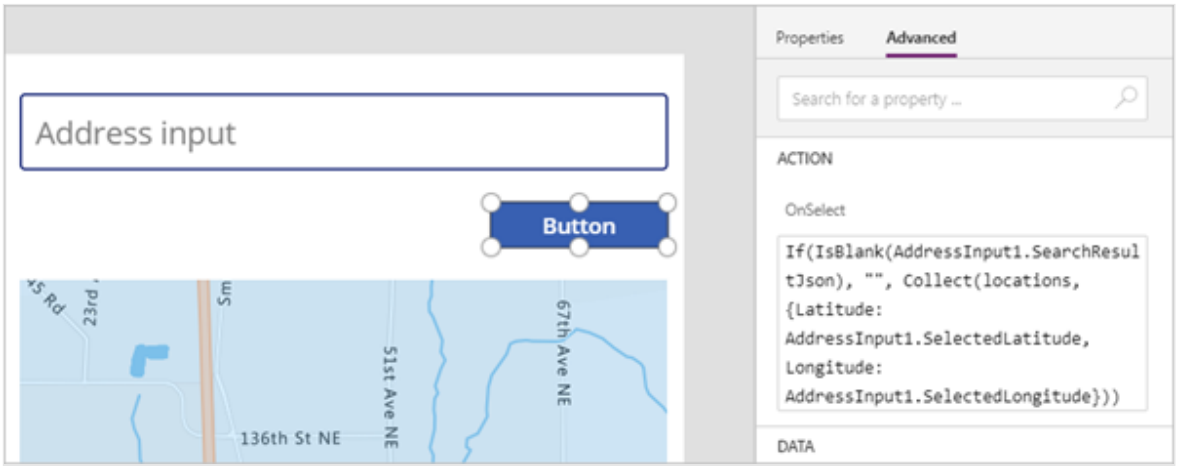
1. Add a map control and an address input control to your app.
2. Insert and place a **Button** control.
3. Change the **OnSelect** property of the button control as follows. (Hint: Copy the formula and paste it in the formula bar or on the **Advanced** properties tab, whichever you prefer.)
4. Enter a longitude, latitude, and radius (in meters).

   The control will start searching at the latitude and longitude, out to the distance specified in the radius field.

   Power Fx

   ```
   If(IsBlank(AddressInput1.SearchResultJson), "", Collect(locations,
   {Latitude: AddressInput1.SelectedLatitude, Longitude:
   AddressInput1.SelectedLongitude}))
   ```

   The formula saves the current latitude and longitude to a collection named *locations*, as long as the search results aren't blank.

5. Select the map control. Change its properties as follows:

Expand table

Property name	Value	Where
Items	"Locations"	**Properties** tab
ItemsLatitudes	"Latitude"	**Advanced** tab
ItemsLongitudes	"Longitude"	**Advanced** tab

When the user selects the button, the result from the address input control is added to the map as a new pin.

Properties

Change an address input control's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.

Expand table

Property	Description	Type	Tab
Default	Sets the initial value of the control.	String	Properties; Advanced: **Default**
Hint text	Sets the hint that appears in the control before the user enters text.	String	Properties; Advanced: **HintText**
Font	Sets the name of the family of fonts used for the control text.	Dropdown list	Properties; Advanced: **Font**
Font size	Sets the size of the control text.	Floating point number	Properties; Advanced: **FontSize**
Font weight	Sets the weight of the control text, either *Bold*, *Lighter*, *Normal*, or *Semibold*.	Dropdown list	Properties; Advanced: **FontWeight**
Text alignment	Sets the horizontal alignment of the control text, either *Center*, *Justify*, *Left*, or *Right*.	Dropdown list	Properties; Advanced: **TextAlignment**
Line height	Sets the vertical distance between lines of text in the control.	Floating point number	Properties; Advanced: **LineHeight**

Property	Description	Type	Tab
Display mode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Dropdown list	Properties; Advanced: DisplayMode
Font style	Sets the style of the control text, either *Italic*, *Underline*, *Strikethrough*, or none.	Dropdown list	Properties; Advanced: **Italic**, **Underline**, **Strikethrough**
Search result limit	Sets the number of suggested addresses the control displays.	Integer	Properties; Advanced: **SearchResultLimit**
Search within radius	Determines whether the control should suggest addresses within the **Radius** of the **Latitude** and **Longitude**.	Boolean	Properties; Advanced: **SearchWithinRadius**
Latitude	Sets the latitude coordinate of the center point used for address suggestions. Requires **Search within radius** to be on.	Floating point number from -90 to 90	Properties; Advanced: **Latitude**
Longitude	Sets the longitude coordinate of the center point used for address suggestions. Requires **Search within radius** to be on.	Floating point number from -180 to 180	Properties; Advanced: **Longitude**
Radius	Sets the radius, in meters, around **Latitude** and **Longitude** to constrain address suggestions. Requires **Search within radius** to be on.	Floating point number	Properties; Advanced: **Radius**
Language	Sets the language that address suggestions are returned in.	String	Properties; Advanced: **Language**
Country set	Identifies a comma-separated list of countries/regions to constrain address suggestions to, in ISO 3166 alpha-2 format; for example, *US,CA,MX*.	String	Properties; Advanced: **CountrySet**
Visible	Shows or hides the control.	Boolean	Properties; Advanced: Visible
Padding top	Sets the distance between the control text and the top of the	Floating point number	Properties; Advanced: PaddingTop

Property	Description	Type	Tab
	control.		
Padding bottom	Sets the distance between the control text and the bottom of the control.	Floating point number	Properties; Advanced: **PaddingBottom**
Padding left	Sets the distance between the control text and the left edge of the control.	Floating point number	Properties; Advanced: **PaddingLeft**
Padding right	Sets the distance between the control text and the right edge of the control.	Floating point number	Properties; Advanced: **PaddingRight**
Position	Places the upper-left corner of the control at the screen coordinates specified in *X* and *Y*.	Integer	Properties; Advanced: **X**, **Y**
Size	Determines the size of the control using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Border radius	Determines the corner radius of the control border.	Floating point number	Properties; Advanced: **BorderRadius**
Color	Sets the colors of the control text and the control background.	Not applicable	Properties; Advanced: **FillColor**, **TextColor**
Border	Determines the style, width, and color of the control border.	Not applicable	Properties; Advanced: **BorderStyle**, **BorderThickness**, **BorderColor**
Tab index	Specifies the order the control is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **TabIndex**
Tooltip	Determines the text to display when the user hovers over the control.	String	Properties; Advanced: **Tooltip**
Hover color	Sets the colors of the control text, the control background, and the control border when the user hovers the mouse pointer over it.	Not applicable	Properties; Advanced: **HoverFontColor**, **HoverFillColor**, **HoverBorderColor**

Property	Description	Type	Tab
Disabled color	Sets the colors of the control text, the control background, and the control border if **DisplayMode** is *Disabled*.	Not applicable	Properties; Advanced: **DisabledFontColor**, **DisabledFillColor**, **DisabledBorderColor**
Pressed color	Sets the colors of the control text, the control background, and the control border when the user selects the control.	Not applicable	Properties; Advanced: **PressedFontColor**, **PressedFillColor**, **PressedBorderColor**
ContentLanguage	Determines the display language of the control, if it's different from the language that's used in the app.	String	Advanced
OnAddressSelect	Contains code that runs when the user selects a suggested address.	Event	Advanced
OnChange	Contains code that runs when a control property is changed.	Event	Advanced

Output properties

Other properties become available when a user interacts with the address input control. You can use these *output properties* in other controls or to customize the app experience.

Expand table

Property	Description
UserInput	The text the user typed in the input box
SelectedLatitude	The latitude of the address that the user selected
SelectedLongitude	The longitude of the address that the user selected
SearchResultJson	The search result, based on **UserInput**, displayed as a string in JSON format
FreeformAddress	The address that the user selected from the list of suggested addresses
LocalName	The name of a geographic area or locality that groups a number of addressable objects for addressing purposes, without being an

Property	Description
	administrative unit
PostalCode	The postal code
ExtendedPostalCode	The extended postal code
CountryCode	The country code
Country	The country/region name

Power Apps visual for Power BI

Article • 03/04/2025

Power BI enables data insights and better decision-making, while Power Apps enables everyone to build and use apps that connect to business data. Using the Power Apps visual, you can pass context-aware data to a canvas app, which updates in real time as you make changes to your report. Now, your app users can derive business insights and take actions from right within their Power BI reports and dashboards.

Using the Power Apps visual

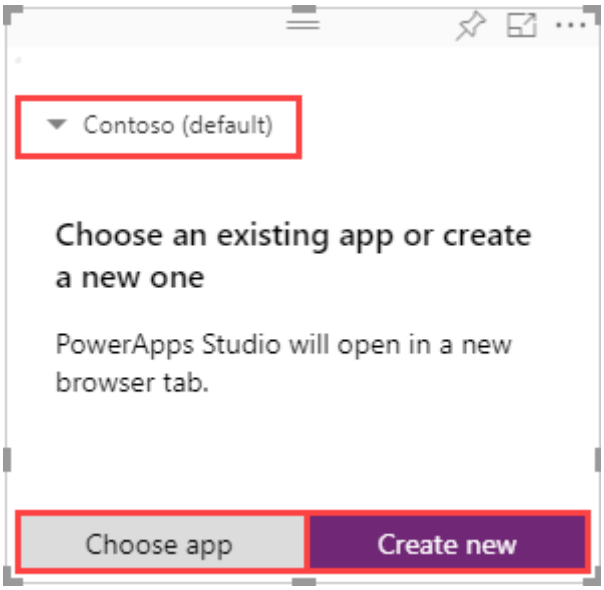
Let's look at the steps required to use the Power Apps visual in your Power BI report.

1. Power Apps visual is available by default in the Power BI service. If you're using Power BI Desktop and don't see it, you must upgrade to the latest version of Power BI Desktop.

2. Add the Power Apps visual to your report, and set the data fields associated with it.

   You can choose an existing app or create one, but the report must be published to the Power BI service and opened in Microsoft Edge or Google Chrome.

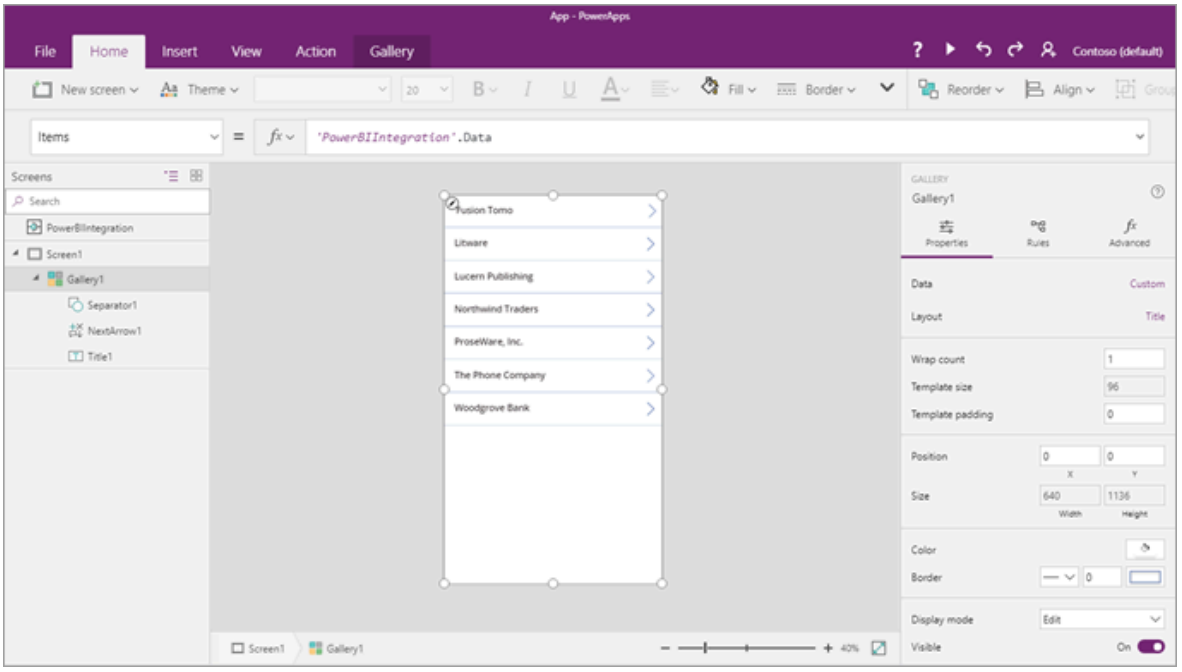
3. If you choose to create an app, you can choose in which environment to create it.



If you choose to use an existing app, the visual prompts you to open the app in Power Apps. The visual then sets up the required components in your app so that Power BI can send data to Power Apps.

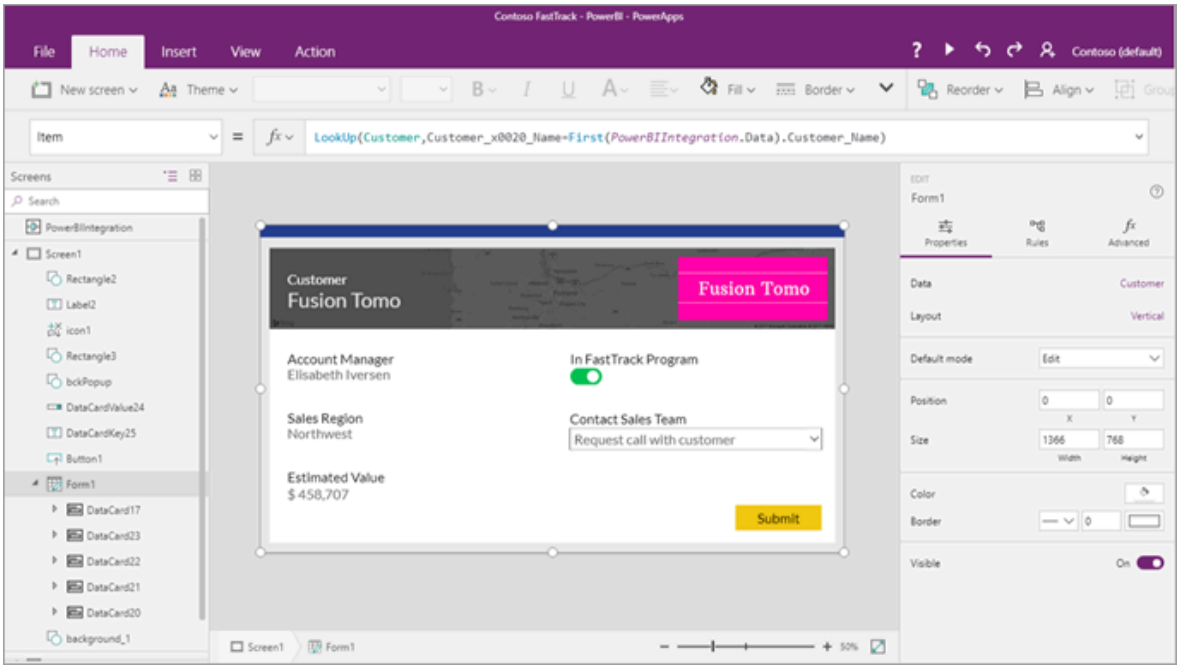
If you create a new app, Power Apps creates a simple app with the required components already set up.

> **Note**
>
> You must create a new app from Power Apps visual in Power BI report for the `PowerBIIntegration.Refresh()` function to be available in the app.



4. Now in Power Apps Studio, you can use the data fields you set in step 2. The `PowerBIIntegration` object acts like any other Power Apps read-only data source

or collection. You can use the object to populate any control, or join and filter with other data sources.



This formula joins Power BI data with the Customer data source:

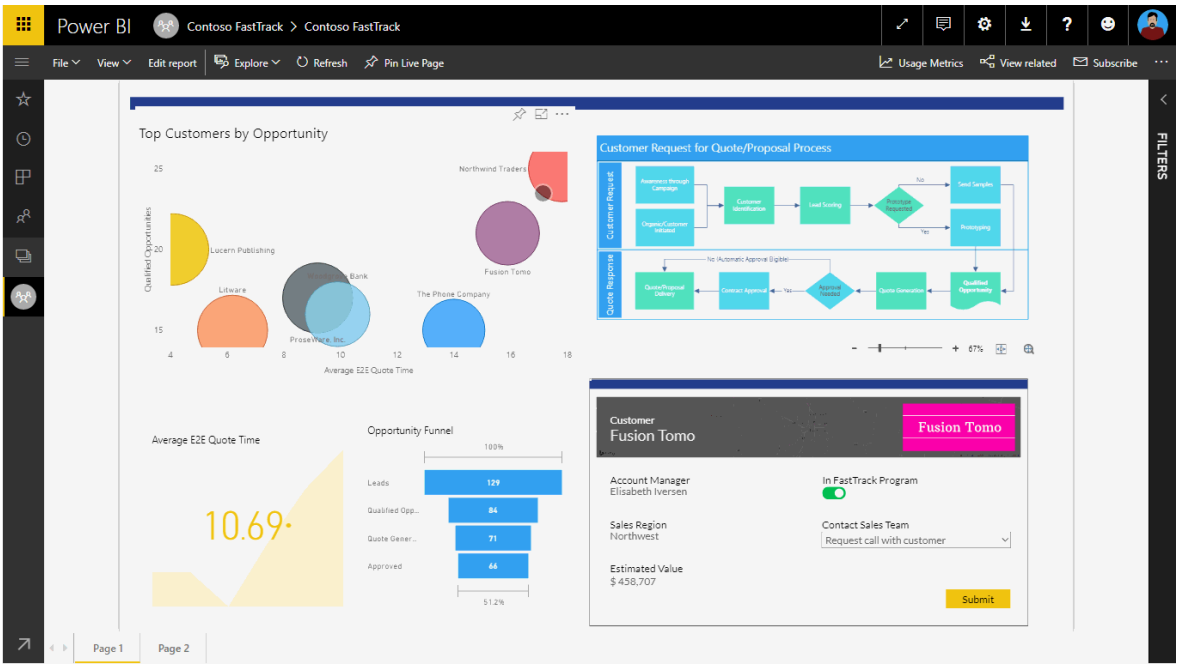
```
LookUp(Customer,Customer_x0020_Name=First(PowerBIIntegration.Data).Customer_Name)
```

The Power BI report and the instance of Power Apps Studio that was launched share a live data connection. While they're both open, you can filter or change the data in your report to see the updated data reflect immediately in your app in Power Apps Studio.

5. After you have completed building or making changes to your app, save and publish the app in Power Apps to see your app in the Power BI report.

6. Once you're satisfied with your changes, make sure to share the app with users of your report and then save your report.

7. You've created a report in which your users can take actions as they gain insights from your data.



If you need to make changes to an app, open the report in edit mode, select **More options** (. . .) on the Power Apps visual and select **Edit**.

Limitations of the Power Apps visual

The following limitations apply to the Power Apps visual:

- Only **https** is supported for the Launch function in the Power Apps Visual.
- Power Apps visual is only supported for Embed for your organization. Embed for your customers is not supported.
- The maximum number of records that can be passed from Power BI to Power Apps visual using "PowerBIIntegration" object is limited to 1000.
- Power Apps visual is only supported for guest users when the following conditions are met:
  - The canvas app URI (weblink) includes the tenantId of the app in the query string.
  - The Power BI portal authenticates the user, instead of allowing anonymous access.
  - The canvas app is shared with the guest user attempting to see the contents of the app.
- Power Apps visual doesn't support multi-level embedding of Power Apps in Sovereign clouds. For example, embedding a Power BI report with Power Apps

visual to a SharePoint page, or further embedding that SharePoint page to a Teams channel isn't supported on sovereign clouds.

- If you change the data fields associated with the visual, you must edit the app from within the Power BI service by selecting the ellipsis (...) and then selecting **Edit**. Otherwise, the changes won't be propagated to Power Apps, and the app will behave in unexpected ways.
- The Power Apps visual can't trigger a refresh of Power BI reports and Power BI data sources from within Power BI Desktop. If you write back data from the app to the same data source as the report, your changes won't be reflected immediately in Power BI Desktop. Changes are reflected on the next scheduled refresh.
- The Power Apps visual can't filter the data or send any data back to the report.
- You'll need to share the app separately from your report. Learn about sharing apps in Power Apps.
- Power BI Report Server doesn't support the Power Apps visual.
- Following limitations apply when using the `PowerBIIntegration.Refresh()` function:
  - You must create a new app from Power Apps visual in Power BI report for this function to be available in the app.
  - You must use a source that supports DirectQuery and the data connection must be created using DirectQuery method.
- Power Apps in Power BI Desktop provides data to Power Apps Studio when creating apps but not while editing. Use Power BI Web to preview the data while editing apps.
- The Power BI mobile app doesn't support microphone control in Power Apps visuals.

> **Note**
>
> We recommend that you first publish your report to the Power BI service and then create or modify apps.

Browser support

The following table lists the browser supportability for view, create, and modify actions of the Power Apps visual. Supported browsers and actions are identified by a check mark (✓).

Expand table

Browser	View	Create	Modify
Microsoft Edge	✓	✓	✓
Google Chrome	✓	✓	✓
Safari *	✓		
Mozilla Firefox			
All other browsers			

* In Safari, you must enable cross site tracking (**Preferences** > **Privacy**, and clear **Prevent cross site tracking**) to view Power Apps visual.

Accessibility support

To navigate the Power Apps visual using the keyboard, follow these steps:

1. Focus selection on the Power BI Report for the Power Apps visual that you want.
2. Use the **Tab** key on the keyboard until the visual is highlighted.
3. Use the **Ctrl+Right** key on the keyboard to enter the visual.
4. Use the **Tab** key on the keyboard until the component of the visual you want is selected.

For more information, go to Power BI Accessibility Documentation

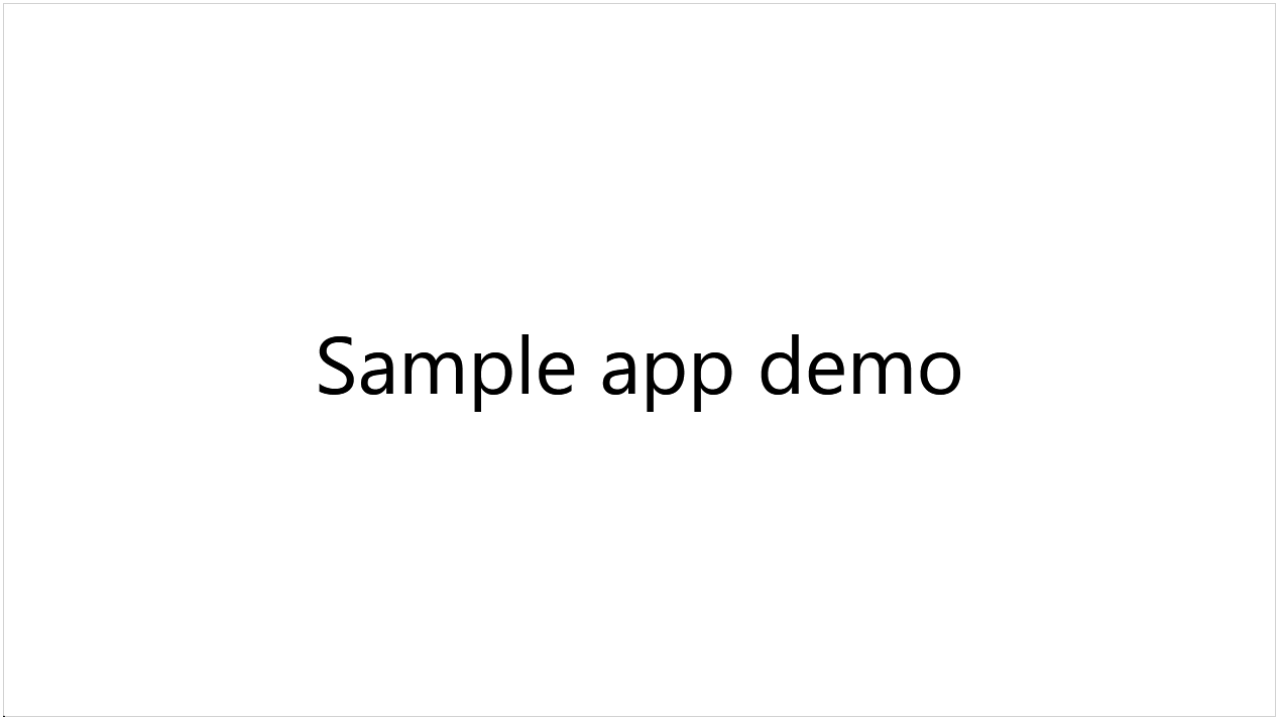
Create an app to edit tables in canvas apps

Article • 12/16/2022

Designing a productivity application to have related data and functions in one place enables you to achieve more without having to switch back and forth between the screens. Microsoft Excel is one such example that allows editing data real time in fast and efficient way.

Using Power Apps, you can apply the same concept by providing it as a front end to any data source. You're also able to customize it even more.



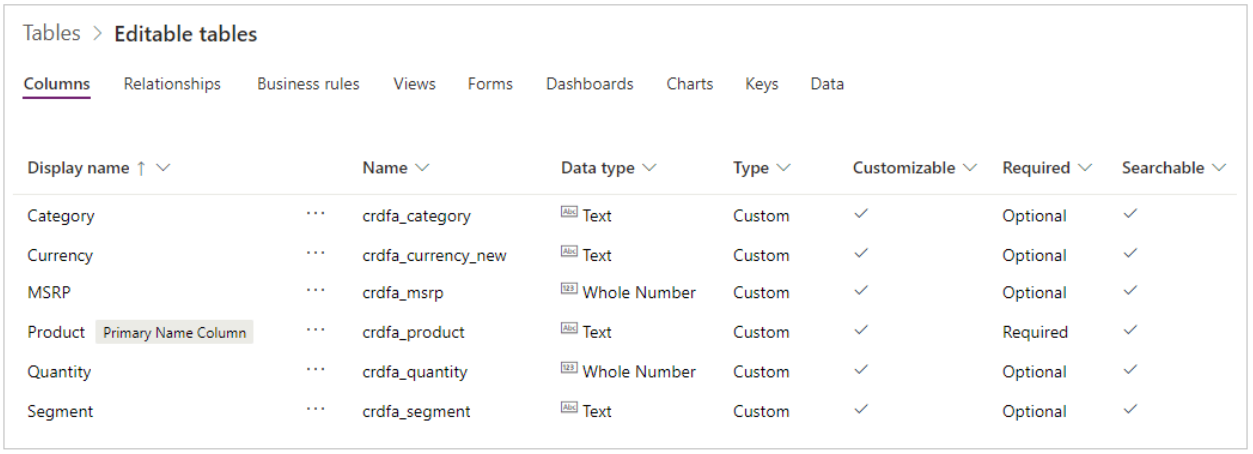
This tutorial uses the following components to make a sample app:

- A data source (Microsoft Dataverse, you can also use Excel instead)
- Form—For new items
- Gallery—To display existing items and
- Text input controls—To update existing items

Prerequisites

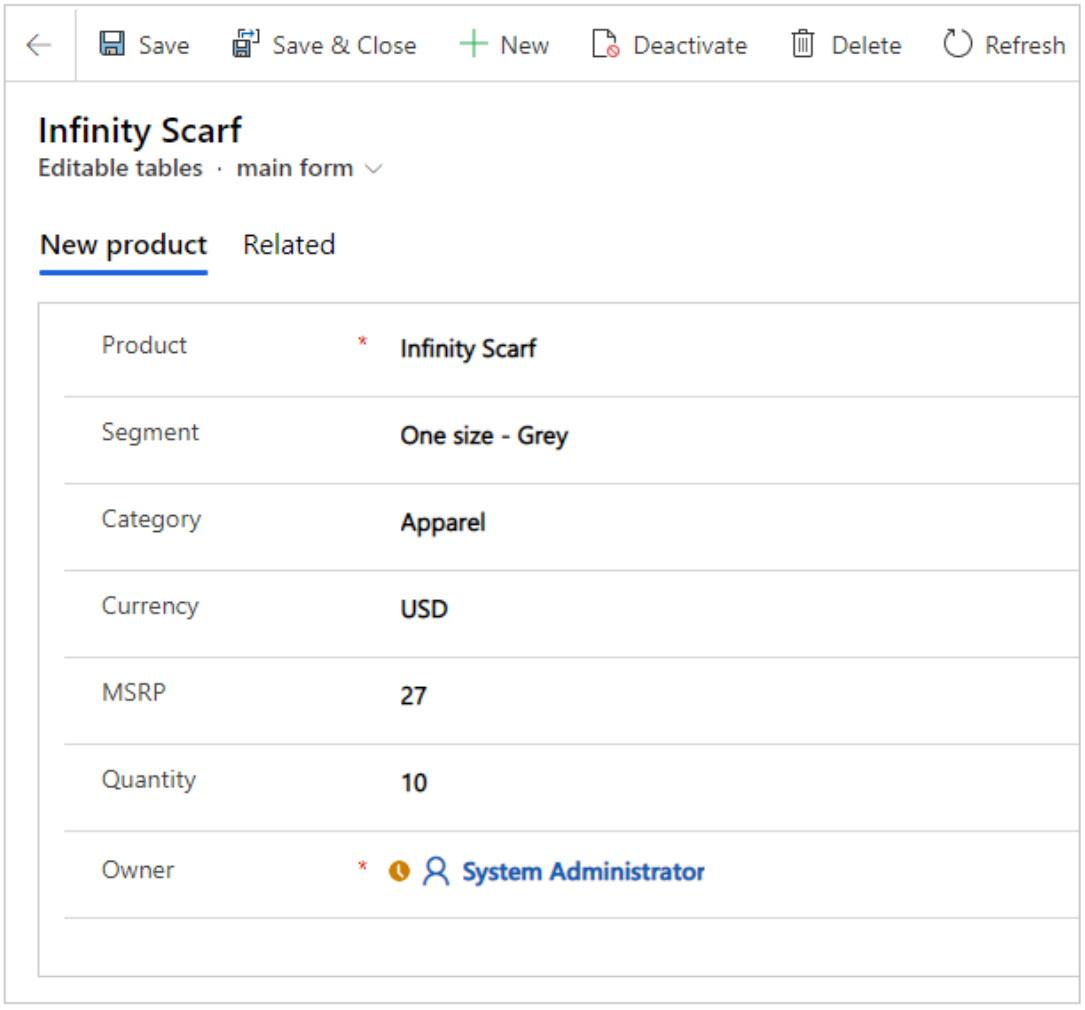
To follow this tutorial, you'll need access to a Power Platform environment, and the ability to create tables in Microsoft Dataverse.

The tutorial uses the following structure to create the sample app:



To learn about how to add columns, see Work with table columns.

A new main form has been created to add sample data:



To learn about how to create a main form with the required columns, see Create a form. Be sure to use the correct form order for adding records using the new form.

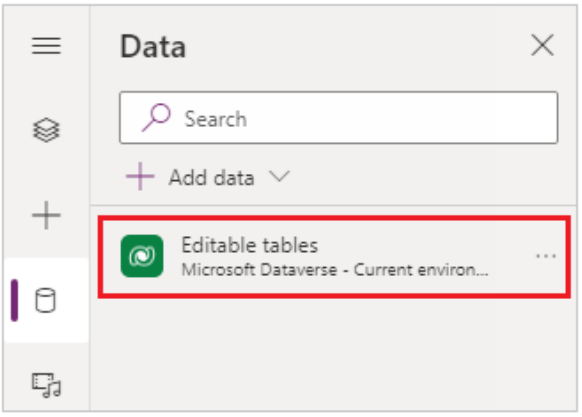
Step 1: Create blank app

Create a blank canvas app with the name "Catalog Management app" and **Tablet** layout.

Step 2: Add a data source

This section shows how to add a Dataverse table as the data source for the sample app. You can also use an Excel file from a SharePoint site, or OneDrive as the data source; or any other data source type of your choice.

1. From the left-pane, select **Data** > **Add data**.
2. Select **See all tables**.
3. Select **Editable tables**, or the table that you created earlier.

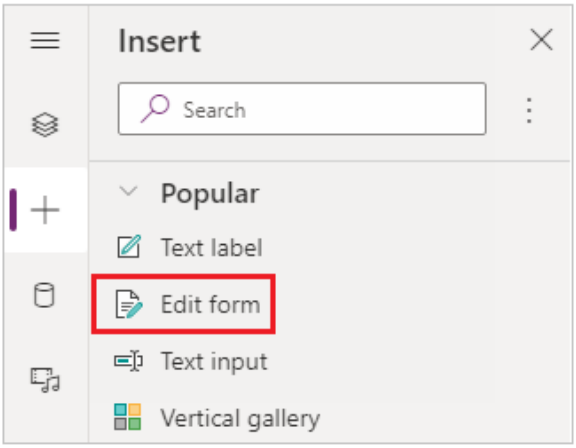


For more information about adding a connection to a canvas app, see Add data source.

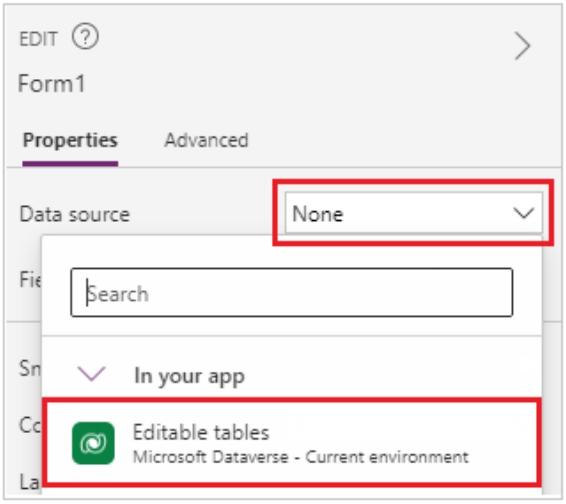
Step 3: Set up a form control

This step adds a form control to add new items.

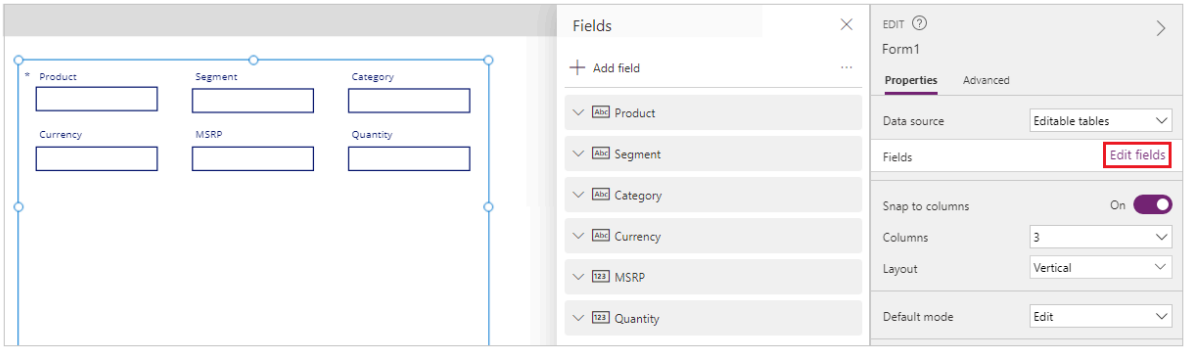
1. Select + (Insert) > **Edit form**.



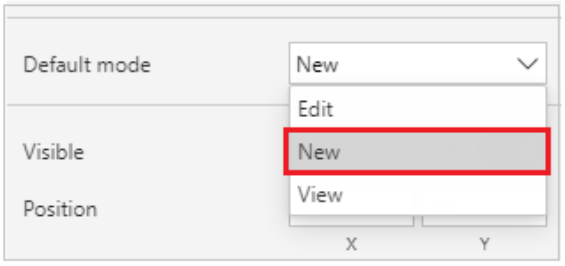
2. On the right-pane, choose the table as the data source for the edit form control.



3. Use the **Edit fields** properties option to select the columns to show on the edit form control. You can also change the column order as appropriate.



4. Choose the **Default mode** for the form to **New**.



5. Adjust the **Width**, **Height** properties for size of the data cards to fill the canvas as appropriate.

6. On the left-pane, select + (Insert) > **Button**.

7. Update the button text to **Add product**.

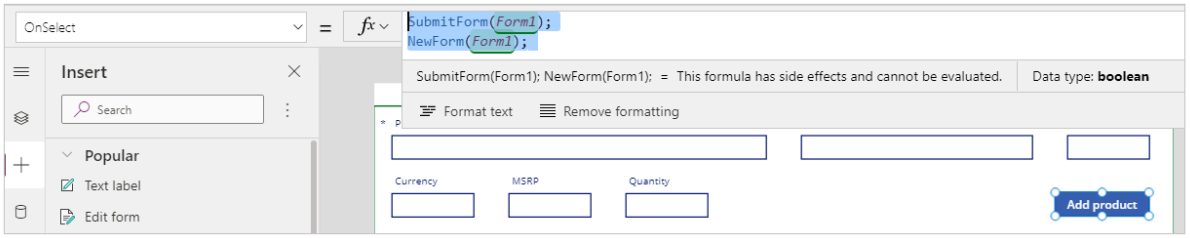
8. Select **OnSelect** property for the button control from the top-left side of the screen.

9. In the formula bar, enter the following formula.

Power Fx

```
SubmitForm(Form1);
NewForm(Form1);
```

- SubmitForm function submits the new product details to the Dataverse table.
- NewForm changes the mode of the form back to new form to add new products after submitting new product details.
- **Form1** in this formula is the name of the edit form control added earlier. Update the form name in this formula if your form name is different.



Step 4: Set up gallery as editable table

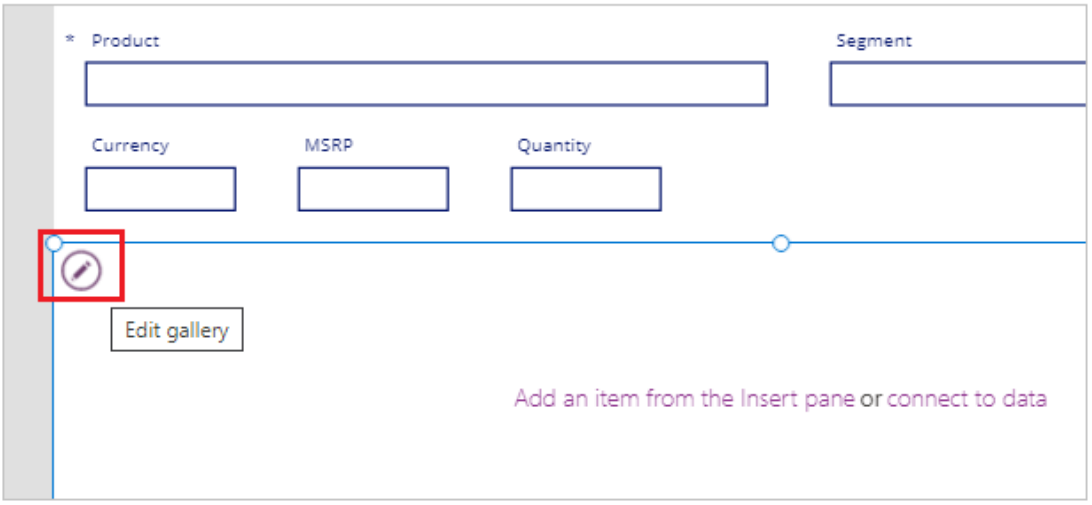
This step adds a blank vertical gallery to edit the items as an editable table.

1. On the left-pane, select + (Insert) > **Layout** > **Blank vertical gallery**.

2. Select the table from Dataverse as the data source.

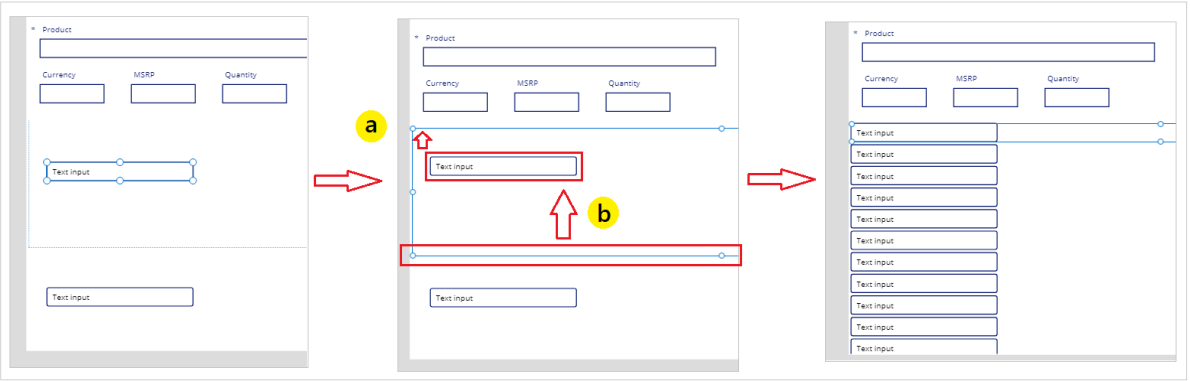
3. Resize the gallery to take over remaining half of the entire canvas since this gallery will contain all editable columns from the data source.

4. Select **Edit gallery**.



5. On the left-pane, select + (Insert) > **Input** > **Text input**.

6. Align gallery with the following actions:



a. Move the top-most row for text input control to the top-left corner within the gallery. Moving this top-most row automatically moves remaining rows for same column.
b. Resize the first row height within the gallery to occupy the size of the first row you just moved to top-left.

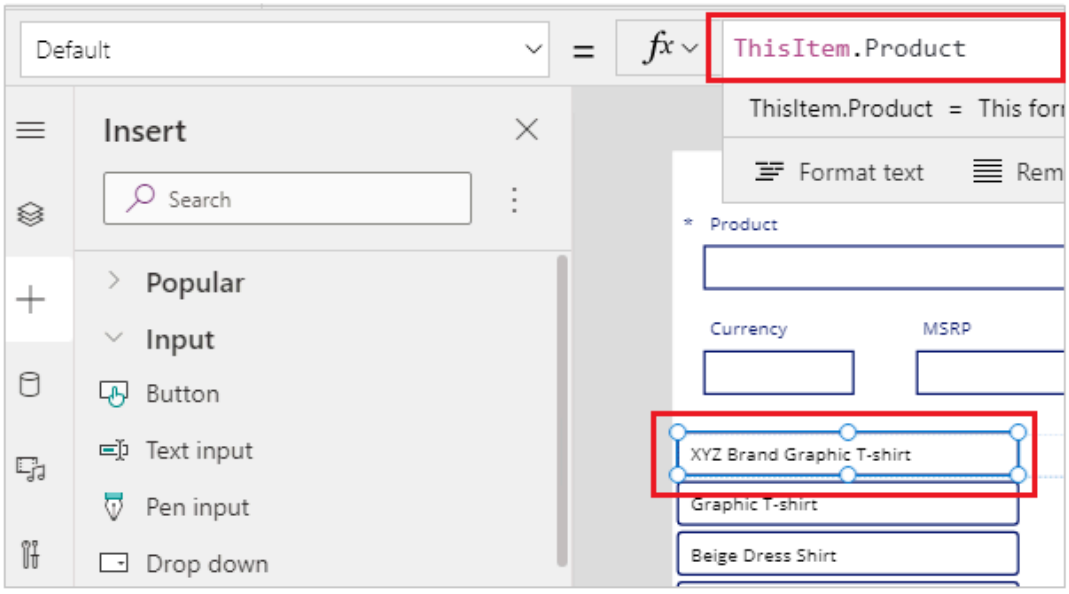
At the end, you should see all rows stacked on left-side of the gallery.

7. Update the **Default** property formula for the first text input row within the gallery:

```
Power Fx

ThisItem.Product
```

- ThisItem in this formula relates to the item within the selected data source; which in this example is the Dataverse table.
- "Product" is the name of the column within the table.
- When this formula is updated for the first row in gallery, it automatically updates the entire column with product names. If you see an error, check if you've connected the gallery to the Dataverse table.



8. Repeat previous steps to add a text input control for each column that you want to show up inside the app as editable field. Ensure you choose the correct columns in the formula replacing "Product" with the appropriate column names.

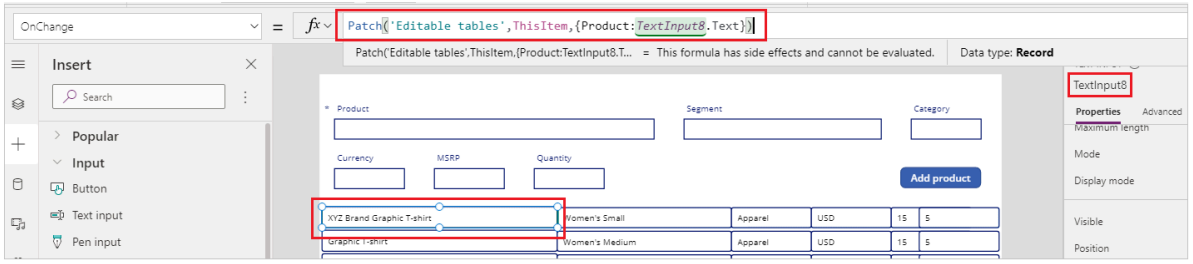
> **Tip**
>
> To resize width, use **Width** property, or the drag using the buttons around the first row in each column.

9. Select the first row from the first column inside the gallery, and add the following formula to the **OnChange** property with changes to column and control names as appropriate:

```
Power Fx

Patch('Editable tables',ThisItem,{Product:TextInput8.Text})
```

   - Patch function in this formula updates the table selected as the data source with the values when changed.
   - "Editable tables" is the sample data source name.
   - ThisItem relates to the item within the selected data source for this column.
   - "Product" is the name of the column within the selected data source.
   - "TextInput8" is the name of the text input control added to the gallery attached to the "Product" column for the selected data source.
   - "Text" for "TextInput8" is the text entered in the selected cell within the editable table on the canvas.

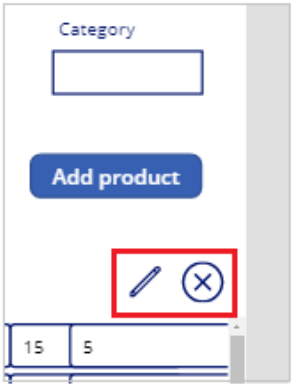


10. Repeat the previous step for each text input control added for rest of the columns from the connected data source. Ensure the formula is updated to use the correct column and control names.

Step 5: Set up edit and cancel options

This step adds the options to edit and cancel the edit progress. Gallery having text input controls editable by default may be subject to unintentional updates. Having an explicit edit option, and then to stop edit capability, ensures the edits are always expected.

1. Select **Insert** from the top menu > **Icons**, and add two icons - **Edit**, and **Cancel (badge)**.



2. Select **Tree view** from the left-pane, and then select **App**.

3. Select the app **OnStart** property, and add the following formula with changes to gallery name as appropriate:

```
Power Fx

Gallery2.DisplayMode = "galleryDisplayMode";
Set(galleryDisplayMode, DisplayMode.Disabled);
```

   - "Gallery2" in this formula is the name of the gallery.
   - **DisplayMode** is the DisplayMode property for the selected gallery.
   - "galleryDisplayMode" is the new variable that this formula creates to store the value of the gallery's display mode.
   - Set function sets the "galleryDisplayMode" variable defined in the previous line with the value of "Disabled" using "DisplayMode.Disabled". With disabled display mode, the gallery isn't editable by default when the app starts (app OnStart).

4. Select the blank vertical gallery, and then select the **DisplayMode** property.

5. Update the property value from `Edit` to `galleryDisplayMode`. This change ensures the gallery's mode is always defined using the value of the "galleryDisplayMode" variable created in the previous step.

6. Update the properties and formulas for the icons as below:

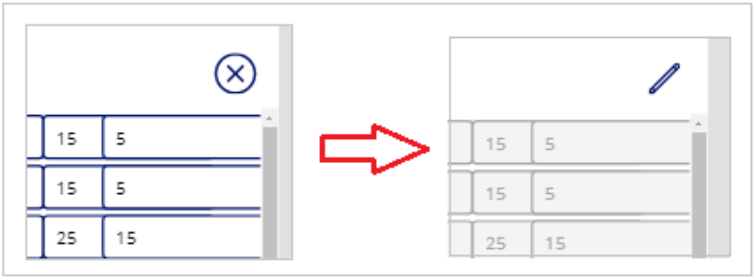
Expand table

Icon	Property	Formula
Edit	OnSelect	`Set(galleryDisplayMode, DisplayMode.Edit)`
Edit	Visible	`galleryDisplayMode = DisplayMode.Disabled`
Cancel	OnSelect	`Set(galleryDisplayMode, DisplayMode.Disabled)`
Cancel	Visible	`galleryDisplayMode = DisplayMode.Edit`

   - Set function sets the display mode of the gallery depending on which icon is selected.

- The variable "galleryDisplayMode" controls the visibility of the edit or cancel icons. When the gallery is editable, only cancel button appears. And only edit button appears when gallery is disabled.

7. Overlap edit and cancel icons, since we're managing the visibility for both icons depending on the state of the gallery.



> **Tip**
>
> You can use the **Preview** button from top-right side of the screen to preview the app, or use F5 key on the keyboard. Another quick alternative for testing is to press the **Alt** key on the keyboard, and select the button while keeping the key pressed. This method also simulates app's preview functionality for the specific selection while key remains pressed.

Step 6: Add search capability

As the data in the connected data source grows, it becomes difficult to find a specific row. This step adds search capability to the app to filter the gallery with searched keywords making it easier to find relevant data.

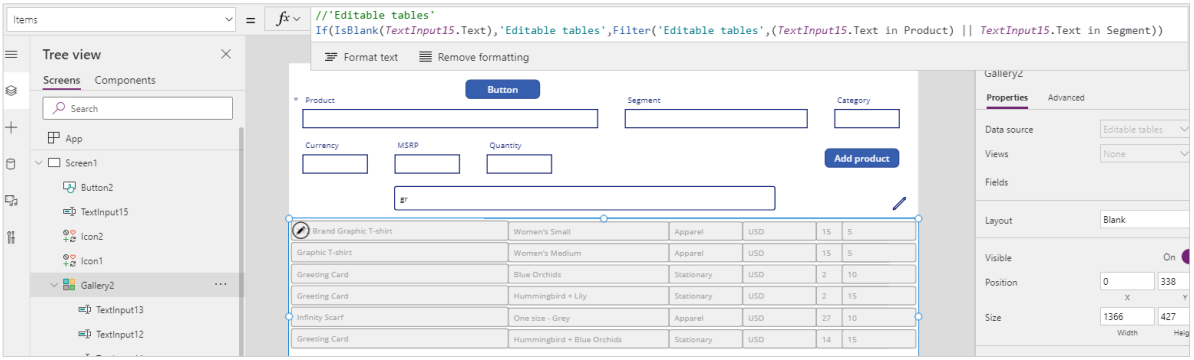
1. Add a text input control in the middle of the canvas, above the gallery.

2. Update the **Items** property for the gallery with the following formula instead of the table name, replacing table, and control names as appropriate.

```
Power Fx
If(IsBlank(TextInput15.Text),'Editable tables',Filter('Editable tables',
(TextInput15.Text in Product) || TextInput15.Text in Segment))
```

- If function checks for condition whether the search terms are specified, or blank. The gallery is populated depending on the listed items.
- IsBlank function checks the condition whether the search text is specified, or not.
- "Editable tables" is the name of the connected sample data source in this example. This value is set as the default if no search term is specified.
- Filter function filters the items in the gallery depending on the text criteria set within this function. This function is used to filter the gallery depending on the searched term.
- "TextInput15" is the name of the text input control being used as the search box to filter the gallery.

- "Product" and "Segment" are the names of the columns that are searched for using the text defined in the "TextInput15" control using the `.Text` syntax.
- "In" checks for the value of text input control to the specified column in the connected data source.
- "||" is the "OR" condition, signifying the search should be performed for Product, or Segment columns. Likewise, you can update formula to suite your specific business needs.



> **Tip**
>
> You can retain older functions, or add comments, using "//" inside the formula bar. This method can be more useful for more complex formulas, or to keep older functionality in case if you'd want to revert later.

Step 7: Miscellaneous changes such as branding, profile information, and reset

The sample app is complete with the expected functionality in this tutorial. However, extra considerations can be added—such as—the ability to reset the filter text input control, branding such as title for the gallery and app, and user profile details. You can also do more, start with Add, and configure controls in canvas apps.

The following table summarizes all the branding, profile, and reset information added to the sample app. Use the method described earlier in this article to work with different controls and properties. Ensure to replace the table, connector, and control names as appropriate.

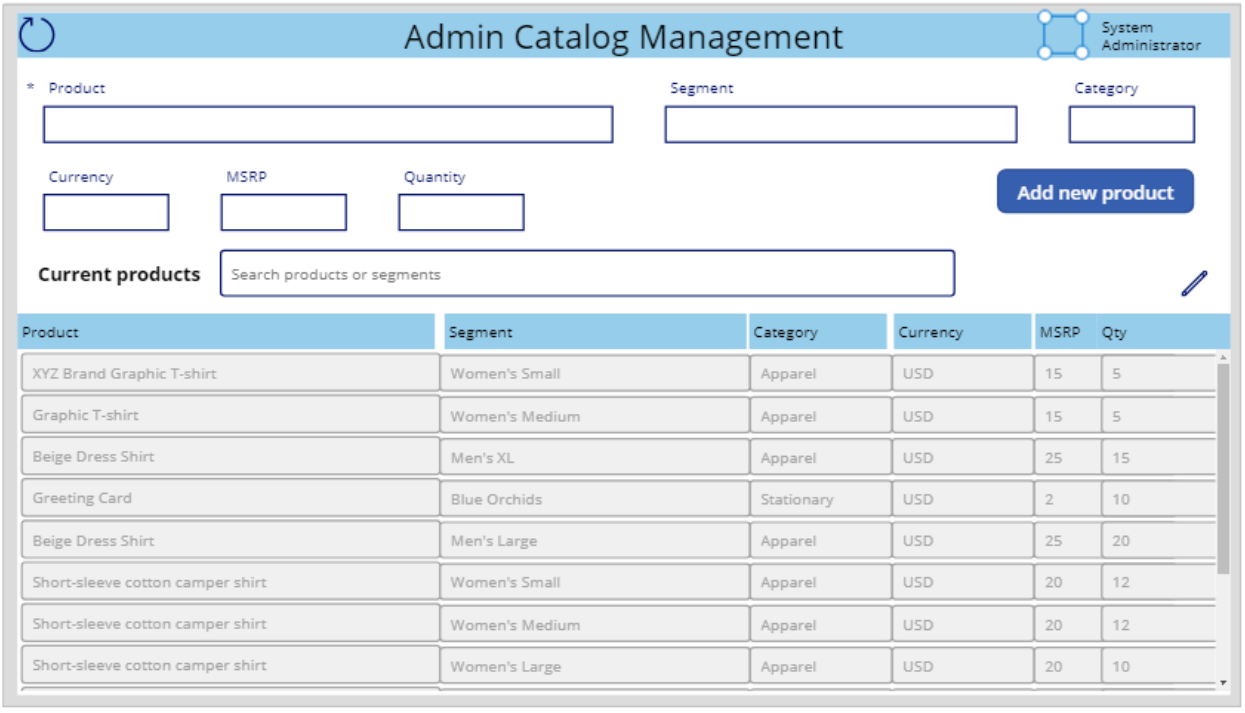
Expand table

Capability	Control	Properties	Additional information
App banner/label at the top of the screen	Text label	**Text** - "Admin Catalog Management" **Font size** - 28 **Fill color** - Blue **Text alignment** - Align center	Change all values as appropriate.
Add user display name to the	Text label	**Text** - `Office365Users.MyProfileV2().displayName`	Connect to Microsoft 365 first by

Capability	Control	Properties	Additional information
top-right side of the screen			adding a connection to Office 365 Users.
Add user profile photo on the left-side of the user display name on the top-right side of the screen	Image	**Image** - `Office365Users.UserPhotoV2(Office365Users.MyProfileV2().userPrincipalName)`	Connect to Microsoft 365 first by adding a connection to Office 365 Users.
Reset the search text box on the top-left corner of the screen	Icon of type "Reload"	**OnSelect** - `Reset(TextInput15)` where "TextInput15" is the text input control used as the search box.	When selected, it will reset the search text box resulting in the gallery to display all data by default.
Update text for **Add product** button	Add product button	**Text** - "Add new product"	Change as appropriate.
Add a label above the gallery, on the left-side of the search input box to signify current products	Text label	**Text** - "Current products" **Font size** - 16 **Font weight** - Bold	Change as appropriate.
Add hint text for search text input box	Text input	**Hint Text** - "Search products or segments"	Change as appropriate, and ensure the list of fields (such as Products, Segments) aligns with the column names in

Capability	Control	Properties	Additional information
			your data source.

For example, the completed screen looks like this with the controls and properties configured above:



Step 8: Save, publish and share

Now that you've completed the sample app, save, publish and share the app within your organization, or with guests.

Show, sort, and filter data in a canvas app gallery

Article • 12/16/2022

Create a gallery to show images and text about several products, and sort and filter that information.

In Power Apps, you can use a gallery to show several related items, just as you see in a catalog. Galleries are great for showing information about products, such as names and prices. In this topic, we create a gallery and sort and filter the information using Excel-like functions. Also, when an item is selected, a border is placed around the item.

> **Note**
>
> This topic uses a tablet app. You can use a phone app but you will need to resize some of the controls.

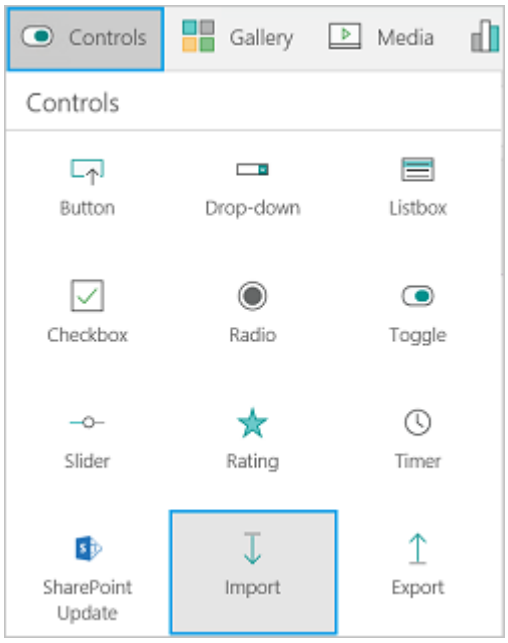
Prerequisites

- Sign up for Power Apps, and then sign in using the same credentials that you used to sign up.
- Create a tablet app from a template, from data, or from scratch.
- Learn how to configure a control.
- These steps use the CreateFirstApp as sample input data, which includes .jpg images. The zip file includes an XML file that can be converted to Excel. Otherwise, Power Apps automatically reads the files in the .zip files and imports it successfully. You can download and use this sample data, or import your own.

Show data in a gallery

1. Create a collection named **Inventory** using the sample data. Steps include:

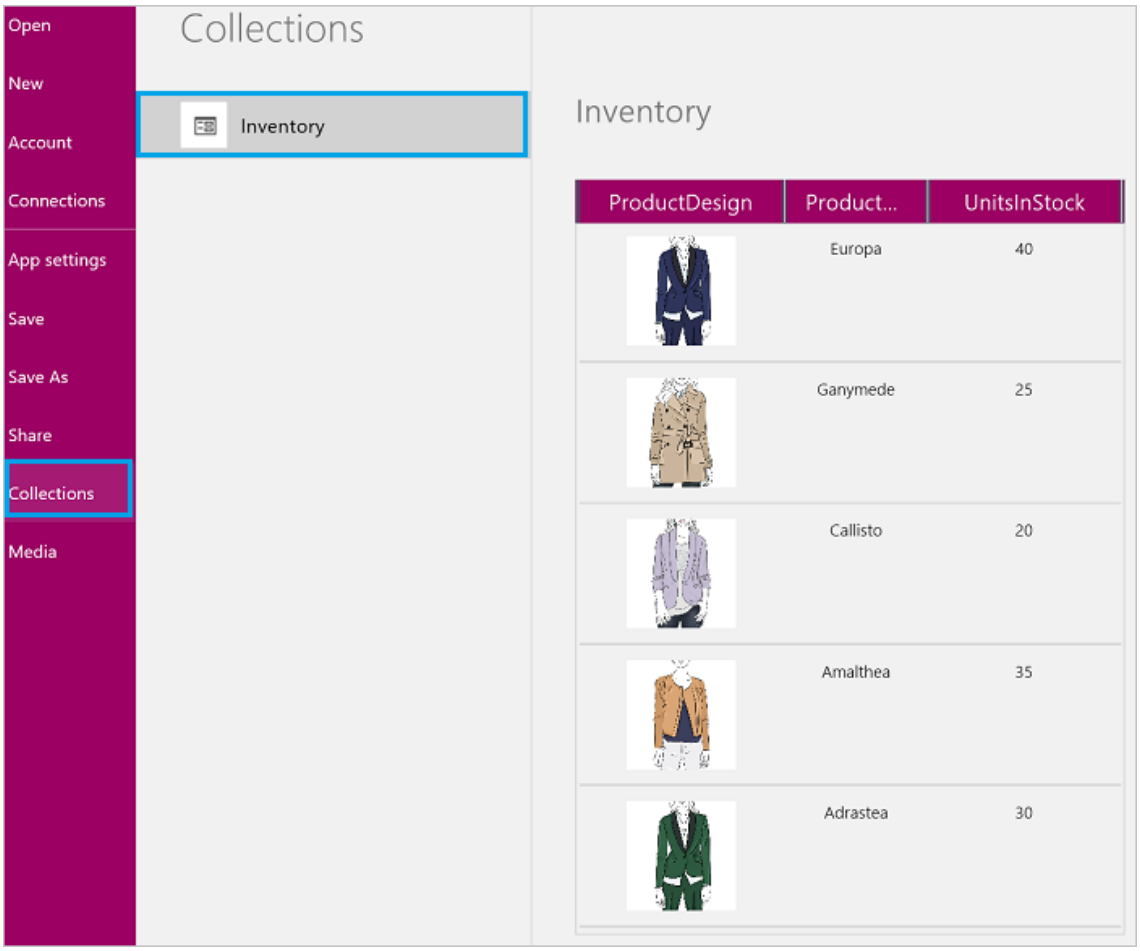
    a. On the **Insert** tab, select **Controls**, and then select **Import**:



b. Set the OnSelect property of the import control to the following formula: **Collect(Inventory, Import1.Data)**

c. Select the **Import Data** button to open Windows Explorer. Select *CreateFirstApp.zip*, and select **Open**.

d. In the **File** menu, select **Collections**. The Inventory collection is listed with the data you imported:

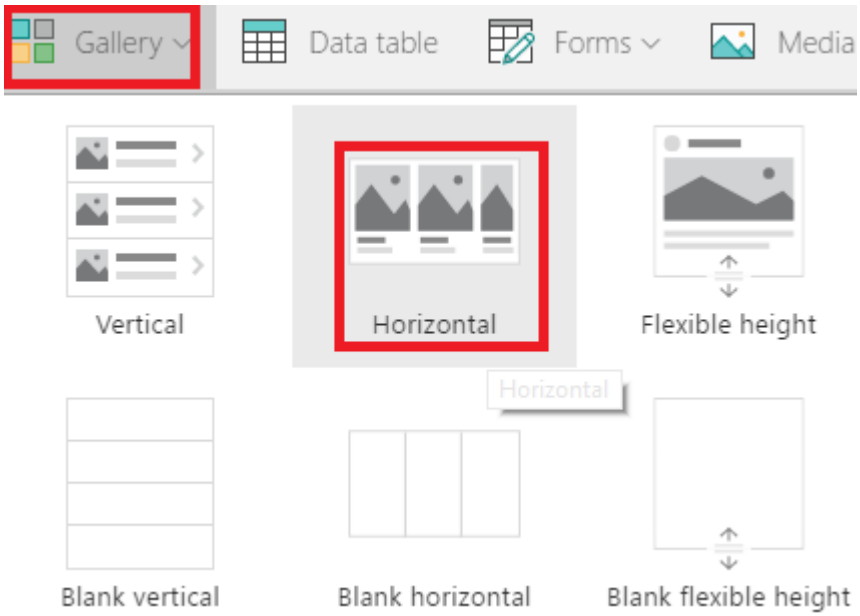


You've just created the Inventory collection, which contains information about five products, including a design image, the name of the product, and the number of units in stock.

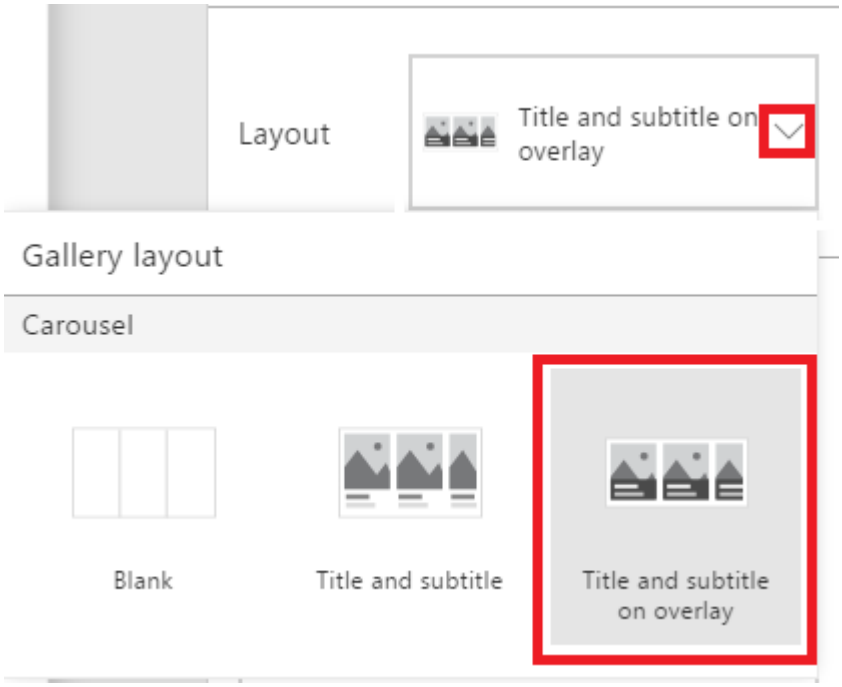
> ⓘ **Note**
>
> The import control is used to import Excel-like data and create the collection. The import control imports data when you are creating your app, and previewing your app. Currently, the import control does not import data when you publish your app.

2. Select the back arrow to return to the designer.

3. On the **Insert** tab, click or tap **Gallery**, and then click or tap the **Horizontal** gallery.

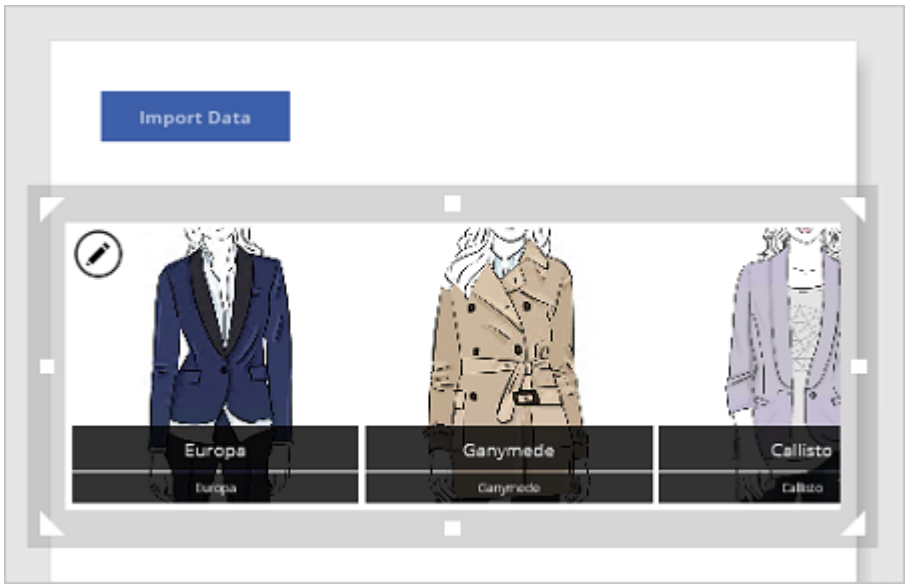


4. In the right-hand pane, click or tap the option in which the title and the subtitle overlay the graphic:

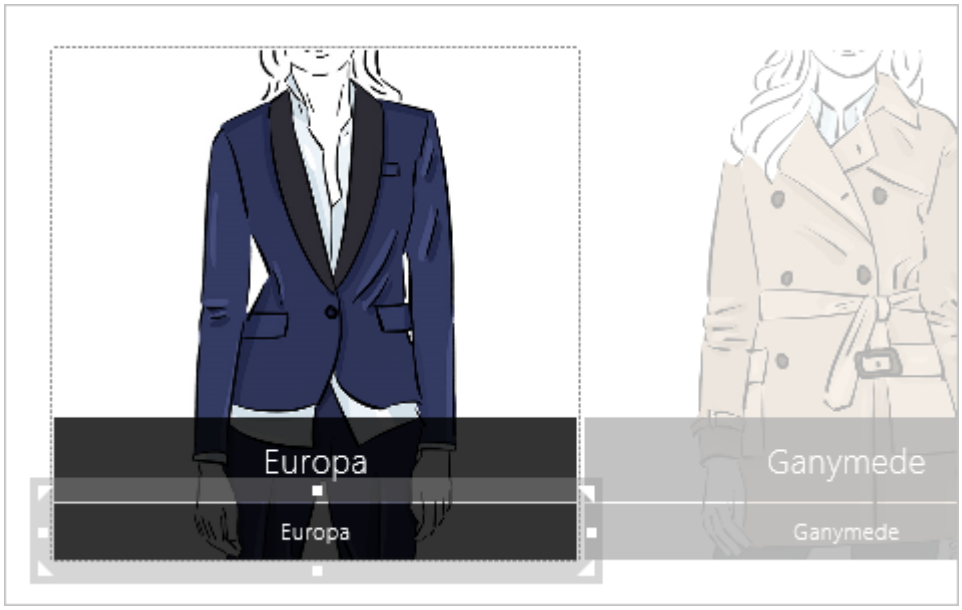


5. Set the Items property of the gallery to **Inventory**:

6. Rename the gallery to **ProductGallery**, and move the gallery so it doesn't block the other controls. Resize the gallery so it shows three products:



7. In the first item of the gallery, select the bottom label:



> **Note**
>
> When you change the first item in any gallery, you automatically change all other items in the gallery.

8. Set the **Text** property of the label to the following expression:
   ThisItem.UnitsInStock

   When you do this, the label shows the units in stock for each product:

> ⓘ **Note**
>
> By default, the Text property of the top label is set to `ThisItem.ProductName`. You can change it to any other item in your collection. For example, if your collection has *ProductDescription* or *Price* fields, you can set the label to `ThisItem.ProductDescription` or `ThisItem.Price`.

Using these steps, you imported data that includes .jpg images into a collection. You then added a gallery that displays the data and configured a label to show the units in stock for each product.

Highlight the gallery item you select

1. Select any item in the gallery *except* the first one. The edit icon displays (upper left corner). Select the edit icon:

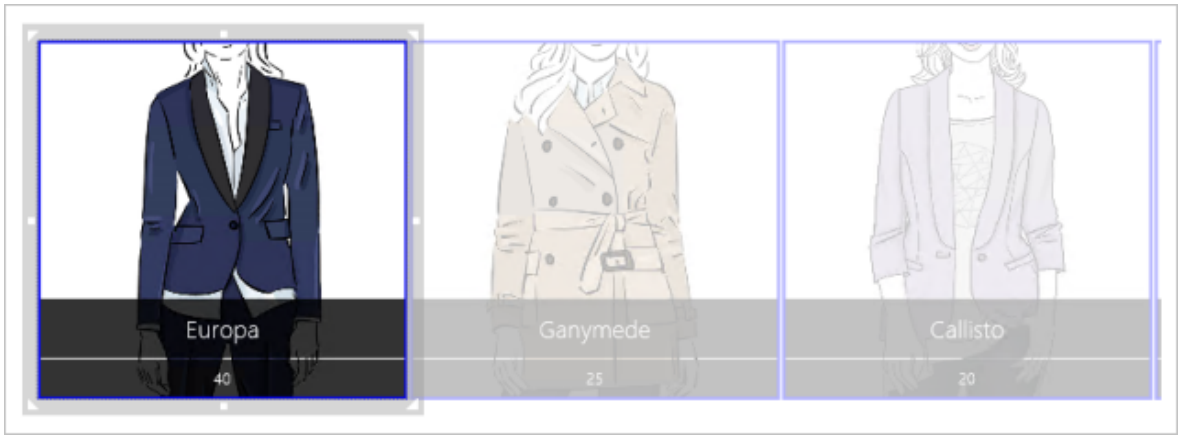
2. On the **Insert** tab, select **Shapes**, and then select the rectangle. A blue solid rectangle appears in each gallery item.

3. On the **Home** tab, select **Fill**, and then select **No Fill**.

4. Select **Border**, select **Border Style**, and then select the solid line.

5. Select **Border** again, and set the thickness to 3. Resize the rectangle so that it surrounds the gallery item. The items in your gallery now have a blue border and

should look similar to the following:



6. On the **Shape** tab, select **Visible**, and then enter the following formula in the Formula Bar:

   If(ThisItem.IsSelected, true)

   A blue rectangle surrounds the current selection in a gallery. Select a few gallery items to confirm that the rectangle appears around each item that you select.

   Remember, you can also open **Preview** to see and test what you're creating.

> **Tip**
>
> Select the rectangle, select **Reorder** on the **Home** tab, and then select **Send to Back**. Using this feature, you can select a gallery item without the border blocking anything.

Using these steps, you added a border around the current selection in the gallery.

Sort and filter items in the gallery

In these steps, we are going to sort the gallery items in ascending and descending order. Also, we'll add a slider control to 'filter' gallery items by the units in stock that you choose.

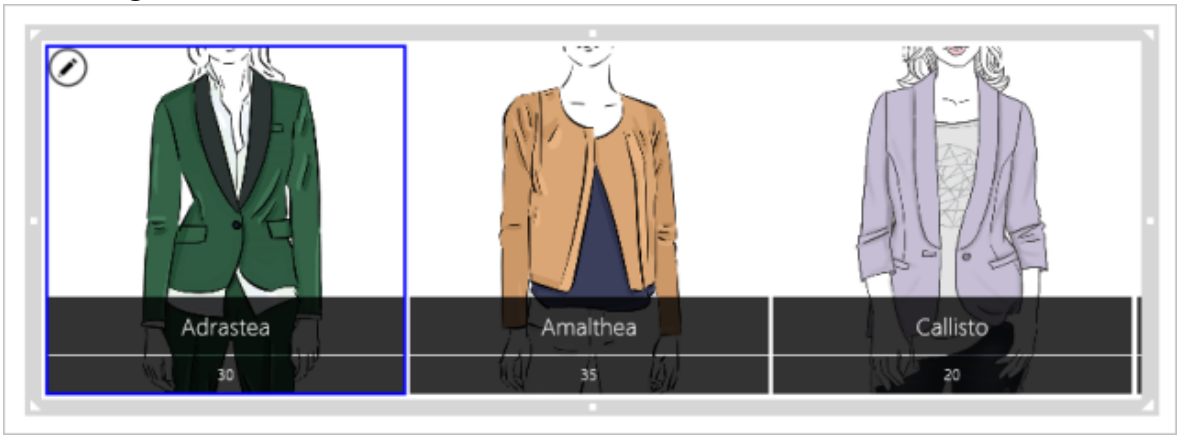
Sort in ascending or descending order

1. Select any item in the gallery *except* the first one.

2. The **Items** property is currently set to Inventory (the name of your collection). Change it to the following:

   Sort(Inventory, ProductName)

When you do this, the items in the gallery are sorted by the product name in ascending order:



Try descending order. Set the **Items** property of the gallery to the following formula:

Sort(Inventory, ProductName, Descending)

Add a slider control and filter items in the gallery

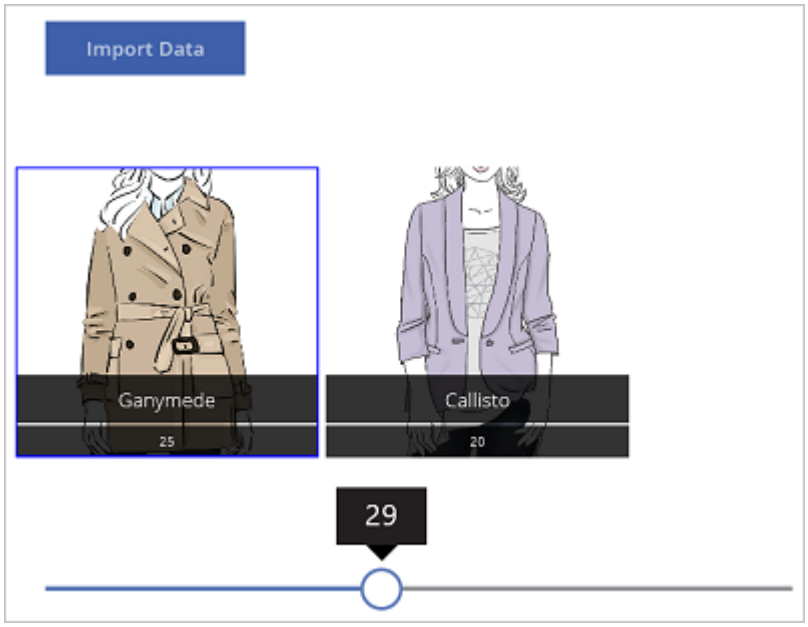
1. Add a Slider control (**Insert** tab > **Controls**), rename it to **StockFilter**, and move it under the gallery.

2. Configure the slider so that users can't set it to a value outside the range of units in stock:
   a. On the **Content** tab, select **Min**, and then enter the following expression:
   `Min(Inventory, UnitsInStock)`
   b. On the **Content** tab, select **Max**, and then enter the following expression:
   `Max(Inventory, UnitsInStock)`

3. Select any item in the gallery *except* the first one. Set the **Items** property of the gallery to the following expression:
   `Filter(Inventory, UnitsInStock<=StockFilter.Value)`

4. In **Preview**, adjust the slider to a value that's between the highest and the lowest quantity in the gallery. As you adjust the slider, the gallery shows only those

products that are less than the value you choose:



Now, let's add to our filter:

1. Go back to the designer.
2. On the **Insert** tab, select **Text**, select **Input Text**, and rename the new control to **NameFilter**. Move the text control below the slider.
3. Set the **Items** property of the gallery to the following expression:
   `Filter(Inventory, UnitsInStock<=StockFilter.Value && NameFilter.Text in ProductName)`
4. In **Preview**, set the slider to *30*, and type the letter *g* in the text-input control. The gallery shows the only product with less than 30 units in stock *and* has a name with the letter "g":

Tips and Tricks

- At anytime, you can select the preview button () to see what you created and test it.
- When designing your app, you can re-size the controls and move them around using click-and-drag.
- Press **ESC** or select the **X** to close the preview window.
- When using a gallery, select the first item in the gallery to change all items in the gallery. For example, select the first item to add a border to all items in the gallery.
- To update the properties of the gallery, select any item in the gallery *except* the first one. For example, select the second item to update the *Items*, *ShowScrollbar*, and other properties that apply to the gallery (not the items in the gallery).

What you learned

In this topic, you:

- Created a collection, imported data that includes .jpg images into that collection, and showed the data in a gallery.
- Under each image in the gallery, configured a label that lists the units in stock for that item.
- Added a border around the item that you select.
- Sorted the items by product name in ascending and descending order.
- Added a slider and an input text control to filter the products by units in stock and product name.

Use modern themes in canvas apps

Modern themes are preestablished style sets that transform the look of your canvas app in Power Apps. These themes, based on Microsoft's Fluent design language, modify various style aspects such as color, typography, borders, and shadows, ensuring a visually pleasing interface that streamlines app development.

Modern themes enable makers to effortlessly design apps with unified and consistent visual appeal, reducing customization time while maintaining professional aesthetics.

Prerequisites

Enable the modern themes feature in the settings of an app:

1. Open your app or create a new app.
2. From your app, open **Settings** from the app authoring menu or modern command bar.
3. Go to **Updates** > **New** > **Modern controls and themes**.
4. Set the **Modern controls and themes** toggle to **On**.
5. Close the **Settings** popup.

For more information, see Enable modern controls and themes for your app.

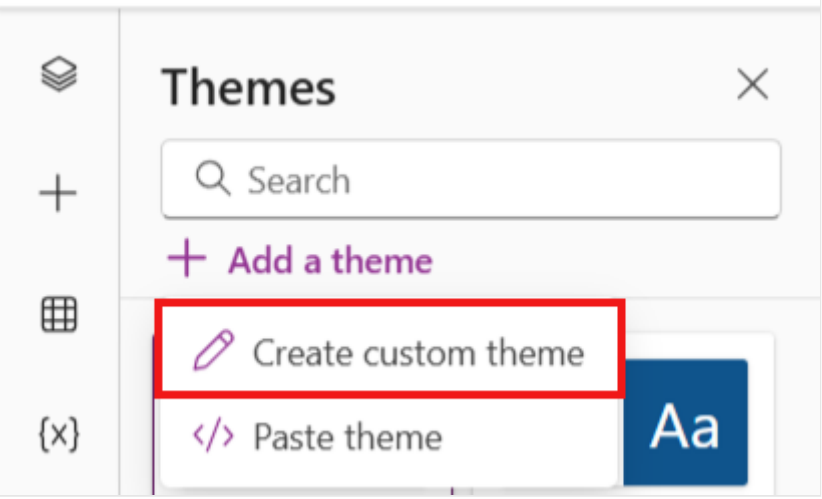
> **Note**
>
> When you enable modern controls and themes, you can't select classic themes from the command bar. To use *retired* classic themes, go to **Retired** > **Keep classic themes** in **Updates** and toggle it to **On**.

Create a theme

Use the available themes to style your app. Or, design your own theme for a more personalized visual aesthetic. You can also paste a theme from YAML format.

1. On the app authoring menu, select **Themes**.
2. On the **Themes** pane, select **Add a theme**.
3. Select **Create custom theme** to design a new theme, or select **Paste theme** to import a theme from YAML format. For more information about pasting themes, see Copy and paste themes.

   The **Create a theme** dialog appears.

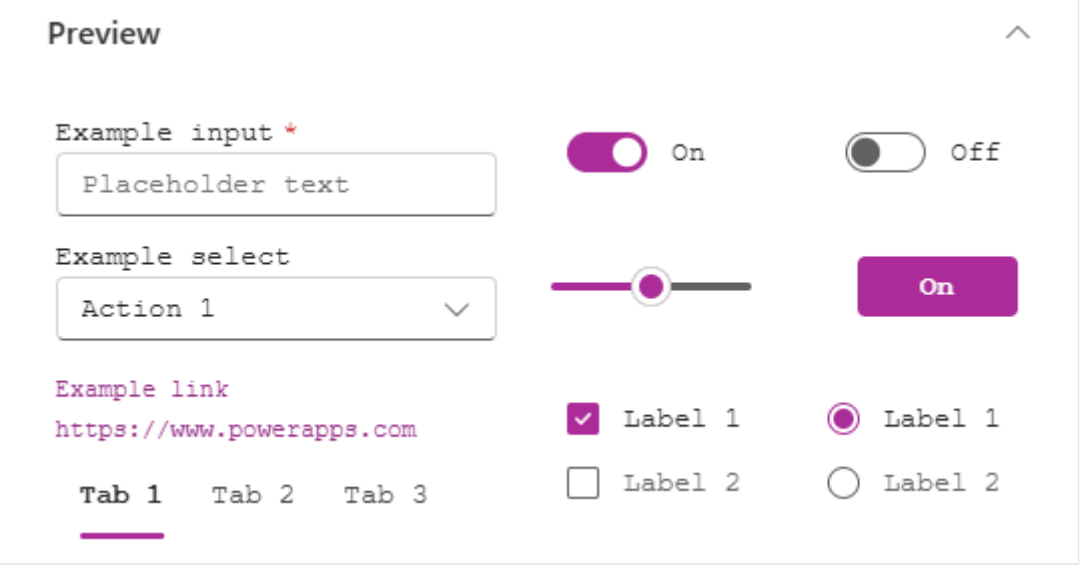


4. In the **Create a theme** dialog, choose or enter the following information:

Expand table

Feature	Action or description
Primary (seed) color	Choose a color from the color picker. You can, alternatively, enter the hexadecimal or RGB manually.
Lock primary color (preview)	The 16-slot theme palette is generated using the seed color. - Toggled off: The 16-slot palette is optimized for accessibility. Toggled off is the default option. - Toggled on: The seed color is placed in the primary (middle) slot of the palette. The remaining colors are generated by making the colors incrementally lighter on one side and darker on the other side. The generated palette might not meet contrast ratio accessibility requirements.
Theme name	Enter a unique theme name.
Font	Choose your default font used by the controls in the app.
Torsion	Impacts the tint, shade, or tone of the palette. Torsion isn't applicable if you choose **Lock primary color**.
Vibrancy	Impacts the muteness or brightness of the palette. Vibrancy isn't applicable if you choose **Lock primary color**.
Palette overrides	Override the color used for one or more slots in the palette by selecting a slot and choosing a new color. Select **Reset** to return to the generated value for that slot.

You can also look at a static preview of your new theme. Interact with the sample controls to see how your theme is applied to the rest state and various interaction states.



5. Select **Create**. Your new theme is created and applied to your app.

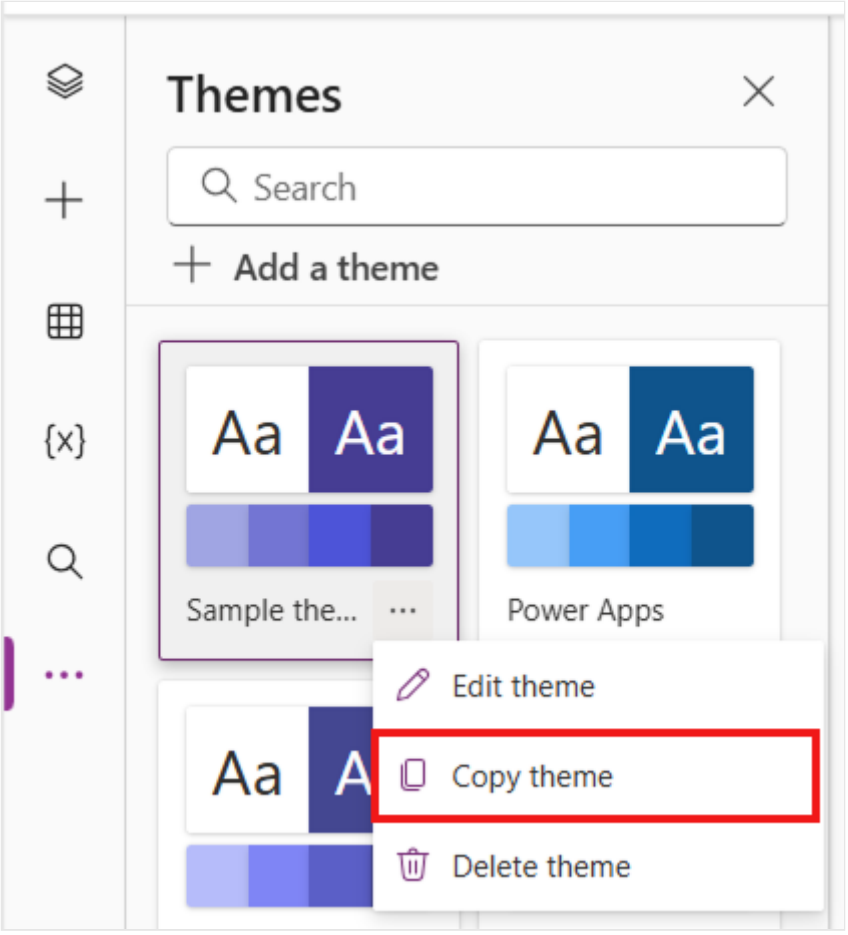
Copy and paste themes

You can copy and paste themes in YAML format to duplicate themes within your app or share them across different apps. This approach makes it easy to maintain consistent branding across multiple applications or back up your custom theme configurations.

Copy a theme

To copy a theme's YAML definition:

1. On the app authoring menu, select **Themes**.
2. On the **Themes** pane, locate the theme you want to copy.
3. Select the **More options** (...) button on the theme card, and then select **Copy theme**.

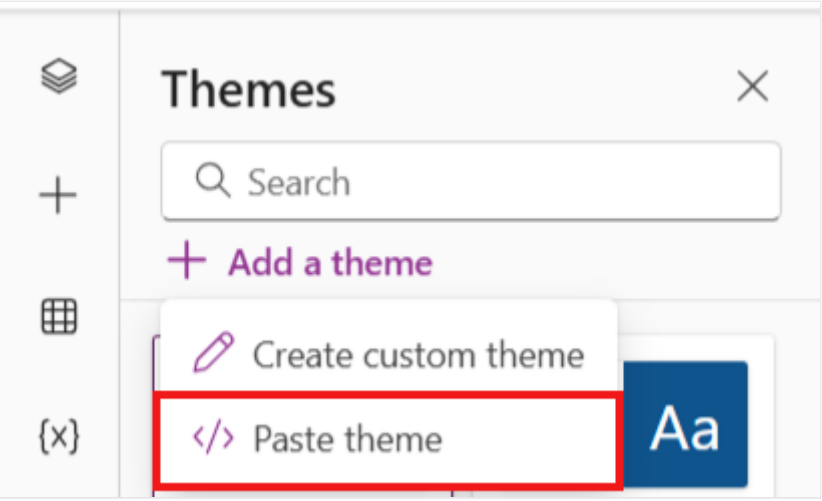


The theme definition is copied to your clipboard in YAML format.

Paste a theme

To paste a theme from YAML:

1. Copy a valid theme YAML definition to your clipboard.
2. On the app authoring menu, select **Themes**.
3. On the **Themes** pane, select **Add a theme**.
4. Select **Paste theme**.



The new theme is created and appears in your themes list with the name specified in the YAML. If a theme with the same name already exists, the pasted theme is automatically renamed to avoid conflicts.

YAML format

Theme definitions use the following YAML structure:

YAML

```yaml
Themes:
  Theme Name:
    Font: "'Segoe UI', 'Open Sans', sans-serif"
    BasePaletteColor: '#2e4bf0'
    HueTorsion: -27
    Vibrancy: -52
    ColorOverrides:
      Lighter30: '#bd3535'
      Darker10: '#1a2d8f'
```

The following table describes each property in the YAML format:

Expand table

Property	Description	Required
Theme Name	The display name for your theme. Must be unique within the app.	Yes
Font	CSS font family specification. Use standard web font names.	Yes
BasePaletteColor	The seed color for palette generation in hex format (for example, '#2e4bf0'). This color determines the base for all 16 color slots.	Yes
HueTorsion	Adjusts the hue rotation of generated colors. Range: -100 to 100. Negative values shift toward cooler tones, positive values toward warmer	Yes

Property	Description	Required
	tones.	
Vibrancy	Adjusts the saturation and brightness. Range: -100 to 100. Negative values create more muted colors, positive values create more vibrant colors.	Yes
ColorOverrides	Optional overrides for individual color slots (Lighter30, Lighter20, Lighter10, Base, Darker10, Darker20, Darker30, Darker40). Specify only the colors you want to customize.	No

Example: Share a corporate brand theme

This example shows a theme configured with corporate brand colors:

YAML

```yaml
Themes:
  Corporate Brand:
    Font: "'Segoe UI', 'Open Sans', sans-serif"
    BasePaletteColor: '#0078d4'
    HueTorsion: 0
    Vibrancy: 10
    ColorOverrides:
      Base: '#0078d4'
      Darker10: '#106ebe'
      Darker20: '#005a9e'
      Lighter10: '#2b88d8'
      Lighter20: '#c7e0f4'
```

To use this theme in another app:

1. Copy the YAML code.
2. Open the target app in Power Apps Studio.
3. In the **Themes** panel, select **Add a theme** > **Paste theme**.

The Corporate Brand theme is now available in your app.

Tips for using copy and paste with themes

- **Save themes externally**: Copy and save your custom themes to a text file or documentation system for backup and version control.
- **Share across teams**: Share theme YAML definitions with team members to ensure consistent branding across multiple apps.
- **Duplicate and modify**: To create theme variations, copy an existing theme, paste it, then modify the YAML properties rather than starting from scratch.

- **Font availability**: When pasting themes across apps or organizations, ensure the specified font families are available and properly licensed.
- **Minimal overrides**: For easier maintenance, only specify `ColorOverrides` for colors that must differ from the generated palette. Let the `BasePaletteColor`, `HueTorsion`, and `Vibrancy` properties handle the rest.
- **Test accessibility**: After pasting a theme, test it on both desktop and mobile views to ensure color contrast and readability meet accessibility standards (WCAG 2.1 AA minimum).

Apply modern theme

1. On the app authoring menu, select **Themes**.
2. On the **Themes** pane, select one of the default themes.
3. If you have classic controls in your app, you're prompted to apply the modern theme to these controls. You can always select **Undo** from the command bar if you don't like the theme.

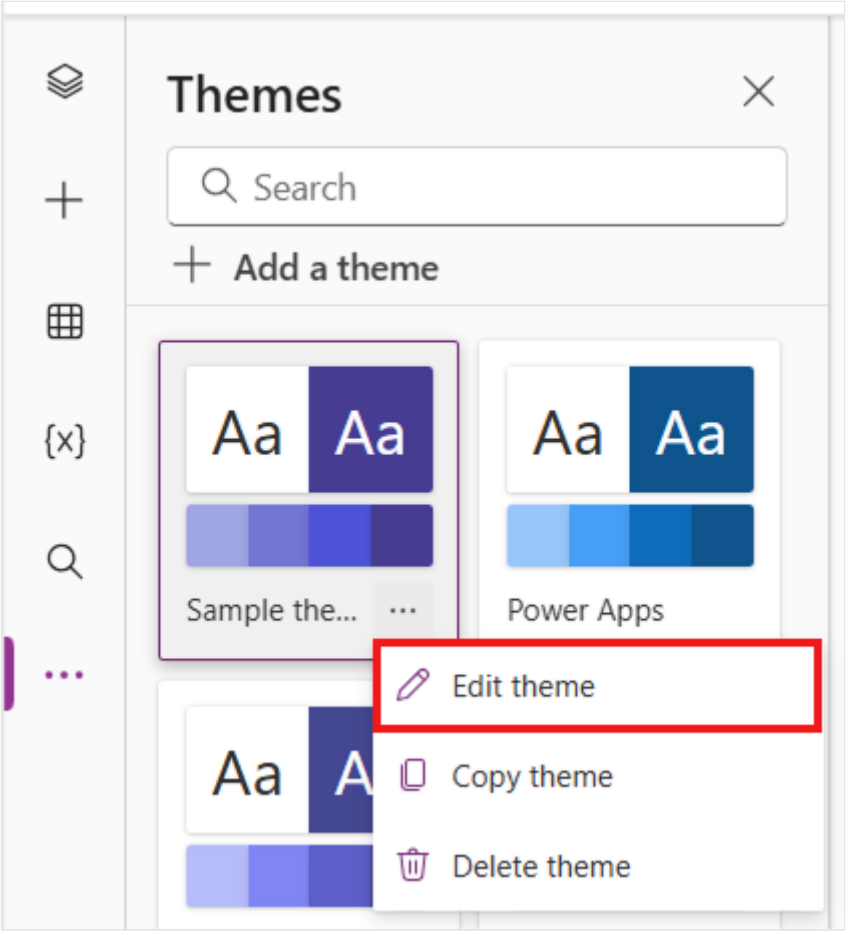
   > **Note**
   >
   > When you choose to apply modern themes to classic controls, Power Fx formulas are set on properties of the impacted controls that reference variables from the modern theme. Visually, classic controls might not align exactly with their modern control counterparts, as the classic controls aren't based on Fluent v9.

When you select a modern theme, the style of the theme automatically applies to the controls in your app. This action sets the **App.Theme** property.

Edit a theme

You can edit a theme and change one or more parameters of the custom theme.

1. On the app authoring menu, select **Themes**.
2. On the **Themes** pane, find the tile of the theme you want to edit. Select the overflow menu and then select **Edit**.



3. On the **Edit theme** pane, adjust the theme as needed.
4. Select **Save** or cancel out of the dialog.

> **Note**
>
> You can't edit default themes. Changes that you make through the visual theme editor update the underlying YAML properties. If you copy, modify, and re-paste a theme's YAML, those changes appear in the visual editor and anywhere the theme is applied.

Delete a theme

If you no longer need a custom theme in your app, you can delete it.

1. On the app authoring menu, select **Themes**.
2. On the **Themes** pane, find the theme that you want to delete, select the overflow menu, and then select **Delete**.
3. On the confirmation dialog box, select **Delete theme**.

If your app has any Power Fx formulas that reference this theme, you need to manually update the formula.

> **Note**
>
> You can't delete built-in themes.

> **Tip**
>
> Before deleting a custom theme, consider copying its YAML definition for backup. You can easily restore the theme later by pasting the YAML.

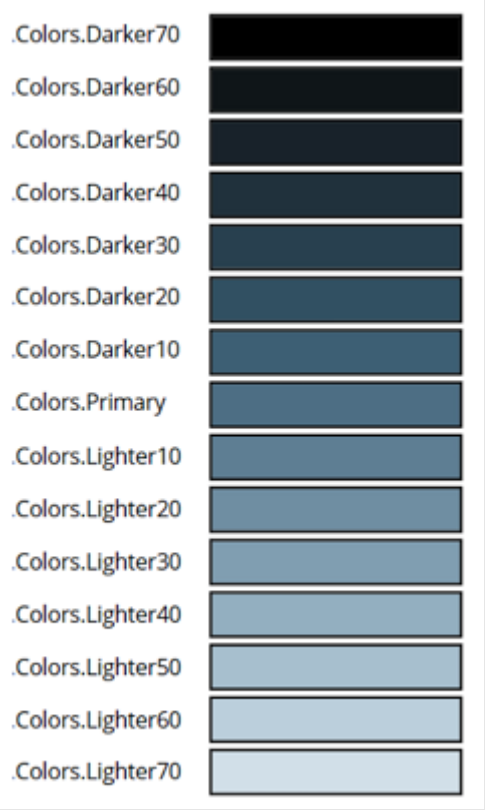
Use themes with Power Fx

Makers can use modern theme objects through Power Fx. Reference the currently active theme object by using **App.Theme**. Reference any theme loaded into the app by its instance name, such as **RedTheme**. To ensure that the color selections adapt to theme changes, reference the theme object by using **App.Theme**.

Each theme object includes the following information:

- **Name** of the theme
- **Colors**, a 16-color brand ramp collection that you can access individually by name; **Primary foreground color** is the default text color, such as the color of text on a background
- **Font** used in the theme

The following image shows the slot variables inside the **Colors** collection and, as an example, the corresponding colors for the **Steel** theme.



By using the theme brand ramp, you can manually style a classic control based on the current modern theme. For example, set `Button.Fill = App.Theme.Colors.Primary`.

Overview of modern controls and themes in canvas apps

Summarize this article for me

Canvas apps now support modern controls and theming based on the Microsoft Fluent 2 design system. Modern controls offer improved accessibility, performance, and usability compared to classic controls. The accompanying theming system lets you customize your app's appearance from a central location.

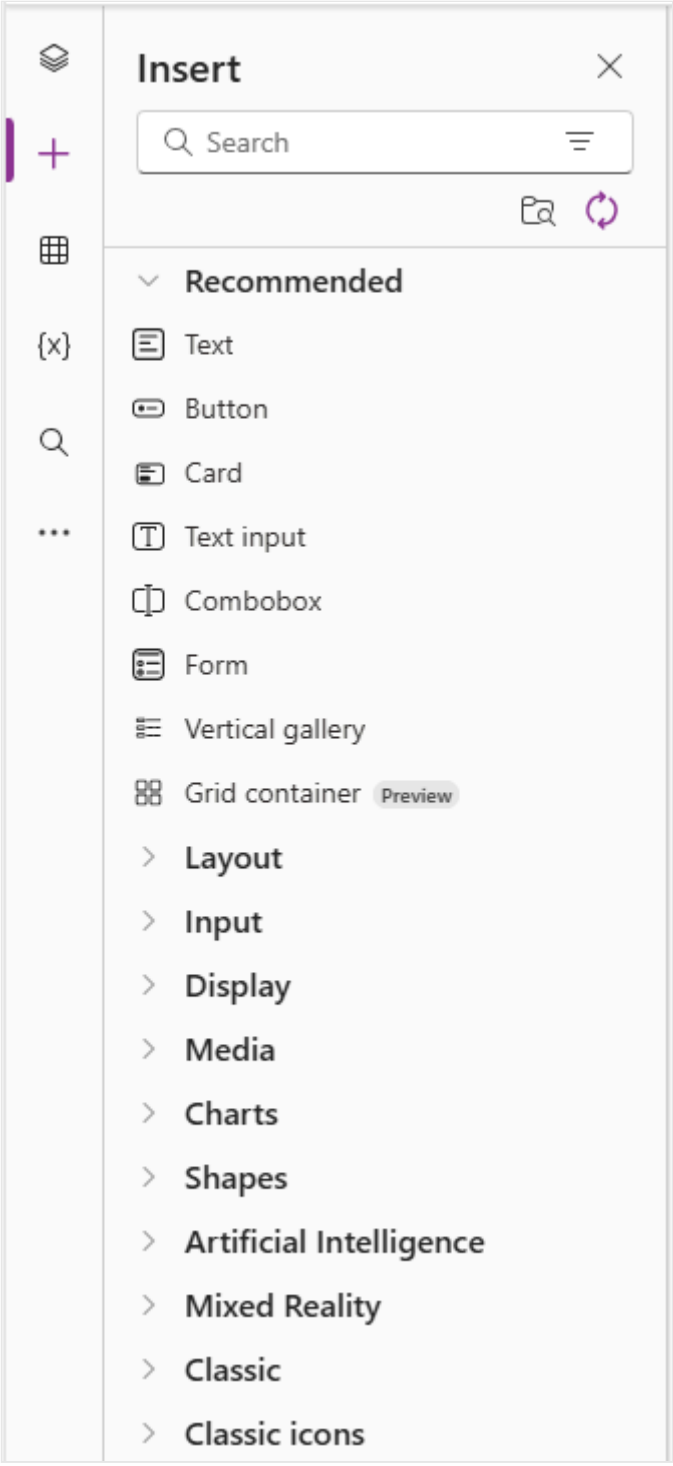
This article explains how to enable modern controls and themes in your canvas apps and provides information about ongoing development.

Enable modern controls and themes for your app

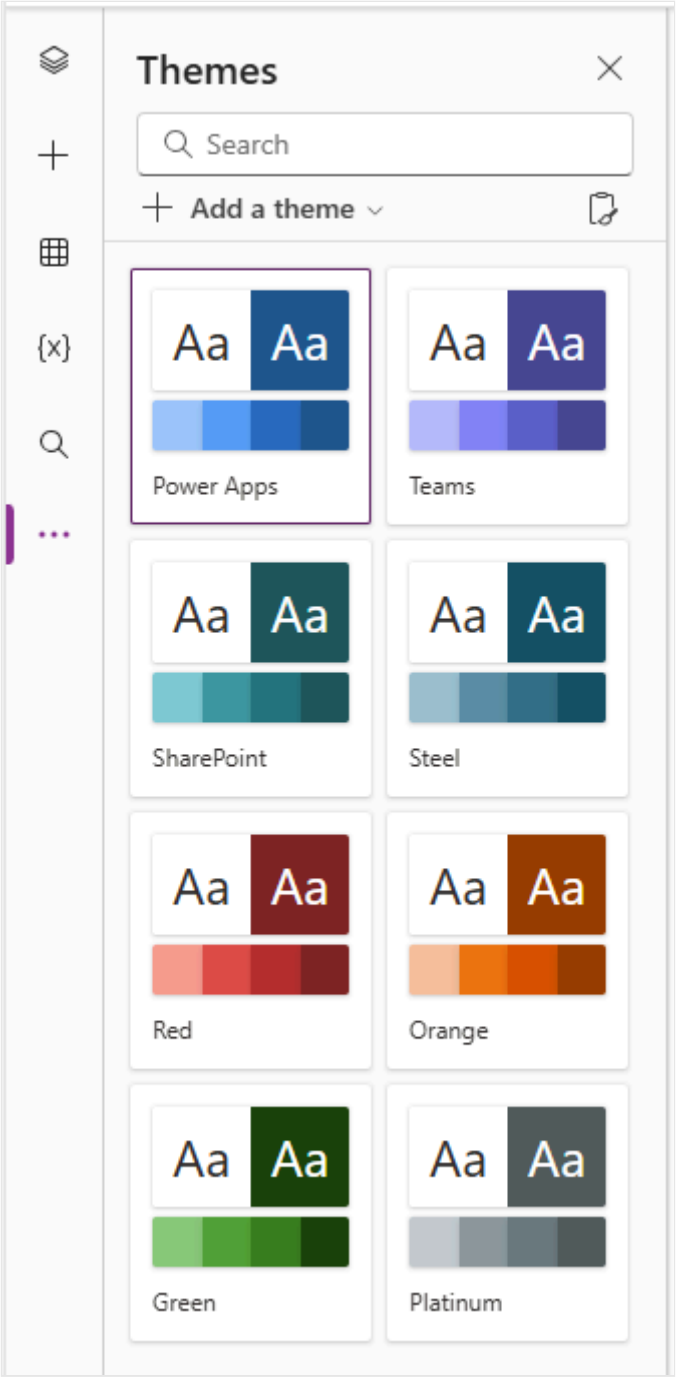
With your canvas app open for editing:

1. On the command bar, select **Settings** > **Updates**.
2. Select the **New** tab and then turn on **Modern controls and themes**.

- The app refreshes with the new app authoring menu. Modern controls are part of existing categories. Two additional categories exist for legacy controls - Classic and Classic icons.



- To see modern themes, on the app authoring menu, select **Themes**. For information, see Use modern themes in canvas apps.



What's next for these controls and themes?

The Power Apps team is consistently improving and adding new capabilities for modern controls and themes. They publish updates to the Power Apps blog every month on the progress made for modern controls.

Provide feedback to Microsoft

To provide feedback, offer suggestions, or report problems, go to the community forum.

You can also provide feedback for individual controls in the Power Apps Studio from the control properties by selecting the thumbs up or down and comments option. The same

feedback mechanism is available for modern themes in the **Themes** pane.

Modern controls and properties in canvas apps

Modern controls in Power Apps provide an enhanced user experience with updated styling, improved accessibility, and better performance compared to classic controls. These controls follow Microsoft's Fluent Design System and offer a consistent, professional appearance across your canvas apps.

This reference guide covers the available modern controls and their properties. Each control serves a specific purpose - from basic interactions like buttons and text inputs to advanced features like Copilot integration and data visualization. Use these controls to build intuitive, accessible applications that align with modern design standards.

Before implementing modern controls in your app, review the overview of modern controls to understand key concepts and best practices.

Modern controls

Avatar – A control that shows a graphic representation of a user, team, or entity.

Badge – A badge is a visual decoration for UI elements.

Button – Interact with the app by clicking or tapping.

Card (preview) - Cards help makers create clean, responsive object summaries such as contact tiles, document previews, or product listings in either horizontal or vertical orientation.

Checkbox - Select or clear an option to specify **true** or **false**.

Combobox - A control that users can use to make selections from provided choices and supports search and multiple selections.

Copilot answer (preview) - A control that makers can use to add predefined questions that end users can use to get generated answers.

Data Grid (preview) - A control that displays records from a data source in a scrollable, sortable, and searchable grid.

Date picker - A control that the user can select to specify a date.

Dropdown (preview) – Select a value from the list of items.

Header – A control that creates a modern app header.

Info button – Use this control to provide additional information to users.

Link – Open hyperlinks in new tab.

Number input - A number input control the user can modify.

Progress bar – Displays the progress, can be configured as determinate showcasing exact progress or indeterminate for ongoing progress.

Radio group – An input control that shows multiple options, of which users can select only one at a time.

Spinner – Displays state in motion, for example, loading a page or table.

Slider - A control with which the user can specify a value by dragging a handle.

Stream (preview) - A control that lets you add Steam videos in your app.

Table (preview) – A control that shows a set of data in a tabular or list format.

Tabs or tab list – Select a tab to move screens or take action on app.

Text – Display text on the app, can also be used as label for fields.

Text input – A box in which the user can type text, numbers, and other data.

Toggle – A control that the user can turn on or off by moving the handle.

Rename controls in canvas apps with Copilot (preview)

05/30/2025

[This article is prerelease documentation and is subject to change.]

Canvas apps often have many controls, so it's important to give them meaningful names for easier maintenance and collaboration. With the new **Proactive control rename** feature, Copilot suggests names for controls. Makers review the suggestions and apply changes to multiple controls at once. When a control's name is updated, the change appears across all its references.

Currently, the most frequently renamed and supported controls are:

- Labels
- Buttons

Additional support for more controls will be incorporated based on feedback from preview.

> **Important**
>
> - This is a preview feature.
> - This feature is available in English only.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so customers can get early access and provide feedback.

Prerequisites

Make sure you meet the prerequisites and region availability in Copilot in Power Apps overview (preview).

By default, the **Proactive control rename** setting is on for new apps.

To use this feature for an existing app, follow these steps:

1. Open your canvas app for editing in Power Apps Studio. On the command bar, select **Settings** > **Updates**.
2. On the **Preview** tab, find and turn on the **Proactive control rename** setting.

3. On the **New** tab, find and turn on the **New analysis engine** setting.

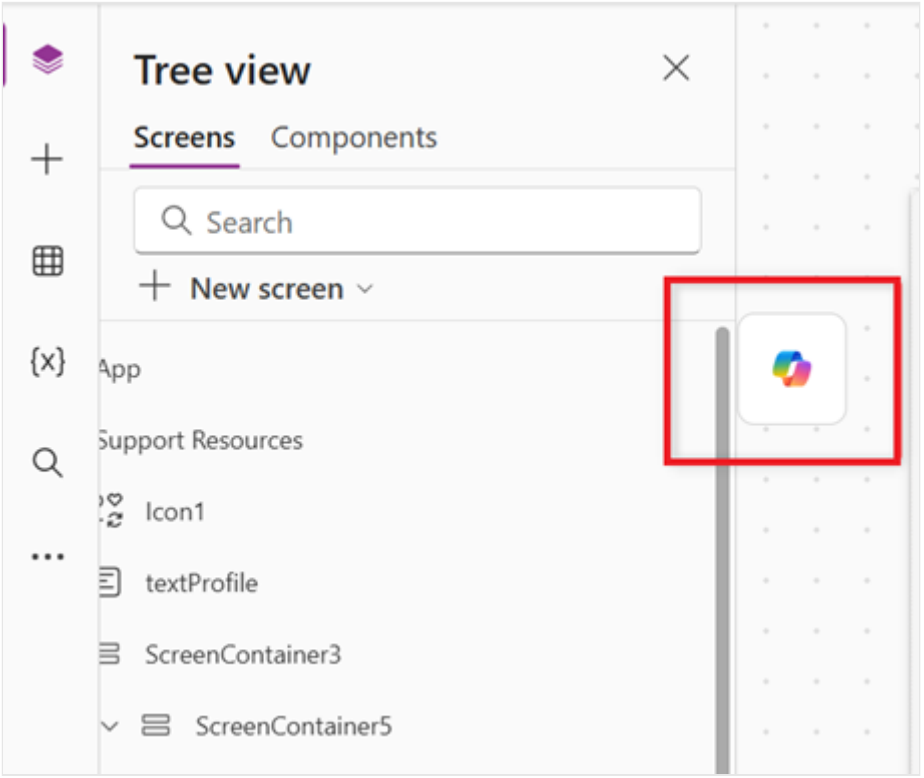
Rename controls

When you rename a control like the **Button** control, Copilot suggests names for other **Button** controls that have similar properties.

1. Open your canvas app for editing in Power Apps Studio.
2. In the **Tree view**, select a control, and then select **More options** (...).
3. Select **Rename**, type a new name for the control, and then press Enter.

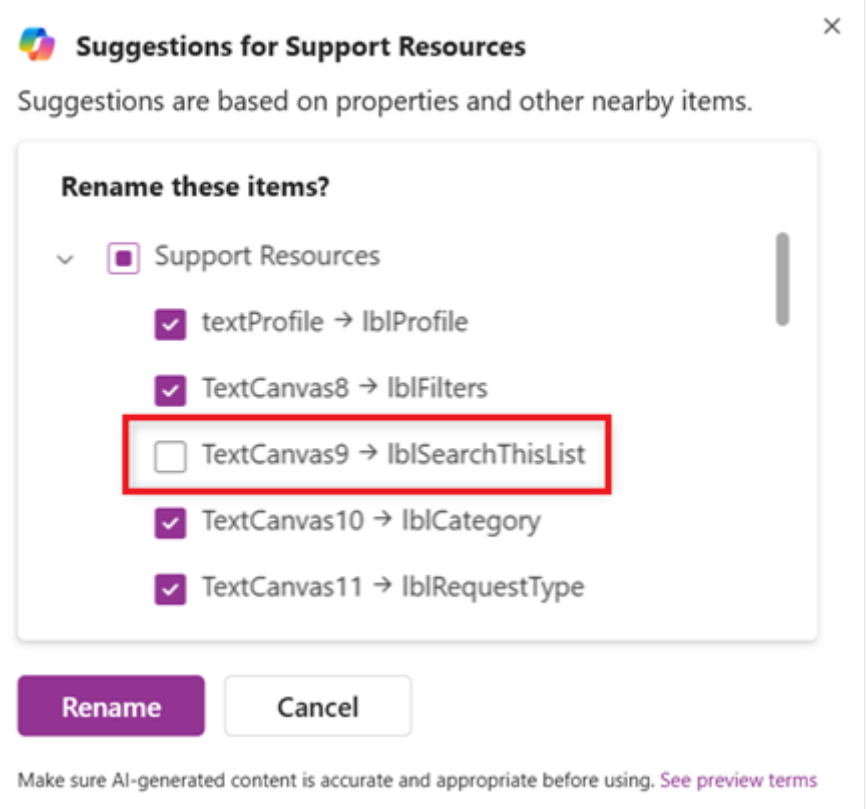
> **Note**
>
> When you manually rename a control, Copilot only appears if there are other controls on the same screen that can be renamed.

4. Copilot appears with suggestions to rename other controls of the same type.



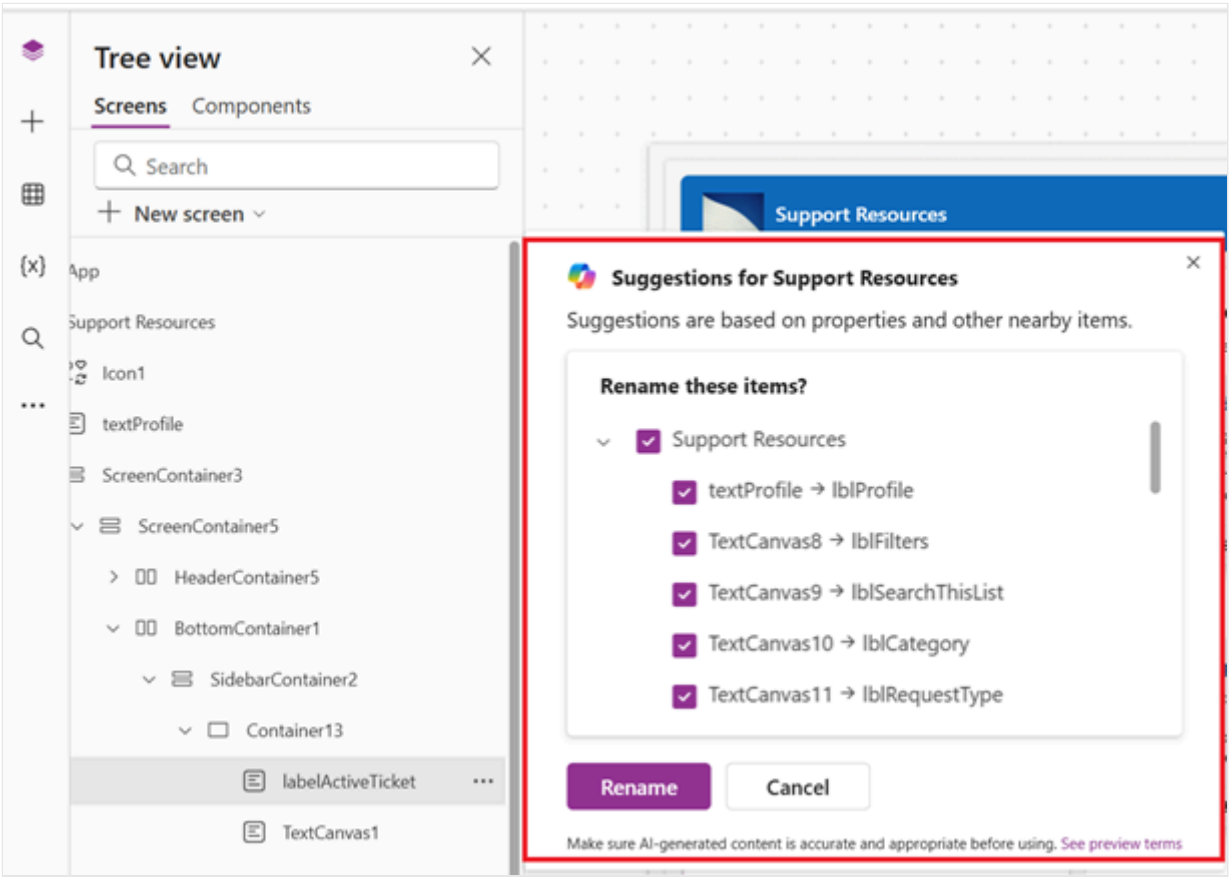
5. Select **View Suggestions**.

6. Review the suggested names, and clear any item that you don't want to rename.



7. When you're done, select **Rename** to apply the changes.

   If a formula references a control, the control name is automatically updated in the formula.



Best practices and recommendations

To get the best results from Copilot, use this feature after you set the **Text** property of a control. For example, Copilot doesn't suggest names for a button with the default Text property value **Button** or an invalid **Text** property value like **If()**.

If you still don't get the results you want, send us your feedback.

When you manually rename a control, use standard, relevant names and naming patterns so Copilot can reference them when suggesting renames. Avoid special characters and spaces. For example, renaming a **Button** to **collectResponse** gives better renaming suggestions for other buttons than using a name like **collect_1**.

Limitations

- Only the **Label** and **Button** controls are supported.
- When you rename a label manually, Copilot appears only if there are other labels under the same screen that can be renamed.
- Only controls with a valid **Text** property are considered for renaming by Copilot.
- The **Text** property can be a **Text** literal or a formula returning **Text** type.
- Only controls with nondefault **Text** property are considered for renaming. For example, the **Text** property value can't be the default value, such as **Button** or **Text**.

Recent updates to modern controls in canvas apps

Starting February 2026, modern controls in canvas apps have updated versions with new property names, enum-based values, and behavior changes. This article explains what changed and how to update your existing apps.

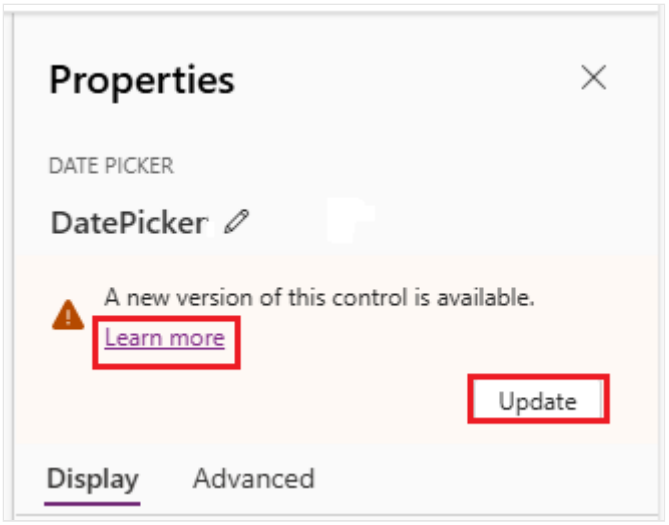
> **Important**
>
> These updates might require you to update formulas in your existing apps. Before you update any control, review the update guide for that control and fix any affected formulas.

Why update?

- **Better performance** — Events like OnChange fire less often, reducing unnecessary recalculations.
- **Better mobile experience** — Controls use touch-friendly sizes and font defaults on mobile layouts.
- **More styling options** — Separate corner radius properties and new border styles give you more design control.
- **IntelliSense and validation** — Enum-based values replace plain strings, so you get autocomplete and compile-time checks in your formulas.

Find and update controls in your app

When you open an app that uses an older version of a modern control, you see a notification on the control. The notification tells you that an update is available, and includes a **Learn more** link and an **Update** button.



Steps to update a control

1. Select **Learn more** to open the update guide for that control.
2. Review property renames, enum changes, and behavior differences listed in the guide.
3. Find formulas in your app that use renamed or removed properties, and update them.
4. Select **Update** to upgrade the control to the new version.
5. Test your app to make sure everything works as expected.

> **Tip**
>
> The **Update** button might not appear for all controls right away. Check back if you don't see it yet.

Controls with available updates

The following table lists each control that has an updated version, with a link to its specific update guide and a summary of what changed.

Expand table

Control	Update guide	Key changes
Text	Updates to Text control	Nine property renames, enum values, new OnSelect event, DisplayMode removed
Number Input	Updates to Number Input	OnChange on blur plus step clicks, TriggerOutput removed, new styling properties
Date Picker	Updates to Date Picker	View mode fixed, format honored, DateTimeZone respected, gallery crash fixed

Control	Update guide	Key changes
Text Input	Updates to Text Input	OnChange on focus out only, TriggerOutput default = Keypress, View mode truly read-only
Tab List	Updates to Tab List	New Appearance property, item order preserved, Items auto-refresh
Combo Box	Updates to Combo Box	SelectMultiple default = true, toggle to unselect, OnChange fires on every selection
Radio	Updates to Radio	Item order preserved, View mode read-only (not disabled), new styling properties
Link	Updates to Link	URL security validation (XSS protection), FontWeight fix, Wrap fix
Info Button	Updates to Info Button	Content flyout expansion fixed, click reliability improved, AcceptsFocus removed
Button	Updates to Button	Six property renames, enum values for Appearance/Layout/IconStyle, new Tooltip and border properties, AcceptsFocus removed
Dropdown	Updates to Dropdown control	Fluent-themed flyout on desktop, DefaultSelectedItems renamed to Default, FontSize renamed to Size, enum format changes
Icon	Updates to Icon control	OnSelect support, TabIndex removed, Style renamed to IconStyle, new border and padding properties
Slider	Updates to Slider	Value renamed to Default, Layout renamed to LayoutDirection, enum values for Size and LayoutDirection, new Tooltip property

Property changes across modern controls

This section covers changes that affect multiple controls. If you only need to update one control, use the update guide linked in the table above.

Property renames

Many properties were renamed for consistency across controls. If your formulas reference the old names, you need to update them to the new names:

Expand table

Old name (Previous)	New name (New)	Affected controls
`FontColor`	`Color`	Text, Link, Info Button, Radio, Text Input, Tab List, Number Input, Date Picker, Combo Box,

Old name (Previous)	New name (New)	Affected controls
		Button
`FontSize`	`Size`	Text, Link, Info Button, Radio, Text Input, Tab List, Number Input, Date Picker, Combo Box, Button, Dropdown
`FontItalic`	`Italic`	Text, Link, Info Button, Radio, Text Input, Tab List, Date Picker, Combo Box, Button
`FontStrikethrough`	`Strikethrough`	Text, Link, Info Button, Radio, Text Input, Date Picker, Combo Box, Button
`FontUnderline`	`Underline`	Text, Link, Info Button, Radio, Text Input, Date Picker, Combo Box, Button
`Weight`	`FontWeight`	Text only
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`	All controls with borders

New enum patterns

Properties that previously accepted plain text strings (like `"Bold"` or `"Start"`) now require typed enum values (like `FontWeight.Bold` or `Align.Left`). If your formulas hardcode the old string values, you need to update them.

Using enums gives you IntelliSense autocomplete, compile-time validation, and localization safety in your Power Fx formulas. Each control's update guide lists the specific enum changes for that control.

Align

Used by: Text, Text Input, Number Input, Link, Tab List, Date Picker, Combo Box

Expand table

Enum value	Description
`Align.Left`	Aligns text to the left edge
`Align.Center`	Centers text horizontally
`Align.Right`	Aligns text to the right edge

Enum value	Description
`Align.Justify`	Stretches text to fill the full width (Text, Link only)

The previous string values `"Start"` or `""` (empty string) map to `Align.Left`. The previous value `"End"` maps to `Align.Right`.

VerticalAlign

Used by: Text, Link

Expand table

Enum value	Description
`VerticalAlign.Top`	Aligns text to the top of the control
`VerticalAlign.Middle`	Centers text vertically (default)
`VerticalAlign.Bottom`	Aligns text to the bottom of the control

The previous Text control defaulted to `""` (empty/undefined). The new default is `VerticalAlign.Middle`.

FontWeight

Used by: Text, Text Input, Number Input, Link, Tab List, Radio, Combo Box, Date Picker, Info Button

Expand table

Enum value	Description
`FontWeight.Bold`	Bold weight
`FontWeight.Semibold`	Semibold weight
`FontWeight.Normal`	Normal/regular weight (default)
`FontWeight.Lighter`	Lighter weight

> **Important**
>
> **FontWeight.Medium removed**: The `Medium` value isn't available in the new controls. If your previous control used `FontWeight.Medium`, it automatically maps to `FontWeight.Normal`

during the update.

The previous Text control property was named `Weight` with string values (`"Regular"`, `"Bold"`, and so on). The new property is `FontWeight` with enum values. Both the property name and the value format changed.

ValidationState

Used by: Date Picker, Text Input, Number Input, Combo Box, Dropdown, Radio

Expand table

Enum value	Description
`ValidationState.None`	No validation styling (default)
`ValidationState.Error`	Shows error styling (red border)

> **Note**
>
> Only two values are available: `None` and `Error`. There's no `Valid` or `Success` state.

Appearance

Used by: Date Picker, Text Input, Number Input, Combo Box, Dropdown

Expand table

Enum value	Description
`Appearance.Filled`	Filled background style
`Appearance.FilledDarker`	Darker filled background (default for most controls)
`Appearance.Outline`	Outlined border with transparent background

BorderStyle

Used by: Text, Text Input, Number Input, Date Picker, Combo Box, Tab List, Link, Radio, Icon, Dropdown

Expand table

Enum value	Description
`BorderStyle.Solid`	Solid line border (default)
`BorderStyle.Dashed`	Dashed line border
`BorderStyle.Dotted`	Dotted line border
`BorderStyle.None`	No border

IconStyle

Used by: Icon, Button

Expand table

Enum value	Description
`IconStyle.Outline`	Renders the icon in outline (unfilled) style (default)
`IconStyle.Filled`	Renders the icon in filled style

Replace the previous string values `"Outline"` and `"Filled"` with `IconStyle.Outline` and `IconStyle.Filled`.

BorderRadius split into corner-specific properties

Controls that previously had a single **BorderRadius** property now have four separate properties for each corner:

```
// Previous version
Control.BorderRadius = 8

// New version
Control.RadiusTopLeft = 8
Control.RadiusTopRight = 8
Control.RadiusBottomLeft = 8
Control.RadiusBottomRight = 8
```

This change gives you more flexibility to create controls with different corner radii, such as rounded top corners only.

OnChange behavior improvements

Several controls changed *when* the **OnChange** event fires. This is one of the most impactful changes — if your app logic depends on OnChange, review this table:

Expand table

Control	Previous OnChange	New OnChange	Impact
Text Input	Every keystroke	Focus out (blur) only	**CRITICAL** - Major performance improvement, might require formula updates
Number Input	Every keystroke	Focus out + step button clicks	Major performance improvement
Combo Box	Delayed/Focus out	Every selection/deselection	More responsive interaction
Radio	Sometimes inconsistent	Every selection reliably	Improved reliability

> **Tip**
>
> If you need per-keystroke updates (for example, live search), reference the control's output property (such as `TextInput1.Text`) directly in your formulas instead of relying on OnChange.

TriggerOutput changes

The **TriggerOutput** property controls when a control pushes its value to dependent formulas. Here's what changed:

Expand table

Control	Change	Impact
Text Input	Default changed from **FocusOut** to **Keypress**	Text updates immediately on keystroke (Delayed in forms)
Number Input	**TriggerOutput** property removed entirely	No longer available
Combo Box	No longer fires OnChange	TriggerOutput and OnChange are now independent

Control	Change	Impact
Text Input	No longer fires OnChange	TriggerOutput and OnChange are now independent

Improved mobile defaults

When you add an updated control to a mobile layout canvas, it automatically uses touch-friendly defaults:

- Larger widths and heights for easier tapping
- Larger font sizes (typically 24 pt)
- Appropriate padding and spacing

You don't need to do anything extra — these defaults apply automatically for new controls on mobile layouts.

Updated command bar and right-click menus

Updated controls include refreshed command bar and right-click menus in the Studio authoring experience, giving you quick access to common style properties like font, color, fill, alignment, and borders.

Badge control in Power Apps

Article • 03/19/2024

A badge is a visual decoration for UI elements.

Description

Badge can be used to display content in a visually better way. The key properties for this control are **Content**, **Shape**, and **Appearance**.

General

Content – The content to be displayed inside Badge control

Visible - Whether a control appears or is hidden.

Size and position

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

Appearance – A Badge can be filled, outline, ghost, inverted.

Shape – The shape of the badge can be circular, square, or rounded.

ThemeColor – The style of the badge has different visual representations based on the selected scenarios: brand, danger, important, informative, severe, subtle, success, or warning.

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color. This property is on in effect if the **Color** property has a value of **Brand**.

Font - The name of the family of fonts in which text appears.

FontSize - The font size of the text that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

FontWeight - The weight of the text in a control: **Bold**, **Lighter**, **Normal**, or **Semibold**.

FontItalic - Whether the text in a control is italic.

FontUnderline - Whether a line appears under the text that appears on a control.

FontStrikethrough - Whether a line appears through the text that appears on a control.

Additional properties

AccessibleLabel – Label for screen readers.

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

Button modern control in canvas apps

The **Button** modern control provides a clickable element that triggers actions in a canvas app, offering flexible styling and comprehensive interaction capabilities.

Description

The **Button** modern control provides a clickable element that triggers app logic when selected. Use it for form submissions, navigation, confirmations, and any interaction that requires user input. The control supports icon and text combinations, full font styling, and multiple appearance styles through Fluent theming. Key properties for this control are **Text**, **Appearance**, and **OnSelect**.

> **Note**
>
> This article describes the updated Button modern control. For information about what changed from the previous version, see Recent updates.

General

Text – The label displayed on the button. Supports any text or Power Fx formula that evaluates to a string. Use this property to set or change the button text.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the button based on app state.

Behavior

OnSelect – Use the **OnSelect** property to define what happens when the button is selected. It's how the app responds when the user selects the button. The control is accessible: **OnSelect** also triggers when the user presses Enter or Space while the control has keyboard focus.

> **Tip**
>
> Common OnSelect actions include:
>
> - `Navigate(Screen2)` - Navigate to another screen

- `SubmitForm(Form1)` - Submit a form
- `Set(varName, value)` - Set a variable
- `Notify("Message", NotificationType.Success)` - Show a notification
- `Patch(DataSource, Record, Updates)` - Update data

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). When **Disabled**, the button is visually dimmed and **OnSelect** doesn't fire.

Getting started

The **Button** modern control is one of the most commonly used controls in Power Apps. At its core, a button has two essential elements: the text that users see (the **Text** property) and the action that happens when selected (the **OnSelect** property). Once you understand these basics, you can create interactive apps that respond to user input.

Set button text

To change what text appears on your button, set the **Text** property:

- **In the Properties pane**: Enter text directly in the **Text** field
- **Using a formula**: `Text = "Click Me"` or `Text = "Save " & TextInput1.Text`

Make buttons interactive

Define what happens when users selects the button using the **OnSelect** property:

1. Select the button in your app.
2. In the Properties pane, find the **OnSelect** property.
3. Enter your Power Fx formula, such as `Navigate(NextScreen)`.

Configure button properties

Power Apps uses a streamlined approach for editing controls.

- Select the button on the canvas:
  - **Use the Properties pane** on the right to modify basic properties.
  - **Use the formula bar** at the top for advanced formulas.
  - **Switch to Advanced properties** for detailed customization.

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **96**.

Height – Distance between the control's top and bottom edges. Default is **32**.

Align – The horizontal alignment of the button content within the control. Accepts `Align` enum values: `Align.Left`, `Align.Center`, `Align.Right`, `Align.Justify`.

VerticalAlign – The vertical alignment of the button content. Accepts `VerticalAlign` enum values: `VerticalAlign.Top`, `VerticalAlign.Middle`, `VerticalAlign.Bottom`.

PaddingTop – Distance between the button content and the top edge of the control.

PaddingBottom – Distance between the button content and the bottom edge of the control.

PaddingLeft – Distance between the button content and the left edge of the control.

PaddingRight – Distance between the button content and the right edge of the control.

Style and theme

Appearance – The visual style of the button. Accepts `ButtonAppearance` enum values:

Expand table

Value	Description
`ButtonAppearance.Primary`	Filled button using the brand color. Default.
`ButtonAppearance.Secondary`	Subtle filled style, secondary emphasis.
`ButtonAppearance.Outline`	Outlined button with no background fill.
`ButtonAppearance.Subtle`	Minimal styling, no border or fill.
`ButtonAppearance.Transparent`	No visible styling; blends with the background.

BasePaletteColor – The base color used by the theme to generate the control's color palette. Change this property to apply a different theme color to the button.

Icon – The Fluent icon name to display alongside the button text (for example, `"Add"`, `"Save"`, `"Delete"`). Leave blank for a text-only button.

IconStyle – Whether the icon renders in outline or filled style. Accepts `IconStyle` enum values: `IconStyle.Outline` (default) or `IconStyle.Filled`.

IconRotation – Rotation in degrees applied to the icon. Default is **0**.

Layout – The position of the icon relative to the button text. Accepts `ButtonLayout` enum values:

Expand table

Value	Description
`ButtonLayout.IconBefore`	Icon appears to the left of the text. Default.
`ButtonLayout.IconAfter`	Icon appears to the right of the text.
`ButtonLayout.IconOnly`	Only the icon is shown; no text label.

Font – The font family used for the button label.

Size – The font size of the button label, in points.

Color – The color of the button label text.

FontWeight – The weight (thickness) of the button label. Accepts `FontWeight` enum values: `FontWeight.Bold`, `FontWeight.Semibold`, `FontWeight.Normal` (default), `FontWeight.Lighter`.

Italic – Whether the button label appears in italic style.

Underline – Whether a line appears under the button label text.

Strikethrough – Whether a line appears through the middle of the button label text.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Additional properties

AccessibleLabel – Label read by screen readers. Provide a meaningful description when the button label alone isn't sufficient (for example, when using an icon-only button).

Tooltip – Explanatory text that appears when the user hovers over the button.

ContentLanguage – The display language for the control content, if different from the app language.

Example

The following YAML example shows a submit button and a cancel button with OnSelect actions:

YAML

```yaml
- SubmitButton:
    Control: ModernButton@1.0.0
    Properties:
      Text: ="Submit"
      OnSelect: |
        SubmitForm(DataForm1);
        Navigate(SuccessScreen)
      Appearance: =ButtonAppearance.Primary
      Icon: ="Checkmark"
      IconStyle: =IconStyle.Outline
      Layout: =ButtonLayout.IconBefore
      AccessibleLabel: ="Submit the form"
      Tooltip: ="Submit your response"
      Width: =120
      Height: =36

- CancelButton:
    Control: ModernButton@1.0.0
    Properties:
      Text: ="Cancel"
      OnSelect: =Navigate(HomeScreen)
      Appearance: =ButtonAppearance.Outline
      Width: =120
      Height: =36
```

Common button patterns

Here are typical button implementations:

Navigation button:

```powerfx
OnSelect = Navigate(DetailsScreen, ScreenTransition.Fade)
```

Data submission:

```powerfx
OnSelect = SubmitForm(Form1); Notify("Data saved!", NotificationType.Success)
```

Variable update:

```powerfx
OnSelect = Set(IsVisible, !IsVisible)
```

Confirmation dialog:

```powerfx
OnSelect = If(
    Confirm("Are you sure you want to delete this item?"),
    Remove(Collection1, ThisItem)
)
```

Recent updates

The updated version of the **Button** modern control includes the following improvements and behavior changes.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontSize`	`Size`
`FontColor`	`Color`
`FontItalic`	`Italic`
`FontUnderline`	`Underline`
`FontStrikethrough`	`Strikethrough`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Removed properties

Expand table

Removed property	Notes
`AcceptsFocus`	Removed. The modern Button control always accepts keyboard focus. No replacement needed.

Bug fixes and improvements

- **Updated enums**: `Appearance`, `Layout`, and `IconStyle` now use typed Power Fx enums (`ButtonAppearance`, `ButtonLayout`, `IconStyle`) instead of string values, improving IntelliSense and reducing formula errors.
- **Tooltip support**: New `Tooltip` property shows explanatory text on hover.
- **Border improvements**: Added `BorderStyle` and `BorderThickness` for more precise border control. Four corner-specific properties replace `BorderRadius` for independent corner control.
- **Full font control**: Font properties are now consistent with other modern controls. Use `Font`, `Size`, `Color`, `Italic`, `Underline`, and `Strikethrough`.

Card modern control

Cards help makers create clean, responsive object summaries such as contact tiles, document previews, or product listings in either horizontal or vertical orientation.

Description

Use a Card when you want to show a concise overview of an item with optional imagery and text.
The control adapts its layout to the sections a maker chooses to configure, enabling consistent patterns without requiring multiple independent controls.

General

Direction – Determines whether the card layout is vertical or horizontal

Title – Header title text displayed on the card

Subtitle – Supplemental text displayed under or beside the title in the header

Description – Description text displayed below the header of the card

Image – Main preview image for the card

ImageAltText – Alt text for the preview image for accessibility

HeaderImage – Small avatar or icon displayed in the header with the title and subtitle

HeaderImageAltText – Alt text for the header image

ImagePosition – Determines whether the preview image appears before or after the header section

Behavior

OnSelect – Action triggered when the user selects the card

DisplayMode – Controls whether the card is interactive, view-only, or disabled

Visible – Shows or hides the card

Style and theme

Radius – Controls corner roundness of the card container

DropShadow – Defines the shadow style applied to the card

Size and position

X, Y – Position of the control on the canvas

Width, Height – Dimensions of the control

Examples

The following examples show three Card configurations you can copy and paste directly into your app configuration.

Vertical card with description

YAML

```yaml
- VerticalCardwithDescription:
    Control: ModernCard@1.0.0
    Properties:
      Description: ="This is a sample description"
      Height: =240
      Width: =329
      X: =50
      Y: =45
```

Horizontal card with long description and no image

YAML

```yaml
- HorizontalCardwithLongDescriptionNoImage:
    Control: ModernCard@1.0.0
    Properties:
      Description: ="This is a long description text. It provides a rich, narrative
overview designed to help users understand the purpose, value, and key capabilities
of the experience. This section typically expands beyond a short summary by
offering contextual background, explaining how the feature solves real user
problems, and detailing what makes it uniquely impactful."
      Height: =240
      Image: =Blank()
      LayoutDirection: =LayoutDirection.Horizontal
      Width: =300
```

```
      X: =40
      Y: =40
```

Vertical card with header on top

YAML

```
- VerticalCardwithHeaderOnTop:
    Control: ModernCard@1.0.0
    Properties:
      HeaderImage: =Blank()
      Height: =240
      ImagePlacement: =ImagePlacement.AfterHeader
      Subtitle: ="This is subtitle which can take whole of single line."
      Title: ="Title for the card"
      Width: =350
      X: =40
      Y: =40
```

Checkbox modern control in Power Apps

Article • 07/17/2024

A control that the user can select or clear to set its value to **true** or **false**.

Description

The user can specify a Boolean value by using this familiar control that is used in Graphical User Interface (GUI) for decades. The key properties for this control are **Checked**, **Label**, **OnCheck**, and **OnUncheck**.

General

Label – The Checkbox's label.

AccessibleLabel – Label for screen readers.

Visible - Whether a control appears or is hidden.

Behavior

Checked – The controlled value for the checkbox.

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

Size and position

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color.

Font - The name of the family of fonts in which text appears.

FontSize - The font size of the text that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

FontWeight - The weight of the text in a control: Bold, Lighter, Normal, or Semibold.

FontItalic - Whether the text in a control is italic.

FontUnderline - Whether a line appears under the text that appears on a control.

FontStrikethrough - Whether a line appears through the text that appears on a control.

Additional properties

OnCheck - Actions to perform when the user checks the control.

OnSelect - Actions to perform when the user selects a control.

OnUncheck - Actions to perform when the user unchecks the control.

Combo box modern control in canvas apps

A searchable, multiselect dropdown control for selecting one or more items from a list.

Description

The **Combo box** modern control provides a flexible, searchable dropdown interface that enables users to select one or more items from a list of options. This control combines the functionality of a traditional dropdown with advanced search capabilities, making it ideal for scenarios where users need to choose from large datasets or multiple selections.

Key properties for this control are **Items**, **DefaultSelectedItems**, and **SelectMultiple**.

General

Items – The data source that contains the items shown in the combo box. Can be a collection, table, or Power Fx formula that returns a table.

ItemDisplayText – A formula that determines what text to display for each item in the dropdown list. Use `ThisItem` to reference the current item. Example: `ThisItem.DisplayName` or `ThisItem.Value1`.

DefaultSelectedItems – The initial items selected in the control before the user makes a change. Must be a table of records from the **Items** data source.

InputTextPlaceholder – Hint text that appears in the input field when no items are selected. Default is "**Find items**".

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

SelectMultiple – Whether users can select multiple items. When `true`, users can select multiple items and each selected item can be toggled on or off by clicking it again. When `false`, only one item can be selected at a time. Default is **true**.

IsSearchable – Whether the search box is enabled. When `true`, users can type to filter the list. When `false`, the control acts as a simple dropdown without search. Default is **true**.

OnChange – How the app responds when the user selects or deselects an item. This event fires immediately on every selection or deselection, making it ideal for real-time filtering or dependent dropdowns.

AllowMultipleSelection – (Display property) A toggle that controls whether users can select multiple items. Maps to the **SelectMultiple** property.

AllowSearching – (Display property) A toggle that controls whether search is enabled. Maps to the **IsSearchable** property.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, the selection is shown but can't be changed.

DelayOutput – When set to `true`, delays updates to the **SearchText** output property until the user pauses typing. When `false`, **SearchText** updates immediately on each keystroke. This property does not affect when **OnChange** fires — **OnChange** fires immediately on every selection and deselection regardless of this setting. Default is **false**.

Data

SelectedItems – (Output) A table of records representing the items currently selected by the user. Use this property to reference the user's selections in formulas.

Selected – (Output) When **SelectMultiple** is `false`, returns the single selected item as a record. When **SelectMultiple** is `true`, returns the first selected item.

SearchText – (Output) The current text typed by the user in the search box. Use this to create custom filtering logic or to track search behavior.

> ⓘ **Note**
>
> Output properties such as **SelectedItems** in a Combo box control return a table of the currently selected records and can’t be set directly. Instead, other controls and formulas use this property to access the current selection. For example, reference `ComboBoxName.SelectedItems` in a label, gallery, or formula to work with the selected records.

MultiValueDelimiter – The separator character used when displaying multiple selected items in the input field. Default is **", "** (comma and space).

Validation

Required – Whether the control must have at least one item selected before the form can be submitted. When `true`, the control shows a validation error if empty.

ValidationState – The current validation state of the control. Accepts `ValidationState` enum values:

Expand table

Value	Description
`ValidationState.Error`	The control value has an error
`ValidationState.None`	No validation applied (default)

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **320**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the text and the top edge of the control.

PaddingBottom – Distance between the text and the bottom edge of the control.

PaddingLeft – Distance between the text and the left edge of the control.

PaddingRight – Distance between the text and the right edge of the control.

Style and theme

Appearance – The visual style of the control. Accepts `Appearance` enum values:

Expand table

Value	Description
`Appearance.Filled`	Filled background style
`Appearance.FilledDarker`	Filled with darker background
`Appearance.Outline`	Outline style with border

Default is `Appearance.FilledDarker`.

BasePaletteColor – The base color used by the theme to generate the control's color palette. Changes this property to apply a different theme color to the control.

Font – The name of the font family in which text appears.

Size – The font size of the text, in points. Default is **14**.

Color – The color of the text in the control.

FontWeight – The weight (thickness) of the text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the text appears in italic style.

Underline – Whether a line appears under the text.

Strikethrough – Whether a line appears through the middle of the text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Example

The following YAML example shows combo box controls with single and multiselect modes:

YAML

```
- DepartmentComboBox:
    Control: ModernCombobox@1.0.0
    Properties:
      Items: =["Engineering", "Sales", "Marketing", "Support"]
      ItemDisplayText: =ThisItem.Value
      InputTextPlaceholder: ="Select a department..."
      SelectMultiple: =false
      IsSearchable: =true
      Required: =true
      X: =40
      Y: =100
      Width: =320
      Height: =32

- TeamMemberComboBox:
    Control: ModernCombobox@1.0.0
    Properties:
      Items: =["Alice Smith", "Bob Johnson", "Carol Williams", "David Brown"]
      ItemDisplayText: =ThisItem.Value
      InputTextPlaceholder: ="Select team members..."
      SelectMultiple: =true
      IsSearchable: =true
      MultiValueDelimiter: ="; "
      X: =40
      Y: =150
      Width: =320
      Height: =32
```

Accessibility

AccessibleLabel – A label for screen readers to announce what the control is for. Describe the purpose of the combo box, not the current selection.

TabIndex – The tab order of the control relative to other controls. Controls with lower **TabIndex** values receive focus before controls with higher values.

Recent updates

The updated version of the **Combo box** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Enum format changes

The following properties now require typed enum syntax instead of plain string values:

Expand table

Property	Previous format	New format
`Appearance`	`"FilledDarker"`	`Appearance.FilledDarker`
`ValidationState`	`"None"`	`ValidationState.None`

Behavioral changes

- **SelectMultiple defaults to true**: The **SelectMultiple** property now defaults to `true`. If your app requires single selection, explicitly set `SelectMultiple = false`.
- **Toggle selection behavior**: Clicking a selected item now unselects it, making it easier to remove selections without clearing the entire list.
- **Immediate OnChange firing**: The **OnChange** event now fires immediately on every selection or deselection, enabling real-time filtering and dependent dropdowns. Note: **DelayOutput** controls when **SearchText** updates — it does not affect **OnChange** timing.
- **Search text clears on selection**: When an item is selected, the search text automatically clears.
- **Reset() includes SearchText**: The `Reset()` function now clears both the selection and the search text.

Removed and replaced properties

Expand table

Removed property	Replacement	Notes
`TriggerOutput`	`DelayOutput`	`TriggerOutput = "Keypress"` → `DelayOutput = false`. `TriggerOutput = "FocusOut"` → `DelayOutput = true`.
`Fields`	`ItemDisplayText`	Replace `Fields = ["FieldName"]` with `ItemDisplayText = ThisItem.FieldName`.

Other improvements

- **Improved data handling**: Better support for Dataverse many-to-one relationships and increased item limit handling (previously limited to about 800 items).
- **Mobile-optimized defaults**: When adding the control in a mobile layout, defaults are automatically adjusted (font size 24, width 560, height 64).

Limitations

- The control works best with lists that have up to several thousand items. For very large datasets (more than 10,000 items), consider using server-side filtering by using the **SearchText** output property.
- In the current version, chevron and checkbox icons don't scale with font size.

Date picker modern control in canvas apps

Summarize this article for me

The **Date picker** modern control provides an intuitive calendar interface for date selection in canvas apps. This control combines visual calendar navigation with flexible formatting options to create a seamless date input experience for users.

Description

Use this control when you need users to select specific dates, such as appointment scheduling, event planning, or filtering data by date ranges. The control supports customizable date formats, timezone handling, and date range restrictions to meet diverse application requirements.

Key capabilities include:

- Visual calendar interface with month and year navigation
- Flexible date formatting using predefined formats or custom patterns
- Date range validation to restrict selectable dates
- Timezone support for local or UTC display
- Accessibility features for screen readers and keyboard navigation

The control outputs the selected date through the SelectedDate property, which you can use in formulas throughout your app.

Key properties for this control are **SelectedDate**, **Format**, and **DateTimeZone**.

General

Placeholder – Hint text that appears when no date is selected. Default is **"Select a date"**.

DefaultDate – The initial date selected in the control before the user makes a change. Use this property to set a default date when the picker first loads.

Format – The display format for the selected date. Accepts `DatePickerFormat` enum values or a custom format string:

Enum values:

Expand table

Value	Description	Example
`DatePickerFormat.LongAbbreviated`	Abbreviated month with full year (default)	Jan 15, 2024
`DatePickerFormat.Short`	Short numeric format	1/15/2024
`DatePickerFormat.Long`	Full month name with year	January 15, 2024

Custom format strings:

You can also use custom date format patterns as strings to create specific date representations:

Expand table

Format string	Example output
`"dd-mm-yyyy"`	15-01-2024
`"dd-mm"`	15-01
`"yyyy-mm-dd"`	2024-01-15
`"dd/mm/yyyy"`	15/01/2024
`"mm/dd/yyyy"`	01/15/2024

Use custom format strings when you need a specific date representation not available in the enum values. Example: `Format = "dd-mm-yyyy"`.

DateTimeZone – The timezone used for date display and storage. Accepts `DateTimeZone` enum values:

Expand table

Value	Description
`DateTimeZone.Local`	User's local timezone (default)
`DateTimeZone.UTC`	Coordinated Universal Time

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnChange – How the app responds when the user selects a different date. This event fires when the date selection changes.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, the selected date is shown but the calendar can't be opened.

IsEditable – Whether the user can type a date directly into the input field or must use the calendar picker. When `false`, users must select the calendar icon to choose a date. Default is **false**.

Date range

StartDate – The earliest date that can be selected in the calendar. Dates before this date are disabled. Default is **Date(1900, 1, 1)**.

EndDate – The latest date that can be selected in the calendar. Dates after this date are disabled. Default is **Date(Year(Today())+100, 12, 31)**.

StartOfWeek – The day that appears as the first column in the calendar view. Accepts `StartOfWeek` enum values:

Expand table

Value	Description
`StartOfWeek.Sunday`	Week starts on Sunday (default)
`StartOfWeek.Monday`	Week starts on Monday
`StartOfWeek.Tuesday`	Week starts on Tuesday
`StartOfWeek.Wednesday`	Week starts on Wednesday
`StartOfWeek.Thursday`	Week starts on Thursday
`StartOfWeek.Friday`	Week starts on Friday
`StartOfWeek.Saturday`	Week starts on Saturday

Data

SelectedDate – (Output) The date currently selected by the user. Returns a date value that you can use in formulas. Returns `Blank()` if no date is selected.

Validation

ValidationState – The current validation state of the control. Accepts `ValidationState` enum values:

Expand table

Value	Description
`ValidationState.Error`	The control value has an error
`ValidationState.None`	No validation applied (default)

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **320**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the text and the top edge of the control.

PaddingBottom – Distance between the text and the bottom edge of the control.

PaddingLeft – Distance between the text and the left edge of the control.

PaddingRight – Distance between the text and the right edge of the control.

Style and theme

Appearance – The visual style of the control. Accepts `Appearance` enum values:

Expand table

Value	Description
`Appearance.Filled`	Filled background style
`Appearance.FilledDarker`	Filled with darker background (default)

Value	Description
`Appearance.Outline`	Outline style with border

BasePaletteColor – The base color used by the theme to generate the control's color palette. Change this property to apply a different theme color to the control.

Font – The name of the font family in which text appears.

Size – The font size of the text, in points. Default is **0** (uses theme default).

Color – The color of the text in the control.

FontWeight – The weight (thickness) of the text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the text appears in italic style.

Underline – Whether a line appears under the text.

Strikethrough – Whether a line appears through the middle of the text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Accessibility

AccessibleLabel – A label for screen readers to announce what the control is for. It should describe the purpose of the date picker, not the current selection.

ContentLanguage – The language used for formatting dates and calendar display. The app settings provide the value if you don't specify it.

Example

The following YAML example shows date picker controls for selecting dates:

YAML

```yaml
- StartDatePicker:
    Control: ModernDatePicker@1.0.0
    Properties:
      Placeholder: ="Select start date"
      DefaultDate: =Today()
      StartDate: =Today()
      EndDate: =Today() + 365
      StartOfWeek: =StartOfWeek.Monday
      X: =40
      Y: =100
      Width: =280
      Height: =32

- EndDatePicker:
    Control: ModernDatePicker@1.0.0
    Properties:
      Placeholder: ="Select end date"
      Format: =DatePickerFormat.Short
      DefaultDate: =Today() + 7
      StartOfWeek: =StartOfWeek.Monday
      X: =340
      Y: =100
      Width: =280
      Height: =32
```

Recent updates

The updated version of the **Date picker** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Removed properties

Expand table

Removed property	Notes
`Required`	Use `ValidationState` instead to control validation styling.

Bug fixes and improvements

- **DisplayMode.View properly enforced**: In **View** mode, the control is now properly read-only and the calendar can't be opened. Previously, the picker was still editable in View mode.
- **Format property fully honored**: All format values are now properly applied. Previously, certain format values were ignored until another change was made.
- **DateTimeZone respected**: The **DateTimeZone** property now correctly applies to date display and storage. Previously, this property value was sometimes ignored.
- **Blank value handling**: When the control is in **View** mode with a blank value, it no longer incorrectly shows a previous value.
- **Mobile calendar improvements**: Calendar flyout is now properly sized for mobile devices, with optimized defaults (width 560, height 64, font size 24).
- **Month/Year flyout positioning**: Fixed issue where the month/year selector went off-screen on smaller displays.

- **Gallery and data card stability**: Resolved crashes that occurred when adding the date picker to galleries or data cards.
- **Color palette inheritance**: The calendar flyout now properly respects the **BasePaletteColor** override.
- **Command bar integration**: The authoring command bar and right-click menu now show Font, Font Size, Font color, and Background color for quick access.
- **DefaultDate property**: New property allows setting an initial date when the picker first loads.

Limitations

- The calendar icon doesn't scale with font size in the current version.
- On mobile devices, the control shows the Fluent calendar view instead of the native mobile date picker.

Dropdown modern control in canvas apps

Let users pick a single value from a collapsible list.

Description

The **Dropdown** modern control presents a list of choices in a compact, collapsible format. Users select one item and the list collapses back to a single line. Use the **Dropdown** control when you need users to choose one option from a list of more than seven items, for required fields with a fixed set of choices, or for forms where screen space is limited. For fewer options (two to seven), consider using a Radio group instead. If users need to select multiple items, use a Combo box.

Key properties for this control are **Items**, **Default**, **ValidationState**, and **OnChange**.

> **Note**
>
> This article describes the updated Dropdown modern control. For information about what changed from the previous version, see Recent updates.

On desktop, the updated control opens a **Fluent-themed flyout** that matches the app's visual theme. The previous version opened the browser's HTML `<select>` element, which couldn't be themed.

General

Items – The source of data that contains the items that appear in the control. Accepts a table, a collection, or an inline array (for example, `["Option A", "Option B", "Option C"]`).

ItemDisplayText – A Power Fx formula evaluated for each item in **Items** to determine the text shown in the list. Use `ThisItem` to reference the current item. Defaults to `ThisItem.Value` for string arrays and `ThisItem.Value1` for table data sources. Change this when your data source has a specific column to display (for example, `ThisItem.Name`).

Default – The initial selected value before the user makes a change. Set this to a value that exists in **Items** (for example, `="Option A"`). Leave blank for no default selection.

AccessibleLabel – Label read by screen readers. Describe the purpose of the dropdown (for example, `"Select a country"`).

Visible – Whether the control appears or is hidden.

Behavior

OnChange – Actions to perform when the user changes the selection. Use `Self.Selected.Value` inside the formula to read the newly selected item. For example, `Notify("You selected " & Self.Selected.Value)` displays a message each time the selection changes.

Required – Whether the user must make a selection. When **true**, an indicator appears beside the dropdown. Default is **false**.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

ValidationState – Applies validation styling to the control. Accepts `ValidationState` enum values:

Expand table

Value	Description
`ValidationState.None`	No validation styling. Default.
`ValidationState.Error`	Highlights the control border in red to indicate an error.

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **320**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the control content and the top edge of the control.

PaddingBottom – Distance between the control content and the bottom edge of the control.

PaddingLeft – Distance between the control content and the left edge of the control.

PaddingRight – Distance between the control content and the right edge of the control.

Style and theme

Appearance – The visual style of the dropdown field. Accepts `Appearance` enum values:

Expand table

Value	Description
`Appearance.FilledDarker`	Filled with a slightly darker background. Default.
`Appearance.Filled`	Filled with a standard background.
`Appearance.Outline`	Outlined border with a transparent background.

BasePaletteColor – The base color used by the theme to generate the control's color palette. Use this value to apply a different theme color to the control.

Font – The font family used for the dropdown text.

Size – The font size of the dropdown text, in points. Default is **14**.

Color – The color of the dropdown text.

FontWeight – The weight (thickness) of the dropdown text. Accepts `FontWeight` enum values: `FontWeight.Bold`, `FontWeight.Semibold`, `FontWeight.Normal` (default), `FontWeight.Lighter`.

Italic – Whether the dropdown text appears in italic style.

Underline – Whether a line appears under the dropdown text.

Strikethrough – Whether a line appears through the middle of the dropdown text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Additional properties

ContentLanguage – The display language for the control content, if different from the app language.

Output properties

Selected – The currently selected item, returned as a record. For a string array, use `Dropdown1.Selected.Value` to read the selected text. For a table data source, use `Dropdown1.Selected.<ColumnName>`.

> ⓘ Note
>
> **Selected** is an output property. You can reference it in other controls and formulas, but you can't set it directly.

Examples

Basic dropdown with inline options

This example creates a required country dropdown with inline validation. When the user hasn't selected a value, the control shows an error state.

YAML

```
- CountryDropdown:
    Control: ModernDropdown@1.0.0
    Properties:
      AccessibleLabel: ="Select your country"
      Default: ={Value:"United States"}
      ItemDisplayText: =ThisItem.Value
      Items: =["Australia", "Canada", "United Kingdom", "United States"]
      Required: =true
      ValidationState: =If(IsBlank(CountryDropdown.Selected.Value),
ValidationState.Error, ValidationState.None)
      Width: =240
```

Dropdown bound to a data source

This example binds the dropdown to a table data source and displays the **Name** column. The **OnChange** action stores the selected record in a variable.

YAML

```
- DepartmentDropdown:
    Control: ModernDropdown@1.0.0
    Properties:
      AccessibleLabel: ="Select a department"
      Appearance: =Appearance.Outline
      ItemDisplayText: =ThisItem.Name
      Items: =Departments
      OnChange: =Set(varSelectedDept, Self.Selected)
      Width: =320
```

Recent updates

The updated version of the **Dropdown** modern control includes the following improvements and behavior changes.

Property renames

Expand table

Previous property	New property	Notes
`DefaultSelectedItems`	`Default`	Set the initial selection through `Default`. Change any formula referencing `Dropdown1.DefaultSelectedItems` to `Dropdown1.Default`.
`FontSize`	`Size`	Renamed to match other modern controls. Default changed from **0** (inherits from theme) to **14**.
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`	Split into four independent corner radius properties for greater styling flexibility.

Enum format changes

Expand table

Property	Previous value	New value
`Appearance`	`"FilledDarker"`	`Appearance.FilledDarker`
`Appearance`	`"Filled"`	`Appearance.Filled`
`Appearance`	`"Outline"`	`Appearance.Outline`
`ValidationState`	`"None"`	`ValidationState.None`
`ValidationState`	`"Error"`	`ValidationState.Error`

Bug fixes and improvements

- **Fluent-themed flyout**: On desktop, the dropdown list now opens as a Fluent-themed flyout that matches the app's visual design. The previous version used the browser's HTML `<select>` element, which couldn't be themed. On mobile, both versions use the device-native picker and it remains unchanged.
- **ItemDisplayText**: New property that controls which field of a data source record to show in the list. For string arrays, this property defaults automatically. For table data sources, set this property to the column you want to display (for example, `ThisItem.Name`).
- **Full font control**: New `Font`, `Color`, `FontWeight`, `Italic`, `Underline`, and `Strikethrough` properties give full text styling control, consistent with other modern controls.
- **Updated enums**: `Appearance` and `ValidationState` now use typed Power Fx enums, improving IntelliSense and reducing formula errors.

Accessibility

AccessibleLabel – Set this property to a meaningful description so screen readers can announce the purpose of the dropdown (for example, `"Select your country"`).

Required – When set to **true**, screen readers announce the field as required.

Keyboard users can press **Enter** or **Space** to open the dropdown, use **Arrow** keys to move between items, and press **Enter** to confirm a selection.

Limitations

- The Fluent-themed flyout is available on desktop only. On mobile, the control uses the device-native picker.
- Very large data sources may cause the dropdown list to load slowly. Filter or limit the data where possible.

Header modern control in Power Apps

Article • 03/19/2024

A control that creates a modern app header.

Description

The **Header** control is a fundamental control that lets you design a user interface for a common app with ease. With minimal configuration, this control responds to themes that use modern theming and dynamic responsiveness, adjusting to the size of the parent container or app. The **Header** control supports a logo, a page title, and displays the user picture, while providing various unique style options. The key properties for this control are **Logo**, **OnSelectLogo**, and **Title**.

General

Title – The title label displayed in the header. Default value is the current screen name.

IsTitleVisible – Whether the title is displayed in the header.

Logo – The image displayed in the header.

IsLogoVisible – Whether the logo image is displayed.

IsProfilePictureVisible – Whether the user picture is displayed in the header. By default, a picture of the current user using the app is shown.

Visible - Whether a control appears or is hidden.

Size and position

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color. This property has no effect if the **ThemeStyle** property is set to **Neutral**.

Style – Header color variant, based on theme colors.

Font - The name of the family of fonts in which text appears.

TitleFontSize - The font size of the title that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

Additional properties

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

LogoMaxHeight – The maximum height the logo can be placed within the control.

LogoToolTip - Tooltip for the logo.

OnSelectLogo - Actions to perform when the user selects the logo.

Unsupported capabilities

The following features aren't supported:

- Customization of colors
- App navigation

> ⓘ **Note**
>
> This list will change over time as we're working to support these capabilities.

The header doesn't automatically replicate across app screens, so it needs to be manually added to each screen.

Icon modern control in canvas apps

Displays a Fluent icon that can optionally respond to user interaction.

Description

The **Icon** modern control displays a Fluent icon from the Fluent icon library. You can use it in two ways:

- **Decorative** – Display a static icon as a visual indicator (for example, a status badge or label prefix). Leave the **OnSelect** property empty.
- **Interactive** – Respond to user input. Set the **OnSelect** property to a formula, and the control automatically renders with button semantics so it works with keyboard navigation and screen readers.

Common uses include toolbar actions, status indicators, inline navigation, and lightweight call-to-action elements.

The key properties for this control are **Icon**, **IconStyle**, and **OnSelect**.

> **Note**
>
> This article describes the updated Icon modern control. For information about what changed from the previous version, see Recent updates.

Add an icon to your app

1. Open your canvas app for editing.
2. On the left pane, select **Insert** (+).
3. Expand **Modern controls** and choose **Icon**.
4. In the property pane on the right, set the **Icon** property to a Fluent icon name such as `"Add"`, `"Delete"`, or `"Edit"`.
5. (Optional) Set **OnSelect** to a formula to make the icon interactive.

General

Icon – The name of the Fluent icon to display (for example, `"Add"`, `"Delete"`, `"Edit"`). Accepts any valid Fluent icon name as a string.

Visible – Whether the control appears or is hidden.

Behavior

OnSelect – Actions to perform when the user selects the icon. When this property contains an active formula, the icon renders with button semantics for keyboard and screen reader accessibility.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **32**.

Height – Distance between the control's top and bottom edges. Default is **32**.

Rotation – The angle in degrees to rotate the icon clockwise. Default is **0**.

PaddingTop – Distance between the icon and the top edge of the control.

PaddingBottom – Distance between the icon and the bottom edge of the control.

PaddingLeft – Distance between the icon and the left edge of the control.

PaddingRight – Distance between the icon and the right edge of the control.

Style and theme

IconStyle – Whether the icon renders in outline or filled style. Accepts `IconStyle` enum values:

Expand table

Value	Description
`IconStyle.Outline`	Renders the icon in outline (unfilled) style. Default.
`IconStyle.Filled`	Renders the icon in filled style.

IconColor – The color of the icon.

BasePaletteColor – The base color used by the theme to generate the control's color palette. Use this value to apply a different theme color to the icon.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Accessibility

AccessibleLabel – Label read by screen readers. When you set **OnSelect**, always provide a meaningful description of the action (for example, `"Delete item"`). Because an icon has no visible text, this label is the only way assistive technology can communicate the control's purpose.

> **Tip**
>
> For decorative icons that don't perform an action, you can leave **AccessibleLabel** empty so screen readers skip the control.

Additional properties

Tooltip – Explanatory text that appears when the user hovers over the control.

ContentLanguage – The display language for the control content, if different from the app language.

Examples

Interactive delete icon

This example shows a filled red delete icon that performs an action when selected. The `AccessibleLabel` and `Tooltip` properties ensure the control is usable with keyboard, screen readers, and mouse hover.

YAML

```yaml
- DeleteIcon:
    Control: ModernIcon@1.1.0
    Properties:
      AccessibleLabel: ="Delete this item"
      Icon: ="Delete"
      IconColor: =RGBA(176, 0, 32, 1)
      IconStyle: =IconStyle.Filled
      OnSelect: =Remove(MyDataSource, ThisItem)
      Tooltip: ="Delete this item"
```

Decorative status icon

This example shows a non-interactive icon used as a visual status indicator. Because `OnSelect` isn't set, the icon renders as a decorative element.

YAML

```yaml
- StatusIcon:
    Control: ModernIcon@1.1.0
    Properties:
      Icon: ="CheckmarkCircle"
      IconColor: =RGBA(16, 124, 16, 1)
      IconStyle: =IconStyle.Filled
      Width: =24
      Height: =24
```

Formula examples

Change the icon based on a condition:

Power Apps

```
If(ThisItem.Status = "Complete", "CheckmarkCircle", "Clock")
```

Toggle between outline and filled styles:

Power Apps

```
If(ThisItem.IsSelected, IconStyle.Filled, IconStyle.Outline)
```

Recent updates

The updated version of the **Icon** modern control includes the following improvements and behavior changes.

Property renames

Expand table

Previous property	New property	Notes
`Style`	`IconStyle`	Renamed for clarity; also changed from string to typed enum.

Removed properties

Expand table

Removed property	Notes
`TabIndex`	Removed. The control automatically handles focus management.

Bug fixes and improvements

- **OnSelect support**: The icon now triggers actions when selected. When you set `OnSelect` to an active formula, the control renders with button semantics, making it fully accessible via keyboard and screen readers.
- **AccessibleLabel**: New property for screen readers - especially important for interactive icons where the glyph alone doesn't convey meaning.
- **Updated enum**: `IconStyle` now uses a typed Power Fx enum (`IconStyle.Outline`, `IconStyle.Filled`) instead of a plain string, improving IntelliSense and reducing formula errors.

- **Full border and fill control**: New `Fill`, `BorderColor`, `BorderStyle`, `BorderThickness`, and four corner radius properties (`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`) provide complete styling options.
- **Padding support**: New `PaddingTop`, `PaddingBottom`, `PaddingLeft`, `PaddingRight` properties control spacing between the icon glyph and the control boundary.
- **BasePaletteColor**: Apply a custom theme color to the icon.

Best practices

- **Always set AccessibleLabel for interactive icons.** Icons don't have visible text, so the accessible label is essential for screen reader users.
- **Use Tooltip for discoverability.** A tooltip helps sighted users understand what an icon does when they hover over it.
- **Choose Filled vs. Outline intentionally.** Use `IconStyle.Filled` for active or selected states and `IconStyle.Outline` for default states to give users a visual cue.
- **Keep icon sizes consistent.** Use the same **Width** and **Height** values for icons that appear together (for example, in a toolbar) so the layout looks uniform.

Info button modern control in canvas apps

Summarize this article for me

An interactive information icon that displays detailed content in a flyout when clicked or hovered.

Description

The **Info button** control provides contextual help and additional information in your canvas apps. When users select or hover over this interactive information icon, it displays detailed content in a flyout panel without disrupting their workflow.

Use this control to:

- Provide contextual help for form fields and complex features
- Display tooltips with additional guidance
- Offer explanatory content without cluttering your app interface
- Enhance user experience with on-demand information

The **Info button** appears as a standard information icon and supports rich text content, customizable styling, and accessibility features.This modern control integrates seamlessly with your app's design system through theme-based colors and flexible positioning options.

Key properties for this control are **Content**, **IconColor**, and **OnSelect**.

General

Content – The information text displayed in the flyout when the user clicks or hovers over the info button icon. Supports plain text and formatted content.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnSelect – How the app responds when the user clicks the info button. Use this property to trigger extra actions beyond showing the flyout, such as logging analytics or updating variables.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, the icon is shown but the flyout can't be opened.

Size and position

X – Distance between the left edge of the control and the left edge of its parent container. If there's no parent container, the screen acts as the parent.

Y – Distance between the top edge of the control and the top edge of its parent container. If there's no parent container, the screen acts as the parent.

Width – Distance between the control's left and right edges. The default value is **32**.

Height – Distance between the control's top and bottom edges. The default value is **32**.

PaddingTop – Distance between the icon and the top edge of the control.

PaddingBottom – Distance between the icon and the bottom edge of the control.

PaddingLeft – Distance between the icon and the left edge of the control.

PaddingRight – Distance between the icon and the right edge of the control.

Style and theme

BasePaletteColor – The base color that the theme uses to generate the control's color palette. Change this property to apply a different theme color to the control.

Font – The name of the font family used for text in the flyout content.

Size – The font size of text in the flyout, in points. The default is **15**.

Color – The color of text in the flyout content.

FontWeight – The weight (thickness) of text in the flyout. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the text in the flyout appears in italic style.

Underline – Whether a line appears under the text in the flyout.

Strikethrough – Whether a line appears through the middle of the text in the flyout.

IconColor – The color of the information icon button itself. Use this value to match your app's theme or draw attention to important information.

Accessibility

AccessibleLabel – A label for screen readers to announce what the info button provides information about. It should describe the purpose or topic of the information, not just "info button".

ContentLanguage – The language used for the flyout content. If you don't specify this property, the app settings provide the language.

Example

The following YAML example shows contextual help buttons for form fields with conditional styling and tooltip content:

YAML

```yaml
- EmailInfoButton:
    Control: ModernInformationButton@1.0.0
    Properties:
      Content: ="We'll use this email to send you order confirmations and account
notifications. Your email is never shared with third parties."
      IconColor: =Color.Blue
      AccessibleLabel: ="Email address information"
      X: =200
      Y: =100
      Width: =28
      Height: =28

- PasswordInfoButton:
    Control: ModernInformationButton@1.0.0
    Properties:
      Content: '="Password requirements: At least 8 characters, one uppercase
letter, one number, and one special character (!@#$%)"'
      IconColor: =Color.Orange
      AccessibleLabel: ="Password requirements"
      X: =200
      Y: =150
      Width: =28
      Height: =28

- GeneralInfoButton:
```

```
    Control: ModernInformationButton@1.0.0
    Properties:
      Content: ="Click the info icon to view additional details and helpful tips."
      IconColor: =Color.Gray
      Size: =14
      X: =200
      Y: =200
      Width: =28
      Height: =28
```

Recent updates

The updated version of the **Info button** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`

Removed properties

Expand table

Removed property	Notes
`AcceptsFocus`	Removed. The control now automatically manages focus behavior for accessibility.

Bug fixes and improvements

- **Content expansion fixed**: The information flyout background now properly expands to fit all content. Previously, long text could be clipped or overflow the flyout.
- **Improved reliability**: Resolved intermittent crashes that occurred when you clicked the info button in certain scenarios.
- **Simplified properties**: Streamlined property organization with most styling properties now in the **Design** section for better discoverability.
- **Consistent styling**: Font and color properties now consistently apply to both the icon and flyout content.

Best practices

- **Keep content concise**: While the flyout can display lengthy text, aim for two to three short sentences for better user experience.
- **Use accessible labels**: Always provide descriptive **AccessibleLabel** text that explains what information the button provides.
- **Strategic placement**: Position info buttons next to form fields, labels, or unfamiliar terms where users might need clarification.
- **Consistent iconcolor**: Use consistent colors across your app to help users recognize info buttons quickly.
- **Mobile considerations**: Ensure info buttons are large enough to tap easily on mobile devices (minimum 32x32 pixels).

Link modern control in canvas apps

Summarize this article for me

A clickable hyperlink control that navigates users to web URLs or triggers custom actions.

Description

The **Link** modern control creates clickable hyperlinks that can navigate to external websites or trigger custom actions in your canvas app. Use this control to provide users with quick access to related resources, documentation, or external services while maintaining a consistent visual design with your app's theme.

Key benefits:

- Navigate to external URLs with built-in security validation
- Customize appearance with multiple styling options
- Support for text wrapping and responsive design
- Full accessibility compliance with screen reader support
- Seamless integration with Power Apps theming system

Key properties for this control are **Text**, **Url**, and **Type**.

General

Text – The display text shown for the hyperlink. This is the text users see and click on. Can be different from the actual URL.

Url – The web address to go to when the link is clicked. Must be a valid URL that uses `http://`, `https://`, or other safe protocols. For security, the control blocks URLs that use `javascript:` or other unsafe schemes.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

Wrap – Whether the text wraps to the next line when it goes beyond the control width. When `true`, text wraps to multiple lines. When `false`, text is clipped or continues on a single line. Default is **true**.

DisplayMode – Whether the control accepts user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **Edit** mode, the link is clickable. In **View** mode, it displays as text without being clickable.

Size and position

Align – The horizontal alignment of text within the control. Accepts `Align` enum values:

Expand table

Value	Description
`Align.Left`	Aligns text to the left edge (default)
`Align.Center`	Centers text horizontally
`Align.Right`	Aligns text to the right edge
`Align.Justify`	Stretches text to fill the full width

VerticalAlign – The vertical alignment of text within the control. Accepts `VerticalAlign` enum values:

Expand table

Value	Description
`VerticalAlign.Top`	Aligns text to the top
`VerticalAlign.Middle`	Centers text vertically (default)
`VerticalAlign.Bottom`	Aligns text to the bottom

AutoHeight – Whether the control automatically increases its height when the text content exceeds the visible area.

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **150**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the text and the top edge of the control. Default is **5**.

PaddingBottom – Distance between the text and the bottom edge of the control. Default is **5**.

PaddingLeft – Distance between the text and the left edge of the control. Default is **5**.

PaddingRight – Distance between the text and the right edge of the control. Default is **5**.

Style and theme

Type – The visual style of the link. Accepts `LinkAppearance` enum values:

Expand table

Value	Description
`LinkAppearance.Default`	Standard link appearance with theme color (default)
`LinkAppearance.Subtle`	Subtle appearance with lighter styling

BasePaletteColor – The base color the theme uses to generate the control's color palette. Change this property to apply a different theme color to the control.

Font – The name of the font family for the text.

Size – The font size of the text, in points. Default is **15**.

Color – The color of the link text in the control.

FontWeight – The weight (thickness) of the text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the text appears in italic style.

Underline – Whether a line appears under the text. Links typically have underlines by default.

Strikethrough – Whether a line appears through the middle of the text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Accessibility

AccessibleLabel – A label for screen readers to announce what the link leads to. Use a description of the destination or purpose of the link, not just "link".

ContentLanguage – The language used for the link text. Inherits from app settings if you don't specify it.

Example

The following YAML example shows link controls with different styling options:

YAML

```
- DocumentationLink:
    Control: ModernLink@1.0.0
    Properties:
      Text: ="View Documentation"
      URL: ="https://docs.microsoft.com/powerapps"
      Type: =LinkAppearance.Default
      Size: =16
      FontWeight: =FontWeight.Semibold
      X: =40
      Y: =100
      Width: =200
      Height: =32

- SupportLink:
```

```
    Control: ModernLink@1.0.0
    Properties:
      Text: ="Contact Support"
      URL: ="https://support.microsoft.com"
      Type: =LinkAppearance.Subtle
      Size: =14
      X: =40
      Y: =150
      Width: =200
      Height: =32

- TermsLink:
    Control: ModernLink@1.0.0
    Properties:
      Text: ="Terms and Conditions"
      URL: ="https://company.com/terms"
      Type: =LinkAppearance.Subtle
      Size: =12
      Wrap: =false
      X: =40
      Y: =200
      Width: =150
      Height: =32
```

Recent updates

The updated version of the **Link** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Previous property	New property
`Appearance`	`Type` (uses `LinkAppearance` enum: `LinkAppearance.Default` or `LinkAppearance.Subtle`)

Removed properties

Expand table

Removed property	Notes
`AcceptsFocus`	Removed. The control now automatically manages focus behavior for accessibility.

Bug fixes and improvements

- **Wrap behavior fixed**: The **Wrap** property now correctly controls text wrapping. Previously, changing this property didn't update the text display.
- **Simplified property organization**: Properties are now logically organized into **Data** and **Design** sections for better discoverability.
- **Default padding**: All padding properties now default to **5** pixels for consistent spacing.

Best practices

- **Clear link text**: Use descriptive text that tells users where the link leads. Avoid generic text like "click here" or "link".
- **Accessible labels**: Always provide descriptive **AccessibleLabel** text for screen readers that explains the link's destination.
- **URL validation**: Only use standard `https://` or `http://` URLs. The control blocks unsafe protocols for security.
- **Visual differentiation**: Use the **Type**, **Color**, or **Underline** properties to make links visually distinct from regular text.
- **Test navigation**: Use Alt+Click in edit mode to test that links navigate to the correct destinations.
- **Mobile tap targets**: Ensure links are large enough to tap easily on mobile devices (minimum 32x32 pixels height).

Number Input modern control in canvas apps

Summarize this article for me

A numeric input field with increment and decrement buttons, validation, and decimal precision control.

Description

The **Number Input** control is a modern control in Power Apps that lets users enter numeric values with built-in validation, increment/decrement buttons, and configurable precision settings. This control provides a user-friendly interface for numeric data entry while automatically enforcing data integrity through minimum and maximum value constraints.

Use this control when you need to collect numbers from users, such as quantities, prices, percentages, or measurements. The control includes step buttons for easy value adjustment, supports decimal precision control, and provides visual validation feedback to ensure data quality.

Key capabilities:

- Input validation with customizable min/max boundaries
- Increment and decrement buttons with configurable step values
- Decimal precision control from integers to three decimal places
- Built-in accessibility features and screen reader support
- Responsive design that adapts to different screen sizes

Key properties for this control are **Value**, **Min**, **Max**, **Step**, and **Precision**.

General

Default – The initial value displayed when the control first loads. Use this value to set a default numeric value before user interaction.

Value – The current numeric value in the control. This value is the output property you reference in formulas to get the user's entered number.

HintText – Placeholder text displayed in the input field when it's empty. Use this text to guide users on what value to enter.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnChange – How the app responds when the user changes the value. This event fires when the user moves focus away from the control (on blur) or clicks the increment or decrement step buttons, not on every keystroke.

Min – The minimum allowed value. Users can't enter or step below this number. The control shows a validation error if the user attempts to enter a value below the minimum.

Max – The maximum allowed value. Users can't enter or step above this number. The control shows a validation error if the user attempts to enter a value above the maximum.

Step – The increment or decrement amount when users click the step up or down buttons. Default is **1**.

Precision – The number of decimal places to display and allow. Accepts `DecimalPrecision` enum values:

Expand table

Value	Description
`DecimalPrecision.Auto`	Automatically determines decimal places based on input (default)
`DecimalPrecision.'0'`	No decimal places (integers only)
`DecimalPrecision.'1'`	One decimal place (e.g., 12.3)
`DecimalPrecision.'2'`	Two decimal places (e.g., 12.34)
`DecimalPrecision.'3'`	Three decimal places (e.g., 12.345)

ValidationState – The visual validation state of the control. Accepts `ValidationState` enum values:

Expand table

Value	Description
`ValidationState.None`	No validation styling (default)
`ValidationState.Error`	Shows error styling (red border)

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, the value is shown but can't be edited.

Size and position

Align – The horizontal alignment of text within the control. Accepts `Align` enum values:

Expand table

Value	Description
`Align.Left`	Aligns text to the left edge (default)
`Align.Center`	Centers text horizontally
`Align.Right`	Aligns text to the right edge

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **320**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the text and the top edge of the control.

PaddingBottom – Distance between the text and the bottom edge of the control.

PaddingLeft – Distance between the text and the left edge of the control.

PaddingRight – Distance between the text and the right edge of the control.

Style and theme

Appearance – The visual style of the control. Accepts `Appearance` enum values:

Expand table

Value	Description
`Appearance.Filled`	Filled background style

Value	Description
`Appearance.FilledDarker`	Darker filled background (default)
`Appearance.Outline`	Outlined border with transparent background

BasePaletteColor – The base color that the theme uses to generate the control's color palette. Change this property to apply a different theme color to the control.

Font – The name of the font family for the text.

Size – The font size of the text, in points.

Color – The color of the text in the control.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Accessibility

AccessibleLabel – A label for screen readers to announce what the input field is for. Describe the type of numeric data expected, such as "Product quantity" or "Age in years".

ContentLanguage – The language used for the input text. If you don't specify this property, the app settings provide the value.

Example

The following YAML example shows a product quantity selector with inventory validation and a currency amount input with dynamic formatting:

YAML

```yaml
- QuantityInput:
    Control: ModernNumberInput@1.0.0
    Properties:
      Default: =1
      Min: =1
      Max: =100
      Step: =1
      Precision: =DecimalPrecision.'0'
      HintText: ="Enter quantity"
      AccessibleLabel: ="Product quantity"
      X: =40
      Y: =100
      Width: =200
      Height: =32

- PriceInput:
    Control: ModernNumberInput@1.0.0
    Properties:
      Default: =0
      Min: =0
      Max: =10000
      Step: =0.01
      Precision: =DecimalPrecision.'2'
      HintText: ="0.00"
      Align: =Align.Right
      Appearance: =Appearance.FilledDarker
      AccessibleLabel: ="Purchase amount in dollars"
      X: =40
      Y: =150
      Width: =200
      Height: =32

- DiscountInput:
    Control: ModernNumberInput@1.0.0
    Properties:
      Default: =0
      Min: =0
      Max: =100
      Step: =5
      Precision: =DecimalPrecision.'1'
      HintText: ="0.0"
      AccessibleLabel: ="Discount percentage"
      X: =40
      Y: =200
      Width: =200
      Height: =32
```

Recent updates

The updated version of the **Number input** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Removed properties

Expand table

Removed property	Notes
`TriggerOutput`	Removed entirely. **OnChange** now fires on focus out and step button clicks.

Bug fixes and improvements

- **OnChange optimization**: The **OnChange** event now fires on focus out (when the user leaves the field) and when clicking step buttons, not on every keystroke. This change improves performance and reduces unnecessary formula evaluations.
- **Default value**: The **Default** property allows you to set an initial value when the control loads, separate from the **Value** property.
- **HintText support**: New **HintText** property provides placeholder text to guide users.
- **Color property added**: The **Color** property for text color is now available. This property was missing in the previous version.

- **Fill property added**: The **Fill** property for background color is now available for better styling control.
- **Font property added**: The **Font** property allows you to change the font family.
- **Race condition fixed**: Resolved an issue where entering a new value and immediately submitting a form recorded the previous value instead of the new one.
- **Value overflow fixed**: Numbers no longer overflow or display incorrectly at high values.
- **Min/Max validation improved**: The control now properly validates that Min can't exceed Max.
- **Simplified properties**: Properties are now logically organized into **Data** and **Design** sections for better discoverability.

Best practices

- **Set reasonable boundaries**: Always define **Min** and **Max** values to prevent invalid data entry.
- **Match precision to data**: Use **Precision** to match your data requirements (integers for quantities, two decimals for currency, and so on).
- **Appropriate step values**: Set **Step** to meaningful increments (for example, 5 for ages, 0.01 for currency, 10 for large numbers).
- **Clear hints**: Use **HintText** to show the expected format or example values (for example, "0.00" for currency).
- **Validate input**: Use **ValidationState** to provide visual feedback when values are out of acceptable ranges.
- **Accessible labels**: Always provide descriptive **AccessibleLabel** text that explains what numeric value is expected.
- **OnChange efficiency**: Since **OnChange** fires on blur and step clicks (not every keystroke), it's safe to use for calculations or data updates without performance concerns.

Limitations

- The control doesn't directly support currency symbols. Use separate Text controls to display currency formatting.
- Step buttons might not scale proportionally with control size in all scenarios.

Progress bar modern control in Power Apps

Article • 03/19/2024

Displays the progress, can be configured as determinate showcasing exact progress or indeterminate for ongoing progress.

Description

The progress bar can be configured to show various states of progress in the apps. This versatile control can be used to inform users on their progress as they work on the app or can be used to show loading scenarios. The key properties for this control are **Value**, **Max**, and **Indeterminate**.

General

Value – Number between 0 and 'max', which specifies how much of the task is completed. Only applicable for determinate state.

Max - The maximum value, which indicates the task is complete. The ProgressBar bar is full when value equals max. This is useful when you want to show capacity or how much of the total is uploaded or downloaded.

AccessibleLabel – Label for screen readers.

Visible - Whether a control appears or is hidden.

Behavior

Indeterminate – Set the bar to determinate or indeterminate. In the indeterminate state the value property and max property aren't honored.

Size and position

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

ProgressColor – For determinate state only, the color prop can be used to indicate a "brand" state (default), "error" state (red), "warning" state (orange), or "success" state (green). For indeterminate state, ProgressColor falls back to BasePaletteColor regardless of selected color.

Thickness – The thickness of the progress bar. Current options are only medium and large.

Shape – The shape of the bar and track. The shape property affects the corners of the bar.

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color. If the value is null or zero, then the color is driven by selected Fluent theme.

Additional properties

OnChange – Actions to perform when the value of control gets updated.

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

Radio modern control in canvas apps

Summarize this article for me

A group of mutually exclusive radio button options that users can use to select one item from a list.

Description

The **Radio** modern control provides a user-friendly way to present mutually exclusive options in your canvas apps. Users can select exactly one option from a group of choices, making it ideal for scenarios like selecting shipping methods, rating satisfaction, or choosing payment types.

This control automatically manages the selection state—when a user selects one option, any previously selected option is automatically deselected. The Radio control supports both vertical and horizontal layouts, customizable styling, and comprehensive accessibility features to ensure your apps work for all users.

Use the **Radio** control when you need users to make a single choice from 2-7 clearly defined options. For larger option sets, consider using a Combo Box control instead.

Key properties for this control are **Items**, **ItemDisplayText**, **Default**, and **Selected**.

General

Items – The data source that provides the list of options to display. Can be a table, collection, or list of values. Each item becomes a selectable radio button option.

ItemDisplayText – The formula that determines what text displays for each radio button option. Use `ThisItem` to reference the current item from **Items**. For example, `ThisItem.Title` or `ThisItem.OptionName`.

Default – The item that the control selects by default when it first loads. Must match an item from the **Items** source.

Selected – The currently selected item (output property). Use this in formulas to reference which option the user chooses.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnChange – How the app responds when the user selects a different radio button option. This event fires immediately every time the selection changes.

Layout – The arrangement of radio button options. Accepts `Layout` enum values:

Expand table

Value	Description
`Layout.Vertical`	Stacks options vertically (default)
`Layout.Horizontal`	Arranges options horizontally in a row

Required – Whether the user must select an option before submitting a form. When `true`, the control shows validation styling if no selection exists.

TriggerOutput – Forces the control to output its current selected value. Use this value when you need to manually trigger value updates.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, the selected option appears with a read-only appearance (not grayed out like **Disabled**).

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges.

Height – Distance between the control's top and bottom edges. The control automatically sizes to fit all radio button options.

PaddingTop – Distance between the options and the top edge of the control.

PaddingBottom – Distance between the options and the bottom edge of the control.

PaddingLeft – Distance between the options and the left edge of the control.

PaddingRight – Distance between the options and the right edge of the control.

LineHeight – The spacing between radio button options, measured in pixels or points.

Style and theme

BasePaletteColor – The base color that the theme uses to generate the control's color palette. Change this property to apply a different theme color to the control.

Font – The name of the font family in which option text appears.

Size – The font size of the option text, in points.

Color – The color of the option text in the control.

FontWeight – The weight (thickness) of the option text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the option text appears in italic style.

Underline – Whether a line appears under the option text.

Strikethrough – Whether a line appears through the middle of the option text.

Fill – The background fill color of the control.

HoverColor – The color of an option's text when the user hovers the mouse over it.

PressedColor – The color of an option's text when the user clicks it.

DisabledColor – The color of option text when the control is in **Disabled** mode.

RadioSize – The size of the radio button circles in pixels.

RadioBackgroundFill – The background fill color of the radio button circles.

RadioBorderColor – The border color of the radio button circles.

RadioSelectionFill – The fill color of the inner circle when a radio button is selected.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Accessibility

AccessibleLabel – A label for screen readers to announce what the radio group represents. It should describe the category or question being answered (for example, "Shipping method" or "Payment type").

ContentLanguage – The language used for the option text. Inherits from app settings if not specified.

Example

The following YAML example shows radio button controls with different option sets:

YAML

```yaml
- ShippingRadio:
    Control: ModernRadio@1.0.0
    Properties:
      Items: =["Standard (5-7 days)", "Express (2-3 days)", "Overnight"]
      Layout: =Layout.Vertical
      AccessibleLabel: ="Select shipping method"
      X: =40
      Y: =100
      Width: =300

- SatisfactionRadio:
    Control: ModernRadio@1.0.0
    Properties:
      Items: =["Very Satisfied", "Satisfied", "Neutral", "Unsatisfied", "Very
Unsatisfied"]
      Required: =true
      Layout: =Layout.Vertical
```

```
      AccessibleLabel: ="Service satisfaction rating"
      X: =40
      Y: =200
      Width: =250

- PaymentRadio:
    Control: ModernRadio@1.0.0
    Properties:
      Items: =["Credit Card", "Debit Card", "PayPal", "Bank Transfer"]
      Layout: =Layout.Vertical
      AccessibleLabel: ="Select payment method"
      X: =40
      Y: =350
      Width: =320
```

Recent updates

The updated version of the **Radio** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Bug fixes and improvements

- **Item order preserved**: The control now respects the order of items in the **Items** property and displays them in the same sequence. Previously, the control sometimes reordered items unexpectedly.

- **View mode appearance**: When you set **DisplayMode** to **View**, the control displays a proper read-only appearance instead of appearing disabled or grayed out.
- **OnChange reliability**: The **OnChange** event now fires immediately and reliably on every selection change.
- **Gallery selection fixed**: Radio buttons inside galleries now respond correctly to single clicks. Previously, a double-click was sometimes required.
- **Scrolling support**: Long lists of radio options now scroll properly instead of being cut off.
- **Theme color respected**: The **BasePaletteColor** property is now properly respected and no longer overridden by default colors.
- **Default value matching**: The **Default** property now correctly matches items from the **Items** data source without unexpected errors.
- **Hover and pressed states**: New **HoverColor** and **PressedColor** properties provide visual feedback for user interactions.
- **Radio styling control**: New properties (**RadioSize**, **RadioBackgroundFill**, **RadioBorderColor**, **RadioSelectionFill**) give you fine-grained control over radio button appearance.
- **Disabled state color**: New **DisabledColor** property controls text color when the control is disabled.

Best practices

- **Clear option text**: Use **ItemDisplayText** to provide clear, descriptive labels for each option. Avoid abbreviations or jargon.
- **Reasonable option count**: Radio buttons work best with 2-7 options. For more options, consider using a Combo Box control instead.
- **Default selection**: Always set a **Default** value to guide users toward the most common or recommended choice.
- **Accessible labels**: Provide descriptive **AccessibleLabel** text that explains what the user is choosing between (for example, "Select your preferred contact method").
- **Visual feedback**: Use **HoverColor** and **PressedColor** to provide clear visual feedback for user interactions.
- **Layout consideration**: Use **Layout.Vertical** for most cases. Only use **Layout.Horizontal** when you have short option labels and limited options (2-4).

Limitations

- The control height automatically adjusts to fit all options and you can't manually constrain it to a specific height with scrolling (items scroll if needed).
- Very small or very large width and height values might not be fully respected by the control.

Slider modern control in canvas apps

Let users select a numeric value by dragging a handle along a track.

Description

The **Slider** modern control lets users set a value between a minimum and maximum by dragging a handle along a track. The control supports horizontal and vertical orientation.

Use this control when you want users to pick a value from a continuous range, such as:

- Volume or brightness controls
- Budget or price range selectors
- Quantity pickers
- Rating or satisfaction scales

Key properties for this control are **Default**, **Min**, **Max**, **Value** (output), and **OnChange**.

> ⓘ **Note**
>
> This article describes the updated Slider modern control. For information about what changed from the previous version, see Recent updates.

General

Default – The initial value of the slider before the user makes a change. Resets to this value when `Reset` is triggered. Default is **50**.

Min – The minimum value the user can set. Default is **0**.

Max – The maximum value the user can set. Default is **100**.

Visible – Whether the control appears or is hidden.

Behavior

OnChange – Actions to perform when the user changes the slider value. Use `Self.Value` to read the current value.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

LayoutDirection – The orientation of the slider track. Accepts `LayoutDirection` enum values:

Expand table

Value	Description
`LayoutDirection.Horizontal`	Handle moves left to right. Default.
`LayoutDirection.Vertical`	Handle moves bottom to top.

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **200**.

Height – Distance between the control's top and bottom edges. Default is **35**.

Style and theme

BasePaletteColor – The base color that the theme uses to generate the control's color palette. Change this value to apply a different theme color to the slider track and handle.

Size – The visual size of the slider handle and track. Accepts `SliderSize` enum values:

Expand table

Value	Description
`SliderSize.Small`	Smaller handle and track.
`SliderSize.Medium`	Standard size. Default.
`SliderSize.Large`	Larger handle and track.

Accessibility

AccessibleLabel – Label that screen readers read. Describe the purpose of the slider (for example, `"Volume"`). Always set this property so assistive technologies can identify the control.

ContentLanguage – The display language for the control content, if different from the app language.

Tooltip – Explanatory text that appears when the user hovers over the control. Helpful for sighted users who need additional context about the slider's purpose.

Output properties

Value – The current value of the slider, updated as the user drags the handle. Use this value in formulas to read the slider's current position (for example, `Slider1.Value`).

Examples

Budget selector with a label

This example shows a horizontal slider that lets users set a monthly budget. A label updates in real time as the user drags the handle.

YAML

```yaml
- BudgetSlider:
    Control: ModernSlider@1.0.0
    Properties:
      Default: =500
      Min: =0
      Max: =10000
      LayoutDirection: =LayoutDirection.Horizontal
      Size: =SliderSize.Medium
      AccessibleLabel: ="Monthly budget"
      Tooltip: ="Drag to set your monthly budget"
      Width: =300
      Height: =35

- BudgetLabel:
    Control: ModernText@1.0.0
    Properties:
      Size: =14
      Text: |-
        ="Budget: $" & BudgetSlider.Value
```

Vertical volume slider

This example uses a vertical slider for a volume control and writes the selected value to a variable.

YAML

```yaml
- VolumeSlider:
    Control: ModernSlider@1.0.0
    Properties:
      Default: =30
      Min: =0
      Max: =100
      LayoutDirection: =LayoutDirection.Vertical
      Size: =SliderSize.Small
      AccessibleLabel: ="Volume"
      Width: =35
      Height: =200
```

Recent updates

The updated version of the **Slider** modern control includes the following improvements and behavior changes.

Property renames

Expand table

Previous property	New property	Notes
`Value` (input)	`Default`	The input property that sets the initial value is now `Default`. `Value` is now a read-only output property.
`Layout`	`LayoutDirection`	Renamed for clarity and changed from string to typed enum.

Enum format changes

Expand table

Property	Previous value	New value
`LayoutDirection`	`"Horizontal"`	`LayoutDirection.Horizontal`
`LayoutDirection`	`"Vertical"`	`LayoutDirection.Vertical`
`Size`	`"Small"`	`SliderSize.Small`
`Size`	`"Medium"`	`SliderSize.Medium`

Property	Previous value	New value
`Size`	`"Large"`	`SliderSize.Large`

Bug fixes and improvements

- **Separate Default and Value**: `Default` sets the initial value; `Value` is now a dedicated read-only output property. This change matches the pattern used by Number Input and other modern controls, making formulas more predictable.
- **Tooltip support**: New `Tooltip` property shows explanatory text on hover.
- **Updated enums**: `LayoutDirection` and `Size` now use typed Power Fx enums, improving IntelliSense and reducing formula errors.

Best practices

- **Set meaningful Min and Max values.** A slider from 0 to 100 works well for percentages, but for dollar amounts or quantities, use a range that matches the expected input so each drag movement feels responsive.
- **Always provide an AccessibleLabel.** Screen readers rely on this property to describe the slider's purpose to users with visual impairments.
- **Pair the slider with a label** that displays the current value (for example, `"Budget: $" & Slider1.Value`). Users can see the exact number without guessing from the handle position.
- **Use vertical orientation sparingly.** Horizontal sliders are more familiar to most users. Reserve vertical sliders for cases where the metaphor matches, such as volume faders.

Spinner modern control in Power Apps

Article • 03/19/2024

Displays state in motion such as loading a page or table.

Description

Spinner control can be used to display loading scenarios where an action is in progress. This powerful control provides multiple display options suited for many scenarios. The key properties for this control are **Label**, **Appearance**, and **SpinnerSize**.

General

Label – The label to the spinner. The label slot receives the styling related to the text associated with the Spinner.

AccessibleLabel – Label for screen readers.

Visible - Whether a control appears or is hidden.

Size and position

LabelPosition – Where the label is positioned relative to the spinner.

SpinnerSize – The size of the spinner.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

Appearance – The appearance of the Spinner. Primary or Inverted.

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color.

Font - The name of the family of fonts in which text appears.

FontSize - The font size of the text that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

FontWeight - The weight of the text in a control: Bold, Lighter, Normal, or Semibold.

FontItalic - Whether the text in a control is italic.

FontUnderline - Whether a line appears under the text that appears on a control.

FontStrikethrough - Whether a line appears through the text that appears on a control.

Additional properties

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

OnChange - Actions to perform when the user changes the value of a control.

Tab List modern control in canvas apps

Summarize this article for me

A tabbed navigation control that users can use to switch between different content sections by clicking tab headers.

Description

The **Tab List** modern control enables you to create intuitive tabbed navigation interfaces in canvas apps. Users can switch between different content sections by selecting tab headers, making it ideal for organizing related information or features within a single screen.

This control serves as a navigation component that you combine with other controls to build comprehensive tabbed experiences. When users select a tab, you can use conditional visibility to show or hide content sections accordingly. The **Tab List** control offers flexible styling options and accessibility features to ensure your tabbed interfaces work effectively for all users.

Key capabilities:

- Display multiple clickable tab headers from a data source
- Support various visual styles including transparent, subtle, underline, and filled appearances
- Provide keyboard navigation and screen reader support
- Enable responsive alignment and sizing options
- Trigger events when users interact with tabs

Use the **Tab List** control when you need to organize content into logical sections that users can navigate independently, such as product details, dashboard views, or settings categories.

Key properties for this control are **Items**, **Default**, **Selected**, and **Appearance**.

General

Items – The data source that provides the list of tabs to display. Can be a table, collection, or list of values. Each item becomes a clickable tab header.

Default – The tab that is selected by default when the control first loads. Must match an item from the **Items** source.

Selected – The currently selected tab (output property). Use this in formulas to reference which tab the user chooses and to control visibility of content sections.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnChange – How the app responds when the user clicks a different tab. This event fires every time the selected tab changes. Use this value to update variables, load data, or track navigation.

OnSelect – How the app responds when the user clicks any tab (including the currently selected one). Use this value for additional interactions beyond navigation.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, tabs are displayed but can't be clicked.

Size and position

Align – The horizontal alignment of tab text within each tab button. Accepts `Align` enum values:

Expand table

Value	Description
`Align.Left`	Aligns text to the left edge
`Align.Center`	Centers text horizontally (default)
`Align.Right`	Aligns text to the right edge

Alignment – The alignment and positioning of the entire tab list. Accepts `TabListAlignment` enum values:

Expand table

Value	Description
`TabListAlignment.Start`	Aligns tabs to the left or start edge
`TabListAlignment.Center`	Centers the tab list (default)
`TabListAlignment.End`	Aligns tabs to the right or end edge

X – Distance between the left edge of the control and the left edge of its parent container. If the control has no parent container, the screen acts as the parent container.

Y – Distance between the top edge of the control and the top edge of its parent container. If the control has no parent container, the screen acts as the parent container.

Width – Distance between the control's left and right edges. Default is **300**.

Height – Distance between the control's top and bottom edges. Default is **60**.

PaddingTop – Distance between the tab text and the top edge of each tab button.

PaddingBottom – Distance between the tab text and the bottom edge of each tab button.

PaddingLeft – Distance between the tab text and the left edge of each tab button.

PaddingRight – Distance between the tab text and the right edge of each tab button.

Style and theme

Appearance – The visual style of the tabs. Accepts `TabListAppearance` enum values:

Expand table

Value	Description
`TabListAppearance.Transparent`	Transparent background with text only
`TabListAppearance.Subtle`	Subtle background with minimal styling
`TabListAppearance.Underline`	Tabs with underline indicator for selection
`TabListAppearance.Filled`	Filled tab buttons with solid backgrounds

Font – The name of the font family for the tab text.

Size – The font size of the tab text, in points.

Color – The color of the tab text in the control.

FontWeight – The weight (thickness) of the tab text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text

Value	Description
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the tab text appears in italic style.

Underline – Whether a line appears under the tab text.

Strikethrough – Whether a line appears through the middle of the tab text.

BorderColor – The color of the borders around tabs (when applicable based on Appearance).

BorderStyle – The style of the tab borders. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the tab borders in pixels.

RadiusTopLeft – The corner radius for the top-left corner of tab buttons.

RadiusTopRight – The corner radius for the top-right corner of tab buttons.

RadiusBottomLeft – The corner radius for the bottom-left corner of tab buttons.

RadiusBottomRight – The corner radius for the bottom-right corner of tab buttons.

Accessibility

AccessibleLabel – A label for screen readers to announce what the tab list represents. It should describe the category or sections being navigated (for example, "Product information sections" or "Report views").

ContentLanguage – The language used for the tab text. If you don't specify this property, the app settings provide the value.

Example

The following YAML example shows tab list controls with different appearance styles:

YAML

```yaml
- ProductTabs:
    Control: ModernTabList@1.0.0
```

```
    Properties:
      Items: =["Overview", "Specifications", "Reviews", "Support"]
      Default: ="Overview"
      Appearance: =TabListAppearance.Underline
      Alignment: =TabListAlignment.Center
      Size: =16
      FontWeight: =FontWeight.Semibold
      AccessibleLabel: ="Product information tabs"
      X: =40
      Y: =100
      Width: =600
      Height: =60

- DashboardTabs:
    Control: ModernTabList@1.0.0
    Properties:
      Items: =["Sales", "Inventory", "Reports"]
      Default: ="Sales"
      Appearance: =TabListAppearance.Filled
      Alignment: =TabListAlignment.Start
      Size: =15
      AccessibleLabel: ="Dashboard section tabs"
      X: =40
      Y: =180
      Width: =600
      Height: =60

- SettingsTabs:
    Control: ModernTabList@1.0.0
    Properties:
      Items: =["Account", "Privacy", "Notifications", "Billing"]
      Default: ="Account"
      Appearance: =TabListAppearance.Subtle
      Alignment: =TabListAlignment.Start
      Size: =14
      Align: =Align.Left
      AccessibleLabel: ="Settings categories"
      X: =40
      Y: =260
      Width: =250
      Height: =60
```

Recent updates

The updated version of the **Tab list** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Bug fixes and improvements

- **Appearance property**: The new **Appearance** property with four visual styles (**Transparent**, **Subtle**, **Underline**, **Filled**) gives you more design flexibility for tabbed interfaces.
- **Item order preserved**: Tabs now display in the exact order specified in the **Items** property. Previously, the control sometimes reordered tabs unexpectedly.
- **Items refresh fixed**: Updating the **Items** property now automatically refreshes the tab list. Previously, changes to **Items** didn't always trigger a visual update.
- **Default property**: The new **Default** property allows you to specify which tab is selected when the control loads.
- **Alignment control**: The new **Alignment** property controls the positioning of the entire tab list (start, center, end).
- **Improved tab sizing**: Tab buttons now size more consistently and responsively.

Best practices

- **Clear tab labels**: Use short, descriptive labels for tabs (one or two words). Avoid long phrases that make tabs too wide.
- **Reasonable tab count**: Use two to seven tabs for optimal usability. For more sections, consider alternative navigation patterns like a tree view or menu.
- **Default selection**: Always set a **Default** value to ensure a tab is selected when the control loads.
- **Conditional visibility**: Use the **Selected** output property to control visibility of content sections.

```
ContentSection.Visible = TabList1.Selected.Value = "Overview"
```

- **Accessible labels**: Provide descriptive **AccessibleLabel** text that explains what the tabs navigate between.
- **Consistent appearance**: Use the same **Appearance** style for all tab lists in your app for visual consistency.
- **OnChange for data loading**: Use **OnChange** to load data or update variables when tabs change, improving performance by loading only what's needed.

Limitations

- The Tab List control provides navigation only - you must manually control content visibility using the **Selected** property.
- Very small or very large width and height values might not be fully respected by the control.
- Tab buttons don't automatically scroll horizontally if there are too many tabs to fit the width.

Text modern control in canvas apps

Summarize this article for me

Use this control to display text and labels on your app screen.

Description

The **Text** modern control displays static or dynamic text content in your canvas app. Use it for labels, headings, messages, and any text that doesn't require user input.

This versatile control offers rich formatting options, including font styling, colors, alignment, and automatic sizing. You can display static text strings or dynamic content using Power Fx formulas. The control also supports user interaction through the **OnSelect** event, making it useful for clickable labels and interactive text elements.

Key properties for this control are **Text**, **Size**, and **Color**.

General

Text – The text string to display on the canvas. Supports any text or Power Fx formula that evaluates to a string.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnSelect – How the app responds when the user selects the Text control. The control is accessible: **OnSelect** also triggers when the user presses Enter or Space while the control has keyboard focus.

Wrap – Whether the text wraps to the next line when it exceeds the control width. When set to `false`, text is clipped at the control boundary.

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges.

Height – Distance between the control's top and bottom edges.

AutoHeight – Whether the control automatically increases its height when the text content exceeds the visible area. When **Visible** is `false`, the **Height** output property doesn't update as text changes.

Align – The horizontal alignment of text within the control. Accepts `Align` enum values:

Expand table

Value	Description
`Align.Left`	Aligns text to the left edge
`Align.Center`	Centers text horizontally
`Align.Right`	Aligns text to the right edge
`Align.Justify`	Stretches text to fill the full width

VerticalAlign – The vertical alignment of text within the control. Accepts `VerticalAlign` enum values:

Expand table

Value	Description
`VerticalAlign.Top`	Aligns text to the top
`VerticalAlign.Middle`	Centers text vertically (default)
`VerticalAlign.Bottom`	Aligns text to the bottom

Style and theme

Font – The name of the font family for the text.

Size – The font size of the text, in points. The default is **15**.

Color – The color of the text in the control.

FontWeight – The weight (thickness) of the text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the text appears in italic style.

Underline – Whether a line appears under the text.

Strikethrough – Whether a line appears through the middle of the text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

PaddingTop – Distance between the text and the top edge of the control.

PaddingBottom – Distance between the text and the bottom edge of the control.

PaddingLeft – Distance between the text and the left edge of the control.

PaddingRight – Distance between the text and the right edge of the control.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Example

The following YAML example shows a clickable label with styling that you can use for headings or interactive text elements:

YAML

```yaml
- TitleLabel:
    Control: ModernText@1.0.0
    Properties:
      Text: ="Welcome to Power Apps"
      X: =40
      Y: =40
      Width: =300
      Height: =50
      Size: =24
      FontWeight: =FontWeight.Bold
      Color: =RGBA(0, 120, 212, 1)
      Align: =Align.Center
      VerticalAlign: =VerticalAlign.Middle

- StatusLabel:
    Control: ModernText@1.0.0
    Properties:
      Text: '="Status: Active"'
      X: =40
      Y: =120
      Width: =200
      Height: =40
      Size: =16
      FontWeight: =FontWeight.Semibold
      Color: =Color.Green
      Fill: =RGBA(0, 255, 0, 0.1)
      BorderColor: =Color.Green
      BorderThickness: =2
      RadiusTopLeft: =8
      RadiusTopRight: =8
      RadiusBottomLeft: =8
      RadiusBottomRight: =8
      OnSelect: =Set(varLabelClicked, true)
```

Recent updates

The updated version of the **Text** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`Weight`	`FontWeight`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Removed properties

Expand table

Removed property	Notes
`DisplayMode`	Removed from the property panel. The property still exists for backward compatibility but has no effect. The Text control is display-only; use the **OnSelect** event for interactive behavior.

Bug fixes and improvements

- **OnSelect event**: The control now supports an **OnSelect** event, making it possible to trigger actions when a user clicks or taps the text. This event is fully accessible and also responds to keyboard input (Enter or Space).
- **Vertical alignment default**: The default **VerticalAlign** is now `VerticalAlign.Middle` for better visual balance.
- **Auto height improvements**: Fixed scroll bar appearing in portrait mode and auto height not recalculating when the control is hidden.
- **Text scaling**: Fixed an issue where the text control didn't scale correctly within containers.
- **Updated command bar**: The authoring command bar and right-click menu now show Font, Font size, Alignment, Font color, and Background color for quick access.
- **Mobile-optimized defaults**: When adding the control in a mobile layout, the app automatically adjusts the defaults (font size 15, padding 5, width 150, height 32).

Text Input modern control in canvas apps

Summarize this article for me

A text input field for capturing single-line or multi-line text, with support for password masking and search modes.

Description

Use the **Text Input** control to capture text input from users with flexible formatting options. The control supports single-line text, multi-line text areas, password fields with masking, and search input with appropriate styling. Key properties for this control are **Text**, **Placeholder**, **Type**, and **TriggerOutput**.

General

Default – The initial text displayed when the control first loads. Use this to set a default value before user interaction.

Text – The current text value in the control (output property). This is what you reference in formulas to get the user's entered text.

Placeholder – Hint text displayed in the input field when it's empty. Use this to guide users on what to enter. Default is **"Enter text"**.

Visible – Whether the control appears or is hidden. Use a Power Fx formula to show or hide the control based on app state.

Behavior

OnChange – How the app responds when the user changes the text. This event fires when the user moves focus away from the control (on blur), not on every keystroke. This improves performance and prevents issues with rapid formula execution.

OnSelect – How the app responds when the user clicks or taps inside the control.

Type – The input mode for the text field. Accepts `TextInputType` enum values:

Expand table

Value	Description
`TextInputType.SingleLine`	Standard single-line text input (default)
`TextInputType.Multiline`	Multi-line text area that allows line breaks
`TextInputType.Password`	Password field that masks characters as ***
`TextInputType.Search`	Search input with appropriate styling

TriggerOutput – Controls when the **Text** output property updates. Accepts `TriggerOutput` enum values:

Expand table

Value	Description
`TriggerOutput.Keypress`	Updates on every keystroke (default)
`TriggerOutput.FocusOut`	Updates only when focus leaves the control
`TriggerOutput.Delayed`	Updates after a short delay (used in forms)

> **Note**
>
> When added to a form, **TriggerOutput** automatically defaults to **Delayed** for better form performance.

MaxLength – The maximum number of characters allowed in the input field. Users cannot type beyond this limit.

Required – Whether the user must enter text before submitting a form. When `true`, the control shows validation styling if left empty.

ValidationState – The visual validation state of the control. Accepts `ValidationState` enum values:

Expand table

Value	Description
`ValidationState.None`	No validation styling (default)
`ValidationState.Error`	Shows error styling (red border)

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**). In **View** mode, the text is shown but cannot be edited (truly read-only).

Size and position

Align – The horizontal alignment of text within the control. Accepts `Align` enum values:

Expand table

Value	Description
`Align.Left`	Aligns text to the left edge (default)
`Align.Center`	Centers text horizontally
`Align.Right`	Aligns text to the right edge

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **320**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the text and the top edge of the control.

PaddingBottom – Distance between the text and the bottom edge of the control.

PaddingLeft – Distance between the text and the left edge of the control.

PaddingRight – Distance between the text and the right edge of the control.

Style and theme

Appearance – The visual style of the control. Accepts `Appearance` enum values:

Expand table

Value	Description
`Appearance.Filled`	Filled background style

Value	Description
`Appearance.FilledDarker`	Darker filled background (default)
`Appearance.Outline`	Outlined border with transparent background

BasePaletteColor – The base color used by the theme to generate the control's color palette. Changes this property to apply a different theme color to the control.

Font – The name of the font family in which text appears.

Size – The font size of the text, in points.

Color – The color of the text in the control.

FontWeight – The weight (thickness) of the text. Accepts `FontWeight` enum values:

Expand table

Value	Description
`FontWeight.Bold`	Bold text
`FontWeight.Semibold`	Semibold text
`FontWeight.Normal`	Normal weight (default)
`FontWeight.Lighter`	Lighter weight

Italic – Whether the text appears in italic style.

Underline – Whether a line appears under the text.

Strikethrough – Whether a line appears through the middle of the text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Accessibility

AccessibleLabel – A label for screen readers to announce what the input field is for. Should describe the type of text expected (e.g., "Customer name" or "Feedback comments").

ContentLanguage – The language used for the input text. Inherits from app settings if not specified.

Example

The following YAML example shows text input controls with various input types:

YAML

```yaml
- NameInput:
    Control: ModernTextInput@1.0.0
    Properties:
      Placeholder: ="Enter your full name"
      Type: =TextInputType.SingleLine
      TriggerOutput: =TriggerOutput.Keypress
      Required: =true
      Appearance: =Appearance.FilledDarker
      AccessibleLabel: ="Full name, required field"
      X: =40
      Y: =100
      Width: =300
      Height: =32

- EmailInput:
    Control: ModernTextInput@1.0.0
    Properties:
      Placeholder: ="you@company.com"
      Type: =TextInputType.SingleLine
      TriggerOutput: =TriggerOutput.Keypress
      MaxLength: =100
      Required: =true
      AccessibleLabel: ="Email address, required field"
      X: =40
      Y: =150
      Width: =300
      Height: =32

- PasswordInput:
    Control: ModernTextInput@1.0.0
    Properties:
```

```
      Placeholder: ="At least 8 characters"
      Type: =TextInputType.Password
      TriggerOutput: =TriggerOutput.Keypress
      MaxLength: =50
      Required: =true
      AccessibleLabel: ="Password, must be at least 8 characters"
      X: =40
      Y: =200
      Width: =300
      Height: =32

- CommentsInput:
    Control: ModernTextInput@1.0.0
    Properties:
      Default: =""
      Placeholder: ="Tell us more about your inquiry..."
      Type: =TextInputType.Multiline
      TriggerOutput: =TriggerOutput.FocusOut
      MaxLength: =500
      Align: =Align.Left
      AccessibleLabel: ="Additional comments, optional, maximum 500 characters"
      X: =40
      Y: =250
      Width: =300
      Height: =120

- SearchInput:
    Control: ModernTextInput@1.0.0
    Properties:
      Placeholder: ="Search..."
      Type: =TextInputType.Search
      TriggerOutput: =TriggerOutput.Delayed
      Appearance: =Appearance.Outline
      AccessibleLabel: ="Search by name or description"
      X: =40
      Y: =390
      Width: =300
      Height: =32
```

Recent updates

The updated version of the **Text input** modern control includes improvements and behavior change.

Property renames

The following properties are renamed. Update any formulas in your app that reference the old property names.

Expand table

Previous property	New property
`FontColor`	`Color`
`FontSize`	`Size`
`FontItalic`	`Italic`
`FontStrikethrough`	`Strikethrough`
`FontUnderline`	`Underline`
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`

Bug fixes and improvements

- **OnChange optimization**: The **OnChange** event now fires only when the user leaves the field (on blur), not on every keystroke. This improves performance and prevents issues with rapid formula execution.
- **TriggerOutput flexibility**: The **TriggerOutput** property now defaults to **Keypress** for immediate updates, with **Delayed** used automatically in forms for better performance.
- **Default property**: New **Default** property allows you to set an initial value when the control loads.
- **Password preview**: Password fields now show masked characters (***) even in preview mode, making it easier to design secure forms.
- **DisplayMode.View fixed**: When set to **View** mode, the control is now truly read-only. Previously, users could still edit the text.
- **Null handling improved**: Blank or null values now properly return empty strings instead of null, preventing formula errors.
- **Multiline overflow fixed**: Multi-line text areas no longer have overflow issues when users press Enter to create new lines.
- **OnChange tabbing fixed**: **OnChange** no longer fires when users tab through fields without making changes.
- **Border rendering fixed**: Borders now render correctly even when control height is less than 32 pixels.
- **Color palette override**: The **BasePaletteColor** property in the property panel now properly overrides the global theme.

Best practices

- **Clear placeholders**: Use **Placeholder** to show example text or formatting hints (e.g., "MM/DD/YYYY" for dates).
- **Appropriate type**: Use **Type** appropriately - **Password** for sensitive data, **Multiline** for long text, **Search** for search boxes.
- **MaxLength validation**: Set **MaxLength** to prevent users from entering too much text, especially for database fields with character limits.
- **TriggerOutput consideration**: Use **Keypress** for immediate feedback (search, filters), **FocusOut** for validation, **Delayed** for expensive operations.
- **Required fields**: Mark required fields clearly with **Required** and provide visual feedback with **ValidationState**.
- **Accessible labels**: Always provide descriptive **AccessibleLabel** text that explains what text to enter.
- **OnChange efficiency**: Since **OnChange** fires on blur (not every keystroke), it's safe to use for data updates and validations without performance concerns.
- **Character counters**: For fields with **MaxLength**, consider showing a character count to help users stay within limits.

Toggle modern control in Power Apps

Article • 07/17/2024

A control that the user can turn on or off by moving the handle.

Description

A toggle is a user interface element that has been created for modern graphical user interfaces (GUIs), but it functions in the same manner as a checkbo. The key properties for this control are **Checked**, **Label**, **OnCheck**, **OnSelect**, and **OnUncheck**.

General

Label – The text shown next to the toggle.

AccessibleLabel – Label for screen readers.

Visible - Whether a control appears or is hidden.

Behavior

Checked - The initial value of a control before it's changed by the user.

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

Size and position

LabelPostion – The text shown next to the toggle can be placed before, after, or above the toggle.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color.

Font - The name of the family of fonts in which text appears.

FontSize - The font size of the text that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

FontWeight - The weight of the text in a control: **Bold**, **Lighter**, **Normal**, or **Semibold**.

FontItalic - Whether the text in a control is italic.

FontUnderline - Whether a line appears under the text that appears on a control.

FontStrikethrough - Whether a line appears through the text that appears on a control.

Additional properties

OnCheck – Actions to perform when the value of the toggle changes to **true**.

OnSelect – Actions to perform when the user selects a control.

OnUncheck – Actions to perform when the value of the toggle changes to **false**.

Avatar modern control in Power Apps

10/08/2025

A control that shows a graphic representation of a user, team, or entity.

Description

Use the avatar control to visually represent a user, team, or entity. This control supports both image and initials formats and allows a small badge to be included to help convey status. The key properties for this control are **Name** and **Image**.

General

Name - The name of the person or entity. Name is used to determine the initials displayed when there's no image and is also used for accessibility.

Image – The visual representation for the person or entity.

Badge – A small visual decoration added to convey status of the person or entity.

Visible - Whether a control appears or is hidden.

Size and position

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

Shape - Whether the avatar appears with a circular or square shape.

Appearance – An avatar can have portions of itself styled for greater emphasis or to be subtle.

The following options are available:

- **Brand**: Uses the modern theme to style the avatar. The Color palette property can be used to override this color scheme.
- **Neutral**: Uses a grayscale for the initials background to provide a subtle appearance.
- **Colorful**: Users a color from a predefined set of colors, based on a hash of the provided Name.

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color. If the value is null or zero, then the color is driven by the selected Fluent theme.

Font - The name of the family of fonts in which text appears.

FontSize - The font size of the text that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

FontWeight - The weight of the text in a control: **Bold**, **Lighter**, **Normal**, or **Semibold**.

FontItalic - Whether the text in a control is italic.

FontUnderline - Whether a line appears under the text that appears on a control.

FontStrikethrough - Whether a line appears through the text that appears on a control.

Additional properties

Out of office - Adjusts the Badge icon to show its corresponding "out of office" variant.

Copilot answer modern control in Power Apps (preview)

Summarize this article for me

[This article is pre-release document and is subject to change.]

A control that makers can use to add predefined questions that end users can use to get generated answers.

> **Important**
>
> Starting February 2, 2026, adding a Copilot answer control to new canvas apps will be discontinued. Existing apps with this control will remain functional for a limited time but will eventually no longer be supported. Microsoft 365 Copilot Chat in canvas apps is the new the recommended solution for natural language interactions in canvas apps. To ensure a smooth transition and prevent any disruption, we recommend that you migrate to Microsoft 365 Copilot chat as soon as it becomes available in your environment.

> **Note**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - App Copilot for canvas apps is currently rolling out and might not yet be available in your region.

Description

Makers can use the Copilot answer control to set predefined questions that end users can use to get generative answers with a single click. The control is optimized for mobile users and is powered by Microsoft Copilot.

Key properties

Data source (Items) – The Copilot answer control only supports Dataverse as the data source. The answer to the question comes from the Dataverse table that you select.

Views – A user can select any of the views that are available in the data source.

Fields - Default list of fields available for the table. Users can select **Edit** to see the list of fields. They can also add or modify the fields based on their requirements.

Title – A label that is displayed at the top of the Copilot answer control.

Question for Copilot – This is the question a maker asks the Copilot answer control. The question is used as the prompt to generate a response that is displayed by the answer control that's based on the selected **Data source** property.

Additional properties

Show answer – Should the Copilot answer control answer a question when the user clicks on the 'Arrow' icon (After sending) or as soon as the control loads when the question is defined in the properties window (Immediate).

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

Position - Whether a control appears or is hidden.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Size – The size of the control on the canvas

Last updated on 02/24/2026

Data Grid modern control in canvas apps (preview)

[This article is pre-release document and is subject to change.]

Display records from a data source in a scrollable, sortable, and searchable grid.

Description

The **Data Grid** modern control displays records in a column-and-row layout built on Fluent UI. It supports optional search filtering, sortable columns, and selectable rows. Columns are configured as sub-controls and support multiple types including text, number, phone, email, URL, and button. Use it when you need a high-performance, data-dense view of tabular data with built-in interaction. Key properties for this control are **Items**, **Searchable**, **Sortable**, and **SelectMultiple**.

> ⓘ **Note**
>
> The **Data Grid** control is a new control separate from the existing **Table** control. It is not a replacement for the **Table** control.

Limitations

- **Attachment column not supported**: Attachment-type columns from Dataverse are not currently supported and do not render in the grid.
- **Row virtualization not yet available**: Virtual scrolling for large datasets is not available in this release. It is planned and will be available in the coming weeks.

General

Items – The data source for the grid. Accepts a Dataverse table, collection, or inline table expression.

Visible – Whether the control appears or is hidden.

Behavior

Searchable – Whether a search bar appears above the grid. When **true**, users can type to filter visible rows; the current search string is exposed via the **SearchText** output property. Default is **false**.

Sortable – Whether users can sort by a column by selecting its header. Default is **false**.

SelectMultiple – Whether users can select more than one row at a time. Default is **false**.

ShowHeaders – Whether column header labels appear at the top of the grid. Default is **true**.

ShowSelector – Whether a checkbox appears at the start of each row for row selection. Default is **false**.

Required – Whether the user must select at least one row.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **792**.

Height – Distance between the control's top and bottom edges. Default is **475**.

Style and theme

BasePaletteColor – The base color used by the theme to generate the control's color palette.

Font – The font family used for the grid text.

Size – The font size of the grid text, in points. Default is **14**.

Color – The color of the grid text.

Output properties

Selected – The most recently selected row, returned as a record.

SelectedItems – All currently selected rows, returned as a table. Use this when **SelectMultiple** is **true**.

SearchText – The current value the user has typed in the search bar. Only available when **Searchable** is **true**.

Configuring columns

The Data Grid uses **Data Grid Column** sub-controls to define how each column appears and what data it shows. Columns are added when you connect a data source and configure fields in the authoring panel. Column properties are locked by default — select a column and choose **Unlock** to customize it.

Column properties

Header Text – The label shown in the column header.

Visible – Whether the column appears in the grid.

Width – The width of the column in pixels. Default is **150**.

Text – (Text, Phone, Email, URL, Button columns) A Power Fx formula evaluated per row that returns the value to display. Evaluated in the context of `ThisItem` (for example, `ThisItem.'Full Name'`).

Image – (Image column) A Power Fx formula evaluated per row that returns an image value or URL.

Icon – The Fluent icon shown in the column cell.

AccessibleLabel – (Image column) The accessible label for the image, read by screen readers.

Column types

Expand table

Column type	Description
Text column	Displays a text value.
Number column	Displays a numeric value.
Phone column	Displays a phone number.

Column type	Description
Email column	Displays an email address as a link.
URL column	Displays a URL as a hyperlink.
Button column	Displays a button in each row cell.

Example

The following YAML example shows a searchable grid with two text columns:

YAML

```
- DataGrid2:
    Control: ModernDataGrid@1.1.0
    Properties:
      Items: |-
        =Table({Name: "Alice Contoso", Department: "Sales"}, {Name: "Bob Fabrikam",
Department: "Engineering"}, {Name: "Carol Northwind", Department: "Marketing"})
      Searchable: =true
      X: =40
      Y: =40
    Children:
      - Department_Column1:
          Control: ModernDataGridColumn@1.1.0
          Variant: Textual
          IsLocked: true
          Properties:
            FieldDisplayName: ="Department"
            Text: =ThisItem.Department
      - Name_Column1:
          Control: ModernDataGridColumn@1.1.0
          Variant: Textual
          IsLocked: true
          Properties:
            FieldDisplayName: ="Name"
            Text: =ThisItem.Name
```

Last updated on 04/28/2026

Dropdown modern control in canvas apps

Let users pick a single value from a collapsible list.

Description

The **Dropdown** modern control presents a list of choices in a compact, collapsible format. Users select one item and the list collapses back to a single line. Use the **Dropdown** control when you need users to choose one option from a list of more than seven items, for required fields with a fixed set of choices, or for forms where screen space is limited. For fewer options (two to seven), consider using a Radio group instead. If users need to select multiple items, use a Combo box.

Key properties for this control are **Items**, **Default**, **ValidationState**, and **OnChange**.

> **Note**
>
> This article describes the updated Dropdown modern control. For information about what changed from the previous version, see Recent updates.

On desktop, the updated control opens a **Fluent-themed flyout** that matches the app's visual theme. The previous version opened the browser's HTML `<select>` element, which couldn't be themed.

General

Items – The source of data that contains the items that appear in the control. Accepts a table, a collection, or an inline array (for example, `["Option A", "Option B", "Option C"]`).

ItemDisplayText – A Power Fx formula evaluated for each item in **Items** to determine the text shown in the list. Use `ThisItem` to reference the current item. Defaults to `ThisItem.Value` for string arrays and `ThisItem.Value1` for table data sources. Change this when your data source has a specific column to display (for example, `ThisItem.Name`).

Default – The initial selected value before the user makes a change. Set this to a value that exists in **Items** (for example, `="Option A"`). Leave blank for no default selection.

AccessibleLabel – Label read by screen readers. Describe the purpose of the dropdown (for example, `"Select a country"`).

Visible – Whether the control appears or is hidden.

Behavior

OnChange – Actions to perform when the user changes the selection. Use `Self.Selected.Value` inside the formula to read the newly selected item. For example, `Notify("You selected " & Self.Selected.Value)` displays a message each time the selection changes.

Required – Whether the user must make a selection. When **true**, an indicator appears beside the dropdown. Default is **false**.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

ValidationState – Applies validation styling to the control. Accepts `ValidationState` enum values:

Expand table

Value	Description
`ValidationState.None`	No validation styling. Default.
`ValidationState.Error`	Highlights the control border in red to indicate an error.

Size and position

X – Distance between the left edge of the control and the left edge of its parent container (screen if no parent container).

Y – Distance between the top edge of the control and the top edge of its parent container (screen if no parent container).

Width – Distance between the control's left and right edges. Default is **320**.

Height – Distance between the control's top and bottom edges. Default is **32**.

PaddingTop – Distance between the control content and the top edge of the control.

PaddingBottom – Distance between the control content and the bottom edge of the control.

PaddingLeft – Distance between the control content and the left edge of the control.

PaddingRight – Distance between the control content and the right edge of the control.

Style and theme

Appearance – The visual style of the dropdown field. Accepts `Appearance` enum values:

Expand table

Value	Description
`Appearance.FilledDarker`	Filled with a slightly darker background. Default.
`Appearance.Filled`	Filled with a standard background.
`Appearance.Outline`	Outlined border with a transparent background.

BasePaletteColor – The base color used by the theme to generate the control's color palette. Use this value to apply a different theme color to the control.

Font – The font family used for the dropdown text.

Size – The font size of the dropdown text, in points. Default is **14**.

Color – The color of the dropdown text.

FontWeight – The weight (thickness) of the dropdown text. Accepts `FontWeight` enum values: `FontWeight.Bold`, `FontWeight.Semibold`, `FontWeight.Normal` (default), `FontWeight.Lighter`.

Italic – Whether the dropdown text appears in italic style.

Underline – Whether a line appears under the dropdown text.

Strikethrough – Whether a line appears through the middle of the dropdown text.

Fill – The background fill color of the control.

BorderColor – The color of the control's border.

BorderStyle – The style of the control's border. Accepts `BorderStyle` enum values: `BorderStyle.Solid`, `BorderStyle.Dashed`, `BorderStyle.Dotted`, or `BorderStyle.None`.

BorderThickness – The thickness of the control's border in pixels.

RadiusTopLeft – The corner radius for the top-left corner of the control.

RadiusTopRight – The corner radius for the top-right corner of the control.

RadiusBottomLeft – The corner radius for the bottom-left corner of the control.

RadiusBottomRight – The corner radius for the bottom-right corner of the control.

Additional properties

ContentLanguage – The display language for the control content, if different from the app language.

Output properties

Selected – The currently selected item, returned as a record. For a string array, use `Dropdown1.Selected.Value` to read the selected text. For a table data source, use `Dropdown1.Selected.<ColumnName>`.

> ⓘ Note
>
> **Selected** is an output property. You can reference it in other controls and formulas, but you can't set it directly.

Examples

Basic dropdown with inline options

This example creates a required country dropdown with inline validation. When the user hasn't selected a value, the control shows an error state.

YAML

```
- CountryDropdown:
    Control: ModernDropdown@1.0.0
    Properties:
      AccessibleLabel: ="Select your country"
      Default: ={Value:"United States"}
      ItemDisplayText: =ThisItem.Value
      Items: =["Australia", "Canada", "United Kingdom", "United States"]
      Required: =true
      ValidationState: =If(IsBlank(CountryDropdown.Selected.Value),
ValidationState.Error, ValidationState.None)
      Width: =240
```

Dropdown bound to a data source

This example binds the dropdown to a table data source and displays the **Name** column. The **OnChange** action stores the selected record in a variable.

YAML

```
- DepartmentDropdown:
    Control: ModernDropdown@1.0.0
    Properties:
      AccessibleLabel: ="Select a department"
      Appearance: =Appearance.Outline
      ItemDisplayText: =ThisItem.Name
      Items: =Departments
      OnChange: =Set(varSelectedDept, Self.Selected)
      Width: =320
```

Recent updates

The updated version of the **Dropdown** modern control includes the following improvements and behavior changes.

Property renames

Expand table

Previous property	New property	Notes
`DefaultSelectedItems`	`Default`	Set the initial selection through `Default`. Change any formula referencing `Dropdown1.DefaultSelectedItems` to `Dropdown1.Default`.
`FontSize`	`Size`	Renamed to match other modern controls. Default changed from **0** (inherits from theme) to **14**.
`BorderRadius`	`RadiusTopLeft`, `RadiusTopRight`, `RadiusBottomLeft`, `RadiusBottomRight`	Split into four independent corner radius properties for greater styling flexibility.

Enum format changes

Expand table

Property	Previous value	New value
`Appearance`	`"FilledDarker"`	`Appearance.FilledDarker`
`Appearance`	`"Filled"`	`Appearance.Filled`
`Appearance`	`"Outline"`	`Appearance.Outline`
`ValidationState`	`"None"`	`ValidationState.None`
`ValidationState`	`"Error"`	`ValidationState.Error`

Bug fixes and improvements

- **Fluent-themed flyout**: On desktop, the dropdown list now opens as a Fluent-themed flyout that matches the app's visual design. The previous version used the browser's HTML `<select>` element, which couldn't be themed. On mobile, both versions use the device-native picker and it remains unchanged.
- **ItemDisplayText**: New property that controls which field of a data source record to show in the list. For string arrays, this property defaults automatically. For table data sources, set this property to the column you want to display (for example, `ThisItem.Name`).
- **Full font control**: New `Font`, `Color`, `FontWeight`, `Italic`, `Underline`, and `Strikethrough` properties give full text styling control, consistent with other modern controls.
- **Updated enums**: `Appearance` and `ValidationState` now use typed Power Fx enums, improving IntelliSense and reducing formula errors.

Accessibility

AccessibleLabel – Set this property to a meaningful description so screen readers can announce the purpose of the dropdown (for example, `"Select your country"`).

Required – When set to **true**, screen readers announce the field as required.

Keyboard users can press **Enter** or **Space** to open the dropdown, use **Arrow** keys to move between items, and press **Enter** to confirm a selection.

Limitations

- The Fluent-themed flyout is available on desktop only. On mobile, the control uses the device-native picker.
- Very large data sources may cause the dropdown list to load slowly. Filter or limit the data where possible.

Stream control (based on SharePoint) in Power Apps (preview)

Article • 05/21/2025

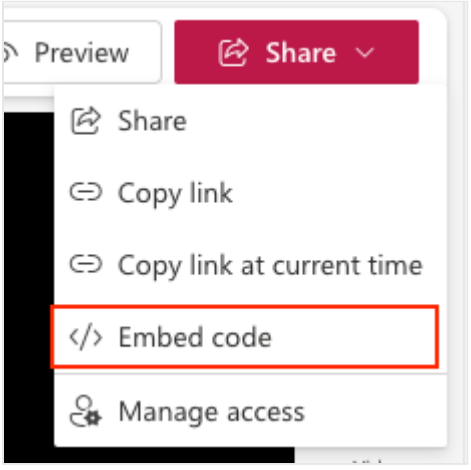
[This article is pre-release document and is subject to change.]

The Stream control in Power Apps lets you embed Microsoft Stream (on SharePoint) videos directly in your canvas app. Adding a Stream video in your app makes a smooth integration of videos hosted on Microsoft Stream in your canvas app. It also improves the user experience.

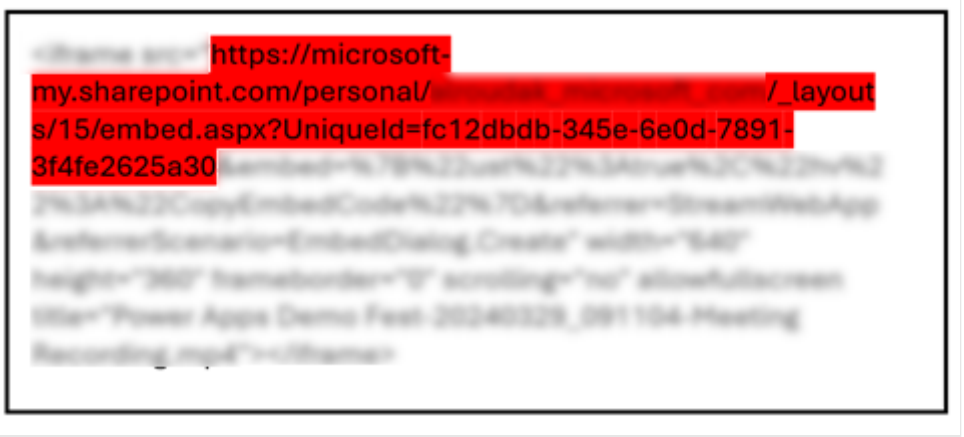
Prerequisites

To add a Stream video in your canvas app, follow these steps to get the embed URL of the video:

1. Open your Stream (on SharePoint) video.
2. Select **Share** > **Embed code**.



3. Copy the URL starting from **https://** to the **UniqueId=** including the Unique ID numbers.



> **Important**

The Microsoft Stream control in Power Apps only supports URLs that follow the *.sharepoint.com pattern. If your SharePoint domain doesn't follow this pattern, the Stream control will show an invalid URL error.

Add Stream control

1. Open your app canvas app for editing.
2. On the command bar, select **Insert** > **Media** > **Stream (preview)**.
3. In the **STREAM** pane, enter the **Stream URL** of the video. This is the embed URL from the Prerequisites section of the article.
4. Customize the size of the embedded video player by setting the width and height properties of the control.

Properties

Stream URL (Required) - The URL of the Stream video that you want to embed. This is the embed URL of the video. The URL should only have Unique ID. If URL detects other parameters, the control detects as invalid URL.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Mobile support for stream control

Stream control is now also supported on mobile. To comply with Apple's privacy policies, iOS users must follow these steps to enable cross-site tracking on Power Apps:

1. On iOS, select **Settings** > go to **Power Apps**.
2. Set the toggle for **Allow Cross-Website Tracking** to **On**.

Limitations

1. Control properties such as auto start, auto play, and start from are coming soon.

2. Don't add more than four videos on a single canvas app screen because it can cause performance issues.
3. The last played state isn't preserved for a video that's in a gallery.

Table modern control in Power Apps (preview)

Article • 03/19/2024

[This article is pre-release document and is subject to change.]

A control that shows a set of data in a tabular or list format.

Description

The **Table** control is a modern responsive control that shows a set of data in a tabular or list format. The tabular format includes column headings for each displayed field and a footer that provides details about the dataset such as the record count. The list format presents the data in a single column and has three fields for each row. As an app maker, you have full control over what fields are added to the control including the order. Although all added fields are visible in the tabular format, only the initial three fields appear in the narrower list format.

Similar to the **Gallery** and **Data** table controls, the **Table** maintains a **Selected** property that points to the selected row that can be used to link the **Table** control to other controls. The key properties for this control are **Items**, **ReflorBehavior**, **Selected**, and **OnSelect**.

Supported capabilities

- Data in a **Table** control is read-only.
- The tabular format offers a modern data browsing experience with infinite scroll, eliminating the need for paging buttons.
- The **Table** control supports linking to Microsoft Dataverse tables and collections.
- When you connect a **Table** control to a compatible connector such as Microsoft Dataverse, a predefined set of fields are displayed by default. You can also display or hide other fields based on your needs.
- The **Table** control can automatically switch between tabular and list formats. You can manually manage this behavior using the **Reflow** property.
- When you run your app, you can adjust column width in the **Table** control. However, your changes aren't saveontrol while you run the app. Your changes aren't saved.
- Change the color palette for the **Table** via the Base palette color property.

Unsupported capabilities

Currently, the listed capabilities aren't supported. However, since the **Table** control is still evolving, check back for any updates.

- Linking the Table to other data connectors.
- Customize the style of the **Table** other than color palette or modify individual columns.

General

Items - The source of data for the items that appear in the table.

NoDataText - The message shown to a user when there are no records to show in the **Table** control.

Visible - Whether a control appears or is hidden.

Behavior

ReflowBehavior - The default responsive behavior of the table. **Reflow** means the table displays in tabular form when the control is 480 or more pixels wide and transitions to a list format in narrower conditions. **GridOnly** (or **ListOnly**) means the table always displays in a tabular (or list) format regardless of the control width, and you can use Power Fx formulas to create your own breakpoints for defining the responsive behavior of the table.

EnableSorting – Allows users to sort the data in the table by using dropdowns from the column headers for supported data types.

EnableRangeSelection – Whether users can select a portion of the table to copy its values. Default is **Yes**.

Size and position

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Width - The distance between a control's left and right edges.

Height - The distance between a control's top and bottom edges.

Style and theme

HeaderFont - The font of the column headings.

HeaderFontSize - The font size of the column headings.

HeaderFontColor - The text color for the column headings.

HeaderFontWeight - The font weight of the column headings.

BasePaletteColor - The color palette applied to a control. This impacts all surfaces of the control that render a theme color.

Font - The name of the family of fonts in which text appears.

FontSize - The font size of the text that appears on a control. If the value is null or zero, then the font size is driven by selected Fluent theme.

FontColor - The color of text in a control.

FontWeight - The weight of the text in a control: Bold, Lighter, Normal, or Semibold.

Additional properties

Selected – The selected row in the **Table** control.

DisplayMode - Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

OnSelect – Defines the action triggered when a single record is selected.

ShowAvatar - Whether the user's avatar appears or is hidden in the list mode.

ShowColumnHeaders – Whether the column headers appear or are hidden.

ShowFooter - Whether the footer appears or is hidden.

Size – The size of the control on the canvas.

AccessibleLabel – Label for screen readers.

Controls and properties in canvas apps

Article • 03/13/2023

Configure the appearance and behavior of a control by setting one of its properties. Each type of control has a different set of properties. Some properties, such as **Height** and **Width**, are common to almost every type of control, but other properties, such as **CheckboxSize**, are specific to one type of control.

Controls

Add picture – Load images from the local device, for upload to a data source.

Address input - See dynamic address suggestions as you type.

Attachments – Download and upload files from the local device to a data source.

Audio – Play an audio clip or the audio portion of a video clip.

Barcode reader – Scans barcodes, QR codes, and data-matrix codes on an Android, iOS, or Windows device.

Barcode scanner (retired) – Scans barcodes, QR codes, and data-matrix codes on an Android or iOS device. Replaced by the barcode reader.

Button – Interact with the app by clicking or tapping.

Camera – Take and save photos in the app or to a data source.

Card – Display and edit an individual field of a record in a **Edit form** or **Display form** control.

Check box – Select or clear an option to specify **true** or **false**.

Column chart – Show values as vertical bars relative to two axes.

Column - Provides the display experience for a single field in a **Data table** control.

Combo box - Allows users to make selections from provided choices. Supports search and multi-select.

Container (experimental) - Create nested hierarchy for accessibility and responsiveness.

Data table (preview) - Show data in a tabular format.

Date picker – Specify a date by clicking or tapping.

Display form – Display records in a data source using a form.

Drop down – Show the first item in a list until a chevron is selected.

Edit form – Edit and create records in a data source using a form.

Display and Edit form - Experimental feature: Add dynamic forms in which users can view, navigate, and edit relational data from the Microsoft Dataverse.

Export – Export data for use elsewhere in Power Apps.

Gallery – Show a list of records that can contain multiple types of data.

HTML text – Convert HTML tags automatically.

Horizontal container – Determines the position of the child components so that you never have to set X, Y for a component inside the container.

Icon – Add graphic appeal and visual interest.

Image – Show an image from, for example, a local file or a data source.

Import – Import data from elsewhere in Power Apps.

Line chart – Show values as data points relative to two axes.

List box – Select one or more items in a list.

Map - View the physical position of objects from a data source, or by inputting new physical locations.

Measuring Camera - Measure distance, area, and volume in mixed reality.

Microphone – Record and save sounds in the app or to a data source.

PDF viewer (experimental) – Show the content of a PDF file on the Internet.

Pen input – Draw an image or text, and save it in the app or to a data source.

Pie chart – Show how values relate to each other.

Power BI tile – Display a Power BI tile inside an app.

Radio – Show options that are mutually exclusive.

Rating – Indicate a value between 1 and a specified number.

Rich text editor – Allows rich text formatting by app users.

Screen – Show and update data about a specific task.

Shape – Display arrows and geometric shapes, such as rectangles.

Slider – Specify a value by dragging a handle.

Stream Video – Play videos and browse through channels from the Microsoft Stream service.

Label – Shows data such as text, numbers, dates, or currency.

Text input – Type text, numbers, and other data.

Timer – Configure your app to respond after a certain amount of time passes.

Toggle – Drag a handle to specify **true** or **false**.

Video – Play a video clip from a local file, a data source, or YouTube.

Vertical container – Determines the position of the child components so that you never have to set X, Y for a component inside the container.

3D object - Rotate and zoom into the model with simple gestures in 3D.

View in MR - See how a particular item might fit within a specified space in mixed reality.

View shape in MR - See if a simple cube might fit within a specified space in mixed reality.

Web barcode scanner (experimental) – The legacy barcode scanner, which is obsolete but might be useful for scanning codes in a web browser.

Common properties by category

Color and border – Configure the color and border of a control that can change as a user interacts with it.

Core – Configure whether the user can see and interact with a control.

Image – Configure what image is shown and how it fills the control.

Size and location – Configure how big a control (or an element of a control) is and where it is in relation to the screen it's on.

Text – Configure how text appears in controls, such as font characteristics, alignment, line height.

All properties

A

AccesibleLabel – Reference information about properties related to accessibility in Power Apps.

ActualZoom – The actual zoom of the control, which may differ from the zoom requested with the **Zoom** property. Applies to the PDF viewer control.

Align – The location of text in relation to the horizontal center of its control. Applies to many controls.

AllItems – All items in a gallery, including additional control values that are a part of the gallery's template. Applies to the Gallery control.

AutoDisableOnSelect – Automatically disables the control while the OnSelect behavior is executing. Applies to Button and Image controls.

AutoHeight – Whether a label automatically increases its height if its Text property contains more characters than the control can show. Applies to the Label control.

AutoPause – Whether an audio or video clip automatically pauses if the user navigates to a different screen. Applies to Audio, Timer, and Video controls.

AutoStart – Whether an audio or video control automatically starts to play a clip when the user navigates to the screen that contains that control. Applies to Audio, Timer, and Video controls.

B

BackgroundImage – The name of an image file that appears in the background of a screen. Applies to the Screen control.

BorderColor – The color of a control's border. Applies to many controls.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**. Applies to many controls.

BorderThickness – The thickness of a control's border. Applies to many controls.

Brightness – How much light the user is likely to perceive in an image. Applies to the Camera control.

C

CalculateOriginalDimensions – Enables the **OriginalHeight** and **OriginalWidth** properties. Applies to the **Image** control.

Camera – On a device that has more than one camera, the numeric ID of the camera that the app uses. Applies to the **Camera** control.

CheckboxBackgroundFill – The background color of the box that surrounds the checkmark in a checkbox control. Applies to the **Check box** control.

CheckboxBorderColor – The color of the border that surrounds the checkmark in a checkbox control. Applies to the **Check box** control.

CheckboxSize – The width and height of the box that surrounds the checkmark in a checkbox control. Applies to the **Check box** control.

CheckmarkFill – The color of the checkmark in a checkbox control. Applies to the **Check box** control.

ChevronBackground – The color behind the down arrow in a dropdown list. Applies to the **Drop down** control.

ChevronFill – The color of the down arrow in a dropdown list. Applies to the **Drop down** control.

Clear – Whether a text-input control shows an "X" that the user can tap or click to clear the contents of that control. Applies to the **Text input** control.

Color – The color of text in a control. Applies to many controls.

ContentLanguage – The language of the control's content, if different from the control's container.

Contrast – How easily the user can distinguish between similar colors in an image. Applies to the **Camera** control.

CurrentFindText – The current search term that is in use. Applies to the **PDF viewer** control.

CurrentPage – The number of the page in a PDF file that is actually being shown. Applies to the **PDF viewer** control.

D

Data – The name of a collection that you want to export to a local file. Applies to the Export control.

DataField – The name of the field within a record that this card displays and edits. Applies to the Card control.

DataSource – The data source that contains the record that the user will show, edit, or create. Applies to Display form and Edit form controls.

Default – The initial value of a control before it is changed by the user. Applies to many controls.

DefaultDate – The initial value of a date control before it is changed by the user. Applies to the Date Picker control.

DefaultMode – The initial mode of a form control, either **Edit**, **New**, or **View**. Applies to the Edit form control.

DelayOutput – When set to true, user input is registered after half a second delay. Useful for delaying expensive operations until user completes inputting text (i.e. for filtering when input is used in other formulas). Applies to the Text input control.

Direction – Whether the first item in a gallery in landscape orientation appears near the left or right edge. Applies to the Gallery control.

Disabled – Whether the user can interact with the control. Applies to many controls.

DisabledBorderColor – The color of a control's border if the control's Disabled property is set to **true**. Applies to many controls.

DisabledColor – The color of text in a control if its Disabled property is set to **true**. Applies to many controls.

DisabledFill – The background color of a control if its Disabled property is set to **true**. Applies to many controls.

DisplayName – The user friendly name for a field in a data source. Applies to the Card control.

DisplayMode – Values can be Edit, View, or Disabled. Configures whether the control allows user input (Edit), only displays data (View) or is disabled (Disabled).

Document – The URL, enclosed in double-quotation marks, of a PDF file. Applies to the PDF viewer control.

Drop shadow - Adds shadow effects around the control. Applies to the Horizontal container and Vertical container control.

- Duration – How long a timer runs. Applies to the Timer control.

E

EnableSpellCheck – Whether a Text input control should use the browser spell check function. Power Apps for Windows doesn't support this property.

EndYear – The latest year to which the user can set value of a date-picker control. Applies to the Date Picker control.

Error – The meaning of this property is dependent on the control:

- Add picture control - If there is a problem uploading an image, this property will contain an appropriate error string.
- Card control – The user friendly error message to display for this field when validation fails.
- Edit form control – A user friendly error message to display for this form when the SubmitForm function fails.

ErrorKind – If an error occurs when **SubmitForm** runs, the kind of error that occurred. Applies to Display form and Edit form controls.

Explode – The distance between wedges in a pie chart. Applies to the Pie chart control.

F

Fill – The background color of a control. Applies to many controls.

FindNext – Finds the next instance of **FindText** in the document. Applies to the PDF viewer control.

FindPrevious – Finds the previous instance of **FindText** in the document. Applies to the PDF viewer control.

FindText – The search term to look for in the document. Applies to the PDF viewer control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears. Applies to many controls.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**. Applies to many controls.

G

GridStyle – Whether a column or line chart shows its x-axis, its y-axis, both, or neither. Applies to Column chart and Line chart controls.

H

HandleActiveFill – The color of the handle for a slider as the user changes its value. Applies to the Slider control.

HandleFill – The color of the handle (the element that changes position) in a toggle or slider control. Applies to the Slider control.

HandleHoverFill – The color of the handle in a slider when the user keeps the mouse pointer on it. Applies to the Slider control.

Height – The distance between a control's top and bottom edges. Applies to many controls.

HintText – Light-grey text that appears in a text-input control if it's blank. Applies to the Text input control.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control. Applies to many controls.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it. Applies to many controls.

HoverFill – The background color of a control when the user keeps the mouse pointer on it. Applies to many controls.

HTMLText – Text that appears in an HTML text control and that may contain HTML tags. Applies to the HTML text control.

I

Image – The name of the image that appears in an image, audio, or microphone control. Applies to Audio, Image, Microphone, and Video controls.

ImagePosition – The position (**Fill**, **Fit**, **Stretch**, **Tile**, or **Center**) of an image in a screen or a control if it isn't the same size as the image. Applies to many controls.

Input – Input. Applies to the Pen input control.

Italic – Whether the text in a control is italic. Applies to many controls.

Item – The record in the **DataSource** that the user will show or edit. Applies to Display form and Edit form controls.

ItemBorderColor – The color of the border around each wedge in a pie chart. Applies to the Pie chart control.

ItemBorderThickness – The thickness of the border around each wedge in a pie chart. Applies to the Pie chart control.

ItemColorSet – The color of each data point in a chart. Applies to Column chart, Line chart, and Pie chart controls.

ItemPaddingLeft – The distance between text in a listbox and its left edge. Applies to the List Box control.

Items – The source of data that appears in a control such as a gallery, a list, or a chart. Applies to many controls.

ItemsGap – The distance between columns in a column chart. Applies to the Column chart control.

L

LabelPosition – The location of labels in a pie chart relative to its wedges. Applies to the Pie chart control.

LastSubmit – The last successfully submitted record, including any server generated fields. Applies to the Edit form control.

Layout – Whether the user scrolls through a gallery or adjusts a slider top to bottom (**Vertical**) or left to right (**Horizontal**). Applies to Gallery and Slider controls.

LineHeight – The distance between, for example, lines of text or items in a list. Applies to List Box, Radio, Label, and Text input controls.

Loop – Whether an audio or video clip automatically starts over as soon as it finishes playing. Applies to Audio and Video controls.

M

Markers – Whether a column or line chart shows the value of each data point. Applies to Column chart and Line chart controls.

MarkerSuffix – Text that appears after each value in a column chart for which the Markers property is set to **true**. Applies to the Column chart control.

Max – The maximum value to which the user can set a slider or a rating. Applies to Rating and Slider controls.

MaxLength – The number of characters that the user can type into a text-input control. Applies to the Text input control.

Media – An identifier for the clip that an audio or video control plays. Applies to Add picture, Audio, and Video controls.

Mic – On a device that has more than one microphone, the numeric ID of the microphone that the app uses. Applies to the Microphone control.

Min – The minimum value to which the user can set a slider. Applies to the Slider control.

MinimumBarWidth – The narrowest possible width of columns in a column chart. Applies to the Column chart control.

Mode – The meaning of this property is dependent on the control:

- Edit form control – The control is in **Edit** or **New** mode.
- Pen input control – The control is in **Draw**, **Erase**, or **Select** mode.
- Text input control – The control is in **SingleLine**, **MultiLine**, or **Password** mode.

N

NavigationStep – How far a gallery scrolls if its ShowNavigation property is set to **true** and the user selects a navigation arrow at either end of that gallery. Applies to the Gallery control.

NumberOfSeries – How many columns of data are reflected in a column or line chart. Applies to Column chart and Line chart controls.

O

OnChange – The behavior of an app when the user changes the value of a control (for example, by adjusting a slider). Applies to many controls.

OnCheck – The behavior of an app when the value of a checkbox or a toggle changes to **true**. Applies to Check box and Toggle controls.

OnEnd – The behavior of an app when an audio or video clip finishes playing. Applies to Audio and Video controls.

OnFailure – The behavior of an app when a data operation has been unsuccessful. Applies to the Edit form control.

OnHidden – The behavior of an app when the user navigates away from a screen. Applies to the Screen control.

OnPause – The behavior of an app when the user pauses the clip that an audio or video control is playing. Applies to Audio and Video controls.

OnReset – The behavior of an app when an Edit form control is reset. Applies to the Edit form control.

OnSelect – The behavior of an app when the user taps or clicks a control. Applies to many controls.

OnStart – The behavior of an app when the user opens it or starts to record with a microphone control. Applies to Audio, Microphone, Screen, and Video controls.

OnStateChange – The behavior of an app when the state of the control changes. Applies to the PDF viewer control.

OnStop – The behavior of an app when the user stops recording with a microphone control. Applies to the Microphone control.

OnStream – The behavior of an app when the Stream property is updated. Applies to the Camera control.

OnSuccess – The behavior of an app when a data operation has been successful. Applies to the Edit form control.

OnTimerEnd – The behavior of an app when a timer finishes running. Applies to the Timer control.

OnTimerStart – The behavior of an app when a timer starts to run. Applies to the Timer control.

OnUncheck – The behavior of an app when the value of a checkbox or a toggle changes to **false**. Applies to **Check box** and **Toggle** controls.

OnVisible – The behavior of an app the user navigates to a screen. Applies to the **Screen** control.

OriginalHeight – Original height of an image, enabled with the **CalculateOriginalDimensions** property. Applies to the **Image** control.

OriginalWidth – Original width of an image, enabled with the **CalculateOriginalDimensions** property. Applies to the **Image** control.

Overflow – Whether a scrollbar appears in a label if its **Wrap** property is set to **true** and the value of the control's **Text** property contains more characters than the control can show at one time. Applies to the **Label** control.

P

Padding – The distance between the text on an import or export button and the edges of that button. Applies to **Add picture**, **Export**, and **Import** controls.

PaddingBottom – The distance between text in a control and the bottom edge of that control. Applies to many controls.

PaddingLeft – The distance between text in a control and the left edge of that control. Applies to many controls.

PaddingRight – The distance between text in a control and the right edge of that control. Applies to many controls.

PaddingTop – The distance between text in a control and the top edge of that control. Applies to many controls.

Page – The number of the page that you want to show. Applies to the **PDF viewer** control.

PageCount – The number of pages in a document. Applies to the **PDF viewer** control.

Paused – *True* if a media playback control is currently paused, *false* otherwise. Applies to **Audio** and **Video** controls.

Photo – The image captured when the user takes a picture. Applies to the **Camera** control.

Pressed – *True* while a control is being pressed, *false* otherwise. Applies to the **Button** control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control. Applies to many controls.

PressedColor – The color of text in a control when the user taps or clicks that control. Applies to many controls.

PressedFill – The background color of a control when the user taps or clicks that control. Applies to many controls.

R

RadioBackgroundFill – The background color of the circles in a radio-button control. Applies to the **Radio** control.

RadioBorderColor – The color of the circle for each option in a radio-button control. Applies to the **Radio** control.

RadioSelectionFill – The color that appears inside the circle of the selected option in a radio-button control. Applies to the **Radio** control.

RadioSize – The diameter of the circles in a radio-button control. Applies to the **Radio** control.

RadiusBottomLeft – The degree to which the bottom-left corner of a control is rounded. Applies to many controls.

RadiusBottomRight – The degree to which the bottom-right corner of a control is rounded. Applies to many controls.

RadiusTopLeft – The degree to which the top-left corner of a control is rounded. Applies to many controls.

RadiusTopRight – The degree to which the top-right corner of a control is rounded. Applies to many controls.

RailFill – The background color of the rectangle in a toggle control when its value is **false** or the color of the line to the right of the handle in a slider control. Applies to **Slider** and **Toggle** controls.

RailHoverFill – When you hover on a toggle control or a slider, the background color of the rectangle in a toggle control when its value is **false** or the color of the line to the right of the handle in a slider control. Applies to **Slider** and **Toggle** controls.

RatingFill – The color of the stars in a rating control. Applies to the Rating control.

ReadOnly – Whether a user can change the value of a slider or rating control. Applies to Rating and Slider controls.

Repeat – Whether a timer automatically restarts when it finishes running. Applies to the Timer control.

Required – Whether a card, editing the field of a data source, must contain a value. Applies to the Card control.

Reset – Whether a control reverts to its default value. Applies to many controls. Also see the Reset function.

S

Selected – The selected item. Applies to Drop down and Gallery controls.

SelectedDate – The date currently selected in a date control. Applies to the Date Picker control.

SelectionColor – The text color of a selected item or items in a list or the color of the selection tool in a pen control. Applies to Drop down, List Box, and Pen input controls.

SelectionFill – The background color of a selected item or items in a list or a selected area of a pen control. Applies to Drop down and List Box controls.

SelectionThickness – The thickness of the selection tool for a pen-input control. Applies to the Pen input control.

SelectMultiple – Whether a user can select more than one item in a listbox. Applies to the List Box control.

SeriesAxisMax – The maximum value of the y-axis for a column or line chart. Applies to the Column chart control.

SeriesAxisMin – A number that determines the minimum value of the y-axis for a column chart. Applies to the Column chart control.

ShowControls – Whether an audio or video player shows, for example, a play button and a volume slider, and a pen control shows, for example, icons for drawing, erasing, and clearing. Applies to Audio, PDF viewer, Pen input, and Video controls.

ShowLabels – Whether a pie chart shows the value that's associated with each of its wedges. Applies to the Pie chart control.

ShowNavigation – Whether an arrow appears at each end of a gallery so that a user can scroll through the items in the gallery by clicking or tapping an arrow. Applies to the Gallery control.

ShowScrollbar – Whether a scrollbar appears when the user hovers over a gallery. Applies to the Gallery control.

ShowValue – Whether a slider's or rating's value appears as the user changes that value or hovers over the control. Applies to Rating and Slider controls.

Size – The font size of the text that appears on a control. Applies to many controls.

Snap – Whether, when a user scrolls through a gallery, it automatically snaps so that the next item appears in full. Applies to the Gallery control.

Start – Whether an audio or video clip plays. Applies to Audio, Timer, and Video controls.

StartTime – The time after the start of an audio or video clip when the clip starts to play. Applies to Audio and Video controls.

StartYear – The earliest year to which the user can set the value of a date-picker control. Applies to the Date Picker control.

Stream – Automatically updated image based on the StreamRate property. Applies to the Camera control.

StreamRate – How often to update the image on the Stream property, in milliseconds. This value can range from 100 (1/10th of a second) to 3,600,000 (1 hour). Applies to the Camera control.

Strikethrough – Whether a line appears through the text that appears on a control. Applies to many controls.

T

TemplateFill – The background color of a gallery. Applies to the Gallery control.

TemplatePadding – The distance between items in a gallery. Applies to the Gallery control.

TemplateSize – The height of the template for a gallery in vertical/portrait orientation or the width of the template for a gallery in horizontal/landscape orientation. Applies to the Gallery control.

Text – Text that appears on a control or that the user types into a control. Applies to many controls.

Time – A media control's current position. Applies to **Audio** and **Video** controls.

Tooltip – Explanatory text that appears when the user hovers over a control. Applies to many controls.

Transition – The visual effect (**Pop**, **Push**, or **None**) when the user hovers over an item in a gallery. Applies to the **Gallery** control.

Transparency – The degree to which controls behind an image remain visible. Applies to the **Image** control. Decimal values range from 0 to 1. Where 0 is opaque, 0.5 is semi-transparent and 1 is transparent.

U

Underline – Whether a line appears under the text that appears on a control. Applies to many controls.

Unsaved – True if the **Edit form** control contains user changes that have not been saved. Applies to the **Edit form** control.

Update – The value to write back to the data source for a field. Applies to the **Card** control.

Updates – The values to write back to the data source for a record loaded in a form control. Applies to the **Edit form** control.

V

Valid – Whether a **Card** or **Edit form** control contains valid entries, ready to be submitted to the data source. Applies to **Card** and **Edit form** controls.

Value – The value of an input control. Applies to **Check box**, **Radio**, **Slider**, and **Toggle** controls.

ValueFill – The background color of the rectangle in a toggle control when its value is **true** or the color of the line to the left of the handle in a slider control. Applies to **Slider** and **Toggle** controls.

ValueHoverFill – When you keep the mouse pointer on a toggle control or a slider, the background color of the rectangle in a toggle control when its value is **true** or the color

of the line to the left of the handle in a slider control. Applies to **Slider** and **Toggle** controls.

VerticalAlign – The location of text on a control in relation to the vertical center of that control. Applies to many controls.

Visible – Whether a control appears or is hidden. Applies to many controls.

W

Width – The distance between a control's left and right edges. Applies to many controls.

WidthFit – Whether a control automatically grows horizontally to fill any empty space of a container control such as an **Edit form** control. If multiple cards have this property set to **true**, the space is divided between them. For more information, see Understand data form layout.

Wrap – Whether text that's too long to fit in a label wraps to the next line. Applies to the **Label** control.

WrapCount – How many records appear in each item of a gallery. Applies to the **Gallery** control.

X

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container). Applies to many controls. For a **Card** control in a container that has multiple columns, this property determines the column in which the card appears.

XLabelAngle – The angle of the labels below the x-axis of a column or line chart. Applies to **Column chart** and **Line chart** controls.

Y

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container). Applies to many controls. For a **Card** control in a container that has multiple rows, this property determines the row in which the card appears.

YAxisMax – The maximum value of the y-axis for a line chart. Applies to the **Line chart** control.

YAxisMin – The minimum value of the y-axis for a line chart. Applies to the **Line chart** control.

YLabelAngle – The angle of the labels next to the y-axis of a line or column chart. Applies to **Column chart** and **Line chart** controls.

Z

Zoom – The percentage by which an image from a camera is magnified or the view of a file in a PDF viewer. Applies to **Camera** and **PDF viewer** controls.

Limitations of controls in Power Apps

Limitations of controls in canvas apps

Article • 03/13/2023

In this article, learn about the general limitations of the controls used in canvas apps. In addition, limitations of controls in Teams lists the control limitations applicable to apps played inside Microsoft Teams. For more information about environments, go to Types of environments.

- Attachments control - see Attachments control limitations.
- Audio, and video controls - see Audio and video alternatives.
- Barcode control, Camera control
  - On iOS, the camera control is supported in the Power Apps for mobile app. It's not supported within the browser or Teams Mobile.
  - On Android, the camera control isn't supported in Teams Mobile.
  - When using desktop browsers, the barcode reader isn't supported. Use the Power Apps for mobile app.
- Container control - see Container control limitations.
- Export and import controls - see Export and import control limitations.
- Gallery control - see Gallery control limitations.
- Image control - only supports external media URLs using HTTPS.
- Power BI tile control - see Power BI tile control limitations for passing a parameter.
- PDF viewer control (experimental) - see PDF viewer control (experimental) limitations.
- Stream Video control - see Stream Video control limitations.

Limitations of controls in Teams

This section lists limitations of canvas apps controls for apps within Microsoft Teams.

General limitations

Apps made with Power Apps in a Dataverse for Teams environment can't be opened outside of Teams. To use controls like *Camera*, upgrade your Power Apps license so that the app can be opened outside of Teams—for example—in the Power Apps mobile app.

Limitations of specific controls

- Barcode control - the barcode reader control isn't supported in Teams Mobile.
- Camera control - the Camera control isn't supported in Teams Mobile. If you're creating a Power Apps app for use inside Teams, use the Add picture control instead.
- Microphone control - the following conditions apply when using the Microphone control in apps created using Power Apps on Teams Mobile:
  - The audio format for microphone recordings in Teams will always be *AAC* with a file extension of .MP4.
  - Teams has its own recording experience. The microphone control inside apps created using Power Apps will be disabled during the recording period.
  - Microphone recordings are limited to a maximum duration of 10 minutes.

Unsupported controls

The following controls aren't supported by apps embedded in Teams:

- Address Input
- Camera (in Teams Mobile)
- Map
- Mixed reality (View in MR, View shape in MR, Measuring Camera)
- Power BI tile control
- Web barcode scanner control

Controls and properties reference

Add picture control in canvas apps

Article • 03/25/2024

Takes a photo or loads images from the local device.

Description

With this control users can take photos or upload image files from their device and update the data source with this content. On a mobile device the user is presented with the device's choice dialog to choose between taking a photo or selecting one already available.

This control is a grouped control containing two controls: an **Image** and an **Add picture button**. The **Image** control shows the uploaded image or a placeholder if no image has been uploaded. The **Add picture button** prompts for an image to be uploaded.

See the Image control reference for **Image** properties.

Limitations

The picture control has these limitations:

- When using the **Add Picture** control on iOS, images imported by using the camera or gallery don't contain meta-data like orientation, location information, or camera settings.

Add picture button properties

AccessibleLabel – Label for screen readers. Should describe the purpose of adding a picture.

Align – The location of text in relation to the horizontal center of its control.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

ChangePictureText – Text that appears on the button when an image has been uploaded.

Color – The color of text in a control.

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Error - If there is a problem uploading an image, this property will contain an appropriate error string.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

Media – An identifier for the clip that an audio or video control plays.

OnChange – Actions to perform when the user changes the value of a control (for example, by adjusting a slider).

OnSelect – Actions to perform when the user taps or clicks a control.

Padding – The distance between the text on an import or export button and the edges of that button.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

Reset – Whether a control reverts to its default value.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Text – Text that appears on the button when an image has not been uploaded.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

UseMobileCamera – Whether to use a mobile camera directly, when available. For Android devices, this property requires the experimental setting **Improved Media Capture** turned on.

VerticalAlign – The location of text on a control in relation to the vertical center of that control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Patch(*DataSource*, *BaseRecord*, *ChangeRecord*)

Examples

Add images to an Image gallery control

1. Add an **Add picture** control, and then triple-click it.

   Don't know how to add, name, and configure a control?

2. In the **Open** dialog box, click or tap an image file, and then click or tap **Open**.

3. Add a **Button** control, move it under the **Add picture** control, and set the **OnSelect** property for the **Button** control to this formula:
   Collect(MyPix, AddMediaButton1.Media)

   Want more information about the **Collect** function or other functions?

4. Add a **Vertical gallery** control, and set its **Items** property to **MyPix**.

5. Select the **Image** control in the gallery and set it's **Image** property to **ThisItem.Value**.

6. Press F5, and then click or tap the **Button** control.

   The image from the **Add picture** control appears in the **Vertical Gallery** control. If your image doesn't have the same aspect ratio as the **Image** control in the **Vertical gallery** control, set the **ImagePosition** property of the **Image** control to **Fit**.

7. Click or tap the **Add picture** control, click or tap another image file, click or tap **Open**, and then click or tap the **Button** control that you added.

   The second image appears in the **Image gallery** control.

8. (optional) Repeat the previous step one or more times, and then return to the default workspace by pressing Esc.

Use the **SaveData** function to save the images locally or the **Patch** function to update a data source.

Accessibility guidelines

The same guidelines for **Button** and **Image** apply. In addition, consider the following:

Color contrast

- **Add picture button** must have adequate contrast between its text and background. Since the uploaded image may have varying colors, use an opaque Fill on the **Add picture button** to ensure consistent contrast.

Screen reader support

- **Add picture button** must have **Text** and **ChangePictureText** that prompts the user to add or change a picture.

Keyboard support

- **Add picture button** must have TabIndex of zero or greater so that keyboard users can navigate to it.
- **Add picture button** must have clearly visible focus indicators. Use FocusedBorderColor and FocusedBorderThickness to achieve this.

Use the address input control to easily enter addresses

Article • 07/15/2022

Entering addresses can be frustrating and error-prone, particularly in mobile apps. Use the address input control to make address entry easier. The control uses fuzzy logic to suggest potential matches as you type. Select the one you want to quickly and easily enter an accurate address.

The control returns the address as structured data. Your app can extract information such as city, street, municipality, and even latitude and longitude coordinates. The data is in a format that's friendly to many locales and international address formats.

Prerequisites

Before you can use the control in your apps, you'll need to enable geospatial features for the environment. Make sure you also review the prerequisites for using geospatial controls. Refer to the privacy and security table for more details on the address input control's data usage.

Add an address input control to your app

With your app open for editing in Power Apps Studio :

1. Open the **Insert** tab and expand **Input**.
2. Select **Address input** to place an address input box in the app screen, or drag the control to the screen to position it more precisely. You must enter at least three characters including one number for the address input control.

Set a default search radius

By default, the control will search around the user's location. You can refine the default search area to help narrow the initial results.

1. On the address input control's **Properties** tab, turn on the **Search within radius** property.
2. Enter a longitude, latitude, and radius in meters.

The control will start searching at the given latitude and longitude, out to the distance specified.

Use the map control with the address input control

You can add a button to your app to save entered addresses as a data collection. Then you can retrieve the addresses and display them in the map control.

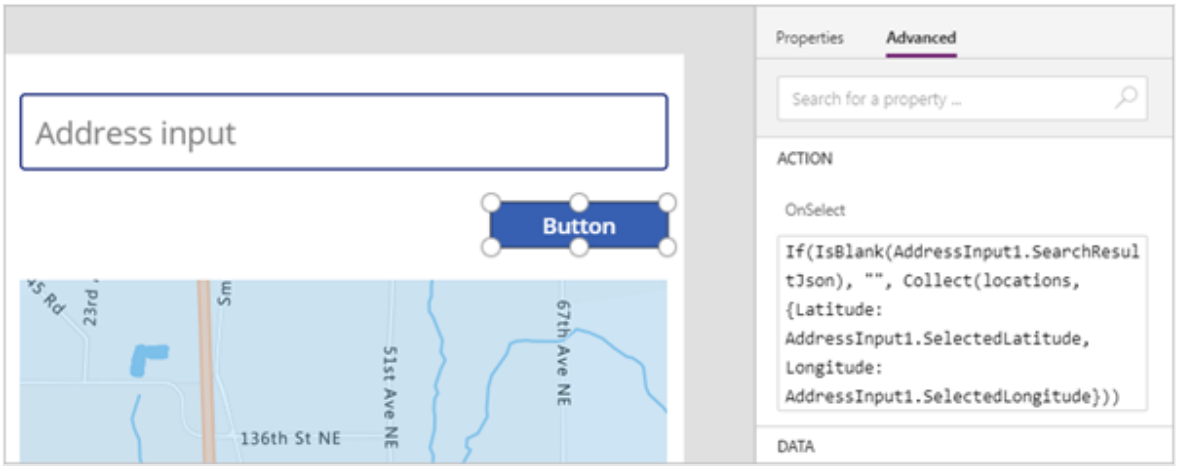
1. Add a map control and an address input control to your app.
2. Insert and place a **Button** control.
3. Change the **OnSelect** property of the button control as follows. (Hint: Copy the formula and paste it in the formula bar or on the **Advanced** properties tab, whichever you prefer.)
4. Enter a longitude, latitude, and radius (in meters).

   The control will start searching at the latitude and longitude, out to the distance specified in the radius field.

   Power Fx

   ```
   If(IsBlank(AddressInput1.SearchResultJson), "", Collect(locations,
   {Latitude: AddressInput1.SelectedLatitude, Longitude:
   AddressInput1.SelectedLongitude}))
   ```

   The formula saves the current latitude and longitude to a collection named *locations*, as long as the search results aren't blank.

5. Select the map control. Change its properties as follows:

Expand table

Property name	Value	Where
Items	"Locations"	**Properties** tab
ItemsLatitudes	"Latitude"	**Advanced** tab
ItemsLongitudes	"Longitude"	**Advanced** tab

When the user selects the button, the result from the address input control is added to the map as a new pin.

Properties

Change an address input control's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.

Expand table

Property	Description	Type	Tab
Default	Sets the initial value of the control.	String	Properties; Advanced: **Default**
Hint text	Sets the hint that appears in the control before the user enters text.	String	Properties; Advanced: **HintText**
Font	Sets the name of the family of fonts used for the control text.	Dropdown list	Properties; Advanced: **Font**
Font size	Sets the size of the control text.	Floating point number	Properties; Advanced: **FontSize**
Font weight	Sets the weight of the control text, either *Bold*, *Lighter*, *Normal*, or *Semibold*.	Dropdown list	Properties; Advanced: **FontWeight**
Text alignment	Sets the horizontal alignment of the control text, either *Center*, *Justify*, *Left*, or *Right*.	Dropdown list	Properties; Advanced: **TextAlignment**
Line height	Sets the vertical distance between lines of text in the control.	Floating point number	Properties; Advanced: **LineHeight**

Property	Description	Type	Tab
Display mode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Dropdown list	Properties; Advanced: DisplayMode
Font style	Sets the style of the control text, either *Italic*, *Underline*, *Strikethrough*, or none.	Dropdown list	Properties; Advanced: **Italic**, **Underline**, **Strikethrough**
Search result limit	Sets the number of suggested addresses the control displays.	Integer	Properties; Advanced: **SearchResultLimit**
Search within radius	Determines whether the control should suggest addresses within the **Radius** of the **Latitude** and **Longitude**.	Boolean	Properties; Advanced: **SearchWithinRadius**
Latitude	Sets the latitude coordinate of the center point used for address suggestions. Requires **Search within radius** to be on.	Floating point number from -90 to 90	Properties; Advanced: **Latitude**
Longitude	Sets the longitude coordinate of the center point used for address suggestions. Requires **Search within radius** to be on.	Floating point number from -180 to 180	Properties; Advanced: **Longitude**
Radius	Sets the radius, in meters, around **Latitude** and **Longitude** to constrain address suggestions. Requires **Search within radius** to be on.	Floating point number	Properties; Advanced: **Radius**
Language	Sets the language that address suggestions are returned in.	String	Properties; Advanced: **Language**
Country set	Identifies a comma-separated list of countries/regions to constrain address suggestions to, in ISO 3166 alpha-2 format; for example, *US,CA,MX*.	String	Properties; Advanced: **CountrySet**
Visible	Shows or hides the control.	Boolean	Properties; Advanced: Visible
Padding top	Sets the distance between the control text and the top of the	Floating point number	Properties; Advanced: PaddingTop

Property	Description	Type	Tab
	control.		
Padding bottom	Sets the distance between the control text and the bottom of the control.	Floating point number	Properties; Advanced: **PaddingBottom**
Padding left	Sets the distance between the control text and the left edge of the control.	Floating point number	Properties; Advanced: **PaddingLeft**
Padding right	Sets the distance between the control text and the right edge of the control.	Floating point number	Properties; Advanced: **PaddingRight**
Position	Places the upper-left corner of the control at the screen coordinates specified in *X* and *Y*.	Integer	Properties; Advanced: **X**, **Y**
Size	Determines the size of the control using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Border radius	Determines the corner radius of the control border.	Floating point number	Properties; Advanced: **BorderRadius**
Color	Sets the colors of the control text and the control background.	Not applicable	Properties; Advanced: **FillColor**, **TextColor**
Border	Determines the style, width, and color of the control border.	Not applicable	Properties; Advanced: **BorderStyle**, **BorderThickness**, **BorderColor**
Tab index	Specifies the order the control is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **TabIndex**
Tooltip	Determines the text to display when the user hovers over the control.	String	Properties; Advanced: **Tooltip**
Hover color	Sets the colors of the control text, the control background, and the control border when the user hovers the mouse pointer over it.	Not applicable	Properties; Advanced: **HoverFontColor**, **HoverFillColor**, **HoverBorderColor**

Property	Description	Type	Tab
Disabled color	Sets the colors of the control text, the control background, and the control border if **DisplayMode** is *Disabled*.	Not applicable	Properties; Advanced: **DisabledFontColor**, **DisabledFillColor**, **DisabledBorderColor**
Pressed color	Sets the colors of the control text, the control background, and the control border when the user selects the control.	Not applicable	Properties; Advanced: **PressedFontColor**, **PressedFillColor**, **PressedBorderColor**
ContentLanguage	Determines the display language of the control, if it's different from the language that's used in the app.	String	Advanced
OnAddressSelect	Contains code that runs when the user selects a suggested address.	Event	Advanced
OnChange	Contains code that runs when a control property is changed.	Event	Advanced

Output properties

Other properties become available when a user interacts with the address input control. You can use these *output properties* in other controls or to customize the app experience.

Expand table

Property	Description
UserInput	The text the user typed in the input box
SelectedLatitude	The latitude of the address that the user selected
SelectedLongitude	The longitude of the address that the user selected
SearchResultJson	The search result, based on **UserInput**, displayed as a string in JSON format
FreeformAddress	The address that the user selected from the list of suggested addresses
LocalName	The name of a geographic area or locality that groups a number of addressable objects for addressing purposes, without being an

Property	Description
	administrative unit
PostalCode	The postal code
ExtendedPostalCode	The extended postal code
CountryCode	The country code
Country	The country/region name
CountryCodeISO3	The country code in ISO alpha-3 format
CountrySubdivisionName	The country/region subdivision name
StreetName	The street name
StreetNumber	The street number
Municipality	The municipality
MunicipalitySubdivision	The municipality subdivision
CountryTertiarySubdivision	The country/region tertiary subdivision
CountrySecondarySubdivision	The country/region secondary subdivision
CountrySubdivision	The country/region subdivision

Other geospatial controls

To visualize and interpret location data, use the **interactive map** control.

Attachments control in Power Apps

Summarize this article for me

A control that users can use to download files to their device, and upload and delete files from a list created by using Microsoft Lists or a Microsoft Dataverse table.

Description

By using an **Attachments** control, you can open, add, and delete files from a list or a Dataverse table.

Limitations

The attachment control has these limitations:

1. The attachment control only supports lists and Dataverse tables as data sources. It doesn't support expressions that transform these data sources into tables, such as with the **ForAll** function.

2. The upload and delete functionality works only inside a form. The attachment control appears disabled when in **Edit** mode and not inside a form. To save file additions and deletions, the app user must save the form. Because of this limitation, the attachment control isn't available from the **Insert** tab but appears in the form when the attachment form field is enabled in a SharePoint or Dataverse form.

3. The attachments control on a web browser lets you select multiple files and use drag and drop functionality. However, when you use the attachments control on Power Apps Mobile, you can only add files one at a time.

4. You might not be able to attach files stored in OneDrive or any other cloud storage. Try downloading these files to the device before attaching them by using the device's file picker.

5. The Power Apps mobile app doesn't support capturing videos directly from the camera or selecting videos from the photo library when using the **Attachments** control. To add a video, users must use the **Browse** option.

    - **On Android**: The **Browse** option displays all file types, including videos, so you can select and attach your video files.
    - **On iOS**: The **Browse** option only shows files stored in the **Files** app. If your video isn't already saved there, you need to move it to the **Files** app before you attach it.

If a video doesn't appear as an option to attach, first save the video to your device's **Files** app and then try again.

6. Uploading and viewing attachments isn't supported when running canvas apps in Microsoft Teams on Android or iOS mobile devices.

Key properties

Items – The **Attachment** column of the list or Dataverse table. Collections and Tables aren't supported.

MaxAttachments – The maximum number of files the control accepts.

MaxAttachmentSize – The maximum allowed file size in MB for each new attachment. 1 MB here is 1,000,000 bytes (10^6 B) or 1,000 KB.

OnAddFile – Actions to perform when the user adds a new file attachment.

OnRemoveFile – Actions to perform when the user deletes an existing attachment.

OnUndoRemoveFile – Actions to perform when the user restores a deleted attachment.

Additional properties

AccessibleLabel – Label for screen readers. Should describe the purpose of the attachments.

AddAttachmentText – The label text for the link used to add a new attachment.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of a control's text.

DisabledBorderColor – The color of a control's border if the control's **DisplayMode** property is set to **Disabled**.

DisabledColor – The color of text in a control if its **DisplayMode** property is set to **Disabled**.

DisabledFill – The background color of a control if its **DisplayMode** property is set to **Disabled**.

DisplayMode – Whether the control allows adding and deleting files (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

[DropTargetBackgroundColor] – The color of the control's drop target background.

[DropTargetBorderColor] – The color of the control's drop target border.

[DropTargetBorderStyle] – Whether the control's drop target border is **Solid**, **Dashed**, **Dotted**, or **None**.

[DropTargetBorderThickness] – The thickness of the control's drop target border.

[DropTargetTextColor] – The color of the control's drop target text.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

MaxAttachmentsText – The text that replaces the "Attach file" link when the control contains the maximum number of files allowed.

NoAttachmentsText – Informational text shown to the user when there are no files attached.

Padding – The distance between the text on an import or export button and the edges of that button.

PressedBorderColor – The color of a control's border when the user selects that control.

PressedColor – The color of text in a control when the user selects that control.

PressedFill – The background color of a control when the user selects that control.

Reset – Reverts all changes to the attachments control and returns to the previously saved state.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

Visible – Whether a control is visible or hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (or screen, if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (or screen, if no parent container).

Example

1. Add a form to your app, and set a list as its data source.
2. Select the **Display Form** control in the tree view on the left-hand side. You can also use **Edit Form** instead.
3. Select **Data Source** in the Properties tab in the options panel on the right and then select the list you connected to.
4. Select **Edit fields** in the *Fields* section and select **Add field**.
5. Select the **Attachments** field and select **Add**.

   The Attachments field associated with the list appears in the form.

Learn how to add and configure a control

Accessibility guidelines

Color contrast

Ensure there's adequate color contrast between:

- **ItemColor** and **ItemFill**

- **ItemHoverColor** and **ItemHoverFill**
- **ItemPressedColor** and **ItemPressedFill**
- **AddedItemColor** and **AddedItemFill**
- **RemovedItemColor** and **RemovedItemFill**
- **ItemErrorColor** and **ItemErrorFill**
- **AddAttachmentColor** and **Fill**
- **MaxAttachmentsColor** and **Fill**
- **NoAttachmentsColor** and **Fill**

This requirement is in addition to the standard color contrast requirements.

Screen reader support

Include the following properties:

- **AccessibleLabel**
- **AddAttachmentsText**
- **MaxAttachmentsText**
- **NoAttachmentsText**

Keyboard support

- Use **TabIndex** with a value of zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this clarity.

Last updated on 03/11/2026

Audio and Video controls in Power Apps (retired)

Article • 04/03/2024

A control that plays an audio file, a video file, or a video on YouTube.

Description

An **Audio** control plays a sound clip from a file, a recording from a Microphone control, or the audio track from a video file.

A **Video** control plays a video clip from a file or from YouTube or any external source. Closed captions can optionally be shown when specified.

> **Important**
>
> Videos on Azure Media services are no longer supported. For more information, see Retirement of the service.

Limitations

The audio and video control has these limitations:

- Power Apps Mobile runs on various types of devices, and some of them have limitations that are specific to that platform:
  - You can play videos in multiple **Video** controls at the same time on all platforms except iPhone devices.
  - You can record audio with multiple **Microphone** controls at the same time on all platforms except the web player.

Key properties

Loop – Whether an audio or video clip automatically starts over as soon as it finishes playing.

Media – An identifier for the clip that an audio or video control plays.

> **Note**

- Use HTTPS for all external videos to ensure compatibility with modern browsers.
- External videos must be accessible anonymously (without any authentication).

ShowControls – Whether an audio or video player shows, for example, a play button and a volume slider, and a pen control shows, for example, icons for drawing, erasing, and clearing.

Additional properties

AccessibleLabel – Label for screen readers. Should be the title of the video or audio clip.

AutoPause – Whether an audio or video clip automatically pauses if the user navigates to a different screen.

AutoStart – Whether an audio or video control automatically starts to play a clip when the user navigates to the screen that contains that control.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

ClosedCaptionsUrl – Video control only. URL of closed captions file in WebVTT format. Both video and captions URLs must be HTTPS. Server hosting both video and captions file needs to be CORS enabled.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

Image – The name of the image that appears in an image, audio, or microphone control.

ImagePosition – The position (**Fill**, **Fit**, **Stretch**, **Tile**, or **Center**) of an image in a screen or a control if it isn't the same size as the image.

OnEnd – Actions to perform when an audio or video clip finishes playing.

OnPause – Actions to perform when the user pauses the clip that an audio or video control is playing.

OnStart – Actions to perform when the user starts to record with a microphone control.

Paused – *True* if a media playback control is currently paused, *false* otherwise.

Reset – Whether a control reverts to its default value.

Start – Whether an audio or video clip plays.

StartTime – The time after the start of an audio or video clip when the clip starts to play.

Time – A media control's current position.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

First(*TableName*)

Examples

Play an audio or video file

1. On the **File** menu, click or tap **Media**, click or tap **Videos** or **Audio**, and then click or tap **Browse**.

2. Browse to the file you want to use, click or tap it, and then click or tap **Open**.

3. Press Esc to return to the default workspace, add an **Audio** or **Video** control, and set its **Media** property to the file that you added.

   Don't know how to add and configure a control?

4. Press F5, and then play the clip by clicking or tapping the play button of the control that you added.

   > **Tip**
   >
   > The play button of the **Video** control appears when you hover over the control.

5. Press Esc to return to the default workspace.

Play a YouTube video

1. Add a **Video** control, and set its **Media** property to the URL of the YouTube video, enclosed in double quotation marks.
2. Press F5, and then play the clip by clicking or tapping the play button of the **Video** control.
3. Press Esc to return to the default workspace.

Accessibility guidelines

Audio and video alternatives

- **ShowControls** must be true so that users can listen or watch multimedia at their own pace. This also allows users to toggle closed captions and full-screen mode on video players.
- Closed captions must be provided for videos.
  - For YouTube videos, use authoring tools provided by YouTube to add captions.
  - For other videos, create captions in WebVTT format, upload them, and set **ClosedCaptionsUrl** to the url location. There are several limitations. Server(s) hosting video and captions needs to be CORS-enabled and serve them using HTTPS protocol.
- Consider providing an audio or video transcript using one of these methods:

  1. Put the text in a **Label** and position it adjacent to the multimedia player. Optionally, create a **Button** to toggle the display of the text.

2. Put the text in a different screen. Create a **Button** that navigates to the screen and position the button adjacent to the multimedia player.
3. If the description is short, it can be put it in the **AccessibleLabel**.

Color contrast

There must be adequate color contrast between:

- **FocusedBorderColor** and the outside color
- **Image** and the multimedia player controls (if applicable)
- **Fill** and the multimedia player controls (if the fill is visible)

Provide closed captions and/or transcript if the video content has color contrast issues.

Screen reader support

- **AccessibleLabel** must be present.

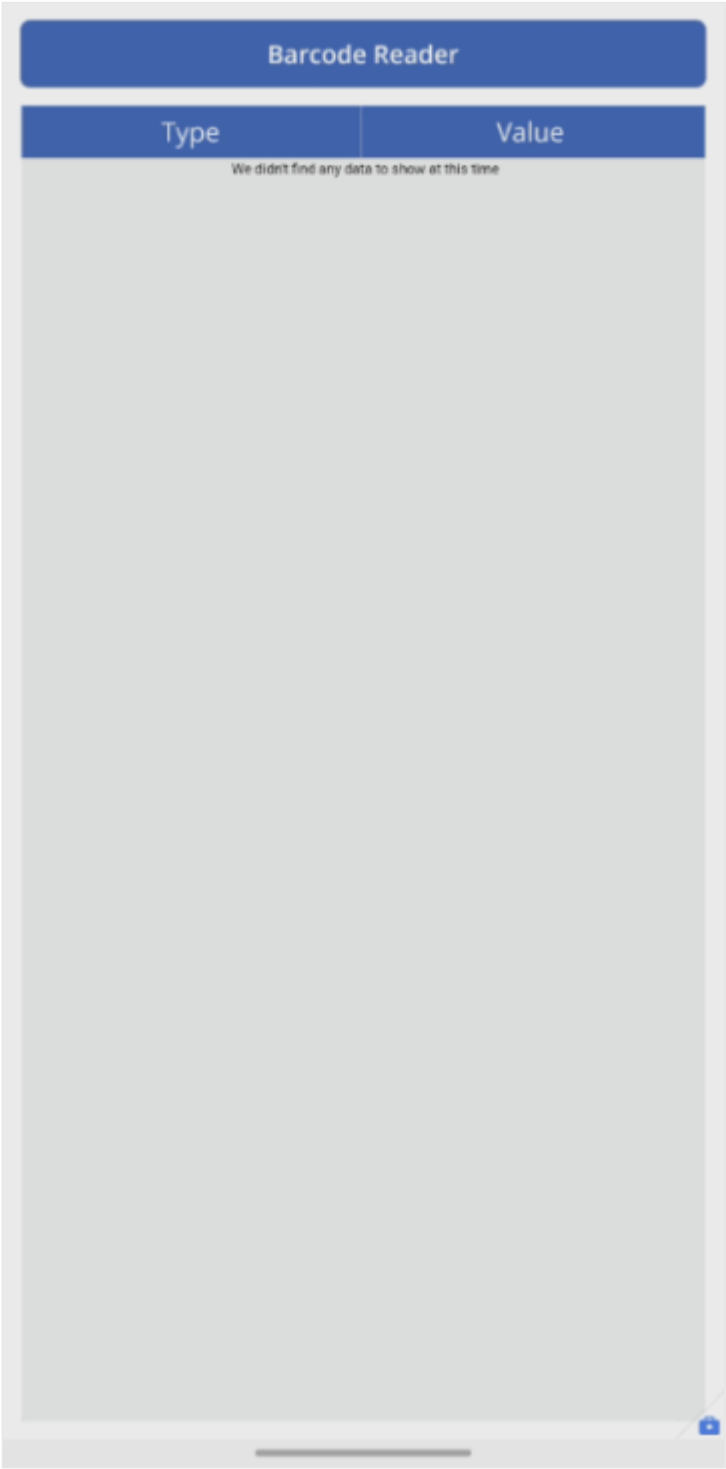
Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this.
- **AutoStart** should be false because it can be difficult for keyboard users to stop playback quickly.

Barcode reader control in Power Apps

Article • 04/25/2023

Scans barcodes, QR codes, and data-matrix codes on Android, iOS, and Windows devices.



Description

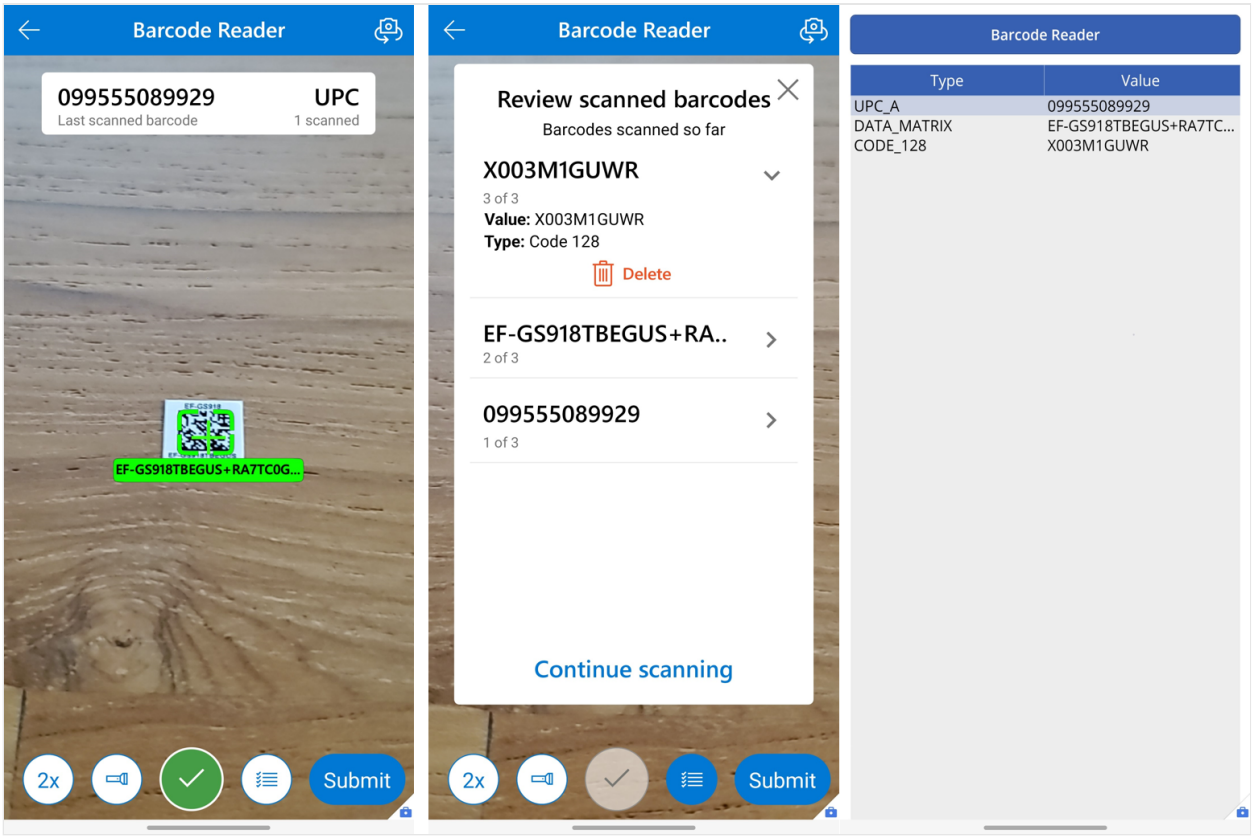
The control opens a native scanner on Android, iOS, and Windows devices. On iOS and Android, the scanner supports the following scanning modes:

- **Automatically scan** – A barcode is scanned as soon as it's detected.
- **Select to scan** – The user can determine which of the detected barcodes to scan. The control doesn't support scanning in a web browser.
- **Scan multiple** – The user can scan multiple barcodes during the barcode session.

On Windows devices, the barcode reader will always **automatically scan**.

The barcode reader control supports different zoom levels and turning on/off the device's flashlight from within the scanning experience.

> **Note**
>
> The barcode scanner control is supported on Android, iOS, and Windows devices. All other platforms will show a warning stating that some features of the app won't work.



Key properties

Barcodes – Output property that contains a table of the barcodes scanned with two columns: **Value**, and **Type**. **Value** is the text value of the code that was scanned, while **Type** is the type of the code that was scanned.

OnScan – Actions to perform when a barcode is successfully scanned.

OnCancel – Actions to perform when a barcode scan is canceled by the user.

OnChange - Actions to perform when a property on the barcode reader control is changed, including output properties.

BarcodeType - The barcode type to scan. You can target multiple barcode types by concatenating them. Ex. `'Microsoft.BarcodeReader.BarcodeType'.Code128 & 'Microsoft.BarcodeReader.BarcodeType'.Code39`. **Default: Auto**

Scanning mode - Whether to `Automatically scan` the first barcode detected in view, to allow the user to `Select to scan` which of the barcodes in view to scan, or to `Scan multiple` barcodes in a single session. On Windows, the barcode reader will always `Automatically scan`.

Scanning quality - The image quality the barcode reader scans at. A higher quality is good for small barcodes, but could lead to slow performance. On Windows, the barcode reader will always scan at the device's camera quality. **Default: Automatic**.

PreferFrontCamera - If enabled the barcode reader will default to using the front facing camera instead of the rear facing camera.

BeepOnScan - If enabled, the barcode reader will play a beep noise when a barcode is scanned.

VibrateOnScan - If enabled, the barcode reader will vibrate when a barcode is scanned.

Additional properties

Text - Text that appears on the button that activates the scanner.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Height – The height of the button that activates the scanner.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The width of the button that activates the scanner.

X – The distance between the left edge of a control and the left edge of its parent container (screen, if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen, if no parent container).

Accessibility guidelines

The same guidelines for the **Button** control apply to the **Barcode reader** control because it's a button that launches the scan.

Visual alternatives

- The barcode scanner is a button that doesn't display the scan result. Consider showing the scan result with a **Label** control. Set the label's **Text** property to `First(BarcodeReader.Barcodes).Value` where `BarcodeReader` is the name of the barcode reader control. Set the label's **Live** property to **Polite** so that screen-reader users are notified of changes. This change makes the scanned value accessible to everyone, irrespective of visual ability.
- Users who have visual and motor disabilities might prefer not to point the camera at a barcode. Consider adding another form of input, such as a **Text input** control, for users to enter barcodes.

Select() barcode reader control

The barcode reader control doesn't support Select(). As a workaround, set the barcode reader fill color to transparent and put it in front of the control you wanted to select the barcode reader with. This will result in the same experience for the app user where selecting the control launches the barcode reader experience as they will be selecting an invisible barcode reader button instead of the actual control.

Limitations of controls in Power Apps

Barcode scanner control (retired) in Power Apps

Article • 03/13/2023

The legacy control for scanning barcodes, QR codes, and data-matrix codes on an Android, iOS, and Windows device.

> **Important**
>
> The barcode scanner control is retired as it is replaced by the barcode reader control. While the legacy barcode scanner's existing functionality will continue to be supported in future versions of Power Apps, the barcode reader includes the latest improvements and should be used where possible.

Prerequisites

The barcode scanner control is retired and needs to be enabled to show up in the insert pane.

With your app open for editing in Power Apps Studio:

1. Open **Settings**
2. Select **Upcoming features** in the left-hand menu and select the **Retired** tab
3. Turn on the **Legacy barcode scanner** setting

Description

The control opens a native scanner on an Android, iOS, and Windows device. The scanner automatically detects a barcode, a QR code, or a data-matrix code when in view. The control doesn't support scanning in a web browser.

> **Note**
>
> The barcode scanner control is supported on an Android, iOS, and Windows device. All other platforms will show a warning that some features of the app won't work.

Key properties

Value – Output property that contains the text value of the code that was scanned most recently.

Type – Output property that contains the type of the code that was scanned most recently.

OnScan – Actions to perform when a barcode is successfully scanned.

OnCancel – Actions to perform when a barcode scan is canceled by the user.

BarcodeType - The barcode type to scan. You can target multiple barcode types by concatenating them. Ex. BarcodeType.Code128 & BarcodeType.Code39 **Default: Auto**

PreferFrontCamera - Whether the front-facing camera, when available, is used for scanning.

FlashlightEnabled - Whether the flashlight is enabled automatically when the scanner is opened.

Additional properties

Text - Text that appears on the button that activates the scanner.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Height – The height of the button that activates the scanner.

Tooltip – Explanatory text that appears when the user hovers over a control.

Type - The type of code that was detected in the scan that succeeded most recently.

Visible – Whether a control appears or is hidden.

Width – The width of the button that activates the scanner.

X – The distance between the left edge of a control and the left edge of its parent container (screen, if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen, if no parent container).

Accessibility guidelines

The same guidelines for the **Button** control apply to the **Barcode scanner** control because it's a button that launches the scan.

Visual alternatives

- The barcode scanner is a button that doesn't display the scan result. Consider showing the scan result with a **Label** control. Set the label's **Text** property to the barcode scanner's **Value** property. Set the label's **Live** property to **Polite** so that screen-reader users are notified of changes. This change makes the scanned value accessible to everyone, irrespective of visual ability.
- Users who have visual and motor disabilities might prefer not to point the camera at a barcode. Consider adding another form of input, such as a **Text input** control, for users to enter barcodes.

Limitations of controls in Power Apps

Button control in Power Apps

Article • 05/23/2025

A control that the user can click or tap to interact with the app.

Description

Configure the OnSelect property of a **Button** control to run one or more formulas when the user clicks or taps the control.

Key properties

OnSelect – Actions to perform when the user taps or clicks a control.

Text – Text that appears on a control or that the user types into a control.

Additional properties

Align – The location of text in relation to the horizontal center of its control.

AutoDisableOnSelect – Automatically disables the control while the **OnSelect** behavior is running.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

ContentLanguage - The language of the control's content, if different from the control's container.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Fill – The background color of a control.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

Pressed – *True* while a control is being pressed, *false* otherwise.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

RadiusBottomLeft – The degree to which the bottom-left corner of a control is rounded.

RadiusBottomRight – The degree to which the bottom-right corner of a control is rounded.

RadiusTopLeft – The degree to which the top-left corner of a control is rounded.

RadiusTopRight – The degree to which the top-right corner of a control is rounded.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

VerticalAlign – The location of text on a control in relation to the vertical center of that control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Navigate(*ScreenName*, *ScreenTransitionValue*)

Examples

Add a basic formula to a button

1. Add a **Text input** control, and name it **Source**.

   Don't know how to add, name, and configure a control?

2. Add a **Button** control, set its **Text** property to "Add", and set its **OnSelect** property to this formula:
   UpdateContext({Total:Total + Value(Source.Text)})

   Want more information about the **UpdateContext** function or other functions?

3. Add a **Label** control, set its **Text** property in the formula bar to **Value(Total)**, and then press **F5**.

4. Clear the default text from **Source**, type a number in it, and then click or tap **Add**.

   The **Label** control shows the number that you typed.

5. Clear the number from **Source**, type another number in it, and then click or tap **Add**.

   The **Label** control shows the sum of the two numbers that you typed.

6. (optional) Repeat the previous step one or more times.
7. To return to the default workspace, press Esc (or click or tap the close icon in the upper-right corner).

Configure a button with multiple formulas

Add a formula that clears the **Text input** control between entries.

1. Set the HintText property of **Source** to "Enter a number".
2. Set the OnSelect property of **Add** to this formula:

   UpdateContext({Total:Total + Value(Source.Text)});
   UpdateContext({ClearInput: ""})

   > **Note**
   >
   > Separate multiple formulas with a semi-colon "**;**".

3. Set the Default property of **Source** to **ClearInput**.
4. Press **F5**, and then test the app by adding several numbers together.

Add another button to reset the total

Add a second button to clear the total between calculations.

1. Add another **Button** control, set its Text property to "Clear", and set its OnSelect property to this formula:

   UpdateContext({Total:0})

2. Press **F5**, add several numbers together, and then click or tap **Clear** to reset the total.

Change a button's appearance

Change a button's shape

By default, Power Apps creates a rectangular **Button** control with rounded corners. You can make basic modifications to the shape of a **Button** control by setting its Height, Width, and Radius properties.

> ⓘ Note
>
> Icons and Shapes provide a wide variety of designs and can perform some of the same basic functions that **Button** controls do. However, Icons and Shapes don't have a Text property.

1. Add a **Button** control, and set its Height and Width properties to **300** to make a large square button.
2. Modify the RadiusTopLeft, RadiusTopRight, RadiusBottomLeft, and RadiusBottomRight properties to adjust the amount of curvature on each corner. Here are some examples of different shapes, each one starting from a 300 x 300 square button:
   - Set all four Radius values to **150** to create a circle.
   - Set the values for RadiusTopLeft and RadiusBottomRight to **300** to create a leaf-shaped **Button**.
   - Set the values for RadiusTopLeft and RadiusTopRight to **300**, and the values for RadiusBottomLeft and RadiusBottomRight to **100** to create a tab-shaped button.

Change a button's color when you hover over it

By default, the fill color of a **Button** control will dim by 20% when you hover over it with a mouse. You can adjust this behavior by changing the HoverFill property, which uses the ColorFade function. If you set the ColorFade formula to a positive percentage, the color becomes lighter when you hover over the button, while a negative percentage makes the color darker.

- Change the ColorFade percentage in the HoverFill property of one of the buttons that you created, and observe the effects.

You can also specify the color of a **Button** control by setting its HoverFill property to a formula that contains the ColorValue function instead of the ColorFade function, as in **ColorValue("Red")**.

> ⓘ Note
>
> The color value can be any CSS color definition, either a name or a hex value.

- Replace the ColorFade function with a ColorValue function in one of the buttons that you created, and observe the effects.

Accessibility guidelines

Color contrast

- Standard color contrast requirements apply.

Screen reader support

- **Text** must be present.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this.

Camera control in Power Apps

Article • 12/16/2022

A control that enables users to take pictures using the camera on a device.

Description

Use the **Camera** control to capture pictures with a device's camera. The device must have a camera and the user must authorize the app to use the camera.

Select the camera control to capture a picture from the camera.

The most recently captured picture is available through the **Photo** property. With this property, the images can be:

- **Viewed with the Image control.** Use the Image control to view the captured image. For more information, see the examples.
- **Temporarily put in a variable or a collection.** Use the Set or Collect functions to store images in a variable or a collection. Use caution when using multiple images in a collection at the same time consuming device's limited memory. Use the SaveData and LoadData functions to move images to the local storage on the device and for offline scenarios.
- **Stored in a database.** Use the Patch function to store images in a database.
- **Transmitted as a base64 encoded text string.** Use the JSON function to base64 encode images.

Use the **Stream**, **StreamRate**, and **OnStream** properties to automatically capture images on a timer, for example snapping a picture every minute to create a time-lapse sequence.

Captured media is referenced by a text string URI. For more information, read the data type documentation.

> **Note**
>
> - The camera control is only supported on Microsoft Edge, Chrome, Firefox, and Opera browsers; and Android and iOS devices. All other browsers and platforms will show a warning that some features of the app won't work.
> - Images generated by the camera control have a maximum resolution of 640 x 480 px. If you need full resolution images, use the Add picture control

instead.

- Depending on the make and model of your mobile device, the device camera might take a few seconds to initialize when using the camera control.

Limitations

The camera control has these limitations:

1. When you use the camera control, the image doesn't contain meta-data information. This is due to a limitation of how we take images with the camera. To mitigate this issue, use the Add picture control
2. If your mobile device is low on memory, the camera is temporarily disabled to avoid crashing the device.
3. Power Apps for Windows might crash if you open an app that uses a camera control. To avoid this problem, use the web player on the Windows platform. Also, multiple cameras aren't supported.

Key properties

AvailableDevices – Table of the available cameras on the device.

Table contains two columns:

- *Id* number to be used with the **Camera** property
- *Name* provided by the device to identify the camera. Some platforms may include *Front* or *Back* to help locate the camera.

Note: Not all devices in the table may be usable in your app. Some may be specialized drivers or applications intended for specific purposes.

Camera – The numeric ID of the camera to use. Helpful on devices with more than one camera.

OnStream – Actions to perform when the **Stream** property is updated.

Photo – The image captured when the user takes a picture.

Stream – Automatically updated image based on the **StreamRate** property.

StreamRate – How often to update the image on the **Stream** property, in milliseconds. This value can range from 100 (1/10th of a second) to 3,600,000 (1 hour).

Additional properties

AccessibleLabel – Label for screen readers. Should describe the purpose of taking a picture.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Brightness – How much light the user is likely to perceive in an image.

Contrast – How easily the user can distinguish between similar colors in an image.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

OnSelect – Actions to perform when the user taps or clicks a control.

TabIndex – Keyboard navigation order compared to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container or screen.

Y – The distance between the top edge of a control and the top edge of the parent container or screen.

Examples

For these examples, you'll need a device with a camera. To test your app, use a web cam accessible from your browser. Or by saving your app and loading it into an iOS or Android device with a camera.

Simple display of a captured picture

1. Add a **Camera** control.
2. Authorize the app to use device's camera if prompted.
3. Add an **Image** control.
4. Set the **Image** property of the **Image** control to the following formula:

   ```
   Power Fx
   Camera1.Photo
   ```

   > **Note**
   >
   > Replace camera control name *Camera1* as appropriate.

5. Press F5 to preview your app.
6. Take a picture by selecting or tapping the camera control. You should see the result in your image control.

Add pictures to an Image gallery control

1. Add a **Camera** control, name it **MyCamera**, and set its OnSelect property to this formula:

   ```
   Power Fx
   Collect( MyPix, MyCamera.Photo )
   ```

   For more information:

   - How to add, name, and configure a control?
   - Read more about Collect function or other functions.

2. Press F5, and then take a picture by selecting or tapping **MyCamera**.
3. Add a Vertical gallery control. And then resize its Image control, its template, and the **Image gallery** control itself to fit in the screen.
4. Set the Items property of the **Image gallery** control to this formula:

```
Power Fx

MyPix
```

5. Set the Image property of the **Image** control in the gallery to this formula:

   ```
   Power Fx

   ThisItem.Url
   ```

   The picture that you took appears in the **Image gallery** control.

6. Take as many pictures as you want, and then return to the default workspace by pressing Esc.

7. (optional) Set the **OnSelect** property of the **Image** control in the **Image gallery** control to the formula:

   ```
   Power Fx

   Remove( MyPix, ThisItem )
   ```

8. Press F5, and then select a picture to remove it.

Use the SaveData function to save the pictures locally or the Patch function to update a data source.

Change the active camera from a drop down

1. Add a **Camera** control.

2. Authorize the app to use device's camera if prompted.

3. Add a Drop down control.

4. Set the **Items** property of the dropdown to:

   ```
   Power Fx

   Camera1.AvailableDevices
   ```

   > ⓘ **Note**

Replace camera control name *Camera1* as appropriate.

5. Set **Camera** property of the camera to:

```
Power Fx

Dropdown1.Selected.Id
```

> **Note**
>
> Replace dropdown control name *Dropdown1* as appropriate.

6. Press F5, and then select an item from the dropdown to change the camera.

Accessibility guidelines

The camera control shows camera feed and also functions as a button that takes a picture. So, there are similar accessibility considerations as with buttons.

Video alternatives

Consider adding an alternative form of input for users with visual disabilities. For example, Add picture to allow users to upload an image from their device.

Color contrast

There must be adequate color contrast between FocusedBorderColor and the outside color.

Screen reader support

AccessibleLabel must be present.

Keyboard support

- TabIndex must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use FocusedBorderColor and FocusedBorderThickness to update the visibility of focus indicators.

Card control in Power Apps

Article • 12/16/2022

Provides the display and editing experience for a single field of a **Display form** or **Edit form** control.

Description

Display form and **Edit form** controls act as containers for displaying and viewing entire records. Each container can hold a set of **Card** controls that display individual fields or provide a way to update those fields. Each card has a **DataField** property that specifies which field of the record it works on.

Predefined cards are defined for different data types and user experiences. For example, there may be a card to edit a number field with a **Text input** control, which is great for use with the keyboard. Another card might support editing a number by using a **Slider** control instead. With the form control selected, you can, in the right-hand pane, easily select a card based on a field.

Cards themselves contain controls. The controls of a card make up the experience for displaying and editing a single field. For example, a number card may consist of a **Label** control to provide the display name of the field and a **Text input** control to provide an editor for the value of the field. The card may also have a **Label** control that shows any validation errors that occur and a **Label** control for the common asterisk to indicate that a field is required.

You can customize the controls of a predefined card by resizing it, moving it, hiding it, adding controls to it, and making other changes. You can also start with an entirely blank card, a "custom card", to which you add controls from scratch.

Predefined cards are *locked* by default. In a locked card, you can modify only certain properties of the card or the controls within the card, and you can't delete a locked card. You can show the card lock and unlock it on the **View** tab of the **Advanced** view. If a property is locked and can't be modified, it appears with a lock icon next to its name. Unlocking a card is an advanced activity and should be done with care, because automatic formula generation will no longer occur for the card, and you can't relock a card.

Within the form's container, the **ThisItem** record is available and contains all the fields of the record. For example, the card's **Default** property is often set to **ThisItem**.*FieldName*.

You can use the **Parent** reference to configure a control to reference the properties of a card. For example, a control should use **Parent.Default** to read the initial state of the field from the data source. By using **Parent** instead of directly accessing the information that you want, the card is better encapsulated, and you can change it to a different field without breaking internal formulas.

See Understand data cards for examples of how to customize, unlock, and create cards.

Key properties

DataField – The name of the field within a record that this card displays and edits.

- Specify the name as a single static string that's enclosed in double quotation marks (for example, **"Name"**), not a formula.
- Unbind a card by setting its **DataField** property *blank*. The **Valid** and **Update** properties are ignored for unbound cards.

Default – The initial value of a control before it is changed by the user.

- For each control in a card, set this property to **Parent.Default** to refer to the default value of the field according to the data source. For example, set a slider's Default property to **Parent.Default** to ensure that the user starts with a generic value for that slider.

DisplayMode – Values can be **Edit, View,** or **Disabled**. Configures whether the control inside the card allows user input (**Edit**), only displays data (**View**) or is disabled (**Disabled**).

- Allows a single card to be used in both edit and view forms, by configuring this property, which is tied to the Form's behavior by default.
- In **View** mode, child controls such as Text input, Drop down, Date Picker will only display the text value and will not render any interactive elements or decorations.

DisplayName – The user friendly name for a field in a data source.

- The DataSourceInfo function provides this metadata from the data source.
- Controls within the card should use **Parent.DisplayName** to refer to the name of the field.

Error – The user friendly error message to display for this field when validation fails.

- This property is set when **SubmitForm** is called.
- The message describes validation problems based on the data source's metadata and checking the card's **Required** property.

Required – Whether a card, editing the field of a data source, must contain a value.

- The **DataSourceInfo** function provides the required metadata from the data source.
- Controls within the card should use **Parent.Required** to determine whether that card's field is required.

Update – The value to write back to the data source for a field.

- Use this property's formula to pull the values from the edit controls of the card in order to write back to the data source. For example, set a card's **Update** property to **Slider.Value** to update the data source with a value from the slider in that card.

Width – The distance between a control's left and right edges.

WidthFit – Whether a control automatically grows horizontally to fill any empty space in a container control such as an **Edit form** control. If multiple cards have this property set to **true**, the space is divided between them. For more information, see Understand data form layout.

Additional properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

Valid – Whether a **Card** or **Edit form** control contains valid entries, ready to be submitted to the data source.

Visible – Whether a control appears or is hidden.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container). For a **Card** control in a container that has multiple columns, this property determines the column in which the card appears.

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container). For a **Card** control in a container that has multiple rows, this property determines the row in which the card appears.

Examples

See Understand data cards and Understand data form layout for examples.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **Fill** and any child controls. For example, if a card contains a **Label** and the label has transparent fill, then the card's **Fill** effectively becomes the background color for the label. Thus, there should be adequate contrast between the card's **Fill** and the label's **Color**.

Screen reader support

- **DisplayName** must be present.

Check box control in Power Apps

Article • 12/16/2022

A control that the user can select or clear to set its value to **true** or **false**.

Description

The user can specify a Boolean value by using this familiar control, which has been used in GUIs for decades.

Key properties

Default – The initial value of a control before it is changed by the user.

Text – Text that appears on a control or that the user types into a control.

Value – The value of an input control.

Additional properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

CheckboxBackgroundFill – The background color of the box that surrounds the checkmark in a checkbox control.

CheckboxBorderColor – The color of the border that surrounds the checkmark in a checkbox control.

CheckboxSize – The width and height of the box that surrounds the checkmark in a checkbox control.

CheckmarkFill – The color of the checkmark in a checkbox control.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

OnCheck – Actions to perform when the value of a checkbox or a toggle changes to **true**.

OnSelect – Actions to perform when the user taps or clicks a control.

OnUncheck – Actions to perform when the value of a checkbox or a toggle changes to **false**.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

Reset – Whether a control reverts to its default value.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

VerticalAlign – The location of text on a control in relation to the vertical center of that control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

If(*Condition*, *Result*)

Example

1. Add a **Check box** control, name it **chkReserve**, and set its **Text** property to show **Reserve now**.

Don't know how to add, name, and configure a control?

2. Add a **Date picker** control, and set its **Visible** property to this formula:
   If(chkReserve.Value = true, true)

   Want more information about the **If** function or other functions?

3. Press F5, click or tap **chkReserve** to set its **Value** property to **true**, and then click or tap **chkReserve** again to set its **Value** property to **false**.

   The **Date Picker** control appears when the **Value** property of **chkReserve** is **true** but not when it's **false**.

4. To return to the default workspace, press Esc.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **CheckmarkFill** and **CheckboxBackgroundFill**
- **CheckboxBackgroundFill** and **Fill**
- **CheckboxBackgroundFill** and **PressedFill**
- **CheckboxBackgroundFill** and **HoverFill**

This is in addition to the standard color contrast requirements.

Screen reader support

- **Text** must be present.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this.

Column chart and Line chart controls in Power Apps

Article • 12/16/2022

Controls that show data as graphs with x- and y-axes.

Description

Column chart and **Line chart** are grouped controls. Each group contains three controls: a Label for the title, the chart graphic, and a **Legend**.

Chart key properties

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

NumberOfSeries – How many columns of data are reflected in a column or line chart.

Additional chart properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Font – The name of the family of fonts in which text appears.

GridStyle – Whether a column or line chart shows its x-axis, its y-axis, both, or neither.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

ItemColorSet – The color of each data point in a chart.

ItemsGap – The distance between columns in a column chart.

- The **ItemsGap** property is available for the **Column chart** control but not the **Line chart** control.

Markers – Whether a column or line chart shows the value of each data point.

MarkerSuffix – Text that appears after each value in a column chart for which the **Markers** property is set to **true**.

- The **MarkerSuffix** property is available for the **Column chart** control but not the **Line chart** control.

MinimumBarWidth – The narrowest possible width of columns in a column chart.

- The **MinimumBarWidth** property is available for the **Column chart** control but not the **Line chart** control.

OnSelect – Actions to perform when the user taps or clicks a control.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

SeriesAxisMax – The maximum value of the y-axis for a column or line chart.

- The **SeriesAxisMax** property is available for the **Column chart** control but not the **Line chart** control.

SeriesAxisMin – A number that determines the minimum value of the y-axis for a column chart.

- The **SeriesAxisMin** property is available for the **Column chart** control but not the **Line chart** control.

Size – The font size of the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

XLabelAngle – The angle of the labels below the x-axis of a column or line chart.

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

YAxisMax – The maximum value of the y-axis for a line chart.

- The **YAxisMax** property is available for the **Line chart** control but not the **Column chart** control.

YAxisMin – The minimum value of the y-axis for a line chart.

- The **YAxisMin** property is available for the **Line chart** control but not the **Column chart** control.

YLabelAngle – The angle of the labels next to the y-axis of a line or column chart.

Related functions

Max(*DataSource, ColumnName*)

Example

1. Add a **Button** control, and set its **OnSelect** property to this formula:
   Collect(Revenue, {Year:"2013", Europa:24000, Ganymede:22300, Callisto:21200}, {Year:"2014", Europa:26500, Ganymede:25700, Callisto:24700},{Year:"2014", Europa:27900, Ganymede:28300, Callisto:25600})

   Don't know how to add and configure a control?

   Want more information about the **Collect** function or other functions?

2. Press F5, click or tap the **Button** control, and then press Esc to return to the default workspace.

3. Add a **Column chart** control or a **Line chart** control, set its **Items** property to **Revenue**, and set its **NumberOfSeries** property to **3**.

   The control shows revenue data for each product over three years.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- each item in **ItemColorSet**
- every item in **ItemColorSet** and the background color
- **Color** and the background color

Screen reader support

- There must be a **Label** immediately before the chart graphic to serve as the title.
- Consider adding a summary of the chart graphic. For example, "The line chart shows a steady increase in sales between March and August this year."

  > ⓘ **Note**
  >
  > Chart graphics and **Legend** are hidden from screen reader users. As an alternative, a tabular form of the data is presented to them. They can also cycle through buttons that select data in the chart.

Low vision support

- There must be a **Legend** if more than one series is shown.
- Consider setting **GridStyle** to GridStyle.All, which shows both axes. This helps all users accurately determine the scale of the data.
- For **Column chart**, consider setting **Markers** to **true**. This helps low-vision users determine the value of a column.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.

Note

When keyboard users navigate to the chart, they can cycle through buttons that select data in the chart.

Column control in Power Apps

Article • 12/16/2022

Provides the display experience for a single field in a Data table control.

Description

The Data table control shows a dataset in a tabular format, and each column in that tabular format is represented by a **Column** control. The **Column** control provides properties that the app maker can use to customize the appearance and behavior of the column.

Capabilities

Now available

- Change the width of a **Column** control.
- Change the text for a **Column** control.
- Navigate by clicking or tapping the value in a **Column** control.

Not yet available

- Customize the styling of a **Column** control.

Known issues

- The **Visible** property doesn't work yet.

Properties

- **DisplayName** – The text that appears in the header for the column.

  > ⓘ Note
  >
  > This property will soon be renamed **HeaderText**.

- **IsHyperlink** – A value that indicates whether the data in the column should be underlined to indicate that it's a hyperlink.

- **Width** – The distance between the **Column** control's left and right edges.

Examples

Resize a column

1. Create a blank tablet app.
2. On the **Insert** tab, click or tap **Data table**, and then resize the **Data table** control so that it covers the whole screen.
3. In the right pane, click or tap the down arrow to the right of **No data source selected**, and then click or tap **Add a data source**.
4. In the list of connections, click or tap the connection for your Microsoft Dataverse database.
5. In the list of tables, click or tap **Account**, and then click or tap **Connect**.

   The **Data table** control is initialized and shows a set of default fields.
6. Click or tap the **Full name** column.

Combo box control in Power Apps

Article • 05/23/2025

A control that allows users to make selections from provided choices. Supports search and multiple selections.

Description

A **Combo box** control allows you to search for items you will select. The search is performed server-side on the SearchField property so performance is not affected by large data sources.

Single or multi-select mode is configured via the SelectMultiple property.

When searching for items to select, for each item you can choose to show a single data value, two values, or a picture and two values (Person) by modifying the Layout settings in the Data pane.

When you view the control on small screens, the items list flyout becomes a full screen control for better usability.

> ⓘ **Note**
>
> If you want to search for items with *numbers*, convert numbers to text with Text() function. For example, *Text(12345)*.

Limitations

The combo box control has these limitations:

- When you use a Combo box control inside a gallery, its selections aren't maintained when the user scrolls the gallery. This isn't an issue if you use a Combo box control inside a gallery that doesn't scroll. A workaround isn't currently available.

People picker

To use **Combo box** as a people picker, choose the **Person** template from the Layout settings in the Data pane and configure the related data properties to be shown for the person below.

Key properties

Items – The source of data from which selections can be made.

DefaultSelectedItems – The initial selected item(s) before the user interacts with the control.

> ⓘ Note
>
> **Default** property is deprecated, use **DefaultSelectedItems** instead.

SelectedItems – List of selected items resulting from user interaction.

Selected – The last selected item resulting from user interaction.

SelectMultiple – Whether the user can select a single item or multiple items.

IsSearchable – Whether the user can search for items before selecting.

> ⓘ Note
>
> **IsSearchable** can be enabled only on a data source that contains at least one text field. The **Items** expression must be delegable for queries to be delegated with searching. That is, **If** statements within the **Items** expression are not supported.

SearchFields - The data fields of the data source searched when user is entering text.

> ⓘ Note
>
> To search on multiple fields, set **SearchFields** property in this format: ["MyFirstColumn", "MySecondColumn"]. Only text fields are supported.

Additional properties

AccessibleLabel – Label for screen readers.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayFields – List of fields shown for each item returned by the search. Easiest to configure via the Data pane in the Properties option tab.

> ⓘ Note
>
> To update multiple display fields in given template, set **DisplayFields** property in this format: `["MyFirstColumn", "MySecondColumn"]`.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

InputTextPlaceholder – Instructional text shown to end users when no items are selected.

OnChange – Actions to perform when the user changes a selection.

OnNavigate – Actions to perform when the user selects an item.

OnSelect – Actions to perform when the user taps or selects a control.

TabIndex – Keyboard navigation order in relation to other controls.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

> ⓘ Note
>
> Flyout border properties are controlled by **Border** properties.

Examples

Basic Combo box

The steps in this example apply to any data source that provides tables, but to follow these steps exactly, use an environment with Microsoft Dataverse database having sample data.

1. Select **Insert** > **Input** > **Combo box**, and name it "Combobox1".
2. On the **Properties** pane on the right-side of the screen, open the **Select a data source** list (next to **Items**), and then add or select a data source such as the Accounts table.
3. On the same pane, select **Edit** (next to **Fields**).
4. In the **Data** pane, open the **Primary text** list, and then select the **Primary Name** column that will show in the **Combo box** control.
5. While holding down the **Alt** key, select the down arrow to open the **Combo box** control.

   The control shows the data from the Primary Name that you specified in the data source that you specified.

(Optional) Show the first record by default

1. Set the **DefaultSelectedItems** property to this expression, replacing *DataSource* with the name of your data source:

```
Power Fx

First(DataSource)
```

(Optional) Display selected Account Name value in a label

1. Select **Insert** > **Text label**, and then select **Label**.
2. Set the **Text** property to this expression, replacing *Text* with the following formula:

```
Power Fx

If(CountRows(ComboBox1.SelectedItems)>0,
Concat(ComboBox1.SelectedItems,'Account Name',", "), "NO SELECTED ITEM")
```

> **Note**
>
> The If statement will check to see how may selected items exist and display them in a comma delimited label or a "NO SELECTED ITEM" message when empty.

Simulate simple drop-down behavior

By setting **IsSearchable** to false and **SelectMultiple** to false, you can achieve the same functionality of a drop-down.

1. Select **Insert** > **Input**, and then select **Combo box**.
2. On the **Properties** pane on the right-side of the screen, open the **Select a data source** list (next to **Items**), and then add or select a data source.
3. On the same pane, select **Edit** (next to **Fields**).
4. In the **Data** pane, open the **Primary text** list, and then select the column that you want to show in the **Combo box** control.
5. Set the **IsSearchable** property to false.
6. Set the **SelectMultiple** property to false.
7. While holding down the **Alt** key, select the down arrow to open the **Combo box** control.

   The control shows the data from the column that you specified in the data source that you specified.

   > ⓘ Note
   >
   > "Find items" text has disappeared, and that you'll only be able to select a single item.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **ChevronFill** and **ChevronBackground**
- **ChevronHoverFill** and **ChevronHoverBackground**
- **SelectionColor** and **SelectionFill**
- **SelectionFill** and **Fill**
- **SelectionTagColor** and **SelectionTagFill**

This is in addition to the standard color contrast requirements.

Screen reader support

- AccessibleLabel must be present.

> **Note**
>
> On touch screens, screen reader users can navigate the contents of the combo box sequentially. The combo box acts as a button that shows or hides its contents when selected.

Keyboard support

- TabIndex must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use FocusedBorderColor and FocusedBorderThickness to achieve this.

> **Note**
>
> The tab key navigates to or away from the combo box. Arrow keys navigate the contents of the combo box. The escape key closes the drop-down when opened.

Container control in Power Apps

Article • 12/16/2022

Groups logically-related controls to create hierarchies.

Description

The container can hold a set of controls and has its own properties.

You can start with inserting a blank container. And then, customize it by adding controls to it, resizing it, moving it, hiding it, and making other changes. You can also start with a number of controls, select them and add using tree view.

Limitations

- Containers don't work within forms.
- The following controls are not supported within a container:
  - Data table
  - PDF viewer
  - Web barcode scanner

Properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

Width – The distance between a control's left and right edges.

Visible – Whether a control appears or is hidden.

X – The distance between the left edge of a control and the left edge of its parent container (screen, if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen, if no parent container).

Frequently asked questions

What is the difference between a container and a group?

When editing an app, you can select controls and group them using Ctrl + G or the context menu. You can modify common properties of controls within the group. Groups are an aid for app making. They don't have properties of their own and don't affect the layout of the app.

In contrast, containers are actual controls with their own properties like **Width** and **BorderColor**. Containers affect app layout and help screen reader users understand the structure of the app.

While you can add any controls in a group, you should only add logically-related controls in a container. For example, controls in a tile should be placed in containers.

Data table control in Power Apps

Article • 04/03/2024

Shows a set of data in a tabular format.

Description

The **Data table** control shows a dataset in a format that includes column headers for each field that the control shows. As an app maker, you have full control over which fields appear and in what order. Like the **Gallery** control, the **Data table** control maintains a **Selected** property that points to the selected row. Therefore, you can link the **Data table** control to other controls.

Limitations

The data table control has these limitations:

- If you copy and paste a **Data Table** control for which the **Items** property is set to a formula that contains a **Filter** function, the formula for the **Items** property on the new **Data Table** control ends up with field names that contain a **_1** suffix. This makes the field names invalid and results in no data showing up in the data table. To work around this issue, before you copy the control, confirm that the **Filter** function doesn't reference any field in the data source that has the same name as a column in the **Data Table** control. If it does, rename the column in the **Data Table** control. Alternatively, remove the **_1** suffix from the invalid field names so that they match the names in the table.

Capabilities

Power Apps introduced the **Data table** control on May 5, 2017. This section provides information about capabilities that are supported and capabilities that aren't supported.

Now available

- Data in a **Data table** control is read-only.
- A single row is always selected in a **Data table** control.
- Link a **Data table** control to a connected or local data source.
- Adjust column widths in a **Data table** control while you run the app, though your changes aren't saved.

- A set of default fields appear in a **Data table** control when you link it to a connector that has implemented this capability, such as the Microsoft Dataverse. You can then show or hide these fields and others as necessary.
- Customize column width and heading text.
- Show hyperlinks in a **Data table** control.
- Copy and paste a **Data table** control.

Not yet available

- Customize the styling of individual columns.
- Add a **Data table** control in a form control.
- Change the height of all rows.
- Show images in a **Data table** control.
- Show fields from related tables.
- Use built-in functionality to filter and sort data by column heading.
- Add a **Data table** control in a **Gallery** control.
- Edit data in the **Data table** control.
- Select multiple rows.

Known issues

- No data appears if you use the **FirstN** function in the **Items** property.

Key properties

- Items – The source of data that appears in the **Data table** control.
- **Selected** – The selected row in the **Data table** control.

Other properties

- **AutoWidth** - The property of a column inside a data table to define if the column width should be automatic, or manual.
- BorderColor – The color of the **Data table** control's border.
- BorderStyle – The style of the **Data table** control's border. The options are **Solid**, **Dashed**, **Dotted**, and **None**.
- BorderThickness – The thickness of the **Data table** control's border.
- Color – The default text color for all data rows.
- **FieldDisplayName** - The property of a column inside a data table that defines display name for the selected column.
- Fill – The default background color for all data rows.

- Font - The default font for all data rows.
- FontWeight – The default font weight for all data rows.
- **HeadingColor** – The text color for the column headings.
- **HeadingFill** – The background color of the column headings.
- **HeadingFont** – The font of the column headings.
- **HeadingFontWeight** – The font weight of the column headings.
- **HeadingSize** – The font size of the column headings.
- Height – The distance between the **Data table** control's top and bottom edges.
- HoverColor – The text color for the row that the mouse pointer is pointing at.
- HoverFill – The background color of the row that the mouse pointer is pointing at.
- **IsHyperlink** - The property of a column inside a data table that defines whether the selected column should be in hyperlink format or not.
- **NoDataText** – The message that the user receives when there are no records to show in the **Data table** control.
- **Order** - The property of a column inside a data table that determines order of the column respective to other columns. The order starts from left to right with first column order value of 1.
- **SelectedColor** – The color of the text in the selected row.
- **SelectedFill** – The background color of the selected row.
- Size – The default font size for all data rows.
- **Text** - The property of a column inside a data table that defines text value of the data to be displayed inside the selected column.
- Visible – A value that determines whether the **Data table** control appears or is hidden.
- Width – The distance between the **Data table** control's left and right edges.
- X – The distance between the left edge of the **Data table** control and the left edge of its parent container (or the left edge of the screen if there is no parent container).
- Y – The distance between the top edge of the **Data table** control and the top edge of its parent container (or the top edge of the screen if there is no parent container).

Related functions

- Filter(DataSource, Formula)(*DataSource*, *Formula*)
- Search(DataSource, SearchString, Column)(*DataSource*, *SearchString*, *Column*)

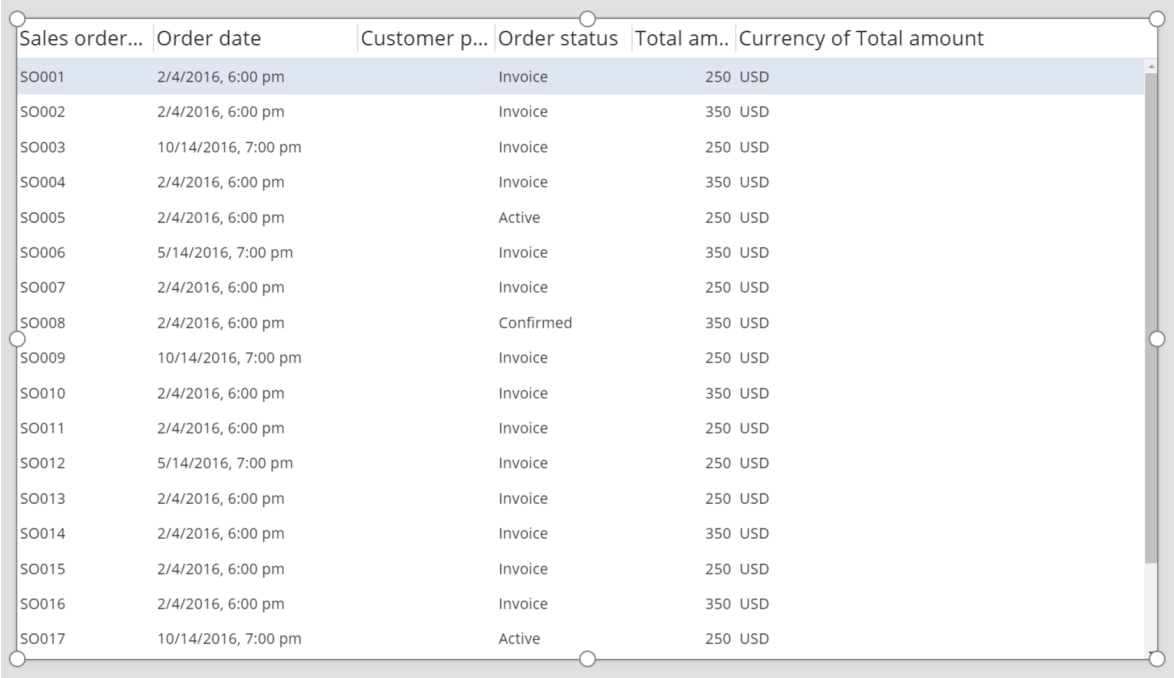
Examples

Basic usage

1. Create a blank tablet app.
2. On the **Insert** tab, click or tap **Data table**.

   
   A **Data table** control is added to the screen.
3. Rename the **Data table** control **SalesOrderTable**, and resize it so that it covers the whole screen.
4. In the right pane, select **Data sources**, and select **Sales orders**. If the table isn't listed, search for the table, and connect to Microsoft Dataverse.

   
   The **Data table** control is now attached to the **Sales order** data source. Several initial fields appear in the **Data table** control, because we're using a connector that supports that capability.



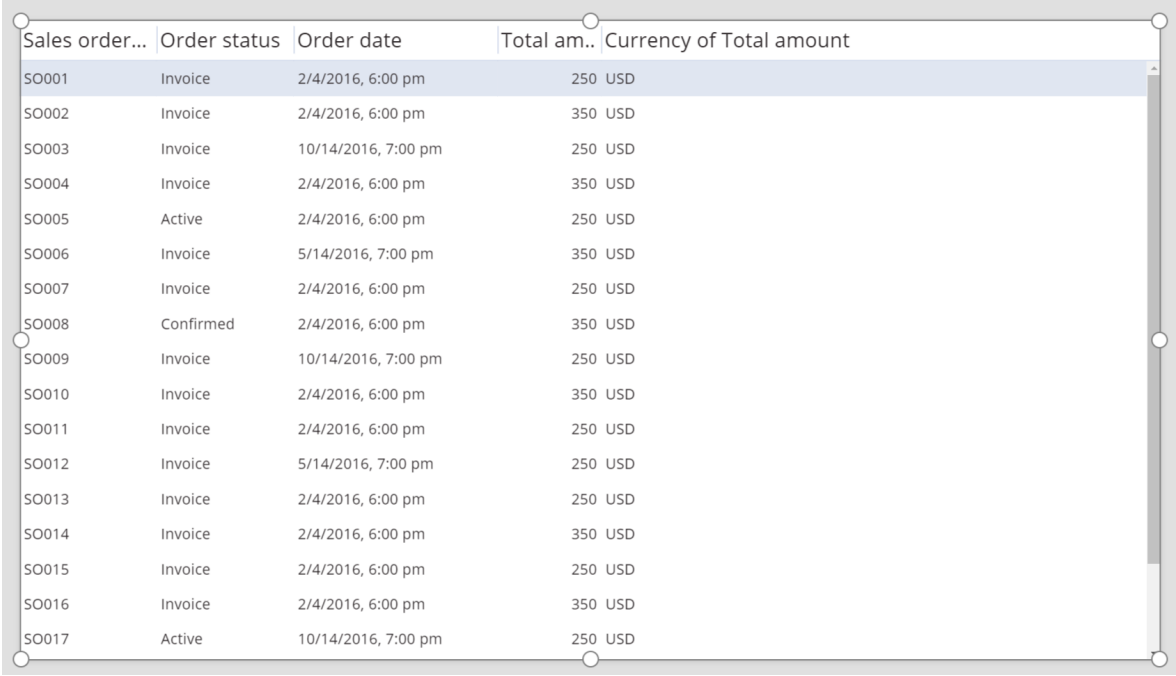
Sales order...	Order date	Customer p...	Order status	Total am..	Currency of Total amount
SO001	2/4/2016, 6:00 pm		Invoice	250	USD
SO002	2/4/2016, 6:00 pm		Invoice	350	USD
SO003	10/14/2016, 7:00 pm		Invoice	250	USD
SO004	2/4/2016, 6:00 pm		Invoice	350	USD
SO005	2/4/2016, 6:00 pm		Active	250	USD
SO006	5/14/2016, 7:00 pm		Invoice	350	USD
SO007	2/4/2016, 6:00 pm		Invoice	250	USD
SO008	2/4/2016, 6:00 pm		Confirmed	350	USD
SO009	10/14/2016, 7:00 pm		Invoice	250	USD
SO010	2/4/2016, 6:00 pm		Invoice	350	USD
SO011	2/4/2016, 6:00 pm		Invoice	250	USD
SO012	5/14/2016, 7:00 pm		Invoice	250	USD
SO013	2/4/2016, 6:00 pm		Invoice	250	USD
SO014	2/4/2016, 6:00 pm		Invoice	350	USD
SO015	2/4/2016, 6:00 pm		Invoice	250	USD
SO016	2/4/2016, 6:00 pm		Invoice	350	USD
SO017	10/14/2016, 7:00 pm		Active	250	USD

5. In the right pane, select one or more check boxes to show or hide individual fields.

   For example, select the check box next to **CustomerPurchaseOrderReference** to hide this field.

6. In the right pane, reorder the fields by dragging them up or down.

   The **SalesOrderTable** control shows the fields in the order that you specified.



Sales order...	Order status	Order date	Total am..	Currency of Total amount
SO001	Invoice	2/4/2016, 6:00 pm	250	USD
SO002	Invoice	2/4/2016, 6:00 pm	350	USD
SO003	Invoice	10/14/2016, 7:00 pm	250	USD
SO004	Invoice	2/4/2016, 6:00 pm	350	USD
SO005	Active	2/4/2016, 6:00 pm	250	USD
SO006	Invoice	5/14/2016, 7:00 pm	350	USD
SO007	Invoice	2/4/2016, 6:00 pm	250	USD
SO008	Confirmed	2/4/2016, 6:00 pm	350	USD
SO009	Invoice	10/14/2016, 7:00 pm	250	USD
SO010	Invoice	2/4/2016, 6:00 pm	350	USD
SO011	Invoice	2/4/2016, 6:00 pm	250	USD
SO012	Invoice	5/14/2016, 7:00 pm	250	USD
SO013	Invoice	2/4/2016, 6:00 pm	250	USD
SO014	Invoice	2/4/2016, 6:00 pm	350	USD
SO015	Invoice	2/4/2016, 6:00 pm	250	USD
SO016	Invoice	2/4/2016, 6:00 pm	350	USD
SO017	Active	10/14/2016, 7:00 pm	250	USD

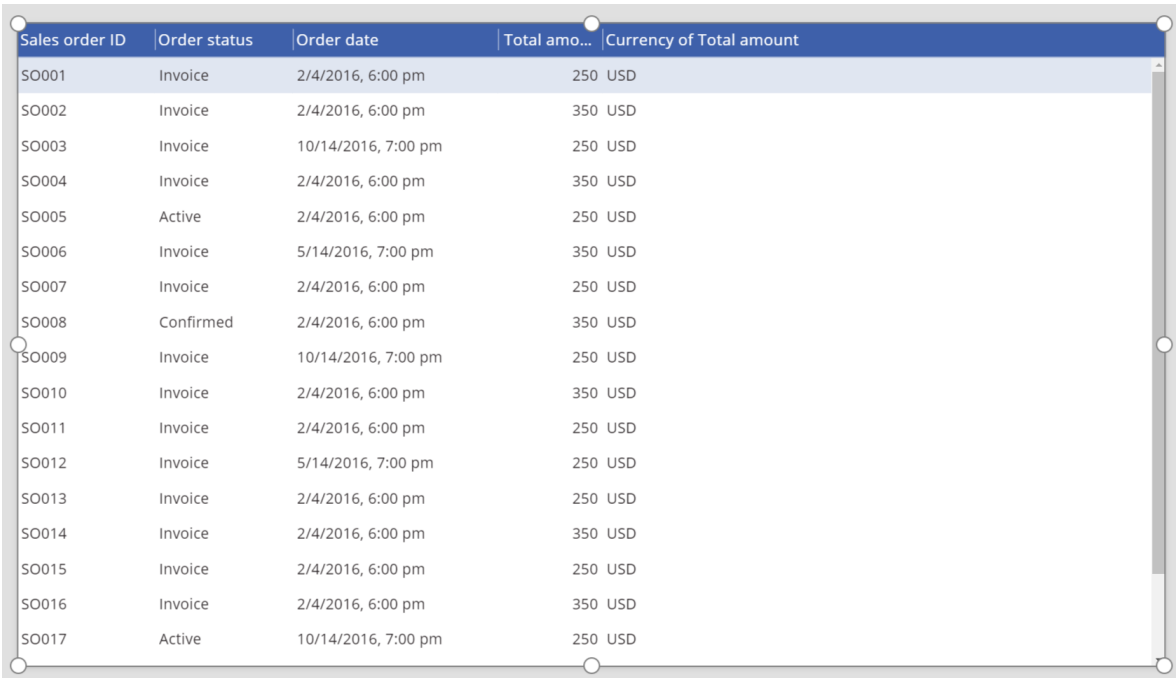
Restyle the header for the Data table control

1. While the **Data table** control is selected, in the right pane, click or tap the **Advanced** tab.

2. Click or tap the field for the **HeadingFill** property, and then change the value to **RGBA(62,96,170,1)**.

3. Click or tap the field for the **HeadingColor** property, and then change the value to **White**.

4. Click or tap the field for the **HeadingSize** property, and then change the value to **14**.

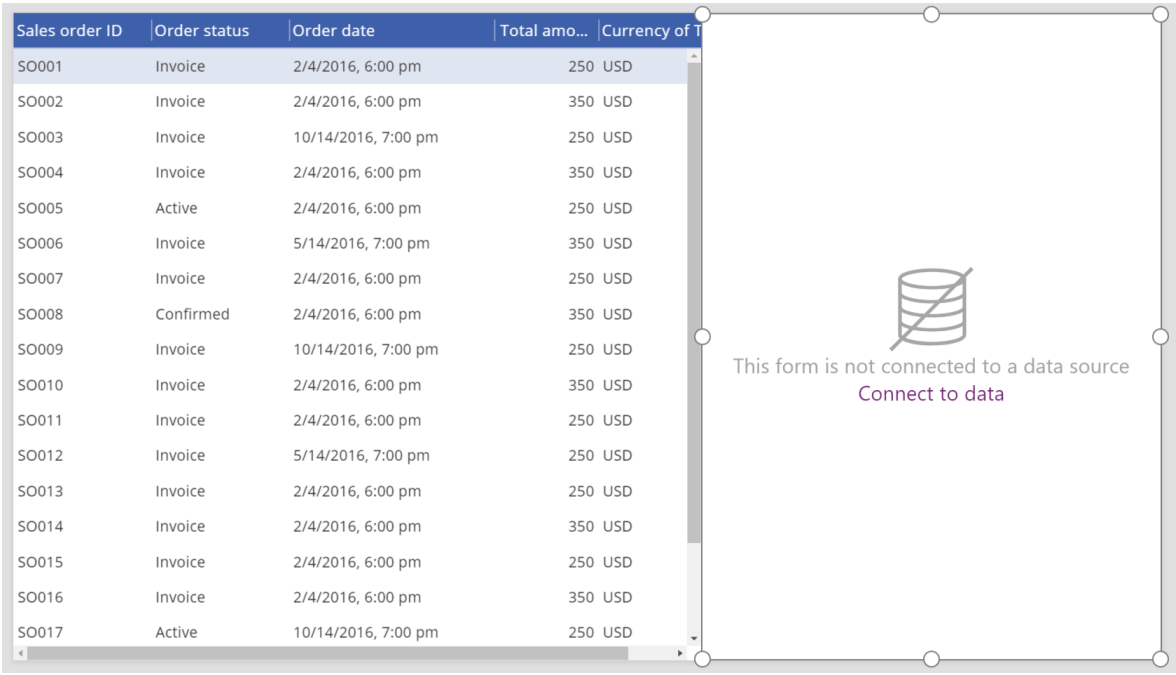


Sales order ID	Order status	Order date	Total amo...	Currency of Total amount
SO001	Invoice	2/4/2016, 6:00 pm	250	USD
SO002	Invoice	2/4/2016, 6:00 pm	350	USD
SO003	Invoice	10/14/2016, 7:00 pm	250	USD
SO004	Invoice	2/4/2016, 6:00 pm	350	USD
SO005	Active	2/4/2016, 6:00 pm	250	USD
SO006	Invoice	5/14/2016, 7:00 pm	350	USD
SO007	Invoice	2/4/2016, 6:00 pm	250	USD
SO008	Confirmed	2/4/2016, 6:00 pm	350	USD
SO009	Invoice	10/14/2016, 7:00 pm	250	USD
SO010	Invoice	2/4/2016, 6:00 pm	350	USD
SO011	Invoice	2/4/2016, 6:00 pm	250	USD
SO012	Invoice	5/14/2016, 7:00 pm	250	USD
SO013	Invoice	2/4/2016, 6:00 pm	250	USD
SO014	Invoice	2/4/2016, 6:00 pm	350	USD
SO015	Invoice	2/4/2016, 6:00 pm	250	USD
SO016	Invoice	2/4/2016, 6:00 pm	350	USD
SO017	Active	10/14/2016, 7:00 pm	250	USD

Connect a Data table control to another control

1. Add an **Edit form** control to the screen.

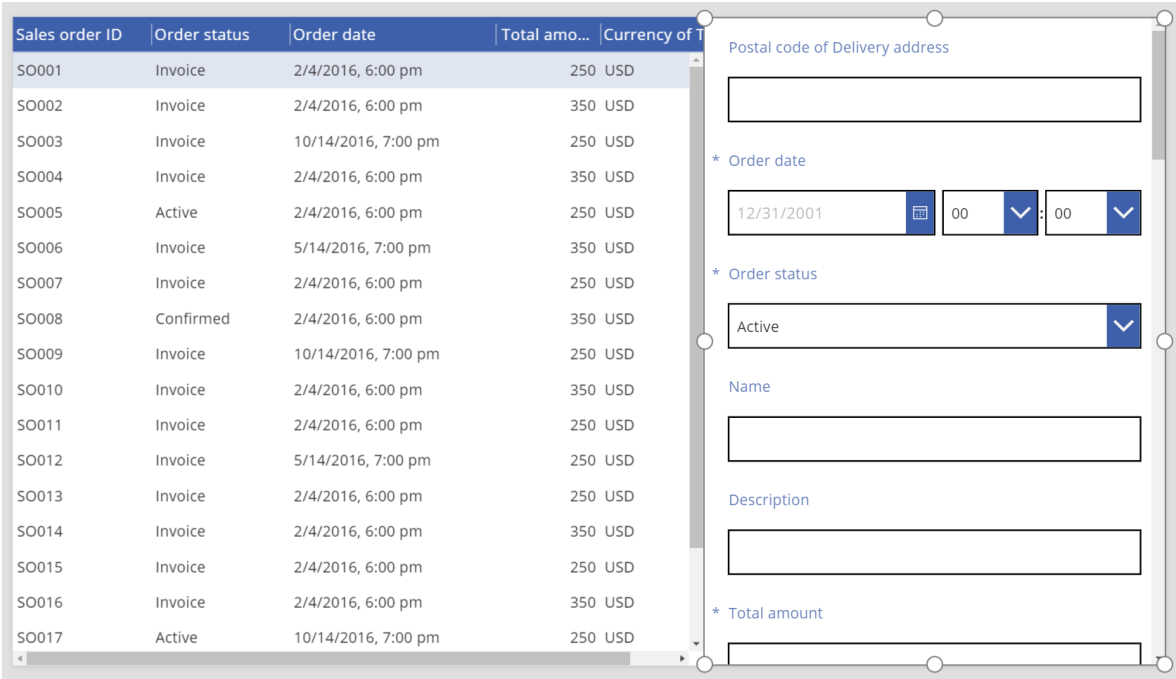
2. Resize the **Data table** and **Edit form** controls so that the **Data table** control appears in the left part of the screen and the **Edit form** control appears in the right part of the screen.



3. While **Form1** is selected, in the right pane, change the number of columns to **1**.

4. Connect **Form1** to the **Sales order** data source.

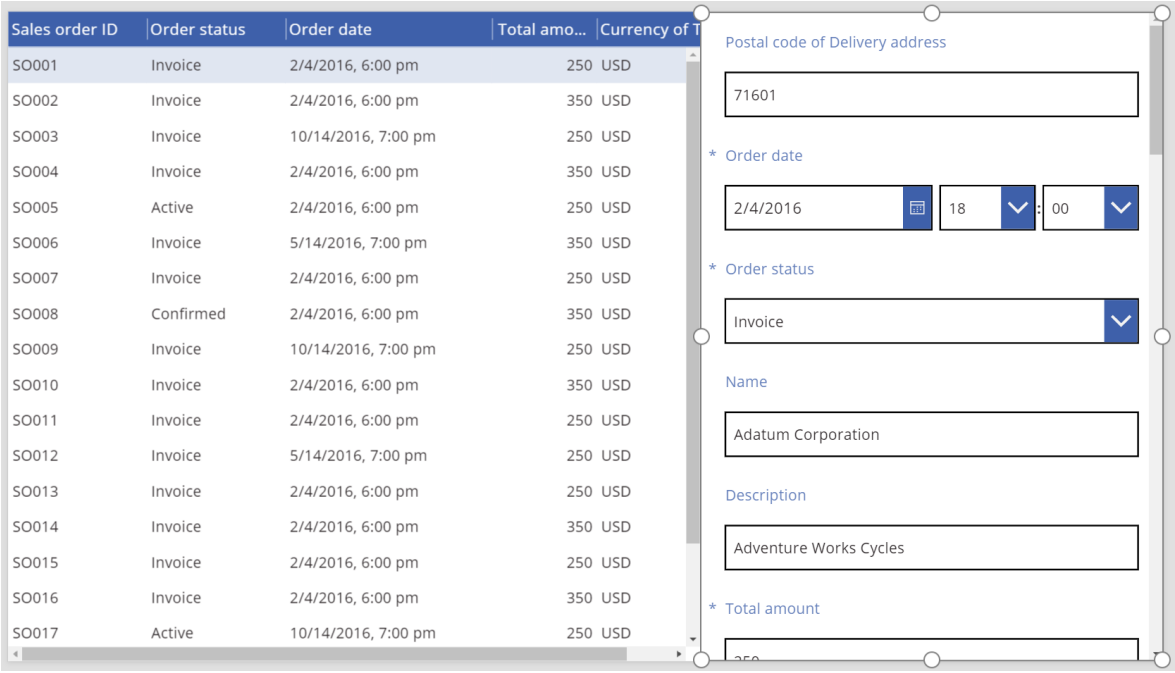
   Several initial fields appear in **Form1**.



5. In the right pane, click or tap the **Advanced** tab.

6. Set the **Item** property for **Form1** to **SalesOrderTable.Selected**.

   Form1 shows information from the row that's selected in the **Data table** control.



Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- Color and Fill
- **HeadingColor** and **HeadingFill**
- **SelectedColor** and **SelectedFill**
- HoverColor and HoverFill

This is in addition to the standard color contrast requirements.

Screen reader support

- **NoDataText** must be present.

Date Picker control in Power Apps

Article • 12/16/2022

A control that the user can select to specify a date.

Description

If you add a **Date Picker** control instead of a **Text input** control, you help ensure that the user specifies a date in the correct format.

Key properties

DefaultDate – The initial value of a date control unless the user changes it.

SelectedDate – The date currently selected in a date control. This date is represented in local time.

Format – The text format in which the control shows the date and the user specifies the date. You can set this property to **ShortDate** (default) or **LongDate** to format dates based on the **Language** property of this control. You can also set this property to an expression, such as **yyyy/mm/dd** if you want the same format regardless of language. For example:

- The control shows **12/31/2017** if the user clicks or taps the last day of 2017, the **Format** property is set to **ShortDate**, and the **Language** property is set to **en-us**.
- The control shows **dimanche 31 decembre 2017** if the user clicks or taps the last day of 2017, the **Format** property is set to **LongDate**, and the **Language** property is set to **fr-fr**.

Language – Determines the language that's used to format dates, including names of months. If this property isn't specified, the user's device setting determines the language. Supported values include "EN-us" and "FR".

Additional properties

AccessibleLabel – Label for screen readers.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DateTimeZone – Whether to display the date in **UTC** or the user's **Local** time.

DisplayMode – Whether the control allows user input (Edit), only displays data (View), or is disabled (Disabled).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

EndYear – The latest year to which the user can set value of a date-picker control.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

IconFill – The foreground color of a the date picker icon.

IconBackground – The background color of a the date picker icon.

InputTextPlaceholder – Instructional text that appears if no dates are entered.

IsEditable – Whether the Date Picker text can be edited. If false, the date can only be changed by using the calendar.

Italic – Whether the text in a control is italic.

OnSelect – Actions to perform when the user taps or clicks a control.

OnChange – Actions to perform when the user changes the value of a control.

Difference between **OnChange** and **OnSelect**: OnSelect and OnChange trigger on the same user action if the user's *click* causes the change. In this case, OnSelect triggers **before** OnChange.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

Reset - Whether the Date Picker control should be reset to the **DefaultDate** value.

Size – The font size of the text that appears on a control.

StartOfWeek – The day of the week to display in the first day column of the date-picker control.

StartYear – The earliest year to which the user can set the value of a date-picker control.

TabIndex – Keyboard navigation order in relation to other controls.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Year(*DateTimeValue*)

Examples

Basic date picker

1. Add a **Date Picker** control, and name it "Deadline".

Don't know how to add, name, and configure a control?

2. Add a **Label** control, and set its **Text** property to the following formula:

```
Power Apps
DateDiff(Today(), Deadline.SelectedDate) & " days to go!"
```

Want more information about the **DateDiff** function or other functions?

3. Press **F5**, choose a date in **Deadline**, and then select **OK**.

The **Label** control shows the number of days between today and the date that you chose.

4. To return to the default workspace, press Esc.

Reset date picker to default date

1. Add a **Date Picker** control, and name it "DateTimeReset".

Don't know how to add, name, and configure a control?

2. Add a **Button** control, and set its **OnChange** property to the following formula:

```
Power Apps
Reset(DateTimeReset)
```

3. Press **F5**, choose a new date in **DateTimeReset**, and then select **OK**.

4. Press the button. The date will reset back to the **DefaultDate** (Today).

5. To return to the default workspace, press Esc.

Accessibility guidelines

Color contrast

- Standard color contrast requirements apply.

Screen reader support

- AccessibleLabel must be present.
- If **IsEditable** is true and **Format** is not what users expect, add a Label to explain accepted date formats.

Keyboard support

- TabIndex must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use FocusedBorderColor and FocusedBorderThickness to achieve this.

> **Tip**
>
> When the calendar is open, press **Page up** and **Page down** to navigate between months and **Shift+Page up** and **Shift+Page down** to navigate between years.

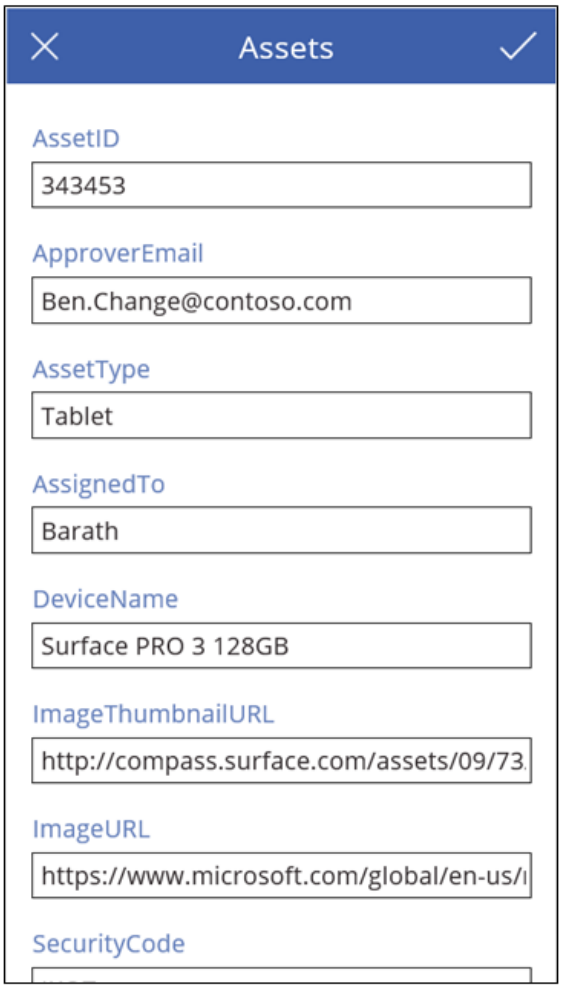
Edit form and Display form controls in Power Apps

Article • 03/26/2024

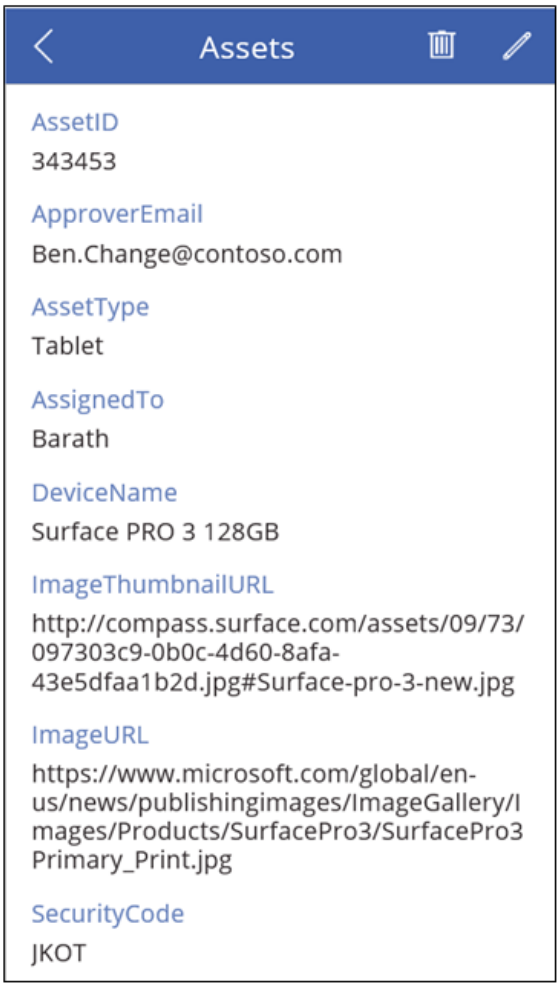
Display, edit, and create a record in a data source.

Description

If you add a **Display form** control, the user can display all fields of a record or only the fields that you specify. If you add an **Edit form** control, the user can edit those fields, create a record, and save those changes to a data source.



Edit form control
Read/Write



Display form control
Read only

If you add a **Gallery** control, you can configure it to show a table in a data source and then configure a form to show whichever record the user selects in the gallery. You can also add one or more **Button** controls that the user can select to save edits, cancel edits, and create a record. By using controls together, you can create a complete solution.

Limitations

The form control has these limitations:

- You can't copy and paste forms into data cards. This is to prevent certain combinations of controls from being created that risk the stability and performance of the app.

Record selection

For either type of form, you set its **DataSource** property to a table of records, and you set the form's **Item** property to show a specific record in that table. For example, you can set the **Item** property of a form to the **SelectedItem** property of a **Gallery** control. When the user selects a record in the gallery, the same record appears in the form, except that the form can show more fields. If the user returns to the gallery and selects a different record, the **SelectedItem** property of the gallery changes. This change updates the **Item** property of the form, which then shows the newly selected record.

You can also set a form's **Item** property by using a **Drop down** control, as Show, edit, or add a record describes, or a function such as **Lookup** or **First**. For example, you can set the **Item** property to either of these formulas to show the Fabrikam entry in the **Accounts** table in Microsoft Dataverse:

```
First(Accounts)
```

```
Lookup(Accounts, "Fabrikam" in name)
```

Each form control contains one or more **Card** controls. By setting the **DataField** property of a card, you specify which field that card shows and other details.

Create a record

When an **Edit form** control is in **Edit** mode, the user can update the record that's specified in the form's **Item** property. If inspected, the **Mode** property returns **Edit**.

When an **Edit form** control is in **New** mode, however, the **Item** property is ignored. The form doesn't show an existing record; instead, the values in each field match the default values of the data source with which you configured the form. The **NewForm** function causes a form to switch to this mode.

For example, you can set the **Text** property of a button to show **New** and its **OnSelect** property to a formula that includes the **NewForm** function. If the user selects that

button, the form switches to **New** mode so that the user can create a record starting with known values.

A form switches back to **Edit** mode if either the ResetForm function runs or the SubmitForm function runs successfully.

- You can set the Text property of a button to show **Cancel** and its OnSelect property to a formula that includes the ResetForm function. If the user selects that button, any changes in progress are discarded, and the values in the form, once again, match the default values of the data source.
- You can set the Text property of a button to show **Save changes** and its OnSelect property to a formula that includes the SubmitForm function. If the user selects that button and the data source is updated, the values in the form are reset to the default values of the data source.

Save changes

If you create a **Save changes** button as the previous section describes, the user can create or update a record and then select that button to save those changes to the data source. You could, instead, configure an Image control or some other control to perform the same task, as long as you configure that control with the SubmitForm function. In any case, the **Error**, **ErrorKind**, **OnSuccess**, and **OnFailure** properties provide feedback on the outcome.

When the SubmitForm function runs, it first validates the data that user wants to submit. If a required field doesn't contain a value or another value doesn't conform to some other constraint, the **ErrorKind** properties are set, and the **OnFailure** formula runs. You can configure the **Save changes** button or other control so that the user can select it only if the data is valid (that is, if the **Valid** property of the form is **true**). Note that the user must not only correct the problem but also select the **Save changes** button again (or discard the changes by selecting a **Cancel** button, as described earlier) to reset the **Error** and **ErrorKind** properties.

If the data passes validation, SubmitForm sends it to the data source, which can take some time depending on network latency.

- If the submission succeeds, the **Error** property is cleared, the **ErrorKind** property is set to **ErrorKind.None**, and the **OnSuccess** formula runs. If the user created a record (that is, if the form was previously in **New** mode), the form is switched to **Edit** mode so that the user can edit the newly created record or a different one.
- If the submission fails, the **Error** property contains a user-friendly error message from the data source, explaining the problem. The **ErrorKind** property is set

appropriately, depending on the issue, and the **OnFailure** formula runs.

Some data sources can detect when two people try to update the same record at the same time In this case, **ErrorKind** is set to **ErrorKind.Conflict**, and the remedy is to refresh the data source with the other user's changes and reapply the change made by this user.

> **Tip**
>
> If you offer a **Cancel** button on your form so that the user can abandon changes in progress, add the **ResetForm** function to the button's **OnSelect** property even that property also contains a **Navigate** function to change screens. Otherwise, the form will retain the user's changes.

Layout

By default, cards are placed in a single column for phone apps and three columns for tablet apps. You can specify how many columns a form has and whether cards should snap to them as you configure the form. These settings aren't exposed as properties because they're used only to set the **X**, **Y**, and **Width** properties of the cards.

For more information, see Understand data form layout.

Key properties

DataSource – The data source that contains the record that the user will show, edit, or create.

- If you don't set this property, the user can't show, edit, or create a record, and no additional metadata or validation is provided.

DefaultMode - The initial mode of the form control. See the description of **Mode** below for the acceptable values and their meanings.

DisplayMode - The mode to use for data cards and controls within the form control.

Derived from the **Mode** property based and cannot be set independently:

Expand table

Mode	DisplayMode	Description
FormMode.Edit	**DisplayMode.Edit**	Data cards and controls are editable, ready to accept changes to a record.
FormMode.New	**DisplayMode.Edit**	Data cards and controls are editable, ready to accept a new record.
FormMode.View	**DisplayMode.View**	Data cards and controls are not editable and optimized for viewing.

Error – A user friendly error message to display for this form when the SubmitForm function fails.

- This property applies only to the **Edit form** control.
- This property changes only when the SubmitForm, **EditForm**, or ResetForm function runs.
- If no error occurs, this property is *blank*, and **ErrorKind** is set to **ErrorKind.None**.
- When possible, the error message returned will be in the user's language. Some error messages come from the data source directly and may not be in the user's language.

ErrorKind – If an error occurs when **SubmitForm** runs, the kind of error that occurred.

- Applies only to an **Edit form** control.
- This property has the same enumeration as the Errors function. An **Edit form** control can return these values:

Expand table

ErrorKind	Description
ErrorKind.Conflict	Another user changed the same record, resulting in a change conflict. Execute the Refresh function to reload the record, and try the change again.
ErrorKind.None	The error is of an unknown kind.
ErrorKind.Sync	The data source reported an error. Check the **Error** property for more information.
ErrorKind.Validation	A general validation issue was detected.

Item – The record in the **DataSource** that the user will show or edit.

LastSubmit – The last successfully submitted record, including any server generated fields.

- This property applies only to the **Edit form** control.
- If the data source automatically generates or calculates any fields, such as an **ID** field with a unique number, the **LastSubmit** property will have this new value after **SubmitForm** successfully runs.
- The value of this property is available in the **OnSuccess** formula.

Mode – The control is in **Edit** or **New** mode.

Expand table

Mode	Description
FormMode.Edit	The user can edit a record by using the form. The values in the form's cards are pre-populated with the existing record, for the user to change. If the SubmitForm function runs successfully, an existing record is modified.
FormMode.New	The user can create a record by using the form. The values in the form's controls are pre-populated with the defaults for a record of the data source. If the SubmitForm function runs successfully, a record is created.
FormMode.View	The user can view a record by using the form. The values in the form's controls are pre-populated with the defaults for a record of the data source.

The form switches from **New** mode to **Edit** mode when any of these changes occurs:

- The form is successfully submitted, and a record is created. If the gallery is set to automatically move selection to this new record, the form will be in **Edit** mode for the created record so that the user can make additional changes.
- The EditForm function runs.
- The ResetForm function runs. For example, the user might select a **Cancel** button that's been configured with this function.

OnFailure – Actions to perform when a data operation has been unsuccessful.

- This property applies only to the **Edit form** control.

OnReset – Actions to perform when an **Edit form** control is reset.

- This property applies only to the **Edit form** control.

OnSuccess – Actions to perform when a data operation has been successful.

- This property applies only to the **Edit form** control.

Unsaved – True if the **Edit form** control contains user changes that have not been saved.

- This property applies only to the **Edit form** control.

- Use this property to warn the user before they lose any unsaved changes. To prevent the user from selecting a different record in a Gallery control before saving changes to the current record, set the gallery's Disabled property to **Form.Unsaved** and, likewise, disable refresh operations.

Updates – The values to write back to the data source for a record loaded in a form control.

- This property applies only to the **Edit form** control.
- Use this property to extract the field values from the cards within the control. You can then use these values to manually update the data source with a Patch function call or another method exposed by a connection. You do not need to use this property if you are using the SubmitForm function.
- This property returns a record of values. For example, if the form control contains card controls for **Name** and **Quantity** fields, and the values of the Update properties for those cards return "Widget" and 10 respectively, then the **Updates** property for the form control would return **{ Name: "Widget", Quantity: 10 }**.

Valid – Whether a Card or **Edit form** control contains valid entries, ready to be submitted to the data source.

- This property applies only to the **Edit form** control.
- A **Form** control's **Valid** property aggregates the **Valid** properties of all the Card controls in the form. A form's **Valid** property is **true** only if the data in all cards in that form is valid; otherwise, the form's **Valid** property is **false**.
- To enable a button to save changes only when the data in a form is valid but hasn't yet been submitted, set the button's **DisplayMode** property to this formula:

  SubmitButton.DisplayMode = If(IsBlank(Form.Error) || Form.Valid, DisplayMode.Edit, DisplayMode.Disabled)

Additional properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

More information

- For a comprehensive overview of how forms work, see Understand data forms.
- See the Power Fx formula reference for EditForm.

Accessibility guidelines

Screen reader support

- Consider adding a heading to the form using a **Label**.

Drop down control in Power Apps

Article • 03/13/2025

A list that shows only the first item unless the user opens it.

Description

A **Drop down** control conserves screen real estate, especially when the list contains many choices. The control takes up only one line unless the user selects the chevron to reveal more choices. The control shows a maximum of 500 items.

Key properties

Default – The initial value of a control before the user specifies a different value.

Items – The source of data that contains the items that appear in the control. If the source has multiple columns, set the control's **Value** property to the column of data that you want to show.

Value – The column of data that you want to show in the control (for example, if a data source has multiple columns).

Selected – The data record that represents the selected item.

AllowEmptySelection – Whether the control can have no selected items. When false, there will always be a selected item, which will initially be the **Default** or the first item.

Additional properties

AccessibleLabel – Label for screen readers.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

ChevronBackground – The color behind the down arrow in a dropdown list.

ChevronFill – The color of the down arrow in a dropdown list.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

OnChange – Actions to perform when the user changes the value of a control (for example, by adjusting a slider).

OnSelect – Actions to perform when the user selects a control.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedBorderColor – The color of a control's border when the user selects that control.

PressedColor – The color of text in a control when the user selects that control.

PressedFill – The background color of a control when the user selects that control.

Reset – Whether a control reverts to its default value.

SelectedText (Deprecated) – A string value that represents the selected item. Use **Dropdown1.SelectedText.Value** instead, replacing "Dropdown1" with drop-down control name in the app.

SelectionColor – The text color of a selected item or items in a list or the color of the selection tool in a pen control.

SelectionFill – The background color of a selected item or items in a list or a selected area of a pen control.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

> ⓘ **Note**
>
> Flyout border properties are controlled by **FocusedBorder** properties.

Examples

Simple list

1. Add a **Drop down** control and set its **Items** property to this expression:

   ```
   ["Seattle", "Tokyo", "London", "Johannesburg", "Rio de Janeiro"]
   ```

   Don't know how to add, name, and configure a control?

2. Show the items in the list by selecting the control's down arrow while pressing the **Alt** key.

List from a data source

The principles in this procedure apply to any data source that provides tables but, to follow these steps exactly, you must open an environment for which a Microsoft Dataverse database has been created and sample data added.

1. Open a blank app and add the **Accounts** table from Dataverse.

2. Add a **Drop down** control and set its **Items** property to this formula:

   ```
   Distinct(Accounts, 'Address 1: City')
   ```

   This formula shows all the cities in the **Accounts** table. If more than one record has the same city, the **Distinct** function hides the duplication in your drop-down control.

3. (Optional) Rename your **Drop down** control to **Cities**, add a vertical **Gallery** control, and set the gallery's **Items** property to this formula:

   ```
   Filter(Accounts, address1_city == Cities.Selected.Result)
   ```

   This **Filter** function shows only those records in the **Accounts** table for which the city matches the selected value in the **Cities** control.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **ChevronFill** and **ChevronBackground**
- **ChevronHoverFill** and **ChevronHoverBackground**
- **SelectionColor** and **SelectionFill**
- **SelectionFill** and **Fill**

This is in addition to the standard color contrast requirements.

Screen reader support

- **AccessibleLabel** must be present.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this.

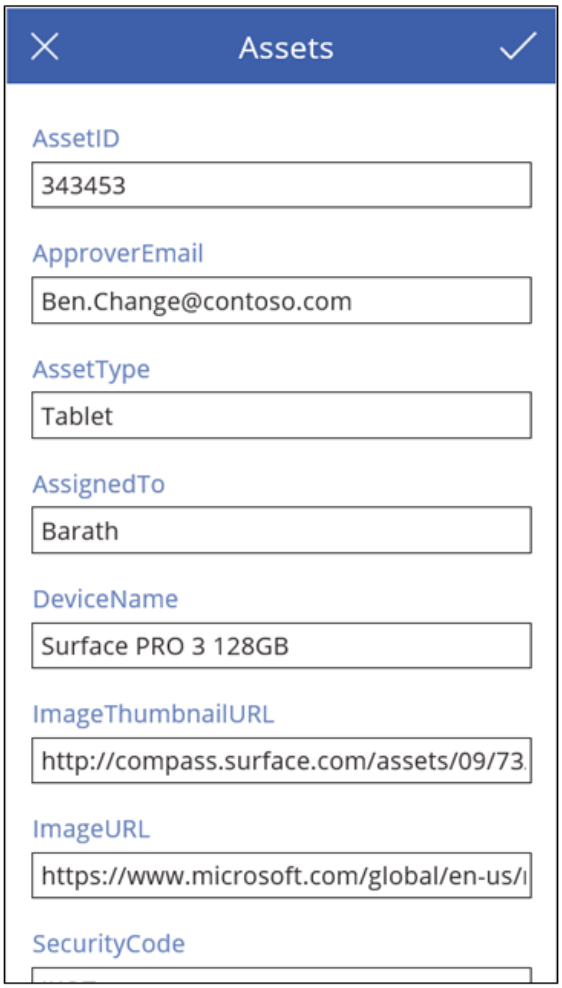
Edit form and Display form controls in Power Apps

Article • 03/26/2024

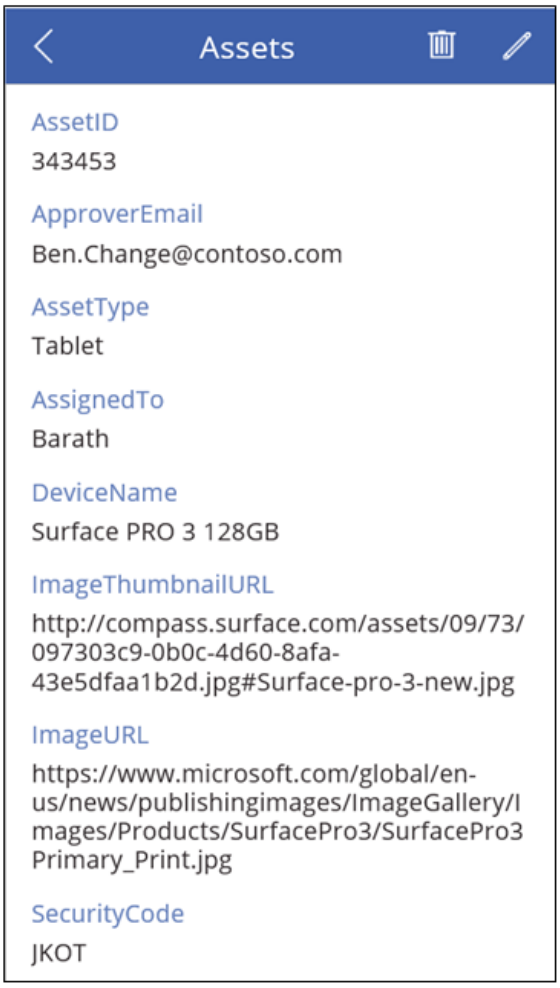
Display, edit, and create a record in a data source.

Description

If you add a **Display form** control, the user can display all fields of a record or only the fields that you specify. If you add an **Edit form** control, the user can edit those fields, create a record, and save those changes to a data source.



Edit form control
Read/Write



Display form control
Read only

If you add a **Gallery** control, you can configure it to show a table in a data source and then configure a form to show whichever record the user selects in the gallery. You can also add one or more **Button** controls that the user can select to save edits, cancel edits, and create a record. By using controls together, you can create a complete solution.

Limitations

The form control has these limitations:

- You can't copy and paste forms into data cards. This is to prevent certain combinations of controls from being created that risk the stability and performance of the app.

Record selection

For either type of form, you set its **DataSource** property to a table of records, and you set the form's **Item** property to show a specific record in that table. For example, you can set the **Item** property of a form to the **SelectedItem** property of a **Gallery** control. When the user selects a record in the gallery, the same record appears in the form, except that the form can show more fields. If the user returns to the gallery and selects a different record, the **SelectedItem** property of the gallery changes. This change updates the **Item** property of the form, which then shows the newly selected record.

You can also set a form's **Item** property by using a **Drop down** control, as Show, edit, or add a record describes, or a function such as **Lookup** or **First**. For example, you can set the **Item** property to either of these formulas to show the Fabrikam entry in the **Accounts** table in Microsoft Dataverse:

```
First(Accounts)
```

```
Lookup(Accounts, "Fabrikam" in name)
```

Each form control contains one or more **Card** controls. By setting the **DataField** property of a card, you specify which field that card shows and other details.

Create a record

When an **Edit form** control is in **Edit** mode, the user can update the record that's specified in the form's **Item** property. If inspected, the **Mode** property returns **Edit**.

When an **Edit form** control is in **New** mode, however, the **Item** property is ignored. The form doesn't show an existing record; instead, the values in each field match the default values of the data source with which you configured the form. The **NewForm** function causes a form to switch to this mode.

For example, you can set the **Text** property of a button to show **New** and its **OnSelect** property to a formula that includes the **NewForm** function. If the user selects that

button, the form switches to **New** mode so that the user can create a record starting with known values.

A form switches back to **Edit** mode if either the ResetForm function runs or the SubmitForm function runs successfully.

- You can set the Text property of a button to show **Cancel** and its OnSelect property to a formula that includes the ResetForm function. If the user selects that button, any changes in progress are discarded, and the values in the form, once again, match the default values of the data source.
- You can set the Text property of a button to show **Save changes** and its OnSelect property to a formula that includes the SubmitForm function. If the user selects that button and the data source is updated, the values in the form are reset to the default values of the data source.

Save changes

If you create a **Save changes** button as the previous section describes, the user can create or update a record and then select that button to save those changes to the data source. You could, instead, configure an Image control or some other control to perform the same task, as long as you configure that control with the SubmitForm function. In any case, the **Error**, **ErrorKind**, **OnSuccess**, and **OnFailure** properties provide feedback on the outcome.

When the SubmitForm function runs, it first validates the data that user wants to submit. If a required field doesn't contain a value or another value doesn't conform to some other constraint, the **ErrorKind** properties are set, and the **OnFailure** formula runs. You can configure the **Save changes** button or other control so that the user can select it only if the data is valid (that is, if the **Valid** property of the form is **true**). Note that the user must not only correct the problem but also select the **Save changes** button again (or discard the changes by selecting a **Cancel** button, as described earlier) to reset the **Error** and **ErrorKind** properties.

If the data passes validation, SubmitForm sends it to the data source, which can take some time depending on network latency.

- If the submission succeeds, the **Error** property is cleared, the **ErrorKind** property is set to **ErrorKind.None**, and the **OnSuccess** formula runs. If the user created a record (that is, if the form was previously in **New** mode), the form is switched to **Edit** mode so that the user can edit the newly created record or a different one.
- If the submission fails, the **Error** property contains a user-friendly error message from the data source, explaining the problem. The **ErrorKind** property is set

appropriately, depending on the issue, and the **OnFailure** formula runs.

Some data sources can detect when two people try to update the same record at the same time In this case, **ErrorKind** is set to **ErrorKind.Conflict**, and the remedy is to refresh the data source with the other user's changes and reapply the change made by this user.

> **Tip**
>
> If you offer a **Cancel** button on your form so that the user can abandon changes in progress, add the **ResetForm** function to the button's **OnSelect** property even that property also contains a **Navigate** function to change screens. Otherwise, the form will retain the user's changes.

Layout

By default, cards are placed in a single column for phone apps and three columns for tablet apps. You can specify how many columns a form has and whether cards should snap to them as you configure the form. These settings aren't exposed as properties because they're used only to set the **X**, **Y**, and **Width** properties of the cards.

For more information, see Understand data form layout.

Key properties

DataSource – The data source that contains the record that the user will show, edit, or create.

- If you don't set this property, the user can't show, edit, or create a record, and no additional metadata or validation is provided.

DefaultMode - The initial mode of the form control. See the description of **Mode** below for the acceptable values and their meanings.

DisplayMode - The mode to use for data cards and controls within the form control.

Derived from the **Mode** property based and cannot be set independently:

Expand table

Mode	DisplayMode	Description
FormMode.Edit	**DisplayMode.Edit**	Data cards and controls are editable, ready to accept changes to a record.
FormMode.New	**DisplayMode.Edit**	Data cards and controls are editable, ready to accept a new record.
FormMode.View	**DisplayMode.View**	Data cards and controls are not editable and optimized for viewing.

Error – A user friendly error message to display for this form when the SubmitForm function fails.

- This property applies only to the **Edit form** control.
- This property changes only when the SubmitForm, **EditForm**, or ResetForm function runs.
- If no error occurs, this property is *blank*, and **ErrorKind** is set to **ErrorKind.None**.
- When possible, the error message returned will be in the user's language. Some error messages come from the data source directly and may not be in the user's language.

ErrorKind – If an error occurs when **SubmitForm** runs, the kind of error that occurred.

- Applies only to an **Edit form** control.
- This property has the same enumeration as the Errors function. An **Edit form** control can return these values:

Expand table

ErrorKind	Description
ErrorKind.Conflict	Another user changed the same record, resulting in a change conflict. Execute the Refresh function to reload the record, and try the change again.
ErrorKind.None	The error is of an unknown kind.
ErrorKind.Sync	The data source reported an error. Check the **Error** property for more information.
ErrorKind.Validation	A general validation issue was detected.

Item – The record in the **DataSource** that the user will show or edit.

LastSubmit – The last successfully submitted record, including any server generated fields.

- This property applies only to the **Edit form** control.
- If the data source automatically generates or calculates any fields, such as an **ID** field with a unique number, the **LastSubmit** property will have this new value after **SubmitForm** successfully runs.
- The value of this property is available in the **OnSuccess** formula.

Mode – The control is in **Edit** or **New** mode.

Expand table

Mode	Description
FormMode.Edit	The user can edit a record by using the form. The values in the form's cards are pre-populated with the existing record, for the user to change. If the SubmitForm function runs successfully, an existing record is modified.
FormMode.New	The user can create a record by using the form. The values in the form's controls are pre-populated with the defaults for a record of the data source. If the SubmitForm function runs successfully, a record is created.
FormMode.View	The user can view a record by using the form. The values in the form's controls are pre-populated with the defaults for a record of the data source.

The form switches from **New** mode to **Edit** mode when any of these changes occurs:

- The form is successfully submitted, and a record is created. If the gallery is set to automatically move selection to this new record, the form will be in **Edit** mode for the created record so that the user can make additional changes.
- The EditForm function runs.
- The ResetForm function runs. For example, the user might select a **Cancel** button that's been configured with this function.

OnFailure – Actions to perform when a data operation has been unsuccessful.

- This property applies only to the **Edit form** control.

OnReset – Actions to perform when an **Edit form** control is reset.

- This property applies only to the **Edit form** control.

OnSuccess – Actions to perform when a data operation has been successful.

- This property applies only to the **Edit form** control.

Unsaved – True if the **Edit form** control contains user changes that have not been saved.

- This property applies only to the **Edit form** control.

- Use this property to warn the user before they lose any unsaved changes. To prevent the user from selecting a different record in a Gallery control before saving changes to the current record, set the gallery's Disabled property to **Form.Unsaved** and, likewise, disable refresh operations.

Updates – The values to write back to the data source for a record loaded in a form control.

- This property applies only to the **Edit form** control.
- Use this property to extract the field values from the cards within the control. You can then use these values to manually update the data source with a Patch function call or another method exposed by a connection. You do not need to use this property if you are using the SubmitForm function.
- This property returns a record of values. For example, if the form control contains card controls for **Name** and **Quantity** fields, and the values of the Update properties for those cards return "Widget" and 10 respectively, then the **Updates** property for the form control would return **{ Name: "Widget", Quantity: 10 }**.

Valid – Whether a Card or **Edit form** control contains valid entries, ready to be submitted to the data source.

- This property applies only to the **Edit form** control.
- A **Form** control's **Valid** property aggregates the **Valid** properties of all the Card controls in the form. A form's **Valid** property is **true** only if the data in all cards in that form is valid; otherwise, the form's **Valid** property is **false**.
- To enable a button to save changes only when the data in a form is valid but hasn't yet been submitted, set the button's **DisplayMode** property to this formula:

  SubmitButton.DisplayMode = If(IsBlank(Form.Error) || Form.Valid, DisplayMode.Edit, DisplayMode.Disabled)

Additional properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

- Consider adding a heading to the form using a **Label**.

Export and Import controls in Power Apps

Article • 12/16/2022

Controls for exporting data to a local file and then importing that data into another app in Power Apps.

Description

If you want to create more than one app that uses the same data but not share that data outside those apps, you can export it and import it by using an **Export** control and an **Import** control. When you export data, you create a compressed file that you can copy to another machine, but you can't read it in any program other than Power Apps.

Warning

Enabling this functionality in your app may expose it to security vulnerabilities and data leakage. It is recommended to advise users to import only recognized and trusted files and only export data that is not confidential or sensitive.

Limitations

The export functionality isn't supported in web browsers.

Key properties

Data – The name of a collection that you want to export to a local file.

- The **Data** property is available for an **Export** control but not an **Import** control.

OnSelect – Actions to perform when the user taps or clicks a control.

Additional properties

Align – The location of text in relation to the horizontal center of its control.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

Padding – The distance between the text on an import or export button and the edges of that button.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

RadiusBottomLeft – The degree to which the bottom-left corner of a control is rounded.

RadiusBottomRight – The degree to which the bottom-right corner of a control is rounded.

RadiusTopLeft – The degree to which the top-left corner of a control is rounded.

RadiusTopRight – The degree to which the top-right corner of a control is rounded.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Text – Text that appears on a control or that the user types into a control.

Underline – Whether a line appears under the text that appears on a control.

VerticalAlign – The location of text on a control in relation to the vertical center of that control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Example

1. Add a **Button** control, and set its **OnSelect** property to this formula:

   ```
   ClearCollect(Products, {Name:"Europa", Price:"10.99"},
   {Name:"Ganymede", Price:"12.49"}, {Name:"Callisto", Price:"11.79"})
   ```

   For more details, read adding, naming, and configuring a control, **ClearCollect** and other functions.
2. Press F5 and select **Button** control, and then press Esc.
3. Add an **Export** control, and set its **Data** property to **Products**.

4. Press F5 and select the **Export** control to download the file *Data.zip*.
5. Select **Save**, then press Esc to return to the default workspace.
6. In a new or existing app, add an **Import** control, name it **MyData**, and set its OnSelect property to this formula:
   Collect(ImportedProducts, MyData.Data)
7. Press F5 and select **MyData**, then select the file that you exported, and then select **Open**.
8. Press Esc and select **Collections** on the **File** menu, and confirm that the current app has the data that you exported.

Accessibility guidelines

The same guidelines for Button apply because **Export** and **Import** are just specialized buttons.

Gallery control in Power Apps

09/15/2025

A control that contains other controls and shows a set of data.

Description

A **Gallery** control can show multiple records from a data source, and each record can contain multiple types of data. For example, use a **Gallery** control to show multiple contacts with each item showing contact information that includes a name, an address, and a phone number for each contact.

Each data field appears in a separate control within the **Gallery** control. And you can configure those controls in its template. The template appears as the first item inside the gallery:

- On the left edge of a **Gallery** control in horizontal/landscape orientation.
- And at the top of a **Gallery** control in vertical/portrait orientation.

Any changes that you make in the template are reflected throughout the **Gallery** control.

Predefined templates for showing images and text in a gallery are available, and a gallery for variable-height items.

Limitations

The gallery control has these limitations:

1. If a user scrolls the **Flexible height** gallery control before all items are loaded, the item that's currently in view may be pushed down and out of view when the data loading is finished. To avoid this issue, use a standard **Gallery** control instead of the **Flexible height** variant.
2. The following controls are not supported within a gallery:

    - Display form
    - Edit form
    - PDF viewer
    - Power BI tile
    - Rich text editor
    - Scrollable screen (Fluid grid)
    - Web barcode scanner

3. You cannot add a gallery inside another gallery if the latter is already inside another gallery. The maximum level of nesting is 2.
4. The minimum **TemplateSize** is one. This can cause controls in the **Gallery** to drift from their expected **X** or **Y** values, when you don't account for the template size.
5. If you generate an app automatically from data, save the app, and then reopen it, the browse gallery might not immediately show any data. To resolve this issue, type at least one character in the search box, and then delete the text that you typed. The gallery will then show the data as expected.
6. If a gallery includes a ComboBox, DatePicker, Slider, or Toggle control with an `OnChange` rule that patches the same data source or collection as the gallery, it may lead to unexpected or reduced performance. This is because an `OnChange` rule that patches the data source of the gallery can create a never-ending cycle of patching and reloading. To avoid this issue, it is advisable not to use `OnChange` rules when these controls are placed within a gallery.

Key properties

Default – The item or record from the data source to be selected in the gallery when the app starts up.

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

Selected – The selected item.

Additional properties

AccessibleLabel – Label of the gallery (not the items it contains) for screen readers. Should describe what the list of items are.

AllItems – Items that are loaded in the gallery. This may be less than the actual number of **Items** of the data source. More items may be loaded when the gallery is scrolled. **AllItems** also contains controls that are used in each gallery item.

AllItemsCount - Count of items that are loaded in the gallery. This may be less than the actual number of **Items** of the data source. More items may be loaded when the gallery is scrolled.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DelayItemLoading - Delay loading of items (rows) until after the screen first loads.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

ItemAccessibleLabel – Label of each gallery item for screen readers. Should describe what each item is.

LoadingSpinner (**None**, **Controls** or **Data**) - When None, spinner will not be shown. When Controls | Data, spinner will be shown when a render pass occurs that results in visible empty rows.

LoadingSpinnerColor - The fill color of the loading spinner. Default is set to BorderColor.

NavigationStep – How far a gallery scrolls if its **ShowNavigation** property is set to **true** and the user selects a navigation arrow at either end of that gallery.

Selectable – Whether gallery items can be selected. When set to **true**, screen readers identify the gallery as a selectable list. And you select an item by selecting it. When set to **false**, screen readers identify the gallery as a regular list, and selecting an item doesn't select it.

ShowNavigation – Whether an arrow appears at each end of a gallery so that a user can scroll through the items in the gallery by selecting an arrow.

ShowScrollbar – Whether a scrollbar appears when the user hovers over a gallery.

TemplateFill – The background color of a gallery.

TemplatePadding – The distance between items in a gallery.

TemplateSize – The height of the template for a gallery in vertical/portrait orientation. Or the width of the template for a gallery in horizontal/landscape orientation. The minimum size is one.

Transition – The visual effect (**Pop**, **Push**, or **None**) when the user hovers over an item in a gallery.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

WrapCount – Number of items shown per row or column based on horizontal or vertical layout.

X – The distance between the left edge of a control and the left edge of its parent container or screen.

Y – The distance between the top edge of a control and the top edge of the parent container or screen.

Related functions

Filter(*DataSource*, *Formula*)

Reset(*Control*) - Resets your gallery back to its initial state. Initial state includes scrolling to the first item and selecting the first item or default if present.

> ⓘ **Note**
>
> **Reset** control does not recursively reset all the children of the gallery.

Examples

Show and filter data

- Show text
- Show images
- Filter data by selecting a list option
- Filter data by adjusting a slider

Get data from the user

- Get text
- Get images
- Get photos
- Get sounds
- Get drawings

Accessibility guidelines

Color contrast

If clicking anywhere in a gallery item is meant to select it, there must be adequate color contrast between:

- BorderColor and the color outside the gallery (if there is a border).
- Fill and the color outside the gallery (if there's no border).

Screen reader support

- AccessibleLabel must be present.

  > ⓘ Note
  >
  > Screen readers will announce when items in the gallery change. The **AccessibleLabel** is also mentioned. This gives context to the announcement and is even more important when there are multiple galleries on the same screen.

- When a gallery item contains multiple controls, use **ItemAccessibleLabel** to show the contents of gallery items.
- Set the value of **Selectable** to **true** if you want users to select a gallery item. Otherwise, set that value to **false**.
- When a gallery item contains multiple controls, use **ItemAccessibleLabel** to provide a summary of the gallery item's contents.
- **Selectable** should be set appropriately, depending on whether users are meant to select a gallery item.

Keyboard support

- Consider setting **ShowScrollbar** to **true**. On most touch screen devices, the scrollbar won't show until scrolling begins.
- If clicking anywhere in a gallery item is meant to select it, there must also be way for keyboard users to select the gallery item. For example, adding a Button that has its **OnSelect** property set to **Select(Parent)**.

  > ⓘ Note

Controls outside the gallery are not considered in the keyboard navigation order within the gallery. **TabIndex** controls inside a gallery are scoped. See **accessibility properties** to learn more.

Use DelayItemLoading and Loading spinner to improve performance in Gallery

Grid container control in Power Apps (preview)

[This article is a pre-release document and is subject to change.]

The **Grid container** control gives you a way to **layout child components in a grid pattern**. You get precise control over where each component goes in terms of rows and columns.

This container works like CSS-style grids. You define the **rows and columns** and set the exact position for each child component using its properties.

> **Important**
>
> - This feature is in preview.
> - Preview features aren't meant for production use and might have restricted functionality These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is in the process of rolling out and might not be available in your region yet.

Description

The **Grid container** control offers a flexible layout system for canvas apps. It enables you to:

- Place child components in a **grid pattern**
- Specify the **row and column start and end** for each child
- Make responsive adjustments when the container or screen size changes
- Control alignment, spacing, and overflow within the grid

By using this approach, you don't need to manually position each component. Your apps become **more maintainable and responsive**.

Display properties

- **Gap** – The spacing in pixels between child components inside the grid.
- **Columns** – The number of columns in the grid layout.
- **Rows** – The number of rows in the grid layout.

Size and position

- **X** – The horizontal distance from the left edge of the parent container (or screen if no parent).
- **Y** – The vertical distance from the top edge of the parent container (or screen if no parent).
- **Width** – The distance between a control's left and right edges.
- **Height** – The distance between a control's top and bottom edges.
- **Padding** - The spacing between the container edges and its child components.

Color and border

- **Color** – Foreground color of the container, used for borders and text if applicable.
- **Border**
  - **Style** – Type of border: Solid, Dashed, Dotted, or None.
  - **Thickness** – Width of the border in pixels.
  - **Color** – Color of the border.
- **Border radius** – The degree to which the corners of the container are rounded. You can apply this setting to all corners uniformly or split it into individual corners in advanced settings.
- **Drop shadow** – Shadow effect applied to the container. Options: None, Light, Medium, or Heavy.

Visibility

- **Visible** – Whether the grid container is displayed. Toggle **On** or **Off**.

Grid layout properties (child-specific)

- **Column Start / Column End** – Defines the starting and ending columns for a child component.
- **Row Start / Row End** – Defines the starting and ending rows for a child component.

Example

1. Create a blank canvas app from scratch with a **Responsive** layout.
2. Create a new screen.
3. From the **Insert** pane under **Layout**, select **Grid container**.

4. Set container properties to occupy the full screen:

    - X = 0
    - Y = 0
    - Width = Parent.Width
    - Height = Parent.Height

5. Add several child components, such as buttons, text inputs, icons, and media. For each child, set grid placement properties:

    - Column Start / End
    - Row Start / End
    - Align in Cell

6. Press **F5** to preview. Resize the screen and observe how child components **remain in their grid positions** and adjust responsively.

Last updated on 12/18/2025

Horizontal container control in Power Apps

Article • 03/23/2023

Horizontal container control determines the position of the child components so that you never have to set X, Y for a component inside the container.

Description

Horizontal container control distributes the available space to its child components based on the settings, as well as determines alignment of the child components.

Properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color - The color of the container control.

Drop shadow - Adds shadow effects around the control.

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

Direction - Defines in what direction the container layouts its child components. **Horizontal** and **Vertical**.

Justify (vertical) - Defines how child elements are aligned with the primary axis. **Start**, **End**, **Center**, **Space Between**.

Align (Horizontal) - Defines how child components are positioned in the container, in the off axis (opposite from `LayoutDirection`). **Start**, **Center**, **End**, **Stretch**.

Gap - Defines the space between containers child components in pixels.

Horizontal Overflow - Defines whether the container shows scrollbars or remove content when it is too large to fit. **Scroll** and **Hide**.

RadiusBottomLeft – The degree to which the bottom-left corner of a control is rounded.

RadiusBottomRight – The degree to which the bottom-right corner of a control is rounded.

RadiusTopLeft – The degree to which the top-left corner of a control is rounded.

RadiusTopRight – The degree to which the top-right corner of a control is rounded.

Vertical Overflow - Defines whether the container shows scrollbars or remove content when it is too large to fit. **Scroll** and **Hide**.

Wrap - Defines whether the content wraps to a new row or column when it cannot fit.

Align in container - Defines how the individual component is aligned to the parent. The default value, **Set by container**, inherits the value from the parent's `LayoutAlignItems` property, while other properties can be used to customize the alignment for the individual child component. **Set by container**, **Start**, **End**, **Center**, and **Stretch**.

Fill portions - Defines how the individual component grows when there is more screen real-estate assigned to its parent. The number represents the portion of the extra space given to the component out of all the available extra space claimed by children of its parent. For example, if child A has `Fill portions` set to 1 and child B has `Fill portions` set to 2, child A gets 1/3 of the extra space available while child B gets 2/3 of the extra available space.

Minimum width - Represent the minimum size of the component in the direction of the `Fill portions` (that is, the parent's `Direction`).

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

Visible – Whether a control appears or is hidden.

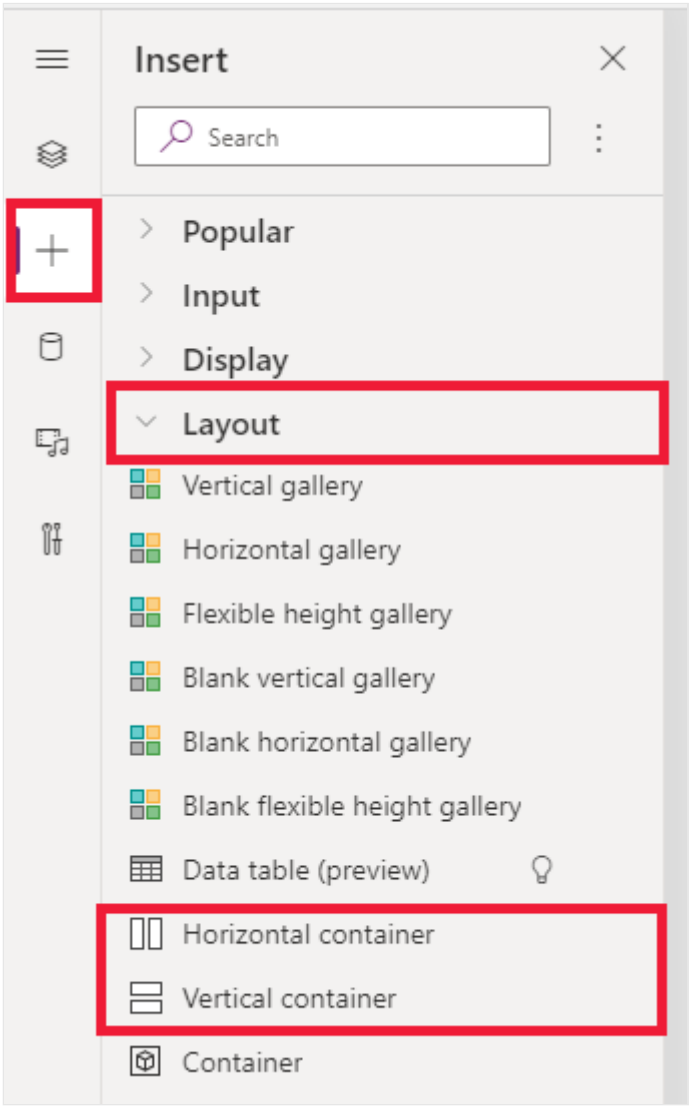
Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Example

1. Create a blank canvas app with **Tablet** layout.
2. Select **File** > **Settings** > **Screen size + orientation** and disable **Scale to fit**, **Lock aspect ratio**, and **Lock orientation** and select **Apply**.
3. Now from the **Insert** panes in the left sidebar, under **Layout** tab, select **Horizontal container**.



4. Set the following properties to occupy the full available space of the screen:
   a. X = 0
   b. Y= 0
   c. Width = Parent.Width
   d. Height = Parent. Height
5. Add few buttons, text inputs, media, icons, and select **F5** to see how the app adjusts to the screen changes.

HTML text control in Power Apps

Article • 05/22/2025

A box that shows text and converts HTML tags to formatting.

Description

An **HTML text** control not only shows plain text and numbers but also converts HTML tags, such as non-breaking spaces.

> **Note**
>
> HTML text control assumes the HtmlText is relatively positioned. If you need to use an absolute position for your HTML text, wrap the text around a relatively positioned div. For example, `"<div style='position:relative'>" & varPageContent & "</div>"`

> **Note**
>
> For some HTML elements default browser styling might be deleted. For instance, for HTML list (`<ul>`, `<ol>`) you will need to write your own inline styles to get the default styling back. For example,

HTML

```
<ul style='display: block;
           list-style-type: disc;
           margin-block-start: 1em;
           margin-block-end: 1em;
           margin-inline-start: 0px;
           margin-inline-end: 0px;
           padding-inline-start: 40px;'>
  ...
</ul>
```

Key properties

Color – The color of text in a control.

Font – The name of the family of fonts in which text appears.

HtmlText – Text that appears in an HTML text control and that may contain HTML tags.

Additional properties

AutoHeight – Set to true to allow the control to auto-grow its height to show all text. Set to false to truncate the text to the height assigned.

> ⓘ Note
>
> Enabling the **AutoHeight** property will grow the **Height** property of the control to a maximum value of 7680.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

OnSelect – Actions to do when the user selects a control.

> ⓘ Note
>
> **OnSelect** is ignored for hyperlinks within the content referenced inside **HtmlText** property.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

Size – The font size of the text that appears on a control.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Find(*FindString*, *WithinString*)

Example

1. Add a **Label** control, name it **Source**, and set its **Text** property to this string:

   "<p>We've done an unusually "deep" globalization and localization. <p>"

   Don't know how to add, name, and configure a control?

2. Add an **HTML text** control, and set its **HtmlText** property to this value:
   Source.Text

   The **HTML text** control shows the same text as the **Label** control but converts the tags to the appropriate characters.

Accessibility guidelines

ARIA mapping for elements inside the **HTML text** control are not defined automatically by Power Apps.

Color contrast

There must be adequate color contrast between:

- **Color** and **Fill**

- Text with custom colors and its background

Keyboard support

- The control can't act as a button. It doesn't have **TabIndex** and keyboard users won't be able to focus on it.
- The control can contain interactive parts in **HtmlText** like `<a>` elements, but the app setting **Simplified tab indexes" must be enabled. Otherwise, the tab navigation order will be wrong.

Shape and Icon controls in Power Apps

Article • 12/16/2022

Graphics for which you can configure appearance and behavior properties.

Description

These controls include arrows, geometric shapes, action icons, and symbols for which you can configure properties such as fill, size, and location. You can also configure their OnSelect property so that the app responds if the user selects the control.

Key properties (icons and shapes)

Fill – The background color of a control.

OnSelect – Actions to perform when the user selects a control.

Key properties (icons only)

Icon - The type of icon to display (for example, **ArrowDown** or **ShoppingCart**).

Rotation - The number of degrees to rotate the icon.

Color - The color of the icon by name or RGBA values.

Additional properties

AccessibleLabel – Label for screen readers.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

PressedBorderColor – The color of a control's border when the user selects that control.

PressedFill – The background color of a control when the user selects that control.

TabIndex – Keyboard-navigation order in relation to other controls.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Navigate(*ScreenName*, *ScreenTransition*)

Example

1. Name the default **Screen** control **Target**, add a **Label** control, and set its **Text** property to show **Target**.

   Don't know how to add and configure a control?

2. Add a **Screen** control, and name it **Source**.

3. In **Source**, add a **Shape** control, and set its **OnSelect** property to this formula:

```
Navigate(Target, ScreenTransition.Fade)
```

1. Press F5, and then select the **Shape** control.

   The **Target** screen appears.

2. (optional) Press Esc to return to the default workspace, add a **Shape** control to **Target**, and set the **OnSelect** property of the **Shape** control to this formula:

```
Navigate(Source, ScreenTransition.Fade)
```

Accessibility guidelines

Color contrast

The following applies only to graphics that are used as buttons or are otherwise not just for decoration.

For icons:

- **Color** and **Fill**
- Other standard color contrast requirements apply (if used as a button)

For shapes with borders:

- **BorderColor** and the color outside the control
- **FocusedBorderColor** and the color outside the control (if used as a button)

For shapes without borders:

- **Fill** and the color outside the control
- **PressedFill** and the color outside the control (if used as a button)
- **HoverFill** and the color outside the control (if used as a button)

Screen-reader support

- **AccessibleLabel** must be set for important graphics.
- If the graphic is for decoration or provides redundant information, leave **AccessibleLabel** empty or set it to the empty string "" . Screen readers will ignore these graphics.

For example, you might place a **Lock** icon next to a **Label** that says **This form cannot be modified**. You don't need an **AccessibleLabel** for the icon because the **Label** already explains its meaning.

> **Important**
>
> When **TabIndex** is zero or greater, the icon or shape becomes a button. Its appearance doesn't change, but screen readers will treat it as a button. They will not ignore the control, even if **AccessibleLabel** is empty. When **TabIndex** is less than zero, screen readers treat the icon or shape as an image.

Keyboard support

- **TabIndex** must be zero or greater if the graphic is used as a button. Keyboard users can then navigate to it.
- Focus indicators must be clearly visible if the graphic is used as a button. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this result.

Image control in Power Apps

Article • 01/19/2023

A control that shows an image from, for example, a local file or a data source.

Description

If you add one or more **Image** controls to your app, you can show individual images that aren't part of a data set, or you can incorporate images from records in data sources.

Key properties

Image – The name or the URL of the image that appears in an image, audio, or microphone control.

> **Note**
>
> - Use HTTPS for all external images to ensure compatibility with modern browsers.
> - External images must be accessible anonymously (without any authentication).

Additional properties

AccessibleLabel – Label for screen readers.

ApplyEXIFOrientation – Whether to automatically apply the orientation specified in the EXIF data embedded with the image.

AutoDisableOnSelect – Automatically disables the control while the OnSelect behavior is executing.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

CalculateOriginalDimensions – Enables the **OriginalHeight** and **OriginalWidth** properties.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FlipHorizontal – Whether to flip the image horizontally before displaying it.

FlipVertical – Whether to flip the image vertically before displaying it.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

ImagePosition – The position (**Fill**, **Fit**, **Stretch**, **Tile**, or **Center**) of an image in a screen or a control if it isn't the same size as the image.

ImageRotation – How to rotate the image before displaying it. Values can be none, clockwise (CW) 90 degrees, counter-clockwise (CCW) 90 degrees and clockwise 180 degrees.

OnSelect – Actions to perform when the user taps or clicks a control.

OriginalHeight – Original height of an image, enabled with the **CalculateOriginalDimensions** property.

OriginalWidth – Original width of an image, enabled with the **CalculateOriginalDimensions** property.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

RadiusBottomLeft – The degree to which the bottom-left corner of a control is rounded.

RadiusBottomRight – The degree to which the bottom-right corner of a control is rounded.

RadiusTopLeft – The degree to which the top-left corner of a control is rounded.

RadiusTopRight – The degree to which the top-right corner of a control is rounded.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Transparency – The degree to which controls behind an image remain visible. Decimal values range from 0 to 1. Where 0 is opaque, 0.5 is semi-transparent and 1 is transparent.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Remove(*DataSource*, ThisItem)

Examples

Show an image from a local file

1. On the **File** menu, click or tap **Media**, and then click or tap **Browse**.
2. Click or tap the image file that you want to add, click or tap **Open**, and then press Esc to return to the default workspace.
3. Add an **Image** control, and set its **Image** property to the name of the file that you added.

   Don't know how to add and configure a control?

   The **Image** control shows the image that you specified.

Show a set of images from a data source

1. Download this Excel file, and save it on your local device.
2. In Power Apps Studio, create or open an app, and then click or tap **Add data source** in the right-hand pane.

   If **Add data source** doesn't appear in the right-hand pane, click or tap a screen in the left navigation bar.
3. Click or tap **Add static data to your app**, click or tap the Excel file that you downloaded, and then click or tap **Open**.
4. Select the **Flooring Estimates** check box, and then click or tap **Connect**.
5. Add a **Gallery** control with images, and set its **Items** property to **FlooringEstimates**.

   Don't know how to add and configure a control?

   The **Gallery** control shows images of carpet, hardwood, and tile products based on links in the Excel file that you downloaded.

Accessibility guidelines

Color contrast

- Standard color contrast requirements apply, if the graphic is used as a button.
- Consider checking for contrast issues within the image, if it is not purely decorative.

Screen reader support

- AccessibleLabel must be set for important graphics.
- If the graphic is for decoration or provides redundant information, leave AccessibleLabel empty or set it to the empty string "" . Screen readers will ignore these graphics.

For example, you might place an **Image** of a padlock next to a Label that says **This form cannot be modified**. You don't need an AccessibleLabel for the image because the **Label** already explains its meaning.

> ⓘ **Important**
>
> When TabIndex is zero or greater, the **Image** becomes a button. Its appearance doesn't change, but screen readers will treat it as a button. They will not ignore the control, even if **AccessibleLabel** is empty.

Keyboard support

- TabIndex must be zero or greater, if the graphic is used as a button. Keyboard users can then navigate to it.
- Focus indicators must be clearly visible, if the graphic is used as a button. Use FocusedBorderColor and FocusedBorderThickness to achieve this result.

Export and Import controls in Power Apps

Article • 12/16/2022

Controls for exporting data to a local file and then importing that data into another app in Power Apps.

Description

If you want to create more than one app that uses the same data but not share that data outside those apps, you can export it and import it by using an **Export** control and an **Import** control. When you export data, you create a compressed file that you can copy to another machine, but you can't read it in any program other than Power Apps.

Warning

Enabling this functionality in your app may expose it to security vulnerabilities and data leakage. It is recommended to advise users to import only recognized and trusted files and only export data that is not confidential or sensitive.

Limitations

The export functionality isn't supported in web browsers.

Key properties

Data – The name of a collection that you want to export to a local file.

- The **Data** property is available for an **Export** control but not an **Import** control.

OnSelect – Actions to perform when the user taps or clicks a control.

Additional properties

Align – The location of text in relation to the horizontal center of its control.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

Padding – The distance between the text on an import or export button and the edges of that button.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

RadiusBottomLeft – The degree to which the bottom-left corner of a control is rounded.

RadiusBottomRight – The degree to which the bottom-right corner of a control is rounded.

RadiusTopLeft – The degree to which the top-left corner of a control is rounded.

RadiusTopRight – The degree to which the top-right corner of a control is rounded.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Text – Text that appears on a control or that the user types into a control.

Underline – Whether a line appears under the text that appears on a control.

VerticalAlign – The location of text on a control in relation to the vertical center of that control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Example

1. Add a **Button** control, and set its **OnSelect** property to this formula:

   ```
   ClearCollect(Products, {Name:"Europa", Price:"10.99"},
   {Name:"Ganymede", Price:"12.49"}, {Name:"Callisto", Price:"11.79"})
   ```

   For more details, read adding, naming, and configuring a control, **ClearCollect** and other functions.
2. Press F5 and select **Button** control, and then press Esc.
3. Add an **Export** control, and set its **Data** property to **Products**.

4. Press F5 and select the **Export** control to download the file *Data.zip*.
5. Select **Save**, then press Esc to return to the default workspace.
6. In a new or existing app, add an **Import** control, name it **MyData**, and set its OnSelect property to this formula:
   Collect(ImportedProducts, MyData.Data)
7. Press F5 and select **MyData**, then select the file that you exported, and then select **Open**.
8. Press Esc and select **Collections** on the **File** menu, and confirm that the current app has the data that you exported.

Accessibility guidelines

The same guidelines for Button apply because **Export** and **Import** are just specialized buttons.

Column chart and Line chart controls in Power Apps

Article • 12/16/2022

Controls that show data as graphs with x- and y-axes.

Description

Column chart and **Line chart** are grouped controls. Each group contains three controls: a Label for the title, the chart graphic, and a **Legend**.

Chart key properties

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

NumberOfSeries – How many columns of data are reflected in a column or line chart.

Additional chart properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Font – The name of the family of fonts in which text appears.

GridStyle – Whether a column or line chart shows its x-axis, its y-axis, both, or neither.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

ItemColorSet – The color of each data point in a chart.

ItemsGap – The distance between columns in a column chart.

- The **ItemsGap** property is available for the **Column chart** control but not the **Line chart** control.

Markers – Whether a column or line chart shows the value of each data point.

MarkerSuffix – Text that appears after each value in a column chart for which the **Markers** property is set to **true**.

- The **MarkerSuffix** property is available for the **Column chart** control but not the **Line chart** control.

MinimumBarWidth – The narrowest possible width of columns in a column chart.

- The **MinimumBarWidth** property is available for the **Column chart** control but not the **Line chart** control.

OnSelect – Actions to perform when the user taps or clicks a control.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

SeriesAxisMax – The maximum value of the y-axis for a column or line chart.

- The **SeriesAxisMax** property is available for the **Column chart** control but not the **Line chart** control.

SeriesAxisMin – A number that determines the minimum value of the y-axis for a column chart.

- The **SeriesAxisMin** property is available for the **Column chart** control but not the **Line chart** control.

Size – The font size of the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

XLabelAngle – The angle of the labels below the x-axis of a column or line chart.

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

YAxisMax – The maximum value of the y-axis for a line chart.

- The **YAxisMax** property is available for the **Line chart** control but not the **Column chart** control.

YAxisMin – The minimum value of the y-axis for a line chart.

- The **YAxisMin** property is available for the **Line chart** control but not the **Column chart** control.

YLabelAngle – The angle of the labels next to the y-axis of a line or column chart.

Related functions

Max(*DataSource, ColumnName*)

Example

1. Add a **Button** control, and set its **OnSelect** property to this formula:
   Collect(Revenue, {Year:"2013", Europa:24000, Ganymede:22300, Callisto:21200}, {Year:"2014", Europa:26500, Ganymede:25700, Callisto:24700},{Year:"2014", Europa:27900, Ganymede:28300, Callisto:25600})

   Don't know how to add and configure a control?

   Want more information about the **Collect** function or other functions?

2. Press F5, click or tap the **Button** control, and then press Esc to return to the default workspace.

3. Add a **Column chart** control or a **Line chart** control, set its **Items** property to **Revenue**, and set its **NumberOfSeries** property to **3**.

   The control shows revenue data for each product over three years.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- each item in **ItemColorSet**
- every item in **ItemColorSet** and the background color
- **Color** and the background color

Screen reader support

- There must be a **Label** immediately before the chart graphic to serve as the title.
- Consider adding a summary of the chart graphic. For example, "The line chart shows a steady increase in sales between March and August this year."

  > ⓘ **Note**
  >
  > Chart graphics and **Legend** are hidden from screen reader users. As an alternative, a tabular form of the data is presented to them. They can also cycle through buttons that select data in the chart.

Low vision support

- There must be a **Legend** if more than one series is shown.
- Consider setting **GridStyle** to GridStyle.All, which shows both axes. This helps all users accurately determine the scale of the data.
- For **Column chart**, consider setting **Markers** to **true**. This helps low-vision users determine the value of a column.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.

Note

When keyboard users navigate to the chart, they can cycle through buttons that select data in the chart.

List Box control in Power Apps

Article • 01/20/2023

A list in which the user can select one or multiple items.

Description

A **List Box** control always shows all available choices (unlike a Drop down control) and in which the user can choose more than one item at a time (unlike a Radio control).

Key properties

Default – The initial value of a control before it is changed by the user.

> **Note**
>
> You can only have one default selected item. If you need multiple selected items please use the Combo Box control.

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

When you add a gallery, a list, or a chart, the property list shows **Items** by default so that you can easily specify the data that the new control should show. For example, you might set the **Items** property of a gallery to the **Account** table in Salesforce, a table named **Inventory** that you created in Excel and uploaded to the cloud, or a list named **ConferenceSpeakers**.

Additional properties

AccessibleLabel – Label for screen readers.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

ItemPaddingLeft – The distance between text in a listbox and its left edge.

LineHeight – The distance between, for example, lines of text or items in a list.

OnChange – Actions to perform when the user changes the value of a control (for example, by adjusting a slider).

OnSelect – Actions to perform when the user taps or clicks a control.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

Reset – Whether a control reverts to its default value.

Selected – The data record that represents the selected item.

> ⓘ **Note**
>
> You can only have one default selected item. If you need multiple selected items please use the Combo Box control.

SelectedItems - **Read-only**. Represents a datatable of selected items for a multiselect listbox.

SelectedItemsText - **Read-only**. Represents a datatable of selected items text for a multiselect listbox.

SelectedText (Deprecated) – A string value that represents the selected item.

SelectionColor – The text color of a selected item or items in a list or the color of the selection tool in a pen control.

SelectionFill – The background color of a selected item or items in a list or a selected area of a pen control.

SelectMultiple – Whether a user can select more than one item in a listbox.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Distinct(*DataSource, ColumnName*)

Example

1. Add a **List box** control, name it **CategoryList**, and set its **Items** property to this formula:
   ["Carpet","Hardwood","Tile"]

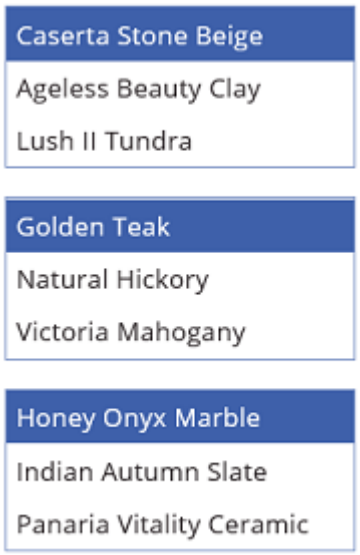
   Don't know how to add, name, and configure a control?

2. Add three **Drop down** controls, move them under **CategoryList**, and name them **CarpetList**, **HardwoodList**, and **TileList**.

3. Set the **Items** property of each **Drop down** control to one of these values:

   - CarpetList: **["Caserta Stone Beige","Ageless Beauty Clay", "Lush II Tundra"]**
   - HardwoodList: **["Golden Teak","Natural Hickory", "Victoria Mahogany"]**
   - TileList: **["Honey Onyx Marble","Indian Autumn Slate", "Panaria Vitality Ceramic"]**



4. Set the **Visible** property of each **Drop down** control to one of these values:

   - CarpetList: **If("Carpet" in CategoryList.SelectedItems.Value, true)**
   - HardwoodList: **If("Hardwood" in CategoryList.SelectedItems.Value, true)**
   - TileList: **If("Tile" in CategoryList.SelectedItems.Value, true)**

     Want more information about the **If** function or other functions?

5. Press F5, and then choose one or more items in **CategoryList**.

   The appropriate **Drop down** control or controls appear based on your choice or choices.

6. (optional) Press Esc to return to the default workspace.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **SelectionColor** and **SelectionFill**
- **SelectionFill** and **Fill**
- **HoverFill** and **Fill**
- **PressedFill** and **Fill**

This is in addition to the standard color contrast requirements.

Screen reader support

- **AccessibleLabel** must be present.

Keyboard support

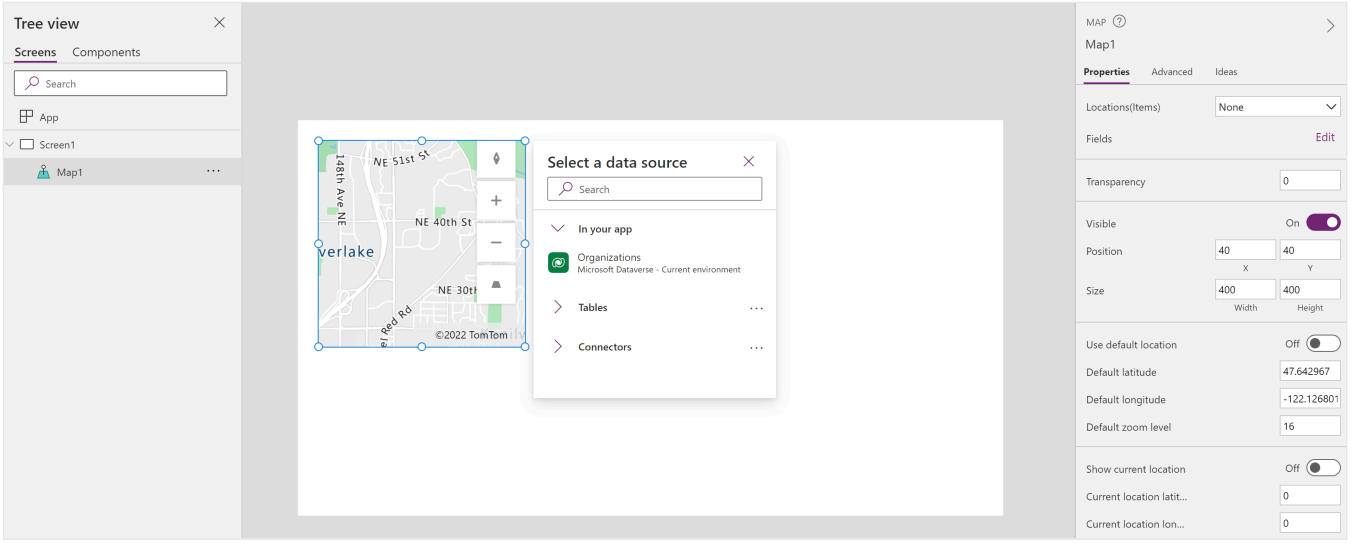
- **TabIndex** must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this.

> ⓘ **Note**
>
> The tab key navigates to or away from the **List box**. Arrow keys navigate the contents of the **List box**.

Interactive map control

Article • 03/15/2023

Easily add an interactive map to your canvas apps. Plot markers from a data source containing addresses or latitude and longitude pairs. As you zoom out, the markers will optionally cluster to condense groups of data. On mobile devices and web experiences, a map can show the user's current position and calculate a route to the user's destination. Maps can be switched between road and satellite views.



Interactive map features

- Use a data source to insert pins
- Display information about map pins
- Show routes between waypoints
- Draw and insert shapes

Prerequisites

You'll need to satisfy a few prerequisites before you can use maps in your canvas apps. Refer to the privacy and security table for more details on how different map features use data.

Add a map to an app screen

With your app open for editing in Power Apps Studio :

1. Select the **Insert** tab and expand **Media**.
2. Select **Map** to place a map in the app screen, or drag the control to the screen to position it more precisely.

Adding pins, routes, and shapes

Pins, routes, and shapes are data set properties that need to both identify a data source, which is a table from a collection or connector, and the relevant columns. The data source is set in the Items property (Items for pins, RouteWaypoints_Items for routes, Shape_Items for shapes) and the relevant columns are set in the related properties (e.g. ItemLatitudes, ItemLongitudes, etc for pins). The Properties section contains additional information about these data sets and their related properties.

For example, if you had a table collection named **Locations** with **Name**, **Longitude**, and **Latitude** columns:

Expand table

Name	Longitude	Latitude
Fourth Coffee (sample)	-98.29277	26.2774
Litware, Inc. (sample)	-96.85572	32.55253
Adventure Works (sample)	-96.99952	32.72058

To display these as labeled pins on the map:

1. Set the **Items** property to Locations
2. Set the **ItemLabels** property to "Name"
3. Set the **ItemLongitude** property to "Longitude"
4. Set the **ItemLatitude** property to "Latitude"

> **Important**
>
> The relevant column names need to be in quotation marks in the related properties. The data source should not have quotation marks.

You can see how to do display pins from an Excel sheet or build an app that uses the address input control to populate pins on the map control as additional examples.

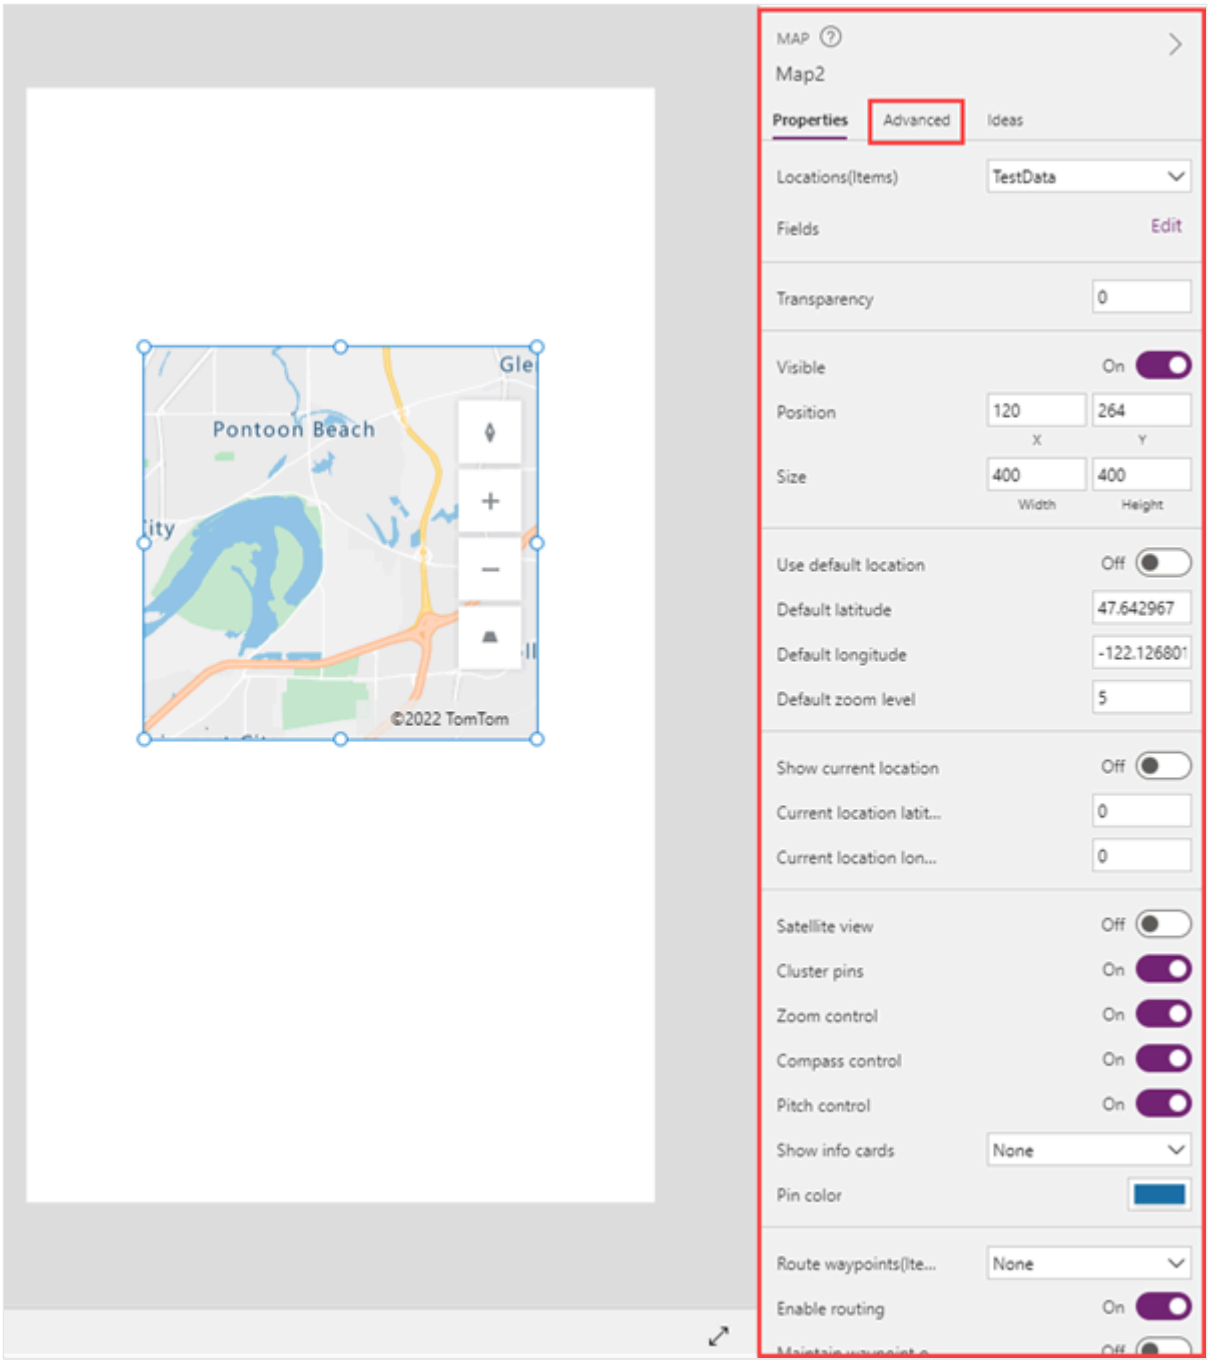
> **Note**
>
> - Each map control can display up to 5000 pins from latitude or longitude and 50 pins from addresses. The pin limit is lower for addresses as the map needs to geocode

these addresses into latitude or longitude to display them. We recommend not using addresses where possible. You can save geocoded addresses back to your data source.

- When both latitude or longitude and an address is given for a single pin, the map control will prioritize using the latitude or longitude to avoid geocoding the address.
- The maximum number of shapes that can be drawn in a map control is limited to 500.

Properties

Change a map's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



The map control has six different types of properties:

1. Styling properties
2. Behavioral properties
3. Pin properties
4. Route properties
5. Shape properties
6. Output properties

Styling properties

Expand table

Property	Description	Type	Tab
Satellite view	Displays the map in satellite view. Leave this property off to display the map in road view.	Boolean	Properties; Advanced: **SatelliteView**
Map style	Sets the map style. Options: Road, Night, Road shaded relief, Satellite, Satellite road labels, High contrast light, High contrast dark, Grayscale light, Grayscale dark.	Enum	Properties
Transparency	Determines the map's transparency, from 0 (opaque) to 100 (transparent).	Integer	Properties; Advanced: **Transparency**
Visible	Shows or hides the map.	Boolean	Properties; Advanced: **Visible**
Position	Places the upper-left corner of the map at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the map using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Border radius	Determines the corner radius of the map border.	Floating point number	Properties; Advanced: **BorderRadius**
Border	Determines the style, width, and color of the map border.	Not applicable	Properties; Advanced: **BorderStyle**, **BorderThickness**, **BorderColor**
DisplayMode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Enum	Advanced

Behavioral properties

Expand table

Property	Description	Type	Tab
Show info cards	Shows information about a mapped location when the user selects it (*On click*) or points to it (*On hover*). If *None*, no information is shown.	Enum	Properties; Advanced: **InfoCards**
Use default location	Initializes the map at a default location.	Boolean	Properties; Advanced: **DefaultLocation**

Property	Description	Type	Tab
Default latitude	Sets the latitude coordinate the map shows if **Use default location** is enabled.	Floating point number	Properties; Advanced: **DefaultLatitude**
Default longitude	Sets the longitude coordinate the map shows if **Use default location** is enabled.	Floating point number	Properties; Advanced: **DefaultLongitude**
Default zoom level	Sets the zoom level if **Use default location** is enabled, from 0 to 22.	Integer	Properties; Advanced: **DefaultZoomLevel**
Show current location	Displays the user's current location.	Boolean	Properties; Advanced: **CurrentLocation**
Current location latitude	Sets the latitude coordinate of the current location pin that the map shows if **Show current location** is enabled. To place the pin at the user's current location, set this property to Location.Latitude.	Floating point number	Properties; Advanced: **CurrentLocationLatitude**
Current location longitude	Sets the longitude coordinate of the current location pin that the map shows if **Show current location** is enabled. To place the pin at the user's current location, set this property to Location.Longitude.	Floating point number	Properties; Advanced: **CurrentLocationLongitude**
Zoom control	Shows the zoom control.	Boolean	Properties; Advanced: **Zoom**
Compass control	Shows the compass control.	Boolean	Properties; Advanced: **Compass**
Pitch control	Shows the pitch (tilt) control.	Boolean	Properties; Advanced: **Pitch**
TabIndex	Specifies the order the map is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **Tab index**
Tooltip	Determines the text to display when the user hovers over a visual.	String	Advanced
ContentLanguage	Determines the display language of the map, if it's different from the language used in the app.	String	Advanced
OnLoad	Contains code that runs when the map is loaded.	Event	Advanced

Property	Description	Type	Tab
OnMapClick	Contains code that runs when the user selects the map. The latitude and longitude of the clicked point is in the **ClickedLocation** output property.	Event	Advanced
OnChange	Contains code that runs when any aspect of the map is changed.	Event	Advanced
OnSelect	Contains code that runs when the user selects something on the map.	Event	Advanced

Pin properties

Expand table

Property	Description	Type	Tab
Locations(Items)	Identifies a data source (**Items**) in the form of a table from which to get locations to show on the map. The table lists sets of longitudes and latitudes, or physical addresses, to display as pins. Using latitude or longitude is recommended as addresses need to be geocoded and so have a more restrictive pin limit. The table can be a collection or from a data source like Excel Online. Each row must have an entry for label, longitude, and latitude, or a physical address, and optionally the pin color and icon.	Not applicable	Properties; Advanced: **Items**
ItemsLabels	Identifies the column in **Items** that contains the labels for the pins.	ColumnName	Advanced
ItemsLatitudes	Identifies the column in **Items** that contains the latitude position of the pins.	ColumnName	Advanced
ItemsLongitudes	Identifies the column in **Items** that contains the longitude position of the pins.	ColumnName	Advanced
ItemsAddresses	Identifies the column in **Items** that contains addresses that represent the location of the pins. There is a limit to how many pins can be displayed from addresses. We recommend geocoding your addresses to latitude, longitude pairs and using those to display pins when possible.	ColumnName	Advanced
ItemsColors	Identifies the column in **Items** that contains the colors of the pins.	ColumnName	Advanced

Property	Description	Type	Tab
ItemsIcons	Identifies the column in **Items** that contains the icons of the pins.	ColumnName	Advanced
Cluster pins	Groups nearby map pins instead of displaying them individually.	Boolean	Properties; Advanced: **Clustering**
Pin color	Determines the default color of pins shown on the map. This color is overridden by the **ItemsColors** property if set	Color picker	Properties; Advanced: **PinColor**
OnItemsChange	Contains code that runs when pins on the map are changed.	Event	Advanced

Route properties

Expand table

Property	Description	Type	Tab
Enable routing	Determines whether the user can request directions to a specified location.	Boolean	Properties; Advanced: **UseRouting**
Route waypoints(Items)	Shows route waypoints, as provided in a data source (**RouteWaypoints_Items**) in the form of a table. The table can be a collection or from a data source like Excel Online. If *None*, no waypoints are shown.	Enum	Properties; Advanced: **RouteWaypoints_Items**
RouteWaypointsLabels	Identifies the column in **RouteWaypoints_Items** that contains the labels for the waypoints.	ColumnName	Advanced
RouteWaypointsLatitudes	Identifies the column in **RouteWaypoints_Items** that contains the latitude position of the waypoints.	ColumnName	Advanced
RouteWaypointsLongitudes	Identifies the column in **RouteWaypoints_Items** that contains the longitude position of the waypoints.	ColumnName	Advanced

Property	Description	Type	Tab
RouteWaypointsAddresses	Identifies the column in **RouteWaypoints_Items** that contains addresses that represent the location of waypoints.	ColumnName	Advanced
Maintain waypoint order	Determines whether a calculated route maintains waypoints in the order provided.	Boolean	Properties; Advanced: **RouteMaintainOrder**
Optimize route	Determines whether a calculated route is optimized for distance, time, or isn't optimized.	Enum	Properties; Advanced: **RouteOptimization**
Route travel mode	Determines whether a route is calculated for a car or a truck, which may require avoiding bridges with certain height or weight restrictions.	Enum	Properties; Advanced: **RouteTravelMode**
OnRouteDirectionChange	Contains code that runs when the app detects the user has changed direction while on a computed route.	Event	Advanced

Shape properties

Expand table

Property	Description	Type	Tab
Show shapes	Shows the shapes in **Shapes_Items**.	Boolean	Properties; Advanced: **ShowShapes**
Shapes_Items	Identifies a data source (**Shapes_Items**) in the form of a table from which to get shapes to show on the map. The table can be a collection or from a data source like Excel Online. Each row must have an entry for the shape (GeoJSON object) and (optionally) a label and color.	TableName	Advanced

Property	Description	Type	Tab
ShapeGeoJSONObjects	Identifies the column in **Shapes_Items** with strings that represent the GeoJSON objects of the shapes, in shape collection or single shape GeoJSON format.	ColumnName	Advanced
ShapeLabels	Identifies the column in **Shapes_Items** that contains the labels for the shapes.	ColumnName	Advanced
ShapeColors	Identifies the column in **Shapes_Items** that contains the colors of the shapes.	ColumnName	Advanced
Show shape labels	Shows the shape labels, if provided.	Boolean	Properties; Advanced: **ShowShapeLabels**
Enable shape drawing	Shows drawing tools on the map.	Boolean	Properties; Advanced: **ShapeDrawing**
Enable shape deleting and label editing	Determines whether the user can delete shapes and edit their labels.	Boolean	Properties; Advanced: **ShapeEditingDeleting**
OnShapeCreated	Contains code that runs when the user adds a shape to the map.	Event	Advanced
OnShapeSelected	Contains code that runs when the user selects a shape on the map.	Event	Advanced
OnShapeEdited	Contains code that runs when the user modifies a shape on the map.	Event	Advanced
OnShapeDeleted	Contains code that runs when the user deletes a shape on the map.	Event	Advanced

Output properties

Other properties become available when a user interacts with a map. You can use these *output properties* in other controls or to customize the app experience.

Expand table

Property	Description	Type
CenterLocation	Captures the map's center point.	Not Applicable

Property	Description	Type
ClickedLocation	Captures the last location the user selected, either *.Latitude* or *.Longitude*.	Record
Selected	Captures the selected pin.	Record
SelectedItems	Captures the selected pin or pins in the selected cluster.	Table
GeocodedItems	Captures the geocoded locations of the pins.	Table
RouteWaypoints_Selected	Corresponds to the record of the selected shape in **RouteWaypoints_Items**.	Record
RouteWaypoints_SelectedItems	Corresponds to the records of the selected overlapping shapes in **RouteWaypoints_Items**.	Table
Shapes_Selected	Corresponds to the record of the selected shape in **Shapes_Items**.	Record
Shapes_SelectedItems	Corresponds to the records of the selected overlapping shapes in **Shapes_Items**.	Table
SelectedShape	Captures the *.Perimeter* and *.Area* of the selected shape.	Record
DeletedShape	Captures the *.Perimeter* and *.Area* of the last deleted shape.	Record
GeoJSON	Captures the list of shapes in Feature Collection GeoJSON format.	String

Other geospatial controls

To see dynamic address suggestions as you type, use the **Address input** control.

Known limitations

- Requires internet connection

Create an app with address input and map controls

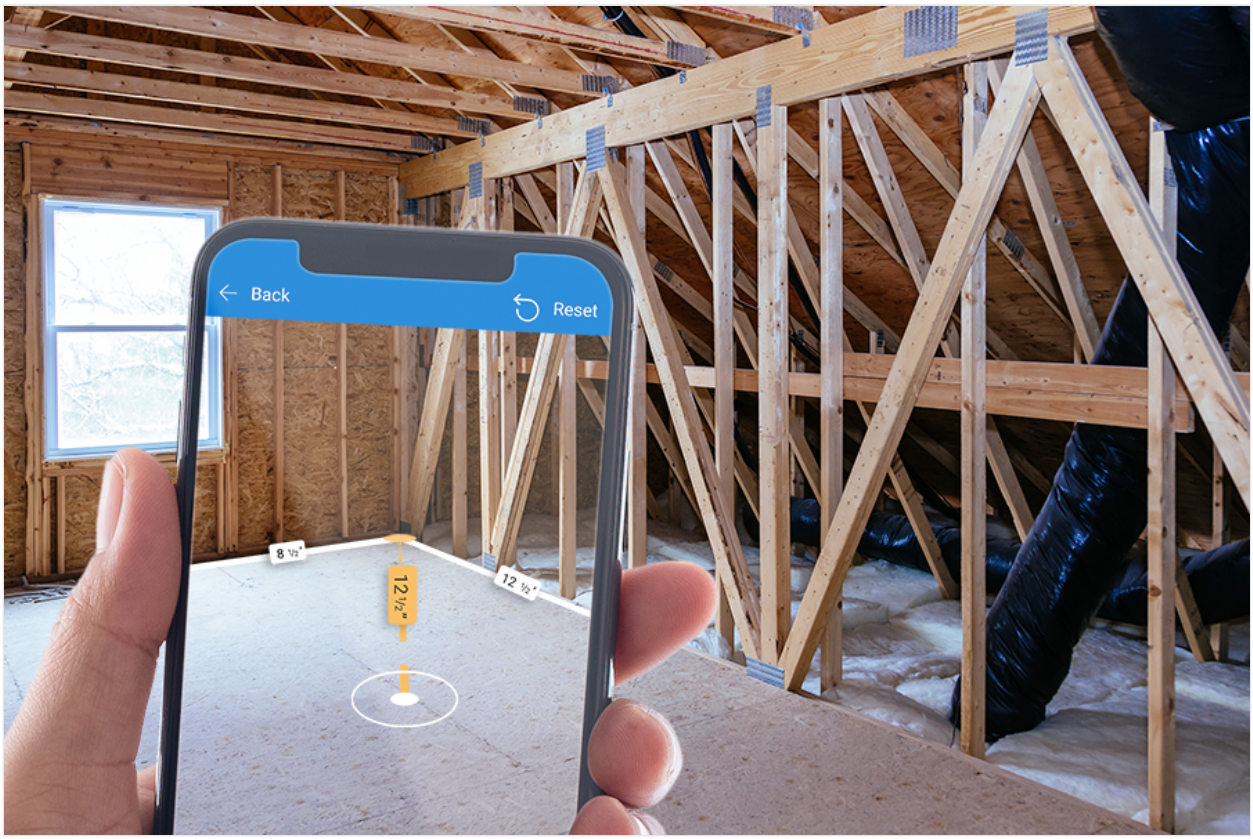
Take measurements in mixed reality

Article • 05/09/2022

Use the **Measuring camera** control in a canvas app to measure distance, area, and volume in the real world. You can also create two- and three-dimensional freeform shapes and see how they fit in a real-world space.

The **Measuring camera** control adds a button to your app. When a user selects the button, the app shows a live feed from the device camera. On-screen instructions direct the user to establish tracking by slowly panning the device from right to left across the surface to be measured. The user identifies a starting point and adds segments as needed until the measurement is complete. Dimensions of the measured space are overlaid on the camera feed.

The user can submit the measurements for capture in the control's **Measurements** output properties. The user can also take screenshots while a space is measured. The screenshots are captured in the control's **Photos** output property.



Tip

The mixed-reality (MR) controls work best in well-lit environments with flat-textured surfaces. Tracking is better on LIDAR-enabled devices.

Add a Measuring camera button to an app screen

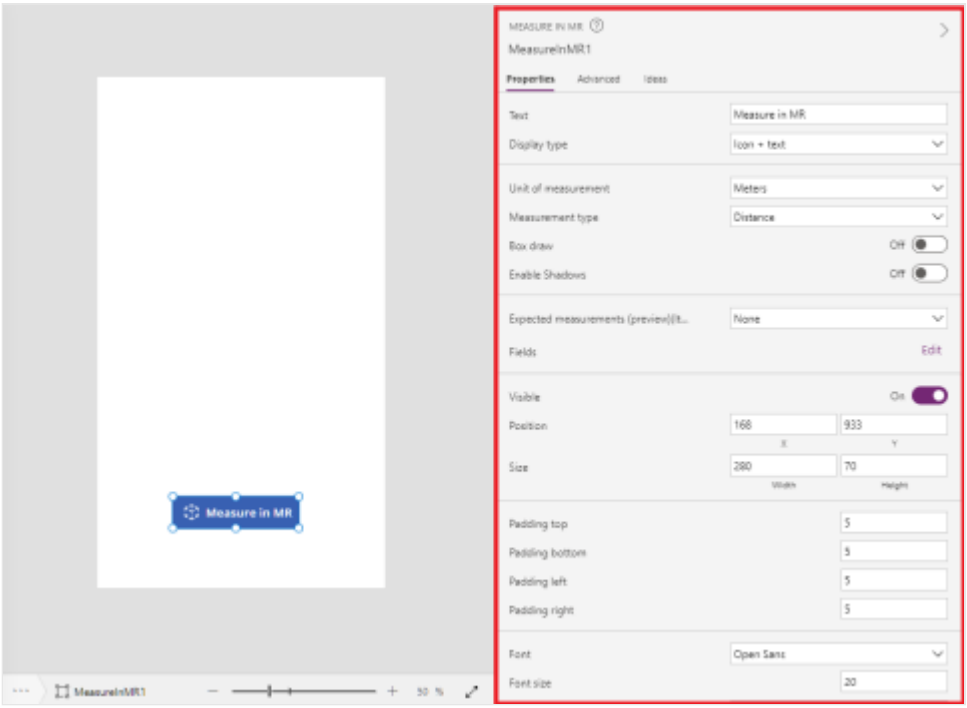
With your app open for editing in Power Apps Studio :

1. Open the **Insert** tab and expand **Media**.
2. Select **Measuring camera** to place the control in the app screen, or drag the control to the screen to position it more precisely.

The control is a button that's labeled with an icon of a cube and the text *Measure*. Change the label and hide the icon if you like in the **Text** and **Display type** properties.

Properties

Change the **Measuring camera** button's behavior and appearance using properties. Some properties are only available on the **Advanced** tab.



Property	Description	Type	Location
Text	Sets the button label text.	String	Properties; Advanced: **Text**
Display type	Determines whether the button label shows an icon of a cube, text, or both.	Dropdown list	Properties; Advanced: **DisplayType**
Unit of measurement	Sets the unit used for the dimensions.	Dropdown list	Properties; Advanced: **Units**

Property	Description	Type	Location
Measurement type	Determines the kind of measurement the user can make, either *Distance*, *Area*, or *Volume* (area plus height or depth).	Dropdown list	Properties; Advanced: **MeasurementType**
Box draw	Locks captured measurements to rectangular shapes.	Boolean	Properties; Advanced: **BoxDraw**
Enable Shadows	Determines whether shadows are used to enhance the 3D effect when a shape is drawn.	Boolean	Properties; Advanced: **EnableShadows**
Expected measurements (Items)	Identifies a data source (**Items**) in the form of a table in an Excel workbook from which to get the measurements the user should capture.	Not applicable	Properties; Advanced: **Items**
Visible	Shows or hides the button.	Boolean	Properties; Advanced: **Visible**
Position	Places the upper-left corner of the button at the screen coordinates specified in *x* and *y*.	Floating point number	Properties; Advanced: **X**, **Y**
Size	Determines the size of the button using the pixel values provided in *Width* and *Height*.	Integer	Properties; Advanced: **Width**, **Height**
Padding top	Sets the distance between the button label text and the top of the button.	Floating point number	Properties; Advanced: **PaddingTop**
Padding bottom	Sets the distance between the button label text and the bottom of the button.	Floating point number	Properties; Advanced: **PaddingBottom**
Padding left	Sets the distance between the button label text and the left edge of the button.	Floating point number	Properties; Advanced: **PaddingLeft**

Property	Description	Type	Location
Padding right	Sets the distance between the button label text and the right edge of the button.	Floating point number	Properties; Advanced: **PaddingRight**
Font	Sets the name of the family of fonts used for the button label text.	Dropdown list	Properties; Advanced: **Font**
Font size	Sets the size of the button label text.	Floating point number	Properties; Advanced: **FontSize**
Font weight	Sets the weight of the button label text, either *Bold*, *Lighter*, *Normal*, or *Semibold*.	Dropdown list	Properties; Advanced: **FontWeight**
Text alignment	Sets the horizontal alignment of the label text in the button, either *Center*, *Justify*, *Left*, or *Right*.	Not applicable	Properties; Advanced: **TextAlignment**
Vertical alignment	Sets the vertical alignment of the label text in the button, either *Bottom*, *Middle*, or *Top*.	Dropdown list	Properties; Advanced: **VerticalAlign**
Font style	Sets the style of the button label text, either *Italic*, *Underline*, *Strikethrough*, or none.	Not applicable	Properties; Advanced: **Italic**, **Underline**, **Strikethrough**
Border radius	Determines the corner radius of the button border.	Floating point number	Properties; Advanced: **BorderRadius**
Color	Sets the colors of the button label text and the button background.	Not applicable	Properties; Advanced: **FillColor**, **TextColor**
Border	Determines the style, width, and color of the button border.	Not applicable	Properties; Advanced: **BorderStyle**, **BorderThickness**, **BorderFillColor**
Disabled	Turns off the button but leaves it visible.	Boolean	Properties; Advanced: **Disabled**
Disabled color	Sets the colors of the button label text, the button background, and the button border if **DisplayMode** is **Disabled**.	Not applicable	Properties; Advanced: **DisabledContentColor**, **DisabledFillColor**, **DisabledBorderColor**

Property	Description	Type	Location
Pressed color	Sets the colors of the button label text, the button background, and the button border when the user selects the button.	Not applicable	Properties; Advanced: **PressedContentColor**, **PressedFillColor**, **PressedBorderColor**
Hover color	Sets the colors of the button label text, the button background, and the button border when the user hovers the mouse pointer over it.	Not applicable	Properties; Advanced: **HoverContentColor**, **HoverFillColor**, **HoverBorderColor**
OnMixedRealitySelect	Contains code that runs when the user exits the measurement screen with new results.	Event	Advanced
OnChange	Contains code that runs when a button property is changed.	Event	Advanced
OnSelect	Contains code that runs when the user selects the button.	Event	Advanced
ItemsLabels	Identifies the column in **Items** that contains the labels for the measurements users should capture.	ColumnName	Advanced
ItemsMeasurementType	(Optional) Identifies the column in **Items** that contains a string (*Distance*, *Area*, *Volume*, or *Freeform*) that specifies the type of measurement users should capture.	ColumnName	Advanced; see **MeasurementType**
ItemsBoxDraw	(Optional) Identifies the column in **Items** that contains a string (*True* or *False*) that locks measurements to rectangular shapes.	ColumnName	Advanced; see **BoxDraw**
Tooltip	Determines the text to display when the user hovers over a visual.	String	Advanced

Property	Description	Type	Location
ContentLanguage	Determines the display language of the control, if it's different from the language used in the app.	String	Advanced
DisplayMode	Determines whether the control allows user input (*Edit*), only displays data (*View*), or is disabled (*Disabled*).	Enum	Advanced
TabIndex	Specifies the order the control is selected if the user navigates the app using the Tab key.	Integer	Properties; Advanced: **Tab index**

Output properties

Your app can make use of more properties when a user interacts with the **View in MR** control. These are known as output properties. You can use these properties in other controls or to customize the app experience.

Property	Description
Photos	Captures, in a collection, information about photos the user takes while a space is measured. Use the collection to upload mixed-reality photos to OneDrive and show them in a gallery.
Measurements	Captures, in a table, the measured distances, volumes, and areas.
Segments	Captures, in a table, information about segments in a measured object.

The Measurements table has the following columns:

- **Label:** A string that identifies the measurement
- **Id:** A number that uniquely identifies the measurement
- **Units:** A string that identifies the unit of the measurement
- **Height:** A number that represents the height of the measured volume (0 if a 2D area was measured)
- **Length:** A number that represents the total length of the measured perimeter or path
- **BoundingWidth:** A number that represents the minimum width that bounds the shape

- **BoundingDepth:** A number that represents the minimum depth that bounds the shape
- **Area:** A number that represents the estimated area of the measured shape in units squared
- **Volume:** A number that represents the estimated volume of the measured shape in units cubed

The Segments table has the following columns:

- **Length:** A number that represents the total distance of a segment in the specified units
- **DirectionX:** A number that represents the X direction of the segment in world (3D) space
- **DirectionY:** A number that represents the Y direction of the segment in world(3D) space (typically 0)
- **DirectionZ:** A number that represents the Z direction of the segment in world (3D) space

Learn more about how to use output properties of the **Measuring camera** control in your apps: Validate measurements in mixed reality using a spatial test filter

Other mixed reality controls

- View 3D content with the **3D object** control.
- View images and 3D content in the real world with the **View in mixed reality** control.
- Create and view predefined 3D shapes with the **View shape in mixed reality** control
- Paint 3D lines or draw 3D arrows to specify an area or asset in your environment with the **Markup in MR** control.

Create an app using the Measuring Camera control

Microphone control in Power Apps

Article • 03/25/2024

A control that enables app users to record sounds from their device.

Description

Use the **Microphone** control to capture audio with a device's microphone. The device must have a microphone and the user must authorize the app to use the microphone.

The most recently recorded audio clip is available through the **Audio** property. With this property, recorded audio can be:

- **Played back with the Audio control.** Use the Audio control to listen to the recording. For more information, see the examples.
- **Temporarily put in a variable or a collection.** Use the Set or Collect functions to store audio clips in a variable or a collection. Use caution with multiple audio clips in a collection at the same time with device's limited memory. Use the SaveData and LoadData functions to move audio clips to the local storage on the device and for offline scenarios.
- **Stored in a database.** Use the Patch function to store audio clips in a database.
- **Transmitted as a base64 encoded text string.** Use the JSON function to base64 encode audio clips.

Format of the recorded audio:

- *3gp* format for *Android*.
- *AAC* format for *iOS*.
- *OGG* format for *web browsers*.

Captured media is referenced by a text string URI. For more information, read the data type documentation.

> **Note**
>
> The microphone control is supported only on Microsoft Edge based on Chromium, Chrome, and Firefox browsers; and Android and iOS devices. All other browsers and platforms will show a warning that some features of the app won't work.

Limitations

The microphone control has these limitations:

- Power Apps Mobile runs on various types of devices, and some of them have limitations that are specific to that platform:
  - You can play videos in multiple **Video** controls at the same time on all platforms except iPhone devices.
  - You can record audio with multiple **Microphone** controls at the same time on all platforms except the web player.

Key properties

Audio – The audio clip captured when the user records with the device's microphone.

Mic – Numeric ID of the microphone on a device that has more than one microphone.

OnStop – Actions to perform when the user stops recording with a microphone control.

Additional properties

AccessibleLabel – Label for screen readers. Should describe the purpose of the microphone.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Image – The name of the image that appears in an image, audio, or microphone control.

ImagePosition – The position (**Fill**, **Fit**, **Stretch**, **Tile**, or **Center**) of an image in a screen or a control if it isn't the same size as the image.

OnSelect – Actions to perform when the user selects a control.

OnStart – Actions to perform when the user starts to record with a microphone control.

PressedBorderColor – The color of a control's border when the user selects that control.

PressedColor – The color of text in a control when the user selects that control.

PressedFill – The background color of a control when the user selects that control.

Reset – Whether a control reverts to its default value.

TabIndex – Keyboard navigation order compared to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container or screen.

Y – The distance between the top edge of a control and the top edge of the parent container or screen.

Examples

Simple direct playback

In this example, we'll directly connect a **Microphone** control with an **Audio** control for immediate playback:

1. Add a **Microphone** control to your app.
2. Authorize the app to use device's microphone if prompted.
3. Add an **Audio** control to your app.
4. Set the **Audio** control's **Media** property to the formula:

   ```
   Power Fx
   Microphone1.Audio
   ```

   > **Note**
   >
   > Replace microphone control name *Microphone1* as appropriate.

5. Preview the app.
6. Select the **Microphone** control to begin recording.
7. Speak to record audio.
8. Select the **Microphone** control again to end the recording.
9. Select the **Audio** control to hear the recording.

Add sounds to a Gallery control

In this example, we'll create a gallery of audio clips stored in a collection that can be individually selected for playback:

1. Add a **Microphone** control.
2. Set its **OnStop** property to this formula using the Collect function:

   ```
   Power Fx
   Collect( MySounds, MyMic.Audio )
   ```

3. Add a **Gallery** control, move it below **MyMic**.
4. Set the Items property for the gallery to this formula:

```
Power Fx

MySounds
```

5. In the template for the **Custom gallery** control, add an Audio control.
6. Set the audio control's **Media** property to this formula:

```
Power Fx

ThisItem.Url
```

7. Press F5 to preview the app.
8. Select **MyMic** to start recording, and then select it again to stop recording.
9. In the **Gallery** control, select the play button in the **Audio** control to play back your recording.
10. Add as many recordings as you want, and then return to the default workspace by pressing the Esc key.
11. (optional) In the template for the **Gallery** control, add a Button control.
12. Set its OnSelect property to the formula:

```
Power Fx

Remove( MySounds, ThisItem )
```

13. Press F5, and then remove a recording by selecting the corresponding **Button** control.

Use the SaveData function to save the recordings locally or the Patch function to update a data source.

Accessibility guidelines

The same guidelines for Button apply because **Microphone** is just a specialized button. Also, consider:

Audio alternatives

Consider adding an alternative form of input for users with speech disabilities or without a microphone. For example, Text input to allow users to enter text.

Color contrast

- Read the standard color contrast requirements.
- Ensure adequate color contrast between Image and the button text and icon (if applicable).

Screen reader support

- AccessibleLabel must be present.

PDF viewer control (experimental) in Power Apps

Article • 01/20/2024

An experimental control that shows the content of a PDF file.

Description

Show text, graphics, and other content in a PDF file by adding this type of control and setting its **Document** property to the URL, enclosed in double quotation marks, of the file that you want to show.

Limitations

1. The PDF viewer control only supports PDF files that conform to the PDF32000 specification.
2. The security architecture of Power Apps requires the PDF Viewer to support only HTTPS links, not HTTP.
3. The **Document** property must link directly to the PDF file. Server redirects or HTML views of the document aren't supported.
4. The file must be accessible anonymously without any authentication.
5. You won't be able to view a PDF document in your app if the document resides on a server that has restrictive cross-origin resource sharing (CORS) settings. To resolve this issue, the server that hosts PDF documents must permit cross-origin requests from powerapps.com.
6. Embedded objects like scripts and buttons won't run.

App users can work around these limitations by opening PDF documents in an external browser, as prompted if the control can't open a document. This option is also available in the control menu for all external documents.

Key properties

Document – The URL, enclosed in double-quotation marks, of a PDF file.

Additional properties

ActualZoom – The actual zoom of the control, which may differ from the zoom requested with the **Zoom** property.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

CurrentFindText – The current search term that is in use.

CurrentPage – The number of the page in a PDF file that is actually being shown.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FindNext – Finds the next instance of **FindText** in the document.

FindPrevious – Finds the previous instance of **FindText** in the document.

FindText – The search term to look for in the document.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

OnSelect – Actions to perform when the user taps or clicks a control.

OnStateChange – Actions to perform when the state of the control changes.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

Page – The number of the page that you want to show.

PageCount – The number of pages in a document.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

ShowControls – Whether an audio or video player shows, for example, a play button and a volume slider, and a pen control shows, for example, icons for drawing, erasing, and clearing.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Zoom – The percentage by which an image from a camera is magnified or the view of a file in a PDF viewer.

Keyboard shortcuts

- **J** - Page down
- **K** - Page up
- **N** - Page down
- **R** - Rotate all pages 90° clockwise

Example

Add a **PDF viewer** control, and set its **Document** property to the URL, enclosed in double quotation marks, of a PDF file as in this example:

"https://blog.mozilla.org/security/files/2015/05/HTTPS-FAQ.pdf"

The control shows the PDF file.

Don't know how to add and configure a control?

Accessibility guidelines

Not all accessibility features of PDF documents are supported because the **PDF viewer** is still in the experimental stage. Therefore, **ShowControls** should be set to **true** to allow users to open the document in an external application.

Learn how to create accessible PDF documents with the WCAG 2.0 and PDF/UA standards.

Screen reader support

- Consider adding a heading using a **Label**, if the PDF document does not have a title. The heading can be positioned immediately before the **PDF viewer**.

Pen input control in Power Apps

Article • 04/03/2024

A control in which the user can draw, erase, and highlight areas of an image.

Description

The user can use this control like a whiteboard, drawing diagrams and writing words that can be converted to typed text.

Limitations

The pen input control has these limitations:

- The pen control only has partial support for drawing using a mouse or touch input in the Windows app. Strokes might be intermittent. For smooth drawing, use a pen or run the app in a browser.

Key properties

Image – Output property that represents the image drawn by the end user.

Color – The color of input strokes.

Mode – The control is in **Draw** or **Erase** mode. Select mode has been deprecated.

Additional properties

AccessibleLabel – Label for screen readers. Can be used to describe the purpose of the control as well as alternative methods of input.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Fill – The background color of a control.

Height – The distance between a control's top and bottom edges.

Input – **Deprecated.** Whether the input supports mouse, pen, or touch inputs. Default value (7) supports all three.

OnSelect – Actions to perform when the user taps or clicks a control.

SelectionColor – The text color of a selected item or items in a list or the color of the selection tool in a pen control.

SelectionThickness – The thickness of the selection tool for a pen-input control.

ShowControls – Whether an audio or video player shows, for example, a play button and a volume slider, and a pen control shows, for example, icons for drawing, erasing, and clearing.

Size – The font size of the text that appears on a control.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Collect(*CollectionName*, *DatatoCollect*)

Example

Create a set of images

1. Add a **Pen input** control, name it **MyDoodles**, and set its **ShowControls** property to **true**.

   Don't know how to add, name, and configure a control?

2. Add a **Button** control, move it below **MyDoodles**, and set the **Text** property of the **Button** control to show **Add**.

3. Set the **OnSelect** property of the **Button** control to this formula:
   Collect(Doodles, {Sketch:MyDoodles.Image})

4. Add an **Image gallery** control, move it below the **Button** control, and shrink the width of the **Image gallery** control until it shows three items.

5. Set the **Items** property of the **Image gallery** control to **Doodles**, and then press F5.

6. Draw an image in **MyDoodles**, and then click or tap the **Button** control.

   The image that you drew appears in the **Image gallery** control.

7. (optional) In the **Pen input** control, click or tap the icon to clear the image that you drew, draw another image, and then click or tap the **Button** control.

8. In the **Image gallery** control, set the **OnSelect** property of the **Image** control to this formula:
   Remove(Doodles, ThisItem)

9. Remove a drawing by clicking or tapping it in the **Image gallery** control.

Use the **SaveData** function to save your drawings locally or the **Patch** function to save them to a data source.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **BorderColor** and the color outside the control (if there is a border)
- **Fill** and the color outside the control (if there is no border)

Screen reader support

- **AccessibleLabel** should be present.

> **Important**

Pen input is not accessible to screen reader users. Always provide an alternative form of input. For example, if a sketch is required, consider adding an Add picture control for users to upload an image. Both methods can be offered and the user can choose the one they are more comfortable with.

Keyboard support

Important

Pen input is not accessible to keyboard users. Always provide an alternative form of input. For example, if a signature is required, consider adding a Text input for users to enter their name. Both methods can be offered and the user can choose the one they are more comfortable with.

Pie chart control in Power Apps

Article • 12/16/2022

A control that shows relative values in comparison to each other.

Description

Add a **Pie chart** control if you want to show relative data from a table that contains labels in the leftmost column and values in the second column from the left.

This control is a grouped control containing three controls: a Label for the title, the chart graphic, and a **Legend**.

Chart key properties

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

ShowLabels – Whether a pie chart shows the value that's associated with each of its wedges.

Additional chart properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

Explode – The distance between wedges in a pie chart.

Font – The name of the family of fonts in which text appears.

Height – The distance between a control's top and bottom edges.

HoverBorderColor – The color of a control's border when the user keeps the mouse pointer on that control.

ItemBorderColor – The color of the border around each wedge in a pie chart.

ItemBorderThickness – The thickness of the border around each wedge in a pie chart.

ItemColorSet – The color of each data point in a chart.

LabelPosition – The location of labels in a pie chart relative to its wedges.

OnSelect – Actions to perform when the user taps or clicks a control.

PressedBorderColor – The color of a control's border when the user taps or clicks that control.

Size – The font size of the text that appears on a control.

TabIndex – Keyboard navigation order in relation to other controls.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Max(*DataSource, ColumnName*)

Example

1. Add a **Button** control, and set its **OnSelect** property to this formula:
   Collect(Revenue2015, {Product:"Europa", Revenue:27000}, {Product:"Ganymede", Revenue:26300}, {Product:"Callisto", Revenue:29200})

   Don't know how to add and configure a control?

   Want more information about the **Collect** function or other functions?

2. Press F5, click or tap the **Button** control, and then press Esc to return to the default workspace.

3. Add a **Pie chart** control, and set its **Items** property to **Revenue2015**.

   The **Pie chart** control shows revenue data for each product in relation to the other products.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- each item in **ItemColorSet**
- every item in **ItemColorSet** and the background color
- **Color** and the background color

Screen reader support

- There must be a **Label** immediately before the chart graphic to serve as the title.

  > **Note**
  >
  > Chart graphics and **Legend** are hidden from screen reader users. As an alternative, a tabular form of the data is presented to them. They can also cycle through buttons that select data in the chart.

Low vision support

- There must be a **Legend**.
- Consider setting **ShowLabels** to **true**. This helps low-vision users quickly determine what each pie slice represents.
- Consider setting **LabelPosition** to **LabelPosition.Outside**. This increases legibility of labels because of a more consistent color contrast.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.

Note

When keyboard users navigate to the chart, they can cycle through buttons that select data in the chart.

Power BI tile control in Power Apps

A control that shows a Power BI tile inside an app.

Don't have Power BI? Sign up.

Description

Take advantage of your existing data analysis and reporting by displaying your **Power BI tiles** inside your apps. Specify the tile that you want to show by setting its **Workspace**, **Dashboard**, and **Tile** properties in the **Data** tab of the options panel.

> **Note**
>
> - Power BI tile control is not supported on some GCC High and DoD environments.
> - Power BI tile control isn't available in China.
> - For licensing requirements when embedding Power BI tile, see Licensing.

Sharing and security

When you share an app that contains Power BI content, you must share not only the app itself but also the dashboard where the tile comes from. Otherwise, the Power BI content won't appear even for users who open the app. Apps that contain Power BI content respect the permissions for that content.

Performance

It's not recommended to have more than three Power BI tiles loaded at the same time within an app. You can control tile loading and unloading by setting the **LoadPowerBIContent** property.

Embedding Options

Embedding is different between versions of the Power BI API. Because of the new Power BI API authentication scheme, your tile may not be accessible on mobile or within other embedded scenarios (Teams or SharePoint).

You can control the use of API version using the **AllowNewAPI** property. For more information, see Key properties.

Expand table

AllowNewAPI property value	Behavior
True	You can embed a dashboard, report, or tile by taking the **Embed URL** from Power BI and making it the **TileUrl** value.
False	You can embed a dashboard tile either by **Embed URL** and making it the **TileUrl** value, or using the graphical interface provided.

> **Note**
>
> Embedding a Power BI URL (for example, in an IFrame) is not supported on Power Apps mobile since authenticating the Power BI URL request is not handled by the mobile player.

Filtering

Filtering differs between the versions of the Power BI API. See the appropriate sections below depending on how you configure the control.

When using the new API to call Power BI service

When **AllowNewAPI** property is set to "True", you're using new API to call Power BI service. For more information, see Filter a report using query string parameters in the URL.

When using the original API to call Power BI service

When **AllowNewAPI** property is set to "False", you're using the original API to call Power BI service. In this case, by passing a single parameter from the app, you can filter the results that appear in a Power BI tile. However, only string values and the equals operator are supported, and the filter might not work if the table name or the column name contains spaces.

To pass a single filter value, modify the value of the **TileURL** property, which follows this syntax:

```
"https://app.powerbi.com/embed?dashboardId=<DashboardID>&tileId=<TileID>&config=
<SomeHash>"
```

To that value, append this syntax:

```
&$filter=<TableName>/<ColumnName> eq '<Value>'
```

For example, using a value from a list box:

```
"&$filter=Store/Territory eq '" & ListBox1.Selected.Abbr & "'"
```

The parameter will filter a value in the dataset of the report where the tile originates. However, filtering feature has the following limitations:

- Only one filter can be applied.
- Only the `eq` operator is supported.
- Field type must be string.
- Filtering is only available on pinned visualization tiles. It's not supported for pinned reports.
- R and Python script visuals cannot be filtered.

You can use computed fields in the Power BI report to convert other value types to string or combines multiple fields into one.

Key properties

AllowNewAPI - Whether to use the new API when calling the Power BI service. Setting the value to **True** will allow the use of the new Power BI API (which isn't supported in mobile and some embedded scenarios, but allows some more advanced filtering). **False** will use the original API. Default value is **false**.

Dashboard – The Power BI dashboard where the tile comes from.

LoadPowerBIContent – When set to **True**, the Power BI content is loaded and shown. When set to **False**, the Power BI content is unloaded, which releases memory and optimizes performance.

PowerBIInteractions - When set to **True**, the Power BI content can be interacted with, but Power Apps **OnSelect** event won't trigger. When set to **False**, the tile can't be interacted with, but Power Apps **OnSelect** event will trigger when the tile is selected.

Tile – The name of the Power BI tile that you want to display.

Workspace – The Power BI workspace where the tile comes from.

Additional properties

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Height – The distance between a control's top and bottom edges.

OnSelect – Actions to perform when the user selects a control. By default, the Power BI report that's associated with the tile opens.

TileUrl – The URL by which the tile is requested from the Power BI service. To add query string filtering to your URL, see the filtering section above.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen—if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen—if no parent container).

Example

1. On the **Insert** tab, open the **Charts** menu, and then add a **Power BI tile** control.

   Don't know how to add and configure a control?

2. On the **Data** tab of the options panel, select **My Workspace** for the **Workspace** setting.

3. Select a dashboard in the list of dashboards, and then select a tile in the list of tiles.

   The control renders the Power BI tile.

Accessibility guidelines

The **Power BI tile** is simply a container for Power BI content. Learn how to create accessible content with these Power BI accessibility tips.

If the Power BI content doesn't have a title, consider adding a heading using a **Label** control to support screen readers. You can position the label immediately before the Power BI tile.

Radio control in Power Apps

Article • 12/16/2022

An input control that shows multiple options, of which users can select only one at a time.

Description

A **Radio** control, a standard HTML input control, is best used with only a few, mutually exclusive options.

The control can have a horizontal or vertical layout.

Key properties

Default – The value of a control before the user changes it.

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

Layout – Whether the options are laid out vertically or horizontally.

Value – The value of an input control.

Selected – The data record that represents the selected item.

All properties

Align – The location of text in relation to the horizontal center of its control.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

Color – The color of text in a control.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

DisabledBorderColor – The color of a control's border if the control's DisplayMode property is set to **Disabled**.

DisabledColor – The color of text in a control if its DisplayMode property is set to **Disabled**.

DisabledFill – The background color of a control if its DisplayMode property is set to **Disabled**.

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Font – The name of the family of fonts in which text appears.

FontWeight – The weight of the text in a control: **Bold**, **Semibold**, **Normal**, or **Lighter**.

Height – The distance between a control's top and bottom edges.

HoverColor – The color of the text in a control when the user keeps the mouse pointer on it.

HoverFill – The background color of a control when the user keeps the mouse pointer on it.

Italic – Whether the text in a control is italic.

LineHeight – The distance between, for example, lines of text or items in a list.

OnChange – Actions to perform when the user changes the value of a control (for example, by adjusting a slider).

OnSelect – Actions to perform when the user taps or clicks a control.

PaddingBottom – The distance between text in a control and the bottom edge of that control.

PaddingLeft – The distance between text in a control and the left edge of that control.

PaddingRight – The distance between text in a control and the right edge of that control.

PaddingTop – The distance between text in a control and the top edge of that control.

PressedColor – The color of text in a control when the user taps or clicks that control.

PressedFill – The background color of a control when the user taps or clicks that control.

RadioBackgroundFill – The background color of the circles in a radio-button control.

RadioBorderColor – The color of the circle for each option in a radio-button control.

RadioSelectionFill – The color that appears inside the circle of the selected option in a radio-button control.

RadioSize – The diameter of the circles in a radio-button control.

Reset – Whether a control reverts to its default value.

SelectedText (Deprecated) – A string value that represents the selected item.

Size – The font size of the text that appears on a control.

Strikethrough – Whether a line appears through the text that appears on a control.

TabIndex – Keyboard-navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Underline – Whether a line appears under the text that appears on a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Distinct(*DataSource, ColumnName*)

Example

1. Add a **Radio** control, name it **Pricing**, and set its **Items** property to this formula:

   ["Standard", "Premium"]

   Don't know how to add, name, and configure a control?

2. Add a **Label** control, move it below the **Radio** control, and set the **Text** property of the **Label** control to this formula:

   If("Premium" in Pricing.Selected.Value, "$200 per day", "$150 per day")

   Want more information about the **If** function or other functions?

3. While holding down the Alt key, select either option in the **Radio** control.

   The **Label** control shows the appropriate text for your choice.

4. (optional) While holding down the Alt key, select the other option to confirm that the appropriate text appears.

Accessibility guidelines

Color contrast

In addition to the standard color contrast requirements, ensure adequate color contrast between:

- **RadioSelectionFill** and **RadioBackgroundFill**
- **RadioBackgroundFill** and **Fill**

Screen-reader support

- Ensure that every option has a **Value**.
- Consider adding a **Label** immediately before the **Radio** control to serve as the heading.

Keyboard support

- Set the **TabIndex** property to zero or greater so that keyboard users can navigate to it.
- Set the **FocusedBorderColor** and **FocusedBorderThickness** properties so that focus indicators are clearly visible.

Rating control in Power Apps

Article • 12/16/2022

A control with which users can indicate a value between 1 and a maximum number that you specify.

Description

In this control, the user can indicate, for example, how much they liked something by selecting a certain number of stars.

Key properties

Default – The initial value of a control before it is changed by the user.

Max – The maximum value to which the user can set a slider or a rating.

Additional properties

AccessibleLabel – Label for screen readers.

BorderColor – The color of a control's border.

BorderStyle – Whether a control's border is **Solid**, **Dashed**, **Dotted**, or **None**.

BorderThickness – The thickness of a control's border.

DisplayMode – Whether the control allows user input (**Edit**), only displays data (**View**), or is disabled (**Disabled**).

Fill – The background color of a control.

FocusedBorderColor – The color of a control's border when the control is focused.

FocusedBorderThickness – The thickness of a control's border when the control is focused.

Height – The distance between a control's top and bottom edges.

OnChange – Actions to perform when the user changes the value of a control (for example, by adjusting a slider).

OnSelect – Actions to perform when the user taps or clicks a control.

RatingFill – The color of the stars in a rating control.

ReadOnly – Whether a user can change the value of a slider or rating control.

Reset – Whether a control reverts to its default value.

ShowValue – Whether a slider's or rating's value appears as the user changes that value or hovers over the control.

TabIndex – Keyboard navigation order in relation to other controls.

Tooltip – Explanatory text that appears when the user hovers over a control.

Visible – Whether a control appears or is hidden.

Width – The distance between a control's left and right edges.

X – The distance between the left edge of a control and the left edge of its parent container (screen if no parent container).

Y – The distance between the top edge of a control and the top edge of the parent container (screen if no parent container).

Related functions

Average(*Value1*, *Value2*, ...)

Example

1. Add a **Rating** control, and name it **Quantitative**.

   Don't know how to add, name, and configure a control?

2. Add a **Text input** control, name it **Qualitative**, and move it below the **Rating** control.

3. Set the **Default** property of the **Text input** control to "", and set its **HintText** to this formula:
   If(Quantitative.Value > 3, "What did you especially like?", "How might we do better?")

   Want more information about the **If** function or other functions?

4. Press F5, and then click or tap either four or five stars in the **Rating** control.

The hint text in the **Text input** control changes to reflect the high rating.

5. Click or tap fewer than four stars in **Quantitative**.

   The hint text in the **Text input** control changes to reflect the low rating.

6. To return to the default workspace, press Esc.

Accessibility guidelines

Color contrast

There must be adequate color contrast between:

- **RatingFill** and **Fill**

This is in addition to the standard color contrast requirements.

Screen reader support

- **AccessibleLabel** must be present.

  > ⓘ **Note**
  >
  > Screen readers treat the **Rating** control as radio buttons.

Keyboard support

- **TabIndex** must be zero or greater so that keyboard users can navigate to it.
- Focus indicators must be clearly visible. Use **FocusedBorderColor** and **FocusedBorderThickness** to achieve this.
- Consider using a different control if there are too many stars. It can be tedious to navigate with a keyboard and difficult to select accurately with a touch screen.

  > ⓘ **Note**
  >
  > The same keyboard interactions for radio buttons can be used on **Rating**.

Rich text editor control in Power Apps

Summarize this article for me

Let users format text in a WYSIWYG editing area. The output format is HTML.

Description

The **Rich text editor** control lets the app user format text in a WYSIWYG editing area.

The input and output format is HTML, but the control isn't an HTML editor. The editor removes script, style, object, and unsupported HTML elements and attributes.

Supported features include:

- Bold, italic, and underline
- Text and highlight color
- Text size
- Numbered and bulleted lists
- Hyperlinks
- Clear formatting

To use the control in a form, select the **Edit multi-line text** card, then customize it by inserting the RTE control.

Key properties

Default – Input property for the initial text value shown in the editor

HtmlText – Output property for the resulting rich text in HTML format

Additional properties

AccessibleLabel – Label for screen readers. Should describe the purpose of the attachments.

DisplayMode – Whether the control lets you add and delete files (**Edit**), only shows data (**View**), or is disabled (**Disabled**).

EnableSpellCheck – Whether the browser spell checker is enabled. This feature only checks spelling in the browser's default language. Power Apps for Windows doesn't support this property.

Height – The distance from the control's top edge to its bottom edge.

TabIndex – Keyboard navigation order in relation to other controls.

Visible – Whether a control is visible or hidden.

Width – The distance from the control's left edge to its right edge.

X – The distance from the control's left edge to the left edge of its parent container, or the screen if there's no parent container.

Y – The distance from the control's top edge to the top edge of its parent container, or the screen if there's no parent container.

Accessibility guidelines

Screen reader support

- Make sure AccessibleLabel is present.

Keyboard support

- Set TabIndex to zero or greater so keyboard users can navigate to it.

> **Tip**
>
> Select `Alt` + `0` while the editor is focused to learn about other keyboard shortcuts.

> **Note**
>
> When the toolbar is focused, select `Tab` or `Shift` + `Tab` to move between toolbar groups. You can't cycle back from the last group to the first group or vice versa.

Limitations

Appearance isn't guaranteed when working with other products

When you use rich text across different products, it might not look exactly the same.

- You can paste rich text from web pages, Microsoft Word, and other apps. However, the appearance might differ depending on the capabilities of the device, browser, and external source.
- Similarly, if you create rich text outside of canvas apps, it might look slightly different because built-in styles of the other app aren't present.
- If you embed the canvas app in another app, the host app might override the styles of the rich text. For example, when you use a canvas app as a custom page in a model-driven app, the host app removes list styles. Bulleted lists don't show bullet points in a custom page.

Sometimes, you might want rich text to display differently based on where it's shown. For example, the primary font might be different in another product, or the text color might change when the user enables dark mode. For a consistent display, compose and show rich text in canvas apps only.

Pasted images may not appear consistently

A pasted image might appear in a browser but not in a mobile app. Or it might appear intermittently or not at all. These are signs that the pasted image isn't supported because of:

- Cross-Origin Resource Sharing (CORS). The image host blocks the image from loading on Power Apps.
- Authentication. The image isn't publicly accessible and can only be accessed after you sign in to the image host.
- Image format support. Common image formats like jpg and png are supported, but less common types might not be supported by the browser or device.

Browsers or devices can represent images in rich text differently. Some copy the image as raw data, while others might simply reference the image's URL. Image URLs might not be accessible for the reasons above.

> **Tip**
>
> Use a screen clipping or screenshot tool to copy and paste images for the best results.

When editing an app, Alt key doesn't allow interaction with the control

In Power Apps Studio, pressing Alt key for quick interaction doesn't work. You can only interact with the rich text editor when previewing the app.

Hyperlinks don’t open in view mode

In view mode, the rich text editor can’t open hyperlinks while the app is running. This is a known limitation of the current editor.

Screen control in Power Apps

Article • 11/14/2024

A UI element that contains one or more other controls in an app.

Description

Most apps have multiple **Screen** controls that contain **Label** controls, **Button** controls, and other controls that show data and support navigation. For information about how to add a screen, reorder screens, and configure navigation, review Add a screen.

Key properties

BackgroundImage – The name of an image file that appears in the background of a screen.

Fill – The background color of a control.

Additional properties

Height - The height of the screen. If the app is responsive (**Scale to fit** is **Off**) and the device on which the app is running is shorter than this property, the screen can scroll vertically.

ImagePosition – The position (**Fill**, **Fit**, **Stretch**, **Tile**, or **Center**) of an image in a screen or a control if it isn't the same size as the image.

LoadingSpinner (**None**, **Controls** or **Data**) - When None, spinner will not be shown. When Controls | Data, will show spinner until all child controls at the screen level are visible. **Note. Nested controls are not considered.**

LoadingSpinnerColor - The fill color of the loading spinner.

Name - The name of the screen.

OnHidden – The behavior of an app when the user navigates away from a screen. If the **Disable non-blocking App.OnStart** rule is enabled in app settings, this property may need to wait until **App.OnStart** is finished executing. By default, this setting is turned on.

OnVisible – The behavior of an app when the user navigates to a screen. Use this property to set up variables and preload data used by the screen. Use the **App.OnStart**

property for set up once when the app is started. If the **non-blocking App.OnStart** is enabled, the **Screen.OnVisible** event can run parallel with it. As a result, it's recommended to refrain from relying on variables or collections that are initialized by **App.OnStart**, as they might not be fully initialized.

Orientation - The orientation of the screen. If its **Width** is greater than its **Height**, the orientation will be **Layout.Horizontal**; otherwise, it will be **Layout.Vertical**.

Size - A positive integer that classifies the size of the screen. The classification is determined by comparing the screen's **Width** property to the values in the App.SizeBreakpoints property. The **ScreenSize** type consists of four values (**Small**, **Medium**, **Large**, and **ExtraLarge**) that correspond to the integers 1 through 4.

Width - The width of the screen. If the app is responsive (**Scale to fit** is **Off**) and the device on which the app is running is narrower than this property, the screen can scroll horizontally.

Related functions

Distinct(*DataSource, ColumnName*)

Example

1. Add a Radio control, name it **ScreenFills**, and set its Items property to this value:

   ```
   ["Red", "Green"]
   ```

   Don't know how to add, name, and configure a control?
