- **New:** These features are new and generally available (GA), fully supported, and documented. Generally these features are on by default for new apps, but might take time to deploy everywhere. Enable for existing apps on your own schedule.
- **Preview:** These features are almost done and will be **New** soon. But at this stage there still might be some changes made. This stage is the last opportunity for feedback. These features are generally turned off by default and are documented. These features aren't GA, shouldn't be used in production, and are covered by the Preview terms of service.
- **Experimental:** An early stage "Preview," these features truly are experiments and might never reach GA. We're assessing the value proposition and design of the feature, and the feature might radically change or be removed completely at any time. These features are off by default and aren't generally documented. These features aren't GA, shouldn't be used in production, and are covered by the Preview terms of service.
- **Retired:** These features are GA features but are on their way to being removed from the product. They're still fully supported and document, but we either have a new, better way

to do the same thing or usage is low. Disable for existing apps on your own schedule. Generally, these features are off by default.

How long does a feature remain in each stage? It varies from feature to feature. We look at many factors, including the number of apps that use the feature, the number of issues reported, and how urgently the feature is needed. Features can remain in a stage for weeks to many months. We might also skip some stages if we don't believe it would be helpful.

New

Enable **New** features for all your new apps, and enable for existing apps when you're ready.

New features are recently added to the product. They're generally available and fully supported. You can use **New** features with confidence.

In general, **New** features are enabled by default when you create a new app. When a **New** feature is first introduced, it might not be enabled in all regions initially, allowing us time to deploy and gather information on usage and any problems. If you run into a problem with a feature, the switch can be used as a workaround to disable it until we can correct the problem.

Eventually, **New** features are no longer "new". If there's no breaking change, the switch is removed and the feature is enabled for all apps. If there's a breaking change, the old behavior is available in the app settings under **Retired** as a disable switch.

New features are fully documented in the Power Apps documentation.

Preview

Enable **Preview** features if you want to test upcoming functionalities before the feature is enabled for everyone.

Preview features are well on their way to being a valued part of the product. But, they aren't generally available yet and aren't fully supported, instead offered under the preview terms of service. **Preview** features shouldn't be used in production.

In general, **Preview** features aren't enabled by default when creating a new app. You should only enable a **Preview** feature for testing purposes and to provide feedback before the feature becomes generally available. This stage is the last stop for feedback before the feature is finalized.

Generally, **Preview** features graduate to **New**.

Preview features are documented in the Power Apps documentation. Use the Power Apps Experimental Features forum or Power Apps blog for more information. Use the "Experimental" forum as many **Preview** features start out as **Experimental** features and there may already be information or comments there that can be helpful to you.

Provide feedback on **Preview** features in the Power Apps Experimental Features forum. Again, "Experimental" also covers **Preview** features in the forum.

Experimental

Enable **Experimental** features if you're an early adopter, see something useful to you, and would like to help test the feature.

Experimental features are in an early-stage preview that is true to the name "experiment". This feature might significantly change or be removed at any time. These features are far from being generally available, aren't fully supported, and are offered under the preview terms of service. **Experimental** features shouldn't be used in production.

Experimental features are never enabled by default when creating a new app. You should only enable an **Experimental** feature for testing purposes and to provide feedback. If you don't know what the feature is referring to or its possible impact, you likely shouldn't turn it on.

Eventually **Experimental** features either graduate to **Preview** or are removed from the product.

Experimental features typically aren't documented. The short description in the **App settings** pane might be the only information about them. Use the Power Apps Experimental Features forum or Power Apps blog for more information.

Provide feedback on **Experimental** features in the Power Apps Experimental Features forum.

Retired

Enable **Retired** features only if you need an old behavior. When appropriate, disable these features in your existing apps.

Retired features, while fully supported and widely available, might be phased out in favor of newer, improved methods or due to low usage. Maintaining every feature alongside ongoing product updates incurs overhead.

When a feature moves from **New** to **Retired**, the meaning of its switch is often inverted. For example, where "Delayed load" was on by default as a **New** feature, the **Retired** version becomes "Disable delayed load" and is off by default.

Retired features are generally not enabled when creating a new app. They're provided for existing apps that still depend on the old behavior.

Retired features will eventually be removed from the product after enough time has passed and usage is low. Removals are well communicated ahead of time for breaking changes.

Retired features are fully documented in the Important changes (deprecations) coming in Power Platform.

Defaults

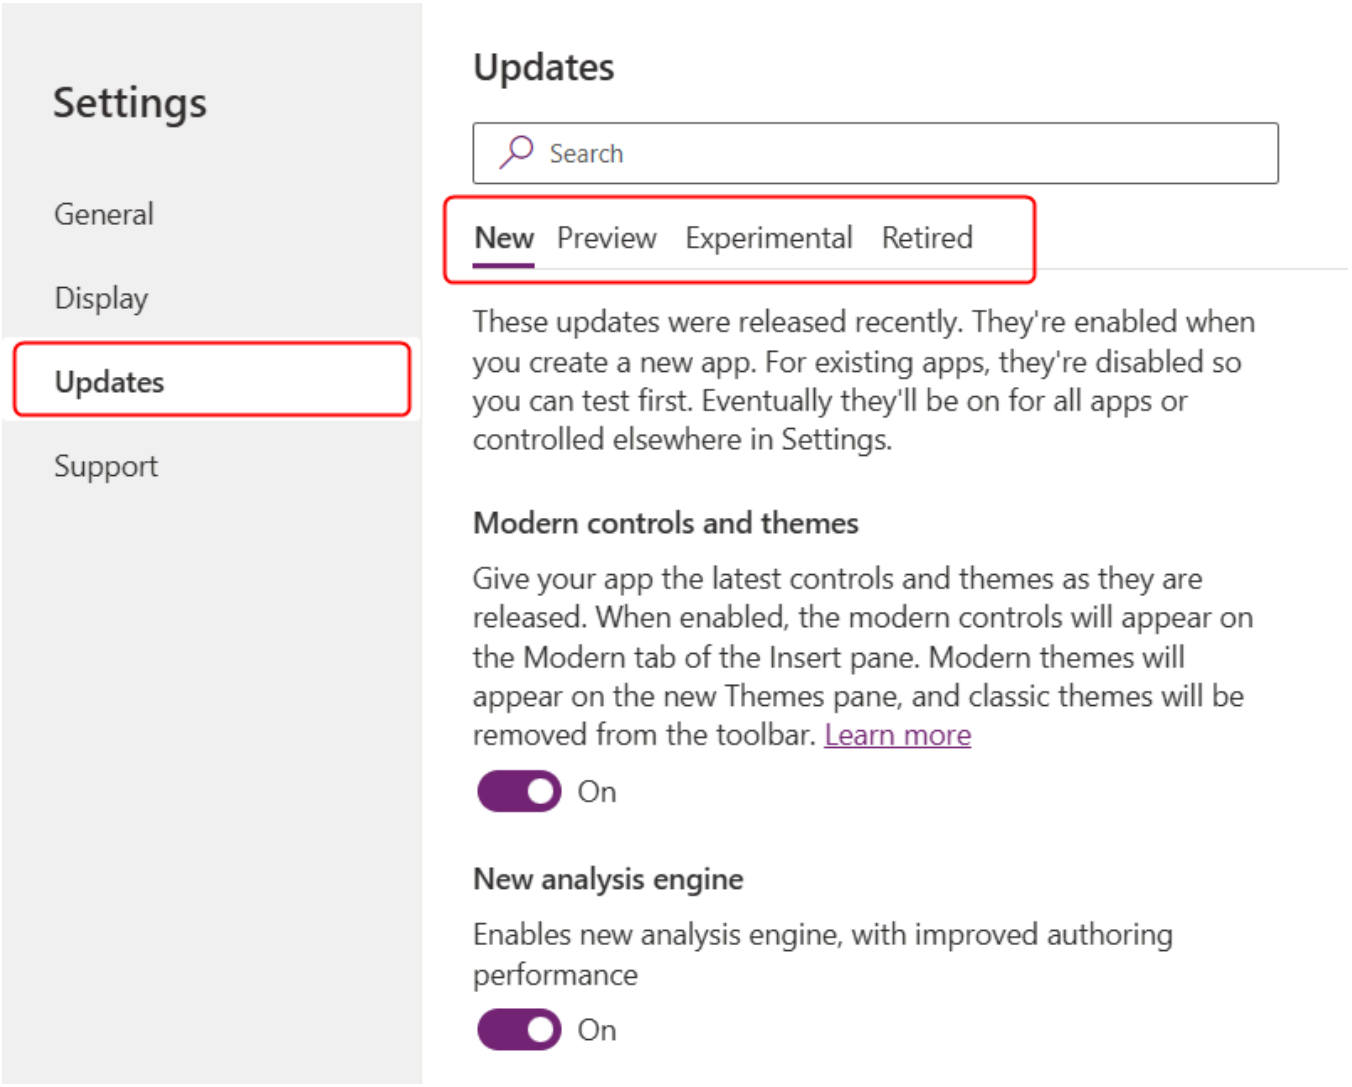
In general, when creating a *new* app:

- **New switches are On.** These features are generally available and fully supported. There might be a small delay for the switch to be turned on by default as we continue rolling out.
- **Preview switches are Off, but can be enabled for testing and feedback.** Enable the features that are interesting to you before they're enabled for all apps, for testing and feedback. Preview features aren't ready for production.
- **Experimental switches are Off.** These features are for early adopters and should only be used with caution; they can be changed or removed at any time. Experimental features aren't ready for production.
- **Retired switches are Off.** These features are generally available and fully supported, but will eventually be removed from the product. Avoid using these features.

As *existing* apps go through their lifecycle, you might want to take advantage of new features or to remove dependencies on retired features by adjusting these switches in your app. Turning **New** switches On and **Retired** switches Off brings existing apps into alignment with new apps and the future of the product.

Controlling which features are enabled

Experimental and preview features are listed in the app's **Settings** > **Updates**. From within the app, select **Settings**, and then select **Updates**. Select **New**, **Preview**, **Experimental**, or **Retired** features using the available tabs.



Each feature has a toggle switch. **Off** generally means that the feature is disabled, except in the **Retired** section where the title of the feature indicates if the switch disables the feature.

In some cases, you might need to close and reopen the app after you change a setting. The feature description should indicate when you must perform this step.

At the top of the **Settings** panel, **General** settings provide control over fully shipped, generally available features that don't belong in any of these feature categories and are a stable part of the product. We limit the number of these settings as much as possible to keep things simple and to reduce the size of our testing matrix.

These settings are specific to each app, so changing a toggle switch affects only the app that's currently open. If you create an app, these switches revert to their default settings for that app.

Preview and Experimental features without a switch

Sometimes a tag is added in the product to indicate that a particular feature is Preview or Experimental without having a switch in **Updates**. For example, a control in an **Insert** menu

might have the name **Grid (Preview)** or the entry point for the Monitor was once **Monitor (Preview)**. In these cases, the feature can't be used without first seeing this tag.

Like the **Preview** and **Experimental** feature categories previously described, these features shouldn't be used in production and are offered under the preview terms of service.

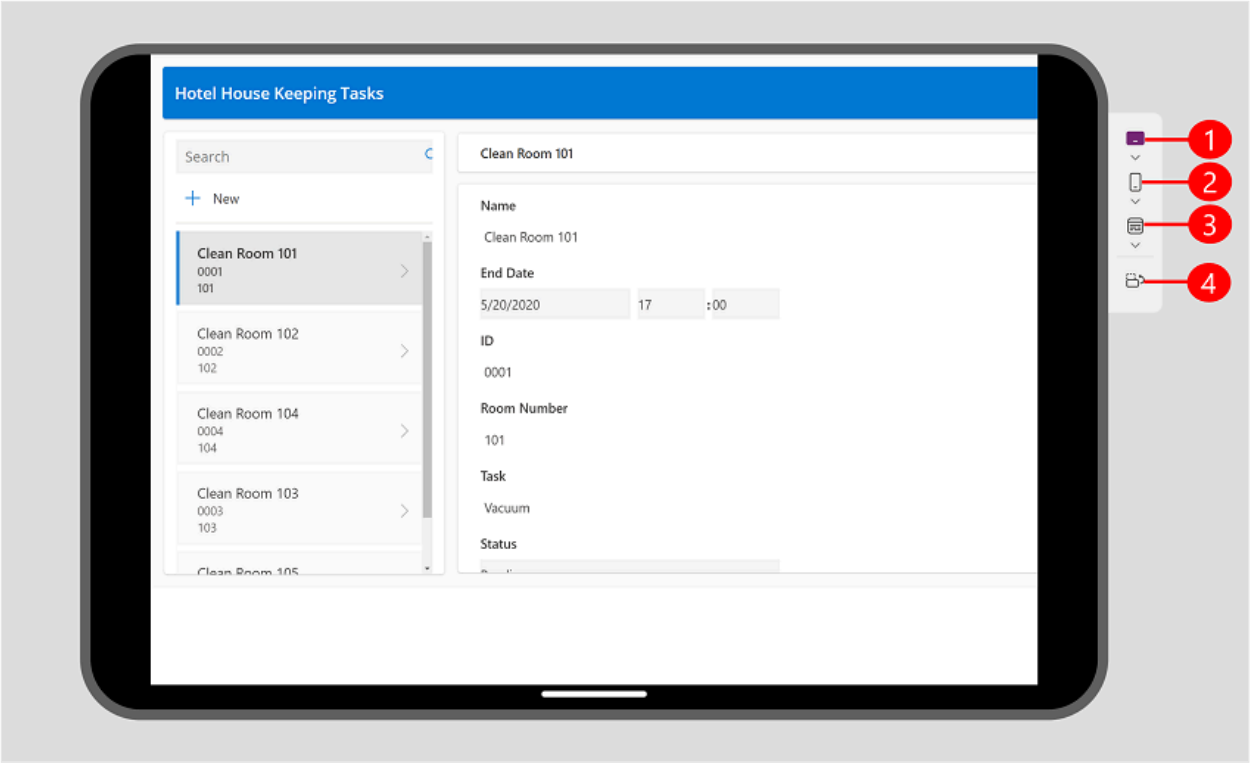
Preview an app

Article • 05/19/2023

When you create an app, it's helpful to preview your app and see how it will look for your users. Use the preview app feature to see how your app appears on various devices and in different sizes. Previewing an app is especially beneficial when you're building a responsive app.

To preview an app, open the app for editing in Power Apps Studio, in the actions menu, select **Preview the app**.

Use the preview options to see how your app looks on different devices using the device picker.



Legend:

1. **Tablet Devices**: Allows you to select from common tablet devices from several manufacturers, along with the ability to select a custom size based on your needs. This option shows a device frame and device safe zone, which is shown as the black area either on the top and bottom or sides depending on the orientation of the device. It also shows a black area with the home bar at the bottom.
2. **Mobile devices**: Lets you select from common phones from different manufacturers, along with the ability to select a custom size based on your needs. This option shows a device frame and device safe zone, which is shown as the

black area either on the top and bottom or sides depending on the orientation of the device. It also shows a black area with the home bar at the bottom.

3. **Web view**: See how your app looks like on a web browser. You can select a window size to fill the browser window, or you can select canvas size to see how the app looks while authoring without leaving the preview.
4. **Orientation Switcher**: Switch between vertical and horizontal orientation. The **Orientation Switcher** option is disabled if the **Lock Orientation** setting turned on.

If you're developing a responsive app, the content within the app adjusts to fit the screen size of the device being used.

Watch this video to learn how the device picker helps you confirm that your app is adjusting correctly.
https://learn-video.azurefd.net/vod/player?id=6fb4ee34-2393-4bf2-b3b9-749b8a7cd257&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fpreview-app

Display settings

The way your app behaves with each preview option is determined by app type and your display settings.

- If an app is created using the phone layout, you can still preview it on the web and tablet devices using the device picker. However, if an app isn't created using a responsive layout, it then appears in a phone shape on the web and selected tablet device. You get a message explaining why the preview is narrow. If you'd like an app to be responsive to phone, tablet, and web sizes then we recommend selecting the tablet option when you create an app. You can use responsive auto layout containers to determine the flow of the content for different screen sizes including phones. More information: Building responsive canvas apps

- Under Display settings:
  - **Scale To Fit**: When set to **On** your entire app is scaled to fit the available space. If a smaller space is available to the app, you may notice empty space on the sides to accommodate the scaling. When a user plays the app, they will also see the empty space.
  - **Lock Orientation**: When set to **On**, the **Switch Orientation** button in the device picker is disabled.

Known Issues

- If **Scale To Fit** setting is on and **Lock Aspect Ratio** is off, your preview won't be accurate. This configuration isn't recommended. More information: Change screen size and orientation of canvas apps
- If **Scale to Fit** is off and you resize your browser window while in preview mode, the preview won't be accurate. To address the issue, close and reopen the preview once your browser window is in the desired size.

Save and publish canvas apps

When you save changes to a canvas app, you save those changes for yourself and anyone else who can edit the app. To make your changes available to everyone the app is shared with, publish the app.

What you'll learn:

- How to save your app with different options
- How to turn AutoSave on or off
- How to publish your app to share changes with users
- How to identify and manage app versions

For more information about sharing an app, see Share an app.

Save your app

Open your app for editing in Power Apps. Save your work in several ways:

- Select **Save** to save any unsaved changes to your app. Each time you save, a new version appears in the app version history.

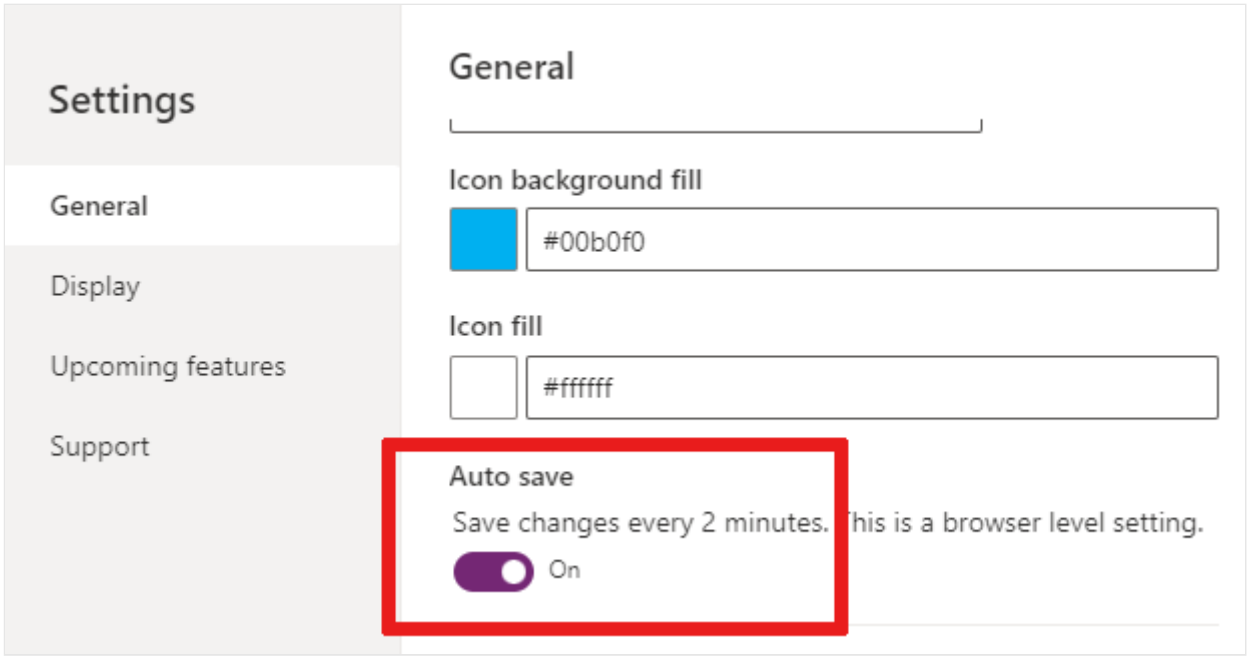
- In the dropdown menu, choose one of the following options:
  - **Save with version notes**: Save and add notes about your update.
  - **Save as**: Duplicate the app with a different name.
  - **Download a copy**: Download a local copy of the app.

Turn AutoSave on or off

Power Apps saves your work automatically every two minutes.

1. On the command bar, select **Settings**, and then go to the **General** tab.

2. In the **Auto save** section, set the **Auto save** toggle to **On** or **Off**.



> [!NOTE]
> - When you publish a canvas app, your app updates and runs on the latest version of Power Apps. Your app gets all the latest features and performance upgrades added since you last published. If you haven't published an update in several months, you see an immediate performance benefit when you republish the app.
> - To retrieve app details faster during startup, some data stores locally on user devices in the browser cache. Information stored includes app environment and connection details. This data stays in the browser based on browser storage limits. Users can clear stored data based on these instructions for each browser.

Publish your app

1. On the command bar, select **Publish**. If the app isn't saved, you're prompted to save it. After you save it, select **Publish** again.

2. Enter your app's description, and then select **Publish this version**.

Create an app description with Copilot (preview)

If your app is in a managed environment, you can use AI to help create a description for your app.

In the **Publishing** dialog box, select **Create descriptions using AI** when you save and publish your app.

You can also generate an app description by going to **Settings** > **General**. Under **Description**, select **Create descriptions using AI**.

Admins can disable this feature for managed environments in Power Platform admin. For more information, see Managed Environments panel.

> **Note**
>
> If you don't add a description before publishing the app, Copilot generates one after the app is published. Makers can edit this description if Copilot doesn't generate it correctly.

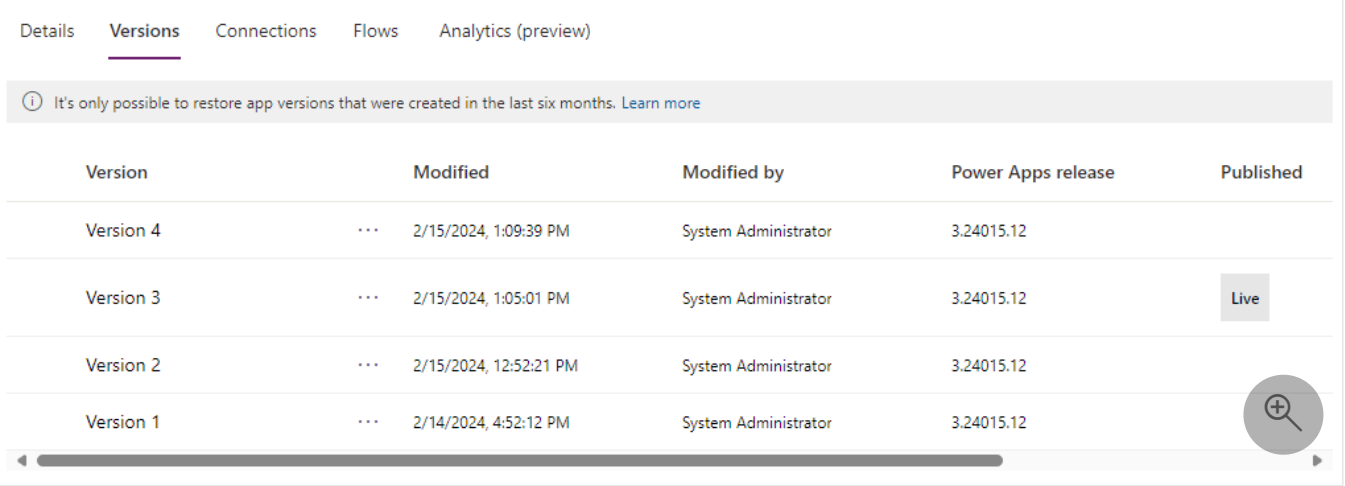
> **Important**
>
> - To use this capability, your app must be in a **managed environment**.
> - Preview features aren't meant for production use and can have restricted functionality. These features are available before an official release so customers get early access and provide feedback.
> - For more information, go to our **preview terms**.
> - This capability is powered by **Azure OpenAI Service**.
> - This capability isn't available in all regions yet and can be subject to usage limits or capacity throttling.
> - To learn about capabilities and limitations of AI-powered and Copilot features in Power Apps, see **Responsible AI FAQs for Power Apps**.

Identify the live version

To see all versions of an app:

1. Go to Power Apps, and in the navigation pane, select **Apps**.
2. Select the **Commands** icon ⋮ next to the app name.
3. Select **Details** > **Details**.
4. Go to the **Versions** tab.

The **Live** version is published for everyone the app is shared with. Only users with edit permissions can use the most recent version of the app.



To publish the most recent version, select the publish icon while editing your app.

> **Note**
>
> - New published changes to an app can take a few seconds to show when you launch the app. Publish time depends on the app's complexity, and it can take a few more minutes to finish.
> - If you already have an app open when a new version is published, reload the app to get the latest changes.
> - To reduce wait time when using your app, the app preload capability is on. You can turn it off. For more information, see Overview of creating performant apps.

In-app notifications for an updated version of the app

When users wait for an app to update, they see a notification that says **A new version of this app is coming. We'll let you know when it's available.**

When the published changes are ready, users see a notification that says **You're using an old version of this app. Refresh to use the latest version.** Users select the **Refresh** button to get the latest version of the app.

Notification availability

Expand table

Scenario	Availability
Canvas app on web	Generally available
Customized SharePoint forms	Not available
Canvas app embedded in Teams	Not available
Canvas app embedded in Power BI	Not available
Power Apps web part	Not available
Canvas app embedded in an iframe	Generally available

Next steps

- Run the app in a browser or on a phone.
- Rename an app from Power Apps.
- Restore an app if you have more than one version of the app.

Last updated on 01/14/2026

Share a canvas app with your organization

10/10/2025

When you create a canvas app, you can define which users in your organization can use the app, modify it, and even re-share it. You can specify individual users by name or designate a security group in Microsoft Entra ID.

Prerequisites

Before you share an app, you must save it (not locally) and then publish it.

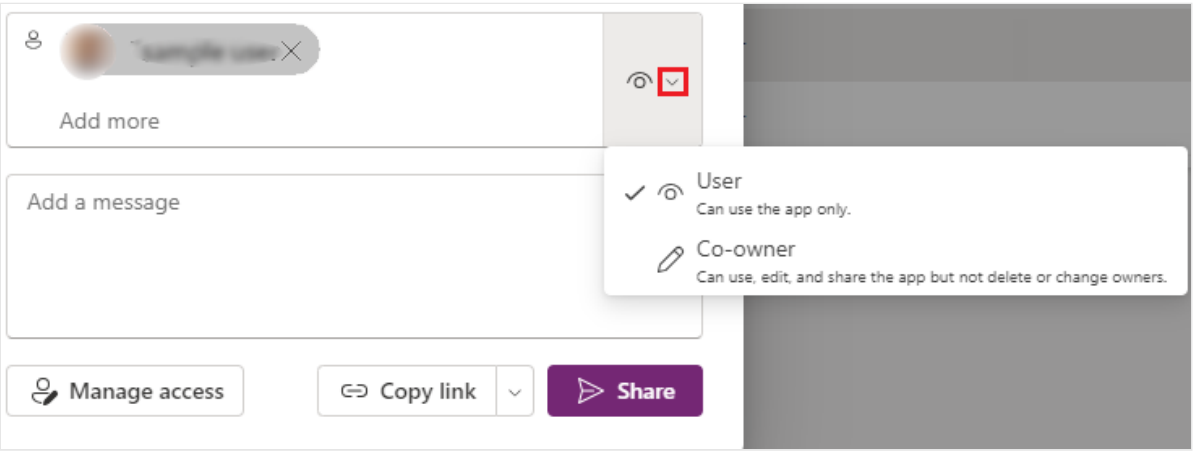
- Give your app a meaningful name and a clear description, so that people know what your app does and they can easily find it in a list. Select **Settings** > specify a name, and then enter a description.
- Whenever you make changes, you must save and publish the app again if you want others to see those changes.

> **Important**
>
> For a shared app to function as you expect, you must also manage permissions for the data source or sources on which the app is based, such as Microsoft Dataverse or Excel. You might also need to share other resources on which the app depends, such as flows, gateways, or connections.

Share an app from Power Apps

1. Sign in to Power Apps.
2. On the left navigation pane, select **Apps**.
3. Select the app that you want to share.
4. On the command bar, select **Share**. Or select the **Commands** menu next to your app name and then select **Share**.
5. In the **Share** dialog box, type the names or alias of the user or security groups in Microsoft Entra ID.
6. Select the down arrow to choose permissions for the app. Options include:
    - **User**: Can use the app only.

- **Co-Owner**: Can use, edit, and share the app but not delete or change owners.



- If your app connects to a Dataverse table, the permissions dropdown will display a **More security roles** option. Select the appropriate security roles, and those roles will be automatically assigned to users when you share the app.

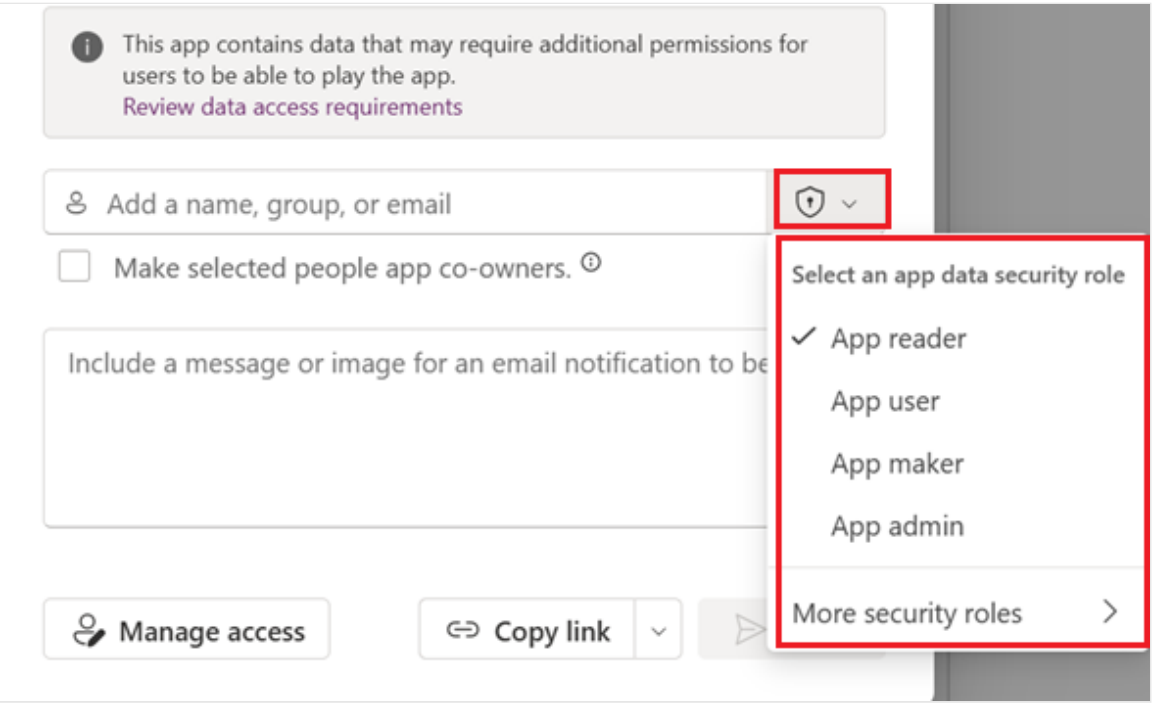
- If your admin enabled app level security roles in Power Platform Admin, makers with the **System Administrator** security role can give collaborators app-level privileges when sharing. Makers assign privileges from the security role picker, with App reader, App user, App maker, or App admin as the security role options. To edit assigned security roles, unshare and reshare the app to assign the appropriate security role under Manage Access.

    - **App reader**: This role gives read privilege for both user or team owned tables and org owned tables.

    - **App user**: This role gives full access to only their own records in user or team owned tables, and read privilege to org owned tables.

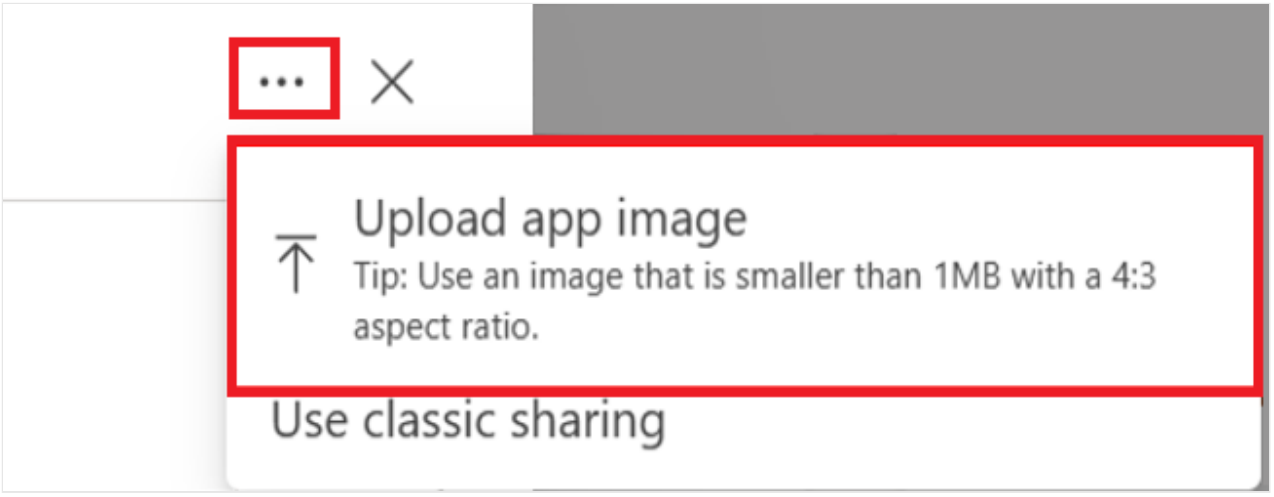
    - **App maker**: This role gives create and read privilege for all records in user or team owned tables, but only write, delete, assign, share, append, and append to privileges for their own records in user or team owned tables. Additionally, it gives read privilege to org owned tables.

    - **App admin**: This role gives full access to all records in user or team owned tables and org owned tables.

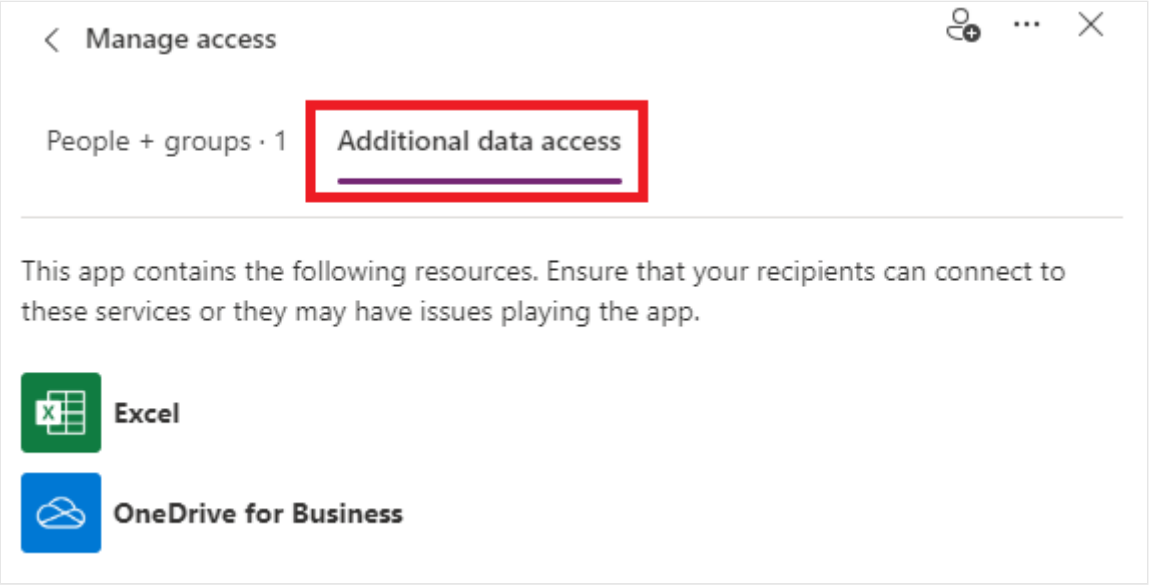


7. Optional steps:

- Select the **overflow menu (...)** at the top-right corner and then select **Upload app image** to include an image of the app in the email.



- Select **Manage access** to displays app access details, including current users and co-owners. You can also edit user access and assign security roles here. The **Additional data access** tab shows app connections to data sources like Dataverse tables or Excel files on OneDrive for Business. To manage security roles for data sources other than Dataverse, such as Excel files on OneDrive, ensure you share these data sources with the app users.



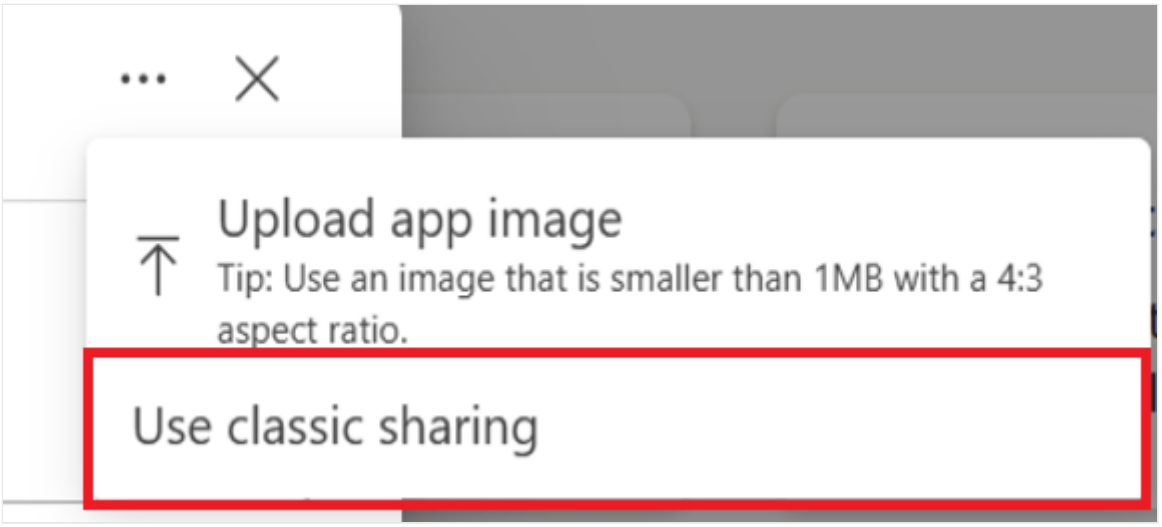
8. Add an optional message and then select **Share**.

> **Note**
>
> - To learn about sharing apps outside of your organization, see Share a canvas app with guest users.
> - To learn about sharing limits applicable to canvas apps in managed environments, see Sharing limits.

Classic app sharing experience

You can still use the classic app sharing experience by selecting the classic sharing option.

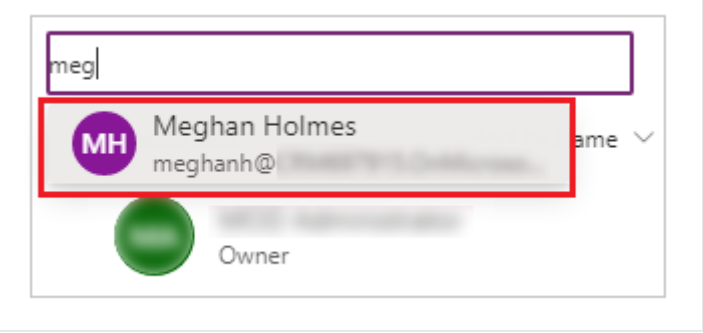
1. Sign in to Power Apps.
2. On the left navigation pane, select **Apps**.
3. Select the app that you want to share.
4. On the command bar, select **Share**. Or select the **Commands** menu next to your app name and then select **Share**
5. Select the **overflow menu (...)** at the top-right corner and then select **Use classic sharing**.



6. Specify the name or alias the users or security groups in Microsoft Entra ID with whom you want to share the app.

   You can share an app with a list of aliases, friendly names, or a combination of those (for example, **Meghan Holmes <meghan.holmes@contoso.com>**) if the items are separated by semicolons.

   If several people have the same name but different aliases, the first person found is added to the list. A tooltip appears if a name or alias already has permission or can't be resolved.

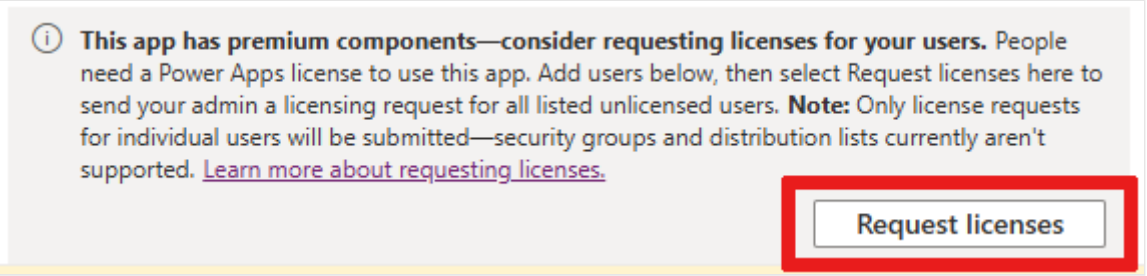


> **Note**
>
> You can't share an app with a distribution group in your organization or with a group outside your organization.

> **Important**
>
> To avoid degraded experiences, use a security group when sharing the app with over 100 users.

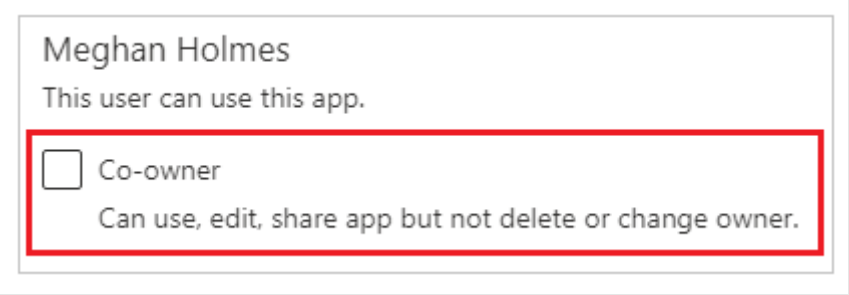
7. If your app contains premium components, such as a map or address input, users must have a Power Apps license to use the app. To request licenses for the users of your app,

select **Request licenses**, which submits the request to your admin.



> **Note**
>
> You can't request licenses for security groups or distribution lists. For more information about requesting licenses, see Request Power Apps licenses for your app users.

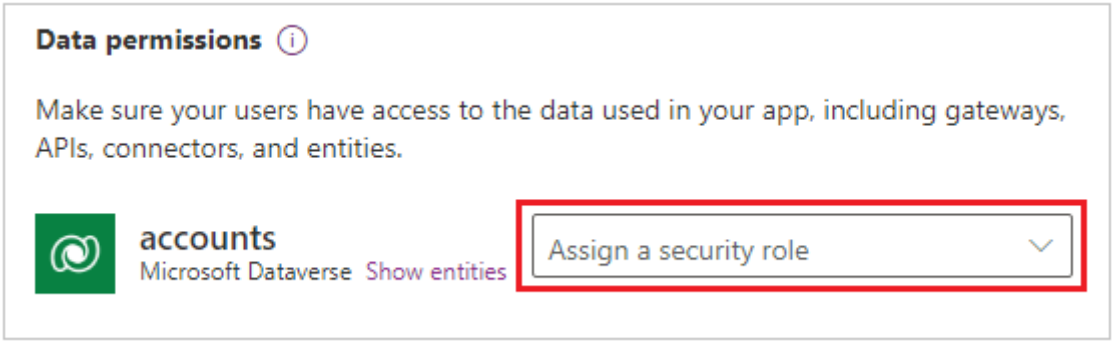
8. If you want to allow users to edit and share the app, select the **Co-owner** check box.



In the sharing interface, you can't grant Co-owner permission to a security group if you created the app from within a solution. However, its possible to grant co-owner permission to a security group for apps in a solution by using the Set-PowerAppRoleAssignment cmdlet.

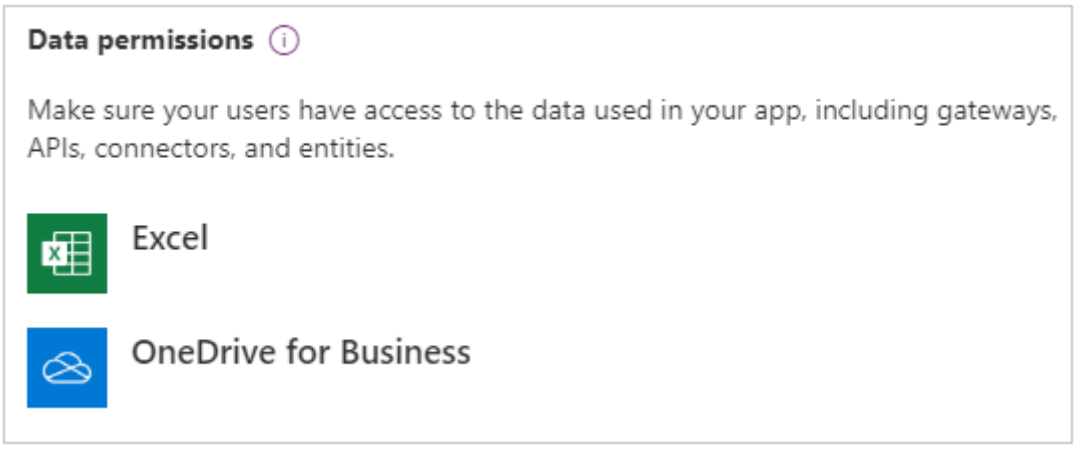
9. If your app connects to data for which users need access permissions, specify security roles as appropriate.

   For example, your app might connect to a table in a Dataverse database. When you share such an app, the sharing panel prompts you to manage security for that table.



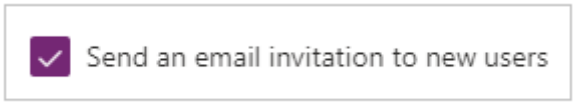
For more information about managing security for a table, go to Manage table permissions.

If your app uses connections to other data sources—such as an Excel file hosted on OneDrive for Business—ensure that you share these data sources with the users you shared the app with.



For more information about sharing canvas app resources and connections, go to Share canvas app resources.

10. If you want to help people find your app, select the **Send an email invitation to new users** check box.



11. At the bottom of the share panel, select **Share**.

Users can now run the app by using Power Apps Mobile on a mobile device or from AppSource on Microsoft 365 in a browser. Co-owners can edit and share the app in Power Apps.

If you sent an email invitation, users can also run the app by selecting the link in the invitation email:

- If a user selects the **Open the app** link on a mobile device, the app opens in Power Apps Mobile.
- If a user selects the **Open the app** link on a desktop computer, the app opens in a browser.
- If a user selects the **Microsoft Teams** link, the app opens in Microsoft Teams.

If you selected **Co-owner** while sharing, the recipients will see a link for **Power Apps Studio** that will open the app for editing using Power Apps Studio.

To change permissions for a user or a security group

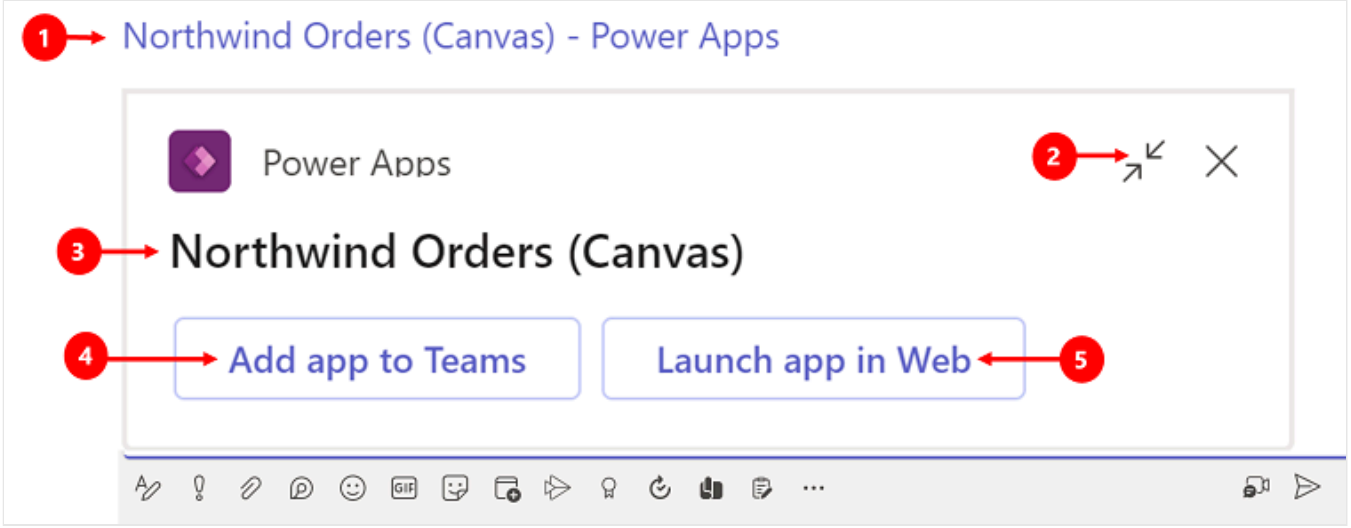
- To allow co-owners to run the app but no longer edit or share it, clear the **Co-owner** check box.
- To stop sharing the app with that user or group, select the **Remove** (x) icon.

Share apps using Teams

You can share a link to your app in a Teams chat. The user that you share the app with needs to be on the same tenant and have access to the app that you're sharing.

> ⓘ **Note**
>
> - To add canvas apps to Teams using the web player:
>   - Your organization must have **Allow interaction with custom apps** turned on. More information: Manage custom app policies and settings in Microsoft Teams
>   - Your organization must allow **Shared Power Apps**. More information: Manage Microsoft Power Platform apps in the Microsoft Teams admin center
> - If you're the sender or receiver and get a **This app cannot be found** error when you select **Add app to Teams**, this means you don't have access to the app. To get access, contact your admin.
> - If you're the sender and you don't have the Power Apps personal app installed in Teams, then a preview card will appear with a **Show Preview** button. To unfurl the full adaptive card, select **Show Preview**.

To share the app, copy the app link from your web browser and paste it into the Teams chat. Before you send the link, you'll see a preview of your message.



Legend:

1. **Link to app**: Select the web link to open the app.
2. **Collapse preview**: Select to close the preview. When you collapse the preview then the user that you send the link to will only get a web link to open the app. They won't see the buttons to add the **App to Teams** or **Launch app in web**.
3. **Name of app**: Shows the name of the app.
4. **Add app to Teams**: Select to add the app to Teams.
5. **Launch app in Web**: Open the app directly in your browser.

Request licenses for your users

When sharing an app that requires a license for use, you can request Power Apps licenses for your users. For more information, see Request Power Apps licenses for your app users.

Security group considerations

- All existing members of the security group inherit the app permissions. New users joining the security group will inherit the security group permissions on the app. Users leaving the group will no longer have access through that group, but those users can continue to have access either by having permissions assigned to them directly or through membership in another security group.

- Every member of a security group has the same permissions for an app as the overall group does. However, you can specify greater permissions for one or more members of that group to allow them greater access. For example, you can give Security Group A permission to run an app. And then, you can also give User B, who belongs to that group, Co-owner permission. Every member of the security group can run the app, but only User B can edit it. If you give Security Group A Co-owner permission and User B permission to run the app, that user can still edit the app.

- Users must explicitly be a member of the security group. If a user is an owner of the group, they must also assign themselves as a member of the group to inherit app permissions.

Share an app with Microsoft 365 groups

You can share an app with Microsoft 365 groups. However, the group must have security enabled. Enabling security ensures that the Microsoft 365 group can receive security tokens for authentication to access apps or resources.

Using Microsoft Graph:

1. Install the Microsoft Graph module.

```PowerShell
Install-Module Microsoft.Graph -Scope CurrentUser
```

2. Connect to Microsoft Graph. For information about the administrator roles required to manage groups, see Microsoft Entra roles for managing groups.

```PowerShell
Connect-MgGraph -Scopes "Group.ReadWrite.All"
```

3. Set the Object ID of Microsoft 365 group.

```PowerShell
$ObjectID = "<ObjectID>"
```

4. Enable security.

```PowerShell
Update-MgGroup -GroupId $ObjectID -BodyParameter @{ SecurityEnabled = $true }
```

5. Verify the update.

```PowerShell
Get-MgGroup -GroupId $ObjectID | Select-Object DisplayName, SecurityEnabled
```

> **Note**
>
> You must be the owner of the Microsoft 365 group to enable security. Setting the **SecurityEnabled** property to **True** doesn't affect how Power Apps and Microsoft 365 features work. This command is required because the **SecurityEnabled** property is set to **False** by default when Microsoft 365 groups are created outside of Microsoft Entra ID.

After a few minutes, you can discover this group in the Power Apps sharing panel and share apps with this group.

Manage table permissions for Dataverse

If you create an app based on Dataverse, you must also ensure that the users you share the app with have the appropriate permissions for the table or tables used by the app. Particularly, those users must belong to a security role that can do tasks such as creating, reading, writing, and deleting relevant records. In many cases, you'll want to create one or more custom security roles with the exact permissions that users need to run the app. You can then assign the role to each user as appropriate.

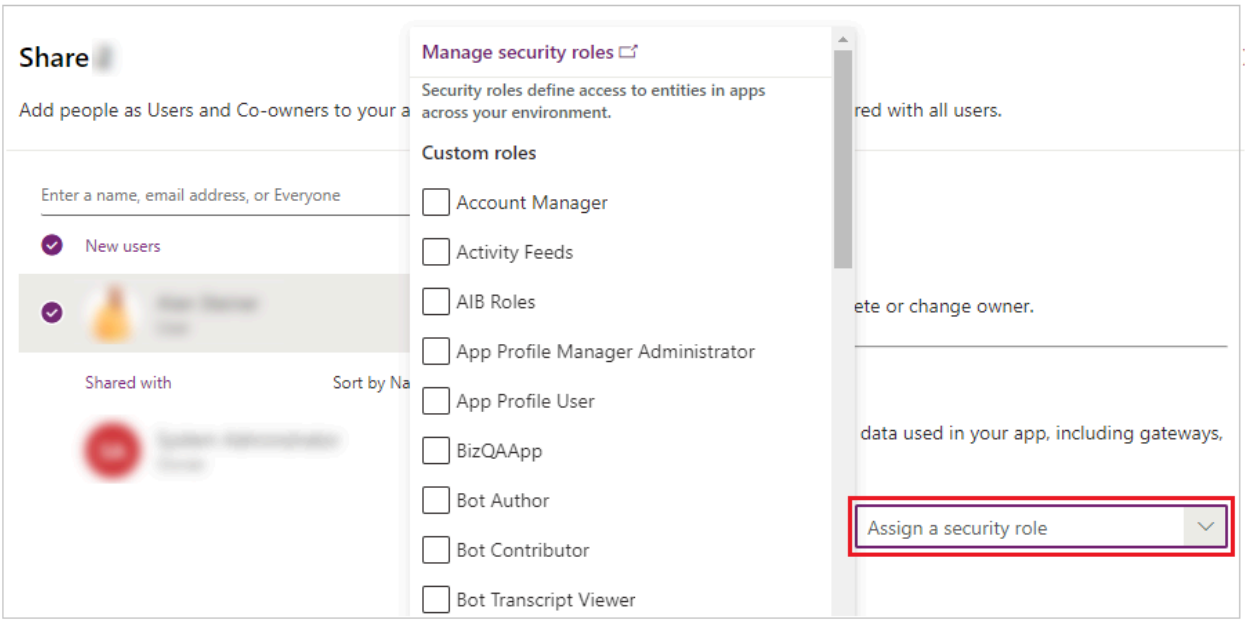
> **Note**
>
> - You can assign security roles to individual users and security groups in Microsoft Entra ID, but not to Microsoft 365 groups.
> - If a user isn't in the Dataverse root business unit, you can share the app without providing a security role, and then set the security role directly.
> - After a security role is assigned to a user or group, you can't unassigned it when you share an app. However, you can still unassign security roles through the admin portal.

Prerequisite

To assign a role, you must have **System Administrator** permissions for a Dataverse database.

To assign a security group in Microsoft Entra to a role

1. In the sharing panel under **Data permissions**, select **Assign a security role**.
2. Select the Dataverse roles that you want to apply to the selected Microsoft Entra users or groups.



> **Note**
>
> When you share an app that's based on an older version of Dataverse, you must share the runtime permission to the service separately. If you don't have permission to do this, see your environment administrator.

Share a canvas app with guest users

06/27/2025

Canvas apps can be shared with guest users of a Microsoft Entra tenant. You can invite external business partners, contractors, and third parties to run your company's canvas apps.

Watch this video to learn how to share an app with guests: https://learn-video.azurefd.net/vod/player?id=84cd1908-2ca9-415b-a819-3ffb61e55eca&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fshare-app-guests

Prerequisites

- In Microsoft Entra ID, enable B2B external collaboration for the tenant. More information: Configure external collaboration settings for B2B in Microsoft Entra External ID

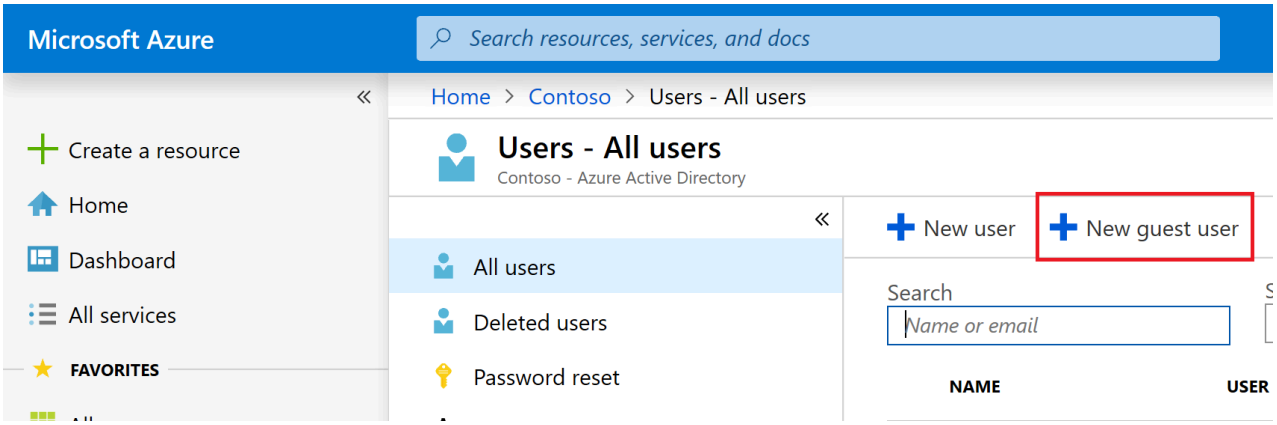
  > **Note**
  >
  > B2B external collaboration is enabled by default. However, you need to verify that the settings weren't changed by a tenant admin. For more information about Microsoft Entra B2B, see Overview: B2B collaboration with external guests for your workforce.

- Access to an account that can add guest users to a Microsoft Entra tenant. Admins and users with the Guest Inviter role can add guests to a tenant.
- To access an app that connects to Dataverse, the guest user must have a license with Power Apps use rights that matches the capability of the app. The exception to this prerequisite is when an app is hosted in a Microsoft Dataverse for Teams environment.

> **Note**
>
> Ensure that you perform these steps on the **resource tenant**, and not on the **home tenant**.
>
> - A **resource tenant** is where the app is expected to exist, and where the user is expected to create the app using Power Apps as a guest.
> - A **home tenant** is where the user's account resides and authenticates against.

Steps to grant guest access

1. In Microsoft Entra ID, select **New guest user**. More information: Quickstart: Add a guest user and send an invitation



2. If the guest user doesn't already have a license in their home tenant, assign a license to the guest user.

   - To assign guest users from admin.microsoft.com, go to Add users and assign licenses at the same time.
   - To assign guest users from portal.azure.com, go to Assign or remove licenses.

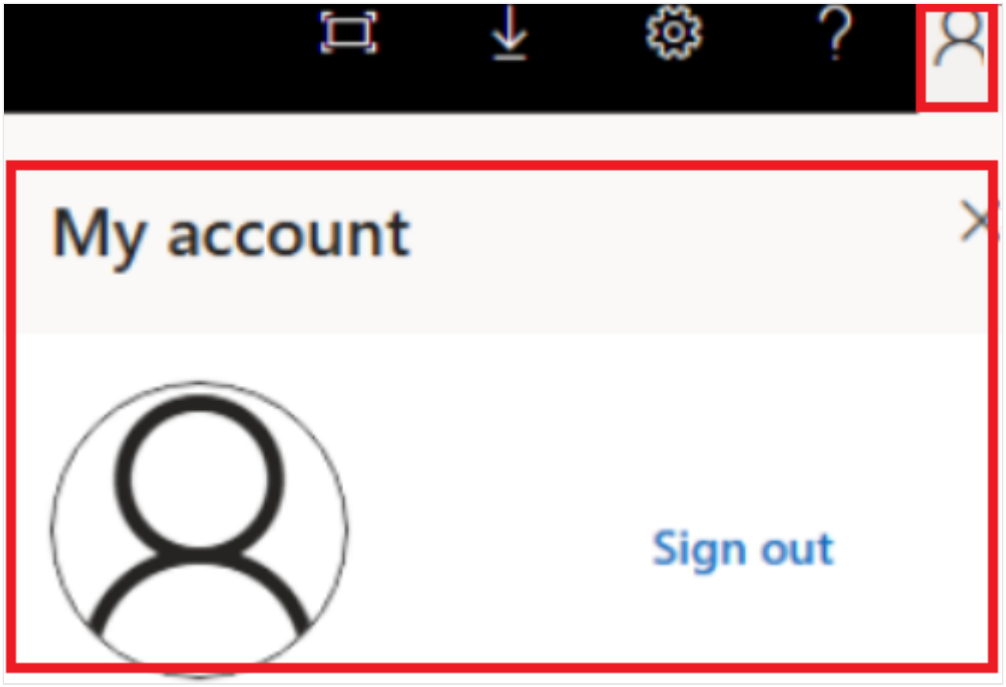
   > **Important**
   >
   > You might need to disable the Microsoft 365 admin center preview to assign a license to a guest.

3. Share an app from Power Apps

Considerations and limitations for guest access

- Users accessing web experiences in different Microsoft Entra tenants must access Power Apps in a standalone browser session (different browser or InPrivate browser session). The standalone browser session insures that Power Apps picks up the correct Azure B2B user identity for the app being accessed.
- Power Apps guest access uses Azure B2B.
- Power Apps Mobile doesn't support authentication using Microsoft Entra direct federation. More information: Sign in using Power Apps Mobile
- Power Apps per app plans are scoped to apps in a specific environment, so they can't be recognized across tenants.
- Power Apps included with Office and Power Apps per user plans have the following characteristics:

- In the Azure public cloud, they're recognized across tenants in guest scenarios because they aren't bound to a specific environment.
- In Azure national or sovereign clouds, they're recognized across tenants in guest scenarios. For more information, see National clouds, Azure geographies
- Licenses aren't recognized across tenants in difference Azure clouds.
- Not all connectors create connections in the resource tenant by default.
- A user that signs in to an app using Azure B2B, doesn't see their identity information in **My account**.



Frequently asked questions

What's the difference between canvas app guest access and Power Pages?

With canvas apps, you can build an app tailored to digitizing business processes, without writing code in a traditional programming language such as C#. Guest access for canvas apps enables teams of individuals made up of different organizations participating in a common business process to access the same app resources that might be integrated with a wide variety of Microsoft and partner sources. More information: Overview of canvas-app connectors for Power Apps

Power Pages provide you with the ability to build low-code, responsive websites that allow external users to interact with the data stored in Dataverse. With Power Pages, organizations

can create websites and share them with users external to their organization either anonymously or through the sign-in provider of their choice, such as LinkedIn, Microsoft, or other commercial sign-in provider.

The following table outlines a few core capability differences between Power Pages and canvas apps.

Expand table

Guest access in	Interface	Authentication	Accessible data sources
Power Pages	Browser-only experience	Allows anonymous and authenticated access	Dataverse
Canvas apps	Browser and mobile apps	Requires authentication via Microsoft Entra ID	Any of approximately 150 out-of-the-box connectors and any custom connector

Can guests access customized forms in SharePoint?

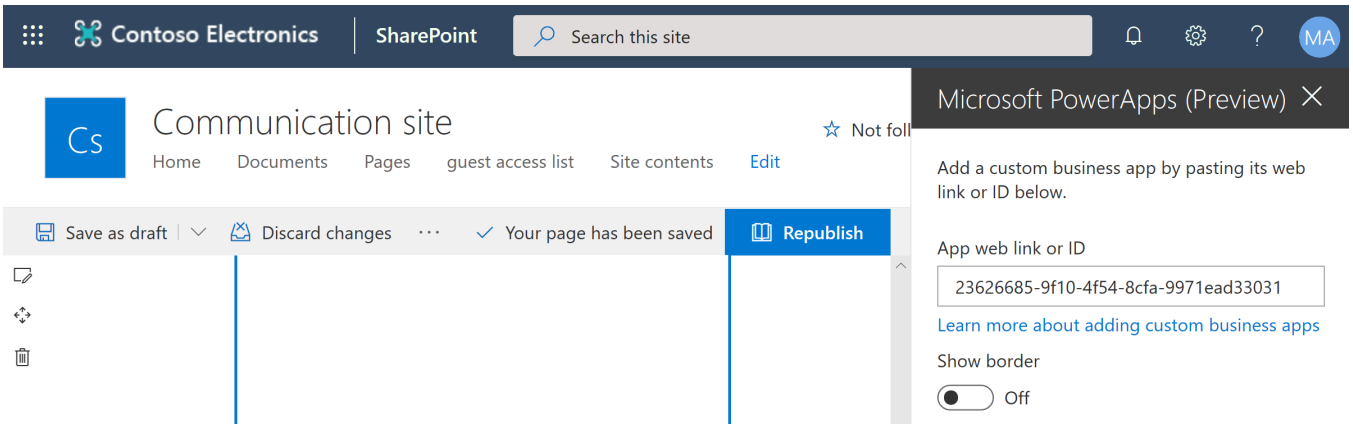
See What license must be assigned to my guest so they can run an app shared with them?

Why is a guest who accesses a customized form in SharePoint prompted for a trial?

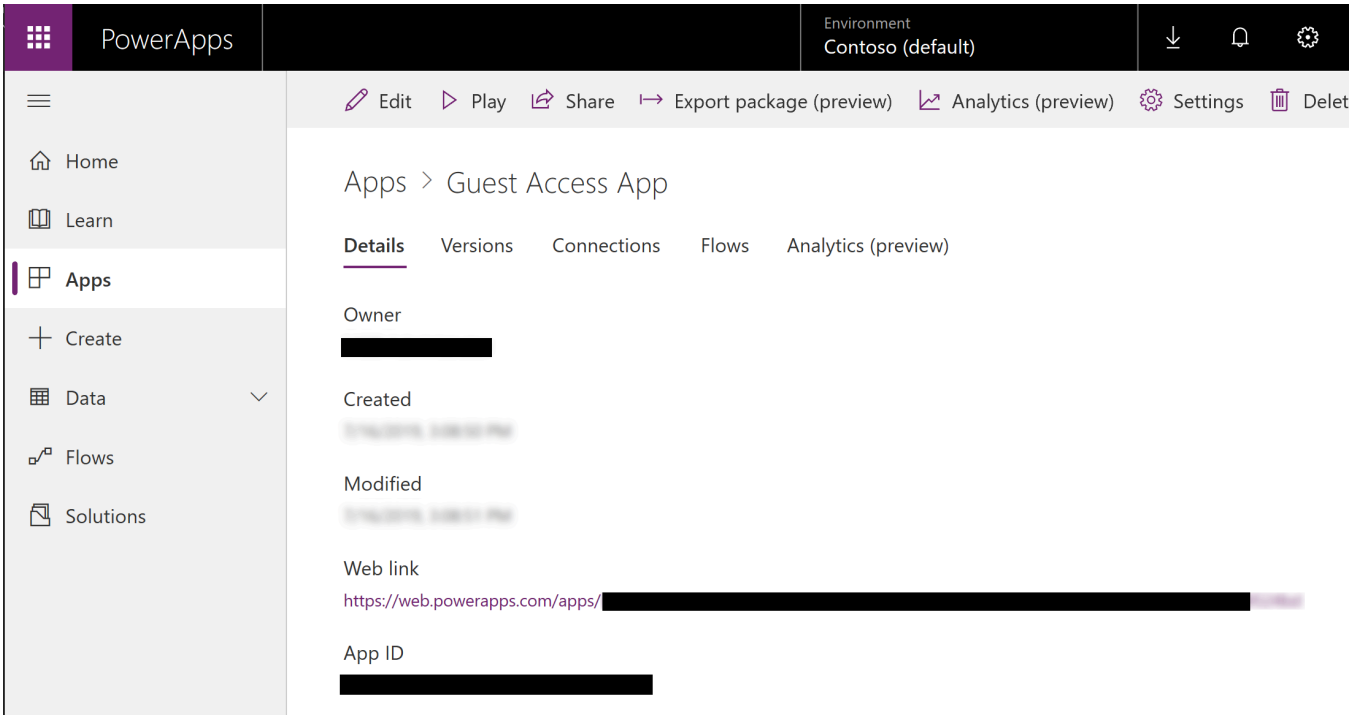
If the custom form uses a premium connector, a guest must have a Power Apps license to access the custom form. If the custom form only uses standard connectors, your tenant must allow Microsoft Power Platform internal consent plans to be assigned to users. For more details about Power Platform internal consent plans, read block trial license commands.

Can guests access apps embedded in SharePoint?

Yes. However, access to canvas standalone apps requires a user license with Power Apps user rights that matches the capability of the app, including embedded apps. When embedding a canvas app in SharePoint with the Power Apps embed control, enter the app ID in the **App web link or ID** box.



When embedding a canvas app in SharePoint via the iFrame HTML tag, reference the app by using the full web URL. To find the URL, sign in to Power Apps, select an app, and then select the **Details** tab. The URL is displayed under **Web link**.



How is it that guests can open the app shared with them, but no data connections are created?

As is the case with nonguests, the underlying data sources accessed by the app must also be made accessible to the guest.

What license must be assigned to my guest so they can run an app shared with them?

The following table explains whether the guests can run (use) customized Microsoft Lists or SharePoint library forms, canvas apps, and model-driven apps using the referenced license.

Expand table

Plan	Customized Microsoft Lists or SharePoint library form (using nonpremium connectors)	Customized Microsoft Lists or SharePoint library (using premium connectors)	Canvas app (using nonpremium connectors)	Canvas app (using premium connectors)	Model-driven app
No license	✓	✗	✗	✗	✗
SharePoint user (without Power Apps license)	✓	✗	✗	✗	✗
Power Apps included with Office	✓	✗	✓	✗	✗
Power Apps per app plan	✓	✓	✓	✓	✓
Power Apps per user plan	✓	✓	✓	✓	✓

For more information about pricing and the capabilities of various plans, go to Microsoft Power Apps and Power Automate Licensing Guide.

In Power Apps Mobile, how does a guest see apps for their home tenant?

When users access a canvas app through a mobile device and the app is published in a non-home Microsoft Entra tenant, they can switch to a different directory.

In Power Apps Mobile, how does a guest see apps in the guest tenant?

The guest user opens the email they received when an app in the guest tenant is shared and selects **Open the app**. This view applies to both Microsoft Entra and Microsoft account users. You can also create a deep link. For more information, see Use deep links with Power Apps mobile.

Must a guest accept the Microsoft Entra guest invitation before an app can be shared with them?

No. If a guest opens an app shared with them before they accept a guest invitation, the guest is prompted to accept the invitation as part of the sign-in experience while opening the app.

In which Microsoft Entra tenant are connections created for a guest user?

Connections for an app are always made in the context of the Microsoft Entra tenant the app is associated with. For example, if an app is created in the Contoso tenant, the connections made for Contoso internal and guest users are made in the context of the Contoso tenant.

Can guests use Microsoft Graph with Power Apps?

By default, Azure B2B users have limited permission to access information from Microsoft Graph. A user's permission in Microsoft Graph determines what's returned when using connectors such as Microsoft Security Graph, Office 365 Users, Office 365 Groups, and custom connectors using Microsoft Graph APIs. For more information about Microsoft Graph permissions, see Default user permissions and Working with users in Microsoft Graph.

Which Intune policies apply to guests who are using my apps?

Intune only applies the policies of a user's home tenant. For instance, if `Lesa@Contoso.com` shares an app with `Wanda@Fabrikam.com`, Intune continues to apply Fabrikam.com policies on Wanda's device, regardless of the apps Wanda runs.

Can I disable cross tenant license recognition?

No. Authorization capabilities can and should be used to control which users access a resource. For instance, Dataverse environments can be bound to a security group that excludes Azure B2B guest users.

Why can an Azure B2B user without a license access a model driven app?

The detection of a previously licensed user no longer having a license isn't immediate. If you expect a user to lose access to an app using Dataverse, then their authorization to the app or

data should be updated. For example, the app should be unshared with the user or Dataverse security roles should be removed from the user.

Which connectors create connections in the resource tenant by default?

Users relying on Azure B2B to access an app only has implications on connectors that use Microsoft Entra ID for authentication. Some Microsoft Entra ID based connectors default to creating a connection in the resource tenant, while others default to creating a connection in the home tenant. Connectors that don't use any type of Microsoft Entra ID authentication work the same for guests and members in a tenant. The following table enumerates all connectors that do use Microsoft Entra ID authentication and default creates connections in the resource tenant. For more information on each connector as there might be restriction, see List of all Power Apps connectors

Expand table

Connector	Creates connection in resource tenant by default
Microsoft Entra	Yes
Azure Automation	Yes
Azure Container Instance	Yes
Azure Data Factory	Yes
Azure Data Lake	Yes
Azure IoT Central	Yes
Azure Kusto	Yes
Azure Log Analytics	Yes
Azure Resource Manager	Yes
Microsoft Dataverse	Yes*
Dynamics 365 AI for Sales	Yes
Microsoft Teams	Yes
Office 365 Groups	Yes
Office 365 Users	Yes
Outlook Tasks	Yes

Connector	Creates connection in resource tenant by default
Power BI	Yes
SharePoint	Yes

* When using the Microsoft Dataverse as the data source, ensure that the guest user is licensed from the same tenant where you have Dataverse data located.

Share Excel data used by your app

Article • 12/16/2022

You can share Excel data with your app users in a cloud account, such as OneDrive.

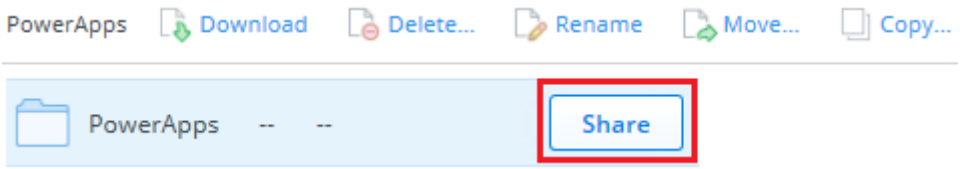
For example, you might create an app that shows the names and phone numbers of the technical-support group at your company. The information is stored in an Excel spreadsheet, which you put in a folder in Dropbox. You then share the folder with your app users so that they can see the names and phone numbers.

You must share the data so that users can run and even modify your app. Users who aren't given the sharing permissions won't see the data in the Excel file.

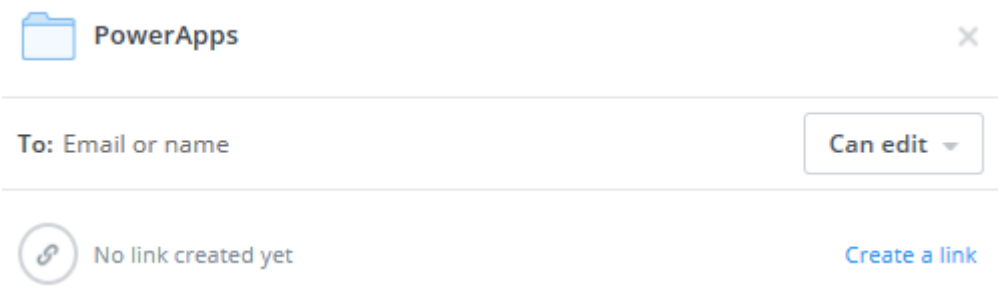
This topic shows you how to share data in an Excel spreadsheet using Dropbox, OneDrive, and Google Drive. To create an app that displays data from an Excel file, see Create an app from a set of data.

Share data in Dropbox

1. Sign in to Dropbox using the same account that you used to create a connection from Power Apps to Dropbox.
2. Select the folder that contains the Excel file, and then select **Share**:



3. In the dialog box, enter the email addresses with which your app users sign in to Dropbox.

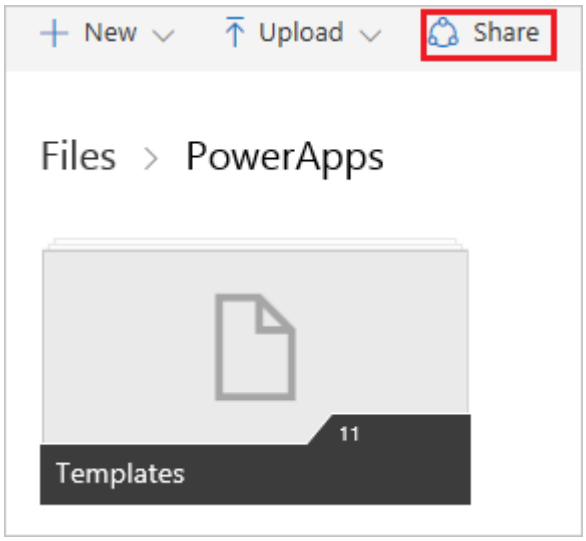


4. If your app users will add, modify, or delete data in your app, select **Can edit**. Otherwise, select **Can view**.
5. Select **Share**.

For more information, see Sharing folders on Dropbox.

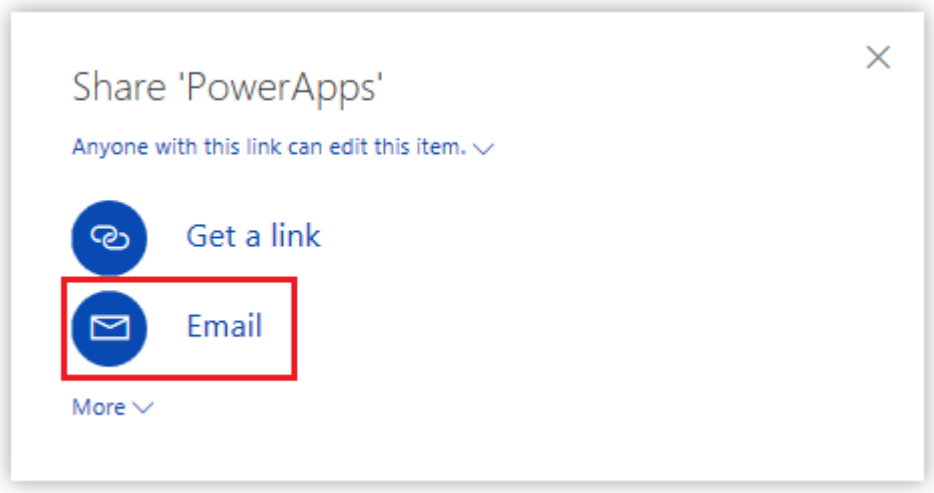
Share data in OneDrive

1. Sign in to OneDrive using the same account that you used when you created a connection from Power Apps to OneDrive.
2. Select the folder that contains the file, and then select **Share**:

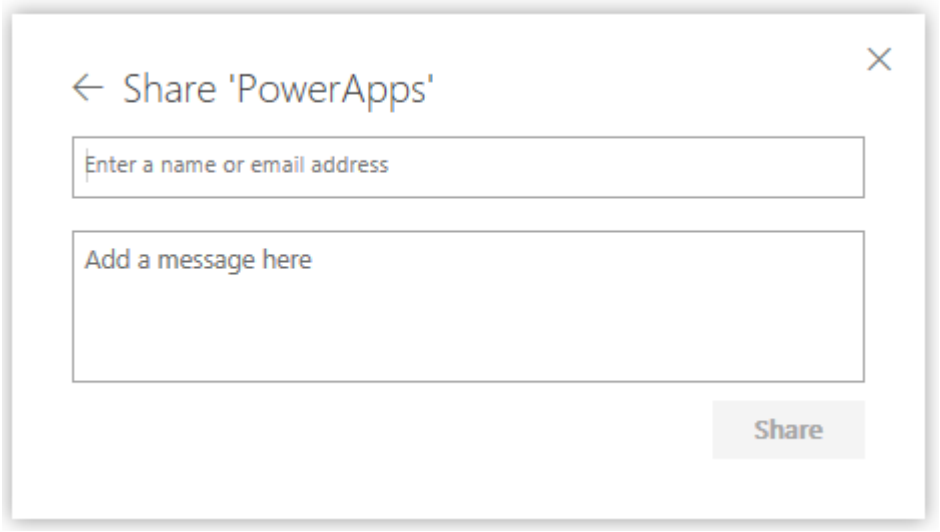


> **Note**
>
> In OneDrive for Business, share the file itself, not the folder that contains the file.

3. In the dialog box, select **Email**.



4. Specify the email addresses with which your app users sign in to OneDrive, and then select **Share**.

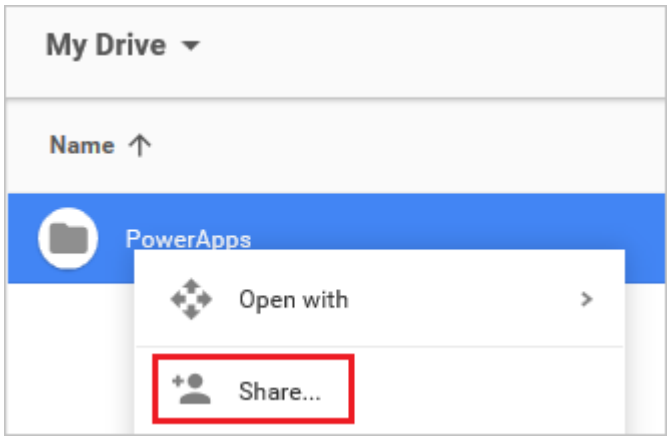


For more information, see Share OneDrive files and folders.

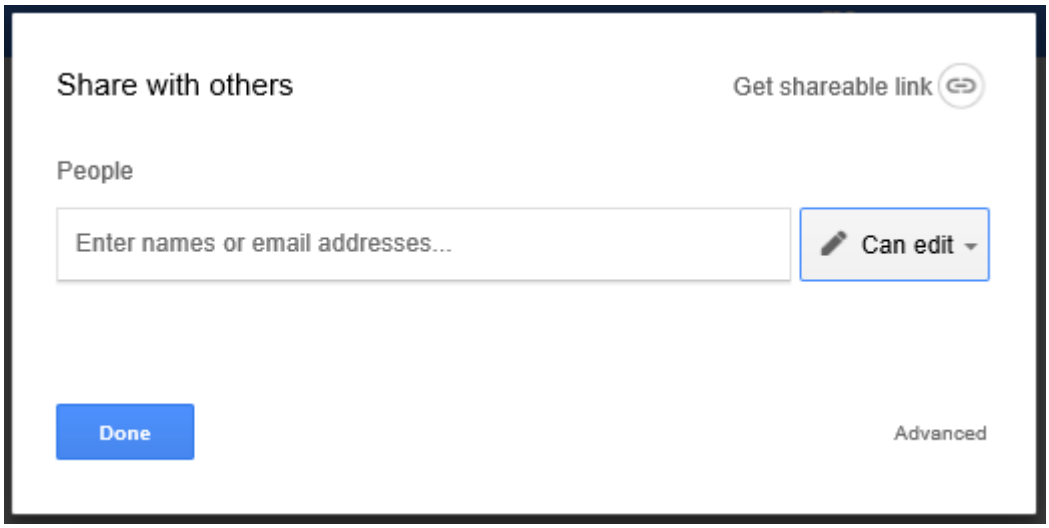
Share data in Google Drive

1. Sign in to Google Drive using the same account with which you created a connection from Power Apps to Google Drive.

2. Right-click the folder that stores your Excel file, and then select **Share**.



3. In the dialog box, enter the email addresses with which your app users sign in to Google Drive:



4. If your app users will add, modify, or delete data in your app, then select **Can edit** in the list of permissions. Otherwise, select **Can view**.

5. Select **Done**.

For more information, see Share Google Drive files and folders.

Known limitations

For information about how to share Excel data within your organization, review these limitations.

Share resources used by canvas apps

07/08/2025

Before you share a canvas app, consider the types of resources on which it relies, such as one or more of the following:

- Tables in Microsoft Dataverse.

  For information about giving users access to this data, see Manage table permissions.

- A connection to a data source.
- An on-premises data gateway.
- A custom connector.
- An Excel workbook or other service.
- A flow.

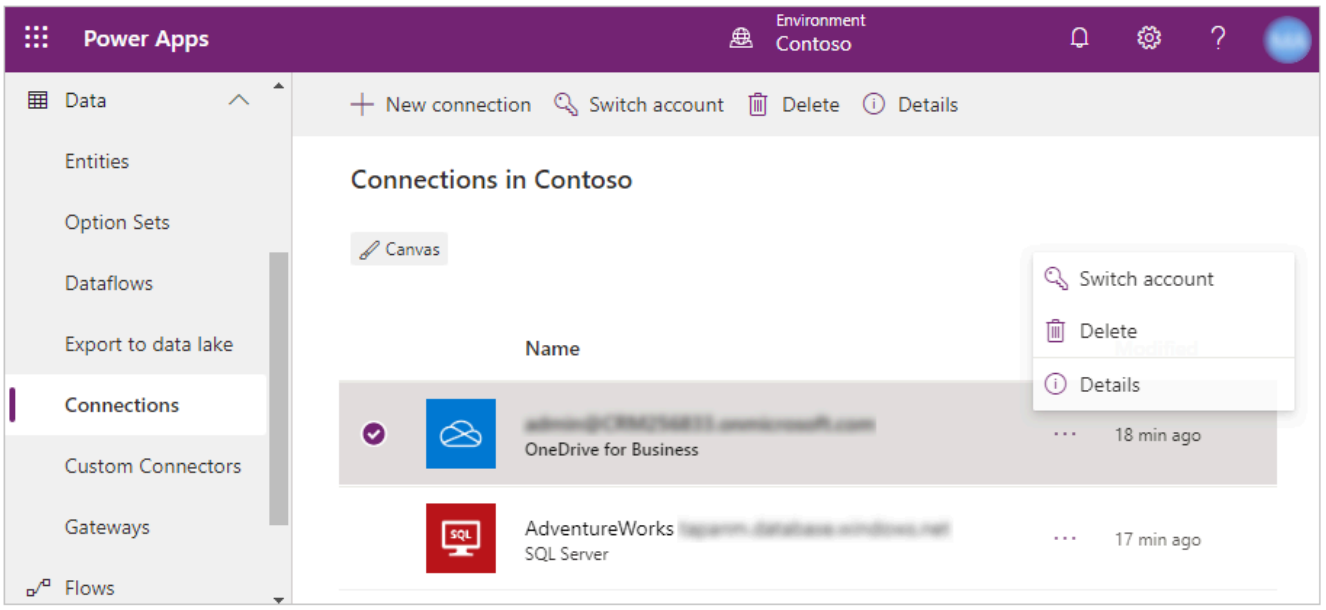
Some of these resources are shared automatically when you share the app. Other resources require you or the people with whom you share the app to take extra steps so that the app works as you expect.

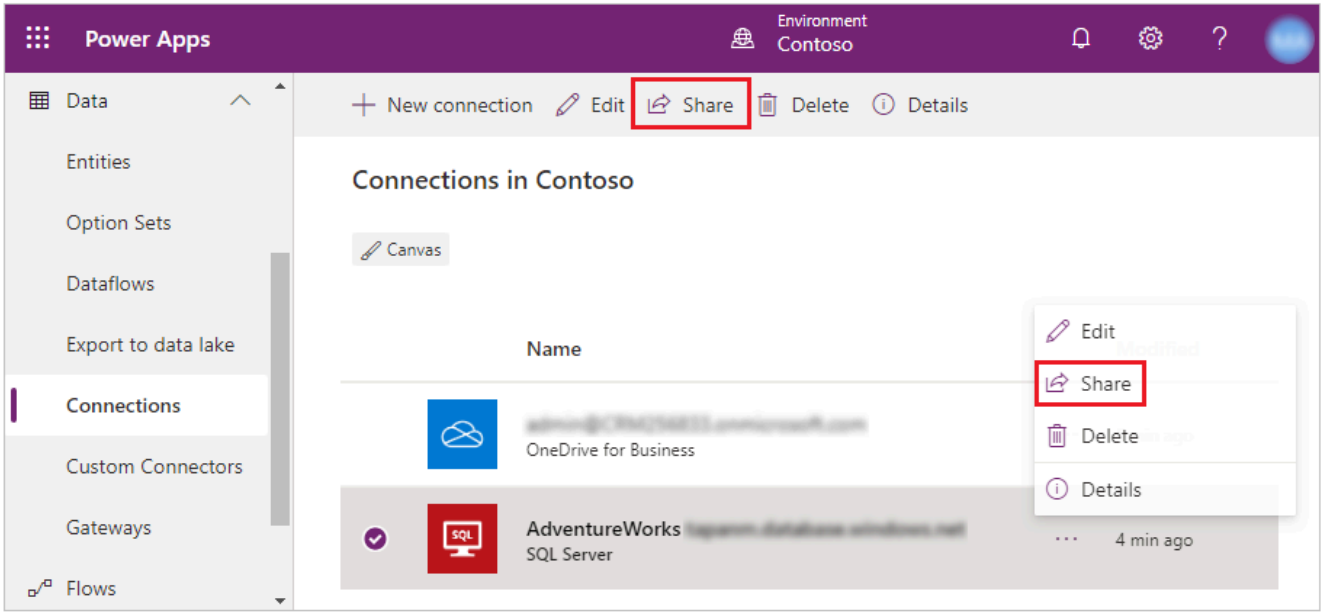
You can also share your connections, custom connectors and on-premises data gateway with your entire organization.

Connections

Some connections (such as SQL Server with SQL or Windows authentication) are implicitly shared with the app when you share the app with other users. Other connections require users to create their own connections and explictly grant security privileges (such as security roles for the Dataverse, OneDrive for Business, SQL Server with Microsoft Entra authentication).

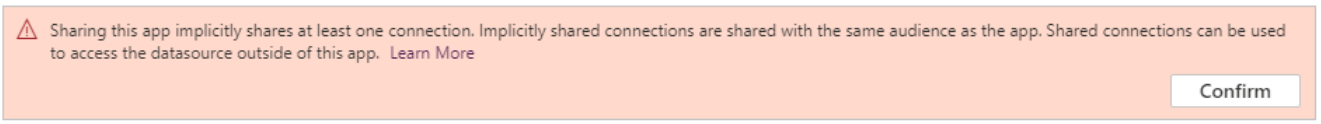
You can determine whether a connection is automatically shared as part of the app when you share the app with other users; allowing you to update sharing permissions. To do this, go to make.powerapps.com and select **Data** -> **Connections** from left navigation. Then select the required connection. If the **Share** button appears on top navigation or if the **Share** option displays when you select *More Commands* (...), the selected connection can be shared with other users.





Implicit sharing

When you share an app that uses a connection that can be shared, the app connection is **implicitly shared** along with the app. For example, following message appears when you go to make.powerapps.com, select **Apps**, choose an app that uses such connection, select *More Commands* (...) and then select **Share**:



If you select **Confirm** and share the chosen app with other users, the app connection is implicitly shared with those users along with the app.

> **Note**
>
> To ensure the app works properly, the user who is sharing the app needs to have sharing permission for all connections used by the app. Without these permissions, the user won't be able to access or use the connections correctly. This applies to all app-sharing activities, including app sharing, app publishing, and solution import.

On-premises data gateways

If you create and share an app that includes data from an on-premises source, the on-premises data gateway itself and certain types of connections to that gateway will be shared automatically. For any connection that isn't shared automatically, you can share it manually (as the previous section shows) or let the app prompt users to create their own connections. To show the connection or connections with which a gateway has been configured:

1. Open powerapps.com, click or tap **Manage** in the left navigation bar, and then click or tap **Gateways**.
2. Click or tap a gateway, and then click or tap the **Connections** tab.

> **Note**
>
> If you share one or more connections manually, you might need to reshare them under these circumstances:

- You add an on-premises data gateway to an app that you've already shared.
- You change the set of people or groups with whom you've shared an app that has an on-premises data gateway.

Custom connectors

When you share an app that uses a custom connector, it is automatically shared, but users must create their own connections to it.

On powerapps.com, you can view or update permissions for a custom connector. In the left navigation bar, click or tap **Manage**, click or tap **Connections**, and then click or tap **New connection** (in the upper-right corner). Click or tap **Custom**, and then click or tap a custom connector to display details about it.

Excel workbooks

If a shared app uses data to which not all users have access (such as an Excel workbook in a cloud-storage account), share the data.

Flows

If you share an app that includes a flow, users who run the app will be prompted to confirm or update any connections on which the flow relies. In addition, only the person who created the flow can customize its parameters. For example, you can create a flow that sends mail to an address that you specify, but other users can't change that address.

Tutorial: Embed a Power Apps visual in a Power BI report

APPLIES TO: Power BI Desktop Power BI service

In this tutorial, you use the Power Apps visual to create a new app that is embedded in a sample Power BI report. This app interacts with other visuals in that report.

If you don't have a Power Apps subscription, create a free account before you begin.

In this tutorial, you learn how to:

- Add a Power Apps visual to a Power BI report
- Work in Power Apps to create a new app that uses data from the Power BI report
- View and interact with the Power Apps visual in the report

Prerequisites

- Google Chrome or Microsoft Edge browser
- A Power BI subscription, with the Opportunity Analysis Sample installed
- An understanding of how to create apps in Power Apps and how to edit Power BI reports

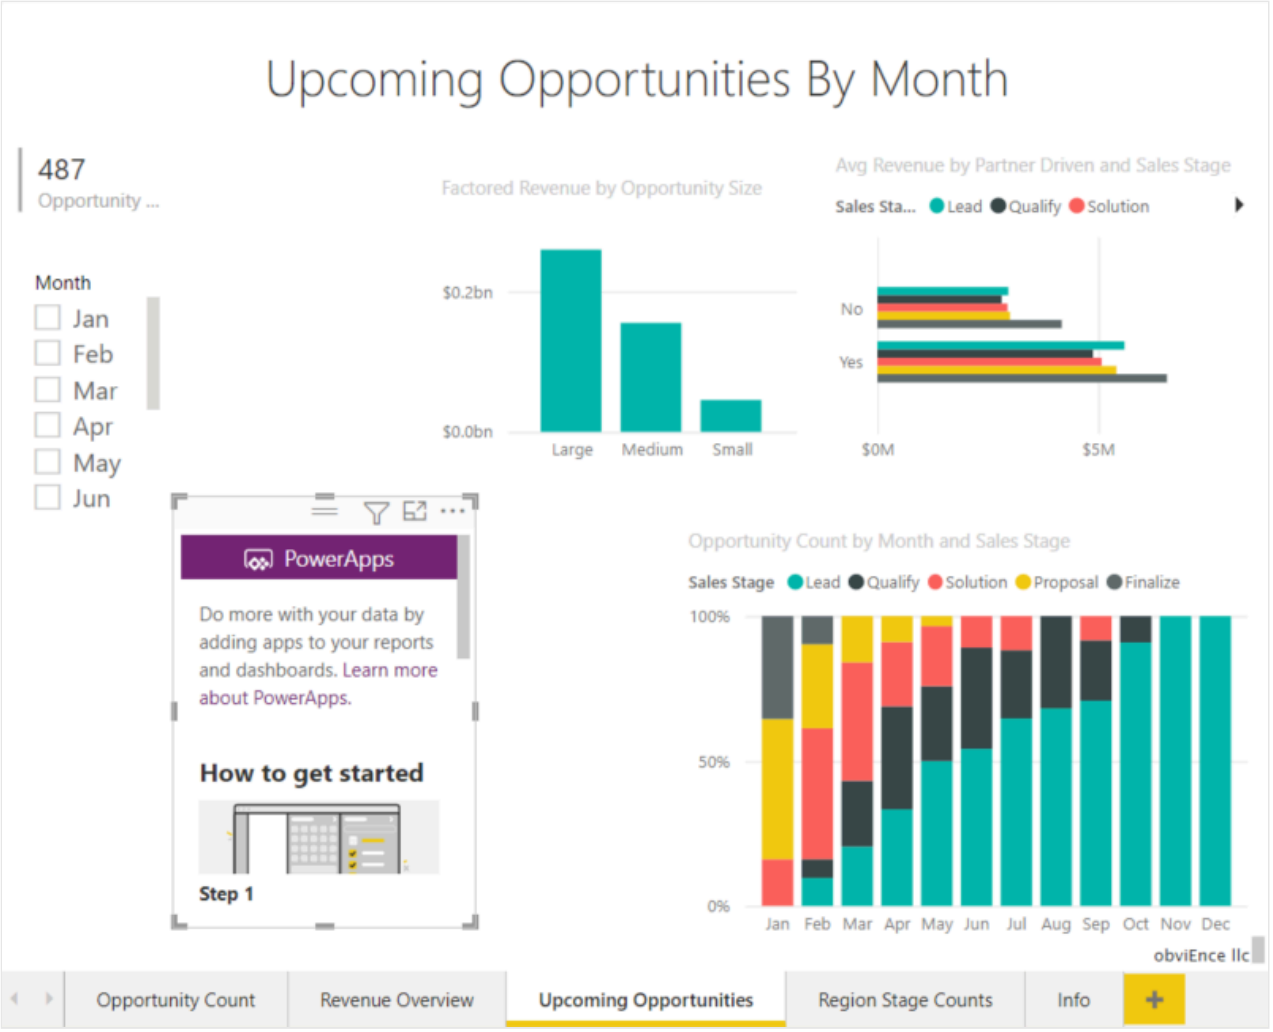
Create a new app

When you add the Power Apps visual to your report, it launches Power Apps Studio with a live data connection between Power Apps and Power BI.

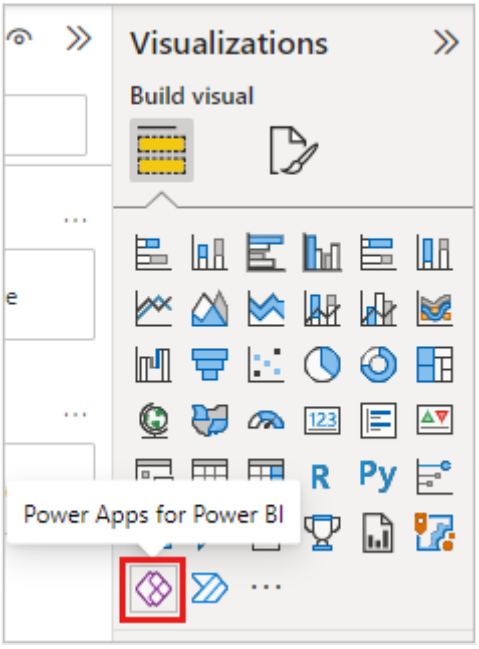
1. Open the Opportunity Analysis sample report and select the *Upcoming Opportunities* page.

2. Open the report in Editing mode by selecting **Edit** from the Options bar.

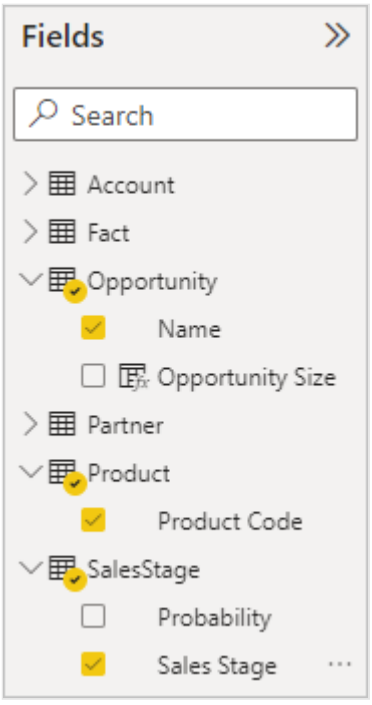
3. Move and resize some of the report tiles to make space for the new visual.



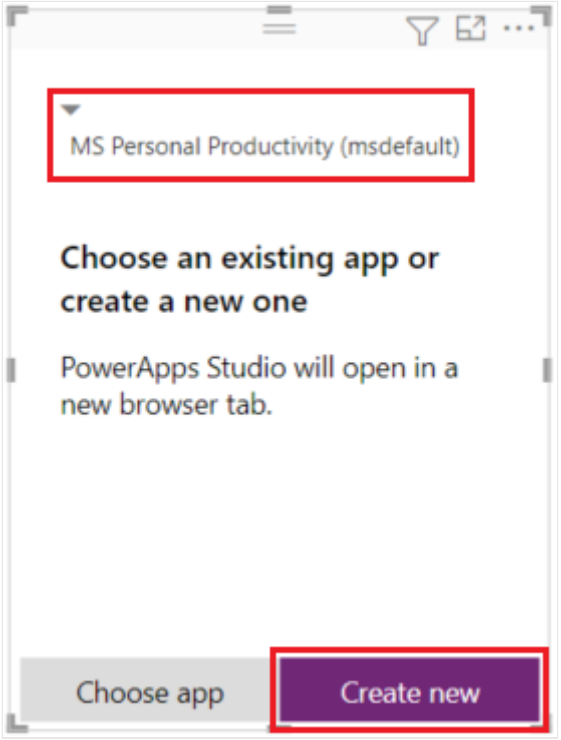
4. From the Visualizations pane, select the Power Apps icon, then resize the visual to fit the space you made.



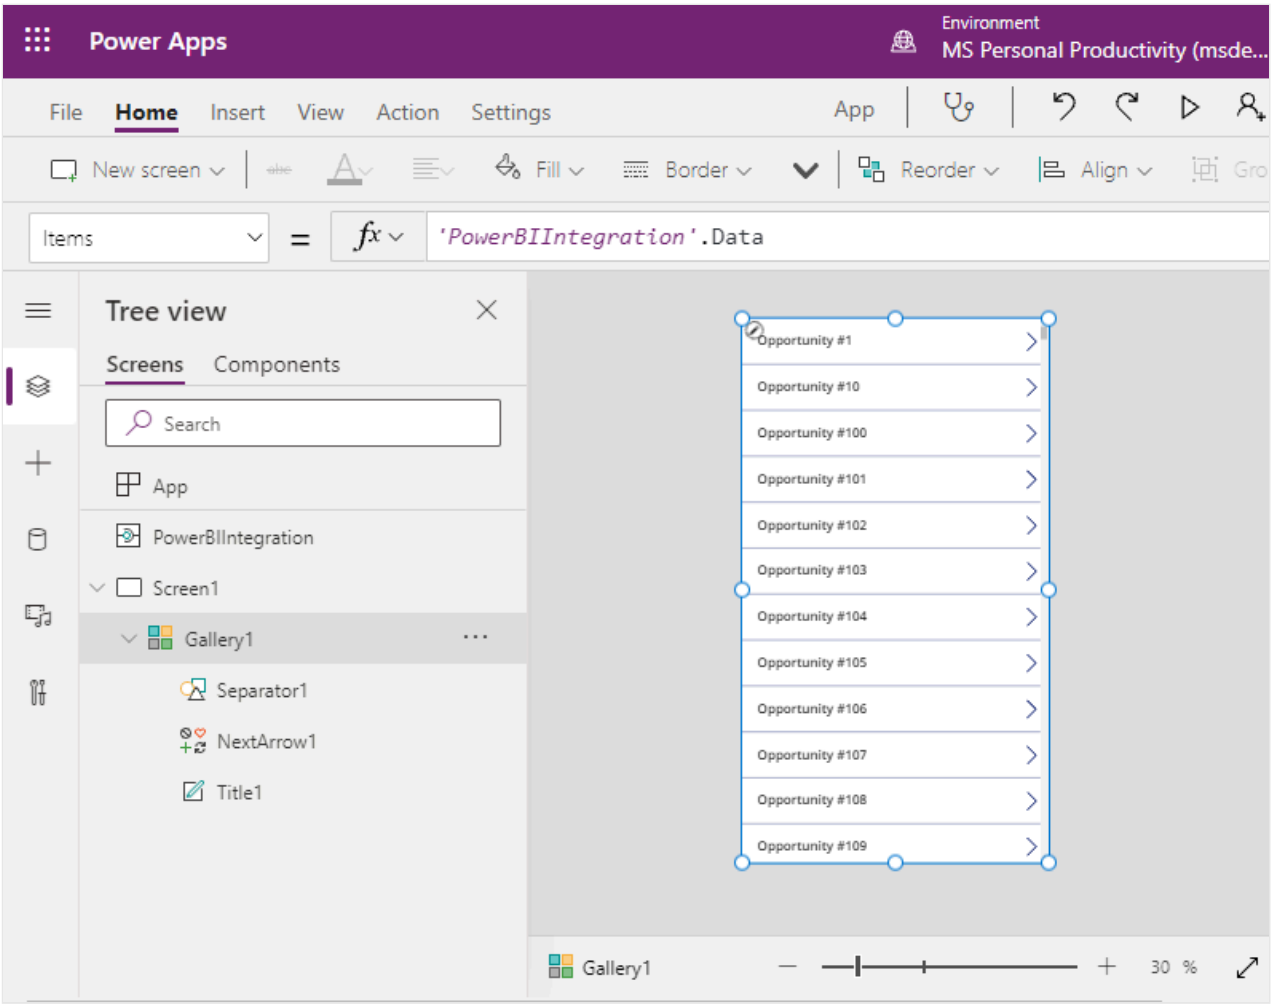
5. In the **Fields** pane, select **Opportunity** > **Name**, **Product** > **Product Code**, and **SalesStage** > **Sales Stage**.



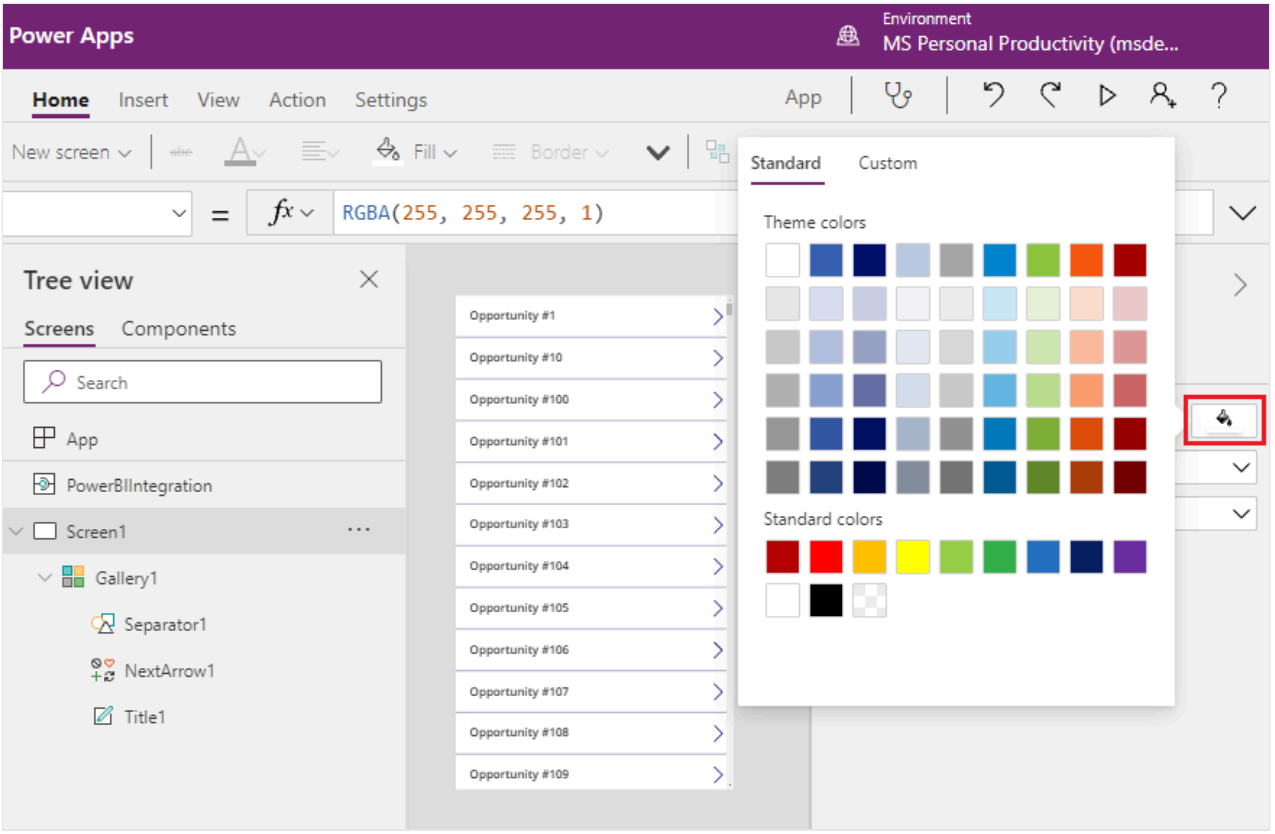
6. On the Power Apps visual, select the Power Apps environment where you want to create the app, then select **Create new**.



In Power Apps Studio, you see that a basic app is created, with a *gallery* that shows one of the fields you selected in Power BI.

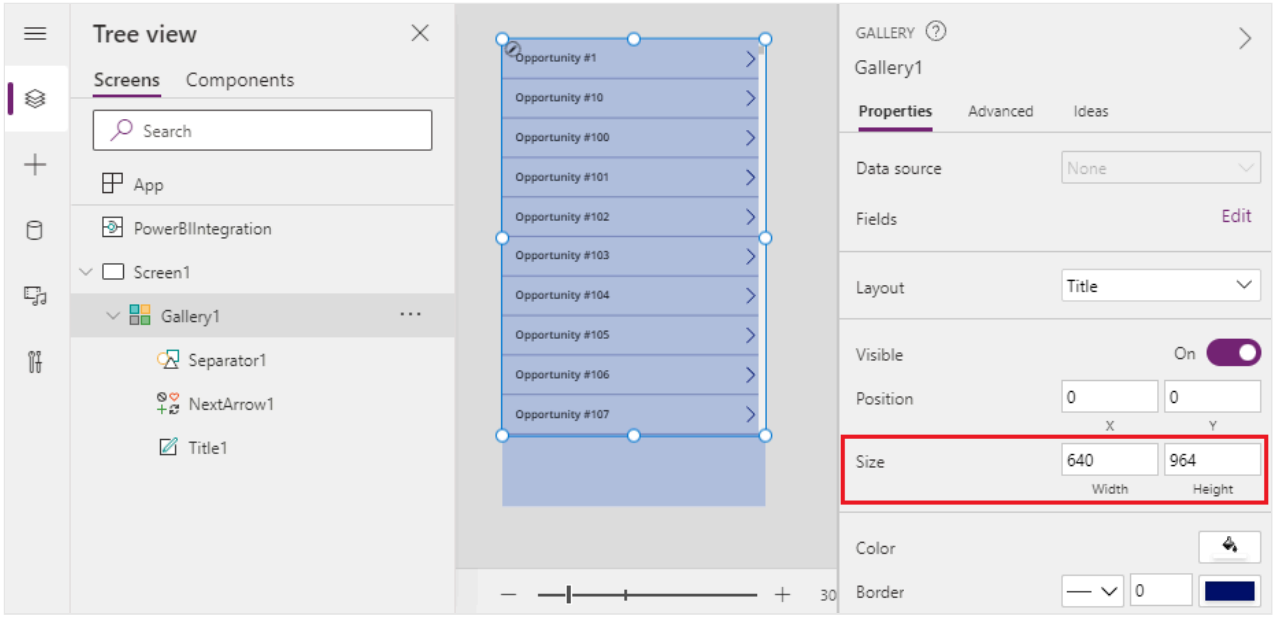


7. In the left pane, select **Screen1**, then set the screen's **Fill** property to "LightBlue" (so it shows up better in the report).

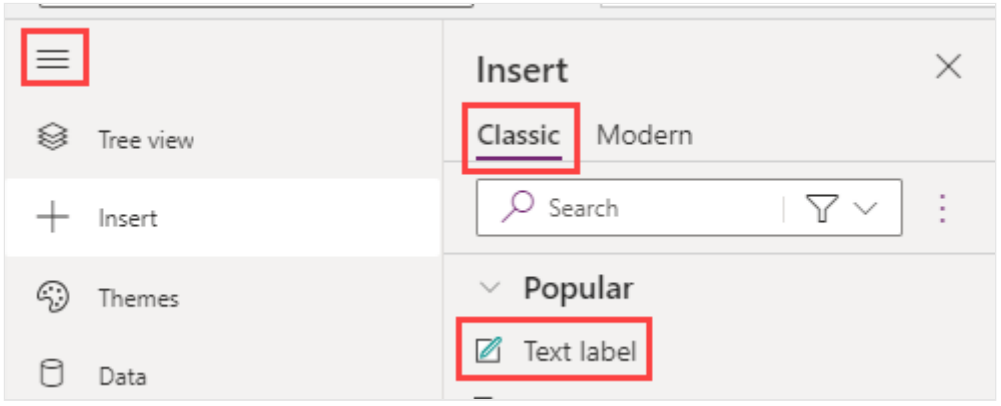


8. Select **Gallery1** and make some room for a label control by changing **Properties** > **Size** > **Height** to 964.

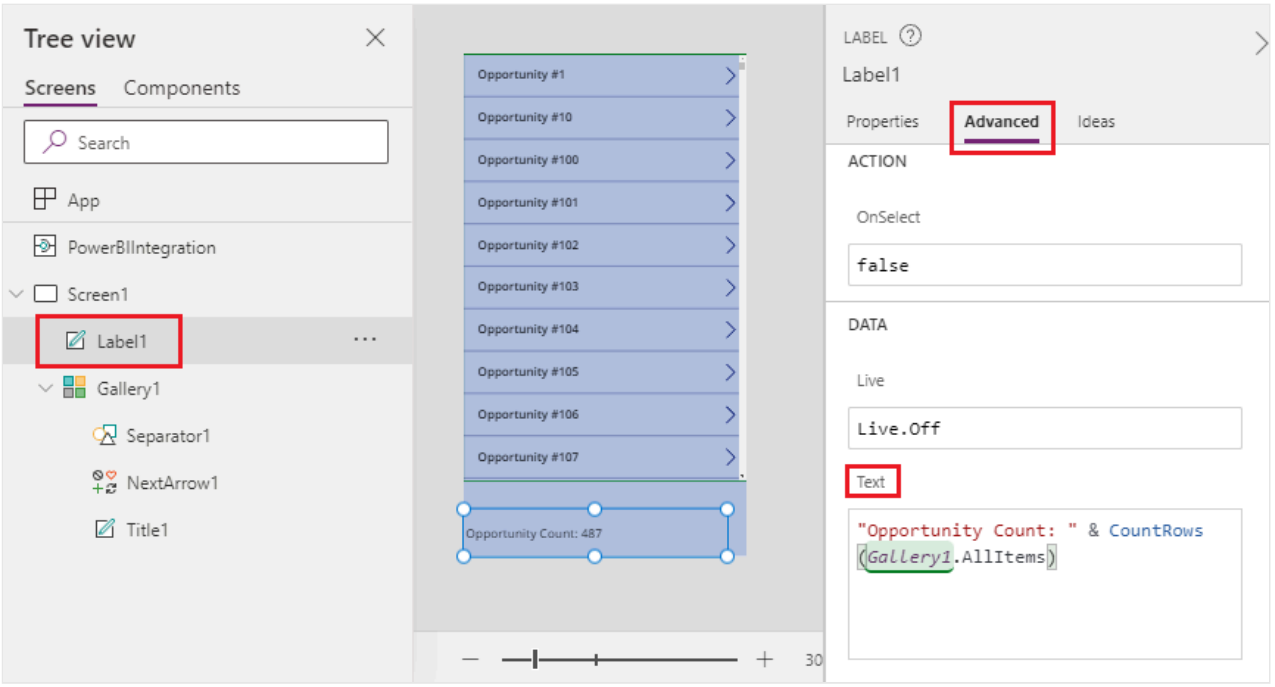
> **Note**
>
> If you can't edit the **Height** field, try adjusting the size of the visual on the canvas first. Select the visual and drag one of the handles. Now edit the **Height** field.



9. Expand the left navigation menu, choose **+ Insert**, and select **Classic** > **Text label** from the list of controls.



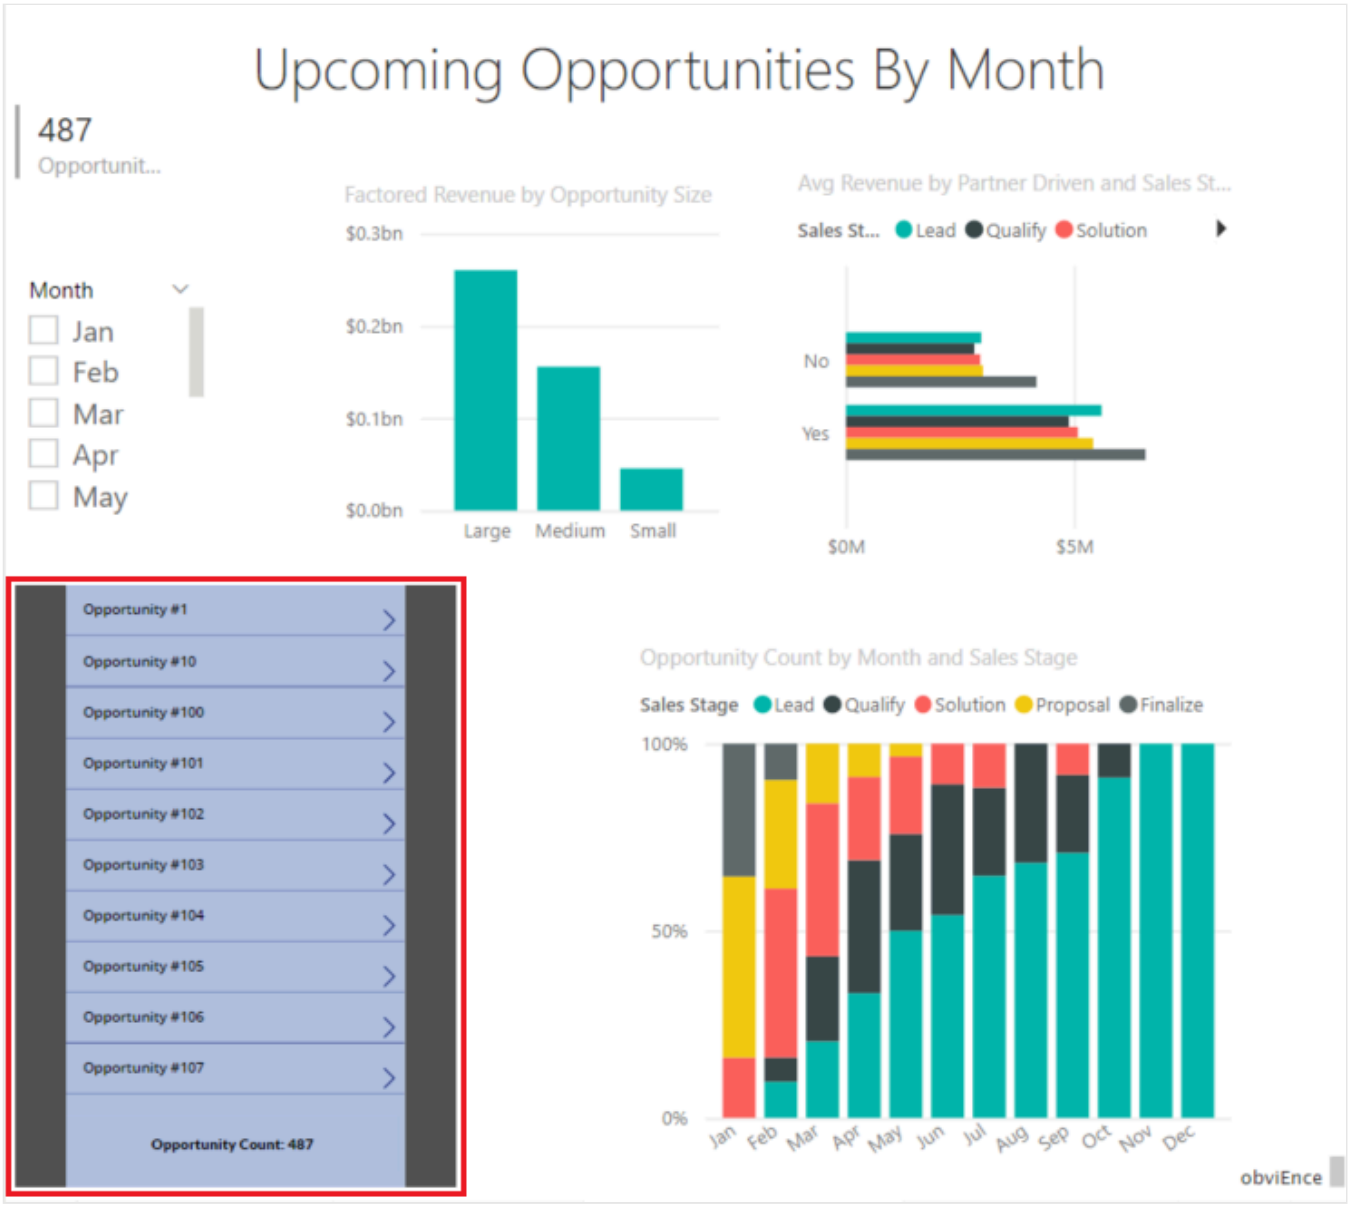
10. Drag the label to the bottom of your visual. Set the **Text** property to `"Opportunity Count: " & CountRows(Gallery1.AllItems)`. The visual on the canvas now shows a total of 487 opportunities in the dataset.



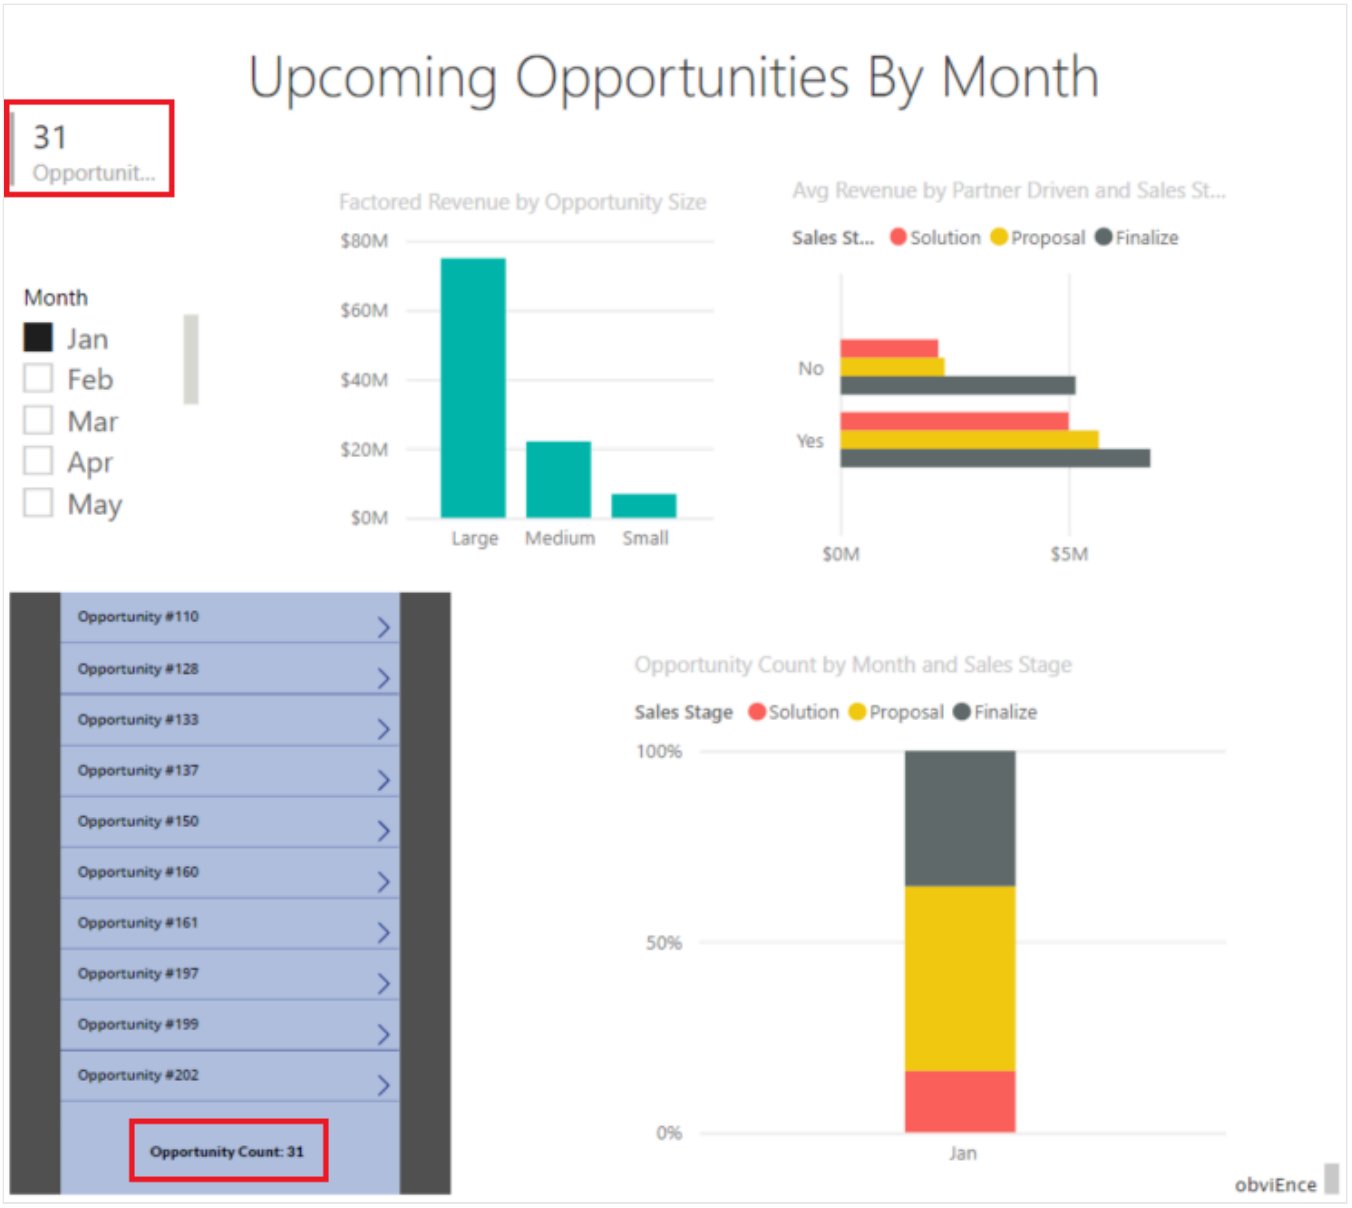
11. Select the **Save** icon from the upper right corner. Save the app with the name "Opportunities App".

View the app in the report

The app is now available in the Power BI report, and it interacts with other visuals because it shares the same data source.



In the Power BI report, select **Jan** in the slicer. This filters the whole report, including the data in the Power Apps visual.



Notice that the updated opportunity count in the Power App visual matches the count in the upper left of the report. You can select other items in the report, and the data in the app updates.

Clean up resources

If you don't want to save the Opportunity Analysis sample with the Power Apps visual, delete the dashboard, report, and semantic model.

Considerations and limitations

For troubleshooting information, see Power Apps visual for Power BI.

Change app name and icon for canvas apps

Article • 12/16/2022

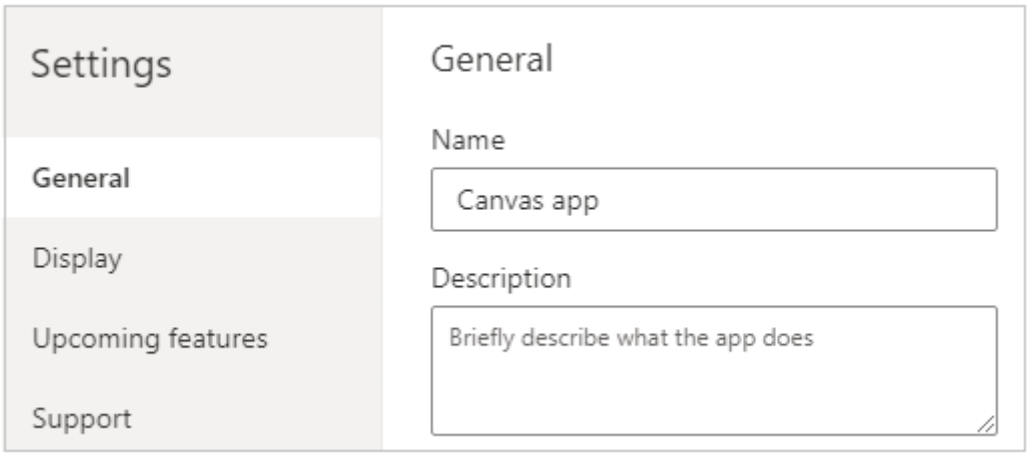
Customize a canvas app by changing its name and icon.

Prerequisites

1. Create an app, or open one for editing.
2. Select **Settings**.

Rename an app

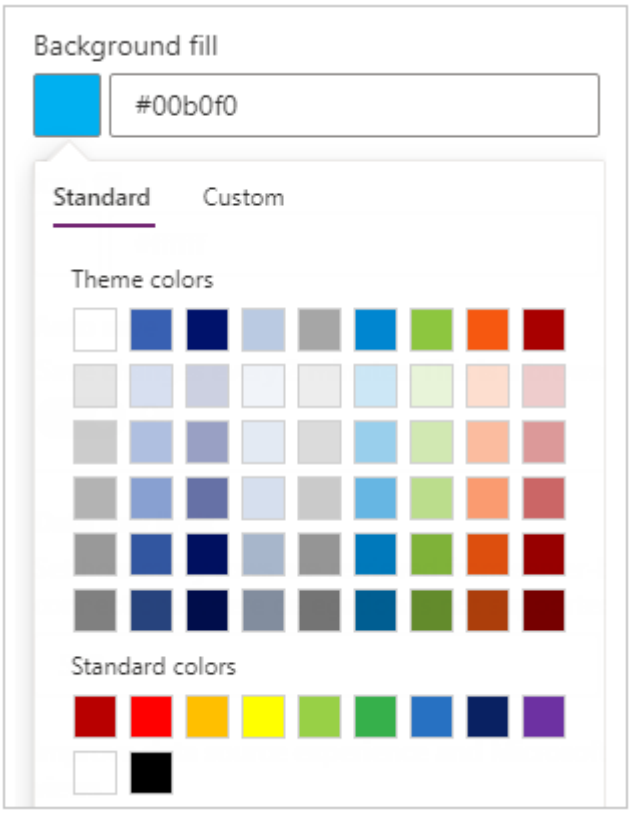
Under **General**, update the app name inside the **Name** text box.



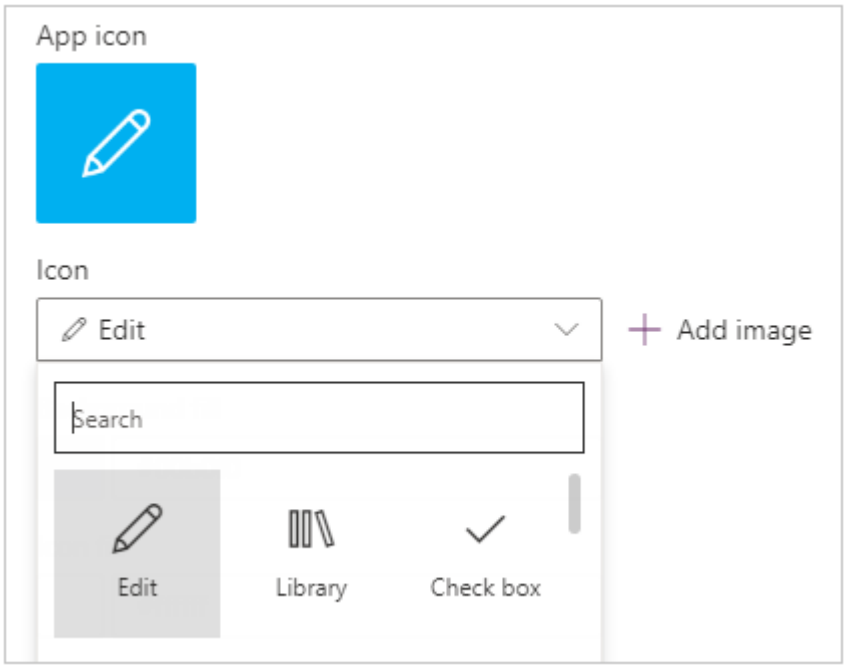
Change an app tile

Follow one or more of these steps:

- Select a different background color from the list of options.



- Select an icon from the list of default icons.



- Select **Browse file**, select the image that you want to use, and then select **Open**.

> **Note**
>
> For best results, use a square-shaped icon.

Next step

On the **File** menu, select **Save** to republish your app with the new settings.

More resources

- Share an app
- Delete an app
- Restore an app to a previous version

Edit a canvas app

Article • 09/07/2023

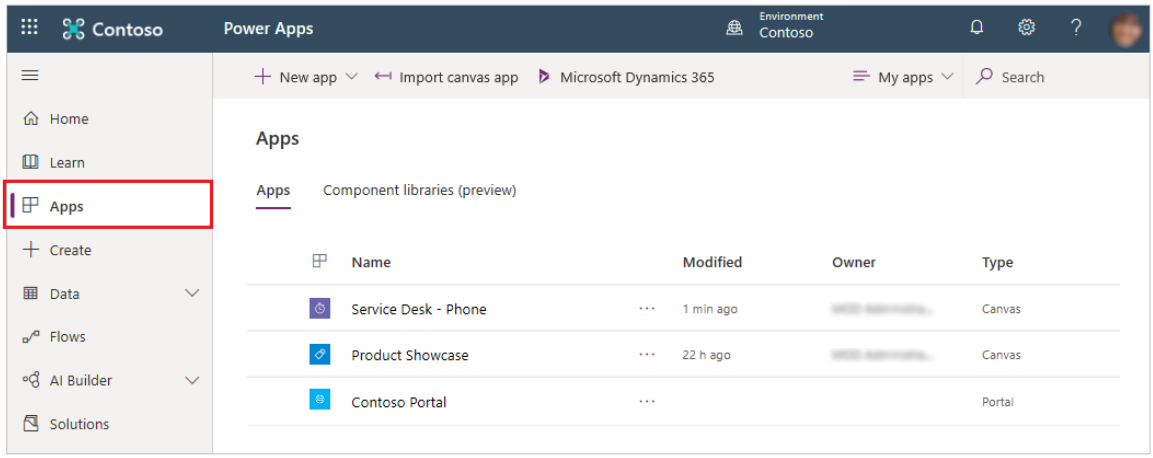
Edit any canvas app that you created, or for which you have **Co-owner** permission. You can edit an app in Power Apps Studio.

If you try to edit an app that's open for editing elsewhere, a message tells you whether you already have it open or another user does.

Edit an app

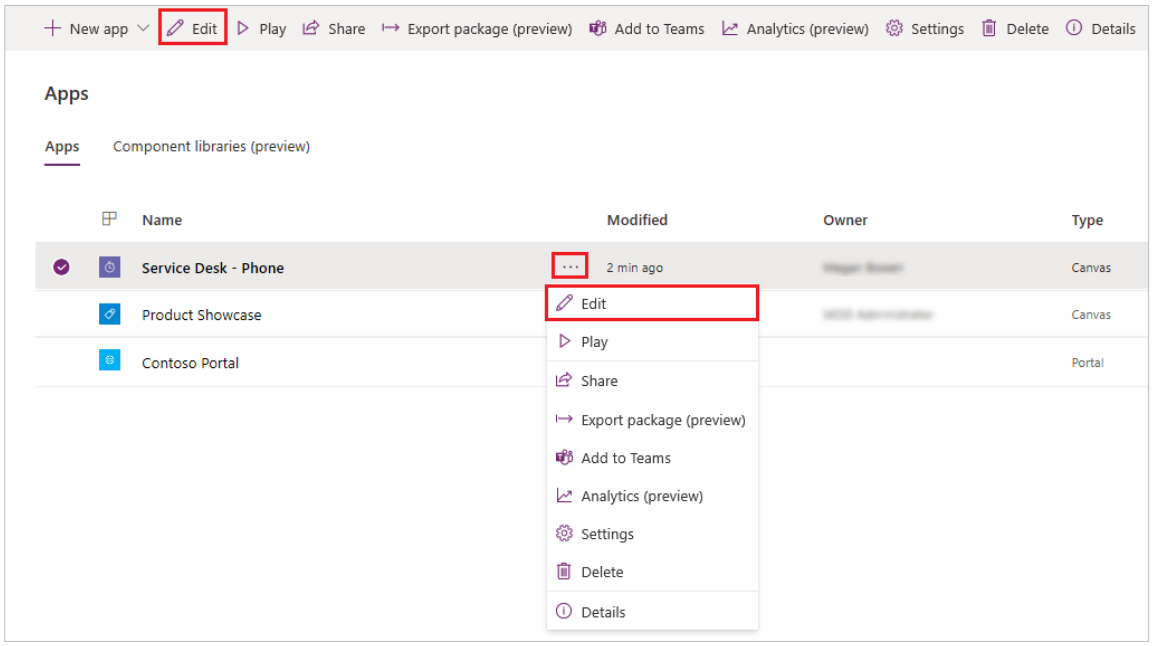
1. Sign in to Power Apps.

2. Select **Apps** in the left navigation pane.

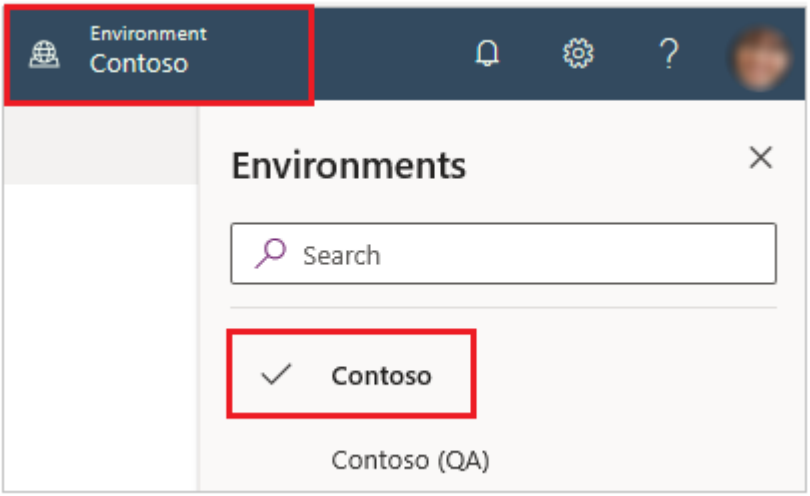


3. Select an app.

4. Select **Edit** from top menu. You can also use "**...**" (More Commands) for the app and then select **Edit** from the drop-down menu.



If you don't see the app that you want to edit, verify that you've selected the correct environment.



Collaborate on an app

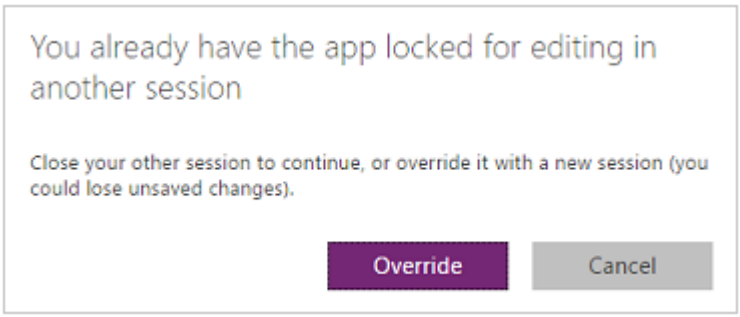
An app can be shared with others. Any **Co-owner** for an app can edit it. Consider the following scenarios when collaborating over an app.

Edit an app already being edited

Only one user can edit an app at a time. For more information, see Find out who's working on the same app.

Edit an app across multiple sessions

Consider that you already have an app open for editing. And then, you try to open the app for editing on another device, or in another browser window. In that case, you'll see the following message.



You can override the previous session, but you might lose any changes that you haven't saved.

Next Steps

Learn more about how to add a screen, a control, or a data connection.

Overview of exporting and importing canvas apps

Article • 05/17/2025

In this article, you'll learn about the different options available to export and import canvas apps in the form of singular app file, app package, and considerations from the application lifecycle management (ALM) perspective. To effectively manage ALM, it's recommended to use solutions. Canvas apps packages don't support ALM and should only be used for basic import and export capabilities when Dataverse isn't accessible.

You can export and import canvas apps using one of the following options:

- Export and import canvas apps as app packages
- Export and import canvas apps as part of solutions
- Export and import a canvas app as a single app file

> **Important**
>
> - Canvas app packages can't be used with Dataverse solution packages because of the package incompatibility.
> - Canvas apps that have Dataverse dependencies, such as flows, connection references, etc. are not supported for canvas app packages. For ALM capabilities in Microsoft Power Platform environments, use Microsoft Dataverse and solutions instead of the canvas app package export and import. More information: ALM overview
> - An App Insights instrumentation key may be present in imported canvas apps. Inspect the instrumentation key after importing an app to ensure it corresponds to the desired App Insights resource.

Export and import canvas apps as app packages

You can export and import canvas apps by using packages. This feature allows you to export an app from one environment and import it to another.

Resources included in canvas apps packages

An app can consume different resources. For example, most apps use connections. Other apps might use Power Automate, have custom connectors, or connect by using gateways to on-

premises resources. Some apps might also use Dataverse customizations

The following table explains different resource types, supportability, and import options.

Expand table

Resource type	Supported	Import options
App	Yes, for canvas apps	There are two options to import an app into an environment: • **Create new**: The app is created as a new app in the environment where the package is imported. • **Update**: The app already exists in the environment and will be updated when this package is imported.
Power Automate	Yes	There are two options to import a flow into an environment: • **Create new**: The flow is created as a new flow in the environment where the package is imported. • **Update**: The flow already exists in the environment and will be updated when this package is imported. **Note:** All resources that the flow depends on will also be included in the app package that's exported and will need to be configured when the package is imported. You can also export and import flows by using solutions. More information: Power Automate solutions
Custom connectors	No	Exporting a custom connector isn't supported. You need to re-create the custom connector on the target environment.
Connections	No	Exporting a connection isn't supported. You need to re-create connections on the target environment.
Dataverse customizations	No	Exporting Dataverse customizations as a part of a canvas app package isn't supported. You need to use Dataverse solutions instead. More information: Dataverse solutions
Gateways	No	You can't export or import gateways. You need to re-create gateways on the target environment.

Permissions

Only the **Owner** or **Co-owner** of an app can export a canvas app package. To import an app, the Environment Maker security role is required on the destination environment, either directly or through a Dataverse team that is part of the **AAD Security Group** category. Custom security roles are not currently supported.

Export and import canvas apps as a package

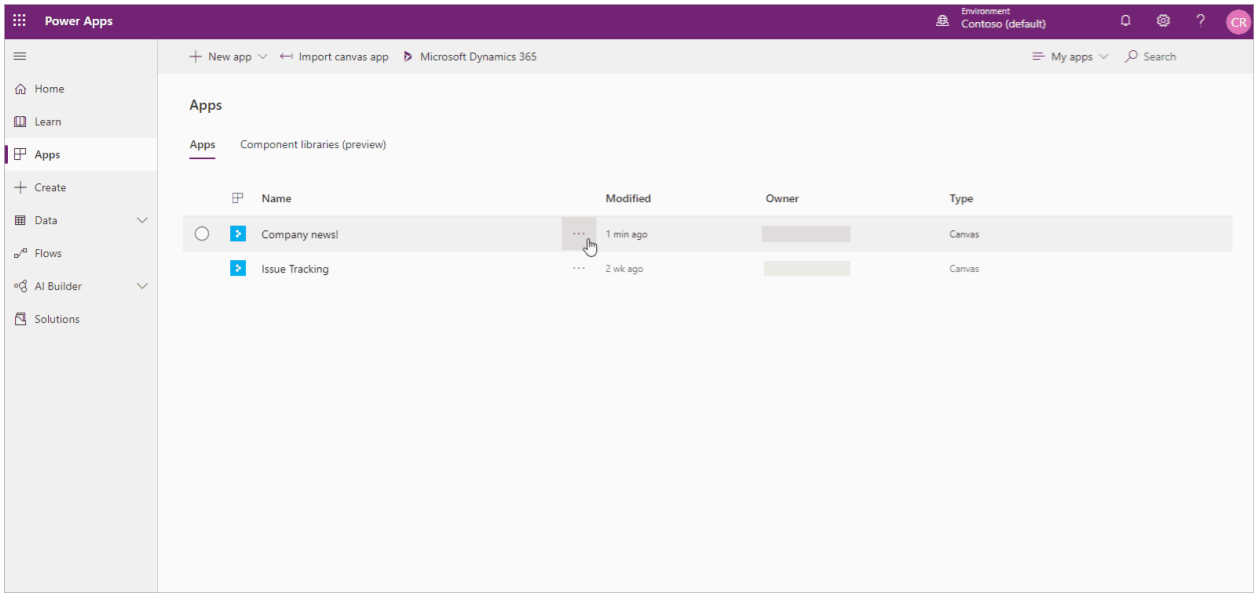
Article • 10/01/2024

This article provides a step-by-step guide for exporting and importing canvas apps. Before you begin, review the overview article to learn about the different export and import options available.

> **Important**
>
> It's recommended to use solutions for application lifecycle management (ALM) to ensure proper management and support.

Export a canvas apps package

To export a canvas apps package, select your app, and then select **Export Package**.



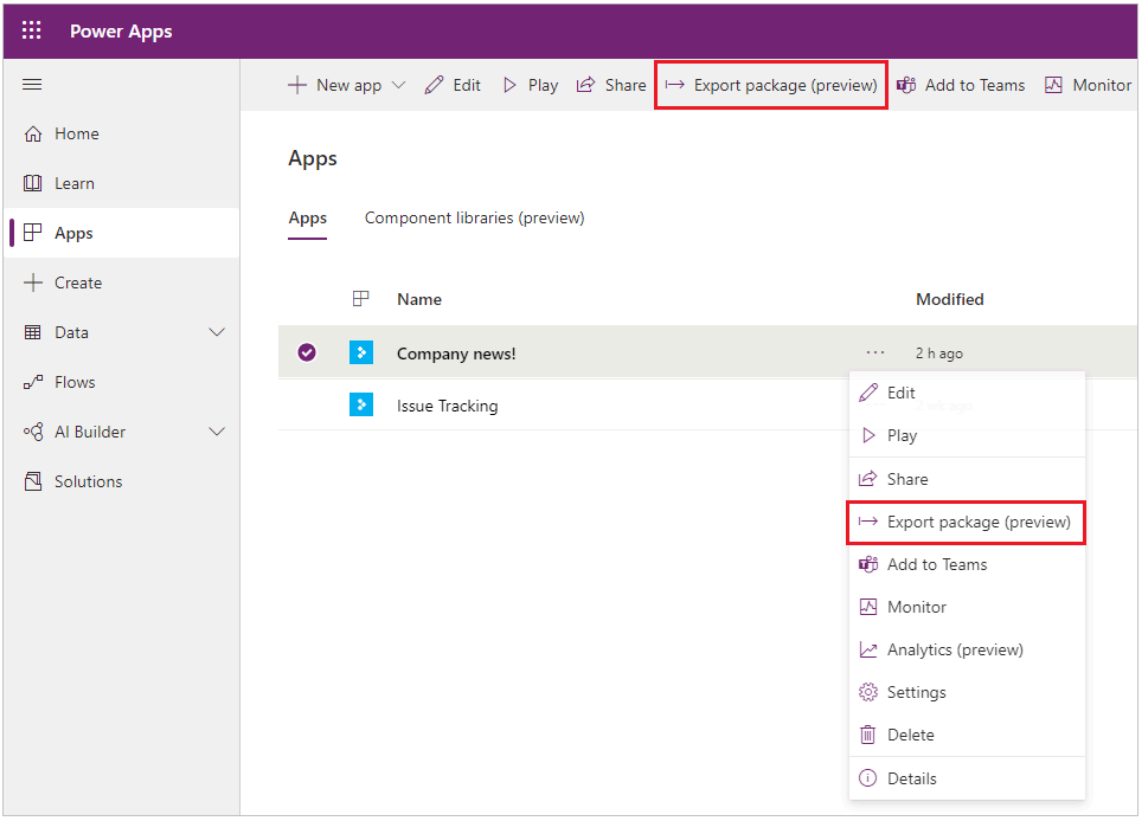
You can change the default **Import Action** for each resource used by your canvas app. By default, resources in a canvas app package, including the app itself, are set to **Update**. However, you have the option to select **Create as new** during import, which will create the resource instead of updating an existing one. The import action you select will be the default action during the app import

> **Important**

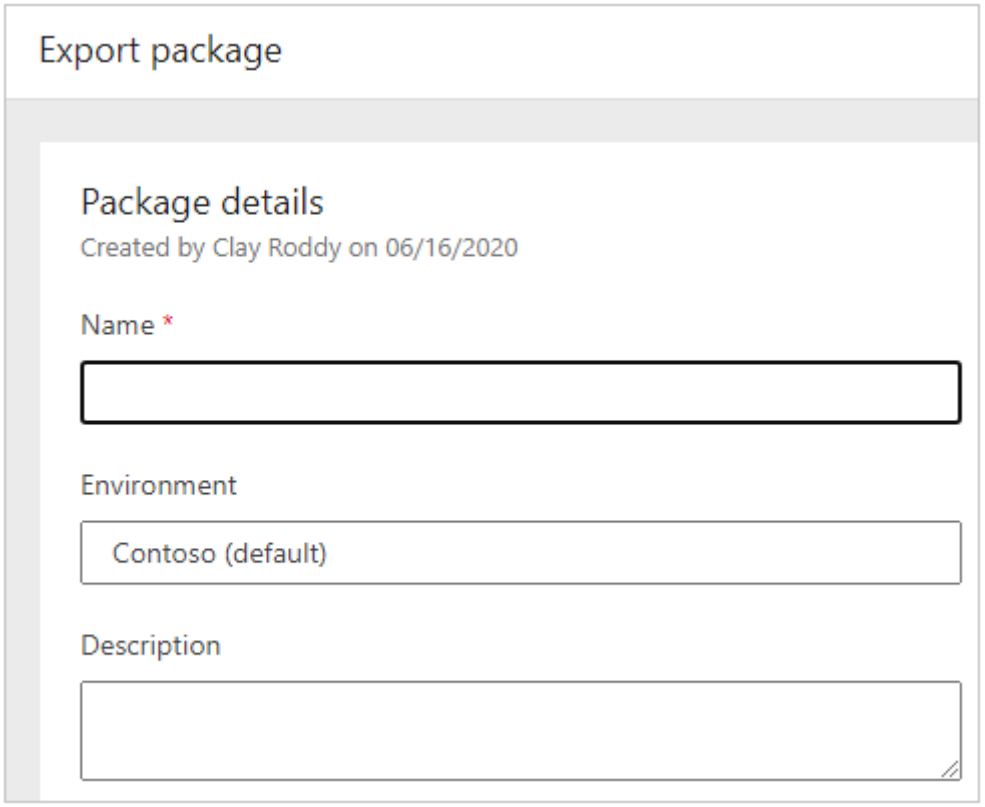
You can only import the exported package. Changes to the exported package file aren't supported.

To export a canvas app package

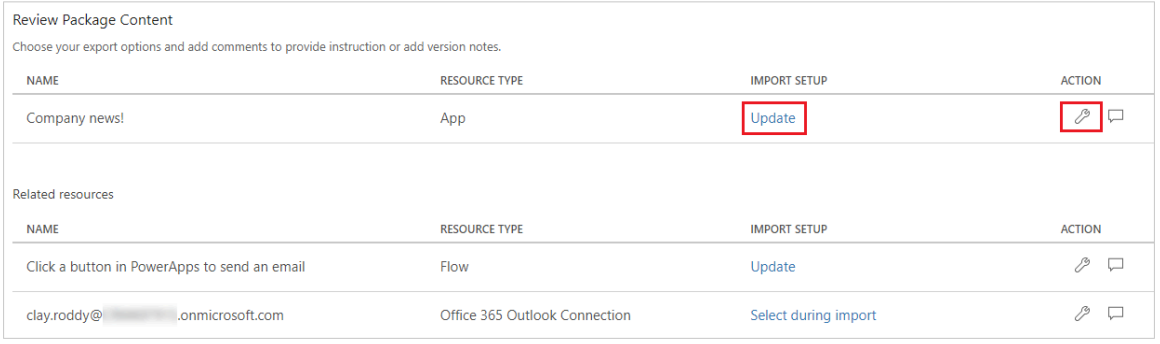
1. Sign in to Power Apps.
2. Select **Apps** from the left pane.
3. Select the app that you want to export.
4. Select **Export Package**.



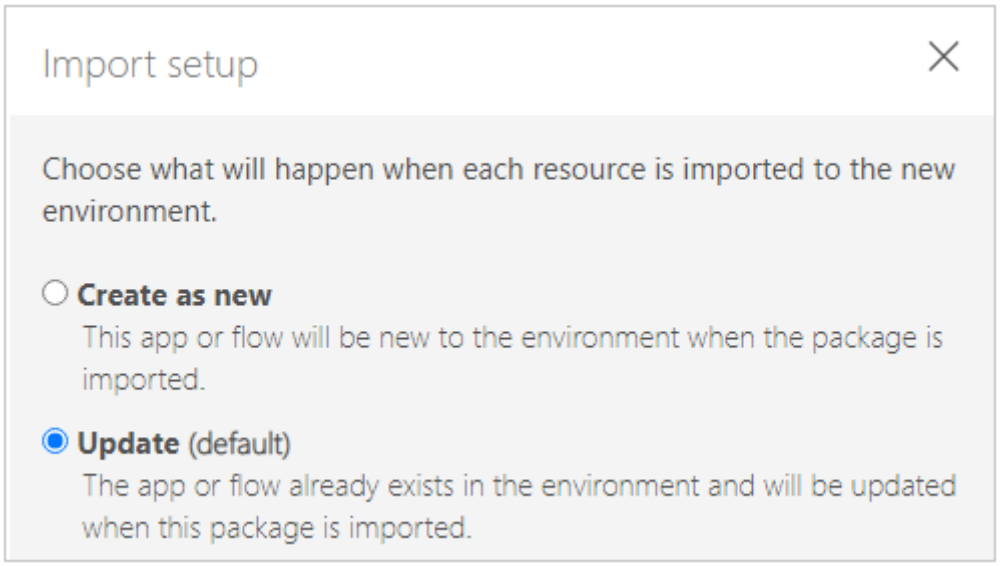
5. Enter the package **Name** and **Description**. You can also change the **Environment** name, if needed.



6. Select **Update** to choose the import action for the app package resource.

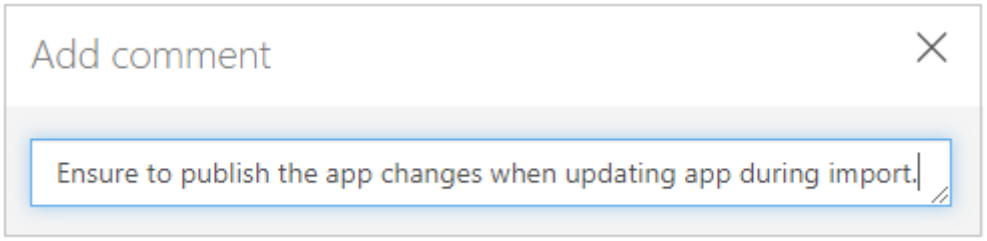


7. Select **Create as new** if the app should be created during import, or **Update** to update an existing app.



> **Note**
>
> The **Import Setup** action text changes depending on your new selection.

8. Repeat the previous step for each additional resource in the app package.
9. (Optional) Select (comment icon) to insert a comment for each resource.

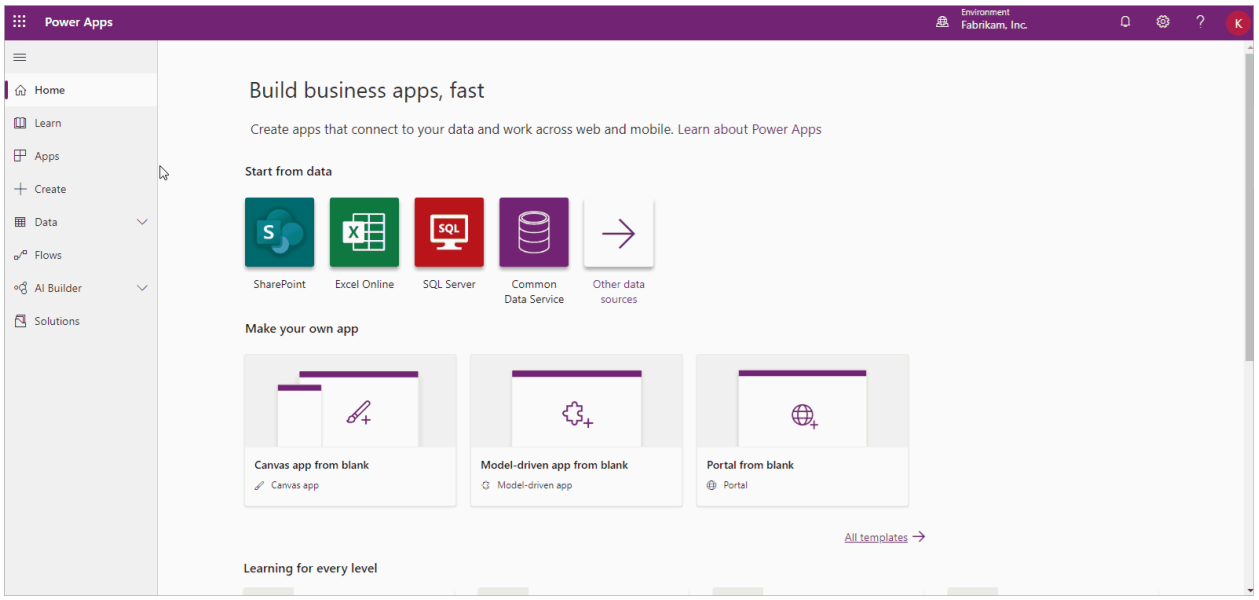


10. Select **Export** to export the package.

The package is downloaded to your browser's default downloads folder.

Importing a canvas app package

To import a canvas app package, select **Import canvas app**. Be sure to select the correct actions for each app package resource—for example, create a new instance of an app or a flow. You can also read additional information in comments that were entered while the app package was being exported.



If you're updating an existing app or resource, be sure to publish the app so users can see the changes.

Tip

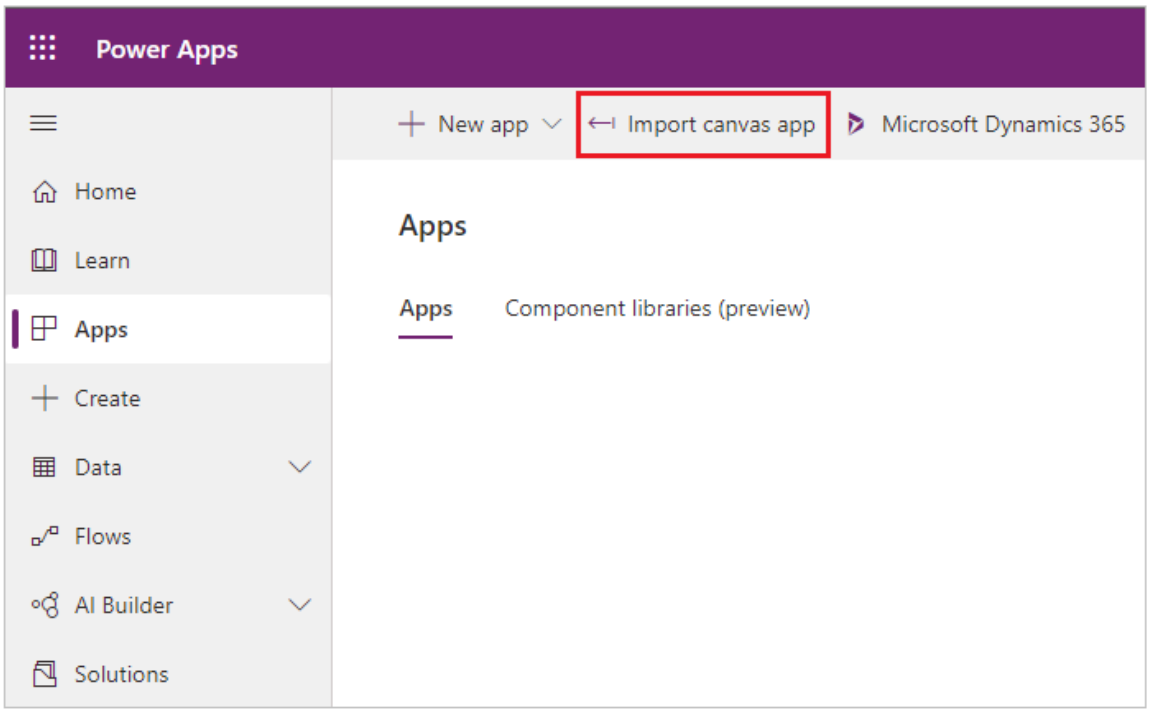
You can quickly confirm selections before importing an app package by viewing the icon changes for each resource type.

Expand table

Icon	Description
	**Create as new**: A new resource will be created.
	**Import action changed**: The import action for the resource has been modified.
	**Action required**: You must select an import action before the app package can be imported.

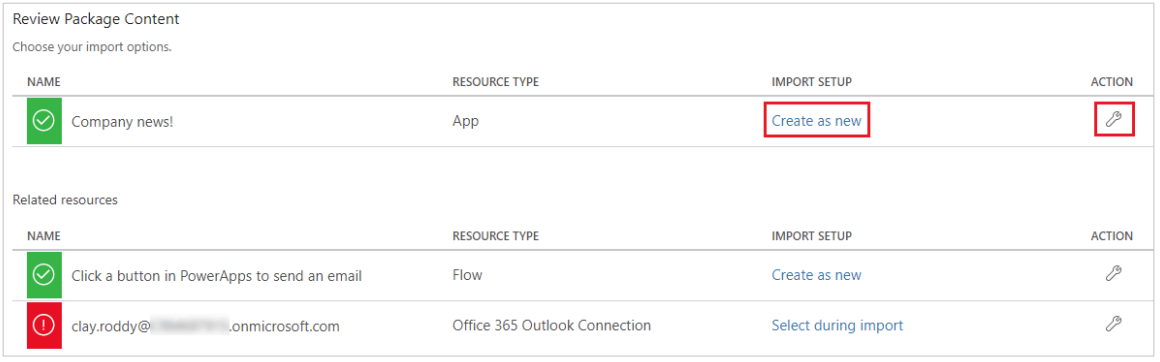
To import a canvas app package

1. Sign in to Power Apps.
2. Select **Apps** from the left pane.
3. Select **Import canvas app**.

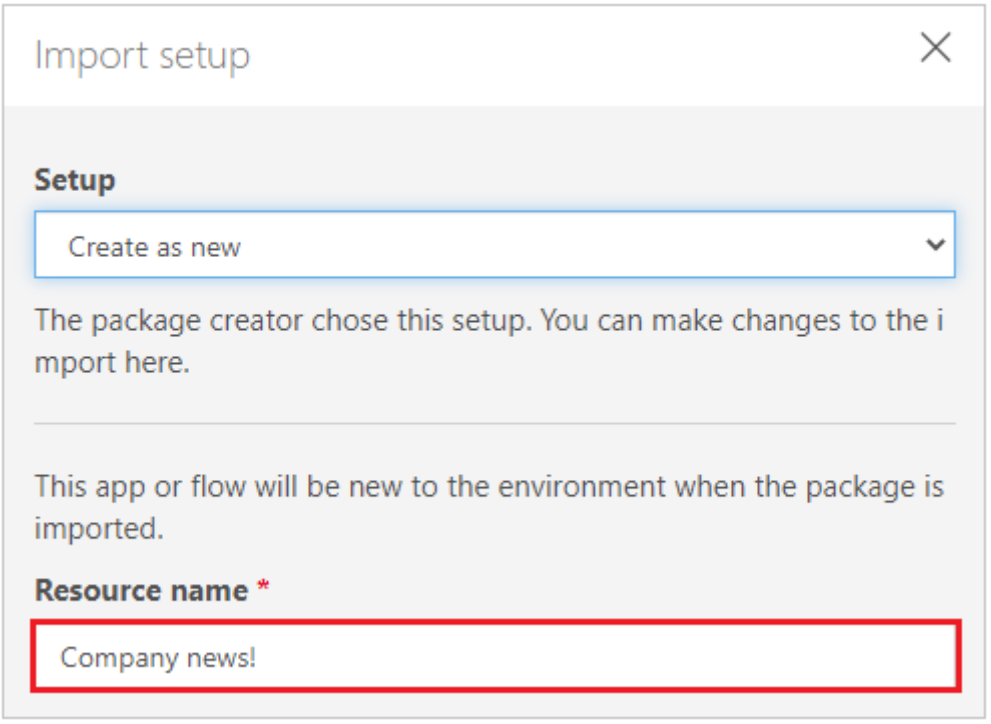


4. Select **Upload**, and select the app package file that you want to import.

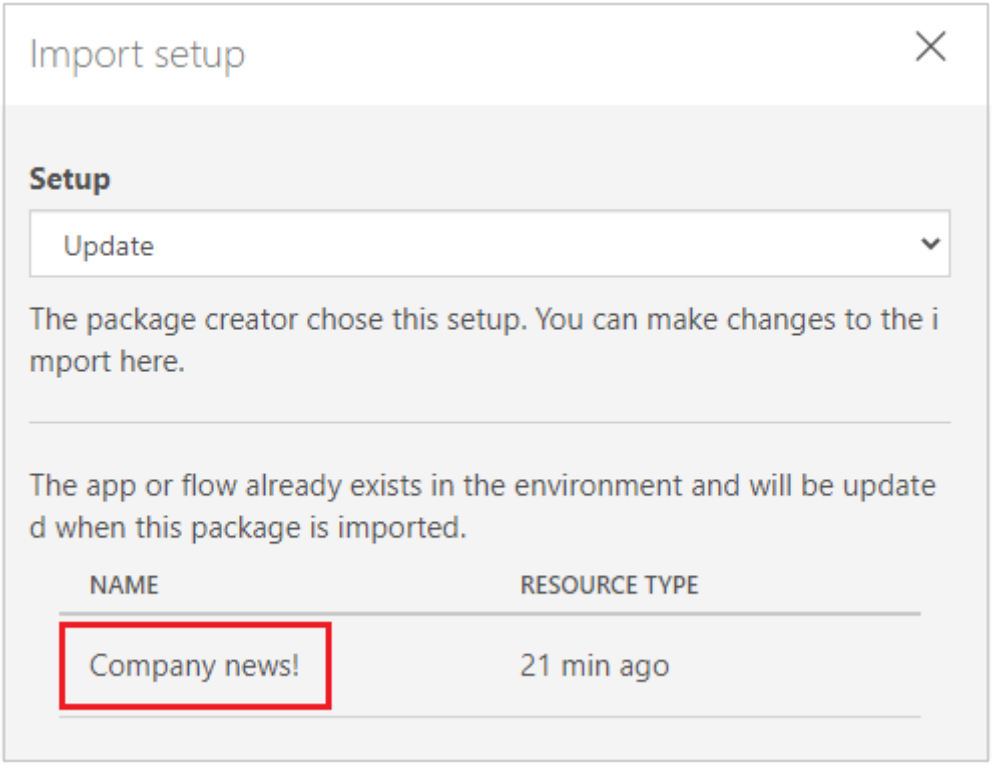
5. Select the **Import Setup** action, or  for a resource.



- If you select **Create as new**, you can change the resource name.

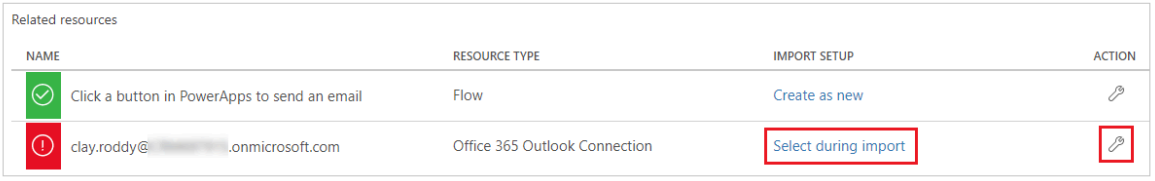


- If you select **Update**, select an app that you want to update during the import.

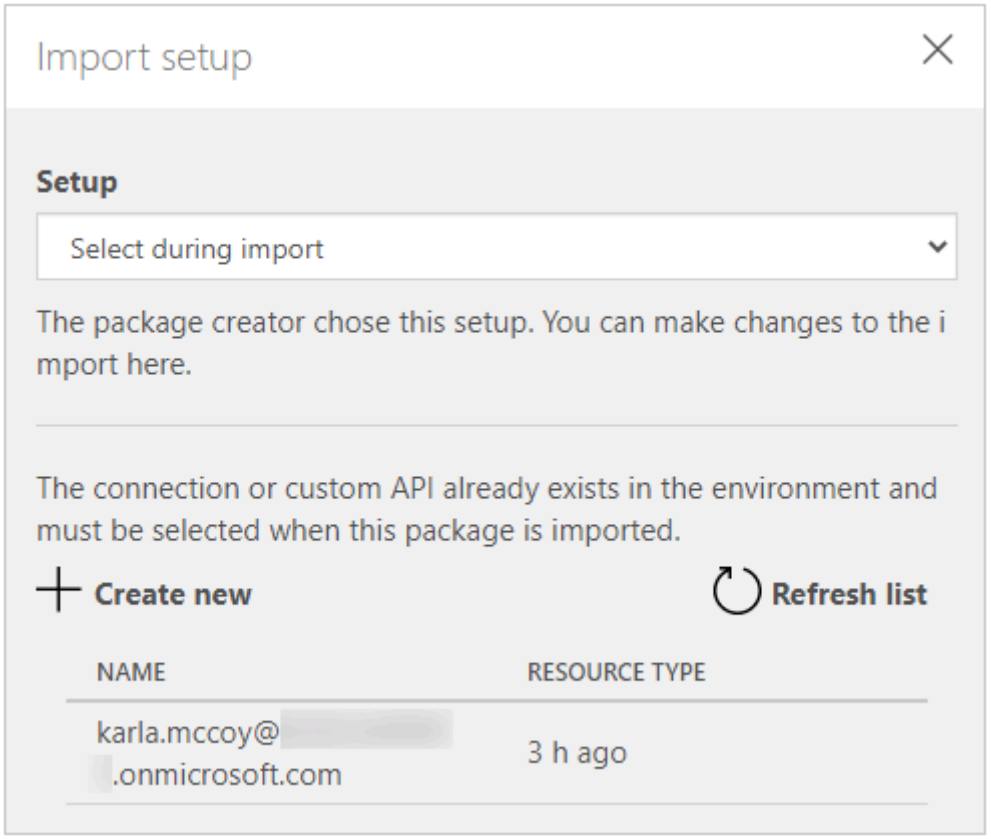


6. Repeat the previous step for each additional resource in the app package.

7. (Optional) If the app package contains references to connections, you can choose the connection from the available connections list.



Select **Select during import** to choose the appropriate connection.



> **Note**
>
> - If no connections are available, or the connection you want isn't listed, select **Create new** to create a new connection in a new browser tab. Ensure that you create the connection for the correct resource type. After creating the connection, return to the import app browser tab and select **Refresh list** to reflect and choose the newly created connection.
> - In some cases, it is necessary to reconfigure the flow association when you import a canvas app with flows. For more information, see Add an existing flow

8. (Optional) If comments were entered for a resource during the export of the app package, the comment icon will appear filled and the text **Comment yes** will appear when you hover over it. Select the comment to view it.

9. Select **Import** to import the app package.

> **Important**
>
> If you select to **Update** an existing app, the new changes will be saved as a draft of the app. You'll need to **publish** the app so users can see the changes.

Export and import a canvas app as a single app file

Article • 05/17/2025

In this article, you'll learn how to export and import a single canvas app. Before you begin, review the overview article to learn about the different export and import options available.

Using this option, you're able to export a single canvas app in the format of a **.msapp** file extension. This allows you to export a single file that contains the canvas app that you're currently editing and import it.

Permissions

Only the **Owner** or **Co-owner** of an app can export a canvas app package. To import an app, the Environment Maker security role is required on the destination environment, either directly or through a Dataverse team that is part of the **AAD Security Group** category. Custom security roles are not currently supported.

Export .msapp files in Power Apps

1. Sign in to Power Apps.
2. Open the canvas app that you want to export in Power Apps Studio.
3. In the Power Apps Studio, select **Save** drop-down menu and then select, **Download a copy**.

The **.msapp** file is downloaded to your device.

Import .msapp files in Power Apps

1. Sign in to Power Apps.
2. From the left navigation pane, select **Apps**.
3. Select **Import app** > **From file (.msapp)**.

When Power Apps Studio opens, you can choose the appropriate **.msapp** file to import. Power Apps Studio will reload with the **.msapp** file opened.

> **Note**
>
> For more information on resources included in the single app file, see Resources included.

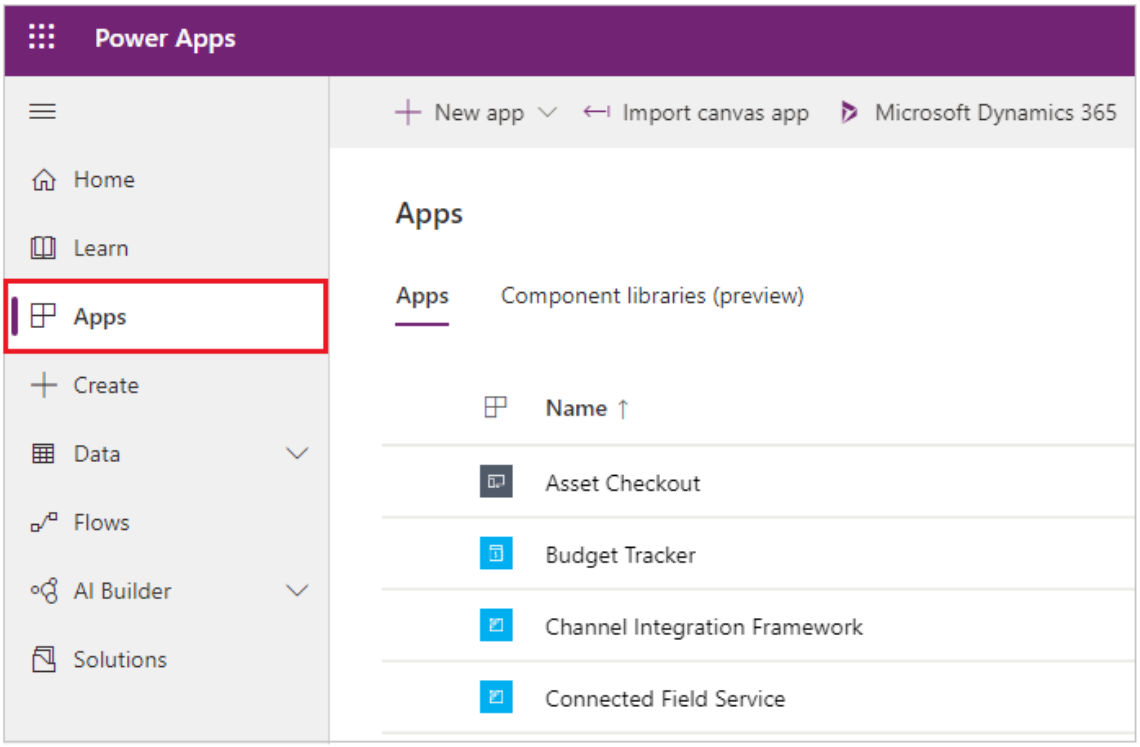
Delete a canvas app

Article • 07/13/2024

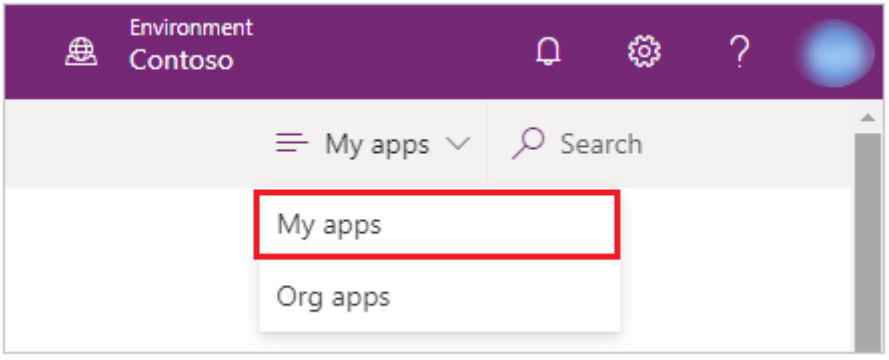
This article shows you how to delete a canvas app.

Delete an app as the owner

1. Sign in to Power Apps.
2. Select **Apps** from the left pane.



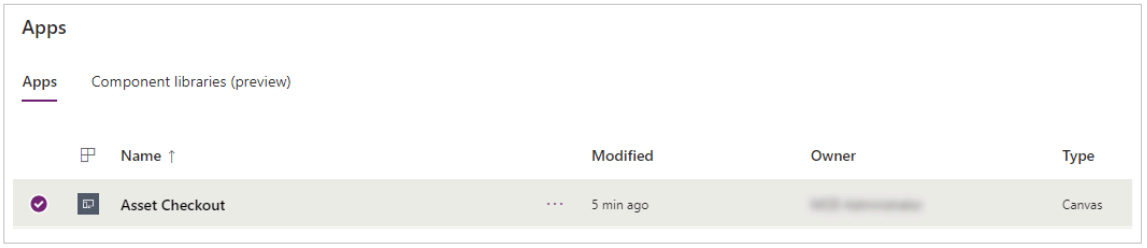
3. (optional) Near the upper-right corner, filter the list of apps to show only those apps that you own.



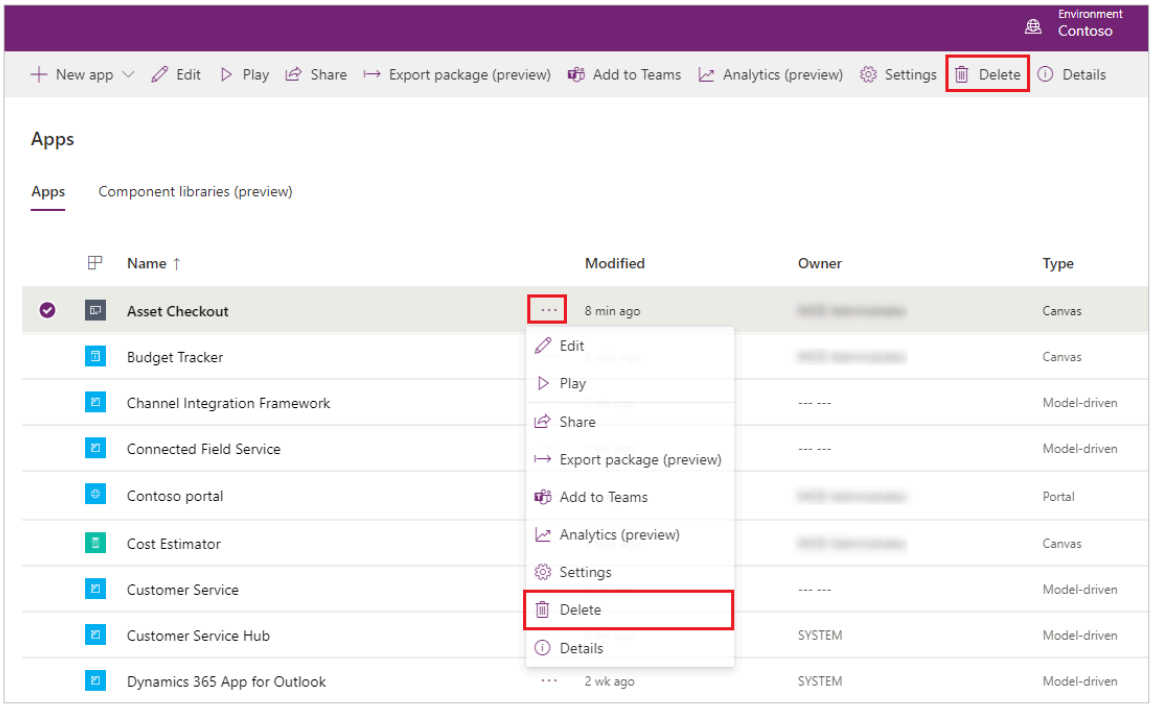
> **Note**

If the app that you want to delete doesn't appear, make sure that you're in the right environment.

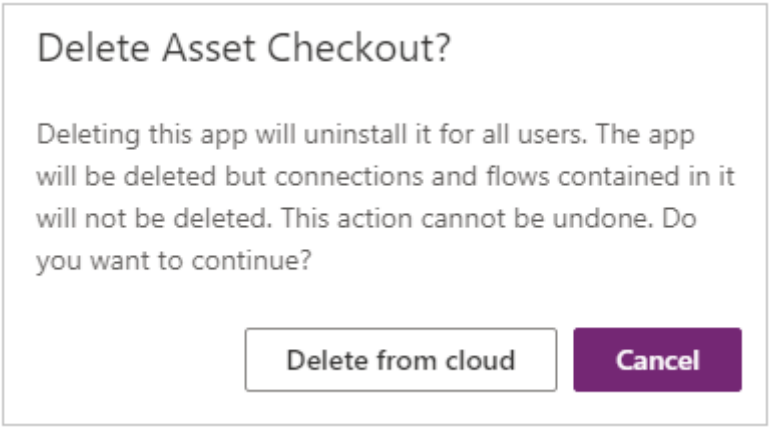
4. Select an app.



5. Select **Delete** from the top menu. You can also select **More Commands** (..) and then select **Delete** instead.



6. Select **Delete from cloud**.



> **Important**
>
> This action deletes the app not only from your account but also from the accounts of all users with whom this app was shared.

Delete an app as the administrator

If owner of an app is unavailable, a Power Platform or Dynamics 365 admin can set the owner of an app. And then, the new owner can delete the app.

To set a user as the owner of an app, use the Power Apps cmdlets for administrators.

> **Tip**
>
> You can also recover a deleted canvas app using **Power Apps cmdlets for administrators** as long as the app is **discoverable**.

How to check license designation for an app

Article • 03/03/2023

Starting October 2019, several connectors are reclassified from Standard to Premium.

Power Apps licensing FAQ outlines reclassified connectors. Apps using these connectors before the reclassification have been granted an extended timeframe allowing users without a premium license to access these apps.

The following table outlines the designations and which license an end user must have to access an app.

Designation	Definition
Standard	An app that only uses standard connectors. An end user must have a Power Apps for Office 365 plan, per app plan, or a per user plan to access this app.
Extended	An app allowed to use connectors promoted to premium on October 1, 2019. An end user must have a Power Apps for Office 365 plan, per app plan or per user plan. Power Apps licensing FAQ outlines which connectors were promoted to premium on October 1, 2019.
Premium	An app that uses at least one premium connector, a custom connector, or an on-premises gateway. An end user must have a per app plan or per user plan to access.

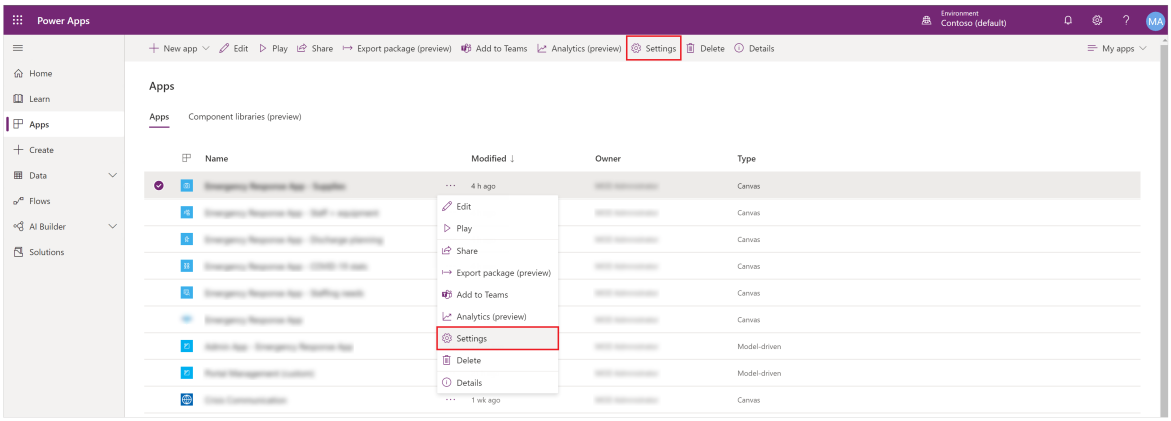
> **Note**
>
> Power Apps built in Microsoft Teams environments that connect to Dataverse for Teams, or use custom connectors have **Premium** license designation.
>
> - End-users with a **Microsoft 365 subscription including Dataverse for Teams use rights** will be able to run these apps in Microsoft Teams.
> - End-users that attempt to run these apps outside of Microsoft Teams are required to have a per app plan or per user plan.

Check app license designation from app settings

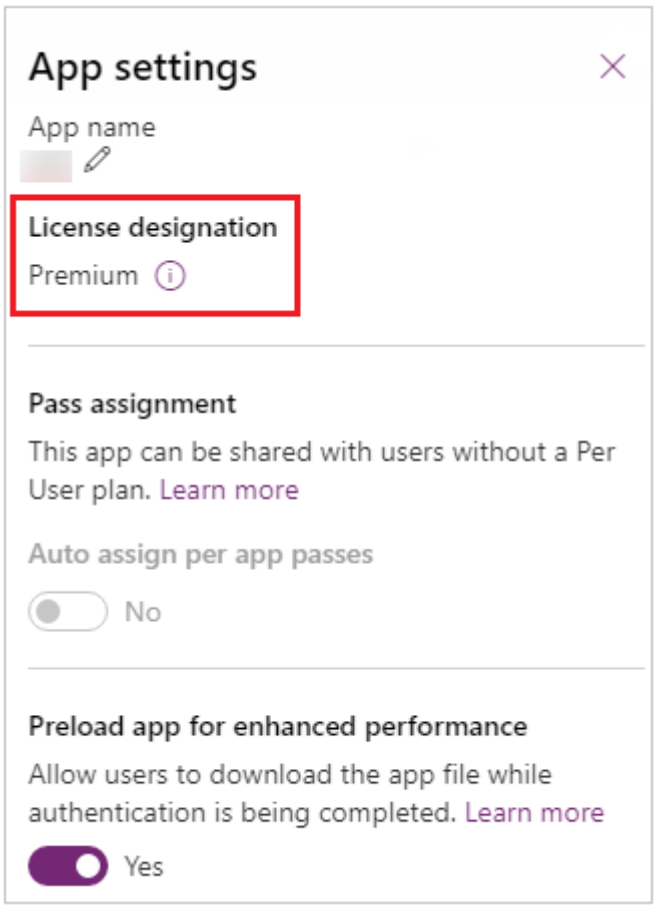
1. Sign in to Power Apps.

2. Select **Apps** from left side.

3. Select an app from the list of app. You can use the **Settings** option from top or, use the **More Commands** (...) and then **Settings** from the drop-down menu:



4. Select **Settings** to see the license designation information:

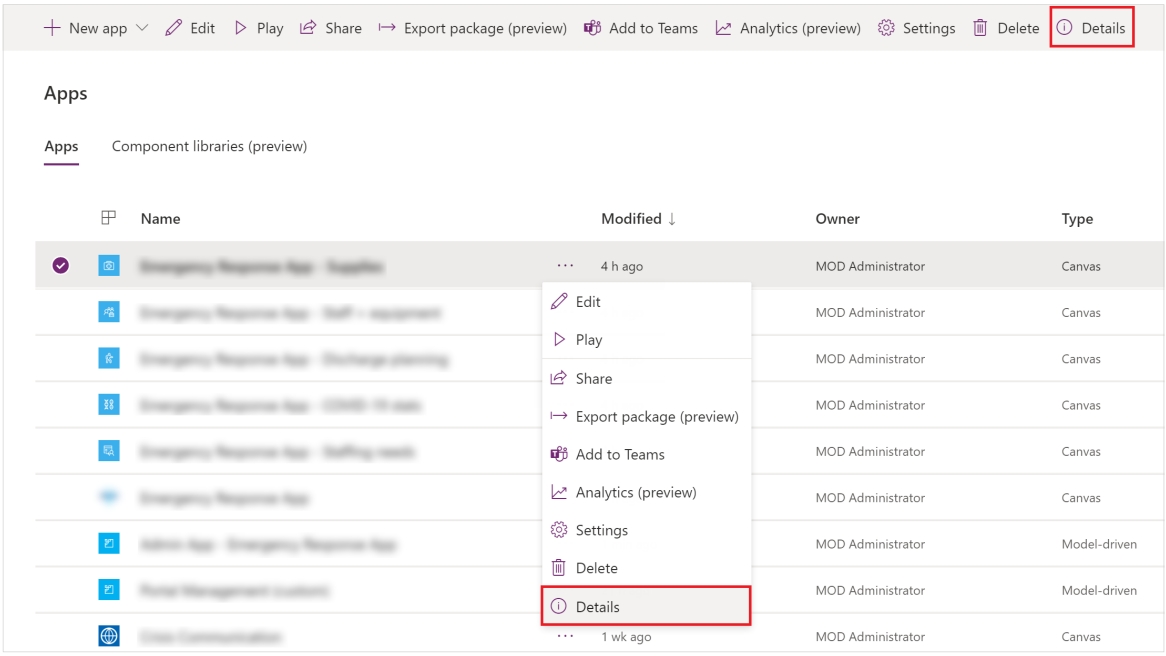


Check app license designation from app details

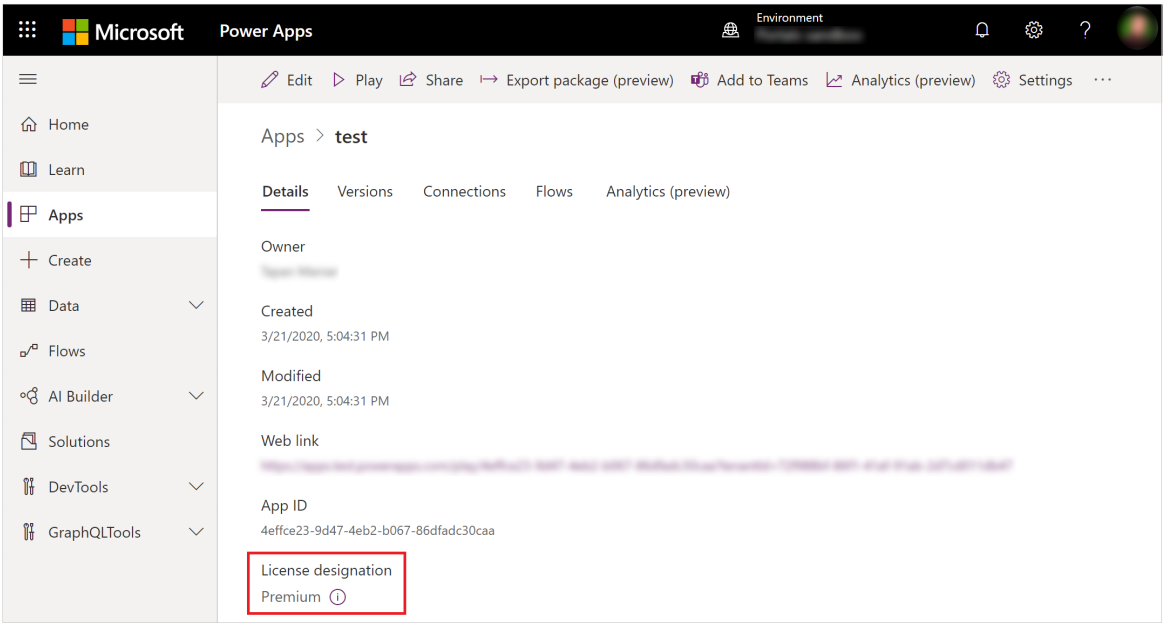
1. Sign in to Power Apps.

2. Select **Apps** from left side.

3. Select an app from the list of app. You can use the **Details** option from top or, use the **More Commands** (...) and then **Details** from the drop-down menu:



4. Select **Details**:



Known issues

- The use of a premium connector in a flow connected to an app isn't recognized by the app's license designation.

  For example, an app that only uses standard connectors and is connected to a flow using a premium connector, like the HTTP connector, will have the license designation as **Standard** although it requires the app users to have **Premium** use rights.

Pass assignment

For information about Pass assignment, read Power Apps per app plans.

Restore a canvas app to a previous version

Summarize this article for me

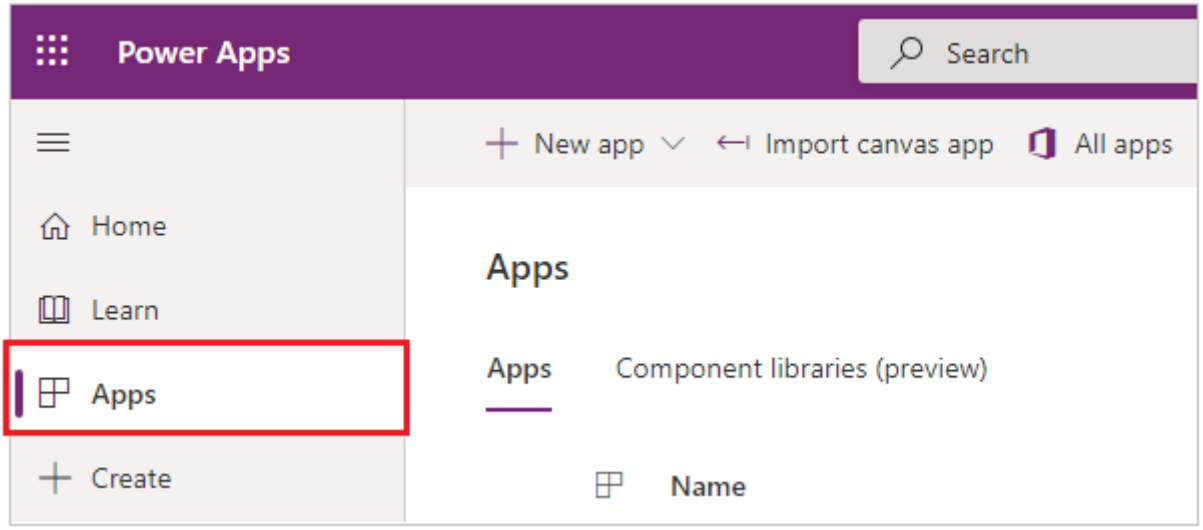
[This article is prerelease documentation and is subject to change.]

This article shows you how to restore a canvas app to a previous version that was saved to the cloud from your Power Apps account.

Restore an app from your account

1. Sign in to Power Apps.

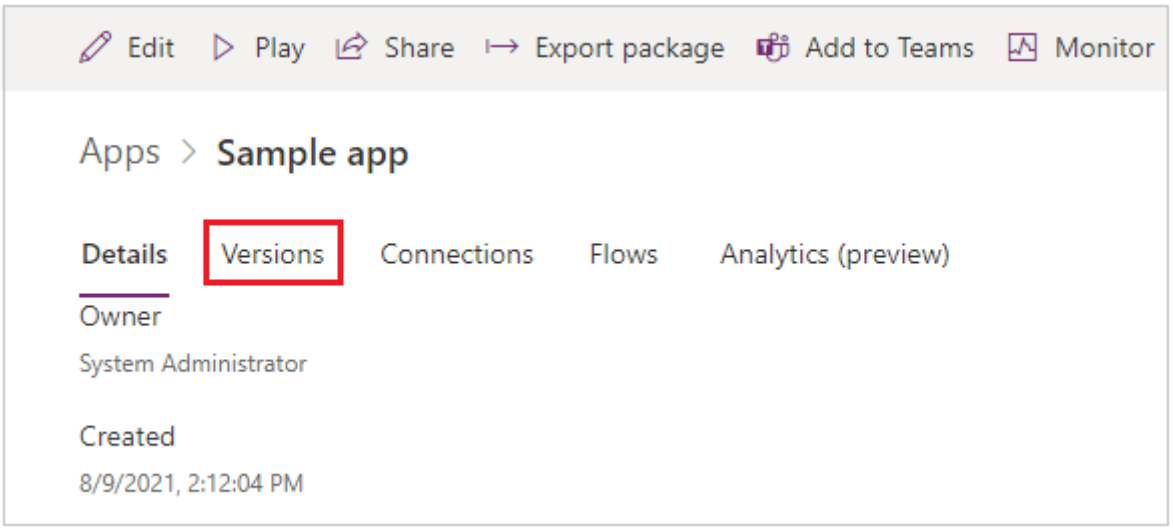
2. On the left navigation pane, select **Apps**.



3. Select your app and then select **Details** on the command bar.

> **Note**
>
> If the app that you want to restore doesn't appear, make sure that you're in the right environment.

4. Select **Versions** and then select the app version that you want to restore.

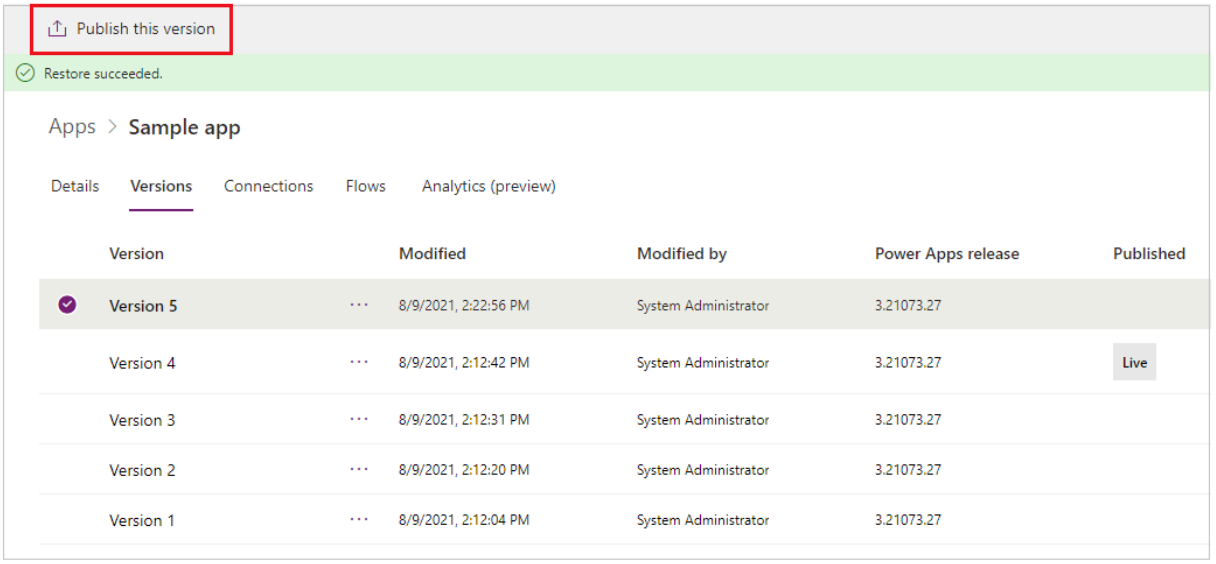


5. Select **Restore** and confirm your changes by selecting **Restore** again.

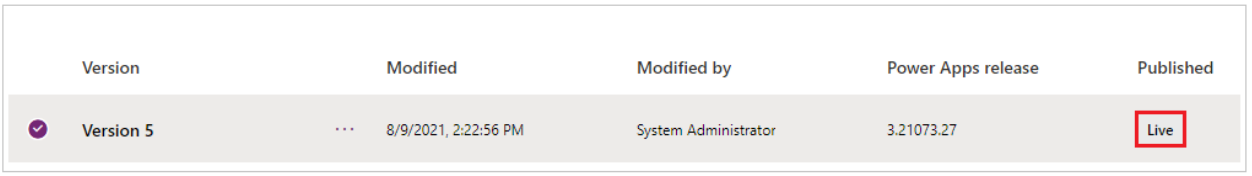
> **Note**
>
> - For apps older than 6 months, this action will repackage the app with the oldest version available. Functionality may have changed from the original packaging of the app

New version is created.

6. (Optional) If you want to publish the restored version, select **Publish this version**, and then select **Publish this version** when prompted to confirm.



Notice the published restore version that shows up as **Live**.



> **Note**
>
> **Publish this version** option only appears for the latest unpublished version of an app.

Test Studio

Article • 05/21/2025

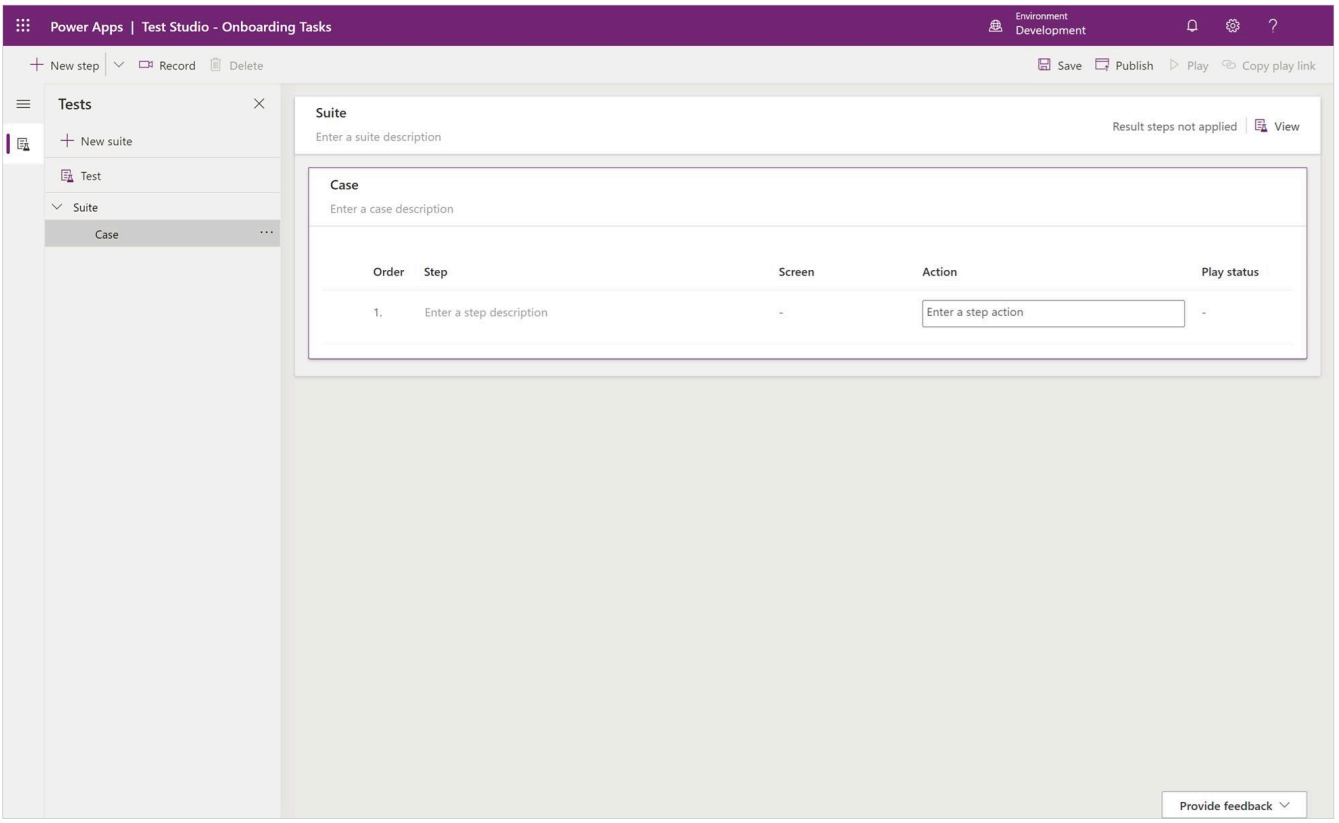
Build end-to-end UI tests for your canvas app using Test Studio. Maintain your app quality by continually validating that your app works as expected when new changes or updates are deployed.

Overview

Testing is an important part of the software development life cycle (SDLC). Testing can help ensure the quality of the app delivered to customers. It can identify issues or defects early in the release process and provides an opportunity to fix these issues to make the app more reliable before releasing changes. Depending on the size and usage of the app, manual testing of new changes might be enough. However, as the app grows in complexity and usage, you might need to consider a test strategy instead of manual testing. If the app is mission-critical, even a small mistake can have a significant impact.

Increased app changes can result in longer testing cycles. Eventually, regression testing of the app might be longer than the time spent to develop new features. In fast-paced development, thoroughly testing every feature in the app becomes a bottleneck to releasing software updates. One option to reduce the time taken during a test cycle and on regression testing is test automation. Test automation can help you test your app with minimal effort, reducing testing time and identifying critical issues before release.

Power Apps Test Studio is a low-code solution to write, organize, and automate tests for canvas apps. In Test Studio, you can write tests using Power Apps expressions or use a recorder to save app interaction to automatically generate the expressions. You can play written tests back within the Test Studio to validate app functionality, and also run the tests in a web browser and build the automated tests into your app deployment process.



Prerequisites

You must be creator or co-owner of an app to test the app with Test Studio.

Test Studio terminology

The following section explains key Test Studio terminology.

Test cases

Test cases are made up of a series of instructions or actions, called test steps. Test cases are executed to validate that your app, or specific features in your app, is working as you expect. For example, in an Expense app, you would like to ensure that only expenses with associated actual cost can be submitted. A test case can help verify that this condition or requirement is always met.

In Test Studio, test steps are written using the Power Apps expression language. Test expressions can consist of both the functions available when building your app and additional expressions to support automated testing.

Test suites

Test suites are used to organize or group test cases together. As the number of test cases in the app grows, you might consider organizing the test cases in specific features or functionality. For example, you might have one test suite with test cases to validate expense report submissions and another test suite that focuses just on expense approvals.

Test cases contained in test suites are run sequentially. The app state is persisted across all test cases in a suite. For example, if you have a test case that completes on Screen 5 in your app, the next test case in your test suite will begin running from Screen 5. It allows you to break down a complex test scenario into multiple test cases within a single suite, and the state is shared across all test cases. If your second test case expects to begin at the start screen of the app, you can navigate to the start screen as the first step in your test case. It's important to remember that the app is not reloaded at the beginning of every test case in a test suite when planning your test execution.

Test assertions

Every test case should have an expected result. To validate the expected result of a test against the actual result of your test, you can write test assertions. An assertion is an expression that evaluates to true or false in the test. If the expression returns false, the test case will fail.

In the expense app example above, you can write an assertion to validate whether an expense report is created with an expense line item having zero cost associated.

Best practices

When testing canvas apps using Test Studio, consider the following best practices to gain maximum benefits to improve your app quality:

1. **Determine which test cases should be automated.**

   It's difficult to automate all tests and we do not recommend that you completely rely on test automation. Manual testing should be performed in addition to test automation. Tests best suited to automation are:

   - Repetitive tests.
   - High business impact functionality tests.
   - Features that are stable and not undergoing significant change.
   - Features that require multiple data sets.
   - Manual testing that takes significant time and effort.

2. **Keep test cases small.**

While a single test case can support testing all functionality in your app, we recommend that you avoid writing a monolithic test case and try to divide it into multiple test cases. Each test case could test a specific feature or functionality in your app. A failed assertion in a large test case might cause other functionality to remain untested. Using multiple test cases contained in a test suite allows other functionality to get tested regardless of whether a previous test case failed. This strategy also makes it easier to isolate test failures.

3. **Keep expressions to a single test action.**

   A test action can contain multiple expressions. Large multi-action test expressions for a single step might impact your ability to debug and isolate any test failures. Consider dividing a test step with multiple actions into more test steps of single actions to identify issues faster.

4. **Every test case should have an expected result.**

   Each test case should have one or more expected results. Test assertions should be used to validate the expected outcomes of your test against the actual outcomes. Multiple assertions can be written for a single test case.

5. **Use test suites.**

   For maintenance, group or categorize similar test cases together and describe the purpose and expected results of your test.

Known limitations

While we work to provide full control coverage in Power Apps Test Studio is in progress, the following functionality is currently unavailable:

- Components.
- Code components written in the Power Apps Component Framework.
- Nested galleries.
- Media controls.
- Formula-level error management experimental feature needs to be turned on for the app.
- Support for controls not listed in the Select and SetProperty functions.
- Person-type columns.
- Test Studio is not compatible with the experimental Git version control feature, and will not work properly if that feature is enabled.

Working with Test Studio

Article • 03/03/2023

In this quickstart, you'll create tests for a canvas app called Kudos. You can also explore and discover testing concepts and apply them to writing tests for your own canvas apps. The sample Kudos app is part of a suite of employee engagement apps available to download from Employee Experience Starter Kit.

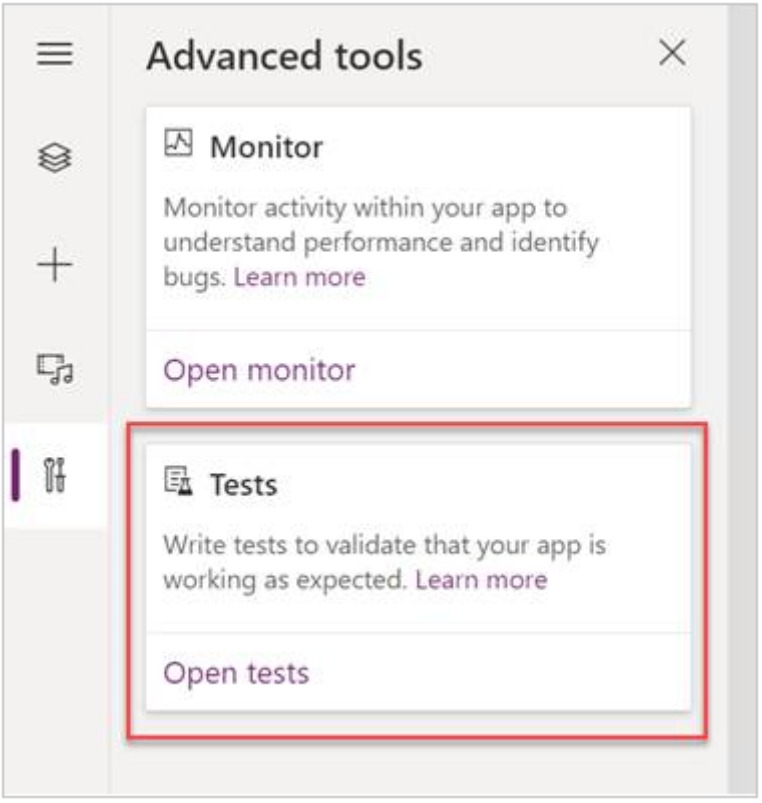
Watch this video to learn how to work with Test Studio:
https://learn-video.azurefd.net/vod/player?id=3fe85f46-745a-411c-aba8-6044cb184e78&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fworking-with-test-studio

Open Test Studio

1. Sign in to Power Apps.
2. Create a new app or edit an existing app.
3. Save your app to Power Apps to open Test Studio.

   > **Note**
   >
   > You must save an app before you can write tests for the app.

4. Select **Advanced tools** in the left navigation.
5. Select **Open tests** to open the Test Studio for this application. This action opens Test Studio in a new browser tab.

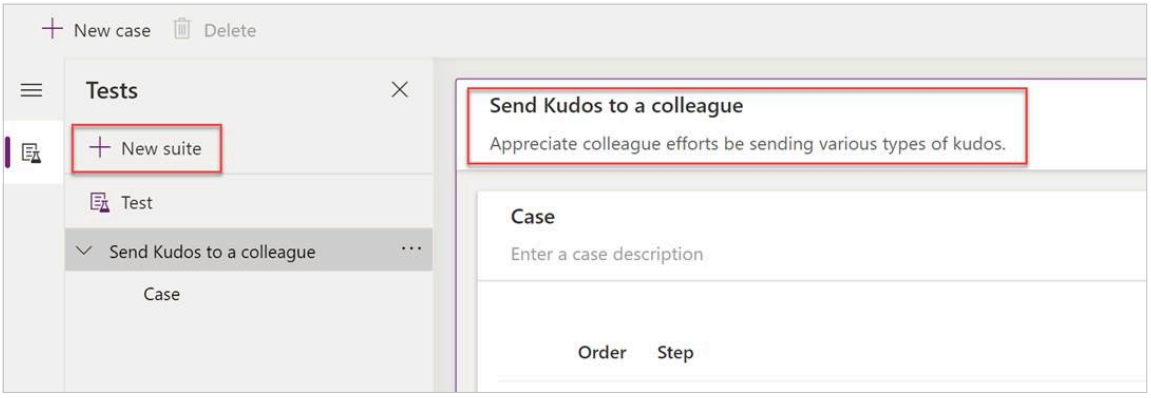


> [!NOTE]
> Tests are published and stored in the app package. Exporting and importing a canvas app package to another environment will also include all the test definitions such as test suites and test cases you have created.

Create a test suite

By default, a test suite and test case are created for you in Test Studio. Test suites are used to organize your test cases. An app can contain one or more test suites. You can use the default test suite and case to begin writing your tests immediately or create a new test suite.

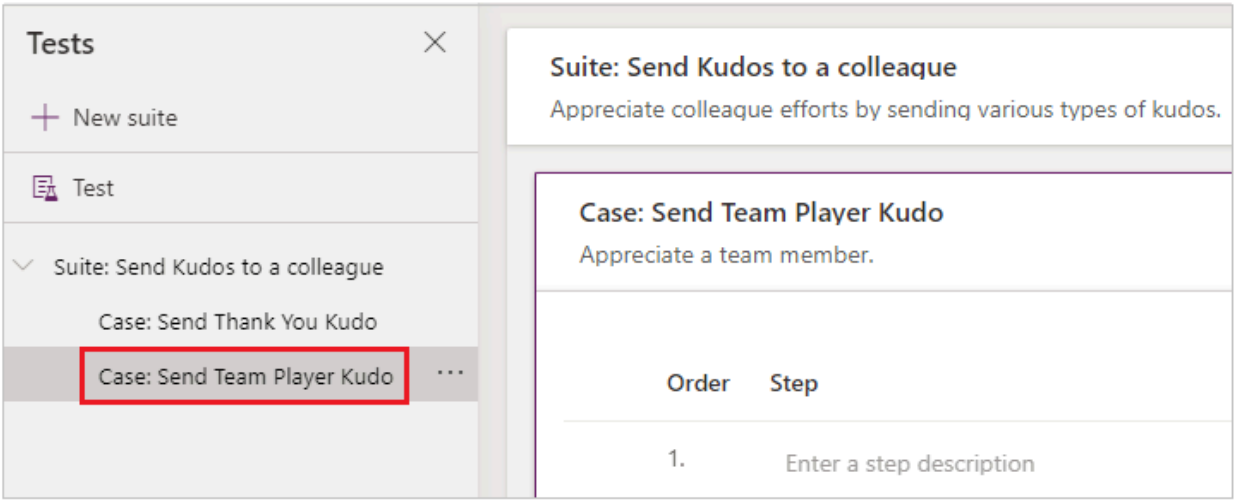
1. Select **New suite**.
2. Update the **Test suite name and description** by selecting the fields on the main grid.



Create a test case

Depending on how you want to organize or group your tests, you can create multiple test cases in a test suite. Each case can test a specific feature or a subset of functionalities in your app.

1. Select a test suite.
2. Select **New Case** in the top menu to create a new case.
3. Update the **Test case name and description** by selecting the fields on the main grid.



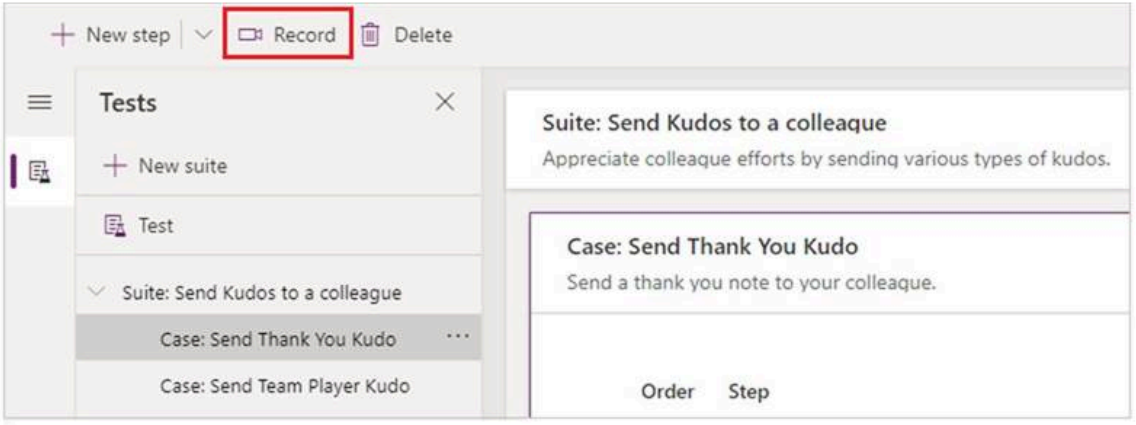
Record a test case

A test case consists of test steps that contain actions. Test actions are written using Power Apps expressions that perform a task. You can use the recorder to automatically generate the test steps as you interact with your app. After you record, you can update the test case, add new steps, delete steps, and write test assertions to validate the result of your test.

> **Note**
>
> Only a published app plays in record mode. Publish any recent changes to the app before you start recording a test case. Recording without publishing recent changes causes the last published version of the app to play in record mode.

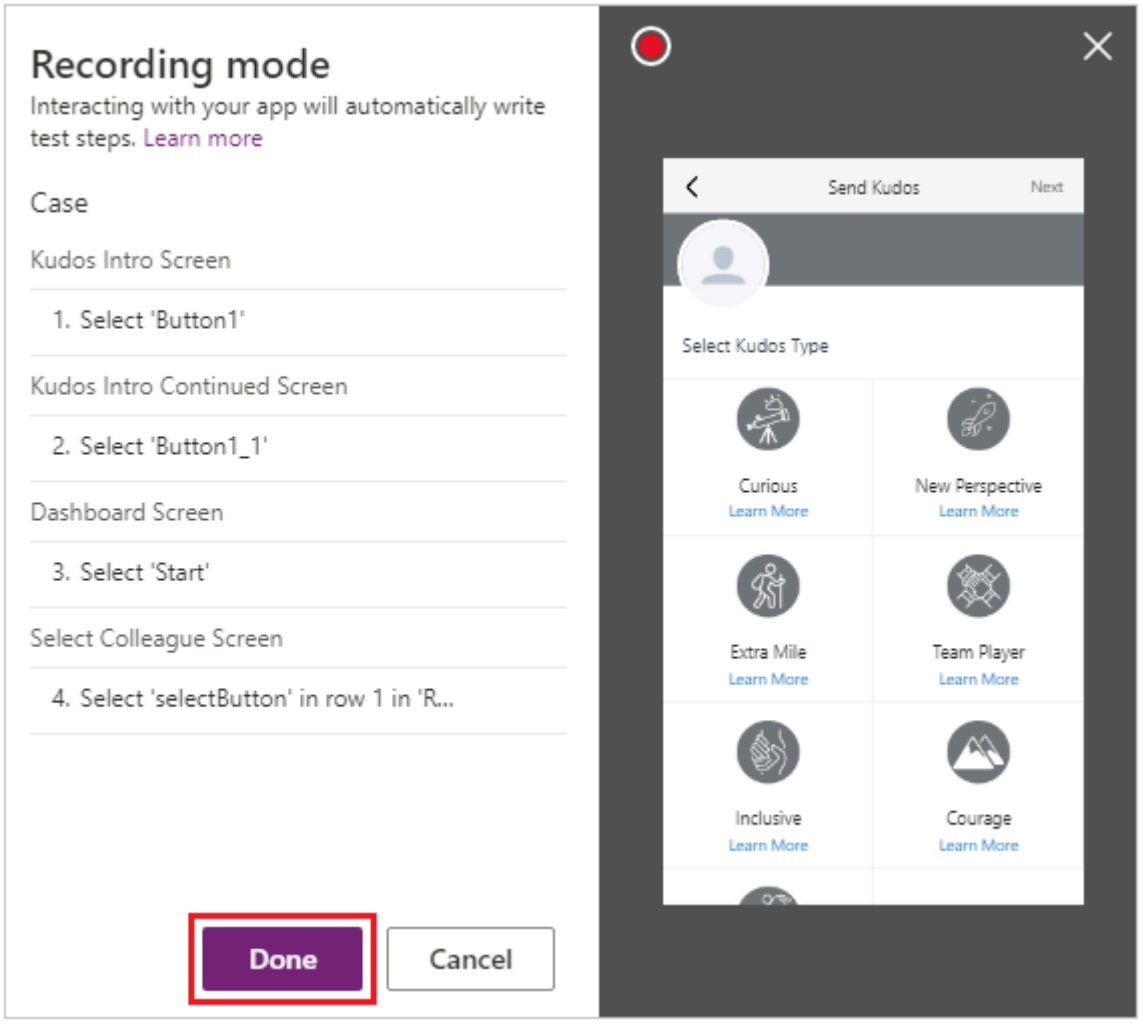
1. Select **Record** from the top menu. This action opens the published app with recording mode in a new browser tab.

   > **Important**
   >
   > Recording on an existing test case overrides any existing test steps already present.

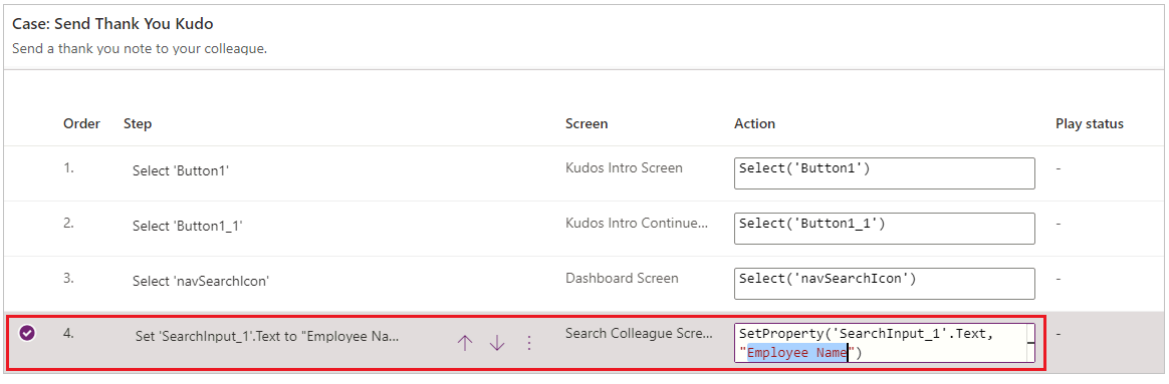
2. Interact with your app. Your actions are **recorded** in the left pane.

3. Once interaction completes, select **Done**. Optionally, you can select **Cancel** to return to Test Studio without your interactions getting recorded.



4. View the test steps and the expressions that were automatically generated for you in Test Studio.

5. Edit the step description text in the main grid if necessary. You can also update the test step actions by selecting the formula on the main grid.



Add test steps and test assertions

Every test case should have an expected result. In the Kudos example, one of the expected results of sending a kudo is creating a new record in the Microsoft Dataverse

(Dataverse) database. You'll now update the test case and add additional test steps to validate that a record was created successfully.

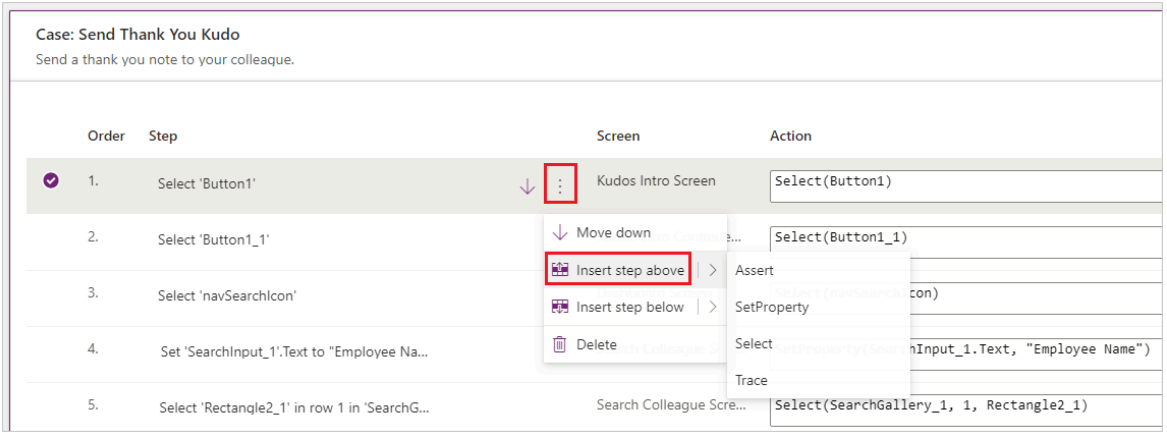
Follow these steps to verify a successful record creation:

- Initialize a variable for the kudo record count in the database at the beginning of the test case.
- Initialize a variable for the kudo record count in the database at the end of the test case.
- Write a test assertion expression to validate it incremented by one count. If the count doesn't increase by one, the test assertion fails, and your test case fails.

To add test steps and test assertions in the Kudos app:

1. Select Step 1 or the step above which you want to insert a new step.

2. Select **Insert a step above** from the top menu or by selecting the option from the active row. This action creates an empty step.



> **Note**
>
> When you select **Insert step above**, a new blank step is added above the current step. You can also use **Assert**, **SetProperty**, **Select** or **Trace** actions instead. This adds a step with a respective action formula that you can edit.

3. Update the step description. For example, "Count Kudo in database".

4. Enter an expression or formula into the action input to count the records in the database before executing the test.

   You can use any supported expression. You can also query any data sources, collections, variables, or run flows that are contained in your app, and create new global variables or collections to use in your tests.

```
Power Fx
```

```
Set(kudosBeforeTest, CountRows(Filter(Kudos, Receiver.Email =
"someone@example.com")))```
```

5. Select Step 2 or the step above which you want to insert a new step.
6. Select **Insert a step above** from the top menu or by selecting the option from the active row. This action creates an empty step.
7. Enter an expression or formula in the action input to Trace and write the *kudosBeforeTest* value to test the results record.

```
Power Fx
```

```
Trace("kudosBeforeTest : " & kudosBeforeTest);
```

8. Go to the bottom of the test case and insert a new step to count the records in the database after the test has completed.

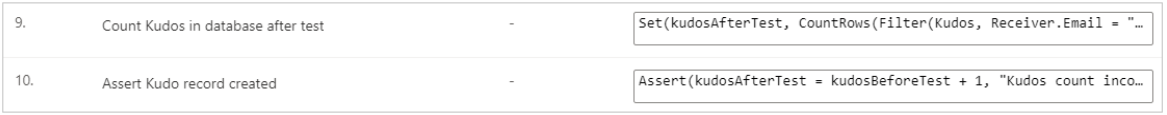
```
Power Fx
```

```
Set(kudosAfterTest, CountRows(Filter(Kudos, Receiver.Email =
"someone@example.com")))```
```

9. Add a final step to validate that the record count in the database has increased by a count of 1, and enter the following assertion action to verify:

```
Power Fx
```

```
Assert(kudosAfterTest = kudosBeforeTest + 1, "Kudos count incorrect.
Expected : " & kudosBeforeTest + 1  & " Actual :" & kudosAfterTest)
```

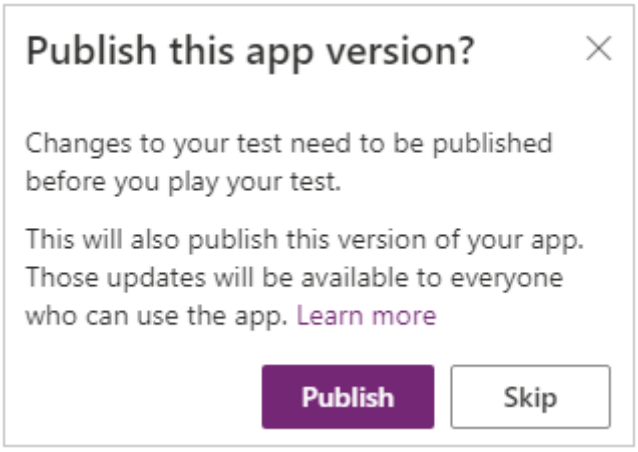


10. Save the test case from the top-right menu in Test Studio.

Play back your test

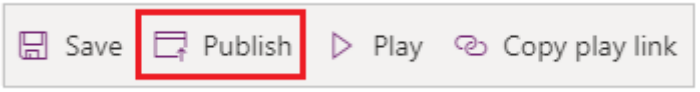
You can play back your recorded test to validate app functionality. You can play back all tests within a single test suite, or a single test case.

Before you play the recording back with recent changes, you must publish the app:

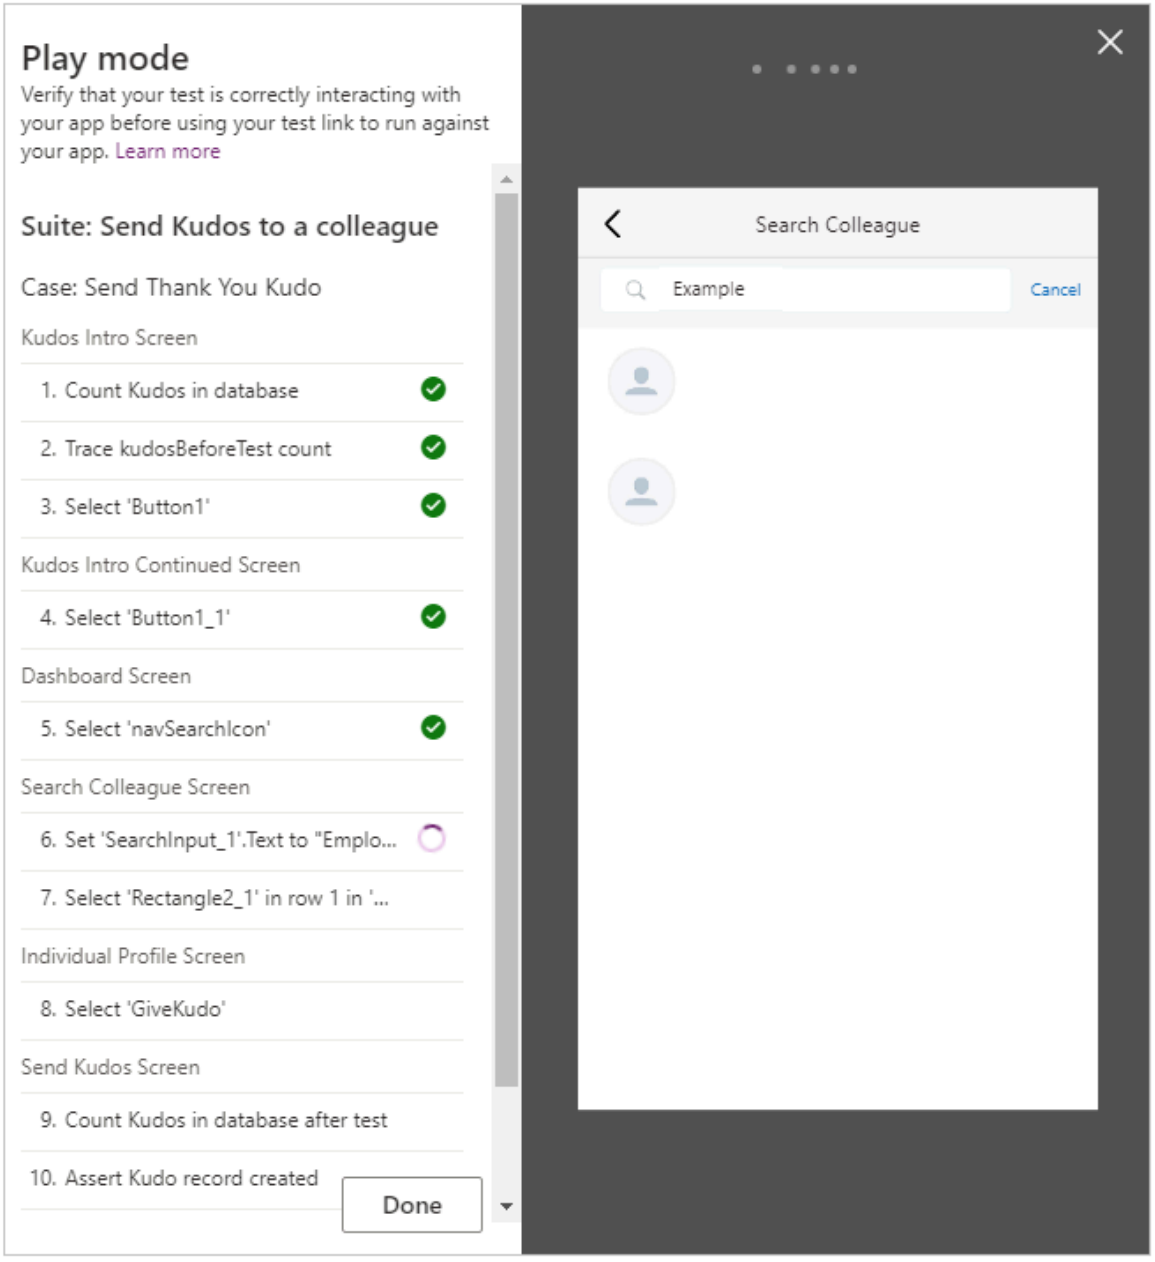


> **Important**
>
> If you skip publishing, the recording playback will not contain your recent test changes. The last published test case or suite will play against the app.

1. Select **Publish** to automatically save and publish your test.



2. Select either a test suite or a single test case.
3. Select **Play**. The published app opens in **Play** mode, and you can see your test steps playing back automatically. A green check mark indicates when a test step is executed successfully. If a step fails, a red failure indicator along with a failure message is displayed.



4. Select **Done** to return to Test Studio.

Failed assertion

In this section, you'll change the test assertion to experience a failed test:

1. Edit the assertion step by selecting the expression box.
2. Update `+ 1` to `+ 2` in test action. This update means that the test expects two records to be created, which is incorrect. If the test is successful, only one record should be created in the database.

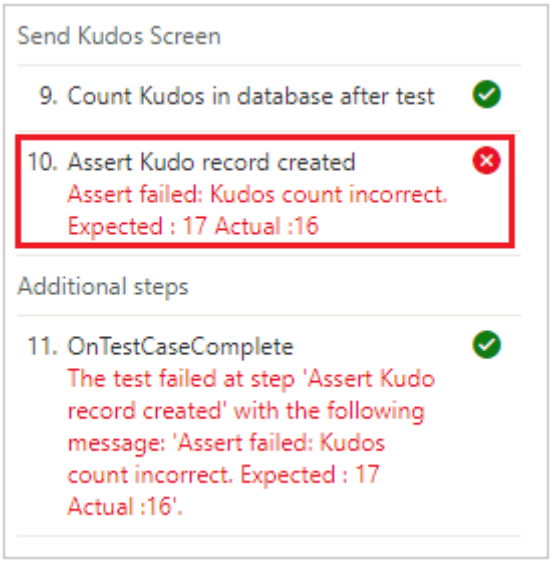
Power Fx

```
Assert(kudosAfterTest = kudosBeforeTest + 2, "Kudos count incorrect.
Expected : " & kudosBeforeTest + 2  & " Actual :" & kudosAfterTest)
```

3. Select **Publish**.

4. Select **Play**.

5. View the test playing back. The final step now fails and shows an error and the message you provided in the assertion step.



Playing tests in a browser

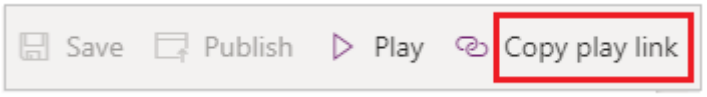
You can copy a link to play a test in separate browser outside Test Studio. It helps integrate your tests in a continuous build and release pipeline such as **Azure DevOps**.

The play link for the selected test is persisted. It doesn't change for the test suite or test case. You can update your tests without the need to modify build and release processes.

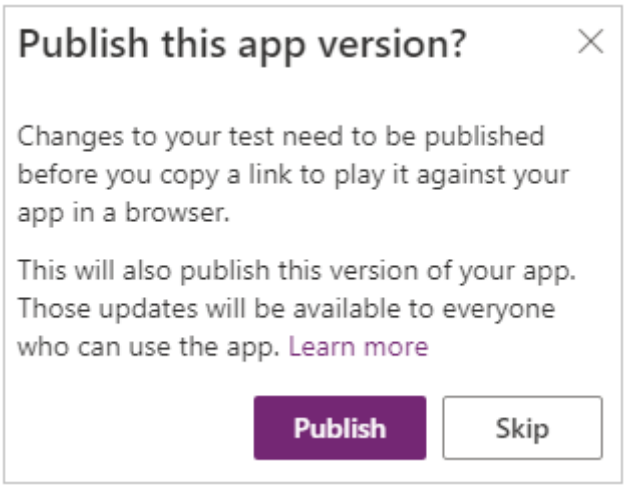
To play tests in your browser:

1. Select a test suite or test case in the right pane.

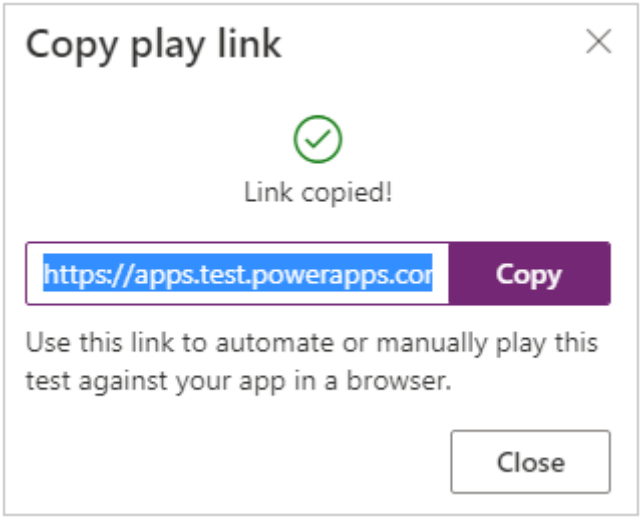
2. Select **Copy play link**.



3. You're prompted to publish your tests if there are any unpublished changes.



4. You can select to skip the publish process and copy the play link. New test changes don't play if you skip.



5. Open a browser and paste the URL into the address bar to play the test.

6. View your test playing back.

Setup your tests

The **OnTestCaseStart** property of a Test Suite can be used to setup your test. The expression entered for this property triggers for every test case in a suite before the case begins executing. **OnTestCaseStart** helps you avoid writing the same test steps at the beginning of every case. You can customize this property to run set up tasks that are common to all cases in the suite such as:

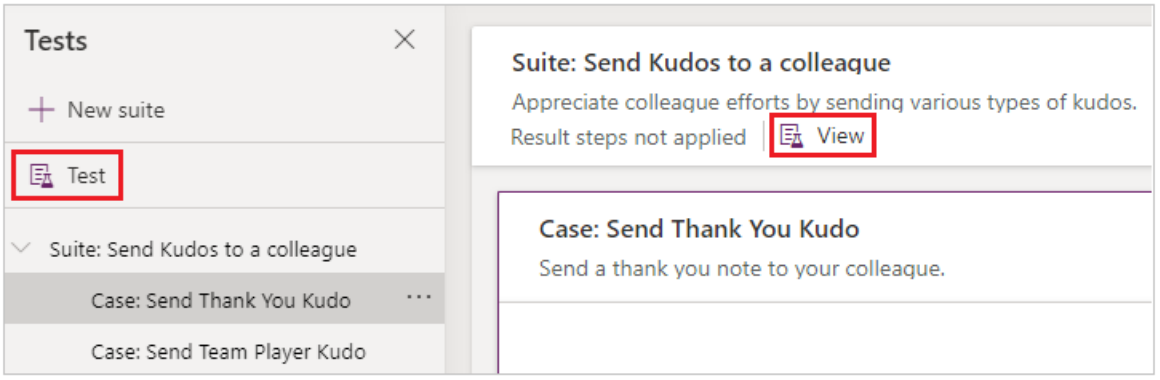
- Always starting test execution from the first screen.
- Initializing common collections or variables.
- Fetching test data from a data source for the current executing test

The **TestCaseInfo** record contains details for the current test that is executing. It contains the following properties:

- *TestCaseName* – the name of the test case.
- *TestCaseDescription* – the description of the test case.
- *TestCaseId* – the ID of the test case.
- *TestSuiteName* – the test suite name that the case belongs to.
- *TestSuiteDescription* – the description of the test suite.
- *TestSuiteId* – the test suite ID that the case belongs to.

In the below example, you'll customize the **OnTestCaseStart** property so every test case begins from the first screen in your app. You'll also fetch the test data from a data source that can be referenced in the steps for the test case.

1. Select **Test** in the left pane or **View** on the suite header.



2. Select the **OnTestCaseStart** action.

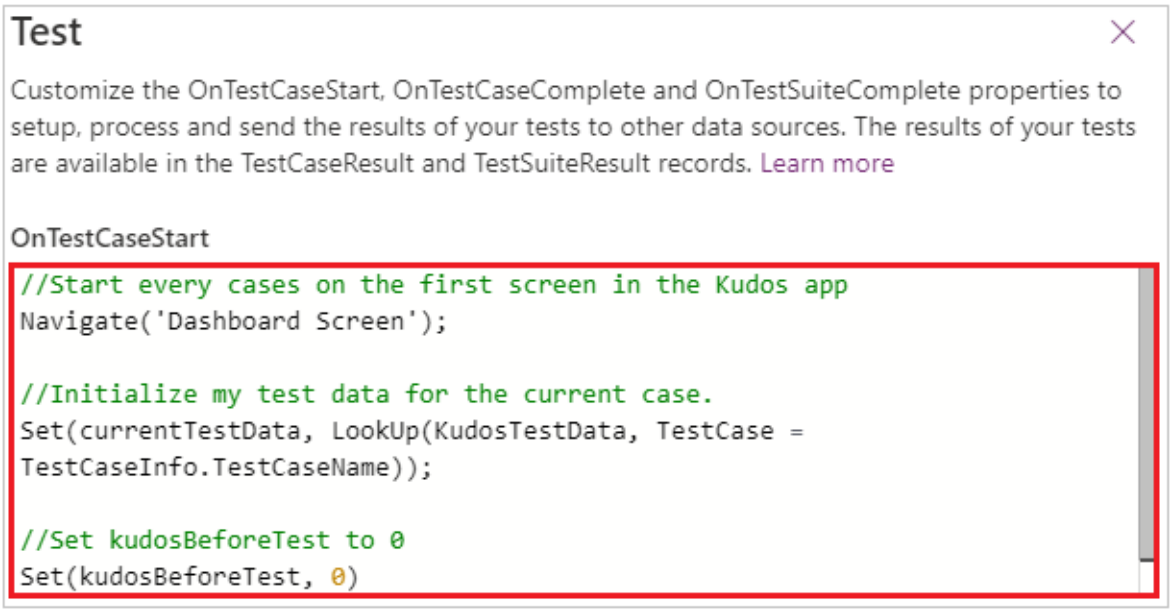
3. Input an expression to Navigate to first screen and fetch the test data for your test.

```
Power Fx

//Start every cases on the first screen in the Kudos app
Navigate('Dashboard Screen');

//Initialize my test data for the current case.
Set(currentTestData, LookUp(KudosTestData, TestCase =
TestCaseInfo.TestCaseName));

//Set kudosBeforeTest to 0
Set(kudosBeforeTest, 0)
```



Processing test results

The test panel visible when playing back tests in Test Studio isn't visible when using a browser. Because of this behavior, you can't determine the specific test step that executes, or if a test passes or fails.

To determine test results outside of Test Studio, there are two properties called **OnTestCaseComplete** and **OnTestSuiteComplete** available in the test object that you can use to process the results of your tests. When integrating tests into a continuous build and release pipeline like **Azure DevOps**, these properties can be used to determine if you should proceed with the app deployment.

The expression entered for these properties triggers when each case or suite completes. You can customize these properties to process and send the results of your tests to various data sources or services such as:

- SQL Server.
- Dataverse.
- Power Automate.
- Email using Office 365.

These settings apply to every test suite or test case in your app. After each test suite or test case completes, the test results and any trace messages contained in the tests are available in the **TestCaseResult** and **TestSuiteResult** records.

The **TestCaseResult** record contains the following properties:

- *TestCaseName* – the name of the test case.
- *TestCaseDescription* – the description of the test case.

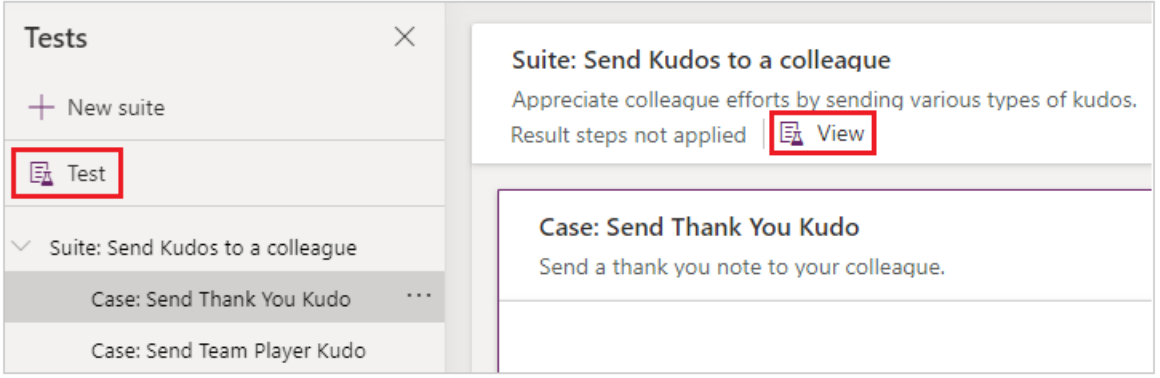
- *TestCaseId* – the ID of the test case.
- *TestSuiteName* – the test suite name that the case belongs to.
- *TestSuiteDescription* – the description of the test suite.
- *TestSuiteId* – the test suite ID that the case belongs to.
- *StartTime* – the start execution time of the test.
- *EndTime* – the end execution time of the test.
- *Traces* – the result of any test assertions and any messages from the Trace function.
- *Success* – indicates if the test case completed successfully.
- *TestFailureMessage* – if the case failed, the failure message.

The **TestSuiteResult** record contains the following properties:

- *TestSuiteName* – the test suite name.
- *TestSuiteDescription* – the description of the test suite.
- *TestSuiteId* – the test suite ID.
- *StartTime* – the start execution time of the test suite.
- *EndTime* – the end execution time of the test suite.
- *TestsPassed* – the number of test cases that completed successfully in the suite.
- *TestsFailed* - the number of test cases that failed in the suite.

In this quickstart, you'll create two custom tables in the Dataverse database to store the test results by customizing the **OnTestCaseComplete** and **OnTestSuiteComplete** properties:

1. Select **Test** in the left pane or **View** on the suite header.



2. Select the **OnTestCaseComplete** action.

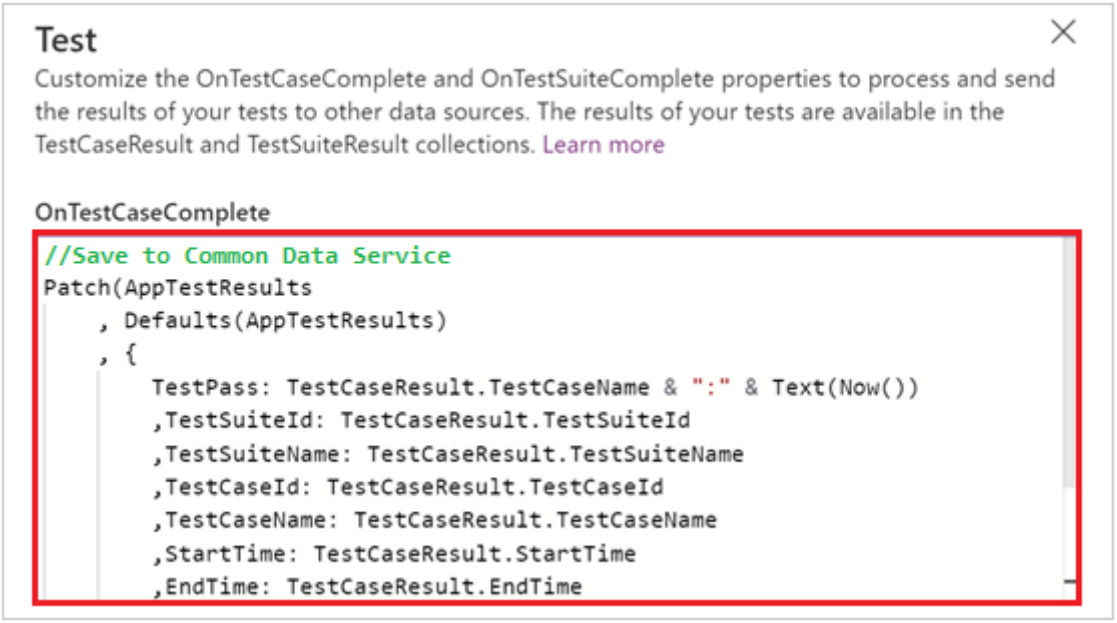
3. Input an expression to process the results of your test. The following sample saves each test case's results to the custom AppTestResults table in Dataverse. The test results can optionally be stored to SQL, SharePoint, or any other data source. You might need to set or increase the Trace field in your data source as required.

> ⓘ **Note**

The following samples connect to Microsoft Dataverse. You can create a simple app or build an app from scratch using Dataverse. Also, refer to the Patch function reference for more details to modify records of a data source used in the following samples.

Power Fx

```
//Save to Dataverse
Patch(AppTestResults
, Defaults(AppTestResults)
, {
        TestPass: TestCaseResult.TestCaseName & ":" & Text(Now())
        ,TestSuiteId: TestCaseResult.TestSuiteId
        ,TestSuiteName: TestCaseResult.TestSuiteName
        ,TestCaseId: TestCaseResult.TestCaseId
        ,TestCaseName: TestCaseResult.TestCaseName
        ,StartTime: TestCaseResult.StartTime
        ,EndTime: TestCaseResult.EndTime
        ,TestSuccess: TestCaseResult.Success
        ,TestTraces: JSON(TestCaseResult.Traces)
        ,TestFailureMessage: TestCaseResult.TestFailureMessage
}
);
```

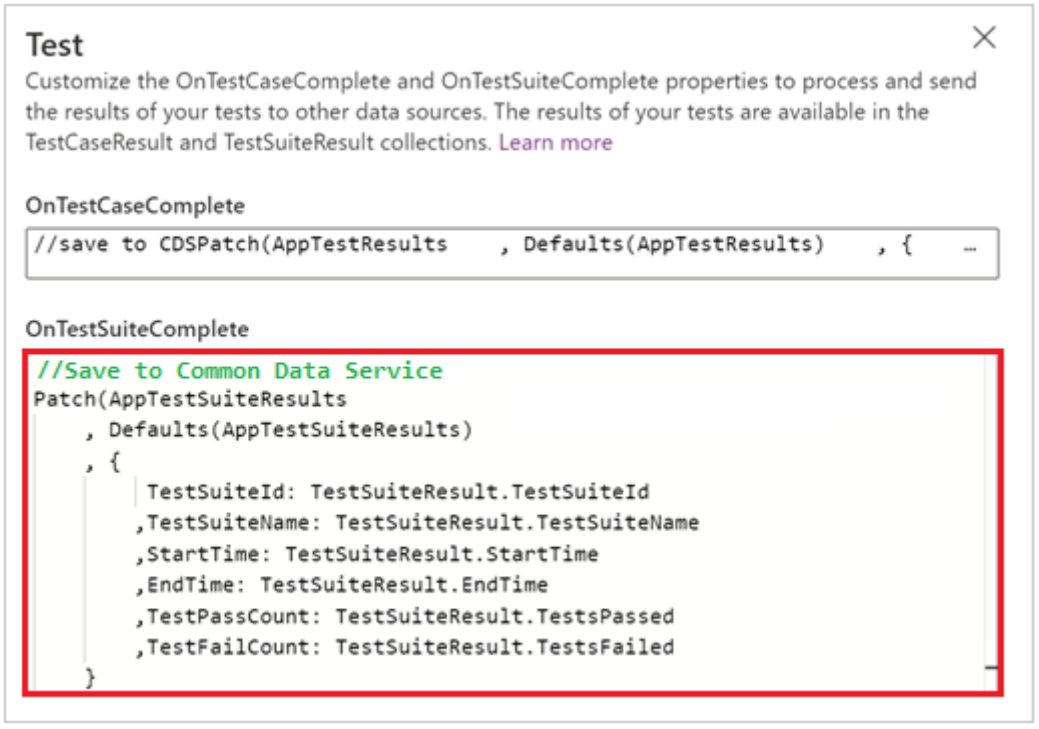


4. Select the **OnTestSuiteComplete** action.

5. Input an expression to process the results of your test. In the following sample, you'll save each test suite's results to the custom AppTestSuiteResults table in Dataverse.

Power Fx

```
//Save to Dataverse
Patch(AppTestSuiteResults
    , Defaults(AppTestSuiteResults)
    , {
        TestSuiteId: TestSuiteResult.TestSuiteId
        ,TestSuiteName: TestSuiteResult.TestSuiteName
        ,StartTime: TestSuiteResult.StartTime
        ,EndTime: TestSuiteResult.EndTime
        ,TestPassCount: TestSuiteResult.TestsPassed
        ,TestFailCount: TestSuiteResult.TestsFailed
    }
);
```



Other examples of expressions you could use in these properties are:

- Send results to a flow in Power Automate.

```
Power Fx

MyTestResultsFlow.Run(JSON(TestCaseResult))
```

- Email your results.

```
Power Fx

Office365.SendMailV2("someone@example.com", "Test case results",
JSON(TestCaseResult, JSONFormat.IndentFour))
```

- Receive an app notification of the test result.

For example, receive a notification after the test completes when playing the test in a browser, outside of Test Studio.

Power Fx

```
Notify(TestCaseResult.TestCaseName & " : "
        & If( TestCaseResult.Success
            , " Passed"
            , TestCaseResult.TestFailureMessage)
        ,If(  TestCaseResult.Success
            , NotificationType.Success
            , NotificationType.Error)
)
```

Test Functions

In addition to the functions available in Power Apps, the following are common functions that you'll typically use when authoring tests:

- Select
- SetProperty
- Assert
- Trace

Automate tests with Azure Pipelines using classic editor

Article • 12/16/2022

In this article, you'll learn how to set up and run your canvas app tests built in Test Studio using the Azure Pipelines classic editor in Azure DevOps Services.

You can use a public project on GitHub - Microsoft/PowerAppsTestAutomation to:

- Automate operations of signing in to your application.
- Open a browser on the build agent and execute a set of test cases and suites.
- View the status of the test execution in the Azure DevOps pipeline.

Prerequisites

Before you begin, you must complete the following steps:

- Fork the Microsoft/PowerAppsTestAutomation project on GitHub.

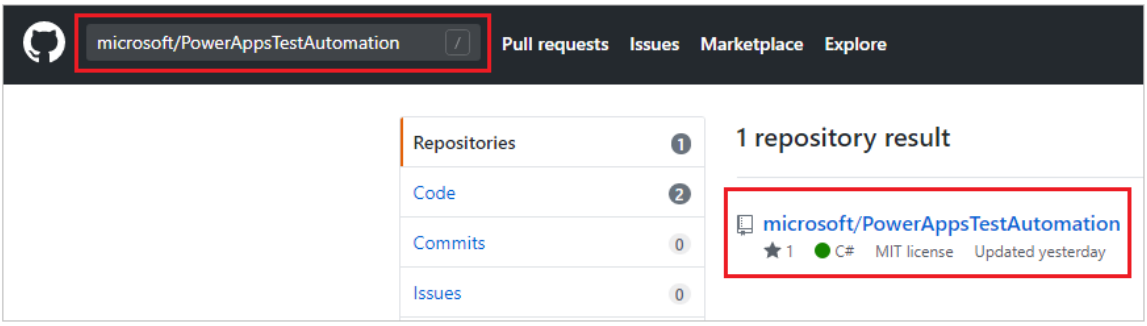
  > **Note**
  >
  > Public forks can't be made private. If you want to create a private repo, please duplicate the repository.

- Create a new *Test URL .json file* in the repo with the App Test URLs you want to run from the pipeline.

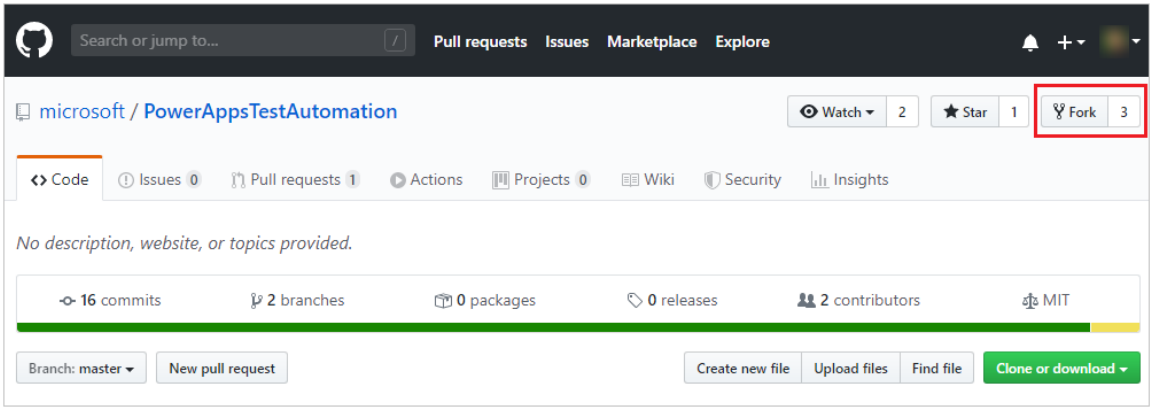
Step 1 - Fork the PowerAppsTestAutomation project

A fork is a copy of a repository. By forking a repository, you can make changes without affecting the original project.

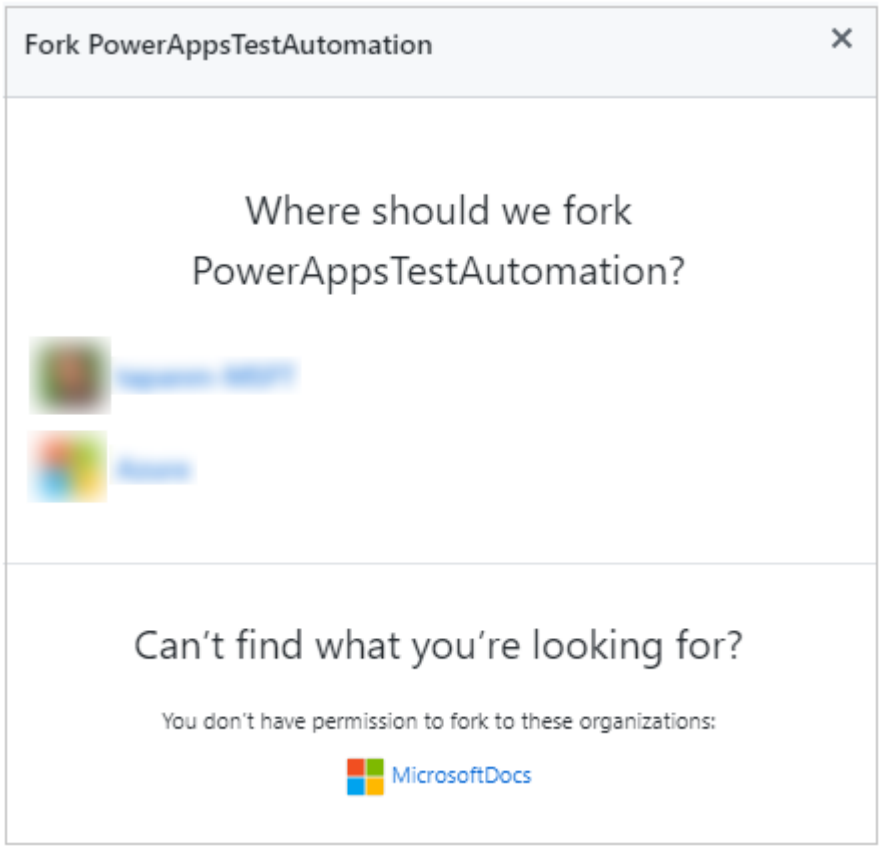
1. Sign in to GitHub.
2. Go to the microsoft/PowerAppsTestAutomation repository. You can also search for **microsoft/PowerAppsTestAutomation** instead, and then select the repository:



3. Select **Fork**:



4. Select where you want to fork:



Your forked repository will now be available.

Step 2 - Create Test URL .json file

The Test URL .json file will contain the test suite and test case URLs for validating your app. The app test suite and test case URLs can be retrieved by selecting the Copy play link in Test Studio.

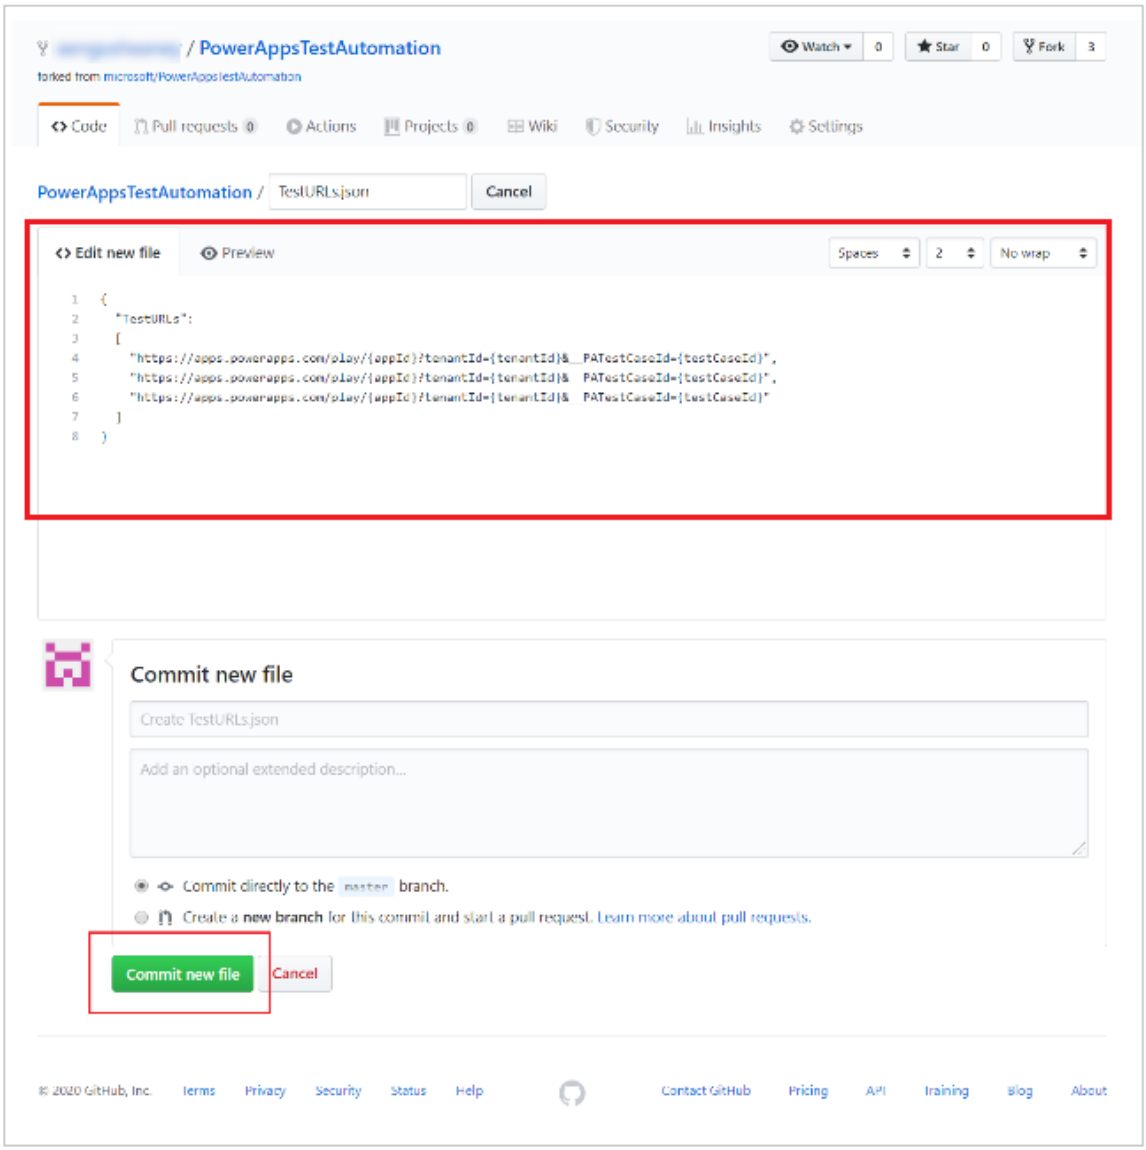
You can find a sample file `Samples/TestAutomationURLs.json` in the repo you created earlier.

1. Create a new `TestURLs.json` file in your repo, or use any other file name.
   The file name and location will be mapped in the pipeline variables later in the document.

2. Copy the format from the `Samples/TestAutomationURLs.json` file.

3. Update the Test URLs section with the tests that you want to validate in your app.

4. Commit the changes to your repo:



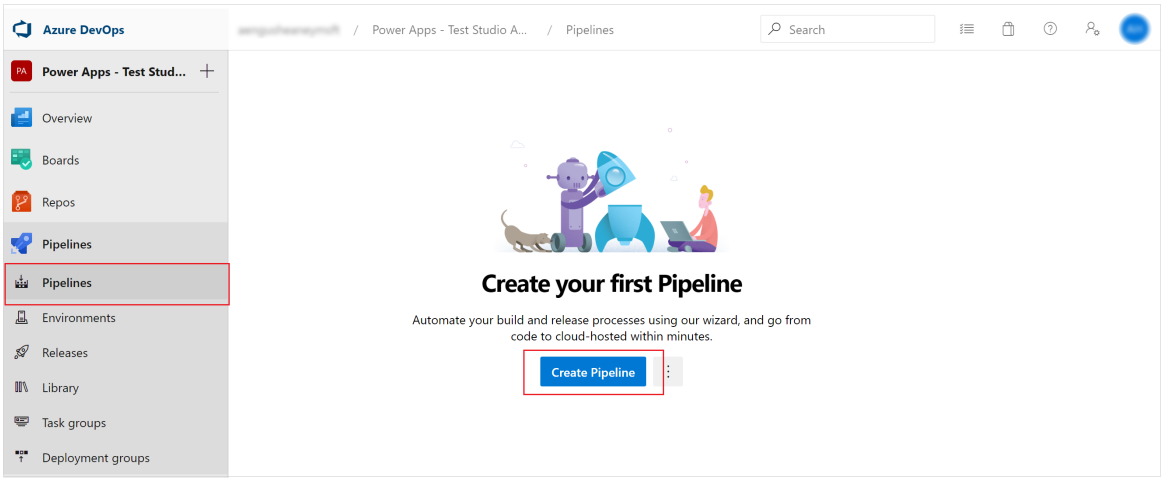
Create a pipeline

1. Sign in to your Azure DevOps instance.

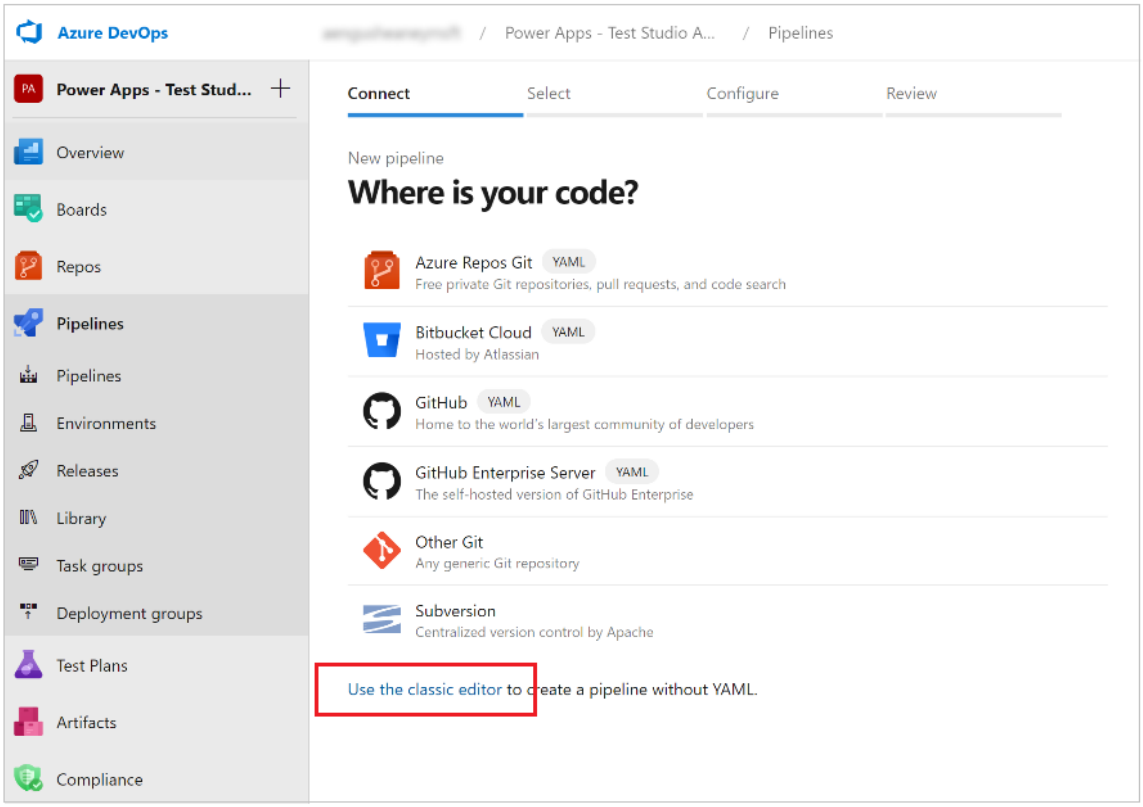
2. Select an existing project or create a new project.

3. Select **Pipelines** in the left menu.

4. Select **Create Pipeline**:

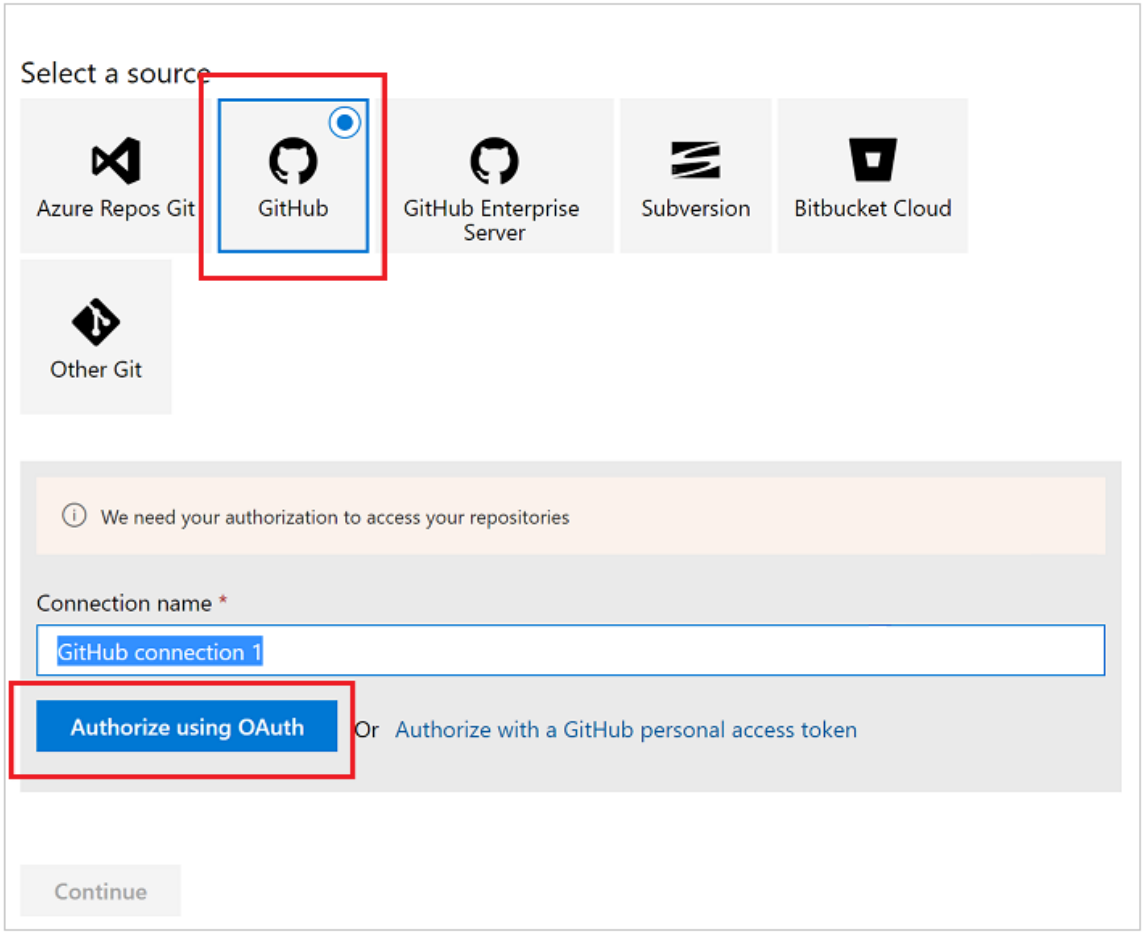


5. Select **Use the classic editor**:



6. Select GitHub as the source.

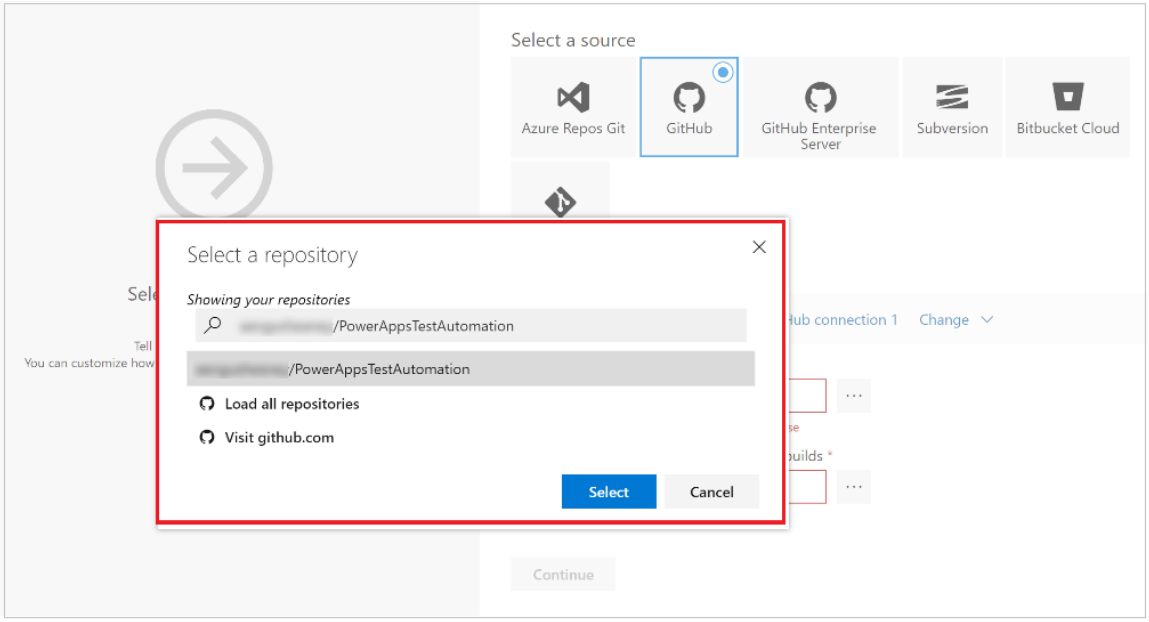
7. If necessary, authorize your GitHub connection using OAuth or using a personal access token:



8. If needed, edit the connection name.

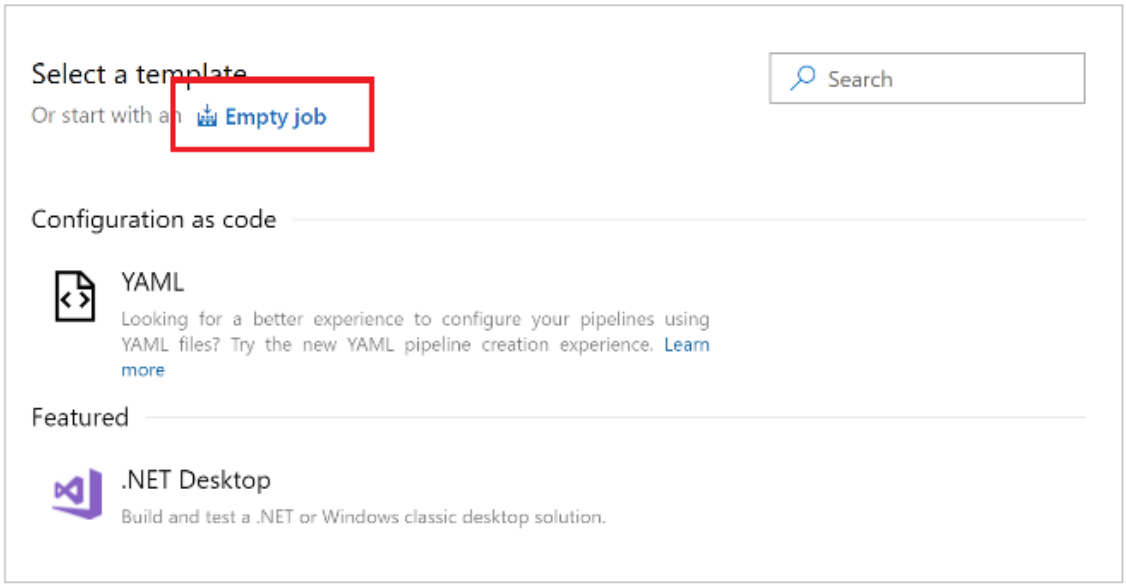
9. Select **...** (ellipsis) from the right side of **Repository** input.

10. Enter the name of your project on GitHub, and then **Select** it:



11. Select **Continue**.

12. In the Select a template screen, select **Empty job**:



13. **Save** your pipeline.

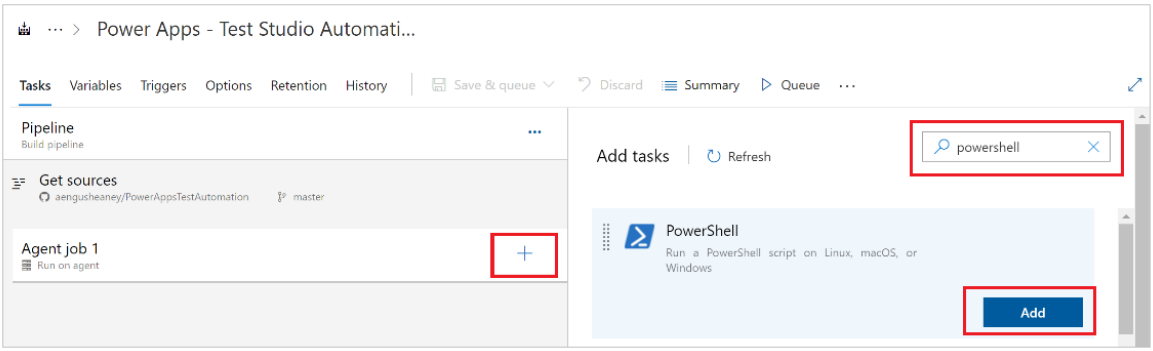
Add tasks to the pipeline

You'll now add new job tasks and configure the tasks to run the tests from the pipeline in this sequence:

1. Configure screen resolution using PowerShell.
2. Restore NuGet packages for the PowerAppsTestAutomation solution.
3. Build the PowerAppsTestAutomation solution.
4. Add Visual Studio Tests for Google Chrome.
5. Add Visual Studio Tests for Mozilla Firefox.

Step 1 - Configure screen resolution using PowerShell

1. Select + next to *Agent job 1*.
2. Search for **PowerShell**.
3. Select **Add** to add a PowerShell task to the job:

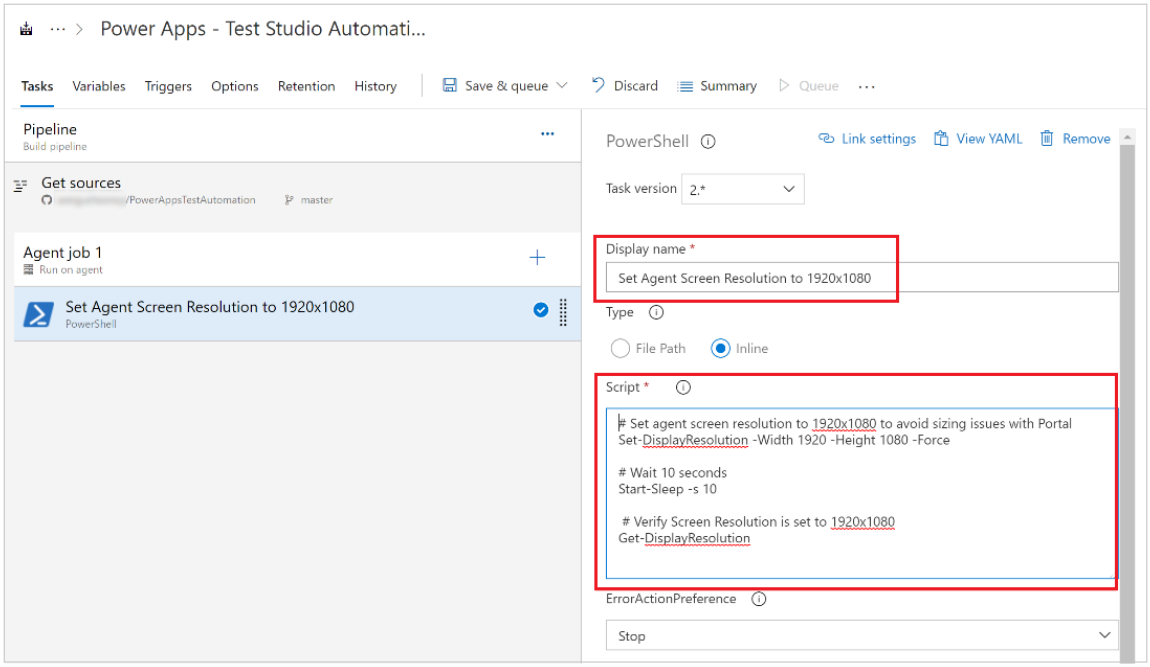


4. Select the task.

   You can also update the display name to *Set Agent Screen Resolution to 1920 x 1080* or similar.

5. Select **Inline** as the script type, and enter the following in the script window:

```PowerShell
# Set agent screen resolution to 1920x1080 to avoid sizing issues with Portal
Set-DisplayResolution -Width 1920 -Height 1080 -Force
# Wait 10 seconds
Start-Sleep -s 10
# Verify Screen Resolution is set to 1920x1080
Get-DisplayResolution
```



Step 2 - Restore NuGet packages

1. Select + next to *Agent job 1*.

2. Search for **NuGet**.

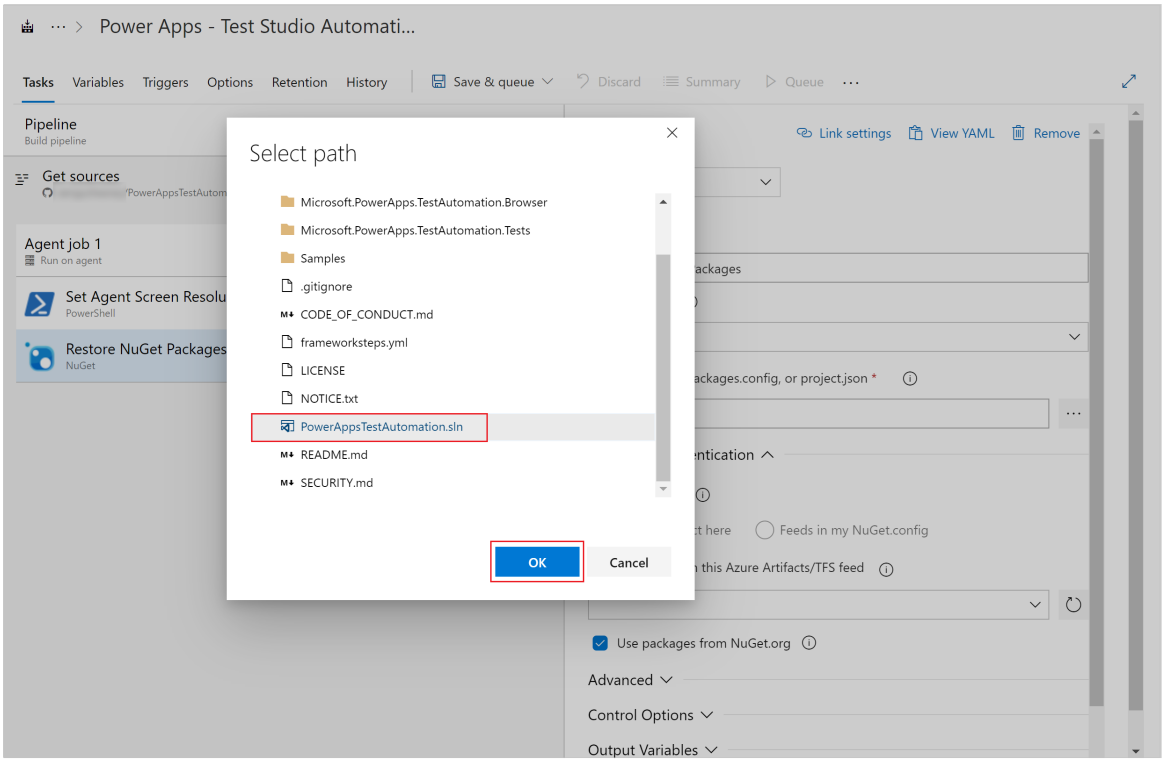
3. Select **Add** to add a NuGet task to the job.

4. Select the task.
   You can also update the display name to **Restore NuGet Packages** or similar.

5. Select **...** (ellipsis) in the **Path to solution, packages.config, or project.json** configuration field.

6. Select the PowerAppsTestAutomation.sln solution file.

7. Select **OK**:



Step 3 - Build the PowerAppsTestAutomation solution

1. Select + next to *Agent job 1*.

2. Search for **Visual Studio build**.

3. Select **Add** to add a Visual Studio build task to the job.

4. Select the task.
   You can also update the display name to **Build Power Apps Test Automation Solution** or similar.

5. Select **...** (ellipsis) in the **Solution** configuration field.

6. Select the PowerAppsTestAutomation.sln solution file.

7. Select **OK**.

Step 4 - Add Visual Studio Tests for Google Chrome

1. Select + next to *Agent job 1*.

2. Search for **Visual Studio Test**.

3. Select **Add** to add a Visual Studio Test task to the job.

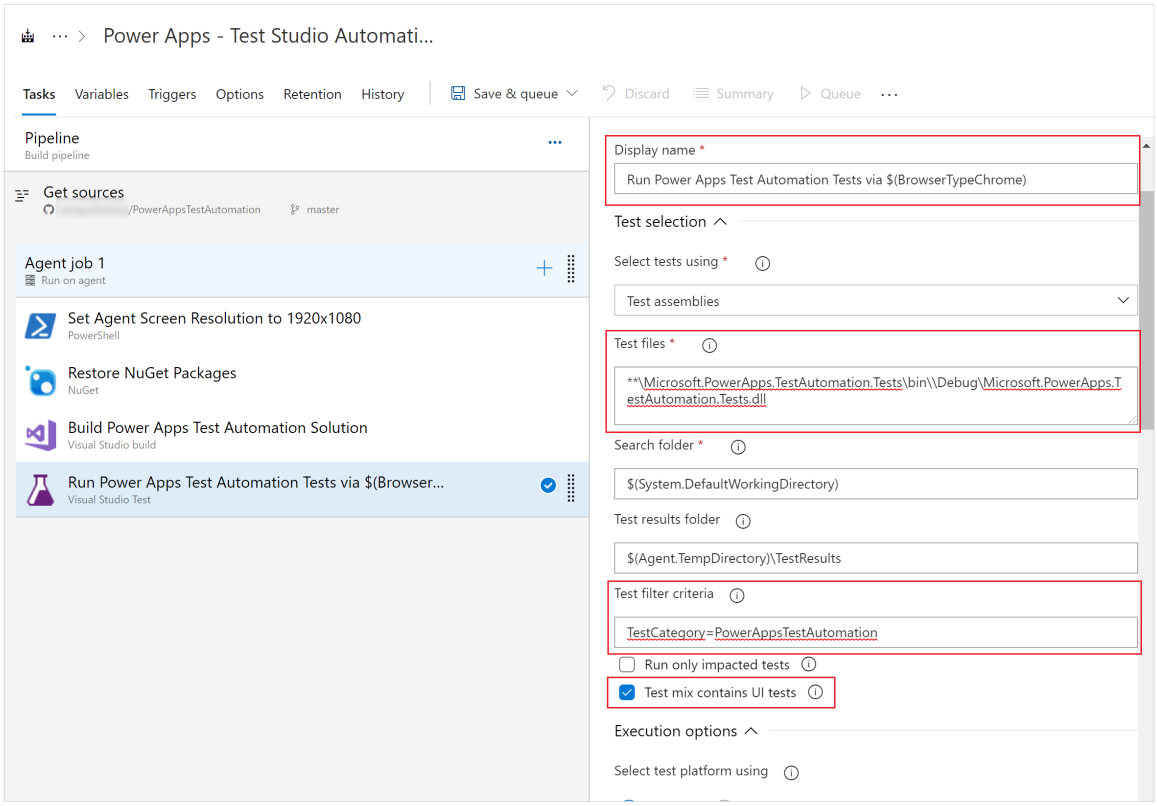
4. Select the task.
   You can also update the display name to **Run Power Apps Test Automation Tests via $(BrowserTypeChrome)** or similar.

5. Remove the default entries in the **Test files** text field and add the following:

   `**\Microsoft.PowerApps.TestAutomation.Tests\bin\\Debug\Microsoft.PowerApps.TestAutomation.Tests.dll`

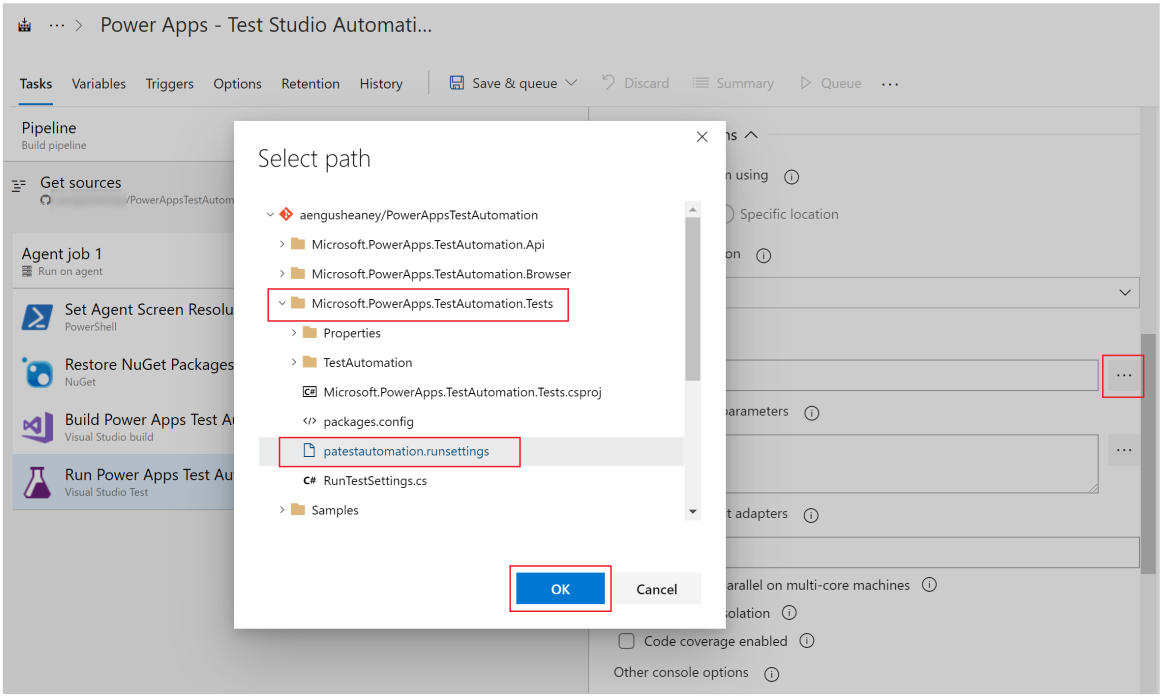
6. Enter `TestCategory=PowerAppsTestAutomation` in the **Test filter criteria** field.

7. Select **Test mix contains UI tests**.



8. Select ... (ellipsis) in the **Settings file** field.

9. Expand the **Microsoft.PowerApps.TestAutomation.Tests**, select the **patestautomation.runsettings** file, and then select **OK**:

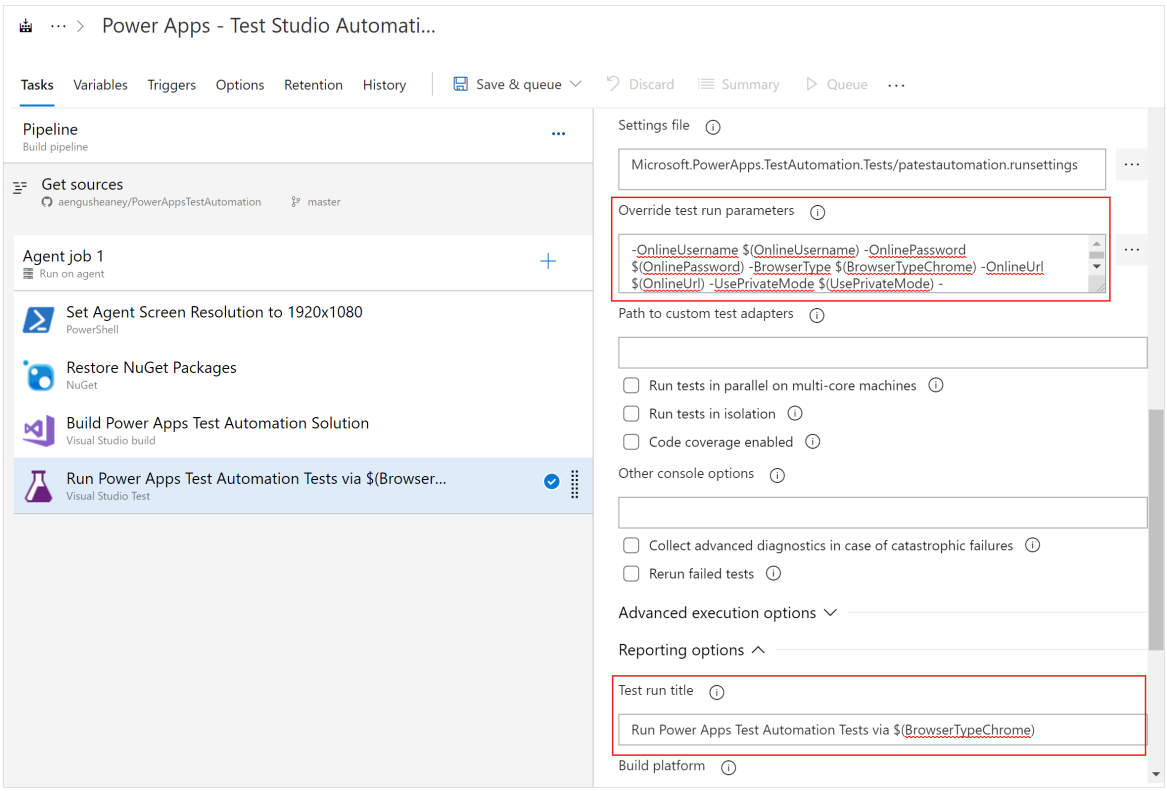


10. Copy the following in the **Override test run parameters** field.

```
-OnlineUsername "$(OnlineUsername)" -OnlinePassword "$(OnlinePassword)"
-BrowserType "$(BrowserTypeChrome)" -OnlineUrl "$(OnlineUrl)" -
UsePrivateMode "$(UsePrivateMode)" -TestAutomationURLFilePath
"$(TestAutomationURLFilePath)" -DriversPath "$(ChromeWebDriver)"
```

> **Note**
>
> This is where the variables in the pipeline are configured, represented above in the form of $(VariableName).

11. Enter **Run Power Apps Test Automation Tests via $(BrowserTypeChrome)** or similar in the **Test run title** field.



Step 5 - Add Visual Studio Tests for Mozilla Firefox

1. Right-click the **Add Visual Studio Tests for Chrome** task and select **Clone task(s)**.

2. Select the task and update the following areas:

   a. **Title**: Run Power Apps Test Automation Tests via $(BrowserTypeFirefox)

   b. **Override test run parameters**

```
-OnlineUsername "$(OnlineUsername)" -OnlinePassword
"$(OnlinePassword)" -BrowserType "$(BrowserTypeFirefox)" -OnlineUrl
"$(OnlineUrl)" -UsePrivateMode "$(UsePrivateMode)" -
TestAutomationURLFilePath "$(TestAutomationURLFilePath)" -
DriversPath "$(GeckoWebDriver)"
```

   c. **Test Run Title**: Run Power Apps Test Automation Tests via $(BrowserTypeFirefox)

Configure pipeline variables

You'll now configure the pipeline variables defined in the tasks you've added earlier.

1. Select the **Variables** tab.

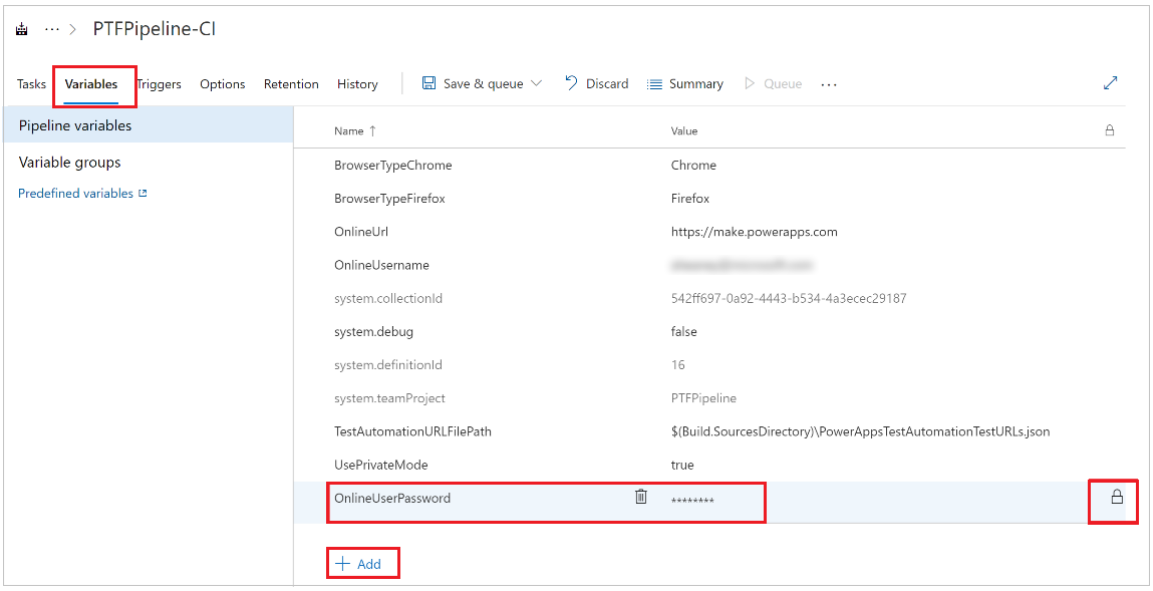
2. Select **Add** and repeat this step to configure the following variables:

Expand table

Variable name	Variable value
BrowserTypeChrome	Chrome
BrowserTypeFirefox	Firefox
OnlineUrl	https://make.powerapps.com
TestAutomationURLFilePath	`$(Build.SourcesDirectory)\<test URL file>.json` **Note:** This is the *Test URLs .json* file you created earlier.
UsePrivateMode	true
OnlineUsername	Enter the Microsoft Entra email address of the user context that will sign in to the application. Tests will run under the context of this user account. Ensure this user has the ability to run the app and connect to any data sources the app might connect to.

1. Select **Add** and enter **OnlinePassword** in the variable name.

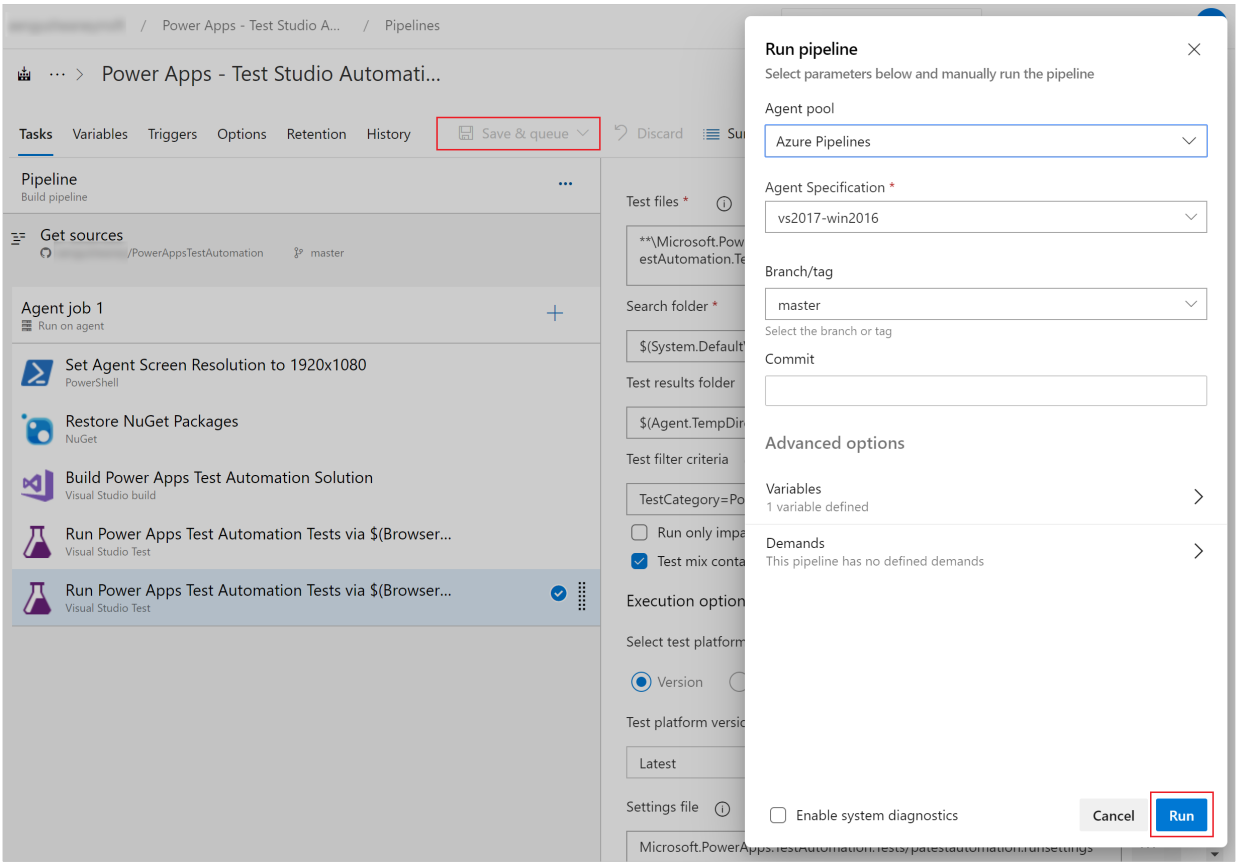
2. Check the lock image to make this variable a secret.



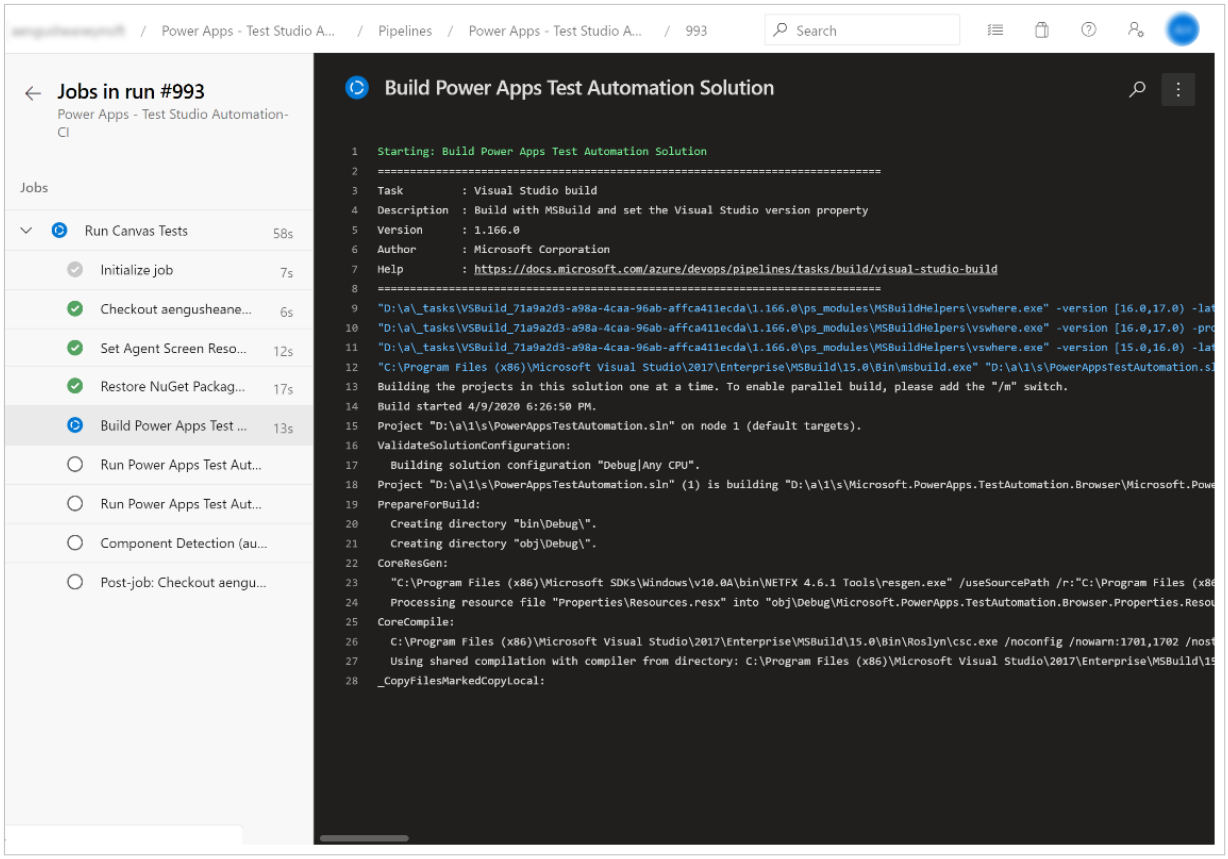
3. **Save** your pipeline configurations.

Run and analyze tests

To validate that your tests are executing successfully, select **Queue** and then select **Run**. Your job will start running.

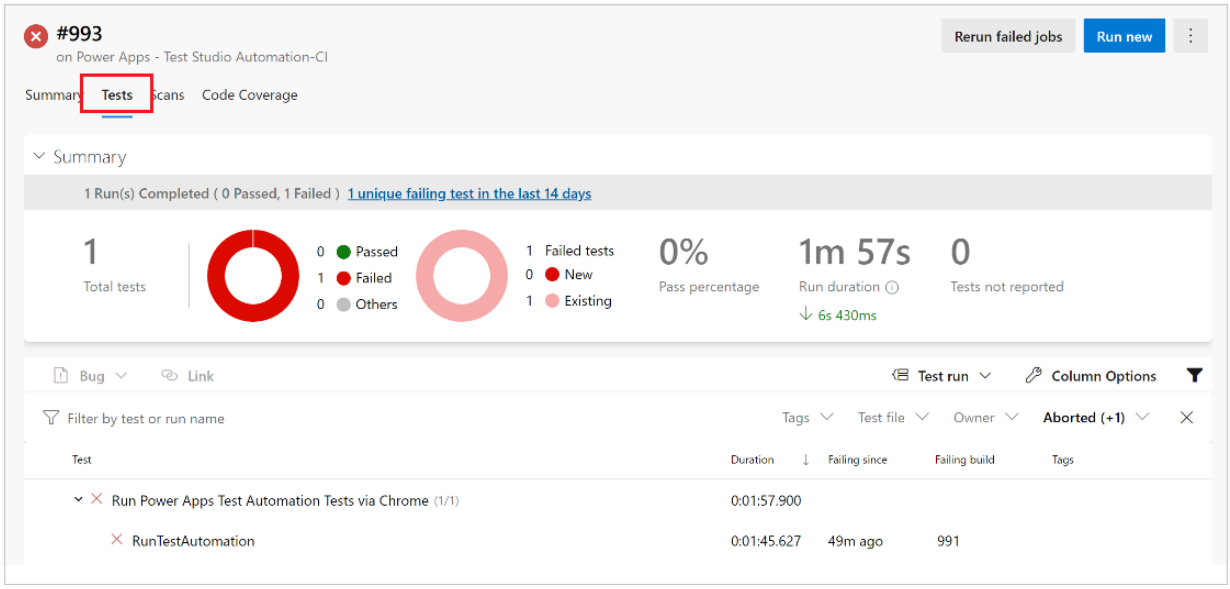


As the job runs, select the job to see a detailed status on each of the tasks running:

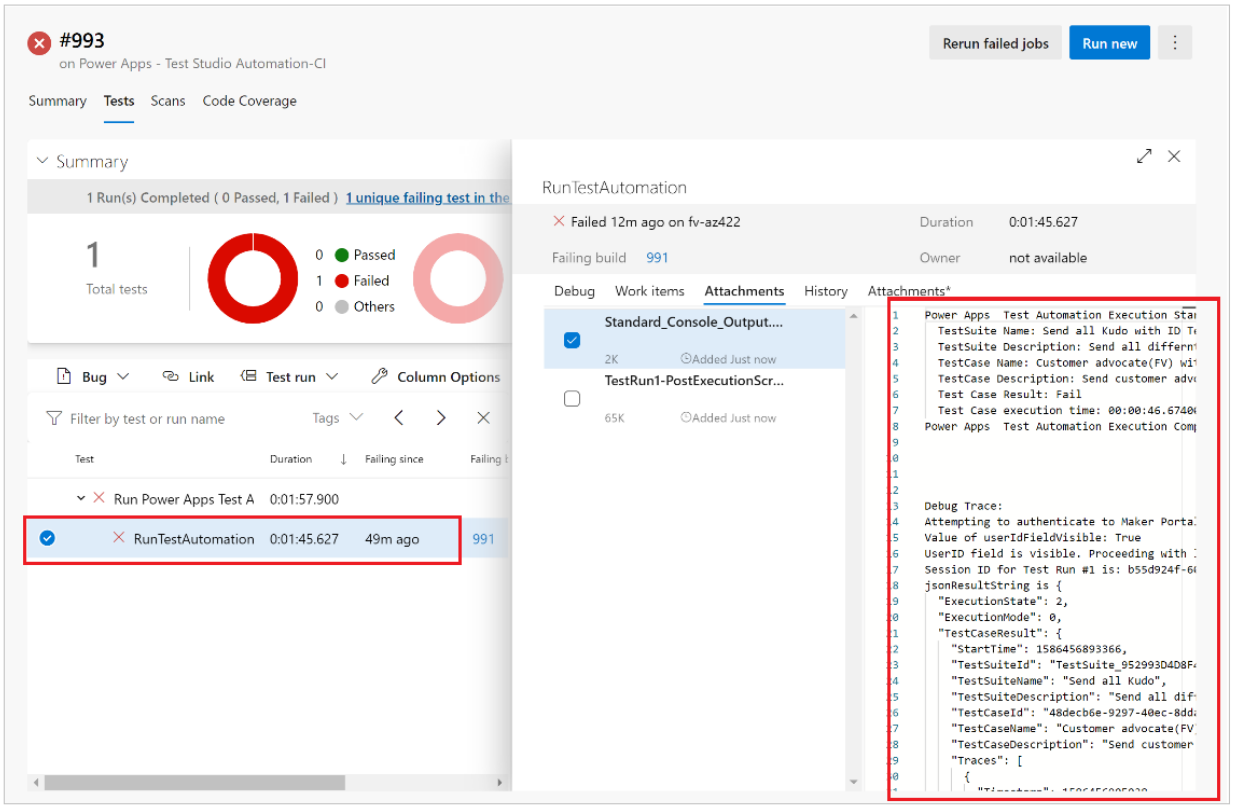


When the job completes, you can view the high-level job summary, and any errors or warnings. By selecting the **Tests** tab, you can view specific details on the test cases you've executed.

The following example indicates at least one of our test cases has failed while executing the tests using the Chrome browser:



Select **RunTestAutomation** test to drill into the details on what test case has failed. In the **Attachments** tab, you can see the summary of the test execution and which test cases have failed or passed in your test suite:



> **Note**
>
> If you execute a test suite, you'll see a summary of test cases passed and failed. If you execute a test case, you'll see specific details on the failure with any trace

information, if available.

Known limitations

- Multifactor authentication isn't supported.
- Test summary will report a single test result per browser. The test result will contain one or more test cases or test suite results.
- Any authentication process other tha Microsoft Entra sign-in flow requires customization of the sign-in process in the **PowerAppsTestAutomation** solution.

Automate tests with Azure Pipelines using YAML

Article • 12/16/2022

In this article, you'll learn how to set up and run your canvas app tests built in the Test Studio by using a YAML pipeline in Azure DevOps Services.

You can use a public project on GitHub—Microsoft/PowerAppsTestAutomation —to:

- Automate the operations of signing in to your application.
- Open a browser on the build agent and execute a set of test cases and suites.
- View the status of the test execution in the Azure DevOps pipeline.

Prerequisites

Before you begin, you must complete the following steps:

- Fork the Microsoft/PowerAppsTestAutomation project on GitHub.

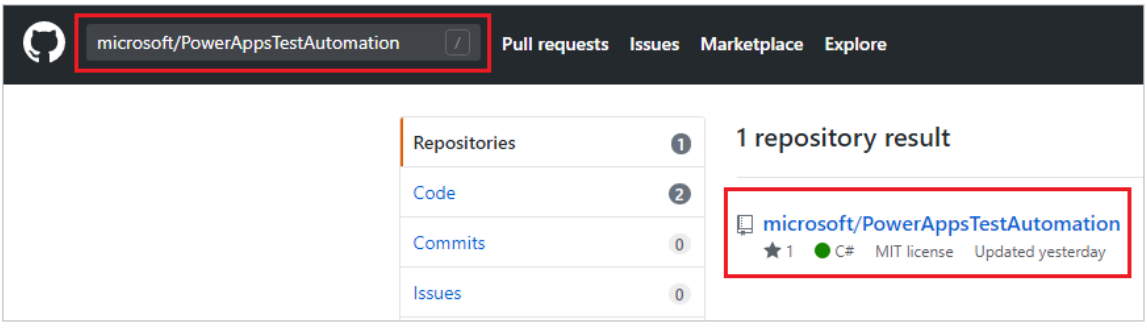
  > **Note**
  >
  > Public forks can't be made private. If you want to create a private repo, you need to duplicate the repository.

- Create a new Test URLs .json file that includes the app test URLs you want to run from the pipeline.
- Create a new Azure Pipelines YAML file.
- Create a GitHub service connection to your repo.

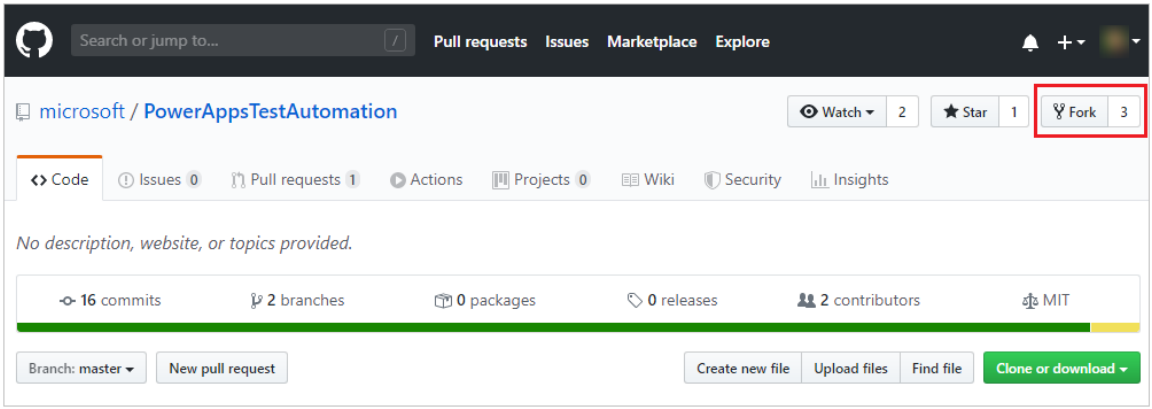
Step 1 - Fork the PowerAppsTestAutomation project

A *fork* is a copy of a repository. By forking a repository, you can make changes without affecting the original project.

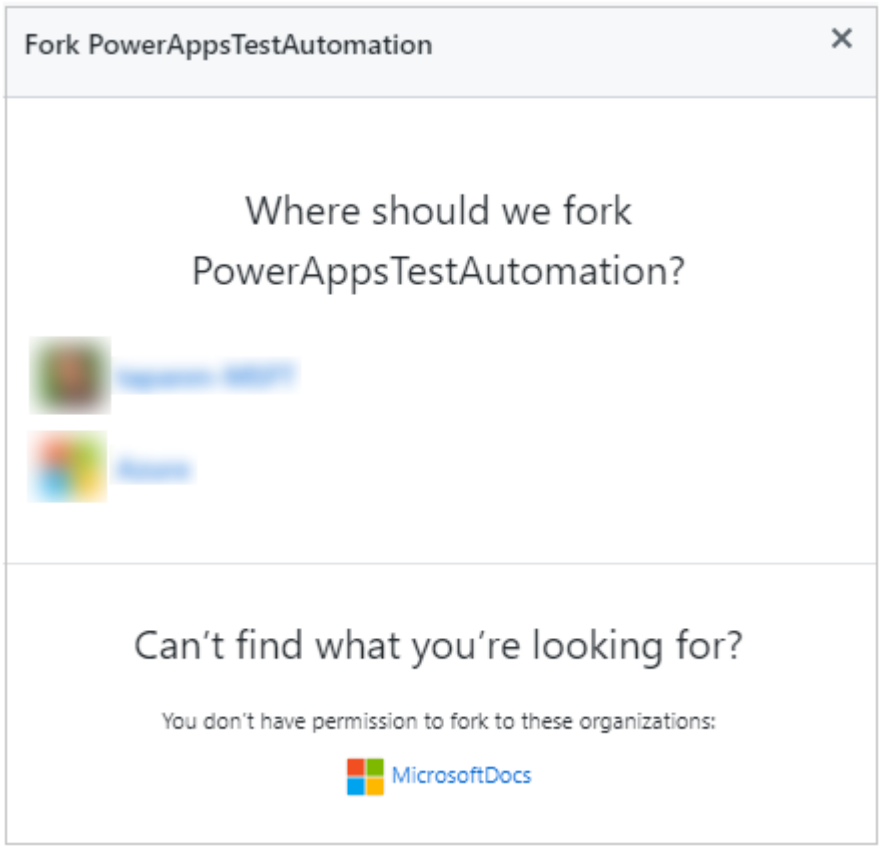
1. Sign in to GitHub.
2. Go to the microsoft/PowerAppsTestAutomation repository. You can also search for **microsoft/PowerAppsTestAutomation** instead, and then select the repository.



3. Select **Fork**.



4. Select where you want to locate the fork.



Your forked repository will now be available.

Step 2 - Create a test URL .json file

The test URL .json file will contain the test suite and test case URLs for validating your app. The app test suite and test case URLs can be retrieved by selecting the copy play link in Test Studio.

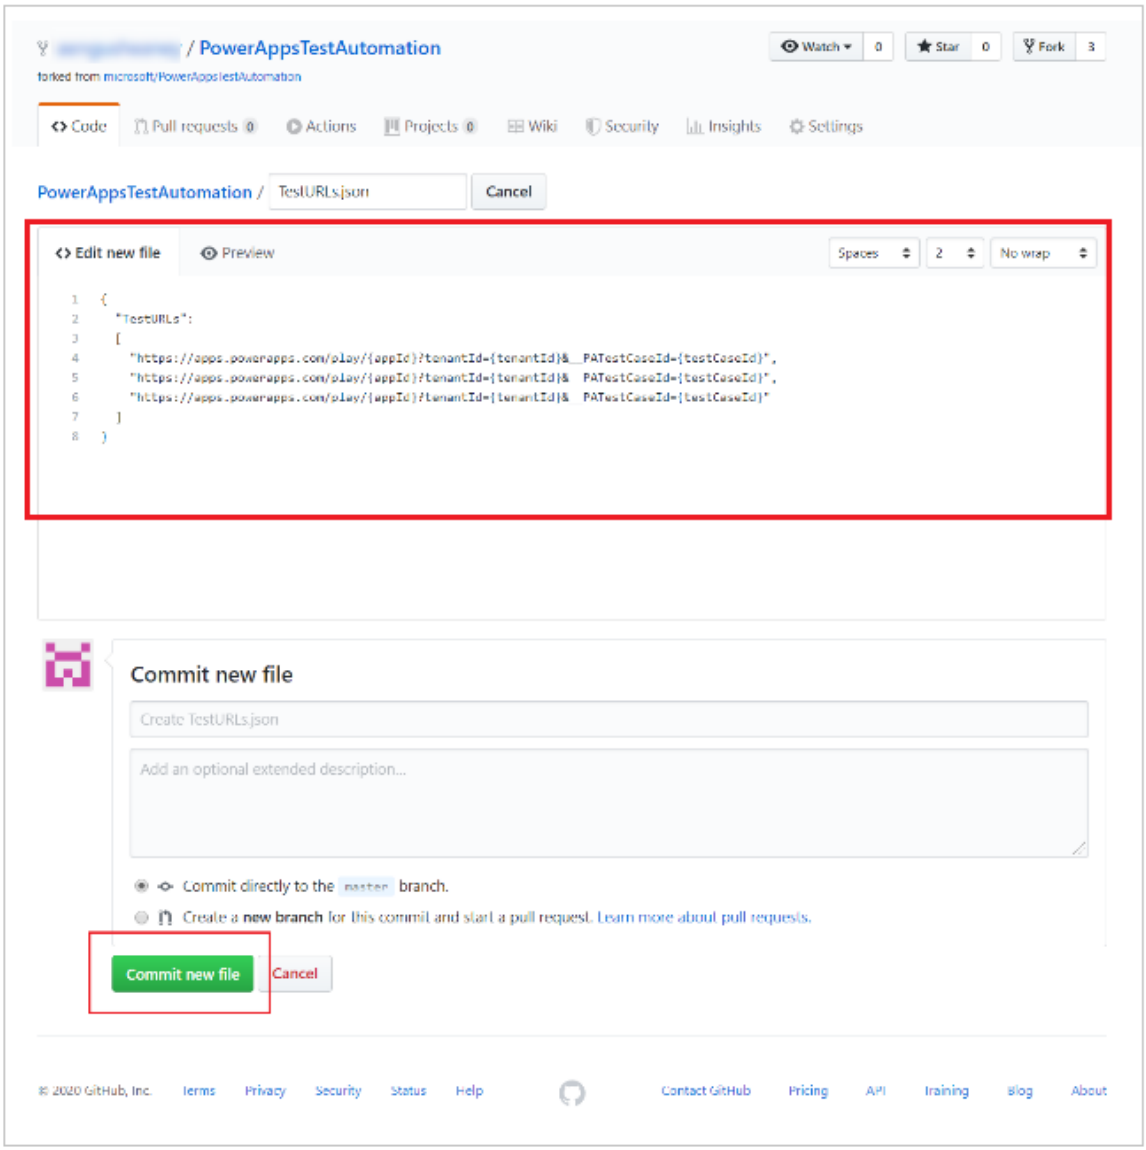
You can find a sample file, Samples/TestAutomationURLs.json, in the repo you created earlier.

1. Create a new file named TestURLs.json file in your repo, or use any file name you want. The file name and location will be mapped in the pipeline variables later in the document.

2. Copy the format from the Samples/TestAutomationURLs.json file.

3. Update the **Test URLs** section with the tests that you want to validate in your app.

4. Commit the changes to your repo.



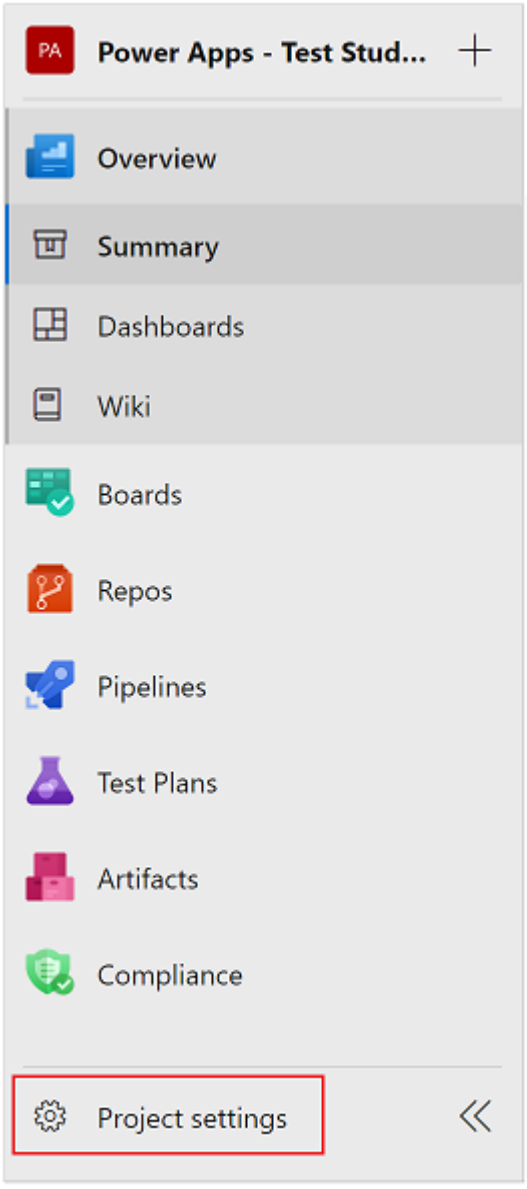
Step 3 - Create an Azure Pipelines YAML file

You can find a sample file, Samples/azure-pipelines.yml, in the repo you created earlier.

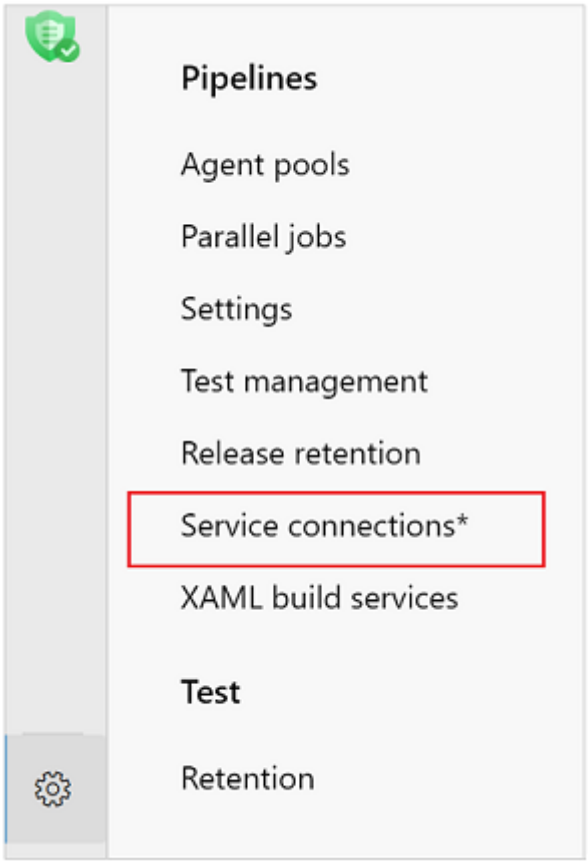
1. Create a new file named azure-pipelines.yml file in your repo.
2. Copy the content from the Samples/azure-pipelines.yml file.
3. Commit the changes to your repo. You'll reference and update the azure-pipelines.yml file when you're configuring your pipeline in Step 4.

Step 4 - Create a GitHub service connection

1. Sign in to your Azure DevOps instance.
2. Select an existing project, or create a new project.
3. Select **Project settings** at the bottom of the left navigation pane.



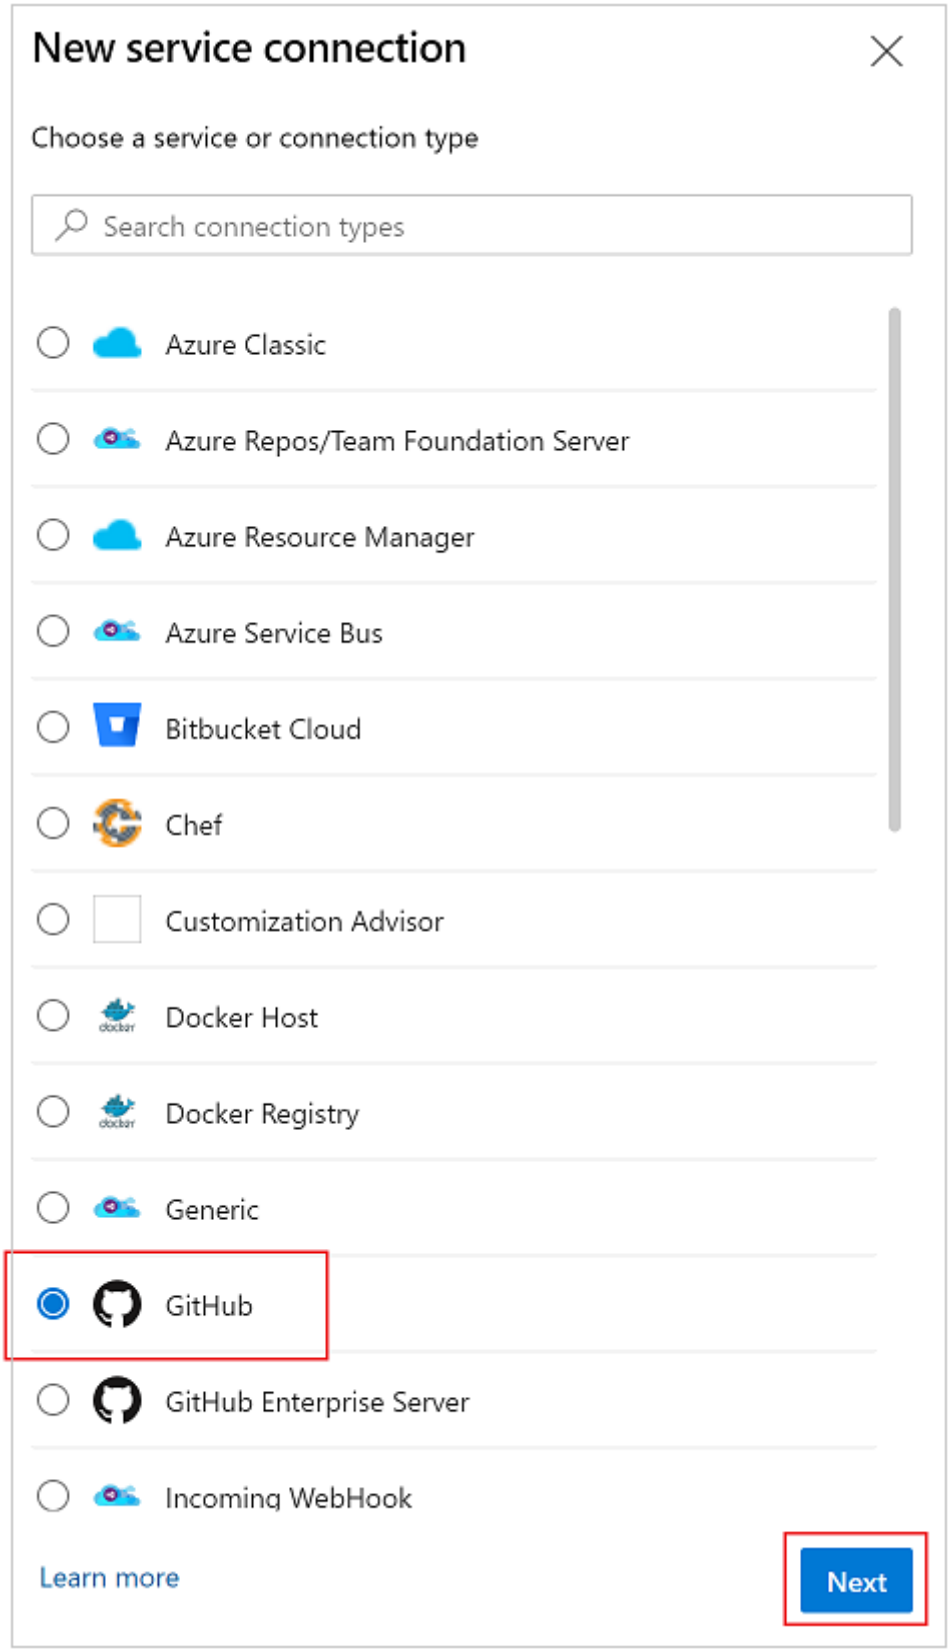
4. Under **Pipelines**, select **Service connections**.



5. Select **Create service connection**.

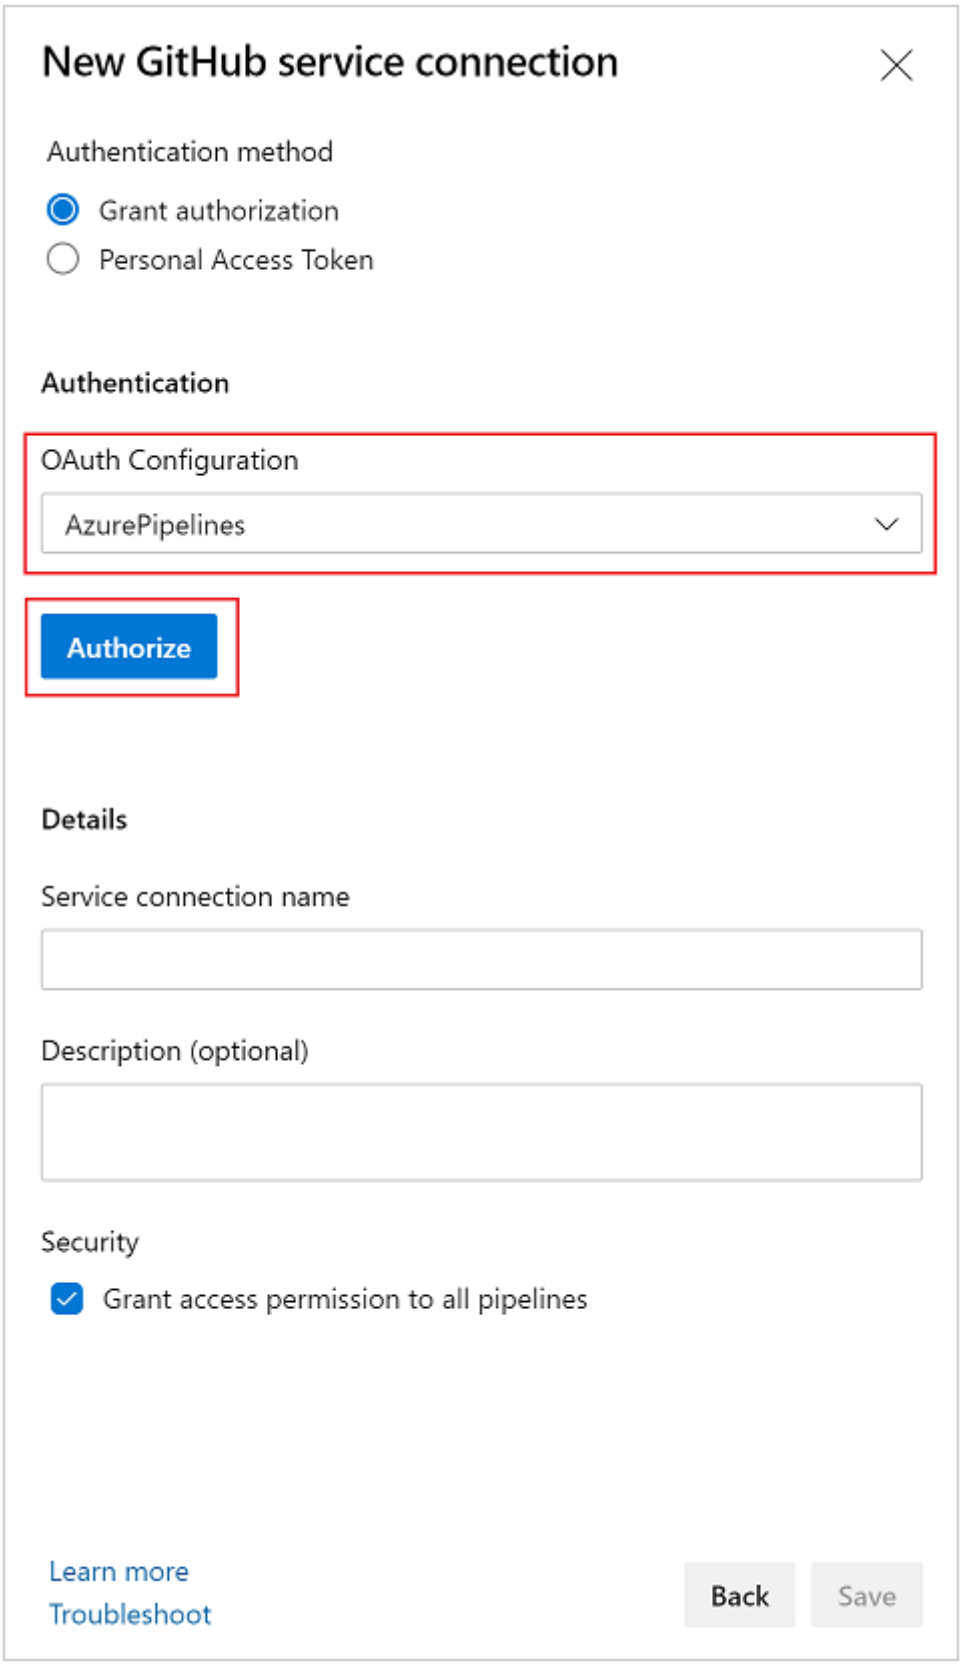
6. Select the **GitHub** service.

7. Select **Next**.



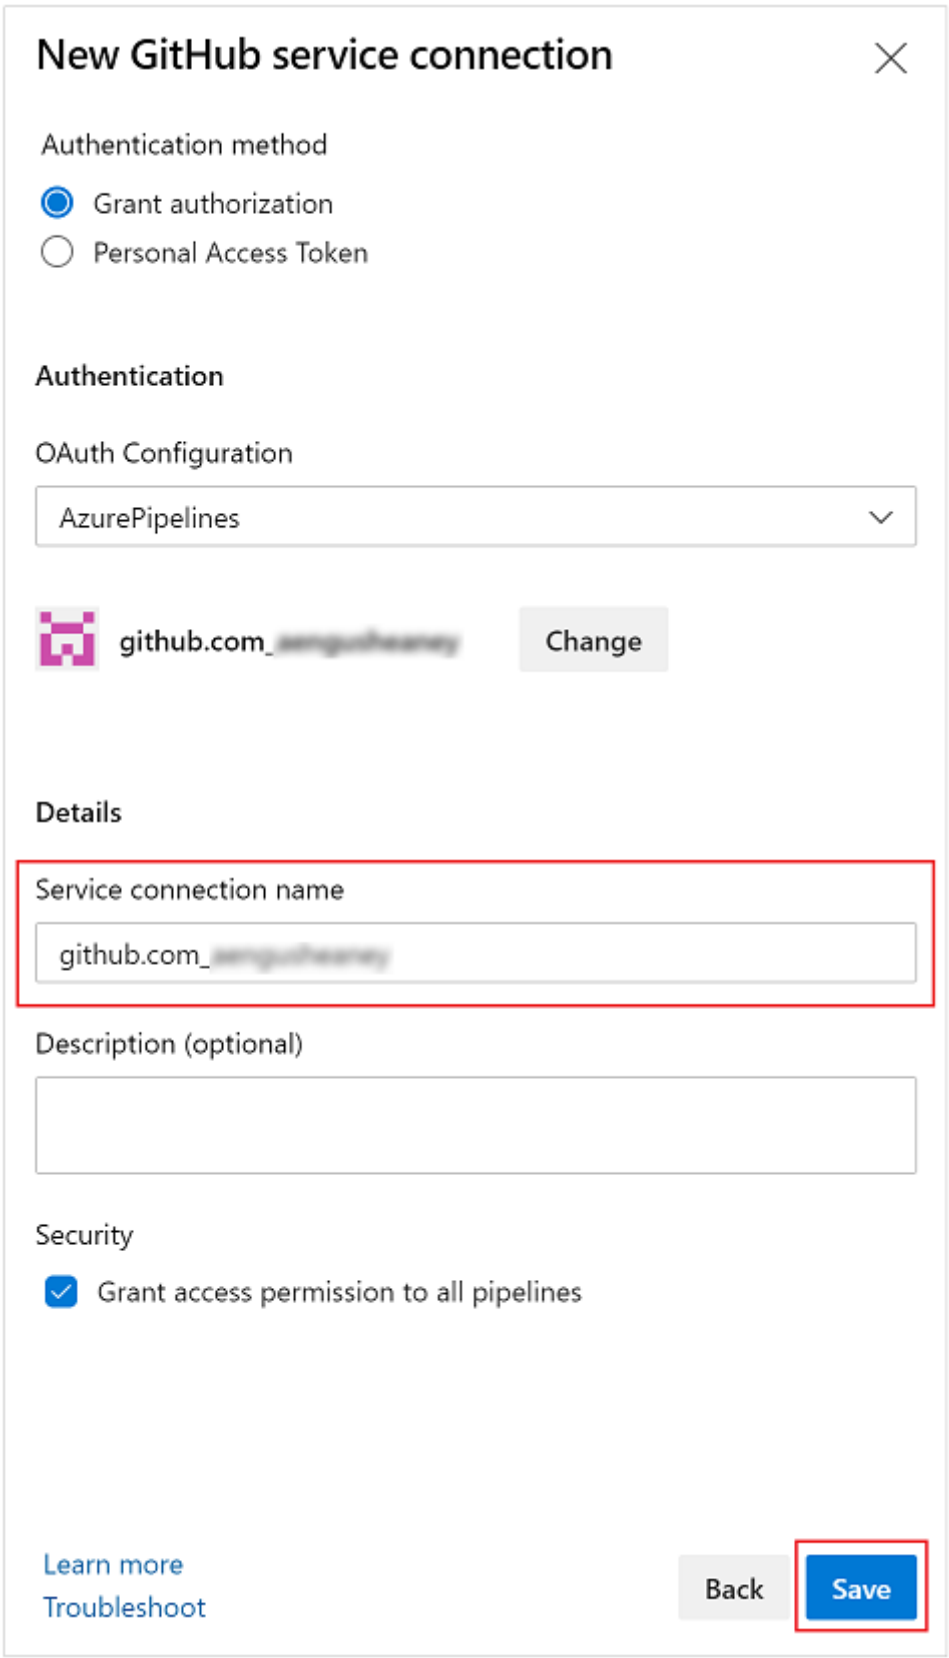
8. Under **OAuth Configuration**, select **AzurePipelines**.

9. Select **Authorize**.



10. Optionally, you can update the **Service connection name**.

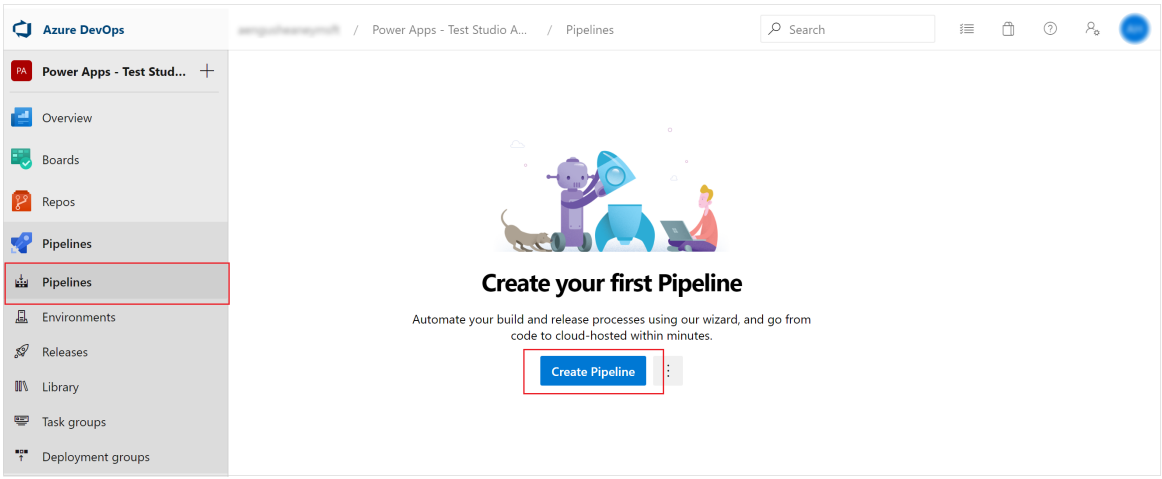
11. Select **Save**.



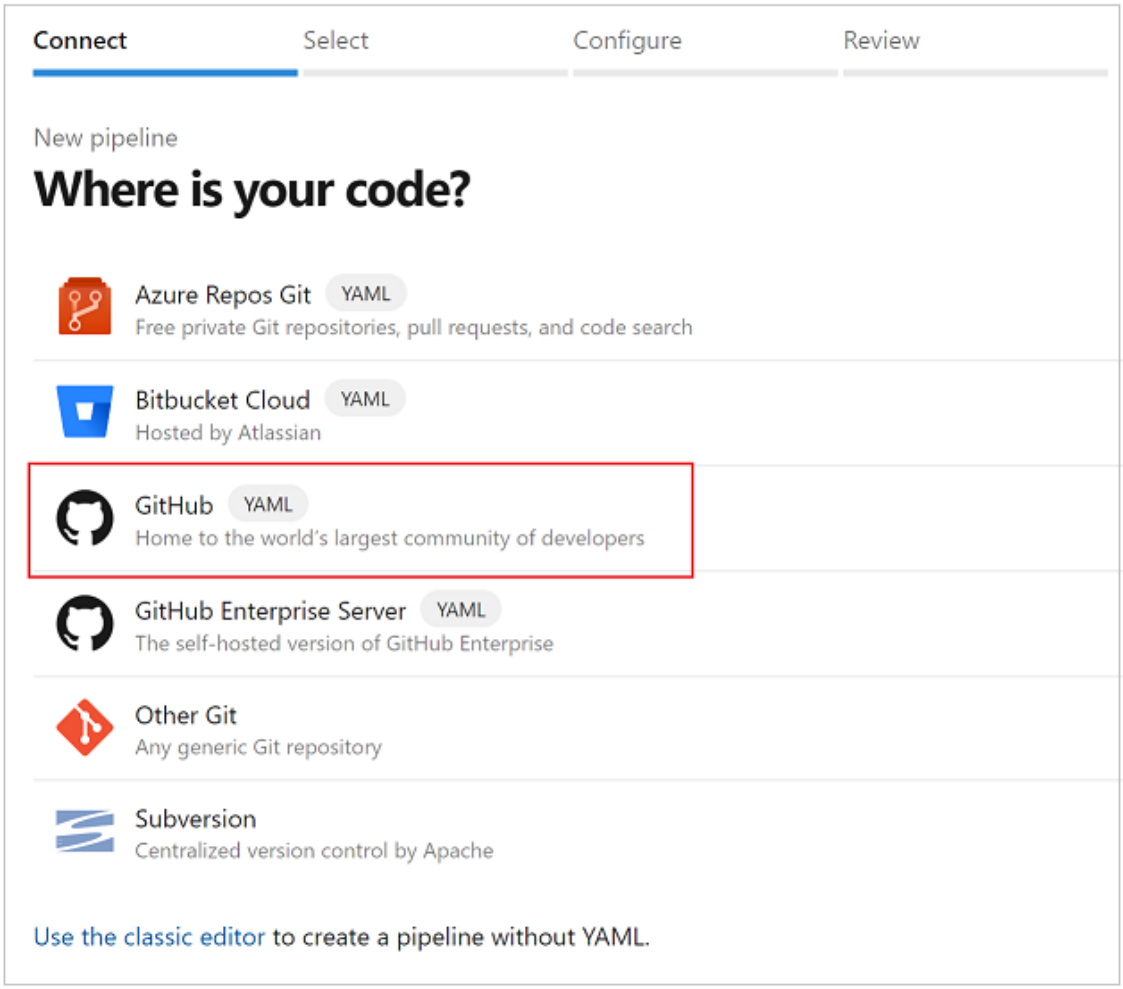
Create a pipeline

1. Select **Pipelines** in the left navigation pane.

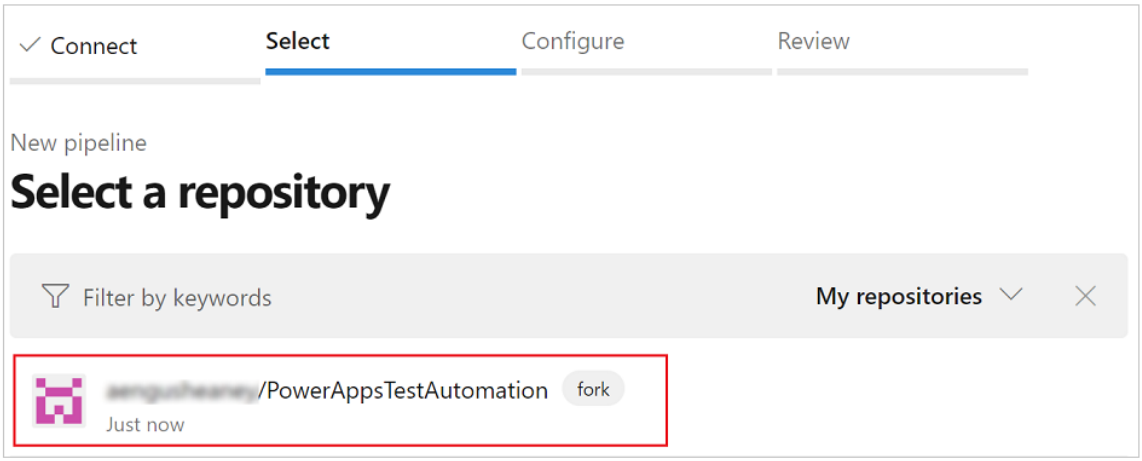
2. Select **Create Pipeline**.



3. Select **GitHub YAML**.



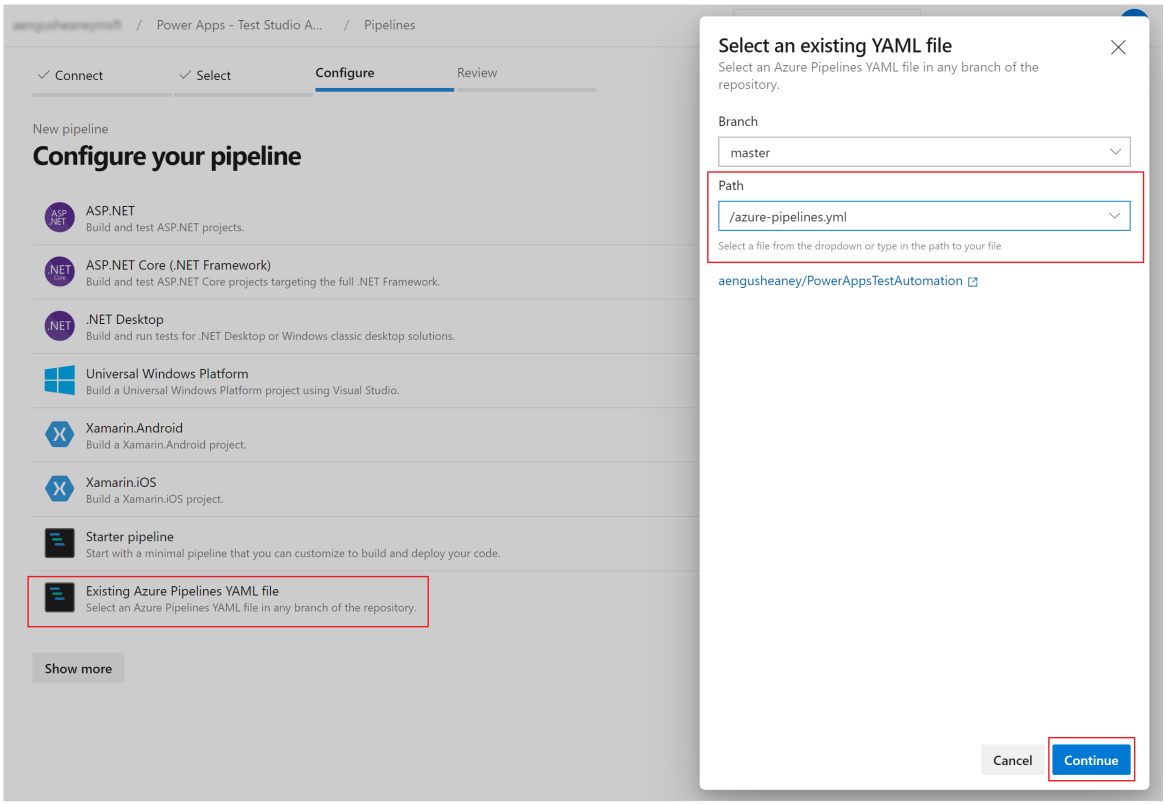
4. Search for or select your repo.



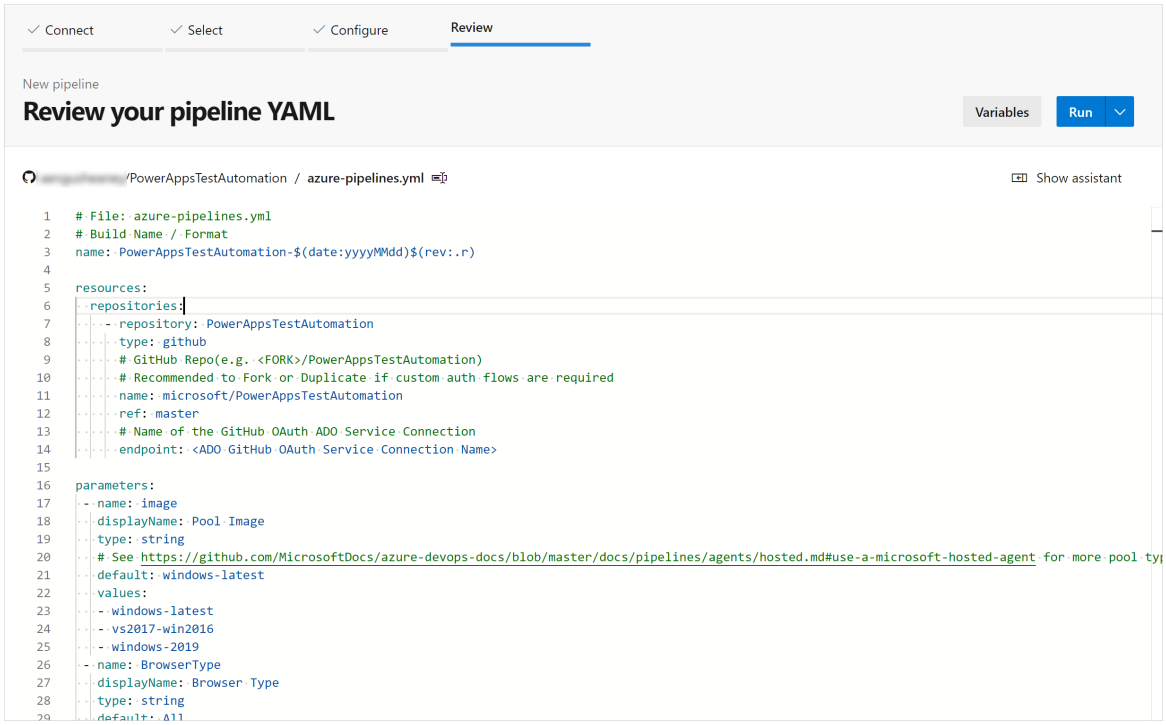
5. Select **Existing Azure Pipelines YAML file**.

6. Set the path to the Azure YAML pipeline file you created earlier.

7. Select **Continue**:

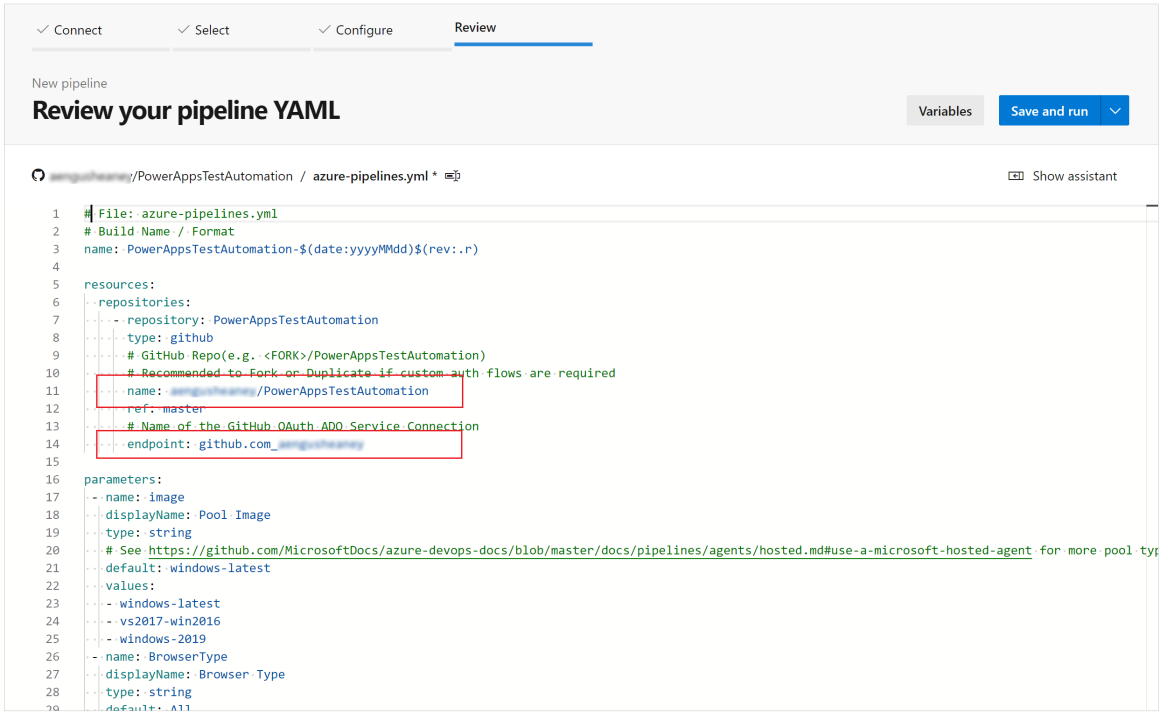


The azure-pipelines.yml file appears.



8. Update **repositories name** to your repo.

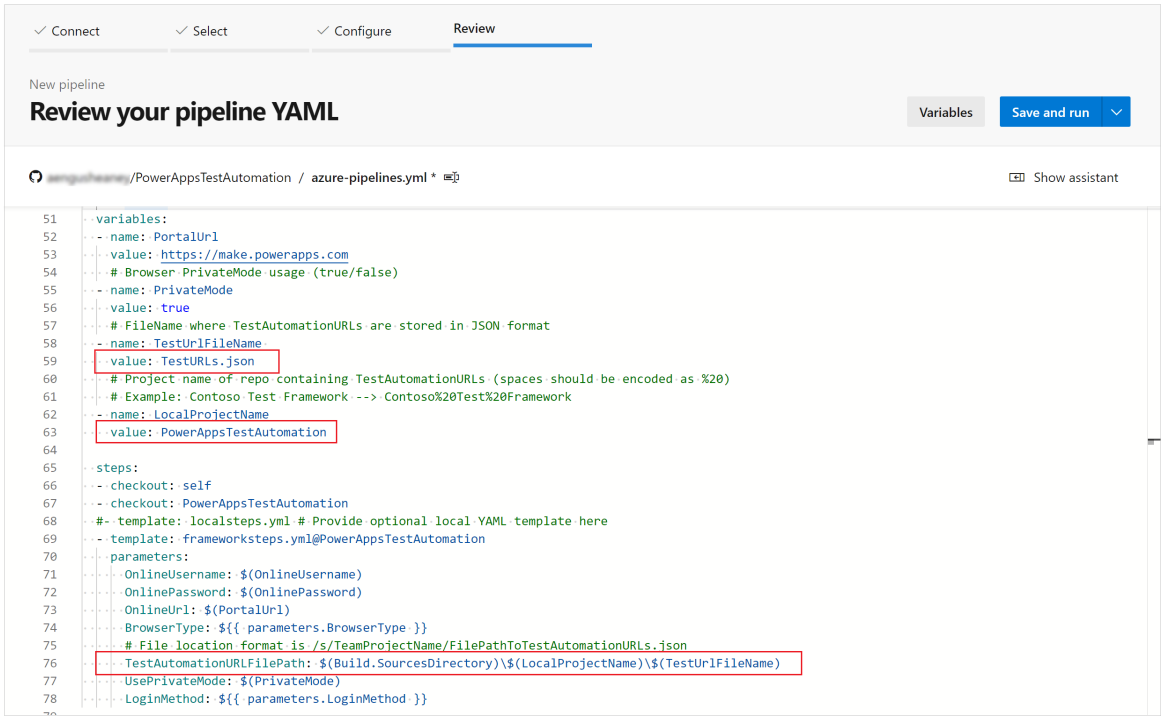
9. Update **endpoint** to the name of the GitHub service connection you created earlier.



10. Update the **TestAutomationURLs** file name. This is the test URLs .json file file you created earlier.

11. Update the **LocalProjectName** value to your repo name, if you changed it.

12. Update the **TestAutomationURLFilePath** to the location of the test URLs .json file in your repo.



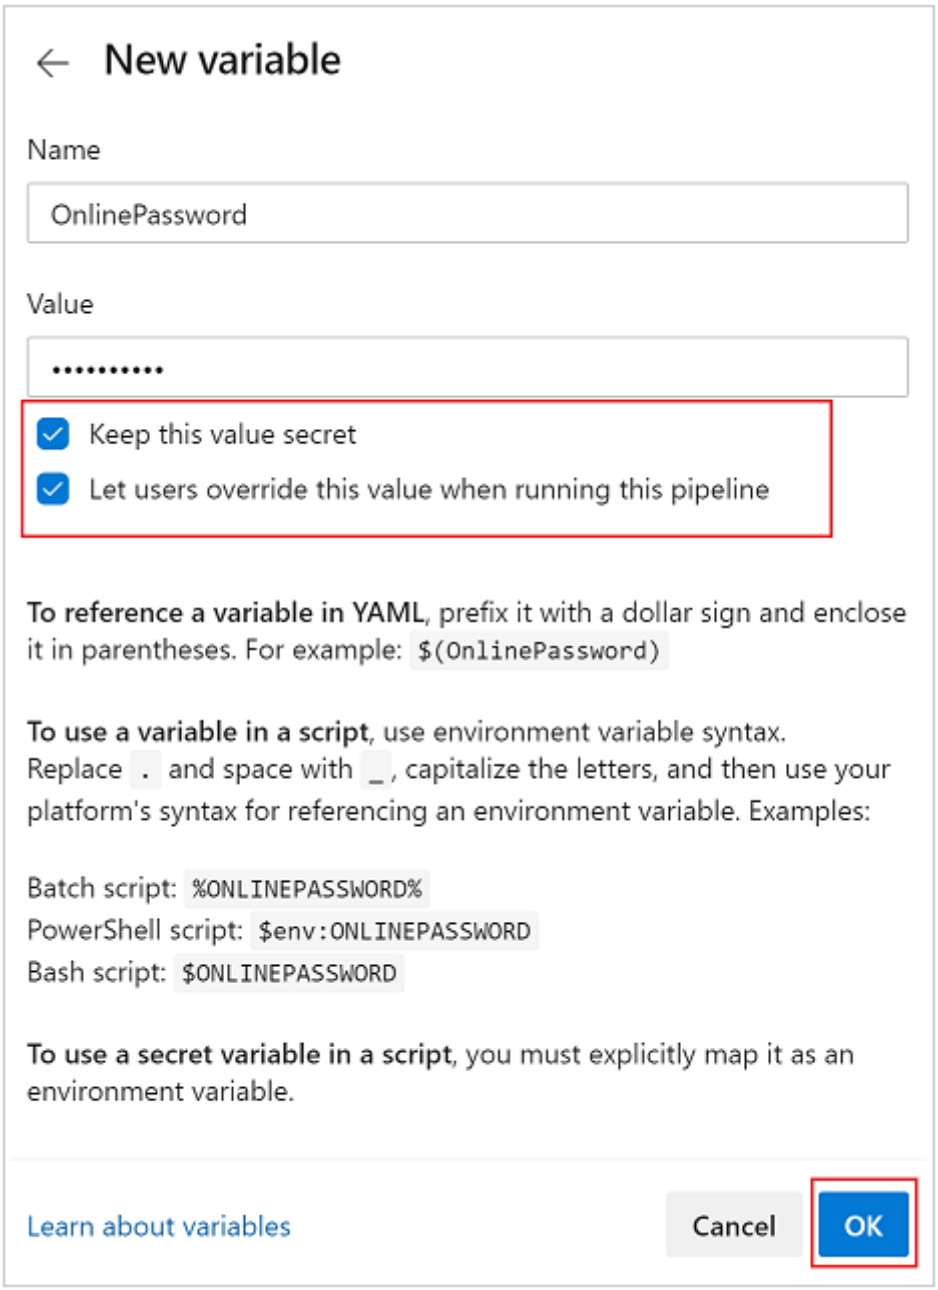
13. Select **Variables**.

14. Add a variable named **OnlineUsername**, and set the value to the Microsoft Entra email address of the user context who will sign in to the application. Tests will run under the context of this user account.

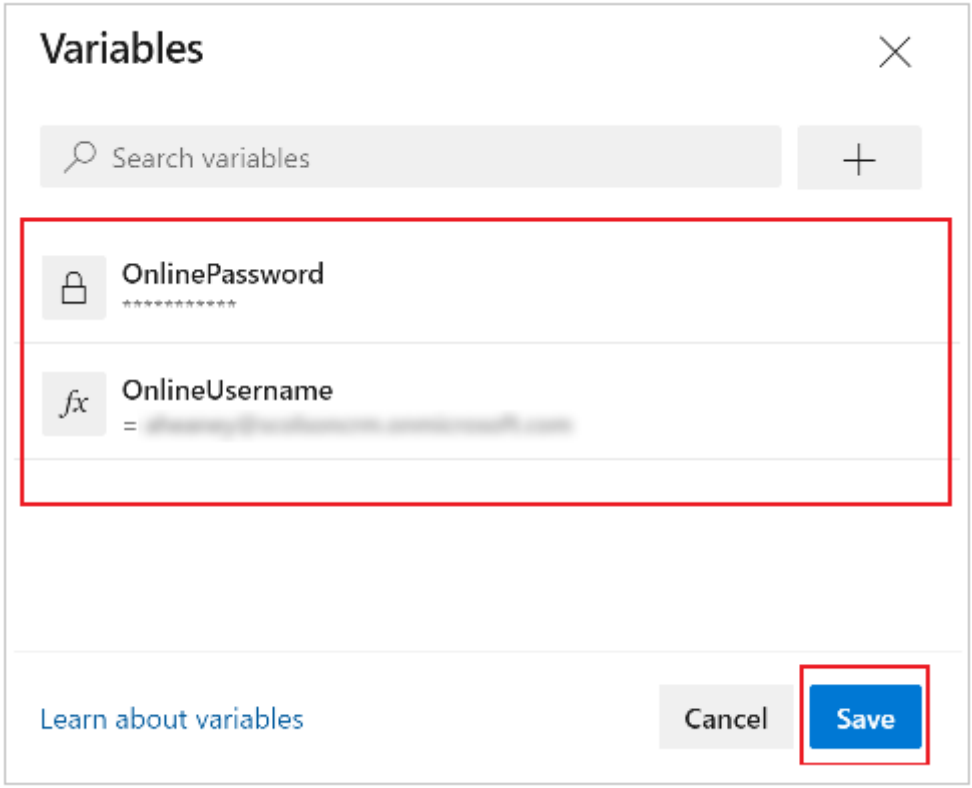
15. Select **OK**.

16. Add another variable named **OnlinePassword**. Set the value to the password of the Microsoft Entra account created earlier.

17. Select **Keep this value secret** and **Let users override this value when running this pipeline**.

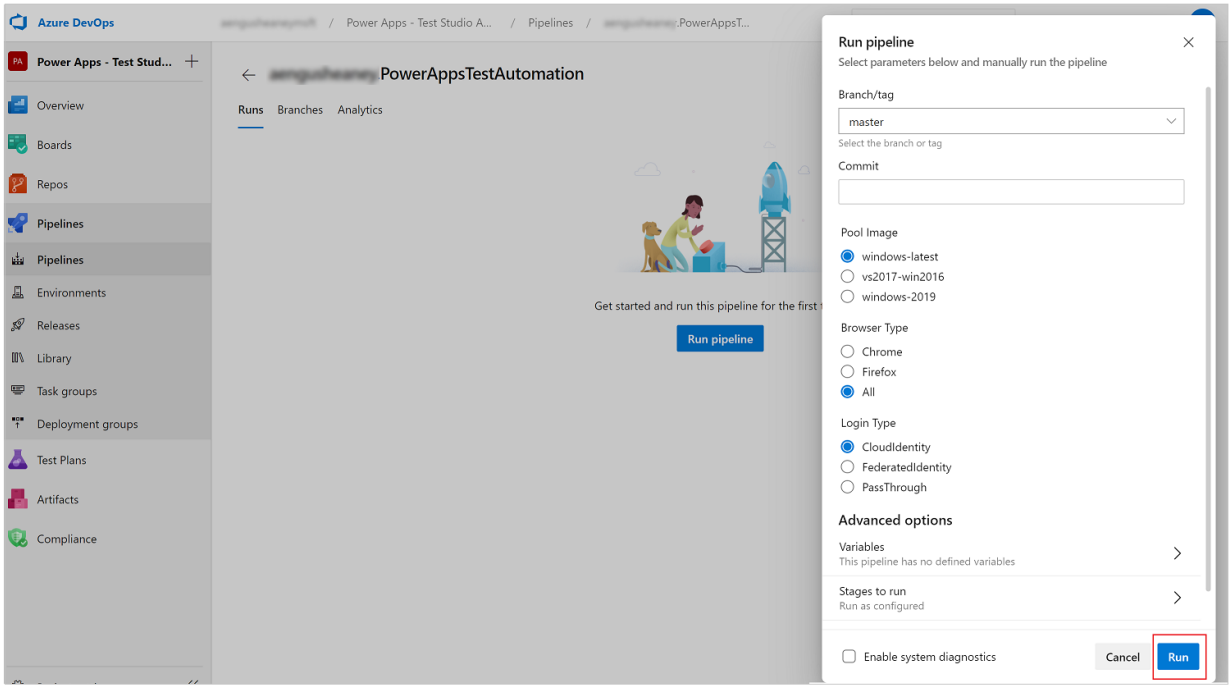


18. **Save** and **Commit** the changes to your repo.

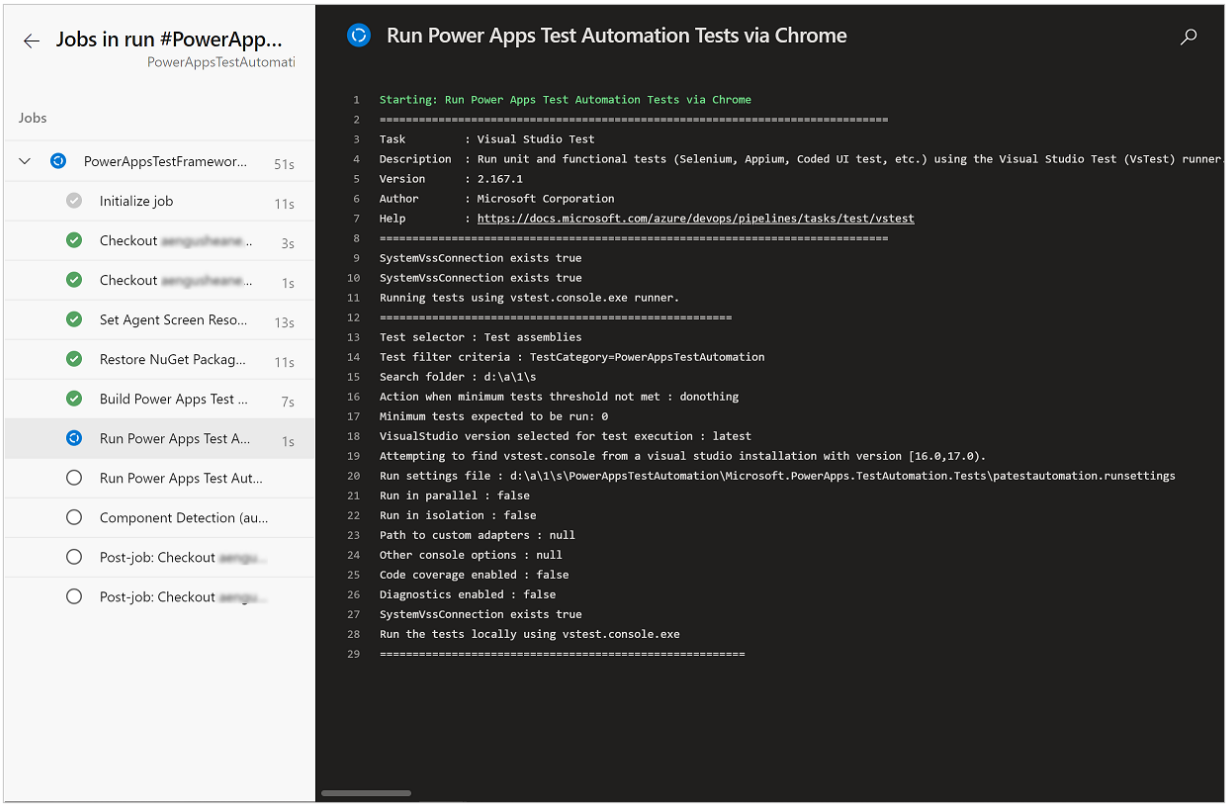


Run and analyze tests

To validate whether your tests are being successfully executed, select **Run**. Optionally, you can optionally select the server image to run your tests and also the browser types.

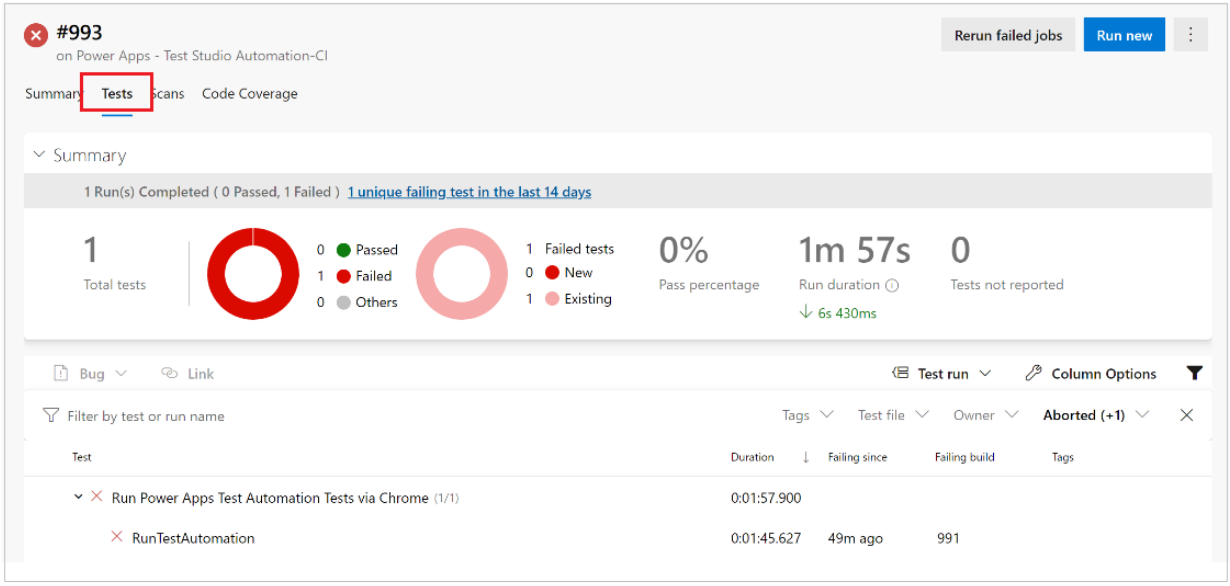


As the job runs, select it to see detailed status for each of the tasks that are running.

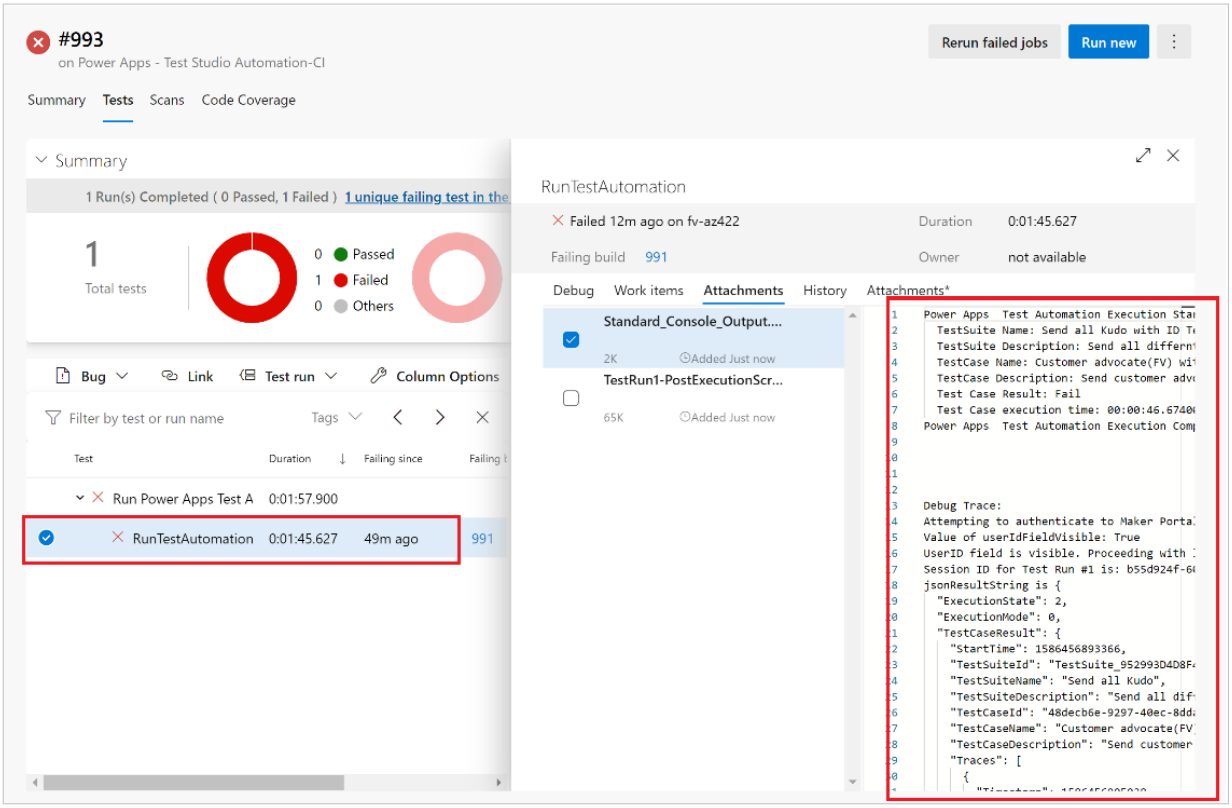


When the job is completed, you can view the high-level job summary and any errors or warnings. By selecting the **Test** tab, you can view specific details on the test cases you've executed.

The following example indicates that at least one of our test cases has failed while executing the tests by using the Chrome browser.



Select **RunTestAutomation** to drill into the details about the failed test cases. On the **Attachments** tab, you can see the summary of the test execution and which test cases have failed or passed in your test suite.



> **Note**
>
> If you execute a test suite, you'll see a summary of test cases that have passed and failed. If you execute a test case, you'll see specific details about the failure with any trace information, if available.

Known limitations

- Multi-factor authentication isn't supported.
- The test summary will report a single test result per browser. The test result will contain one or more test cases or test suite results.
- For any authentication process other tha Microsoft Entra sign-in, you'll need to customize the sign-in process in the **PowerAppsTestAutomation** solution.

Test canvas applications with Test Engine (deprecated)

> **Note**
>
> **Test Engine is deprecated** and will be removed in a future release. Use Power Platform Playwright samples for test automation capabilities in Power Platform and Dynamics 365 services.

Testing canvas apps with Test Engine requires the following steps:

1. Create a test plan
2. Set up your user
3. Run the test
4. View the results

Create a test plan

Test plans are defined using YAML format. You can author your own test plan or download recorded tests from Test Studio.

Author your own test plan

Create a yaml file using the test plan schema explained in Power Apps Test Engine YAML format (deprecated).

When choosing authoring your own test plan, you can take advantage of the following features:

- **Additional Power Fx Functions**: Use the extra registered Power Fx actions to interact with Power Apps component framework (PCF) components, enhancing the capabilities of your test plans.
- **Define Custom Data Structures and Functions**: Make use of User Defined Types (UDTs) and User Defined Functions (UDFs) to create reusable and maintainable test steps.

> **Tip**

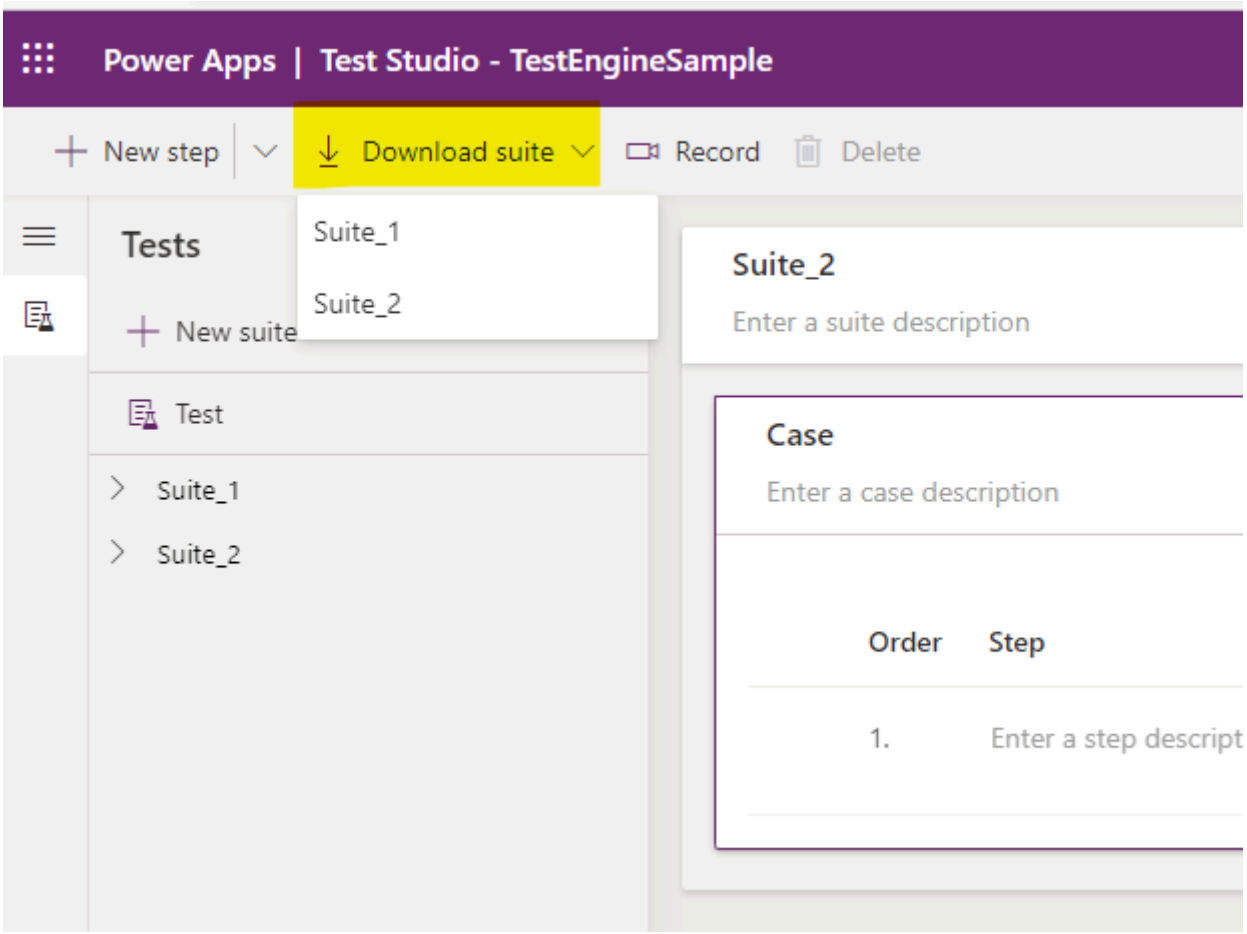
Review available sample plans in the GitHub repository.

Download recorded tests from Test Studio

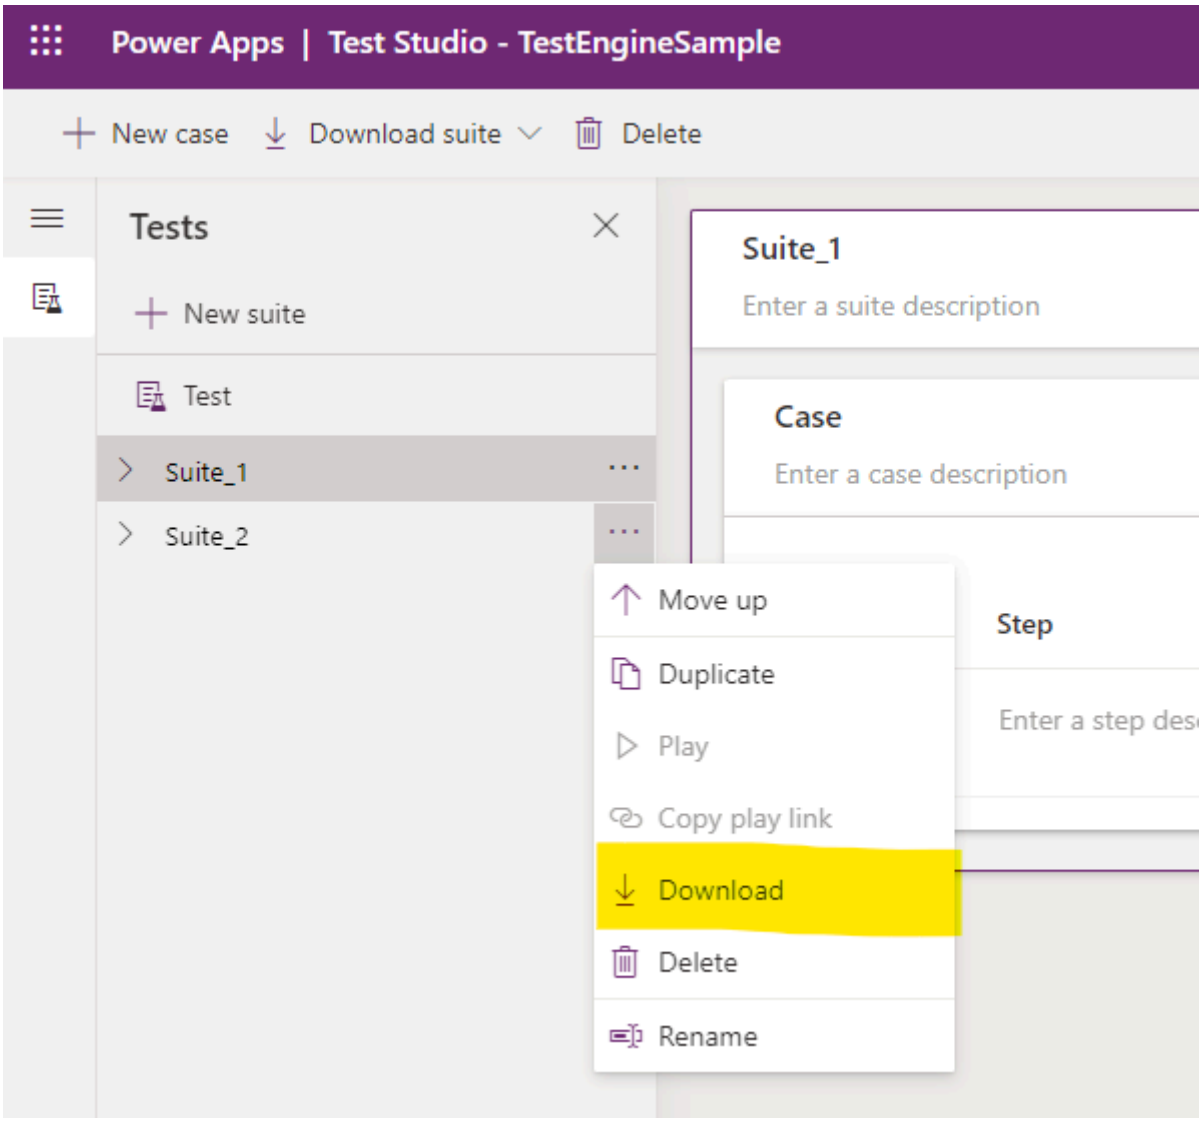
Downloading recorded tests from Test Studio allows quick capture and replay of user interactions with your application. This method is useful for creating basic test cases without writing any code. However, it has limitations in terms of flexibility and the ability to handle complex scenarios.

If you have tests that you recorded in Test Studio, you can download them from Test Studio to reuse in Test Engine.

- Use the **Download suite** button in Test Studio to download the test plan. Choose the test suite to download if you have multiple test suites.



- Alternatively, use the **Download** button available under each test suite.



- Make sure you update the config file and user configurations if you're using a different tenant or environment for this app.

Set up your user

Test Engine currently has these authentication methods:

Expand table

Method	Description
Storage State	Store authenticated user state locally in the user profile using Microsoft Windows Data Protection API
Dataverse	Store authenticated user state inside Dataverse using your own customer managed key encrypted with an X.509 certificate using ASP.NET Core Data Protection

You can't store test credentials in test plan files. You must select `Storagestate` or `Dataverse` as the secure location to store credentials. The test plan file contains references to which

environment variables are used for user persona. For example, the following YAML snippet indicates that the `user1Email` environment variables are used:

YAML

```yaml
environmentVariables:
  users:
    - personaName: User1
      emailKey: user1Email
```

View Users for more information.

Use the following PowerShell script to store the username in your environment variables.

PowerShell

```powershell
$env:user1Email = "someone@example.com"
```

> ⓘ Note
>
> The user password is no longer required in an environment variable. Review authentication for supported options.

Run the test

Use the PAC CLI pac test run command to run your test plan.

Required parameters

You need to provide the following information:

- `--test-plan-file`: Path to your test plan file
- `--tenant`: Your tenant ID
- `--environment-id`: Your environment ID

Example command

Here's an example of running a test for a canvas application:

PowerShell

```
pac test run `
   --provider canvas `
   --test-plan-file your-testplan.te.yaml `
   --tenant your-tenantid-guid-value `
   --environment-id your-environmentid-guid-value
```

You can also use the shorter parameter aliases:

PowerShell

```
pac test run `
   -p canvas `
   -test your-testplan.te.yaml `
   -t your-tenantid-guid-value `
   -env your-environmentid-guid-value
```

Dataverse integration

To enable Dataverse integration with your canvas app tests, you can add the `enableDataverseFunctions` parameter in your test settings:

YAML

```
testSettings:
  extensionModules:
    enable: true
    parameters:
      enableDataverseFunctions: true
```

When you enable Dataverse integration, you're required to open Azure CLI with a user or service principal that has rights to the Dataverse environment. You can use the az login command. More information: Sign in with Azure CLI.

The Dataverse API URL used for integration is obtained either from the host domain name of the pac test run `--domain` parameter or by defining an PowerShell environment variable named `DATAVERSE_URL`.

View the results

When the tests complete, you can view the results of your test in the `.trx` file located in the output directory. This folder contains any screenshots or videos captured by your tests when `recordVideo` is set to `true` in the test plan yaml.

How to create a canvas app connected to Microsoft Dataverse from scratch

Article • 12/16/2022

Microsoft Dataverse is a premier data platform for Power Platform. Dataverse lets you securely store and manage data used by your apps within a set of tables.

In this article, we'll create an app connected to existing data in a Power Platform environment.

Prerequisites

To complete this lesson, you'll need a Power Apps environment with a Dataverse database with at least one table containing data. If you don't have a license, you can sign up for the Power Apps Developer Plan, or use a Power Apps trial.

Create a trial environment

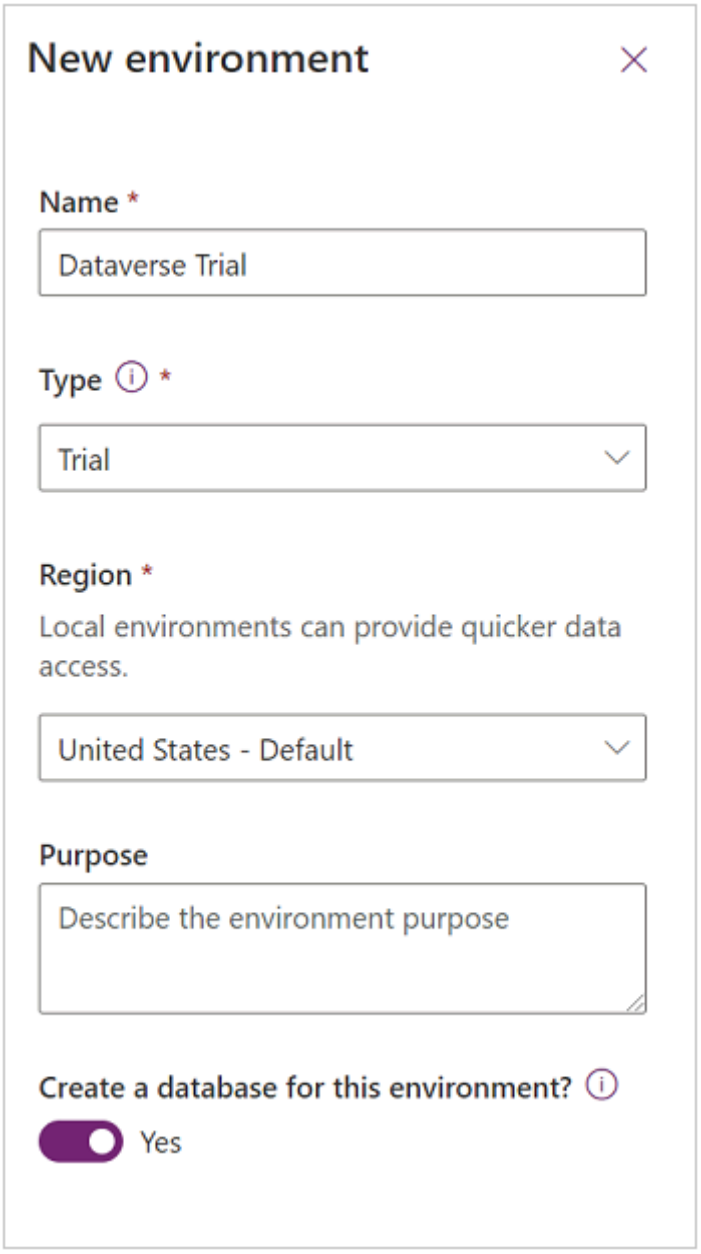
An environment in Power Apps is a space to store, manage, and share your organization's business data, apps, chatbots, and flows. It also serves as a container to separate apps that might have different roles, security requirements, or target audiences. Each environment can have one Dataverse database.

To make sure that you have what you need to complete this lesson, we're going to create a new environment that includes a Dataverse database. This environment is a 30-day trial that will go away at the end of the 30 days, but you can upgrade it to a sandbox or production environment if you want to keep it.

We're going to create a trial environment that will include a Dataverse database, and the sample data used in this article.

1. Go to Power Platform admin center.
2. Select **Environments**.
3. Select **New**.
4. Name the environment **Dataverse Trial**.
5. Select **Trial** for environment type.
6. Toggle **Create Database** to **Yes**.

7. Select **Next**.



8. Toggle **Deploy Sample Apps and Data** to **Yes**.

9. Select **Save**.

Your trial environment will now be created, including a Dataverse database and sample data.

Create a canvas app

Create a canvas app with **Accounts** table in Dataverse. When done, Power Apps will generate an app for you. This app includes the following screens:

- **Browse Screen** - a screen to search, sort, and select an account record, and launch the edit screen to create a new record.

- **Detail Screen** - a read-only screen that displays the details of the record selected on the browse screen.
- **Edit Screen** - an edit form that is used to edit the details of a selected record or create new records.

Try the app

From Power Apps Studio, you can preview your app to try it out.

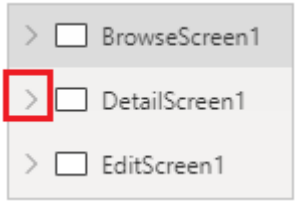
1. Select **Play** from the top-right corner of the screen.
2. From the **Account** list, select **Alpine Ski House**.
3. View the details of Alpine Ski House.
4. Select  to edit the record.
5. On edit form, remove **(sample)** from the account name field.
6. Select  to save the record changes.
7. Back on the account list screen, select + to launch a new record form.
8. Enter the desired fields, such as **Account name**.
9. Save the record.
10. Verify that the newly created record appears in the account list gallery.
11. To exit preview mode, select  in the upper-right corner of the screen.

Using the Tree view

The **Tree View** is on the left-side of the screen (if you don't see it, select ). The tree view gives you easy access to the components in your canvas app, such as screens, galleries, text input controls, and text labels.

The tree view can be collapsed or expanded by screen to make it easy to focus on the part of the app on which you're working.

Currently, the **BrowseScreen1** is expanded. To see the components for other screens, select > next to the name of the screen.



Modify the gallery of accounts

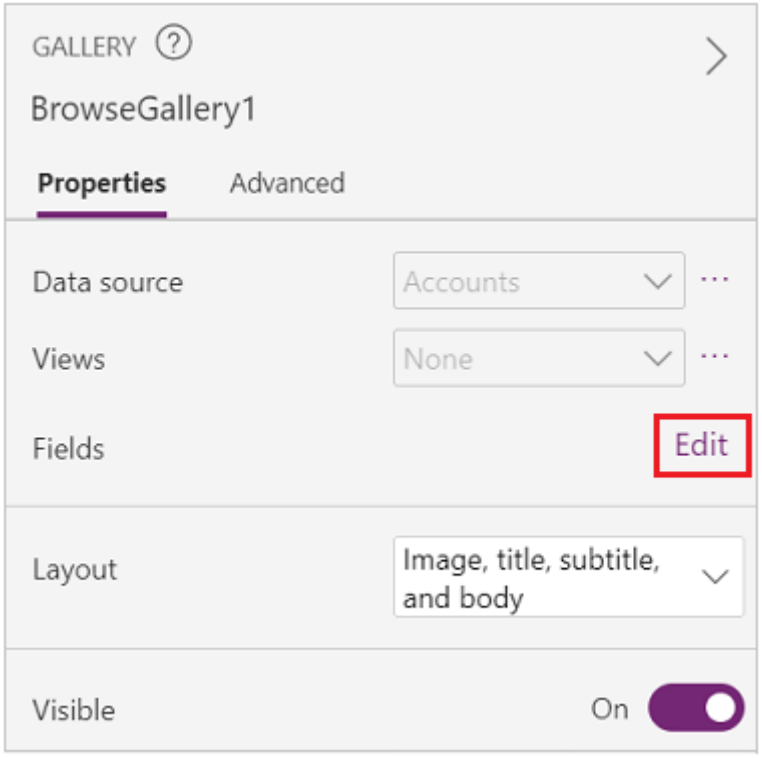
A gallery in Power Apps is used to show several related items. For example, in our app, **BrowseGallery1** displays all of our account records. When one of the items is selected, a border is placed around the item to indicate that it has been selected.

By default, this gallery includes the following three fields: Account name, phone number, and city.

However, we can change the fields included in the gallery.

1. From the tree view, select **BrowseGallery1**.

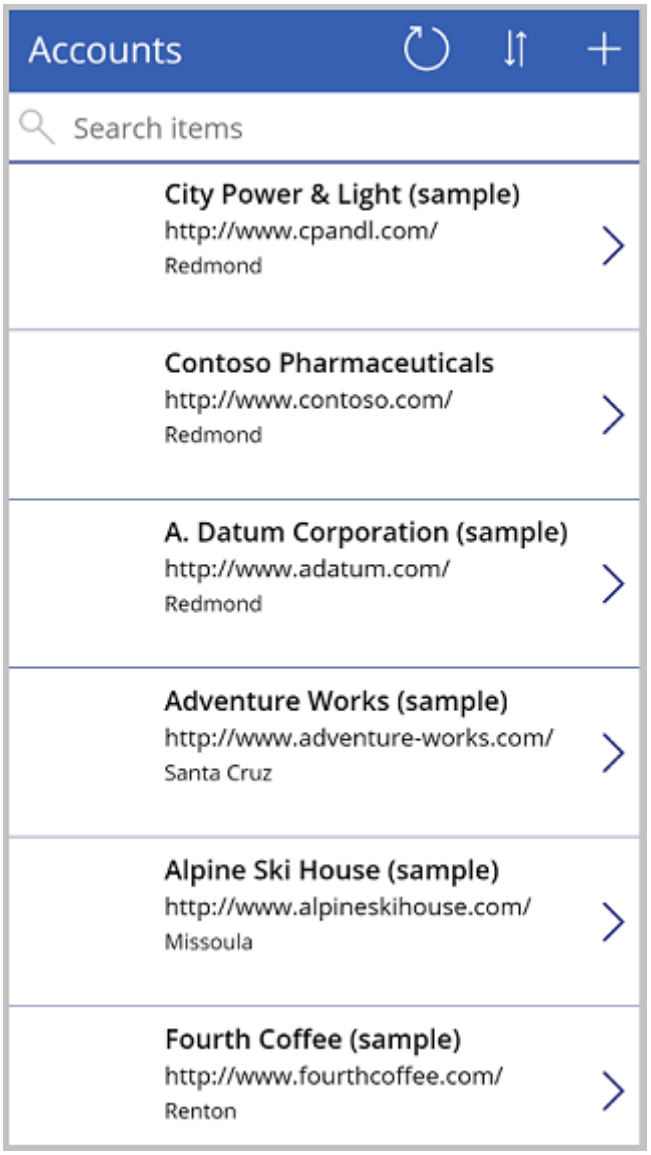
2. In the property pane on the right-side of the screen, select **Edit**.



3. The field data panel will appear. Change Subtitle to Website.

4. Select outside of the field data panel.

5. App will now display the website fields value instead of the phone number.



Update search to include the account name

When you previewed the app, you may have noticed that searching by account name didn't work. That is because the autogenerated app search formula doesn't include the **Account name** field. In this lesson, we'll update to search formula to include the Account name field.

> **Tip**
>
> The account name is stored in a column called **Name**.

1. In the tree view, select **BrowseGallery1**.
2. Verify the **Items** property is selected in the property selector.
3. In the formula bar, update the formula as follows:

```
Power Fx
```

```
SortByColumns(Search([@Accounts], TextSearchBox1.Text,
"name","address1_city","address1_composite"), "name",
If(SortDescending1, Descending, Ascending))
```

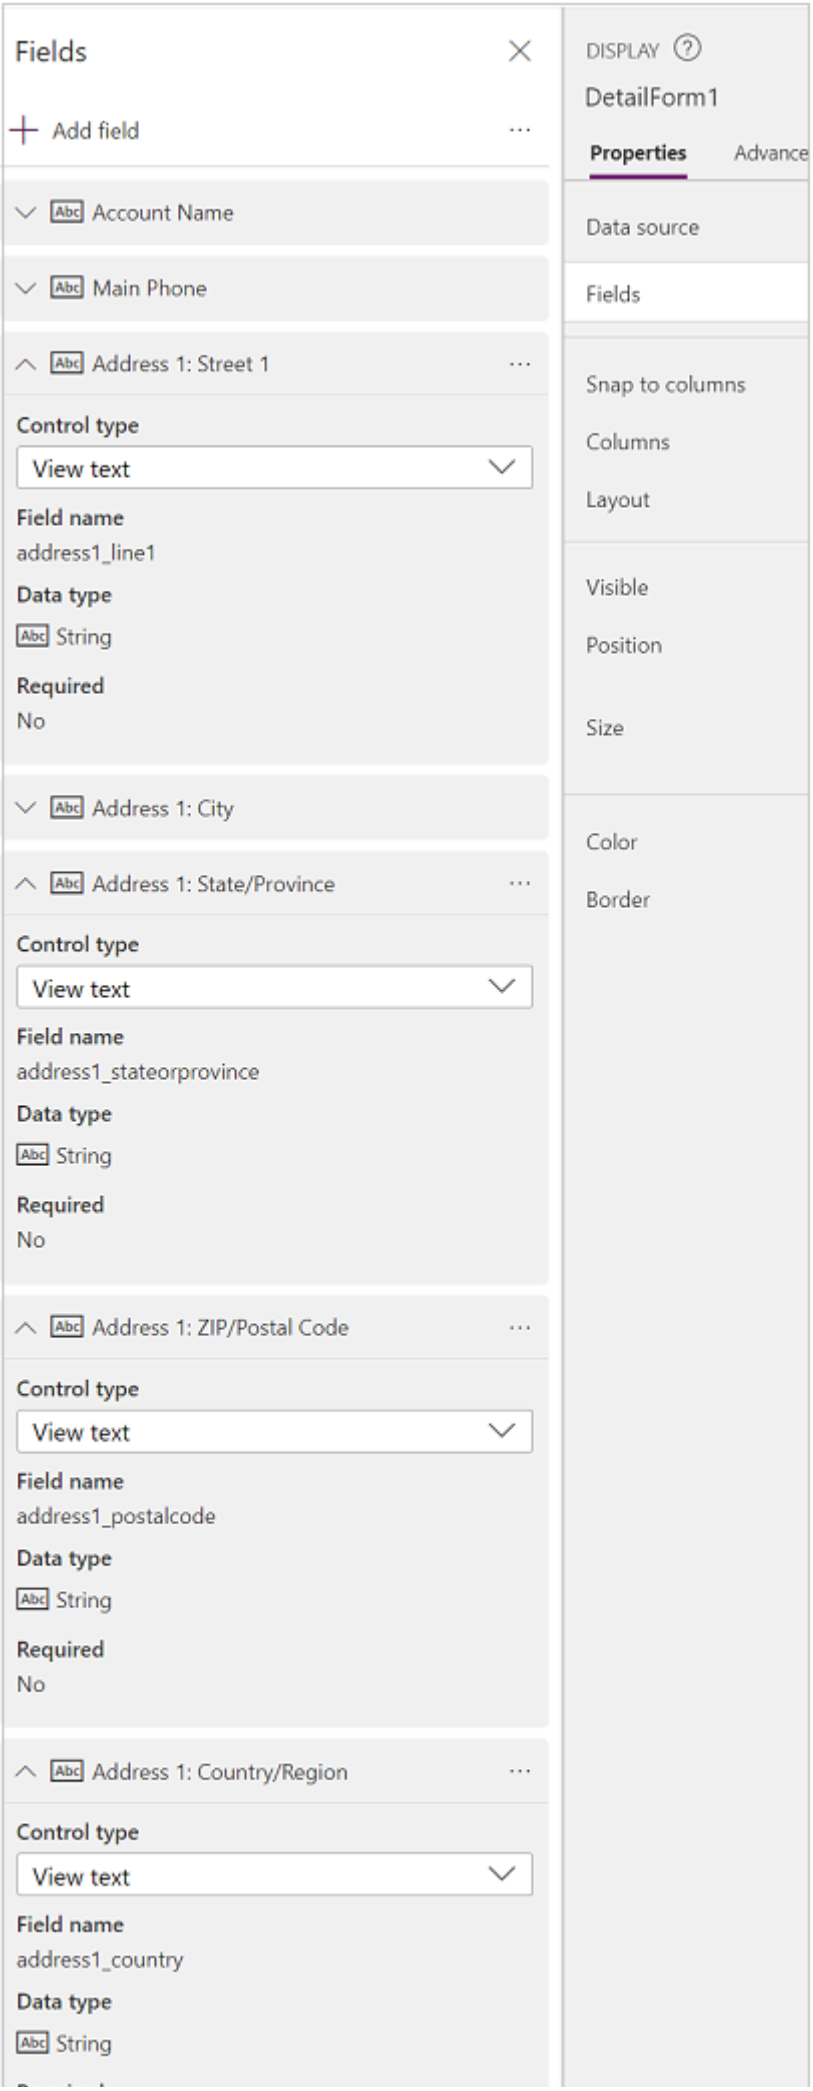
The formula consists of SortByColumns, Search, and If functions to search the **Accounts** table with the text entered in the search box that has the matching data in the name, address1_city, and address1_composite fields, and allow sorting.

The account list can now be searched and sorted by the Account name field.

Add fields to the account detail screen

Datascreen1 includes a display form that displays the data of the record selected on the browse screen. Display form controls are read-only, intended to allow users to read data but not create or edit data.

1. In the tree view, expand **DetailScreen1**.
2. Select **DetailForm1**.
3. In the right-side properties pane, select **Edit Fields**.
4. Select **Add field**.
5. Select the following fields:
    - Address 1: Country
    - Address 1: State/Province
    - Address 1: Street 1
    - Address 1: ZIP/Postal Code
6. Select **Add**.



Fields
Add field
Account Name
Main Phone
Address 1: Street 1
Control type
View text
Field name
address1_line1
Data type
String
Required
No
Address 1: City
Address 1: State/Province
Control type
View text
Field name
address1_stateorprovince
Data type

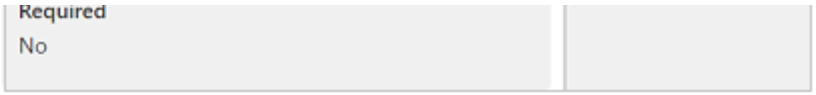
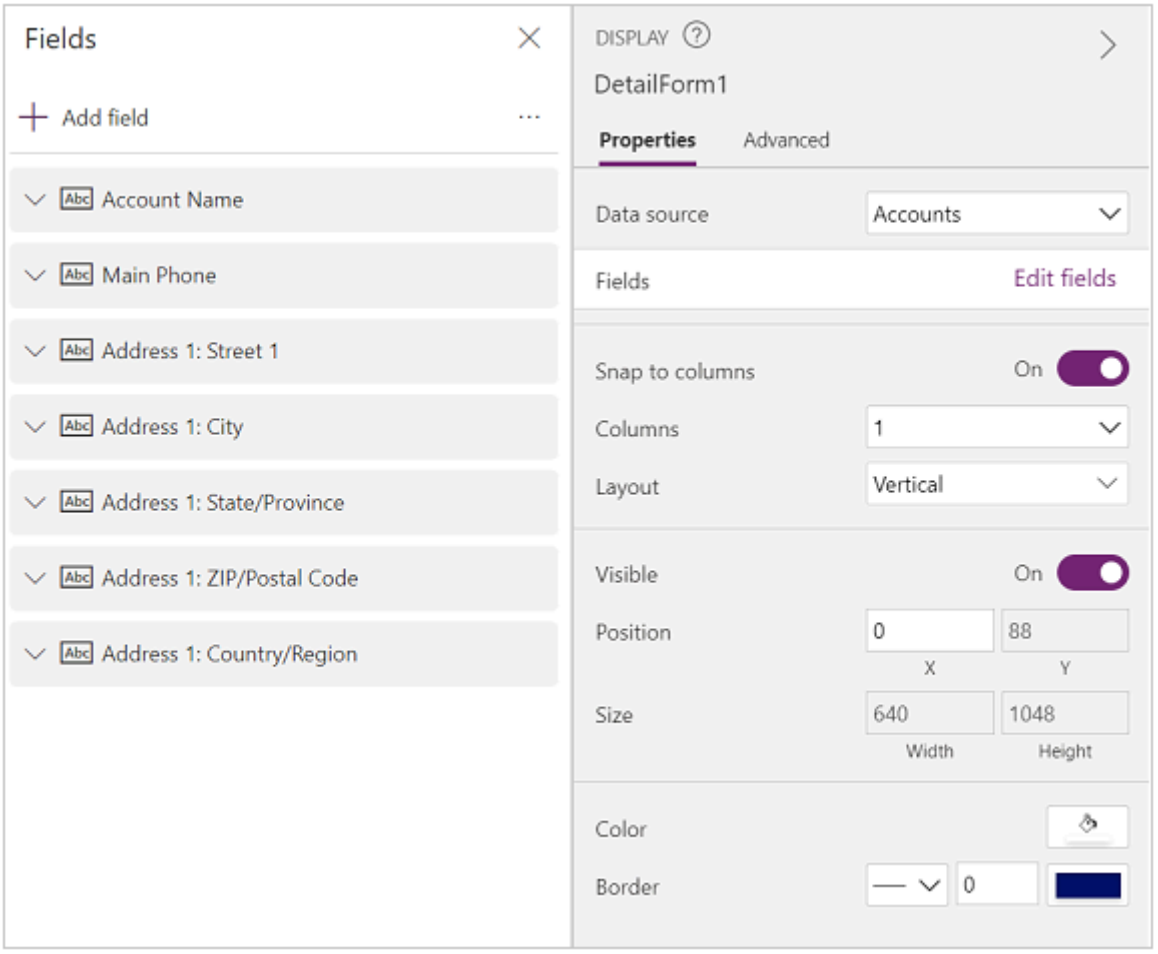
Fields
Snap to columns
Columns
Layout
Visible
Position
Size
Color
Border



7. You'll now see the selected fields in the Field panel. Rearrange the fields by dragging and dropping them or by selecting ... (ellipsis) to the right of the field name, and selecting **Move up** or **Move down.**

8. Arrange the field in the following order:

    - Account Name
    - Main Phone
    - Address 1: Street 1
    - Address 1: City
    - Address 1: State/Province
    - Address 1: Zip/Postal Code
    - Address 1: Country/Region



9. Select anywhere outside of the field pane to close the pane, and return to **DetailScreen1**.

You'll now see the selected fields displayed in the correct order.

Modify account edit screen

EditScreen1 allows users to edit or create account records. This screen includes an Edit Form control called **EditForm1**.

> ⓘ **Note**
>
> Since the edit form is one of the primary methods for creating or updating records, it should include every field that you want your users to be able to submit, and shouldn't include any fields that are read-only or the ones you don't want your users to modify.

In this lesson, we'll add the same fields that we added earlier to the display form, plus the ability to attach files.

1. In the tree view, expand **EditScreen1**.
2. Select **EditForm1**.
3. In the right-side properties panel, select **Edit Fields**.
4. Select **Add field**.
5. Select the following fields:
    - Address 1: Country
    - Address 1: State/Province
    - Address 1: Street 1
    - Address 1: ZIP/Postal Code
6. You'll now see the selected fields in the field pane. Rearrange the fields by dragging and dropping them or by selecting **...** (ellipsis) to the right of the field name, and selecting **Move up** or **Move down.**
7. Arrange the field in the following order:
    - Account Name
    - Main Phone
    - Address 1: Street 1
    - Address 1: City
    - Address 1: State/Province
    - Address 1: Zip/Postal Code
    - Address 1: Country/Region

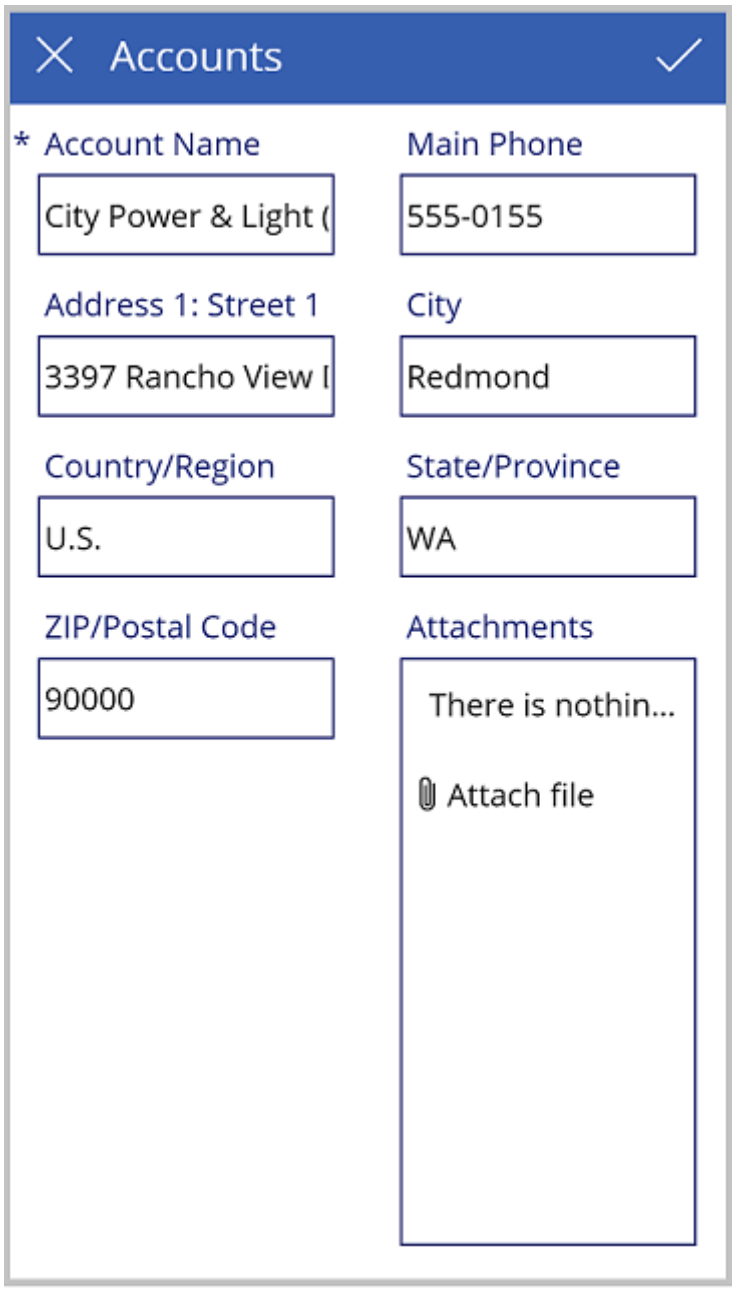
8. Select anywhere outside of the field pane to close the field pane.

9. To minimize unnecessary scrolling in the app, we want the **Edit Form** to arrange the fields into two columns. In the properties pane on the right, select 2 in the **Columns** drop down.

10. To make the form easier to read, we want to remove **Address 1:** part of the address field labels.

    - In tree view, expand **EditForm1**.
    - Select **Address 1: City_DataCard2** control.
    - In the properties pane on right, select **Advanced**.
    - Select **Unlock to change properties**.
    - Change **DisplayName** property to **City**.
    - Follow the above steps to remove **Address 1:** from the Street 1, Country/Region, State/Province, and Zip/Postal Code fields.

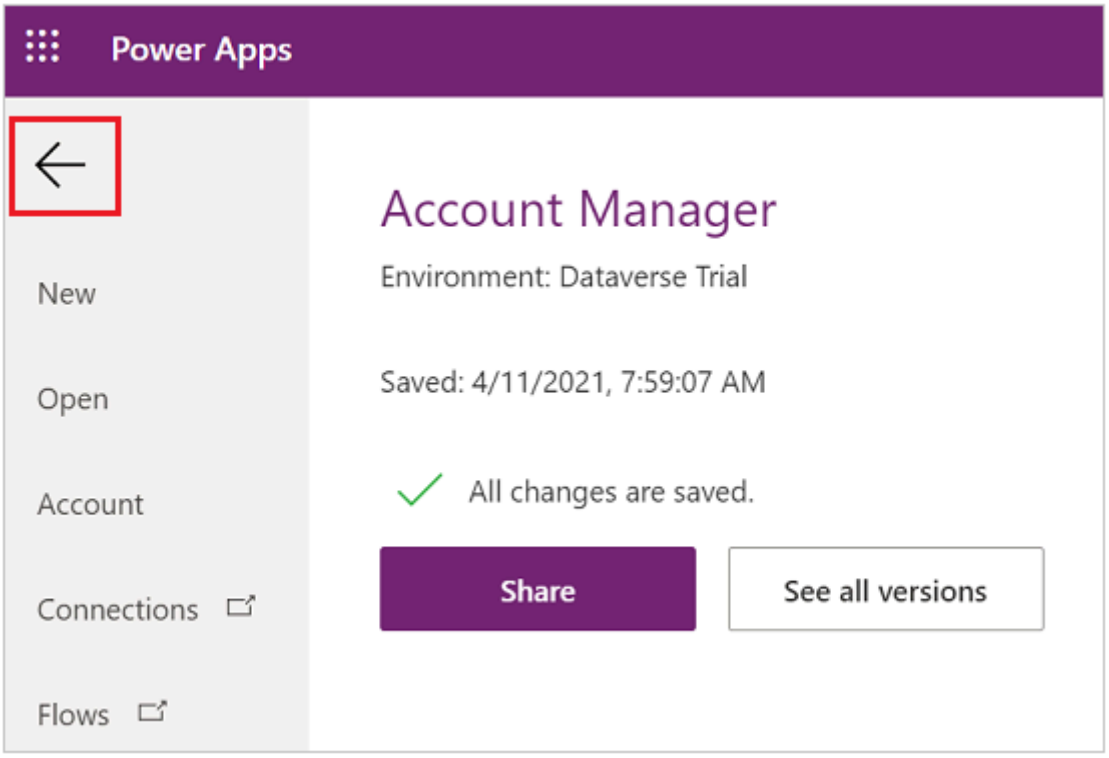
EditScreen1 should now look like the following:



Save the app

By saving the app, your app will become available to use and share with others.

1. In Power Apps Studio, select **File**.
2. In the **Name** field, enter **Account Manager**.
3. Select an icon and background color from the **Icon** area. This will be used to identify your app in the app list.
4. Select **Save**.
5. Select **Save** in the lower right corner.
6. Once app is saved, select the back arrow to return to the Power Apps Studio.



Run the app

1. Sign in to Power Apps.
2. Verify that you're in the environment you used to create the app by looking in the upper-right corner of the screen. If different, select **Environment** and select the appropriate environment.
3. Select **Apps**.
4. From the app list, select **Account Manager**.
5. When the app loads, verify the changes made.
    - Search app list for **Blue Yonder Airlines**.
    - Select the **Blue Yonder** record and verify you see the fields added to the **Display form**.
    - Select to edit the record.
    - Verify form displays two columns of fields.
    - Verify that the field names don't display **Address 1:** in the labels.
    - Select **Attach file** in the Attachment area, select a file, and select **Open**.
    - Verify uploaded file appears in the attachment list.
    - Select to save the record.

Run your app on mobile

To test your Power Apps on your mobile device:

1. Download the app from your mobile app store.
2. Sign in using your work or school account.
3. Select your app from the list.

How to create a canvas app with Power BI visual

Article • 12/16/2022

Microsoft Power BI is a powerful analysis and visualization tool. Power Apps is great at enabling people to take action on the web and mobile. Canvas apps created using Power Apps can be embedded in a Power BI report. Similarly, a Power BI report tile can be added to a canvas app. The best of both worlds can be achieved at the same place and same time.

In this example, we'll create a quick Power BI report and a canvas app, and then see how we can add the report as a tile in the app.

Watch this video to learn how to create a canvas app with Power BI visual: https://learn-video.azurefd.net/vod/player?id=1624717a-18d6-4aba-ae5f-0d0503b2cccb&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fbuild-powerbi-visual

Prerequisites

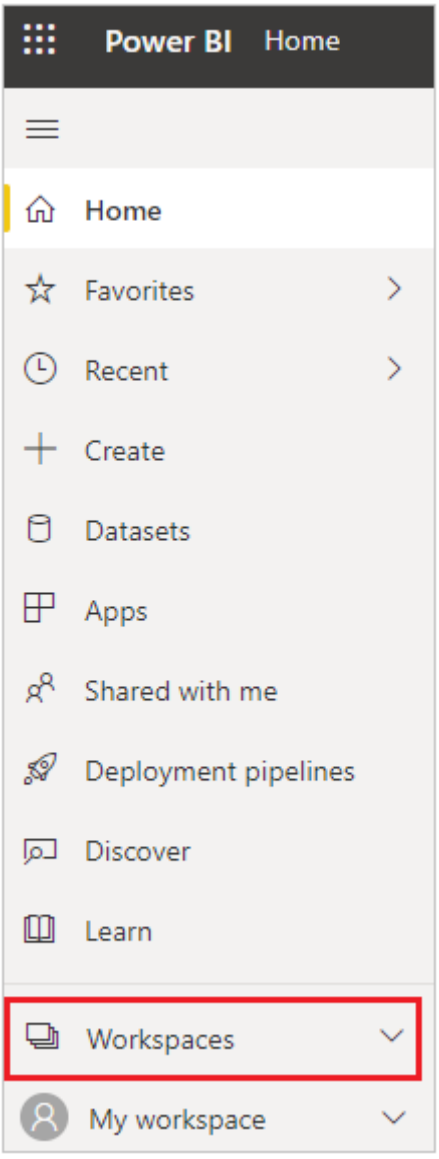
To complete this lesson, we'd need the ability to create Power BI dashboards and reports.

Sign in to Power BI

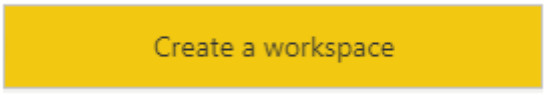
Sign in to Power BI with the same Office license as the one used for creating the Power Apps.

Create a new workspace

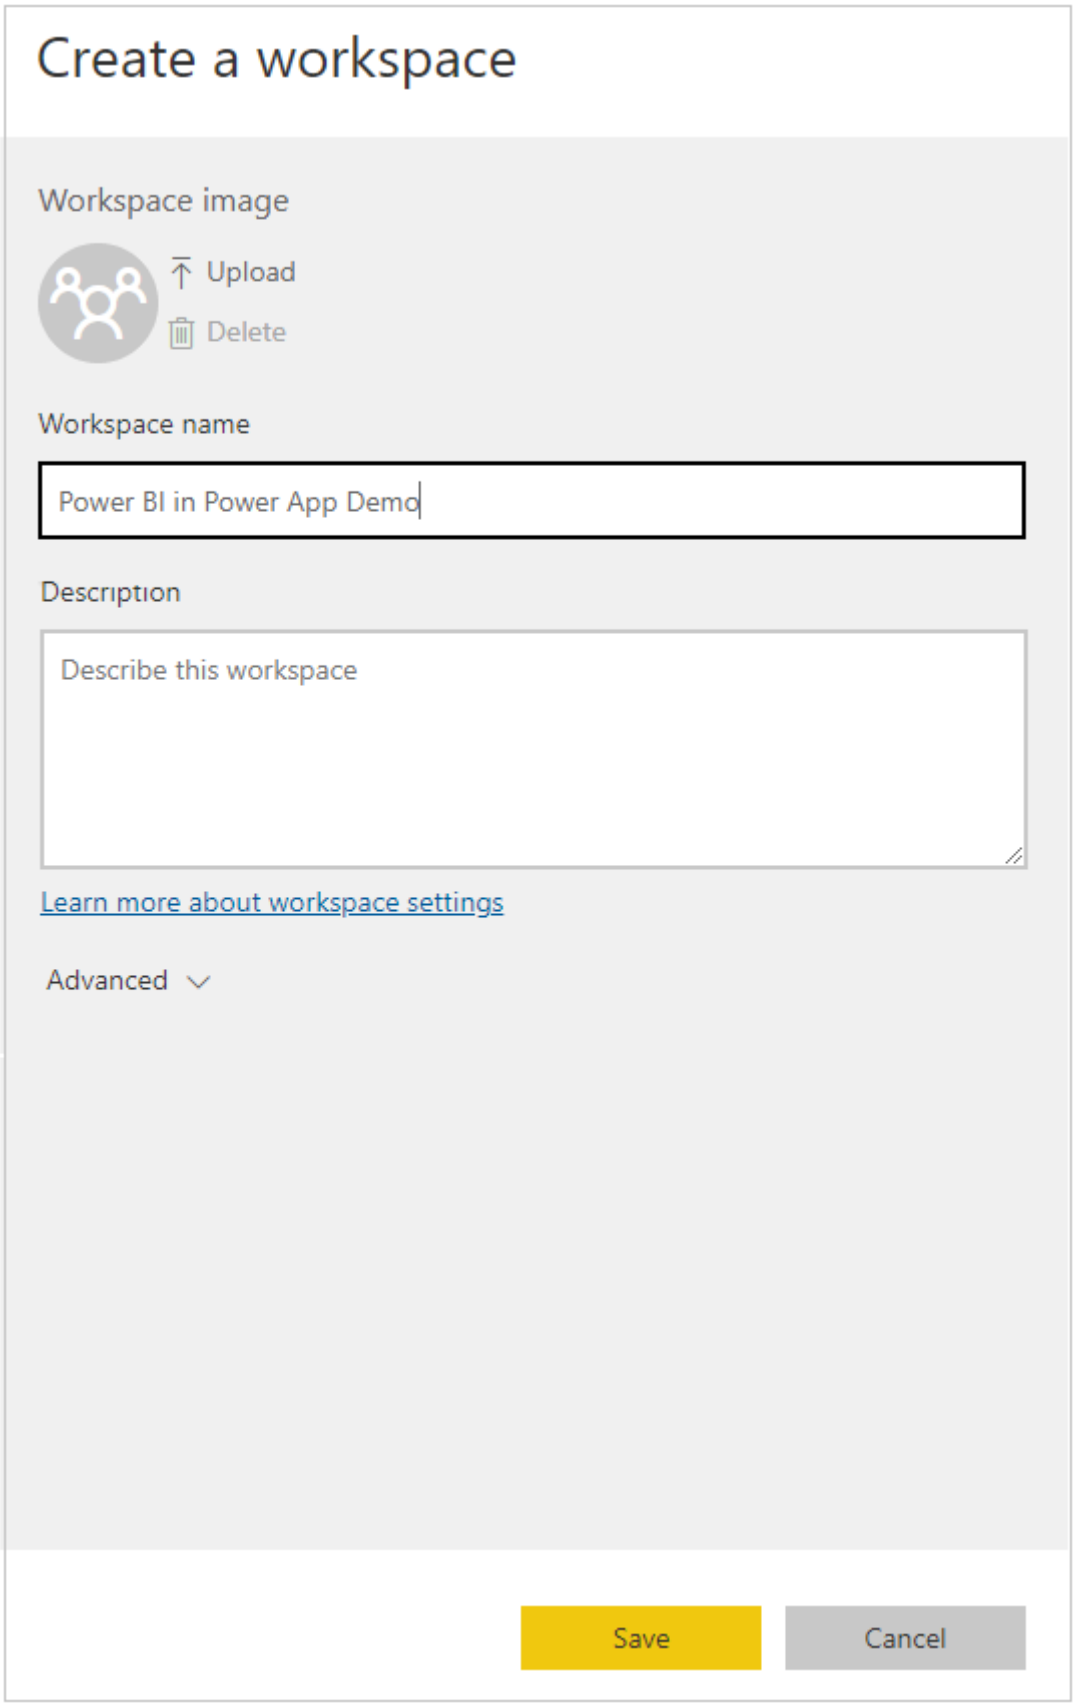
1. Select **Workspaces** from the left-pane.



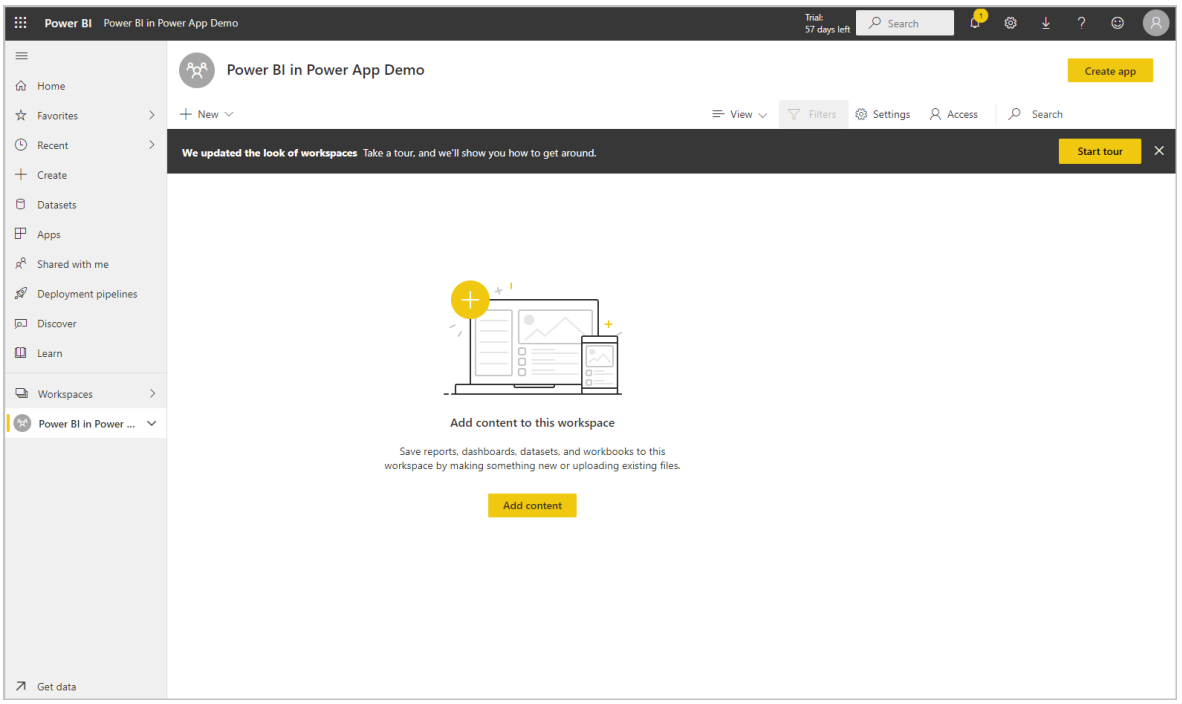
2. Select **Create a workspace**.



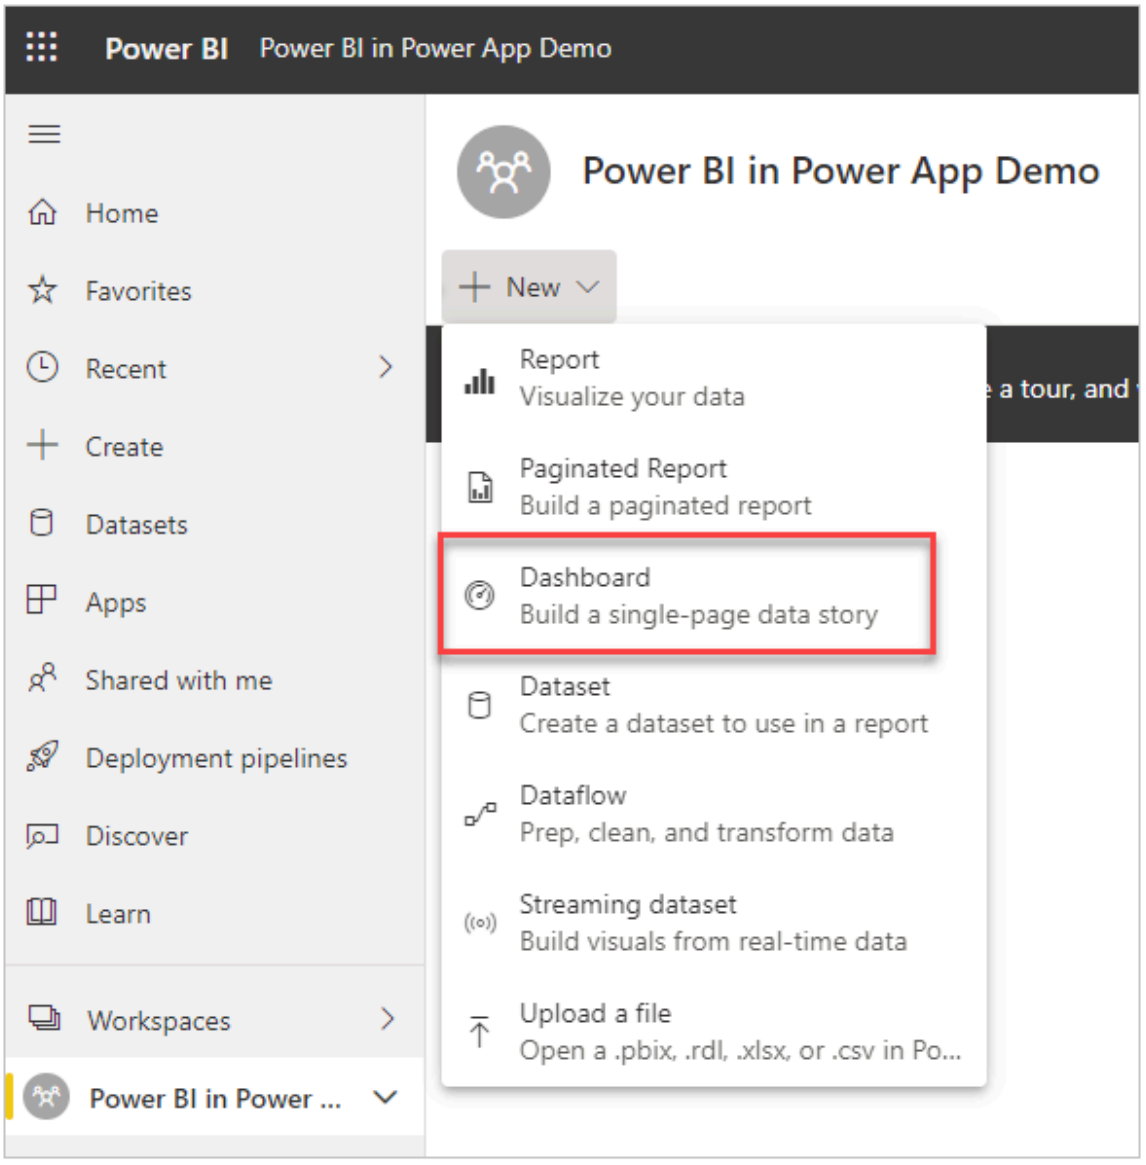
3. Enter a name for the workspace, and then select **Save**.



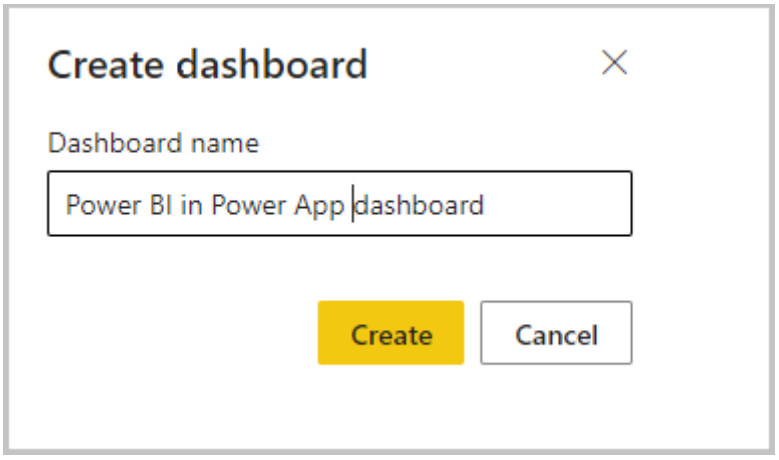
The workspace gets created



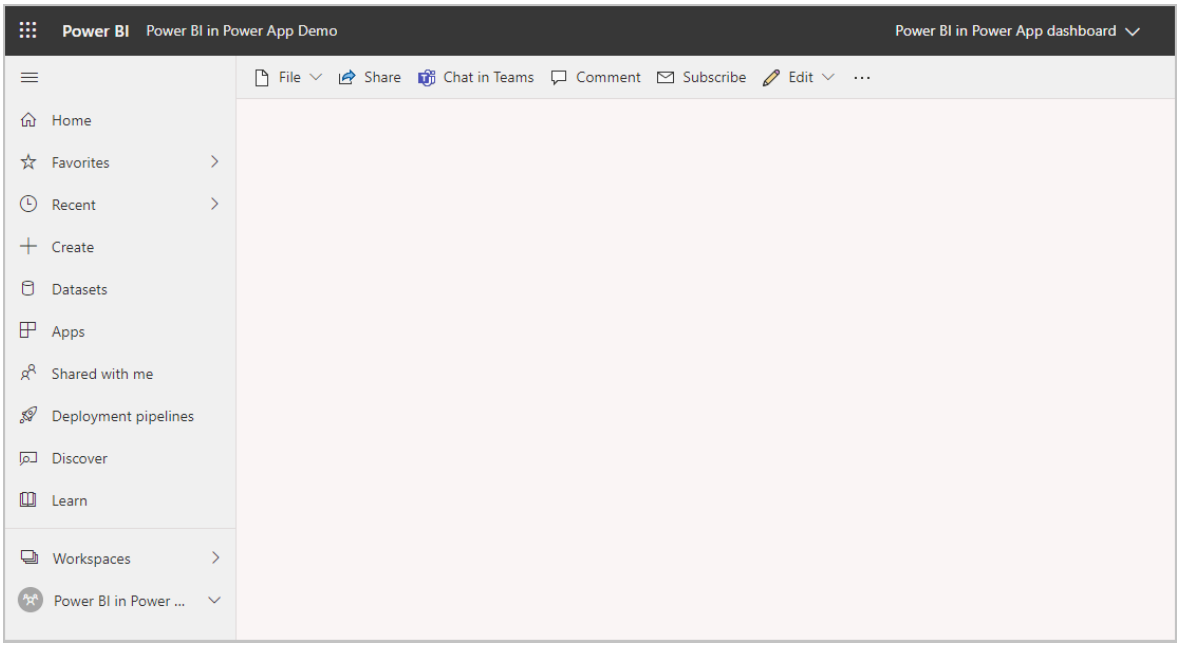
4. Select + **New**, and add a dashboard.



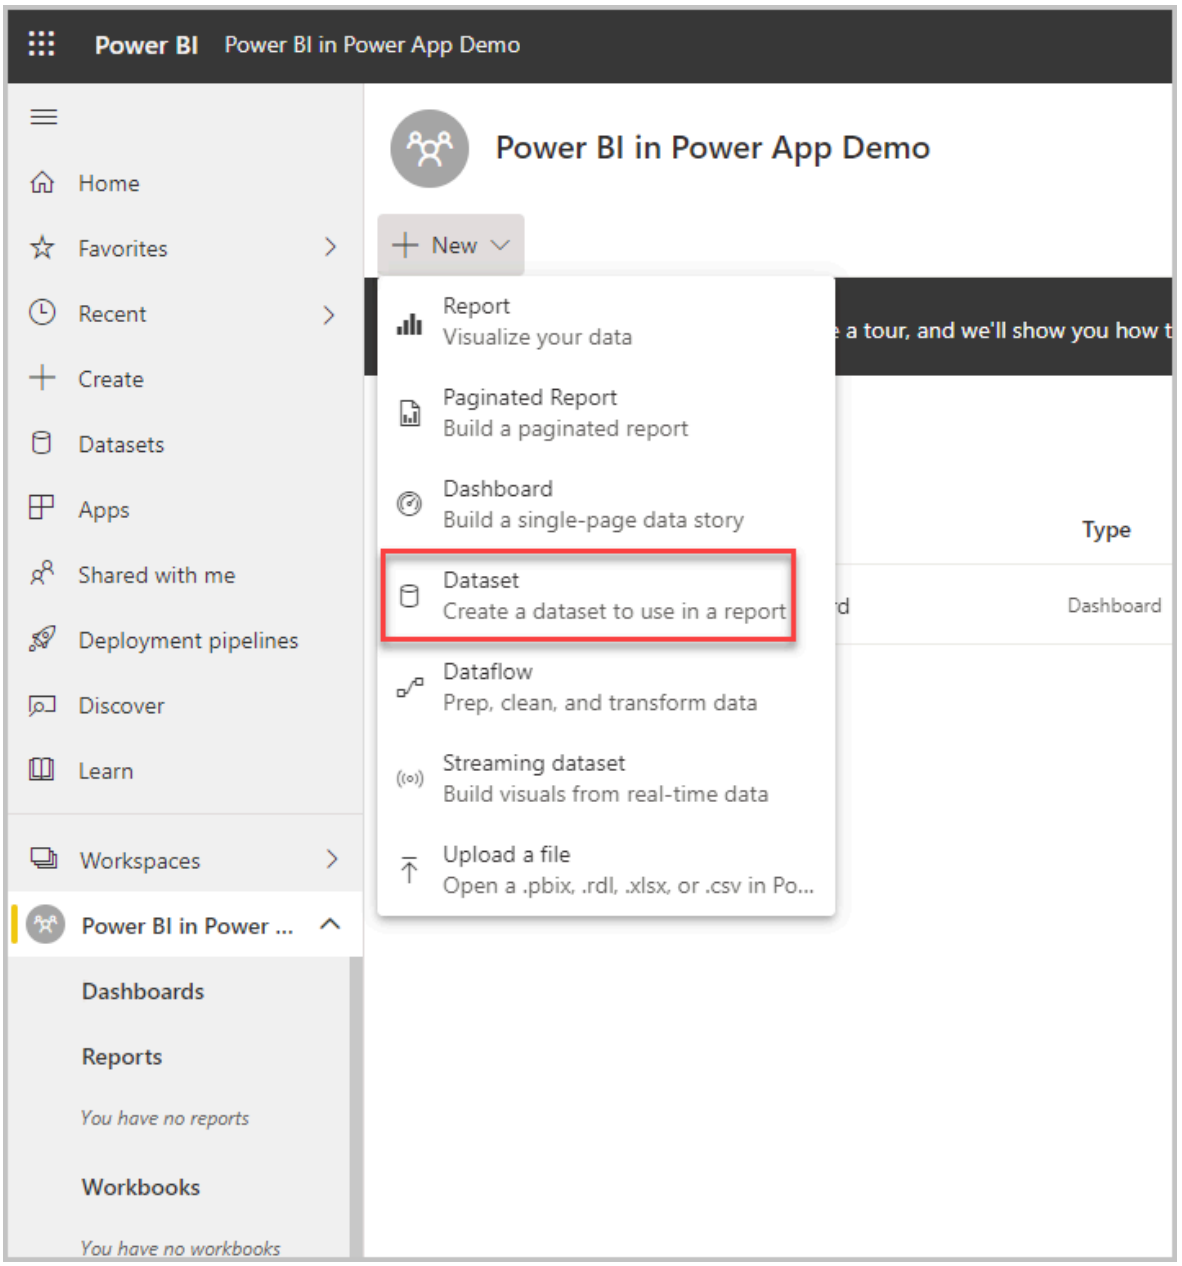
5. Add a name for the dashboard, then select **Create**.



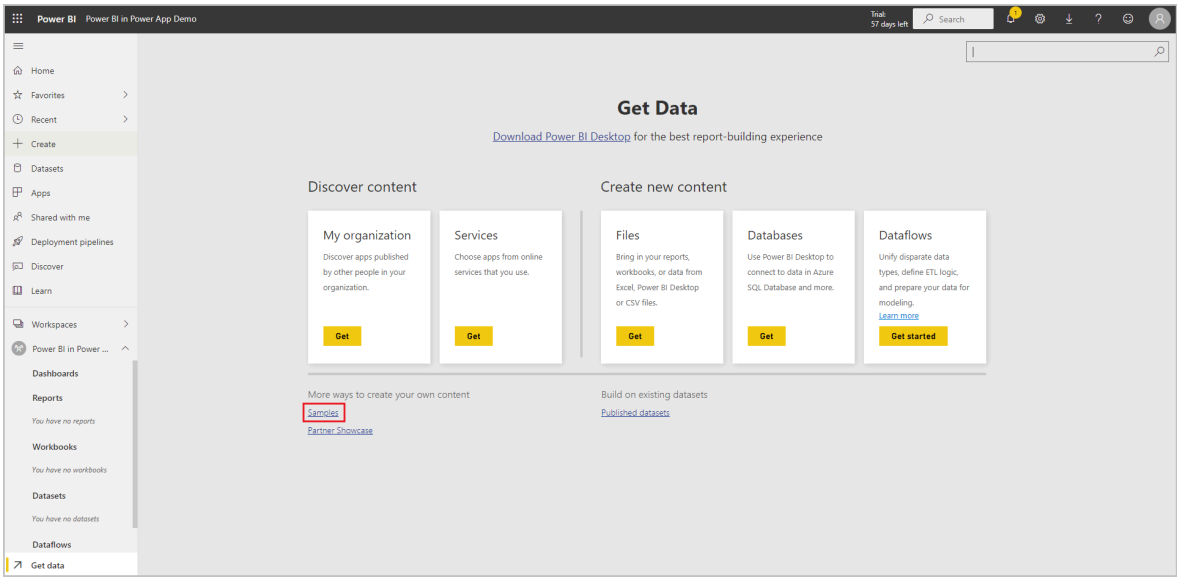
The Power BI dashboard gets created within the workspace we created



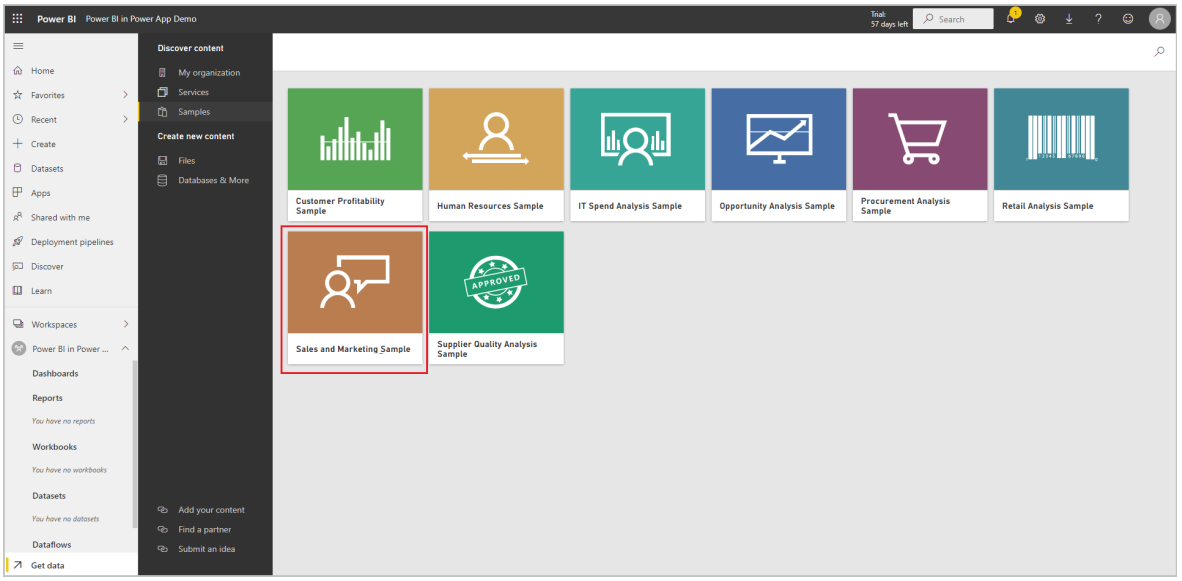
6. Open the workspace, select **+ New**, and then select **Dataset** to create a new dataset.



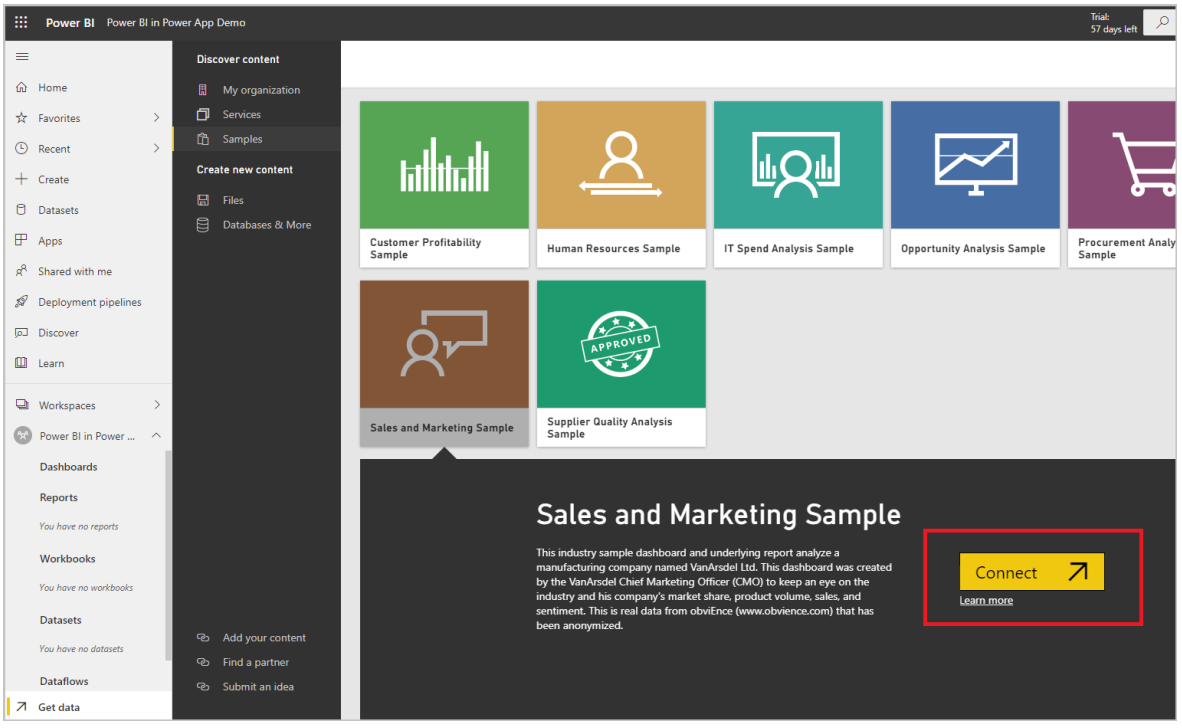
7. Select **Samples** under "More ways to create your own content" to use sample data.



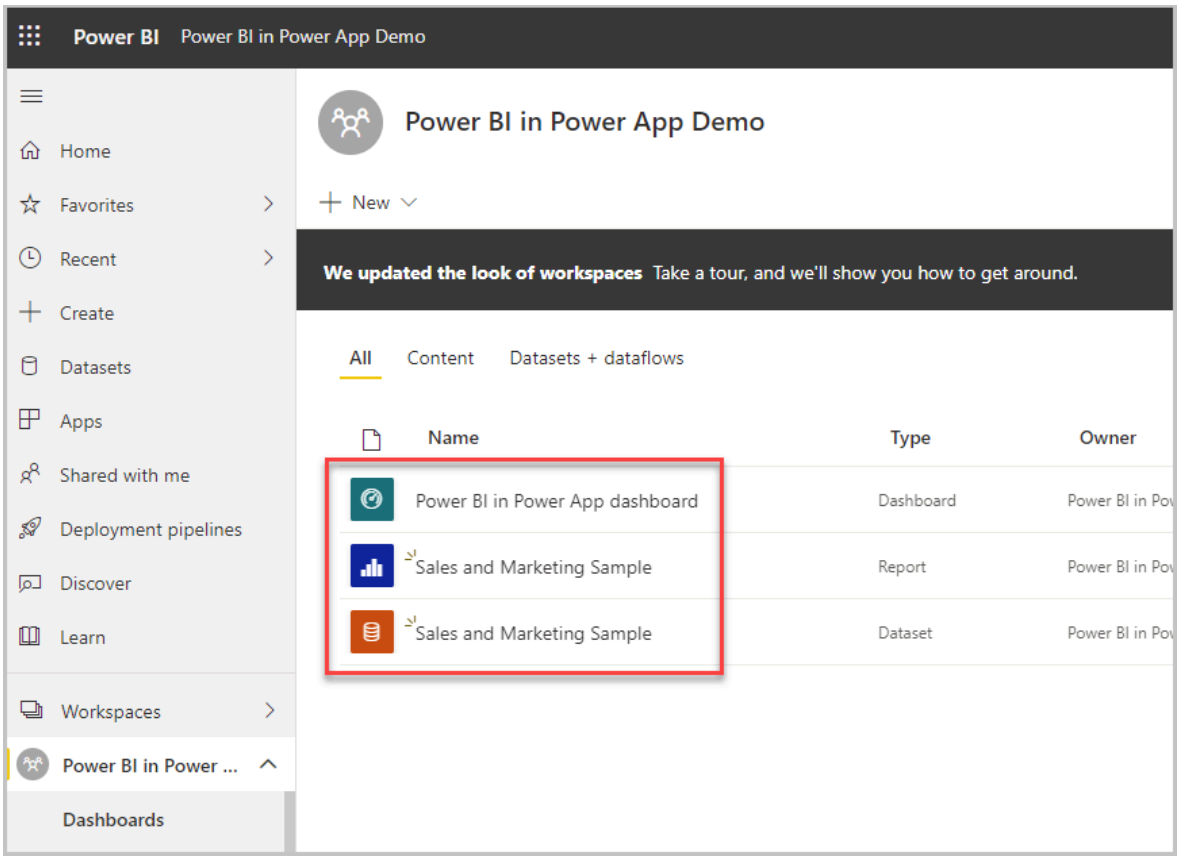
8. Select **Sales and Marketing sample**. You can also select another sample of your choice.



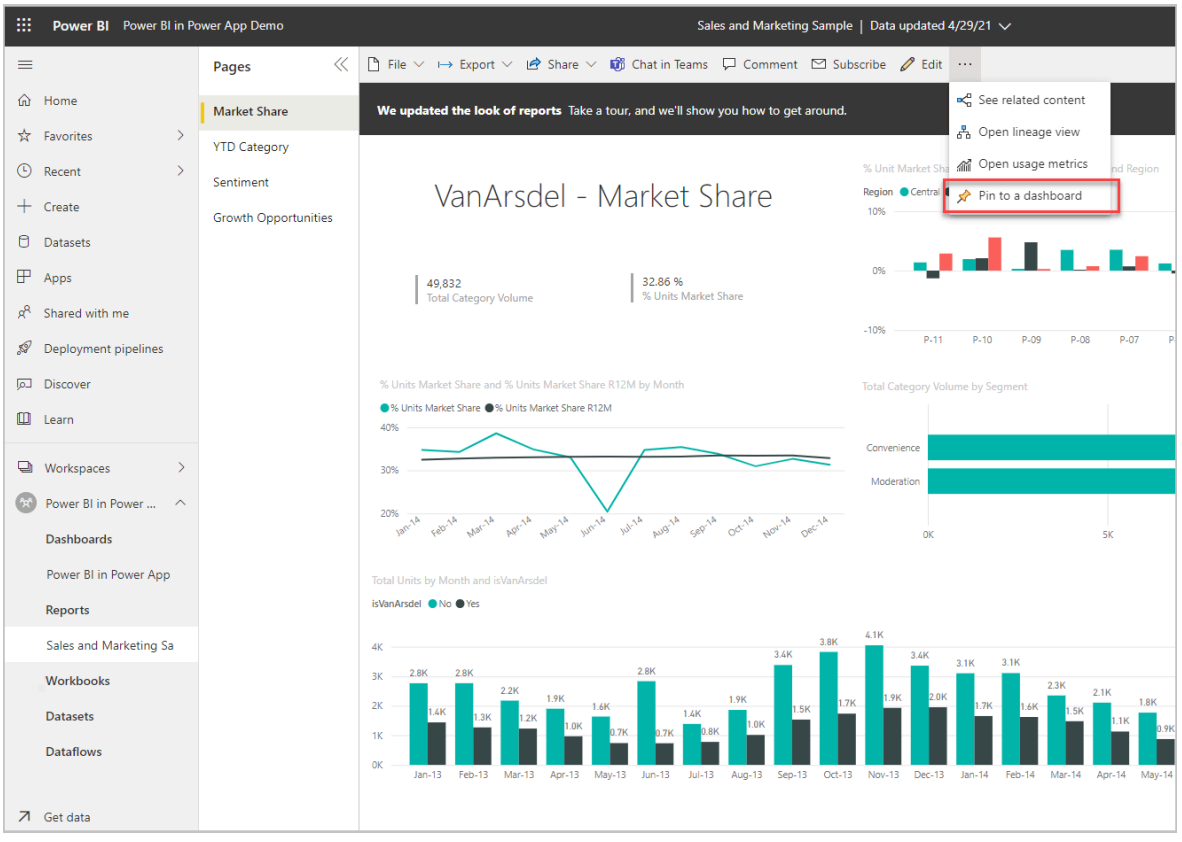
9. Select **Connect** to connect to the sample data.



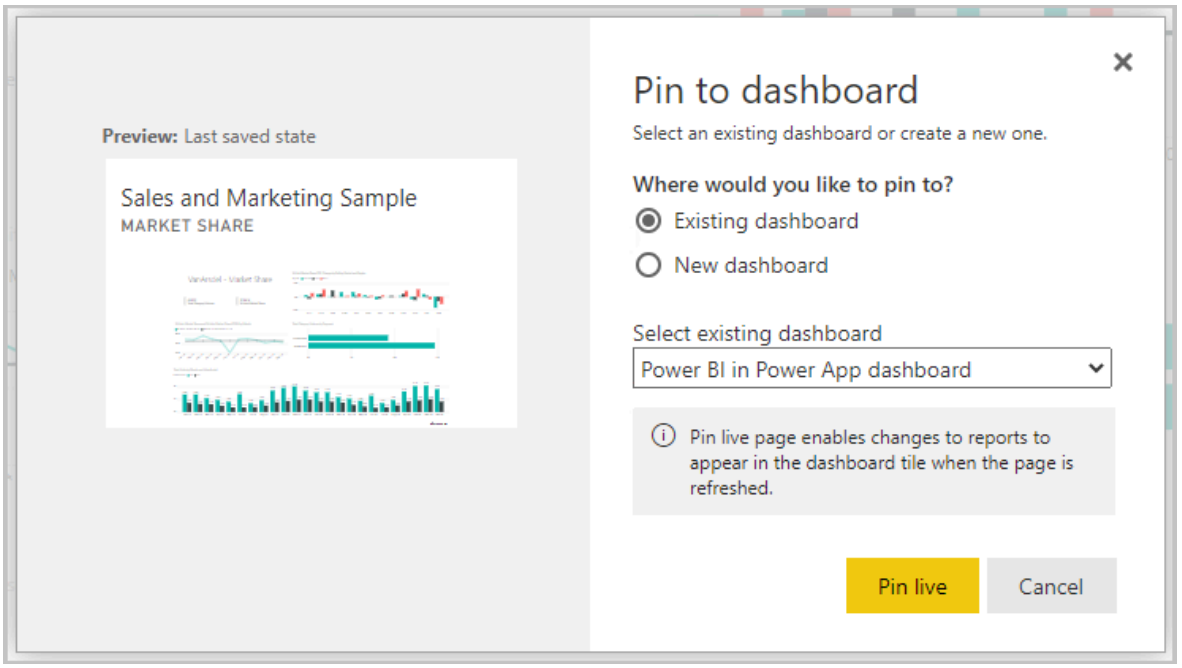
A dataset with the Sales and Marketing sample and a report gets added to the Workspace.



10. From the left-pane, select the report that was created from the dataset, select **...** (ellipsis), and select then select **Pin to a dashboard**.



11. Select **Existing dashboard**, select the dashboard, and then select **Pin live**.

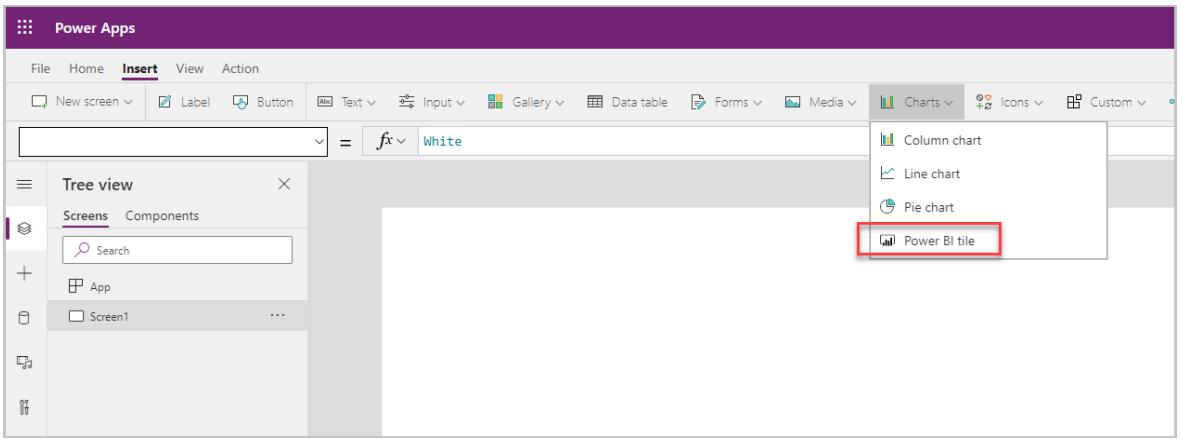


The report gets added to the dashboard, and is ready for use in Power Apps.

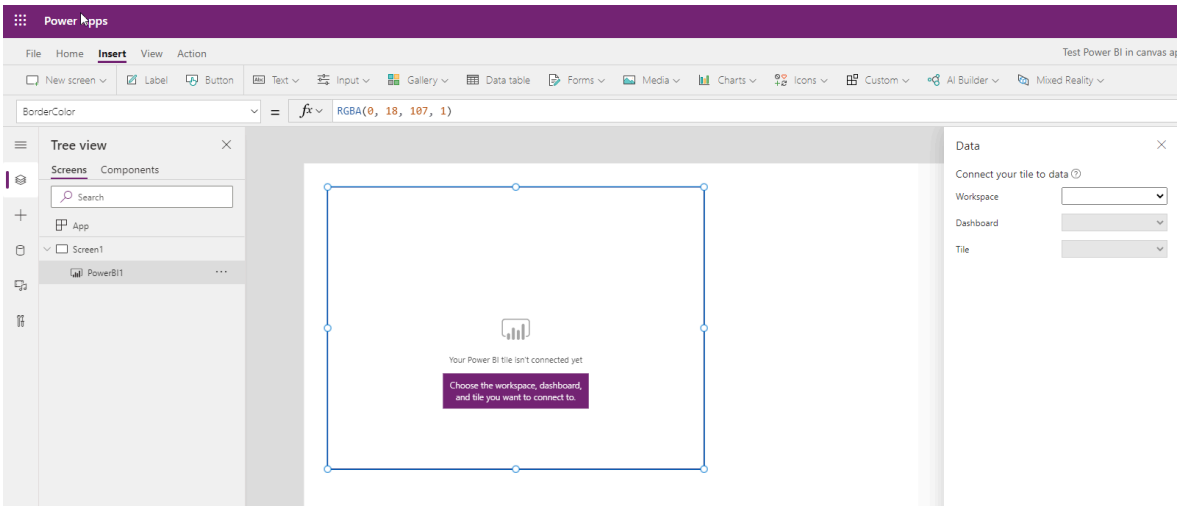
Create a new canvas app

1. Start by creating a blank canvas app.

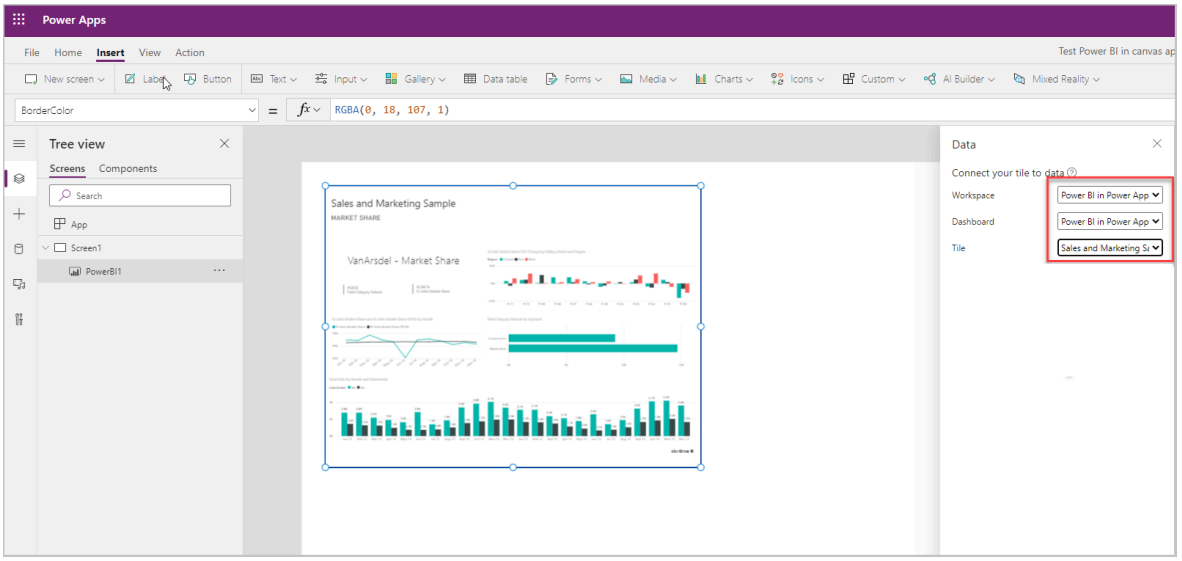
2. Select **Insert** > **Charts** > **Power BI tile**.



The Power BI Tile gets added to the screen.



3. Select the Workspace, dashboard and tile created earlier to add the Power BI tile to the canvas app.



4. Save and publish the app.

You've created a canvas app with Power BI tile.

Create a canvas app that can trigger a Power Automate flow

Article • 12/16/2022

Power Automate can be used to create logic that performs one or more tasks when an event occurs in a canvas app. For example, a button can be configured so that, when a user selects it, an item is created in a list, an email, or meeting request is sent, a file is added to the cloud, or all of these. Any control in the app can be configured to start the flow, that continues to run even if you close the app.

In this article, we'll learn how create and trigger a flow using canvas apps.

Watch this video to learn how to create a canvas app that can trigger a flow: https://learn-video.azurefd.net/vod/player?id=97f1d303-9f0d-4817-9f9d-c899d023d9b1&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Ftrigger-flow

Prerequisites

To complete this lesson, you'll need Power Automate and Power Apps environment with a Dataverse database. If you don't have a license, you can sign up for the Power Apps Developer Plan or use Power Apps trial.

Create a trial environment

An environment in Power Apps is a space to store, manage, and share your organization's business data, apps, chatbots, and flows. It also serves as a container to separate apps that might have different roles, security requirements, or target audiences. Each environment can have one Dataverse database.

To make sure that you have what you need to complete this lesson, we're going to create a new environment that includes a Dataverse database. This is a 30-day trial that will go away at the end of the 30 days, but you can upgrade it to a sandbox or production environment if you want to keep it.

We're going to create a trial environment that will include a Dataverse database, and the sample data used in this article.

1. Go to Power Platform admin center.

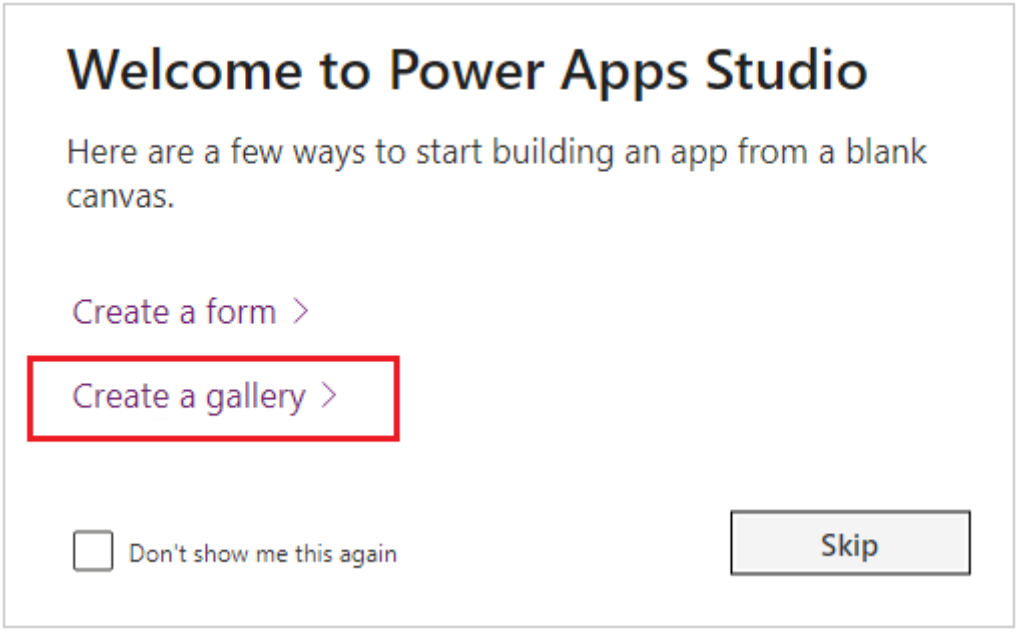
2. Select **Environments**.
3. Select **New**.
4. Name the environment **Dataverse Trial**.
5. Select **Trial** for environment type.
6. Toggle **Create Database** to **Yes**.
7. Select **Next**.
8. Toggle **Deploy Sample Apps and Data** to **Yes**.
9. Select **Save**.

Your trial environment will now be created, including a Dataverse database and sample data.

Create a canvas app

In this lesson, we'll create an app to search, view, and create customer accounts using the **Accounts** table in Dataverse.

1. Start by creating a blank canvas app.
2. Select **Create a gallery**.

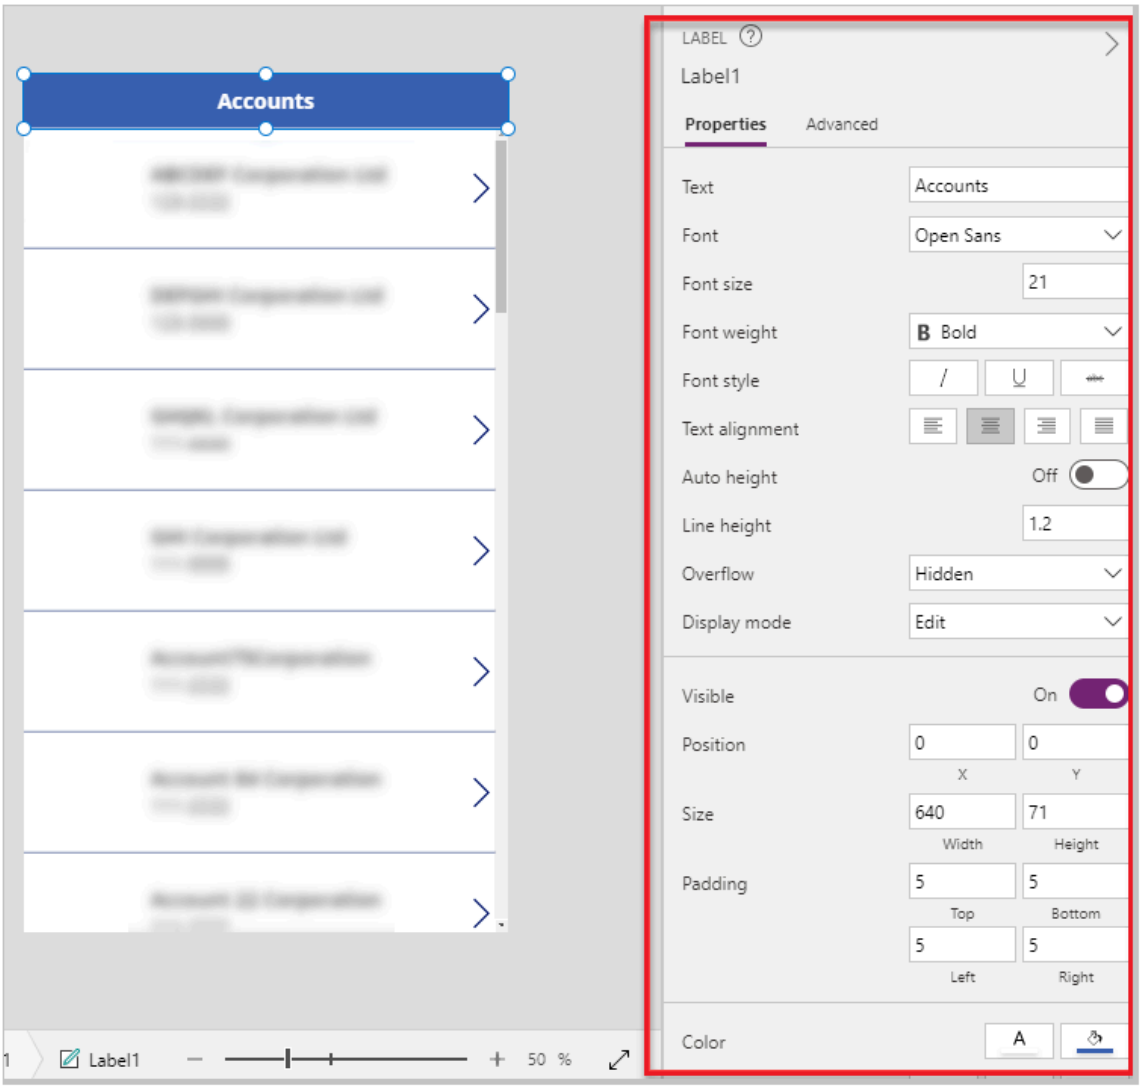


3. Select **Accounts** table.

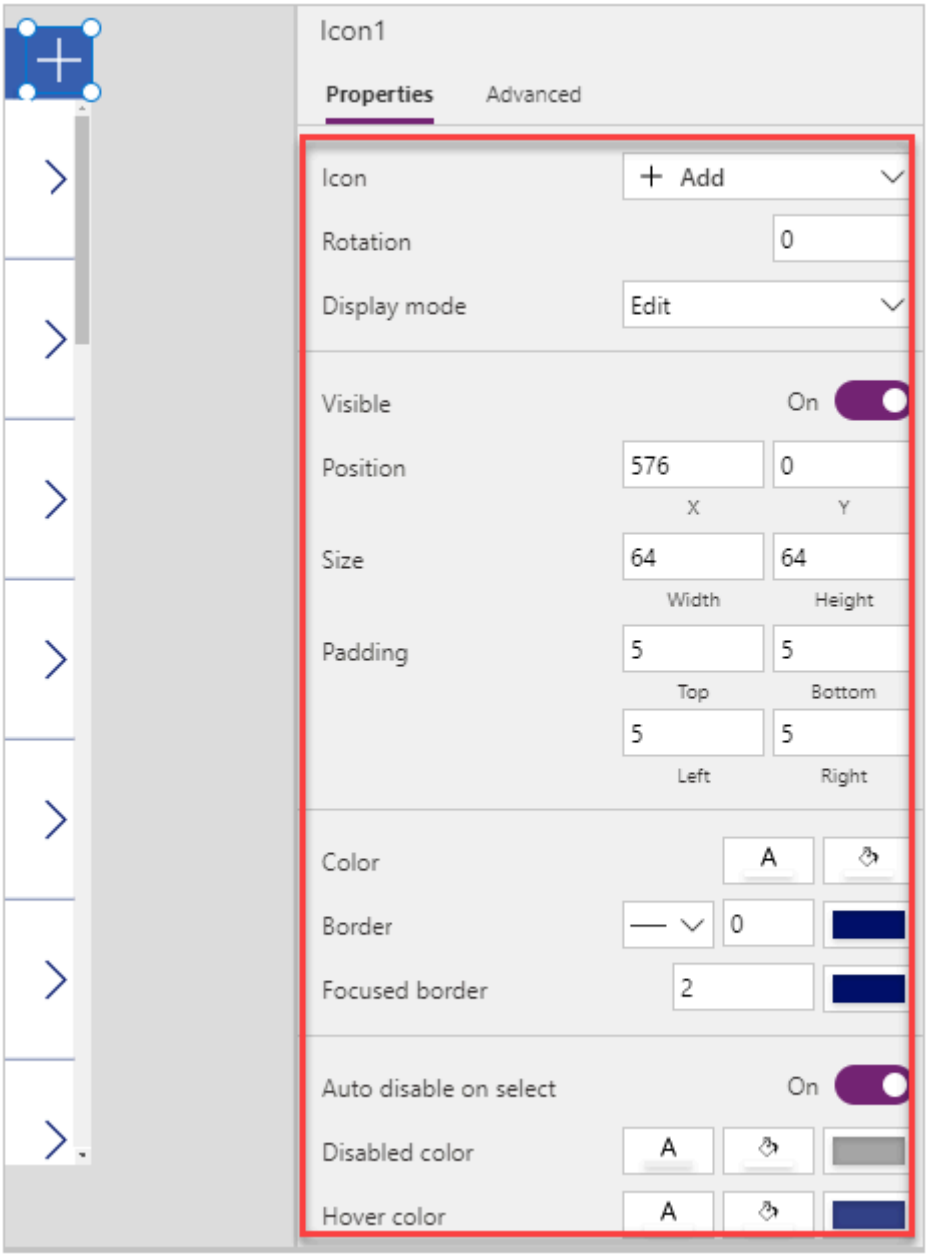
4. Stretch the gallery to the bottom of the screen, and add a label to the top with the text **Accounts**. And then, update the other properties as listed below.

Expand table

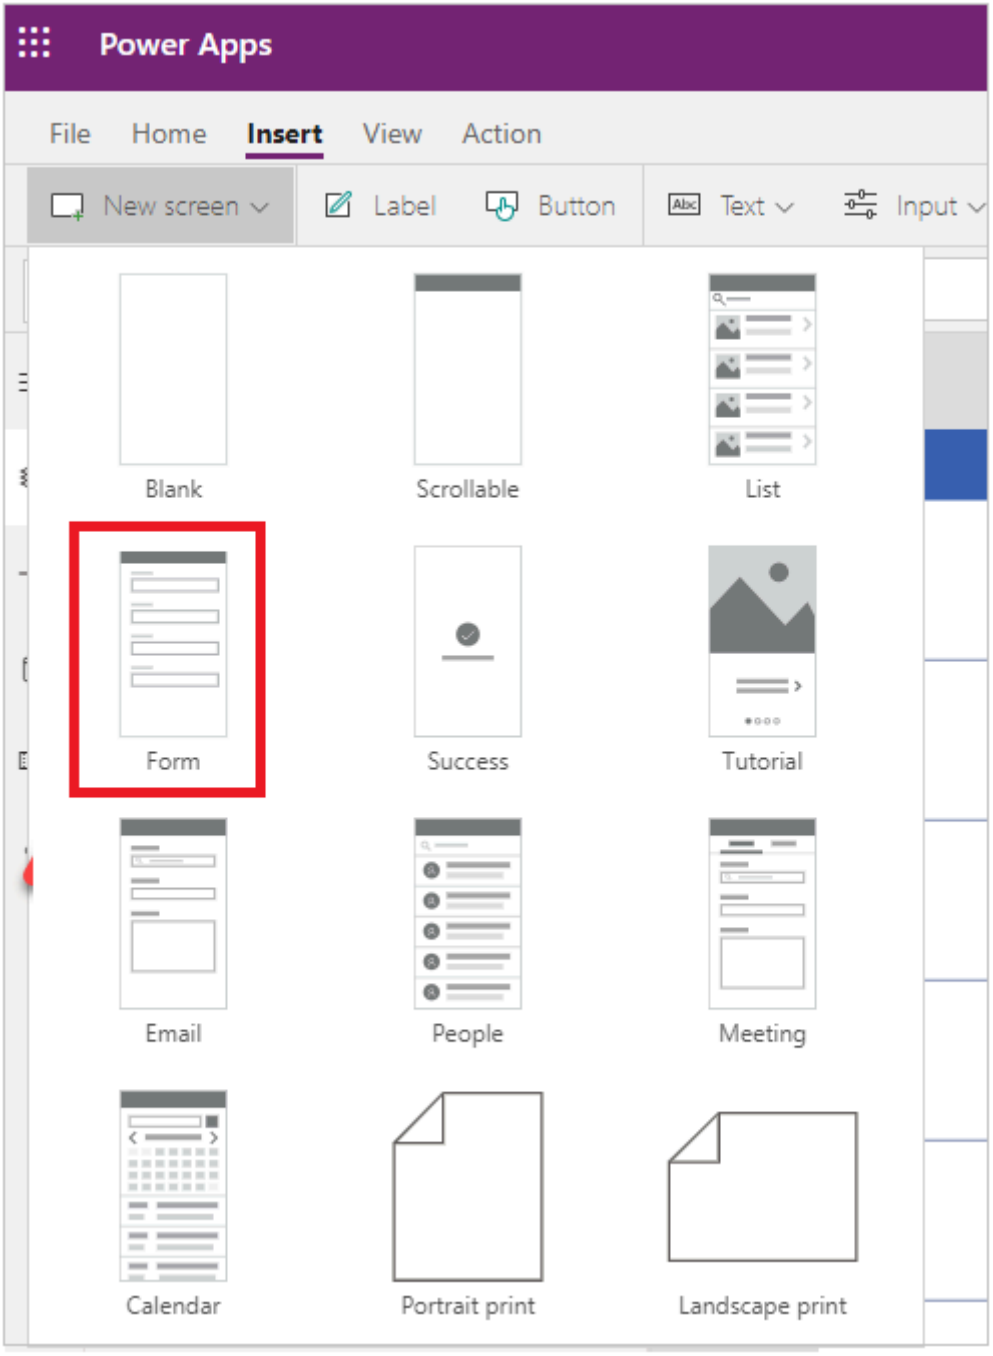
Property	Value
Font	Open Sans
Font size	21
Font weight	Bold
Text alignment	Center
Auto height	Off
Line height	1.2
Overflow	Hidden
Display mode	Edit
Visible	On
Position (X, Y)	0, 0
Size (Width, Height)	640, 71
Padding	5 Top, 5 Bottom, 5 Left, 5 Right



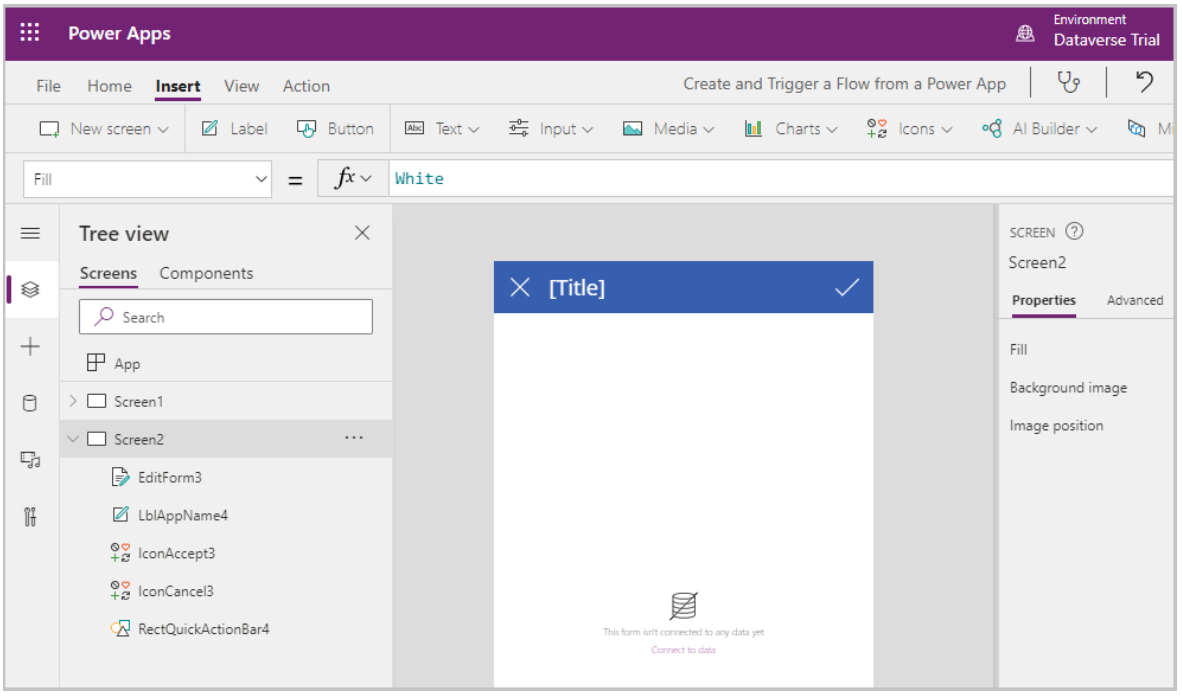
5. Add an **Add** icon to the top-right of the screen by selecting **Insert** > **Icon** > **Add**. And then, update the properties of the icon to color white and padding of 5 from all sides.



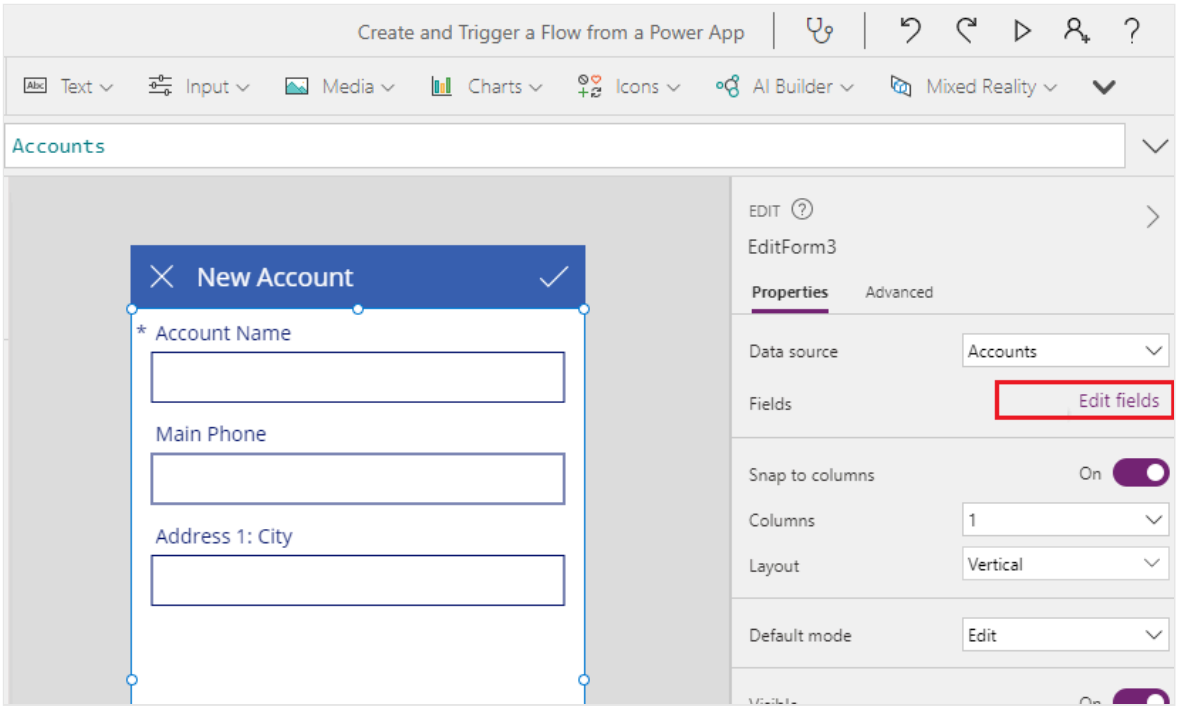
6. From the top-left side of the screen, select **New screen** > **Form**.



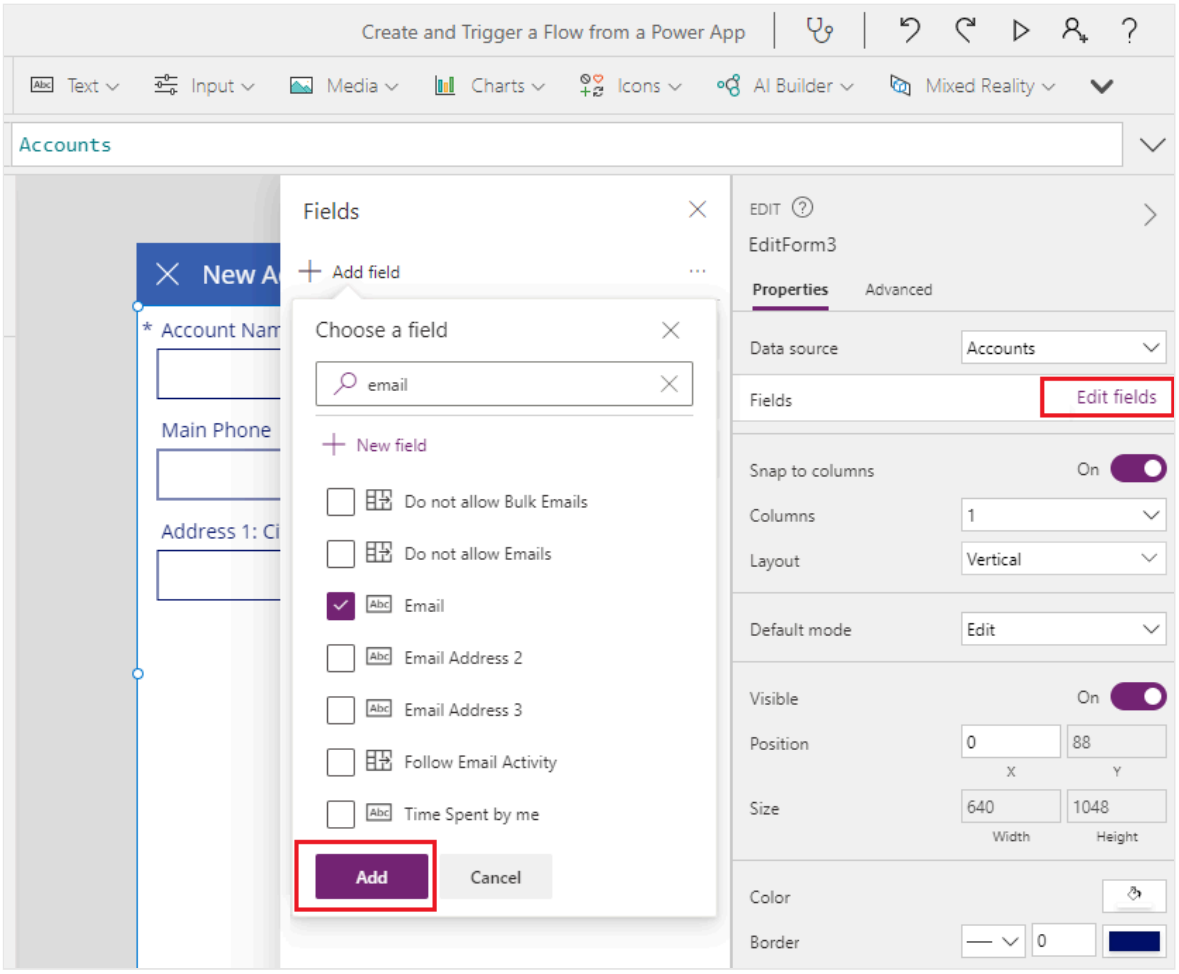
7. Update the title of the form to **New Account**, and select the data source as **Accounts** from the pane on the right-side of the screen.



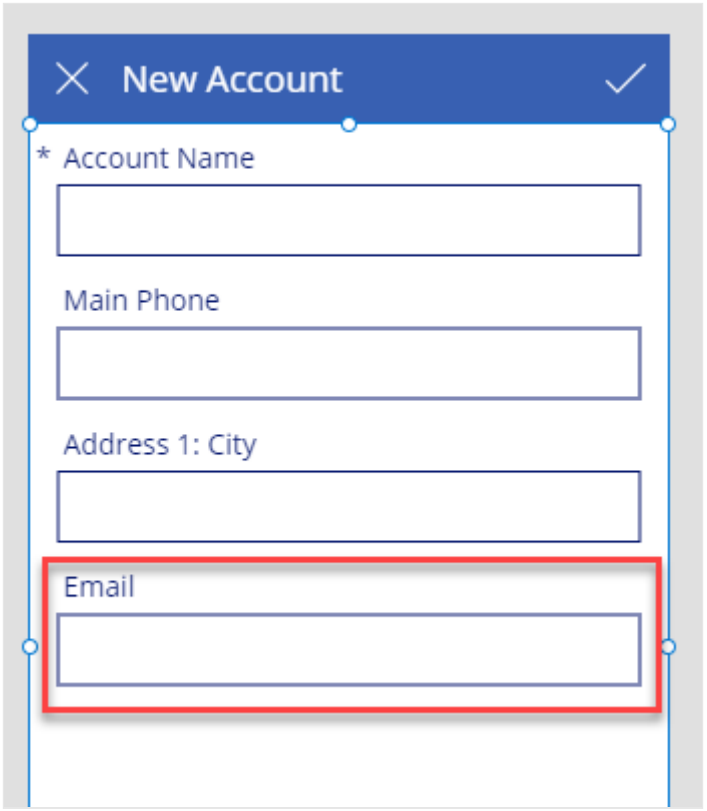
8. Select **Edit fields** on the right-pane.



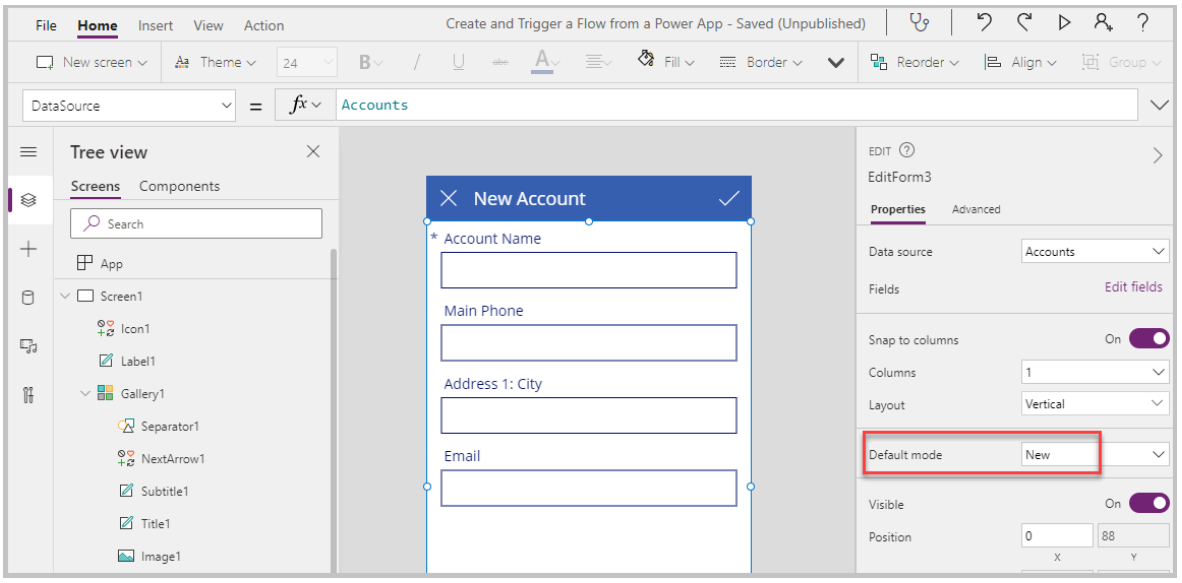
9. Select **Add field** and add **Email** to the form.



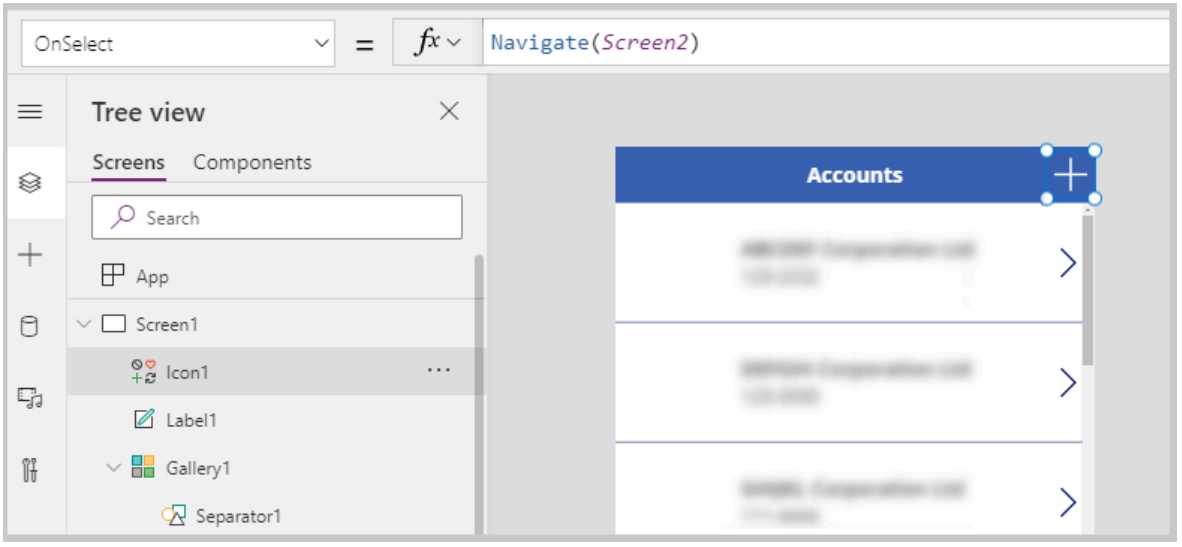
The email field gets added to the form.



10. Set the default mode of the form to **New**.

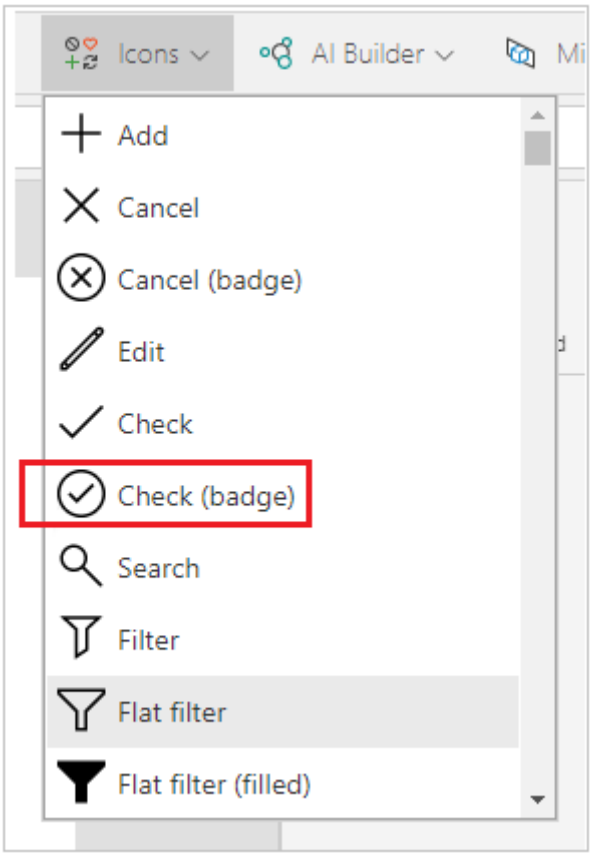


11. Select Screen1 that has the accounts gallery, and set the **OnSelect** property of the + icon to `Navigate(Screen2)`.

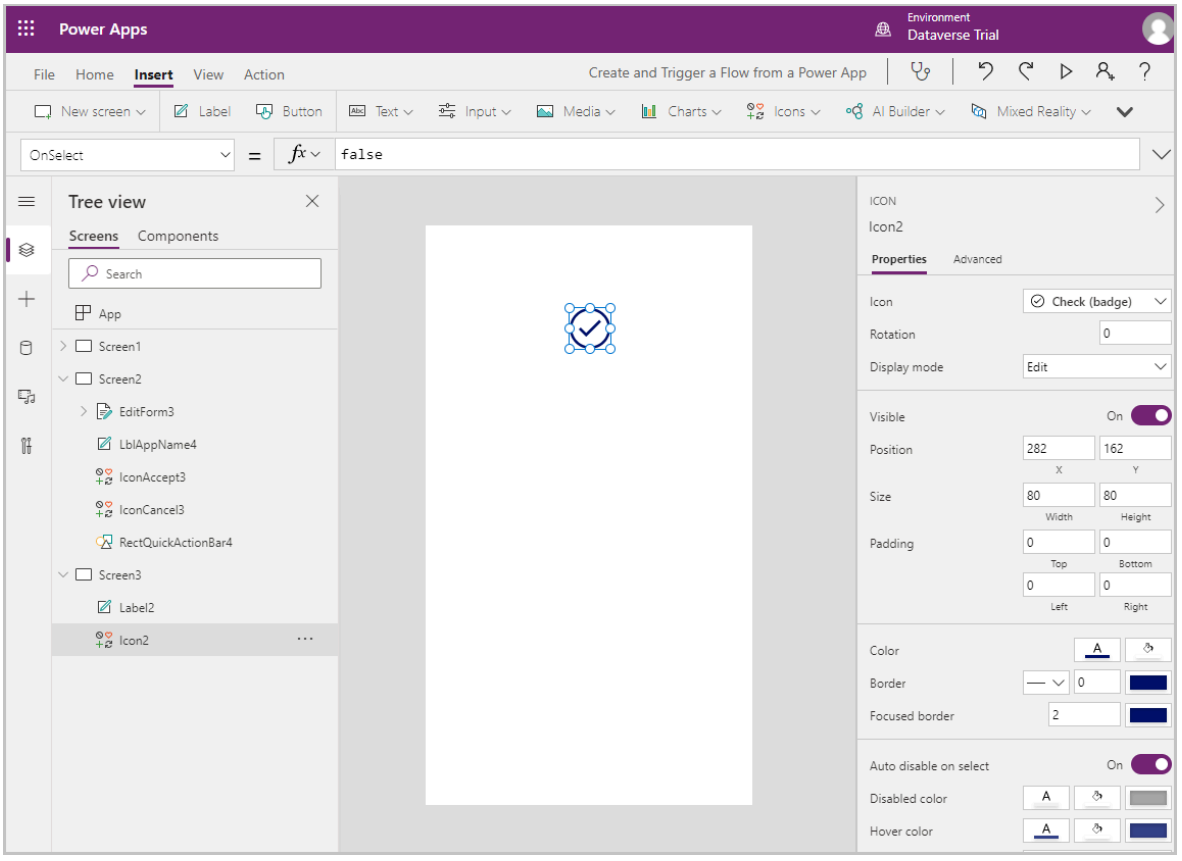


12. Select **Insert** > **New screen** > **Blank screen** to add a new screen to the app.

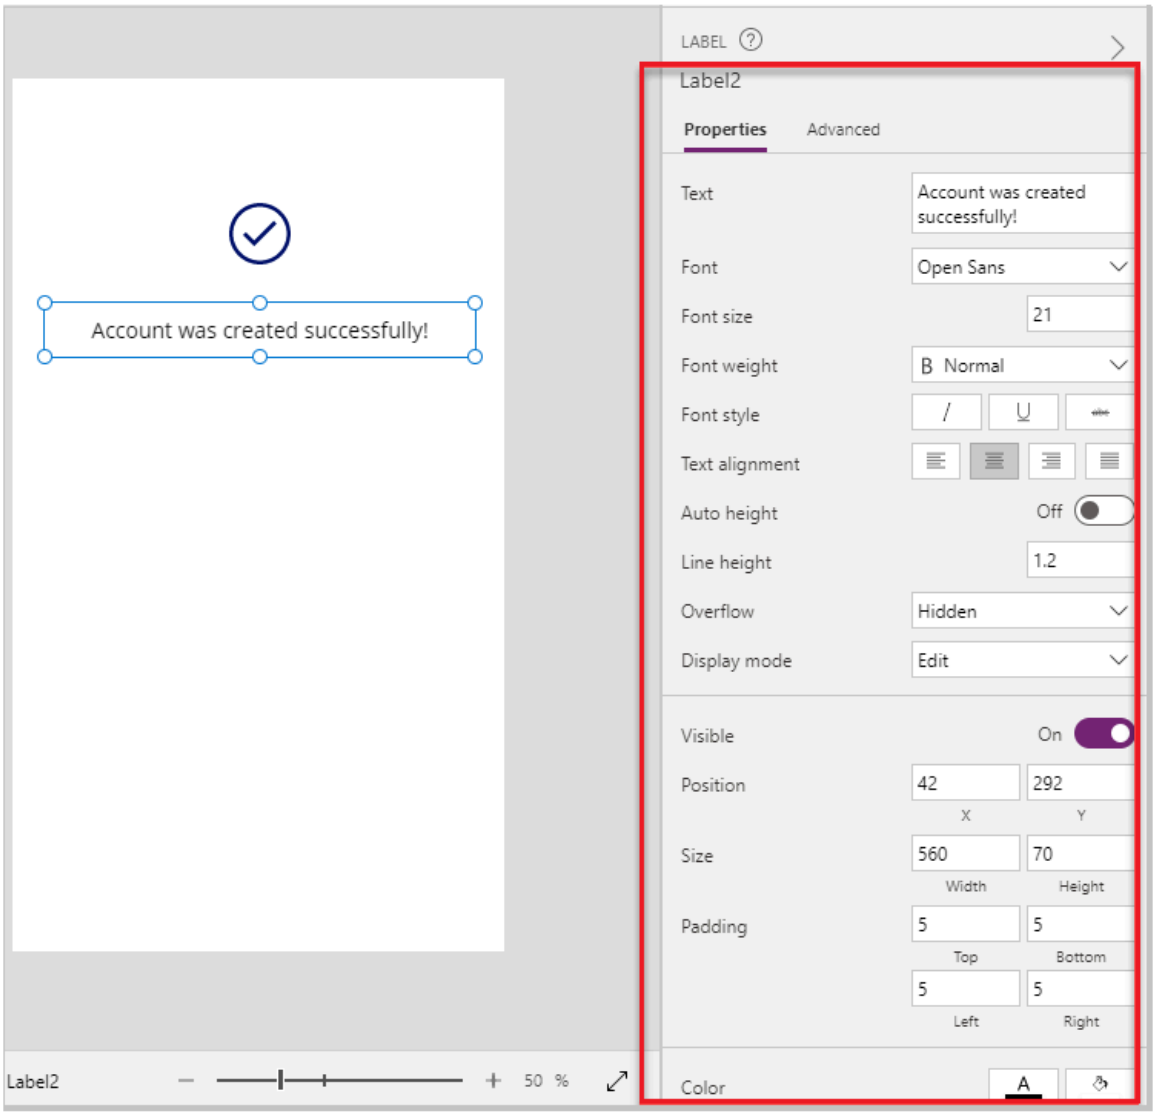
13. Select **Insert** > **Icon**, and then select the Check (badge) icon to add it to the screen.



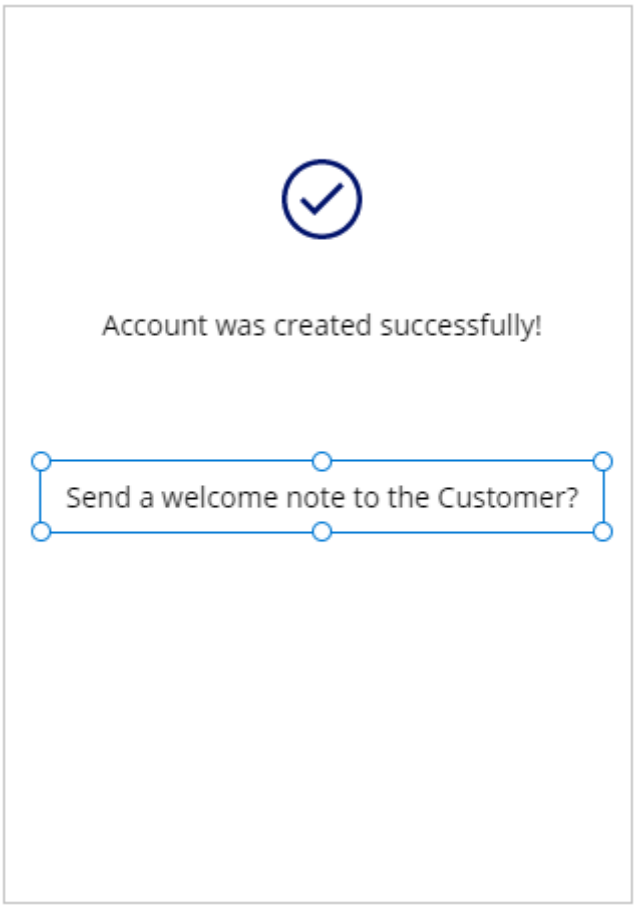
14. Move the icon to the top center of the canvas.



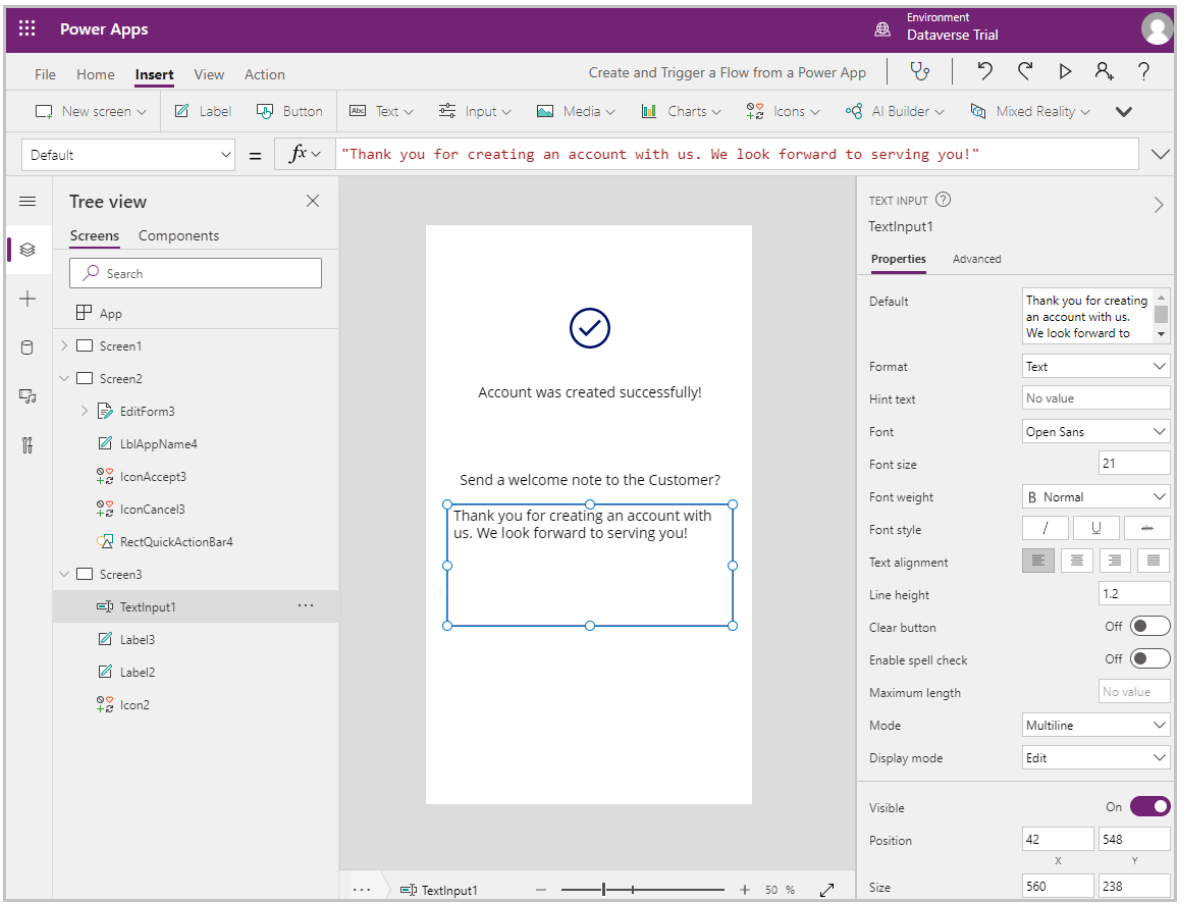
15. Add a label with text **Account was created successfully!**, and move it under the icon added in the earlier step.



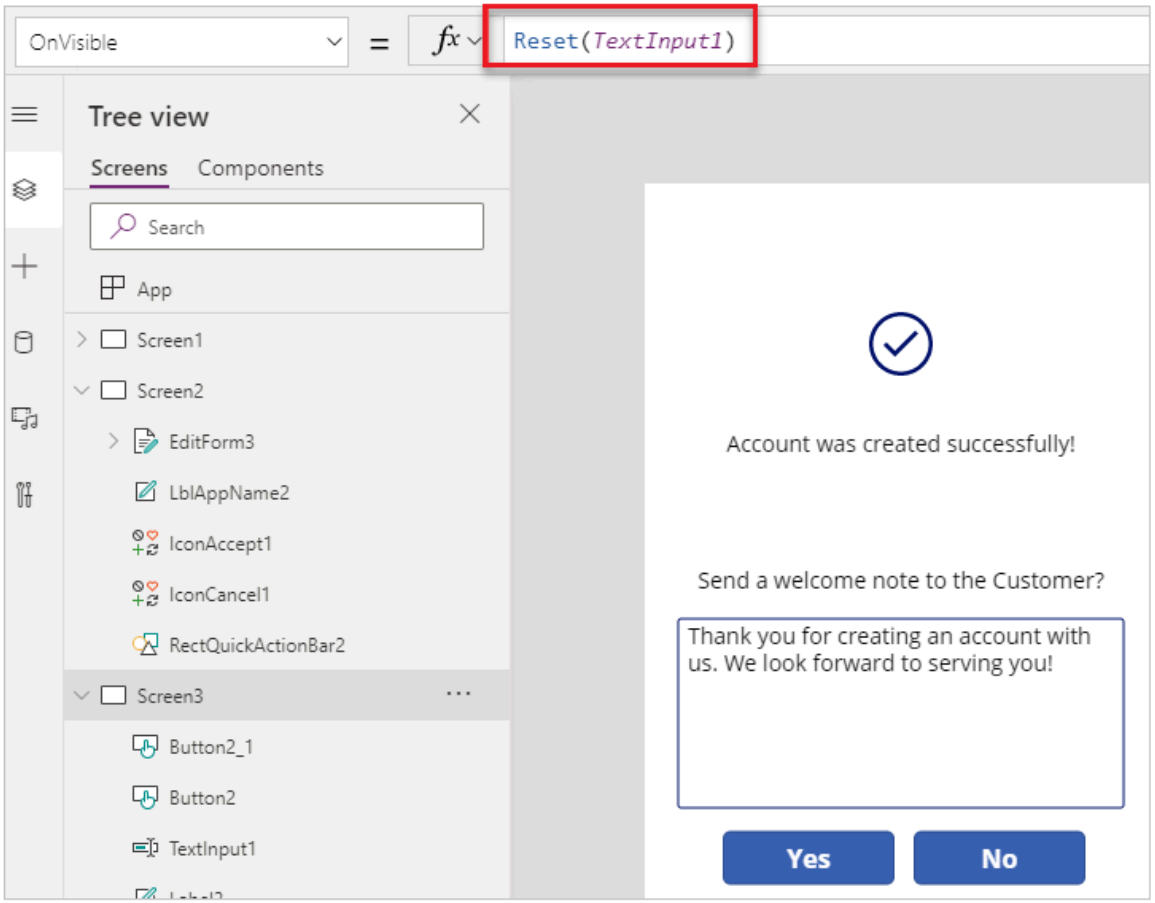
16. Add an additional label below the label added in the previous step with text **Send a welcome note to the Customer?**.



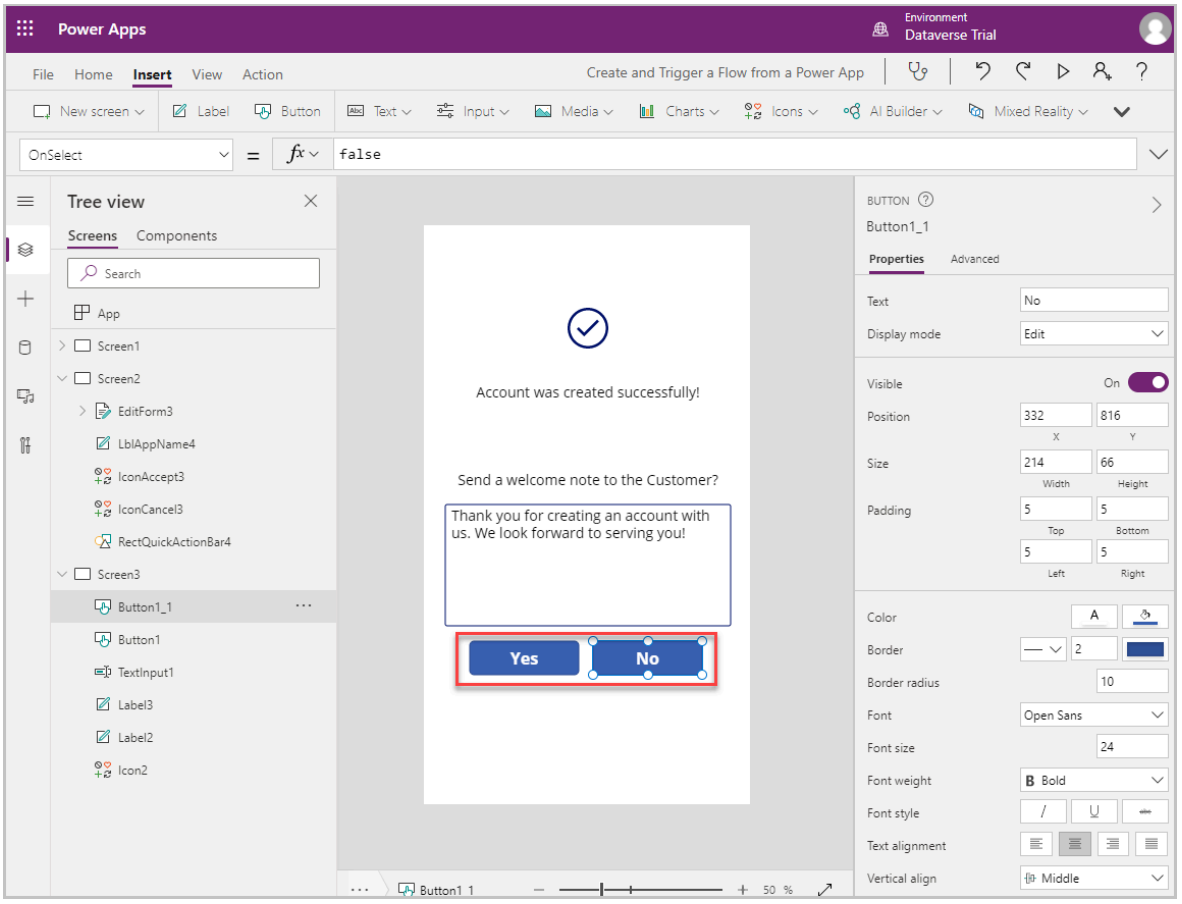
17. Add a **Text Input** box by selecting **Insert** > **Input** > **Text Input**. Set the **Mode** of the control to **Multiline**, and default text to **Thank you for creating an account with us. We look forward to serving you!**. And move the control below the label added in the previous step.



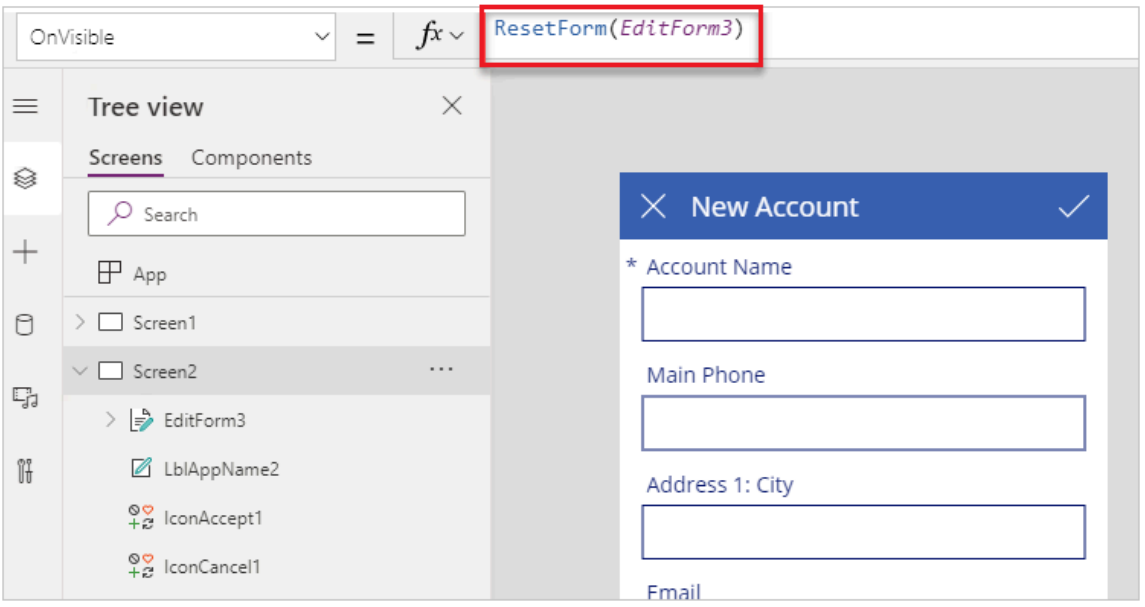
18. Set the **OnVisible** property of **Screen3** to `Reset(TextInput1)`.



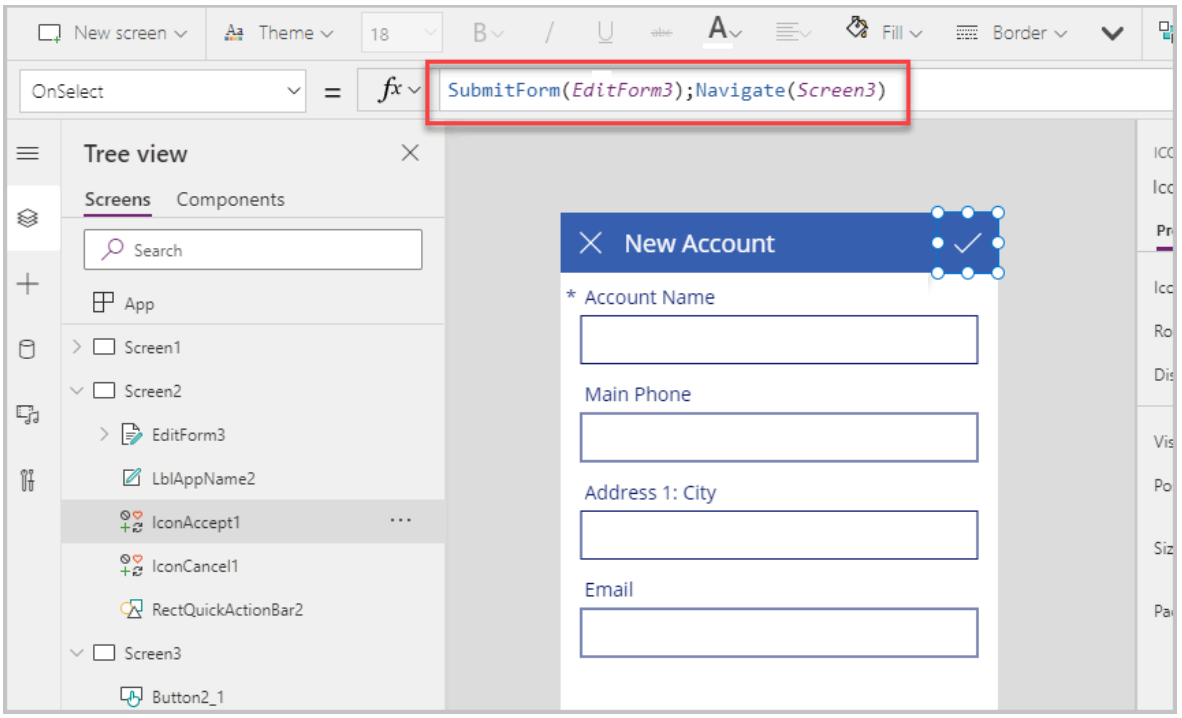
19. Add two buttons to the screen with text **Yes** and **No**, and place them below the input text box added in the previous step.



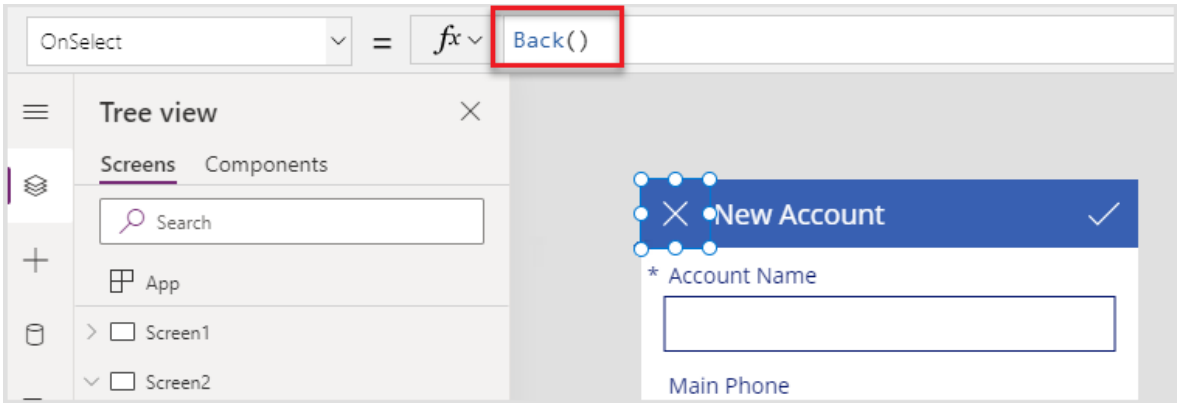
20. Go to the **New Account** form screen, and set the **OnVisible** property of the screen to `ResetForm(EditForm3)`.



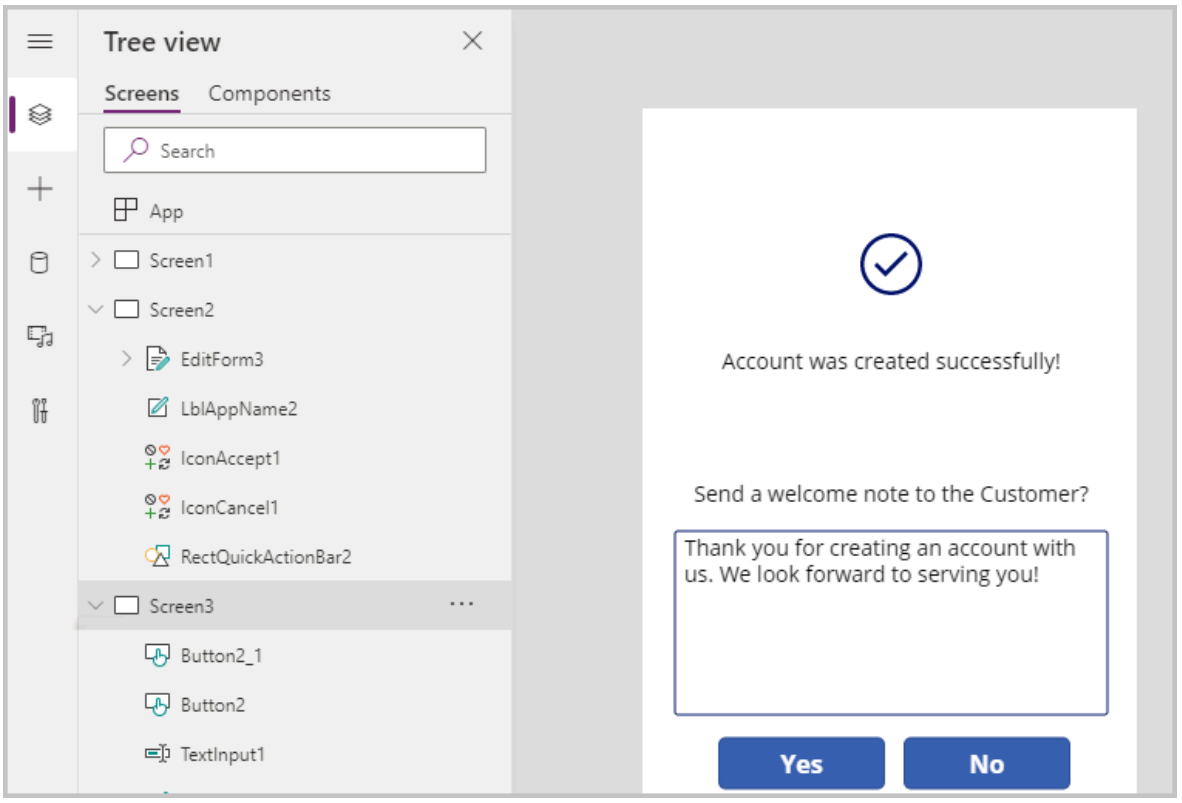
21. Select the check icon on the top-right, and set the **OnSelect** property to `SubmitForm(EditForm3);Navigate(Screen3)`.



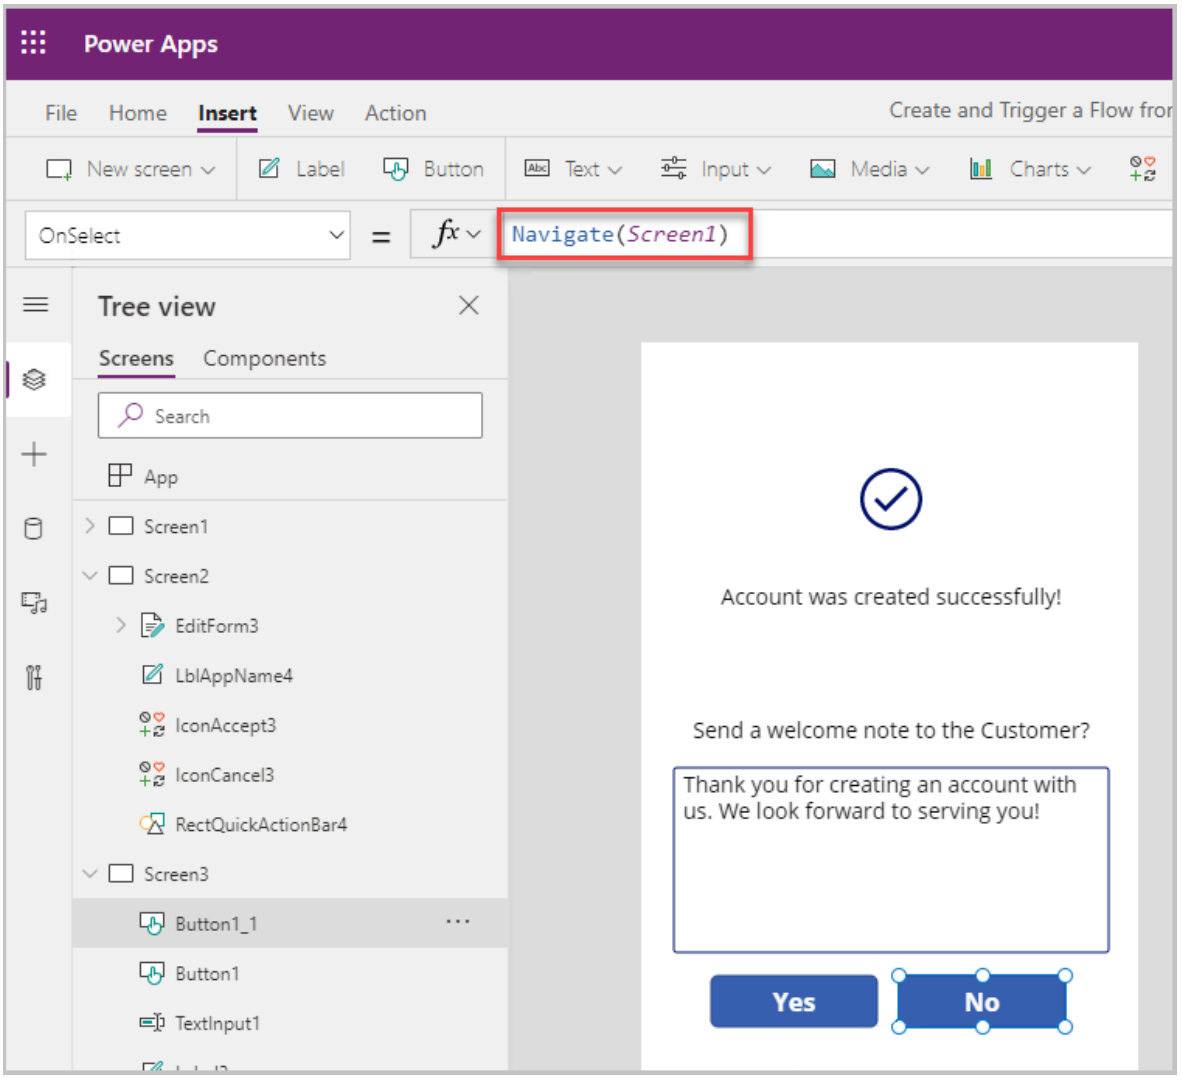
22. Select the X button on the top-right, and set the **OnSelect** property to `Back()`.



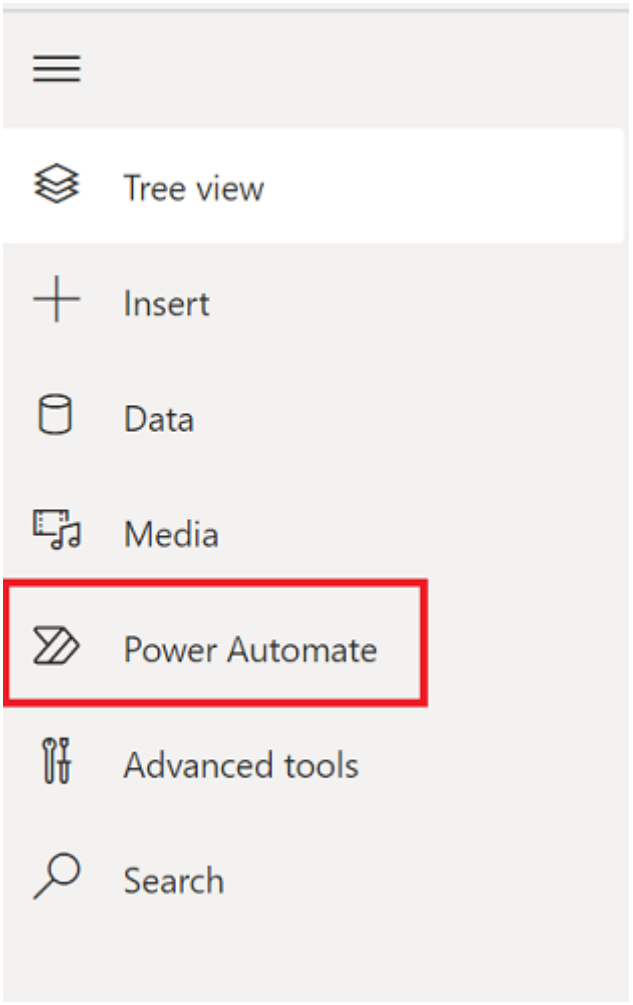
23. Go back to **Screen3** by selecting **Screen3** in the tree view.



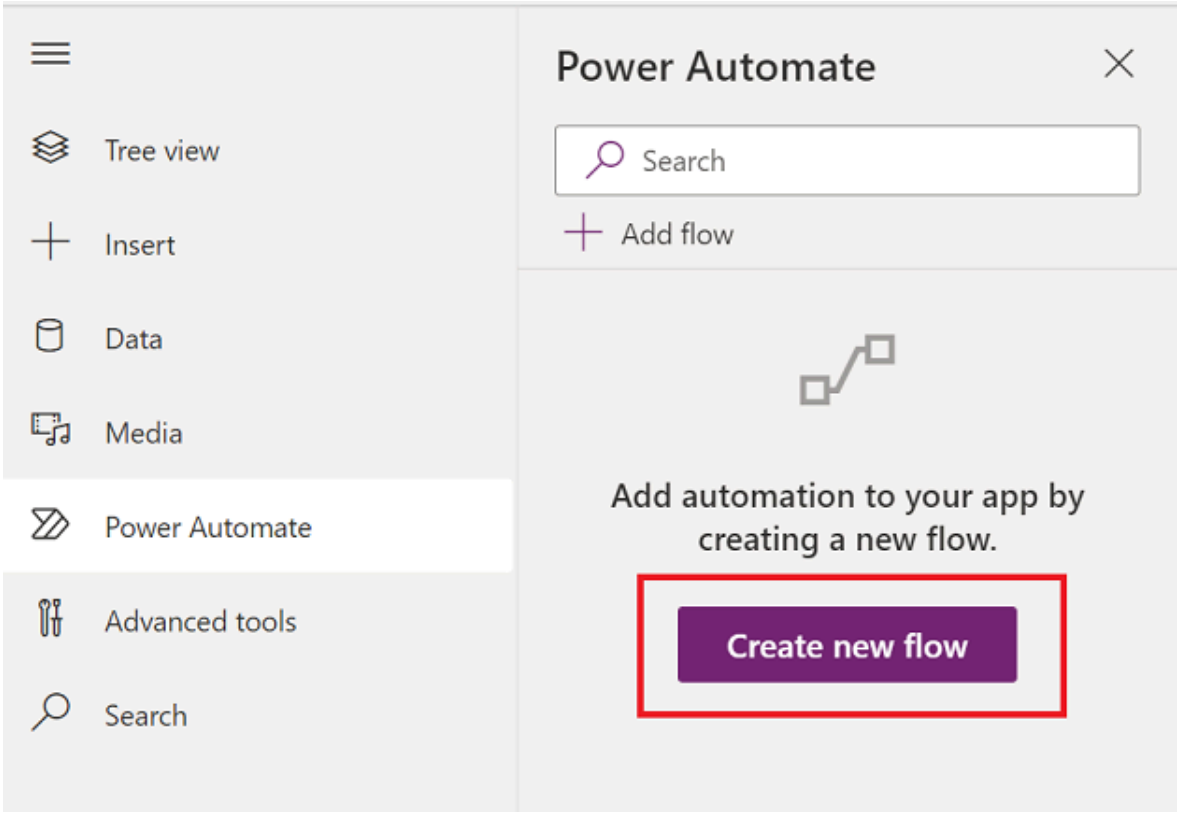
24. Select the **No** button, and set the button's **OnSelect** property to `Navigate(Screen1)`.



25. Select the **Yes** button, on the app authoring menu select **Power Automate**.

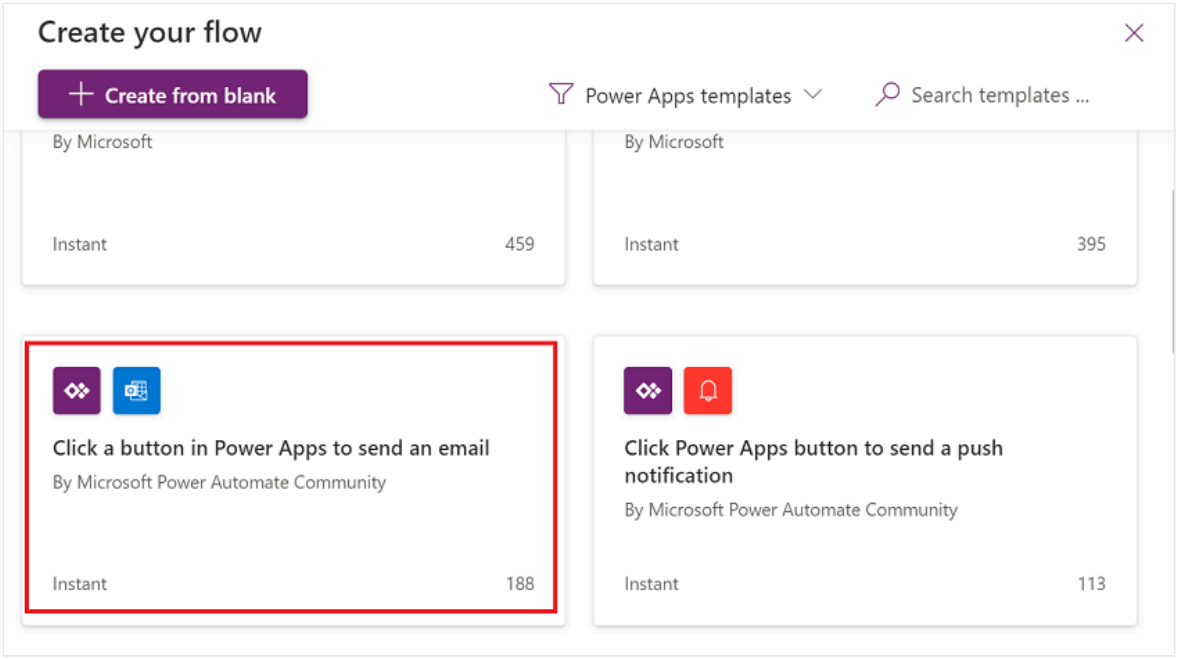


26. Select **Create a new flow** to create a new Power Automate flow.

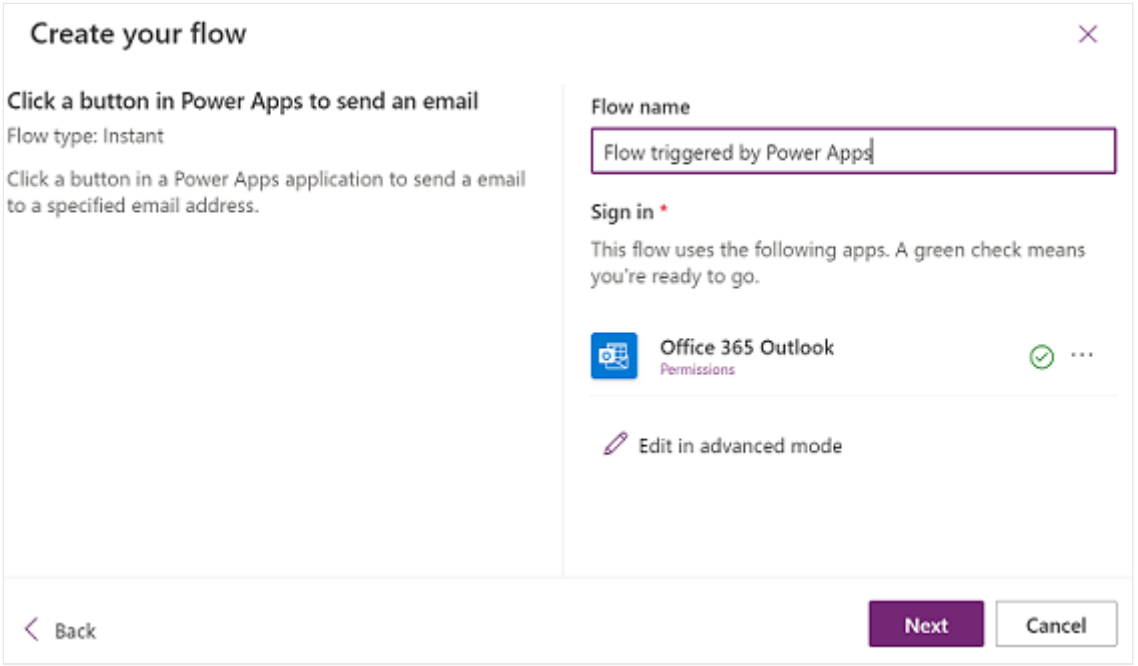


Create the Power Automate Flow

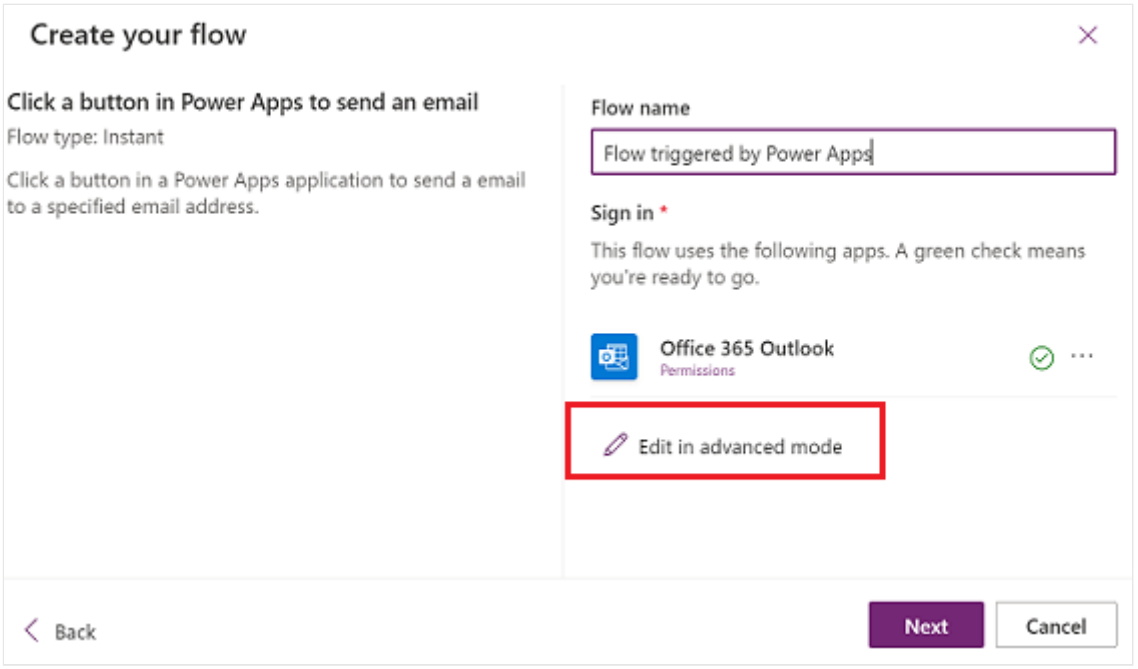
1. On the **Create your flow** screen, from the list of instant templates, select **Click a button in Power Apps to send an email**.



2. Enter a name for the flow as "Flow triggered by Power Apps", and select **Power Apps** as the trigger.



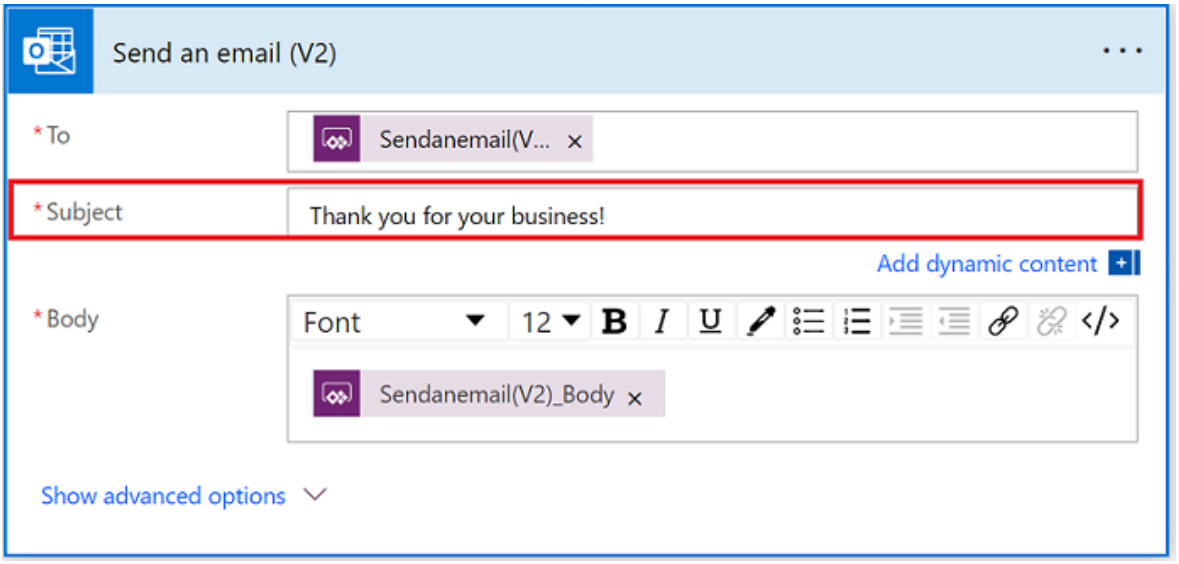
3. Select **Edit in advanced mode** and then select, **Continue**.



4. The **To** field and the **Body** field are automatically auto-populated with the following:

    - To: **Sendanemail(V2)_To**.
    - Body: **Sendanemail(V2)_Body**

5. In **Subject** field, delete **Sendanemail(V2)_To** and enten **Thank you for your business!** in the **Subject** field.



6. Select **Save** to save the flow.

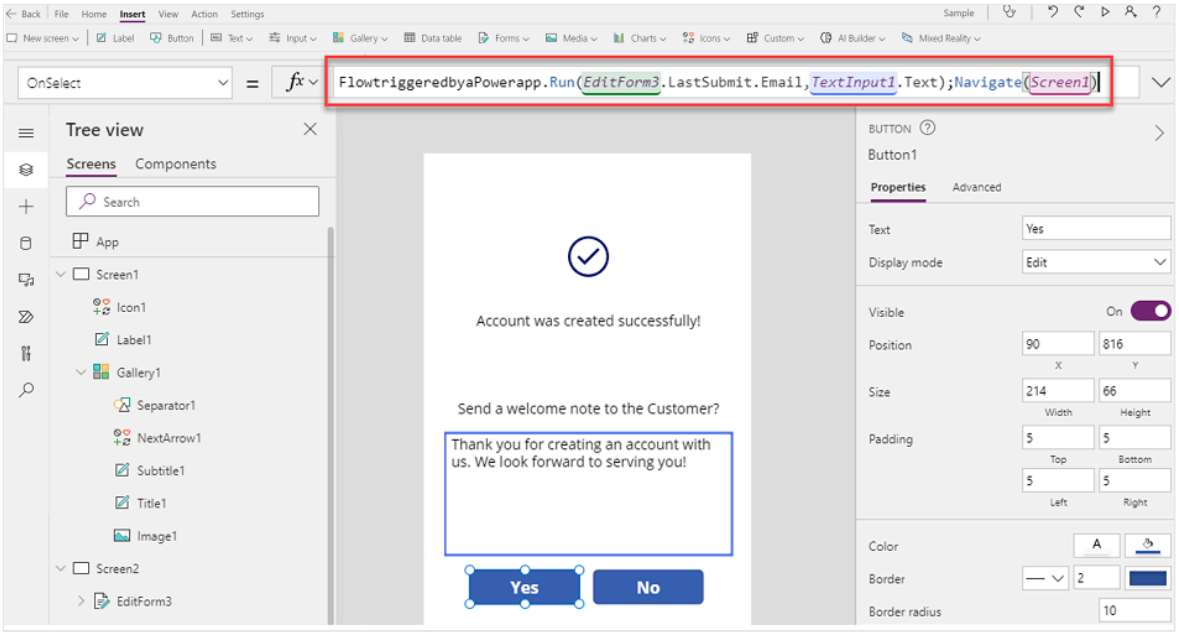
Trigger the flow from within the canvas app

1. Select the **Yes** button > in the **OnSelect** property enter the two parameters for the To email address and the Body of the email as follows:

Power Fx

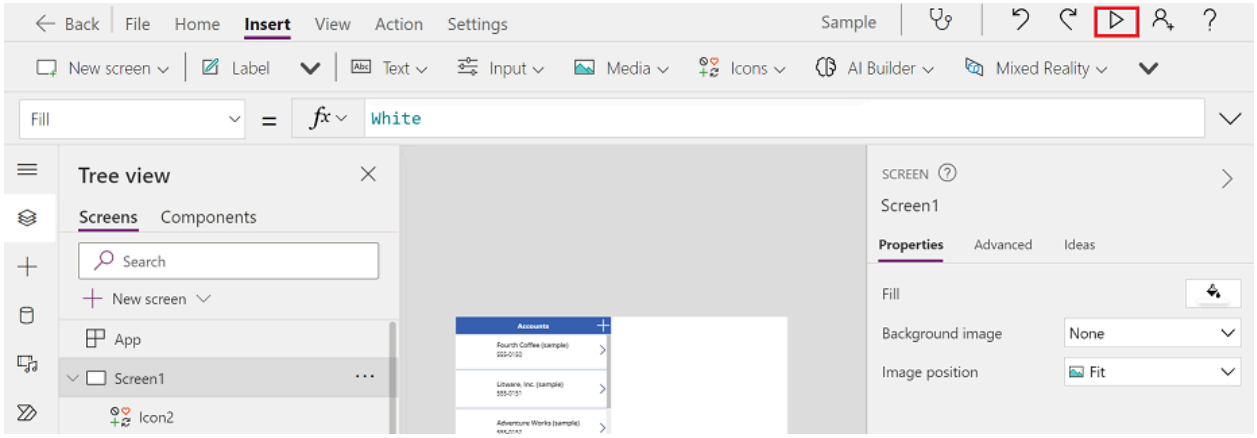
```
FlowtriggeredbyaPowerapp.Run(
   EditForm3.LastSubmit.Email,
   TextInput1.Text
);
Navigate(Screen1);
```

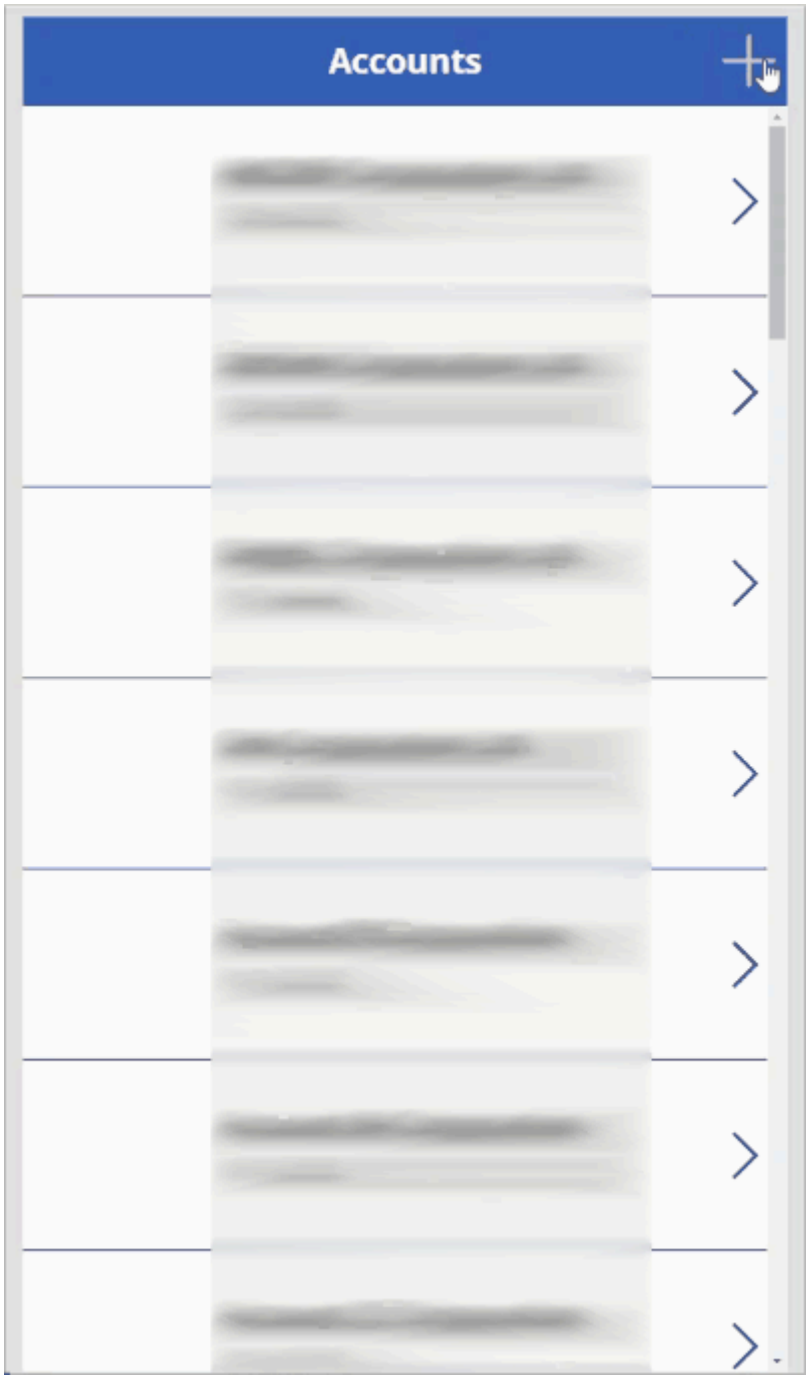
> **Note**
>
> The email address is picked up from the new account record created on the previous screen. and the body for the email is picked from the text box text captured on this screen.



Test the app

Run the app in preview mode. In this test, we'll create a new account by entering details like account name, phone number, city, and email address on the **New Account** screen. On saving the new account details, we'll be prompted to send an email to the customer where we can update the verbiage of the email, and then select **Yes** to send the email. This will trigger the flow, and email will be sent to the email address on the account.





An email like this should appear in your inbox

Create a canvas app with the barcode reader control

Article • 03/13/2023

The barcode reader control in Power Apps lets you use your phone or mobile device to scan barcodes from various formats.

Some of the common uses of barcode reader control in a canvas app are:

- An app to check in items like books into a collection
- An inventory management app that uses barcode to identify items
- An employee app to check in and badge scanning for security

In this article, we'll create a canvas app with barcode reader and display scanned items in a gallery.

Watch this video to learn how to create an app with barcode reader: https://learn-video.azurefd.net/vod/player?id=8714cb52-ce37-452c-bc47-1af24b1f6b93&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fcreate-app-barcode-scanner

Prerequisites

- Power Apps license
- Before you create an app from scratch, familiarize yourself with Power Apps basics by generating an app and then customizing that app's controls, gallery, forms, and cards.
- To create an app, you must be assigned to the Environment Maker security role.

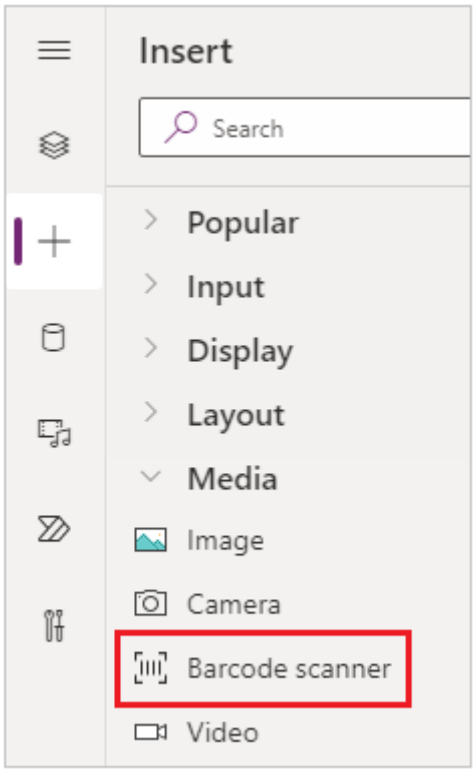
Open a blank app

Create a blank canvas app.

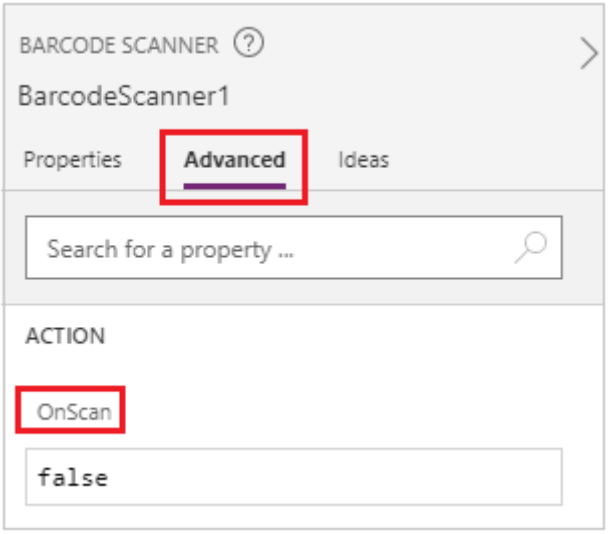
Add barcode scanner

1. From the left-pane, select **Screen1**.

2. From the left-pane, select **+ Insert** > expand **Media** > select **Barcode reader** control.



3. From the properties list on the right-side of the screen, select **Advanced** tab, and then select the **OnScan** property.

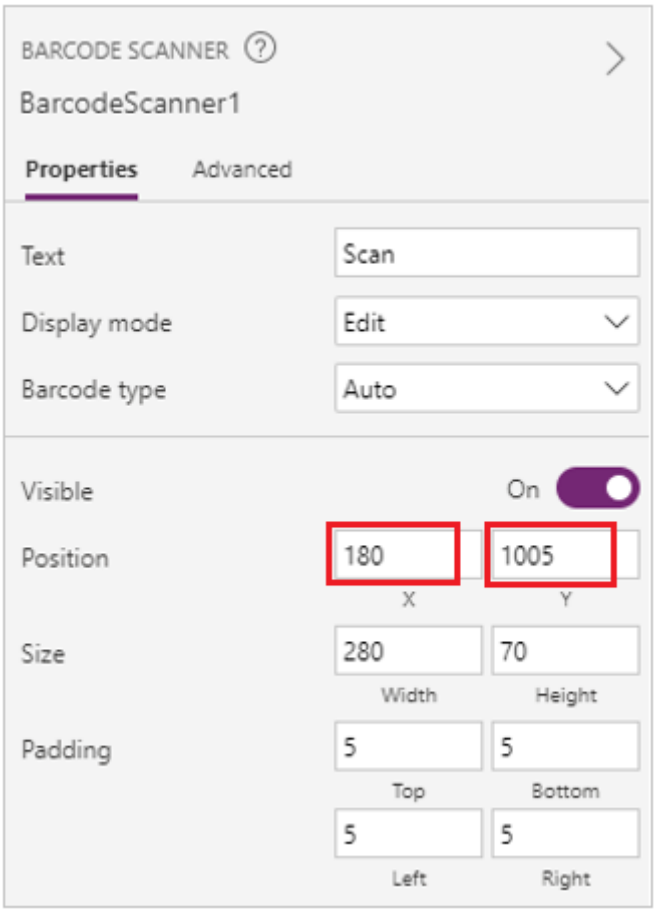


4. Set the **OnScan** property of the Barcode scanner control to this expression by typing or pasting it in the formula bar.

Power Fx

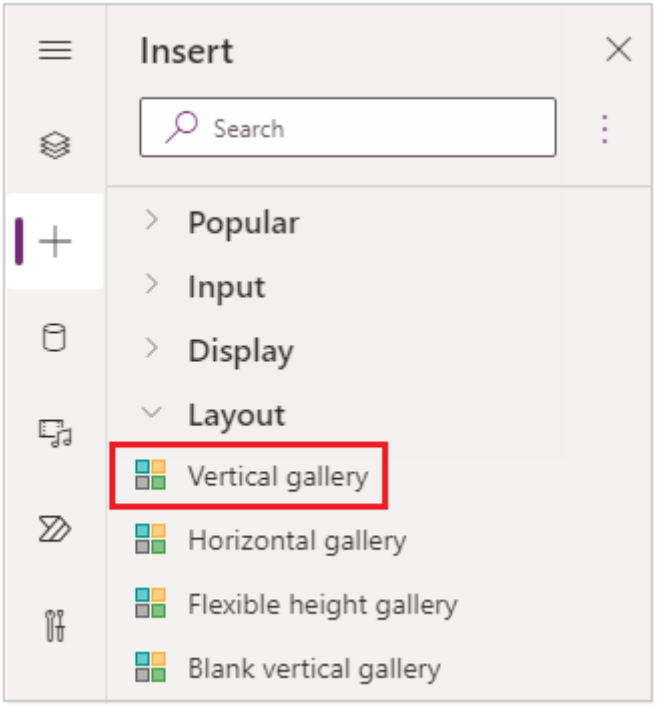
```
Collect(
    colScannedItems,
    {ScannedItem: First(BarcodeReader1.Barcodes).Value, ScannedTime:
Now()}
)
```

5. From the **Properties** pane, set **X** property to "180" and the **Y** property to "1005".

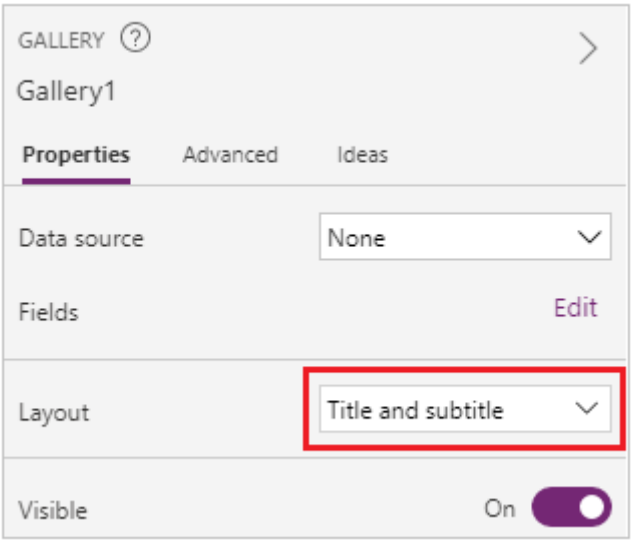


Add gallery

1. Select + **Insert** > expand **Layout** > select **Vertical gallery** control.



2. From the properties pane, select the layout for the gallery as **Title and subtitle**.

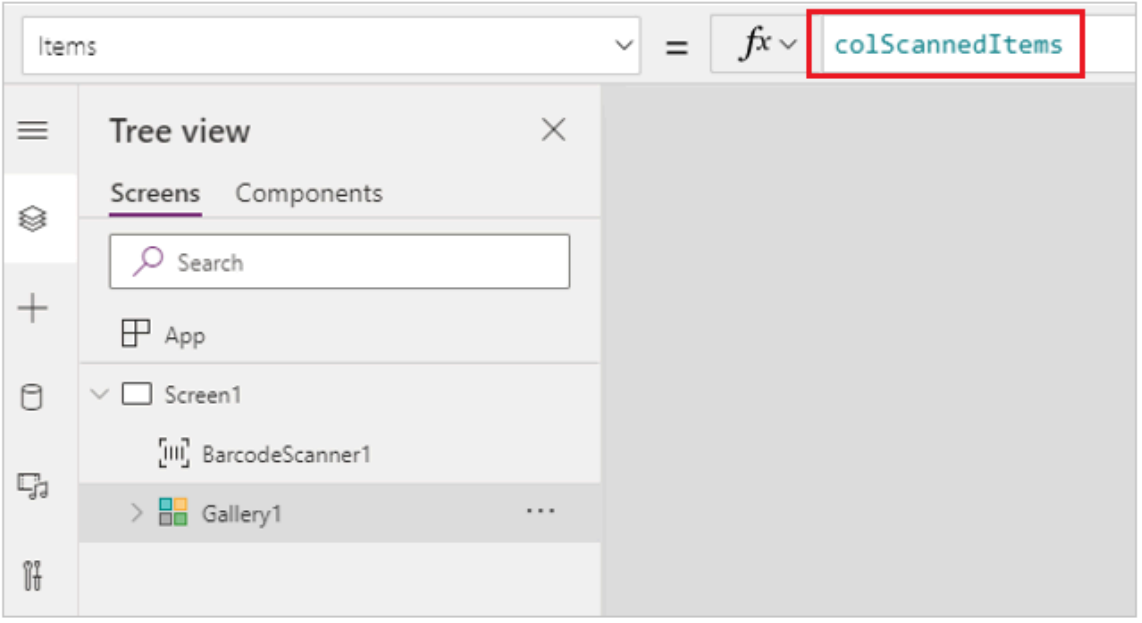


3. Select the gallery control on canvas.

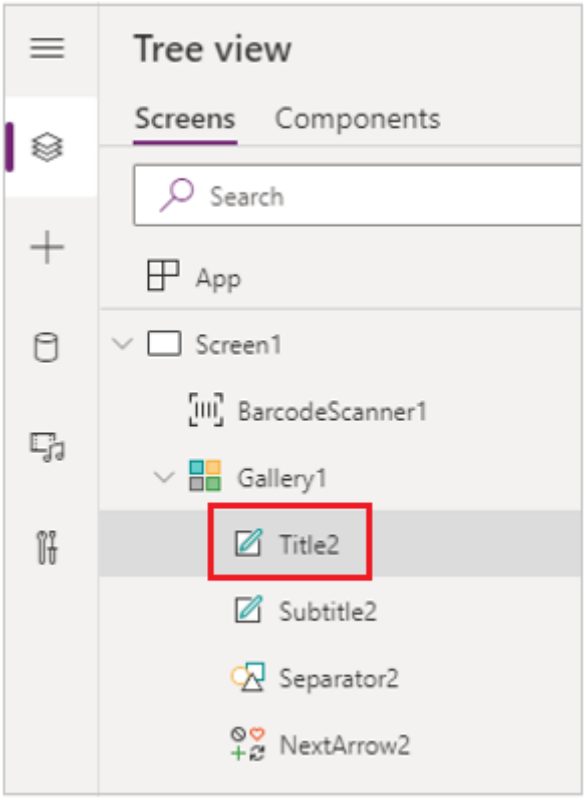
4. Set the **Items** property of the gallery control to this expression by typing or pasting it in the formula bar.

```
Power Fx

colScannedItems
```



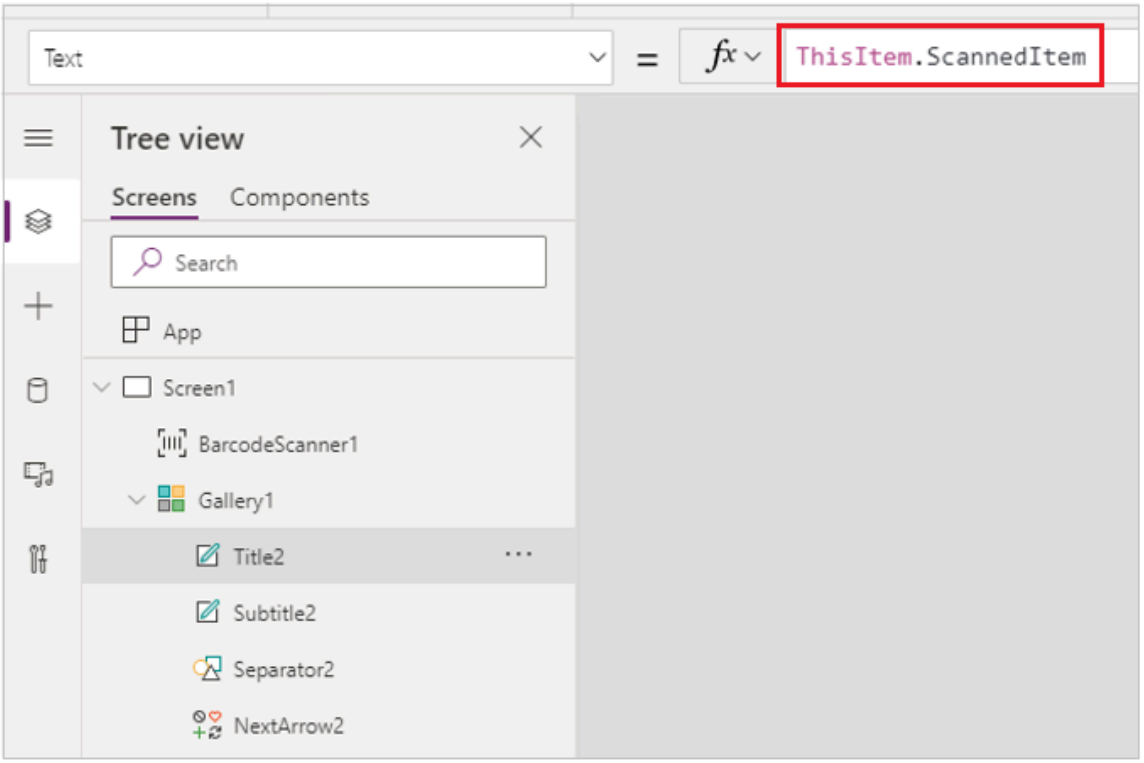
5. In the left-pane, expand the **Gallery1**, and select **Title2**.



6. Set the **Text** property of **Title2** to the following expression.

Power Fx

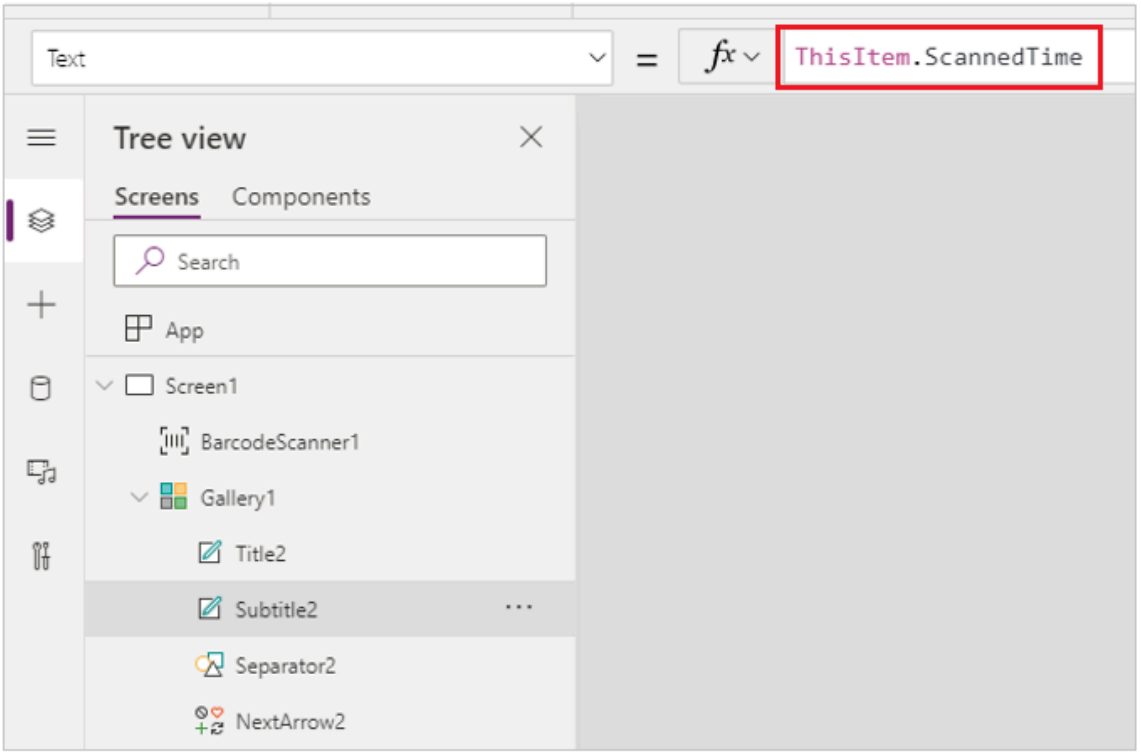
```
ThisItem.ScannedItem
```



7. Select **Subtitle2** label, and set it's **Text** property to this expression.

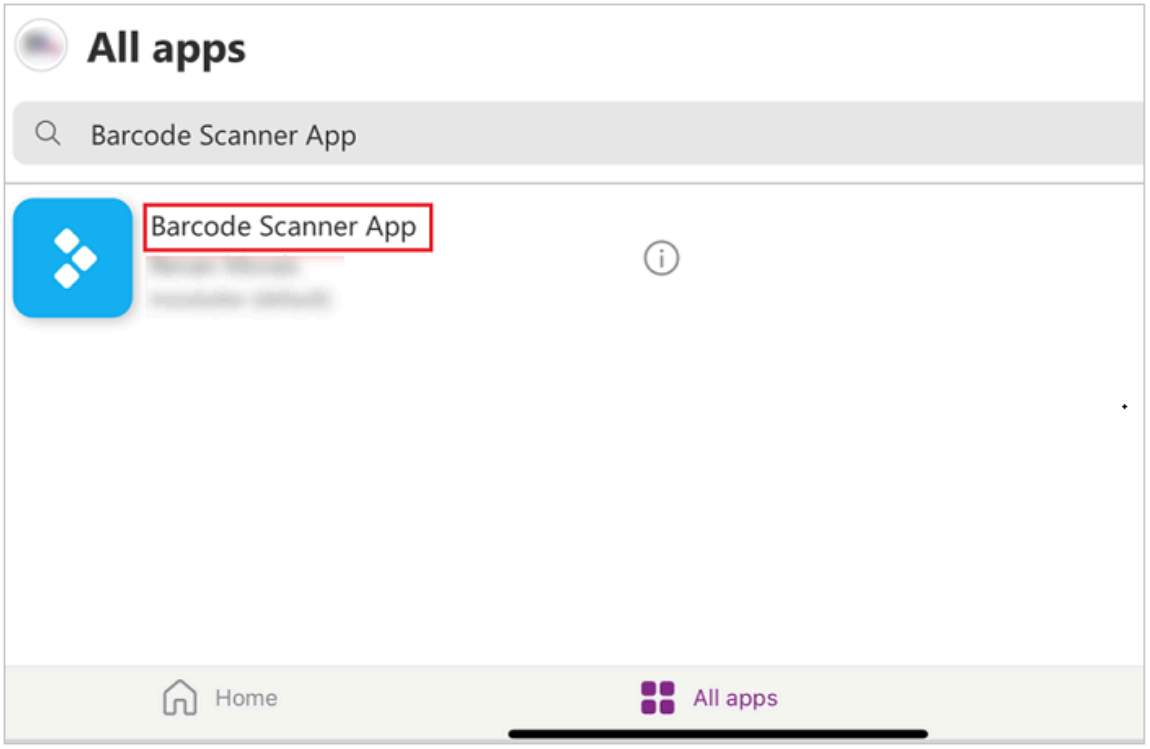
Power Fx

```
ThisItem.ScannedTime
```



Try the app

1. To test the app, select **Screen1**, and then press **F5** on the keyboard.
2. After testing, save and publish the app.
3. Download Power Apps Mobile on your phone.
4. Open the **Power Apps** app, and sign in.
5. Select and open the barcode reader app.



6. Select **Scan**, and scan any barcode label (for example, barcode label on a book).

Final Results

You'll see the scanned barcode information is saved inside the app.

Create an app that uses mobile sensors

Article • 12/16/2022

Sensors enable you to add richer functionality into your apps by leveraging the capabilities of your phone. In this article, you'll learn about using sensors on your mobile device within Power Apps.

To do this, you'll be making a sample app with two screens. The first screen will display the current compass heading, latitude, longitude, altitude, and can scan NFC tags to obtain text information. The second screen will showcase how to display accelerometer data to produce the angle of the device along the X and Y axes.

To set up the scenario behind the first screen, imagine that you are building an app for an NFC-based scavenger hunt. Each participant will use the app to scan an NFC tag which will provide them with a compass heading, latitude, and longitude that will point them to their next destination. At that destination, the participant will then scan another tag and repeat the process until they reach the end of the hunt.

For the second screen, imagine needing a tool to roughly measure angles. When on the second screen, the participant will be able to place or hold their device on a surface, and get the angles on the X and Y axis of the device as well as view a visual representation of those angles.

Watch this video to learn how to build an app that uses mobile sensors:
https://learn-video.azurefd.net/vod/player?id=01899fa6-7a02-4ed6-9ab1-4bc8b5bf17b9&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fmobile-sensors

Prerequisites

- Any level of Power Apps license can be used for this app, as no data connections are being used.
- A mobile device such as a mobile phone or tablet with GPS and accelerometer capabilities will be needed as most PCs might not have the necessary sensors.
- An NFC capable device is needed for the NFC scanning feature. It's also assumed that the NFC tags to be scanned have been pre-configured to produce text values in the following example format:

  ```
  ```

```
"<b>Heading: </b> 80 degrees <br>
<b>Latitude: </b> 44.4604788 <br>
<b>Longitude: </b> -110.82813759"
```

This will provide the text in an HTML-friendly format for the app. The setup of the NFC tags is beyond the scope of this article, and the NFC elements can be ignored if needed; the primary focus is using the mobile sensors in Power Apps.

Add header and HTML text for the device sensor outputs

Header label

With an app open for editing in Power Apps, add a **Text label** to the screen by dragging and dropping it from the **Insert** pane. Position it at the top-left corner of the screen, and modify the following properties in the Properties pane:

Expand table

Property	Value
Text	"Scavenger Hunt"
Font size	24
Font weight	FontWeight.Semibold
Text alignment	Align.Center
Width	Parent.Width

Then in the **Advanced** pane, modify the following properties:

Expand table

Property	Value
Color	RGBA(255, 255, 255, 1)
Fill	RGBA(56, 96, 178, 1)

This will provide a header for the screen.

HTML text for the device sensor outputs

Next, add an **HTML text** control. This will be used to display all the device sensor outputs in one place. Use this code in the **HtmlText** property:

```
Power Fx

"<b><u>Current Location</u></b><br>
<br>
<b>Compass Heading: </b>" & Round(Compass.Heading, 2) & Char(0176) &
"<br>
<br>
<b>Lat: </b>" & Location.Latitude & "<br>
<b>Long: </b>" & Location.Longitude & "<br>
<b>Alt: </b>" & Round(Location.Altitude, 2) & " m"
```

Change the following properties in the Advanced pane:

Expand table

Property	Value
Size	21
BorderStyle	BorderStyle.Solid
BorderThickness	2
Width	560
Height	576
PaddingTop	16
PaddingRight	16
PaddingBottom	16
PaddingLeft	16

If you examine what was put in the HtmlText, you may notice that there are two sensor types that are being used.

First is the **Compass** sensor, which is using the **Heading** property to provide the compass heading from the device.

Second is the **Location** sensor, which provides the **Latitude**, **Longitude**, and **Altitude**. There are two considerations about Location. First, if you use just Location without the dot operator and property, you'll get a record that has fields for Latitude, Longitude, and

Altitude. Second, the Altitude property is in meters by default. If you would like to convert it to feet, replace the following formula:

Use meters:

```
Power Fx

Round(Location.Altitude, 2) & " m"
```

Use feet:

```
Power Fx

Round(Location.Altitude \* 3.2808, 2) & " ft"
```

> **Note**
>
> Many sensor properties might not work correctly if you preview the app inside Power Apps Studio. To work with sensor properties for testing, prefer to use a mobile phone instead.

Now position the **HTML text** control near the lower half of the screen.

Add Button for the NFC scan and HTML text control

NFC scan button

Add a button to the app, positioning in below the **HTML text** control that you added in the last step, and change the following properties in the Advanced pane:

Expand table

Property	Value
OnSelect	ClearCollect(colNFCScan, ReadNFC())
Text	"Scan NFC Tag"

The code in the **OnSelect** property is utilizing the ReadNFC() function, which activates the NFC reader. It then stores what is read from the NFC tag in a collection called

colNFCScan. This collection will have four fields: **RTD**, **Text**, **TNF**, and **URI**. While a full explanation of these fields is beyond the scope of this article, some explanation may be helpful. **TNF** stands for **Type Name Format** and is used to define the structure of the **Record Type Definition**, or **RTD**, which in turn defines the type of record contained in the **Text** and/or **URI** fields. **URI** stands for **Uniform Resource Identifier**, which is essentially the address of a resource. For the NFC tags being used in this example, in addition to the **Text** field containing the example text from the introduction of this topic, they would contain a **TNF** value of *1*, an **RTD** value of *T*, and a blank **URI** value.

Add HTML text control to display the NFC scan information

Add a second **HTML text** control and use the following formula in the **HTMLText** property:

```
Power Fx

"<b><u>Next Destination</u></b><br>
<br>" &
First(colNFCScan).Text
```

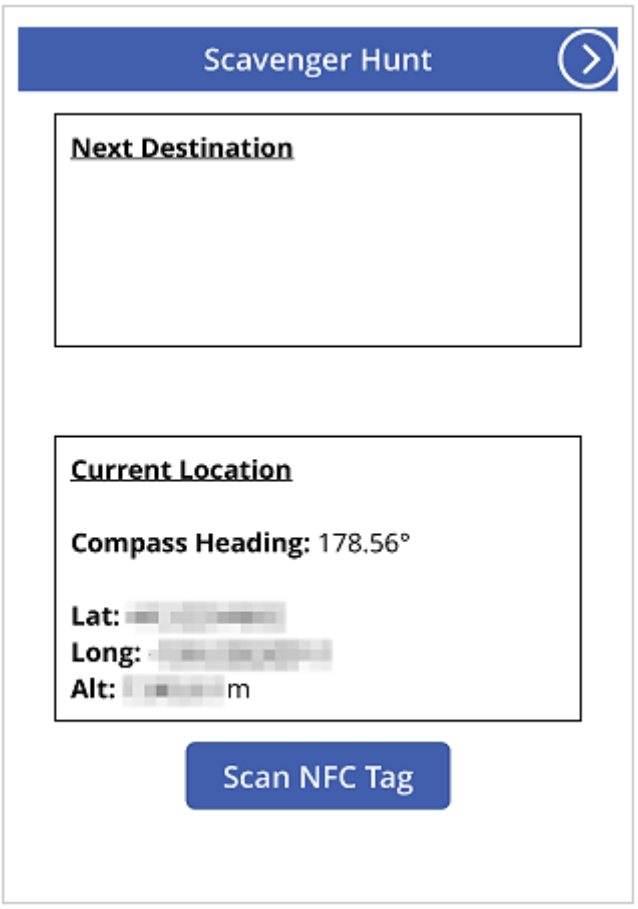
Change the following properties in the Advanced pane:

Expand table

Property	Value
Size	21
BorderStyle	BorderStyle.Solid
BorderThickness	2
Width	560
Height	248
PaddingTop	16
PaddingRight	16
PaddingBottom	16
PaddingLeft	16

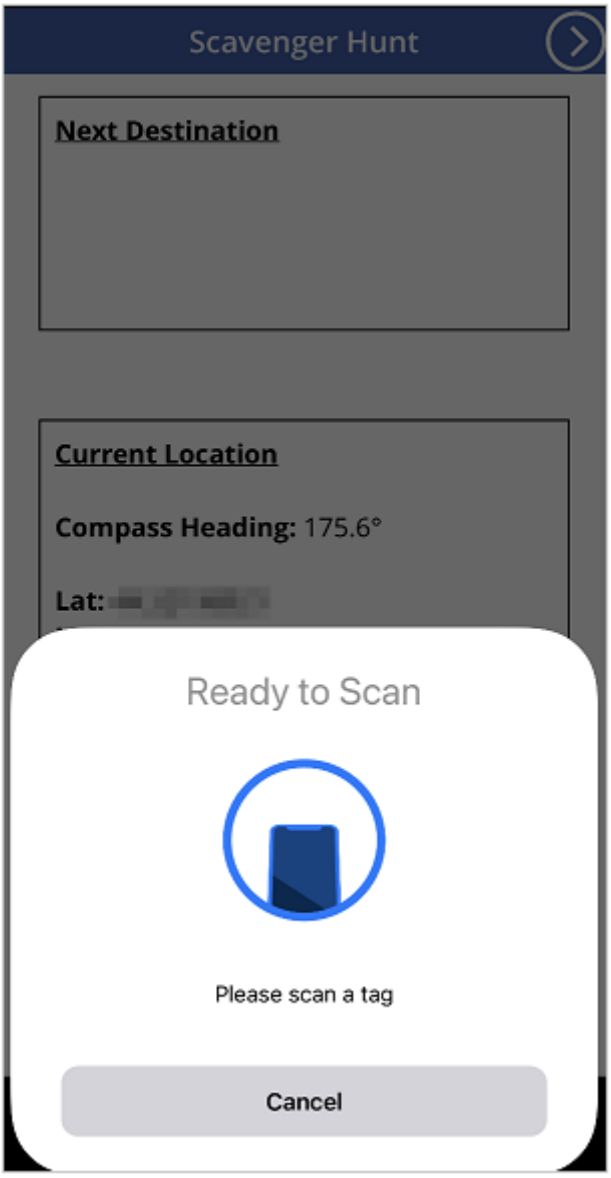
Without any NFC data present, the control will display **Next Destination**. When an NFC tag is scanned, it'll display **Next Destination**, and then the data from the **Text** field in the data collected from the scan.

Assuming the data for the NFC tags has been configured as described in the introduction, the user will see the next compass heading, latitude, and longitude values for the next scavenger hunt location after scanning one of those tags.

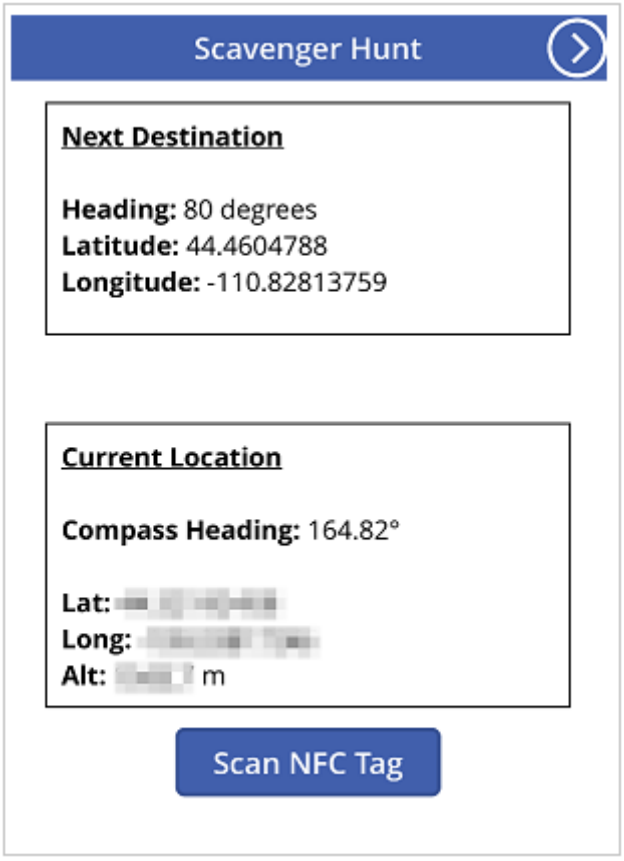


Test the app

Save and publish the app. On a mobile device with the necessary sensors, open the app and observe the compass heading, latitude, longitude, and altitude values. Try walking around while turning in various directions to see changes in the various sensor readings.



Press the **Scan NFC Tag** button to observe the NFC reader control. If you have an NFC tag that can produce a **Text** value, scan the tag to observe the text in the app. If not, select **Cancel**.



Add and configure second screen

Add a new **Blank screen** for the angle measurement portion of the app.

After adding the screen, go back to the first screen and add a **Next Arrow** icon from **+ Insert** > **Icons** > choose the **Next Arrow** icon. Position it in the top-right corner of the screen, and change the following properties in the Advanced pane:

Expand table

Property	Value
OnSelect	Navigate(Screen2)
Color	RGBA(255, 255, 255, 1)

If you have renamed the second screen that was just added, substitute that name for **Screen2** in the **Navigate** function.

Preview the app, selecting the icon that was just added to verify that it navigates you to the blank screen that was just added.

Add configuration for X and Y angles

Add a **Text label** to the screen by dragging and dropping it from the **Insert** pane. Position it at the top-left corner of the screen and modify the following properties in the **Properties** pane:

Expand table

Property	Value
Text	"2 Axis Level"
Font size	24
Font weight	FontWeight.Semibold
Text alignment	Align.Center
Width	Parent.Width

Then in the Advanced pane, modify the following properties:

Expand table

Property	Value
Color	RGBA(255, 255, 255, 1)
Fill	RGBA(56, 96, 178, 1)

This will provide a header for the second screen.

Next, add a **Back Arrow** icon from **+ Insert** > **Icons** > choose the **Back Arrow** icon. Position it in the top-left corner of the screen and change the following properties in the **Advanced** pane:

Expand table

Property	Value
OnSelect	Navigate(Screen1)
Color	RGBA(255, 255, 255, 1)

If you've renamed the first screen that was just added, substitute that name for **Screen1** in the **Navigate** function.

Finally, add an **HTML text** control. This will be used to display all the device sensor outputs in one place. Use the following formula in the HTML Text property:

Power Fx

```
"<b><u>Angles:</u></b><br>
<br>
<table width='100%'>
<tr>
<td width='50%'><b>X: </b>" & Abs(Round(Acceleration.X * (90 / 9.81),
0)) & Char(0176) & "</td>
<td width='50%'><b>Y: </b>" & Abs(Round(Acceleration.Y * (90 / 9.81),
0)) & Char(0176) & "</td>
</tr>
</table>"
```

Change the following properties in the Advanced tab:

Expand table

Property	Value
Size	21
BorderStyle	BorderStyle.Solid
BorderThickness	2
Width	560
Height	168
PaddingTop	16
PaddingRight	16
PaddingBottom	16
PaddingLeft	16

Position this control near the top of the app screen.

If you examine what was put in the **HtmlText**, you may notice that it is using the **Acceleration** sensor, with **X** and **Y** properties. There is also a **Z** property that we are not using in this scenario.

This sensor detects gravitational forces on the device over three planes. Using a mobile phone as an example, imagine a line extending out of the sides of the phone. This would be the **X** plane. Lifting the right side of the phone will produce a positive value and lifting the left side will produce a negative value. A line extending out of the top and bottom of the phone would represent the **Y** plane. Lifting the top of the phone will produce a positive value and lifting the bottom will produce a negative value. Finally, a

line coming out of the screen and back of the phone would represent the **Z** plane. Causing the screen to face upwards will produce a positive value and facing it downward will result in a negative value.

The accelerometer will measure forces acting on the device both in motion, such as if you dropped the device, and at rest, such as tilting the device on one or more of the axes described earlier. At rest, the theoretical values should be between 0 and +/- 9.81 m/s2, with 0 indicating that the relative axis is parallel to the Earth with no gravity acting on the sensor and a reading of 9.81 indicating that the relative axis is perpendicular to the Earth and the full force of gravity is acting on the sensor.

Looking at the code in the **HTML text** control you just added, notice the following section:

```
Power Fx

Abs(Round(Acceleration.X * (90 / 9.81), 0))
```

In this formula, from inside-out, first, the **Acceleration** on the **X** plane is being multiplied by **(90 / 9.81)**. This is using the theoretical maximum at-rest value to convert the sensor reading into degrees. The value of *90* is present because at the maximum theoretical value, the device would be perpendicular to the Earth on that plane, giving a measure of 90 degrees.

That value in degrees is then rounded to zero decimal places to provide a whole number degree value. Last, the absolute value of that rounded number is calculated to give a positive reading. This is so it will not matter if the angle is measured from one side or another.

> ⓘ **Note**
>
> The values shared above are approximates, and don't represent exact measurement.

Add the level visuals

In this step, we're going to use some controls in unconventional ways to achieve a visual goal.

Circular bubble level-like visual

To begin, add a **Button** control to the screen, renaming it to **btnCircleLevel** and change the following properties in the **Advanced** pane:

Expand table

Property	Value
Text	""
BorderColor	RGBA(56, 96, 178, 1)
FocusedBorderThickness	2
Fill	Transparent
DisabledFill	Self.Fill
X	(Parent.Width - Self.Width) / 2
Y	(Parent.Height - Self.Height) / 2
Width	400
Height	Self.Width

The result of these changes should produce a circular button in the center of the screen that cannot be pressed due to being disabled.

Next, add a **Circle** shape, set it's Border Radius to 400 and change the following properties in the **Advanced** pane:

Expand table

Property	Value
FocusedBorderThickness	0
X	(Parent.Width - Self.Width) / 2 + (Round(Acceleration.X / 9.81 * 90, 0) / 90 * btnCircleLevel.Width / 2)
Y	(Parent.Height - Self.Height) / 2 - (Round(Acceleration.Y / 9.81 * 90, 0) / 90 * btnCircleLevel.Width / 2)
Width	42
Height	Self.Width
Width	400
Height	Self.Width

The **X** and **Y** properties allow the **Circle** shape to move about the center of the app screen, relative change in the **Acceleration** sensor values but contained within the circular area of **btnCircleLevel**.

X and Y Axis bubble level-like visuals

Add a **Slider** control to the app, rename it to **sldXValue**, and change the following properties in the **Advanced** pane:

Expand table

Property	Value
Min	-90
Max	90
Default	Round(Acceleration.X * (90 / 9.81), 0)
ValueFill	Self.RailFill
X	(Parent.Width - Self.Width) / 2
Y	btnCircleLevel.Y + btnCircleLevel.Height + 30
Width	btnCircleLevel.Width
Height	70

This **Slider** control will display the angle similar to how a bubble level does: the **Handle** will move towards the raised side of the device, similar to the air bubble in a bubble level.

Next, copy **btnCircleLevel** by selecting it, pressing **Ctrl + C** and then **Ctrl + V**. Rename the control to **btnXValueOverlay** and change the following properties in the **Advanced** pane:

Expand table

Property	Value
X	sldXValue.X - sldXValue.HandleSize / 2
Y	sldXValue.Y
Width	sldXValue.Width + sldXValue.HandleSize

Property	Value
Height	sldXValue.Height

These changes will position it over the **sldXValue** control, preventing the user from changing its value and providing a visual border.

Copy and paste **sldXValue**, using the same method used to copy **btnCircleLevel**. Rename it to **sldYValue** and change the following properties:

Expand table

Property	Value
Layout	Layout.Vertical
X	btnCircleLevel.X - Self.Width - 30
Y	(Parent.Height - Self.Height) / 2
Width	sldXValue.Height
Height	sldXValue.Width

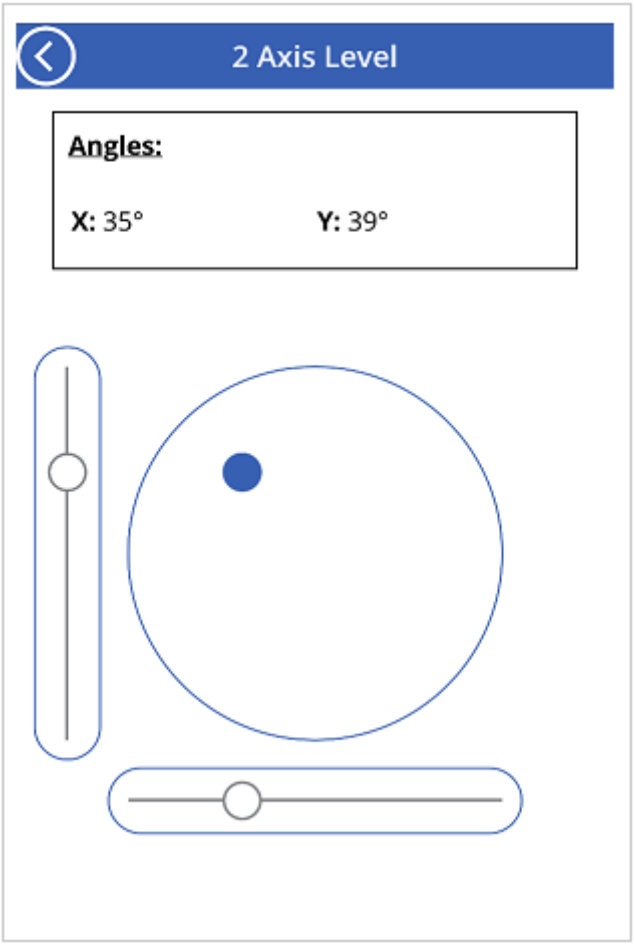
Copy and paste **btnXValueOverlay**, renaming it to **btnYValueOverlay**, changing the following properties:

Expand table

Property	Value
X	sldYValue.X
Y	sldYValue.Y - sldYValue.HandleSize / 2
Width	sldYValue.Width
Height	sldYValue.Height + sldYValue.HandleSize

This completes the bubble level-like visuals.

Test the level app



Save and publish the app. On a mobile device with the necessary sensors, open the app and navigate to screen with the bubble level visuals. Tilt the device from left to right, then up and down, and finally in all directions, noting the changes in angle properties as well as the changes in the visuals. Find an angled surface to place the device on and again note the angles and visuals.

Create an app with 3D and mixed reality controls

Article • 12/16/2022

You can use the 3D object and View in MR controls to view items in 3D, or to see how a particular item might fit within a specified space.

In this article, you'll learn how to use the 3D and mixed reality controls in Power Apps.

Watch this video to learn how to build mobile apps with View in MR control: https://learn-video.azurefd.net/vod/player?id=7651a5f3-4886-4910-97b0-290116a9fa89&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fbuild-view-in-mr-3d-apps

Prerequisites

See prerequisites for mixed-reality capable devices.

Create an app with View in MR control

The **View in MR** control creates a button in your app. When app users selects the button, it overlays a selected 3D model (in the .glb file format) or image (in .jpg or .png file formats) onto the live camera feed of the device.

> **Tip**
>
> You can also take photos and **upload them to OneDrive**.

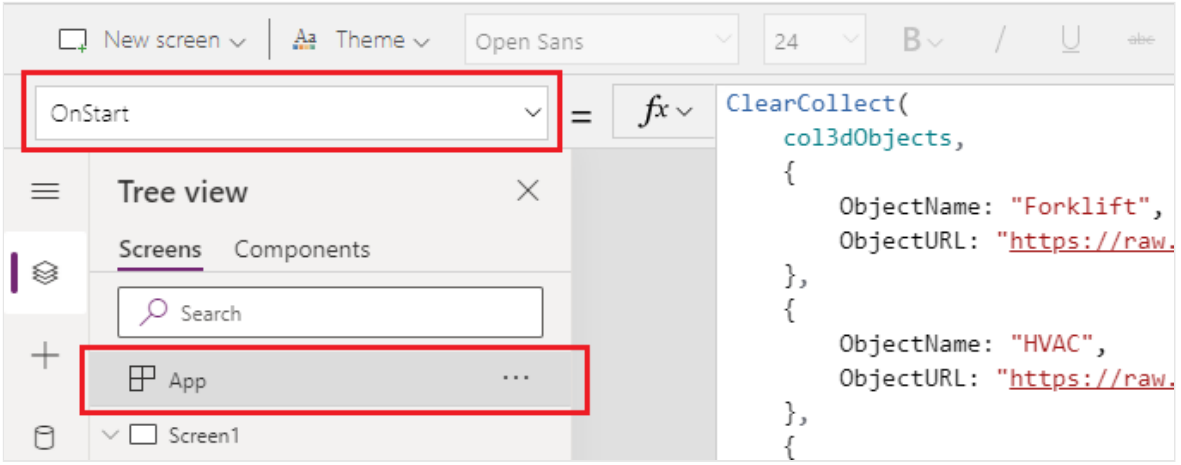
In this section, we will build a screen in an app that will allow a user to view the selected item in mixed reality using the **View in MR** control.

1. Open an app in Power Apps Studio.
2. Select the **OnStart** property of the app, copy and paste the following:

```
Power Fx

ClearCollect(
    col3dObjects,
    {
        ObjectName: "Forklift",
```

```
        ObjectURL:
"https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/forklift.glb"
    },
    {
        ObjectName: "HVAC",
        ObjectURL:
"https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/hvac.glb"
    },
    {
        ObjectName: "Machine",
        ObjectURL:
"https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/machine.glb"
    },
    {
        ObjectName: "Pallet w/ Boxes",
        ObjectURL:
"https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/pallet_with_boxes.glb"
    },
    {
        ObjectName: "Robot Arm",
        ObjectURL:
"https://raw.githubusercontent.com/microsoft/experimental-pcf-control-
assets/master/robot_arm.glb"
    }
)
```



This formula will create a collection containing the names and links of the 3D objects to be viewed in mixed reality.

3. Add a **Text label** to the screen by dragging and dropping it from the **Insert** tab.

4. Position the added text label at the top-left corner of the screen, and modify the following properties in the **Properties** tab:

Expand table

Property	Value
Text	"View In MR"
Font size	24
Font weight	`FontWeight.Semibold`
Text alignment	`Align.Center`
Width	640

5. In the Advanced tab, modify the following properties for the text label:

Expand table

Property	Value
Color	`RGBA(255, 255, 255, 1)`
Fill	`RGBA(56, 96, 178, 1)`

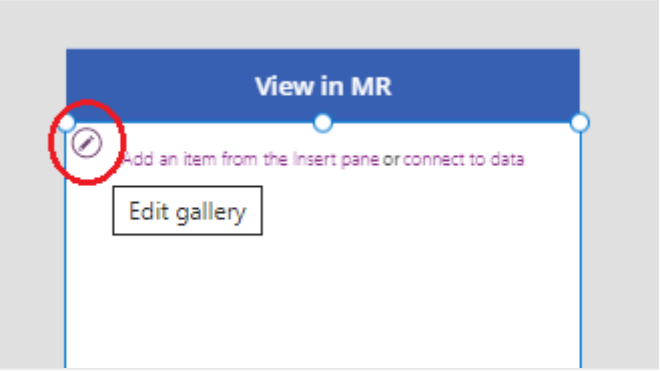
This change provides a header for the screen.

6. Insert a **Blank vertical gallery** from the **Layout** section of the **Insert** tab.
7. Position the gallery below the "View in MR" header you added earlier and expand it to use rest of the screen.
8. Change the following properties of the gallery:

Expand table

Property	Value
Data source	`col3dObjects`
Template size	80
X	0
Y	92
Width	640
Height	1044

9. Select **Edit gallery** to edit the gallery.



10. Insert a **Text label** into the gallery.

11. Change the following properties of the added text label:

Expand table

Property	Value
Text	`ThisItem.ObjectName`
X	10
Y	5
Width	540

12. Edit the gallery again.

13. From the **Mixed Reality** section of the **Insert** tab, drag and drop the **View in MR** control into the gallery.

14. Change the following properties of the **View in MR** control.

Expand table

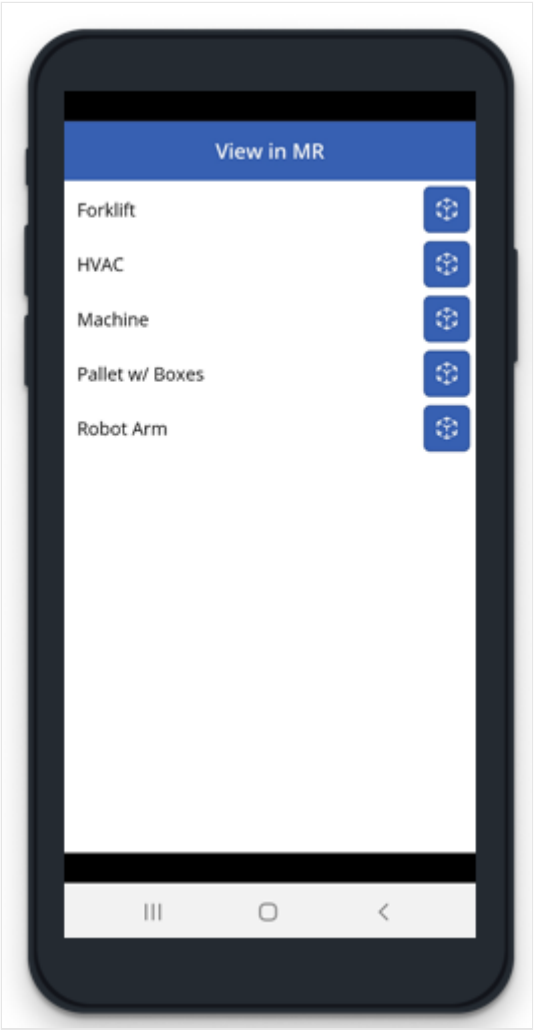
Property	Value
Text	"View In MR"
Display type	Icon
Source	`ThisItem.ObjectURL`
X	`Parent.TemplateWidth - Self.Width - 5`
Y	5

Property	Value
Width	70

This change will provide a gallery that has a list of 3D objects and a button to press for the user to view those objects in mixed reality.

Test the mixed reality control

Now that all the controls have been added, save and publish the app. On a mixed-reality capable device, open the app, and press the button that corresponds with the object you would like to view. This will open the **View in MR** experience.



Follow the on-screen instructions to calibrate the device by slowly moving it left and right while pointing the camera at a surface to be measured. Once the calibration is complete, you'll see an array of dots on the surface as well as a circle near the center of the screen. This circle shows where the 3D object can be placed initially. Once the cube has been placed it can be moved or rotated by using touch controls.

To move the object, press on it and slide it to where you would like it to be placed. To rotate the object, press one finger to the screen then swipe with another finger right or

left.

Use the back button in the top left corner to return to the app screen and select another object. Repeat this process as desired to view each of the objects.

Create an app with 3D object control

The **3D object** control allows you to view an item in 3D inside Power Apps. When app loads, it shows the 3D models (in the .glb file format) or image (in .jpg or .png file formats) inside the app through the control. You can select the 3D model to rotate, zoom in or out.

In this section, we will build a screen in an app that will allow a user to view the selected items in 3D using the **3D object** control.

1. Follow the steps 1 and 2 from the Create an app with View in MR control section to create an app with the collection of 3D objects for the app.

2. Add a **Text label** to the screen by dragging and dropping it from the **Insert** tab.

3. Position the added text label at the top-left corner of the screen, and modify the following properties in the **Properties** tab:

Expand table

Property	Value
Text	"3D object"
Font size	24
Font weight	`FontWeight.Semibold`
Text alignment	`Align.Center`
Width	640

4. In the Advanced tab, modify the following properties for the text label:

Expand table

Property	Value
Color	`RGBA(255, 255, 255, 1)`
Fill	`RGBA(56, 96, 178, 1)`

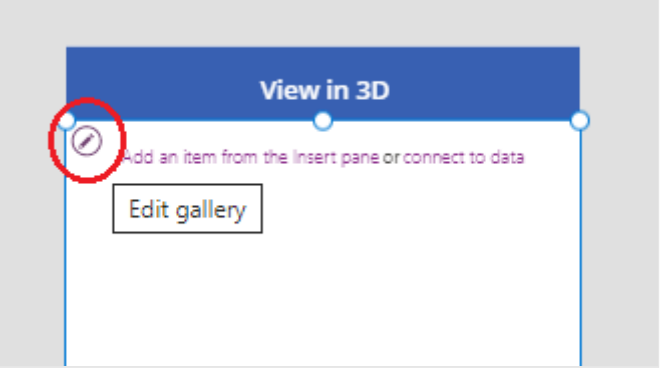
This change provides a header for the screen.

5. Insert a **Blank vertical gallery** from the **Layout** section of the **Insert** tab.
6. Position the gallery below the "View in MR" header you added earlier and expand it to use rest of the screen.
7. Change the following properties of the gallery:

Expand table

Property	Value
Data source	`col3dObjects`
Template size	80
X	0
Y	92
Width	640
Height	1044

8. Select **Edit gallery** to edit the gallery.



9. Insert a **Text label** into the gallery.
10. Change the following properties of the added text label:

Expand table

Property	Value
Text	`ThisItem.ObjectName`
Width	640

11. Edit the gallery again.
12. From the **Media** section of the **Insert** tab, drag and drop the **3D object** control into the gallery.
13. Change the following properties of the **View in MR** control.

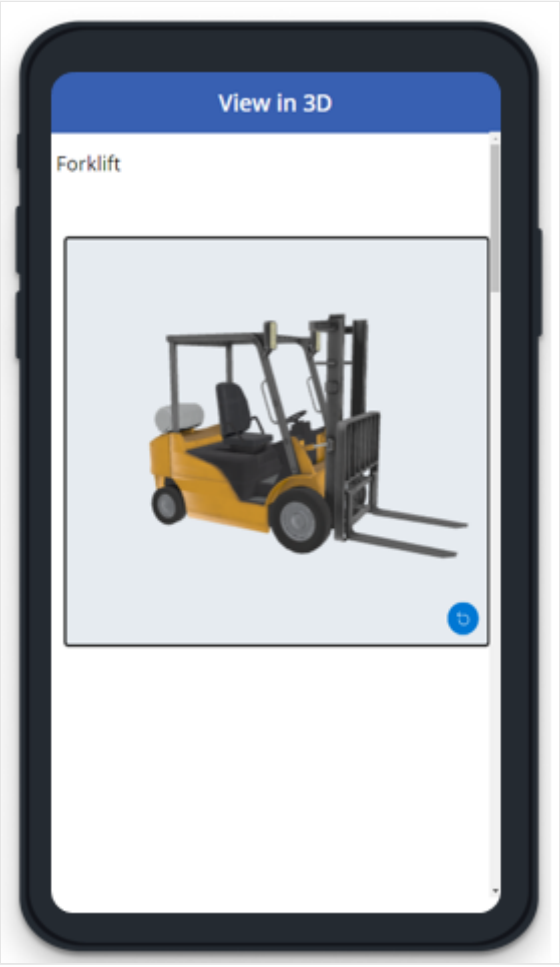
Expand table

Property	Value
Source	`ThisItem.ObjectURL`
X	18
Y	138
Width	600
Height	550

This change will provide a gallery that has a list of 3D objects that you can view in 3D.

Test the 3D control

Now that all the controls have been added, save and publish the app. On a mixed-reality capable device, open the app, touch the screen to zoom in, zoom out, or turn the object being viewed in 3D.



Since the gallery contains several objects in 3D, swipe down on the screen to see other objects and use the zoom or turn capabilities to work with the objects in 3D.

Create an app to view a shape in mixed reality

Article • 12/16/2022

You can use the **View Shape in MR** control in your app to let users see if a simple cube might fit within a specified space. They might want to do this to see how a certain object that you provide would fit in their space. If you have a 3D model or a head-on picture for the object, you'd like to fit test consider using the View in MR instead.

The control creates a button in your app. When app users select the button, it overlays a cube onto the live camera feed of the device. You set up the dimensions of the cube when you edit the control in Power Apps.

Watch this video to learn how to build mobile apps with View Shape in MR control: https://learn-video.azurefd.net/vod/player?id=2b6080fd-8236-48a5-b9b2-48285eccdba6&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fmobile-apps-view-shape-in-mr

In this article, we'll create a screen in an app that will allow users to create a custom cube shape by inputting unit to be used (centimeters, feet, inches, or meters), and defining the height, width, and depth of the cube.

Prerequisites

See prerequisites for mixed-reality capable devices.

Add controls for cube's dimensions and units

Add header and labels to define cube's dimensions and units to the app screen.

Header label

With an app open for editing in Power Apps Studio, add a text label to the screen. Position it at the top-left corner of the screen and modify the following properties in the Properties tab:

Expand table

Property	Value
Text	`"Place A Cube"`
Font size	`24`
Font weight	`FontWeight.Semibold`
Text alignment	`Align.Center`
Width	`Parent.Width`

Then in the Advanced tab, modify the following properties:

Expand table

Property	Value
Color	`RGBA(255, 255, 255, 1)`
Fill	`RGBA(56, 96, 178, 1)`

This change will provide a header for the screen.

Labels and controls to specify cube properties

1. Add four text labels to the screen. These labels will be used to identify the controls we'll add later. For each label, modify the **Text** property to one of the following:

   - `Unit Type`
   - `Width`
   - `Height`
   - `Depth`

2. Set the **Width** property of these labels to 160 and position them so they're stacked vertically in the order described above, near the top of the screen and to the left side.

3. Add a dropdown control and three text entry controls. The dropdown will be used to select a unit type for the cube dimensions and the three text entry controls will be used to enter the width, height, and depth of the cube.

4. Select the drop-down, rename it to *drpUnitType*, and change the following properties:

Expand table

Property	Value
Items	`["Centimeters", "Feet", "Inches", "Meters"]`
Default	`"Feet"`
Width	`280`

5. Position the control to the right of the Unit Type label.

6. Add three text input controls, and rename them to *txtShapeHeight*, *txtShapeWidth*, and *txtShapeDepth*. Change the following properties for all three controls:

Expand table

Property	Value
Default	`2`
Format	`TextFormat.Number`
Width	`144`

7. Position the text input control named *txtShapeWidth* to the right of the Width label. Likewise, position the controls named *txtShapeHeight* and *txtShapeDepth* to the right of the Height and Depth labels, respectively.

Next, you'll add the View Shape in MR control and configure it to use the controls that were created to provide dynamic dimensions to the MR cube it'll generate.

Insert the View Shape in MR control

Insert the control into your app.

1. Open the **Insert** tab.

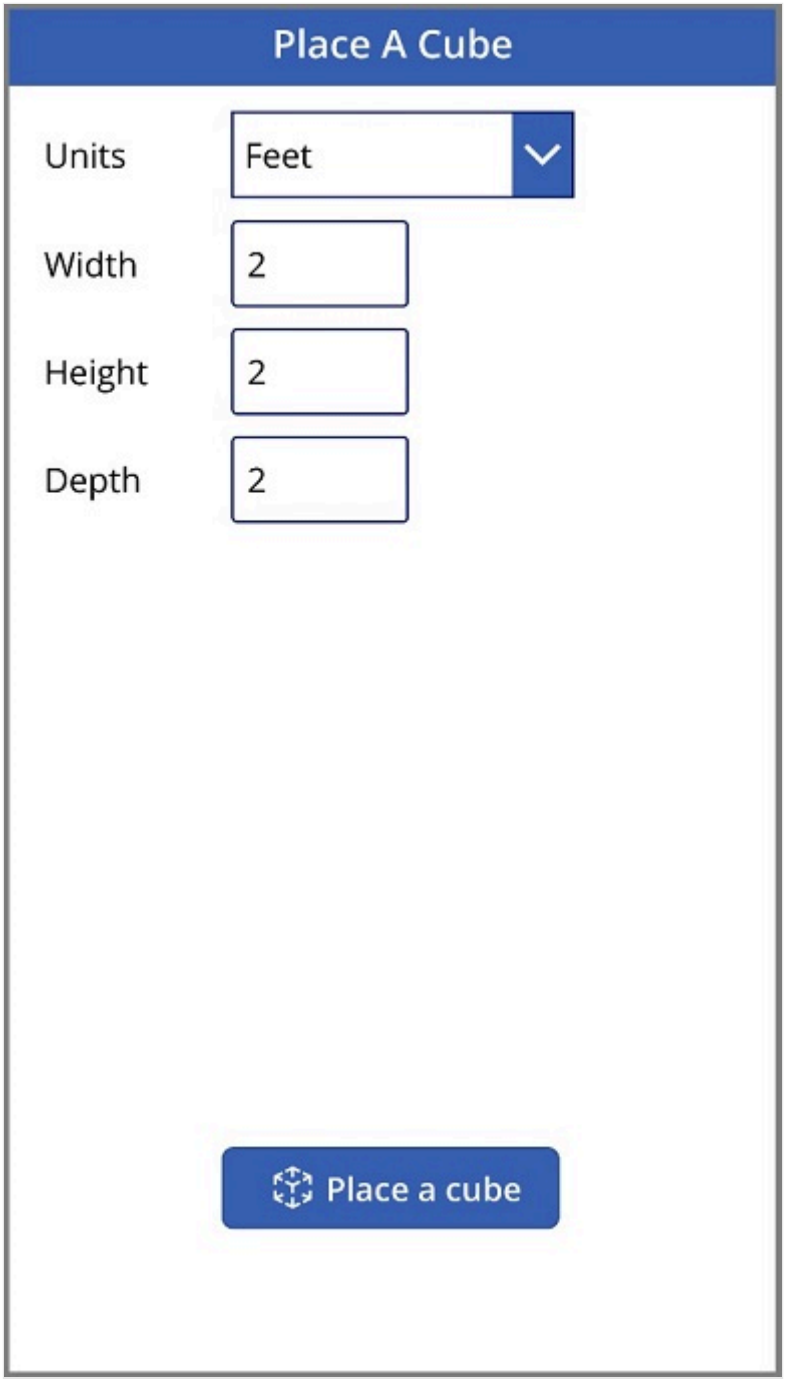
2. Expand **Mixed Reality**.

3. Select the control **View Shape in MR** to place it in the center of the app screen, or drag and drop it to position it anywhere on the screen.

4. Once the control has been added, position it near the bottom of the screen and change the following properties:

Expand table

Property	Value
Text	`"Place a cube"`
ShapeWidth	`txtShapeWidth.Text`
ShapeHeight	`txtShapeHeight.Text`
ShapeDepth	`txtShapeDepth.Text`
Units	`drpUnitType.Selected.Value`
Width	`280`



Test the app

Now that all the controls have been added, save and publish the app. On a mixed-reality capable device, open the app, and press the **Place a cube** button. This will open the **View Shape in MR** experience, allowing the user to define an area to be measured.

Follow the on-screen instructions to calibrate the device by slowly moving it left and right while pointing the camera at a surface to be measured. Once the calibration is complete, you'll see an array of dots on the surface and a circle near the center of the screen. This circle shows where the cube can be placed initially. Once the cube has been placed, it can be moved or rotated by using touch controls.

To move the cube, press on it and slide it to where you would like it to be placed. To rotate the cube, press one finger to the screen, and then swipe with another finger right or left.

Use the back button in the top-left corner to return to the app screen and change one or more of the width, height, depth, or unit type settings. Select the **Place a cube** button and place the new cube.

Create an app with address input and map controls

Article • 12/16/2022

There are many scenarios where users are expected to enter addresses in an app. Historically, there have been multiple fields capturing each element of an address where the user provides the street address, city and the postal code, and selects state. Entering addresses can be frustrating and error-prone, particularly in mobile scenarios.

The address input control presents the user with dynamic address suggestions as they type. Using fuzzy matching logic, the control suggests multiple potential address matches from which the user can select—making it quicker and easier to enter accurate addresses.

The control returns the address as structured data, allowing the application to extract information like city, street, municipality, and even latitude and longitude. The data is in a format friendly to many locales and international address formats.

To use the control, you need to enable the Geospatial Services for the environment.

- Watch this video to learn how to use the address input control: https://learn-video.azurefd.net/vod/player?id=ff56e551-756f-4796-8af9-419b40b1dbfd&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fmobile-apps-address-map
- Watch this video to learn how to use the map control: https://learn-video.azurefd.net/vod/player?id=c62bc98b-cf1f-4289-af11-82618c5e6d02&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fmobile-apps-address-map

In this article, we'll learn how to use the address input control in canvas apps.

Prerequisites

To complete this lesson, you'll need a Power Apps environment with a Microsoft Dataverse database. If you don't have a license, you can sign up for the Power Apps Developer Plan or use a Power Apps trial.

Create a trial environment

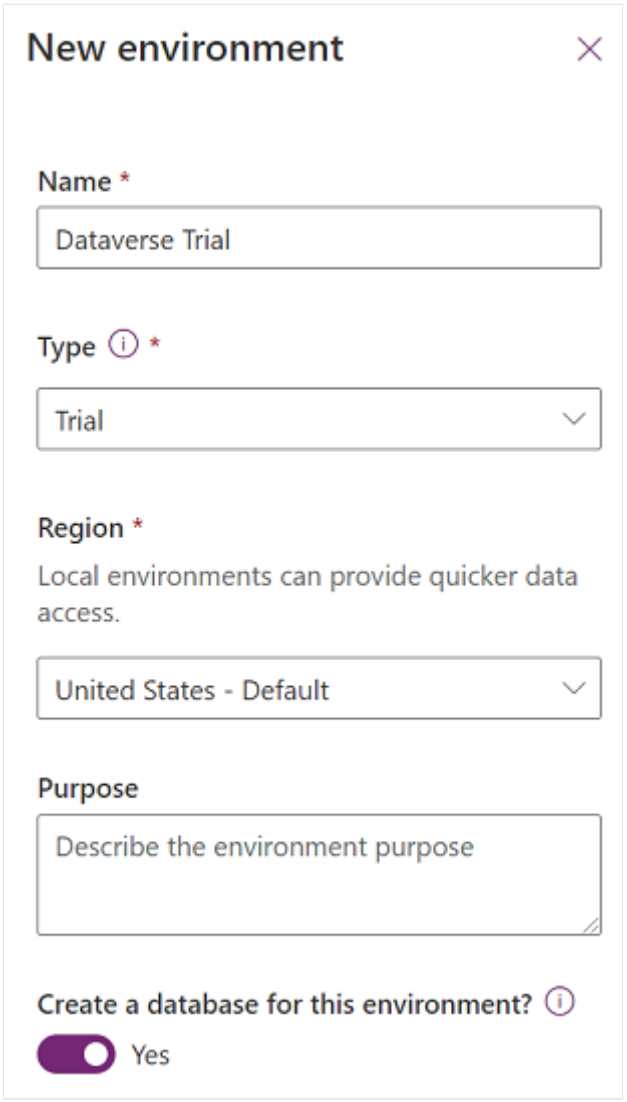
An environment in Power Apps is a space to store, manage, and share your organization's business data, apps, chatbots, and flows. It also serves as a container to separate apps that might have different roles, security requirements, or target audiences.

Each environment can have one Dataverse database.

To make sure that you have what you need to complete this lesson, we're going to create a new environment that includes a Dataverse database. This is a 30-day trial that will go away at the end of the 30 days, but you can upgrade it to a sandbox or production environment if you want to keep it.

We're going to create a trial environment that will include a Dataverse database, and the sample data used in this topic.

1. Go to Power Platform admin center in a web browser.
2. Select **Environments**.
3. Select **New**.
4. Enter a name, for example "Dataverse Trial".
5. Select **Trial** for the environment type.
6. Toggle **Create Database** to **Yes**.
7. Select **Next**.



8. Toggle **Deploy Sample Apps and Data** to **Yes**.

9. Select **Save**.

Your trial environment will now be created, including a Dataverse database and sample data in Dataverse tables.

Enable the Geospatial Services for the environment

Before we can use the Geospatial Services in canvas apps, an admin must enable access to the features for the environment where we want to create the app.

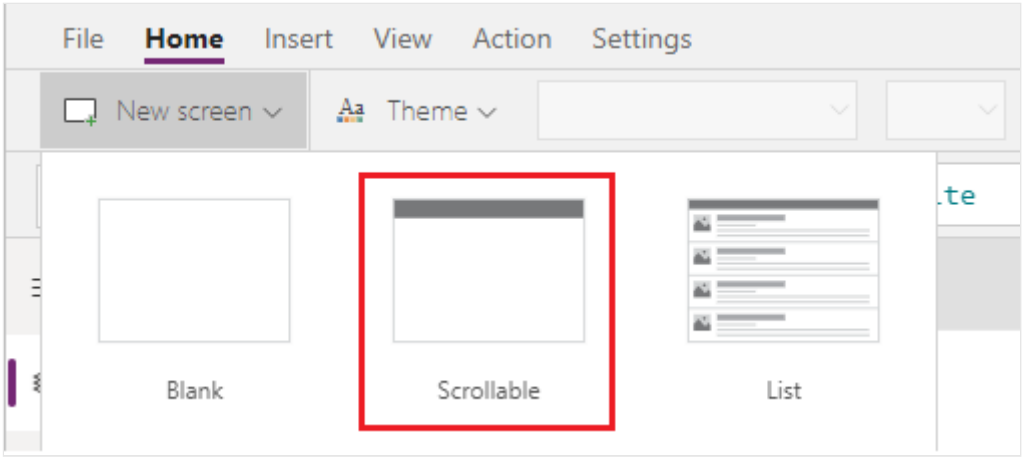
To learn about how to enable **Geospatial services** in your environment, see Enable the geospatial features for the environment.

Build a canvas app

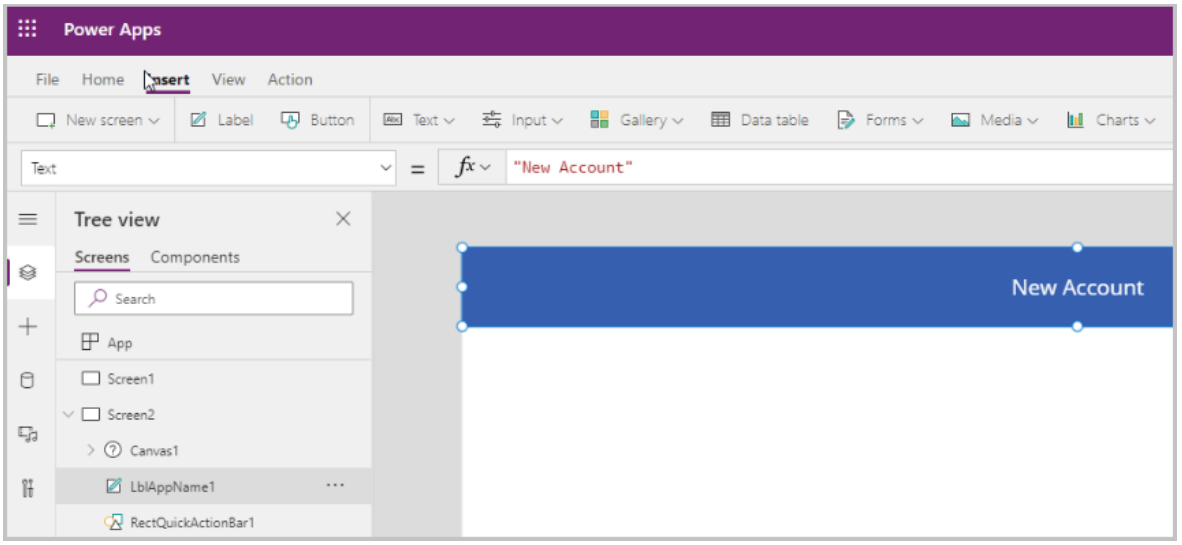
We'll start with creating an app and then, we'll create a header control to use within the app to standardize the look and feel of the header on different screens.

1. Create a blank canvas app in the environment you created earlier.

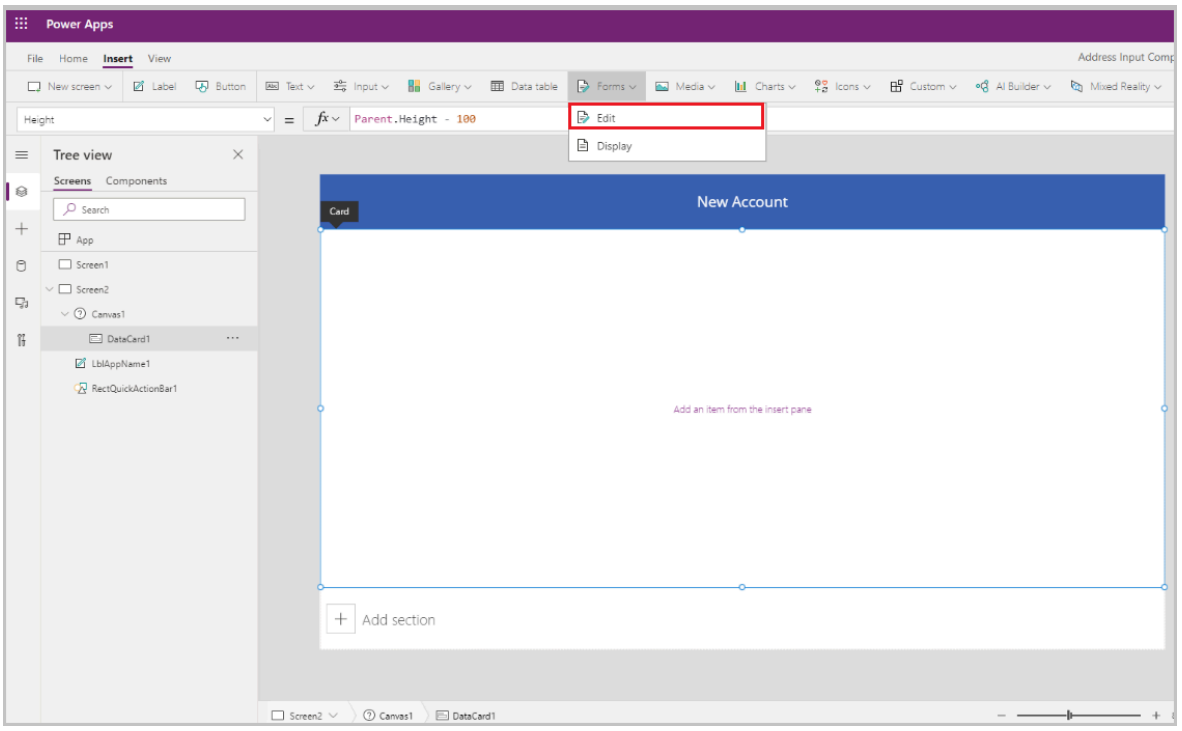
2. Select **Insert** > **New Screen** > **Scrollable** to add a new screen.



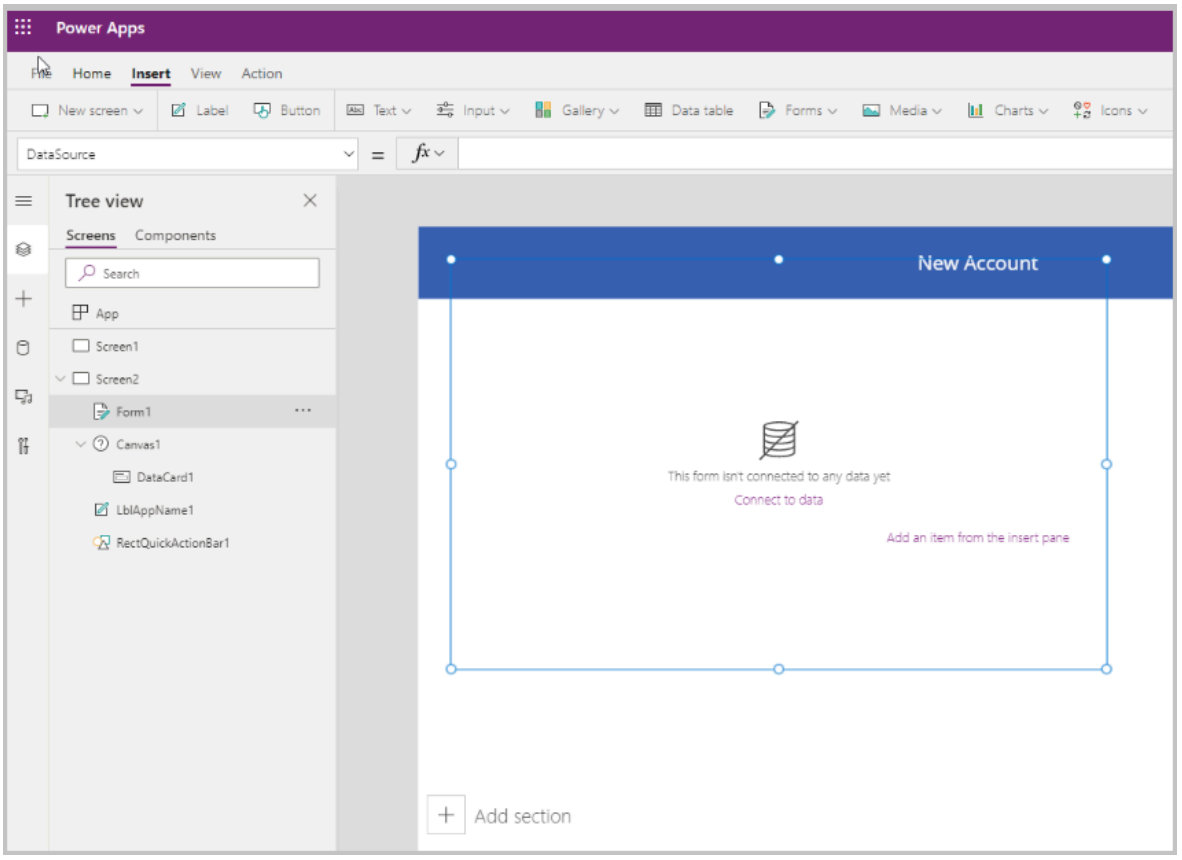
3. Change the label text to "New Account".



4. Select **Insert** > **Forms** > **Edit** to add a form to the screen.



The form control gets added



5. Update the following properties of the form:

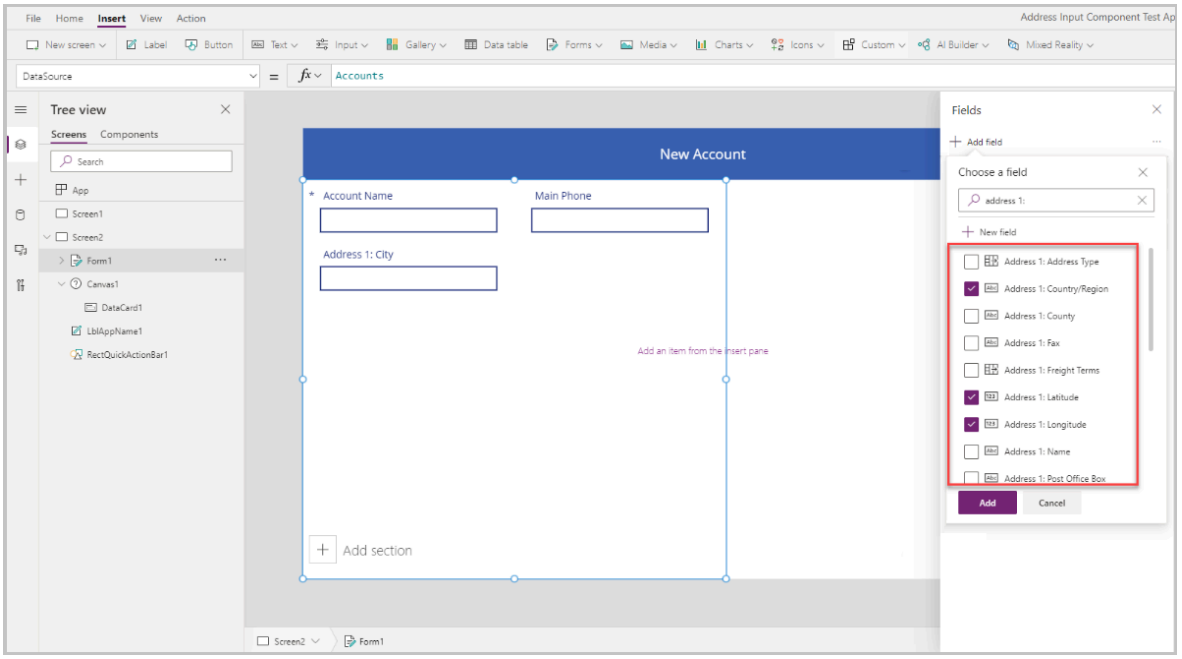
Expand table

Property	Value
Data source	Accounts

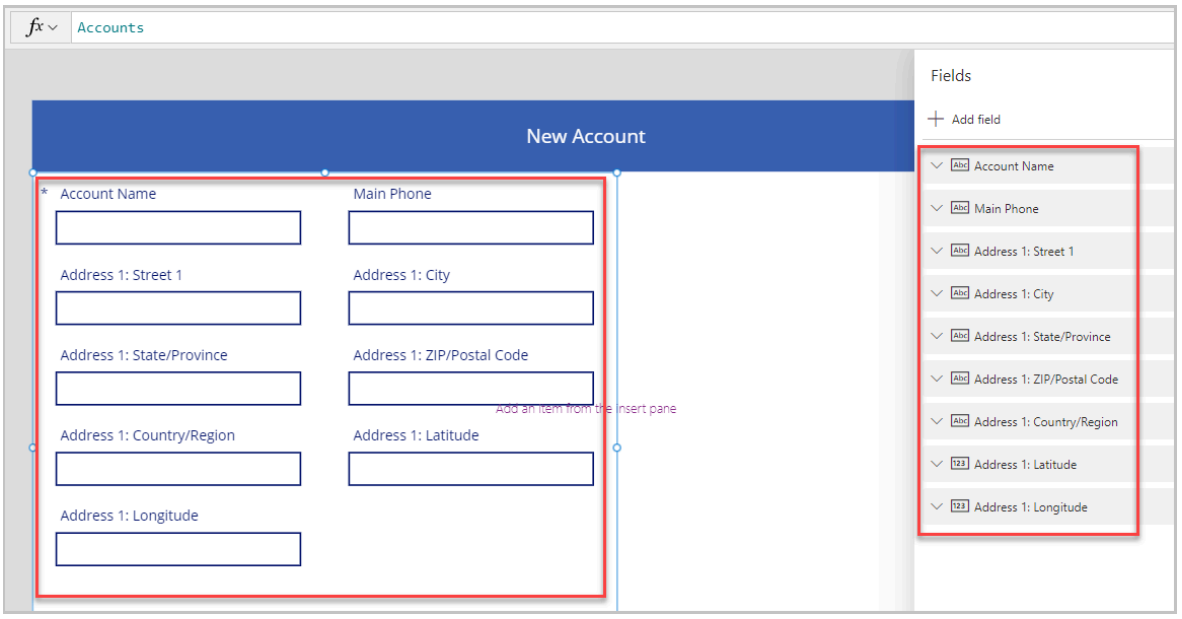
Property	Value
Columns	2
DefaultMode	`FormMode.New`

6. Select **Edit** next to fields to add more fields to the form, and select the following address fields:

    - Address 1: Street 1
    - Address 1: City
    - Address 1: State
    - Address 1: Zip/Postal Code
    - Address 1: Country/Region
    - Address 1: Latitude
    - Address 1: Longitude



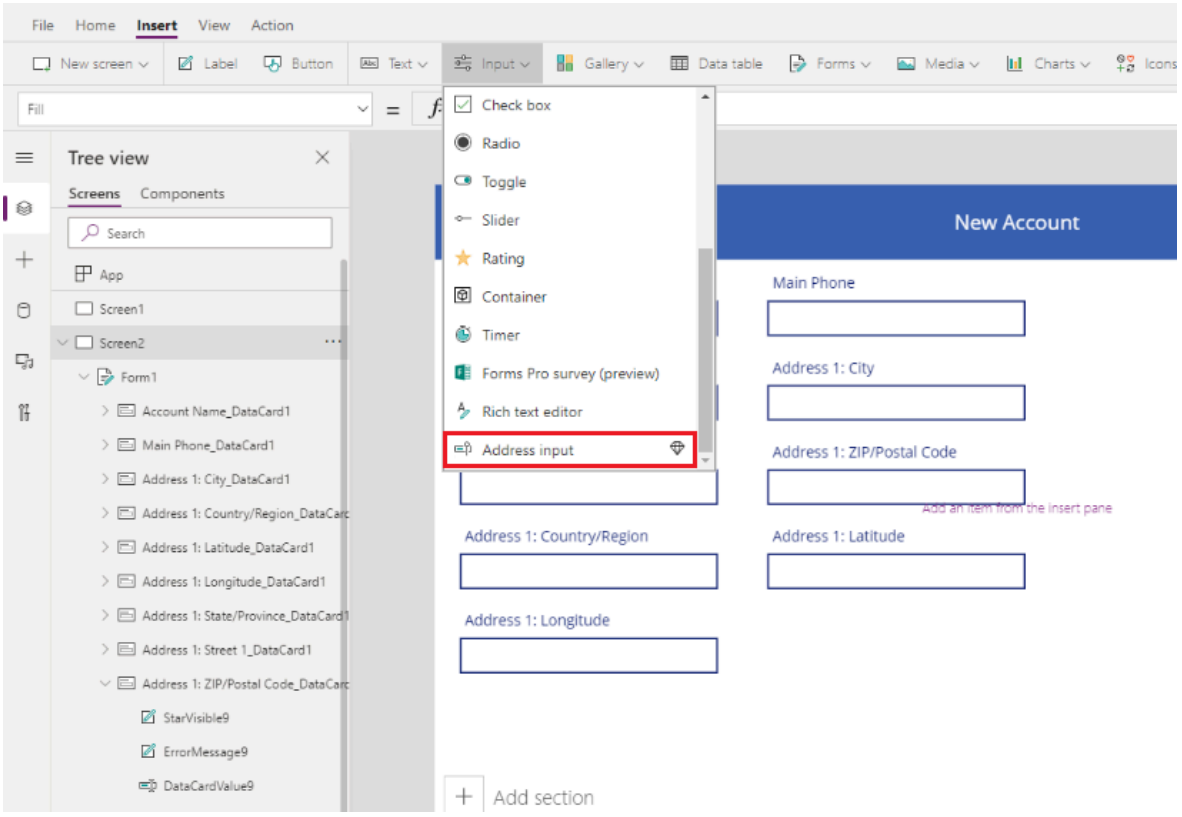
7. Adjust the order of the fields as shown below.



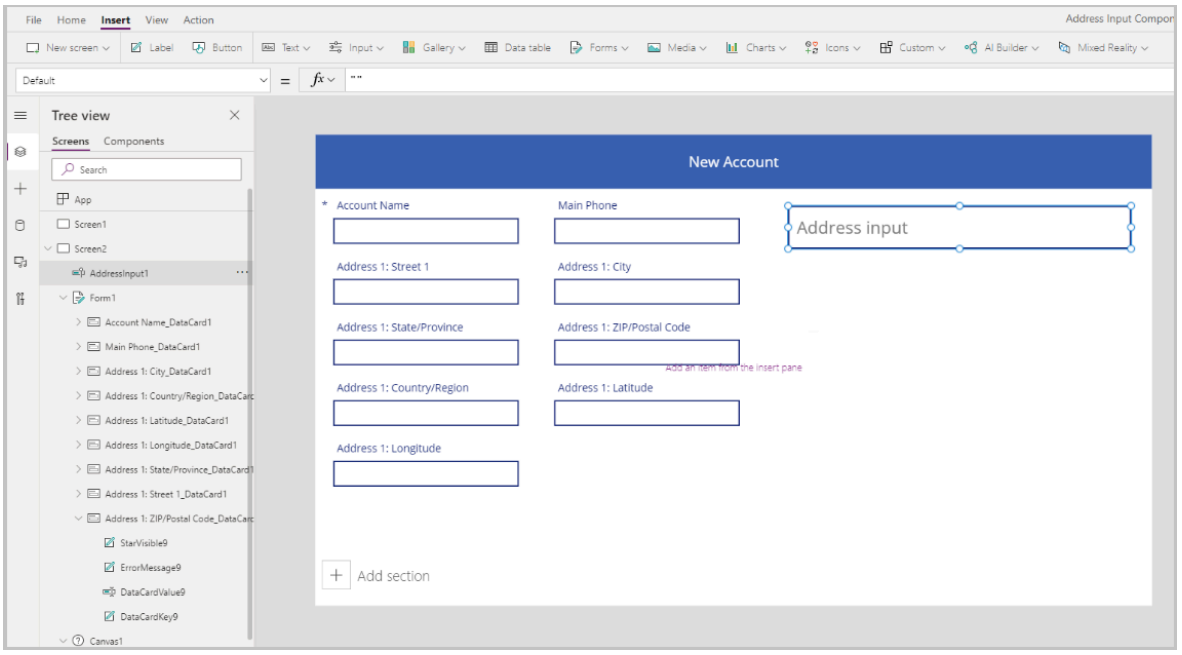
Address Input control

In this section, we'll add the **Address Input** control to the app.

1. Select **Insert** > **Input** > **Address Input** to add the control to the screen.

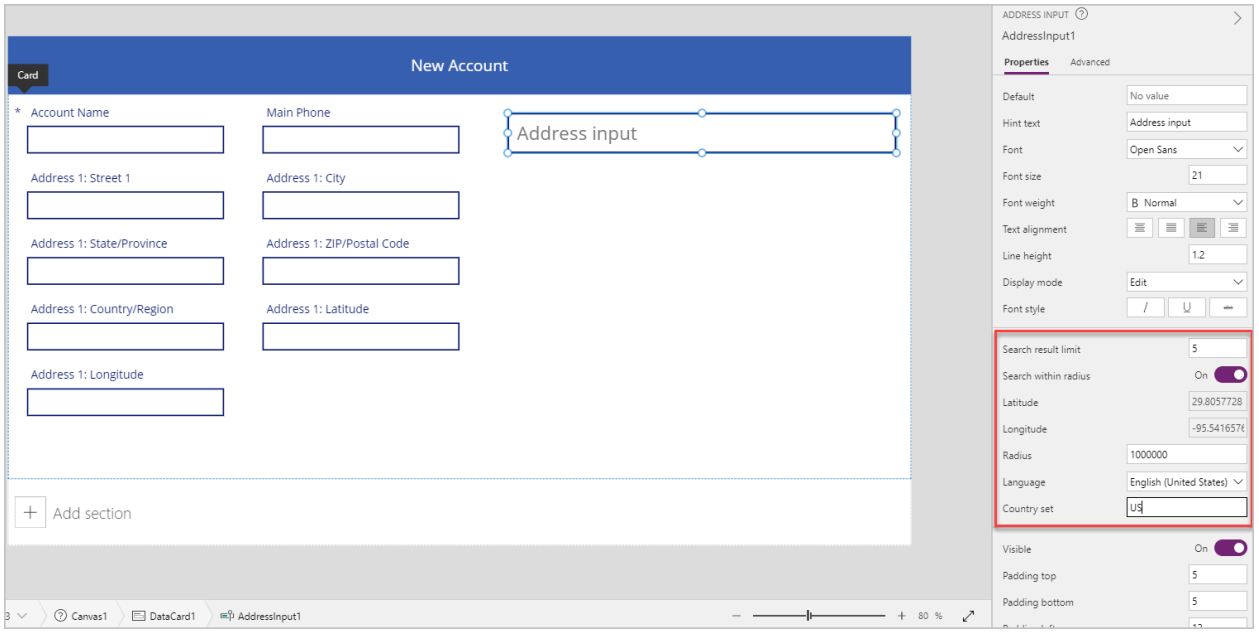


2. Move the control to the top-right side of the screen.



Configure properties for the Address Input control

In this section, we'll review and if necessary, set various properties of the address control. There are a few **Address Input** control-specific properties.



Expand table

Property	Description
Search result limit	The number of suggested addresses the control displays. We've set it to 5 in this example, so not more than five addresses will show up in search.
Search within radius	Whether the control should suggest addresses within the user-defined **Radius** of the **Latitude** and **Longitude**. We've set it to **Yes** in this example.

Property	Description
Latitude	The latitude of the center point used to geo-bias address suggestions. Requires **Search within radius** to be on. We've set it to the formula `Location.Latitude` in this example to return the latitude of the current location.
Longitude	The longitude of the center point used to geo-bias address suggestions. Requires **Search within radius** to be on. We've set it to the formula `Location.Longitude` in this example to return the latitude of the current location.
Radius	The radius, in meters, around **Latitude** and **Longitude** to constrain the address suggestions. Requires **Search within radius** to be **On**. We've set it to 100000 in this example.
Language	The language the address suggestions are returned in. We've left it with the default - "English (United States)".
Country set	Comma-separated list of countries/regions to constrain the address suggestions to, in ISO 3166 alpha-2 country codes. Examples: "US", "FR", "KW". We've it as US in this example.

Configure output properties for the Address Input control

The control outputs various properties when a user interacts with it inside an app. You can use these outputs in other controls or to customize the experience.

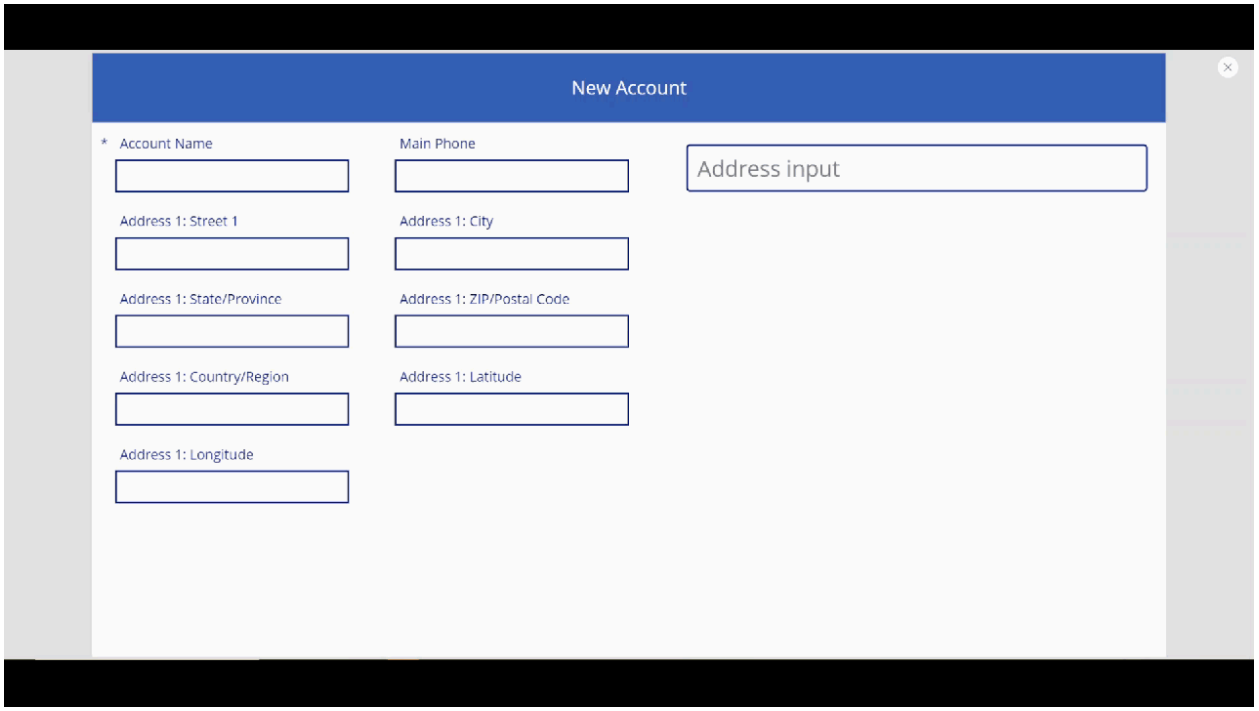
The following table lists the output properties available.

Expand table

Property	Description
UserInput	Text the user has typed in the input box.
SelectedLatitude	Latitude of the user-selected address in the input field.
SelectedLongitude	Longitude of the user-selected address in the input field.
SearchResultJson	The search result (based on the UserInput property), displayed as a string in JSON format.
FreeformAddress	Selected address from the list of suggested addresses.
LocalName	An address control that represents the name of a geographic area or locality that groups multiple addressable objects for addressing purposes, without being an administrative unit.
PostalCode	Postal code.

Property	Description
ExtendedPostalCode	Extended Postal Code.
CountryCode	Country code.
Country	Country.
CountryCodeISO3	Country code in ISO alpha-3 format.
CountrySubdivisionName	Country subdivision name.
StreetName	Street name.
StreetNumber	Street number.
Municipality	Municipality.
MunicipalitySubdivision	Municipality subdivision.
CountryTertiarySubdivision	Country tertiary subdivision.
CountrySecondarySubdivision	Country secondary subdivision.
CountrySubdivision	Country subdivision.

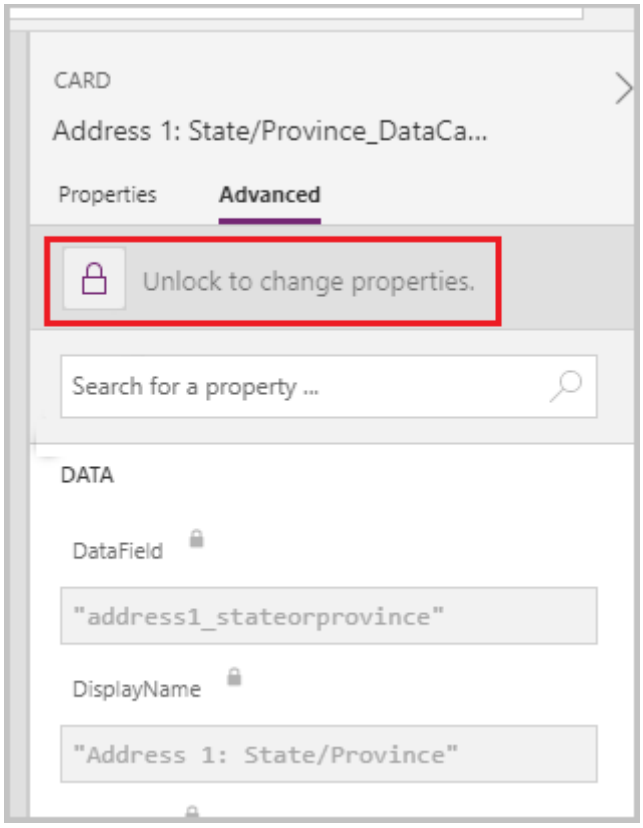
When you run the app and start typing an address, it will show addresses that match the entered value and are located only within 100,000 meters of the current location. Also, notice that it doesn't show more than five address suggestions at a time when you start typing in the address.



Using the above control, we'll capture the address in the address fields of the form to create a new account. This step is useful so that the user doesn't have to type in each of the address elements individually.

We'll set the data card values to the appropriate property value from the address input.

> **Tip**
>
> The default values of the data card might be locked. To unlock them, select the data card and go to the **Advanced properties**, and then select **Unlock to change properties**.

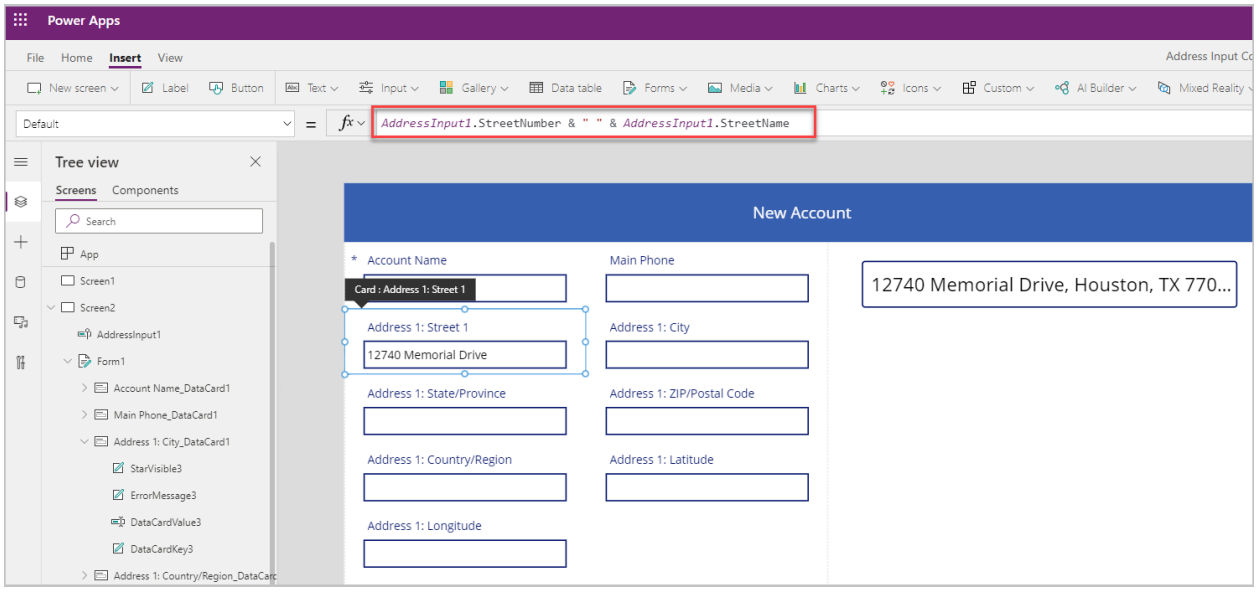


Expand table

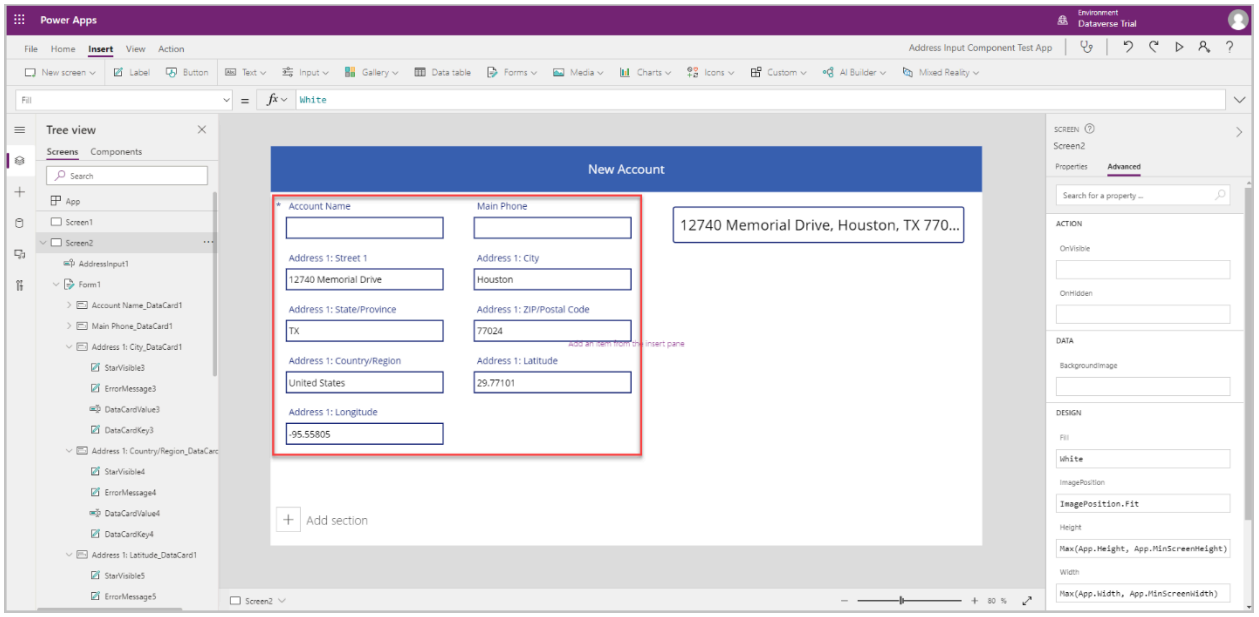
Data card	Value
Address 1: Street 1	`AddressInput1.StreetNumber & " " & AddressInput1.StreetName`
Address 1: City	`AddressInput1.Municipality`
Address 1: State/Province	`AddressInput1.CountrySubdivision`
Address 1: Zip/Postal Code	`AddressInput1.PostalCode`
Address 1: Country/Region	`AddressInput1.Country`

Data card	Value
Datacard	
Address 1: Latitude	`AddressInput1.SelectedLatitude`
Address 1: Longitude	`AddressInput1.SelectedLongitude`

Example for **Address 1: Street 1** data card:



The form gets populated with all the address fields when an address is selected in the **Address Input** control.



Map control

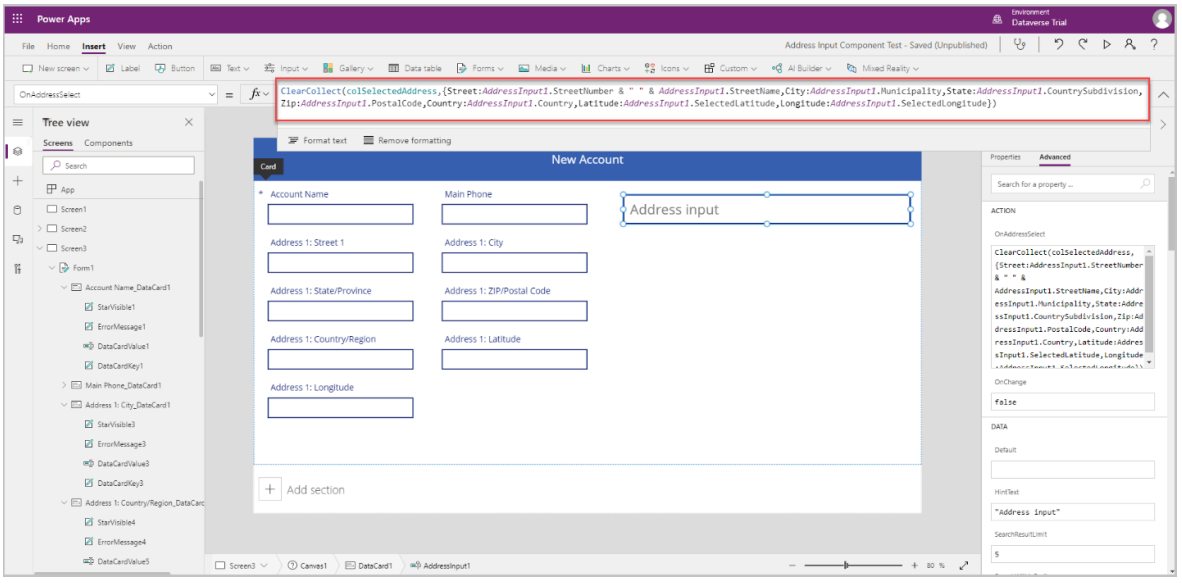
In this section, we'll see how to add the **Map** control on the app to show the selected location on the map.

1. Before adding the **Map** control, we need to create a collection to capture the address from the address input – this collection will be used as the data source for the map.

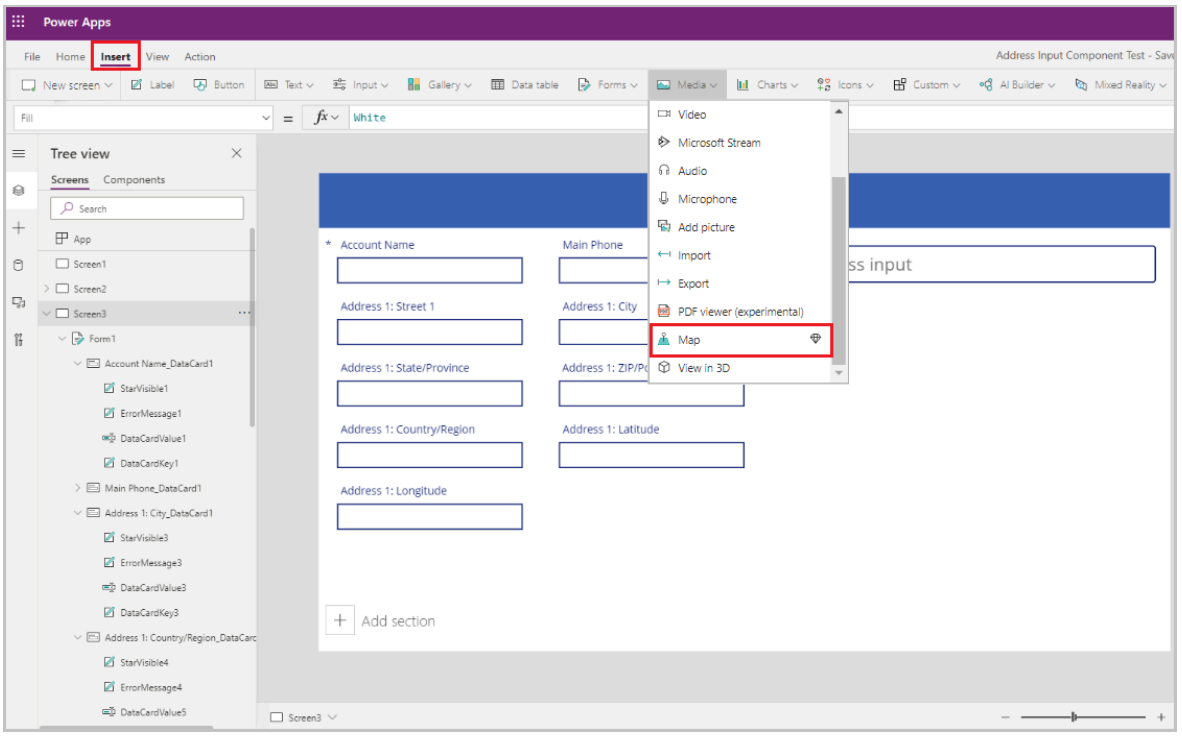
   On the **OnAddressSelect** property of the **Address Input** control, enter the following formula to create a collection that captures the address data.

```
Power Fx

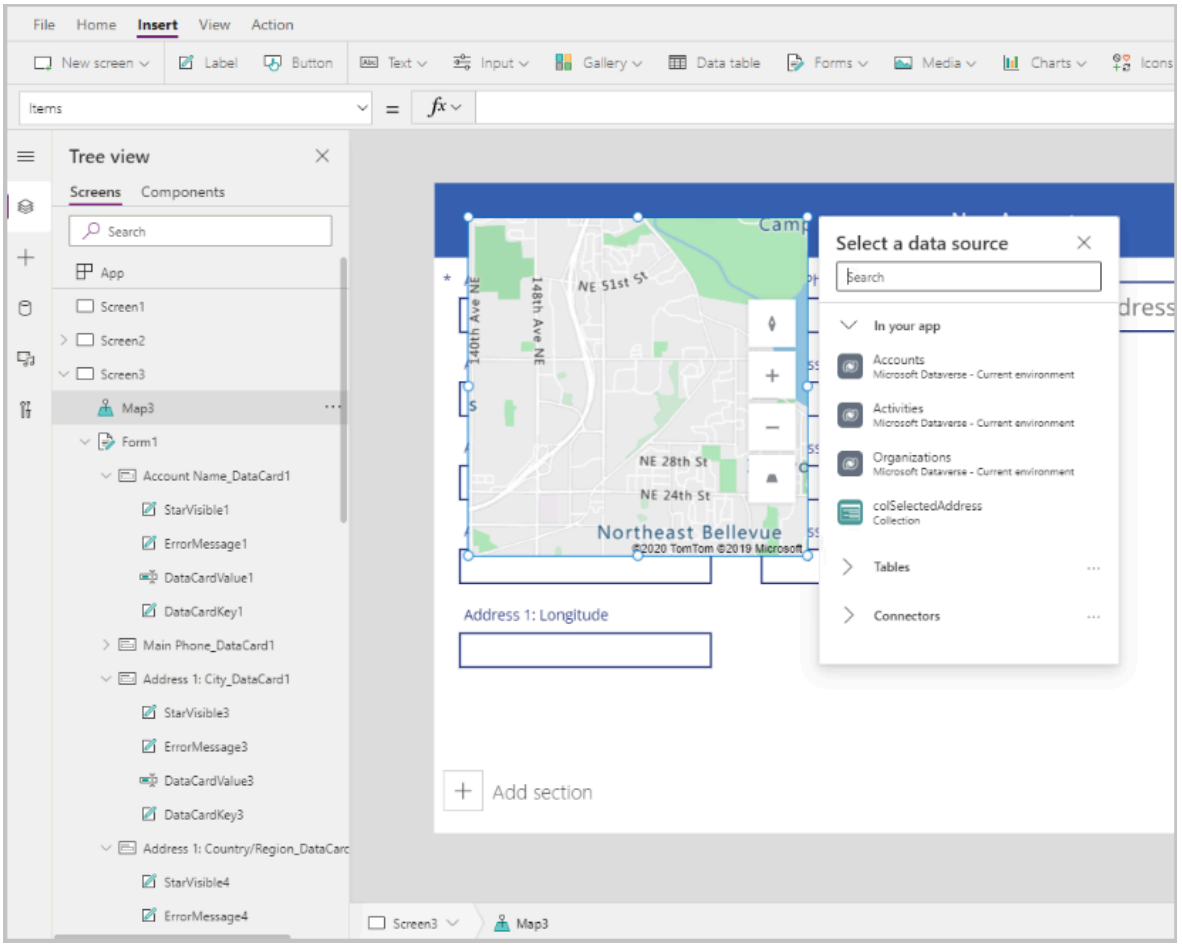
ClearCollect(
    colSelectedAddress,
    {
        Street: AddressInput1.StreetNumber & " " &
AddressInput1.StreetName,
        City: AddressInput1.Municipality,
        State: AddressInput1.CountrySubdivision,
        Zip: AddressInput1.PostalCode,
        Country: AddressInput1.Country,
        Latitude: AddressInput1.SelectedLatitude,
        Longitude: AddressInput1.SelectedLongitude
    }
)
```



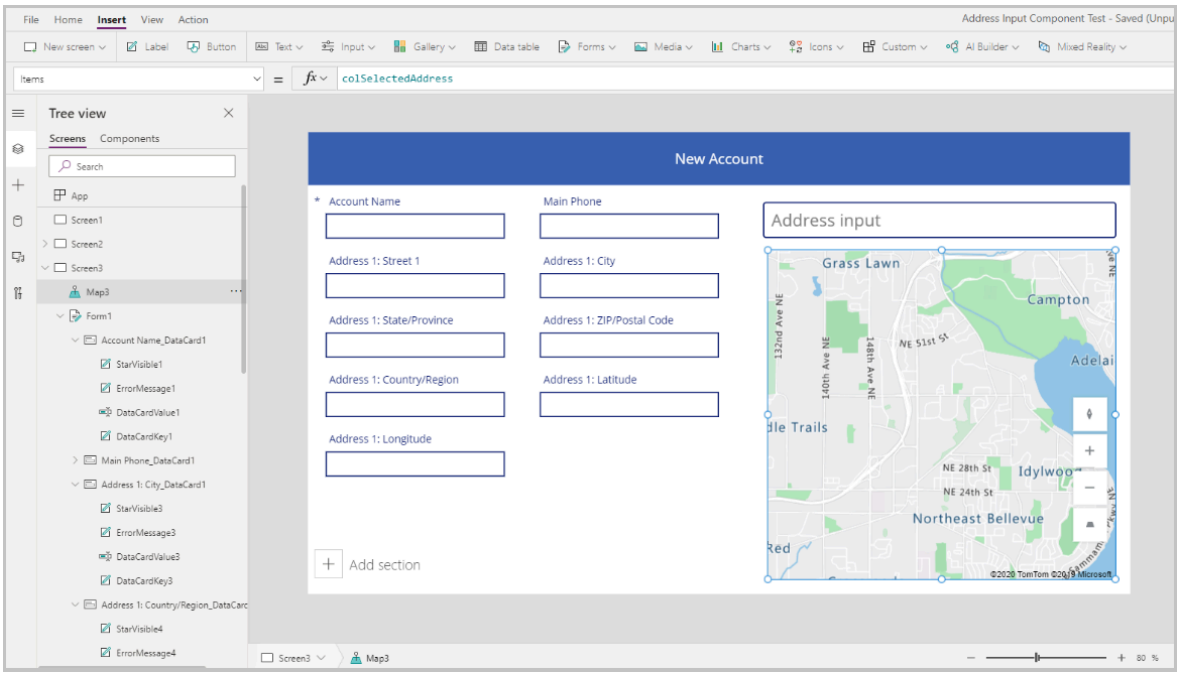
2. Select an area outside of the **Address Input** control, and select **Insert** > **Media** > **Map** to add the map control to the screen.



3. Select the collection as the data source.



4. Move the map below the address input section.



Configure properties for the Map control

In this section, we'll review and if necessary, set various properties of the map control.

The following table lists the properties available.

Expand table

Property	Description
Data source(Items)	Data source (table) that lists a predefined set of longitudes and latitudes to display as map pin on the map when it's loaded. Map each of the columns in your data by using the *ItemAddresses*, *ItemLongitudes*, *ItemLatitudes*, and *ItemLabels*.
Use default location	Whether the map initializes at a default location set by the user.
Default longitude	Longitude the map would go to when it's loaded if **Use default location** is enabled.
Default latitude	Latitude the map would go to when it's loaded if **Use default location** is enabled.
Default zoom level	Zoom level the map would be set to when it's loaded if **Use default location** is enabled.
Show current location	Whether the map should display the current location of the user.
Current location latitude	The latitude of the current location of the user if **Show Current Location** is enabled.

Property	Description
Current location longitude	The longitude of the current location of the user if **Show Current Location** is enabled.
Satellite view	Whether the style of the map is a satellite view or a road view.
Cluster pins	Whether the map pins are clustered.
Zoom control	Whether the zoom control appears on the map.
Compass control	Whether the compass control appears on the map.
Pitch control	Whether the pitch control appears on the map.
Pin color	The color of the pins.
ItemsLabels	A column in Items with the strings you want to use as labels for the pins.
ItemsAddresses	A column in Items with the strings that represent the location of the pins.
ItemsLongitudes	Name of the column in the table in your data source with floating-point numbers that represent the longitude position of the pins.
ItemsLatitudes	Name of the column in the table in your data source with floating-point numbers that represent the latitude position of the pins.
ItemsColors	Color of the pins.
ItemsIcons	Icon of the pins.
Items	Name of the table in your data source that contains all the records that you want to plot in the map by using pins. Each row must have an entry for the label, longitude, and latitude for each row.
OnMapClick	How the map responds when any location is selected.
OnSelect	How the app responds when a map pin is selected.
OnLoad	How the app responds when the map finishes loading.
OnItemsChange	How the app responds when the map pins change.
Show info cards	Whether the informational cards appear on the pins of the map.
Show shapes	Whether the shapes in **Shapes_Items** appear on the map.
Show shape labels	Whether the labels appear on the shapes of the map.
Enable shape drawing	Whether the drawing tools control appears on the map.

Property	Description
Enable shape deleting and label editing	Whether shapes can be deleted and their labels can be edited on the map.
Shapes_Items	Name of the table in your data source that contains all the records with the GeoJSON objects that you want to show in the map as shapes.
ShapeGeoJSONObjects	Name of the column in the table in your data source with strings that represent the GeoJSON objects of the shapes.
ShapeLabels	A column in **Shapes_Items** with the strings you want to use as labels for the shapes.
ShapeColors	Color of the shapes.
OnShapeSelected	How the app responds when a shape on the map is selected.
OnShapeCreated	How the app responds when a shape on the map is created.
OnShapeEdited	How the app responds when a shape on the map is edited.
OnShapeDeleted	How the app responds when a shape on the map is deleted.

Configure output properties for the Map control

The Map control outputs various properties when a user interacts with it inside an app. You can use these outputs in other controls or to customize the experience.

The following table lists the output properties available.

Expand table

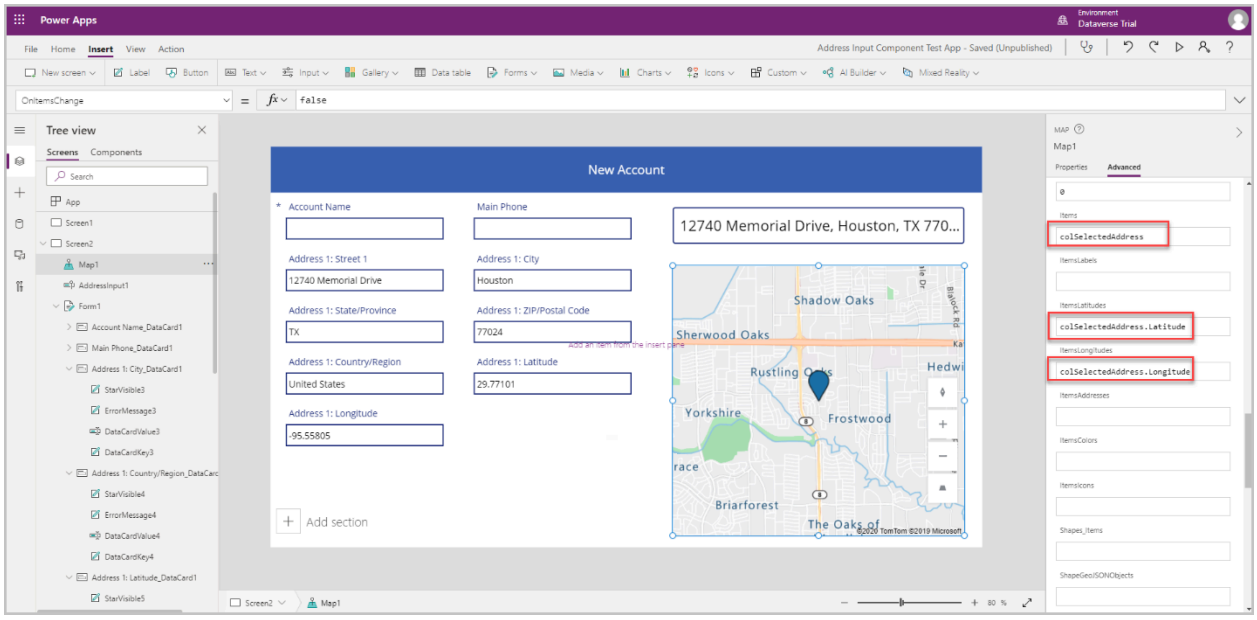
Property	Description
CenterLocation	Center location of the map as either `.Latitude` or `.Longitude`. The output will be an integer. For example, calling `Map1.CenterLocation.Latitude` will output a single integer such as "47.60357".
Selected	The selected pin on the map.
SelectedItems	The selected pin or pins of the selected cluster on the map.
GeocodedItems	The geo-coded locations of the pins on the map.
ClickedLocation	The last clicked location on the map as either `.Latitude` or `.Longitude`.

Property	Description
Shapes_Selected	The record of the selected shape from **Shapes_Items**.
Shapes_SelectedItems	The records of the selected overlapping shapes from **Shapes_Items**.
SelectedShape	The selected shape on the map with `.Perimeter` and `.Area`.
DeletedShape	The last deleted shape on the map with `.Perimeter` and `.Area`.
GeoJSON	The list of shapes on the map in Feature Collection GeoJSON format.

To drop a pin on the address entered in the address input, we'll use the collection we created on the **OnAddressSelect** property and use that in the map control.

Expand table

Property	Value
Items	`colSelectedAddress`
ItemsLatitudes	`colSelectedAddress.Latitude`
ItemsLongitude	`colSelectedAddress.Longitude`



Some of the properties of the pin can be customized per location pin are explained below:

1. **ItemsColors** - To update the color of the pin to a different color for each location, add a column to the collection **Color: Red**, and use that in the **ItemsColors** data property of the **Map** control.

2. **ItemsLabels** - To update the label of the pin to a different label showing the address for each location, add a column to the collection **Label:AddressInput1.FreeformAddress**, and use that in the **ItemsLabels** data property of the **Map** control.

3. **ItemsIcons** - To change the icon of the pin for each location, add a column to the collection and use that in the **ItemsIcons** data property of the **Map** control. In this example, we'll add a triangle icon with the formula as `Icon: triangle`.

   > **Tip**
   >
   > For the complete list of icons, go to **List of image templates**.

   Power Fx

   ```
   ClearCollect(
       colSelectedAddress,
       {
           Street: AddressInput1.StreetNumber & " " &
   AddressInput1.StreetName,
           City: AddressInput1.Municipality,
           State: AddressInput1.CountrySubdivision,
           Zip: AddressInput1.PostalCode,
           Country: AddressInput1.Country,
           Latitude: AddressInput1.SelectedLatitude,
           Longitude: AddressInput1.SelectedLongitude,
           Label: AddressInput1.FreeformAddress,
           Color: Red,
           Icon: Triangle
       }
   );
   ```

After adding these to the collection, go to the **Advanced** tab of the **Map** control, and update the **ItemsColors**, **ItemsLabels** and **ItemsIcons** properties.

Run the app in preview mode to test. The map shows the location selected in the address input with a triangle icon and the address shows up as a label on the map.

Create an app using the Measuring Camera control

Article • 12/16/2022

You can use the Measuring Camera control in your app to let users measure distance, area, and volume. During the measurement, you create two-dimensional and three-dimensional polygons that can be used to confirm how a certain-sized object would fit within a space.

The control creates a button in your app. When app users select the button, it shows a live camera feed of the device. App users can then specify a starting point, and one or multiple sequential endpoints to measure between. The instances of measured segments are shown directly on the live camera feed.

When the user exits the control, the measurements that were taken are captured in the **Measurements** property so they can be saved or stored.

Screenshots taken during the mixed reality experience are stored in the **Photos** property for viewing within the app.

In this article, we'll create a screen in an app to use the **Measuring camera** control to measure the area of a user-defined space as well as view a photo of the space that was measured.

Watch this video to learn how to build mobile apps with Measuring Camera control: https://learn-video.azurefd.net/vod/player?id=94d7ae60-3cb4-41e5-80bd-d8212fa3e4a8&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fhow-to%2Fbuild-apps-measure-in-mr

Prerequisites

See prerequisites for mixed-reality capable devices.

Create the app with Measuring Camera control

1. Open an app in Power Apps Studio.
2. Select the **Insert** tab.
3. Expand **Media**.

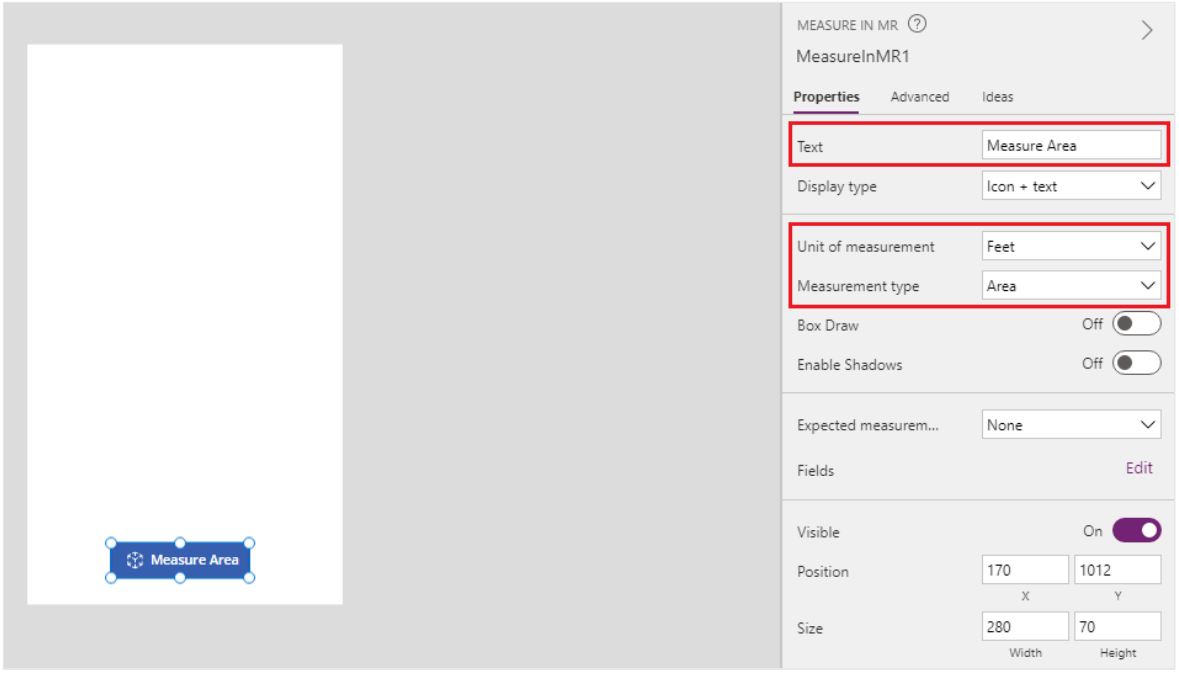
4. Select the **Measuring camera** control to insert it on the screen.

5. Position the control near the bottom of the screen.

6. Change the following properties for the control using the property pane on the right-side of the screen.

Expand table

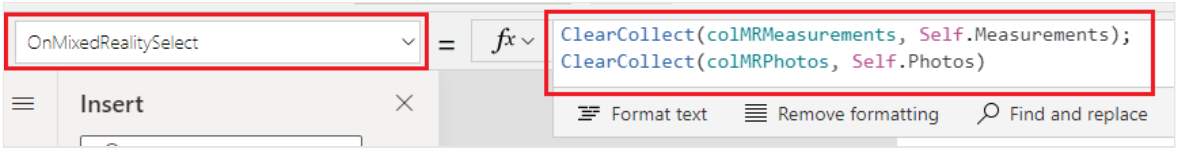
Property	Value
Text	Measure Area
Unit of measurement	Feet
Measurement type	Area



7. Select the Advanced tab and change the **OnMixedRealitySelect** property to the following formula:

Power Fx

```
ClearCollect(colMRMeasurements, Self.Measurements);
ClearCollect(colMRPhotos, Self.Photos)
```



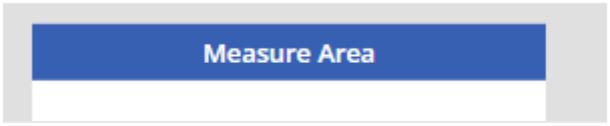
This formula will allow the user to define areas to be measured in square feet and store the most recent results of the measurements in a collection named **colMRMeasurements**, and the most recent photos in a collection named **colMRPhotos**.

8. Add a text label to the screen and move it to the top-left corner of the screen.

9. Change the following properties of the added text label:

Expand table

Property	Value
Text	Measure Area
Font size	24
Font weight	Semibold
Text alignment	Center
Width	Parent.Width
Color	`RGBA(255, 255, 255, 1)`
Fill	`RGBA(56, 96, 178, 1)`



This label provides a header for the screen.

10. Add an image control, and move it just below the header label.

11. Change the following properties for the image control:

Expand table

Property	Value
Image	`First(colMRPhotos).ImageURI`
Border Thickness	2

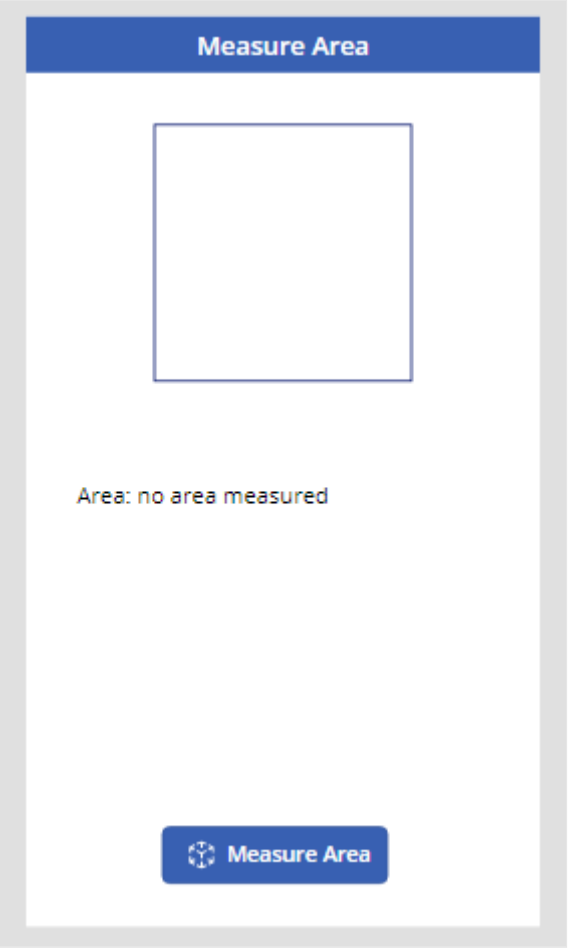
The image control will display the first image taken from the **Measuring camera** control.

12. Add another label to the screen, positioning it below the image control.

13. Change the **Text** property of the label to the following formula:

```
Power Fx

"Area: " & If(IsEmpty(colMRMeasurements), "no area measured",
First(colMRMeasurements).Area & " sq. " &
First(colMRMeasurements).Unit)
```



This label will display the first area measurement and unit type that is collected from the **Measuring camera** control. If there's no measurement to be returned, the text will show **Area: no area measured** to let the user know that no value is present.

Test the app

> **Tip**
>
> Watch the video embedded at the top of this article to see how the app works.

Now that all the controls have been added, save and publish the app. On a mixed-reality capable device (as defined in the Prerequisites section), open the app, and press the **Measure Area** button. This action will open the **Measuring camera** experience, allowing the user to define an area to be measured.

Follow the on-screen instructions to calibrate the device by slowly moving it left and right while pointing the camera at a surface to be measured. Once the calibration is complete, you'll see an array of dots on the surface as well as a circle and dot reticle in the center of the screen. This reticle is used to define lengths, areas, and volumes by using the + button to add points and line segments.

Photos can be captured using the camera button. These photos will show the lengths, areas, and volumes defined by the user.

There's an undo button to undo any placed points.

Begin by placing a point using the + button. You'll notice that an orange line and measurement now appear connected to the point you placed. Place a second point and notice how a line with measurement appears between the two points you place. Continue placing points until the desired shape has been fully defined. To close a shape, place the reticle on the first point made and use the + button. You'll notice that the center point of the reticle changes color from white to green, indicating that the shape can be closed. If two of the sides of the shape intersect, or you try to close a shape using any other point than the first one. You'll notice that the center point of the reticle changes from white to red, indicating that a point cannot be placed there.

Once an area has been fully defined, position the device so that a picture can be taken of the area you defined and use the camera button to do so. The select the **Submit** button. A confirmation dialog will appear, asking if you've finished with your measurements. If you have more measurements to enter, select **Cancel** to return to the MR environment. If you're finished, select **Submit** to be taken back to the app screen.

You'll see the first picture taken as well as the calculated area of the shape you defined as well as the units, in this case square-feet.

The measurement and photo can then be used like any other photo or text field in Power Apps, for instance to be sent in an email or stored in a table in Microsoft Dataverse.

Create a canvas app with deep link to a specific screen

Article • 12/16/2022

A common scenario when building apps is the need to share a "deep link" to a specific screen. Deep links are useful when you want to get users straight to a specific screen and data rather than asking them to navigate from the "home" screen of your app.

To deep link into Power Apps, you'll use this URL syntax: `https://apps.powerapps.com/play/{App ID}?{Query}`.

In this syntax:

- **App ID**—ID of the app. Go to Power Apps > **Apps** > Select your app > **Details**.
- **Query**—The query text allows you to supply the data to deep link to. You'll need to make some code changes to your canvas app to use the provided parameters to open the app using the query URL.

In this article, you'll learn about how to:

- Set up a canvas app to handle the query parameter.
- Create a UI for emailing a deep link directly from a screen of your app.
- Use the app to browse to a specific account, send an email with the deep link, and use the link from the received email to open the app directly to that account.

Prerequisites

- Power Apps license
- If you're new to Power Apps, familiarize yourself with Power Apps basics by generating an app and then customizing that app's controls, gallery, forms, and cards.
- To create an app, you must be assigned to the Environment Maker security role.

Create the app

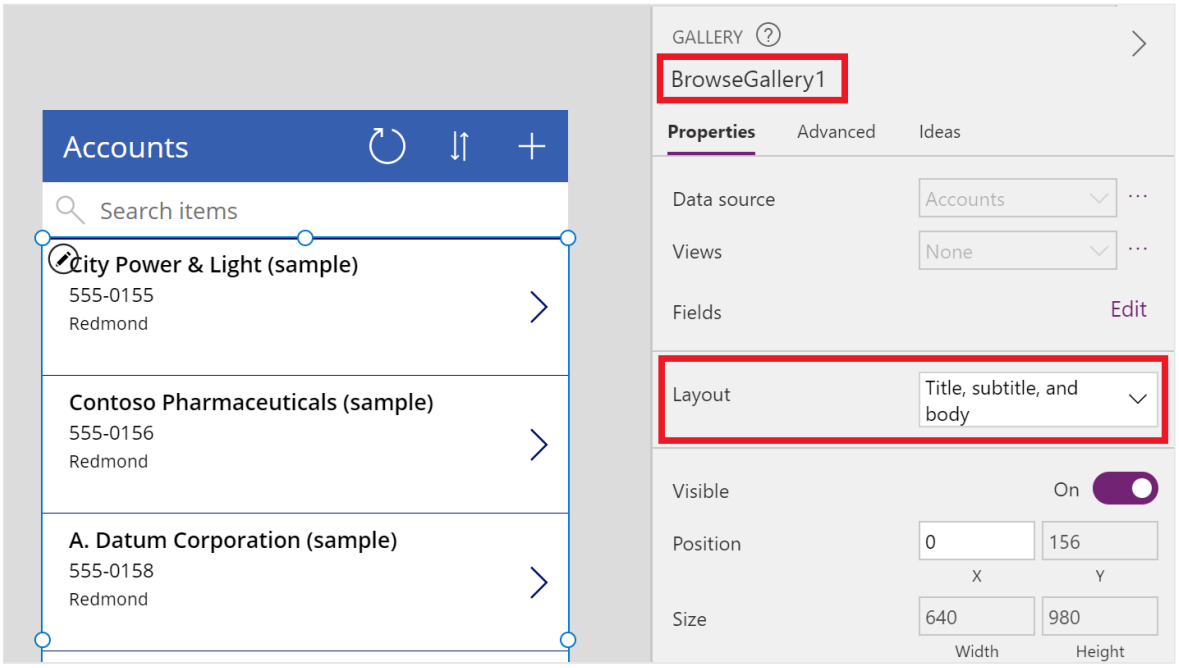
Create an app using the **Accounts** table in Microsoft Dataverse.

Your app opens to the **BrowseScreen**, that shows a list of accounts in a gallery. By default, this gallery shows an email address, a city, and an account name. The app also contains **DetailScreen** and **EditScreen**.

Update navigation

Now you'll set the navigation to use a context that we'll use to take the user to another screen.

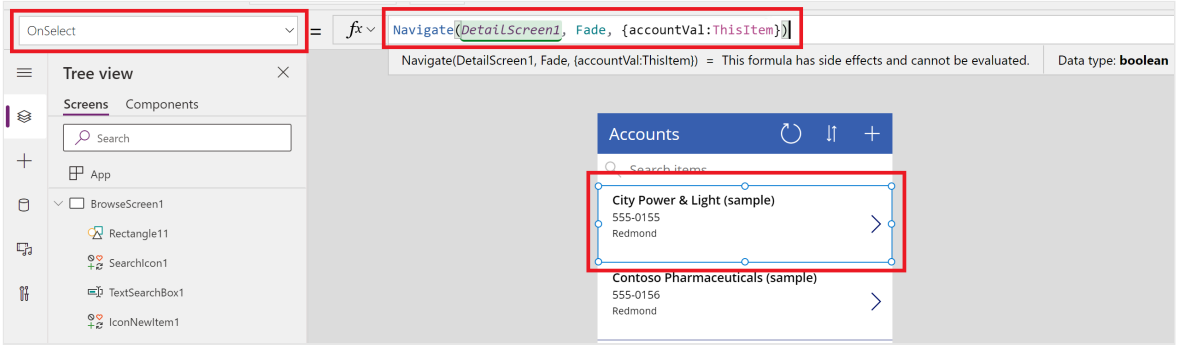
1. On **BrowseScreen** screen, select **Layout** under gallery properties, and select **Title, subtitle and body**



2. Select first record of **BrowseGallery** gallery. And then, under **OnSelect**, enter the following:

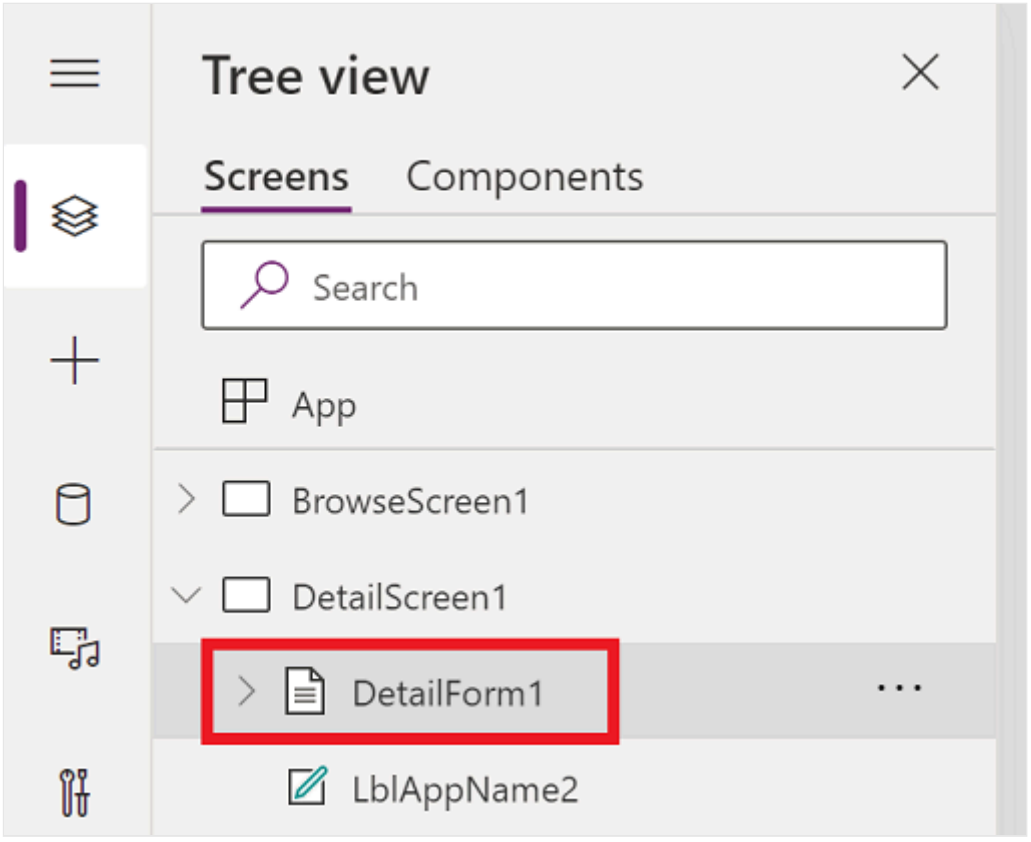
```
Power Fx

Navigate(DetailScreen1, Fade, {accountVal:ThisItem})
```

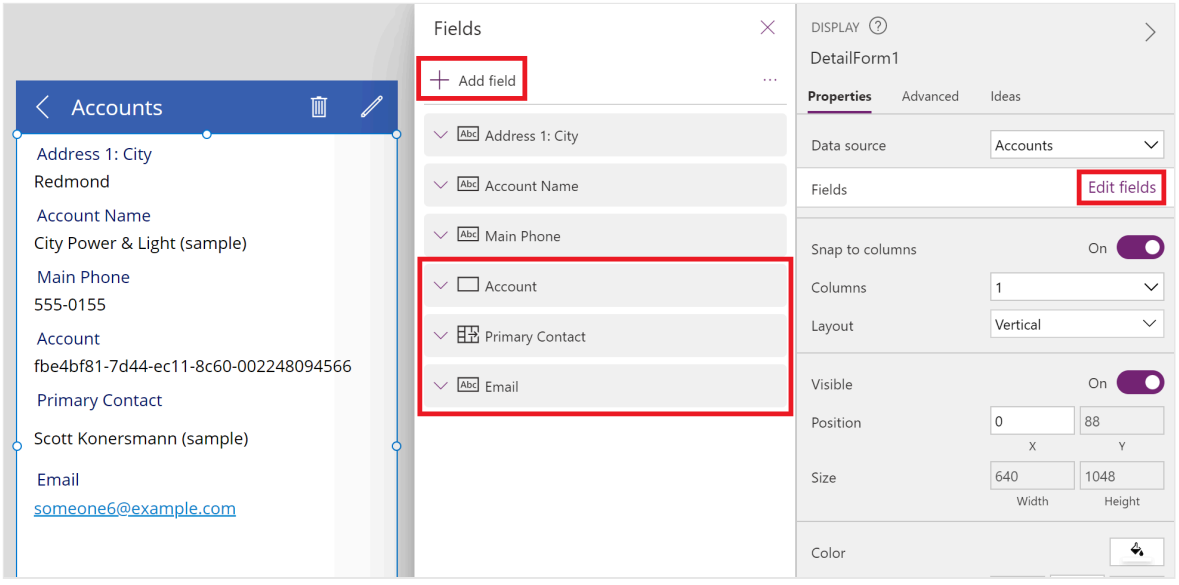


The Navigate() function creates a context variable called **accountVal**. This variable is populated whenever you select a record from the gallery. Upon selecting record, you'll be taken to the **DetailScreen** with the selected value (in this example, account) in **accountVal**.

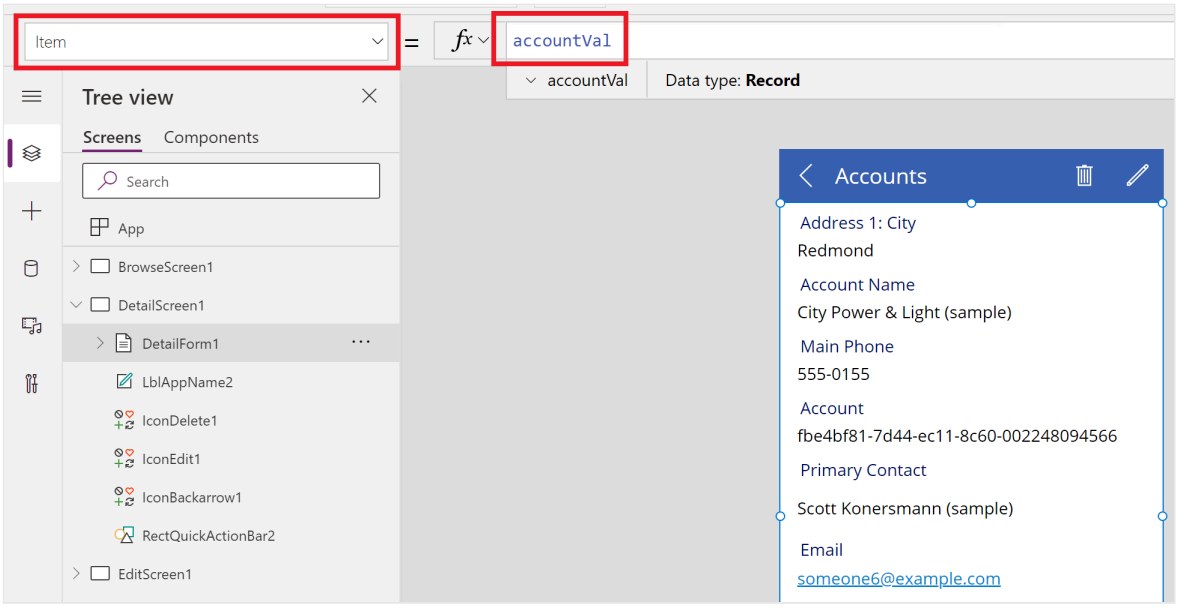
3. From the **Tree view** on the left-side of the screen, expand **DetailScreen1**, and select **DetailForm1**.



4. From the properties pane on the right-side of the screen, select **Edit fields**, and add **Account**, **Primary Contact**, and **Email** fields.



5. Select **DetailForm**, and set **Item** to **accountVal**.

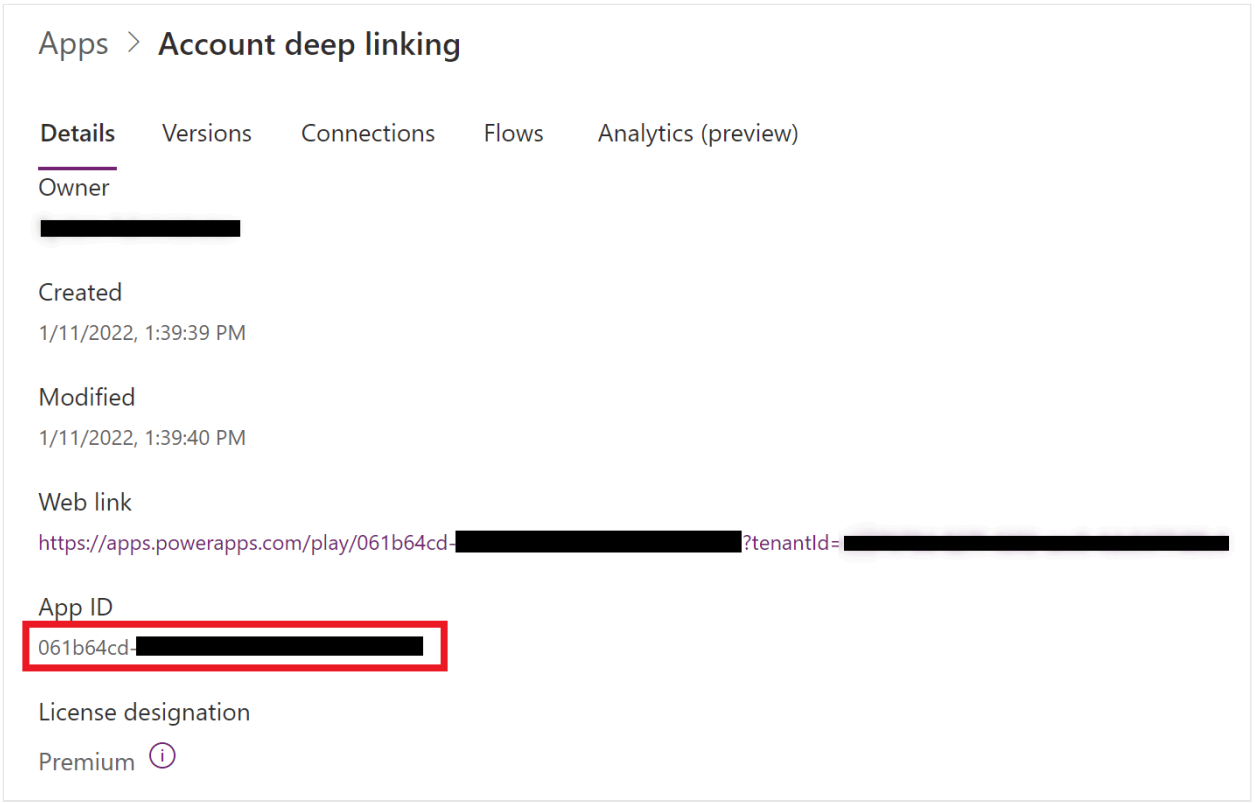


6. Save with the name "Account deep linking".

Get the App ID

App ID is a unique GUID representing a given app, and generated when you save the app to cloud.

To get the **App ID**, open a new tab and go to Power Apps > **Apps** > Select your app > **Details**. More information: Get an App ID



Enable deep link to a screen

The goal of this example is to take users to the **DetailsScreen1** when the app is launched with the **accountId** query parameter as part of the app URL. For this purpose, we'll use function Param() that retrieves the query string parameter supplied while launching the app.

1. Select **App** from the **Tree view** on the left-side of the screen.

   > **Tip**
   >
   > If you've closed Power Apps Studio, reopen the saved "Account deep linking" app by **editing** the app.

2. Select **OnStart** property from the list of properties.

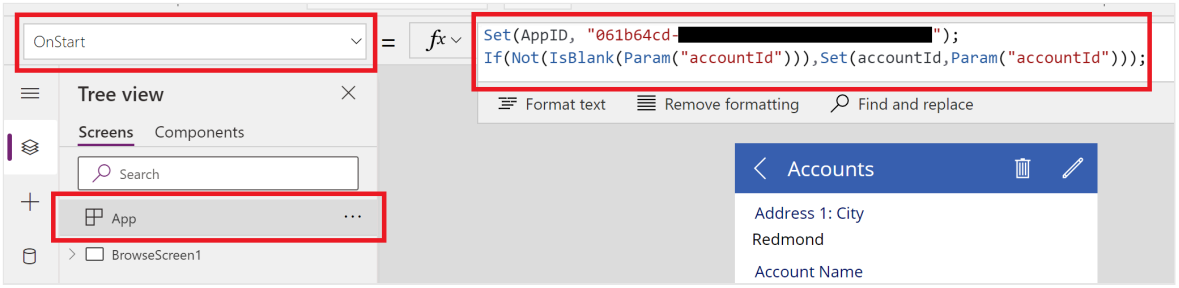
3. To store the **App ID** value, update the **OnStart** property formula as below.

   ```
   Power Fx

   Set(AppID, "GUID");
   If(Not(IsBlank(Param("accountId"))),Set(accountId,Param("accountId")));
   ```

   In this formula, function Set() sets the **App ID** to the GUID of the app. And function Param() stores the value in the **accountId** variable, when not blank.

   > **Note**
   >
   > Ensure you replace "GUID" in the above formula to your App ID as appropriate.

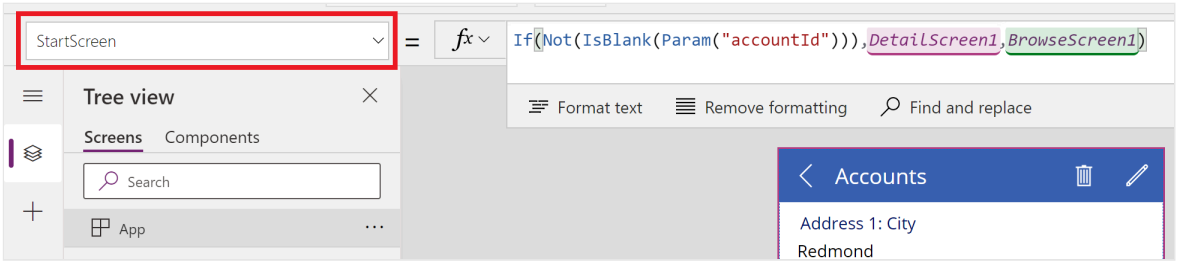
   


4. Select **StartScreen** property for the app, and add the following:

   ```
   Power Fx

   If(Not(IsBlank(Param("accountId"))),DetailScreen1,BrowseScreen1)
   ```

This function checks if the Param is blank, then stay on the **BrowseScreen1**. Else, go to **DetailScreen1**.



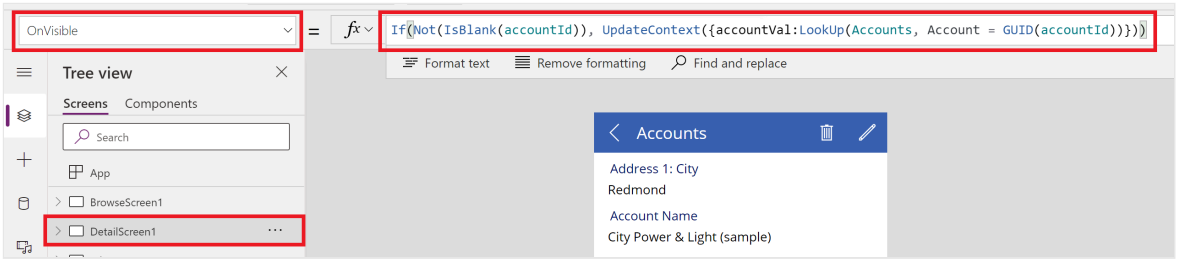
5. Select **DetailScreen1** from the **Tree view**.

6. Select **OnVisible** property, and enter the following:

```
Power Fx

If(Not(IsBlank(accountId)), UpdateContext({accountVal:LookUp(Accounts,
Account = GUID(accountId))}))
```

This function uses **accountId** stored from the previous step to set **accountVal** variable.



Create the deep link URL

Your app is now configured to receive **accountId** as the parameter that contains the GUID for an account from the **Accounts** table. And when this parameter is provided with the request to the app, the app will directly open the details screen (**DetailScreen1**) with the given **accountId**.

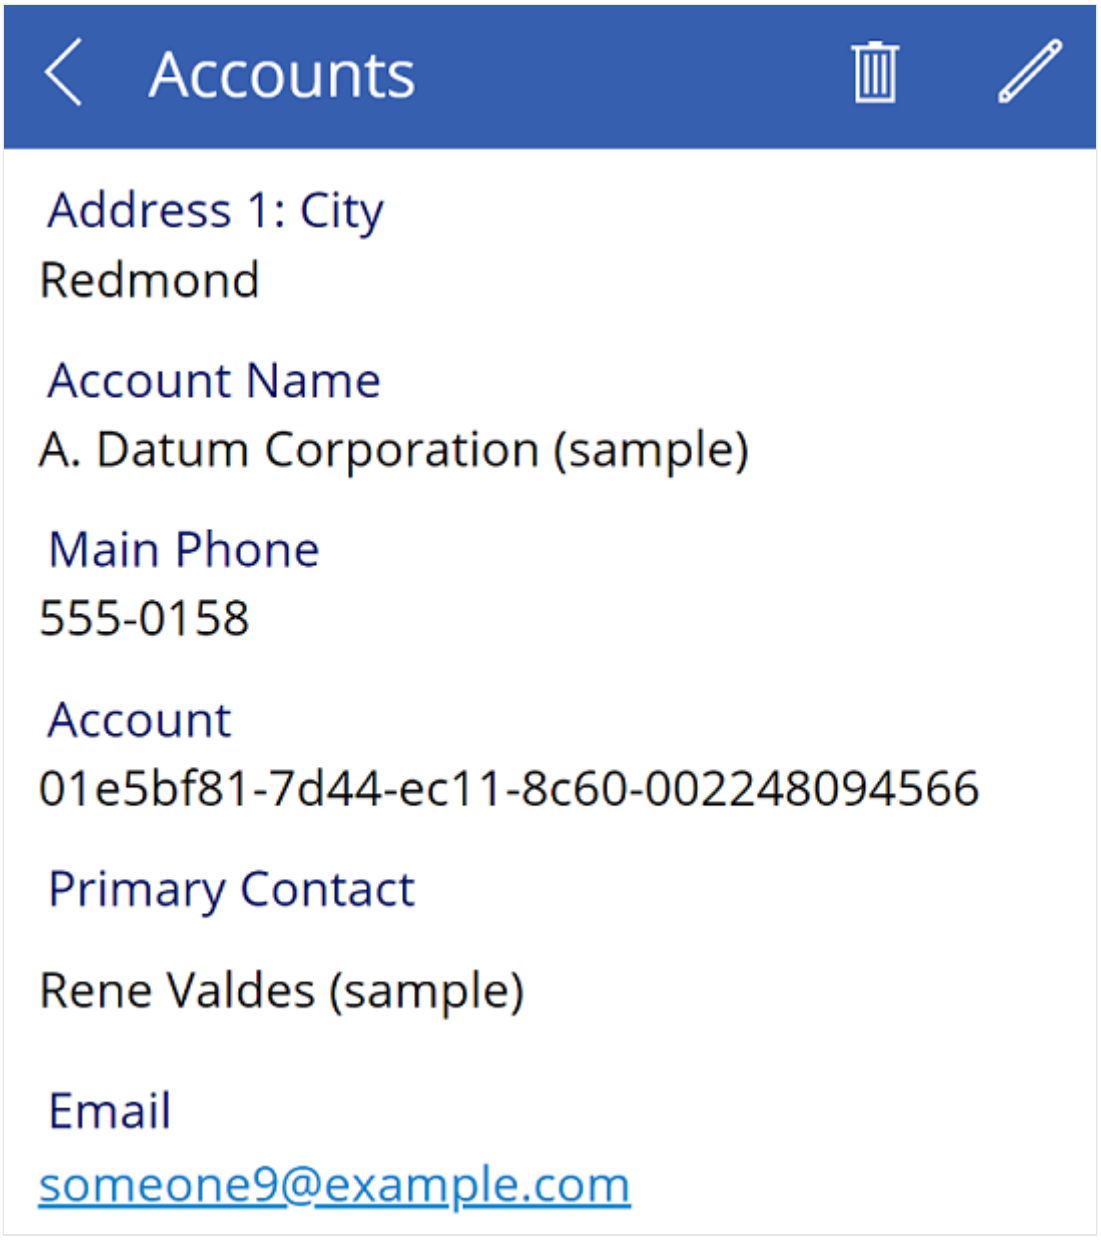
To invoke app with the parameter value, we have to use the following syntax:

`https://apps.powerapps.com/play/{App ID}?{Query}`

In the above syntax, we have to add the **App ID** and the query that contains **accountId** variable with its value.

For example, when the following URL was entered in a browser for the sample tenant, the app **Account deep linking** opened directly with the supplied **accountId** parameter

value (in this example, "A. Datum Corporation (Sample)"):
`https://apps.powerapps.com/play/061b64cd-e5a0-4a7a-a77f-b6f8586dd6c7?accountId=01e5bf81-7d44-ec11-8c60-002248094566`



Send deep link in email

We can also supply a variable **accountVal** to point to the account's ID instead of using absolute link explained above while invoking the URL for the given account from inside the app.

For this purpose, we'll create a button and add the ability to invoke an email from within the app with the deep link to the selected account's details screen from the **Account deep linking** app.

1. Select **Data** from the left-side of the screen.

2. Select **Add data** > search for and select **Office 365 Outlook** > select **Connect**.

> **Note**
>
> This action adds the Microsoft 365 Outlook connection so that we can use the next steps to invoke composing an email to share the account information.

3. Select **DetailScreen1** from the **Tree view**.

4. Insert a button at bottom-right of the screen, and rename it to **Share Account**.

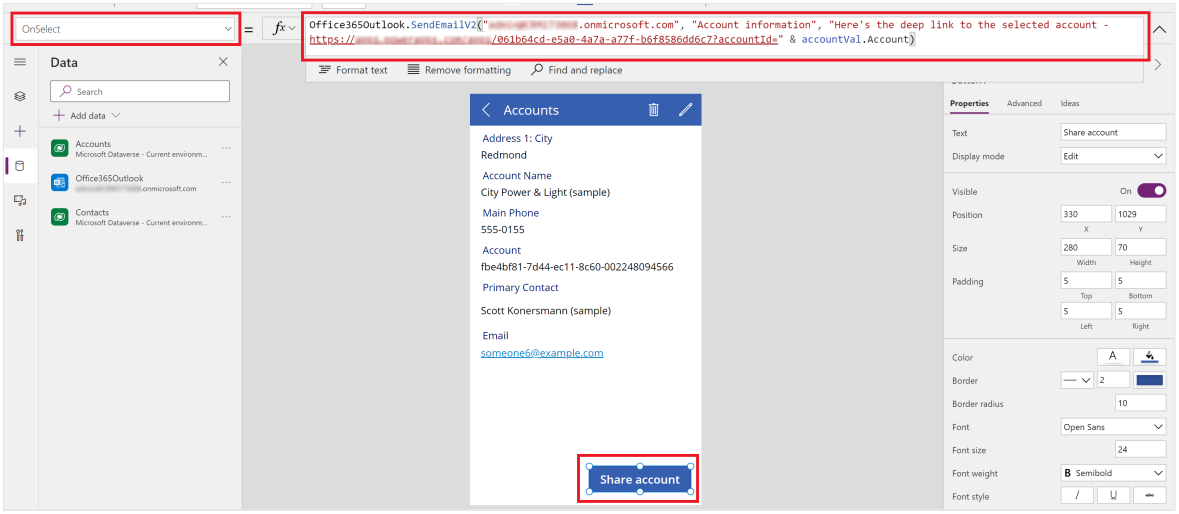
5. On the button's **OnSelect** property, enter the following:

```
Power Fx

Office365Outlook.SendEmailV2("Recipient", "Subject", "Here's the deep
link to the selected account - https://apps.powerapps.com/play/{App
ID}?accountId=" & accountVal.Account)
```

This formula uses the Microsoft 365 connector for Outlook to send an email using the SendEmailV2 operation.

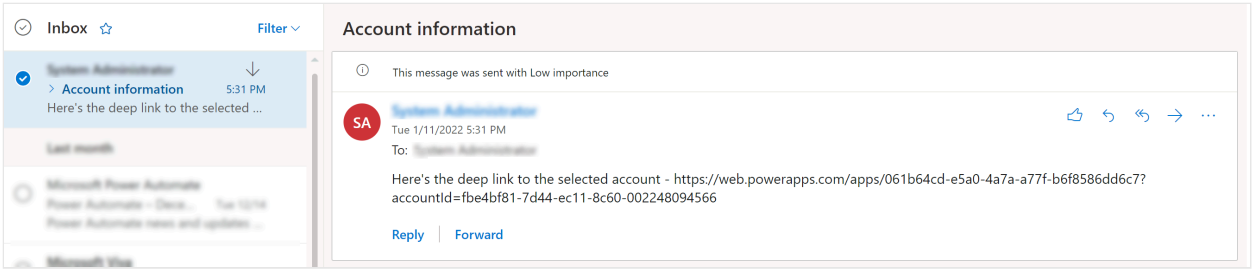
> **Note**
>
> Replace **Recipient**, **Subject**, and **AppID** in the above formula with the email address of the recipient, subject for the email, and the ID of the app.



6. Save and publish the app.

Test the app

Run the app, and go to the details screen for any account. And then, select the button **Share account**. The **OnSelect** button formula triggers an email to the recipient with the subject and body configured earlier. Here's a sample email sent by the configured app:



Open the email, and copy the deep link that points to the selected account, and you'll be taken directly to the account details screen in the **Account deep linking** app, instead of the default browse screen.

Work with the PDF function (experimental)

Article • 04/11/2023

The PDF function in Power Apps generates a PDF document from the contents of a screen or certain types of controls. You can pass the generated file to an action connector—for example, to send it in an email using the Office 365 Outlook connector—or to a Power Automate flow as part of an automation scenario.

> **Important**
>
> - This is an experimental feature. Experimental features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback. **Understand experimental, preview, and retired features in canvas apps**.
> - You must turn on the PDF function in **Settings > Upcoming features > Experimental**. As an experimental feature, it's disabled by default.
> - Send your feedback in the **Power Apps experimental features community forum**.

Turn on the PDF function

Since the PDF function is an experimental feature, it's turned off by default. To use it in your apps, you need to turn it on manually.

1. Sign in to Power Apps and create a canvas app or open an existing app.
2. In Power Apps Studio, on the command bar, select **Settings**.
3. Select **Upcoming features**.
4. On the **Experimental** tab, turn on **PDF function**.

Use the PDF function to generate a PDF file

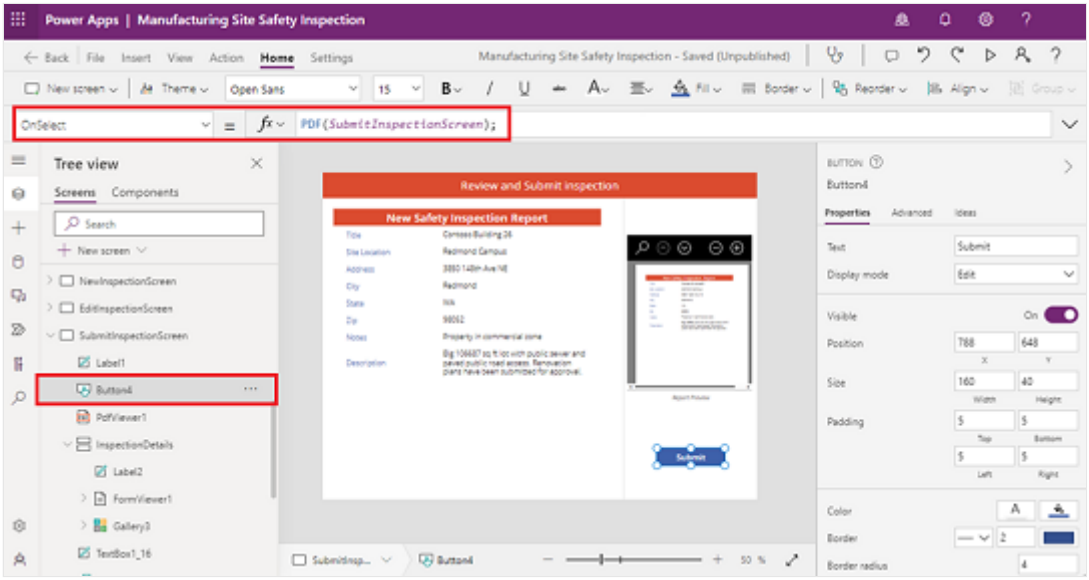
In the following example, we use the PDF function in the `OnSelect` property of a button to generate a PDF file. You can also use the PDF function in `OnVisible`, `OnHidden`, or any

other behavior property.

1. Select an existing button or add a new button to your canvas app.

2. In the button's `OnSelect` property, add the PDF function and enter the target of the function as a parameter. Enter the formula: `PDF(SubmitInspectionScreen);`

   In this example, we're targeting the screen `SubmitInspectionScreen` to generate a PDF file from the contents of our sample app's Inspection screen. Replace it with the name of a screen in your app.



3. Select **Save and publish**.

Play the app and select the button you added. The PDF file is generated and stored in memory for future use. The following section suggests a few ways to work with the PDF file in your app.

The PDF function can only target the screen that's currently visible. You can pass the entire screen, as in our example, or enter more parameters to specify a container or gallery to limit the content to pass.

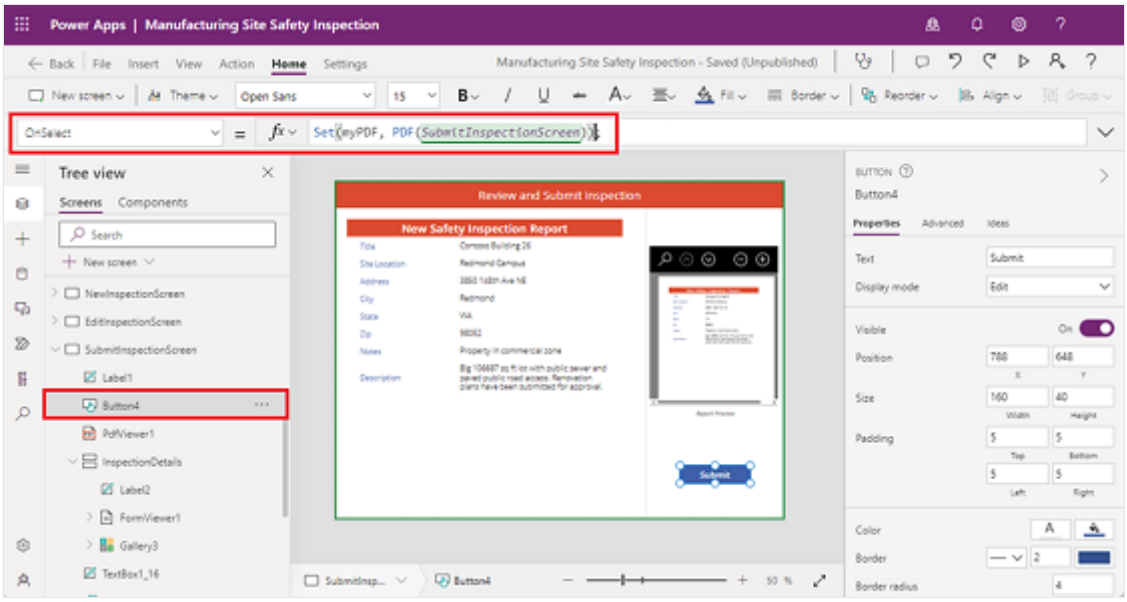
Work with the generated PDF file

You can use the generated PDF file in many ways. Here are a few, using the example in the previous section.

View the file with the PDF viewer control

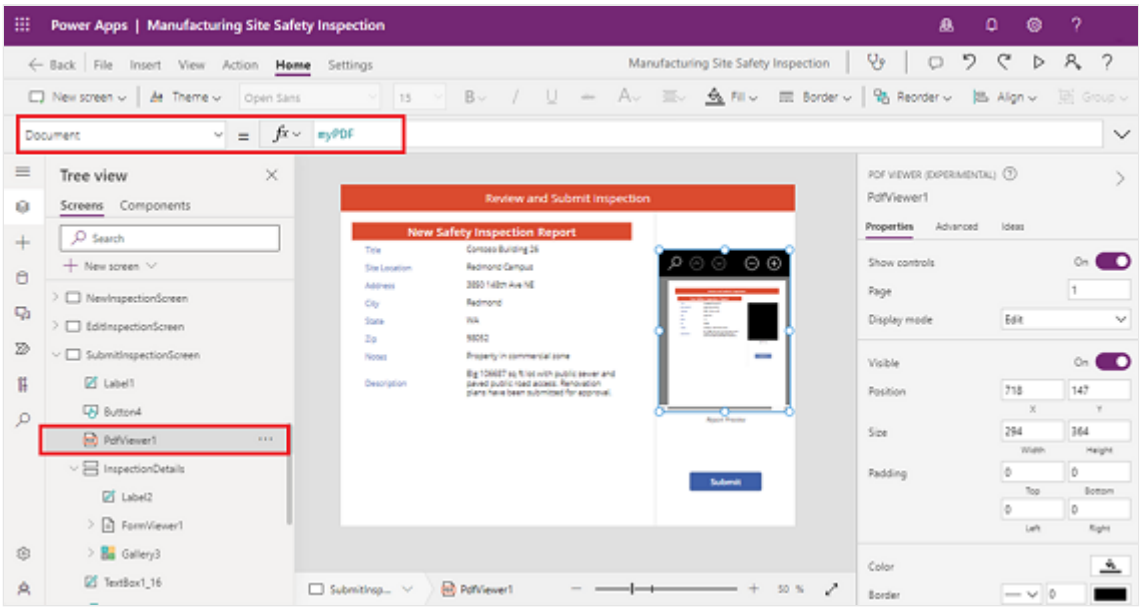
1. In your canvas app, select the button that you created in the previous example or add a new button.

2. In the button's `OnSelect` property, enter the following formula, replacing `SubmitInspectionScreen` with the name of a screen in your app: `Set(myPDF, PDF(SubmitInspectionScreen));`



3. Select **Insert** > **PDF viewer (experimental)**.

4. From the properties list, select the **Document** property and then enter **myPDF** in the formula bar.



5. Select Save and publish.

Play the app and select the button you added. The PDF file is generated, stored in the variable `myPDF`, and visible in the PDF viewer control.

The PDF viewer control appears as a black shape inside the generated PDF file. To exclude the control from the generated file, place the content you want to turn into a

PDF file inside a container or gallery and target that instead of the screen; for example, `PDF(Container1)` or `PDF(Gallery1).`

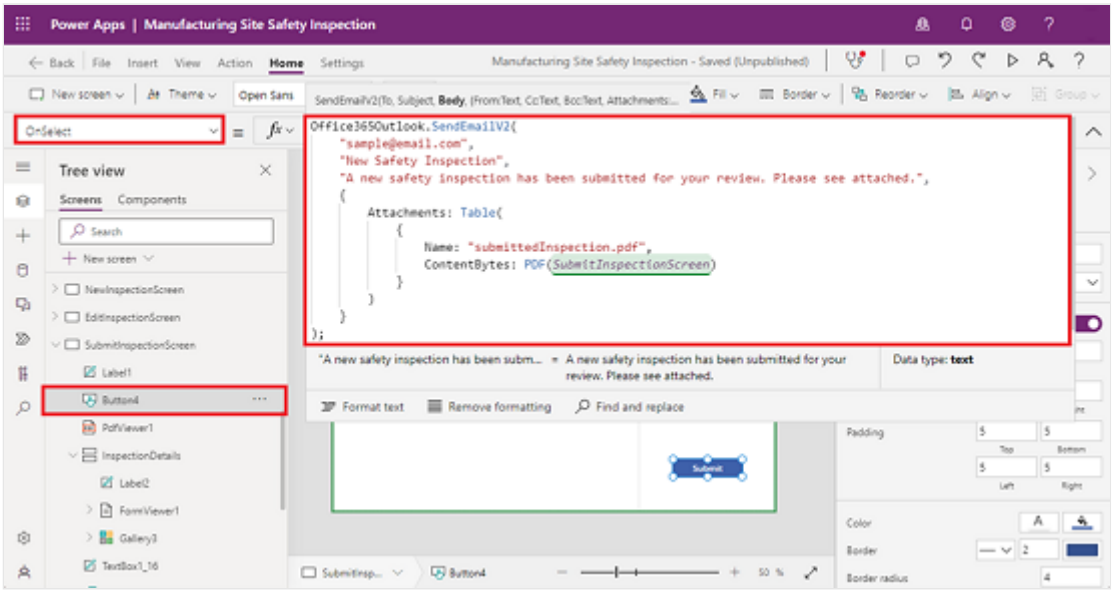
Use an action connector

In this example, we generate a PDF file that we send as an email attachment using the Office 365 Outlook connector.

1. In your canvas app, select the button that you created in the previous example or add a new button.

2. In the button's `OnSelect` property, enter the following formula:

```
Office365Outlook.SendEmailV2(
   "sample@email.com",
    "New Safety Inspection"
    "A new safety inspection has been submitted for your review. Please
see attached.",
    {
        Attachments: Table(
             {
                 Name: "submittedInspection.pdf",
                 ContentBytes: PDF(SubmitInspectionScreen)
             }
         )
    }
 );
```



3. Select Save and publish.

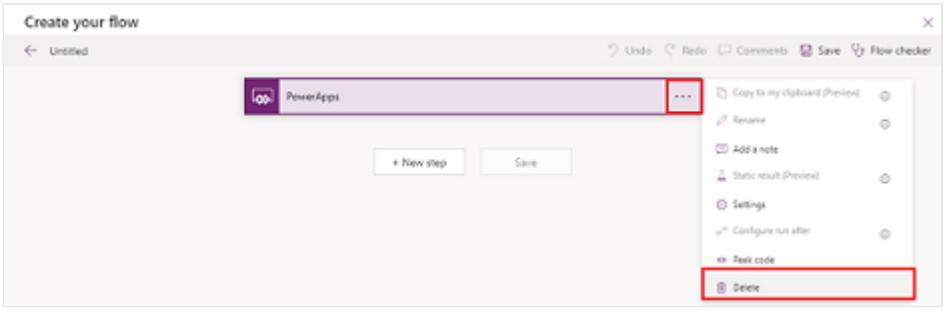
Play the app and select the button you added. The PDF file is generated, and an email is sent to the specified email address with the generated PDF file attached.

Use in a Power Automate flow

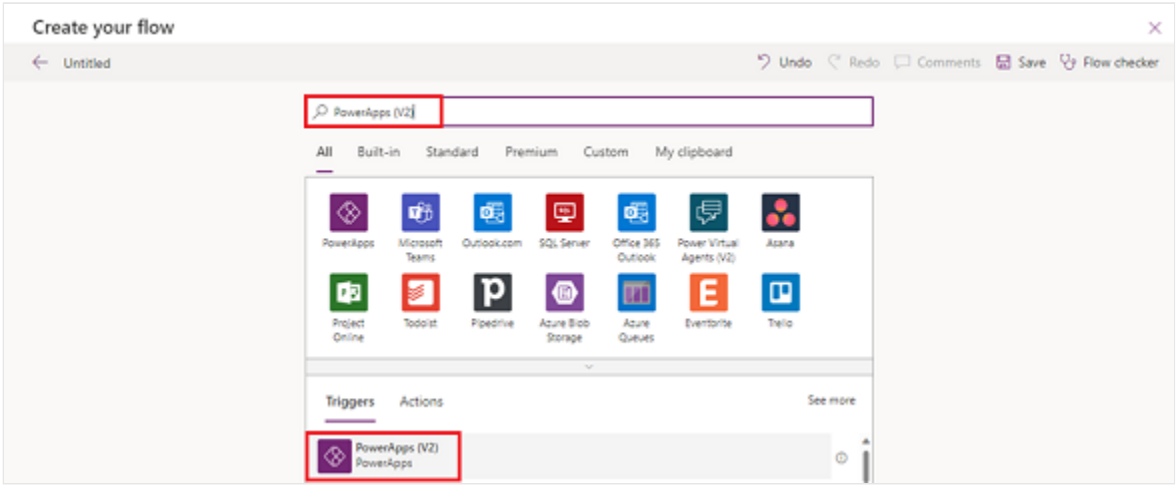
In this example, we generate a PDF file and pass it to a Power Automate flow that stores the file in a document library using the SharePoint connector. This example replaces the default PowerApps trigger in Power Automate with the PowerApps (V2) trigger.

Create a flow to use in your app

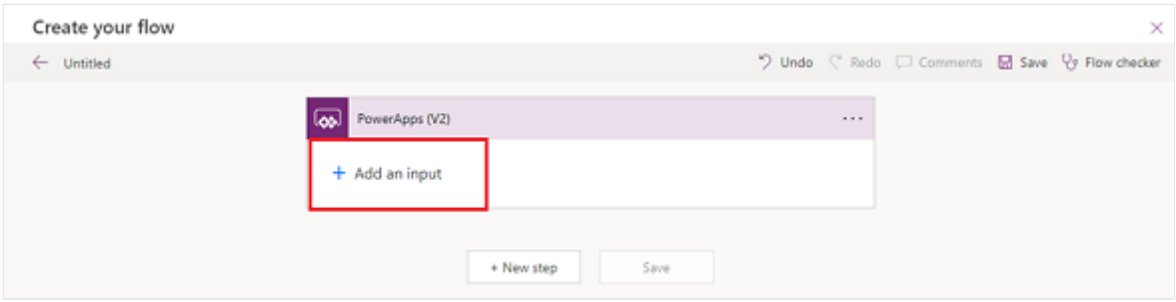
1. In your canvas app, select the button that you created in the previous example or add a new button.
2. In the app authoring menu, select **Power Automate** > **Create new flow**.
3. Select **Create from blank**.
4. To delete the default PowerApps trigger, select the trigger menu (**...**), and then select **Delete**.



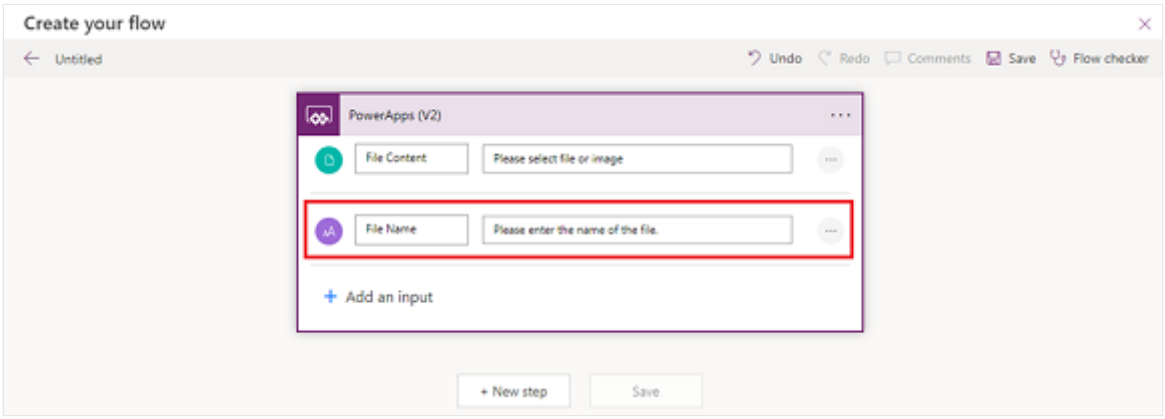
5. Search for and select **PowerApps (V2)**.



6. Select the **PowerApps V2** trigger to expand the node, and then select **Add an input**.

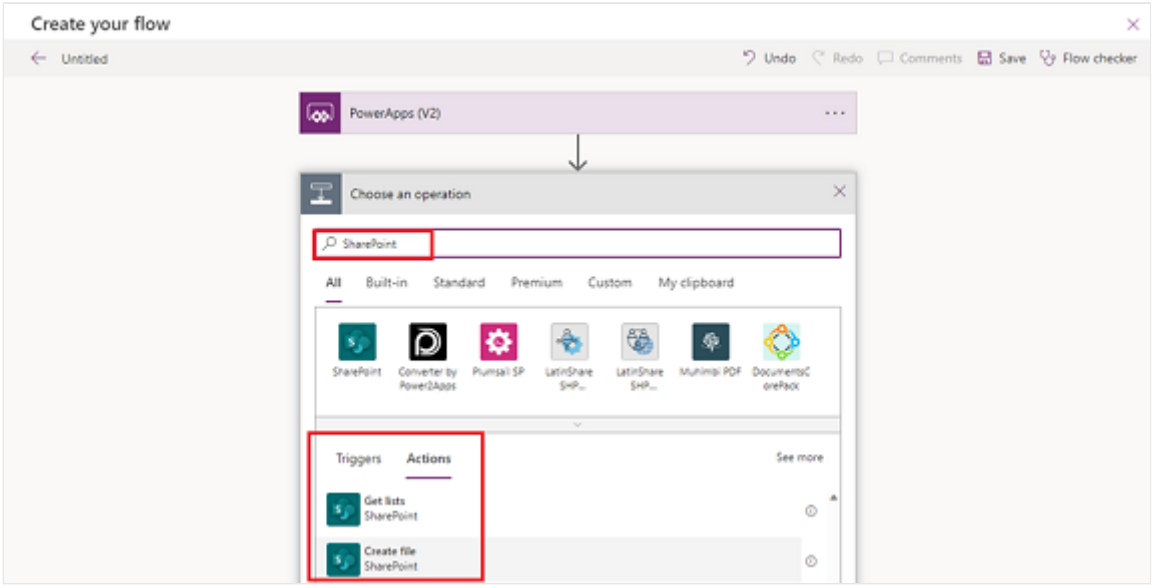


7. Select **File** as the type of user input.
8. Select **Add an input** again, and then select **Text** as the type of user input.
9. Rename the input **File Name** and change the description to **Please enter the name of the file**.



Add the SharePoint connector to the flow

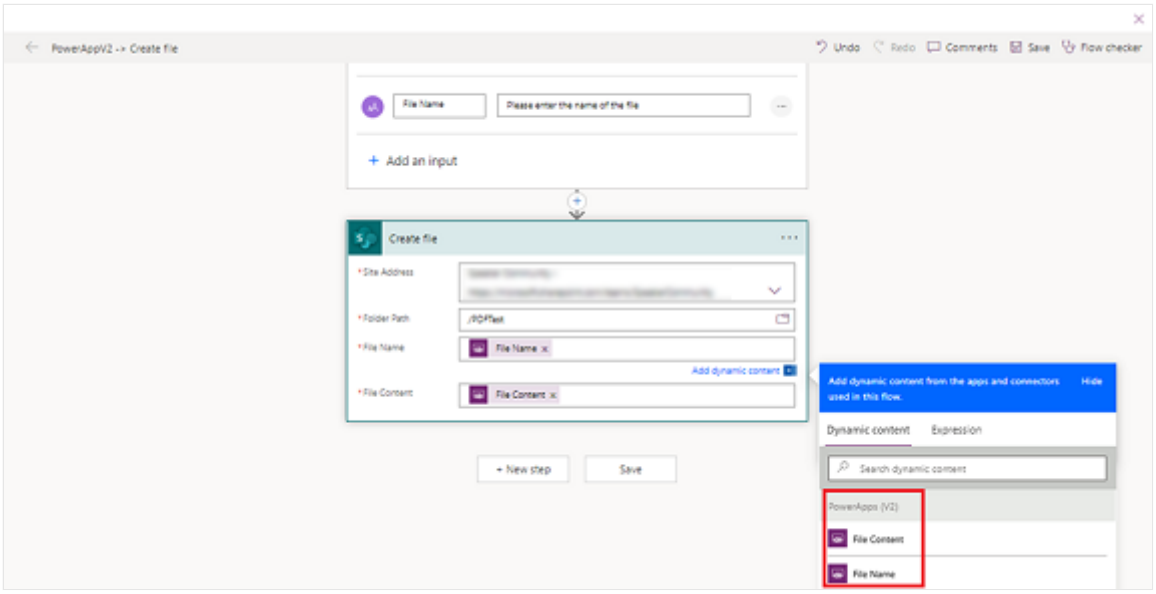
1. Select **New step** to add an action. Search for **SharePoint** and select **Create file**.



2. In **Site Address**, select a SharePoint site that you have permission to add files to.
3. In **Folder Path**, select a document library that you have permission to add files to.

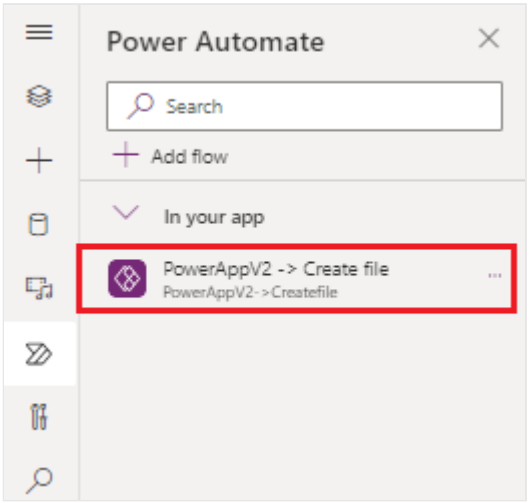
4. Select the **File Name** input. In the **Dynamic content** tab, select a file name under **PowerApps (V2)**.

5. Select the **File Content** input, and then select **File Content** in the list.



6. Select **Save**, and then select the **x** in the upper-right corner to close the Power Automate window.

7. The Power Automate pane refreshes, and the new PowerApps (V2) flow, **Create file**, appears in the list.

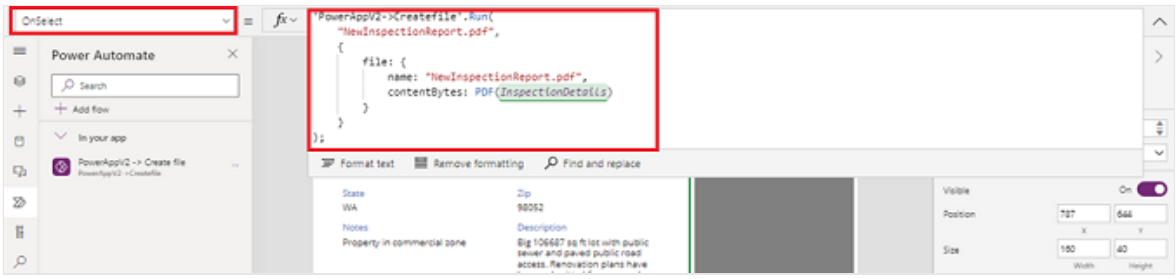


Add the flow to a button in your app

1. Select the button in your app canvas. In the button's `OnSelect` property, enter the following formula, replacing the flow name and generated PDF file name with your own:

```
```

```
'PowerAppV2->Createfile'.Run(
   "NewInspectionReport.pdf",
    {
       file: {
            name: "NewInspectionReport.pdf",
            contentBytes: PDF(InspectionDetails)
        }
    }
);
```



2. Select **Save and publish**.

Play the app and select the button you added. The Power Automate flow runs and adds the generated PDF file into the document library.

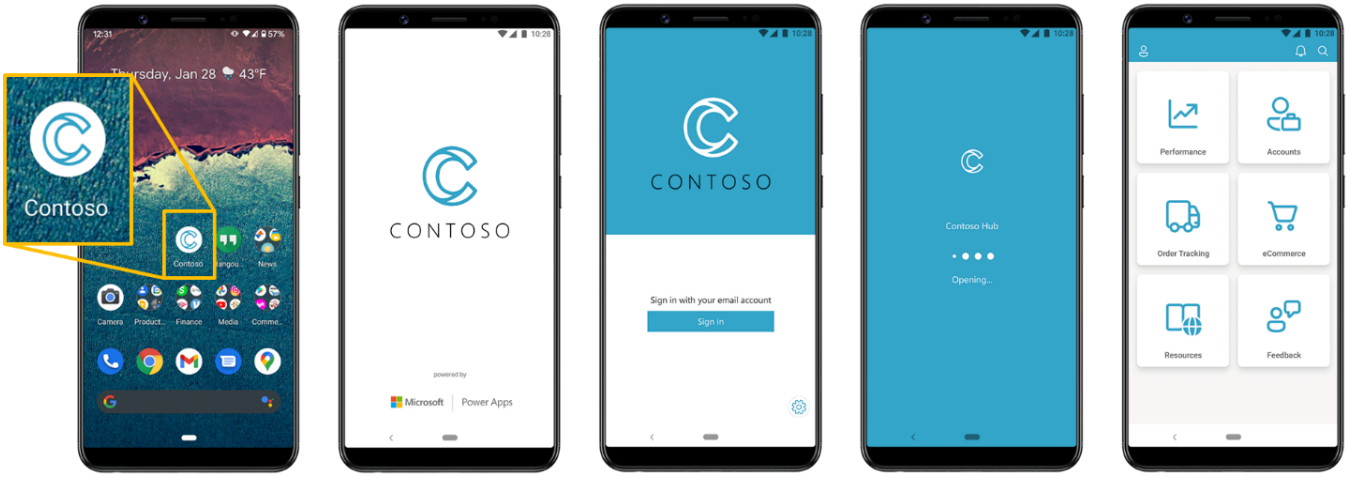
Overview of wrap

06/16/2025

The **wrap** feature in Power Apps lets you package your canvas app as a custom-branded Android or iOS app for native distribution to mobile users. Distribute these wrapped native mobile apps to users through the Google Play Store, Apple Business Manager, or Microsoft Intune.



Key capabilities

With wrap, you can:

- Package one or more Power Apps canvas apps in the same native mobile app package.
- Customize your mobile app startup experience to match your organization's branding.
- Specify the app icon, splash screen image, welcome screen image, and color palette.
- Update wrapped mobile apps by publishing changes to the included canvas app through the Power Apps maker portal.
- Distribute apps using MDM.

> **Note**
>
> All published changes to the included canvas app(s) are downloaded automatically by existing, released versions of your wrapped mobile apps.

Benefits of wrap

Wrap brings native mobile application development platform (MADP) capabilities to Power Apps:

Expand table

Benefit	Description
No-code mobile app development	Create mobile apps with no previous experience
Managed mobile app builds	We generate the app for you
Seamless end-to-end branding	Use your own logo and color palette
Multiple canvas apps support	Bundle multiple apps in a single mobile app
Enterprise governance with Microsoft Intune	Protect your data with app management

Software and device requirements

Platforms supported

- **iOS**: Version 14.0 or later.
- **Android**: Version 8.0 (API level 26) or later.

Device requirements

- **iOS**: iPhone 6S or later, iPad 5th generation or later.
- **Android**: Any device that runs Android 8.0 or later.

Developer requirements

- Microsoft Power Apps account with appropriate licenses.
- Access to Microsoft Entra ID (formerly Azure AD) for app registration.
- Azure subscription (for Azure Key Vault and Blob Storage).
- For manual code signing:
  - iOS: macOS device with Xcode installed.
  - Android: Windows PC with Android Studio installed.

Wrap process overview

The **wrap** feature packages your canvas app in a native mobile app shell and produces a mobile package. You can digitally sign and distribute this mobile package as your custom-branded Android and iOS app through native distribution channels, like Google Play Store and Apple Business Manager.

Step-by-step process

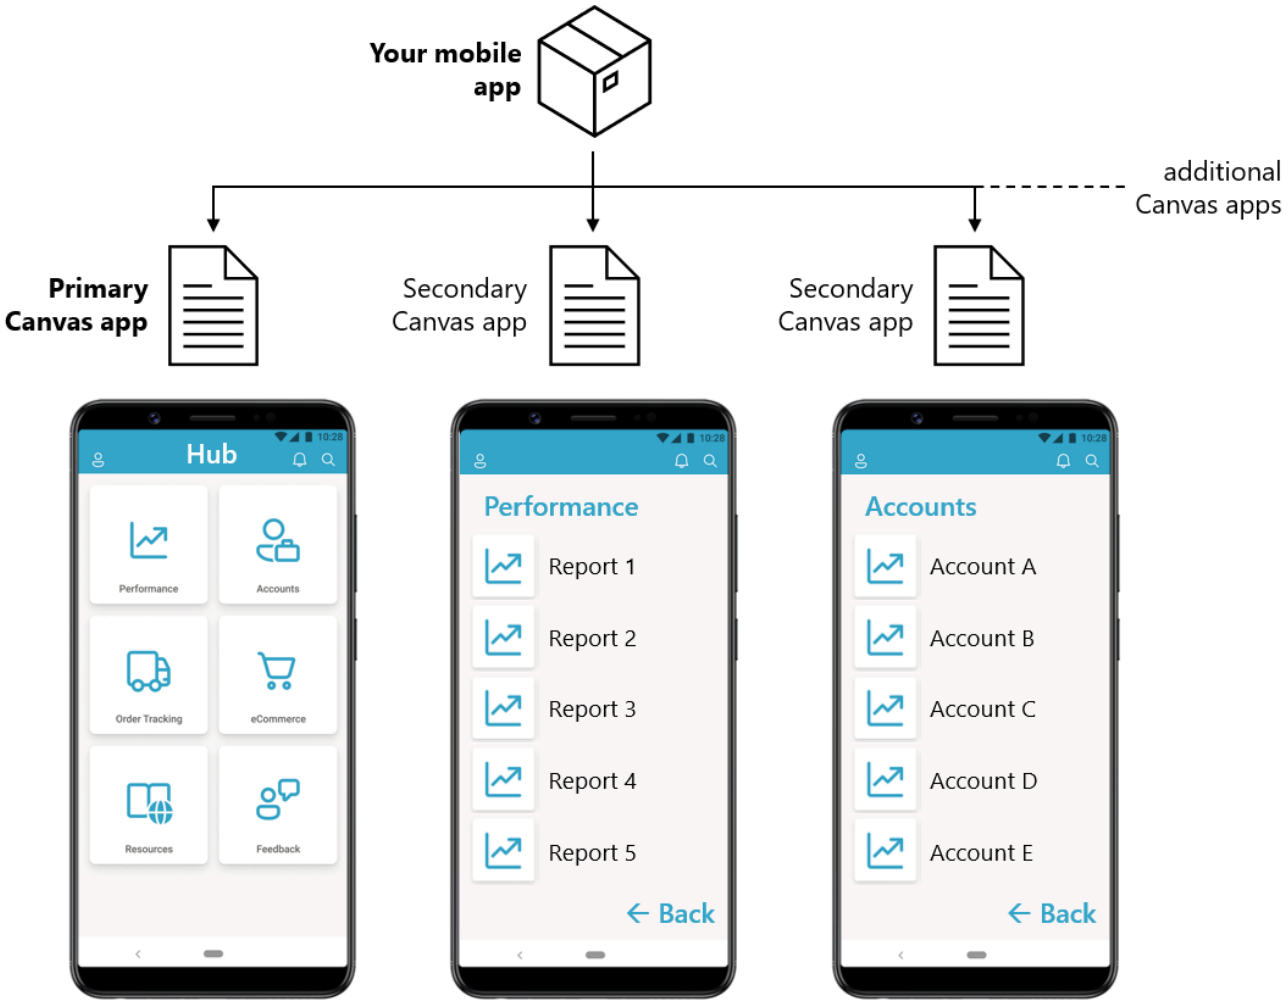
1. Select your **primary canvas app** and start the wrap wizard. A primary canvas app provides the initial experience users see when launching your mobile app. Your canvas apps must be part of a solution. More information: Add canvas app to solution.
2. Optionally, add **secondary canvas apps** to your mobile app in the wrap wizard. More information: Wrapping multiple canvas apps together.
3. Select the **target platforms** (iOS and Android) for your mobile app. Optionally, select **automatically code sign** your mobile app package.
4. Register your app. Use an existing **app registration** or create a new one in the wrap wizard.
5. Customize **app branding** with icons, images, and a color palette to personalize your mobile app.
6. Add the **Azure blob storage account name and container name**. Use an existing **Azure blob storage** or create a new one.
7. Start the build process in the **Wrap up** step to generate your custom branded mobile app.
8. Download your mobile app from the **App blob storage location**.
9. If you don't select **automatically code sign** in the wrap wizard, code sign the mobile app package manually. More about signing your mobile app package manually: Signing your mobile app package manually.
10. Test the app package.
11. Distribute the app package to mobile users.

Wrap multiple canvas apps together

You can wrap more than one canvas app into a single mobile app package. The mobile app package needs a home app, called the primary app. This app becomes the entry point for all other canvas apps included in the mobile app package, which are called secondary apps.

Secondary apps are optional. When you wrap only one canvas app, that app is considered the primary app, and the mobile app package has no secondary apps.

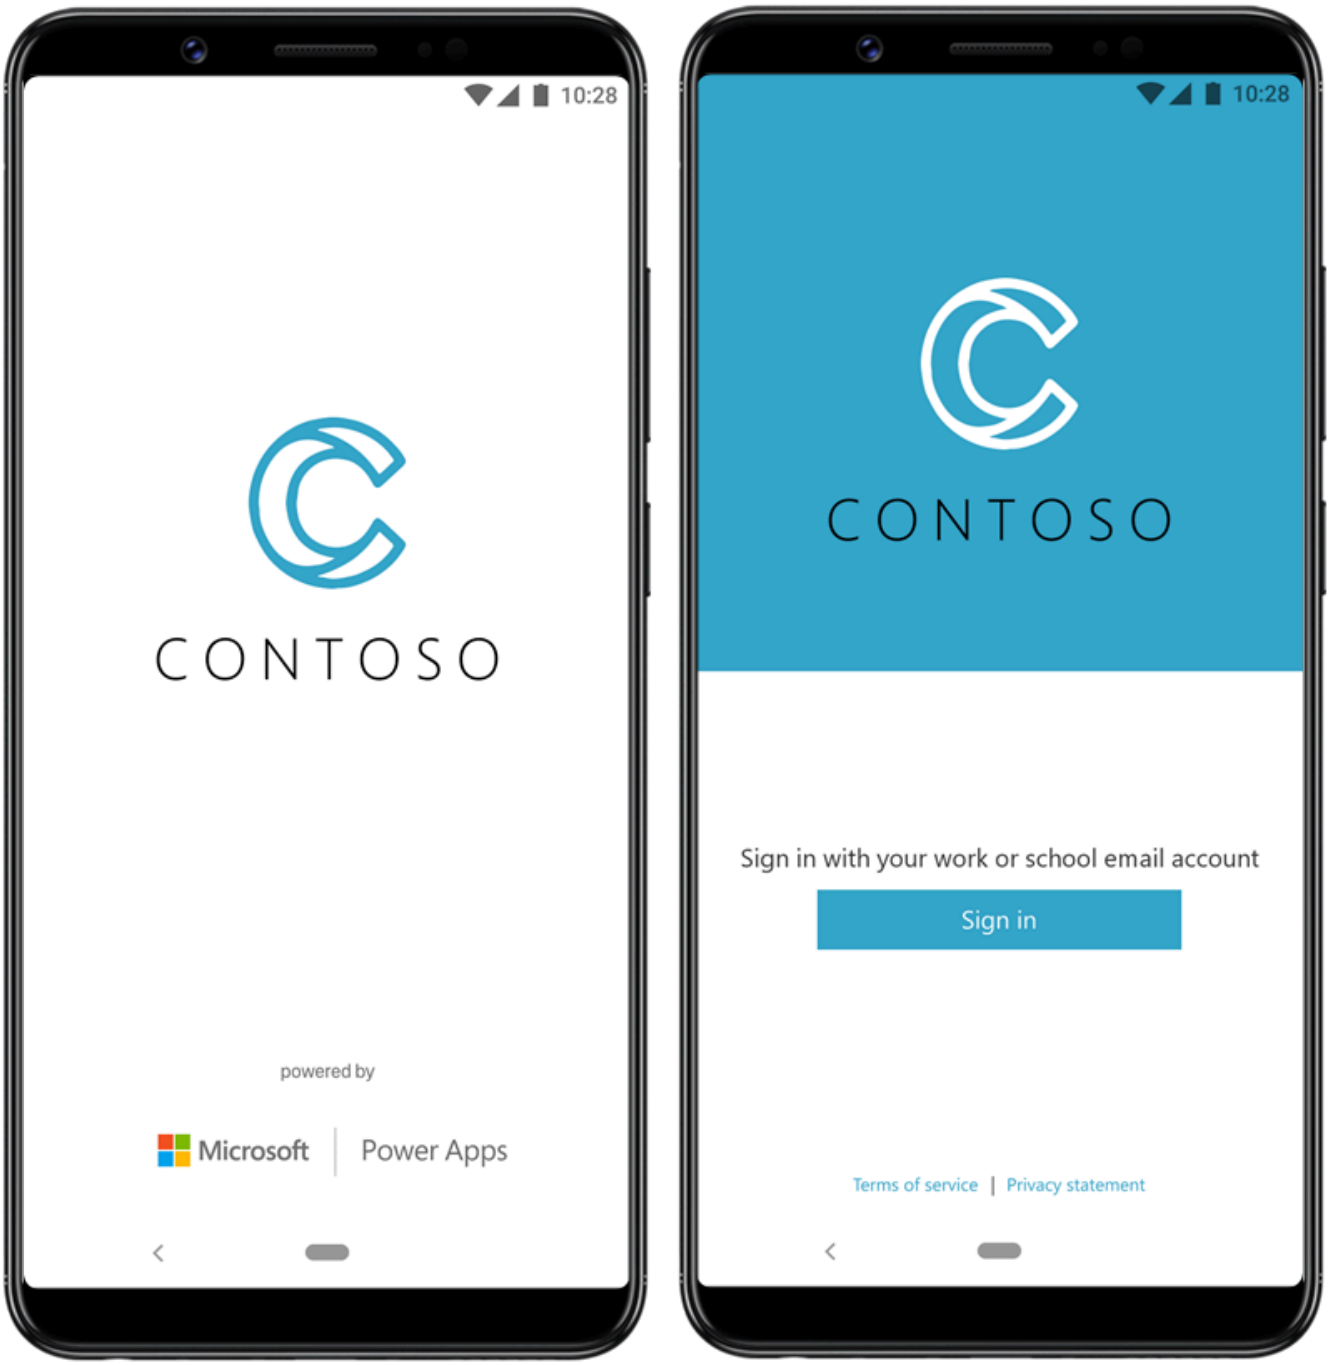
As shown in the illustration below, a primary app can have links to multiple secondary apps. You can manage navigation between primary and secondary apps using the Launch() function.



Brand your mobile app

Wrap supports customization of the mobile app bootstrap experience to match your organization's branding requirements. You can specify:

- App icon
- Splash screen image
- Welcome (sign in) screen image
- Color palette for native experiences



Branding customization options are available when building your wrap project. More information: Configure branding

---

Wrap terminology

Wrap involves multiple components across Power Apps and third-party platforms such as iOS and Android. Understanding these components is important when working with the wrap functionality.

App platform(s)

Target platforms for your app during the build process. You can create builds for:

- **iOS** — creates IPA package
- **Android** — creates APK package
- **Google Play Store** — creates AAB package for distribution

Bundle ID

The bundle ID is a unique identifier for your app that follows a reverse domain name pattern. It must contain one period (.) and no spaces. Example: `com.contoso.myapp`.

This bundle ID is used when creating the Azure key vault for wrap after iOS or Android certificates are created and uploaded. If you've already created the Azure key vault, verify the bundle ID in the **Tags** section of the Azure portal. Use this same bundle ID in Step 2: Target platform.

Code signing

Code signing completes a mobile app before distribution to end users. A code-signed app assures users it comes from a known source and the app code hasn't changed since it was last signed by the trusted source.

Primary app

A primary app is the entry point or home app for the mobile app experience when wrapping multiple canvas apps together. If only one canvas app is wrapped, it's considered the primary app.

Secondary app

Secondary apps are optional canvas apps that you wrap in the same build for mobile app distribution along with the primary app.

Redirect URI

A redirect URI (reply URL) is the location where the authorization server sends the user after successful app authorization and access token grant. The authorization server sends the code or token to the redirect URI, so registering the correct location during app registration is important. More information: Redirect URI

Common issues and limitations

Known limitations

- The wrap feature only supports canvas apps (not model-driven apps)
- All canvas apps in a wrap project must be from the same environment
- Users must have a Power Apps license to use wrapped apps

Common issues

- **Bundle ID conflicts**: Ensure your bundle ID is unique across your organization
- **Image format issues**: All images must be in PNG format
- **Signing certificate problems**: Verify certificate validity and expiration dates
- **Azure Key Vault access**: Make sure proper permissions are configured

For troubleshooting details, see Troubleshoot issues with the wrap feature in Power Apps.

Next steps

System requirements and prerequisites for Wrap

See also

- Use the wrap wizard to build your mobile app
- Manual code sign on iOS
- Manual code sign on Android

- Benefits and limitations of Wrap

System requirements and prerequisites for Wrap

07/09/2025

Before you use Wrap to create native mobile apps from your Power Apps canvas apps, check that your system meets these requirements.

Software and device requirements

- You need a Mac device for manual code signing with iOS.
- You need a Windows PC for manual code signing with Android.
- To run the wrapped mobile app:
  - Android device with version 10 or higher
  - iOS device with version 14 or higher

> **Note**
>
> You need an Apple Developer Program account to develop apps for iOS.

Permissions and access requirements

1. You need access to:

   - One or more canvas apps to build the wrap project.
   - Azure blob storage, including the account name and container name. More information: Create an Azure storage account.
   - The Azure portal to create app registration and register your app, which should be in the same environment as your Power Apps.

2. An Azure admin must grant you access to use the specific wrap app. More information: API permissions.

3. Your apps must be part of a managed or unmanaged solution. If not, add them to an existing or new solution. More information: Create a canvas app from within a solution.

4. You need an Azure key vault to perform the automatic sign-in process through Wrap wizard. More information: Create a key vault using the Azure portal.

5. Check the policies enabled for your application. More information: Conditional Access policy templates

6. If multifactor authentication (MFA) is enabled, make sure MFA is enabled for the accounts you'll use to sign in, or disable the conditional access policies.

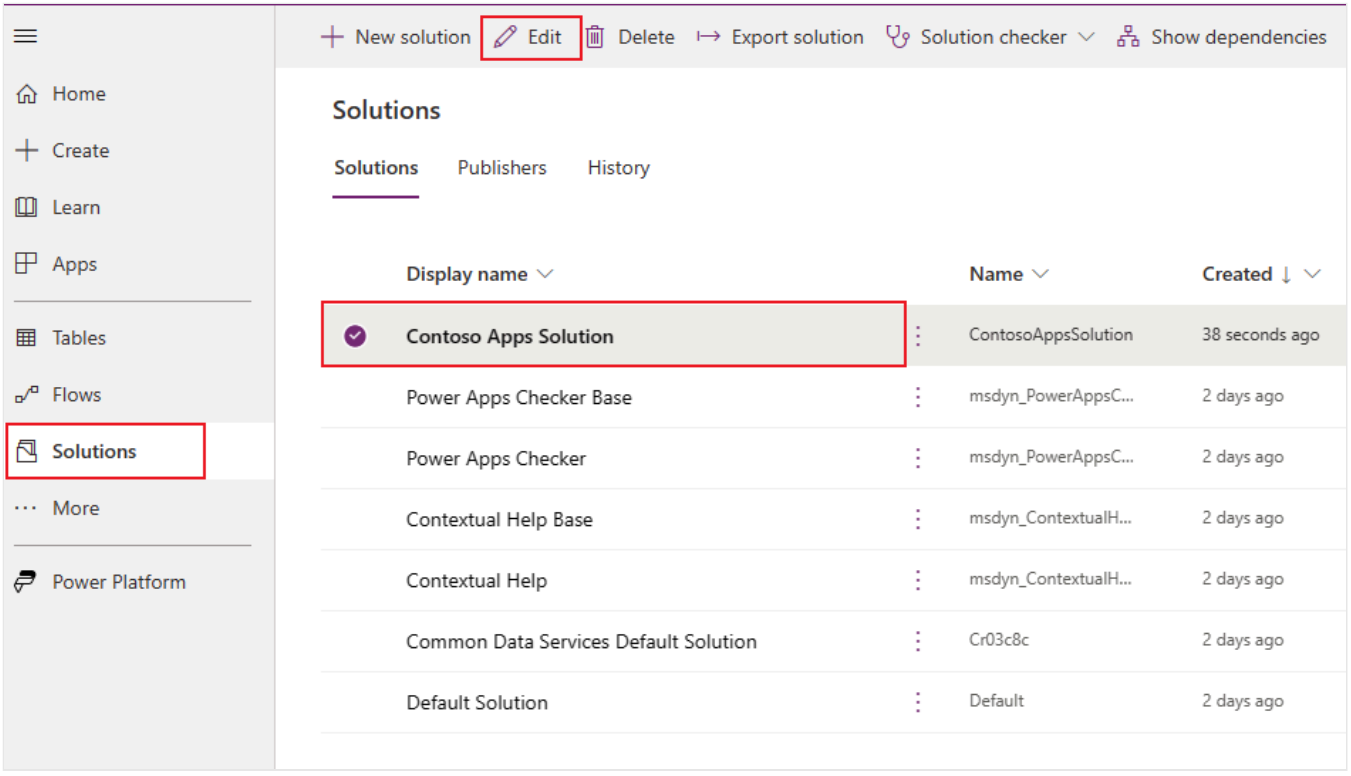
Sign-in options in Wrap

- **Manual code sign-in for Android and iOS**: This option is best for most scenarios. For Android, generate keys and generate a signature hash before you start. You need the signature hash to set up the Redirect URI. More information: manual code sign-in for Android.
- **Automatic sign-in using Wrap wizard**: This option requires an Azure key vault. More information: creating a key vault using the Azure portal.

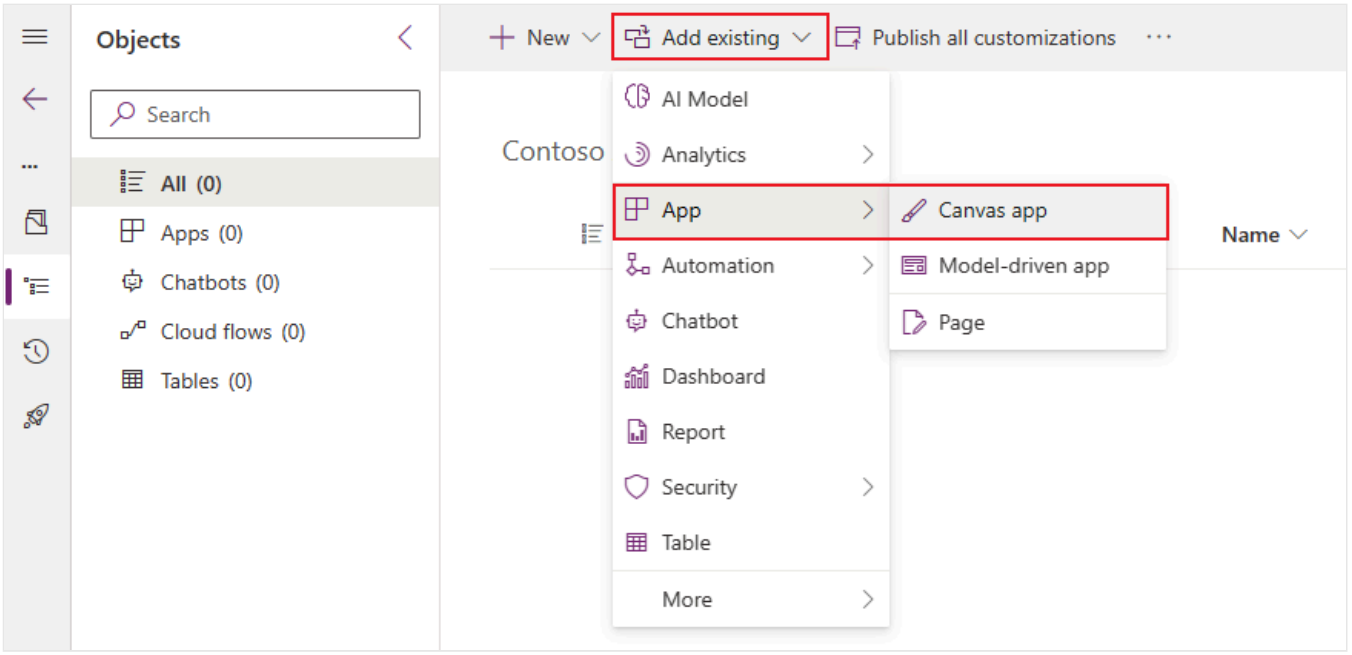
Add canvas app to a solution

Wrap requires your apps to be part of a solution. If your canvas apps aren't already in a solution, add them to an existing or new solution.

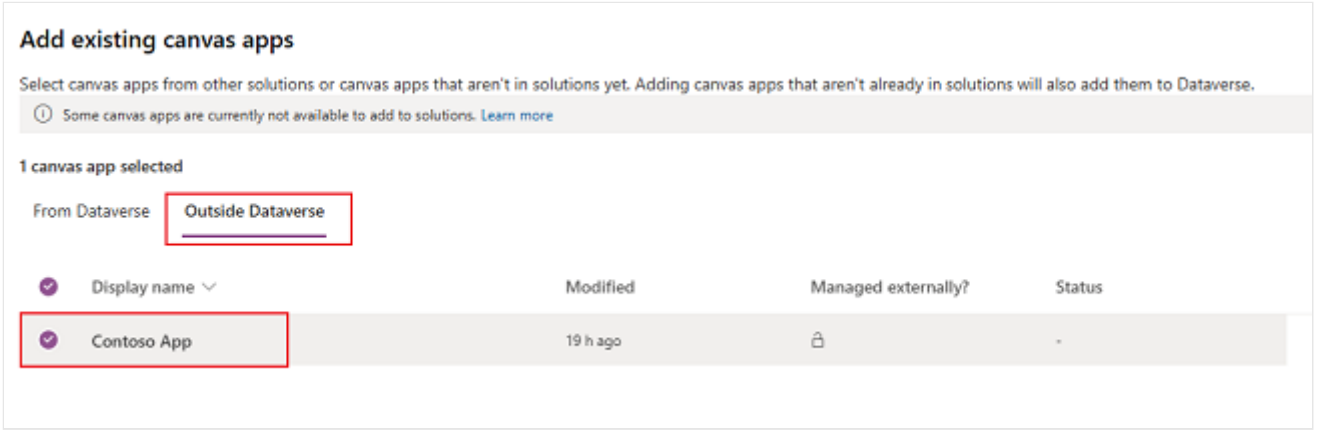
1. In the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select a solution, and then select **Edit**.



Select + **Add existing** from the top menu, and then select **App** > **Canvas app** from the dropdown.



Select the **Outside Dataverse** tab, select your app from the list, and then select **Add** to add the app to the solution.



More information: Add an app to a solution

Next steps

Use the wrap wizard to build your mobile app

Wrap wizard: Step-by-step guide to building your native mobile app

Use this guide to convert one or more canvas apps into a single custom-branded app package that you can deploy on Google Play and the iOS App Store.

The wrap feature in Power Apps enables you to create native mobile versions of your canvas apps as custom-branded Android and iOS mobile apps (IPA, APK, AAB packages). You can distribute these wrapped native mobile apps to end users through Google Play, Apple Business Manager, or other native distribution methods.

When you update and republish your app, the wrapped app is automatically updated for users.

Steps to create a custom-branded native app using the wrap wizard

Follow these steps to configure, build, sign, and distribute a custom-branded native mobile app package (APK, AAB, or IPA) from your canvas apps using the wrap wizard in Power Apps.

1. Sign in and start a wrap project

1. Sign in to Power Apps maker portal.
2. Select **Wrap** from the left navigation pane. If the item isn't in the side panel pane, select ... More and then select the item you want.
3. Select the app you want to wrap, then select **Wrap** on the command bar.

2. Select apps

1. On the **Select the app(s) to wrap** screen, select your primary and secondary app.

    - **Primary app**: The main app end users see when the mobile app launches.
    - **Secondary app(s)**: Optional other apps bundled in the same mobile app package.

    > **Note**
    >
    > - You can use the same primary app in multiple wrap projects.

- If the primary app name appears incorrect, proceed to the next step and return to refresh the name.

2. Select **Next**.

3. Choose target platform

1. On the **Choose mobile platform to target** screen, enter a **Bundle ID**.

> ⓘ Note
>
> The **Bundle ID** is a unique identifier for your app. It must contain one period (.) and no spaces. Use this same bundle ID when creating the Azure key vault after generating and uploading your iOS or Android certificates. If you have already created the Azure Key Vault, verify the bundle ID in the **Tags** section of the Azure portal.

2. Under **Target platform(s)**, select all the mobile platforms that your end users use on their mobile devices.

3. You need to have Azure key vault, to upload your build to Azure blob storage. If you haven't already created, create one. Create an Azure key vault right within the Wrap wizard, or follow the instructions manually.

4. Turn on the **Autosigning** toggle to automate the signing process.

> ⓘ Note
>
> Manual signing options:
>
> - Code sign for iOS
> - Code sign for Android
> - Code sign for Google Play Store You must manually sign AAB files regardless of the signing option selected in the wizard.

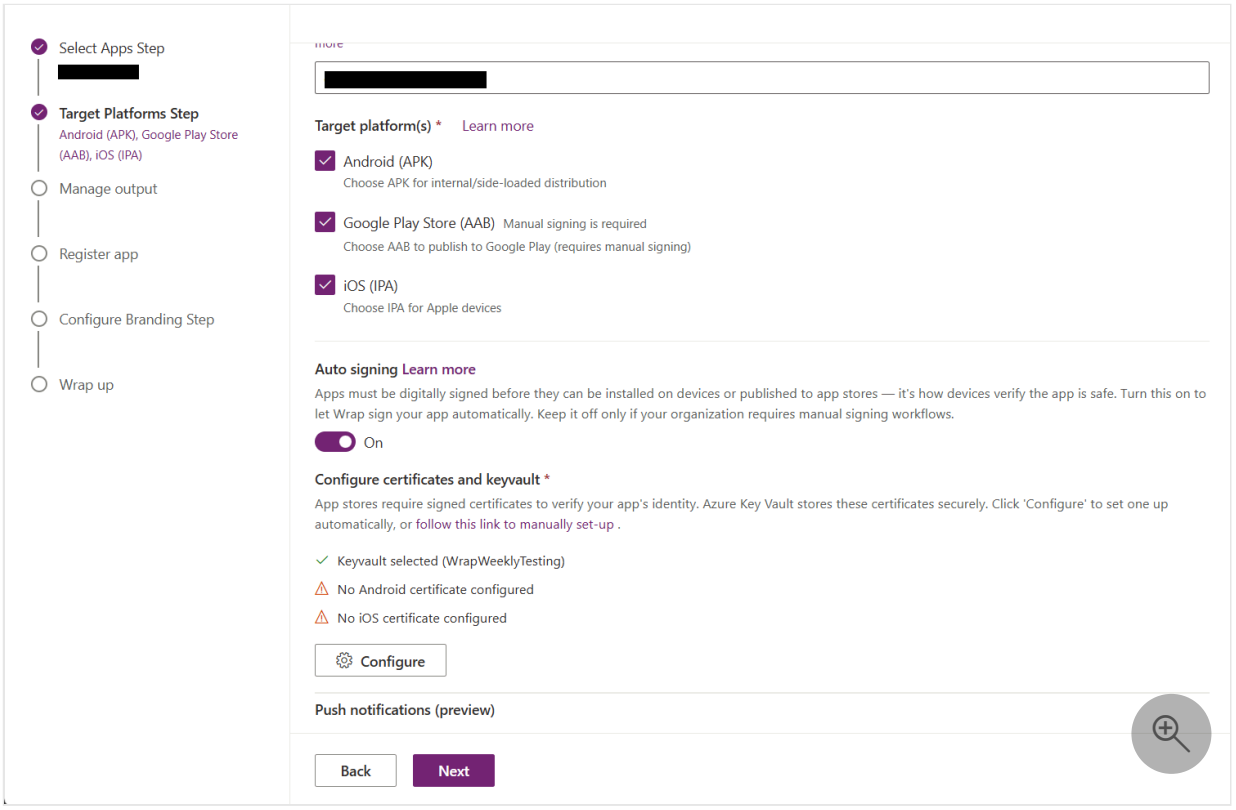
5. Set up autosigning through the wizard.

   a. In the target platform step, toggle on **Autosigning**. The service checks if key vault and certificate are already attached.

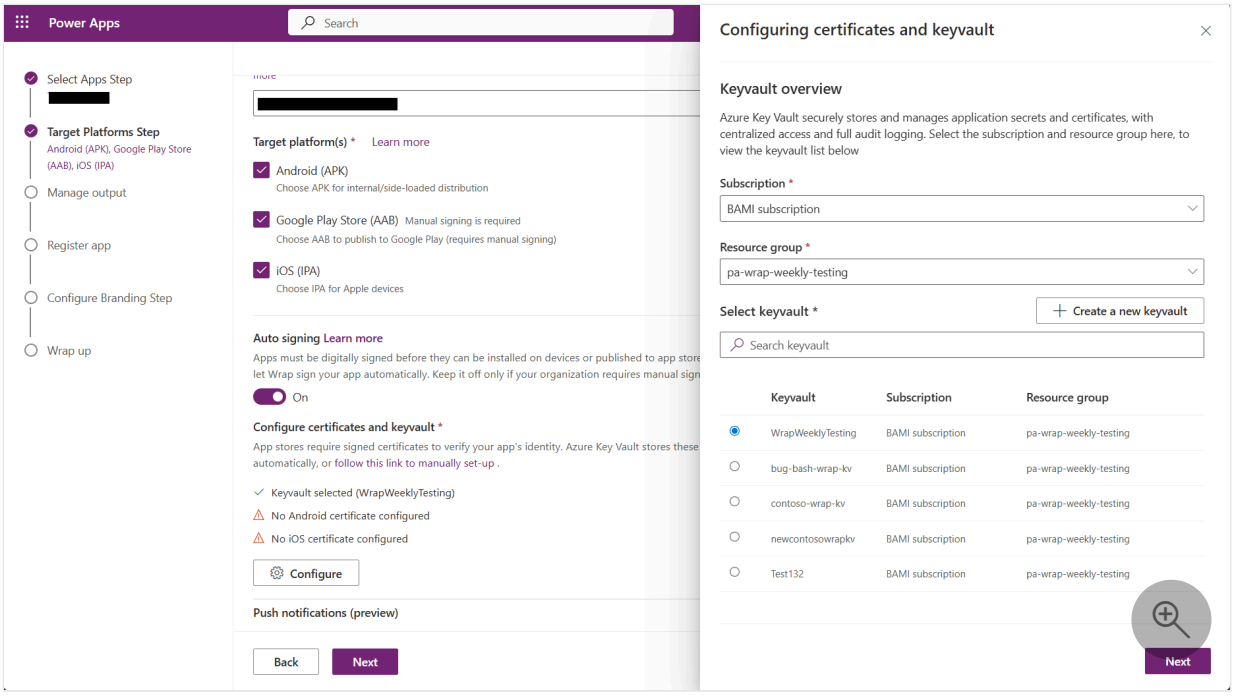
> **Note**
>
> Azure Key Vault is used to securely store and manage application secrets and certificates, with centralized access and full audit logging.

b. If you don't have key vault and certificate or want to change them, select **Configure**.

> **Note**
>
> Only Azure admins can create a key vault from the wrap wizard. Other users need to follow the manual key vault creation process.



c. On the side panel, select the subscription and resource group, and choose the key vault. To create a new key vault, select **Create a new keyvault**. After you select the key vault, select **Next**.

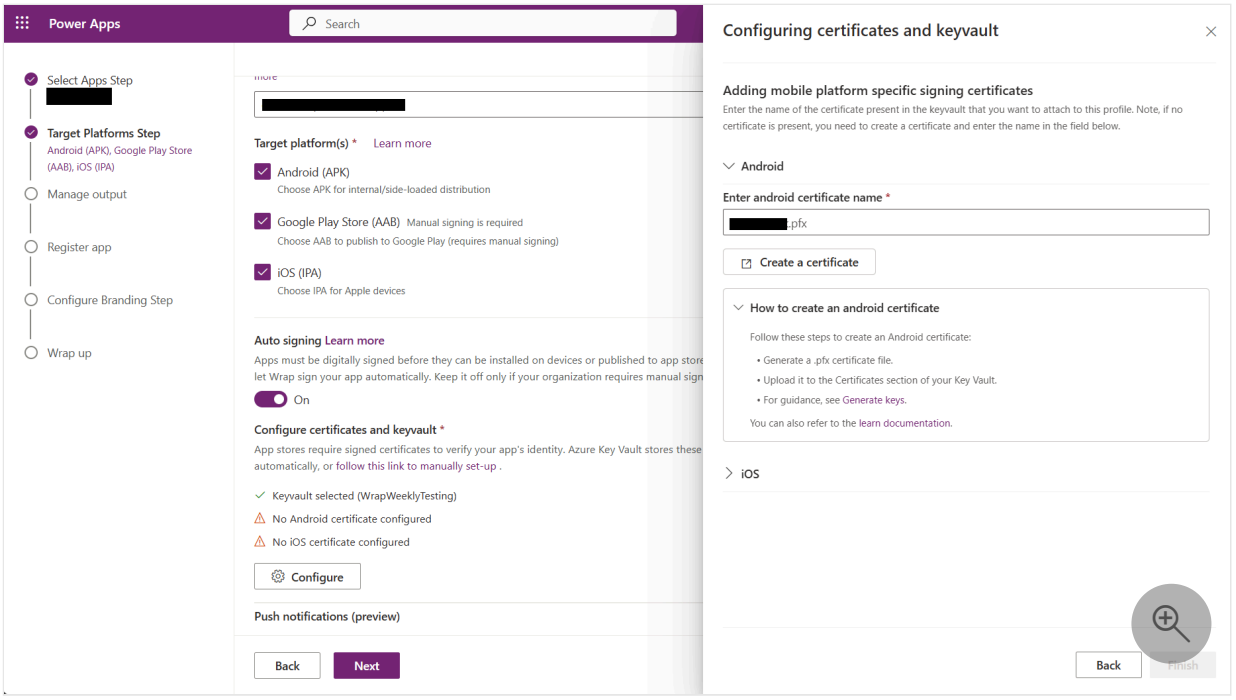


d. The service checks if the appropriate service principal, reader role, access policies, and environment variables are set up for the key vault. If errors appear, fix them. After all checks pass, select **Next**.

e. On the next screen, enter the name of the certificate in the key vault.

f. If no certificate exists or you want to change the certificate, see Generate key and signature hash to create a new certificate. Then select **Create a certificate** on this screen. This action takes you to the Azure portal key vault location. Upload the generated certificate into the configured key vault.

> **Note**
>
> Users are responsible for creating the certificate.

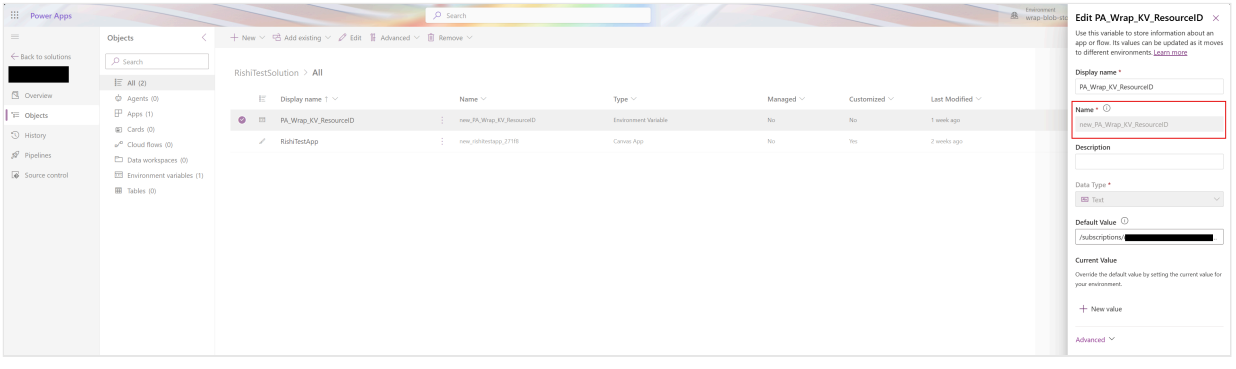


g. Select **Finish**.

h. On the main screen, the Azure Key Vault and certificate appear as confirmed.

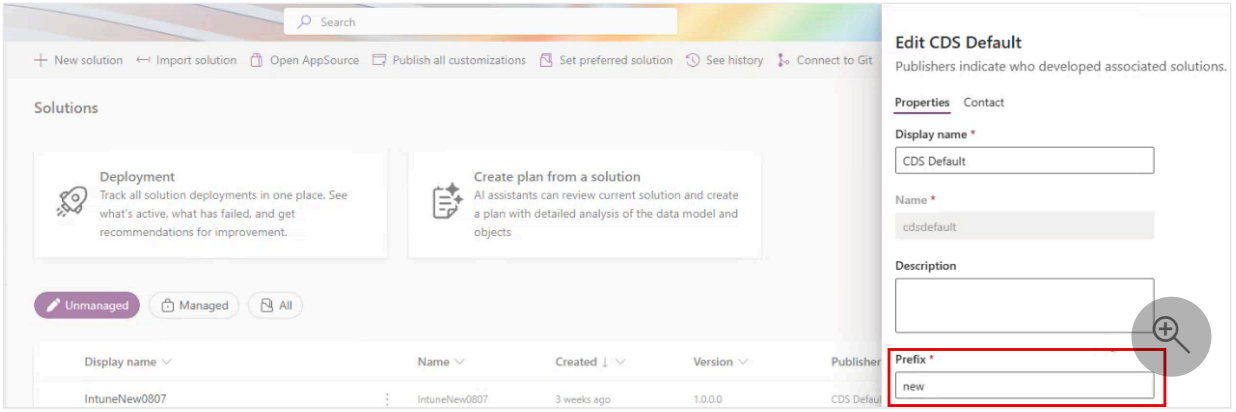
i. On the main screen, select **Next**.

6. Set up autosigning from within Azure portal.
   a. Refer to instructions in create an Azure key vault to create an Azure key vault. Once the vault is created, you need to add the required tags, secrets, and certificates. Add the environment variable if not created already.
   b. To create the environment variable, go to Power Apps > **Solutions** > **Default solution**. Then select **New** > **More** > **Environment variable**, add the display name as "PA_Wrap_KV_ResourceID".

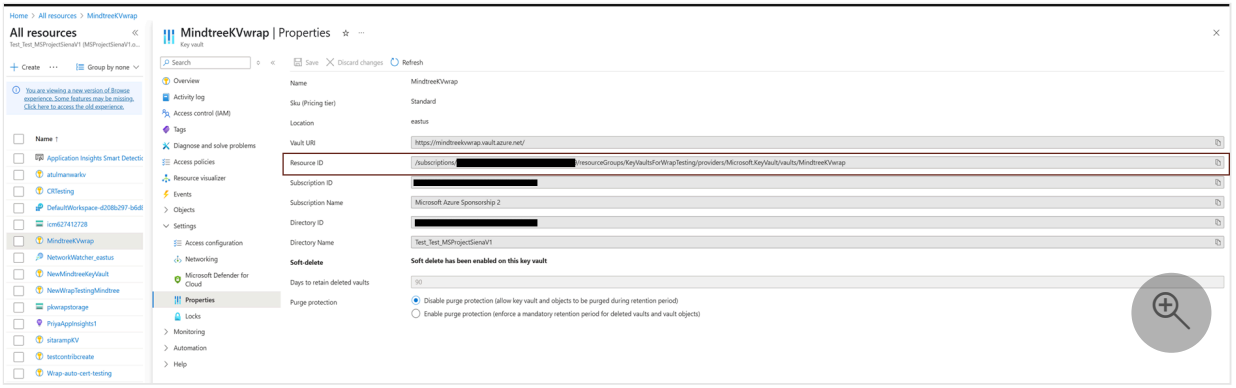


The name of the new environment variable must have the prefix "new." If it doesn't,

see Set Environment Variable Prefix for detailed steps.



c. To add vault information to your environment variables, access the **Azure** portal as an admin. Navigate to **All Resources** > **Your Key Vault** > **Properties**, and then copy the **Resource ID**.



d. To add the input to the environment variable, go to **Power Apps** > **ApplicationName** > **All** > **Environment variable**. Click the three dots, select **Edit**, add the copied value to **Default value**, and save.

e. To check whether the table value has been updated, go to **Power Apps** > **Tables** > **Environment variable definition** > **new_PA_Wrap_KV_ResourceID** . The value in **Default value** must be same as that of the resourceID for which you want to add the vault.

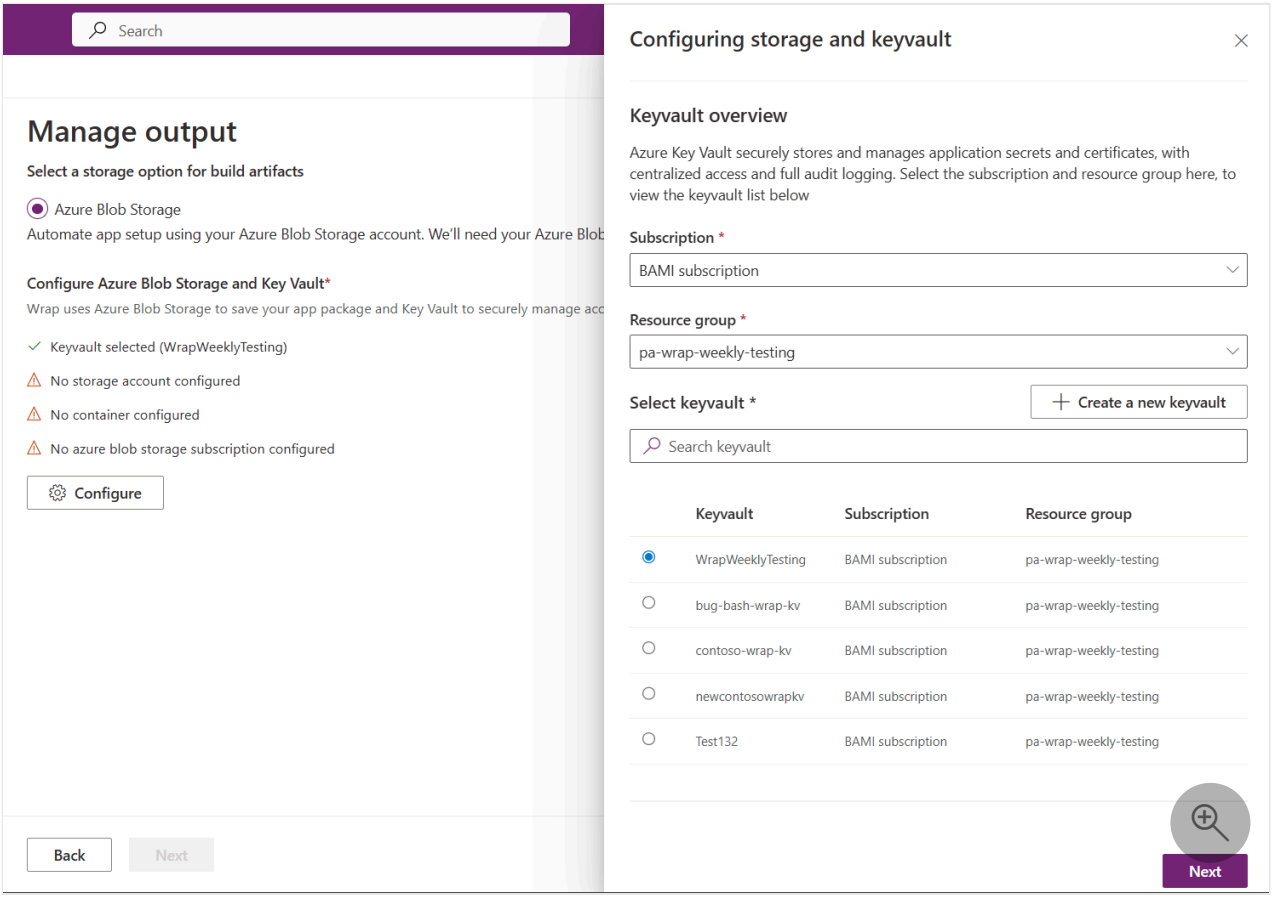
> **Note**
>
> Guidelines for adding the input behind the environment variables for Key vault information:
>
> - Environment variables must not be empty or can contain multiple entries.
> - Ensure that the resourceID added is correct (verify spelling).
> - Ensure that the resourceID added has non-empty tags and includes all the tags expected with the bundle ID used in the wrap wizard.

f. Follow the steps in Steps for automated code signing to create the tags, secrets, and certificates required during the automatic signing process.

4. Manage output

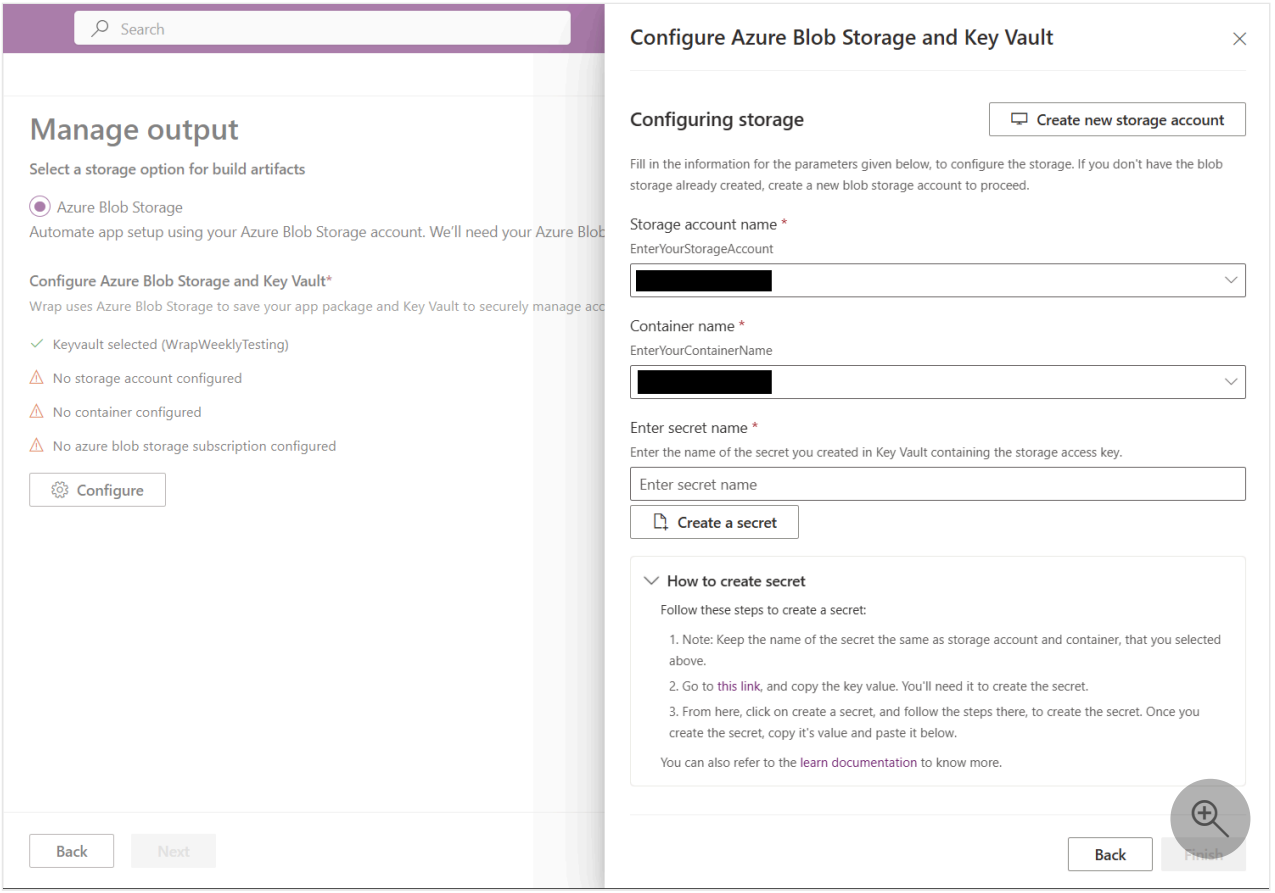
To upload your build to Azure blob storage, you need an Azure blob storage account and container. If you don't have one, create one.

1. On **Manage output**, select **Configure** to add your key vault, storage account, and container information.
2. In the **Configure keyvault** side panel, select the key vault that stores access credentials to your Azure blob storage, and then select **Next**.



3. In the **Configure storage** screen, select the storage name and container name, and then enter the name of the secret that contains access to the storage. To create a new secret,

follow the instructions in the "How to create a secret" section on the same screen.



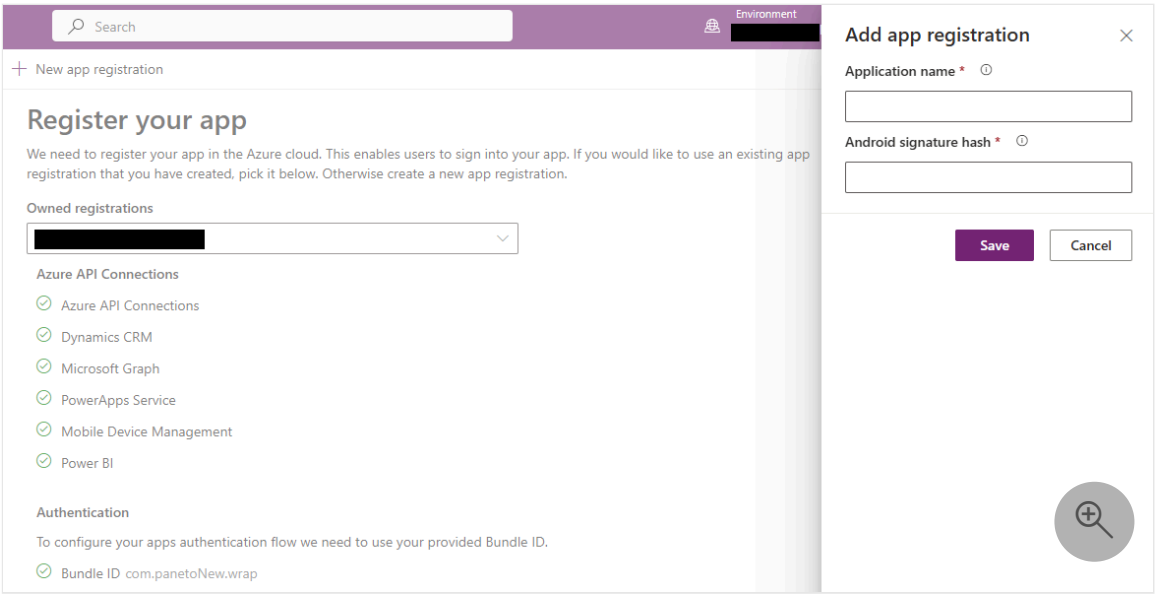
4. Select **Finish**.

5. Register your app

On the **Register your app** screen, register your application in Azure to establish trust with the Microsoft identity platform.

- **If you have already registered an app**:
  - Find your registration in the owned registration field.
- **If you do not see your registered app**:

  1. Select **New app registration** to create a new registration.
  2. Provide:
     - **Application name**: The customer-facing name of your app
     - **Android signature hash** (if targeting Android): A 28-character alphanumeric string



3. Save your changes.

Configure admin allowed third-party apps as an azure tenant admin

The registered app must be configured as a third-party app. To configure the app, the Azure tenant admin follows these steps.

For Windows

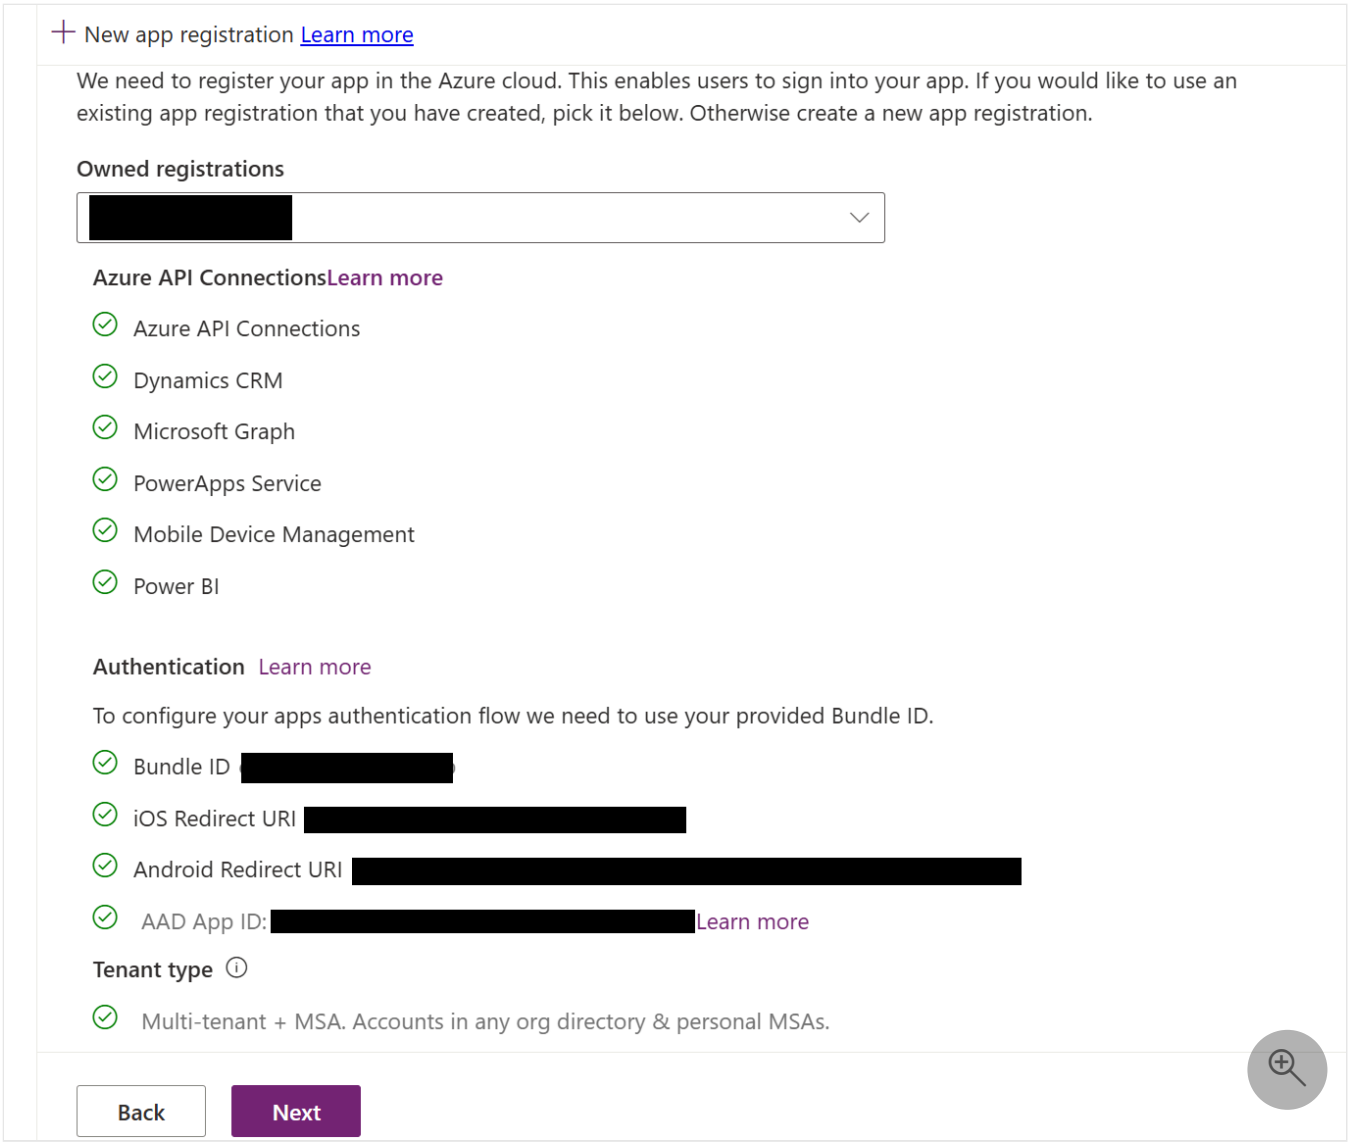
1. Open Windows PowerShell as administrator.
2. Run these commands:

PowerShell

```
Install-Module -Name Microsoft.PowerApps.Administration.PowerShell -
AllowClobber -Force
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned
Import-Module -Name Microsoft.PowerApps.Administration.PowerShell
Add-AdminAllowedThirdPartyApps
Get-AdminAllowedThirdPartyApps
```

3. Provide the App ID when prompted.

After completing these steps, the registration screen will look like this:



Grant API permissions as an Azure tenant admin

The app requires the following API permissions to function correctly.

Required API permissions

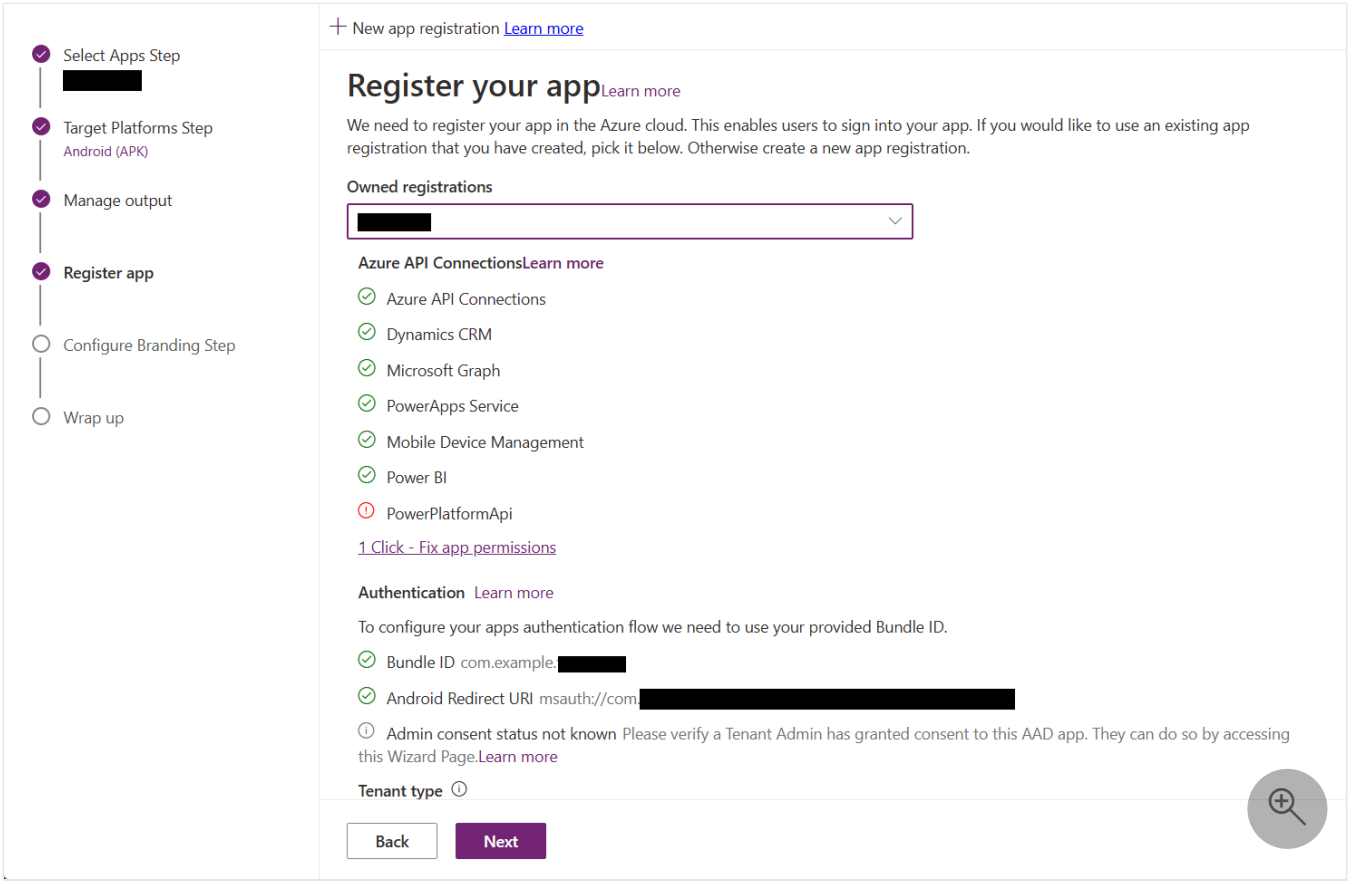
Expand table

API Type	Specific API	Reason
Microsoft APIs	Dynamics CRM	The application needs `user_impersonation` to call Dataverse for the user.
APIs my organization uses	Azure API Connections	The application needs `Runtime.All` to call any connector from Power Platform.
APIs my organization uses	PowerApps Service	The application needs the `User` permission to contact Power Apps backend services from Power Platform.
APIs my	Power BI	The application needs Power BI permissions to access

API Type	Specific API	Reason
organization uses		or embed Power BI content.
APIs my organization uses	Microsoft Mobile Application Management	The application needs this permission because Power Apps uses Intune SDK internally.

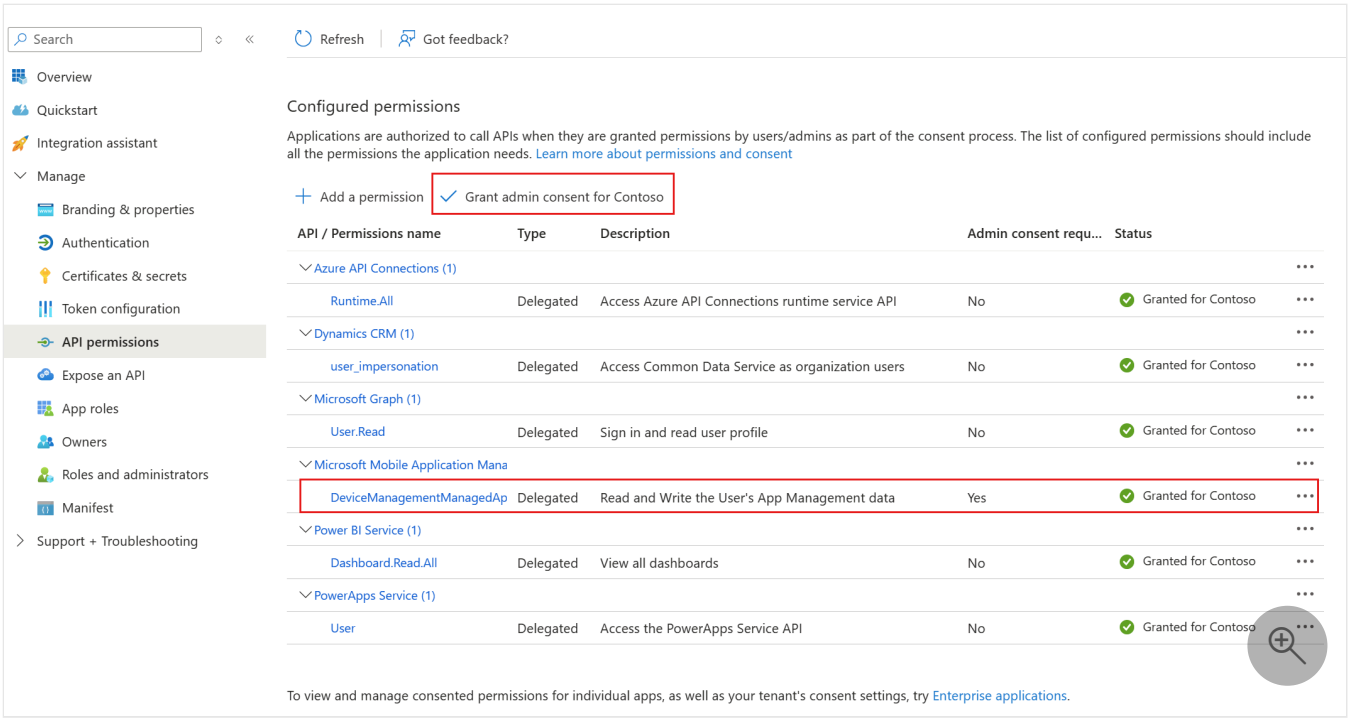
Configure permissions from within Wrap wizard

The wrap wizard checks and flags permissions that aren't available with the app. As an Azure admin, select one click access in the wrap wizard to grant the pending permissions. Alternatively, you can configure permissions through the Powershell commands below.



Configure permissions through Powershell commands:

Make sure **DeviceManagementManagedApplication** is set to **Yes** when you grant admin consent for your app.



Run these PowerShell commands as an Azure admin if you don't see permissions under **APIs my organization uses**:

1. Ensure the module Microsoft Graph is available or install it:

   PowerShell

   ```powershell
   Install-Module -Name Microsoft.Graph
   ```

2. Grant *Azure API Connections* permission for the static AppId fe053c5f-3692-4f14-aef2-ee34fc081cae:

   PowerShell

   ```powershell
   Connect-MgGraph -TenantId <your tenant ID>
   New-MgServicePrincipal -AppId fe053c5f-3692-4f14-aef2-ee34fc081cae -
   DisplayName "Azure API Connections"
   ```

3. Grant *PowerApps Service* permission for the static AppId 475226c6-020e-4fb2-8a90-7a972cbfc1d4:

   PowerShell

   ```powershell
   Connect-MgGraph -TenantId <your tenant ID>
   New-MgServicePrincipal -AppId 475226c6-020e-4fb2-8a90-7a972cbfc1d4 -
   DisplayName "PowerApps Service"
   ```

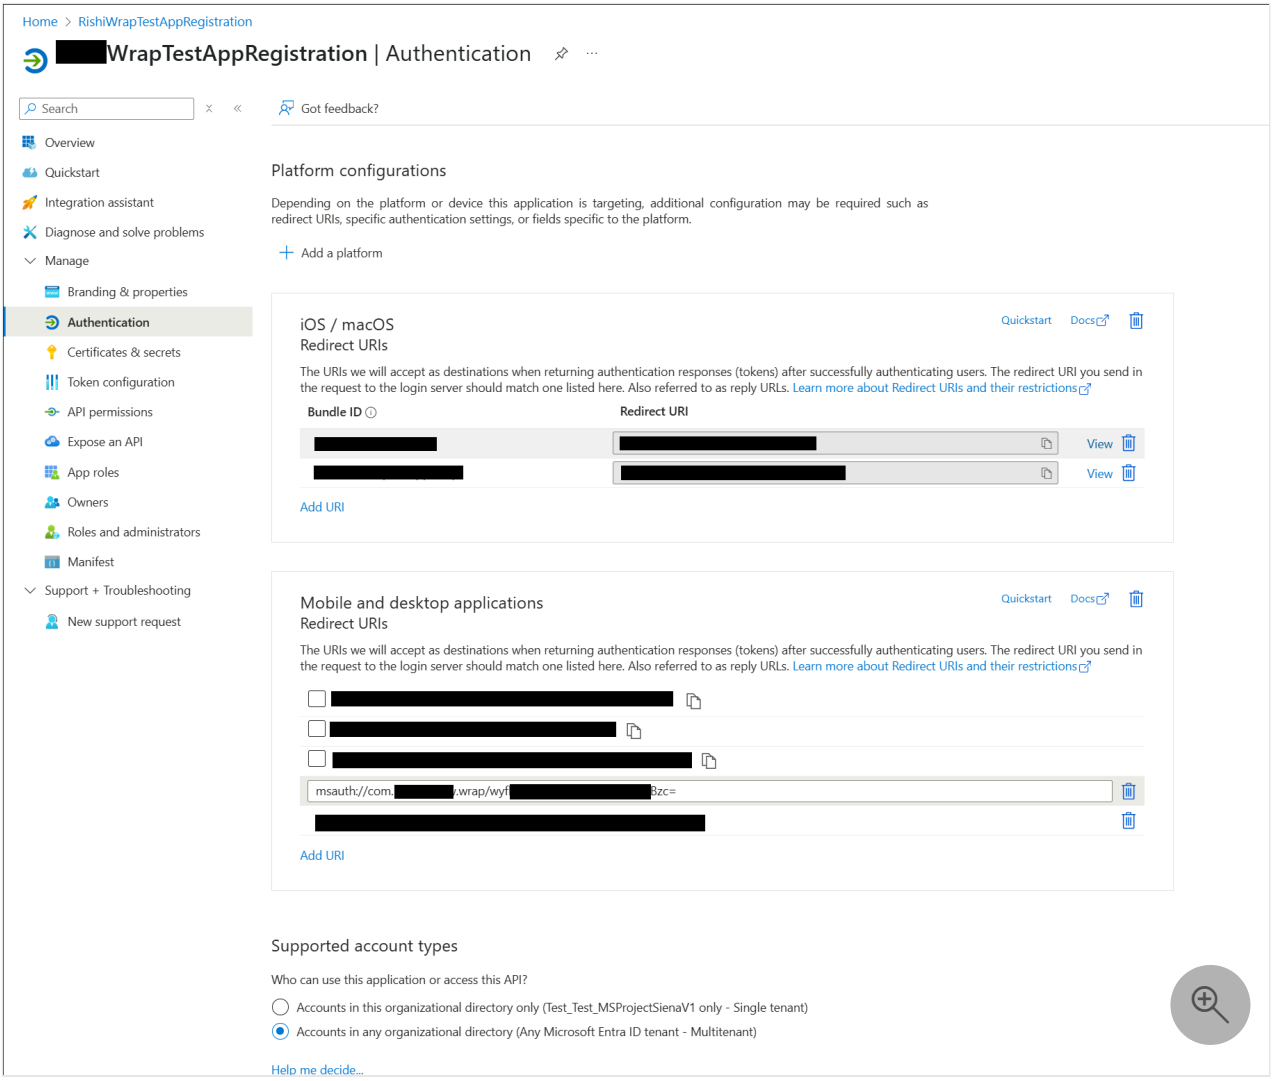
> **Note**
>
> If only the **Application name** field is visible, continue to the next steps and select **Android** as a target platform to display the signature hash field.

Configure API permissions manually (optional)

If you get errors, manually configure API permissions. For more information, see Add and configure.

Add Redirect URIs as an app admin

1. In the Azure Portal, go to your app registration > **Authentication**.
2. Select **Add a platform** and choose **iOS** or **Android**.
3. For iOS, enter the **Bundle ID**. For Android, enter both the **Bundle ID** and **Signature hash key**.



6. Configure branding

1. On the **Configure Branding** step, set the following options for your app:

> **Note**
>
> All images must be in .png format. Default images will be used if no custom images are selected.

Expand table

Setting	Description	Requirements
App icons	Icons for your app	iOS: 1024x1024 px or larger Android: 432x432 px or larger
Splash screen image	Image shown while the app loads	.png format
Welcome screen image	Image shown on the sign-in screen	.png format
Background fill color	Color for welcome screen background	Hexadecimal color code
Button fill color	Color for buttons	Hexadecimal color code
Status bar text theme	Color for the status bar text	Light or Dark

2. Select **Next**.

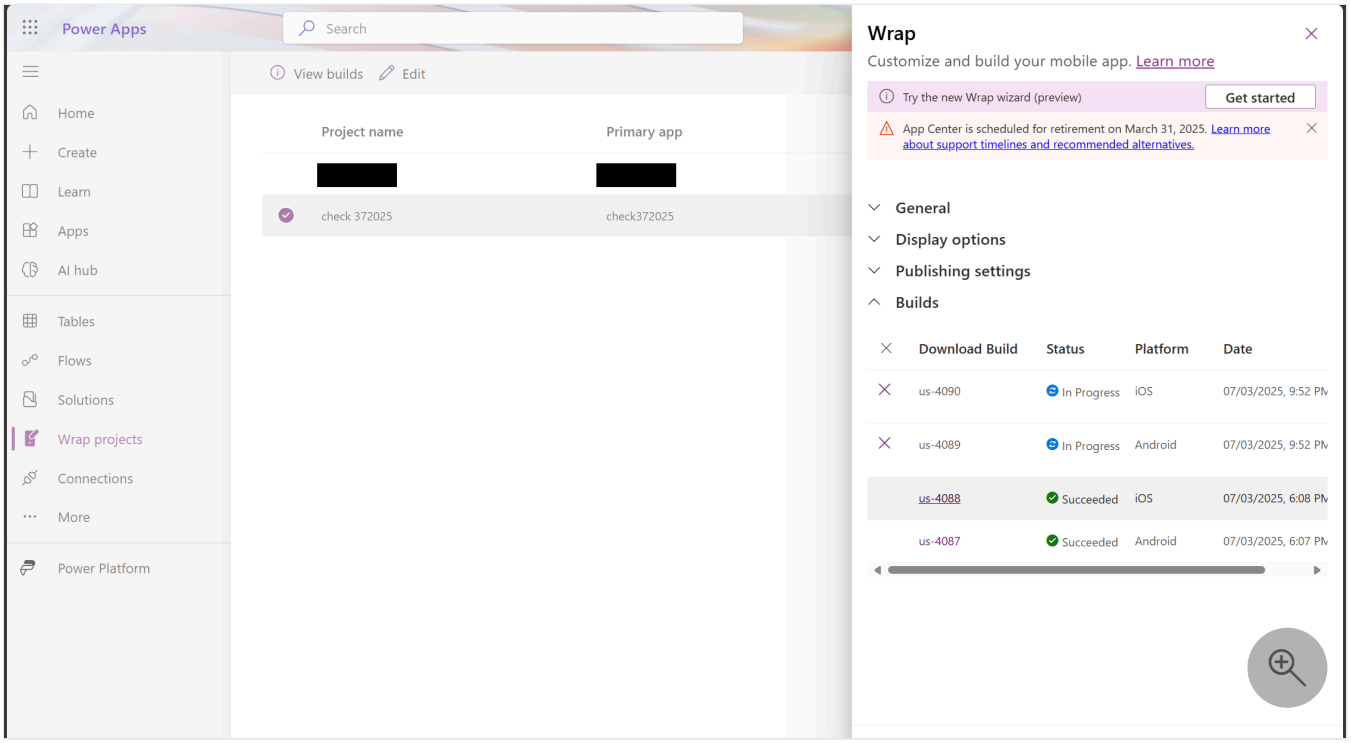
7. Wrap up and build

1. On the **Wrap up** screen, review your app details and select **Build**.
2. After a successful build, your app package will be available in the Azure blob storage you specified.

View your build

You can view your build in several ways:

- After building, select **View Builds**
- Go to **Wrap projects** in the side pane, hover over the required project, and select it
- Select the **View builds** option in the top header



> **Note**
>
> To manually code sign an iOS app, unzip the IPA file using a Mac device.

Test and distribute your app

Test your app and distribute it as needed. If you encounter issues, see the troubleshooting page.

Set environment variable prefix

The name of the new environment variable must have the prefix "new." If it doesn't, follow these steps:

1. Go to **Solutions** > **New solution**.
2. Select a **Publisher** or create one.
3. Select the edit icon next to the **Publisher** to view or change the prefix.
4. If the prefix isn't "new," change it to "new."
5. Save your changes.

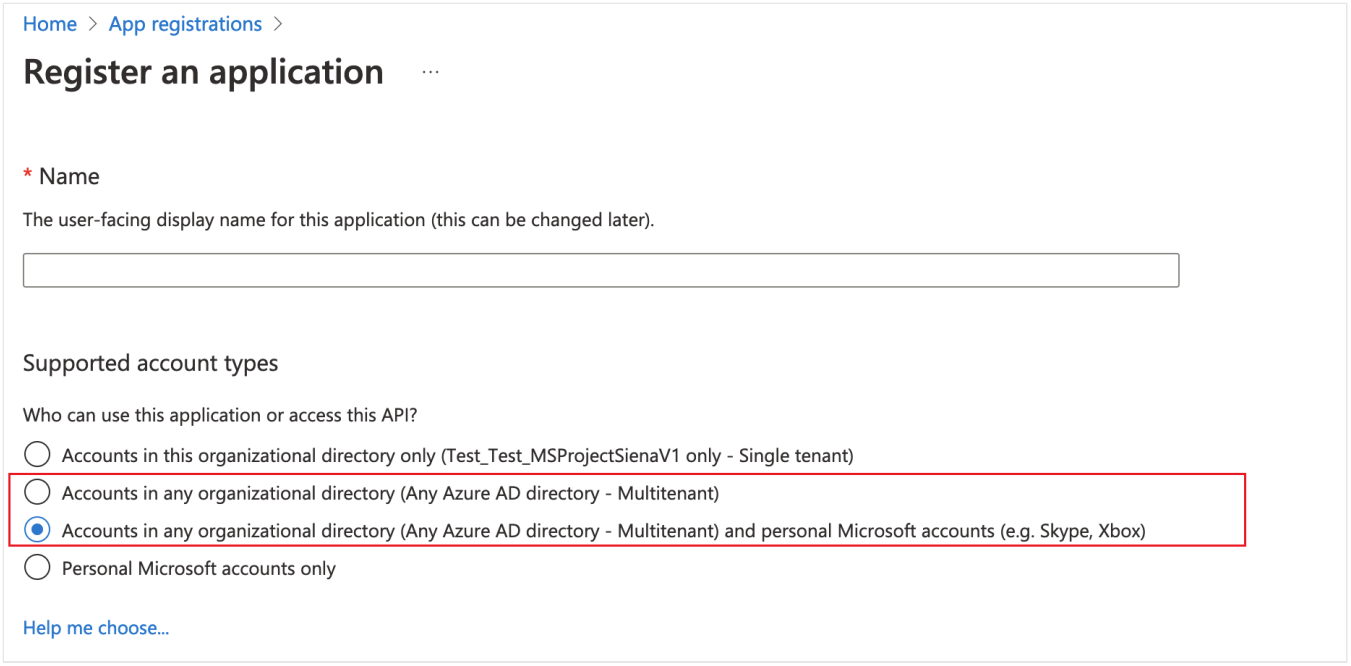
Register your app on Azure portal manually (optional)

You can create your app registration automatically in the wizard or manually in Azure. More information: Quickstart: Register an application with the Microsoft identity platform.

> **Note**
>
> Both single tenant and multitenant customers can use wrap to create native mobile apps based on their Power Apps canvas apps.

When registering, select an account type containing **Any Microsoft Entra directory - Multitenant**:

- Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant)
- Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant) and personal Microsoft accounts such as Skype or Xbox



> **Important**
>
> - Wrap only supports **Multitenant** account types currently. The single tenant account type is not yet supported. More information: Account types in Microsoft identity platform.
> - You must create a separate **Redirect URI** for each platform (iOS, Android).

Sign your mobile app package manually (optional)

You can sign your app automatically in **Step 2** or manually after building. Code signing is different for Android and iOS.

Advantages of automatic signing for iOS and Android (APK):

- You don't need to repeat the signing process during rewrapping.
- You don't have to wait for app developers to finish the process.
- You don't need to set up Android Studio or remember passwords.
- You don't need a Mac device for iOS signing.

Expand table

Platform	Signing Method
iOS	Manual code sign for iOS
Android	Manual code sign for Android
Google Play Store	Code signing for Google Play Store

Manual code sign for iOS

06/16/2025

This article explains how to code sign for iOS. You need to sign your app for iOS if you selected iOS as one of the platforms while creating and building your wrap project.

> **Important**
>
> Using Xcode to digitally sign your wrapped mobile apps for iOS is not supported. Follow the instructions below to sign your wrapped mobile app packages for iOS correctly.

Before you begin

Prerequisites

Before you start, make sure you have:

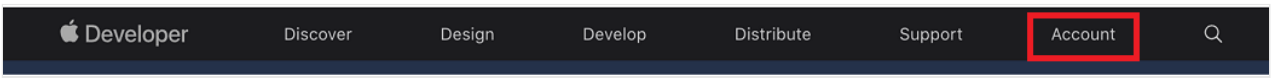
- App ID
- Device UDIDs (only for testing and development purposes)
- A macOS device to code sign for iOS

Set up your Mac

1. Install **Xcode**. More information: Xcode
2. Install PowerShell for macOS. More information: Installing PowerShell on macOS
3. Enroll in the Apple Developer Program
4. For organization distribution, sign up for the Apple Enterprise Developer Program

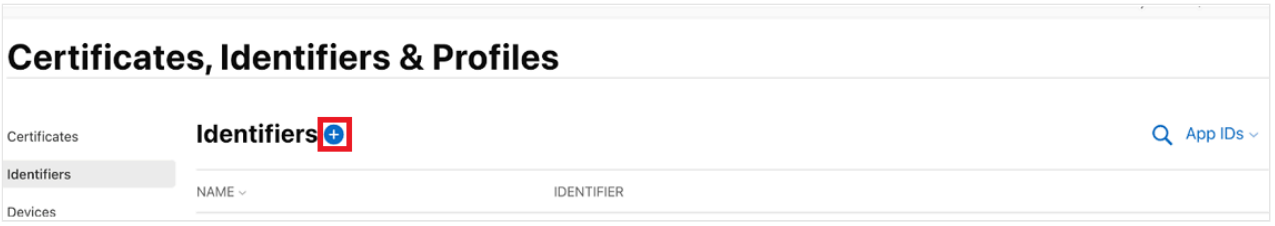
Create App ID

1. Sign in to your developer account at https://developer.apple.com and select the **Account** tab.

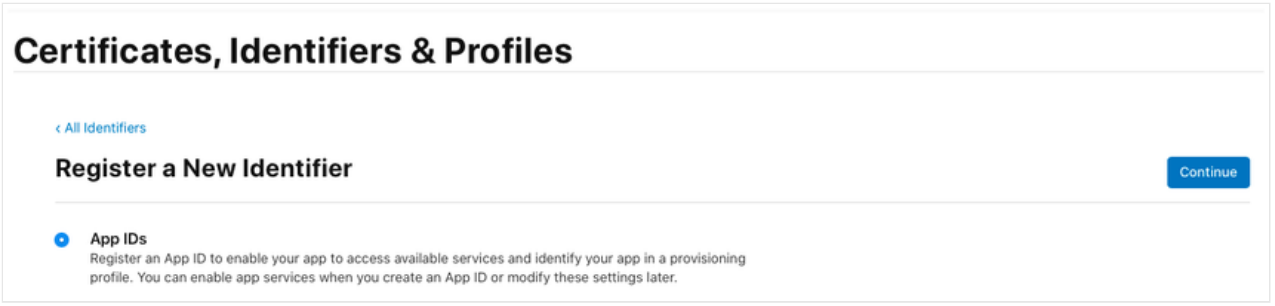


2. Go to **Certificates, IDs & Profiles > Identifiers**.

3. Select + to create a new identifier.



4. Select **App IDs**, then select **Continue**.



5. Select the type as **App**, then select **Continue**.

6. Register an **App ID**:

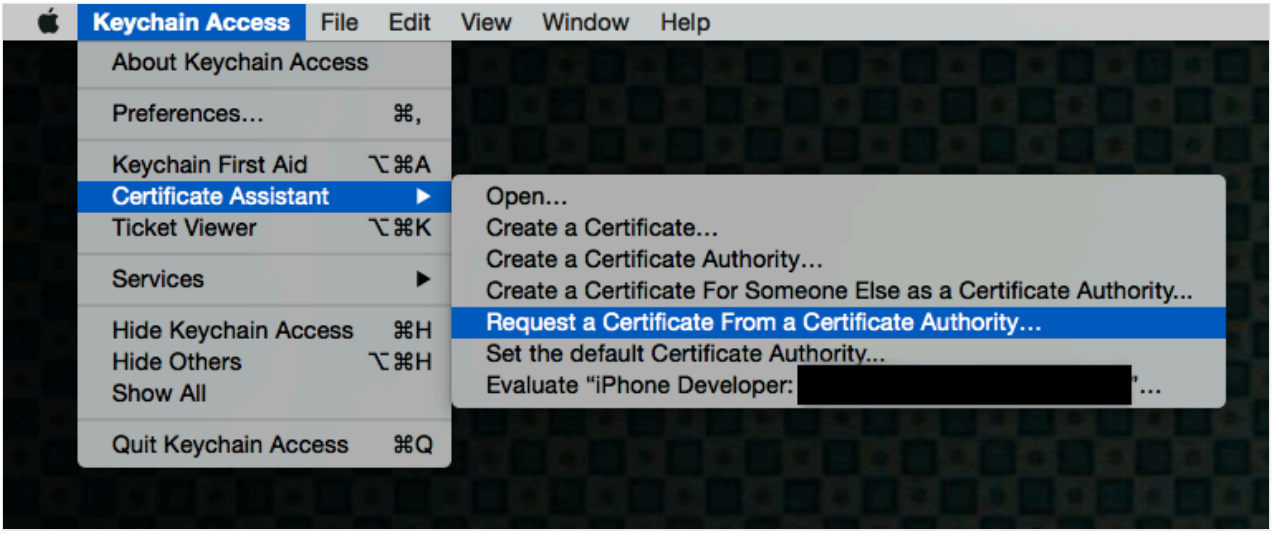
   - **Description** - Name of your app.
   - **Bundle ID** - Select **Explicit Bundle ID**.
   - Enter the bundle ID that you used while creating the wrap project. More information: Bundle ID
   - Enable these capabilities:
     - Associated Domains
     - iCloud
     - NFC Tag Reading
     - Push Notifications
   - Select **Continue**.

7. Review and register the App ID.

Create distribution certificate

Create Certificate Signing Request (CSR)

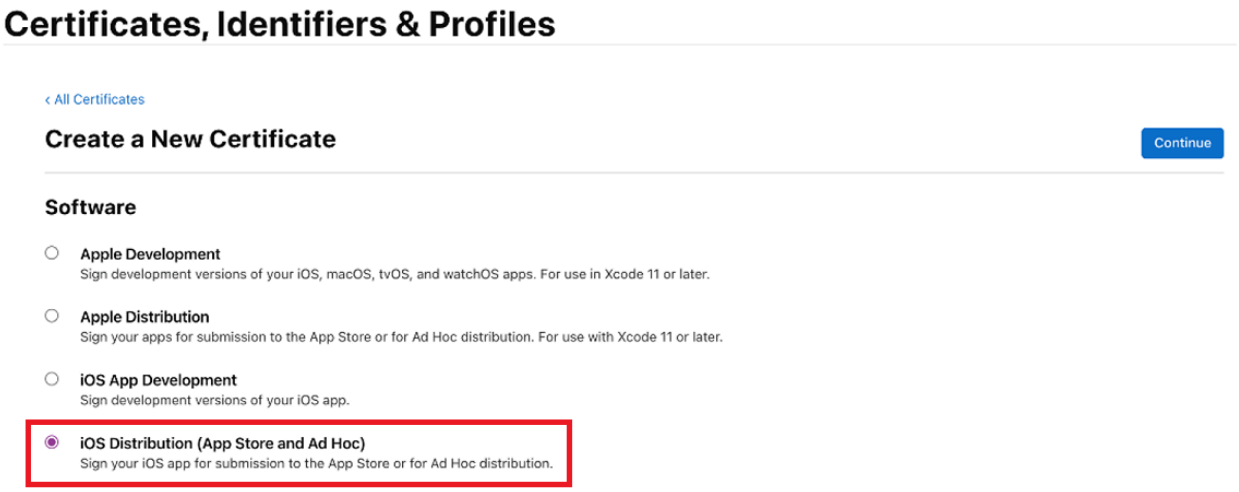
1. On your Mac, go to the **Applications** folder > **Utilities** > open **Keychain Access**.
2. Select **Keychain Access** > **Certificate Assistant** > **Request a Certificate from a Certificate Authority**.



3. Fill out the **Certificate Information**:
    - In the **User Email Address** field, enter your Apple ID email address.
    - In the **Common Name** field, enter your name.
    - In the **Request** group, select **Saved to disk**.
    - Save the file to your Mac.
    - Select **Continue**.

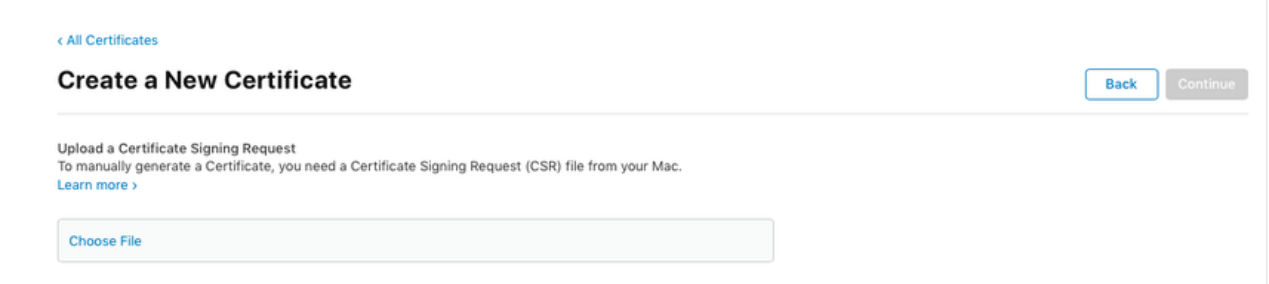
Upload and install certificate

1. Sign in to your developer account at https://developer.apple.com by selecting the **Account** tab.
2. Go to **Certificates, IDs & Profiles > Certificates**.
3. Select + to create a new certificate.
4. Select **App Store and Ad Hoc** > **Continue**.



> **Note**
>
> If you have an Enterprise Developer Account, you'll have the option to create an Enterprise Distribution certificate.

5. Upload the Certificate Signing Request (CSR) file that you generated in the previous steps.



6. Select **Continue**, and download the certificate to your Mac.
7. Double-click the downloaded .cer file to install it in Keychain Access.
8. Make note of the **Name** of the certificate (usually formatted as **iPhone Distribution: Name (Team ID)**). This value is the code signing identity needed for signing.

Register devices for testing

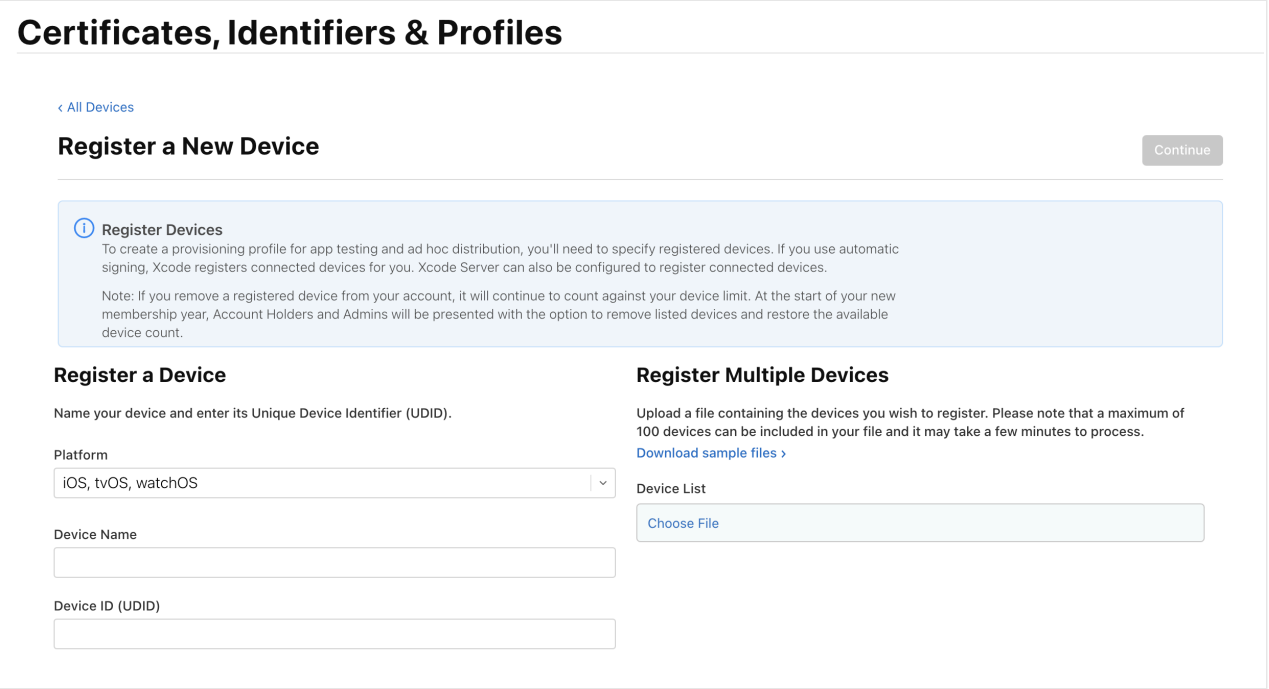
> **Note**
>
> This step is only necessary if you're distributing the app to external users. It's not required if the app is only for internal users.

1. Sign in to your developer account at https://developer.apple.com by selecting the **Account** tab.

2. Go to **Certificates, IDs & Profiles > Devices**.

3. Select + to register one or more devices.

4. Enter the **Device Name** and **Device ID (UDID)**.



5. Select **Save**.

> **Tip**
>
> You can register multiple devices at once by uploading a list of UDIDs.

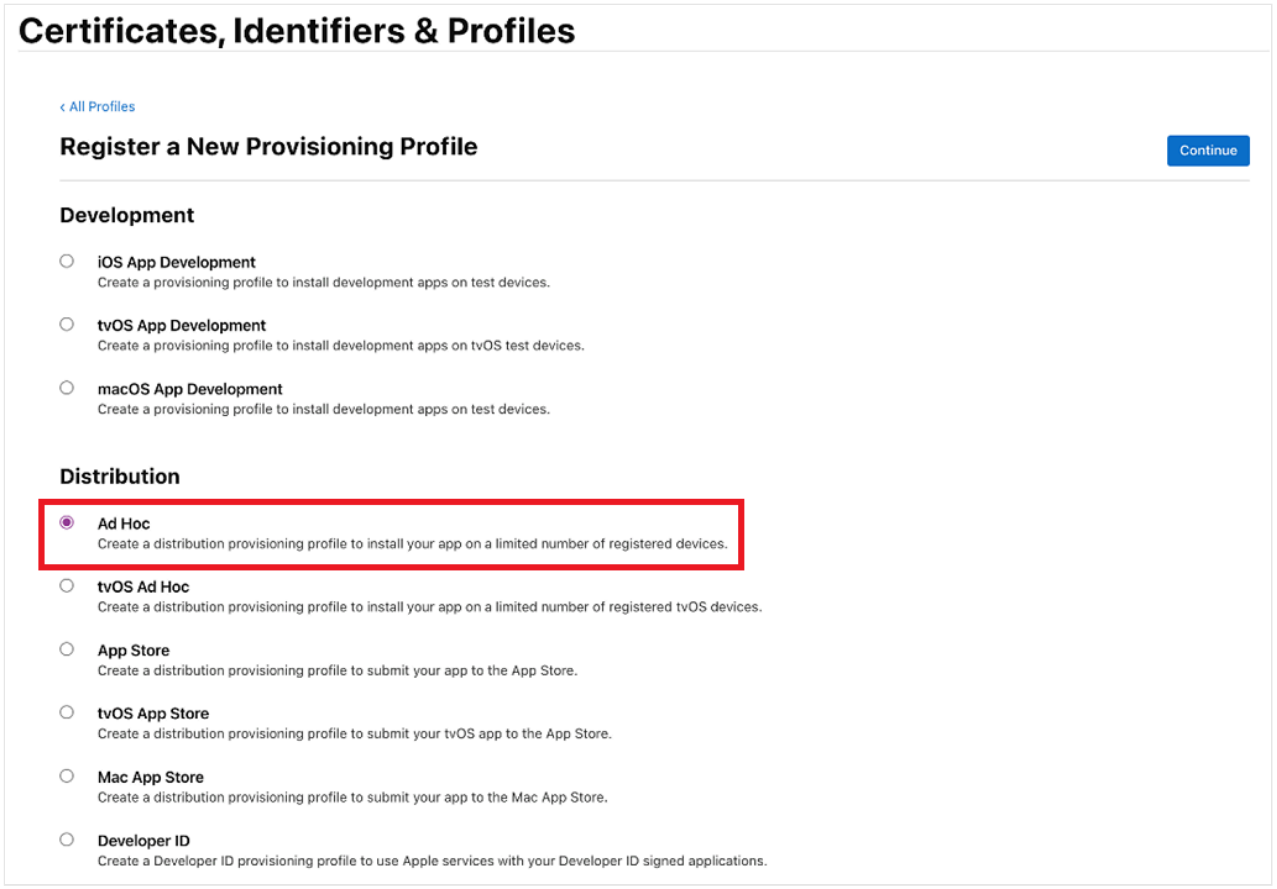
Create iOS Provisioning Profile

1. Sign in to your developer account at https://developer.apple.com and select the **Account** tab.

2. Go to **Certificates, IDs & Profiles > Profiles**.

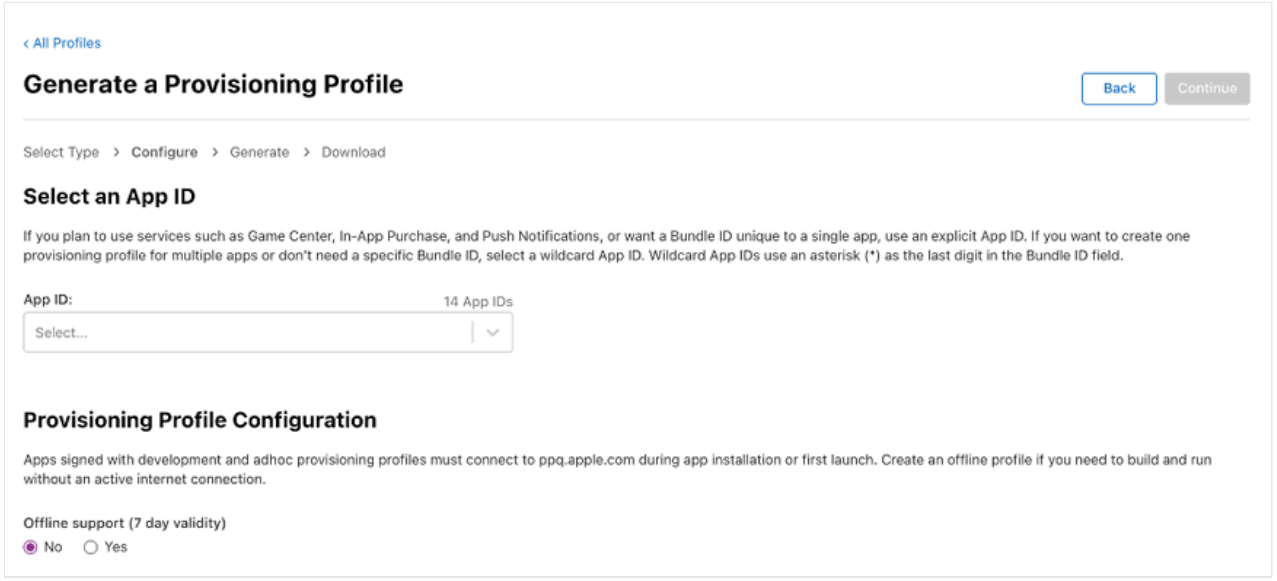
3. Select + to create a new profile.

4. Select **Ad Hoc** > **Continue**.

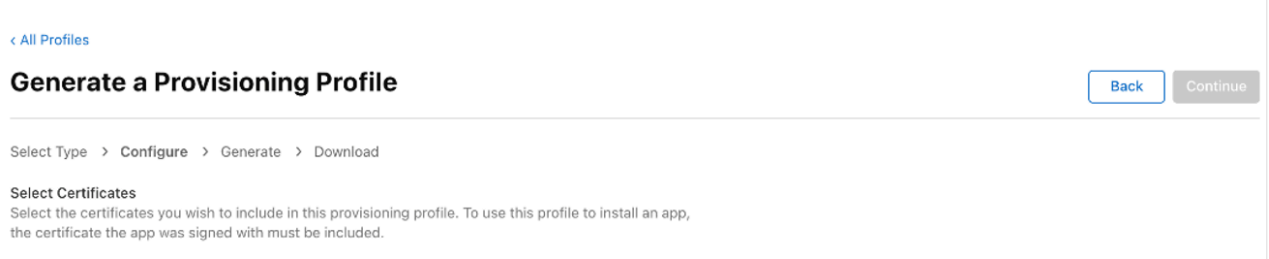


> ⓘ Note
>
> For production use, select the **App Store** distribution method.

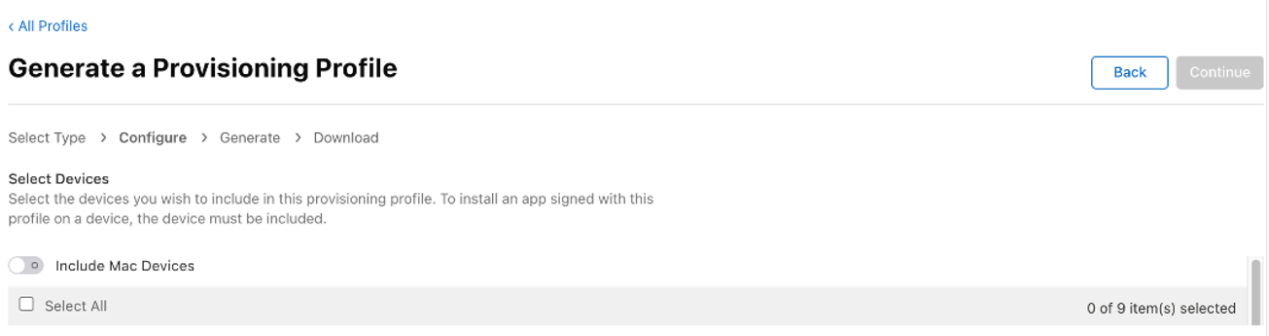
5. Select the App ID you created earlier, then select **Continue**.



6. Select the certificate you created earlier, then select **Continue**.



7. Select all the test devices where you want to install your app, then select **Continue**.



8. Name your provisioning profile and note down the name.
9. Select **Generate** and download the profile to your Mac.
10. Double-click the downloaded file (*.mobileprovision) to register it with Xcode.

Sign the iOS Archive

1. Download and unzip the **iOS-Archive.zip** file from your Azure blob storage. This creates a folder named after the Bundle ID. In the example below, the Bundle ID is **com.single.wrap**.
2. For enterprise signing only: Open the file **Distribution-exportOptions.plist** with Xcode and change the value for the **method** field to **enterprise**.

   > ⓘ **Note**
   >
   > Enterprise signing is not supported with Key Vault signing.

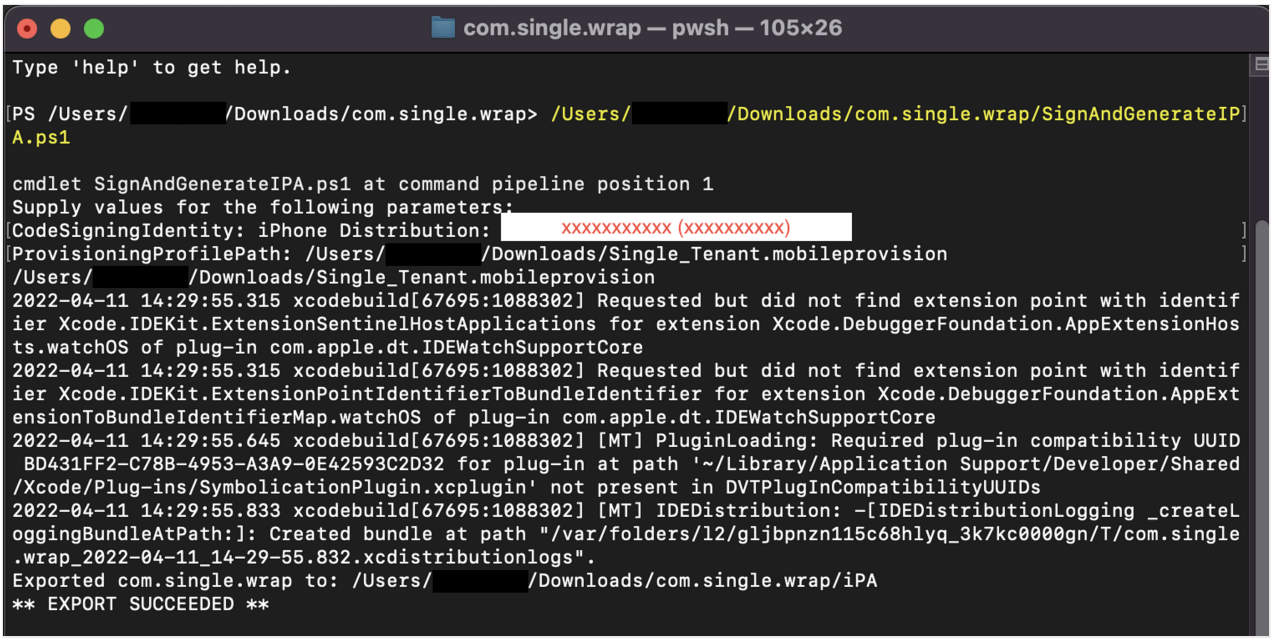
3. Open Terminal and change directory to the unzipped folder.
4. Enter `pwsh` to start PowerShell in the terminal.
5. Run the PowerShell script with your certificate and provisioning profile information:

```
```

```
./SignAndGenerateIPA.ps1 -CodeSigningIdentity "YOUR_CODE_SIGNING_IDENTITY" -
ProvisioningProfilePath "PATH_TO_PROVISIONING_PROFILE"
```

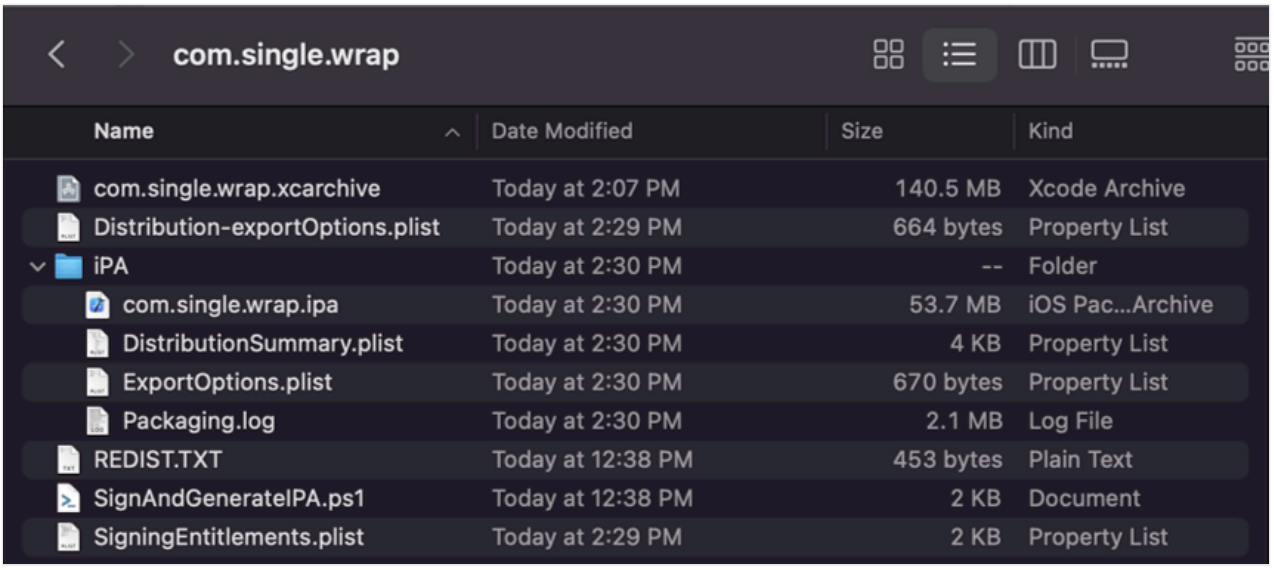
> **Note**
>
> To find your **CodeSigningIdentity** value, right-click on the **.mobileprovision** file, select **More Info** > **Preview**. Look for the **Name** field under **Certificates**.

> **Tip**
>
> The **ProvisioningProfilePath** is the path to the .mobileprovision file you downloaded. For example: `/Users/username/Downloads/MyProvisioningProfile.mobileprovision`



6. When the script completes, a **.ipa** file is created (for example, **com.single.wrap.ipa**).

> **Important**
>
> If the script fails, delete the unzipped folder and files as they might be corrupted. Unzip **iOS-Archive.zip** again before retrying.



Distribute the app

Install the **.ipa** file on registered devices using the **Finder** app.

For enterprise distribution with Microsoft Intune:

- Add an iOS/iPadOS line-of-business app to Microsoft Intune
- Give your app access to the Intune app protection service

Code sign for Android

07/30/2025

This article explains how to manually code sign your Android (APK) app for Power Apps wrap. Sign your app for Android if you select Android as one of the platforms when you create and build your wrap project.

> **Important**
>
> To sign an AAB app for Google Play distribution, see Sign your app.

Before you begin

Required software

Before you begin, install and set up:

- Android Studio
- OpenSSL
- apksigner tool (included with Android Studio)

Prerequisites

You need:

- The application name to create the hash key.
- The latest APK file to sign in.

> **Note**
>
> Use the `.jks` extension for manual signing and the `.pfx` extension for automatic signing.

Generate key and signature hash

> **Note**

Skip to Manual signing if you already generated keys and the signature hash when you created the app registration.

Set up environment variables

If you don't set environment variables:

1. Download and install Android Studio and OpenSSL.
2. Add `keytool` and `openssl` to your PATH environment variable:

    - Add `C:\Program Files\Android\Android Studio\jbr\bin` to your PATH.
    - Add the path of `openssl.exe` (for example, `C:\Program Files\OpenSSL-Win64\bin`) to your PATH.

For manual signing process

Generate signature hash key and certificate

Run this command in the command prompt:

```
keytool -genkey -alias powerappswrap -keyalg RSA -keystore powerappswrap.jks -
keysize 2048 -validity 10000
```

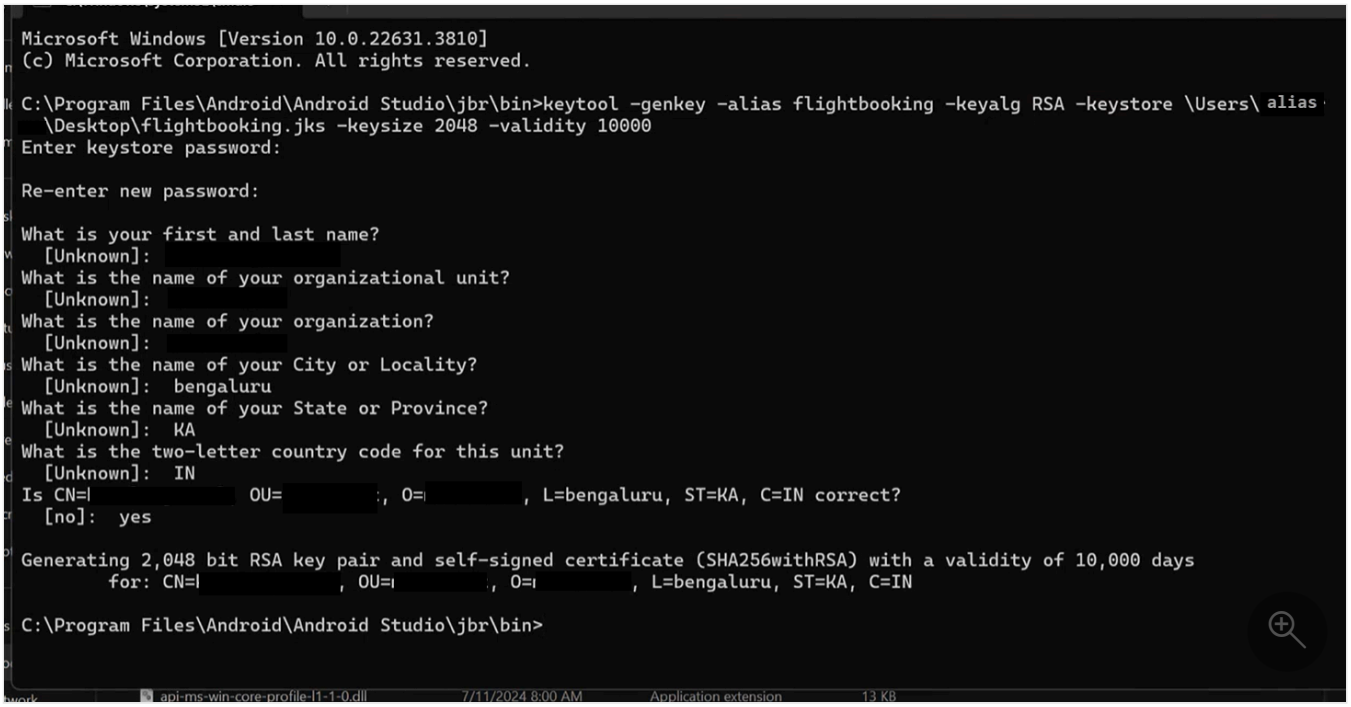
When prompted:

1. Enter a password for your keystore.
2. Enter your name, organization, location, and other required details.
3. Confirm the information.

Run this command to generate key and certificate:

```
keytool -exportcert -alias powerappswrap -keystore powerappswrap.jks | openssl
sha1 -binary | openssl base64
```

When prompted, enter the keystore password you created earlier.



Parameters explained:

Expand table

Parameter	Description
genkey	Command to generate a key
alias	Alias for the keystore entry
keyalg	Key algorithm name
keystore	Name of the keystore
keysize	Size of each key
validity	Validity of the key in days
exportcert	Reads the certificate from the keystore
openssl	Generates SHA1 key for Android

For automatic key vault signing process

Generate signature hash key and certificate

Run this command in the command prompt:

```
keytool -genkey -alias powerappswrap -keyalg RSA -keystore powerappswrap.pfx -
keysize 2048 -validity 10000
```

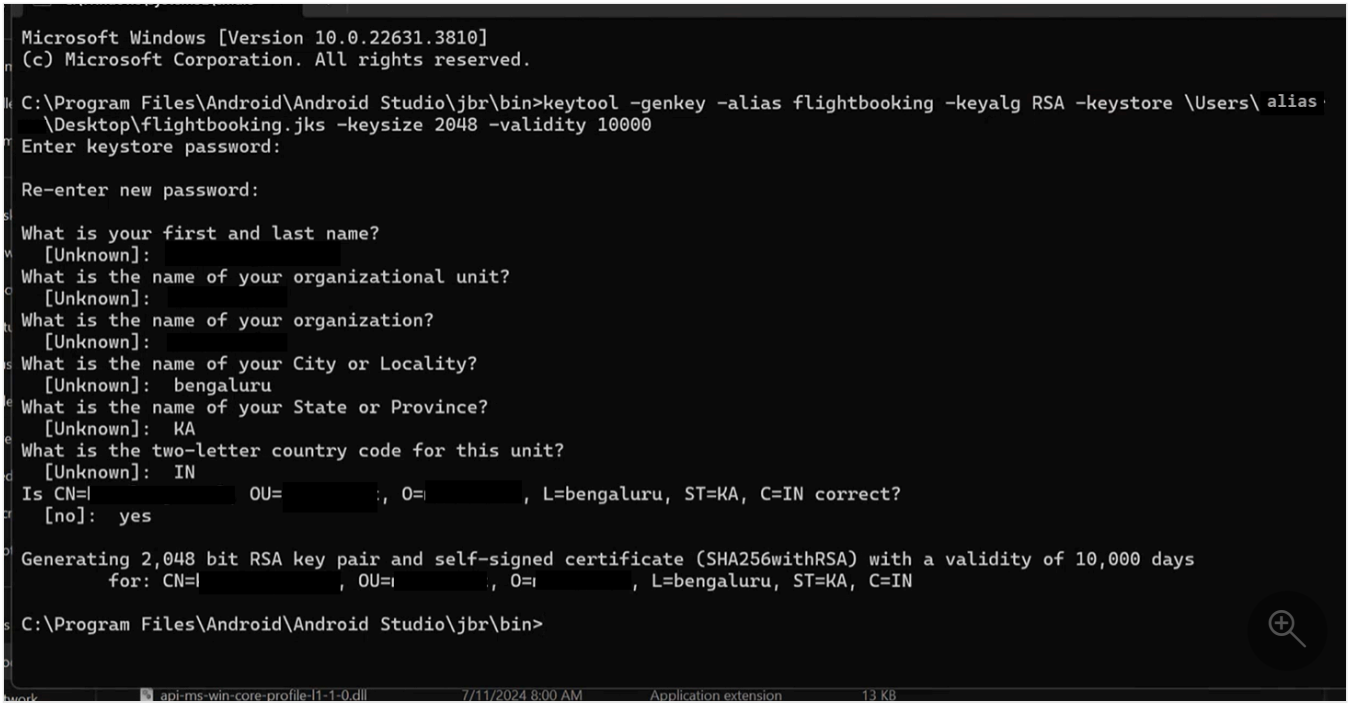
When prompted:

1. Enter a password for your keystore.
2. Enter your name, organization, location, and other required details.
3. Confirm the information.

Run this command to generate key and certificate:

```
keytool -exportcert -alias powerappswrap -keystore powerappswrap.pfx | openssl
sha1 -binary | openssl base64
```

When prompted, enter the keystore password you created earlier.



Parameters explained:

Expand table

Parameter	Description
genkey	Generates a key.
alias	Alias for the keystore entry.
keyalg	Key algorithm name.

Parameter	Description
keystore	Name of the keystore.
keysize	Size of each key.
validity	Validity of the key in days.
exportcert	Reads the certificate from the keystore
openssl	Generates SHA1 key for Android

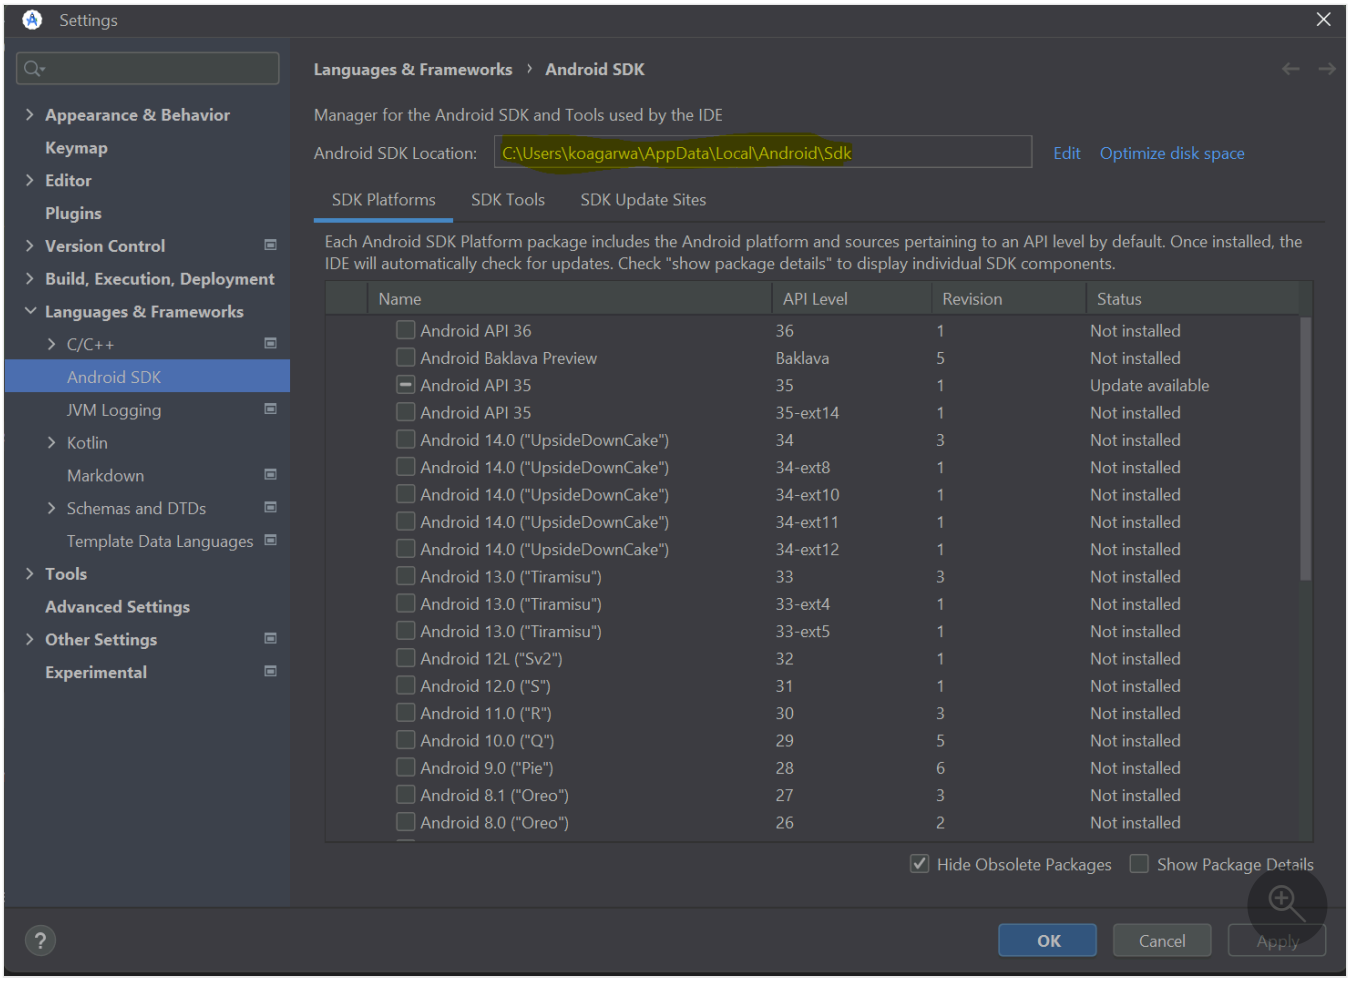
Manual signing of APK package (Not for KV signing)

Follow these steps if you don't use automatic sign-in during wrap or if you try to upload an AAB file for Play Store. To avoid repeating this process, use automatic sign-in when possible.

Locate the apksigner tool

1. Open Android Studio.
2. Go to **Tools** > **SDK Manager** > **Android SDK Location** to find your SDK path.
3. In the SDK directory, navigate to:

    - **build-tools** > **[version number]** > find **apksigner.bat** (Windows) or **apksigner** (Mac/Linux)
    - Or: **build-tools** > **[version number]** > **lib** > find **apksigner.jar**



Sign the APK file

Run this command to sign your APK:

```
apksigner.bat sign --ks PATH_TO_KEYSTORE --ks-key-alias KEY_ALIAS PATH_TO_APK
```

Parameters explained:

Expand table

Parameter	Description
ks	Path to your keystore file (for example, `C:\Users\name\Desktop\powerappswrap.jks`)
ks-key-alias	The alias you used when generating the key (for example, `powerappswrap`)
PATH_TO_APK	Full path to your APK file (for example, `C:\Users\name\Downloads\MyApp.apk`)

When prompted, enter the keystore password.

Example:

```
apksigner.bat sign --ks C:\Users\name\Desktop\powerappswrap.jks --ks-key-alias
powerappswrap C:\Users\name\Desktop\MyApp.apk
```

Verify the signature

After signing, verify the APK signature with:

```
apksigner.bat verify --verbose PATH_TO_APK
```

A successful verification confirms your APK is properly signed and ready for distribution.

For more information, see Android Studio command line tools: apksigner.

Distribute the app

After signing your app, you can distribute it using several methods:

Distribution options

- **Microsoft Intune**: To distribute using Microsoft Intune, see Add an Android line-of-business app to Microsoft Intune.
- **Intune app protection**: To give your app access to the Intune app protection service, see Give your app access to the Intune app protection service.
- **Direct distribution**: You can also distribute the signed APK directly to users for manual installation.

Code signing process for AAB file

06/16/2025

This article explains how to manually code sign an AAB file.

Prerequisite

1. Set up Android Studio.
2. Install bundletool for converting AAB file to APK file. You can download the latest version from the official site.
3. Install jarsigner for signing in the AAB file. You can install jarsigner by downloading and setting up the Java Development Kit (JDK).

Signing process for AAB file

> **Note**
>
> You need to sign the AAB file even if you select the automatic signing process in the wrap wizard.

To sign an AAB file, follow these steps:

1. Open a terminal or command prompt.
2. Go to the directory where `jarsigner` is installed.
3. Run the commands shown in the image.

```bash
jarsigner -verbose -sigalg SHA256withRSA -digestalg SHA-256 \
-keystore "<path-to-your-keystore>.jks" \
-signedjar "<output-signed-aab-file>.aab" \
"<input-unsigned-aab-file>.aab" \
<bundle-id>
```

Replace the placeholders: - `<path-to-your-keystore>.jks` – Path to your .jks keystore file - `<output-signed-aab-file>.aab` – Output file name. - `<input-unsigned-aab-file>.aab` – Unsigned .aab file. - `<bundleid>` – Bundle ID used while wrapping.

Convert AAB to APK file for manual debugging

To convert an AAB file to an APK file, follow these steps:

1. Open a terminal or command prompt.
2. Run the commands shown in the screenshot.

   Replace the placeholders: - `<path-to-signed-aab-file>.aab` – Path to the signed AAB file. - `<output-directory>` – Output directory for the .apks file.

- Sign the APK if you use the manual signing process. For more information, see Code sign for Android - Power Apps.

Set up Azure Key Vault for wrap wizard code signing

08/19/2025

Azure Key Vault is a cloud service that securely stores secrets like certificates, passwords, encryption keys, and other sensitive data. Use Key Vault to manage certificates and secrets for automated code signing in wrap wizard. For more information, see Introduction to Azure Key Vault.

This guide explains how new users create and configure an Azure Key Vault.

Prerequisites

Before you begin, ensure you have the following:

- A Microsoft Entra subscription to create a key vault.
- Admin access to your Azure tenant.
- An Apple Developer account enrolled in the Apple Developer Program or Apple Enterprise Developer Program.
- An Apple distribution certificate and either an ad-hoc provisioning profile or an enterprise provisioning profile.

Step 1: Create an Azure Key Vault

If you do not already have a Key Vault, follow the steps in Create a vault using the Azure portal.

Step 2: Create a service principal for wrap Key Vault access

A service principal is required so wrap wizard can access your Key Vault.

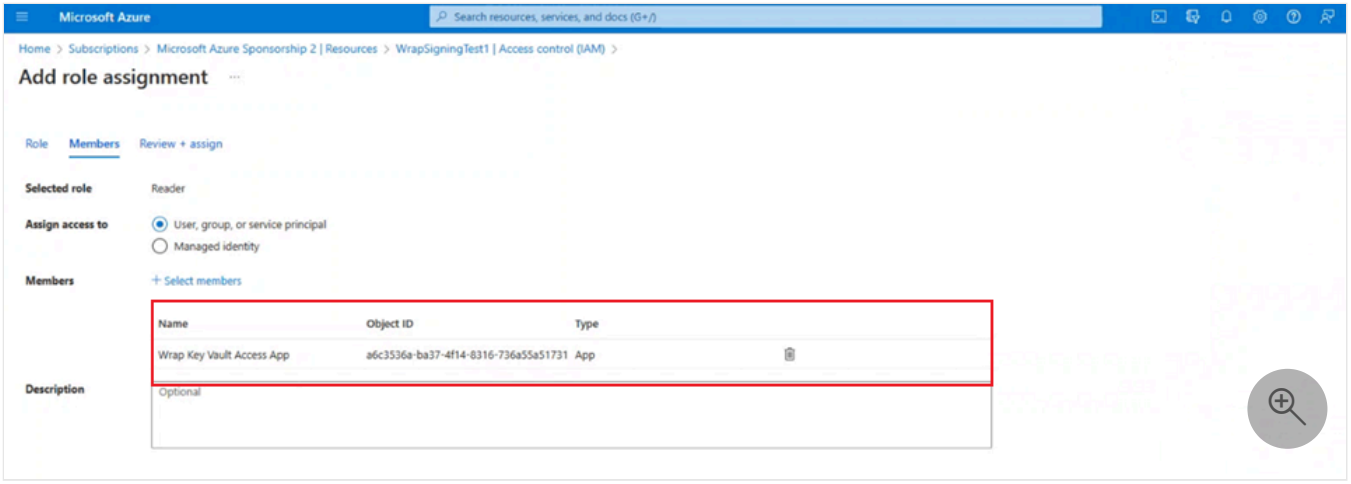
1. Sign in to your tenant as an admin.
2. Open PowerShell and run the following command:

```
Connect-AzureAD -TenantId <your tenant ID>
New-AzureADServicePrincipal -AppId 4e1f8dc5-5a42-45ce-a096-700fa485ba20 -
DisplayName "Wrap KeyVault Access App"
```

Step 3: Assign Reader Role to the Service Principal

Give the service principal permission to read your Key Vault.

1. In the Azure portal, navigate to your Key Vault.
2. Select **Access control (IAM)**.
3. Select **Add** > **Add role assignment**.
4. On the **Members** tab, select **Job function roles**, and then choose **Reader**.
5. Select **Select member**, search for "Wrap KeyVault Access App", and select it.
6. Select **Review + assign**.

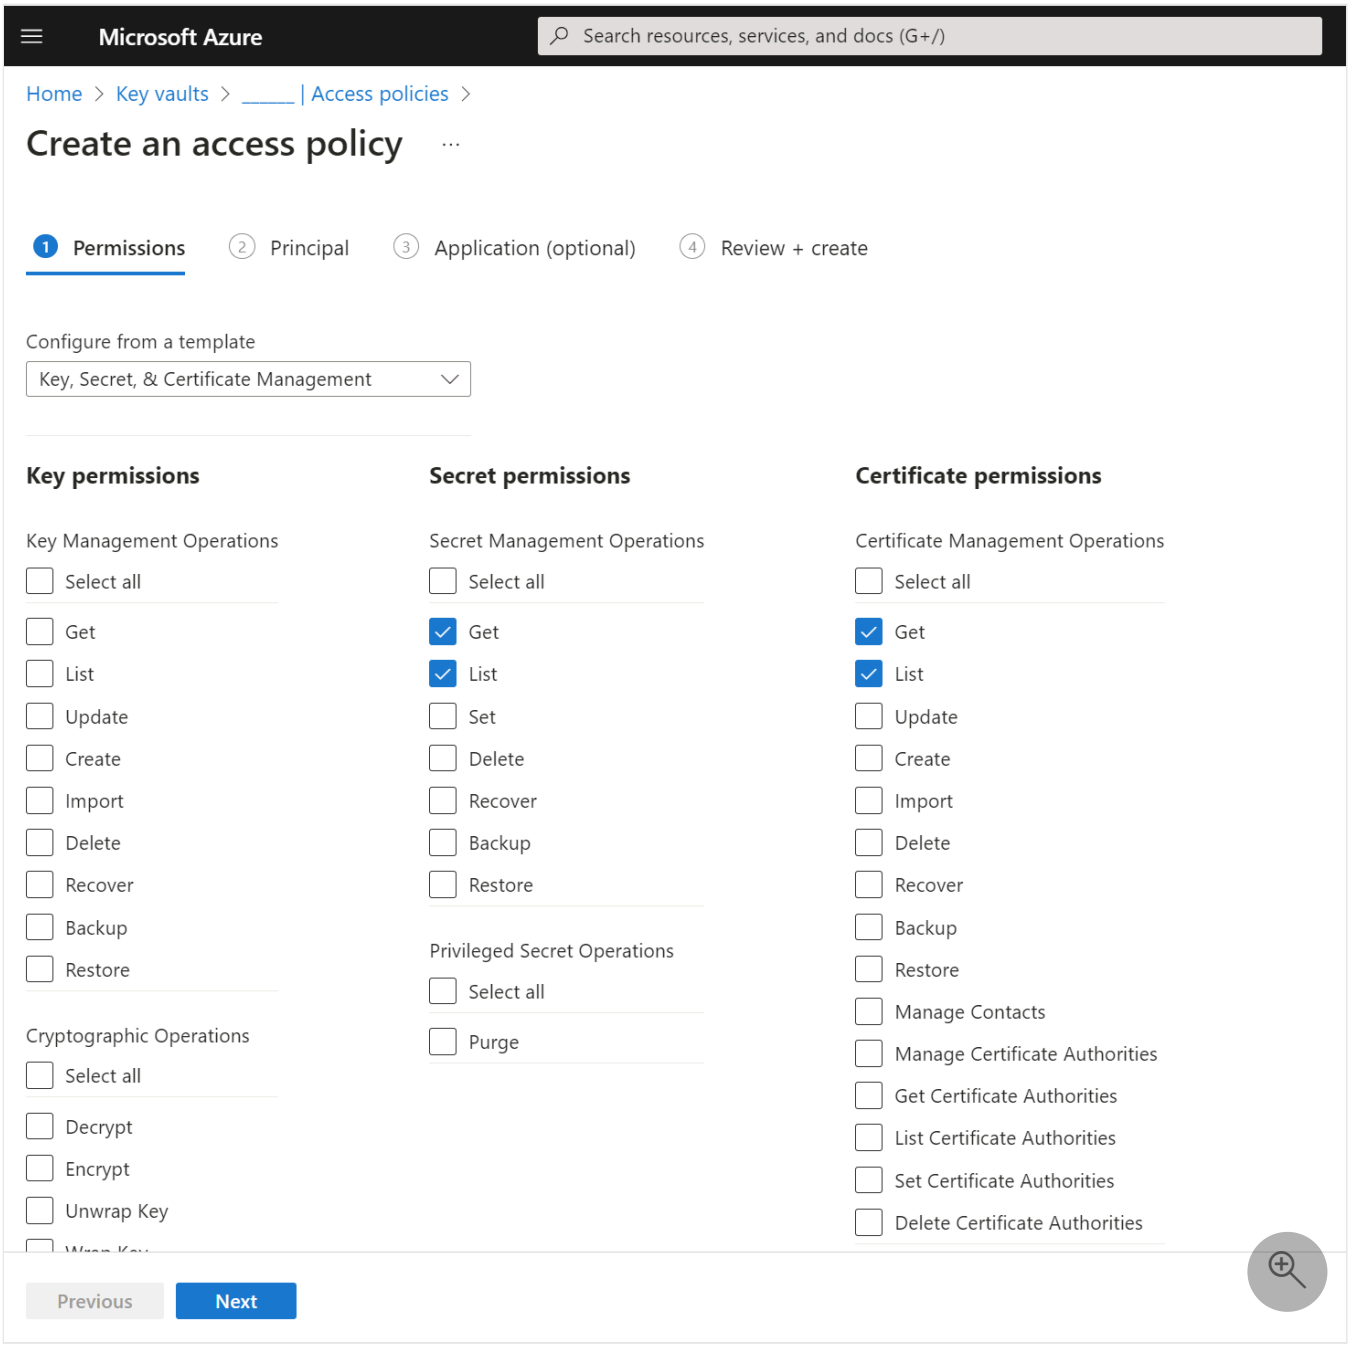


Repeat these steps to add user access permissions to your account.

Step 4: Configure access policies for Key Vault

1. Go to Key Vault settings.
2. In **Access configuration**, select **Vault access policies**.
3. Add a policy for the service principal and your user account.

    - For **Secret permissions** and **Certificate permissions**, select **Get** and **List**.

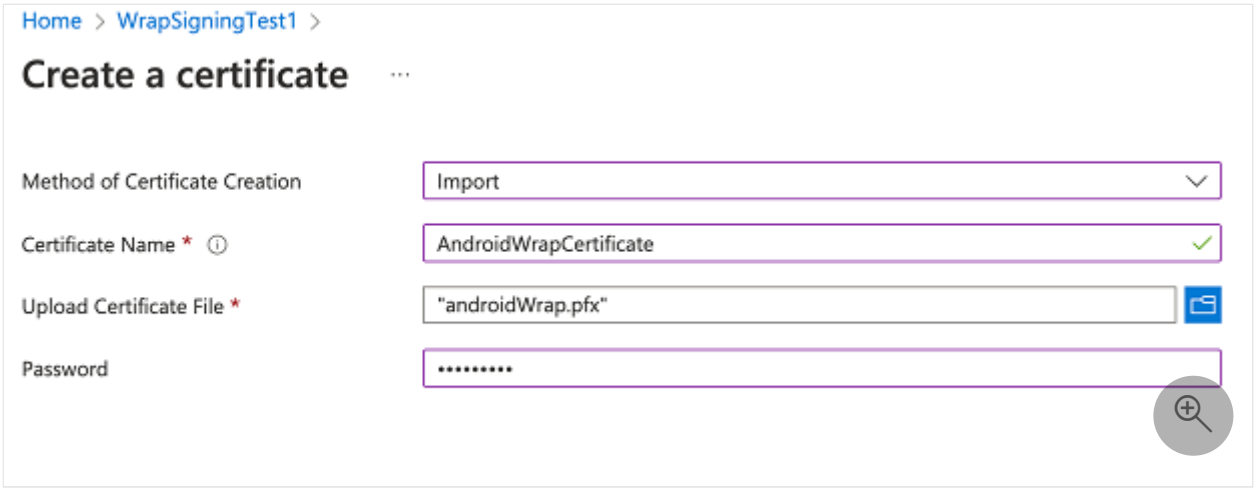


Step 5: Upload Certificates and Secrets

You need platform-specific certificates and secrets for Android and iOS apps.

For Android

- Generate a `.pfx` certificate file.
- Upload it to the **Certificates** section of your Key Vault.
- For guidance, see Generate keys.



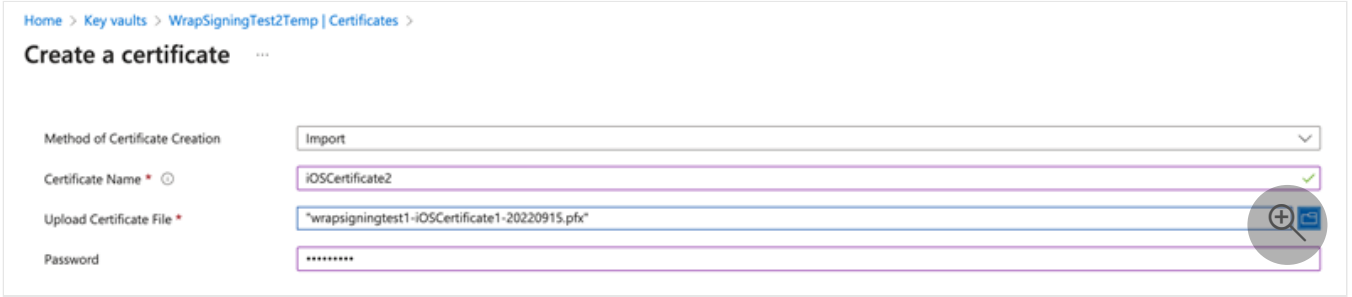
> **Note**
>
> Ensure the certificate name is included in the tag step, and its password matches the store pass parameter you set when creating the `.pfx` file.

For iOS

1. Install your `.cer` file using Keychain Access. For more information, see Create the distribution certificate.
2. Export the certificate as a `.p12` file and rename its extension to `.pfx` (required by Key Vault).
3. Upload the `.pfx` file to your Key Vault and provide the password you set for the `.p12` file.
4. Create a provisioning profile. For more information, see Create the provisioning profile.
5. Encode the provisioning profile to base64:

    - On Mac, run: `base64 -i example.mobileprovision`
    - On Windows, run: `certutil -encode data.txt tmp.b64`

6. Upload the base64 string as a secret in Key Vault and the `.pfx` file as a certificate.



Step 6: Add Certificate Tags

After uploading your iOS or Android certificates, add three tags:

- Tag name: Use your app's bundle ID.
- Tag value: Use the name of the uploaded certificate.

Use the same bundle ID that you'll use in the wrap wizard.

Use deep links with wrapped mobile apps

Article • 12/06/2022

Deep links let users move from one application to another on computers and mobile devices. For example, a mobile app can deep link to Facebook to sign in. Deep linking an email address could open an email app to allow users to start composing a message. A website could use a deep link to an app store to start download for a specfic mobile app.

You can deep link to a wrapped native mobile app from other apps. Deep links for wrapped mobile apps should start with the following:

```
ms-mobile-apps:///providers/Microsoft.PowerApps/apps/<appID>?tenantId=<tenantId>
```

Expand table

Parameter	Description
<app-id>	Opens the correct app module
<tenantId>	Connects to the correct tenant

For information on how to deep link into other apps in Power Apps, see Use deep links with Power Apps mobile.

Benefits and limitations of Wrap

06/17/2025

Wrap gives app makers benefits like improved adoption, better branding, and flexible distribution options. But it also has some limitations you need to consider.

Benefits of wrap

1. **Improved app adoption**: Users easily find and use your app by searching for its name in the App Store or Play Store. This direct access streamlines the experience and increases adoption rates.
2. **Enhanced branding flexibility**: Makers customize their app's branding, improving both distribution and user engagement.
3. **Custom distribution channels**: Distribute your apps through preferred channels, so you have more control and can reach your target audience more effectively, instead of relying only on standard platforms.
4. **Power Apps mobile for frontline workers (FLWs)**: Power Apps Mobile is for frontline workers. The wrap APK lets guest accounts sign in, so frontline workers outside your organization can use it. For details, see Frequently asked questions for wrap: Why am I not able to sign into my wrapped application?.
5. **Access without MFA or Intune**: You can use the Power Apps mobile app without multifactor authentication (MFA) or Microsoft Intune if your organization's conditional access policies allow it.
6. **Offline features**: Wrap apps support offline capabilities.

Limitations of Wrap

1. **Logout button**: There's no visible sign out button.

   > ⓘ Note
   >
   > Users can select and hold the indented application to sign out. Makers should let users know about this method.

2. **Push notifications**: Push notifications aren't supported.
3. **Navigation between apps**: You can't go directly from a specific screen in one app to a specific screen in another app. Only the home screen of the other app opens.
4. **APK size limit**: APK files distributed through the Google Play Store are limited to 100 MB. To support larger apps (up to 150 MB), create an AAB file during the wrap process.

5. **Android hardware back button**: The Android hardware back button doesn't always sync with the application back button.
6. **Feedback**: You can't provide feedback in the wrap app.
7. **Surveys**: Surveys aren't available for wrap users.
8. **Sovereign cloud**: Wrap doesn't support sovereign cloud environments.
9. **Full image view (offline)**: Offline-enabled wrap apps only show image thumbnails, not full image views.
10. **VPN**: The wrap wizard doesn't support creating a wrapped app while you're connected to a VPN. Updates are in progress.

- Troubleshoot issues with the wrap feature in Power Apps
- Frequently Asked Questions

Frequently asked questions for wrap

Frequently asked questions about the **wrap** feature are listed below.

Can single tenant customers use wrap with Power Apps?

Yes. Both single tenant and multitenant customers can use wrap. When registering your app manually in Azure, ensure you select the correct account type. See App registration for directions.

Does the wrap feature in Power Apps support Customer-Managed Keys (CMK) or Lockbox capabilities?

No. The wrap feature in Power Apps doesn't support Customer-Managed Keys (CMK) or Lockbox. Wrap uses Azure DevOps build pipelines, and customer assets might be exposed to Microsoft service operators during the build process.

Can I create mobile apps with Power Apps?

Yes. See Creating mobile apps with Power Apps.

If I create a mobile app with Power Apps, does Microsoft release it for me?

No. Microsoft wraps your app in a native mobile app shell for you to digitally sign and distribute.

How do I digitally sign my mobile app?

You can automatically sign your mobile app package in Step 2 of the wrap wizard if you have set up Azure Key Vault. For manual signing, see Android, iOS, and Google Play Store.

Can I use Xcode to digitally sign my mobile apps for iOS?

No. Signing your mobile app with Xcode isn't supported in wrap. To digitally sign your wrapped mobile app package for iOS, see Code sign for iOS.

How do I distribute my mobile app?

You can use Microsoft Intune, Google Play, or Apple Business Manager.

How do I configure my mobile app for distribution through Microsoft Intune?

Wrap wizard automatically configures your app for distribution with Microsoft Intune. To troubleshoot, you can manually grant all the canvas app(s) that you intend to wrap *Microsoft Mobile Application Management* API permission manually. More information: Configure the API permissions for your app manually.

Do I need to rewrap and redistribute my mobile app frequently?

Power Apps Mobile is updated periodically. To ensure compatibility and benefit from bug fixes and new features, we recommend that you rewrap and redistribute your mobile app at least monthly.

Do I need to rewrap and redistribute my mobile app after making changes to the canvas app(s) included in the package?

No. Published changes to the included canvas app(s) are downloaded automatically by existing, released versions of your mobile app. However, we recommend that you rewrap and redistribute your mobile app on a monthly basis to benefit from platform bug fixes, updates, and new features.

How do I update the icons and colors in my mobile app?

Update icons and colors by rewrapping your apps with new assets and redistributing the updated mobile app package.

How do I add or remove canvas apps in my wrapped mobile app?

Add or remove canvas apps by rewrapping your mobile app package with the desired set of apps and redistributing your mobile package.

What are Primary and Secondary apps in the context of wrap?

The Primary app provides the main experience of your mobile app. Secondary apps are bundled for performance reasons and must be linked from your primary app. See wrap multiple canvas apps together.

What are the advantages of including Secondary apps in the bundle, if I can still Launch() them without doing so?

Including Secondary apps in the bundle provides better launch performance when opening them for the first time. However, it's optional. If you have many Secondary apps, you may choose not to bundle them to reduce the total app size.

Can I add apps that use Power BI data to wrap?

Yes. Wrap wizard automatically configures your mobile app to be able to use Power BI. To troubleshoot, you can manually grant *Power BI* API permission to all your apps that use Power BI data. More information: Configure the API permissions for your app manually.

Can I deep link into a wrapped mobile app?

Yes. You can use `ms-mobile-apps:///providers/Microsoft.PowerApps/apps/<appID>?tenantId=<tenantId>` schema to deep link into your wrapped mobile apps. Refer to Using deep links with wrapped mobile apps for more information.

Why do I see this error message when I try to open my wrapped native app on a mobile device: You can't get there from here error message

Your organization might have a **Require Approved Client App** conditional access policy that restricts access to mobile apps. To fix this issue, see Edit your conditional access policy.

Can I create B2C mobile apps with Power Apps?

No. Power Apps is a platform for business applications and uses Microsoft Entra authentication. The wrap feature wraps existing canvas apps for the same set of end users.

Do I need a premium license to package the app?

No, you don't need a premium license for wrap. However, if your APK uses certain connectors, you will need to pay according to the requirements of those connectors.

Can I delete wrap projects?

No, wrap projects can't be deleted but you can delete the project APK files from your storage location.

How can I ensure that customers outside the home tenant can't access the app even

if I enable multitenant access during registration?

Users outside the home tenant can't access wrap projects unless both the Azure admin and the maker explicitly share the app with the user. The app ensures proper data separation across organizations by embedding the tenant identifier in the authentication token.

Can we allow users from outside home tenant to access wrap projects?

The Wrap App supports multi-tenancy. To enable this feature, the Azure admin must:

1. Add users from outside the home tenant as guests in Azure.
2. Include these guests in the Azure Conditional Access process.
3. The maker must share the app with these guest IDs within Power Apps.

Why am I not able to Sign into my wrapped Application?

1. Verify if the user has access to the PowerApps application. More information: Share a canvas app with your organization
2. If access is confirmed, check the app's Azure conditional policies. Admin access is required to review these policies. More information: View applied Conditional Access details in the Microsoft Entra activity logs
3. To troubleshoot sign-in errors, copy the correlation ID from the mobile screen where the sign-in is failing and refer How to troubleshoot Microsoft Entra sign-in errors to understand the error and the failing policies.
4. Check Microsoft Entra authentication and authorization error codes.
5. One common error code is 50194 (tag- 9n555). During the app registration stage, the supported account type isn't configured for multi-tenant. Configure it to support multi-tenant.

When do you need to re-wrap?

- If you're an existing customer who has already created and successfully distributed a wrapped app, you don't need to go through the wrapping process again. To ensure users

receive the latest published changes, follow the steps mentioned in Power Apps for Makers: Get App Versions.

- For new customers, we recommend re-wrapping if you have completed all the registration steps mentioned in Use the wrap wizard to build your mobile app: Register app and have either manually or automatically completed the sign-in process mentioned in Use the wrap wizard to build your mobile app: Sign your mobile app package manually.
- To ensure platform changes benefit end users, we recommend re-wrapping monthly and distributing the updated app to users.

How to find your Azure admin?

- Go to the Microsoft Entra roles and administration portal. More information: Microsoft Entra admin center
- Search for *global administration* in the search bar.
- Select the **Active assignments** tab.
- Review the list of owners for the active assignments.

Why is Azure key vault a mandatory step?

The Azure key vault securely stores the access key needed for Azure blob storage.

Do you need to pay for Azure key vault & Azure blob storage?

Yes. See Key Vault pricing .

What should I do if I don't have access to the resource group while creating the key vault?

Contact your Azure tenant admin to create a key vault for you or request permission.

How can Entra B2B guest users access the wrapped apps?

1. Add users from outside the home tenant as guests in Azure. See Quickstart: Add a guest user and send an invitation.
2. Include these guests in the Azure Conditional Access process. Share the app with these guest IDs in Power Apps. See Share a canvas app with your organization.
3. Replace the app ID and the user account in the following link: `ms-mobile-apps:///providers/Microsoft.PowerApps/apps/<appID>?tenantId=<tenantID>`
4. Share the link with your client.
5. Install the APK on Android and the IPA on iOS.
6. Open the weblink and enter the external IDs to sign in.

Troubleshoot issues with the wrap feature in Power Apps

Troubleshoot common issues when using the wrap feature

08/04/2025

This guide provides solutions to common issues you might encounter when using the wrap feature in Microsoft Power Apps.

Issue 1: Wrap build fails

If your wrap build fails, try the following actions:

Verify image formats

Ensure that all images in your wrap project are in PNG format. Using other formats can cause the build to fail. Use an image converter to convert your images to `.png` format.

> **Important**
>
> Renaming a file extension to `.png` doesn't convert the image to PNG format.

Check Azure key vault setup

- Ensure you create an Azure service principal and assign the correct role.
- For more information, see Azure key vault for wrap in Power Apps.

Your key vault must contain:

- **For iOS**: two tags, one certificate, and one secret.
- **For Android**: one tag and one certificate.

Issue 2: Wrap button is disabled

Confirm you have edit permissions for the app and try again. For a list of requirements, see Permissions and access requirements for wrap.

Issue 3: Unable to save your wrap project or trigger a build

Update to the latest version of the wrap solution and try again.

Issue 4: Unable to install a wrapped mobile app

Ensure your app is properly signed by configuring a key vault during the build process or by signing the app manually.

For more information, see:

- Set up Key vault for automated signing
- Code sign for iOS
- Code sign for Android

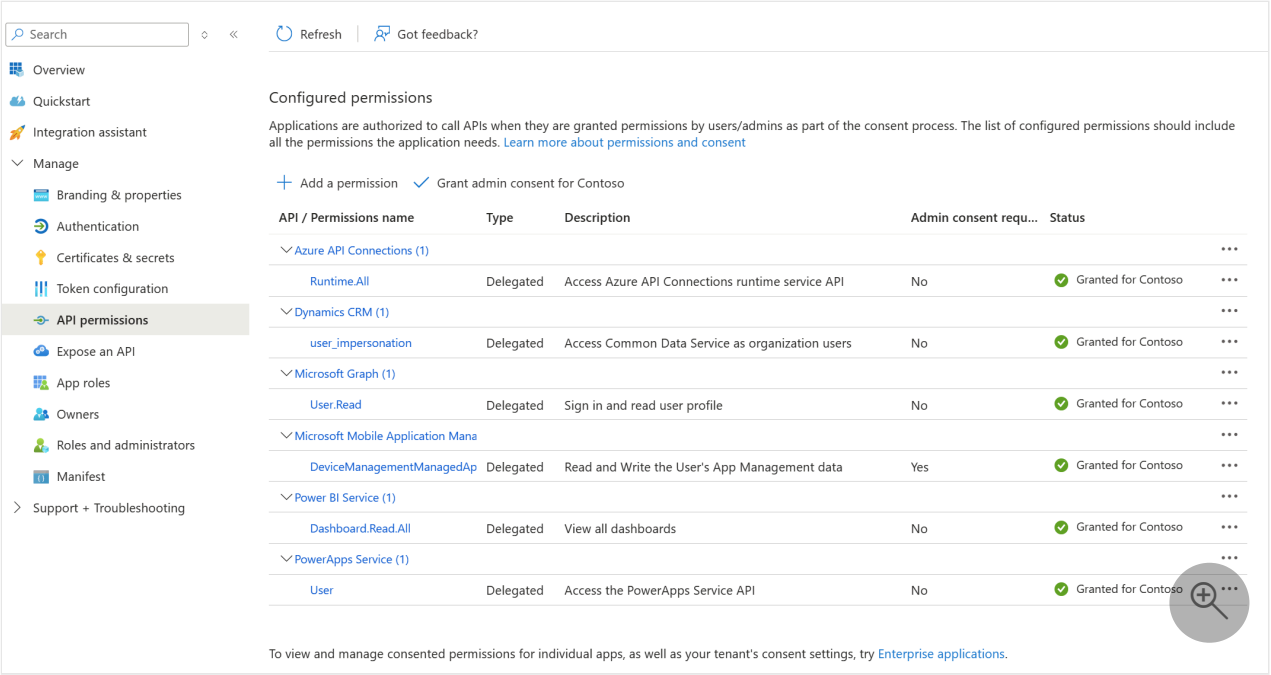
Additionally, verify your device meets the minimum requirements.

Issue 5: Can't sign in or see data in a wrapped app

If you can't sign in or see data in your wrapped app, try the following actions:

Verify API permissions and access

- Ensure all required API permissions are configured and that admin permissions are granted.



- Ensure the `Add-AdminAllowedThirdPartyApps` script runs successfully.
  For more information, see Allow registered apps in your environment.

Check account types and redirect URIs

- Verify the Microsoft Entra app type is set to **Multitenant** and that the supported account type is **Accounts in any organizational directory (Any Microsoft Entra ID tenant)**.
- Configure proper redirect URIs for iOS and Android:
  - For Android, confirm the hash is correct.
  - For more information, see Configure platform settings and redirect URIs.

Issue 6: Fail to sign in to a wrapped app

1. Ensure the user has access to the app. For more information, see Share a canvas app with your organization.
2. If the user has app access but still can't sign in, check the Conditional Access policies in the Microsoft Entra admin center.
3. To troubleshoot sign-in errors, copy the correlation ID from the mobile screen where the sign-in failed and refer to How to troubleshoot Microsoft Entra sign-in errors to understand the error and the failed policies.
4. Check Microsoft Entra authentication and authorization error codes.

Other issues

If your issue isn't covered here, or if the preceding steps don't resolve your problem, search for more support resources or contact Microsoft support with detailed steps to reproduce the problem.

Collect diagnostic information

For sign-in issues, you can collect session details and include them when you contact Microsoft support:

- For the wrap wizard: On the sign-in screen, tap the gear icon in the upper-right corner and select **Session Details**.
- For mobile devices: After opening the app, press and hold the screen, and then select **Session Details**.

Use code view for canvas app controls

Article • 05/21/2025

Use the code view feature to look at the underlying code for each control on your app's screens. The code uses an improved format that's a subset of YAML.

With code view you can:

- View the code for each control on your screen.
- Copy the code for a control and share it outside of Power Apps Studio.
- Paste the code for a control and create a new control based on it.

View, copy, and paste code

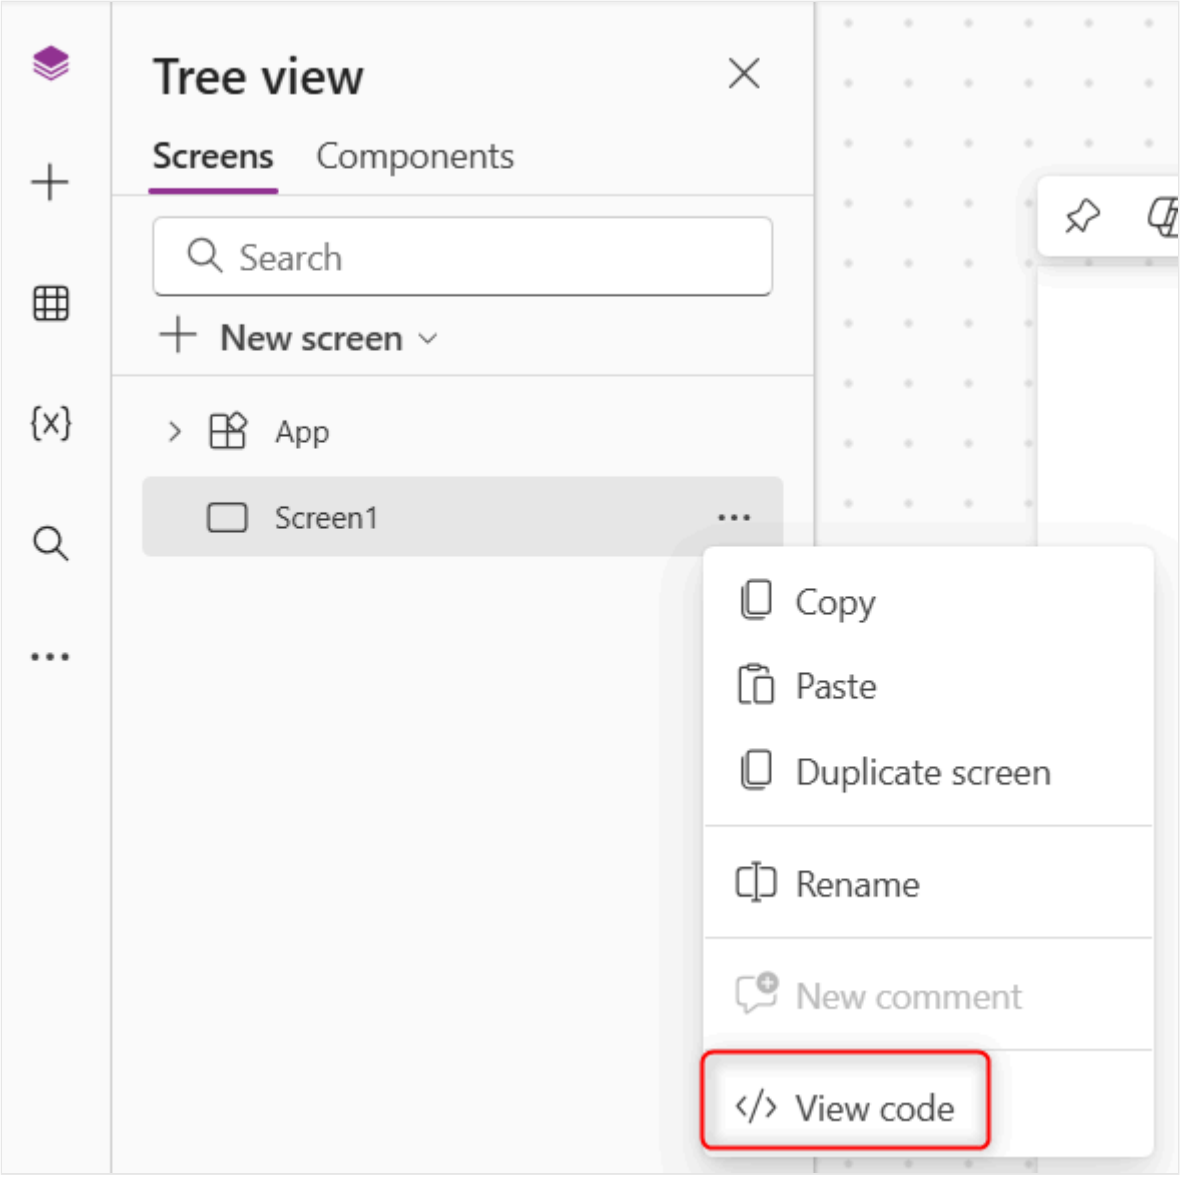
Code view shows the code for the selected control and all its child controls.

Code view lets you copy and paste code to any screen in your app or outside of Power Apps to duplicate the control. This feature is helpful when controls are highly customized and you want to share or duplicate them.

View code

1. Open your app for editing in Power Apps Studio.

2. Right-click the control in the tree view or on the screen, and then select **View code**.



> **Tip**
>
> Use the keyboard shortcut `Ctrl+F` to find a specific string in the code.

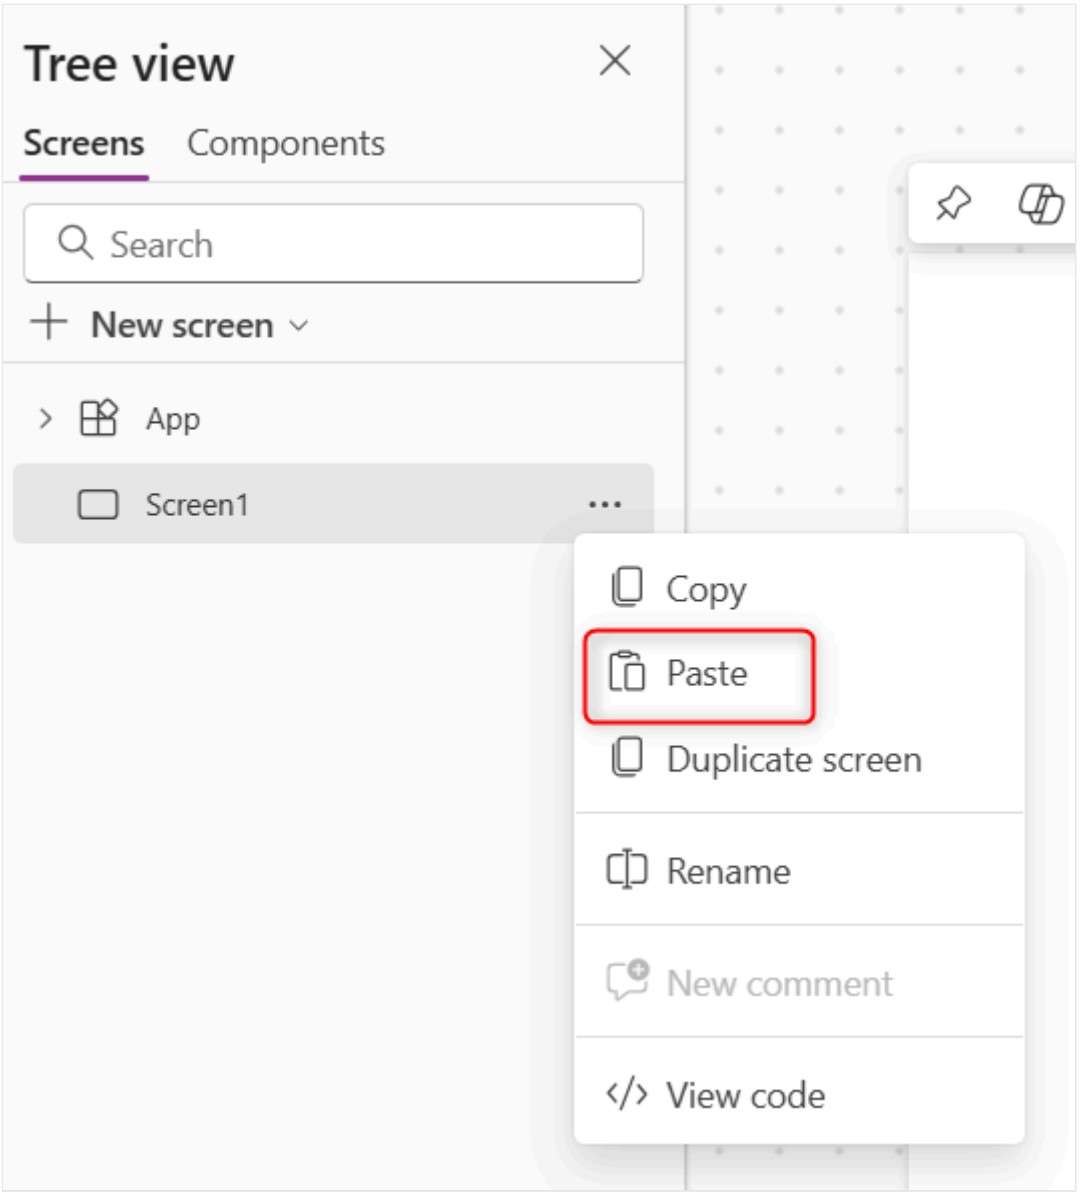
Copy and paste code

1. To copy the code of a selected control:

   - Use the menu to copy.
   - Use the shortcut `Ctrl` + `C`.
   - When viewing your code in the code view popup, select **Copy code**.

2. To add a new control from the code:

   - Use the menu to paste.
   - Use the shortcut `Ctrl` + `V`.



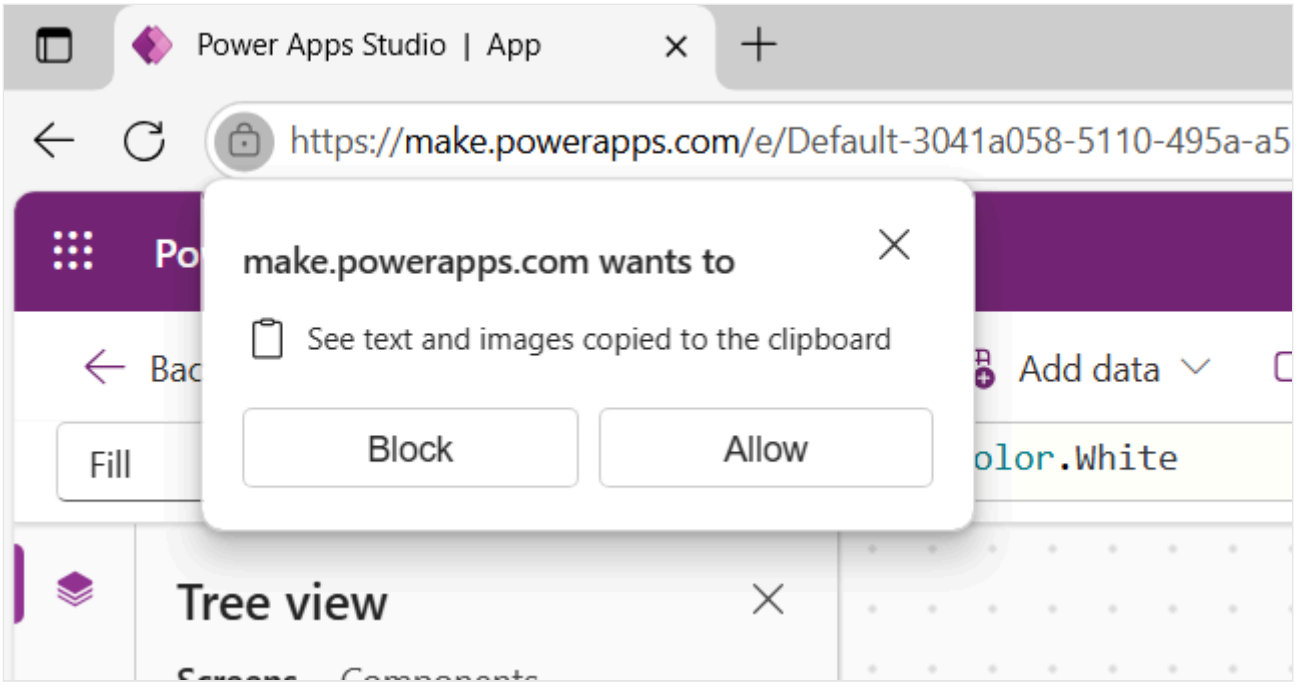
Important

Use the YAML format that Power Apps Studio generates. The code is validated before the new control is created.

Browser clipboard access required

To paste code into Power Apps Studio using code view, your browser must have access to the clipboard. If you encounter issues pasting code, check your browser settings and ensure clipboard permissions are enabled for the site.

The first time you paste code, your browser will prompt you to grant clipboard access. Approve this request to enable pasting functionality in Power Apps Studio.



> **Tip**
>
> If pasting doesn't work, check if clipboard access to Power Apps is blocked in your browser. In Microsoft Edge, you can manually add https://make.powerapps.com to the allowed sites for clipboard access in your browser settings.

Known limitations

- You can't copy and paste or view the code for the **App Object**.
- You can't edit the code in the code view.

View source code files for canvas apps

10/23/2025

Use the source code for a canvas app to review changes made by makers in Power Apps Studio. The generated canvas app YAML code is read-only and can't be modified. Any changes to the file are ignored and might be lost.

> - The YAML schema is in active development, and the content might be incomplete.
> - The current static schema for ***.pa.yaml** files is available here.

Power Fx and YAML are the languages used for Power Apps source code. YAML is valued for its human-readable format and benefits from a wide array of editors, tools, and libraries for manipulation.

Access source code files

You have access to the source code files if you're using the Power Platform Git Integration, eliminating the need for **.msapp** files.

The Power Apps Studio creates the source code for canvas apps, which is stored as *.pa.yaml files within the **.msapp** file. The **.msapp** file is a binary file that contains a collection of files, including the source code.

> **Tip**
>
> To effectively use application lifecycle management (ALM), it's recommended to use solutions. Canvas apps package doesn't support ALM and should only be used for basic import and export capabilities when Dataverse isn't available.

You can also get the source code files either from the **.msapp** file or by using Power Platform CLI.

The ***.pa.yaml** files can be found in the **\Src** folder of the extracted **.msapp**.

> **Important**
>
> Only files located in the **\Src** directory of the extracted **.msapp** are intended for use with source control. The JSON files in the **.msapp** shouldn't be used as source code because those aren't stable between save and load cycles.

Download and Extract the pa.yaml files using Power Platform CLI

Connect to your environment using Power Platform CLI and then use the following commands:

1. To list the canvas apps in your current environment, use the command: pac canvas list.
2. To extract the source code files, use the command: pac canvas download with the parameter -d.

Extract source code files from a .msapp file

To extract source code files from a .msapp file, you have two options:

1. Manually unzip the **.msapp** file.
2. Alternatively, you can use the following command:

```
PowerShell

 Expand-Archive -Path "C:\path\to\yourFile.msapp" -DestinationPath
"C:\path\to\destination"
```

File structure for a .msapp file

For older **.msapp** files without the \src folder, follow these steps to generate source code files:

1. Import and resave and download the new **.msapp** in Power Apps Studio.
2. After that, you can proceed to extract the source code files.

In the **\src** folder, find the following files and folders:

- **App.pa.yaml**: Represents the App.
- **[screen Name].pa.yaml**: One file for each screen, representing the screen.
- **\Component**: A folder containing one file for each component, represented as [component Name].pa.yaml.

Only ***.pa.yaml** files within the **\src** folder can be used as source code. Any other file shouldn't be used as source code.

Power Apps YAML schema versions

Currently, the only active schema version of Power Apps source code is Source Code (*.pa.yaml). The following table shows the other historical formats:

Expand table

Format name	File extension	Description
Experimental	*.fx.yaml	Retired. Version used by the experimental Power Apps Git version control and pac canvas unpack—no longer in development.
Early preview	-	Retired. The version used by code view, copy code, and paste code. There's no version information in this schema.
Source code	*.pa.yaml files	Active. Includes enhancements and version details for source control.

Experimental format (*.fx.yaml)

This schema is retired.

This schema describes an experimental format used by the Power Platform CLI to process and convert canvas apps into a source code format. This format isn't actively developed anymore.

You can't directly convert ***.fx.yaml** files to the new formats. To convert older apps, package the canvas app as a **.msapp** file and import it into Power Apps Studio.

Preview

This schema is retired.

This version was used by Code view during the preview period. It is designed to create canvas apps in Power Apps Studio, letting you easily copy and paste controls. In this version, the source code is used in Power Apps Studio instead of being converted, like the experimental format.

The format during preview was temporary and is no longer in use. You cannot paste code from the preview format.

Here are the changes made from the experimental format:

1. **ZIndex property removal**: The ZIndex property is removed. Instead, a screen is represented as an array of controls. The order of controls determines their stacking order. Normal controls are ordered in ascending order, while responsive controls are ordered in descending order.
2. **JSON object representation replacement**: The "As" syntax is no longer used to define the control type. Instead, the left side of the control's name identifier remains unique. Only

properties that differ from the default values are serialized. Two new properties define the control type and default values:

- **Control**: Represents the control type in YAML.
- **Variant**: Identifies a variant of a control type, which might alter default property values, add or remove properties, or modify the behavior or layout of the control.

These properties are used for instantiating controls and don't accept Power Fx expressions.

Source code (*.pa.yaml)

> **Important**
>
> - The YAML source code for canvas apps is actively being developed. The content may be incomplete and subject to change.
> - The **.pa.yaml** files are read-only and should only be used to review changes made in Power Apps Studio. These files are not used when an app is loading.
> - External editing, merging, and conflict resolution is supported only in Power Platform Git Integration.

This schema is designed for source control purposes and allows the use of a single YAML file.

Updates from the previous format include:

1. Grouping of Top-Level Node Elements:
    - The top-level keywords "App" and "Screens" are examples of how elements are now grouped in a top-level node.
2. Control Version Specification:
    - You can now specify the version of a control using the Control Keyword followed by the @ operator. If no version is specified, the most current version of the control is used. The version is used to deserialize the properties of the source code. Runtime version of the control is defined by the authoring version.
3. Simplified Variant Names:
    - Not all controls require a variant.
4. Consistent ZIndex for All Controls:

- All controls now use an ascending order to determine the ZIndex value, starting from 1. This behavior aligns with the CSS 2 spec.

Disconnect Git version control to edit canvas apps

Article • 05/14/2025

Git version control for editing apps has been removed and is no longer supported.

If your app currently uses this feature, follow these steps to disconnect it:

1. Open your canvas app for editing in Power Apps Studio. On the command bar, select **Settings**.
2. Select **Git version control** and then select **Disconnect**.

If you are using PASopa, download your app from your Git provider and pack the .zip file to an .msapp file. Once your .msapp file is uploaded to Power Apps, follow the steps above to disconnect.

> **Note**
>
> Git version control is replaced with the source control integration feature. More information: Source code integration

Canvas apps for enterprise developers, partners, and ISVs

As a developer, you can extend canvas apps in Power Apps, enabling even more powerful solutions for organizations and customers.

Canvas apps for enterprise developers

As an enterprise developer, empower your organization to build robust, tailored solutions on Power Apps:

- **Build custom connectors**: Develop custom connectors to connect to your organization's data and web services. Learn more
- **Create canvas apps using Power Platform CLI**: Use Microsoft Power Platform CLI to create, pack (preview), and unpack (preview) canvas apps using a custom connector. More information: Power Platform CLI - **pac canvas**
- **Build Azure Functions**: Craft Azure Functions to extend apps with custom server-side logic. Learn more
- **Embed apps**: Embed apps directly into your website experiences to create integrated solutions, surfacing apps where people in your organization already do their work. Learn more
- **Build offline-capable apps**: Develop offline-capable apps so your users are productive whether they are online or offline. Learn more

Canvas apps for ISVs and Microsoft partners

As a Microsoft partner or Independent Software Vendor (ISV), accelerate customer adoption by extending your products to integrate with your customers' data and business processes:

- **Build and certify custom connectors**: Bring your product into the Microsoft cloud by building a connector that enables Power Apps to talk to your service. Learn more
- **List your solution on Microsoft Marketplace**: Generate new leads for your business by building an app with Power Apps and publishing it to Microsoft Marketplace for new customers to find. Learn more
- **Get started today for free**: Sign-up for the Power Apps Developer Plan for free and start building apps in a dedicated developer environment. Learn more

Custom connectors for canvas apps

Article • 02/08/2023

Without writing any code, you can build workflows and canvas apps with Azure Logic Apps, Power Automate, and Power Apps. To help you integrate your data and business processes, these services offer 180+ connectors - for Microsoft services and products, as well as other services, such as GitHub, Salesforce, and Twitter.

Sometimes though, you might want to call APIs, services, and systems that aren't available as pre-built connectors. To support more tailored scenarios, you can build *custom connectors* with their own triggers and actions. We have a complete set of basic and advanced tutorials for custom connectors on the Connectors documentation site. We recommend that you start with the custom connector overview, but you can also go straight to the following topics for details on a specific area:

- Create a custom connector from an OpenAPI definition
- Create a custom connector from a Postman collection
- Create a custom connector from scratch
- Use a custom connector from Power Apps
- Share custom connectors in your organization
- Submit your connectors for Microsoft certification
- Custom connector FAQ

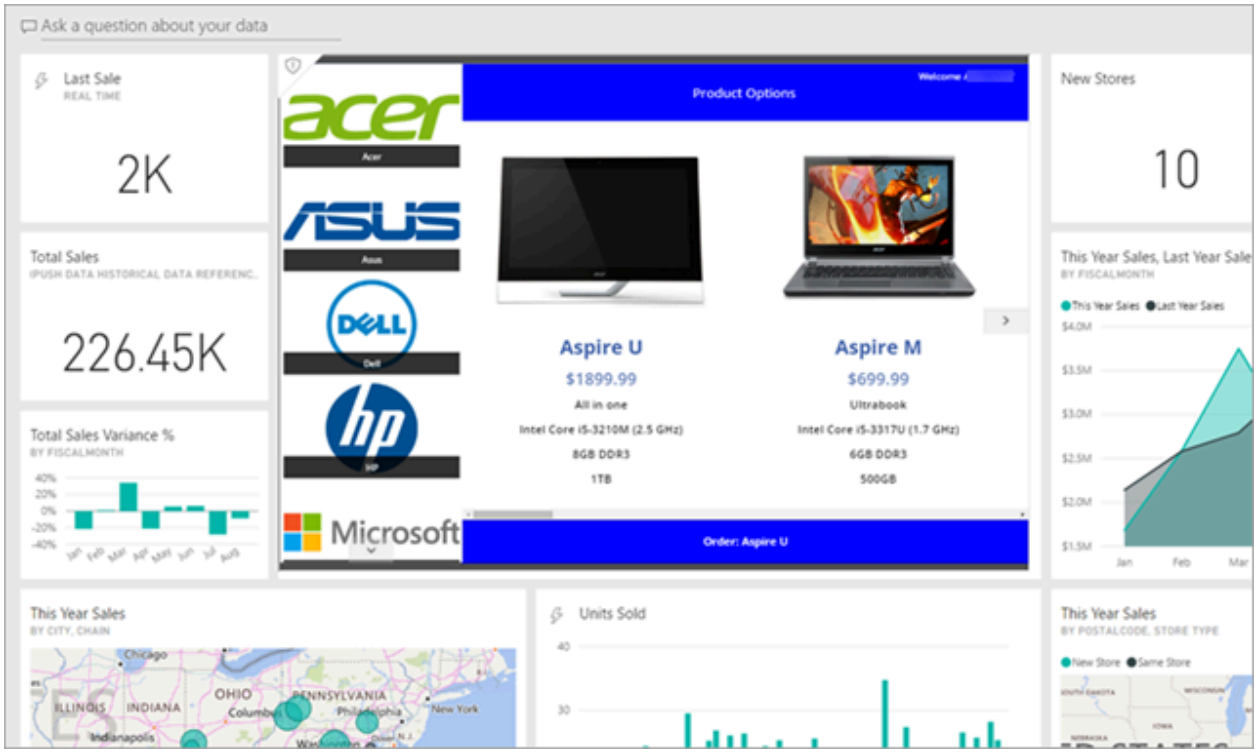
Integrate canvas apps into websites and other services

Article • 03/12/2025

The apps that you build are often most useful when they're available right where people do their work. By embedding canvas apps in an iframe, you can integrate those apps into websites and other services, such as Power BI or SharePoint.

In this topic, we'll show you how to set parameters for app embedding; then we'll embed our Asset Ordering app in a website.



> **Note**
>
> - Only Power Apps users in the same tenant can access the embedded app.
> - Embedding canvas apps in any native desktop application isn't supported, which includes Andrioid and iOS. This excludes first-party integrations such as Power Apps in Teams.

You can also integrate canvas apps into SharePoint Online without using an iframe. More information: Use the Power Apps web part.

Set URI parameters for your app

If you have an app you want to embed, the first step is to set parameters for the Uniform Resource Identifier (URI), so that the iframe knows where to find the app. The URI is in the following form:

```
https://apps.powerapps.com/play/[AppID]?source=iframe
```

For GCC users

```
https://apps.gov.powerapps.us/play/[AppID]?source=iframe
```

> **Important**
>
> As of August 2019, the URI format has changed from https://web.powerapps.com/webplayer to https://apps.powerapps.com/play. Please update any embedded iframes to use the new URI format. References to the previous format will be redirected to the new URI to ensure compatibility.
>
> Previous format:
>
> https://web.powerapps.com/webplayer/iframeapp?source=iframe&appId=/providers/Microsoft.PowerApps/apps/[AppID]

The only thing you have to do is substitute the ID of your app for [AppID] in the URI (including '[' & ']'). We'll show you how to get that value shortly, but first here are all the parameters available in the URI:

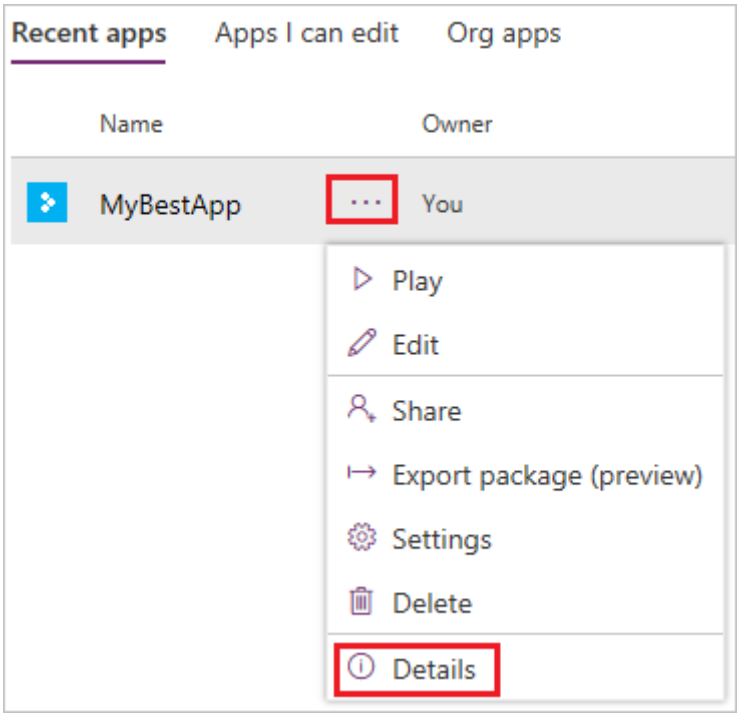
- **[appID]** - It provides the ID of the app to run.
- **tenantid** - is an optional parameter to support guest access and determines which tenant to open the app from.
- **screenColor** - is used to provide a better app loading experience for your users. This parameter is in the format RGBA (red value, green value, blue value, alpha) and controls the screen color while the app loads. It is best to set it to the same color as your app's icon.
- **source** - does not affect the app, but we suggest you add a descriptive name to refer to the source of the embedding.
- Lastly, you can add any custom parameters you want using the Param() function, and those values can be consumed by your app. They are added to the end of the URI, such as `[AppID]?source=iframe&param1=value1&param2=value2`. These

parameters are read only during launch of the app. If you need to change them, you must relaunch the app. Note that only the first item after [appid] should have a "?"; after that use the "&" as illustrated here.

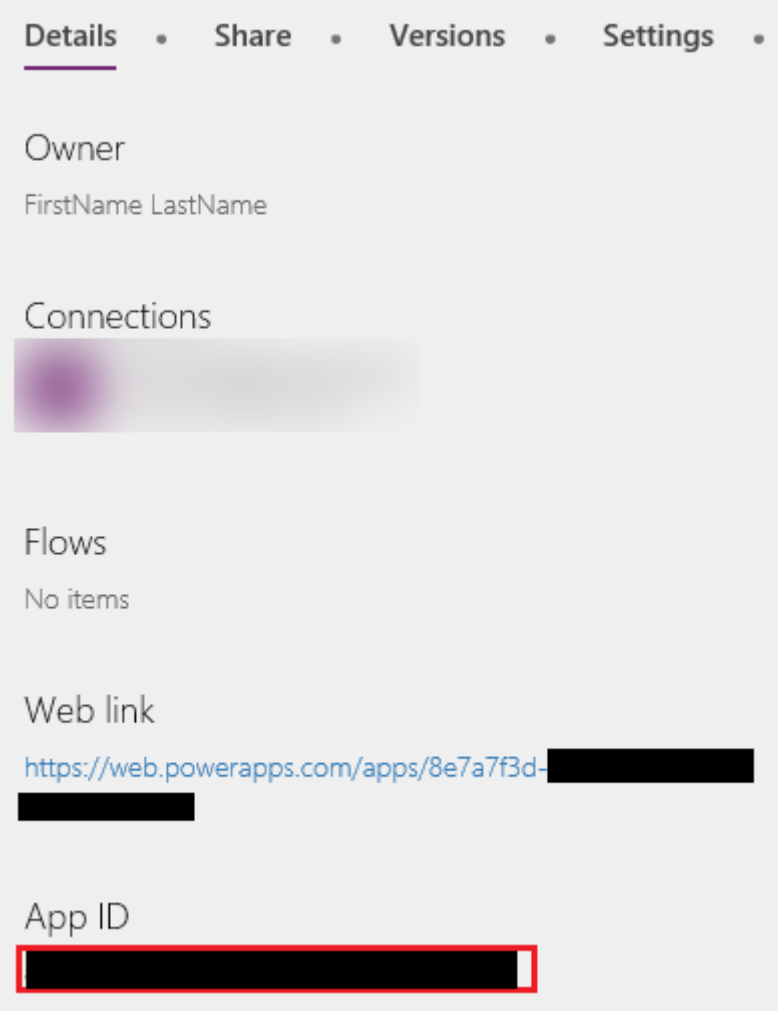
Get the App ID

The app ID is available on powerapps.com. For the app you want to embed:

1. In powerapps.com, on the **Apps** tab, click or tap the ellipsis (. . .), then **Details**.



2. Copy the **App ID**.



3. Substitute the `[AppID]` value in the URI. For our Asset Ordering app, the URI looks like this:

```
https://apps.powerapps.com/play/76897698-91a8-b2de-756e-fe2774f114f2?
source=iframe
```

You may need to allow pop-ups in browser when you embed an app in your website that uses Launch() function to launch a webpage or an app.

Embed your app in a website

Embedding your app is now as simple as adding the iframe to the HTML code for your site (or any other service that supports iframes, such as Power BI or SharePoint):

HTML

```
<iframe width="[W]" height="[H]"
src="https://apps.powerapps.com/play/[AppID]?
```

```
source=website&screenColor=rgba(165,34,55,1)" allow="geolocation;
microphone; camera"/>
```

Specify values for the iframe width and height, and substitute the ID of your app for `[AppID]`.

> **Note**
>
> Include `allow="geolocation; microphone; camera"` in your iframe HTML code to allow your apps to use these capabilities on Google Chrome.

The following image shows the Asset Ordering app embedded in a Contoso sample website.

Keep the following points in mind for authenticating users of your app:

- If your website uses Microsoft Entra ID based authentication, no additional sign-in is required.
- If your website uses any other sign-in mechanism or is not authenticated, your users see a sign-in prompt on the iframe. After they sign-in, they will be able to run the app as long as the author of the app has shared it with them.

As you can see, embedding apps is simple and powerful. Embedding enables you to bring apps right to the places you and your customers work – websites, Power BI dashboards, SharePoint pages, and more.

Develop offline-capable canvas apps

Article • 03/18/2024

Mobile users often need to be productive even when they have limited or no connectivity. When you build a canvas app, you can perform these tasks:

- Open Power Apps Mobile and run apps when the device is not connected to the network.
- Determine when an app is offline, online, or in a metered connection by using the Connection signal object.
- Synchronize data between your device and the server.

If your app connects to Dataverse, offline support is **built-in**. Power Apps will allows you to download data to your device and upload changes back to Dataverse. If your app does not use Dataverse, you can use collections and leverage the **LoadData** and **SaveData** functions for basic storage when offline.

> **Note**
>
> - Offline capability for canvas apps is available while running the apps using the native Power Apps Mobile players on iOS, Android, and Windows.
> - Canvas apps running in web browsers can't run offline, even when using a web browser on a mobile device.
> - Canvas apps in Teams are limited to 1 MB of data through the LoadData and SaveData functions—useful for a small number of text strings, numbers, and dates. Use of images or other media is inappropriate for this limit. More information: LoadData and SaveData function reference

Enable offline support in a Dataverse-based canvas app

For Microsoft Dataverse-based canvas apps, you must use the offline capability built-in with the offline-first experience. For more information, see Set up mobile offline for canvas apps and Working with canvas apps offline. With the flip of a switch, your app can work with Dataverse data wherever you are, with or without a network connection. Just build your app with standard Power Fx formulas and the offline feature handles all the complexity for you.

Use LoadData and SaveData for all other connectors

This section includes an example using Twitter data. An even simpler example that doesn't require a connection is included in the **LoadData** and **SaveData** function reference.

Watch this video to learn how to create offline enabled canvas apps which don't use Dataverse data:
https://learn-video.azurefd.net/vod/player?id=60fd9b60-80a9-445b-bd4e-b7f4f068431e&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Foffline-apps

Limitations

LoadData and **SaveData** combine to form a simple mechanism to store small amounts of data on a local device. By using these functions, you can add simple offline capabilities to your app.

These functions are limited by the amount of available app memory because they operate on an in-memory collection. Available memory can vary depending on the device, the operating system, the memory that Power Apps Mobile uses, and the complexity of the app in terms of screens and controls. If you store more than a few megabytes of data, test your app with expected scenarios on the devices on which you expect it to run. You'll generally have 30-70 megabytes of available memory.

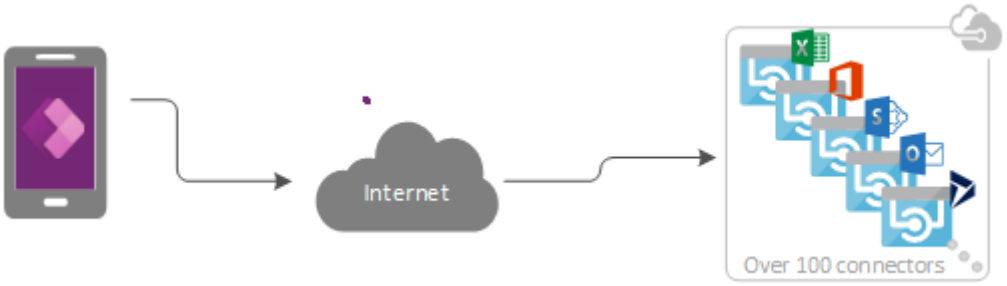
The functions also don't automatically resolve merge conflicts when a device comes online. Configuration on what data is saved and how to handle reconnection is up to the maker when writing expressions.

For updates on offline capabilities, return to this topic, and subscribe to the Power Apps blog.

Overview

When you design offline scenarios, you should first consider how your apps work with data. Apps in Power Apps primarily access data through a set of connectors that the platform provides, such as SharePoint, Office 365, and Microsoft Dataverse. You can also build custom connectors that enable apps to access any service that provides a RESTful endpoint. This could be a Web API or a service such as Azure Functions. All these

connectors use HTTPS over the Internet, which means your users must be online for them to access data and any other capabilities that a service offers.



Handling offline data

In Power Apps, you can filter, search, sort, aggregate, and manipulate data in a consistent way regardless of the data source. Sources range from in-memory collections in the app to lists created using Microsoft Lists to SQL databases and Dataverse. Because of this consistency, you can easily retarget an app to use a different data source. More importantly for offline scenarios, you can use local collections for data management with almost no changes to an app's logic. In fact, local collections are the primary mechanism for handling offline data.

Build an offline app

To keep the focus on the offline aspects of app development, this topic illustrates a simple scenario focused around Twitter. You'll build an app that enables you to read Twitter posts and submit tweets while being offline. When the app comes online, the app posts tweets and reloads the local data.

At a high level, the app performs these tasks:

- When the user opens the app:
  - If the device is online, the app fetches data through the Twitter connector and populates a collection with that data.
  - If the device is offline, the app loads the data from a local cache file by using the LoadData function.
  - The user can submit tweets. If the app is online, it posts the tweets directly to Twitter and refreshes the local cache.
- Every five minutes while the app is online:
  - The app posts any tweets in the local cache.
  - The app refreshes the local cache and saves it by using the SaveData function.

Step 1: Add Twitter to a blank phone app

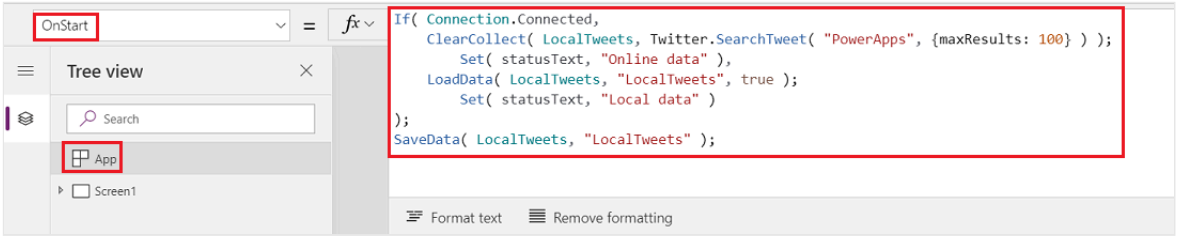
1. Create a blank canvas app with **Phone** layout.
2. On the **View** tab, select **Data sources**.
3. In the **Data** pane, select **Add data source**.
4. Select **New Connection** > **Twitter** > **Create**.
5. Enter your credentials, create the connection, and then close the **Data** pane.

Step 2: Collect existing tweets

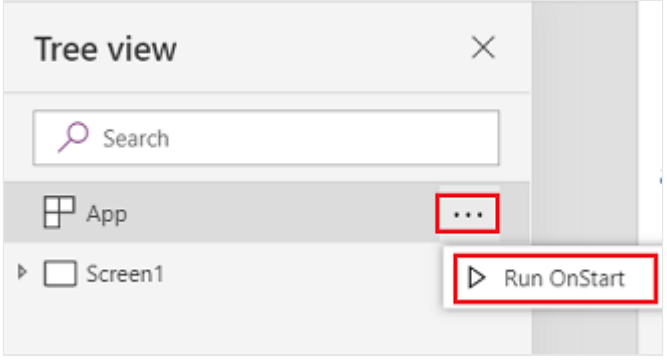
1. In the **Tree view** pane, select **App**, and then set its **OnStart** property to this formula:

```
Power Fx

If( Connection.Connected,
    ClearCollect( LocalTweets, Twitter.SearchTweet( "PowerApps",
{maxResults: 10} ) );
        Set( statusText, "Online data" ),
    LoadData( LocalTweets, "LocalTweets", true );
        Set( statusText, "Local data" )
);
SaveData( LocalTweets, "LocalTweets" );
```



2. In the **Tree view** pane, select the ellipsis menu for the **App** object, and then select **Run OnStart** to run that formula.



> **Note**

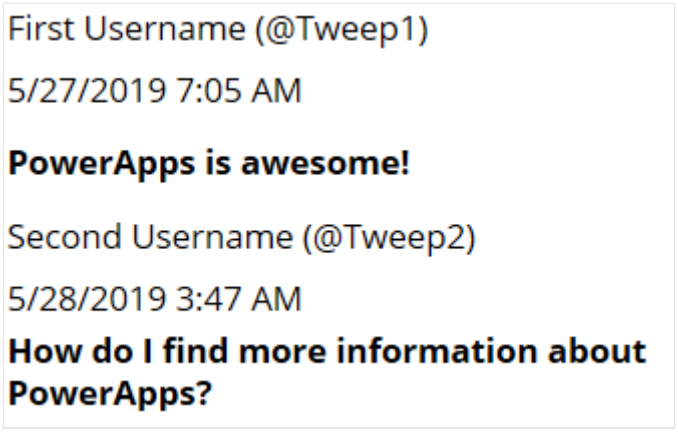
> The **LoadData** and **SaveData** functions might show an error in Power Apps Studio because browsers don't support them. However, they'll perform normally after you deploy this app to a device.

This formula checks whether the device is online:

- If the device is online, the formula loads up to 10 tweets with the search term "PowerApps" into a **LocalTweets** collection.
- If the device is offline, the formula loads the local cache from a file called "LocalTweets" if it's available.

Step 3: Show tweets in a gallery

1. On the **Insert** tab, select **Gallery** > **Blank flexible height**.
2. Set the **Items** property of the Gallery control to `LocalTweets`.
3. In the gallery template, add three Label controls, and set the **Text** property of each label to one of these values:
   - `ThisItem.UserDetails.FullName & " (@" & ThisItem.UserDetails.UserName & ")"`
   - `Text(DateTimeValue(ThisItem.CreatedAtIso), DateTimeFormat.ShortDateTime)`
   - `ThisItem.TweetText`
4. Make the text in the last label bold so that the gallery resembles this example.



Step 4: Show connection status

1. Under the gallery, insert a label, and then set its **Color** property to **Red**.
2. Set the newest label's **Text** property to this formula:

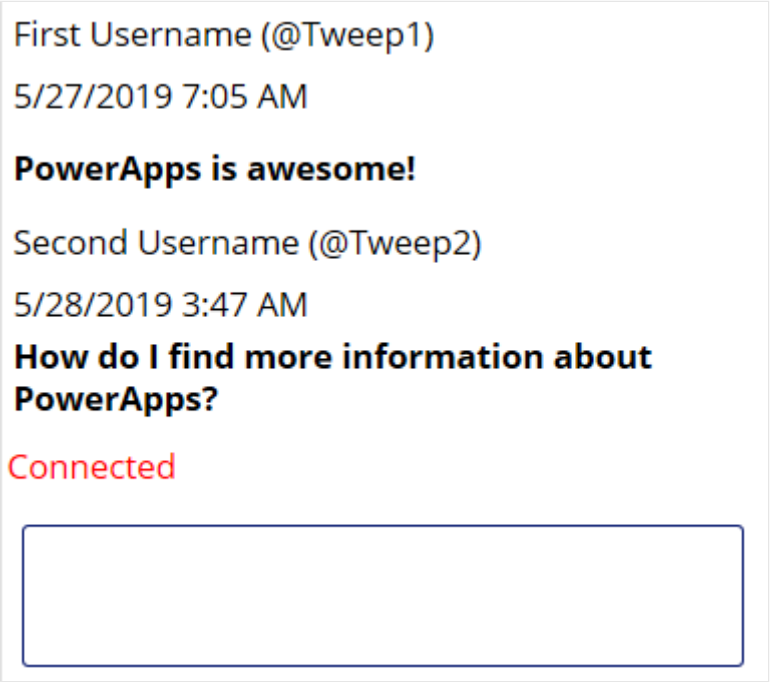
```
If( Connection.Connected, "Connected", "Offline" )
```

This formula determines whether the device is online. If it is, the label shows **Connected**; otherwise, it shows **Offline**.

Step 5: Add a box to compose tweets

1. Under the connection-status label, insert a Text input control, and rename it **NewTweetTextInput**.

2. Set the text-input box's **Default** property to `""`.



Step 6: Add a button to post the tweet

1. Under the text-input box, add a **Button** control, and set its **Text** property to this value:

   `"Tweet"`

2. Set the button's **OnSelect** property to this formula:

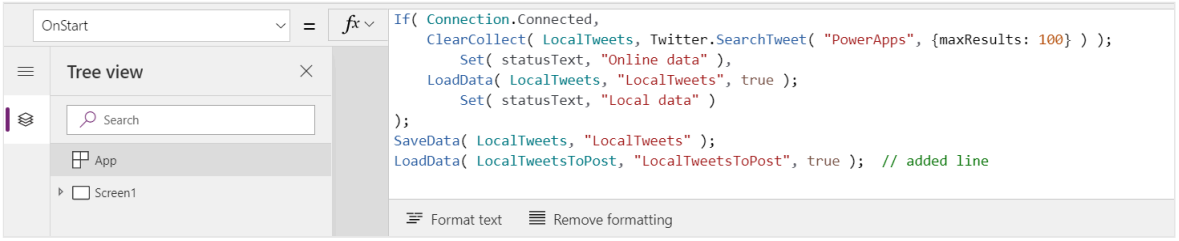
Power Fx

```
If( Connection.Connected,
    Twitter.Tweet( "", {tweetText: NewTweetTextInput.Text} ),
    Collect( LocalTweetsToPost, {tweetText: NewTweetTextInput.Text} );
        SaveData( LocalTweetsToPost, "LocalTweetsToPost" )
);
Reset( NewTweetTextInput );
```

3. In the **OnStart** property for the **App**, add a line at the end of the formula:

```
Power Fx

If( Connection.Connected,
    ClearCollect( LocalTweets, Twitter.SearchTweet( "PowerApps",
{maxResults: 100} ) );
        Set( statusText, "Online data" ),
    LoadData( LocalTweets, "LocalTweets", true );
        Set( statusText, "Local data" )
);
SaveData( LocalTweets, "LocalTweets" );
LoadData( LocalTweetsToPost, "LocalTweetsToPost", true );  // added
line
```



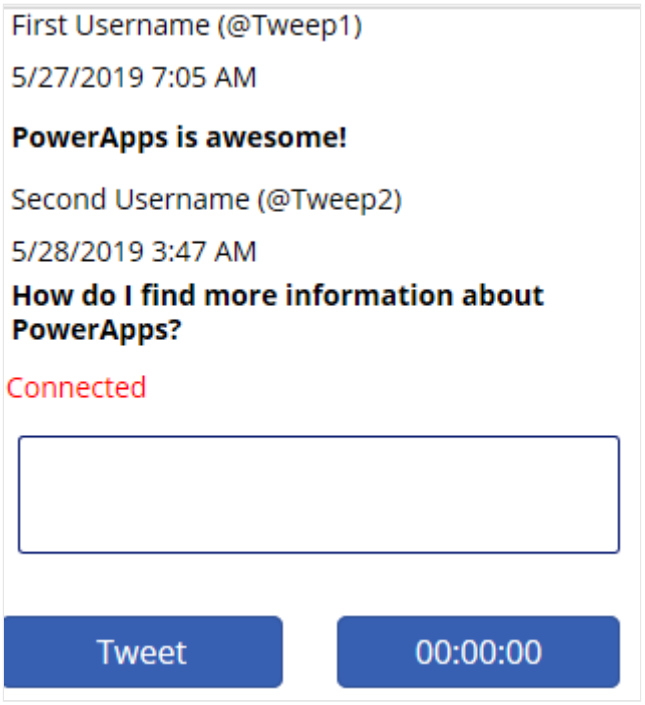
This formula determines whether the device is online:

- If the device is online, it posts the tweet immediately.
- If the device is offline, it captures the tweet in a **LocalTweetsToPost** collection and saves it to the device.

Then the formula resets the text in the text-input box.

Step 7: Check for new tweets

1. On the right side of the button, add a **Timer** control.



2. Set the timer's **Duration** property to **300000**.

3. Set the timer's **AutoStart** and **Repeat** properties to **true**.

4. Set the timer's **OnTimerEnd** to this formula:

```
Power Fx

If( Connection.Connected,
    ForAll( LocalTweetsToPost, Twitter.Tweet( "", {tweetText:
tweetText} ) );
    Clear( LocalTweetsToPost );
    ClearCollect( LocalTweets, Twitter.SearchTweet( "PowerApps",
{maxResults: 10} ) );
    SaveData( LocalTweets, "LocalTweets" );
)
```

This formula determines whether the device is online. If it is, the app tweets all the items in the **LocalTweetsToPost** collection and then clears the collection.

Test the app

1. Open the app using Power Apps Mobile on a mobile device that's connected to the Internet.

   Existing tweets appear in the gallery, and the status shows **Connected**.

2. Disconnect the device from the Internet by enabling the device's airplane mode and disabling wi-fi.

The status label shows that the app is **Offline**.

3. While the device is offline, write a tweet that includes **Power Apps**, and then select the **Tweet** button.

   The tweet is stored locally in the **LocalTweetsToPost** collection.

4. Reconnect the device to the Internet by disabling the device's airplane mode and enabling wi-fi.

   Within five minutes, the app posts the tweet, which appears in the gallery.

We hope this article gives you an idea of the capabilities that Power Apps has for building offline apps. As always, please provide feedback in our forum and share your examples of offline apps in the Power Apps community blog.

Canvas component overview

> **Note**
>
> - This section explains canvas components that encompass low-code UI extensibility capabilities. Professional developers can also use the Power Apps component framework to build code components.
> - You can also use canvas components in model-driven apps by using custom pages and the component library. For more information, see Add canvas components to a custom page in a model-driven app.

Components are reusable building blocks for canvas apps. App makers can create custom controls to use inside an app, or across apps by using a component library. Components can use advanced features such as custom properties and enable complex capabilities. This article introduces component concepts and some examples.

Components are useful when building larger apps that have similar control patterns. If you update a component definition inside the app, all instances in the app reflect your changes. Components also reduce duplication of effort by eliminating the need to copy and paste controls and improve performance. When you use a component library, components help create collaborative development and standardize the look and feel in an organization.

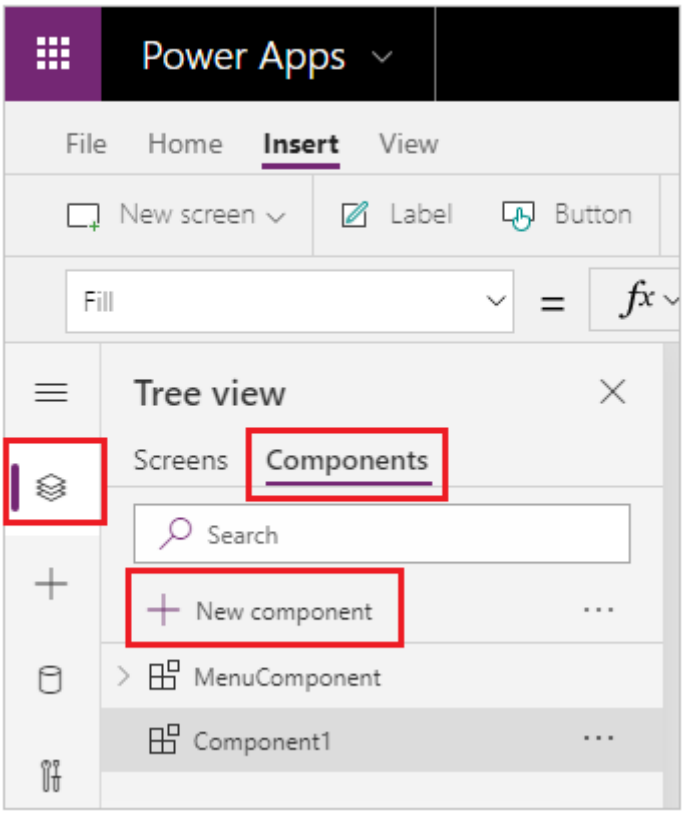
To learn how to use components in canvas apps, watch this video:

https://learn-video.azurefd.net/vod/player?id=7ec063b0-df8e-4cf8-b407-72ce6132115f&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fcanvas-apps%2Fcreate-component

Components in canvas apps

You can create a component from within an app as explained in this article, or by creating a new component inside a component library. Use a component library when you need to use components across multiple app screens. You can also copy existing components into an existing or a new component library.

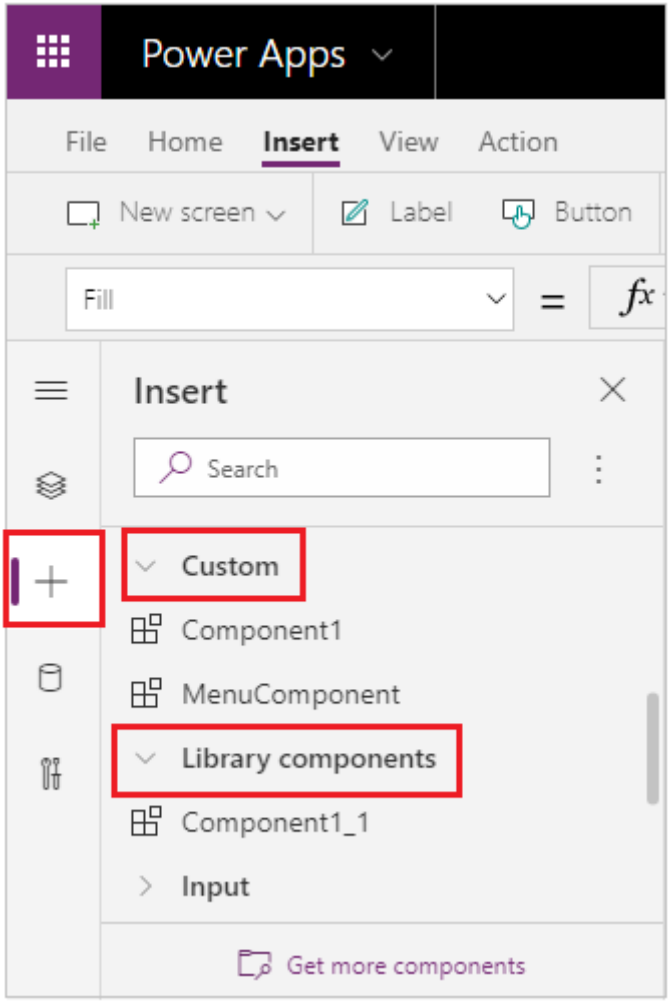
To create a component within an app, go to **Tree View**, select the **Components** tab, and then select **New component**:



Selecting **New component** opens an empty canvas. Add controls as part of the component definition on the canvas. If you edit a component in the canvas, you update instances of the same component in other app screens. Apps that reuse an already created component can also receive component updates after you publish component changes.

You can select a component from the list of existing components in the left pane after you select a screen. When you select a component, you insert an instance of that component onto the screen, just as you insert a control.

Components available inside the app appear under the **Custom** category in a list of components inside the tree view. Components imported from component libraries appear under the **Library components** category:



> **Note**
>
> The components discussed in this article are different from the Power Apps component framework that enables developers and makers to create code components for model-driven and canvas apps. For more information, see Power Apps component framework overview.

Custom properties

A component can receive input values and emit data if you create one or more custom properties. These scenarios are advanced and require you to understand formulas and binding contracts.

> **Note**
>
> An experimental feature for enhanced component properties provides even more options for properties, including functions and behavior functions. For more information, see Canvas component properties (experimental)

Input property is how a component receives data to be used in the component. Input properties appear in the **Properties** tab of the right-hand pane if an instance of the component is selected. You can configure input properties with expressions or formulas, just as you configure standard properties in other controls. Other controls have input properties, such as the **Default** property of a **Text input** control.

Output property is used to emit data or component state. For example, the **Selected** property on a **Gallery** control is an output property. When you create an output property, you can determine what other controls can refer to the component state.

The following walk-through further explains these concepts.

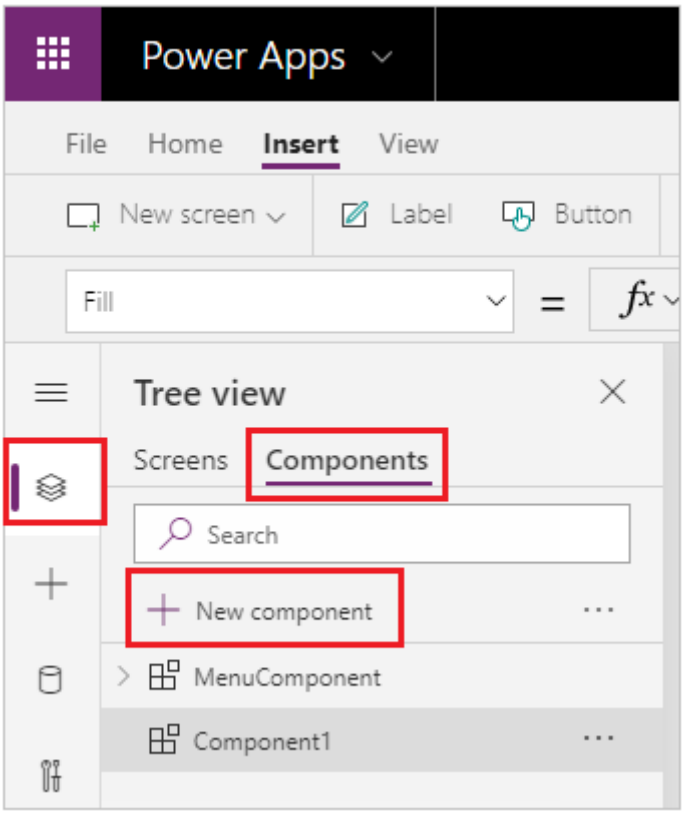
Create an example component

In this example, you'll create a menu component that resembles the following graphic. And you can change the text later to use it in multiple screens, apps, or both:

> **Note**
>
> We recommend that you use a component library when creating components for reuse. Updating components inside an app only makes the component updates available inside the app. When using a component library, you get prompted to update components if components inside a library are updated and published.

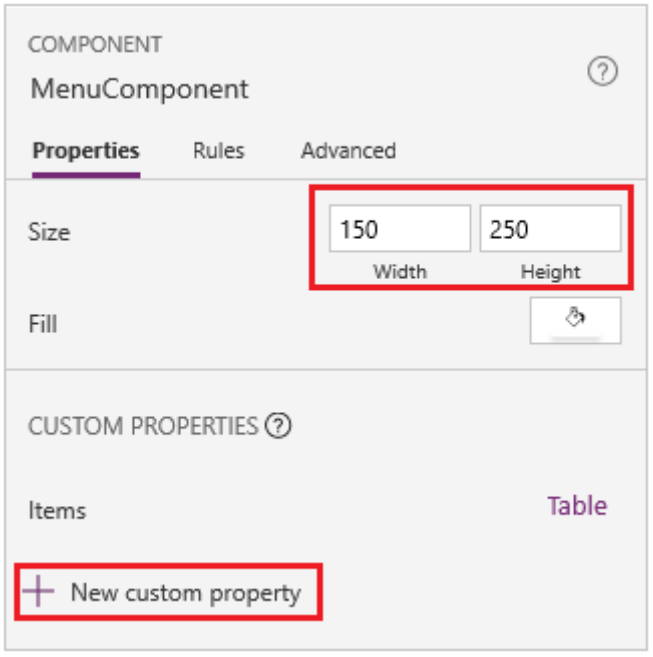
Create a new component

1. Create a blank canvas app.
2. In the **Tree View**, select **Components** and then select **New component** to create a new component.

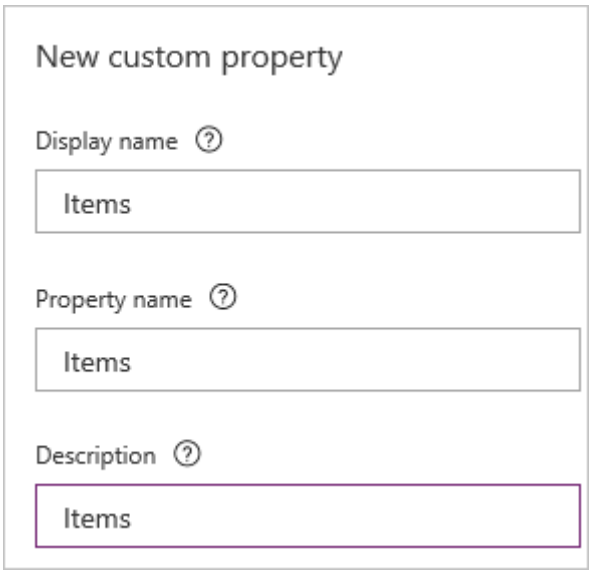


3. Select the new component in the left pane, select the ellipsis (...), and then select **Rename**. Type or paste the name as **MenuComponent**.

4. In the right-hand pane, set the component's width as **150** and its height as **250**, and then select **New custom property**. You can also set the height and width to any other value as appropriate.



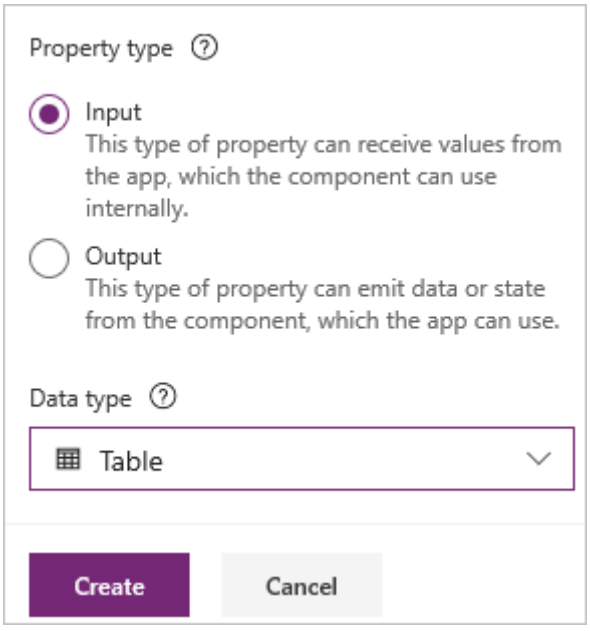
5. In the **Display name**, **Property name**, and **Description** boxes, type or paste text as *Items*.



Don't include spaces in the property name because you'll refer to the component by this name when you write a formula. For example, **ComponentName.PropertyName**.

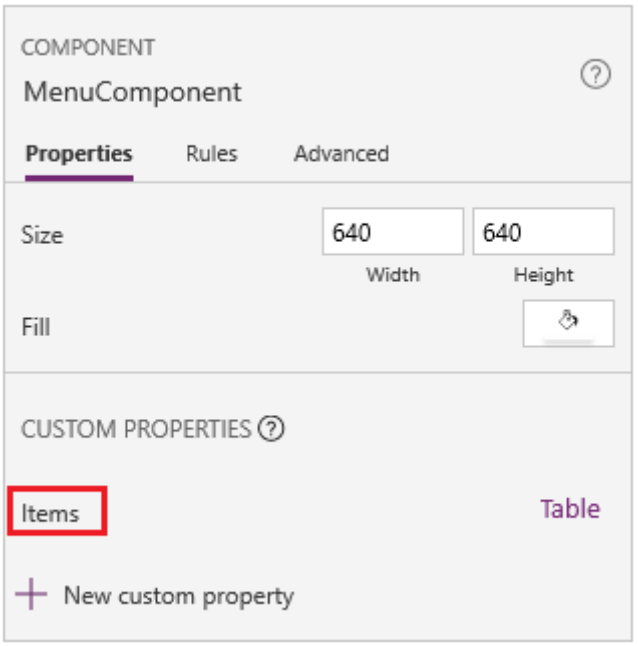
The display name appears on the **Properties** tab of the right-hand pane if you select the component. A descriptive display name helps you and other makers understand the purpose of this property. The **Description** appears in a tooltip if you hover over the display name of this property in the **Properties** tab.

6. In the **Data type** list, select **Table**, and then select **Create**.



The **Items** property is set to a default value based on the data type that you specified. You can set it to a value that suits your needs. If you specified a data type of **Table** or **Record**, you might want to change the value of the **Items** property to match the data schema that you want to input to the component. In this case, you'll change it to a list of strings.

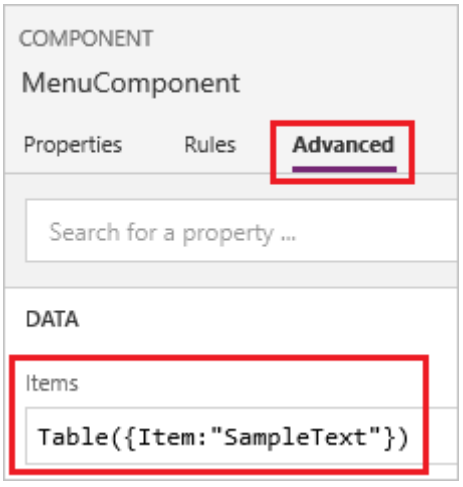
You can set the property's value in the formula bar if you select the name of the property on the **Properties** tab of the right-hand pane.



As the next graphic shows, you can also edit the property's value on the **Advanced** tab of the right-hand pane.

7. Set the component's **Items** property to this formula:

```
Power Fx
Table({Item:"SampleText"})
```



8. In the component, insert a blank vertical **Gallery** control and select **Layout** on the property pane as **Title**.

9. Make sure that the property list shows the **Items** property (as it does by default). Then set the value of that property to this expression:

```
Power Fx
MenuComponent.Items
```

This way, the **Items** property of the **Gallery** control reads and depends on the **Items** input property of the component.

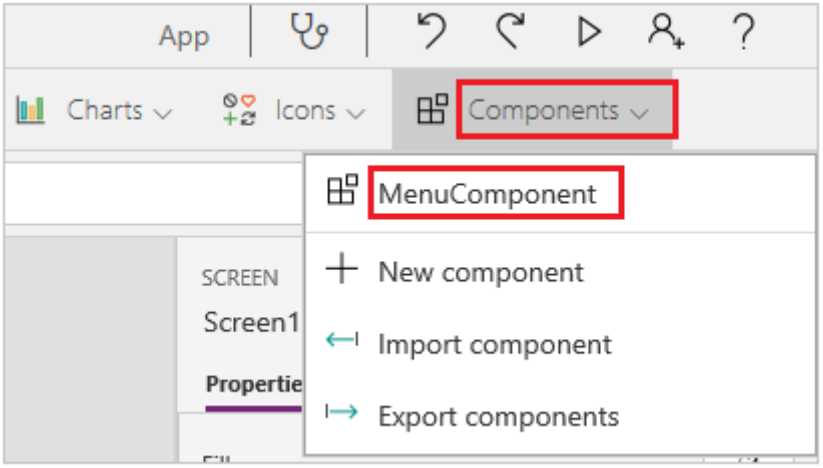
10. (Optional) Set the **Gallery** control's **BorderThickness** property to **1** and its **TemplateSize** property to **50**. You can also update values for border thickness and template size to any other value as appropriate.

Add component to a screen

Next, add the component to a screen and specify a table of strings for the component to show.

1. In the left pane, select the list of screens, and then select the default screen.

2. On the **Insert** tab, open the **Components** menu, and then select **MenuComponent**.



The new component is named **MenuComponent_1** by default.

3. Set the **Items** property of **MenuComponent_1** to this formula:

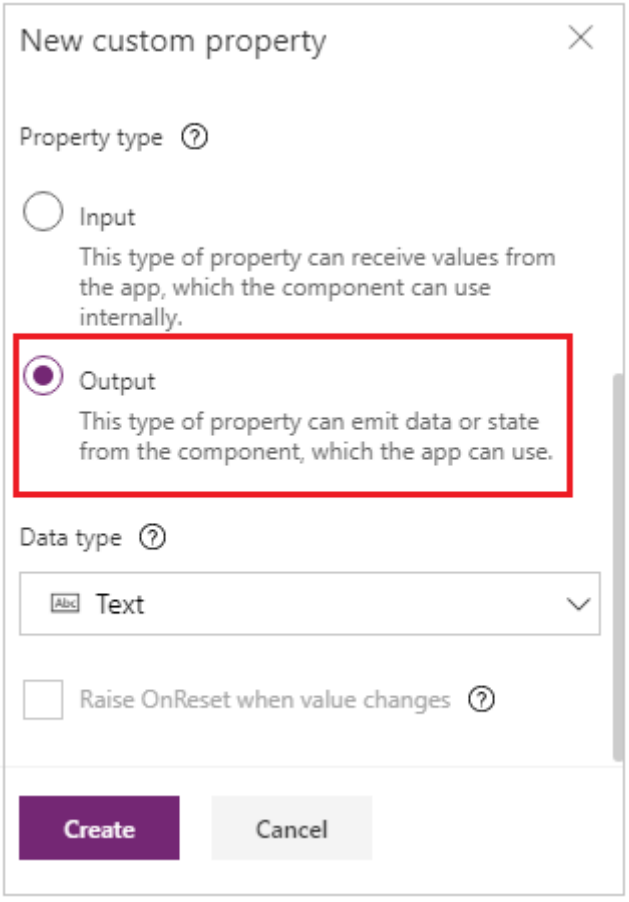
```
Power Fx
Table({Item:"Home"}, {Item:"Admin"}, {Item:"About"}, {Item:"Help"})
```

This instance resembles this graphic, but you can customize the text and other properties of each instance.

Create and use output property

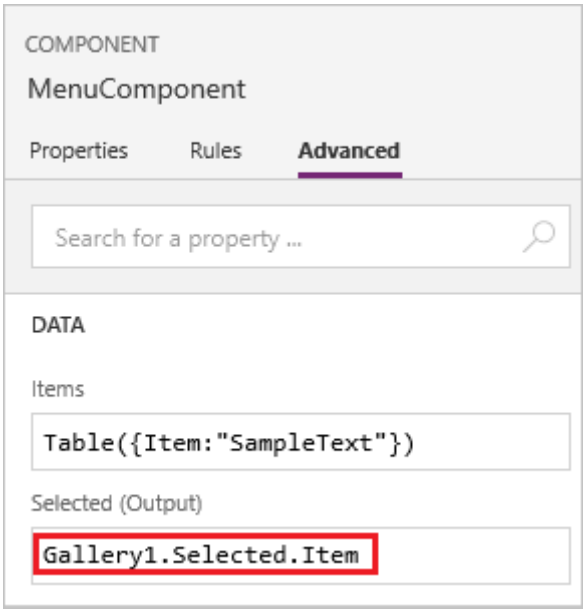
So far, you created a component and added it to an app. Next, create an output property that reflects the item that the user selects in the menu.

1. Open the list of components, and then select **MenuComponent**.
2. In the right-hand pane, select the **Properties** tab, and then select **New custom property**.
3. In the **Display name**, **Property name**, and **Description** boxes, type or paste **Selected**.
4. Under **Property type**, select **Output**, and then select **Create**.



5. On the **Advanced** tab, set the value of the **Selected** property to this expression, adjusting the numeral in the gallery name if necessary:

```
Power Fx
Gallery1.Selected.Item
```



6. On the default screen of the app, add a label, and set its **Text** property to this expression, adjusting the numeral in the component name if necessary:

   ```
   Power Fx
   MenuComponent_1.Selected
   ```

   MenuComponent_1 is the default name of an instance, not the name of the component definition. You can rename any instance.

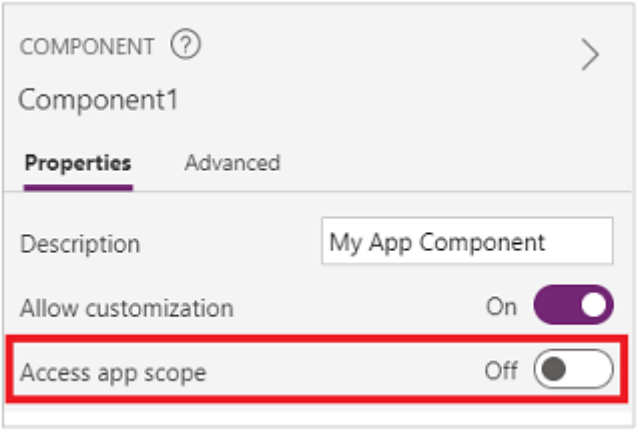
7. While holding down the Alt key, select each item in the menu.

   The **Label** control reflects the menu item that you selected most recently.

Scope

Input and output properties clearly define the interface between a component and its host app. By default, the component is encapsulated so that it's easier to reuse the component across apps, requiring the use of the properties to pass the information in and out of the component. Scope restrictions keep the data contract of a component simple and cohesive, and it helps enable component-definition updates—especially across apps with component libraries.

But there are times when a component might want to share a data source or a variable with its host. This sharing is especially useful when the component is only intended for use in one particular app. For these cases, you can directly access app level information by turning on the **Access app scope** switch in the component's property pane:



When you turn on **Access app scope**, the following items are accessible from within a component:

- Global variables
- Collections
- Controls and components on screens, such as a TextInput control
- Tabular data sources, such as Dataverse tables

When you turn this setting off, the component can't access any of the preceding items. Set and Collect functions are still available but the resulting variables and collections are scoped to the component instance and aren't shared with the app.

Non-tabular data sources, such as Azure Blob Storage or a custom connector, are available whether this setting is turned on or off. Think of these data sources more like referencing an environment resource rather than an app resource. When a component is brought into an app from a component library, these data sources from the environment are also brought in.

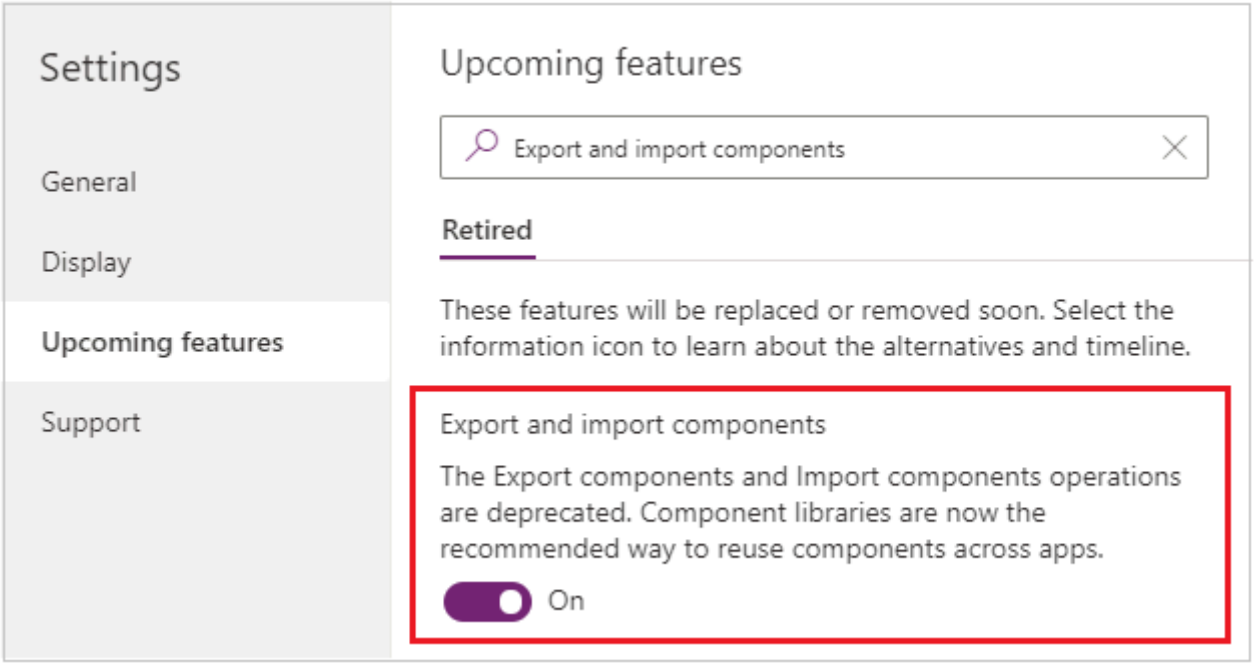
Components in a component library can never access app scope, as there's no single app scope to refer to. So, this setting isn't available in this context, and is effectively off. Once imported into an app, and if customization is allowed by the component maker, the switch can be enabled, and the component can be modified to use the app scope.

> **Note**
>
> - You can insert instances of components into a screen within a component library, and preview that screen for testing purposes.
> - Component library doesn't display when using Power Apps Mobile.

Import and export components (retired)

> **Note**
>
> This feature is retired. Component libraries are the recommended way to reuse the components across the apps. When using component library, an app maintains dependencies on the components it uses. The app maker is alerted when the updates to dependent components become available. Hence, all new reusable components should be created within the component libraries instead.

The ability to import and export components is disabled by default since this feature is retired. While the recommended method to work with components is to use component libraries, you can still enable this feature on a per-app basis as an exception until the feature is removed. To do this, edit your app in Power Apps Studio and then, go to **Settings** > **Upcoming features** > **Retired** > Set **Export and import components** to On.



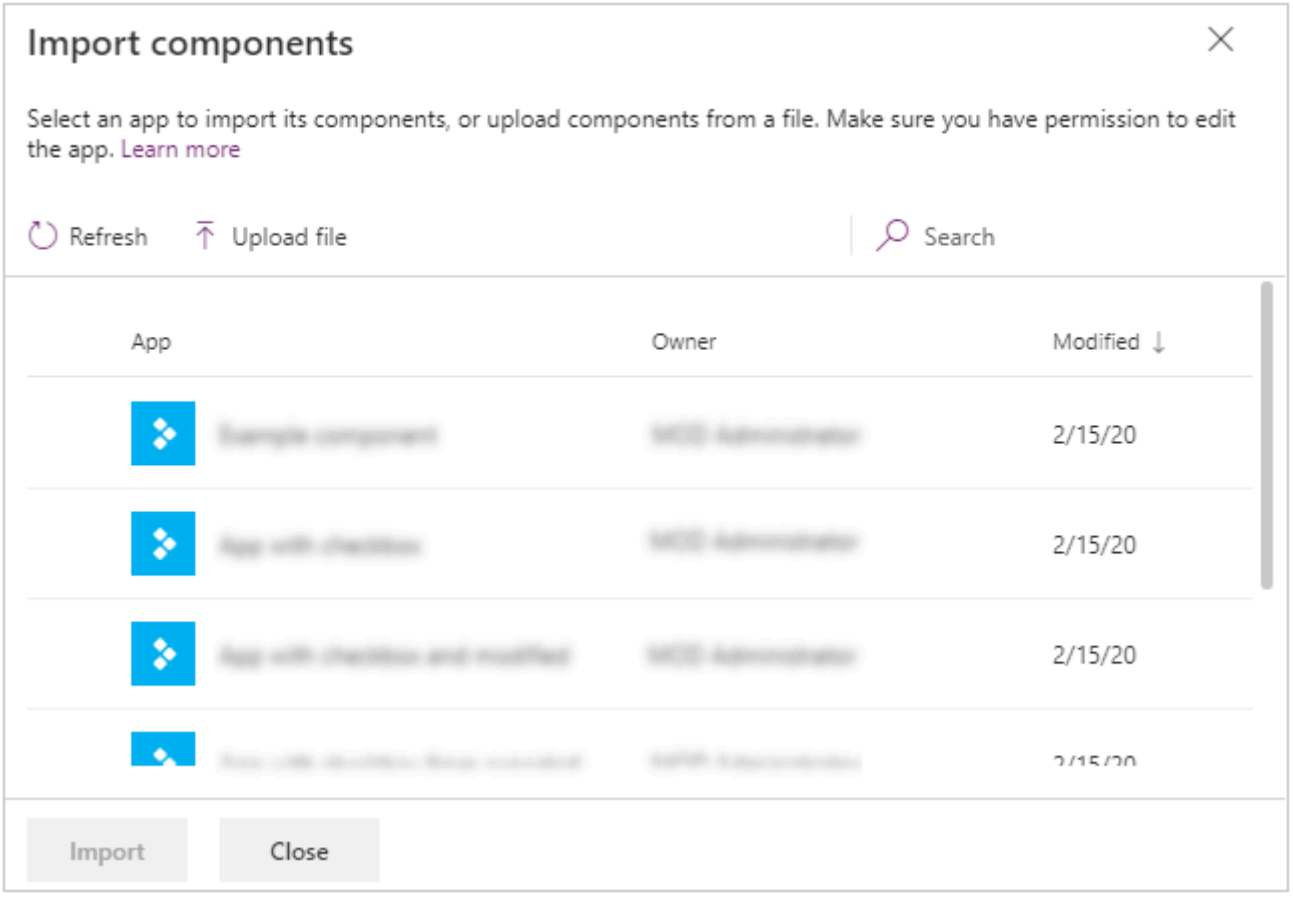
After you enable this feature, you can use the following capabilities to import and export components.

Import components from another app

To import one or more components from one app into another app, select **Import components** from the **Insert** menu and then use the **Custom** drop-down menu. Or use **Components** in the tree view on the left pane.

A dialog box lists all apps that contain components that you have permission to edit. Select an app, and then select **Import** to import the most recent published version of all of the

components in that app. After you import at least one component, you can edit your copy and delete any that you don't need.



You can save an app with existing components to a file locally and then reuse the file by importing it. You can use the file to import components to another app.

If the app contains a modified version of the same component, you're prompted to decide whether to replace the modified version or cancel the import.

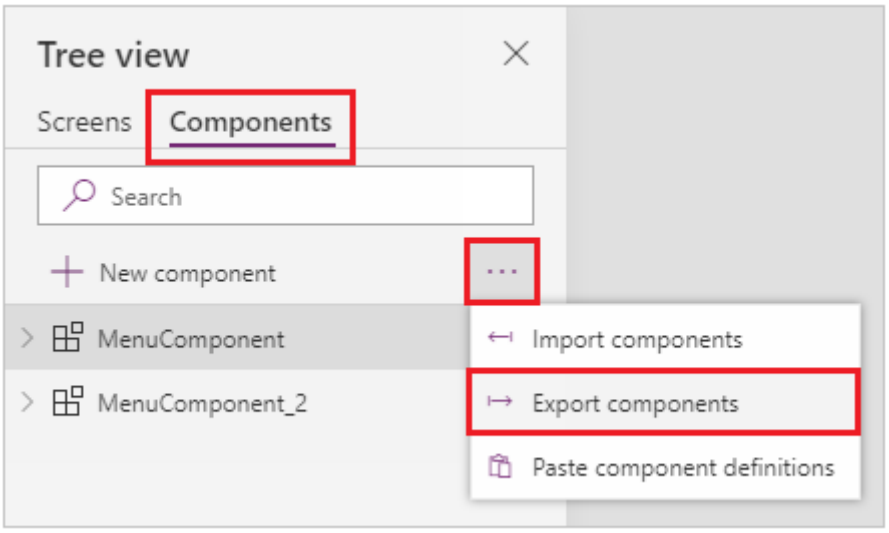
After you create components in an app, other apps can consume the components from this app by importing them.

> **Note**
>
> If a component that you imported from another app is modified in the original app, you must manually import the component again in the consuming app to receive latest component changes. Use component libraries instead to work with component updates more efficiently.

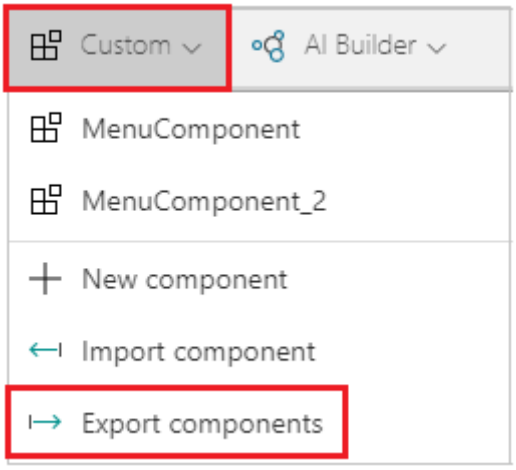
Export components from your app

You can export components to a file and download them for import to another app.

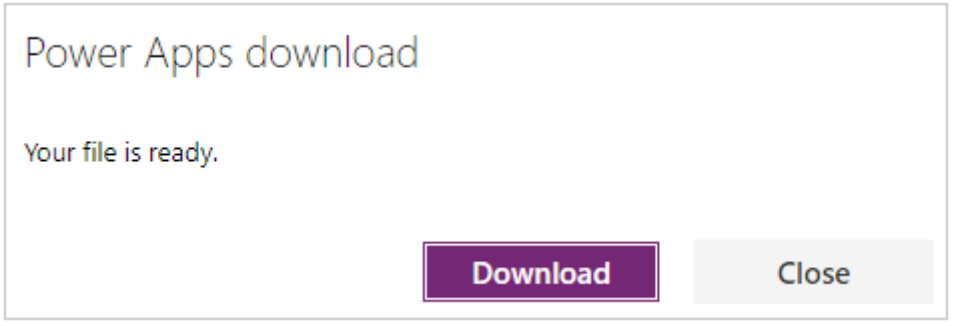
Select the **Export components** option from the **Components** section in the tree view on the left pane:



You can also use the **Insert** menu and then select the **Custom** drop-down menu instead.



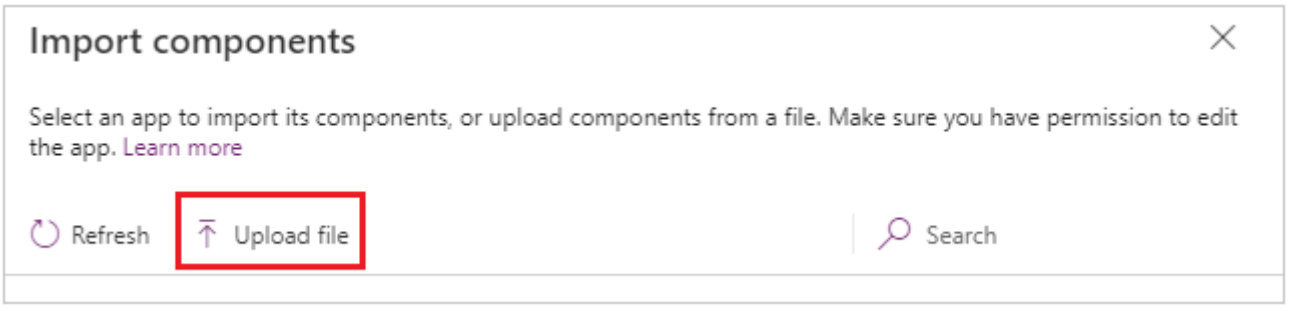
Selecting **Export components** downloads the components to a file:



The downloaded component file uses the *.msapp* file name extension.

Import components from exported components file

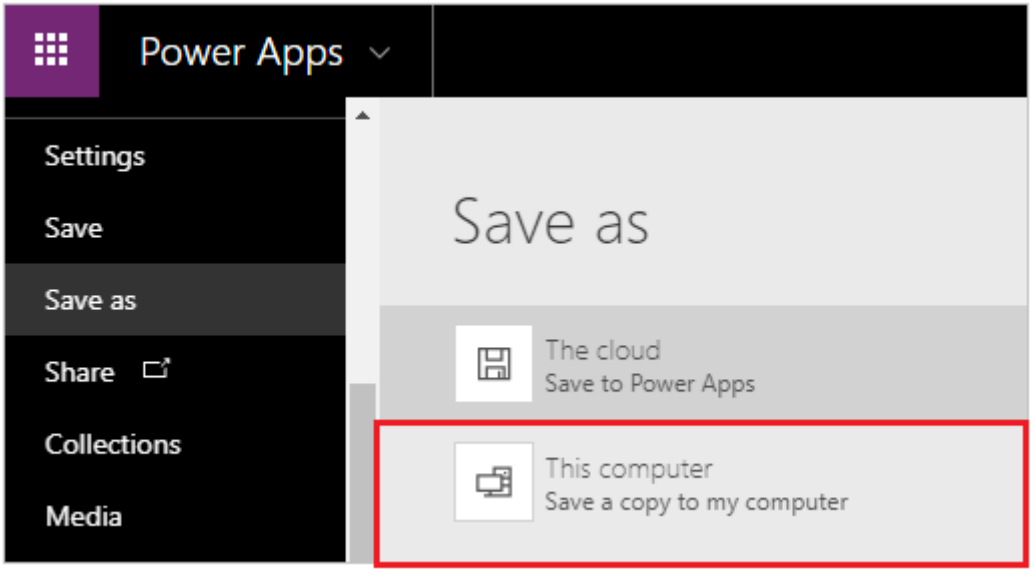
To import components from an exported components file, select **Import components** from either **Insert** menu and then use the **Custom** drop-down menu or use **Components** in the tree view on the left pane. From the components dialog box, select **Upload file** instead of selecting any other components or apps:



From the **Open** dialog box, browse to the location of the component file and select **Open** to import components inside the app.

Import components from exported app

You can save an app locally by selecting **File** > **Save As**:



After you save the app, you can reuse its components by importing them from a file. For more information, see the previous section on importing components from an exported components file.

Known limitations

- When you have two or more instances of the same component in an app, you can't configure a custom input property to a custom output property value across same or

different instances. This action results in a circular reference warning message. To work around this limitation, create a copy of the component inside your app.
- Adding and running Power Automate flows in component libraries isn't supported.
- You can't save data sources or controls that include data from those data sources (such as forms, fluid grids, or data tables) with components.
- You can't insert a component into a gallery or a form (including SharePoint form).
- Components don't support the **UpdateContext** function, but you can create and update variables in a component by using the **Set** function. The scope of these variables is limited to the component, but you can access them from outside the component through custom output properties.

Next steps

Learn to use a component library to create a repository of reusable components.

Component library

Article • 12/19/2023

In the overview article for creating components, you're introduced to components inside canvas app. As you create components inside an app, you can also create a library of components that can be reused. By creating a component library, app makers easily share and update one or more components with other makers.

Component libraries are containers of component definitions that make it easy to:

- Discover and search components.
- Publish updates.
- Notify app makers of available component updates.

> **Note**
>
> Component libraries are the recommended way to reuse components across apps. When using a component library, an app maintains dependencies on the components it uses. The app maker will be alerted when the updates to dependent components become available. Hence, all new reusable components should be created within the component libraries instead. An earlier Power Apps feature that allowed importing components from one canvas app to another is retired.

Difference between an app and a component library

A component library provides a centralized and managed repository of components for reusability.

The **Insert** pane on the left navigation defaults to a components tab if you create a component library. When you create an app, this view shows screens instead of components.

The screens inside a component library are available for testing only. It provides library creators a way to quickly test the created components on an actual screen and also validate the update behavior as components are enhanced over time. To use the components from the component library, you must create an app that uses the component library.

You can preview component library components using the screens inside the library with the play option. When you select the component tab, the play option is disabled. The component library doesn't display when using Power Apps Mobile.

> **Note**
>
> The component library discussed in this article is different from the Power Apps component framework that enables developers and makers to create code components for model-driven and canvas apps. For more information, go to Power Apps component framework overview.

Working with component library

You can create a new component library or edit an existing component library from the same interface. Go to Power Apps > select **More** from left navigation > select **Discover all** > select **Component libraries** from the **App enhancements** section. You can also pin **Component libraries** option to your Power Apps interface. More information: Left navigation in Power Apps

Create an example component library

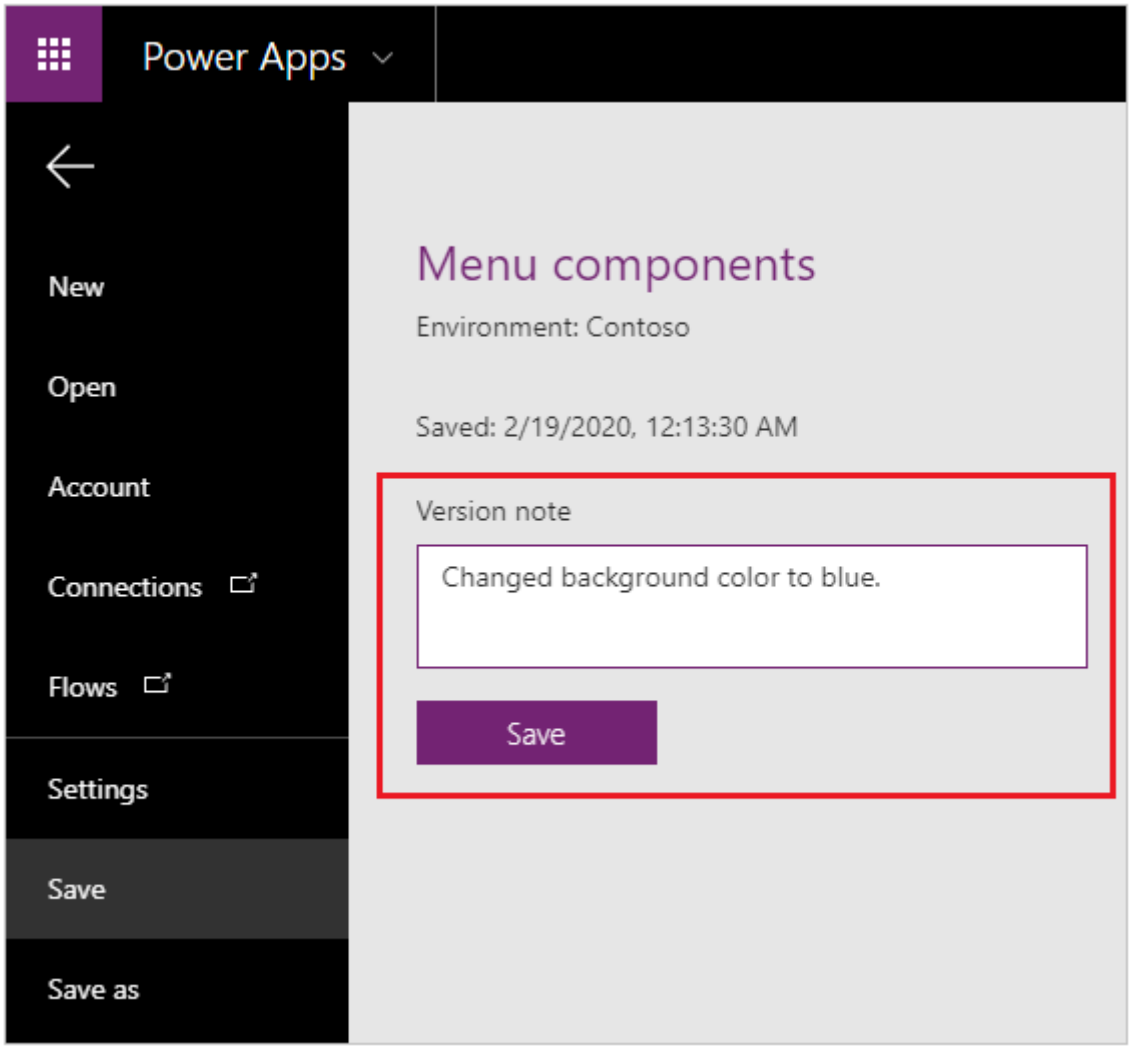
The steps to create components inside a component library are the same as creating components inside an app. You'll create a component library and then reuse the steps for creating components from components overview example. Then you'll use the component library to provide the reusable components in a new app.

1. Sign in to Power Apps.
2. Select **Component libraries** in the left navigation, and then select **New component library**. Alternatively, select **More** from left navigation > select **Discover all** > select **Component libraries** from the **App enhancements** section.
3. Name the component library as *Menu components*; you can also provide a different name of your choice.
4. Follow the steps to create components from components overview example. You don't have to open Power Apps Studio or create a new blank app, since you already have created a new component library. Start with step 2.

   After following the steps to create components, follow the next set of steps to also add components to a screen and the steps to create output property.

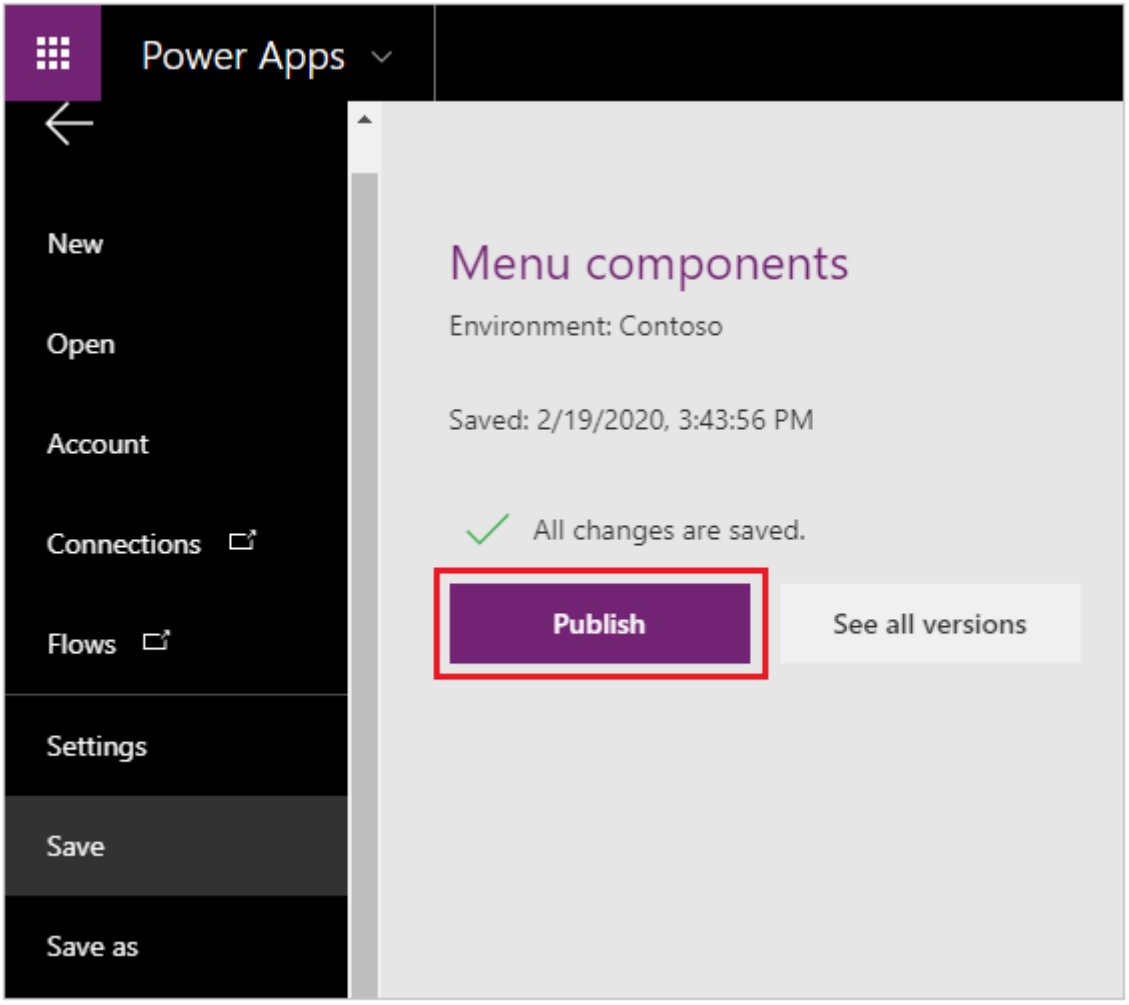
5. After you complete the components creation and testing, save the component library by selecting the **File** menu and then selecting **Save**.

   You also have an option to save a **version note**. A version note is useful to retrieve versions of a component library and for upgrading the components used in apps from this component library.



> **Tip**
>
> A version note is useful when reviewing versions of a component library and for the app makers using your component library to review changes and update apps consuming these components as needed. Go to update a component library for more details.

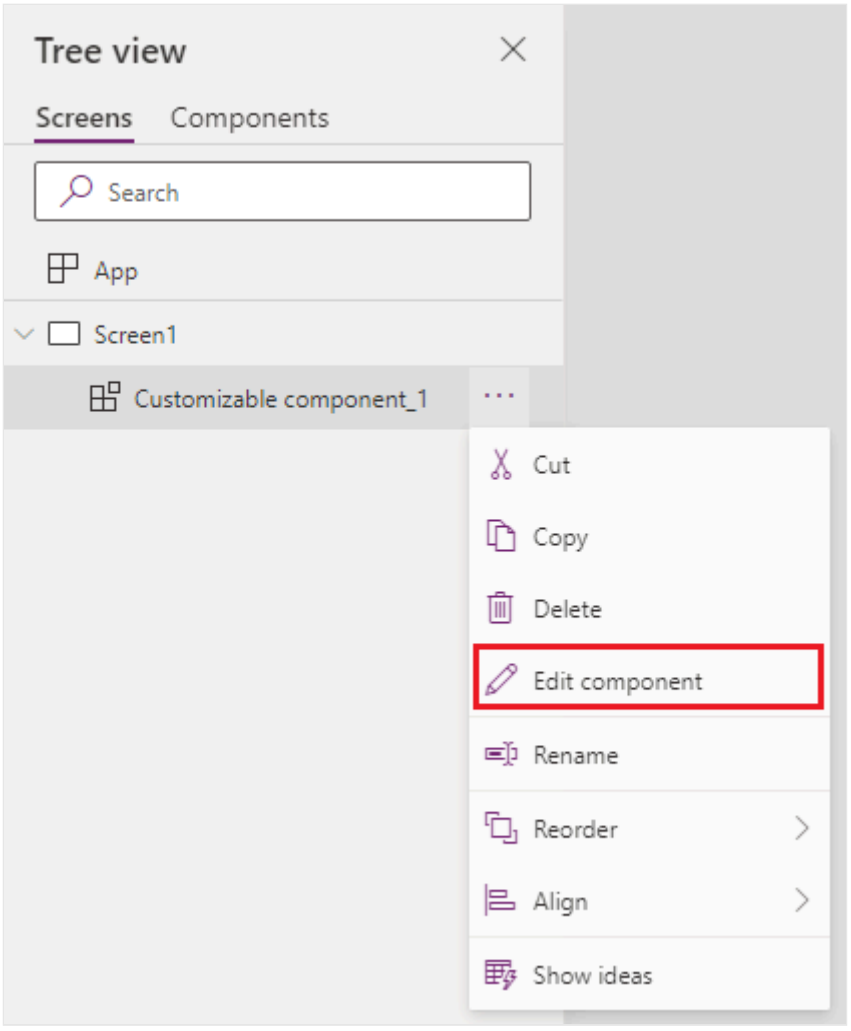
6. A saved component library can be published. Only published component library updates are available for apps that consume a component library. Select **Publish** to publish the component library version:



Library component customization

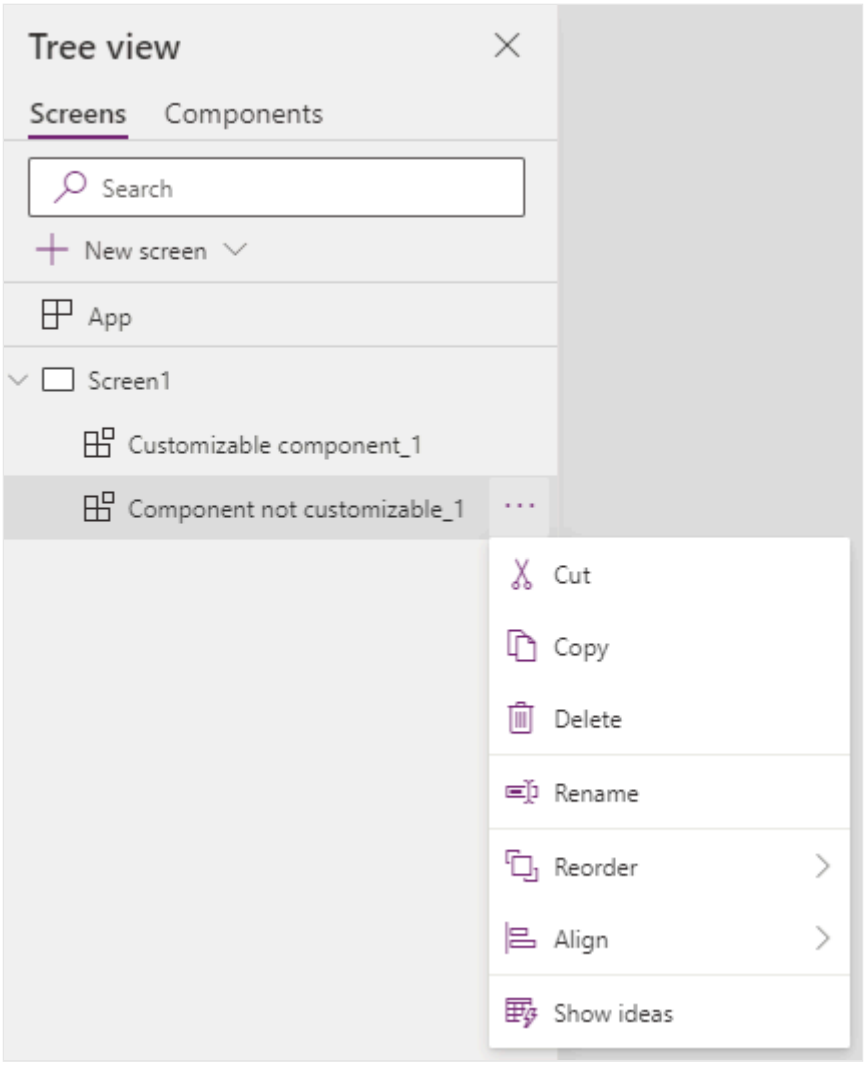
When creating component inside a component library, you have the option to allow the component to be customized when used by apps consuming the library components. By default, this setting is turned **On**. Turn this setting to **Off** to remove the ability to customize component while using in other apps.

When you add a component that allows customization, you'll see an option to edit this component for more customization. App makes a local copy and you can make changes to local component copy. The association with the component library is removed once the component is edited.



Selecting **Edit component** prompts you to copy the component locally for customization.

However, when you don't allow the components to be customized, the consuming apps won't show the option to edit the component.

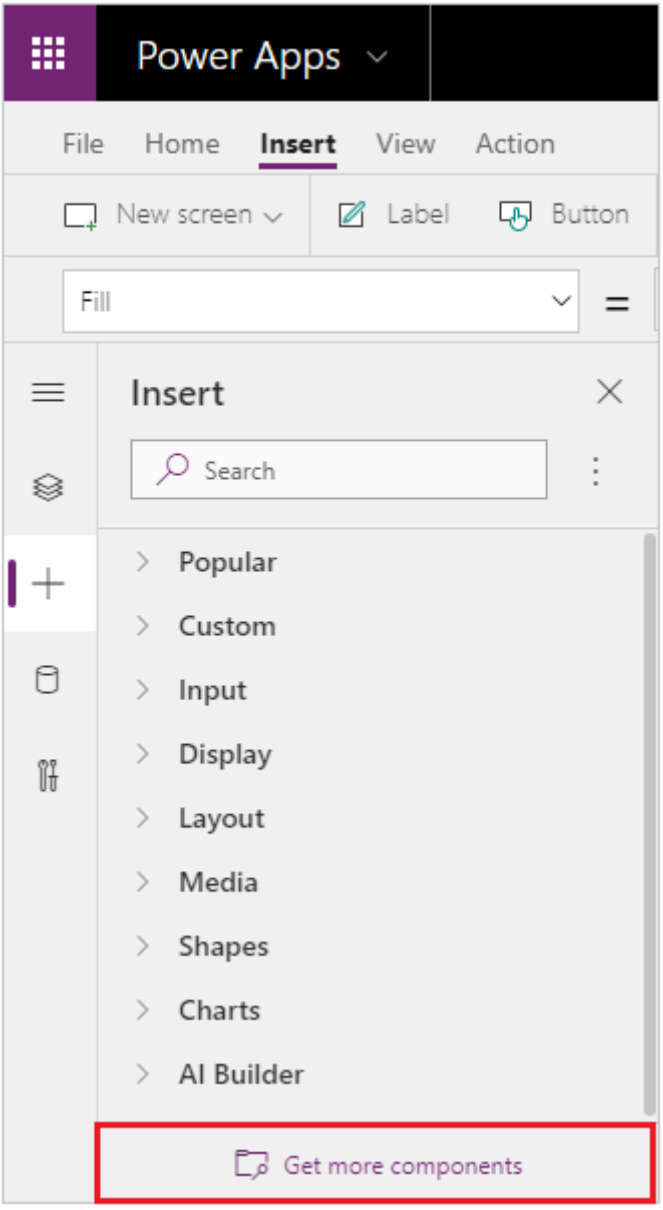


In this case, the only way to edit the component is to edit the component library where the component is stored.

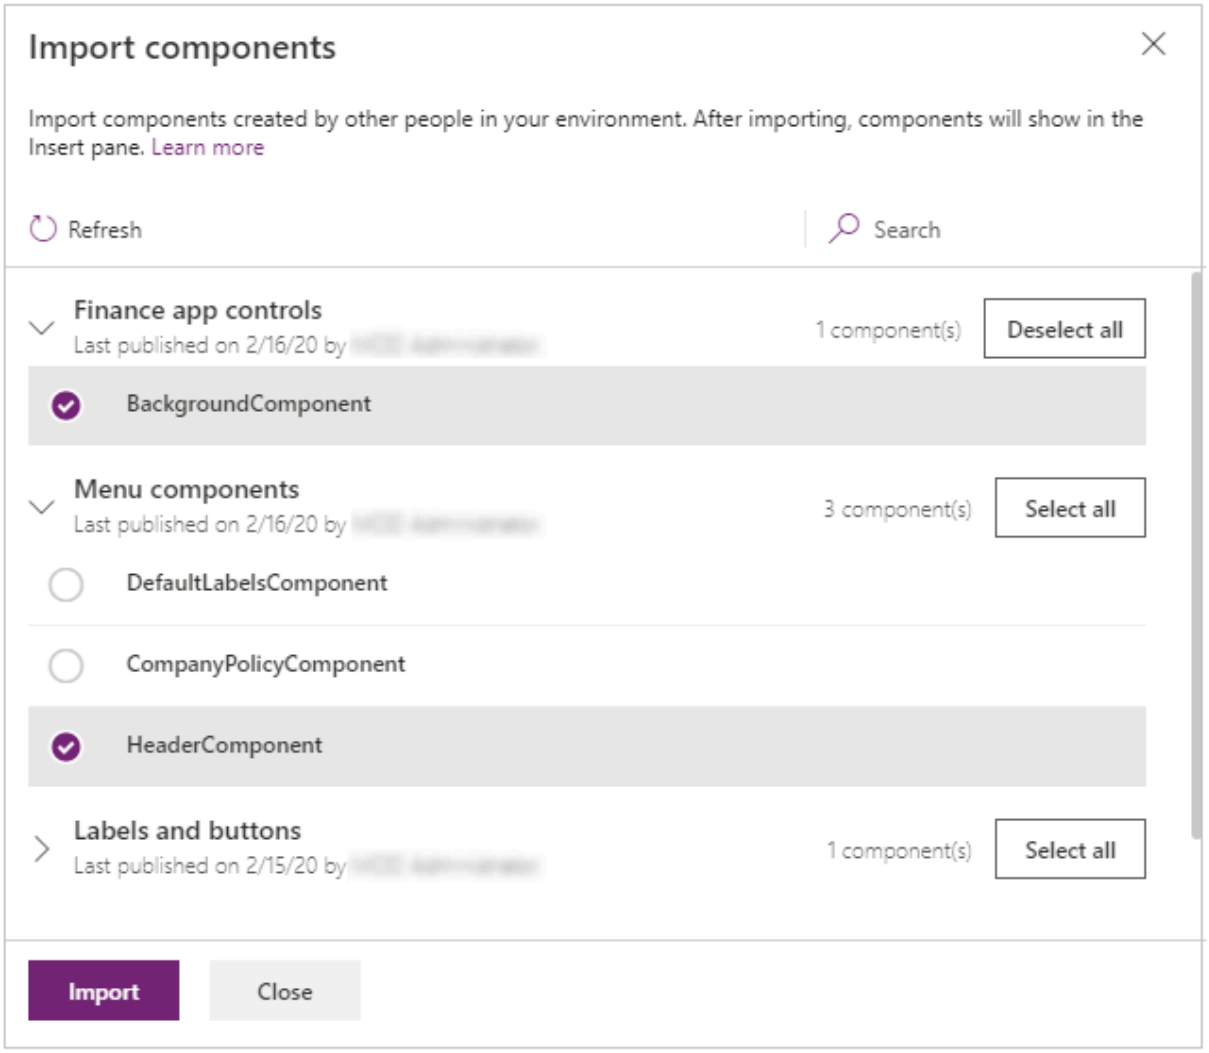
Import from a component library

After you create a component library and publish, apps can consume the components from this component library by importing the library. You can also share a component library.

To import from a component library, edit an existing app or create a new app. After the app opens in canvas app studio, select **Insert** or the + on the left navigation. Then select **Get more components** to list the component libraries available in the current environment:



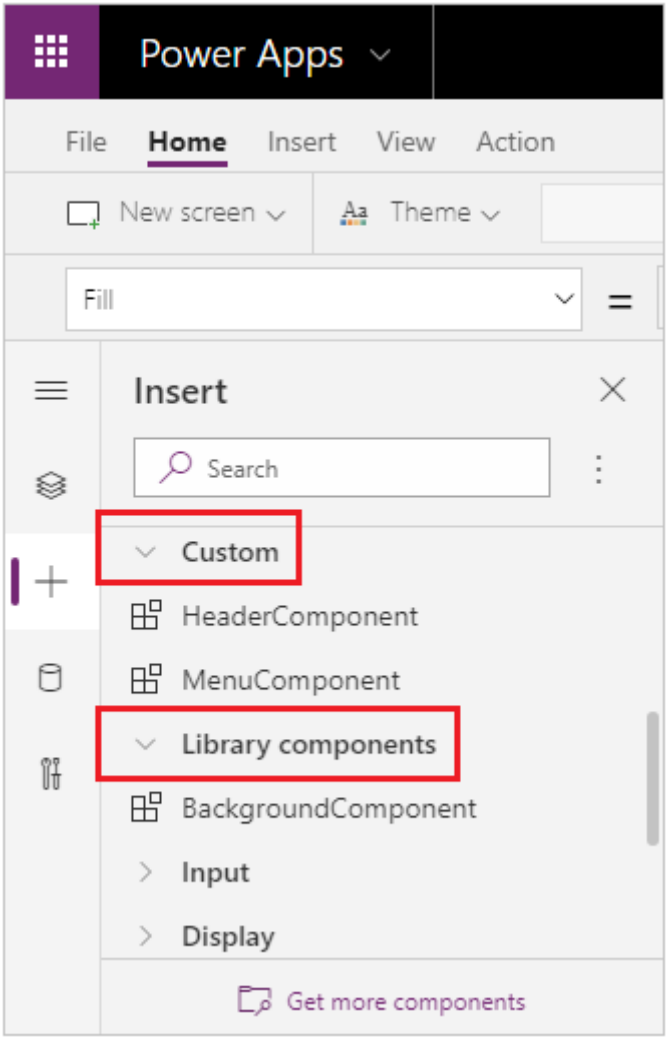
You'll see the list of component libraries available in the current environment on the right side of the screen. Select an individual component from a component library. Or use **Select all** to import all of the components from the library at once:



> **Note**
>
> If a maker doesn't see the component library listed in the import section, ensure the component library is shared with the maker. For more details, go to component library permissions.

Notice you can select and import more than one component and across different component libraries.

Components available inside the app are listed under the **Custom** category in the list of components in the **Insert** pane. Components available from imported component libraries are listed under the **Library components** category:



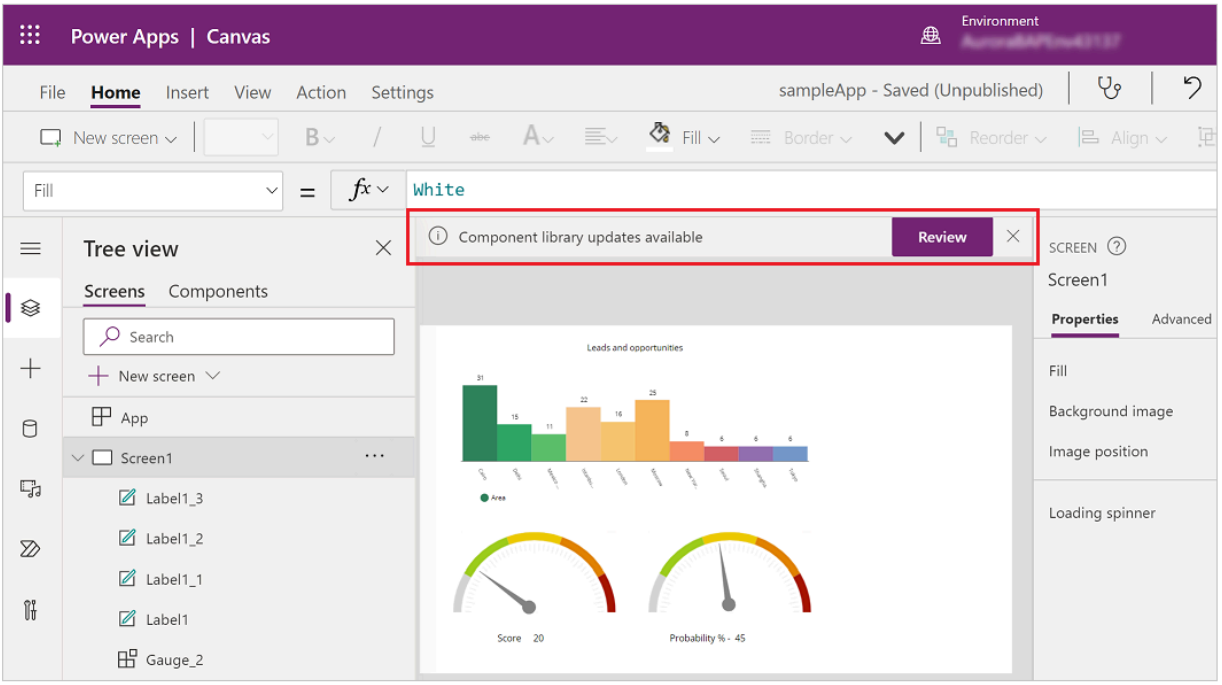
Update a component library

You can modify an existing component library and save any changes with other version notes. However, the updated component library version must be published for use in existing apps that use the component library. The example component library steps above explain how to publish a component library after saving it.

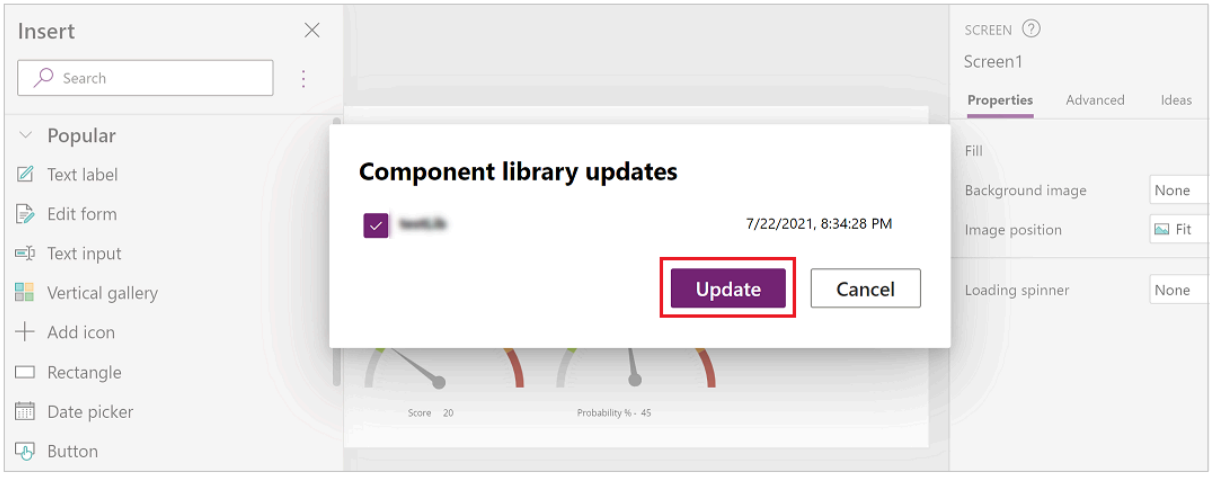
There are two ways apps using the components from library can get the latest changes.

Method 1: Component update notification on app edit

Makers of other apps are notified of updated components being available. The notification appears when makers edit the apps in canvas app studio. They can choose to update the components:

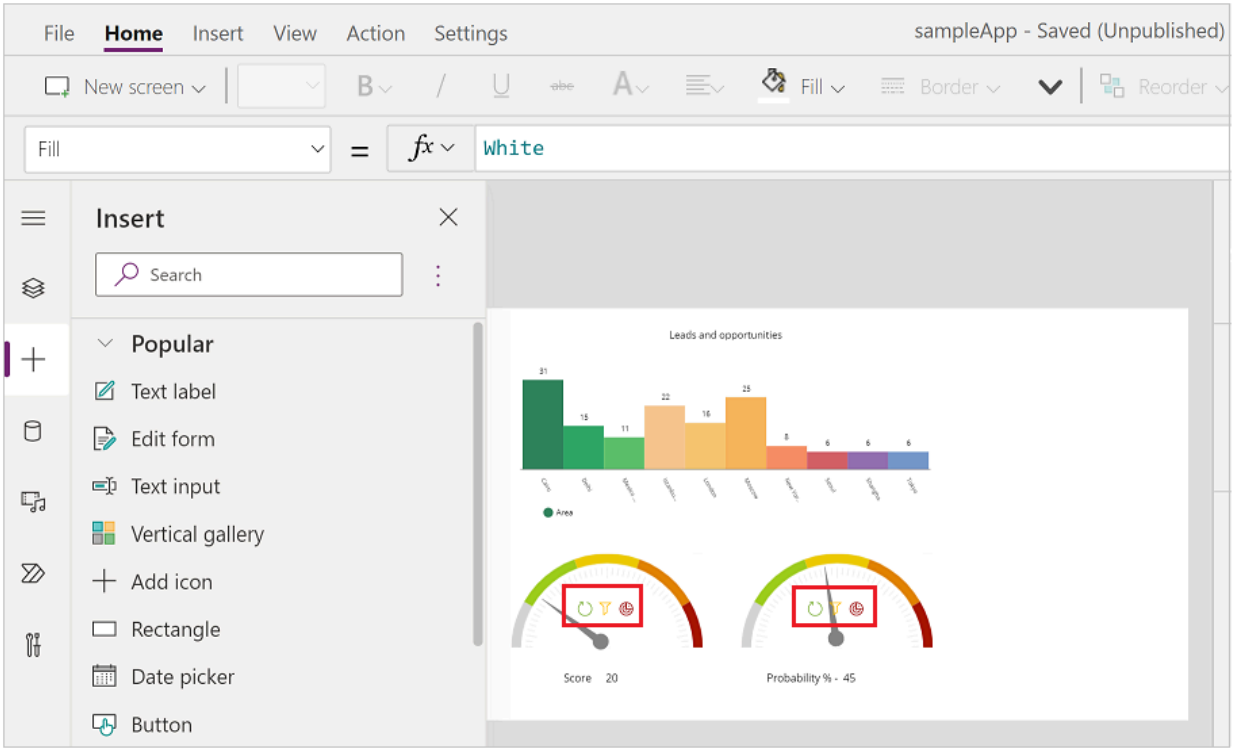


Select **Review**, and you'll see the option to update the component:



Notice that the version note you added when publishing the component library version shows up here.

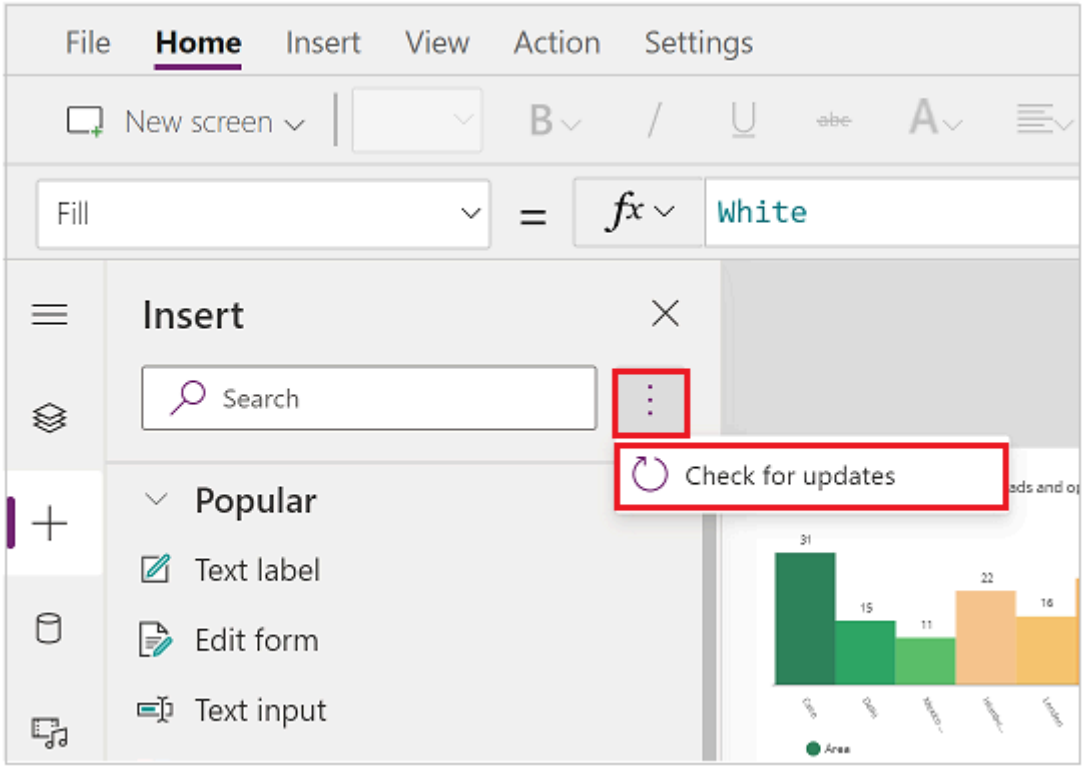
Select **Update** to update the components.



Method 2: Proactive check for updates

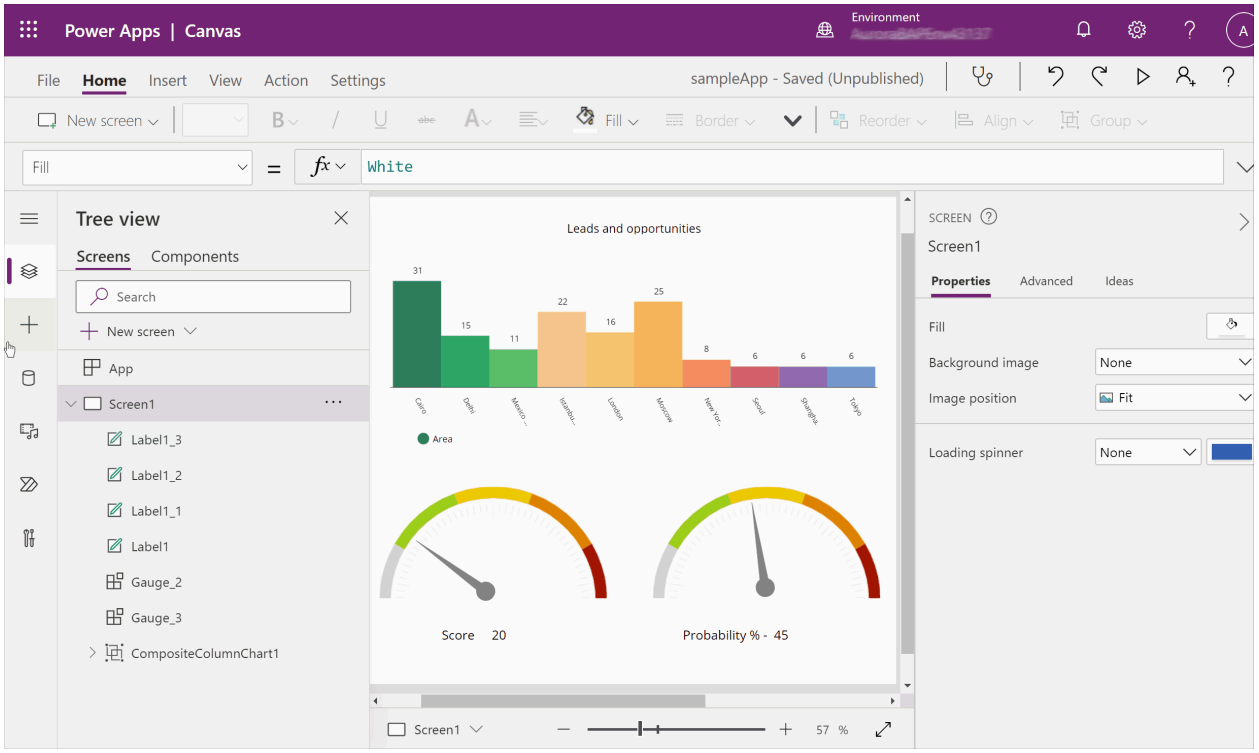
This method is to check for the app update proactively while working on the app in Studio.

To do this check, select Insert component panel on the left-side, and then select ... (ellipsis) next to the search button. And then, select **Check for updates**.



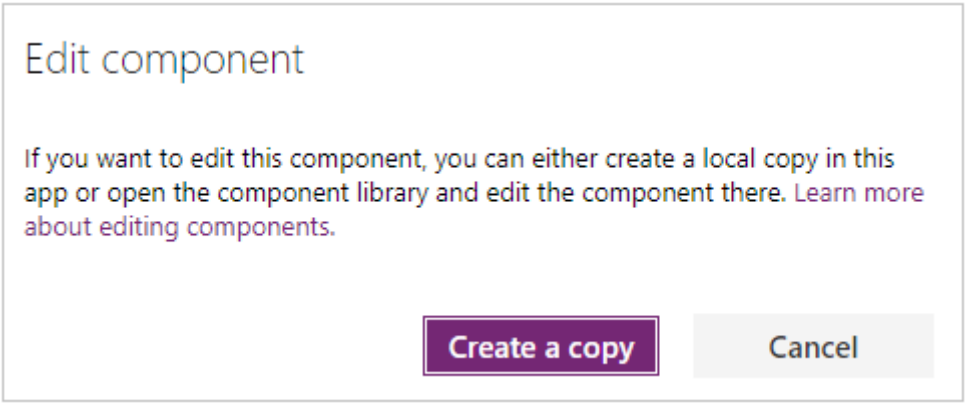
If there are updates in the components used from library, maker will get the message to review and get the latest changes. Upon review and update, the app gets updated with the latest components.

The following animation shows the process to get the latest components.



Updating component from a component library in a consuming app

If you import a component from a component library, you can't edit it inside the consuming app. If you select **Edit component**, you'll see an option to create a copy of the component inside the current app for you to make changes:



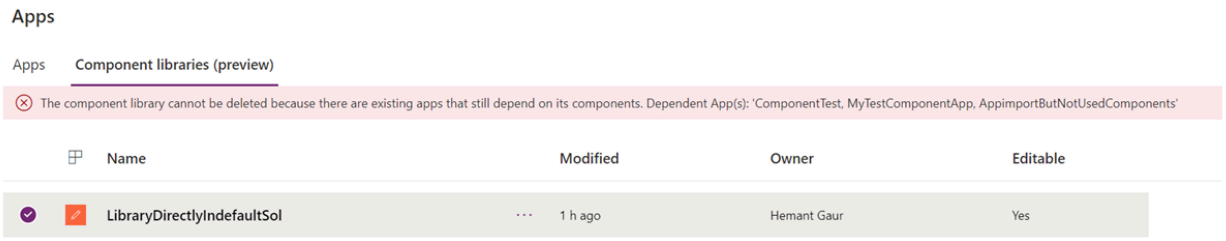
If you select **Create a copy**, the component is copied to the local app. The local copy of the component appears under the **Custom** category in the **Insert** pane. This local copy

of the component won't receive updates if a new version of the originating component library is published later.

> **Note**
>
> The in-use instances of components from the component library won't be affected after you create a local copy of a component, and will remain linked to the component library definition. Only instances of the locally copied components (from **Custom** category) are considered to be the local app components.

Deleting a component library

If a component library is referenced by a canvas app, it can't be deleted. This is true for both Power Platform and non-Power Platform environments. Remove the component from the app before deleting the library. You can find information about the apps using the component library in either solution dependencies view or in the message, which is shown when you try to delete library.



Component library permissions

Sharing a component library works the same way you share a canvas app. When you share a component library, you allow others to reuse the component library. Once shared, others can edit the component library and import components from this shared component library for creating and editing apps. If shared as a co-owner, a user can use, edit, and share a component library but not delete or change the owner.

Additional considerations when sharing component libraries to security groups:

- You can't use the sharing UI when sharing component libraries created as part of a solution. Instead, use Set-PowerAppRoleAssignment cmdlet with **CanEdit** permission level to share the component libraries with the selected security group.
- Component libraries created in a Power Platform environment without a Dataverse database shared as **Co-owner** automatically grant **CanEdit** permission to the selected security group.

Known limitations

- Known limitations applicable to components also applies to component libraries.
- You can't import components from a locally saved component library. It's possible to save a component library using **File** > **Save As** > **This Computer**. But if you try to import such saved component library, you'll see the following error message:

- If you're importing an app and a component library in an environment for the first time, ensure the app uses the latest version of the component included with the component library. Otherwise, the app won't receive updates after the import. The app will recognize and prompt for the updated version upon subsequent component library imports to the same environment.
- Code components aren't supported inside component libraries.

Component library application lifecycle management (ALM)

Article • 01/24/2023

A component library is a special type of canvas app that can contain one or more canvas components. These library components can then be used by all the other canvas apps in the environment. This capability enables you to create reusable shared components across all apps in an environment, unlike app-level components that are restricted to one app.

To use a component from a component library, you have to first import the component into the canvas app. Once imported, you can then add the component to any app screen. Any updates in the component definition from the component library will prompt you to review and incorporate the change on demand or when the app is opened for editing. Component libraries and dependent apps can also be moved to another environment using standard Microsoft Dataverse solutions.

> **Note**
>
> In this article, the term "import" refers to importing a component from a component library to an app, and shouldn't be confused with importing a solution into Dataverse.

When a component from a component library is imported into a canvas app, that component's definition is copied into the definition of the canvas app. Once a component definition has been imported, the app is "self-contained" as far as that component definition is concerned. The app maker can choose to edit the component, and create local instances of the component within the app. At this point there's no direct link to the component library from where the component originated. This self-containment characteristic also applies if the canvas app is then migrated to a different environment where the component library isn't present. You can continue to create instances of the imported component definition within the apps in the target environment, and the apps can still be published and played. No new updates will be prompted or received in the consuming app in this case.

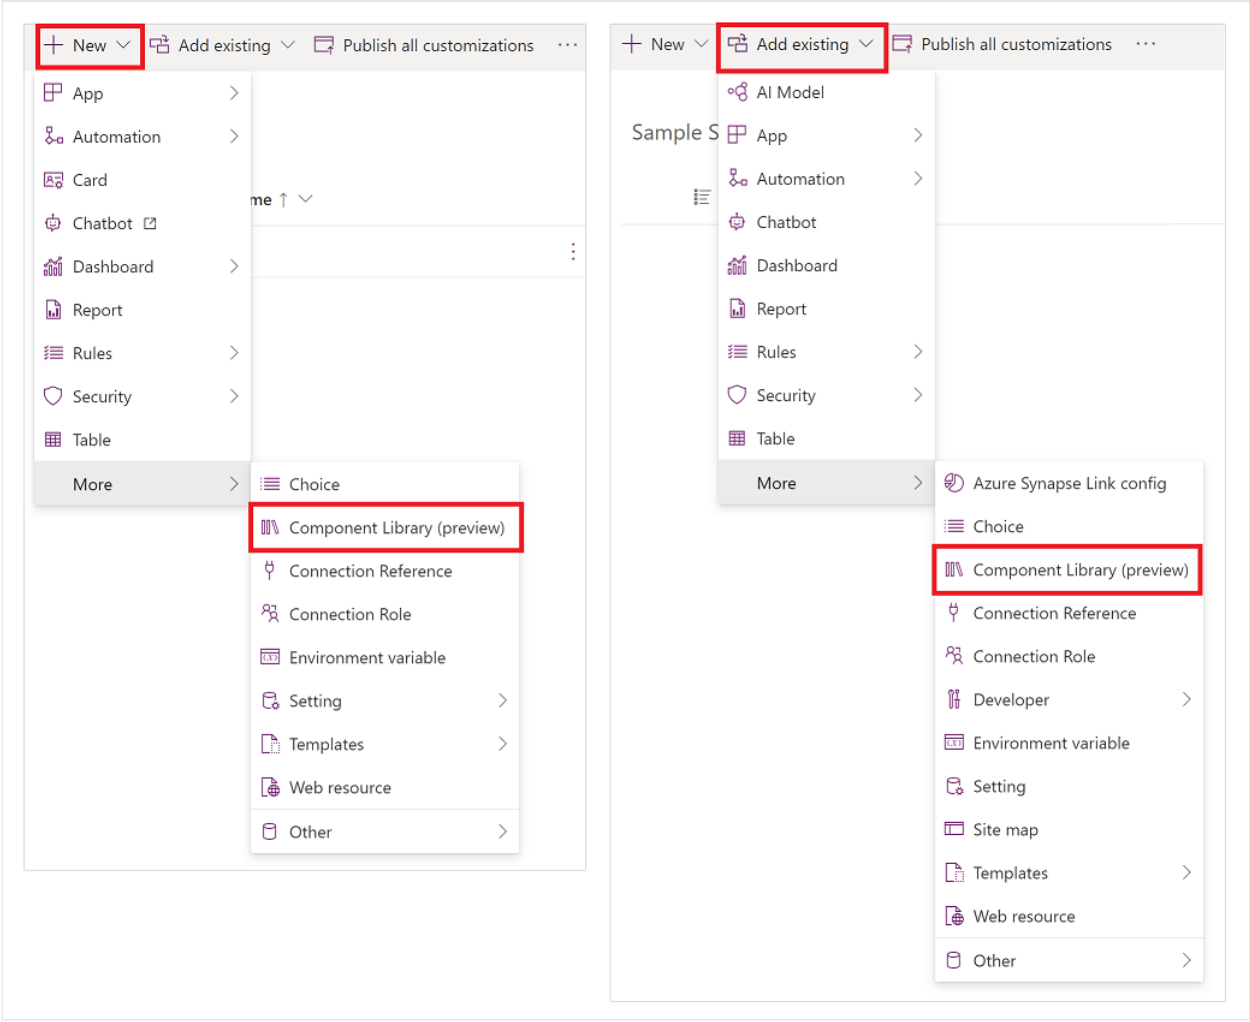
In order to maintain the relationship from the app to the component library, ensure that you use the component library to make any changes to the component, instead of editing the component within the consuming app.

Canvas apps and component libraries solution support

Consistent with the other solution object dependencies, if a canvas app imports a canvas component from a component library, it will have a dependency on that component library. In order to move an app to the new environment, you'll need to either package the component library inside the same solution or install it as a pre-requisite. App to component library dependency is maintained in the target environment. At a later point, when a component library with the updated component is imported using a solution into the target environment, existing apps will get the new component definitions using the regular component update flow.

Creating and exporting component library in a solution

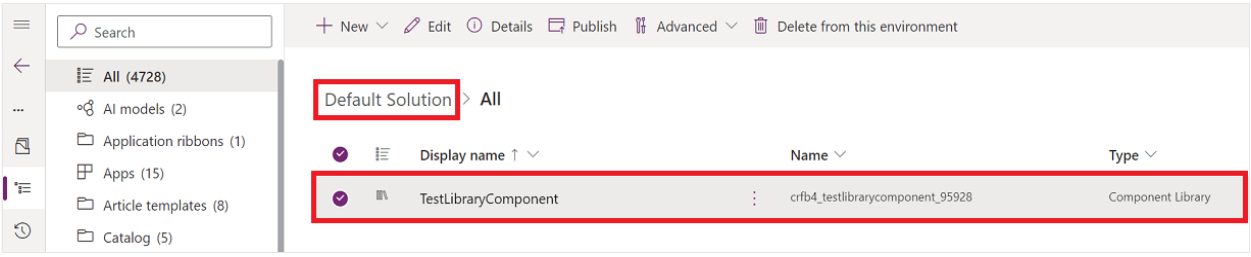
You can either create a component library directly from within the solution, or add it to an existing solution.



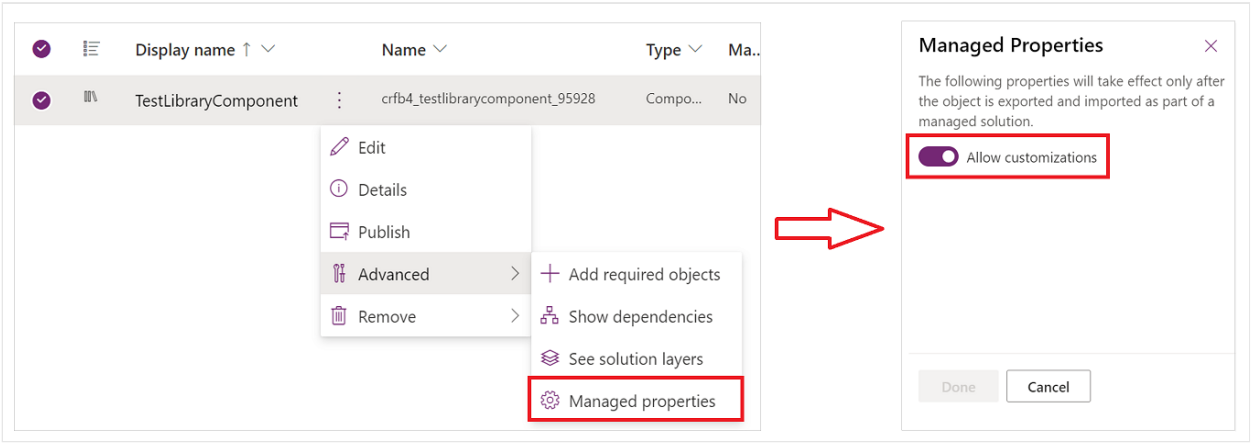
When a component library is saved in an environment that has Dataverse available, component library is automatically added to the default solution. A unique logical name

is generated for the component library with the **Default CDS Publisher** prefix. This behavior is to ensure that the solution system is aware of its presence, and can link the dependencies from the apps that use the component library's logical name.

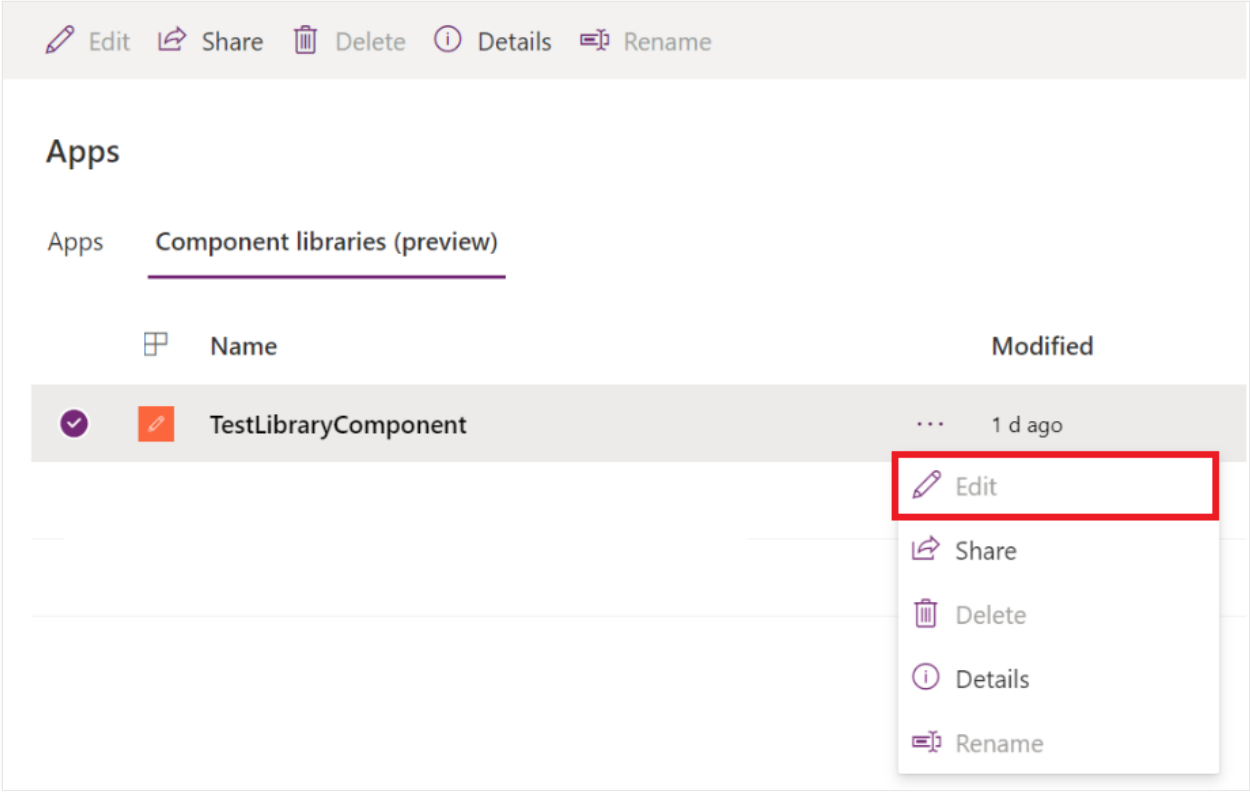
> **Note**
>
> Component libraries created before the rollout of the component library ALM feature need to be edited, published, and the editor must be closed explicitly before they're enabled for the ALM capabilities. You can check the component library ALM readiness by its presence in the default solution.



Component libraries inside a solution also support **Allow customizations** managed properties that govern the behavior of the component library in the target environment.

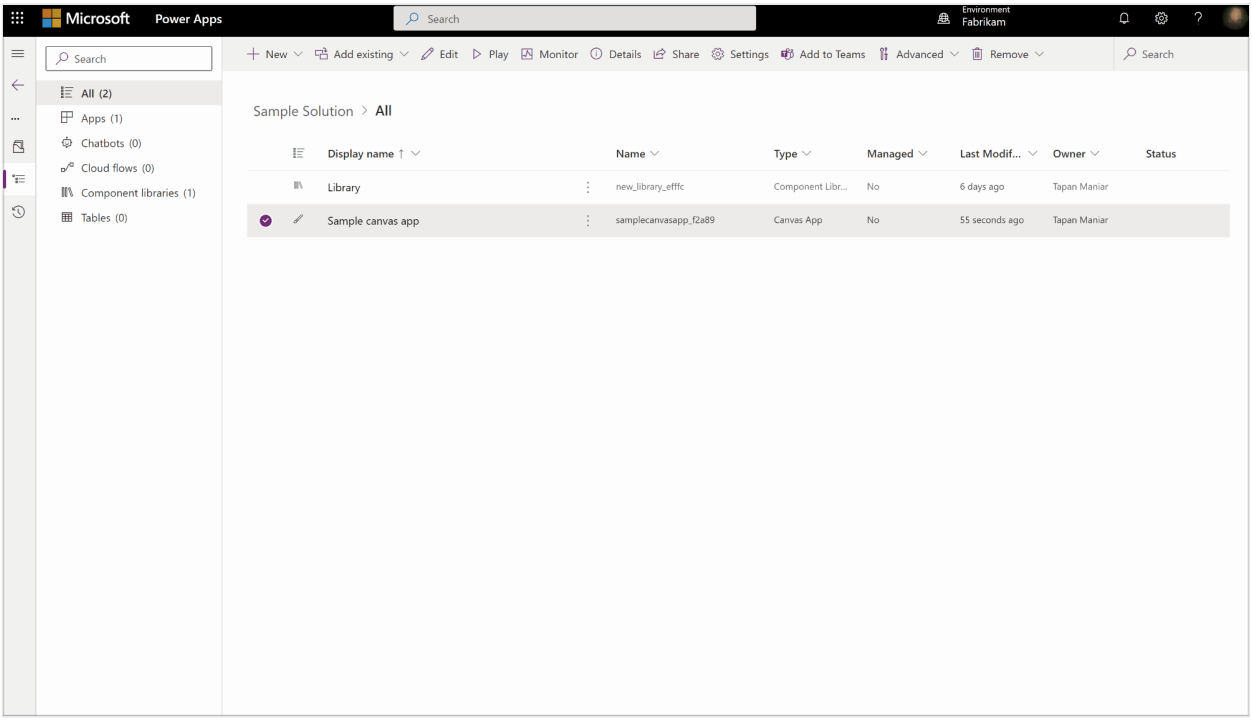


If you turn off this setting, and export the solution to a target environment, you won't be able to edit the component library.



Component library dependencies

Apps that use components from the component library will be marked as dependent in the solutions infrastructure. This behavior applies to all apps that are added to any Dataverse solution in a given environment. You can still create apps outside of solutions, but those apps won't have any solution dependencies. You can later add these apps to solutions to make them part of the solution ALM.



If you import a solution that only has an app that uses a component from a component library, but excludes the component library, you'll see the following message:

"Import failed due to missing dependencies for <app name>".

In this case, you can choose to install the component library solution first, or bundle the component library with the solution that contains the canvas app. Either of the steps would ensure the app will have the dependency created in the target environment.

When the library is updated and a newer component version is imported through the solutions, the app will get a notification and receive the updates when the app is opened for editing.

> **Note**
>
> If the component library managed property **Allow customizations** is turned off, the component library can't be edited in the target environment.

Dependencies are calculated based on the latest published state of an app. If you restore an older version of the app that doesn't use a library component, the dependency will be removed from the app, and the solution. Importing a component into an app from a component library without actually using it also creates a dependency since the unused library component remains available within the app for a future use.

> **Tip**
>
> Editing a component from a component library inside the consuming app creates a local copy. At this point, the library component is still available for use through the **Insert** pane. In order to remove the dependency completely, delete the component from **Insert** > **Library components** > **...** (ellipsis) > **Remove from app**.

Best practices and troubleshooting

- Limit the number of components in a library to 20 to get optimal performance. Plan and create multiple component libraries in advance as the number of components in them will likely grow over time. This approach will also reduce the solution payload as apps are moved across the environment.
- There's a delay from when the component library is published to when it's available to the application, and can take up to 5 minutes.

- If the app isn't able to receive the update from the library component in the target environment where the solution is installed, check using the below actions:
  - Changes made to a component library in a target environment reside at the top layer of a component. Subsequently, these customizations define the runtime behavior of the component. To remove these unmanaged customizations, see Remove an unmanaged layer.
  - Determine the component library logical name from the solution view. Use the default solution if library isn't explicitly added to solution.
  - Download app using the library component to local computer using **File** > **Save as** > **This computer**. Rename the downloaded file to have a .zip extension, and unzip the package. Open the **Properties.json** file, and then search for the keyword "LibraryDependencies". You should see a matching library logical name.
  - If you're consuming the solution, check that the canvas app has properly identified the component libraries as solution dependencies. If the solution doesn't properly identify the component libraries as solution dependencies, that means the app dependency to the component library link hasn't been created properly. In that case, check with the solution provider to resolve the issue.
  - If you're the solution publisher, check that the component libraries are saved with the library logical name in the solution, and that it's same as the one referenced in the component library .msapp package.

- Solution export always exports the latest version of the component library. Hence, always update the apps with the latest component version before exporting them through solutions. This action ensures that the apps have the same component version as available in the latest version of the component library. Apps and library are considered to be synchronized with each other when they're moved to a target environment for the first time; and hence, you're not prompted for any update being available when editing the app.

Map input fields of a component

Article • 01/24/2023

A component can receive input values to emit or process data using custom input properties. In this article, you'll learn about working with such components expecting one or more input properties with a specific schema for the given table or record, and how to map the component input fields to the columns of the data source.

> **Tip**
>
> To learn about what the custom input and output properties in components are, see **Custom properties in components**.

Map columns

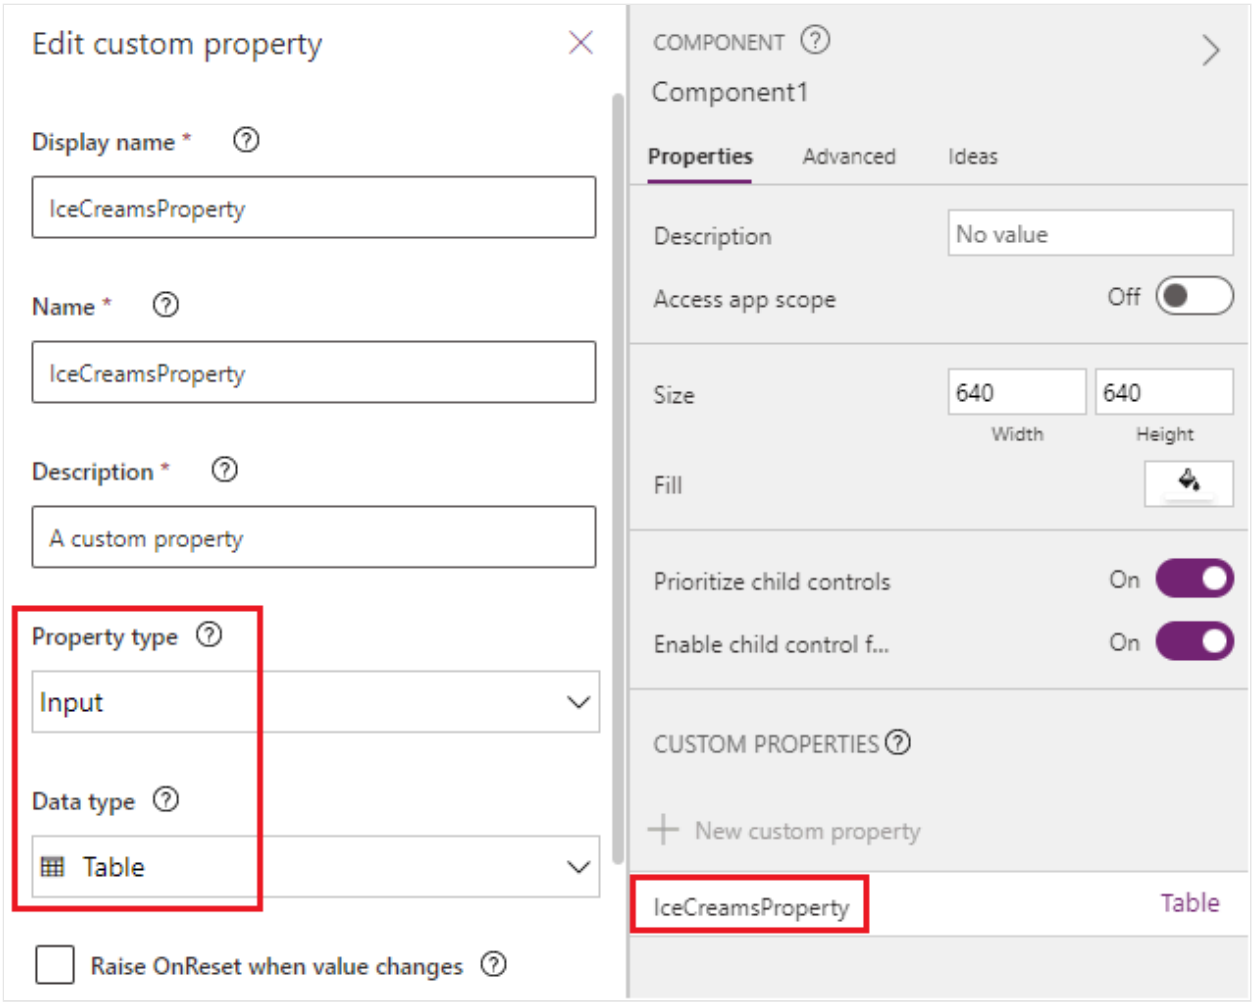
Use the RenameColumns() function to rename one or more columns of a table to match the input property schema for input column selection.

For example, consider a component that expects a table input with the following format:

Expand table

Flavor	UnitPrice	QuantitySold
Strawberry	1.99	20
Chocolate	2.99	45

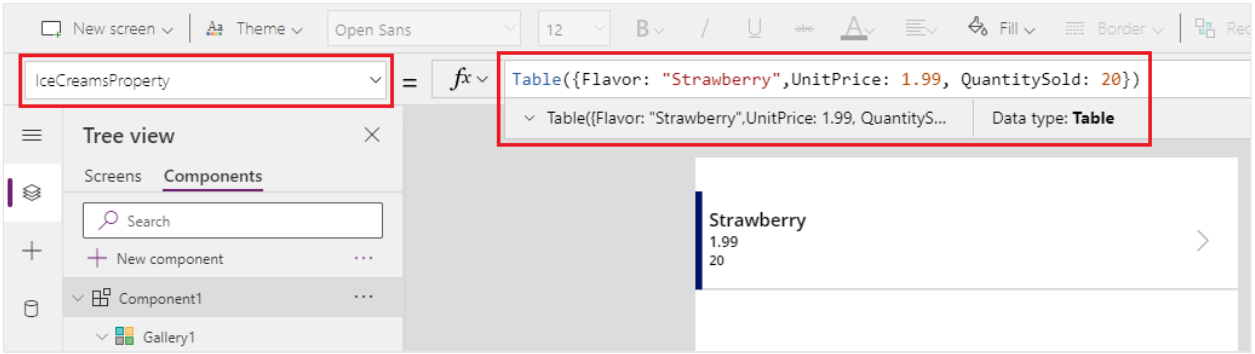
The input property expects table data type:



The schema of the input property looks like the following formula:

```
Power Fx

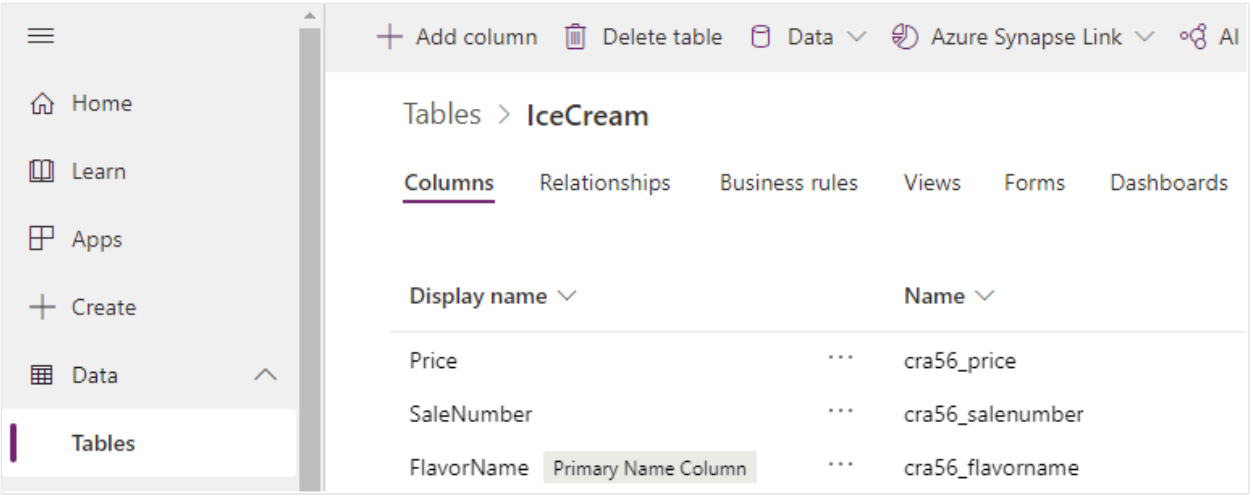
Table({Flavor: "Strawberry",UnitPrice: 1.99, QuantitySold:20})
```



The app consuming this component has the following **IceCreams** table that doesn't match with the component schema:

Expand table

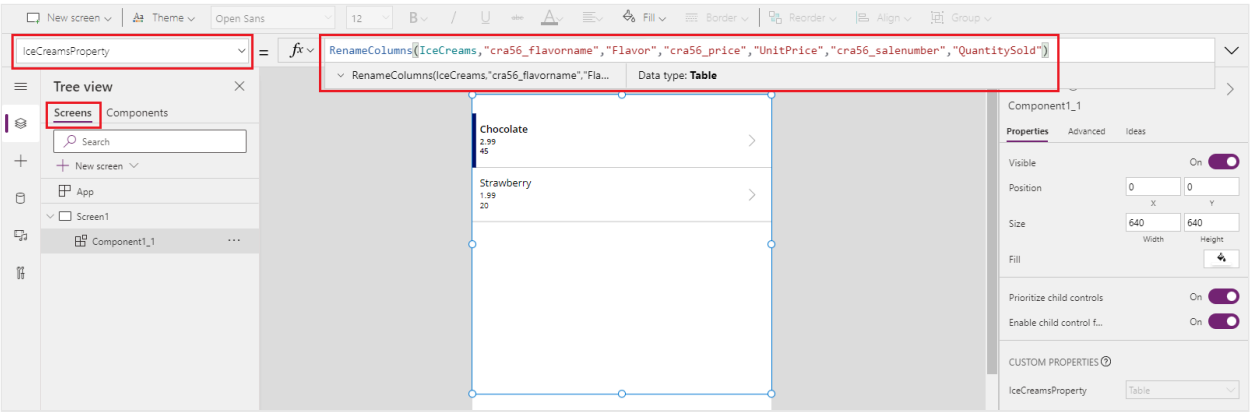
FlavorName	Price	SaleNumber
Strawberry	1.99	20
Chocolate	2.99	45



To map the correct fields, use **RenameColumn()** function to rename expected columns.

Power Fx

```
RenameColumns(IceCreams,"cra56_flavorname","Flavor","cra56_price","UnitPrice","cra56_salenumber","QuantitySold")
```



The input fields that the component expects are now mapped with the matching columns from the data source.

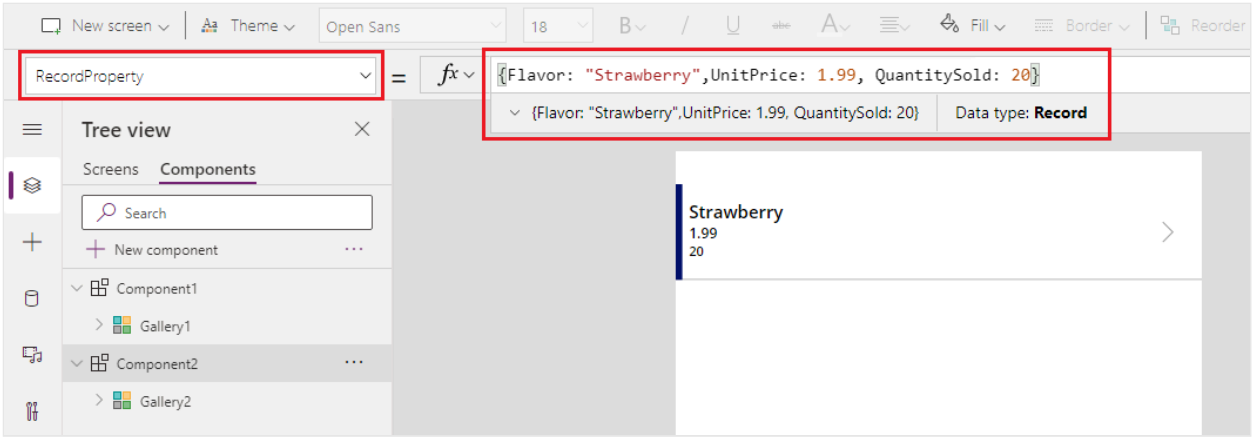
Map records

Use With() function to map a single record.

For example, continuing from the earlier example for mapping columns, the custom input property of a component inside an app expects a record type with the following schema:

Power Fx

```
{Flavor: "Strawberry",UnitPrice: 1.99, QuantitySold: 20}
```

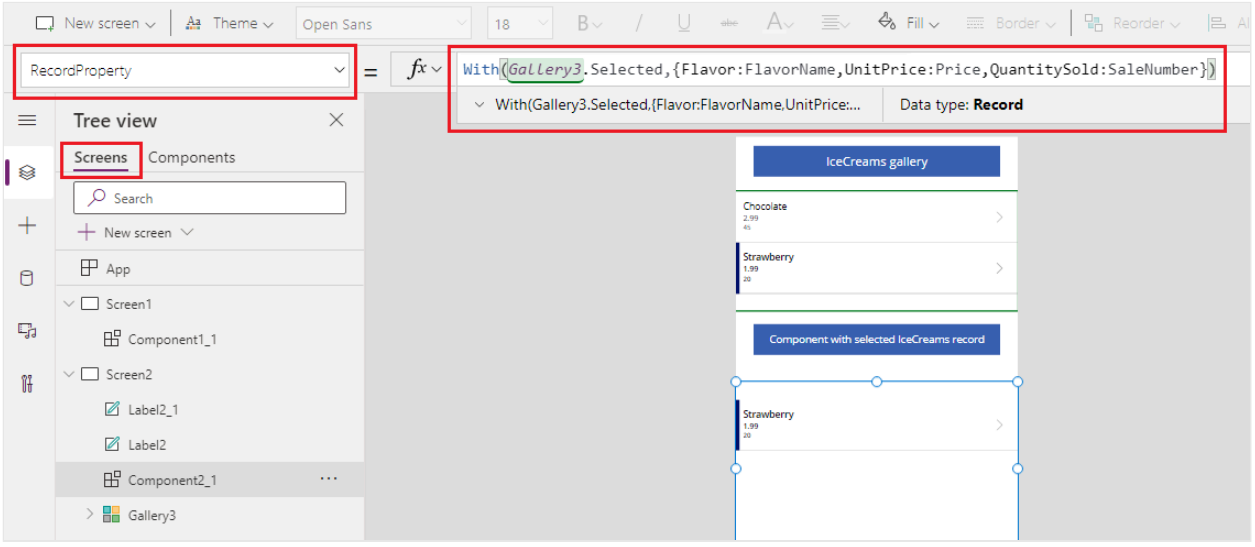


Since the **IceCreams** data source expects column names as **FlavorName**, **Price**, and **SaleNumber**, we'll need to change the mapping for the record once the component is added to the app.

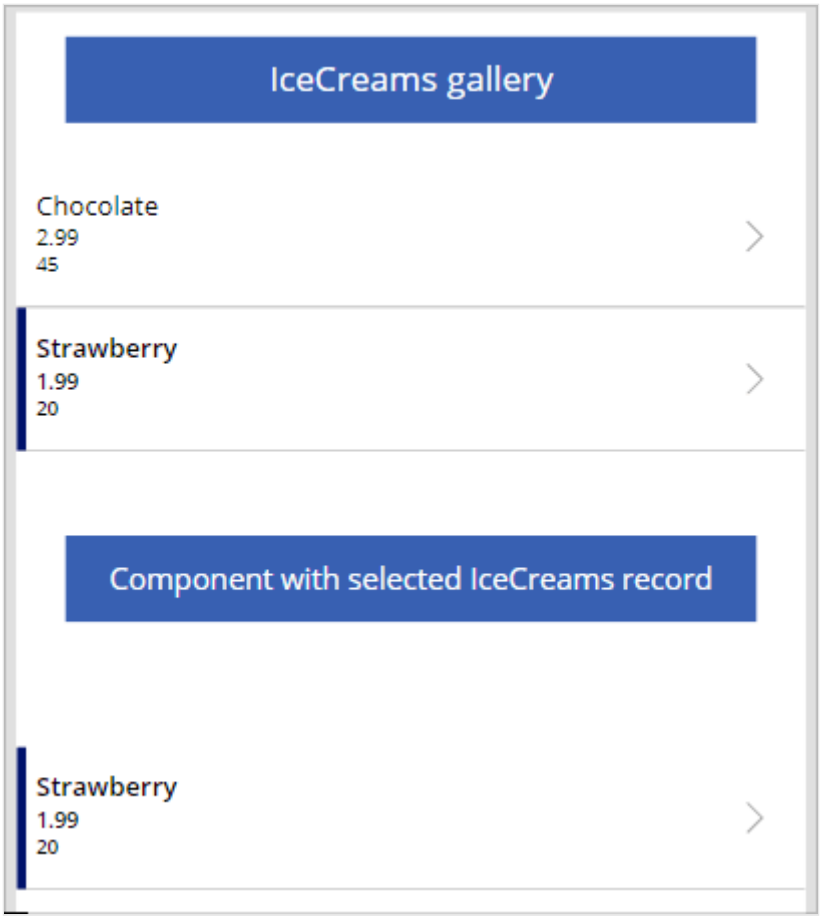
Use **With()** function to select the columns of the **IceCreams** table, and map them to the input fields of the component:

Power Fx

```
With(Gallery3.Selected,
{Flavor:FlavorName,UnitPrice:Price,QuantitySold:SaleNumber})
```



The following animation shows the example of a component added to the app that shows the selected record from the gallery (above the component):



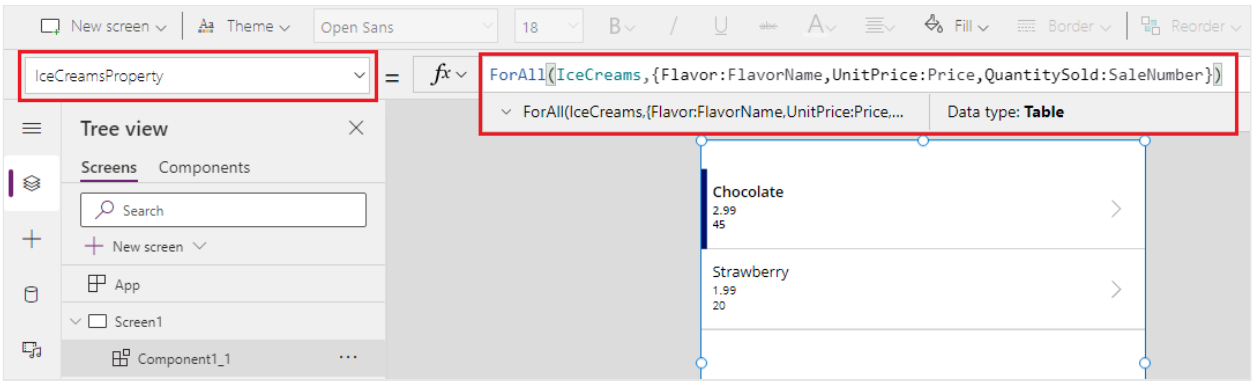
Map tables

Use ForAll() function to map a table of records with the records expected by the component added to the app.

For example, at the end of the map columns example, you can use the **ForAll()** function to map the entire table with the specific columns to point to the fields from the component for each row:

Power Fx

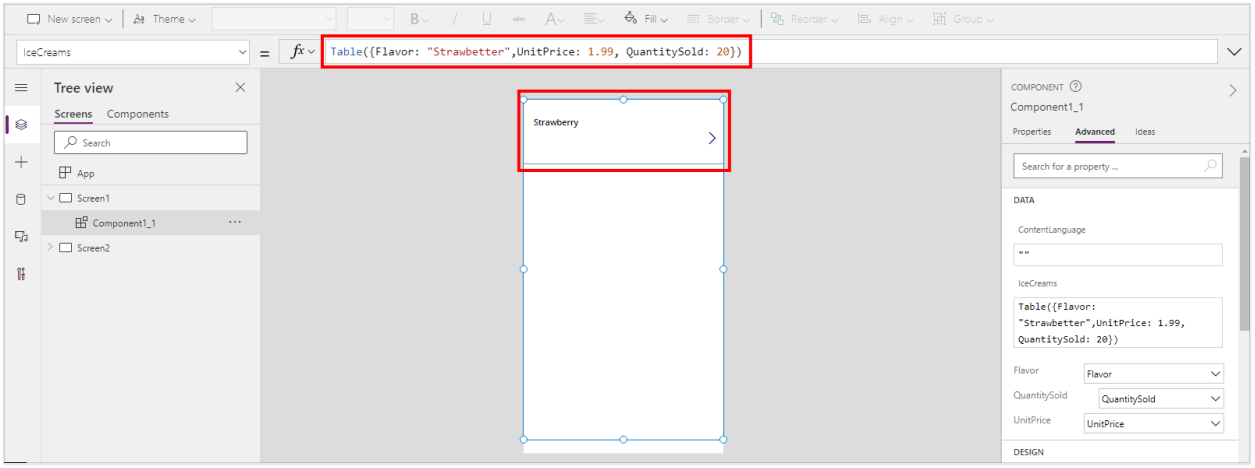
```
ForAll(IceCreams,
{Flavor:FlavorName,UnitPrice:Price,QuantitySold:SaleNumber})
```



Map using dropdown (deprecated)

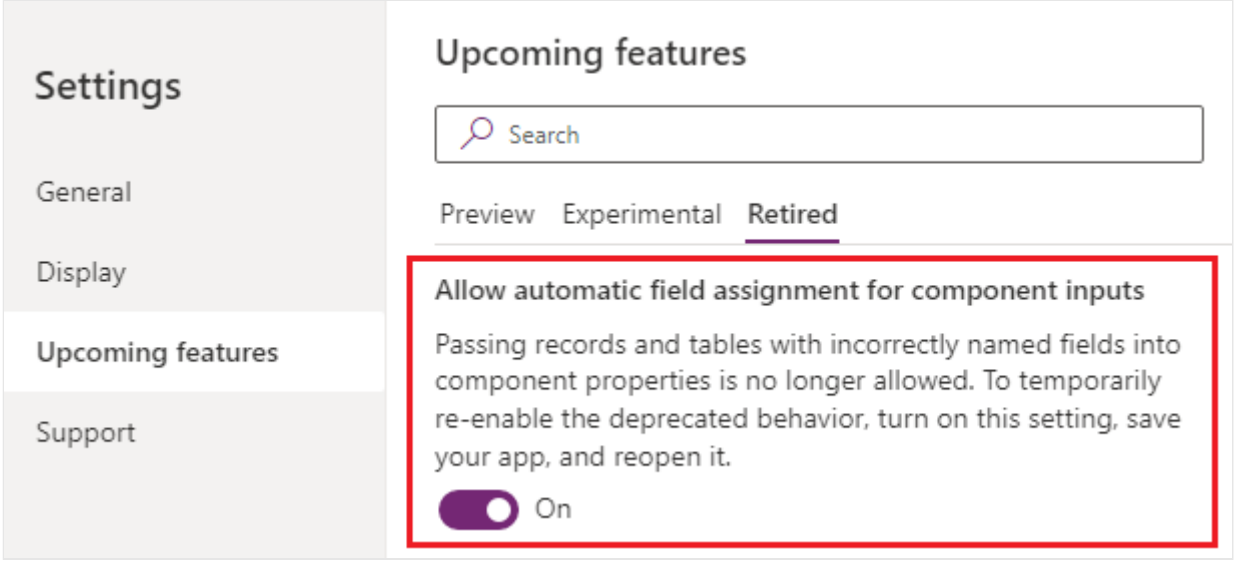
You can use the **Advanced** tab for a component added to an app that expects input property of table or record type, and select the field mappings using the dropdown option. This mapping is assigned by default, and unless you manually select the appropriate mapping fields, the mapping might not yield expected results.

For example, the following animation shows the formula being updated to rename columns. The component on screen doesn't change the field mapping since the default field selection using this dropdown needs to be updated manually.



This method of selecting the mapping using the dropdown has been deprecated. Instead, use the column, record, or table mapping methods as described earlier in this article.

You can still use the dropdown option to choose mapping for existing apps, though not recommended. For new apps, this option will be unavailable by default. To turn this deprecated capability on or off, go to **Settings** > **Upcoming features** > **Retired**, and choose **Allow automatic field assignment for component inputs**.



When turning the setting on, ensure you save and reopen the app in Power Apps Studio. Once reopened, update the input property formula to trigger formula validation so that the dropdown options start to appear in the Advanced properties pane.

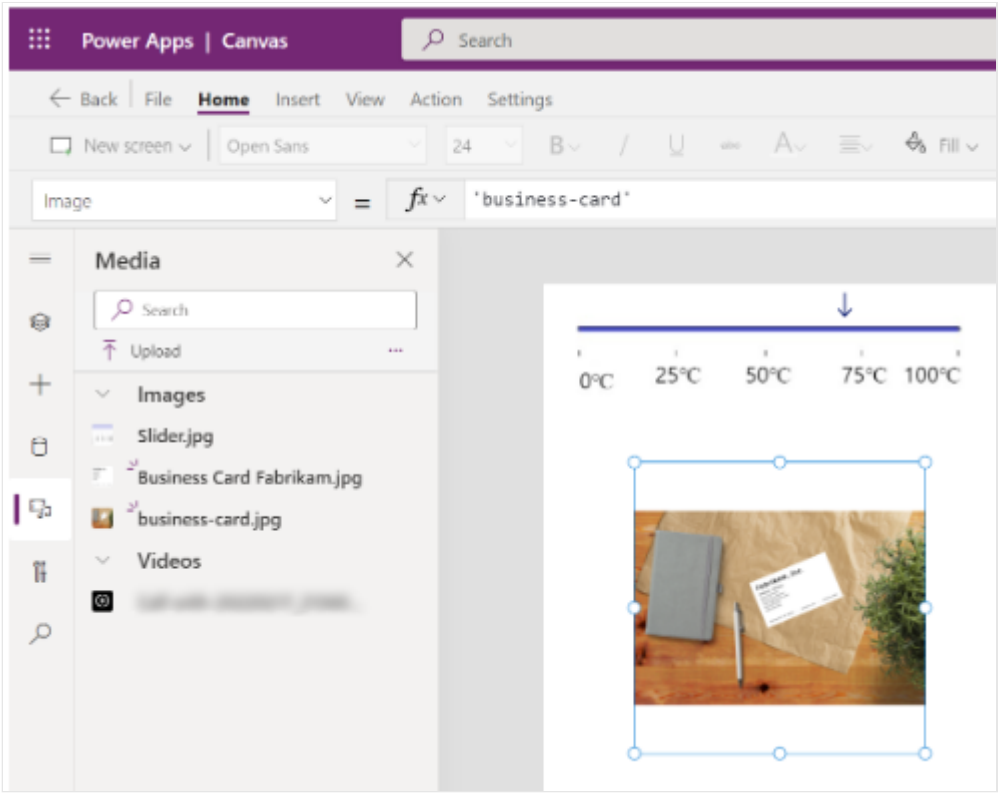
Add multimedia to a component

Article • 01/24/2023

You can add multimedia files to the components inside a library. These components can then be used by all apps in an environment and can be moved across environments using standard component application lifecycle management (ALM) through solutions in Microsoft Dataverse.

To add multimedia to a component, use the same steps that you'd follow when adding multimedia files in a canvas app. More information: Using multimedia files in canvas apps

After adding multimedia files to a component inside the component library, the files will appear under the media pane as they do for canvas apps:



Media resources in a component library are defined at the library level, and not tied to individual components. Importing any component from the component library will import all media resources from the library to the app. However, you can remove the unused media when app customization is complete. More information: Remove unused media

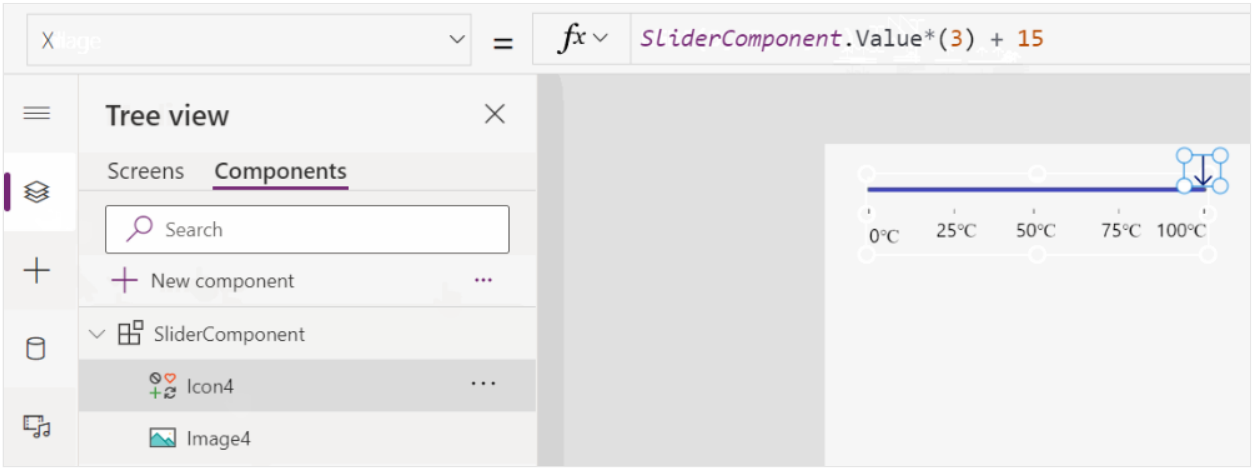
Tip

Prefix the media resources in a component library with a unique namespace or library name so that those names don't conflict with existing resources in an app during import.

During the component import to your app, if the component library multimedia has a resource with the same name as the multimedia that already exists inside your app, the import process adds an underscore ("_") and a random number to enforce name uniqueness.

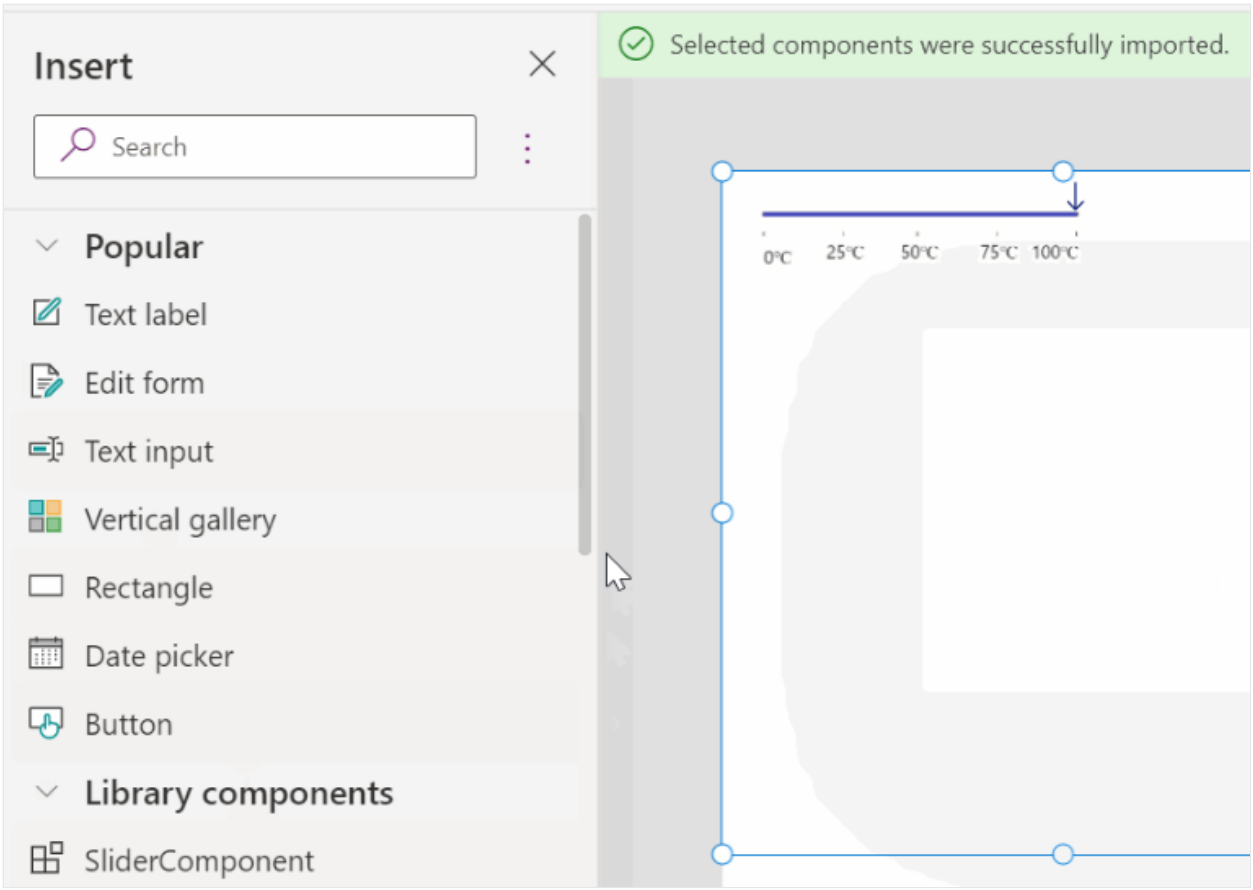
Example

Consider that you created a component library with a slider image that uses an icon with an input property for the component named "value" to set it's `X` property.

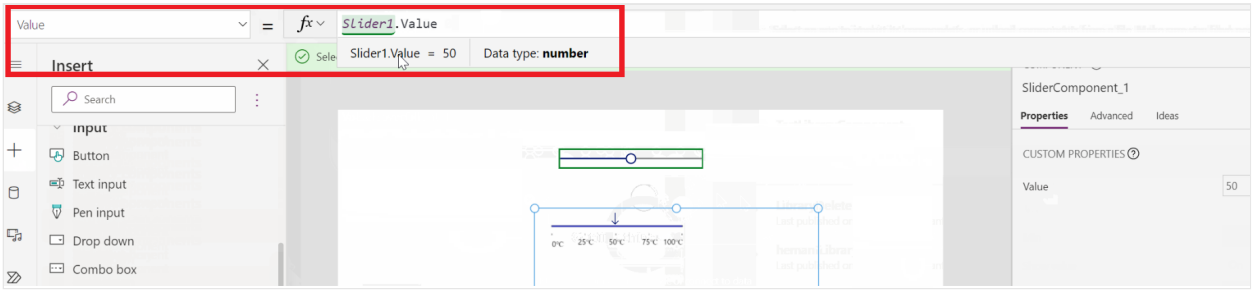


To reuse this multimedia component in your app, all you have to do is import the component, and link the component's input property with the value you'll supply from within the app.

Start with importing the component to your app:



After the import, you can insert a slider control, and set the imported component's value to the slider's value:



When you play this app, the slider movement in the app would then move the imported slider component:

Behavior formulas for components (experimental)

Article • 01/24/2023

[This article is pre-release documentation and is subject to change.]

> **Important**
>
> This is an experimental feature. For more information, see **Experimental and preview features**.

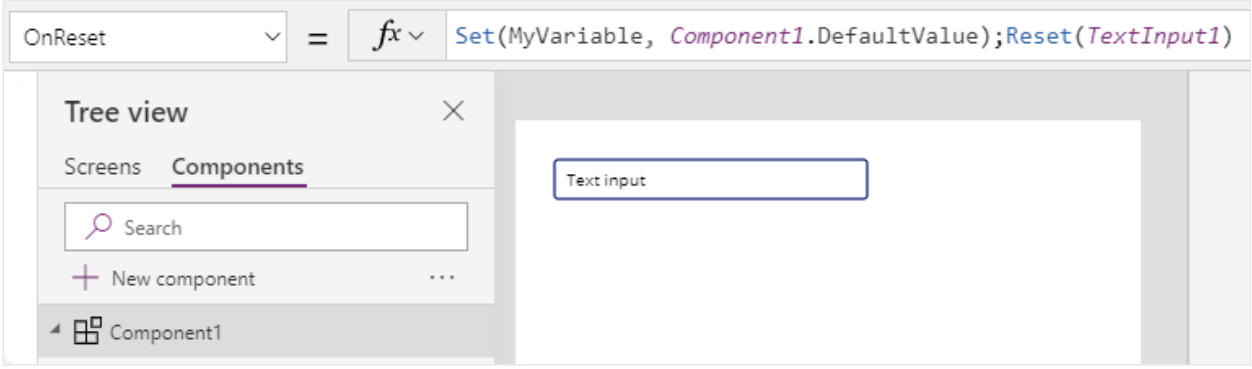
Specify one or more behavior formulas that run when an event triggers a change in component instances.

For example, set a component's **OnReset** property to one or more formulas that do initialization and clear input. Reset values when the **Reset** function runs on the component instances.

> **Note**
>
> The feature to create custom behavioral properties is currently experimental. However, you can use the default **OnReset** property that is available on all components in your production environment.

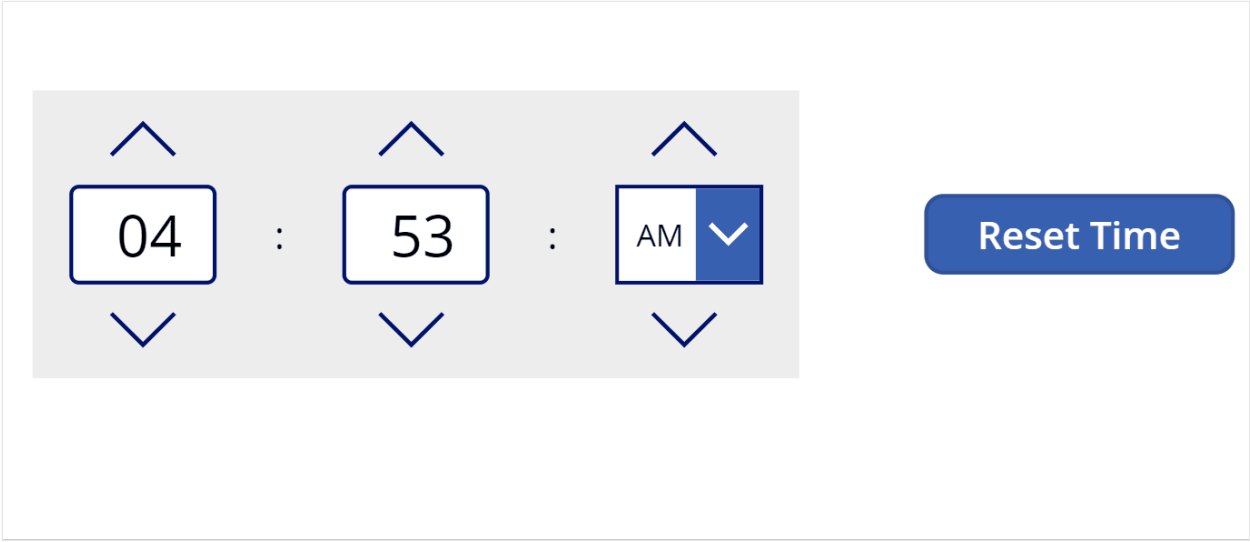
OnReset

With a component master selected, select **OnReset** in the drop-down list of properties (on the left side of the formula bar), and then enter one or more formulas.



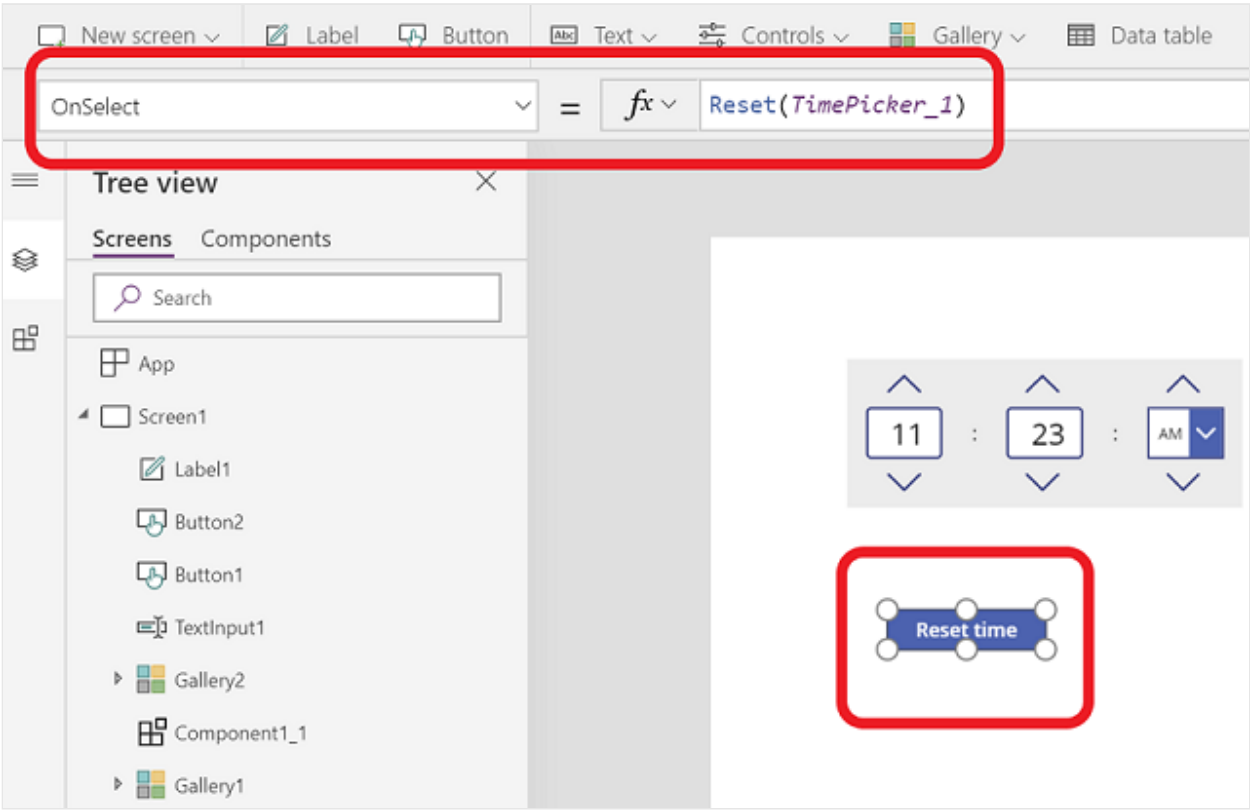
To test **OnReset**, configure a control to reset the component. For example, set the **OnSelect** property of a button to this formula: **Reset**(*ComponentName*).

Example - Reset timer



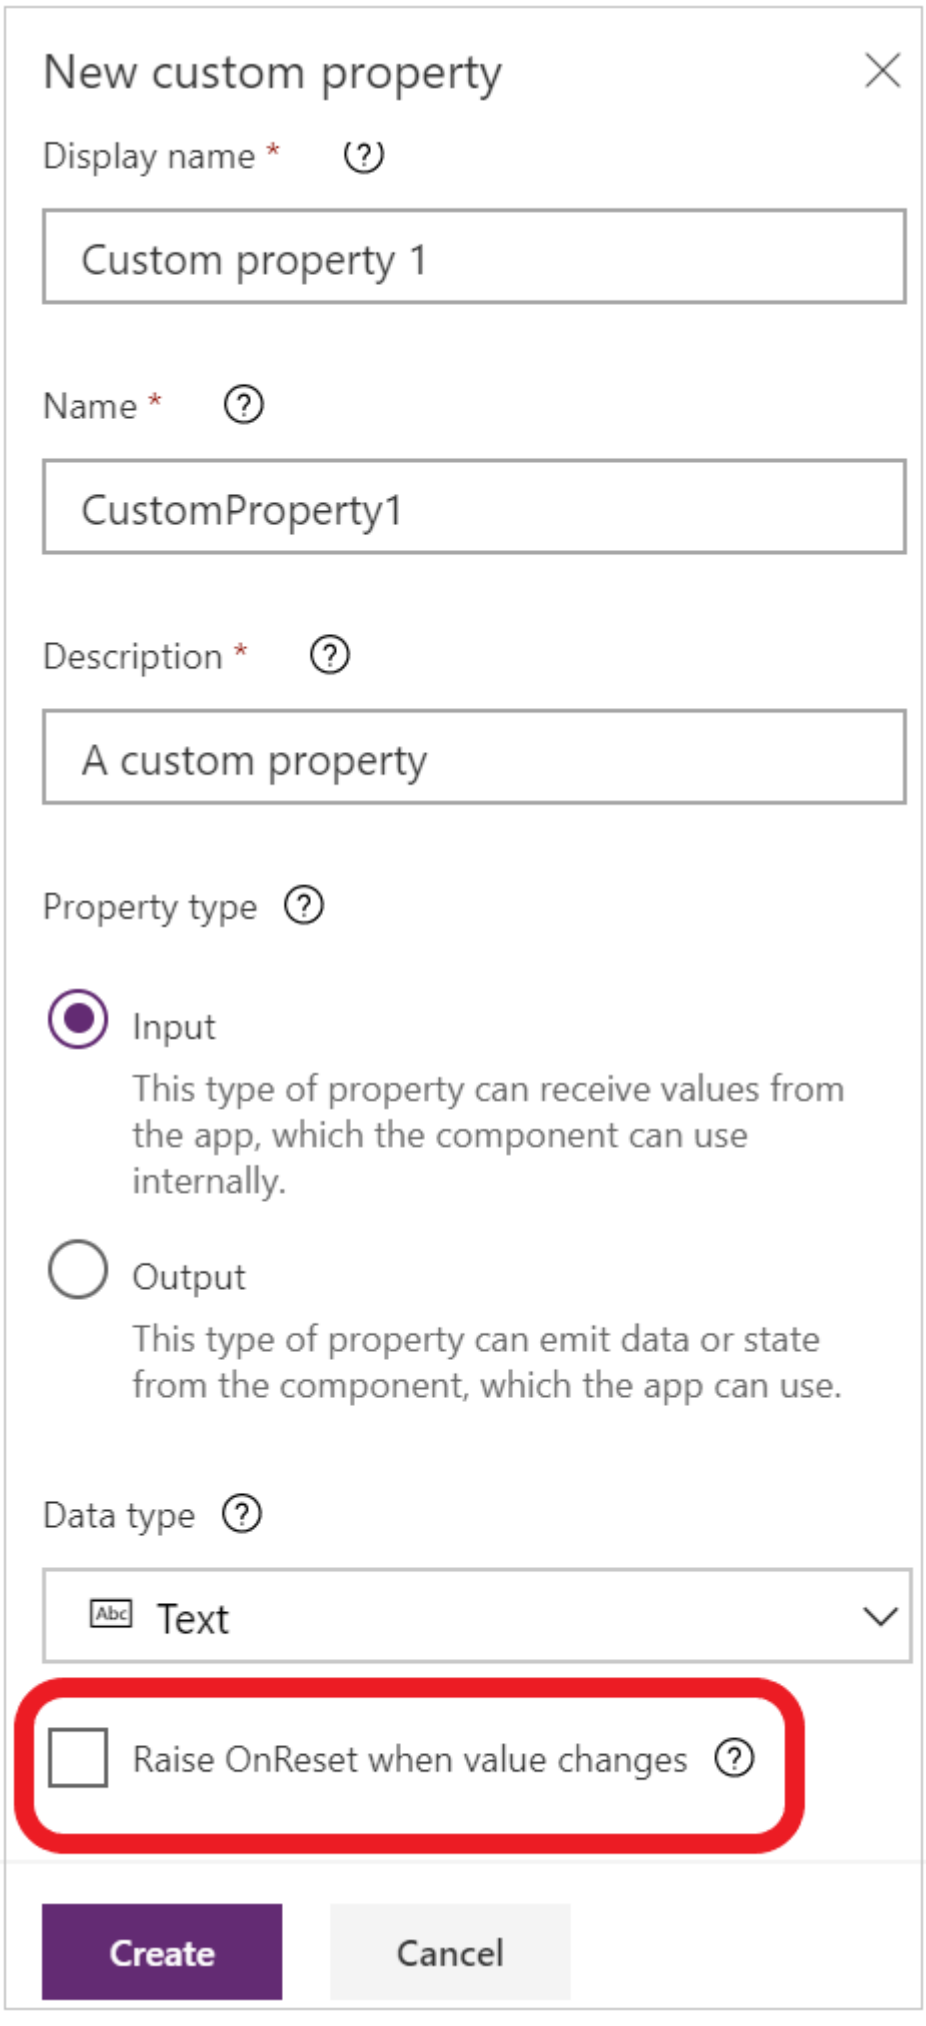
In this time picker component, two variables are used to display the time _selectedHour and _selectedMinute. When the picker gets reset, these variables should be reset to a default value, say 12: 12. The OnReset property for the component has the following formula: **Set(_selectedHour,12); Set(_selectedMinute,12)**

To trigger reset, go to a screen and insert an instance of the component. Add a button and configure OnSelect of the button to call **Reset(TimerComponent_instance)** to trigger OnReset.



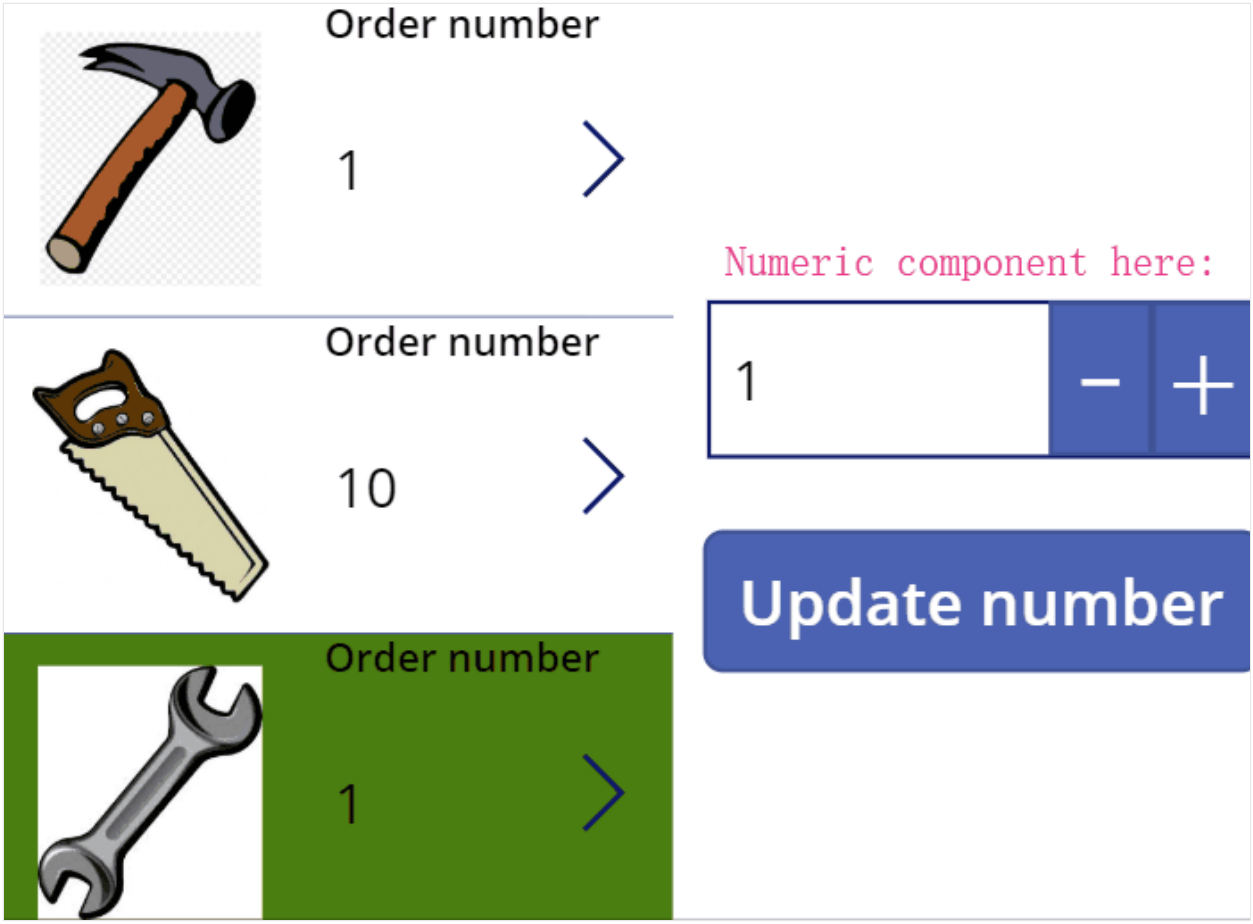
Update OnReset using custom property

Besides resetting a component instance from outside of the component, there's another method to trigger the OnReset from the inside. "**Raise OnReset when value changes**" is an option when creating a custom input property. It allows the value changes of this property to trigger OnReset of the component. This method is designed to set and reset the default value easily.



New custom property
Display name *
Custom property 1
Name *
CustomProperty1
Description *
A custom property
Property type
Input
This type of property can receive values from the app, which the component can use internally.
Output
This type of property can emit data or state from the component, which the app can use.
Data type
Text
Raise OnReset when value changes
Create
Cancel

Example



The example above shows reviewing order numbers and updating the numbers. The numeric up and down component is used to increase or decrease number of orders. When selecting the gallery on the left, the default number of the numeric up and down component is reset to display the order number of the selected tool. **Raise OnReset when value changes** made it possible to reset the default value when the input changes.

To do so, check **Raise OnReset when value changes** of the default input property. **OnReset** of the component is set to **Set(_numericValue,'Numeric up down'.DefaultValue)**. _numericValue is the variable to store the value of the current order value. Set the **Default** of the text input control to **If(IsBlank(_numericValue), 'Numeric up down'.DefaultValue, _numericValue)**.

Canvas component properties

06/07/2025

Canvas components let makers create different types of properties to pass values or logic between the component and the app that hosts the component. Properties are essential for building interactive, reusable components.

Prerequisites

This feature is on by default for new apps. For existing apps, you need to turn it on in your app settings.

1. Open your canvas app for editing in Power Apps Studio. On the command bar, select **Settings** > **Updates**.
2. On the **New** tab, find and turn on the **Enhanced component properties** setting.

Types of properties

There are four types of properties available to makers.

1. Data properties: Data properties pertain to data, like a color or text value. A **Data** property can be set to be **Input** or **Output**, which indicates if the component provides data to the app (**Output**) or the app provides data to the component (**Input**). **Data** properties are the only properties that participate in app data flow.
2. Function properties: Function properties are related to logic, such as performing a calculation based on specific parameters or altering text. A **Function** property can be set to be **Input** or **Output**, which indicates if the component provides a function the app can call (**Output**), or the app provides a function the component can call (**Input**). **Function** properties do not participate in an app's data flow, and cannot use component or app variables.
3. Action properties: Action properties are a type of property that deals with logic and behaves like an **Output Function**. Thus, the component has the logic defined, and that logic can use chained expressions and manipulate collections or variables ("behavior"). For example, a `Clear()` **Action** property could provide functionality the app can call to clear out some values in the component, or a `Save()` **Action** property that updates a datasource.
4. Event properties: Event properties are a category of property that involves logic and functions as an **Input Function**. Thus, the app defines the logic, which the component can call and that logic can use chained expressions and manipulate collections or variables

("behavior"). Typically these properties' names reflect an event such as `OnSelect` or `OnChanged`.

Data property

A data property's usage is easy to imagine. Standard controls in apps typically have several data properties, to set default values, text color, size, etc. Let's look at a simple example where you want to make properties of a control within the component available to the hosting app. In this example, the component is named `Component1`. Put a slider control inside the component. Add an **Input** property to specify the color from the consuming app, and an **Output** property so the component can tell the app the current value of the slider. This example assumes the component has a **Slider** control named `Slider`.

1. In the property pane of the component, select **New custom property**.
2. On the **New custom property** pane, enter display name `Slider Color`.
3. Select **Property type** of **Data** and select **Property definition** value **Input**.
4. Finally, from the **Data type** dropdown, select **Color**.
5. Click **Create**.

Next, select the `Slider1` **Slider** control. Find its **ValueFill** property and in the formula bar, enter `Component1.SliderColor`. `Component1` is the name of the component, and `SliderColor` is the name of the property you added.

Now the component has a `SliderColor` property that can be set in the consuming app to pass a color into the component and set the slider's **ValueFill** property.

You might also want to provide the value of the slider to the consuming app. To do this, add an **Output** property.

1. In the property pane of the component, select **New custom property**.
2. On the **New custom property** pane, enter display name `Slider Value`.
3. Select **Property type** of **Data** and select **Property definition** value **Output**.
4. Finally, from the **Data type** dropdown, select **Number**.
5. Click **Create**.

When a **Data** property is **Output**, the component provides the value to the consuming app. To set the formula, set the new `SliderValue` property in the component to the **Value** property of the slider.

1. In the property pane of the component, click on the `Slider Value` property.
2. In the formula bar, replace the default value of `100` with the following formula: `Slider1.Value`.

Now the component's `SliderValue` property reflects the value of the slider inside the component, which the consuming app can read.

Function property

A function property contains an expression that returns a value. Typically, the function takes arguments that it uses to calculate the value to return.

> ⓘ **Note**
>
> Function properties currently cannot access variables or component values and properties, and cannot trigger data flow. Any required values have to be passed in as arguments.

An **Output** function is a simple way to create a custom function for Power Apps. The component defines an **Output** function with an expression that takes some arguments and returns a value. This function can then be used in an app using the component's name (say `Component1`) by calling `Component1.MyFunction(arg1, arg2)`.

An **Input** function lets a consuming app provide logic to a component, similar to a function pointer or callback function. For example, if the component works with people's names, it can have an input function with arguments `firstname` and `lastname` and expects a string back. The app can define the function expression to return `$"{firstname} {lastname}"` or `$"{lastname}, {firstname}"`. The component calls the function the app maker provides and uses the returned string.

Action property

Action properties are similar to function properties of type **Output**, but they allow side-effect formulas and expression chaining. A component can have an action property named `AddRecord` that lets the app add a record to a collection inside the component, or a `Reset` action that clears variables or collections inside the component.

In the earlier slider example for the **Data property**, you can add an action property called `ResetValue` to set the slider back to its default value. Use the formula `Reset( Slider1 )` for this. Now, instances of the component in the app can call `Component1.ResetValue()` to set the slider back to the default value.

Event property

Many standard controls have common **Event**-type properties, which are input behavior function properties. **OnSelect** on the button control is a common example. A component can define event properties and call these events like a function. For example, a component with a button control can have an event property named `OnButtonClicked`. In the button control's **OnSelect**, the component can call its `Component1.OnButtonClicked()` property. A consuming app can define its own logic for this property to act when the button inside the component is pressed.

Default values for properties or arguments

Default values give an argument or property a value if none is set. This doesn't make sense for some types of properties. In some cases, you can use default values to show the expected schema for a record. By providing a default record, you set the record type as the expected schema.

For example, an **Action** property named `AddRecord` takes a record to add to a local collection. To show the schema of the expected record, add a default value for the `AddRecord` property's argument.

Overview of creating performant apps

06/27/2025

Creating performant Power Apps ensures your apps run efficiently and providing a better user experience. This article explains key patterns, anti-patterns to avoid, and design principles to help you build high-performing Power Apps for your organization.

- **App patterns and Power Apps productivity gain**: Power Apps makes it easier to build enterprise-grade apps by using established app patterns. Patterns are groups of Power Apps elements that work together, like data sources, collections, controls, Power Automate, and pages. Power Apps includes key performant patterns by default, so low-code developers quickly build functional enterprise apps. Deployment and administration tasks are also straightforward. With Power Apps, your team is more productive because many elements don't need your attention.

- **Power Apps steers towards performant patterns**: Power Apps guides you toward well known performant patterns by default. These patterns include streamlined data loading at launch, automatic incremental paging, caching data for collections, and loading only essential data for each page. These proven patterns work well for data-heavy enterprise apps. Many successful Power Apps implementations use more than 100 tables and over 50 screens while keeping excellent performance.

- **Falling into anti-patterns**: When you build an app on any development platform, you risk making it perform poorly because of anti-patterns. These patterns can cause slow loading, slow page transitions, and make it hard to update or get data. Common anti-patterns include loading too much data, turning everything into collections, and overloading OnStart. People often use these patterns to work around real or perceived Power Apps limitations. Even with guidance, you might still use a bad pattern and end up with a slow app.

Key performance design principles

When building your app, consider these key performance principles to ensure it runs efficiently. These principles cover most aspects needed to enhance your app's speed. Some performance suggestions might appear in multiple sections due to their interrelated nature.

- Optimize page loads: Optimize your apps for app and page load speed. Minimize, delay, or eliminate actions that prevent fast app or page load.
- Small data payloads: Keep the amount of data that is bulk retrieved small.
- Optimize query data patterns: Do data mashups on the server, not in your app.
- Fast calculations: Work with Power Fx, not against it.

For a deeper understanding, also see Execution phases of a Power App article.

Additional performance guidance

Other performance considerations can affect your app. For more information, see these articles:

- Other performance considerations: Discusses other factors that might affect performance.
- Build large complex apps: Lists key factors to consider when building a large app.
- Canvas app coding standards and guidelines : Lists general coding and development guidelines that help you build an app.

Use Monitor to get insights and recommendations for your app

Summarize this article for me

Monitor in Power Apps offers insights and recommendations to enhance app performance. It provides makers with detailed information on their app's performance and actionable steps to improve their apps.

Prerequisites

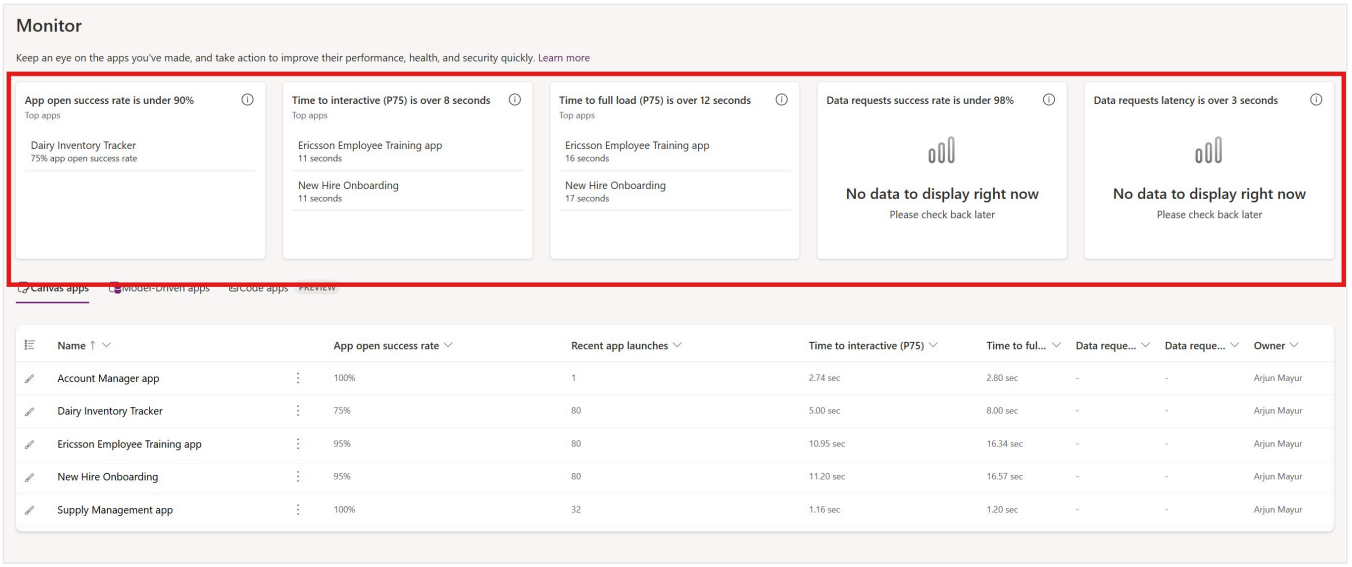
To use this feature, your administrator must enable certain analytics and monitoring settings in the Power Platform Admin Center. For more information, see Monitoring experiences for makers. When you sign in to Power Apps and open Monitor, make sure you've selected the correct environment and that you're a member of that environment with an assigned role (for example, Basic User). Otherwise, you won't be able to access Monitor.

Open and pin Monitor

1. Sign in to Power Apps.
2. On the left navigation, select **Apps**.
3. On the command bar, select **Monitor**.
4. On the left navigation pane, select the  pin button next to **Monitor**.

Use Monitor

The **Monitor** page displays metric cards at the top, highlighting the top three underperforming apps for each metric. If all apps perform well on a specific metric, the card doesn't list any apps. Use the tabs under the cards to switch between viewing your model-driven, canvas, and code apps.



Expand table

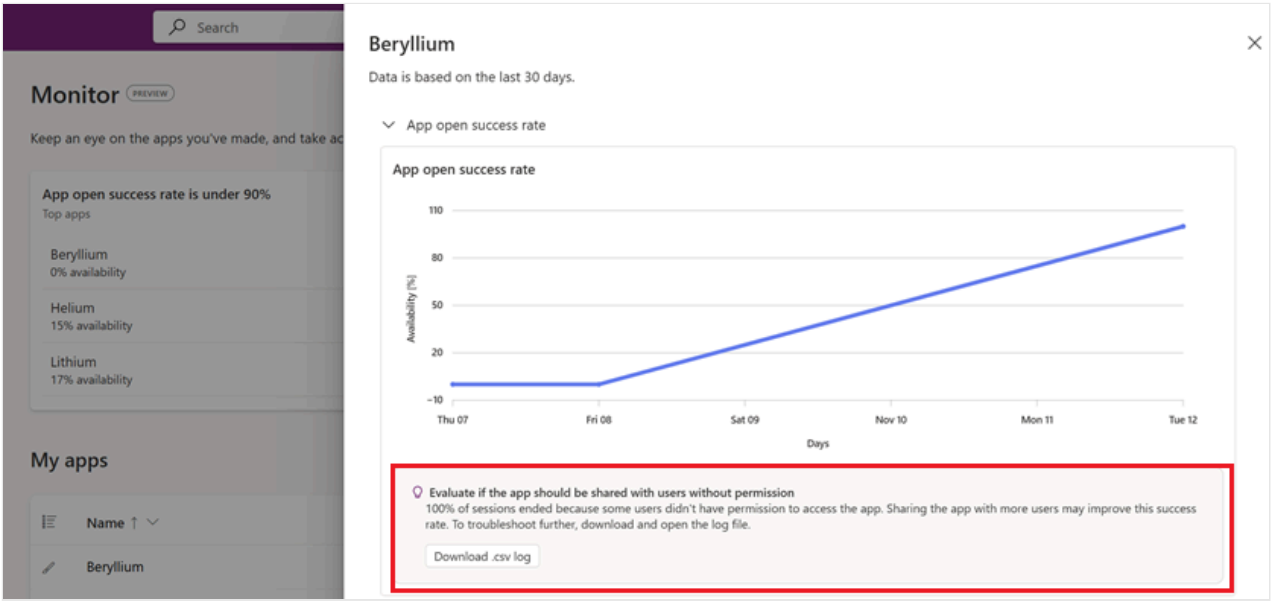
Metric	Definition	Available for Canvas apps	Available for Model-driven apps	Available for Code apps
App open success rate	Indicates the percentage of app launch attempts that successfully allowed end-users to access the app. This metric is calculated once every 24 hours.	Yes	Yes	Yes
App session count	The number of distinct user sessions in an app in one day. A session begins when a user opens the app and ends after a period of inactivity or when the app is closed.	Yes	Yes	Yes
Time to interactive (TTI)	Measures the time end-users wait to access the first screen of an app. It doesn't include the time users wait to see all data presented on the first screen, such as filling in rows of a gallery. This metric is calculated every 24 hours and is measured using percentiles, with the 75th percentile being reported.	Yes	No	Yes
Time to full load (TTFL)	Measures the time end-users wait to see all data displayed on the first screen of an app. In the app launch lifecycle, this metric follows the **Time to interactive** phase. This metric is calculated every 24 hours and is measured using percentiles, with the 75th percentile being reported.	Yes	No	No
Data request success rate	A percentage that describes how often data requests coming from an app are successful	Yes	No	No

Metric	Definition	Available for Canvas apps	Available for Model-driven apps	Available for Code apps
Data request latency	The average time (in seconds) it takes for all data requests made by the app to complete during a session.	Yes	No	No
Row summary dwell time	The time (in seconds) that end users spend on the expanded AI row summary of a main form.	No	Yes	No

View metrics and recommendations for an app

When you select an app on the **Monitor** page, a side pane opens and displays more data for each metric, including a data chart for the last 30 days.

1. On **Monitor** page, select an app.
2. To view recommendations for an app, select the app's name to open the side panel. The chart shows a callout with a recommended action for improving the metric.



> **Important**
>
> Recommendations are only available in Managed Environments. Contact your admin to enable Managed Environments for access to recommendations.

Last updated on 03/05/2026

Analyze system-generated logs using Application Insights

Article • 04/09/2025

Connect your canvas apps to Application Insights, which is a feature of Azure Monitor. Application Insights includes analytics tools that help diagnose issues and understand user behavior in apps. Use the collected information to make better business decisions and improve app quality.

Prerequisites

- You need access to the Azure portal.
- You need permission to create Azure resources.

> **Note**
>
> To view telemetry information, your tenant admin needs to enable **Canvas app insights**. Sign in as an admin at the Power Platform admin center. Select **Settings** > **Tenant settings** > **Canvas app insights**. In the **Canvas app insights** pane, turn the toggle **On** and save your changes. Learn more in Tenant settings.

Create an Application Insights resource

Send system-generated logs from an app by creating an Application Insights resource to store events.

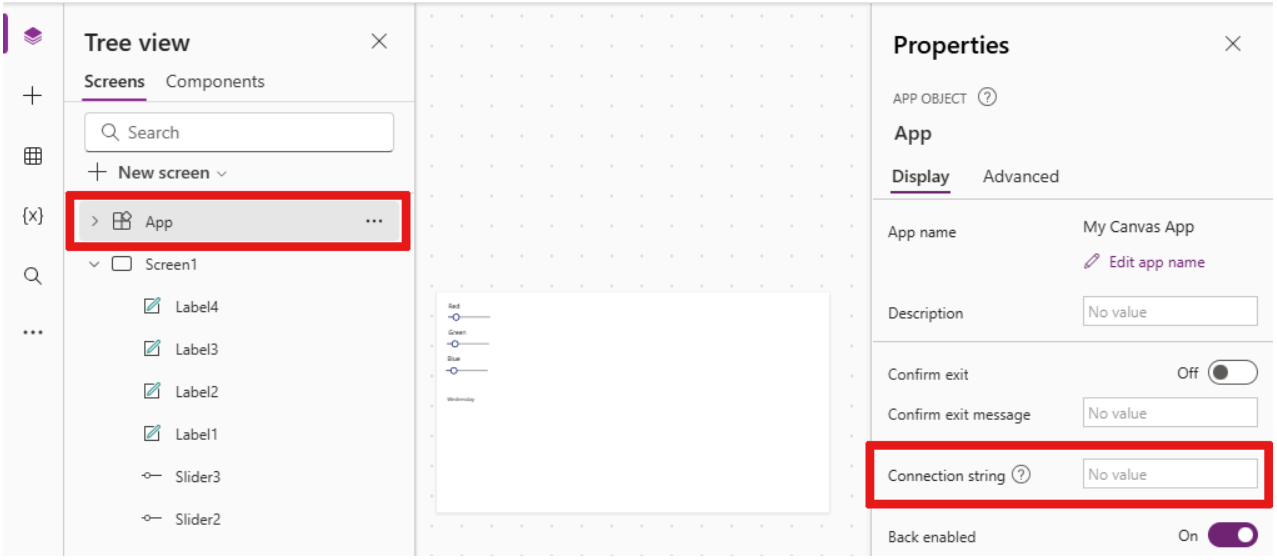
Learn how to create a workspace-based resource for Application Insights in the Azure portal.

Connect your app to Application Insights

> **Note**
>
> - When you specify a connection string, remember that data can be sent across tenants. Trace events are sent to the App Insights resource that corresponds to the connection string you set for your app, even if the target App Insights instance is in a different tenant than the app.

- Be cautious when importing existing .msapp files because connection strings for App Insights might be present. Manually open the app after import to check that the correct App Insights connection string is used.

1. Sign in to Power Apps.
2. Open an app to edit it.
3. Select the **App** object in the left navigation tree view, and paste the **Connection string** from your Application Insights resource.



4. **Save** and **Publish** your app.
5. **Play** the published app and browse the different screens.

When you browse the app screens, events are automatically logged to Application Insights. These include usage details like:

- Where users access the app from
- Which devices users use
- The types of browsers users use

> **Important**
>
> Play the published app to send events to Application Insights. Events don't send to Application Insights when you preview the app in Power Apps Studio.

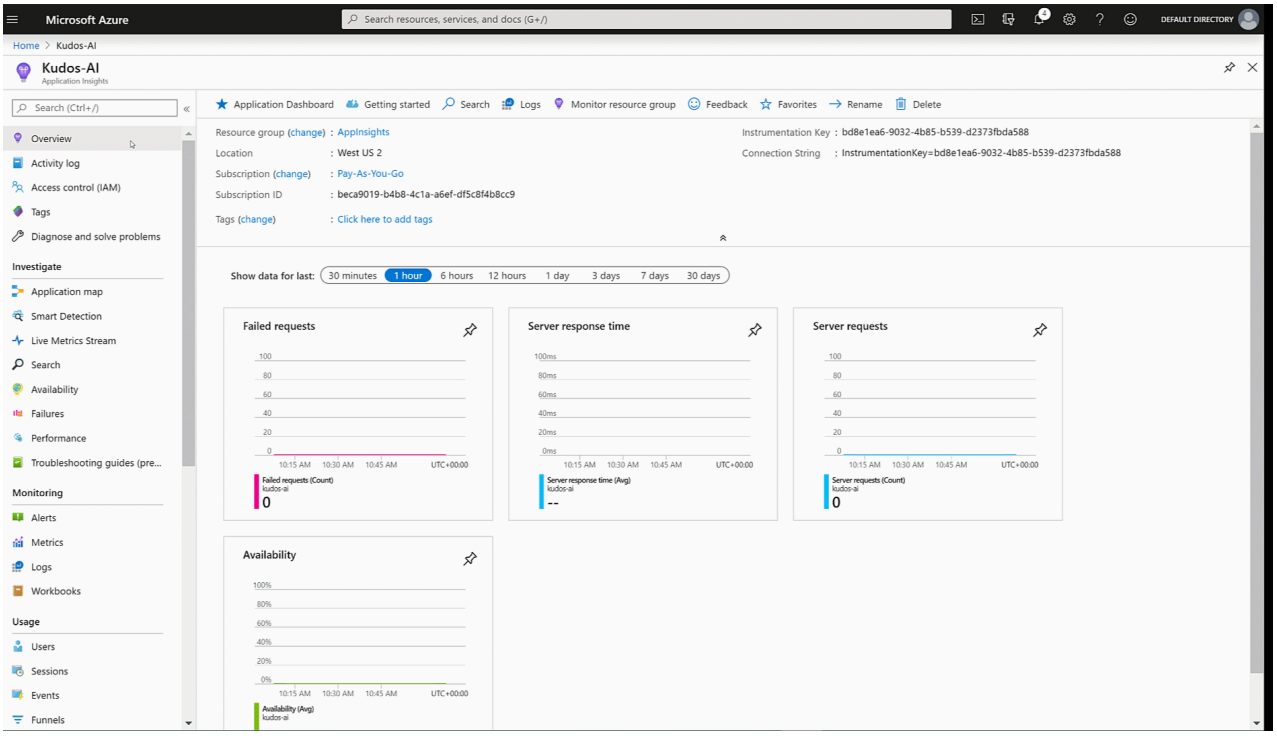
View events in Application Insights

1. Sign in to the Azure portal and open the Application Insights resource you created previously.

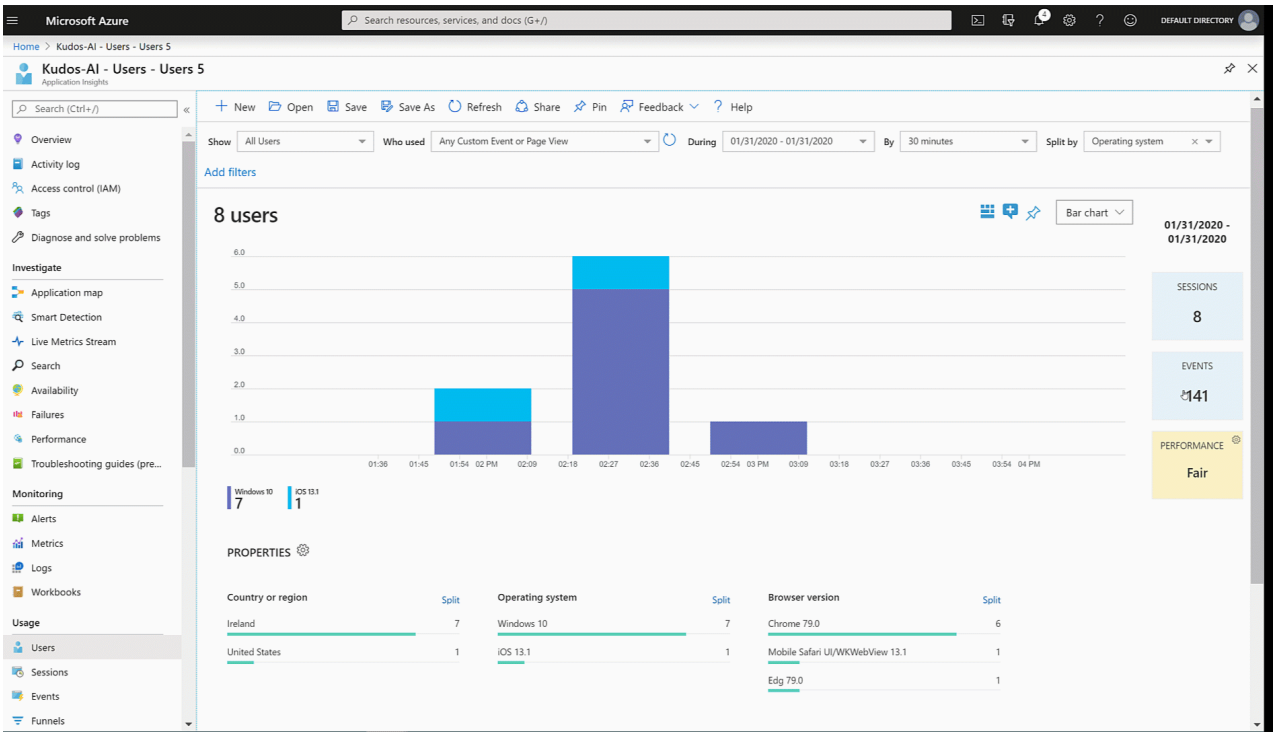
2. In the left navigation pane, select **Users** under the **Usage** section.

> **Note**
>
> The **Users** view shows app usage details, such as:
>
> - Number of users who viewed the app
> - Number of user sessions
> - Number of events logged
> - Users' operating systems and browser version details
> - Users' region and location
>
> Learn more about users, sessions, and events analysis in Application Insights.

3. Select a user session to view specific details, such as session length and screens visited.



4. In the left navigation pane, select **Events** under the **Usage** section. You can view a summary of all the screens viewed across all app sessions.



> **Tip**
>
> Explore more Application Insights features, such as:
>
> - Funnels
> - Cohorts
> - Impact analysis
> - Retention analysis
> - Usage flows

Create custom trace events

Write custom traces to Application Insights to analyze information specific to your app. The Trace function allows you to collect:

- Detailed usage information for controls on the screens
- Which specific users are accessing your app
- What errors occur

Tracing helps you diagnose issues by sending a trail of information as users browse your app and take actions. Trace messages sent to Application Insights have one of three severities:

- Information
- Warning
- Error

Send a trace message with the appropriate severity based on the situation. You can query the data and take specific actions based on the severity.

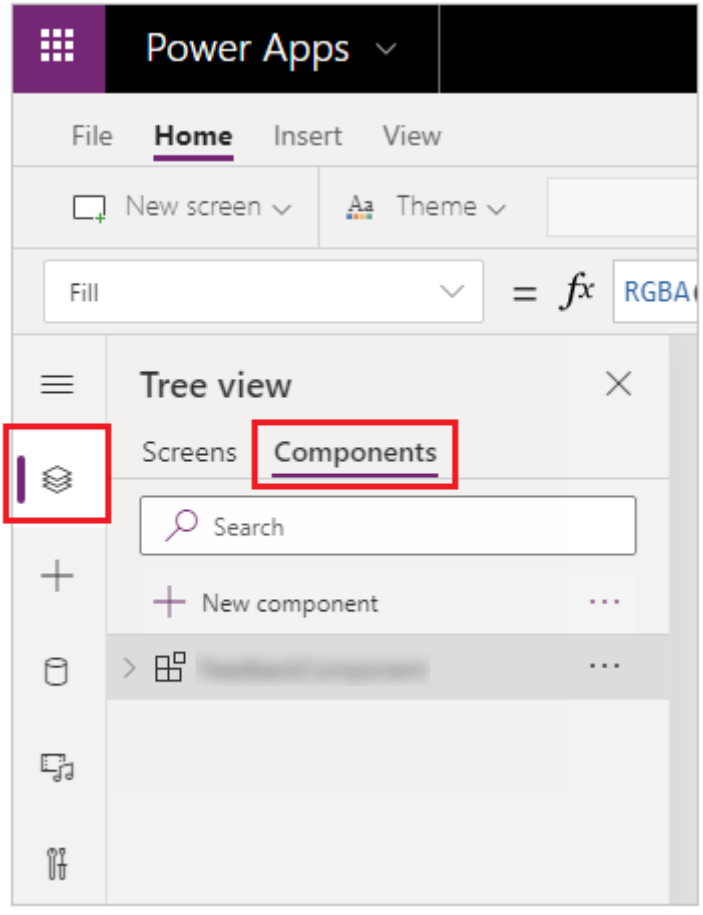
> **Note**
>
> If you are logging any personal data, be aware of your obligations with respect to various privacy laws and regulations. Refer to the Microsoft Trust Center and the Service Trust Portal for more information.

Create a component in your app to collect feedback on each screen and log events to Application Insights.

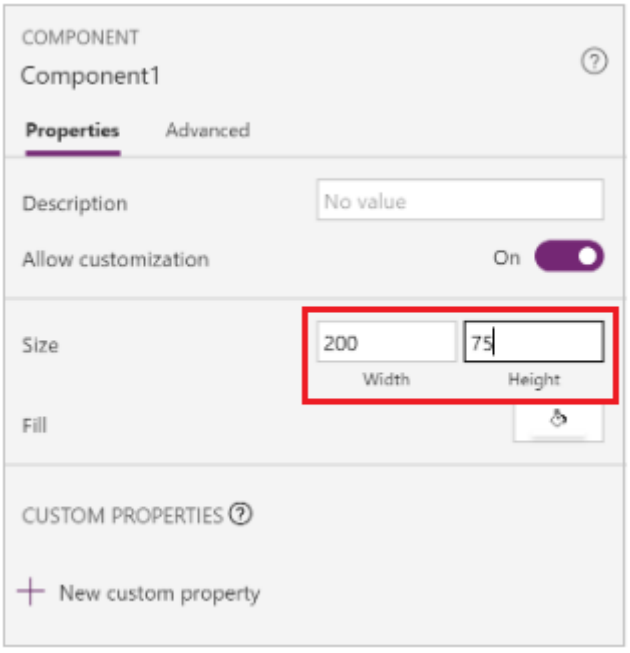
1. Sign in to Power Apps.
2. Select **Apps** in the left navigation pane. From the list of apps, select the **Kudos** app, and then select **Edit**.

   > **Note**
   >
   > You can also create a new app or edit an existing app instead.

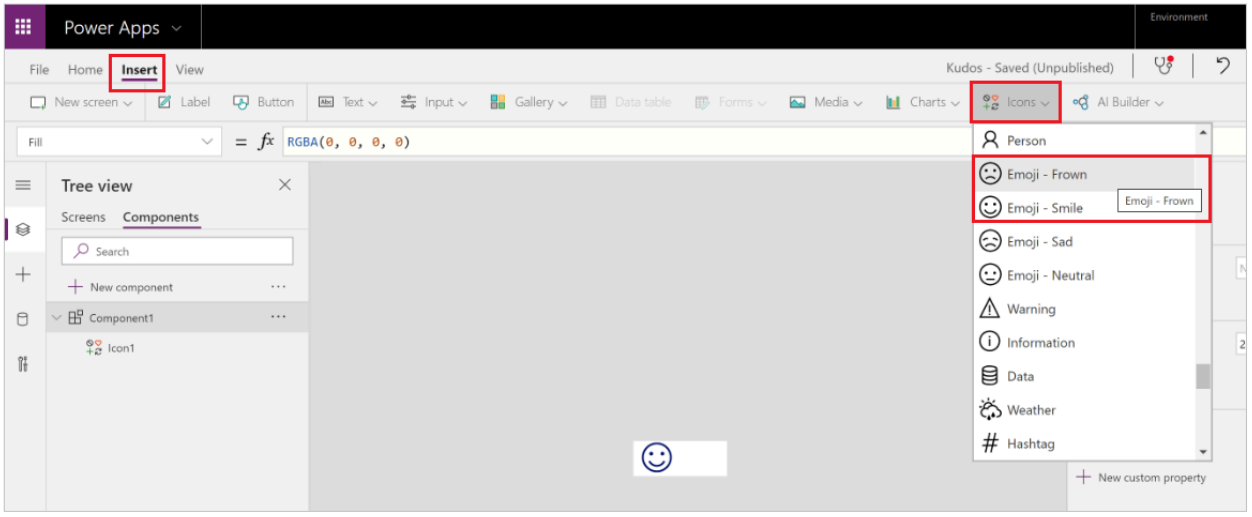
3. Select **Components** in the **Tree view**:



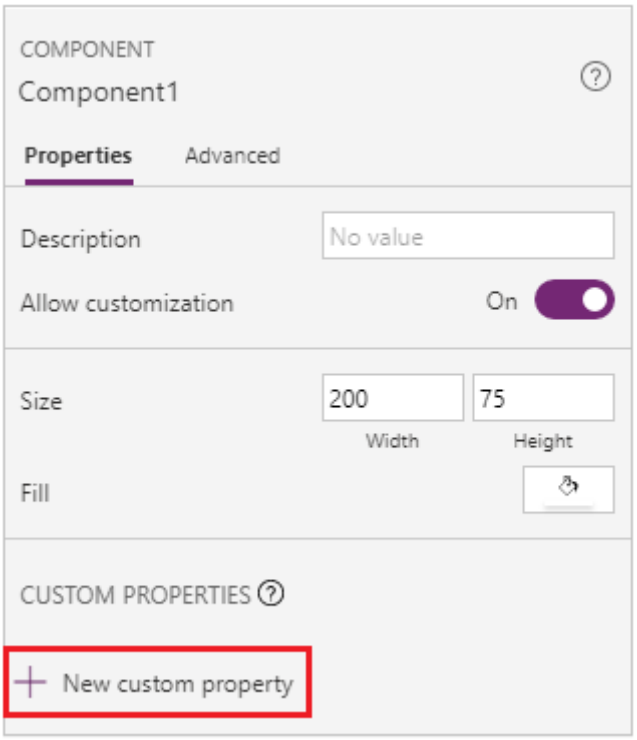
4. Select **New component**, then resize the width to 200 and the height to 75:



5. Select **Insert** from the menu and then select **Icons** to add *Emoji - Frown* and *Emoji - Smile*:



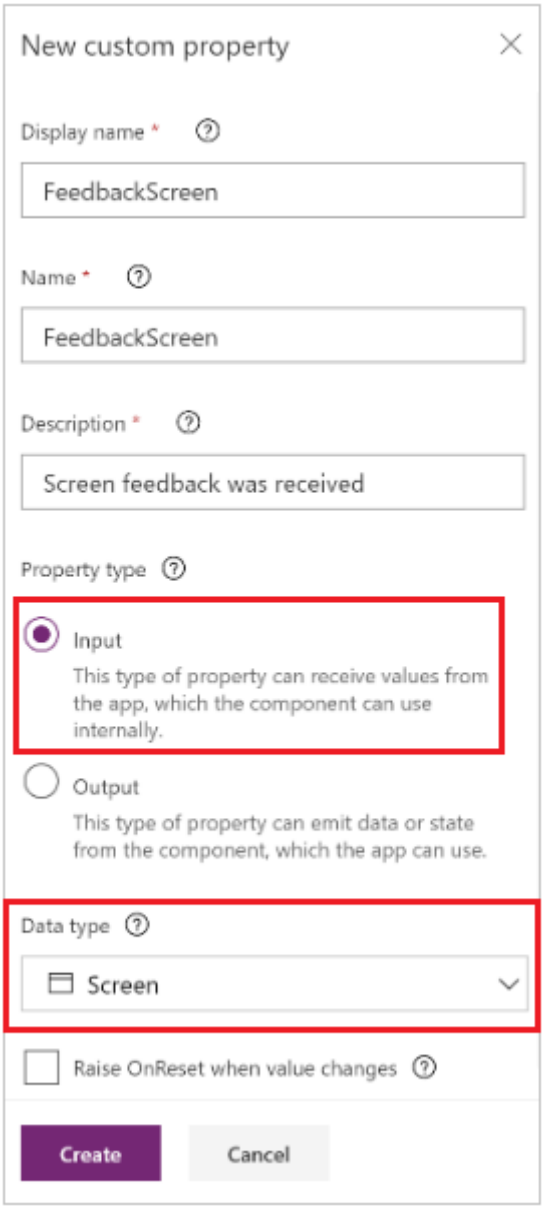
6. Select **New custom property** to create a custom property:



7. Enter the property *Name* and *Display name* (for example, *FeedbackScreen*).

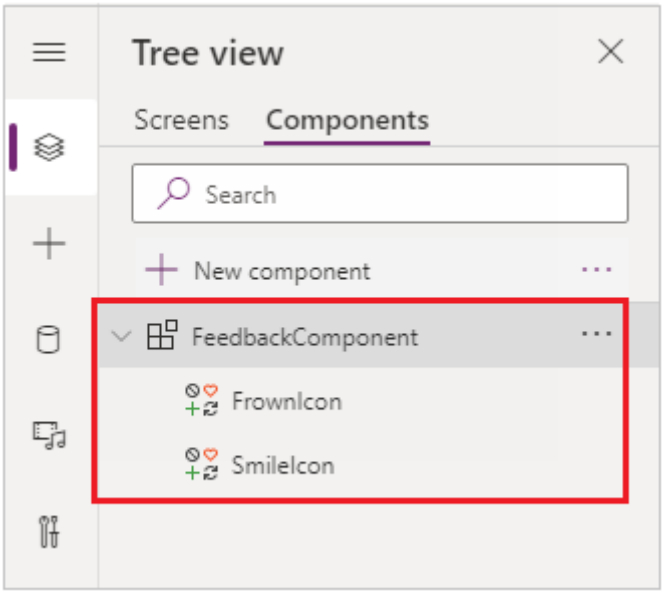
8. Enter a property *Description*.

9. Select **Property type** as **Input** and **Data type** as **Screen**:



> **Note**
>
> An input property lets you capture the screen name and its component to log this information to Application Insights.

10. Select the component in the **Tree view**, select **More actions** (...), and select **Rename** to give the component a meaningful name, such as *FeedbackComponent*.

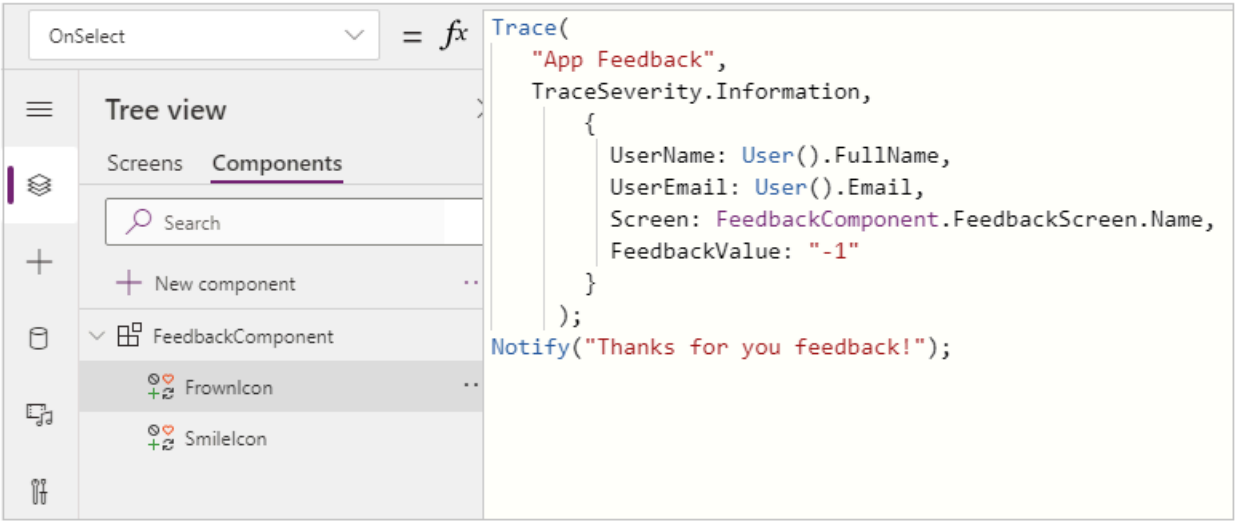


11. Select the icons, select **More actions** (...), and then select **Rename** to rename the icons with meaningful names, such as *FrownIcon* and *SmileIcon*.

12. Select **FrownIcon**, select the **OnSelect** property, and enter the following expression in the formula bar:

```
Power Fx

Trace(
   "App Feedback",
   TraceSeverity.Information,
       {
         UserName: User().FullName,
         UserEmail: User().Email,
         Screen: FeedbackComponent.FeedbackScreen.Name,
         FeedbackValue: "-1"
       }
     );
Notify("Thanks for your feedback!");
```



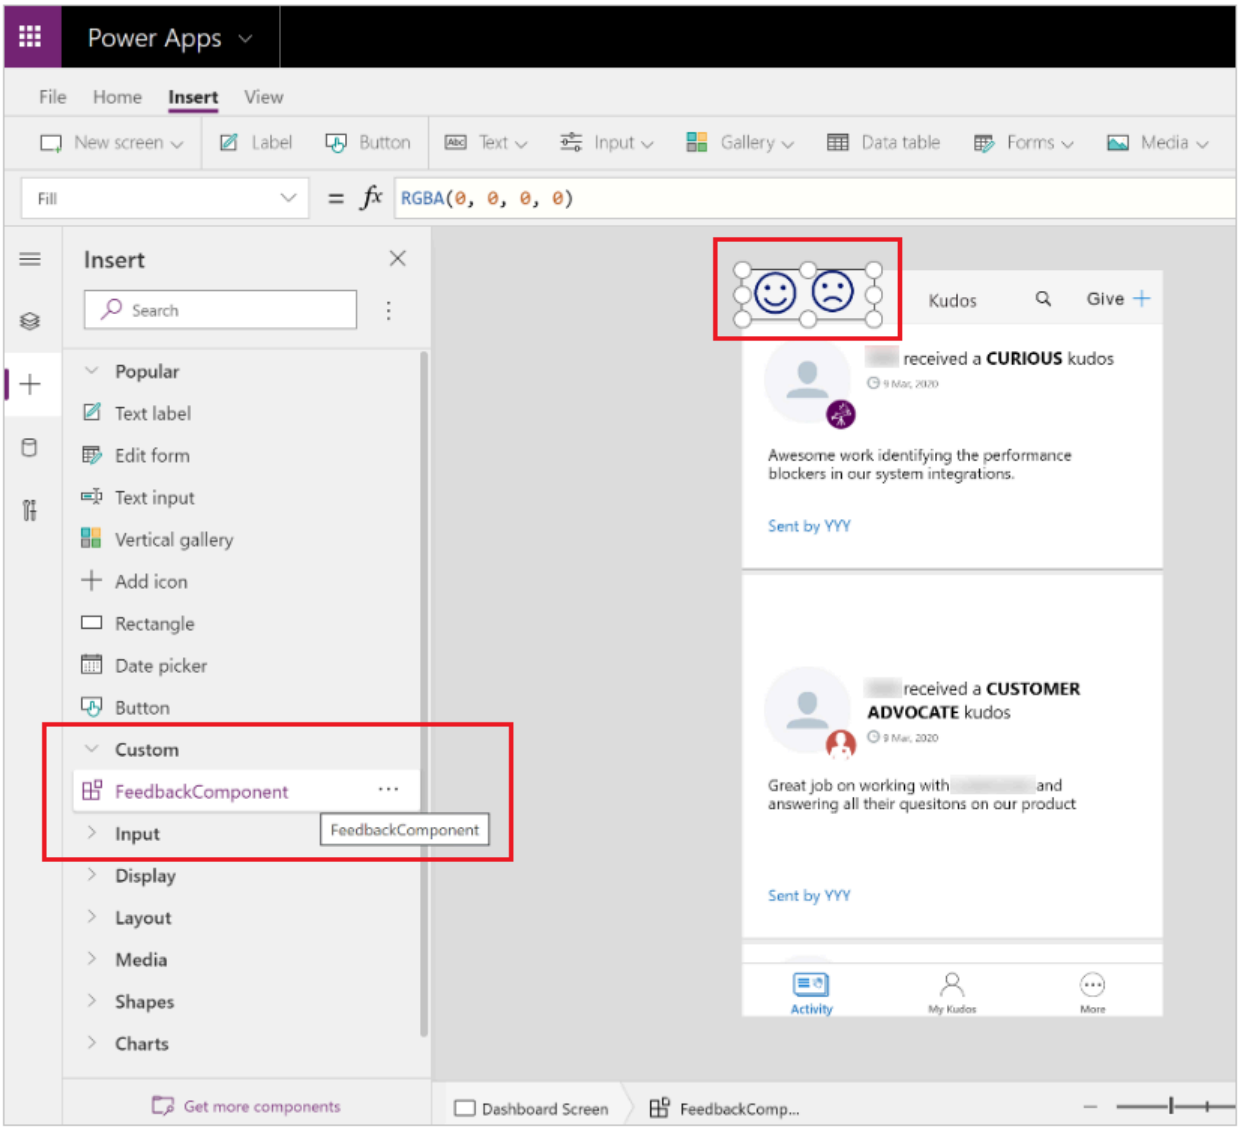
> **Note**
>
> The formula sends *UserName*, *UserEmail*, *Screen*, and *Feedback* (with the value *-1*) to Application Insights.

13. Select **SmileIcon**, select the **OnSelect** property, and then enter the following expression in the formula bar:

```
Power Fx

Trace(
   "App Feedback",
   TraceSeverity.Information,
       {
         UserName: User().FullName,
         UserEmail: User().Email,
         Screen: FeedbackComponent.FeedbackScreen.Name,
         FeebackValue: "1"
       }
     );
Notify("Thanks for your feedback!");
```

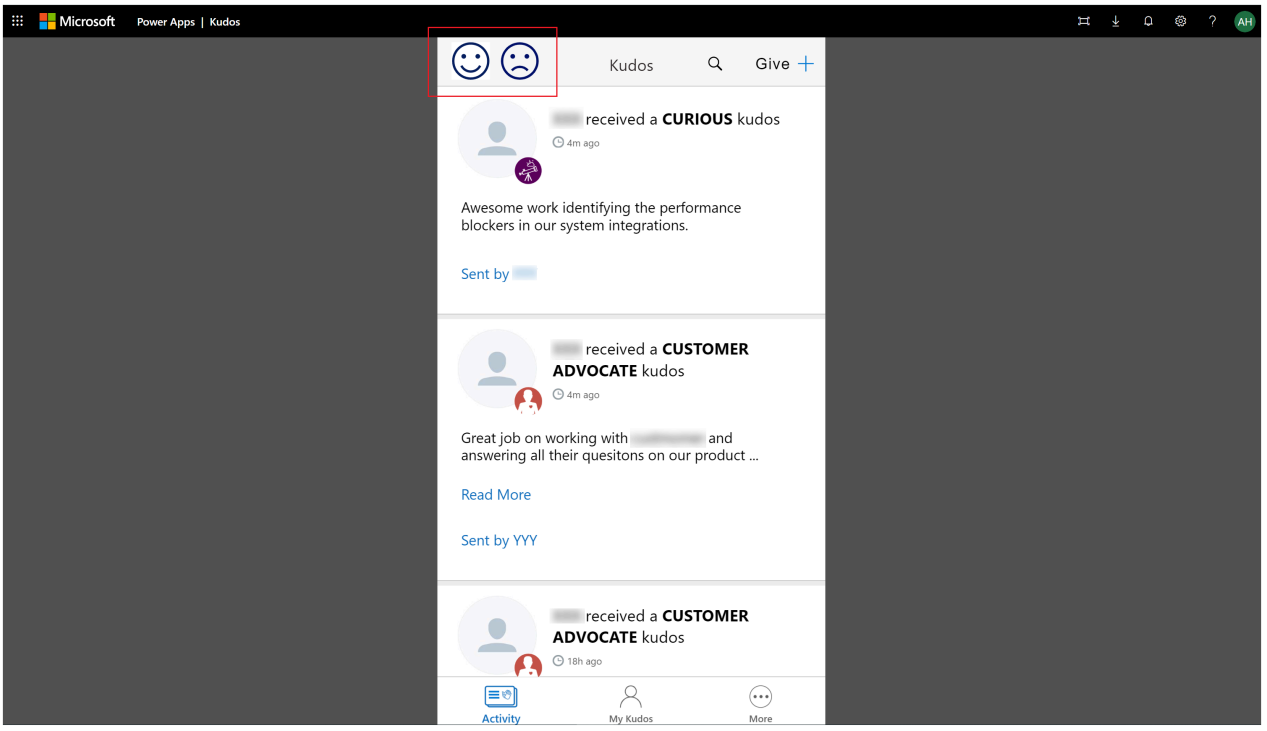
14. Add the component to one of the screens in your app:



15. Select **Save** and then select **Publish** to save and publish your app.

16. Play the published app and send smile or frown feedback from its screens.

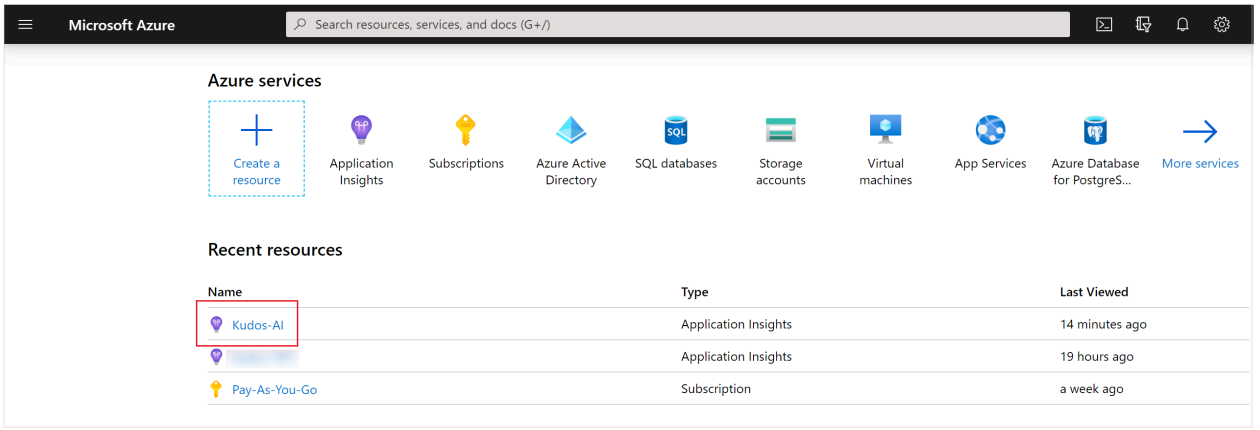
> **ⓘ Important**
>
> You must play the published app to send events to Application Insights. Events are not sent to Application Insights when you preview the app in Power Apps Studio.



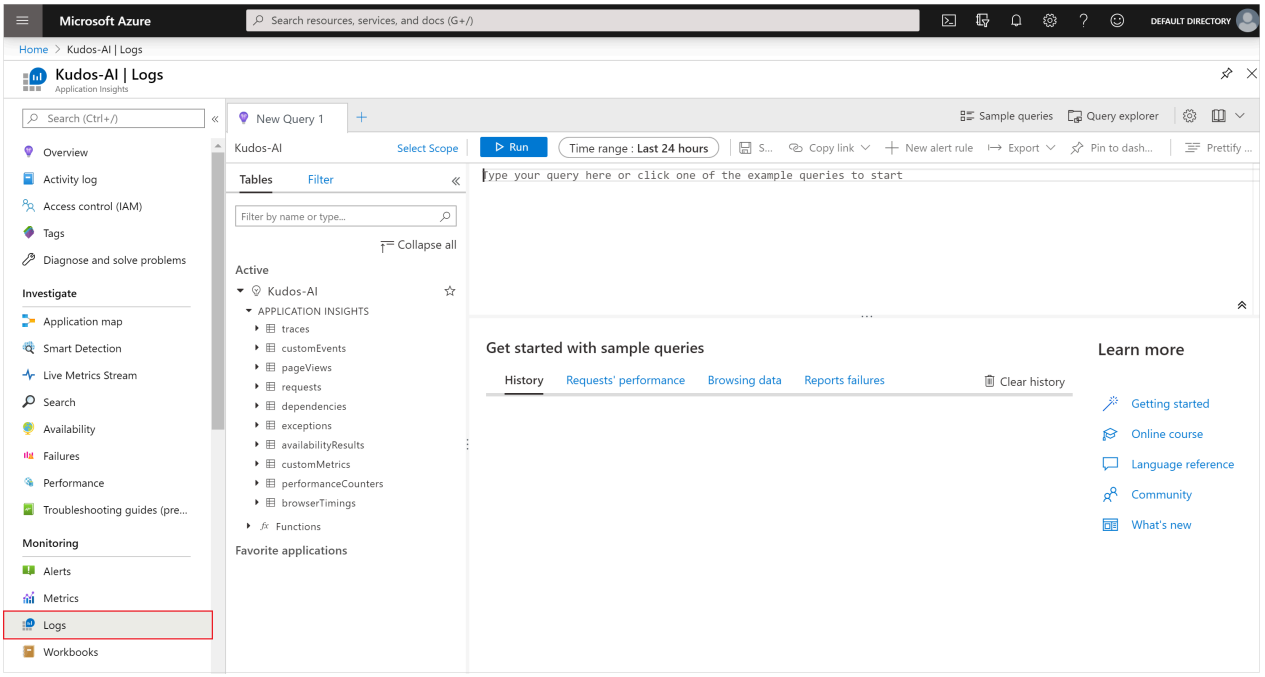
Analyze custom data in Application Insights

You can now begin to analyze the data you sent using the Trace function from your app in Application Insights.

1. Sign in to the Azure portal and open the application insights resource you created earlier.



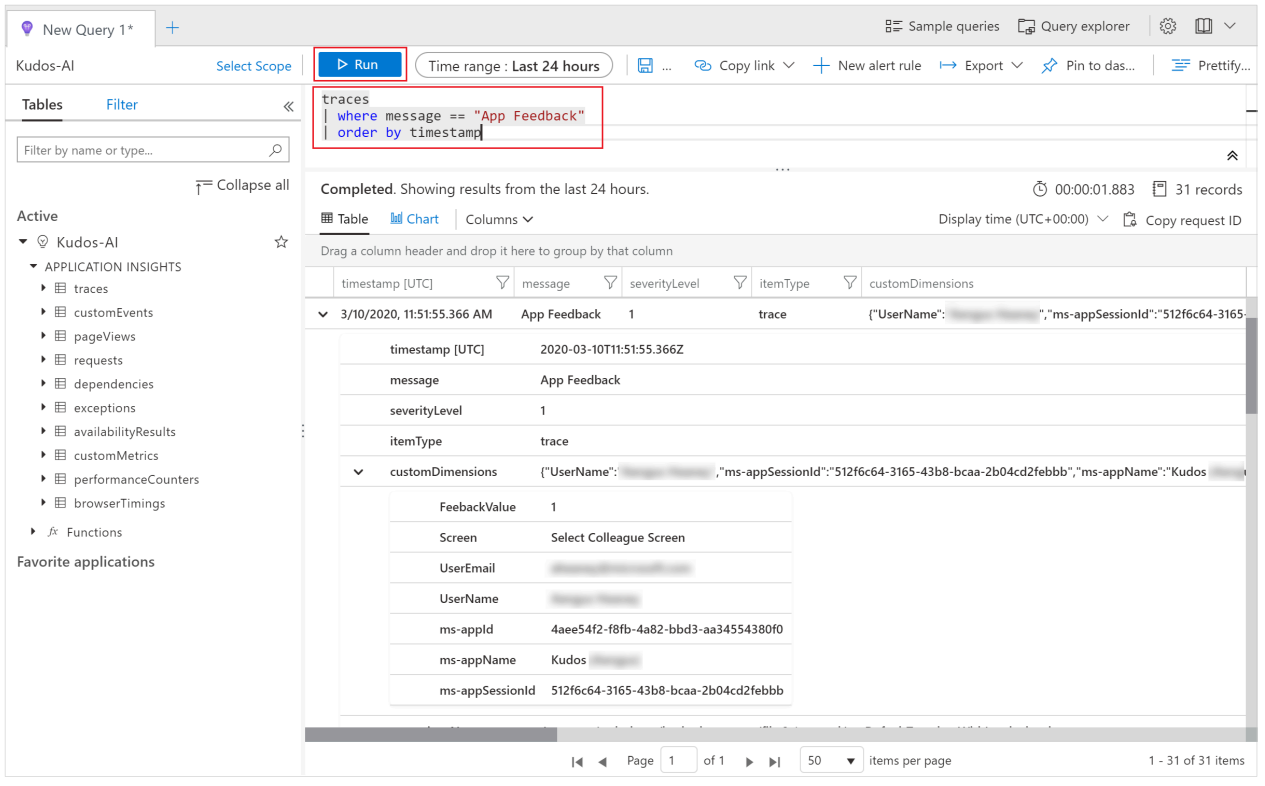
2. Select **Logs** under **Monitoring** in the left navigation pane.



3. Enter the following query and select **Run** to view the feedback from your app:

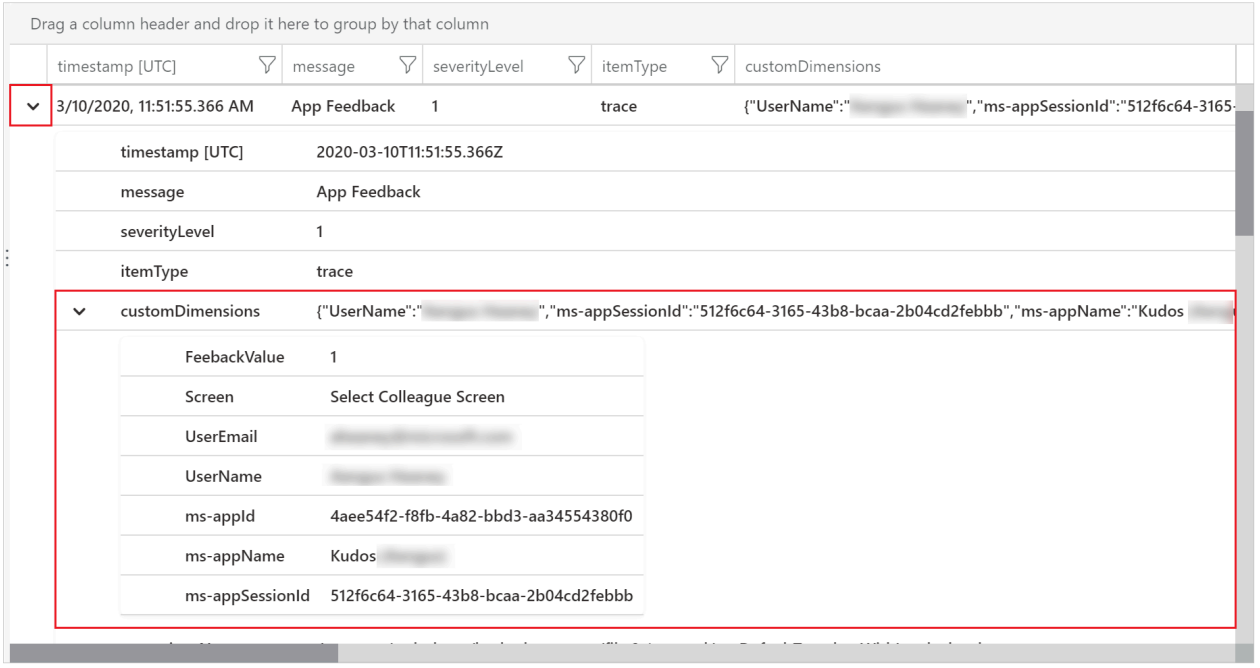
```
Kusto

traces
| where message == "App Feedback"
| order by timestamp
```



4. Select a row in the results and expand the *customDimensions* field.

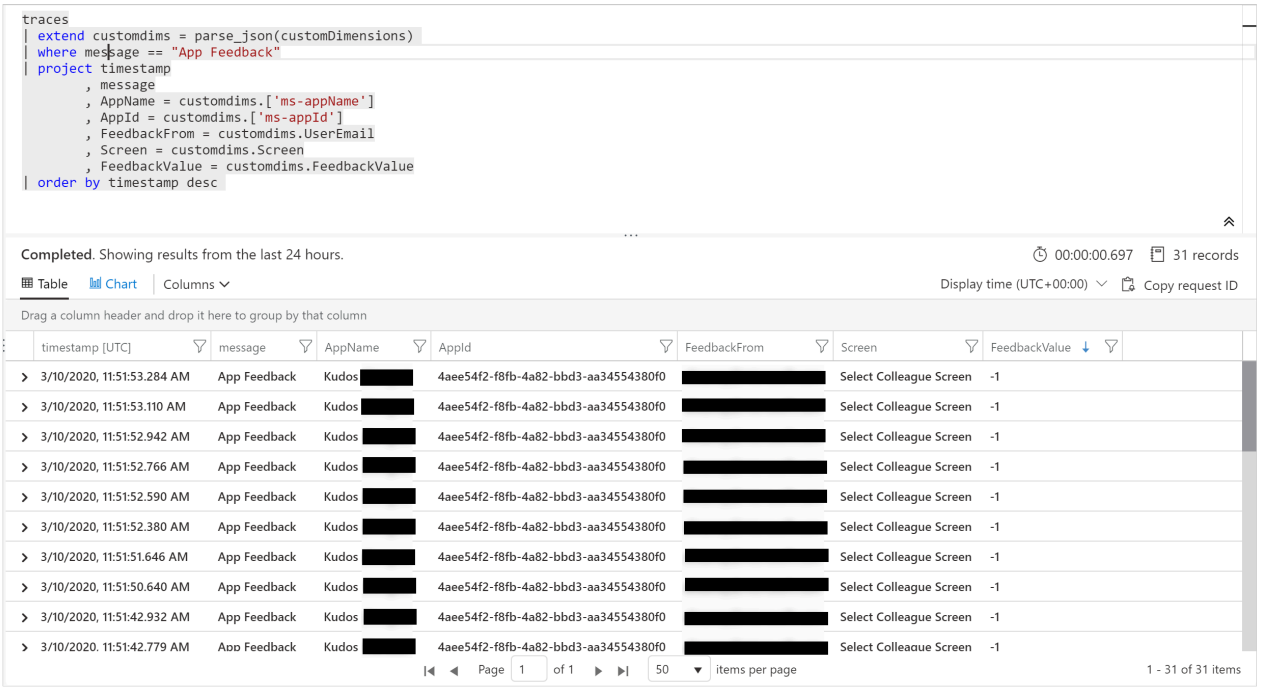
The values for **Screen**, **UserName**, **UserEmail**, and **FeedbackValue** for the **OnSelect** event of the smile or frown icon in your component are recorded. Values are also recorded for each event sent to Application Insights, such as the **appId**, **appName**, and **appSessionId**.



5. Use the following example query to extend the properties of the JSON custom dimensions and project the columns in the results view.

Kusto

```
traces
    | extend customdims = parse_json(customDimensions)
    | where message == "App Feedback"
    | project timestamp
        , message
        , AppName = customdims.['ms-appName']
        , AppId = customdims.['ms-appId']
        , FeedbackFrom = customdims.UserEmail
        , Screen = customdims.Screen
        , FeedbackValue = customdims.FeedbackValue
    | order by timestamp desc
```



> **Tip**
>
> *Log queries* are powerful. Use them to join multiple tables, aggregate large amounts of data, and run complex operations. Learn more about log queries.

Analyze app lifecycle data in Application Insights

The session summary event is logged once per session and contains information on app open success, app open optimal vs non-optimal sessions, and app open performance metrics.

Limits

These events are accurate for canvas apps running in a web browser. They aren't available for apps running in Power Apps mobile, and their values might not always be available or accurate for custom pages.

Here is an example query showing how to access the session summary event and all available fields:

Kusto

```
customEvents
| where name == "PowerAppsClient.PublishedApp.SessionLoadSummary"
//
| extend cd = parse_json(customDimensions)
//
| extend sessionSummary = parse_json(tostring(cd["ms-sessionSummary"]))
```

```
| extend successfulAppLaunch = tobool(sessionSummary["successfulAppLaunch"])
| extend unsuccessfulReason = tostring(sessionSummary["unsuccessfulReason"])
| extend appLoadResult = tostring(sessionSummary["appLoadResult"])
| extend appLoadNonOptimalReason =
tostring(sessionSummary["appLoadNonOptimalReason"])
//
| extend timeToAppInteractive = todouble(sessionSummary["timeToAppInteractive"])
| extend timeToAppFullLoad = todouble(sessionSummary["timeToAppFullLoad"])
//
| project
    timestamp,
    session_Id,
    successfulAppLaunch,
    unsuccessfulReason,
    appLoadResult,
    appLoadNonOptimalReason,
    timeToAppInteractive,
    timeToAppFullLoad
| limit 5
```

The following fields help measure app open success and latency of performance markers tied to end-user experiences.

Expand table

Field	Description
successfulAppLaunch	Boolean value indicating whether the session successfully launched the app
unsuccessfulReason	If the session failed to launch the app, this indicates the reason / error. This field will be an empty string if the session was successful.
appLoadResult	Indicates if the session was optimal or not. Possible values: optimal, other
appLoadNonOptimalReason	If the session was not optimal, this indicates the reason. Possible values: interaction-required, throttled, screen-navigated-away, other
timeToAppInteractive	Duration in milliseconds for the app session to reach an interactive state. In this state, users can start to interact with the first screen, but data may not be fully loaded.
timeToAppFullLoad	Duration in milliseconds for the app session to reach a fully loaded state, where all data requests for the first screen have finished loading.

Sample queries

App Open Success rates

This query will show the app open success rate by day. This can be used to evaluate spikes or trends in issues that users may be experiencing

Kusto

```
customEvents
| where name == "PowerAppsClient.PublishedApp.SessionLoadSummary"
| extend cd = parse_json(customDimensions)
| extend sessionSummary = parse_json(tostring(cd["ms-sessionSummary"]))
| extend successfulAppLaunch = tobool(sessionSummary["successfulAppLaunch"])
| summarize
sessions_total = dcount(session_Id),
sessions_success = dcountif(session_Id, successfulAppLaunch == true)
by bin(timestamp, 1d)
| extend successRate =
100.0 * (todouble(sessions_success) / todouble(sessions_total))
| project timestamp, successRate
| render timechart
```

Count of Unsuccessful Sessions by Reason

This query will show counts of unsuccessful sessions by reason / error. This can be used to debug app open failures or evaluate trends in issues that users may be experiencing.

Kusto

```
customEvents
| where name == "PowerAppsClient.PublishedApp.SessionLoadSummary"
| extend cd = parse_json(customDimensions)
| extend sessionSummary = parse_json(tostring(cd["ms-sessionSummary"]))
| extend successfulAppLaunch = tobool(sessionSummary["successfulAppLaunch"])
| extend unsuccessfulReason = tostring(sessionSummary["unsuccessfulReason"])
| where successfulAppLaunch == false
| summarize
count()
by unsuccessfulReason, bin(timestamp, 1d)
| render timechart
```

App Open Performance

This query will show app open performance metrics by day. This can be used to evaluate performance trends over time or after making changes. We recommend:

1. Using the 75th percentile of the timeToAppInteractive and timeToAppFullLoad fields to avoid noise caused by outliers.

2. Filtering to only optimal sessions to avoid noise in the data caused by expected cases like sessions with user interaction, sessions where the app was loaded in a background tab, etc.

Kusto

```
customEvents
| where name == "PowerAppsClient.PublishedApp.SessionLoadSummary"
| extend cd = parse_json(customDimensions)
| extend sessionSummary = parse_json(tostring(cd["ms-sessionSummary"]))
| extend appLoadResult = tostring(sessionSummary["appLoadResult"])
| extend timeToAppInteractive = todouble(sessionSummary["timeToAppInteractive"])
| extend timeToAppFullLoad = todouble(sessionSummary["timeToAppFullLoad"])
| where appLoadResult == "optimal"
| summarize
percentile(timeToAppInteractive, 75),
percentile(timeToAppFullLoad, 75)
by bin(timestamp, 1d)
| render timechart
```

App Load State on HTTP Calls

There is a new request header x-ms-app-load-state that indicates if an HTTP call contributed to app startup. Specifically, this can be used to determine which HTTP calls impacted the timeToAppFullLoad above.

The header can be one of two values:

Expand table

Value	Description
TTFL	indicates that the request contributed to timeToAppFullLoad
PostTTFL	indicates that the request did not contribute to timeToAppFullLoad

Here is an example query showing how to access the header value and projecting it in the appLoadState column:

Kusto

```
dependencies
| extend cd = parse_json(customDimensions)
| extend requestHeaders = parse_json(tostring(cd["requestHeaders"]))
| extend appLoadState = tostring(requestHeaders["x-ms-app-load-state"])
| project timestamp, session_Id, appLoadState, name, duration
| limit 5
```

Count of HTTP calls contributing to Full Load

This query will show the average count of HTTP calls that are contributing to timeToAppFullLoad by day. This can be used to evaluate the number of calls the app is making at startup that may be contributing to poor performance.

Kusto

```
dependencies
| extend cd = parse_json(customDimensions)
| extend requestHeaders = parse_json(tostring(cd["requestHeaders"]))
| extend appLoadState = tostring(requestHeaders["x-ms-app-load-state"])
| where appLoadState == "TTFL"
| summarize httpCalls = count() by session_Id, bin(timestamp, 1d)
| summarize avg(httpCalls) by timestamp
| render timechart
```

Duration of HTTP calls contributing to Full Load

This query will show the total duration of HTTP calls that are contributing to timeToAppFullLoad by day. This can be used to evaluate the overall impact of HTTP calls to app startup performance.

Kusto

```
dependencies
| extend cd = parse_json(customDimensions)
| extend requestHeaders = parse_json(tostring(cd["requestHeaders"]))
| extend appLoadState = tostring(requestHeaders["x-ms-app-load-state"])
| where appLoadState == "TTFL"
| summarize httpCallDuration = sum(duration) by session_Id, bin(timestamp, 1d)
| summarize percentile(httpCallDuration, 80) by timestamp
| render timechart
```

Duration of HTTP calls contributing to Full Load by URL

Similar to above, this query will show the count and duration of HTTP calls contributing to timeToAppFulLoad by URL. This can be used to identify specific slow HTTP calls that are impacting app startup performance.

Kusto

```
dependencies
| extend cd = parse_json(customDimensions)
| extend requestHeaders = parse_json(tostring(cd["requestHeaders"]))
| extend appLoadState = tostring(requestHeaders["x-ms-app-load-state"])
```

```
| where appLoadState == "TTFL"
| summarize
count(), percentile(duration, 80) by name
```

Monitor unhandled errors (experimental)

[This section contains pre-release documentation and is subject to change.]

> **ⓘ Important**
>
> - This is an experimental feature.
> - Experimental features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

You can't always anticipate or plan for every error that might occur while your app runs. Unhandled Power Fx formula errors are reported to users as banner messages. They can also be reported to Application Insights to show their frequency and severity without relying on your app's users to report issues. You can also set up real-time alerts when runtime errors occur to take a more proactive approach.

Enable error passing to Application Insights

Enable the setting that lets Power Apps pass unhandled runtime errors to Azure Application Insights.

> **⚠ Warning**
>
> Enabling the **Pass errors to Azure Application Insights** setting might incur additional costs for storing Application Insights logs.

1. Open the canvas app for editing.
2. Select **Settings** > **Updates** > **Experimental**, and turn on **Pass errors to Azure Application Insights**.
3. Save and then publish your app.

Error events in Application Insights

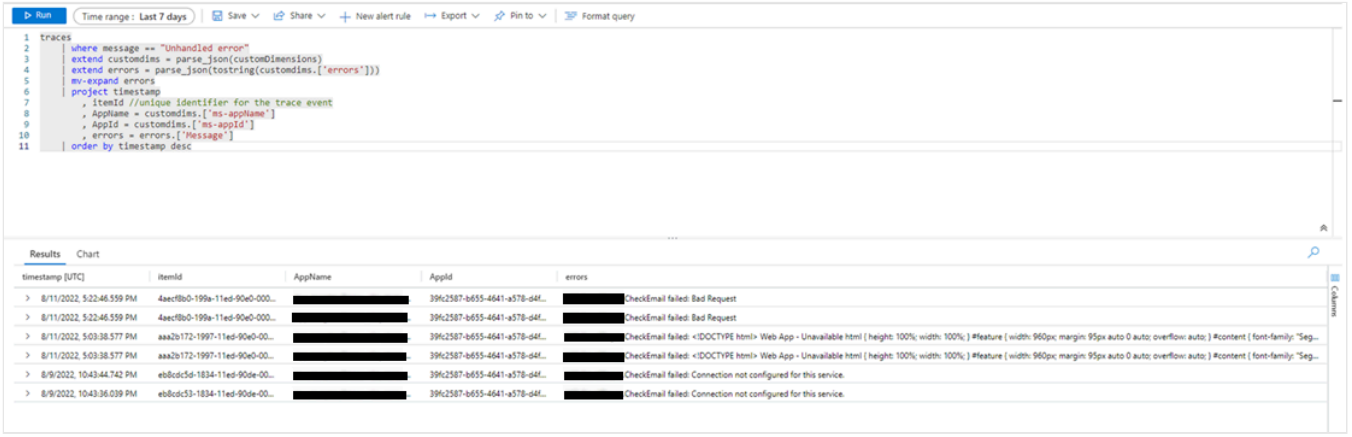
Unhandled Power Fx errors that users encounter at app runtime are reported to the **traces** table. Unhandled errors can be identified and distinguished from other error events by the event message "Unhandled error." The "severityLevel" dimension of these events is 3 (TraceSeverity.Error).

Detailed error messages are provided in the "errors" dimension of the *customDimension* property. In situations where multiple errors occurred during the same operation, the errors are consolidated in the "errors" dimension of a single trace event. The error messages match those reported in Monitor during a live debug session.

This example query identifies unhandled errors and expands all error messages in the trace event:

Kusto

```
traces
    | where message == "Unhandled error"
    | extend customdims = parse_json(customDimensions)
    | extend errors = parse_json(tostring(customdims.['errors']))
    | mv-expand errors
    | project timestamp
        , itemId //unique identifier for the trace event
        , AppName = customdims.['ms-appName']
        , AppId = customdims.['ms-appId']
        , errors = errors.['Message']
    | order by timestamp desc
```



Correlation tracing (experimental)

[This section contains pre-release documentation and is subject to change.]

> **Important**
>
> - This is an experimental feature.

- Experimental features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

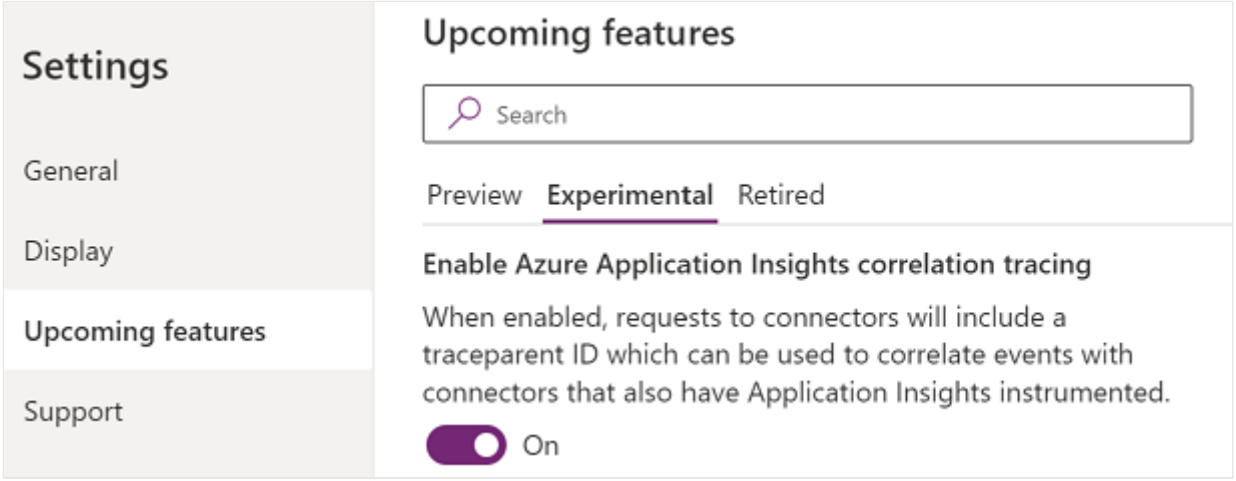
Connecting to external data and services is essential for most apps. Correlation tracing generates and propagates context information to link system-generated logs across a canvas app and its connections, subject to certain limitations. For example, your app might call a custom connector that then calls an Azure Function or another REST API. Correlation tracing allows you to correlate actions taken in the app with the underlying API calls across tiers. This is useful for troubleshooting.

Canvas app correlation tracing implements context tracing and follows the W3C specification.

Enable correlation tracing

> ⚠ **Warning**
>
> Enabling this setting might incur additional costs related to storing Application Insights logs.

1. To enable correlation tracing, open your cavas app for editing.
2. Select **Settings** > **Udates** > **Experimental** > and turn on **Enable Azure Application Insights correlation tracing**.
3. Save and publish the app.

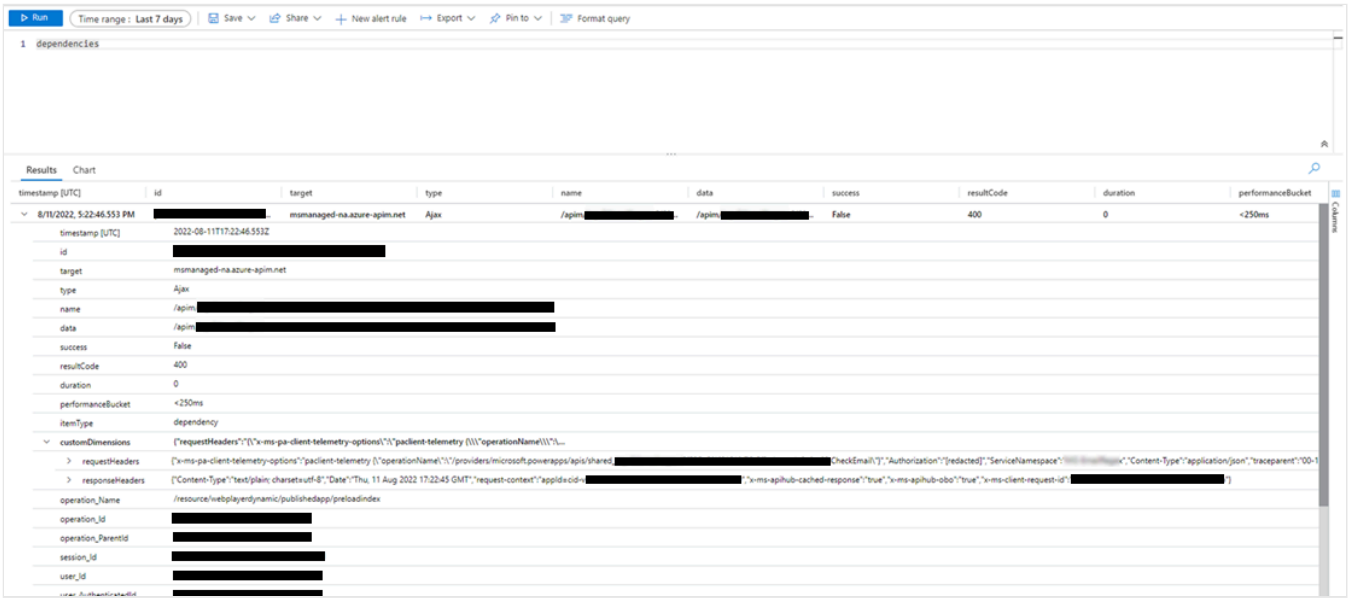


Limitations

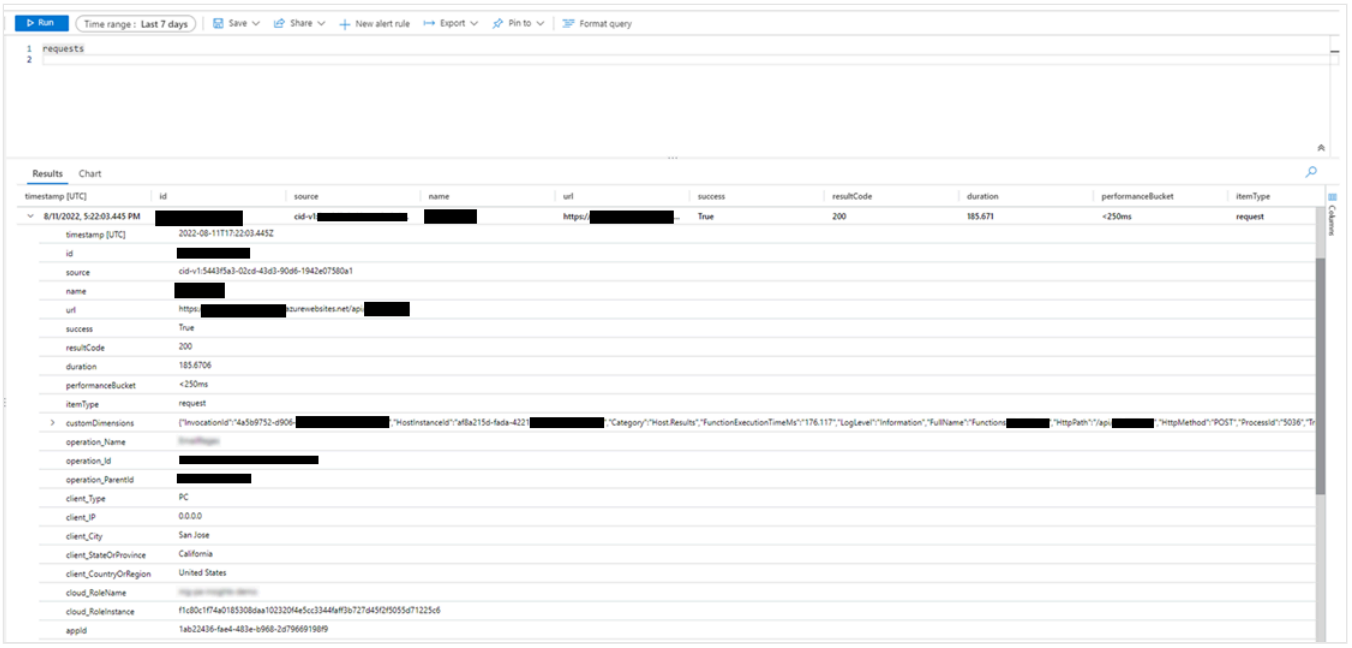
- Correlation tracing works only with custom connectors. Other connector types aren't supported.
- HTTP requests are captured in Application Insights only if the connected service is also connected to Application Insights.

Using correlation tracing

When enabled, correlation tracing adds a new system-generated log event in the **dependencies** table of the canvas app's Application Insights instance. This event is recorded at the time a response from a network call is received. Dependency events capture details of the network call, including the request and response headers, response status code, and duration of the call.



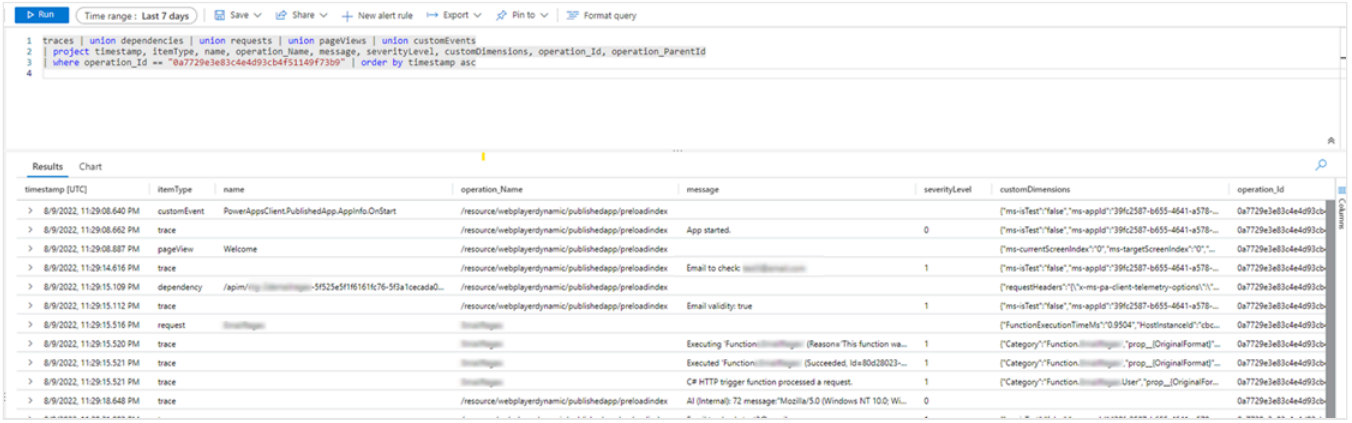
If the connected service is also connected to Application Insights, an additional system-generated log event capturing the request is generated in the **requests** table of the service's Application Insights instance. Some Azure services, such as Azure Functions, can be connected without any coding from the Azure portal. Both the canvas app or multiple apps and connected services can be connected to the same Application Insights instance.



Join network calls for supported connectors with other system-generated logs on the "operation_Id" dimension. The following query shows a network call alongside trace events emitted during an app session.

Kusto

```
traces | union dependencies | union requests | union pageViews | union
customEvents
| project timestamp
    , itemType
    , name
    , operation_Name
    , message
    , severityLevel
    , customDimensions
    , operation_Id
    , operation_ParentId
| where operation_Id == "0a7729e3e83c4e4d93cb4f51149f73b9" //placeholder
operation_Id, replace
| order by timestamp asc
```



Export data to Power BI

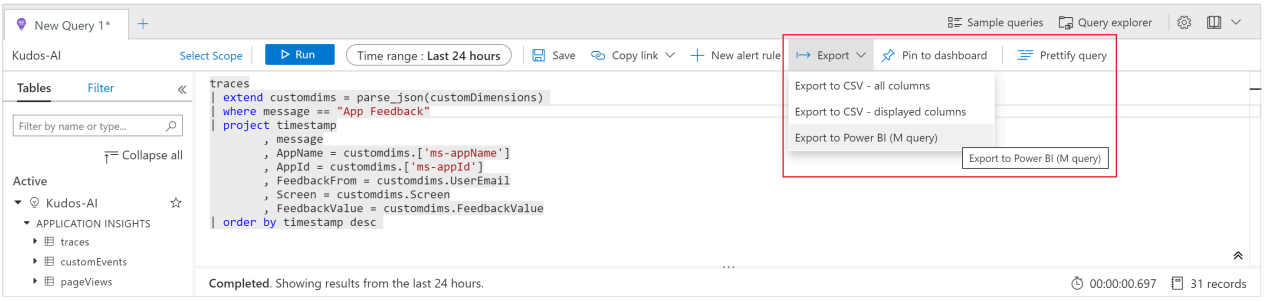
You can export your Application Insights data and query results to Power BI for analysis and data presentation.

1. Sign in to the Azure portal and open the Application Insights resource you set up earlier.

2. Select **Logs** under **Monitoring** in the left navigation pane.

3. In the log analytics query window, select the **Export** menu.

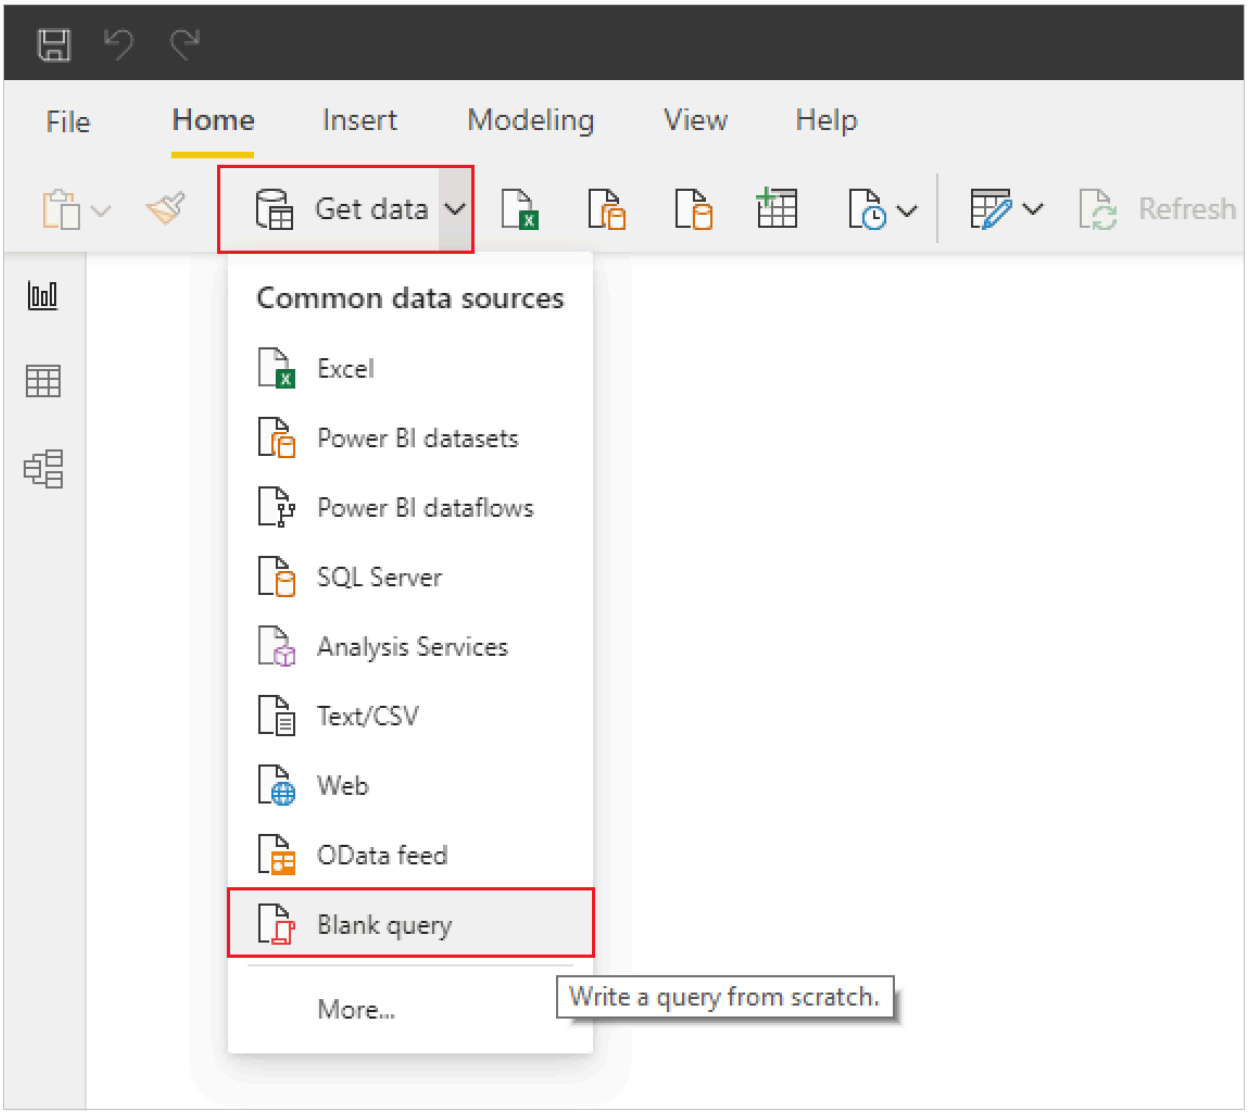
4. Select **Export to Power BI (M query)** to download a Power BI query file.



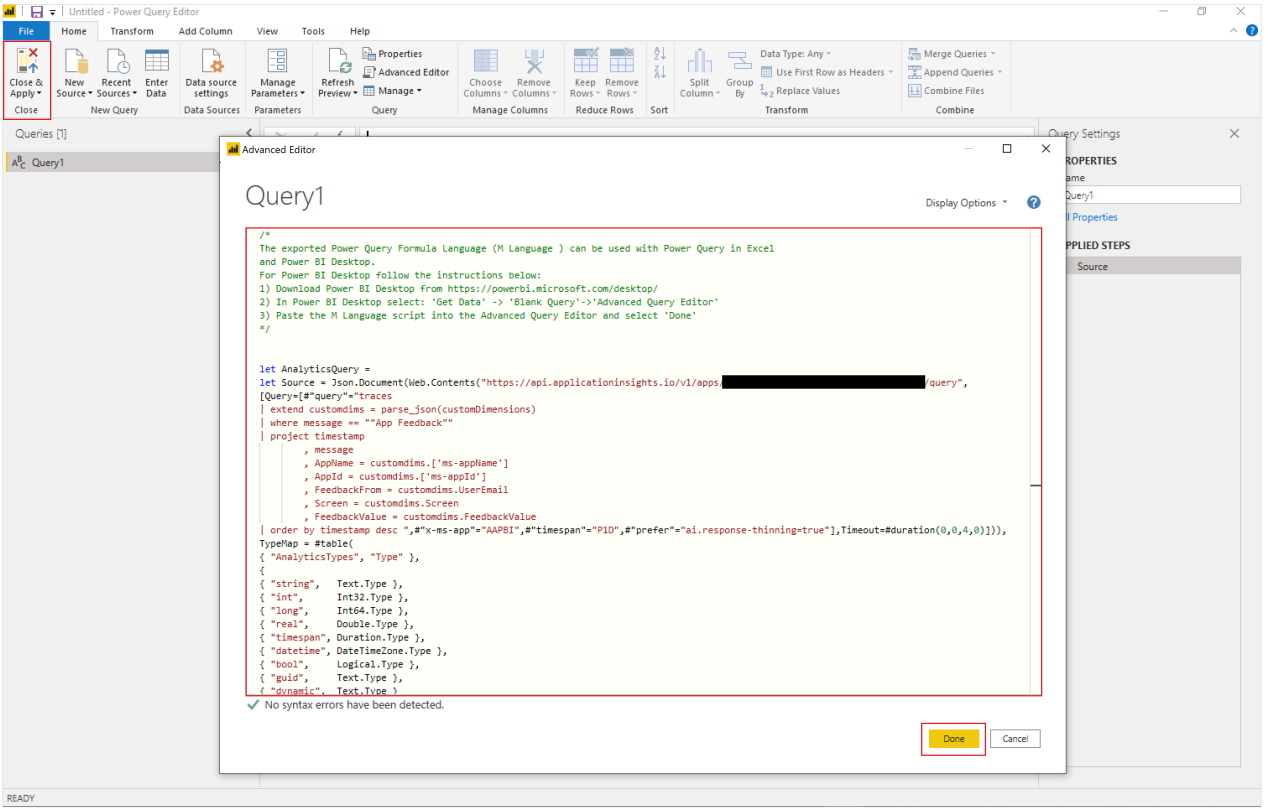
5. Open the downloaded file in a text editor, and copy the query to the clipboard.

6. Open Power BI.

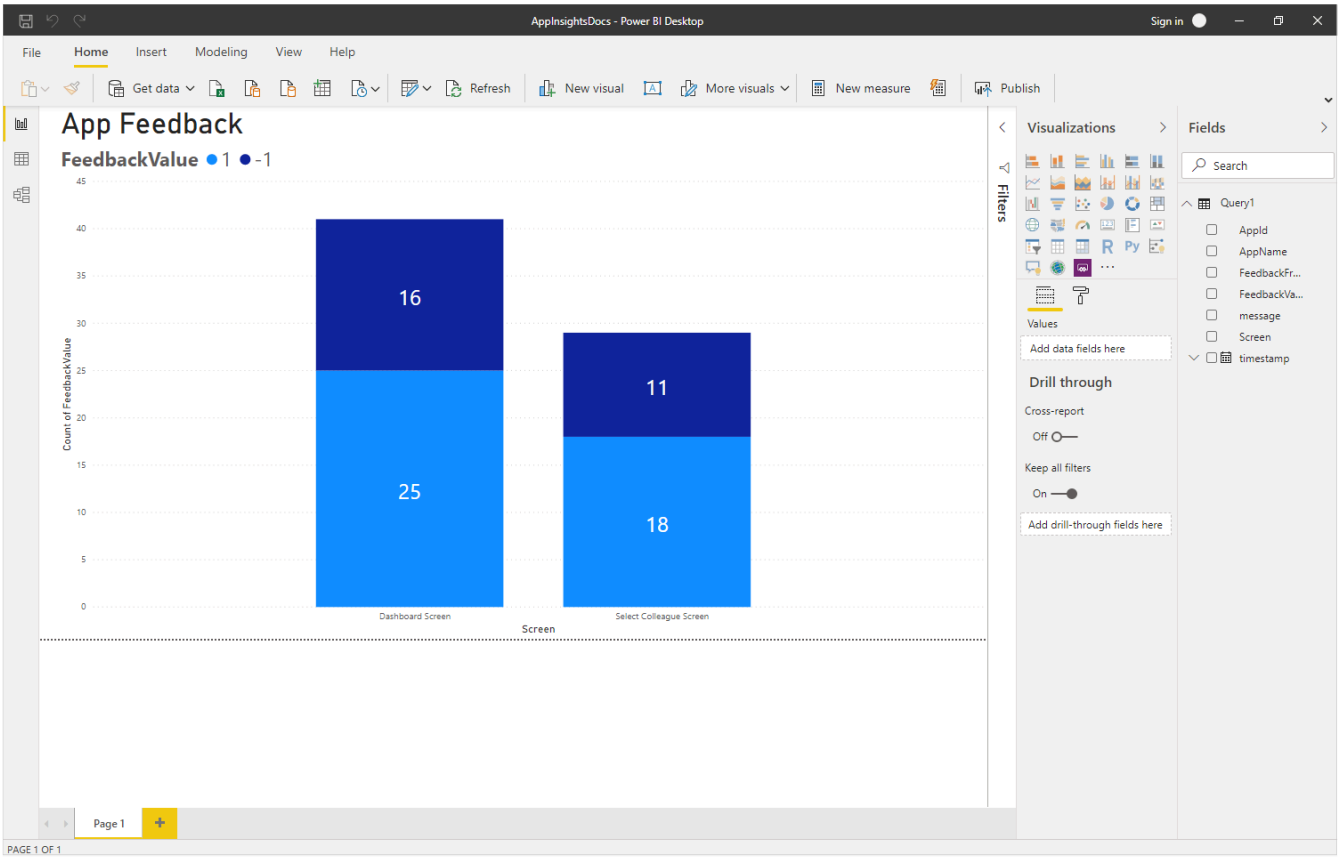
7. Select **Get Data** in the **Home** ribbon, and then select **Blank query**.



8. In the query window, select **Advanced Editor**, paste the query into the window, select **Done**, and then select **Close & Apply**.



Create charts and visualizations in Power BI to represent feedback from your app and make data-driven decisions.



Default Trace event context and dimensions

Default dimensions are added to the *customDimensions* property on each Trace event. These dimensions identify the application and application sessions where the events occur. If you log additional custom data using the Trace function, it also appears in the custom dimensions.

Expand table

Dimension Name	Represents
ms-appId	The Application ID of the app that sent the event.
ms-appname	The Application name of the app that sent the event.
ms-appSessionId	The application session ID. This value might not be populated in some scenarios. When available, this value overrides the standard Application Insights sessionID dimension.
ms-tenantID	The unique identifier of the tenant where the application is published.
ms-environmentId	The name of the environment where the application is published.
userId	A unique identifier for the user associated with the session.
ms-duration	An imputed value measuring the time it takes for a user to navigate from one screen to another. This value overrides the standard Application Insights PageView duration dimension.
sessionId	A session ID that can be used to correlate all events associated with a single application session. This value is always present and is recommended for understanding unique session count. This value is taken from the player's session ID and is shown when viewing the session details while playing the app. Session ID might sometimes get a default, random, unique Application Insights-generated value. This default value isn't reliable and doesn't correlate with any app-specific parameters.
Duration	An imputed value measuring the time it takes for a user to navigate from one screen to another. This value matches the duration reported by the ms-duration dimension.
ms-isTest	Indicates whether the session is associated with the Test Studio test runner.
ms-currentScreenName	The name of the page the user navigates from (available for page navigation events).
ms-targetScreenName	The name of the page a user is navigating to (present for page navigation events).

Unsupported scenarios

Application Insights doesn't support these scenarios.

- Offline player events aren't recorded.
- Events from mobile apps (iOS and Android) aren't recorded when the app is suspended.

Understand canvas app execution phases, data call flow, and performance monitoring

Article • 12/12/2023

When a user opens a canvas app, the app goes through several phases of execution before showing any user interface. While the app loads, it connects to different data sources—such as SharePoint, Microsoft Dataverse, SQL Server (on-premises), Azure SQL Database (online), Excel, and Oracle.

In this article, you'll learn about these different phases of execution and how an app connects to data sources and about tools you can use to monitor performance.

Execution phases in canvas apps

A canvas app goes through the following phases of execution before showing the interface to a user:

1. **Authenticate the user**: Prompts the first-time user to sign in with credentials for whatever connections the app needs. If that user opens the app again, that person might be prompted again, depending on the organization's security policies.

2. **Get metadata**: Retrieves metadata, such as the version of the Power Apps platform on which the app runs and the sources from which it must retrieve data.

3. **Initialize the app**: Performs any tasks specified in the OnStart property.

4. **Render the screens**: Renders the first screen with controls that the app populates with data. If the user opens other screens, the app renders them by using the same process.

Data call flow in canvas apps

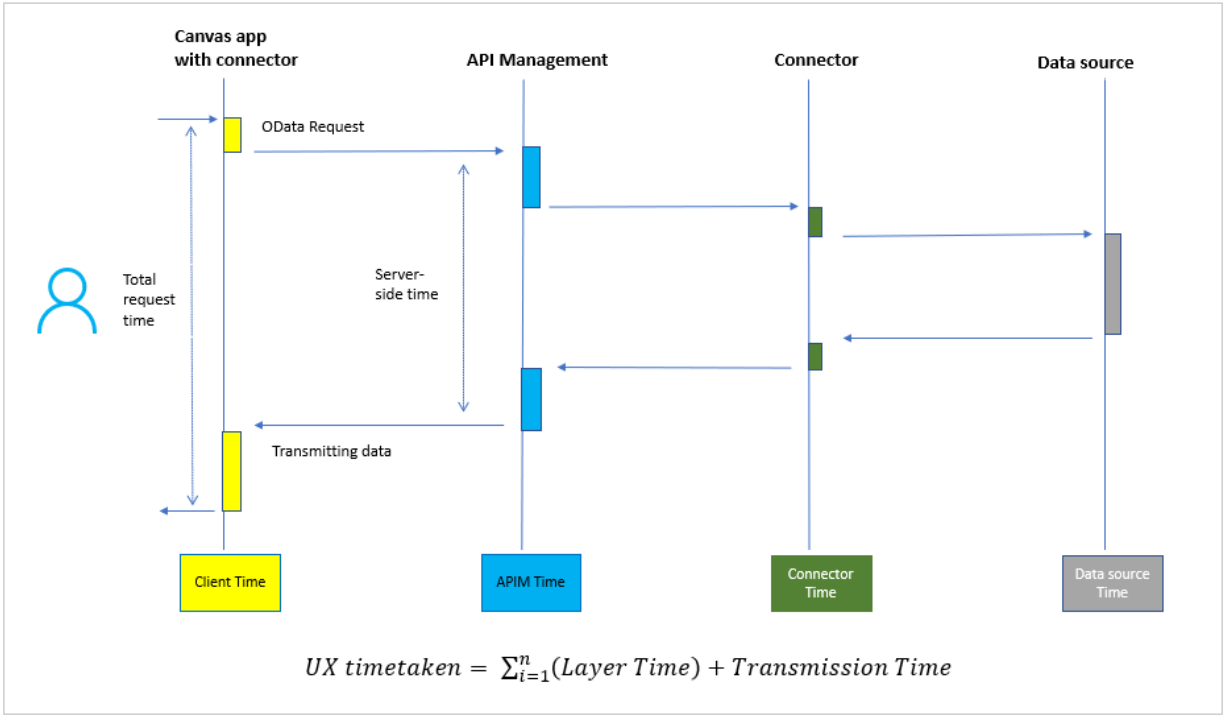
Data calls from canvas apps send data to tabular data sources by using connectors over the OData protocol.OData requests flow to back-end layers to reach out to the target data source and retrieve data for the client, or commit data to the data source. Action based connectors that enable APIs work in the same way.

Understanding how OData and API requests travel in canvas apps can help you to optimize your canvas app performance and your back-end data sources.

In this section, you'll learn about how the data call flows in canvas apps with different data source types.

Data call flow with online data sources

The following diagram shows how a typical data request in a canvas app (on the left side) travels server-side layers, reaches out to the target data source (on the right side), and then returns the data to the client.



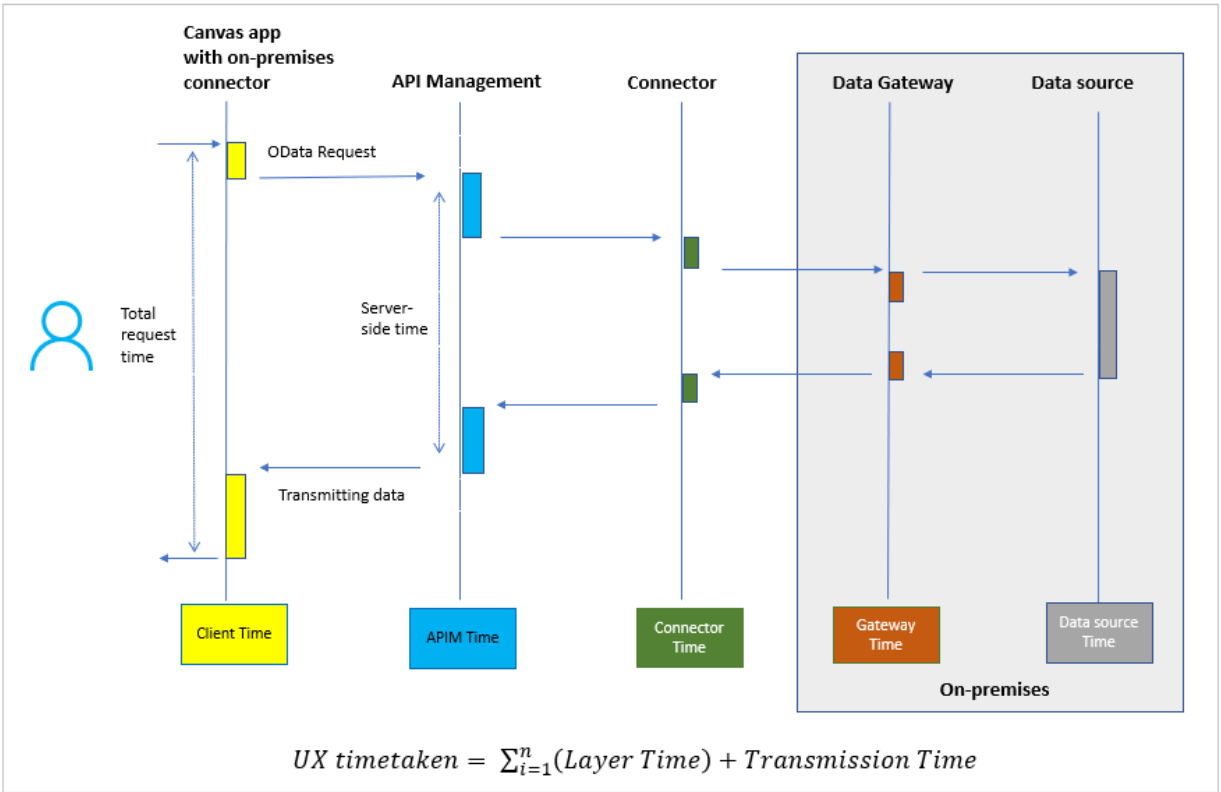
Each layer in the preceding diagram can perform quickly or encounter some overhead while processing the request. In many apps, two particular spots commonly present noticeable overhead:

- **Back-end data source** while processing the request.
- **Client** while sending the request—or while manipulating the received data on the heap memory and executing the associated JavaScript functions to process data to show in screens.

Data call flow with on-premises data gateway

If a canvas app connects to an on-premises data source like SQL Server, you need to have another layer called an *on-premises data gateway*. This gateway is mandatory for accessing on-premises data sources. It takes charge of converting OData protocol requests to SQL Data Manipulation Language (DML) statements.

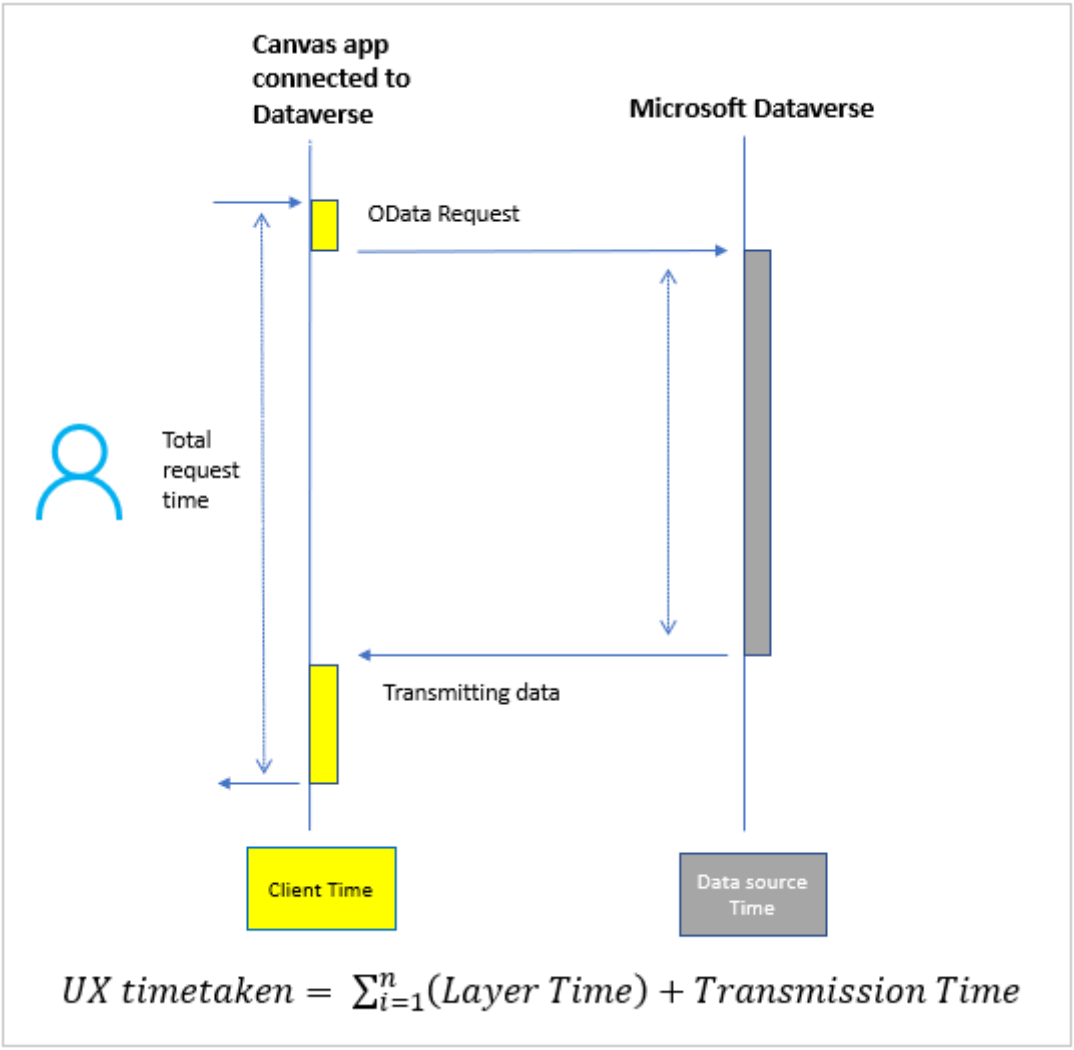
The following diagram shows where and how the on-premises data gateway is put in place to process data requests.



If the app uses a data source on-premises, the location and the specification of the data gateway also affect the performance of data calls.

Data call flow with Microsoft Dataverse

When you use Microsoft Dataverse as the data source, data requests go to the environment instance directly—without passing through Azure API Management. Because of this, the performance of data calls is faster compared to the rest of the data sources. The app is by default connected to Microsoft Dataverse when you create a new canvas app.



With the understanding of this high-level concept of how data calls travel, you can get into the details of reviewing the performance of your app. In summary, performance overhead can happen at any of the layers—from client, API Management, connector, on-premises data gateway, or back-end data sources.

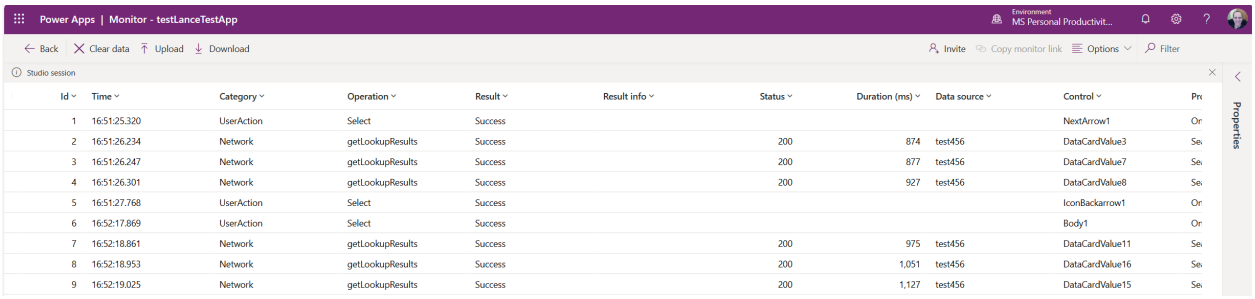
Measuring performance

Power Apps Monitoring tool

While you can use the browser's developer tools to see performance, Power Apps subsets the set of calls in the Monitoring tool to just those that are Power Apps.

The Power Apps monitoring tool can help you track what is actually sent to the data source and timestamps for when requests are sent and responses come from the server.

You can learn more about the monitoring tool in this article: Debugging canvas apps with Monitor .



Id	Time	Category	Operation	Result	Result info	Status	Duration (ms)	Data source	Control	Pr
1	16:51:25.320	UserAction	Select	Success					NextArrow1	On
2	16:51:26.234	Network	getLookupResults	Success		200	874	test456	DataCardValue3	Se
3	16:51:26.247	Network	getLookupResults	Success		200	877	test456	DataCardValue7	Se
4	16:51:26.301	Network	getLookupResults	Success		200	927	test456	DataCardValue8	Se
5	16:51:27.768	UserAction	Select	Success					IconBackarrow1	On
6	16:52:17.869	UserAction	Select	Success					Body1	On
7	16:52:18.861	Network	getLookupResults	Success		200	975	test456	DataCardValue11	Se
8	16:52:18.953	Network	getLookupResults	Success		200	1,051	test456	DataCardValue16	Se
9	16:52:19.025	Network	getLookupResults	Success		200	1,127	test456	DataCardValue15	Se

Measuring memory pressure on the client

To see memory consumption graphically, you can use the developer tools for your browser to profile memory. It helps you visualize heap size, documents, nodes, and listeners. Profile the app's performance by using a browser, as described in Microsoft Edge (Chromium) Developer Tools overview. Check the scenarios that exceed the memory threshold of the JS heap. More information: Fix memory problems

Troubleshooting issues for Power Apps

Small data payloads - limit the amount of data you get

Article • 12/12/2023

One of the most important patterns for enterprise data apps is to limit the size of the data you fetch into Power Apps. If the data payloads are small, nearly everything else gets easier. The Gallery and Table controls do this for you automatically when you connect directly to the data source in the Items property. For instance, when connected directly to a remote data source, a Gallery control pages in data in small increments, for example, 100 records. This default leverages the fact that an end user rarely really needs more than a hundred records for a user task.

Use delegation

One key way to keep data payloads small is to rely on the data source to do work for you before it gets to Power Apps. **Delegation** is when Power Fx can translate a Power Fx expression into a query expression that a data source such as Dataverse, SQL Server, SharePoint, and Excel can handle on its own. And, then Power Fx delegates that query, or gives the responsibility of doing the query work, the data mashup, to the data source. The data source produces the correct data and returns it to Power Apps.

When the data source is bound directly to a gallery or table, then the data is paged or handed back the data to Power Apps in small performant increments of 100 records. Different data sources have different capabilities. Dataverse, for example, has many more capabilities to filter data on the server than Excel. A good example is CountRows and CountIf. Dataverse supports CountRows in a limited way. Dataverse calculates the size of the table periodically and keep that value around. When CountRows is called, you're given that value. That way it doesn't have to perform a full table scan to get the exact number for every CountRows call. But Dataverse also supports an exact count with CountIf up to 50,000 rows. It supplies these two different capabilities as a way to help preserve good performance of Dataverse server. In contrast, SharePoint doesn't support this function. So, a Power Fx expression with CountRows or CountIf for SharePoint isn't delegated. Instead, Power Apps downloads a limited number of rows, 500 – 2000. Power Fx works on the 500/2000 records locally and returns a result. If your data is always less than 500/2000 records this approach can work. But if it's greater than 500/2000 records you might get incorrect results.

Avoid too many columns

By default, Power Apps computes the actual columns you need for a given query using a feature call **Explicit Column Selection**. This feature is on by default for all new apps. To turn on the explicit column selection feature on the canvas app, go to **Settings** > **Upcoming features** > **Preview**> turn on **Explicit column selection** toggle.

Suggestions

To achieve the goal of a small data payload, consider the following questions and suggestions:

1. Aim for the default query for a gallery or table to only return approximately 100 – 200 records. If you use a delegable query, this happens automatically. If you're querying an API, or other source that doesn't support delegation, use parameters to refine the results.

    - Consider using a data source based view that automatically filters the data. Most enterprise-grade apps make heavy use of views on the data source.
    - Consider using default lookup or filter values to scope the data.
    - Consider requiring search arguments in the UI before you show data.
    - Consider these questions about your app:
        - What is necessary on a given screen by default?
        - What data does the end user really need to take a given business action?
        - Users generally don’t need thousands of records on an initial screen to accomplish a task.

2. Start building your query for a gallery or table by using the delegation tables for your data source. Only choose the functions supported for your query. If your query isn't delegable, what can you do to make it delegable?

Optimized query data patterns

Article • 12/13/2023

The simplest and fastest data query pattern is:

1. A single table or view
2. Prefiltered on the server to what you need
3. Columns are indexed correctly for the expected queries

When you design your app, you need to think about how to query the data quickly. The best way to query data is to use a single table or view that has all the information you need, and filter it on the server before you display it in your app. You also need to make sure that the columns you use to filter or sort the data are indexed properly. This makes your app faster and smoother.

For example, suppose you have a gallery that shows a list of customers and their salespersons. If you store the customer and salesperson information in separate tables, you need to use lookups to get the salesperson name for each customer. This slows down your app because it needs to run many queries to the other table. A better way is to create a view that combines the customer and salesperson information in one table, and use that view as the data source for your gallery. Then your app only needs to run one query to get all the data it needs.

There's a trade-off between query speed and data normalization. Data normalization means that you store the data only once, and avoid duplication. This helps to keep the data consistent and accurate. However, sometimes you need to duplicate some data to make the queries faster and easier. You need to balance these two goals in your app design and table structure. Otherwise your app will be slow and laggy because it needs to do numerous work to filter and join the data from different tables.

Use server-side views

Views are probably the most common tool to help balance these goals. They present a single table structure for queries, prefilter data for what you need in the query, and enable lookups and joins to other tables. Because the filters, lookups and joins for the view are computed on the server, both the payload and client-side compute are minimized.

Avoid too many lookups on a gallery

A gallery can display many records from a data source. But sometimes, you need to show additional information from another data source that is related to the original one. For example, you have a gallery that shows a list of customers, and you want to show the name of the salesperson who is assigned to each customer. The salesperson's name is stored in a different data source than the customer's information. To show the salesperson's name, you need to use a lookup function that finds the matching record in the other data source. This expands the original table with the lookup values.

However, expanding the table can be very slow if you have many records and many lookups. For each record in the gallery, the app needs to run a separate query to the other data source and get the lookup value. This means that the app may need to run many queries for each record, which can take a long time and affect the app performance. This anti-pattern is sometimes known as "N squared, (n^2)" or an "N+1" problem.

Use StartsWith or Filter

Power Fx provides several ways to search data. In general, use an expression that leverages an index like **StartsWith** or **Filter** instead of one that reads the entire table like **In**. The In operator is fine for in-memory collections or if the external data source table is very small.

Consider duplicating data

Sometimes data is slow to access in a query because it is stored in a different location or format. To make the query faster, you can copy the slow data and store it locally in a table that is fast and easy to query. However, this means that the local data may not be the most updated version of the original data. Then run another process to update the local data periodically. This process can be a Power Automate flow, a plugin, a stored procedure, or any other method that can move data from one place to another.

The frequency requirement of updating the local data depends on your business needs. How fresh does the data need to be for your app? For example, suppose you work for Contoso, a company that sells bicycles. The list of available bicycles is stored in a Products database that you can access through an API in a custom connector. But say the API call is slow, and so you decide to copy the product data and store it locally in a table. Then you create a view that combines your table with other relevant data for your app. You also create a Power Automate flow that runs every day and updates your table with the latest product data from the API. Then your app can query the local data faster, and the data is only one day old at most.

Duplicating data is a common type of technique in enterprise-grade applications to ensure good performance. You can use Dataverse plugins, stored procedures, or data movement to duplicate data into a single table that is optimized for querying. The key question is: how up to date must this data be? If you can afford some delay, you can use this technique to speed up your app.

Suggestions

To achieve this goal, consider the following questions and suggestions:

1. How important is it for a customer to see the data value in a gallery or data grid? Would it be acceptable to first select a record and then show the data in a form?
2. Can a view do the prework necessary to see data in the right format?
3. Are you using an "IN" operator where a "StartsWith" will work?
4. How current does your data need to be? Is there a data duplication strategy you can use to get your query to work over a single table by default?

Optimize app or page load for peak performance

Article • 01/05/2024

One of the key factors that shape a user's perception of an app is how quickly it opens and becomes functional. Therefore, prioritizing this goal is crucial in building a performant app. To achieve optimal app performance, there's three main areas that require attention:

1. Load data fast
2. Efficient calculations
3. Minimizing required resources

Each of these areas has several common anti-patterns.

Load data fast

Follow these guidelines to achieve fast data loading apps.

Avoid directly populating a collection with large amounts of data

Sometimes authors use ClearCollect() to copy data from a server to a collection in their app. This practice is a work-around for delegation limitations in the source or because they plan to use collections in the app for other purposes. Using ClearCollect() can potentially increase the speed of the app when the collection is later utilized. However, it's important to exercise caution while implementing it. Using ClearCollect in this manner can lead to slower app load times or when navigating between pages. ClearCollect() must finish before you can see the data in a gallery or a table. This step can take a long time if there's lots of data or if you use this approach for too many data sources. Collections are best used for situations where the data is small and you need to do many calculations on the collection. For example, a good use of collections is an Online order basket. The customer may update and remove items several times before choosing to commit the order. Additionally, you may augment the collection with more data items like potential discounts, highlights, etc. Data that is 'read-only' should be accessed natively - without bringing it into a collection.

Consider avoiding calling Power Automate to populate a collection

This issue is a slight variation of the previous section. Sometimes authors also use Power Automate to populate their collection in Power Apps. There's approximately a 0.6-second performance cost to instantiate Power Automate. Power Automate must be independently launched each time it's called. It must allocate memory, get situated with the right components, and be ready to run. As with the above advice, one or two calls to Power Automate might not be an issue depending on your app. But, almost universally, the worst performing apps overuse this approach. The performance cost can add up quickly and ruin the performance of your app.

Avoid using SaveData() and LoadData() as a full offline scenario

Some authors use ClearCollect() and then SaveData() to store data for general purpose offline use. You can use SaveData() to save the collection to your device, and LoadData() to load it when you're offline. However, this approach isn't recommended for instances where there's a large amount of data or if the data is complex. It makes your app slower because it has to wait for ClearCollect() to finish before it can show the data. You should only use SaveData() and LoadData() for small and simple data scenarios such as preferences and short lists. A better way to work with large amounts of offline data is to use the Power Apps offline feature that works with Dataverse. This feature can handle larger and more complex data more efficiently.

Use Explicit column selection

Explicit column selection is on by default. However, some authors turn this feature off. The issue is that with Explicit column selection (ECS) turned on, columns are sometimes not retrieved from the data source if the data is first retrieved into a collection. As some tables may have many columns, ECS automatically computes which columns are necessary to retrieve based on their usage in controls (for example, galleries and forms.) As some tables can many columns, reducing the size of the download can speed up performance. Some tables can have a hundred columns or more. If your app only needs to use 10 columns, and you bring down all the columns from a 100 column table, you are bringing down ten times as much data as you actually need.

Most issues arise when bringing data into collections. If a column is explicitly referenced in a control then ECS works well. And, ECS generally does work for collections. However, the column lineage is occasionally lost when the data moves through collections and

variables. And, and so Power Apps may lose track of the column it should retrieve. To resolve this issue, you can force Power Apps to "remember" the column by using the `ShowColumns` function. For example:

```
Power Fx

    ClearCollect(
        MyColTable,
        ShowColumns(Filter(BankAccounts, AcountNo = 32),
        "Col1",
        "Col2",
        "Col3")
    );
```

Where `Col1`, `Col2`, and `Col3` are columns you expect to be retrieved from the data source (for example, the `Account` data source).

Alternatively, you can add a hidden control to your form that references the column. This forces Power Apps to "remember" the column.

Fast calculations

Fast (or efficient) calculations are a performance goal in its own right. For more information, see Fast (efficient) calculations. However there are some common anti-patterns that can affect app load as well and so we discuss them here. Below is a list of optimizations you should consider that might affect app launch or page navigation.

Use App.Formulas

Historically many authors have put a large number of calculations in OnStart. When you place an expression in OnStart, it forces Power Apps to run that expression precisely when the app starts and before everything else. However, with the introduction of App.Formulas you can let Power Apps decide when to run an expression. Power Apps can run the formula 'Just-in-time' before it's needed. For more information, see App formulas. Use App.Formulas to split up your formula into pieces that Power Apps can arrange more efficiently for execution.

Use Concurrent

Use the Concurrent function to allow formulas to be executed at the same time. It's common to use this function to populate collections as it allows for parallel execution.

While this can provide some modest speed ups, adding many data sources can cause timing and throttling issues.

Use Enhanced performance for hidden controls

When enabled by default in all new apps created since December 2022, Power Apps doesn't render any control that isn't initially visible.

Minimize required resources

Minimize the resources required to launch your app or screen. This effort includes carefully scoping or partitioning the resources your app or screen needs. Below are several approaches to help you.

Use a low dependency start screen and eliminate unused screens.

Use a low-dependency first screen such as a welcome on your application. Create a screen that doesn't load a gallery or table or reference data. This manages the user's perception of speed and allow Power Fx to properly delay some calculations to later. If you have any unused screens, remove them.

Keep cross screen dependencies between screens low

Cross page references force the load of additional pages via references, for example, referencing controls on pages and putting into collections. Some references might be unavoidable. Centralize common references to a single page if possible so that only page is loaded.

Consider embedded media

Authors sometimes embed media in their apps to ensure fast loading. If you have embedded media consider whether or not, you're using it. If not, delete it. If you have embedded a .png file, consider substituting a .svg file which is smaller. Note that if you use a .svg, the font for the .svg must be on the client machine. Consider the embedded media resolution. Is it too high for the device it will used on?

Don't forget App.StartScreen

If you use App.StartScreen, ensure the first screen is a blank screen. Due to current packaging of the app, the first logical screen is always bundled with the app init logic and will get initialized, regardless of whether we ever navigate to it.

Consider splitting up the app

If your app is large, consider partitioning it into smaller apps. If the functionality is separate enough in different parts of your app, this approach might work. In this scenario, you create an actual separate app that you launch with parameters that include context from the first or parent app.

Suggestions

To achieve the goal of a fast app and page start, consider the following questions and suggestions:

1. Are you loading lots of data in a first screen? Can you use a different first screen?
2. Are you running many commands or Power Fx expressions at the beginning of the app load? Can you defer these commands and expressions to a later point in the application? Only get the data you actually need to start the app? 1 Can you convert expressions in App.OnStart to named formulas with App.Formulas? This allows Power Fx to decide when to actually execute the formula rather than forcing it to happen on load or navigate events.
3. Can you use a separate Power Automate flow to create a temporary table in a local data store such as Dataverse that combines data from different sources? And then access that data in your Power App?
4. For business process kick offs, can you use Server triggered actions rather than calling a Power Automate Flow?
5. Can you create a view on the server that joins the data for you?
6. If you want to use offline data in your app, can you use the Power Apps offline feature that works with Dataverse? If your data isn't in Dataverse, can you move it there?

Fast calculations

Article • 12/13/2023

Power Fx expressions are powerful and do many background calculations for you automatically. While Power Fx automates many things for you, it's possible to fine-tune your calculations so there as fast as possible.

Data retrieval

Use Explicit column selection

The Explicit Column Selection (ECS) feature is enabled by default for all new apps. If it isn't enabled for your app, you should enable it. ECS automatically reduces the number of columns retrieved to only the ones that are used in the application. If ECS isn't enabled, you might be retrieving more data than you need, which can affect performance. Occasionally, when an app pulls data in through collections, the original lineage or source of a column can be lost. We don't know if it's being used and we drop it using ECS. You can usually force ECS to work for a missing column by using the PowerFx expression **ShowColumns** after a collection reference or by using it in a control.

Use images on galleries, tables, and forms carefully

Use Dataverse thumbnail versions of images for galleries and tables. Dataverse thumbnails are small about 1 kilobyte and are stored inline as part of the record, and are useful and fast for display on controls that show collections. All other image references including all SharePoint images require a separate call and shouldn't be placed on a gallery or table. Place images that require a separate call on detail forms. Consider never showing a full image by default. Full detailed images can be useful and important to users. However, you can make these images available to users through an explicit user action, for example, a button or navigation to a separate page. SharePoint has a range of intermediate sized images you can use for use on a form short of the full image. Dataverse only has two sizes: Thumbnail and Full.

Calculations

Split up formulas with App.formula

The use of App.formulas and named formulas can help with the speed of app load and page navigation because it allows Power Fx to decide when to evaluate a formula. That means it doesn't have to necessarily evaluate it in OnStart. In addition, named formulas can generally help speed as well. In particular if you have a long script, breaking it up into named formulas allow for more efficient calculations as Power Fx can schedule the work and it enables reuse. For more information, see App formulas.

Use Concurrent

Use the Concurrent function to allow formulas to be executed at the same time. Carefully choose where concurrent is used. It can provide some modest speed ups but if you're running items that depend on each other it can cause timing and throttling issues.

Defer significant updates to a nonblocking UI step

Large updates to a data source may take a while to complete. But users expect the UI to return control to them quickly. Tasks may be either sequential where the update must finish before the user can take another actions or asynchronous (the update can finish separate of user actions.)

An example of a time-consuming synchronous task is confirming a seat at a concert. For most time-consuming synchronous tasks like this, it’s common to put up a progress bar. This UI actually blocks the user but ensures that the task is complete before other UI elements are updated. This approach may not work for your application. Businesses normally handle longer sequential steps as an explicit business step. You're approved to go the next step via a business process signal. An example is an approval. An approval may come quickly or may be delayed. In the UI you can signal that the process is complete several ways. You can enable a button, show a message, send e-mail, or enable a part of the UI such as a menu item.

An example of an asynchronous task is the completion of an order. A customer updates an order basket, works through their order and then places the order. But several updates must happen before the customer is given a confirmed ship date. In this example, the Ship Date isn't something you can easily provide right away. , you can defer this part of the update to an e-mail that is sent to the customer later.

For synchronous tasks, you'll often use the code in Power Apps for UI blocking tasks. For instance, the code waits until it gets a return value and then releases the progress bar. It is best to minimize these types of situations. But for tasks that use an explicit business

step or asynchronous tasks it's common to use an external service to complete the task such as a Dataverse action, stored procedure, or a Power Automate flow.

Place 'ForAll' appropriately

If you have an expression with ForAll and collect that looks like this:

```
Power Fx

ForAll(x, Collect(y, { … }))
```

Then, invert this to

```
Power Fx

Collect(y, ForAll(x, { … }))
```

In the first pattern, any dependent rule on collection y is notified of changes and evaluated for each iteration of x. In the second pattern, these rules are only evaluated once.

Consider avoiding references to Gallery.AllItems

When working with Power Apps, it’s best to avoid referencing Gallery.AllItems unless you need out user values. This is because every time AllItems is read, a new output table is generated. Instead, use Gallery.AllItemsCount if you just want to know how many items are loaded.

Carefully use Gallery.TemplateSize

To ensure that flexible-height galleries are rendered correctly, it’s important to set a reasonable default size. Initially, we try to render as many rows as possible based on this value. If you set the default size to 0, we try to render everything, except for a few edge cases. If you’re using a formula, make sure to set a minimum value for when the formula might evaluate to 0. For example, you could use Max (20, varFoo + rectBar.Height). This way, if varFoo and rectBar.Height aren’t yet available, we at least use a reasonable value of 20.

Note DelayOutput especially for search

There's one second delay before the changes is detected, which allows you to complete the typing instead of detecting the changes for every typing.

Other performance considerations

Article • 12/11/2024

In addition to the four key performance principles, there are several other possible reasons for poor performance typically due to external factors.

Consider the differences in Client browsers, devices, and locations

Canvas apps can be used on different devices, browsers, and locations with varying network conditions. As the Power Apps client is executed, be sure to use modern, updated, and supported browsers. The performance of an app might vary when loading large sets of data on different platforms like iOS or Android. This variation happens because of different network request limitations on each platform. For example, the number of concurrent network requests allowed differs by platform. These differences can have a major impact act on the data load time for large datasets.

Consider the differences in Geographic location of the on-premises data gateway and environment

Users can access canvas apps globally. However, we recommend that you locate the data source near most of your users. For example, when your app accesses your on-premises data gateway, it's best to place the gateway near the users who is accessing the app most frequently.

General Server-side issues

Poor performance might be caused by problems at the server source of the data. This can happen for various reasons. You can use the monitoring tool to assess the specific issue by measuring the data call timings.

Possible bottlenecks issues in the data source

There are many possible causes of bottlenecks in the data source. Usually, a few tables in the data source are at the center of activity for many queries. Queries might be slow if:

- The data source is missing or has incorrect indexes.
- The query is joining extra-ordinary large amounts of data on the server.
- The query requires a table SCAN, for example, **In** operator instead of using an index like **StartsWith**.
- The back-end machine hosting the data source is low on resources.
- The back-end SQL instance has blockings, deadlocks, or resource contention.
- The on-premises data gateway is unhealthy.
- The on-premises data gateway should be scaled out.

When these problems occur, tune the back-end data source to avoid slowing the app's performance.

Specific data sources

Azure SQL Database

It's important to select the right tier for your business requirements. For more information, see Azure SQL Database documentation. A lower tier has some limitations and constraints. From a performance perspective, CPU, I/O throughput, and latency are important. Therefore, we recommend that you check the performance of the SQL database periodically, and check whether resource usage exceeds the threshold. For example, on-premises SQL Server normally sets the threshold of CPU usage to around 75 percent.

SharePoint

The SharePoint connector can be used to create apps that use data from SharePoint Lists. Here are some common performance problems and resolutions for SharePoint:

Avoid too many dynamic lookup columns: SharePoint supports various data types, including dynamic lookups such as Person, Group, and Calculated. If a list defines too many dynamic columns, it takes more time to manipulate these dynamic columns within SharePoint before returning data to the client running the canvas app. To avoid this, don't overuse the dynamic lookup columns in SharePoint. For example, use static columns to keep email aliases or people's names.

Carefully use the picture column and attachment: The size of an image and an attached file can contribute to a slow response while retrieving to the client. Review your list, and ensure that only necessary columns have been defined. The number of columns in the list affects the performance of the data requests. This is because the matched records, or the records up to the defined data row limits, are retrieved and transmitted

back to the client with all the columns defined in the list—even if the app doesn't use all of them.

Consider breaking up large lists: If you have a large list with hundreds of thousands of records, consider partitioning the list or splitting it into several lists based on parameters such as categories, or date and time. For instance, your data might be stored in different lists on a yearly or monthly basis. In such a case, you can design the app to let a user select a time window and retrieve the data within that range.

Dataverse

When you use Microsoft Dataverse as the data source, data requests go directly to the environment instance without passing through Azure API Management. So, it tends to be faster than other data sources. For more information, see Data call flow when connecting to Microsoft Dataverse.

Check custom table configurations: If custom tables are used in Dataverse, additional security configuration might be required for users to view the records with canvas apps. For more information, see Security concepts in Dataverse, Configure user security to resources in an environment, and Security roles and privileges.

Excel

The Excel connector allows a canvas app to connect to a table in an Excel file. However, this connector has limitations compared to other data sources. For example, it restricts the canvas app to loading data from the table only up to 2,000 records due to limited delegable functions. To load more than 2,000 records, partition your data in different data tables as other data sources.

Use the new Excel connector: Be sure to use the new Excel connector - Excel business online. It allows for multi-user access and handles contention issues better.

Only use the columns you need from large data lists in Excel: An app can perform slowly if the Excel file that has too many data tables or data tables that contain an immense amount of data over several columns. To ensure that your app isn't affected by this problem, define only the columns you need on the data table in an Excel file.

Note the limitations of Excel as a database. Excel isn't a relational database system : Any changes from an app are managed by Excel in the same way as if a user were changing data in an Excel file directly. If the app has a high number of reads, but fewer update operations, it might perform well. However, if the app requires heavy transactions, it can adversely affect the performance of the app. There's no specific

threshold value for the number of transactions. It also depends on the data being manipulated. Several other aspects also affect the app's performance, such as network overhead or the user's device.

Consider the differences in geographic location: The geographic location of the data and its distance from customer locations can be a performance issue. This issue can be amplified if a mobile client has limited bandwidth.

Enable Preload app for enhanced performance

You can optionally preload your app to increase performance.

1. Sign in to Power Apps.
2. On the left navigation pane, select **Apps**.
3. Select the app and then select **Settings** on the command bar.
4. In the **App settings** pance, set the **Preload app for enhanced performance** to **Yes**. The app will then pre-load.
5. For the changes to take effect for apps embedded in Teams, remove and add your app into Teams again.

> **Note**
>
> This makes the compiled app assets accessible via unauthenticated endpoints to enable loading them before authentication. However, users can still only use your app to access data via connectors only after authentication and authorization completes. This behavior ensures that the data an app retrieves from data sources won't be available to unauthorized users. Compiled app assets include a collection of JavaScript files containing text authored in app controls (such as PCF controls), media assets (such as images), the app name, and the environment URL the app resides in.
>
> In general, apps should retrieve media and information from data sources, through connections. If media and information must be added to the app, without coming from a connection, and it is considered sensitive you may want to disable this setting. Note, disabling this setting will result in users waiting a bit longer to access an app.

Build large and complex canvas apps

Article • 04/11/2023

Most of the articles in this section of the documentation cover the runtime performance of apps as experienced by the people who use them. This article covers app performance as experienced by the people who make them.

As apps become larger and more complex, Power Apps Studio needs to load and manage larger numbers of controls, formulas, and data sources, all with interdependencies that grow exponentially. Power Apps Studio can take longer to load, and features such as IntelliSense and color coding can lag. Use the recommendations that follow to better work with large and complex apps in Power Apps Studio. They can also help to improve your apps' runtime performance.

The examples in this article use the Hospital Emergency Response sample solution.

Use App.Formulas instead of App.OnStart

> **Tip**
>
> You can use **With** function and canvas component custom output properties as an alternative to named formulas.

The best way to reduce loading time for both Power Apps Studio and your app is to replace variable and collection initialization in **App.OnStart** with named formulas in **App.Formulas**.

Let's look at the following example, which uses App.OnStart.

Power Fx

```
// Get the color of text on a dark background.
Set(varColorOnDark,RGBA(0, 0, 0, 1));

// Get the color of the menu icons.
Set(varColorMenuIcon,"#0070a9");

// Get the styles for a form.
Set(varFormStyle,
    {
        DataCard: { Height: 50 },
        Title: { Height: 50, Size: 21, Color: varColorOnDark },
        Control: { Height: 50, Size: 18 },
        Label: { Size: 18, Color: varColorOnDark }
```

```
    }
);

ClearCollect(
    FacilitiesList,
    ForAll(
        Facilities,
        { Name: 'Facility Name', Id: Facility }
    )
);
If(
    Not IsBlank(Param("FacilityID")),
    Set(ParamFacility,
        LookUp(
            FacilitiesList,
            Id = GUID(Param("FacilityID"))
        ).Name
    );
);
```

Because they're a sequence of statements, your app must evaluate these **Set** and **Collect** calls in order before it can display the first screen, which makes the app load more slowly. And because the entire **App.OnStart** must be considered as a whole, order preserved, and errors aggregated before returning the final result, the formula is complex for Power Apps Studio to analyze.

There's a better way. Use **App.Formulas** instead and define these variables and collections as named formulas, as in the following example.

Power Fx

```
// Get the color of text on a dark background.
varColorOnDark = RGBA(0, 0, 0, 1);

// Get the color of the menu icons.
varColorMenuIcon = "#0070a9";

// Get the styles for a form.
varFormStyle =
    {
        DataCard: { Height: 50 },
        Title: { Height: 50, Size: 21, Color: varColorOnDark },
        Control: { Height: 50, Size: 18 },
        Label: { Size: 18, Color: varColorOnDark }
    };

FacilitiesList =
    ForAll(
        Facilities,
        { Name: 'Facility Name', Id: Facility }
    );
```

```
ParamFacility =
    If( Not IsBlank(Param("FacilityID")),
        LookUp(
            FacilitiesList,
            Id = GUID(Param("FacilityID"))
        ).Name,
        Blank()
    );
```

This change may seem small, but it can have a huge impact. Because each named formula is independent of the others, Power Apps Studio can analyze them independently, effectively splitting a large **App.OnStart** into smaller pieces. We've seen Power Apps Studio load time drop by as much as 80% with this change alone.

Your app also loads faster because it doesn't have to evaluate these formulas until it needs the result. The first screen of the app is displayed immediately.

Named formulas can't be used in all situations because you can't modify them or use them with **Set**. Some situations require the use of a state variable that can be modified. **Set** is perfect for these situations and you should continue to use it. But, more often than not, you're using global variables in **OnStart** to set up static values that don't change. In those cases, a named formula is the better choice.

Since named formulas are immutable, the prefix `var` (short for "variable") as a naming convention is no longer appropriate. We didn't change the names in this example because it would require changes to the rest of the app to match.

It's tempting to place a named formula in **App.OnStart**, but don't. They don't belong there. As an **On** behavior property, **App.OnStart** evaluates each of its statements in order, creating global variables, and talking to databases *only once, when the app is loaded*. Named formulas are formulas that define how to calculate something *whenever needed* and are always true. It's this formula nature that allows them to be independent and allows the app to finish loading before they're evaluated.

Split up long formulas

App.OnStart is one of the worst offenders for long formulas and definitely where you should start, but it isn't the only case.

Our studies have shown that nearly all apps with a long load time for Power Apps Studio have at least one formula of more than 256,000 characters. Some apps with the longest load times have formulas of more than 1 million characters. Formulas that long put a significant strain on Power Apps Studio.

To make matters worse, copying and pasting a control with a long formula duplicates the formula in the control's properties without it being realized. Power Apps is modeled after Excel, where multiple copies of a formula are common. However, in Excel formulas are limited to one expression and are capped at 8,000 characters. Power Apps formulas can grow much longer with the introduction of imperative logic and the chaining operator (`;` or `;;`, depending on locale).

The general solution is to split long formulas into smaller parts and reuse the parts, as we did in the previous section when we changed **Set**/**Collect** statements in **App.OnStart** to named formulas in **App.Formulas**. In other programming languages, reusable parts are often referred to as subroutines or user-defined functions. You can think of named formulas as a simple form of user-defined function with no parameters or side-effects.

Use named formulas everywhere

In the earlier example, we used named formulas as a replacement for **App.OnStart**. However, you can use them to replace a calculation anywhere in an app.

For example, one of the screens in the Hospital Emergency Response sample solution includes this logic in **Screen.OnVisible**:

Power Fx

```
ClearCollect(
    MySplashSelectionsCollection,
    {
        MySystemCol: First(
            Filter(
                Regions,
                Region = MyParamRegion
            )
        ).System.'System Name',
        MyRegionCol: First(
            Filter(
                Regions,
                Region = MyParamRegion
            )
        ).'Region Name',
        MyFacilityCol: ParamFacility,
          MyFacilityColID:  LookUp(
            FacilitiesList,
            Id = GUID(Param("FacilityID"))
        ).Id
    }
);
```

This formula can be split into a set of named formulas. It also makes the formula easier to read.

Power Fx

```
MyRegion = LookUp(
                    Regions,
                    Region = MyParamRegion
           );

MyFacility = LookUp(
                    FacilitiesList,
                    Id = GUID(Param("FacilityID")
            );

MySplashSelectionsCollection =
    {
        MySystemCol: MyRegion.System.'System Name',
        MyRegionCol: MyRegion.'Region Name',
        MyFacilityCol: ParamFacility,
        MyFacilityColID:  MyFacility.Id
    };
```

We extracted **ParamFacility** as a named formula earlier when we moved most of the **Set** calls from **App.OnStart** to named formulas in **App.Formulas**.

Named formulas are evaluated only when their values are needed. If the original intent of using **Screen.OnVisible** was to defer work until the screen is shown, then the work is still deferred as global named formulas in **App.Formulas**.

Use the With function

You can also use the **With** function in a formula to split up logic. Create a record in the first parameter with the values you want to use as fields, and then use those fields in the second parameter to calculate the return value from **With**. For example, the previous example can be written as just one named formula:

Power Fx

```
MySplashSelectionsCollection =
    With( { MyRegion: LookUp(
                            Regions,
                            Region = MyParamRegion
                        ),
            MyFacility: LookUp(
                            FacilitiesList,
                            Id = GUID(Param("FacilityID")
                        )
```

```
        },
        {
            MySystemCol: MyRegion.System.'System Name',
            MyRegionCol: MyRegion.'Region Name',
            MyFacilityCol: ParamFacility,
            MyFacilityColID:  MyFacility.Id
        }
    )
```

One downside to using **With** this way is that `MyFacility` can't use `MyRegion` because they're defined in the same **With** function, a problem that's not present with named formulas. One solution is to nest **With** functions and use the **As** keyword to name the record for each to give easy access to all the **With** variables.

Use canvas components

Canvas components are most often used to create a UI control that can be placed on the canvas just like a control. You can also use them without placing them in the UI to perform calculations with custom output properties as an alternative to named formulas. Canvas components are easy to share across apps with component libraries and, unlike named formulas, are fully supported. However, they're harder to configure and use than named formulas.

To split logic:

1. In Power Apps Studio, switch to the **Components** tab in the **Tree view**.
2. Create a new component.
3. In the **Properties** pane, turn on **Access app scope**.
4. Add a custom property.
5. Set the **Property type** to **Output** and the **Data type** as appropriate.
6. Select **Create**.
7. In the property picker next to the formula bar at the top of the screen, select the new property.
8. Write the formula for the logic to split and reuse.

To use the logic:

1. Switch to the **Screens** tab in the **Tree view**.
2. In the **Insert** pane, expand **Custom** and insert your component.
3. To calculate a value with the property, use *ComponentName.PropertyName*.

Use Select with a hidden control for imperative logic

Imperative logic is used to modify state with **Set** and **Collect**, notify the user with **Notify**, navigate to another screen or app with **Navigate** and **Launch**, and write values to a database with **Patch**, **SubmitForm**, or **RemoveIf**.

Named formulas and canvas component custom output properties don't support imperative logic. A common way to split up imperative logic is to use the **OnSelect** property of a hidden control.

1. Add a **Button** control to a screen.
2. Set the **OnSelect** property to the imperative logic you want to execute.
3. Set the **Visible** property to false, since there's no need for the user to see or interact with it.
4. Call `Select( Button )` when you want to execute the imperative logic.

For example, one of the screens in our sample has the following **OnSelect** property on a **Button** control. (This simple example is for illustration purposes only. Normally, you would only use this technique for longer formulas.)

Power Fx

```
btnAction_17.OnSelect =
    Trace("Feedback Screen: Submit Button",TraceSeverity.Information);
    If(
        // Proceed if all forms are validated.
        And(
            FormFeedback.Valid
        ),

        // Set the updates to static variables.
        Set(updatesFeedback,Patch(Defaults('App Feedbacks'),
FormFeedback.Updates));
        // Submit the first form. Subsequent actions can be found in the
OnSuccess.
        SubmitForm(FormFeedback);
        ,

        Notify("Please complete all fields before proceeding",
               NotificationType.Warning,2000)
    );
```

To split this logic into parts, we can put portions onto separate **Button** controls and **Select** them from the original:

Power Fx

```
btnTrace.OnSelect =
    Trace("Feedback Screen: Submit Button",TraceSeverity.Information);
```

```
btnSubmit.OnSelect =
    If(
        // Proceed if all forms are validated.
        And(
            FormFeedback.Valid
        ),

        // Set the updates to static variables.
        Set(updatesFeedback,Patch(Defaults('App Feedbacks'),
FormFeedback.Updates));
        // Submit the first form. Subsequent actions can be found in
OnSuccess.
        SubmitForm(FormFeedback);
        ,

        Notify("Please complete all fields before proceeding",
               NotificationType.Warning,2000)
    );

btnAction_17.OnSelect =
    Select( btnTrace );
    Select( btnSubmit );
```

This technique only works on the same screen. Other techniques that are slightly more complicated work across screens, like using the **Toggle** control, setting **OnCheck** to the logic you want to run, and setting **Default** to a global variable and then toggling the global variable with `Set( global, true ); Set( global, false )` at the point you want to run the logic.

In this example, some logic splitting had already been done. The comment mentions that "Subsequent actions can be found in OnSuccess." This event runs imperative logic after the record has been successfully submitted, a solution specific to the **SubmitForm** function.

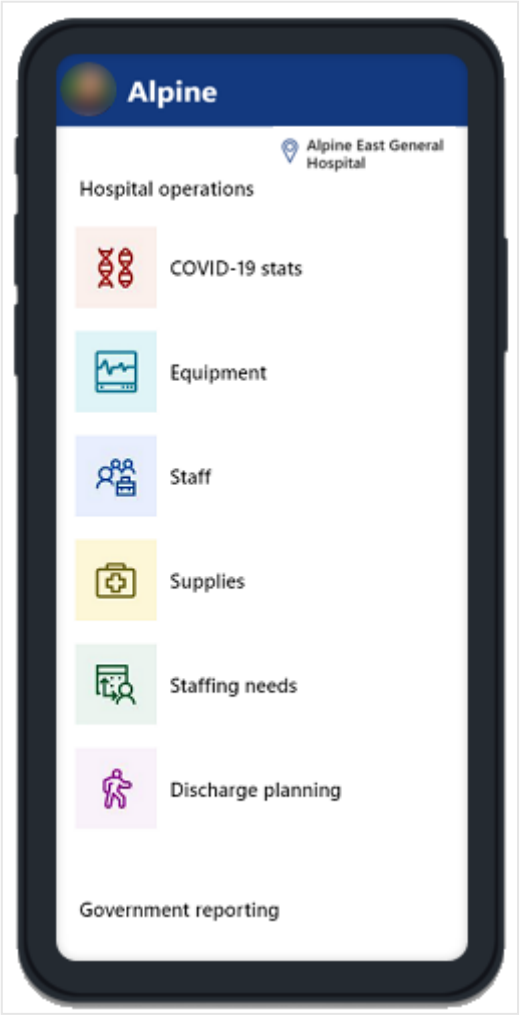
Partition the app

Some apps grow to thousands of controls and hundreds of data sources, which slows Power Apps Studio. As with long formulas, large apps can be split into smaller sections that work together to create one user experience.

Separate canvas apps

One approach is to implement sections in separate canvas apps and use the **Launch** function to navigate between the separate apps and pass needed context.

This approach was used in the Hospital Emergency Response sample solution. Separate apps manage each of the major areas of the overall app. The apps share a common switchboard component through a component library that each app shows on its startup screen:



When the user selects an area, the component uses metadata about the apps available and which app is hosting the component. If the desired screen is in this app (that is, **ThisItem.Screen** is not blank), then a **Navigate** call is made. But if the desired screen is in a different app (that is, **ThisItem.PowerAppID** is not blank), then a **Launch** function is used with the App ID of the target and the FacilityID context:

Power Fx

```
If(
    IsBlank(ThisItem.Screen),
    If(IsBlank(ThisItem.PowerAppID),
        Launch(ThisItem.URL),
        Launch("/providers/Microsoft.PowerApps/apps/" & ThisItem.PowerAppID,
               "FacilityID", Home_Facility_DD.Selected.Id)
    ),
    Navigate(
        ThisItem.Screen,
        Fade
```

```
    )
);
```

State in the original app is lost when another app is launched. Be sure to save any state before you call the **Launch** function. Write it to a database, call **SaveData**, or pass state to the target app with parameters that are read with the **Param** function.

Model-driven app with custom pages

Sections can also be implemented as custom pages. Custom pages act as a mini canvas app with a model-driven app container for navigation.

Build business logic

Article • 10/22/2024

Power Platform offers various capabilities for makers to build business logic for Power Apps. In this article, you find an overview of the key methods and offer guidance to help determine the most suitable approach building business logic for Power Apps.

Use Power Fx in your app

Power Fx is the low code functional programming language shared by Excel and Power Platform. When used with Power Platform connectors, makers can access data and create custom app logic. Power Fx supports the following characteristics:

- **Live** – Canvas apps recalculate just as Excel spreadsheets do. As users interact with the app, Power Fx is in the background making data requests and keeping the state of the app up to date with Dataverse.
- **Delegation** – Power Fx optimizes data handling by delegating operations to the server whenever possible. Functions like Filter(), Lookup(), and Search() enable server-side data filtering, ensuring that only the necessary data is retrieved to support the app's functionality and user experience. In cases where delegation isn't possible, functions run locally within the JavaScript environment of the browser.
- **Optimized for Dataverse** – Dataverse serves as the primary data storage option for Power Apps, offering direct, and low-latency access due to fewer intermediary layers. Power Fx is also compatible with Dataverse's diverse relationship types, including many-to-one and one-to-many associations.
- **Offline** – The Power Apps mobile app enables offline use of Dataverse data, allowing users to use the app in the field allowing a seamless connection. Any changes made offline are synchronized when internet connection is available. The app's predefined business logic remains operational, even without an internet connection.

Use cloud flows in your app

Power Automate is a low code workflow service built on top of the Power Platform connector ecosystem. Power Automate adds the following capabilities when building Power Apps:

- **Asynchronous** – A Power Automate cloud flow is inherently asynchronous. This means that when a flow is initiated, it's using a queuing system to manage the various subtasks. The asynchronous nature of Power Automate means makes it well-suited for longer running complex sequences of logic.
- **Detailed logging** – All flows create a record of what happened when they executed in the form of Run History providing traceability and ensuring auditing record for what happened and why.
- **Multi-connector** – Although it's possible to create multi-connector Power Apps logic, due to the live nature of Power Apps, as you increase the number of connectors performance degrades. These complex multi-connector scenarios are a great place to use Power Automate which can offload these cases from live execution in the app.

Choose between Power Fx and cloud flows for your app

We recommend using Power Fx for developing business logic in Power Apps. While it's a powerful tool, there are scenarios where integrating other tools might be more appropriate.

Low latency use cases

Power Fx excels in delivering low latency for Power Apps, making it the go to choice for developing responsive business logic. However, the actual latency experienced can vary based on the complexity of the operations and the volume of data being processed. It's crucial to understand that while Power Fx can facilitate swift interactions, the design, and objectives of your application play a pivotal role in its overall performance. For more information, see performance and optimization articles earlier in this section.

When it comes to accessing data efficiently, the combination of Dataverse and Power Fx offers the quickest solution.

For more information, see Data call flow with Microsoft Dataverse.

Complex sequences and use of multiple connectors

When dealing with complex sequences of action that span various connectors, Power Automate serves as an effective asynchronous solution to delegate processing away

from Power Apps. This asynchronous capability lets Power Apps kick off a workflow and proceed with other tasks without having to pause for a response.

Design app experience around inherent task latency

When designing user experiences, it's essential to consider the latency that comes with executing complex tasks.

There are two strategies:

1. Pause the user experience until the task finishes, providing a visual indicator of progress.
2. Offload the complex task to Power Automate, allowing the user experience to continue uninterrupted.

Power Apps coding guidelines

Summarize this article for me

Creating a simple canvas app is straightforward, but as the application's complexity grows, maintaining high code quality becomes essential. These guidelines describe standards for naming objects, collections, and variables, and provide recommendations for developing consistent, performant, and easily maintainable apps.

The guidelines offer essential guidance for developers who design, build, test, deploy, and maintain Power Apps apps in various environments, including small businesses, corporations, and government entities.

> **Tip**
>
> Use the Power CAT Toolkit to perform code reviews. The toolkit incorporates many of the coding guidelines from this documentation, ensuring that your solutions are efficient and maintainable. The toolkit automatically flags any patterns that don't adhere to these best practices, so you can address potential issues early in the development process. This proactive approach enhances the quality of your code and helps streamline the review process, making it easier to maintain high standards across your projects. Integrating the Power CAT Toolkit into your development workflow ensures that your solutions are built on a solid foundation and leads to more reliable and scalable solutions.

Power Apps and Microsoft Teams integration

09/03/2025

Microsoft Teams enables people around the world to create, collaborate, and communicate. With more than 75 million daily active users, Teams is how people are getting work done.

Power Apps can be used in four scenarios with Teams.

Expand table

Scenario	Description
Embed a canvas app as a tab app	Use the **Power Apps tab** for Teams to embed a canvas app as a tab app in Teams. The canvas app integrates business data from a wide variety of Microsoft and third-party data sources, including Dataverse.
Embed a canvas app as a personal app	Embed a canvas app as a first-class Teams personal app. The canvas app integrates business data from a wide variety of Microsoft and third-party data sources, including Dataverse.
Embed a model-driven app as a tab app (preview)	Use the **Power Apps tab** for Teams to embed a model-driven app as a tab app in Teams.
Embed a model-driven app as a personal app (preview)	Embed a model-driven app as a first-class Teams personal app.
Create apps in Teams backed by Microsoft Dataverse for Teams	Use the new Power Apps app in Teams to create canvas apps within Teams backed by Dataverse for Teams, the new built-in, low-code data platform for Teams. Dataverse for Teams empowers users to build custom apps, bots, and workflows—by using Power Apps, Microsoft Copilot Studio, and Power Automate, respectively—without ever leaving the Teams interface.

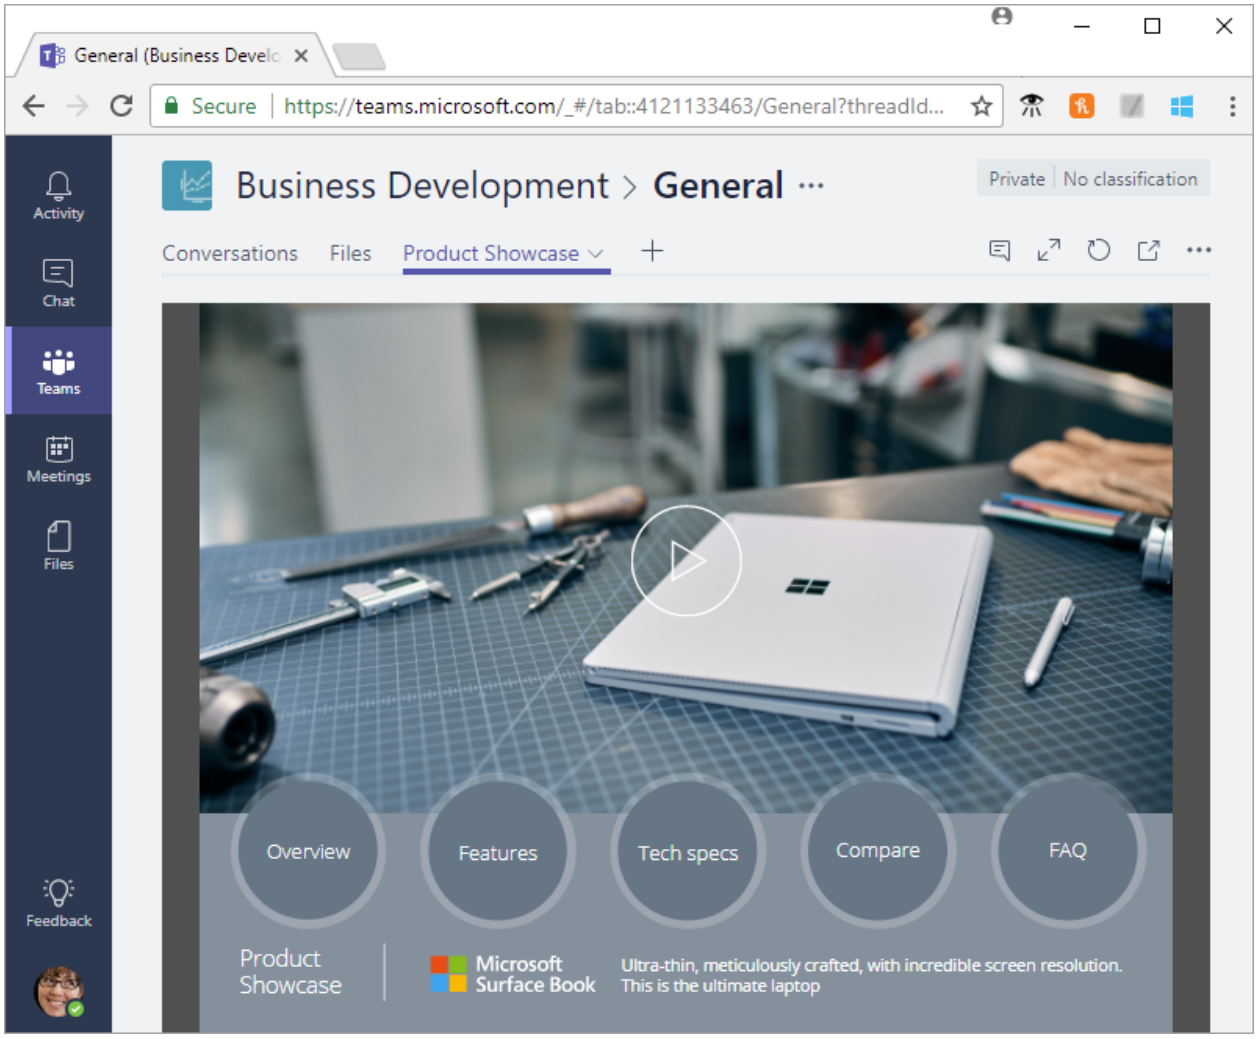
Embed a canvas app as tab app in Teams

Article • 01/30/2024

You can customize the Teams experience by adding Power Apps canvas apps to your channels in Teams using the **Power Apps** tab. In this topic, you learn how to add the Product Showcase sample app template to a Teams channel, and then open the app from that channel.



If you're not signed up for Power Apps, sign up for free before you begin.

Prerequisites

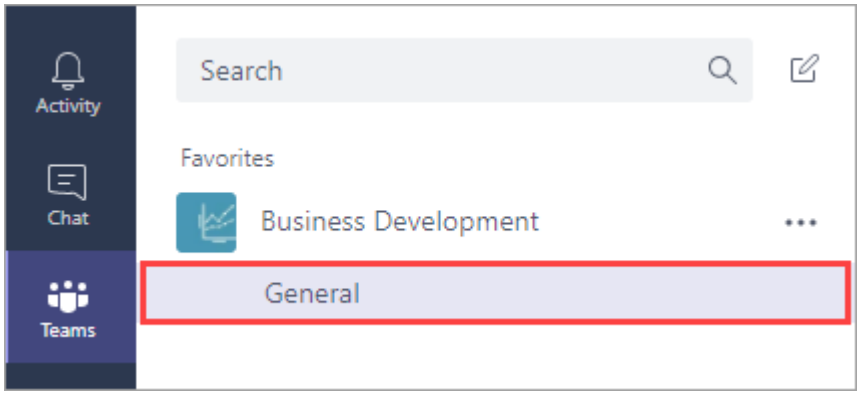
To follow this procedure, you need an Office 365 subscription and a channel in Teams.

Sign in to Power Apps

Sign into Power Apps at https://make.powerapps.com.

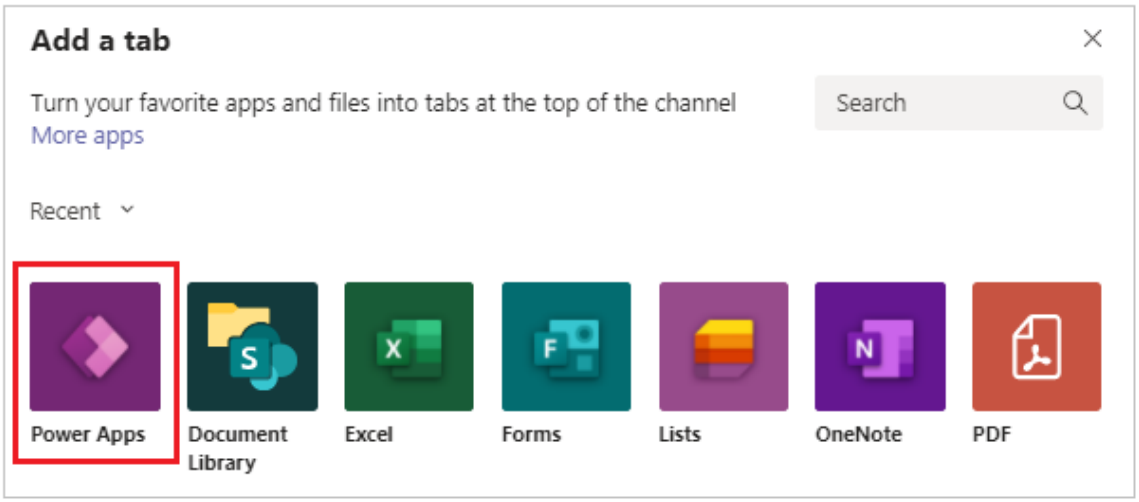
Add an app

1. In Microsoft Teams, select a team, and a channel under that team. In this example, it's the **General** channel under the **Business Development** team.

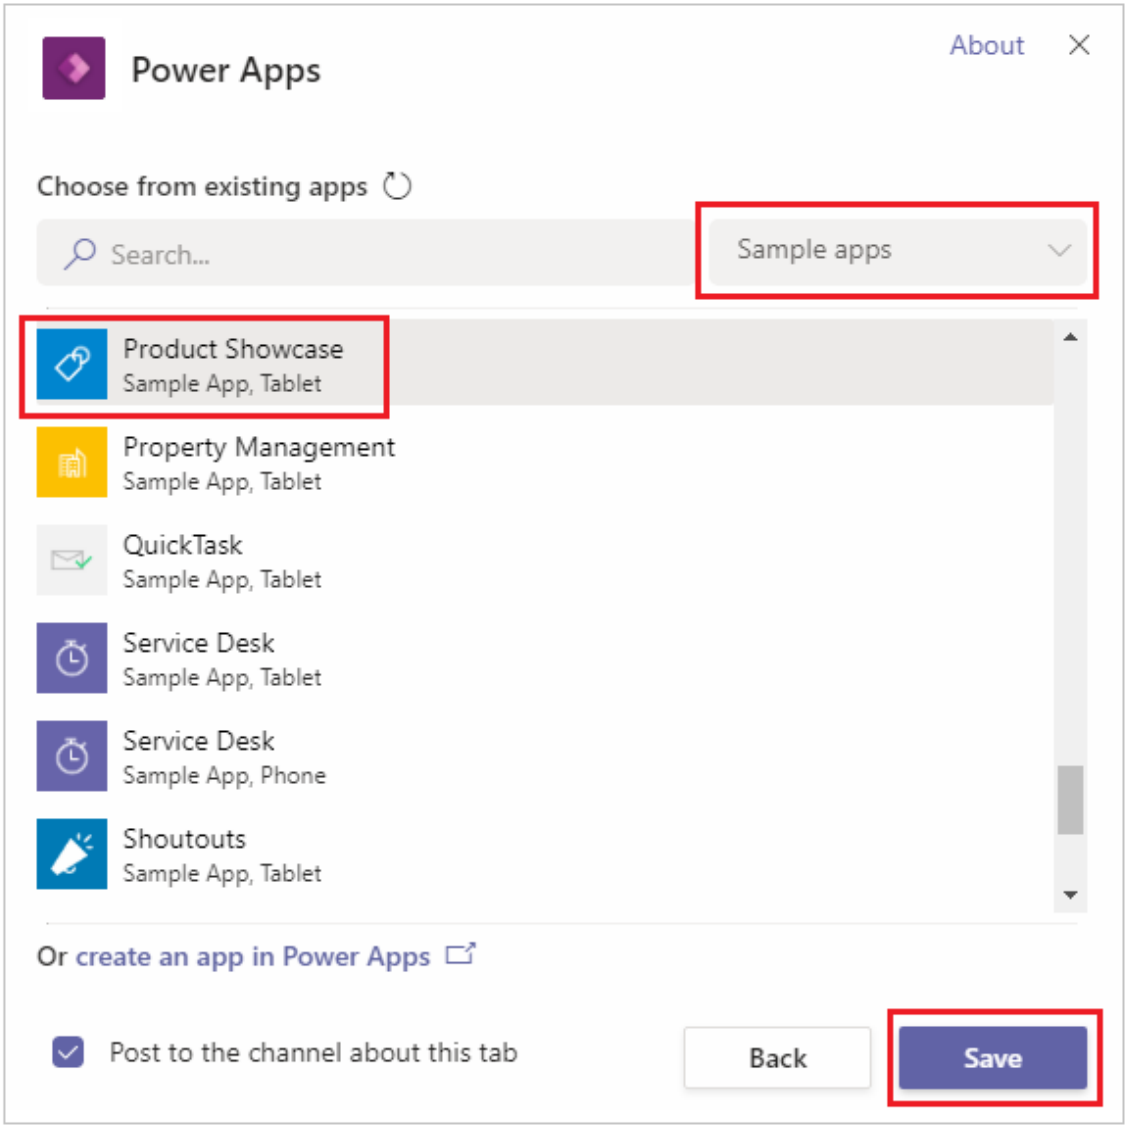


2. Choose + to add a tab.

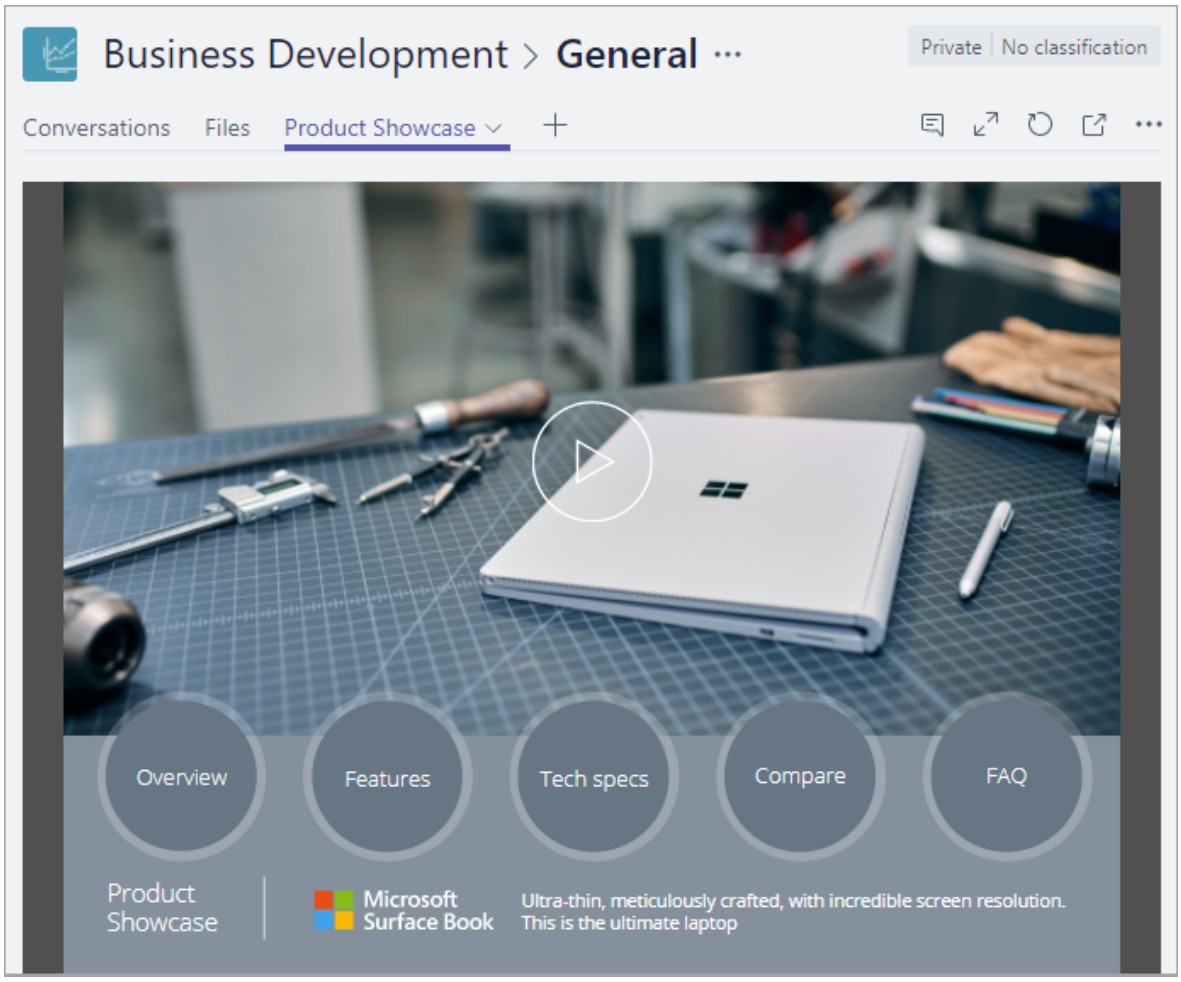
3. In the **Add a tab** dialog box, choose **Power Apps**.



4. Choose **Sample app templates** > **Product Showcase** > **Save**.



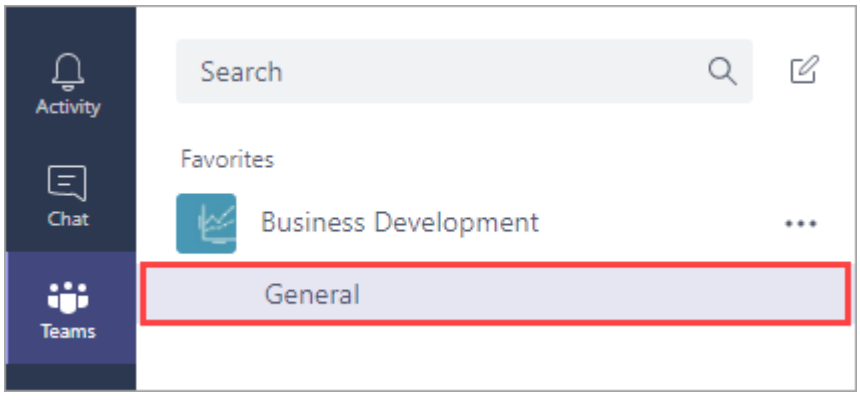
The app is now available to use in the channel.



> ⓘ **Note**
>
> You must **share** your own apps before you add them to Teams (sample app templates are shared by default).

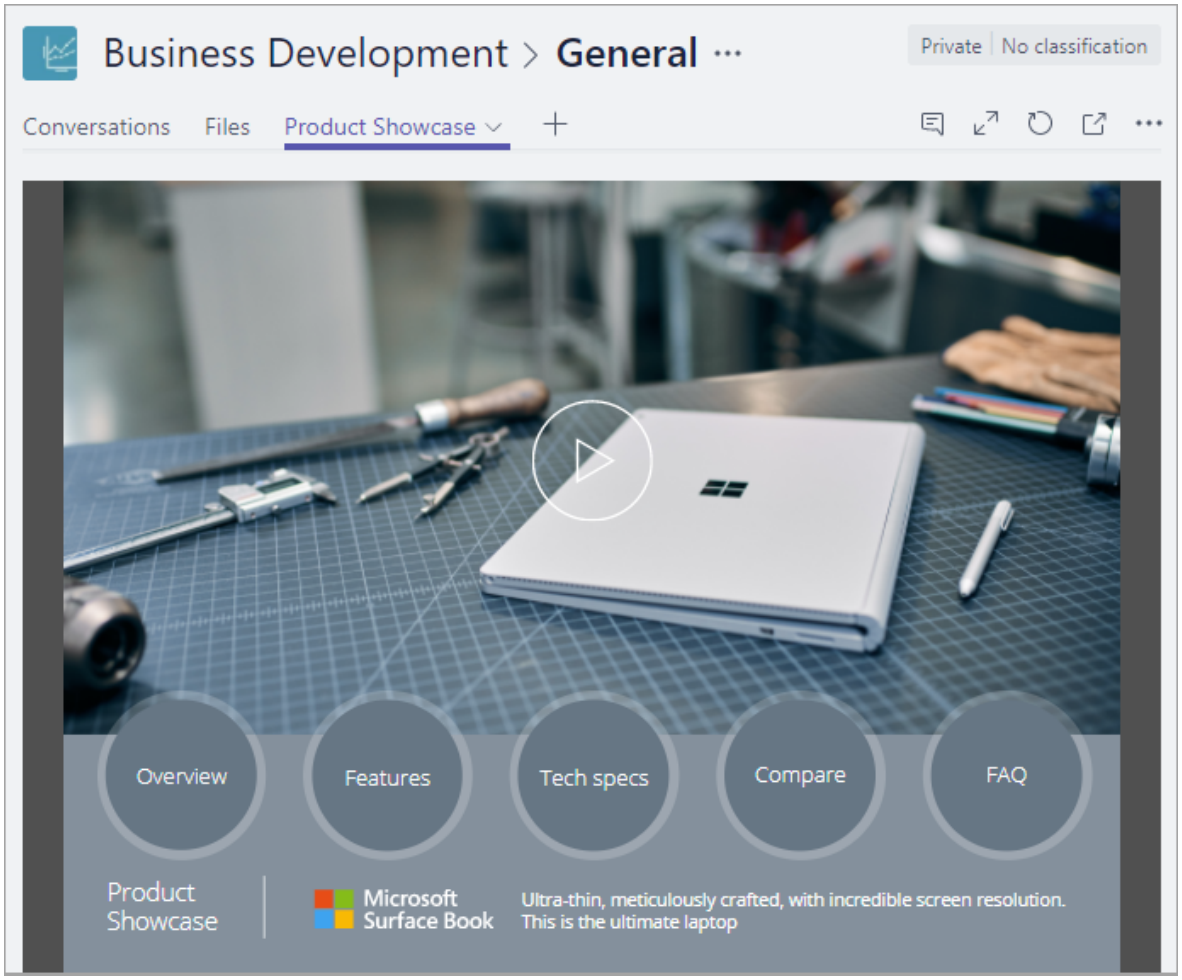
Open an app

1. In Microsoft Teams, choose the team and the channel that contains the app.



2. Choose the **Product Showcase** tab.

The app opens in the channel.



Known issues

In the desktop app for Microsoft Teams:

- Apps must load content such as images and .pdf files over a secure (https) connection.
- Not all sensors, such as **Acceleration**, **Compass**, and **Location**, are supported.
- Only these audio formats are supported: AAC, H264, OGG Vorbis, and WAV.

In the mobile app for Microsoft Teams:

- End users can't download attachments from canvas apps. As a workaround, use Microsoft Teams desktop to access the canvas app and download the attachment.

Clean up resources

To remove the app from the channel, choose the **Product Showcase** tab > **Remove**.

Embed a canvas app as personal app in Teams

08/19/2025

You can share an app you've created by embedding it directly into Microsoft Teams. When completed, users can select + to add your app to any of **your** team channels or conversations in the team you are in. The app appears as a tile under **Tabs for your team**.

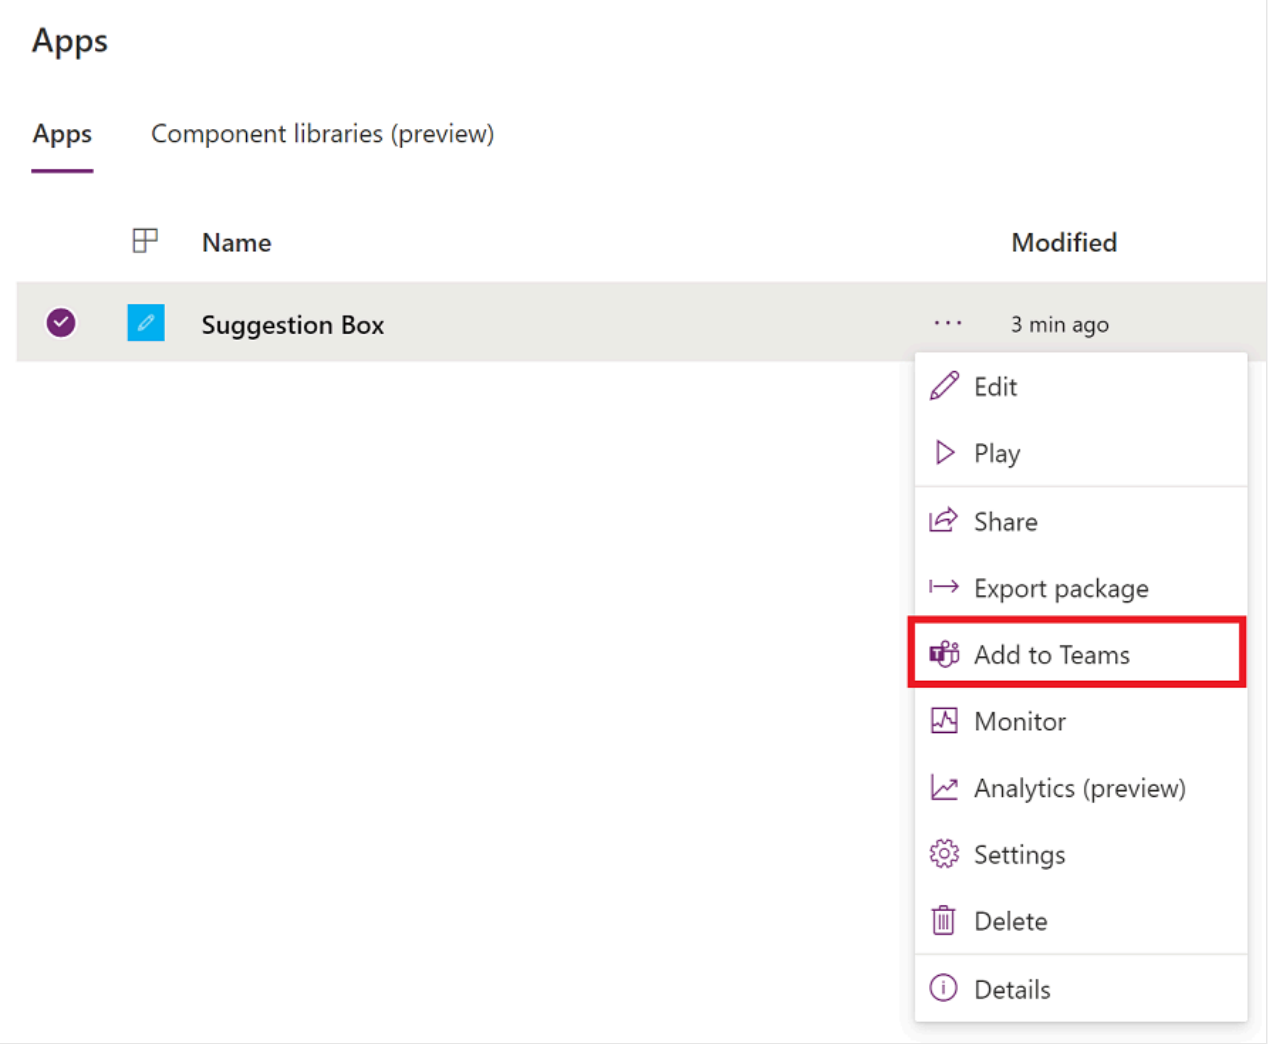
> **Note**
>
> Team custom app policies must be set to allow uploading custom apps. If you are unable to embed your app in Teams, check with your administrator to see if they've setup custom app settings.

Prerequisites

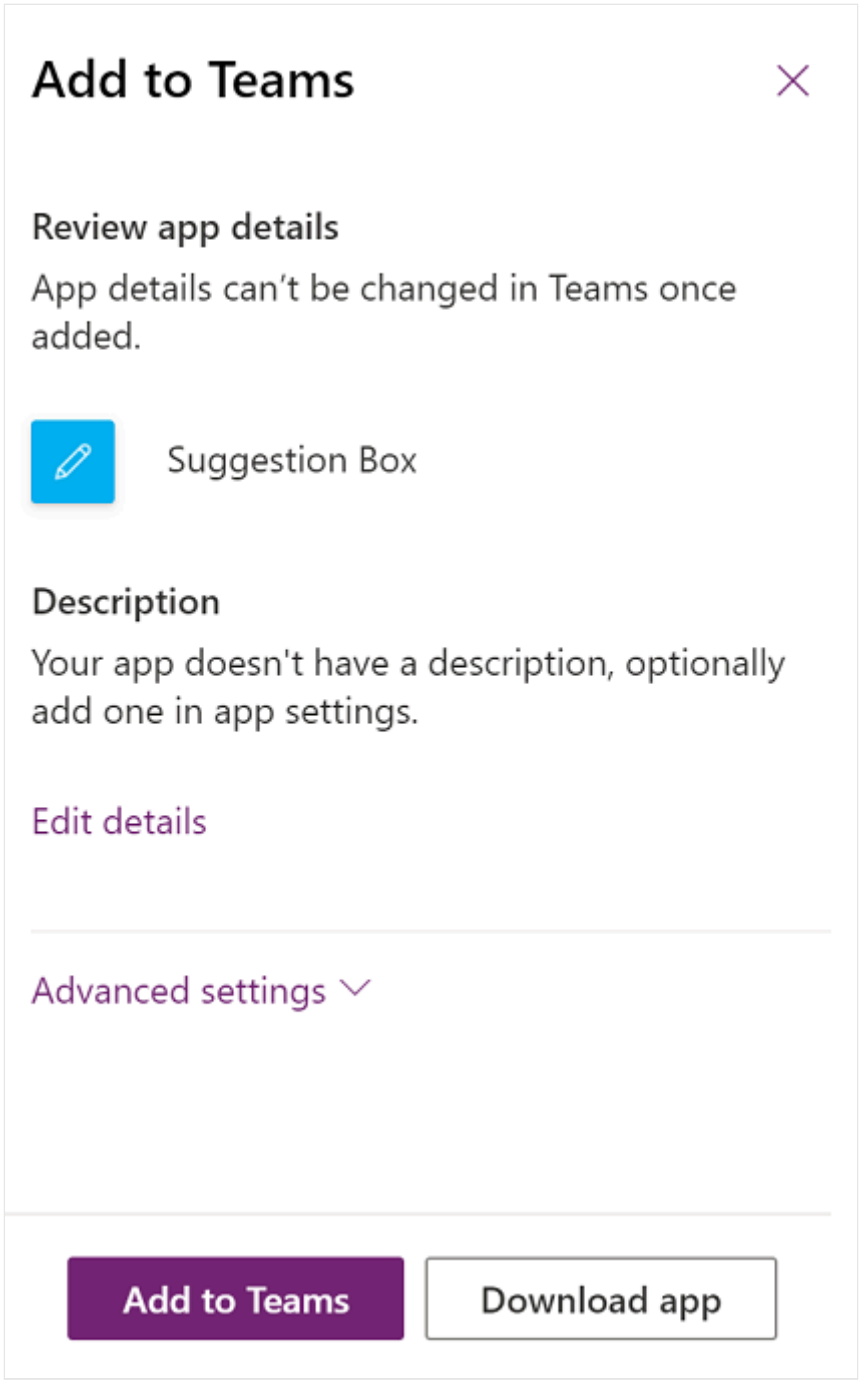
- You need a valid Power Apps license.
- To embed an app into Teams, you need an existing app created using Power Apps.

Add to Teams

1. Sign in to Power Apps, and then select **Apps**.
2. Select **More actions** (...) for the app you want to share in Teams, and then select **Add to Teams**.

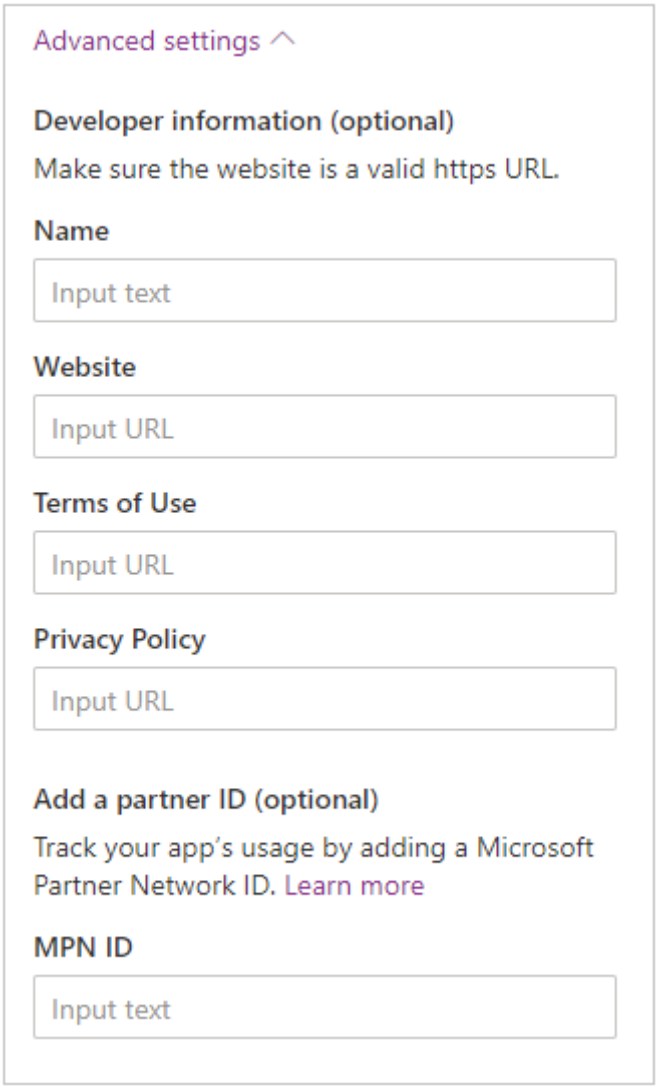


Add to Teams panel opens on the right-side of the screen.

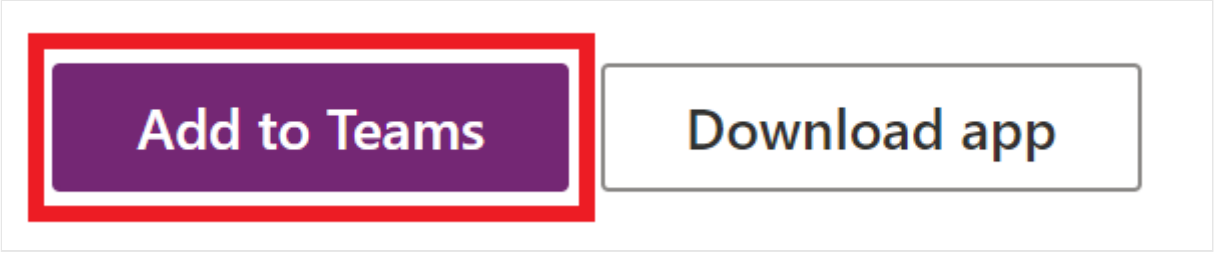


3. (Optional) If the app doesn't have any description, select **Edit details** to open the app in Power Apps Studio to add.

4. (Optional) Select **Advanced settings** to add additional details such as *Name*, *Website*, *Terms of Use*, *Privacy Policy*, *MPN ID* (Microsoft Partner Network ID).



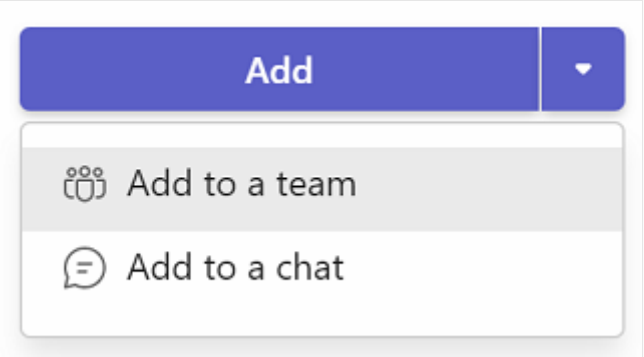
5. Select **Add to Teams** and you'll be asked to open Teams.



> **Tip**
>
> If you want, you can also choose **Download app** to download the app, and then use the steps described in Upload your app in Microsoft Teams article to upload the app to Teams.

6. Select **Open Microsoft Teams** to open Teams app, or select **Cancel** followed by **Use the web app instead** to open Teams web.

7. Select **Add**. You can also choose to add the app to a specific team using **Add to team**, or a specific chat using **Add to chat**.



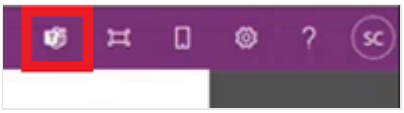
The app is now added to Teams.

> **Tip**
>
> You can also pin the app for easy access.

Add to Teams using the web player

You can also add canvas apps to Teams using the web player.

1. Go to Power Apps > **Apps** > select the app to launch in a new browser tab.
2. Edit the app > select ▷ or press **F5** to play the app.
3. After the app is open using the web player, choose the **Add to Teams** button from the top-right side of the screen.



4. When prompted, select **Cancel**.
5. Select **Launch it now** to open the Teams app. Alternatively, you can also choose **Use the web app instead** to open the app in Teams web.

> **Note**
>
> - To add canvas apps to Teams using the web player:
>   - Your organization must have **Allow interaction with custom apps** turned on.
>
>   More information: Manage custom app policies and settings in Microsoft Teams

- Your organization must allow **Shared Power Apps**. More information: Manage Microsoft Power Platform apps in the Microsoft Teams admin center
- You can only add apps to Teams that belong to the same tenant as your Teams account. Otherwise, you'll see an error "App was not found in tenant".

Publish the app to the Teams catalog

If you're an admin, you can also publish the app to the Microsoft Teams catalog.

Use context from Teams

To build deeply integrated apps with Teams, you can use Team's context variables with the `Param()` function. For example, use the following formula in screen's **Fill** property to change the background of app based on user's theme within Teams:

```
Switch(
        Param("theme"),
        "dark",
        RGBA(
            32,
            31,
            31,
            1
        ),
        "contrast",
        RGBA(
            0,
            0,
            0,
            1
        ),
        RGBA(
            243,
            242,
            241,
            1
        )
    )
```

To test the app, publish it and then play it within Teams.

The following context variables from Teams are supported:

- locale
- channelId
- channelType
- chatId
- groupId (not supported with private channels)
- hostClientType
- subEntityId
- teamId
- teamType
- theme
- userTeamRole

> **Note**
>
> This feature was added in March, 2020. If you embedded your app within Teams before this, you may need to re-add your app to Teams to use this functionality.

Improve the performance of your app

You can optionally preload your app within Teams to increase performance. For mor information: Enable Preload app for enhanced performance.

Welcome to Microsoft Teams

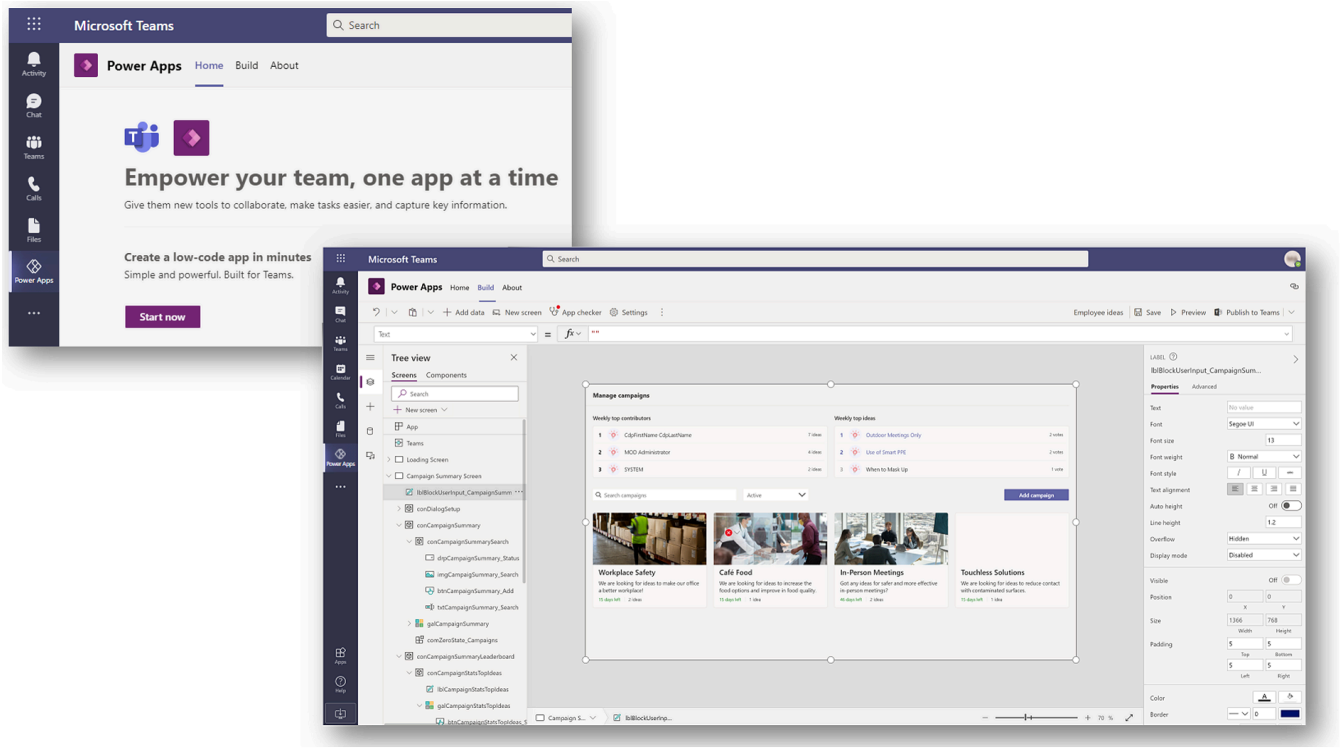
Create apps in Microsoft Teams by using Power Apps

09/03/2025

With the significant number of enterprise employees working remotely, and millions of them meeting and collaborating through Microsoft Teams, there's significant interest in building low-code and no-code applications that can make remote work easier and more productive.

Introducing Microsoft Dataverse for Teams (formerly called Project Oakdale), a built-in, low-code data platform for Teams that empowers you to build custom apps and workflows in Teams by using Power Apps and Power Automate. Dataverse for Teams, built on Microsoft Dataverse (formerly called Common Data Service), provides relational data storage, rich data types, enterprise-grade governance, and one-click solution deployment to the Teams app store.

The new Power Apps app in Teams provides an integrated experience for app makers to create and edit apps and workflows within Teams, and quickly publish and share them for anyone on the team to use, without having to switch between multiple apps and services. With Power Apps Studio embedded in the Power Apps app in Teams and the new built-in data platform providing an easy-to-use, editable data table, you can quickly build apps based on custom data tables that are Teams-specific and scenario-specific.



To help organizations realize value faster, you can use *templates*, which are purpose-built apps for common application patterns that can be easily discovered and installed by members of the

team. Although these templates can work without modification, members of the team can customize and extend them to meet the specific needs of their business.

Access and authorization align with the Microsoft Teams security model and include security groups that enable access for owners, members, and guests of the team that your app is associated with.

Licensing requirements

The ability to create apps within Microsoft Teams will be available as part of select Microsoft 365 subscriptions. For detailed information, see Licensing and restrictions in the Power Platform admin guide.

Get started with creating apps in Teams

There are two ways to use the apps created by using Power Apps in Teams:

- You can use the Power Apps app from the default Teams catalog as a personal app and create apps to share with teams in Teams. More information: Install the Power Apps personal app

When you create an app in Teams with the Power Apps app for the first time, or install an app created with Power Apps from the app catalog for the first time, a new Dataverse for Teams environment is created for the selected team. The Dataverse for Teams environment is used to store, manage, and share team-specific data, apps, flows, and chatbots. Each team can have one Dataverse for Teams environment, and all data, apps, and flows created with the Power Apps app inside a team are available from that environment. More information: About the Dataverse for Teams environment

When you create an app in Teams with the Power Apps app for the first time, or install an app created with Power Apps from the app catalog for the first time, you get to choose which team is responsible for customizing, maintaining, and sharing the app.

After selecting a team, we will create a new Dataverse for Teams environment if one doesn't already exist. This will provide the necessary workspace for your team to collaborate on all your data, apps, flows, and bots. More information: About the Dataverse for Teams environment

Get started with creating flows and chatbots in Teams

You can create:

- Power Automate flows by using the new Power Apps app in Teams. More information: Create flows using the Power Apps app in Teams
- Chatbots by using the new Microsoft Copilot Studio app in Teams. More information: Microsoft Copilot Studio in Teams

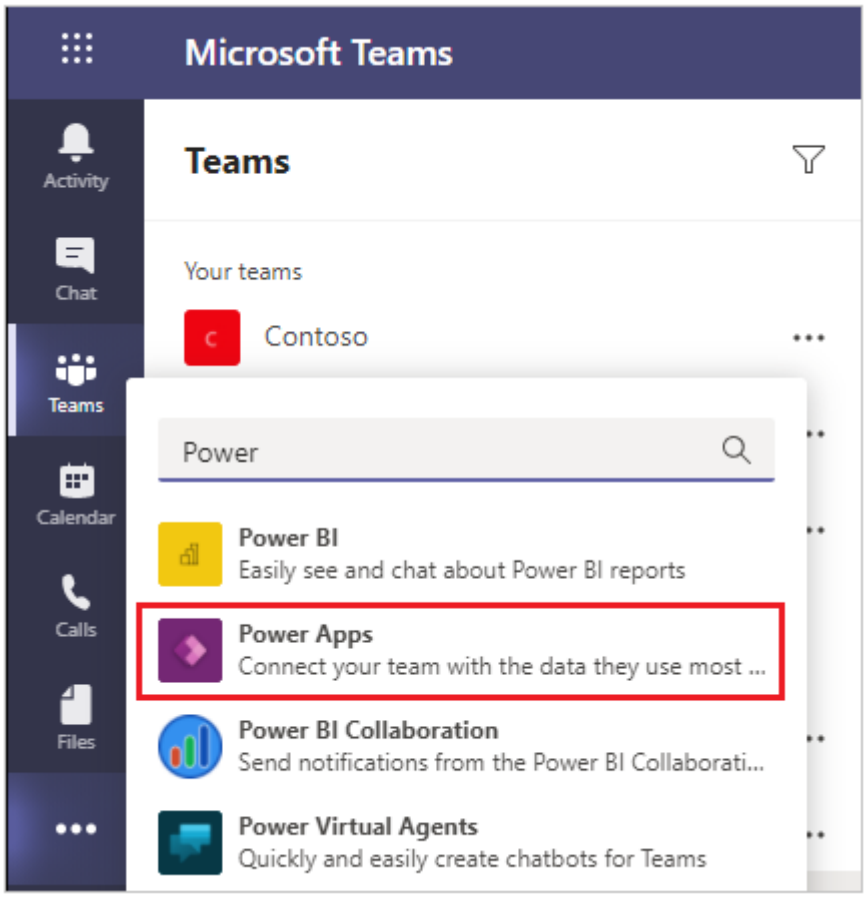
Administer Dataverse for Teams environment

Install the Power Apps personal app in Microsoft Teams

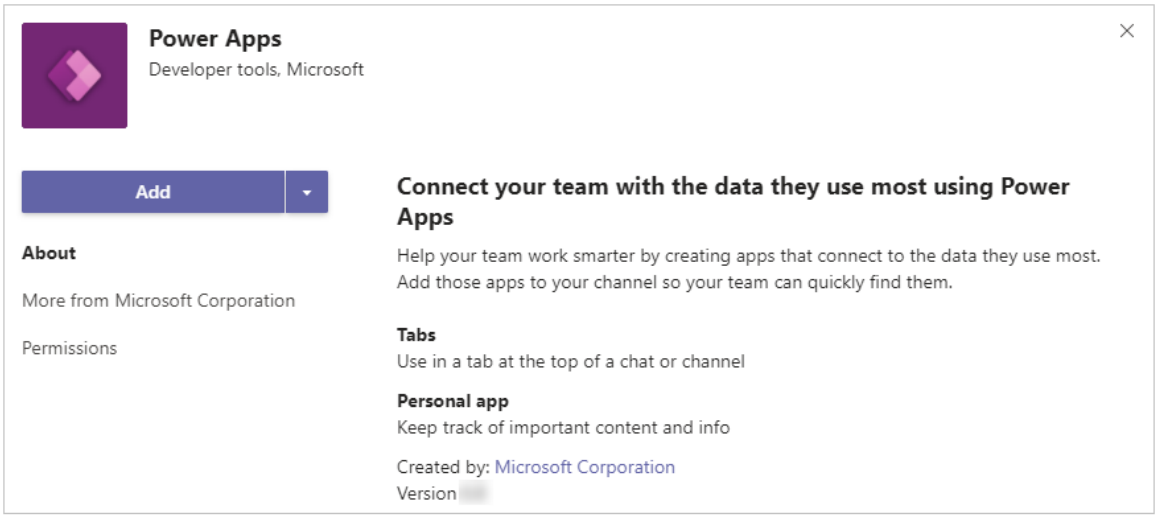
Article • 03/03/2023

A *personal app* is a Teams application that has a personal scope. Power Apps is by default available for you to select and add to a tab in the Teams channel of your choice. More information: Personal apps

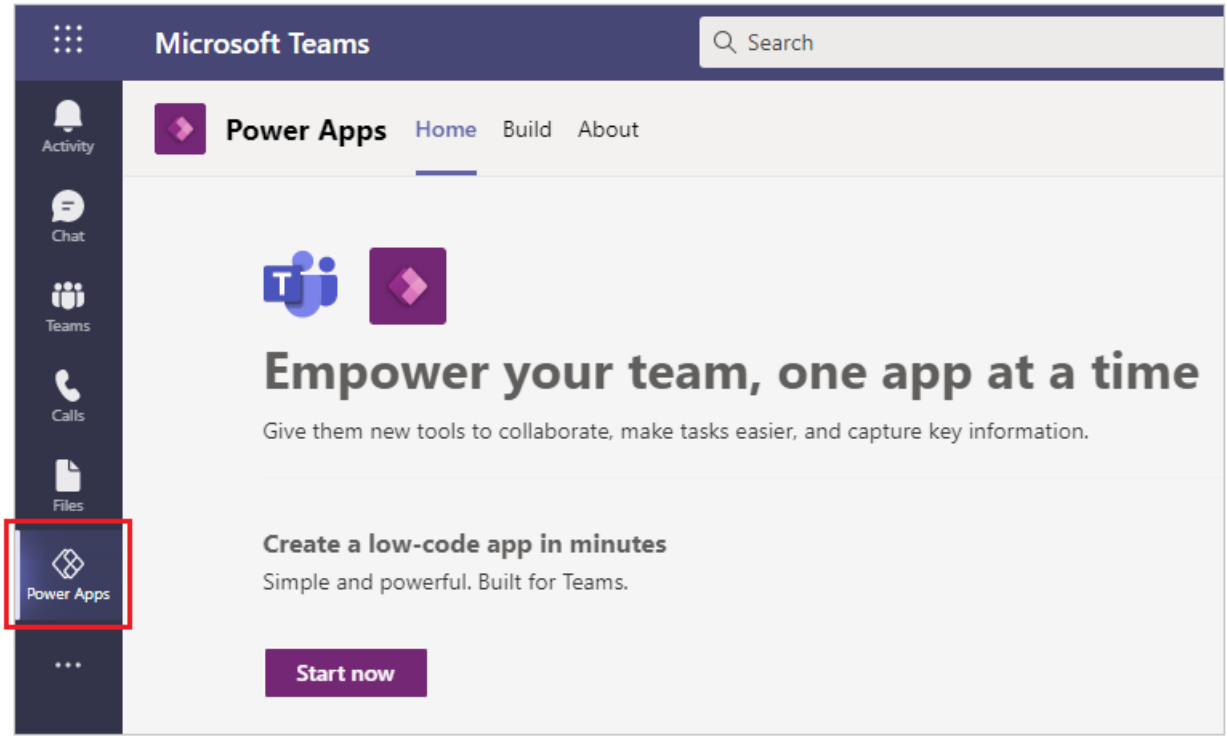
1. Open Microsoft Teams, and then select **More added apps** (...).
2. Search for **Power Apps**.



3. Select **Add**.



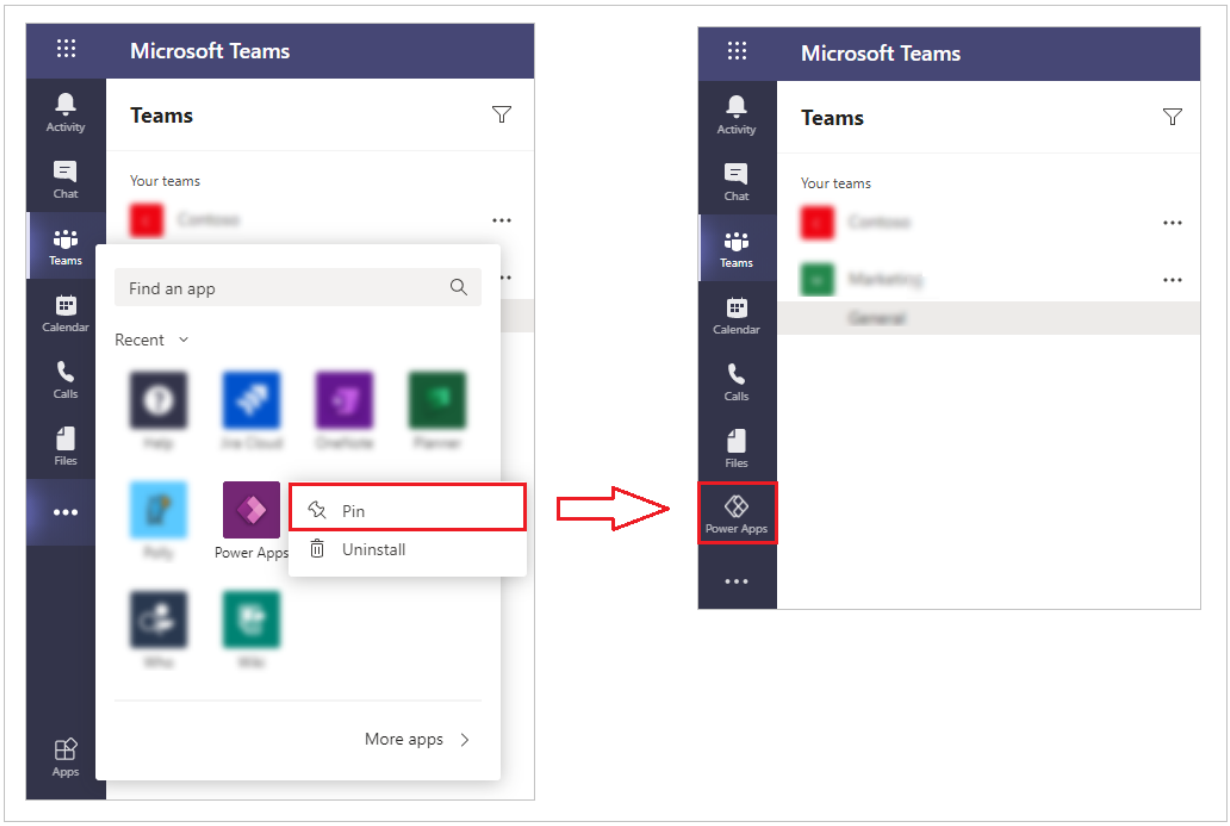
Power Apps is now added to Teams. You can access the app in Teams from the left pane.



> **Tip**
>
> As an alternative to using the flyout menu, you can select **Apps** from the lower-left corner in Teams, and then search for **Power Apps** to install the app.

Pin Power Apps to Teams

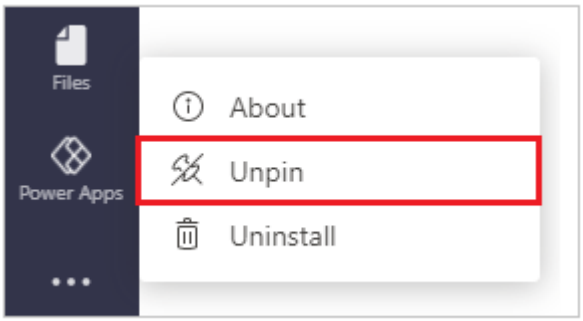
To easily access Power Apps app, **right click** the Power Apps app from ..., and then select **Pin**.



This action adds Power Apps to the Teams left rail for quick access.

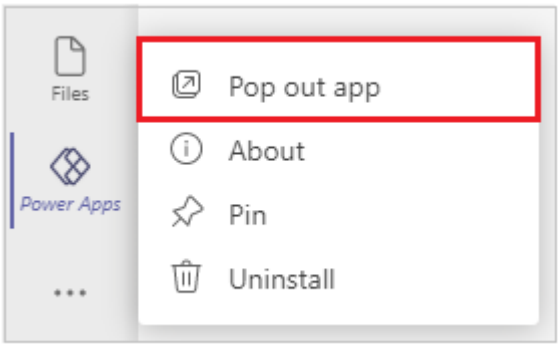
When you pin Power Apps app, the text of the app icon in the Teams rail changes from italicized to normal to reflect the pinned app.

You can unpin Power Apps app anytime with a **right click** on the Power Apps app from the left rail, and then by selecting **Unpin**.



Pop out app

If you're using Microsoft Teams desktop app, you can use the **Pop up out** option to open Power Apps in a separate window for ease of use.



This way, you can continue to use Microsoft Teams for day-to-day interactions and still be able to interact with Power Apps separately.

Next steps

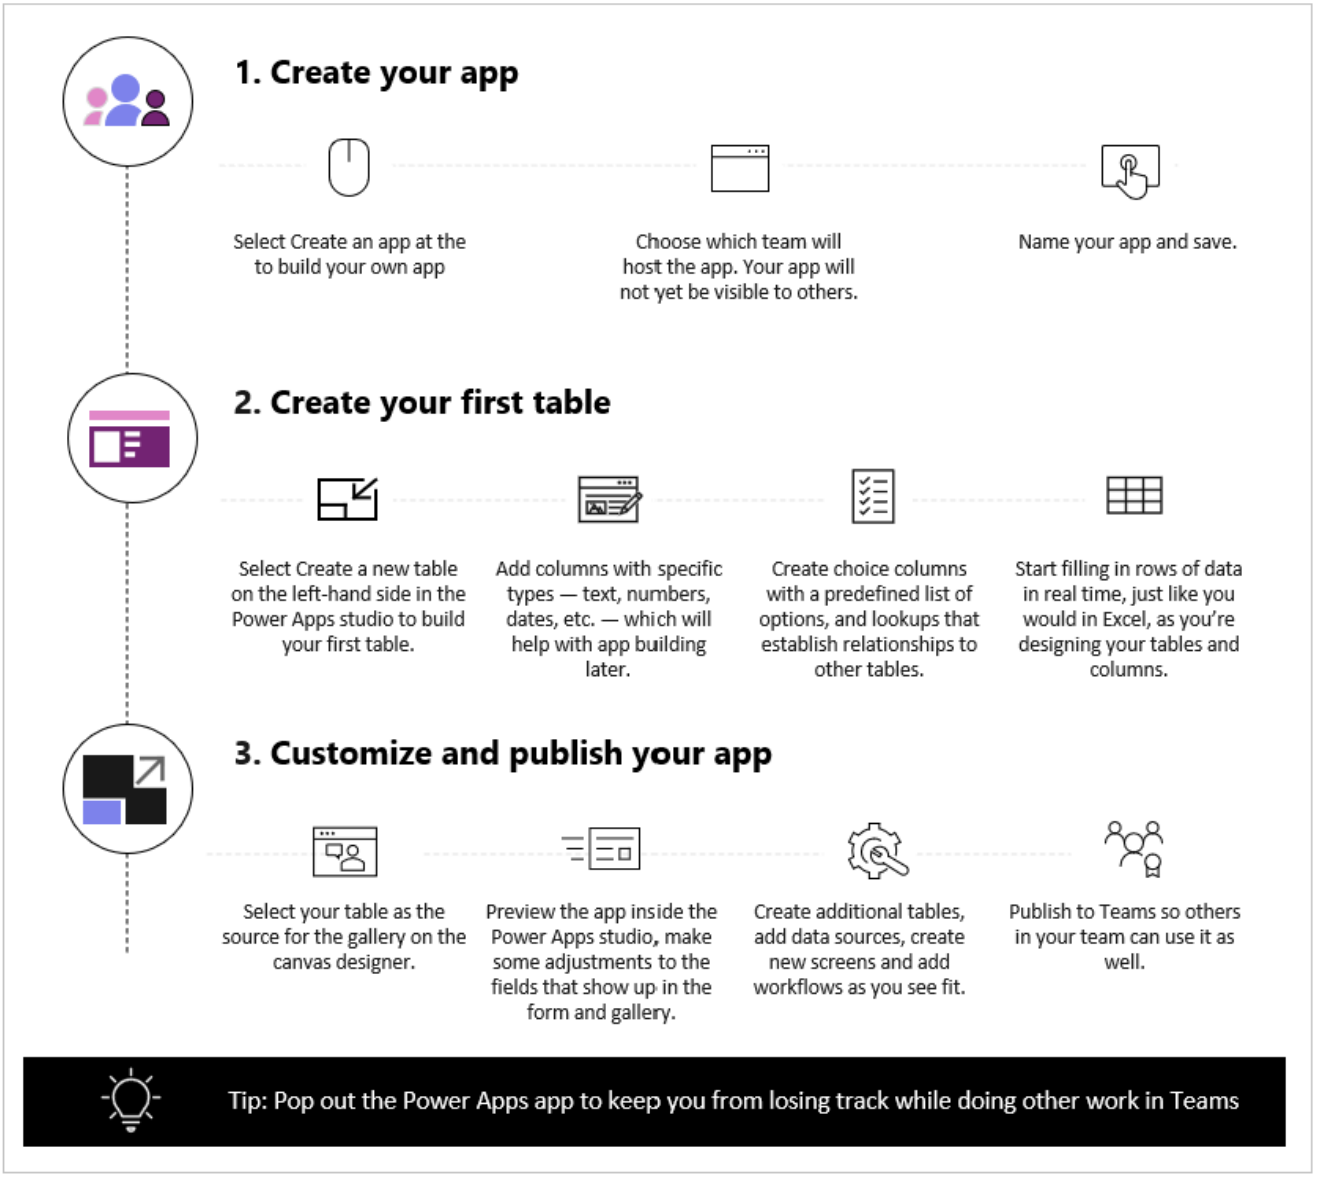
Create your first app in Teams
Overview of the Power Apps app

Create your first app in Microsoft Teams

You can create, edit, and delete canvas apps in Teams. If you're creating an app by using Power Apps in a Teams team for the first time, you also create a new Dataverse for Teams environment. For more information, see About the Dataverse for Teams environment.

Creating an app in Microsoft Teams is a quick and easy three-step process.

1. Create your app
2. Create your first table
3. Customize and publish your app



Watch this video to learn how to create your first app.

https://learn-video.azurefd.net/vod/player?id=3e63d41c-d4eb-411e-b99a-7cc87bb2992d&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fcreate-first-app

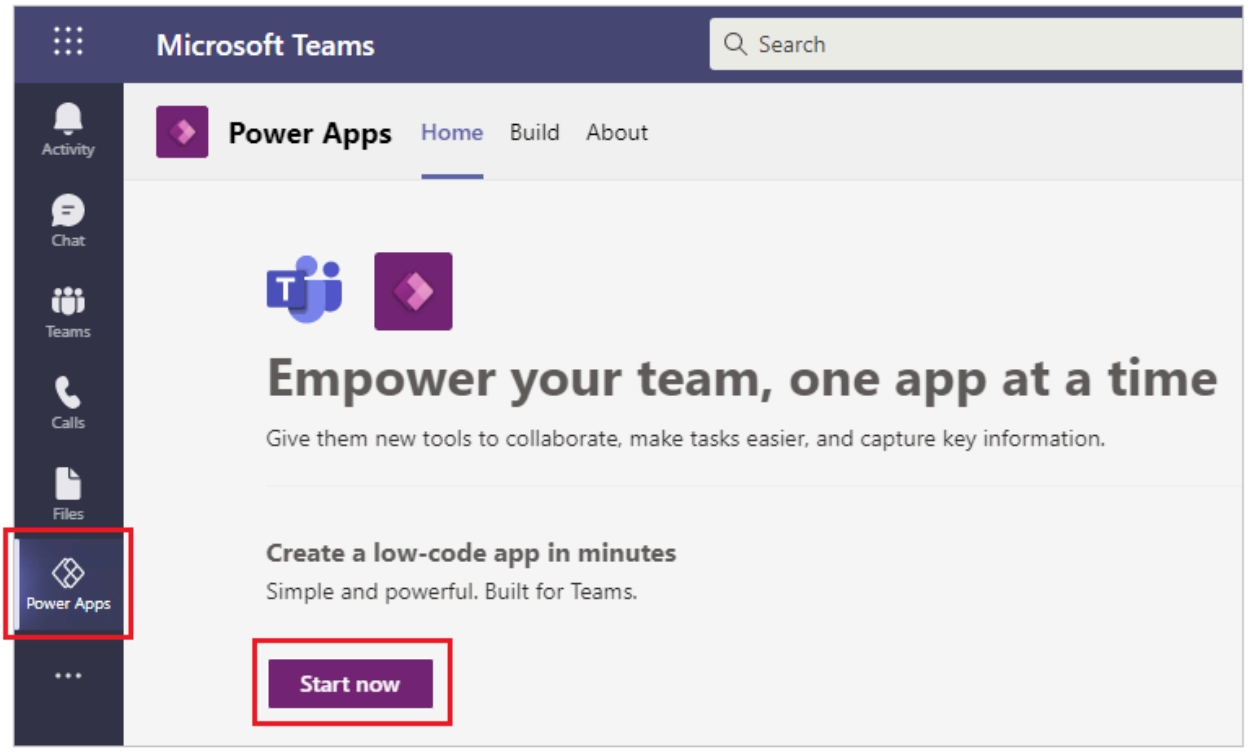
Ensure you refer to the latest steps when creating the table.

Now let's go through each step in detail.

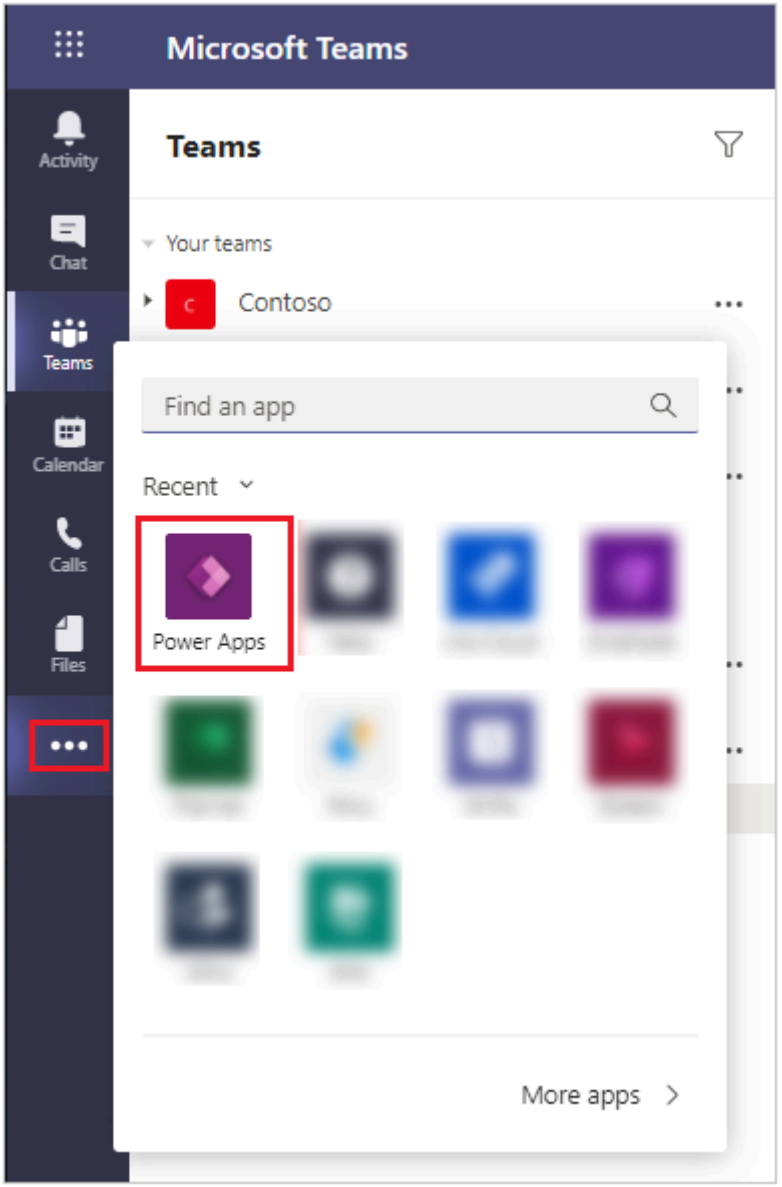
Create your app

After installing the Power Apps app template:

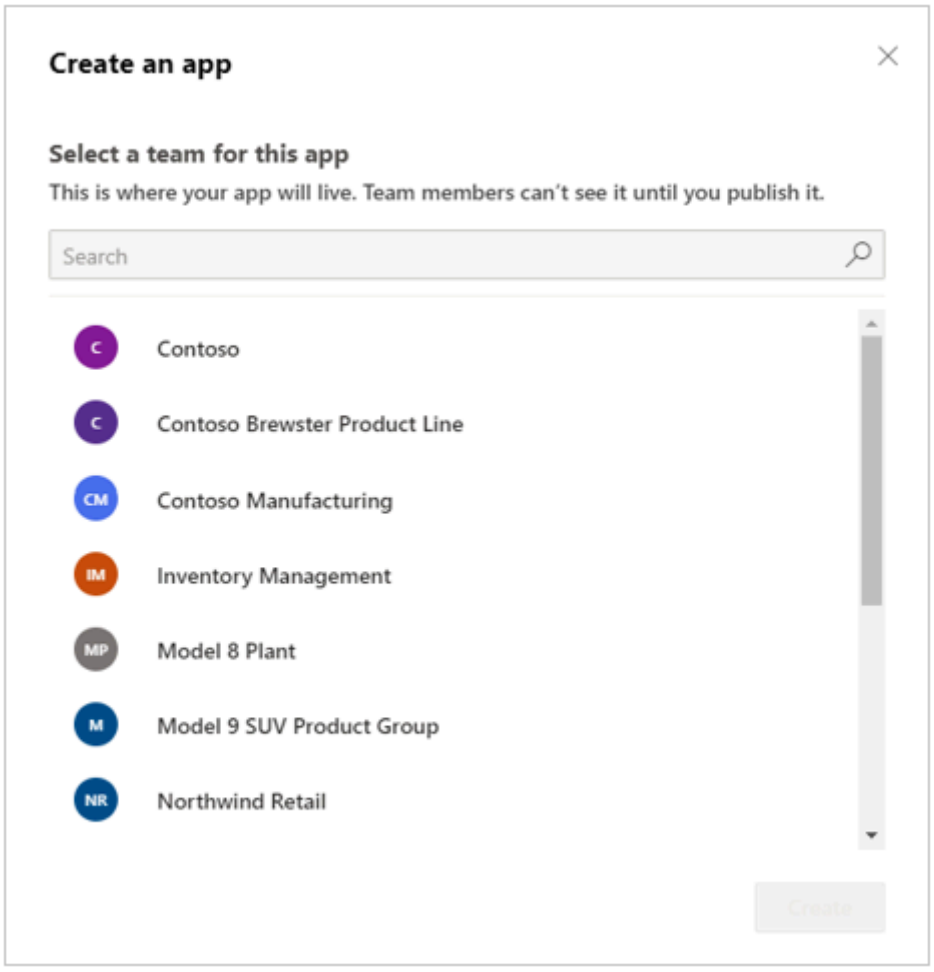
1. Start Teams, and sign in.
2. In the left pane, select **Power Apps**, and then select **Start now**.



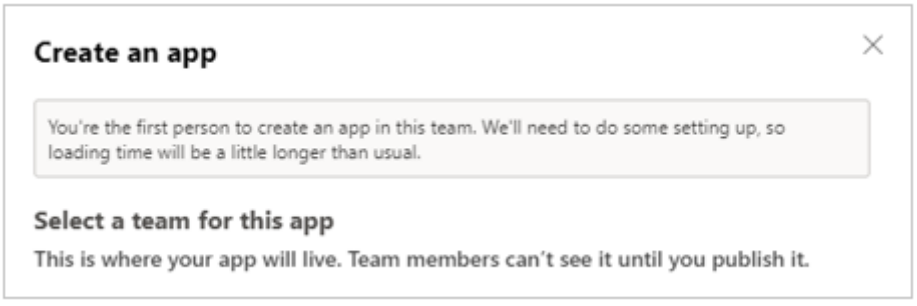
> **Tip**
>
> If you don't see the **Power Apps** app in the left pane, select ... (*More added apps*), and then select **Power Apps**.



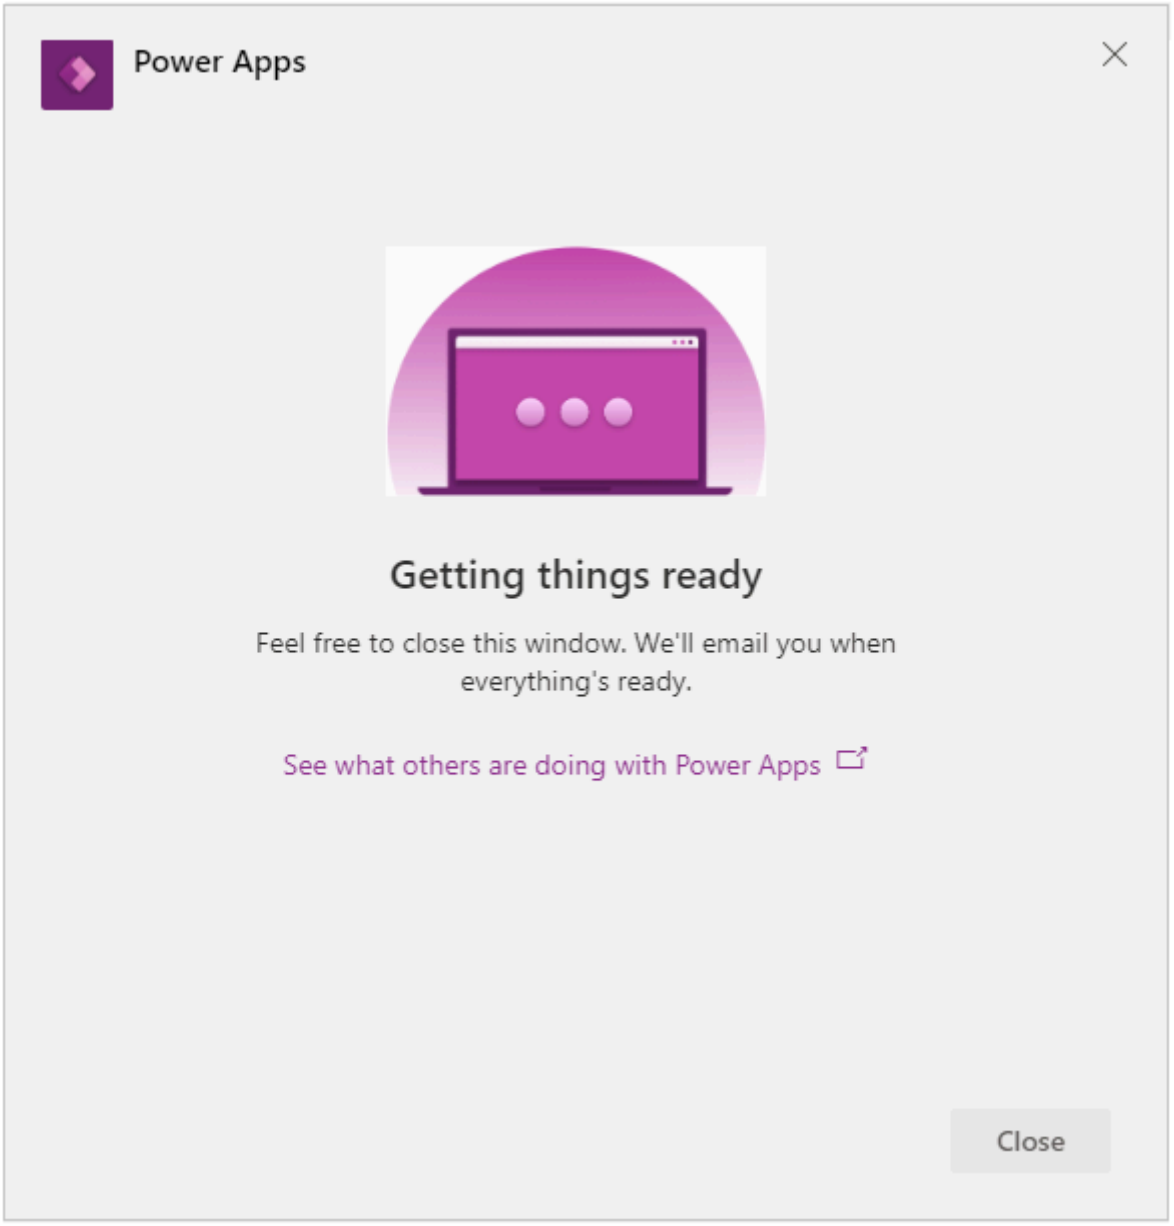
3. Select a team where you want to create the app. This is where the app lives. Team members can't see the app until you publish the app. You can also share the app with colleagues within your company that are not part of the team. For more information, see Set permission and share apps with colleagues.



If this is the first app you're creating in the selected team, a new Dataverse for Teams environment is created for the selected team. You see a message about this when you select the team. For more information, see About the Dataverse for Teams environment.

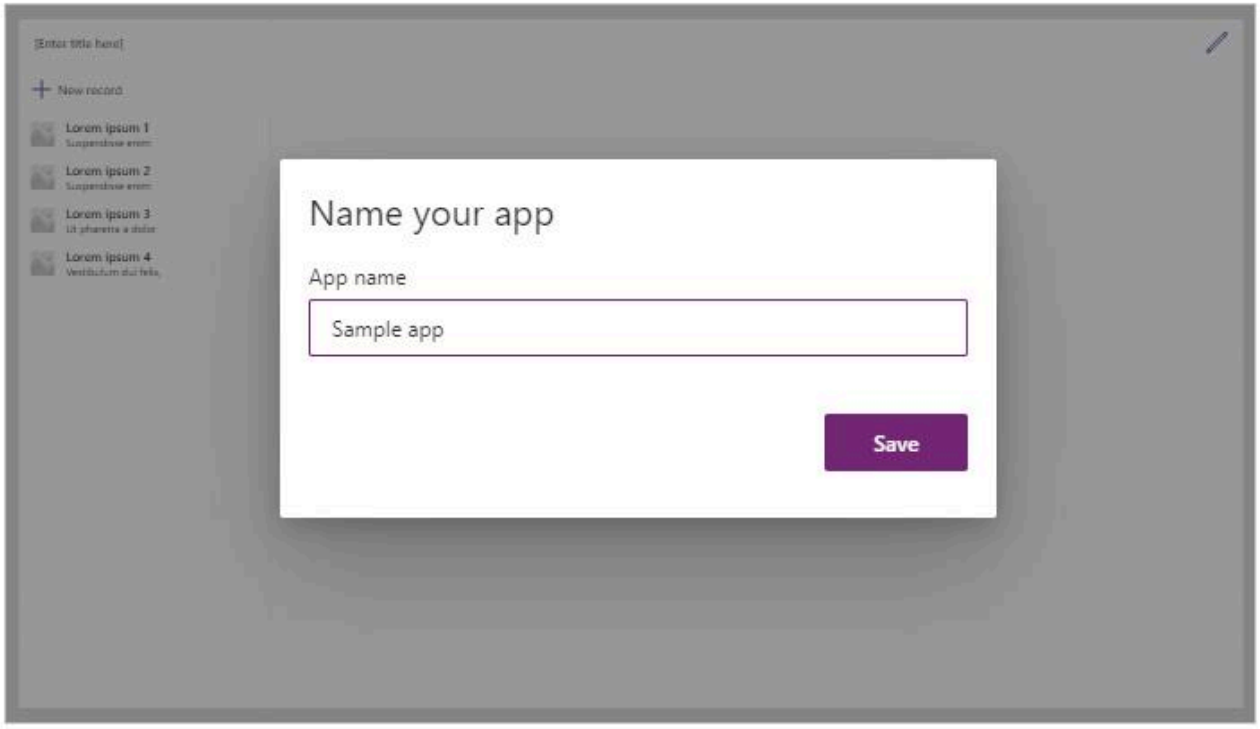


4. Select **Create**. You see a confirmation about the Dataverse for Teams environment being created, which might take some time. You're notified when the environment is available for you to create your first app by using an email and a Teams notification.



> **Note**
>
> Environment creation fails if the Teams team that you selected has *Hiddenmembership* enabled. If this happens, try creating the app in a different team. For more information, see Hidden membership groups.

5. Enter an app name, and then select **Save**.



> **Tip**
>
> An app template is included with the app by default, so that you can get started with creating your table and using the app. For more information, see Understand Power Apps Studio.

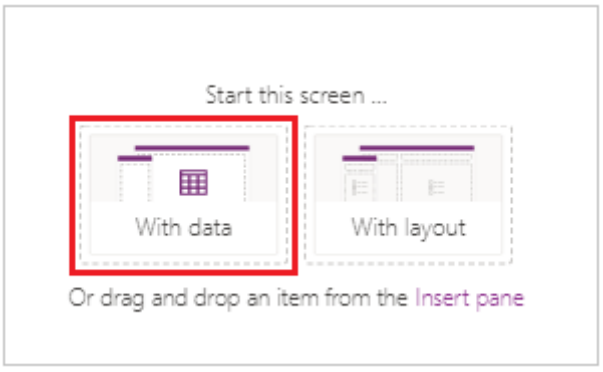
Create your first table

Data for apps built in Teams lives in Dataverse for Teams environments as tables. Like other data experiences, you can add extra columns to track different attributes of each record before filling the table with multiple rows of data.

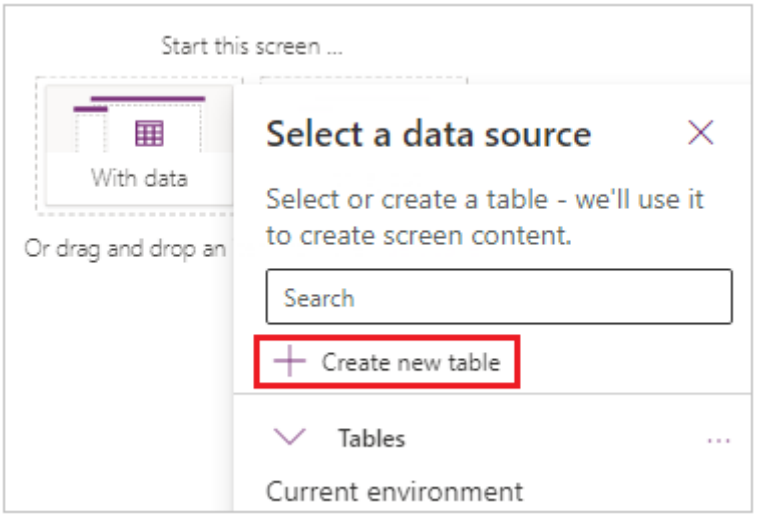
> **Tip**
>
> For more information about Dataverse for Teams tables, see Overview of Dataverse for Teams.

To create your first table:

1. Select **With data**.



2. Select **Create new table** > **Start with blank table**.



3. In the **Create a table** dialog box, select **Edit table properties** and type a meaningful name for your new table that describes this dataset, and then select **Save**.

4. After the table is created, add columns of different types, add rows, and work with data in the visual editor.

Add columns to the table

To add a new column to track new data:

1. Select **New column.**
2. Enter a name that best describes your new column.
3. Select the type for your column.

> **Tip**
>
> For more information about column types supported by the visual editor, go to Supported column types. To add columns that aren't supported by the visual editor, create a table by using the solution explorer. More information: Create tables

4. If required, change **Advanced options** for the selected column type.
5. Select **Save**.
6. Repeat the previous steps to add the rest of the data columns.

Add rows to the table

Select **Add row** to add rows.

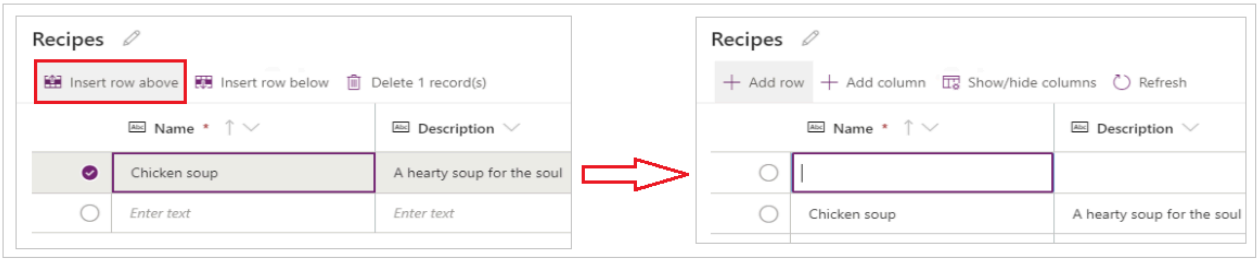
Paste the copied data into the table

You can paste up to **50 rows** of data into a table. To create new rows from the copied data, add empty rows in the table first. Adding new empty rows ensures pasting data from clipboard doesn't accidentally overwrite your existing data.

> **⊗ Caution**
>
> Paste operations are automatically saved, and there's no undo option. Use caution when pasting data over existing rows since this action overwrites your existing data in the table.

To paste the data from clipboard into the table:

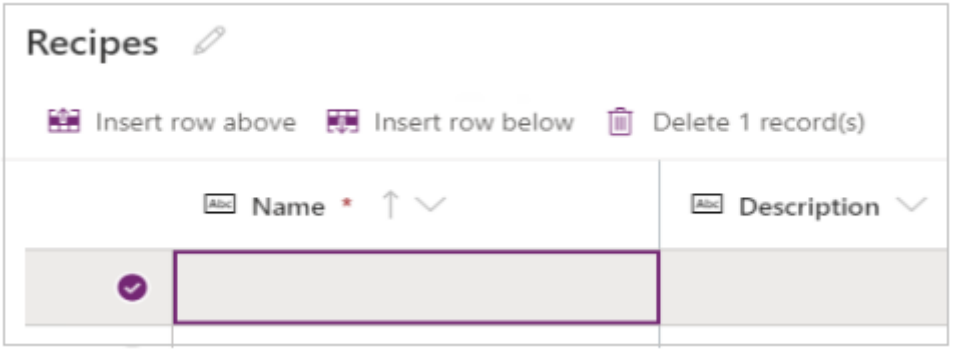
1. Select the record that you want to add new records above or below.
2. Select **Insert row above**, or **Insert row below** to insert rows before or after existing rows. For example, inserting row above the selected row:



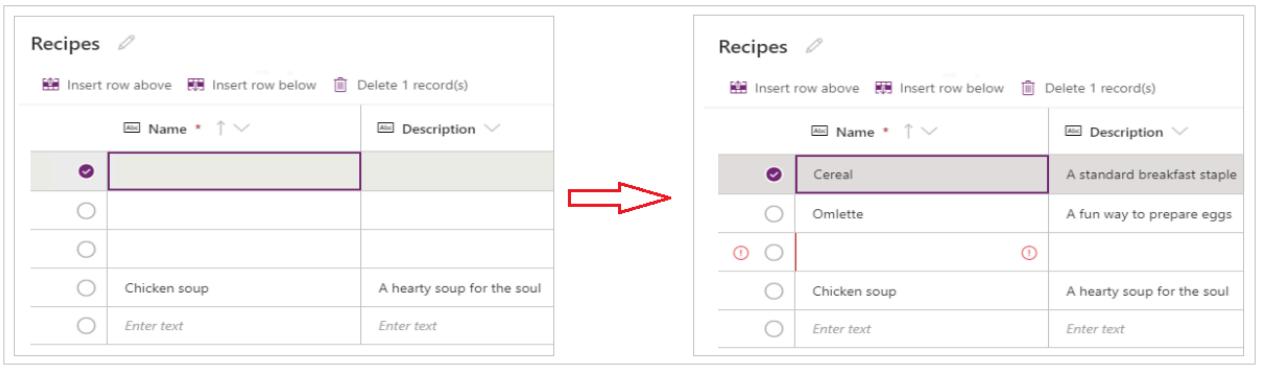
3. Repeat the preceding step to add more empty rows, as needed.

> **Tip**
>
> If you're unsure of how many rows you need, create additional empty rows before pasting data. You can delete extra empty rows later.

4. Select the top-left cell from the newly created rows.

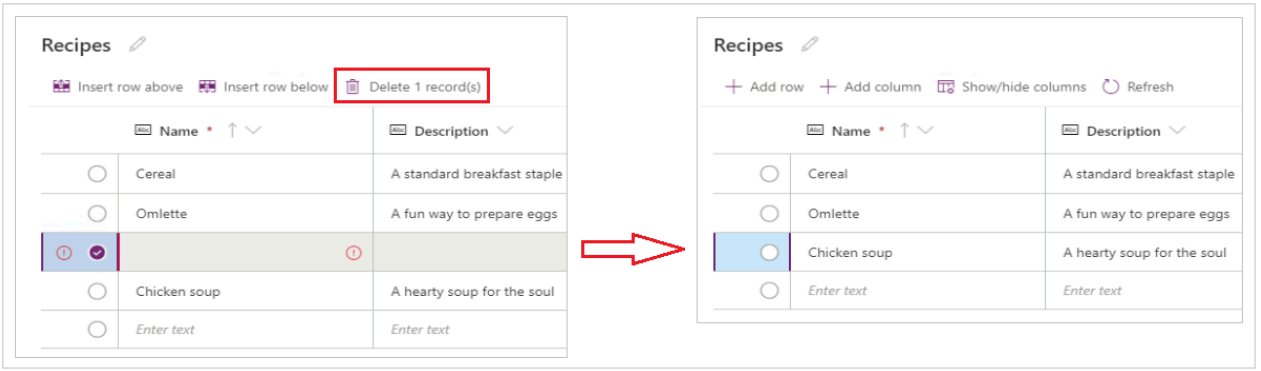


5. Paste the copied data.

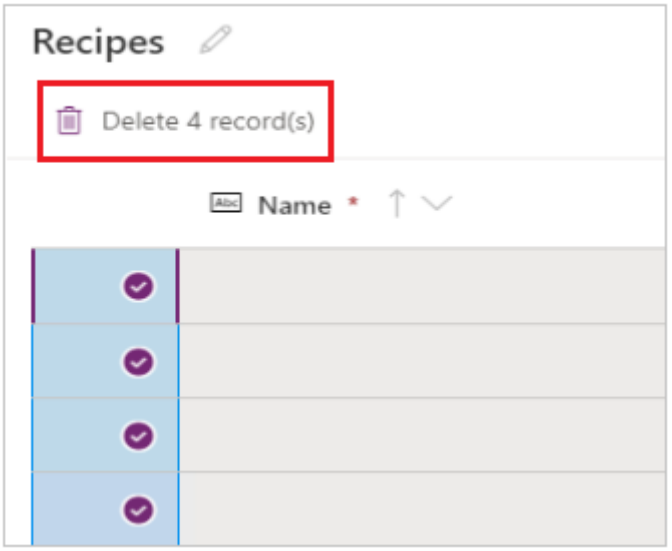


> **Note**
>
> If you paste data when the cell is in edit mode (if you *double-clicked* top-left cell), the data is pasted inside the cell. If this problem happens, delete the incorrectly pasted data, select any other cell, select the top-left cell, and try to paste again.

6. Remove any extra empty rows.



> **Tip**
>
> To delete multiple rows that are together, select the top row, and press the **Shift** key on the keyboard. Keep the key pressed, select the last row in the chunk of the rows that you want to delete. Then, select **Delete X record(s)**.

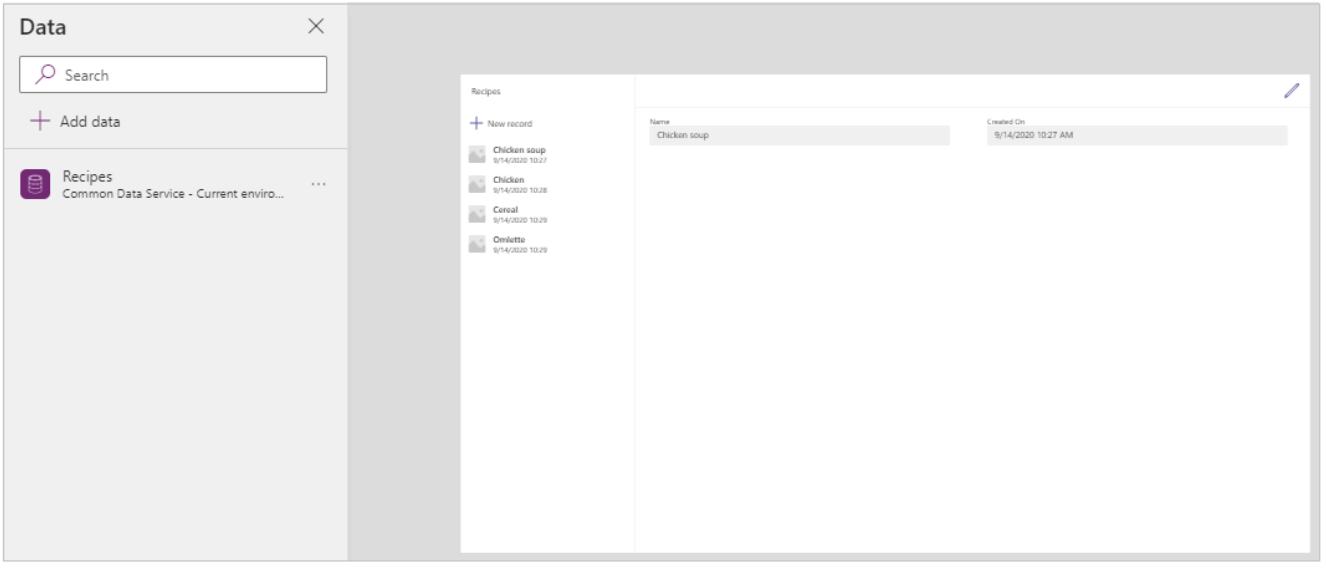


Changes to the table are automatically saved. However, check for errors, and fix them before you close the visual editor.

Customize and publish your app

When you close the table, the app template that you added to the app screen by default automatically refreshes to use the new table.

> **Note**
>
> To add new data sources, such as a new table, or to reopen the app, see Manually connect data to the app for steps to manually refresh the app with the new data.



Depending on the number of fields you add to your table, you might need to update the form and the gallery in the app template.

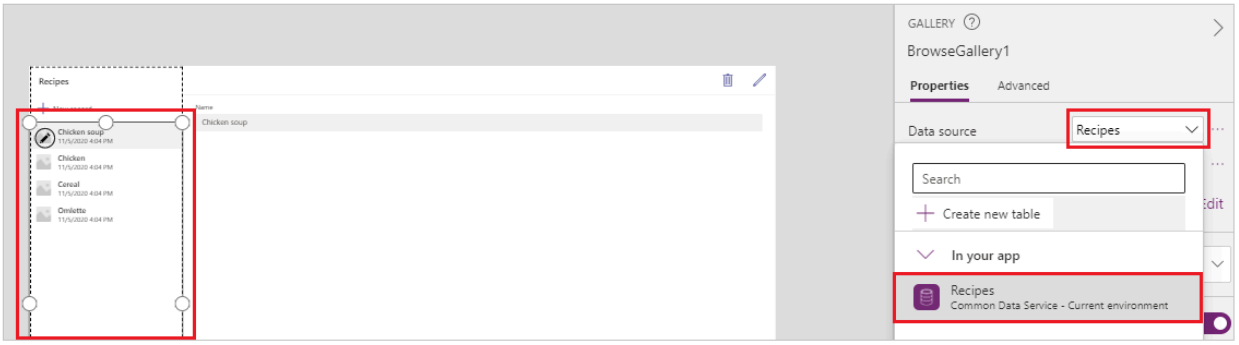
Manually connect data to the app

The gallery and the edit form components on the screen automatically refresh with the data only for the first data source. If you add extra data sources, such as a new table, or if you reopen the app, you need to manually connect the data to the template gallery and form.

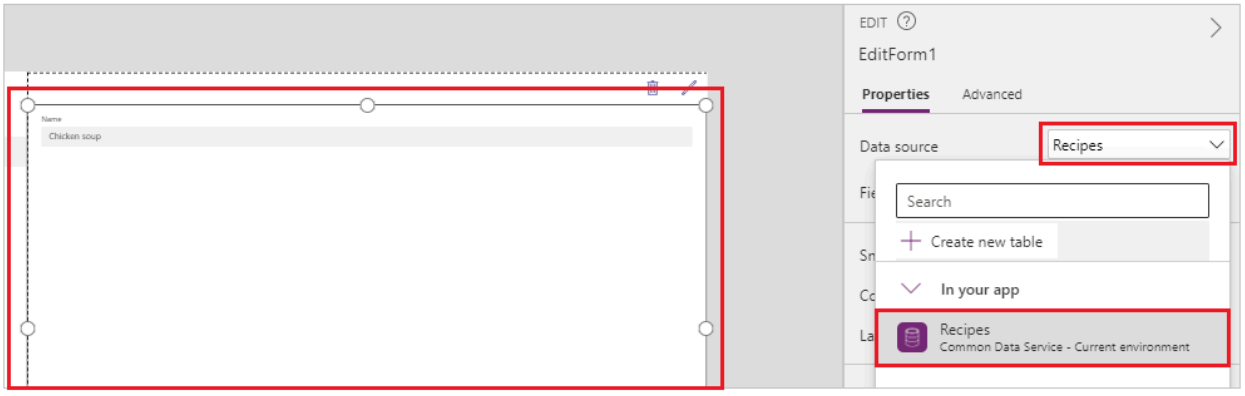
> **Tip**
>
> Skip these steps if the app screen is already connected to the table that you created.

To manually connect to the new data:

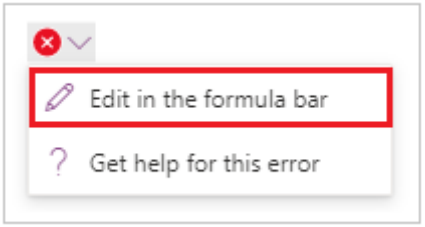
1. Select the gallery, and then select the correct data source.



2. Select the form, and then select the correct data source.



3. If you see any formula error, select **Edit in the formula bar**, and update the formula with the data source name.



For example, to change from using *Instructions* as the data source name for the edit form to *Recipes*, replace the name of the data source.

Change from:

```
Power Fx
Remove(Instructions, selectedRecord); If(IsEmpty(Errors(Instructions,
selectedRecord)),UpdateContext( {itemSelected:false, editMode:false,
newMode:false, deleteMode:false}); Set(CurrentItem,First(Instructions)););
```

Change to:

```
Power Fx
Remove(Recipes, selectedRecord); If(IsEmpty(Errors(Recipes,
selectedRecord)),UpdateContext( {itemSelected:false, editMode:false,
newMode:false, deleteMode:false}); Set(CurrentItem,First(Recipes)););
```

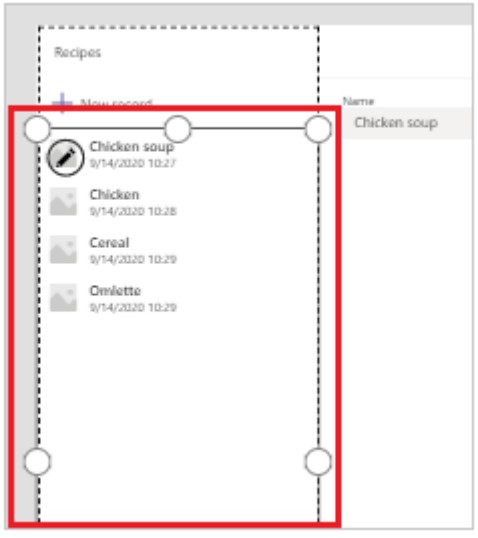
4. Repeat the earlier step to fix any extra formula errors.

Update background color for the selected gallery record

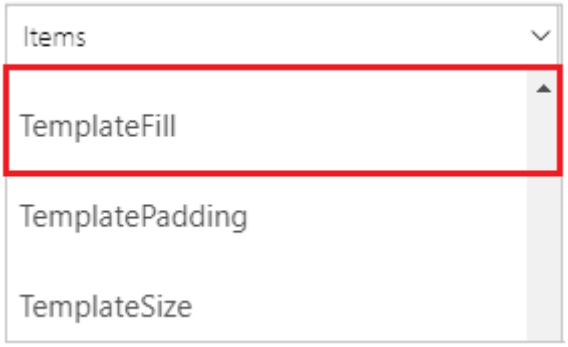
The gallery shows records you created earlier. However, you need to change the background color for a record when you select it from the gallery to show the selection.

To update the selected item background color:

1. Select the gallery.



2. Select *TemplateFill* property from the property drop-down on the top-left.



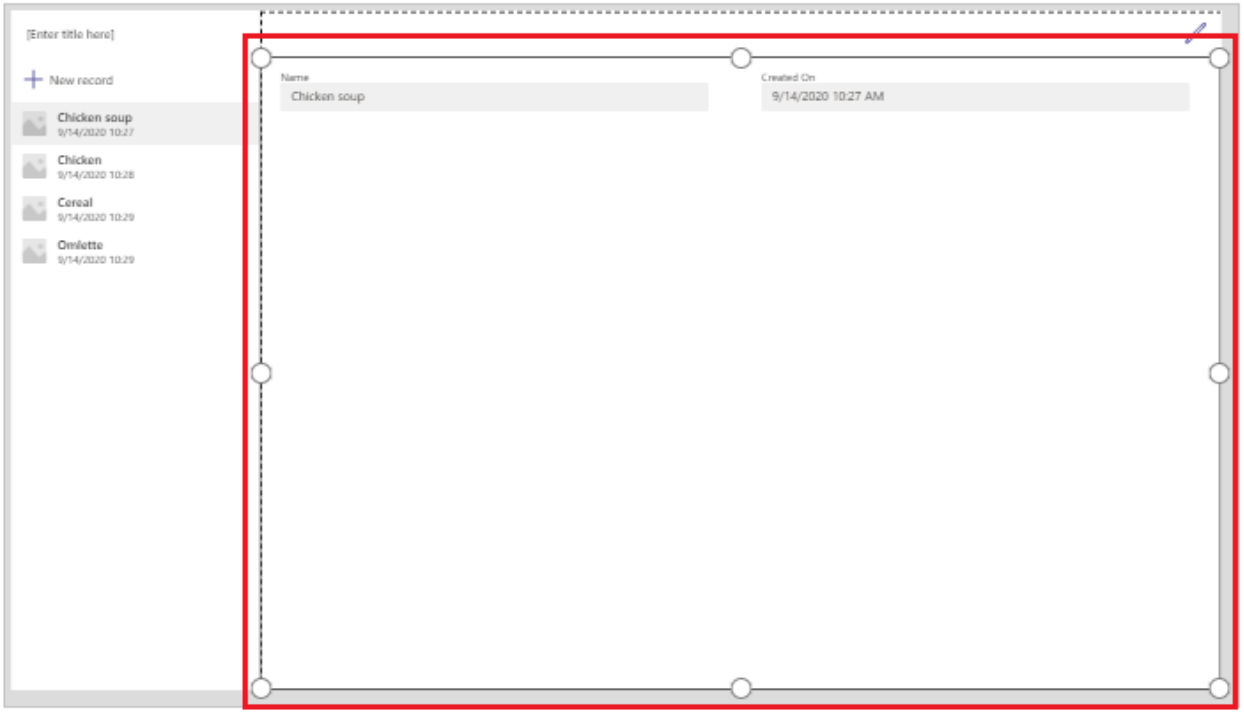
3. Update the *TemplateFill* property value in the formula bar to the following formula:

```
Power Fx
If(ThisItem.IsSelected, RGBA(0,0,0,.05), RGBA(0,0,0,0))
```

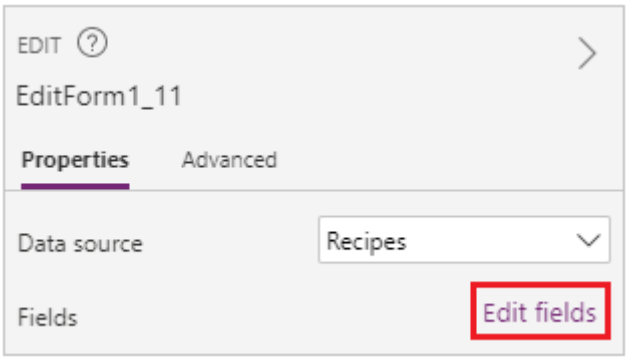
Update fields on the form

The template shows two fields inside the form by default. To add more fields to the form:

1. Select the form.

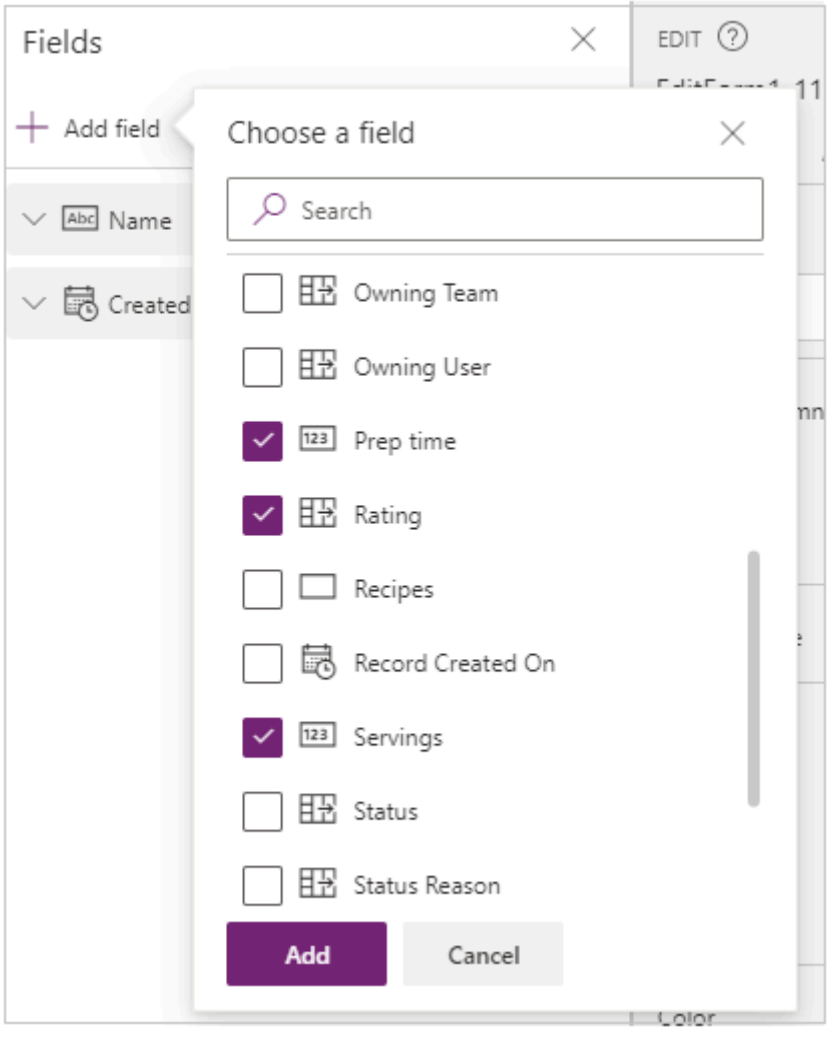


2. Select **Edit fields** from the property pane on the right.



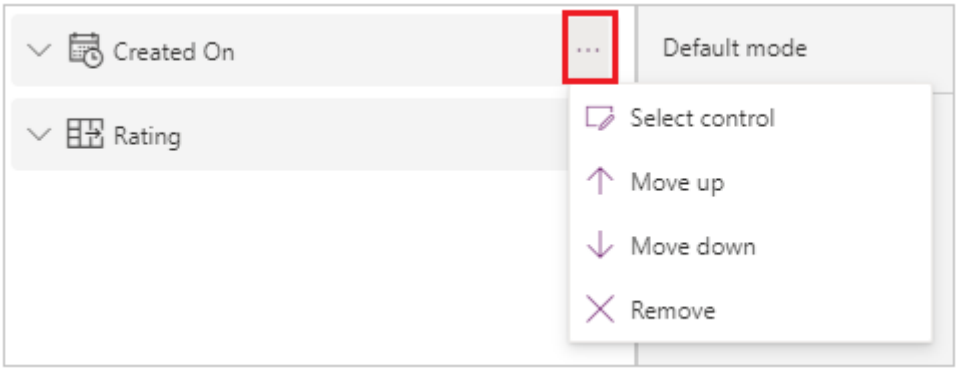
3. Select **Add fields**.

4. Select the fields that you want to add on the form.



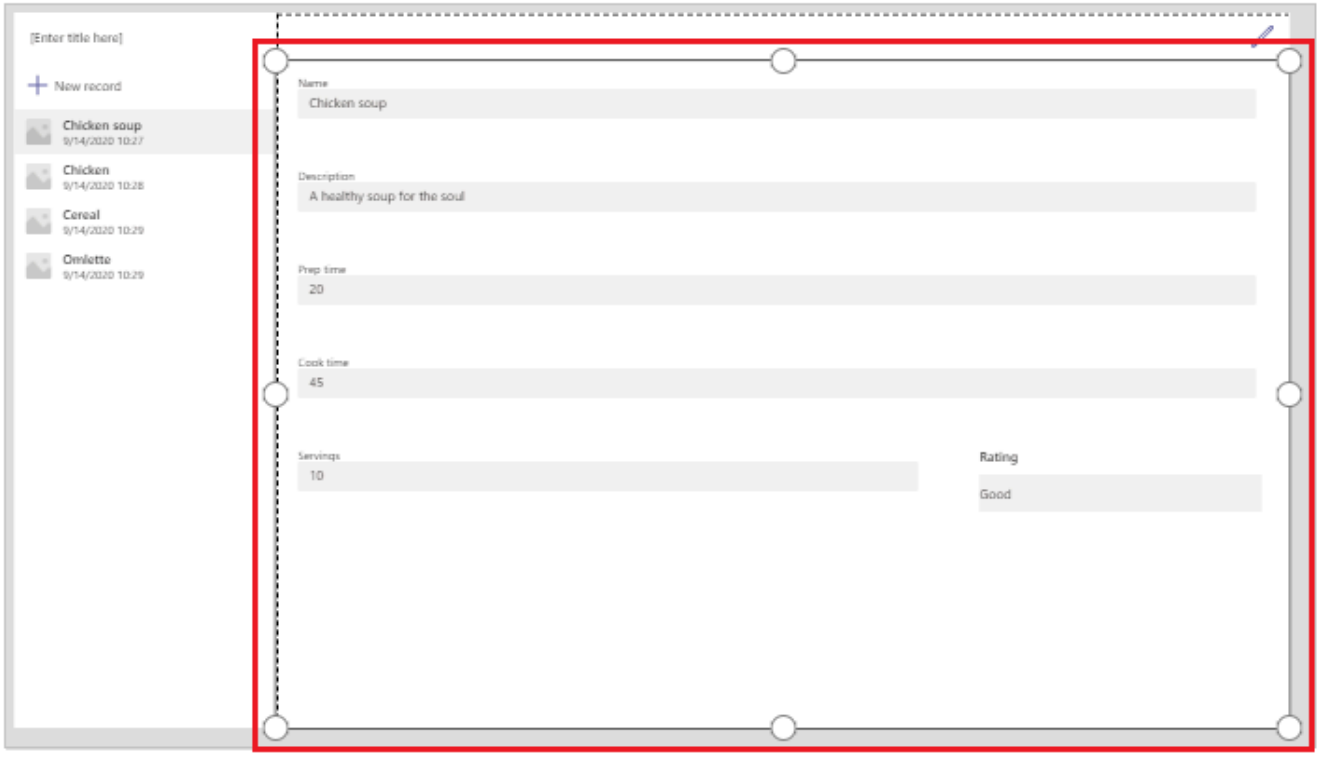
5. Select **Add**.

6. (Optional) Select fields to move up or down, or remove unwanted fields by selecting **Remove**.



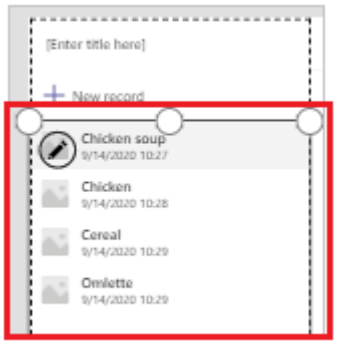
7. Close the fields pane.

When you add, remove, or reorder fields, the form updates automatically.



Update fields in the gallery

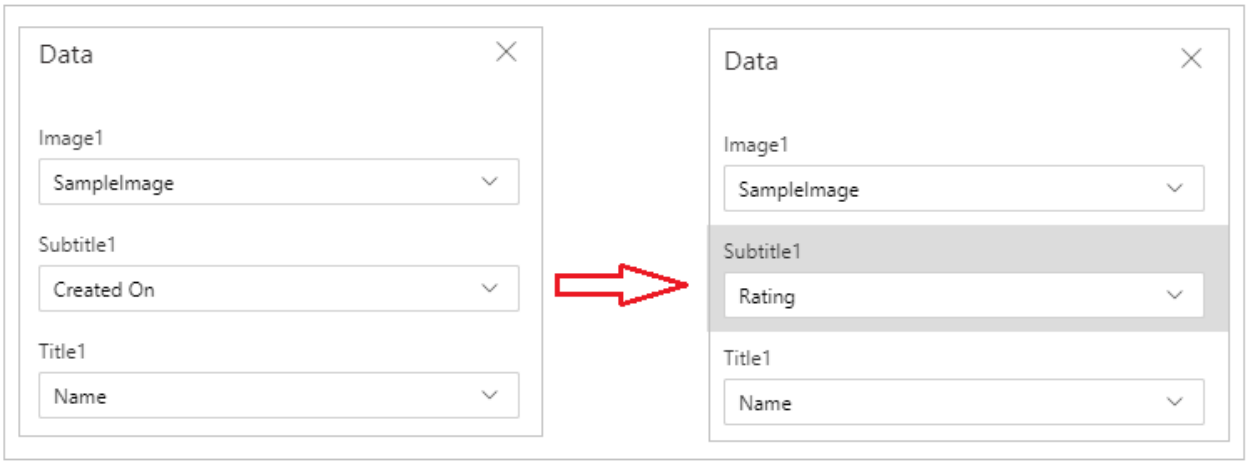
You might need to update the gallery on the default app template to reflect the fields from the table you created.



To update the fields in the gallery:

1. Select **Edit fields** from the property pane on the right.

2. Select the drop-down menu for a gallery component (such as image, title, or subtitle) and change the selection to the field you want.



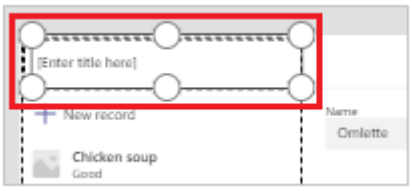
3. Close the data pane.

The gallery updates with the selected changes.

Update the app title

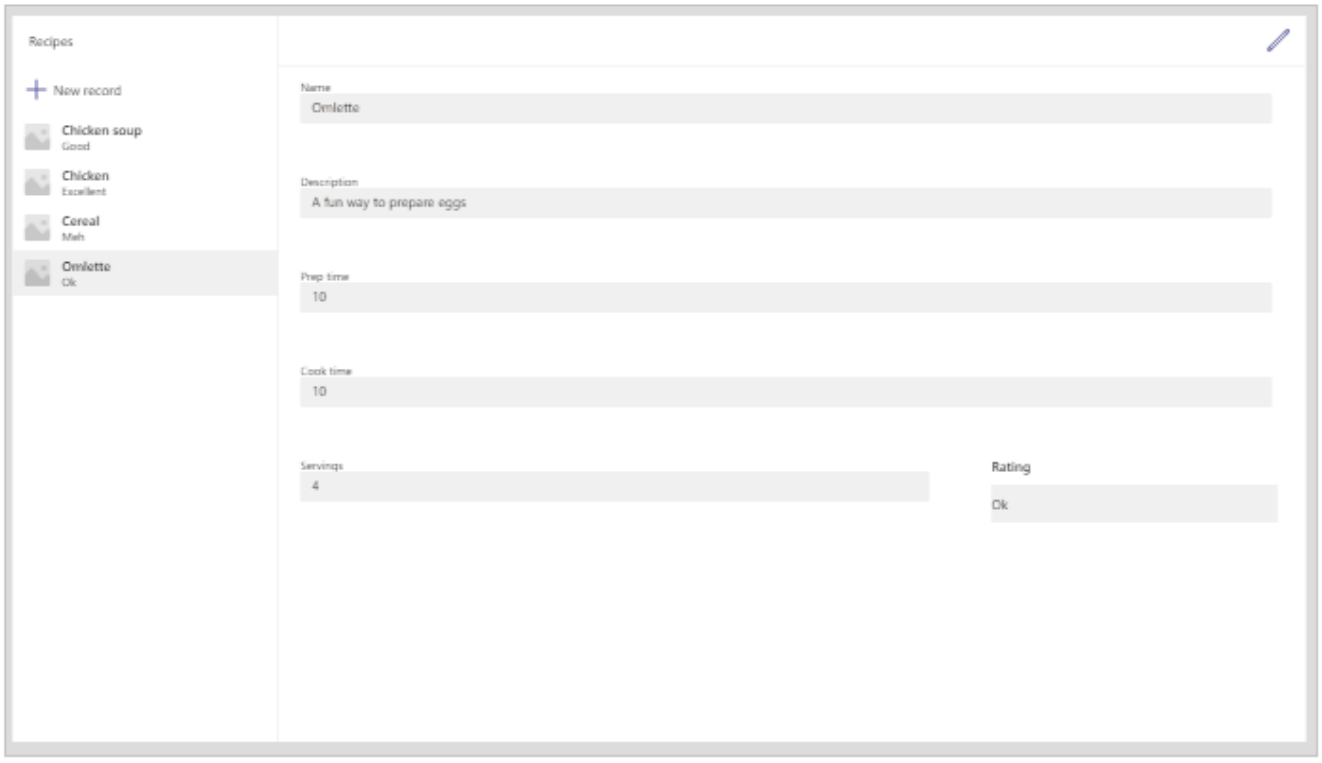
To update the app title:

1. Select the label from the upper-left corner of the screen.



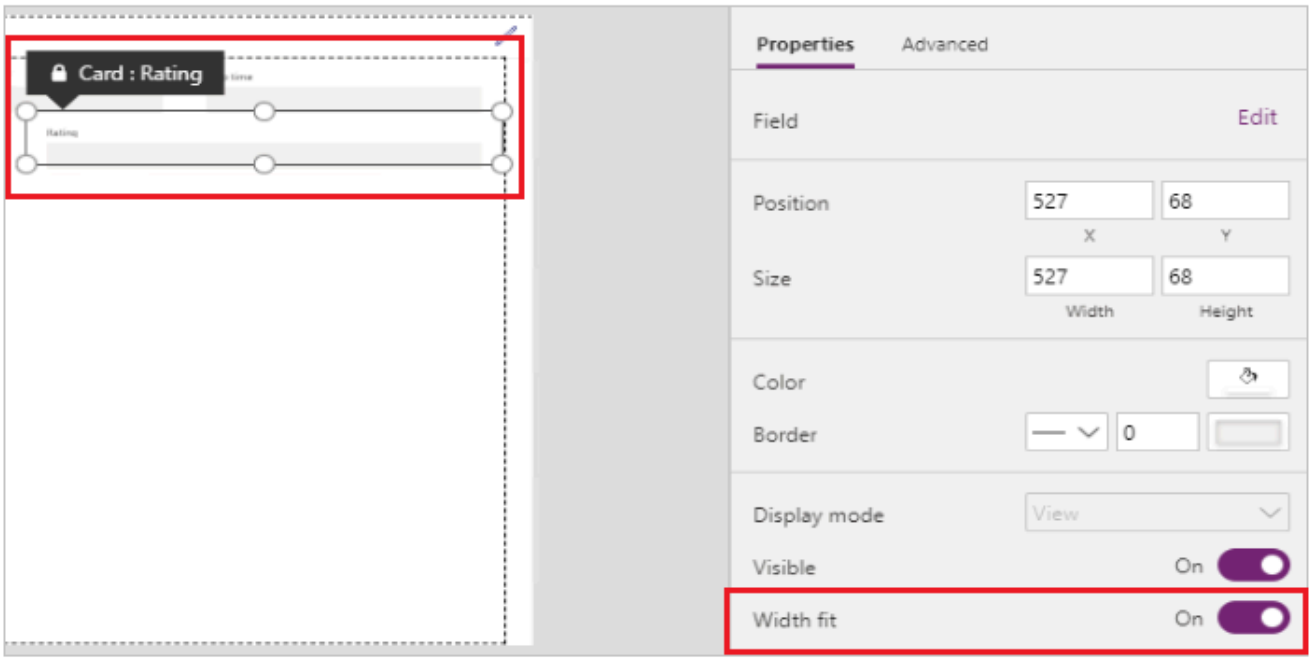
2. Change the *Text* property value from the properties pane on the right.

Verify all the changes you made to the app.



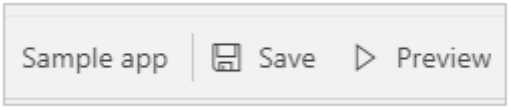
Tip

For better responsiveness, the data cards by default have the Width fit property set to *On*. If you want to resize the data cards manually, select the data cards and then set the **Width fit** property to *Off*.



Save and preview the app

Now that you've created your first app with data, you can save your changes and preview the app.



1. Select **Save**.
2. Select **Preview**.
    - To add a new record, select **New record** and fill in the form.
    - To edit a record, select the record from the left pane, and edit the values.
    - To close the preview, select **Close** or the **Esc** key.

Publish and add app to Teams channel

Select **Publish to Teams** to publish the app so others in your team can use the app, and add the app to Teams channel. More information: Publish and add an app to Teams

Now that you've created your first app from a blank table, let's go through the Power Apps interface, Studio, controls and how to create additional apps in detail.

Additional considerations for Microsoft 365 Group

When you select **Create** to create an app in the selected team, Power Apps automatically enables the selected team's Microsoft 365 Group for security. However, if the group can't be enabled for security, you see the following error:

`The request failed with error: 'Insufficient privileges to complete the operation.' The tracking Id is '[xxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx]'`.

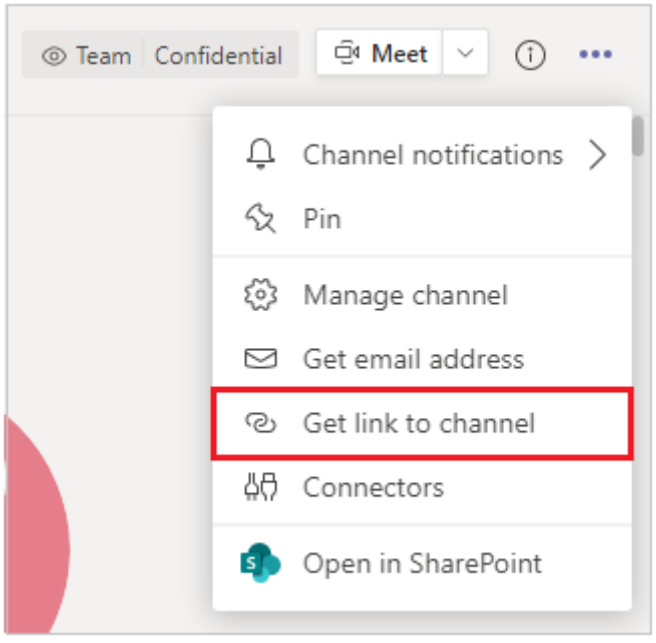
To fix this issue, manually update the Microsoft 365 Group setting *SecurityEnabled* from *False* to *True* by using PowerShell. For detailed steps, see Share an app with Microsoft 365 Groups. For more information, see Microsoft 365 Groups and Microsoft Teams.

Enabling security for teams with same names

Team names aren't always unique. It's possible for more than one team in Teams to share the same display name. For example, there might be more than one team with the name "Inspection" in a tenant. However, the Microsoft 365 Group associated with each team has a different *ObjectId* in Azure Active Directory (Azure AD), even when the team names are the same. The *ObjectId* in Azure AD for a Microsoft 365 Group is the same as the *GroupId* in Teams for the associated team.

To find the **GroupId** (ObjectID in Azure AD) of a team:

1. Go to the team in Teams.
2. Select any channel in the team.
3. Select **More options** (...) from the upper-right corner, and then select **Get link to channel**.



4. Copy the *GroupID* from the link.

You can also copy the channel link by selecting **Copy**, and then pasting it into a text editor to get the *GroupID* value.

```
https://teams.microsoft.com/l/channel/19%3a06f038959c9f4387a35f5d776484cff2%40thread.tacv2/General?groupId=40b7e373-a788-4e29-a590-5a86db7550e3&tenantId=00000000-0000-0000-0000-000000000000
```

5. Now that you have the correct team's **GroupID** (ObjectID in Azure AD), use the instructions in Share an app with Microsoft 365 Groups to enable security for the team's Microsoft 365 Group.

Overview of the Power Apps app

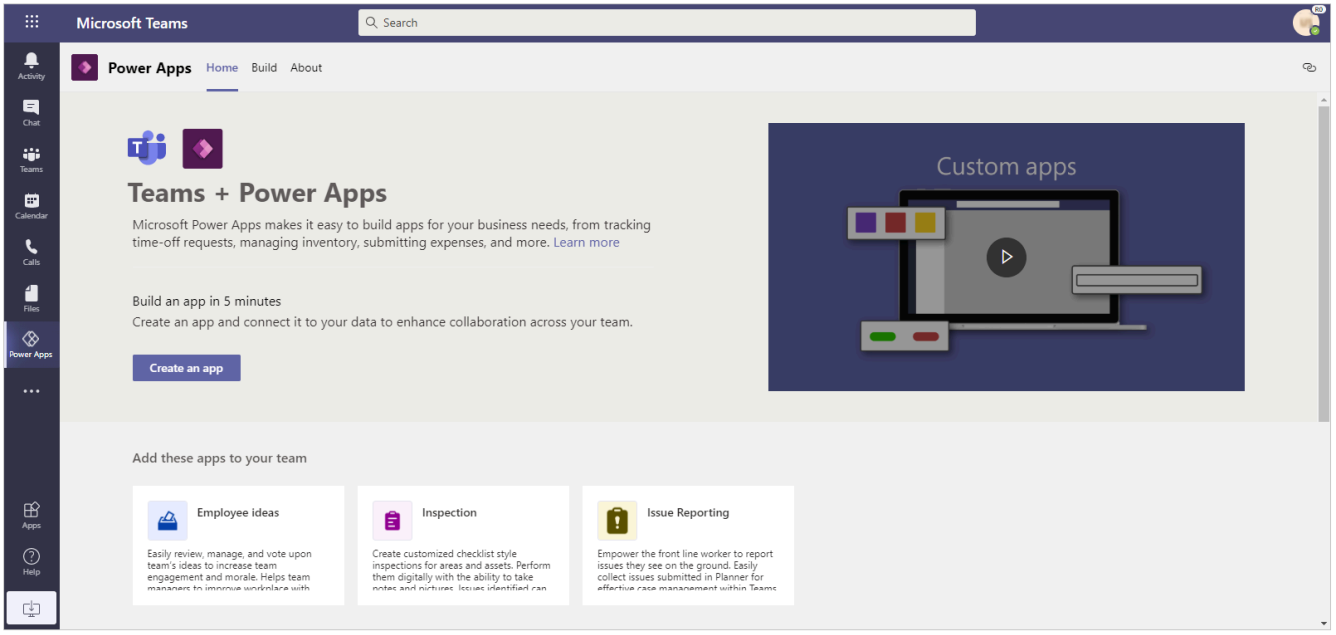
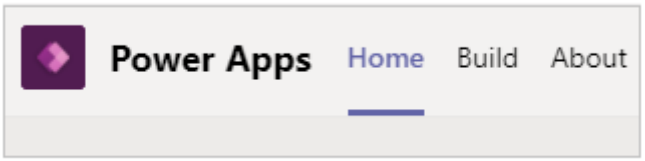
Use the Power Apps app to create and manage apps across the available environments for your teams. Select the Power Apps app from the left pane in Microsoft Teams to open the Power Apps interface.

> **Note**
>
> If **Power Apps** doesn't appear on the left pane, you can install it. After you install the app, you need to create your first app to create an environment. For more information, see About Teams environments.



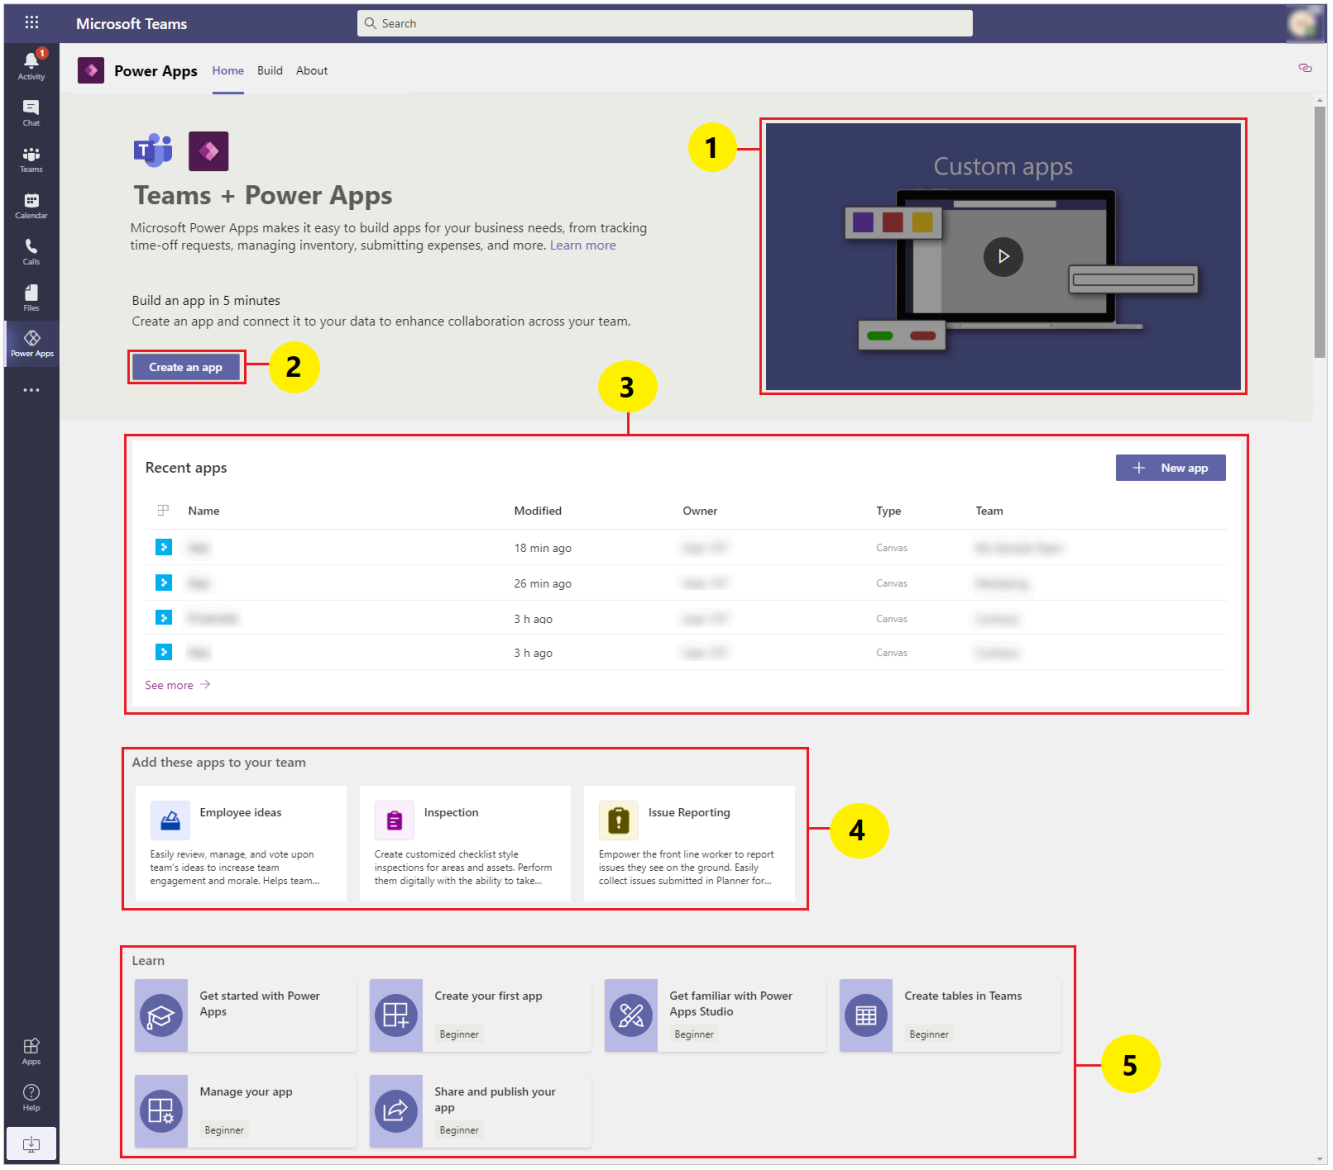
Three tabs are available: **Home**, **Build**, and **About**. You can start creating a new app by selecting **Create an app** on the **Home** tab.



Let's understand each tab in detail.

Home

Your **Power Apps** experience in Teams starts with the **Home** tab. Use the **Home** tab to get started creating new apps with Power Apps.



1. **Introduction Video**: Watch a one-minute video to find out what Power Apps in Teams is all about.

2. **Create an app**: Select **Create an app** to enter the Power Apps Studio integrated inside Teams and start building a Power Apps app. As you learned from Create your first app in Teams, a new environment is created for your team when you first create an app. Creating additional apps in the same team uses the environment that you already created for the team.

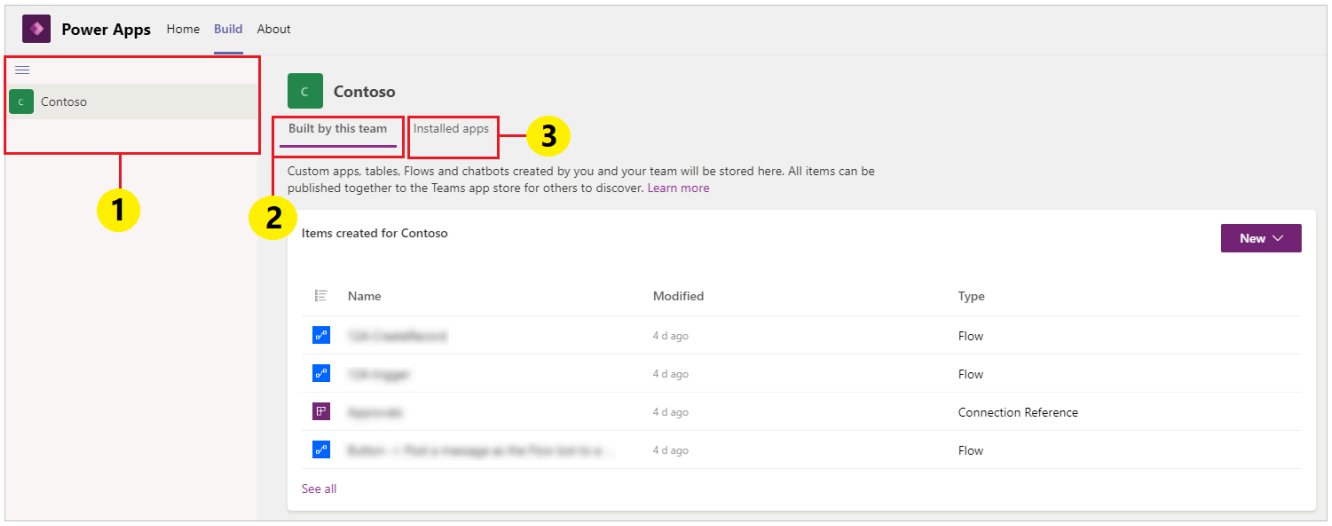
3. **Recent apps**: Find the apps that you recently edited in this section. Select an app from this section to directly open the app inside the Studio. This section is empty if you didn't edit any app yet.

4. **Sample app templates**: This section shows available sample app templates.

5. **Learn**: Find helpful articles in this section to get you started with Power Apps in Teams.

Build hub

Select the **Build** hub to see the list of environments for each team that you're a member of, and the list of apps or objects that the team created or installed.



1. **Environments**: Each Microsoft Teams team with an environment that you have access to is listed here.

   If you have more than one team with environments, select the team or environment you want from the left pane.

   Select  to collapse or expand the environment list.

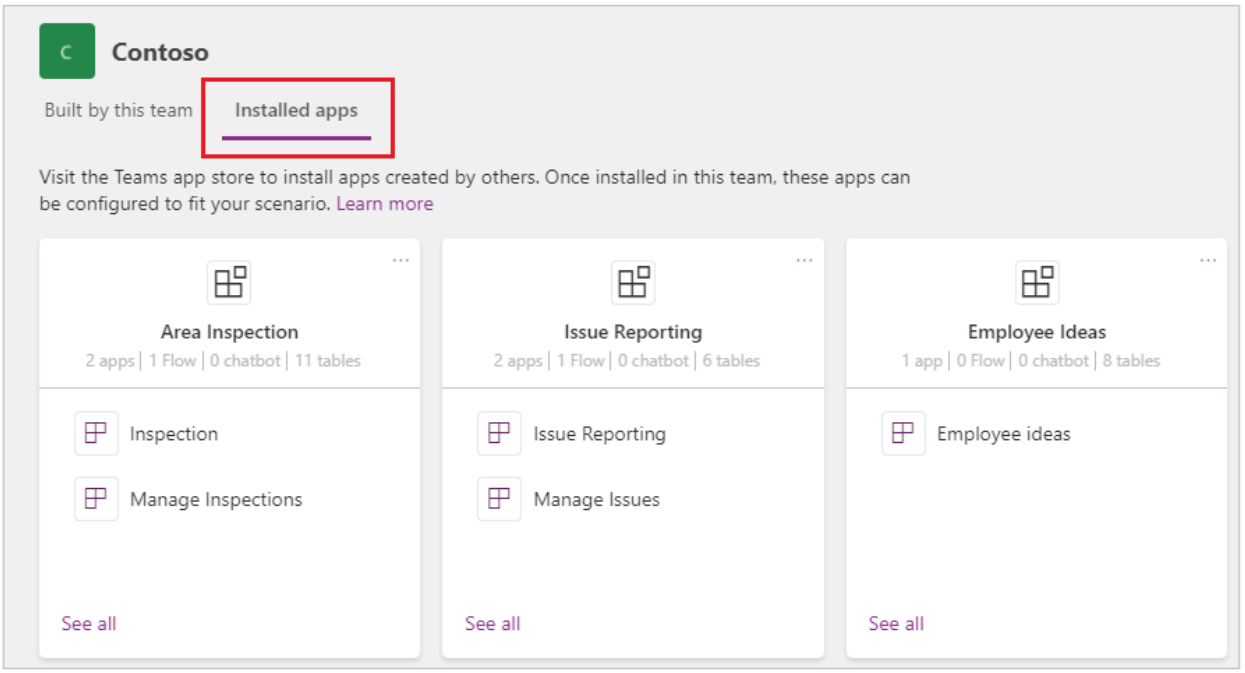
When you select an environment from the list, you see the recent resources built by the selected environment's team, or the apps installed in the selected environment on the right side of the screen.

2. **Built by this team**: This list shows all Power Apps objects such as apps, flows, and tables created in the selected environment (the Teams team). Select **New app** to create a new app. Select **See all** to open the solution explorer for the environment. More information: Solution explorer

   Select **See all** to view all the components in the selected environment, and to create new apps or components.

   In the *Items created for* list, select an app, or a table to directly open the selection in the respective editor.

3. **Installed apps**: Shows a list of installed apps in the environment (Teams team) from the Teams app store.



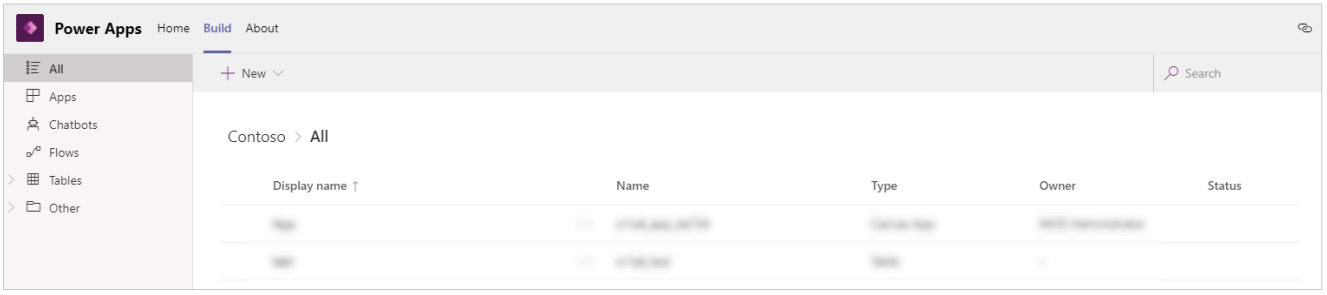
Select an app, or a table to directly open the selection in the respective editor.

Solution explorer

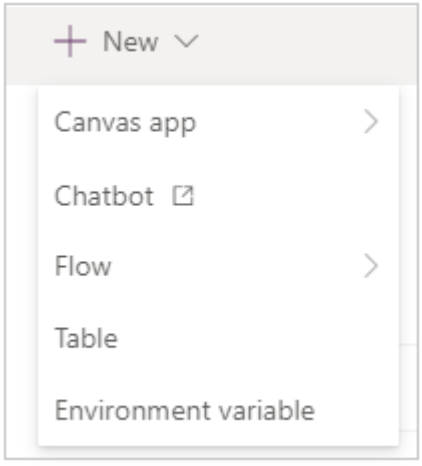
When you select **See all** from the environment list on the **Build** hub, you see the Power Apps solution explorer with a tree view of the pages for the environment. To get started, select a page from the solution explorer on the left.

All

Shows all available Power Apps objects such as apps, flows, and chatbots in the selected environment.

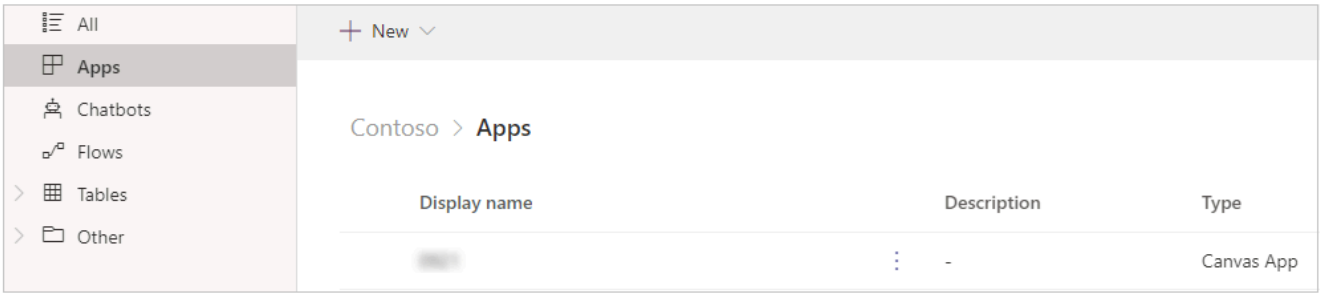


Select **New** to create new apps, flows, or tables.



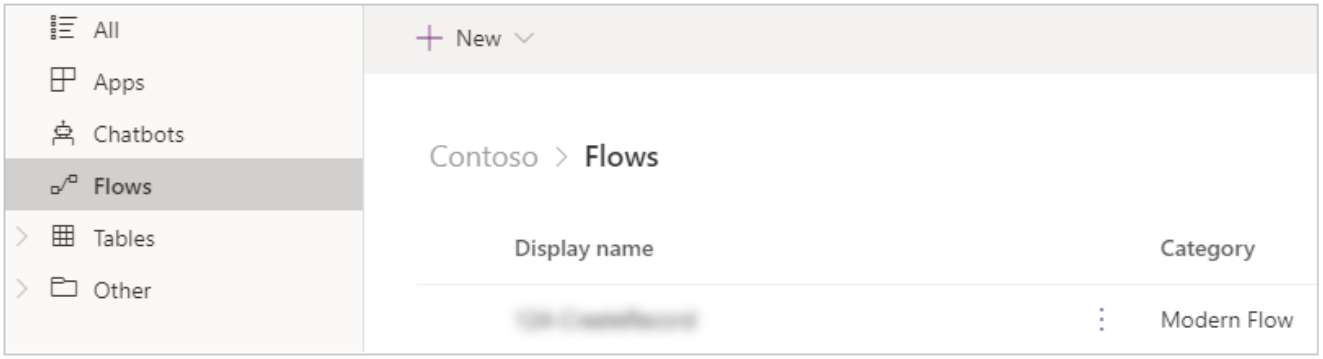
Apps

Shows the apps created with Power Apps. More information: Manage your apps



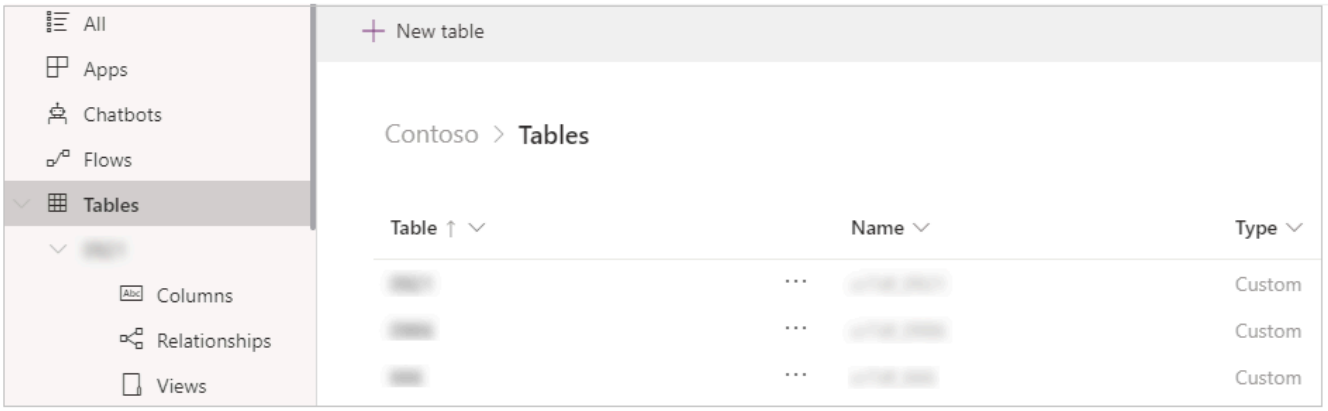
Flows

Shows all the Power Automate flows in the selected team's environment. Power Automate is a service that helps you create automated workflows between your favorite apps and services to synchronize files, get notifications, collect data, and more. Different types of flows are available. More information: Get started with Power Automate



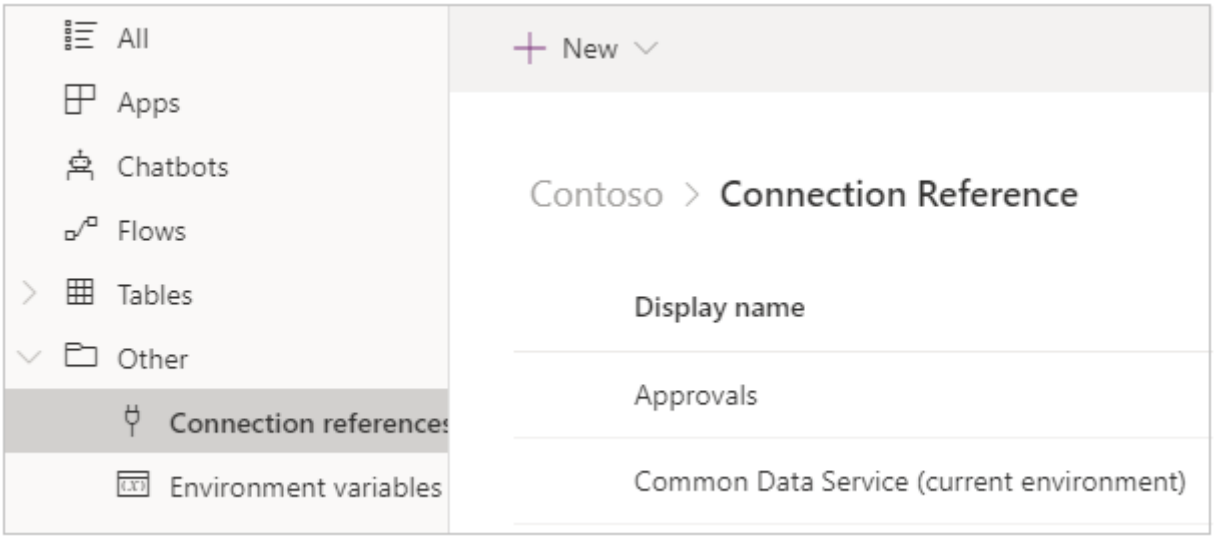
Tables

In Power Apps, a *table* defines information that you want to track in the form of records, which typically include properties such as company name, location, products, email, and phone. You can then surface that data by creating an app that refers to the table. For more information about tables, go to Tables overview.



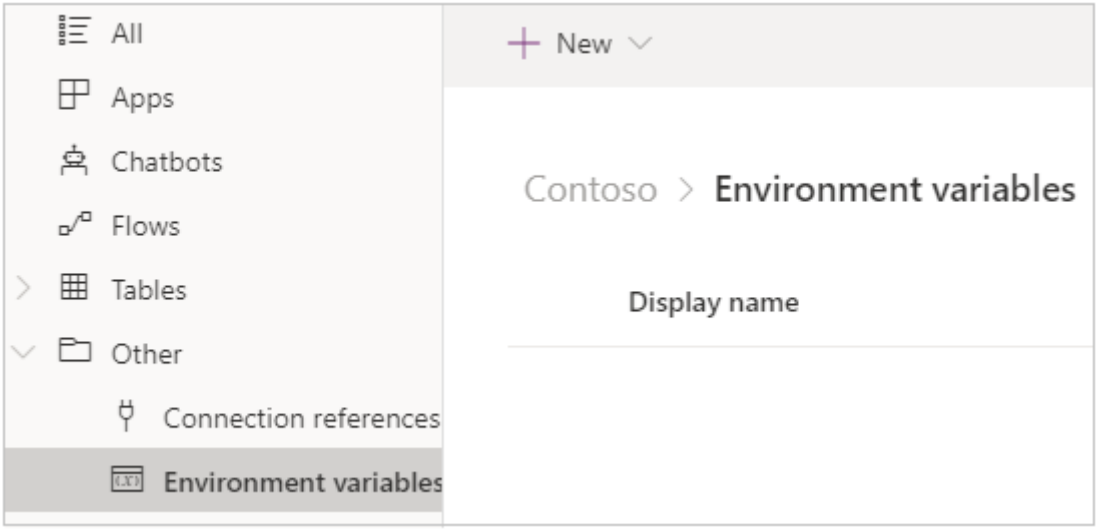
Other - Connection references

Lists connections available to the environment. Data is stored in a data source, and you bring that data into your app by creating a connection. A Power Apps connection connects your app to such a data source. You can use several other types of connections to connect to the Dataverse for Teams environment within the team. More information: Overview of canvas-app connectors



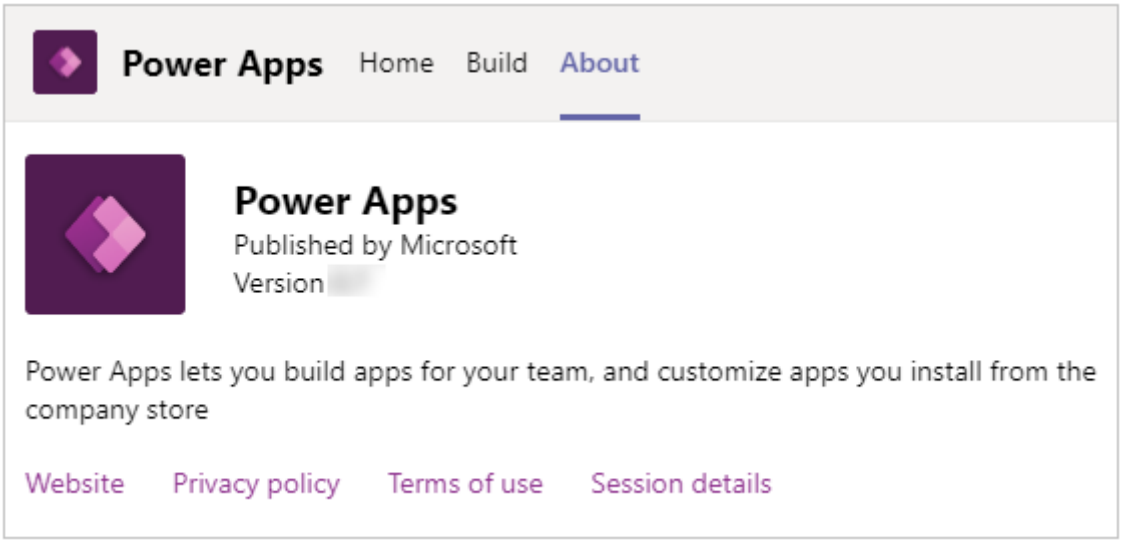
Other - Environment variables

Lists the environment variables for your selected team's environment. Apps and flows often require different configuration settings across environments. You can use environment variables as configurable input parameters separately to manage data, rather than hard-coding values in your customization or using additional tools. More information: Environment variables overview.

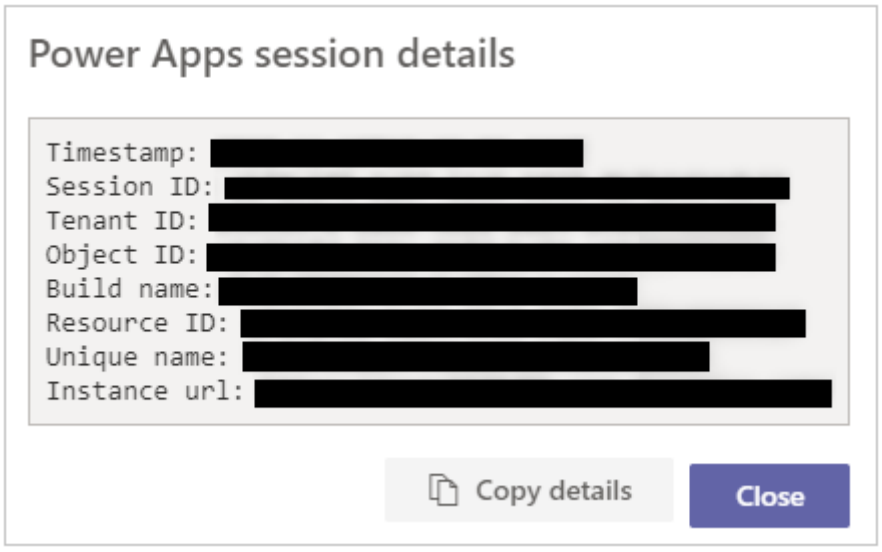


About

Select the **About** tab to view the version of the installed Power Apps app.



You can get your current session details by selecting the **About** tab and then selecting **Session details**. The session details include useful information that you can share with others when investigating an issue or working with support teams.



- **Timestamp**: Date and time in Coordinated Universal Time (UTC).
- **Session ID**: Unique GUID representing the current Power Apps session.
- **Tenant ID**: Tenant ID of Teams and Power Apps.
- **Object ID**: Object ID of the user account in Azure Active Directory.
- **Build name**: Build and version details of the Power Apps app.
- **Resource ID**: ID of the resource.
- **Unique name**: Unique name of the Dataverse organization.
- **Instance url**: URL of the Dataverse instance.

> **Note**
>
> Use session details only when you contact Microsoft Support to investigate an issue.

Canvas apps terminology reference and definitions

When you create canvas apps by using Power Apps from the Teams interface, you need to understand the terms and definitions for various objects, options, and actions in an app. The following table defines these canvas app terms.

Expand table

Component or action	Description
Power Apps Studio	An application used to make or author a canvas app.
Canvas app	An app that you can create from scratch or by using any available template through Power Apps Studio.
Model-driven app	An application based on Dataverse forms, views, tables, columns, and other components.
Connector	A connection object that connects an app with a data source. For example, a connector for SharePoint or a connector for OneDrive.
Control	An object that you add on the canvas to provide certain app functionality.
Property	Behaviors representing the controls available in an app.
Function	Readily available functionality to extend the behavior of a control or app.
Formula	A combination of one or more functions to accomplish a certain task or action.
Screen	The visible area of an app enclosing available visible controls. An app can have multiple screens.
Component	Reusable combinations of controls that you can define, save, and use for new apps.
Save an app	Saving an app for the first time, or saving new changes to an app.
Publish an app	Making an app available to the app store for general consumption.
Versions	Each time you save an app, you create a new version that you can restore.
Share an app	Allowing users or groups to use the app, as consumers or co-owners.

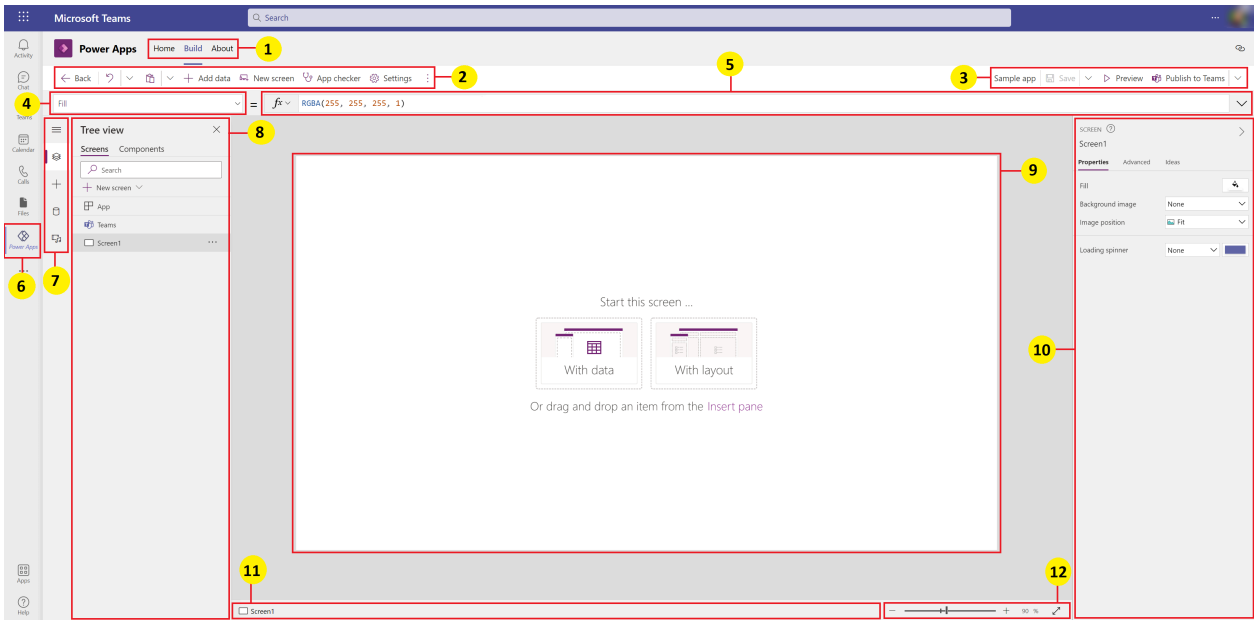
Understand Power Apps Studio in Dataverse in a Teams environment

Article • 12/16/2022

When you create a canvas app by using any method, you're taken to the canvas app builder called Power Apps Studio. You can use Power Apps Studio to design, build, and manage your canvas app.

Overview of Power Apps Studio



1. Build hub – select different pages in the Power Apps app.
2. Power Apps Studio options – options relevant to the settings in a Power Apps Studio session.
3. App actions - options to rename, save, preview, or publish the app.
4. Properties list - list of properties for the selected object.
5. Formula bar - compose or edit a formula for the selected property with one or more functions.
6. Power Apps app – Power Apps app in Microsoft Teams.
7. App authoring menu - selection pane to switch between data sources and insert options.

8. App authoring options - details pane with options relevant to the selected menu item for authoring the app.
9. Canvas/screen - primary canvas for composing the app structure.
10. Properties pane - properties list for the selected object in UI format.
11. Screen selector - switch between different screens in an app.
12. Change canvas screen size - change the size of the canvas during an authoring experience in Power Apps Studio.

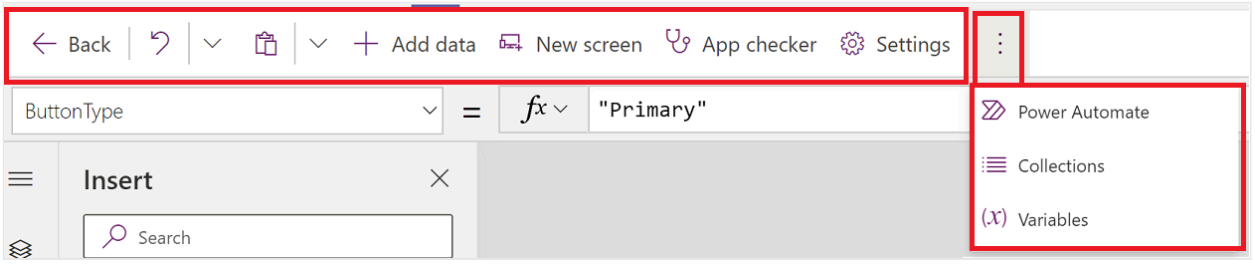
Let's understand each option in Power Apps Studio in detail.

1 - Build hub

Opening Power Apps Studio from the build hub opens an app authoring experience that inherits the Teams interface and options. The **Home**, **Build**, and **About** tabs are described in Overview of the Power Apps app.

2 – Power Apps Studio options

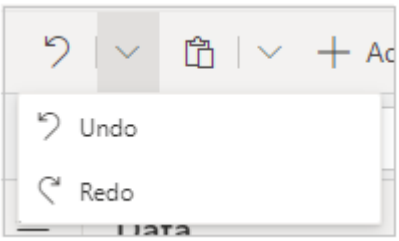
Power Apps Studio options are available on the menu in the upper-left corner. The options are relevant to the current session and app-related settings.



Back

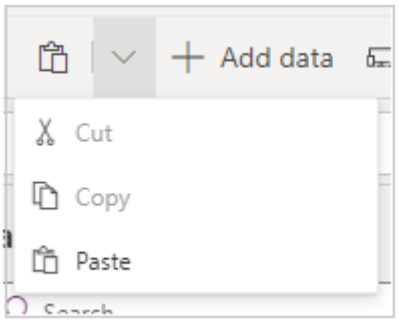
Takes you back to the build hub, closing the current Power Apps Studio session.

Undo and redo



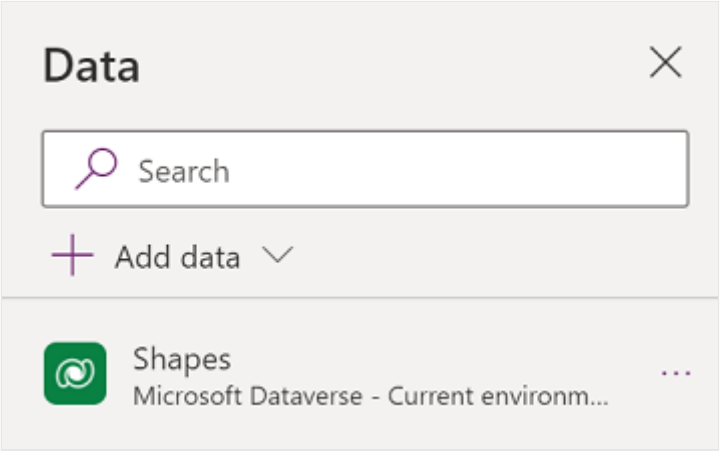
- **Undo** – undo the last action.
- **Redo** – repeat the last action.

Cut, copy, and paste



- **Cut** – Cut the selection, and store it in the clipboard.
- **Copy** – Copy the selection, and store it in the clipboard.
- **Paste** - Paste the last cut, or copied selection from the clipboard.

Add data



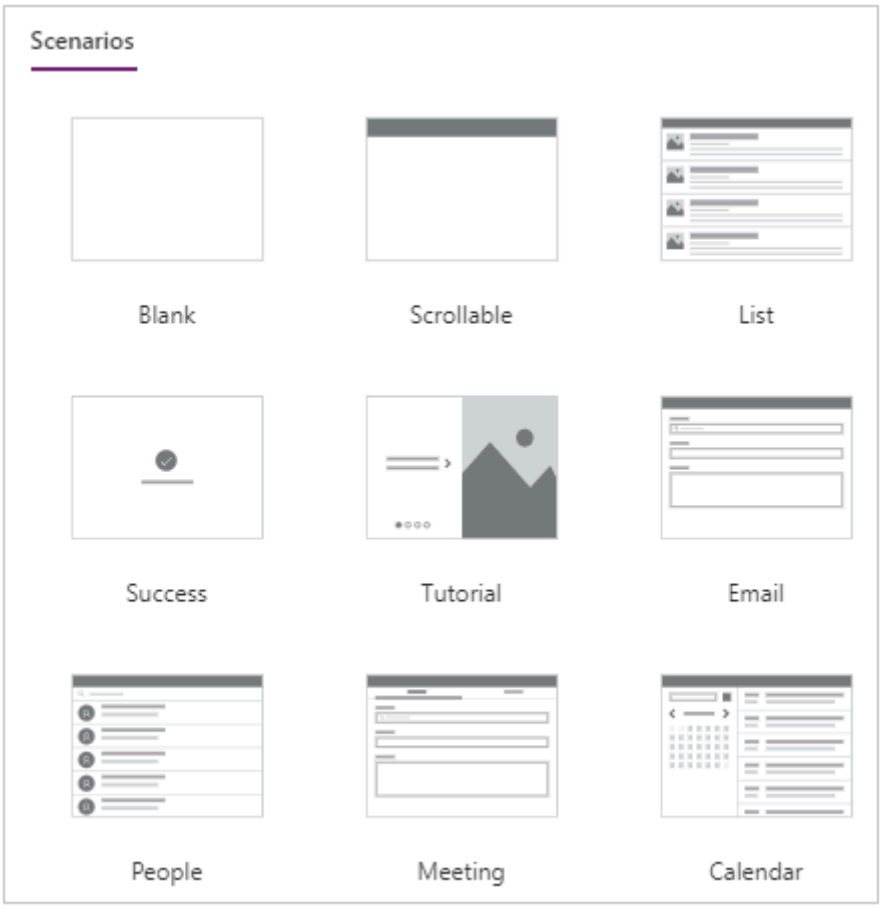
- Create a new table by selecting **Create new table**.
- Select any other existing tables from the current environment.
- Search and select a connector, such as **SharePoint** or **SQL Server**.

New screen

Add screens based on the available layouts.

Layouts

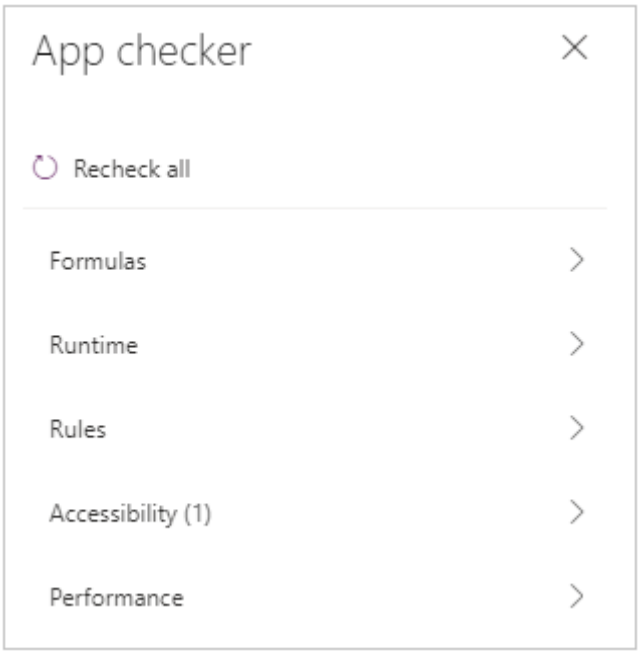
Select a new screen to add to the app based on the layout of the screen.



Select a screen type based on the available scenarios, such as **Blank**, **Scrollable**, **List**, **Success**, **Tutorial**, **Email**, **People**, **Meeting**, or **Calendar**.

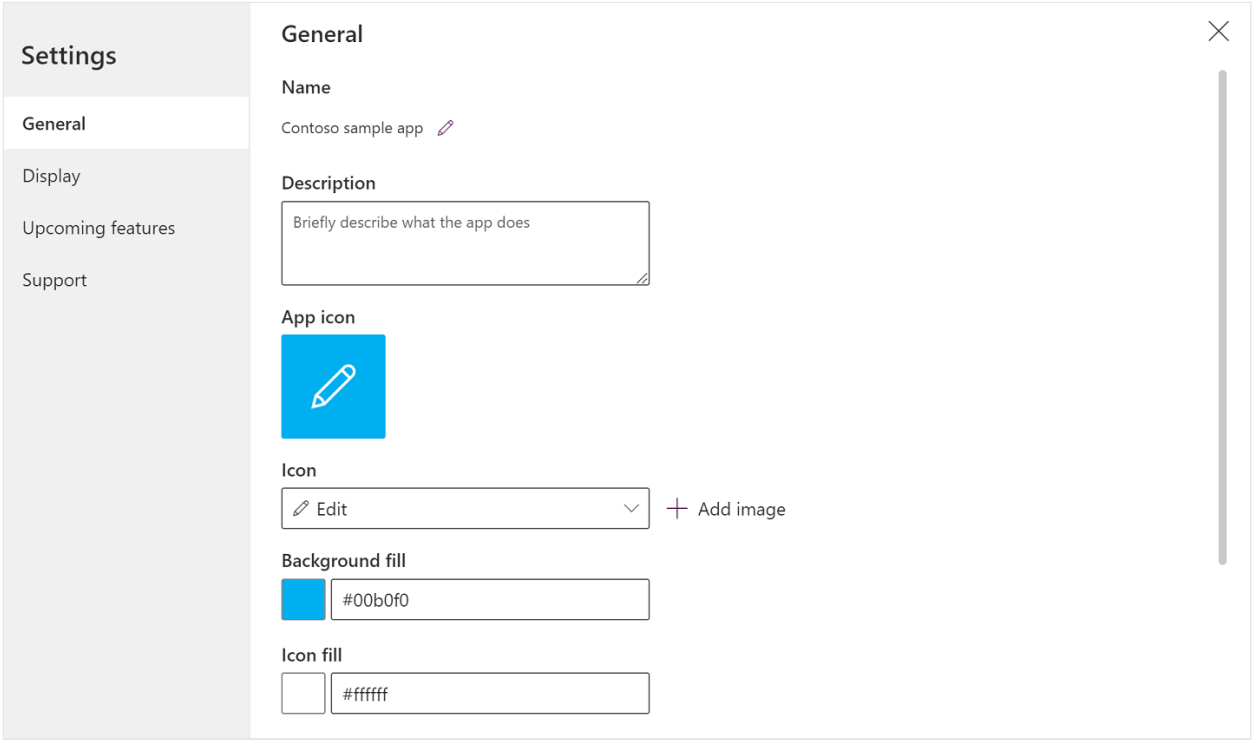
App checker

Runs the App checker with available rules and shows the results.



Settings

Configure the app's general settings.



General

Shows app name, and allows changing the app icon. To update the icon, select a new icon or background color. To add or update description, enter text in the text box. You can also upload a custom icon for the app using the **Browse** option.

Display

Shows the screen size and orientation. To change, select the radio buttons for **Orientation** and **Size**.

Advanced settings allow you to further customize the app screen configuration.

- **Scale to it**: Scales the app to fit available space.
- **Lock aspect ratio**: Locks the height and width ratio.
- **Lock orientation**: Maintains app orientation when device rotates.

To change the setting, toggle the switch.

More information: Change screen size and orientation

Upcoming features

Allows you to configure advanced settings for the app that include features under preview, experimental or retired features.

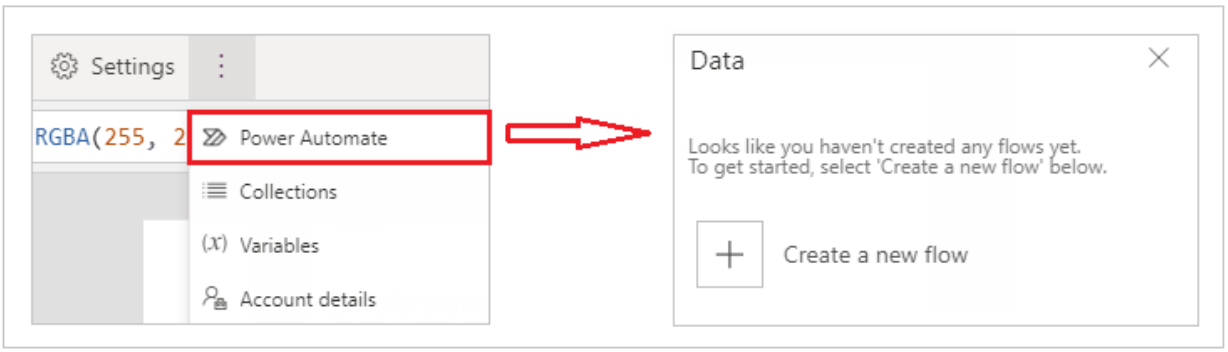
More information: Understand experimental, preview, and deprecated features in Power Apps

Support

Shows current Power Apps Studio session details, version, and other information useful when working with Microsoft support.

Power Automate

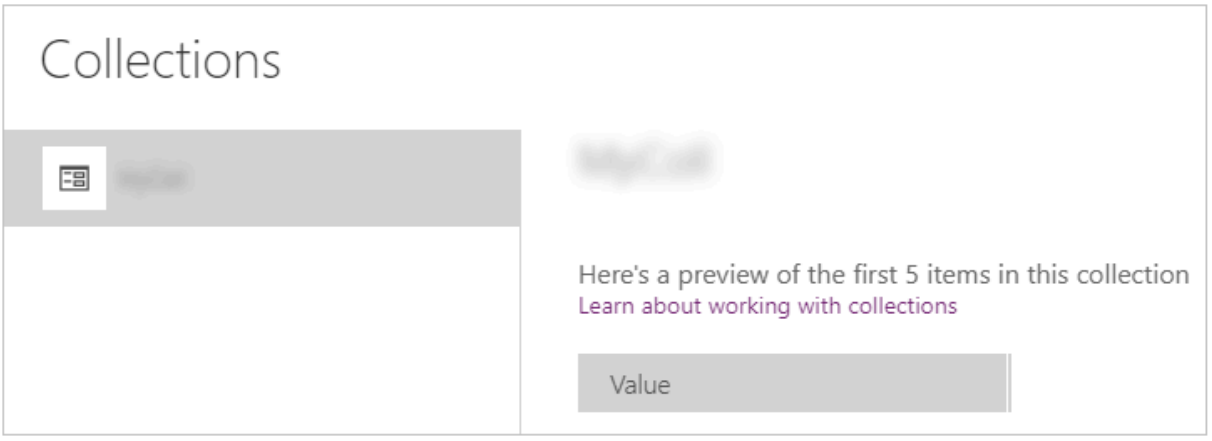
Create a new flow with Power Automate, or select any available flow.



More information: Create flows using the Power Apps app in Teams

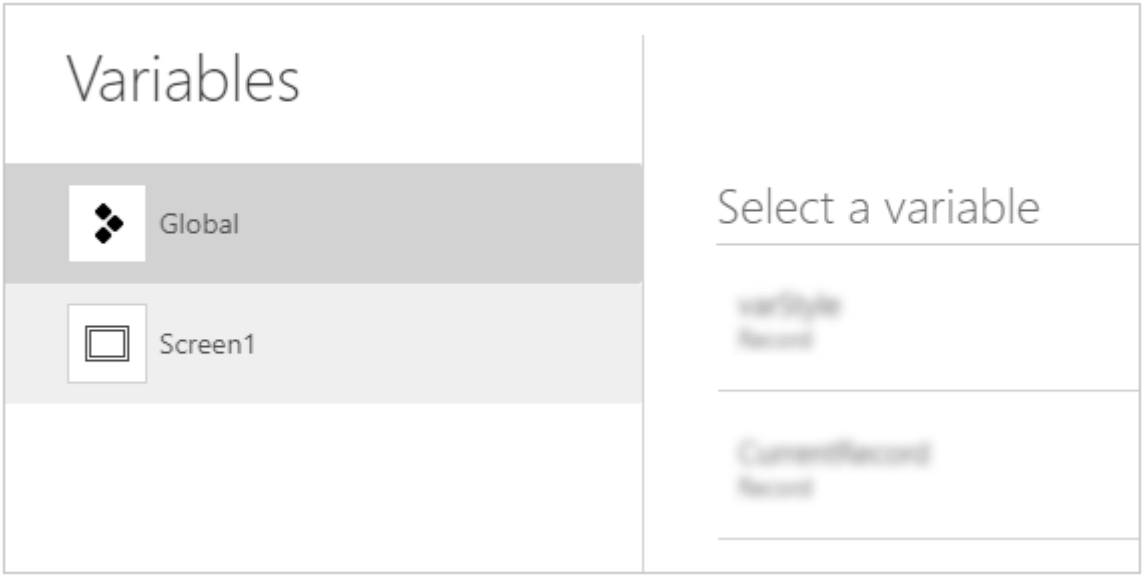
Collections

A collection is a group of items that are similar, such as products in a product list. This section lists the collections used by the current app. More information: Collections in canvas apps used by the app.



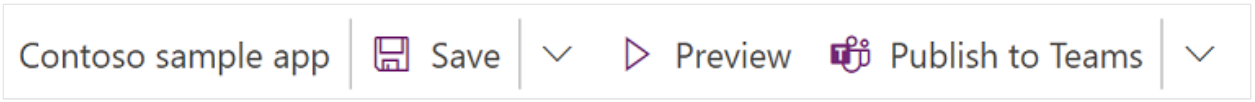
Variables

You can save data such as the result values from a data set into temporary storage by using variables. This section lists variables used by the current app. More information: Variables in canvas apps used by the app.



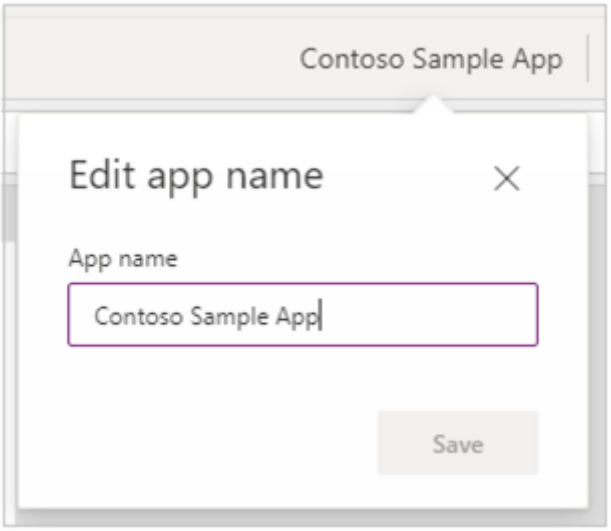
3 – App actions

Use the options in the upper-right corner of Power Apps Studio to work with app-specific actions.

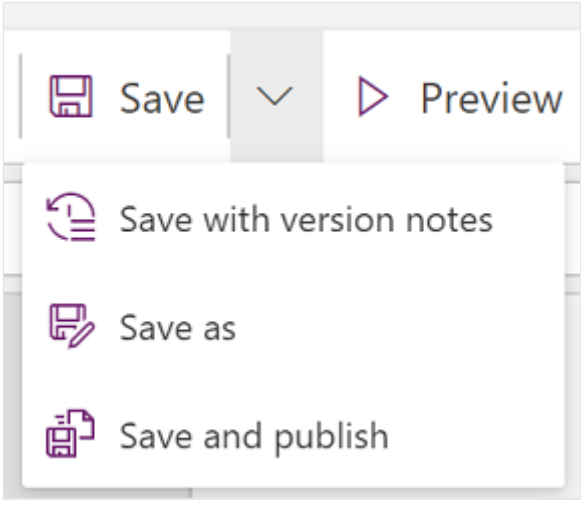


App name editor

Select the name of the app to edit it.



Save



Save allows you to perform the following actions:

- **Save** - Saves recent and unsaved changes you made to the app in Power Apps Studio. Each time you save changes, a new version is created.
- **Save as** - Duplicate the app by saving the app with a different name.
- **Save and publish** - Allows you to both save the app, and publish it at the same time.

Preview

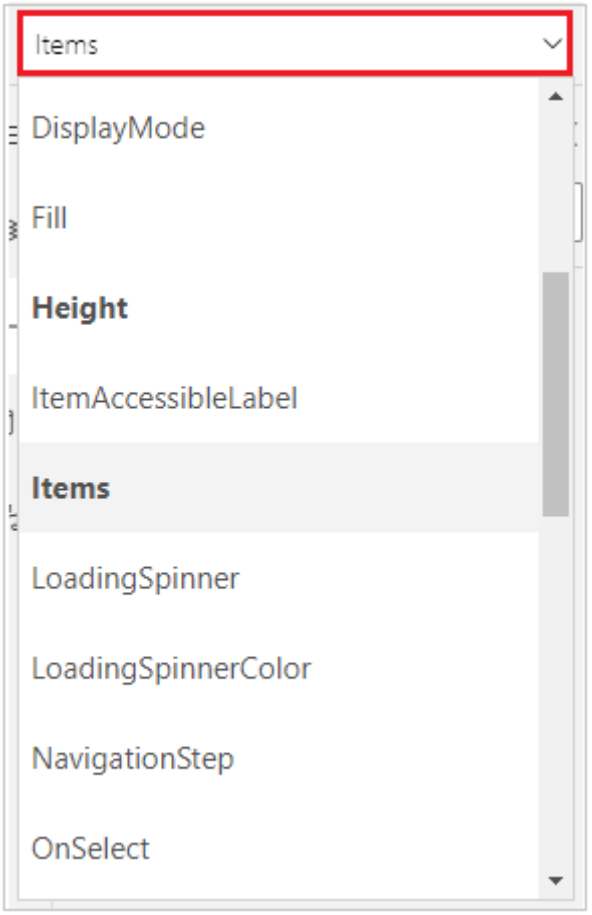
This will show a preview version of the app in Microsoft Teams that you can interact with.

Publish to Teams

Publishes the app's current version to a channel within Microsoft Teams. For more information about publishing an app, go to Publish an app.

4 – Properties list

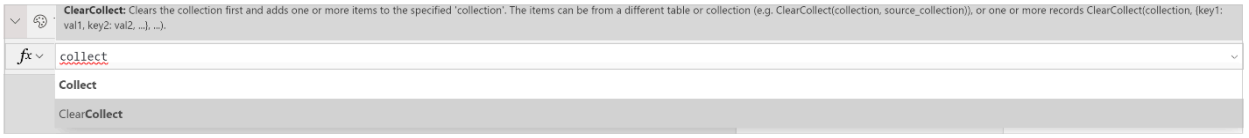
Shows the list of available properties for the selected object on the canvas. The properties list changes based on your selection. For a complete list of all properties, go to All properties.



5 – Formula bar

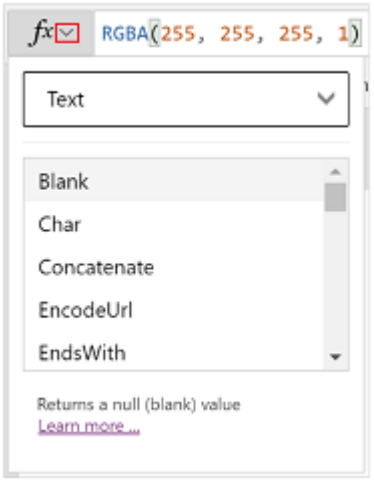
Use the formula bar to add, edit, or remove functions relevant to the selected object and the property selected from the properties list. For example, select the screen to update the background by using the RGBA function.

The formula bar is IntelliSense-enabled, and provides tips as you enter text to help you with the function syntax. If a formula returns an error, tips relevant to the syntax error and mitigation steps are displayed. When you start entering text that matches one or more functions, the formula bar shows inline function help and highlights help text relevant to the cursor position.

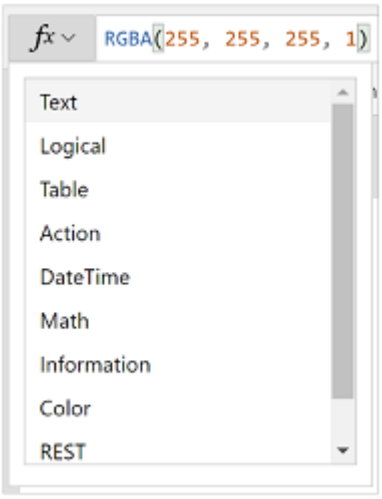


Similarly, you'll find help when working with complex functions, nested functions, or when correcting a formula syntax.

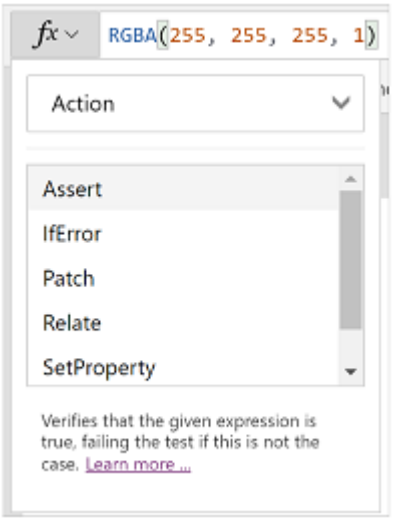
For a quick and easy function reference, you can also select the formula drop-down menu.



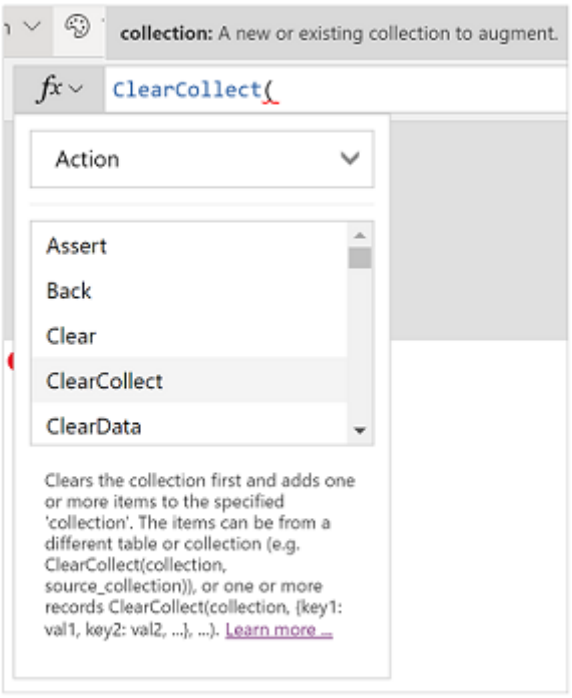
Select an event type from the drop-down menu at the top of the dialog box, such as **Action** instead of **Text**.



Select an action that you want to add a function for.



The available functions for the selected event type are dynamically updated depending on the object you select. For example, if you selected a button on the canvas, the available **Action** functions also include the function *ClearCollect()*.



You can read the description of the selected **Action** function. Double-clicking a function name adds it into the formula bar.

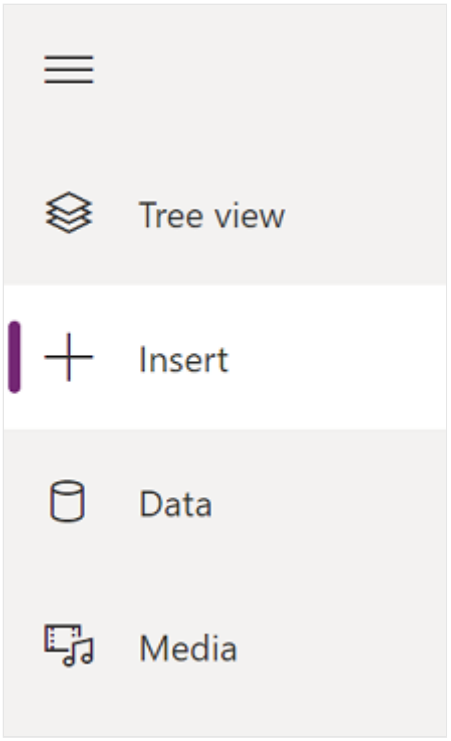
For a complete list of all canvas app functions, go to Formula reference.

6 – Power Apps app

The Power Apps app in Teams is described in detail in Overview of the Power Apps app.

7 – App authoring menu

Switch between various authoring options while working with the app.



> **Tip**
>
> You can also select the expand button to expand the list to include names instead of just icons.

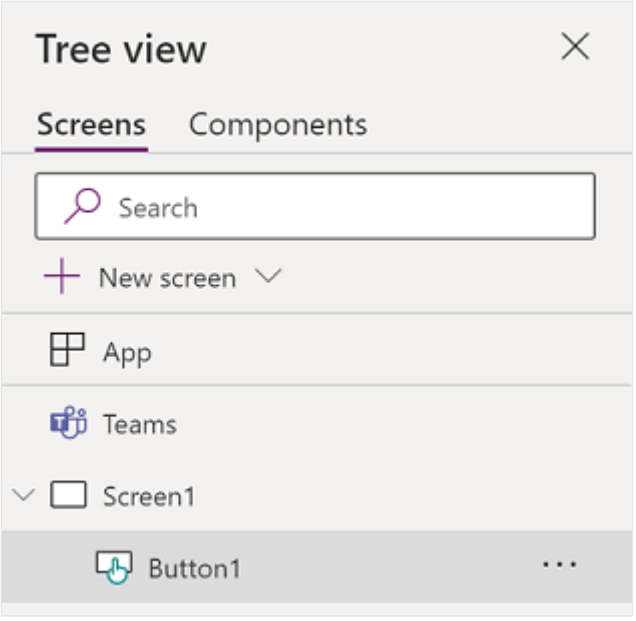
- **Tree view** - Shows a tree view of all screens and controls in the current app.
- **Insert** - Allows you to add different controls to the screen.
- **Data** - Add or remove data such as tables that the app connects to.
- **Media** - Insert or remove media from the app.

8 – App authoring options

The options for working with canvas apps change depending on the selection on the left pane.

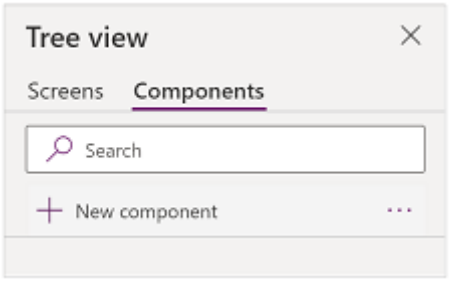
Tree view

Select the tree view to show the screens available in the app,



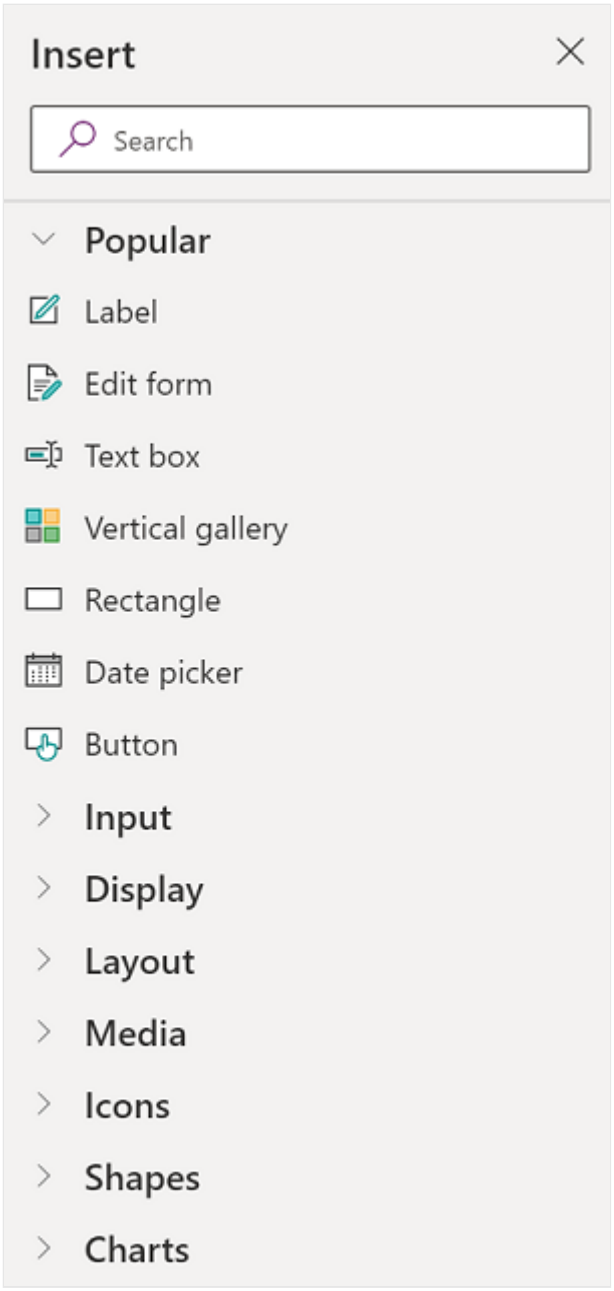
> **Tip**
>
> Select **App** in the tree view to work with app-specific controls or to change app behavior, such as adding a formula on *OnStart* event of the app.

Switch to the **Components** tab to work with component library features. You can add new components or reuse those that were already published from published component libraries. More information: Component library



Insert

Insert shows all the popular objects or controls that you can add on the selected screen in your canvas app. You can also expand other choices or use the components option to insert controls from a component library.



To insert controls on the canvas, you can drag the control to the canvas, select the control, or select **(...)** and then select **Add to canvas**.

> **Tip**
>
> Dataverse for Teams provides new components built on the Fluent UI framework. More information: Fluent UI controls.

Popular controls

Expand table

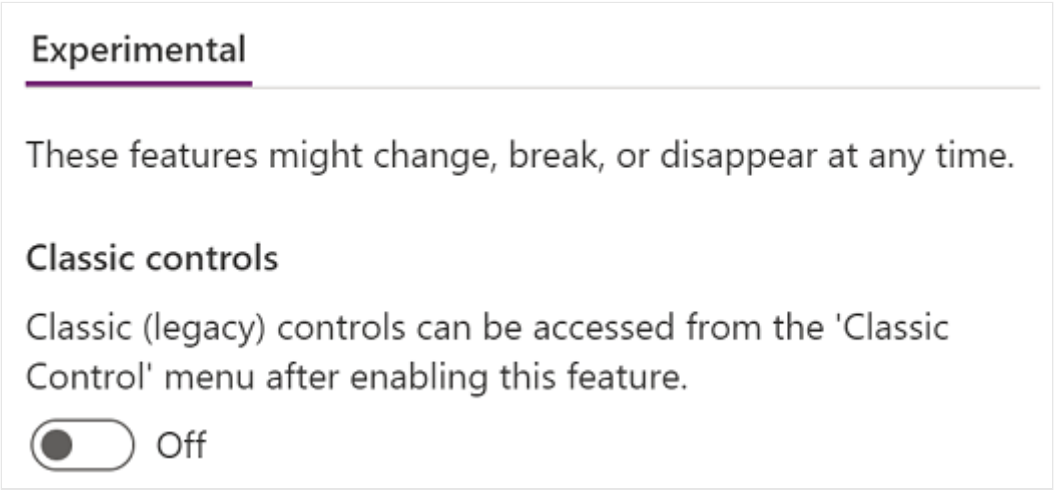
Name	Description
Label	A box that shows data such as text, numbers, dates, or currency.
Edit form	Display, edit, or create a record in a data source.
Text	A box that shows text.
Text box	A box in which the user can enter text, numbers, and other data.
Vertical gallery	A control that contains other controls and shows a set of data.
Add icon	Graphics for which you can configure appearance and behavior properties.
Rectangle	A rectangular shape to configure the canvas appearance.
Date Picker	A control that the user can select to specify a date.
Button	A control that the user can select to interact with the app.

For more information about the controls that you can insert, and their properties and definitions, go to Controls and properties in Power Apps.

Classic controls

Dataverse for Teams uses Fluent UI controls by default. If necessary, you can enable classic controls by using the experimental feature setting. To do this, go to **Settings** > **Upcoming features** > **Experimental** > toggle **Classic controls** to **On**.

After you enable classic controls, you'll be able to see and add them from the **Classic** category.

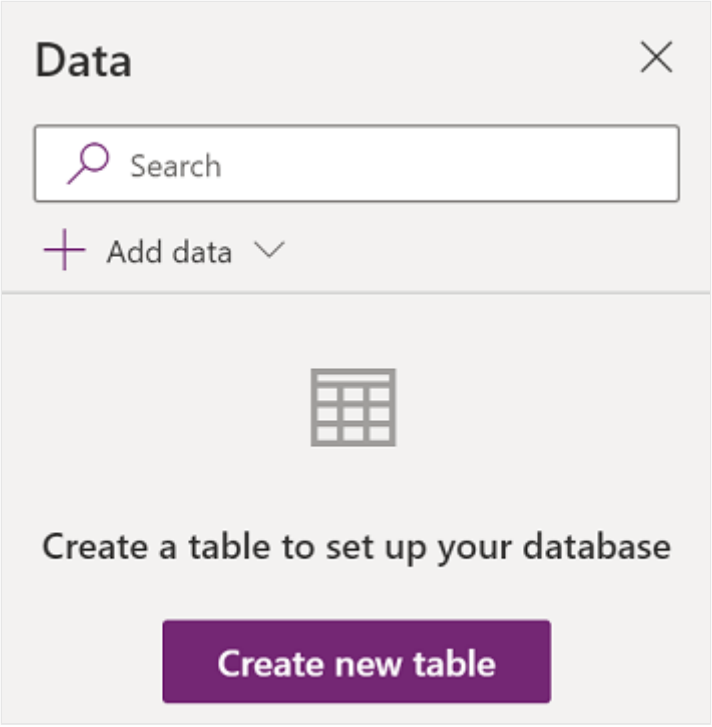


For example, you may need to enable classic controls when using dependent drop-down lists when using Dataverse for Teams.

Data

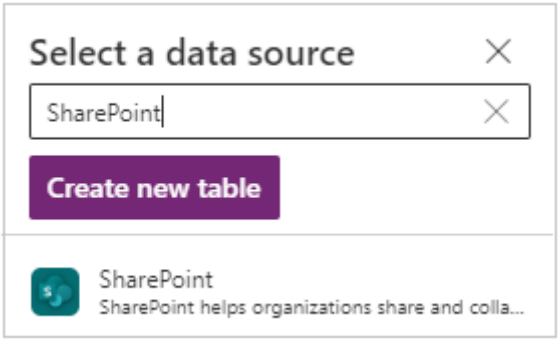
Add, refresh, or remove data sources from your canvas app. You can add one or more connections by using data sources.

In addition to data stored within tables, there are many connectors available to interact with data in popular SaaS, services, and systems.



Select **Create new table** to create a new table in the Dataverse for Teams environment.

To choose other connectors such as SharePoint, OneDrive, or SQL Server, you can enter text in the data source search box or select from the list of connectors.

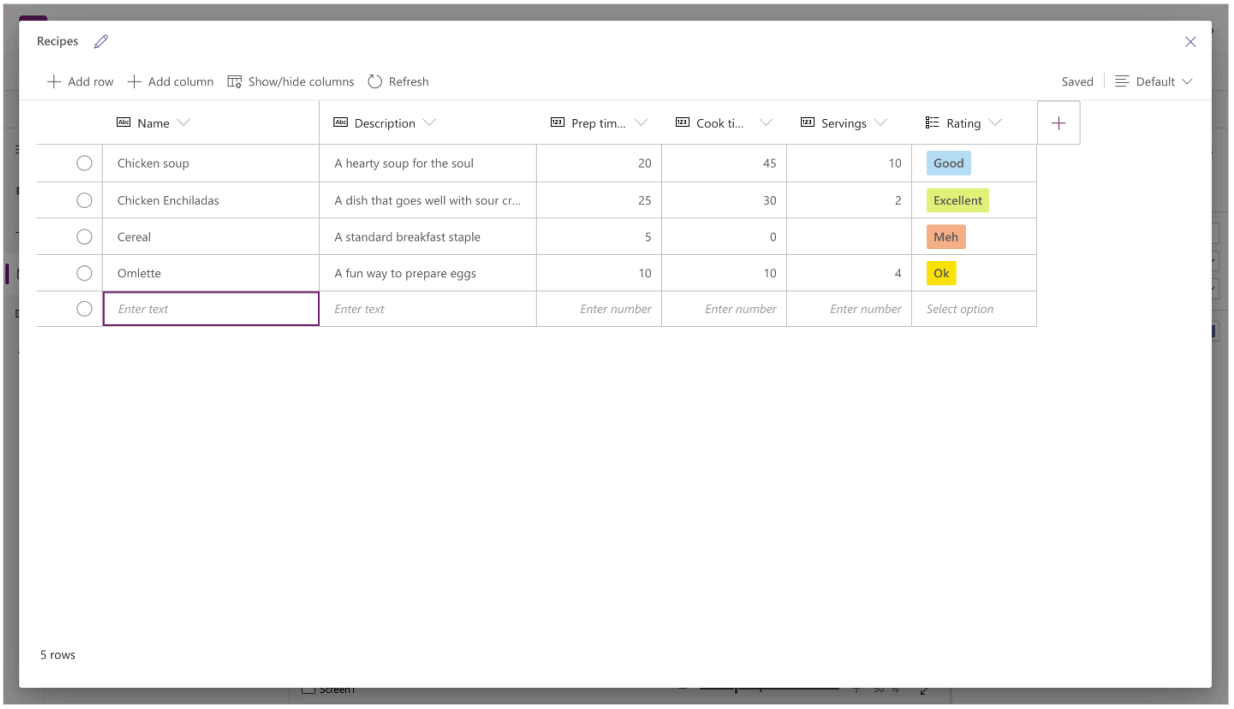


More information: List of all Power Apps connectors

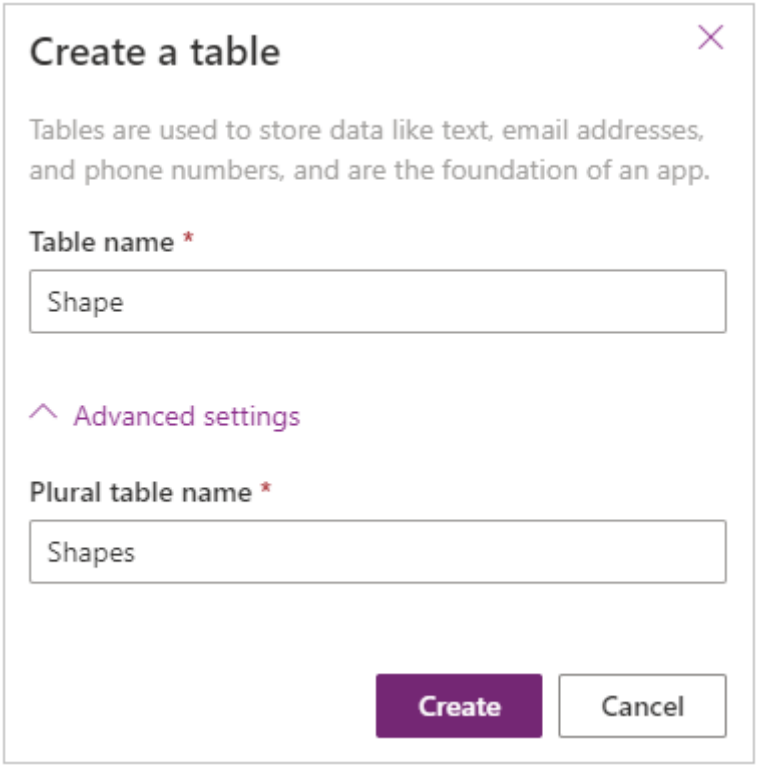
Visual editor

When you select **Create new table** and enter a name for the new table, you open visual editor where you can design the table, add columns of different data types, enter data in

rows, and save the changes.



To get started with visual editor, select **Create a table** and enter the table name. You can also expand the *Advanced settings* to update the table's plural name. For example, a table name can be *Shape*, and the plural table name can be *Shapes*.



Watch this video that shows you how to quickly create table and columns.
https://learn-video.azurefd.net/vod/player?id=40f4f29f-77df-420a-a182-cb71b39f4613&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Funderstand-power-apps-studio

> **Note**
>
> You can use visual editor in Power Apps Studio to quickly create a table while authoring an app. However, you can also use the Build tab to edit or delete the tables you create by using Power Apps Studio. Go to Create tables in Microsoft Teams for more information about creating tables by using the **Build** tab.

Understand visual editor

Visual editor allows you to work with table rows, columns, and data.

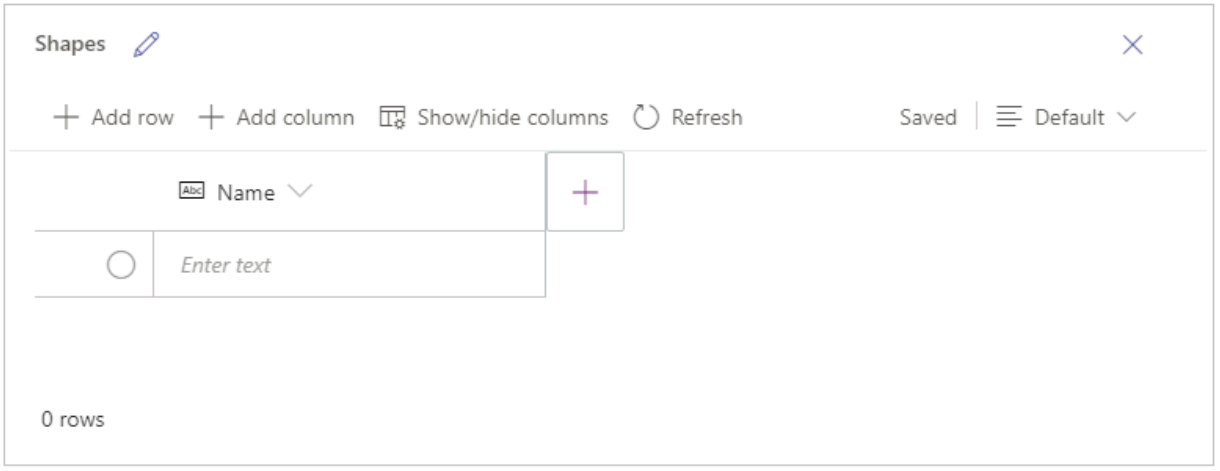


Table name

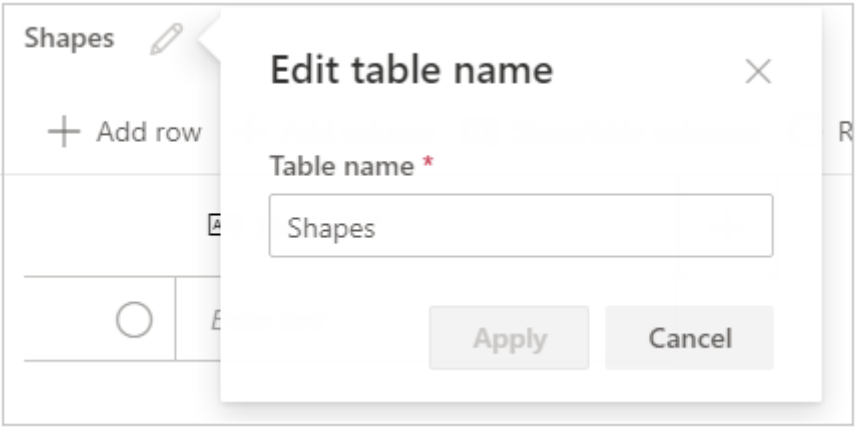
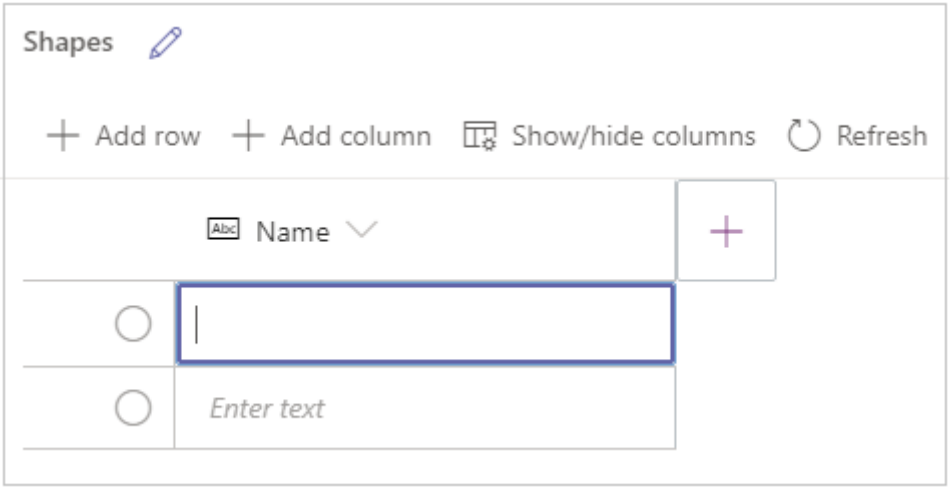
Select **Edit** to edit the name of the table.



Add row

Select **Add row** to add a new row to the table.



Add columns

Select **Add columns** to add new columns of the available column types supported by visual editor.

Supported column types

Visual editor supports specific data types as columns. The following options are available when creating a new column using visual editor inside Power Apps Studio:

- Text
- Email
- URL
- Phone
- Auto number
- Number
- Date (Only dates without the user locale (time zone) settings are supported.)
- Decimal
- Lookup
- Choice
- Yes/No

> **Important**
>
> To add columns of types that aren't supported by visual editor, such as file or image, create a table by using the solution explorer instead.

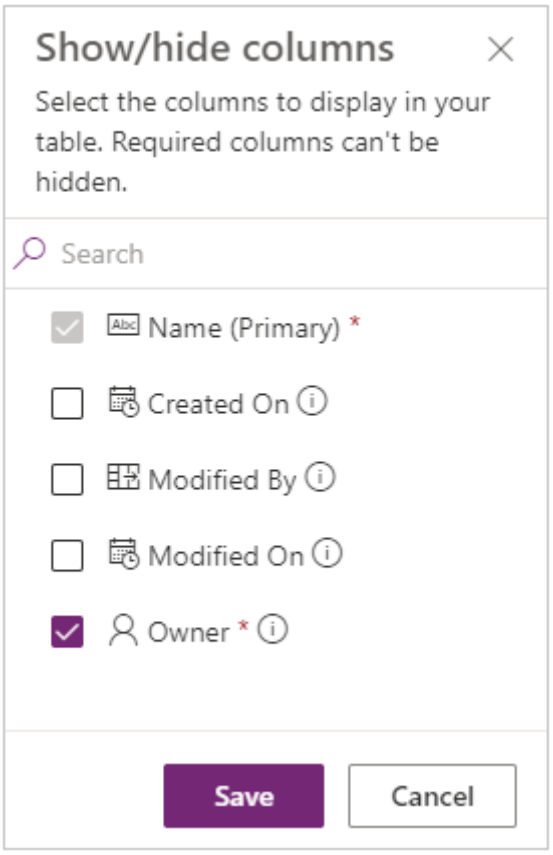
Advanced options

The advanced options for columns change depending on the type of column. For example, a **Text** column type has an advanced option for **Max length**. By contrast, an **Auto number** column type has options such as the type of autonumbering, prefixes, and maximum number of digits. More information: Types of fields

Show/hide columns

Use the **Show/hide columns** option to show or hide available columns, including columns automatically created as part of the table metadata.

For example, you can add an *Owner* column created by default to the existing table.

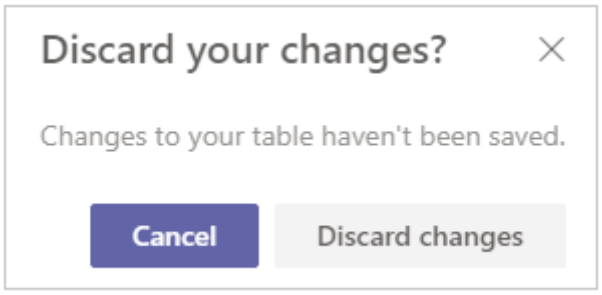


Refresh

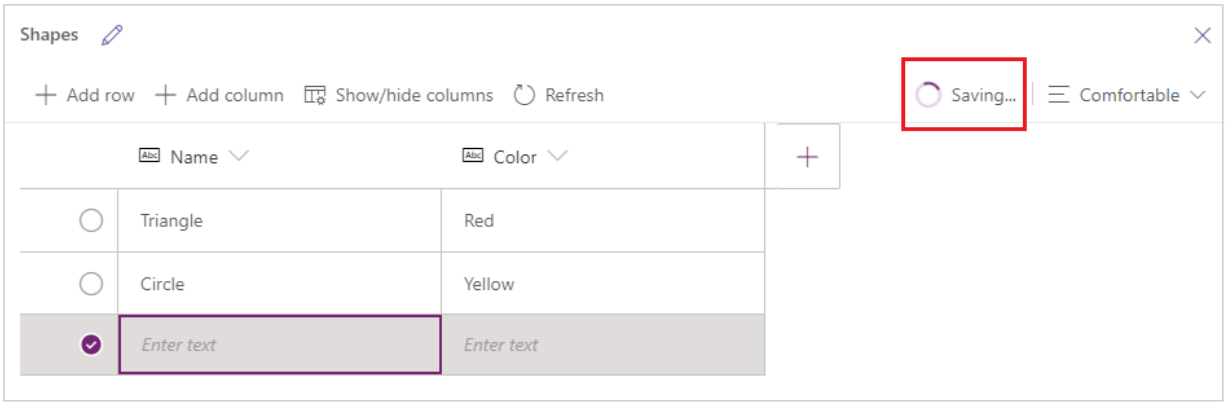
Refreshes the current table with data.

Save

To save changes to a table, select **Save.** When you change a table and try to close it without saving changes, you're prompted to discard changes.



To ensure that changes to the table are saved, you can select the next row inside the table, or select any other cell after editing a cell to trigger the auto save functionality.



After you close a saved table, you'll see the table added to the list of available data sources in **Data** on the left pane.

Visual editor view

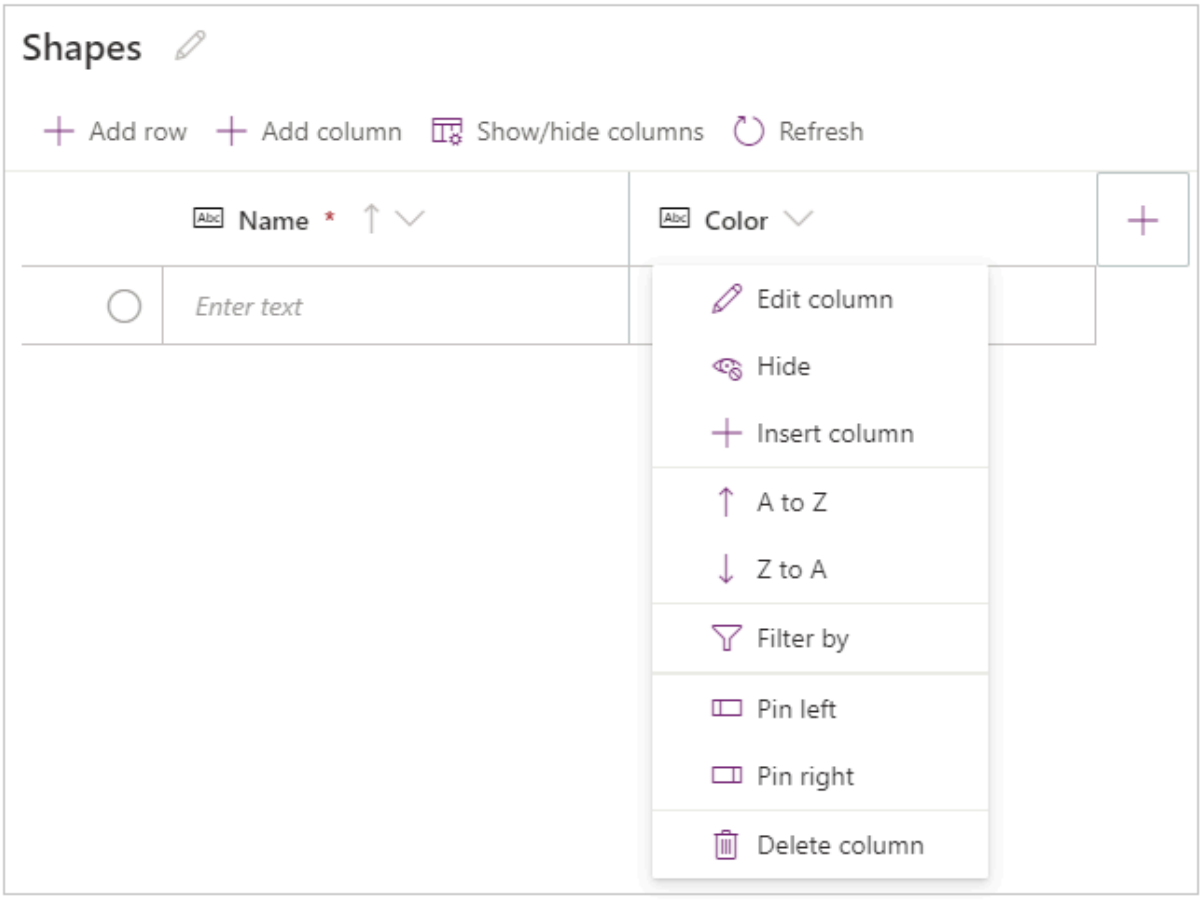
Select from the options of **Compact**, **Default**, or **Comfortable** layouts to switch the view with columns and rows spacing to change visual editor layout.

Row count

Shows the row counts in the table.

Column options

Select the drop-down menu next to the column heading to view column-related options.



Expand table

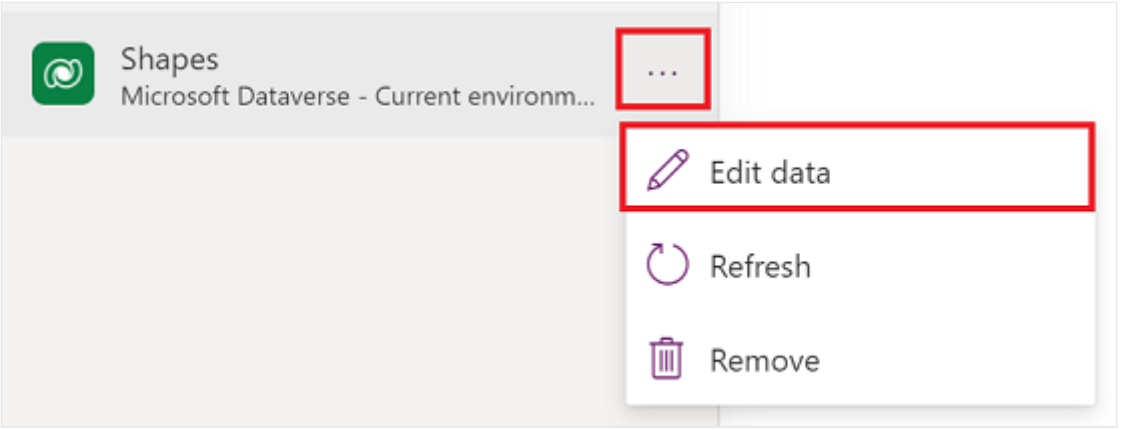
Option	Description
Edit column	Edit the column name or advanced options. After it's created, you can't change the name of the column.
Hide	Hide or unhide the column.
Insert column	Insert a new column at the selected column location.
A to Z	Sort records in ascending order.
Z to A	Sort records in descending order.
Filter by	Filter column data based on the filter criteria you define.
Move left	Move the column to the left from the current position.
Move right	Move the column to the right from the current position.
Pin left	Pin the column to the left side of the table.
Pin right	Pin the column to the right side of the table.

Option	Description
Delete column	Delete the column.

Edit existing table

After you add rows and columns, and add data, you can close the table and use it as the data source in your app. To edit content in the table, you can use the app controls or go back to visual editor.

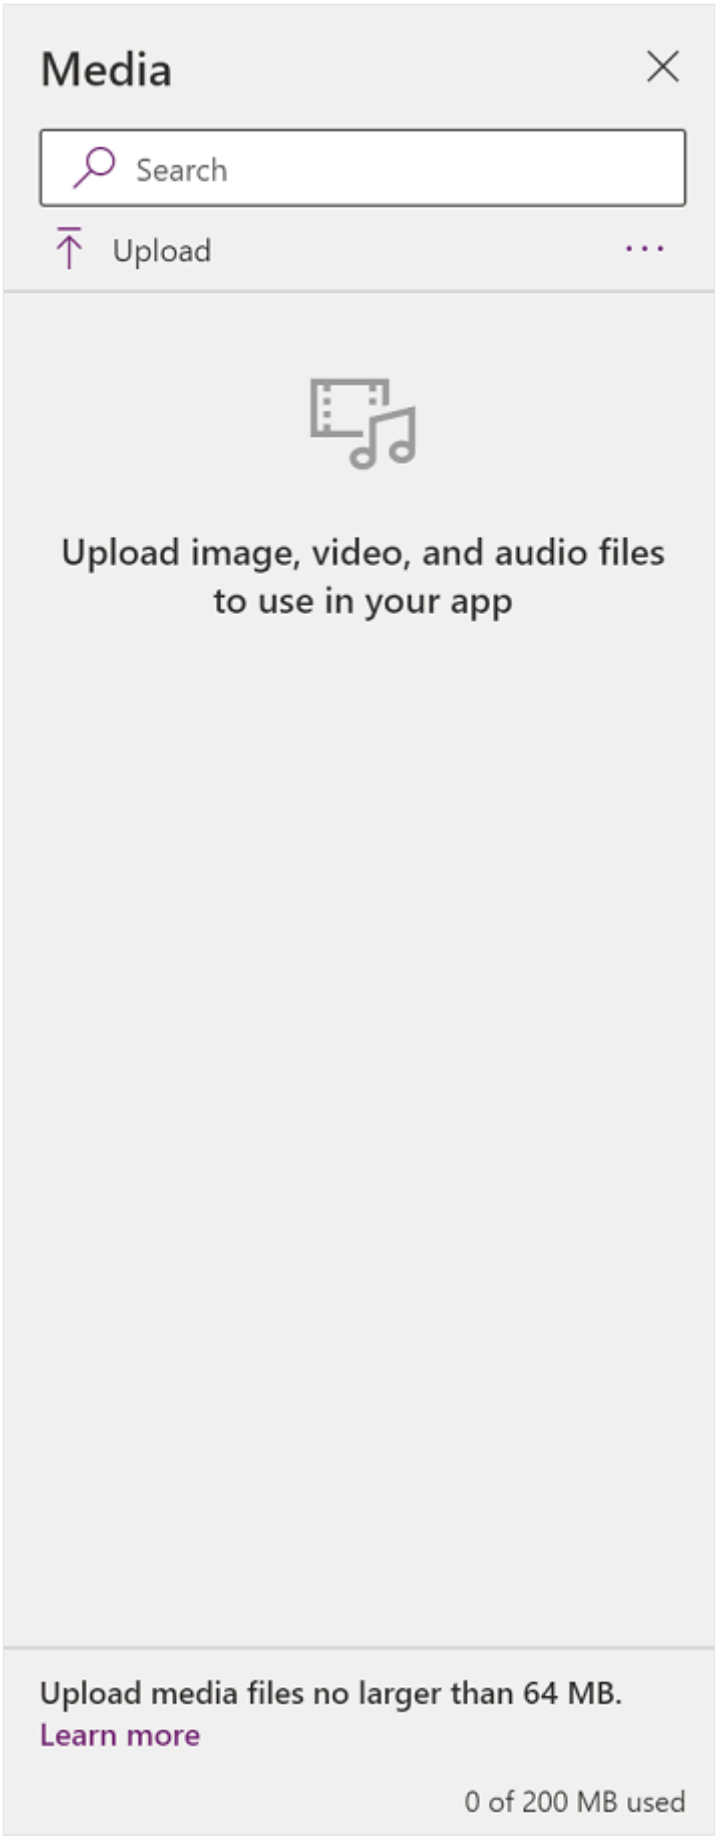
To edit the table, select the table data source, and then select **Edit data** to open the table in visual editor.



After you close visual editor, the data source is automatically refreshed to reflect the updated data in Power Apps Studio. You can also select **Refresh** to manually refresh Power Apps Studio to reflect the data in the controls you added on the canvas.

Media

Select **Media** to add images, video, or audio files to your app. Adding media directly to your app uploads the files to the app and uses the app storage. Each file uploaded to the app as media must be 64 MB or smaller, and the size of all media files uploaded to an app can't exceed 200 MB.



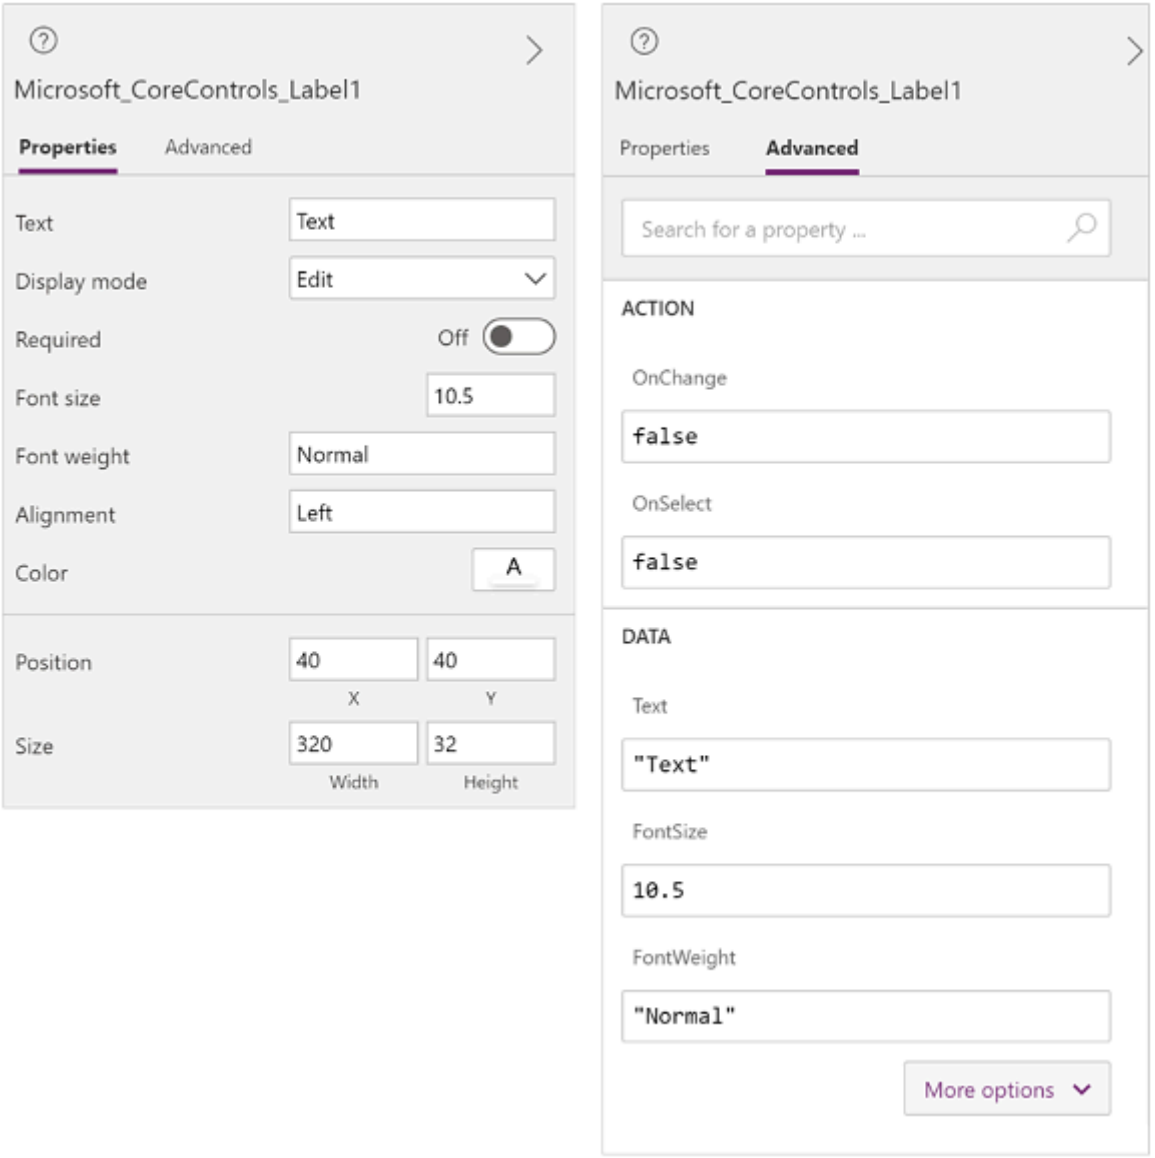
If you want to reference more media, consider using audio and video controls with URLs, using media from Azure Media Services, or from Microsoft Stream. More information: Using multimedia files in Power Apps

9 – Canvas/screen

The canvas shows the currently selected screen from the left pane.

10 – Properties pane

The properties pane shows properties and options available for the currently selected object on the canvas. The **Properties** tab shows generic options such as the name, color, size, or position. The **Advanced** tab shows more options for advanced customization. The advanced properties might sometimes be locked for editing, such as when working with data cards. You can select Unlock to change properties in such situations.



11 – Screen selector

Use the screen selector to switch between screens when your canvas app has multiple screens. You can also select a screen from the left pane by selecting the tree view. If the

current selection is inside a container, or inside an individual cell in a gallery, the selector shows the breadcrumbs for the parent elements at each level.

12 – Change canvas screen size

You can zoom in or zoom out while authoring the canvas app. Select **Ctrl+0 Fit to window** to fit the screen size based on the current authoring window size. The zoom percentage or screen size you use while authoring a canvas app has no impact on the aspect ratio configured for the app when you preview your app or play a published app.

Use Fluent UI controls

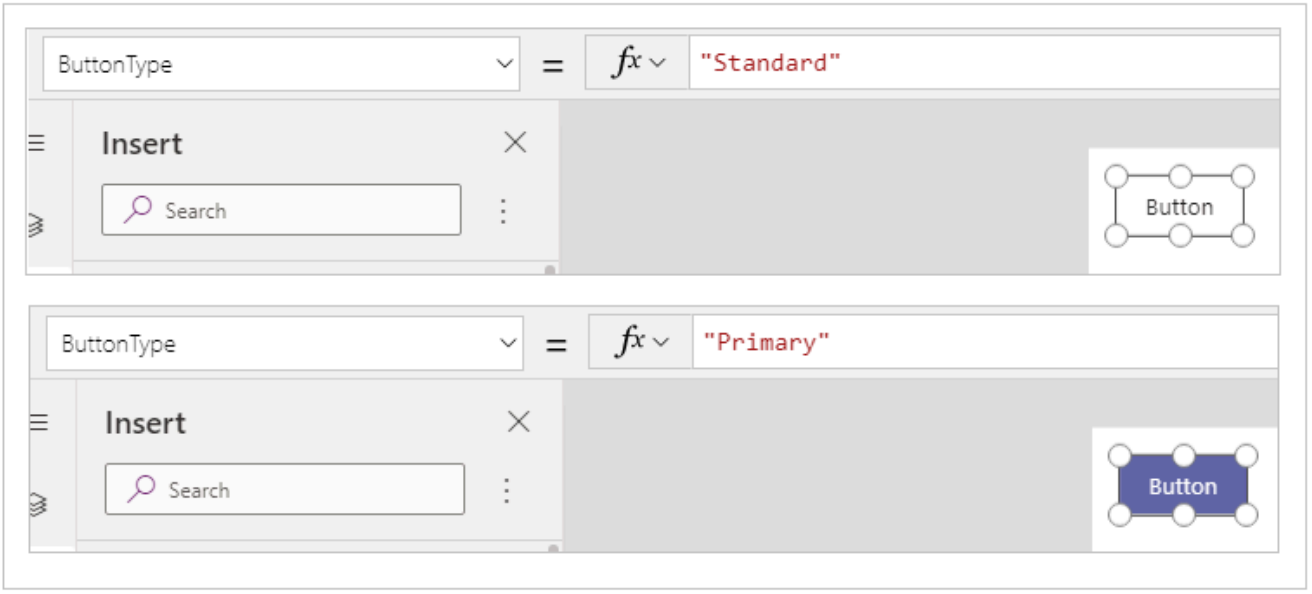
Article • 05/23/2025

Creating apps that look great in Microsoft Teams will be easier with our new components. Built on the Fluent UI framework, the new components will look great with Teams styles and will automatically adjust to the Teams default theme. The new controls are Button, Check box, Combo box, Date picker, Label, Radio group, Rating, Slider, Text box, and Toggle.

Let's take a look at each Fluent UI control and its most useful properties. For a complete list of controls and properties in Power Apps, go to Controls and properties in Power Apps.

Button

A control that the user can select to interact with the app.



Description

Configure the OnSelect property of a **Button** control to run one or more formulas when the user selects the control.

Key properties

ButtonType – The style of button to show, Standard, or Primary. Default value: **Standard**.

OnSelect – How the app responds when the user selects a control.

Text – Text that appears on a control or that the user enters into a control.

Check box

A control that the user can select or clear to set its value to **true** or **false**.

Description

The user can specify a Boolean value by using this familiar control, which has been widely used in the user interface.

Key properties

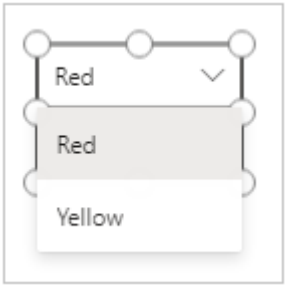
Box side – The side of the control on which the check box is displayed.

Label – Text that appears on a control.

Checked – Whether the control is checked or not.

Combo box

A control that allows users to make selections from provided choices. Supports search and multiple selections.



Description

A **Combo box** control allows a user to search for items to select.

Single-select or multiple-select mode is configured via the *SelectMultiple* property.

Key properties

Items – The source of data from which selections can be made.

DefaultSelectedItems – The items that are initially selected before the user interacts with the control.

SelectMultiple – Whether the user can select a single item or multiple items.

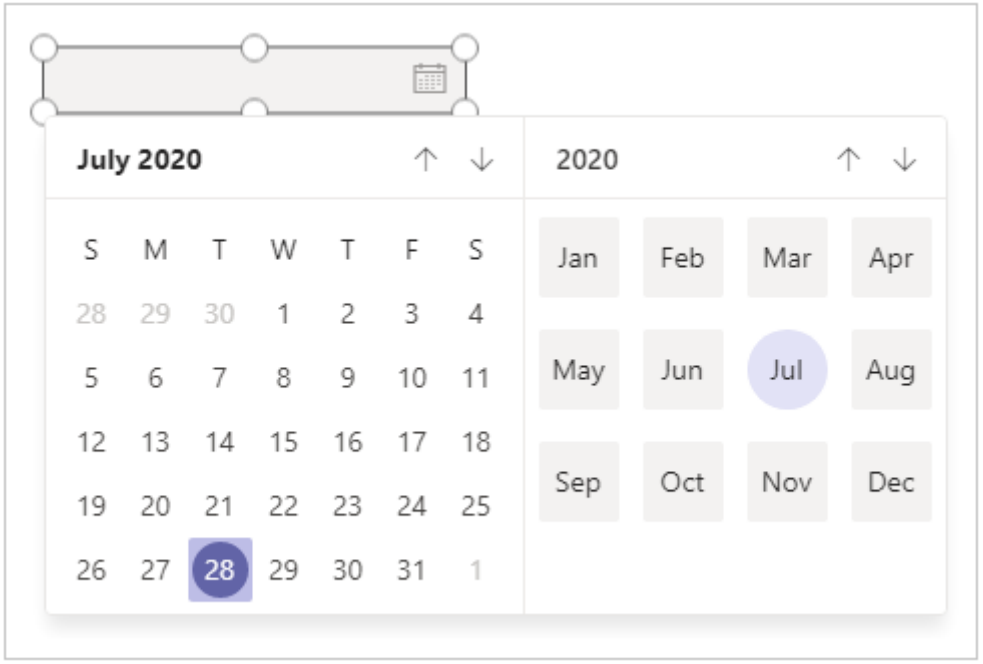
IsSearchable – Whether the user can search for items before selecting.

Limitations

1. The list of Options doesn't support Data Paging. It's limited to show the first 500 records.
2. Filtering the list of Options by typing in the Text Box area of the Control works inside the browser, not on the Server. This, coupled with the previous limitation, means that Filtering will not match any Option(s) beyond the first 500 entries, even when the Text matches.

Date picker

A control that the user can select to specify a date.



Description

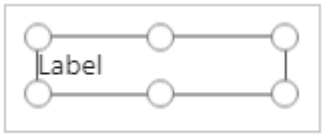
If you add a **Date picker** control instead of a text input control, you help ensure that the user specifies a date in the correct format.

Key properties

Value – The date currently selected in a date control. This date is represented in local time.

Label

A box that shows data such as text, numbers, dates, or currency.



Description

A label shows data that you specify as a literal string of text or as a formula that evaluates to a string of text. Labels often appear outside of any other control (such as a banner that identifies a screen), as a label that identifies another control (such as a rating or audio control), or in a gallery to show a specific type of information about an item.

Key properties

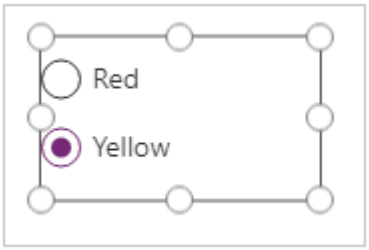
Color – The color of text in a control.

Font – The name of the family of fonts in which text appears.

Text – The text that appears on a control.

Radio group

An input control that shows multiple options, only one of which users can select at a time.



Description

A **Radio group** control, a standard HTML input control, is best used with only a few, mutually exclusive options.

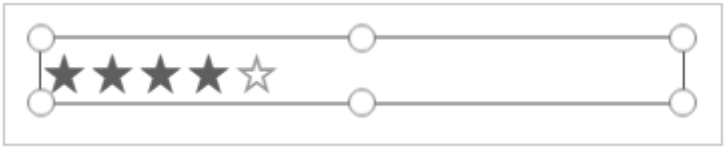
Key properties

Items – The source of data that appears in a control such as a gallery, a list, or a chart.

Selected – The data record that represents the selected item.

Rating

A control with which users can indicate a value from 0 through a maximum number that you specify.



Description

In this control, the user can indicate, for example, how much they liked something by selecting a certain number of stars.

Key properties

Value – The initial value of a control before it's changed by the user.

Max – The maximum value to which the user can set a slider or a rating.

Slider

A control with which the user can specify a value by dragging a handle.

Description

The user can indicate a value, between a minimum and a maximum value that you specify, by dragging the handle of a slider left to right or up and down, depending on the direction that you choose.

Key properties

Max – The maximum value to which the user can set a slider or a rating.

Min – The minimum value to which the user can set a slider.

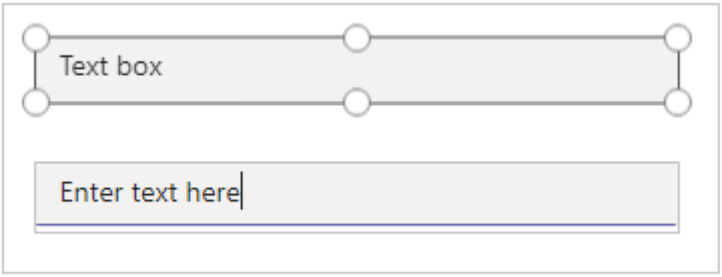
Value – The value of an input control.

Layout – Whether a control is displayed horizontally or vertically.

Show value – Whether a control should display the value.

Text box

A box in which the user can enter text, numbers, and other data.



Description

The user can specify data by typing into a **Text box** control. Depending on how you configure the app, that data might be added to a data source, used to calculate a temporary value, or incorporated in some other way.

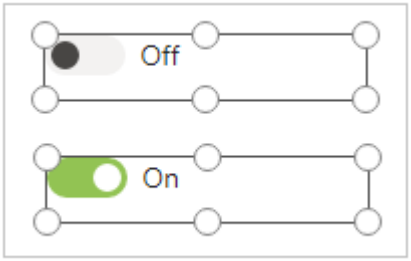
Key properties

Font – The name of the family of fonts in which text appears.

Text – Text that appears on a control or that the user enters into a control.

Toggle

A control that the user can turn on or off by moving its handle.



Description

A **Toggle** control is designed for the modern user interface, but behaves the same way as a check box.

Key properties

Checked – Whether the control is checked or not.

OffText – The text of the off state.

OnText – The text of the on state.

Difference between Fluent UI and classic controls

Properties of controls have been simplified for the ease of use. The following table lists differences between Fluent UI controls and classic control property names.

Expand table

Control type	Classic	Fluent UI
Button	Fill Background TabIndex	ColorFill ColorBackground AcceptsFocus
Check box	Default TabIndex	Checked AcceptsFocus
Combo box	InputTextPlaceholder TabIndex	Text AcceptsFocus
Date picker	SelectedDate TabIndex	Value AcceptsFocus
Label	Size	FontSize

Control type	Classic	Fluent UI
Radio group	TabIndex	AcceptsFocus
Rating	Default TabIndex	Value AcceptsFocus
Slider	Default TabIndex	Value AcceptsFocus
Text box	Color Default Fill SpellCheck TabIndex	ColorText Value ColorBackground EnableSpellCheck AcceptsFocus
Toggle	Size Default TabIndex	FontSize Checked AcceptsFocus

Understand Power Apps Studio

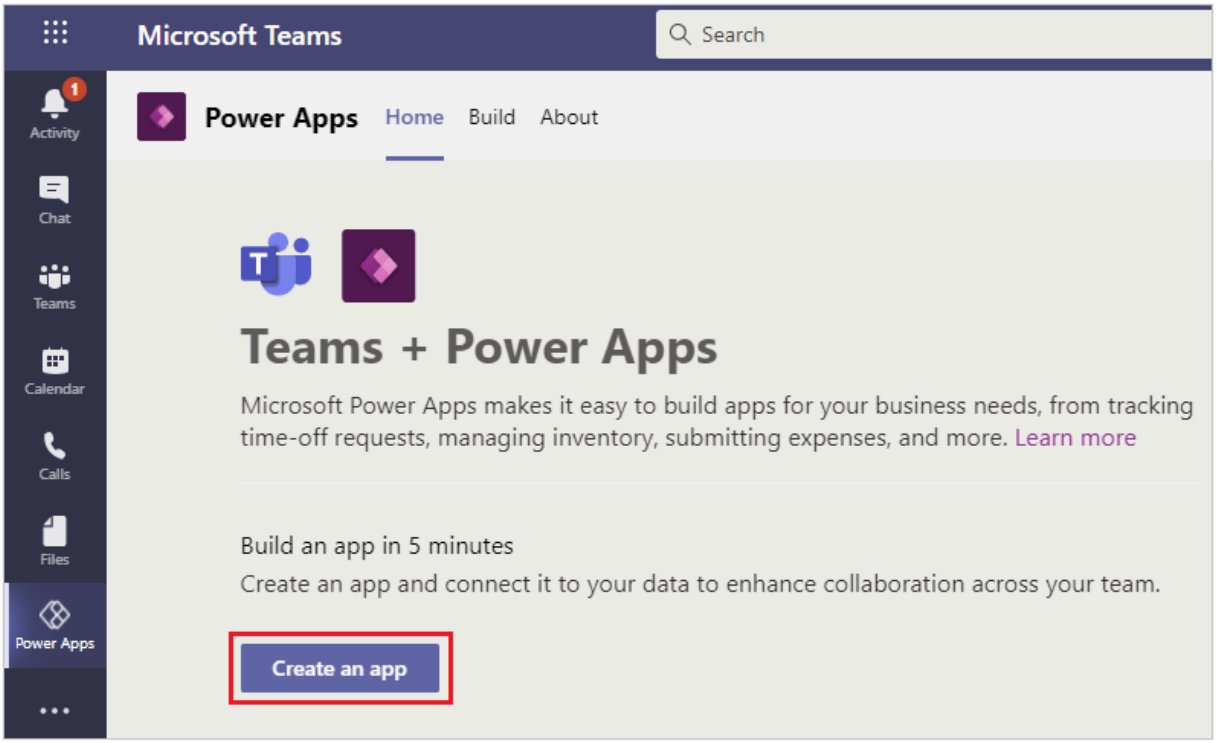
Create additional apps from Microsoft Teams

Article • 12/16/2022

Using the Power Apps app to create the first app in a team creates an environment. After an environment is available, you can create additional apps in the team by using several methods. Let's take a look at them.

Create an app from the Power Apps home

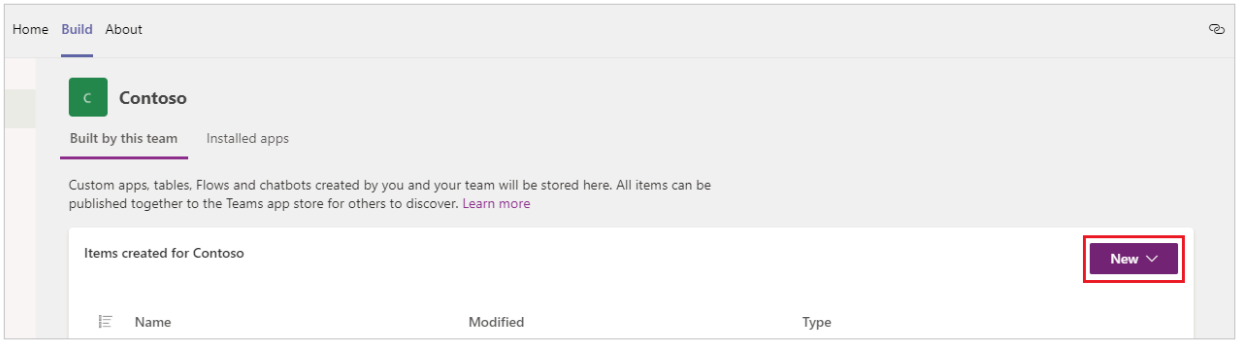
Select **Create an app** from the Power Apps app to get started with creating an app.



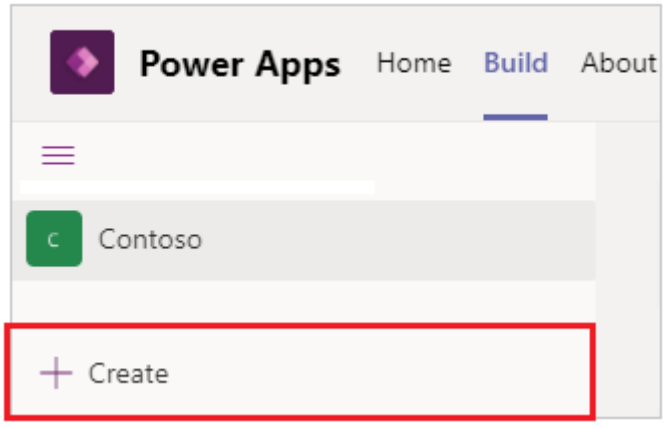
When the team that you select already has an environment available, you're not prompted to install an environment. Instead, you can select **Create** to create the app.

Create an app from the environment home

To create an app for the environment, you can also select the environment on the left pane, and then select **New**.



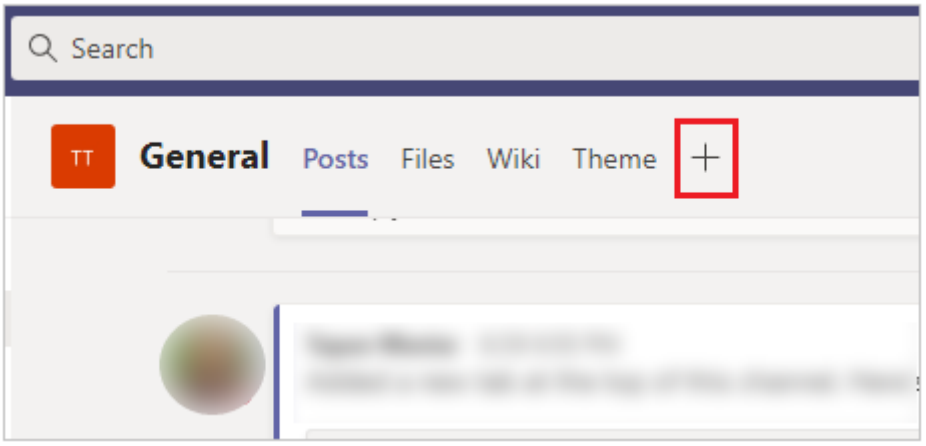
You can also select **Create** at the bottom of the environment list.



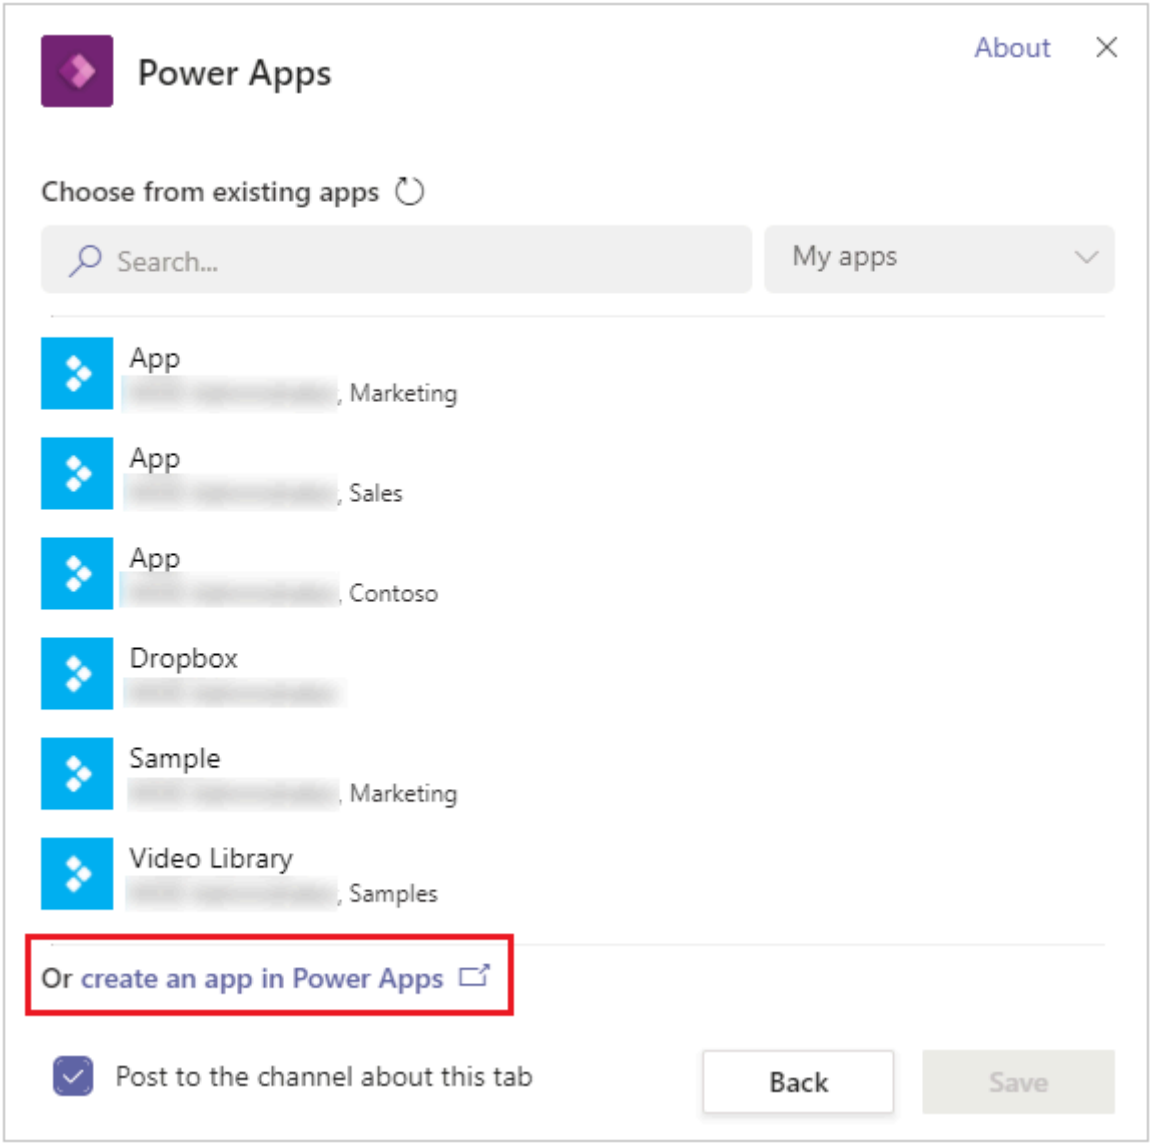
Create an app while inside a team

To create an app while you're inside a team, go to the team and select the channel.

Select **Add a tab** +.



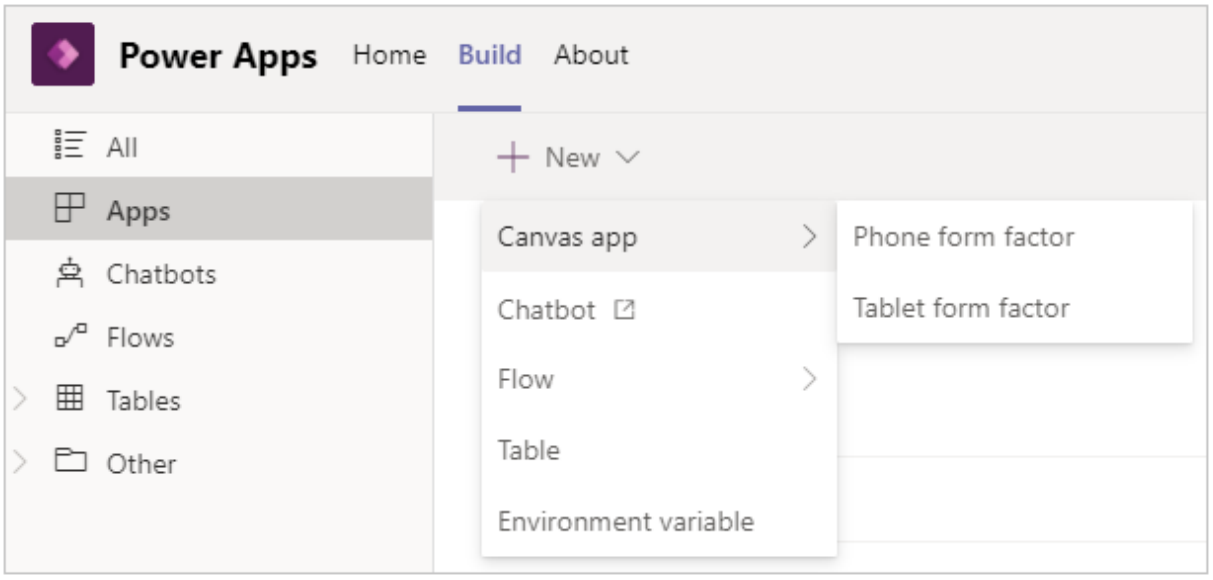
In the dialog box, select **Power Apps**, and then select **Create an app in Power Apps**.



Create an app from the solution explorer

You can also select **New** > **Canvas app**, and then select an app layout to create an app. A canvas app is an app that you can create from scratch or using any available template

through Power Apps Studio. More information: Canvas apps terminology reference and definitions



Tip

Creating a canvas app using different methods doesn't affect which app features are available. If you want to change the app orientation and size after you selected a layout, go to **Change screen size and orientation of a canvas app**.

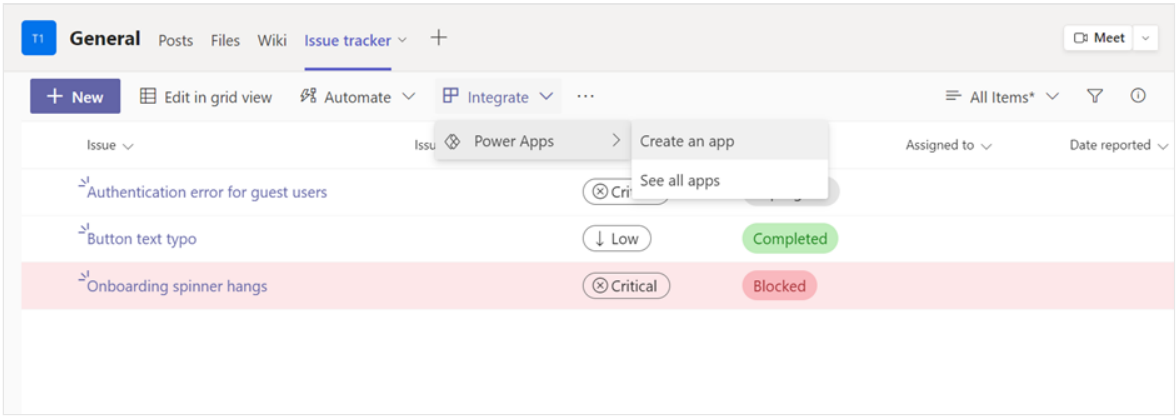
Create an app from a list in Microsoft Teams

Article • 12/16/2022

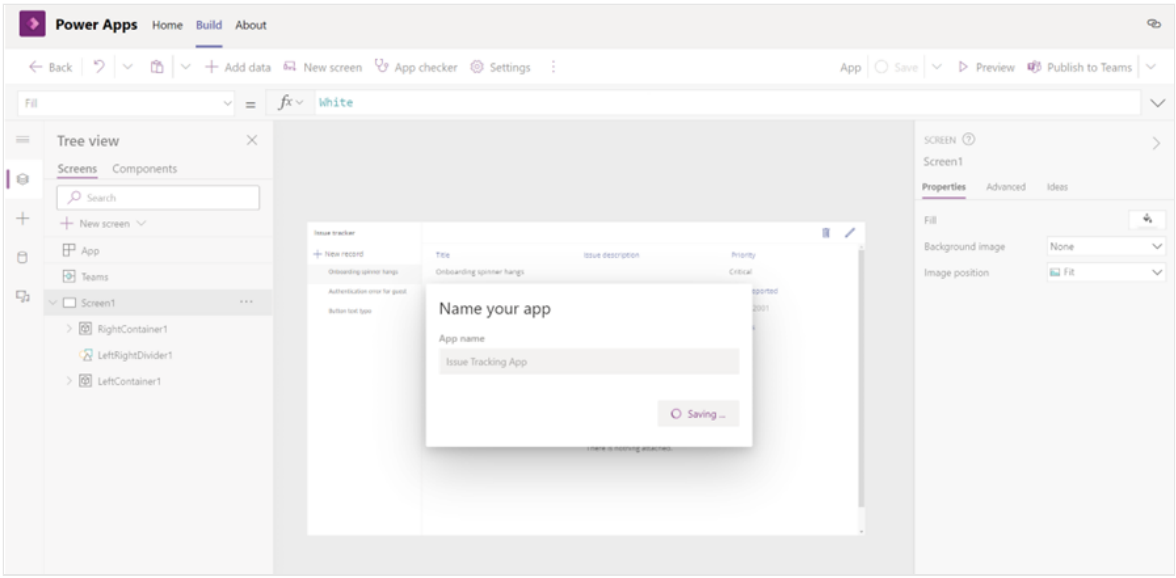
You can create an app from within a list in a Microsoft Teams channel.

> **Tip**
>
> To learn more about the **Lists** app in Teams, go to **Overview of the Lists app in Microsoft Teams**.

1. Create a list in a Teams channel.
2. From the list, select **Integrate** > **Power Apps** > **Create an app**.



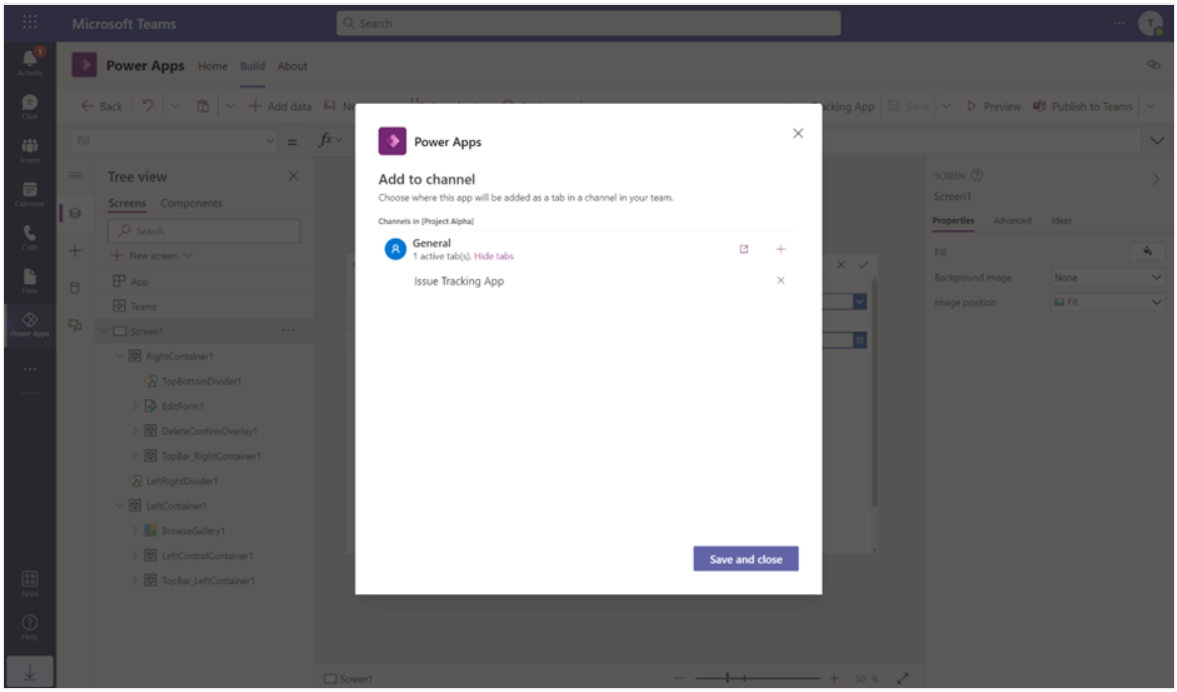
3. If you have never used Power Apps in Teams before, you'll be prompted to add the Power Apps app to Teams. Select **Add** to install the Power Apps app in Teams. More information: Install the Power Apps personal app in Microsoft Teams
4. In the modal that appears, enter a name for your app and then select **Save**.



The app will be created using the data from your list.

5. (Optional) Customize your app by adding and configuring controls.

6. (Optional) Select **Publish to Teams** to publish your app to a channel of any team that you have access to, including the team where your Microsoft list is located.



> **Note**
>
> Apps created in Teams are only accessible within Teams. You may view your apps created in Teams by selecting **Integrate** > **Power Apps** > **See all apps** from the command bar of a list in Teams or by going directly to the **Build** tab in Power Apps in Teams. In the **Build** tab, a link is available to navigate to the rest of your apps in Power Apps web.

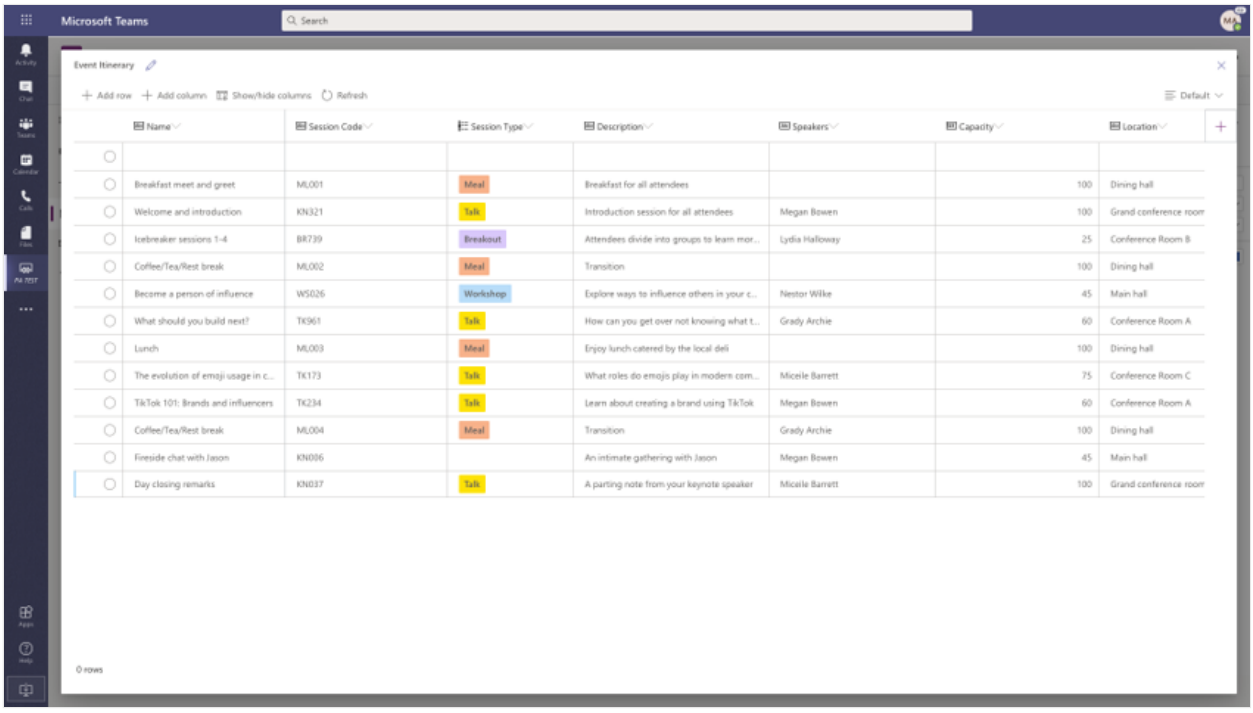
Overview of Microsoft Dataverse for Teams

Article • 02/16/2022

Microsoft Dataverse for Teams delivers a built-in, low-code data platform for Microsoft Teams. It provides relational data storage, rich data types, enterprise-grade governance, and one-click solution deployment. Dataverse for Teams enables everyone to easily build and deploy apps.



Some of the benefits of Dataverse for Teams include:

- Support to build low-code and no-code apps, flows, and chatbots for and within Teams.
- Core data capabilities from the same platform behind Microsoft Power Platform and Dynamics 365.
- Storage, rich data types with enterprise capabilities, and one-click solution deployment.
- A new visual editor that makes it even easier to define and populate table data.
- Enterprise security that's easy to use and aligned with the approach used in Teams.
- Inclusion in most existing Teams licenses.
- Storage of 2 GB per team, and support for up to 1 million rows.

- Support for 5 teams plus 1 additional team for every 20 licensed users.
- The capability to be upgraded to Dataverse.

See also: Dataverse for Teams FAQs

Tables in Dataverse for Teams

Dataverse for Teams tables provide the ability to create, populate, and query data within Dataverse for Teams. Tables represent different types of entities important to an organization, such as a table to store products or another to store orders.

Each of these tables includes columns that contain data about the subject of the table. For example, a table named *Product* might have columns that contain a product name, product identifier, manufacturer identifier, and price. Each of these columns can contain different types of data. For example, the type of data for a product name is text, identifiers could be numbers, and so on.

A solution often has multiple tables that are used together in an application. For example, an Order table might reference multiple other tables, such as Customer, Product, and Country. These tables are "related" to one another, and tables provide the way to create those relationships.

You can create and populate these tables with a new visual editor that makes it even easier to work with these tables.

> **Note**
>
> All the capabilities found in tables are powered by Dataverse for Teams. Although this will satisfy many situations, in some situations an organization might want to have additional capacity, capabilities, or control over their solution. In these scenarios, Dataverse for Teams environments can be upgraded to Microsoft Dataverse. The upgrade process has several considerations discussed in **Upgrade process** in the Microsoft Power Platform admin guide.

Security in Dataverse for Teams

These tables and the applications that use them are secured with enterprise-grade security that's easy to understand and use for low-code and no-code developers. Security in Dataverse for Teams aligns to how security is handled in Teams, with a focus on Owners, Members, and Guests.

Administer Dataverse for Teams environment

You can administer and manage Dataverse for Teams environment using the Power Platform admin center. More information: About the Dataverse for Teams environment in the Power Platform admin guide.

Dataverse for Teams FAQs

How are Dataverse for Teams and Dataverse different?

Article • 05/28/2025

Applications within a team in Microsoft Teams have access to a Dataverse for Teams environment. Dataverse for Teams is a common platform that allows all these interfaces to have a unified understanding of how the data is modeled and consumed. Dataverse for Teams delivers a targeted set of the features commonly needed for creating apps, flows, and more within Teams. If your organization requires more capabilities, such as more granular control for security and governance, or capacity beyond the approximately 1 million rows a Dataverse for Teams environment can contain, Dataverse for Teams can be upgraded to Dataverse.

Table features

Following are the differences between a Dataverse for Teams and Dataverse table features.

Expand table

Feature	Dataverse for Teams	Dataverse
Basic data types	Yes	Yes
Advanced data types (customer, multiple transaction currencies)	No	Yes
Relational storage	Yes	Yes
Non-relational storage (logs)	No	Yes
Managed data lake	No	Yes
File and image support	Yes	Yes
Find, filter, sort	Yes	Yes
Advanced and Dataverse search	No	Yes
Mobile offline	No	Yes

Most of the standard tables that are provided with a Power Platform environment won't be present as part of Dataverse for Teams.

Business intelligence, professional developer, and maker features

This table describes the differences between Dataverse for Teams and Dataverse business intelligence and professional developer features.

Expand table

Area	Feature	Dataverse for Teams	Dataverse
Business intelligence	Data visualization	Yes	Yes
	Paginated reports (SQL Server Reporting Services)	No	Yes
Professional developer	API access	No	Yes
	Plug-ins	No	Yes
	Power Apps component framework	No	Yes
Maker	Create canvas apps	Yes	Yes
	Create model-driven apps	No	Yes

Environments

In Dataverse for Teams and Dataverse, data is stored within an environment. Dataverse for Teams creates a single environment for each team in Teams where you create data, apps, chatbots, and workflows. Environments support backups, point-in-time restore, and disaster recovery. With Dataverse for Teams, capacity is measured with relational, image, and file data. The 2-GB capacity provided to a team can typically store up to 1 million rows of data.

To make management easier, the lifecycle of the Dataverse for Teams environment is connected to that of the associated team. For example, when a team is deleted, the associated environment is also deleted.

Whereas Dataverse for Teams focuses on one environment per team for up to 10,000 teams, Dataverse supports unlimited environments in addition to capabilities that are relevant for multiple environments, such as copy and reset.

Expand table

Environment lifecycle	Dataverse for Teams	Dataverse
Environments	1 per Team	Unlimited

Environment lifecycle	Dataverse for Teams	Dataverse
Maximum size	1 million rows or 2 GB	Unlimited
Upgrade to Dataverse	Yes	N/A

Security

Because collaboration in Teams happens with people inside and outside your organization, the security model needed to support this is easy to use. In Dataverse for Teams, access is preconfigured with a security role based on membership type such as owners, members, or guests.

Because Dataverse isn't specific to the Teams environment, it delivers more options for admin and user roles. It also includes many other security capabilities such as customer-managed keys, field-level security, hierarchical security, sharing, and support for legacy authentication.

> **Note**
>
> Because Dataverse for Teams environments are specific to a team, they only contain one business unit.

Expand table

Security feature	Dataverse for Teams	Dataverse
Admin roles	System Administrator and System Customizer	System Administrator and System Customizer and other service admin roles. More information: Use service admin roles to manage your tenant
User roles	Team owners, members, and guests	Several standard security roles and custom roles can also be created. More information: Security roles and privileges
Activity logging	No	Yes
Auditing	No	Yes
Business units	One	Unlimited
Customer-managed environment encryption key	No	Yes
Field-level security	No	Yes

Security feature	Dataverse for Teams	Dataverse
Hierarchical security	No	Yes
Record sharing	No	Yes
Create Owner Teams**	Yes	Yes
Create Microsoft Entra group Teams	No	Yes
Record sharing to Group Teams	No	Yes
Assign Teams Roles to Owner Teams[1]	Yes	Yes
Change record ownership**	Yes	Yes

[1] *Can be done via a custom app in Power Apps*

Integration

Integration with Dataverse for Teams is delivered primarily through connectors. Support for both standard connectors and the ability to use the Dataverse connector to connect to a Dataverse for Teams for a Teams environment is included. Users with Premium licenses have access to the full set of over 350 standard and premium connectors available. This allows you to bring data into or retrieve data from tables in Dataverse for Teams, execute workflows when data in those tables change, and also use data from tables in workflow logic.

Dataverse can also use connectors. Additionally, Dataverse includes other built-in integration capabilities that can export data to a data lake or publish events to an event hub, service bus, or by using webhooks. Dataverse also supports the TDS protocol, which provides integration with SQL Server.

Dataverse can also be used with server-side sync to synchronize with Exchange or POP3, and with Data Export Service, which synchronizes data to Azure SQL Database.

Expand table

Integration feature	Dataverse for Teams	Dataverse
Power Automate	Yes	Yes
Azure Synapse Link for Dataverse	No	Yes

Integration feature	Dataverse for Teams	Dataverse
Data Export Service	No	Yes
Events to Azure Event Hubs	No	Yes
Events to Azure Service Bus	No	Yes
Webhooks	No	Yes
Server-side sync	No	Yes
SQL Server Management Studio	No	Yes

Comparing Microsoft Lists, Dataverse for Teams, and Dataverse

Article • 10/26/2022

Whether you're using Power Apps to build a small app for your team or a mission critical app for your business, there are many great options for data.

This article focuses on three of the most popular data technologies used in Microsoft Power Platform: Microsoft Lists, Microsoft Dataverse for Teams, and Microsoft Dataverse. With the answers to the questions below, you can quickly understand and apply the key considerations that will help you pick the correct one for your application.

The questions are broken out into four categories:

Expand table

Category	Questions
Data	What types of data (and how much of it) will your application require? How do you want to search the data?
Application	How will the app be made available? For example, will it be a Teams app, custom code, or something else? Will guests be accessing your application? Who will build the app; low-code or pro developers? What special capabilities does your application need?
Integration	What do you want to integrate the system with? For example, databases, services, and so on?
Admin and governance	What are your organizations requirements related to security and compliance? Are there special requirements for backing up and restoring the data?

Key considerations and differences between Lists, Dataverse for Teams, and Dataverse

Using the answers to the questions above, use the table below to help identify the right technology for your application.

Expand table

Considerations	Lists	Dataverse for Teams	Dataverse
Types of data	Lists, File, Image	Relational, File, or Image	Relational, File, Image, Lake, Log, Dataverse Search Virtual tables
Number of data types	15	23 (Currency is basic version)	24 (Currency is advanced version)
Common Data Model	N/A	User table only	Full support
Capacity	Up to 30M rows (considerations for lists > 100k)	Up to 1M rows Small number of files or images For limits on API requests per day, go to the entitlements available for Microsoft 365 apps with Power Platform access in the article: Request limits based on user licenses	No specified limit on rows. No specified limit of files or images. For limits on API requests per day, with option of capacity add-ons, go to this article: Request limits based on user licenses
Data movement	Create from/Export to Excel	Dataflows In	Dataflows In/Out Server-side sync Synapse Integration (Bring Your Own Data Lake, Data Factory)
Security	Owners, Members, Visitors, Designers, Approvers roles Customizable permissions	Owner, Member, Guest roles Share app with Azure AD group	Robust options to satisfy complex enterprise scenario requirements, such as roles, business units, auditing, CMK, hierarchical/field-Level security, and so on
Clients	Lists, Teams[1], custom code	Teams	Teams, Power Apps, Power Pages, Dynamics 365, custom code
Guest limitations	Can't create or delete a list	Can't make, install, or edit apps	Must be in Azure AD using Azure B2B
Pro developer capability	REST API Graph API	N/A	REST API Software Development Kit (SDK) Plug-in Support Integration (Event Hub,

Considerations	Lists	Dataverse for Teams	Dataverse
			Service Bus, Webhook, Export to Lake) SQL Server Management Studio Integration
Package and deploy	Package and deploy Lists	Single unmanaged solution per environment	Unlimited
Additional capabilities	Calculations and rollups	N/A	Business workflows Business rules Calculations and rollups Mobile offline

[1]You can't create or pin lists on Power Apps mobile.

What is Dataverse?

Create tables in Microsoft Teams

Article • 07/02/2024

In Teams, data is defined by *tables*. To create a table, you must be a member of a team.

Types of tables

Whereas Dataverse has two types of tables (a standard table with ownership defined and an activity table), you can only create standard tables in Dataverse for Teams.

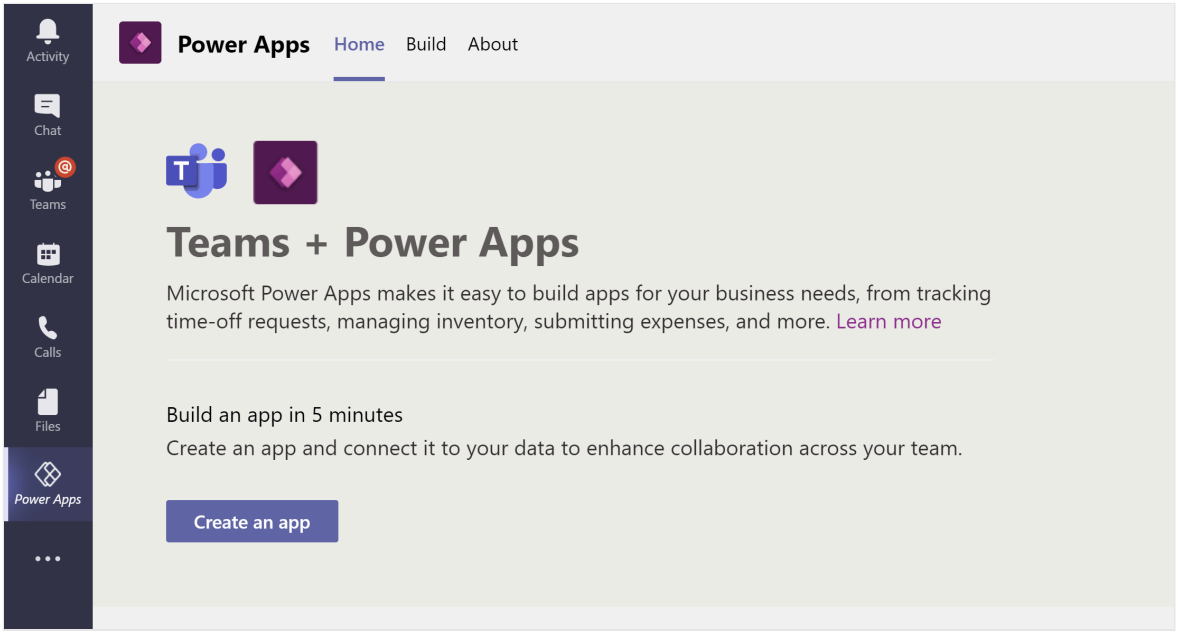
You define the type of table by selecting **More settings** when you create a table.

There are four different types of table ownership. When you create a table, the only options are **user**, **team owned**, or **organization-owned**, but you should be aware that other tables have different ownership types. More information: Types of tables in Dataverse

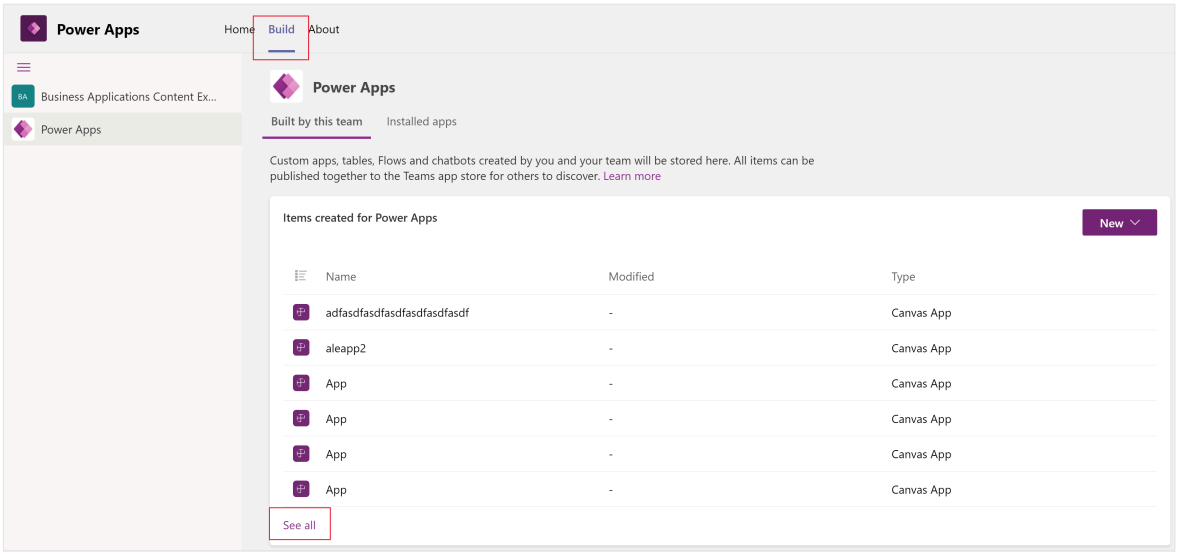
Create a table

Watch this video for a quick overview about how to create a table in Dataverse for Teams:
https://learn-video.azurefd.net/vod/player?id=a7b07bc4-1e08-4ed9-8675-b700a8e1a6a3&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fcreate-table

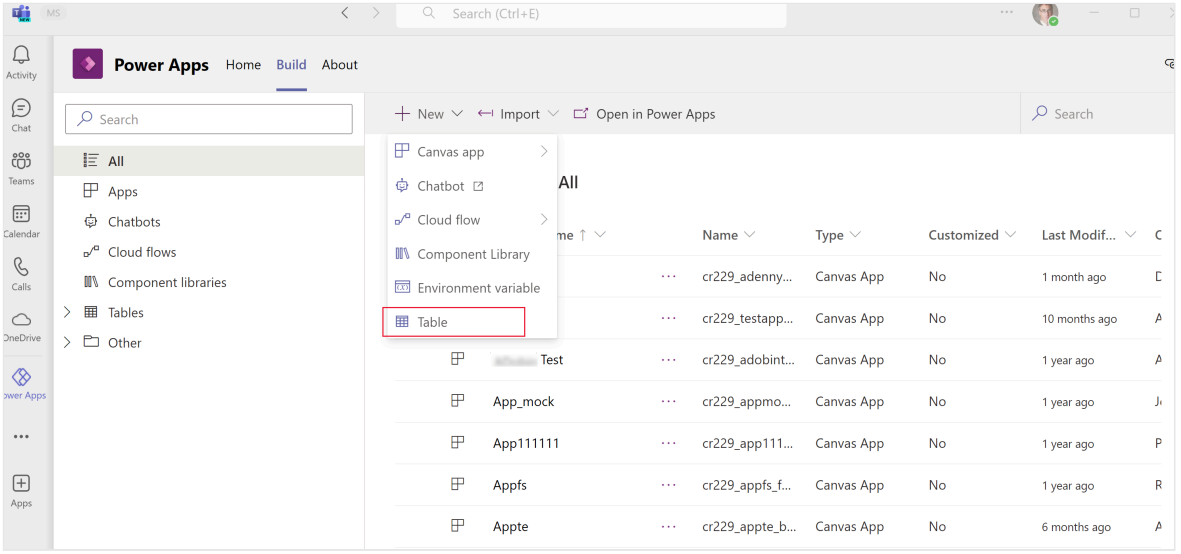
1. Sign in to Teams, and then select the link for **Power Apps**.



2. Select the **Build** tab, and then select **See all**.



3. Select **New** on the command bar, and then select **Table**.

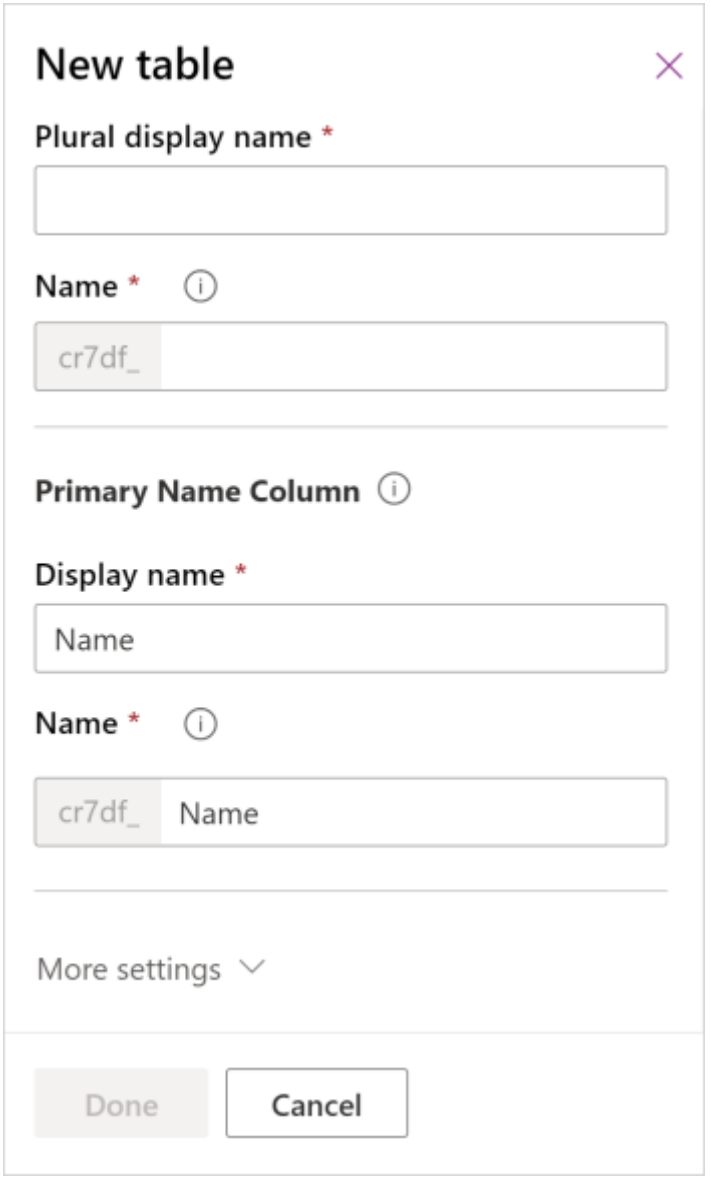


4. In the **New table** pane, enter the following information. Required columns are designated with an asterisk (*) next to the column label.

   - **Display name**: The name of the table to be displayed. For example, **Product**.
   - **Plural display name**: The name used to reflect multiples of what the table contains. For example, **Products**.
   - **Name**: A unique internal name for the table. Unlike the display name, after it's saved this value can't be changed.

   > ⓘ Note
   >
   > Each Dataverse for Teams environment is assigned a prefix when it's created, such as **cr628**. The name for every table and column you create will be prefixed with this value. This value can't be changed.

- **Display name** (Primary name column): Every table contains a primary name column, which is used by lookup fields when establishing relationships with other tables. Typically the primary name column stores the name or primary description of the data stored in the entity.
- **Name** (Primary name column): This column is pre-populated based on the primary name column name you enter. It includes the prefix. You cannot change this after the table is saved.
- **More settings**: This area provides additional settings that are available. More information: Create a custom table.



5. Select **Done**.

Edit or delete a table

Article • 02/15/2022

With Dataverse for Teams, you can perform the following types of operations on a table:

- Create table columns.
- Delete a table.
- Create, edit, and delete table relationships. More information: Work with table relationships

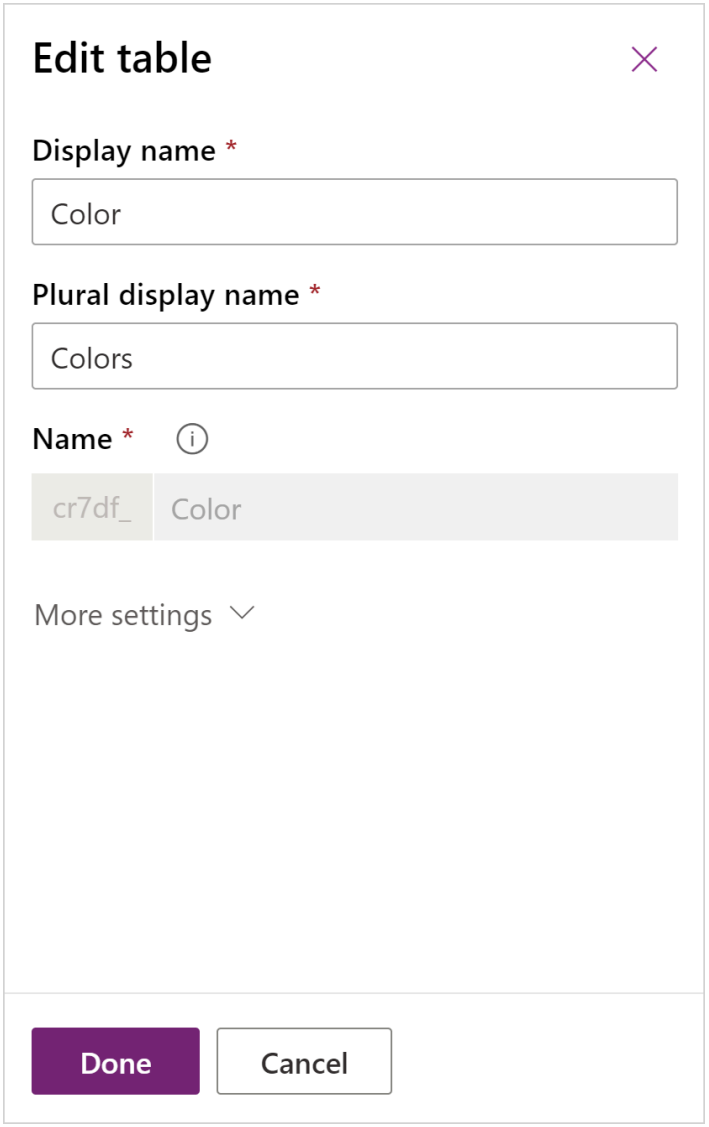
Edit table properties

In Microsoft Teams, you can edit four table properties:

- **Display name**: The name you want to display for the table.
- **Plural display name**: The plural of the table name, when needed for display.
- **Description**: A brief description of the purpose of the table.
- **Quick create settings**: This enables quick creation of records for client apps that support this feature.

> ⓘ Note
>
> - You can also edit a table using the visual editor. More information: Create your first table
> - Each Dataverse for Teams environment is assigned a prefix when it's created, such as **cr1a3**. The name for every table and column you create will be prefixed with this value. This value can't be changed.

1. On the left pane, select **Tables**.
2. Select the table you want and then select **Settings** on the command bar to display the **Edit table** dialog box.



For more information about these settings, see Create a table.

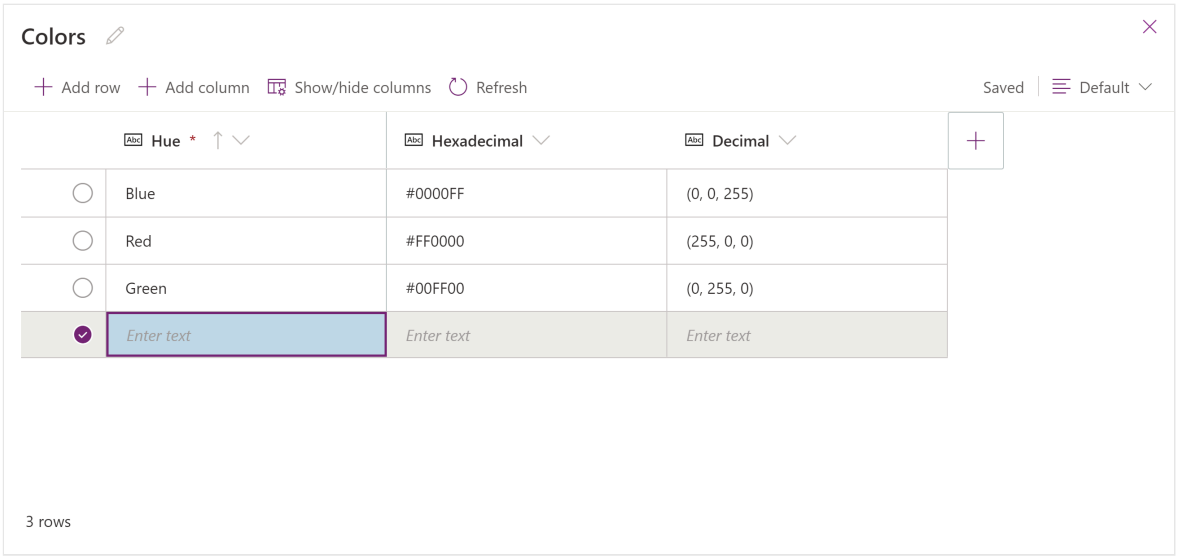
3. Make the changes you want, and then select **Done**.

Edit table columns

You can edit table columns using the visual editor.

1. On the left pane, select **Tables**.

2. Select the table you want, select **Edit data** on the command bar to display the visual editor.



More information: Create your first table

Delete a table

Anyone who's a member of the team can delete tables that aren't part of a managed solution.

In the **Tables** list, select **...** next to the table you want to delete, and then select **Delete table**. Alternatively, while viewing a table, select **Delete table** on the command bar.

Work with table relationships

Article • 02/15/2022

Table relationships define the ways that table records can be associated with records from other tables or the same table. There are three types of table relationships. Dataverse for Teams allows for the creation of the same relationship types as Dataverse does:

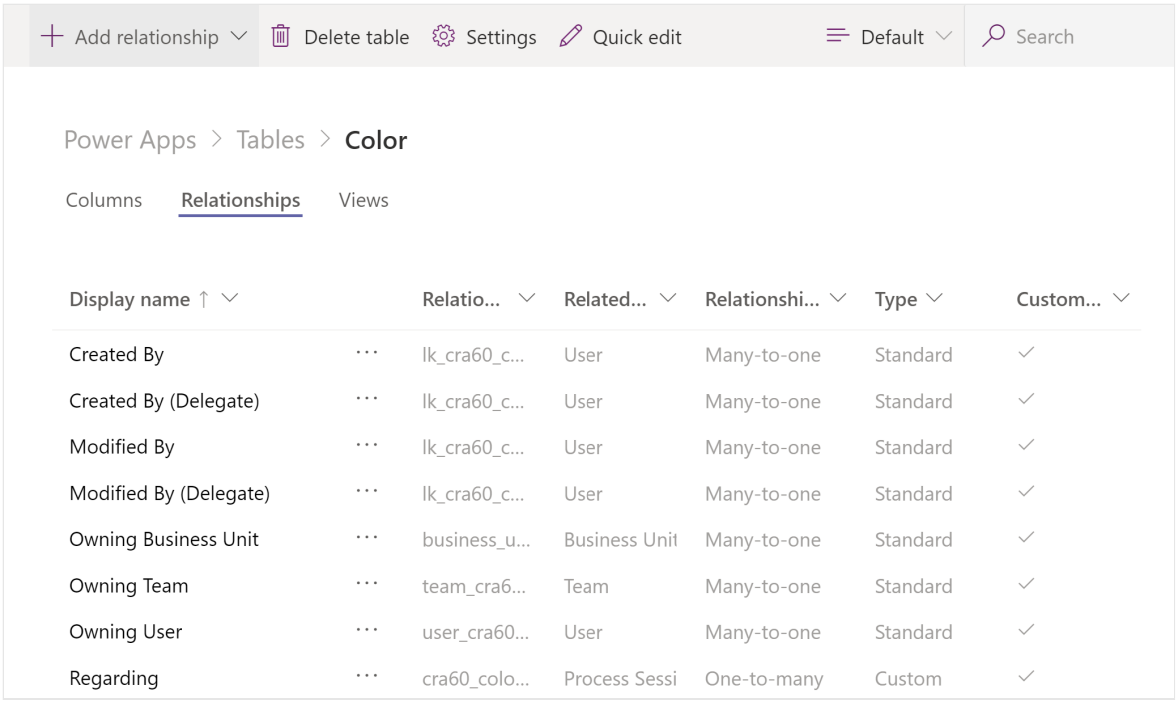
- **One-to-many relationships**. In this type of relationship, each row in table A can match more than one row in table B, but each row in table B can match only one row in table A. For example, a class of students have a single classroom.
- **Many-to-one relationships**. In this type of relationship, each row in table B can match more than one row in table A, but each row in table A can match only one row in table B. For example, one single teacher teaches many classes.
- **Many-to-many relationships**. In this type of relationship, each row in table A can match more than one row in table B, and vice versa. For example, students attend many classes, and each class can have multiple students.

More information: Entity relationships

Create a table relationship

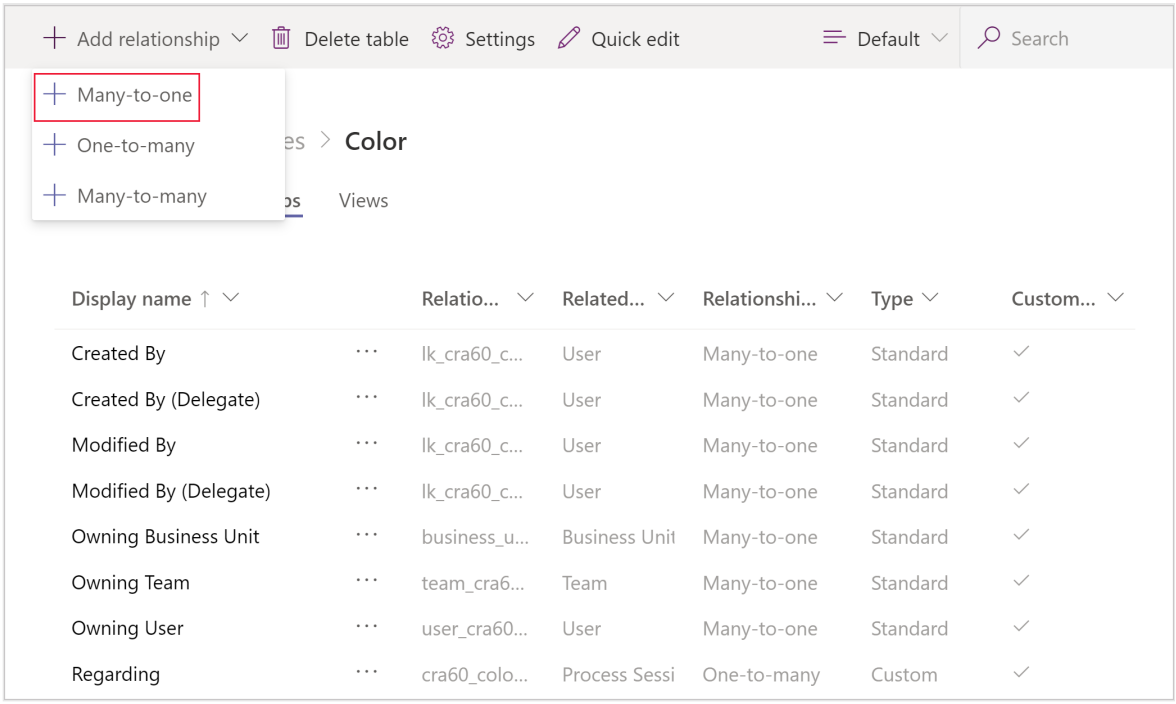
To add a lookup relation to a table, create a relation on the **Relationships** tab and specify the table with which you want to create a relationship.

1. In the **Power Apps** section of Microsoft Teams, select the table to create a relationship. This can be done by opening the table and selecting the **Relationships** tab.



Or, on the left pane, expand **Tables**, expand the table you want, and then select **Relationships**.

2. When the relationships page is open, select **Add relationship**, and then select the type of relationship you want to create (for example, **Many-to-one**).



More information: Create a relationship between entities

> **Note**
>
> When defining columns of type lookup within a table, a many-to-one relationship is created automatically.

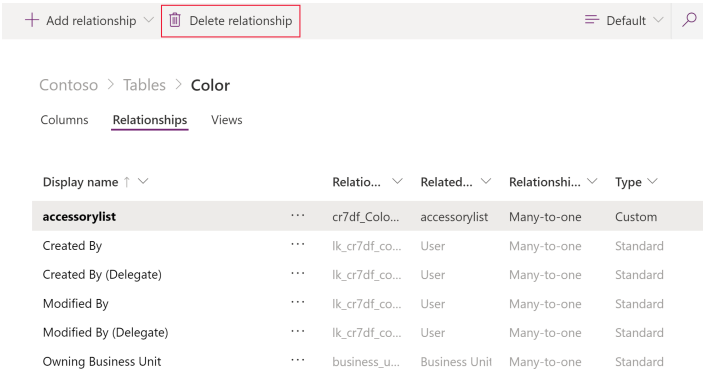
Edit a table relationship

Editing relationships in Dataverse for Teams works the same as Dataverse except that you can't manage collaboration functions, such as allowing feedback or enabling SharePoint document management. More information: Relationship actions

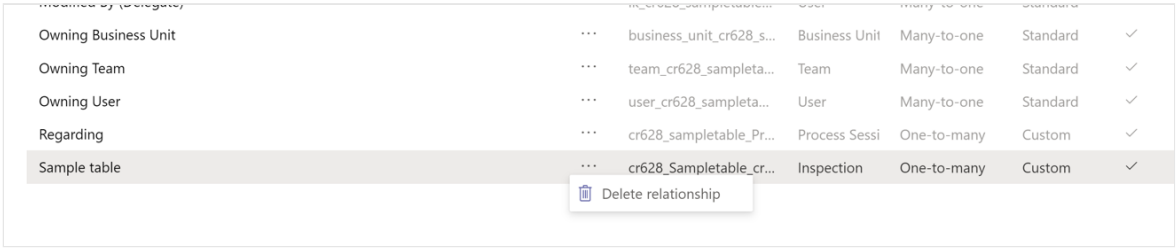
Delete a table relationship

While viewing table relationships, select the table relationship you want to delete, and then do one of the following:

- Select **Delete relationship** on the command bar.



- Select **...** next to the relationship, and then select **Delete relationship**.



See also

Work with table columns

Work with table columns

Article • 02/15/2022

With the exception of the Customer column, all column types in Dataverse are available in Dataverse for Teams as *columns*. This article covers the content you'll need for working with table columns in Dataverse for Teams.

Watch this video for a quick overview about column data types in Dataverse for Teams: https://learn-video.azurefd.net/vod/player?id=416d5037-a701-436d-bd77-e7fcb5329ead&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Ftable-columns

Notice that the currency feature will always use the default currency for the country/region that was selected during Dataverse for Teams environment creation. This can't be changed, and additional transaction currencies or exchange rates can't be added. However, you can upgrade from Dataverse for Teams to Dataverse for full currency functionality.

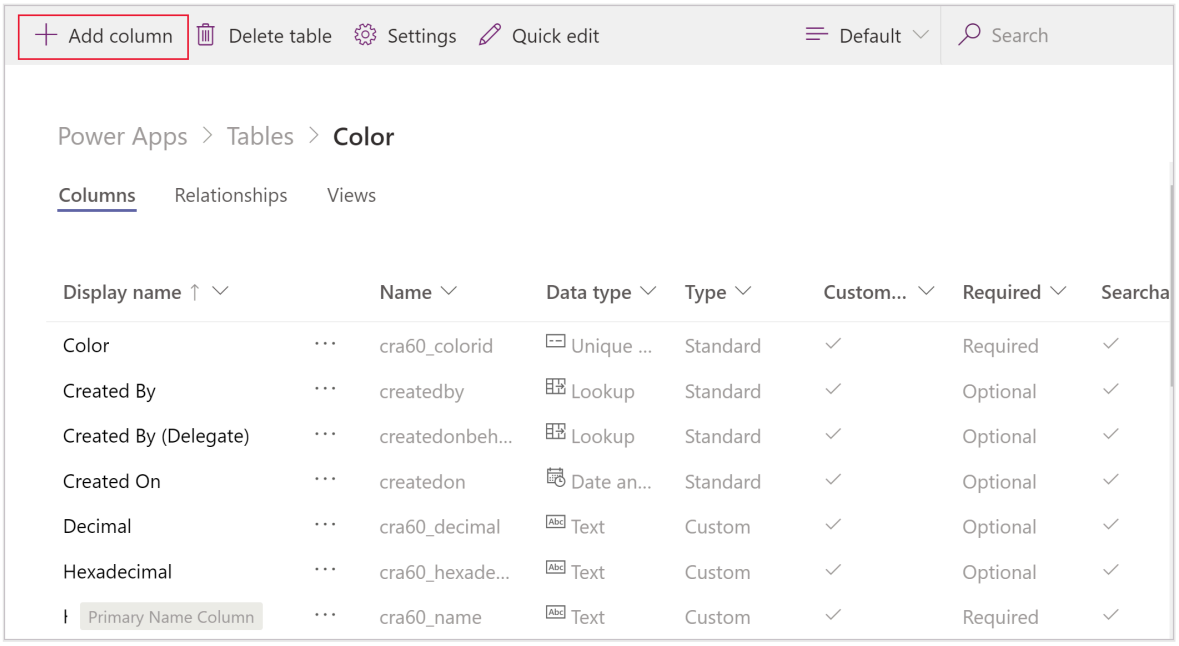
For more information about the columns available, see these Dataverse articles:

- Columns overview
- Create and edit global option sets overview
- Autonumber columns
- Set managed properties for columns
- Behavior and format of the Date and Time column

Create a column

Watch this video to learn how to create columns in Dataverse for Teams: https://learn-video.azurefd.net/vod/player?id=9a5cecc2-2fce-4ad5-adc9-0d68afb3426c&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Ftable-columns

1. On the **Build** tab, select **See all**, and then expand **Tables**.
2. Select the table you want to add a column to, and then select **Add column** on the command bar.



The rest of the process to add and manage columns is the same as in Dataverse, which is documented in these articles:

- Create and edit columns for Dataverse using Power Apps portal
- Manage custom columns in an entity

Choice columns

In Dataverse for Teams, choices can only be created as a column within a table. Creating choices is otherwise the same as creating an option set in Dataverse. More information: Create an Option set

Calculated and rollup columns

Calculated columns and rollup columns are not currently supported in Dataverse for Teams.

Work with formula table columns (preview)

Article • 01/01/2023

[This topic is pre-release documentation and is subject to change.] More information: Power Apps preview program

Formula columns are a data type in Microsoft Dataverse for Teams that are built on Power Fx. You can add a formula column to a table in real time. The Dataverse table stores the logic and gives you the values during fetch operations. Formula columns use the Power Fx syntax that's similar to Office Excel. As you enter the formula, Intellisense helps you with recommendations for formula, syntax, and errors.

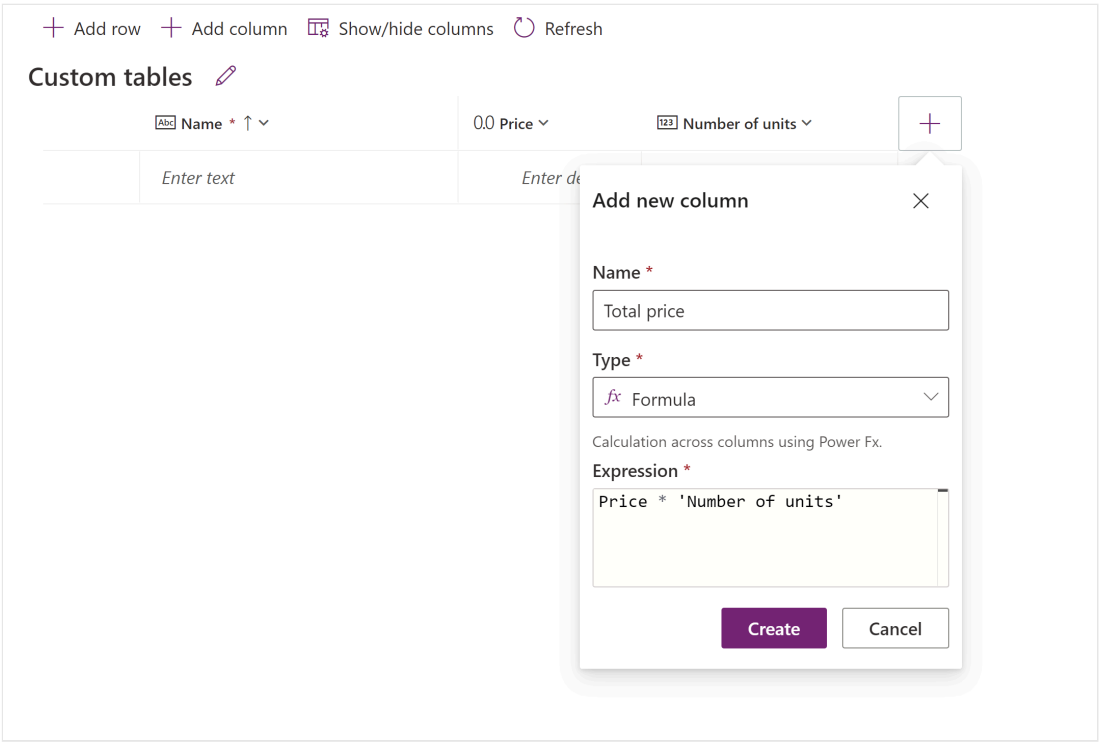
> **Note**
>
> Formula columns can be added as a calculated field. Currently, formula columns can't be used in roll-up fields or with plugins.

Add a formula column

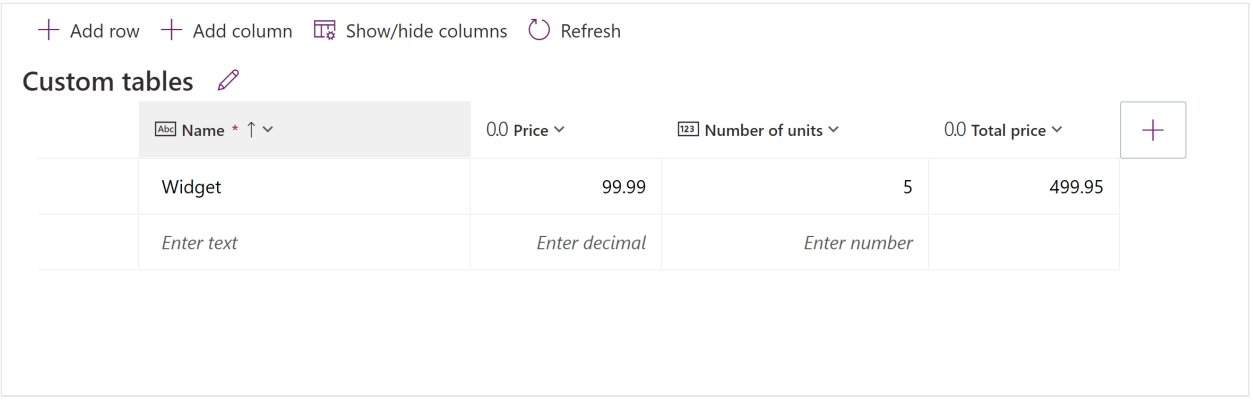
1. On the **Build** tab, select **See all**, and then expand **Tables**.
2. From the list of tables in Power Apps app for Teams, select the table you want.
3. Select **Add column** or select **Edit data** > **Add column**. When you select **Edit data**, you can also select + on the column where you want to add the formula column.
4. In the **Add new column** pane:

    - Enter a **Name** for the column, such as *Total price*.
    - Select **Formula** as the **Type**.
    - Enter the formula in the **Expression** box. In this example, the *Price* column (Decimal data type) is multiplied by the *Number of units* column (Number

data type). Select **Create**.



When you create a record, the formula column executes the formula and displays the data for the record. If the formula column value for a record doesn't update, select **Refresh** on the command bar to execute the formula.



Notice that the column type is determined by the formula. You can change the formula after you've created it if it doesn't change the column type. For example, the formula *price * discount* creates a column type of number, whereas the formula *First & " " & Last* creates a column type of string. You can change a *price * discount* formula to *price * (discount +10%)* because that doesn't change the column type. However, once saved, you can't change the *price * discount* formula to *Text(price * discount)* because that would require changing the column type to string.

Data types

The following data types can be displayed in a formula column:

- Text
- Decimal Number
- Yes/No (boolean)
- Date

> **Note**
>
> The Currency data type is not currently supported.

Function types

The following function types are supported with the formulas used in a formula column:

- Decimal
- String
- Boolean
- Option Set
- DateTime (TZI)
- DateTime (User local) (limited to comparisons with other user local values and the DateAdd function)
- DateTime (Date only) (limited to comparisons with other date-only values, and the DateAdd function)
- Currency
- Whole Number, promoted to Decimal

Operators

These operators are supported with the formulas used in a formula column:
+, -, *, /, %, ^, in, exactin, &

More information: Operators in Power Apps

Available functions

The following scalar functions are available with formula columns.

Abs

And

Average

Blank

Char

Concatenate

DateAdd

DateDiff

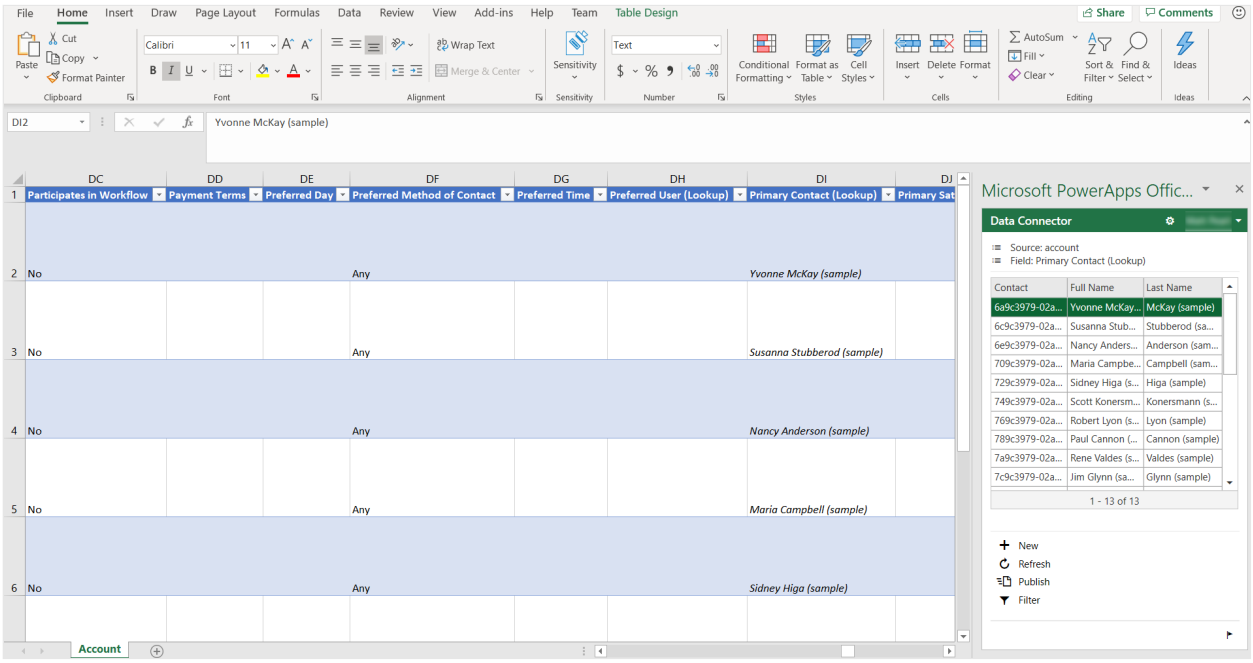
Edit table data in Excel and publish it back to Dataverse for Teams

Article • 02/15/2022

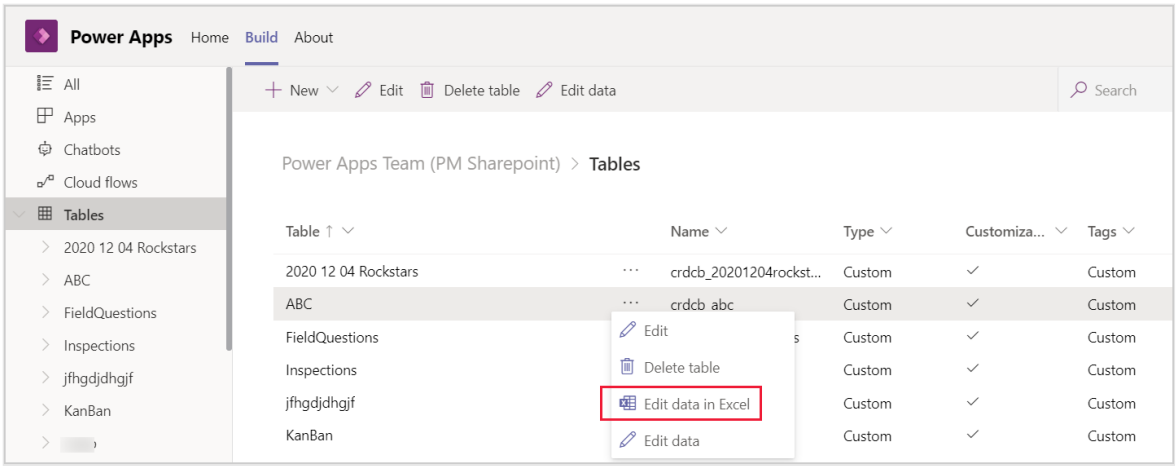
By opening Dataverse for Teams table data in Microsoft Excel, you can quickly and easily view and edit the data by using the Microsoft Power Apps Office Add-in.



To install the Power Apps Excel Add-in, see Microsoft PowerApps Office Add-in. For more information about how to add or remove an Office Excel Add-in, see Add or remove add-ins in Excel.

Open table data in Excel

1. Sign in to Teams, and then in the left pane, select the **Power Apps**.
2. Select the **Build** tab, and then select **See all**.
3. In the left navigation pane, select **Tables**, next to the table you want, select **...**, and then select **Edit data in Excel**.



4. Open the Excel worksheet that is downloaded to your browser's default download folder named similar to *crdcb_table-name (1591125669213).xlsx*.

5. In Excel, select **Enable editing** to enable the Power Apps Excel Add-in to run. The Excel Add-in runs in a pane on the right side of the Excel window.

> **Important**
>
> - If the pane displays an error message, see **Office Store Add-in download disabling**.
> - If this is the first time that you've run the Power Apps Excel Add-in, you must **Trust this Add-in** to allow the Excel Add-in to run.
> - The maximum table size when editing in Excel is one million cells. If there are too many rows or columns, not all data will be read or published.

Next steps

- View and refresh data in Excel
- Edit data in Excel
- Configure the add-in to adjust tables and columns
- Troubleshooting

Move customizations between environments

Article • 06/17/2022

Microsoft Dataverse for Teams provides a simplified way to transport customizations between Dataverse for Teams environments. Additionally, customizations can also be moved between Dataverse and Dataverse for Teams environments.

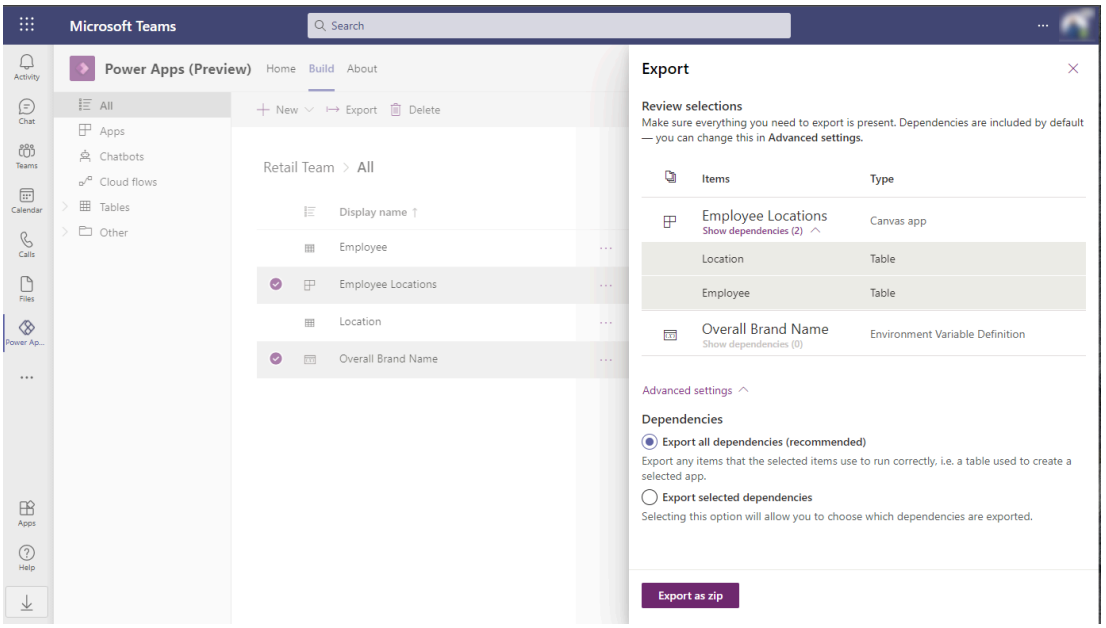
Export customizations from Dataverse for Teams

Take the following steps to export your customizations from Dataverse for Teams. Notice that the solution packages you export from Dataverse for Teams are unmanaged.

1. From the Power Apps personal app in Teams, select the **Build** tab of the team where you want to export your customizations. More information: Install the Power Apps personal app in Microsoft Teams
2. Select **See all**, and select the items you want to export.
3. On the command bar, select **Export**.
4. You can now review your selected items. By default, all dependencies of the items you selected are added too.

    - We recommend that you keep the option **Export all dependencies** under **Advanced settings** selected. By including all dependencies, you're optimizing your success when importing your customizations into another environment.

    - If you prefer to manually select the dependencies of your items, you can change the value to **Export selected dependencies** under **Advanced settings**. Importing customizations that don't include all dependencies will fail if those dependencies aren't already in the destination environment.



5. Select **Export as zip**. The selected items are exported as a compressed solution file (.zip). The solution file is automatically offered for download when the export completes.

    - Files you download from Microsoft Teams will show up in your device's downloads folder. In Microsoft Teams desktop, you can navigate to the **Downloads** section by select **Files** on the left side of the Teams client.

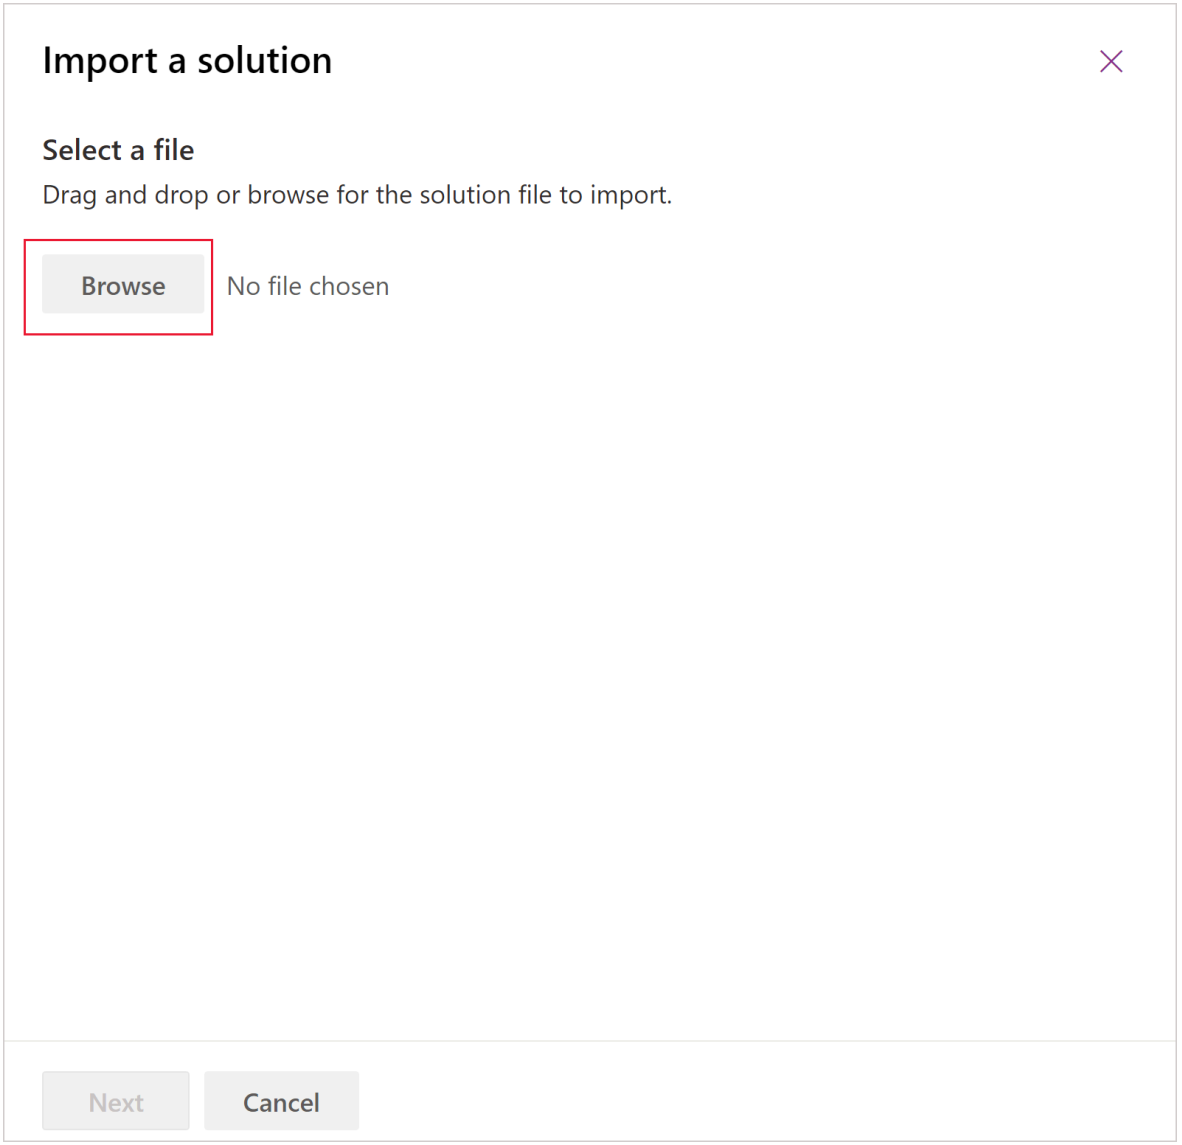
Import customizations into Dataverse for Teams

Take the following steps to import your customizations into Dataverse for Teams:

1. From the Power Apps personal app in Teams, select the **Build** tab of the team where you want to import your customizations. More information: Install the Power Apps personal app in Microsoft Teams

2. Select **See all**, and then on the command bar, select **Import**.

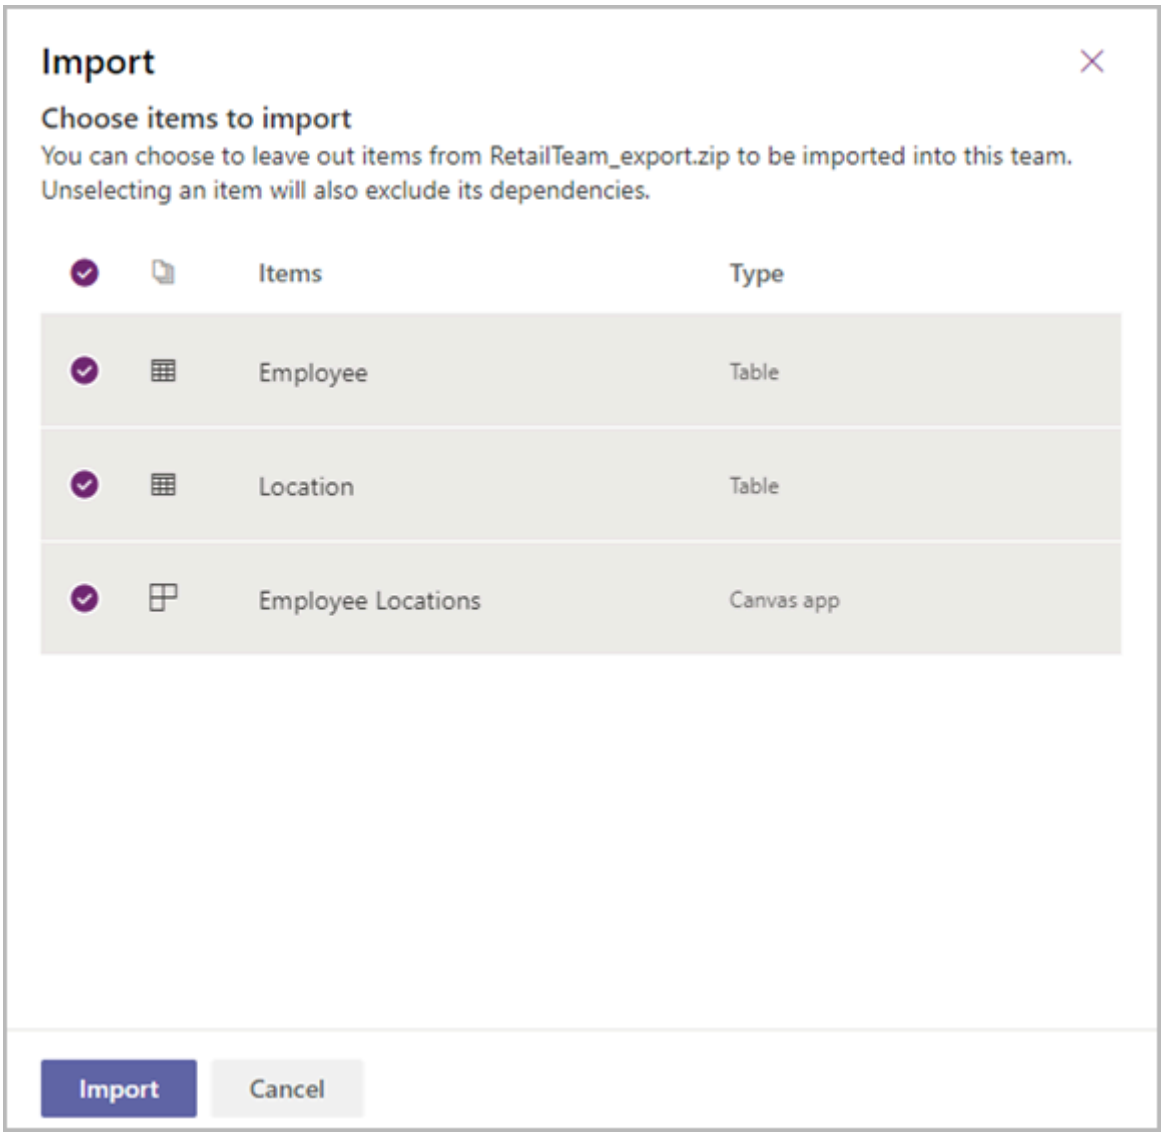
3. On the **Import a solution** page, select **Browse**.



4. Locate the compressed (.zip) file that contains the solution you want to import, select **Open**, and then select **Next**.

5. Review the items that you want to import.

    - If you're importing an unmanaged solution, you can select the item that you want to import into your team. We recommend that you keep the default selection and import all of the items. This helps ensure that all items and their dependencies are imported. Import will fail when you exclude an item that isn't already in the team and another item in the import is dependent on it.
    - If you're importing a managed solution, all the items will be imported.

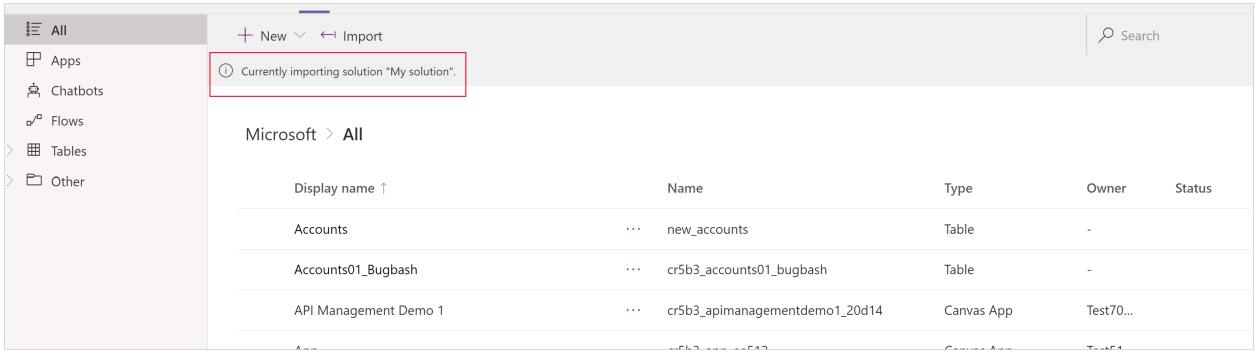


6. Depending on the components in the solution, you might be prompted for additional information when you select **Next**.

    - If your solution contains connection references, you'll be prompted to select the connections you want. If a connection doesn't already exist, create a new one.
    - If your solution contains environment variables, you'll be prompted to enter values. You won't see this page if values are already present in your solution or the target environment.

7. Select **Import**.

Your solution imports in the background and might take a while. A notification appears on the **Build** tab as the solution is imported.



After the import completes, a success or failure notification is displayed.

The location of your solution components is different depending on whether you imported a managed or unmanaged solution:

- With a managed solution, all your customizations appear on the **Build** tab under **Installed apps** using the name of the solution.
- With an unmanaged solution, all your customizations appear on the **Build** tab under **Built by this team**.

Move customizations from Microsoft Dataverse to Dataverse for Teams

Create a solution in a Power Platform environment

The first step to move your customizations from Microsoft Dataverse to Dataverse for Teams is to create a solution in Dataverse. Include only components that are fully supported for Dataverse for Teams. Solutions that include components that aren't supported by Dataverse for Teams won’t import.

The following custom components can be imported into Dataverse for Teams:

- Canvas apps
- Tables
- Flows
- Bots
- Connection references
- Environment variables

> **Note**

Only include items that you or your team have created. Solutions that contain any of the standard Dataverse or Dynamics 365 tables, such as account or contact, won't import.

For information about the differences between Dataverse for Teams and Dataverse, go to How are Dataverse for Teams and Dataverse different?

For information about how to create a solution with Dataverse, go to Create a solution.

Export the solution from Dataverse

Typically, you want to export your solution from Dataverse as managed. However, if your goal is to transport your customizations to Dataverse for Teams and continue your development from there, export your solution as an unmanaged solution. More information: Export solutions

You can now import your solution into Dataverse for Teams. More information: import customizations into Dataverse for teams.

Troubleshooting import failures

If the import isn't successful, you'll see a notification on the solutions page that displays error or warning messages that were captured. Select **Download Log File** to capture details about what caused the import to fail. The most common cause for an import to fail is that the solution didn't contain some required components.

When you download the log file, you'll find an XML file in your browser's default download folder that you can open using an XML reader, such as Microsoft Excel, to view the contents.

Known issues

When you're working with a new Dataverse for Teams environment, the **Import** command is missing because the **See all** link located on the **Build** tab isn't displayed for that environment.

To work around this issue, create and save an app in the environment. When an item exists in the environment, the **See all** link is available and you'll be able to browse to the **Build** tab.

View Dataverse for Teams table data in Power BI Desktop

Article • 02/28/2023

You can use Power BI Desktop to view data from tables in Dataverse for Teams. This enables you to create sophisticated reports to analyze data from your Dataverse for Teams tables. This is possible using a new connector that can use direct query mode for real-time data while enforcing the Dataverse for Teams security model when accessing data. Additionally, the connector automatically maps relationships.

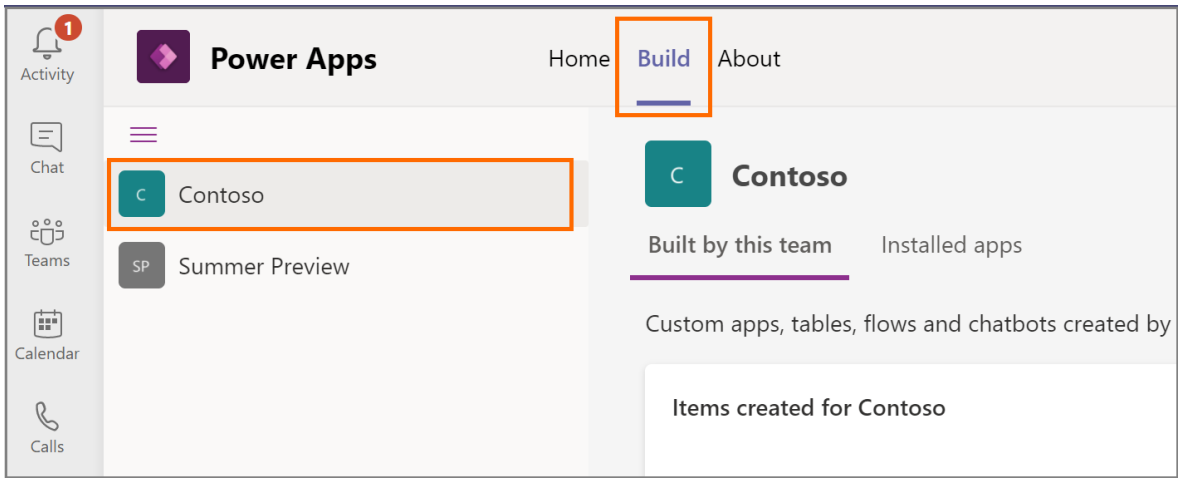
Prerequisites

You must have the appropriate Power BI license to build and share Power BI reports.

Step 1: Get the environment URL

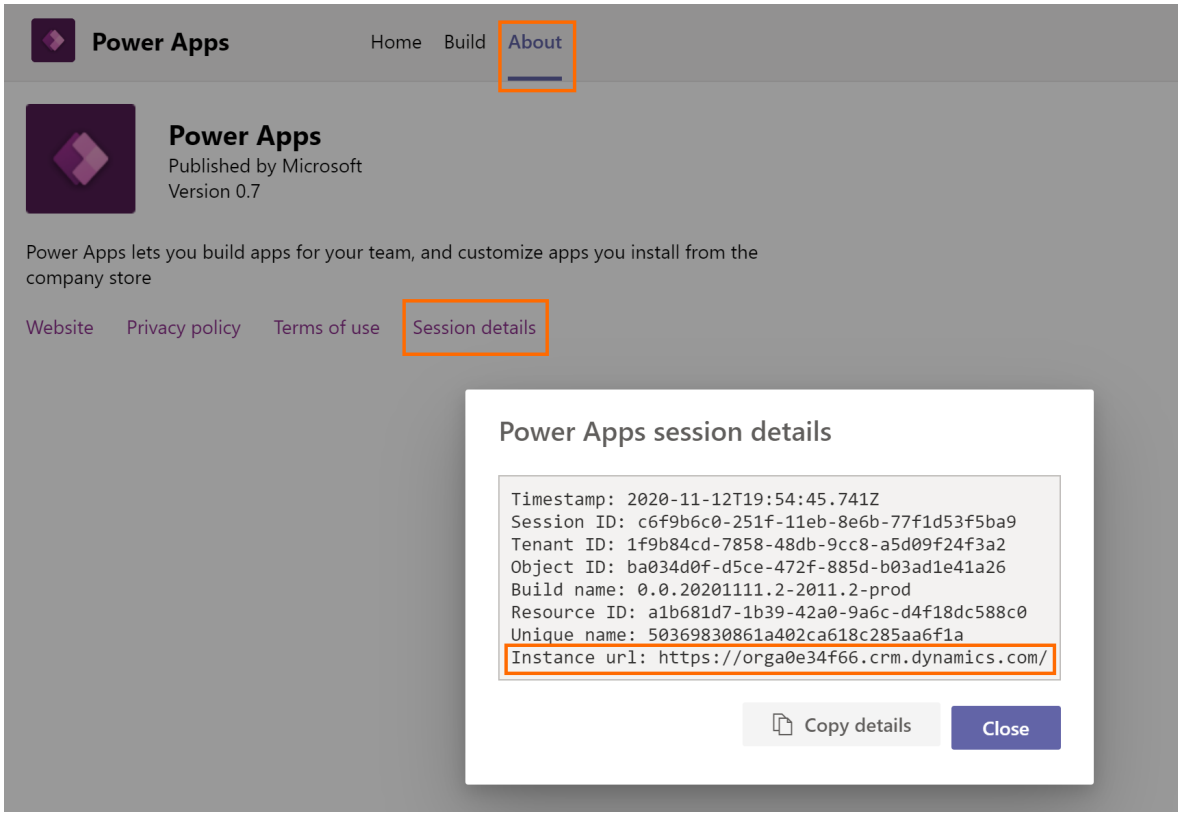
Follow the steps to get the URL of your Dataverse for Teams environment, which is required to connect from the Power BI Desktop.

1. Start Teams, and sign in.
2. In the left pane, select **Power Apps**, and then select the **Build** tab.
3. Select the team in the left pane that contains the data you want to view in Power BI.



4. Select the **About** tab, and then select **Session Details** to display the session details information.
   Copy the Instance url value to notepad. This is the environment URL of your

Dataverse for Team environment. For example:
`https://orga0e34f66.crm.dynamics.com/`



Step 2: View the table data in Power BI

1. Open Power BI Desktop, and sign in. Don't have Power BI Desktop? Get it now.

2. Select **Get data**.

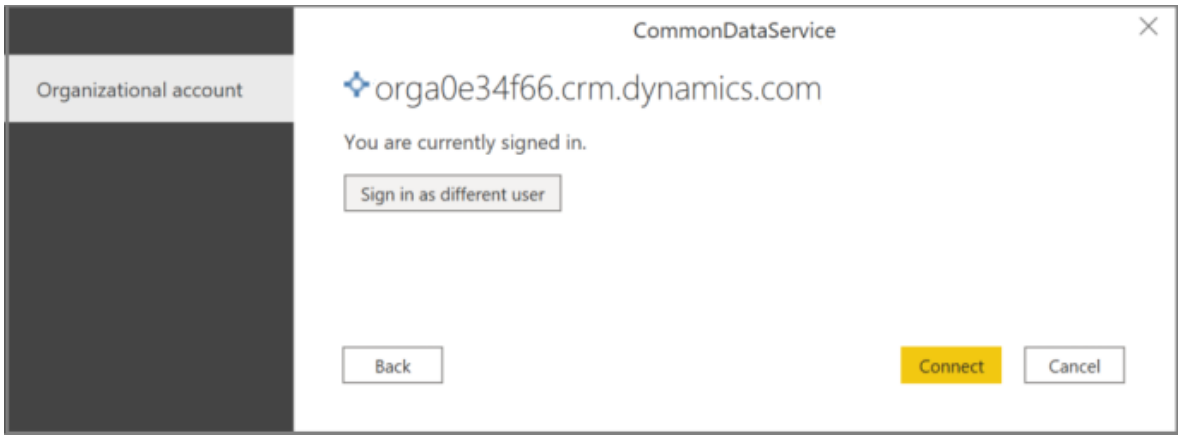
3. On the **Get Data** page, select **Power Platform** > **Dataverse**. Select **Connect**.

4. Read the preview disclaimer and select **Continue**.

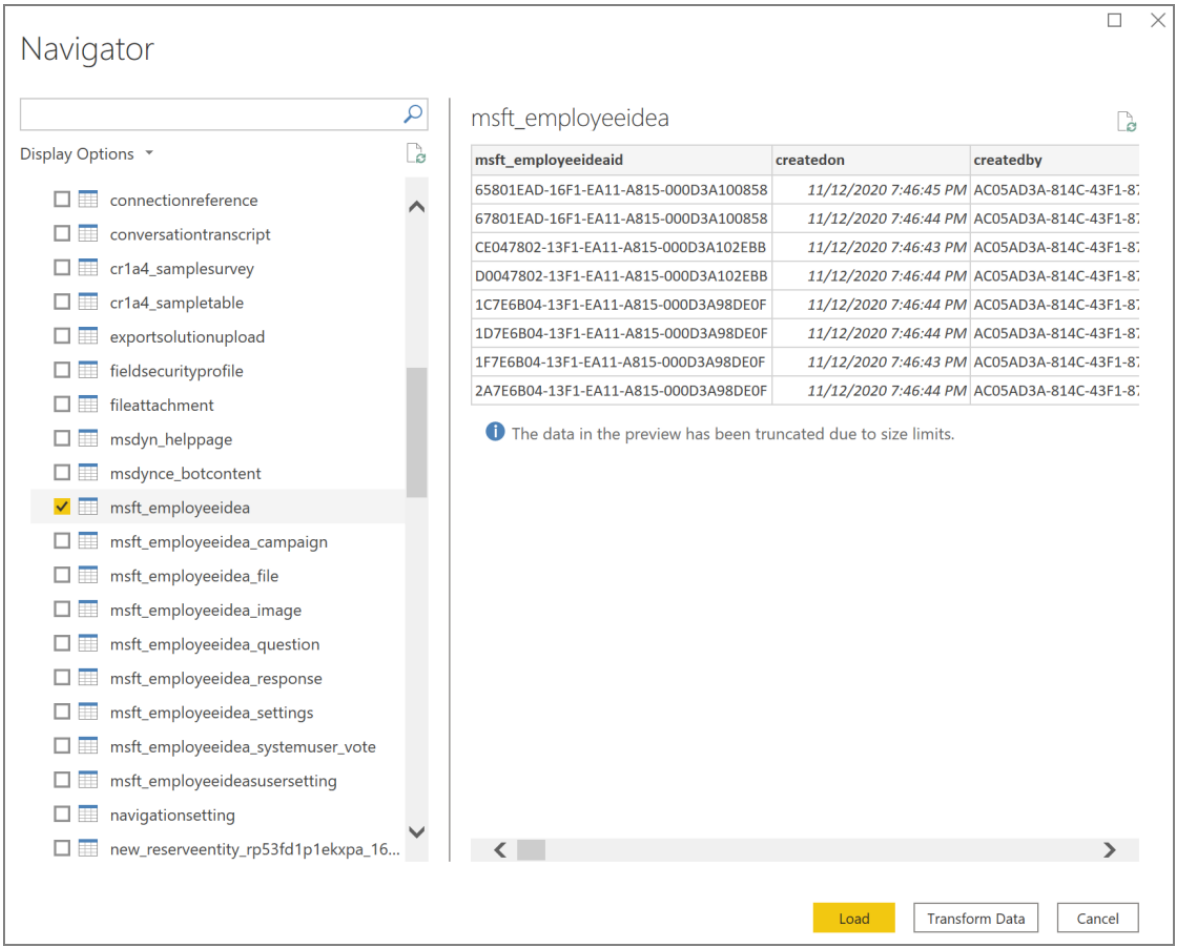
5. On the next page, specify the environment URL that you copied earlier. Make sure you remove `https://` and the trailing `/` from the URL. So, in this case you will add `orga0e34f66.crm.dynamics.com`.
   Select the data connectivity mode and select **OK**.

6. On the next page, select **Sign in**. You'll be prompted to specify your credentials to sign in to your Dataverse for Teams environment. Specify your credentials and submit.

7. On successful sign in, the **Connect** button becomes available. Select **Connect**.



The environment appears in the Power BI Desktop **Navigator** window. Expand it to view the tables available to analyze. Select a table to view its data.



For more information about working with Power BI Desktop, see Get started with Power BI Desktop.

Dataverse for Teams FAQs

Dataverse for Teams environment language

Article • 02/15/2022

A Dataverse for Teams environment is automatically created when a Teams user *either* creates an app in a team using the Power Apps app for the first time *or* installs an app (created using Power Apps app) in a team for the first time from the Teams app catalog. During the environment creation, the environment's language is set to the tenant default language.

The language settings for the environment define the language, sorting, and search formats of the tables in the environment. The *default* language set during the automatic creation of the environment can't be changed thereafter.

When a user accesses the Power Apps app within a team in Microsoft Teams, the user's language setting is compared against the default language of the Dataverse for Teams environment for the team. Depending on the match of the languages, the following happens:

- If the user's language setting matches the default language of the environment, the default language is used to display existing information and for creating new tables and columns.
- If the user's language setting is different from the default language of the environment and the environment:
    - Doesn't have the required language pack installed, the new language pack matching the user's language setting will automatically be installed in the environment. It might take up to 15 minutes for the language pack installation to complete. This is a one-time installation, and will only occur the first time a new language is used.
    - Already has the required language pack installed, the environment will use the user's language.

    Also, this does not change the default language of the environment, but provides a localized user experience for the user when viewing the existing information in the team, and allows all new tables and columns created by the user to have localized labels that match their language.

> **ⓘ Important**

- Any existing tables or columns at the time of the language change will not be translated to another language. They will continue to use the existing names.
- In some cases, a language supported by Teams might not be available in Dataverse for Teams and other Power Platform features. When this happens, the nearest fallback language is used for the interface. More information: **Supported languages and fallbacks** later in this topic.

Example

User A's language is English (United States) in Teams and they create an app in a team called Team 1.

User B's language is set to French in Teams and they access the Power Apps app in Team 1.

- If the Dataverse for Teams environment doesn't have the French language pack installed, it will be automatically installed in the environment for Team 1. The user interface for User B immediately changes to French while the language pack is installed. After the language pack is installed, any new tables and columns will be created in the French language.
- If the Dataverse for Teams environment for Team 1 already has the French language pack installed, no additional installation is required.

If the User B changes their language in Teams again and accesses the Power Apps app in the team next time, the new language pack will be installed if the language isn't already installed in Dataverse for Teams environment.

Supported languages and fallbacks

The languages supported across Teams, Dataverse for Teams, and other Power Platform features vary slightly. When a language is not supported by Dataverse for Teams and other Power Platform features, these will use an identified fallback language. Here is a list of the languages supported across Teams, Dataverse for Teams, and other Power Platform features and their fallback languages.

The fallback languages are denoted in *italics*.

FAQs for Dataverse for Teams

Article • 12/16/2022

Here is a list of frequently asked (FAQs) for Dataverse for Teams; also see Dataverse for Teams licensing FAQs in the Power Platform admin guide.

What does Dataverse for Teams enable and how does this impact Microsoft Power Platform and Teams users?

Power Apps developers and Power Virtual Agents chatbot creators will now be able to make and manage their apps and bots directly in Teams with embedded Power Apps and Power Virtual Agents apps. This enables a streamlined end-to-end user experience and allows makers to deploy to Teams with one click through the Teams app store. These new features are powered by Power Platform enhancement in Teams that provide enterprise datastores with rich data types to Microsoft 365 users and is now included in Microsoft 365 and Office 365 licenses.

Also, apps built with Power Apps and used in Teams will be responsive to the form factor that they're loaded on, meaning a creator can build an app once for users to view full screen on both mobile devices and desktops.

What value does Dataverse for Teams offer for professional developers?

Dataverse includes a robust set of capabilities for professional developers, including API access, the ability to create plug-ins, and so on.

Dataverse for Teams is initially focused on the low-code and no-code developer and does not provide access to these capabilities at launch. However, Dataverse for Teams capability along with premium functionality through Power apps provides professional developers the ability to create robust solutions with far less code, including extending the out-of-the-box capabilities of Power Automate with their own custom logic in Azure functions, connect their own web services, etc.

When should customers use Lists versus Dataverse for Teams?

Lists is great for quickly tracking data in Teams. All your lists are instantly usable inside of Teams. Additionally, you can build canvas apps and flows on top of your Lists just like

you can today in SharePoint.

Dataverse for Teams is great for building Microsoft Power Platform solutions in Teams. With support for files, images, and multiple related tables, Dataverse for Teams can meet your needs today and be promoted to the full Dataverse if you need additional capacity or capabilities in the future.

How does security and governance differ between Dataverse and Microsoft Dataverse for Teams?

Dataverse for Teams is enterprise grade and designed to work within Teams. Focused on Teams, it aligns with the core roles identified in the environment: Owners, Members, and Guests.

For Dataverse for Teams, access to the environment is restricted just to the Teams owners, members, and guests. Granting access to the environment is managed by Teams Owner by adding or removing the Teams members. Key benefits include -

- Supports Teams Azure AD security group with runtime (JIT) user access and privilege checks.
- Auto assignment of System Administrator security role to Teams Owners.
- Ability to assign different security roles to Teams Owners and Members.
- No security settings management for Business Unit and Teams is required.

Dataverse is designed to be used in any application (not just Teams) and includes additional security features such as auditing, sharing, field level and hierarchical security.

How do users import data into tables in Dataverse for Teams?

Makers have the opportunity to bring in data through both the apps they develop as well as via connectors in Power Apps and Power Automate.

Which tables are available to developers in Dataverse for Teams?

Dataverse for Teams makes it easy for users to create custom tables for all of their scenarios.

It also includes a User table that represents the Common Data Model's User entity. Data stored in the User table corresponds to a user in Azure Active Directory (Azure AD).

Does Dataverse for Teams include support for Common Data Model?

The User table is included in Dataverse for Teams. A broader set of Common Data Model entity support is available out-of-the-box in Dataverse.

Can I use tables from other environments?

Applications can include data from environments that the maker has access to within the current tenant.

Where can I use the new visual editor?

In addition to the table designer experience previously found in Dataverse, Dataverse for Teams includes a new, easy-to-use editable grid that helps user be even more productive. You can also use tables from other environments subject to the normal permission model. The new visual editor is currently available only in Dataverse for Teams.

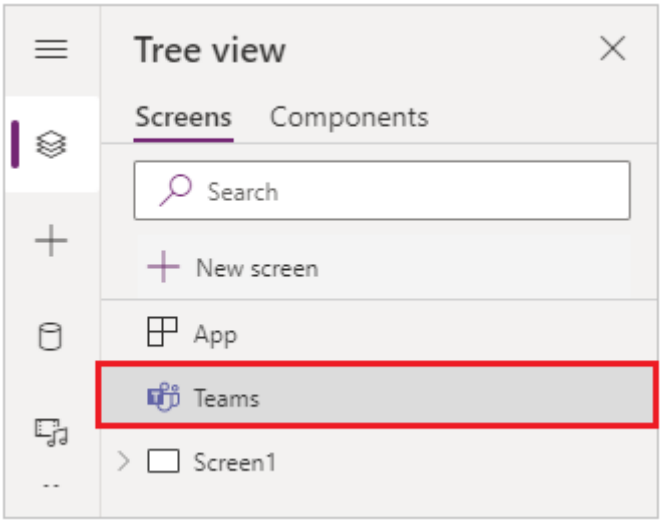
Microsoft Teams integration object

Article • 12/16/2022

You can use the Teams integration object to easily find and access the Teams integration features and use the improved usability of expressions while integrating your canvas app with Teams. The availability of a *Teams integration object* can be validated by checking the presence of **Teams** control from the tree view.



There are two features available with the integration of Power Apps with Teams. You can get a Teams theme inside a canvas app, and you can filter data depending on the team or channel context.

> **Note**
>
> To further integrate with Teams, you can use the Microsoft Teams connector with actions such as post a message, create a Teams meeting, list channels, and more.

Get the Teams theme

Teams uses three themes: *Default*, *Dark*, and *High contrast*. When using the expressions to retrieve theme names, you can use the names as *Default*, *Dark*, and *Contrast* in the Power Apps formula bar.

To retrieve a theme name, use the following formula.

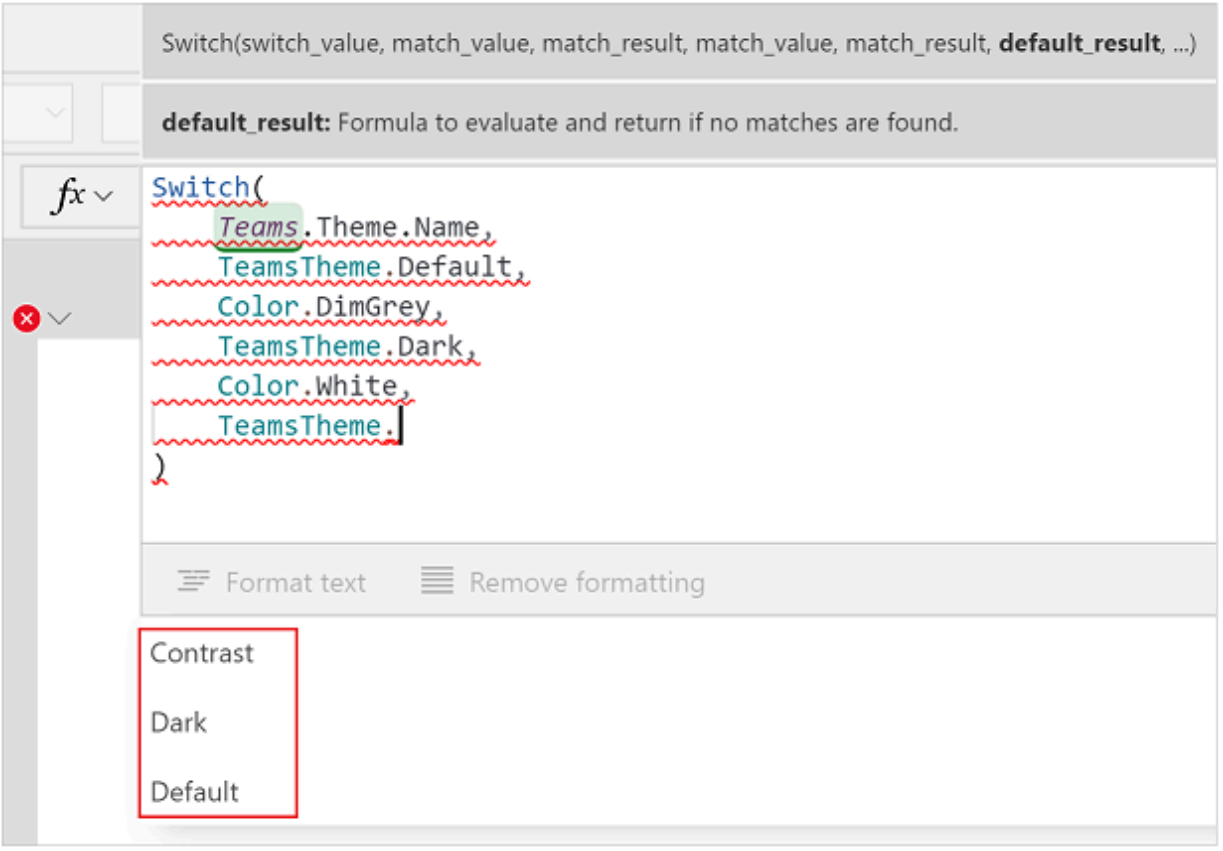
Power Fx

```
Switch(
    Teams.Theme.Name,
```

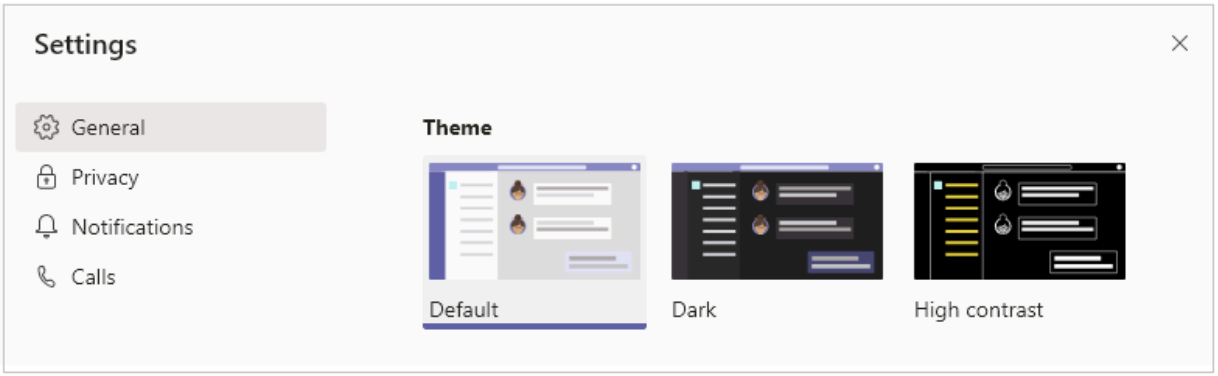
```
    TeamsTheme.Default,
    Color.DimGrey,
    TeamsTheme.Dark,
    Color.White,
    TeamsTheme.Contrast,
    Color.Black
    )
```

In the above formula, the expression *Teams.Theme.Name* is used to evaluate theme names of *Default*, *Dark*, or *Contrast* and the color of the selected canvas app object is changed depending on the color entered in the formula.

The Switch() function evaluates a formula and determines whether the result matches any value in a sequence that you specify.



This function results in changing the background of canvas app, depending on the change in the theme selection in Teams.



For example, use this formula in the *Fill* property of a control (such as, a rectangle) to change the fill color based on the selected Teams theme.

Expand table

Teams theme	App background
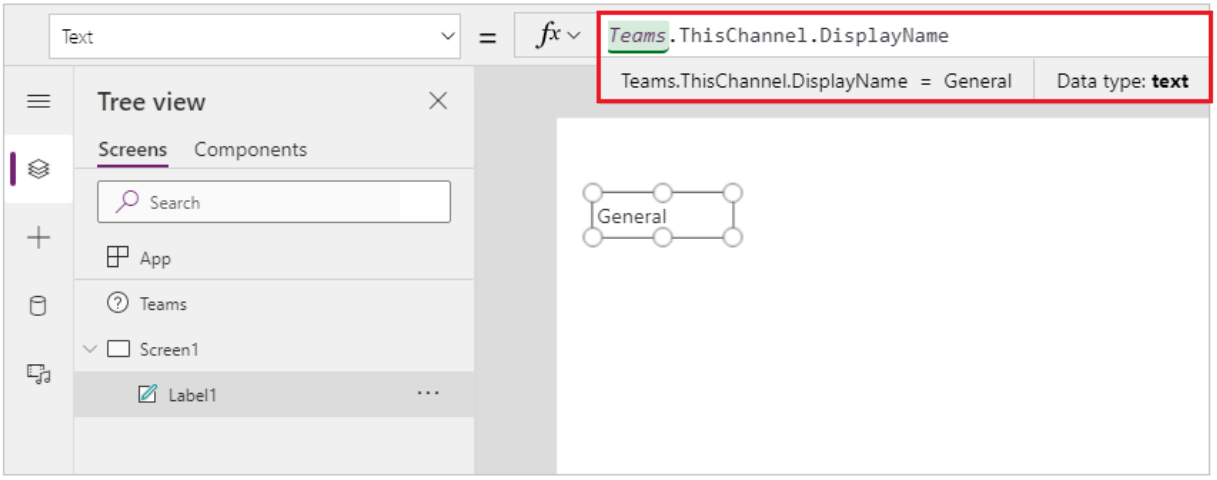
Default (App background color: DimGrey)	Dark (App background color: White)	High contrast (App background color: Black)	
Get the Teams channel name to filter app data

You can get the Teams channel name in canvas app functions, such as function Filter(). To get a Teams channel name, use the following syntax:

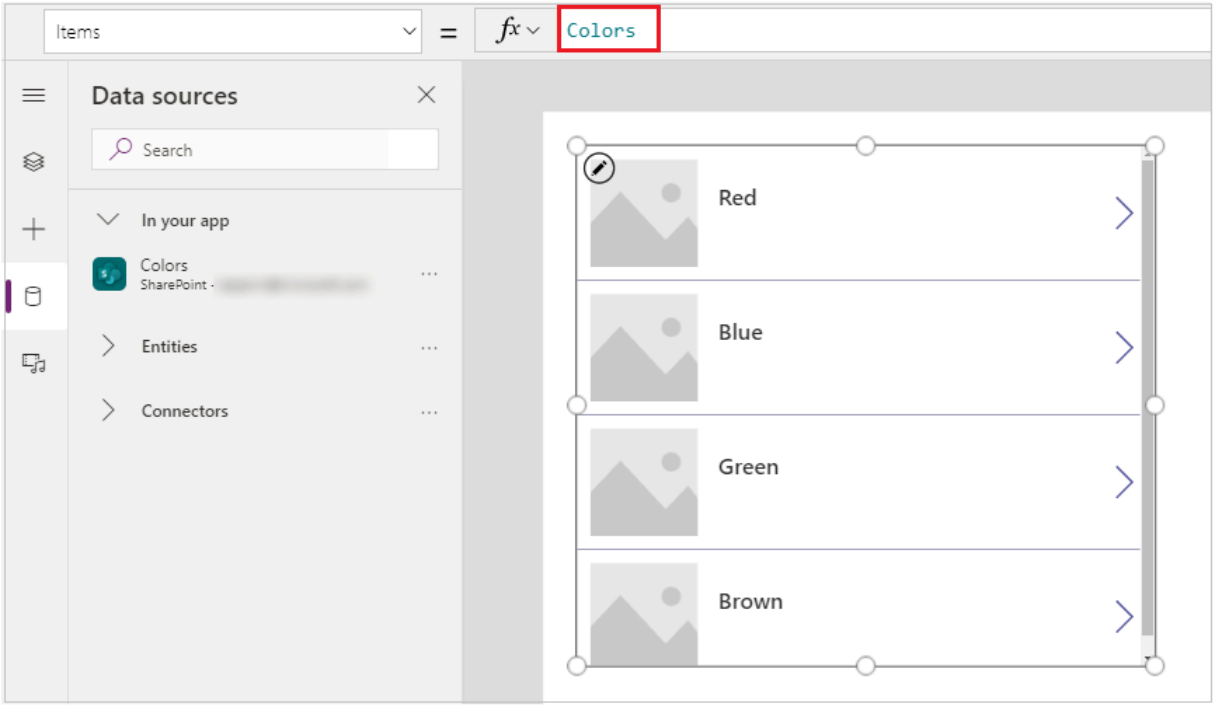
Power Apps

```
Teams.ThisChannel.DisplayName
```

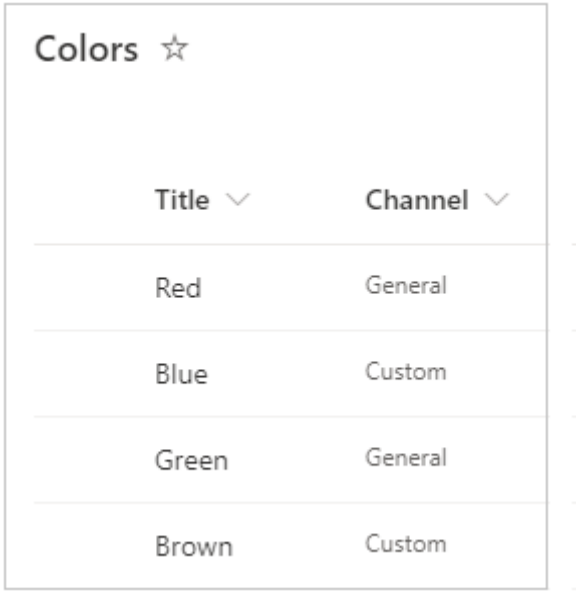
For example, you can add a label and set the *Text* property to display the name of the Teams channel.



For example, connecting to a list hosted on a SharePoint site, you can list the items in a default gallery.

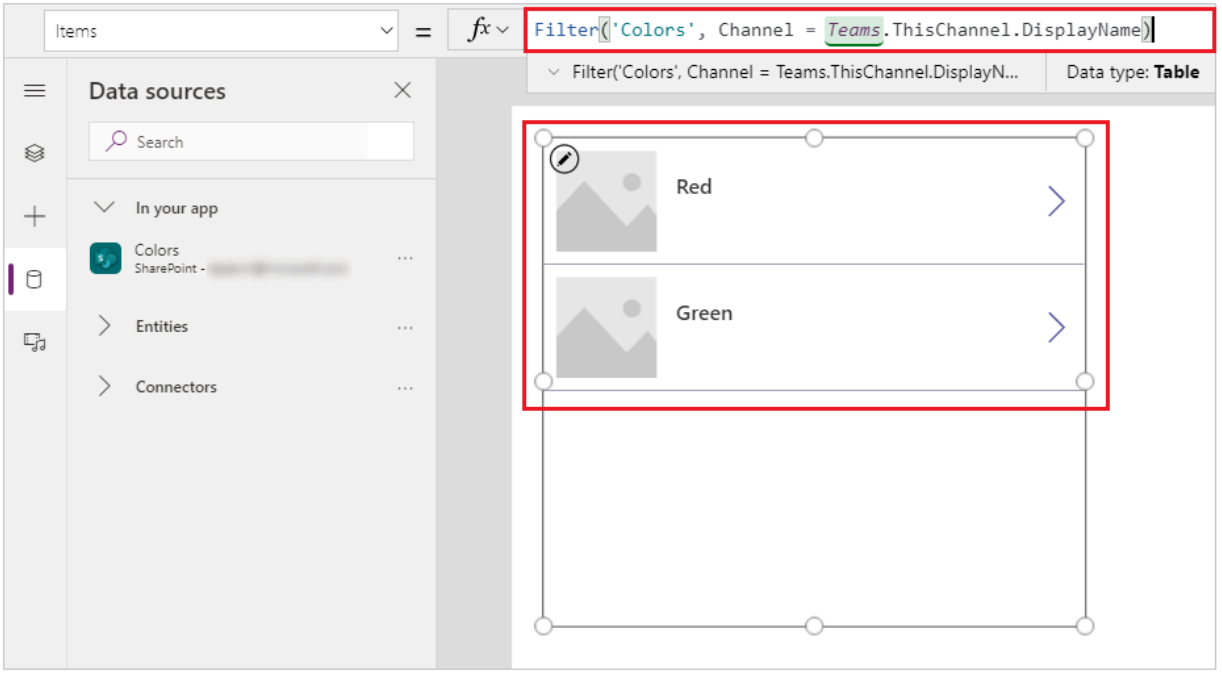


The list shows all items and a column representing the Teams channel name.



Considering the Teams channel name as *General*, you can use the following formula to filter the gallery content depending on the name of the channel.

Filter('Colors', Channel = Teams.ThisChannel.DisplayName)



For more information about the Teams client SDK, go to Context interface. For more information about using context from Teams, go to Use context from teams.

How to build apps for Microsoft Teams

Article • 02/04/2023

The sample app templates for Microsoft Teams are designed, and built with the following goals:

- Provide fully functional apps for Teams that have relevance across multiple industries.
- Provide examples of deeper integration of line-of-business data from Power Apps into collaborative elements of Teams to drive better more productive workloads.
- Provide examples of using good UX design with Teams and Power Apps.
- Provide extensible apps which users can modify and extend to suit their business requirements.

In this article, we'll review the process that we used to build these apps, and the steps that you can follow when building your own Power Apps.

> **Tip**
>
> This article highlights some of the approaches taken when designing the Teams template apps. For additional resources on bet practices for building Power Apps, please refer to **Power Apps guidance documentation** section of the Power Apps docs.

Watch this video to learn how the Power Apps templates for Microsoft Teams were made:
https://learn-video.azurefd.net/vod/player?id=a16dd643-8d23-4c54-a619-a4fe0d38c07d&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fhow-templates-built

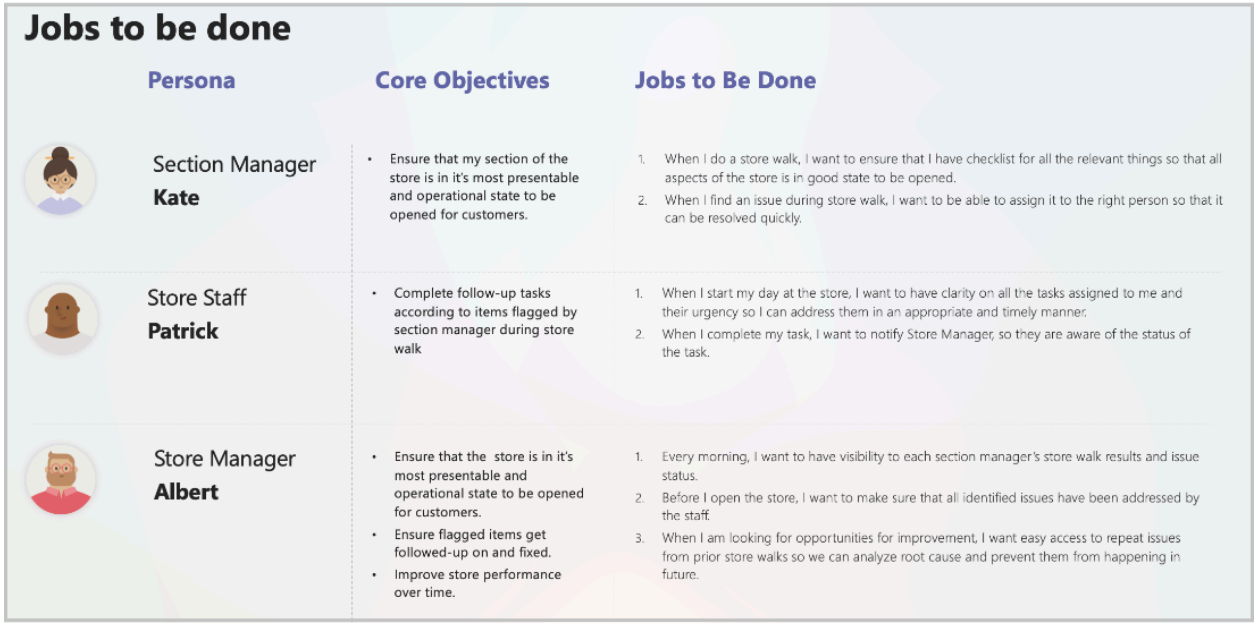
Define

Before designing and building, you need to have an idea—can be an idea for a solution to a business problem, an idea for modernizing a legacy or manual process, or an idea for an app that will make the life of your users easier.

Look to see if there are any existing solutions for the problem. Talk to the stakeholders, customers, or potential users of the app and get their input. Capture their requirements or user stories and prioritize based on what is the highest priority need or opportunity.

Identify “personas” or roles of users who will use your application. At this point, you want to focus on defining the user’s key problems—what are their unmet needs? How important is it for them to solve this problem?

Many teams tend to dive into solutioning before they've fully understood the user’s problem. One way to avoid this trap is to use the “Jobs to be done” framework. This framework helps us identify and understand the needs and goals of the users that are the original drivers of their actions or decisions. This artifact documents each of the persona’s core objective and jobs they want to accomplish in their language.



The above example shows personas and jobs to be done for Inspection sample app template for store walk scenario.

Design

Once you've identified and validated your idea, personas, and their jobs to be done, now is time to design your app. It can be tempting to jump into development at this point, but a bit more design planning will serve you well.

Having a plan will ensure a consistent user experience while enabling you to make the best design decisions for the app.

Design user experience

Make your design plan by creating user flow and wireframes (blueprints) for each job statement. This process helps to ensure the process your solution takes are logical, efficient, and tackles the core of the problem at hand.

Playing with the flow can help you better understand the various pros and cons of different processes. This understanding allows you to select the flow and screen that will enable users to achieve their end goal smoothly. There are many tools available to help you achieve the design outcome. For example, Microsoft applications such as PowerPoint, Visio, or 3rd-party applications such as Figma, Adobe XD, Sketch, or even simple pen and paper.

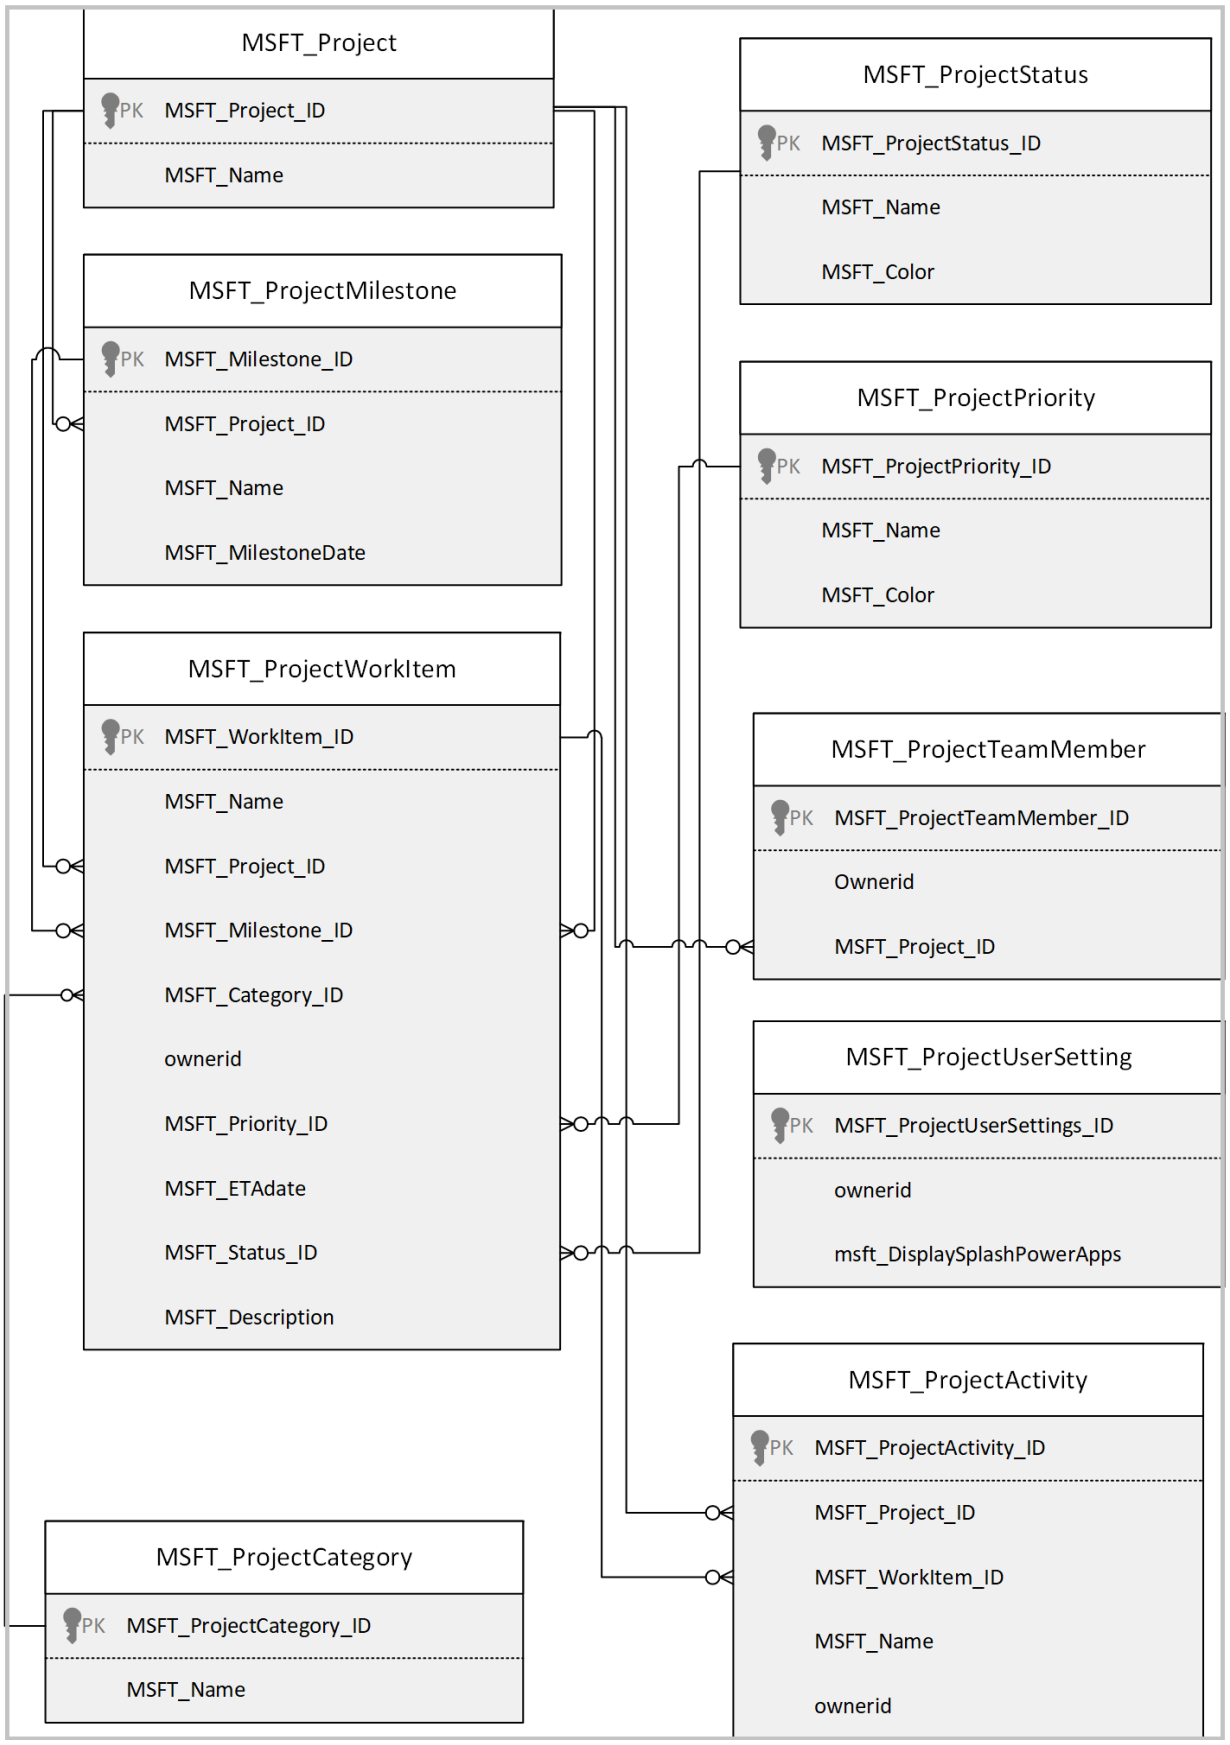
This is also a good check point to get the feedback from end users. Share these high-level flows with your app users and get their feedback on the end to end experience. The iteration at this stage is lower risk as you can quickly make changes and compare options.

Once the base layout is in, now you can have some fun. Do you want a clean and crisp app? Or something more playful. Think about the state of mind of the user and what would work best for them. Wireframing the app screens also helps you to plan out what data connectors will be needed, and giving you an artifact you can review with the stakeholders to get feedback before building the app to verify that the proposed design addresses the requirements.

Once you have identified the requirements and personas and prioritized the backlog, identify the set of features that will be needed to satisfy the "must have" items in the backlog. This is called the Minimum Viable Product (MVP).

Design data model

Along with the user experience, designing the data model of the app is also important. While Power Apps can connect to data from anywhere, you want to think through the data that is needed in the app and how it will be used. In Visio, or some other data diagraming tool, plan out the tables, fields, and relationships that will be needed to support your desired app functionality. Here's an example of the data model for Milestones app tables, and their relationships.



Think through how users will need to interact with the data as you plan what field data types to use. For example, drop-downs for Status, Priority, and Category are updatable in Milestones—that's why we created a table for these options and used a lookup to link them to the work item. For other infrequently changing list options that aren't editable

by users in the app, we used choice data type fields. Make sure your data design fits the purpose and usage patterns of your app and users.

Develop

Now that you've got an idea and a design, start building the app in Power Apps. If you're building an app using Power Apps in Teams, we recommend creating a private team and limiting the members of the team to only those involved in the app development process.

Be sure to periodically review progress with stakeholders to get feedback. Once they see the app coming together, it will build excitement for the finished product, and they'll also provide feedback that you can use to iterate and improve the app experience.

Validate

Once the app functionality is complete, thoroughly test the app:

- Test as each Persona
- Test in Teams Desktop
- Test in Teams Mobile
- Test as user who isn't a member of the team if your app will be shared for broad distribution (sharing with colleagues outside of the team).
- Verify **App Checker** to determine if there are any issues or accessibility problems with your app and address them.
- Run the app through the Power Apps Code Review Tool. This tool has been purpose built to highlight specific areas of potential improvement in the app across a range of areas such as performance, maintainability, and security.

Deploy

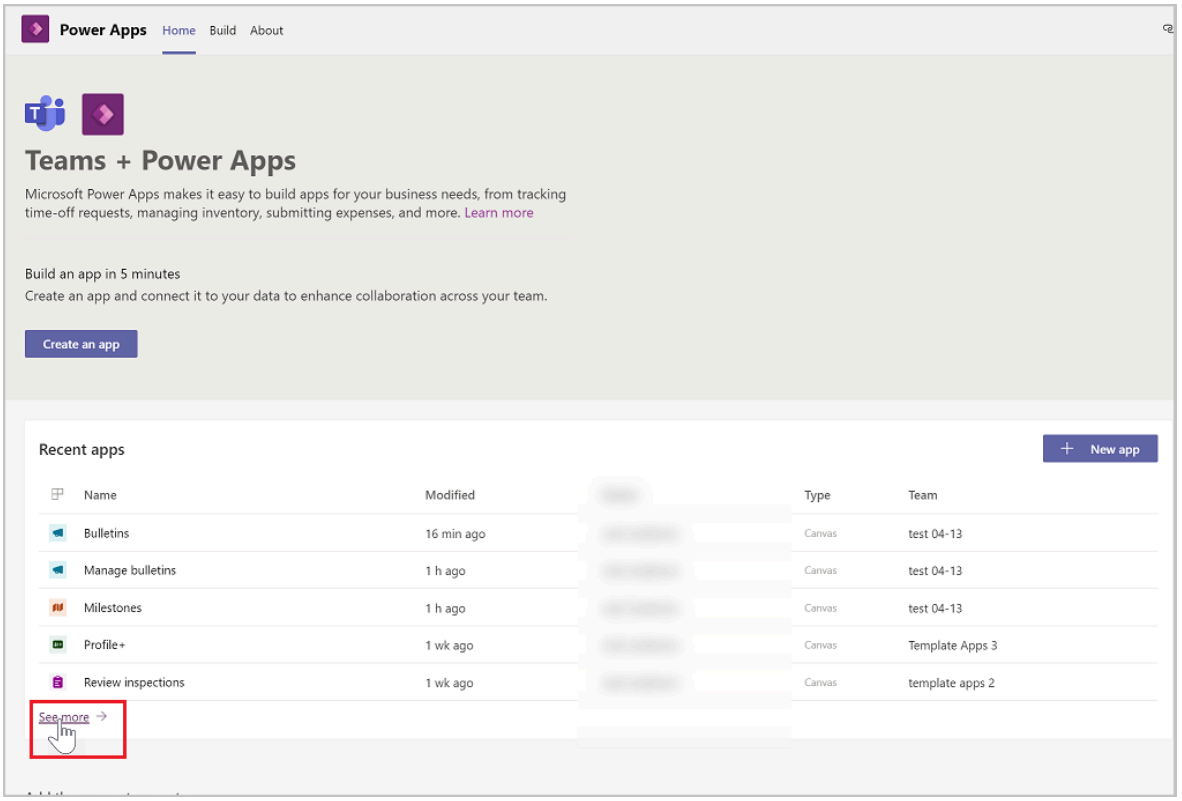
Your app is now complete and fully tested. Now it's time to onboard users. With Teams, you've several options that you can use to give users access to your app:

- Add members to the team in which you developed the app.
- Create a solution and move the app and underlying tables to a different Team environment.

- Share the app for broad distribution.

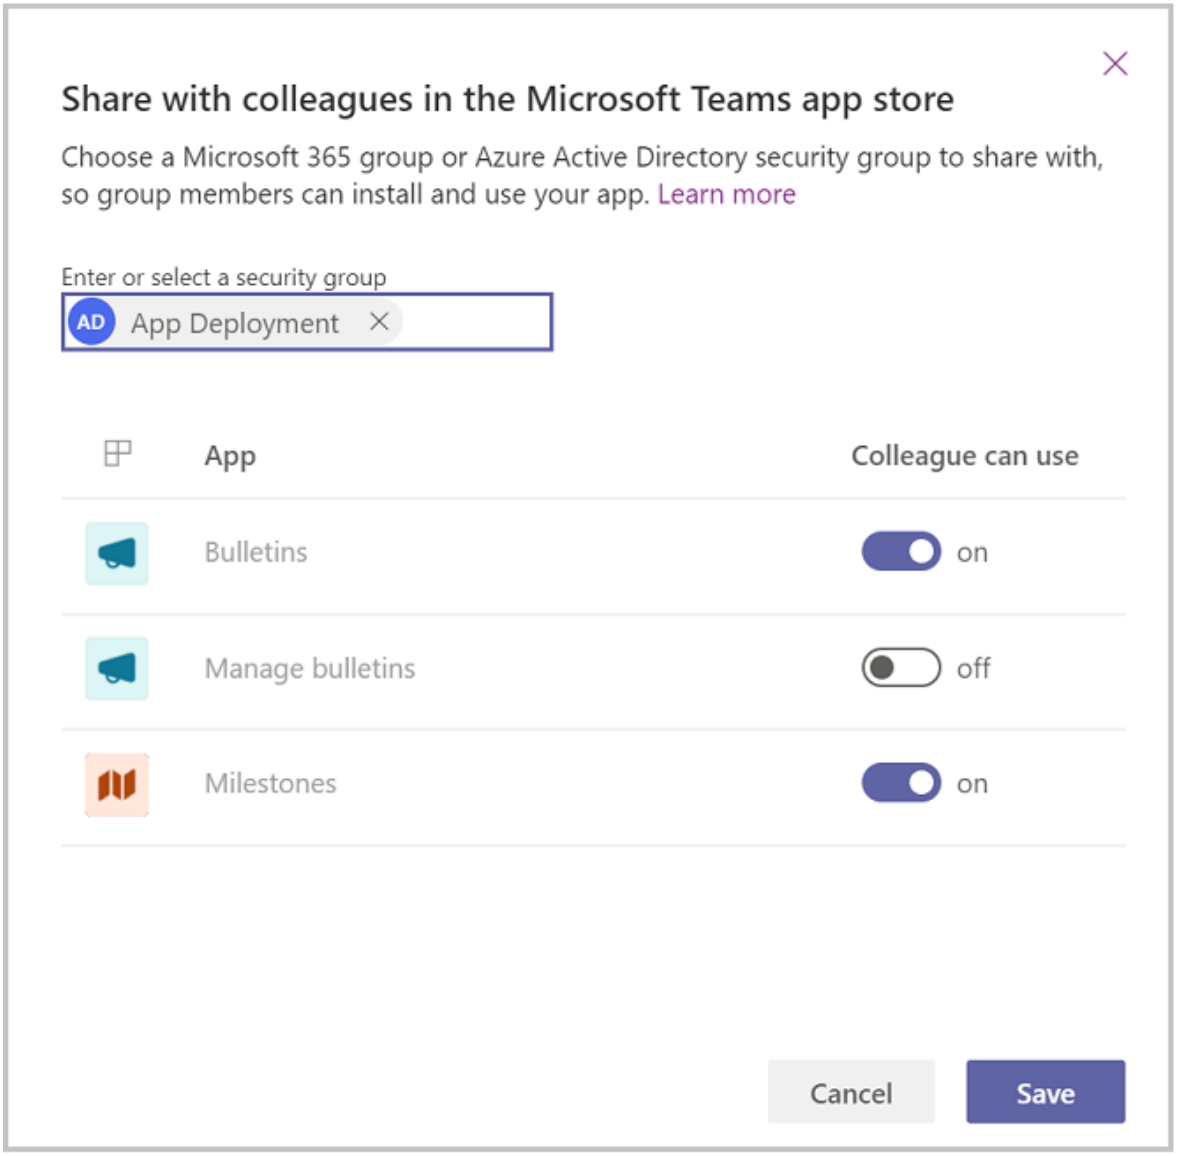
To share an app for broad distribution, follow these steps:

1. In Teams, open the Power Apps app.
2. Under **Recent apps** select **See more**.



3. Select the team where your app is installed.
4. Select **Share with colleagues**.

5. In the **Enter or select a security group** field, enter a security group or team with which you want to share access to your app.
6. Toggle **Colleague can use** to **on** for the app that you wish to share.



7. Select **Save**.

> **Note**
>
> You'll need to set table permissions for the Microsoft Dataverse tables included in your app before users will be able to use it. For more information on table permissions, see Set permission and share apps with colleagues.

Add notifications to make your apps collaborative

Article • 01/20/2023

Apps in Microsoft Teams are designed to enable collaboration between people in your organization. When you have an app that has a hand-off of information, such as group A doing something that group B then needs to process, if everything happens in the app, users may miss important updates, and processes might stall.

Using notifications for critical events in your apps in Teams enhances collaboration by proactively letting users know that something needs their attention or needs to be done.

Teams and Power Platform give you many options in the ways that you can notify people.

- Email notifications
- SMS/text notifications
- Teams messages
- Adaptive cards
- Channel posts

Watch this video to learn how to add notifications to make your apps collaborative: https://learn-video.azurefd.net/vod/player?id=c17e7bd1-aa38-434e-8120-e26b90cb3618&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fadd-app-notifications

Choose the right notification type

How should you decide what type of notification to use? Many people default to email notifications, but many people also complain that they receive too many emails. Email is an acceptable type of notification, but it should be used sparingly. Especially for urgent notifications, as frequent emails are only seen after a period of time.

Here are some questions to ask when defining the appropriate type of notification:

1. **Is the notification urgent?**

   If you're creating an app to track safety issues, and there's an urgent issue that requires immediate attention, a notification like SMS text, push notification, or high priority Teams message should be used so the notification is immediately noticed.

But don’t over-use these types of notifications for non-urgent notifications, or you risk irritating your users.

2. **Is the notification informational or actionable? If you're creating a notification, what do you want to have the notification recipient do with the notification?**

   Informational notifications are to notify users, but they're for information purposes only. For example, in the Employee Ideas sample app template for Teams, when a new idea is created, a message is posted in a Teams channel notifying people that a new idea has been created.

   Actionable notification enable one or more follow-up activities by the recipient. In the extending Employee Ideas article, we show how to change the notification to an adaptive card so users can open the submitted idea and vote for it.

   If the notification requires that the user be able to do something with the notification, such as open a record or respond, an actionable notification should be used—such as an interactive card, or add a hyperlink to deep link to the app.

   Also, Teams makes other types of notifications more actionable by enabling conversations around the notification—when you post a message to a Teams channel, users can respond to it in the channel, facilitating the ability for multiple people to discuss the notification.

3. **Is the notification personal, or to a group?**

   Is there a specific person that should be notified? Or, is there a group of people that needs to know about the notification? For personal notifications, consider sending a message, email, or text message so that other users aren't overloaded with non-applicable notifications. If the message should be seen by multiple people in a group, a post In a Teams channel is a better choice, as the users in the group can all see the message and collaborate on it.

4. **What is the frequency of notification?**

   In the Inspection sample app template for Teams, by default, a message is posted to a Teams channel when an inspection is completed. However, if you've a high frequency of inspections, many messages will be posted to the channel. And when many notifications are posted to a channel, individual notifications can get lost. Think of your phone notification center—when you've a few apps giving you notifications, they're helpful, but if you've many apps posting updates, notifications become noise. In this case, you'd want to reevaluate your notifications, and either change the notification to only notify on urgent inspections, or issues.

5. **What is the impact on the users?**

   Your colleagues are probably busy, and each interruption can add stress to their lives—especially in high quantities. Notifications are good if they make important information more available. But they can also have negative impact if too frequent or unnecessary. Also, arbitrary notifications can diminish a user's sense of control—if many messages start arriving that a user has no control over. And it can be a frustrating experience. Consider giving users an option in the app to control their notifications—this can be a settings toggle to opt in to notifications, or a preference to select what type of notification to receive. See extending bulletins for an example.

Notifications: Power Apps or Power Automate

When creating a notification, you have two options:

- Have your app create the notification directly.
- Or, trigger a Power Apps flow to post the notification.

The decision as to which approach you should use depends on what type of notification you're using, and how the notification should be triggered. Some notification types—such as adaptive cards, require Power Automate. Others, like sending emails, text messages, or Teams channel messages can be sent from a Power Automate formula, or a Power Automate flow. While there isn't a "right or wrong" answer to this question, here are some rules to consider:

- Notifications sent directly from an app without flow will be in the context of the user making the change in the app. That means that the user will need access to the service sending the message, and some types of messages like emails may come from their personal account. If you want to send messages from a service account or general notification mailbox, a Power Automate flow can be owned by a different user account, and send a message when triggered by a data condition (like a record being created).

- If a flow sends a notification, and is triggered directly by the app, the flow needs to be shared or assigned with the user triggering the flow. If a flow sends a notification, and is triggered by a data condition (like a record creation or update), the flow doesn't need to be shared or owned by the triggering user.

- By using Power Automate to send notifications, you can update your notifications without having to republish your app. If your notification details frequently change, or users other than the maker of the app need to modify them, having the

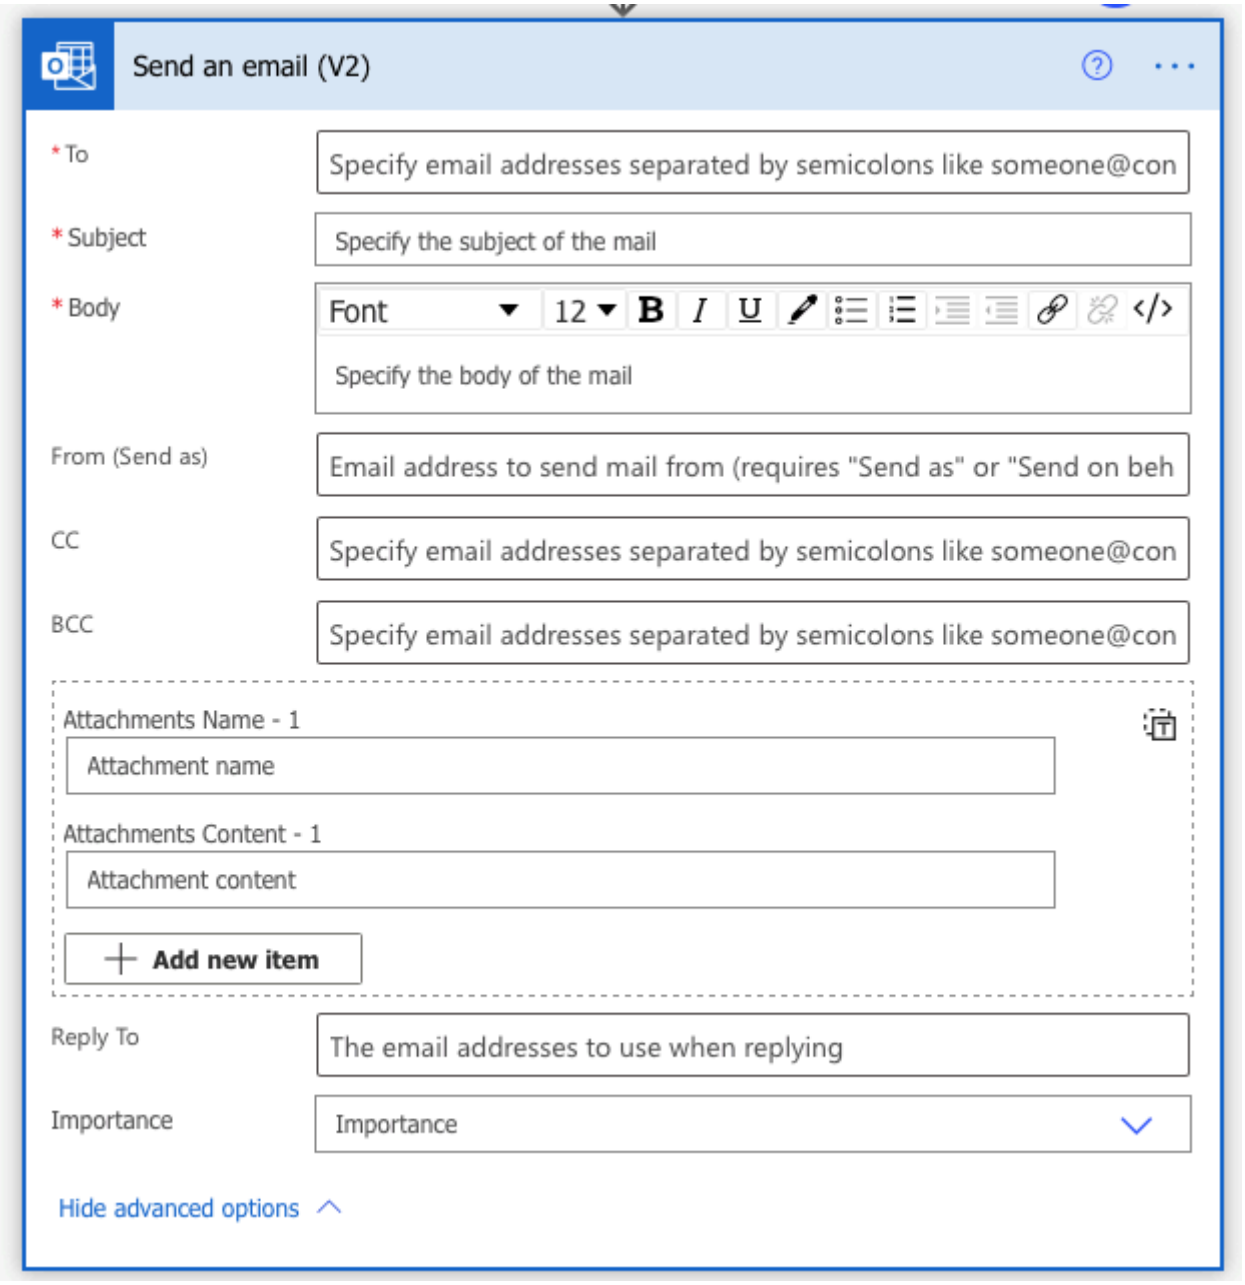
notification sent by Power Automate can segment your workloads and enable other users to work on the notifications while you work on the app.

- Power Apps sending notifications directly use formulas to define the notification logic, Power Automate flow uses a more graphical interface to set the properties of a notification. For example, from a Power Apps app, you can use the following formula to send email with the Outlook connector:

```
Power Fx

Microsoft365Outlook.SendEmail("mailbox@contoso.com", Summary, Description)
```

In Power Automate instead, the send an email action is presented in a graphical manner, allowing users to populate the fields in a manner similar to how they send an email in Outlook.



Sending an email from Power Apps directly is faster for experienced makers, but the more details are required—such as attachment files and formatted text. For the less experienced makers, sending the email with Power Automate flow might be easier.

Integrate with Microsoft Planner

Article • 01/20/2023

In this article, we'll learn how to integrate Power Apps with Planner to create and assign tasks to users within the organization.

Power Apps in Microsoft Teams enables collaboration between people and groups. Employees already use Teams to work, communicate, and collaborate. Apps in Teams have deep integration with other Teams capabilities. For example, in Teams, you can assign tasks to team members using Planner in your Teams channel. Apps that require follow-up by others in your team, such as to address issues reported in the Issue Reporting app, can leverage Planner in the Teams channel and create Tasks where users already manage their tasks.

Watch this video to learn how to integrate Power Apps with Planner: https://learn-video.azurefd.net/vod/player?id=37312c36-393d-44fd-ba8a-9b3dbdf8d60e&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fintegrate-planner

Prerequisites

To complete this lesson, we'd need the ability to create apps within Teams that will be available as part of select Microsoft 365 subscriptions. We'll also need the ability to connect to Planner.

Login into Teams

Login into Teams using either the Desktop app or the web app.

Create a new Team

In this section, we'll create a new Teams team and then create an app within that team. Skip this section if you already have a team that you want to use instead.

1. To create a new team, select the **Teams** tab > select **Join or create a team** > select **Create Team** > select **From Scratch** > select **Public**, and give the team a name such as "Planner Integration". And then, select **Create**.

2. Select and add any members in your organization that you'd like to add to the team for testing purposes, and select **Add**.

3. Select **Close**.

   The new team gets created and is listed under the Teams tab.

Create a new app

We'll create an app with five fields capturing details that will be used to create a Task in Planner.

1. Open Teams.
2. Select Power Apps from the left-pane.
3. Select + **New app** under **Recent apps**.
4. Select the team created earlier, and select **Create** to open Power Apps Studio.
5. Enter a name for the app, such as "Integrate with Planner", and select **Save**.

   The app shows a default gallery
6. Select the database option from the left-pane to connect to the Planner.
7. Select + **Add data**, and then select **Connectors**.
8. Enter "Planner" in the search box to look for the Planner connector.
9. Select **Planner**.
10. If prompted, sign in.

    Planner gets added as a data connection to the app
11. Select to open the Tree view.
12. Select + **New screen** > **Blank layout**.
13. Add the following controls.

    a. Title (text input)

Expand table

Property	Value
Name	Title
Type	Text box

Property	Value
X	Screen2.Width/2
Y	135
Width	320
Height	35

b. From Date (date picker)

Expand table

Property	Value
Name	FromDate
Type	Date picker
X	Screen2.Width/2
Y	235
Width	320
Height	35

c. Due Date (date picker)

Expand table

Property	Value
Name	DueDate
Type	Date picker
X	Screen2.Width/2
Y	335
Width	320
Height	35

d. Assigned To (combo box)

Expand table

Property	Value
Name	AssignedTo
Type	Combo box
X	Screen2.Width/2
Y	435
Width	320
Height	35

e. Planner ID (combo box)

Expand table

Property	Value
Name	PlannerID
Type	Combo box
Items	Planner.ListGroupPlans(Param("groupID")).value
X	Screen2.Width/2
Y	535
Width	320
Height	35

14. Add the following labels.

a. Title

Expand table

Property	Value
Name	Label_Title
X	365
Y	135
Width	320

Property	Value
Height	35

b. From Date

Expand table

Property	Value
Name	Label_FromDate
X	365
Y	235
Width	320
Height	35

c. Due Date

Expand table

Property	Value
Name	Label_DueDate
X	365
Y	335
Width	320
Height	35

d. Assigned To

Expand table

Property	Value
Name	Label_AssignedTo
X	365
Y	435
Width	320

Property	Value
Height	35

e. Planner ID

Expand table

Property	Value
Name	Label_PlannerID
X	365
Y	535
Width	320
Height	35

15. Add a button to the bottom of the screen with the following properties.

Expand table

Property	Value
Name	Button_CreateTask
X	526
Y	635
Width	320
Height	35

16. Copy the following formula in the **OnSelect** property of **Button_CreateTask**.

Power Fx

```
Planner.CreateTaskV3(
    Param("groupId"),
    PlannerID.Selected.id,
    Title.Value,
    {
        startDateTime: FromDate.Value,
        dueDateTime: DueDate.Value,
        assignments: AssignedTo.Selected.'User Name'
```

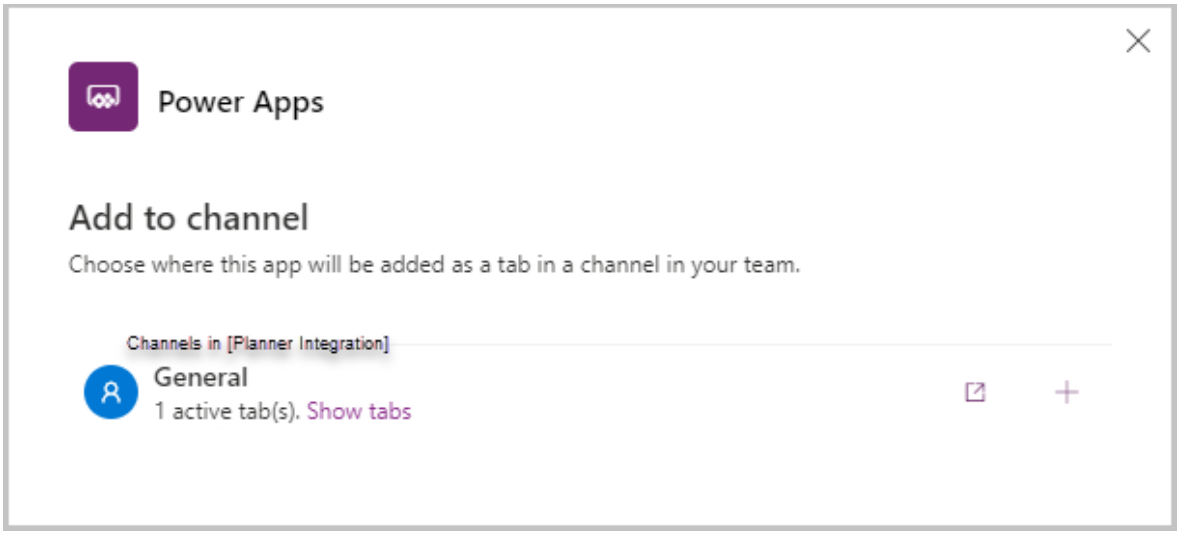
```
    }
)
```

> ⓘ Note
>
> Upon selecting the **Create Task** button, it'll use the parameters provided in the formula to figure out the team for which the task is being created, the planner within the team the task is to be created, the Title from the text box captured on the screen, and the From and Due dates captured on the screen.

17. Move **Screen2** up above **Screen1**. If you want, you can also delete **Screen1** instead.

Save and publish the app

1. Select **Save** on the top-right side of the screen to save the app.
2. Select **Publish**.
3. Select **Next**.
4. Under **Add to Channel**, make sure the channel under which the app should be shown is listed and shows as at least "1 active tab(s)" and not "0 active tab(s)".



5. Select **Save and Close**.

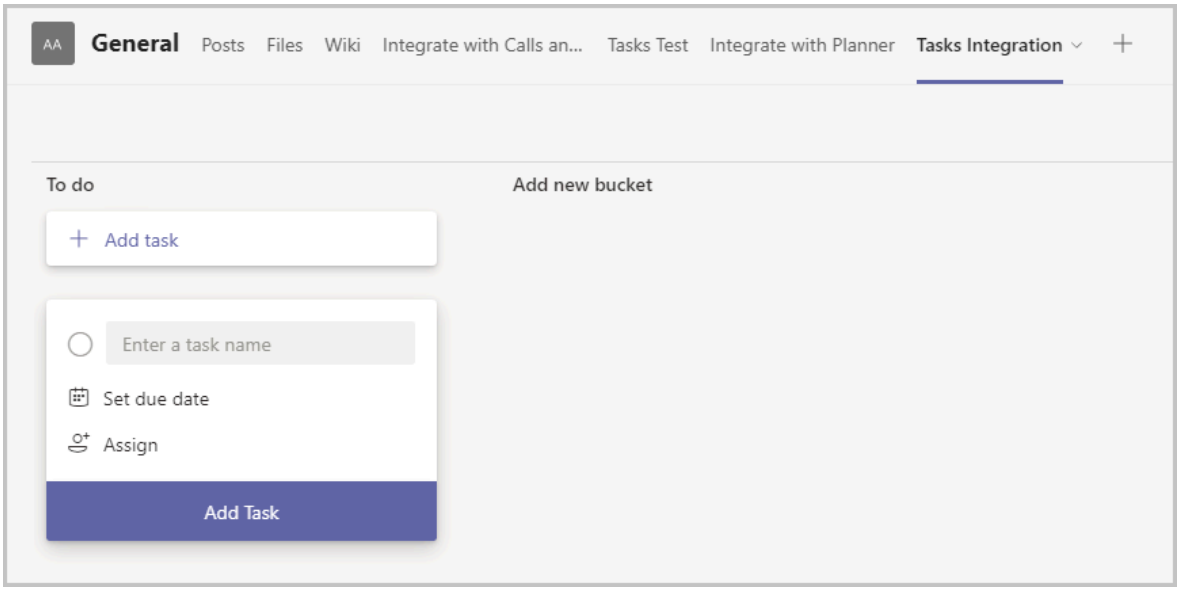
Test the app

1. Open the team under which the app is created.
2. Select **+ Add a tab**.

3. Search for tasks by Planner to add a planner tab to the team.

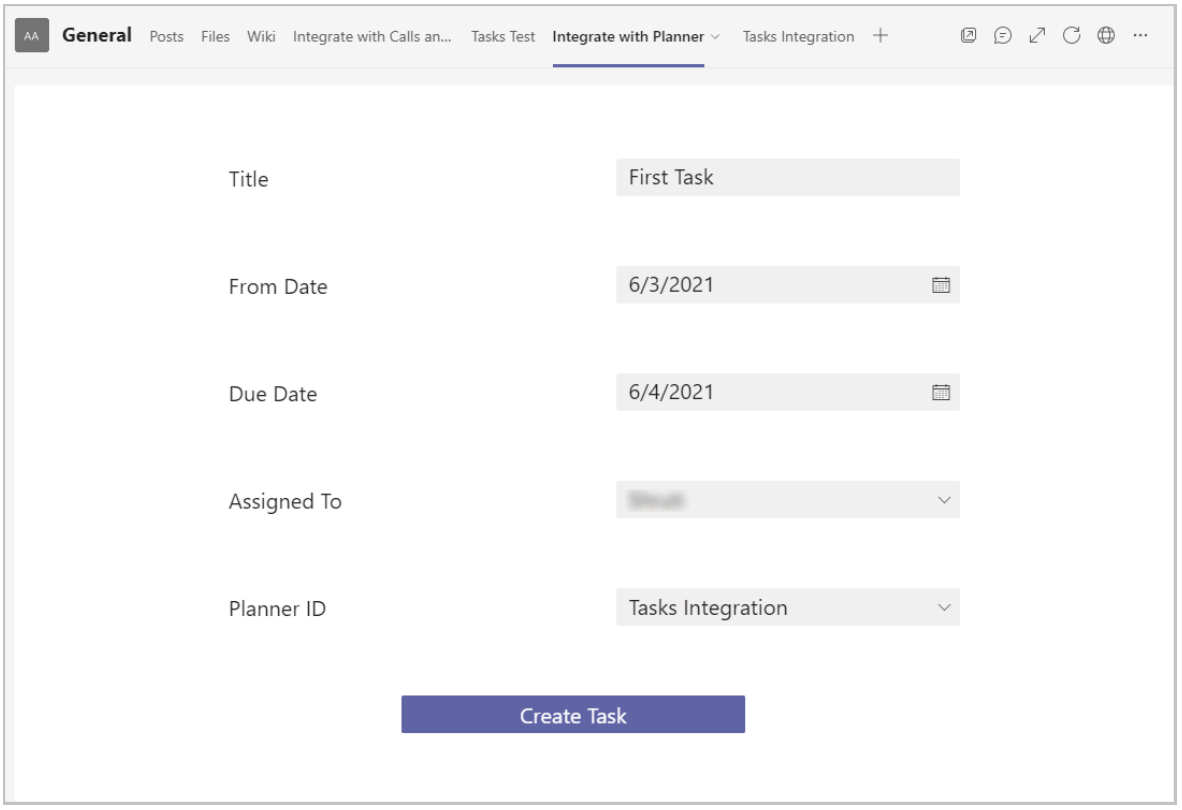
4. Enter tab name under **Create a new plan**, for example "Tasks Integration". And then, select **Save**.

   The tab gets added to the Team



5. Run the app in preview mode or from within the team.

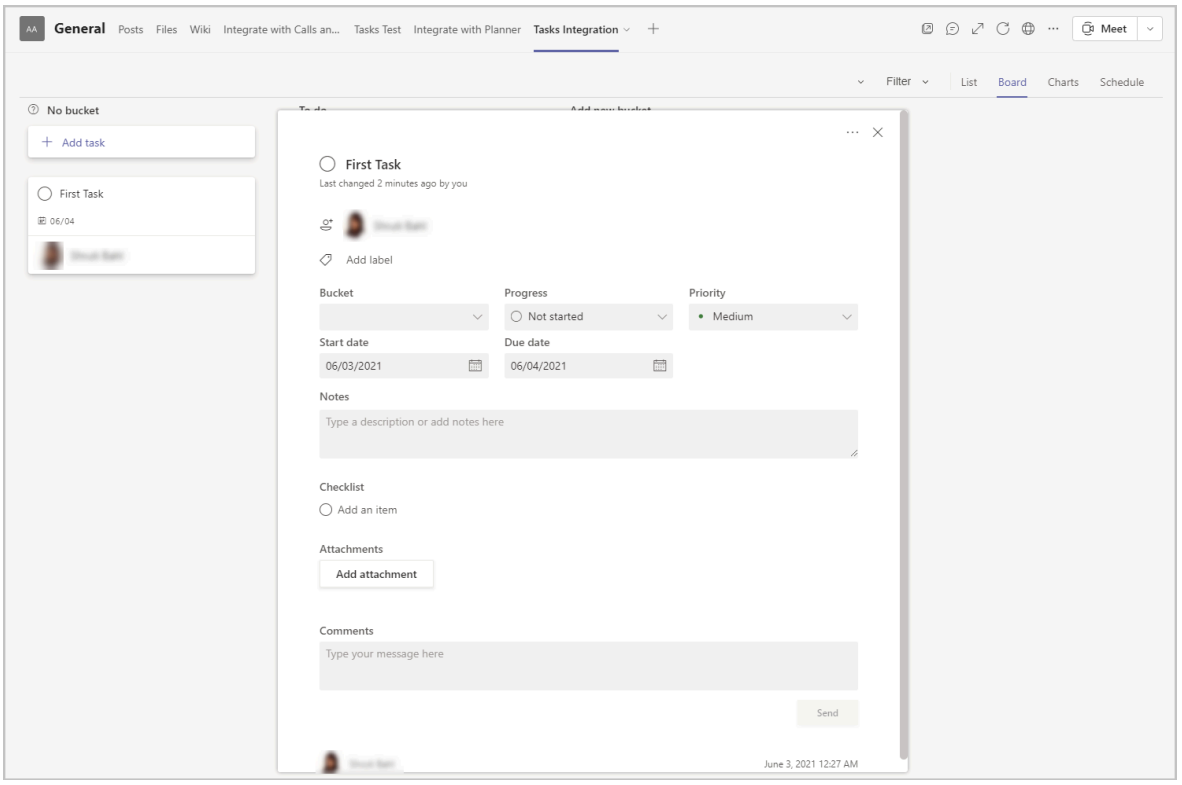
6. Populate the columns with appropriate values.



7. Select **Create Task**.

8. Go to the Planner tab for which the task is being created—in our example, "Tasks Integration Planner".

   A new task with the details should be added to the list.



See Planner integration in action

To see an example of Planner integration, check out the Issue Reporting sample app template for Teams. Issue Reporting makes it easy for users to report issues. These issues are created in Planner and assigned for follow-up.

This integration can be easily extended to add logic to automatically assign the Planner Tasks or provide notifications for issue tasks.

Integrate with Azure Active Directory

Article • 01/20/2023

In this article, we'll learn about how to integrate apps created using Power Apps in Microsoft Teams with Azure Active Directory (AD).

Integration with Azure AD enables many deep capabilities within your organization hierarchy, the people in your organizations, and groups. For example, you can get information about a person, their job title, department, or photo. You can also get information about the user's organization hierarchy, such as their manager.

This integration can also be used to grant access to app functionality based on their role or group membership, and therefore, be used to control security to sensitive data or functionality.

In this article, we'll create a Power Apps app with a button with administrative access on it. The visibility of the button will depend on whether the user is a member of the admin group or not.

Watch this video to learn how to integrate Power Apps app with Azure Active Directory: https://learn-video.azurefd.net/vod/player?id=9fabda9a-e9b5-43af-addd-a27d3f381f18&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fintegrate-azure-ad

Prerequisites

To complete this lesson, we'd need the ability to create apps within Teams that will be available as part of select Microsoft 365 subscriptions. We'll also need access to Azure AD to create the admin group and assign members to it.

Sign in to Teams

Login into Teams using either the Desktop app or the web app.

Create a new Team

In this section, we'll create a new team, and then create an app within that team. Skip this section if you already have a team that you want to use instead of creating a new one.

1. To create a new team, select the Teams tab, and then select **Join or create a team** on the left bottom of the screen.
2. Select **Create Team** > **From Scratch** > **Public**, give the team a name such as "Azure AD Integration", and select **Create**.
3. (Optional) If you have any members in your organization that you'd like to add to the team for testing purposes, select them, and add them in the popup for adding members.
4. Select **Close**.

The new team gets created, and is listed under the Teams tab.

Create a new Azure AD Group

1. Sign in to Azure portal with the same account that you logged into Teams with earlier.
2. On the top search bar, search for and select **Groups**.
3. Select **+ New Group**.
4. Set up the group with the following values:

Expand table

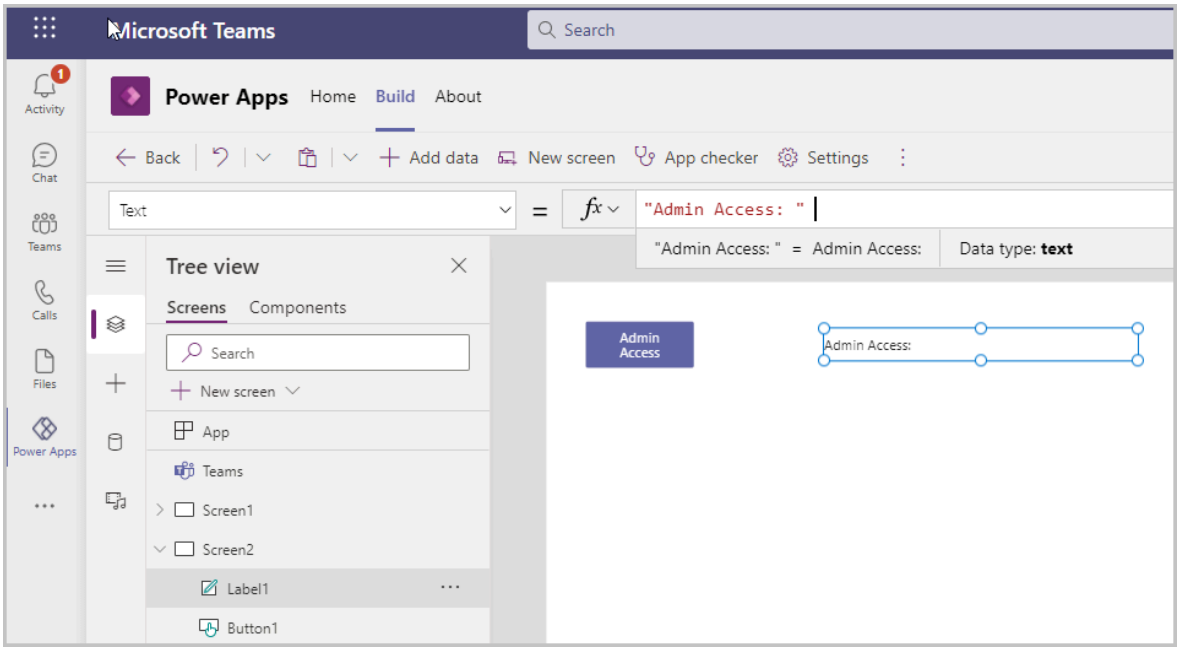
Option	Value
Group type	Microsoft 365
Group name	Admin Access
Group email address	Automatically updated
Group description	Group for users with Admin access

5. Select **Create**.
6. Copy the group's object ID from the group overview screen for use later.

Create a new app

We'll create an app with a button that will only show up if the user is a member of the team we created above.

1. Open the Teams app.
2. Select **Power Apps**.
3. Select **+ New app** under **Recent apps**.
4. Select the team created earlier, and then select **Create**.
5. The app gets created, and the Power Apps Studio opens to allow editing the app.
6. Enter a name for the app, such as "Integrate with Azure AD", and then select **Save**.
7. Select **Data** > **Add data**.
8. In the connectors list, search for Azure AD, and select it to add that as a connection.
9. Select **Connect**.
10. Sign in, and select **Accept** to connect.
11. In the **Tree view**, select **+ New screen** to add a new screen to the app.
12. Select **+** (Insert) icon on the left-pane.
13. Select **Button**.
14. Set the "Text" property of the button to “Admin access”.
15. Select **+** (Insert) again, and then select label control to add.
16. Update the label text to "Admin level: ".



17. Select the app from the tree view, and open the **OnStart** property from the top-left of the screen.

18. Enter the following formula for the app OnStart:

```
Power Fx

If(
    !IsEmpty(
        AzureAD.CheckMemberGroups(
            User().Email,
            ["Enter your Azure group ID here"]
        ).Value
    ),
    Set(varAdmin,true),
    Set(varAdmin,false)
)
```

> **Note**
>
> Update the formula with the group ID (GUID) for the group you copied earlier.

19. Select ... (ellipsis) next to the app, and then select **Run OnStart**.

20. Select ... (ellipsis) next to **Settings** on the top ribbon, and select to view variables. **varAdmin** is set to False.

21. Select Screen 2 from the Tree view, and update the Text formula for the label to `"Admin Level: " & varAdmin`. The label will currently show as "Admin level: false" on the screen.

    We'll now control the visibility of the Admin Access button so that it only shows up when the user is an admin (for example, belongs to the Admin access group in Azure AD)

22. Select the button, and set the **Visible** property to "varAdmin".

    The button doesn't show up anymore since we don't have admin access.

Testing the integration

1. Sign in to Azure portal.

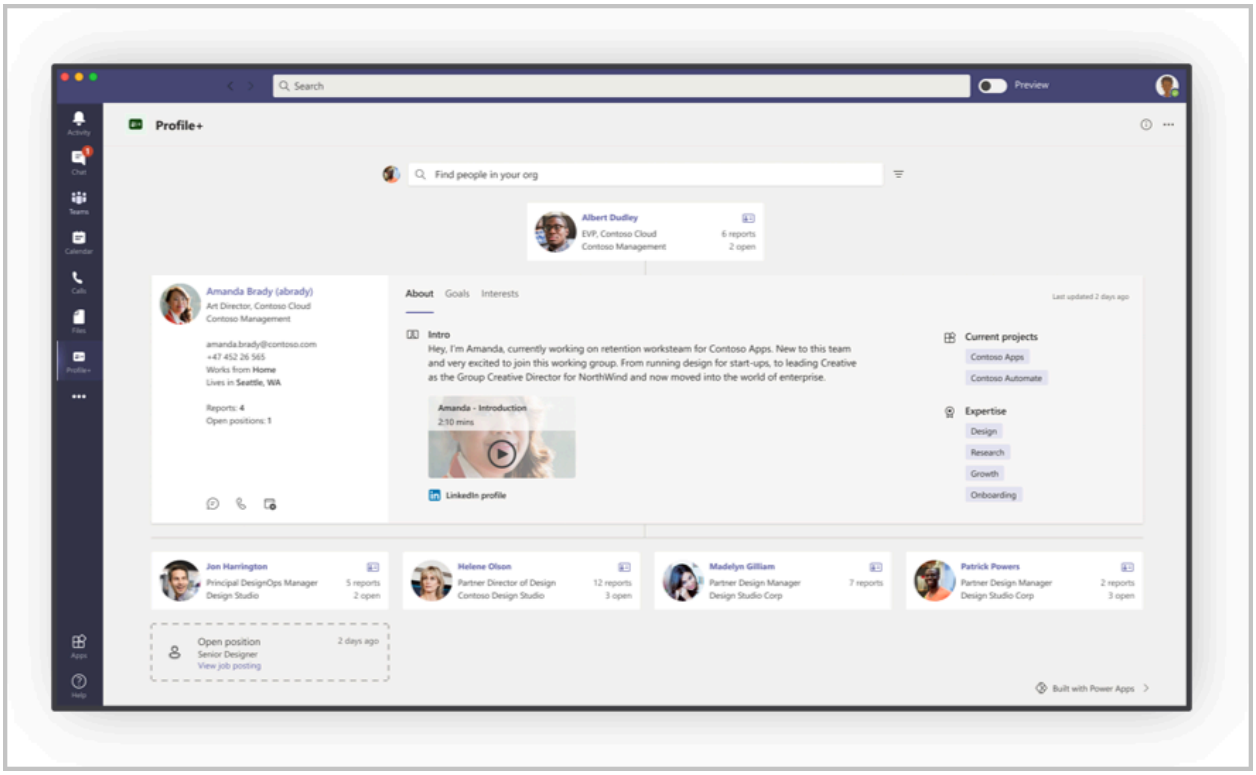
2. Select the group created earlier.

3. Select **Members** under **Manage** from the left-pane.
4. Select + **Add members** to add members to the group/
5. Select users from the list of users under **Add members** to add to the group.
6. Select **Select**. Selected users get added to the group.
7. Go back to Teams.
8. Select **Tree view**.
9. Select the app > **Run OnStart**.

The admin access button is now visible on Screen 2, and the label shows admin level as **true** since we're now members of the Admin access group.

See Azure AD integration in action

You can see an example of Azure AD integration in the **Profile+** sample app template for Teams.



- **Office 365 Users** connector is used to retrieve the user profile, including name, photo, manager, and other details.
- **Office 365 Groups** connector is used to retrieve the people who report to a selected user.

Integrate with calls and meetings

Article • 01/20/2023

Apps in Microsoft Teams drive collaboration by enabling users to do work where they communicate and collaborate. Many apps require a “back and forth” communication or passing items between people. For example, in the Inspection sample app template for Teams, managers create inspection forms, users complete the inspection, and reviewers review the inspections.

Power Apps in Teams can leverage deep integration with other Teams capabilities to make apps collaborative. In this article, we'll learn how we can integrate Power Apps with Teams to make calls or schedule meetings with other users within the organization.

Watch this video to learn how to integrate Power Apps with calls and meetings: https://learn-video.azurefd.net/vod/player?id=022e5ad1-7a6d-49bb-99de-93dd4041bebd&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fintegrate-calls-and-meetings

Prerequisites

To complete this lesson, we'd need the ability to create apps within Teams that will be available as part of select Microsoft 365 subscriptions.

Log in into Teams

Log in into Teams using either the Desktop app or the web app

Create a new team

In this section, we'll create a new Teams team, and then create an app within that team. Skip this section if you already have a team that you want to use.

1. To create a new team, select the Teams tab > select **Join or create a team** on the bottom-left side of the screen > select **Create Team** > select **From Scratch** > select **Public**, and give the team a name such as "Calls and Meetings Integration". And then, select **Create**.

2. If you have any members in your organization you'd like to add to the team for testing purposes, add them in the pop-up, and then select **Add**.

3. Select **Close**.

The new team gets created and is listed under the Teams tab

Create a new app

Well create an app with a gallery of users and buttons on each of the display forms to either call, chat or schedule a meeting with a user from the list.

1. Open Teams app.
2. Select **Power Apps** from the left-pane.
3. Select **+ New app** under **Recent apps**.
4. Select the team created earlier, and select **Create** to open the app in Power Apps Studio.
5. Enter a name for the app, such as "Integrate with calls and meetings".
6. Select **Save**.

   The app shows a default gallery
7. Select the gallery, and search for users in the **Add a data source** search box.
8. Select **Users** from the list of data sources.

   The list of users shows in the gallery on the left-side of the screen. The right-side of the screen shows details of the selected user record.
9. Select the app from the left-pane, and update the **OnStart** property of the app with the following formula:

   ```
   Power Fx
   ```

   ```
   Set(gblIsHostClientWeb,Param("hostClientType")="web")
   ```

   > ⓘ **Note**
   >
   > This formula checks if the user is accessing Teams from a web browser, desktop, or a mobile app.
10. Select **Screen1** from the Tree view.

11. Select + (Insert) > **Button** to add a button.

12. Move the button to the details pane on the right-side of the screen.

13. Set the following properties of the button.

Expand table

Property	Value
Text	"Call"
Width	150
Height	45
X	500
Y	300

Copy the following formula in the **OnSelect** property of the button:

Power Fx

```
If(
    gblIsHostClientWeb,
    Launch(
        "https://teams.microsoft.com/l/call/0/0?
users="&BrowseGallery1.Selected.'Primary Email',
        {},
        LaunchTarget.New
    ),
    Launch(
        "msteams://teams.microsoft.com/l/call/0/0?
users="&BrowseGallery1.Selected.'Primary Email',
        {},
        LaunchTarget.New
    )
)
```

Note

- If the user is accessing Teams using a web browser, this will launch the call window in the browser itself because of `https://` protocol identifier. If the user is accessing Teams using the Teams desktop or mobile app, then it launches the call window in the Teams app itself because of `msteams://` instead.

- The format to launch a call through a deep-link is:
  `https://teams.microsoft.com/l/call/0/0?users=\<user1\>,\<user2]`.
  More information: Generate a deep link to a call

14. Add another button with the following properties:

Expand table

Property	Value
Text	"Schedule a Meeting"
Width	150
Height	45
X	Button1.X + 200
Y	Button1.Y

15. Copy the following formula in the **OnSelect** property of the new button:

Power Fx

```
If(
    gblIsHostClientWeb,
    Launch(
        "https://teams.microsoft.com/l/meeting/new?
subject=New%20Meeting&attendees="&BrowseGallery1.Selected.'Primary
Email',
        {},
        LaunchTarget.New
    ),
    Launch(
        "msteams://teams.microsoft.com/l/meeting/new?
subject=New%20Meeting&attendees="&BrowseGallery1.Selected.'Primary
Email',
        {},
        LaunchTarget.New
    )
)
```

16. Add a third button with the following properties

Expand table

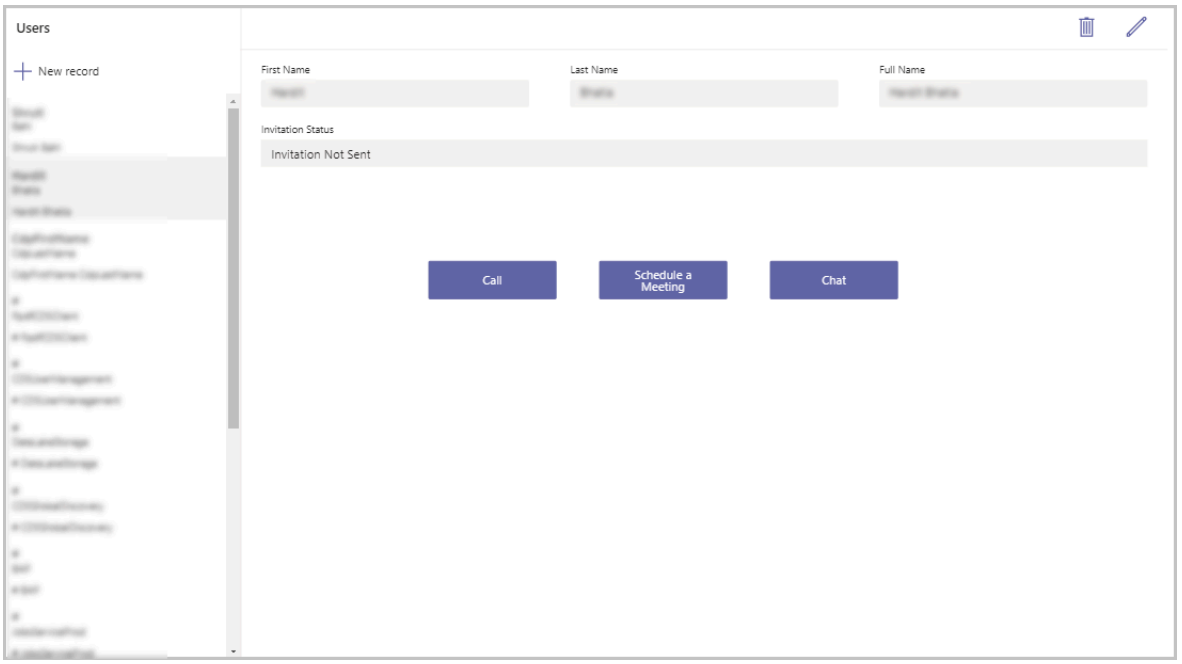
Property	Value
Text	"Chat"
Width	150
Height	45
X	Button2.X + 200
Y	Button1.Y

17. Copy the following formula in the **OnSelect** property of the new button:

```
Power Fx
```

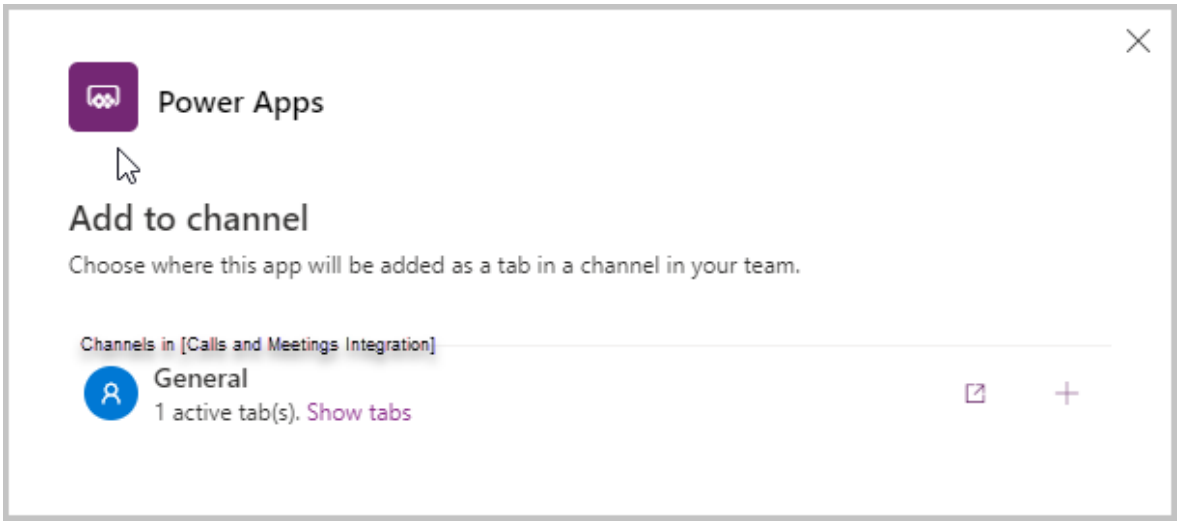
```
If(
    gblIsHostClientWeb,
    Launch(
        "https://teams.microsoft.com/l/chat/0/0?
users="&BrowseGallery1.Selected.'Primary
Email'&"&topicName=&message=Hi!",
        {},
        LaunchTarget.New
    ),
    Launch(
        "msteams://teams.microsoft.com/l/chat/0/0?
users="&BrowseGallery1.Selected.'Primary
Email'&"&topicName=&message=Hi!",
        {},
        LaunchTarget.New
    )
)
```

The screen should appear as shown below



Save and publish the app

1. Select **Save** on the top-right side of the screen to save the app.
2. Select **Publish** to publish the app.
3. Select **Next** in the pop-up.
4. Under **Add to Channel**, make sure the channel under which the app should be shown is listed and shows as "1 active tab(s)" and not "0 active tab(s)".



5. Select **Save and Close**.

Test the app

1. Run the app in the preview mode.

2. Select a user from the list on the left.
3. If you don't have a user showing up in the list, share the app with another colleague/user. Once that user logs in into the app, they'll show up in this list of users.
4. Select the user from the list.
5. Test the options.

The call button launches a new call. The meeting button creates a meeting invitation with the selected person

See chat, call, and meeting integration in action

For an example of chat, call, and meeting integration in action, check out the Profile + sample app for template Teams.

When opened from within a Team, the app displays the other members of the team. You can select the **Select people to connect with** and select one or more people, then start a call or chat with the selected people, or schedule a meeting.

Enable consistent experience across sessions using LoadData and SaveData functions

Article • 01/20/2023

Microsoft Dataverse for Microsoft Teams delivers a built-in, low-code data platform for Teams. It provides relational data storage, rich data types, enterprise-grade governance, and one-click solution deployment. Dataverse for Teams enables everyone to easily build and deploy apps.

While there are numerous advantages of using Power Apps in Teams, one of the biggest design considerations is the ability to keep consistent experience across sessions.

While using an app, if we switch a tab in Teams to look at Wiki or Planner, or even chat with someone, the session data of the app is lost and we'd have to start the session from scratch. For example, if we're in the middle of an inspection using the Inspections app and we switch tabs even for a moment, all the data that was captured on the inspection would be lost and we'll have to recapture all that information.

In this article, we'll learn how to use the LoadData() and SaveData() functions to store the session data within the app to avoid any loss of work because of switching tabs in Teams.

Watch this video to learn how to enable consistent experience across sessions: https://learn-video.azurefd.net/vod/player?id=e669c7fe-3f11-43ad-8233-0dbbb374bec5&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fconsistent-experience-across-sessions

Prerequisites

To complete this lesson, we'd need the ability to create apps within Teams that is available as part of select Microsoft 365 subscriptions.

Log in into Teams

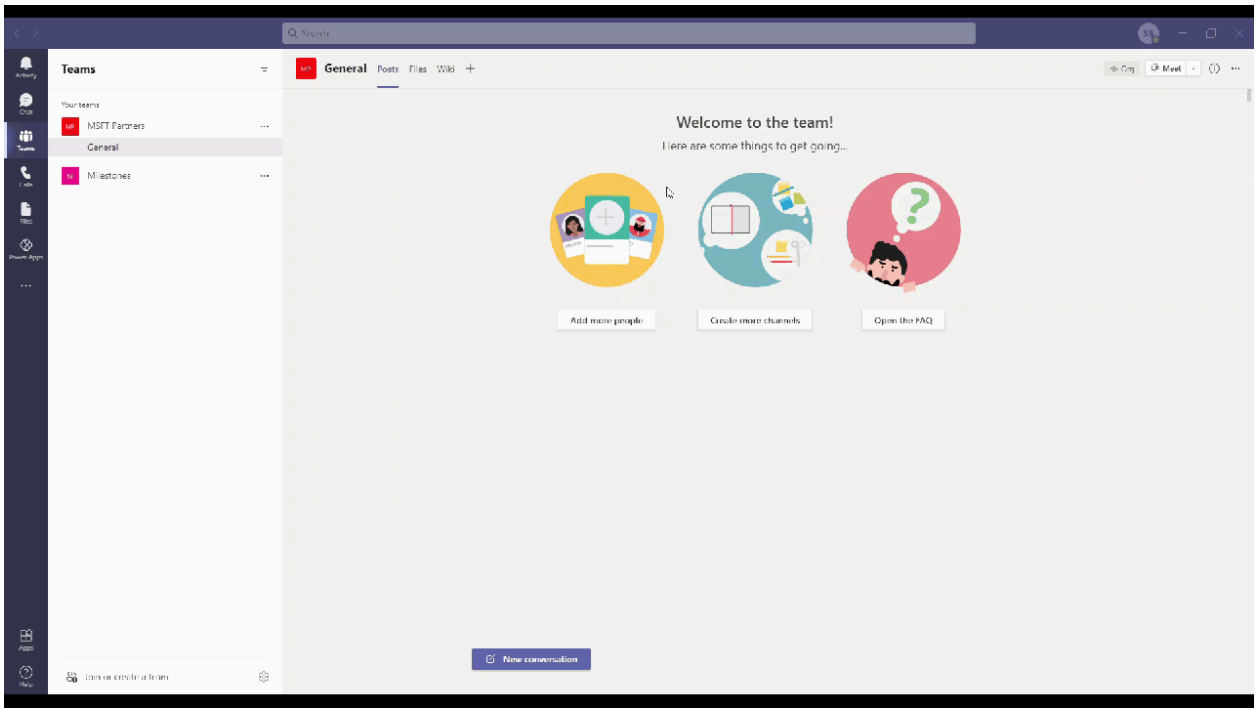
Log in into Teams using Teams Desktop.

Create a new Team

To create a new team:

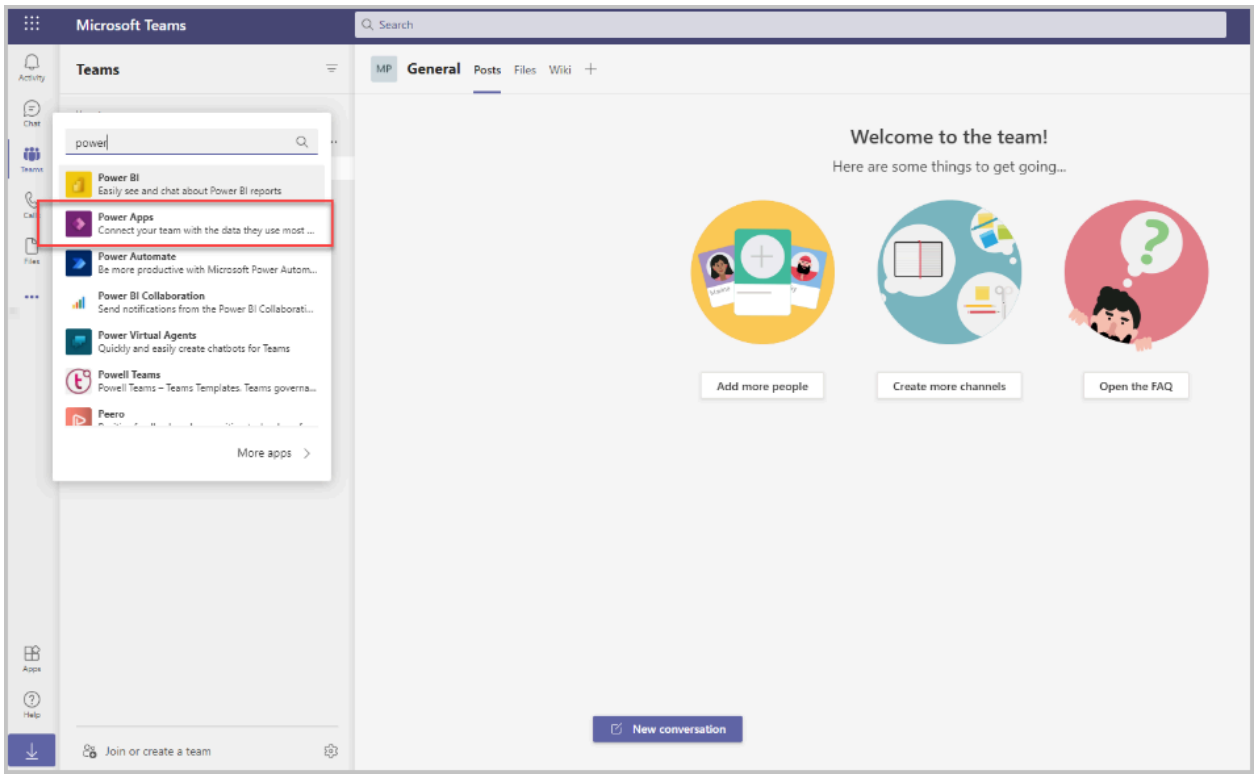
1. Select the Teams tab.
2. Select **Join** or create a team on the bottom-left of the screen.
3. Select **Create a team from scratch**.
4. Select **Public** and give the team a name. In this example, we'd use "MSFT Partners".
5. Select **Create**.

The new team gets created and is listed under the Teams tab.

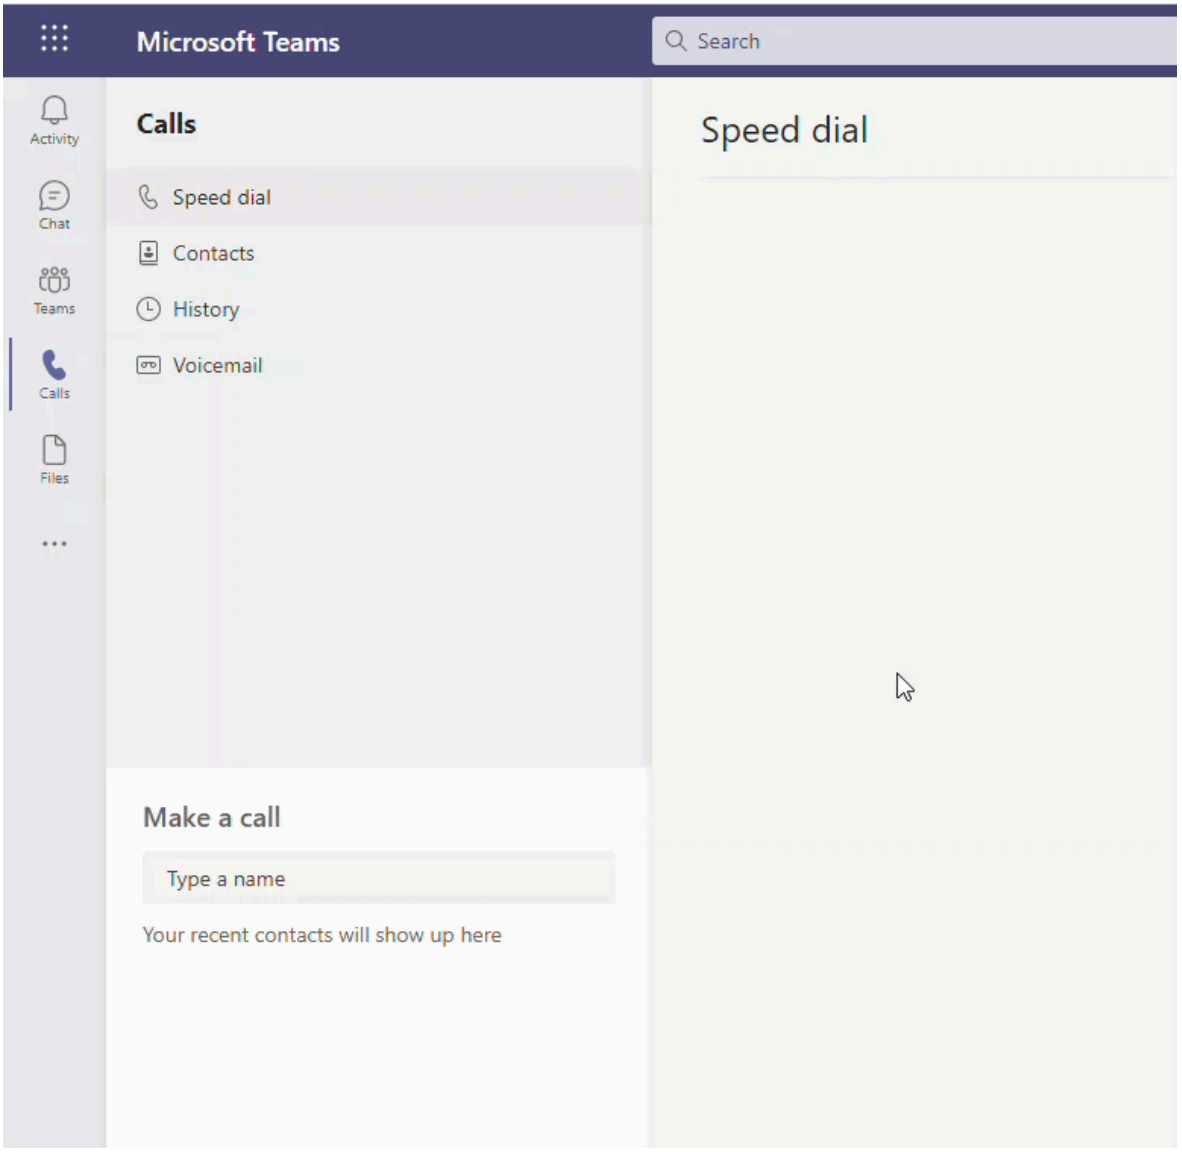


Create a Power Apps app in Teams

To create a Power Apps app in teams, we need to open Power Apps Studio in Teams as shown below.



1. Select **Power Apps** from the list of apps and pin it to the left-pane, and then select it.



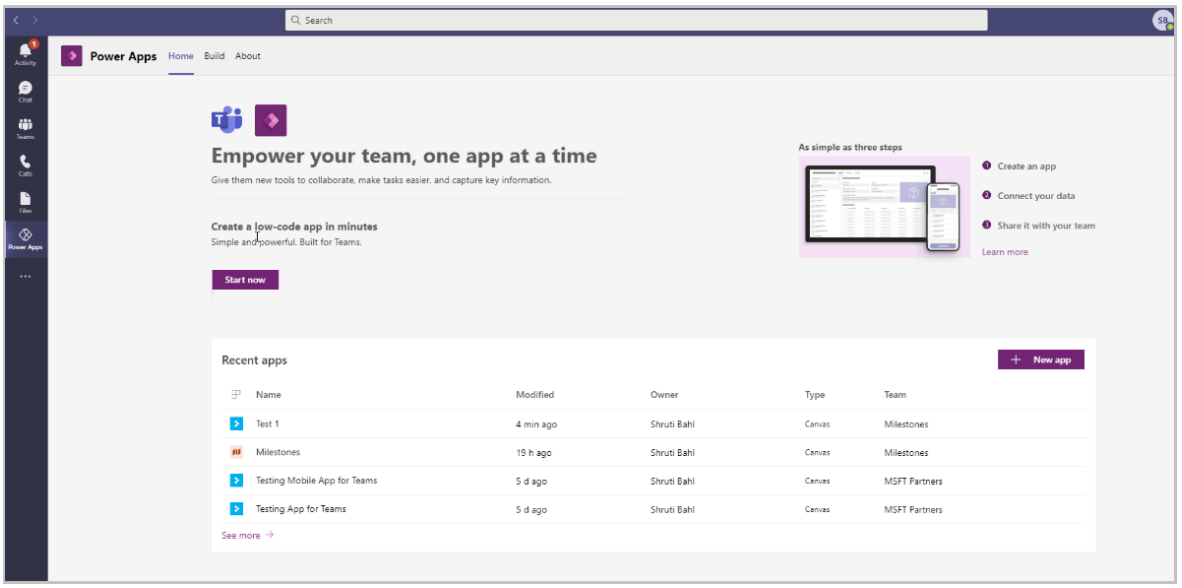
2. Select **Start now** to create the first app.

3. Select the team for which this app is to be created—a Power Apps environment is created for that team (there's one Power Apps environment per team).

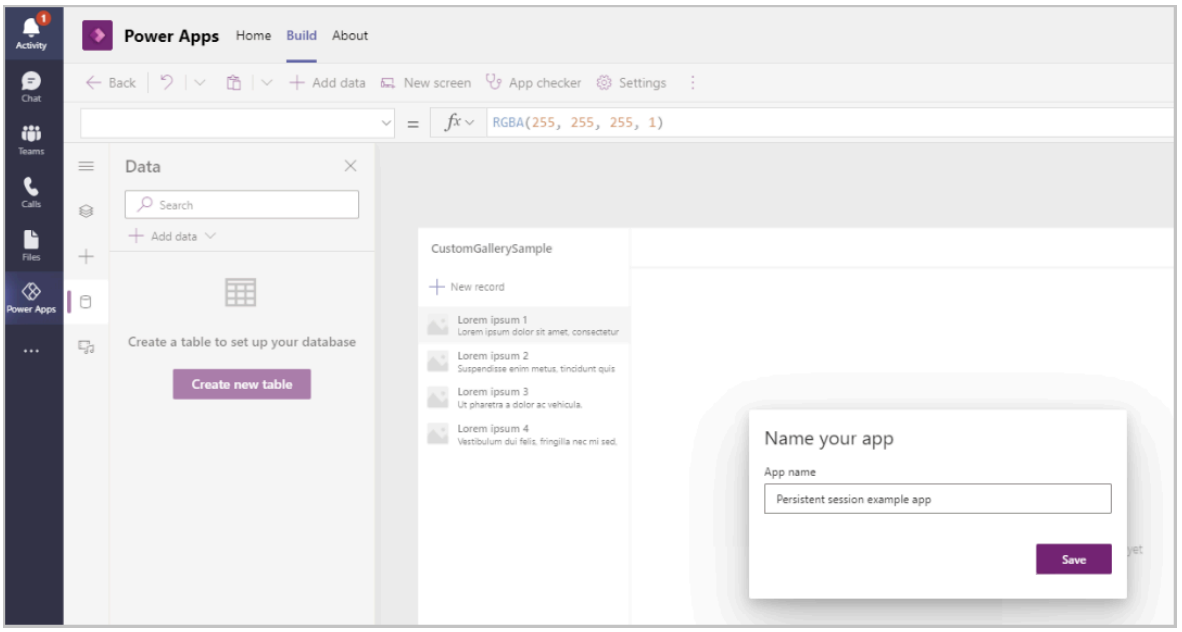
4. While the environment is being created, close the dialog box that says **Getting things ready**.

5. Select the **Build** tab on top, and in a few seconds the created app should appear in the list.

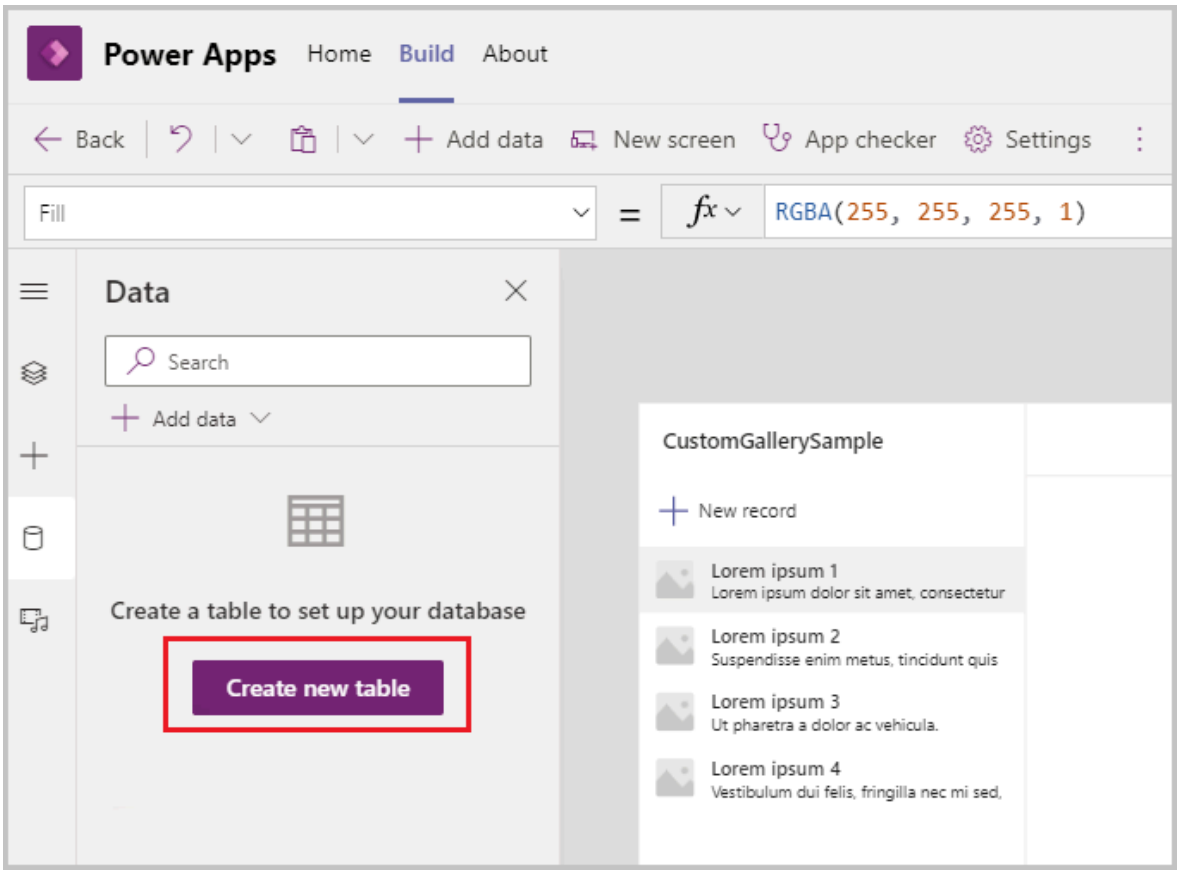
6. Open the app, and notice it gets created in the tablet layout/form factor by default.



7. Enter a name for the app **Persistent session example** app, and select **Save**.

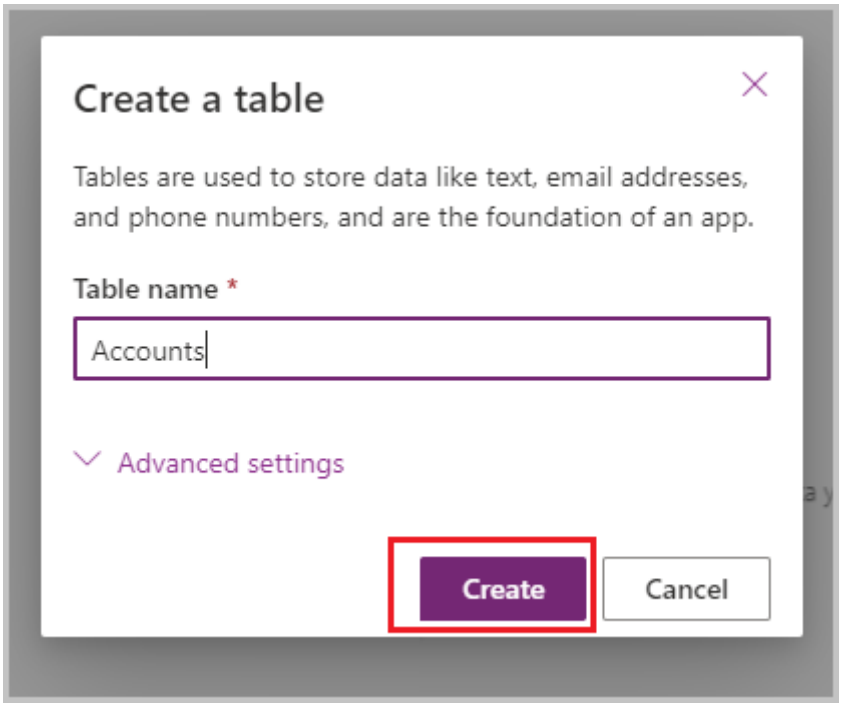


The app gets created with a gallery.

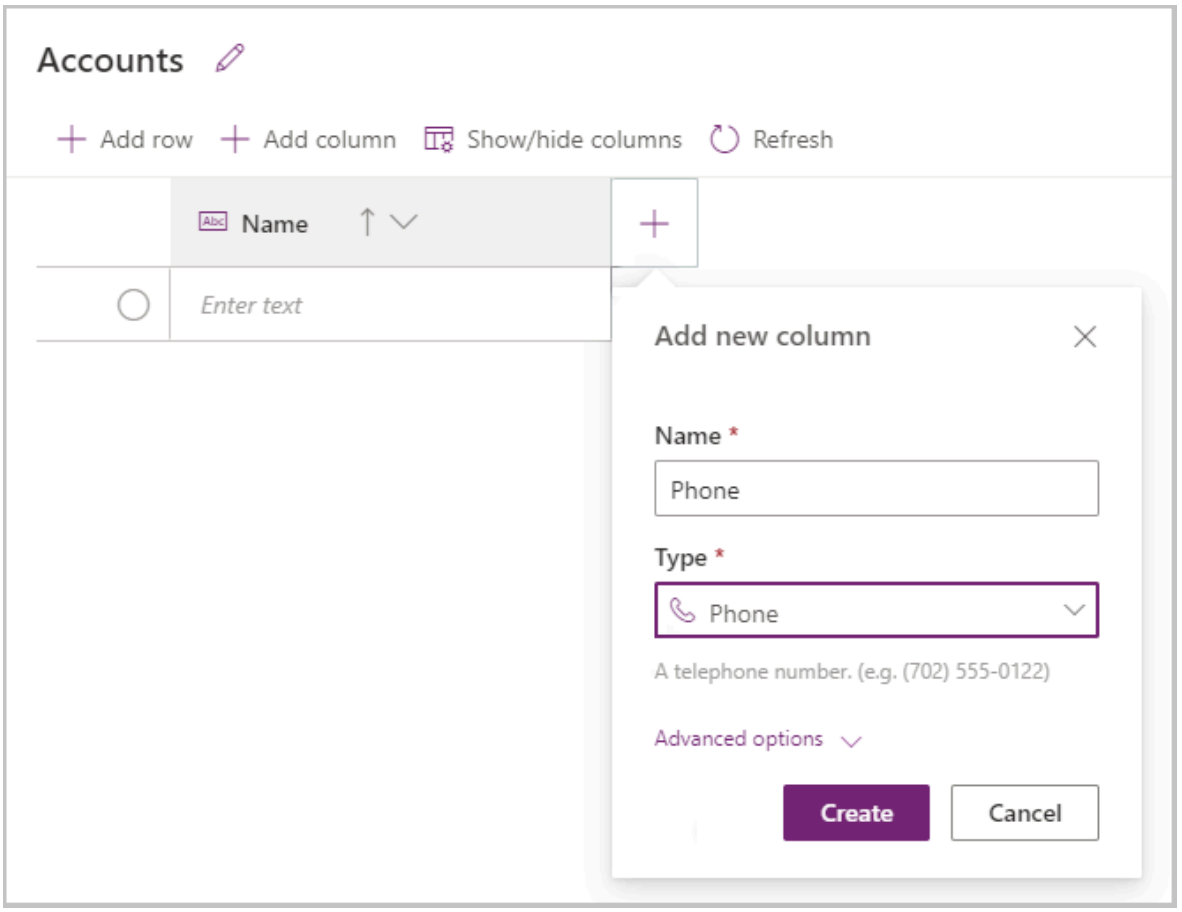


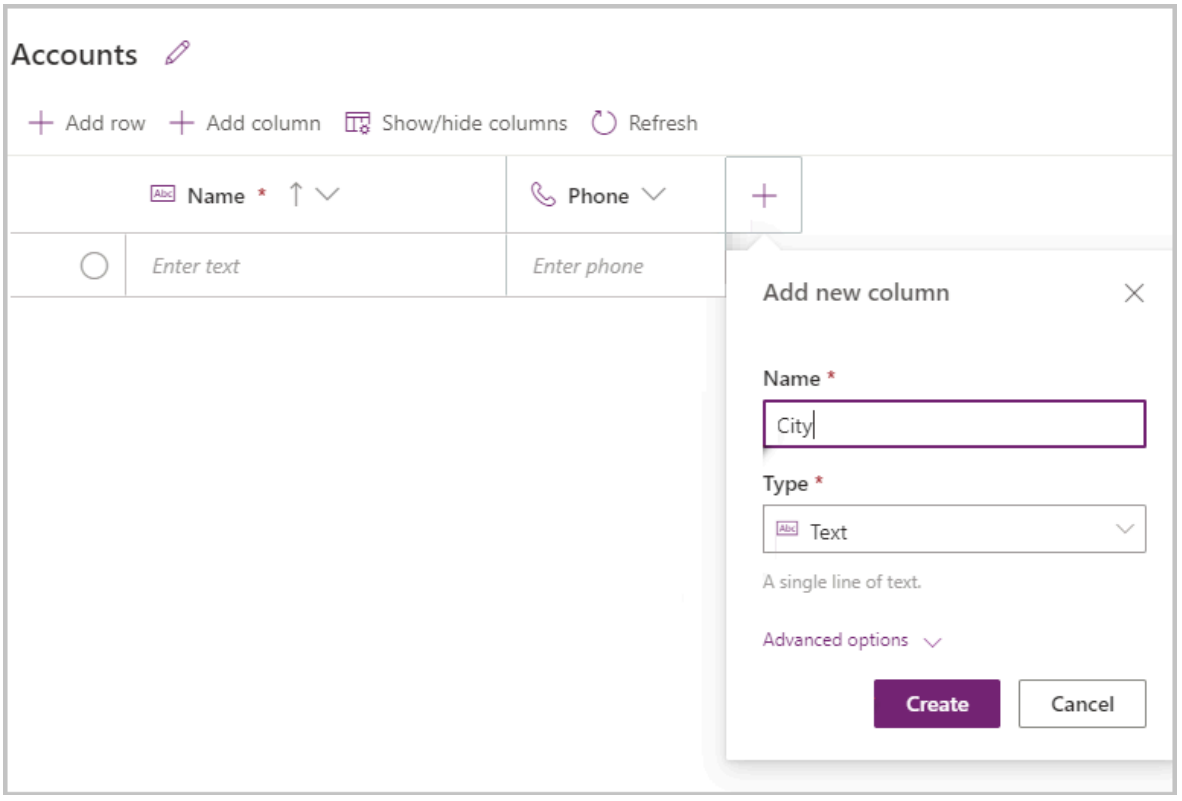
8. Select **Create new table** to create a new table.

9. Enter **Accounts**, and select **Create**.



10. Add two columns—**Phone** with data type of Phone, and **City** with data type of Text.

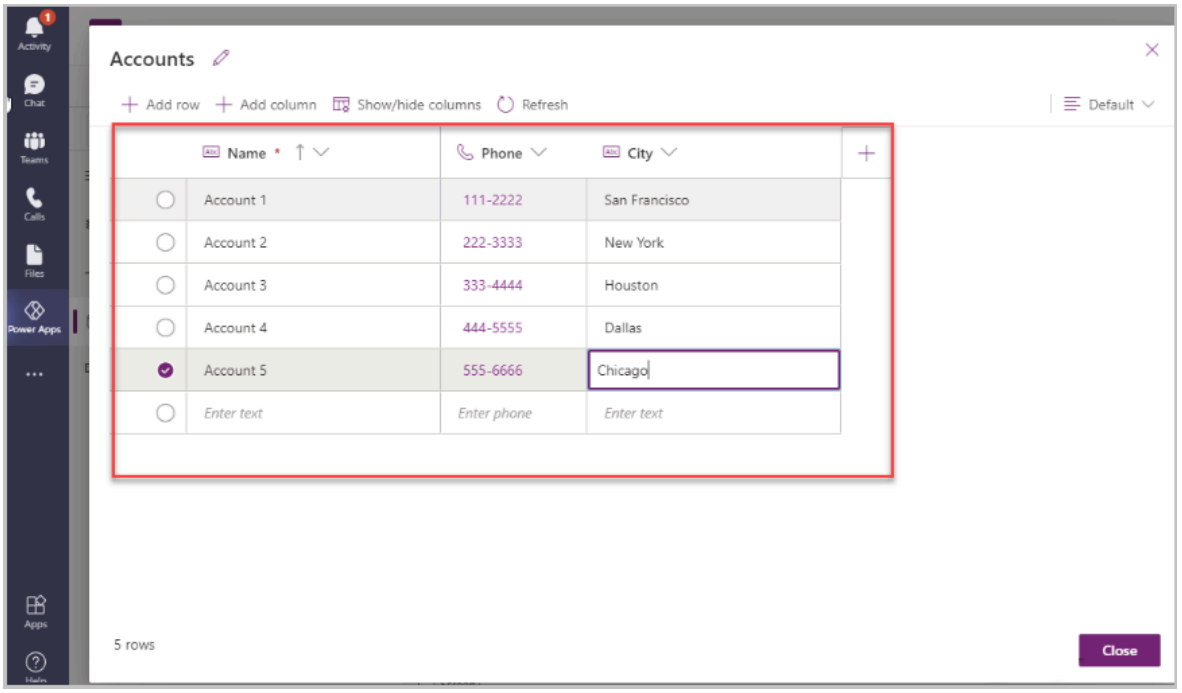




11. Add sample data to the three columns.

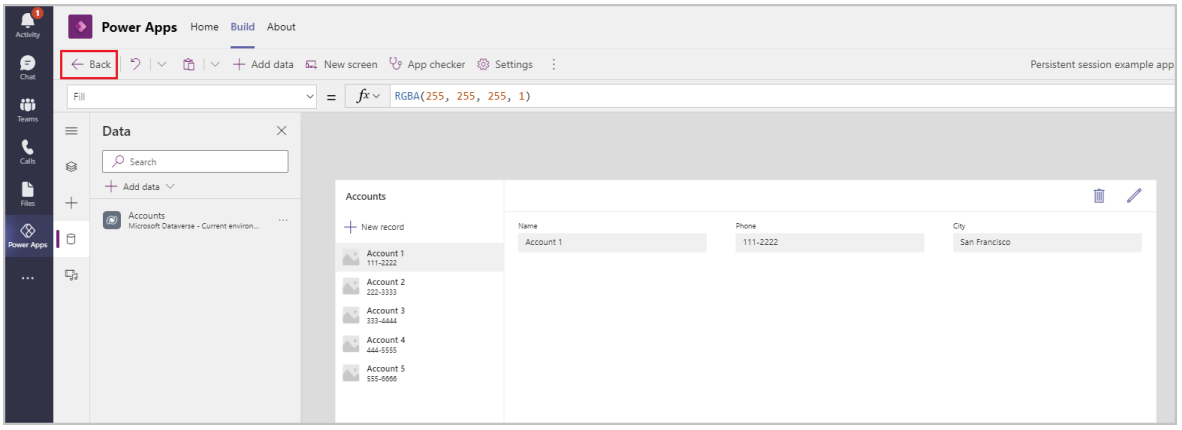
12. Repeat to add at least five records.

13. Select **Close**.



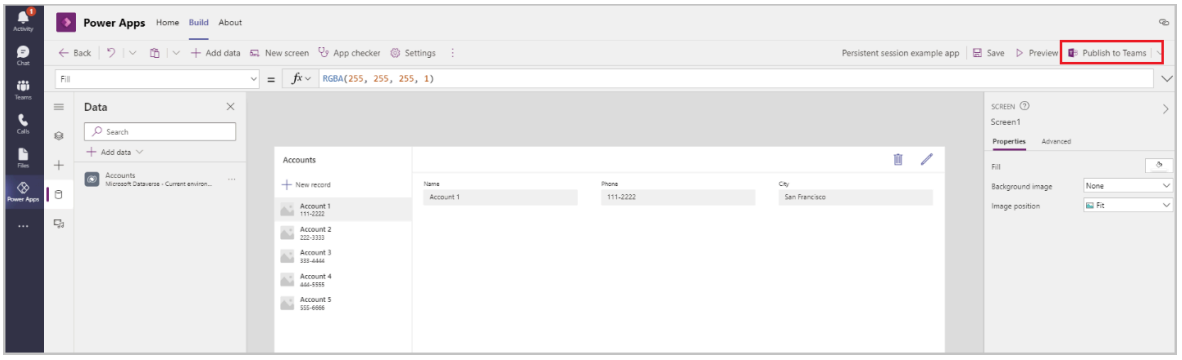
The accounts table gets added as a data table

14. Select **Tree View** > Select **BrowseGallery1** > Select **Accounts** as the data source.

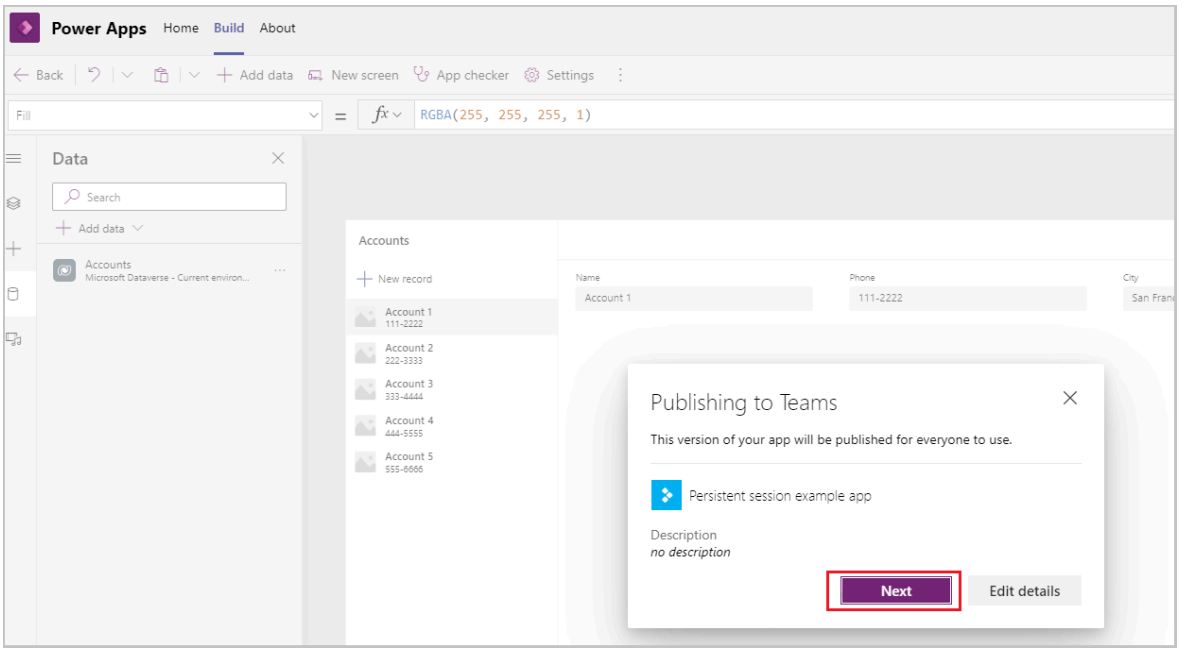


Publish the app in Teams

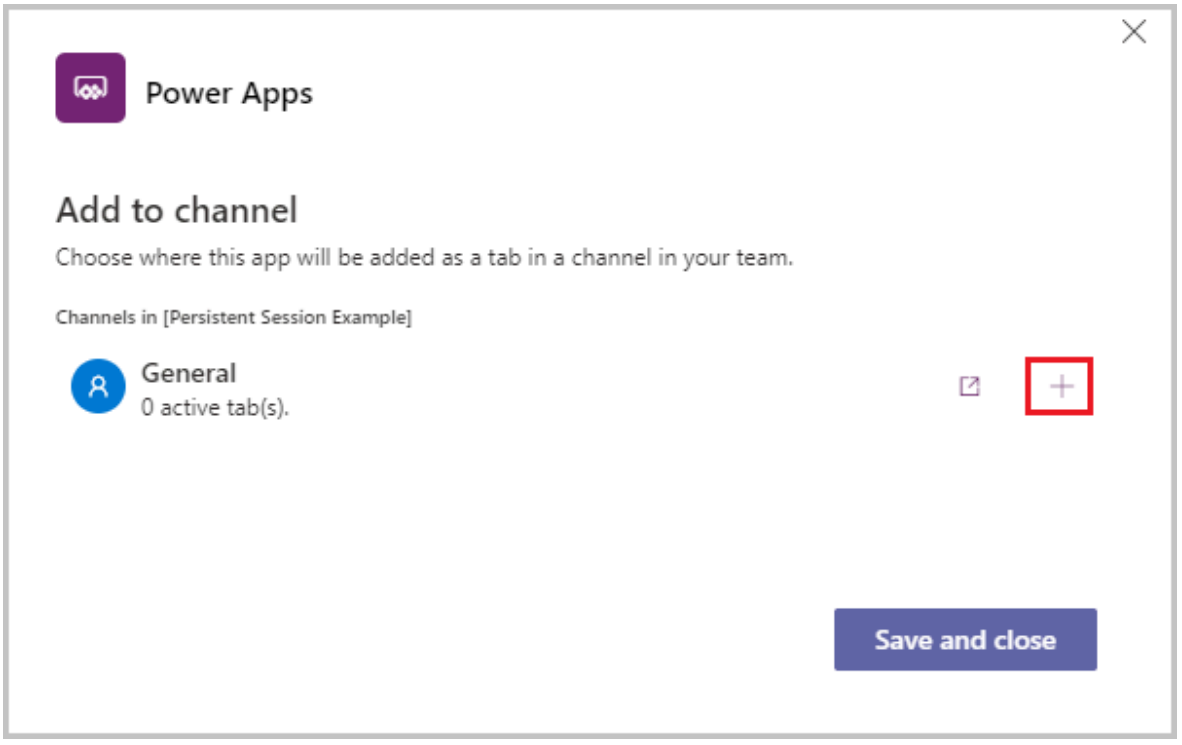
1. Select **Publish to Teams**.

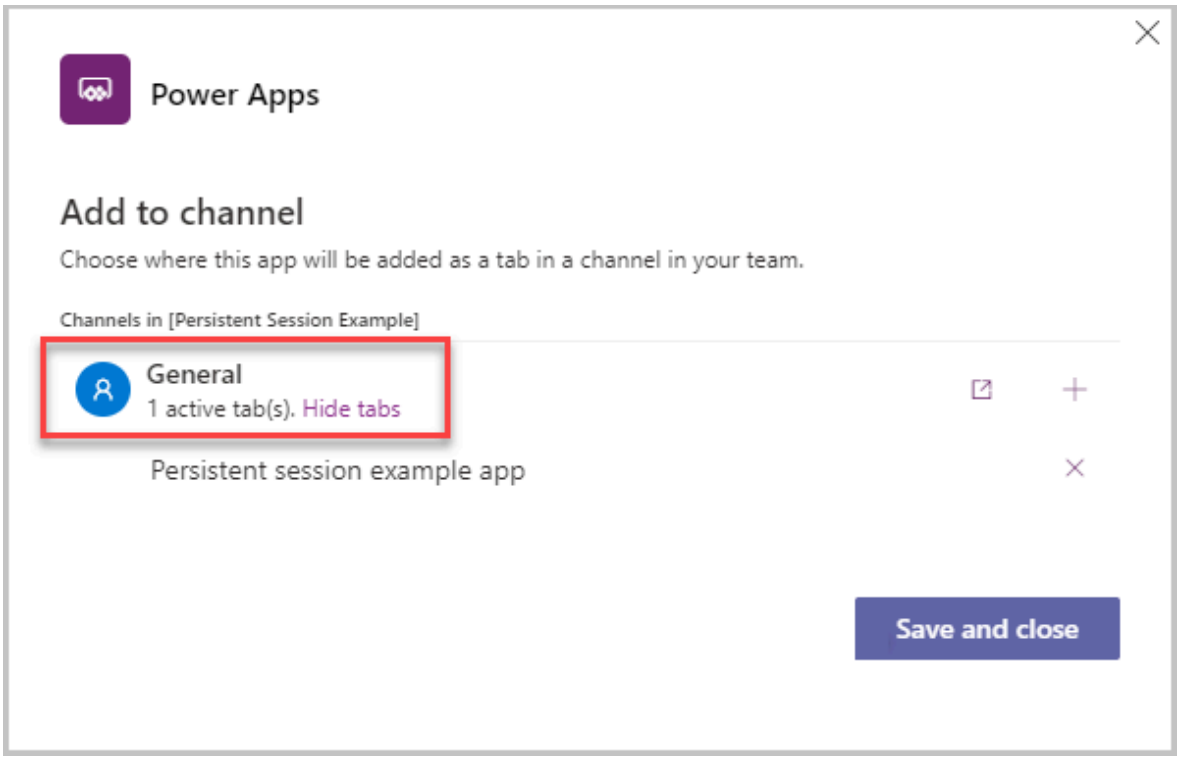


2. Select **Next**.

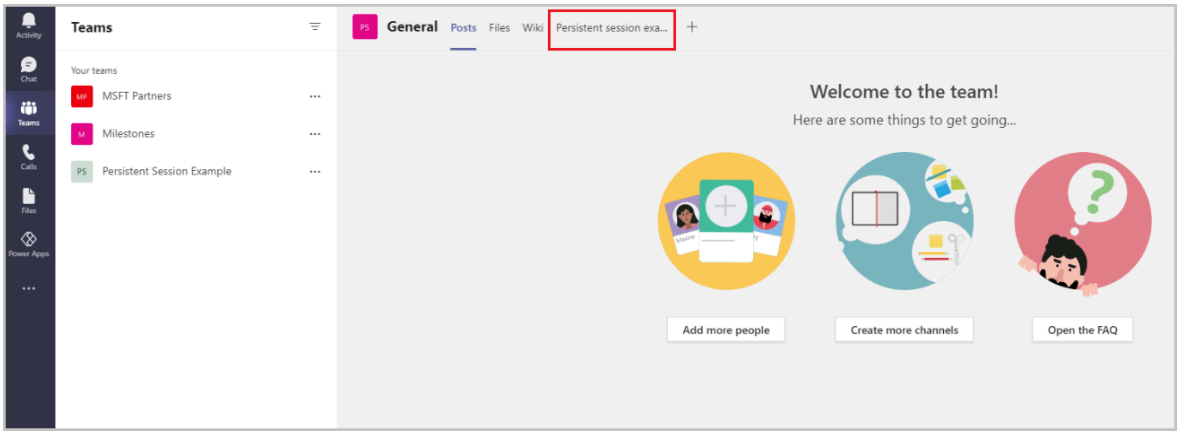


3. Select + to add the app to the "General" channel.



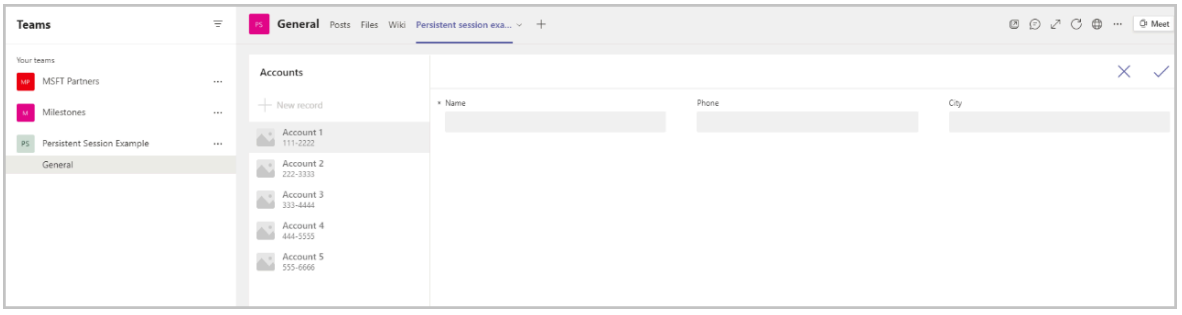


4. Go to the **Persistent Session Example** team, and notice the **Persistent session example** app shows up on the top as a tab.



Testing the issue

1. Open the **Persistent session example** app from the **Persistent Session Example** team.

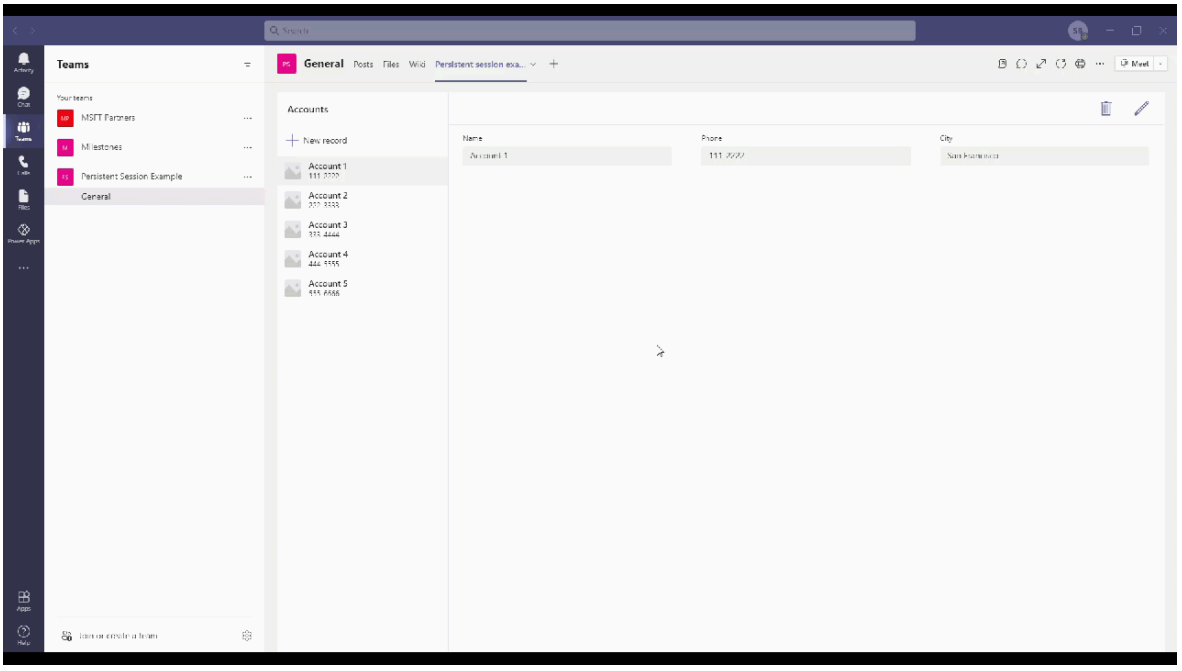


2. Select **New Record** to create a new account in the app.

3. Enter the name and phone number

4. Before you enter **City** and save the record, switch to a different tab (like Files or Wiki on top or a different team), and then come back to the app.

5. Notice that the data entered in the two columns is no longer available on the screen and is lost



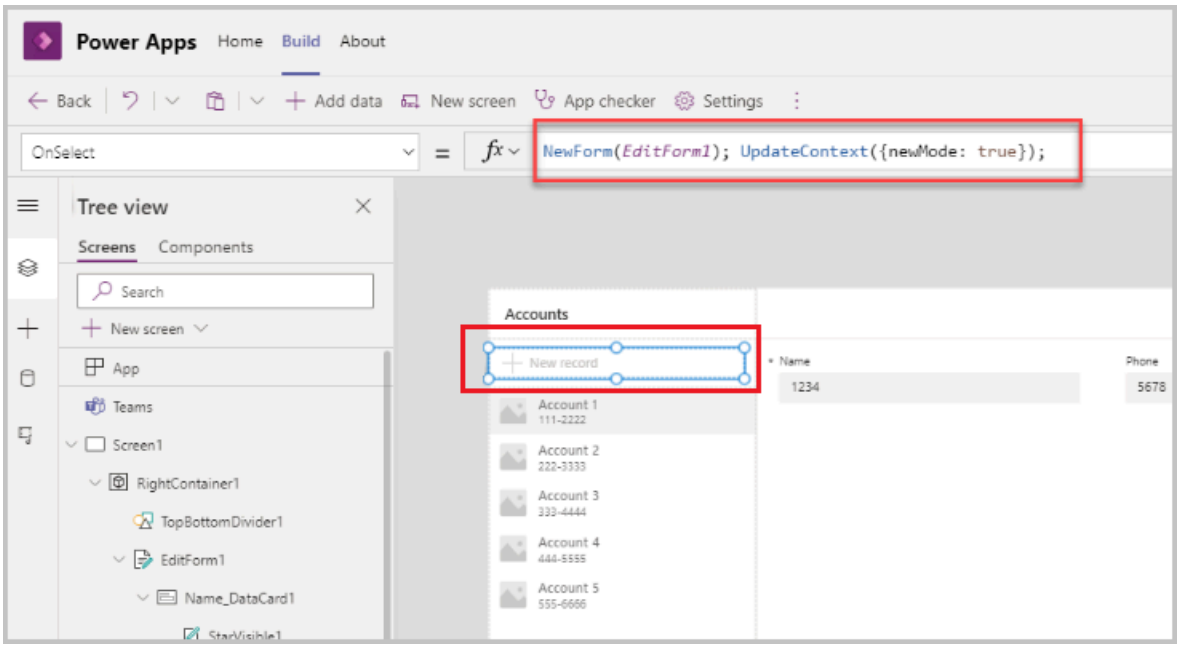
Solution: Use SaveData() and LoadData() functions

To resolve the above issue, we'll use the LoadData() and SaveData() functions. We'll create a collection for the data entered on a form as and when data is entered, and keep saving the data in the collection until the record has been committed or saved. This way, if the record hasn't been saved and we must tab out of the screen for some reason, the collection would have the saved data that would get loaded once we're back in the app. We'll also clear the collection once the record has been saved so that the collection is ready to capture new data when the next new record is being created.

1. Start with making sure that the changes we're applying are applicable only in the case of a new record. So, we're updating the variable **newMode** that will be used as a condition on the edit form to figure out what data needs to be displayed. Select **New record** and add the following formula on the **OnSelect** property of the button:

```
Power Fx
```

```
NewForm(EditForm1);
UpdateContext({newMode: true})
```

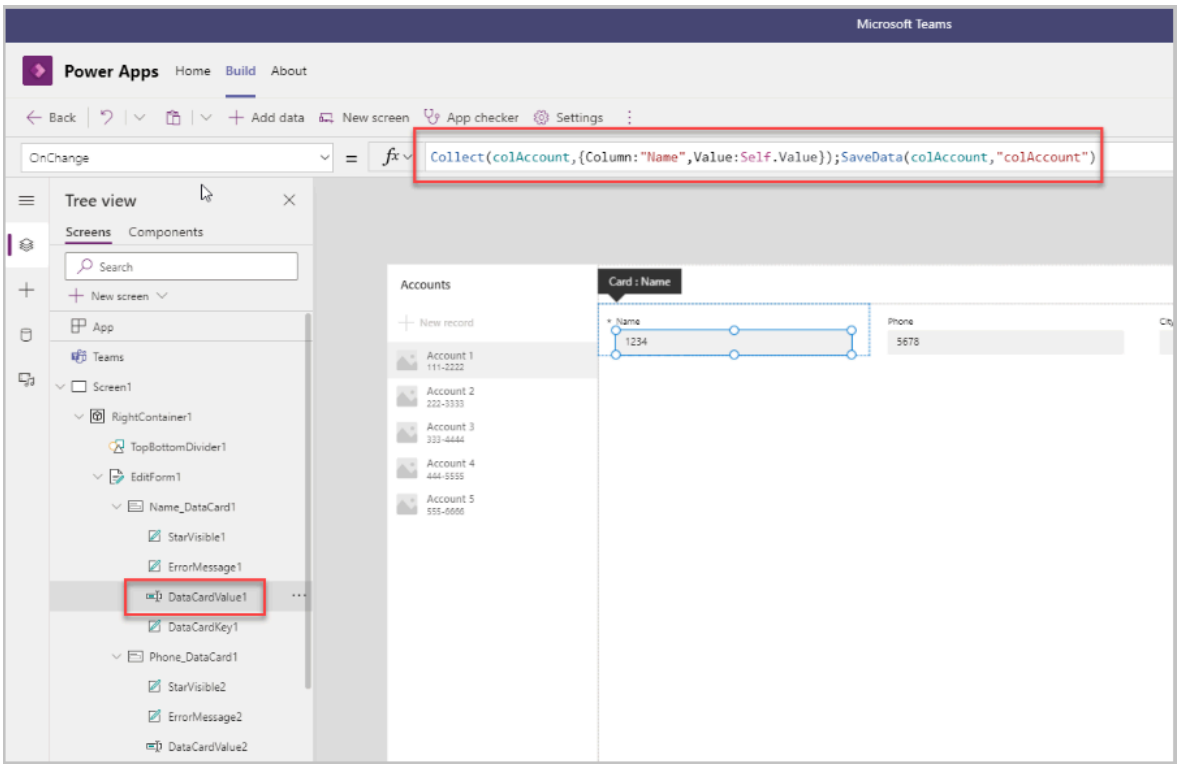


2. Next, we'll add the data from the individual input controls to a collection, and then we'll save the data to a local file from that collection. Select the text input box—in our example it's the "DataCardValue1" of the "Name_DataCard1" on "EditForm1" for the **Name** field—enter the following formula in the **OnChange** property of the input field:

Power Fx

```
Collect(
    colAccount,
    { Column:"Name",Value:Self.Value}
);
SaveData(colAccount,"colAccount").
```

With this change, we're adding the data to a local cache so that if the user leaves the app, their data won't be lost.



Similarly, enter the following code in the **OnChange** property for **Phone** (DataCardValue2):

```
Power Fx

Collect(colAccount, {Column:"Phone",Value:Self.Value});
SaveData(colAccount,"colAccount");
```

And enter the following code in **OnChange** property for **City** (DataCardValue3):

```
Power Fx

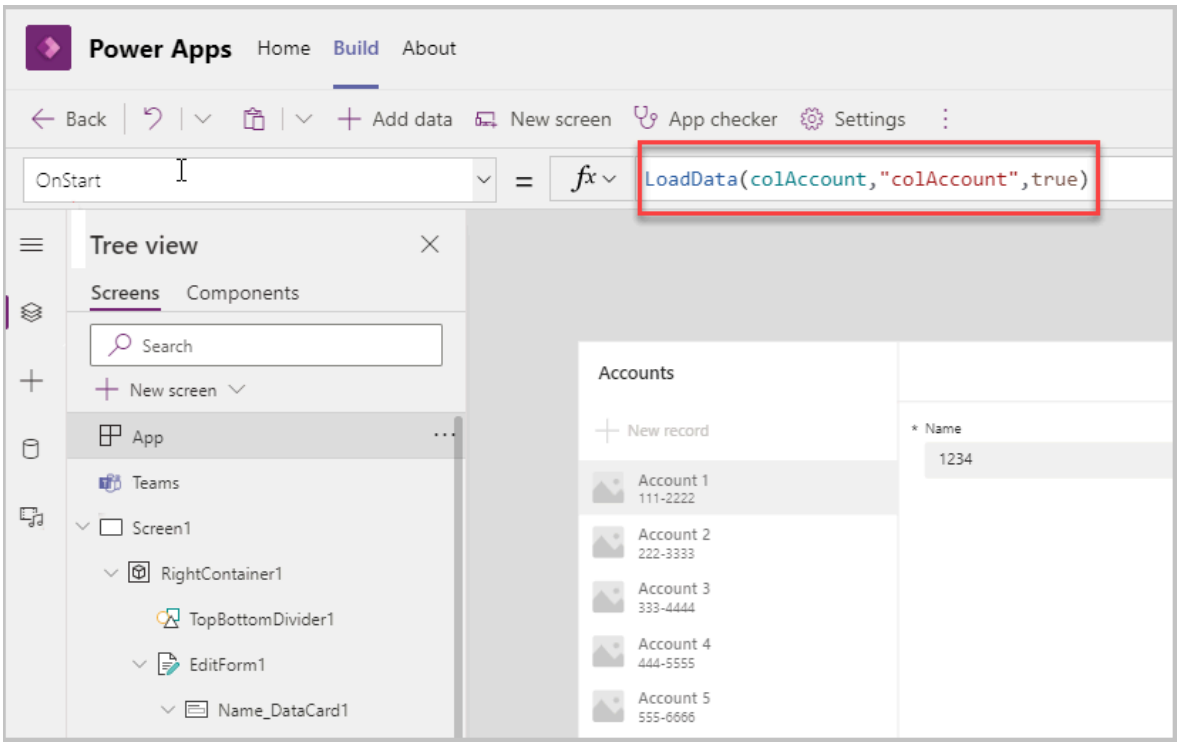
Collect(colAccount {Column:"City", Value:Self.Value});
SaveData(colAccount, "colAccount");
```

3. Now we'll update the App OnStart so that if there's any data saved in the collection, that would get loaded on the start of the app.

   Go to the **App** > **OnStart** property, and add the following formula:

```
Power Fx

LoadData(colAccount,"colAccount", true)
```



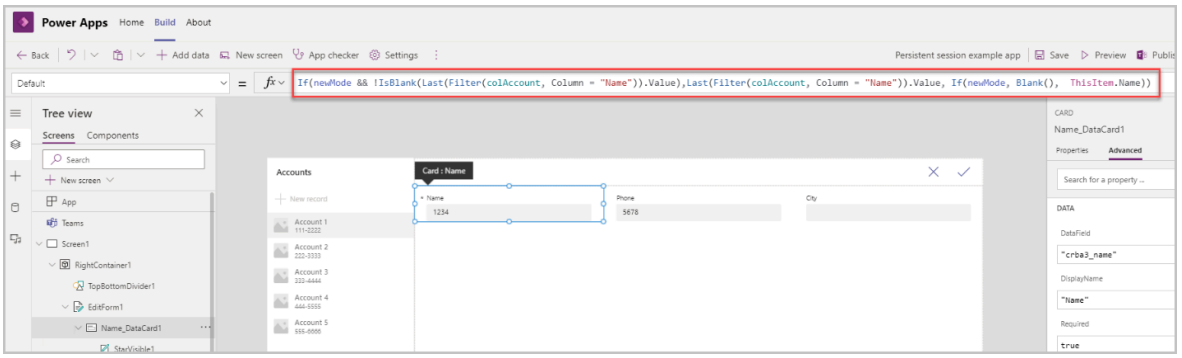
4. Next, we need to update the **Default** property of the data fields so that when the page loads once we come back to the app, if data exists in the collection, it should show the data from the collection by default.

   Select the field **DataCard** and update the **Default** property of the data card to the following formula for the listed fields.

   For **Name** field, enter **Name_DataCard1:**

```
Power Fx
```

```
If(
    newMode && !IsBlank(
        Last(
            Filter(colAccount, Column = "Name")
        ).Value
    ),
    Last(
        Filter(colAccount, Column = "Name")
    ).Value,
    If(newMode, Blank(), ThisItem.Name)
)
```



Similarly, enter the following formula in the **Default** property formula for **Phone** (Phone_DataCard1):

```
Power Fx
```

```
If(
    newMode && !IsBlank(
        Last(
            Filter(colAccount, Column ="Phone")
        ).Value
    ),
    Last(
        Filter(colAccount, Column = "Phone")
    ).Value,
    If(newMode, Blank(), ThisItem.Phone)
)
```

And use the following formula for **City** (City_DataCard1):

```
Power Fx
```

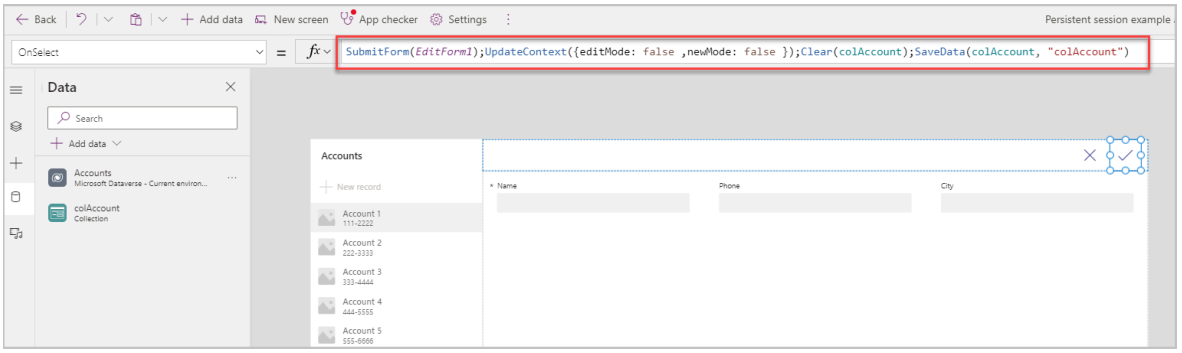
```
If(
    newMode && !IsBlank(
        Last(
            Filter(colAccount, Column = "City")
        ).Value
    ),
    Last(
        Filter(colAccount, Column = "City")
    ).Value,
    If(newMode,Blank(), ThisItem.City)
)
```

5. Now, we need to clear the collection in two scenarios:
   a. When the user submits the form, and the changes get saved.
   b. When the user selects the cancel button to cancel the changes.

Use the following formula in the **OnSelect** property of the **Submit** button.

Power Fx

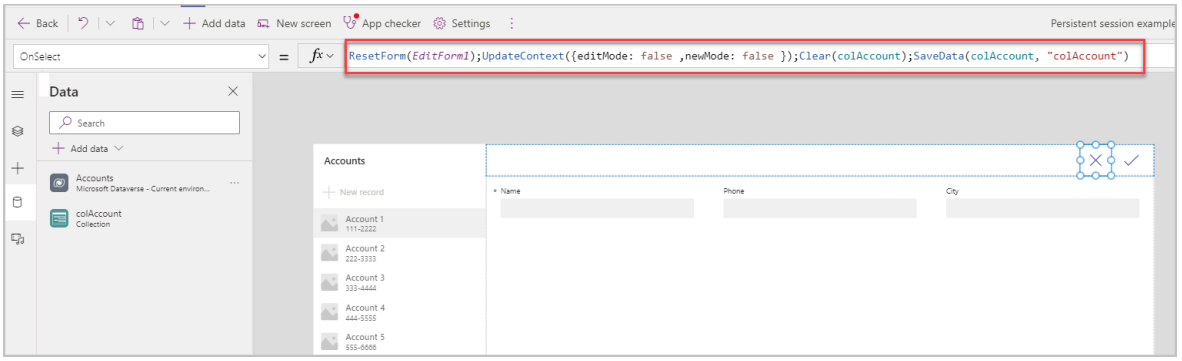
```
SubmitForm(EditForm1);
UpdateContext({editMode: false, newMode: false});
Clear(colAccount);
SaveData(colAccount, "colAccount");
```



Select the **Cancel** button, and enter the following formula:

Power Fx

```
ResetForm(EditForm1);
UpdateContext({editMode: false, newMode: false});
Clear(colAccount);
SaveData(colAccount, "colAccount");
```

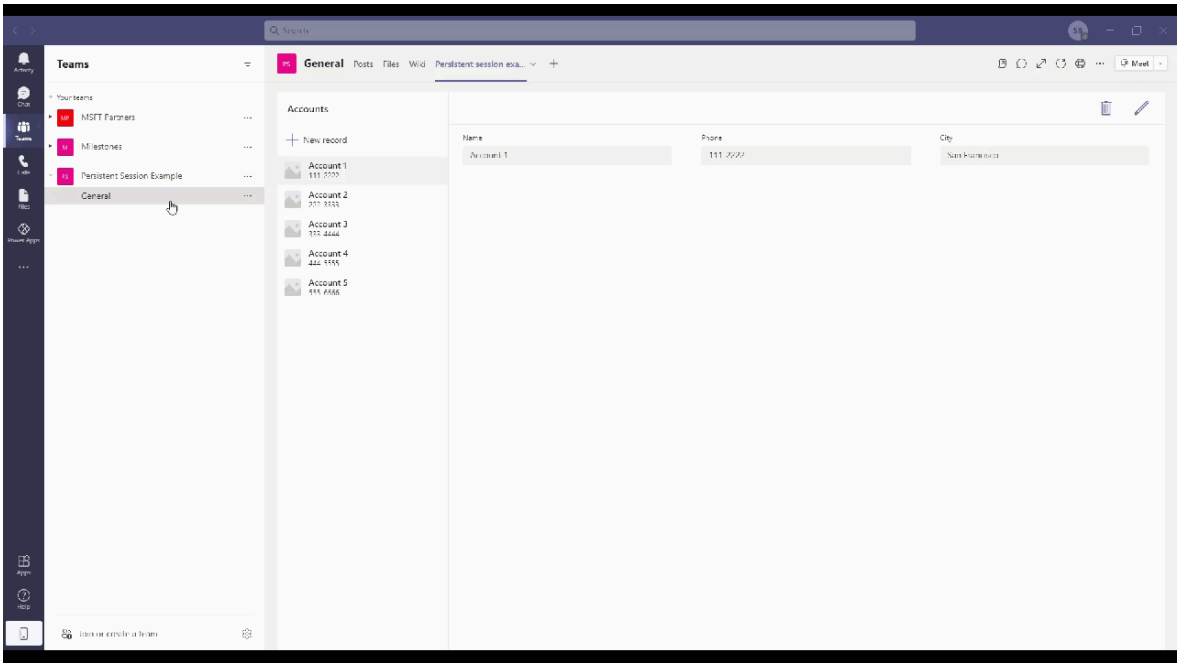


6. Publish the apps after making all the above changes by selecting **Publish to Teams**.

Test the app again

1. Go to the team and run the app.
2. Select **+ New** record, and add the name and phone details for the new record.
3. Select another tab to move out of the app.
4. Come back to the app—it shows details of the first account.

5. Now, when we select + **New** again, we'll see the Name and Phone details populated in those text input fields already. And we can resume adding the account we were adding before we had to tab out of the app.



How we use SaveData and LoadData in the Inspection app

In the Inspection sample app template, we use load data and save data on the inspection form—if a user is in the middle of an inspection, and they switch away from the apps in Teams (like to send someone a message), we don't want them to lose their place in the inspection. When they return to the app tab in Teams, the app gives them the option to resume the in-progress inspection.

Considerations

In Dataverse for Teams, there are some limits to the SaveData() and LoadData() capabilities.

- 1-MB limit on Teams Desktop.
- Doesn't work in a browser.
- Apps in mobile are limited by the amount of local storage available to the app.

Have a conversation about your business data in a Teams app

Article • 01/20/2023

Apps in Microsoft Teams drive collaboration by enabling users to do work where they communicate and collaborate. One way to make your apps collaborative is by adding the ability to have a conversation about your app or the data in your app. Teams is your go-to place to have such conversations.

For example, in the Profile+ sample app template for Teams, when you select one or more profile cards in the app, you can start a chat with the selected people directly in Teams.

You might also want to use this capability for your apps. For example, if you're building a sales opportunity tracker for the sales manager to review upcoming deals, you might want to add a button for the user to chat with the sales person about the opportunity.

This way, Power Apps in Teams can use deep integration with other Teams capabilities to make apps collaborative. In this article, we'll learn how we can integrate Power Apps with Teams to facilitate conversations.

Watch this video to learn how to configure having conversations about business data in Teams app: https://learn-video.azurefd.net/vod/player?id=aeacd56d-232b-4187-83f0-e15dc4103f43&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fbusiness-data

Prerequisites

To complete this lesson, we'd need the ability to create apps within Teams that will be available as part of select Microsoft 365 subscriptions.

Log in into Teams

Log in into Teams using either the Desktop app or the web app

Create a new Team

In this section, we'll create a new Teams team and then create an app within that team. Skip this section if you already have a team you want to use instead.

1. To create a new team, select the Teams tab, and then select **Join or create a team** on the left bottom of the screen.
2. Select **Create Team** > **From Scratch** > **Public**, give the team a name such as "Calls and Meetings Integration", and select **Create**.
3. (Optional) If you have any members in your organization that you'd like to add to the team for testing purposes, select them, and add them in the popup for adding members.
4. Select **Close**.

The new team gets created, and is listed under the Teams tab.

Create a new app

We'll create an app where the user can start a conversation for a particular team and Channel by selecting a button and typing in a message in a text box. The user can then select the **Submit** button to post the message in the particular team and channel in Teams, then other user can join the conversation.

1. Open Teams.
2. Select **Power Apps** from the left-pane.
3. Select **+ New app** under **Recent apps**.
4. Select the team created earlier, and then select **Create**.

   The app gets created and Power Apps Studio opens to allow editing the app.
5. Enter a name for the app, such as "Conversation app", and select **Save**.

   The app is created with a default gallery on Screen 1.

Add Teams as a connector

We need to add Teams as a connector to the app since we want to be able to access the teams and channels from the logged in user's account.

1. Select **Data** from the left-pane.
2. Select **+ Add data**, and then select **Connectors**.
3. Scroll down and select **See all connectors**.
4. Search for and select Teams connector.

Add a new table to capture company record

We need to add a table to maintain a list of companies we'll use as the company record, and to start a conversation about it.

1. Select **Data** from the left-pane.
2. Select **+ Add data** and then create a new table with the name "Company", and plural name as "Companies".
3. Add a few company names to the table, and then select **Close**.

Add a new screen to select the customer

Next, we'll add a screen to the app so that users can select the customer that they want to have the conversation about.

1. In the tree view, select **+ New screen** > select **Scenarios** tab > select **List**.

   A new screen gets added with a gallery list.
2. Update the title of the gallery to "Companies List".
3. Select **Companies** as the data source for the gallery.

The list of companies that was added shows up in the gallery **TemplateGalleryList1**.

4. Delete **Screen1** from the tree view, and rename the new screen to **Screen1**.

Add a new table to capture the conversation details

We need to add another table to capture the details such as the Teams conversation ID, team, and channel related to a conversation started in the app.

1. Select **Data** > **+ Add data** > **Create new table**.
2. Enter table name as **Conversation** and plural name as **Conversations**.
3. Change the default **Name** column name to **ID**.
4. Add the following columns to the conversation table:

Expand table

Column	Type
Team	Text
Team Channel	Text
Team Name	Text
Channel Name	Text
Company	Lookup, related table= Company

5. Save and close the table.

Add a new screen to start or join a conversation

Now, we'll add a new screen where the app user can start or join a conversation.

1. In the tree view, select **+ New screen** > **Blank layout**.
2. Update the **Fill** property of the screen to something other than white color.

   In our example, we've set the Fill property of the screen to `RGBA(224, 224, 237, 1)`.
3. Select **+** (Insert) > **Input** > **Button**.
4. Update the following properties of the button.

Expand table

Property	Value
Name	startaconversation_Button
Text	"Start a conversation"
Width	200
Height	32

Property	Value
Font size	12
X	`Parent.Width/2 - startaconversation_Button.Width/2`
Y	100
OnSelect	`Set(enterMessage,true)`

5. Select + (Insert) > **Input** > **Combo box**.

6. Update the following properties of the Combo box.

Expand table

Property	Value
Name	team_Combobox
Items	`MicrosoftTeams.GetAllTeams().value`
Width	320
Height	32
X	`Parent.Width/2 - team_ComboBox.Width/2`
Y	200
Text	"Team"
Tooltip	"Team"
Visible	enterMessage

7. Add another combo box and update the following properties.

Expand table

Property	Value
Name	channel_Combobox
Items	`If(!IsBlank(team_ComboBox.Selected.id),MicrosoftTeams.GetChannelsForGroup(team_ComboBox.Selected.id).value)`
Width	320
Height	32
X	`Parent.Width/2 - channel_ComboBox.Width/2`
Y	200
Text	"Channel"
Tooltip	"Channel"
Visible	enterMessage

8. Select + (Insert) > **Input** > **Text box**.

9. Update the following properties of the Textbox.

Expand table

Property	Value
Name	message_TextBox
Value	""
Width	500
Height	180
X	`Parent.Width/2 - message_TextBox.Width/2`
Y	300
Placeholder	Type message here
Visible	enterMessage

10. Select + (Insert) > **Input** > **Button**.

11. Update the following properties of the button.

Expand table

Property	Value
Name	submit_Button
Value	"Submit"
Width	96
Height	32
Font size	12
X	`Parent.Width/2 - submit_Button.Width/2`
Y	500
Visible	enterMessage

12. Copy the following formula in the **OnSelect** event of the button.

Power Fx

```
Patch(Conversations,Defaults(Conversations),
{ID:MicrosoftTeams.PostMessageToChannelV3(team_ComboBox.Selected.id,channel_ComboBox.Selecte
d.id,{content:message_TextBox.Value,contentType: "text"},{subject:"New
conversation"}).id,Team:team_ComboBox.Selected.id,'Team
Channel':channel_ComboBox.Selected.id, 'Team
Name':team_ComboBox.Selected.displayName,'Channel
Name':channel_ComboBox.Selected.displayName, Company: TemplateGalleryList1.Selected});
Set(enterMessage,false); Reset(team_ComboBox);Reset(channel_ComboBox);Reset(message_TextBox)
```

> **Note**

- In the above formula, we're using the **Patch** function to create a row in the **Conversations** table to capture the conversation ID along with the team, team name, channel and channel came. At the same time, we're also posting a message in the appropriate team and channel using the **PostMessageToChannelV3** function. We then set the **enterMessage** variable back to "false" to hide some of the fields and buttons whose visibility depends on this variable.
- The subject is hardcoded to “New conversation" to keep the app simple ,and not add another text box control to capture. But a text box can be added for subject to the screen and can be captured by the user. This formula will need to be adjusted accordingly to reference that control. The **Reset** function doesn't work for the **Fluent UI Combobox** control. This is needed to not have any team or channel selected once a message is posted.

13. Select + (Insert) > **Input** > **Button**.

14. Update the following properties of the button.

Expand table

Property	Value
Name	joinconversation_Button
Text	"Join conversation"
Width	200
Height	32
Font size	12
X	`Parent.Width/2 - submit_Button.Width/2`
Y	500
Visible	enterMessage

15. Copy the following formula in the **OnSelect** event of the button.

Power Fx

```
Launch(Concatenate("msteams://teams.microsoft.com/l/message/",Last(Sort(Conversations,
'Created On', Ascending)).'Team Channel',"/",Gallery1.Selected.etag,"?
tenantId=",Param("tenandId"),"&groupId=",Last(Sort(Conversations, 'Created On',
Ascending)).Team,"&parentMessageId=",LookUp(MicrosoftTeams.GetMessagesFromChannel(Last(Sort(
Conversations, 'Created On', Ascending)).Team,Last(Sort(Conversations, 'Created On',
Ascending)).'Team Channel').value,id = Last(Sort(Conversations, 'Created On',
Ascending)).Team).etag,"&teamName=",Last(Sort(Conversations, 'Created  On',
Ascending)).'Team Name',"&channelName=",Last(Sort(Conversations, 'Created On',
Ascending)).'Channel Name'),{},LaunchTarget.New)
```

Note

- In the above formula, we're using the **Launch** function to launch Teams using the team and channel parameters of the last record that was created in the **Conversations** table. We're doing this so that when a user starts a conversation and submits a message to post to a channel, the user can then select the **Join Conversation** button to go to the Teams post directly.

- We're using the last function here to keep it simple. If you anticipate using this app more extensively and anticipate having multiple conversations, you could get creative by using a gallery of conversations, and letting the user select which conversation they'd want to join.*

Update the gallery OnSelect Property

Next, we'll update the **OnSelect** property of the company gallery so that when a user selects a company from the list, the app will go to the second screen.

1. Select **Screen1** from the tree view to open the **Companies** gallery.
2. Set the **OnSelect** property of the gallery item to `Navigate(Screen2)`.

Save and publish the app

1. Select **Save** on the top-right to save the app.
2. Select **Publish** on the top-right to publish the app.
3. Select **Next**.
4. Under **Add to Channel**, make sure the channel under which the app should be shown is listed and shows as "1 active tab(s)" and not "0 active tab(s)".
5. Select **Save and Close** to complete the publishing of the app.

Testing the app

Run the app in preview mode or go to the team in which the app is created.

1. The Companies gallery should show up as the first screen.
2. Select one of the companies.
3. You should only see two buttons: **Start a conversation** and **Join a conversation**.
4. Select **Start a conversation**.
5. Additional fields should show up:
    - Team (dropdown with a list of teams)
    - Channel (dropdown list of channels within the selected team)
    - Message box (text box to type in the message to be sent to the team)
    - Submit button (to submit the message)
6. Select a team.
7. Select a channel within the team.
8. Enter message.
9. Select **Submit**. All the additional fields/controls get hidden.
10. Select **Join conversation** to be taken to the team and channel chat where the last message was sent.

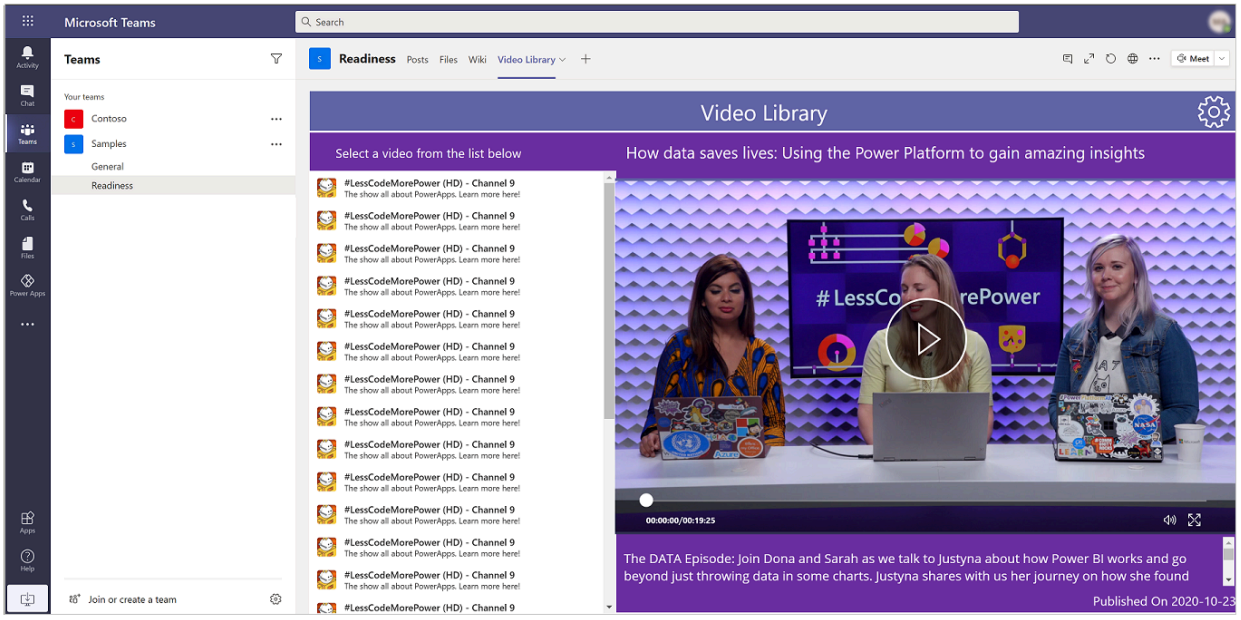
Build an app to retrieve Power Platform videos for readiness

Article • 02/04/2023

In this tutorial, you'll build a solution that retrieves, lists, and displays content that can be used for readiness.



Objective

The focus of this tutorial will be on finding, retrieving, browsing, and playing video content available on YouTube or RSS Feeds with MP4 video files. It will continually monitor these channels and feeds for new content, and send a message to a specified Microsoft Team when new content is available.

The channels and feeds in the tutorial will focus on Power Platform content but can easily be used for other topics.

In this tutorial, you'll use:

- Power Apps to build the application to specify the YouTube channels and RSS feeds.
- Power Automate to retrieve information about new and existing videos.
- Microsoft Dataverse for Teams to create tables to store the feed and video information.
- Power Automate to send a message to Microsoft Teams when a new video is delivered.

Prerequisites

- Identify an existing Microsoft Team or create a new Microsoft Team that you'll build your app for.
- Identify an existing channel or create a new channel within Microsoft Teams to post the messages sent, to specify that a new video has been retrieved.

If you're unfamiliar with how to create a Team or a channel in a Team, see Create a channel in Teams.

In this tutorial, we'll use a channel named "Readiness".

Step 1: Install and pin Power Apps in Teams

In this section, you'll install the Power Apps app in Teams and pin it to the left rail so you can easily access it. To learn how to do install and pin the Power Apps app, see Install the Power Apps personal app in Microsoft Teams.

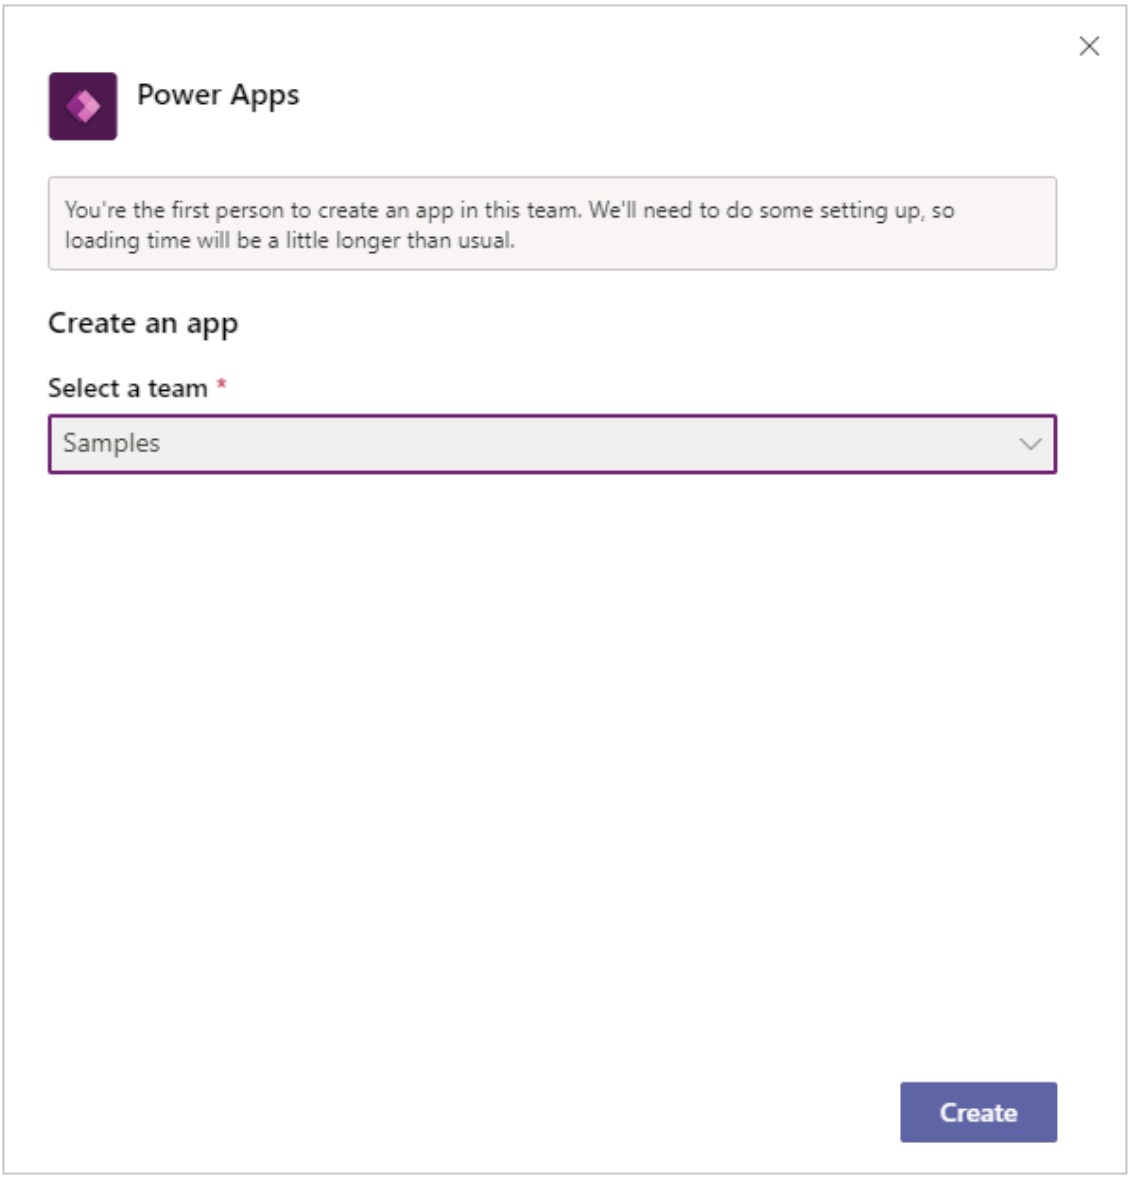
If you've already done installed and pinned the Power Apps app, you can skip to the next step.

Step 2: Create the app and the tables

In this section, you'll take the initial steps to create the application.

1. Select the Power Apps app.
2. Select the **Build** tab at the top of the screen.
3. Select **Create** shown in the lower left of the screen.

   This action will display the **Create an app** dialog box.
4. Select the name of the team from the drop-down list and select **Create**.



> **Note**
>
> If this is the first time you've tried to create an app in this Microsoft Teams team, it will take a moment to set up.

5. When prompted for the name of the app, enter **Video Library** and select **Save**.

Step 2.1: Create the table for the feeds

In this section, you'll create a table to store the names and details for the feeds that will be used by the application.

1. Select **Create new table** on the left side of the screen.

2. When prompted for the name of the table, enter **Feeds**.

3. Select **Create**.

Step 2.1.1: Edit the Name column

1. In the visual editor, select the drop-down menu for the **Name** column and then **Edit column**.
2. Change the name to *Title*.
3. Select **Advanced options** and then change the value for **Max length** to *255*.
4. Select **Save**.

Step 2.1.2: Create the Description column

1. Select + to create a new column.
2. Specify the name as *Description*.
3. For **Type**, select **Text** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.
5. Select **Create**.

Step 2.1.3: Create the Image Link column

1. Select + to create a new column.
2. Specify the name as *Image Link*.
3. For **Type**, select **URL** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.
5. Select **Create**.

Step 2.1.4: Create the Image Title column

1. Select + to create a new column.
2. Specify the name as *Image Title*.
3. For **Type**, select **Text** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.

5. Select **Create**.

Step 2.1.5: Create the Last Retrieved column

1. Select + to create a new column.
2. Specify the name as *Last Retrieved*.
3. For **Type**, select **Text** from the list.
4. Select **Create**.

Step 2.1.6: Create the Link column

1. Select + to create a new column.
2. Specify the name as *Link*.
3. For **Type**, select **URL** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.
5. Select **Create**.

Step 2.1.7: Create the Published On column

1. Select + to create a new column.
2. Specify the name as *Published On*.
3. For **Type**, select **Text** from the list.
4. Select **Create**

Step 2.1.8: Add a row

In the visual editor, add a row for the Microsoft show "#LessCodeMorePower" that will be used in testing.

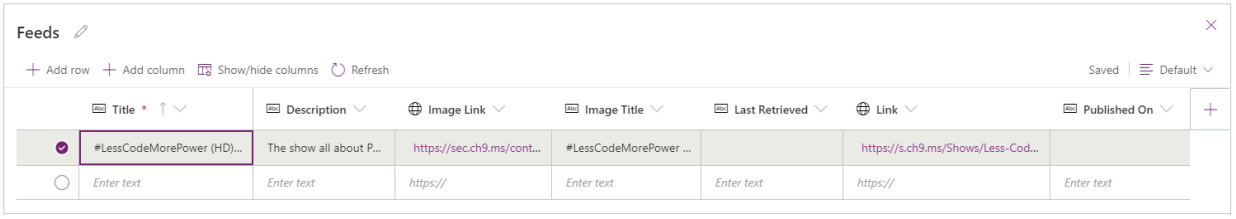
Expand table

Title	**#LessCodeMorePower (HD) - Channel 9**
Description	The show all about Power Apps. Learn more here!

Title	**#LessCodeMorePower (HD) - Channel 9**
Image Link	https://sec.ch9.ms/content/feedimage.png
Image Title	#LessCodeMorePower (HD) - Channel 9
Link	https://s.ch9.ms/Shows/Less-Code-More-Power/feed/mp4high

> **Note**
>
> Leave the **Published On** column empty.

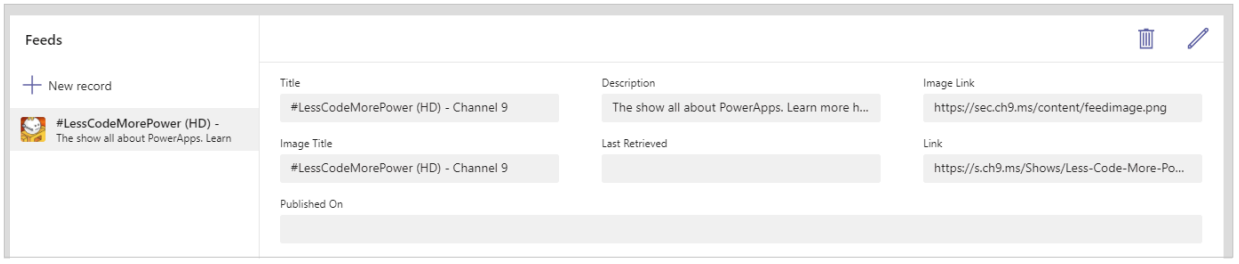
The visual editor should resemble the image below.



Select **Close** to close the visual editor.

The screen created automatically in the app, named **Screen1**, should automatically bind to the table, displaying the fields in the table and the record you added.

The screen should resemble the image below.

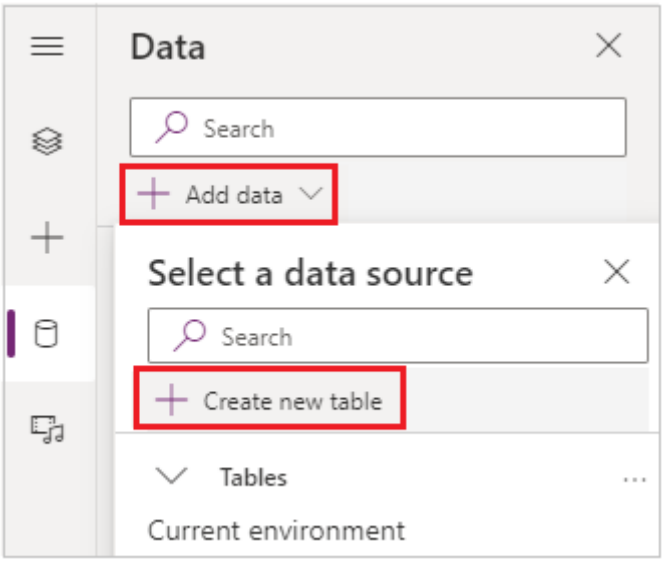


Step 2.2: Create the table for the feed items

In this section, you'll create a table to store the details for the videos stored in the Feed Items for the YouTube channel or RSS feed.

1. Select **Add data** on the left side of the screen.

2. Select **Create new table**.



3. When prompted for the name of the table, enter *Feed Items*.

Step 2.2.1: Edit the Name column

1. In the visual editor, select the drop-down for the **Name** column, and then select **Edit column**.
2. Change the name to *Feed Item ID*.
3. Select **Advanced options** and then change the value for **Max length** to *255*.
4. Select **Save**.

Step 2.2.2: Create the Feed column

1. Select + to create a new column.
2. Specify the name as *Feed*.
3. For **Type**, select **Lookup** from the list.
4. For the table, select **Feeds** from the list
5. Select **Create**.

Step 2.2.3: Create the Title column

1. Select + to create a new column.
2. Specify the name as *Title*.

3. For **Type**, select **Text** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.
5. Select **Create**.

Step 2.2.4: Create the Description column

1. Select + to create a new column.
2. Specify the name as *Description*.
3. For **Type**, select **Text** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *2500*.
5. Select **Create**.

Step 2.2.5: Create the Primary Feed Link column

1. Select + to create a new column.
2. Specify the name as *Primary Feed Link*.
3. For **Type**, select **URL** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.
5. Select **Create**.

Step 2.2.6: Create the Video Link column

1. Select + to create a new column.
2. Specify the name as *Video Link*.
3. For **Type**, select **URL** from the list.
4. Select **Advanced options** and then change the value for **Max length** to *255*.
5. Select **Create**.

Step 2.2.7: Create the Published On column

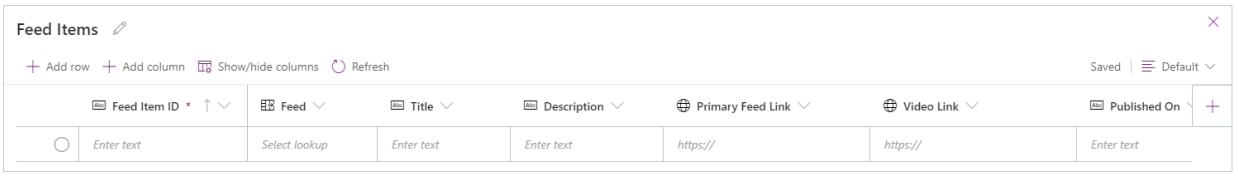
1. Select + to create a new column.

2. Specify the name as *Published On*

3. For **Type**, select **Text** from the list.

4. Select **Create**.

The visual editor should resemble the image below.



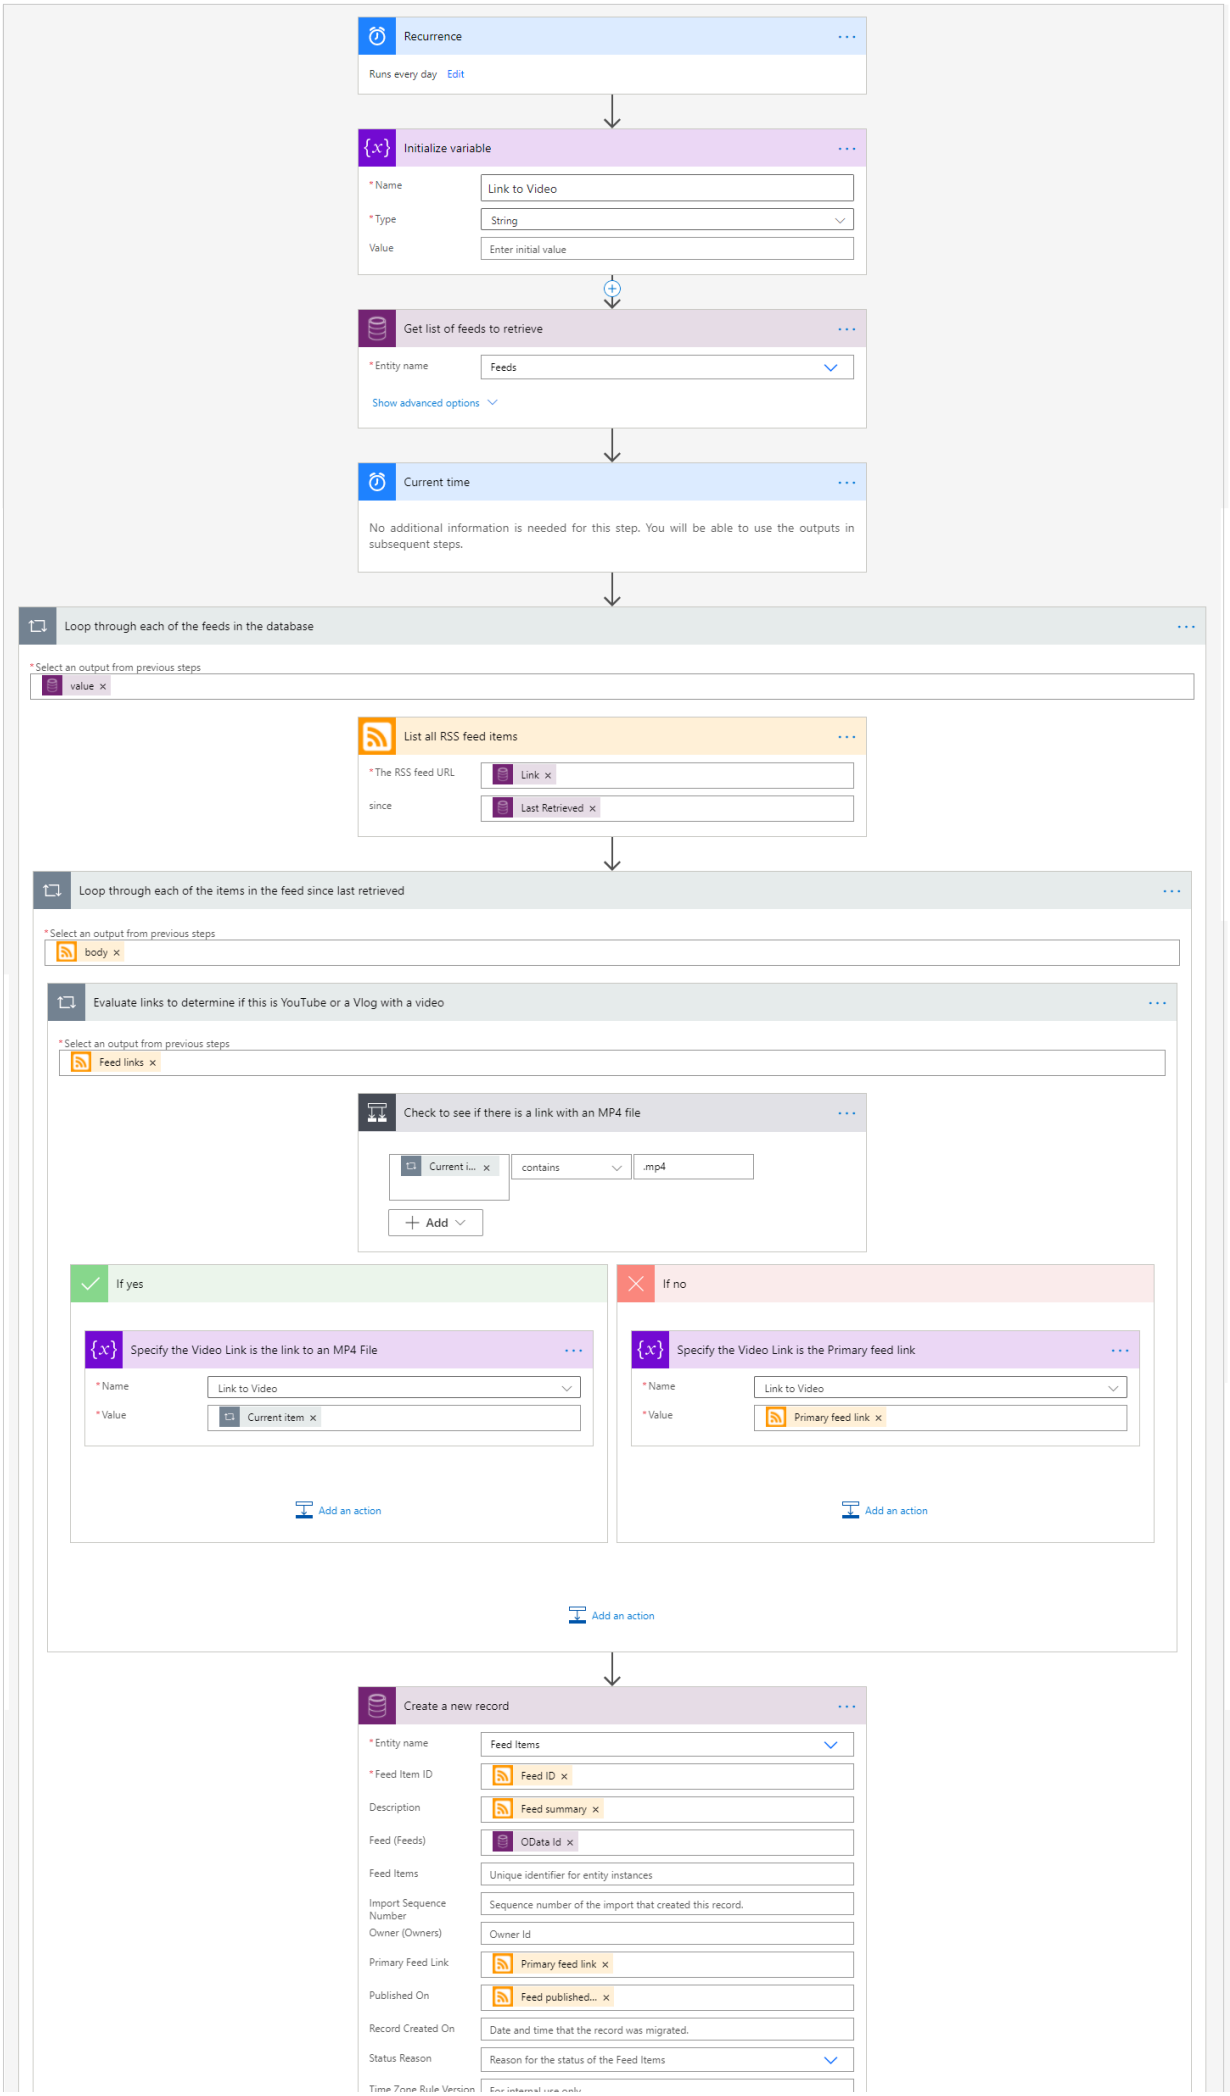
Select **Close** to close the visual editor.

Now that you've created the required tables, select **Save** on the upper-right corner to save the app and close the Power Apps Studio.

Step 3: Create flows to get the video details for configured feeds

In this section, you'll create flows in Power Automate to retrieve videos for each of the configured feeds. This flow will monitor the RSS feeds for the addition of new videos, retrieve details for the videos, and save those details in the database.

When you've completed this section, your flow should resemble the diagram below.



Recurrence
Runs every day Edit
Initialize variable
*Name

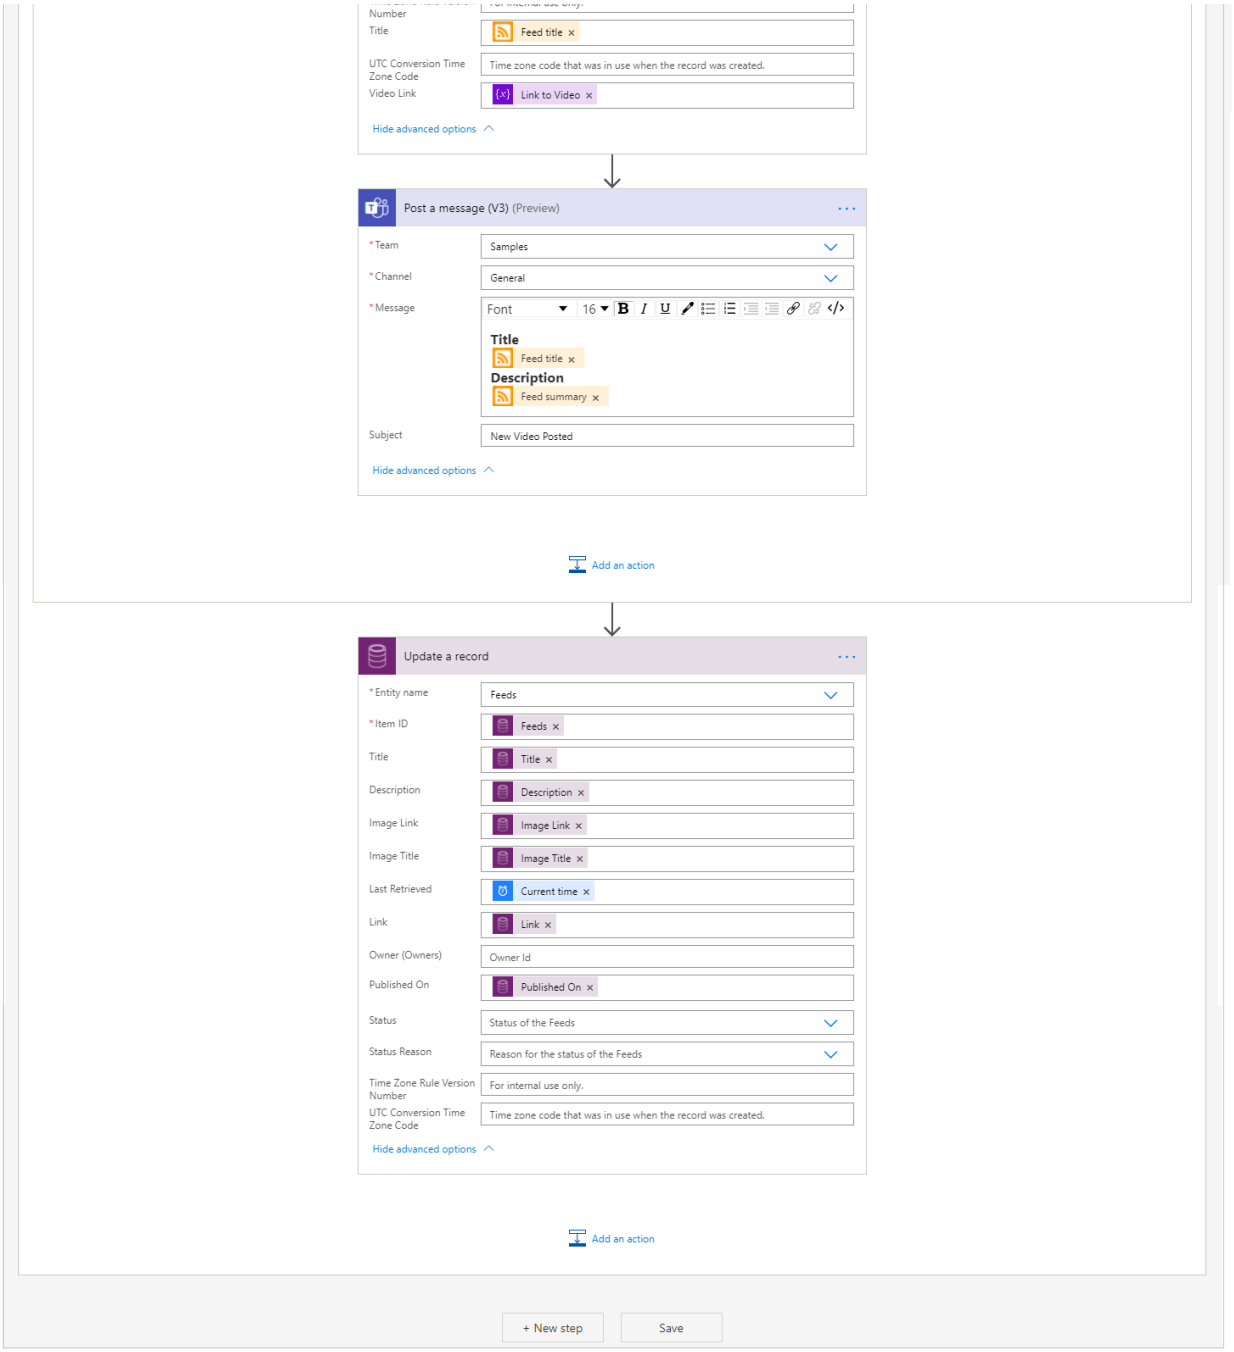
Status Reason
Reason for the status of the Feed Items



> **Note**
>
> Power Automate has a trigger that allows you to detect when a new item is added to a feed for an individual feed. When tracking multiple feeds, this would require multiple feeds and would require the same number of flows to match the number of feeds. The approach taken in this lab is more complex but with the benefit of having a single flow that supports any number of configured feeds in a single flow.

Step 3.1: Create the flow

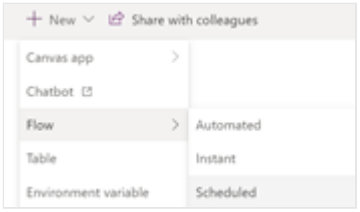
1. Select the **Build** tab.

2. From the list on the left, select the name of your team in which you created the tables earlier.

3. Select **See all** under the *Built by this Team* tab.

4. Select **New**.

5. Select **Flow** > **Scheduled**.

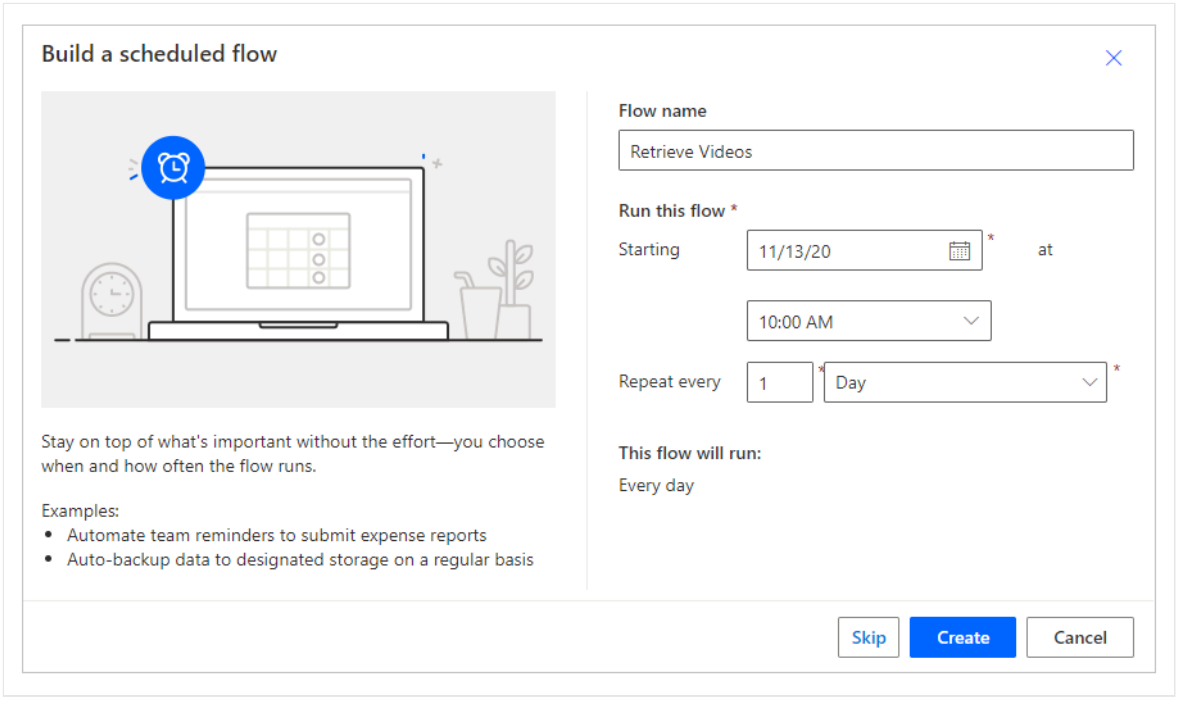


6. In the **Build a scheduled flow** dialog,

   a. Enter the name as "Retrieve Videos".

   b. Select **Day** as the frequency.

   c. Select **Create**.



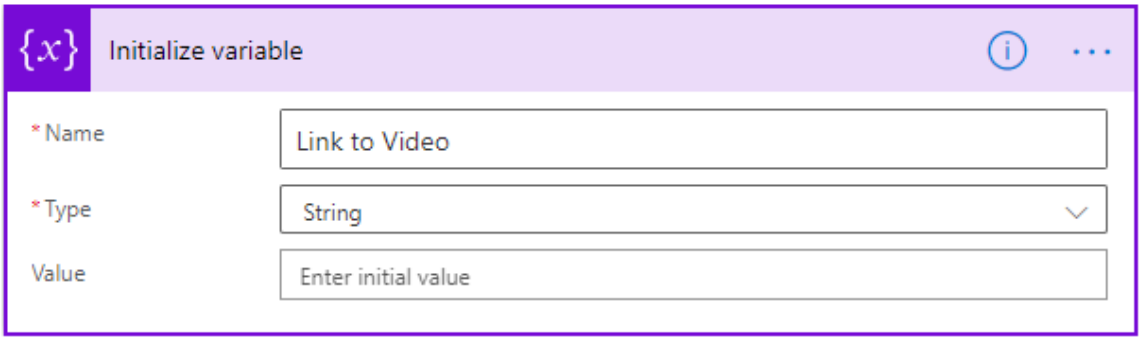
Step 3.2: Add the initialize variable action

1. Select **New step**.

2. Enter *Initialize variable* in the search box.

3. Select the **Initialize variable** action.

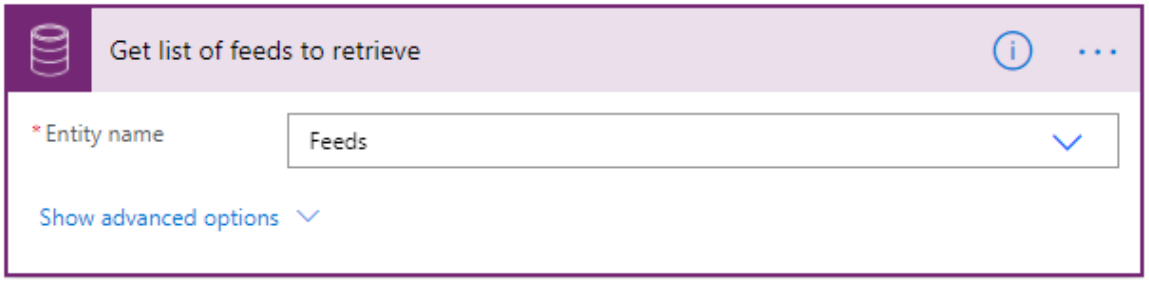
4. Enter *Link to Video* in the **Name** field.
5. Select **String** in the drop-down for **Type**.



> **Note**
>
> Don't enter any value in the **Value** field.

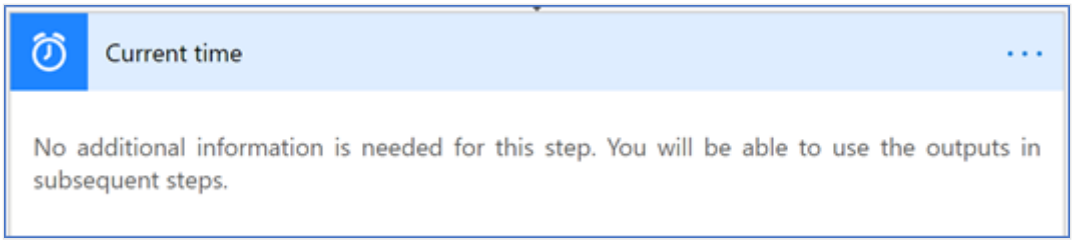
Step 3.3: Add the List Records action

1. Select **New Step**.
2. Enter *Microsoft Dataverse* in the search box and select the action named **List records**.
3. Select **Feeds** in the **Entity name** property.
4. Select ellipsis (...) in the header of the action and select **Rename**.
5. Rename the action to *Get list of feeds to retrieve*.



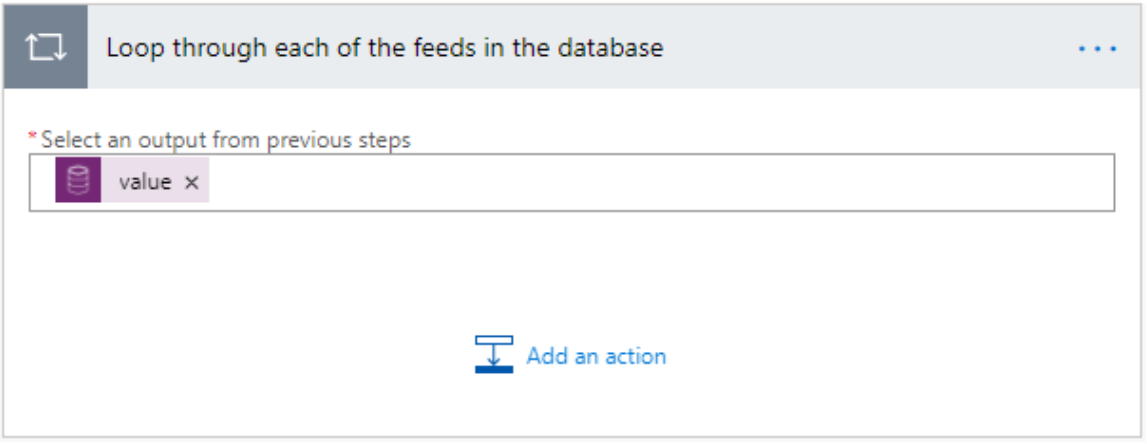
Step 3.4: Add the Current time action

1. Select **New Step**.
2. Enter *Date Time* in the search box and select the action named **Current time**.



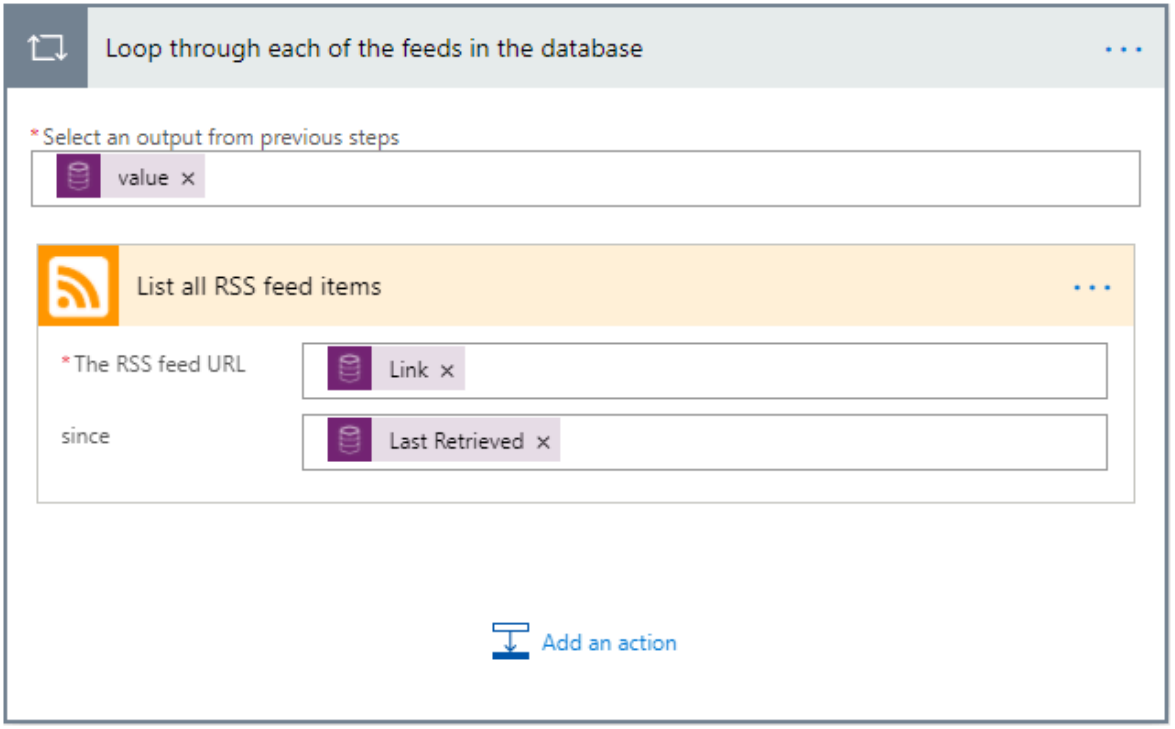
Step 3.5: Add the Apply to each action

1. Select **New Step**.
2. Enter *Apply to each* in the search box, and then select the action named **Apply to each**.
3. Select the text box under **Select output from previous steps**.
4. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **value**.
5. Select ellipsis (...) in the header of the action and select **Rename**.
6. Rename the action to *Loop through each of the feeds in the database*.



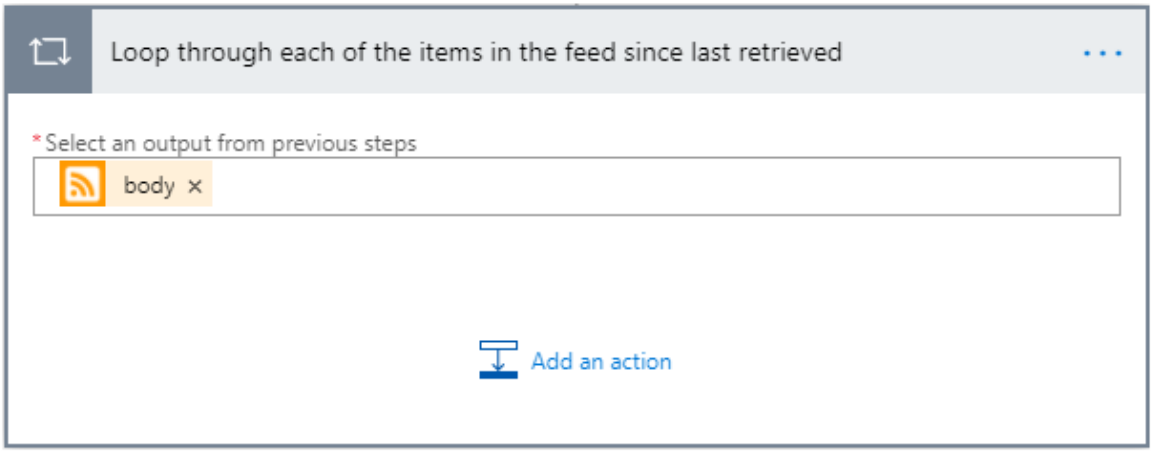
Step 3.6: Add the List all RSS Feed Items action

1. Select **Add an action**.
2. Enter *RSS* in the search box and select the action called **List all RSS feed items**.
3. Select the box for the property **The RSS feed URL**.
4. In the **Dynamic content**, scroll down to the section **Get list of feeds to retrieve**, and then select **Link**.
5. Select in the box for the property **since** and select **Last Retrieved**.



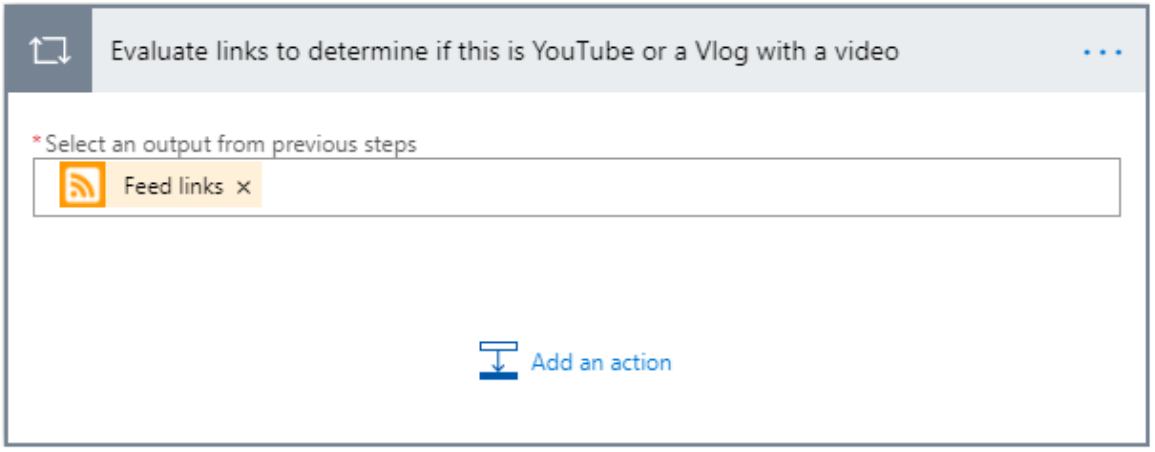
Step 3.7: Add the Apply to Each Action

1. Select **Add an action**.
2. Enter *Apply to each* in the search box and select the action named **Apply to each**.
3. Select the text box under **Select output from previous steps**.
4. In the **Dynamic content** list, scroll down to the section called **List all RSS feed items**, and then select **body**.
5. Select ellipsis (...) in the header of the action, and then select **Rename**.
6. Rename the action to *Loop through each of the items in the feed since last retrieved*.



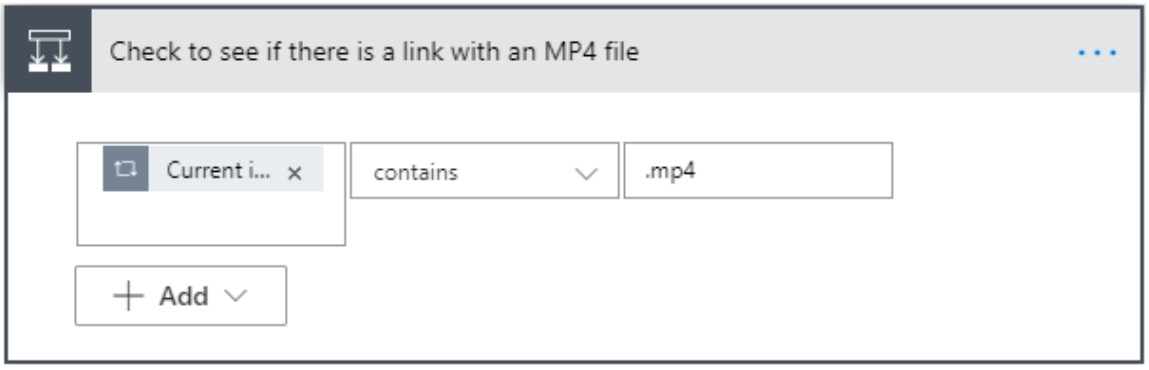
Step 3.8: Add the Apply to Each action

1. Select **Add an action** inside *Loop through each of the items in the feed since last retrieved*.
2. Enter *Apply to each* in the search box and select the action named **Apply to each**.
3. Select the text box under **Select output from previous steps**.
4. In the **Dynamic content** list, scroll down to the section **List all RSS feed items**, and then select **Feed links**.
5. Select ellipsis (...) in the head of the action, and then select **Rename**.
6. Rename the action to *Evaluate links to determine if this is YouTube or a Vlog with a video*.



Step 3.9: Add the Condition action

1. Select **Add an action**.
2. Enter *Condition* in the search box, and then select the action named **Condition**.
3. Select the text box containing text **Choose a value**.
4. In the **Dynamic content** list that is displayed, scroll down to the section called **Evaluate links to determine if this is YouTube or a Vlog with a video**, and then select **Current item**.
5. Select the drop-down that shows **is equal to**, and then select **contains**.
6. Select the text box text **Choose a value** and enter the value **.mp4**.
7. Select ellipsis (...) in the header of the action, and then select **Rename**.
8. Rename the action to *Check to see if there is a link with an MP4 file*.



9. In the **If yes** path on the left, select **Add an action**.

    a. Enter *Set variable* in the search box, and then select the action named **Set Variable**.

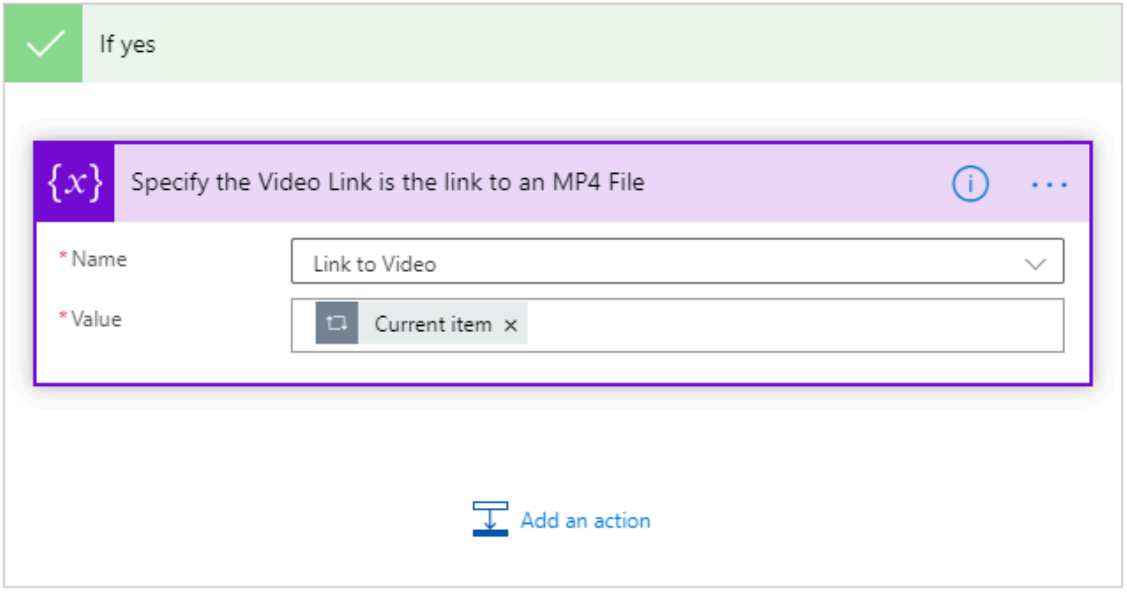
    b. Select **Link to Video** in the drop-down for the *Name* property.

    c. Select the textbox for the **Value** property.

    d. In the **Dynamic content** list, scroll down to the section called **Evaluate links to determine if this is YouTube or a Vlog with a video** and select **Current item**.

    e. Select ellipsis (...) in the header of the action, and then select **Rename**

    f. Rename the action to *Specify the Video Link is the link to an MP4 File*.



10. In the **If No** path on the left, select **Add an action**.

    a. Enter *Set variable* in the search box, and then select the action named **Set Variable**.

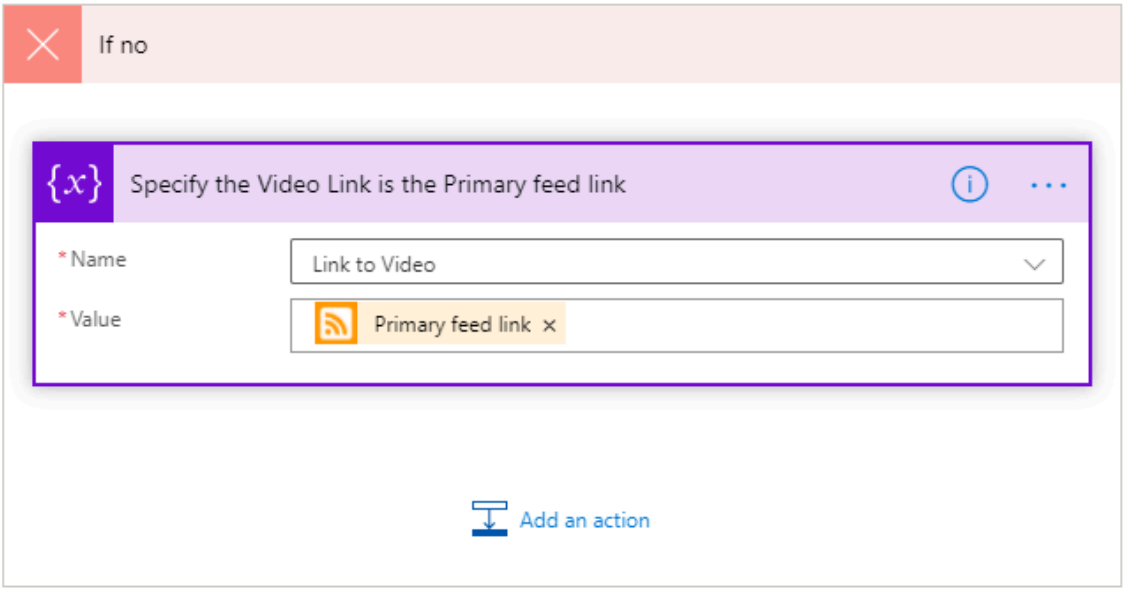
    b. Select **Video Link** in the drop-down for the **Name** property.

c. Select the textbox for the **Value** property.

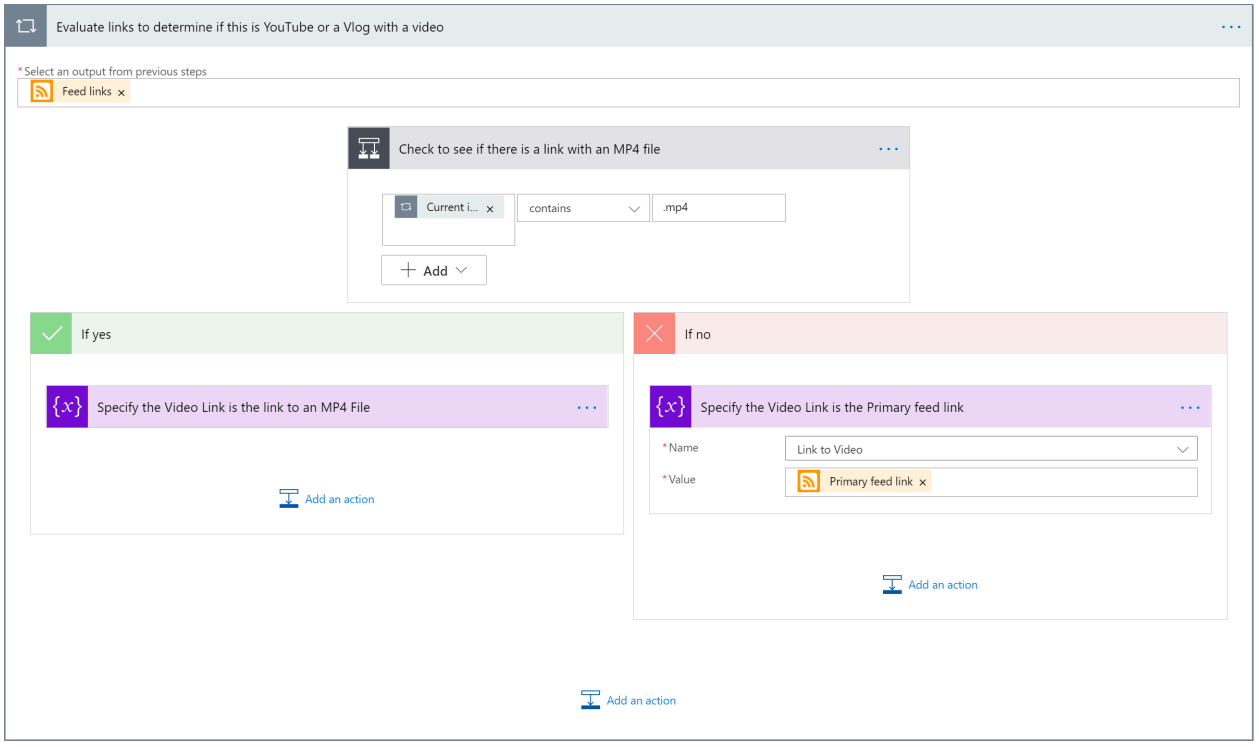
d. In the **Dynamic content** list, scroll down to the section **List all RSS feed items**, and then select **Primary feed link**.

e. Select ellipsis (...) in the header of the action, and then select **Rename**.

f. Rename the action to *Specify the Video Link is the Primary feed link*.

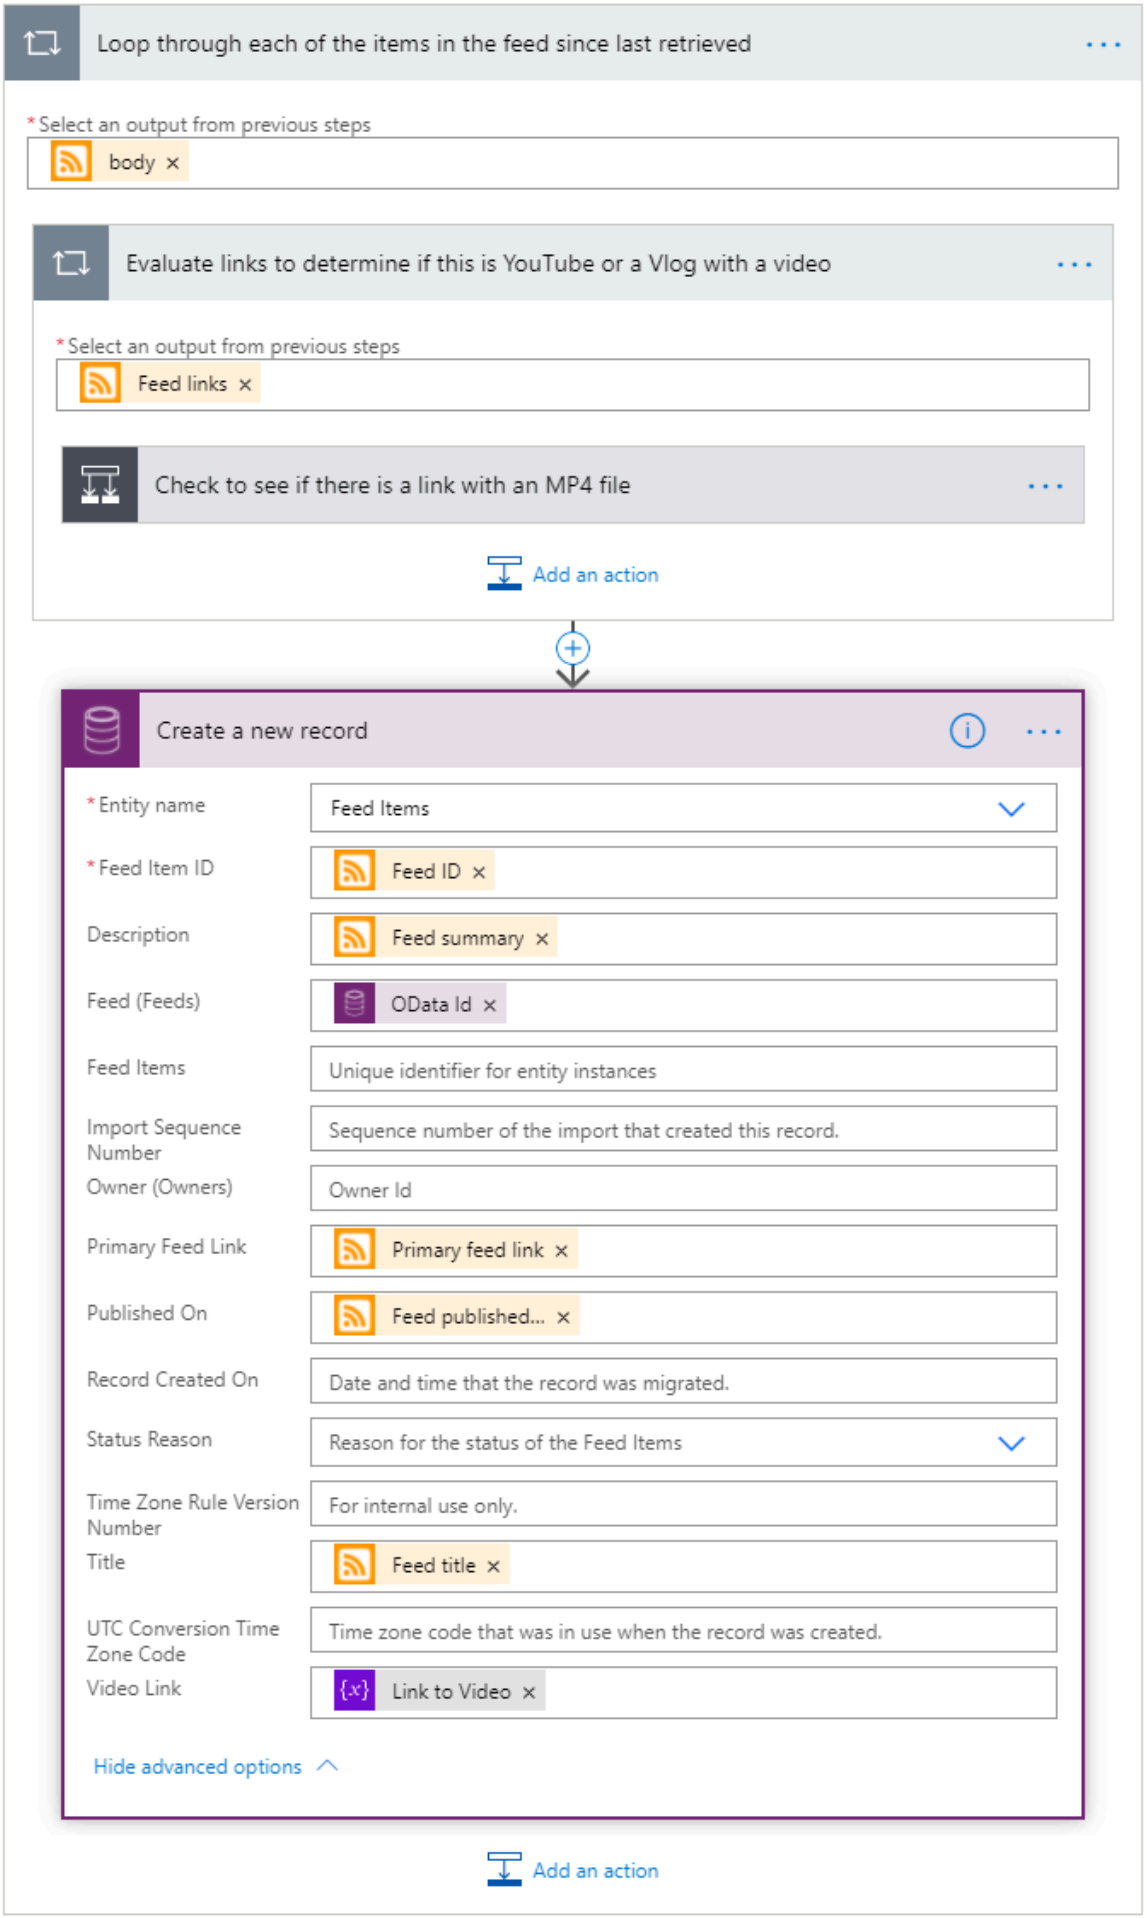


Select the header of the action to show the title of **Evaluate links to determine if this is YouTube or a Vlog with a video**.



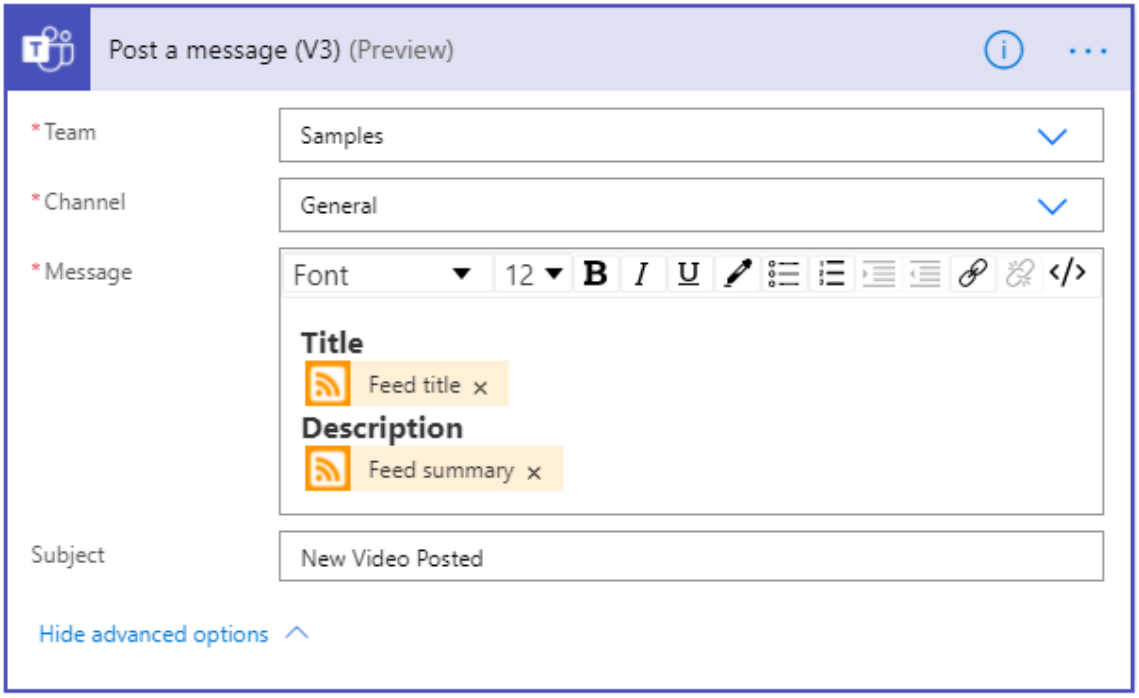
Step 3.10: Add the Create a New Record action

1. Inside *Loop through each of the items in the feed since last retrieved* action, select **Add an action**.
2. Enter *Microsoft Dataverse* in the search box, and then select the action called **Create a new record**.
3. Select **Feed Items** in the *Entity name* property.
4. In the **Dynamic content** list scroll down to the section **List all RSS feed items**, and then select **Feed ID**.
5. Select the textbox next to *Field Item ID*.
6. Select **Show advanced options** link in the action to display all the fields in the table.
7. Select the textbox next to *Description*.
8. In the **Dynamic content** list, scroll down to the section called **List all RSS feed items** and select **Feed summary**.
9. Select the textbox next to *Feed (Feeds)*.
10. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **OData Id**.
11. Select the textbox next to *Primary Feed Link*.
12. In the **Dynamic content** list scroll down to the section **List all RSS feed items**, and then select **Primary feed link**.
13. Select the textbox next to *Published On*.
14. In the **Dynamic content** list, scroll down to the section **List all RSS feed items**, and then select **Feed published on**.
15. Select the textbox next to *Title*.
16. In the **Dynamic content** list, scroll down to the section **List all RSS feed items**, and then select **Feed title**.
17. Select the textbox next to *Video Link*.
18. In the **Dynamic content** list, scroll down to the section **Variables**, and then select **Link to Video**.



Step 3.11: Add the Set Variable action

1. Select **Add action** after *Create new record*.
2. Enter **Teams** in the search box, and then select the **Post a message (V3) (preview)** action.
3. In the drop-down for the **Team** property, select the team to send the message.
4. In the drop-down for the **Channel** property, select the channel to send the message.
5. Select **Show advanced options** link.
6. In the *Message* property, create a message with details about the item. An example message is shown in the image below.

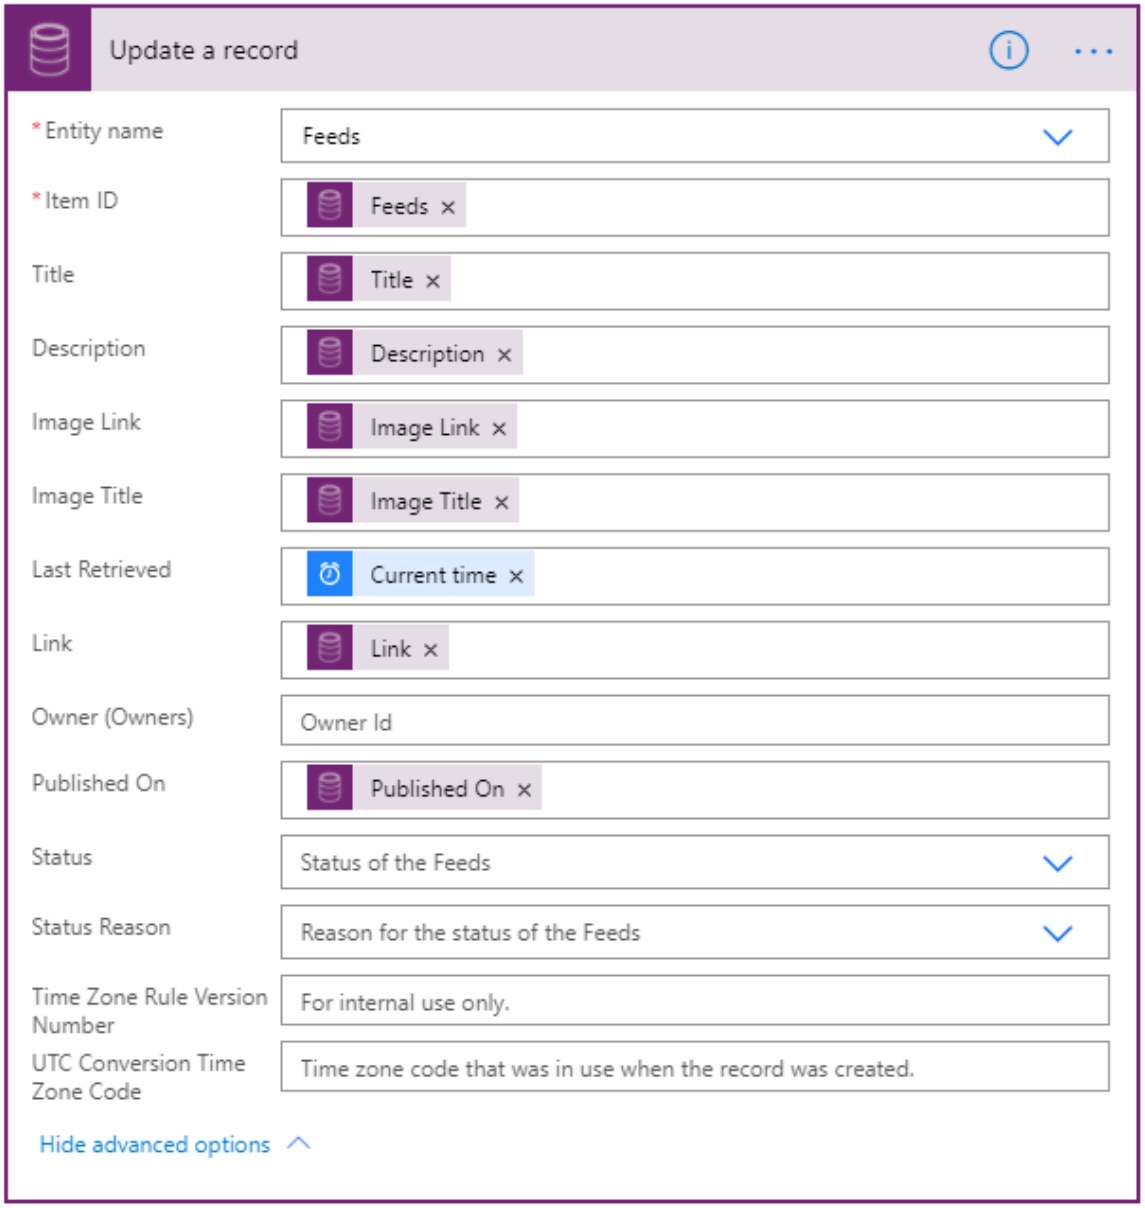


Select the header of the action to show the title of **Loop through each of the items since last retrieved**.

Step 3.12: Add the Update Record action

1. Inside *Loop through each of the feeds in the database* action, select **Add an action**.
2. Enter *Microsoft Dataverse* in the search box, and then select the action **Update a record**.
3. Select **Feeds** for the *Entity Name*.
4. Select textbox next to *Item ID*.

5. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Feeds**.
6. Select textbox next to *Title*.
7. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Title**.
8. Select **Show advanced options** link in the action to display all the fields in the table.
9. Select textbox next to *Description*.
10. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Description**.
11. Select textbox next to *Image Link*.
12. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Image Link**.
13. Select textbox next to *Image Title*.
14. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Image Title**.
15. Select textbox next to *Last Retrieved*.
16. In the **Dynamic content** list, scroll down to the section **Current time** and select **Current time**.
17. Select textbox next to *Link*.
18. In the **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Link**
19. Select textbox next to *Published On*.
20. In **Dynamic content** list, scroll down to the section **Get list of feeds to retrieve**, and then select **Published On**.



Your complete flow should look like the following image:

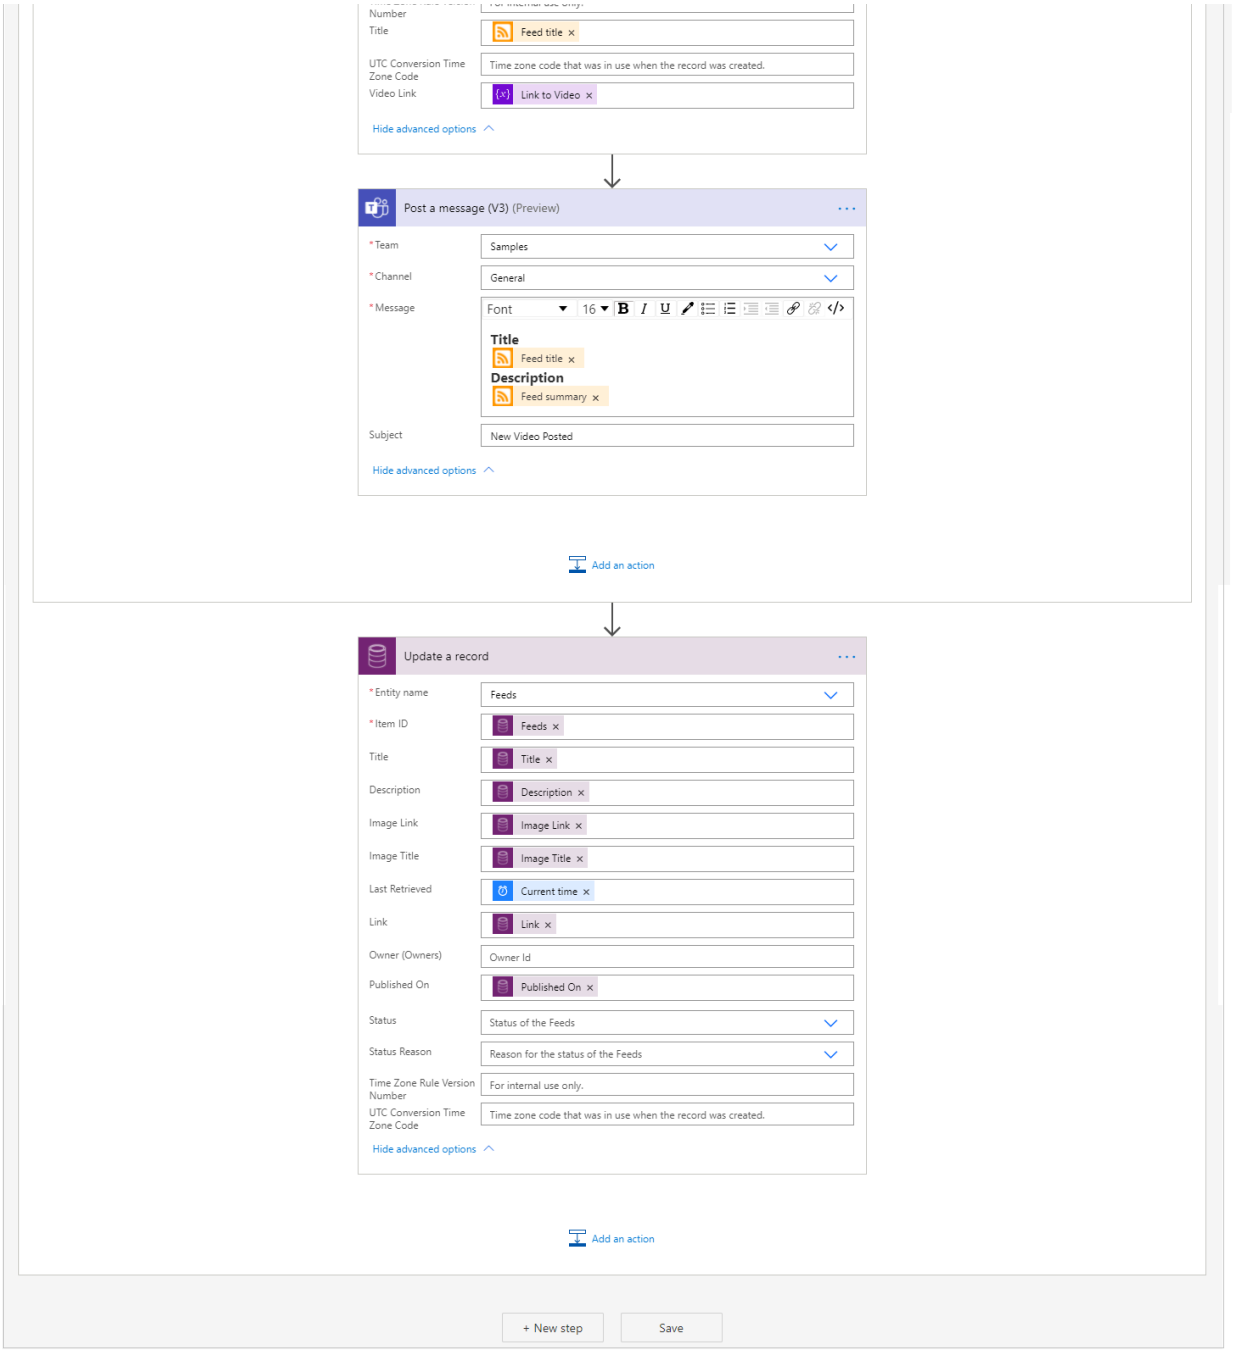
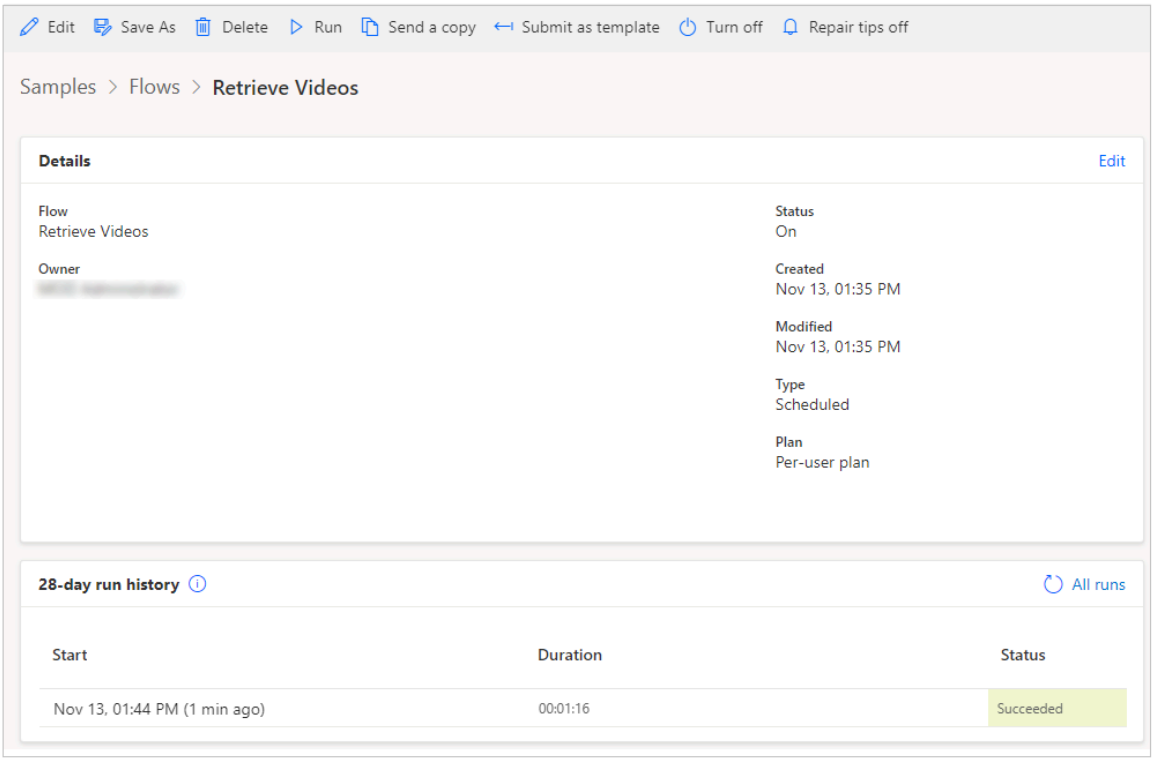
Reason for the status of the Feed Items



Step 3.13: Save the Flow

1. From the upper-right side of the screen, select **Save**.
2. Select the back arrow in the upper left.
3. Select the flow **Retrieve Videos**.
4. Select **Run** in the command bar.
5. From the panel on the right side of the screen, select **Run flow**.
6. Select **Done**.
7. Select the refresh button in **28-day run history** to show the details of the flow run.



If the flow doesn't show as succeeded, select **Run** and it will display the failed action with any associated error message.

Step 4: Edit the app to add the video library interface

In this section, you'll create a new screen in the app that enables you and other members of the team to browse through videos, see the video details, and play them directly within Teams.

To start editing the app:

1. Select Power Apps from the left rail in Teams.
2. Select the **Build** tab.
3. From the left pane, select the team environment where the app is created.
4. Under *Built by this team**, select the **Video Library** app.

Now create a new screen and configure the screen controls using the following steps.

Step 4.1: Create new screen

1. Select **Tree view**.

2. Select **New screen**.
3. Select **Blank** layout.
4. Select + to begin adding controls to screen.

Step 4.2: Add the header

1. Enter **Rectangle** in the search box.
2. Drag the rectangle control onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
X	0
Y	0
Width	1365
Height	60
Color	Purple

Step 4.3: Add the header label

1. Enter **Label** in the search box.
2. Drag the label onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
Text	Video Library
Display Mode	View
Font size	24
X	576

Property	Value
Y	0
Width	191
Height	61
Color	White

Step 4.4: Add a rectangle for the Video List Header

1. Enter **Rectangle** in the search box.
2. Drag the rectangle control onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
X	0
Y	61
Width	1365
Height	58
Color	Purple

Step 4.5: Add a label for the Video List Header

1. Enter **Label** in the search box.
2. Drag the label onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
Text	Select a video from the list below
Display Mode	View

Property	Value
Font size	14
X	39
Y	74
Width	320
Height	32
Color	White

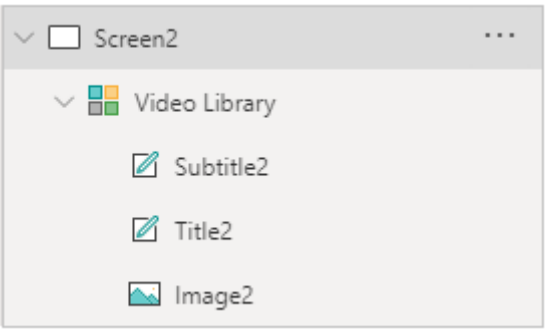
Step 4.6: Add a Vertical Gallery

1. Enter **Vertical Gallery** in the search box.
2. Drag the label onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
Name	Video Library
Data Source	Feed Items
Layout	Image, title, and subtitle
X	0
Y	119
Width	450
Height	649

In the tree view on the left side of the screen, there are three controls underneath the Video Gallery with names starting with Subtitle, Title, and Image.



Step 4.6.1: Set the Subtitle

1. Select the control that starts with **Subtitle**.
2. Select the **Text** property from the property list on top-left.
3. Update the property value to the following formula:

```
Power Fx

ThisItem.Feed.Description
```

Step 4.6.2: Set the Title

1. Select the control that starts with **Title**.
2. Select the **Text** property from the property list on top-left.
3. Update the property value to the following formula:

```
Power Fx

ThisItem.Feed.Title
```

Step 4.6.3: Set the Image

1. Select the control that starts with **Image**.
2. Select the **Text** property from the property list on top-left.
3. Update the property value to the following formula:

```
Power Fx
```

```
ThisItem.Feed.'Image Link'
```

Step 4.7: Add the background for the feed item

1. Enter **Rectangle** in the search box.
2. Drag the rectangle control onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
X	451
Y	61
Width	915
Height	707
Color	Purple

Step 4.8: Add the feed item title header label

1. Enter **Label** in the search box.
2. Drag the label onto the screen.
3. Set the following properties with these values:

Expand table

Property	Value
Font size	18
X	466
Y	51
Width	883
Height	78

Property	Value
Color	White

4. Select the **Text** property from the property list on top-left.

5. Set the **Text** property value to the following formula:

```
Power Fx
'Video Library'.Selected.Title
```

Step 4.9: Add a Video Control

1. Enter **Video** in the search box.

2. Drag the video control onto the screen.

3. Set the following properties with these values:

Expand table

Property	Value
X	450
Y	129
Width	916
Height	523

4. Select the **Media** property from the property list on top-left.

5. Set the **Media** property value to the following formula:

```
Power Fx
'Video Library'.Selected.'Video Link'
```

Step 4.10: Add the feed description HTML Text control

1. Enter **HTML text** in the search box.

2. Drag the HTML text control onto the screen.

3. Set the following properties with these values:

Expand table

Property	Value
Font size	14
X	458
Y	651
Width	908
Height	82
Color	White

4. Select the **HtmlText** property from the property list on top-left.

5. Set the **HtmlText** property value to the following formula:

```
Power Fx
'Video Library'.Selected.Description
```

Step 4.11: Add the Published On label

1. Enter **Label** in the search box.

2. Drag the Label onto the screen.

3. Set the following properties with these values:

Expand table

Property	Value
Font size	14
X	1153
Y	732
Width	213
Height	36

Property	Value
Color	White

4. Select the **Text** property from the property list on top-left.

5. Set the **Text** property value to the following formula:

```
Power Fx

Concatenate("Published On ",Text('Video Library'.Selected.'Published
On'))
```

Step 4.12: Enable toggle between screens

Currently there are two separate screens, but no way to toggle between them. The ability to toggle between the screens will be important to enable the addition of more feeds.

Step 4.12.1: Add the gear icon

1. Select **Screen2**.

2. Select **Add icon** from the properties pane.

3. Select the **Settings** icon type.

4. Set the following properties with these values:

Expand table

Property	Value
X	1307
Y	6
Width	48
Height	51
Color	White

5. Select the **OnSelect** property from the property list on top-left.

6. Set the **OnSelect** property value to the following formula:

```
Power Fx

Navigate(Screen1)
```

Step 4.12.2: Configure the back button

1. Select **Screen1**.
2. Select **Add icon** from the properties pane.
3. Select the **Back** icon type.
4. Set the following properties with these values:

Expand table

Property	Value
X	225
Y	12
Width	32
Height	32

5. Select the **OnSelect** property from the property list on top-left.
6. Set the **OnSelect** property value to the following formula:

```
Power Fx

Navigate(Screen2)
```

When you select the gear icon, the app will now show the form to edit the list of feeds. Selecting the back button will return to the list of videos.

Step 5: Test the app

Before publishing the application to teams, it's important to test core functionality.

Step 5.1: Test the Power Automate Flow

1. Run the Power Automate flow.

2. Confirm that new items have been added to the **Feed Items** table.
3. Confirm that the flow has posted new messages to the Channel you specified when configuring the application.

Step 5.2: Test the app functionality

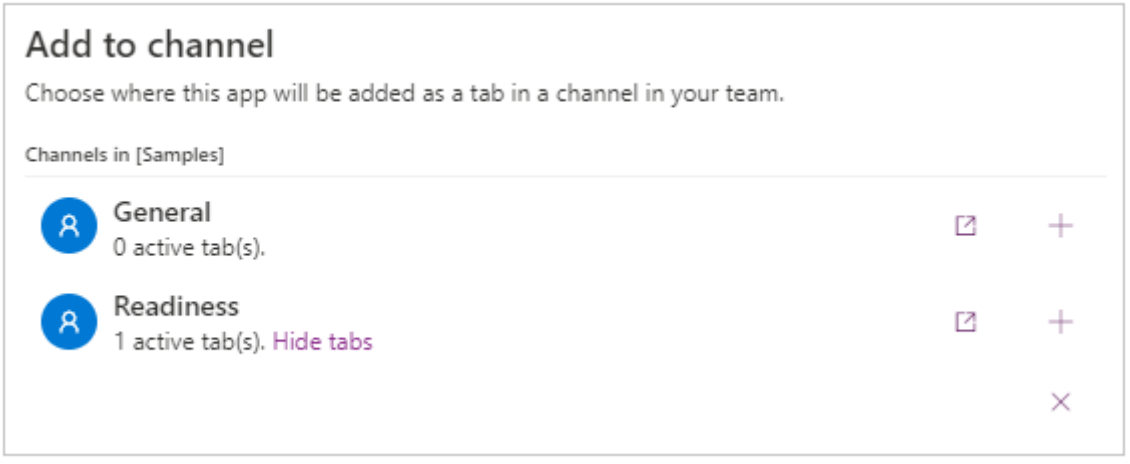
1. Open the app in Power Apps Studio.
2. From upper-right side of the screen, select **Preview**.
3. Select the list of feed items in the gallery on the left.
4. When you select an item, confirm that the *Title*, *Description*, *Publish Date*, and the Video details are displayed.
5. Select the video and confirm the video plays.

Step 5.3: Test additions to the Feeds table

1. Add another feed to the **Feeds** table.
2. Rerun the Power Automate flow.
3. Repeat the above steps.

Step 6: Publish the app

1. Select the **Publish to Teams** icon in the upper right.
2. Select **Next**.
3. Select + next to the channel, such as **Readiness** to add the app to.



4. Select **Save and close**.

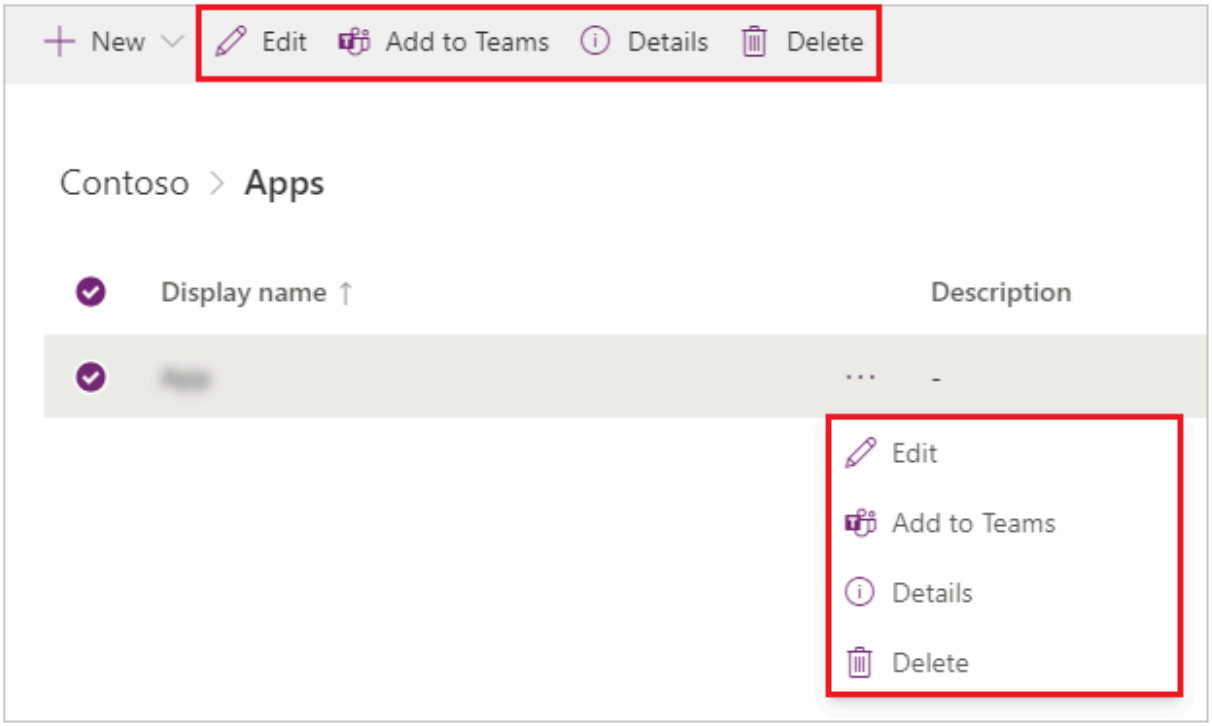
Manage your apps in Teams

Article • 12/16/2022

To manage an app, select **Apps** from the solution explorer. Then select the app that you want to manage, or select **Commands** (...) next to the app name, and then select commands from the drop-down menu.



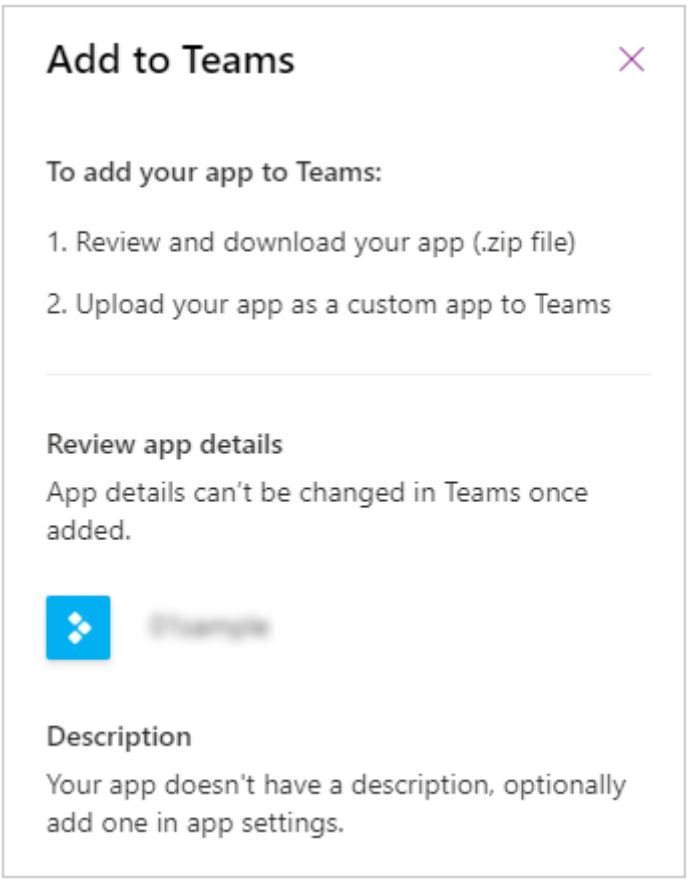
Edit an app

Select **Edit** to edit the app in Power Apps Studio. More information: Edit a canvas app in Power Apps and Understanding Power Apps Studio

> **Tip**
>
> Use this option if you want to rename an app, or change app icon and description. For detailed steps, go to rename an app or change app icon and description.

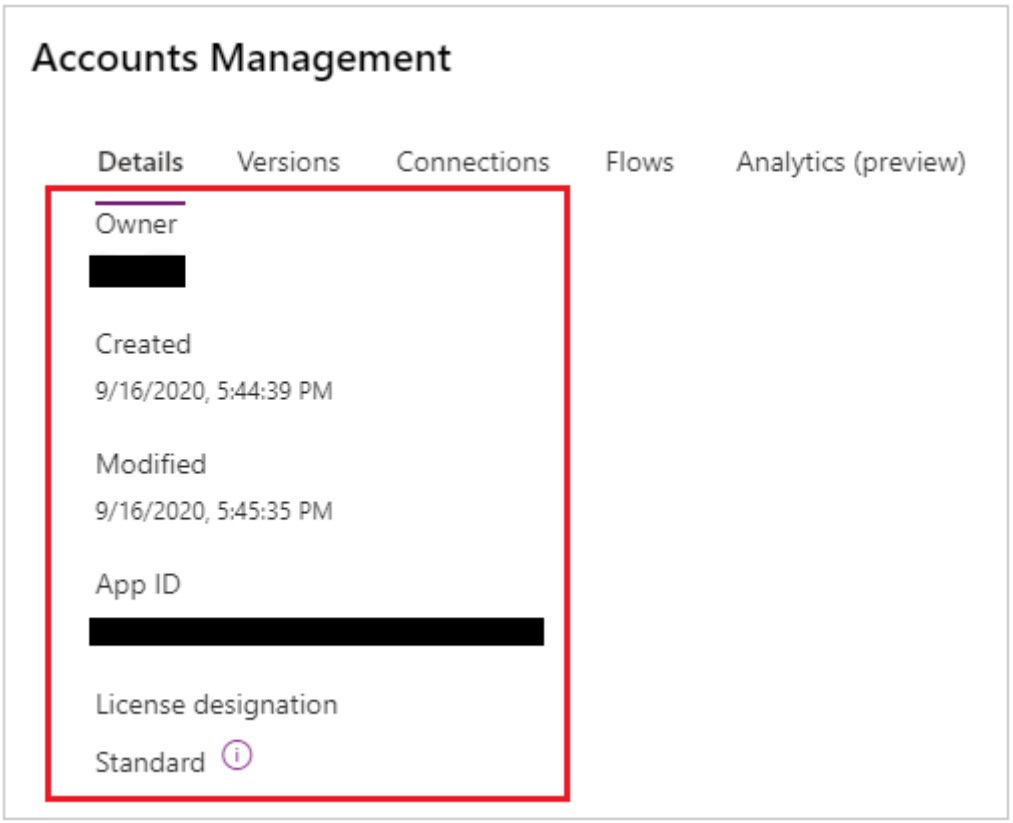
Add to Teams

Allows you to download the app, and then upload to Teams. To learn how to add an app to Teams, go to Embed a canvas app in Teams.



App details

The **Details** option shows the owner of the app, when the app was created and last modified, app ID and license designation.

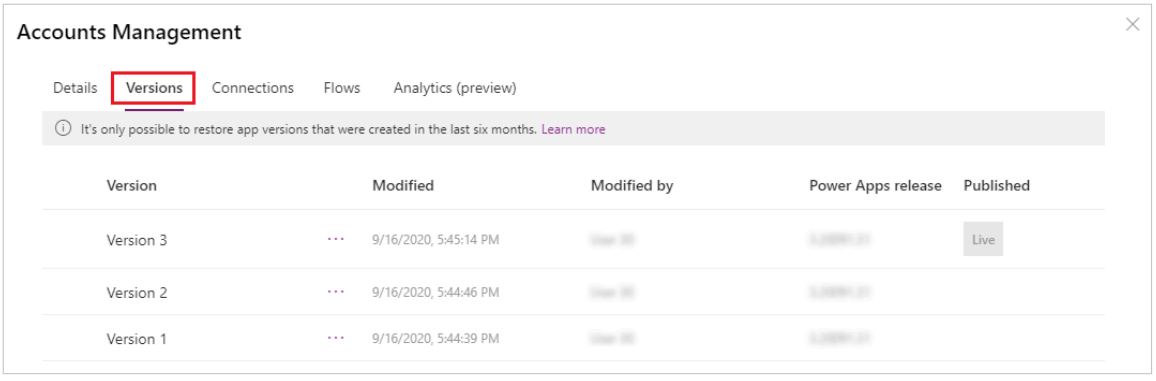


Restore an app

A canvas app can have multiple versions. You can restore an app to an available published version.

To restore an app to a specific version:

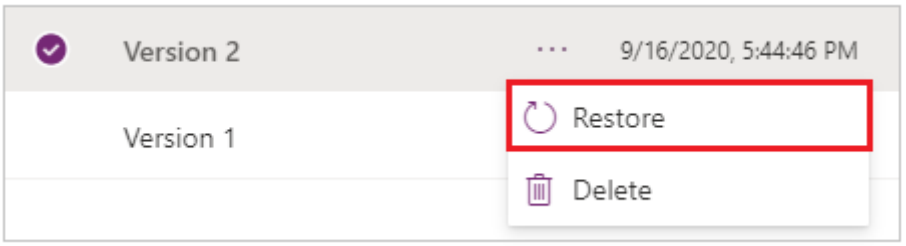
1. Select **Versions** from the app details screen.



2. Select a version other than *Live* that you want to restore.

3. Select ···.

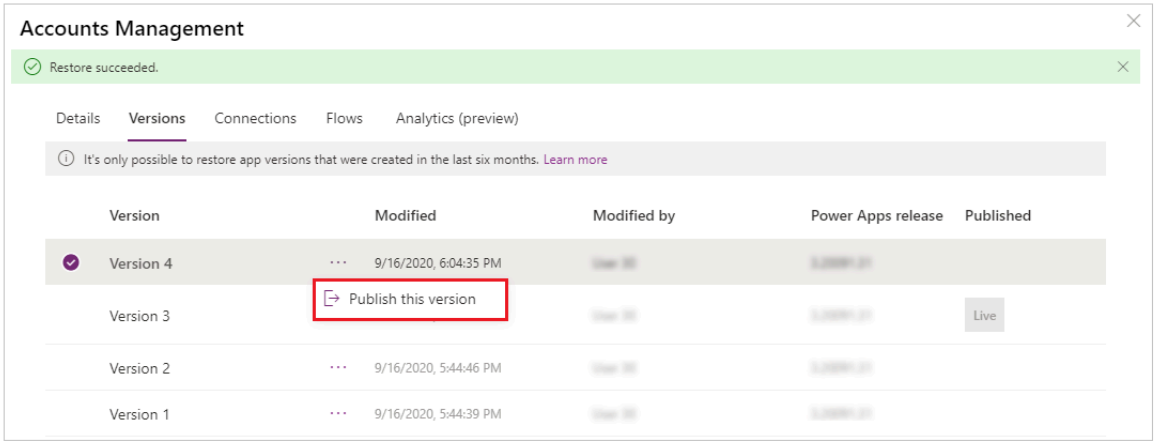
4. Select **Restore**.



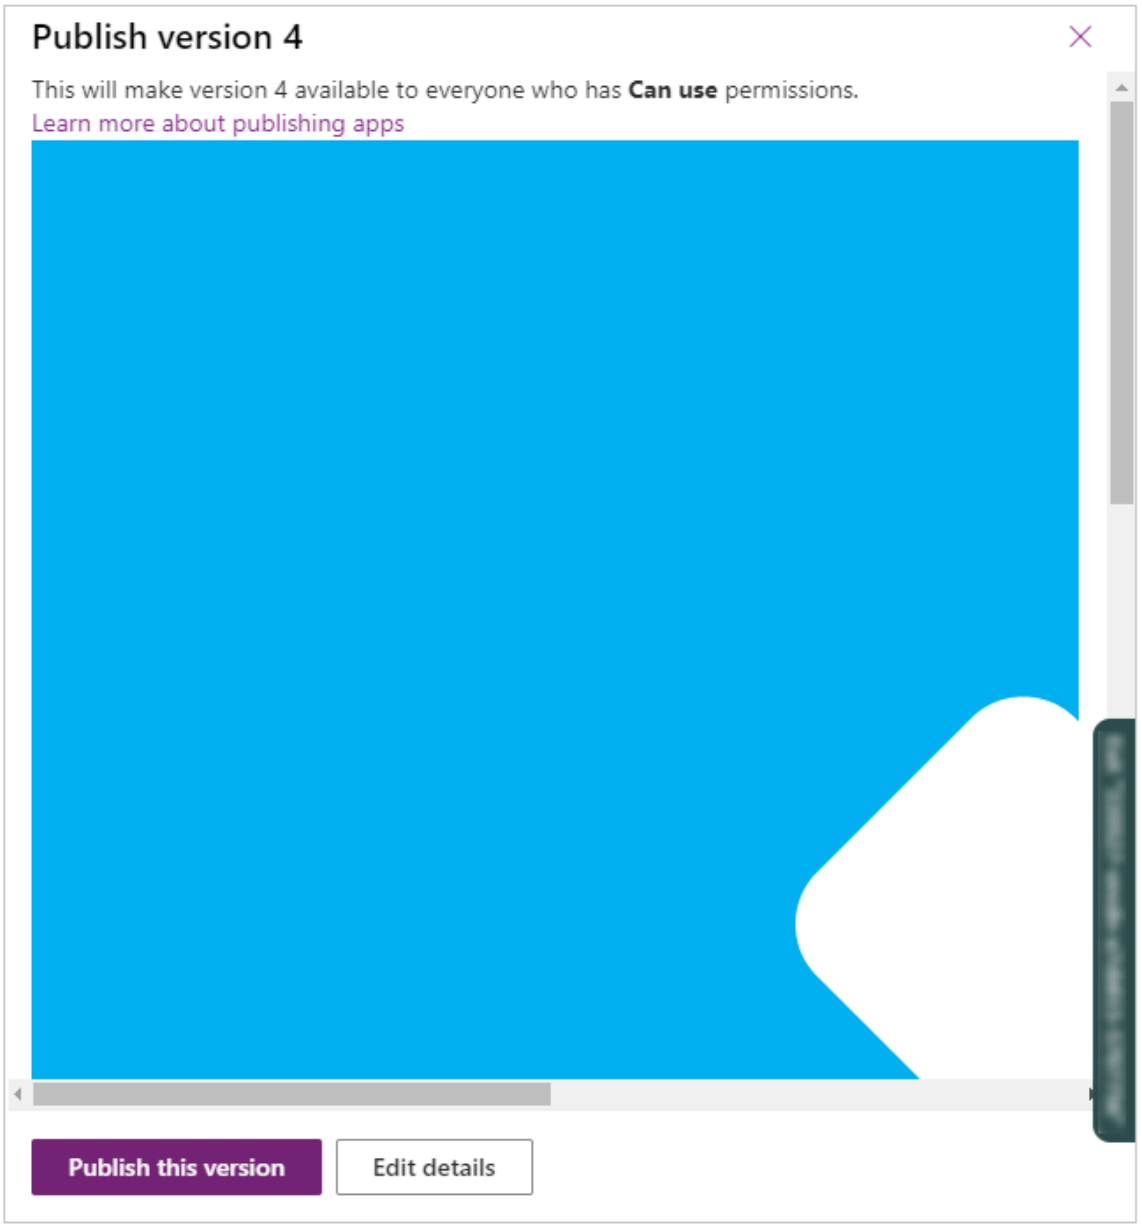
> **Note**
>
> The restored app becomes the latest version of the app. However, the latest version is not yet live. You must publish the restored version to make the restored version available to all users.

5. Select ··· for the restored version.

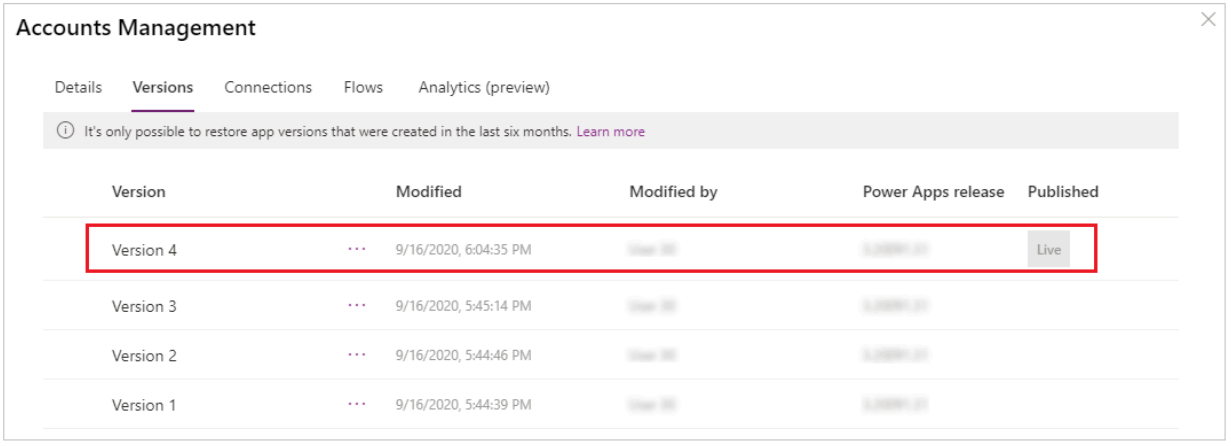
6. Select **Publish this version**.



7. Review the app preview and select **Publish this version** to confirm.



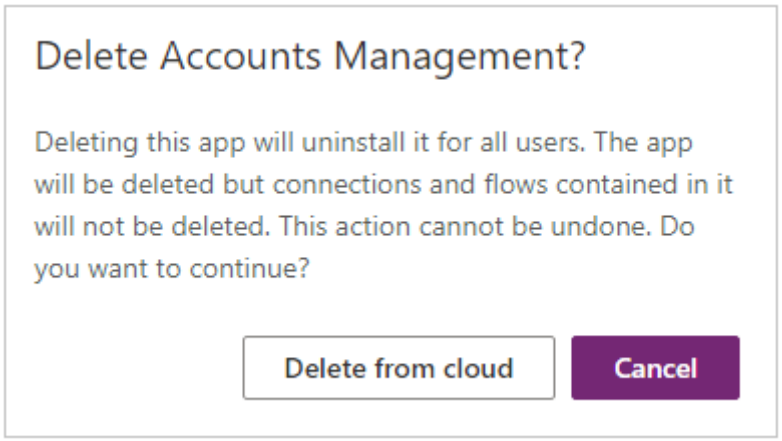
The **Versions** tab now shows the restored version as *Live*:



More information: Restore an app

Delete an app

Select **Delete** to delete an app. When prompted, select **Delete from cloud** to delete the app.

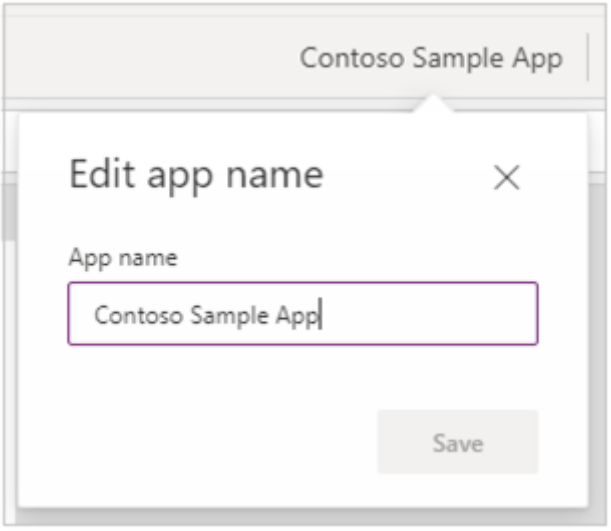


For more information about deleting an app, go to Delete an app.

Rename an app

To rename an app:

1. Edit the app in Power Apps Studio.
2. Select the app name from the top-right.
3. Update the name.



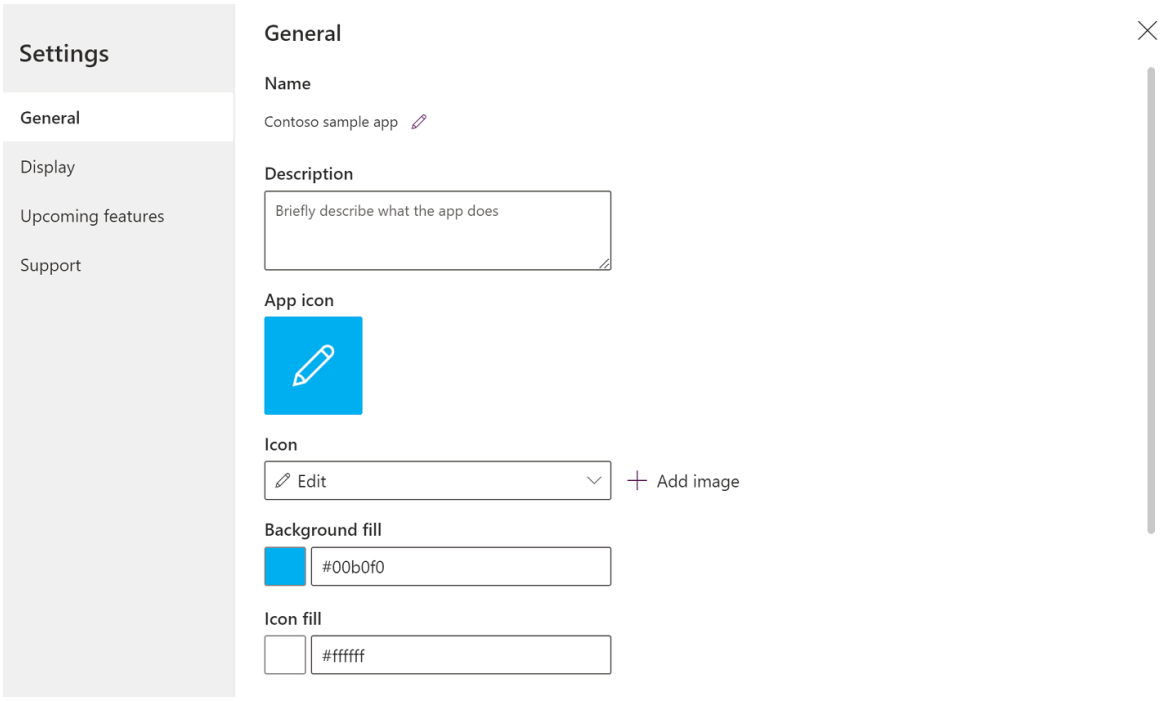
4. Select **Save**.

More information: Edit app editor

Change app icon and description

To change the app icon and description:

1. Edit the app in Power Apps Studio.
2. Select **Settings**.
3. Update the icon and description.



4. Select **Save**.

More information: Change app settings

Set permission and share apps with colleagues

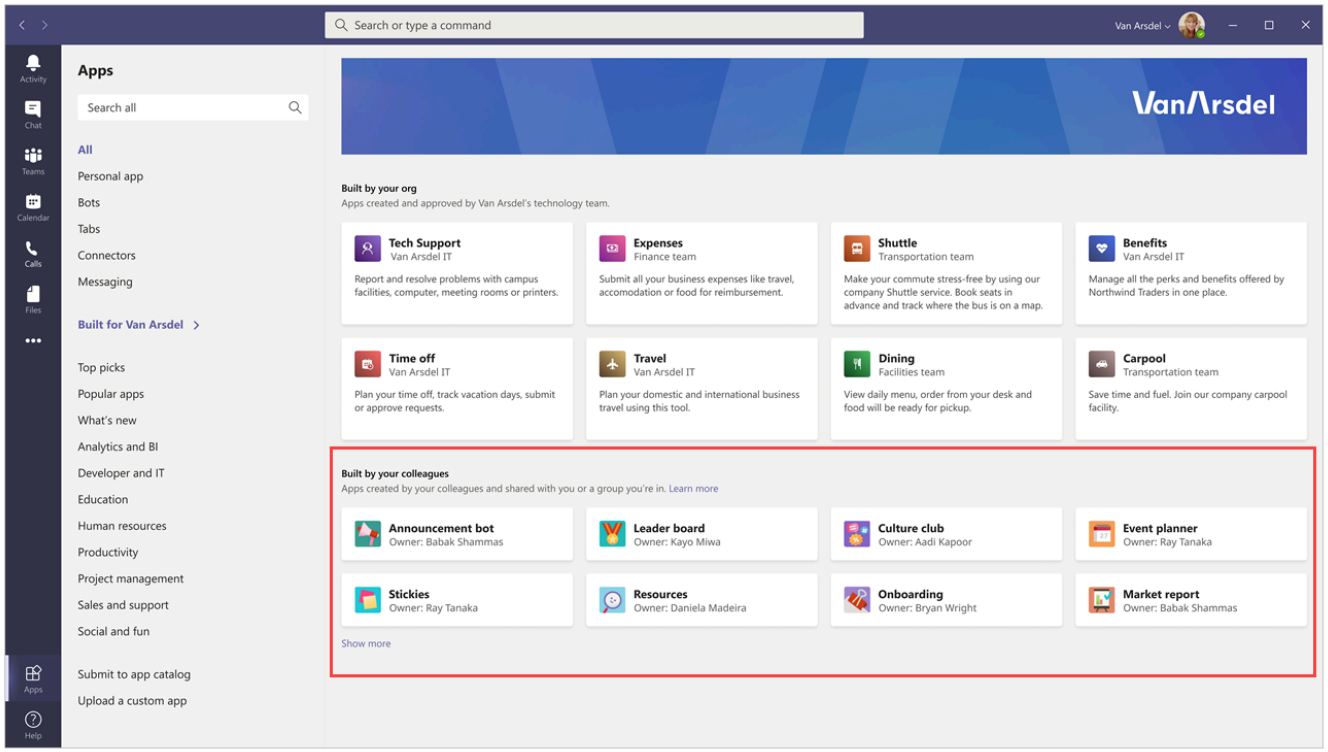
Article • 05/12/2025

After collaboration with your team to build an app, as an owner of the team, you can share the app and its underlying data with other colleagues within your company that don't belong to your development team.

To share an app:

1. Assign the correct permissions for the tables in your app for the **Colleagues with access** role.
2. Select a security group you would like to assign to the **Colleagues with access** role.
3. Choose which apps the **Colleagues with access** role should have access to.

Once you're done sharing your apps, they'll appear in the Built for your colleagues section within the Teams app store. If you're a Teams admin, you can also pin apps for users in the Teams app bar for even easier discovery.



> **Note**
>
> - If your app doesn't appear in the **Built by your colleagues** section, your Teams app might be caching information. If this happens, try signing out, and sign back in if

you're using the Teams desktop app. If you're using Teams web app, try refreshing your browser.

- You need to be an owner within the team to share apps and edit table permissions. If you are not an owner, the **Manage permission** and **Share with colleagues** options won't appear.

Assign table permissions

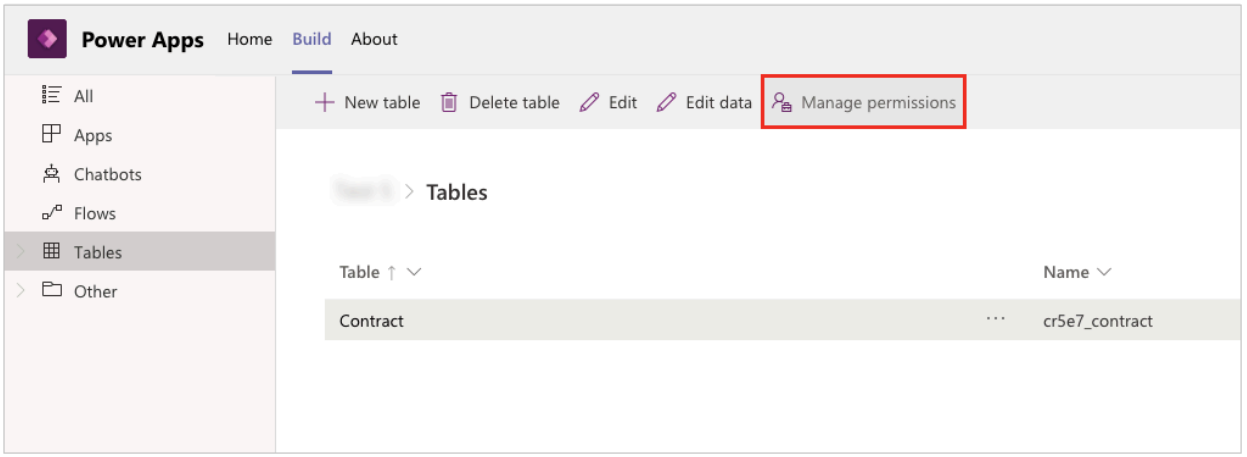
By default, the **Colleagues with access** role has no access to the data inside any of the custom tables you built using Dataverse for Teams. If you would like users outside of your team to access this data, you'll need to change the default access to one of these four permission sets:

- **Full access** – Allows end users to see and edit all records in the table.
- **Collaborate** – Allows end users to see all records, but they can only edit their own records.
- **Reference** – Provides a read-only view of data for end users.
- **Private** – Allows end users to only view and edit their own data.

> ⓘ **Note**
>
> You can also use this experience to alter the default access rights for members and guests within your team. By default, Team members are given **Full access** and guests are given **Private** access to new custom tables.

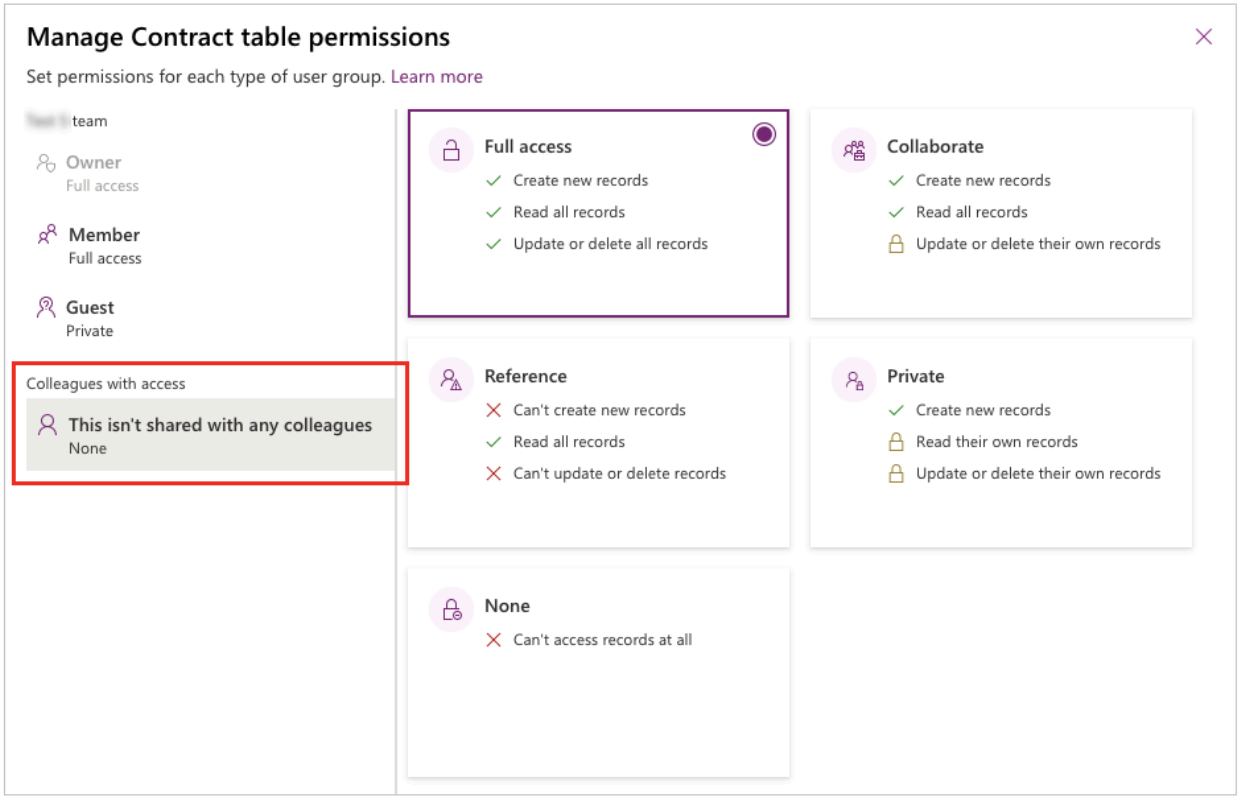
To set the permissions of a table:

1. Select **Build** tab.
2. Select the team that contains the app and tables you want to share.
3. Select **See all** under the list of resources in the team.
4. Select **Tables** from the left pane.
5. Select the table you want to share.



6. Select the **Manage permissions** in the command bar.

7. Under the **Colleagues with access** role, and select the permission set that you want to grant this role.



> **Tip**
>
> After you assign a security group to the **Colleagues with access** role, you'll see the name of the security group reflected in the table permission panel.

8. Select **Save**.

9. Repeat the above steps for the remaining tables in your app.

> **Important**
>
> When using **Share app with Colleagues in the Microsoft Teams app store** and the security group doesn't exist in the Dataverse organization, the Teams app will be created and assigned the **Basic User** role.

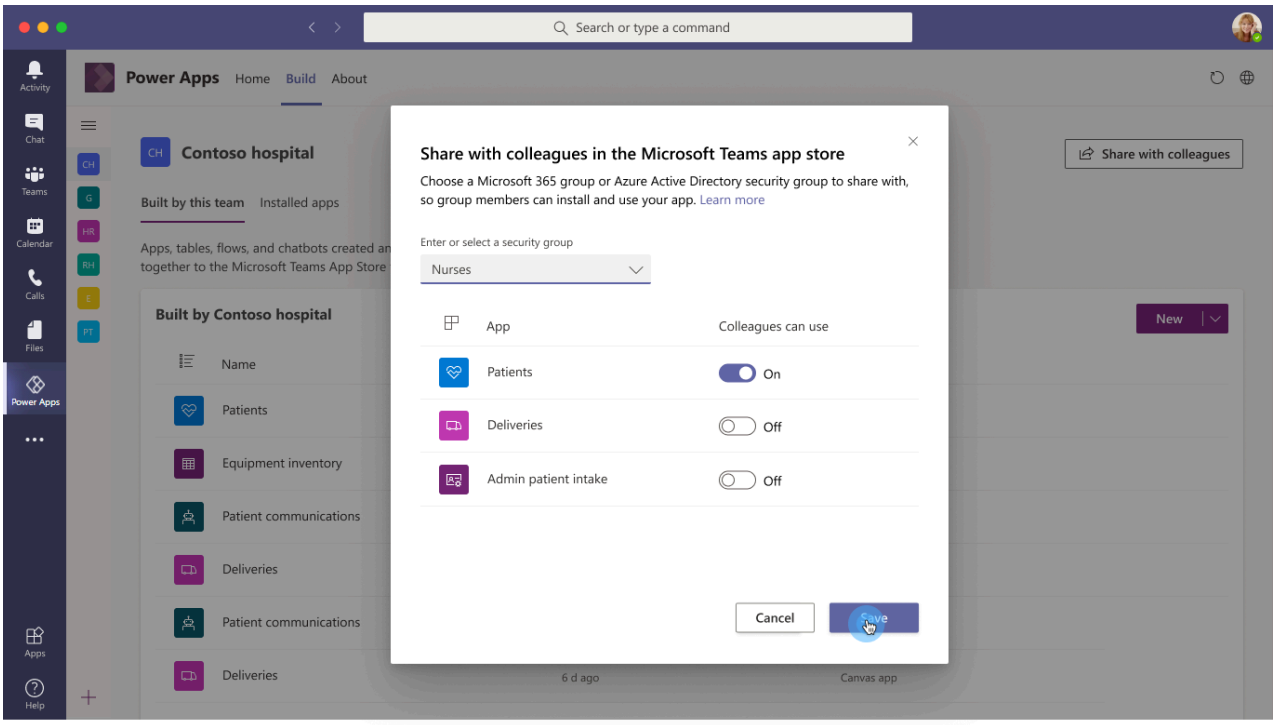
Assign the colleagues with access role to a security group and share the app

After you've completed setting the permissions to all your tables, you're now ready to share the app with an existing security group.

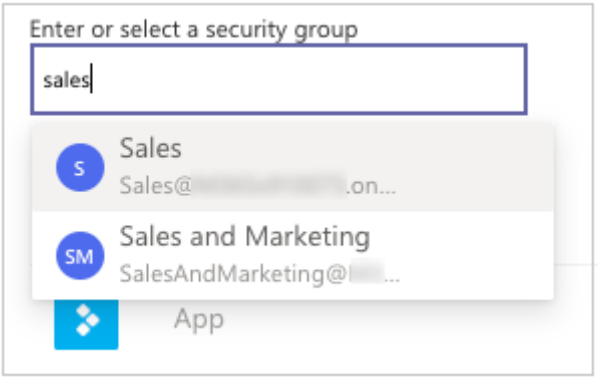
> **Note**
>
> - You can share an app to a single security group.
> - If you want to share the app to a Microsoft 365 group, it must be security enabled.
> - The security group's membership type must be **Assigned**. More information: Group membership types in Azure Active Directory
> - Your Power Apps administrator may have applied the limit to the maximum size of the security group. By default, this limit is 10,000 members. More information: List tenant settings (preview) - powerPlatform.teamsIntegration.shareWithColleaguesUserLimit, Set-TenantSettings

To share an app:

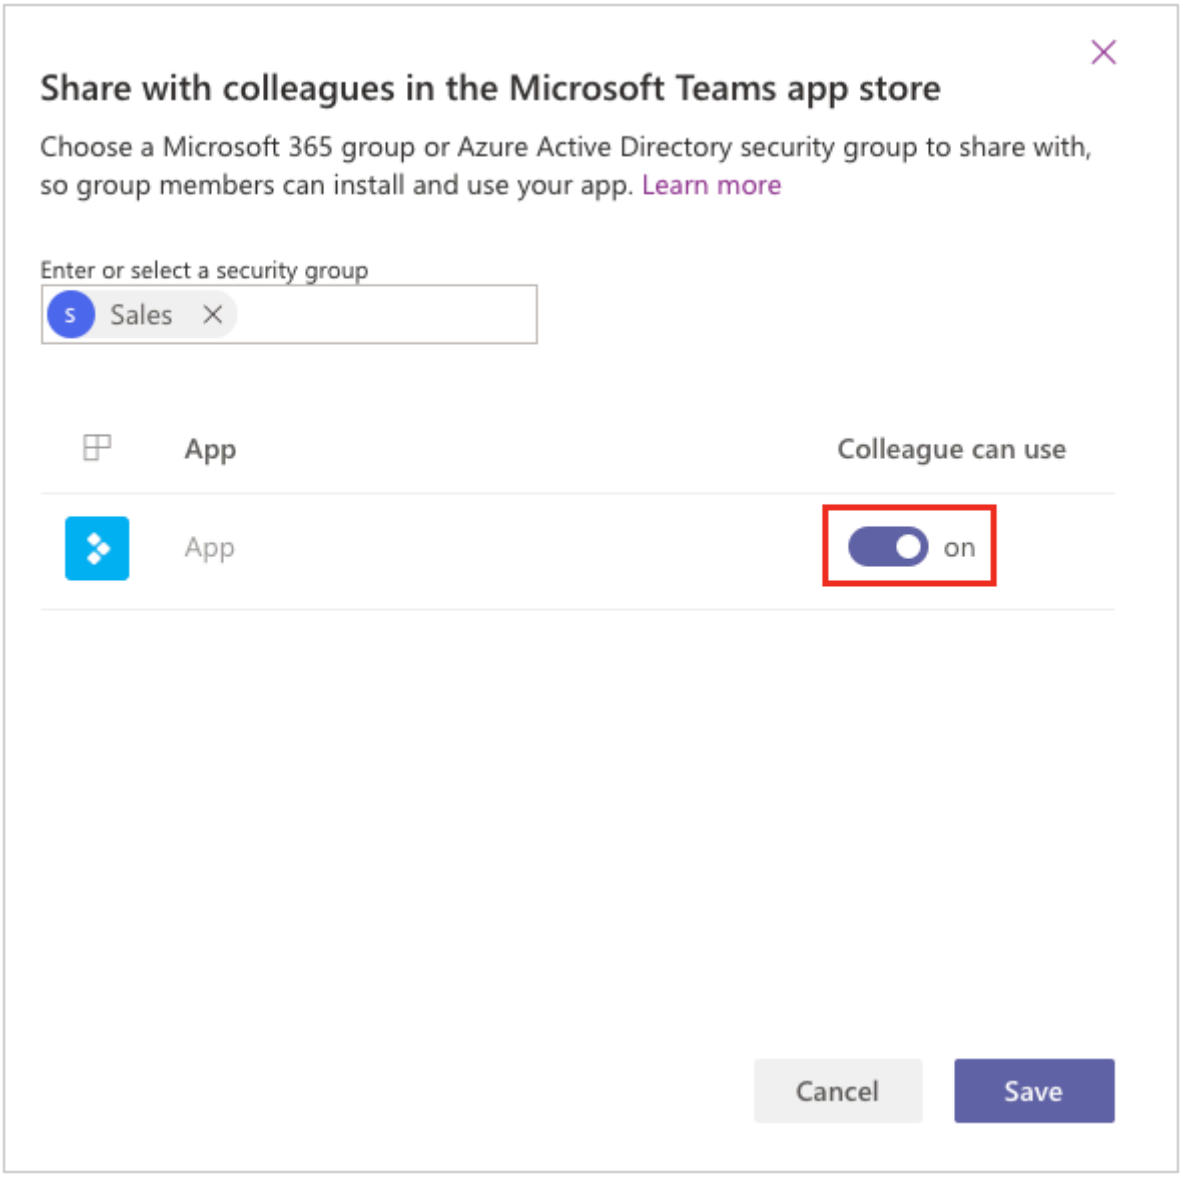
1. Select **Build** tab.
2. Select the team that contains the app you want to share.
3. In the top-right, select the **Share with colleagues**.



4. Search for, and select the security group you want to share the apps and tables with.



5. Set **Colleague can use** toggle to **On** for the apps and tables that you want to share with the security group selected in the previous step.



6. Select **Save**.

The apps you selected will now appear in the Built for your colleagues section within the Teams app store.

Optional: Pin the app to the app bar as a tenant administrator

If you're a tenant administrator, you can go one step forward and pin the apps for end users in Teams. To pin apps in Teams, follow the steps to add an app to the app catalog, and then, edit or create a new Teams app setup policy with your app.

Publish your app in Teams

Publish your app in Teams

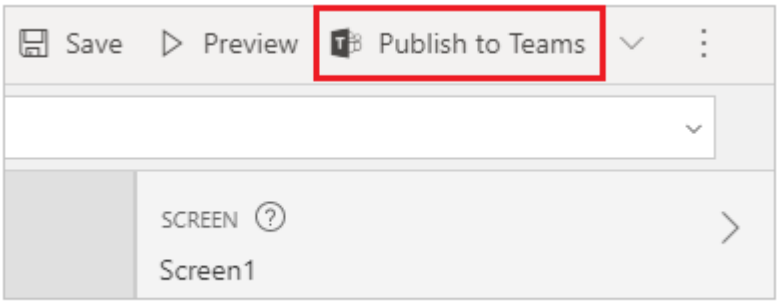
Article • 12/16/2022

In this article, learn about how you can publish and add apps to Microsoft Teams team.

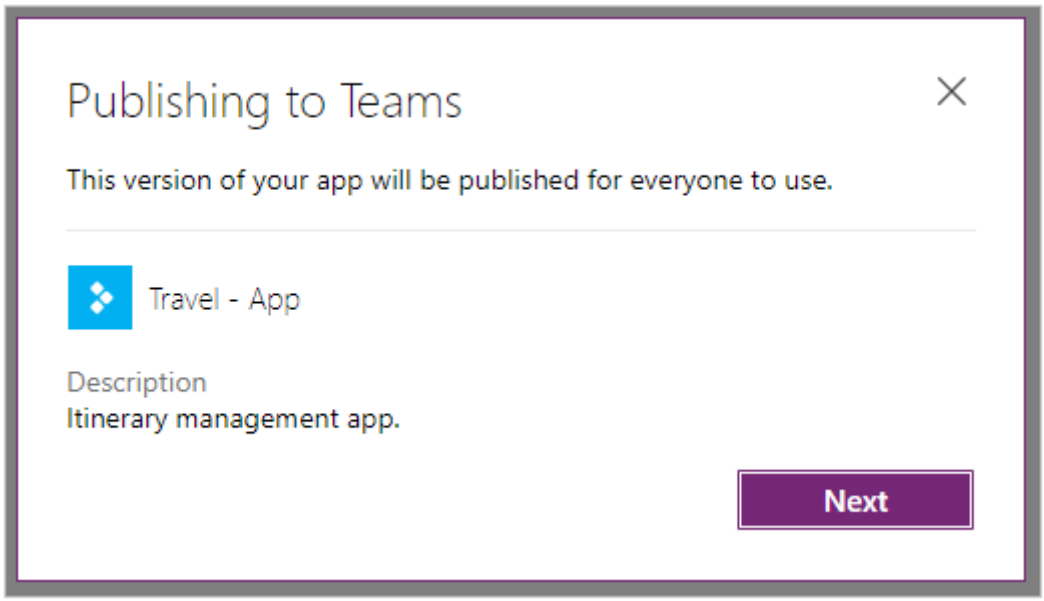
Publish and add an app to Teams

Whenever you save changes to a canvas app, you automatically publish them only for yourself and anyone else who has permissions to edit the app. When you finish making changes, you must explicitly publish them to make them available to everyone the app is shared with.

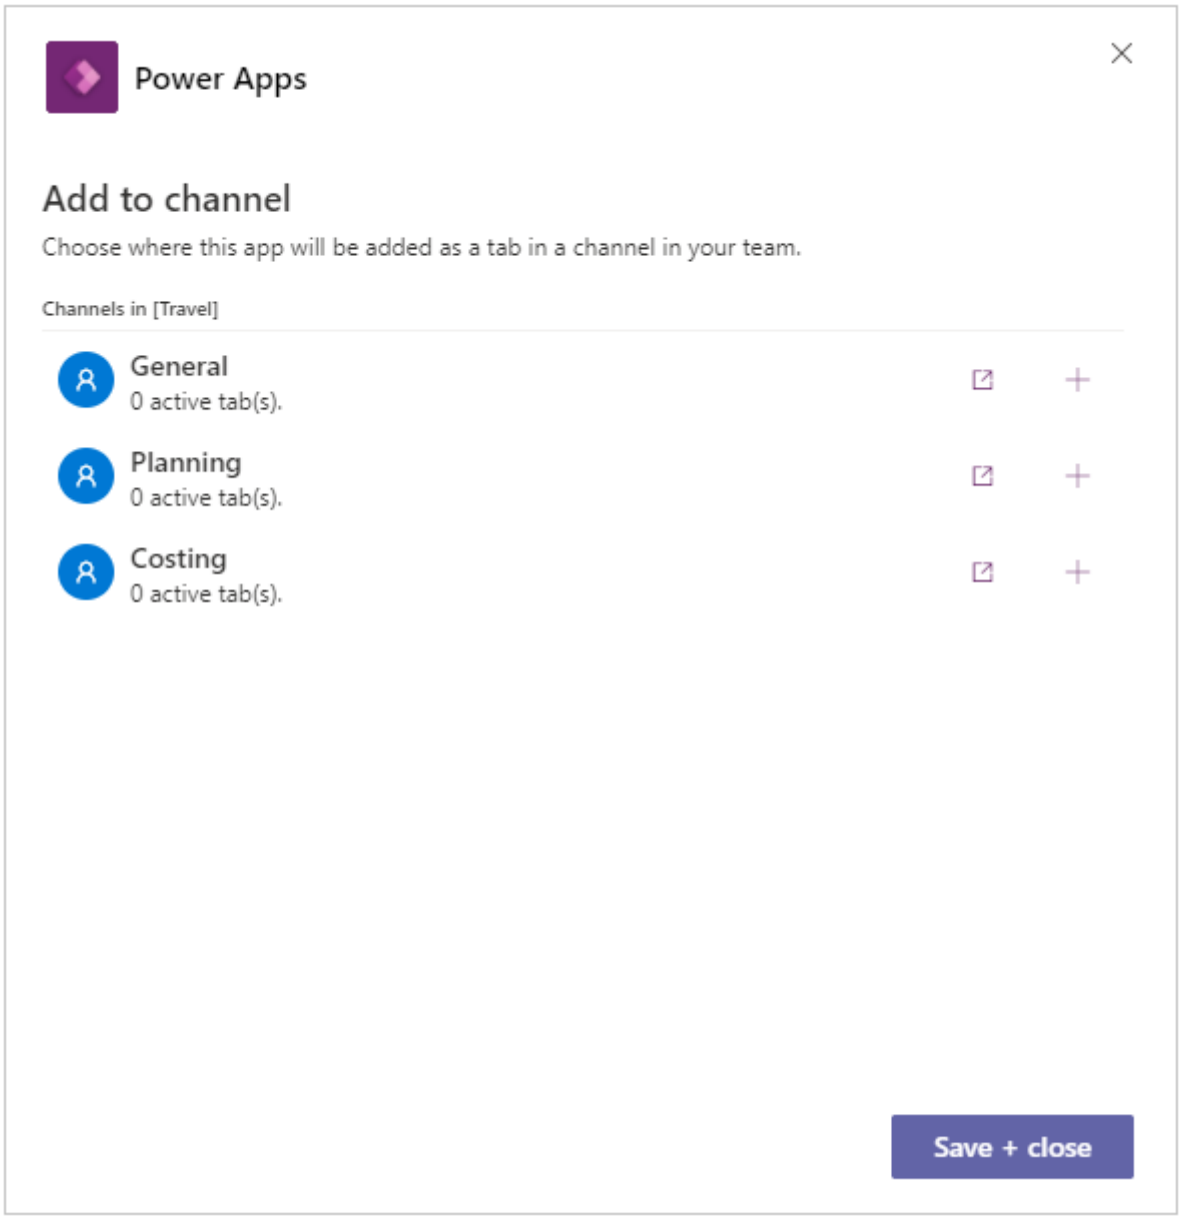
To publish an app, select the **Publish to Teams** button from the top-right side of Power Apps Studio.



Select **Next.** Publishing an app creates a new version of the app and makes the published version of the app available to everyone else the app is shared with.

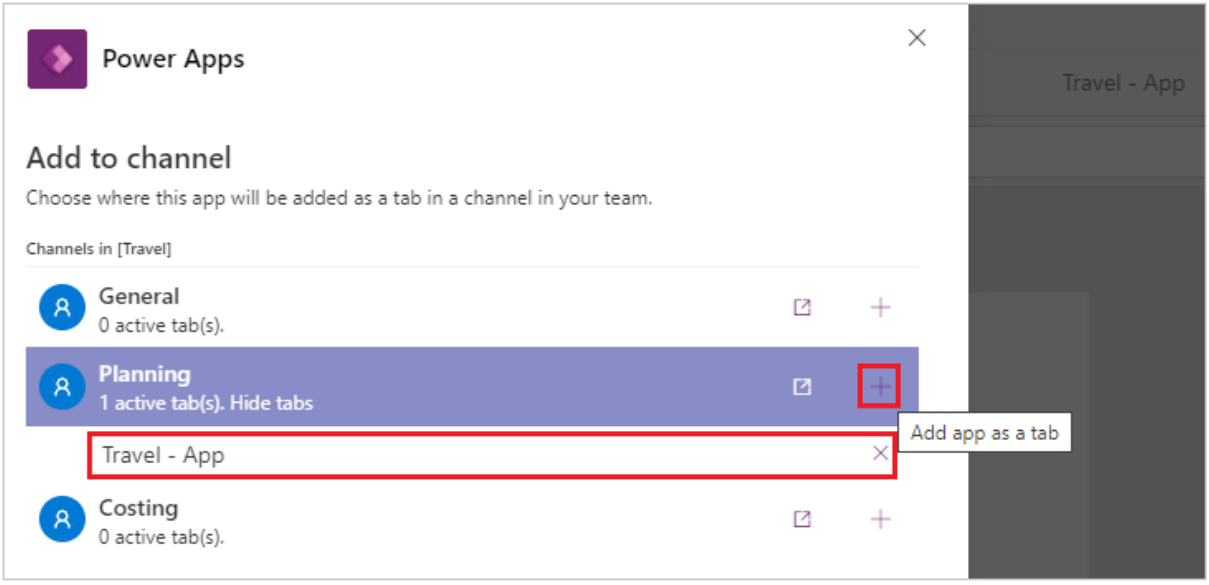


A list of all channels is displayed. You can add the app to one or more channels as a tab in the team.



Select **Add a tab** +, and then select **Save + close**.

> **Tip**
>
> If the app is already published to a Teams channel as a tab, you'll have the option to **Show tabs**.
> To publish updated version of an app to an existing active tab, select **Save + close** without adding a new tab.
> To add published version of an app to a new tab in a different channel, Select **Add a tab** + for the channel you want, and then select **Save + close**.



More information: Publish an app

Move an app to another Teams channel in the same team

Moving an app to another Teams channel in the same team requires publishing the app to the new channel, and then, removing the app from the old channel.

- To publish an app to the new channel: Follow the steps to publish and add an app to Teams. But before you select **Save + close**, select **Add a tab** + for the new channel you want. And then, select **Save + close** to publish the app to the new channel.
- To remove the app from a channel: Follow the steps to remove an app.

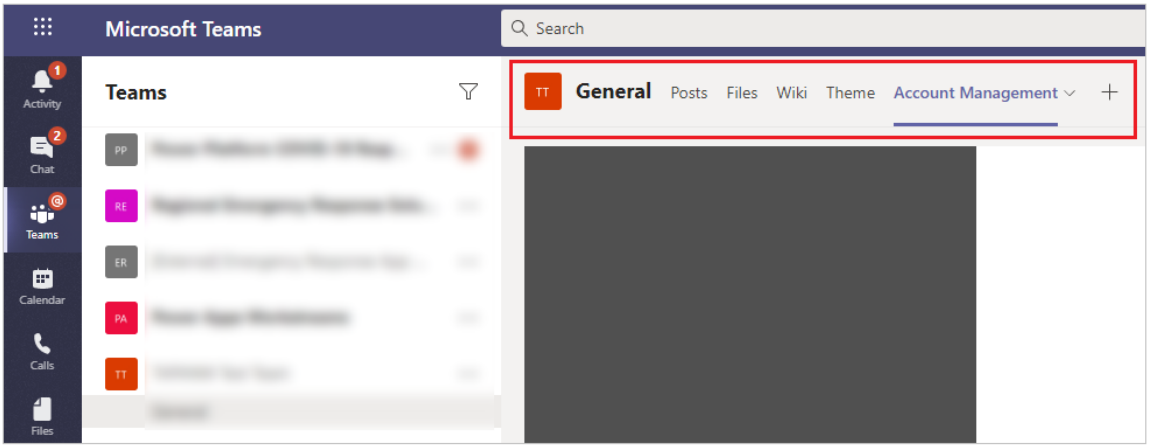
Remove an app from your team

Article • 12/16/2022

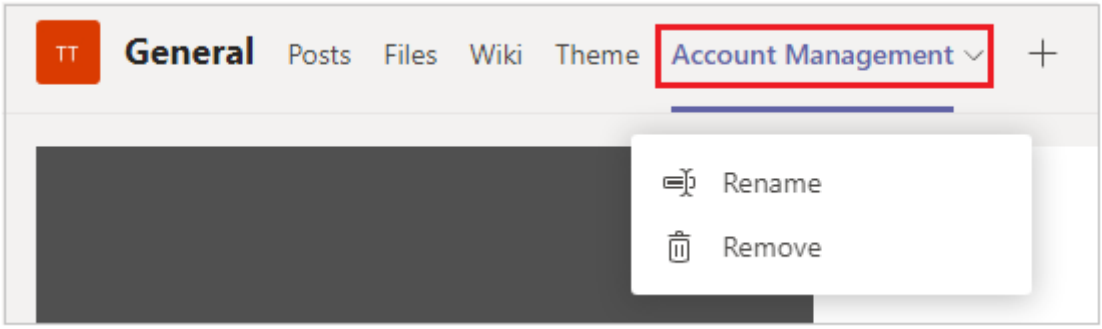
Removing an app that was added as a tab from a Microsoft Teams channel makes it inaccessible from the Teams tab for all members of the Teams channel.

To remove an app from your team:

1. Go to the team that you added the app to.

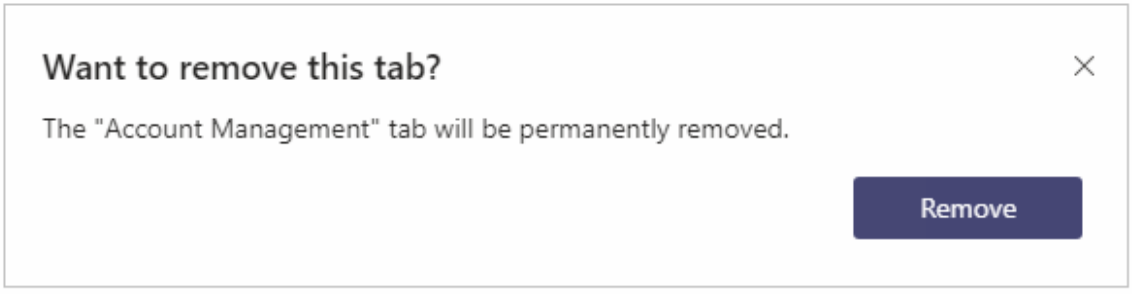


2. Select the drop-down for the tab.



3. Select **Remove**.

4. Confirm **Remove**.



The app is now removed from your Teams channel.

Uninstall the Power Apps personal app

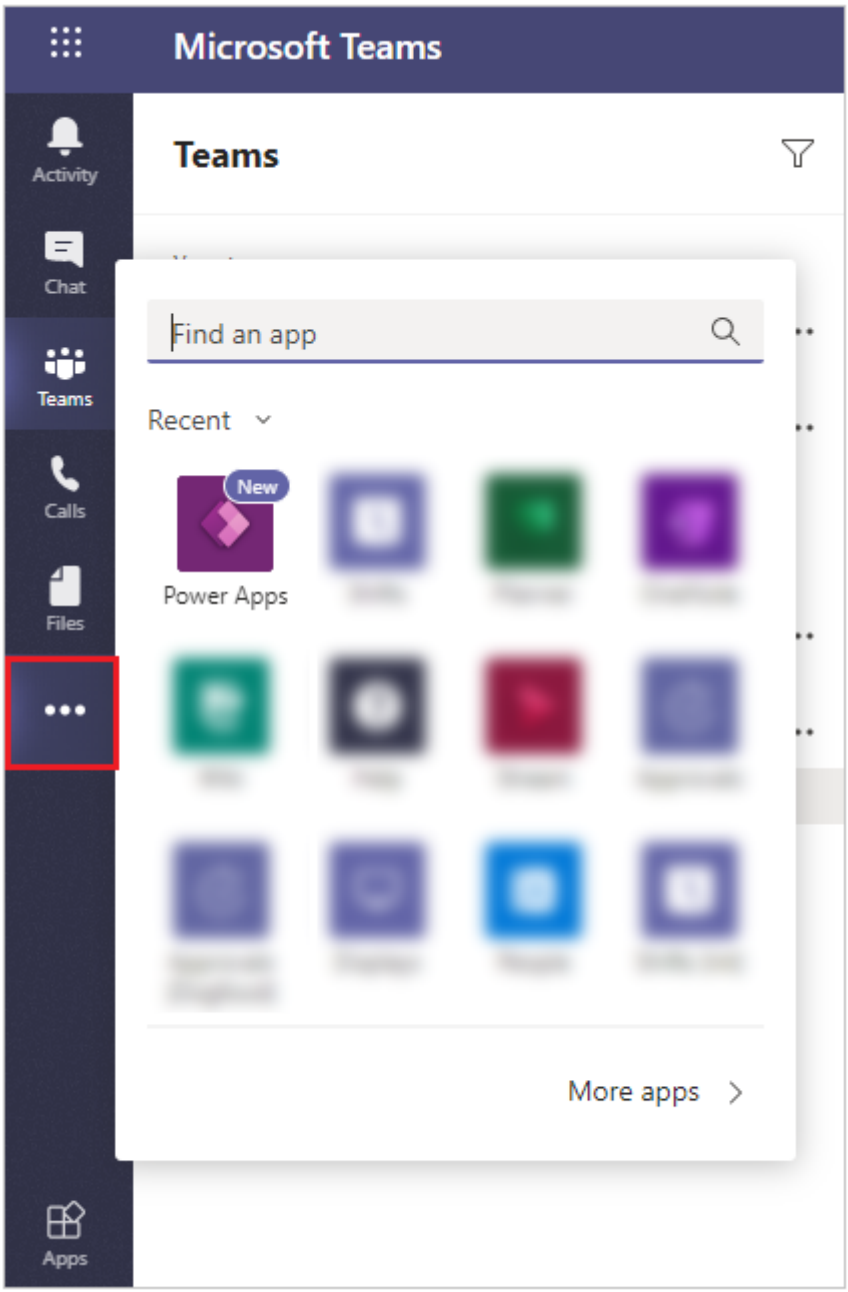
Uninstall the Power Apps personal app

Article • 03/03/2023

Uninstalling the Power Apps app removes the app as a personal app available to your account. Uninstalling the Power Apps app doesn't uninstall or remove the apps created by using Power Apps from the respective Microsoft Teams channels.

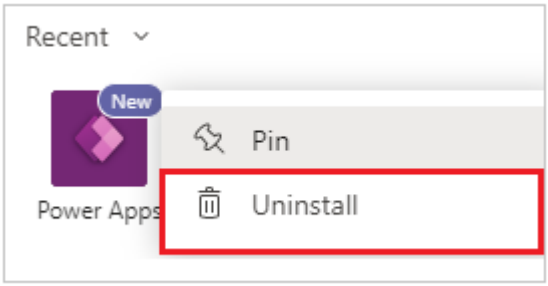
To uninstall the Power Apps personal app:

1. Select ••• on the left pane in Teams.

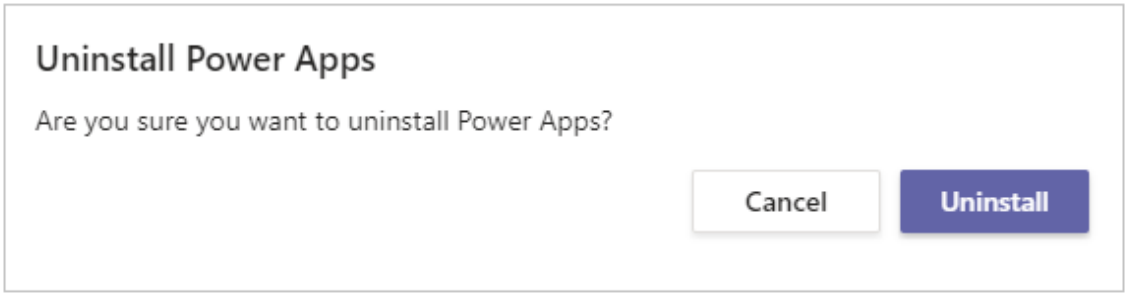


2. Find the Power Apps app by using search, if it's not visible in your most recent view.

3. Right-click to select **Power Apps** app, and then select **Uninstall** from the shortcut menu.



4. In the window that appears, select **Uninstall**.



The Power Apps app is now uninstalled from Teams.

Use sample app templates in Microsoft Teams

Article • 02/15/2023

Several sample app templates are available for use in Microsoft Teams that you can download from here. You can choose the sample app template that best fits your business requirement and quickly install it to get started. Sample app templates created with Power Apps typically consist of multiple components such as apps, flows, and tables.

> **Important**
>
> Sample app templates available for **download** are provided as-is. For any issues, feedback, support, or changes related to sample app templates, go to **https://github.com/microsoft/teams-powerapps-app-templates/issues** and submit an issue or a pull request.

Available sample app templates

The following table lists sample app templates available for download.

Boards

A simple way to connect and share with people in your organization with similar interests.

Bulletins

Manager and user apps for company communications.

Employee ideas

App for campaigns and ideas.

How to

Learn how to be a Power Apps maker.

Inspection

Manager and user apps for area inspections.

Issue reporting

Manager and user apps for issue reporting.

Milestones

App to keep track of projects, and initiatives.

Perspectives

A simple way to add topics and extend the topics with Q&A for discussions.

Profile+

Quickly find out about people in your organization.

Get connected
Connect with people in your organization with similar skills.

The following tutorial shows how to install the Employee ideas app. You can use similar steps to install other sample app templates.

Install the sample app template

To learn about installing sample app templates, go to https://github.com/microsoft/teams-powerapps-app-templates.

> **Note**
>
> - Installing sample app templates automatically enables the selected team's Microsoft 365 Group for security. More information: **Enable security for the selected team's Microsoft 365 Group**
> - If you can't upload or install uploaded sample app templates, check your **app permission policies in Microsoft Teams**.

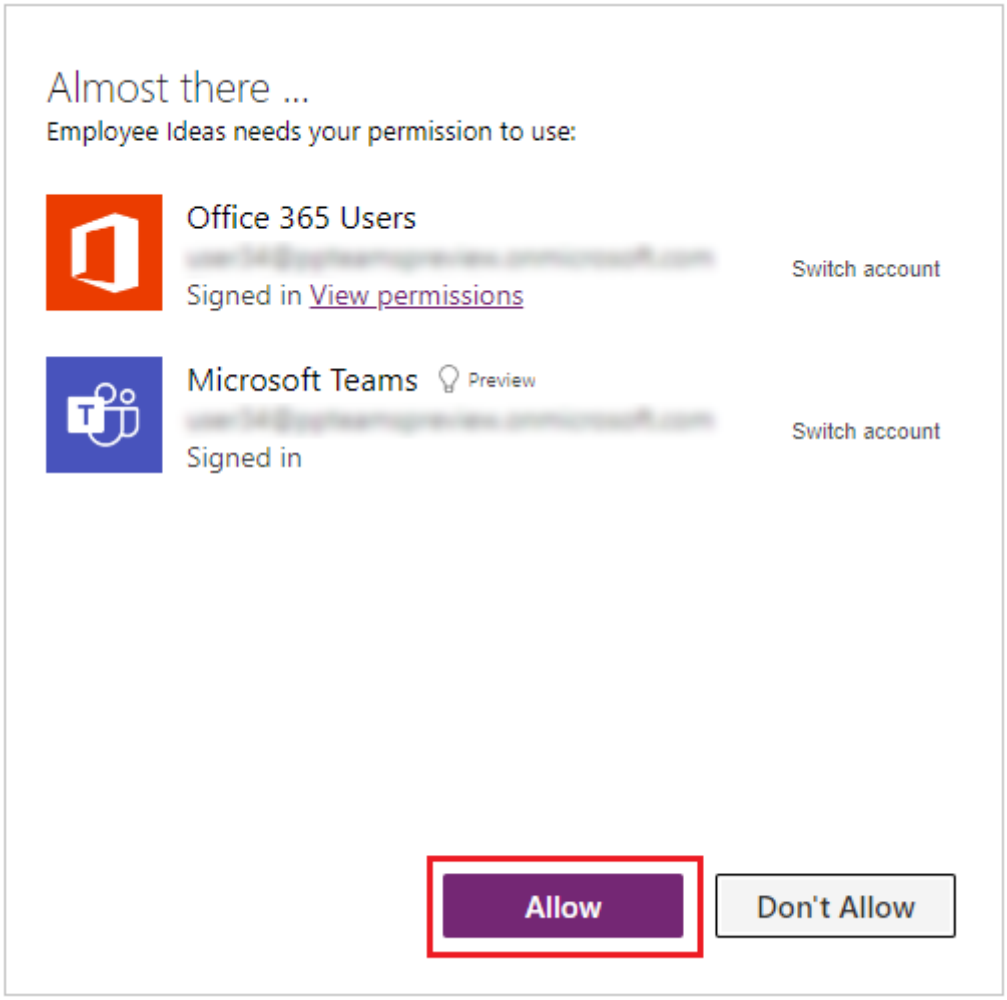
Run the sample app template

To run the installed app, select the app's tab from the team channel. In this example, we'll use **Employee ideas**.

Step 1 - Allow connections

Before you can use the app, it might ask your permission to use connections.

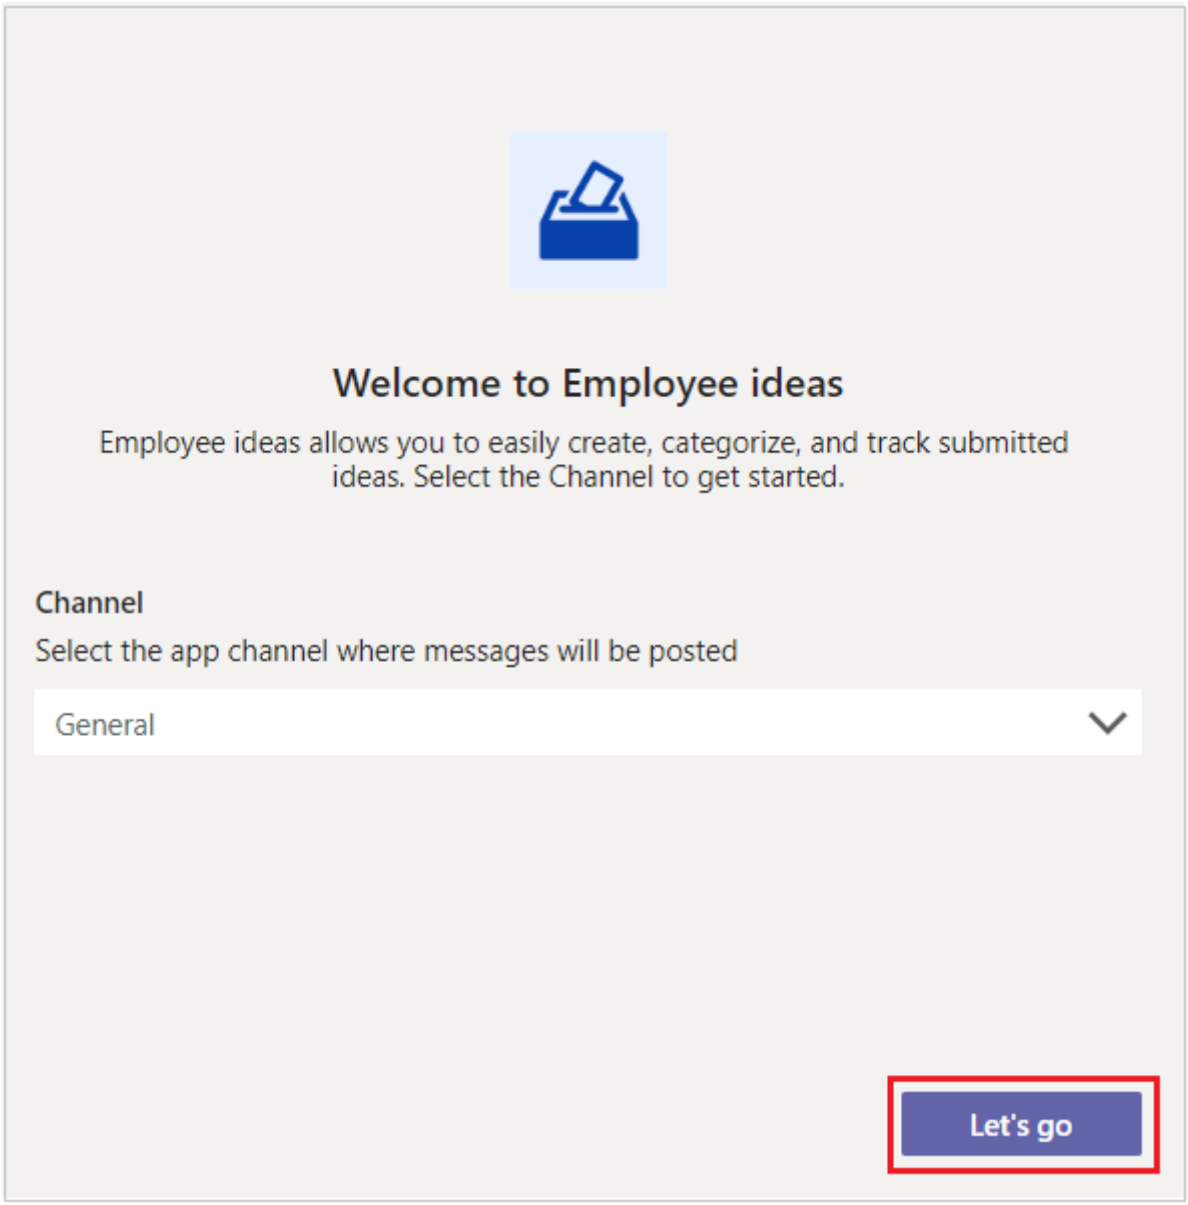
> **Note**
>
> The list of connections you see below is an example. The number and types of connections asking for your permissions may vary depending on the app you install.



Select **Allow**, so the app can use connections.

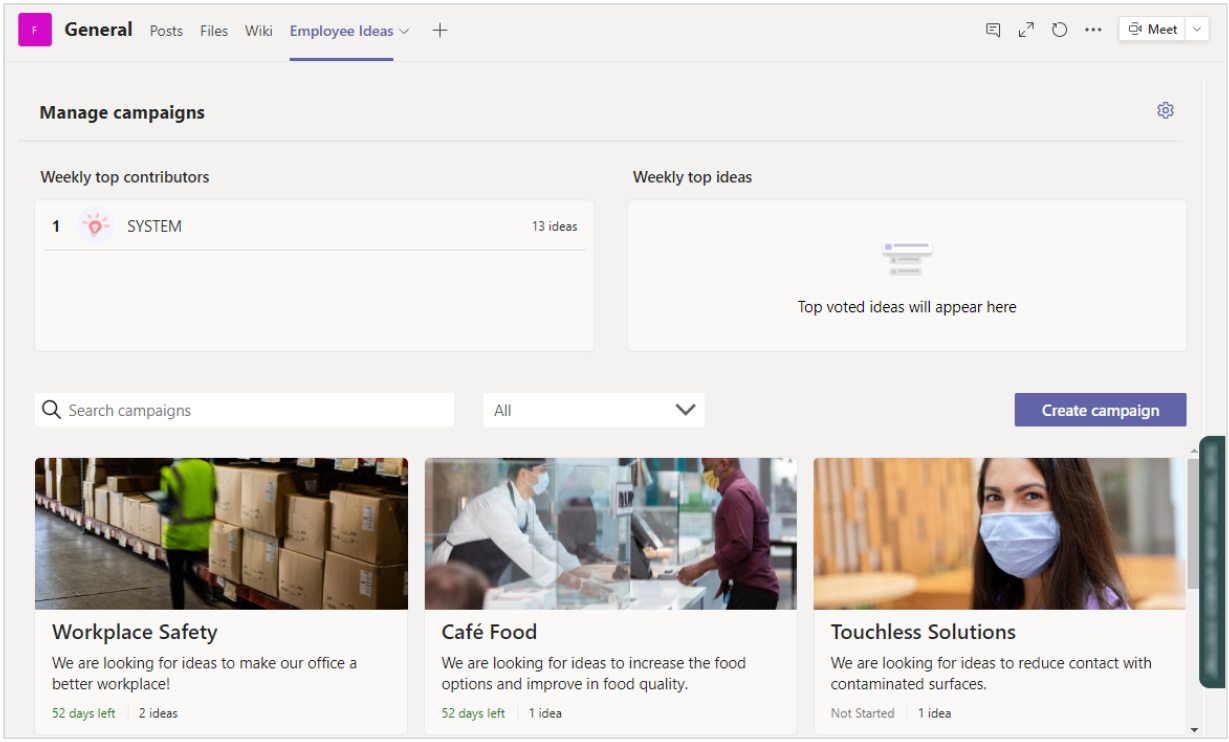
Step 2 - Select the channel

Select the channel (in this example, the channel is populated automatically), and then select **Let's go**.



Step 3 - Use the app

The **Employee ideas** app is now open and ready for your use.



For more details about using the **Employee ideas** app, go to Employee ideas.

Edit the sample app template

You can further customize and edit the components of an installed Power Apps app in Teams. More information: Manage your apps

Report installation errors

If you get any errors during the installation process, you can help us troubleshoot the problem much more effectively by selecting **Ctrl**+**Alt**+**A** on the keyboard to get the session details. For more information about session details, go to About tab.

For issues related to the sample app templates, report an issue at https://github.com/microsoft/teams-powerapps-app-templates.

Sample app template updates

Updates to the sample app templates are published immediately. If you already have a sample app template in use when this happens, a new version of the app is created with these updates and published as the live version. If you customized a sample app, you can restore the app to a previous version with your customizations, or recreate the customizations on top of the updated live version. When restoring the app to preserve

your customizations, ensure to check the app functionality for compatibility with the updates.

Sample app templates FAQs

For Frequently Asked Questions about sample app templates, go to Sample app templates FAQs.

Customize sample app templates

Article • 02/08/2023

In this article, you'll learn about customizing sample app templates. For example, you may need to change the company logo, update the data inside the sample app templates to fit your business requirement, add or remove controls on the screens to extend the app.

Prerequisites

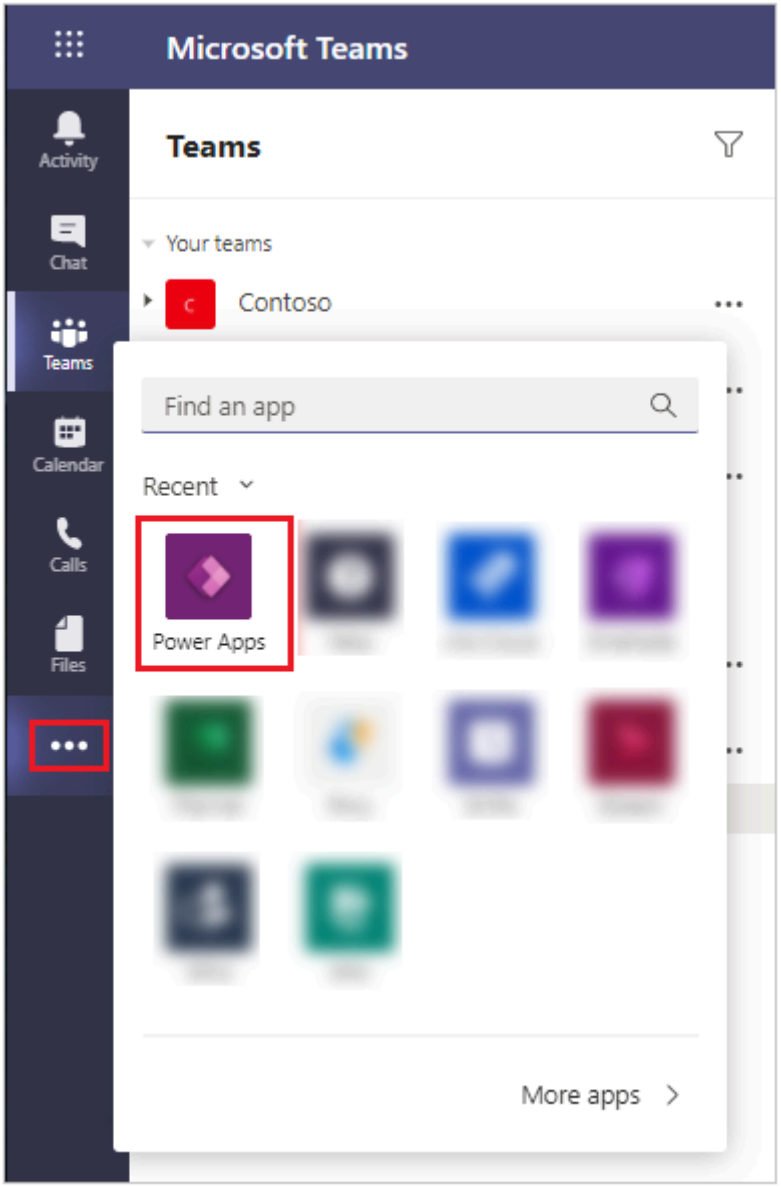
Install a sample app template. More details: Use sample app templates in Microsoft Teams.

> **Note**
>
> - Sections of this article uses one of the available sample app templates as an example. The tables, controls, screens and other components of the apps may vary depending on the app you installed. Use discretion when customizing the app that you select.
> - Read **Sample app template updates** before you customize sample app templates to understand the impact of new releases to the sample app template versions.

Open the sample app templates in Power Apps Studio

To start with customizing the sample app templates, the first step is to open the app inside Power Apps Studio.

1. Sign in to Teams.
2. Select  (*More added apps*).
3. Select Power Apps.



4. Select Build tab.
5. Select the team environment where you installed the sample app template.
6. Select **Installed apps**.
7. Select the sample app template that you installed.
8. If prompted, select the location.

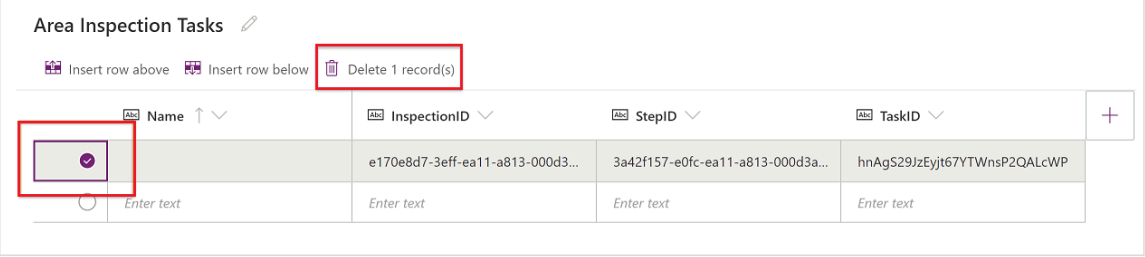
More information: Edit an app in Power Apps Studio

Remove sample data

When you install sample app templates, the tables might be pre-populated with sample data. The following table lists the sample app templates and the list of tables with the sample data to be removed:

To remove data from the sample app templates:

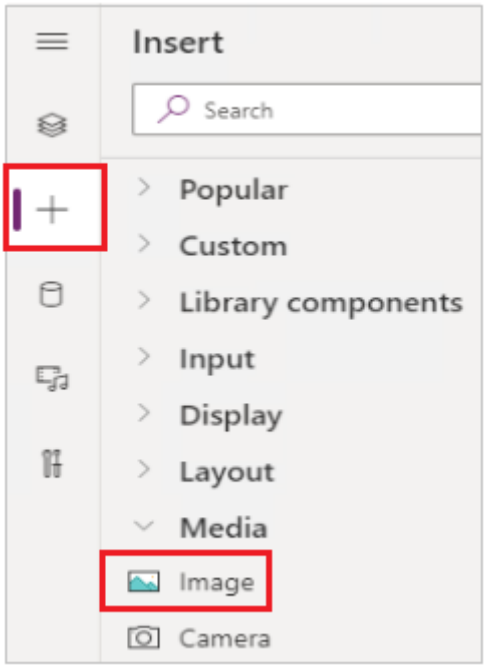
1. Open the sample app template (for example, **Manage inspections**) in Power Apps Studio.
2. Select **Data** from the left pane.
3. Select ... next to the table name (for example, *Area Inspection Task* for **Manage inspections** app).
4. Select **Edit data**.
5. Delete all rows containing sample data.



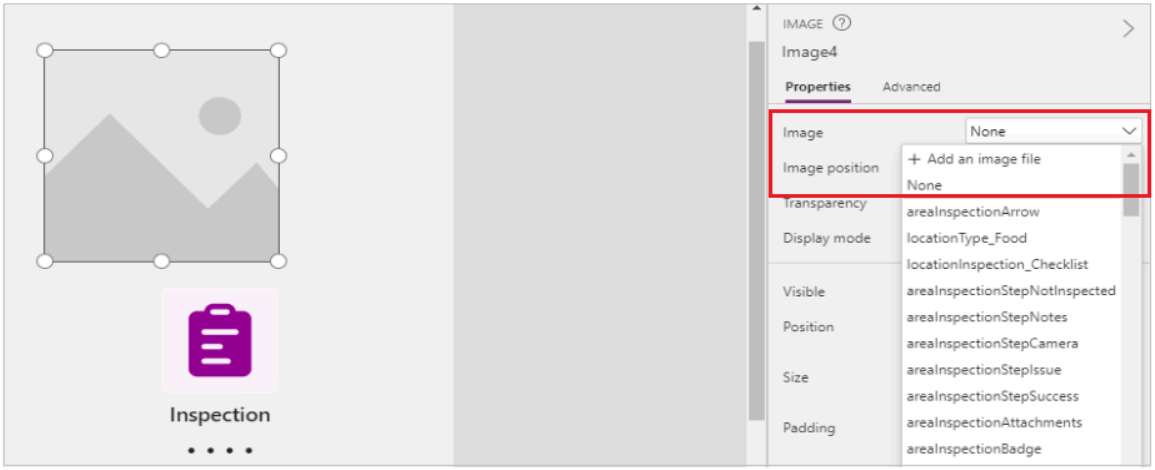
6. Close the visual editor.
7. Repeat the previous steps for the remaining tables.

Add your logo to the loading screen

1. Open the sample app template (for example, **Inspection**) in Power Apps Studio.
2. Select Tree view from the left pane.
3. If not already selected, select **Landing Screen**.
4. Select **Insert**.
5. Select **Image** control in *Media*.

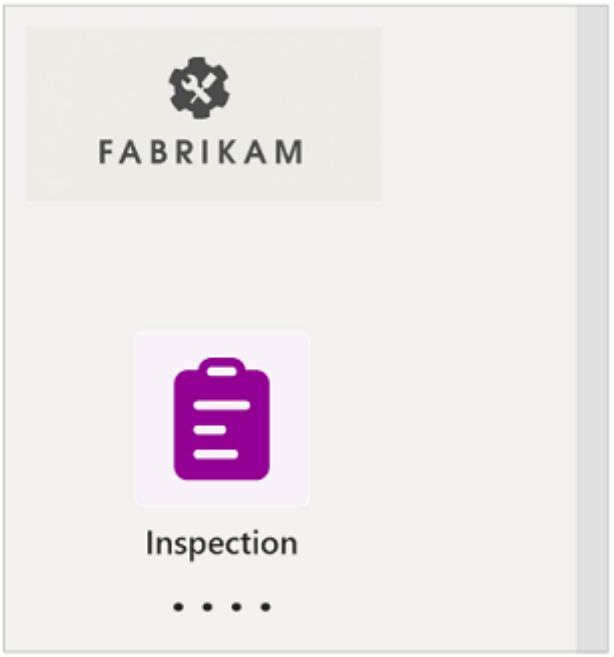


6. From the properties pane on the right side, select the **Image** drop-down, and then select **+ Add an image file**.



7. Select image for your company logo, and then select **Open**.

8. Position and size image control to the position you want on loading screen.



Change the welcome screen text

> **Note**
>
> The Inspection app welcome screen greeting text uses a formula containing global variables to correctly display the desired terminology for inspections and items being inspected. Use caution when changing this formula.

1. Open the sample app template (for example, **Inspection**) in Power Apps Studio.
2. Select the text label control with the greeting text **Glad to have you here**.

   The formula for the greeting text is in this format:

```
Power Fx

"Glad to have you here, we are ready for you to " &
If(Lower(gblWorkType)="inspection", "inspect", Lower(gblWorkType)) &
Switch(
Left(
    Lower(areaLabel),
    1
),
"a",
" an ",
"e",
" an ",
"i",
" an ",
"o",
```

```
" an ",
"u",
" an ",
" a "
) & Lower(areaLabel)
```

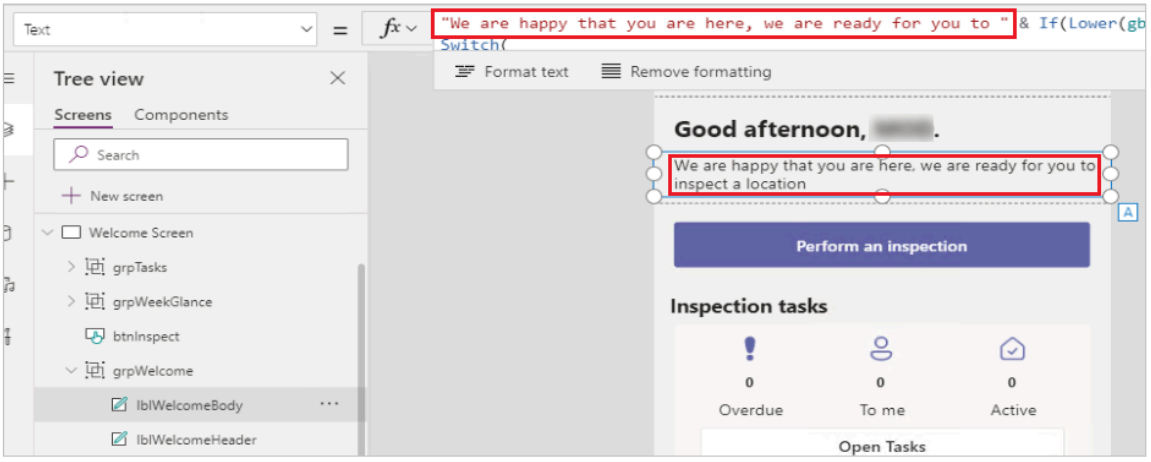
3. Select the formula bar.

4. Select the phrase **Glad to have you here**.

5. Update the greeting text, such as **We are happy that you are here**.

Power Fx

```
"We are happy that you are here, we are ready for you to " &
If(Lower(gblWorkType)="inspection", "inspect", Lower(gblWorkType)) &
Switch(
Left(
    Lower(areaLabel),
    1
),
"a",
" an ",
"e",
" an ",
"i",
" an ",
"o",
" an ",
"u",
" an ",
" a "
) & Lower(areaLabel)
```

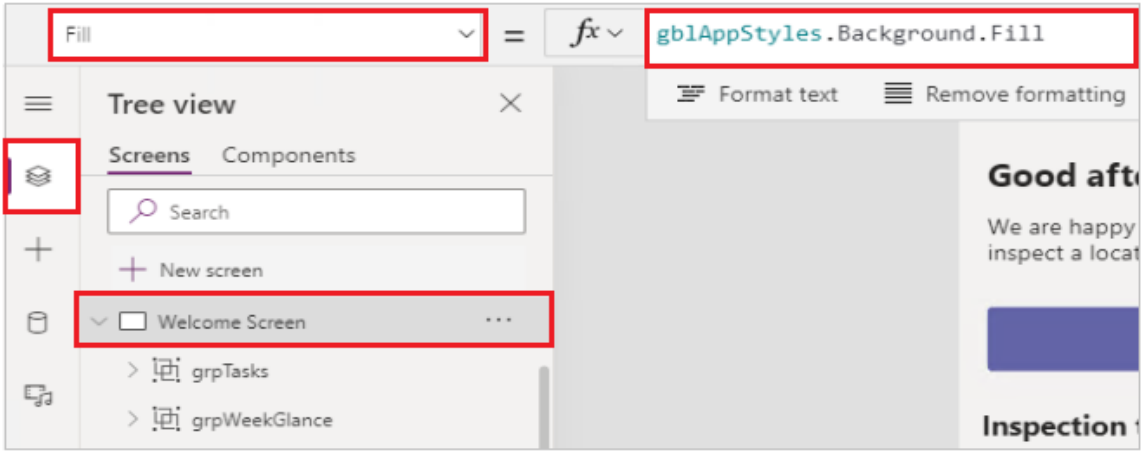


Change the screen background color

> **Note**
>
> The Inspection app leverages global theme variables to ensure consistent user experience. If you modify a screen fill, the modified screen will no longer use the standard app theme.

1. Open the sample app template (for example, **Inspection**) in Power Apps Studio.
2. Select Tree view from the left pane.
3. Select **Welcome Screen** from Tree view.
4. Select Fill from the property list on the top-left.
5. In formula bar, replace the formula with the color that you want.

   Screen background fill color will be set to the selected background color.



Bulk edit data

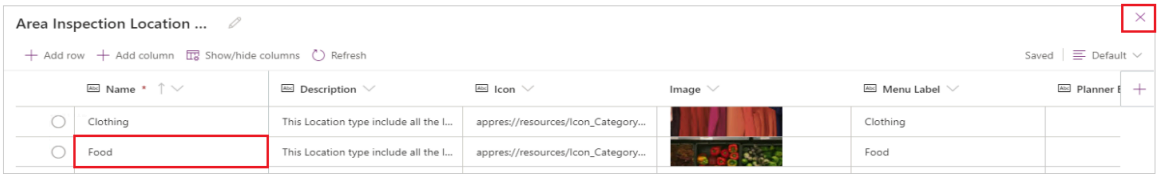
If you want to quickly edit the data in the app, you can open the table and modify or delete data.

> **Caution**
>
> Sample app templates uses several related tables, such as Area Inspection Locations and Area Inspection Location Types for Inspection app. Use caution when deleting records from the tables without checking data relationship and dependencies.

1. Open the sample app template (for example, **Inspection**) in Power Apps Studio.

2. Select **Data** from the left pane.
3. Select ... next to the table name (for example, *Area Inspection Location Types* for Inspection app).
4. Select the cell inside the Visual Editor, for example **Food** in the **Name** column.
5. Replace the text with the value you want.
6. Close the visual editor.

   Data in the app should reflect the updated value, such as the location name in this example.



Add a column to the app

> **Important**
>
> The Inspection app customization steps in this section covers some of the advanced configuration options. This example requires that you have familiarity with the Power Apps Studio, are comfortable with modifying formulas, and work with controls such as containers.

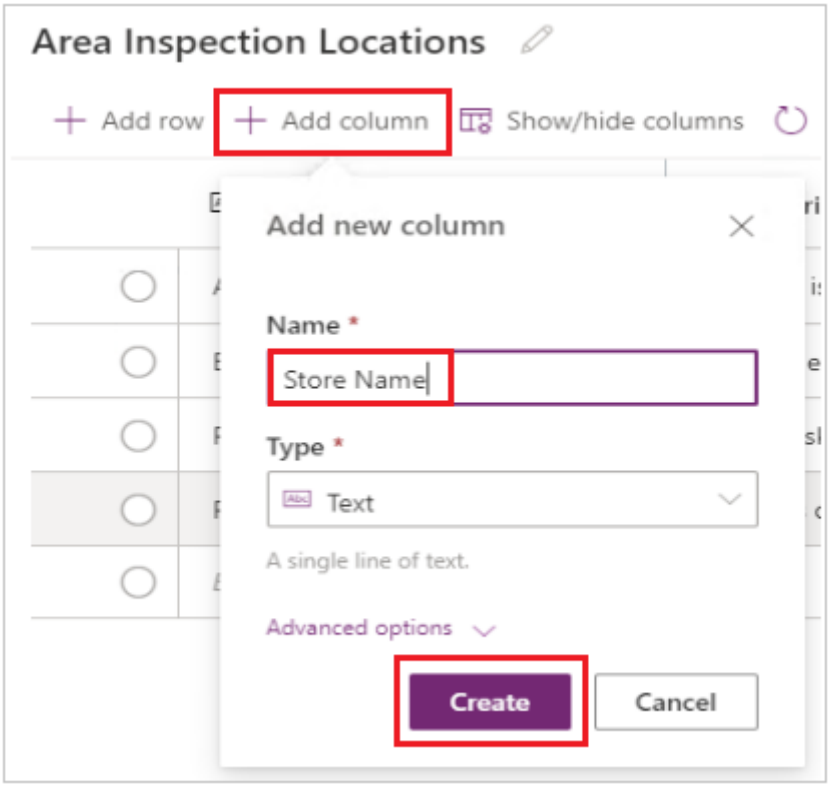
Consider a scenario where you have multiple stores, and you want to associate locations and inspections with specific stores.

Add Store Name text column to the Location table

1. Open the **Manage inspections** app in Power Apps Studio.
2. Select **Data** from the left pane.
3. Select ... next to the table name (for example, *Area Inspection Locations* for **Manage inspections** app).
4. Select **Add column**.
5. Enter **Name** as "Store Name".

6. Select **Create**.

7. Close the visual editor.



Add Store Name column to the location form

1. Select the **Locations Screen**.

> **Tip**
>
> You can ignore the error about the use of the preview connectors in this app.

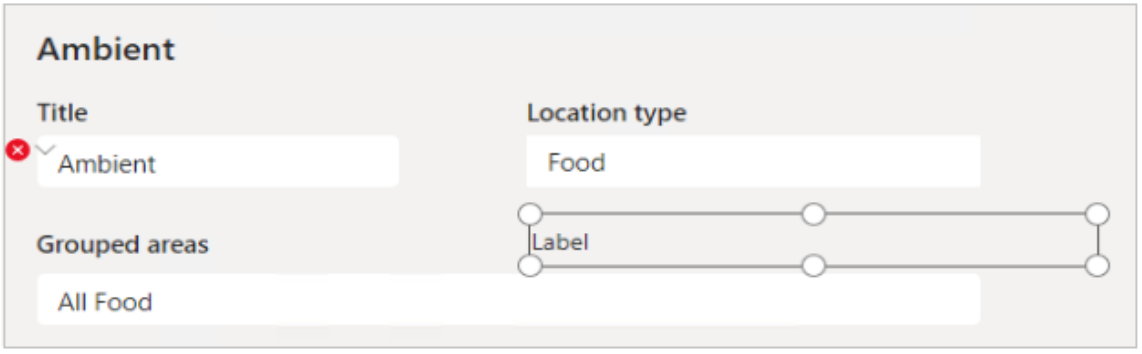
2. In Tree view, search for `btnArea_GroupedAreas`.

3. In the **Grouped Areas** on the form, drag the left edge to be parallel with the edge of the **Title** field.

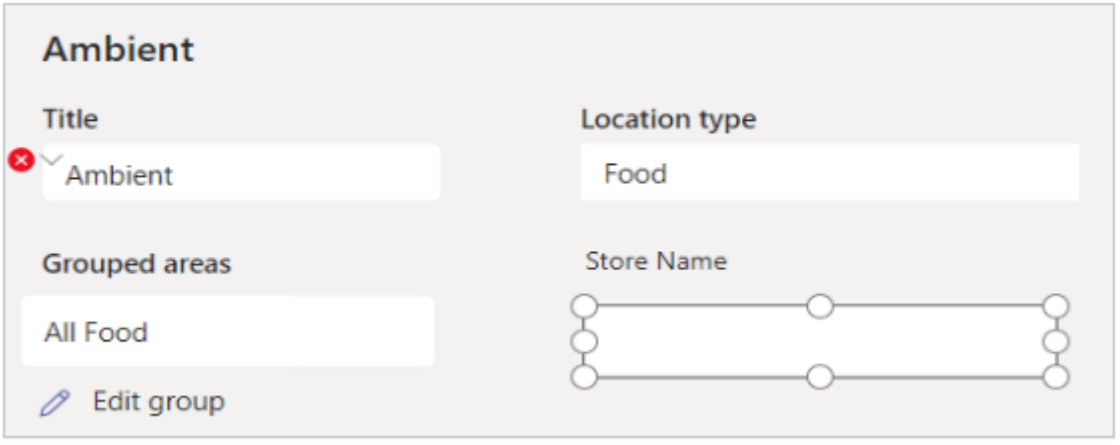
> **Note**
>
> The Grouped Areas field control is in a container. Hence, the selected area may appear in a different part of the screen than where you see the column. Dragging the selected area resizes the column.

4. Select **Insert** from the left pane.

5. Select **Label** control.
6. Position the **Label** so that it's aligned horizontally with **Grouped areas**, and vertically with the **Area type**.



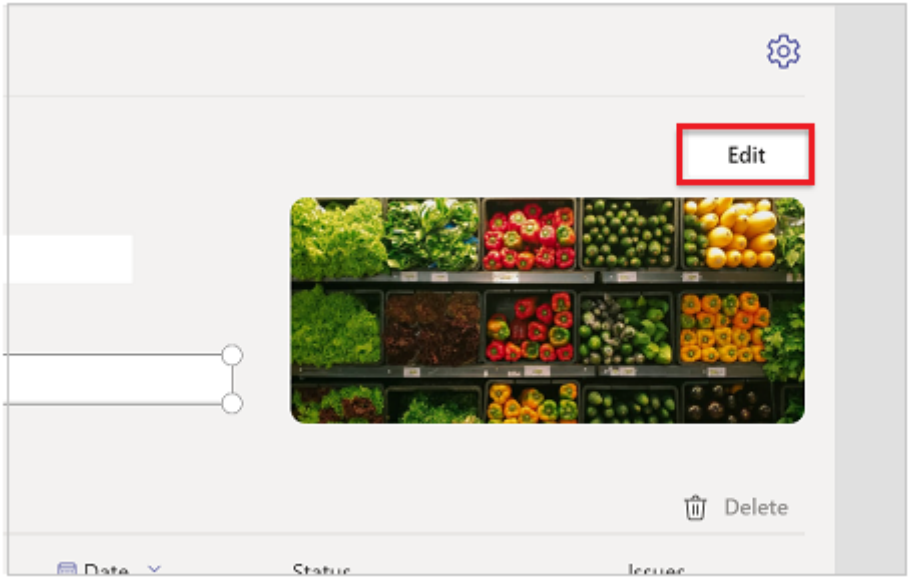
7. Select **Text** from the property list on the top-left.
8. Select the formula bar.
9. Change the formula to **Store Name**.
10. Select **Insert** from the left pane.
11. Select **Text box** control.
12. Drag the text box control to be aligned horizontally with **Grouped area** and vertically with **Area type**.
13. Select **Value** from the property list on the top-left.
14. In the formula bar, replace the current value with `gblLocation.'Store Name'`
15. Select **ColorBackground** from the property list on the top-left.
16. In the formula bar, enter "White".



17. Select **Display mode** from the property list on the top-left.

18. In the formula bar, enter "Edit" if not already present.

19. Hold the **ALT key** on your keyboard, and select the **Edit**.



20. Select **Tree view** from the left pane.

21. Search for `btnAreaDetails_Save` and select the returned control.

22. Expand the formula bar.

23. At the end of the 17th line, add a comma and this formula:

```
Power Fx
'Store Name':Microsoft_CoreControls_TextBox1.Value
```

This section of the formula should now look like the following:

```
Power Fx
{
    msft_name: txtArea_EditTitle.Text,
    'Location Type': cmbAreaDetails_AreaType.Selected,
    'Primary Image': picArea_UploadedImage.Image, 'Store
Name':Microsoft_CoreControls_TextBox1.Value
}
```

> **Note**

> If the updated formula shows error, verify the text box name for the store name. For example, it may be `Microsoft_CoreControls_TextBox2` instead of `Microsoft_CoreControls_TextBox1`, depending on your changes.

24. Select the label control added in step 5.
25. Select the **Y** property from the property list on the top-left.
26. Select the formula bar.
27. Change the formula to:

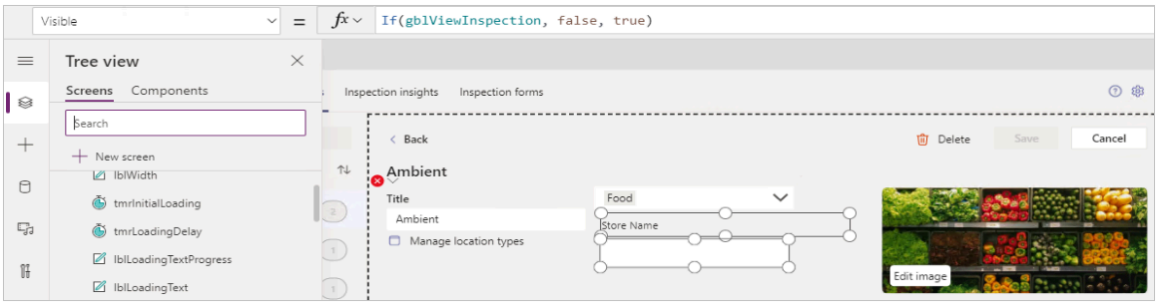
```
Power Fx
If(gblEditLocation,250,200)
```

28. Select text box added in step 11.
29. Select the **Y** property from the property list on the top-left.
30. Select the formula bar.
31. Change the formula to:

```
Power Fx
If(gblEditLocation,282,232)
```

32. Hold the **CTRL key** on your keyboard, and select both the store name label and the text box.
33. Select Visible property from the property list on the top-left.
34. Select the formula bar.
35. Change the formula to:

```
Power Fx
If(gblViewInspection, false, true)
```



Publish app updates to Teams

To save and publish the changes to the sample app:

1. Select **Save** from the top-right.
2. Select **Publish to Teams**
3. Select **Next**.
4. To publish updated version of an app to an existing active tab, select **Save + close**.

   To add published version of an app to a new tab in a different channel, Select + (Add a tab) for the channel you want, and then select **Save + close**.

Localize sample app templates

Article • 02/08/2023

The sample app templates for Microsoft Teams have been localized to support eight different languages so that they can be used by people with different languages. Depending on the user's language, you can see the text in an app in the appropriate language, if that language has been included in the app localization.

For example, consider that you use the Russian language. Russian isn't a language included in the standard localization; however, you can still use the app in Russian—if you add that language and localize the app labels.

This article covers the approach used for localization of the sample app templates for Teams, and how to extend it to add support for another language (such as Russian). In this example, we'll use the Milestones app; but this same approach is used consistently across all of the Teams template Power Apps, and you can follow the same approach for localization of your own canvas apps.

Watch this video to learn how to localize sample app templates:
https://learn-video.azurefd.net/vod/player?id=2b55d792-7cde-4948-9072-5d38d33e844f&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Flocalizing-sample-apps

Prerequisites

To complete this lesson, we'd need the ability to create Power Apps within Teams, which is available as part of select Microsoft 365 subscriptions.

Understanding localization in Power Apps

In canvas apps, text labels and other visual text components can be localized by loading a static Excel data source to your app containing the localized value for each text string in each language. For more information about this process, see Language function.

For example, Milestones app contains an Excel data source called **StaticLocalizationsjon** with three columns—"OOBTextID", "LanguageTag", and "LocalizedText".

- **OOBTextID** is the identifier of the text that is to be localized.
- **LanguageTag** is the identifier of the language in which the text is to be localized. Language tag is a standard abbreviated text defining a language and the

country/region its being used in (for example, "en-US" means "English-United States").

- **LocalizedText** is the text in the appropriate language that needs to be displayed.

Here's an example with localized text for each text ID.

Expand table

OOBTextID	LanguageTag	LocalizedText
lblLoadingText_AppLoading__locText	en-US	Getting things ready ...
lblLoadingText_AppLoading__locText	de-DE	Dinge fertig machen ...
lblLoadingText_AppLoading__locText	es-ES	Preparando las cosas ...
lblLoadingText_AppLoading__locText	fr-FR	Préparer les choses ...
lblLoadingText_AppLoading__locText	it-IT	Preparare le cose ...
lblLoadingText_AppLoading__locText	ja-JP	準備をする..。
lblLoadingText_AppLoading__locText	nl-NL	Dingen klaarmaken ...
lblLoadingText_AppLoading__locText	pt-BR	Preparando as coisas ...
lblLoadingText_AppName__locText	en-US	Milestones
lblLoadingText_AppName__locText	de-DE	Meilensteine
lblLoadingText_AppName__locText	es-ES	Hitos
lblLoadingText_AppName__locText	fr-FR	Jalons
lblLoadingText_AppName__locText	it-IT	Passaggi fondamentali
lblLoadingText_AppName__locText	ja-JP	マイルストーン
lblLoadingText_AppName__locText	nl-NL	Mijlpalen
lblLoadingText_AppName__locText	pt-BR	Etapas
lblLoadingText_BuiltWith__locText	en-US	Built with Microsoft Power Platform
lblLoadingText_BuiltWith__locText	de-DE	Erstellt mit Microsoft Power Platform
lblLoadingText_BuiltWith__locText	es-ES	Creada con Microsoft Power Platform
lblLoadingText_BuiltWith__locText	fr-FR	Créé avec Microsoft Power Platform
lblLoadingText_BuiltWith__locText	it-IT	Creata con Microsoft Power Platform

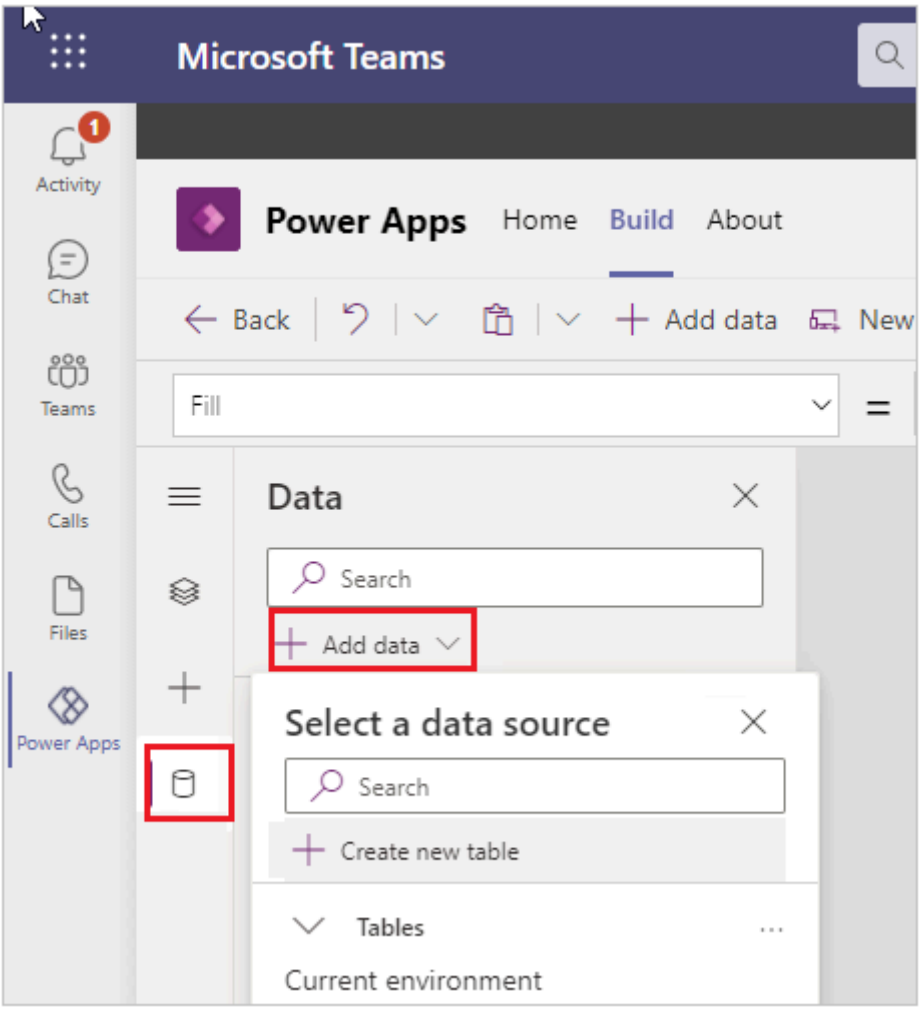
OOBTextID	LanguageTag	LocalizedText
lblLoadingText_BuiltWith__locText	ja-JP	Microsoft Power Platform でビルド
lblLoadingText_BuiltWith__locText	nl-NL	Gebouwd met Microsoft Power Platform
lblLoadingText_BuiltWith__locText	pt-BR	Criado com o Microsoft Power Platform

> **Note**
>
> The above table is from the master file that contains localized text for all the screens in the app. However, it's been filtered to show only the rows relevant to earlier discussions.

How to use Excel as a static data source in your app

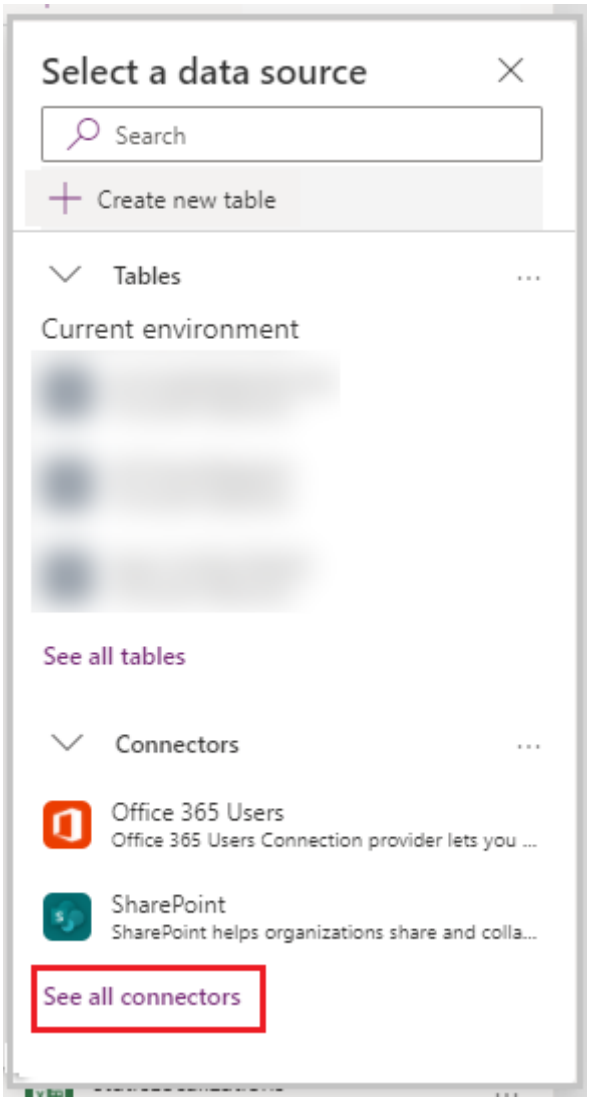
Static data is data loaded into Power Apps from Excel. This data isn't editable in the app. If you want to add a static data source to your app, perform the following steps.

1. In Teams, right-click on **Power Apps**, and pop out the app.
2. Select the **Build** tab.
3. Open the desired app to edit in Studio. In this example, we'll use **Milestones** app.
4. Select the **Data** tab.
5. Select **Add data**.



6. Select **Connectors**.

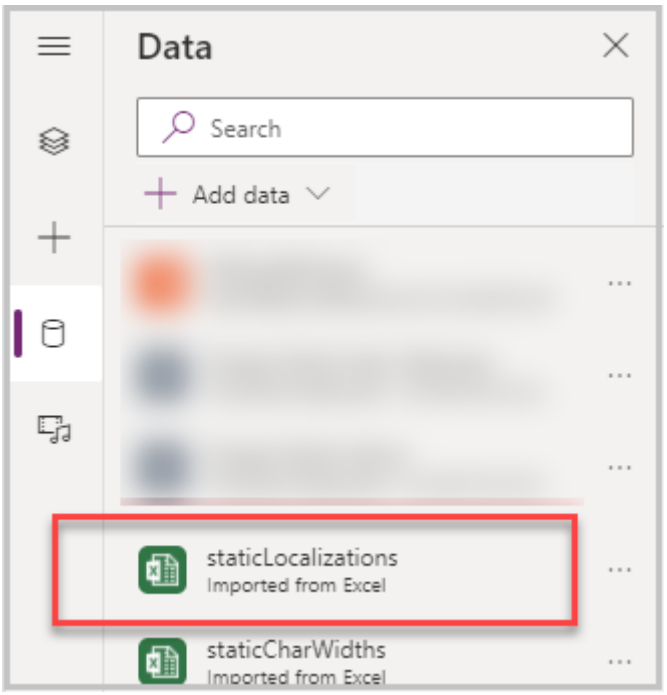
7. Select **See all connectors**.



8. Select **Import from Excel**.

9. Select the **LocalizationMilestones_AllLanguages** file, and select **Open**.

10. On the right of the screen, you're asked to choose a table. Select the table **staticLocalizations**, and select **Connect**. The table gets added as a data source and can be used in the app.



Adding a new language to your app

Now that you understand how localization is handled in Power Apps, if you want to add an additional language to the app, you don't have to update every text control in the app. The text formulas are built to dynamically display the appropriate localized copy of text strings based on the user's language.

To add Russian, you would first add Russian translation to the spreadsheet for each **OOBTextID**. In this example, we'll show how we can add localized text for the text on the first page of the app.

1. Open **LocalizationMilestoes_AllLanguages.xlsx** file.

2. Add the following rows to the Excel:

Expand table

OOBTextID	LanguageTag	LocalizedText
lblLoadingText_AppName__locText	ru-RU	Вехи
lblLoadingText_BuiltWith__locText	ru-RU	Создано на платформе Microsoft Power Platform
lblLoadingText_AppLoading__locText	ru-RU	Готовимся ...

3. To add Russian text for all pages, we'd have to add rows for all the OOBTextIDs as they exist for any other language, then add **ru-RU** as the Language tag. and then add the Russian translation for each of those OOBTextIDs.

4. Save Excel file.

> **Note**
>
> Since the Excel file already exists as a data source in the data sources list for the app, we'll have to remove the excel from the list of data sources and then readd it as shown above.

5. Update the app OnStart function **gblUserLanguage** to include the language that you added to the Excel file. In the example below we've added Russian:

```
Power Fx

//user language
Set(gblUserLanguage,Switch(Left(Language(),2),"de","de-DE","en","en-
US","es","es-ES","fr","fr-FR","it","it-IT","ja","ja-JP","nl","nl-NL",
"pt","pt-BR","ru-RU",
//default
"en-US"));
//build localization collection, with user's language
ClearCollect(colLocalization,Filter(staticLocalizations,LanguageTag =
gblUserLanguage));Collect(colLocalization,Filter(staticLocalizationsNew
Messages,LanguageTag = gblUserLanguage));
```

6. Save and publish the app.

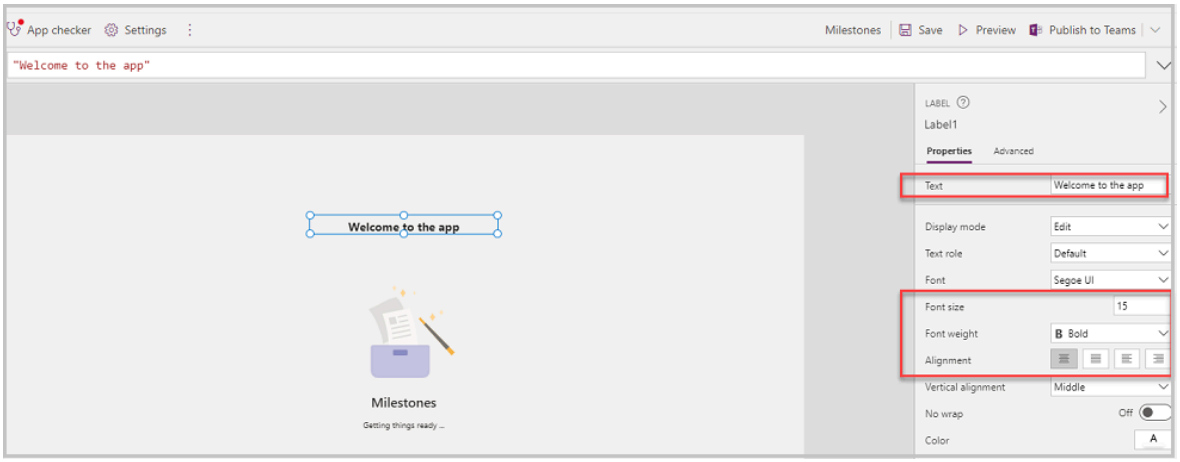
Since the formulas dynamically retrieve the localized content, there's no need to update the formulas to reflect the newly added language.

Adding and localizing a new label

As an extension to the default Milestones app, we'll add a new label and learn how to localize it. Let us add a label to the Loading screen:

1. Select **Insert**, and select label control.

2. Update the Text and properties of the label.



For now, we'll set the text to "Welcome to the app" until it's ready for localization.

3. Open the Excel file to add rows for this text.

4. Create eight rows in the Excel file with **OOBTextID** value **lblLoadingText_Welcome_locText**, and **LanguageTag** for the 8 rows:

Expand table

en-US
de-DE
es-ES
fr-FR
it-IT
ja-JP
nl-NL
pt-BR

5. For the third column—**LocalizedText**, translate the text "Welcome to the app" in the 8 different languages:

   - en-US (US English)
   - de-DE (German)
   - es-ES (Spanish)
   - fr-FR (French)
   - it-IT (Italian)
   - ja-JP (Japanese)

- nl-NL (Dutch)
- pt-BR (Portuguese)

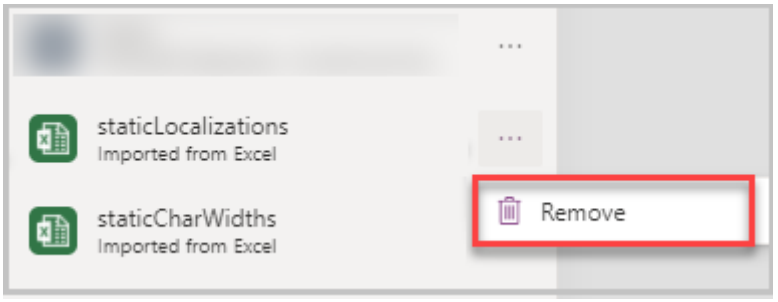
6. Update the spreadsheet with all the translated text as shown below.

	OOBTextID	LanguageTag	LocalizedText	D
2993	lblLoadingText_AppName__locText	nl-NL	Mijlpalen	
2994	lblLoadingText_AppName__locText	pt-BR	Etapas	
3796	lblLoadingText_BuiltWith__locText	en-US	Built with Microsoft Power Platform	
3797	lblLoadingText_BuiltWith__locText	de-DE	Erstellt mit Microsoft Power Platform	
3798	lblLoadingText_BuiltWith__locText	es-ES	Creada con Microsoft Power Platform	
3799	lblLoadingText_BuiltWith__locText	fr-FR	Créé avec Microsoft Power Platform	
3800	lblLoadingText_BuiltWith__locText	it-IT	Creata con Microsoft Power Platform	
3801	lblLoadingText_BuiltWith__locText	ja-JP	Microsoft Power Platform でビルド	
3802	lblLoadingText_BuiltWith__locText	nl-NL	Gebouwd met Microsoft Power Platform	
3803	lblLoadingText_BuiltWith__locText	pt-BR	Criado com o Microsoft Power Platform	
3804	lblLoadingText_Welcome_locText	en-US	Welcome to the app	
3805	lblLoadingText_Welcome_locText	de-DE	Willkommen in der App	
3806	lblLoadingText_Welcome_locText	es-ES	Bienvenido a la aplicación	
3807	lblLoadingText_Welcome_locText	fr-FR	Bienvenue sur l'appli	
3808	lblLoadingText_Welcome_locText	it-IT	Benvenuto nell'app	
3809	lblLoadingText_Welcome_locText	ja-JP	アプリへようこそ	
3810	lblLoadingText_Welcome_locText	nl-NL	Welkom bij de app	
3811	lblLoadingText_Welcome_locText	pt-BR	Bem vindo ao app	
3812				

7. Save the spreadsheet.

8. Go back to the app editor in Teams.

9. To refresh the Excel data source (since we updated it), select **Data** > **...** (ellipsis), and then select **Remove** next to the **staticLocalizations** Excel spreadsheet.



Removing the table will cause some errors in the app. However, we'll readd the updated Excel file in the next steps.

10. Readd the spreadsheet as a connector, and select **staticLocalizations** table as the data source (make sure to select the correct excel file that was updated).

11. Select the label with the text "Welcome to the app".

12. Open the **Text** property of the label and paste the following formula:

Power Fx

```
With({varDefault: "Welcome to the app", varOOBTextId:
"lblLoadingText_Welcome_locText"}, With({varLocalizedText:
LookUp(colLocalization;OOBTextID = varOOBTextId, LocalizedText)},
Coalesce(varLocalizedText;varDefault)))
```

13. To test the localization of the label we created, change the language of our user in Teams to one of the languages that is in our localization Excel spreadsheet. You can change your Teams language by selecting your photo in the upper-right corner, and then selecting settings.

14. Select Milestones to open the app and the **Welcome to the app** label has been localized to the language that was selected in the previous step. You can verify the same by going to the specific Team channel where the app was installed and playing the published app.

Theming in sample app templates

Article • 02/08/2023

The most attractive feature about canvas apps is the ability to customize the user interface per the user or organization's branding and liking. Theming strategy provides us with the ability to create apps that match the organizational brand. A **theme** contains a collection of styles that define multiple design properties for controls and components such as colors, fonts, and borders.

In this article, we'll learn how to use global variables to define themes, and how the colors and properties can be easily changed throughout the app by just updating the global variables.

Watch this video to learn about theming in sample app templates: https://learn-video.azurefd.net/vod/player?id=c8ddd966-a7fc-431b-8b2c-375e85b862ba&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fsample-app-theming

Prerequisites

To complete this lesson, we'd need the ability to create apps within Microsoft Teams that will be available as part of select Microsoft 365 subscriptions. You'll also need the Milestones sample app template for Microsoft Teams installed in your Team. You can install it in your team at https://aka.ms/TeamsMilestones.

Defining the theming strategy

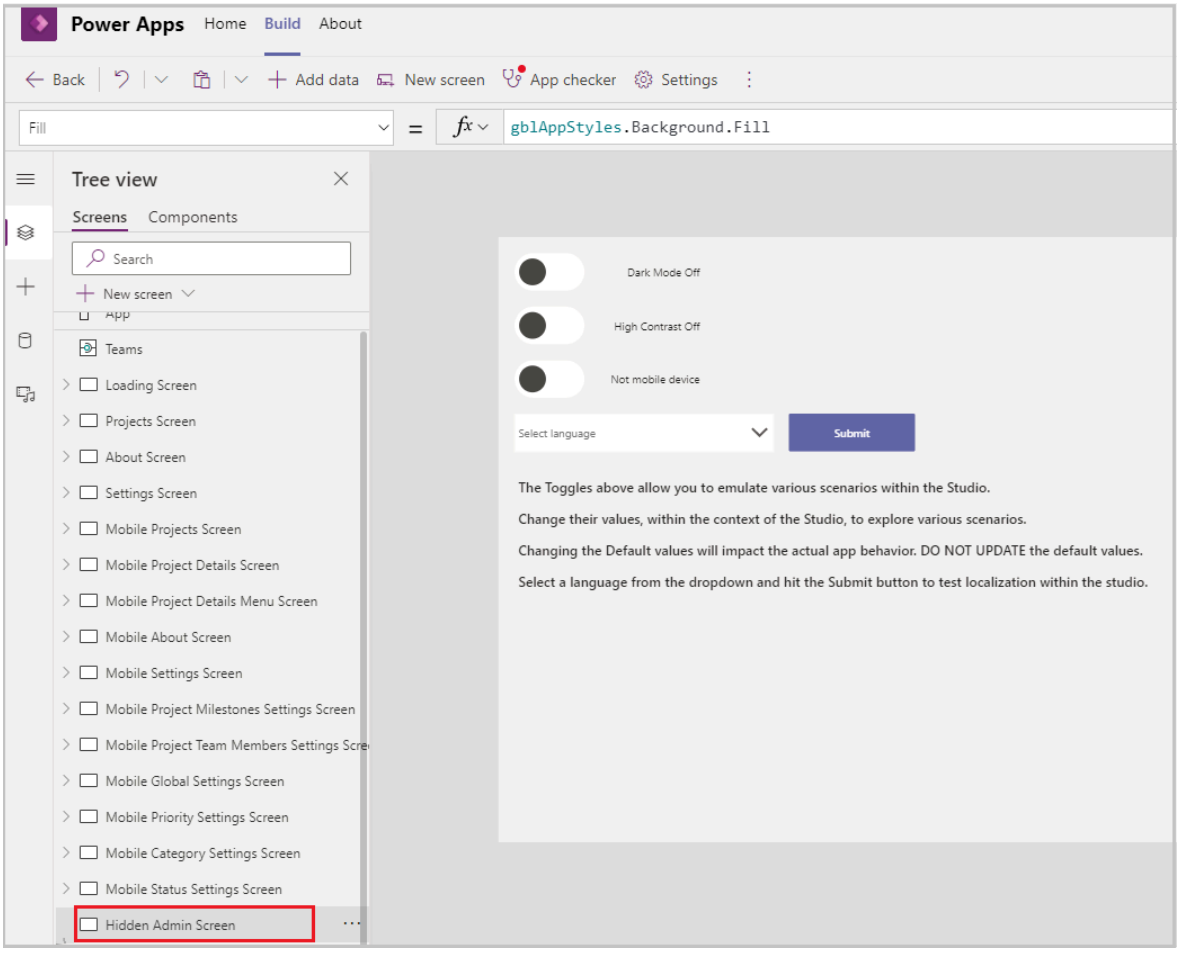
In this example, we'll see how global variables have been used to define colors and styles for theming in the Milestones app. The following global variables have been defined in the **OnVisible** property of the **Loading screen**.

- **gblAppColors** to define colors so they can be referenced easily
- **gblAppSizes** to define different sizes of fonts for mobile and web apps
- **gblAppStyles** properties of every single control using **gblAppColors**
- **gblThemeDark** set to true when the Teams theme is dark so all controls adapt to the dark theme
- **gblThemeHiCo** set to true when the Teams theme is high contrast so all controls adapt to the high contrast high contrast

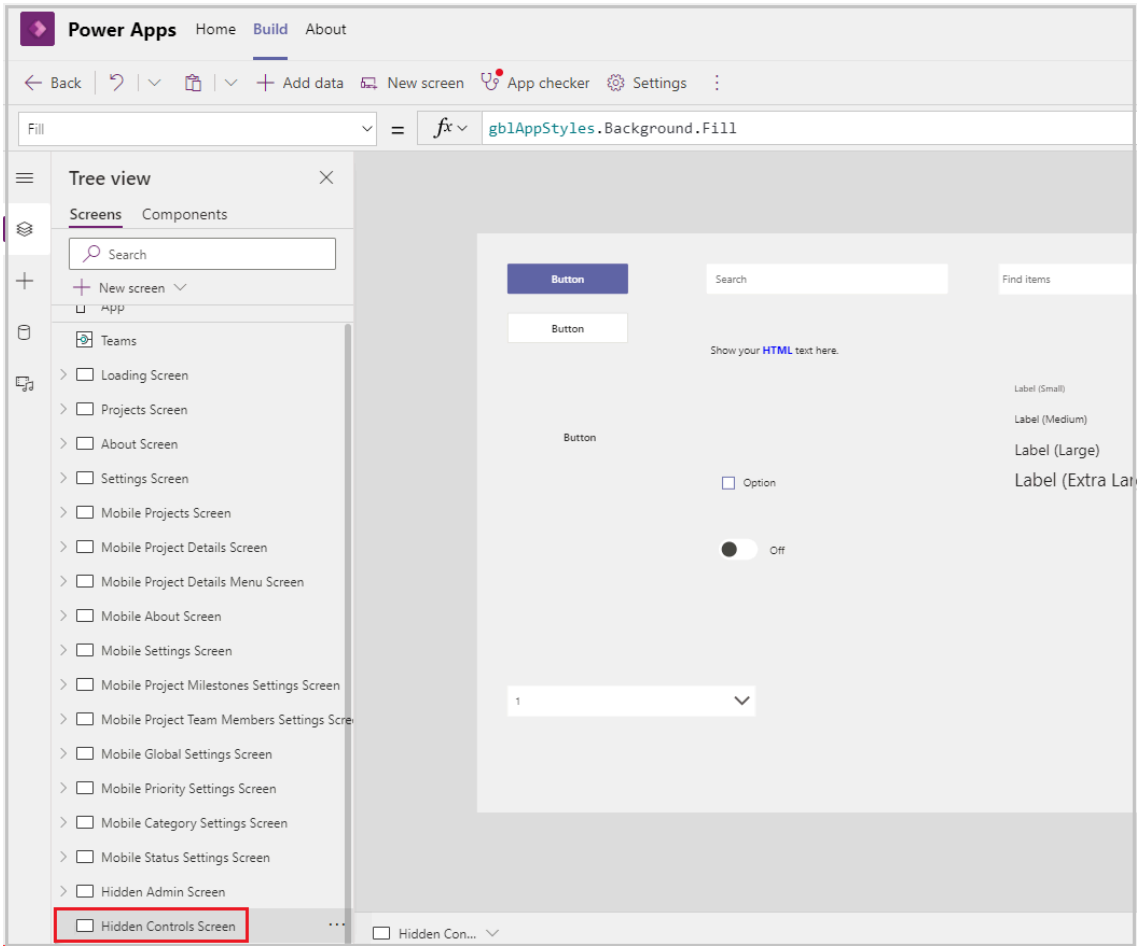
Testing the theming Strategy

Two hidden screens have been defined for testing the theming strategy:

- Hidden Admin Screen – This screen has two toggles defined **tglAdmin_DarkMode** and **tglAdmin_ContrastMode**. This screen helps with quick testing of dark and contrast modes without having to change the theme of teams for testing



- Hidden Controls Screen – This screen has every single control with properties set using gblAppStyles.
    - Helps in testing out theme changes.
    - Helps in copying a particular control and pasting it on the required screen so that the formula for the control doesn't need to be typed repeatedly.



Using the theming variables for a sample app templates

1. To understand the usage of theming in the Milestones app, select **Projects Screen** in the Tree view to open the screen and then select **+New Project**.

2. Select the **Color** property of **+New Project**.

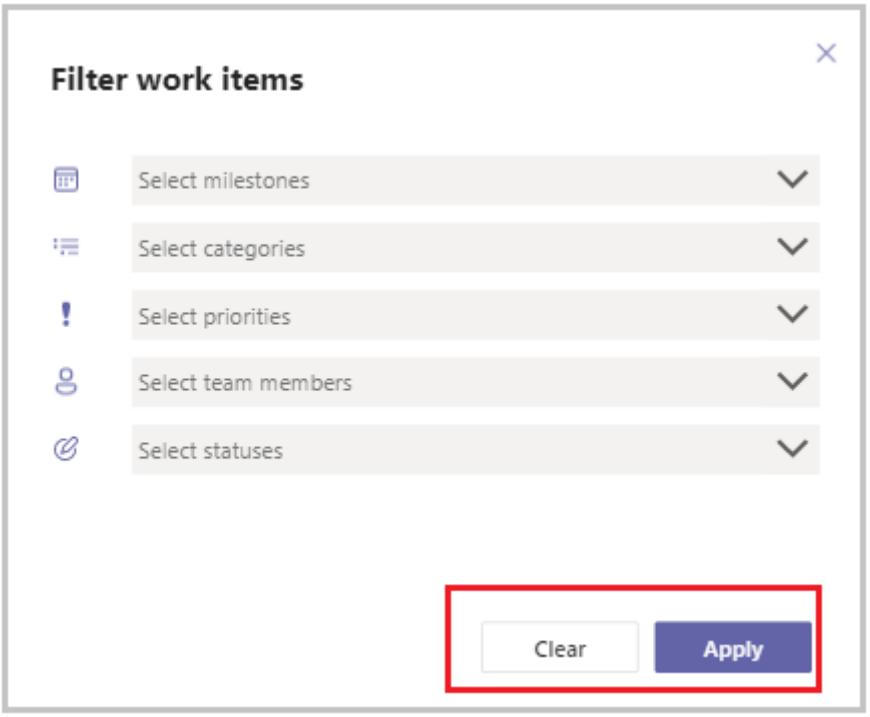
   Notice that the formula references **gblAppStyles** > **ButtonTransparent** > **Color** formula from the **OnVisible** property of the Loading screen.

   So now, if the theme of the app is High Contrast, then the color defined in **gblAppColors** > **HighContrastHyperlinks** formula will be used.

3. Another example would be to look at the Primary and Secondary buttons.

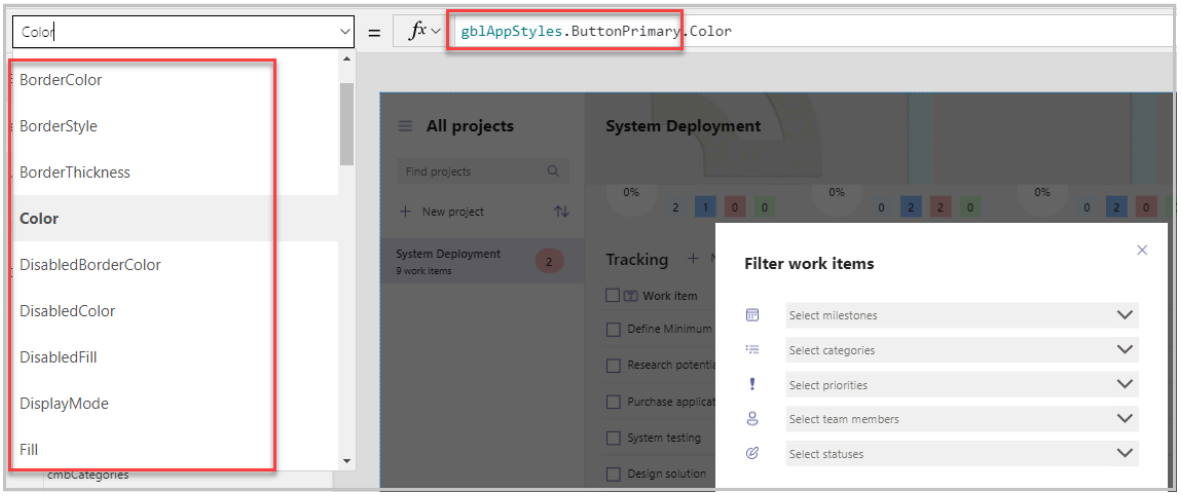
   - Select the Project Screen in the editor.
   - Hold down the Alt key and select the Filter icon on the Projects Screen.

     The Filter work items pop-up opens up. Notice the two buttons: **Clear** and **Apply**.



Apply is an example of a primary button and **Clear** is an example of a secondary button.

4. Select the **Apply** button, and select any Border/Thickness/Color related property and notice the formula defined.



5. The **Apply** button is defined as the Primary button and uses all the properties defined on **Loading Screen** > **OnVisible**> **ButtonPrimary** formula.

   Depending on the theme and color variables selected in the ButtonPrimary formula, the styling properties of the button will get updated.

   Similarly, **Clear** is defined as a Secondary button and uses all properties defined under **gblAppStyles** > **ButtonSecondary**.

> ⓘ Note

Another possible extension to the app would be to add Font as a Property, either as one variable to be used across all controls, or once per control (like how the other styling properties are defined separately for primary buttons, or secondary buttons). The font throughout the Milestones app is Segoe UI and there was no need identified for theming of the font.

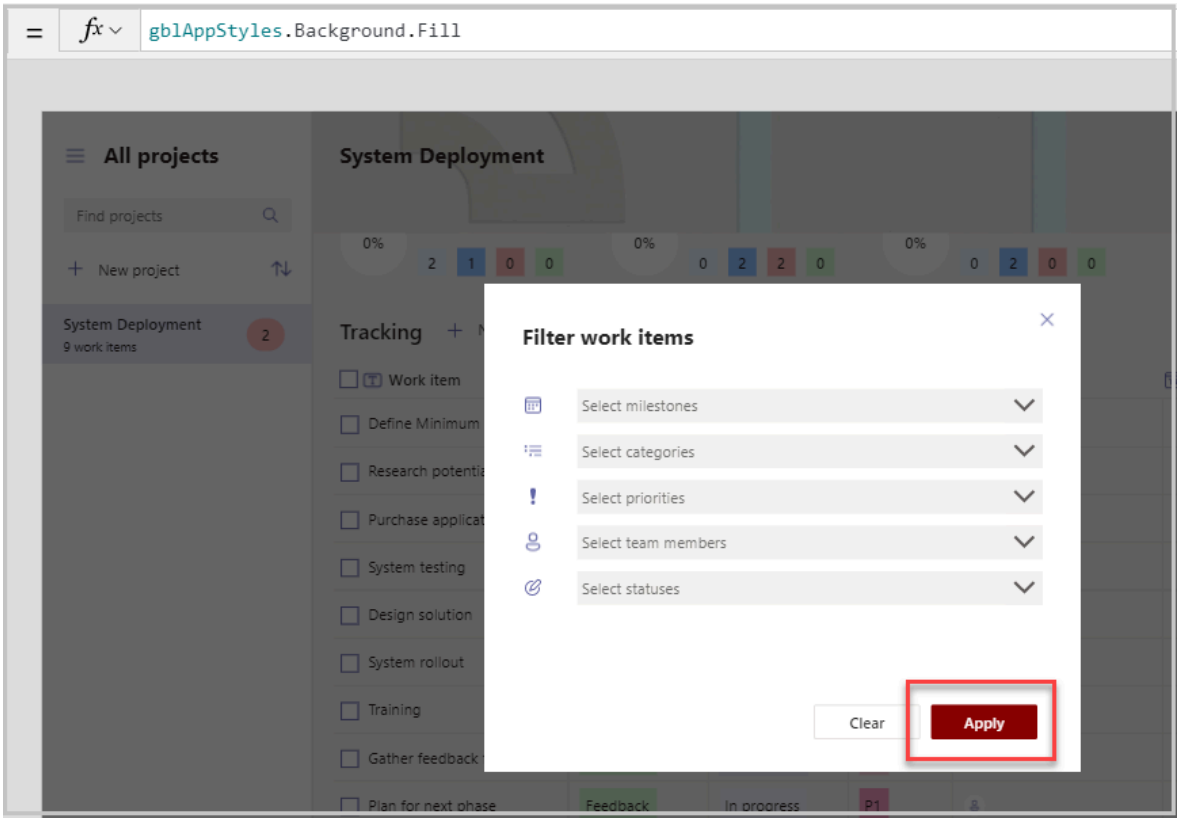
Updating the theme in the sample app template

In this section, we'll see how we can change a property of a particular control and how the control gets updated across various screens. In our example, we'll update the Fill property of the Primary button and see how the button color changes in the Dark mode, and the Default mode.

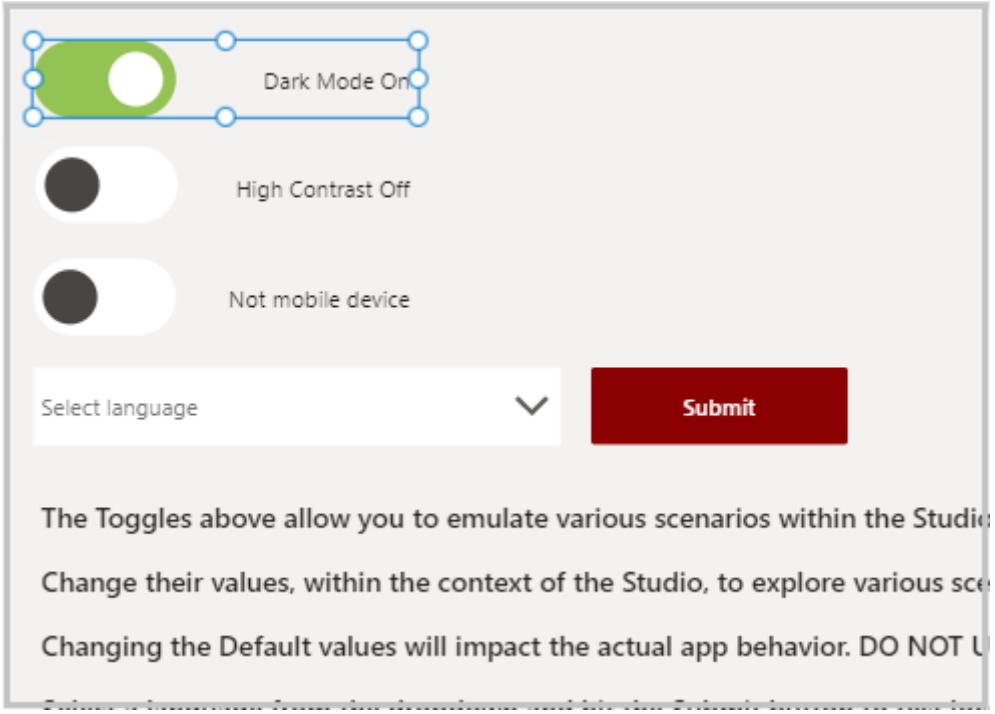
1. Go to the **Loading Screen** and select the OnVisible property in the dropdown.
2. Expand the formula bar and scroll down to the **ButtonPrimary** > **Fill** function.
3. Update the last two parameters to Red and DarkRed.

4. Go to another screen and then back to Loading Screen for the **OnVisible** function to run.

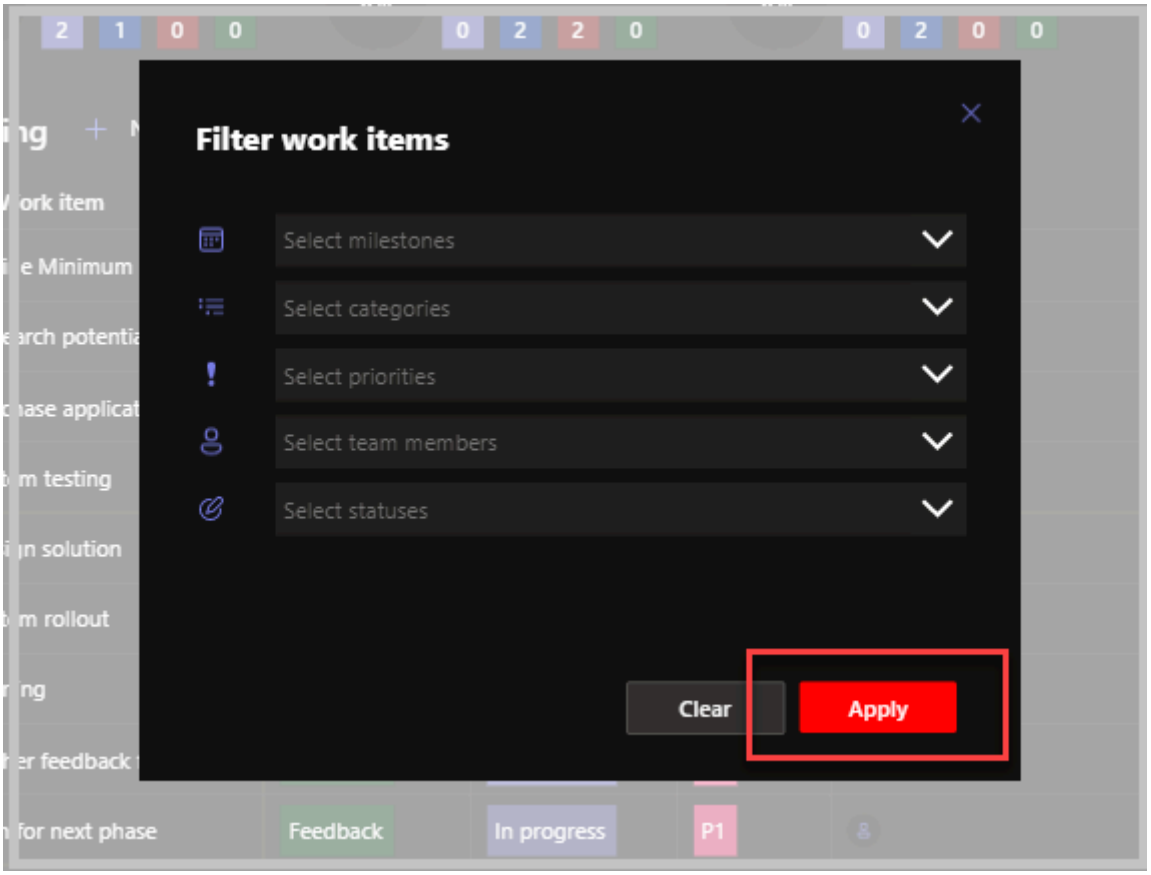
5. Go to the **Projects** screen, select the **Filter** button to open the Filter pop-up and notice the color of the Apply button is now DarkRed.



6. Go to the **Hidden Admin Screen**, hold **Alt** key on the keyboard, and select the **Dark Mode On** toggle.



7. Go to the Loading Screen again for the function to load and then come back to the Projects screen. Notice the screen is now in dark mode (with the background dark), and the Apply button color has now changed to **Red**.



8. Similarly, changing properties of the **SecondaryButton** would have changed colors for the secondary button, such as the **Clear** button.

> **Note**
>
> Updating the fill function directly is a quick way of testing theming as shown earlier. If the color needs to be changed for not just the Primary Button control but for all other controls where it is being used as well, then the color palette under the variable gblAppColors should be updated with the formula of the desired colors and names that makes the most sense to your organization. For example, `companynameDefaultHeader: ColorValue("#30D5C8")` would be the formula for turquoise blue.

Granting permission to tables in Dataverse for Microsoft Teams

Article • 01/20/2023

When building Power Apps, one important consideration is data security. Your apps drive important business processes, and if users can see sensitive data or delete records that they shouldn't have access to, it can disrupt your business.

For example, if you've an app with sensitive customer data, unauthorized access to the data could put your company at risk of compliance with privacy laws.

You may think "I'll just obscure access to sensitive data in my app!" However, if the underlying data source is shared with users, they can still get to the data, or build new apps on the data source, giving them access to the restricted records.

One of the advantages of building Power Apps in Teams with Dataverse for Teams is that it provides the ability to set the table permissions to your specific business needs that map the security roles in Teams—such as Owners, Members, Guests, and App Users.

For example, if there's a table that the users should only be able to modify for the records that they own, Dataverse for Teams offers a table permission called **Collaborate** that gives users the ability to only edit records that they own. In this article, we'll review the table permissions in Dataverse for Teams, and learn about how you can use them to secure your important business applications.

> ⓘ **Note**
>
> Only team owners have the ability to edit table permissions currently.

Watch this video to learn how to configure table permissions:
https://learn-video.azurefd.net/vod/player?id=23f33cc0-7db3-40fc-85e9-d6c3057b2489&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fdataverse-for-teams-table-permissions

Understanding team roles

Permission to apps and the data that they use in Teams are based on the following roles in Teams team.

- **Owner** - A team member with the owner role. This includes the creator of the team, and anyone who has been given the owner role by another users. Owners get full access to the data used in apps in the team.
- **Member** - A team member who isn't an owner. By default, team members get full access like owners, but you can also change the permission for team members. You might want to restrict members from being able to edit certain tables.
- **Guest** - A guest is someone outside of your organization who is added to the team. By default, guests can create records, but not view records created by others.
- **Colleagues with access**: With Power Apps for Teams, you can share an app with Azure AD security group whose members need not be part of the Teams team where the app was built. This enables you to add users to the application without having to add them to the specific team, and opens up “Broad Distribution” scenarios. For example, you may want to build an app that is enabled for every accountant in the organization, or even every employee in that organization.

Understanding table permissions

When assigning security to a table, the following are the permissions that you can assign:

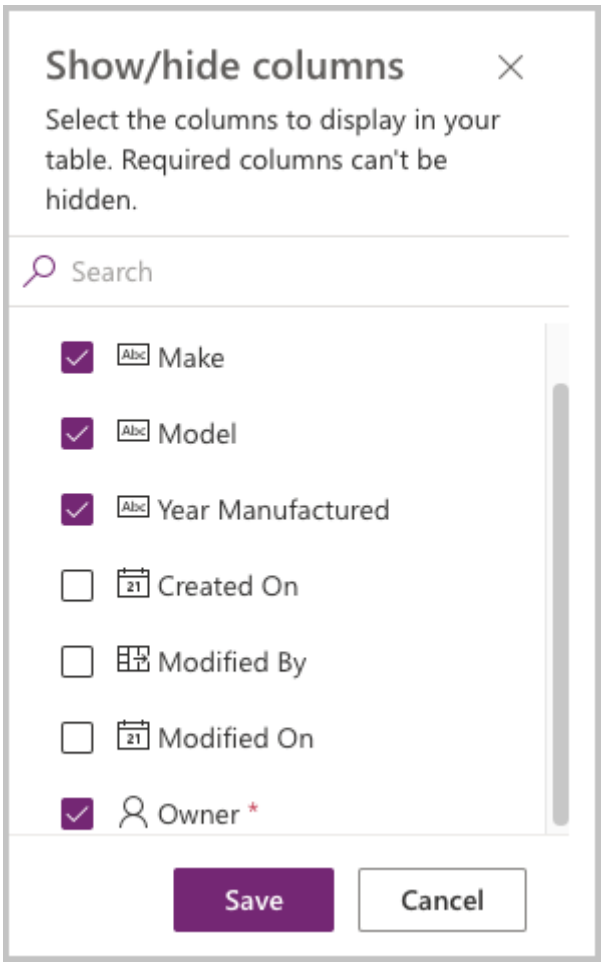
- **Full Access** – Allows end users to see and edit all records in the table.
- **Collaborate** – Allows end users to see all records and create new records. But they can only edit or delete their own records. An example for when you want to use collaborate is "up votes" in the Ideas the Perspectives app. You want each user of the app to view the up-votes of other users. But they shouldn't be able to change the votes for any users other than their own.
- **Reference** – Provides a read-only view of data. Users can't create, edit, or delete any records. An example is in Bulletins app—if you want users to read bulletin records but not edit them, you'd give them **Reference** permission on the **Bulletin** table.
- **Private** – Users can create new records. Additionally, they can view, edit, or delete their own records only. An example is in the Issue reporting app—if you want users to only be able to create and see their own issue records in Dataverse, you'd give them **Private** permission on the **Issue Report** table.

Table permissions in real-world scenario

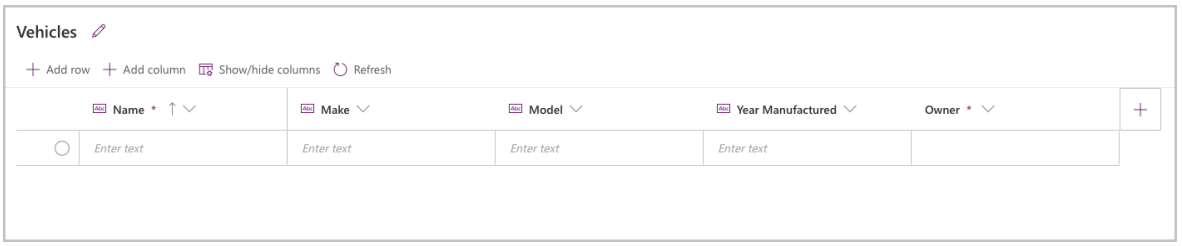
Let’s take a look at how table permissions work in practice. We'll create a table, and then show what two different users see.

> **Note**
>
> To complete this part of the lesson, you'll need an environment with two user logins. One of them having the team owner role and another with team member (a member of the team but not granted owner role)

1. Sign in to Teams as the Team owner.
2. Create an app and the table in team with a Dataverse for Teams database.
3. Right-click on the Power Apps icon and pop out the app.
4. Create a new app.
   a. App name: "Vehicle Manager"
   b. Select **Create new table** and name it "Vehicle".
   c. Add columns: "Make", "Model", "Year Manufactured".
   d. Select **Show/hide columns**.
   e. From Show/hide column dialog, select the **Owner** field and select **Save**.



Your table should now look like this:



5. Add a record to the table:
   a. Select **Add row**.
   b. Enter record details.
   c. The owner field of the created record will reflect your logged-in user account.

6. Select the area outside of the table definition screen to return to the app.

7. Save and Publish the app. You'll need to select a channel in which the app will be displayed—select + next to the desired channel name to select the channel.

Configure and verify table permissions

We're going to set the permissions for the vehicles table for Team members:

1. In Teams, open the **Power Apps** app. Right-click on the Power Apps icon in Teams, and select **Pop out app**. This will pop out the app in a new window, so if you move somewhere else in Teams, you won't lose your changes.

2. Select the **Build** tab.

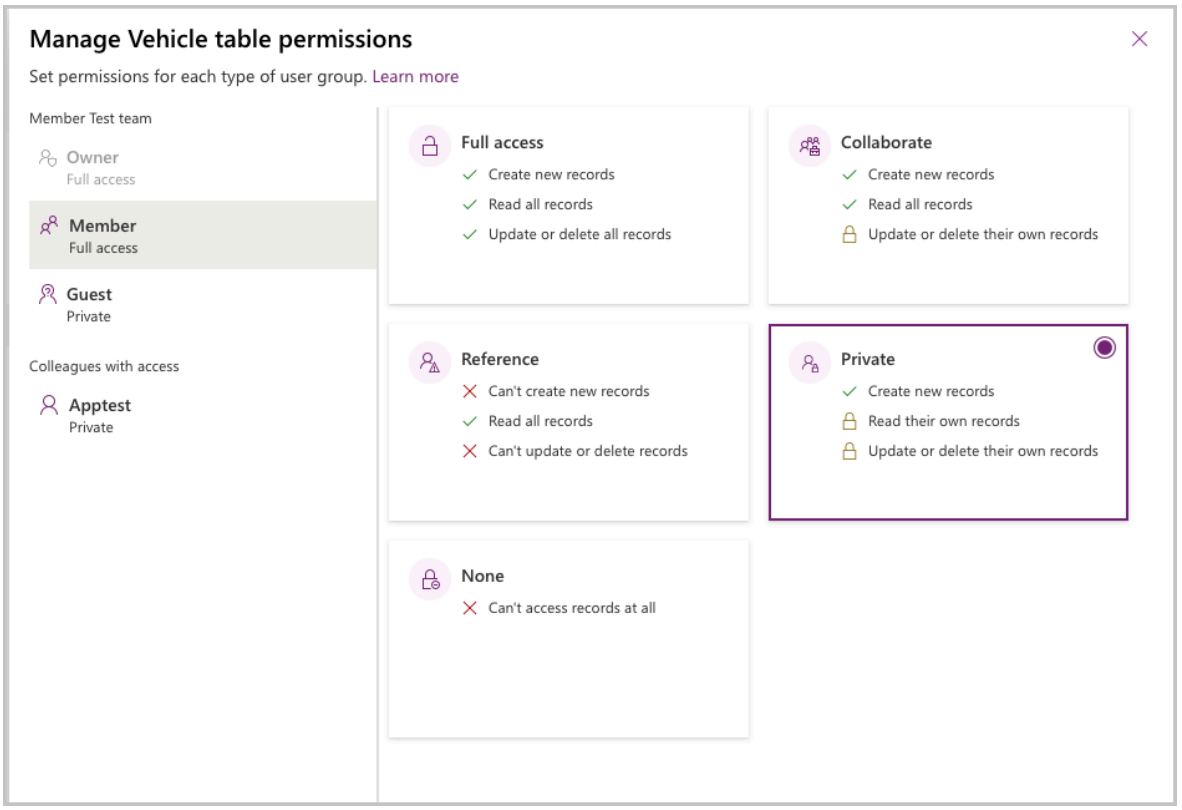
3. Select the team that contains the Vehicle Manager app.

4. In the **Items created for...** area, select **See all**.

5. Select **Tables** from the solution components bar.

6. Select the Vehicle table and then select **Manage permissions**.

7. Select the **Member** node. The initial permission will show Full access. Select the permission **Private** and select **Save**.



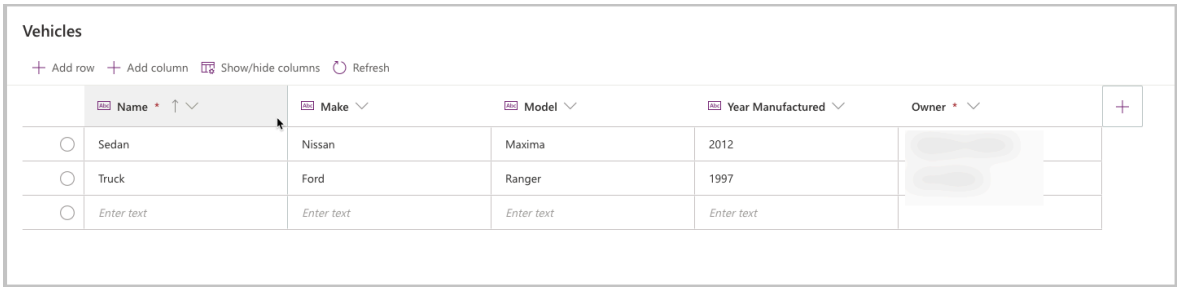
Next, we'll log in to Teams as a user who is a non-owner Team member to observe their experience.

1. Log into Teams using a user who is a member of the team in which the app is installed.
2. Select the channel where the app is installed.
3. Select the tab for the Vehicle Manager app.
4. The app should open for the user, but no records will show in the gallery, as the user only has visibility to their own records.
5. Select **New record** to create a new vehicle record, select the check mark to save the record.
6. You should now see one record in the gallery.

Log out of Teams and log back in as the Team owner. We'll now go to the table and see the created data.

1. Log in to Teams using the Team owner personal.
2. Right-click on the Power Apps icon and pop out the app.
3. Select the **Build** tab.
4. Select the team in which the Vehicle Manager app is installed
5. Select the Vehicle table
6. Select **Edit**.

7. You'll now see two records in the Vehicle table, each with a different owner.



So how would this apply to one of the sample app templates for Teams?

For example, with Bulletins we might set the following permissions for the tables in the app:

Expand table

Table	Permission	Reason
Bulletin	Reference	Users should read all bulletins, but not edit or create bulletins.
Bulletin Bookmark	Private	Users should create their own bulletins, but not view or edit other users' bookmarks.
Bulletin Category	Reference	Users should read all categories but not edit or create categories.
Bulletin Category Preference	Private	Users should create their own category preferences but shouldn't be able to read or edit other users category preferences.
Bulletin Contact	Reference	Users should read all contact records but not create or edit contacts.
Bulletin FAQ	Reference	Users should read all FAQ records but not create or edit existing FAQ records.
Bulletin FAQ Category	Reference	Users should read all FAQ categories but not create or edit existing FAQ records
Bulletin Link	Reference	Users should read all links but not create or edit existing link records.
Bulletin Link Category	Reference	Users should read all link categories but not create or edit existing link categories.
Bulletin Read Receipts	Private	Users should be able to create new read receipts when they view a bulletin, but not read or edit other users read receipts.
Bulletin User Settings	Private	Users should be able to create new user setting records but not read or edit other users setting records.

What permissions should I share?

Before assigning permissions, you should plan your security based on the personas of users of your app. Who will administer the app? Who will use the app? How will they use it?

For example, the Inspection sample app template for Teams is designed to address the following personas:

- **Inspection manager** - Creates Inspection forms and manages the list of locations or assets.
- **Inspection reviewer** - Reviews inspection data and approves inspections.
- **Inspection User** - Completes the inspections.

Once we have the personas defined, relate these personas to the team role to which they should be assigned:

- **Inspection manager** - Since inspection managers will need full access to create inspection forms and other system table records, we'll make them owners in the team.
- **Inspection reviewer** - Since inspection reviewers should be able to edit all inspections, but they won't create inspection forms, we'll make them team members. This will enable us to give them reference access to the Area **Inspection Checklist** table (where inspection form data is stored), but full access to **Area Inspection** table (where inspection records are stored).
- **Inspection user** - Inspection users should only be able to submit new inspections, but not create new inspection forms or see other user's inspections. So we won't make them members of the team in which the app is installed—we'll share the app with them as colleagues, and give them **Reference** permission to **Area Inspection Checklist** and **Private** permission to **Area Inspection**. This will allow users to view inspection forms and create their own inspection records.

For more details about the recommended table permissions for the sample app templates for Teams, see articles about deploying sample app templates broadly, such as Deploy Profile + as broad distribution app.

Frequently Asked Questions (FAQs) for sample app templates

Article • 02/08/2023

In this article, learn about the frequently asked questions and the answers about using the sample app templates.

> **Important**
>
> For any issues, feedback, support, or changes related to sample app templates, go to **https://github.com/microsoft/teams-powerapps-app-templates/issues** and submit an issue or a pull request.

When I try to install a sample app template, I get an error that the app is already in the team.

You may see the following error when you try to install a sample app template in a team that already has the app installed, but you're not the app owner, or the team owner.

```
This app is already in this team
To update it, you must be its owner or a team owner.
```

When this happens, use the installed app, or install the app in a different team.

How can I move an app to another channel in the same Team?

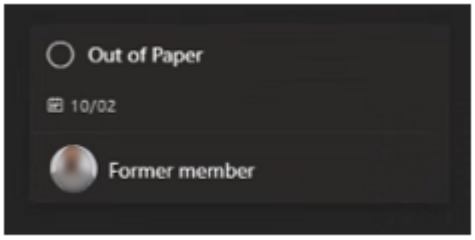
For the steps to move an app, go to Move an app to another Teams channel in the same team.

How do I delete the sample data from the sample app templates?

For the steps to delete sample data from the sample app templates, go to Remove sample data.

Planner tasks are created with “Former Member” instead of the name of the assigned user

When you assign a task in the Issue reporting, or Inspection apps who isn't a member of the Teams team, the user's name on the task will show as "Former member". To correctly display the user's name, add the user to the Team where the app is installed.



Why can't I create tasks in Inspection app?

If a user isn't allowed to create tasks using a mobile device in the Inspection app:

1. Open **Manage inspections** in Power Apps Studio.
2. Select **Settings**.
3. In the Planner drop-down, select the Planner that you want to use.
4. **Save**

Inspection app forms are slow

If your inspection forms are loading slowly, reduce the size of images used in the inspection steps. Users can't interact with the form before all images on the form are loaded.

Known issues and limitations

09/03/2025

This article provides details about the known issues and limitations when using **Dataverse for Teams environments**.

Additional components

The following components aren't supported:

- Model-driven apps
- AI Builder

> **Note**
>
> Custom connectors are supported only if both of these conditions are met:
>
> - The app or flow is running in the context of Microsoft Teams.
> - And, the custom connector points at an APIM endpoint in Azure.

Controls

To learn about the limitations of controls in Dataverse for Teams environments, go to Limitations of controls in Power Apps.

Region availability

Dataverse for Teams currently isn't available in:

- Power Apps operated by 21Vianet in China

Hidden membership groups

Dataverse for Teams doesn't support hidden membership groups. You'll receive the following error when you try to create an app in a team that has the group visibility set to *Hiddenmembership*.

```
Existing limits on this team
```

```
You're unable to continue due to an administrative setting on this team. You can try
```

`again with another team.`

The group may have hidden membership enabled by your administrator. Try using Dataverse for Teams on a new Teams team, an existing team that doesn't have hidden membership enabled, or contact your administrator.

Localization

Localization of Power Apps Studio isn't supported.

Power Apps component framework

Power Apps component framework isn't supported.

Required fields

There's no enforcement of user-created required table fields. Rows that have empty values in those fields can be saved successfully. System required fields are enforced and cannot be saved without a value.

Studio

Classic controls

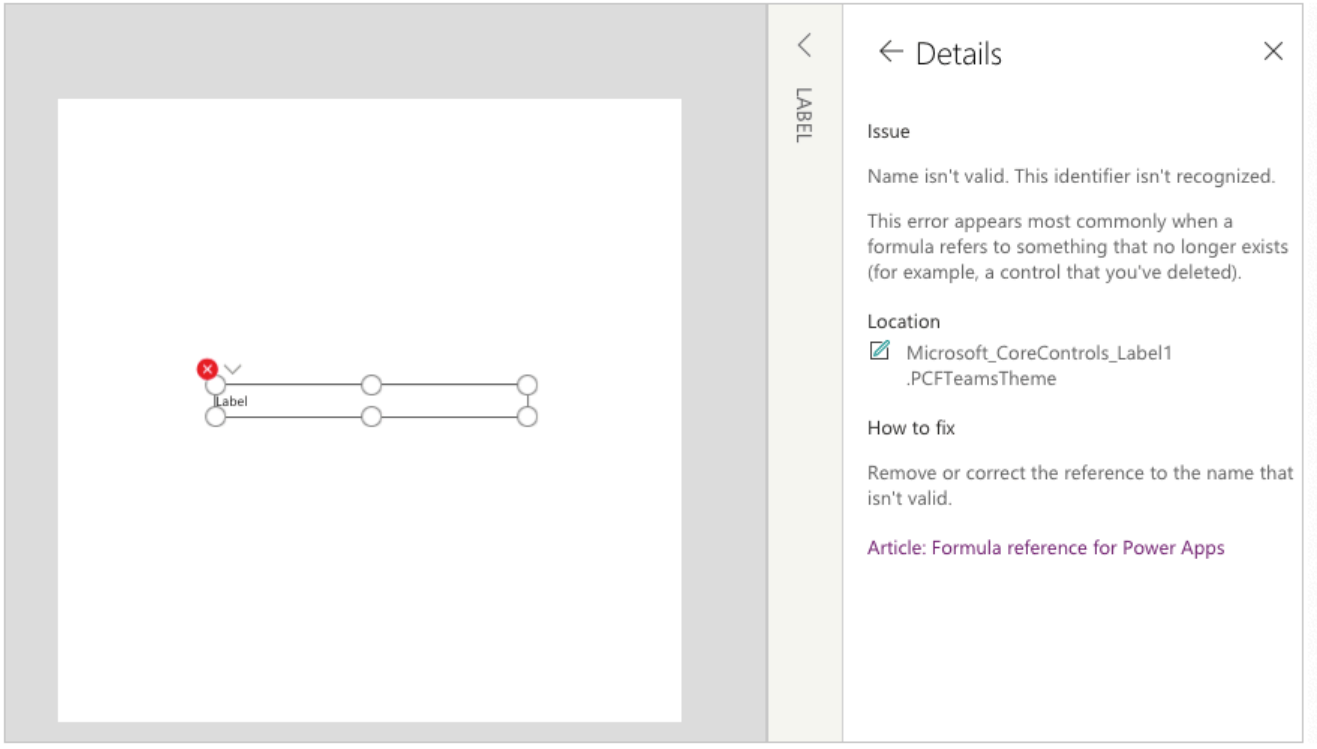
Enabling classic controls requires a refresh of Power Apps Studio.

Fluent UI date picker control

The Fluent UI date picker control doesn't yet support format string. If you need to support special formatting, you'll need to enable classic controls and use the classic Date Picker.

Canvas components

You may see red errors while using the modern controls in canvas components. These errors won't functionally impact your app, and you can ignore them.



New connections

Connections in the Power Apps Studio that require an authentication dialog fails in the Teams desktop client. Open the Studio in the Teams web client to add these connectors.

Studio and visual editor synchronization

Power Apps Studio doesn't reflect the changes to tables after:

1. Renaming tables.
2. Adding relationships within the inline visual editor.

To see the new changes, refresh Power Apps Studio.

Studio version

It's currently not possible to change your Studio version.

Visual editor

Currency, Duration, Language, Ticker, and Timezone fields can't be added using visual editor. To create these fields, use the experience to work with tables as available using solution explorer.

Load time limit

Apps embedded in Teams are required to load within 30 seconds as per Teams requirements. If an app exceeds this 30 seconds limit, Teams assumes that the app has timed-out, and will display an error screen. If your app is encountering this 30 second timeout, review tips to improve performance for boosting your app's performance.

Theme

Power Apps Studio and apps currently don't support **Dark theme**.

Others

- If a user is an owner of the Azure Active Directory (Azure AD) group associated with a team but isn't also a member of that group, they may not be able to see that team in the Power Apps and Microsoft Copilot Studio apps.
- It may take up to 2 hours for deleting, renaming, or restoring a team to reflect correctly within the Power Apps and Microsoft Copilot Studio apps.
- It may take up to 15 minutes for new team users to be able to see the team within the Power Apps and Microsoft Copilot Studio apps.
- Users with the **Teams Guest** role con't trigger flows embedded in canvas apps.

Migrate Microsoft Access data to Microsoft Dataverse for Teams (preview)

Article • 02/15/2022

[This topic is pre-release documentation and is subject to change.]

Microsoft Access users can now choose to migrate their data into Dataverse or Dataverse for Teams to make use of Azure Cloud security and Power Platform functionality. Migrating Access data to Dataverse provides many new opportunities for interaction and management of data.

Watch this short video about migrating Access data to Dataverse for Teams.
https://learn-video.azurefd.net/vod/player?id=de255c2b-7a20-47a7-a7fe-f0cbdf19ee99&locale=en-us&embedUrl=%2Fpower-apps%2Fteams%2Fmigrate-access-to-dvft

Next steps

- Migrate Microsoft Access data to Microsoft Dataverse (preview)
- Data types and sizes for Access data migration to Dataverse (preview)
- System columns and tables in Dataverse and Dataverse for Teams (preview)

Important upcoming changes (deprecations) in canvas apps

The announcements for changes (deprecations) described in this article apply to canvas apps.

Makers, developers, and IT professionals can use this information to prepare for future releases.

> **Important**
>
> "Deprecated" means we intend to remove the feature or capability from a future major release. The feature or capability will continue to work and is fully supported until it is officially removed. This deprecation notification can span a few months or years. After removal, the feature or capability no longer work. This notice is to allow you sufficient time to plan and update your code before the feature or capability is removed.

Enhanced deep link creation requirement

Starting May 1, 2026, for canvas apps, all deep links for Power Apps mobile must include the environment ID as a required parameter. Existing deep links without these parameters will stop working after the deprecation date. You also need to create new shortcuts. Update your links now to avoid disruptions. Old links have slower performance until support ends. Learn more in Use deep links with the Power Apps mobile app.

Deprecated endpoints

For information about deprecated endpoints, see Deprecated endpoints

New addition for restrictive firewall rules to filter subdomains

Effective February 14, 2022, if you're using restrictive firewall rules to filter subdomains instead of `*.powerapps.com`, you'll also need to allow access to `*gateway.prod.island.powerapps.com` for a continued Power Apps authoring and runtime experience. To see the complete list of the subdomains, go to Required services.

Rules feature in canvas apps is deprecated

Effective October 14, 2019, the rules feature in canvas apps in Power Apps is deprecated. Few people have made use of rules in their canvas apps. From feedback collected through research and discussions with makers of Power Apps, the rules feature was confusing, and expressions were easier to learn, use, and debug. For more information about the rules feature deprecation, see Blog: Canvas Rules feature deprecation .

Map component fields using dropdown option

The capability to map component fields using dropdown option available through the **Advanced** tab for the selected component that's added to an app has been deprecated. To learn more about mapping component fields, alternatives, and this deprecation, go to Map input fields of a component.

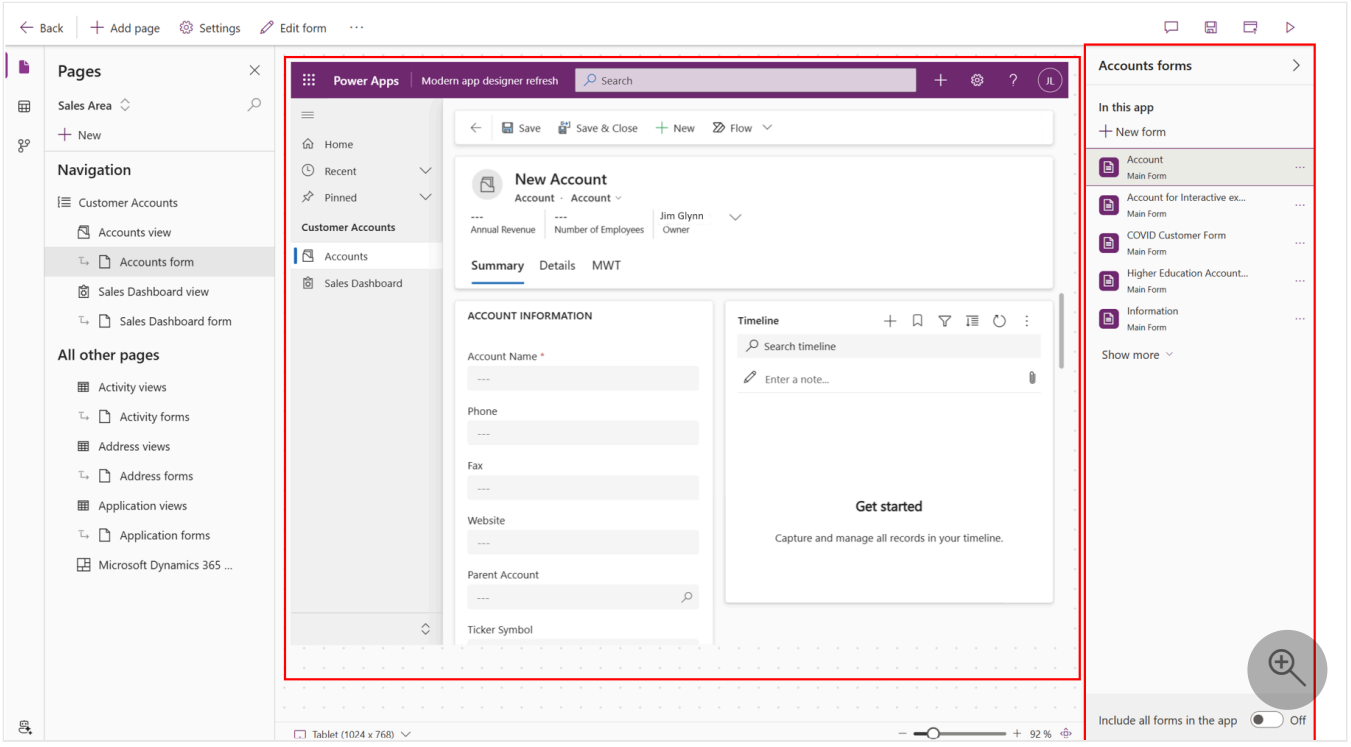
What are model-driven apps in Power Apps?

Model-driven apps overview

Model-driven app design is an approach that focuses on adding components such as forms, views, charts, and dashboards to tables using an app designer tool. Additionally, relationships connect tables together in a way that permits navigation between them and ensures that data isn't repeated unnecessarily.

Using the app designer with little or no code, you can build apps that are simple or complex.



Process driven apps

Model-driven apps are especially well suited to process driven apps that are data dense and make it easy for users to move between related records. For example, if you're building an app to manage a complex process, such as onboarding new employees, managing a sales process, or member relationships in an organization such as a bank, a model-driven app is a great choice.

Data modeling

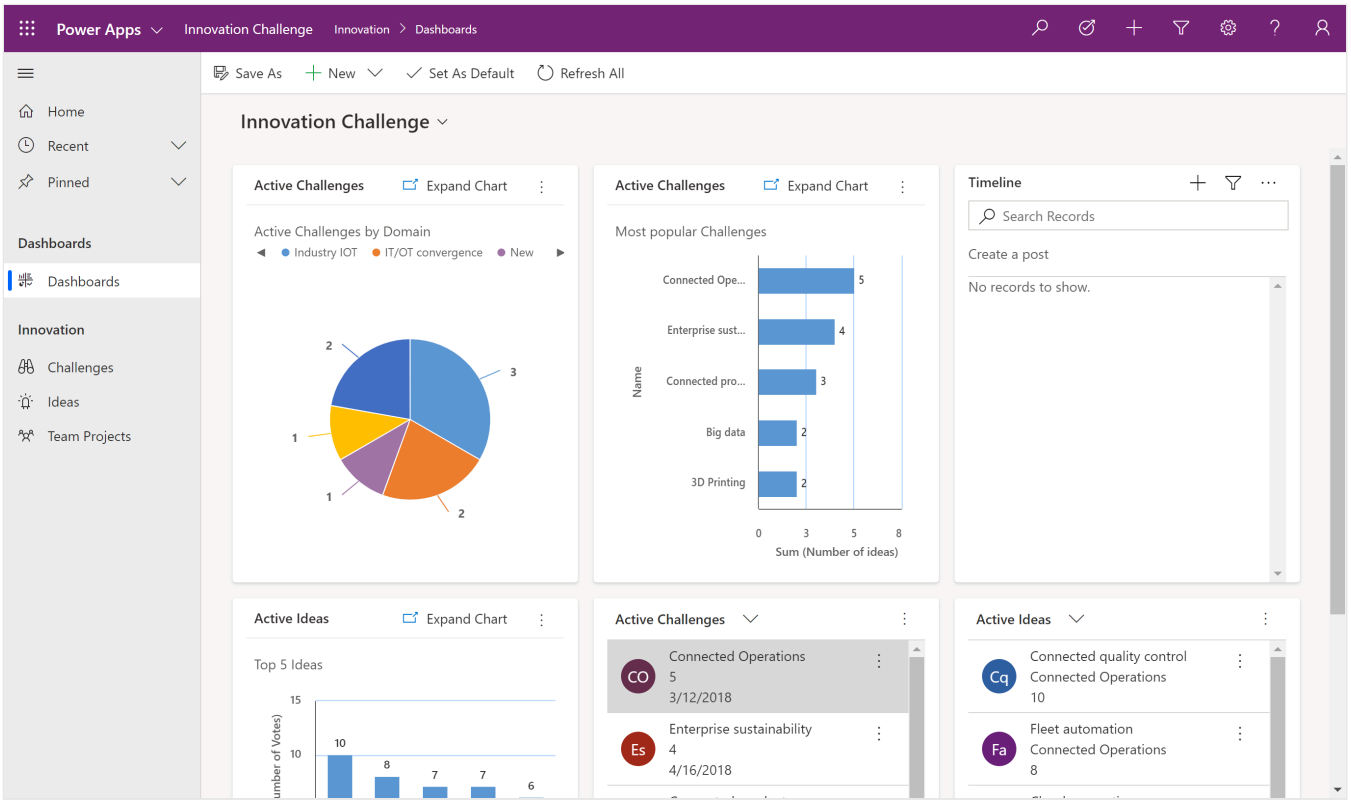
Although we call them *model-driven apps*, it's often easier to think of them as data model driven apps. This is because, without a data model housed within Microsoft Dataverse, you

can't create a model-driven app.

User experience

From the user's perspective, all model-driven apps offer a similar experience, which is both accessible to many users and to the device used. The experience is similar to the diagram shown here.

In this example, the app contains three tables (challenges, ideas, team projects), one dashboard, and multiple charts and views. Users navigate between the tables using the left pane or via the dashboard.



Benefits of the model-driven approach

Unlike canvas app development where the designer has complete control over app layout, with model-driven apps much of the user interface is determined for you and is largely designated by the components you add to the app.

There are some notable advantages to this method of application development.

- Once the data model and relationships are created, the build process is relatively rapid due to rich component-focused no-code designers.
- Apps have a similar user interface across various devices from desktop to mobile.
- The apps are **accessible** and **responsive** automatically.

- The user experience is consistent across all model-driven apps. Once a user is confident with one model-driven app, later apps are easier to adopt within an organization.
- Migrating apps between development, test, and production environments is relatively straightforward by using solutions.

Learn more about the benefits of the model-driven approach

Model-driven and canvas apps compared

In canvas apps, the app maker has total control over the app layout. With model-driven apps, much of the layout is determined by the components you add. The emphasis is more on quickly viewing your business data and making decisions instead of on intricate app design.

Expand table

Category	Model-driven apps	Canvas apps
Data platform	Dataverse only	Dataverse + many others using connectors
Design experience	No-code component focused design	Manipulation of control properties using Power Fx expressions
UI control	Limited, predominantly customization	Full control
App consistency	High – differs predominantly based on the tables and views chosen	Often low, given the significant control the designers have of the user experience
Migration between environments	Simple	Potentially complex given that the datasources might need to be updated
Speed of creation	Rapid	Relative to the complexity of the design
Responsive	Automatically responsive	Only responsive if designed in this way
Navigation through relationships	Automatic, provided relationships exist	Only where designed and applied using Power Fx formulas
Accessibility features	Built in	Designed into the app: Create accessible canvas apps

Steps to building and sharing a model-driven app

At a fundamental level, model-driven app making consists of the following areas.

- Modeling business data
- Defining business processes
- Composing the app
- Configuring security roles
- Sharing your app

A large part of the time spent building the app is dedicated to modeling the business data and in some case to defining the business processes. Customizing security roles depend on the needs of the organization.

Learn more about the steps to building a model-driven app

Using a model-driven app

Documentation has been developed that helps users successfully navigate around and interact with model-driven apps in a way that helps make them more productive.

Learn more about using model-driven apps

You can use model-driven apps on a mobile device and run them in offline mode.

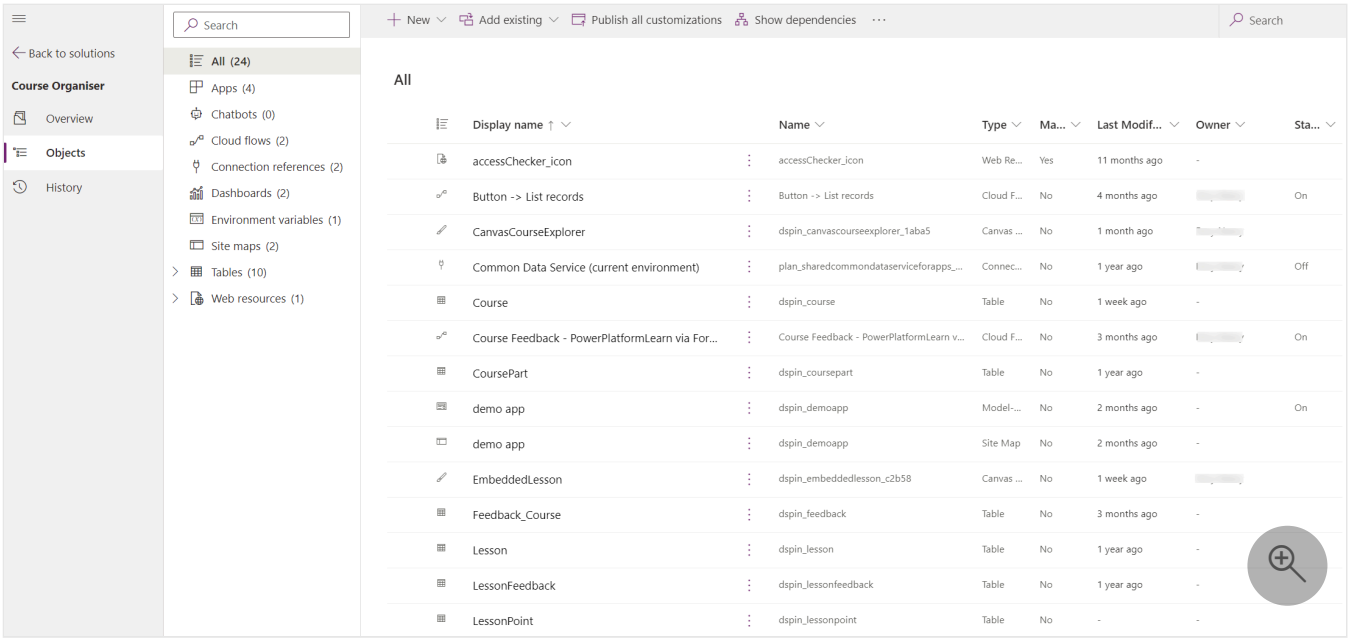
- Get started with Power Apps mobile
- Mobile offline overview (preview)

Using solutions to assist with application lifecycle management

Application lifecycle management (ALM) is the way in which we develop an app from conception to end of life.

Solutions are used to act as wrappers for all the elements required to deliver a product for use within a business.

As a minimum, a model-driven app requires a single table, a site map, plus the app itself. However, model-driven apps generally include a considerable amount more, and this includes canvas apps, security roles, environment variables, and much more.



Solutions offer the means by which these objects can be migrated between environments. Consequently, solutions are an important part of any application lifecycle management strategy.

When you create a model-driven app, you should create it within a solution.

- Learn more about solutions
- Create a solution

Minimum requirements for building a model-driven app

Model-driven apps can be complex. However, the minimum requirements for building them are relatively straightforward.

- A Microsoft Power Apps license.
- Capacity to create a Power Platform environment. This is a feature of the Power Apps and Dynamics 365 licenses held.
- A Power Platform environment.
- A Dataverse database within the environment. This is selected when you create an environment. More information: Create an environment with a database
- Privileges for the maker to work as a system customizer or environment maker in the environment where the model-driven app is created. More information: About predefined security roles
- A table. (There are many standard tables, including account, which exist by default.)
- One table column. (Every table has at least one column, and many system columns.)
- One table view, to view records. (There are a number by default.)
- One table form, to enter data. (There will be one by default.)

Using the app designer, a model-driven app is created by adding a page, which adds navigation to the app, and is typically based on a table or custom page.

The benefits of the model-driven approach

Article • 02/15/2022

Model-driven apps are familiar to anyone who has worked with Dynamics 365 apps. To others, they're a new business productivity tool.

Dynamics 365 apps, such as Dynamics 365 Sales, Dynamics 365 Marketing, or Dynamics 365 Customer Service, are essentially a set of line-of-business apps, built on Dataverse. The utility of the Dynamics 365 model was recognized as being powerful and by making Dataverse fully customizable, has enabled more bespoke solutions to be created.

Model-driven apps are worth considering in your organization for the following reasons.

Security

- The platform is reliable. It is the same as is used by Dynamics 365 apps, to cover complex business processes and govern millions of transactions in the biggest businesses in the world.
- Model-driven apps have tried and tested application lifecycle management options.
- Dataverse supports a strong and flexible data security model affecting the degree to which users can interact with table records and columns.

Extendability

- Any Dataverse table component can be used and reused, such as contacts, accounts, or any custom tables created.
- Model-driven apps integrate with Office 365.
- Industry accelerators exist to enable a quicker entry into markets such as insurance or healthcare.
- Dataverse is extendable through use of Azure services, such as Azure Synapse Link for Dataverse.
- Canvas app integration possibilities are integral to the platform. More information: Design a custom page for your model-driven app (preview)
- Extensible with code to allow for a user experience that fits the organization more tightly.
- There is a pool of competence worldwide covering the platform through Dynamics consultants in addition to Power Platform practices.

Usability for all

- Model-driven apps are responsive by design. This means they render better on a wide range of devices.
- Model driven apps are accessible to users with disabilities including those that require screen readers.
- Offline capabilities are native to model-driven apps.
- Multilingual label support to ensure that your apps can be used worldwide.

Empowers citizen developers

- Minimal user interface maintenance as much of the experience is delivered via configuration versus outright coding.
- Predominantly a low code development platform.

Business logic

- Logic can be introduced to ensure that columns contain the data that adheres to the business rules. More information: Create business rules and recommendations to apply logic in a model-driven app form
- Business process flows to guide users to update records in the correct order and in the correct way.
- Power Automate native integration exists and flows exist as separable solution components.

Next steps

Build your first model-driven app

Release channels for your model-driven app

Microsoft regularly provides new and updated features for your model-driven apps. You can control how often the users in your organization get these new features by specifying the release channel. The concept of multiple release channels originated from Microsoft 365 channels and provides Power Platform admins with a choice of how often end user impacting features are released.

The existing cadence of twice-yearly release waves is called the *Semi-annual channel* and is currently the default for all existing apps and environments. The *monthly channel* option enables GA-ready features to be turned on each month with a four week preview notification period to allow customer validation with existing customizations.

This table provides a comparison of monthly channel and semi-annual channel.

Expand table

Category	Monthly channel	Semi-annual channel
Recommended use	Provide your users with new end user impacting features only once a month and on a predictable schedule.	For users in your organization where more training and extensive testing are needed before rollout out of new end user impacting features.
Release frequency	Once a month, on the first release for the month and following the gradual weekly rollout.	Twice a year, starting early April and early October and following the gradual weekly rollout.

Security and non-end user impacting changes continue to be delivered with the weekly releases and changes outlined in Microsoft Unified Interface versions.

The key idea is that GA-ready end user impacting features release monthly instead of waiting for the twice-yearly release cadence. The same number of features are delivered in 12 smaller releases instead of two larger releases.

Microsoft 365 products experience consistently higher user satisfaction for monthly channel compared to the semi-annual channel. Currently, we observe a user satisfaction drop with the twice-yearly releases, and we're looking to improve this experience by following the Microsoft 365 channel approach.

Configuring release channel

Release channel can be configured on the environment, app, or user level. The release channel is primarily managed on the environment or app. The user level is an override, which can be used for gradual rollout or to revert specific users.

Environment admins use the Power Platform admin center to select the channel for the environment. Makers use app designer or the solutions area to select the channel for one or more apps.

To allow gradually switching the default from semi-annual channel to monthly channel, the default value for both environment release channel and app release channel were renamed to **Auto**. There's an explicit choice for **Semi-annual** and **Monthly**. More information: Changing release channels.

With 2024 release wave 1, the Power Platform environments were changed to treat **Auto** app release channel as **Monthly** and newly created model-driven apps default to **Monthly**. With 2024 release wave 2, the Dynamics 365 environments changed to treat **Auto** app release channel as **Monthly**. Admins and makers can select **Semi-annual** if they need the slower cadence. More information: Keeping semi-annual release channel.

Monthly release schedule

Model-driven apps release updates every week, which is gradually rolled out to groups of regions over several weeks. These are the region groups with each group happening in successive weekend updates.

1. First release environment (FRE)
2. Canada, South America, India, France, South Africa, Germany, Switzerland, Norway, Korea, Singapore
3. United Arab Emirates, Japan, Asia Pacific, Great Britain, Australia
4. Europe
5. United States

The monthly release is the first weekly release of each month. The release typically matches `YYMM.1` where `YY` is the release year and `MM` is the release month. The monthly release notes are published to Released versions for Power Apps four weeks before the release reaches the region group 2. Region group 2 is used because it's the first region group for production customer environments and region group 1 is used for customer early validation.

Expand table

Monthly release	Doc published	Feature release	Group 1	Group 2	Group 3	Group 4	Group 5
Aug 2024	Jul 19	2408.2	Aug 16	Aug 23	Aug 30	Sep 6	Sep 13
Sep 2024	Aug 16	2409.1	Sep 6	Sep 13	Sep 20	Sep 27	Oct 4
Oct 2024	Sep 20	2410.1	Oct 11	Oct 18	Oct 25	Nov 1	Nov 8
Nov 2024	Oct 18	2411.1	Nov 8	Nov 15	Nov 22	Dec 6	Dec 13
Dec 2024	Nov 15	2412.2	Dec 13	Dec 20	Jan 10	Jan 17	Jan 24

Last updated on 03/30/2026

Change release channels for model-driven apps

The release channel affects the features that impact users. When the monthly channel is enabled for an environment, makers need to validate that their customizations work with each monthly release. This article describes different approaches for a maker to change channels and validate an upcoming release.

Flexible channel configuration

The release channel for model-driven apps can be changed in two primary ways.

- App channel
- Environment channel

In addition, the release channel can be overridden with either of these options.

- User channel override
- Browser session channel override

> **Note**
>
> When you change the release channel at the environment level, a user must refresh the browser tab twice to update the release channel information. The first refresh triggers a background update of feature configuration to a local cache. The second refresh uses the feature configuration local cache.

Ordering of channel release usage

The order of checks to determine which setting controls the channel is:

1. URL override.
2. User channel override.
3. App release channel value other than Auto (for example, Monthly, Semi-annual).
4. Environment release channel value other than Auto (for example, Monthly, Semi-annual).
5. App release channel and environment release channel are both Auto.
   a. With 2024 release wave 1, Power Apps environments use monthly channel.
   b. Starting with 2024 release wave 2, Dynamics 365 environments use monthly channel.

Dynamics 365 app release channel settings

With 2024 release wave 1, the following Dynamics 365 apps changed their app release channel to **Monthly**:

- Customer Service workspace
- Customer Service Hub
- Customer Service admin center
- Field Service
- Field Resource Hub
- Field Service Mobile
- Resource Scheduling
- Resource Scheduling Optimization
- Customer Insights - Journeys
- Business performance analytics
- Project Operations Team Member
- Power Platform environment settings

With 2024 release wave 2, this app is changing the app release channel to **Monthly**:

- Sales Hub

Keep semi-annual release channel

When an environment needs to have a slower release cadence, these configurations are recommended.

Change apps with explicit app release channel

Model-driven apps with the app release channel set to a value other than **Auto** need to be changed to **Semi-annual**. These apps can be deployed to all environments as a managed solution.

1. Customize any out of box Dynamics 365 app.
2. Update any custom app created after 2024 release wave 1 when the new app started defaulting to **Monthly**.

The preferred approach is to follow Change app channel in app designer and then deploy the app's solution to all environments.

> **Note**
>
> Model-driven apps in Power Platform environments use **Monthly** when the app release channel is **Auto** regardless of the environment release channel. All model-driven apps in

Power Platform environments need to set the app release channel explicitly.

Override apps when no explicit app release channel

Model-driven apps in a Dynamics 365 environment that have **Auto** for app release channel can choose either option:

- Change each environment release change to **Semi-annual**.
- Change each app to **Semi-annual**.

Changing the environment channel

The environment channel can be set using the Power Platform admin center or with code.

Expand table

Environment release channel	Environment setting value	Behavior
Auto	0	Environment default value is currently **Semi-annual**, but changes to **Monthly** with 2024 release wave 2.
Monthly	1	Environment explicitly set to **Monthly Channel**.
Semi-annual	3	Environment explicitly set to **Semi-Annual Channel**.

Power Platform admins can change the release channel using the environment's behavior settings. More information: Manage behavior settings.

Developers can change the environment channel by updating the ReleaseChannel column value for the row in the Organization table. There's always a single row in the organization table. More information:

- Update a record using Web API
- Update a record using the SDK for .NET

Changing the app channel

Use the app channel to override the release channel for a model-driven app by using Power Apps app designer or the **Solutions** area.

Expand table

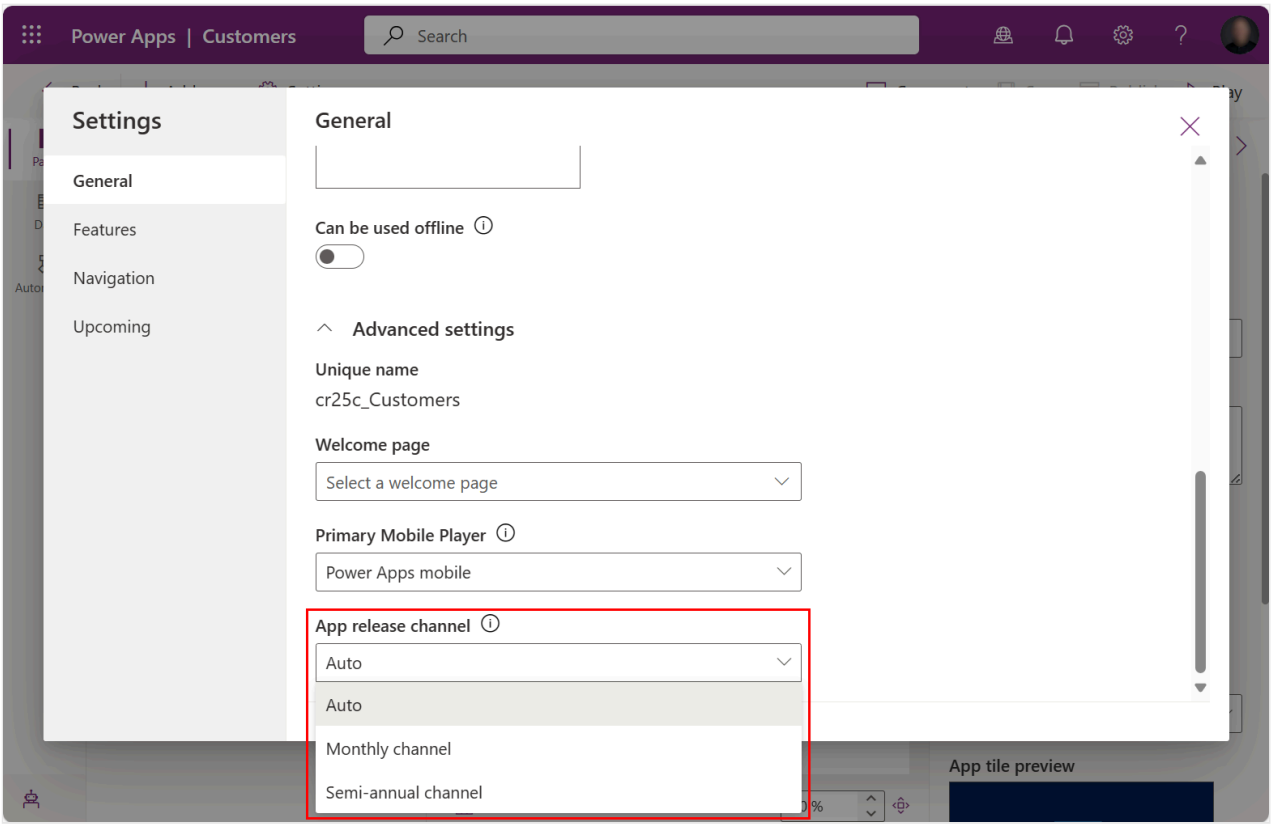
App release channel	App setting value	Behavior
Auto	0	App default value is **Semi-annual** for Dynamics 365 environments and **Monthly** for Power Apps environments. With 2024 release wave 2, the default changes to **Monthly**.
Monthly	1	App explicitly set to **Monthly Channel**.
Semi-annual	3	App explicitly set to **Semi-Annual Channel**.

> **Note**
>
> App release value `2` is used for internal testing and receives updates faster than monthly channel so isn't supported for production usage.

Change app channel in app designer

A maker can use the app designer to explicitly set the release channel for an app, which overrides the environment channel.

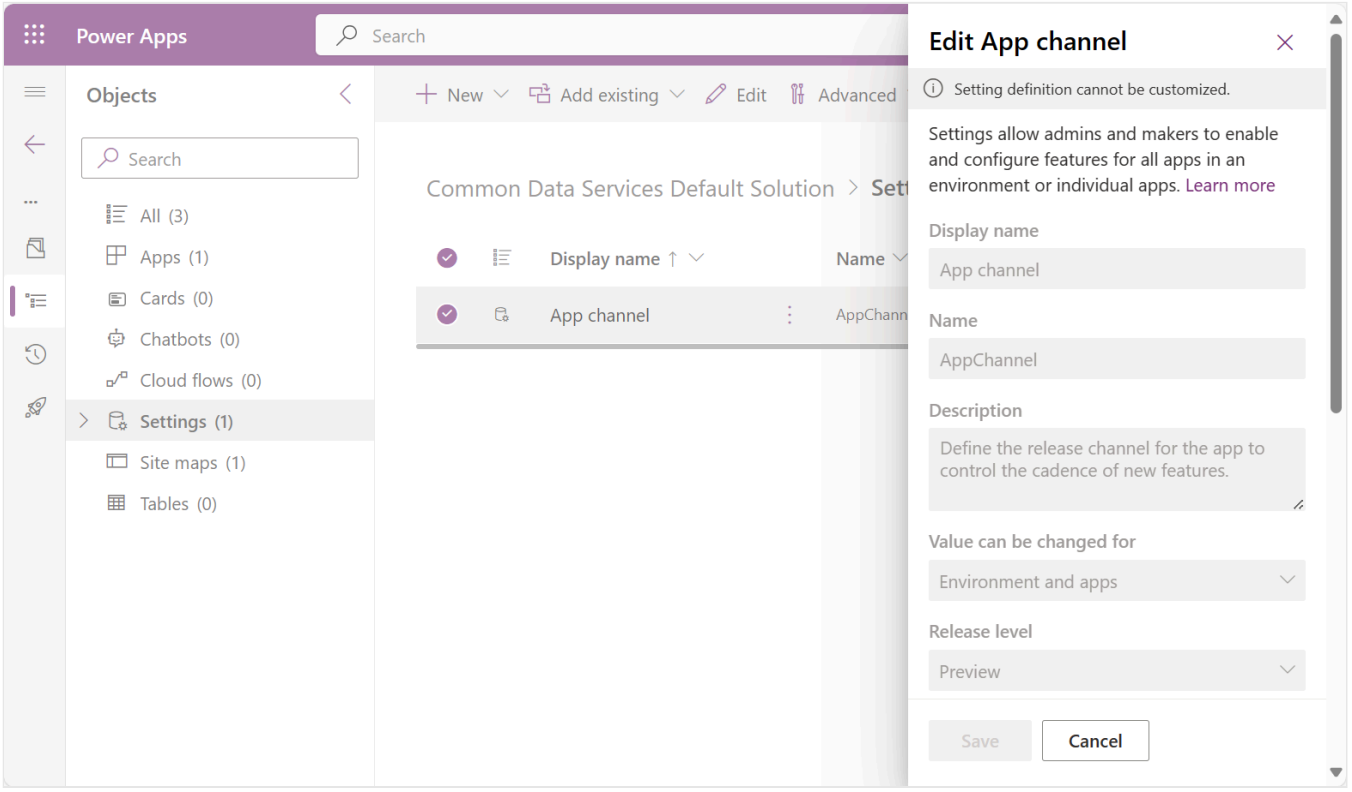
1. Open https://make.powerapps.com/ .
2. Under **Solutions** open an existing solution containing a model-driven app.
3. Open the app in the app designer.
4. Open **Settings** dialog.
5. Under the General tab, expand **Advanced settings**.
6. Use **App release channel** to change the app release value. More information: Changing the app channel



7. Save and publish the app.

Change app channel in the solutions area

As an alternative, a maker can use the **Solutions** area to explicitly set the release channel for all apps within the environment.



1. Open https://make.powerapps.com/ .

2. Under **Solutions** open an existing solution with one or more model-driven apps:
3. Add the existing app setting **Allow new app channel default** into the solution:
    a. Select **Add existing** > **More** > **Setting**.
    b. Search for *app channel*.
    c. Select the item **App channel**.
    d. Select **Add**.
4. To change the app channel for all apps in the environment:
    a. Edit the setting **App channel**.
    b. Find the section **Setting environment values**.
    c. Select **New environment value** and then enter the integer for the channel.
    d. Select **Save** which publishes the Setting Definition.

> ⓘ **Note**
>
> When the setting definition is used to change one or more apps as part of a single solution, you must republish the apps for the change to take effect. Also, making this change causes the apps to have dependencies on the solution with the customization.

Set the default for new apps to monthly channel

As part of the gradual migration to default all apps to use monthly channel, newly created model-driven apps gradually start seeing the app channel defaulted. Admins or makers can control the release channel default for new apps using an app setting. The app setting **Allow new app channel default** defaults to **Yes**, which means a newly created app is set to **Monthly**.

To override this behavior, change the app setting to **No** in the environment or apply to multiple environments by including in a solution that is imported into the environments.

Prevent new app default to monthly channel

The new app default can be prevented by switching **Allow new app channel default** to **No**. This change causes the new app to be created with release channel **Auto** value.

The following steps change the default for all new apps within an environment. This app setting override can also be put into a solution and imported into environments to prevent new apps from having a default set.

1. Go to **Solutions** and open an existing or create a new solution.
2. Add the existing app setting **Allow new app channel default** into the solution:
    a. Select **Add existing** > **More** > **Setting**.
    b. Search for *app channel default*.

c. Select the item **Allow new app channel default**.
d. Select **Add**.

3. Edit the setting **Allow new app channel default**:
   a. Select **Allow new app channel default**.
   b. Select **New environment value**.
   c. Change the environment value to **No**.
   d. Select **Save**.

Changing the user channel

The user channel can be used to override both the environment channel and the app channel using the Power Platform admin center or with code.

Power Platform admins can change the release channel using the settings in the environment's user list. More information: Manage user channel override.

Developers can change the user release channel by updating the ReleaseChannel column value for the row in the UserSettings table. The user channel can be programmatically updated with the same approach as the environment channel.

Changing the browser session channel

A single browser session can be changed by adding the URL parameter `&channel=<channelname>` as a temporary override. This URL parameter is used for all navigation within the browser tab. It might not be copied to a new browser tab.

Expand table

Channel	URL parameter
Semi-annual	`&channel=semiannual`
Monthly	`&channel=monthly`

When the channel is monthly, the monthly release can be changed using the URL parameter `&channelrelease=<releasename>`. The release name format is the two digit year and two digit month, like *YYMM*. Additionally the next monthly release can be set using `&channelrelease=next`.

Expand table

Monthly Release	Release Name Parameter
October 2023	`&channelrelease=2310`
November 2023	`&channelrelease=2311`
December 2023	`&channelrelease=2312`
January 2024	`&channelrelease=2401`

> ⓘ Note
>
> Any valid `YYMM` release can be entered but future dates might not have any features defined.

Validating the next monthly release

Validation should be done for each monthly channel release before it is automatically enabled for users. Users can test when the validation build version reaches the environment.

The easiest way to validate is by appending `&channelrelease=next` that automatically sets the release channel to the next upcoming monthly release.

1. Find the current monthly release for a model-driven app by selecting **Settings** > **About**. The release version follows **Channel: Monthly** and is a date like *July 2023*.
2. Append `&channelrelease=next` to the URL.
3. Repeat the first step to observe an updated release version.

To validate against a specific monthly release, use the following steps:

1. Find the current monthly release for a model-driven app by selecting **Settings** > **About**. The release version follows **Channel: Monthly** and is a date like *July 2023*.
2. Find the monthly release short name by opening Unified Interface monthly channel releases.
3. A specific release can be set with the URL parameter ```&channelrelease=`` with the next release short name like *2308*.

Comparing features across channels and releases

When a user running the monthly channel observes unexpected behavior, the following steps can help investigate where the behavior occurred.

- Check if the unexpected behavior exists in the semi-annual channel by using the URL parameter `&channel=semiannual`. If the behavior also exists in the semi-annual channel, it's unrelated to the monthly channel and should follow normal support processes.
- Check if the unexpected behavior exists in the previous monthly release by using the URL parameter `&channelrelease=` with the prior release short name like *2308*. If the two monthly releases behave the same, then it's likely unrelated to a specific monthly channel release and should follow normal support processes.
- When a change is noticed between monthly releases, review the changed features in Unified Interface monthly channel releases to learn more.

Meet the model-driven app designers

Article • 02/15/2022

In order to fully develop a model-driven app, multiple designers are required at different stages in the development process.

Broadly speaking, app development breaks down into the following stages:

- Data model development
- App development
- Data security

Assets created, such as tables, cloud flows, or model-driven apps, have the capacity to be held inside solutions to enable secure application lifecycle management.

This article focuses on the first two stages. For more information about data security, go to Security in Microsoft Dataverse

> **Note**
>
> It isn't necessary to use all the editors to create a model-driven app. As a minimum, concentrate on the table column editor, form designer, and view designer in addition to adding any required relationships. Then use the app designer to pull the components of the app together.

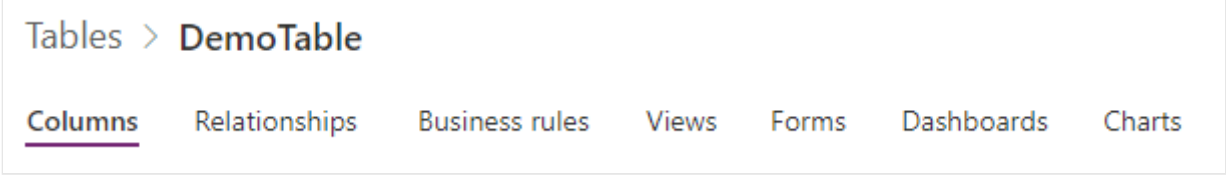
Data-model development

The value of model-driven apps centers around having a strong, secure, reusable data-model. Once the data-model is in place, the process of developing the app is straightforward.

The table designer, and related designers

Development of the data-model starts with using the table designer. A table is a significant artifact of a model-driven app. There is a table designer, which defines the table structure, and includes access to the other designers for relationships, views, forms, and so on.

The table designer is shown below.



The following table describes the designers, what they do, and provides links about how to open them.

Editor	Description	Link
Table designer	Tables hold record metadata in columns for a wide range of data types such as text, email, image, currency, and more. Many standard tables are available. You can customize a non-system standard table. You can also create a new custom table from scratch. The table designer is effectively an entry point to the other designers, such as view and form. In many cases, the designers are native to the table designer and in others a new browser tab opens where editing can take place. The columns area of the table designer allows the developer to define the table columns.	Create a custom table
Relationships	Part of the table designer. Relationships are fundamental to the operation of any model-driven app. Without them all tables are isolated.	Create a relationship
Business rule designer	A separate designer accessed via the table designer. Business rules apply rules or recommendation logic to a form to set column requirements, hide columns, validate data, and more. App designers use a simple interface to implement and maintain fast-changing and commonly used rules.	Create a business rule for a table
View designer	Part of the table designer. Views are tied to the table and present table data in columns by selecting, positioning, and filtering them.	Create a view
Form designer	A separate designer accessed via the table designer. Forms allow users to interact with data held in table records.	Create a form
Dashboard designer	A separate designer accessed via the table designer. Used to create and edit dashboards presenting different data visualizations, such as embedded Power BI reports, data charts, and views.	Create a dashboard
Chart designer	A separate designer used to create table charts.	Create a system chart

Editor	Description	Link
Business process flow designer	Business process flows walk users through a standard business process. While they are a part of the solution, they are created using Power Automate.	Create a business process flow

Business logic development

Business logic can be introduced in the form of business rules and business process flows.

In addition, Power Automate cloud flows can be used in a model-driven app that leverage cloud flow functionality, which can access hundreds of data connectors, not just Dataverse.

Learn more about using Power Automate with Dataverse

App designer

The app designer is the tool that is used to create the app and to configure the tables used in the app. It is important to understand that the quality of the app has much less to do with the edits performed at this stage than those using the other designers.

Makers can choose the views, forms, charts, and dashboards relevant to the app in development.

Create an app using the app designer

Next steps

Steps to building a model-driven app

Build your first model-driven app

Steps to building a model-driven app

This article describes the steps for building a model-driven app in Power Apps.

At a fundamental level, model-driven app making consists of the following stages.

Expand table

Stage	Purpose
Modeling business data	To ensure that the data is constructed in the correct way to address the business problem.
Defining business processes	To help users update the relevant tables and complete their work efficiently and accurately.
Composing the app	To create the app and select tables, and elements of tables, that are relevant to the app.
Configuring security roles	To ensure that app users can only interact with data relevant to their roles.
Sharing the app	App distribution.

Each stage requires a range of designers and editors to ensure that the application can be created, whether the app maker is updating the data model or going through the process of composing the app.

While it might seem strange to have multiple designers or editors, these tools reflect the various technologies that have been brought to bear within Microsoft Dataverse. Often makers move seamlessly through the editors to construct the app.

For a simple walk-through of building a first app, go to building a first model-driven app.

Modeling business data

To model business data, you determine what data your app needs and how that data relates to other data. Model-driven design uses a metadata-driven architecture so that designers can customize the application without writing code. Metadata means “data about data” and it defines the structure of the data stored in the system.

> **Note**

With the exception of model-driven apps that have a custom page, model-driven apps can't be created without Dataverse tables. However, Dataverse tables can be used by many Power Platform services, including canvas apps and Power Automate.

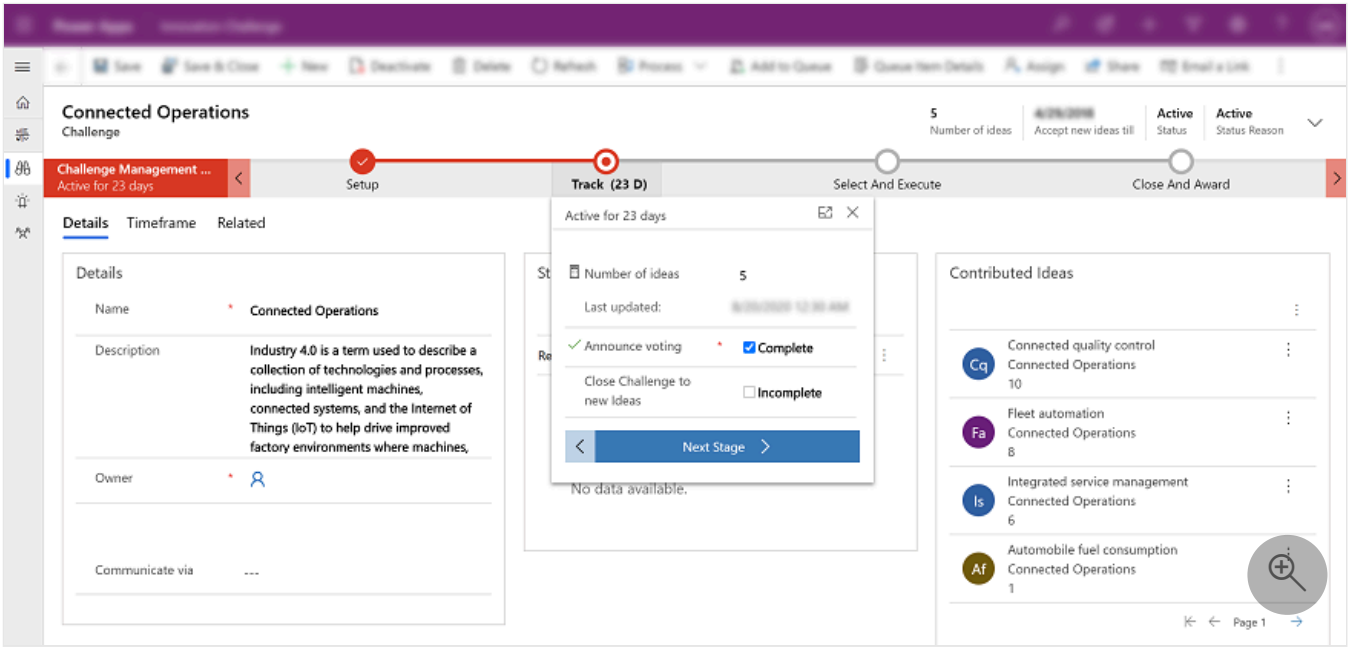
Tutorial: Create a custom table that has components in Power Apps

Defining business processes

Defining and enforcing consistent business processes is an important aspect of model-driven app design. However, you can create a model-driven app without a business process configured around it.

Consistent processes help ensure your app users focus on their work and not on remembering to perform a set of manual steps. These processes can be simple or complex and can contain operations on multiple tables.

The screenshot here illustrates the impact of having a business process flow in place.



Business process flows are created and configured using the business process flow designer.

More information: Business process flows overview and Apply business logic with Microsoft Dataverse.

Composing the model-driven app

After you create a data model and define business processes where necessary, you can build the app.

This is done by building an app using the modern designers and editors.

With the modern designers and editors, makers can see the effects of the changes that they make while designing, whereas with the legacy interfaces there was a level of abstraction between the final user experience and the design experience. More information: Learn how to build a modern app

When you build an app, a site map is created, defining the navigation experience for users. With the modern app designer, this is a part of the app design process.

More information: Building a site map

Playing the app

Play your app through the app designer.

Once these stages are complete, you can move onto the final phases associated with distributing your app.

Configuring security roles

Access to tables is defined using security roles and these roles govern the actions that users can perform with the tables within Dataverse. Without this, users have no meaningful access to the app.

These actions cover Create, Read, Write, Delete, Append, Append To, Assign, and Share. Security roles need to be first configured and then users are assigned to roles at the point of sharing.

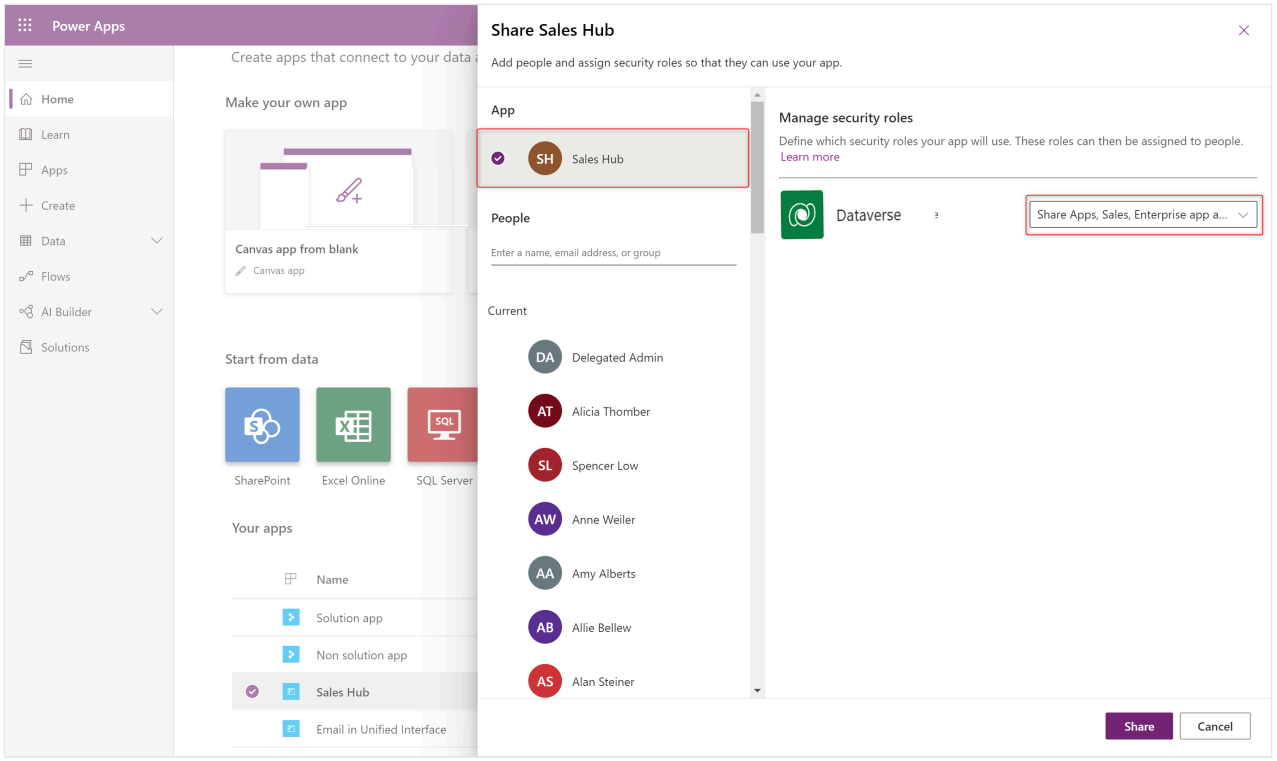
For more information on understanding, creating and configuring security roles go to:

- Power Platform documentation
- Get started with security roles in Dataverse

Sharing the app

To share an app, two actions are required:

- Assign the user a security role. This means that they have permission to see the data.



- Share a link to the app. To get the link:

1. Sign in to Power Apps, and then select **Apps** on the left navigation pane.
2. Select the model-driven app you want, and then select **Details** on the command bar.
3. Copy the **Web link**. Alternatively, you can make a copy of the **Mobile QR code** for mobile users.
4. Paste the app URL in a location so that your users can access it, such as by posting it on a SharePoint site or send via email.

Sharing an app and security roles are intrinsically linked. To properly share an app, you need to have a strong understanding of both. Discover more about sharing apps and establishing security

Using a model-driven app

Documentation is available that helps users of model-driven apps successfully navigate around and interact in ways that help make them more productive. Learn more about using model-driven apps

Next steps

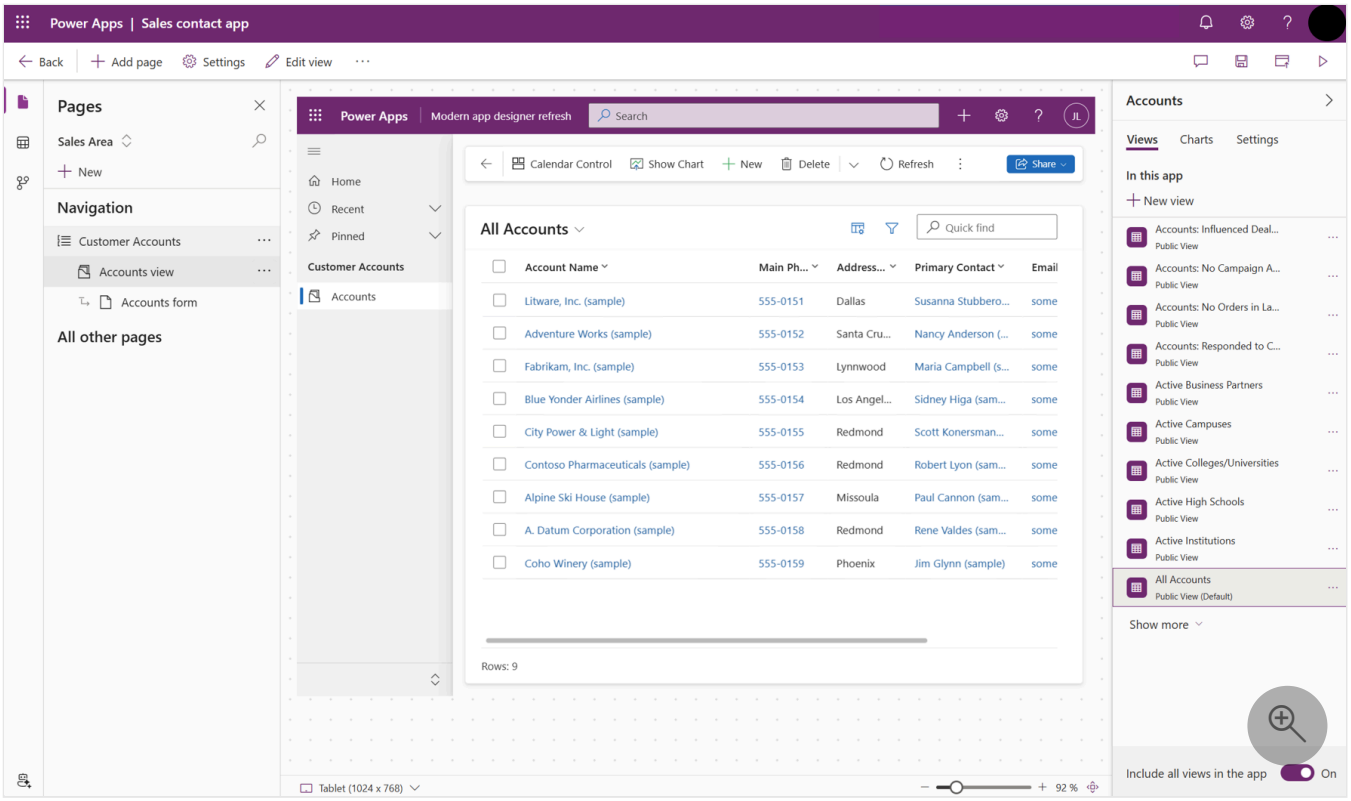
Build your first modern app

Meet the model-driven app designers

Last updated on 04/08/2026

Build your first model-driven app

In this tutorial, you create a model-driven app by using one of the standard tables that is available in Microsoft Dataverse, the account table.



1. Sign in to Power Apps. If you don't already have a Power Apps account, select the **Get started free** link.

2. Select an environment. An environment in Power Apps is a space to store, manage, and share your organization's business data, apps, chatbots, and flows. It also serves as a container to separate apps that might have different roles, security requirements, or target audiences.

   Each environment can have one Dataverse database.

   Select the environment you want. If your tenant allows you to create your own environment, select the current environment from the top right, and then select **Try it now**. More information: Get your developer environment (preview)

3. We recommend creating your model-driven app from a solution. A solution is a package that can contain Dataverse tables, forms, views, apps, flows, and other components. By building your model driven-app in a solution, you can easily move it to other environments or preserve a copy in your source control repository.

   Select **Solutions** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

4. Select **New solution**, enter a **Display name** for your solution, such as *Power Apps Training*, select a publisher (the **CDS Default Publisher** is okay for this tutorial), and then select **Create**. For more information about creating a solution, go to Create a solution.

5. In your solution, select **Add existing**, and then select **Table.**

6. In the **Add existing tables** list, select the **Account** table, and then select **Next**.

7. Since this is a standard table, leave the default setting for account table objects and metadata and select **Add.**

   Now that you have a solution and have added the account table to it, you're ready to create a model-driven app.

8. In your solution, select **New**, select **App**, and then select **Model-driven app.**

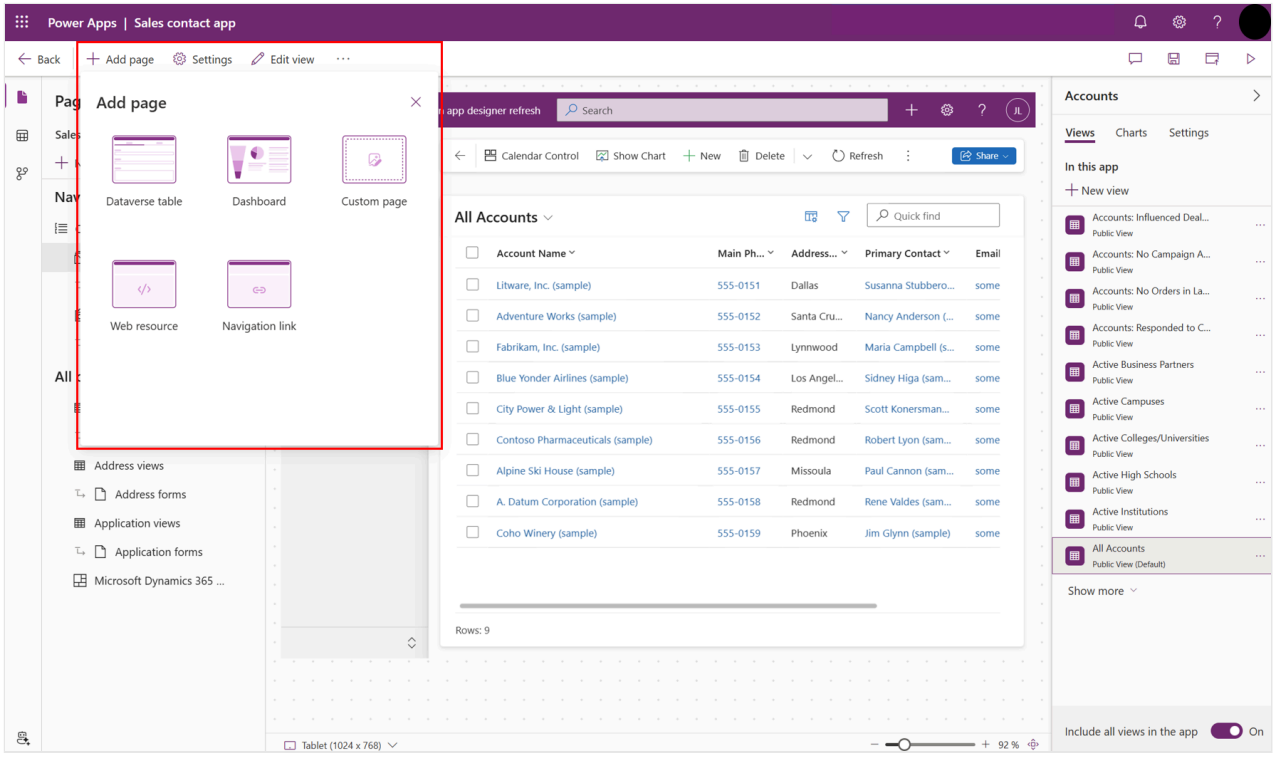
9. Enter a name for the app, such as *My new custom app*, and then select **Create**.

   Your app loads in the model-driven app designer.

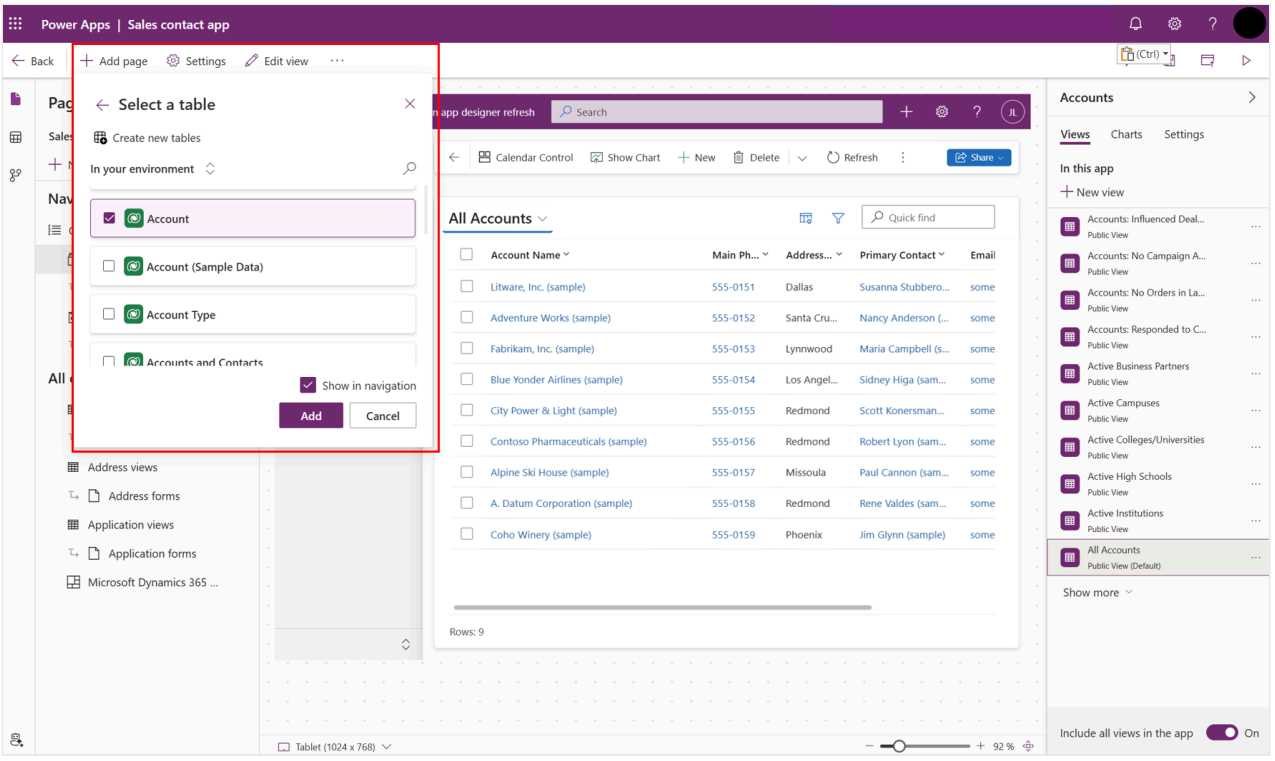
Add a page to your app

Next, you add a new page to the model-driven app in the app designer.

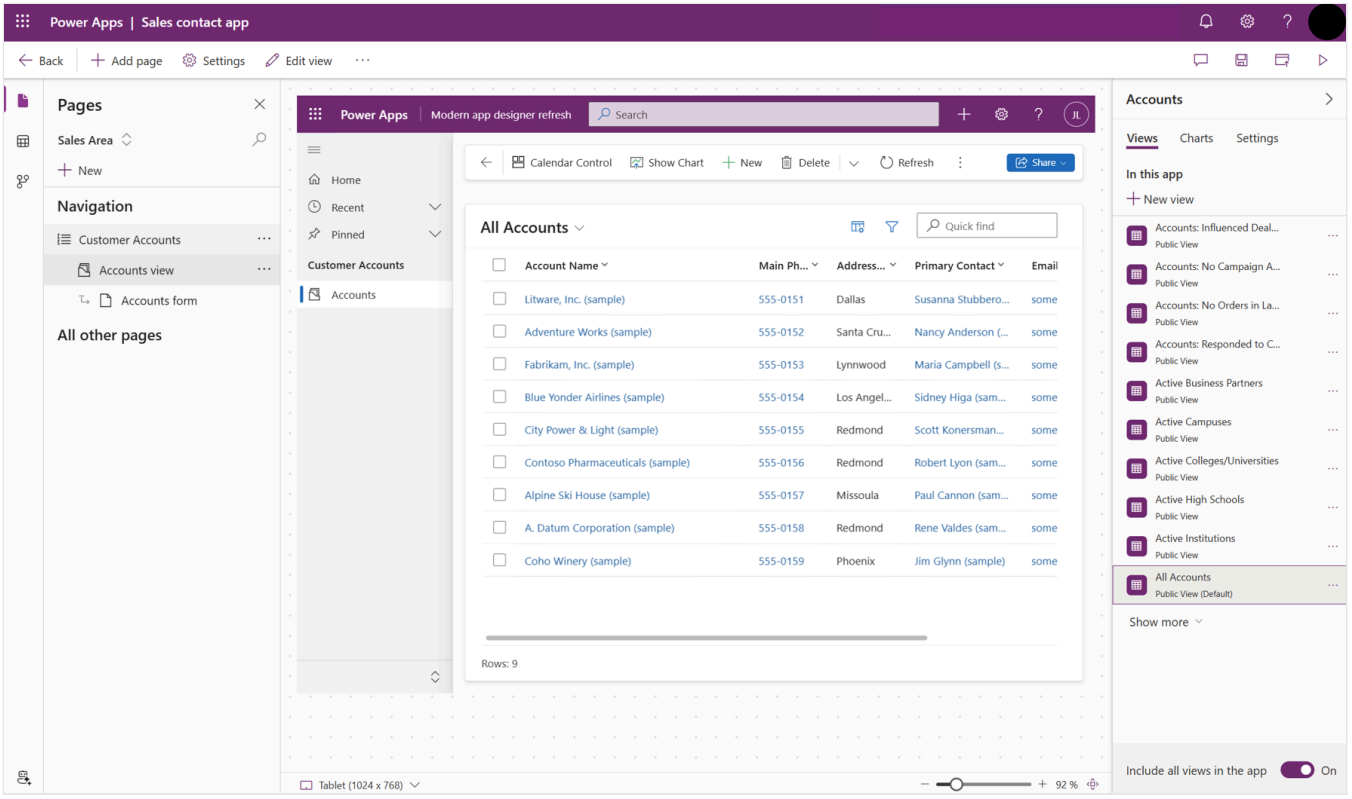
1. Select **Add page** on the command bar, and then select **Dataverse table**.



2. Select **Account**, and then select **Add**.



Your app with the account table is displayed similarly to how it appears to users at run time when published. If your environment has sample data, the sample list of active accounts might appear in the **All Accounts** view.



Save and publish your app

Save your app so that your app and changes aren't lost. To make it available to users, publish it.

To save without publishing, on the app designer command bar, select **Save**.

To save and publish, on the app designer command bar, select **Publish**.

Create an app description with Copilot

If your app is in a managed environment, you can use AI to help you create a description for your app.

> **Important**
>
> - To use this capability your app must be in a **managed environment**.
> - This capability is powered by **Azure OpenAI Service**.
> - This capability might be subject to usage limits or capacity throttling.
> - To understand capabilities and limitations of AI-powered and Copilot features in Power Apps, go to **Responsible AI FAQs for Power Apps**

When you save and publish your app, on the **Publish** dialog box select, **Create descriptions using AI** to replace your current description or, if your app doesn't have a description, Copilot generates one for you.

You can also generate an app description by going to, **Settings** > **General**. Under **Description** select, **Create descriptions using AI**.

For information that describes the AI impact of Power Apps generate app descriptions with Copilot feature, go to FAQ for generate app descriptions with Copilot.

Enable or disable AI-generated app descriptions

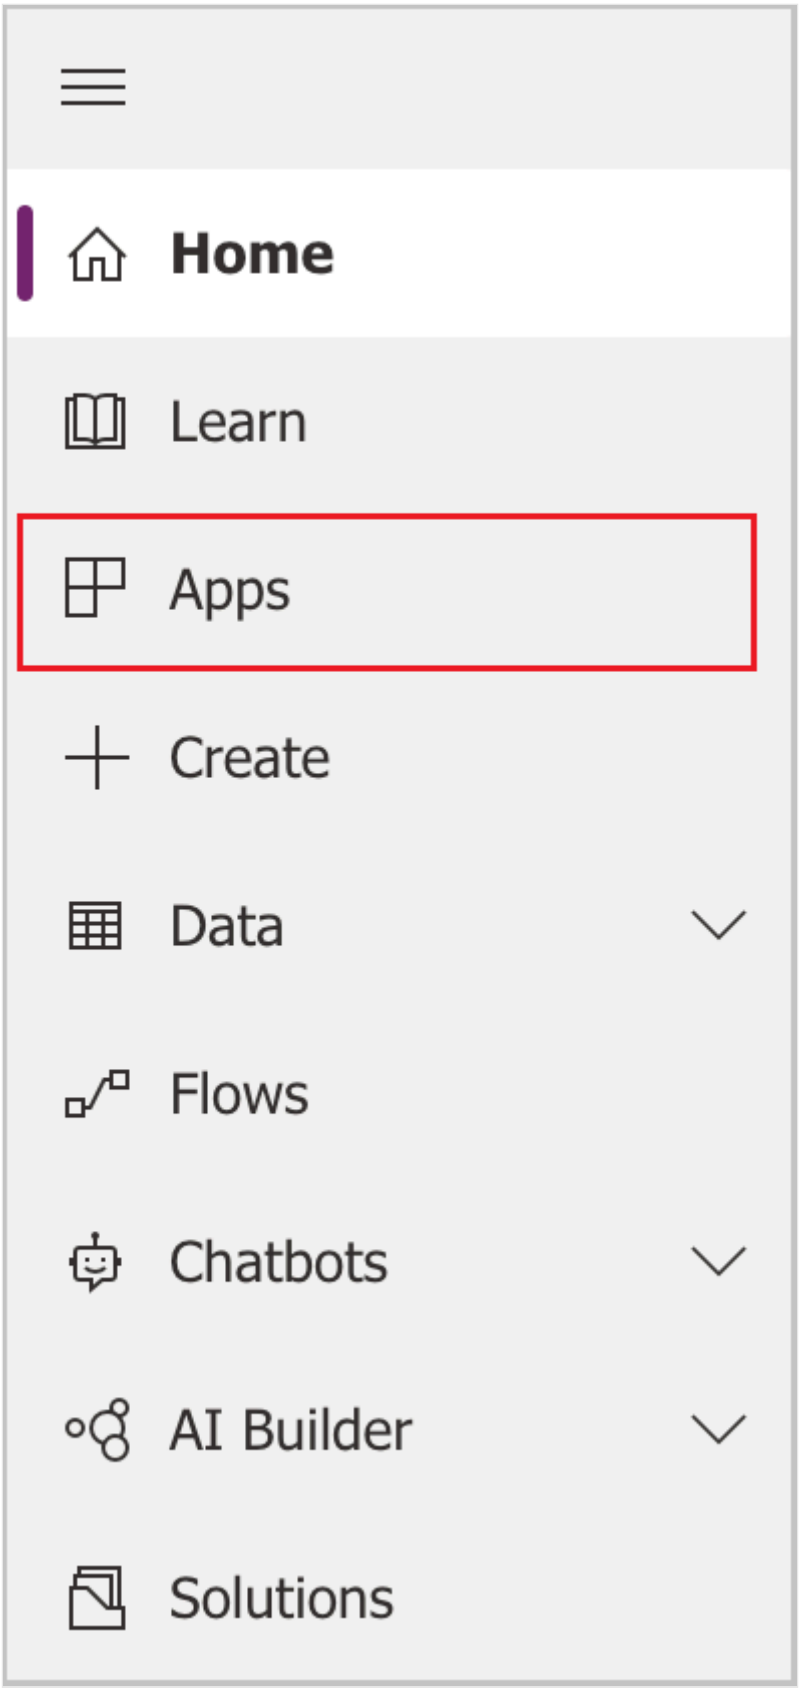
App AI-generated descriptions are managed by a setting in the Power Platform admin center.

1. Open https://admin.powerplatform.microsoft.com/environments
2. Select an environment, and then select **Edit managed environments**.
3. Under the section titled **Enable AI-generated app descriptions**, select or clear **AI-generated app descriptions**
4. Select **Save**.

Clear the browser cache and close any active Power Apps (make.powerapps.com) browser windows. The feature is now be enabled or disabled.

Run your app on a desktop computer

1. To run your app, sign in to Power Apps, and on the left navigation pane, select **Apps**.



2. Select the app from the app list. The app opens in your browser. If you want to show the chart, use the button **Show Chart**.

Run your app on mobile

To run your app on your mobile device, follow these steps:

1. Download the app from your device's mobile app store:
    - IOS: Power Apps on the App Store (apple.com)
    - Android: Power Apps - Apps on Google Play
2. Open the app, tap **Sign in**, and then enter your Microsoft work or school account.
3. Select your app from the list to run it.

Next steps

Add additional pages and configurations to make your app do more!

Understand model-driven app components

Article • 01/22/2025

A well designed model-driven app consists of several components you select using the app designer to build the appearance and functionality of the finished app. The components and component properties that makers use to create an app become the metadata.

To understand how each of these components relates to app design, they're separated here into *data*, *UI*, *logic*, and *visualization* categories.

Data components

These components determine what data the app is based upon and what designer is used to create or edit the component.

Data components are either designed at a table level within an environment, or within a solution contained within the environment.

Expand table

Component	Description	Designer
Table	A container for records with properties that you track, such as a contact or account. Many standard tables are available. You can customize a nonsystem standard table (production table) or create a custom table from scratch.	Power Apps table designer
Relationship	Table relationships define how tables can be related to each other. There are 1:N (one-to-many), N:1 (many-to-one), and N:N (many-to-many) types of relationships. For example, adding a lookup column to a table creates a new 1:N relationship between the two tables and lets you put that lookup column on a form.	Power Apps table designer
Column	A property that is associated with a table. A column is defined by a data type, which determines the type of data that can be entered or selected. Examples include text, number, date and time, currency, or lookup (creates a relationship with another table). Columns typically are used with forms, views, and searches.	Power Apps table designer
Choice column	This is a special type of column, which provides the user a set of predetermined options. Each option has a number value and label. When added to a form, this column displays a control for the user	Power Apps choice designer

Component	Description	Designer
	to select an option. There are two kinds of choices; choices, where the user can only select one option, and multi-select choices, which allow more than one selection.	

More information: Define data for your model-driven app

UI components

These components determine how users interact with the app.

Expand table

Component	Description	Designer
App	Determines the application fundamentals such as components, properties, client type, and URL for your app.	App designer
Site map	Specifies the navigation for your app.	App designer
Form	A set of data-entry columns for a given table that matches the items that your organization tracks for the table. For example, a set of data-entry columns where users input relevant information to track a customer's previous orders along with specific requested reorder dates.	Form designer
View	Views define how a list of rows for a specific table is displayed in your application. A view defines the columns to display, width of each column, sort behavior, and the default filters.	View designer or app designer
Custom page (preview)	A canvas based page which allows flexible layout, low-code Power Fx functions, and Power Apps connector data. For more information, go to Model-driven app custom page overview (preview)	Canvas designer

Logic components

Determines the business processes, rules, and automation the app has. Power Apps makers use a designer that is specific to the type of process or rule.

Expand table

Type of logic	Description	Designer
Business process flow	An online process that walks users through a standard business process. For example, use a business process flow if you want everyone to handle customer service requests the same way, or to require staff to gain approval for an invoice before submitting an order.	Business process flow designer
Workflow	Workflows automate business processes without a user interface. Designers use workflows to initiate automation that doesn't require any user interaction.	Workflow designer
Actions	Actions are a type of process that let you manually invoke actions, including custom actions, directly from a workflow.	Process designer
Business rule	Used to apply rule or recommendation logic to a form, such as to set column requirements, hide columns, or validate data. App designers use a simple interface to implement and maintain fast-changing and commonly used rules.	Business rule designer
Power Automate Flow	Power Automate is a cloud-based service that lets you create automated flows between apps and services to get notifications, synchronize files, collect data, and more.	Power Automate

More information: Apply business logic in your model-driven app

Additional options for adding custom business logic

Use plug-ins to extend business processes
Workflow extensions

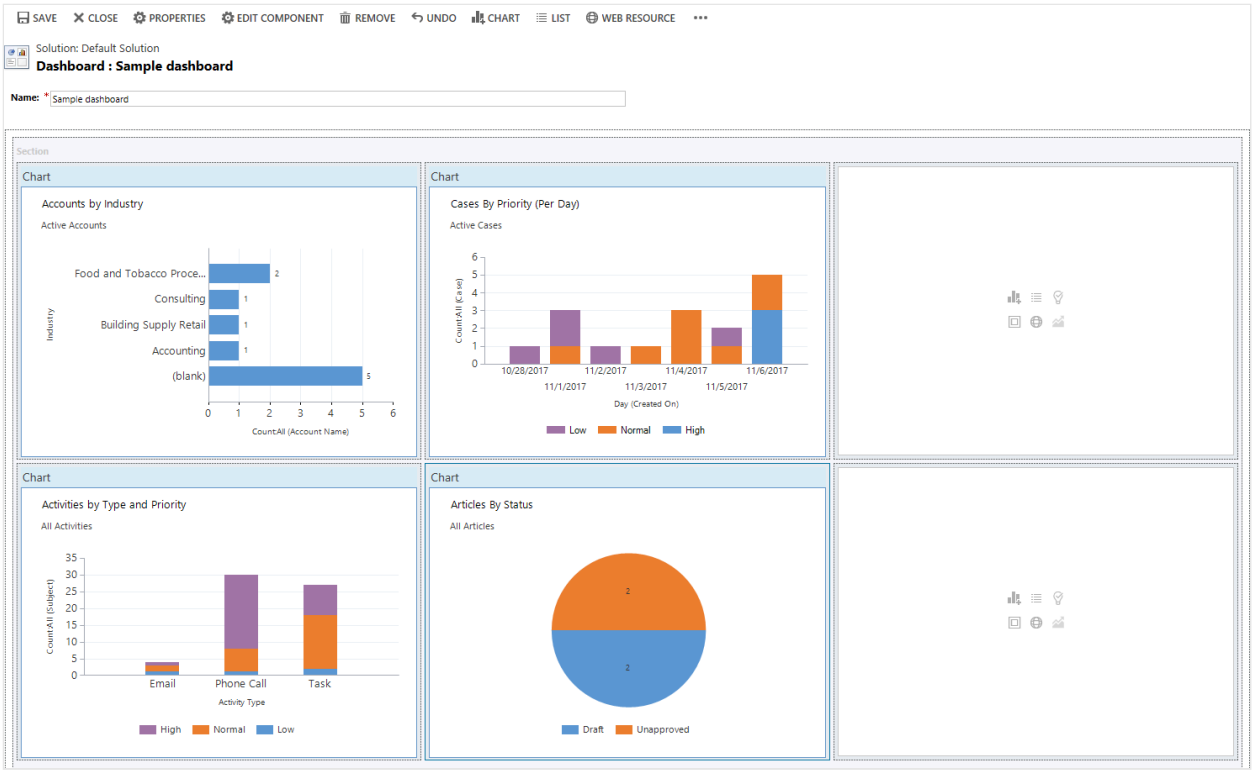
Visualizations

Determines what type of data visualizations and reporting the app has available.

Expand table

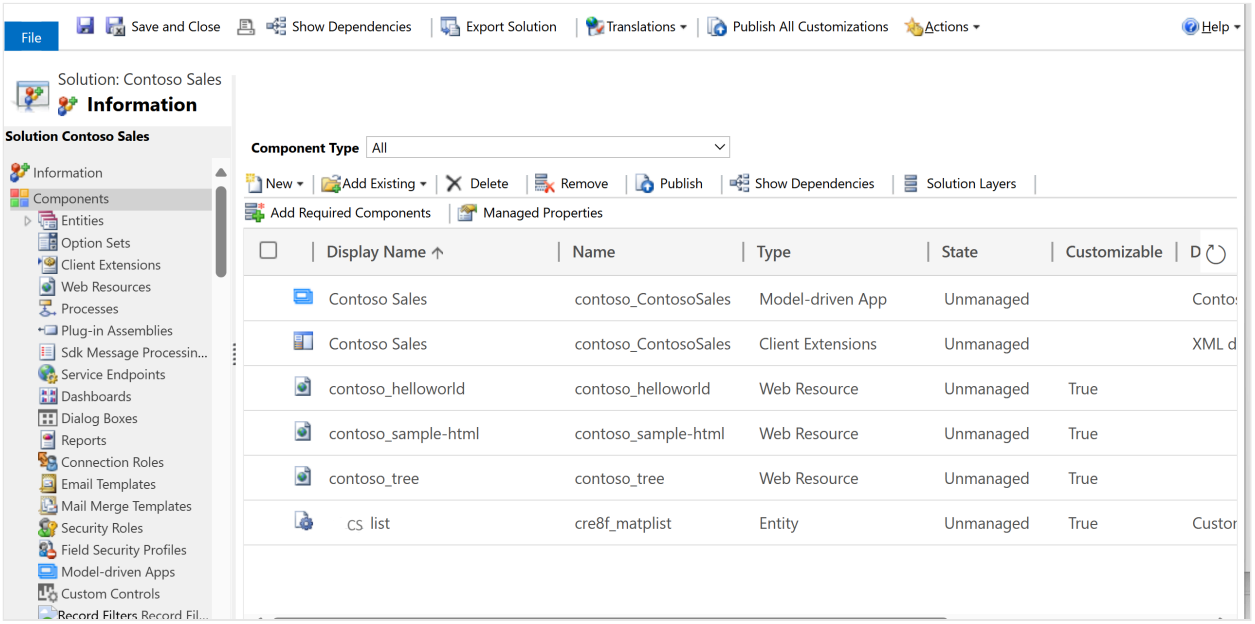
Component	Description	Designer
Chart	A single graphic visualization that can be displayed within a view, on a form, or be added to a dashboard.	Chart designer
Dashboard	Functions as a palate for one or more graphic visualizations that provide an overview of actionable business data.	Dashboard designer

Component	Description	Designer
Embedded Power BI	Add embedded Power BI tiles and dashboards to your app. Power BI is a cloud-based service that provides business intelligence insight.	Combination of chart designer, dashboard designer, and Power BI



Advanced model-driven app making

The solution explorer is a comprehensive tool used for advanced model-driven app building. Within the solution explorer, you can navigate through a hierarchy that consists of all app components using the navigation pane on the left side of the tool.



To open solution explorer:

1. On the Power Apps Home page, select **Settings**, and then select **Advanced Settings**.
2. On the Dynamics 365 Business Management page, select **Settings**, select **Customizations**, and then select **Customize the System**.

Define data for your model-driven app

Summarize this article for me

Model-driven apps behave according to the nature of the data model that underpins them. App users observe and interact through views of data housed within tables and the forms used to enter data into records based on those tables.

In addition to editing table views and forms, charts and dashboards are also defined at the level of the table.

Finally, business rules ensure consistent business logic is applied to table records.

While it is possible to create a table without a business rule, chart, or dashboard, it isn't possible to design a meaningful table without a view or a form.

Finally, while business process flows are highly relevant to tables and the app user experience, they aren't authored at the level of the table. Business process flows can be created and managed in Power Apps (make.powerapps.com).

The process of designing an app using the app designer in most instances comes *after* the data model is prepared. However, an iterative approach is possible using the platform.

How to define a data model

The data model for a model-driven app is defined in Microsoft Dataverse. Power Apps model-driven apps can only be defined using Dataverse.

The apps data-model is defined using the components: *table*, *column*, and *relationship*. Once these are created, then the forms and views can be developed further to meet the needs of the organization.

For detailed information about working with these components in Dataverse to define data for your model-driven app, go to the following articles:

Model-driven app common column properties

Summarize this article for me

Common properties of table columns for a model-driven app can be viewed using Power Apps (make.powerapps.com). Power Apps provides an easy way to create and edit table columns with Microsoft Dataverse.

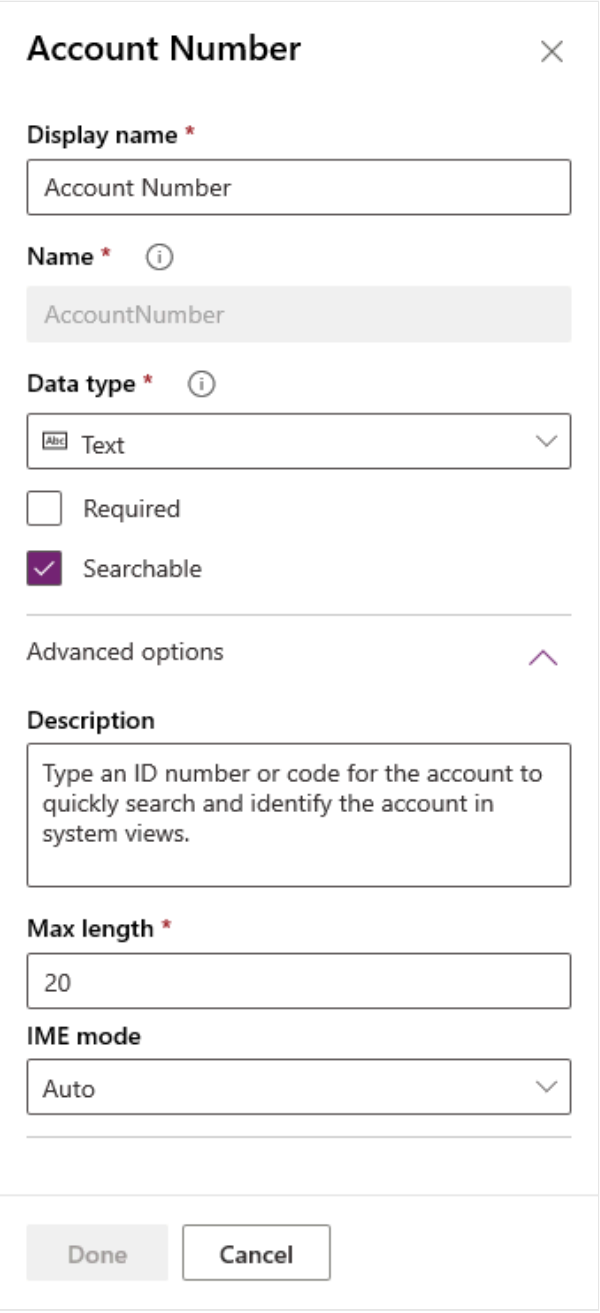
In addition to configuring aspects of the Dataverse column, such as its type and whether or not it's required, it's possible to configure aspects of how the column is used in the context of a form. This approach allows for different forms to permit users to have different interactions with the data column.

Common column properties in Power Apps

1. From Power Apps make.powerapps.com, select **Tables**, and then select the table that has the columns you want to view. If the item isn't in the side panel pane, select ...More and then select the item you want.

   > **Note**
   >
   > Customizations to a table take should place within a solution. To update a table within a solution, open your **solution**, open the **table**, and then select the **Columns** area.

2. Select the column that you want to view.



The following table describes the common properties of columns. Certain types of columns have special properties. These are described in Create and edit columns for Dataverse.

Expand table

Property	Description
Display Name	The text to display for the column in the user interface.
Name	The unique name across your environment. Power Apps generates a name based on the display name that you enter. However, you can edit this name before saving. Once you create a column, you can't change the name as your applications or code might reference it. The **Dataverse Default Publisher** customization prefix is prepended to the name.
Data type	Controls how values are stored and how they're formatted in some applications. Once you save a column, you can't change the data type except for converting text columns to

Property	Description
	autonumber columns.
Required	A row can't be saved without data in this column.
Searchable	This column appears in Advanced Find and is available when customizing views.
Calculated or Rollup	Use to automate manual calculations. Use values, dates, or text.
Advanced Options	Add a description, and specify a maximum length and IME mode for the column.

There are many different types of columns, but you can only create some of them. For more information about all types of columns, see Types of columns and column data types.

Common column properties in solution explorer (classic)

In addition to using Power Apps (make.powerapps.com), you can also review columns by using the solution explorer.

Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

Navigate to a column for a table using the solution explorer

To update the column, follow these steps.

1. Sign in to Power Apps.

2. On the left navigation pane, select **Tables**. If the item isn't in the side panel pane, select ... More and then select the item you want.

   > **Note**

Customizations to a table should take place within a solution. To update a column within a solution, open your **Solution**, and then open the **Table**.

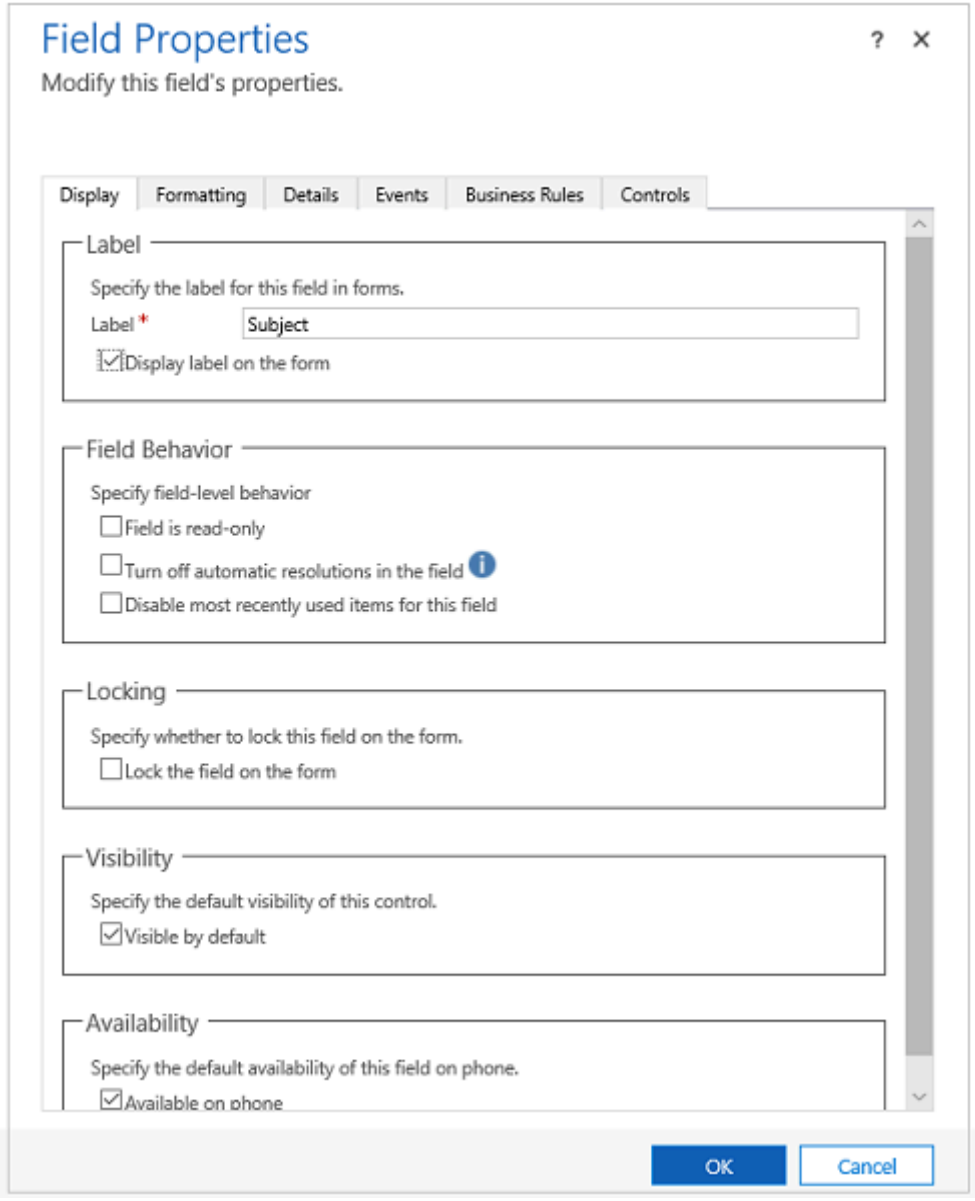
3. Select a table, such as the account table.

4. Select **...** on the command bar, and then select **Switch to classic**.

> **Note**
>
> In the solution explorer, tables are known as entities and columns are known as fields.

5. Select the column that you want.

6. Select **Change properties** from the command bar, or double-click the column.



7. Make the necessary property changes (see the classic editor field properties options), and then select **OK**.

8. **Save** and **Publish** the form.

Field properties within the classic editor

There are six tabs shown for a field. **Display**, **Formatting**, **Details**, **Events**, **Business Rules and Components**.

The following table describes properties that all columns have. Certain types of columns have special properties. These are described in Special column properties.

Expand table

Tab	Property	Description
Display	**Label**	**Required**: By default the label will match the display name of the column. The name for the form can be overridden by entering a different label here.
	Display label on the form	This contains the option not to display the label at all.
	Field Behavior	Specify the column level behavior using the check boxes.
	Locking	This will prevent the column from being removed from the form accidentally. This will prevent any configuration applied to the column, such as event handlers, from being cleared if the column were removed. To remove this column, a customizer would need to clear this setting first.
	Visibility	Showing the column is optional and can be controlled using scripts. More information: Visibility options
	Availability	Choose if you want the field to be available on the phone.
Formatting	**Select the number of fields the control occupies**	When the section containing the columns has more than one column this can set the column to occupy up to the number of columns that the section has.
Details	**Display Name**, **Name**, and **Description**	These read-only columns are for reference. Select **Edit** for access to the column definition if you want to edit it. Each instance of a column in the form has a name property so that they can be referenced in form scripts, but this name is managed by the application. The first instance of the column is the name of the column specified when it was created. More information: Create and

Tab	Property	Description
		edit columns For each additional time that a column is included in a form, the name appends a number starting with 1 to the end. So if the column name is 'new_cost', the first instance is 'new_cost', the second is 'new_cost1', and so on, for each instance of the column in the form. **Note:** The column **Description** value provides tooltip text for the column when people place their cursor over it.
Events	**Form Libraries**	Specify any JavaScript web resources that will be used in the column `OnChange` event handler.
	Event Handlers	Configure the functions from the form libraries that should be called for the column `OnChange` event. More information: Configure Event Handlers
Business Rules	**Business Rules**	View and manage any business rules that reference this column. More information: Create business rules and recommendations
Controls	**Controls**	Add controls and specify their availability on **Web**, **Phone**, and **Tablet**.

Editing form level column properties

In some scenarios, it is desirable to render a data column within a form field in one form in a way that differs in the way it is presented in another. This allows the user experience to be tailored to the individual using the form.

1. Sign in to Power Apps.
2. On the left navigation pane, select **Tables**. If the item isn't in the side panel pane, select ... More and then select the item you want.

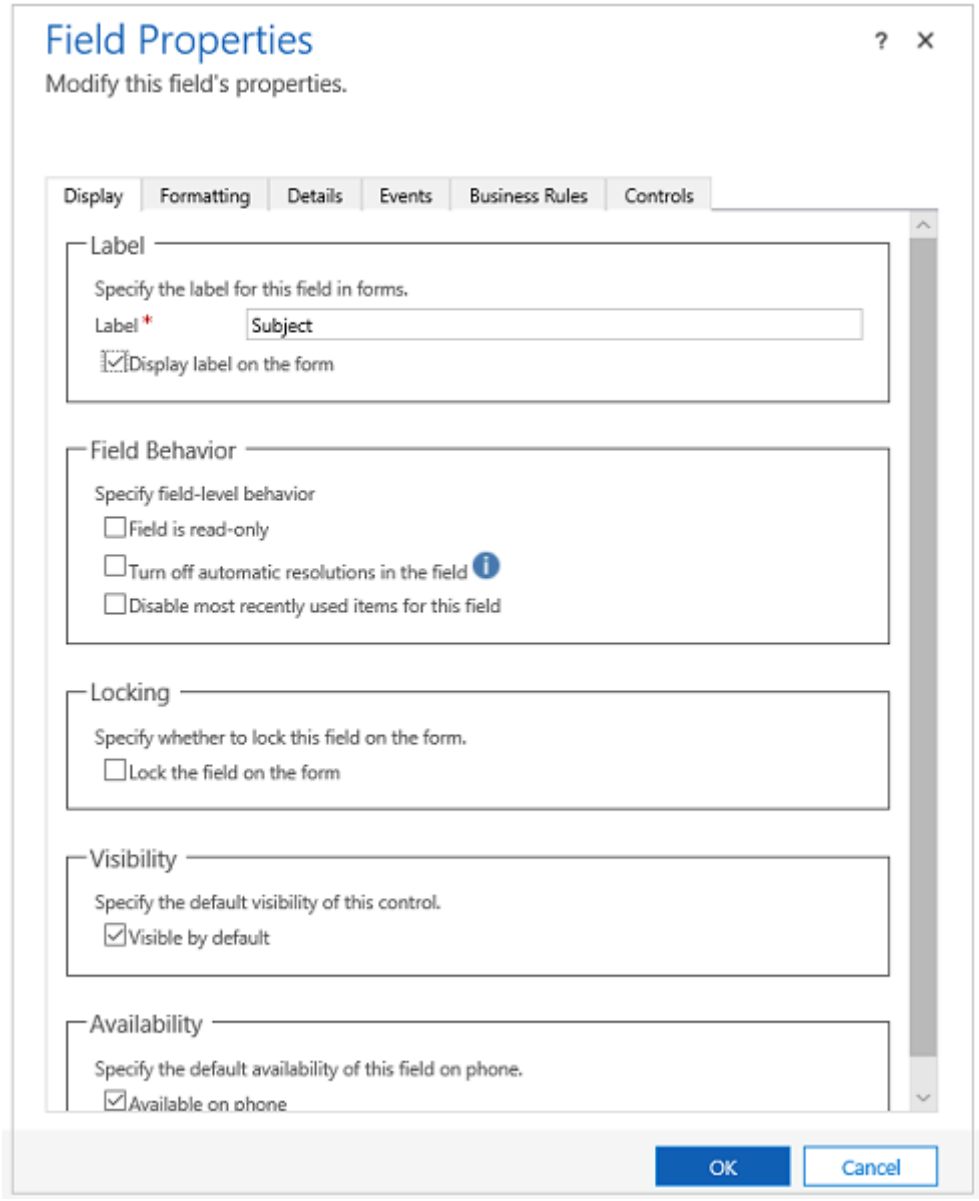
   > **Note**
   >
   > Customizations to a table should take place within a **solution**. To update a form within a solution, first navigate to your **Solution**, open the **Table**, and then select the **Forms** area.

3. Select a table, such as the account table, and then select the **Forms** area.
4. Select the form where customizations are required.

5. Select **Switch to classic**. The form opens in the classic experience.

6. Select the form field where an updated experience is required.

7. Select **Change properties** from the command bar or double-click the field.



8. Make the necessary changes, and then select **OK**.
9. **Save** and **Publish** the form.

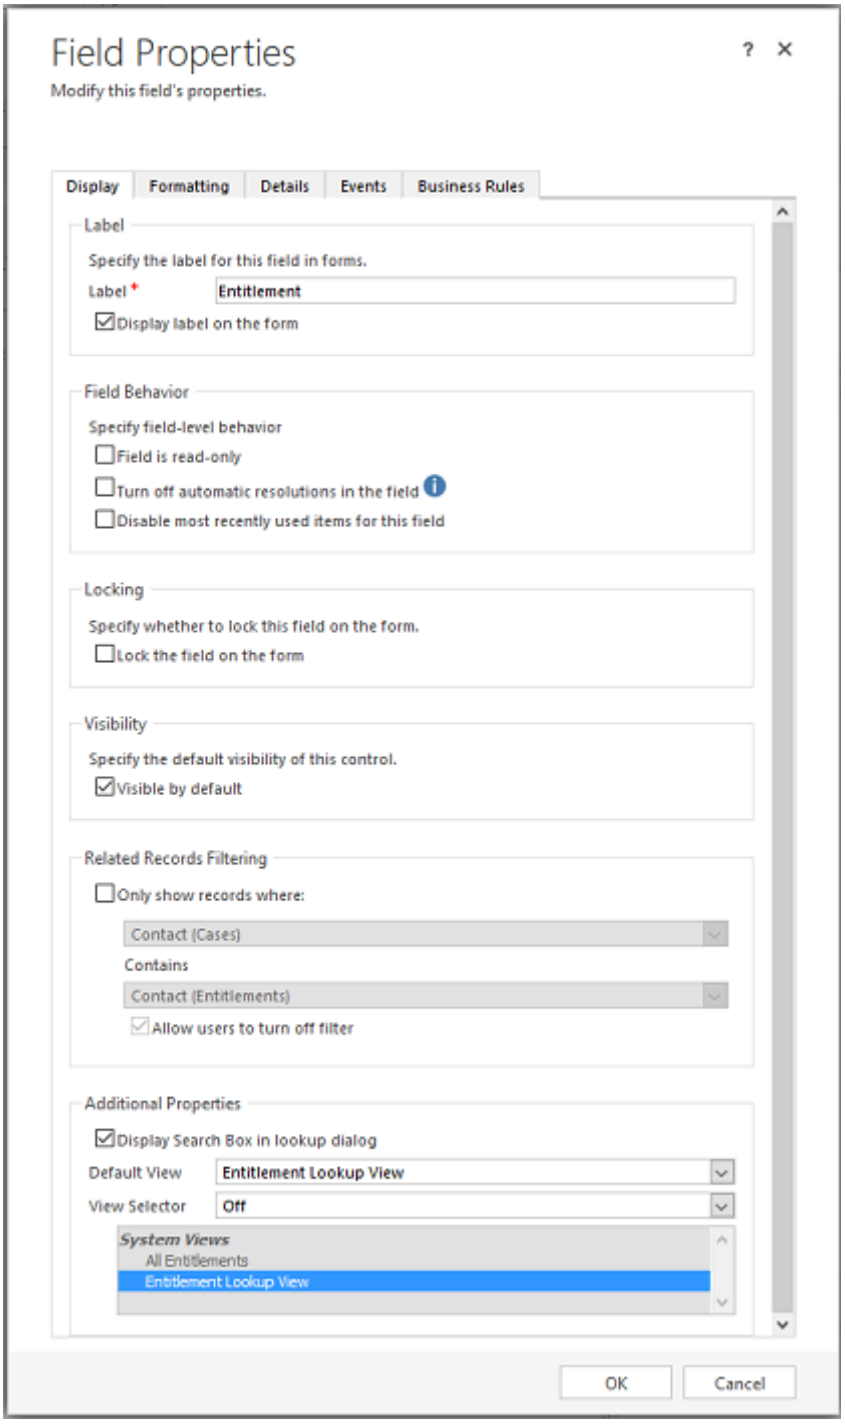
Overview of special column properties

Last updated on 03/04/2026

Overview of model-driven app special column properties

Summarize this article for me

All columns have the properties listed in Common column properties, but certain columns have additional properties, such as this entitlement column that can be opened from the main form for the case table.



> **Note**

This article describes properties for the classic experience. For information about lookup column properties in the modern for designer, go to Configure a lookup component on a form.

Lookup column properties

> **Note**
>
> The options described in the table below are available only for single-table lookup columns.

Expand table

Section	Property	Description
Related Records Filtering	**Only show records where**	When this is enabled, the records that display when users search for a record will have additional filtering applied. This helps provide more relevant searches when setting the value of the lookup. By default, this is turned off. The relationship combinations that are possible when you filter related records are listed in the table following this one. The first list is populated with all the potential relationships you can use to filter this lookup. Select one. The second list is then populated with all relationships that connect the related table (selected in first list) to the target table. Select one. Select the **Allow users to turn off filter** check box to give users the option to turn off the filter you define here. When users select the **Look Up More Records** option while setting the value for a lookup, they see this dialog box.

Section	Property	Description
		 If you've selected the **Allow users to turn off filter** option while configuring the lookup column, users will see the check box to turn off the filter. This makes it possible for them to see a wider range of records. If you want to make sure that users only see a limited range of records defined by this filter, clear the **Allow users to turn off filter** check box.
Additional Properties	**Display Search Box in lookup dialog**	You can choose not to display the search box in the lookup dialog.
	Default View	This view is used to filter the results of the inline search and set the default view shown in the lookup dialog when users select the **Look Up More Records** option. The default view also controls which columns are included in the inline lookup. For lookups that only allow selection of a single table type, the columns displayed in the inline lookup are set to be the first two columns

Section	Property	Description
		included in the default view. In this example, **Main Phone** and **Email** are the first two columns in the default view configured for an account lookup. For system lookups that allow for multiple table types, the first two columns of the table lookup view are shown.
	View Selector	You can choose from three options: - **Off**: Don't allow users to choose a different view. - **Show All Views**: All views are available. - **Show Selected Views**: When you choose this option you can use the Ctrl key and your cursor to choose which views to show. The Lookup view for the table can't be de-selected.

Possible relationship combinations

Expand table

First list relationship	Second list relationship	Available?
N:1	1:N	Yes
N:1	N:1	Yes
N:1	N:N	Yes
1:N	1:N	Yes
1:N	N:1	No
1:N	N:N	No
N:N	1:N	Yes
N:N	N:1	No
N:N	N:N	No

Yes/No column properties

On the formatting tab, Yes/No columns have the following formatting choices:

- **Two radio buttons**: Two labeled controls with labels. Only one may be selected.
- **Checkbox**: A single checkbox to set the true value, otherwise false.

- **List**: A drop-down list containing both values.

Multiple lines of text column properties

Multiple lines of text and single line of text columns that use the `Text Area` format have a **Record Layout** property. With this property you can specify a value for **Number of Records** or select **Automatically expand to use available space**.

Last updated on 02/12/2026

Translate localizable text for model-driven apps

Summarize this article for me

If you customize table or column text, such as column labels or drop-down list values, you can provide users in your environment who aren't working with the base language version of your environment with this customized text in their preferred languages.

The process has the following steps:

1. Enable other languages for your environment
2. Export the localizable text
3. Get the localizable text translated
4. Import the localized text

Enable other languages for your environment

If you haven't already enabled the languages for your environment, use the steps described in Enable the language to enable them.

> **Important**
>
> Each language can take several minutes to enable. During this time, other users of the environment might not be able to use your app. Enable languages at a time that is least disruptive to users.

> **Tip**
>
> While you enable the languages, note the LCID values used for each language. This value represents the language in the exported data for the localizable text. Language codes are four-digit or five-digit locale IDs. Valid locale ID values can be found at Locale ID (LCID) Chart).

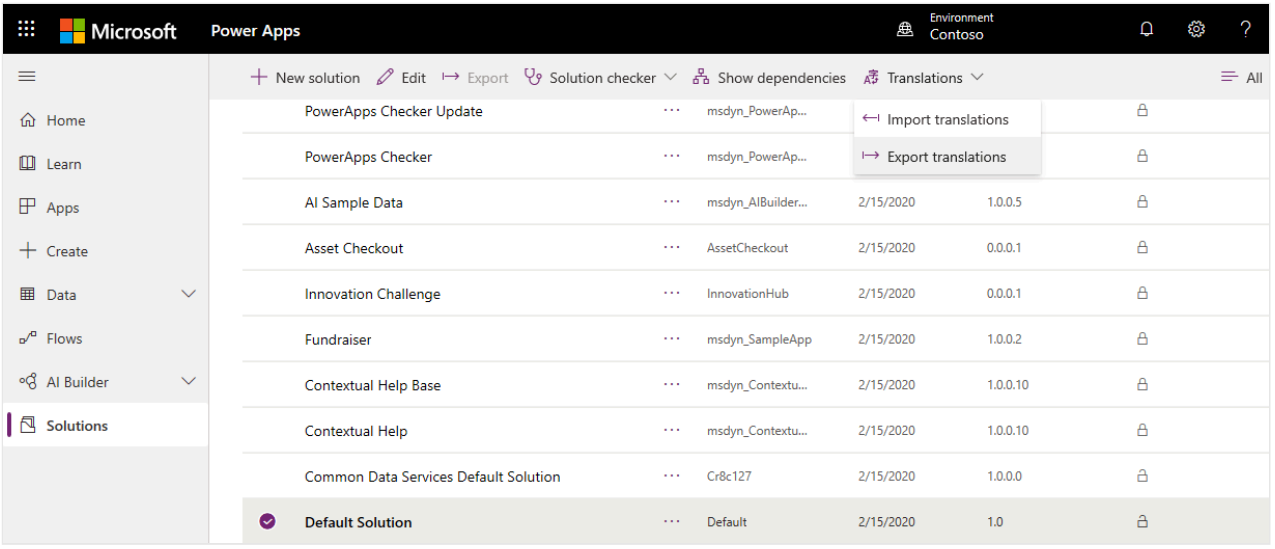
Export the localizable text

The localizable text that you export comes from the unmanaged solution that contains the localizable text.

1. From Power Apps, select **Solutions**. If the item isn't in the side panel pane, select ... More and then select the item you want.

2. In the **All Solutions** list, select the unmanaged solution that contains the localizable text you want.

3. On the command bar, select **Translations** > **Export Translations**.



You could see an alert:

> Exporting customized labels for translation can take several minutes. Do not click the export link again until the first export has finished. Are you sure that you want to export now?
>
> Select **OK** if you want to continue.

When the export is completed, save the translations zip file. The file is named something like `CrmTranslations_{0}_{1}.zip`, where `{0}` is the unique name of the solution and `{1}` is the version number of the solution.

Get the localizable text translated

You can send this file to a linguistic expert, translation agency, or localization firm.

If you have the knowledge to translate the text, or if you just want to see the format, you can extract the zip file that you exported you see that it contains two XML files.

- `[Content_Types].xml`
- `CrmTranslations.xml`

You can open the CrmTranslations.xml file with Microsoft Office Excel.

> **Tip**
>
> Unless you normally open XML files with Excel, it might be easier to open Excel, then choose to open the file by pasting in the path to the extracted CrmTranslations.xml file.

> **Important**
>
> Don't change the file format. If you save the file in another format, you can't import it back.

When you view the data in Excel, look at the **Localized Labels** tab.

	A	B	C	D	E	F
1	Entity nam	Object ID	Object Column Name	1033	1041	3082
642	account		description	Shows the total number	取引先企業の合計数	Muestra la cantidad total d
643	account		name	Accounts by Industry	業種別取引先企業	Cuentas por sector
644	account		description	Shows the total number	取引先企業の合計数	Muestra la cantidad total d
645	account		name	Accounts by Owner	所有者別取引先企業	Cuentas por propietario
646	account		description	Shows the number of ne	1か月の新規取引先数	Muestra la cantidad de cue
647	account		name	New Accounts By Month	月別新規取引先企業	Nuevas cuentas por mes
648	cr2b3_car		Description	A motor vehicle intende		
649	cr2b3_car		LocalizedCollectionNa	Cars		
650	cr2b3_car		LocalizedName	Car		
651	cr2b3_car		Description	Unique identifier for the		
652	cr2b3_car		DisplayName	Owning User		
653	cr2b3_car		Description	Status of the Car		
654	cr2b3_car		DisplayName	Status		
655	cr2b3_car		DisplayName	Status		
656	cr2b3_car		Description	Status of the Car		
657	cr2b3_car		DisplayName	Active		

Information | Display Strings | **Localized Labels**

Any custom tables or columns have empty cells for the localizable text. Add the localized values for those items.

> **Note**
>
> If you have changed the display name or description for any standard table or table column, the localized strings will still reflect the translations for the original value. Those should be localized to reflect the new value.

The **Display Strings** tab contains text that is displayed for other UI elements such as ribbon commands, error messages, and form labels.

Update localizable text in the base language

If you change the display name for any standard table or table column, which is included in any special message, update the information in the **Display Strings** tab to use the customized

name.

> **Tip**
>
> Although the UI exposed to edit system table messages includes many references to table names, it doesn't include all of them. Using this technique might find more. More information: Edit system table messages

For example, if you change the display name for the Account table to *Company*, search through the base language column in the **Display Strings** for the following matches: `account`, `accounts`, `Account`, and `Accounts` then make appropriate replacements to `company`, `companies`, `Company`, and `Companies` respectively.

> **Important**
>
> Don't do a general find and replace in the file for this. Make sure that the matching text actually refers to the names that you changed.

Import the localized text

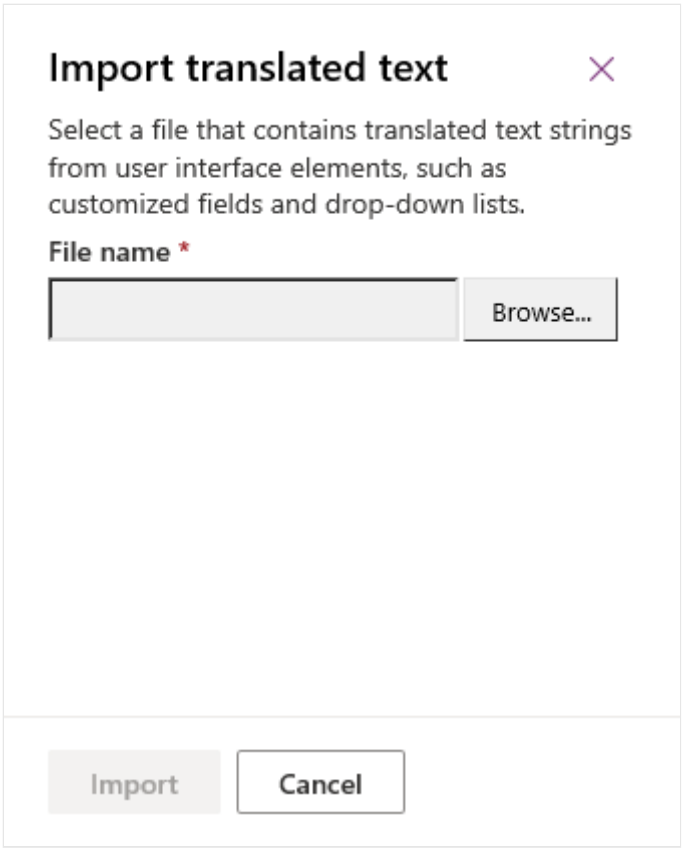
Importing the text requires compressing the files and importing them into the system.

Compress the files

After you make changes to the `CrmTranslations.xml` file, compress the file together with the `[Content_Types].xml` file into the zip format. Select *both files* and then right-click to open the context menu. In the context menu, choose **Send to** > **Compressed (zipped) folder**.

Import the files

From the same unmanaged solution that you exported the translations from, in the menu choose **Translations** > **Import Translations**.



Select the file that contains the compressed translated text and select **Import**.

After you import the translated text, publish all customizations to see the changes in your apps.

Model-driven app interface design overview

Article • 04/23/2025

Model-driven app interface design includes working with table views and forms. To work with these components in your app, you create pages.

Creating pages in a model-driven app builds the app site-map that describes the navigation experience within the app.

App interface design can include changing the command bar menu in an app.

This article mentions the classic approach to developing apps. This includes the creation of apps in addition to working with forms, views, and other elements.

Model-driven app design

Here's an overview of the model-driven app design process.

Designing a model-driven app requires a range of skills. There are many design tools that enable a model-driven app to be created. At times the app maker plays the role of a database designer, a user experience customizer, and even a process designer.

Model-driven apps are essentially a selection of Microsoft Dataverse components (tables, charts, dashboards) that work alongside each other to achieve a business outcome. These components are delivered in conjunction with the Dataverse security roles to create a user experience that meets the needs of members of different parts of an organization.

This means that the same app can be used by colleagues in different departments. In some cases, users only want to review data and might only have interest in specific areas in order to complete their daily objectives.

The design of tables and table columns is covered under a documentation dedicated to this article. Learn more about creating Dataverse tables.

App interface design resources

The following table describes the resources in this section.

Overview of the model-driven app designer

Article • 01/27/2025

The model-driven app designer provides a modern WYSIWYG authoring experience when you work with model-driven apps.

Changes to the app are instantly reflected in the preview, enabling you to see exactly how the app will appear to users when published.

The app designer interface has the following areas:

1. Command bar – Displays the available actions:

    - **Back**. Closes the model-driven app designer and returns you to the Power Apps website (make.powerapps.com).
    - **Add page**. Creates a new page, which can include table forms and views, table dashboards, or a custom page for the app.
    - **Settings**. Opens the app properties such as name and description.
    - **Edit form**: Open the form designer to edit the default form shown in app preview.
    - **Comments**. Add a comment to the app. More information: Add comments in the model-driven app designer
    - **Save**. Saves the app.
    - **Publish**. Makes the changes made available to other users.
    - **Play**. Opens the app in a new tab in run mode.

2. App preview – Displays a real-time preview of the form as it will appear to users when published.

3. Panes - The left navigation pane consists of the following areas:

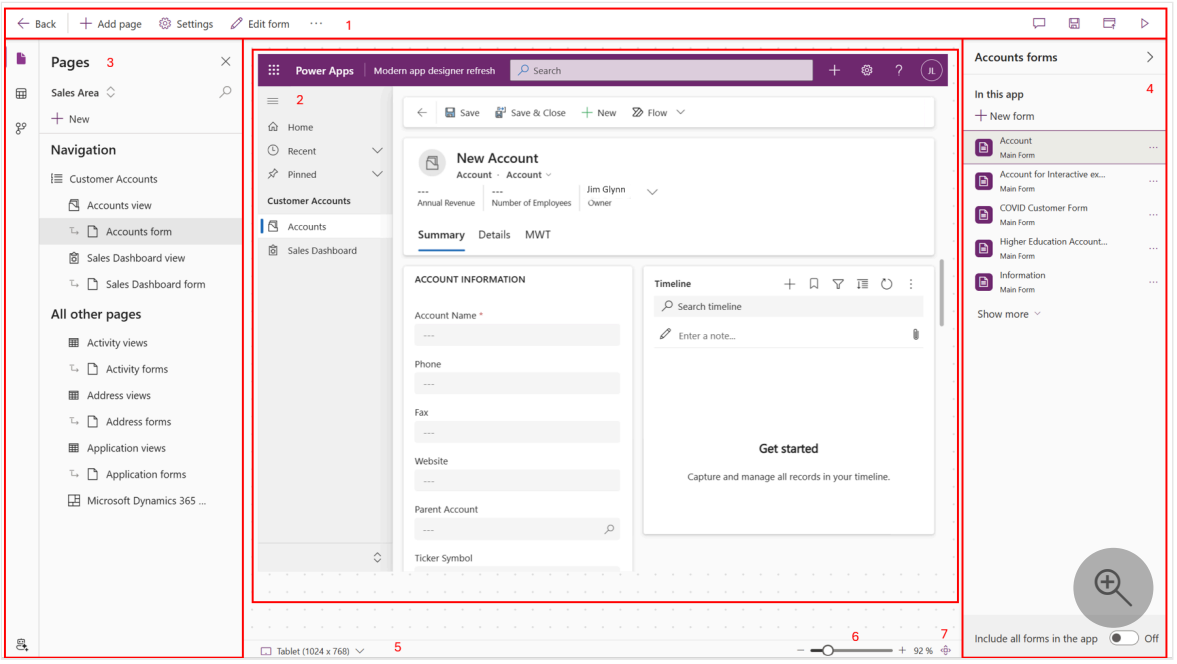
    - **Pages**. The **Navigation** section displays a layout of your app that is formed using areas, groups, and subareas. You can add or remove groups and subareas to the navigation. The **All other pages** portion displays the components in your app. From this section, you can choose to add or remove forms, views, and dashboards for each table.
    - **Data**. Provides a view of all available tables that are currently used within your app and a view of all tables that are available in your environment.
    - **Automation**. Displays business process flows that are a part of this app. You can add, remove, or create new business process flows to the app.

4. Property pane – Displays properties of the selected component and associated forms and views with the selected table. Selecting the pencil or ellipsis opens the form or view designer.

5. Preview size switcher - Changes the size of the form preview helping you to see how the form will appear on various screen sizes.

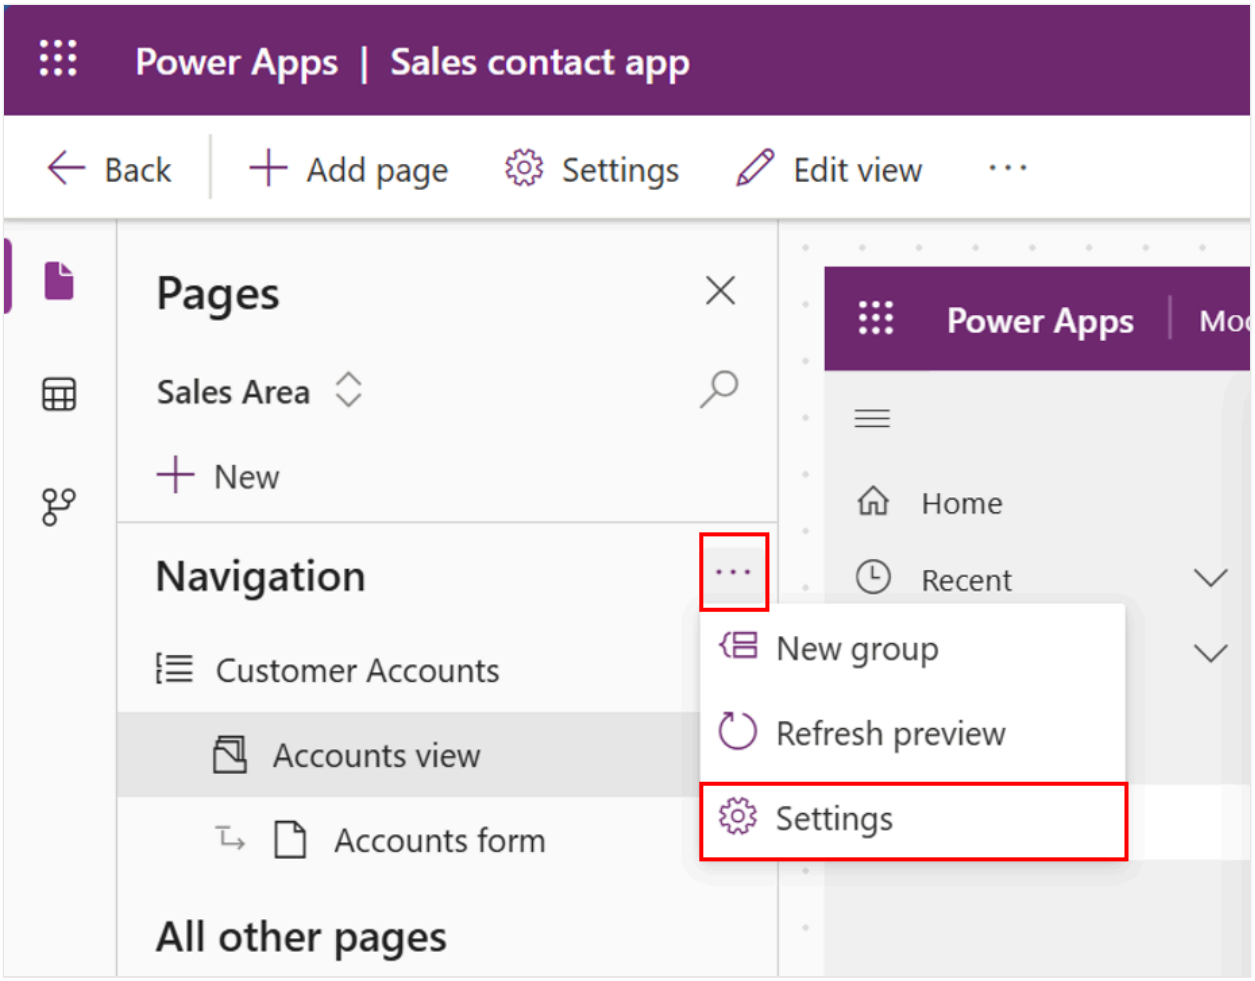
6. Zoom slider - Zooms in or out of the app preview helping you take a closer look.

7. Fit to screen - Quick action to fit the app preview to the available screen size.



Navigation pane options

To edit the app's navigation, select ... next to **Navigation**, and then select **Settings**.



The following options are available:

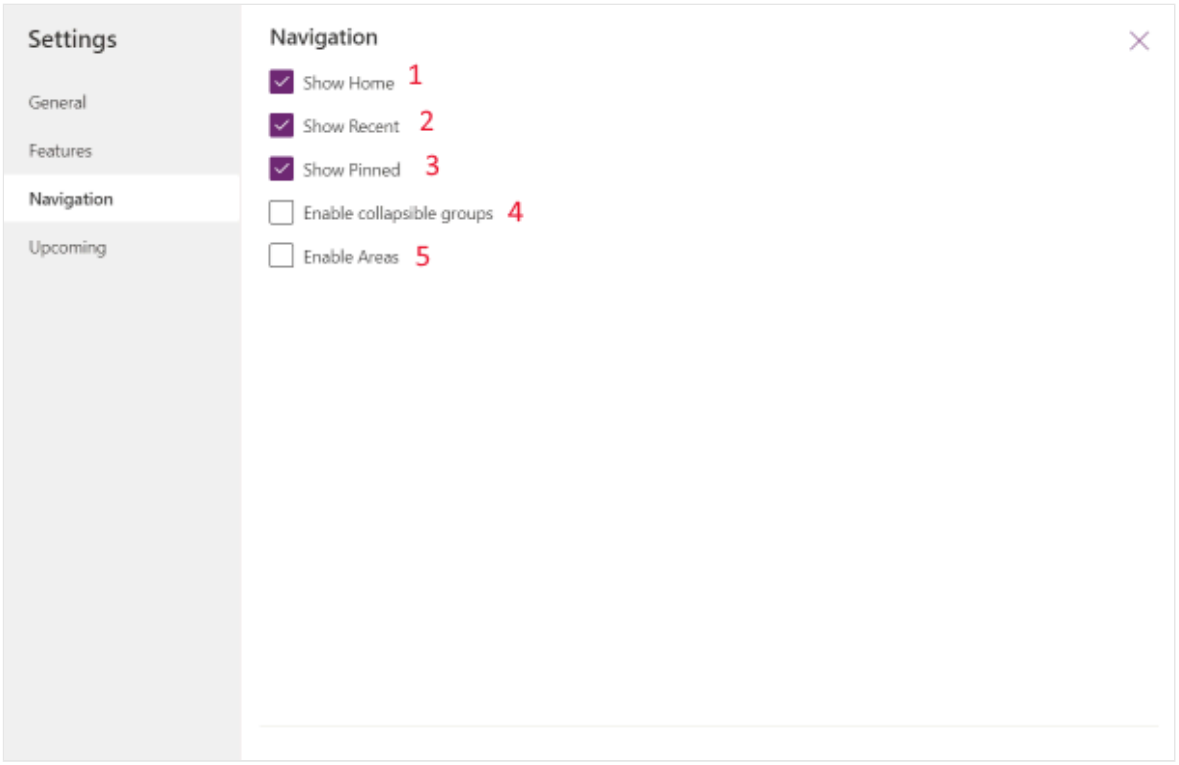
1. **Show Home**. Enabled by default. When selected, displays the **Home** page link for the app.

2. **Show Recent**. Enabled by default. When selected, displays the recently viewed pages link. Selecting the link displays all recently viewed pages.

3. **Show Pinned**. Enabled by default. When selected, displays the pages that have been pinned. App users select the push-pin icon next to a record listed under **Recent** to add it to their pinned rows.

4. **Enable collapsible groups**. Disabled by default. When selected, subareas displayed under groups in the site map can be expanded or collapsed.

5. **Enable Areas**. Disabled by default. When selected, new areas can be added to the app. For apps with existing multiple areas, this setting is enabled by default. You can't disable this setting while the app has multiple areas.



Known limitation

- The app's URL can't be specified.

Create a model-driven app with the app designer

In this article, you learn the basics of how to create a model-driven app that can be shared and distributed to other environments.

Prerequisites

Verify the availability of the following prerequisites before you start to create a model-driven app:

- A Power Platform environment used for app development.
- An environment maker, system administrator, or system customizer security role.

For more information, go to the following articles:

- Create an environment
- Environment strategy for ALM
- About predefined security roles

Create an app

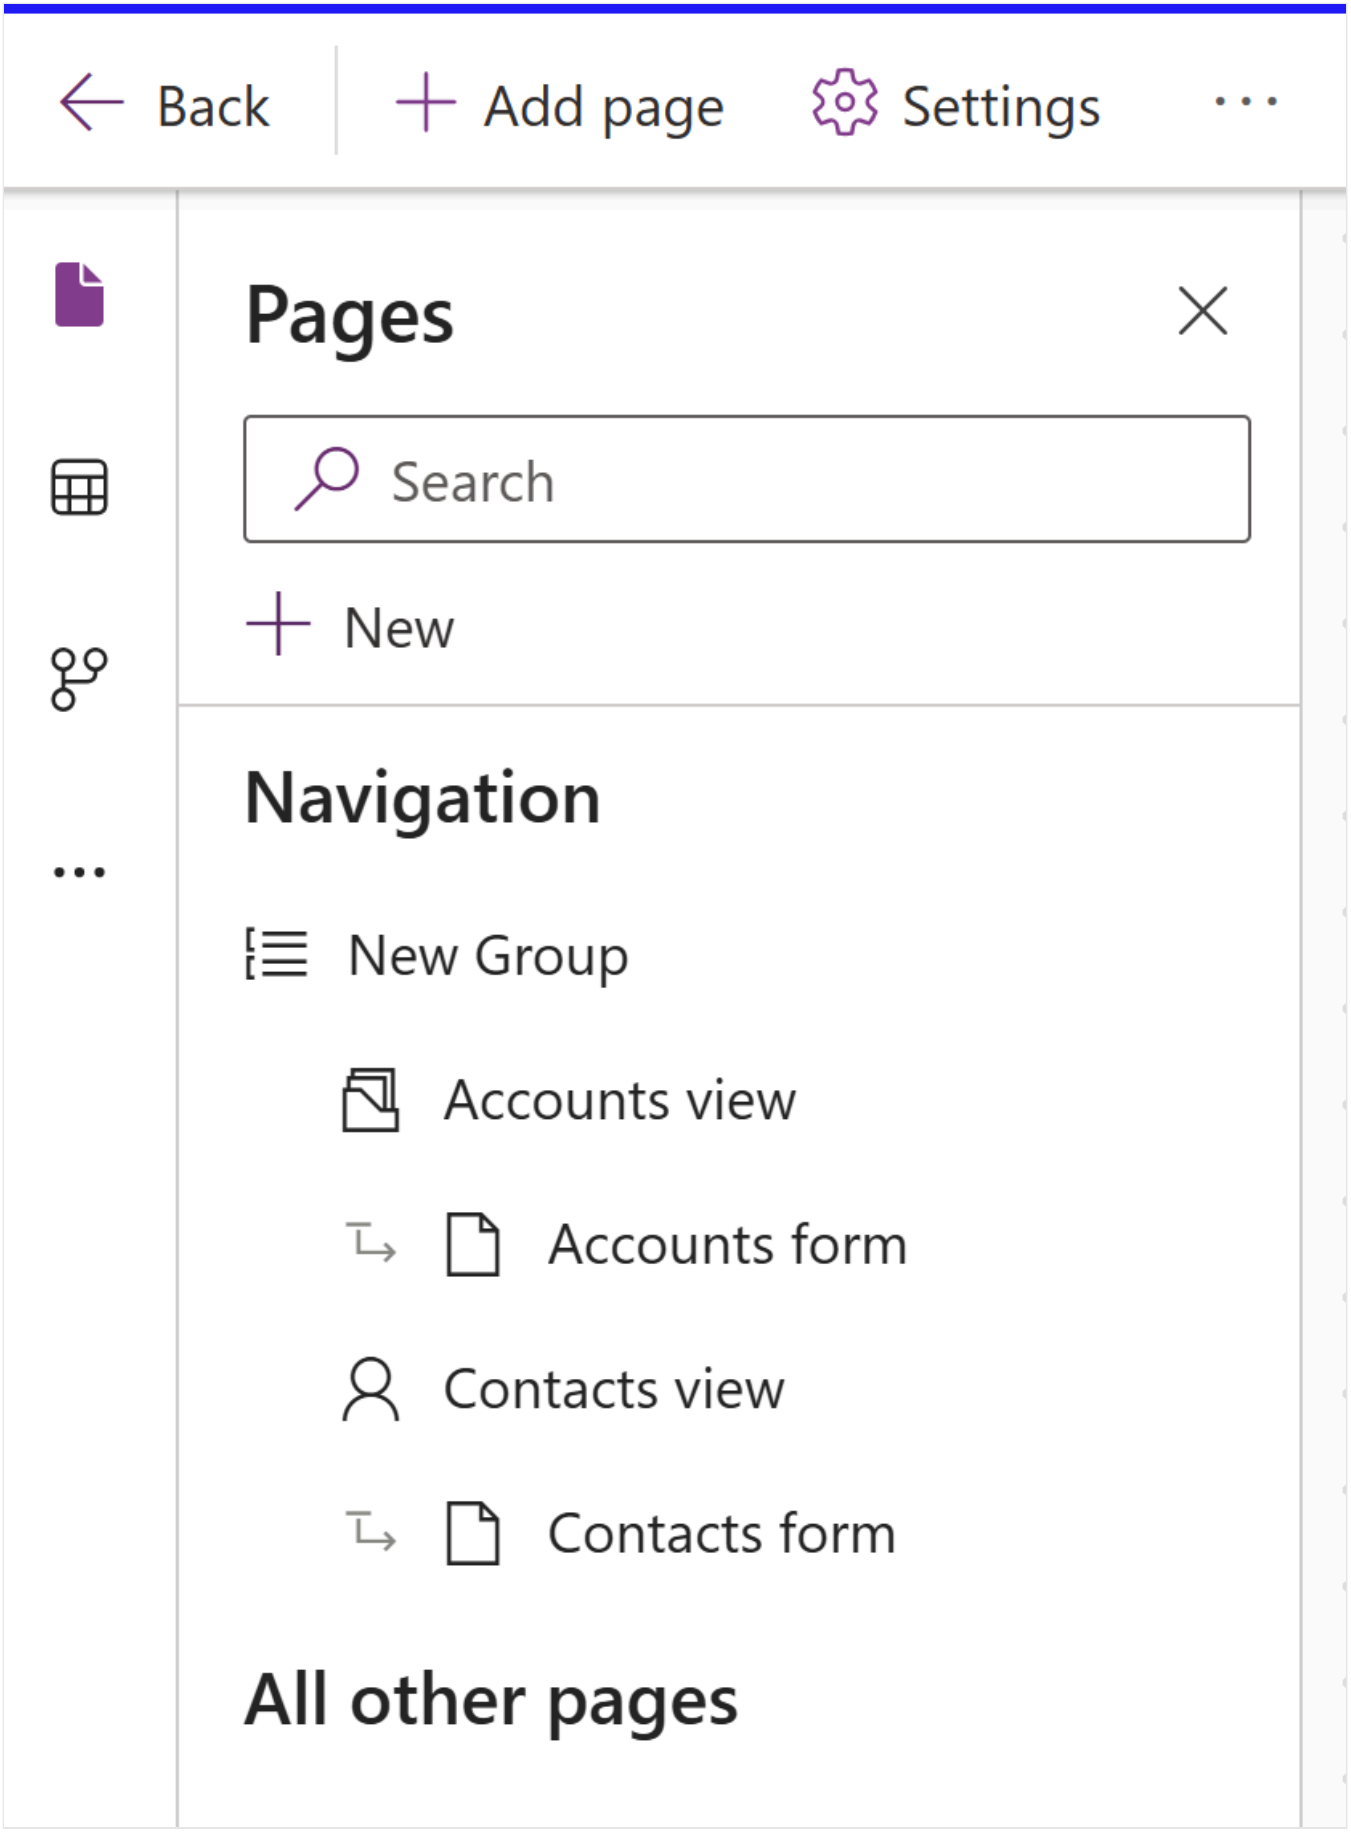
1. On the Power Apps **Home** page, select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open an unmanaged solution or create a new solution.

   > **Note**
   >
   > Unmanaged solutions are displayed when the **Unmanaged** filter is selected in the **Solutions** area.
   >
   > Although the **Default Solution** is an unmanaged solution, it is in most circumstances not recommended to create or edit customizations in the default solution.

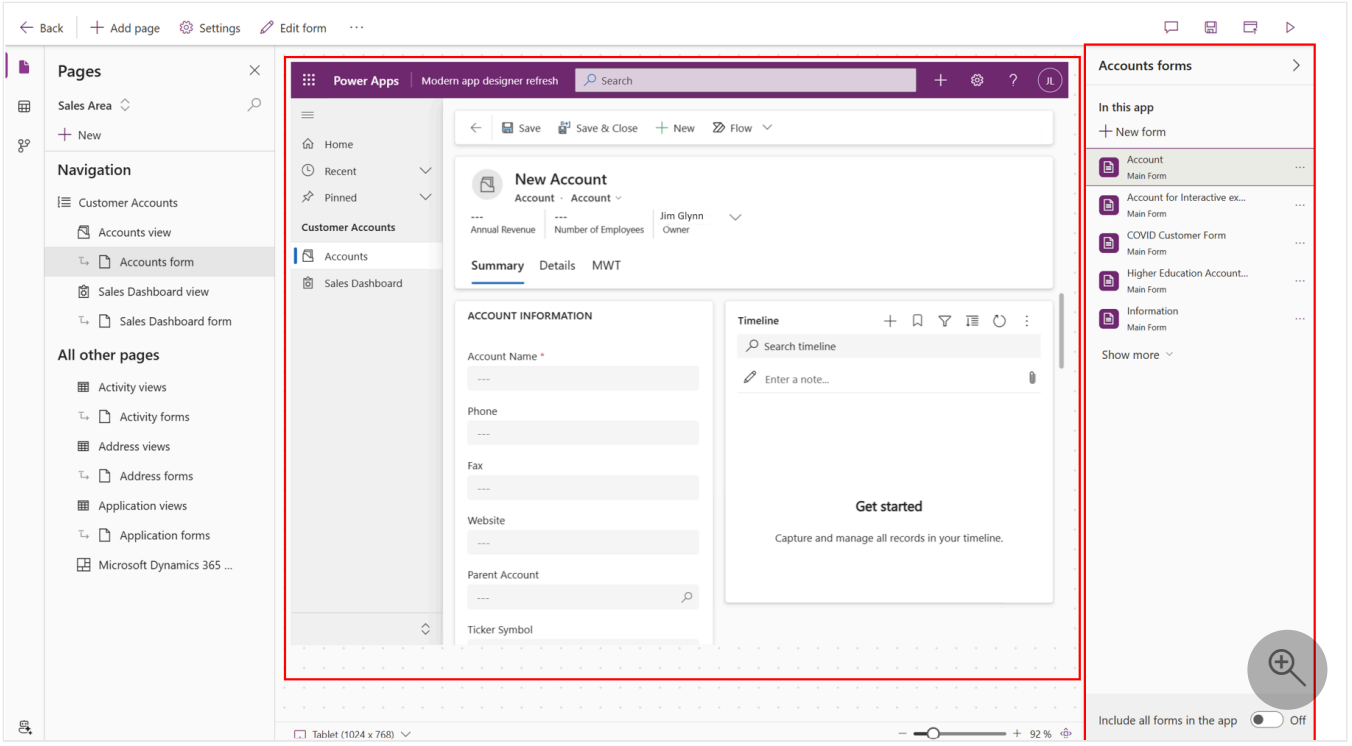
3. Select **New** > **App** > **Model-driven app**.
4. On the **New model-driven app** dialog box, enter a **Name** and optionally, a **Description**, and then select **Create**.
5. On the command bar, select **Add page** > **Dataverse table**.

6. From the list of tables, select **Account**, select **Contact**, and then select **Add**.

On the **Pages** left pane, under **Navigation** the layout for the app is displayed.



Notice the preview pane displays your app. When you select a component, such as the **Accounts form**, it affects what's displayed in the preview and property panes. If your environment includes data that you have access to view, that also appears in the preview.



To save and publish the app, select **Save and Publish**.

To see how the app runs in a full browser window, on the command bar, select **Play**.

Create an app description with Copilot

If your app is in a managed environment, you can use AI to help create a description for your app.

> **Important**
>
> - To use this capability your app must be in a managed environment.
> - This capability is powered by Azure OpenAI Service.
> - This capability is in process of rolling out, and might not be available in your region yet.
> - This capability might be subject to usage limits or capacity throttling.
> - To understand capabilities and limitations of AI-powered and Copilot features in Power Apps, go to Responsible AI FAQs for Power Apps

When you save and publish your app, on the **Publish** dialog box select **Create descriptions using AI** to replace your current description or, if your app doesn't have a description, Copilot

generates one for you.

You can also generate an app description in app designer by going to, **Settings** > **General** tab. Under **Description** select, **Create descriptions using AI**.

For information that describes the AI impact of Power Apps generate app descriptions with Copilot feature, go to FAQ for generate app descriptions with Copilot.

Enable or disable AI-generated app descriptions

The app AI-generated descriptions are managed by a setting in the Power Platform admin center.

1. Go to **Environments** in the Power Platform admin center.
2. Select an environment, and then select **Edit managed environments**.
3. Under the section titled **Enable AI-generated app descriptions**, select or clear **AI-generated app descriptions**
4. Select **Save**.

Clear the browser cache and close any active Power Apps (make.powerapps.com) browser windows. The feature is now be enabled or disabled.

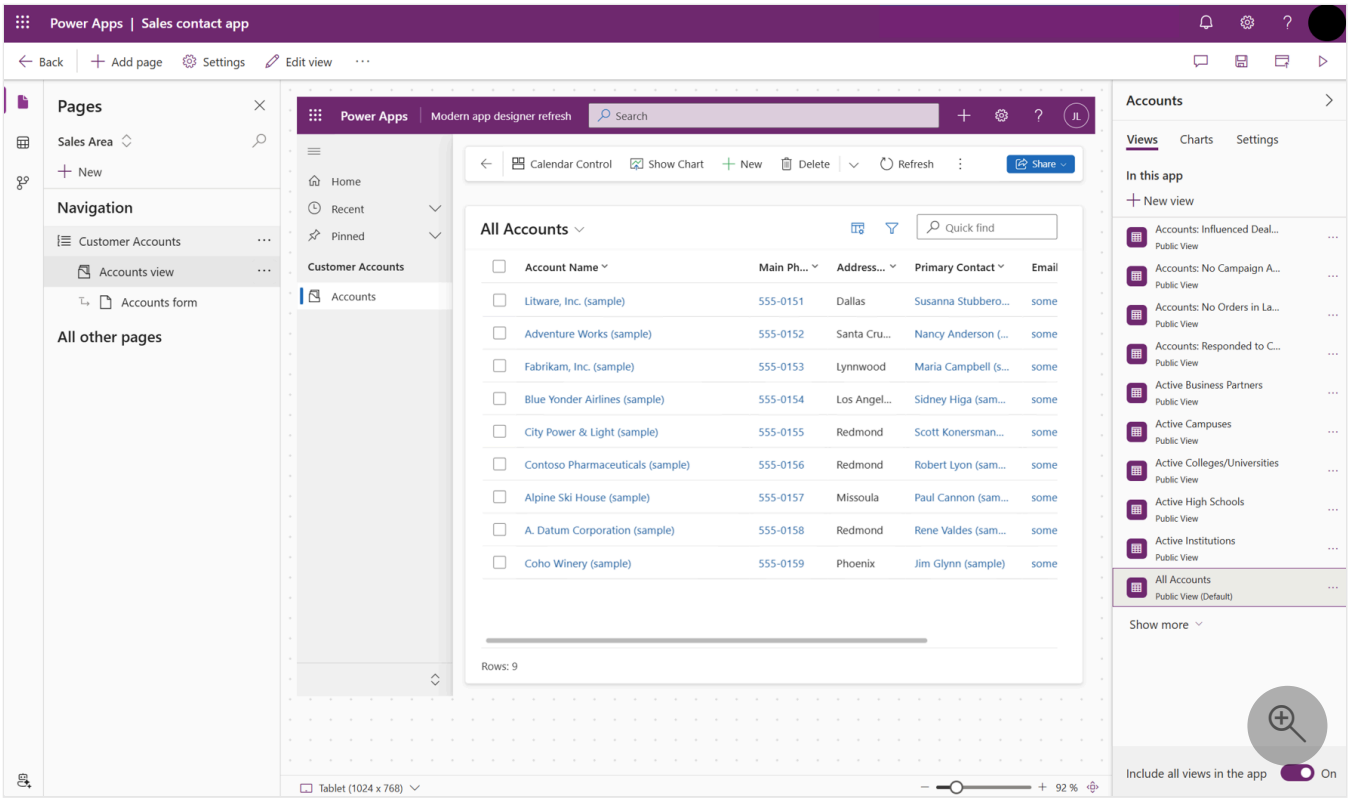
Next steps

- Add areas, groups, and subareas for app navigation
- Create, add and remove forms, views or dashboards
- Create and remove pages
- Configure app properties (Preview)
- Configure app properties

Last updated on 01/09/2026

Build your first model-driven app

In this tutorial, you create a model-driven app by using one of the standard tables that is available in Microsoft Dataverse, the account table.



1. Sign in to Power Apps. If you don't already have a Power Apps account, select the **Get started free** link.

2. Select an environment. An environment in Power Apps is a space to store, manage, and share your organization's business data, apps, chatbots, and flows. It also serves as a container to separate apps that might have different roles, security requirements, or target audiences.

   Each environment can have one Dataverse database.

   Select the environment you want. If your tenant allows you to create your own environment, select the current environment from the top right, and then select **Try it now**. More information: Get your developer environment (preview)

3. We recommend creating your model-driven app from a solution. A solution is a package that can contain Dataverse tables, forms, views, apps, flows, and other components. By building your model driven-app in a solution, you can easily move it to other environments or preserve a copy in your source control repository.

   Select **Solutions** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

4. Select **New solution**, enter a **Display name** for your solution, such as *Power Apps Training*, select a publisher (the **CDS Default Publisher** is okay for this tutorial), and then select **Create**. For more information about creating a solution, go to Create a solution.

5. In your solution, select **Add existing**, and then select **Table.**

6. In the **Add existing tables** list, select the **Account** table, and then select **Next**.

7. Since this is a standard table, leave the default setting for account table objects and metadata and select **Add.**

   Now that you have a solution and have added the account table to it, you're ready to create a model-driven app.

8. In your solution, select **New**, select **App**, and then select **Model-driven app.**

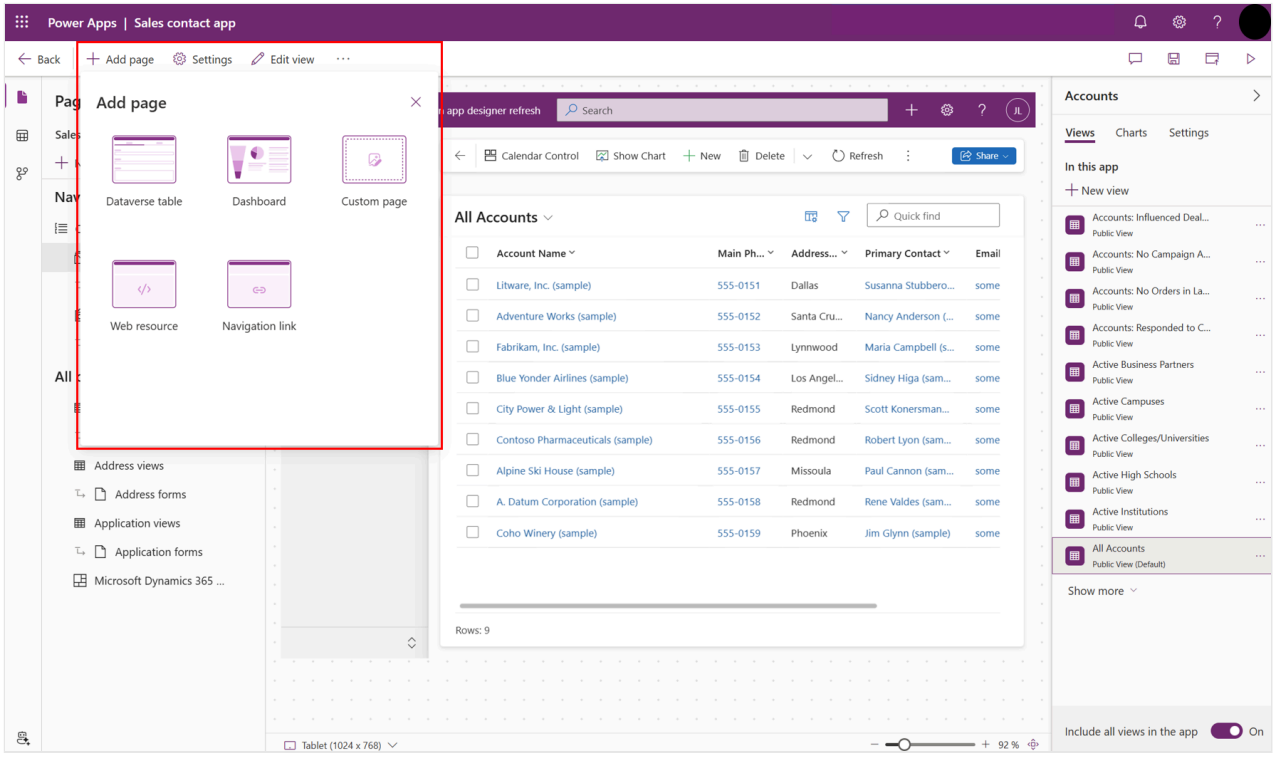
9. Enter a name for the app, such as *My new custom app*, and then select **Create**.

   Your app loads in the model-driven app designer.

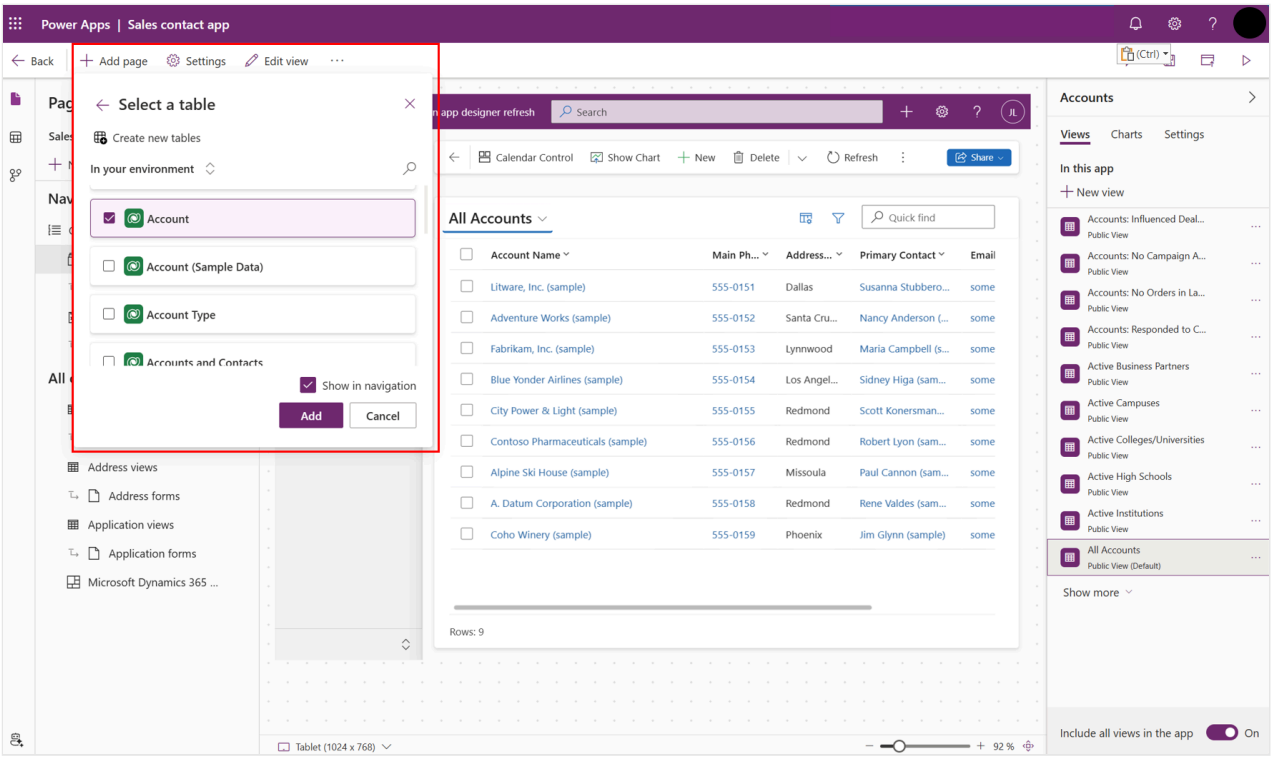
Add a page to your app

Next, you add a new page to the model-driven app in the app designer.

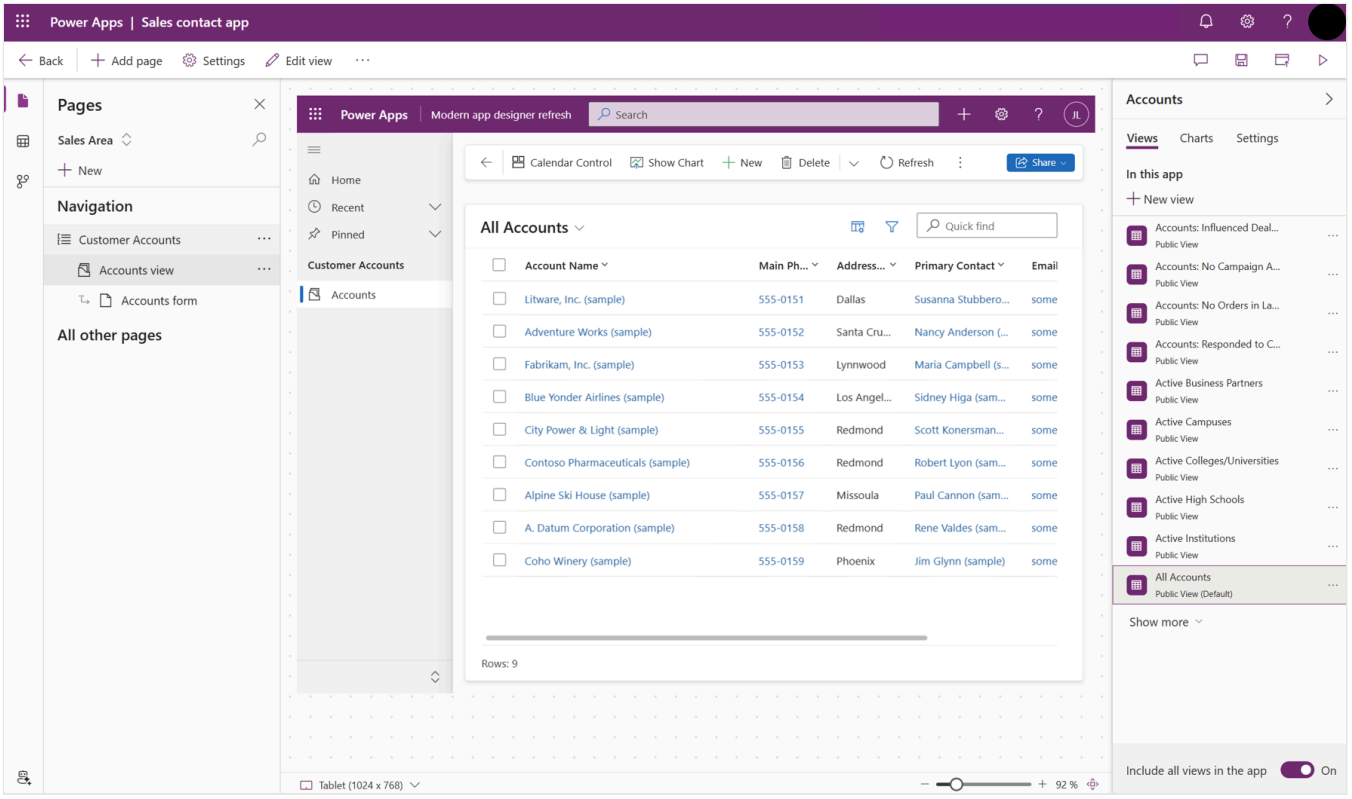
1. Select **Add page** on the command bar, and then select **Dataverse table**.



2. Select **Account**, and then select **Add**.



Your app with the account table is displayed similarly to how it appears to users at run time when published. If your environment has sample data, the sample list of active accounts might appear in the **All Accounts** view.



Save and publish your app

Save your app so that your app and changes aren't lost. To make it available to users, publish it.

To save without publishing, on the app designer command bar, select **Save**.

To save and publish, on the app designer command bar, select **Publish**.

Create an app description with Copilot

If your app is in a managed environment, you can use AI to help you create a description for your app.

> **Important**
>
> - To use this capability your app must be in a **managed environment**.
> - This capability is powered by **Azure OpenAI Service**.
> - This capability might be subject to usage limits or capacity throttling.
> - To understand capabilities and limitations of AI-powered and Copilot features in Power Apps, go to **Responsible AI FAQs for Power Apps**

When you save and publish your app, on the **Publish** dialog box select, **Create descriptions using AI** to replace your current description or, if your app doesn't have a description, Copilot generates one for you.

You can also generate an app description by going to, **Settings** > **General**. Under **Description** select, **Create descriptions using AI**.

For information that describes the AI impact of Power Apps generate app descriptions with Copilot feature, go to FAQ for generate app descriptions with Copilot.

Enable or disable AI-generated app descriptions

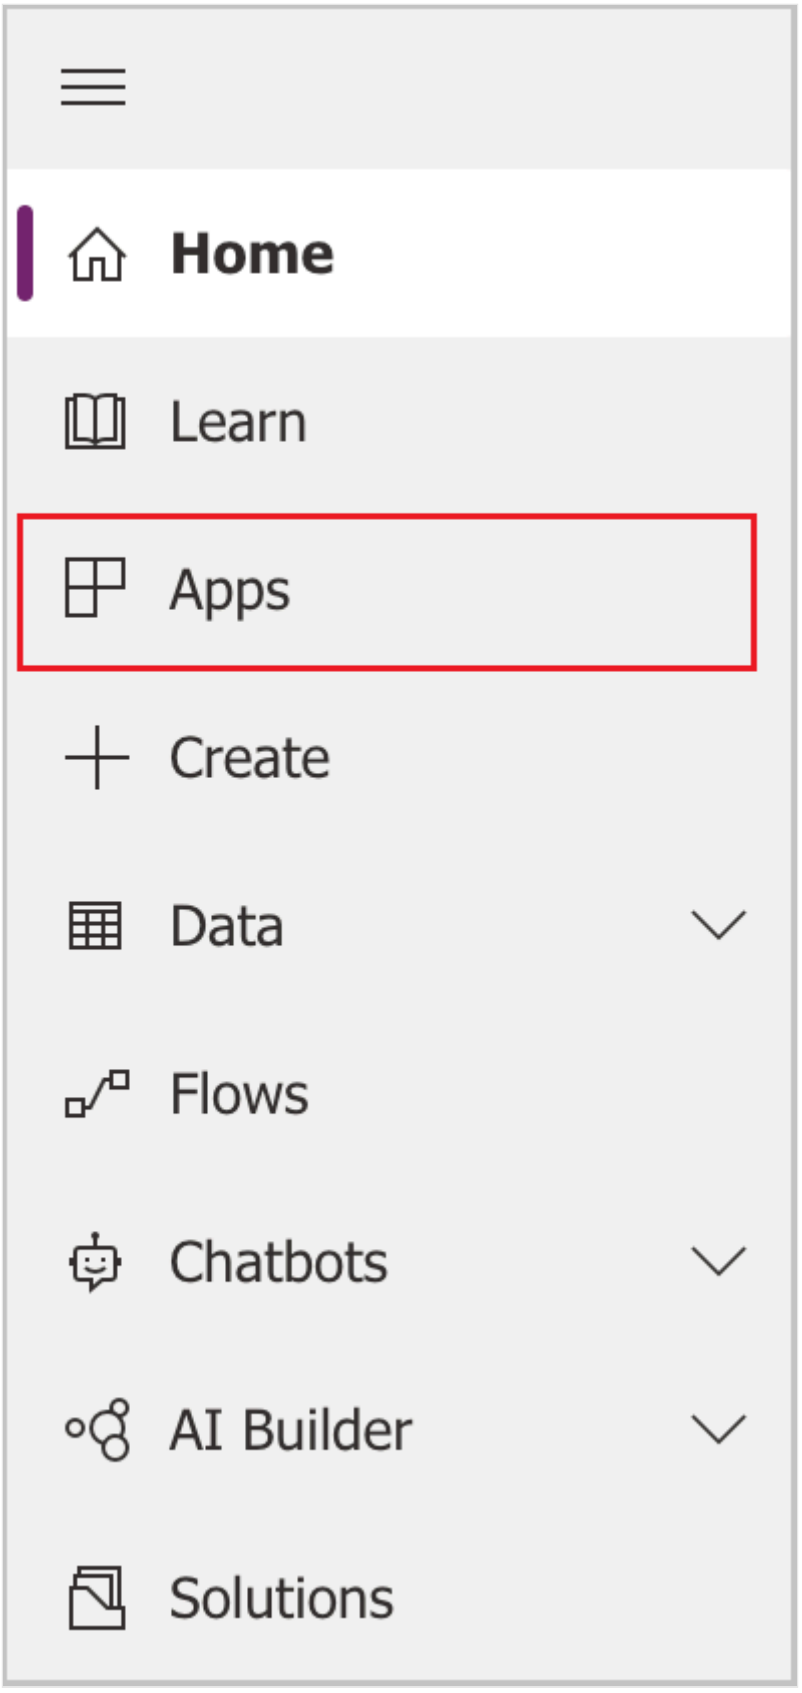
App AI-generated descriptions are managed by a setting in the Power Platform admin center.

1. Open https://admin.powerplatform.microsoft.com/environments
2. Select an environment, and then select **Edit managed environments**.
3. Under the section titled **Enable AI-generated app descriptions**, select or clear **AI-generated app descriptions**
4. Select **Save**.

Clear the browser cache and close any active Power Apps (make.powerapps.com) browser windows. The feature is now be enabled or disabled.

Run your app on a desktop computer

1. To run your app, sign in to Power Apps, and on the left navigation pane, select **Apps**.



2. Select the app from the app list. The app opens in your browser. If you want to show the chart, use the button **Show Chart**.

Run your app on mobile

To run your app on your mobile device, follow these steps:

1. Download the app from your device's mobile app store:
    - IOS: Power Apps on the App Store (apple.com)
    - Android: Power Apps - Apps on Google Play
2. Open the app, tap **Sign in**, and then enter your Microsoft work or school account.
3. Select your app from the list to run it.

Next steps

Add additional pages and configurations to make your app do more!

- Add a custom page where a canvas app runs from your model-driven app. More information: Overview of custom pages for model-driven apps
- Create Dataverse custom tables that you can add to your app the same way as you added the account table in this tutorial. More information: Create and edit tables using Power Apps
- Identify the URL of your model-driven app. More information: Run a model-driven app in a browser
- Share your app. More information Share a model-driven app.
- Learn more about building model-driven apps. More information: Understand model-driven app components

App navigation in model-driven apps

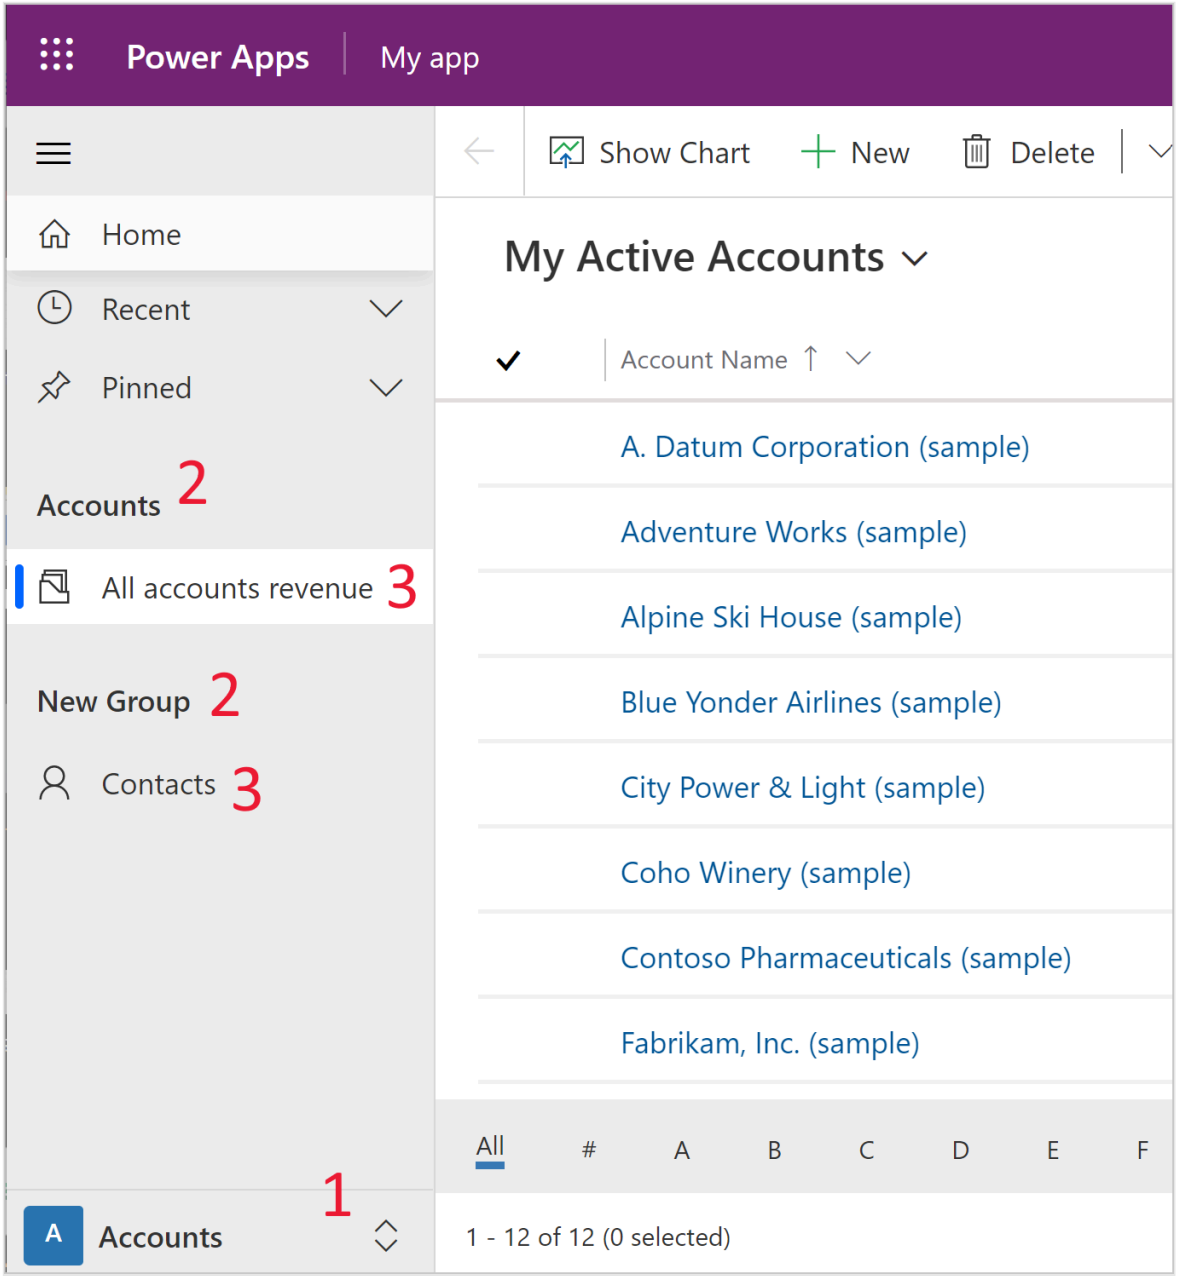
Article • 02/05/2025

In a model-driven app, there are the three main app runtime navigation components.

1. *Areas* - For apps with more than one area, a switch control is displayed in the lower left navigation pane. In the screenshot below, the current area is named *Accounts*.

2. *Groups* - Group names appear as a navigation element in an app with the subarea names within the group listed beneath it. In the screenshot below, one group is named *Accounts* and one is named *New Group*.

3. *Pages* - Pages appear under the group that they're configured within in the app designer. In the screenshot below, one page is named *All accounts revenue* and another page is named *Contacts*.



Create an area

By default, the ability to create additional areas is disabled. Areas are enabled by default for apps with existing multiple areas.

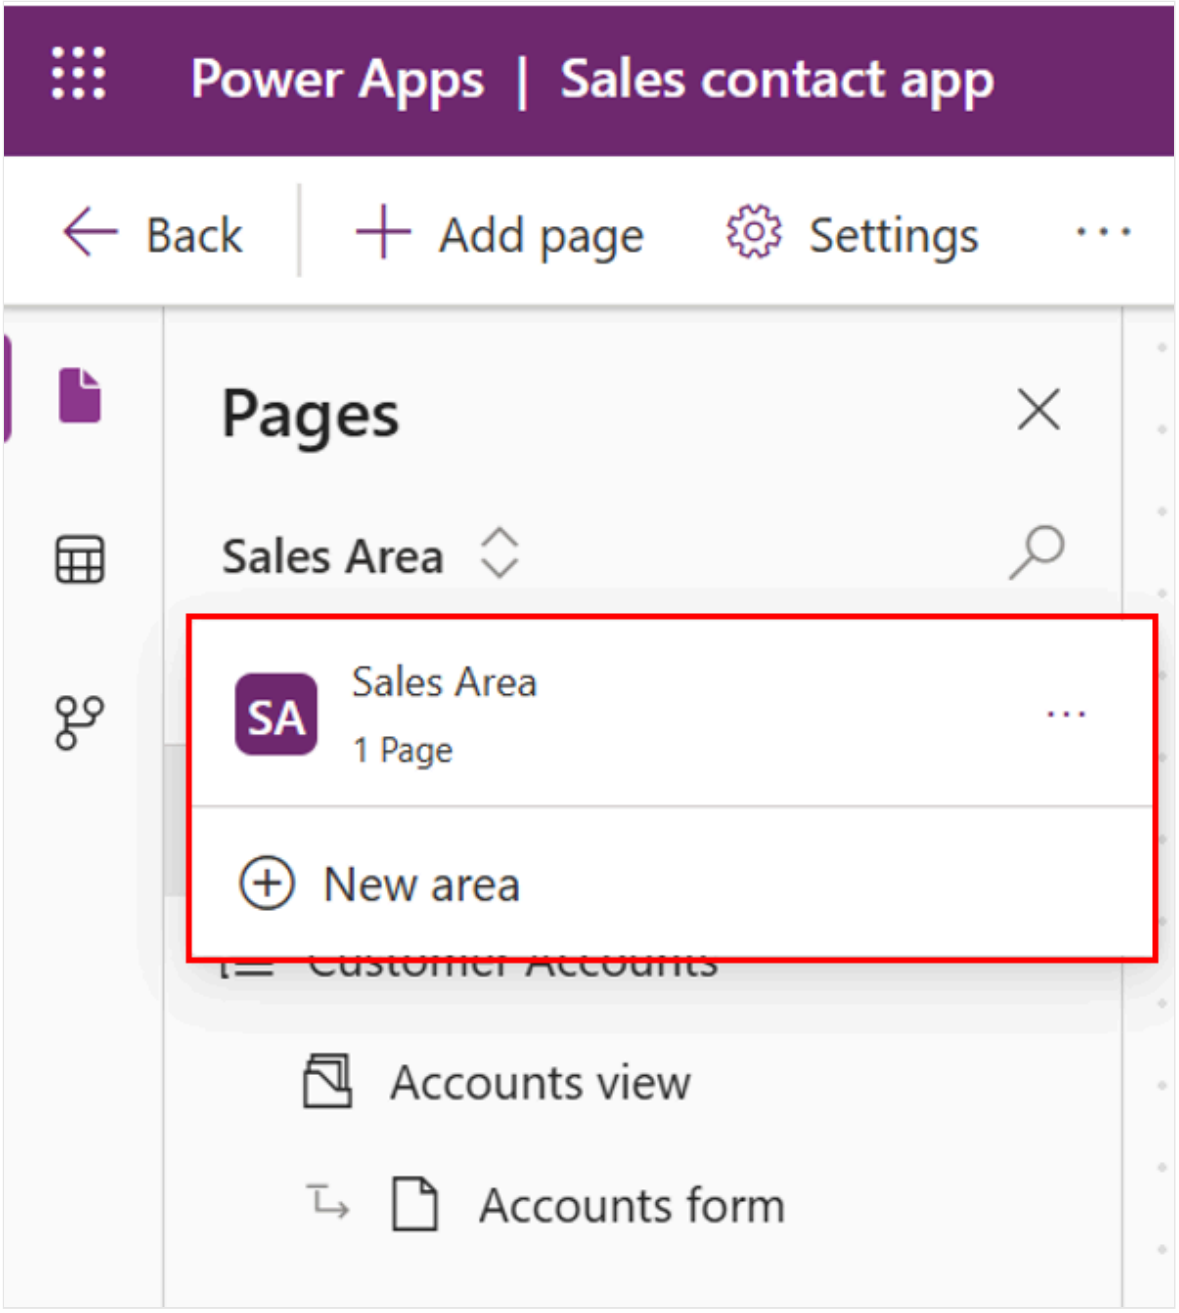
Enable areas

1. On the command bar select **Settings**.
2. Select **Navigation** on the left pane, and then select **Enable Areas**.
3. Close the **Settings** dialog.

Add a new area

1. On the left navigation pane, select **Pages**.

2. Select the area switcher under **Pages**, and then select **New area**. If the area switcher is missing, you need to enable areas.



3. Complete the properties pane for the area:

   - **Title**: Enter a title used to describe the area.
   - **Icon**: Optionally set an icon for the area. More information: Create or edit model-driven app web resources to extend an app
   - **ID**: The system generates an identifier for the area. Accept the system generated ID or enter a new one.

4. To save your app navigation changes select **Save**.

5. To publish the changes and make them available to other users, select **Publish**.

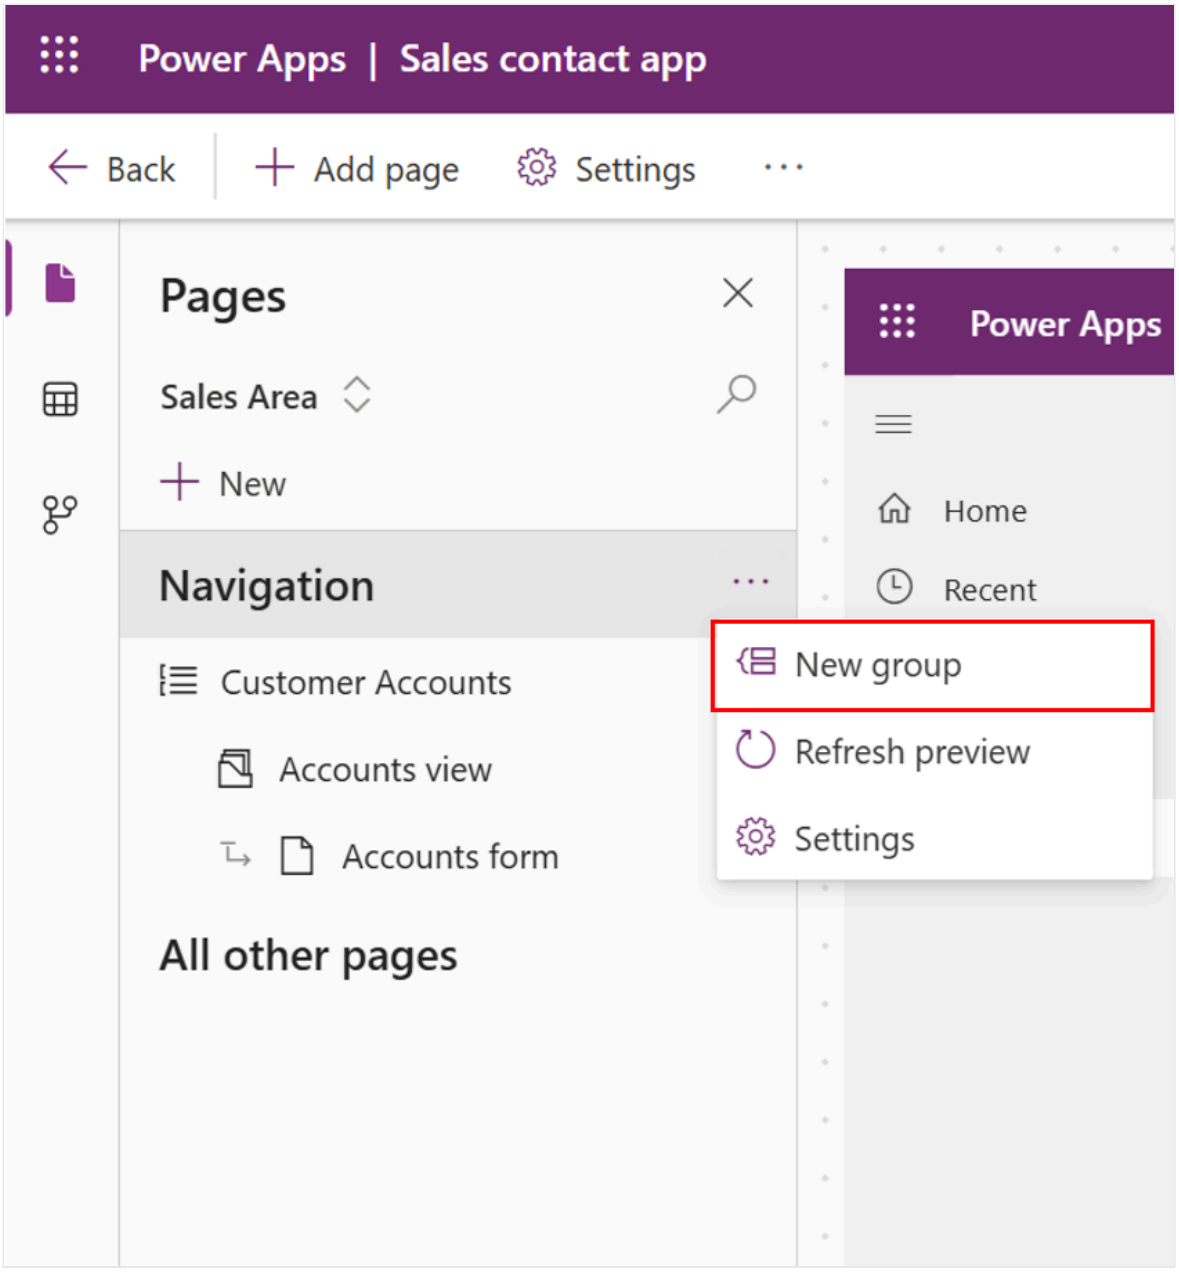
Create a group

To create a new group, complete the following steps:

1. On the left navigation pane, select **Pages**.

2. Select **...** next to **Navigation**.

3. Select **New group**.



4. Complete the properties pane for the group:

   - **Title**: Enter a title used to describe the group.
   - **ID**: The system generates an identifier for the group. Accept the system generated ID or enter a new one.
   - **Advanced Settings**:
     - **Localized titles**: Add localized titles for the group title. More information: Translate localizable text for model-driven apps
     - **Localized descriptions**: Add localized descriptions for the group description. More information: Translate localizable text for model-driven apps

5. To save your app navigation changes select **Save**.

6. To publish the changes and make them available to other users, select **Publish**.

Create a page

Pages were formerly called *subareas* in the app designer. To create a new page, complete the following steps:

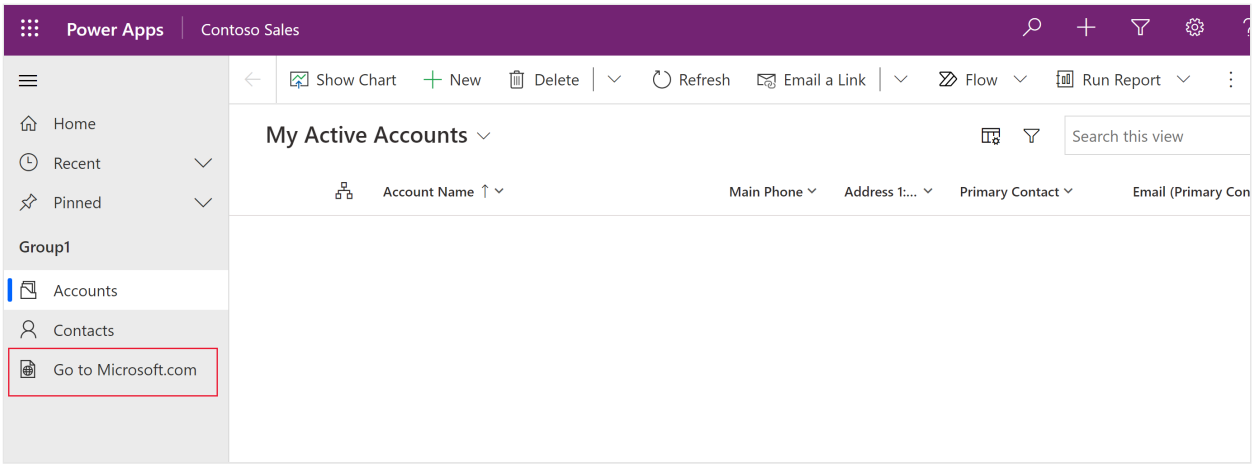
1. On the command bar, select **Add page**.
2. Select the content type you want.

    - **Dataverse table**. Select an existing table or create a new one. More information: Create a custom table
    - **Dashboard**. Select a dashboard. More information: Create or edit model-driven app dashboards
    - **Custom page**. Add a custom page, such as a canvas app page. More information: [Overview of custom pages for model-driven apps]
    - **Web resource**. Web resources represent files that can be used to extend an application such as HTML files, JavaScript, and CSS, and several image formats.
    - **Navigation link**. Add a URL, such as a website address. More information: Add a URL to an app (model-app-page-overview.md)

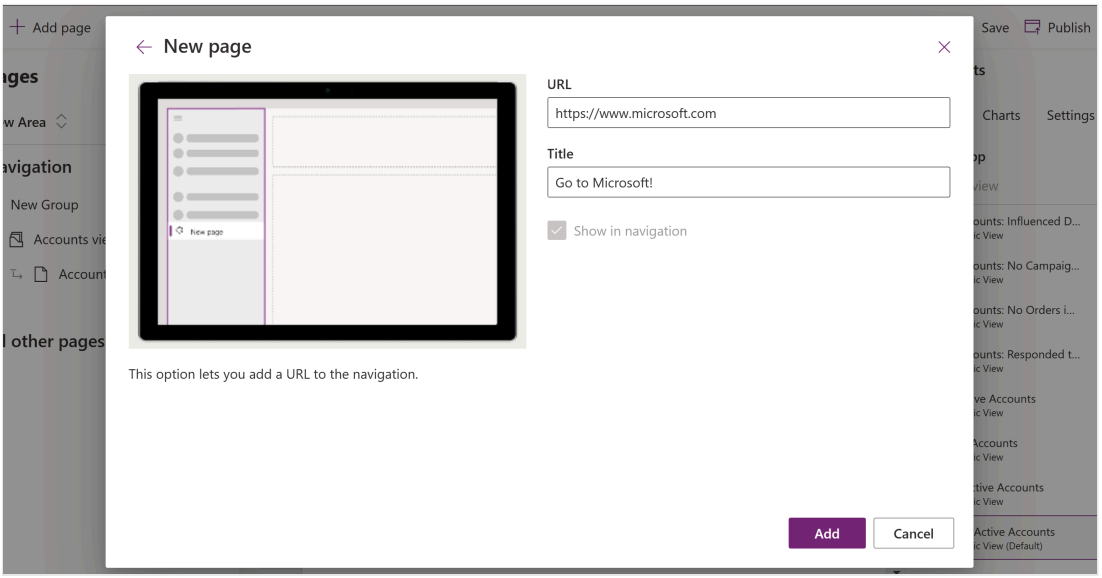
3. Complete the choices that are on you screen to create the page, and then select **Add**.
4. To save your app navigation changes select **Save**.
5. To publish the changes and make them available to other users, select **Publish**.

Add a URL to an app

A URL is a type of page in the app navigation. When the user selects the page, the URL opens in a new tab in the web browser.



1. In the model-driven app designer, select **Add page** on the command bar.
2. On the **New page** screen, select **URL**, and then select **Next**.
3. In the properties pane for the URL, enter the following information, and then select **Add**:
   - **URL**: Enter the full URL, such as *https://www.microsoft.com*.
   - **Title**: Enter a title for the URL component.



4. To save your app navigation changes select **Save**.
5. To publish the changes and make them available to other users, select **Publish**.

Remove a group or page

1. On the left navigation pane, select **Pages**.
2. Select the group or page you want, select the ellipses (...) and then select **Remove from navigation**.

Remove an area

1. On the left navigation pane, select **Pages**.
2. Select the area switcher under **Pages**, select **...** next to the area you want to remove, and then select **Remove from navigation**.

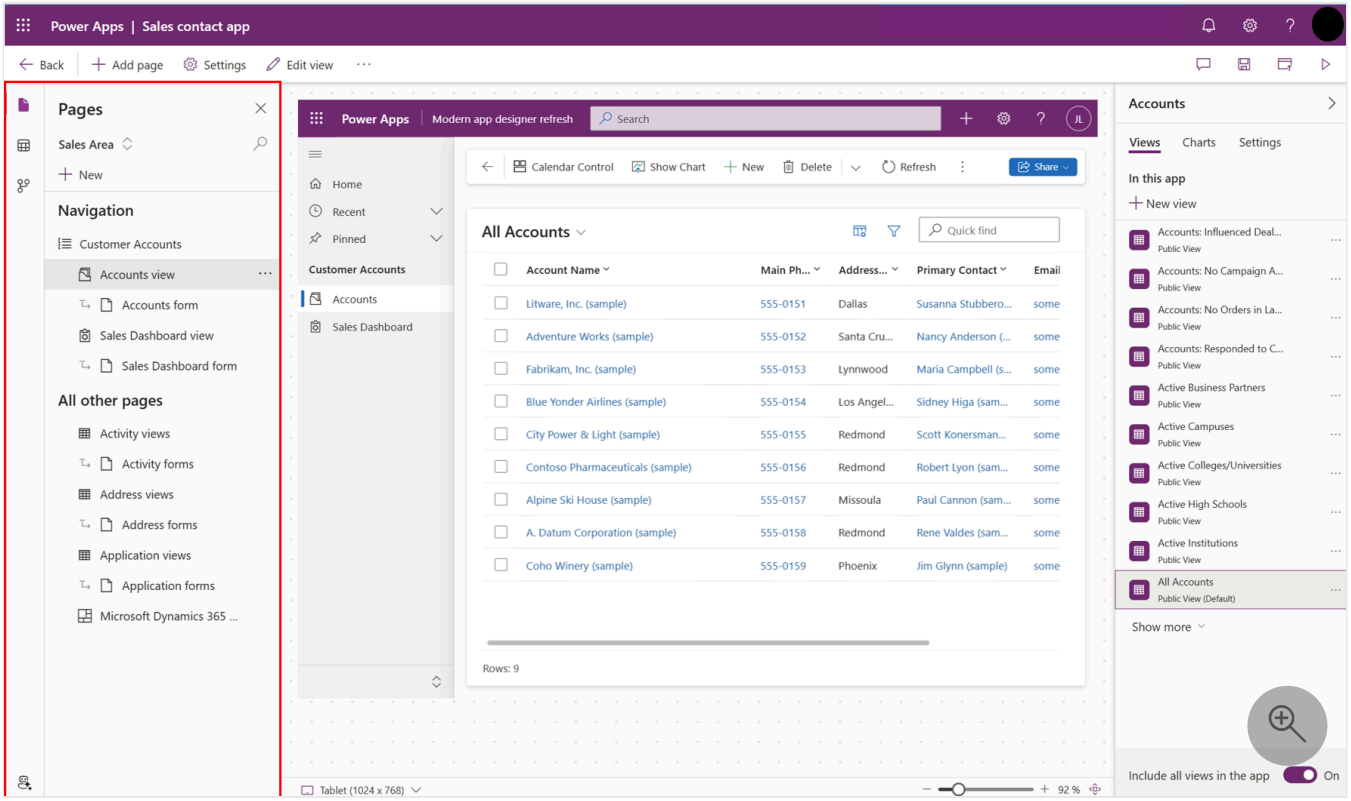
Work with model-driven app pages

07/17/2025

App designer pages are containers for tables, dashboards, custom pages, or web resources. Pages determine your app's assets and navigation. You can choose whether to have the page appear in the app navigation (site map) or not.



Create a page

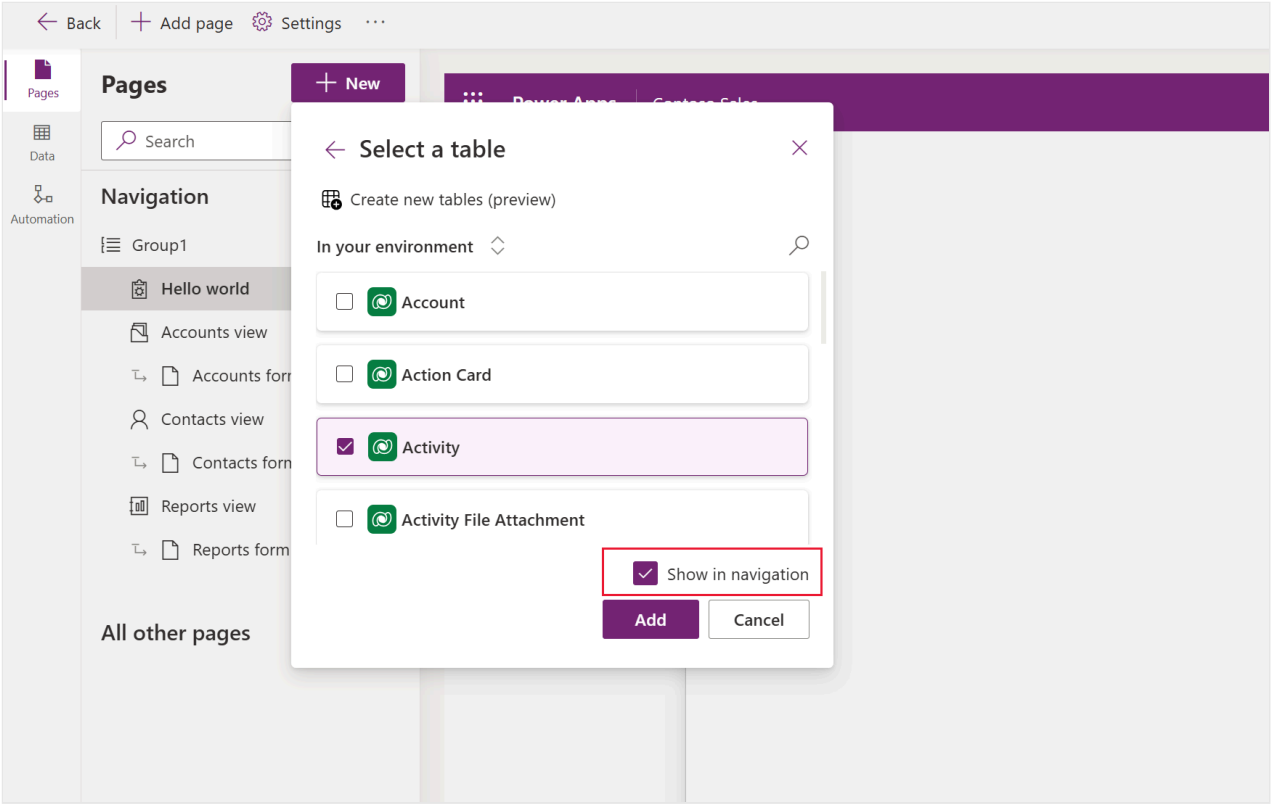
To create a page, follow these steps:

1. Sign in to Power Apps, select **Apps**, and then **Edit** the app you want.
2. In the app designer on the **Pages** tab, select **New**.
3. Select the page type, and then select **Next**:

   - **Describe a page**. Use natural language to create a generative page that's generated using AI. More information: Describe a page using natural language (preview)
   - **Dataverse table**: Display records of a standard or custom table in a full-page list view. Creating a data view page also adds an associated form page for viewing and editing data on a selected record. More information: Tables in Dataverse
   - **Dashboard**: Display charts and tables from multiple entities to visualize data on a single page. Select one or more system, interactive, or Power BI dashboards. More information: Create or edit model-driven app dashboards

- **Custom page**: Design and build a page that's based on a canvas app. More information: Overview of custom pages for model-driven apps
- **Web resource**: Select a web resource from a list of web resources. More information: Create or edit model-driven app web resources to extend an app
- **Navigation link**: Enter a direct link to a web resource. Create or edit model-driven app web resources to extend an app

4. If you don't want your page to appear in the app's site map, clear the **Show in navigation** option.



5. Select **Add**.

Work with tables on a page

Create and edit tables directly from the app designer.

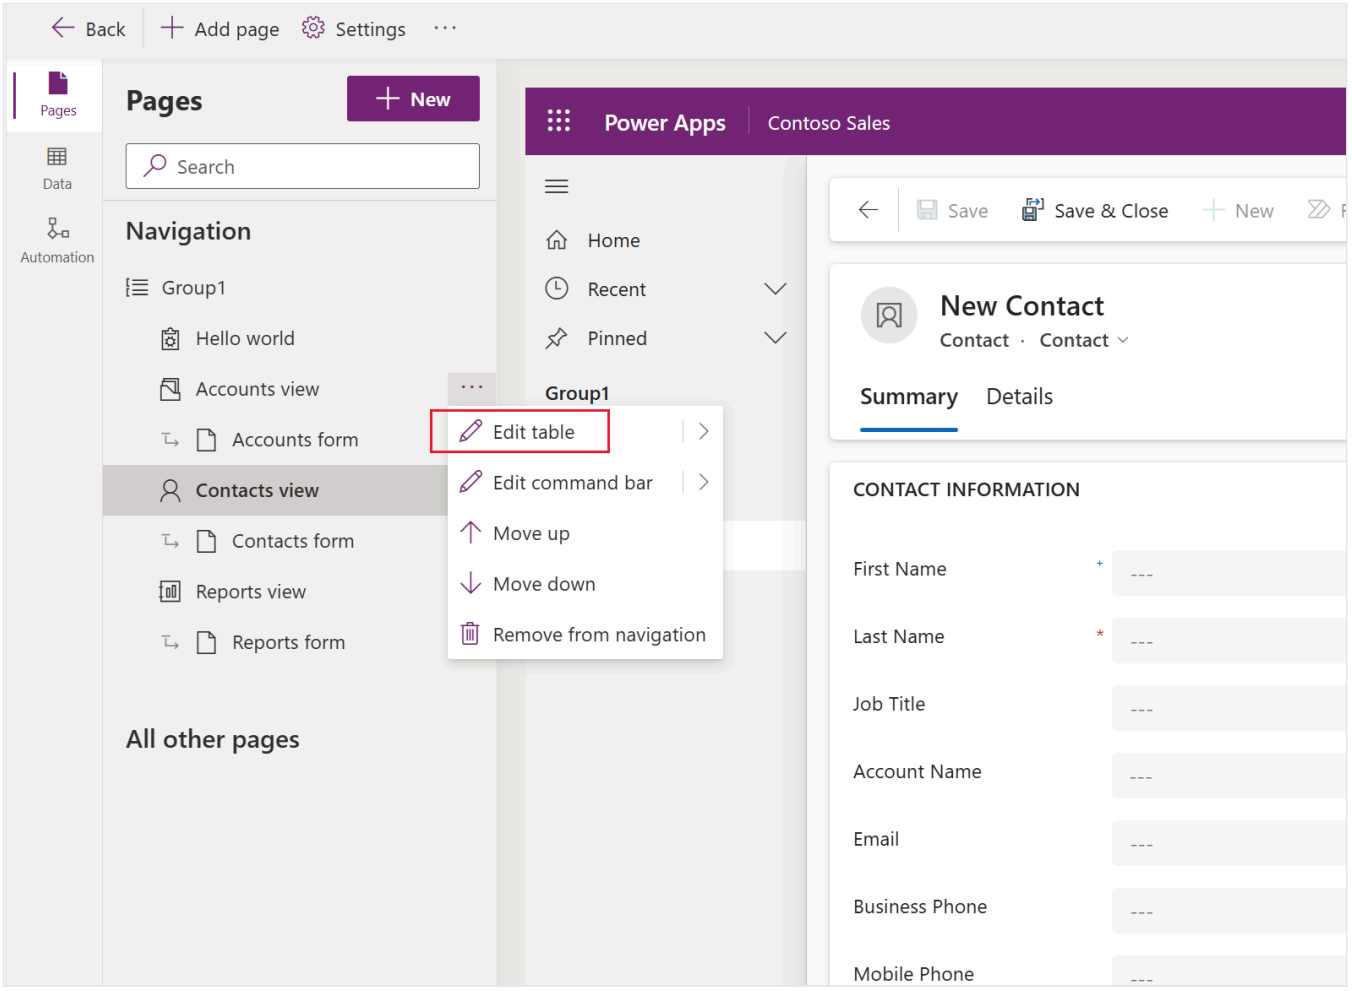
Create a table for a page

1. In the model-driven app designer, select **Add page**, select **Dataverse table** as the page type.
2. Select **Create new tables**. Otherwise, if your table is already created select it from the list.
3. If you selected **Create a new tables**:

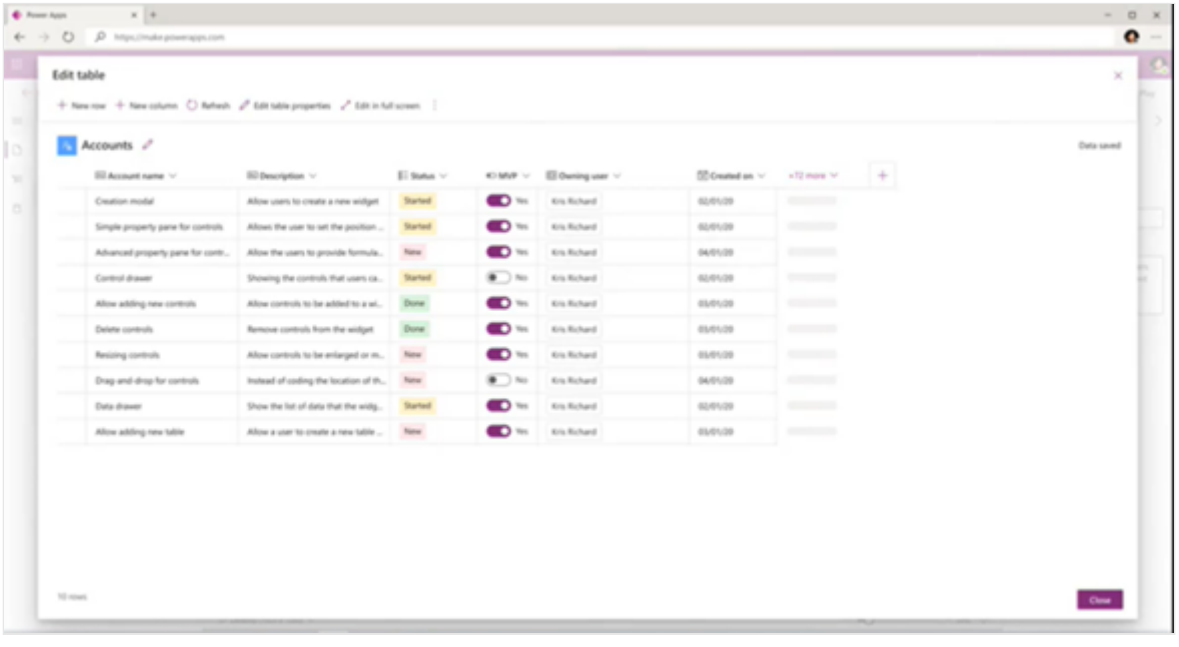
   - Select the option you want to create a table and follow the instructions on your screen.
   - More information: Create new tables

Edit a table for a page

From the **Pages** tab in app designer, select **...** to the right of the table name, and then select **Edit table**.



The table designer opens for you to make changes to the table.



To delete the table, **Close** the table hub, select **...** to the right of the table name, and then select **Remove**.

Edit a table view

To edit a view for a table that's added to your app in a page, complete these steps:

1. In the model-driven app designer, select a page that is based on a table.
2. On the command bar, select **Edit view**.

The view designer is displayed where you can edit the table view. More information: Edit public views from a table

Remove a page

To remove a page, complete these steps:

1. In the model-driven app designer, select a page.
2. Select the ellipses (**...**), and then select **Remove from navigation**.

Next steps

Create and customize a model-driven app form

Create or edit model-driven app dashboards

Add a custom page to your model-driven app

Manage model-driven app settings in the app designer

App settings define important details about the app, like its title. You define app settings when you create an app. If you want to change those settings later, you can do that in the app designer.

You must select **Publish** to activate an app settings change.

1. In the app designer select **Settings** on the command bar.

2. View and change the information, as required:

Expand table

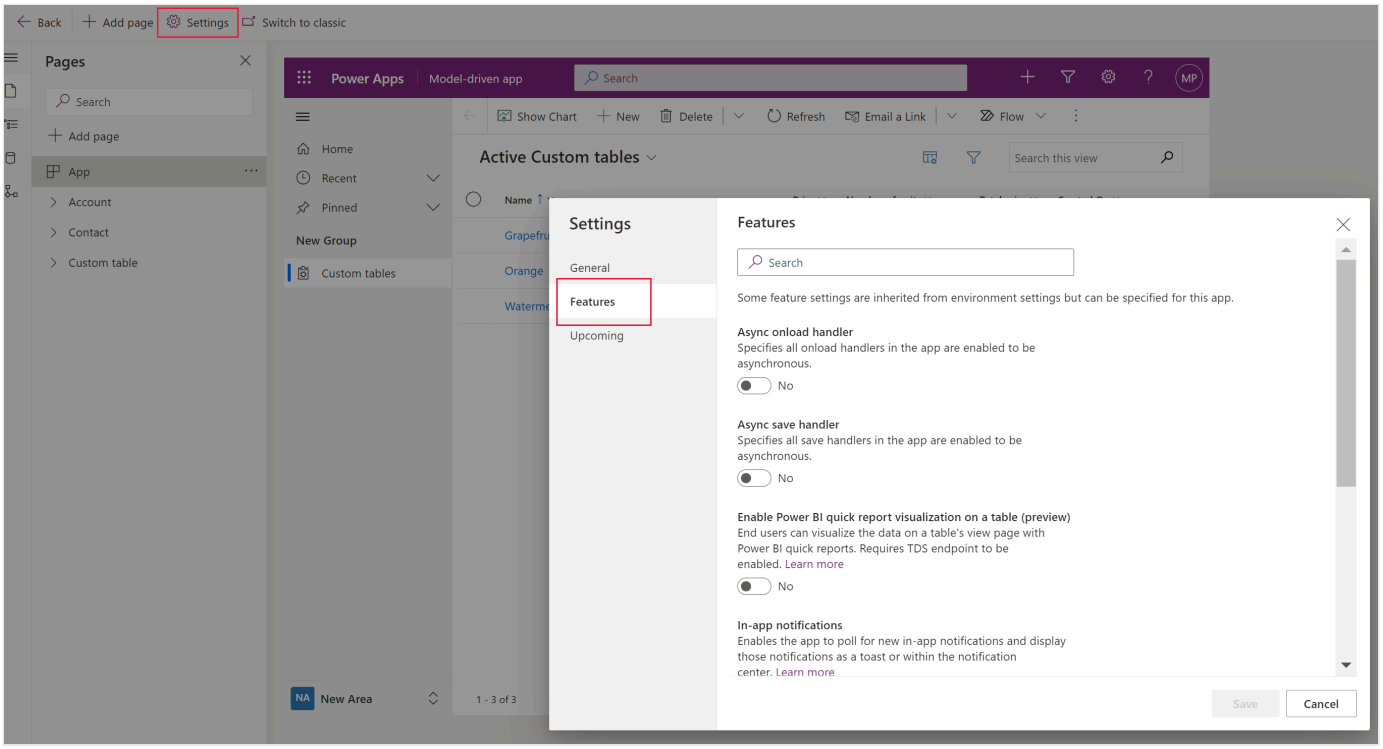
Area	Setting	Description
General	**Solution**	Read-only property that displays the solution name where the app is located.
General	**App name**	The friendly name for the app.
General	**Description**	The description of the app (optional). If your app is in a managed environment, you can select **Create description using AI** to have Copilot generate one for you. More information: Create an app description with Copilot
General	**Icon**	Change the app icon by selecting **Select icon**, to browse and select an image web resource. This icon is displayed on the preview tile of the app. More information: Create or edit model-driven app web resources to extend an app
Advanced settings	**Unique name**	Read-only property that displays the app unique name including the publisher prefix.
Advanced settings	**Welcome page**	This option allows a maker to select from the web resources available in your organization. The welcome pages created contain information that's useful to users, such as links to videos, upgrade instructions, or getting started information. The welcome page is displayed when an app is opened. Users can select **Do not show this Welcome Screen next time** on the welcome page to disable the page so it doesn't appear the next time the app starts. Notice that the **Do not show this Welcome Screen next time** option is a user-level setting and can't be controlled by administrators or app makers. More information: Create or edit model-driven app web resources to extend an app

Area	Setting	Description
Advanced settings	**Primary mobile player**	Determines which mobile player you want the model-driven app to be available from. By default, **Power Apps mobile** is selected. For example, if you want the model-driven app only available from the Dynamics 365 Sales mobile app, select **Dynamics 365 Sales**. - **Power Apps Mobile**. More information: Use model-driven apps on Power Apps mobile - **Dynamics 365 Sales**. More information: Overview of Dynamics 365 Sales mobile app - **Field Service (Dynamics 365)**. More information: Overview of the Field Service (Dynamics 365) mobile app

3. **Save** and **Publish** the app.

Features

When you select **Settings** from the command bar, select **Features** to enable or disable model-driven app features for the app.



Here are a few of the features available to app makers:

- **Enable Power BI quick report visualizations on a table**. Enabled by default, this feature allows app users to create a Power BI quick report from a table view by selecting the **Visualize this view** command on the app command bar. More information: Visualize data in a view with Power BI service

- **In app notifications**. When enabled, the app polls for new in-app notifications and displays them. More information: Send in-app notifications within model-driven apps
- **Lock tabs at the top of forms on mobile and tablets**. When enabled, tabs remain visible at the top of a form while users scroll through the data on the form. More information: Lock tabs at the top of forms
- **Mobile commanding improvements**. When enabled, optimizes the command bar for phone and tablet providing easy access to contextual commands to users helping increase productivity and satisfaction. More information: Mobile commanding improvements
- **Enable offline classic**. Enable mobile offline classoc
- **Tablet optimization for command bar**. When enabled, replaces the native command bar at the bottom of the screen with the web command bar located at the top of the screen on tablets. More information: Tablet optimization for command bar
- **New look for model-driven apps**. Enabled by default, this feature determines whether end users see the modern refresh app experience or the classic look. This setting is hidden and ignored with the **2026 Wave 1** release when the new look becomes mandatory. More information: Modern, refreshed look for model-driven apps
- **Form fill assist toolbar**. When enabled, the form fill assist toolbar is visible at the top of a form, providing easy access to Copilot form fill assistance capabilities like smart paste and files. For more information about AI form fill assistance environment settings, go to AI form fill assistance. For more information about using this feature, go to Use Copilot's form fill assistance feature in model-driven apps.

Navigation

Controls navigation features for the app.

- **Home**. Displays a link to the home page for the model-driven app.
- **Recent**. Displays the list of links for the model-driven app that were recently visited.
- **Pinned**. Pin items from the **Recent** list to locate them easily.
- **Enable collapsibile groups**. Disabled by default. Allows groups to be collapsed or expanded. More information: Create a group
- **Enable Areas**. Disabled by default. Areas can contain multiple groups. For apps with multiple areas, a user must select the area switch located at the bottom left in the app to change to a different area. Add a new area

Upcoming

[This topic is pre-release documentation and is subject to change.]

The **Upcoming** tab displays preview features currently available:

> **Important**
>
> Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

- **Microsoft 365 Copilot in model-driven apps**. Microsoft 365 Copilot chat makes it easier for users to work with model-driven apps by offering AI-powered insights through natural language conversations. With this feature, users can quickly find information, navigate apps more easily, and get help to boost their productivity. More information: Add Microsoft 365 Copilot chat for app users in model-driven apps (preview)

Known limitations

The following app properties can't be edited in the app designer:

- App Url Suffix
- Manage App

Overview of custom pages for model-driven apps

The custom page is a new page type within a model-driven app, which brings the power of canvas apps into model-driven apps. Custom pages increase the convergence of model-driven and canvas apps and can be used to add full pages, dialogs, or panes with the flexibility of Power Apps Studio. It also includes a low-code page authoring experience with expressions and custom Power Apps component framework controls.

A custom page is more flexible than a model-driven app form, view, or dashboard page. You can include one or more tables. Then, you define the data and component interactions. The custom page is a separate solution element, which means one maker can edit one custom page at a time. Like other model-driven app pages, the page state comes from the parameters passed or is retrieved from persisted tables.

> **Important**
>
> Custom pages are a feature with significant product changes and currently have a few known limitations outlined in Custom Page Known Issues.

Expand table

Capability	Status	Notes
Runtime for custom pages	General Availability	
Solution and ALM for custom pages	General Availability	
Connectors in custom pages	General Availability	List of all Power Apps connectors
Modern controls in custom pages	General Availability	List of supported controls
Code components in custom pages	General Availability	
Monitor support for custom pages	General Availability	
Authoring custom pages	General Availability	Use the modern app designer and Power Apps Studio to author custom pages that are supported at runtime.

Capability	Status	Notes

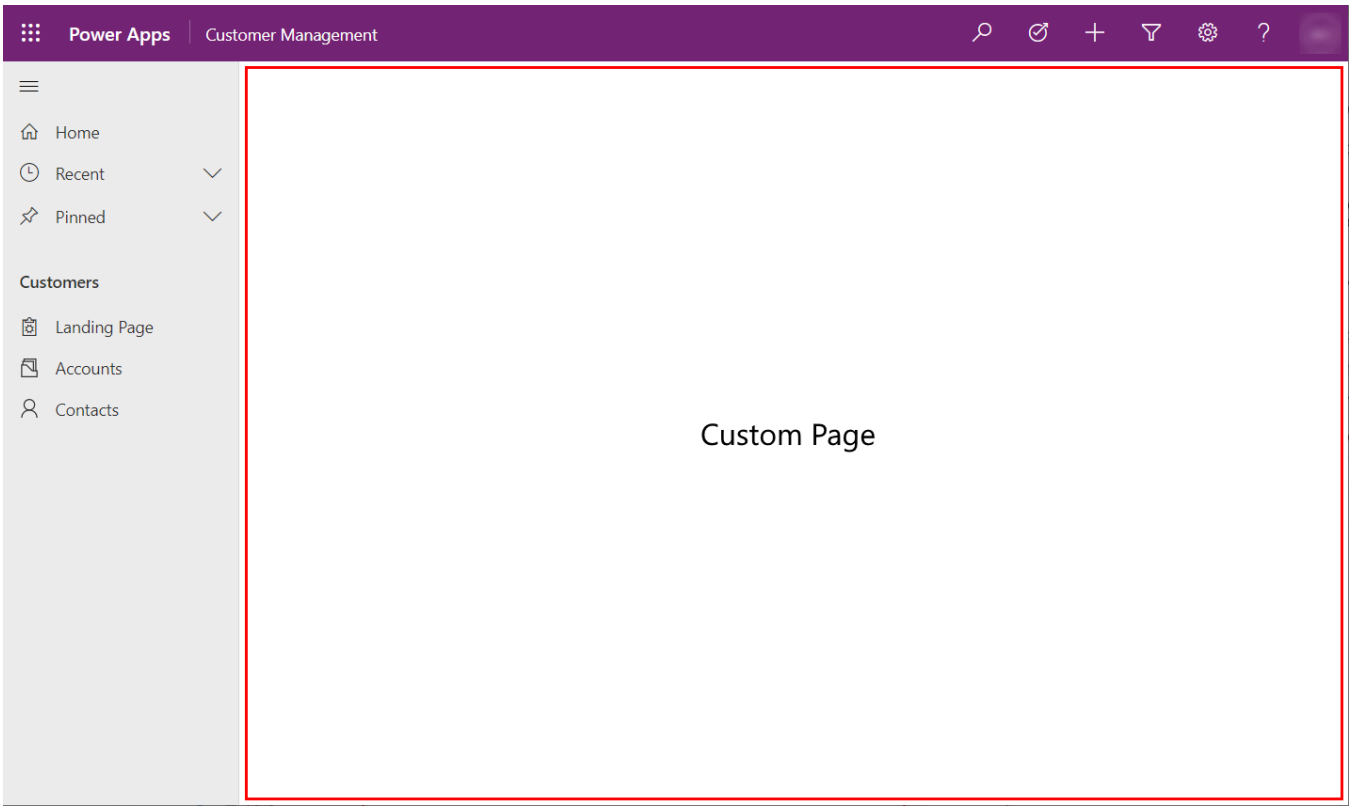
Custom page in mobile online	Public preview	iOS must allow enabling “Allow cross site tracking” that can be prevented by device management

Examples of custom pages

These images show the custom page inline within the model-driven app. The model-driven app has the full-page space in the images without the header and navigation.

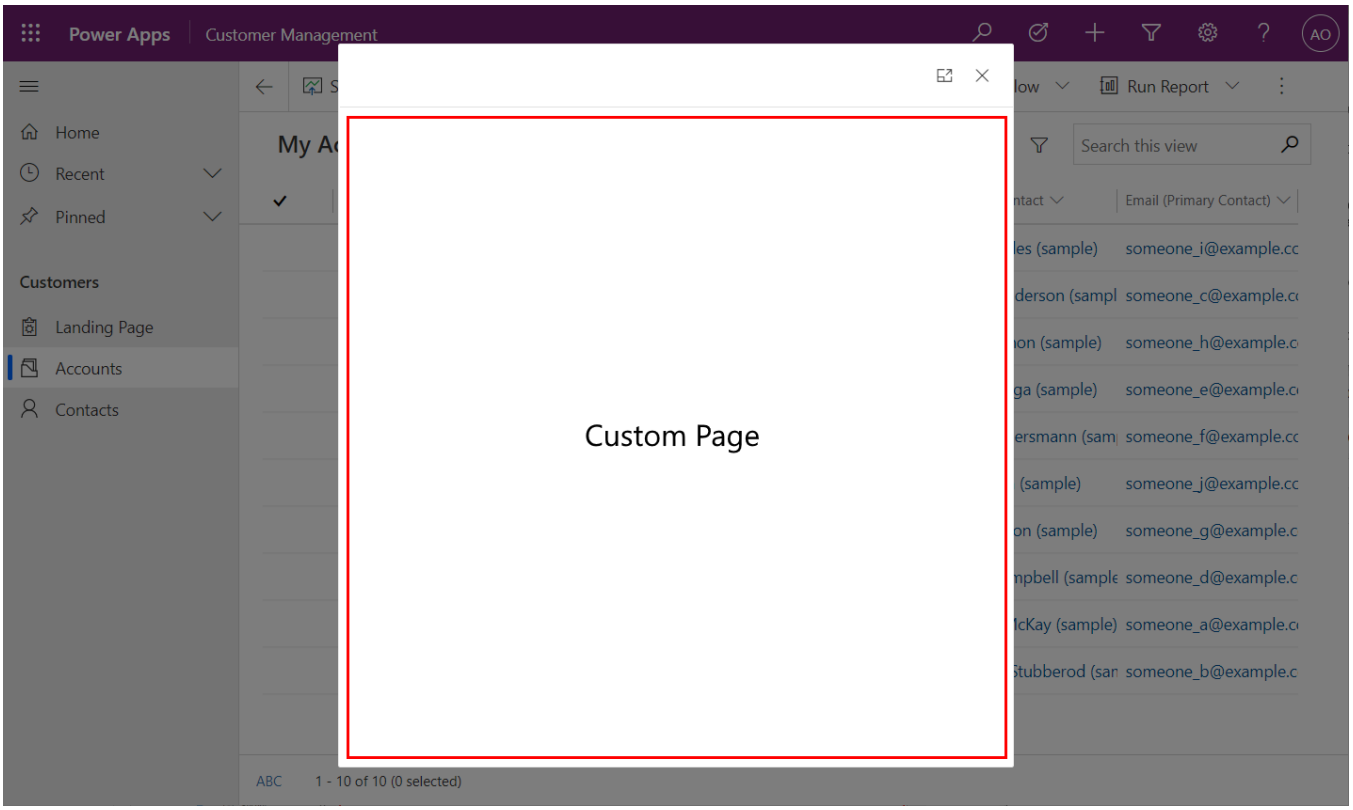
Custom page as main page.

[!div class="mx-imgBorder"]



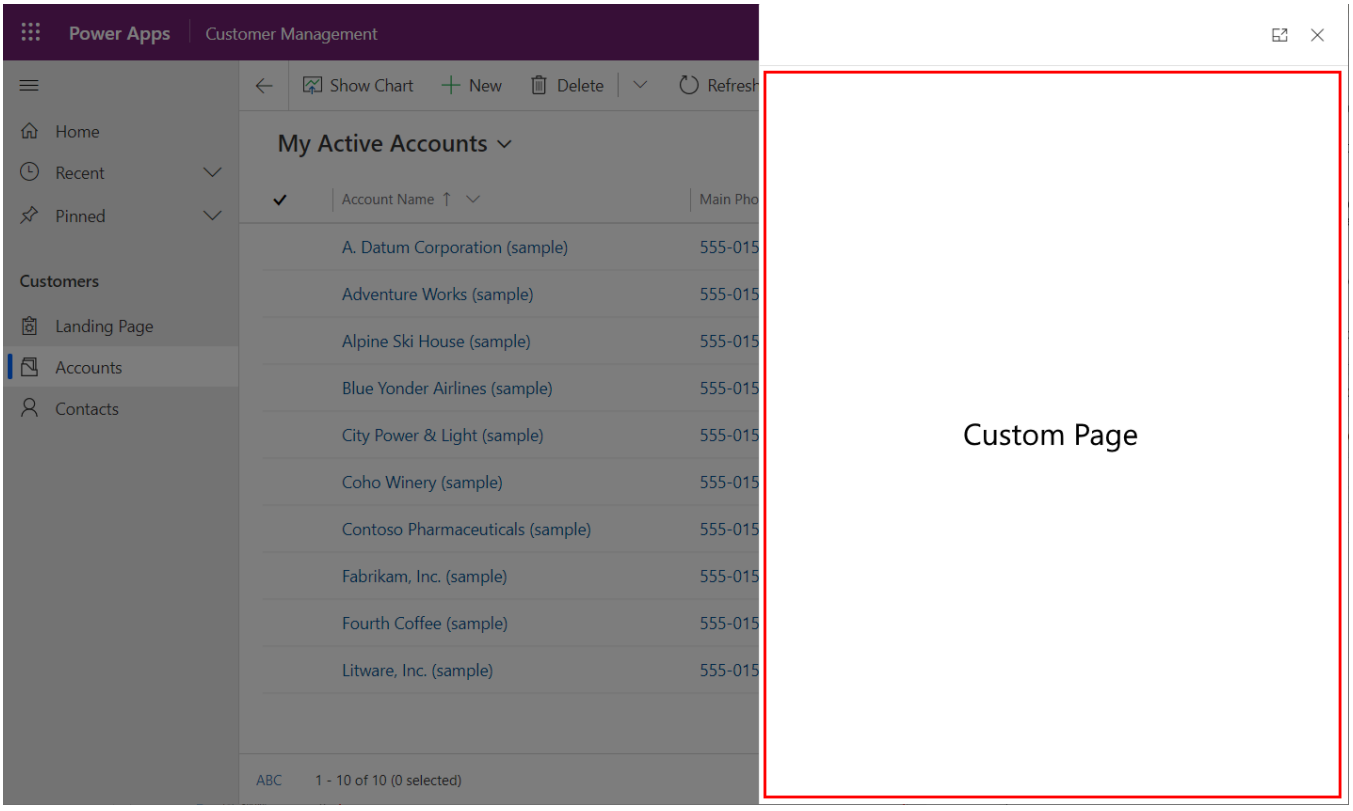
Custom page as a center dialog.

[!div class="mx-imgBorder"]



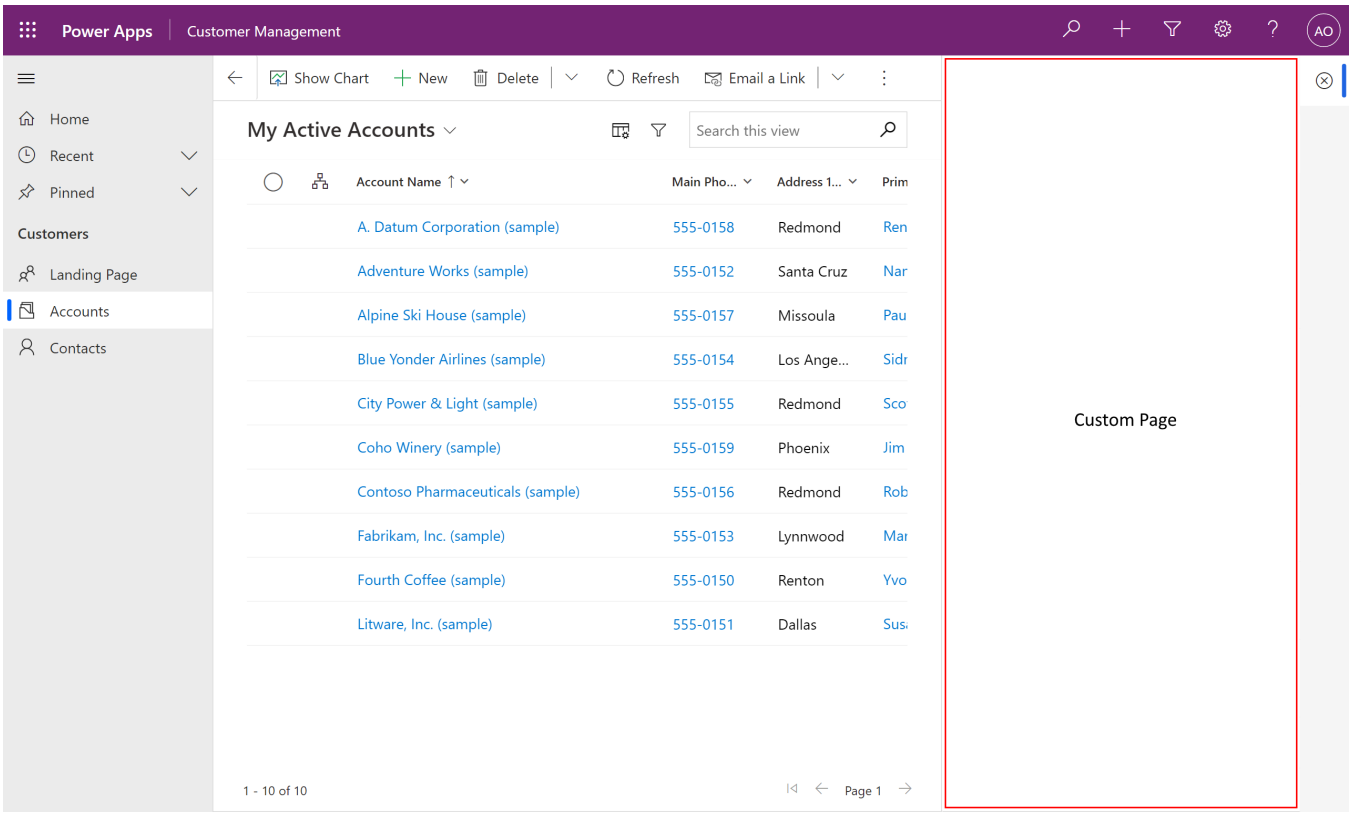
Custom page as a side dialog.

[!div class="mx-imgBorder"]



Custom page as an app side pane allows opening a custom page within the new app side pane on the right side of the app.

[!div class="mx-imgBorder"]



Custom pages must be created from a solution either from the modern app designer or the **Solution** area in Power Apps using **New** > **Page**. More information: Add a custom page to your model-driven app

Custom pages are different than embedded canvas apps

By using a custom page, you can create a new page experience by using the canvas app capabilities. This approach provides a low-code authoring experience with more flexible layouts, more control with styling options, the ability to add connector data, use expressions, and more. You create custom pages in Power Apps Studio with increasing context of the model-driven app that the page runs in.

Embedded canvas apps also use the canvas capabilities with a hosting approach that isn't as integrated as a custom page. The simpler integration of an embedded canvas app means the current limitation on number of embedded canvas apps hasn't changed. The advanced integration of the custom page addresses those limits. The embedded canvas app can only be placed on a model-driven form acting like a low-code component. More information: Embed a canvas app on a model-driven form.

In most cases, use custom pages instead of embedded canvas apps for tighter integration and better performance.

> **Note**
>
> Don't exceed 25 custom pages in a model-driven app. If you add more custom pages, it can increase the wait time that an app user experiences when they play an app with custom pages, after the last app publish. The increased user wait time affects only the first app launch, by the first user, after the last publish of the model-driven app.

Migrate standalone canvas app content to custom pages

Existing standalone canvas apps aren't supported for use as a custom page and the expected app structure is different. A standalone canvas app often has many screens with global access to all controls and variables. The custom page is expected to typically be a single screen with loose coupling to provide performance and co-development capabilities.

To migrate an existing standalone canvas app, start by identifying a mapping of screens to separate custom pages. For each separate custom page, complete these steps:

1. Create a blank custom page from the model-driven app designer. More information: Add a custom page to your model-driven app
2. Add a canvas app data source for data used by the screen.
3. Copy the screen from the original canvas app in Power Apps Studio.
4. Paste the screen into the blank custom page in Power Apps Studio.
5. Change the navigate calls to use the custom page name instead of the screen name.
6. Add the custom page into the model-driven app designer site map.

Frequently asked questions

- What data can the custom page use?

  A custom page can use Microsoft Dataverse and all of the connectors for Power Apps. More information: List of all Power Apps connectors.

- What interactions can the custom page have with the model-driven app?

  Custom pages can be added to the site map for direct navigation using Add custom page to sitemap. Model-driven app pages can open a custom page using the `navigateTo` Client API. Custom pages can navigate to other custom pages or to a model-driven app page such as a form, view, or dashboard with the Power Fx navigate function. More information: Navigating to a custom page

- How is the custom page made responsive?

  The responsive container controls enable building a responsive app page without formulas. More information: Building responsive pages. More custom page design guidance can also be found in Design a custom page for your model-driven app.

- How is the custom page managed in a solution?

  Each custom page is a separate component in the solution, which allows one maker to edit one custom page at a time. Most custom pages will have a single screen. Instead of multiple screens, they use the custom page's navigation functions to move to another custom page or model-driven app page. When a custom page has multiple screens, it's still a single solution component so only one maker can be working on the contained set of screens.

- What licenses are allowed to use a custom page and does a custom page impact app counts?

  The custom page uses a special canvas app type, which allows it to be managed differently. The custom page is considered part of the model-driven app infrastructure and can only be used within a model-driven app. So, it follows the license for the model-driven app. Also, custom pages don't count toward the app limits because they're treated as a page instead of an app.

- Do custom pages need to be shared like standalone canvas apps?

  The custom page aligns with the model-driven app page sharing, which relies on the model-driven app sharing without sharing individual pages for app users. Makers might need to share the custom page to allow editing.

Model-driven app custom page known issues

Last updated on 03/31/2026

Add a custom page to your model-driven app

This article shows you how to create and edit a custom page for a model-driven app by using the modern app designer.

This article walks you through opening a model-driven app in the app designer, which you use to add a custom page to a model-driven app. If you need to create a new model-driven app, go to Create a model-driven app with the app designer.

For information about the limitations and known issues with custom pages, see Custom page known issues.

Create or edit a custom page

Custom pages can be created from two places. The first is while authoring a model-driven app in the modern app designer. The other is from the **Solutions** area in Power Apps. Custom pages can be edited from the **Solutions** area but won't appear in the **Home** or **Apps** areas of make.powerapps.com.

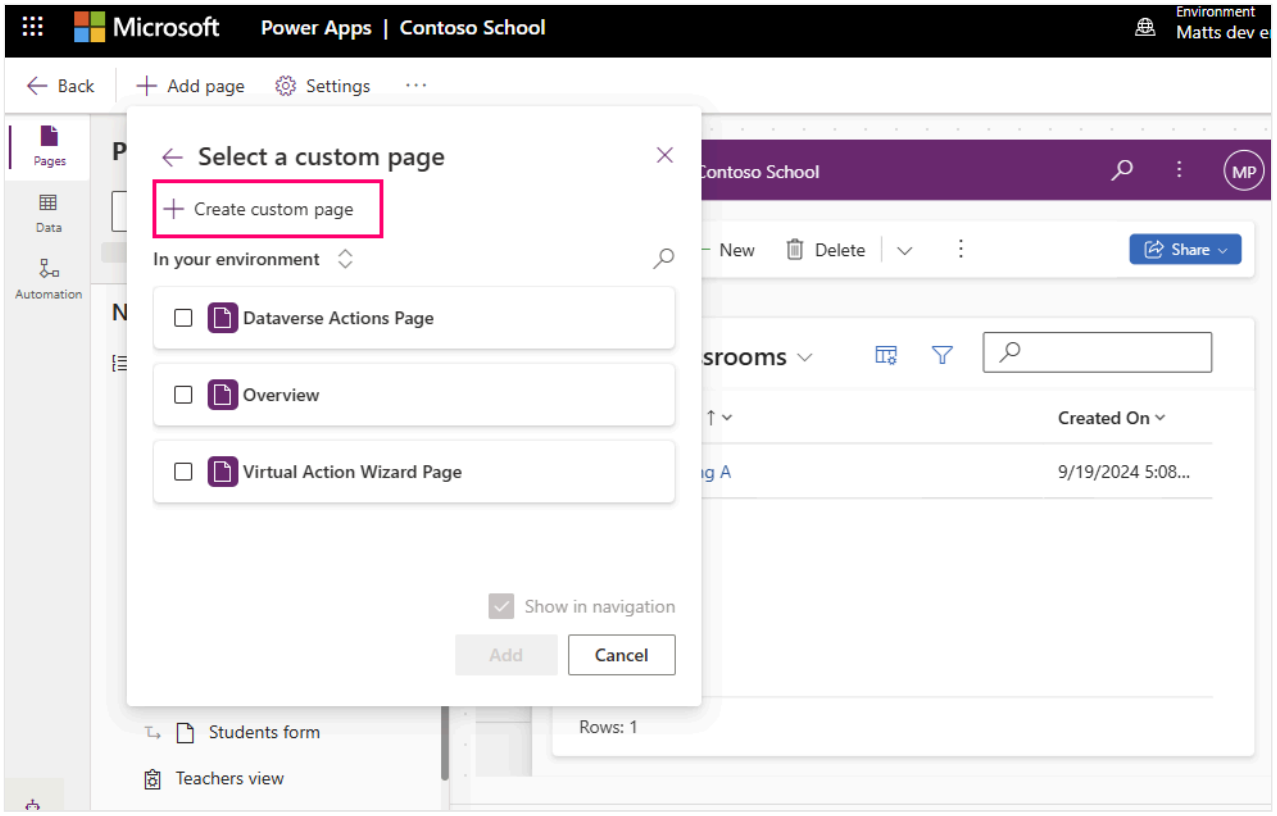
> **Note**
>
> Custom pages must be created from a solution either from the modern app designer or the **Solutions** area in Power Apps using **New** > **App** > **Page**. The custom page is a different canvas app type than the normal standalone canvas app.

Create new custom page from modern app designer

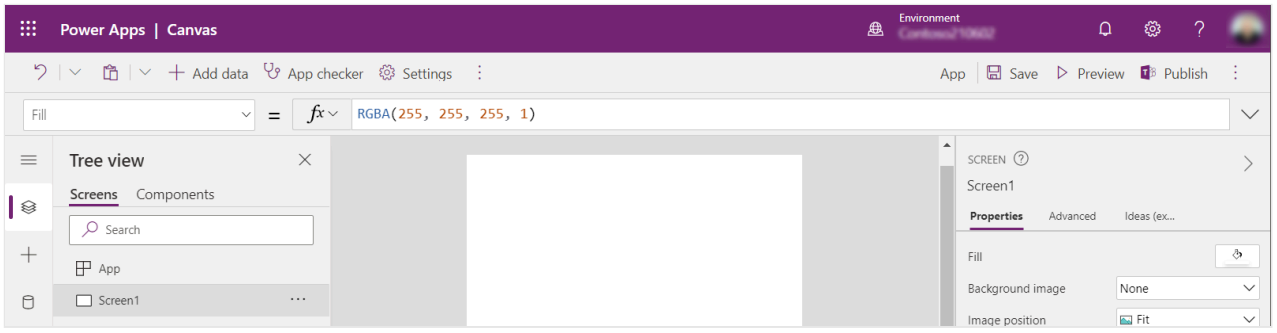
1. Open make.powerapps.com.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution containing the existing model-driven app.
4. Select the model-driven app where you want to add a custom page, and then select **Edit** on the command bar.

5. In the app designer, select **Add page** > **Custom page** on the command bar.

6. Select **Create custom page**.



7. Power Apps Studio opens for page authoring.



8. When you're finished creating your canvas app custom page, **Save**, **Publish**, and then close the Power Apps Studio browser tab to return to the model-driven app designer.

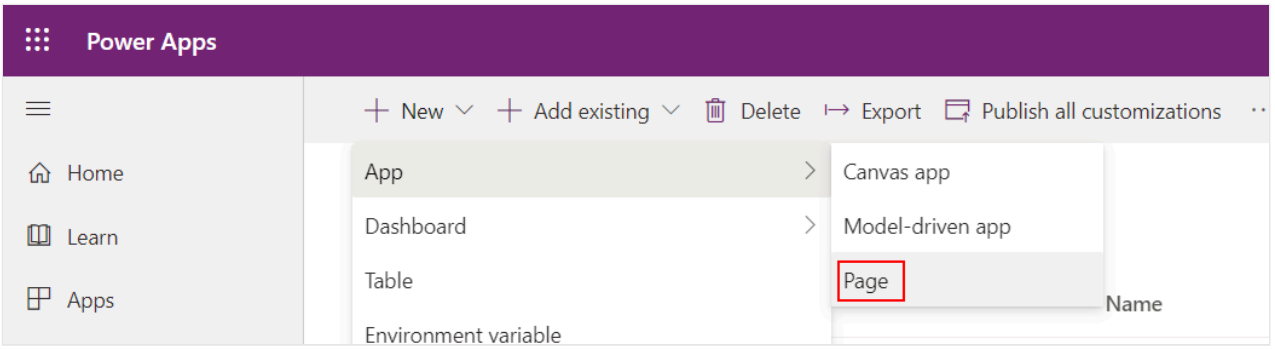
Create new custom page from the solutions area

1. Sign in to Power Apps.

2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Open or create a solution to contain the new custom page.

4. Select **New** > **App** > **Page**.



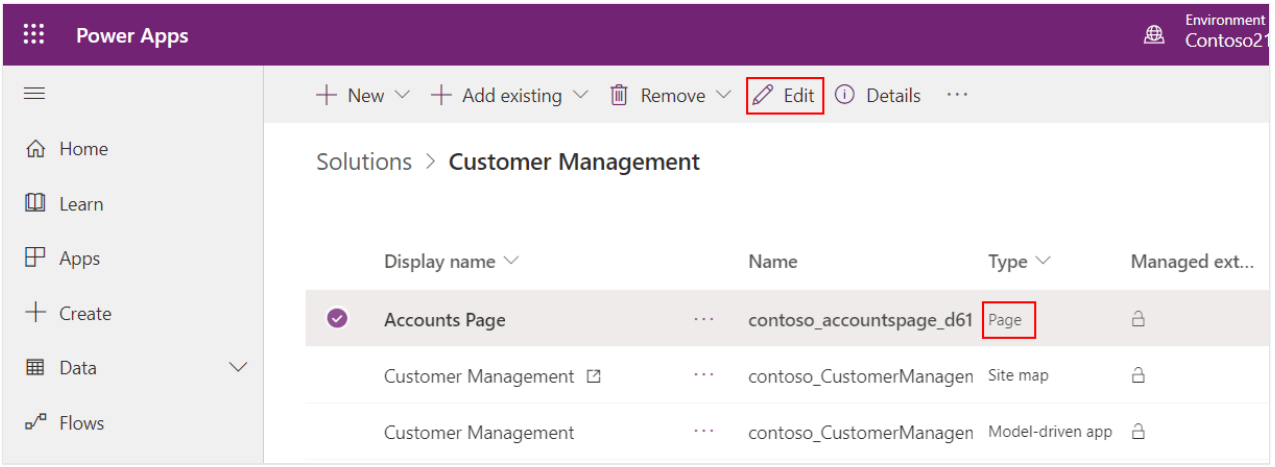
Edit an existing custom page

1. Open make.powerapps.com.

2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Open or create a solution to contain the new custom page.

4. Select the custom page with **Page** type, and then select **Edit**.



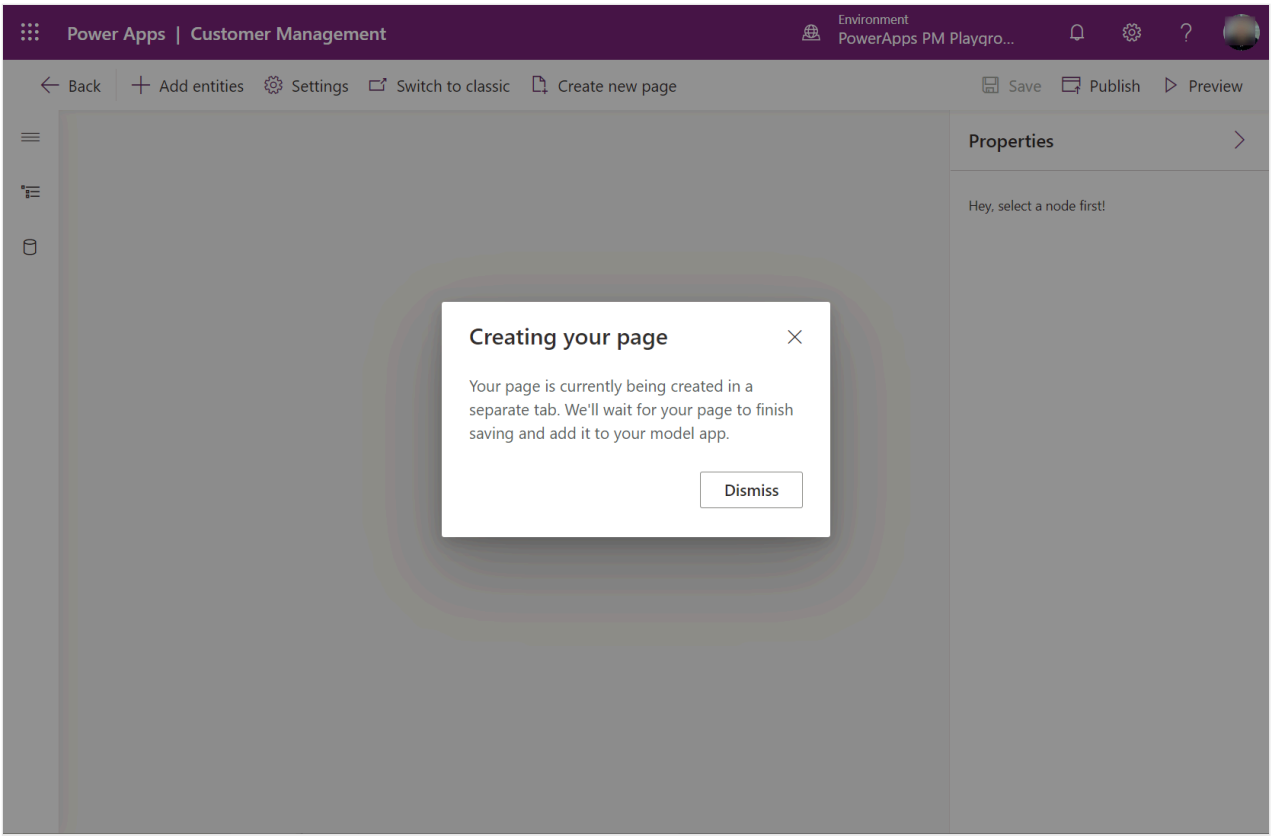
Author custom page content

1. Design the custom page content. More information: Design a custom page for your model-driven app

2. Save and publish the custom page.

3. Close Power Apps Studio.

4. Return to the app designer browser tab and refresh the app designer by selecting **Dismiss**.



5. Select **Publish** in the app designer to add the changed custom page into the model-driven app.

6. Select **Preview** to play the app in a new browser tab.

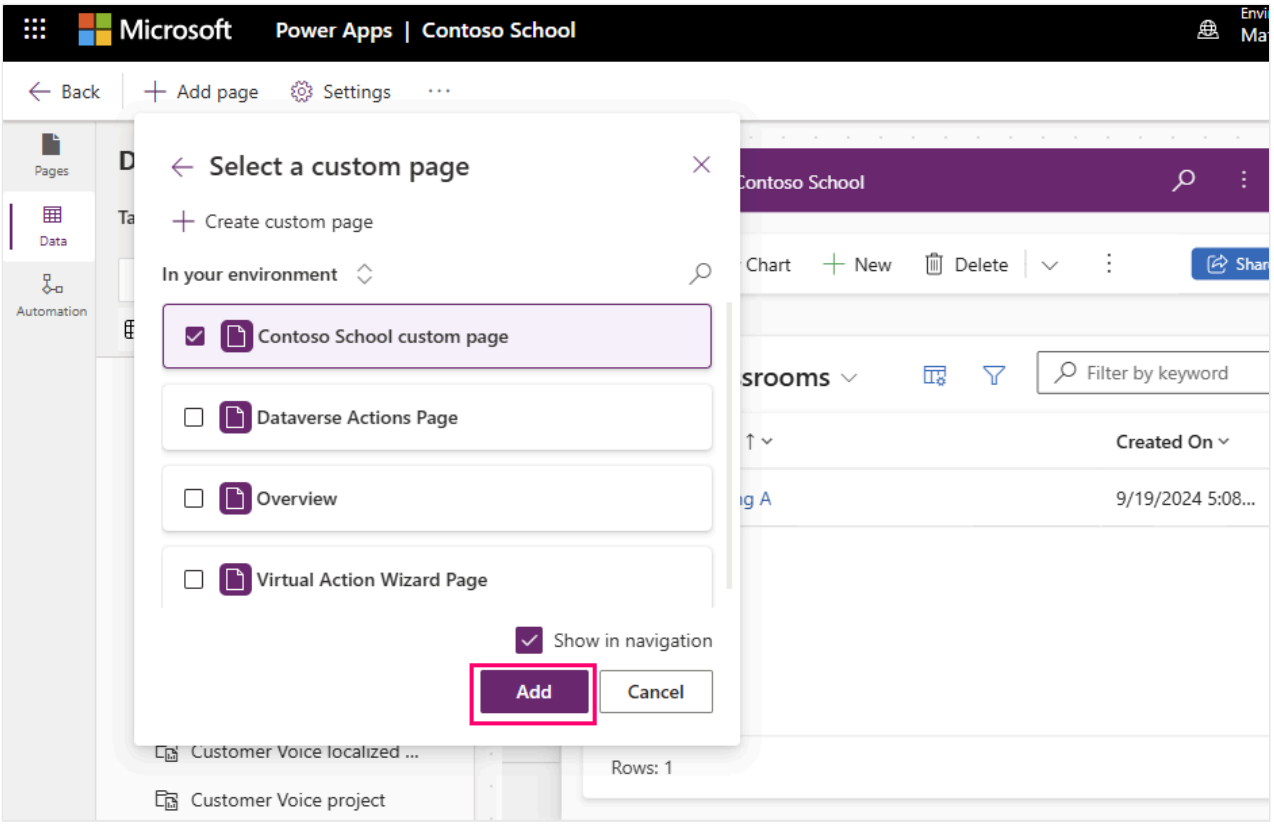
Add an existing custom page into a site map

1. Sign in to make.powerapps.com.

2. Open an existing model-driven app using modern app designer.

3. Select **Add page** > **Custom page** on the command bar.

4. Select the custom page in the list of custom pages available in the environment, and then select **Add**.



5. Select **Publish**, which also saves the app if there are changes.

6. Select **Play** to run the app in a new browser tab.

7. To close the app designer select **Back** and return to the solution.

Publishing a custom page

> **Important**
>
> Currently, model-driven apps must be re-published after a custom page is published. Otherwise the model-driven app continues to use the previous published custom page.

After saving changes to a custom page in Power Apps Studio, the custom page must be first published by Power Apps Studio. Then all model-driven apps referencing that custom page need to be published.

1. From Power Apps Studio, select **Publish**.

2. From app designer or solutions area, select **Publish** on each model-driven app referencing the custom page.

Design a custom page for your model-driven app

Article • 01/29/2025

This article provides tips for designing a custom page for use in a model-driven app. A custom page lets you create a page that's similar to a canvas app in your model-driven app.

> **Important**
>
> Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in Custom page known issues.

Supported controls in a custom page

Custom page authoring currently supports a subset of canvas app controls. The table here lists the currently supported controls.

Expand table

Control	Control Type	Notes
Label[1]	Display	
Text Box[1]	Input	
Date Picker[1]	Input	
Button[1]	Input	
Combo Box[1]	Input	
Check Box[1]	Input	
Toggle[1]	Input	
Radio Group[1]	Input	
Slider[1]	Input	
Rating[1]	Input	
Vertical Container	Layout	New responsive horizontal layout container

Control	Control Type	Notes
Horizontal Container	Layout	New responsive horizontal layout container
Rich Text Editor	Input	
Gallery	List	
Icon	Media	
Image	Media	
Edit Form	Input	
Display Form	Input	
Code components	Custom	Add code components to a custom page
Canvas components (preview)	Custom	Add canvas components to a custom page

[1] Control is a new modern control. The control was introduced for canvas apps in Teams. The control is based on Fluent UI library wrapped with Power Apps Component Framework.

Custom components support for custom page

You can add both low-code (canvas components) and pro-code (code components) custom UX components to your environment and make them available for all makers. For custom page specific UX extensibility articles, go to add canvas components to a custom page for your model-driven app and add code components to a custom page for your model-driven app.

In general, the low-code extensibility approach is simpler to build, test, and has a lower maintenance cost. We recommend evaluating canvas components first and then use code components only if there's a need for more complex and advanced customization.

More information:

- Canvas component gallery
- Code components samples
- Code components community resources

Enable responsive layout with container control

Responsive custom page layouts are defined by building a hierarchy of **Horizontal layout container** and **Vertical layout container** controls. These controls are found in the canvas app designer under **Layout** on the **Insert** tab.

Set the minimum screen height and width on the **App** object to prevent page level scroll bars and use a vertical body scroll bar.

PowerApps Formula

```
MinScreenHeight=200
MinScreenWidth=200
```

Optionally, the custom page design size can be adjusted in **Settings** > **Display** with **Size** set to **Custom**. Then set the **Width** and **Height** to a more typical desktop custom page size like width 1080 and height 768. Changing this setting after controls are added to the screen might cause some layout properties to reset.

Set the topmost container to fill the entire space and resize based on available space.

PowerApps Formula

```
X=0
Y=0
Width=Parent.Width
Height=Parent.Height
```

Horizontal wrapping of a flexible height container

To support pages adjusting from desktop down to a narrow width, enable these properties on a horizontal container with flexible height. Without these settings, the page clips the control when the page is narrow.

PowerApps Formula

```
Direction=Horizontal
FlexibleHeight=true
Justify=Stretch
Align=Stretch
VerticalOverflow=Scroll
Wrap=True
```

Child containers or controls directly under this container should be set to have a minimum width that allows the page to fit within a 300 pixel width. Consider the padding on the container or control as well as parent containers.

Vertical wrapping of a flexible width container

To support pages adjusting from desktop down to a narrow width, enable these properties on a vertical container with flexible width. Without these settings, the page clips the control when the page is narrow.

PowerApps Formula

```
Direction=Vertical
FlexibleWidth=true
Justify=Stretch
Align=Stretch
HorizontalOverflow=Scroll
Wrap=True
```

Child containers or controls directly under this container should be set to have a minimum height that allows the page to fit within a 300 pixel width. Consider the padding on the container or control as well as parent containers.

More information: Building responsive layout.

Vertical container with fixed header, flexible body, fixed footer

1. On the **Vertical Container**, set **Align (horizontal)** to **Stretch**
2. Insert three **Horizontal Container** controls within the parent **Vertical Container**.
3. On the first and third child horizontal container controls, set **Stretch height** off and reduce height to the amount of space needed, such as *Height=80*.

Horizontal container with two even child containers

1. On the parent horizontal container, set **Align (vertical)** to **Stretch**.
2. Insert two **Vertical Container** controls within the parent **Horizontal Container**.

Styling custom page controls to align to model-driven app controls

By creating the custom page from the modern app designer, these features use the default values.

- Theme for the custom page. Theme values for the controls used in a custom page are automatically set to match the default blue theme of the Unified Interface. This default theme is used both in the studio and at application runtime. Explicit theme selecting is removed from custom page authoring experience.
- Controls need to use a different font size, which is based on their position in the page hierarchy.

  > **Note**
  >
  > Custom page text has an upscaling of 1.33 so you need to divide the target **FontSize** by 1.33 to get the desired size.

  Expand table

Label Type	Target FontSize	FontSize to use
Page title	17	12.75
Normal labels	14	10.52
Small labels	12	9.02

- Primary and secondary button controls need the following styling changes:

  Primary buttons

  PowerApps Formula

  ```
  Color=RGBA(255, 255, 255, 1)
  Fill=RGBA(41,114,182,1)
  Height=35
  FontWeight=Normal
  ```

  Secondary buttons

  PowerApps Formula

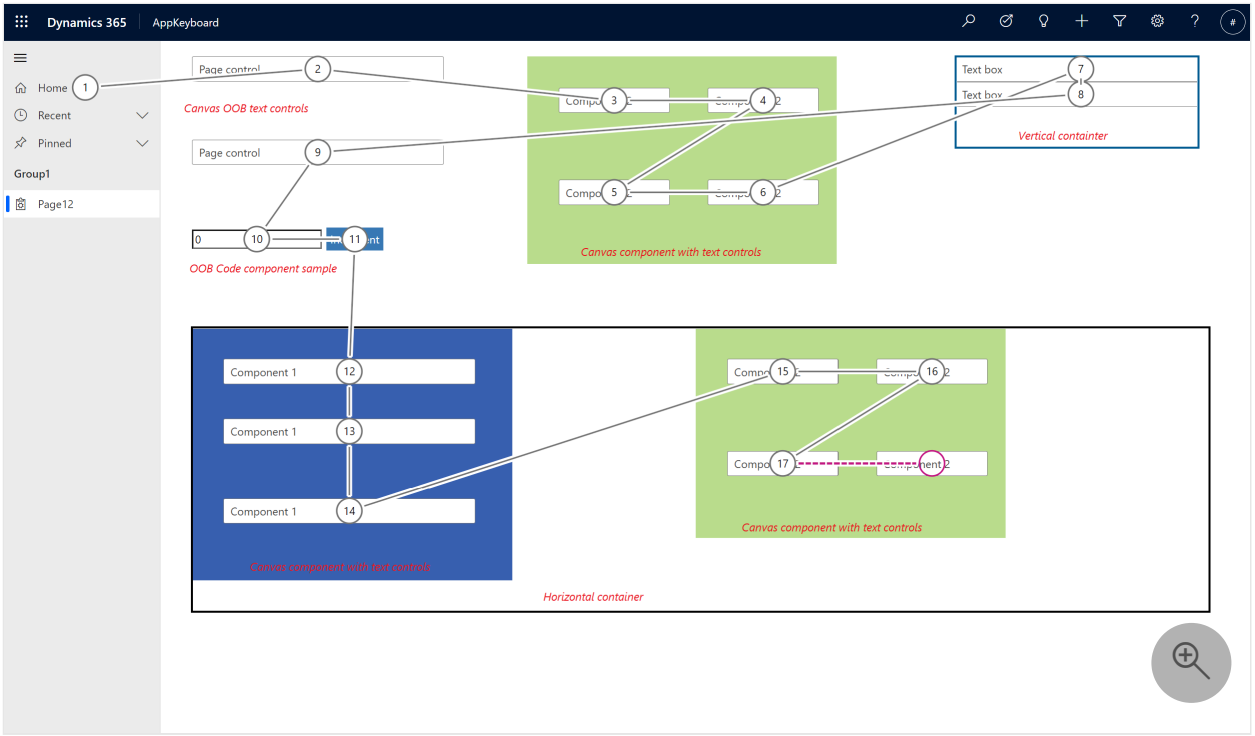
  ```
  Color=RGBA(41,114,182,1)
  Fill=RGBA(255, 255, 255, 1)
  BorderColor=RGBA(41,114,182,1)
  Height=35
  FontWeight=Normal
  ```

Tab navigation and keyboard accessibility for custom pages

Custom pages follow the same tab navigation design that's used by the hosting model-driven app. Visually aligned semantic HTML structure helps users navigate the custom pages seamlessly when using a keyboard or a screen reader. Unlike stand-alone canvas apps, custom page controls, and other UX elements don't need explicit tab numbers assignments. Modern controls don't have a `TabIndex` property and utilize the semantic HTML structure for navigation.

Various elements like controls, canvas and code components, containers, and so on, can be tabbed based on their position in the custom page layout. The tab navigation follows Z order navigation. Individual tab-stops inside larger grouping elements like components, containers are navigated first before the tab moves out to the next element in the document object model (DOM) tree.

Here's an example navigation with the page containing controls, code, and canvas components and containers.



> **Note**
>
> Overlapping controls and elements on the custom page don't have their DOM merged so tab stops can be out of sync from the visual layout. The same is true for the dynamic element positioning using formulas.

Navigate to a custom page using client API

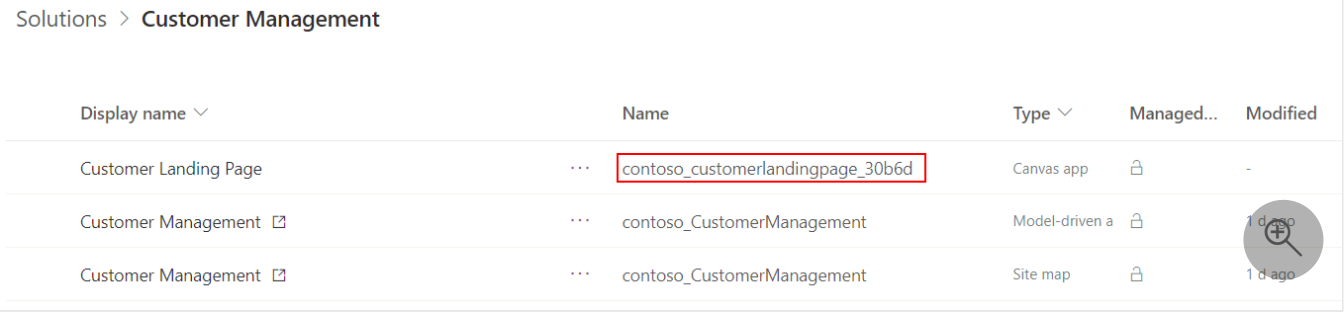
This article provides examples of navigating from a model-driven app page to a custom page using Client API. Learn how to open custom pages as full-page, dialog, or pane views in model-driven apps.

This article outlines the steps to use client API to open a custom page as a full-page, dialog, or pane. It provides examples of **custom** as a `pageType` value in navigateTo (Client API reference).

> **Important**
>
> Custom pages are a new feature with significant product changes. They currently have a number of known limitations outlined in Custom Page Known Issues.

Find the logical name

Each of the following client API examples takes the logical name of the custom page as the required parameter. The logical name is the **Name** value of the page in the solution explorer.



Open as an inline full page without context

Within a model-driven app client API event handler, call the following code and update the **name** parameter to be the logical name of the page.

JavaScript

```
// Inline Page
var pageInput = {
    pageType: "custom",
    name: "<logical name of the custom page>",
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
```

```
    .then(
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open as an inline full page with a record context

This example uses the `recordId` parameter within the NavigateTo function to provide the custom page with the record to use.

JavaScript

```
// Inline Page
var pageInput = {
    pageType: "custom",
    name: "<logical name of the custom page>",
    entityName: "<logical name of the table>",
    recordId: "<record id>",
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

The `Param` function within the custom page retrieves the value and uses the Lookup function to retrieve the record.

PowerApps Formula

```
App.OnStart=Set(RecordItem,
    If(IsBlank(Param("recordId")),
        First(<entity>),
        LookUp(<entity>, <entityIdField> = GUID(Param("recordId"))))
    )
```

> **ⓘ Important**
>
> The `recordId` parameter must be a GUID because it updates the URL and an app start from the URL validates the `recordId` is a GUID.

Open as a centered dialog

Within a model-driven app client API event handler, call the following code and update the **name** parameter to be the logical name of the custom page. This mode supports the sizing parameters similar to the Main form dialogs.

JavaScript

```
// Centered Dialog
var pageInput = {
    pageType: "custom",
    name: "<logical custom page name>",
};
var navigationOptions = {
    target: 2,
    position: 1,
    width: {value: 50, unit:"%"},
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open as a side dialog

Within a model-driven app client API event handler, call the following code and update the **name** parameter to be the logical name of the custom page.

JavaScript

```
// Side Dialog
var pageInput = {
    pageType: "custom",
```

```
    name: "<logical page name>",
};
var navigationOptions = {
    target: 2,
    position: 2,
    width: {value: 500, unit: "px"},
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open from a grid primary field link as a full page with record ID

This example uses the `recordId` parameter within the navigateTo function to provide the custom page with the record to use. The `Param` function within the custom page retrieves the value and uses the `Lookup` function to retrieve the record.

You can find a more complete example at Override the default open behavior of data rows in an entity-bound grid.

1. Create a web resource of type **JScript** and update the **name** parameter to be the logical page name. Add the following code to the web resource.

   JavaScript

   ```
   function run(selectedItems)
   {
       let selectedItem = selectedItems[0];

       if (selectedItem) {
           let pageInput = {
               pageType: "custom",
               name: "<logical page name>",
               entityName: selectedItem.TypeName,
               recordId: selectedItem.Id,
           };
           let navigationOptions = {
               target: 1
           };
           Xrm.Navigation.navigateTo(pageInput, navigationOptions)
   ```

```
            .then(
                function () {
                    // Handle success
                }
            ).catch(
                function (error) {
                    // Handle error
                }
            );
    }
}
```

2. Customize the table ribbon **CommandDefinition** for **OpenRecordItem** to call the function earlier and include the **CrmParameter** with the value **SelectedControlSelectedItemReferences**.

XML

```
    <CommandDefinition Id="Mscrm.OpenRecordItem">
        <Actions>
            <JavaScriptFunction FunctionName="run"
Library="$webresource:cr62c_OpenCustomPage">
                <CrmParameter Value="SelectedControlSelectedItemReferences" />
            </JavaScriptFunction>
        </Actions>
    </CommandDefinition>
```

3. In the custom page, override the **App**'s **OnStart** property to use the `Param` function to get the `recordId` and `lookup` record.

PowerApps Formula

```
App.OnStart=Set(RecordItem,
    If(IsBlank(Param("recordId")),
        First(<entity>),
        LookUp(<entity>, <entityIdField> = GUID(Param("recordId"))))
    )
```

> **Note**
>
> After changing the `OnStart` property, you need to run `OnStart` from the App context menu. This function performs only once within a session.

4. Then, the custom page can use the **RecordItem** parameter as a record. The following example shows how to use it in an EditForm.

PowerApps Formula

```
EditForm.Datasource=<datasource name>
EditForm.Item=RecordItem
```

Open from a selected record in editable grid as a centered dialog with record ID

Use an editable grid to trigger the OnRecordSelect event when you want to perform an action after selecting a particular record in a view. This example uses the `recordId` parameter within the navigateTo function to provide the custom page with the record to use. The `getId` method in the GridEntity object retrieves the record ID. The `Param` function within the custom page retrieves the value and uses the `lookup` function to retrieve the record.

1. Enable editable grid control in the table.
2. Create a web resource of type **JScript** and update the **name** parameter to be the logical page name. Add the following code to the web resource.

JavaScript

```
function RunOnSelected(executionContext) {
// Retrieves the record selected in the editable grid
var selectedRecord = executionContext.getFormContext().data.entity;
var Id = selectedRecord.getId().replace(/[{}]/g, "");

// Centered Dialog
var pageInput = {
    pageType: "custom",
    name: "<logical page name>",
    recordId: Id,
};
var navigationOptions = {
    target: 2,
    position: 1,
    width: { value: 50, unit: "%" },
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
```

```
    );
}
```

3. In the custom page, override the **App**'s **OnStart** property to use the `Param` function to get the `recordId` and `lookup` record.

PowerApps Formula

```
App.OnStart=Set(RecordItem,
    If(IsBlank(Param("recordId")),
        First(<entity>),
        LookUp(<entity>, <entityIdField> = GUID(Param("recordId"))))
    )
```

> **Note**
>
> After changing the `OnStart` property, you need to run `OnStart` from the App context menu. This function performs only once within a session.

4. Then, the custom page can use the **RecordItem** parameter as a record. The following example shows how to use it in an EditForm.

PowerApps Formula

```
EditForm.Datasource=<datasource name>
EditForm.Item=RecordItem
```

Use Power Fx in a custom page for your model-driven app

Article • 01/23/2025

This article outlines how the common Microsoft Power Fx functions work differently between a standalone canvas apps and a custom page. Functions work differently because a custom page is a component within the model-driven app. Other Microsoft Power Fx formulas continue to behave in the same way.

> **Important**
>
> Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in Custom Page Known Issues.

Add notifications to a custom page

A notification can be shown to the user in a custom page by calling the Notify function. When the notification messages appear, they're docked above the default page to stay visible until disabled. If a time-out interval is provided, the notification message disappears after the time out interval. We recommend that you don't use a time-out interval of 10, as this is no longer considered as a time-out interval. More information: Notify function.

Power Fx

```
Notify( "Custom page notification message" )
```

Power Fx

```
Notify( "Custom page notify warning message", NotificationType.Warning )
```

Navigating to a custom page

This section provides examples of navigating from a model-driven app form to a custom page, navigating from a custom page to other custom pages or model-driven app form using Power Fx.

Navigating from a custom page

The Navigate function allows users to navigate either from model-driven app forms or custom pages. This function is only applicable when the custom page is running within a model-driven app. During custom page authoring or previewing in canvas designer, this function has no effect.

Navigate to another custom page

To navigate from one custom page to another, pass the display name of the custom page as the first parameter.

Power Fx

```
Navigate( CustomPage2  )
```

Navigate to the default view of the table

To navigate to the default view of the table, pass table name as the first parameter.

Power Fx

```
Navigate( Accounts )
```

> ⓘ **Important**
>
> Make sure you add the accounts Microsoft Dataverse table to the custom page before publishing and testing.

Navigate to specific system view of the table

To navigate to a specific system view of the table, pass the GUID of the view.

Power Fx

```
Navigate( 'Accounts (Views)'.'My Active Accounts' )
```

Navigate to the default form of the table

To navigate to the default form of the table, pass the record as the first parameter.

Power Fx

```
Navigate( Gallery1.Selected )
```

Navigate to a specific form of a table

To pass a Dataverse record to a specific form, pass the form name in the second parameter's `Page` attribute.

Power Fx

```
Navigate(
  AccountGallery.Selected,
  { Page: 'Accounts (Forms)'.Account  } )
```

Navigate to a specific custom page with a record input

To pass a Dataverse record to a specific custom page, pass the custom page name in the second parameter's `Page` attribute.

Power Fx

```
Navigate(
  AccountGallery.Selected,
  { Page: 'Account Record Page'  } )
```

In the target custom page, the record is retrieved using `Param` function to get the `etn` and `id` values.

Here's an example of loading the record into an `EditForm` control.

Power Fx

```
AccountEditForm.DataSource = Accounts
AccountEditForm.Item =
```

```
  LookUp( Accounts, accountid = GUID( Param("id") ) )
```

Navigate to the default form of the table in create mode

To navigate to the default form of the table in create mode, pass a Dataverse record created from the Defaults function. Defaults opens the default form with the record as a new record. The `Defaults` function takes the table name to create the record.

Power Fx

```
Navigate( Defaults( Accounts ) )
```

Navigate to the default form of the table in create mode with field defaulted

To navigate to a new record with some fields defaulted, use the `Patch` function to set fields on the default record for the table.

Power Fx

```
Navigate(
    Patch(
        Defaults(Accounts), { 'Account Name': "My company", Phone: "555-
3423" } )
  )
```

Navigate back to the prior page or close a dialog

To navigate back to the last page or to close a dialog, the Back function is called in a custom page. The `Back` function closes the current page and returns to the last model-driven app or custom page in the model-driven app. If the custom page has multiple screens, go to the article Navigating back when custom page has multiple screens.

Power Fx

```
Back()
```

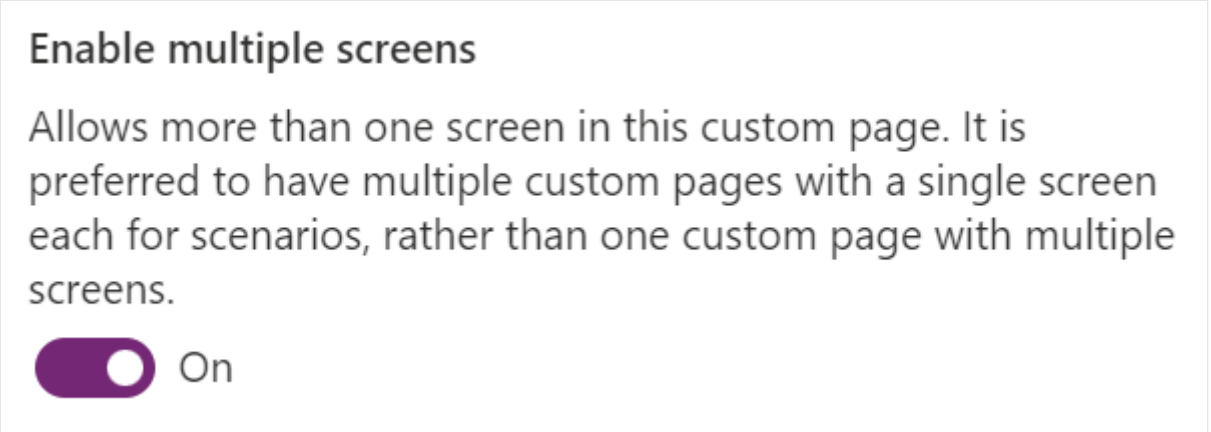
Navigating back when custom page has multiple screens

The default configuration for a custom page is to have one screen. In this case, the `Back` function call closes the custom page unless the custom page is the last in the page stack in model-driven app. The last page is kept open.

An app maker can enable multiple screens in a custom page. These should be considered like full page controls within the custom page that can be stacked. Opening a custom page has no means of specifying the screen to use. When a custom page contains multiple screens, the maker is responsible for managing the screen stacking. Calling the `Navigate` function to a screen adds to the screen stack with the custom page. Each `Back` function call removes a screen from the screen stack. When there's only one screen on the screen stack, the custom page is closed.

Enabling multiple screens

By default a custom page uses a single screen to encourage separation of the app into a screen per page. Single screen can be switched by enabling **Settings** > **Display** > **Enable multiple screens**.



Known issues

- The `Navigate` function doesn't have support for opening a model-driven app or custom page to a dialog. All navigation from a custom page opens inline.
- Navigate function doesn't support opening:
  - A dashboard collection or a specific dashboard.
  - A specific model-driven app form.
- A custom page can only open into the current session's current app tab in a multi-session model-driven app.

Add canvas components to a custom page for your model-driven app

Article • 06/01/2022

This article outlines the use of low-code canvas components to build custom UX for a custom page by utilizing shared canvas component library capability. For code first custom UX extensibility, see Add code components to a custom page for your model-driven app.

> **Important**
>
> Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in **Custom Page Known Issues**.

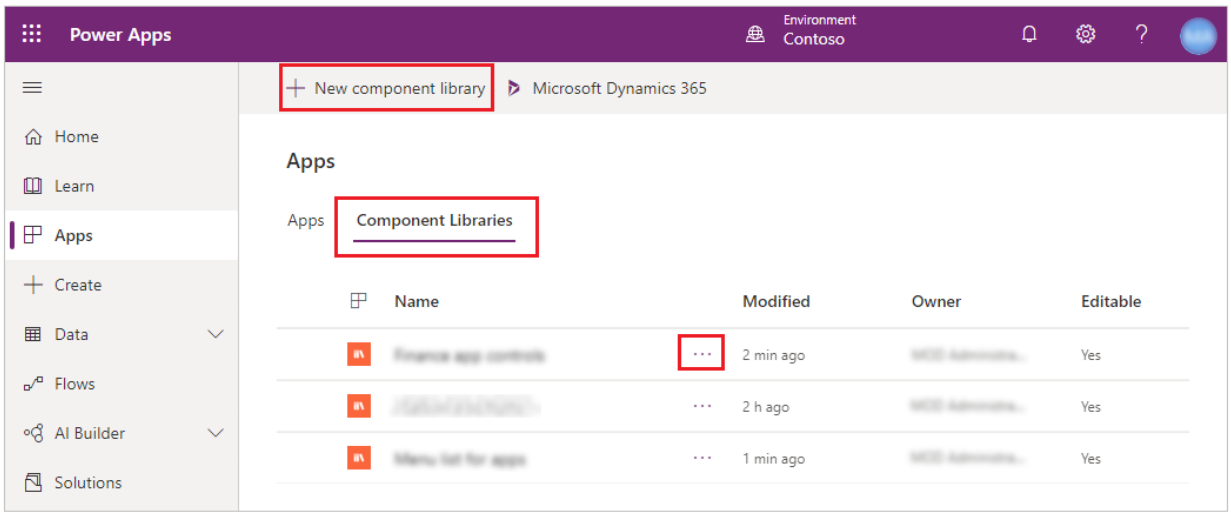
> **Note**
>
> - Custom page currently supports a **limited set of controls** and only the currently supported controls should be used to create canvas components for the custom page.
> - **Modern controls** are currently only supported with custom pages and not with standalone canvas apps. Make sure that the modern control experimental setting is used only for component libraries used with custom pages.

Canvas components provide app makers the ability to create custom components in a low-code fashion. These components cannot only then be reused across custom pages and applications, but also can be centrally updated, packaged, and moved using Microsoft Dataverse solutions. More information: Create a component for canvas apps

Since custom page authoring is limited to only one page, canvas components can only be authored inside a component library. This is different from the standalone canvas apps, which have the ability to create components at the app level.

Create a canvas component using the component library

You can create a new component library or edit an existing one either from the **Solutions** area or the **Component Libraries** tab in the **Apps** area.

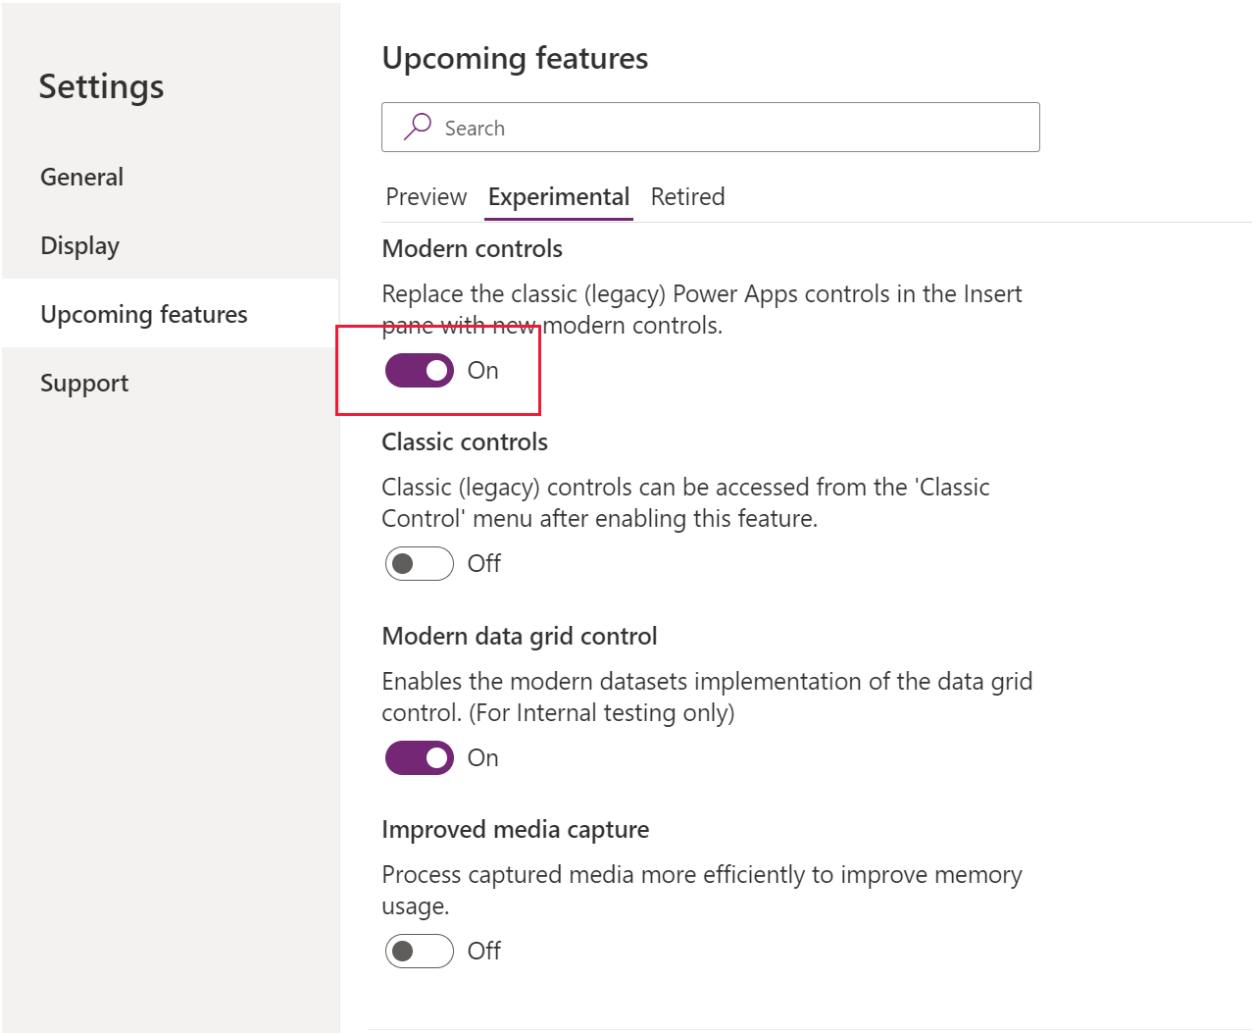


Create a canvas component for use in a custom page

This section explains how to create a canvas component that you can use in a custom page.

Enable modern controls for the component library

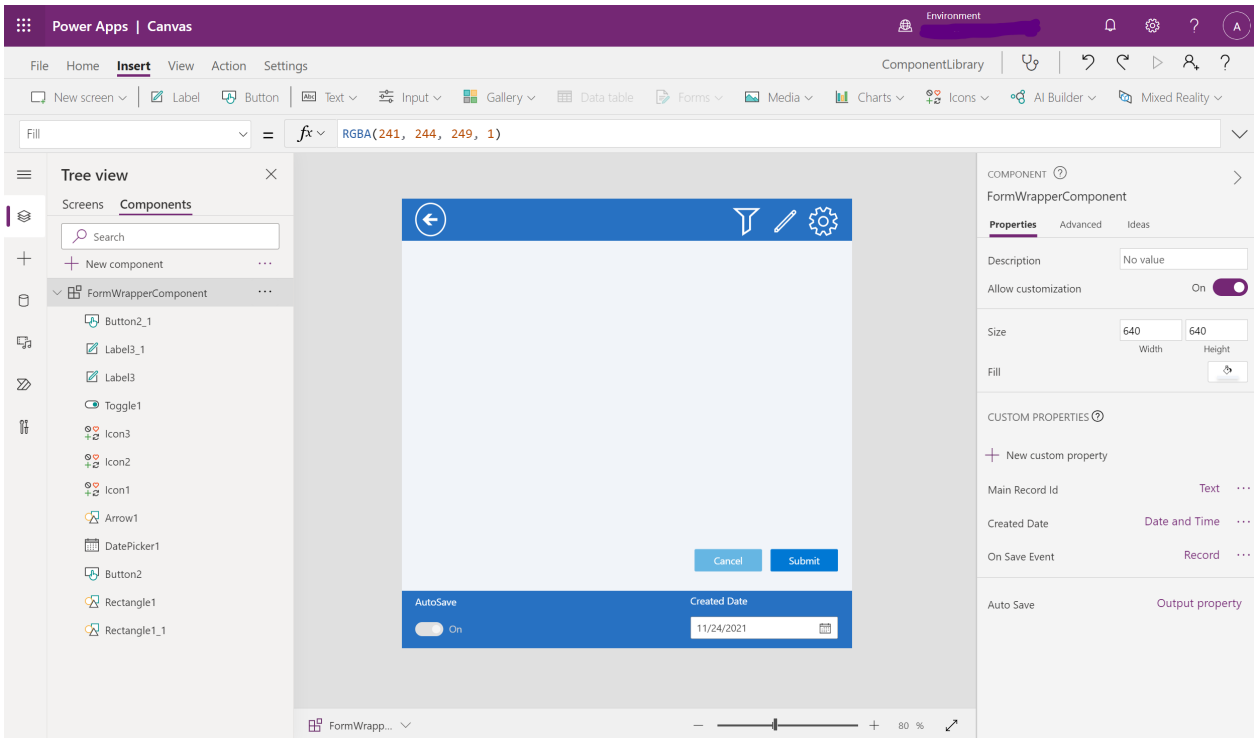
First, enable the **Modern controls** setting in the canvas app designer. To do this, go to **File** > **Settings** > **Upcoming features** > **Experimental**.



Make sure that only the supported set of controls are used to create components for custom page.

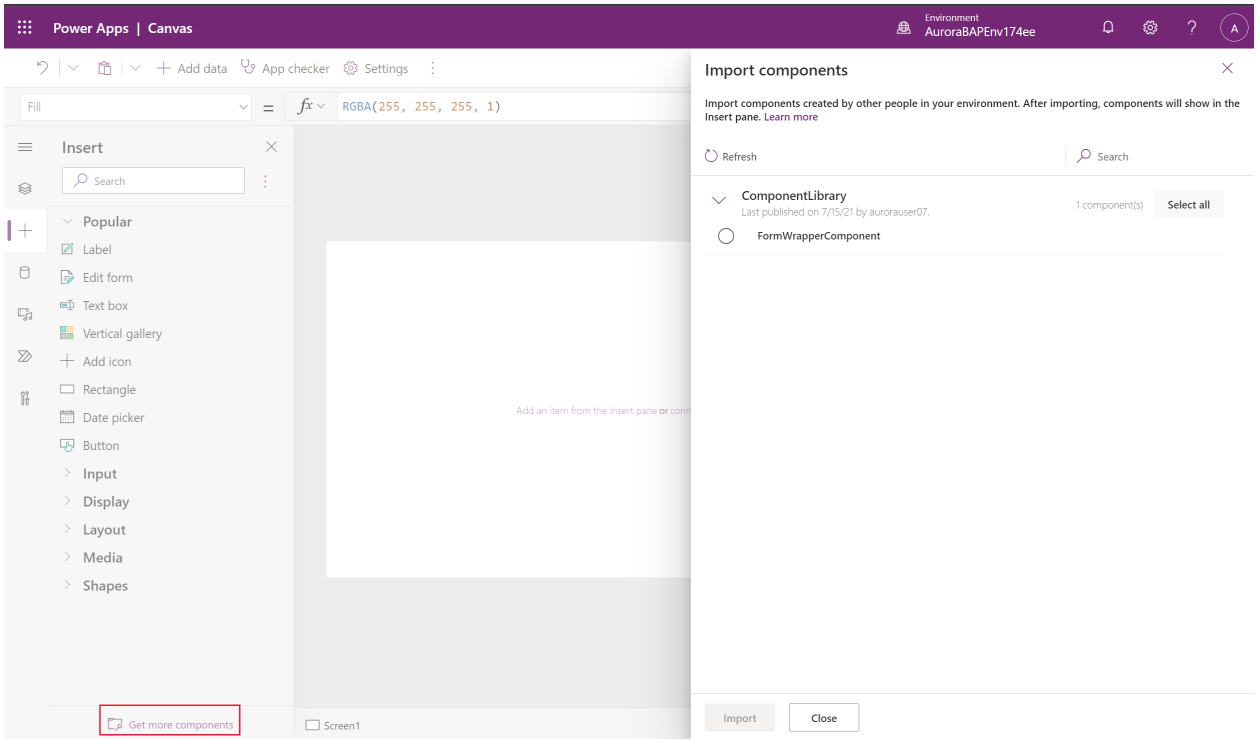
Create a canvas component

Once the modern controls are enabled, you can now create desired components inside the library and publish them once the components are ready.

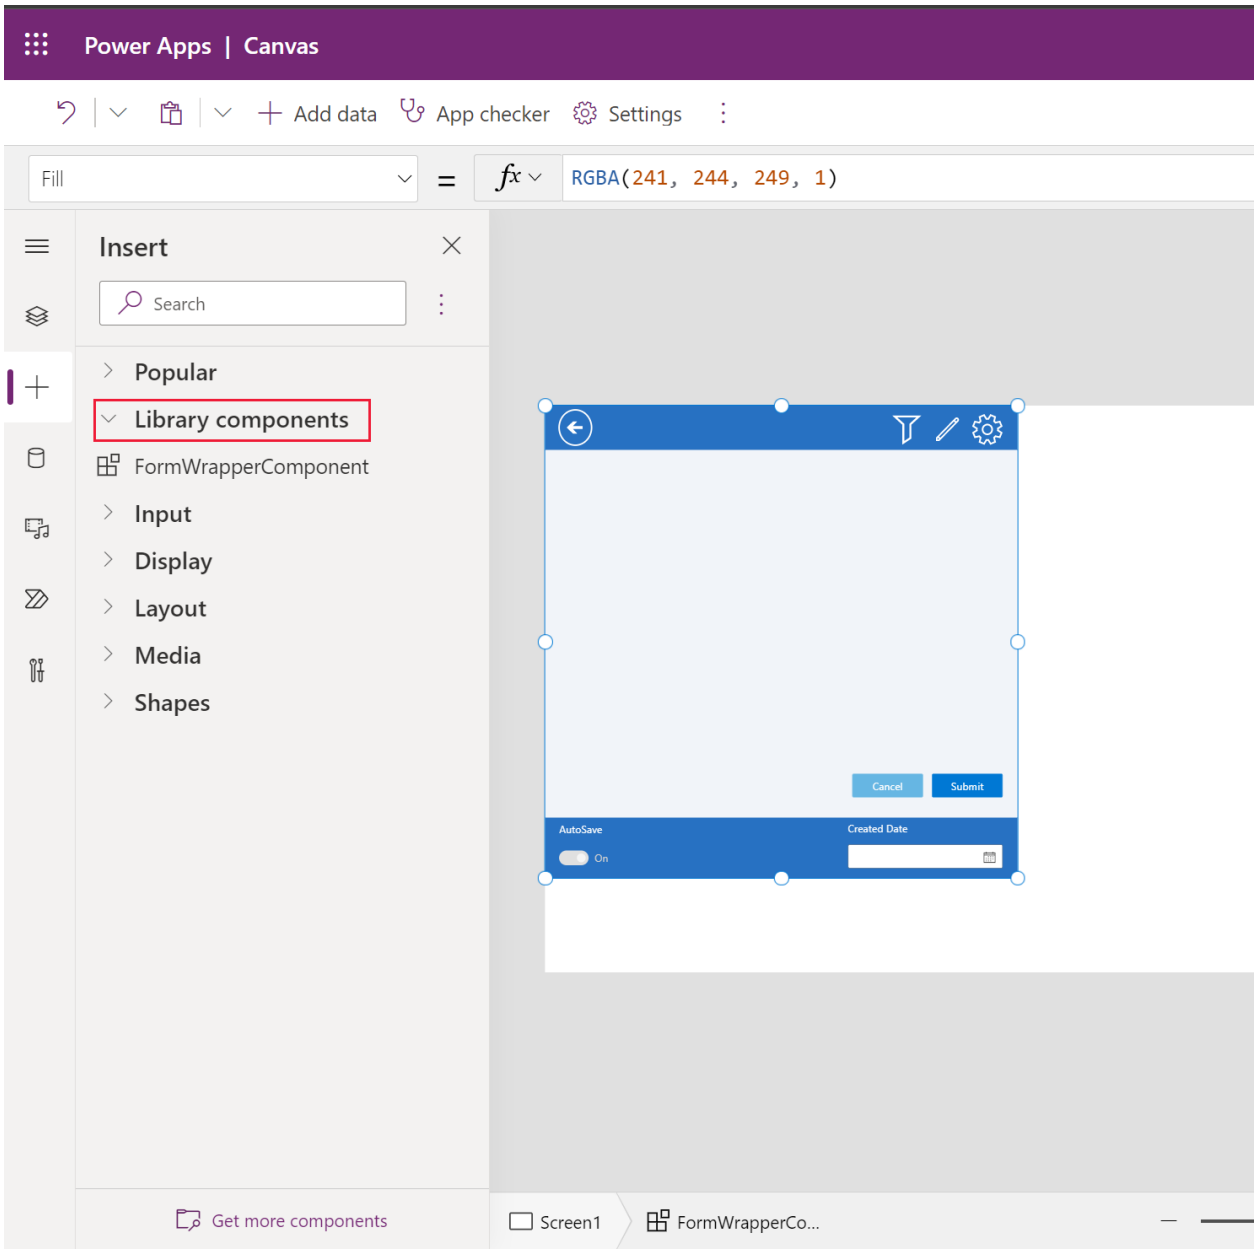


Import and use a canvas component in a custom page

Custom pages can use the components from the canvas component library created or imported in the current environment. You can select **Get more components** at the bottom of the add control left navigation area.

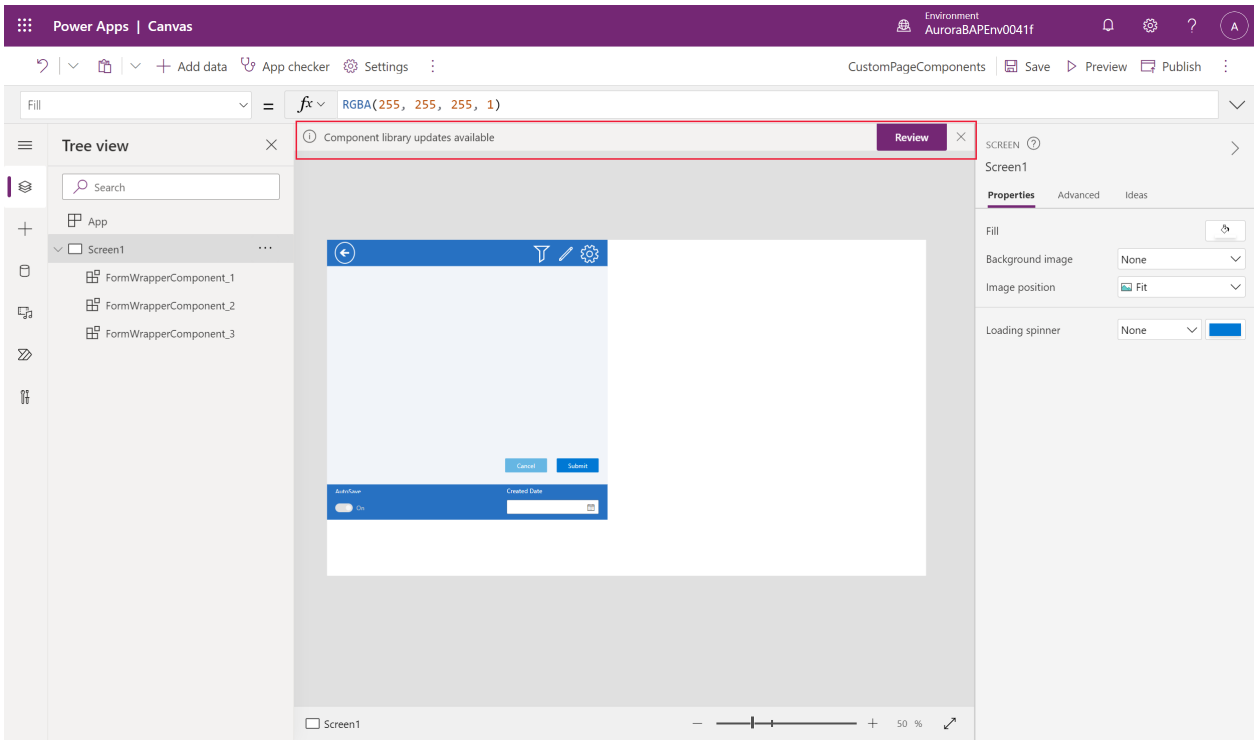


The canvas component is available under the **Library components** section and can be added to the custom page.



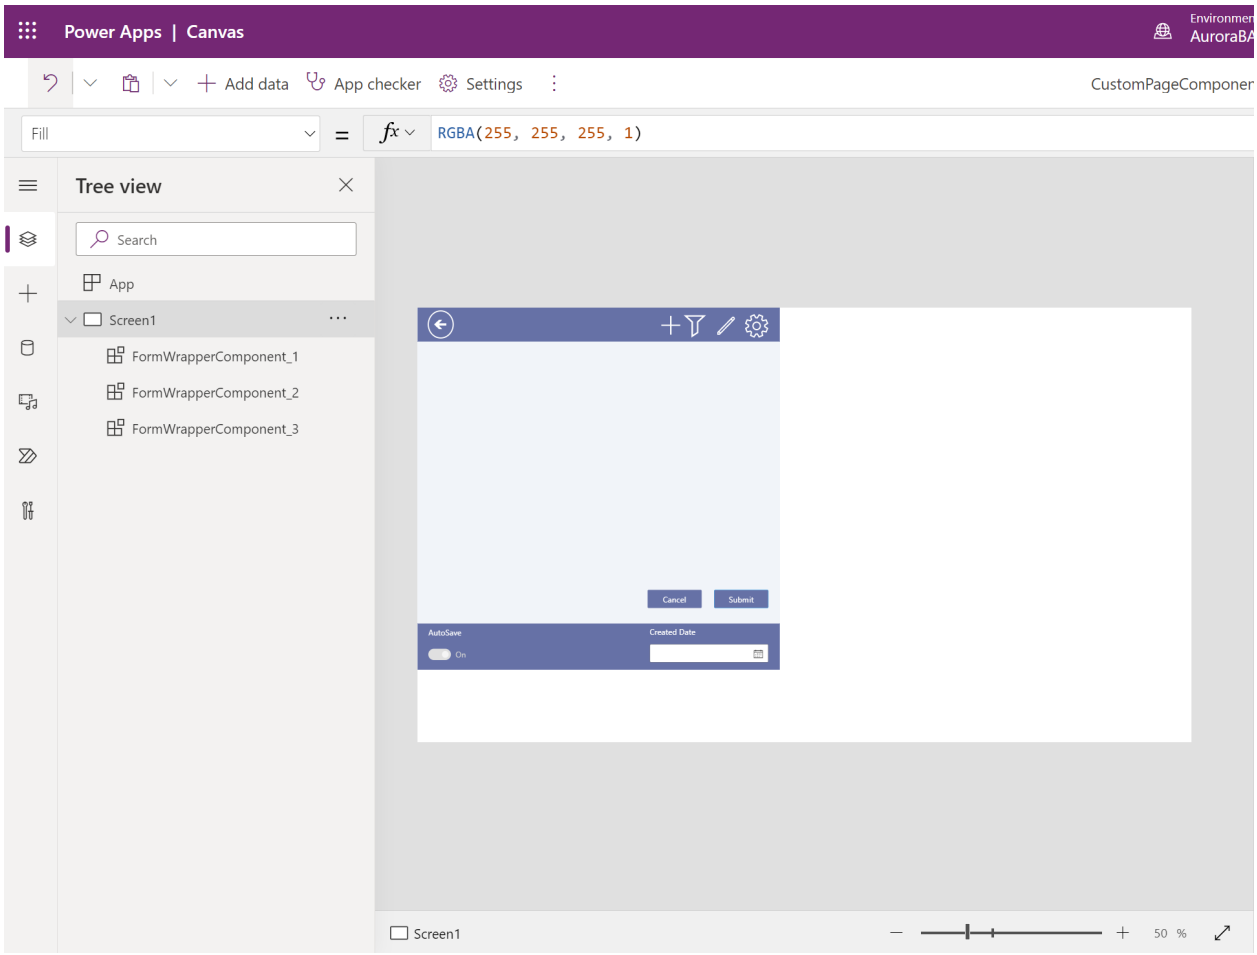
Component updates to the custom page

When the component is added to the custom page via the component library, it maintains the reference to the library. When the library owner publishes the newer library version with updated components, the custom page inline with the canvas app displays an update available message. This message is displayed when the custom page is opened for editing.



Select **Review** to review the updates, and then select **ok** to get the component refreshed with the latest changes from the canvas library.

> **Note**
>
> Individual custom pages present in a model-driven app should be opened individually for editing inside canvas app studio to get the latest updates from the shared component library.



You can now publish the custom page and model-driven app to get the latest changes reflected.

Additional canvas component resources

You can evaluate and use canvas component samples from Microsoft and other Power Apps community developers, which are hosted on the Canvas app components gallery.

Add code components to a custom page for your model-driven app

Article • 06/03/2022

This article outlines the use of code components built by professional developers using Power Apps component framework within a custom page. For low-code custom UX extensibility, see add canvas components to a custom page for your model-driven app.

Important

- Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in **Custom Page Known Issues**.

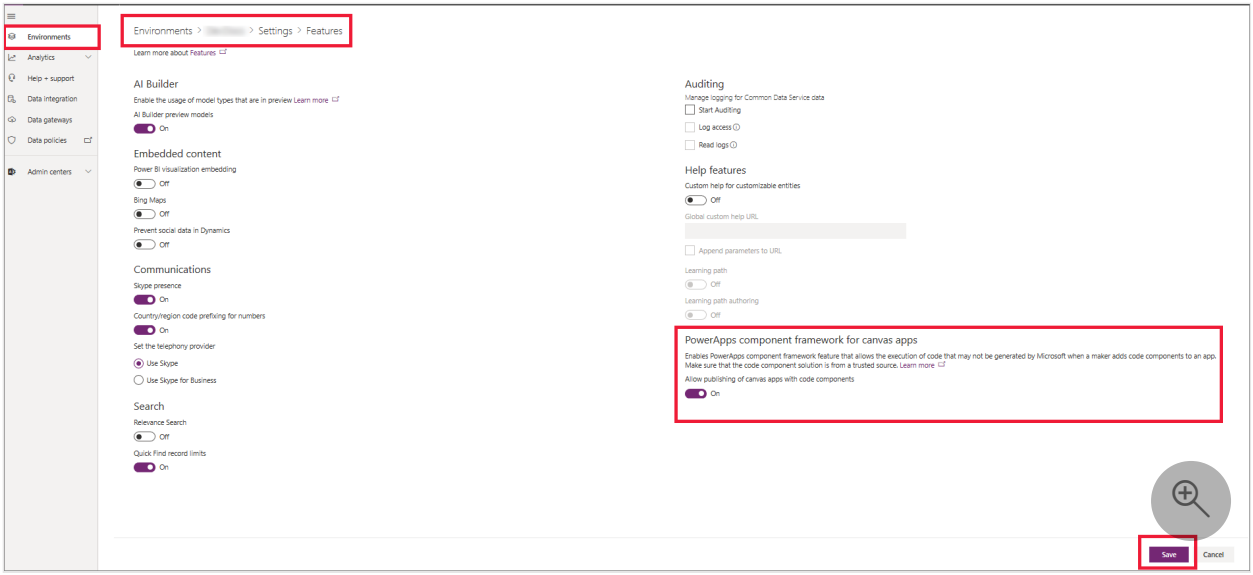
Note

- Custom pages support all the component framework APIs that are currently supported for canvas apps.
- Certain model-driven app specific APIs like **WebAPI** and **Navigation** have published app support for custom pages. These APIs can be used in the code component for custom pages and works on the final published app.
- For individual API support status on each platform, see **Power Apps component framework API reference**

Code components provide professional developers the ability to create custom code components for use within an app. This pro-code extensibility mechanism provides first-class application lifecycle management (ALM) to seamlessly extend the components available to all the app makers across the organization. Code components can be reused across custom pages, canvas, and model-driven apps. They can be centrally updated, packaged, and moved using standard Microsoft Dataverse solutions. More information: Power Apps component framework overview

Enabling Power Apps component framework for custom pages

To use code components inside a custom page, you need to enable Power Apps component framework feature. More information: Enable the Power Apps component framework feature



Create code components for use in a custom page

This section outlines how to create, import, and test code components.

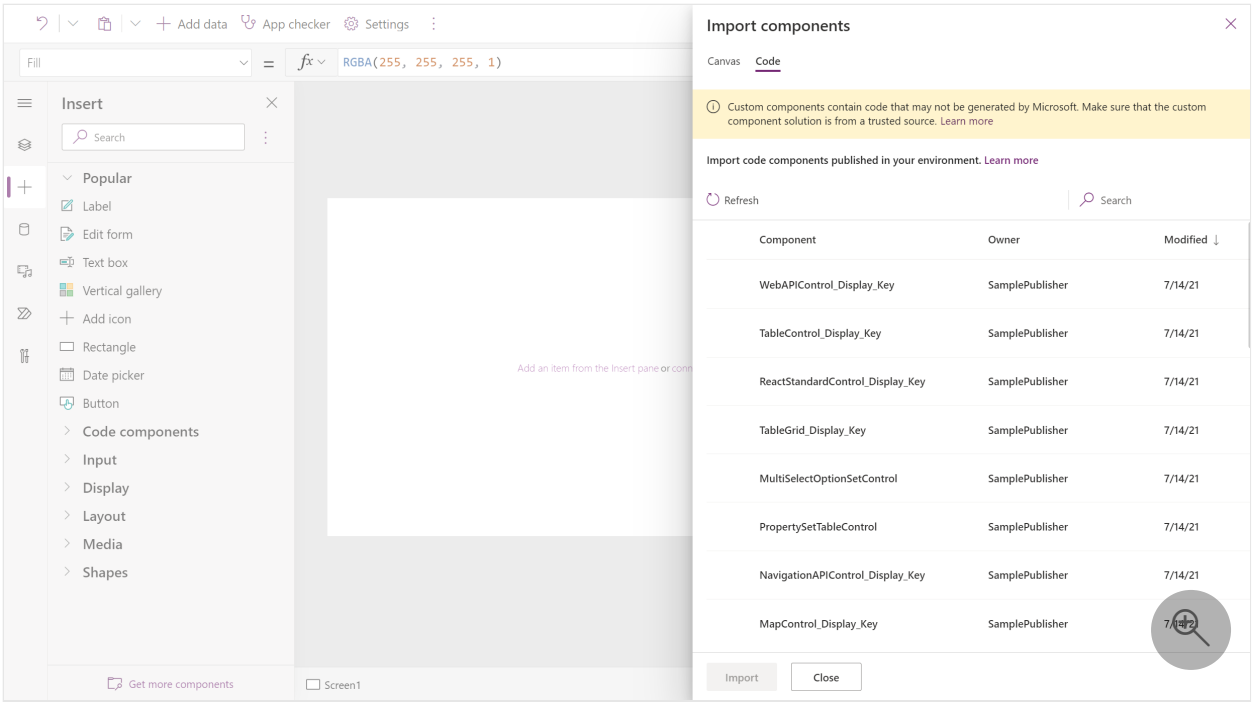
Creating and importing code components in Dataverse

Code components for custom pages follow the same pattern as they do with canvas app. Code components need to be implemented first before they can be added to a custom page. To create a code component, see Create your first component.

You can also try OOB sample components to jump-start. Once you are done implementing your code component, it can be packaged into a solution and added to Dataverse, making it available for use in all the custom pages in line with model-driven and canvas apps. More information: Code components application lifecycle management (ALM).

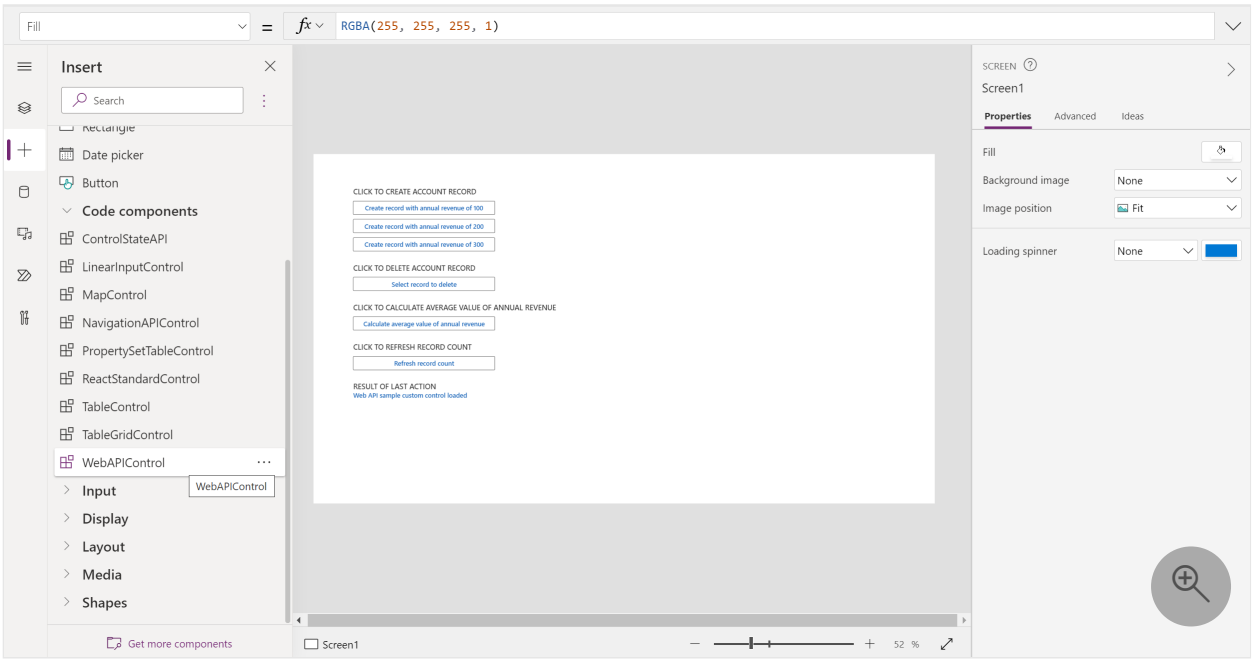
Importing and using code component in a custom page

In an environment, custom pages can use all the code components previously imported into Dataverse using solutions. On the left pane, select **Add (+)**, and then select **Get more components** at the bottom of the page. You will see a code tab on the **Import components** pane showing all code components present in the environment.



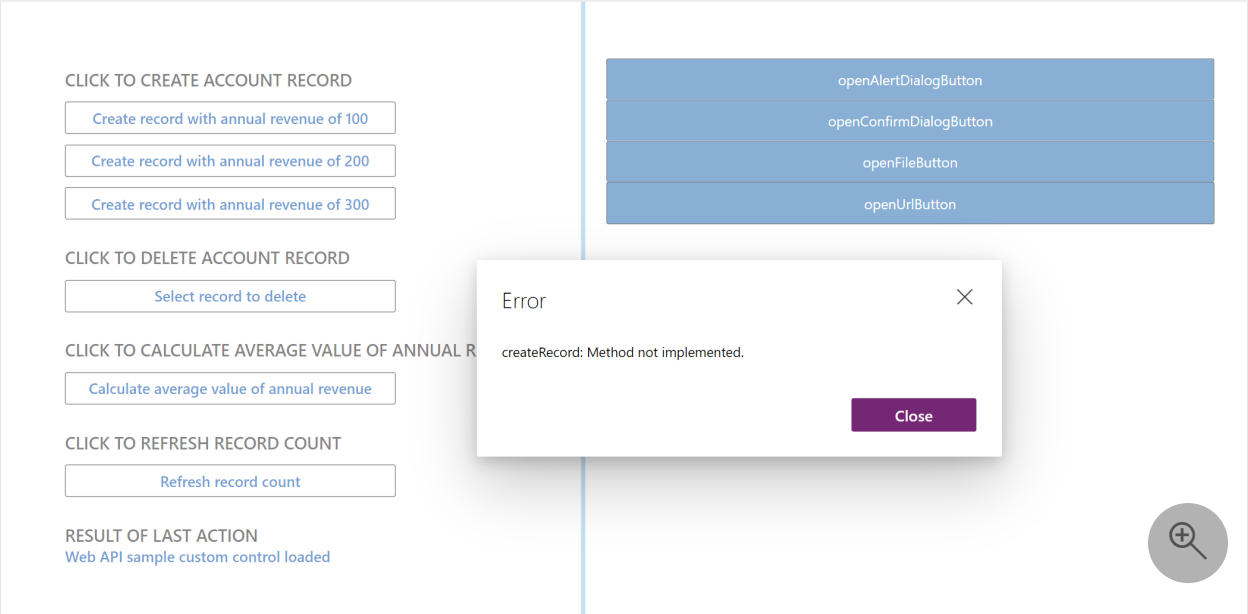
> **Note**
>
> - If the code tab doesn't show up in the **Import component** pane, verify that the Power Apps component framework feature setting for canvas apps is enabled. More information: **Enable Power Apps component framework feature**
> - Also, ensure that you are working on the latest canvas app studio authoring version.

The newly added code components are now available under the **Code components** section. It can be added to a custom page.



Testing the code component inside the studio and published app

Like canvas apps, code components are interactive and can be tested in the custom page studio authoring environment. However, specific APIs like `Web APIs` and `Navigation`, which only have the custom page runtime support when invoked, will show the error message "Method not implemented".

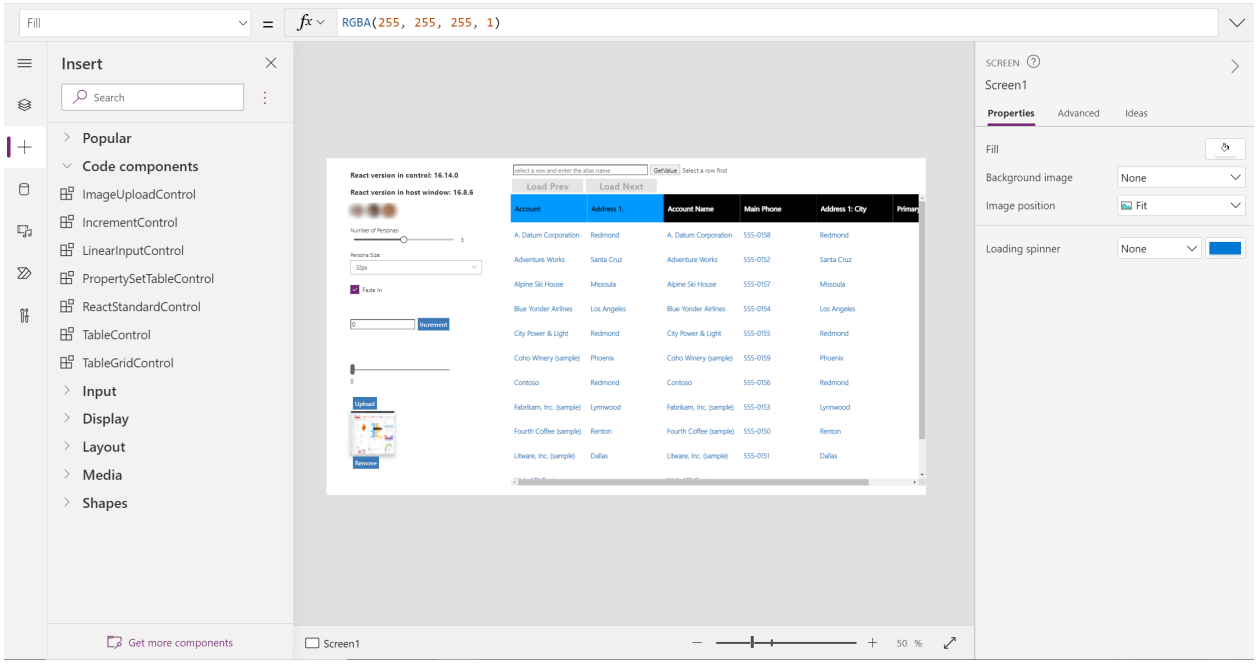


You can dismiss this error and publish the custom page. Then, add this custom page to the model-driven app and publish the app to see the custom page web API in action.

The image below shows the standard Web API sample control and Navigation API control added to custom page working inside a published model-driven app.

Additional code component resources

You can also use other sample components from Microsoft.



Or try some from the Power Apps community gallery.

Using PowerFx in custom page

Overview of Power Apps connectors

Add data connection in canvas designer

Overview of connectors for canvas apps

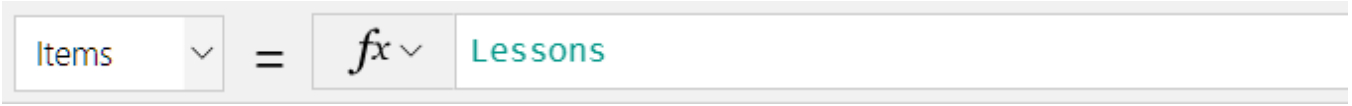
Data is at the core of most apps, including apps you build in Power Apps. You store data in a *data source*, and you bring that data into your app by creating a *connection*. The connection uses a specific *connector* to talk to the data source. Power Apps has connectors for many popular services and on-premises data sources, including SharePoint, SQL Server, Office 365, Salesforce, and Twitter. To get started adding data to a canvas app, see Add a data connection in Power Apps.

A connector might provide **tables** of data or **actions**. Some connectors provide only tables, some provide only actions, and some provide both. Also your connector might be either a standard or custom connector.

> **Note**
>
> Keep the number of connectors in a canvas app to a maximum of 10, and connection references to no more than 20. Going beyond these limits can lead to longer loading times for users when launching the app and can cause problems when saving the app.

Tables

If your connector provides tables, add your data source, and then select the table in the data source that you want to manage. Power Apps retrieves table data into your app and updates data in your data source automatically. For example, add a data source that has a table named **Lessons**, and then set the **Items** property of a control, such as a gallery or a form, to this value in the formula bar:



Specify the data that your app retrieves by customizing the **Items** property of the control that shows your data. Continuing the previous example, sort or filter the data in the **Lessons** table by using that name as an argument for the **Search** and **SortByColumn** functions. In this graphic, the formula set for the **Items** property specifies that the data is sorted and filtered based on the text in **TextSearchBox1**.

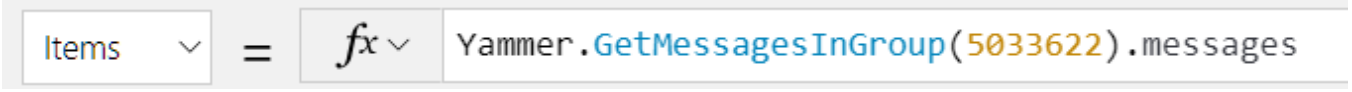
For more information about customizing your formula with tables, see these articles:

Understand data sources in Power Apps
Generate an app from Excel data
Create an app from scratch
Understand tables and records in Power Apps

> **Note**
>
> To connect to data in an Excel workbook, host it in a cloud storage service like OneDrive. For more information, see Connect to cloud-storage from Power Apps.

Actions

If your connector provides actions, select your data source as you did before. Instead of selecting a table as the next step, manually connect a control to an action by editing the **Items** property of the control that shows your data. The formula you set for the **Items** property specifies the action that retrieves data. For example, the app doesn't retrieve any data if you connect to Yammer and then set the **Items** property to the name of the data source. To populate a control with data, specify an action such as **GetMessagesInGroup(5033622).messages**.



To handle custom data updates for action connectors, build a formula that includes the **Patch** function. In the formula, identify the action and the fields that bind to the action.

> **Note**
>
> For action-based connectors, galleries and other controls don't automatically page in more data like they do for tabular connectors. For example, if you bind a tabular data source to a gallery, it retrieves the first set or page of records (for example, 100 records), and then it pages in more data as the control requests it. For an action-based connector, it retrieves a "page" of data, but if the data requested exceeds the page size, the control doesn't automatically get the next page.

For more information about how to customize your formula for custom updates, see these articles:

Patch
Collect
Update

Dynamic schema is a common type of result for action based connectors. Dynamic schema refers to the possibility that the same action might return a table with different columns depending on how it's called. Conditions that might cause the columns in the table to differ include input parameters, the user or role executing the action, and the group in which the user is working, among others. For example, SQL Server stored procedures might return different columns if run with different inputs, or an Azure DevOps instance might use custom fields that aren't available by default.

> **Note**
>
> The connector documentation shows dynamic schema results with this message **"The outputs of this operation are dynamic."** as the return value.

For more information about how to work with dynamic schema in Power Apps, see Working with Dynamic values for an overview and Connect to Azure DevOps from Power Apps for a detailed example.

Popular connectors

This table links to more information about popular connectors. For a complete list, see All connectors.

Expand table

Microsoft Dataverse	Cloud storage **
Dynamics AX	Excel
Microsoft Translator	Office 365 Outlook
Office 365 Users	Oracle
Power BI	SharePoint
SQL Server	Twitter

** Applies to Azure Blob, Box, Dropbox, Google Drive, and OneDrive.

Standard and custom connectors

Power Apps provides *standard* connectors for many commonly used data sources. If Power Apps has a standard connector for the type of data source you want to use, use that connector. To connect to other types of data sources, like a service you built, see Register and use custom connectors.

All standard connectors

Standard connectors don't require special licensing. For more information, see Power Apps plans.

Ask questions about a specific connector in the Power Apps forums, and suggest connectors you want to add or other improvements in Power Apps Ideas.

Security and types of authentication

As you author your app and create a connection to a data source, you might see that your choice of connector offers different ways to authenticate. For instance, the SQL Server connector allows you to use Microsoft Entra Integrated, SQL Server Authentication, and Windows Authentication. Each type of authentication has different levels of security. Understand what information and rights you share with users who use your application. The primary example in this article is SQL Server. However, the principles apply to all types of connections.

> **Note**
>
> - For detailed information about security considerations when using a relational database server, such as Microsoft SQL Server or Oracle, as the data source for an app, see Use Microsoft SQL Server securely with Power Apps.
> - Power Apps doesn't support **External member** identities. For more information, see Properties of a Microsoft Entra B2B collaboration user.
> - Gateway selection isn't supported for custom connectors that use the anonymous authentication type.

Microsoft Entra ID

This authentication is a secure type of connection. For example, SharePoint uses this type of authentication. SQL Server also allows for this type of authentication. When you connect, the Microsoft Entra service identifies you separately to SharePoint on your behalf. You don't have to supply a username or password. As an author, you can create and work with the data source

by using your credentials. When you publish your application, your application user signs in by using their credentials. If the data is appropriately secured on a back-end, your users can only see what they're authorized to see based on their credentials. This type of security allows you to change rights for specific application users on the back-end data source after the application is published. For instance you can grant access, deny access, or refine what a user or set of users can see all on the back-end data source.

Open-standard authorization (OAuth)

This type of connection is also secure. For example, Twitter uses this type of authentication. When you connect, **you must supply your user name and password.** As an author, you can create and work with the data source by using your credentials. When you publish your application and your application user signs in, they must also supply their credentials. Therefore this type of connection is secure as your users must use their own credentials to access the data source service.

Shared connections and secure implicit connections

In a shared connection, the Power Apps author provides the user name and password for the connection when creating the data source in the application. The connection authentication to the data source is then **implicitly shared** with end users. Once the application is published, the connection is also published and available to your users.

Before January 2024, your end users could take the connection that you shared with them and create separate new applications. Your users can't see the user name or password, but the connection is available to them. However, **after January 2024, all newly created shared connections are secured.** To secure existing apps, republish them. The connection is no longer shared with end users. The published Power App talks to a connection proxy. The connection proxy only talks to the specific Power App for which it's linked. The connection proxy limits the actions that are sent to the connections to the ones in the Power App **{Get, Put/Patch, Delete}** for a given data source. If you have an app using the connections published before January 2024, republish your application and unshare any connections with end users that shouldn't have them.

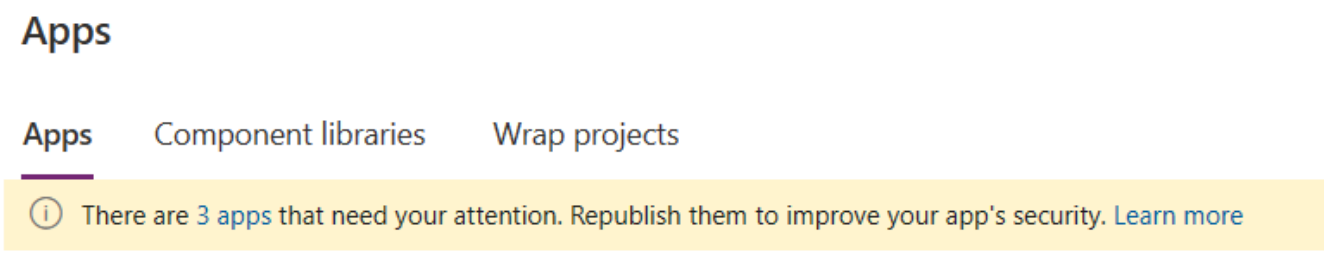
In SQL Server, an example of this type of connection is **SQL Server Authentication**. Many other database data sources provide a similar capability. When you publish your application, your users don't need to supply a unique user name and password.

> ⓘ **Note**

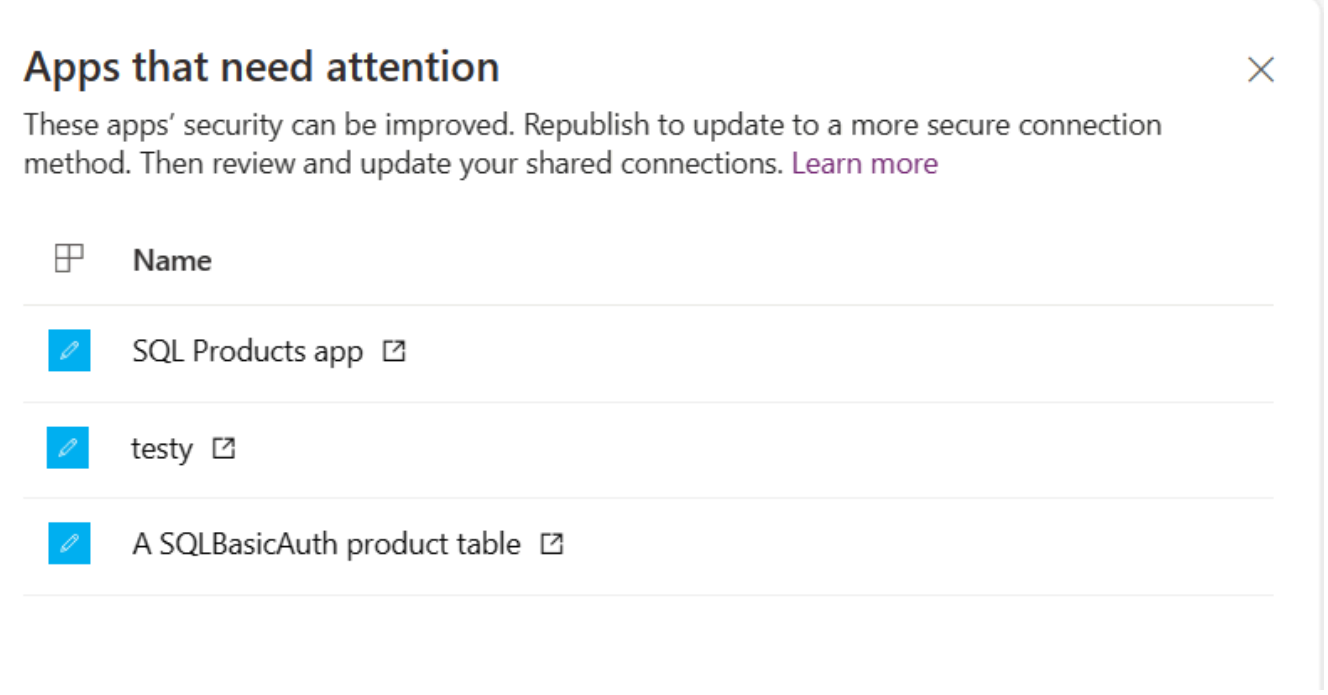
Your end-users might encounter the error message **You do not have correct permissions to use this connection** in the consent dialog. Two situations might cause this error. First, the application might have a shared implicit connection that **isn't** a secure implicit connection. Sharing the connection with the end user resolves this issue but isn't recommended because all shared connections should be secure implicit connections. The author should convert all connections in the application to be secure implicit connections to resolve this issue. Second, the connection might already be a secure implicit connection. Republishing might resolve this issue. If it doesn't, then a product bug should be filed.

Notification to update your apps (secure implicit connections)

If you have applications that might be upgraded to use this feature, you see a message on the **Apps** page. It indicates the number of apps that need your attention.



Select the link and it opens a side panel that lists all of the apps that need attention.



Select the **open** icon to the right of the app name to open and republish it. Continue with the following directions.

Enable secure implicit connections for an existing app

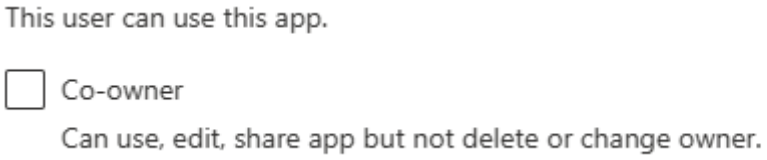
Open an existing app open for editing with implicitly shared connections already published:

1. On the command bar, select **Settings** and search for "**Secure**".
2. Update the feature switch appropriately to enable secure implicit connections.
3. Save and publish the app.

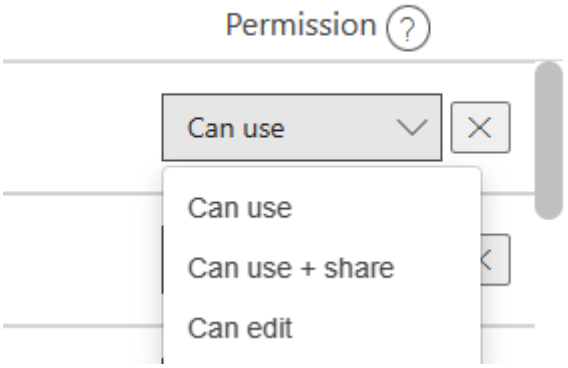
Unsharing

Once you publish the app, follow these steps to verify that sharing works correctly:

- Check if connections are shared with co-owners. If you don't want an end-user to get a connection, then uncheck the **Co-owner** checkbox.



- To verify the feature works correctly, share the app with a different user who isn't an owner. Once you share the app, check the **Connections** list in the **Dataverse** tab in Power Apps for that user. Verify that the user doesn't have a connection available.
- Open the **Sharing** panel to change the end-user's right to the connection. Choose the **X** to remove the user's access to the connection.



Use apps with a new secure implicit connection

When you republish and share your app, end-users don't have access to the connection but work with the hidden proxy connection. Users can't create a new app based on your original connection.

Limitations

1. All types of implicitly shared connections work, such as action and tabular.
2. Server and database names are hidden in network traces but visible in the consent dialog. Column names aren't hidden.
3. For tabular connectors, the feature only limits CRUD actions such as Get, Post, Put, or Delete. If you have permissions to **Put**, then you have access to **Post**.
4. Action based connectors limit based on the specific API being used in the application.
5. Warnings are still enabled in sharing. The warning around implicitly shared connections still warns while in preview. However, your connection with this feature is secure – despite the warning.
6. Publishing to an entire tenant, as opposed to specific groups or individuals isn't supported.
7. There's a known issue when importing an implicitly shared secure connection via a connection reference. The security isn't set properly in the target environment.
8. There's a known issue importing a solution using a service principal, causing import failure. A workaround is to share the connection with the service principal.

Windows Authentication

This type of connection isn't secure because it doesn't rely on end-user authentication. Use Windows authentication when you need to connect to a data source that is **on-premises**. An example of this type of connection is to an on-premises server that has a SQL Server. The connection must go through a gateway. Since it goes through a gateway, the connector has access to all of the data on that data source. As a result, any information that you can access with the Windows credentials you supply is available to the connector. When you publish the application, you also publish the connection and make it available to your users. This behavior means that your end users can create applications by using this same connection and access the data on that machine. Connections to the data source are also **Implicitly Shared** with users that the app is shared with. This type of connection might be valid when your data source only lives on an on-premises server and the data on that source is freely shareable.

Data sources in solutions

Solutions help with application lifecycle management and offer other ways to manage the lifecycle of **data sources**. If a canvas app is in a solution, you can create connection references and environment variables to store information about the data sources. This setup makes it easy to change or reconnect data sources when you move solutions to different environments.

Rename data sources in apps

Learn how to rename data sources in an app, and understand the difference between tabular and action-based data sources. For more information, see Rename Power Apps action-based data sources.

Connection consent dialog

When users open an app that uses connectors for the first time, they see a connection consent dialog for the following purposes.

1. To inform users about the data sources accessed by the app.
2. To outline the actions a connector might or might not perform in an app. For example, for apps using the **Office 365 Users** connector:

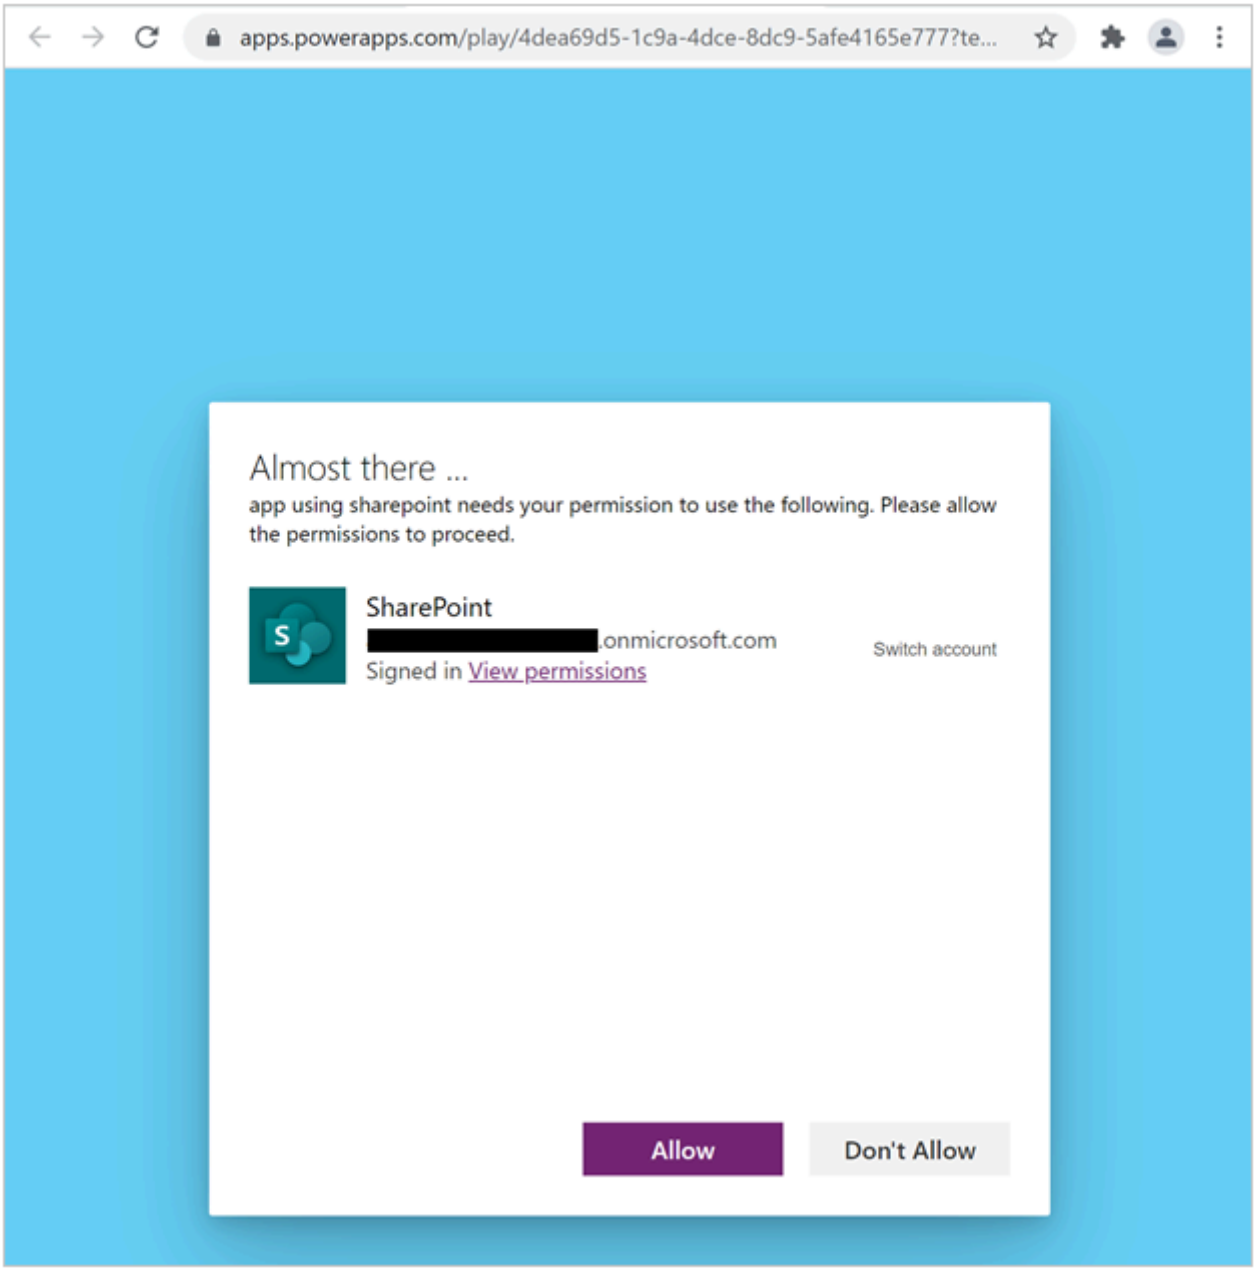
- This app is able to:
  - Read your full user profile
  - Read the full profile of all users
- The app can't:
  - Modify or delete any user-profile information

1. To capture end-user consent to connect to the data sources that the app uses.
2. To facilitate manual end-user authentication, when needed.

For some connections, Power Platform can automatically authenticate a user to access a data source. However, if the automatic sign-in fails, this dialog prompts users to fix a connection by manually signing in. Power Platform can only attempt automatic sign-in for a connection when a data source preauthorizes Microsoft's Azure API connections service principal, granting it permission to perform single sign-on for a user when a connection is created. For more information on single sign-on, see What is single sign-on (SSO)?

For model-driven apps that use custom pages, when there are multiple custom pages in an app, the consent dialog asks for data permissions for all of the connectors in all the custom pages even if users don't open them.

The following image is an example of the connection consent dialog for an app connecting to a SharePoint site.



For select connectors, admins can suppress this dialog and consent on behalf of end users to connect to a data source. The following table explains which types of connectors the consent dialog might be suppressed for an app.

> **Note**
>
> If an admin suppresses the consent dialog but the platform can't perform single sign-on for an end-user, the dialog is presented to the user when they launch the app.

Expand table

Connector type	Consent dialog suppressible?	Reference
Microsoft connectors that support single sign-on (such as SharePoint, Office 365 users)	Yes	Power Apps admin cmdlet
Connector accessing a non-Microsoft, partner service, such as Salesforce	No	Not applicable
Custom connectors using OAuth with Microsoft Entra ID as the identity provider. These custom connectors are built by organizations, and are only accessible by the users within the organization (for example, built by Contoso for only Contoso users)	Yes	Manage Connections

Microsoft Power Platform can only suppress the consent dialog for connections to data sources where all the following conditions are true:

1. The data source doesn't require an explicit consent UI.
2. The data source preauthorizes Microsoft's Azure API connections service principal to enable single sign-on.
3. An admin configures an app to suppress the consent for the preceding connections.

Microsoft's Azure API connections service principal preauthorization exists for Microsoft's first-party data sources. Custom applications registered in a Microsoft Entra tenant that are used by custom connectors might configure this preauthorization. An admin manages consent suppression on a per-app basis (as opposed to connector basis), so suppression is managed at the most granular app experience level. This level of granularity prevents consent suppression for an organization's "approved apps" from inadvertently suppressing consent for apps that aren't approved or reviewed.

Last updated on 01/13/2026

Localize labels, messages, and tooltips on a custom page

Article • 03/13/2023

[This topic is pre-release documentation and is subject to change.]

This article outlines how to add localized content to a custom page by uploading web resource RESX files for each language into your solution.

This article shows you how to use Power Fx to set the content of a control on a custom page. You can use similar steps for tooltips and any messages that use a text control on the custom page.

Localizing labels on a custom page

Providing localized content on a custom page in a model-driven app is vital when building apps that support global users or a multilingual organization. Translation can be done by uploading text files in a .resx format as a web resource. The files contain the translated text that you want to use for labels on your custom pages.

The process has the following steps:

1. Enable languages for your environment.
2. Add localized RESX web resource files into your solution.
3. Add the localized files to your custom page.
4. Manage localized web resources.
5. Add the localized strings to your controls.
6. Run your app with localized content.

Enable languages for your environment

To add languages for a custom page, you need to first enable the languages you want to support in the model-driven app where your custom page will run. Make sure you have enabled languages from the Power Platform admin center. More information: Enable the language

After completing the steps to enable languages in the environment, create a RESX file for each language in the proper format for the strings you want localized on your custom page for your model-driven app.

After you have the created the RESX files with the localized strings, add them into your solution as a web resource. There are two ways to accomplish this task, the first is to open your solution in make.powerapps.com and select the option to add a web resource to your solution in your environment or you can add a web resource while working on a custom page. More information: RESX web resources

Adding a web resource while working on a custom page is covered later in this article in the section Add localized files to your custom page.

Localized content will be based on the user or organizational locale for the application the custom page is running. The language for your application is based on user or admin defined language preferences in the user app settings or admin settings in the Power Platform admin center. If neither has been set, the base language set when the environment was created is used.

> **Note**
>
> Content shown in a Power Apps Control Framework (PCF) control will localize to the applications locale language without additional changes needed on the custom page. More Information **Localizing PCF Controls**

Add localized RESX Web resource files to your solution

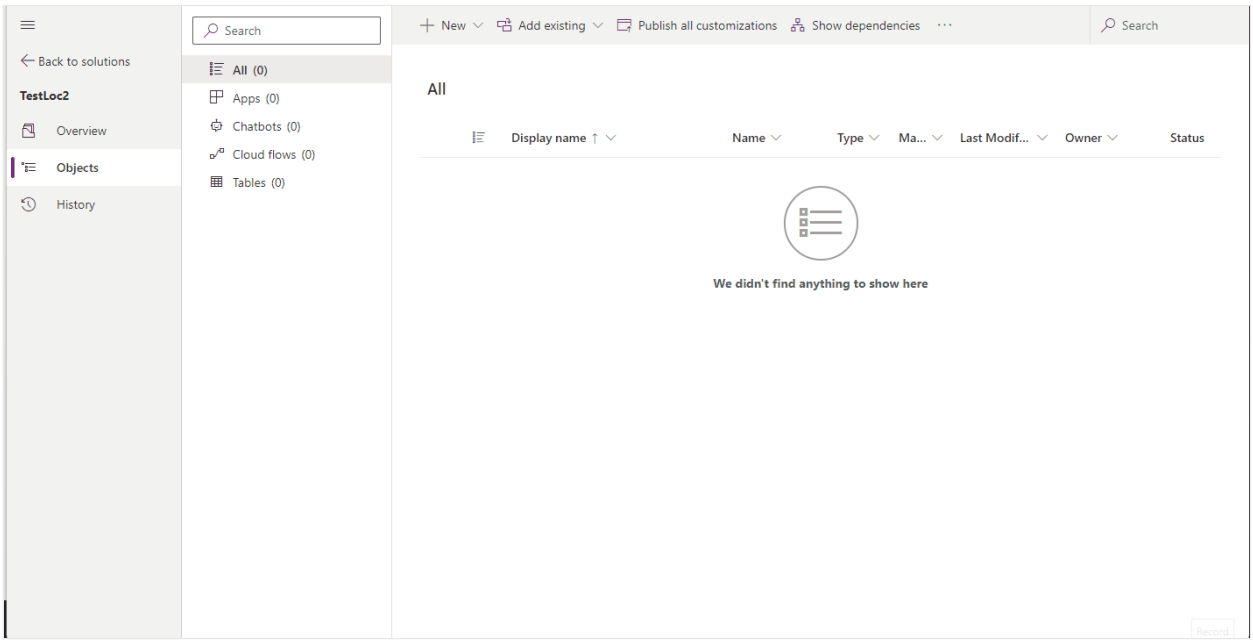
1. Go to make.powerapps.com, select the **Solutions** area, and then open the solution you want.
2. On the command bar, select **New** > **More** > **Web Resource**. This opens a panel to add your RESX web resource file.

All files added to your solution need to follow a specific format that includes **{filename}.LanguageID.resx**, where the language ID is the numeric value for that language. This format is necessary because the framework relies on the naming convention to identify which resource file should be used to associate the appropriate localized string to a label control.

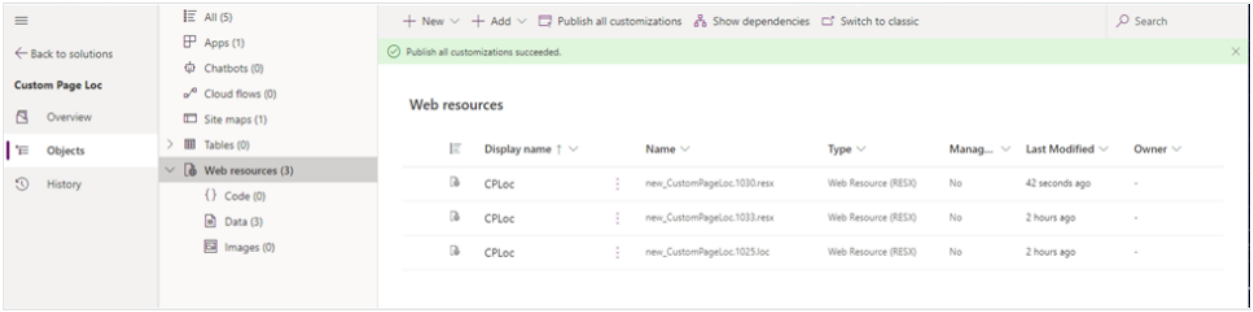
> **Important**
>
> The RESX {filename} must be the same for all your files.

For example, all localized string files have the name `CustomPageLoc.LanguageID.resx`, which means for English it is `CustomPageLoc.1033.resx`, for French `CustomPageLoc.1036.resx`, and for Arabic `CustomPageLoc.1025.resx`. The display name for every file added must also be the same name.

In the example below all files have `CPLoc` as the display name. *The display name must be the same to ensure all localized content is used properly on a custom page for each language*. We recommend that you add the corresponding name for the language in the **Description** field to help identify the content when you view the files in the custom page designer. Also, you'll need to add the same language's RESX file that you're working in. For example, if you are authoring in English, be sure to add the English RESX file.



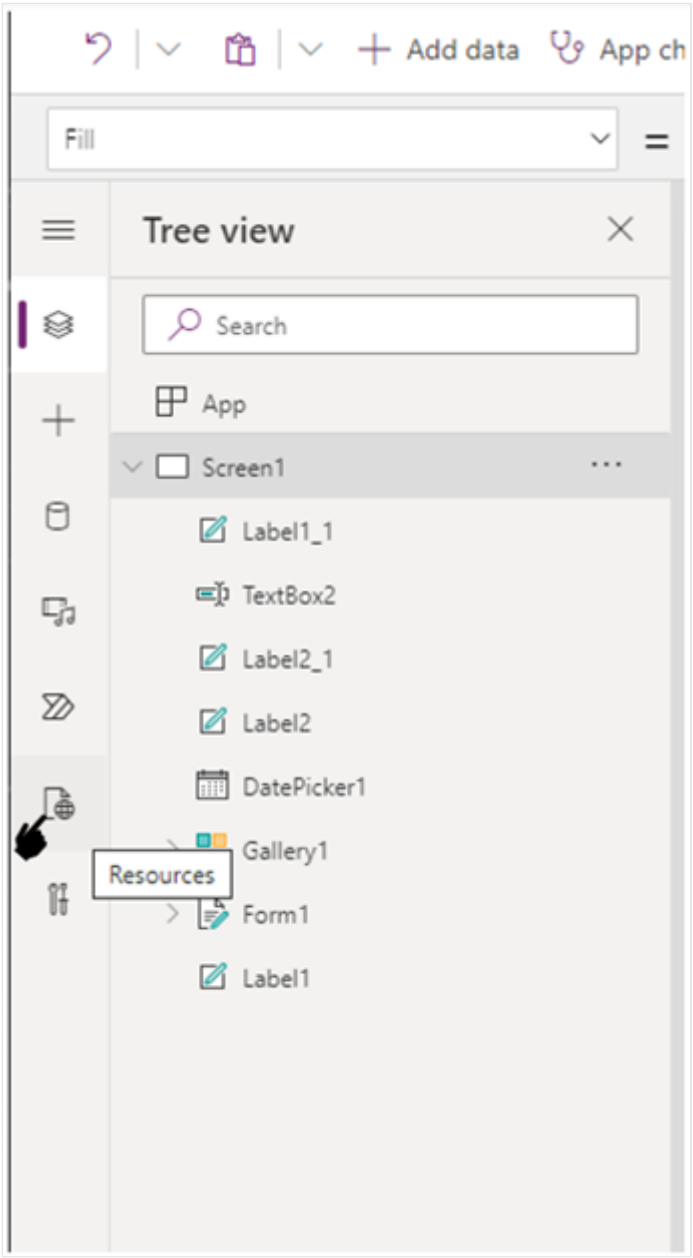
After you have added your web resource to your solution, make sure to publish the changes. Publishing ensures the file is available to add to your custom page. Here's an example of the web resource RESX files that have been added to a solution and are now available to add to a custom page.



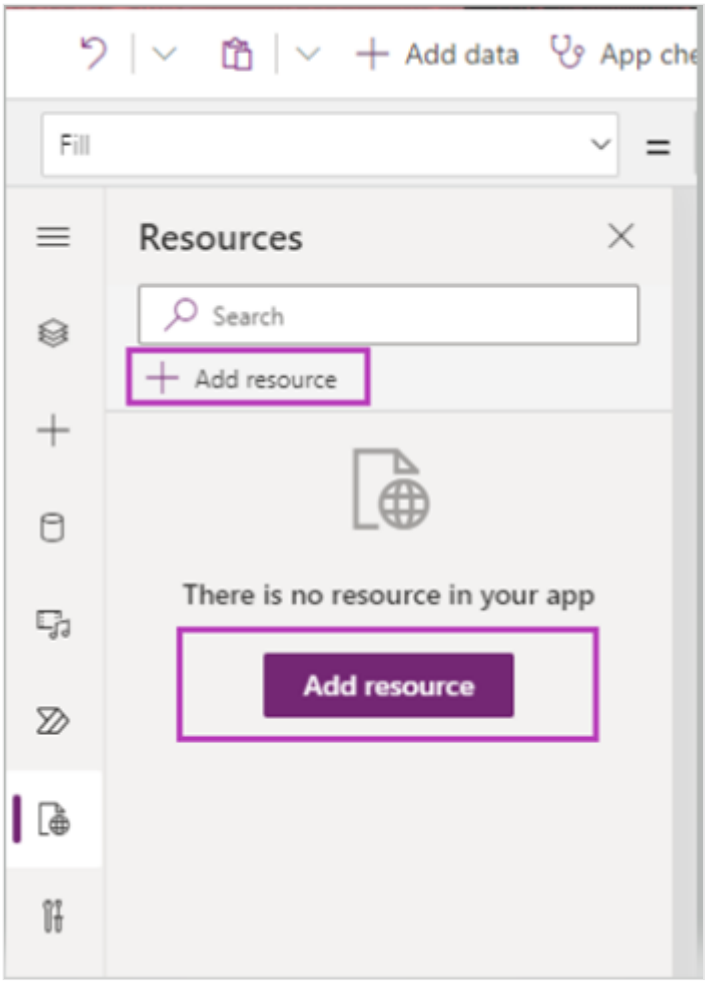
Add localized files to your custom page

Add localized files to your custom page when you're creating or editing a page.

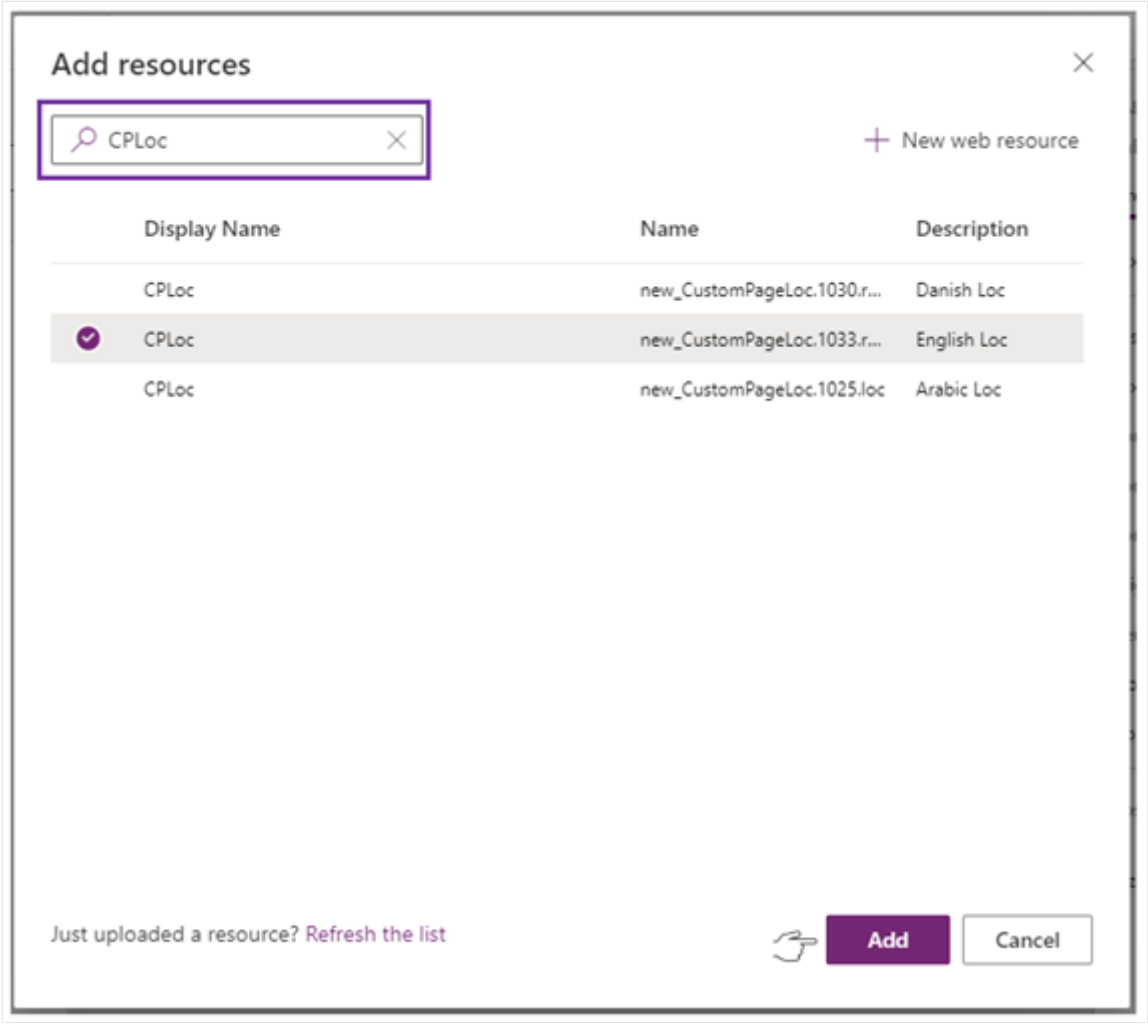
To add a language to your page, select the **Resources** icon on the left to open the **Resources** pane.



Select **Add resource** in either one of two places.



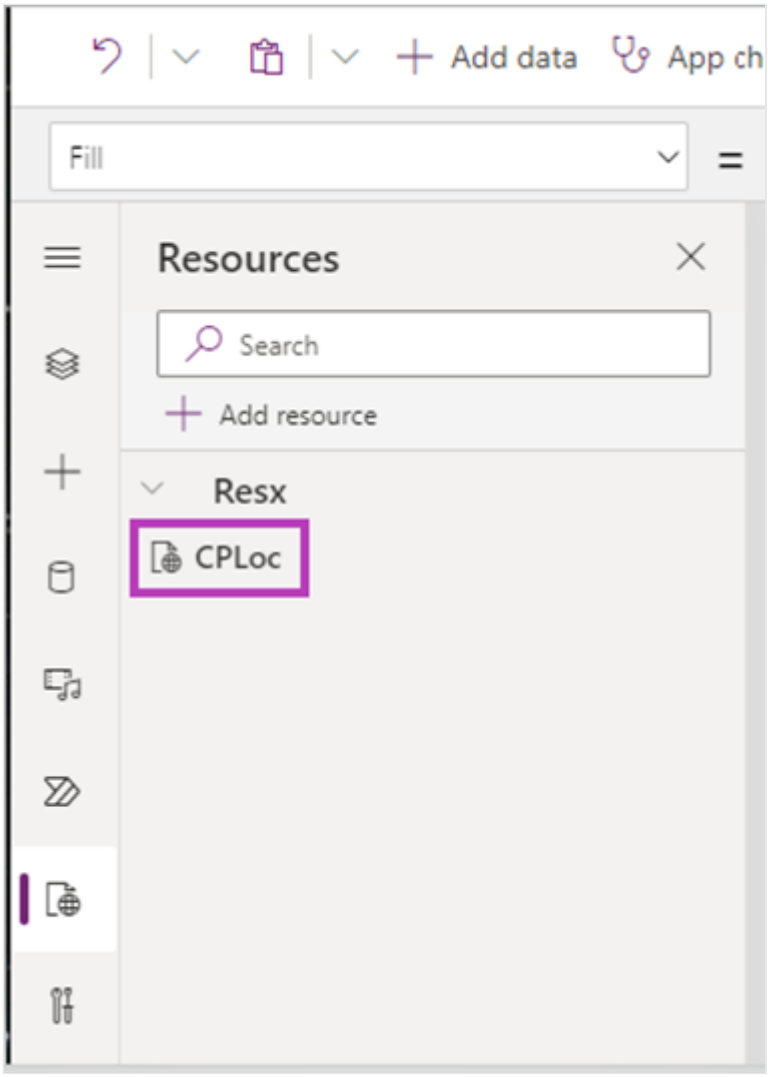
A dialog opens that lists all the available web resources in your solution. To find your files quickly, you can use the search at the top of the dialog to search for the **Display name** that displays all your localized RESX files. You only need to select and add the file that matches the language that you are using to author your page. In this example, the English file is the only file you need to add.



> **Note**
>
> It isn't necessary to add every file-you only need to add one. The solution and platform maps the uploaded languages based on the display name to the language web resource files that you added to your solution. When you add multiple files, a dialog is displayed with an error message, which states that files have already been loaded to your page.

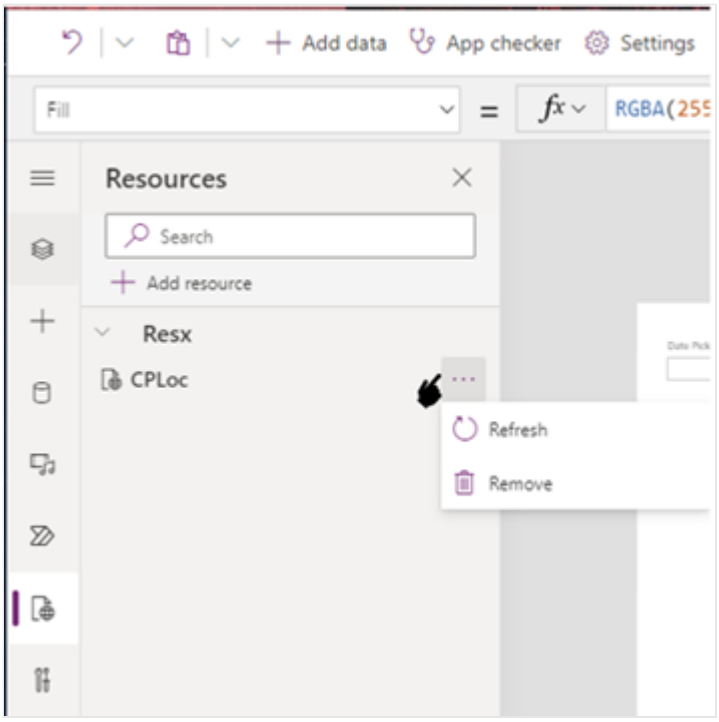
If you don't see the RESX web resource with the language you want to add in the dialog, you'll need to add the file to your solution using the steps described earlier in this article.

After selecting **Add**, the panel closes, and the web resource is listed in the **Resources** pane.



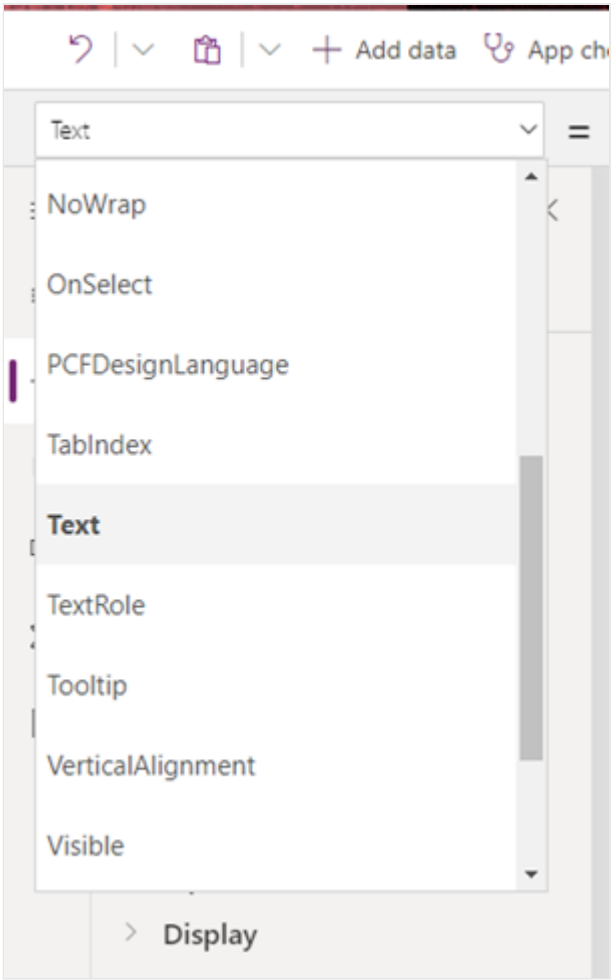
Manage localized web resources

After a web resource language has been added to your page, you can manage the file by selecting the ... ellipses next to the file. A flyout opens where you can refresh the web resource if it has been updated. You can also remove the resource from your page. You'll need to refresh the RESX resources on your page if the display name has changed or any of the string keys have been updated in the RESX file that's been published to your solution. Note that updating the translations in the RESX file and publishing the solution doesn't require the RESX on your page to be refreshed.

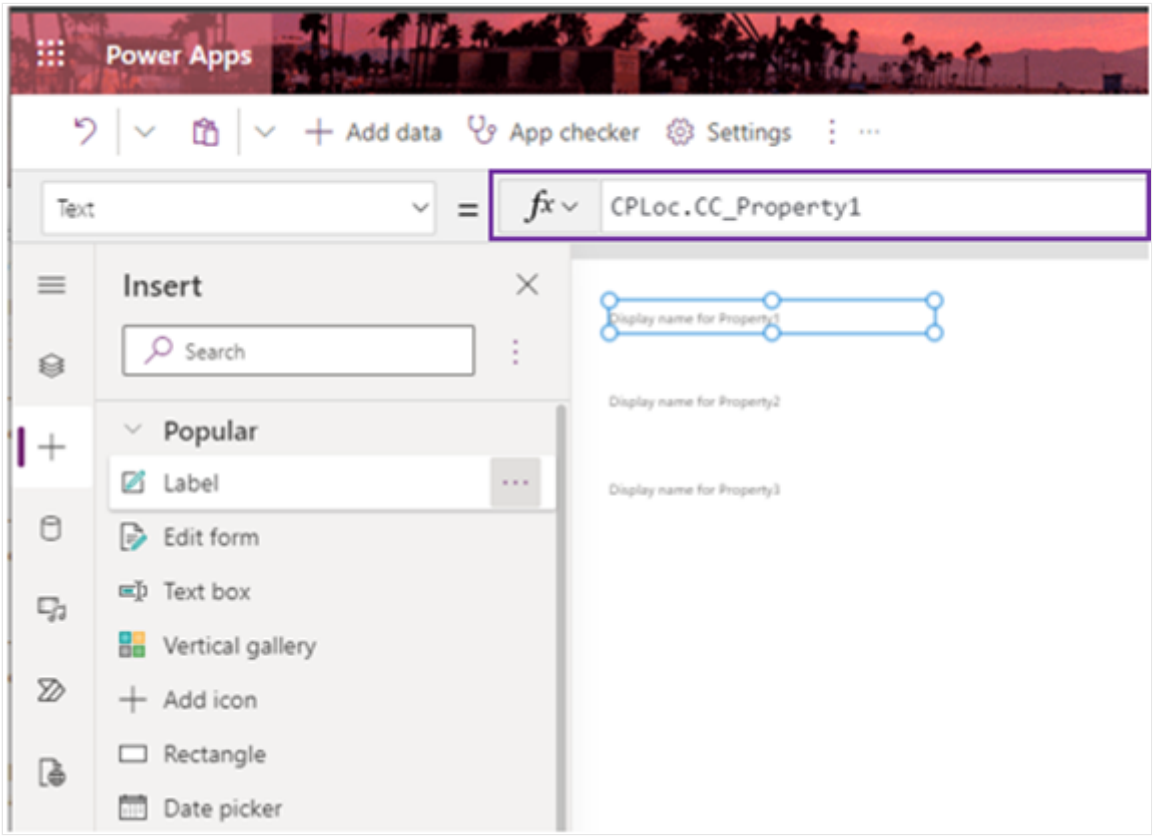


Add the localized string to your label controls

To add localized content to your label control, select the label and set the function to the resource using the Power Fx text function of the control. To do this, select the label control, and then select the **Text** function.



Using the text function, set the value to the web resource and the value you want that is in your web resource RESX file. After setting the expression, the content will appear in the preview for the page.

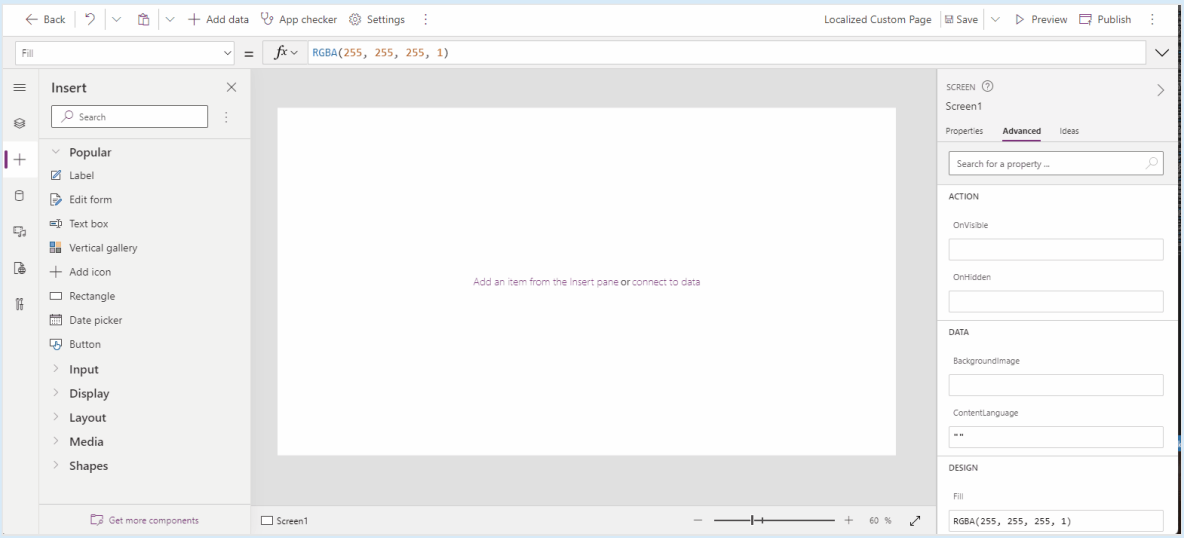


Save and publish your changes to the page.

> **Note**
>
> Make sure you also save and publish your changes to the app. Saving and publishing both the page and app are needed to ensure your localized labels render with the appropriate strings at runtime.

> **Important**
>
> When you add form controls, make sure you localize the labels. They do not automatically pull localized labels when you bind the control to a Microsoft Dataverse table. Currently, you'll need to add strings for the labels to your resx files, unlock the form control, and then set the `displayName` property to your localized

string using the same expression for your custom labels, text, tooltips, etc.

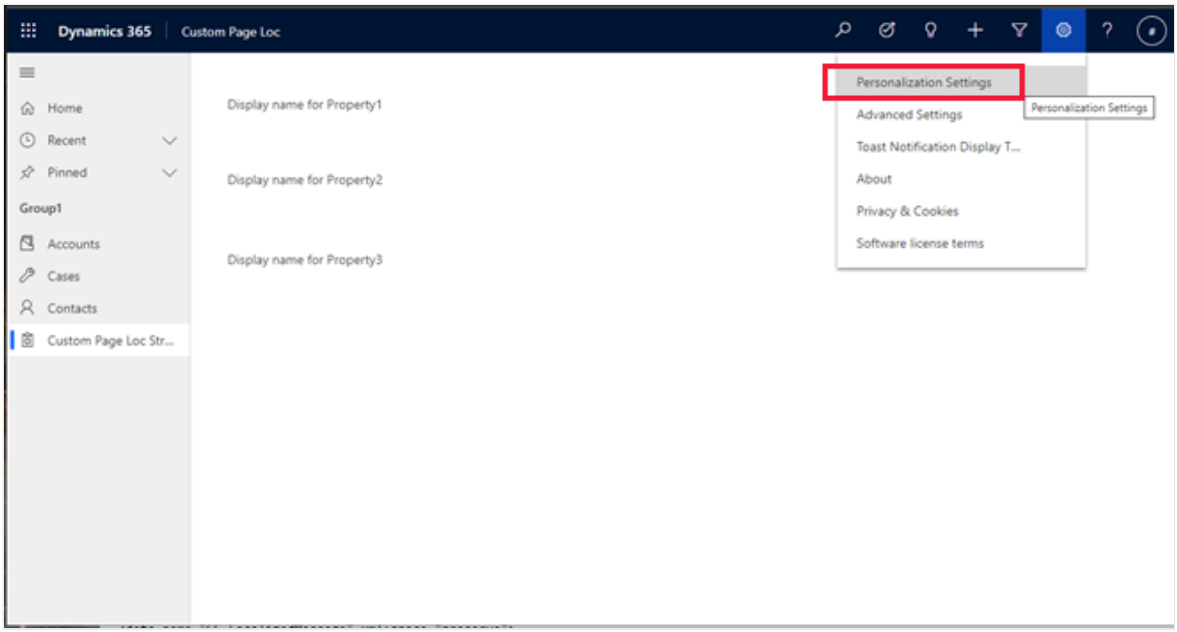


Run your app with the localized content

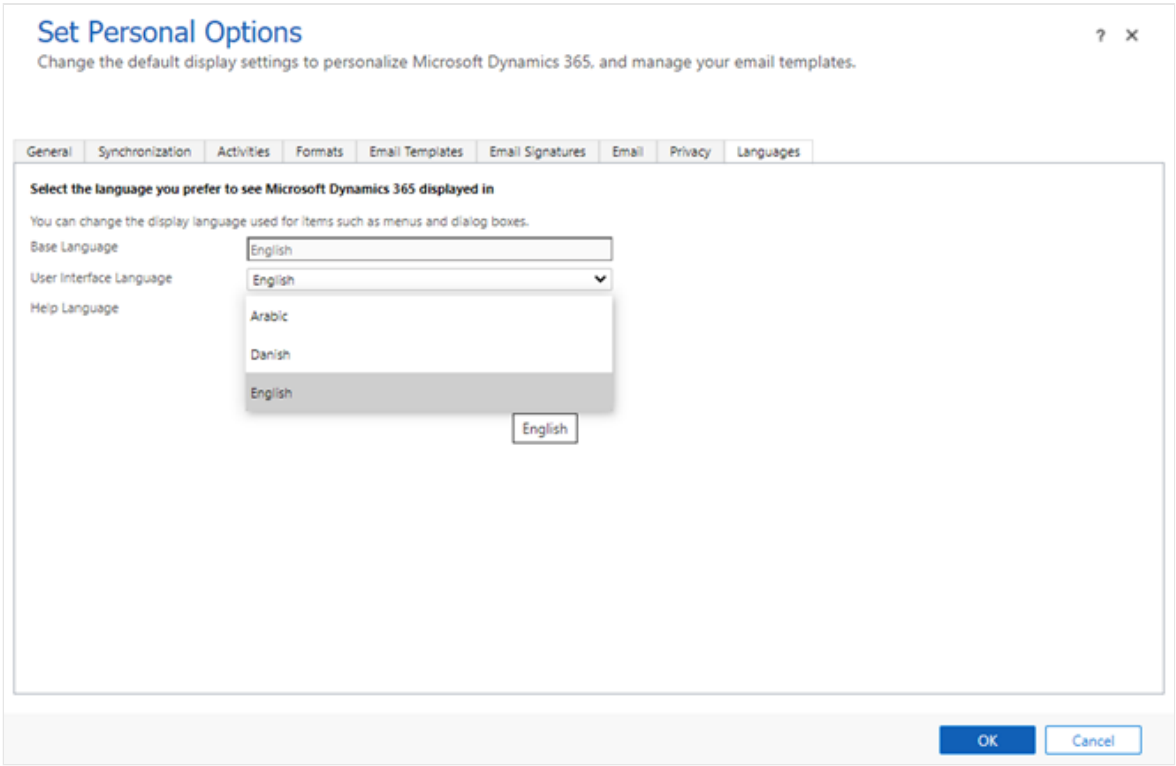
1. After publishing your page and your app, select **Play** in the app designer to open the app in a separate browser tab.

2. Select your custom page on the site map.

3. The labels for your controls display the localized content. Test each language added to your app and pages by selecting **Personalization Settings** under **Settings** (gear icon) at the top of the app.



4. Then, on the **Languages** tab, set the **User Interface Language** to the language you would like to test.



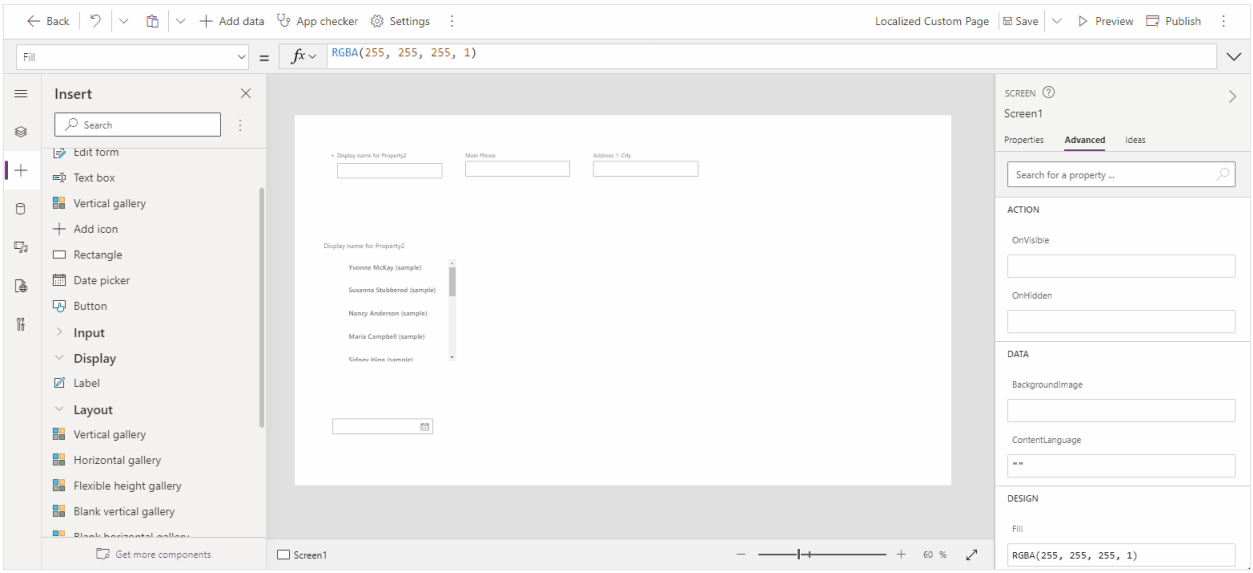
Right-to-left support for custom pages

With localized content, there are several languages that require a right-to-left orientation for content rendered on your page. Right-To-Left (RTL) is fully supported for languages like Arabic and Hebrew and the page will change at runtime automatically for these languages.

> ⓘ **Important**

Right-to-left orientation for icons, shapes, and images aren't currently supported in custom pages. If you add an icon, shape, or image it may not behave as expected, so please be careful when using these types of controls on your custom page.

To review RTL when building a custom page, you will need to go to the page settings, select upcoming features, search for RTL, and enable the setting. Setting this option shows an RTL or LTR button in the preview window where you can switch between orientation without having to run your app. If you would like to see your custom page running RTL, you can add &`flags=isRTL=true` to the end of the URL in your browser when running your app to test RTL for your page.



Known limitation for exporting solutions with resx files

Resx files don't automatically get added when you export your solution and import it into a new environment. This is a known limitation and will require you to upload your resx files into your new environment. So, if you have a developer environment, and you export your solution and import into a production environment, you'll need to add your resx localization files into your production environment solution.

Overview of custom pages for model-driven apps

Known issues with custom pages in a model-driven app

Article • 04/16/2025

The custom page is a new page type within model-driven apps. Custom pages bring the power of canvas apps into model-driven apps. Below are the known issues to be aware of.

> **Important**
>
> Using custom pages with mobile devices is currently in public preview. Offline and device capability controls like barcode scanning, capturing photos from device, or attaching files isn't supported.
>
> Custom pages aren't supported within **App for Outlook** and return an error on loading.

Maker-related issues

- When a custom page is modified, such as saved and published, the model-driven app isn't aware of the change. The model-driven app continues to use the last version of the custom page when the model-driven app was published. A model-driven app published through app designer, solution explorer, or **Publish all** updates all custom pages in the model-driven app.
- Images, icons, and shapes aren't currently supported with Right-To-Left (RTL) languages.
- The App.ConfirmExit property isn't supported in custom pages.
- The ability to get the current data formats from users settings including date, time, numbers, and currency isn't supported.
- Custom pages use a canvas app hosting session that can time out after 8 hours. However, the Unified Interface session has a longer timeout. When the timeout happens, an error message bar appears that prompts the user to refresh the browser.

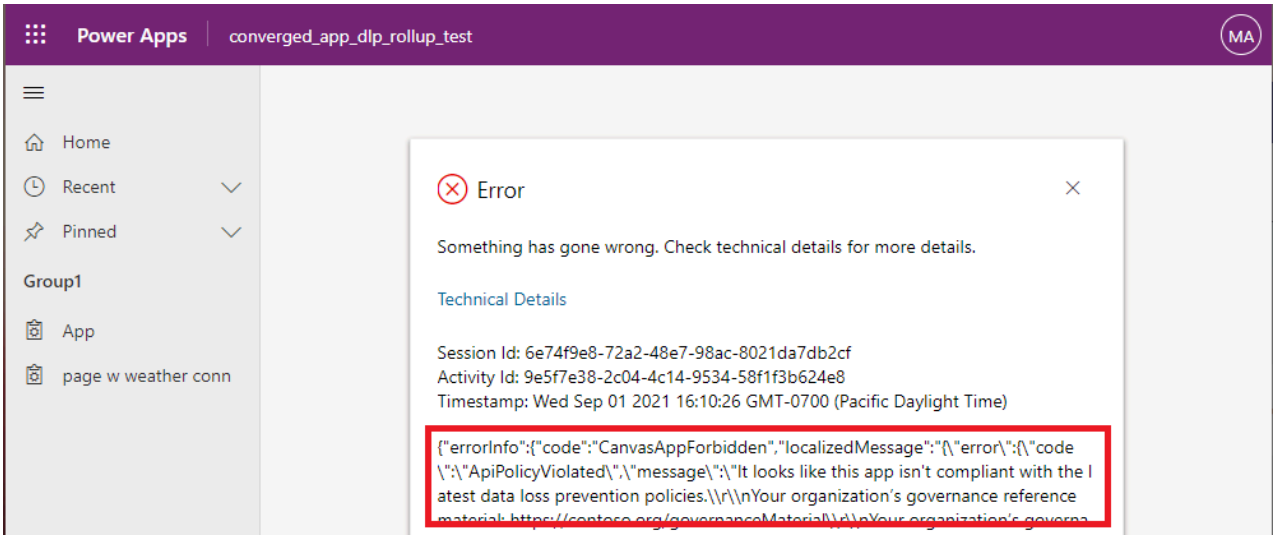
- When a custom page with code component is opened for editing, a security dialog is shown. Selecting **Go back** on the security dialog doesn't navigate back to the parent context. The user can close the browser tab to leave Power Apps Studio.

- Not all canvas app controls are available with custom pages. However, custom pages support the most common canvas app controls and custom pro-dev components. For more information about what is available, see Design a custom page for your model-driven app
- Makers need to share custom pages to allow another maker to make changes, which is a different behavior than the typical model-driven app components. If a custom page can't be shared from the **Solutions** area, open the environment in Power Platform admin center, and then open **Resources** > **Power Apps** > **Page** > **Share**. Similarly, to reuse the canvas app components inside the custom page, the corresponding canvas app component library also needs to be shared with the custom page makers.
- The maker experience for the custom page doesn't have support for certain Power Apps component framework APIs like `Navigation` and Web APIs, which is in line with the stand-alone canvas apps. However, these APIs are available in the published app where the custom page is added to model-driven apps. More information: Add code components to a custom page for your model-driven app.
- The maker experience for the custom page is currently not enabled in sovereign clouds. If you would like to enable it for a maker session, append "powerappsPortalApps.enableEditInShellAppDesigner=true" as a query parameter to the https://make.powerapps.com/ url.
- Makers can't use cross-environment Dataverse references in a custom page.

User-related issues

- When a user with no Power Apps user privileges opens a custom page in the model-driven app, they see an error mentioning no active entitlements to use Power Apps. More information: Licensing overview for Microsoft Power Platform and the associated licensing guide.
- Custom pages require third-party cookies to be enabled, which is required by the canvas app runtime.
- When a user is prompted for consent with connectors and selects **Don't allow**, the custom page renders but without data. The user doesn't get notified that data retrieval is skipped.
- After a model-driven app or custom page is changed and published, loading a custom page can take longer than normal, and no page loading spinner is shown.

- Native player support is available for iOS, Android, and Windows in online-only mode. Offline support currently isn't supported.
- When you go back to a custom page from another page, the page state isn't restored so the page appears like a new navigation. State is also not persisted when switching between multi-session tabs in multi-session apps. For more information about multi-session support with model-driven apps, go to Customer Service workspace sessions and tabs.
- While attempting to sign in, the current behavior caused by a user selecting anywhere away from the sign in box causes the pop out window for sign in to shift behind the app browser.
- When a user runs an app that isn't compliant with their organization's Data Loss Prevention (DLP) policies, they see an error dialog and the 'Technical details' reflects the app isn't DLP compliant.



- When there are multiple custom pages in an app, the consent dialog asks for data permissions for all of the connectors in all the custom pages even if they haven't yet been opened.

Connections

- All custom pages share the connection infrastructure, as if they were part of the same canvas app. For instance, if a model-driven app has two custom pages and one is connected to SQL Server while the other isn't, the consent dialog will still appear and require permission for SQL access even if the page being opened doesn't require it.
- Custom pages in model-driven apps don't support connection detection through the *Connected.connected* property.

- The number of connectors in a model-driven app, across all custom pages, shouldn't exceed 10. The number of connection references, across all custom pages, shouldn't exceed 20. The number of connectors and connection references can increase the wait time an app user experiences when the user plays an app with custom pages.
- The **App Permissions** dialog is not opened when a custom page is first opened by a user in the Power Apps mobile app. This behavior can cause the page to appear frozen, but is expected behavior. To resolve this issue, open the app in a browser to approve the permissions before playing it in the Power Apps mobile app. You can also run the AdminPowerAppApisToBypassConsent PowerShell command to bypass the need for the permissions dialog by a Power Platform administrator.

Model-driven app custom page overview

Use live monitor to troubleshoot page behavior in model-driven apps

07/19/2025

Live monitor can help you debug and diagnose problems, which help you build faster, more reliable model-driven apps. Live monitor provides a deep view into how an app runs by providing a log of all activities in your app as it runs.

> **Important**
>
> Live monitor must be run on the model-driven app and not directly on a custom page.

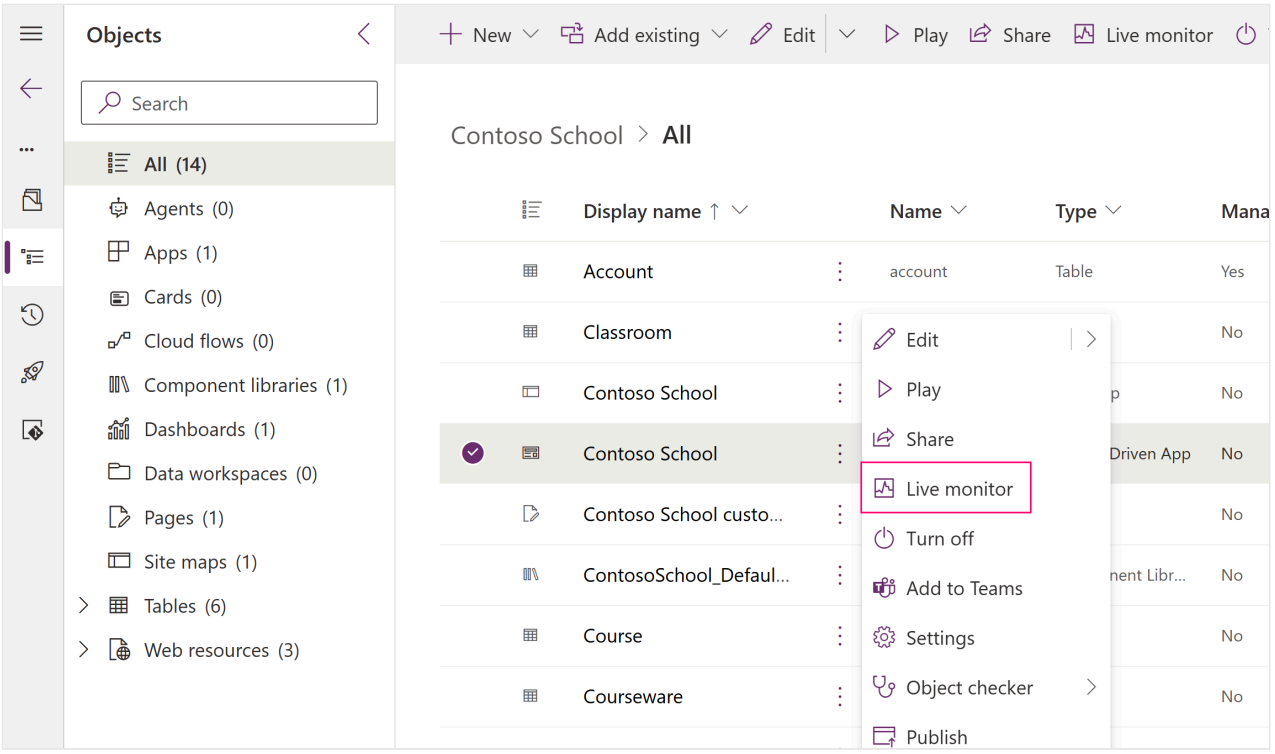
Start a live monitor session

There are two ways to open a live monitor session.

- From Power Apps
- From a model-driven app

From Power Apps

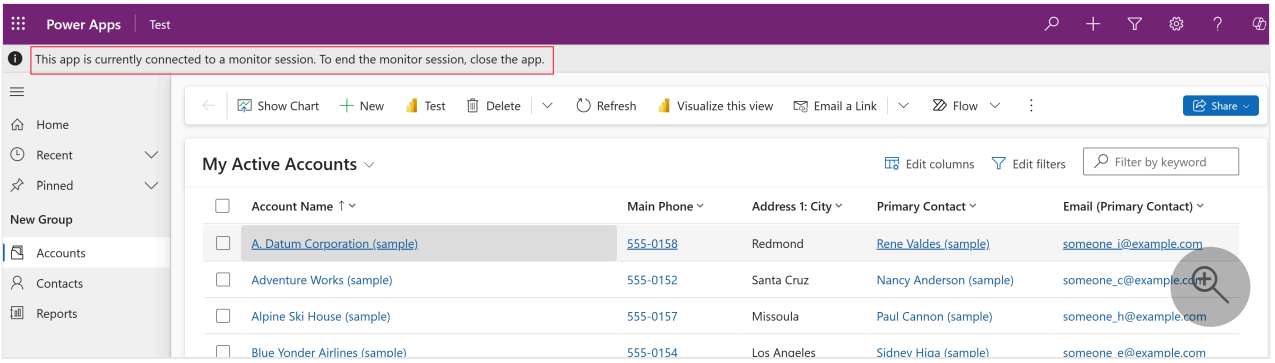
1. Sign in to Power Apps, select **Apps**.
2. Select **...** next to the model-driven app or on the global command bar, and then select **Live monitor**.



3. On the **Live monitor** browser tab that opens, select **Play model-driven app** on the command bar.

4. When prompted, select **Join**.

5. The app loads in a new browser tab with a message indicating the monitoring session. Switch back to the live monitor tab to view activity.

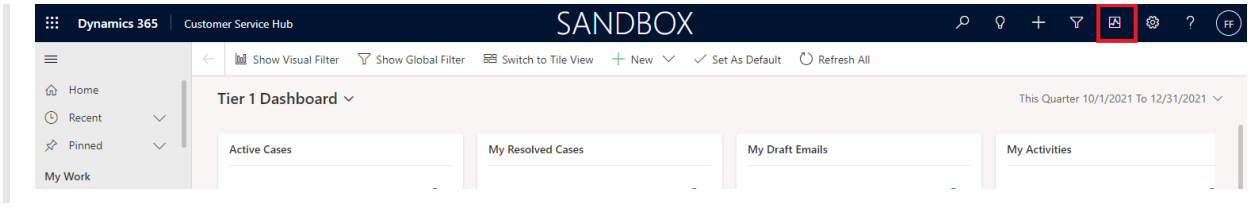


From a model-driven app

1. Play your model-driven app.

2. Add `&monitor=true` to the end of the URL in your web browser, and then refresh the page.

3. Select **Live monitor** on the command bar.



Filter monitored activity

When you filter on a model-driven app custom page-related events in live monitor, you can get information about related tables, tables, controls, and components, such as on a custom page, in live monitor as your app runs.

	Time	Cate...	Operation	Result	R	Status	Dura...	Data source	Control	Property	Resp...
1	10:40:11.9...	ScreenLoad	LoadScreen (Screen1)	Success			276				
2	10:40:12.1...	ScreenLoad	Navigate (Screen1)	Success			176				
3	10:40:12.1...	Network	getRows	Success		200	152	Contacts	Gallery1	Items	
4	10:40:07.3...	Network	XMLHttpRequest	Success			204	https://bugbash.cr...			
5	10:40:07.3...	Network	XMLHttpRequest	Success			6	https://bugbash.cr...			
6	10:40:07.8...	Network	Fetch	Success		200	193	https://bugbash.cr...			
7	10:40:07.9...	Network	Fetch	Success		200	190	https://bugbash.cr...			

For example, to filter on the custom page that uses the `Gallery1` control, select the **Control** column header > **Filter by**, enter *Gallery1*, and then select **Apply**.

For more information about model-driven app monitoring, go to Debug a model-driven app with live monitor

Close a live monitor session

To close the monitoring session, close the browser tab where the monitored model-driven app is playing.

Next steps

Use live monitor to troubleshoot model-driven app form behavior

Generate a page using natural language

Use natural language to build a *generative page* that's created using AI. Generative pages are an AI-driven experience designed to simplify, accelerate, and improve your app design process in model-driven apps. By interacting with the app agent, you create fully functional pages in your model-driven apps by describing what you need in natural language and specifying which Microsoft Dataverse tables to reference. You can even attach an image of what you'd like the page to look like.

After you describe the page, the system then processes your requirements and specifications and intelligently generates React code that covers both the front-end user experience by selecting the right components and determining the best layout, and the corresponding business logic. Through an interactive, conversational experience, you can refine the page design in real time, adjusting elements, layout, and functionality to perfectly match your vision.

Development approaches

You can create generative pages using two approaches:

- Power Apps (make.powerapps.com): As described in this article, makers can create and iterate on generative pages directly in the browser by using a conversational UI experience. Available in the United States, Great Britain, Australia, and Singapore.
- AI code generation tools: Developers who prefer working with local development tools and direct access to TypeScript and React code can use external tools like Claude Code to develop generative pages locally with a code-first approach and CLI-based deployment. Available worldwide on public clouds. More information: Create and edit generative pages with AI code generation tools

Prerequisites

- The Power Platform environment must be located in one of the following regions: United States, Great Britain, Australia, or Singapore.

Create a generative page in model-driven apps

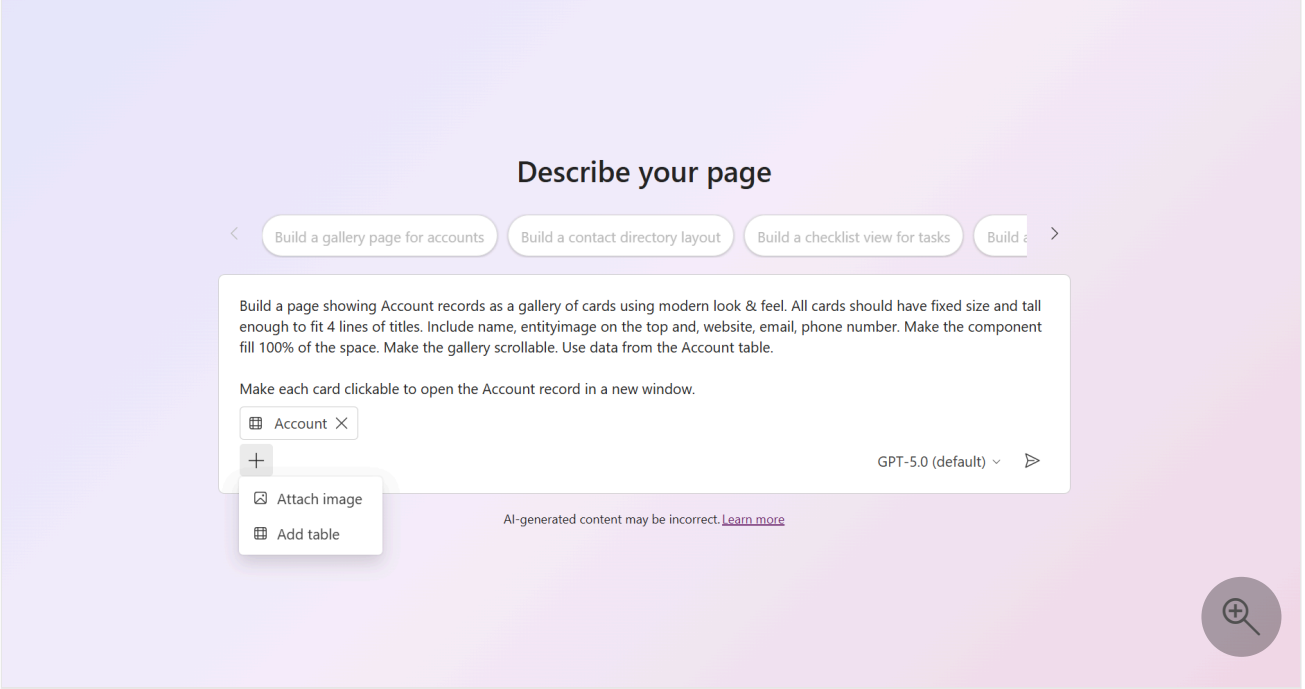
1. Sign in to Power Apps.
2. Open a model-driven app for editing.

3. In the app designer, select **Add a page** > **Describe a page**.

   A full-page generative page experience opens.

4. In the text box, type a description of the type of page you want to create. Include functional requirements and optionally any UX specifications. For example, you could enter *Build a page showing Account records as a gallery of cards using a modern look and feel. Include name, entityimage on the top, and website, email, phone number. Make the gallery scrollable by using data from the Account table*. If you want the page to support multiple languages, follow the guidance in Localize a generative page.

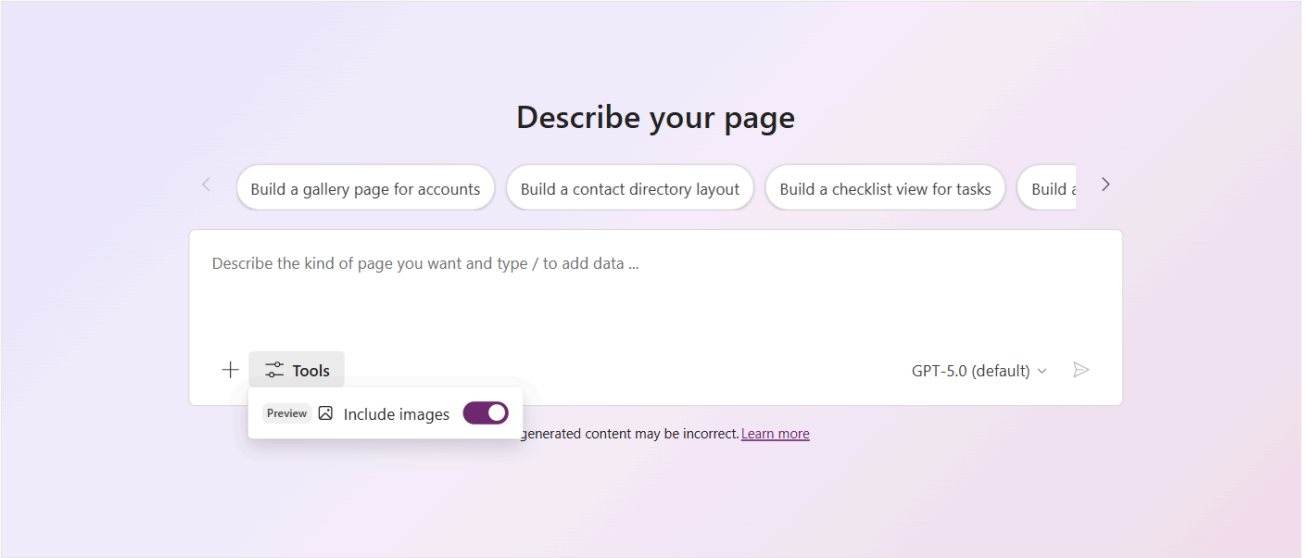
5. Add tables and images as appropriate by selecting **Add data** > **Add table**. You can link up to six Dataverse tables. In the screenshot, the account table is added.



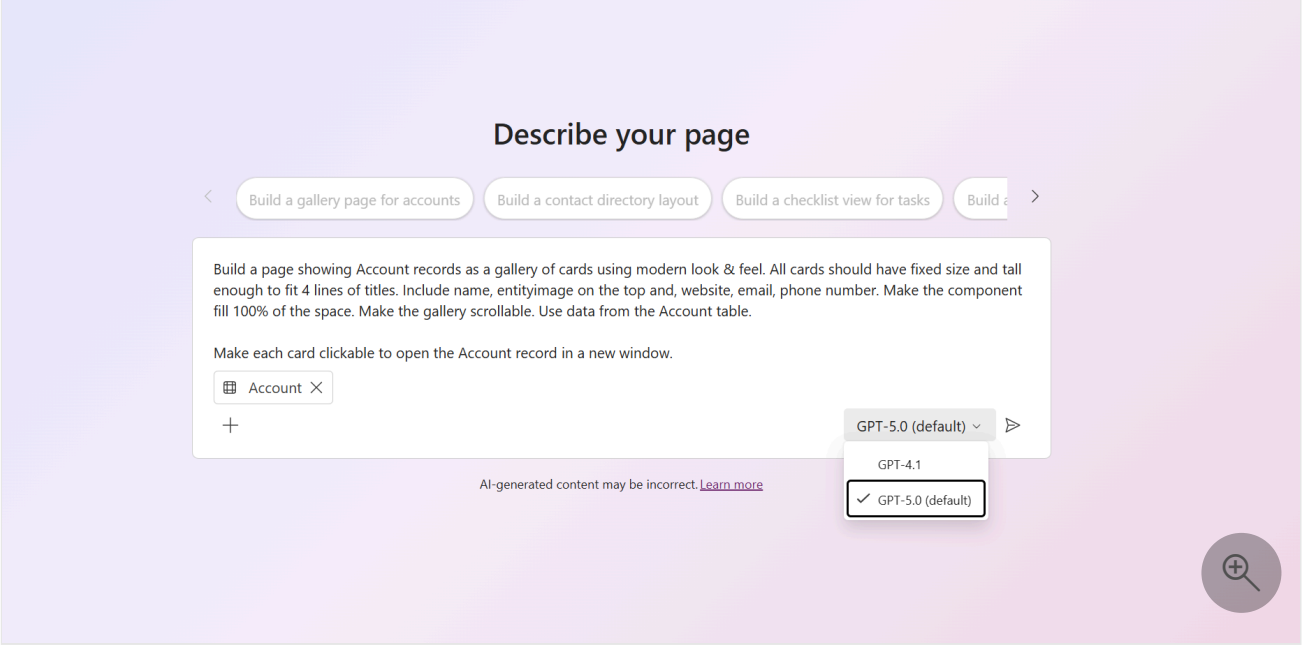
6. Optionally upload one or more images to guide the UI of your generated page by selecting **Add data** > **Attach image**. This can be a rough napkin sketch or a higher resolution image. The image can represent the structure or layout of the entire page you want to create or it can be visuals for a certain section or component you want to mimic.

> **Note**
>
> If you want the generated page to display a particular image, instead of attaching the image to the prompt, you can (1) include the image in a referenced Datatable table and have the agent retrieve the image from there, (2) host the image publicly and give the agent the URL, or (3) add the image as a web resource and give the agent the URL for the web resource.

7. Optionally enable or disable the **Include images** (preview) tool to allow the agent to utilize images from a curated, safe library of 25,000 stock images to support use cases like default/placeholder images, decorative backgrounds, static content blocks, and richer empty or error states.



8. Optionally choose the AI model you want to use to generate the page.



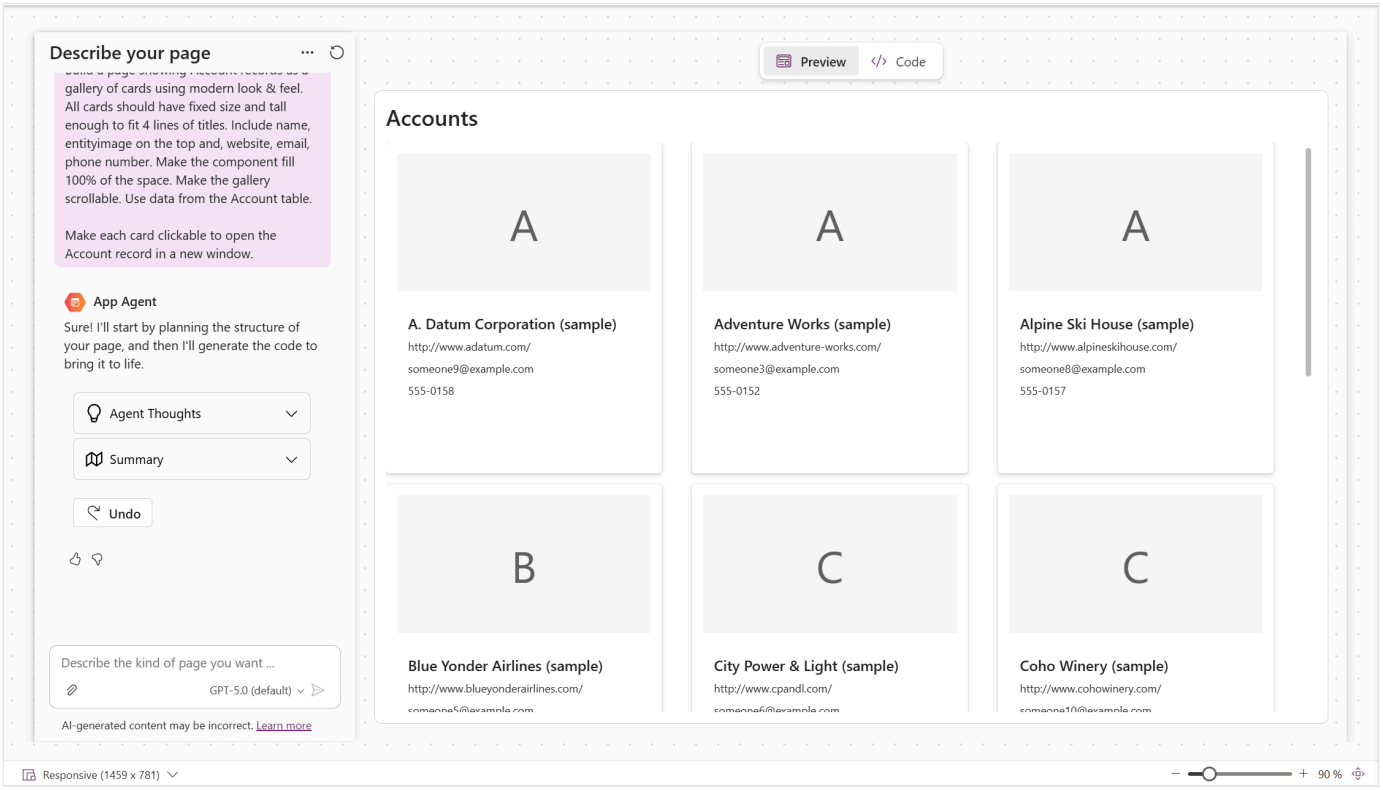
> **Note**
>
> GPT-4.1 is currently the only available model for generative pages.

9. When you're finished describing the page, select **Generate page**.

The agent begins a multistep build process that you can observe in real time:

- **Thought streaming**: The agent first outlines its interpretation of your prompt, listing requirements, assumptions, and an execution plan.
- **Code generation**: Next, it writes the underlying code for your page based on the plan.
- **Transpilation**: The generated code is then transpiled to ensure compatibility and proper rendering.
- **Final rendering**: Finally, the completed user experience is displayed.

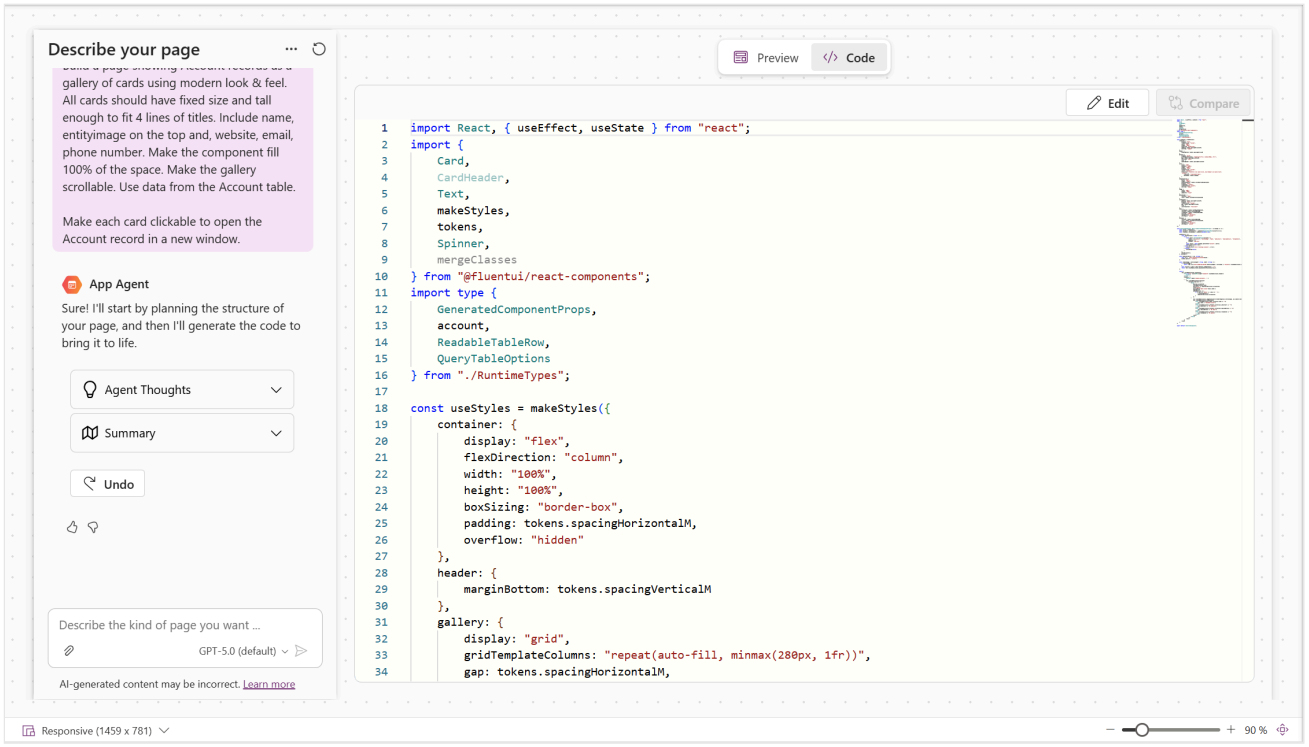
If the user experience isn't displayed at the end of this process, you can view it by selecting the **Preview** tab.



View the generated code, iterate, and publish

After generating your page, you have several options to refine and finalize it:

1. **View and edit the generated code** Select the **Code** tab to view the code generated by the app agent.



You can refine the output in two ways:

- Iteratively chat with the app agent to fix errors, adjust layout, or add functionality.
- Manually edit the code by selecting **Edit** on the Code tab. After making some edits, you can select **Save** to commit your changes as a new iteration, or **Cancel** to discard your changes.

Learn about the dataApi object methods used for data operations

2. **Compare iterations** After completing two or more iterations with the agent, you can select **Compare** on the Code tab to view a code diff between the current and previous iteration.

> **Note**
>
> This capability is currently only available starting with the second iteration in the current session.

3. **Attach a screenshot for quick reference** In the chat experience, select **Attach** > **Add screenshot** to include a screenshot of the current preview with your next interaction with the app agent. A screenshot is useful for helping to adjust the visuals of the page. You can alternatively attach other images to help refine the visuals of the entire page or a particular piece of the page.

4. **Check for accessibility issues (new)** After each iteration of code generation, the **Accessibility assistant** at the bottom of the screen scans the generated code assessing it

with respect to accessibility. You can see a high level status update directly on screen and can choose to open the detailed results in a panel. Select **Auto fix** to pass any violations directly to the agent for it to try to automatically resolve.

5. **Save and publish** In the command bar, select **Save** to avoid losing progress on your page. When you're satisfied with your page, select **Save and Publish** to publish all pending changes for the app, including any generative pages.

> **ⓘ Important**
>
> While the agent makes a best-effort attempt to generate complete, production-ready code, including considerations for accessibility and security best practices, you're ultimately responsible for validating the code. Ensure the generated code meets your organization's standards and compliance requirements.

Common tasks with generative pages

This section covers common scenarios and tasks when working with generative pages in your model-driven apps.

Set up a page to accept input parameters

Generative pages can accept the input parameters `recordId`, `entityName`, and `data` enabling them to receive contextual data when navigated to. To configure a page to accept parameters, describe what the page should accept in your prompt and the agent wires up the initialization code automatically. For example:

```
Set up the page to accept an account recordId. When the page loads, use these to fetch and display the corresponding account details.
```

```
Configure this page to accept a data parameter containing a custom filter object. Use it to filter the displayed records when the page loads.
```

Navigate to a generative page

You can navigate to a generative page programmatically using `Xrm.Navigation.navigateTo`, passing input parameters if the target page is set up to receive them. For examples and full API details, see Navigate to and from a generative page using Client API.

Use specific images in a page

There are three approaches to using specific images in your generative pages.

Store images in a Dataverse table

Include the image in a Dataverse table that's referenced by your generative page, and instruct the agent to retrieve the image from there. When creating your page, tell the agent how to get the right image from your table.

```
Build a product catalog page showing products from the Product table. Display the product image from the ProductImage column, along with the name, description, and price.
```

Host images externally and reference by URL

Host your images on an external server or content delivery network (CDN) and provide the agent with the URL to the image:

```
Display the company logo using this URL: https://example.com/images/logo.png at the top of the page.
```

Add images as web resources

Upload the image as a web resource in your solution and reference it by its web resource URL:

1. Add the image as a web resource in your solution.
2. Note the web resource name (for example, `new_/images/banner.png`).
3. Reference it in your prompt or code using the web resource URL format described here:

```
Use the banner image from web resource new_/images/banner.png as the page header background.
```

Adding generative pages to solutions

Generative pages are solution-aware and can be added to a solution (via an app) to facilitate moving between environments. To add a generative page to a solution, do the following:

> **Important**
>
> If your generative page was created during the preview phase, you must load the generative page in the model app designer to initiate a one-time migration to the new solution-aware data model. When the page loads in the designer, you observe an "Upgrading your page" progress message. Don't close the window until migration completes.

1. Add the app containing your generative pages to a solution

    - In Power Apps, select **Solutions** on the left navigation pane, and open the desired solution.
    - Select **Add existing** > **App** > **Model-driven app**.
    - Select the app that contains the generative pages.

2. **Export the solution** (as managed or unmanaged)

    - Ensure the app sitemap is included in the solution. If not, it should be requested during dependency checks.
    - Generative pages (shown as **UX Agent Project** rows) are also requested based on their dependency on the sitemap.

> **Note**
>
> Check these items if no generative pages are requested during dependency checks:
>
> - Pages created during preview will only appear if they've been migrated. Load them in the designer to trigger migration.
> - If the sitemap is included in the solution and your generative pages have been migrated, try making a minor change to the sitemap, such as reordering or renaming a page, republishing the app, and then trying the export again.

After export, you can import the app and generative pages into another environment. When opened in the designer in the target environment, only the first prompt and published code are available. The full agent conversation doesn't transfer with the page.

Localize a generative page

To localize a generative page, ensure your prompt covers the follow items:

- Specify your languages. Tell the agent which languages you want the page to support, ideally language name and LCID.
- Request translated text. Ask the agent to create a translation dictionary for all user-visible labels and text in the page for each language.
- Enable RTL support. If your environment includes an RTL language like Arabic or Hebrew, ask the agent to implement the appropriate right-to-left layout support.
- Use regional formatting. Ask the agent to format dates, numbers, and currency using each user's preferences from their Dataverse user settings, rather than using hardcoded formats or locale codes.

For detailed implementation guidance and code patterns, go to the localization instructions in the Power Platform Skills repository.

> **Note**
>
> The sitemap entry for a generative page isn't localized by default. Sitemap localization needs to be handled separately in the app designer.

Limitations

These are the current limitations of generative pages:

- Your page can connect to only Dataverse tables (up to 6 for a single page). No other data sources can be used.
- Your prompt can have a maximum of 50,000 characters.
- When you create generative pages through in Power Apps (make.powerapps.com), only US English is a supported prompting language.
- Collaboration isn't supported. Ensure only one maker is working on a generative page at a time to avoid unintended conflicts.
- Only these data types are supported:
  - Choice
  - Currency
  - Customer
  - Date and Time

- Date Only
- Decimal Number
- Floating Point Number
- Image
- Lookup
- Multiline Text
- Status
- Status Reason
- Text
- Whole Number
- Yes/No
- Unique Identifier

Frequently asked questions

Can I start designing my app in Plan Designer and then use generative pages?

Yes, while there's currently no direct integration between plans and generative pages, you can use plans to define your tables and apps, and then switch to the model-driven app designer to create any desired generative pages.

Are there any additional fees or credits needed to use generative pages?

No, the maker experience for generative pages (and plans) don't require any additional AI or message credits.

What kind of images work best for guiding the UI generation?

It depends on your goal. If you know exactly how you want the final page to look, clear and detailed sketches or wireframes (whether hand-drawn or digital) are most effective. If you only have a general concept and want the agent to fill in the details, quick whiteboard sketches or even napkin drawings can work well.

Can I use generative pages with canvas apps or other app types?

No, generative pages are currently only supported in model-driven apps.

Is there a way to reuse or clone a generative page across environments?

Yes, generative pages are solution-aware elements that can be moved across environments. Only the last published version of the code and the first prompt are maintained with the solution; the full revision history remains on the original environment.

Can I edit the generated code manually?

Yes. You can manually edit the generated code by selecting **Edit** on the **Code** tab. Your changes are saved as a new iteration. Select **Cancel** to cancel your edits if you choose not to keep them.

Is the code generated by generative pages guaranteed to be production-ready and compliant with my organization's standards?

No. While the agent makes a best-effort attempt to produce high-quality, production-ready code with accessibility and security best practices in mind, it's your responsibility to validate the output. Always review the generated code to ensure it aligns with your organization's standards, policies, and compliance requirements.

How do I give feedback on the feature?

The best way to give feedback on generative pages is to use the thumbs up/down buttons in the chat experience that are available after each iteration. We also strongly encourage you to select **Yes** on **Share relevant content samples and additional log files** so that we can debug or attempt to recreate any issues you encountered with the feature.

What if I don't see generative pages enabled in my environment?

Confirm that your environment is in one of the supported regions for the Power Apps maker studio experience: United States, Great Britain, Australia, or Singapore. If your region isn't listed, you can still create and edit generative pages using AI code generation tools, which are available worldwide on public clouds. Create and edit generative pages with AI code generation tools

This article describes how to use AI code generation tools, such as GitHub Copilot CLI and Claude Code, to create and edit generative pages for model-driven apps in Power Apps. This approach allows you to integrate advanced code generation capabilities directly into your development workflow, allowing you to create new generative pages or iterate on existing ones using natural language instructions.

Using AI code generation tools with generative pages provides an alternative development approach that complements the UI-based experience in Power Apps (make.powerapps.com). This code-first approach is designed for developers and technical makers who prefer working with local development tools and CLI-based workflows.

What you can do with code generation tools

- *Create new generative pages* using plain-language requirements
- *Update existing generative pages* by requesting changes or enhancements through your AI tool
- *Deploy directly* to your Power Apps environment using PAC CLI commands
- *Work locally* with your preferred IDE and development tools

How it works

1. You describe what you want to build in natural language, for example, "Create a generative page dashboard showing top accounts by revenue."
2. The AI code generation tool uses installed generative page skills or other context about generative pages to ask clarifying questions about your requirements.
3. The tool generates production-ready TypeScript and React code for your generative page.
4. The tool deploys the code to your environment using generative page PAC CLI commands.
5. Your generative page appears in your model-driven app.

Prerequisites

Before you start, ensure you have the required software and permissions described here.

Software requirements

Expand table

Component	Minimum version	More information
Node.js	18.0 or later	Download Node.js
Power Platform CLI (PAC CLI)	Latest	Install PAC CLI
GitHub Copilot CLI, Claude Code, or other code generation tool	Latest	GitHub Copilot CLI or Claude Code

Additional requirements

- A Power Platform environment with a model-driven app to deploy pages.
- An *authenticated PAC CLI session* connected to your target environment.
  - Go to Authenticate Power Platform CLI for more details on getting connected.

> **Note**
>
> This capability is available worldwide in public clouds.

Install the plugin

Run the installer to set up all Power Platform plugins in either PowerShell or a Windows command window.

PowerShell

```
iwr https://raw.githubusercontent.com/microsoft/power-platform-skills/main/scripts/install.js -OutFile install.js; node install.js; del install.js
```

dos

```
curl -fsSL https://raw.githubusercontent.com/microsoft/power-platform-skills/main/scripts/install.js | node
```

The installer automatically:

- Detects available tools (Claude Code, GitHub Copilot CLI)
- Registers the plugin marketplace and installs all plugins

- Enables auto-update so plugins stay current

After installation, restart your AI tool if needed.

Install only the generative page plugin

To install only the generative page plugin for GitHub Copilot CLI or Claude Code:

1. Add the Power Platform Skills marketplace plugin: `/plugin marketplace add microsoft/power-platform-skills`
2. Install the Power Apps plugin: `/plugin install model-apps@power-platform-skills`

> **Note**
>
> For Claude Code, you can install the plugin with different scopes, such as global, local, or user. Depending on the scope, you need to be in the correct directory for Claude Code to use the plugin. Go to Extend Claude with skills

Once installed, you can use the plugin by either:

- Running the `/genpage` command explicitly.
- Describing the page you want to create. The tool automatically detects and uses the plugin.

> **Tip**
>
> Turn on auto-update to automatically receive updates to the marketplace and skills. Use the `/plugin` command, navigate to **Marketplaces**, choose the marketplace, and turn on auto-update.

Using other AI code generation tools

For other AI code generation tools, ensure your tool has access to the generative page resources from the Power Platform skills GitHub repository. The model-apps plugin folder includes component documentation, sample code, PAC CLI command reference, and workflow instructions necessary to create code adhering to generative page requirements, including how to create pages that support multiple languages and regions. Consult the repository readme for information about accessing and using these resources with your preferred tool.

Skills overview

The Power Apps plugin provides this skill for working with generative pages.

Expand table

Skill	Command	Description
Generative pages	`/genpage`	Create code for generative pages (for creation or editing scenarios)

This skill enables you to describe what you want to build and have the AI tool generate complete TypeScript and React code for your generative page, then deploy it directly to your Power Apps environment.

Create a new generative page

Follow this workflow when building a new page from scratch.

1. Start a conversation with your AI tool. Describe what you want to create, including what data you want to include (which Dataverse tables or whether to create sample mock data). Be as specific as you want—the more vague you are with the request, the more details the agent tries to fill in itself. You can also attach or provide an image or other materials to help guide the visuals, theming, and layout. For example:

    - "Create a generative page dashboard showing our top 10 accounts by revenue using the Account table"
    - "Build a generative page form for creating and editing contact records with sample data"
    - "Make a generative page for displaying incident reports on a map using the Incident table"
    - "Create a generative page for a sales pipeline visualization with opportunities using the modern blue theme"

2. Answer clarifying questions. The AI tool asks questions to understand your requirements. Be specific about business needs and data requirements, identify mobile requirements early, and mention any specific UI components or layout preferences.

3. Review the implementation plan. The AI tool presents a plan describing the components to be built, Dataverse tables and columns to be used, key features and interactions, and data retrieval approach. Confirm the plan meets your requirements or request changes.

4. Review code and deploy. The AI tool generates complete TypeScript code. Ask the tool to publish or deploy your page when you're ready, optionally specifying a sitemap name (the tool generates a meaningful name by default).

5. Test and iterate. Open your model-driven app in Power Apps and navigate to the new page using the sitemap. If you need to make changes, return to your AI tool and describe the updates using natural language.

> **Note**
>
> You can change the name or position of the generative page in the sitemap at any time from the model-driven app designer.

Edit an existing generative page

Use this workflow to update a page that already exists in your environment.

1. Retrieve the existing page. In your AI code generation tool, request to retrieve the existing generative page by providing the page ID (GUID) or the page name in the sitemap and the app it's in. For example, "I want to update the Pet Adoption generative page from the Demo app."

2. Describe your updates. Tell the AI tool what changes you want to make. For example:

   - "Add a filter to show only active records"
   - "Change the layout to display cards in a grid instead of a list"
   - "Add a chart showing adoption trends over time"
   - "Update the form to include the new custom field for pet temperament"

3. Review, publish, test, and iterate. The AI tool generates updated TypeScript code based on your requested changes. Follow the same review, publish, and test process described in the "Create a new generative page" section. Continue iterating with natural language instructions until the page meets your requirements.

Set up a page to accept input parameters

Generative pages can accept the input parameters `recordId`, `entityName`, and `data`, enabling them to receive contextual data when navigated to from other pages or code. When you

instruct the AI tool to configure input parameters, it generates the appropriate initialization code so the page reads and uses those values when it loads.

Describe the parameters you want in your prompt:

- "Set up the page to accept an Account recordId and entityName. When the page loads, use these parameters to fetch and display the corresponding account details."
- "Configure this page to accept a data parameter containing a custom filter object. Use it to filter the displayed records when the page loads."

To navigate to the page and pass these parameters, see Navigate to and from a generative page using Client API.

Localization

When you create a generative page using the Power Apps plugin for Claude Code or GitHub Copilot CLI, localization is handled automatically. The agent detects all languages enabled in your environment and generates code so that the page works with all of those languages. The page respects each user's preferred language and regional formatting preferences for dates, numbers, and currency.

If you want to target a different set of languages than those enabled in your environment, you can ask the agent to adjust, for example:

> "Update this page to support English, French, and Spanish only."

> **Note**
>
> The sitemap entry for a generative page isn't localized by default. To localize sitemap entries, update them separately in the app designer.

For more information, go to the localization instructions in the Power Platform Skills repository.

Troubleshooting

Page fails to load in Power Apps

If you navigate to your generative page and observe an error message or blank screen:

1. Open browser developer tools (F12 in most browsers).
2. Select the **Console** tab.
3. Copy the complete error message, including the stack trace.
4. Return to your AI code generation tool and paste the error with context:

   "I'm getting this error when opening the page: [paste error here]. Please fix the issue."

   The AI tool analyzes the error, identifies the root cause, and generates a fix.
5. Review the fix and ask the tool to republish the page.

Reverting to a working version

If recent changes broke your page or made issues worse, you can ask the AI tool to roll back to a previous working version:

"The recent changes broke the page. Please revert to the last working version."

The AI tool then:

1. Identifies the changes that were made
2. Restores the previous working code
3. Redeploys the stable version

Best practices

- Start simple. Begin with a basic version of your page and iterate to add complexity.
- Test frequently. Deploy and test your page after each significant change.
- Be specific. Provide detailed requirements to get better initial results.
- Use existing patterns. Reference similar pages or UI patterns when describing your requirements.
- Validate generated code. Always review the generated code to ensure it meets your organization's standards and compliance requirements.

> **ⓘ Important**
>
> While AI code generation tools make a best-effort attempt to generate complete, production-ready code with accessibility and security best practices, you're ultimately

responsible for validating the code. Ensure the generated code meets your organization's standards, policies, and compliance requirements.

Limitations

The limitations for generative pages created with AI code generation tools are the same as those for generative pages created in the Power Apps maker portal:

- Your page can connect to only Dataverse tables.
- Collaboration isn't supported—ensure only one maker is working on a generative page at a time.
- Only these data types are supported: Choice, Currency, Customer, Date and Time, Date Only, Decimal Number, Floating Point Number, Image, Lookup, Multiline Text, Status, Status Reason, Text, Whole Number, Yes/No, Unique Identifier.

Navigate to and from a generative page using client API

This article provides examples of navigating to generative pages in model-driven apps by using the client API navigateTo method. Learn how to open generative pages inline or in a dialog, and how to pass input parameters such as a record ID or custom data.

> ⓘ Note
>
> This method is supported only on Unified Interface.

Find the page ID

Each of the following examples requires the ID of the target generative page. To find the page ID:

1. Open the model-driven app containing the generative page in the app designer.
2. Select the generative page in the pages list.
3. In the properties pane, copy the GUID shown in the **Generative page** field.

Open a generative page inline without parameters

Opens a generative page as a full-page inline view with no input parameters.

JavaScript

```
var pageInput = {
    pageType: "generative",
    pageId: "<genPageID>"
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
```

```
        }
    );
```

Open a generative page inline with record context

Passes a `recordId` and `entityName` to the generative page so the page can load and display a specific record. The target generative page must be set up to accept these parameters.

JavaScript

```
var pageInput = {
    pageType: "generative",
    pageId: "<genPageID>",
    entityName: "account",
    recordId: "00aa00aa-bb11-cc22-dd33-44ee44ee44ee" // replace with actual record
GUID
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open a generative page inline with custom data

Passes a `data` object containing custom key-value pairs to the generative page. The target generative page must be set up to accept these parameters.

JavaScript

```
var pageInput = {
    pageType: "generative",
    pageId: "<genPageID>",
    data: { status: "active", category: "premium" }
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
```

```
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open a generative page as a centered dialog

Opens a generative page in a centered dialog, passing both record context and custom data. Adjust `width` and `height` as needed.

JavaScript

```
var pageInput = {
    pageType: "generative",
    pageId: "<genPageID>",
    entityName: "account",
    recordId: "00aa00aa-bb11-cc22-dd33-44ee44ee44ee", // replace with actual record
GUID
    data: { view: "summary" }
};
var navigationOptions = {
    target: 2,
    position: 1,
    width: { value: 70, unit: "%" },
    height: { value: 80, unit: "%" },
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open a generative page as a side dialog

Opens a generative page as a side dialog using `position: 2`.

JavaScript

```
var pageInput = {
    pageType: "generative",
    pageId: "<genPageID>"
};
var navigationOptions = {
    target: 2,
    position: 2,
    width: { value: 500, unit: "px" },
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Unsupported: Open a generative page in a side pane

> **ⓘ Important**
>
> Opening a generative page by using `Xrm.App.sidePanes.createPane()` isn't currently supported.

JavaScript

```
// Not supported — page content doesn't render
const pane = await Xrm.App.sidePanes.createPane({
    title: "My Generative Page",
    paneId: "GenPage",
    canClose: false,
    width: 400
});
pane.navigate({ pageType: "generative", pageId: "<genPageID>" });
```

Use a centered or side dialog via `Xrm.Navigation.navigateTo` instead.

Navigate from within a generative page using client API

When you navigate from inside a generative page component, use `(window as any).Xrm` to access the Xrm object, since the React component scope doesn't provide direct access to it.

Navigate to another generative page with record context and custom data

TypeScript

```
const xrm = (window as any).Xrm;
xrm.Navigation.navigateTo({
    pageType: "generative",
    pageId: targetPageId,
    entityName: "account",
    recordId: selectedRecordId,
    data: { view: "summary" }
});
```

> **Note**
>
> When you navigate within model-driven apps, avoid constructing raw URLs or manipulating `window.location`.

Navigate to a generative page via URL (external callers only)

You can navigate to a generative page by constructing a URL with the following structure:

```
https://<your-org>.crm.dynamics.com/main.aspx?appid={app-id}&pagetype=genux&id={page-id}&recordid={recordId}&entityname={entityName}&data={encoded-json}
```

You must URL-encode the `data` parameter as JSON. For example, to pass a custom filter object:

```
https://<your-org>.crm.dynamics.com/main.aspx?appid={app-id}&pagetype=genux&id={page-id}&data=%7B%22status%22%3A%22active%22%7D
```

You must set up the target generative page to accept these parameters.

Add or remove forms, views, or charts

Article • 07/11/2024

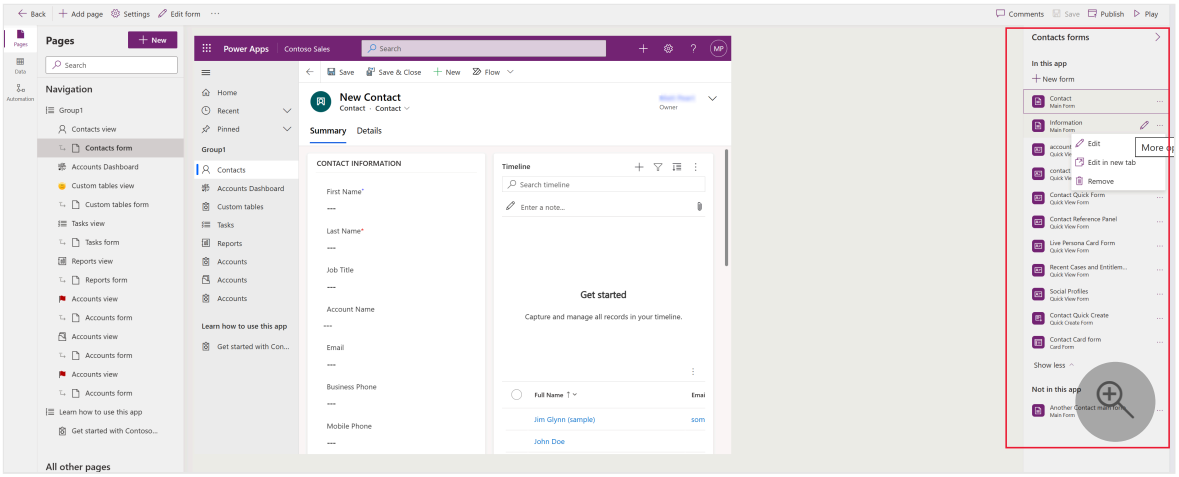
Add or remove one or more forms, views, or charts for a model-driven app.

Add or remove forms from an app

To add or remove forms for a model-driven app, follow these steps:

1. In the app designer, on the left navigation pane select **Pages** and then select a table form, such as the **Contact form**.

2. On the right forms pane, the list of available forms is displayed. Forms that are available in the app appear under **In this app**. Forms available to add but not displayed in the app appear under **Not in this app**. To remove a form that's displayed, select **...** > **Remove**. To add a form that isn't displayed, select **...** > **Add**.



> **Note**
>
> By default, all forms are selected and made available in the app. Select specific forms to enable only those forms you want available in the app.

3. Select **Publish** to make the changes available to other users.

Manage views and charts

To add or remove one or more views or charts for a model-driven app, follow these steps:

1. In the app designer, on the left navigation pane select **Pages** and then select the table you want to update, such as the **Accounts view**.
2. On the right properties pane, select the **Views** or **Charts** tab.
3. Next to the views or charts you want to add or remove, select ..., and then select **Remove**, or if the item is under **Not in this app**, select **Add**.
4. Select **Save**.
5. Select **Publish** to make the changes available to app users.

> **Note**
>
> By default, all views and charts are selected and made available in the app. Select specific views or charts to enable only those components you want available in the app.

Enable your app and custom tools in Microsoft 365 Copilot

[This topic is pre-release documentation and is subject to change.]

Power Apps in Microsoft 365 Copilot lets users interact with your model-driven app directly from Copilot. When a user talks to the agent, it can surface your app's data as interactive widgets, a grid for browsing records or a form for viewing, editing, or creating them, all without leaving the Copilot experience. Additionally, you can add custom MCP tools and interactive UI to the app's declarative agent. This functionality is achieved via MCP apps which is an extension to MCP that enables MCP servers to deliver interactive user interfaces to hosts. The feature works by generating an MCP server and declarative agent from your app.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

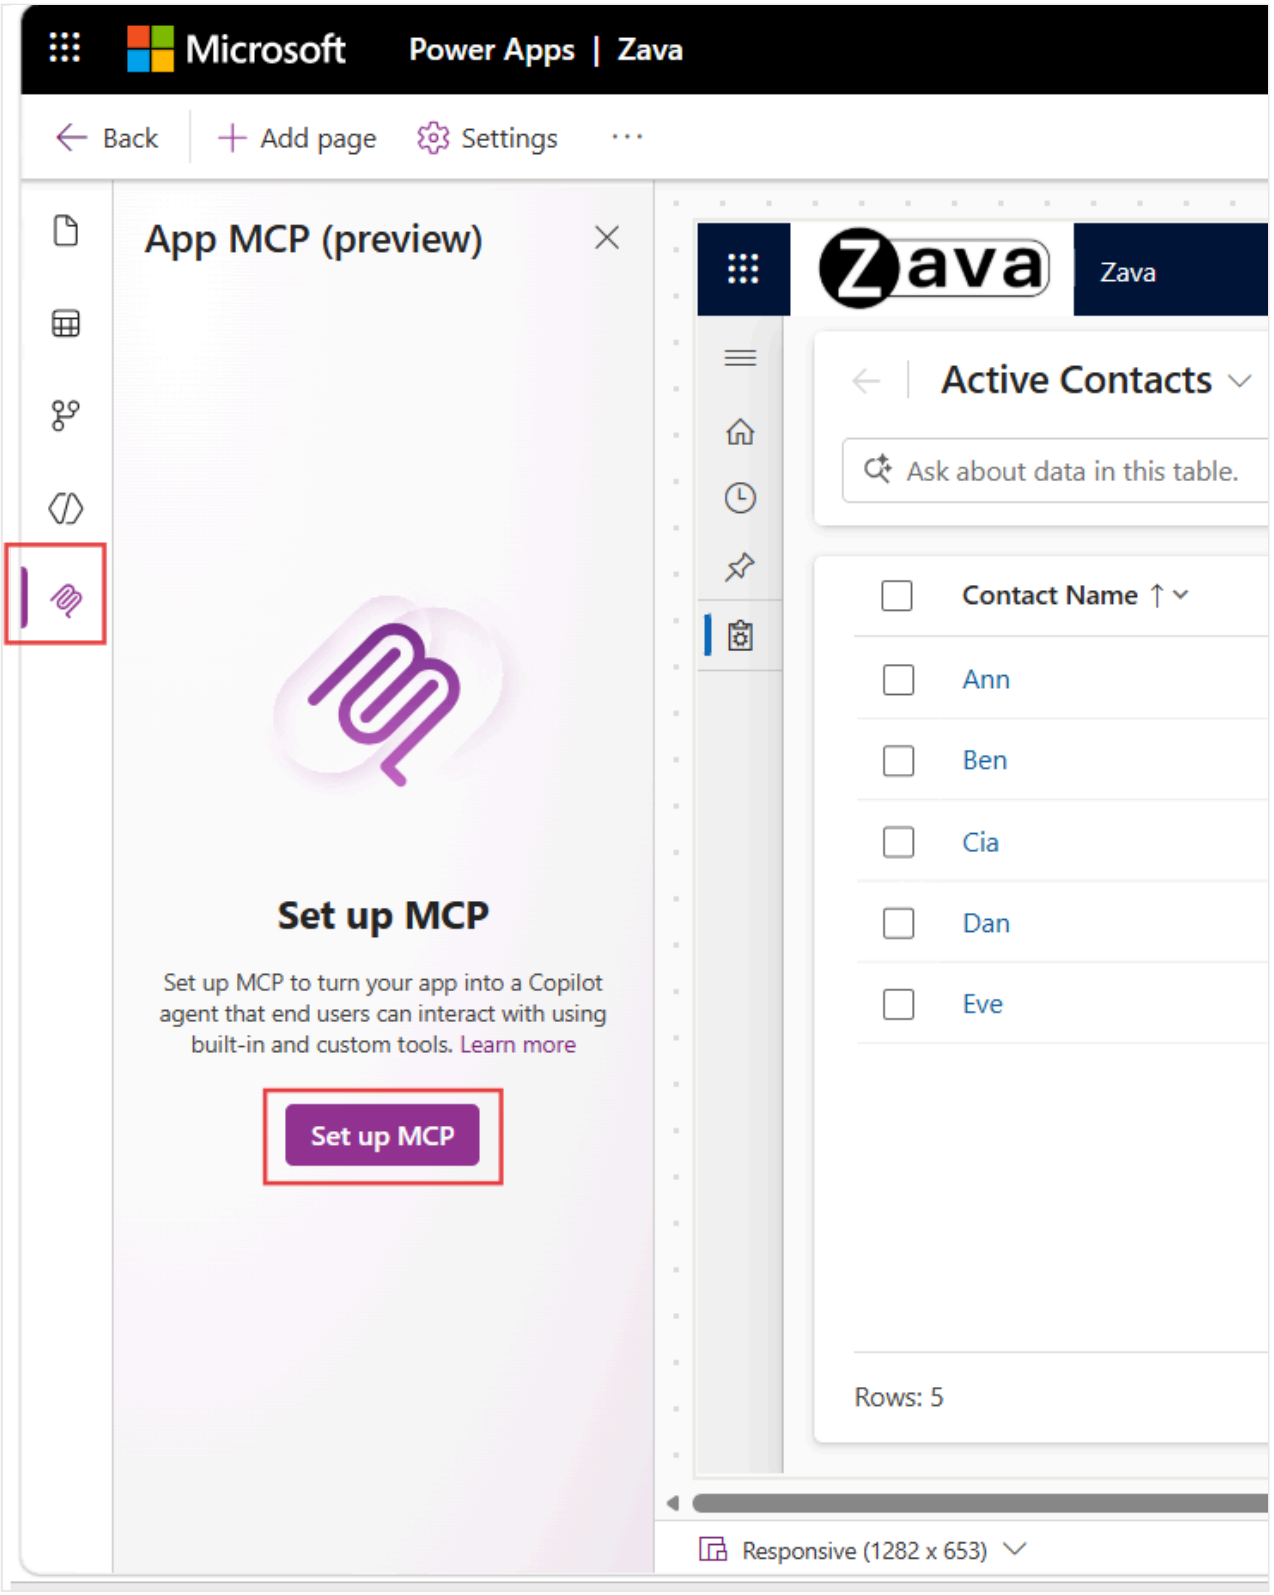
Prerequisites

- A model-driven app. Currently, this feature is only available with model-driven apps.
- Microsoft 365 Copilot license. Required for both the maker deploying the agent and end users interacting with it.
- Permission to upload custom apps in Microsoft Teams. Your Microsoft 365 admin might need to enable this. Check your Teams admin settings if the upload option is not visible.

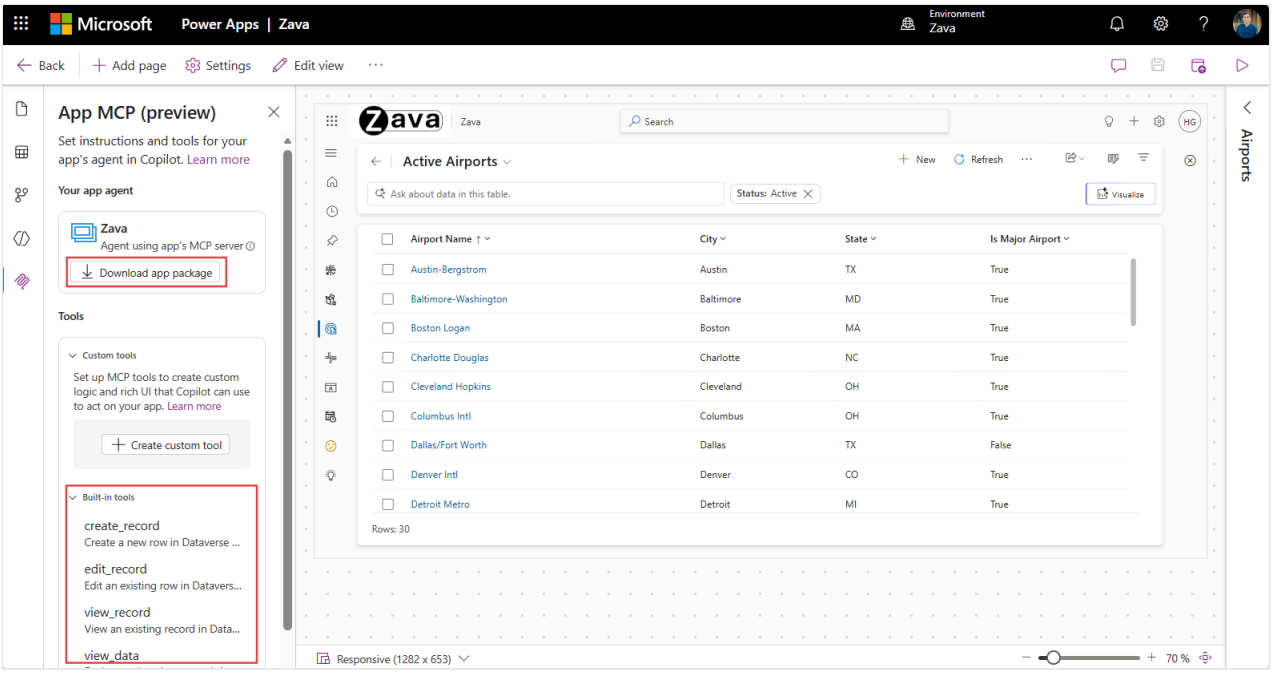
Set up Power Apps in Copilot

1. Go to Power Apps, select the environment you want, and then open the desired model-driven app.

2. Select the **App MCP** icon on the left navigation bar, and then select **Set up MCP**. This action sets up the MCP server for the app, which provides MCP tools for Copilot conversations. This is a one-time step and may take a few seconds to complete.



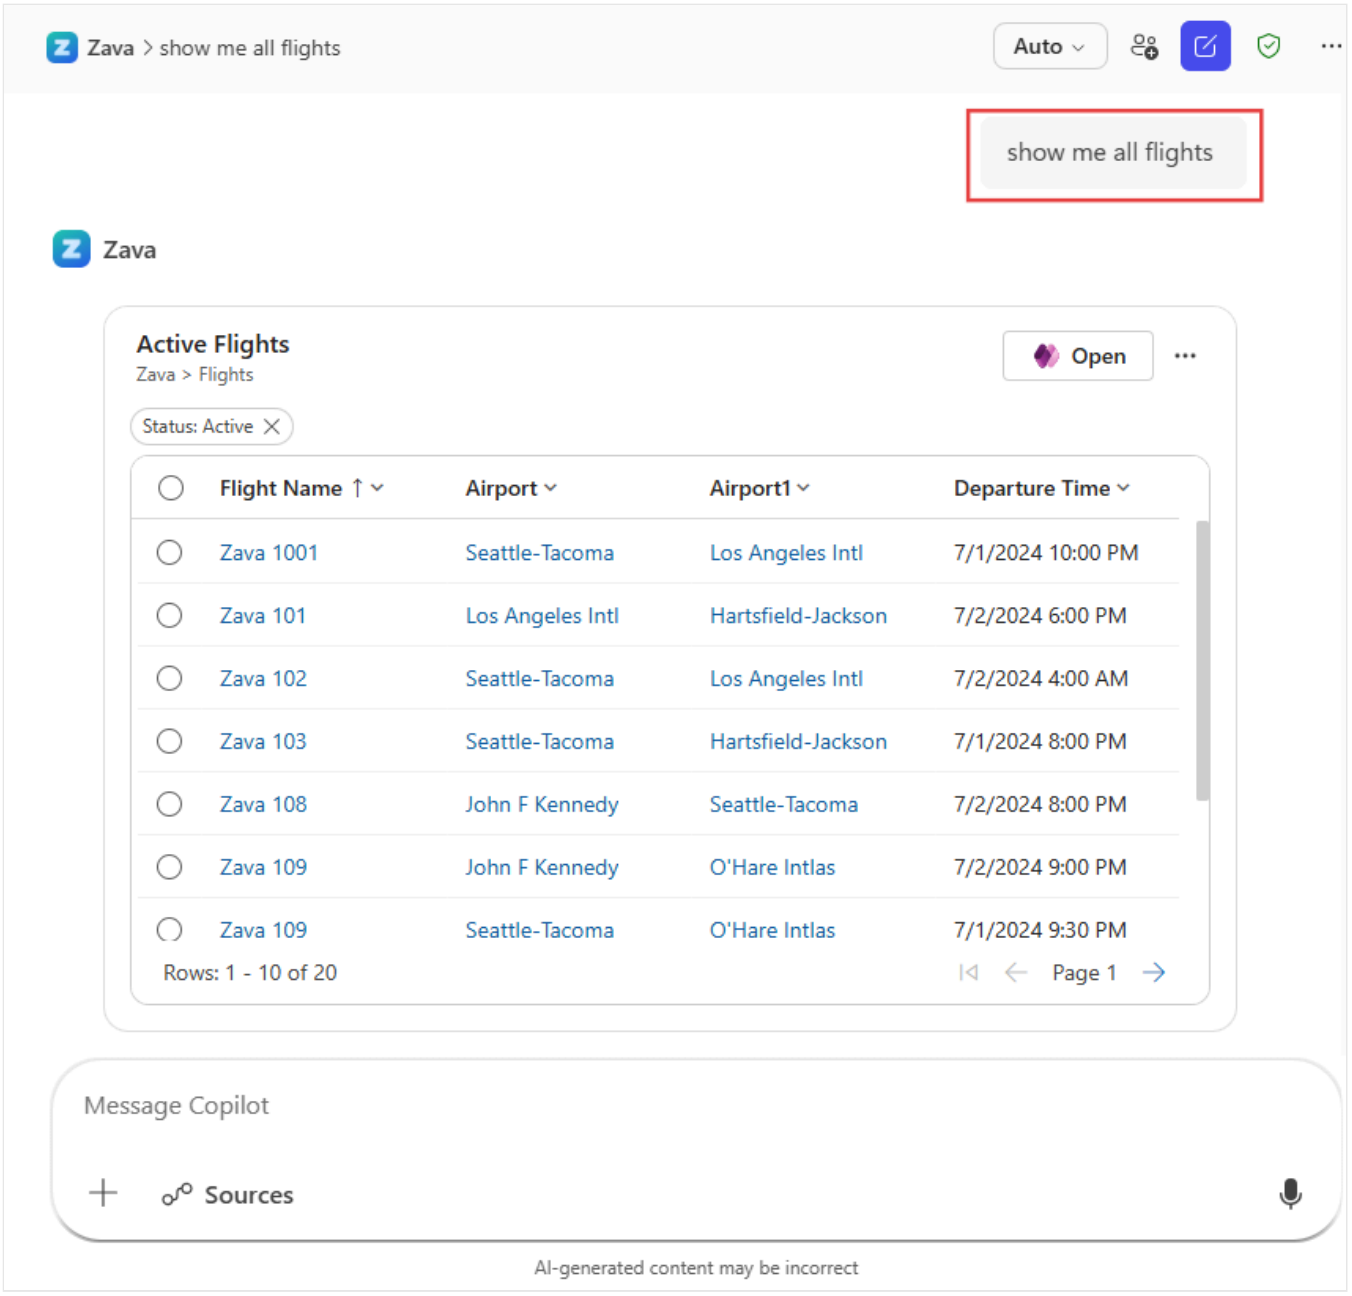
3. Select **Download app package** to download declarative agent generated by your app's MCP. This package contains the agent definition, built-in tools for record and data along with the configuration needed to deploy your app's experience to Microsoft 365 copilot.



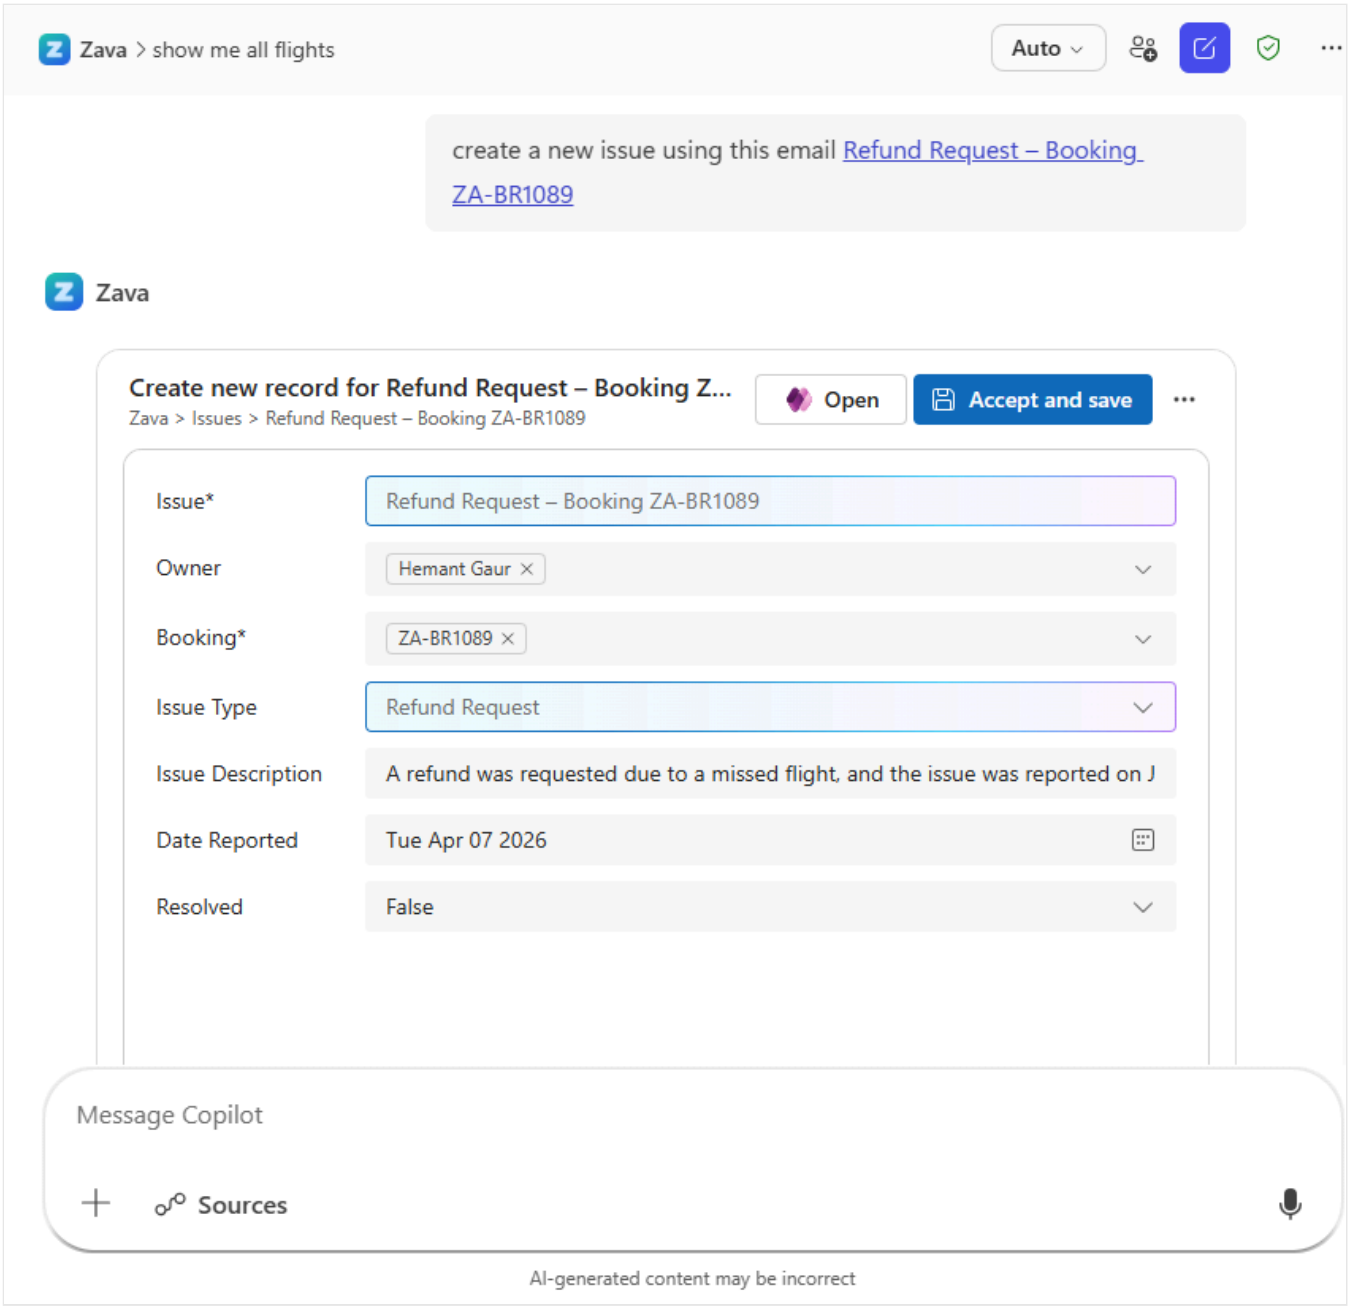
4. Upload the compressed file that is named similar to *declarative-agent-app name.zip* to Microsoft Teams or Microsoft 365 Agents:

    - Teams: Upload for personal use as a custom app in Teams. More information Upload your app in Teams
    - Microsoft 365 Agents: Publish the package for a team or group from the Microsoft 365 admin center. More information: Publish agents

You can now ask questions about the tables in the app from this declarative agent. Built-in tools can show an interactive grid for the dataset queries.



Additionally, intelligent forms can be used to create, view, and edit records within the Microsoft 365 Copilot context.



> **Note**
>
> You can customize the declarative agent included in the app package at you own discretion. To reduce the possibility of unexpected behavior when using AI agents, use caution when you customize the declarative agent code. More information: Declarative Agents for Microsoft 365 Copilot.

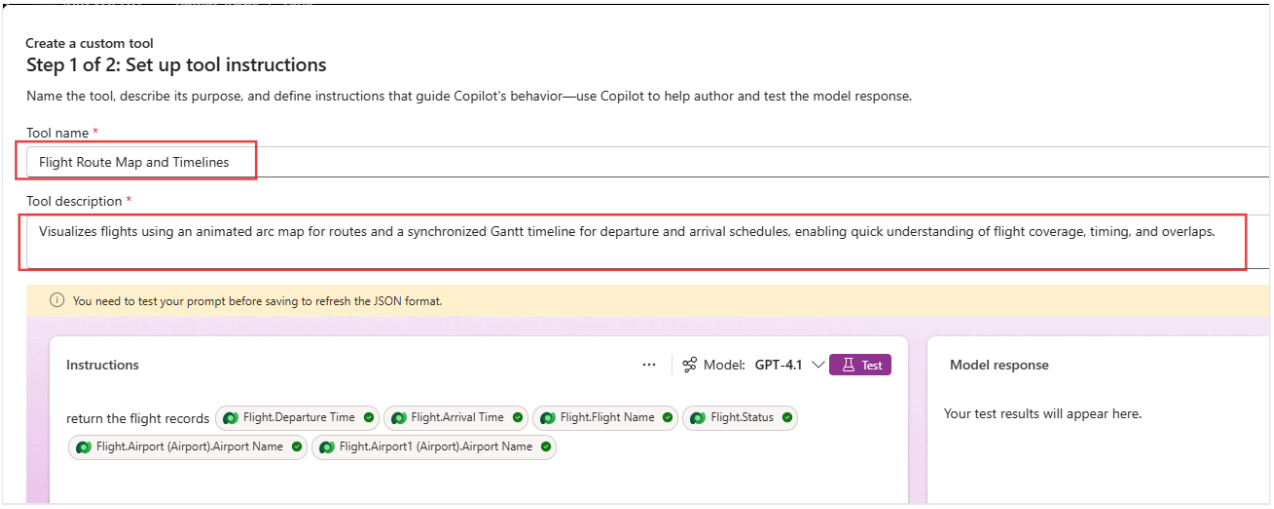
Create custom tools

In addition to the built-in tools available within the app's declarative agent, its functionality can be extended by incorporating custom tools and widgets. A prompt builder–based designer can be used to integrate custom MCP tools and interactive UI components into the app's

declarative agent. For example, in the Zava Airlines app, a custom tool can be added to display the flight map alongside the flight timeline as a Gantt chart in a side-by-side view.

> **Note**
>
> Custom tools and UX is based on Microsoft 365 Copilot extensibility for declarative agents. More information: Microsoft 365 Copilot Extensibility and Supported capabilities

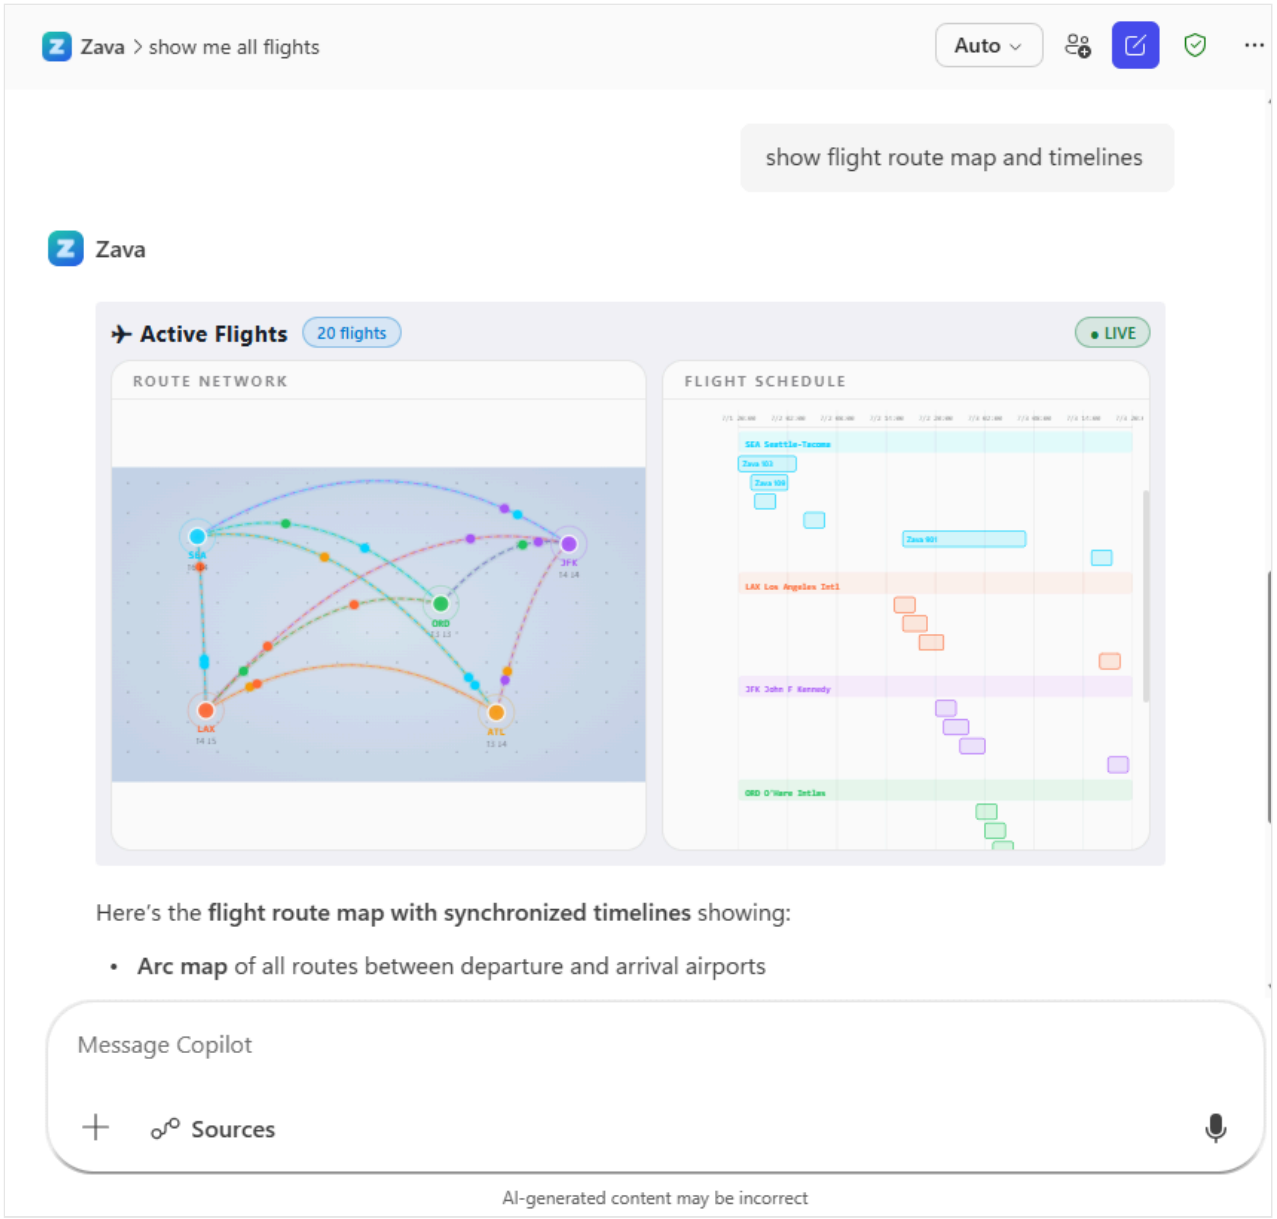
1. Select **Create custom tool** under the **Tools** section of the **App MCP** tab.
2. Provide a clear, descriptive **name** and **description** for the tool, as Microsoft 365 Copilot uses this information to determine when to invoke it.
3. Add the instructions to output data for the tool that defaults to JSON format. You can change it to text if the tool doesn't have UX associated with it. Instructions can include queries for specific records of the table in the app or it could be an input parameter to the tool to be used in tool-chaining. Make sure to experiment and choose the right prompt AI model.



4. Select **Test** to check and validate tool's output and then select **Next**. You can now create and paste optional custom HTML specific to this tool. This HTML can be created using the `/generate-mcp-apps-ui skill` or your own development tool. Select **Save**.

5. Download the updated app package zip and upload the latest version to Microsoft Teams or Microsoft 365 agents.

6. Invoke the tool by issuing the relevant query in the app agent to see the custom UI in action.



> **Note**
>
> You can issue '-developer on' command to Microsoft 365 Copilot to see agent debug info and tools invoked.

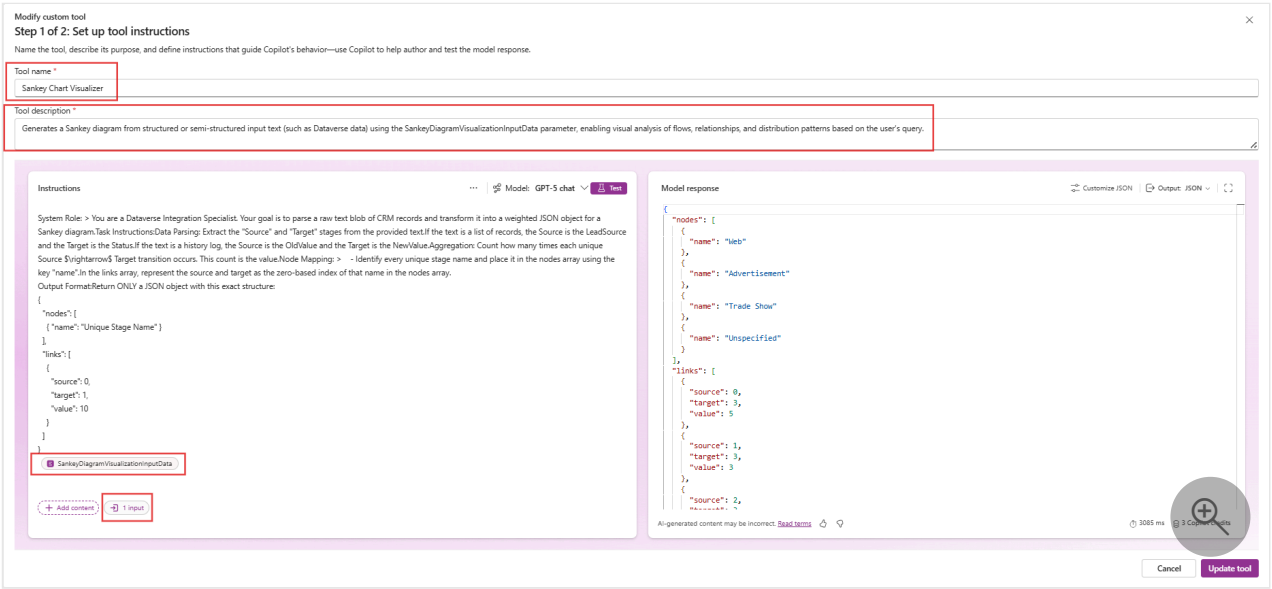
Dynamic tool chaining

Tool chaining in Power Apps declarative agents uses the Microsoft 365 Copilot orchestrator to reason over user intent and dynamically invoke multiple MCP-powered actions (tools) in sequence to complete a task. The orchestrator selects, parameterizes, and executes the right combination of MCP app actions based on context and function descriptions, enabling end-to-end workflows across Power Apps and enterprise systems. Here's how to create a tool with parameterized input.

1. Select **Create custom tool** under the **Tools** section of the **App MCP** tab.

2. Provide a clear, descriptive **name** and **description** for the tool, as Microsoft 365 Copilot uses this information to determine when to invoke it.

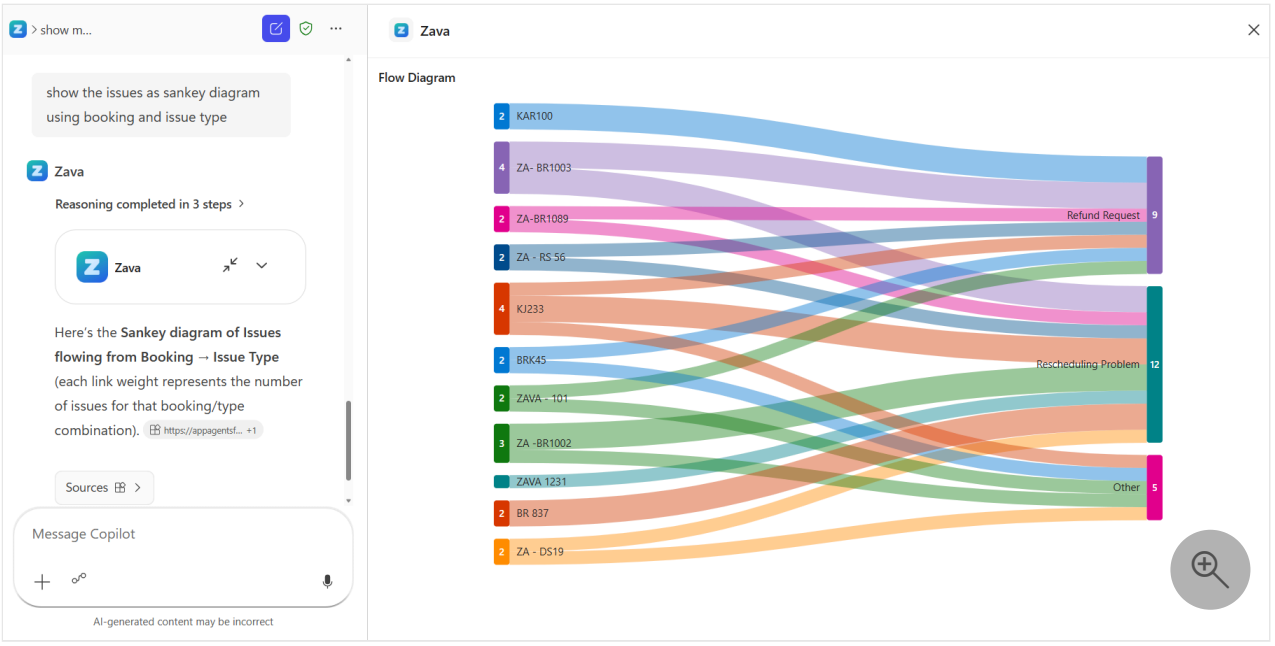
3. In this example, we use a Sankey chart visualizer. First, define the JSON input schema required to generate a Sankey chart. Next, create a prompt for the Sankey chart visualizer tool. The tool exposes an input parameter named `SankeyDiagramVisualizationInputData`. This parameter is interpreted by the tool and transformed into the JSON structure expected by the visualizer. Choose a clear and descriptive input parameter name so the LLM can correctly identify and invoke the tool.



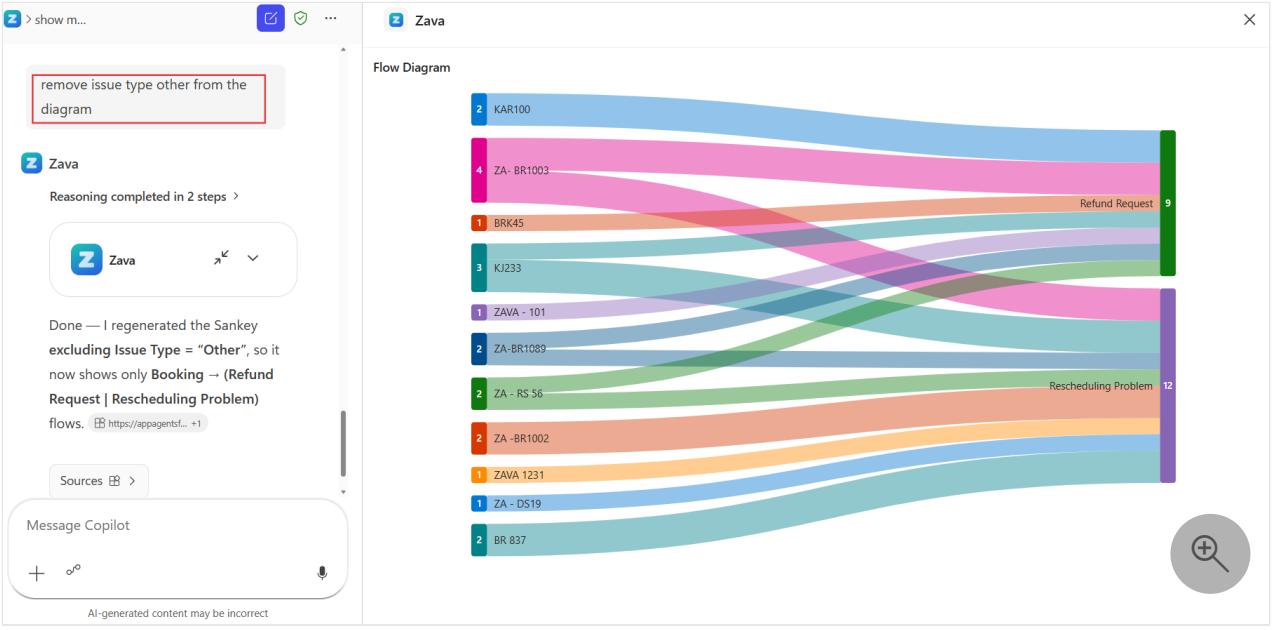
4. You can now create and paste custom HTML specific to this tool. This HTML can be created using the `/generate-mcp-apps-ui skill` or your own development tool. Select **Save**.

5. Download the updated app package zip and upload the latest version to Microsoft Teams or Microsoft 365 Agents.

6. Copilot can now use natural language queries to fetch the data and pass it to the tool for visualization. For example you can use a complex query to dynamically get inputs from the 'issues' table data and visualize them using Sankey Chart Visualizer tool.



7. You can further refine the Sankey chart by continuing the conversation.



Full screen example

In this example, an expand button is rendered only if the host supports fullscreen mode.

js

```
function renderExpandButton(app) {
  const ctx = app.getHostContext();

  // Don't render the button if the host doesn't support fullscreen
  if (!ctx?.availableDisplayModes?.includes('fullscreen')) {
    return null;
  }

  const btn = document.createElement('button');
```

```
  btn.addEventListener('click', async () => {
    const result = await app.requestDisplayMode({ mode: 'fullscreen' });
    // Always use result.mode — the host may grant a different mode than requested
    console.log('Granted mode:', result.mode);
  });
  return btn;
}
```

The same guard applies to any host capability. Check `getHostContext()` before use:

js

```
const ctx = app.getHostContext();

// Theme
if (ctx?.theme) applyTheme(ctx.theme);

// Current display mode
if (ctx?.displayMode === 'fullscreen') { /* adjust layout */ }

// Available modes
if (ctx?.availableDisplayModes?.includes('inline')) { /* show collapse option */ }
```

React to capability changes at runtime via `onhostcontextchanged` — the host context can update after `connect()`:

js

```
app.onhostcontextchanged = (ctx) => {
  if (ctx.theme) applyTheme(ctx.theme);
  if (ctx.displayMode) updateLayout(ctx.displayMode);
};
```

Using fullscreen mode with tool results

A common pattern is to switch to fullscreen automatically when the widget receives data, giving the content more space to render.

js

```
app.ontoolresult = async (result) => {
  const data = result.structuredContent;
  if (!data) return;

  // Expand to fullscreen when data arrives, if the host supports it
  const ctx = app.getHostContext();
  if (ctx?.availableDisplayModes?.includes('fullscreen') && currentMode !==
'fullscreen') {
```

```
    const granted = await app.requestDisplayMode({ mode: 'fullscreen' });
    currentMode = granted.mode;
    document.body.classList.toggle('mode-fullscreen', currentMode ===
'fullscreen');
  }

  renderData(data);
};
```

You can also let the user decide — render into the current mode first, then offer the expand button:

js

```
app.ontoolresult = (result) => {
  const data = result.structuredContent;
  if (!data) return;

  renderData(data);         // render in whatever mode is active
  updateExpandBtn();        // show the expand button now that there is content
};
```

Generate MCP app widgets with AI code generation tools

[This topic is pre-release documentation and is subject to change.]

This article explains how to use AI code generation tools like GitHub Copilot CLI or Claude Code to generate interactive model context protocol (MCP) apps for your model-driven Power Apps MCP tools. MCP apps are self-contained HTML files that render a tool's JSON output visually as cards, charts, dashboards, or maps inside any MCP Apps compatible host, including Microsoft 365 Copilot, Claude, and Visual Studio Code.

If you have an MCP tool that returns JSON data, the `generate-mcp-app-ui` skill can produce a polished, theme-aware widget that displays that data in a compact visual format directly inside a chat conversation.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.
> - MCP apps support in Microsoft 365 Copilot Chat is generally available as of March 2026. Power Apps support for MCP apps in declarative agents is currently in public preview. For the full announcement, see MCP Apps now available in Copilot Chat.

What you can do with the generate-mcp-app-ui skill

- *Create visual widgets* for any MCP tool by describing what you want and pasting the tool's JSON output.
- Choose the right visual for your data, such as charts for numeric trends, cards for structured records, tables for comparisons, maps for coordinates, and so on.
- Support light and dark themes automatically through Fluent UI design tokens.
- Add interactivity so widgets can call your tool again at runtime (for example, a refresh button).
- Refine the UX iteratively by describing changes in natural language. For example, "make the gallery compact," "add a chart," or "use a card layout."

Prerequisites

Software requirements

Expand table

Component	Minimum version	More information
GitHub Copilot CLI, Claude Code, or other code generation tool	Latest	Claude Code, GitHub Copilot CLI
A modern browser	Any	For previewing generated widgets locally

Additional requirements

- An MCP tool that returns JSON output. Your tool's output type must be set to **JSON**.
- A working internet connection. Widgets load Fluent UI and other libraries from the Content Delivery Network (CDN) at runtime.

Install the plugin

Run the following installer command from GitHub Copilot CLI or Claude Code. The installer automatically detects available tools and installs all Power Platform plugins, including `generate-mcp-app-ui`.

```
/plugin marketplace add microsoft/power-platform-skills
```

To install only the MCP App widget skill:

```
/plugin install mcp-apps@power-platform-skills
```

> **Tip**
>
> Turn on auto-update to automatically receive skill updates. Use the `/plugin` command, navigate to **Marketplaces**, choose the marketplace, and turn on auto-update.

Skills overview

Expand table

Skill	Command	Description
MCP Apps widget generator	`/generate-mcp-app-ui`	Generate a self-contained MCP app widget (HTML file) for an MCP tool's JSON output

The skill is also triggered by natural language phrases such as "create a widget," "build a widget for my tool," or "make an MCP app."

Generate a widget

Follow these steps to create a new widget for an MCP tool.

1. **Create and test a custom tool** from model-driven app designers and copy the full JSON output. Make sure the tool's output type is set to JSON. More information: Create custom tools

2. **Invoke the skill** and describe what you want displayed, pasting the JSON output into the conversation:

   ```
   /generate-mcp-app-ui Visualizes flights using an animated arc map for routes and a synchronized Gantt timeline for departure and arrival schedules, enabling quick understanding of flight coverage, timing, and overlaps. Here's an example of the tool's output: {"flight_records":[{"Departure Time":"2024-07-02T05:00:00Z","Arrival Time":"2024-07-02T07:30:00Z","Flight Name":"Zava 1001","Status":"Active","Airport":"Seattle-Tacoma","Airport1":"Los Angeles Intl"},{"Departure Time":"2024-07-02T03:00:00Z","Arrival Time":"2024-07-02T10:00:00Z","Flight Name":"Zava 103","Status":"Active","Airport":"Seattle-Tacoma","Airport1":"Hartsfield-Jackson"}]}
   ```

3. **Review the generated HTML file.** The skill writes a self-contained HTML file, for example, `flight-map.html`, to your working directory.

4. **Preview in a browser.** Open the HTML file locally as widget has the fallback option for testing. You can ask chat agent to add standalone HTML preview if missing.

5. **Iterate.** Describe any changes directly in the chat:

   - "Make the map larger"
   - "Add tool tips on the Chart"
   - "Decrease the height and fit in 250 pixels with responsive layout and no scroll bars"

> ⓘ Note

The skill requires actual JSON from your tool—not sample or mock data. The data shape drives the widget generation. If you paste mock data, the generated widget might not work correctly when connected to the real tool.

Deploy your widget

Once your widget is ready, copy the HTML file to the UX input for corresponding tool and it will be returned as the tool's UI response. Refer to your create custom tools documentation for details.

Add interactivity with callServerTool

If you also provide your tool's name when invoking the skill, the generated widget can include interactive tool-call integration. This allows the widget to call your tool again at runtime. For example a refresh button on the tool UX can call itself.

```
/generate-mcp-app-ui Show the current weather conditions with a refresh button.
Tool name: get_weather. Tool output:
{"city":"Seattle","temp_f":54,"condition":"Overcast","humidity":78,"forecast":
[...]}
```

The skill wires up `app.callServerTool` in the widget so that when users select **Refresh**, the widget fetches updated data directly from your tool. If you don't provide a tool name, the widget is read-only and renders only the data delivered through the `ontoolresult` callback.

- **Microsoft 365 Copilot chat**: See MCP apps in Copilot Chat for deployment paths including sideloading for testing, deploying through the Microsoft 365 admin center for organizational use, and publishing to the Microsoft 365 agent store.
- **Power Apps declarative agents**: See Power Apps MCP declarative agent documentation for how to connect MCP tools with model-driven apps.
- **Other MCP hosts**: Consult your host's documentation for the MCP apps widget registration process.

Widget technical details

MCP apps protocol

Widgets communicate with the chat host using the `App` class from the `@modelcontextprotocol/ext-apps` package. The protocol manages these callbacks and methods.

Expand table

Callback / method	Description
`app.ontoolresult`	Fires when the host delivers tool data. *Your data is always at* `result.structuredContent` —not `result.data` or `result` itself.
`app.onhostcontextchanged`	Fires when the host context changes, including theme (`ctx.theme` is `'light'` or `'dark'`).
`app.onteardown`	Fires when the widget is removed from the conversation.
`app.connect()`	Establishes communication with the host. All event handlers must be registered *before* calling `connect()`.
`app.getHostContext()`	Returns the current host context (including initial theme) after `connect()` completes.
`app.callServerTool({ name, arguments })`	Calls a tool interactively. Returns `result.isError` and `result.structuredContent`.

CDN imports

Widgets load all dependencies from CDN. No build step or local installation is required. Dependencies come in two formats:

- **ECMAScript Modules (ESM)** — imported inside `<script type="module">` using a URL ending in `/+esm`
- **Universal Module Definition (UMD)** — loaded via a plain `<script src>` tag; registers itself globally as a side effect

Expand table

Library	Format	URL	Purpose
`@modelcontextprotocol/ext-apps`	ESM	`cdn.jsdelivr.net/npm/@modelcontextprotocol/ext-apps/+esm`	MCP apps `App` class
`@fluentui/tokens`	ESM	`cdn.jsdelivr.net/npm/@fluentui/tokens/+esm`	`webLightTheme` / `webDarkTheme` token sets
`@fluentui/web-components@beta`	UMD	`unpkg.com/@fluentui/web-components@beta/dist/web-components.min.js`	Fluent UI custom elements

Visual states

Every widget handles three states:

Expand table

State	Guidance
Loading	Show a `<fluent-spinner>` with a contextual message ("Finding attractions..." not just "Loading...").
Loaded	Render the content compactly. Use the full available width.
Error	Show a friendly message and a "Try again" button. If the widget uses `callServerTool`, the button re-invokes the tool.

Fluent UI components

The following Fluent UI web components are available in widgets:

`<fluent-card>`, `<fluent-button>`, `<fluent-text-input>`, `<fluent-textarea>`, `<fluent-dropdown>`, `<fluent-listbox>`, `<fluent-option>`, `<fluent-checkbox>`, `<fluent-spinner>`, `<fluent-divider>`, `<fluent-badge>`, `<fluent-switch>`, `<fluent-tooltip>`

Theme support

Widgets support light and dark themes through Fluent UI design tokens. The widget applies the correct token values when the host's theme changes via `onhostcontextchanged`. Always use token variables, for example, `var(--colorNeutralForeground1)`, rather than hardcoded color values to ensure correct rendering in both themes.

Color tokens

Expand table

Use	Token
Primary text	`var(--colorNeutralForeground1)`
Secondary text	`var(--colorNeutralForeground2)`
Primary background	`var(--colorNeutralBackground1)`
Card/hover background	`var(--colorNeutralBackground2)`
Brand/accent	`var(--colorBrandBackground)`
Text on brand surface	`var(--colorNeutralForegroundOnBrand)`

Use	Token
Borders	`var(--colorNeutralStroke1)`
Error text	`var(--colorStatusDangerForeground1)`
Success text	`var(--colorStatusSuccessForeground1)`

Never use hardcoded hexidecimal or RGB values. Don't invent token names not listed here.

Best practices

- Provide real test data. The skill analyzes the actual JSON structure to select the right visual. Mock data produces widgets that break when connected to the real tool.
- Be specific about the visual. Describe the format you want, such as map, chart, table, or card layout. Vague descriptions lead to generic results.
- Start with one view. Widgets are compact conversation cards, not full applications. No tabs, page navigation, or search bars that duplicate the chat input.
- Test with both themes. Preview in light and dark mode to verify contrast and readability.
- Match the visual to the data. Maps for coordinates, charts for numeric or trend data, cards for structured records, tables for comparisons.

Limitations

- Widgets must load all external libraries from CDN. An internet connection is required at runtime.
- Full screen display mode requires additional implementation beyond what the skill generates.
- The skill doesn't handle MCP server registration or deployment to the Microsoft 365 admin center. You must complete those steps separately.
- Authentication (OAuth 2.1, Microsoft Entra SSO) is handled by the MCP host environment, not the widget HTML itself.

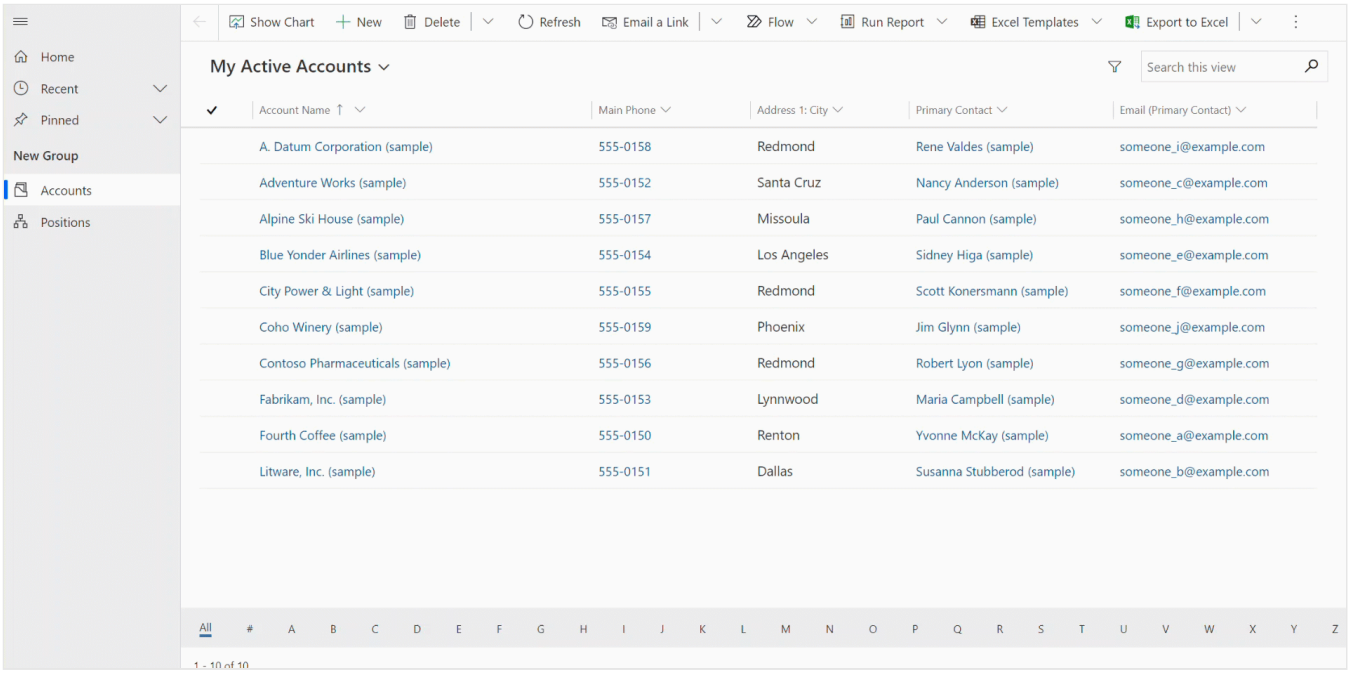
Understand model-driven app views

Model-driven apps use views to define how a list of records for a specific table are displayed in an application.

A view defines:

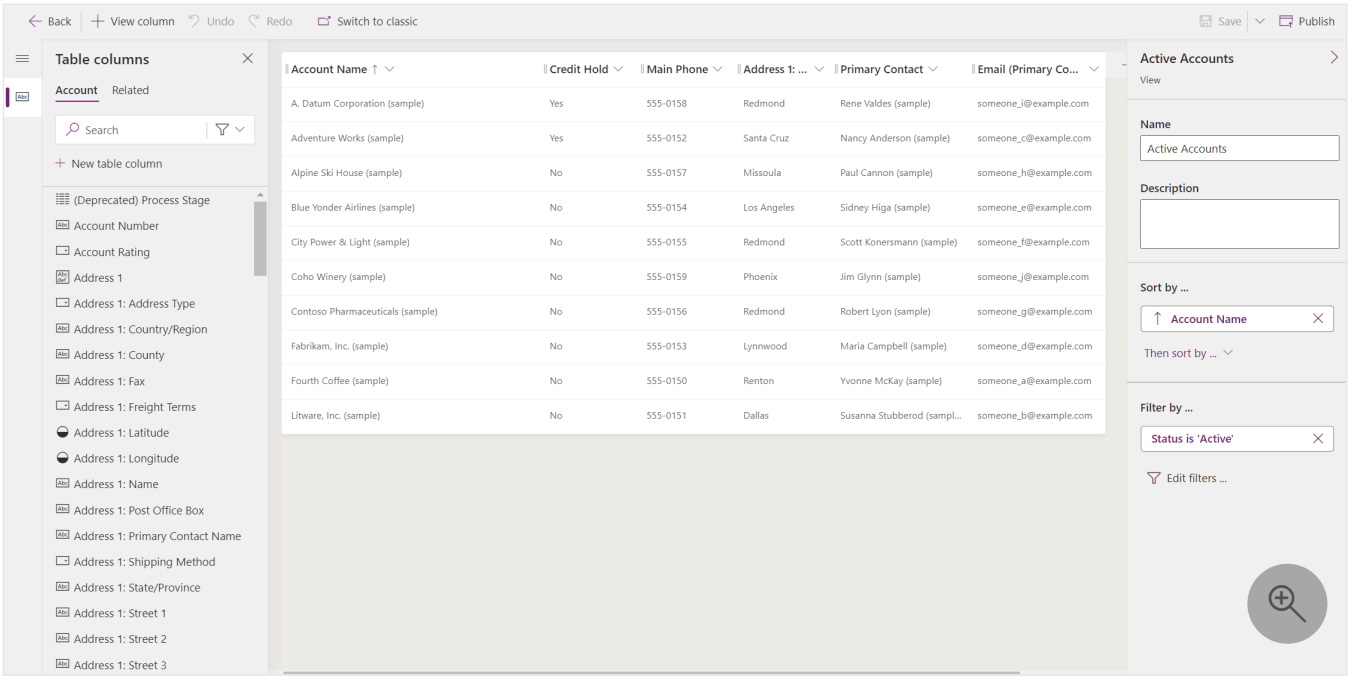
- The columns to display.
- The order of the columns.
- How wide each column should be.
- How the list of records should be sorted by default.
- The default filters applied to restrict the records that appear.

Once a view is available to the app, the user can select it.



When makers design an app, they decide which of the public views to make available to app users. These decisions are typically based on the type of user, such as sales or marketing, that use the app.

Views can be developed through the table designer or the app designer.



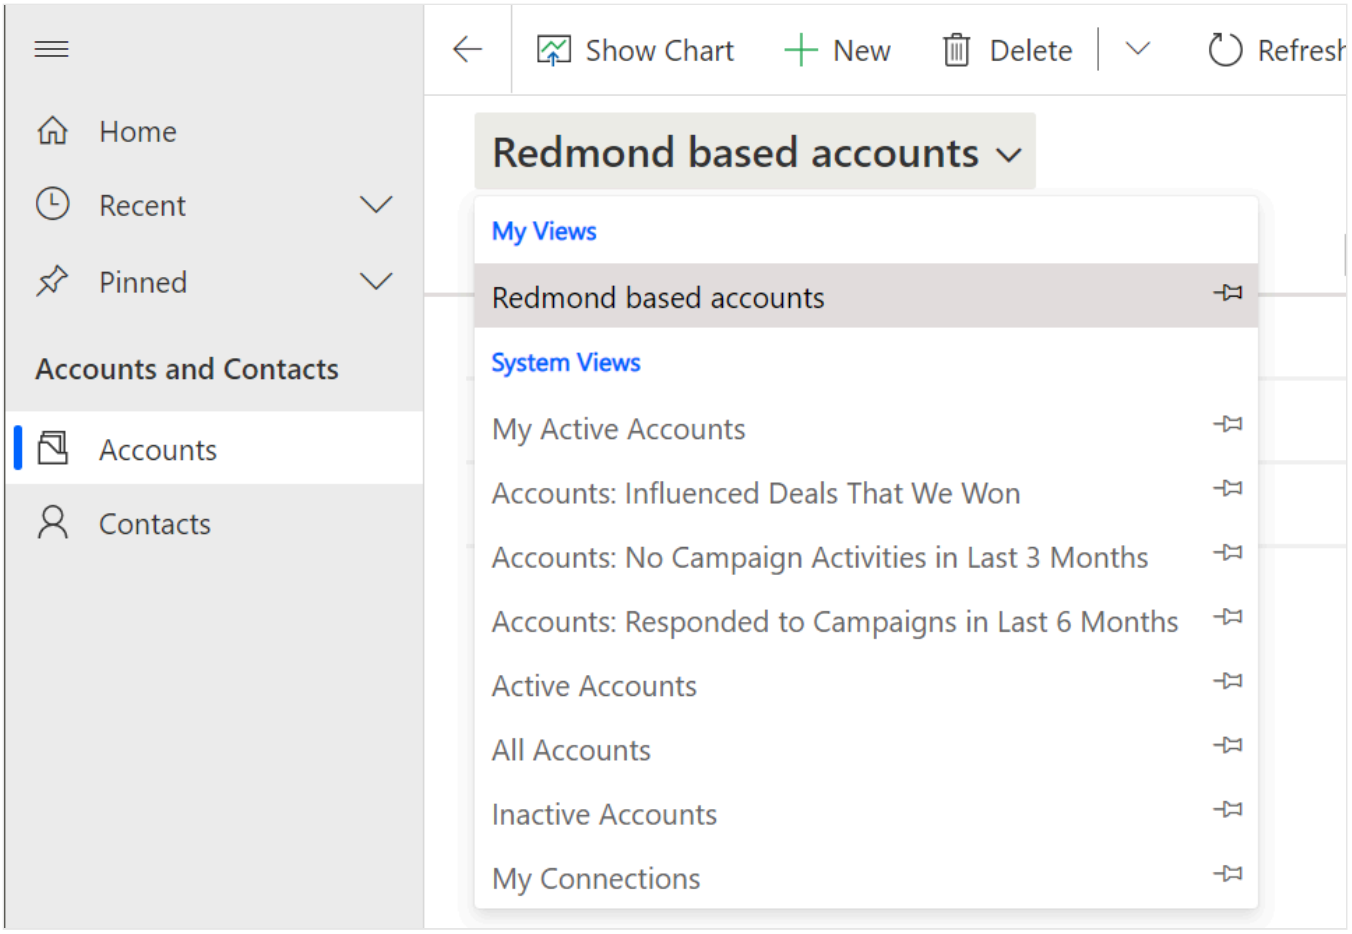
Types of views

There are three types of views: *personal*, *system*, and *public*.

- **Personal view** - Personal views are owned by individuals and only visible to that person unless they share their personal views with others.
- **System view** - As a system administrator or system customizer, you can edit system views. System views are special views the application depends on, which exist for system tables or are automatically created when you create custom tables. These views have specific purposes and some additional capabilities.
- **Public view** - Public views are general purpose views that you can customize as you see fit. They're important because all app users can access them, when they're made available, by using the view selector. It's possible to use public views in subgrids on a form or as a list in a dashboard.

Views within model-driven apps

Users might want to view data in relation to a table in a range of ways. A drop-down list of views is frequently displayed in the application so these can be selected.



Personal views are included above the list of system or public views that are available in the app. This makes it easier for users to find the data that is important to them.

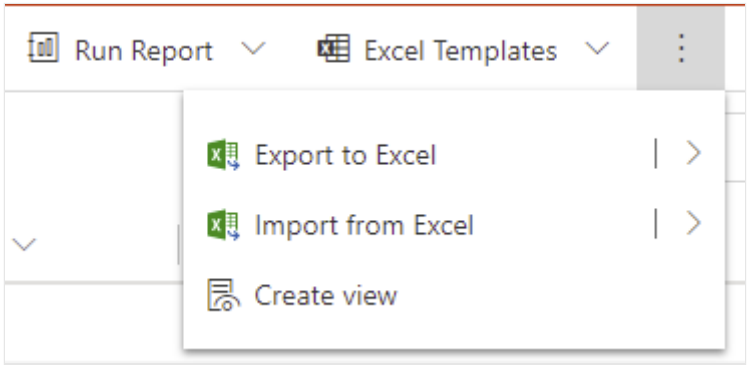
The records that are visible in views are displayed in a list. Views frequently provide options for users to change the default sorting, column widths, and filters to more easily find the data that's important to them.

Views aren't only used by users within model-driven apps. Views can also be used to define the data source in, for example, charts that are used in the application.

Personal views

Personal views can be created by following these steps:

1. Select **Create view** from the command bar in your model-driven app.



2. Define the view filters.
3. Select **Save**.

> **Note**
>
> While you can create a new personal view based on a system or public view, you can't create a system or public view based on a personal view.

Personal views can be created by users who have at least User level access to actions for the Saved View table.

As system administrator, you can modify the access level for each action in the security role to control the depth to which people can create, read, write, delete, assign, or share personal views.

System views

Expand table

System views	Description
Quick Find	The default view used when searches are performed using Quick Find. This view also defines which columns are searched when using search capabilities of Quick Find and Lookup column views.
Advanced Find	The default view used to display results when using Advanced Find. This view also defines the columns used by default when new custom public views or personal views are created without defining a view to use as a template.
Associated	The default view that lists the related tables for a record.
Lookup	The view that is displayed when you select a record to set for a Lookup column.

System views aren't shown in the view selector and you can't use them in sublists in a form or as a list in a dashboard. You can't delete or deactivate these views. However, Power Platform admins can control whether system views are available or not to users with security roles. More information: Manage access to public system views (preview)

For information about removing views, go to Remove views.

System views are owned by the organization so that everyone can view them. For example, everyone has organization-level access to read records for the view (`savedquery`) table. These

views are associated with specific tables and are visible within the Solutions area in Power Apps (make.powerapps.com). You can include these views in solutions because they're associated with the table.

> **Note**
>
> System views are cached for performance optimization purposes and therefore plug-ins on the `savedquery` table aren't supported.

Public views

Some public views exist by default for system tables and for any custom table. For example, when you create a new custom table, it has the following combination of public and system views.

Expand table

Name	Type
Active *table plural name*	Public
Inactive *table plural name*	Public
Quick Find Active *table plural name*	Quick Find
Table name Advanced Find View	Advanced Find
Table name Associated View	Associated
Table name Lookup View	Lookup

You can create custom public views. You can delete any custom public views you create in an unmanaged solution.

You can't delete any system-defined public views.

Custom public views added by a managed solution should only be deleted by uninstalling or updating the managed solution.

How to access the view editor to create or edit views

- App designer: If you're working in an app, you might want to use the app designer, which provides a simple and intuitive user interface with drag-and-drop capabilities for creating views. More information: Tutorial: Create and edit public or system views by using the app designer
- Solution area: In Power Apps, go to **Solutions** > open the solution you want > open the table you want, and then select the **Views** area. Selecting a view opens it in the view designer.

Customize views

As a system customizer you can customize views and subgrids through controls by making them read-only or editable as well as display an alphabetic list at the bottom of views or subgrids (jump bar).

The following controls are available:

Expand table

Grid control name	Read-only or editable?	Description
Power Apps grid control	Read-only or editable	This grid control includes accessibility enhancements and will become the default grid control used in views and subgrids. This control will eventually replace all other grid controls. More information: Power Apps grid control
Power Apps read-only grid (deprecated)	Read-only	Modern grid with accessibility enhancements released in October 2021 and became the default read-only grid experience in April 2022. More information: Power Apps read-only grid control
Editable grid (deprecated)	Editable only	Legacy grid control. More information: Make model-driven app views editable using the editable grid control
Read-only grid (deprecated)	Read-only	Legacy grid control that is deprecated. More information: The legacy read-only grid in model-driven apps is deprecated

Opening the view designer

Manage access to system views (preview)

Last updated on 04/03/2026

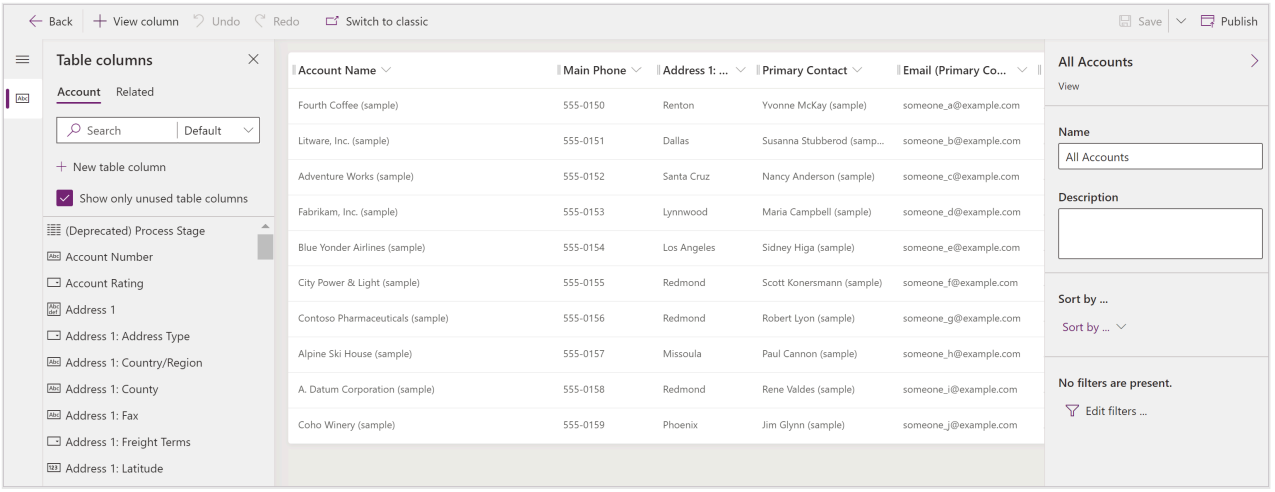
Open the view designer

09/09/2025

In this article, a view definition is opened that displays properties and options to configure a table view using the view designer for use with model-driven apps.

Open a view for editing in Power Apps

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and then open the solution that needs to be modified. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the table that contains the required view, such as the **Account** table.
4. Select the **Views** area.
5. Select the view, such as the account table **All Accounts** view.



6. From the view editor, the following tasks can be performed:

- Sort rows in a view
- Choose and configure columns in views
- Filtering data within views

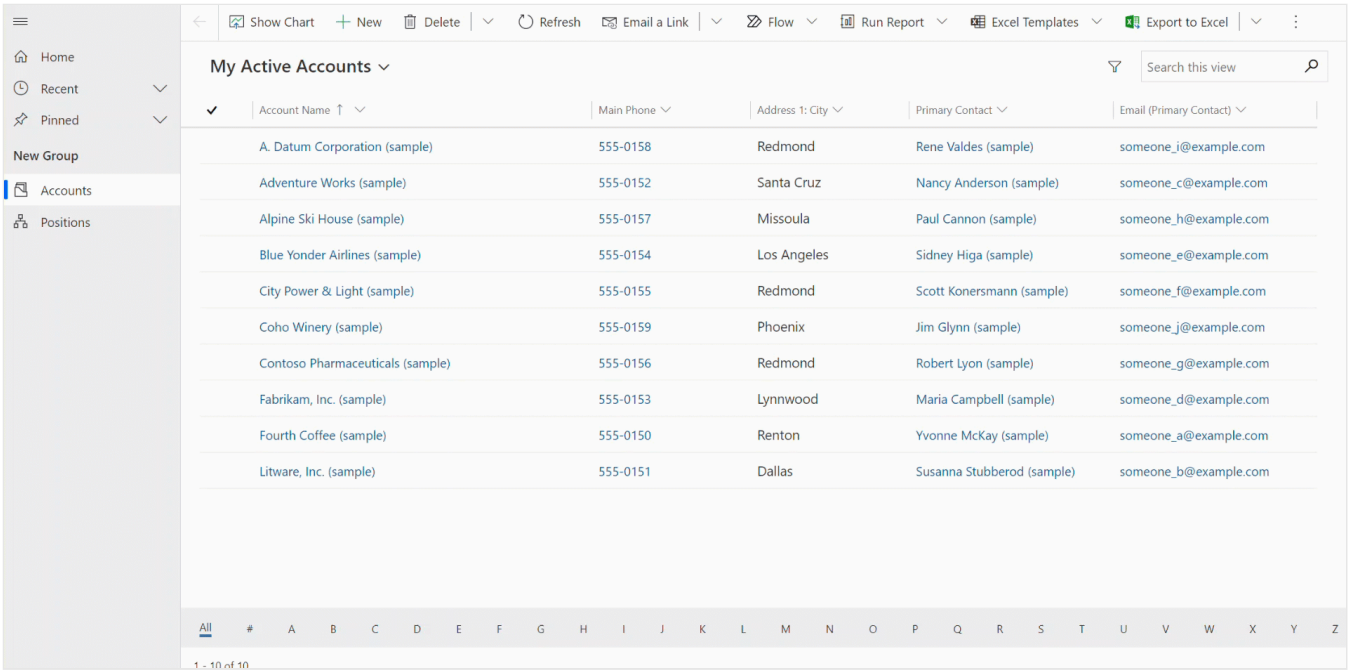
Next steps

Creating and editing public views

Create and edit public or system views

Model-driven apps can contain a range of views, so that app users can open the most suitably presented and filtered version of the table. Views can be **Personal**, **System, or **Public**.

> **Note**
>
> Views are tied to a given table. However, you can select views during the process of creating a model-driven app. By default, ALL views are made available in an app.



> **Tip**
>
> For a general introduction into views, go to Understand views in model-driven apps

Create a public view in Power Apps

Public views are available for users to display table records. App makers can create and configure public views using Power Apps.

1. Sign in to Power Apps and select an environment
2. On the left navigation pane, select **Solutions**, and open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open a table, such as the account table, and then select the **Views** area.
4. Select **New view** on the command bar, and then enter a **View name**, and optionally enter a **Description**.

5. If you want to have suggestions from Copilot for the columns to create for the form based on the **View name** and **Description** values, select **Get AI-generated column suggestions**. For more information about using this AI feature, go to Column suggestions by Copilot.
6. Select **Create**.

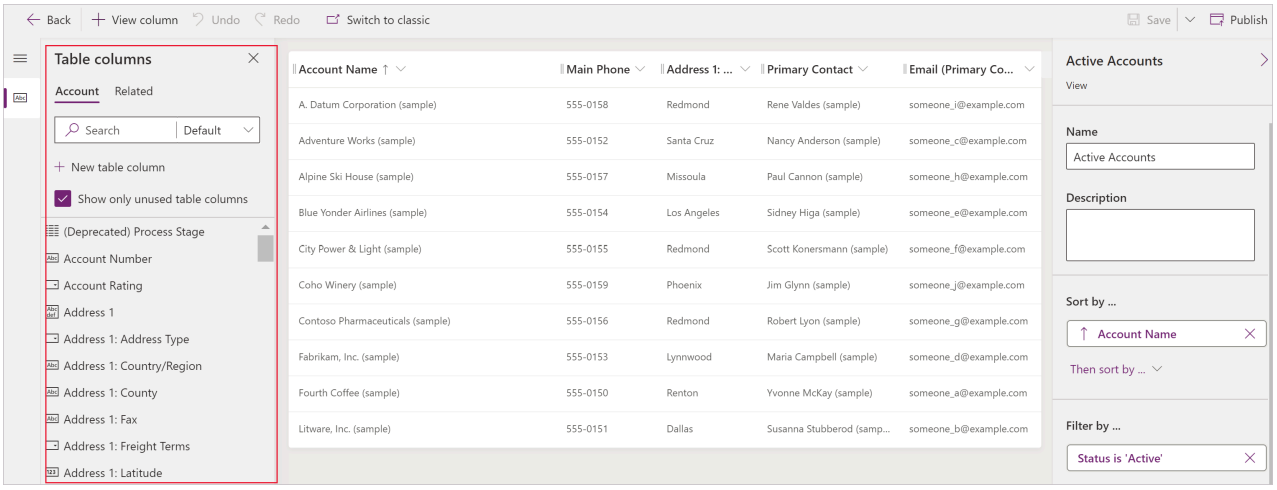
> **Note**
>
> Public views created in Power Apps that include **Contains data** or **Does not contain data** filters don't appear in the list of saved views in Advanced Find.

Edit public views from a table

In the solution that you opened earlier, create a new table or find an existing table where the public views need to be edited.

1. Sign in to Power Apps and select an environment
2. On the left navigation pane, select **Solutions**, and open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open a table, such as the account table, and then select the **Views** area, and then open the view you that want to edit.
4. In the view designer, select **+ View column** to add additional columns needed within the view. Or, in the **Table columns** left navigation pane drag the table columns onto your view.

   > **Tip**
   >
   > Only include the specific columns you need for the view, as larger numbers of columns in a view can cause degradation of grid performance.



> **Tip**
>
> The **Default** view in the **Add column** pane displays all columns. If preferred, select **Standard** or **Custom** to display a subset of columns.
>
> >

5. In the view designer, the following tasks can be performed:

   - To change the column filtering select the header of the column where the filter is required, and then in the dropdown list select **Filter by**.
   - To change the column sorting select the header of the column where sorting is needed then select **Sort A-Z**, **Sort Z-A**, **Sort descending**, or **Sort ascending**.
     - You can configure multi-column sorts by holding Shift when selecting a sort option to add a sort condition to the set of the existing sorts.

- Configure column width by selecting and dragging the column to the desired position.
- Reorder columns by dragging a column to the desired position.

> **Note**
>
> Depending on the data type of the column the term **Sort A-Z/Sort Z-A** or **Sort ascending/Sort descending** is used

> **Tip**
>
> It is also possible to change column order by selecting the column header and then selecting **Move Right** or **Move Left**.

6. Select **Save and publish** to save the view and make it available for other users in your organization.

Choose and configure columns in model-driven app views

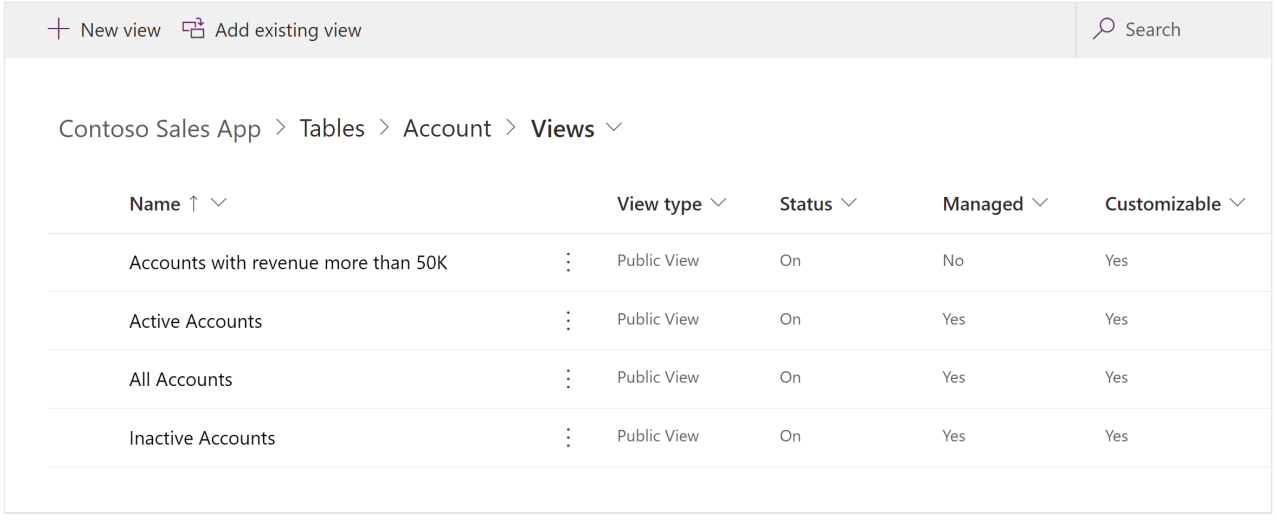
Summarize this article for me

Along with the filter criteria, the columns visible in a Power Apps view are very important to the value provided by the view. In this article, you create or edit views by performing the following tasks:

> **Important**
>
> The latest version of the view designer is currently in preview. Some features, like enabling or disabling presence for a column and adding a find column, aren't yet supported. To accomplish these tasks, open the view in the classic view designer.
>
> - Enable or disable presence for a column
> - Add find columns

Opening the view editor

1. Sign in to Power Apps.
2. Select **Tables**, and then open the table that you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Views**. The list of views for the table is displayed. You can also navigate to the table and views via solutions as shown below.



4. Select an existing view to open it or on the toolbar select **New view**.

Adding columns

You can include columns from the current table or any of the related tables that have a 1:N table relationship with the current table.

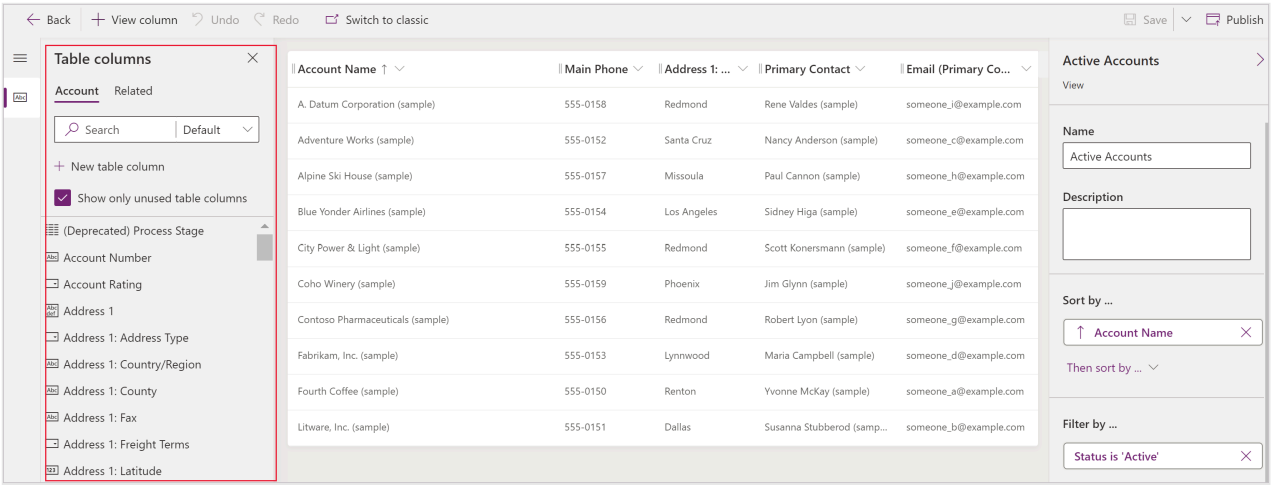
For example, you might want to display the owner of a user-owned table in a column. You can choose the **Owner** column of the current table to display the name of the owner. This appears as a link to open the **User** row for the person who is the owner.

If you want to display the phone number for the owner of the row, you must select **Owning User (User)** from the **Row type** drop-down and then select the **Main Phone** column.

> **Tip**
>
> Only include the specific columns you need for the view. A larger numbers of columns in a view can cause degradation of view and grid performance.

Add columns to views

1. While creating and editing views, ensure that the **Table columns** panel is open. If it isn't, select **View column** on the toolbar.



2. Select the columns you want to add to the view designer. This adds the column as a column on the right-hand of the view.

3. Select the **Related** tab to see related tables and their corresponding columns.

As you add columns, you increase the width of the view. If the width of the view exceeds the space available to show it in the page, horizontal scrollbars appear to allow people to scroll and view the hidden columns.

> **Tip**
>
> If your view filters on data for a certain column so that only rows with a certain value are shown, don't include that column in the view. For example, if you are only showing active rows, don't include the status column in the view. Instead, name the view to indicate that all the rows shown in the view are active.

> **Note**
>
> When you add columns to Lookup views for updated tables, only the first three columns are displayed.

Removing columns

1. Select the header of the column you want to remove.
2. In the dropdown, select **Remove**.

Changing column widths

1. Hover over the area between columns in the view.
2. A line appears and your cursor becomes a double sided arrow.
3. Drag the column to the appropriate width.

Moving a column

Click and drag the column header to the correct position.

> **Tip**
>
> You can also select the header of the column you want to move and from the dropdown select **Move Right** or **Move Left**.

Create or edit view filters

Last updated on 02/21/2026

Create or edit filters in model-driven app views

Article • 01/29/2025

The filters in a Power Apps view define the records that a user is able to see when selecting the view for the current table. You can add or edit a filter for the columns that you include in a view by selecting the column and selecting **Filter by** in the view designer.

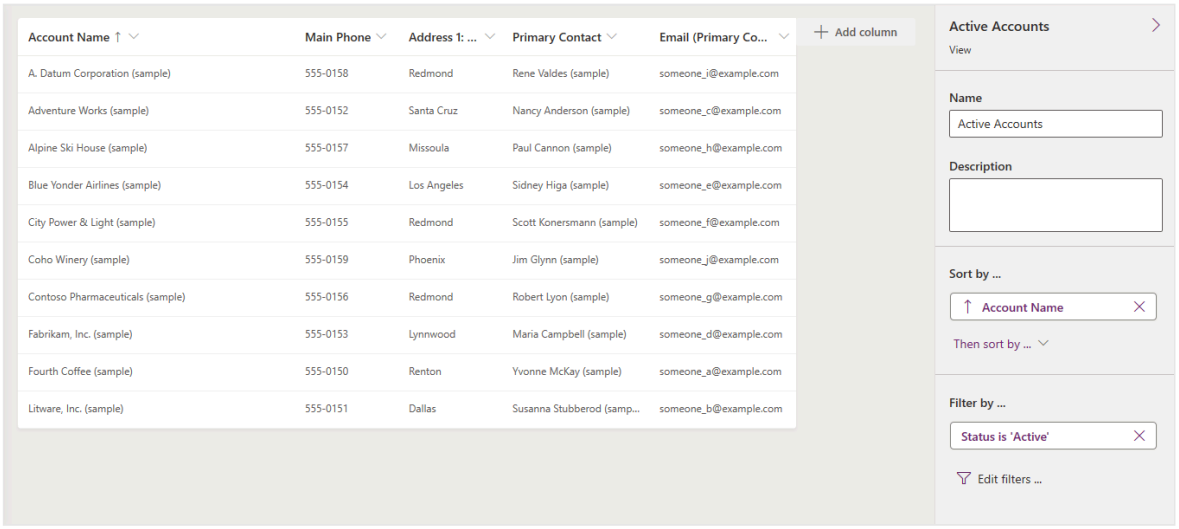
You can also use the expression builder in the view designer. Use the expression builder to add or edit filters for any columns of the table in the current view or any columns in a related table.

In this article, you create or edit filters by performing the following tasks:

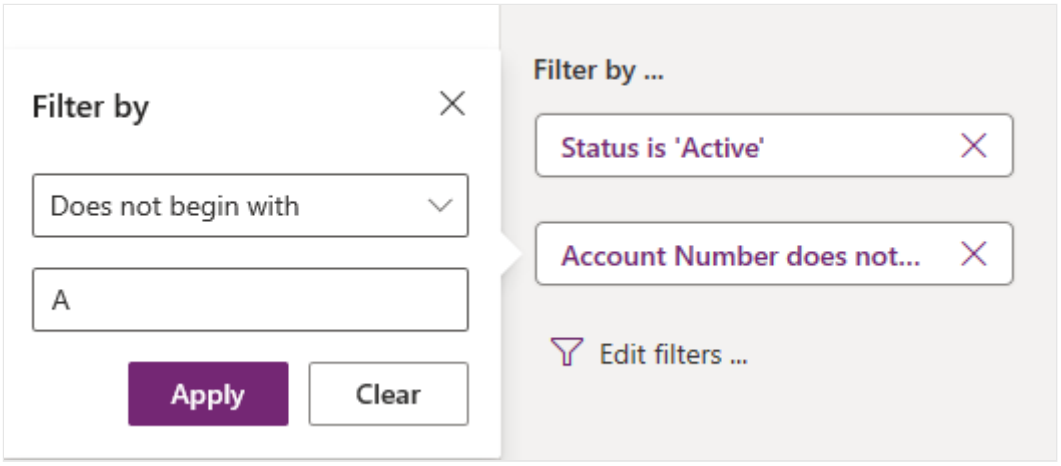
- Edit or remove a filter condition
- Open the expression builder
- Add conditions to a filter
- Add a group condition to a filter
- Add a related table to a condition
- Group conditions of a filter

Edit or remove a filter condition

1. Sign in to Power Apps.
2. On the left pane, select **Solutions**, and then open the solution you want.
3. Open the table that you want, and then select the **Views** area.
4. Open the view that you want to edit. The view properties panel lists existing filters.



5. On the view properties panel, select a filter condition.

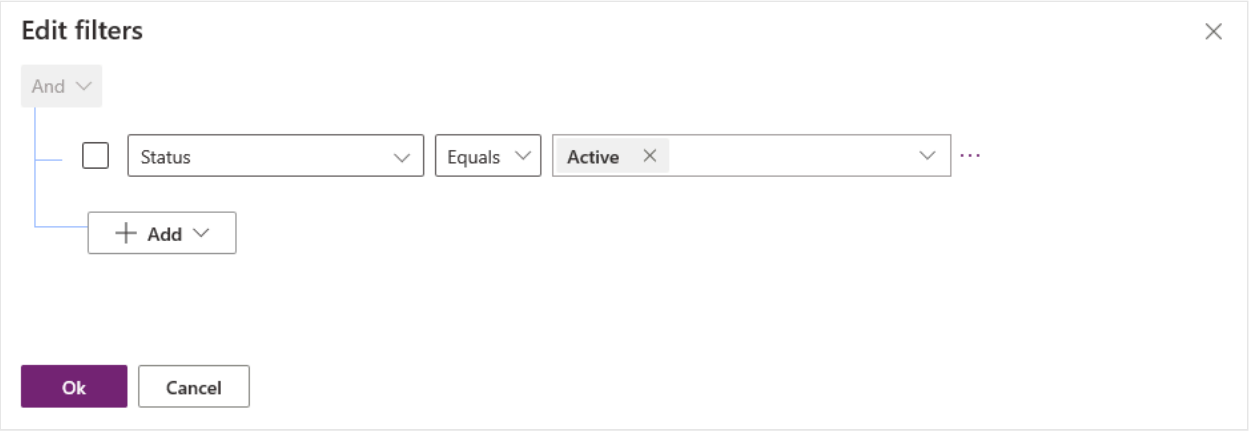


6. Select the conditional operator that you want to use.
7. Type or select the comparison value for the condition.
8. Select **Apply**.
9. To remove a condition, select **Close**. The condition is removed without confirmation.

Open the expression builder

Use the expression builder to redefine existing filters and add additional clauses.

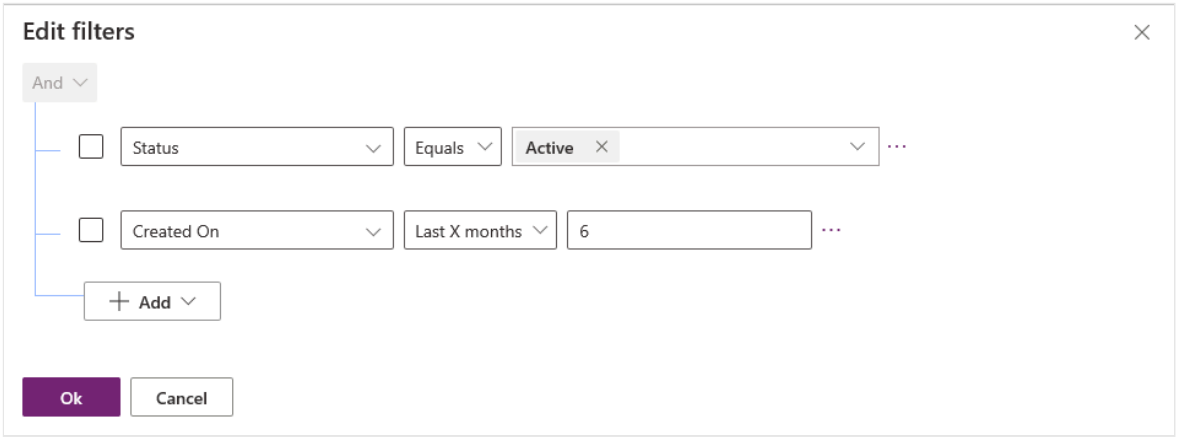
On the view properties right panel in the view designer, select **Edit filters**.



Add conditions to a filter

1. In the expression builder, select **Add** > **Add row**.
2. Select a column for the condition.
3. Select a conditional operator.
4. Select a comparison value.

   Some filter conditions don't require a comparison value for the condition. For example, the operator **Contains data** doesn't require a comparison value. With other filter conditions, you choose the comparison value from an option set. For example, the **Status** column has the values **Active** and **Inactive**.

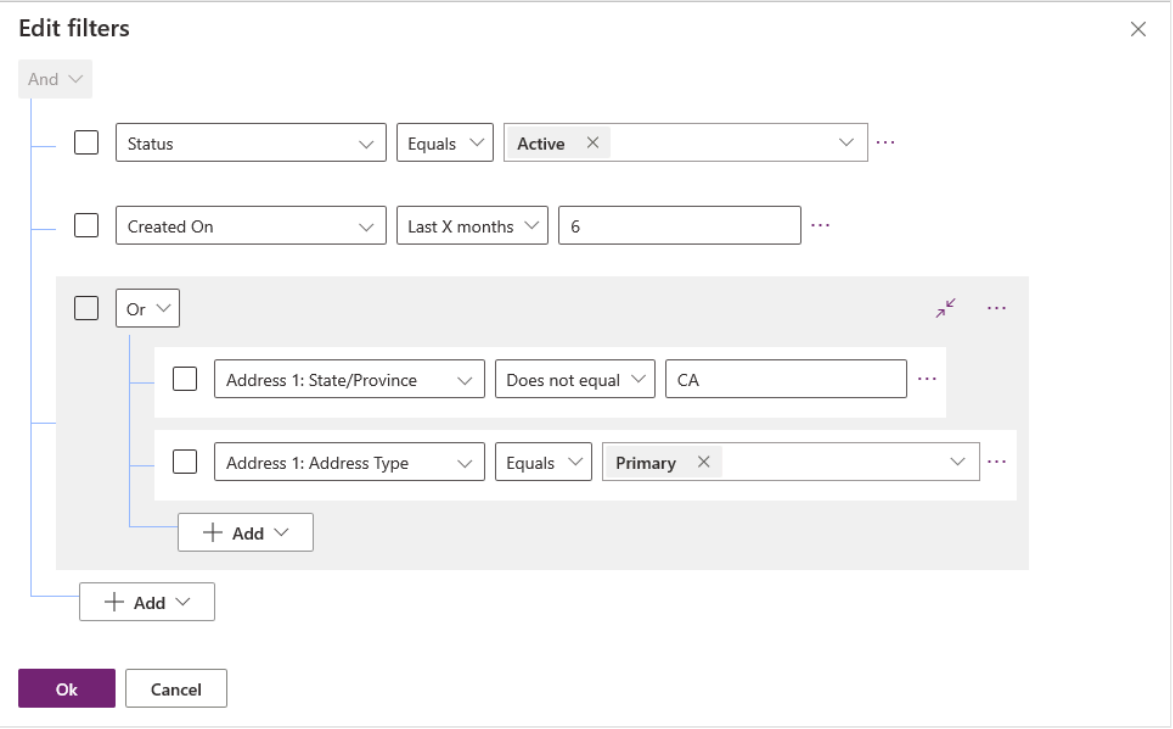
   


5. Select **OK**.

Add a group condition to a filter

1. In the expression builder, select **Add** > **Add group**.
2. Select the relational operator **Or** for the group. **And** is the default relational operator.

3. Specify the first clause of the grouped condition. Select the column, conditional operator, and comparison value.
4. Select **Add** > **Add group**.
5. Specify the second clause of the grouped condition.



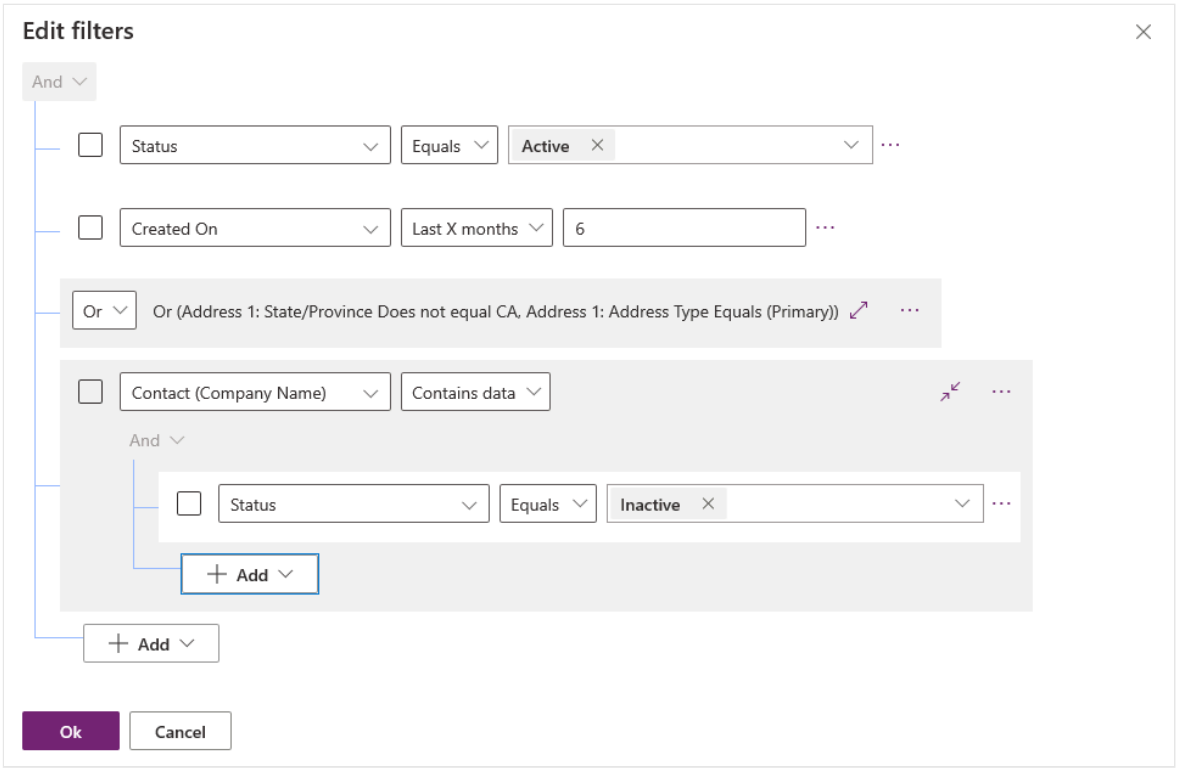
You can select **Collapse** to display the group as a conditional expression.

Add a related table to a condition

1. In the expression builder, select **Add** > **Add related table**.
2. Select a column from the current table that is related to another table. The table related to the column is shown in parenthesis. You can select columns that have a many-to-one, one-to-many, or many-to-many relationship with the related table.
3. Select a column of the related table for the condition.
4. Select a conditional operator.

> **Note**
>
> **Contains data** is the only conditional operator that can be used with a related table in a view filter.

5. Select or enter a comparison value.



Group conditions of a filter

1. In the expression builder, select the check box for the conditions that you want to group.
2. Select **More commands** (...) for one of the conditions, and then select **Make group**.
3. To ungroup a group, select **More commands** (...) for the group, and then select **Ungroup**

Sort rows in a model-driven app view

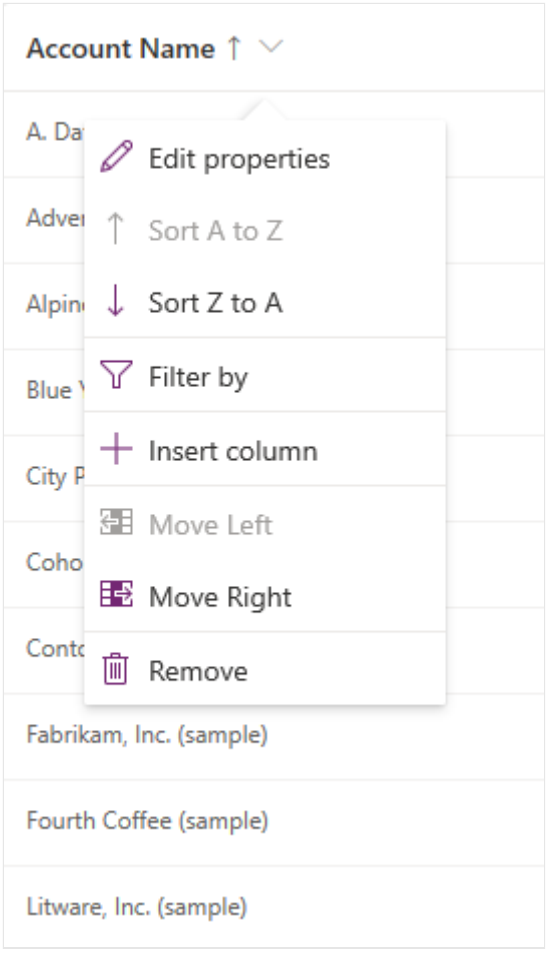
Article • 11/12/2024

When you create or edit a view, you can configure the sort order for either ascending or descending.

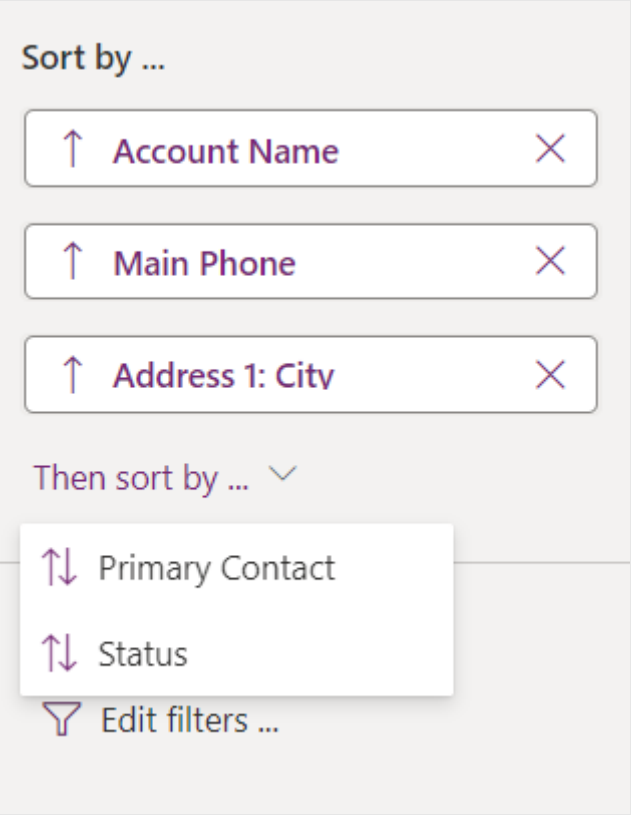
To change the sort order in the view designer, go to Create a public view in Power Apps.

Change the sort order of a view

1. Sign in to Power Apps.
2. Select **Solutions**, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Tables**, open the table you want, and then select the **Views** area.
4. Select a view to open it in the view designer.
5. Select the leftmost column head, such as **Account Name** in the example here, and from the column menu, select **Sort A to Z** or **Sort Z to A**. The sort order is indicated in the column head with an up arrow or a down arrow.



6. If a sort order hasn't been set for the view, select **Sort by**, and then select the primary sort by column.
7. To sort the view by additional columns, select **Then sort by** on the view properties pane on the right, and then select a sort by column for the view.



8. To remove a filter expression, under **Filter by** in the view properties pane, select **X** next to the filter expression you want to remove.
9. Select **Save and publish** to save the view and make it available to apps that include the table.

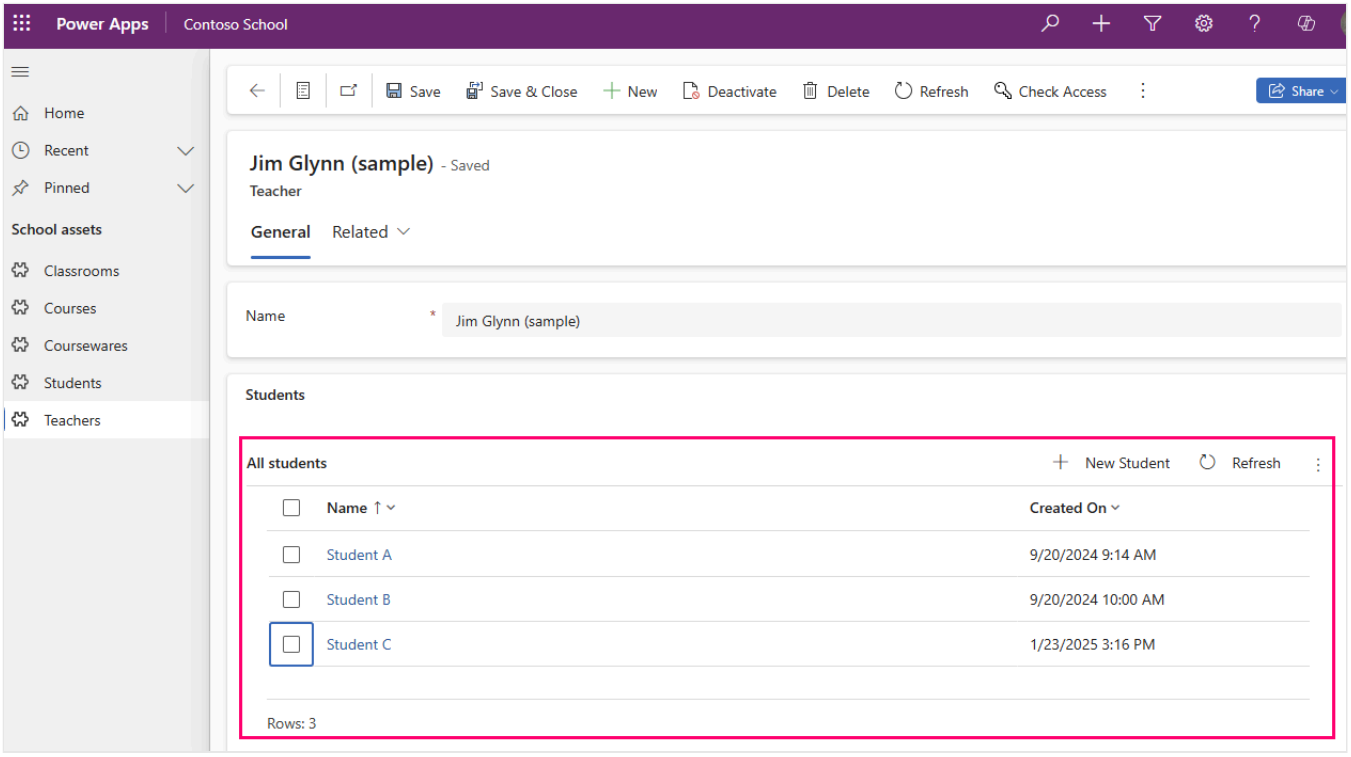
Power Apps read-only grid control

Summarize this article for me

> **Important**
>
> The Read-only Grid control is deprecated. Use the Power Apps grid control instead. More information: Deprecation of Editable Grid and Power Apps Read-Only Grid controls

The Power Apps read-only grid control lets users view and open records from views and subgrids. The control supports the latest Microsoft accessibility standards and is built to be performant and easily extensible for the future. The Power Apps read-only grid control also aligns with the latest Microsoft design guidance for fonts, sizing, and styling.

> **Note**
>
> As of April 2022, the Power Apps read-only grid control is the default control for all read-only views and subgrids.



Add the Power Apps read-only grid as a subgrid on a form

When you add a subgrid to a form, the subgrid only appears on that form and not other forms or views.

More information: Add and configure a subgrid component on a form

Add the Power Apps read-only grid control to views for a table

When you configure the Power Apps read-only grid control for a table, *all* views for that table display using that grid.

1. Open solution explorer.
2. Expand **Entities**, in the list of tables, open the table you want, select the **Controls** tab, and then select **Add Control**.
3. In the **Add Control** dialog box, select **Power Apps Read-only Grid**, and then select **Add**.

Configure the Power Apps read-only grid control

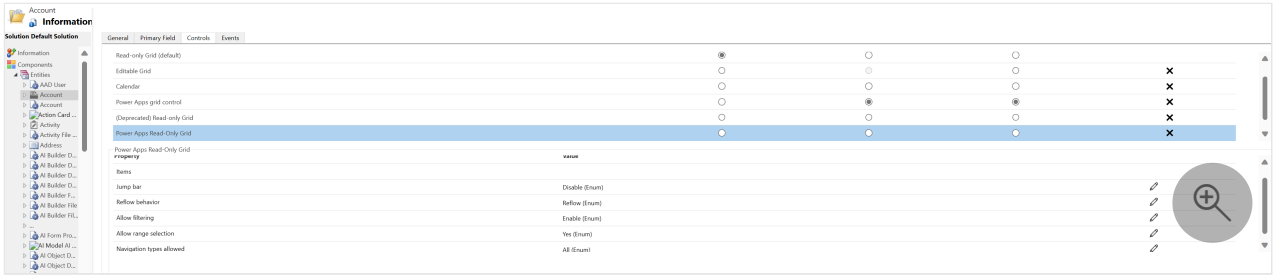
1. In the **Power Apps Read-Only Grid** row, select the app types you want to apply the grid to. This selection makes the control the default control for the selected clients.

2. Select the pencil icon next to the following properties to make the changes you want:

   - **Jump bar**: By default, the jump bar is disabled. To display an alphabetic list at the bottom of views or subgrids (the jump bar), select the pencil icon in the **Jump bar** row. Under **Bind to static options**, select **Enable** in the dropdown list. Below is a screenshot of the jump bar enabled for the contact table in a model-driven app.

   - **Reflow behavior**: Use this parameter to specify when the grid reflows into a list format or a grid format. Reflowing the control into a list is often better suited for small displays such as a mobile device. The default value is Reflow.
     - **Reflow**: Allows the grid to render into list mode when there's not enough display space.
     - **Grid only**: Displays only as a grid even on smaller displays such as a mobile device.

    - **List only**: Displays only as a list even when there's enough space to display as grid.
- **Allow filtering**: Determines whether filtering options are available to users in the grid column header dropdowns. The default value is Enable.
    - **Enable**: Filtering options are available to users.
    - **Disable**: Filtering options aren't available to users.
- **Allow range selection**: Controls whether users can select a subset of the grid and copy that data to another application like Excel. The default value is Yes.
    - **Yes**: Users can select and copy data from the grid.
    - **No**: Users can't select and copy data from the grid.
- **Navigation types allowed**: Determines which lookup controls in the grid render as hyperlinks. The default value is All.
    - **All**: All table lookup columns render in the grid as a hyperlink.
    - **Primary only**: Suppresses hyperlinks on all lookup fields except the primary column for the selected table.



3. To save your changes, select **Save** on the command bar. When you're ready to make the changes available to app users, select **Publish** on the command bar.

Add the Power Apps read-only grid control to a subgrid

1. Open solution explorer.
2. Open the form that contains the subgrid.
3. Select the subgrid where you want to configure this grid, and then select **Change Properties** on the command bar.
4. In the **Set Properties** dialog box, select the **Controls** tab, select **Add Control**, and then select **Power Apps Read-only Grid**.
5. To continue with configuring and publishing the control, see Configure the Power Apps read-only grid control.

Opt out of the Power Apps read-only grid control

While the Power Apps read-only grid control became the default grid experience in April 2022, you can opt your organization out of the automatic switch to this grid by following the steps here.

1. Go to the Power Platform Admin Center **Manage** > **Environments**. Select **Settings** on the command bar, and then select **Product** > **Features**.
2. Turn off the **Enable the modern read-only grid experience** option in the **Grids and views** section.

> **Note**
>
> As the legacy read-only grid is deprecated, this toggle to opt out of the automatic switch to the Power Apps read-only grid is eventually be removed.

Known issues and limitations

Grid rendering performance

In general, grid performance can be increased by limiting the number of records fetched at once and limiting the number of columns in a view.

If the page size is sufficiently large, the grid might take a long time to render. The current recommendation is to ensure the page size isn't too large, ideally no more than 25 rows.

UI limitations and differences

- The grid doesn't currently support any theme customizations
- Cells with no data are blank instead of displaying three dashes ---.
- The owner column doesn't show online status and a people card for the user.
- Reordering columns from the grid column headers isn't supported.
- If the dataset displayed in the grid contains duplicate rows, the duplicates might not display in the grid. This can lead to the reported record count showing more records than are actually in the grid, or more records appearing when exporting the data to Excel or viewing the data in legacy Advanced Find. This behavior applies to all grid controls, not just the Power Apps read-only grid.

Limitations with card form lists

When a view or subgrid is narrow, it changes into a card list format that is better for small screens, such as mobile devices. The Power Apps read-only grid control displays the following

behavior in a card list:

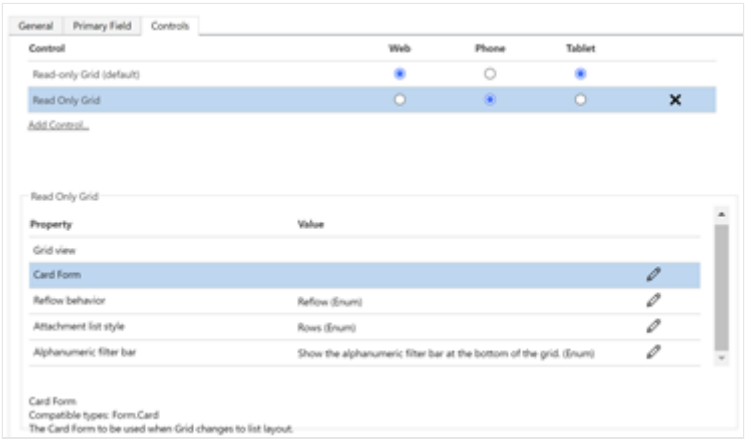
- Sort isn't currently available in a card list view. To work around this, create views with the sort order you want.
- **Select all** and **Clear all** aren't available in a card list view.
- The jump bar isn't available in a card list view. To work around this, select **Search** to filter records. Type the desired letter, and then press Enter.
- Images on a record in the list don't display in a card list view. This includes table icons, web resource images, custom images, and conditional images. The only image displayed for a record in the list are the initials of the record.
- There are no icons for context menu commands in a card list view.
- When there are no records, some lists have a prompt to create a new item. This button isn't displayed in a card list view that uses the Power Apps read-only grid control.

The list view doesn’t display custom cards for the table

To work around this issue, display a custom card by configuring the table to use the card form of the legacy read-only grid control.

1. Go to Power Apps (make.powerapps.com) > **Settings** > **Advanced Settings** > **Settings** > **Customizations** > **Customize the System** > expand **Entities** > select the entity you want to customize > **Controls** tab > **Add Control**.

2. Select **Read Only Grid**, and then select **Add**. Choose to display that grid on one or more client form factors.



3. Select **Configure property** (pencil icon) for the **Card Form** property, and select the custom card form from the drop-down list.

4. Select **OK**, and then **Publish** the customization.

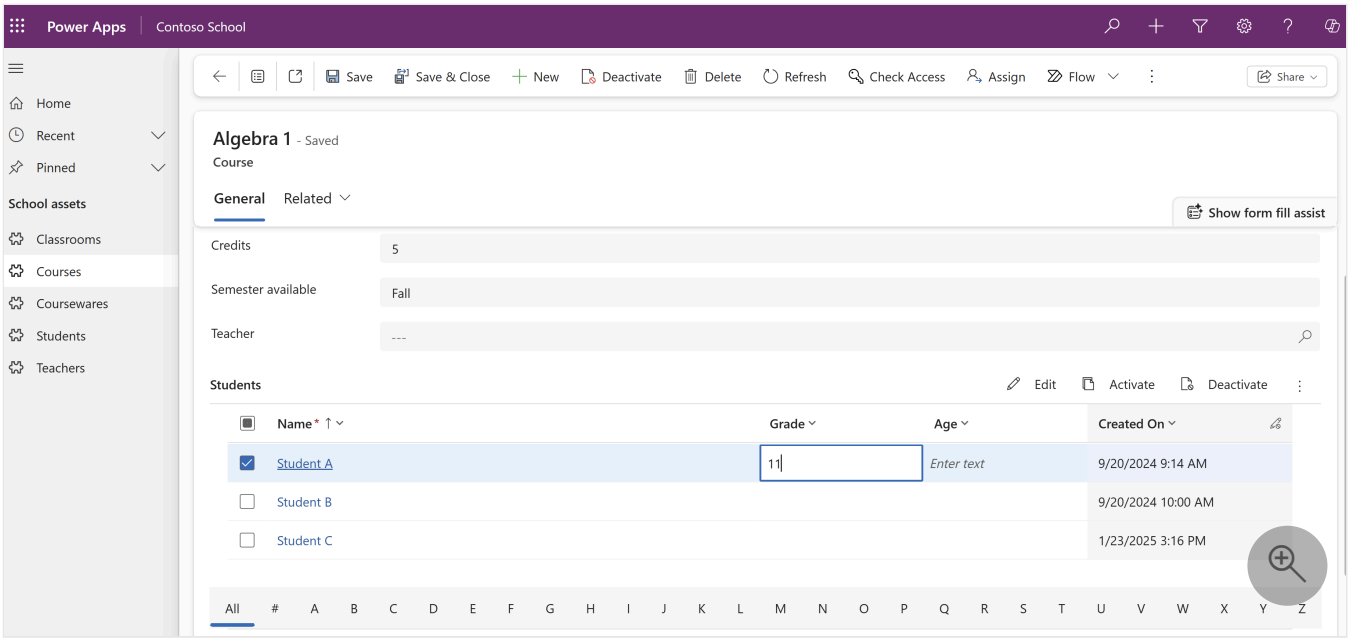
Explore data in a view on a grid page

Last updated on 02/28/2026

Power Apps grid control

The Power Apps grid control represents the next evolution of the classic Power Apps read-only grid control, allowing users to view, open, and edit records from views and subgrids. In addition to inline editing, the control provides a number of other powerful capabilities including infinite scrolling, nested grids, grouping, aggregation, and is customizable. Like the read-only grid control, this control supports the latest Microsoft accessibility standards and aligns with the latest Microsoft design guidance. This control eventually replaces all read-only and editable grids in model-driven apps.

- **Infinite scroll**: A modern data browsing experience in which users can scroll indefinitely through data until they find the records they're interested in. Since there are no page boundaries, users can select more rows at once (up to 1,000 rows) to facilitate taking action against a set of records or perform bulk editing.
- **Inline editing**: This singular grid control can be utilized for read-only or edit scenarios.
- **Nested grids**: Makers can configure the grid to show surface related records. When configured, users can expand a row to see a subgrid of related records. Multiple rows in the grid can be expanded simultaneously. This functionality is an improvement over older grid experiences.
- **Grouping**: Users can organize tabular data in interesting ways by grouping the data based on a single column. Each group is collapsed initially, but users can expand and collapse the groups as desired. Grouping is exposed on most data types with the notable exception of lookup columns. Grouping isn't supported when paging on the grid is enabled.
- **Aggregation**: Users can surface meaningful insights from their data by enabling aggregation on one or more numeric columns in a grid. For each column, users can choose to see the total, minimum value, maximum value, or average of values from that column. If grouping is applied, this aggregate value is also displayed for each group.
- **Customizable**: Makers have the ability to modify various experiences inside the grid component.

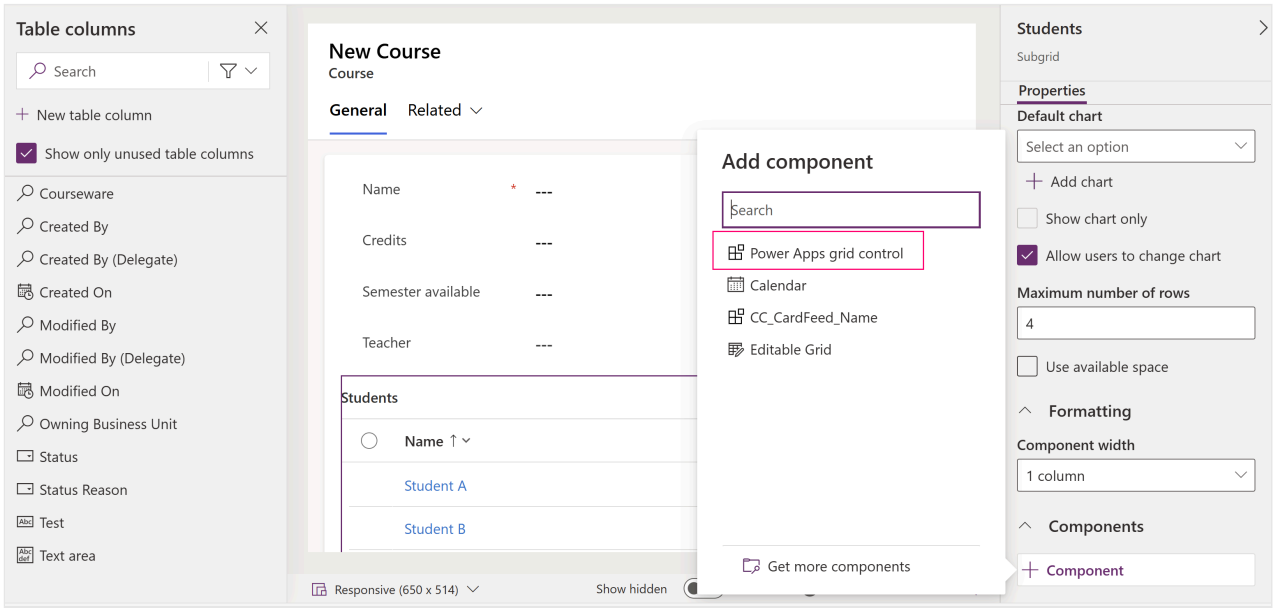


Add the Power Apps grid control using form designer

1. Sign in to Power Apps, select **Solutions** on the left navigation pane, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select the **Table** within the solution, and then select the **Forms** area. Open the **Main Form** that contains the subgrid for editing.

3. In the form designer, select **Components** on the left navigation pane, expand **Grid**, and then select **Power Apps grid control**. If the component isn't listed, select the subgrid on the form canvas, expand **Components** on the right property pane, select **+ Component**, and then select **Power Apps grid control** from the **Add component** page.



4. Configure the Power Apps grid control

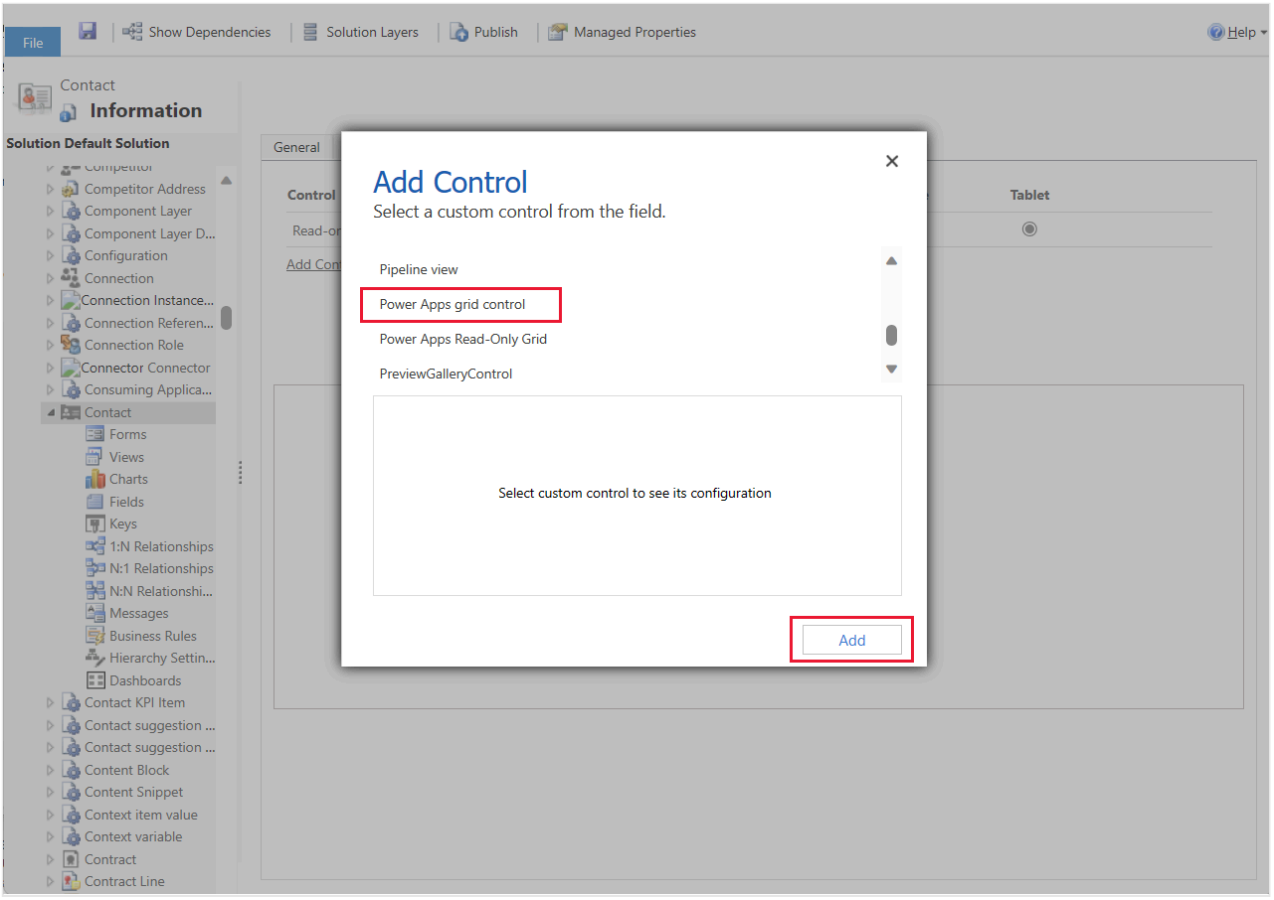
5. Select **Done**.

6. **Save and publish** the form to save and make it available to app users.

Add the Power Apps grid control to views using classic solution explorer

When you configure the Power Apps grid control for a table, all views for that table display using that grid.

1. Open the solution explorer.
2. Expand **Entities**. Browse to the table you want and select it. On the **Controls** tab, select **Add control**.
3. In the **Add control** dialog box, select **Power Apps grid control**, and then select **Add**.



4. Configure the Power Apps grid control
5. After configuring the Power Apps grid control to meet your needs, select **Save** on the command bar to save your changes. When you're ready to make the changes available to app users, select **Publish** on the command bar.

Add the Power Apps grid control to a subgrid using classic solution explorer

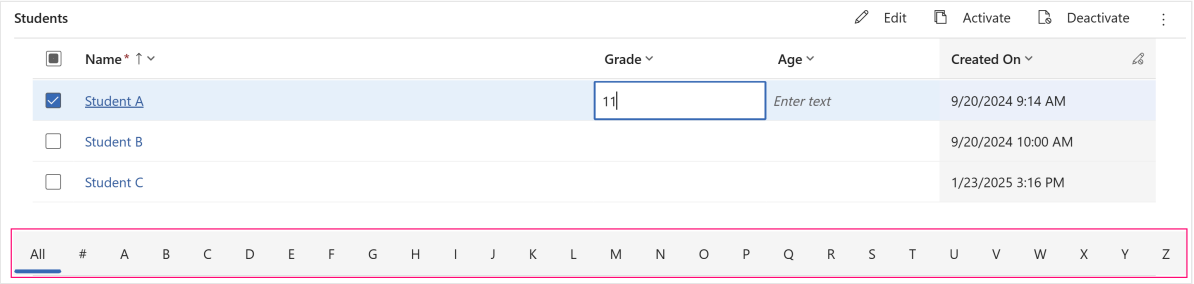
1. Open the solution explorer.
2. Expand **Entities**, expand the table you want, and then select **Forms**.
3. Open the form where you want to add the Power Apps grid control.
4. On the form canvas, select the subgrid where you want to configure this grid (usually located on a form section), and then select **Change properties** on the command bar.
5. In the **Set properties** dialog box, select the **Controls** tab, select **Add control**, and then select **Power Apps grid control**.
6. To configure the control, go to Configure the Power Apps grid control.
7. Select **OK** to close the **Set properties** dialog box.
8. To save and make available to apps, select **Save**, and then select **Publish**.
9. After configuring the Power Apps grid control to meet your needs, select **Save** on the command bar to save your changes. When you're ready to make the changes available to app users, select **Publish** on the command bar.

Configure the Power Apps grid control

1. Select the **Power Apps grid control** components. More information: Configure components on a form
2. There are several properties included with the control to let you tailor the grid experience for that table. To modify any of these properties, select **Edit** in the corresponding row, and then change the value using the dropdown list under **Bind to static options**.

    - The **Enable editing** property determines whether the grid is read-only or editable. The default value is **No**. Select **Yes** to make the grid editable. Editable grids have subtle visual differences to read-only grids including boolean columns showing toggle switches and dropdown and date fields displaying chevrons and date picker icons on hover or focus.
    - The **Enable filtering** property determines if filtering options are available to users in the grid column header dropdowns. The default value is **Yes**.
    - The **Enable sorting** property determines if sorting options are available to users in the grid column header dropdowns. The default value is **Yes**.
    - The **Enable grouping** property determines if grouping options are available to users in the grid column header dropdowns. The default value is **No**.

- The **Enable aggregation** property determines if aggregation options (sum, minimum, maximum, average) are available to users in numeric columns of the grid. The default value is **No**.
- The **Allow column reordering** property controls whether users can reorder columns from directly within the grid. This control includes drag-and-drop of the column headers or using **Move left** and **Move right** actions from the column header dropdowns. The default value is **No**.
- The **Enable multiselect** property determines whether users can select multiple rows in the grid simultaneously or just a single row. The default value is **Yes**.
- The **Allow range selection** property controls whether users can select a subset of the grid and copy that data to another application like Excel. The default value is **Yes**.
- The **Enable jump bar** property can be used to display an alphabetic list at the bottom of views or subgrids. The default value is **No**. Below is a screenshot of the jump bar enabled for a subgrid in a model-driven app.



- The **Enable pagination** property can be used to decide between modern data browsing (infinite scroll) and paging buttons. The default value is **No**. Select **Yes** to disable infinite scrolling and surface paging buttons. Note that the **Select all** action isn't currently available when using infinite scroll, but users can still perform range selection.
- The **Enable OptionSet colors** property can be used to increase the visual appeal of choice columns by showing each value with its configured background color. The default value is **No**. Be sure to verify the configured color for each choice column to ensure readability and accessibility before enabling this property for a table.
- The **Show row status icons** property controls whether users see status icons (invalid, save in progress, saving, and so on) at the beginning of a grid row during the editing experience. The default value is **Yes**.
- The **Show data type icons** property determines whether column headers display an icon corresponding to the data type next to the column name. The default value is **No**.
- The **Navigation types allowed** property determines which lookup controls in the grid render as hyperlinks. The default value is **All**. Select **Primary only** to suppress

hyperlinks on all lookup fields except the primary column for the selected entity, or **None** to suppress all hyperlinks in the grid.

- The **Reflow behavior** property determines whether the grid components render always in a tabular fashion (**Grid only**), always as a list (**List only**), or switches between tabular and list depending on the available width (**Reflow**). The default value is **Reflow**.
- The **Show avatar** property determines if the avatar is shown while the grid is in a list view. This avatar is typically represented as a colored icon with text showing the first letters of the row value. The default value is **Yes**.
- The **Number of columns for list view** property allows you to define the number of columns to render while the grid is in list view. The default number of columns for a list is 3, the maximum number of columns is 10.
- The **Enable banded rows for list view** property applies alternating color band to rows in the list view to improve record differentiation. The default value is **No**.
- The **Show column labels for list view** property displays column labels before values in a list view. The default value is **No**.
- The **Child items** property is used to configure the nested grid capability, which allows users to expand rows to see related records in a subgrid. To set up this property, specify the **Entity** where the related records come from and the **View** that defines the filters, sorts, and columns to show in the subgrid. The default value is no nested grid configured.
    - The **Child items parent ID** property is also needed to configure a nested grid and specifies the column (and relationship) to use to link the parent and child tables together.
    - The **Disable editing in child items grid** property provides some control over the editability of the nested grid. By default, the nested grid inherits the editability of the parent grid, but this property can be used to suppress editing in the nested grid when the parent grid is editable. The default value is **No**.
- The **Customizer control** property allows the maker to link to a single customizer Power Apps component framework control with definitions for changing the visuals or interactions for one or more columns in the grid or the empty grid visual.
- The **Use first column for lookup edits** property allows makers to select the column used for editing lookup cells. When set to **Yes** the cell shows and filters by the first column of the target table's lookup view. When set to **No** the cell shows and filters by the primary column. The default value is **No**.

Customization

For information about how to customize the Power Apps grid control using extensibility APIs, go to Customize the editable grid control.

Known issues and limitations

Limitations with card form lists

When a view or subgrid is narrow, it changes into a card list format that's better for small screens, such as mobile devices. The Power Apps grid control displays the following behavior in a card list:

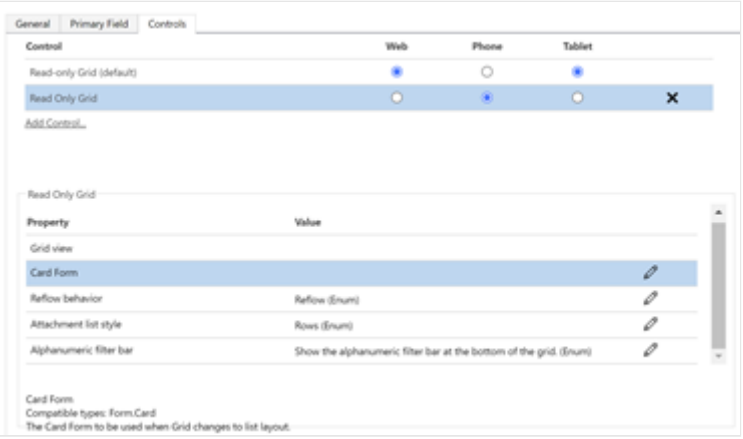
- Sort isn't currently available in a card list view. To work around this limitation, create views with the sort order you want.
- **Select all** and **Clear all** aren't available in a card list view.
- The jump bar isn't available in a card list view. To work around this limitation, select **Search** to filter records. Type the desired letter, and then press Enter.
- Images on a record in the list don't display in a card list view. This limitation includes table icons, web resource images, custom images, and conditional images. The only image displayed for a record in the list are the initials of the record.
- There are no icons for context menu commands in a card list view.
- When there are no records, some lists have a prompt to create a new item. This button isn't displayed in a card list view that uses the Power Apps read-only grid control.

The list view doesn't display custom cards for the table

To work around this, you can display a custom card by configuring the table to use the card form of the legacy read-only grid control.

1. Go to Power Apps (make.powerapps.com) > **Settings** > **Advanced Settings** > **Settings** > **Customizations** > **Customize the System** > expand **Entities** > select the table you want to customize > **Controls** tab > **Add Control**.

2. Select **Read Only Grid**, and then select **Add**. Choose to display that grid on one or more client form factors.



3. Select **Configure property** (pencil icon) for the **Card Form** property, and select the custom card form from the drop-down list.

4. Select **OK**, and then **Publish** the customization.

UI limitations and differences from the read-only grid control

- The grid doesn't currently support legacy theme customizations.
- Cells with no data are blank instead of displaying three dashes ---.
- The owner column doesn't show online status and a people card for the user.
- Columns lookup filters, when using the 'Equals' or 'Does not equal' operator, only show lookup options available within the current set of applied filters.
    - For example, if the contact table has users 'Person A', 'Person B', and 'Person C' but account table data only has rows referencing 'Person B' and 'Person C', then the column filter lookup for the contact column in the account grid only shows the options for 'Person B' and 'Person C'. This is a change in behavior from previous grids.

Known issues

- Column grouping isn't supported when paging on the grid is enabled.
- If the dataset displayed in the grid contains duplicate rows, the duplicates might not display in the grid. This can lead to the reported record count showing more records than are actually in the grid, or more records appearing when exporting the data to Excel or viewing the data in legacy Advanced Find. This behavior applies to all grid controls, not just the Power Apps grid control.
- If a user has read-only privileges to the main list and then navigates through a form to a subgrid representing an entity to which they have write privileges, the subgrid still won't allow the user to make changes as access is determined first by the main entity, then by the related entity.

- When using the Power Apps grid control in editable mode, lookup field cell customization options aren't supported.
- When the Power Apps grid control is configured as read-only at the table level but editable for a subset of views, events might not fire uniformly across the different configuration states.

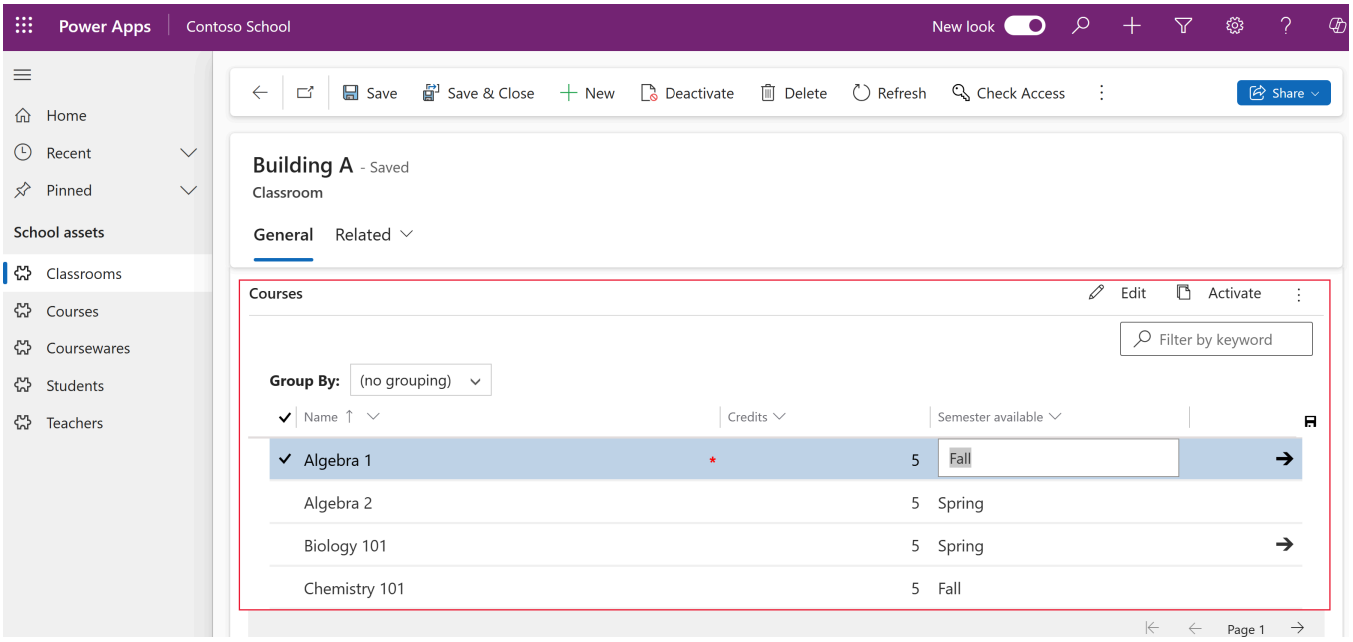
Make model-driven app views editable using the editable grid control

Summarize this article for me

> **Important**
>
> The Editable Grid control is deprecated. Use the Power Apps grid control instead. More information: Deprecation of Editable Grid and Power Apps Read-Only Grid controls

By default, users can't enter data directly using the read-only view control for views and subgrids on forms. Users select the row in the grid to open a form, edit the data, and then save, which requires multiple steps. With editable grids, users can do rich in-line editing directly from views and subgrids whether they're using a web app or tablet. This editing experience isn't available on phones.



When editable grids are enabled through the editable grid control, users can edit the data inside most types of columns, including basic lookup columns and choices columns. Editable grids avoid the need to open a form.

Add an editable grid to a main form

1. Sign in to Power Apps, select **Solutions** on the left navigation pane, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select the **Table** within the solution, and then select the **Forms** area. Open the **Main Form** that contains the subgrid for editing.
3. In the form designer, select **Components** on the left navigation pane, expand **Grid**, and then select **Editable Grid**.
4. Select the following for the grid.

Expand table

Area	Property	Description
Grid	Table	Select the table you want that will display records in the grid.
Grid	View	Select the table view you want displayed in the grid.
Grid	Lookup view	Select to add a lookup. Select the lookup column to add (for example, select **Primary Contact**) and in the **Default view** list, select the data source for the lookup column.
Subgrid	Table	If you have a nested grid select the **Table** and **View** for the nested grid (phones and tablets only).
Subgrid	Subgrid parent id	For the subgrid parent id, select the relationship for the tables. For example, the subgrid parent id table column connects the **Account** and **Contact** tables.
Group by	Enable or Disable	If you don't want to allow the user to group data by any column in the view (you want to save space, for example), in the **Group by** value select **Disable**.
Layout	Vertical or Horizontal	Determines how the grid displays on the form.
Allow filtering	Enable or Disable	Disable if you don't want users the ability to filter the grid by keyword.
Hide nested grid column header	Show column header or Hide column header	Determines whether the grid header displays.
Alphanumeric filter bar	Show the alphanumeric filter bar or Hide the alphanumeric filter bar	Determines whether the filter bar located at the bottom of the grid is displayed.
Show component	Web, Mobile, Tablet	Determines the client type that can use the

Area	Property	Description
on		editable grid control.

5. Select **Done**.

6. **Save and publish** the form to save and make it available to app users.

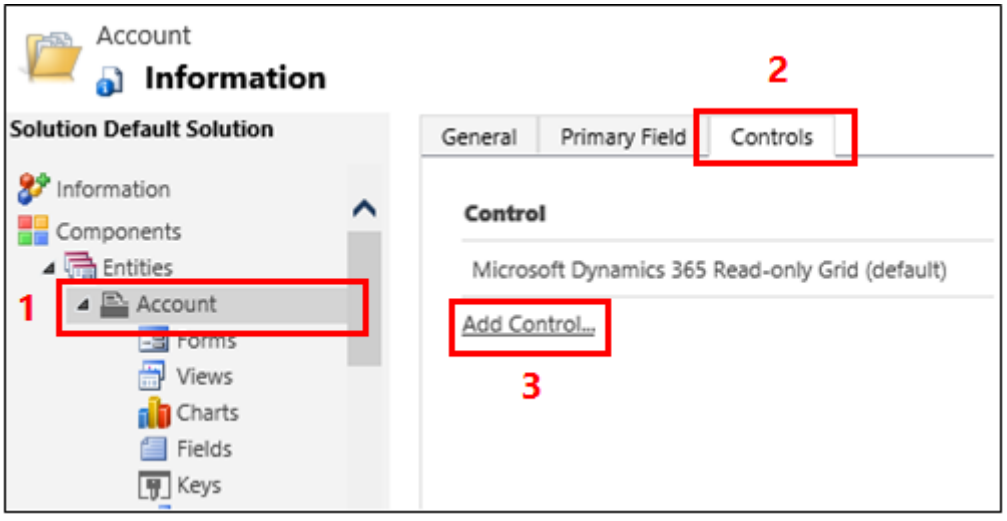
For information about editing the properties of an existing subgrid on a form, go to Configure a subgrid component.

Make main grids editable for views using the classic solution explorer

1. Sign in to Power Apps, select **Solutions** on the left navigation pane, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. On the toolbar select **...** > **Switch to classic**. This opens solution explorer in a new browser window.

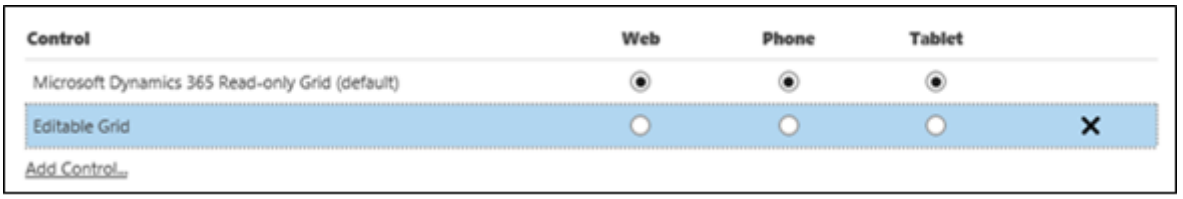
3. In the **Entities** list (these represent Dataverse tables), open the table you want, select the **Controls** tab, and then select **Add Control**.



4. In the **Add Control** dialog box, select **Editable Grid**, and then select **Add**.

5. In the **Editable Grid** row that's added, select the client type you want to apply the grid to, web, phone, and tablet. This makes the editable grid control the default control for the selected client type. Since the control doesn't work with phones, you should select **Web** for desktop app users. At runtime, users are able to toggle between editable grids and read-only grids.

> ⓘ **Note**
>
> Since the editing experience is not available on the **Phone** form factor, if this control is configured for phones, you will see a read-only version of the list control.



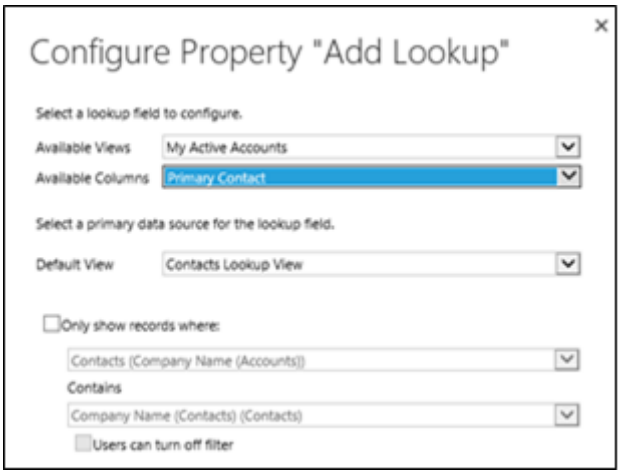
1. To add a lookup, in the **Editable Grid** area, select **Add Lookup**, and then in the **Configure Property "Add Lookup"** dialog box:

   a. In the **Available Views** list, select the view to add the lookup to (for example, select **My Active Accounts**).

   b. In the **Available Columns** list, select the lookup column to add (for example, select **Primary Contact**).

   c. In the **Default View** list, select the data source for the lookup column.

   d. If you want to limit the rows displayed, select the **Only show rows where** check box, and then select your criteria from the list, and then select **OK**.

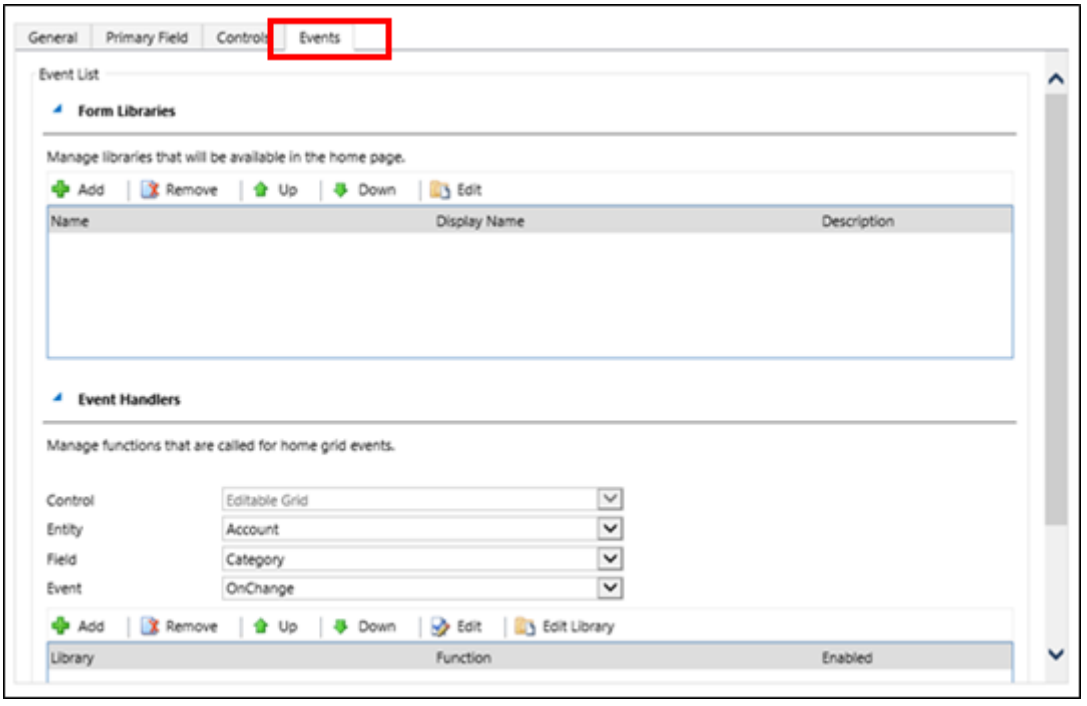
2. If you have a nested grid, select the pencil button for **Nested grid view**, and then select the table and view for the nested grid. For the **Nested grid parent ID** select the relationship for the tables. For example, the **ParentAccountID** column connects the **Account** and **Contact** tables.

   > ⓘ **Note**
   >
   > Nested grids are only available for phones and tablets, not the web.

3. If you don't want to allow the user to group data by any column in the view (you want to save space, for example), in the **Group by Column** row, select the pencil button, and then in the **Configure Property "Group by Column"** dialog box, select **Disabled**, and then select **OK**.

   > **Tip**
   >
   > This is mostly useful for sub-grids on forms.

4. If you want to add JavaScript events, select the **Events** tab, and then select the appropriate tables, columns, and events. More information: Developer Documentation: Use editable grids



5. To save your changes, select **Save** on the action bar.

6. When you're ready to make changes available to your team, select **Publish** on the action bar.

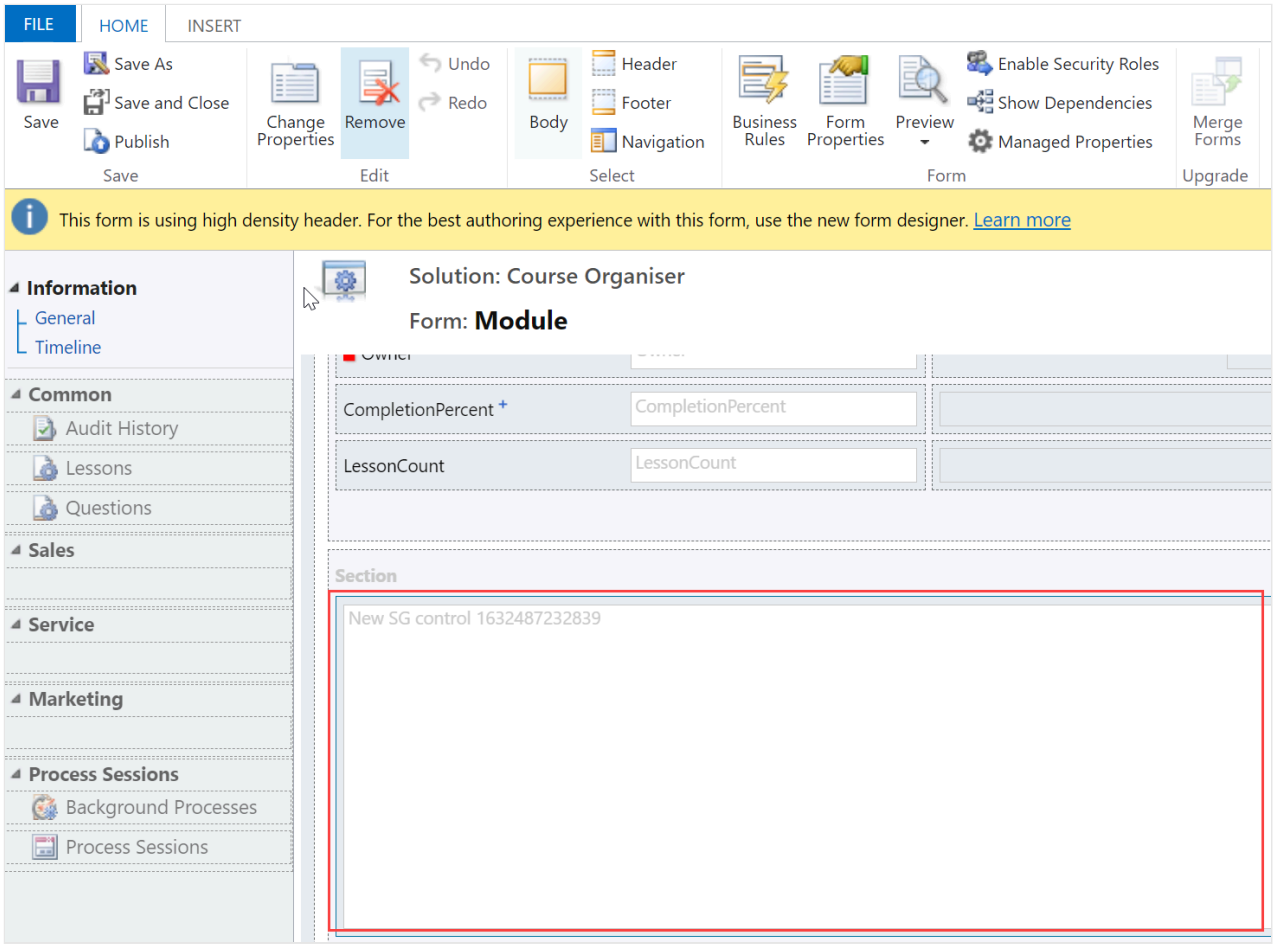
7. To test your changes, go to the view you specified in the previous step, and then make some in-line editing changes.

Make a subgrid on a form editable using classic solution explorer

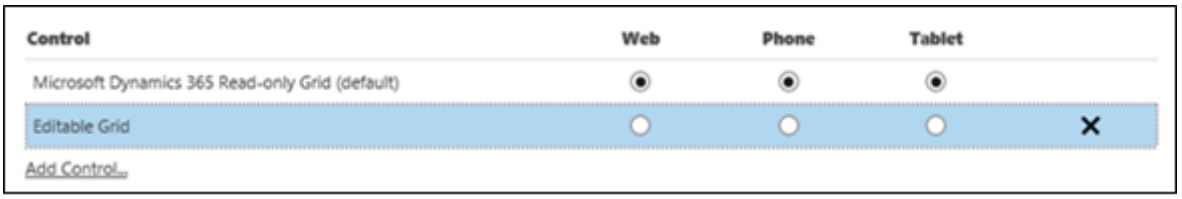
> **Note**

To save an editable grid change within a sub-grid, the user must explicitly save before navigating out of the form.

1. Sign in to Power Apps.
2. Select **Solutions**, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Table** within the solution, and then select the **Forms** area. Open the **Main Form** that contains the subgrid.
4. On the form designer command bar, select **...** > **Switch to classic**. This action opens a new tab in your browser.
5. Select the appropriate control, and then select **Change Properties** on the ribbon.



6. In the **Set Properties** dialog box, select **Controls**.
7. Select **Add Control**, select **Editable Grid**, and then select **Add**.
8. In the **Editable Grid** row that's added, select the client types you want to apply the grid to. This makes the editable grid control the default control for the selected form factor. For most instances, select **Web**.



9. Select **Save**, and then select **Publish**.

Editable grids support

- In-line editing of rows at the table or subgrid level (includes custom tables).
- System views and personal views.
- Web and mobile clients.
- Navigation with a keyboard or mouse.
- Grouping and sorting (you can group by/sort rows on the client-side by any column in the current view).
- Filtering.
- Moving and resizing columns.
- Pagination.
- Lookup configuration.
- Calculated columns and rollup columns.
- Business rules (Show error message, Set column value, Set business required, Set default value, Lock, or unlock column).
- JavaScript events.
- Enabling or disabling of cells based on security role.
- Users can continue to use search and charts, and can access the action bar as with read-only grids.

Supported standard tables

Limitations

Data types that aren't editable in an editable grid

The following data types aren't editable in editable grids: Customer and Partylist Lookup columns; Composite (address) columns; State/Status columns; Lookup table-related columns (for example, the Account table includes a contact lookup, where the Contact column is editable but the EmailAddress(Contact) column isn't editable).

Group by views work on client side only

Grouping behavior works only on the client side and doesn't span pages. Group by is a client only function and works only on one page of data. Group by doesn't show you all options based on your complete data set on the server. Group by shows grouping only on the current page. You can disable the grouping by using the property on custom control configuration. More information: Make a subgrid on a form editable using classic solution explorer

Inline grid modifications aren't persisted

Changes made to the structure of the editable grid from within the grid, such as column resizing, column reordering, grouping, filtering, and sorting, will be reset the next time the user visits the page. These types of changes aren't saved across sessions or within views.

Business rules work only if conditional column is a column on the grid

Business rules on an editable grid are supported only if the conditional column is also a column on the grid. If the column isn't a column the business rules won't work. Verify that each column referenced in the business rule is also included on the form. Note that business rules on an editable grid don't fire if the editable grid is configured on a dashboard.

Editable grids don't work on phones

Based on customer feedback, we have removed the editable grid experience from phones. When using an editable grid on a phone, you see a read-only version of the list control.

Duplicate rows in a dataset might not be displayed in the grid

If the dataset displayed in the grid contains duplicate rows, the duplicates might not display in the grid. This can lead to the reported record count showing more records than are actually in the grid, or more records appearing when exporting the data to Excel or viewing the data in legacy Advanced Find.

Setting managed properties for views

Keyboard shortcuts for editable grids (views)

Last updated on 02/27/2026

Model-driven app managed properties for views

Summarize this article for me

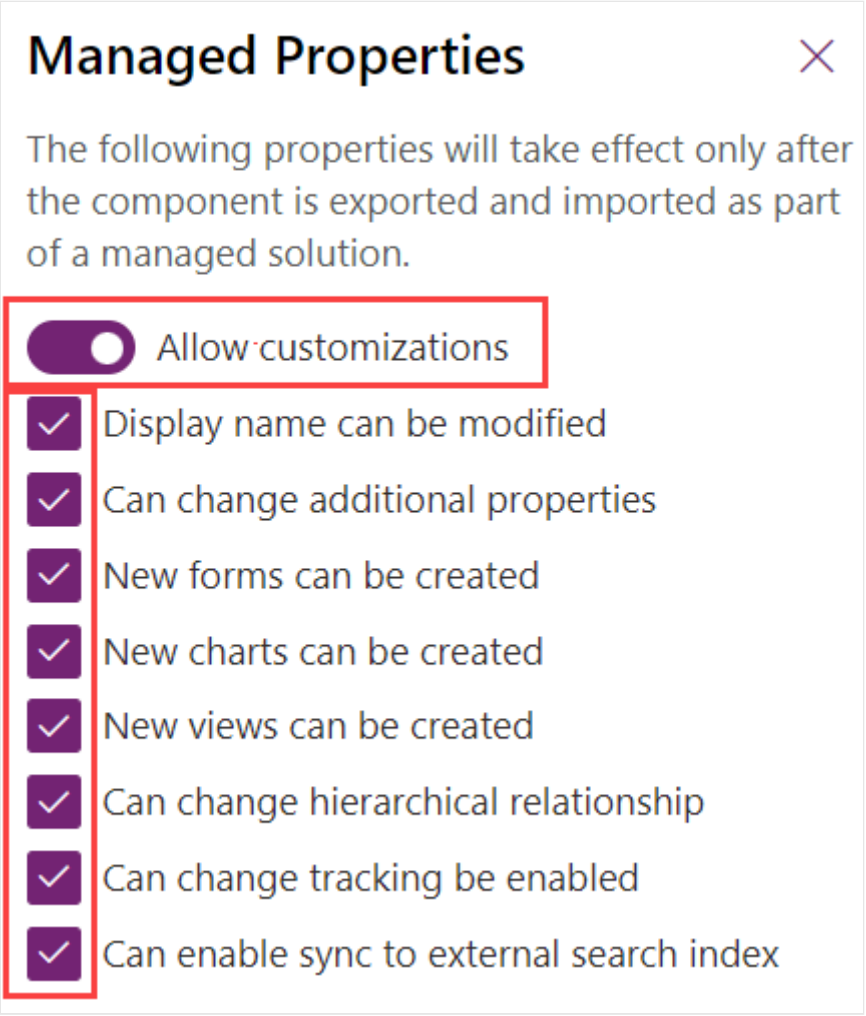
When you create a custom public view for a table in Power Apps that's included in a managed solution, there's the option to limit the ability of anyone who is installing the solution from customizing the view.

Additionally, there are high-level options that you can set on the table that apply to all views.

By default, most views have their **Customizable** managed property set to true so that people can customize them. Unless there's a good reason to change this, we recommend you allow people to customize views in the table.

Set managed properties for all views

1. Sign in to Power Apps.
2. Select **Solutions**, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the table you want. Select **Advanced**, and then select **Managed properties** on the command bar.
4. There are a range of options relevant to the current table to either prevent any customizations or to prevent the creation of new views.



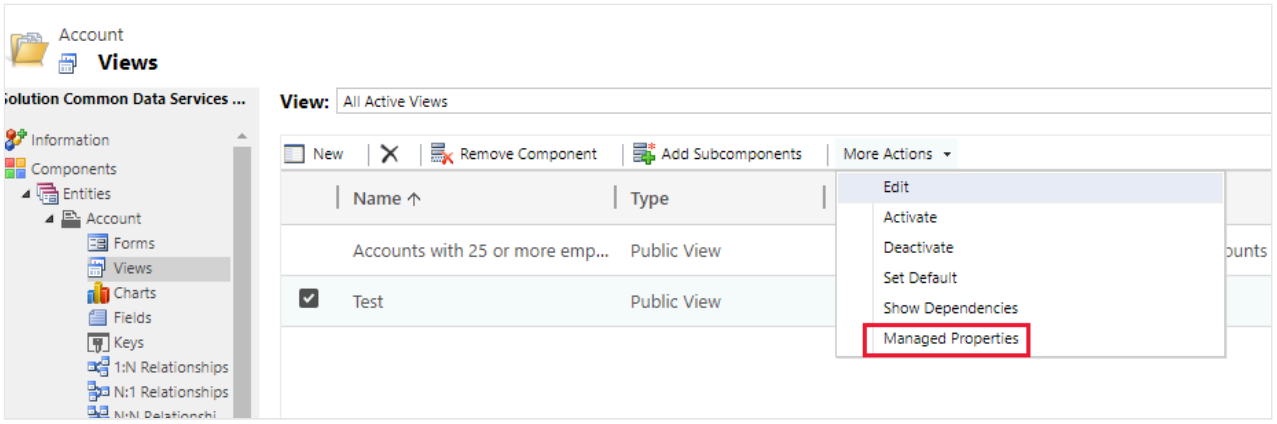
5. Make any necessary changes and when finished, select **Done**.

> **Note**
>
> The setting doesn't take effect until the solution is exported from the development environment and imported as a managed solution into another environment.

Set managed properties for a view (classic)

With this approach, the ability for the view to be changed can be set at the level of the individual view.

1. Open solution explorer, expand **Entities**, select the table required, and then select **Views**.
2. Select a custom public view.
3. On the command bar, select **More Actions** > **Managed Properties**.



4. Set the **Customizable** or **Can Be Deleted** options to **True** or **False**.

Specify read only grid properties

Article • 04/19/2023

Model-driven apps use responsive design principles to provide an optimal viewing and interaction experience for any screen size or orientation. As the size of the screen or the container decreases—for example, on phones and smaller viewports—the grid is transformed into a list.

The Read Only Grid control specifies how a grid should respond to different screen sizes. As an app maker working with a model-driven app, you can configure the Read Only Grid control and its properties for custom grids and lists.

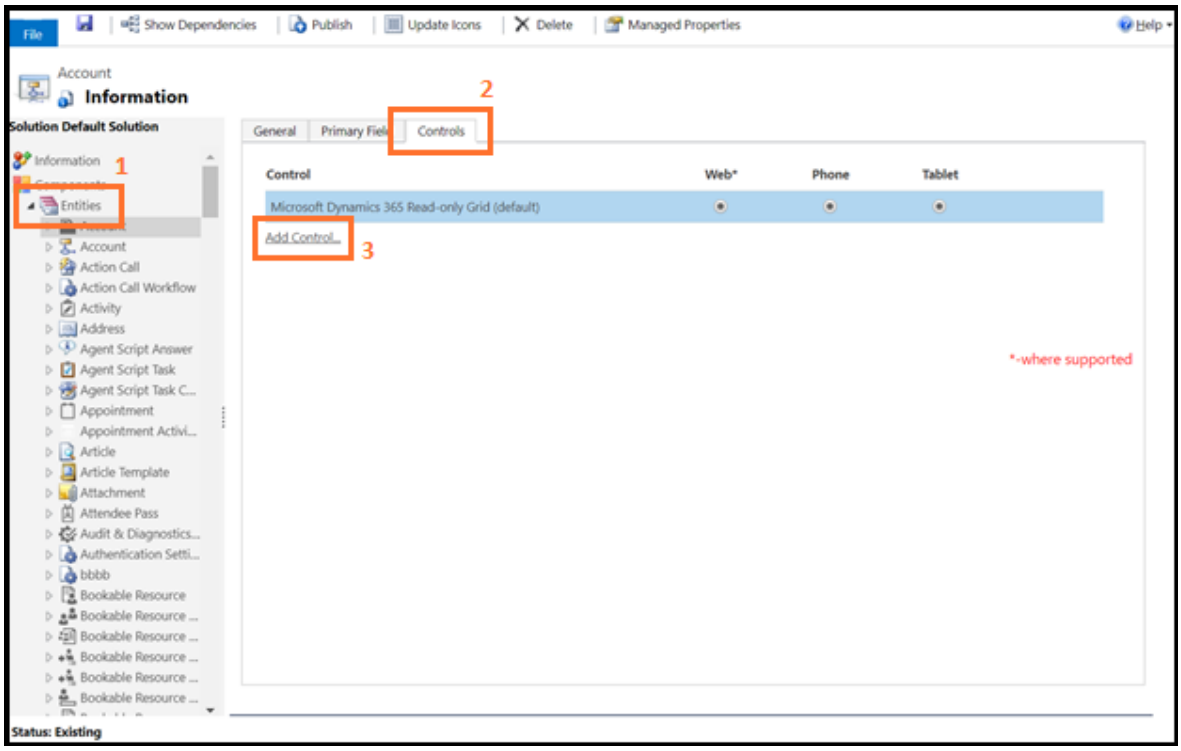
- **Card Form** property: Use a card form for lists instead of the default list template. Card forms provide more information for list items than the default list template.
- **Reflow behavior** property: Use this parameter to specify a grid to reflow in to a list or not.

Allow grid to reflow into list

Configure the following features after you add the Read Only Grid control to a table:

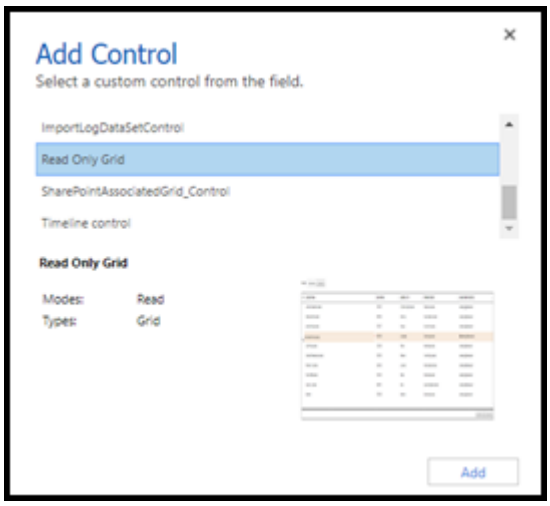
- Allow a grid to reflow into a list on small displays such as mobile.
- Specify the rendering mode as grid-only or list-only.

1. Go to Power Apps
2. Select **Tables** on the left navigation pane. Alternatively, select **Solutions**, and then open the solution. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Open the table, such as **Account**.
4. Select the **Forms** area, and select the form that you want to edit.
5. Select **Switch to classic**. The classic form editor opens as a new tab in your browser. (You may need to select **...** before selecting **Switch to classic**.)
6. In the navigation pane expand **Entities**, select the table (such as **Account** or **Contact**), and then on the **Controls** tab, select **Add Control**.

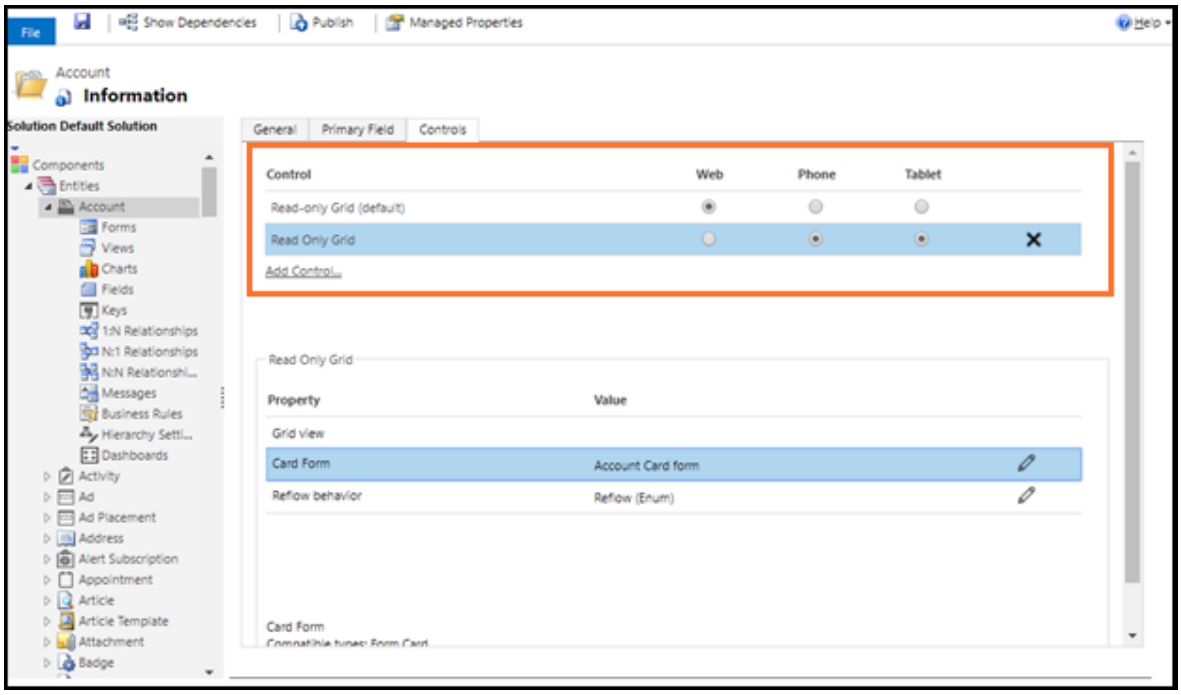


7. Select **Read Only Grid** from the list of controls, and then choose **Add**.

   The control is added to the list of available controls.



8. Select the devices (**Web**, **Phone**, or **Tablet**) for which you want to make the grid read-only.

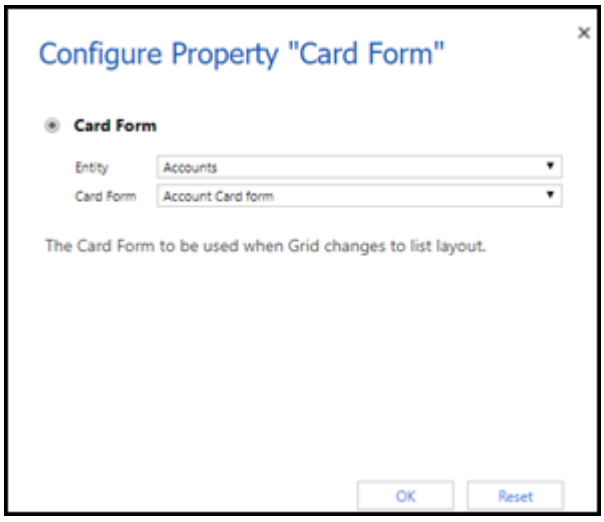


9. Configure the **Card Form** property.

   You can use the Card Form property to show list items instead of the default list template. Card forms provide more information for list items than the default list template does.

   a. Choose the pencil icon next to **Card Form**.

   b. Select the **Entity** and **Card Form** types.



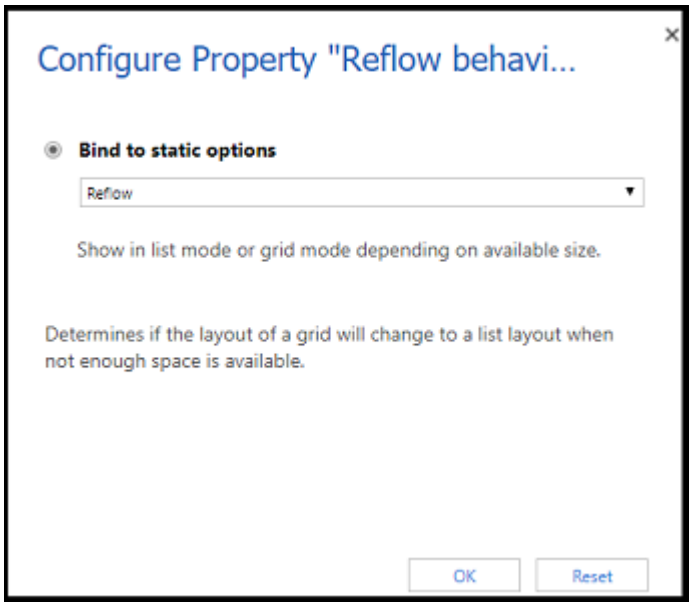
c. Choose **OK**.

10. Configure the **Reflow behavior** property.

    a. Choose the pencil icon next to **Reflow behavior**.

    b. Select the grid flow type from **Bind to static options** drop down.

Flow Type	Description
Reflow	Allows the grid to render into list mode depending when there is not enough display space.
Grid Only	Restricts the grid to reflow into list even when there is not enough display space.
List Only	Displays only as a list even when there is enough space to display as grid.



c. Choose **OK**.

11. Save and publish the changes.

Conditional image

You can display a custom icon instead of a value in a list and establish the logic used to select them based on a column's values by using JavaScript. For more information about conditional images, see Display custom icons instead of values in list views.

Known issue

If the dataset displayed in the grid contains duplicate rows, the duplicates might not display in the grid. This can lead to the reported record count showing more records than are actually in the grid, or more records appearing when exporting the data to Excel or viewing the data in legacy Advanced Find. This behavior applies to all grid controls, not just the Read-only grid control.

Next steps

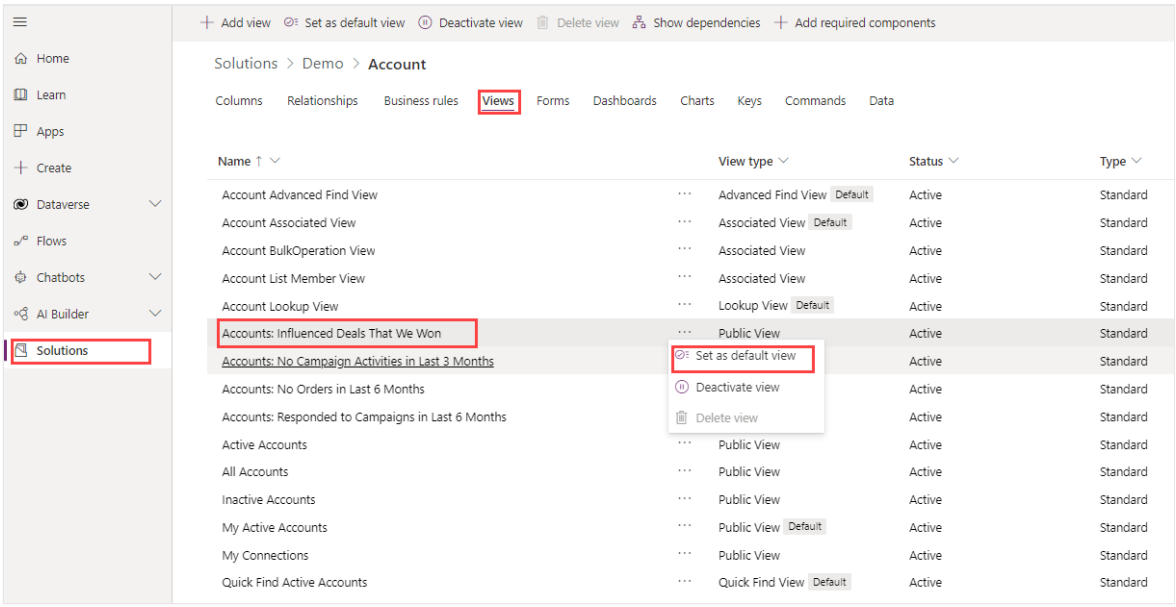
Model-driven app views overview

Specify a default view for a table

Article • 02/23/2023

Unless someone has 'pinned' a different view in your app as their personal default, they will see the default view specified by the app maker. Any of the public views can be set as the default view for a table.

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Open the solution where the table is located.
4. Open the table, and then select the **Views** area.
5. Select **More commands** ••• next to the view, and then select **Set as default view**. This can also be set on the command bar.



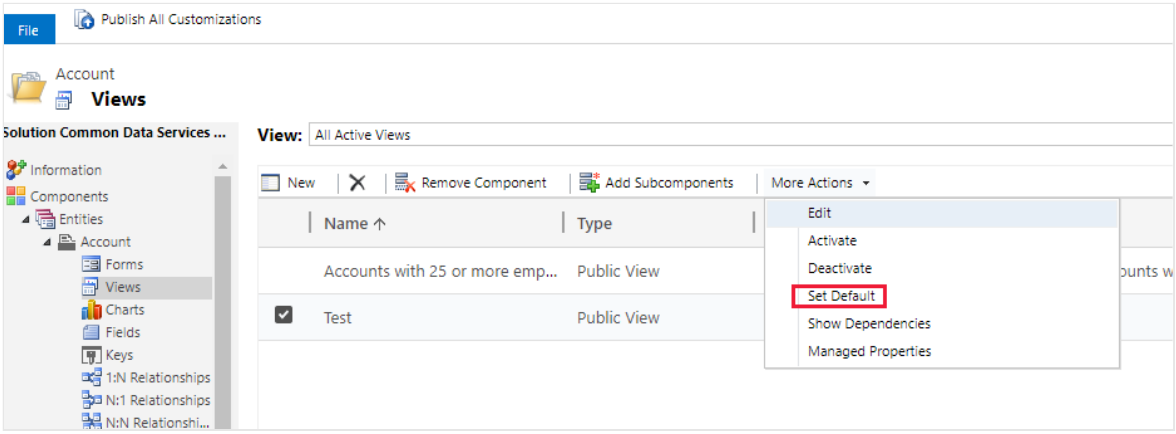
> **Note**
>
> You can also specify the views that can be displayed in a model-driven app using the model-driven app designer. More information: **Manage views and charts**

Set the default view for a table in solution explorer

1. Open solution explorer, expand **Entities**, select the table that you want, and then select **Views**.

2. Select one of the public views.

3. On the menu bar, select **More Actions** > **Set Default**.



4. On the solution explorer toolbar, select **Publish All Customizations**.

Next steps

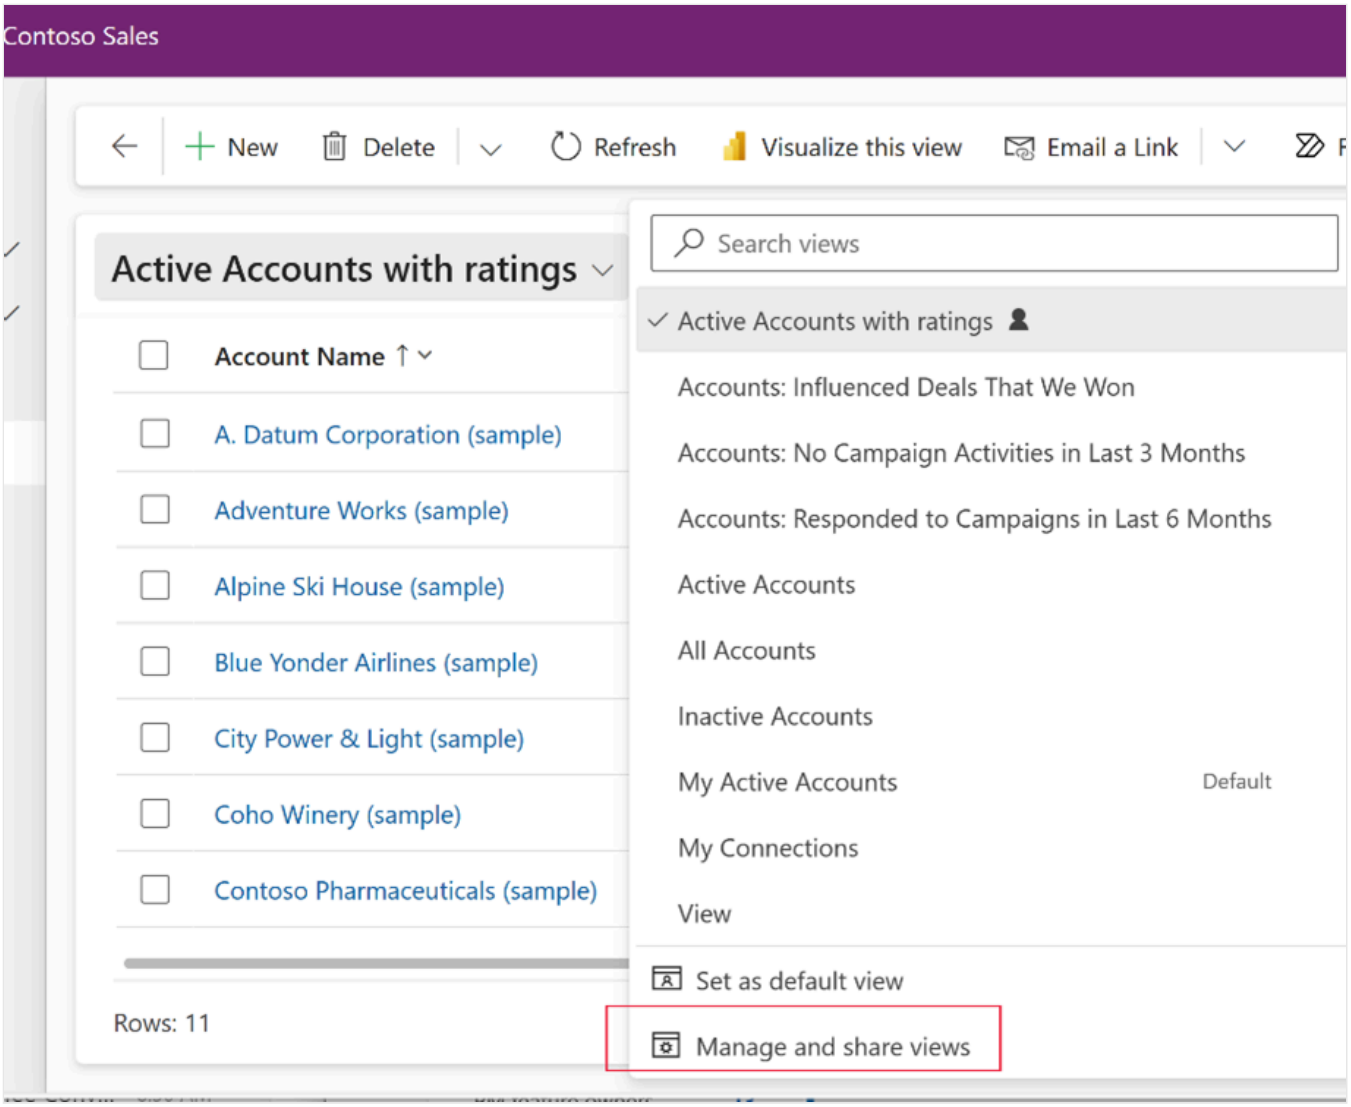
Delete or deactivate a view

Manage access to public system views

Admins can manage the views that users can access in model-driven apps by using security roles. When a user plays a model-driven app, they only have access to the system views that apply to the security roles they're assigned.

System views are special views that model-driven apps depend on, which exist for system tables or are automatically created when you create custom tables. These views have specific purposes and some additional capabilities. By default, all system views are for **everyone**. When a Power Platform admin manages a view with a security role, only the users who are assigned with the selected security role are able to see the view in the view selector. The other system views aren't filtered from the view selector dropdown list. Users can still access all the views when they navigate to the **Manage and share views** option.

After a Power Platform admin turns on the manage table list views feature, users can set their own default view from the list of views that the admin manages and their own personal views from the **Manage and share views** option in a model-driven app.



Data access continues to be secured with security role privileges, which means only records that a user has access to are displayed by the views. Having access to a particular view doesn't mean you also have access to the data that's available in the view.

> **Note**
>
> This feature filters views that appear in the table list view selector. All system and associated views continue to display in subgrids and associated grids that have a view selector.

Prerequisites

- Confirm that the orgdbsettings `EnableRoleBasedSystemViews' property is set to **true** using the OrganizationSettingsEditor tool.
- System administrator security role membership in the Microsoft Dataverse environment.
- Turning on auditing is recommended, but not required.

System views in a Dataverse environment

System views are predefined views that exist for all system tables. These views can include Public, Quick Find, Advanced Find, Associated, or Lookup. When an admin or maker creates a view from Power Apps (make.powerapps.com), the view becomes a public view. You can manage public views with security roles.

Commonly used public view examples

You can manage the table list of views with your business users based on the users' security role assignment. Admins select the applicable system views and manage these views with security roles. When the user navigates to a table list form, they can access the system views that were managed with the security roles that are assigned to them. The selected system views with security role aren't visible to users who don't have the security role assigned.

Examples of public views:

Expand table

Table	Public view
Account	My Active Accounts
Account	Accounts: No Campaign Activities in Last 3 months
Lead	My Open Leads
Lead	All Leads
Case	All Cases
Case	Cases I follow
Case	My Cases
Case	My Resolved cases
Contact	All Contacts
Contact	Contact I follow
Contact	Inactive contacts

Turn on manage table list views

1. Make sure you enable the table list views feature in your environment. More information: Prerequisites
2. You manage public views with security roles. If you need to create new security roles, go to Security roles and privileges for more information about security roles.
3. Create a solution and add the tables and their corresponding views that you manage.
4. Export the solution.
5. Import the solution into your production environment.

> **Tip**
>
> Inform your users that their system views are now filtered based on their security role assignment.

Manage public views with security roles

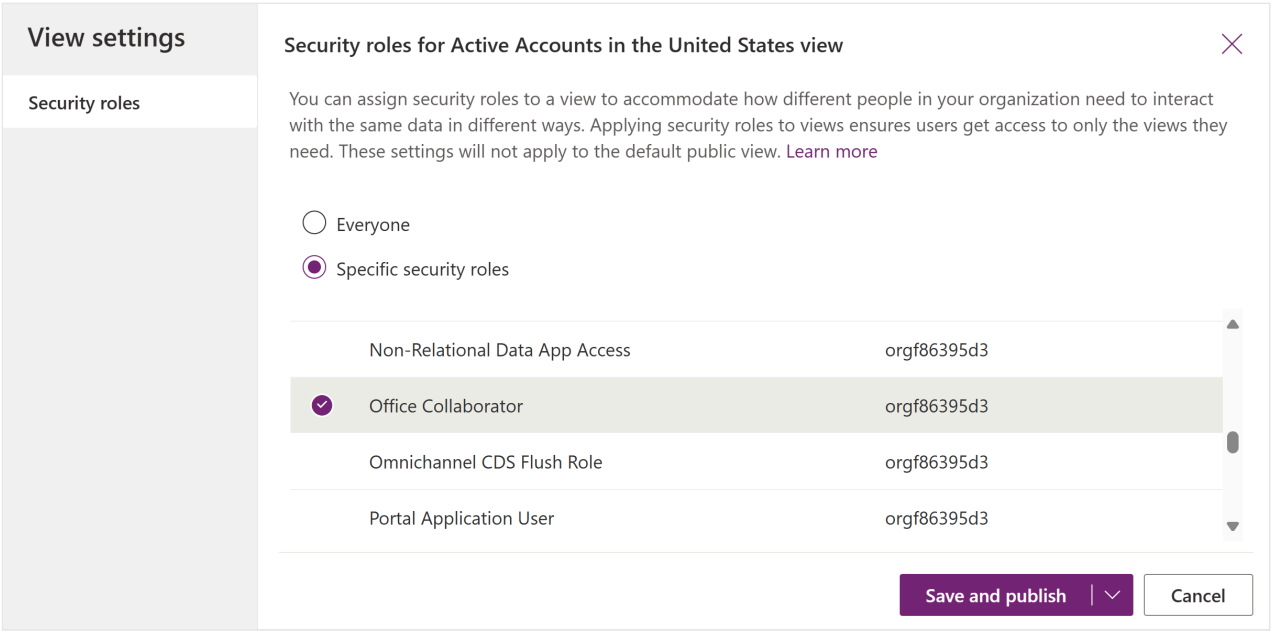
All system views can be managed with security roles. Once they're managed, users with the assigned security roles only view these views in the view selector.

> **Note**
>
> System views are denoted as **Public** view type in Power Apps (make.powerapps.com). Only public views can be managed. Default public views can't be assigned security roles for access.

Manage system views with security roles

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**, and then open the solution that has the table with the view you want to manage. If the item isn't in the side panel, select **...More** and then select the item you want.
3. Open a table, such as the account table, and then select the **Views** area.
4. Select the nondefault public view that you want, and then on the command bar, select **View settings**.
5. Select the **Specific security roles** option.
6. Select the security roles that you want to assign to the public view.

7. When you're done selecting the security roles, select **Save and Publish**.



> **Note**
>
> When you make changes to the 'EnableRoleBasedSystemViews' and **View settings**:
>
> 1. Setting the OrganizationSettingsEditor tool `EnableRoleBasedSystemViews` property to **true** is effective immediately.
> 2. Setting a view with security roles is effective immediately after you select **Save and publish**.
> 3. Changing a view setting from 'Specify security role' to 'Everyone' can take up to 24 hours to be effective or until the user signs out and back in.
>
> If you select multiple views and go to the view settings, only the first selected Views can be updated. You're required to select individual view to update the view settings.

> **Important**
>
> The security roles as listed under **View settings** are from the *root business unit*. Business unit level security roles are inherited from the root business unit. When you select the security roles from **View settings**, the system automatically applies filtering to users who are assigned the corresponding business unit level security roles.

Delete or turn off a model-driven app view

Article • 10/09/2024

Views allow the data in Microsoft Dataverse tables to be presented in a way that meets a business need at a given time.

The views that are required in an organization might change over time. It's good practice to maintain views in order to keep your model-driven apps as simple as possible to use and maintain.

System views versus public views

Depending on the type of view, you can either turn it off or delete it. Turned off views can be turned on again, while the deletion of a view is permanent.

- Custom table public views can both be deleted and turned off/on. Public views that are standard with Dataverse, such as the active accounts and inactive accounts standard public views can be turned off/on.
- System views can't be deleted or turned off/on. This includes public views created by the system.

Turn on or turn off views

Custom public views can be turned off and these turned off views can be turned on. While a view is turned off, the view isn't available in the associated model-driven apps for users to select. Public views set as the default view for the table can't be turned off.

1. Sign in to Power Apps, open the environment you want, select **Solutions** on the left navigation pane, and then open the unmanaged solution you want.
2. Open the table you want, and then select the **Views** area under **Data experiences**.
3. Select the view you want to turn on or off, and then select either **Turn off** or **Turn on** on the command bar.

Delete a view

Deleting a view permanently removes it from the environment.

1. Sign in to Power Apps, open the environment you want, select **Solutions** on the left navigation pane, and then open the unmanaged solution you want.
2. Open the table you want, and then select the **Views** area under **Data experiences**.
3. Select the view you want to remove, and then select **Remove** > **Delete from this environment** on the command bar.

> **Note**
>
> - Where a model-driven app specifies a view this creates a dependency between the app and the view. If this is the case the view will need to first be removed from the app using the app designer.
> - If the view has been added to more than one solution, you can select **Remove** > **Remove from this solution** to remove from the solution but keep available in the environment.

Delete or activate and deactivate views in classic solution explorer

Delete a view in classic solution explorer

You can delete any custom public view. Use the steps in Access view definitions to find the view you want to delete and use the **Delete** command. Once you verify that you really want to delete it, the view is permanently deleted.

Deactivate or activate views in classic solution explorer

1. Navigate to **System Views** as described in Access view definitions.
2. Select a public view. To see inactive views, use the **Inactive Public Views** view.
3. On the menu bar, select **More Actions**, and then select either **Deactivate** or **Activate**.
4. Select **Publish All Customizations**.

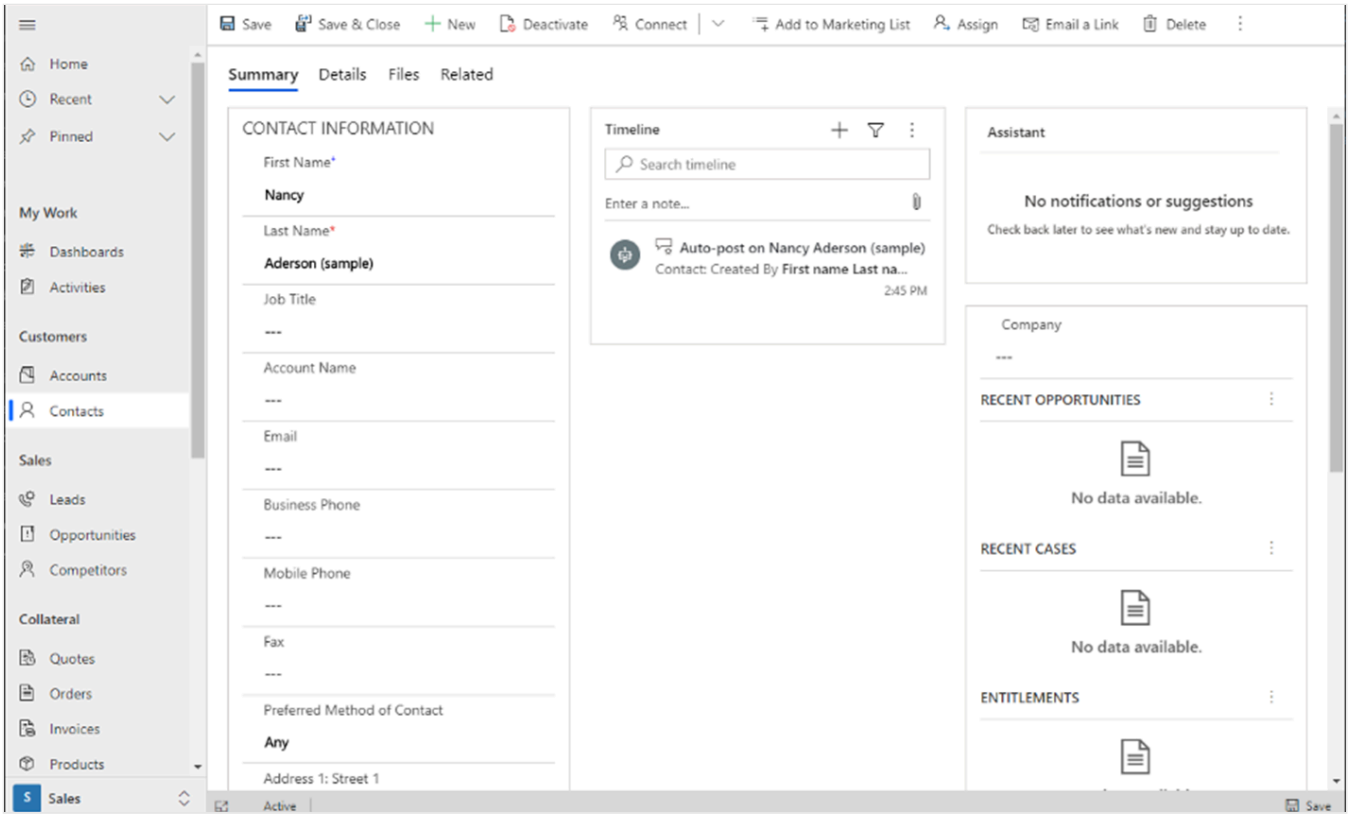
Create and design model-driven app forms

With Power Apps model-driven apps, forms provide the user interface that people use to interact with the data they need to do their work. It's important that the forms people use are designed to allow them to find or enter the information they need efficiently.

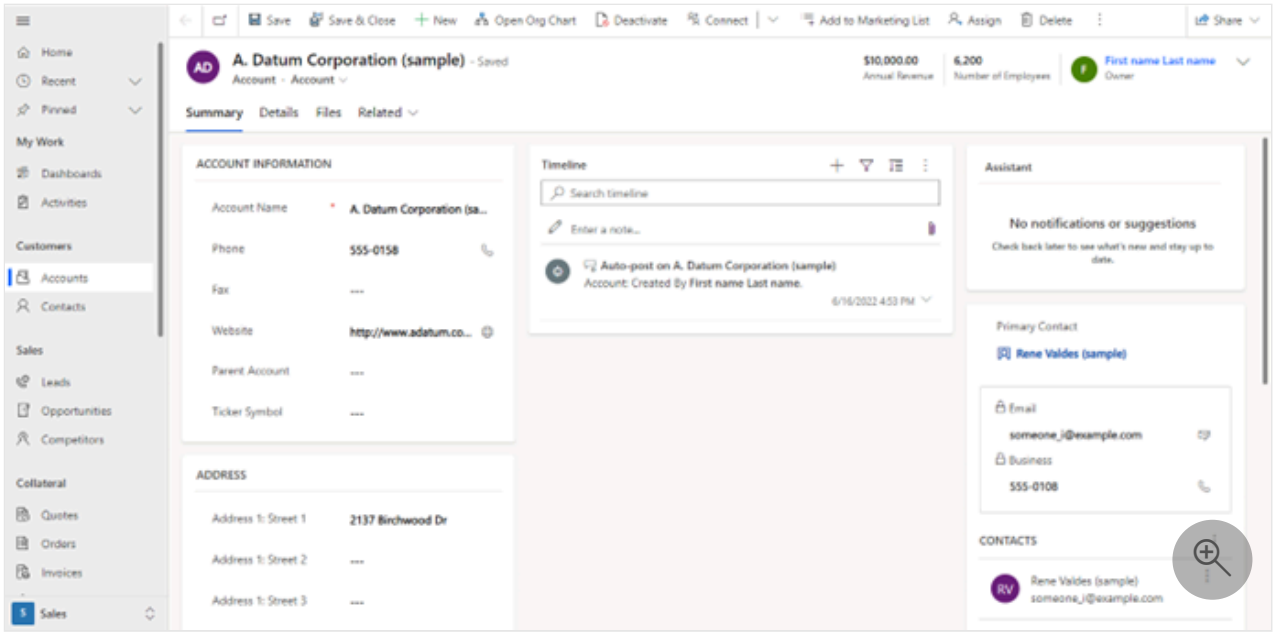


In the default solution or an unmanaged solution, it's possible to create new forms or edit existing forms for all tables that allow form customization.

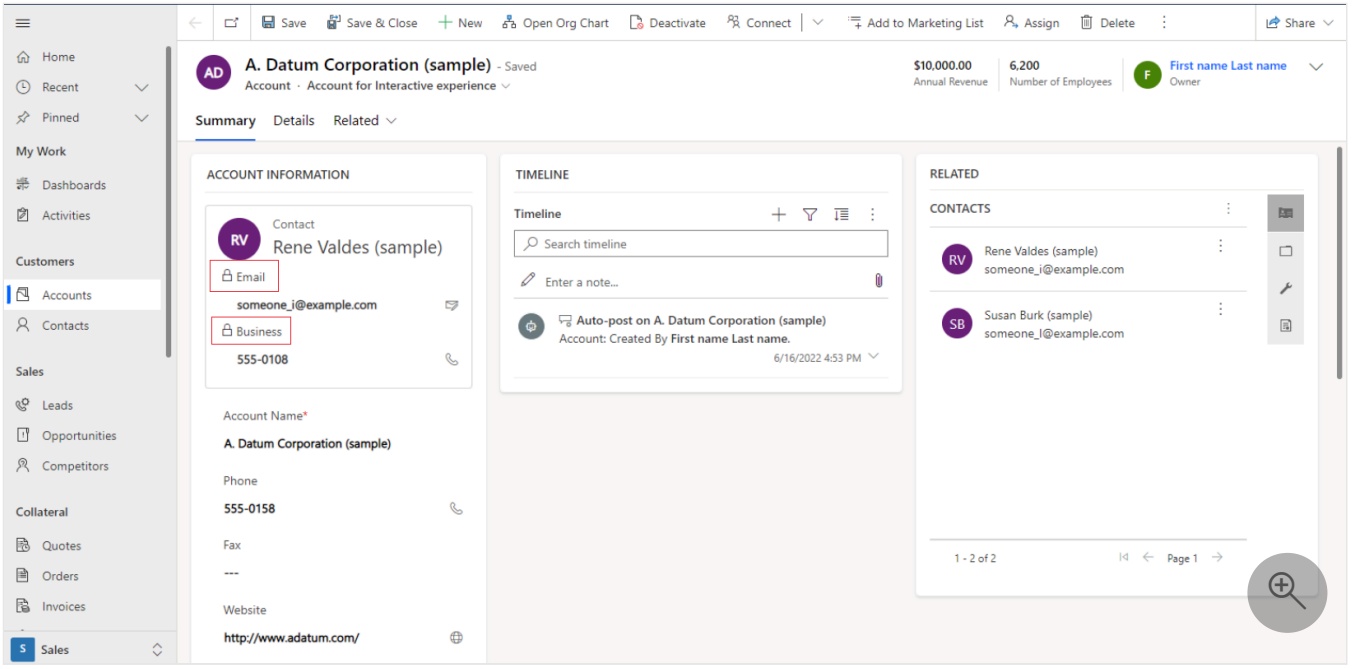
Model-driven app form UI enhancements

Form UI enhancements consist of multiple small changes to improve data presentation and usability of model-driven app forms:

- Forms have a light gray background, which removes the white-on-white section treatment that helps users by providing easier visual navigation.
- There's a better delineation between sections as white space is reduced and shadow and rounded corners to borders are added.
- Form field dividers are removed and consistent font styling is used across section labels.
- The **Related** tab has an added chevron to indicate the dropdown flyout, which opens-ups when you select it.



Also, quick view form labels are displayed on top instead of icons.



Forms and solutions

This section describes form customization when the form is in an unmanaged or managed solution.

Forms inside unmanaged solutions

In an unmanaged solution, it's possible to edit the properties, including columns, views, and forms, for an unmanaged custom table that was created for the solution. Unmanaged solutions are where app makers and developers go to author changes that they require. Unmanaged solutions typically exist in a development environment.

Forms inside managed solutions

In a managed solution, typically in a production environment, it isn't possible by default to create new forms or edit existing forms for tables. However, if the managed properties for a table in the managed solution are set to allow customization, you can add or edit forms for that table.

Learn more about solutions

Form types

There are different types of forms, and each type has a specific functionality or use. Here are the form types:

- Main. The main user interface.
- Quick create. For rapid data entry.
- Quick view. Used to see related data.
- Card form. Shows a compact display of the form.

More information: Types of forms in Power Apps.

Create or edit a form

The fundamentals of building a model-driven app include creating a table, configuring data views, and creating and editing forms.

Before you begin to build forms, it's worth determining whether you have all the columns necessary to solve your business problem. Additionally, you should have an understanding how to organize columns by using sections and tabs. Broadly speaking, the complexity of your forms are a reflection of the number of columns in your table in addition to the complexity of your business process.

Learn to create, edit, or configure forms using the form designer

Delete a form

To delete a form, sign in to Power Apps and go to **Solutions** > Open the solution you want > select the table that you want > **Forms** area. Select the form, and then select **Delete** on the command bar.

There are a couple of reasons you might not be able to delete a form.

Expand table

Reason	Work around
Every table requires at least one main form and it's the only main form for the table.	Create a new main form for the table. Then delete the main form you tried earlier. More information: Create a form
Every table requires one designated fallback form and it's the only fallback form.	Create a new form for the table and set it as the fallback. Or designate another existing form as the fallback form. Then delete the form you tried earlier. More information: Set the fallback form for a table

Controlling the display of a form within an app

Tables can have multiple forms. The use of a form is controlled through the model-driven app. This control allows makers to use the same table in different ways depending on the audience, by controlling the display.

By default all forms are made available to users. However, through the app designer a specific form can be restricted.

Change the forms displayed and form order

Makers change the forms displayed in an app from the app designer. More information: Add or remove forms from an app

Makers can also change the form order, fallback forms, and the default form for a table from the Forms area. More information: Set the form order

Updated versus classic tables

Power Apps provides many options for designing forms using the form designer.

There are still a number of tables, referred to here as classic tables, that retain the appearance and capabilities from earlier versions. These tables are used less often. They're listed here:

Types of model-driven app forms in Power Apps

Summarize this article for me

There are different types of forms and each type has a specific functionality or use. This table describes the types of forms available.

Expand table

Form type	Description	More information
Main	Used in model-driven apps, Dynamics 365 for tablets, and Dynamics 365 for Outlook. These forms provide the main user interface for viewing and interacting with table data.	Design considerations for main forms
Quick Create	Used in model-driven apps, Dynamics 365 for tablets, and Dynamics 365 for Outlook. These forms provide a basic form optimized for creating new records.	Create and edit quick create forms
Quick View	Used in model-driven apps, Dynamics 365 for tablets, and Dynamics 365 for Outlook. These forms appear within the main form to display additional data for a row that is referenced by a lookup column in the form. Users can view data from related tables without having to leave the form.	Create and edit quick view forms
Card	Used in views for model-driven apps. Card forms are designed to present information in a compact format that is suitable for mobile devices.	Create a card form

While each form type has specific needs, when designing forms you use the form editor. More information: Overview of the form editor user interface

How model-driven app main forms appear on different devices

Article • 04/20/2022

There are four types of form. Main, quick view, quick create, and card.

The main form is a fundamental building block of any model-driven app and is used by all devices used to run them.

A main form can be rendered using a web browser, Dynamics 365 for phones, Dynamics 365 for tablets, or Dynamics 365 for Outlook, and its design adjusts to accommodate the device. This responsive design is an important feature of model-driven apps.

Additionally, the main form is an intrinsic part of the table and it travels with the table as part of any solution. This helps with application lifecycle management.

Learn more about all the form types

Notes on Microsoft Dynamics 365

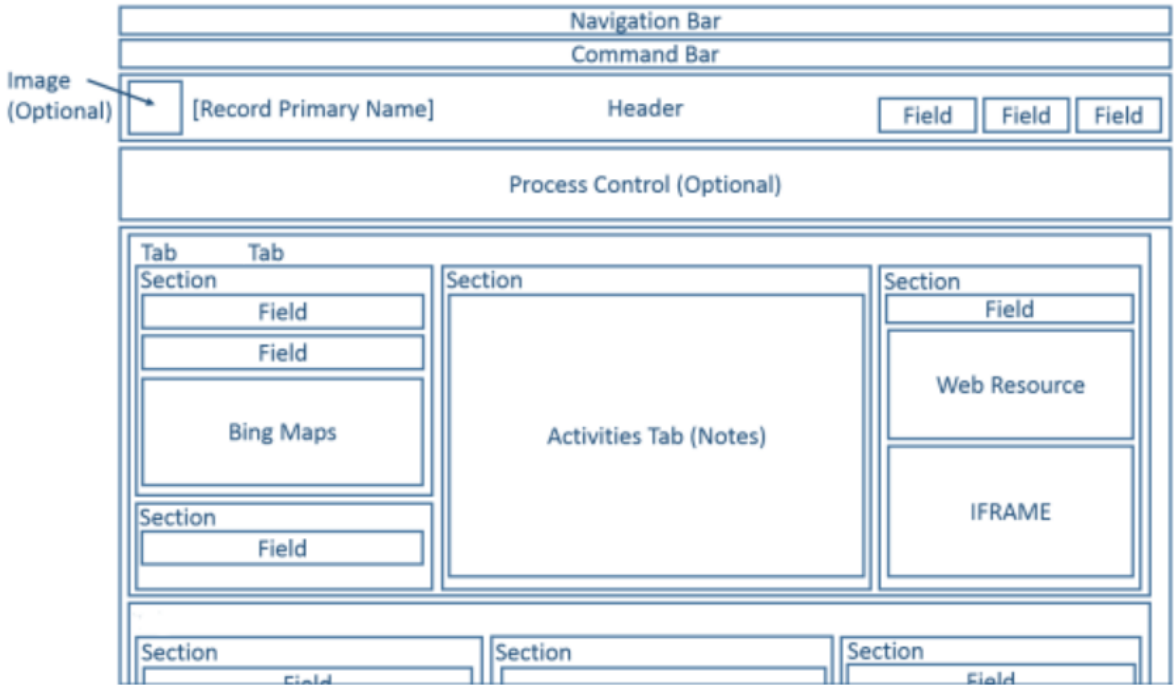
Main form presentation options

Any main forms that exist for a table may be displayed differently depending on the factors in the following table below. When you design a main form, consider how it works in each presentation tool.

Presentation	Description
Current	Most of the standard tables and all custom tables created use the current form, which provides a modern user experience. The current forms have a layout with an improved command bar design, and support features such as AutoSave and business process flows.
Dynamics 365 for tablets	Dynamics 365 for tablets presents the content of the main form in a manner optimized for a tablet.
Dynamics 365 for phones	Dynamics 365 for phones presents the content of the main form in a manner optimized for a phone.

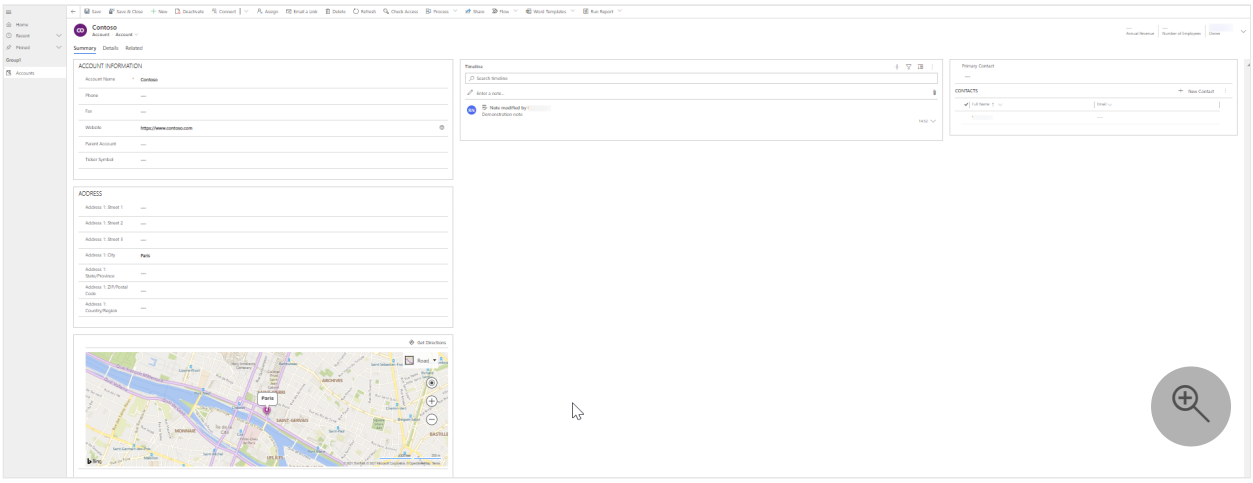
Presentation	Description
Classic	Classic forms are from earlier versions of Dynamics 365 Customer Engagement apps. They use the ribbon rather than the command bar and the navigation pane on the left side of the form. These forms have a two-column layout. Notice that there are a few tables that still use the classic forms. More information: Updated verses classic tables

This diagram represents common components found in main table forms.



The layout of the form works with a wide range of displays and window sizes. As the width of window decreases, section columns move down so that you can scroll down to work with them instead of being compressed or requiring you to scroll to the right.

The image below illustrate the accounts table main form as it would be viewed through a web browser.



The following table summarizes available components of the main form for tables.

Component	Summary
Navigation bar	In the context of the table, the navigation bar provides access to managing records, such as search, create, and advanced find.
Command bar	The first several commands are displayed followed by a vertical ellipsis that provides a menu to choose additional commands.
Image	When a table has an image column and the table **Primary Image** option is set to **Default Image**, an image can be displayed in the header when the form is configured to show the image.
Header	Columns placed in the header remain visible when people scroll down through the body of the form. Up to four columns can be placed in the header. Multiple lines of text, web resources, or iFrames aren't allowed in the header. The header shares some properties with sections.
Process Control	When a table has active business process flows, the process control displays below the header. More information: Business process flows
Body	The body is the scrollable part of the form that contains the sections.
Tabs	In the body of the form, tabs provide horizontal separation. Tabs have a label that can be displayed. Tabs contain up to three columns and the width of each column can be set to a percentage of the total width. When you create a new tab, each column is prepopulated with a section.
Sections	A section occupies the space available in a tab column. Sections have a label that can be displayed and a line may be shown below the label. Sections can have up to four columns and include options for displaying how labels for columns in the section are displayed.
Columns	Section columns display fields and controls people use to view or edit data in a table record. A section can be formatted to occupy up to four columns within the section.
Spacer	A spacer allows for an empty space to be added to a section column.
Sub-grids	Subgrids allow for the display of a list within the form.
Quick View Form	A quick view form displays data from a record referenced by a lookup column on the form. The table that is the target of the lookup must have a quick view form before one can be added to the form. More information: Create and edit quick view forms

Component	Summary
Web Resources	HTML and Microsoft Silverlight web resources can be added to main forms but they won't be displayed when using Dynamics 365 for phones and tablets.
iFrame	An inline-frame that you configure to show a webpage from another website. **Important:** • When the page displayed in an iFrame is on another domain, browsers apply a higher level of security. This may complicate the requirements for the contents of an iFrame to interact with data in the form. • Displaying a table form within an iFrame embedded in another table form isn't supported.
Bing Maps	When this control is present in a form for a table and the system setting **Enable Bing Maps** is enabled with a valid Bing Maps key, this control can be used one time in a form to show the location for one of the addresses in a table. More information: Configuring Bing maps

Dynamics 365 for phones and tablets forms

Most system tables and custom tables are available for Dynamics 365 for phones and tablets. The main form for these tables is transformed to a presentation optimized for phones or tablets.

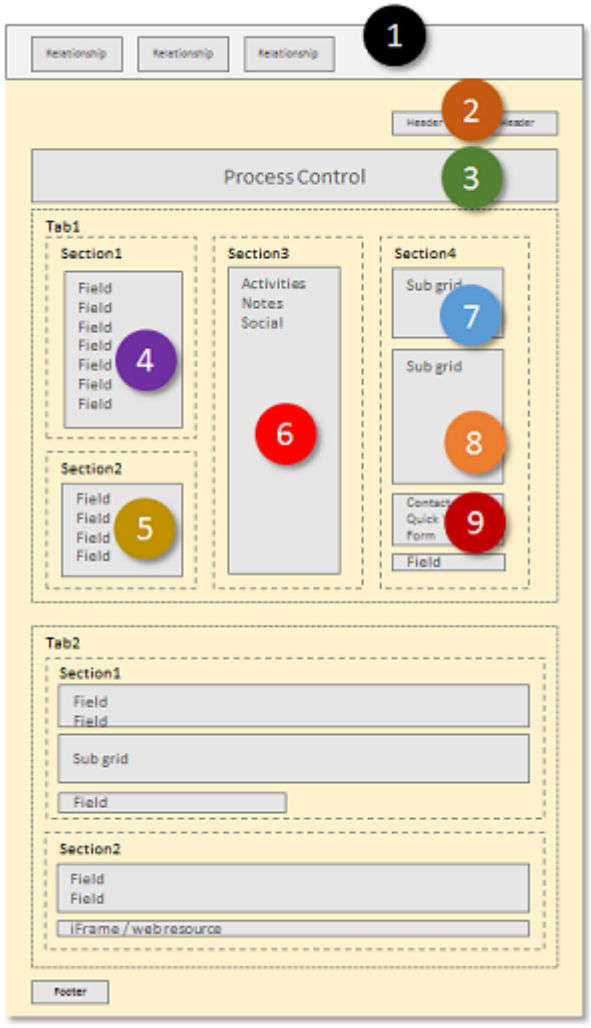
Tables enabled for Dynamics 365 for phones and tablets

Only tables that are enabled for Dynamics 365 for phones and tablets use this presentation of the main form. More information: Entities displayed in Dynamics 365 for phones and tablets

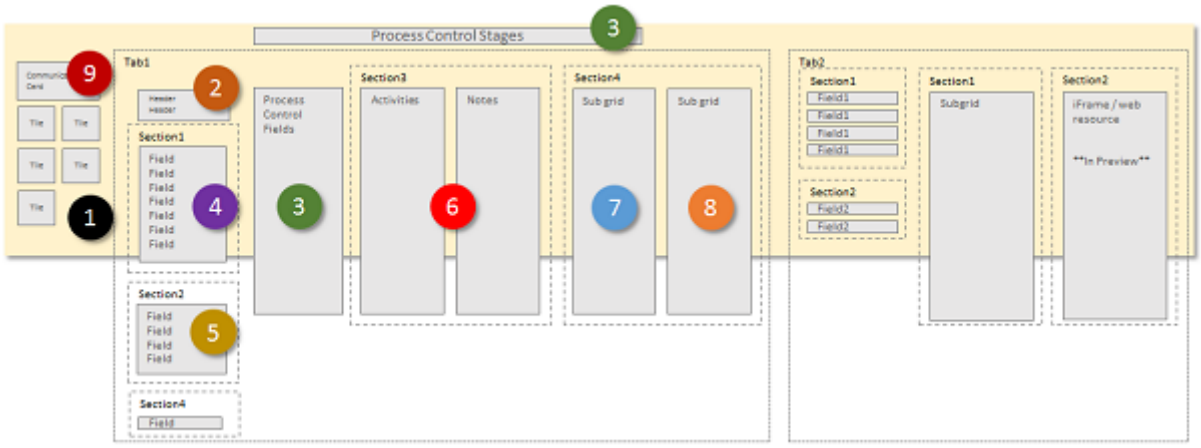
Form design

Dynamics 365 for phones and tablets takes many of the main form elements and presents them in a way optimized for phones or tablets. The following diagrams show the reflow from the web app to the tablet and phone apps.

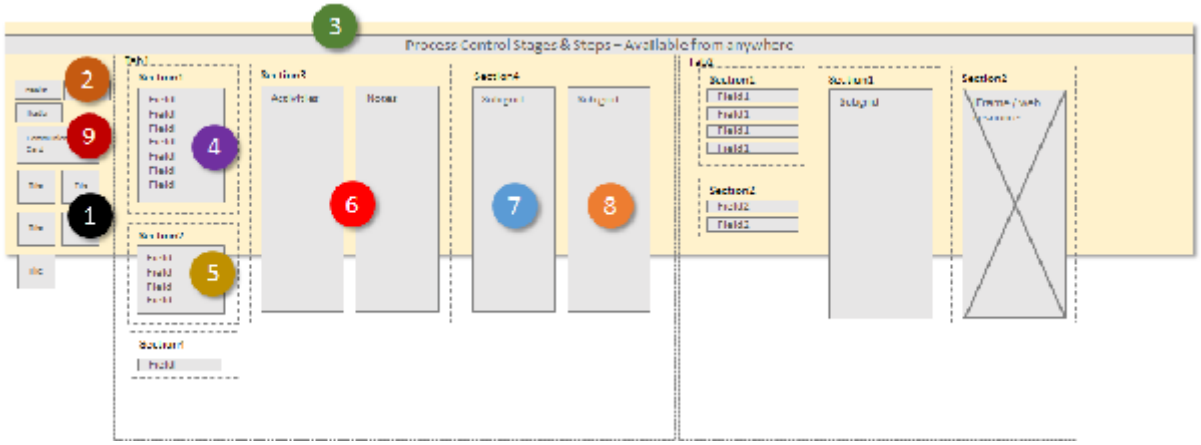
Web app



Tablet app



Phone app



The form elements are transformed to a wide panorama layout in Dynamics 365 for tablets, where users swipe the screen to change elements visible within a view port. In Dynamics 365 for phones, users swipe the screen to see a different column, or pane of elements, and the process control appears over every column.

View port element

The following items are always visible within the view port in the context of a form:

Nav bar
The nav bar is a presentation of the sitemap that is optimized for touch. More information: Change navigation options

Home
The home button takes users to the dashboard that is the starting page for Dynamics 365 for phones and tablets.

Process Control
If the table has a business process enabled, it will appear in the top-right corner next to the search control in Dynamics 365 for tablets, and at the top of the screen in Dynamics 365 for phones.

Search
People can tap the search control to open the screen to search for records.

Command Bar
By default, some of the commands that appear in the app running in a web browser don't appear in the Dynamics 365 for phones and tablets apps. Similar to the web application, the command bar is context-sensitive, so the available commands change depending on what is currently viewed or selected. More information Change commands

Form elements

The form elements displayed are taken from the main form and presented as a series of panels that users see through the view port.

In Dynamics 365 for tablets, the first panel displays contact information about relationships that exist for the record. In Dynamics 365 for phones, the first panel also displays header columns from the form above the relationship tiles.

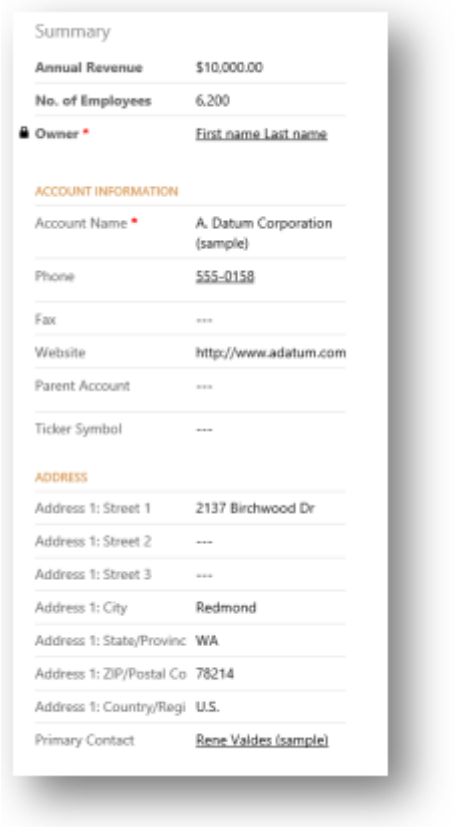
For Contact and User forms, the top item displays a communication card for the record. The communication card provides buttons to initiate communication with the person. For other tables, a communication card is displayed if there's a Contact quick view form embedded in the main form.

You can show additional tiles based on table relationships, but you can't customize the tiles for the following tables:

Entity	**Tiles**
Account	Owner
Contact	Company Name, Owner
Lead	Owner
Opportunity	Account, Owner

You can customize the remaining tiles with the form editor. The order is fixed, but you can set which elements are visible in the relationship panel.

In Dynamics 365 for tablets, the second panel begins with the name of the first tab on the form. Any columns that are included within the header are included and then the contents of the first tab. In Dynamics 365 for phones, headers appear in the first column.



If there is a process flow active for the form, the third tab displays tasks for the current stage of the process in Dynamics 365 for tablets. In Dynamics 365 for phones, the process control floats above the panes, expands over the user's current pane when it's selected, and is always visible and actionable.

The remaining panels of the form contain the contents of the tabs in the form. Any subgrids found display as a separate panel.

The Dynamics 365 for phones and tablets form always displays the labels for tabs and subgrids. The **Display Label on the Form** setting isn't applied.

> ⓘ **Note**
>
> To optimize performance on mobile devices, the number of objects is limited to 5 tabs or 75 columns and 10 subgrids.

Forms for Dynamics 365 for phones and tablets don't support the following features:

- Bing maps
- Yammer

- Activity feeds
- Theming

In addition, table images are visible in list views and contact cards, but not within the actual form.

Multiple forms

Dynamics 365 for phones and tablets supports multiple forms but doesn't provide a way for people to switch between forms if they can access more than one. People will see the first form in the form order that they have access to.

For example, if you have the following main forms for the opportunity table and have assigned the following security roles for each one, you'll see the form order shown in the following table.

Form Order	Form Name	Security roles
1	**Sales Form One**	Salesperson
2	**Sales Form Two**	Salesperson and Sales Manager
3	**Sales Form Three**	Sales Manager
4	**Sales Form Four**	Vice President of Sales

- People with the Salesperson role will always see **Sales Form One**.
- People with the Sales Manager role will always see **Sales Form Two**.
- People with the Vice President of Sales role will always see **Sales Form Four**.

Classic forms

For information about the classic forms available with Dynamics 365 Customer Engagement (on-premises), see Classic forms.

Create or edit a main form overview

Design considerations for model-driven app main forms

Summarize this article for me

Main forms are the primary user interface where people view and interact with their data. Main forms provide the widest range of presentation options that are available for model-driven apps.

Other form types include Quick view, Quick Create, and Card.

A fundamental quality of model-driven apps is that they're responsive to the size and type of device used when interacting with them. This responsiveness affects the position of the controls on the form and the way in which they behave. This quality is most notable with main forms.

One of the main design objectives for main forms is that they are designed once per table and deployed everywhere required.

There are several important factors to consider in designing forms for model-driven apps.

Custom forms for different groups

Because multiple main forms can be created and assigned to different security roles, it's possible to present different groups in an organization with a form that is optimized for how the group uses the application. It's also possible to provide each group with different options so that they have different forms to choose from. More information: Control access to forms

Managers and decisions makers want forms that are optimized to provide quick reference to key data points. They often like to see charts more than lists and they might not perform a lot of data entry.

People who interact directly with customers need forms tailored to tasks they perform most frequently. They often want forms that allow for the most efficient data entry.

Form creation might be an iterative process where input is gathered and the user interface is developed. Keep in mind that there are a variety of tools available to developers and that not everything has to be done within the form. Use business rules, workflow processes, dialogs, and business process flows together with main forms to provide a solution that works for the organization.

Creating and editing forms is relatively easy, but as more forms are created more forms need to be maintained.

Form presentation differences

Although it isn't necessary to manage multiple forms for each delivery mechanism (web, tablet, phone), a maker must consider how differences in the presentation can be accounted for in the main form.

Main form appearance describes the different ways that the main form can be presented. The primary things to take into consideration are:

- Dynamics 365 for tablets doesn’t support image, HTML, or Silverlight web resources to be added to forms.
- The layout of Dynamics 365 for tablets forms is autogenerated based on the main form. There is no special form editor for Dynamics 365 for tablets forms. It is necessary to verify that the form presentation works well for both clients.
- If there are unsupported scripts that interact with DOM elements found in the web application, those scripts won’t work in the Dynamics 365 for tablets forms because the same DOM elements aren’t available.
- Dynamics 365 for Outlook Reading Pane forms don’t allow for scripting. The visibility of form elements depend on the default settings and can’t be changed at runtime using scripts.

Form performance

Forms that load slowly or don’t respond quickly might affect productivity and user adoption of the app. Design forms for performance in model-driven apps provides a number of recommendations to consider when you design forms so that customizations don’t adversely affect form performance.

Design forms for efficiency

Form layout and design are important to building better forms. Designing forms where tasks can be completed quickly and effectively is crucial to user satisfaction. More information: Design productive main forms in model-driven apps

Create or edit a model-driven app main form for a table

Summarize this article for me

This article describes how to create or edit a main form for a table.

When a new form is created for a table, its form type is **Main**. When the new form opens, it is identical to the form named **Information**. Columns, sections, tabs, navigation, and properties associated with the form can be edited and the form can then be saved.

Each main form is composed of one or more tabs. Each tab can have one or more sections. Each section contains one or more columns, also called form fields. Forms can be cloned to provide a simpler starting point for form development. To clone a form, open the form you want to copy in the form editor, on the command bar select **Save a copy**, enter a **Display Name** and optionally a **Description**, and then select **Save**.

> **Note**
>
> Make sure that you have the System Administrator or System Customizer security role or equivalent permissions within your environment to perform this task.

How to create or edit a main form

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane, select the table you want, and then select the **Forms** area. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. To create a new main form, on the toolbar select **Newform** > **Main form** > **Create**.
4. Change the form design in any of the following ways, as needed:
   - Add a column to or remove a column from a form
   - Add a section to or remove a section from a form
   - Add a tab to or remove a tab from a form
   - Add or edit a subgrid on a form
   - Edit form headers
   - Edit form footers
5. Edit the properties for parts of the form, as needed:

- Edit form properties
- Edit form column properties
- Edit tab properties
- Edit section properties

6. When you finish editing the form and are ready to make it available in apps, select **Save and publish**.

Create and edit a main form walkthrough

Last updated on 02/13/2026

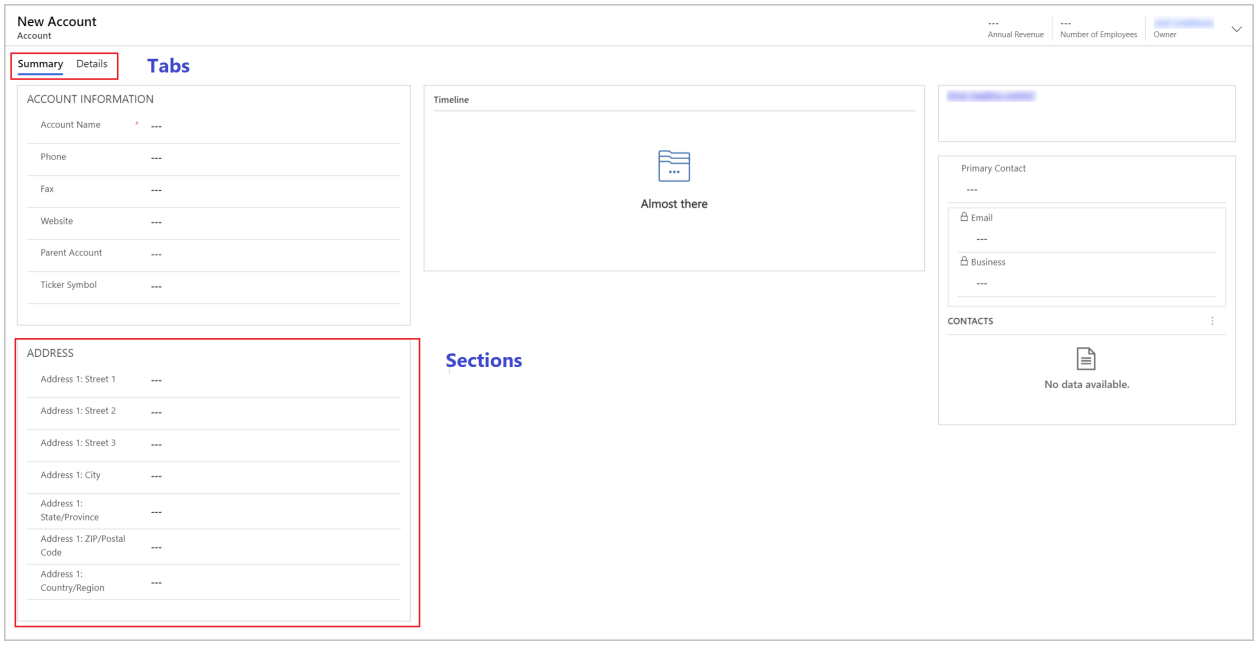
Create and customize a model-driven app form

Article • 03/13/2023

In model-driven Power Apps, forms provide the user interface that people use to interact with the data with which they need to work. A table can have one or more forms, and forms come in different types. The different types are main, quick create, quick view, and card. For more information about form types, see Type of model-driven app forms in Power Apps.

In this tutorial, you create a main type form and then add the form to a model-driven app. The main form is the primary form type that users see when they open records in model-driven apps.

Main forms have a default three-column layout. Model-driven form fields and components are grouped into tabs (primary grouping) and sections (secondary grouping). Tabs separate the form into logical pages, while sections separate the content within a tab.

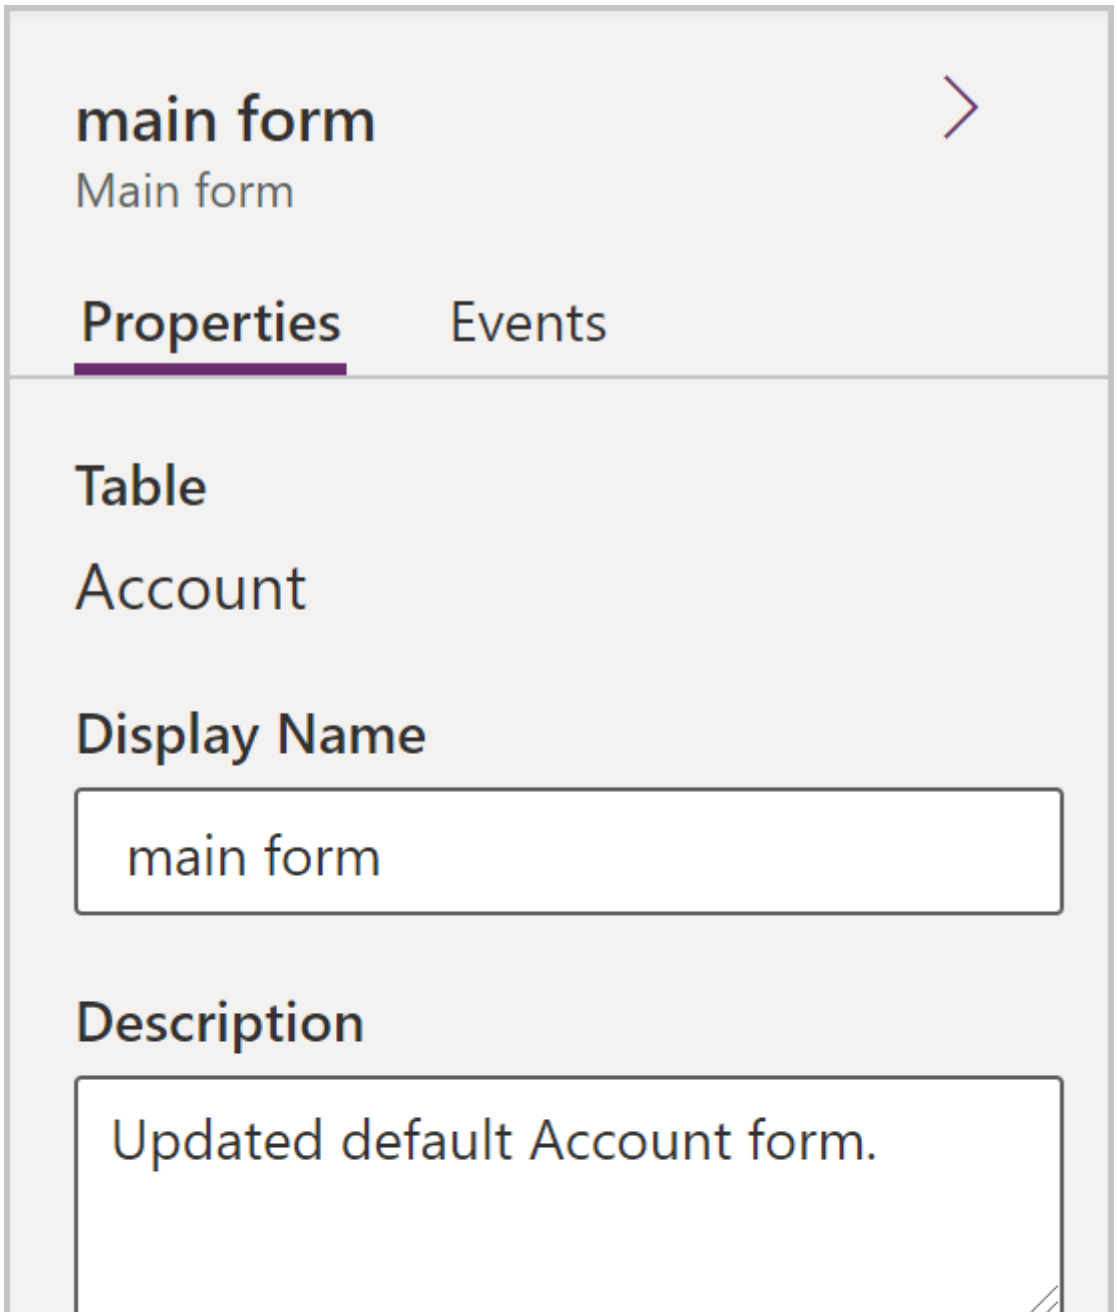


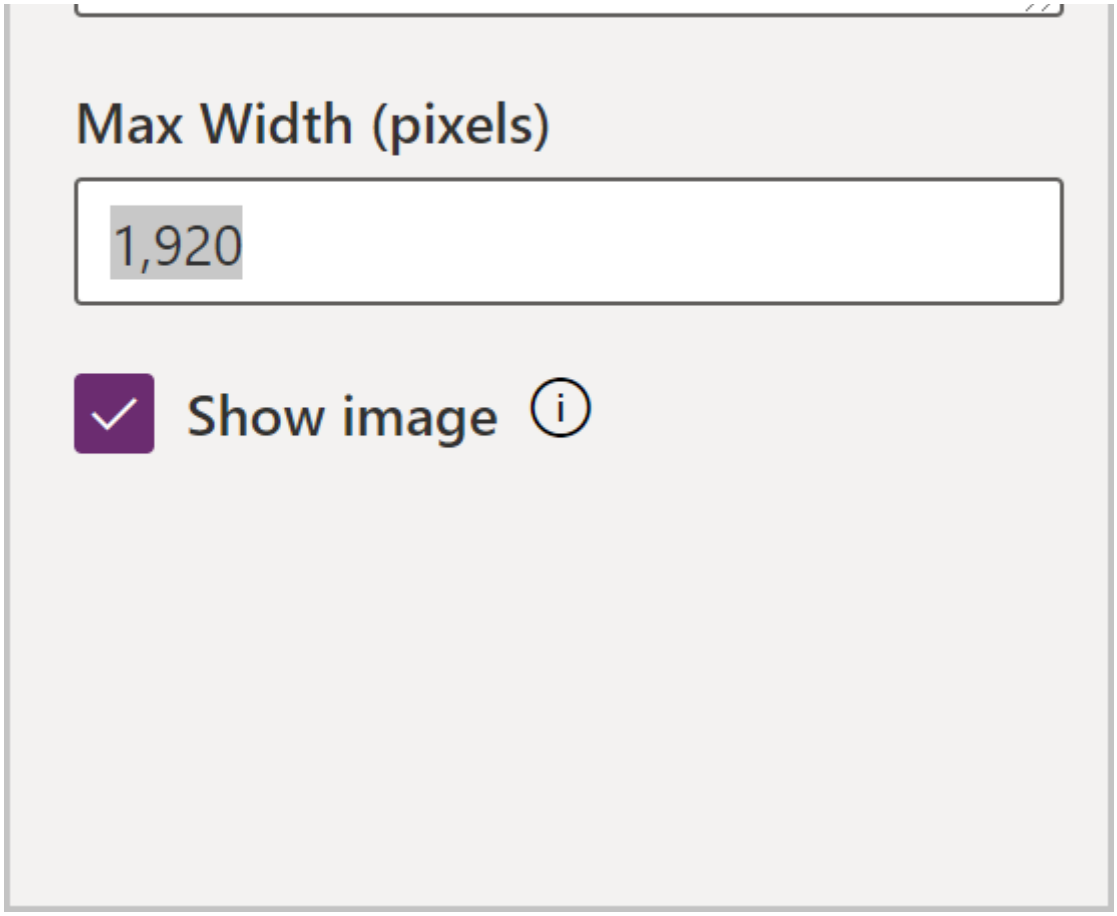
Create and configure a form

1. Sign in to Power Apps.
2. Select **Tables**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Open the **Account** table, and then select the **Forms** area.
4. Select **Add Form** from the command bar, and then select **Main Form**.

5. The form designer opens to enable you to configure the properties for the form.

Property	Description
Title	Enter a name that is meaningful to other makers and app users. This name is shown to app users. If users have access to multiple forms for a table, they will use this name to differentiate between the available forms. This property is required.
Description	Enter a description that explains how the form is different from other main forms. This description is only shown to makers in the form designer and in the list of forms for a table in the solution explorer.
Max Width	Set a maximum width (in pixels) to limit the width of the form. The default value is 1900. This property is required.
Show image	Show the table's **Primary Image** if it has one set. This setting will enable showing the image column in the header of the form. For more information about table options, see Enable or disable table options .

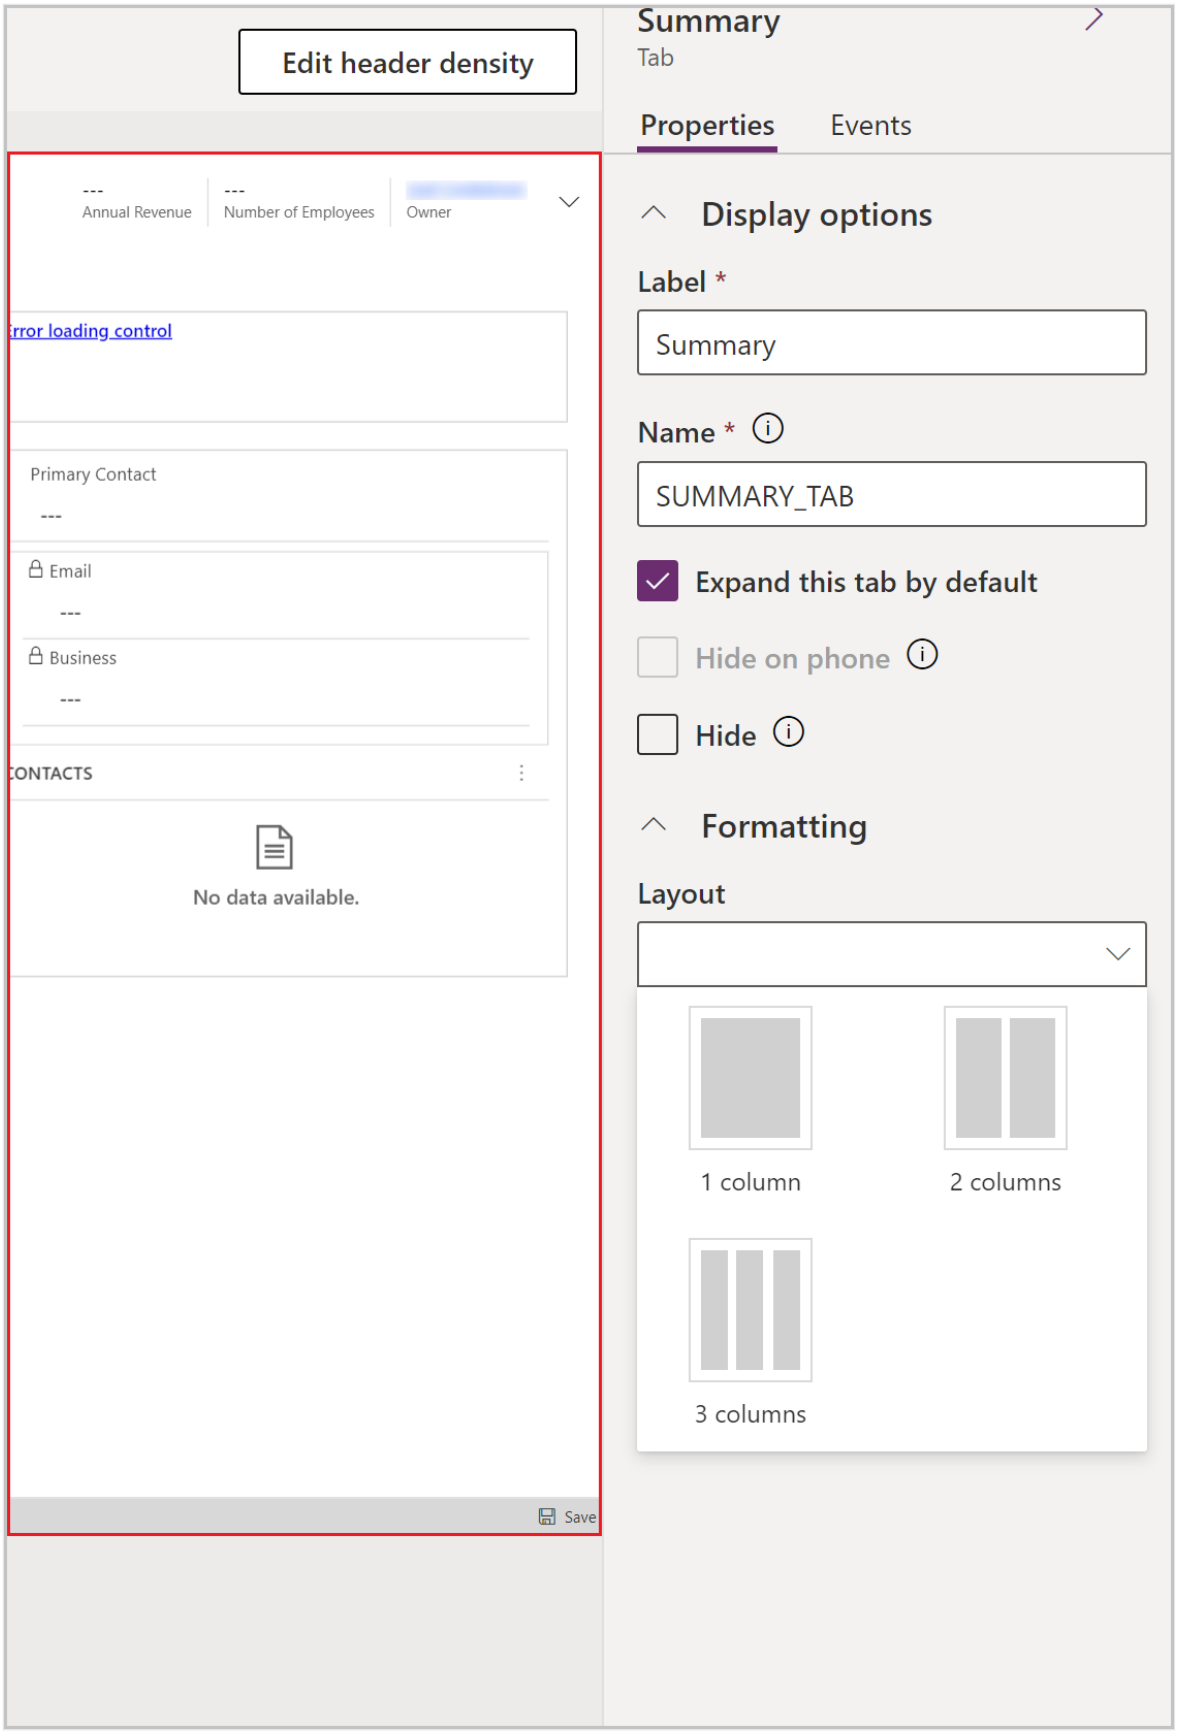




Change the tab layout

If you wish to use a different layout than the default three columns in a tab, follow these steps:

1. Select the tab name, such as **Summary**.
2. In the **Properties** pane on right, select the **Formatting** area to expand it.
3. Select the **Layout** drop-down list, and then select your desired layout, such as **1 column** or **2 columns**.



Add items to the form

Using the left side panel in the form designer, you can add different items to the form depending on which tab you select.

Components

From this tab you can add new form tabs, sections, or visual controls. More information: Add, configure, move, or delete components on a form

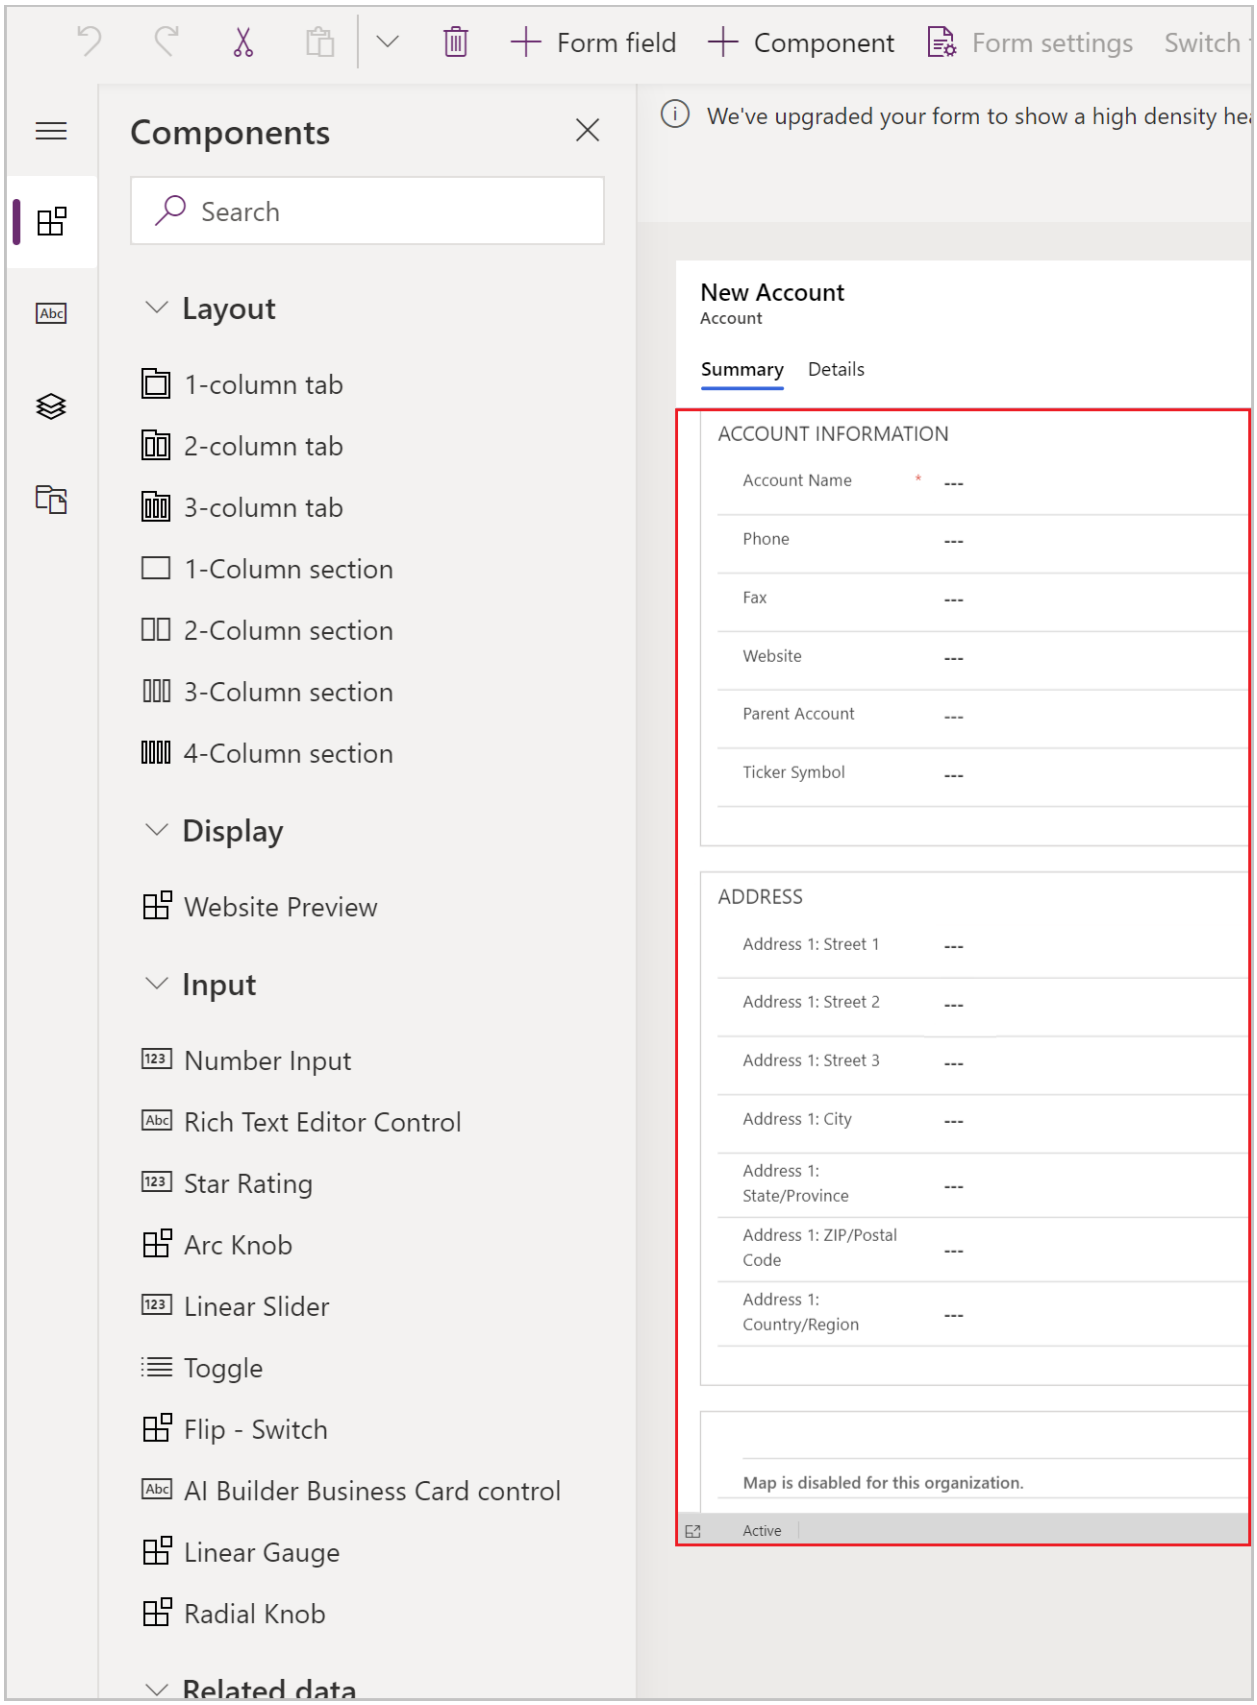


Table columns

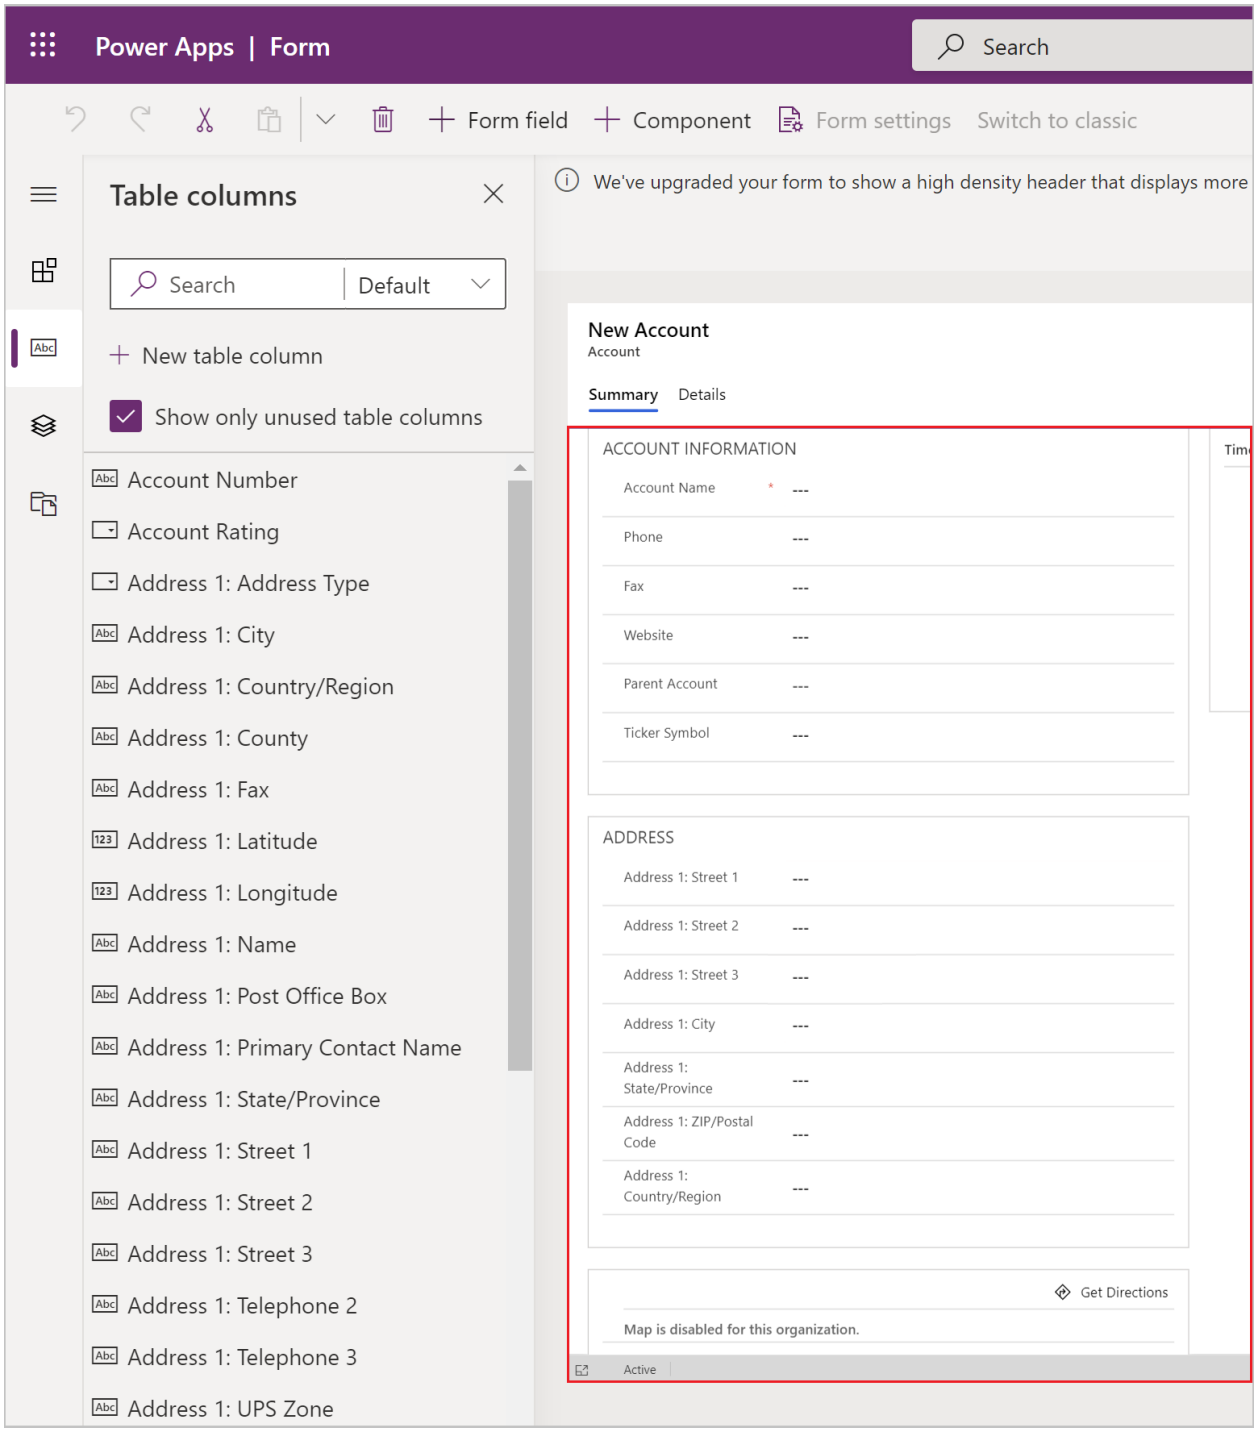
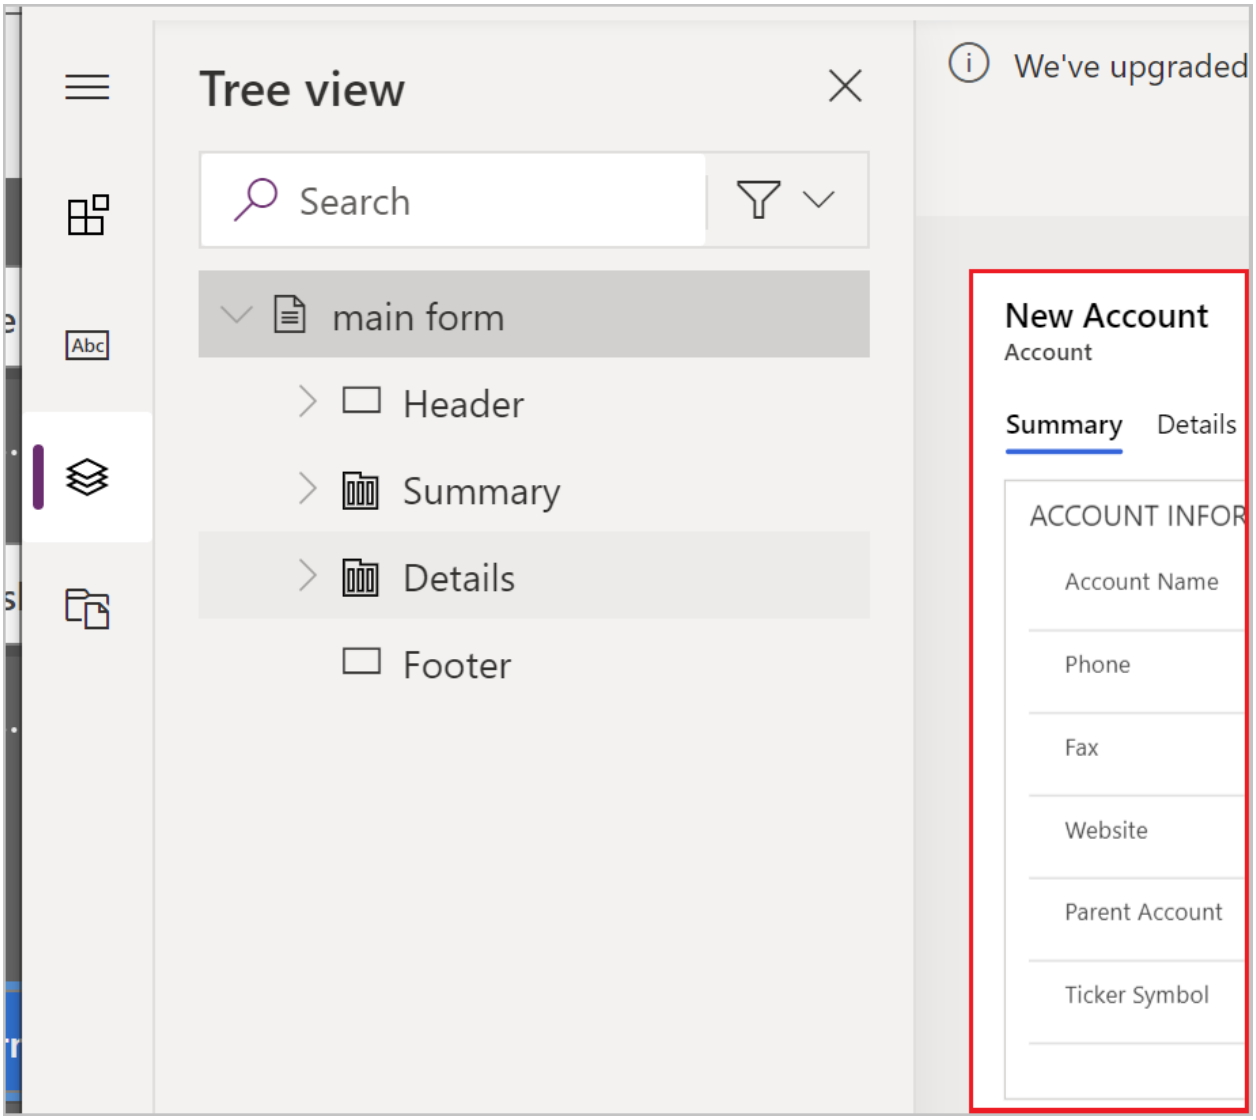
From this tab you can add form fields, also called table columns. More information: Add, configure, move, or delete columns on a form



Tree view

From this tab you can select to navigate to the form header, footer, or any tab or section on the form. This is useful when configuring forms with many tabs. More information: Using the tree view in the form designer



Form libraries

Model-driven forms allow you to add JavaScript libraries to further extend your form behavior.

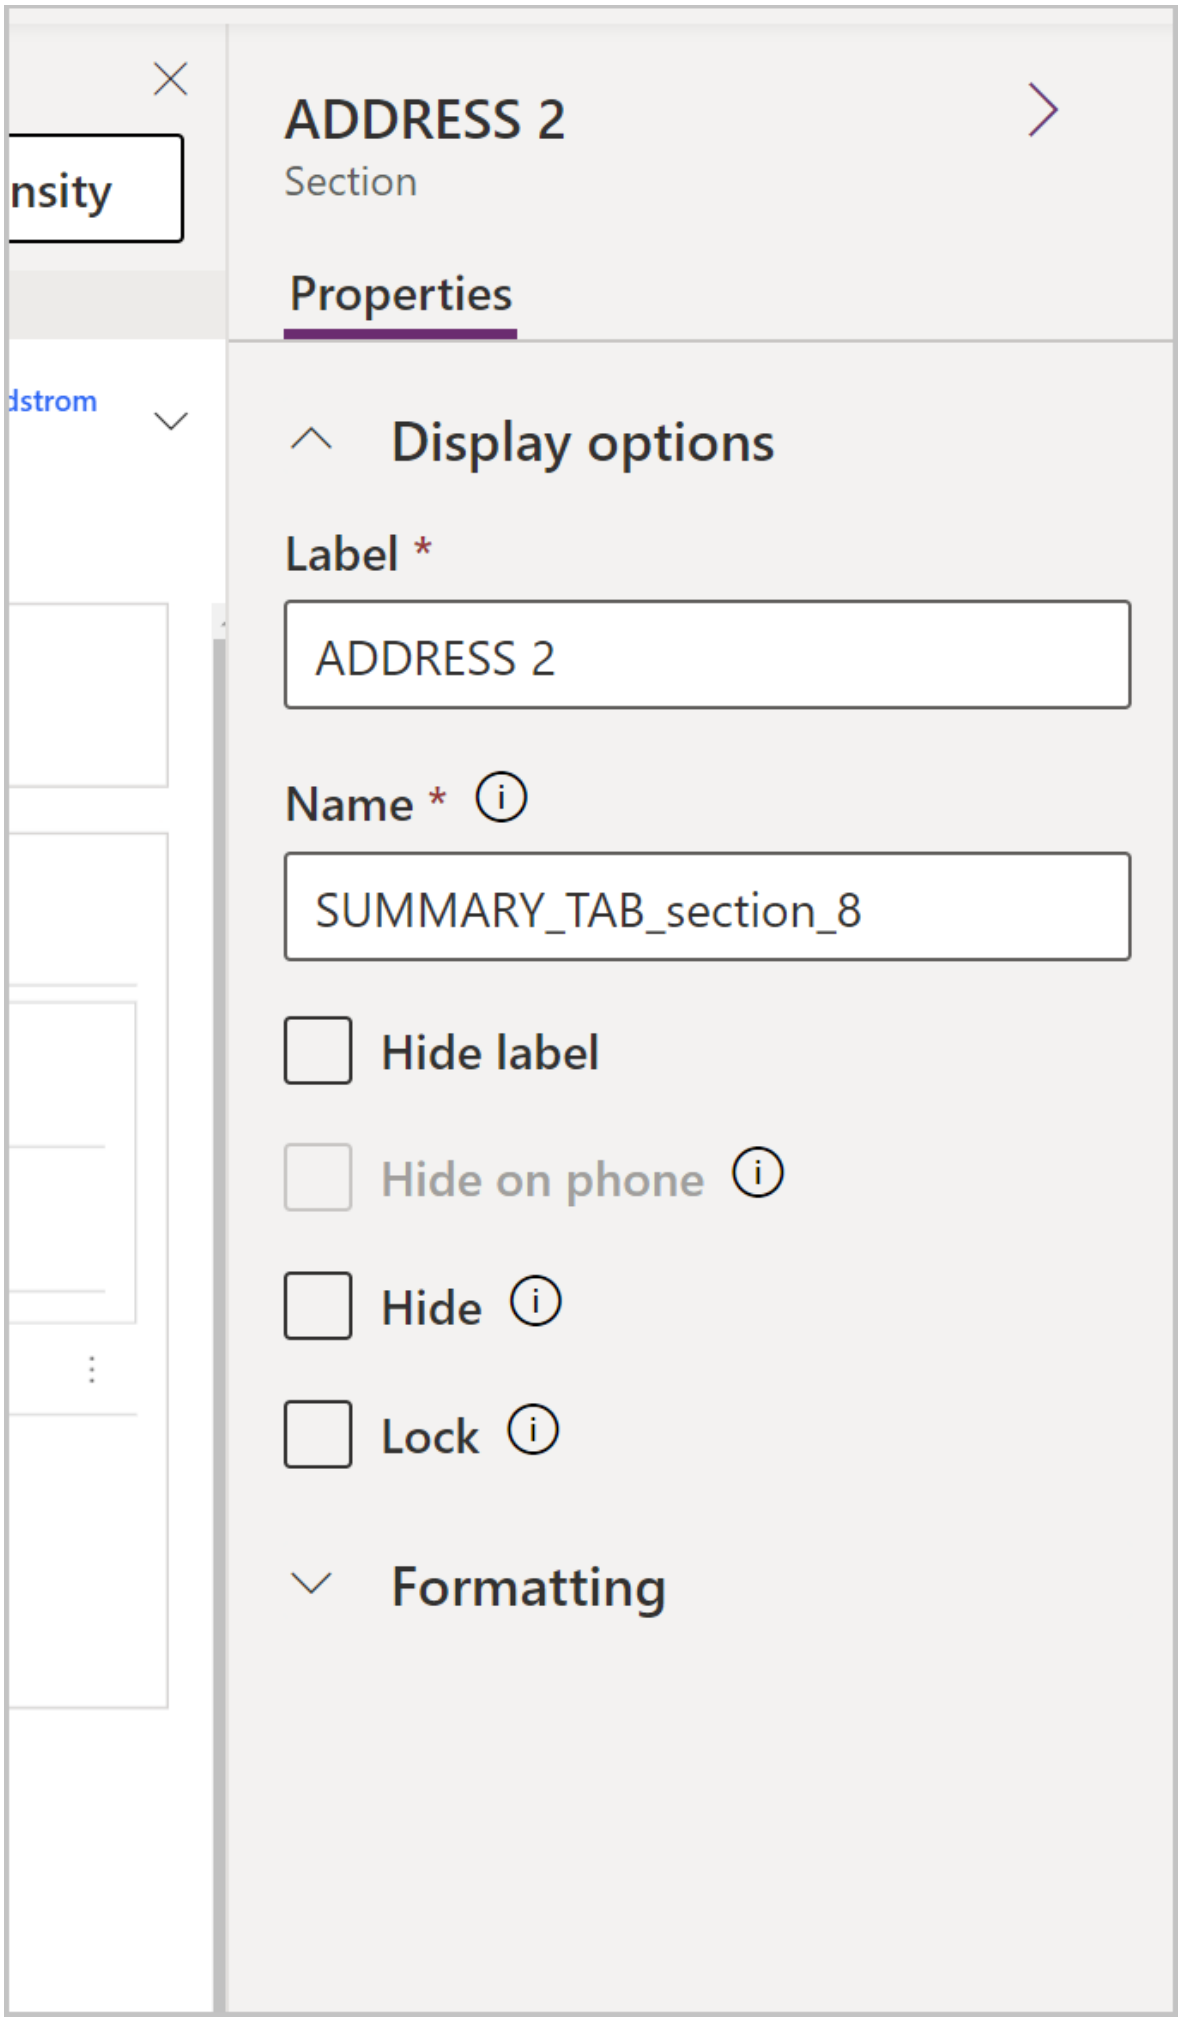
Exercise: Add a new section and fields to the form

By default, the account form includes a single address section. However, the account table also includes a second address set. In cases where you need to track shipping and billing addresses, it's common to add the second address set to the form. Follow these steps to add a new **ADDRESS 2** section and associated columns to the form.

1. Select the **Address** section of the form in the form designer.

2. On the left pane of the form designer select the **Components** tab, and then select **1 Column Section**. A new section is added below the **ADDRESS** section.

3. In the right **Properties** pane, change the **Label** from **New Section** to *ADDRESS 2*.

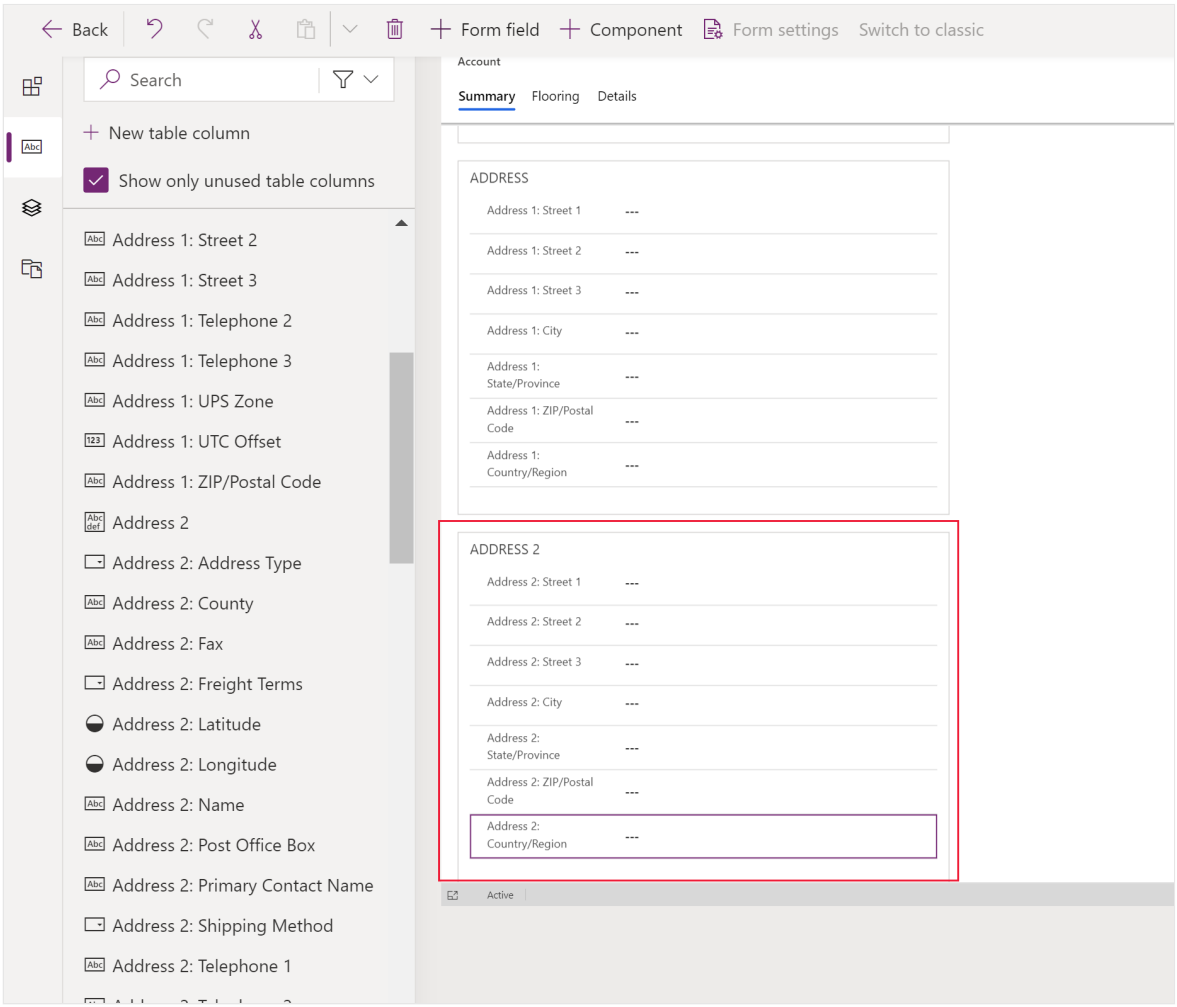


4. On left pane, select the **Table columns** tab.

5. With the *ADDRESS 2* section still selected, select **Address 2: Street 1** from the table column list to add the field to the **ADDRESS 2** section.

6. Repeat the previous step to add the following fields:

    - **Address 2: Street 2**
    - **Address 2: Street 3**
    - **Address 2: City**
    - **Address 2: State/Province**
    - **Address 2: Zip/Postal Code**
    - **Address 2: Country/Region**



> **Note**
>
> You can also drag and drop fields. This is especially useful when you want to move columns to a different area or section.

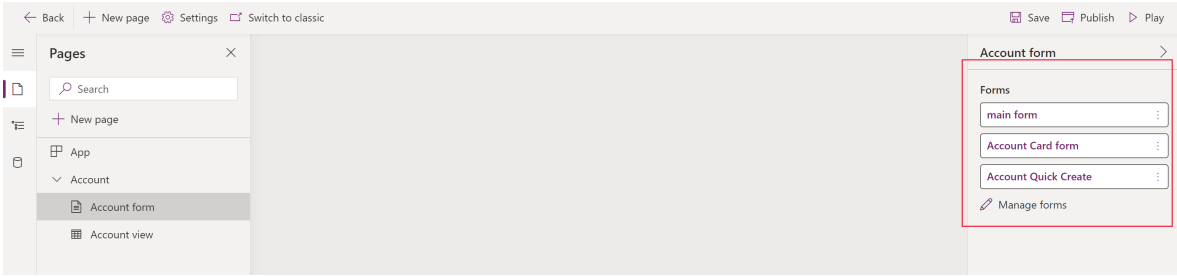
7. On the form designer command bar select **Save**, and then select **Publish**.

8. Close the form designer tab in your browser.

Control which form is visible in your model-driven app

If your app includes multiple model-driven main forms, users can select which form to view. If you want to restrict users of your app to only view records with your newly configured form, follow these steps.

1. Sign in to Power Apps.
2. Go to **Apps**, select **...** next to a model-driven app, such as the Account Tracking app you can create following this article: Build your first model-driven app, and then select **Edit**.
3. In app designer, select a form, such as the account main form.
4. On the right pane, select **Manage forms**.
5. Select the forms that you want to display in the app, such as **main form**, **Account Card form**, and **Account Quick Create**. Clear the other forms, such as **Account**.



6. Select **Save**, and then select **Publish** to reflect the changes in the app.

Controlling access to your forms

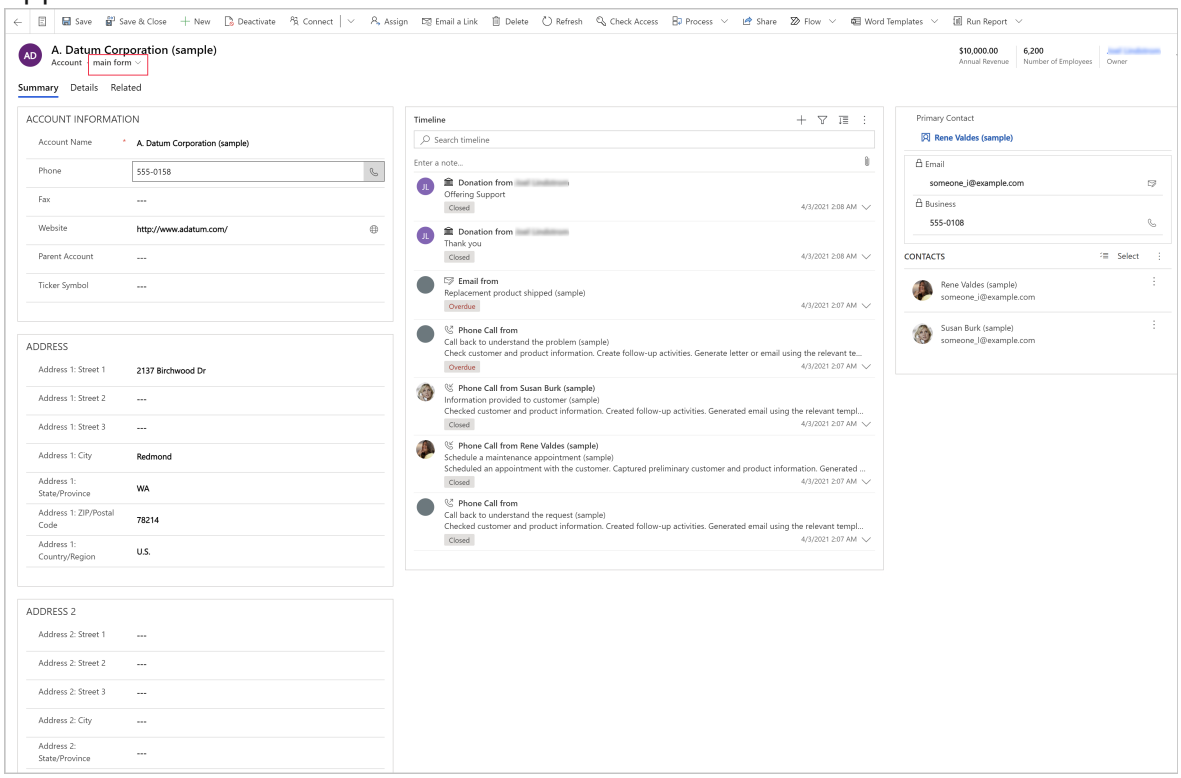
We recommend that you select all quick view forms and quick create type forms, unless you have specific reasons to not check them. Only select the main form or forms that you want users to see. You must also ensure that your new form is enabled for a security role that users of the app have been assigned. You can further control how users will access forms in an app by configuring the form order and fallback form. For more information, see these articles:

- Set security roles for a form
- Set the form order
- Set the fallback form for a table

View your new form

Now that you have created and modified a new form, let's test it out. Follow these steps to view your new form:

1. In app designer, select **Play**.
2. Open an account record.
3. The new main form with the section for **ADDRESS 2** is displayed. If your new account **main form** isn't displayed, select **main form** from the form selector in the upper left of the form.



Next steps

Create or edit quick create forms

Create or edit model-driven app quick create forms

Article • 01/23/2025

With quick create forms, an app can have a streamlined data entry experience with full support for logic defined by form scripts and business rules. In a Power Apps model-driven app, quick create forms appear when the **Create** button is selected in the navigation bar or when **+ New** is chosen when creating a new row from a **lookup** or **subgrid**.

Model-driven apps and Dynamics 365 mobile apps use quick create forms for creating new rows. If a table already has a quick create form configured for it, the mobile apps use that form. If a table doesn't have a configured quick create form, Power Apps generates a quick create form for creating rows in the mobile apps based on the main form definition.

Here's the quick create form for the standard Microsoft Dataverse account table.

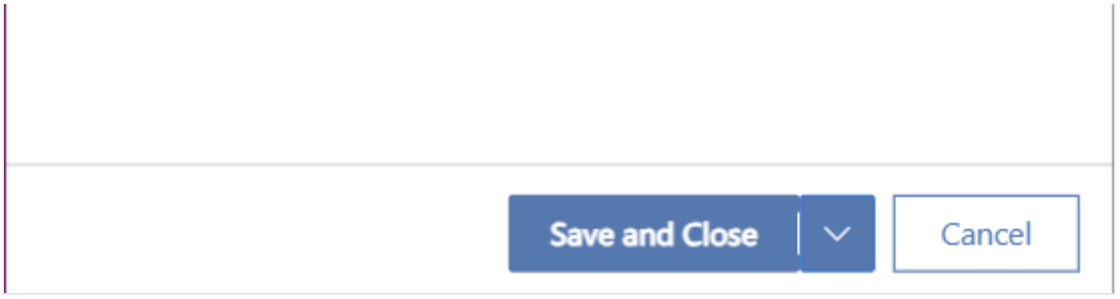
Quick Create: Account

Details

Account Name	*	---
Main Phone		---
Primary Contact		---
Annual Revenue		---
Number of Employees		---
Description		---

Address

Street 1	---
Street 2	---
City	---
ZIP/Postal Code	---



Tables with quick create forms

By default only these system tables have quick create forms: account, [1]campaign response, [1]case, [1]competitor, contact, [1]lead, [1]opportunity.

[1]Requires a customer engagement app.

Although it's possible to create quick create forms for system activity tables (except for the appointment table), system activity tables don't support quick create forms. Currently, the option to disable the quick create form for the appointment table isn't supported. Any of the other updated tables and any custom tables can be enabled to support these forms by selecting **Enable quick create forms** in the table definition and creating a quick create form for the table.

Custom activity tables that support quick create forms can be enabled, and it's possible to create quick create forms for those tables. However, the quick create form for custom activity tables aren't used when app users select **Create** on the navigation bar. These quick create forms can be used only when users add a new row for a subgrid that displays that specific custom activity table.

Create a quick create form

Although you can define multiple quick create forms, only one quick create form can be used by everyone. The form everyone uses is set using the form order. Quick create forms can't be assigned to security roles and they don't provide the capability for the user to switch forms.

> **Note**
>
> - The table must have the **Enable quick create forms** option enabled for the quick create form to be available as an option for the table.
> - The table must be added to your app.

- Some columns, such as the `CREATEDON` column, aren't available to add to a quick create form.

How to create a quick create form

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Tables**, select the table, and then select the **Forms** area.
4. On the toolbar, select **Add form** > **Quick create form**.
5. In the form designer, drag any columns from the **Table columns** left pane into the sections on the form.
6. When you're finished, select **Save and publish** to display the new form in the application.

Edit a quick create form

While quick create forms support form scripts and business rules, their purpose is different from main forms and they don't support all the capabilities of main forms. Quick create forms always have one section with three columns. You can't add more sections or columns.

The following controls can't be added to quick create forms:

- Subgrids
- Quick view forms
- Web resources
- iFrames
- Notes
- Bing Maps

If you add a composite column to a quick create form, it's displayed as separate columns.

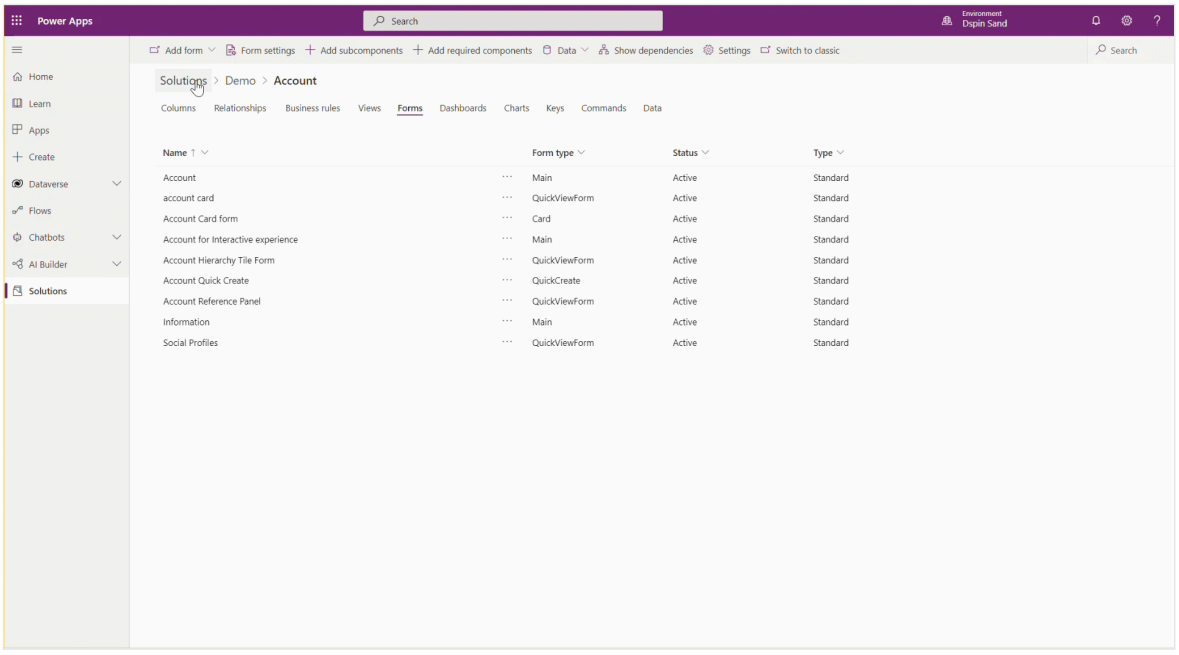
To edit a quick create form

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you

want.

3. Open the table, and then select the **Forms** area.
4. In the form list, select a form where the form **Type** is **Quick create**.
5. Drag any columns from the **Table columns** left pane into the sections in the form.

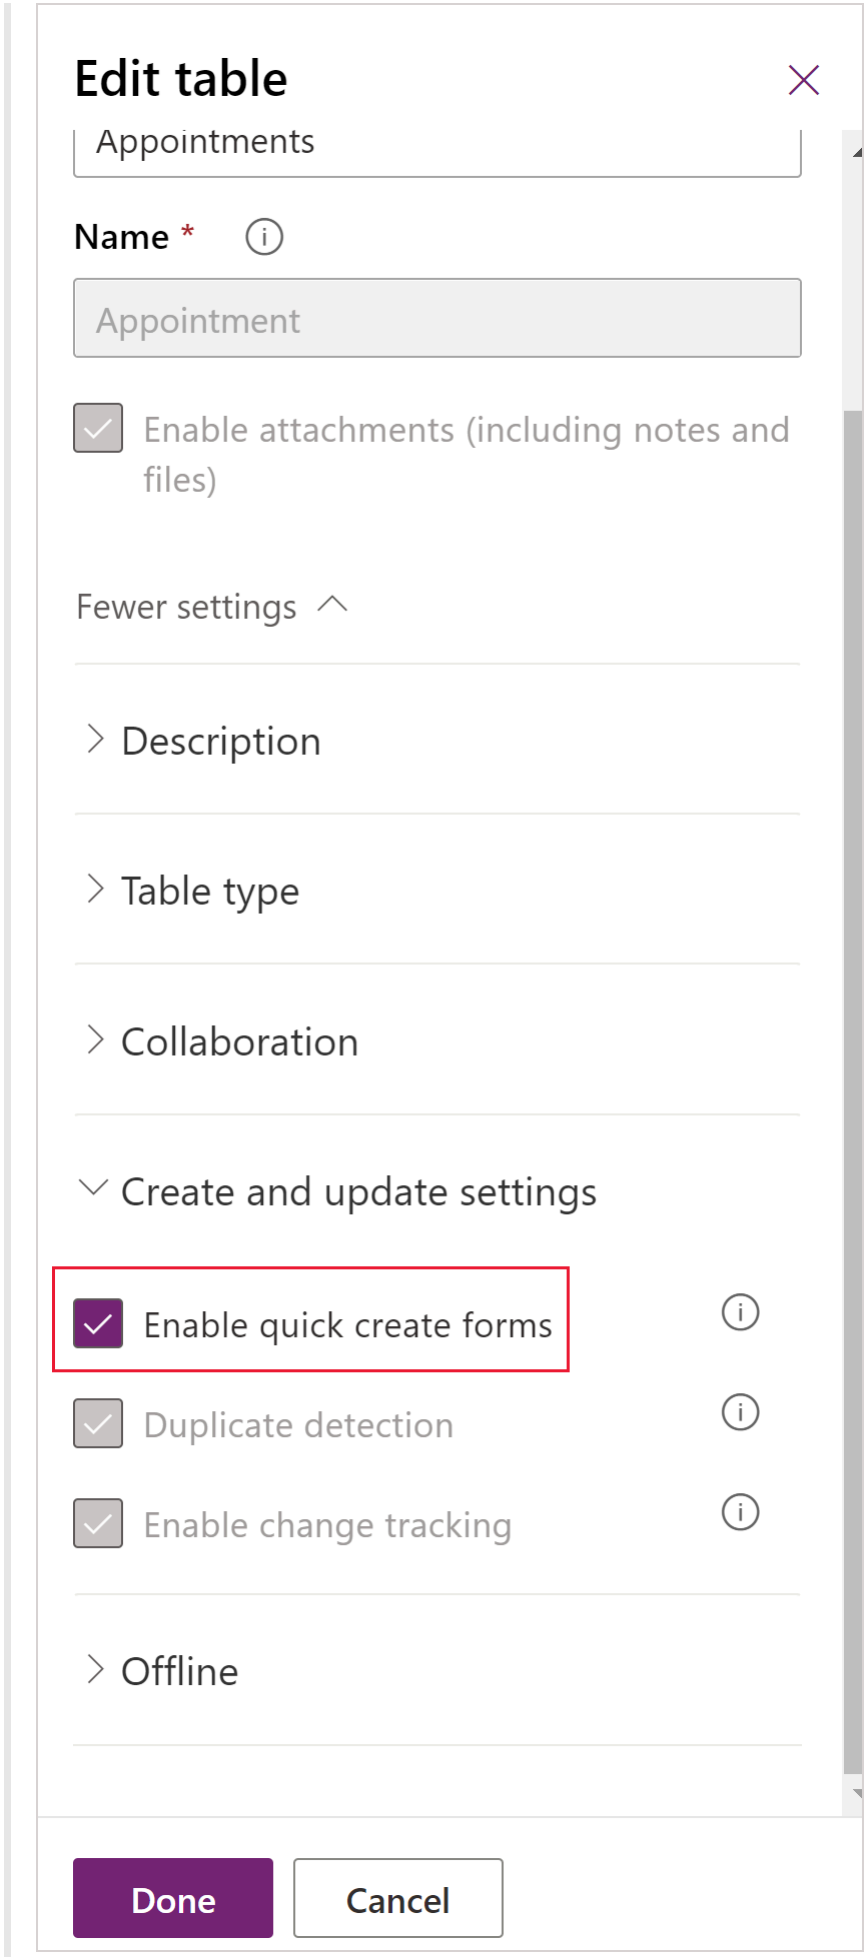
   See Configure event handlers for information about editing event handlers for form scripts.



6. When you're finished, select **Save and publish** to display the modified form in the application.

Enable quick create form property behavior for activities

The **Enable quick create forms** property can be enabled or disabled for all standard activities except recurring appointments. This property allows the form that is displayed by default for most activities to display. By default, the **Enable quick create forms** property is enabled and the quick create form is the form displayed in the app areas and activity tables that support it.



Unified Interface client form display behavior

The following table indicates what form is displayed by default when the **Enable quick create forms** property is *enabled* in the Unified Interface client.

Expand table

Location where form is accessed	Form displayed
Specific activity associated grid	Quick create
Specific activity sub grid	Quick create
Activities (`activitypointer`) grid	Quick create
Activities (`activitypointer`) associated grid	Quick create
Activities (`activitypointer`) sub grid	Quick create
Global command bar + button [1]	Quick create
Timeline wall	Quick create
Activities (`activitypointer`) grid	Main
Specific activity grid	Main

[1]Activities appear in the global **Create** or **+ New** buttons when the **Enable quick create forms** property is enabled. In this case, the quick create form is used if it exists or the main form if it doesn't. If **Enable quick create forms** is disabled, the entry for the table won't appear.

Classic web client form display behavior

The following table indicates what form is displayed by default when the **Enable quick create forms** property is *enabled* in the classic web client.

Expand table

Location where form is accessed	Form displayed
Specific activity associated grid	Quick create
Specific activity sub grid	Quick create
Activities (`activitypointer`) grid	Main
Activities (`activitypointer`) associated grid	Main
Activities (`activitypointer`) sub grid	Main

Location where form is accessed	Form displayed
Global command bar + button	Main
Specific activity grid	Main

Classic web client social pane behavior

The social pane is a special case because it doesn't use the **Enable quick create forms** property but uses different forms for different activity tables as indicated here.

Expand table

Activity	Form displayed
Task	Quick create
Phone Call	Quick create
Email	Main
Appointment	Main
Custom activity	Main

Solution import Allow Quick Create value behavior

When a solution from version 8.2 is imported, regardless of the value of the **Enable quick create forms** property in the solution, the following tables are reset to the default form display value. Also, the main form displays: task, phone call, email, and appointment. In this situation, you'll need to reset the **Enable quick create forms** option back to *enabled* for those activity tables after the import.

If there's a customization made in a version 9.0 solution to tables where **Enable quick create forms** is enabled, the value won't change after import. However, if the **Enable quick create forms** option is set to *disabled* for the task, phone call, email, and appointment tables, the value is overwritten to enabled. In this situation, the **Enable quick create forms** option needs to be reset back to disabled for those activity tables after the import.

Important

- If a quick create form exists for a table but isn't included in the app, the Unified Interface runtime will still open the quick create form. This behavior

occurs with lookup controls and subgrids. If you don’t want a quick create form to appear in your app you must delete it.

- Be aware of the behavior that occurs when a parent relationship is created with the same table. For example, if Account has a relationship to Account and lookup is created that is used by a quick create form that creates a parent row, the first row won't be saved with the lookup that has the parent row value. This is because of the circular reference introduced by using the same table. If you experience this issue, you can resolve it by removing the parent row ID on the quick create form before saving the row.

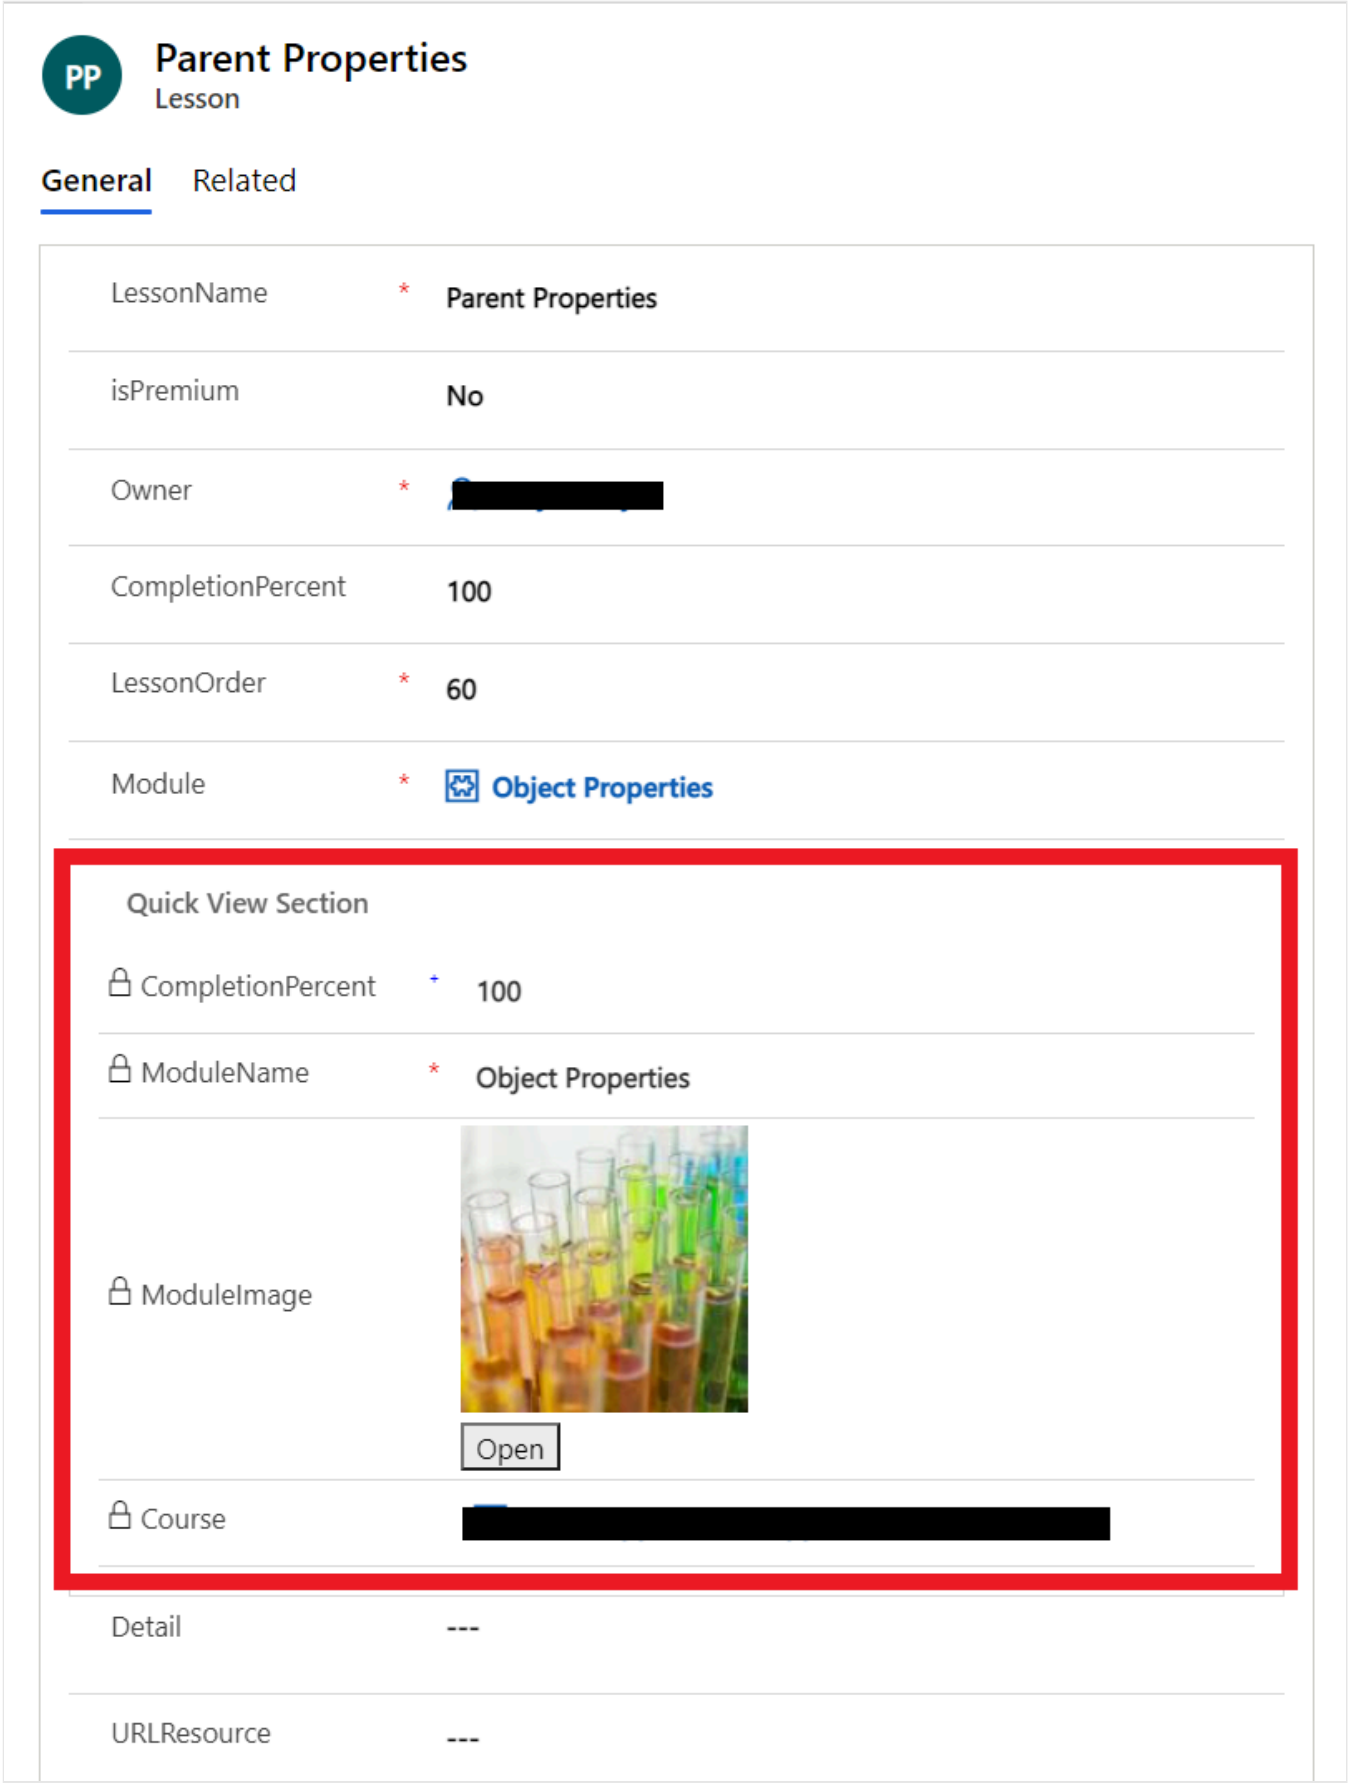
Create a quick view form to view information about a related table

This article describes how to create a quick view form and how to add a quick view control to a main form.

You can add a quick view form to another form as a quick view control. It provides a template to view information about a related table row within a form for another table row. This means app users don't need to navigate to a different row to see the information they need to do their work.

Note that while a quick view form can appear over a view or a form, it is authored as a form, rather than a view.

In the example here, notice the module that relates to a given lesson within the quick view form. A one-to-many relationship exists between the two tables for this to be possible. You can see additional columns of metadata, including the image associated with the module. The form then continues with the metadata associated with the lesson table record.



Quick view controls are associated with a lookup column that is included in a form. If the lookup column value isn't set, the quick view control is not visible.

> **Note**

- You can't edit data in quick view form controls and they don't support form scripts.
- Because quick view forms are viewed using a quick view control in a form, they don't include header, footer, or navigation areas.
- Security roles can't be assigned to quick view forms and they can't be activated or deactivated.
- Custom controls aren't supported in quick view forms, and there is limited customization support for complex controls such as subgrids. If this is required, consider using a Form component control

Create a quick view form

You create quick view forms by using the form editor, similar to how you create other forms. Quick view forms are read-only. Use them to create forms that are for reading purposes only.

1. Sign in to Power Apps and then select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the table where you want to create a quick view form, select the table that you want, and then select the **Forms** area.
3. On the toolbar, select **New form** > **Quick view form**.
4. Enter a **Form name** and **Form description** to differentiate this quick view form from others.
5. Optionally, clear **Get AI-generated column suggestions** if you don't want suggestions from Copilot for the columns to create for the form based on the **Form name** and **Form description** values.
6. Select **Create**.
7. The form designer opens. Drag columns you want to add from the left **Table columns** pane into the form canvas. To remove columns you don't want, select the column, and then select **Delete** on the command bar.

   > **Important**
   >
   > Required columns can't be removed from a form. If you add a required column to the form and want to remove it, you must delete the form and then re-create it. When you set the required property for a column, a row can't be saved without data in the column.

8. Select **Save and publish** to make your changes available to users of the apps that use the form.

Edit a quick view form

Quick view forms have a simplified layout because they are designed to be viewed within a form section. Only one single column tab is available with quick view forms. You can add only additional single column sections, columns, subgrids, and spacers.

1. Sign in to Power Apps.
2. Open the solution that has the table where you want to edit the form, and open the table you want, and then select the **Forms** area.
3. Open the quick view form.
4. Add or remove the table columns you want.

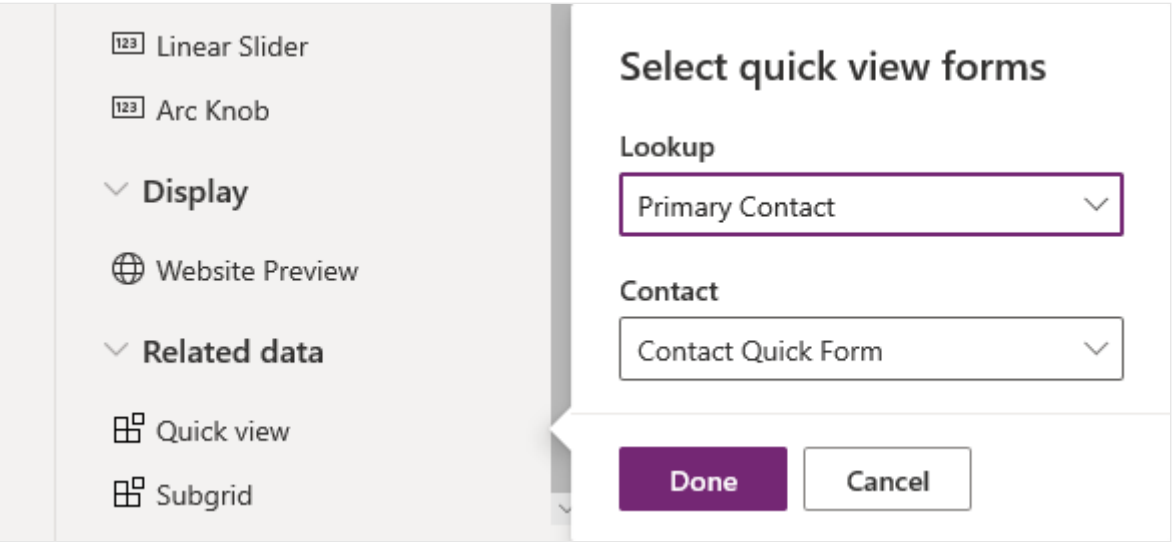
   > **Important**
   >
   > You can't delete required columns. If you add a required column to the form, you can't delete it. If you don't want the column in the form, you must delete the form and then re-create it.

5. When you're done editing a quick view form, select **Save and publish** to publish your changes so they're visible in the application.

Add a quick view control to a main form

You can add quick view forms to a main form only when a lookup column exists that targets the table of the quick view form.

1. Sign in to Power Apps.
2. Open the solution that has the table where you want to edit the form, and open the table you want, and then select the **Forms** area.
3. Open a form, which **Type** is **Main**
4. In the form designer, select **Quick view** from the **Components** pane.
5. In the **Select quick view forms** dialog box, select the **Lookup** column, and then select the lookup column value. More information: Quick view control properties.



6. Select **Done** to close the **Select quick View forms** dialog box. The quick view form appears on the form.

7. To save and publish the form select **Save and publish**.

> **Important**
>
> Be aware of the behavior that occurs when you create a parent relationship with the same table. For example, if Account has a relationship to Account and a lookup is created that is used by a quick create form that creates a parent row, the first row will not be saved with the lookup that has the parent row value. This is because of the circular reference introduced by using the same table. If this issue is experienced it can be resolved by removing the parent row ID on the quick create form before saving the row.

Quick view form properties

When the quick view form is used in a main form the following properties can be set or updated.

Expand table

Property	Description
Name	**Required**: Enter a unique name for the quick view form. Use this name when referencing the form in scripts.
Label	**Required**: Enter a label to display for the quick view form.
Display label on the Form	Choose whether to display the label on the form.

Property	Description
Lookup Column	Choose one of the lookup columns included in the form.
Related table	This value depends on the **Lookup Column** chosen. It's usually the primary table for the 1:N table relationship for the lookup. If the table includes a **Potential Customer** lookup that can accept either an account or contact, in the **Quick View Form** column you can choose a quick view form for both account and contact by changing this value and then choosing another quick view form.
Quick View Form	If the **Related table** has any quick view forms these can be selected here. Otherwise, select **New** to create one.

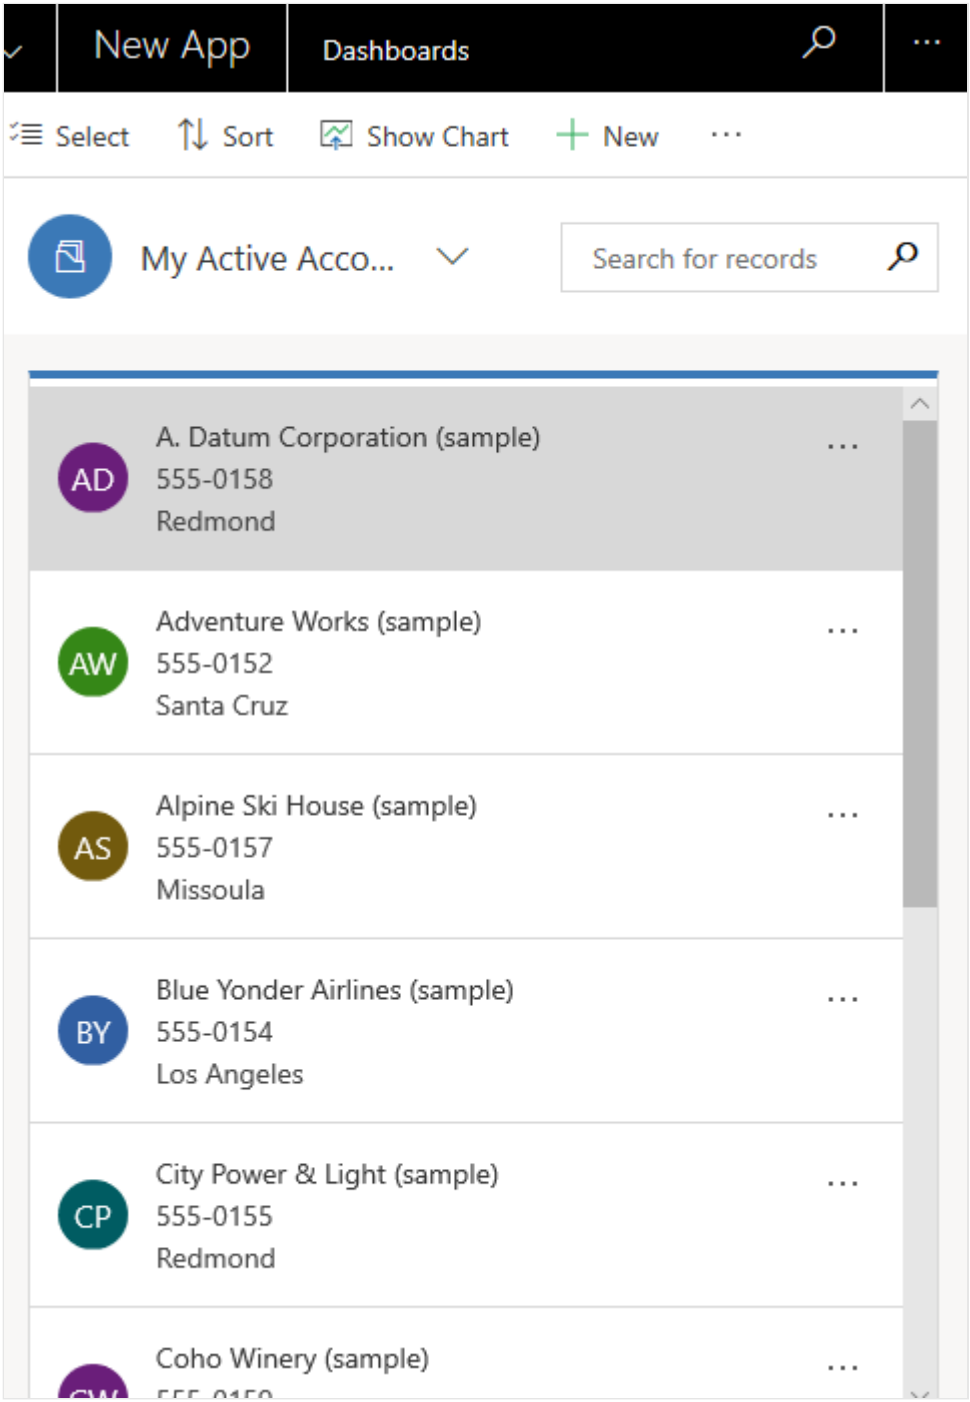
Create and edit a card form

Last updated on 03/31/2026

Create a card form

Article • 03/13/2023

Card forms are used in views for model-driven apps. Card forms are designed to present information in a compact format that is suitable for **mobile devices**. For example, the default card form for the My Active Accounts view defines the information displayed for each account row.



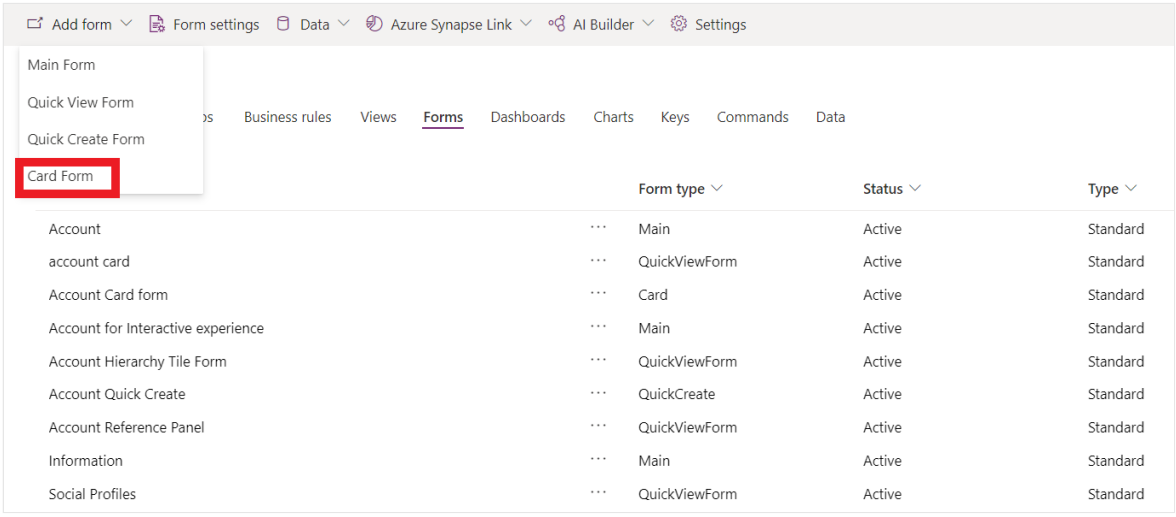
Although card forms can be created and edited in the same way as other form types, card forms are added to apps differently. Instead of adding a form as an app component, custom card forms are added to views by using the **Read-only Grid** control.

Create a card form

1. To create a card form, sign in to Power Apps.

2. Select **Tables**, select the table you want, and then select the **Forms** area. If the item isn't in the left navigation pane, select ...More and then select the item you want.

3. On the toolbar select **Add form**, and then select **Card form**. Alternatively, you can open an existing **Form type** that's a **Card** form to edit it.



4. Add the columns that you want. We recommend that you limit the number of columns so that the form displays well on small screens.

5. Select **Save**, and then select **Publish**.

Add a card form to a view

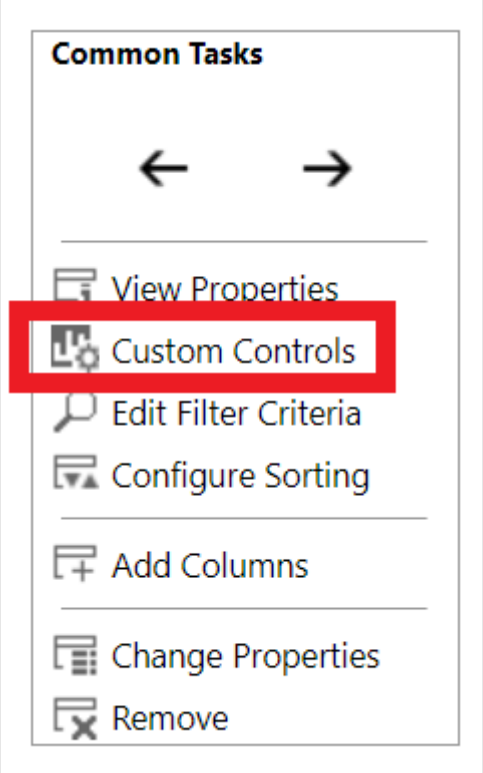
> **Important**
>
> To add a custom card form to a view requires the deprecated **Read-only Grid** control. The **Read-only Grid** has been deprecated so it is no longer the default grid control for tables in Dataverse. However, while the control remains available you can select it for a table to use to create a card form view. More information: **Configure a grid control for a table**

1. Sign in to Power Apps.

2. Select **Tables**, select the table you want, and then select the **Views** area. If the item isn't in the left navigation pane, select ...More and then select the item you want.

3. Select the view that you want, and then on the view designer toolbar, select **Switch to classic**.

4. Select **Custom Controls** from the **Common Tasks** pane.

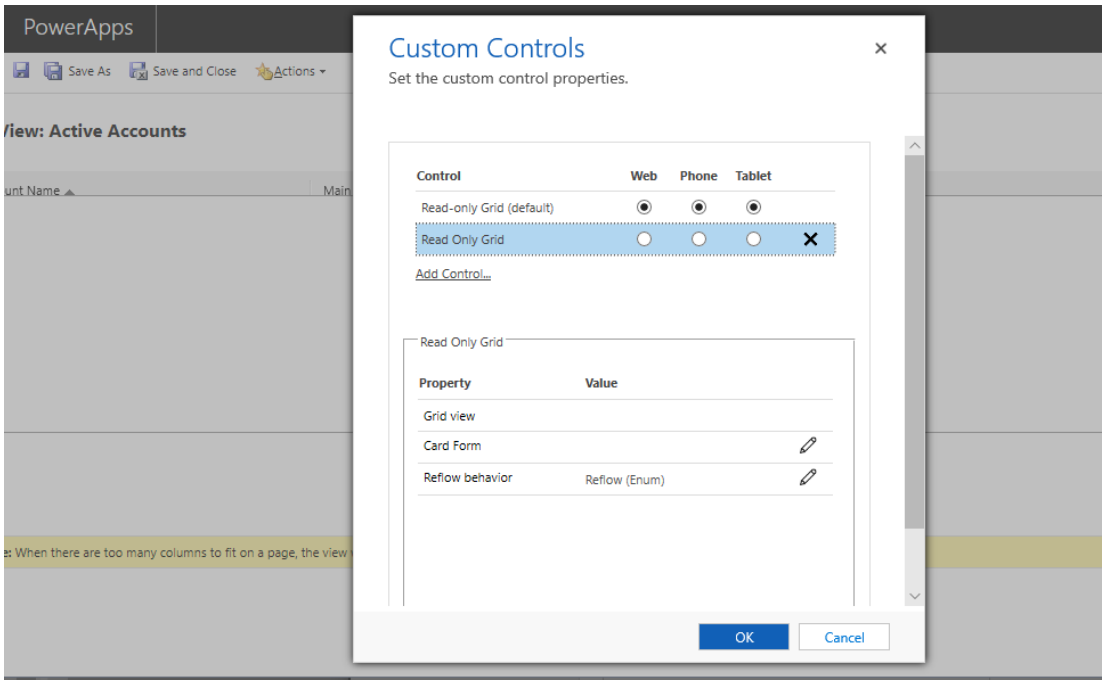


5. Select **Add Control**, from the list of controls select **Read Only Grid**, and then select **Add**.

> ⓘ **Note**
>
> There are two read only grid controls. The default read only grid control that is named **Read-only Grid (default)** doesn't support custom card forms.

6. From the **Read Only Grid** properties page configure the following properties, and then select **OK**.

   - **Card Form**. Select the pencil icon and then select the card form you want to display in the view. By default, the primary table associated with the view is already selected, but you can change it.
   - **Reflow behavior**. If you want to change whether the card form displays when resized, select the pencil icon . More information: Allow grid to reflow into list
   - Select the client types, **Web**, **Phone**, or **Tablet**, where you want the **Read Only Grid** control to display.



7. Select **OK** to close the **Custom Controls** properties page.

8. On the classic view designer toolbar, select **Save and Close**.

Assign model-driven app form order

Summarize this article for me

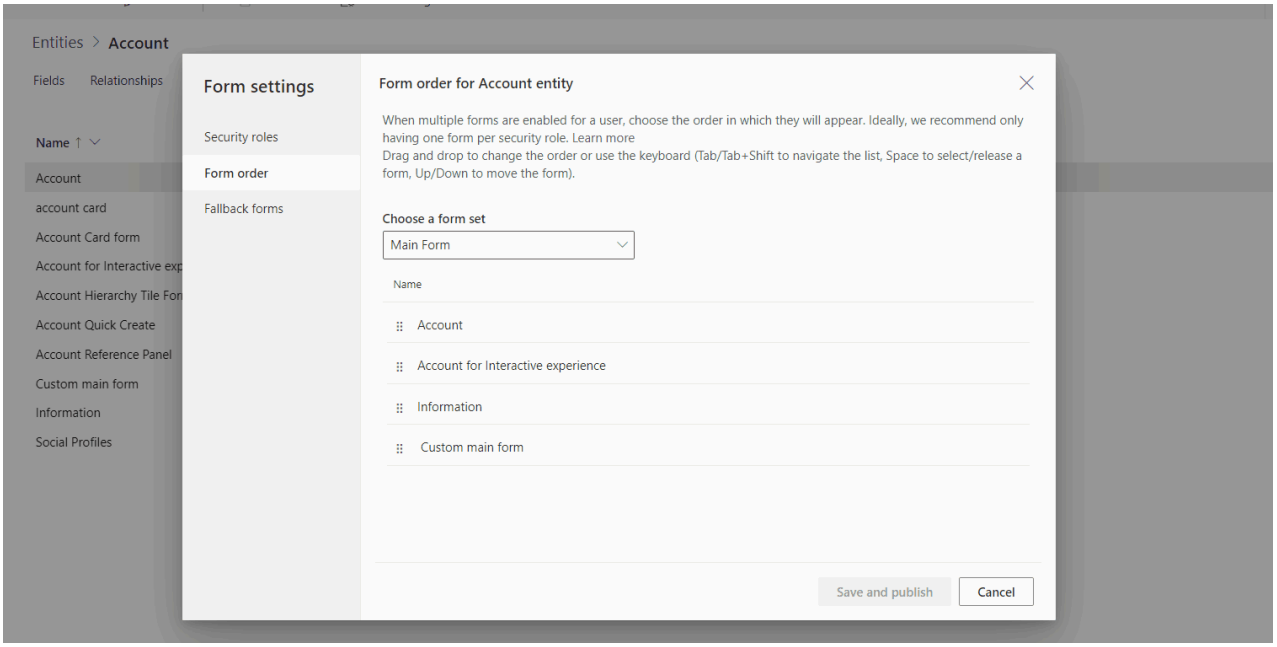
When there are multiple main, quick create, quick view, or card forms for a table, a form order can be assigned. The form order determines which of the available forms are shown by default.

The available main forms can be further controlled by assigning security roles to the form. More information: Control access to forms

It isn't possible to assign security roles to quick create, quick view, or card forms, so the only form that is used by everyone is the one at the top of the form order.

Set the form order

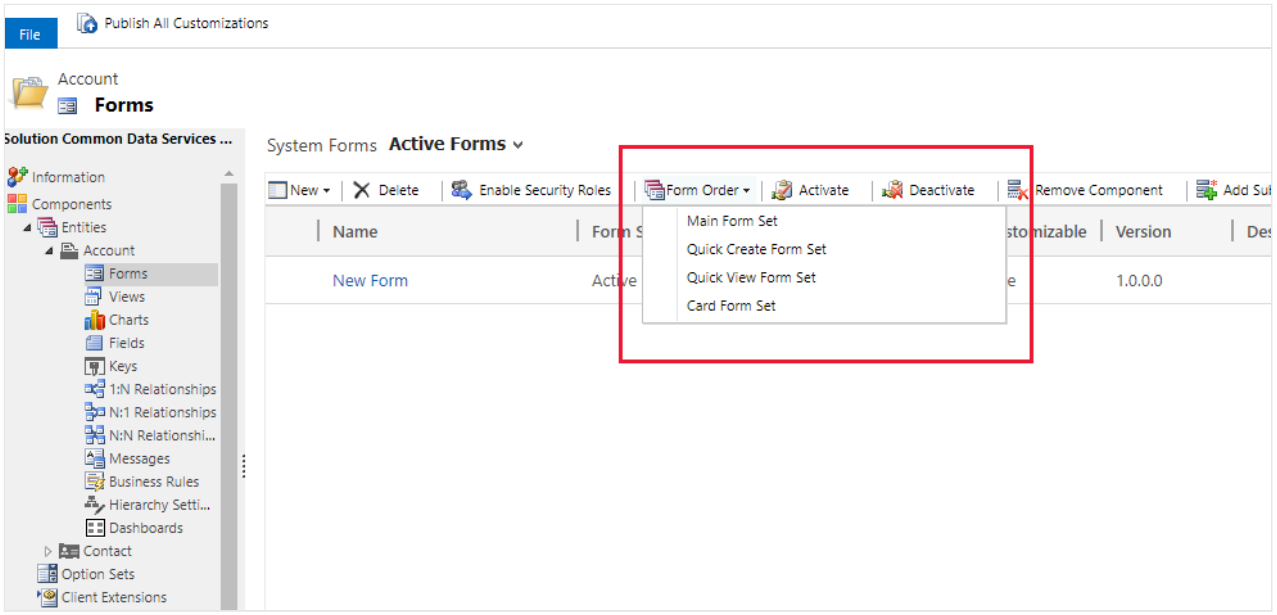
1. Sign into Power Apps, select **Solutions**, open the solution you want, select a table on the left navigation pane, and then select the **Forms** area. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Next to the main form you want to configure the fallback form for, select ..., and then select **Form settings**.
3. In the left navigation on the **Form settings** page, select **Form order**.
4. Select the form set that is required, such as **Main Form**, **Quick Create Form**, **Quick View Form**, or **Card Form**.
5. Change the order by dragging and dropping the form up and down the list in the order best suited to the users. It is also possible to use these keyboard shortcuts: Tab/Tab + Shift to move the focus, Space to select or release a form, and Down/Up arrow keys to move a form. Select **Save and publish**.



Using the classic editor to assign the form order

> **Note**
>
> To set form order using the new experience, go to Set the form order.

1. Open the solution explorer, expand the table that you want, and then select **Forms**.
2. In the form list toolbar, select **Form Order**.



3. Choose either **Main Form Set**, **Quick Create Form Set**, **Quick View Form Set**, or **Card Form Set** depending on the type of forms you want to work with. More information: Type of forms.
4. The **Form Order** dialog is a simple list where a selected form can be moved up or down in the form order.
5. After the order has been set, select **OK** to close the dialog.

Overview of the model-driven form designer

Article • 02/15/2022

The new model-driven form designer provides a modern WYSIWYG authoring experience when you work with model-driven forms. It includes several improvements not available in the classic model-driven form designer.

The designer shows a real-time WYSIWYG preview (Unified Interface only) while you author a form. Changes to the form are instantly reflected in the preview, enabling you to see exactly how the form will appear to users when published. An always available property pane makes the common task of updating properties quick and easy. Updates to properties are also instantly reflected in the form preview. The columns pane with searching and filtering capabilities helps makers quickly find and add columns to the form. The components pane makes it easy to discover and use components and provide a rich end-user experience. The tree view helps visualize the hierarchy of the form's columns and components and to quickly find and select a particular column or component on the form.

The form designer interface has the following areas:

1. Command bar – Displays available actions such as **Save**, **Publish**, **Undo**, and **Redo**.

2. Form preview – Displays a real-time preview of the form as it will appear to users when published.

3. Panes – Displays panes with specific functions:

    - **Columns** pane to add columns to a form.
    - **Components** pane to add components to a form.
    - **Tree view** to see the hierarchy of components on the form and select them.
    - **Form libraries** pane is where form libraries can be viewed and added. More information: Configure model-driven app form event handlers

4. Property pane – Displays properties of the selected element, and also allows you to make changes.

5. Preview size switcher - Changes the size of the form preview helping you to see how the form will appear on various screen sizes.

6. Show hidden - Displays hidden columns in the form preview area. By default, this option is turned off and hidden columns don't appear on the form preview and are

visible only from the tree view pane. When enabled, columns that are hidden are indicated in the form preview area with  .

7. Zoom slider - Zooms in or out of the form preview helping you take a closer look.

8. Fit to width - Quick action to fit the form preview to the available width.

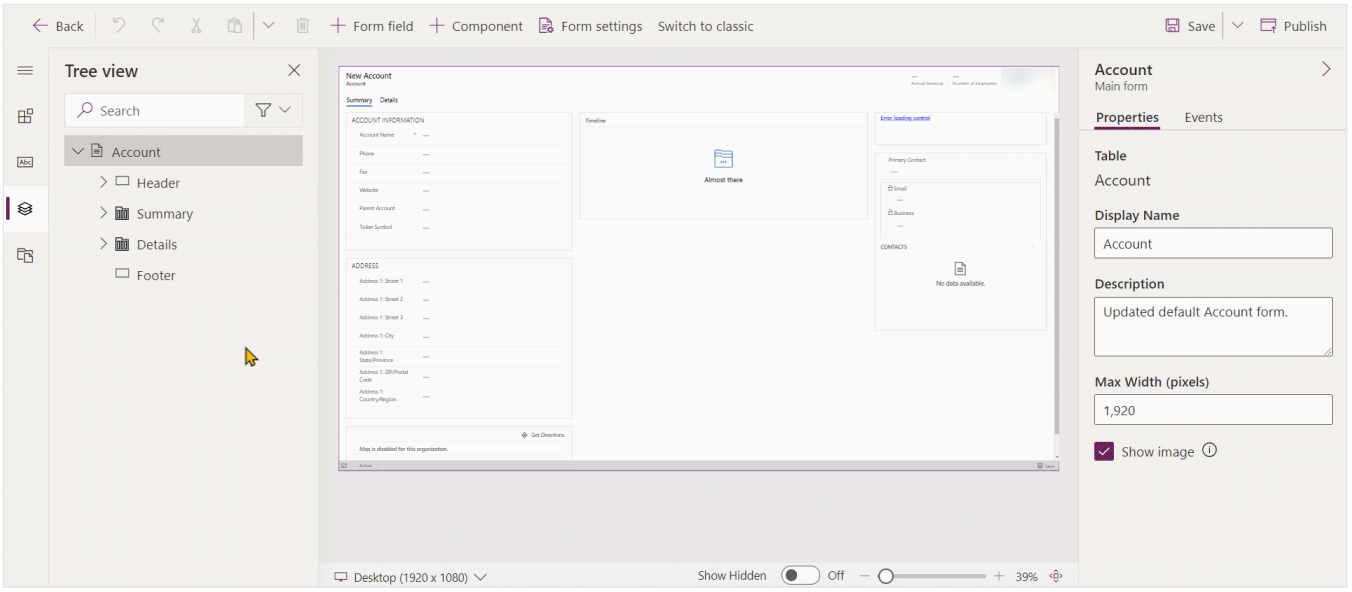
How to open the form editor

Open the model-driven app form editor

Summarize this article for me

Model-driven app forms let users update data within columns, or fields, associated with a given table record.

The form editor is where you design forms by dropping components such as sections, tabs, columns, and controls onto the form editor canvas. In this article, you learn how several different ways to access the form editor.



If you create any new solution components in the process of editing the form, for example web resources, the names of the components will use the solution publisher customization prefix for the default solution and these components will only be included in the default solution. If you want any new solution components to be included in a specific unmanaged solution, you should open the form editor through that unmanaged solution.

Access the form editor from the Power Apps site

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation, and then open the table you want, such as the account table. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Forms** area and then open the form you want, such as the **Account** main form.

Access the form editor for an unmanaged solution

1. Select **Solutions**, on the left naviation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the unmanaged solution you want to work with.
3. Open the table with the form you want to edit. If the table isn't there, you'll need to add it. More information: Add a table to an unmanaged solution
4. Select the **Forms** area, and then open the form you want to edit.

Add a table to an unmanaged solution

1. While in an unmanaged solution, on the toolbar above the list, select **Add Existing** > **Table**.
2. In the **Add existing tables** pane, select the table you want to add, and then select **Next**.
3. Choose the correct option for the table objects:
   - If this is a custom table that doesn't exist in other environments, select **Include all objects**.
   - If this table has been customized but already was exported or otherwise exists in target environments, select **Include table metadata** if only properties for the table have changed, or select **Edit objects** and select specific objects, such as columns, forms, or views that have been changed or added.
   - If no changes have been made, such as if you adding an out-of-box table, don't select any options.
4. Select **Add**.

Access the form editor from the classic solution explorer

1. Open solution explorer.
2. Under **Components**, expand **Tables**, and then the table you want, and select **Forms**.
3. In the list of forms, select the form you want to edit.

Next steps

Create or edit forms

Last updated on 02/13/2026

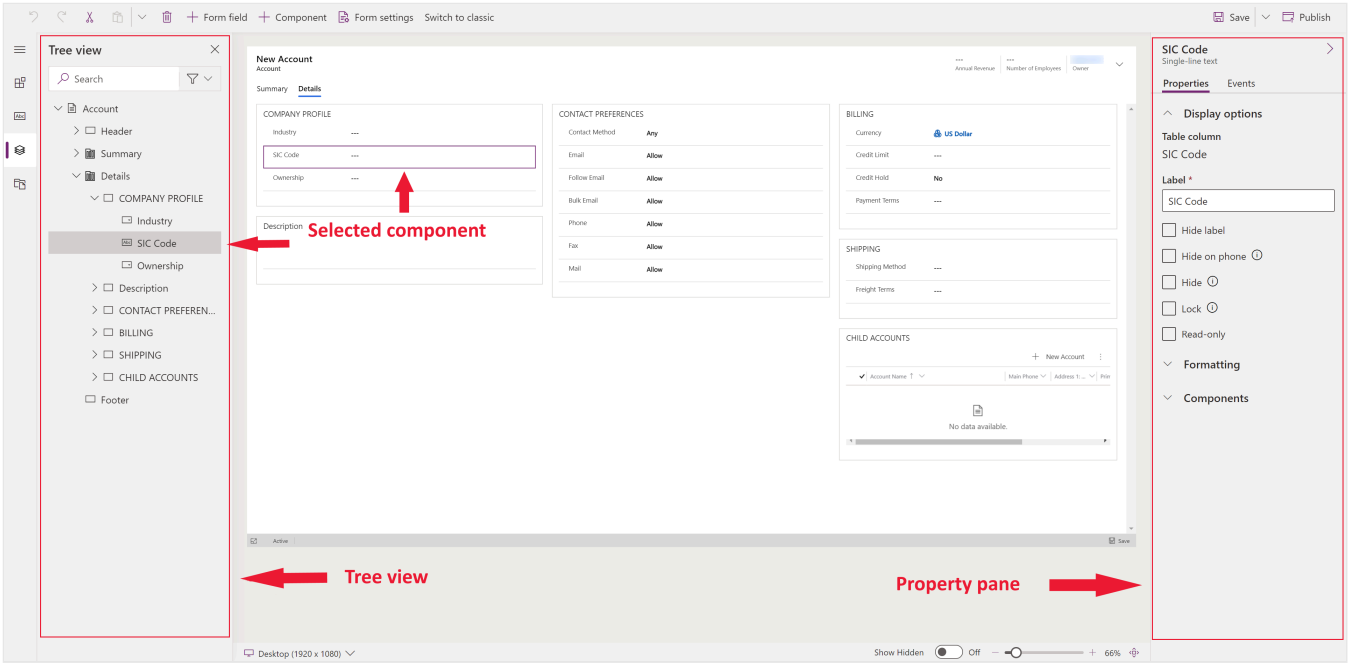
Using the tree view in the form designer

Summarize this article for me

The **Tree view** pane displays a visual hierarchy of the components on the form. The icons in the tree view help an app maker to quickly identify the type of properties of the column, section, tab, or component.

Use the tree view to select columns and other components present on the form. The tree view is helpful when you want to select hidden elements that aren't visible on the form preview.

You can expand or collapse nodes in the tree view to show or hide the elements within a node. When you select an element in the tree view, it becomes highlighted in the form preview, and the property pane displays the properties for the element.



Open the tree view

1. Sign in to Power Apps.
2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution you want, select the table you want, and then select the **Forms** area.
4. Open the form you want. The form designer opens to enable creation or editing of a form.
5. In the left pane, select **Tree view**.

Create, edit, or configure forms using the form designer

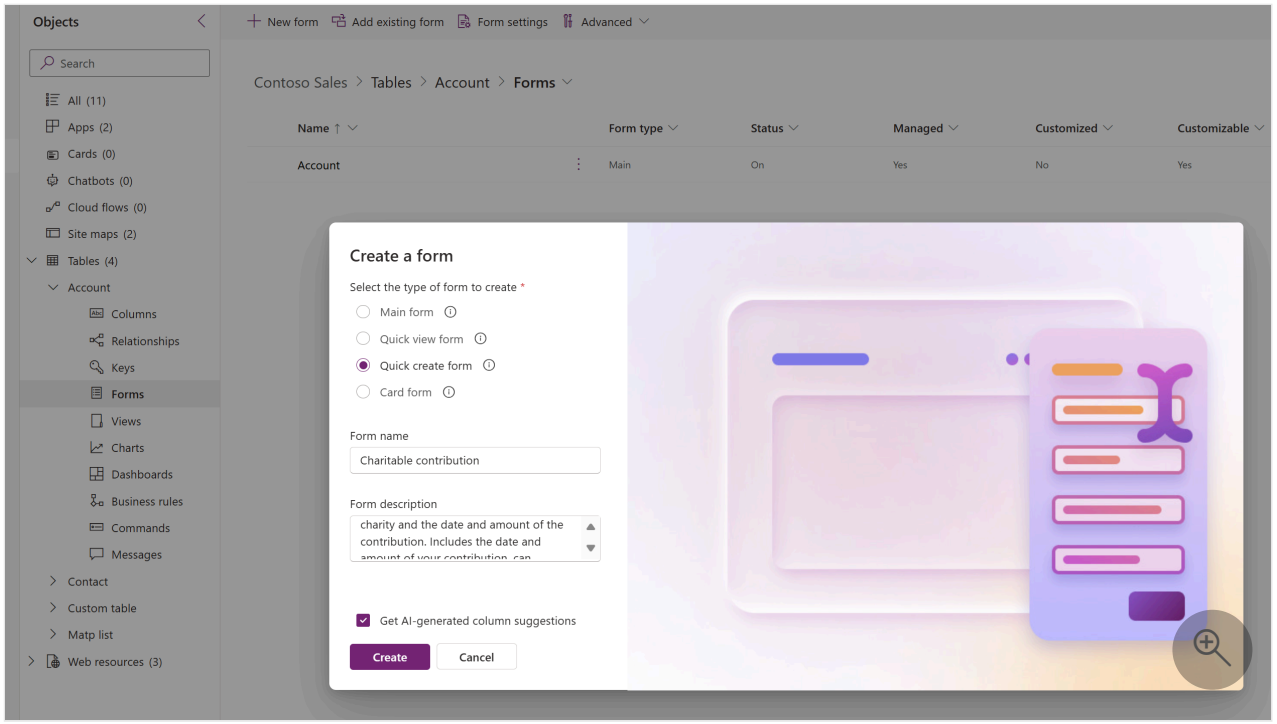
Use the form designer to create, edit, or configure forms for model-driven apps.

Create a form

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**, and open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open a table, such as the account table, and then select the **Forms** area.
4. Select **New form**, and then select one of the following form types:
    - **Main form** The primary form type for interaction by users with record data. The contents of the new form are filled using the existing main form definition. If multiple main forms exist, the form at the top of the list in the form order for your app is used to fill the new form.
    - **Quick view form** Quick view forms appear within a main form to display additional read-only data referencing a lookup column. Learn more about main forms
    - **Quick create form** Best for creating new records quickly where only essential columns are required. Appears in a side panel so users don't navigate away from the current screen.
    - **Card form** For displaying compact data in a layout that is good for small screens or areas in a subgrid or view.
5. Enter a **Form name**, and optionally enter a **Description**.
6. If you want to have suggestions from Copilot for the columns to create for the form based on the **Form name** and **Description** values, select **Get AI generated column suggestions**. For more information about using this AI feature, go to Column suggestions

by Copilot.



7. Select **Create**.

Edit a form

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**, and open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open a table, such as the account table, and then select the **Forms** area.
4. Select the form that you want, and then on the command bar, select **Edit**.
5. Make changes such as adding columns or configuring properties.
6. When you're done making changes to the form, select **Save only** to save the form, or select **Save and Publish** to save and have your changes available to app users.

Column suggestions by Copilot

Use column suggestions by Copilot to select the best columns to display in your model-driven app form. Instead of using the default fields that Power Apps selects, makers can view suggestions from Copilot. The column suggestions are based on the form name and description. Makers review the suggestions and make adjustments as needed, saving time and improving the quality of the app.

Prerequisites

- See if this feature is available in your region: Product availability report
- Learn how to turn on Copilots in your region: Turn on copilots and generative AI features

How column suggestions work

Column suggestions are available when you create a new form or view for a Microsoft Dataverse table.

Column suggestions are available for the following form types:

- Quick view
- Quick create

To understand the AI impact of field suggestions by Copilot in Power Apps, go to FAQs for field suggestions by Copilot.

Form properties

These are the properties available to configure a form when you create or edit a form using the form designer.

Expand table

Name	Description
Title	Enter a name that is meaningful to other makers and app users. This name is shown to app users. If users have access to multiple forms for a table, they will use this name to differentiate between the available forms. This property is required.
Description	Enter a description that explains how the form is different from other main forms. This description is only shown to makers in the list of forms for a table in the solution explorer.
Max Width	Set a maximum width (in pixels) to limit the width of the form. The default value is 1900. This property is required.
Show image	Show the table's **Primary Image** if it has one set. This setting enables showing the image column in the header of the form. More information: Enable or disable table options

Add, move, configure, or delete columns on a form

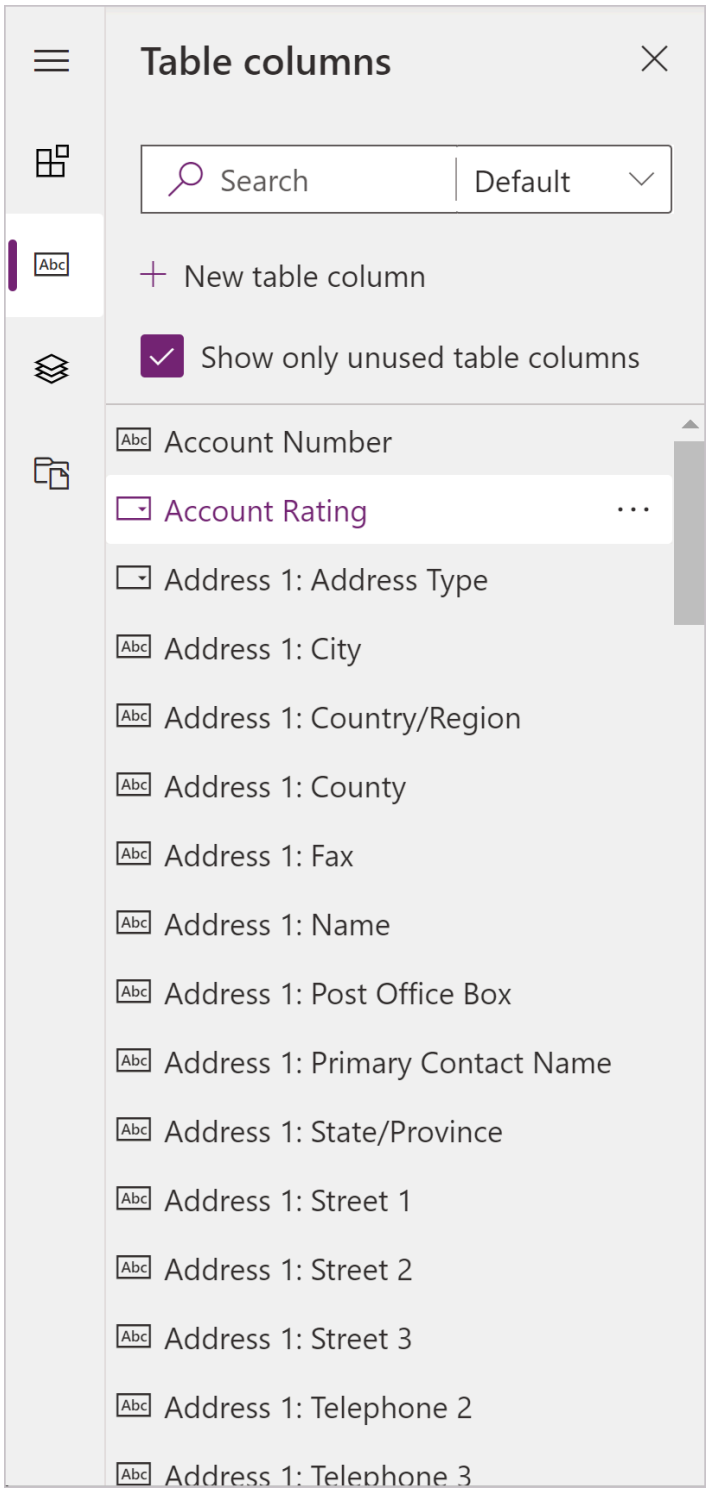
Article • 01/28/2025

Columns define the individual data items that can be used to store information in a table. Create new columns to capture data when existing standard tables don’t have columns that meet your requirements. After you create a new column, be sure to include it on the appropriate forms and views for the table so that they're available in your app. For information about the different column types, go to Types of columns.

Add, configure, move, or delete columns using the form designer.

Add columns to a form

To add columns to a form, use the **Columns** pane. The **Columns** pane lets you search and filter to help you quickly find columns. It also includes the option to show only unused columns.



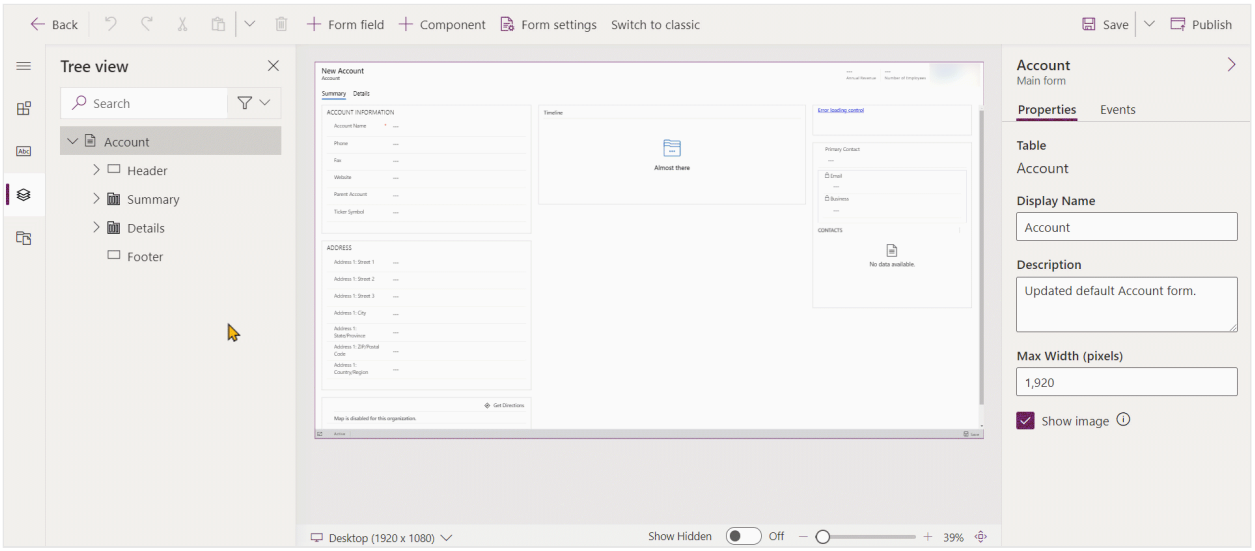
Add columns to a form using drag and drop

> **Note**
>
> When adding or moving columns using drag and drop be aware that the form preview is responsive and might be rendering multiple section columns as stacked. To ensure that the column being added or moved is in the correct section column, drop or paste it anchored to another column that is already in that section.

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. On the command bar, select **Add column**, and then select **Columns**. The **Columns** pane is open by default when the form designer is opened.
3. In the **Columns** pane, search, filter, or scroll to find the column you want to add. If you can't find a column, it might already be on the form. Clear **Show only unused columns** to view all columns, including those already added to the form.
4. In the **Columns** pane, select a column and drag it onto the form preview. As you drag the column on the form preview, you notice drop targets where you can add the column.
5. Drop the column in the location you want. Note the following behavior:

    - Columns can be dropped before or after any existing column or component.
    - Columns can also be dropped in the empty area within a section. In this case, the column is added in an available space so as to evenly distribute columns and components across the section columns.
    - Hovering over a tab header when dragging a column changes the currently selected tab, allowing you to add the column to a different tab.

6. Repeat steps 3-5 above if you want to add more columns.
7. On the command bar, select **Save and Publish** if you want to save and make your changes visible to users.

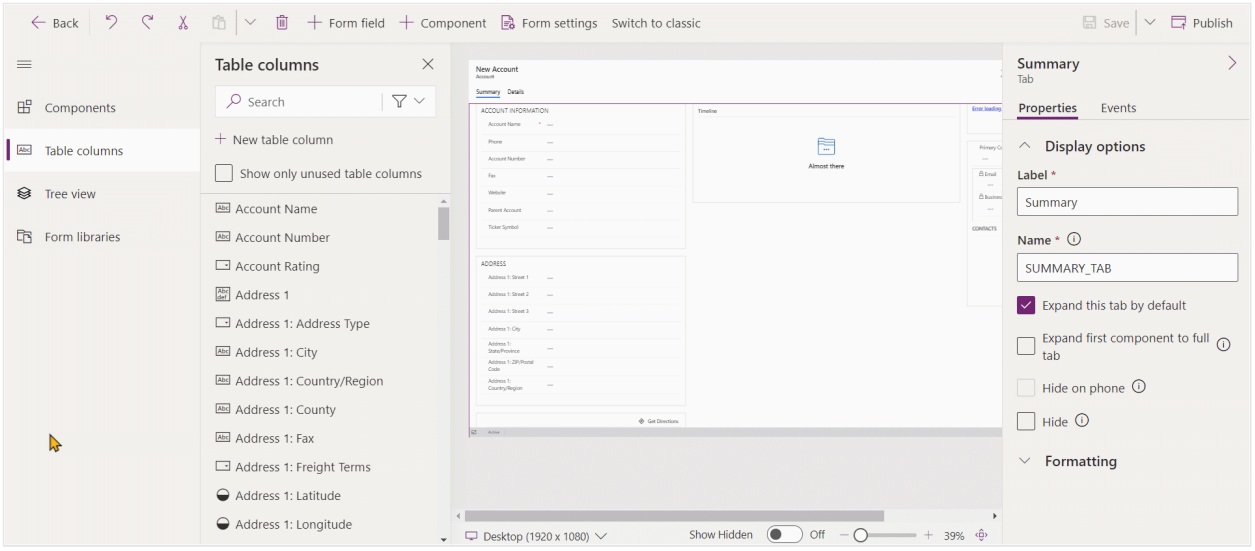


Add columns to a form using selection

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select another existing column or section. Note the following behavior:

- When you select an existing column, the new column is added after the existing column.
- When you select a section, the new column is added in an available space so as to evenly distribute columns across the section columns.

3. In the command bar, select **Add column**, or in the left pane, select **Columns**. The **Columns** pane is open by default when the form designer is opened.
4. In the **Columns** pane, search, filter, or scroll to find the column you want to add. If you can't find a column, it might already be on the form. Clear **Show only unused columns** to view all columns, including those already added to the form.
5. In the **Columns** pane, select a column to add it to the form. Alternatively, select **...** next to the column you want, and then select **Add to selected section**.
6. Repeat steps 2-5 above if you want to add more columns.
7. In the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.



Create a choice column

1. In the form designer on the command bar, select **Form field**.
2. Select **New table column**.
3. In the **New column** pane, enter or select the values for the following complete the properties for the choice column. More information: Configure properties for a local choice

Configure column properties on a form

The properties and events can be configured for column when you create or edit a form using the form designer.

Column properties

The **Properties** tab displays the following properties.

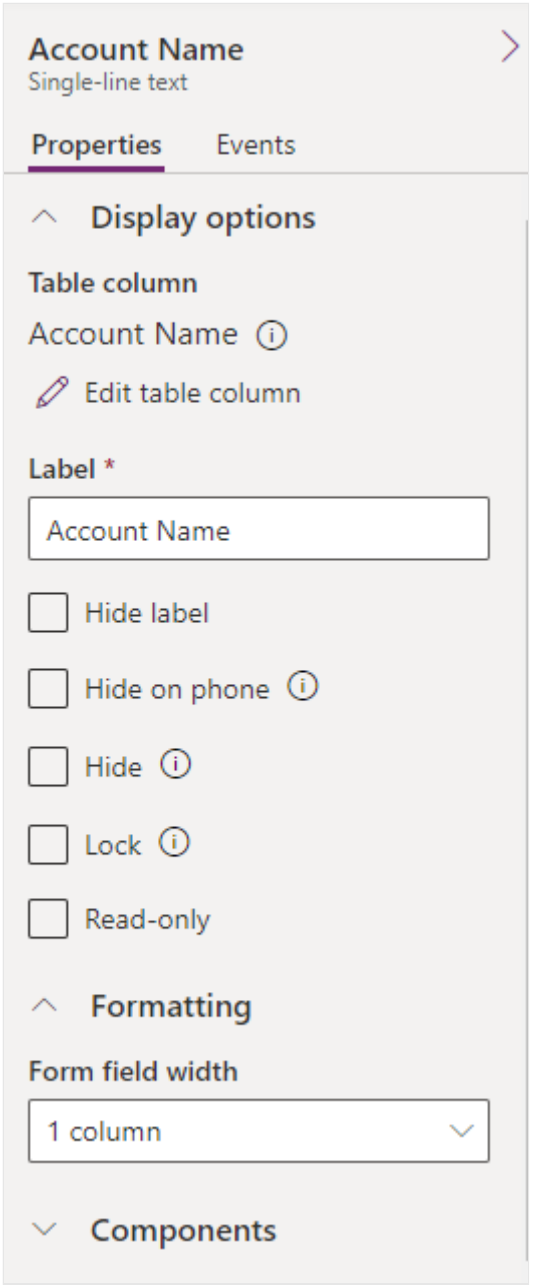
Expand table

Area	Name	Description
Display options	**Table column**	The name of the column. This comes from the column properties on the table and is read-only.
Display options	**Label**	By default the label matches the display name of the column. You can override that name for the form by entering a different label here. This property is required.
Display options	**Hide label**	When selected, the column label is hidden.
Display options	**Hide on phone**	The column can be hidden to render a condensed version of the form on phone screens.
Display options	**Hide**	When selected, the column is hidden by default and can be shown using code.
Display options	**Lock**	Lock this column so it can't be removed from the form.
Display options	**Read-only**	When selected, the column value isn't editable on the form.
Formatting	**Form field width**	When the section containing the columns has more than one column, you can set the column to occupy up to the number of columns that the section has.
Formatting	**Form field height**	Some columns, such as the multiline text column, let you control the height of the column by specifying the number of rows the column occupies.
Formatting	**Use all available vertical space**	Instead of setting the height by a number of rows, some columns, such as the multiline text column, let you set the column height to expand to all the available space on the form.
Components	**+ Component**	Adds a control to the column such as the canvas app control or the AI business card control.

⚠ Warning

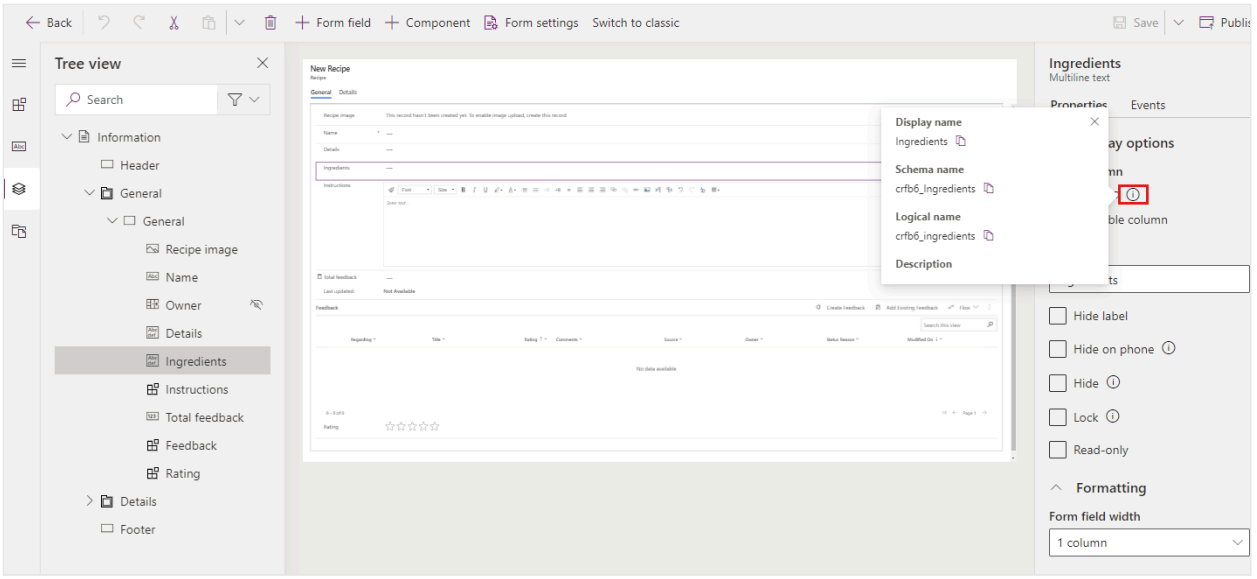
The **Hide** and **Read-only** properties should never be used as a secure way to prevent users from viewing or editing column values. These properties only apply to a form and don't have an effect on a user's data privileges. When a column is hidden on a form, users can still access data in other ways like viewing other forms or by making Web API calls. To secure columns, use column-level security to control access.

> **Note**
>
> In Unified Interface, the label size setting is ignored because the form adjusts width for all columns to ensure proper rendering for screen sizes from very small to extra-large.



Edit a column and view column names

To view column names, such as schema name or to change additional column properties, such as required, searchable, description, and size, select the column, and then in the right column properties pane select the information icon ⓘ next to the column name.



To edit the column data type format, required, and advanced options, follow these steps.

1. On the column **Properties** tab, select **Edit table column** to display the **Edit Table Column** pane where you can make the changes you want.
2. When you're finished making your changes, select **Done**.
3. Select **Save and Publish** to make your changes available to app users.

Column events

The **Events** tab is where event handlers for model-driven app forms can be configured for a column. An event handler consists of a reference to a JavaScript web resource and a function defined within that web resource that will execute when the event occurs, such as when the value for the column changes. More information: Configure model-driven app form event handlers

Move columns on a form

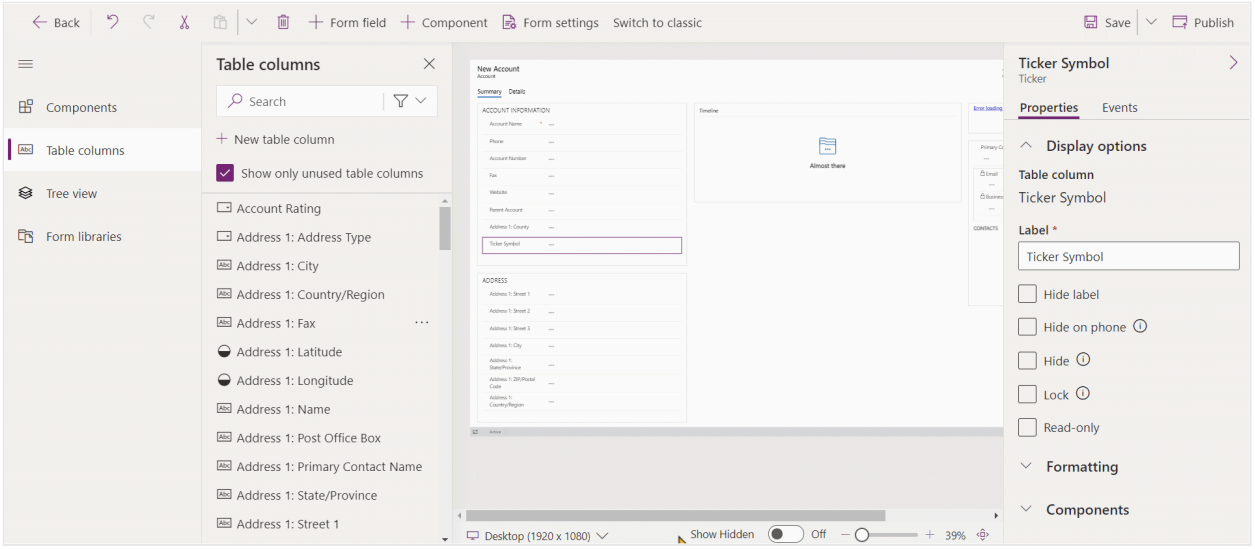
You can move a column on a form using drag and drop or cut and paste actions.

Move columns on a form using drag and drop

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the column that you want to move and drag and drop it. As you drag the column on the form preview, you'll see drop targets where you can move the column to. Note the following:

    - Columns can be dropped before or after any existing column or component.
    - Columns can also be dropped in the empty area within a section. In this case, the column is added in an available space so as to evenly distribute columns and components across the section columns.
    - Hovering over a tab header when dragging a column changes the currently selected tab, allowing you to add the column to a different tab.

3. Repeat step 2 above if you want to move more columns.
4. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.



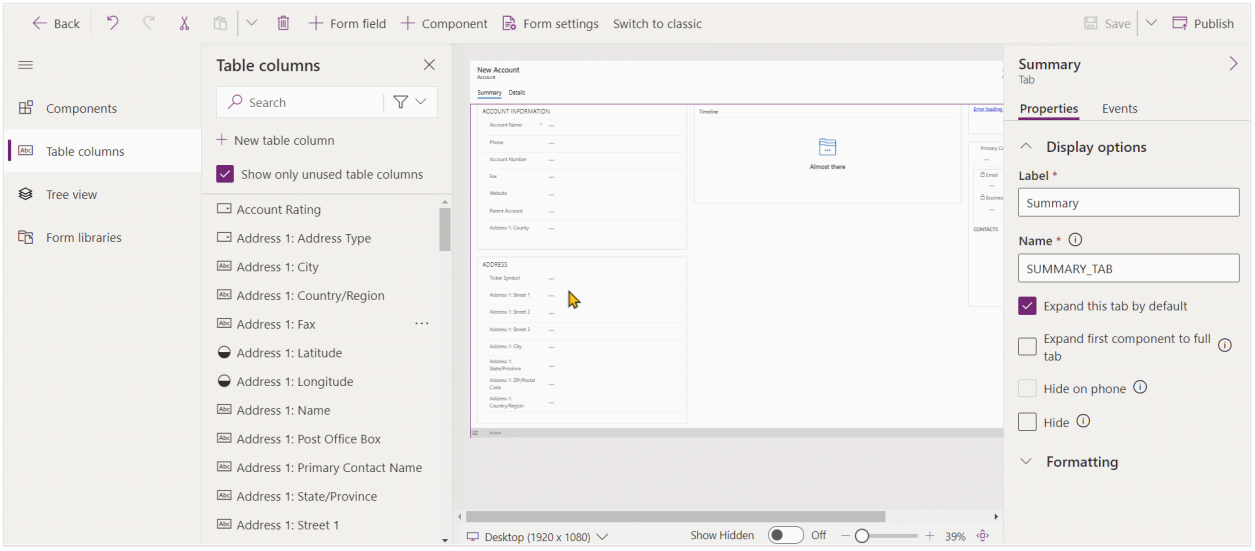
Move columns on a form using cut and paste

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the column that you want to move.
3. On the command bar, select **Cut**.
4. In the form preview, select another existing column, component, or section. You can also switch to a different tab if needed.
5. On the command bar, select **Paste** or select the chevron, and then select **Paste before**. Note the following:

    - When you select **Paste**, the column that is moved is pasted after the existing column or component.

- When you select **Paste before**, the column that is moved is pasted before the existing column or component.
- When you select a section, the column that is moved is added in an available space so as to evenly distribute columns and components across the section columns. The **Paste before** action isn't applicable and therefore not available in this case.

6. Repeat steps 2-5 above if you want to move more columns.
7. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.



Delete columns on a form

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the column that you want to delete from the form.
3. On the command bar, select **Delete**.
4. Repeat steps 2-3 if you want to delete more columns.
5. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

> **Note**
>
> - If you delete a column by mistake, on the command bar, select **Undo** to revert the form to its previous state.

- You can't delete a column that is locked or is required and not present anywhere else on the form.

Create a new column on the table when editing a form (preview)

[This topic is pre-release documentation and is subject to change.]

Create new columns from the form designer. When a column is created on a table, it isn't limited to the current form and is available for use in other forms and views for the table.

ⓘ Important

- This is a preview feature.
- You can use the modern form designer to create any available column type.

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. On the left navigation pane, select the **Table columns** pane, and then select **New table column**.
3. In the **New column** pane, provide the **Display name** for the column.
4. Select the **Data type** and configure any other required properties of the column.
5. Select **Save** to create a new column on the table. The column appears in the **Table columns** pane.
6. If you want to add the newly created column to the form, follow the steps outlined in the **Add columns to a form** section.

Add, configure, move, or delete components on a form

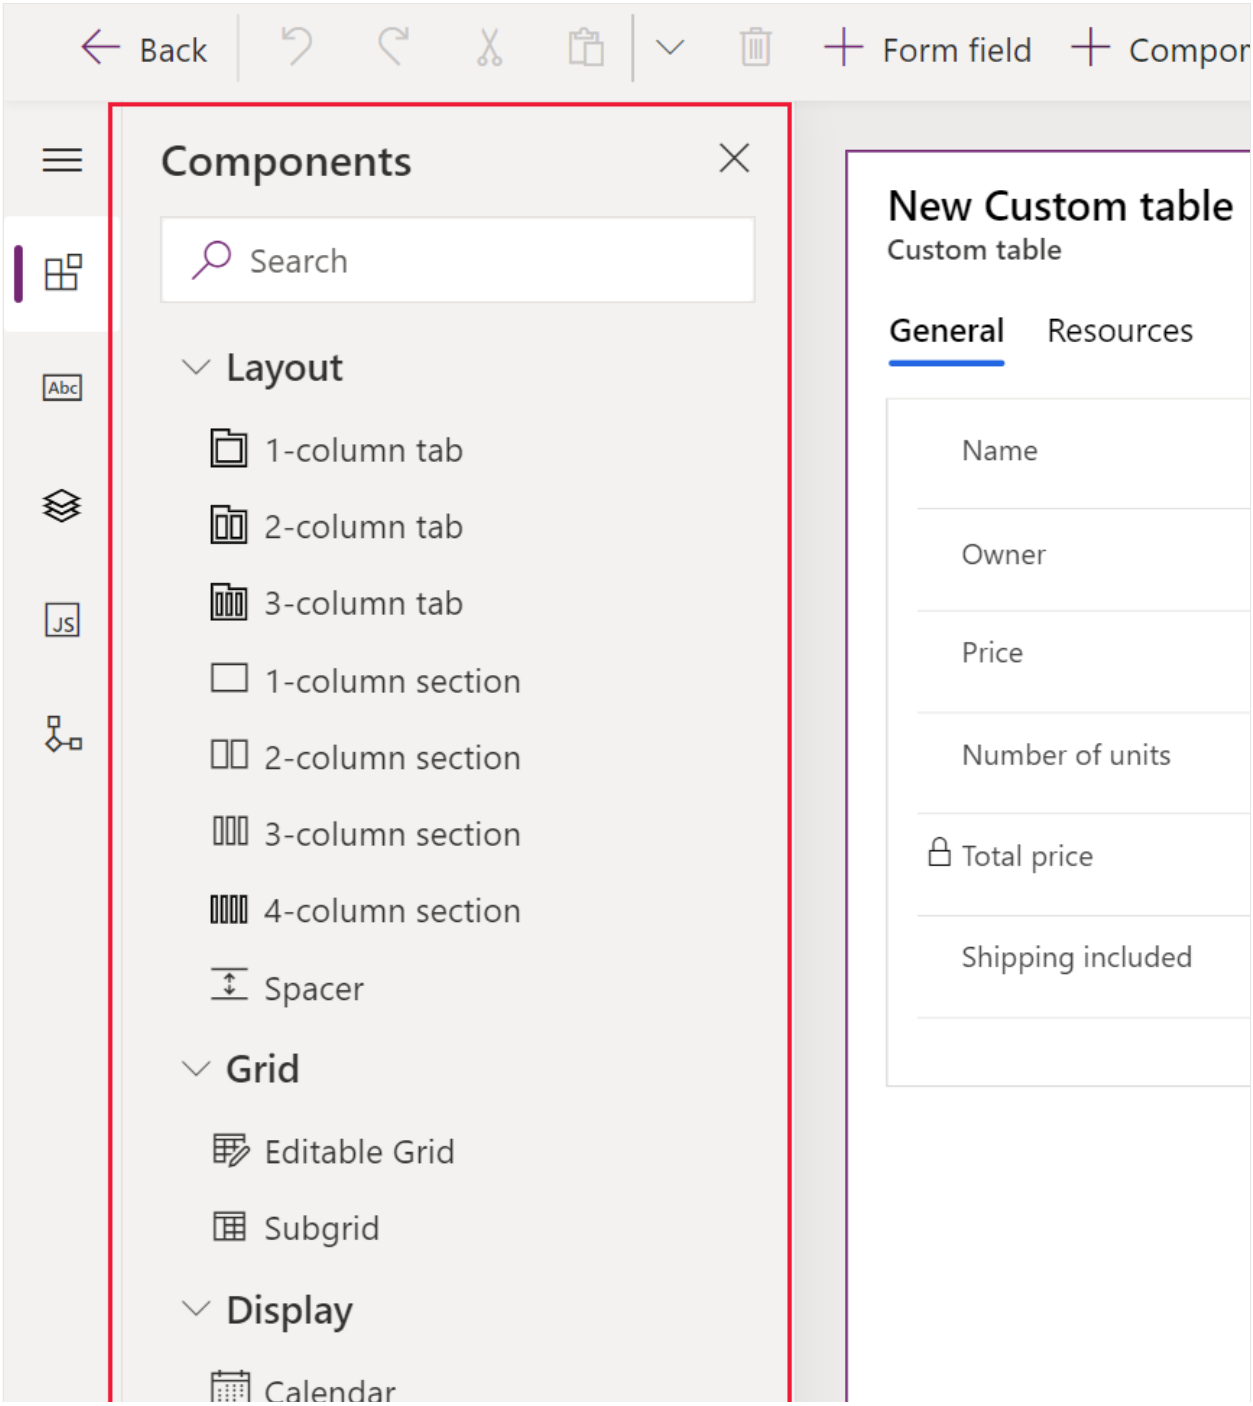
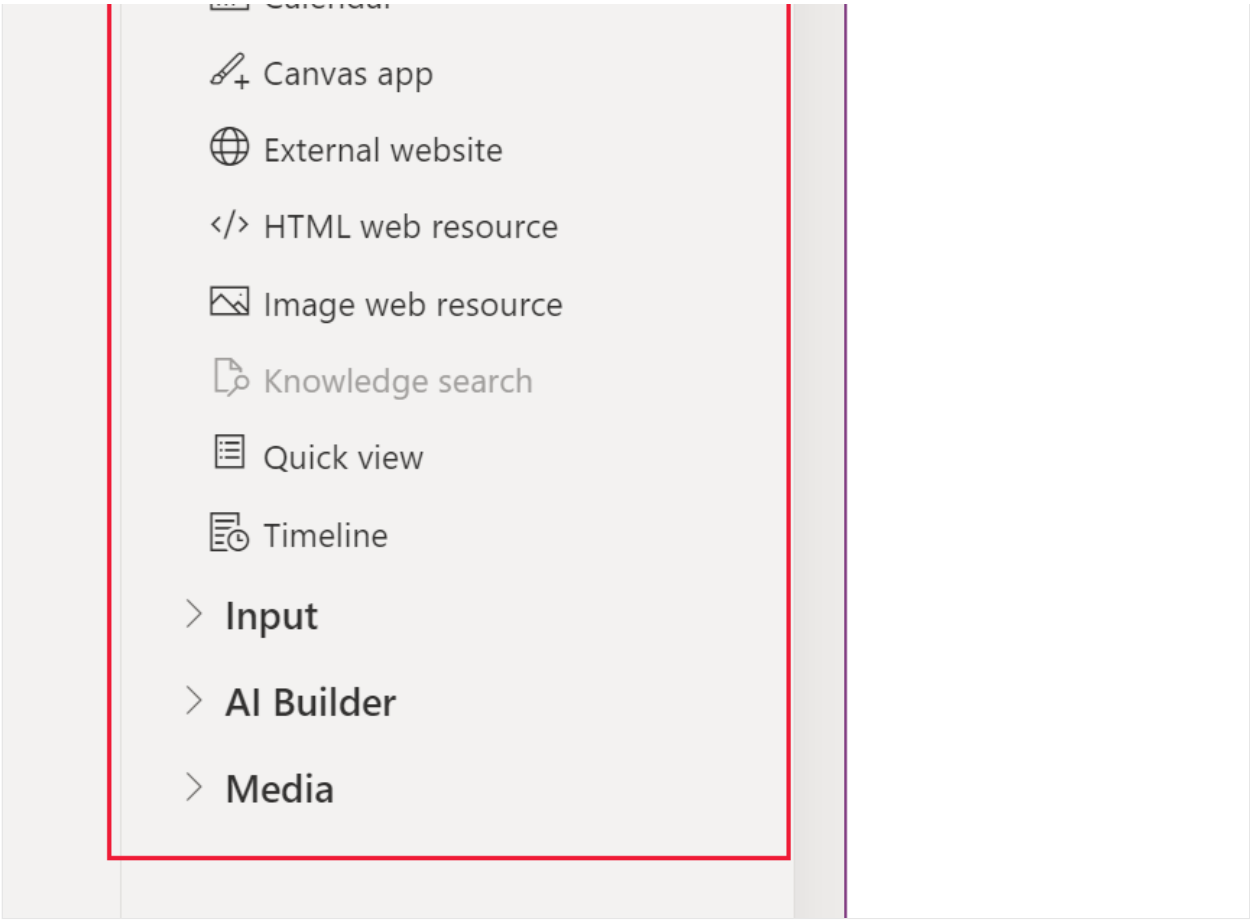
Article • 06/29/2022

By using the form designer, makers can easily add and configure popular components such as subgrid, quick view, web resources, pen input, and more.

Add components to a form

To add components to a form, use the **Components** pane. Components can be found easily using the search in the **Components** pane.





Add components to a form using drag and drop

> **Note**
>
> When adding or moving components using drag and drop, be aware that the form preview is responsive and might render multiple section columns as stacked. To ensure that the component that's added or moved is in the correct section column, drop or paste it anchored to another column or component that is already in that section column.

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. On the command bar, select **Add component**, or in the left pane, select **Components** to see a list of available components. Hover over a component in the list to see a preview image, description, and other details of that component.
3. In the **Components** pane, search or scroll to find the required component then select to add the component.
4. Drag and drop the component onto the form preview. As the component is dragged on the form preview, drop targets appear.

> **Note**
>
> - Components can be dropped before or after any existing component or column.
> - Components can also be dropped in the empty area within a section. In this case the component will be added in an available space so as to evenly distribute columns and components across the section columns.
> - Hovering over a tab header when dragging a component changes the currently selected tab, allowing the component to be added to a different tab.
> - When the component is dropped, in most cases, a dialog to configure the properties of the component will appear. Ensure that all the required properties of the component are configured.

5. In the dialog to configure the properties of the component, under **Show component on**, the **Web**, **Mobile**, and **Tablet** options are selected by default to ensure the component is used when the form is displayed on the web, mobile app, and tablet app. Based on you app's requirements, you might want to clear some of the client types for the component.

6. Select **Done**.

7. Repeat steps 3-6 above to add more components.

8. On the command bar, select **Save** to save the form, or select **Publish** to make the changes visible to users.

Add components for a column on the form

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select an existing column.
3. In the property pane, under the **Components** area, select **+ Component**.
4. The **Add component** dialog displays a list of components that are available for the current column type. Hover over a component in the list to see a preview image, description, and other details of that component.
5. In the **Add component** dialog, search, or scroll to find the required component to add and then select it. In most cases, a dialog is displayed to configure the properties of the component. Ensure that all the required properties of the component have been configured.

6. In the dialog to configure the properties of the component, under **Show component on**, the **Web**, **Mobile**, and **Tablet** options are selected by default to ensure the component is used when the form is displayed on the web, mobile app, and tablet app. Based on the requirements some of these options to limit the usage of the component can be cleared.
7. Select **Done**.
8. Repeat steps 2-7 above to add more components to the same or another column.
9. On the command bar, select **Save** to save the form, or select **Publish** to save and make the changes visible to users.

Configure components on a form

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select an existing column.
3. In the property pane, under the **Components** area, select the component that you want configured.
4. A dialog might appear to configure the properties of the component. Change the properties of the component as needed, and then select **Done**.
5. Repeat steps 2-4 to configure more components on the same or another column.
6. On the command bar, select **Save** to save the form, or select **Publish** to save and make the changes visible to users.

Move components on a form

To move components on a form, either use drag-and-drop or cut-and-paste actions.

Move components on a form using drag and drop

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form

2. In the form preview, select the component to move and drag and drop it. As the component is dragged onto the form preview, drop targets appear where it can be moved.

   > ⓘ **Note**
   >
   > - Components can be dropped before or after any existing component or column.

- Components can also be dropped in the empty area within a section. In this case the component will be added in an available space to evenly distribute components and columns across the section columns.
- Hover over a tab header while using drag and drop to add the component to a different tab.

3. Repeat steps 2-3 above to move more components.
4. On the command bar, select **Save** to save the form, or select **Publish** to save and make the changes available to users.

Move components on a form using cut and paste

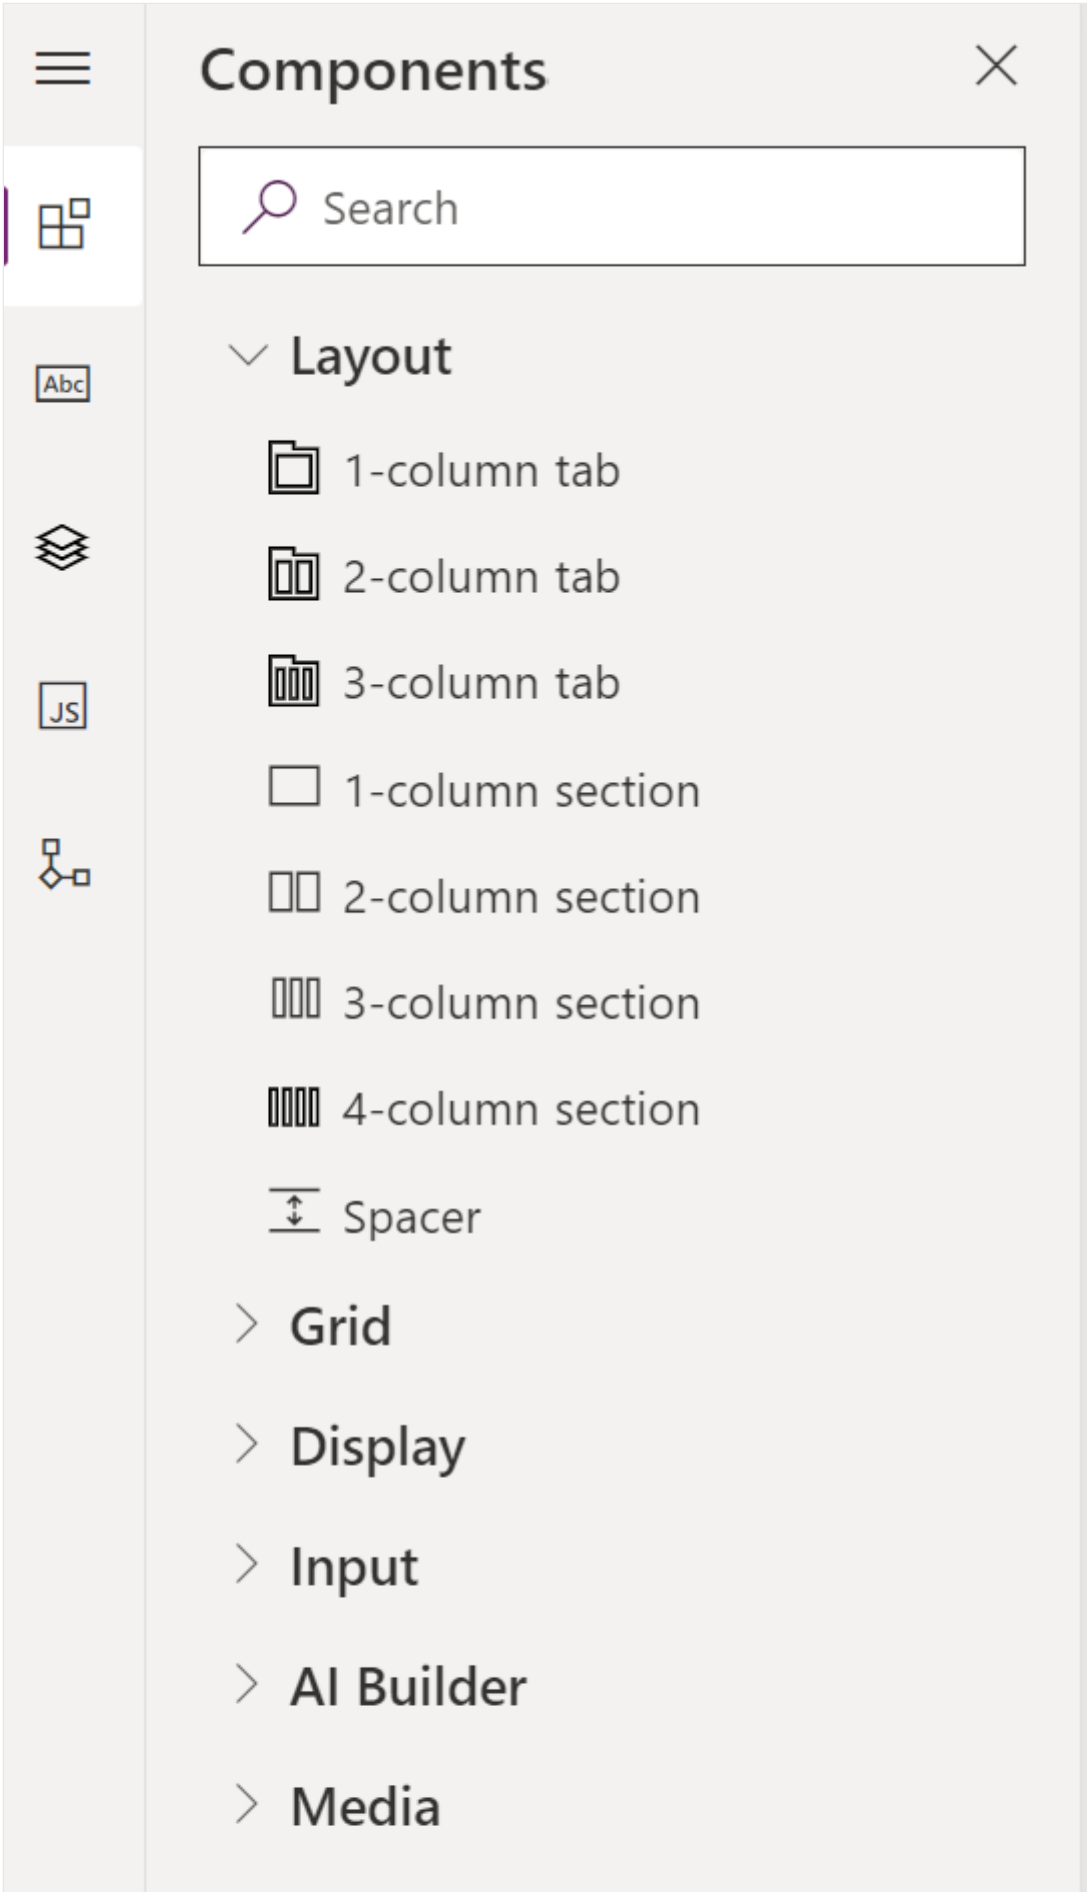
1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the required component to move.
3. On the command bar, select **Cut**.
4. In the form preview, select another existing component, column, or section. It is possible to switch to a different tab if needed.
5. On the command bar, select **Paste** or select the chevron, and then select **Paste before**.

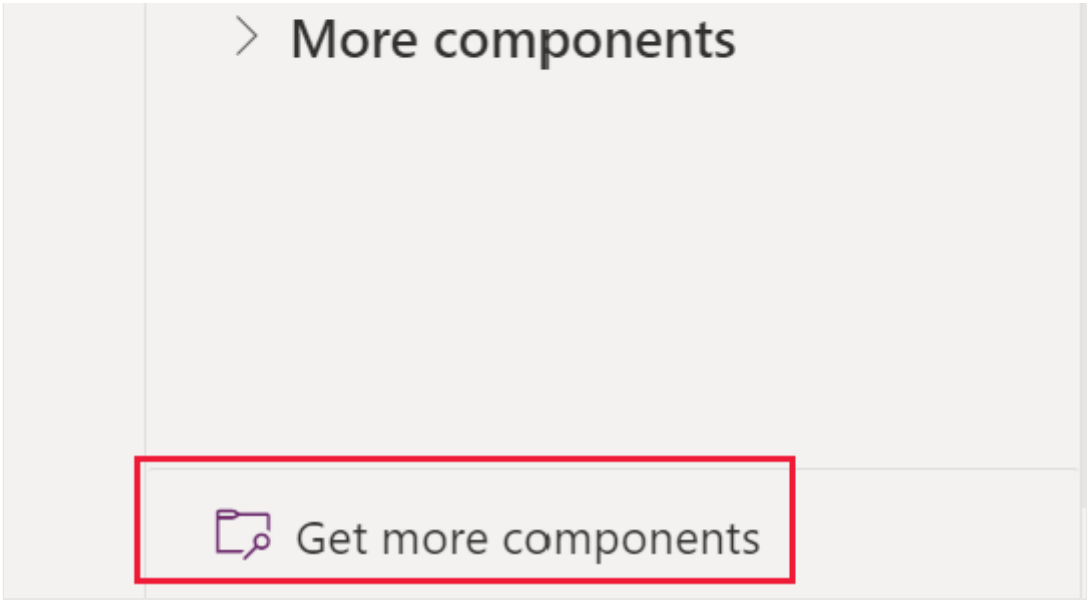
> ⓘ Note
>
> - When **Paste** is selected, the component being moved is pasted after the existing component or column.
> - When **Paste before** is selected, the component being moved is pasted before the existing component or column.
> - When a section is selected, the component being moved is added in an available space so as to evenly distribute components and columns across the section columns.

6. Repeat steps 2-5 above if to move more components.
7. On the command bar, select **Save** to save the form, or select **Publish** to save and make the changes visible to users.

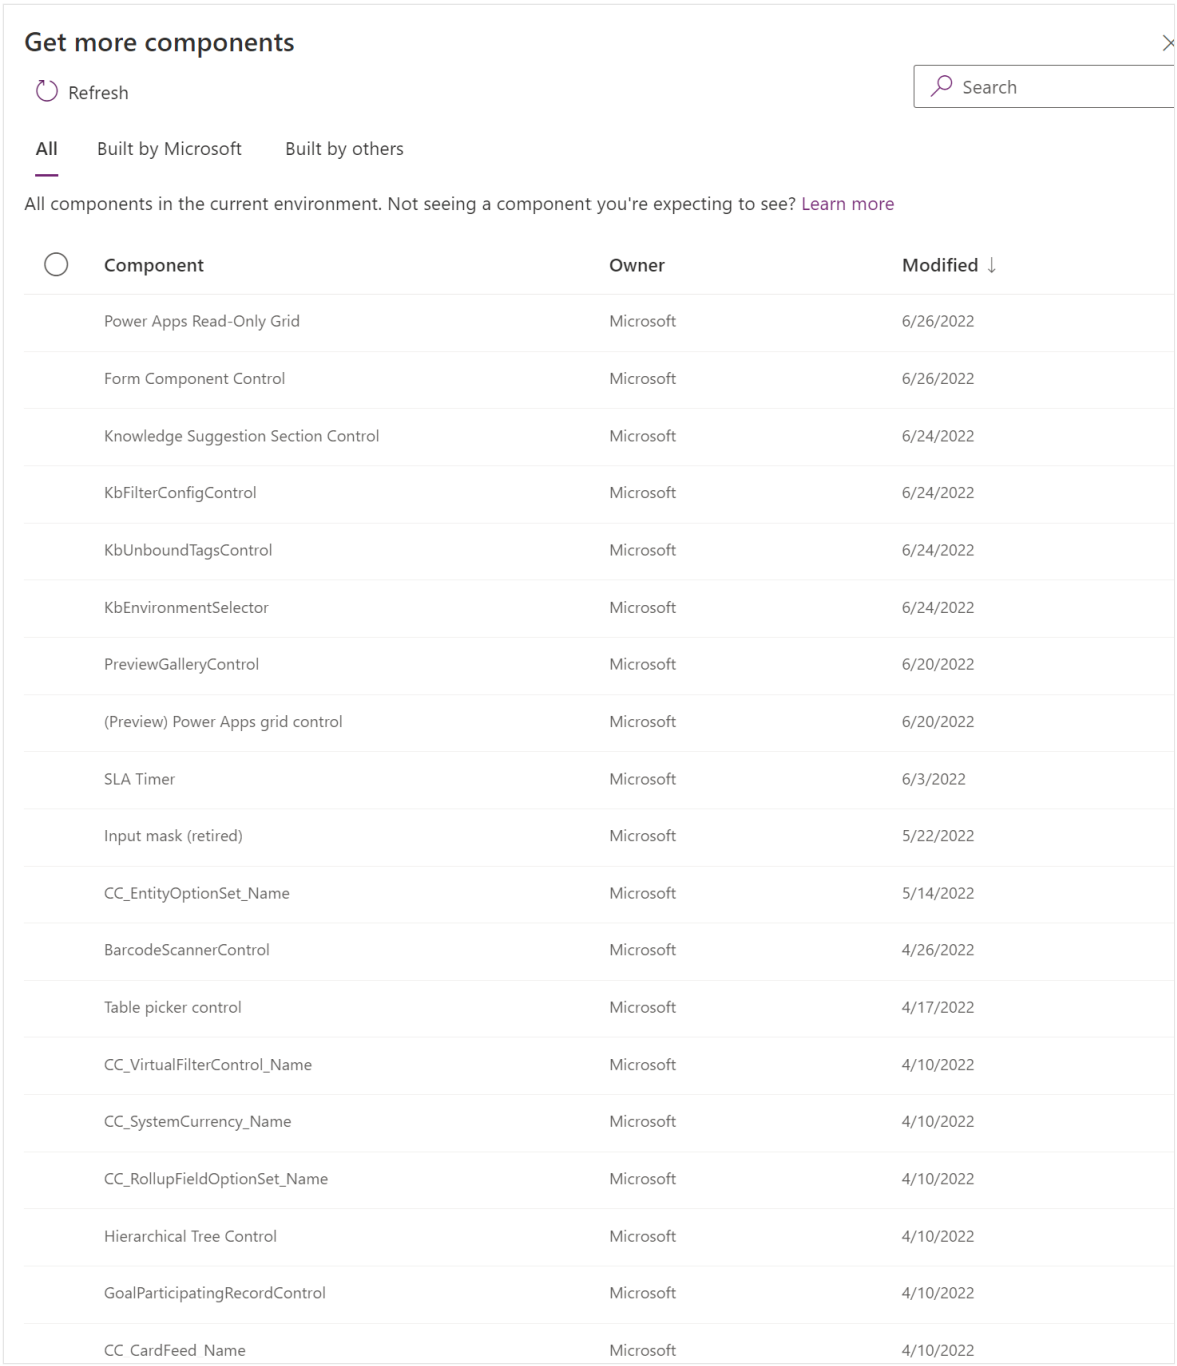
Get more components

1. Select **Get more components** to find and add other Power Apps components as well as custom controls that aren't available by default in the **Component** pane.





2. Select the tab you want, either **Built by Microsoft** or **Built by others**, and then select the component.



3. Select **Add**. The component appears under the **More components** section of the **Component** pane.

Delete components on a form

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form

2. In the form preview, select the component that you want to delete from the form, and then on the command bar, select **Delete**.

3. Repeat step 2 to delete more components.

4. On the command bar, select **Save** to save the form, or select **Publish** to save and make the changes visible to users.

> **Note**
>
> - If a component is deleted by mistake, select **Undo** on the command bar to revert the form to its previous state.
> - A component can't be deleted when it is locked or is using a required column that is not present anywhere else on the form.

Add, configure, move, or delete sections on a form

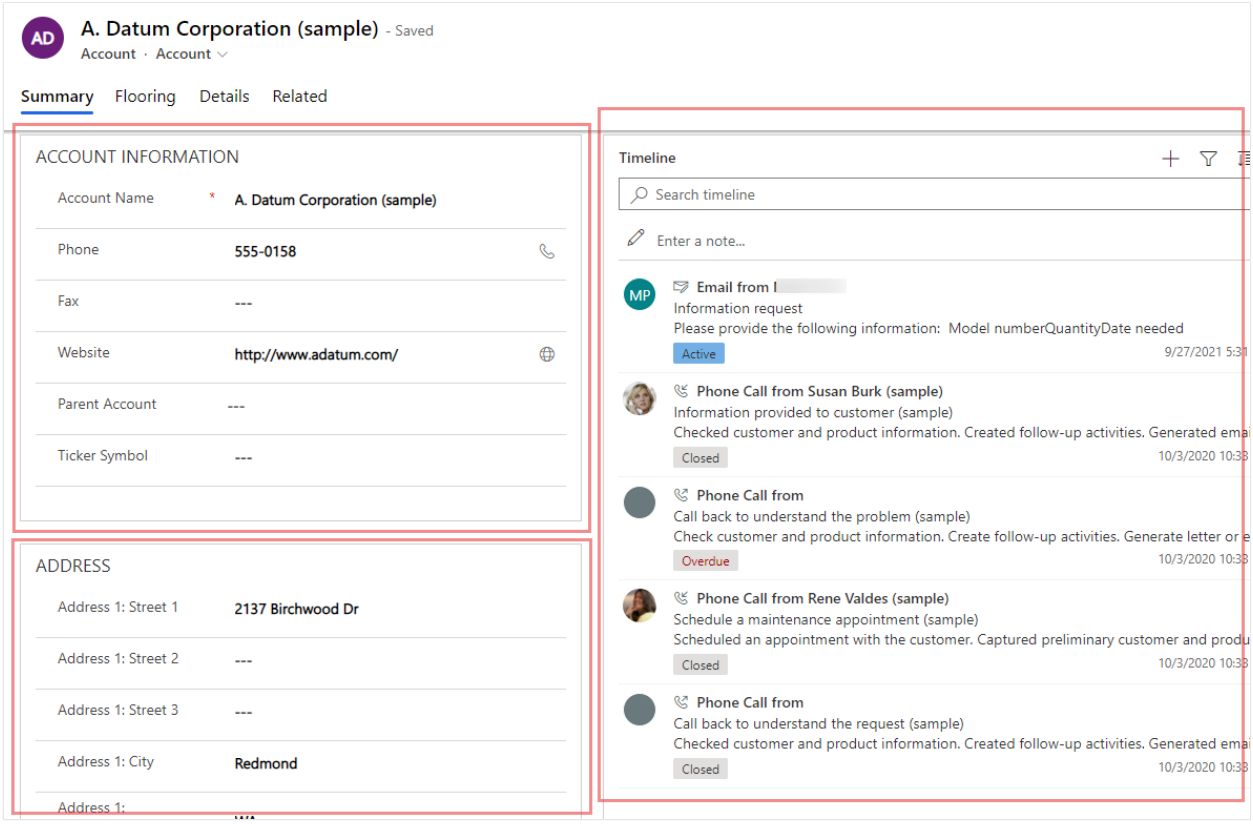
Article • 05/05/2022

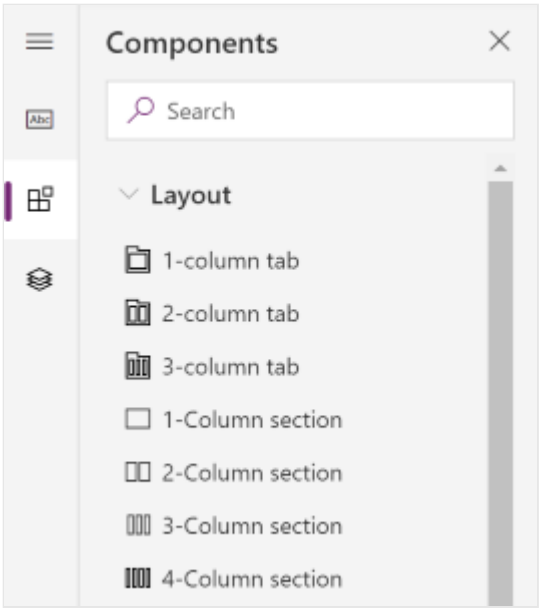
A section on a form occupies the space available in a tab. Sections have several configurable properties including a label that can be displayed.

Sections help you group similar components in an area of a form tab, such as the ACCOUNT INFORMATION, ADDRESS, and Timeline single column sections on the main account form Summary tab. Sections can have up to four columns.



Add sections to a form

To add sections to a form, use the **Components** pane.



> **Note**
>
> Sections can only be added on main forms and quick view forms. More information: **Form types**. In Unified Interface, empty sections will not render in runtime and will be automatically hidden.

Add sections to a form using drag and drop

> **Note**
>
> When adding or moving sections using drag and drop be aware that the form preview is responsive and may be rendering multiple tab columns as stacked. To ensure that the section being added or moved is in the correct tab column, drop or paste it anchored to another section that is already in that tab column.

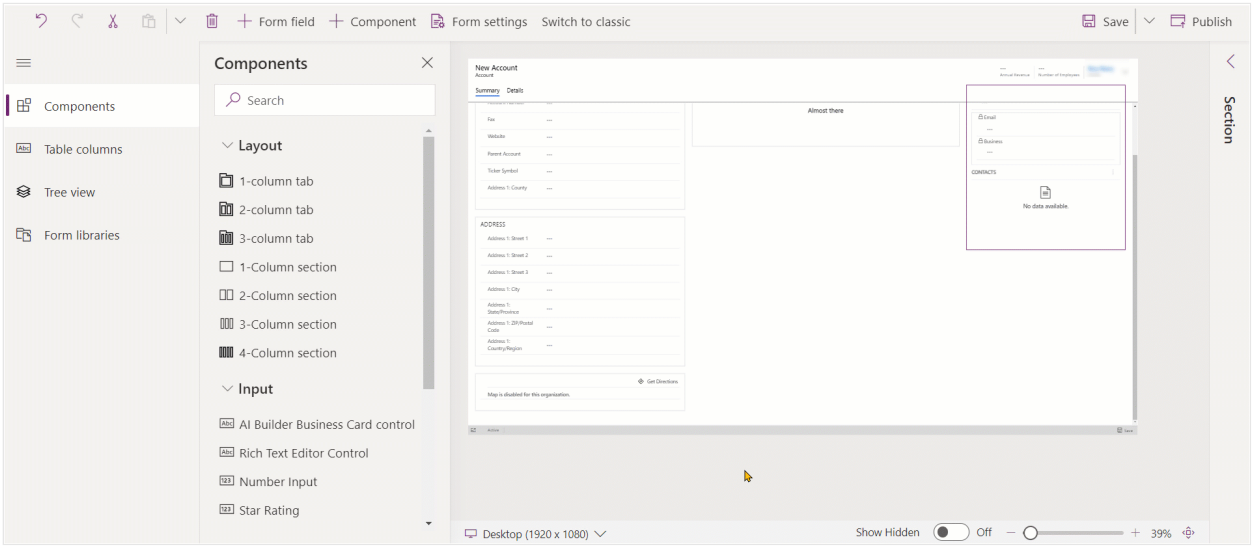
1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. On the command bar, select **Add component**, or in the left pane, select **Components**.
3. In the **Components** pane, select a section component and drag it onto the form preview. As you drag the section on the form preview, you will see drop targets where you can add the section.
4. Drop the section in the location you want. Note the following behavior:

    - Sections can be dropped before or after any existing section.
    - Sections can also be dropped in the empty area within a tab. In this case, the section will be added in an available space so as to evenly distribute sections

across the tab columns.

- Hovering over a tab header when dragging a section changes the currently selected tab, allowing you to add the section to a different tab.

5. Repeat steps 3-4 above if you want to add more sections.
6. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

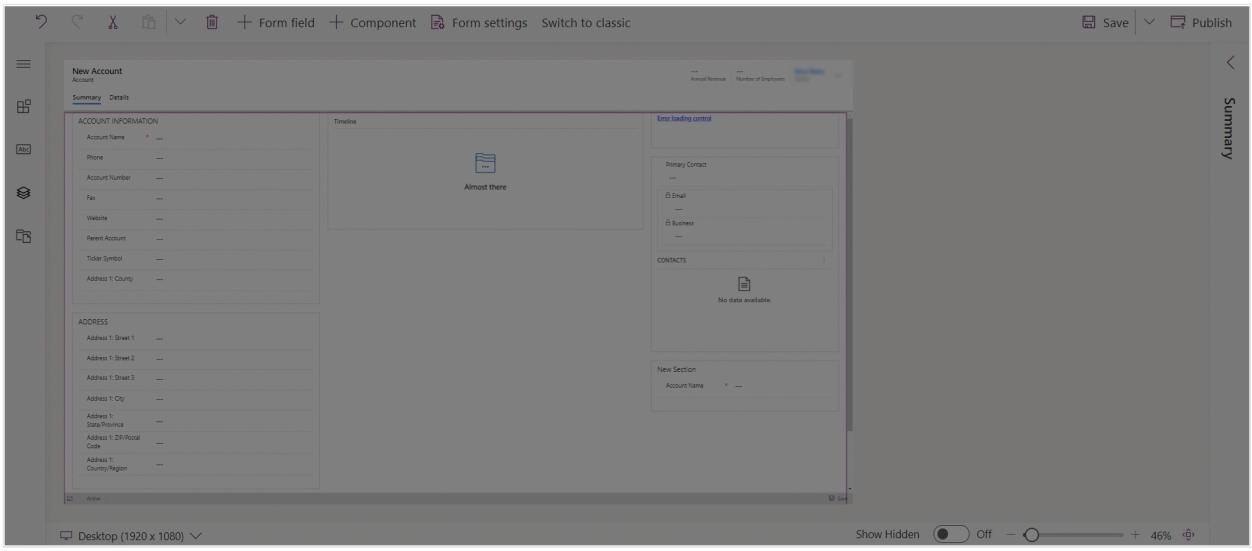


Add sections to a form using selection

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select another existing section or tab. Note the following behavior:

   - When you select an existing section, the new section is added after the existing section.
   - When you select a tab, the new section is added in an available space so as to evenly distribute sections across the tab columns.

3. On the command bar, select **Add component**, or in the left pane, select **Components**.
4. In the **Components** pane, select a section component to add it to the form. Alternatively, select **...** next to the section component you want, and then select **Add to selected tab**.
5. Repeat steps 2-4 above if you want to add more sections.
6. On the command bar, select **Save** to save the form. Select **Publish** to save and make your changes visible to users.



Configure sections on a form

These are the properties available to configure a section when you create or edit a form using the form designer.

Area	Name	Description
Display options	**Label**	The localizable label for the section visible to users. This property is required.
Display options	**Name**	The unique name for the section that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores. This property is required.
Display options	**Hide label**	When selected, the section label is hidden.
Display options	**Hide on phone**	The section can be hidden to render a condensed version of this form on phone screens.
Display options	**Hide**	When selected, the section is hidden by default and can be shown using code.
Display options	**Lock**	Lock this section to keep it from being removed.
Formatting	**Columns**	Specify up to four columns for the section.
Formatting	**Component label position**	Determines the position for the component label. Select **Left** to display the label to the left of the value or **Top** to place the label above the value.

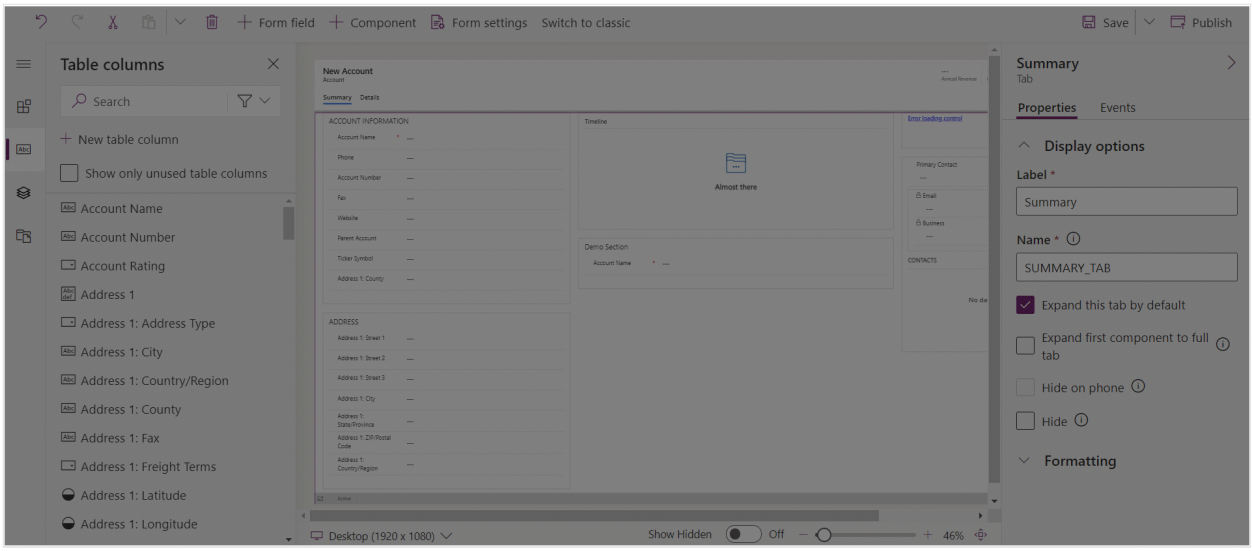
> **Note**
>
> We recommend limiting the length of section label text to about 50 characters. Section label text doesn't wrap and can truncate on devices with small screens.
>
> Sections that don't have any columns or controls will be hidden at runtime in Unified Interface.

Move sections on a form

You can move sections using drag and drop or cut and paste actions.

Move sections on a form using drag and drop

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the section label or empty space within the section that you want to drag and drop. As you drag the section on the form preview, you will see drop targets where you can move the section to. Note the following behavior:
    - Sections can be dropped before or after any existing section.
    - Sections can also be dropped in the empty area within a tab. In this case, the section will be added in an available space to evenly distribute sections across the tab columns.
    - Hovering over a tab header when dragging a section changes the currently selected tab, allowing you to add the section to a different tab.
3. Repeat step 2 above if you want to move more sections.
4. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

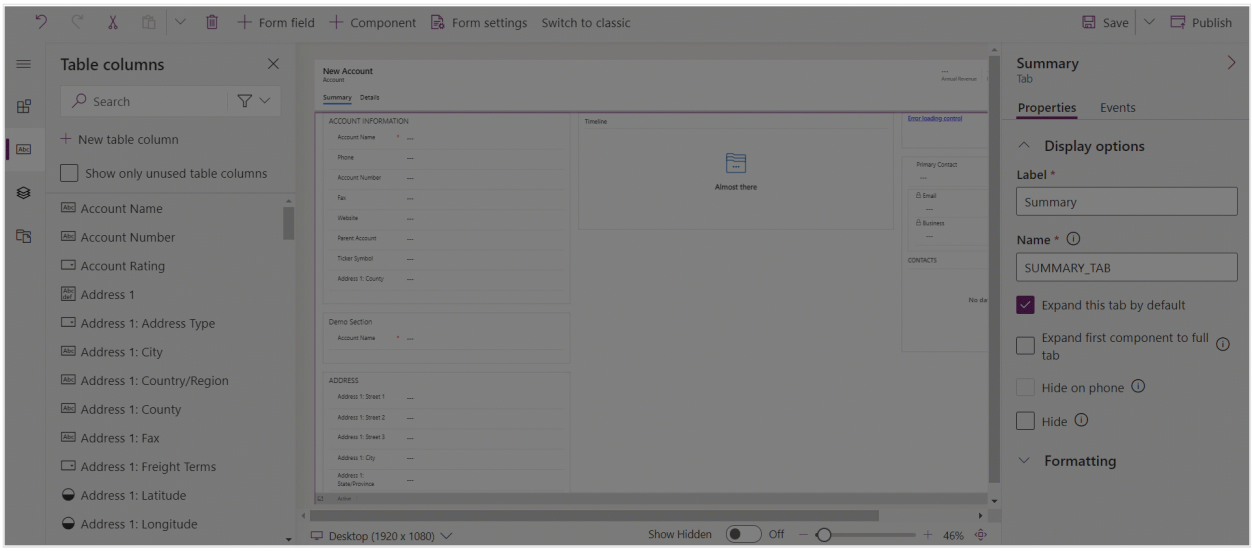


Move sections on a form using cut and paste

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the section that you want to move.
3. On the command bar, select **Cut**.
4. In the form preview, select another existing section or tab. You can also switch to a different tab if needed.
5. On the command bar, select **Paste** or select the chevron, and then select **Paste before**. Note the following behavior:

    - When you select **Paste**, the section being moved is pasted after the existing section.
    - When you select **Paste before**, the section being moved is pasted before the existing section.
    - When you select a tab, the section moved is added in an available space to evenly distribute sections across the tab columns. The **Paste before** action is not applicable and therefore not available in this case.

6. Repeat steps 2-5 above if you want to move more sections.
7. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.



Delete sections on a form

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the section that you want to delete from the form.
3. On the command bar, select **Delete**.
4. Repeat steps 2-3 above if you want to delete more sections.
5. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

> **Note**
>
> - Sections can only be deleted on main forms and quick view forms. More information: **Form types**
> - If you delete a section by mistake, on the command bar, select **Undo** to revert the form to its previous state.
> - You can't delete a section that contains a column that is required or locked.
> - You can't delete a section that is locked.
> - A tab needs to have at least one section in each tab column. If you delete the last remaining section in a tab column a new section will be automatically added.
> - In Unified Interface, sections won't be rendered if you have selected to hide them including the title and the border. This is different than the

legacy web client, and is by design to ensure proper rendering of the form across differing view ports from extra wide to narrow.

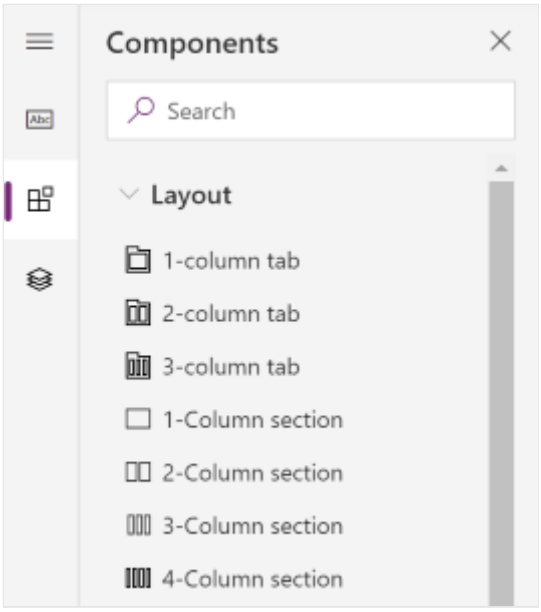
Add tabs to a form

To add tabs to a form, use the **Components** pane.



> **Note**
>
> Tabs can only be added on main forms. More information: Form types

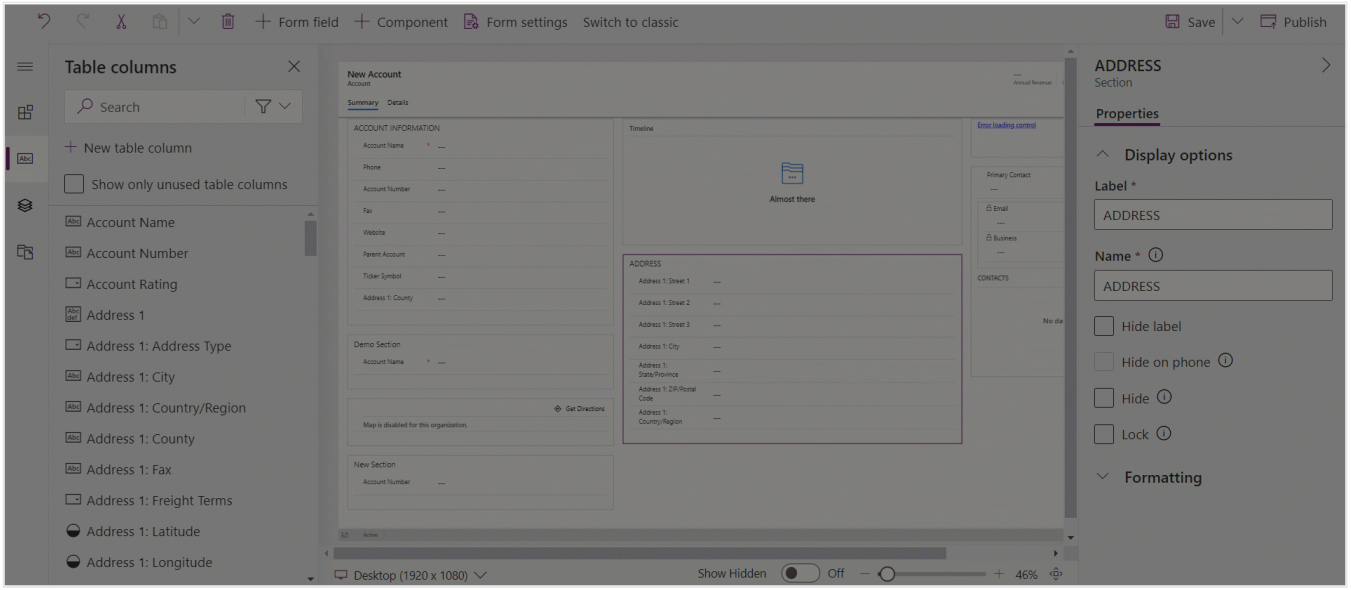
Add tabs to a form using drag and drop

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. On the command bar, select **Add component**, or in the left pane, select **Components**.
3. In the **Components** pane, select a tab component, such as a *1-column tab*, and drag and drop it onto the form preview. As you drag the tab on the form preview, you notice drop targets where you can add the tab. Note the following behavior:

    - Tabs can be dropped before or after any existing tabs by hovering over the tab headers.

- Tabs can also be dropped before or after the current tab by hovering over the left or right edge of the current tab.

4. Repeat step 3 if you want to add more tabs.
5. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

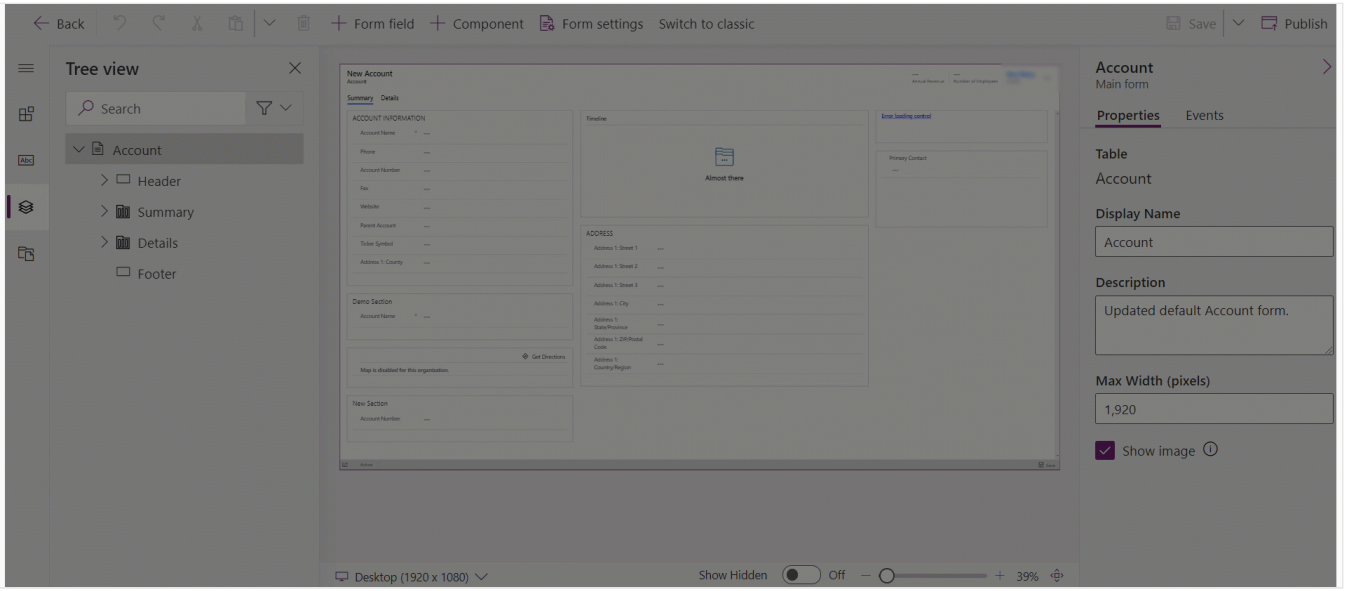


Add tabs to a form using selection

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select another existing tab or the form canvas. Note the following behavior:

   - When you select an existing tab, the new tab is added after the existing tab.
   - When you select the form canvas, the new tab is added as the last tab on the form.

3. On the command bar, select **Component**, or in the left pane, select **Components**.
4. In the **Components** pane, select a tab component to add it to the form. Alternatively, select **...** next to the tab component you want, and then select **Add to form**.
5. Repeat steps 2-4 if you want to add more tabs.
6. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.



Configure tabs on a form

These properties are available to configure a tab when you create or edit a form using the form designer.

Expand table

Area	Name	Description
Display options	**Label**	The localizable label for the tab visible to users. This property is required.
Display options	**Name**	The unique name for the tab that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores. This property is required.
Display options	**Expand this tab by default**	The tab state can toggle between expanded or collapsed using form scripts or by people selecting the label. Choose the default state for the tab.
Display options	**Hide**	When selected, tab is hidden by default and can be shown using code.
Display options	**Hide on phone**	The tab can be hidden to render a condensed version of this form on phone screens.
Formatting	**Layout**	Tabs can have up to three columns. Use these options to set the number of tabs and what percentage of the total width they should fill.
Formatting	**Column Width**	Enter the column width. Valid values are 1 to 100. The default is 100.

Move tabs on a form

You can move a tab on a form using drag and drop or cut and paste actions.

Move tabs on a form using drag and drop

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the tab header of the tab that you want to move and drag and drop it. As you drag the tab on the form preview, you see drop targets where you can move the tab. Note the following behavior:

    - Tabs can be dropped before or after any existing tabs by hovering over the tab headers.
    - Tabs can also be dropped before or after the current tab by hovering over the left or right edge of the current tab.

3. Repeat step 2 if you want to move more tabs.
4. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

Move tabs on a form using cut and paste

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the tab that you want to move.
3. On the command bar, select **Cut**.
4. In the form preview, select another existing tab or the form.
5. On the command bar, select **Paste** or select the chevron, and then select **Paste before**. Note the following behavior:

    - When you select **Paste**, the tab moved is pasted after the existing tab.
    - When you select **Paste before**, the tab moved is pasted before the existing tab.
    - When you select the form, the tab moved is added as the last tab on the form. The **Paste before** action is not applicable and therefore not available in this case.

6. Repeat steps 2-5 if you want to move more tabs.
7. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

Delete tabs on a form

1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form preview, select the tab that you want to delete from the form.
3. On the command bar, select **Delete**.
4. Repeat steps 2-3 above if you want to delete more tabs.
5. On the command bar, select **Save** to save the form, or select **Publish** if you want to save and make your changes visible to users.

> **Note**
>
> - Tabs can only be deleted on main forms. More information: Form types
> - If you delete a tab by mistake, on the command bar, select **Undo** to revert the form to its previous state.
>   - You can't delete a tab that contains sections with required or locked columns.
> - You can't delete a tab that has locked sections.
> - A form must have at least one tab. You can't delete the last remaining tab on the form.

Create and edit columns

Last updated on 03/02/2026

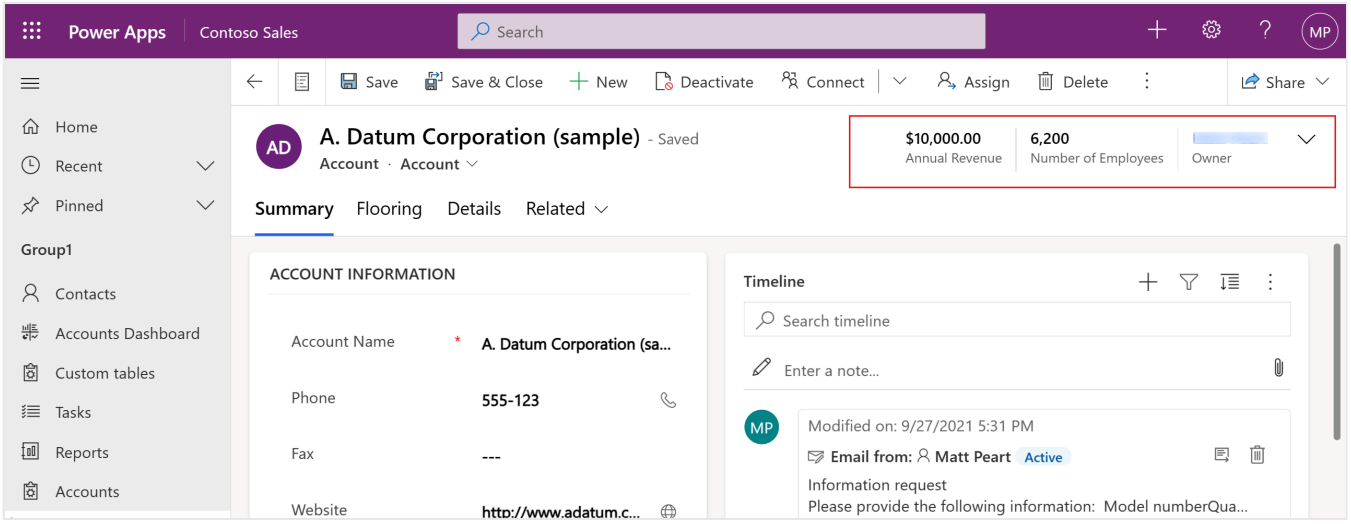
Configure header properties in the form designer

Makers can choose the columns displayed in the form header. Form headers have two main visual components, the form header and the flyout for the form header.

Form header

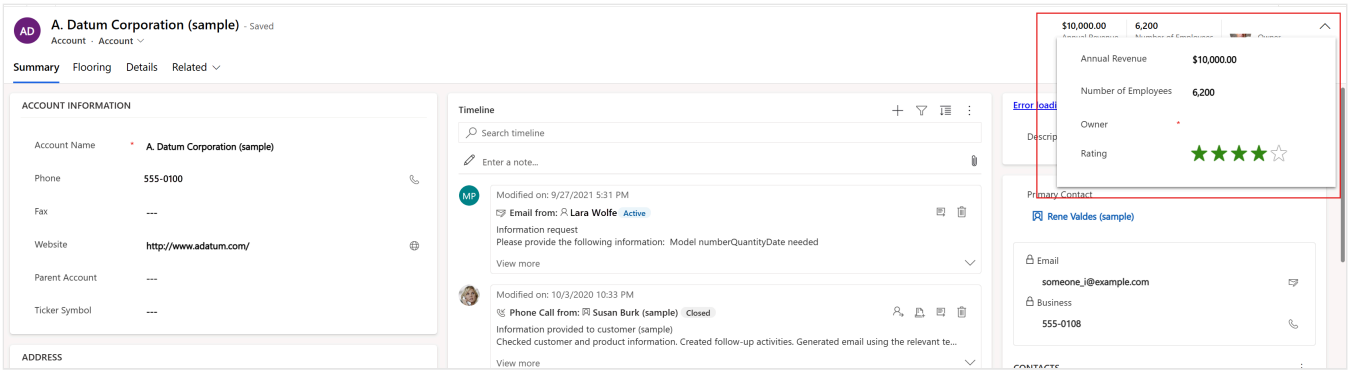
The form header is used to display common columns that are important for the table. Form headers can't display columns that use unsupported controls. More information: Controls that can be displayed on the form header

Most controls that can't be displayed in form header can be displayed in the form header flyout.



Form header flyout

The form header flyout displays when a user selects the chevron located to the right of the form header, which can display more information otherwise hidden in the form header. The header flyout enables users to edit column values.



The header flyout displays all header columns including the four columns that are directly displayed in the header. By default, the header flyout is available for display, but makers can hide it if needed.

Show or hide the header flyout

To show or hide the header flyout for a model-driven form, follow these steps:

1. Open the form designer to create or edit a form.
2. Select the form header in the form preview or use the tree view to select it.
3. In the right property pane, select **Show header flyout** to make the header flyout visible or clear it to hide the header flyout.
4. In the command bar, select **Save** to save the form, or select **Publish** to save and make your changes visible to users.

> **Note**
>
> - Use the new form designer. The classic form designer doesn't provide the ability to show or hide the header flyout.
> - An image for a table is displayed in the header only when the **Primary Image** attribute is defined for the table and the form property **Show image in the form** is enabled. More information: Image columns.
> - Developers can specify an image for a table by using the EntityMetadata.PrimaryImageAttribute attribute.

High-density header

Model-driven app forms use a high-density form header to ensure that key information is always visible to users. High-density headers also make sure the record title never truncates and long record titles are displayed using multiple lines. Similarly, the high-density header also

ensures that up to four column values are directly visible in the header and never truncated or hidden.

To ensure that key information is always visible, the framework displays up to four read-only column values and users can't directly edit the column values in the header. Visualizations such as custom components or web resources don't render on the header, but are available in the flyout.

Controls that can be displayed on the form header

Columns set to these controls can be displayed in the main body of a high-density header:

- `checkbox`
- `datetime`
- `decimal`
- `duration`
- `emailaddress`
- `float`
- `integer`
- `languagepicker`
- `lookup`
- `money`
- `phonenumber`
- `picklist`
- `regarding`
- `textbox`
- `ticker`
- `timezonepicklist`

These controls are replaced with a simplified version in the header. Thus, not all control features are available. For example, for lookup controls, just a link is rendered and control options like **Use Main Form Dialog for Edit** aren't supported.

Any other type of control, including custom Power Apps Component Framework controls or web resources, aren't displayed.

To show these unsupported controls or have full functionality of controls, add them to the form header flyout instead of the form header.

Form designer messages related to form headers

When you edit forms using the new or classic form designer, you might see messages related to form headers. Below, you can find details on each message and why you're seeing it.

We've upgraded your form to show a high density header that displays more data. You can edit this setting in the properties of the header

This message is displayed in the form designer when a maker creates a new main form (including via the Save-as action) or edits a main form that hasn't previously been configured for header density.

The framework defaults to high-density header and this message helps makers become aware of that behavior. Makers can override the framework default at any time by manually configuring the form header density as outlined earlier.

This form isn't using high density header, access the setting in the header properties. High density header helps display more data

This message is displayed in the form designer when a maker opens a main form for editing that is configured to use low-density header.

The message helps increase awareness about the high-density header and its benefits.

Column moved to header flyout: The header supports displaying up to four read-only column values. The column *[field display name]* will now only be available from the flyout

This message is displayed in the form designer when a form is using high-density header with the header flyout visible.

High-density header displays read-only values of the first four columns in the header. When makers add a column in the header in the top four positions, it causes an existing column that was directly displayed in the header to become extended and visible only in the header flyout.

The message informs the maker of the change and confirms whether to proceed with the action.

Header column limit exceeded: The header supports displaying up to four read-only column values. Remove unused columns to add more

This message is displayed in the form designer when a form is using high-density header with the header flyout hidden.

High-density header displays read-only values of up to four columns in the header. Because the header flyout is hidden, users are unable to see the additional columns.

The message informs the maker that there are already four columns in the header and prevents adding additional columns in the header that users won't be able to see.

Header doesn't display custom components: The header supports displaying up to four read-only column values. Remove the custom component from the column before adding it to the header

This message is displayed in the form designer when a form is using high-density header with the header flyout hidden.

High-density header displays read-only values of columns in the header. Because the header flyout is hidden, users are unable to see any custom components associated with the columns in the header.

The message informs the maker that they're trying to add a column with an associated custom component to the header and they must remove the custom component before adding the column to the header. This is because users won't be able to see the custom component in the header.

Header displays read-only column values: The header supports displaying up to four read-only column values. To provide editability to the user, add the column to a section in the form

This message is displayed in the form designer when a form is using high density header with the header flyout hidden.

High-density header displays read-only values of columns in the header. Because the header flyout is hidden, users will be unable to edit column values.

The message informs the maker that any columns added to the header will be read-only and that any columns they want users to edit should also be added to a section in the form.

Header column values aren't editable: Moving a column from the body to the header will display as a read-only value. To maintain editability, copy the column to the header

This message is displayed in the form designer only for forms using high-density header with the header flyout hidden.

High-density header displays read-only values of columns in the header. Because the header flyout is hidden, users will be unable to edit column values.

The message informs the maker that they're trying to move a column from the form body to the form header. Doing so will make it read-only. It gives the maker the choice of moving the column to the header or adding a copy of the column to the header. Moving the column to the header will make the column unavailable in the original location on the form body for users to edit. Adding a copy of the column to the header will leave the column in the original location as-is, ensuring that users can continue to edit it within the form body.

This form is using high density header. For the best authoring experience with this form, use the new form designer

This message is displayed in the classic form designer when a maker opens a main form for editing and it's configured to use high-density header.

The classic form designer doesn't provide a WYSIWYG authoring experience. It also doesn't detect and prevent or warn makers about the implications of changes they make to the form header. For example, when you edit a form that's using high-density header with the header flyout hidden, the classic form designer won't prevent makers from adding more than four columns to the header even though these columns won't be available to users.

The message informs the maker that when editing a form that's using high-density header, they should use the new form designer. This helps ensure the maker is aware of the impact of their changes to the form header.

Add and configure a subgrid component on a form

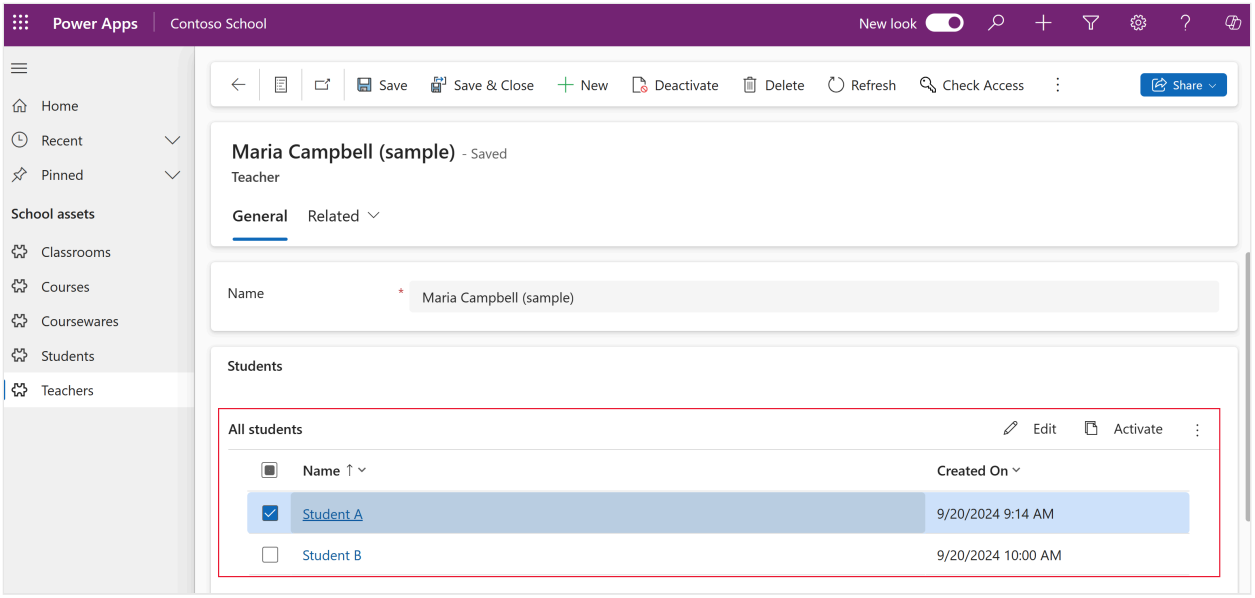
Article • 09/20/2024

A form that displays the details of a table record can use a subgrid component to display a read-only list of related or unrelated records in a tabular format. From the subgrid, app users can create new rows or open an existing row to edit. Makers add and configure a subgrid component using the form designer.



This article explains how makers can add a subgrid component to a model-driven app form. To learn how to add an editable grid to a model-driven app form, go to Make model-driven app views editable using the editable grid control.

Add a subgrid component

1. Sign in to Power Apps, and select the environment you want.
2. Select **Solutions** in the left navigation pane, and then open the solution that contains the table you want.
3. Select **Tables**, and then open the table that you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Select the **Forms** area, and then open the form you want to edit.
5. In the form designer, select **Component** on the command bar.
6. Drag a **1-column section** on the left **Components** pane onto the form.
7. With the **New Section** selected, select **Subgrid** from the left **Components** pane.
8. On the **Select subgrid views** pane:

- Typically app users want to view related records. When **Show related records** is selected, only tables with a relationship are displayed.
- Select the **Table** you want.
- Select the **Default view** from the table. When an existing view isn't suitable for the app, create or edit a view for the table.

9. Select **Done**.
10. Select **Save**, and then select **Publish**.

Configure a subgrid component

These are the properties available to configure when using a subgrid component on a form using the form designer.

Expand table

Area	Name	Description
Display options	**Label**	The localizable label for the subgrid visible to users. This property is required.
Display options	**Name**	The unique name for the subgrid that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores. This property is required.
Display options	**Hide label**	The label can be hidden on the form.
Display options	**Hide on phone**	The subgrid can be hidden to render a condensed version of the form on phone screens.
Display options	**Show related records**	When selected, the subgrid displays only records related to the current record that is displayed on the form. The **Table** drop-down list is also filtered to only list tables that are related to the current table.
Display options	**Table**	The table whose records you want to display in the subgrid. When **Show related records** is selected, the list of tables is filtered to show only tables that are related to the current table. In addition to the table name, the name of the lookup column is also displayed in parentheses.

Area	Name	Description
Display options	Default view	The view of the table selected in the **Table** property that will be used to get and display the list of records in the subgrid.
Display options	Team template	Note: This option is only available with the user table when the **Default view** is **Associated Record Team Members**. When available, sets the team template to use for the subgrid. More information: Create a team template to control access
Display options	Allow users to change view	When selected, app users can change from the **Default view** to another view of the table selected in the **Table** property.
Display options	Show all views	When selected, app users can change from the **Default view** to all other views of the table selected in the **Table** property. This property is only available when **Allow users to change view** is selected.
Display options	Hide search box	When selected, the **Search** box won't appear on the upper right of the subgrid.
Display options	Selected views	A list of views of the table selected in the **Table** property that app users can change from the **Default view**. This property is only available when **Allow users to change view** is selected and **Show all views** is cleared.
Display options	Default chart	Select which chart to show if **Show chart only** is selected.
Display options	Show chart only	Rather than a list of records a chart is displayed.
Display options	Allow users to change chart	When **Show chart only** is selected, app users can change the chart displayed in the subgrid.
Display options	Maximum number of rows	Determines the maximum number of records to display in the subgrid. The minimum number of rows displayed is 2 and the maximum is 250.
Display options	Use available space	Note: This property only works with the legacy web client. It has no effect on Unified Interface. Determines whether the form allows space for two records and will expand the space as the number of records increases. If the number exceeds the **Maximum number of rows**, people can navigate to additional pages to view the records. If **Use available space** isn't chosen the form provides space for the number of

Area	Name	Description
		records defined by **Maximum number of rows** and people can navigate to additional pages to view any additional records.
Formatting	**Component width**	When the section containing the subgrid has more than one column, you can set the column to occupy up to the number of columns that the section has.

Add and configure a quick view component on a form

Summarize this article for me

A main form that displays the details of a record can use a quick view component to display read-only details of a related record. This view of a related record is known as a lookup. The data displayed by the quick view component is defined by the quick view form of the related table. When there is no related record, such as a lookup, the quick view component is automatically hidden.

Add a quick view component

You add a quick view component the same way you add any other component, which is from the **Components** tab in the form designer. More information: Add, configure, move, or delete components on a form

Configure a quick view component

These are the properties you can configure when using a quick view component on a form using the form designer.

Expand table

Area	Name	Description
Display options	**Label**	The localizable label for the quick view visible to users. This property is required.
Display options	**Name**	The unique name for the quick view that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores. This property is required.
Display options	**Hide label**	When selected, the quick view label is hidden.
Display options	**Quick view forms**	A list of quick view forms that are displayed to app users. To configure the list of quick view forms Select **Select forms ...**, and then in the **Lookup** drop-down list select a lookup column where you want to display a quick view form.

Area	Name	Description
		Depending on the lookup column you select in the **Lookup** drop-down list, you see lists that let you select quick view forms for one or more tables.

Configure a lookup component on a form

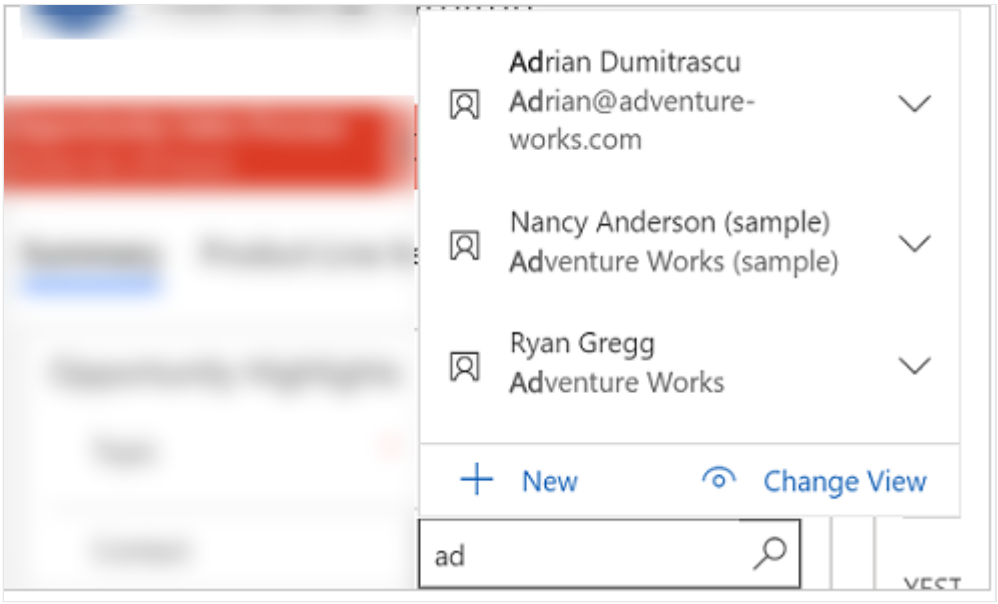
Article • 08/05/2022

Lookups help a user choose records from a **related** table. A lookup component is automatically added when a lookup column is added to a form.

For example, using a lookup component, you can open an account record that relates to a sales invoice record.



Learn more about the lookup field user experience

Configure a lookup component

Makers configure a lookup component using the form designer.

These are the properties available to configure when using a lookup component on a form using the form designer.

Area	Name	Description
Display options	**Label**	The label text that is displayed next to the lookup column.
Display options	**Hide label**	When enabled, the label isn't displayed.
Display options	**Hide on phone**	When enabled, the lookup column won't display when running the app on a phone.

Area	Name	Description
Display options	**Hide**	Don't display the lookup column. The lookup column can then be displayed using code.
Display options	**Lock**	Make this column so that it can't be removed by you or other makers until the **Lock** property is disabled.
Display options	**Read-only**	When this property is enabled, users can't change the value in the lookup column.
Display options	**Disable most recently used items**	Disabling this option allows users to view recently used rows in the lookup dropdown list. Enabling this option disables the recent items.
Display options	**Use Main Form Dialog for Create**	Enabling this option allows users to create rows in a pop out dialog for this lookup field, instead of closing the current form and navigating away.
Display options	**Use Main Form Dialog for Edit**	Enabling this option allows users to edit rows in a pop out dialog for this lookup field, instead of closing the current form and navigating away.
Display options	**Default view**	The view of the table selected in the **Table** property that can be used to get and display the list of rows that app users can select in the lookup drop-down list.
Display options	**Allow users to change view**	When selected, app users can change from the **Default view** to another view of the table.
Display options	**Show all views**	When selected, app users can change from the **Default view** to all other views of the table selected in the **Table** property. This property is only available when **Allow users to change view** is selected.
Display options	**Selected views**	A list of views of the table selected in the **Table** property that app users can change to from the **Default view**. This property is only available when **Allow users to change view** is selected and **Show all views** is unselected.
Formatting	**Form field width**	Determines the width in number of columns for the lookup column.

Area	Name	Description
Filtering	**Filter by related rows**	When this is enabled, you can filter this lookup based on a row related to both the current table and this lookup. The rows that display in this lookup when users search for a row will then have additional filtering applied. This helps provide more relevant searches when setting the value of the lookup. By default, this is turned off.
Filtering	**Relationship to current table**	This dropdown list defines the relationship from the table of the related row you want to filter by to the target lookup's table. The possible relationship combinations will be listed in the table following this one.
Filtering	**Relationship to this lookup's table**	This dropdown list defines the relationship from the table of the related row you want to filter by to the target lookup's table. For the possible relationship combinations, go to Table relationships available for a lookup column.
Filtering	**Allow users to turn off filter**	When this is enabled, users will have the option to turn off the filter you define here.
Components	**+Component**	Configure a control for the lookup column, such as the form component control.

Possible relationship combinations for a lookup column

Relationship to current table (Related table > Current table)	Relationship to this lookup's table (Related table > Lookup's table)	Available?
1:N	1:N	Yes
1:N	N:1	Yes
1:N	N:N	Yes
N:1	1:N	No
N:1	N:1	No
N:1	N:N	No
N:1	Self	Yes

Relationship to current table (Related table > Current table)	Relationship to this lookup's table (Related table > Lookup's table)	Available?
N:N	1:N	No
N:N	N:1	No
N:N	N:N	No
N:N	Self	Yes

Add agent response with the form designer (preview)

08/06/2025

[This article is prerelease documentation and is subject to change.]

Add the agent response component to a model-driven app form, which can directly call a Microsoft Copilot Studio topic and display the response to the user. This component builds on the Agent API executeEvent and simplifies usage by not requiring a new custom component. The implicit context of the app, page, and record are available in Copilot Studio.

This component supports the following responses from Copilot Studio:

- Markdown
- Adaptive card
- Image
- Video

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Prerequisites

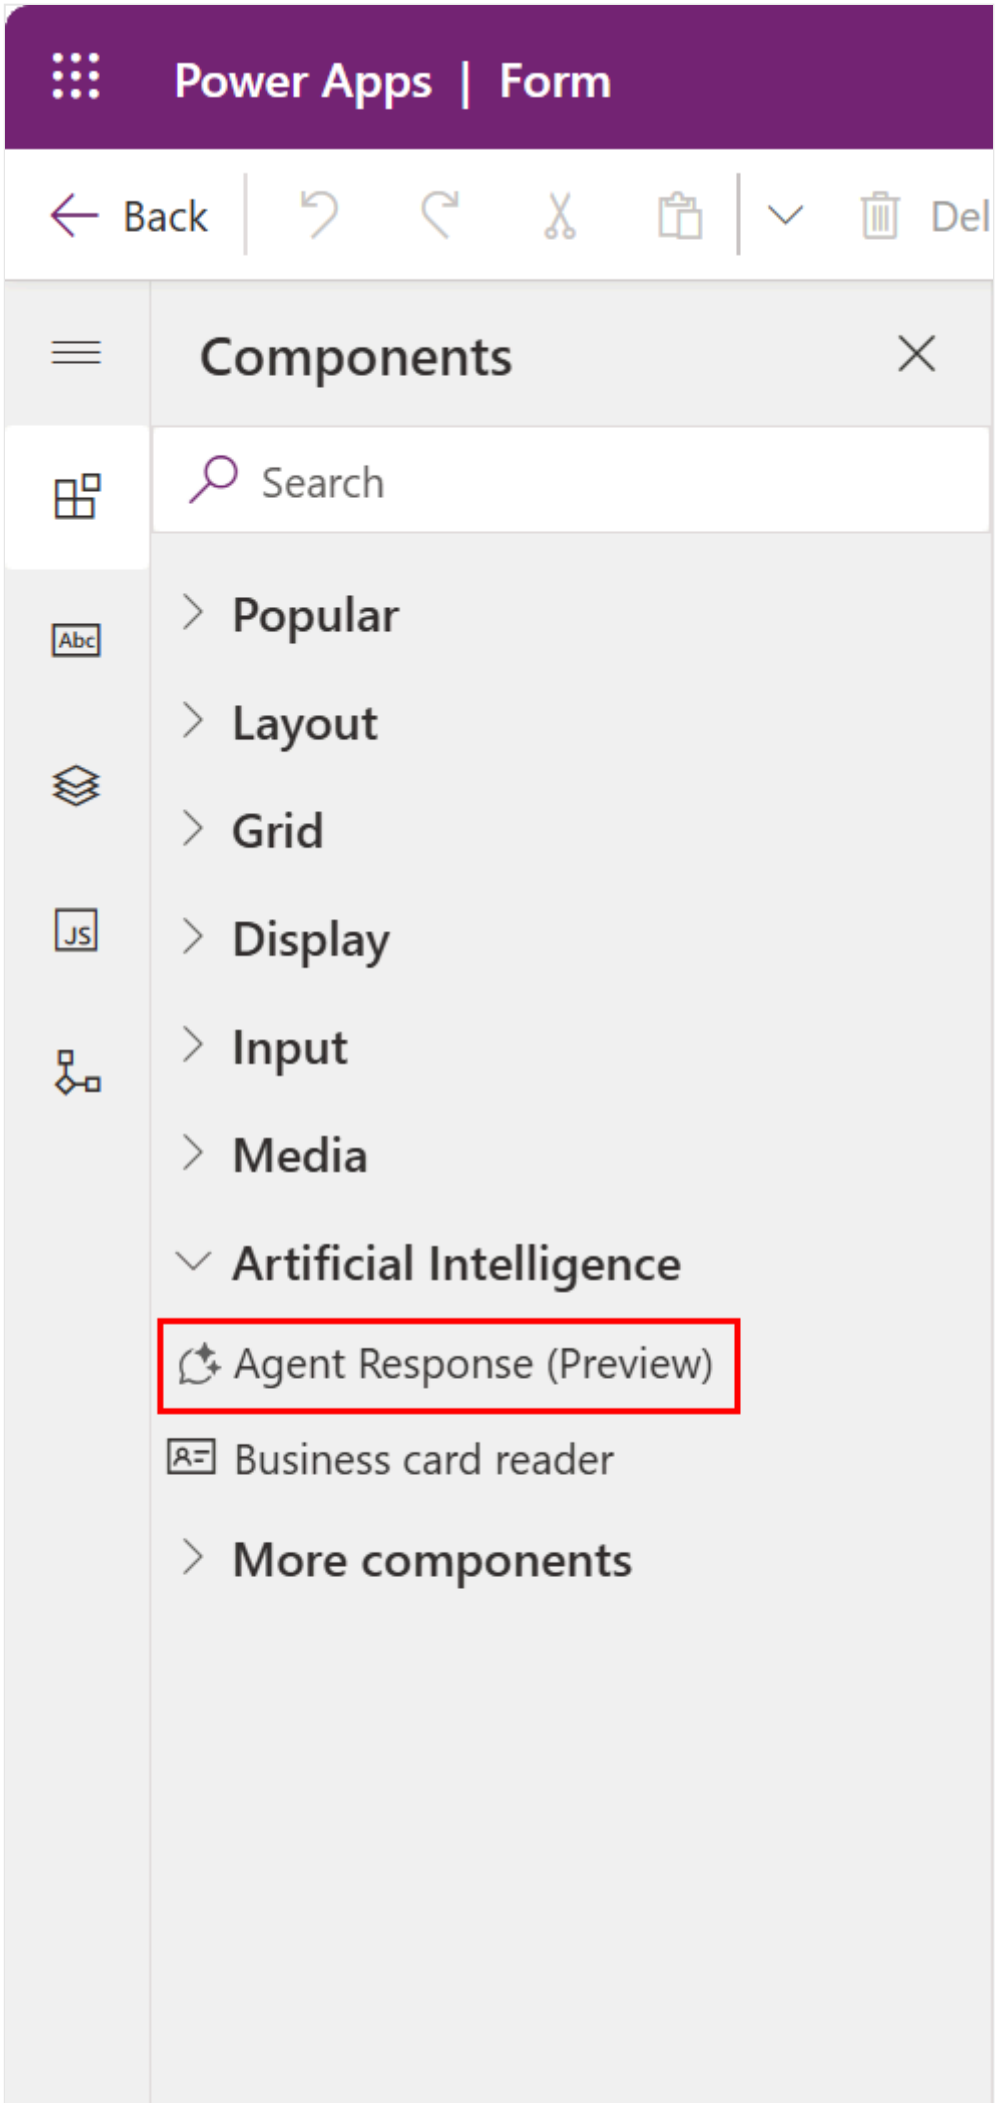
Requires the **Allow users to analyze data using an AI-powered chat experience in canvas and model-driven apps** environment setting enabled for model-driven apps. More information: Copilot environment settings

Add an agent response component to a form

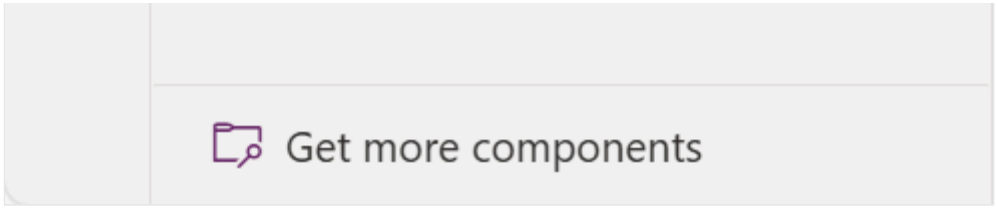
1. Open the form designer to create or edit a form. More information: Create a form or Edit a form
2. In the form designer, select **Component** on the command bar.

3. In the Components pane, expand **Artificial Intelligence**

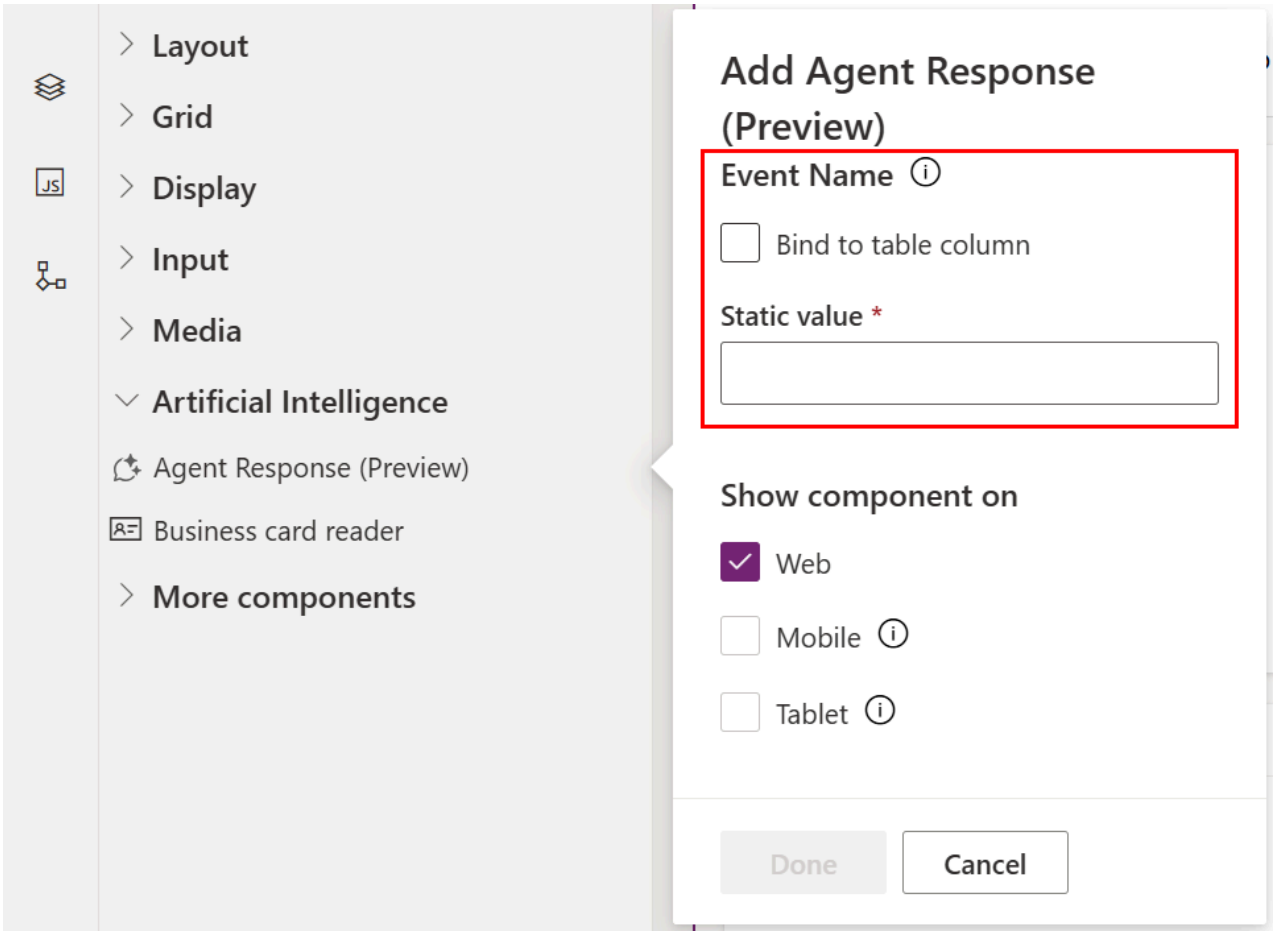
4. Drag **Agent Response** onto the form canvas.



Power Apps | Form
Back
Del
Components
Search
Popular
Layout
Grid
Display
Input
Media
Artificial Intelligence
Agent Response (Preview)
Business card reader
More components



5. In the **Add Agent Response** dialog, enter the **Event name** from the topic in Copilot Studio in the **Static value** box. More information: Find the event name for a topic in Copilot Studio



> **Note**
>
> The **Bind to table column** option isn't supported for this component.

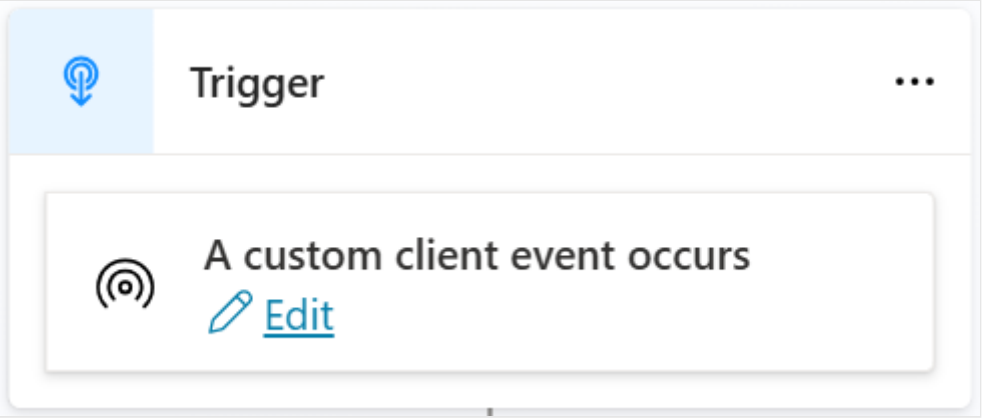
6. Select **Save and publish** on the command bar.

7. Open the form in a model-driven app to test the component.

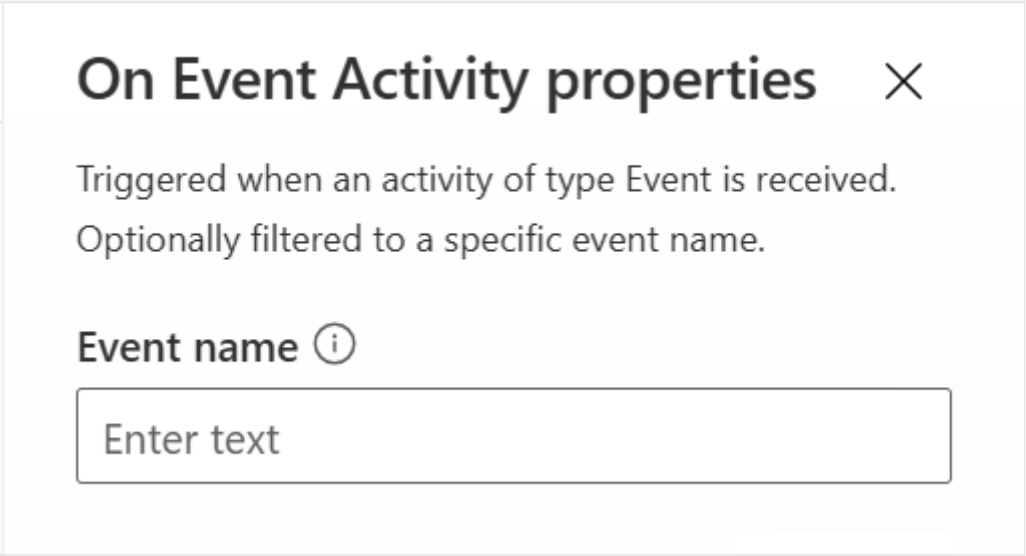
> **Note**
>
> The form designer preview displays the warning message "Agent Response is only available when you play the app" since live preview isn't yet supported.

Find the event name for a topic in Copilot Studio

1. Open the topic in Copilot Studio and find the **Trigger** node.
2. Verify the trigger type is **A custom client event occurs** or **Event received**.
3. Within the **Trigger** node, select **Edit**.



4. Within the **On Event Activity properties** pane, copy the **Event name** property string value to be passed from the agent response component. More information: Change the trigger for a topic



Accessing app context

When the agent response component calls the Copilot Studio topic, it passes context for the app through a set of variables. The following are context variables available as Copilot Studio global variables.

Expand table

Variable	Description
`Global.PA__Copilot_Model_PageContext.pageContext.id.guid`	ID of the table record on the main form
`Global.PA__Copilot_Model_PageContext.pageContext.entityTypeName`	Logical name of the table in the main page
`Global.PA__Copilot_Model_PageContext.pageContext.pageName`	Name of the main page
`Global.PA__Copilot_Model_PageContext.pageContext.pageType`	Type of the main page
`Global.PA__Copilot_Model_AppUniqueNameContext.appUniqueNameContext.appUniqueName`	Unique name of the model-driven app

Accessibility

When the Copilot Studio response is an Adaptive Card, ensure the following best practices are followed to have an accessible experience.

- Design best practices - Adaptive Cards
- Image - Adaptive Cards

Limitations

- Agent response component properties currently not supported:
  - Label
  - Hide label
  - Hide on phone
  - Lock
  - Read-only
  - Component width
  - Component height
  - Bind to table column
- Agent response component doesn't support passing additional context to Copilot Studio. Create a custom component using Agent API executeEvent to support passing more context.

- Agent response component only supports a read-only adaptive card. Create a custom component using Agent API executeEvent to support client side logic.
- Agent response component isn't supported for mobile or tablets.

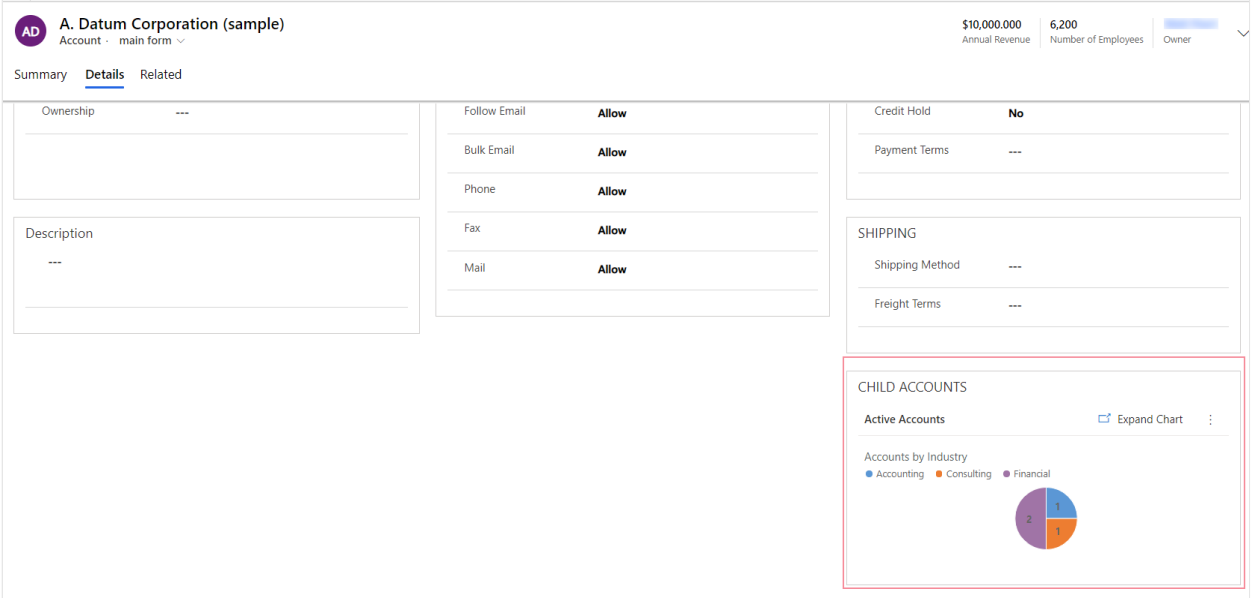
Add, configure, move, or delete components on a form

Add a chart to a form

Article • 03/13/2023

A chart can be added to a form or an existing list to a chart can be updated. For example, the Child Accounts filtered sub-grid can be changed to display a chart instead of a list on the account main form.



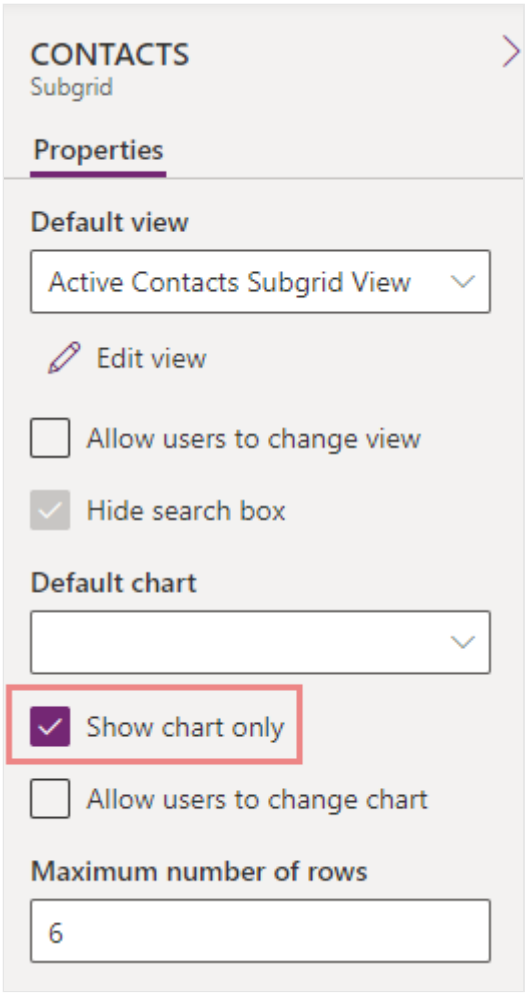
1. Sign into Power Apps, and then select **Solutions** on the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Open the solution and then open the table.

3. Select the **Forms** area, and then open the form where you want to add a chart.

4. On the form canvas, select an existing subgrid or add one. More information: Add and configure a subgrid component on a form

5. On the right properties pane for the subgrid, select the **Show chart only** option. When enabled, this option displays the view in a chart format.



6. Configure the subgrid properties for the chart, such as the default chart to display and whether users can change the chart displayed. More information: Configure a subgrid component

7. **Save** and **Publish** the form to make the customization available to users.

Add a chart to a form (classic)

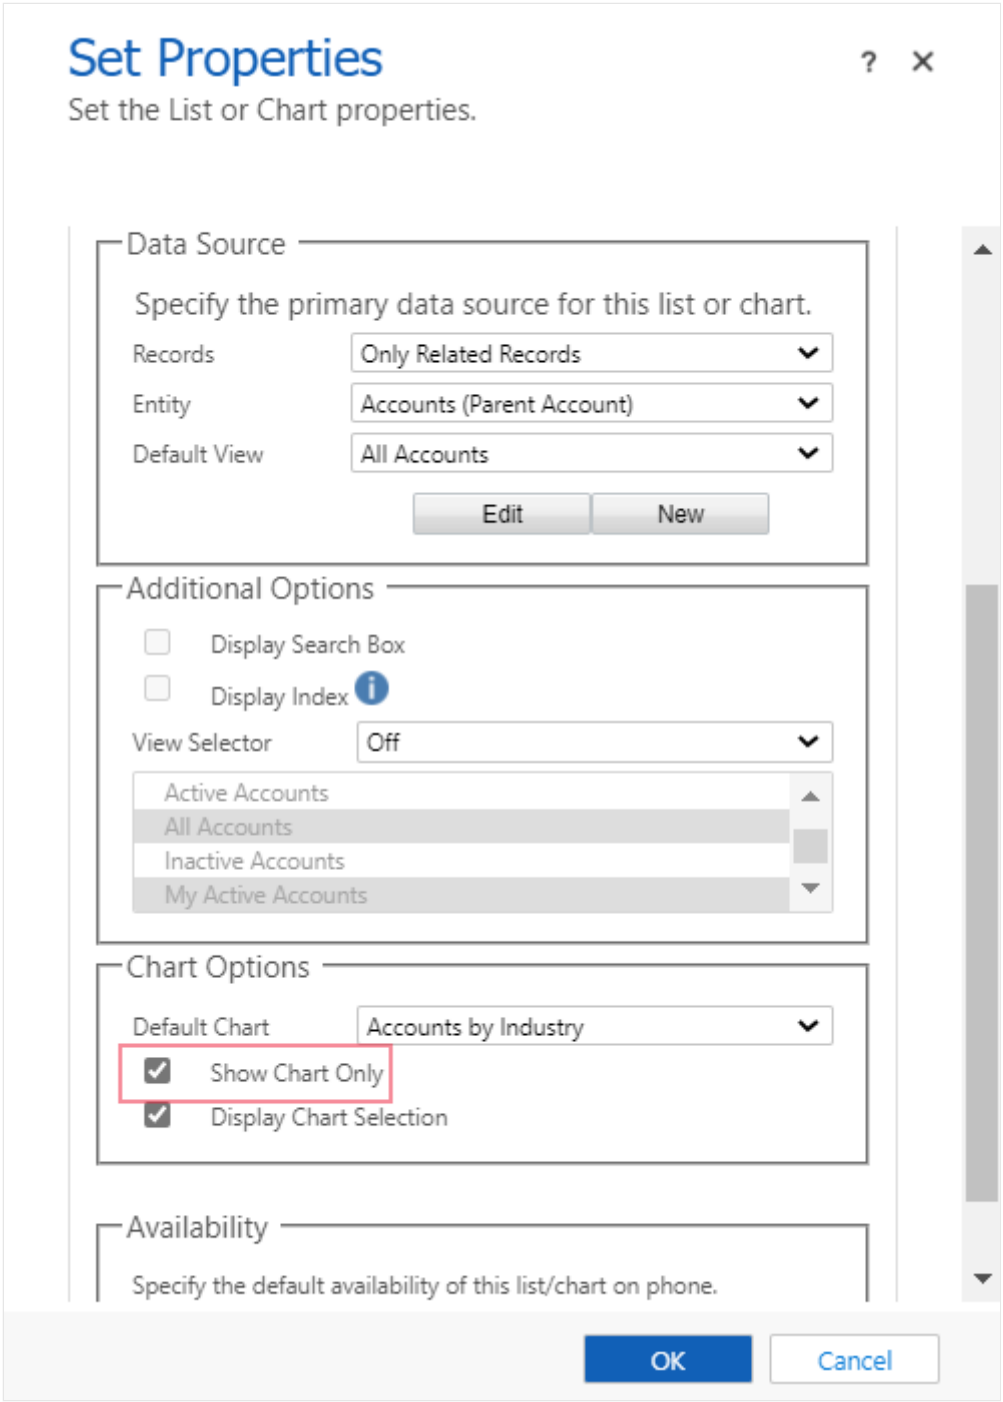
1. Sign into Power Apps, and then select **Solutions** on the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Open the solution with the required table and open this table. Then select the **Forms** area.

3. Open the required form. In the form designer select **Switch to classic** from the command bar.

4. Add a sub-grid to the form, or to change an existing list in a sub-grid, double-click a sub-grid on the form.

5. On the **Set Properties** page for the sub-grid, select the **Show Chart Only** option. When enabled, this option displays the view in a chart format.



6. On the **Set Properties** page for the sub-grid, consider from the following options that affect how the chart is displayed, and then select **OK**. For more information about these properties, see Set properties for a model-driven app chart or list included in a dashboard.

   - **Records**:
     - **Only Related Records**: Shows the rows based on the selected view, but only with rows related to the table row.
     - **All Row Types**: Shows all the rows based on the selected view.

- **View Selector**: When enabled, users can change to a different view, which displays the chart with different data and filtering that are associated with the view:
  - **Off**. Don't display the view selector. Users won't be able to change views at runtime.
  - **Show All Views**. Provide a full list of views associated with the value set in the **Table** property.
  - **Show Selected Views**. Select this setting to limit the list of views available at runtime. To select the specific views to be displayed, hold down the Ctrl key and tap or select each view that needs to be included.

- **Display Chart Selection**: When enabled, users can change the type of chart, such as column, bar, or pie, on the form. If the user changes the type of chart, the settings aren't saved. The chart type reverts to the **Default Chart** setting when the form is closed.

7. Publish your customization.More information: Publish changes

Configure a map on a form

Article • 08/31/2023

By default, the map control is configured on the main form for both the account and contact tables, which provides the ability to display a map on table records. Although not configured by default, the map control can be added to the system user table. The map control can also be used with some Dataverse standard tables and Dynamics 365 apps tables. The map control can't be used with custom tables. More information: Tables that can be used with the map control

When enabled, the map displays the location specified in the address composite columns for the given record.

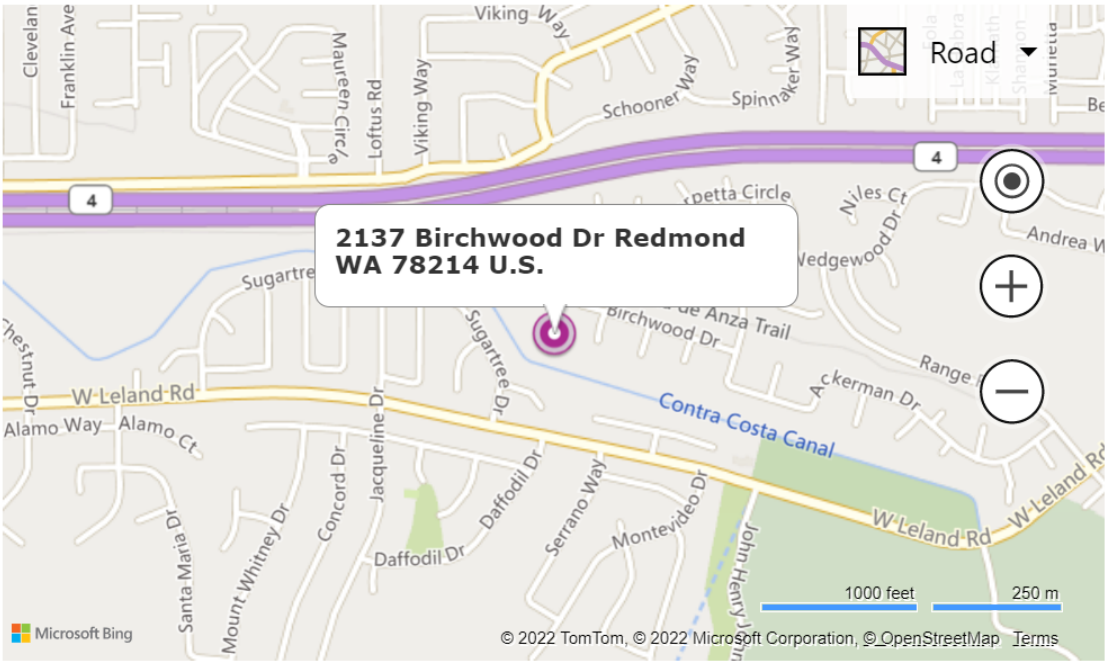
Get Directions



Important

- To use the map component the **Bing Maps** setting must be **On** under the **Embedded content** section of environment settings in the Power Platform admin center. More information: **Manage Bing Maps for your organization**
- A form can only have one map component.

Tables that can be used with the map control

- Contact
- Account
- System User
- Competitor[1]
- Invoice[1]
- Quote[1]
- SalesOrder[1]
- Lead[1]

[1]Requires a customer engagement app.

Add and configure a map for a system form

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane, and then select the table where you want to configure a map on the main form. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Select the **Forms** area, and then open the system main form you want.
4. On the **Components** left pane, expand **Display**, and then select **Map**. Or, if the map component is already on the form, select it on the form designer canvas.

View and edit map properties

Area	Property	Description
Display options	**Label**	**Required**: A label to display for the map.
Display options	**Hide label**	Whether the label should be displayed.

Area	Property	Description
Display options	**Hide**	Showing the map is optional and can be controlled using business rules or scripts. More information: Visibility options
Display options	**Bing Maps address**	Choose which address should be used to provide data for the map.
Formatting	**Component width**	When the section containing the map has more than one column, you can set the column to occupy up to the number of columns that the section has.
Formatting	**Use all available vertical space**	You can allow the map height to expand to available space.

Configure a map using the classic form editor

You can remove the maps area in the form editor or add it back by using the **Bing Maps** button on the **Insert** tab of the classic form editor. More information: Configure Bing Maps to be displayed on forms

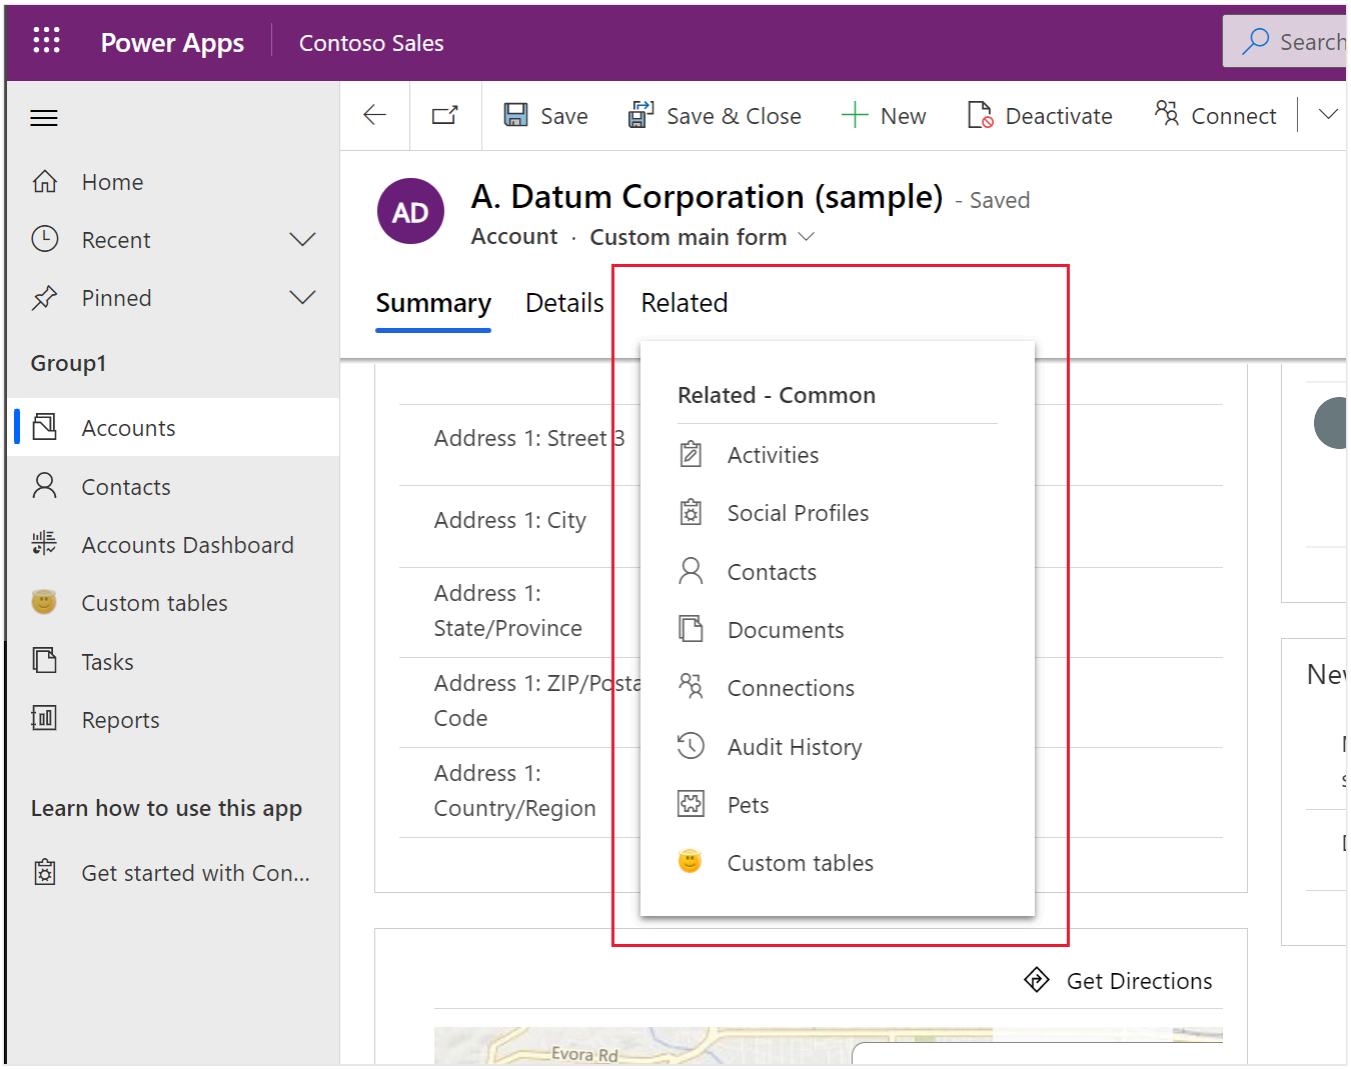
Create and design model-driven app forms

Add table relationships to a form

09/25/2025

Creating a table relationship adds the navigation within a form that allows app users to view a list of related records from the **Related** tab in a model-driven app.



Each table relationship has properties to control the relationship behavior. More information: Table relationship behavior

Table relationships that are configured to be displayed can be hidden using the form designer.

Add, edit, or create a related table in form designer (preview)

[This topic is pre-release documentation and is subject to change.]

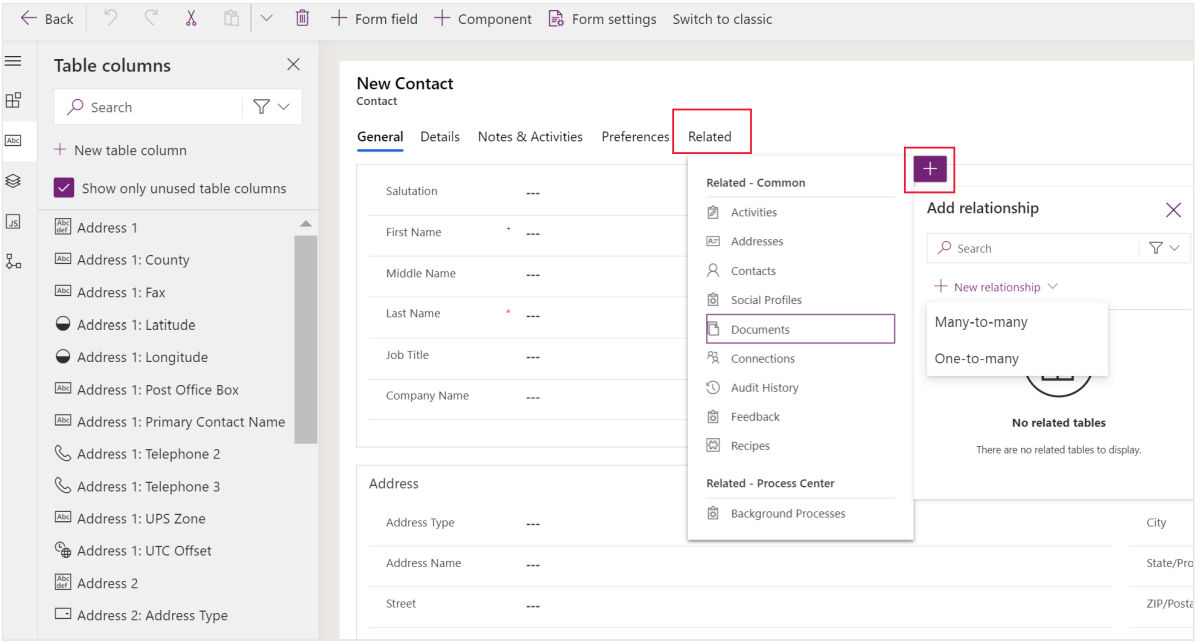
> **Important**

This is a preview feature.

1. Sign into Power Apps
2. Select **Solutions** on the left navigation pane, open the solution that has the table you want, and then open the table. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Forms**, and then open the main form where you want to add a related table.
4. Select the **Related** tab. The **Related** menu appears:

   - Add and edit an existing relationship. Select a table in the list to display the table properties in the right pane. Select **Edit relationship** to make changes to the relationship. More information: Add advanced relationship behavior

   - Add a new relationship. Select + to **Search** for another relationship or select **New relationship** to create either a **One-to-many relationship** or **Many-to-many** relationship. More information: Add a One-to-many relationship and Add a Many-to-many relationship



5. **Save** and **Publish** the change.

Hide a relationship

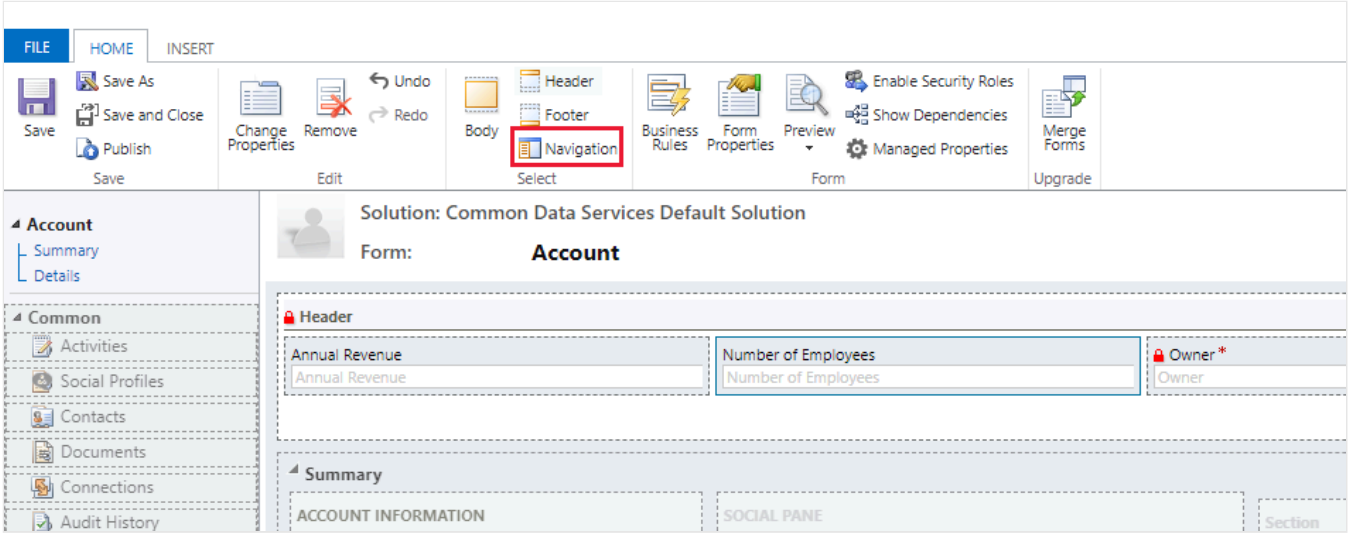
1. In form designer, select the **Related** tab, and then select the table where you want to hide a relationship.
2. On the right properties pane, under **Display options** select **Hide**.
3. **Save and Publish** the change.

Relationship management limitations in form designer

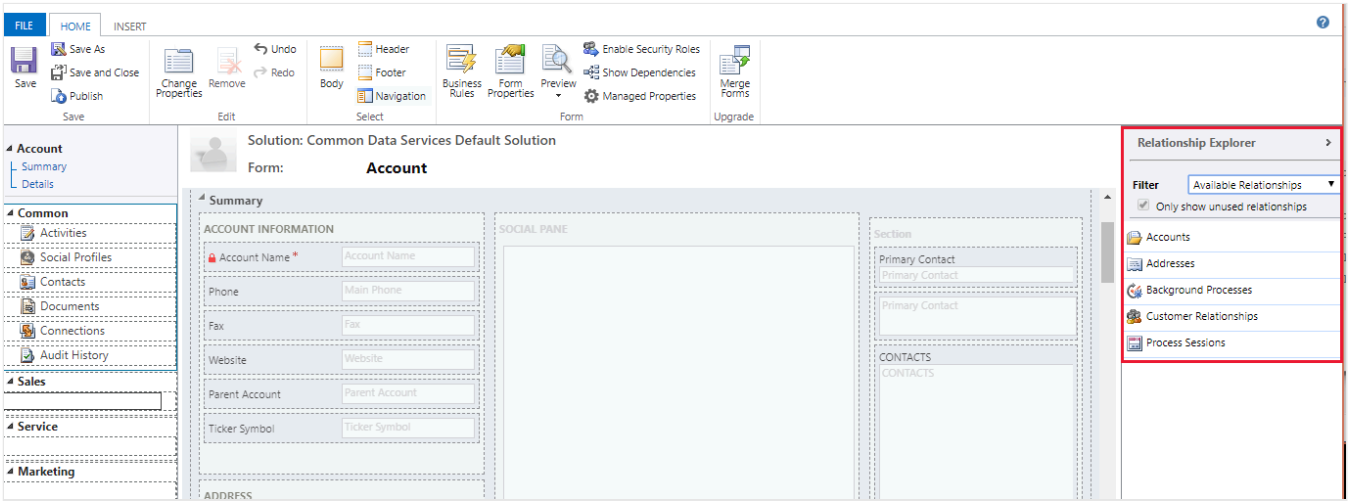
- You can edit display options for system relationships but you can't remove the relationship from the related menu. However, you can hide the relationship. More information: Hide a relationship
- You can't edit or remove self many-to-many relationships.
- You can't add or edit related web resources or external URLs.

Create navigation using the legacy experience

To enable editing navigation first select **Navigation** from the **Select** group on the **Home** tab of the form designer.



In the right pane, from **Relationship Explorer** you can filter by 1:N (one-to-many) or N:N (many-to-many) relationships, or view all available relationships. The **Only show unused relationships checkbox** is disabled and selected. Relationships are added one at a time.

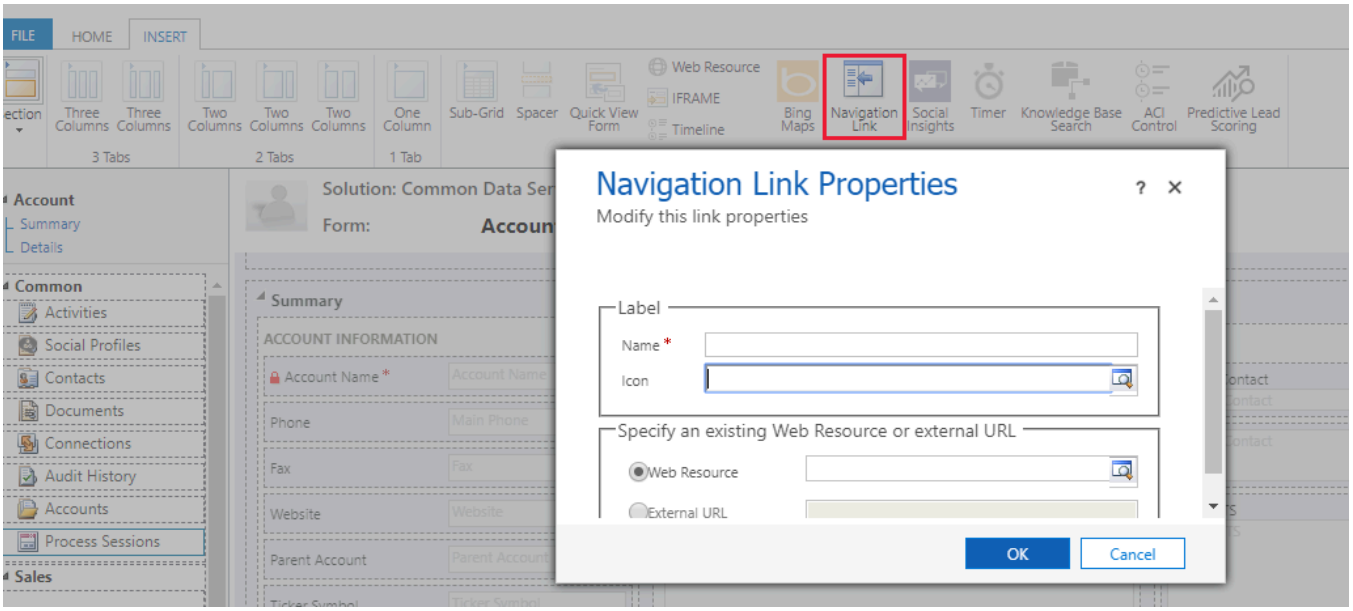


To add a relationship from the **Relationship Explorer** just double-click the relationship and it will be added below the currently selected relationship in the navigation area. Double-click a relationship in the navigation area and you can change the label on the **Display** tab. On the

Name tab you can see information about the relationship. Use the **Edit** button to open the definition of the table.

There are five groups in the navigation area. You can drag them to reposition them and double-click them to change the label, but you can't remove them. These groups will only display when there is something in them. So if you don't want a group to appear, just don't add anything to it.

Use the **Navigation Link** button in the **Control** group of the **Insert** tab to add a link to a web resource or external URL.



Navigation link properties

Navigation links have the following properties:

Expand table

Property	Description
Name	**Required**: Text to display as a label.
Icon	Use a 32x32 pixel web resource. Use a PNG image with a transparent background is recommended.
Web Resource	Specify a web resource to display in the main pane of the form.
External URL	Specify the URL of a page to display in the main pane of the form.

Create and edit table relationships for Microsoft Dataverse

Manage model-driven app forms settings

Article • 01/24/2025

Power Apps forms settings are a set of capabilities that make it easy for model-driven app makers to configure and verify how users access forms in a solution or application. From **Form settings**, there are four different areas a maker can choose from:

- Set security roles for a form.
- Set the form order.
- Set the fallback form for a table.
- Form access checker.

You can access form settings from the **Forms** area in Power Apps or command bar in the form designer.

Set security roles for a form

Different people in your organization might interact with the same data in different ways. Managers might depend on being able to quickly scan information in a row and service people might require a form that streamlines data entry. You can accommodate different requirements by assigning forms to the security roles that different groups of people belong to.

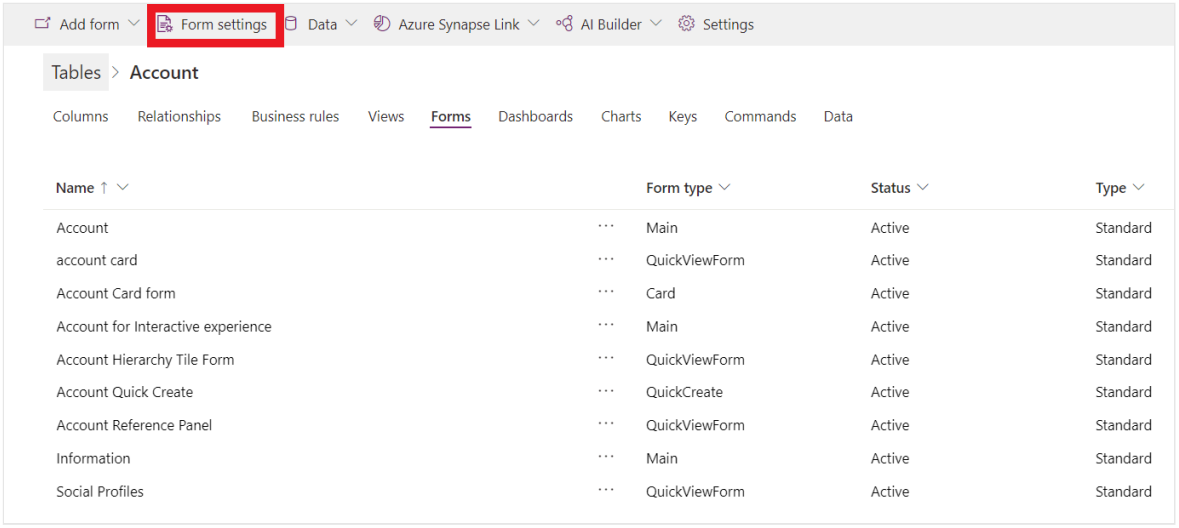
When you have more than one main or other form type defined for a table, you can select which forms users are able to use based on their security roles. Because each table must be able to display a form for any user, at least one form must be designated as a ”fallback” form – a form visible to users whose security roles don't have any forms explicitly assigned to them.

> ⓘ **Note**
>
> - Quick Create, Quick View, and Card forms can't be assigned to security roles.
> - Another option makers have to control form access is to make a main form inactive. You can set an active or inactive state to main forms. This feature was included primarily to manage new forms included when Microsoft Dataverse environments upgrade but you can use it to prevent users from being able to use any main form.

Assign a security role to a form

1. Sign into Power Apps, select **Solutions**, open the solution you want, open a table, and then select the **Forms** area. If the item isn't in the side panel pane, select ... More and then select the item you want.

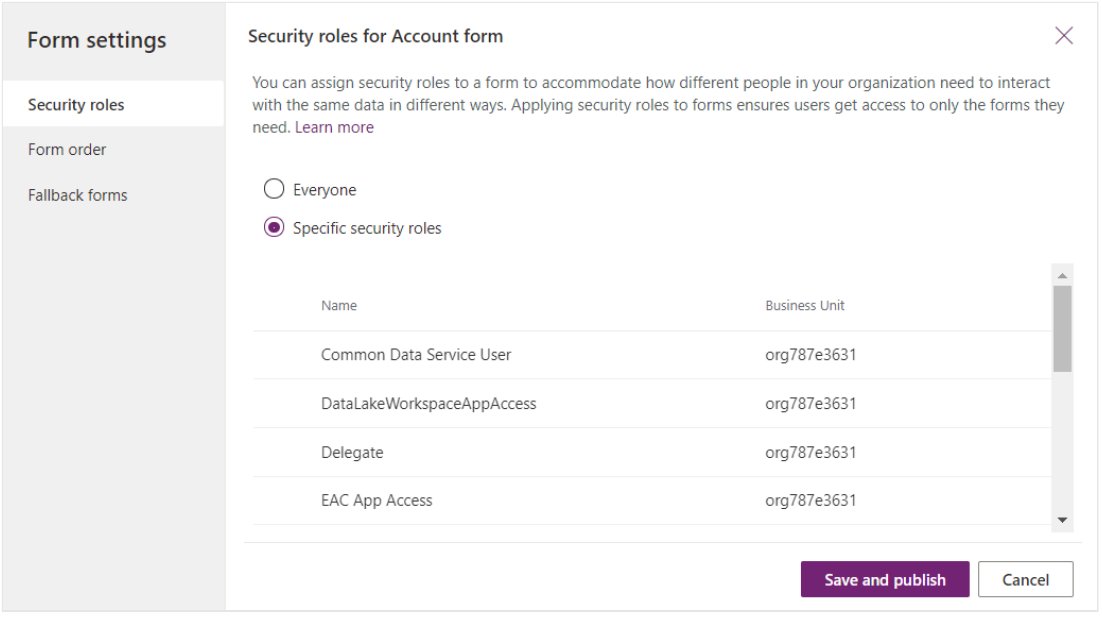
2. Select the main form you want to configure the security roles for a form, and then on the command bar select **Form settings**.



3. In the left navigation on the **Form settings** page, select **Security role**.

4. Choose from the following options:

   - To set the security roles for every user select **Everyone**.
   - To set the access to the form for one or more specific security roles, select **Specific security roles**. Then, select the security roles you want to grant access from the list of security roles that are set up for your environment.



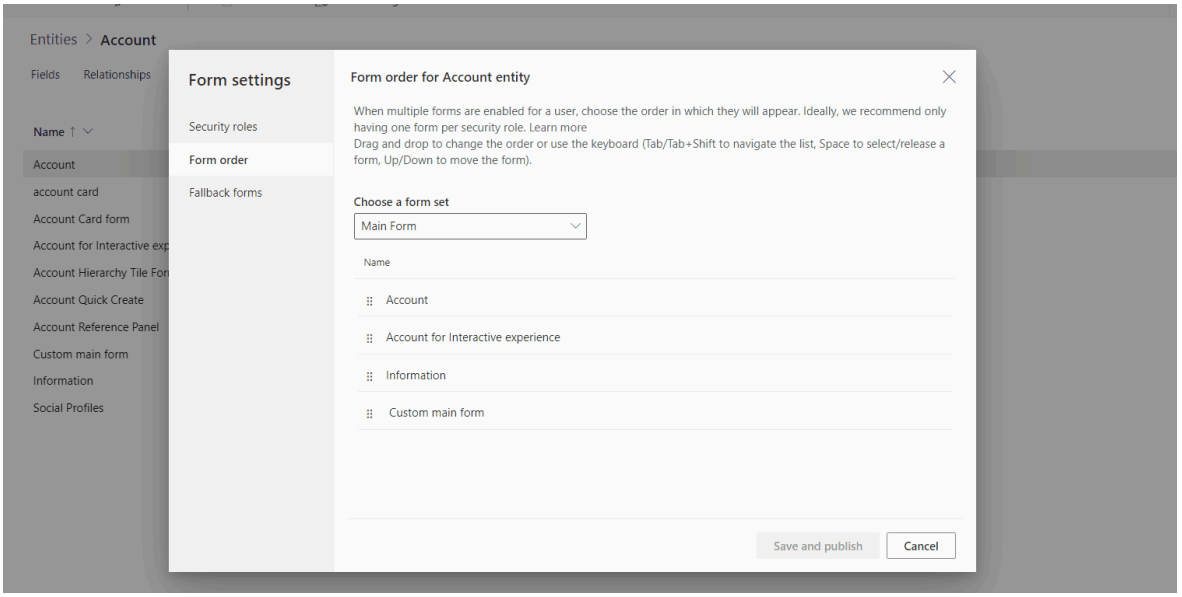
5. Select **Save and Publish**.

Set the form order

When you have multiple main, quick create, quick view, or card forms for a table, you can assign a form order. The form order determines which of the available forms is shown by default. The available main forms can be further controlled by assigning security roles to the form.

Notice that the form order doesn't set who can view the form that is managed by setting security roles. More information: Set security roles for a form

1. Sign into Power Apps, select **Solutions**, open the solution you want, select a table, and then select the **Forms** area. If the item isn't in the side panel pane, select ... More and then select the item you want.
2. Select the main form you want to configure the fallback form for, and then on the command bar select **Form settings**.
3. In the left navigation on the **Form settings** page, select **Form order**.
4. Select the form set that you want, such as **Main Form**, **Quick Create Form**, **Quick View Form, or **Card Form**.
5. Change the order by dragging and dropping the form up and down the list in the order you want it to be shown to your users. You can also use these keyboard shortcuts: Tab/Tab + Shift to move the focus, Space to select or release a form, and Down/Up arrow keys to move a form.
6. Select **Save and publish**.



To set the form order using solution explorer, see Assign model-driven app form order.

Set the fallback form for a table

Setting the fallback form for a table is important to ensure that if a user doesn't have any assigned security roles or there are no assigned security roles for a main form type there's always a “default” form that shows for that table. Fallback forms are only available with main forms and don't apply to quick create, quick view, and card forms.

There are a few different strategies to consider when you manage the fallback form for a table.

All users view the same form

If you don't require multiple forms for a table you don't need a fallback form.

Create a contingency form

If you're using role-based forms because you want to restrict the information people might view or edit, consider creating a form that has a minimum of information displayed. Then, select specific security roles, but don't select any roles except system administrator. The result is that this form will never be seen by anyone except users with the system administrator security role and anyone whose security roles haven't been associated with a specific form. You could include an HTML web resource in the form with information about why little information is visible in the form and a link to information about how to request being added to a security role that is associated with a from or to include a new security role for a form.

Create a generic form

If you use role-based forms to provide a customized experience based on a user’s role, you can set your least specialized form as the fallback form and configure it to display for everyone. Then, create customized forms for specific security roles and configure those forms to only display for security roles that require them. Don't enable these forms for fallback. Finally, in the **Form settings** configure the **Form order** to specify which forms to display ranking them from most exclusive to least exclusive. Your fallback form is at the bottom of the list. This strategy causes people seeing the form that has been customized for their role as the default form, yet they can use the form selector to select the most common form if they want. Whatever form they select remains their default form until they select a different form.

1. Sign into Power Apps, select **Solutions**, open the solution you want, select a table, and then select the **Forms** area. If the item isn’t in the side panel pane, select ... More and then select the item you want.

2. Select the main form you want to configure the fallback form for, and then on the command bar select **Form settings**.
3. In the left navigation on the **Form settings** page, select **Fallback forms**.
4. To disable a form from the fallback order, clear the checkbox. In this example the **Information** form is removed from the fallback order.

   To enable a form for fallback select the checkbox next to the form to enable it.
5. Select **Save and publish**.

Use form scripting

The Client API form context (formContext) provides a reference to the form or to an item on the form, such as, a quick view control or a row in an editable grid, against which the current code is executed. More information: Client API form context

> **Important**
>
> The Xrm.Page object is **deprecated**, and you should use the **getFormContext** method of the passed in execution context object to return reference to the appropriate form or an item on the form.

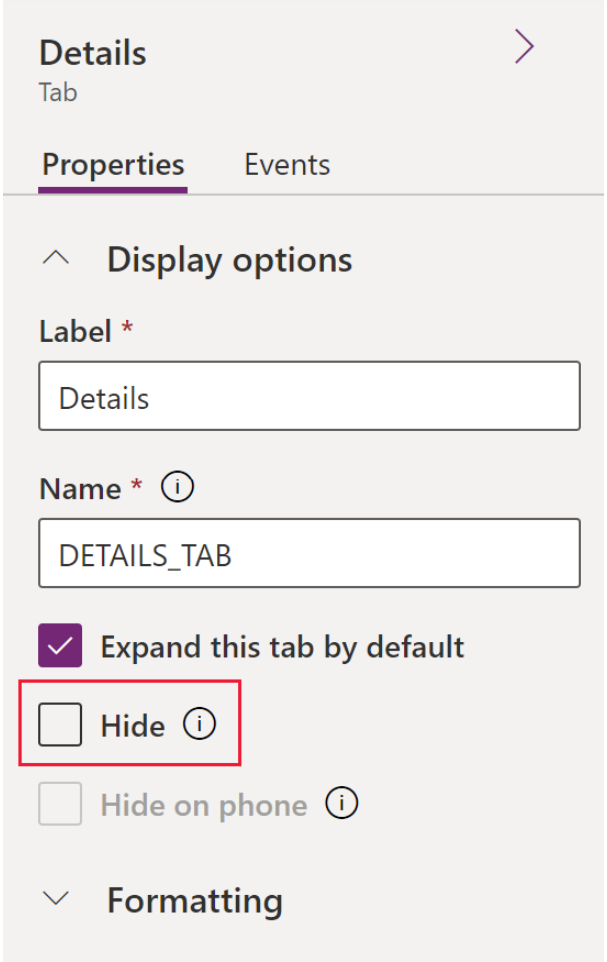
Show or hide model-driven app form elements

Article • 04/08/2022

Several types of form elements have the option to be shown or hidden at app runtime. Tabs, sections, columns, iFrames, and web resources all provide this option. You can change the default setting to view a form element in the form designer by selecting the **Hide** property.



Using form scripts or business rules, the visibility of these elements can be controlled to create a dynamic form to provide a user interface that adapts to conditions in the form.

> **Important**
>
> Hiding form elements is not a recommended way to enforce security. There are several ways people can view all the elements and data in the form when elements are hidden.
>
> Disabling, hiding, or locking a column, control, or form component using the form designer, manually in the form XML, or using a Client API only works to control data access in a Unified Interface or legacy web client app. It doesn't strictly enforce

data access by itself in the apps. Moreover, it doesn't control data access using other ways to connect to Microsoft Dataverse such as using the Web service or a canvas app. It is also important to know that the app will not display an error message or block a save if a required column is null and has been disabled. This ensures that users are never blocked from completing a task. To control access, see **Set security roles for a form** or use **Field-level security**.

Rather than designing forms that depend on scripts to control visibility of options, consider whether a business process flow, a dialog, or switching to a different form may be better suited to meet your requirements. If you do use scripts, make sure that any element that might be hidden is hidden by default. Only show it with scripts when your logic calls for it. This way it will not be displayed in presentations that do not support scripts.

In Unified Interface, for sections where columns don't span more than one column, hiding a column in the section moves the column below up on the form. If a column spans more than two columns in a section, hiding a column in the section that has a control across from it will not move the column below it up on the form. You will see additional white space where the hidden column is in the section.

Client API methods for controlling the visibility of form elements

For information about how to change the form element show or hide status for the header, command bar, and tabs at app runtime, see these client API reference articles:

- formContext.ui.headerSection item (Client API reference)
- formContext.ui.tabs (Client API reference)

Use the model-driven app main form and its components

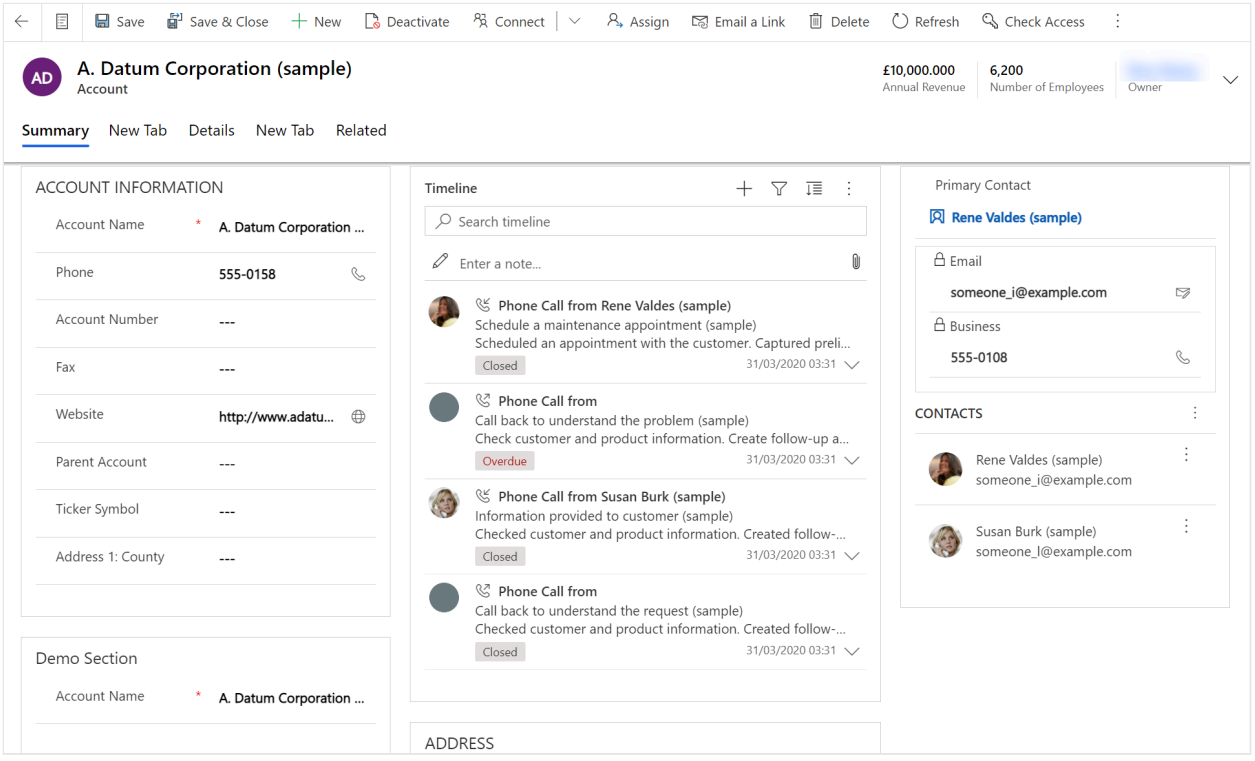
Article • 03/04/2025

Forms in model-driven apps provide the primary means by which users can update records. Forms associated with a table can be accessed via the table designer.

The most versatile form type of the new form is **Main**. However, in addition to main forms, app makers can build quick create, quick view, or card forms. Learn more about other types of forms

This article explains how to edit a main form, and add or change various elements of the form.

Here's an example of a main form within an app. It has several tabs, in addition to exposing the timeline component and a quick view form providing more details associated with the primary contact.



Open the form designer

To edit a form, such as to add or change elements, use the form designer. The form designer lets a maker edit forms for all model-driven apps.

Follow the procedures given below to access the form designer.

> **Note**
>
> If you create any new solution components in the process of editing the form, the names of the components use the solution publisher customization prefix for the default solution and these components are only be included in the **default solution**. If you want any new solution components to be included in a **specific unmanaged solution**, open the form designer through that unmanaged solution. This helps with the application management lifecycle.

Access the form designer for an unmanaged solution

1. Sign in to Power Apps.
2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the unmanaged solution you want to work with. The solution type, managed or unmanaged, is displayed in the **Managed externally?** column.
4. In the list of components, locate the table with the form you want to edit. If the table isn't there, you need to add it.

Add a table to an unmanaged solution

1. With the unmanaged solution opened, on the command bar select **Add Existing** and then select **Table**.
2. All the available tables are listed. Select the table, and then select **Next**.
3. Select the option that's most appropriate, and then select **Add**:
   - For a custom table, select **Include all components**.
   - For a standard table choose **Select components**, and then browse to and select the main form you want to customize, and then select **Add**.
4. The table is added to the solution. In the list of components, open the table, select the **Forms** area, and then open form of type **Main**.
5. In the form designer, make the changes you want.
6. **Save** the form.

Publish the changes for use in the app

Certain customizations that make changes to the user interface require that they be published before people can use them in the application. To publish your customization, on the solution **Objects** area command bar, select **Publish all customizations**.

Access the form designer through the default solution

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane.
3. Select the table that you want, and then select the **Forms** area.
4. In the list of forms, open the form of type **Main**.

> **Note**
>
> If you have made other changes to the app, publish them using the app level publish option. Go to Validate and publish an app using the app designer for more information.

Form designer user interface

To understand in detail the form designer user interface, go to Overview of the model-driven form designer.

Form properties

To learn more about the form properties, go to Form properties.

Visibility options

Several types of form elements have the option to be shown or hidden by default. Tabs, sections, and columns all provide this option. When you use form scripts or business rules, the visibility of these elements can be controlled to create a dynamic form to provide a user interface that adapts to conditions in the form.

> **Note**
>
> Hiding form elements isn't a recommended way to enforce security. There are several ways people can view all the elements and data in the form when elements are hidden. To learn more, go to Show or hide form elements.

Tab properties

In the body of a form, tabs provide horizontal separation. Tabs have a label that can be displayed. If the label is displayed, tabs can be expanded or collapsed to show or hide their content by choosing the label. To know in detail about the tab properties, go to Configure tabs on a form.

Section properties

A section in a form occupies the space available in a tab column. Sections have a label that can be displayed and a line might be shown below the label. To know in detail about the section properties, go to Configure sections on a form.

Timeline

The timeline shows related activities for a specific table.

The types of activities supported are task, appointment, phone call, email, social activity, and custom activity.

The timeline also shows notes and, system, and user posts. Timelines show those activities that have the **Regarding** column set to the table you're viewing. For notes, the **Regarding** column isn't shown to the user; It's implicit when created from the timeline.

Each activity that's shown in the timeline, has the same quick actions that are available on the activity's command bar.

Common column properties

To know in detail about the common column properties, go to Configure column properties on a form.

Special column properties

All columns have the properties listed in Common column properties - legacy, but certain columns have additional properties. To know more, go to Special Column Properties - legacy.

Subgrid properties

You can configure a subgrid on a form to display a list of rows or a chart. To know in detail about the subgrid properties, go to Add and configure a subgrid component on a form.

Quick view control properties

A quick view control on a form displays data from a row that is selected in a lookup on the form. To explore the quick view control properties, go to Add and configure a quick view component on a form.

Web resource properties

You can add or edit web resources on a form to make it more appealing or useful to app users. Form enabled web resources are images or HTML files. These items are under found on the **Components** tab under **Display** in the form designer.

External website

You can add website content as an inline frame (iframe) to a form to integrate content from another website within the form. More information: Add an iframe to a model-driven app main form

Edit navigation

Navigation within the form allows people to view lists of related rows. Each table relationship has properties to control whether it should be shown. More information: Table relationships advanced options

Any table relationships that are configured to display can be overridden within the form editor.

For step-by-step instructions, go to Add form navigation for related tables.

To enable editing navigation, you must first select **Navigation** from the **Select** group on the **Home** tab.

In the Relationship Explorer, you can filter by 1:N (one-to-many) or N:N (many-to-many) relationships, or view all available relationships. The **Only show unused relationships checkbox** is disabled and selected. So you can only add each relationship one time.

To add a relationship from the **Relationship Explorer** just double-click it and it will be added below the currently selected relationship in the navigation area. Double-click a relationship in the navigation area and you can change the label on the **Display** tab. On the **Name** tab, you can see information about the relationship. Use the **Edit** button to open the definition of the table.

There are five groups in the navigation area. You can drag them to reposition them and double-click them to change the label, but you can't remove them. These groups are displayed only when there's something in them. If you don't want a group to appear, just don't add anything to it.

Configure event handlers

An event handler consists of a reference to a JavaScript web resource and a function defined within that web resource that will execute when the event occurs. To know more about configuring event handlers, go to Configure event handlers.

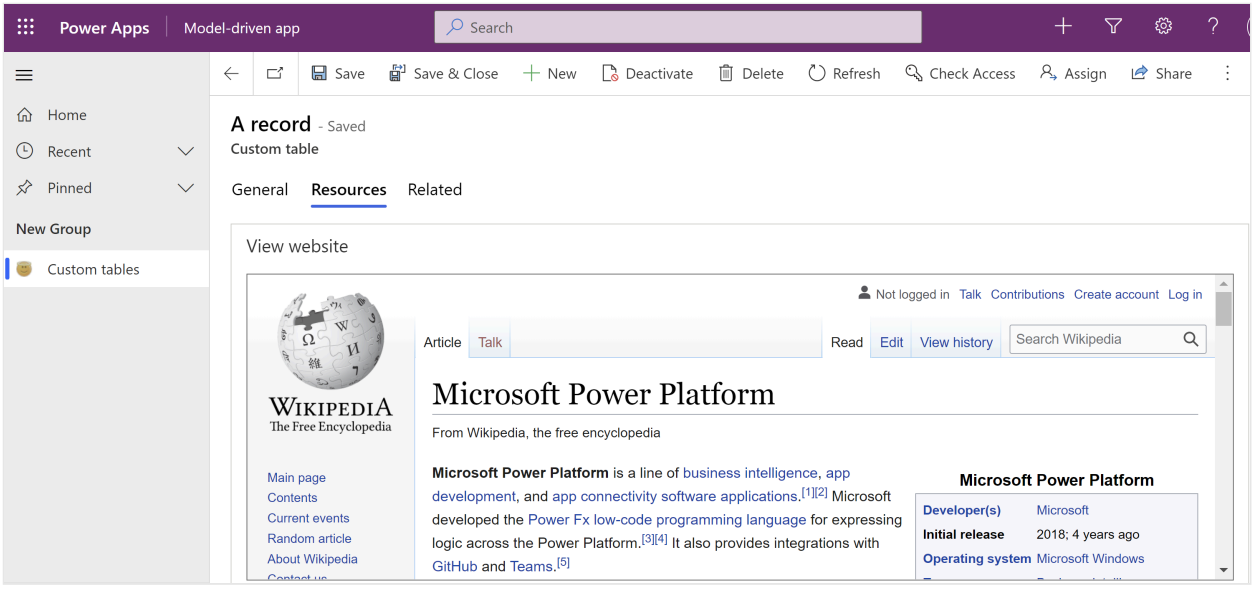
Add an iframe to a model-driven app main form

Article • 03/04/2025

With the external website component, you can add an inline frame (iframe) to a form to integrate content from another website within the form.



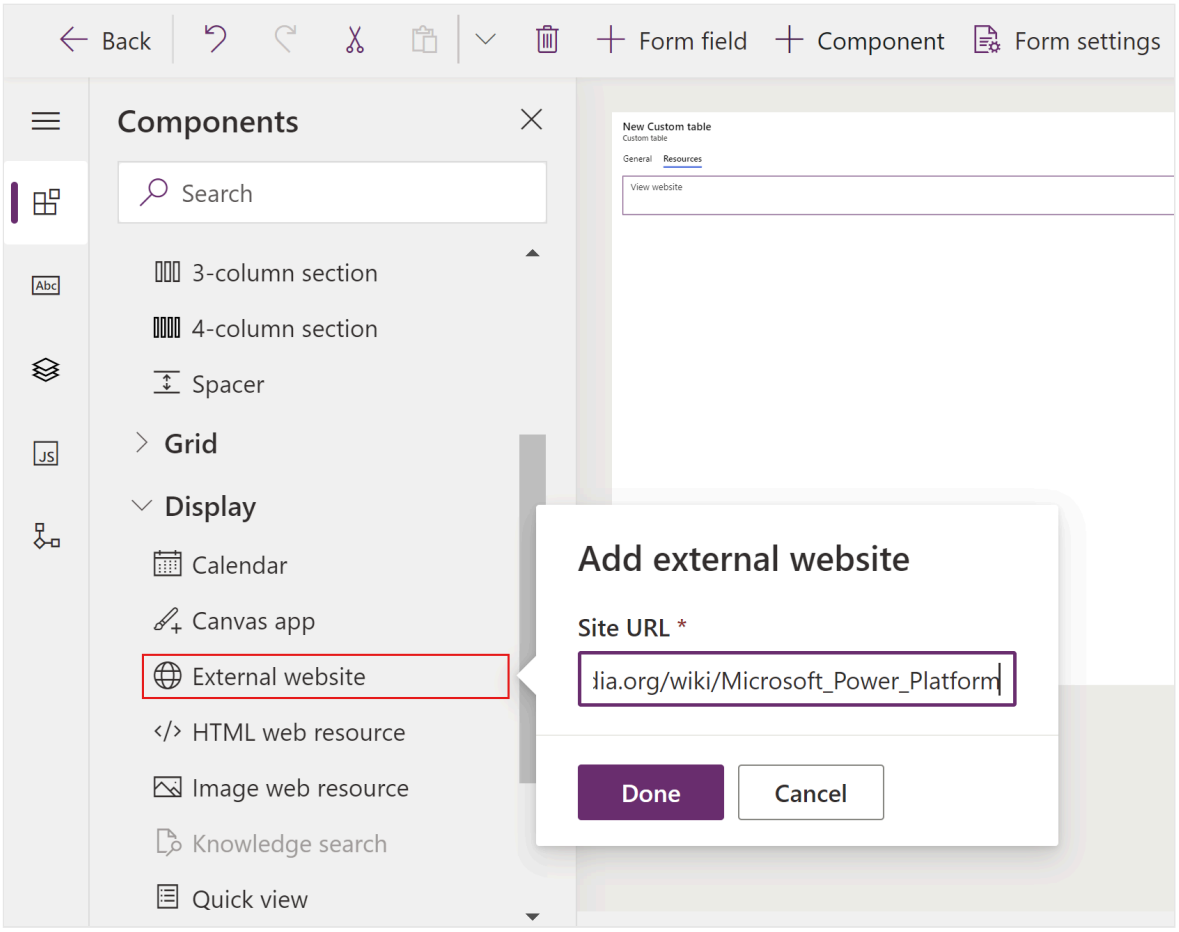
1. Select **Solutions** on the left navigation pane, open the solution you want, and then open the table that you want to edit. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select **Forms** from the **Data experiences** area.

3. In the list of forms, open a form of type **Main**.

4. In the form designer, select the section of the canvas where you want to add the iframe.

5. On the **Components** left pane, expand **Display**, select **External website**, enter the **Site URL**, and then select **Done**.



Expand table

Tab	Property	Description
Display options	Label	**Required**: A label to display for the iframe.
Display options	Name	**Required**: A unique name for the iframe. The name can contain only alphanumeric characters and underscores.
Display options	Hide label	Select if you want the label hidden.
Display options	Hide	You can hide the iframe so that it can be made visible by using scripts. More information: Visibility options
Display options	URL	**Required**: The URL for the page to display in the iframe.
Formatting	Column width	When the section containing the iframe has more than one column, you can set the column to occupy up to the number of columns that the section has.

Tab	Property	Description
Formatting	**Component height**	You can control the height of the iframe by specifying a number of rows the control occupies.
Formatting	**Use all available vertical space**	Instead of setting the height by a number of rows, you can allow the iframe height to expand to available space.
Formatting	**Scrolling**	You have three options for scrolling behavior: - **As Necessary**: Display scrollbars when the size of the iframe is larger than the available space. - **Always**: Always display scrollbars. - **Never**: Never display scrollbars.
Formatting	**Display border**	Display a border around the iframe.
Dependencies	**Table column dependencies**	An iframe might interact with columns in the form using script. If a column is removed from the form the script in the iframe might break. Add any columns referenced by scripts in the iframes to the **Table column dependencies** so that they can't be removed accidentally.
Advanced	**Restrict cross-frame scripting, where supported**	It's considered a security risk allowing pages from a different web site to interact with the app using scripts. Use this option to restrict cross frame scripting for pages you don't have control over.
Advanced	**Pass row object-type code and unique identifiers as parameters**	Data about the organization, user, and the record can be passed to the iframe. More information: Pass parameters to iframes

6. **Save** and **Publish** the form.

> **Note**
>
> - If the web page doesn't appear in the iframe, it might be because the website doesn't allow iframe rendering. When this occurs, the message *URL* **refused to connect** is displayed in the iframe at runtime.
> - Forms aren't designed to be displayed within an iframe.
> - Authentication inside an iframe, either through a redirection or popups, isn't supported on mobile.

Pass parameters to iframes

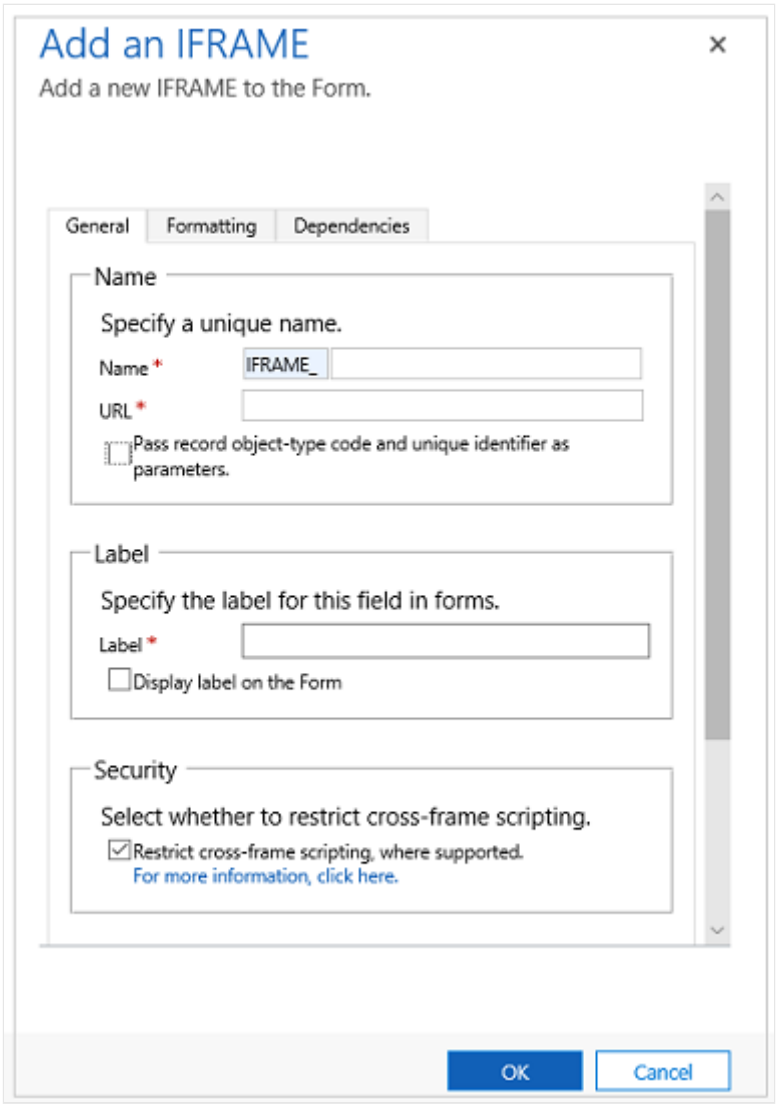
Information about the row can be passed by enabling the **Pass row object-type code and unique identifiers as parameters** option. The values passed are:

Expand table

Parameter	Description
`orglcid`	The organization default language LCID.
`orgname`	The name of the organization.
`userlcid`	The user's preferred language LCID
`type`	The table type code. This value can be different for custom tables in different organizations. Use `typename` instead.
`typename`	The table type name.
`id`	The ID value of the row. this parameter has no value until the table row is saved.

Add an iframe using the classic form designer

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane, and then open the table that you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Forms** area.
4. In the list of forms, open a form of type **Main**.
5. Select **Switch to classic** to edit the form in the classic form designer.
6. On the **Insert** tab, select **IFRAME** to view iframe properties.



Expand table

Tab	Property	Description
General	**Name**	**Required**: A unique name for the iframe. The name can contain only alphanumeric characters and underscores.
	URL	**Required**: The URL for the page to display in the iframe.
	Pass row object-type code and unique identifiers as parameters	Data about the organization, user, and the row can be passed to the iframe. More information: Pass parameters to iframes
	Label	**Required**: A label to display for the iframe.
	Display label on the Form	Whether the label should be displayed.
	Restrict cross-frame scripting, where supported	It's considered a security risk allowing pages from a different web site to interact with the Dynamics 365 application using scripts. Use this option to restrict cross frame scripting for pages you don't have control

Tab	Property	Description
		over.
	Visible by default	Showing the iframe is optional and can be controlled using scripts. More information: Visibility options
	Enable for mobile	Select the checkbox to enable the iframe for mobile.
Formatting	**Select the number of columns the control occupies**	When the section containing the iframe has more than one column, you can set the column to occupy up to the number of columns that the section has.
	Select the number of rows the control occupies	You can control the height of the iframe by specifying a number of rows the control occupies.
	Automatically expand to use available space	Instead of setting the height by a number of rows, you can allow the iframe height to expand to available space.
	Select the scrolling type for the iFrame	You have three options: - **As Necessary**: Show scrollbars when the size of the iframe is larger than the available space. - **Always**: Always show scrollbars. - **Never**: Never show scrollbars.
	Display border	Display a border around the iframe.
Dependencies	**Dependent columns**	An iframe might interact with columns in the form using script. If a column is removed from the form the script in the iframe might break. Add any columns referenced by scripts in the iframes to the **Dependent columns** so that they can't be removed accidentally.

Design productive main forms in model-driven apps

Article • 04/08/2022

Building experiences where tasks can be completed quickly and effectively is crucial to user satisfaction.

Model-driven apps provide many options to build good user experiences, including:

- Application-level options.
- Site map organization options.
- Many form-creation options.

This article shows how to design highly efficient and productive forms in a model-driven app, including how to work with:

- Main forms.
- Main form dialogs.
- Form component controls.
- Quick create forms.
- Quick view forms.

Form layout and design are important to building better forms. However, it's also important to build forms that load quickly and allow for fast navigation within the form and across tabs.

We also recommend an understanding of best practices for optimizing form performance and how to make forms load fast in your model-driven app. More information: Design forms for performance in model-driven apps

Working with main forms

Main forms are used in a model-driven app when working with and editing a specific record's data for a table to ensure that users interacting with that record stay within the constraints of the table structure.

Building around table data

A form allows an app maker to build around the table data, and often requires that you work with and interact with related records from other tables. One important consideration is how a model-driven form is bound to data. The out-of-the-box controls

for a form are bound to fields from the table. These controls allow rapid development of a form for creating and editing data, but without more customization they aren't as flexible when using a form for multiple tasks that need user input, or where additional action is required before saving information.

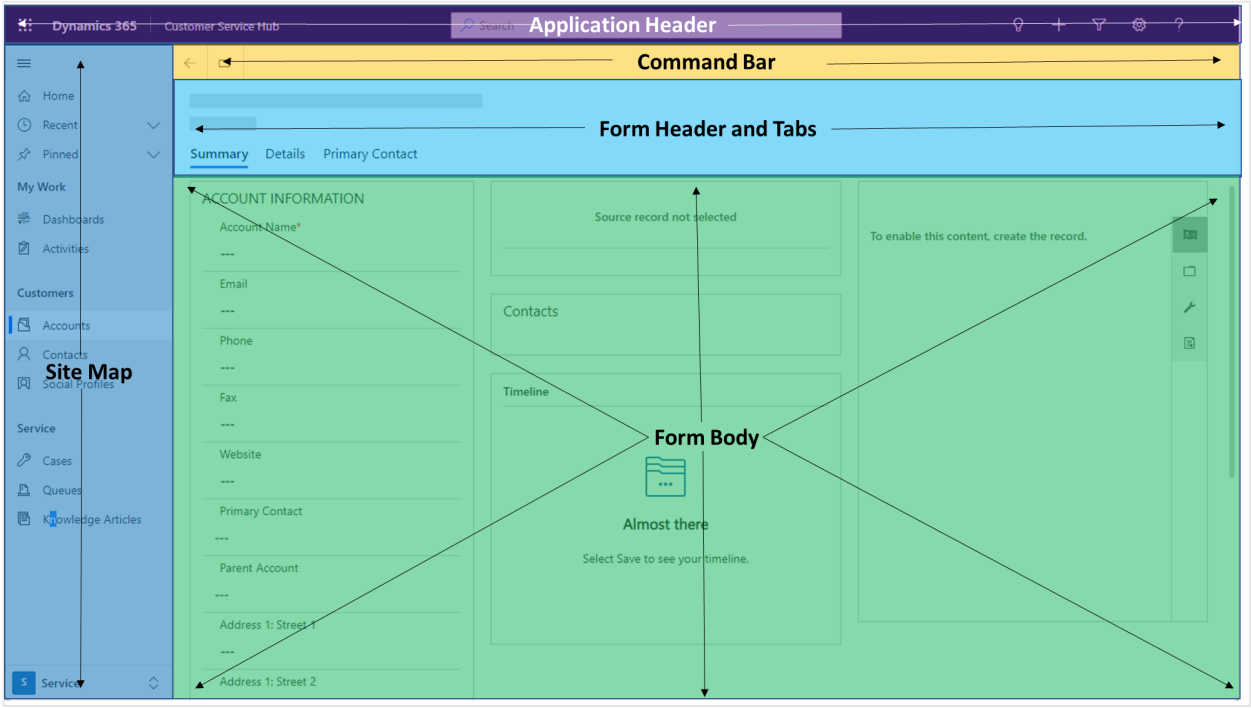
Use of related data

One of the strengths of model-driven forms is the ease of use with standard (out-of-the-box) controls like lookups, subgrids, and reference panels to quickly view or edit **related** records. Forms also support custom Power Apps component framework controls to extend functionality beyond the standard controls. Forms primarily support child or secondary data relationships for a record; they don't easily support tertiary or higher-order relationships. For example, if there is an account record that has a one-to-one or one-to-many relationship with contacts, interactions with both the parent and child data can be quickly added with a form by using lookups that interact with other forms, including a main form dialog or embedded forms like a quick view or form component control. Each of these form types will be covered in more detail later in this article.

Working with related data requires configuration, including using a main form dialog to work with related records of the main form dialog or using a custom canvas page. Multiple-entity forms can be created by using main form dialogs or form component controls. However, a main form doesn't directly support tertiary-related records on the main form.

Understanding the main form layout

The following image shows the layout of a Unified Interface application.



Visual elements that are not a part of the form

- The application header is part of the overall page structure of a model-driven app. The app header contains the application name and app-level actions, which include search, help, assistance, quick create forms, settings (personal and app level for admins), and so on.
- The application site map contains navigation across the application to pages that are included in your application. The navigation experience provided by the site map offers a quick way to access other areas of your application.
- The form command bar is also not part of the main form. It can be configured and set up by using the Ribbon Workbench community plug-in for XrmToolBox. Navigation and interaction on the form can be customized. Several out-of-the-box options include saving, creating a new record, sharing, merging, editing multiple records, and so on.

> **Note**
>
> Resources created by the community aren't supported by Microsoft. If you have questions or issues with community resources, contact the publisher of the resource.

Visual elements that are a part of the form

- The form header is part of the form. It includes the table and record name, the ability to switch to additional forms for the table, four read-only fields of the

record, and the tabs included on the form. Forms only appear in the form selector if they've been enabled and added to the app. More information: Create and design model-driven app forms.

- Form headers also have a mode where more than four fields can be added and provide a simple navigation to edit the fields in the header and any additional field you want a user to easily access from the form header. Additional tabs should be used to access information that isn't primary to the task at hand, or to focus the user on data or information that's specific to a given task but isn't primary to the job. Information that's necessary and is primary to working with data should be on the first tab and should not be hidden.
- The form body is the area on the form that should be used to interact with data of the record and any related records that are essential to completing a task. We recommend that you limit the data to the top tasks that need to be done on the first tab and move secondary tasks to additional tabs. building forms based on specific business needs and roles should also be considered when designing your application.

If some data is rarely used you should consider building another form that can be accessed when a user needs to reference that data or information.

> ⓘ **Important**
>
> **Form footers are deprecated** with the 2021 Release Wave 2 (August 2021 Preview / October 2021 GA). Remove any controls you have added out of the footer.

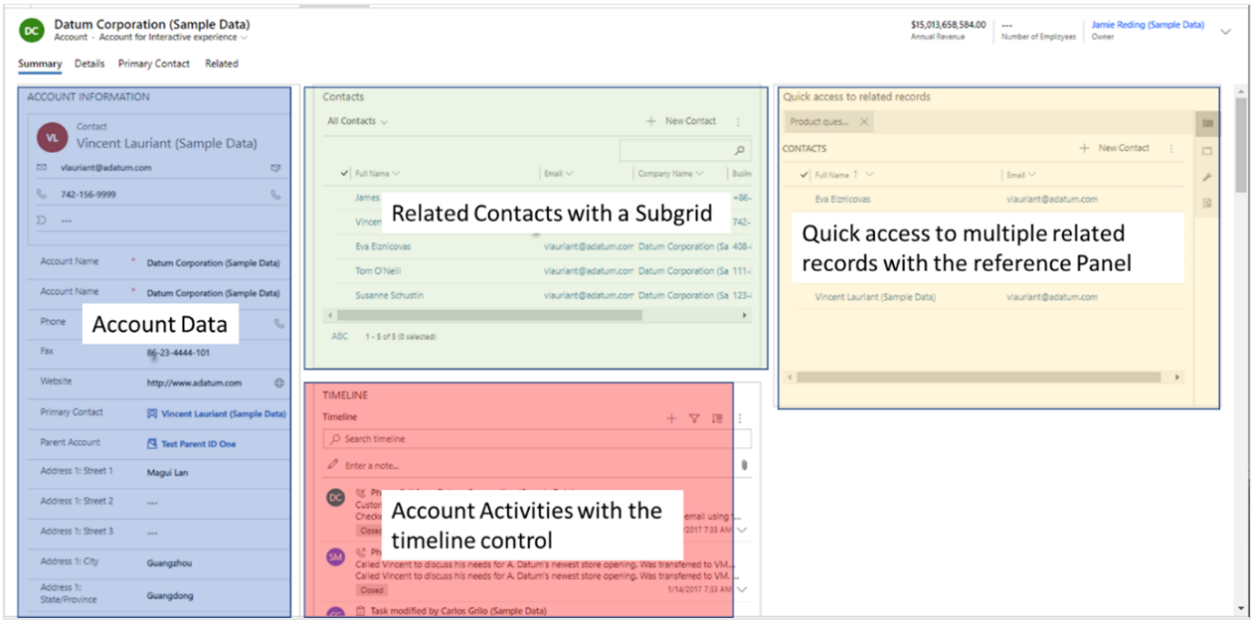
Example scenario of productive form design

The following scenario demonstrates the best use of a model-driven main form over data that uses the available controls.

Imagine a scenario where a salesperson needs to maintain data for an account that also has the following form components:

- A primary contact (lookup).
- Additional contacts (subgrid).
- A reference panel where a user can select to see lists of related records with access to read-only views (quick view) in the reference panel. The reference panel includes a timeline control that's used to quickly access and create activities for that record.

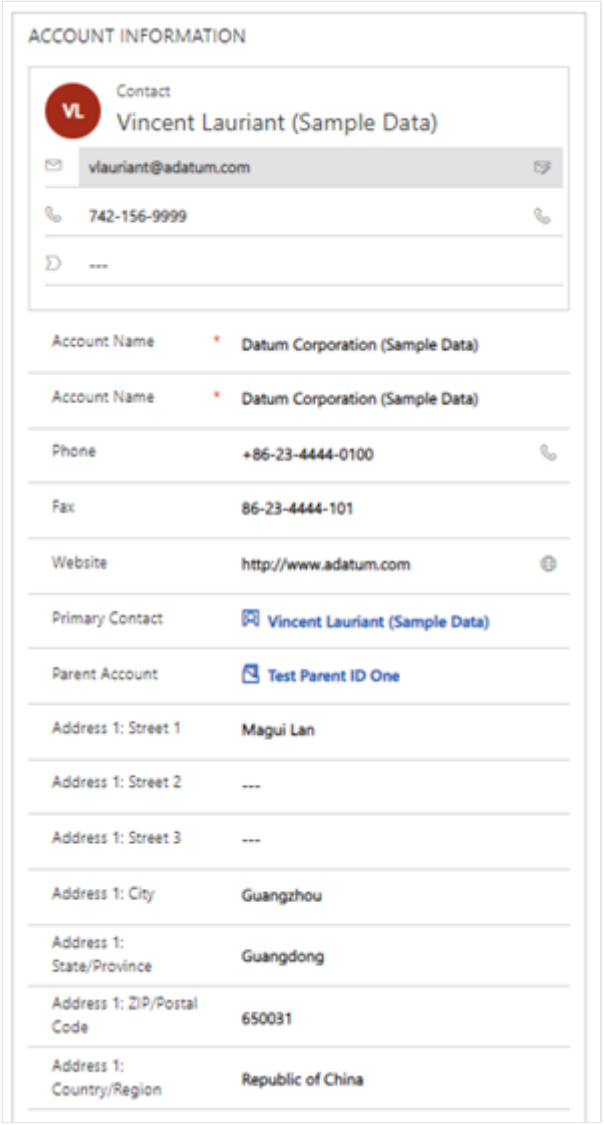
This form is in regular use, so it is worth spending time on the layout to ensure it is simple and efficient to operate.



Account data

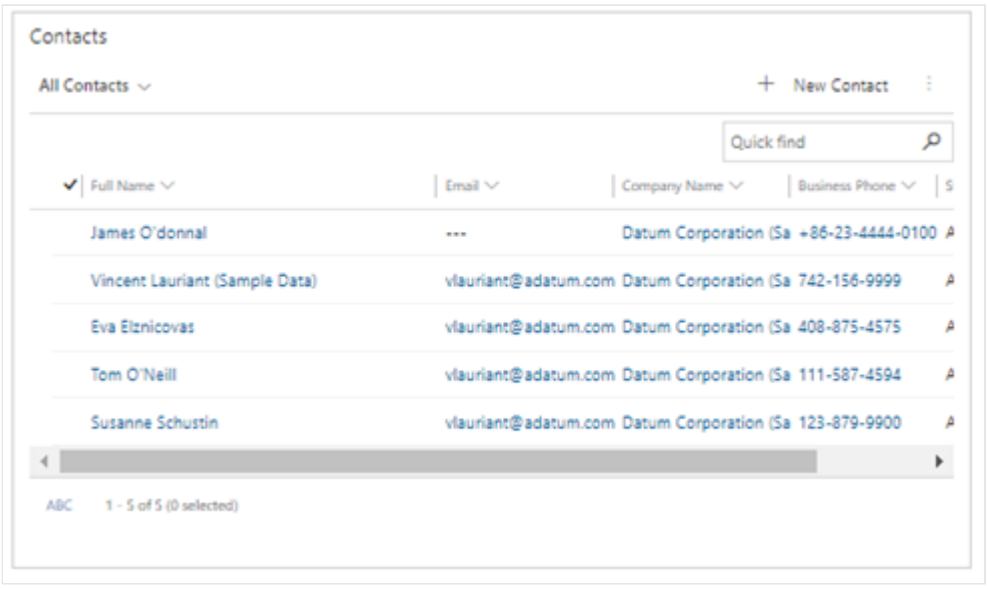
The first section on the form contains the fields that are used to manage the data and information for that record. Here, a user can quickly review and edit information they use throughout their workday. Points to note:

- Required fields and most-used fields are at the top of this section.
- A quick view form of the primary contact is added at the top so users can quickly view and use the information to contact the individual who's important for their daily tasks.



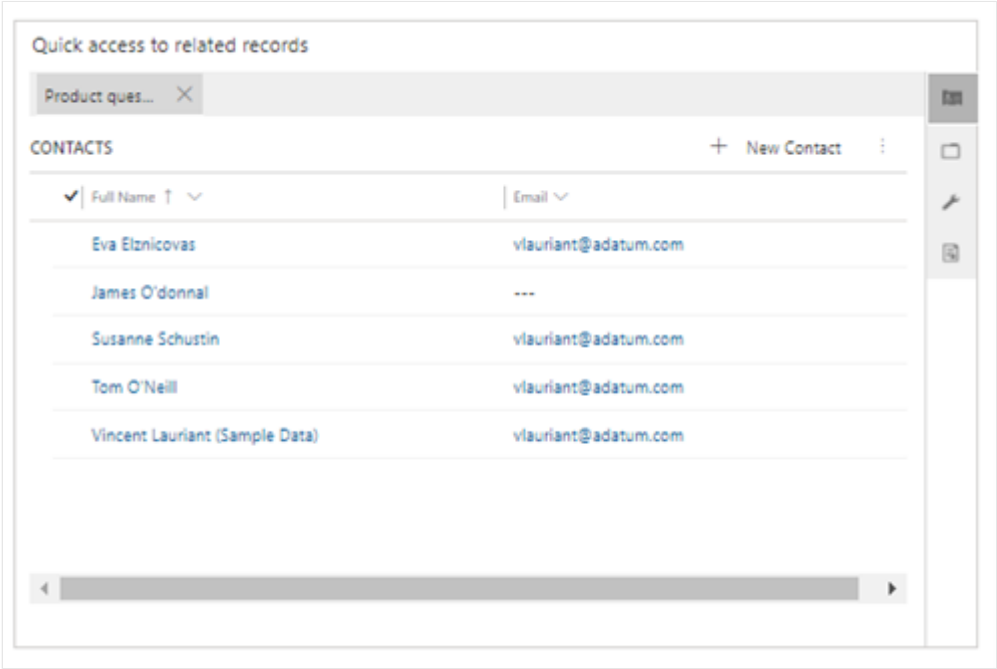
Related contacts with a subgrid

To the right of the account information section is the contact table subgrid. It shows all the contact records that are related to the main record. This allows the user speedy interaction with the contact record related to the account.

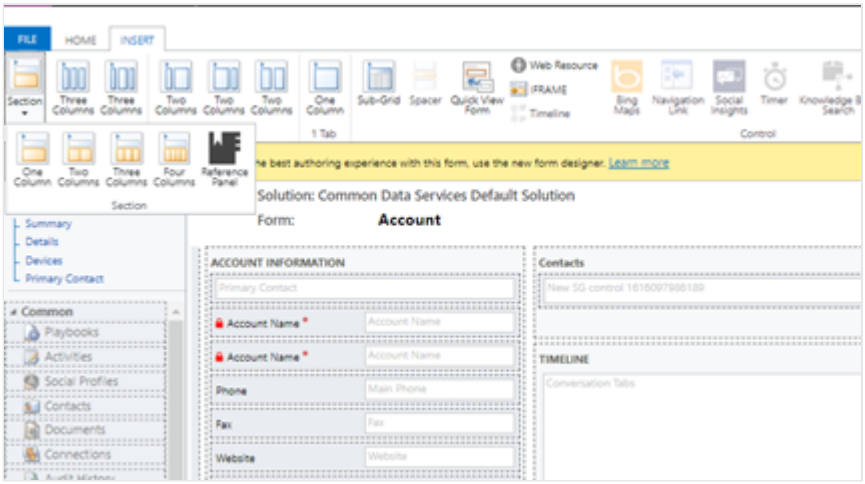


Quick access to multiple related records with the reference panel

Next to the contact subgrid is the reference panel. This control can give even further access to related records that go beyond just the contacts. A subgrid helps drive data density and efficiencies when working across all related records of the main form. In this example, the reference panel includes contacts, opportunities, leads, and products. One limitation of the reference panel is that it only provides read-only views of records. It doesn't support a main form of a related record like a main form dialog or a form component does. Reference panels are best used when you want to quickly view information of a related record.

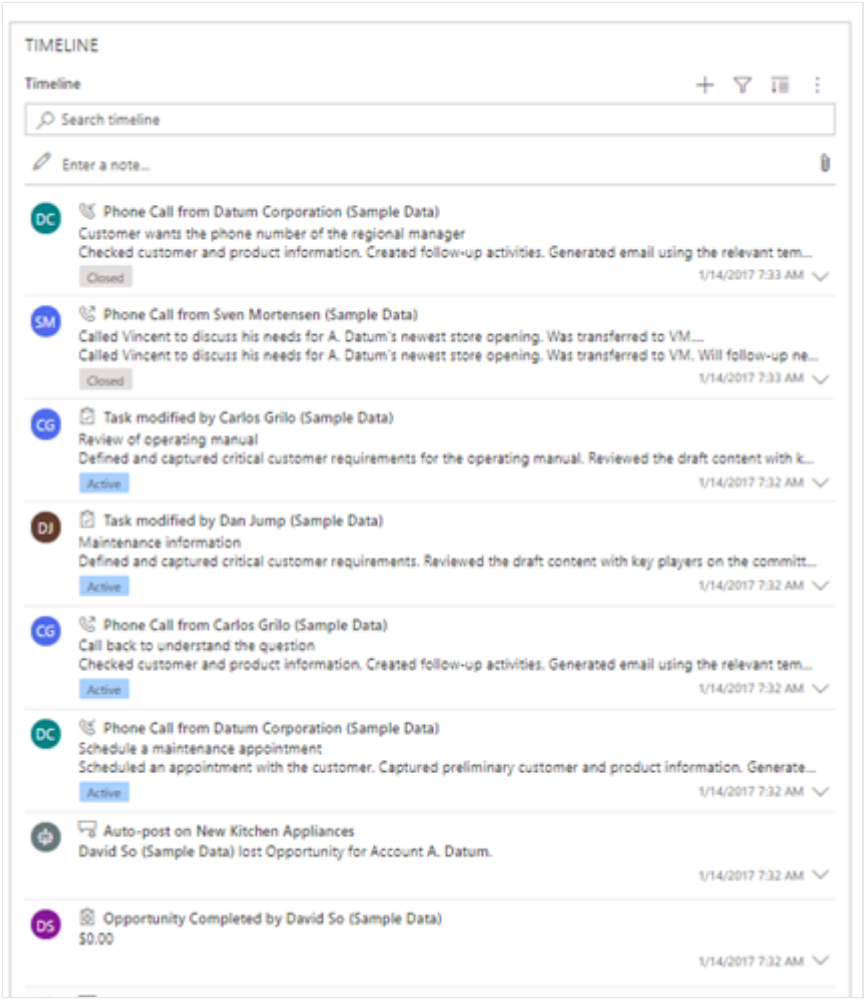


Currently, you add a reference panel control by using the classic form designer. On the **Insert** tab, expand **Sections**, and then select **Reference panel**.



Account activities with the timeline control

Below the contacts subgrid is the activities timeline wall. The timeline control allows a user to quickly view recent information about activities that have an activity record associated to the account. Available activities found in a timeline are emails, phone calls, notes, appointments, and tasks. Users can also send new emails, log new phone calls, and add notes quickly and easily from the control. More information: Set up the timeline control



Working with data on a main form best practices

- If additional requirements are added to data on the form that isn't configured on the table, it's important to make sure that the data that's required is always visible and editable—for example, a required field for a user that's based on a business rule. If a field is required and made read-only, it will block users from completing tasks and can create frustration and dissatisfaction. Although hidden and read-only components are supported by the Power Apps platform, it's important to know that if a user saves data on a form that includes a required field that isn't editable, the save will be processed. This ensures that a user is never blocked from completing a task based on a bad design pattern.

- Hidden fields can be used like read-only fields and are handy when building data-dense forms. However, the same caution applies as when working with required fields: A required field may not be hidden if it can be null when editing a record. Business rules or events can be used to hide or show fields on a form; however, the form will behave the same as a read-only field when it's being saved. Model-driven forms will always allow for the save if a field is required but hidden on the form.

- If data needs to always be available, regardless of the tab a user is on, it's vital to add that data to the header. It's important to know that the high-density headers in Unified Interface will only display up to four read-only fields. However, you can use the high-density headers with a flyout to add additional fields that also allow users to edit fields. This streamlines the experience to quickly access and edit information that you always want to make available without multiple clicks or additional navigation.

Building multiple-entity forms

The previous section provided good examples of how to work with data that's directly related to a record. However, what can drive even further efficiencies is working with related data directly from the main form, without navigating away. This keeps the user in context, and reduces friction and improves satisfaction by streamlining experiences using a main form dialog or a form component control.

The following sections walk through several scenarios that show how to build highly performant multiple-entity forms. The goal is to streamline user experiences that reduce clicks and unnecessary navigation, and speed up daily tasks that often require a user to interact with related records on a main form. Form components used for efficiency described here include:

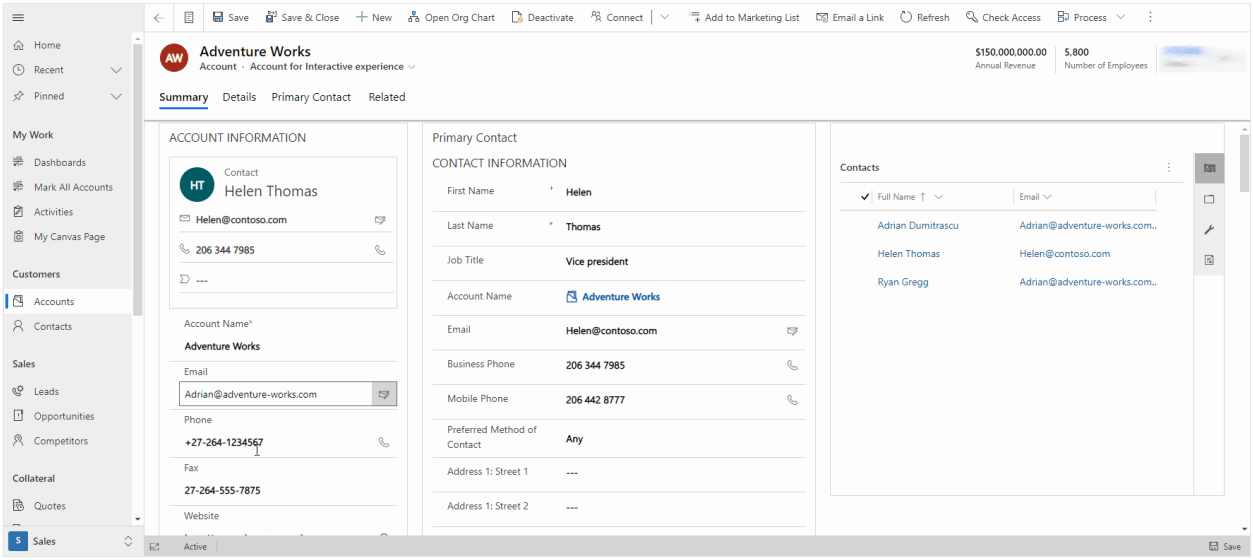
- Main form dialog.
- Main form component control.
- Quick create form.
- Quick view form.

Using a main form dialog

Using a main form dialog is powerful when you need to have users access, and—more importantly—interact with, all the information of a related record. This includes when users need to work with a business process flow, access all the tabs, or access all the related records on the form. This is important when there are business processes that drive requirements on a related record that need to be followed to ensure data integrity.

Users need access to timeline activities or related records of the child record without additional navigation. Note that a main form dialog can be configured directly from the lookup control and can be used on the command bars or with JavaScript by using the `navigateTo` client API. The dialog can be positioned on the left, middle, or right side of the page as a modal dialog overlay. More information: Open main form in a dialog using client API

In this example, a user needs to access the primary contact record, update the phone number, add a note in the activities timeline, and create a new appointment from the contact form. To streamline this experience by reducing clicks and unnecessary navigation, the lookup control is configured to open the contact main form as a dialog. This example shows how the main form dialog can use quick create forms from the related record, incorporate duplicate records, and allow the user to fully interact with data on the related record.

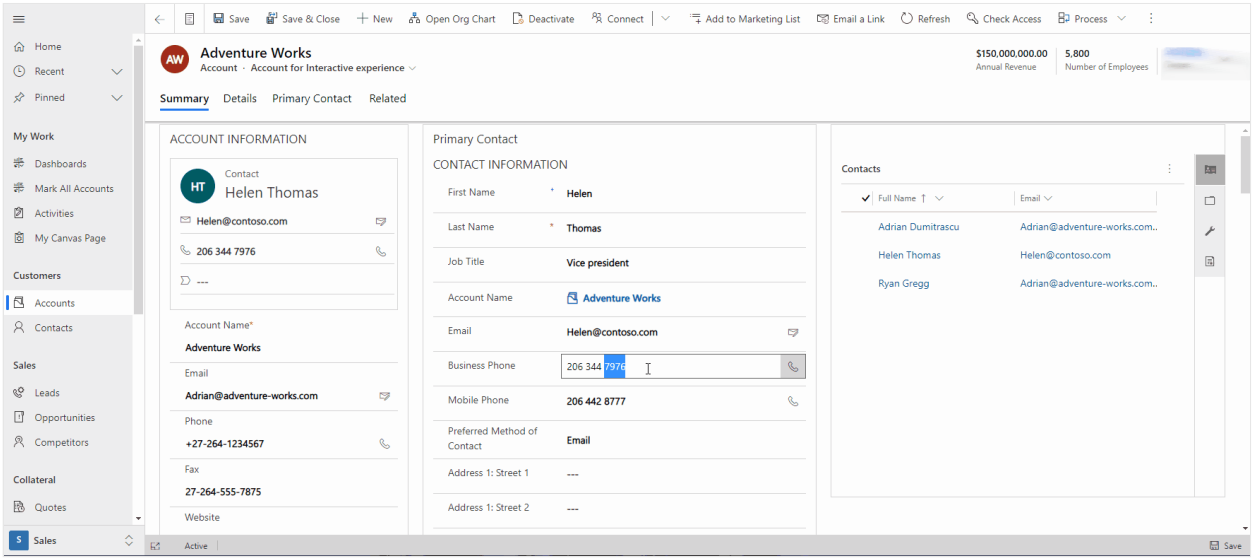


Using the form component control

Often you only need to edit information on a related record that doesn't require the user to interact with the entire form and doesn't require an additional business process flow, but you don't want to give users the ability to navigate to the related form. To accomplish this scenario and streamline managing data inline on the main form, you can use a form component control. The form component control provides the user with access to the related record, including all the sections, controls, and fields on the related record form. Form components can also be used for specific actions with forms designed for only that task. An example of this is the Microsoft Dynamics Field Service Mobile experience. Form components are used to manage work orders and tasks related to those work orders in a streamlined and more efficient process.

Note that a form component control will use any form that you've created for that record and it will honor any event, including loading a form, saving data, or on change information. It will also honor any business rules and actions on the form, including opening a main form dialog from a lookup (if you've configured the form to work in that manner). It will also include any duplicate detection rules and parent/child relationships when working with data in the related record form component. The form control component promotes unsaved changes to the main form, and notifies users when a field is required and if there are data entry errors on the related form component. More information: Edit related table records directly from another table's main form

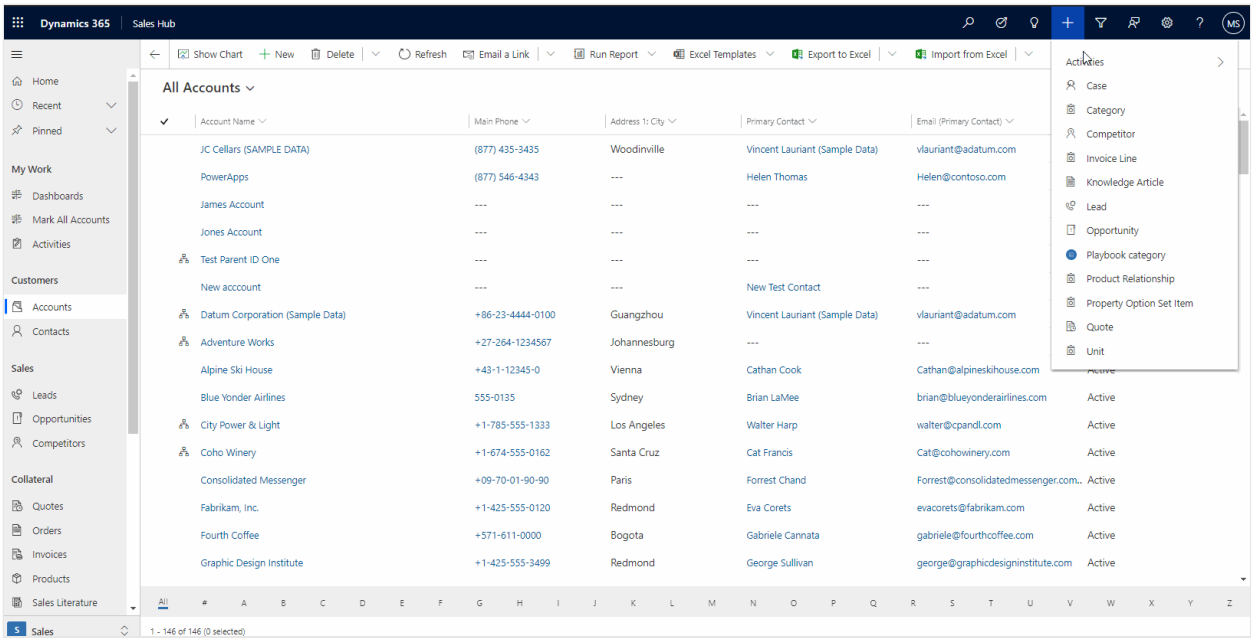
In this example, a user is editing the primary contact information directly on the account main form and scrolls down the form to create a new appointment for the primary contact without leaving the account form.



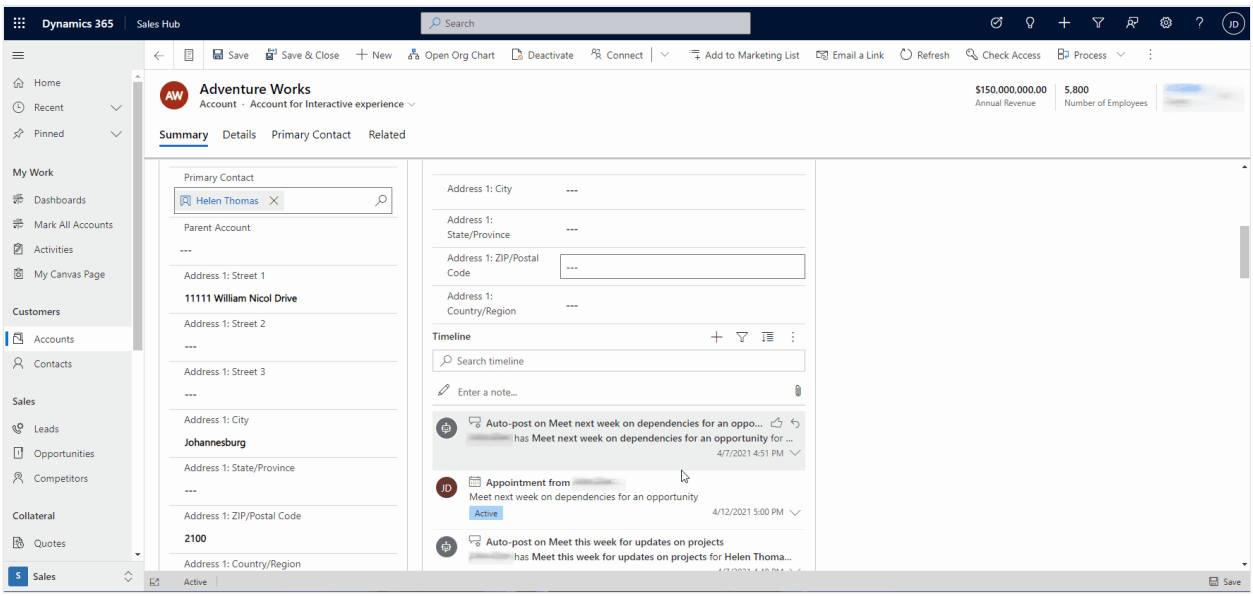
Using quick create forms

There will be times when you want to create an experience where users can quickly create records without additional navigation or clicks. A quick create form is a good solution for this. It can be used in multiple scenarios, which include creating appointments from an activity timeline wall, creating a contact from a lookup if a main form dialog isn't needed, or quickly creating a record—like an account or contact that doesn't require additional relationships for data integrity—from a view page (app menu + option). More information: Create or edit model-driven app quick create forms for a streamlined data entry experience

In the following example, a user needs to quickly create a lead by using the + menu option in the app header.

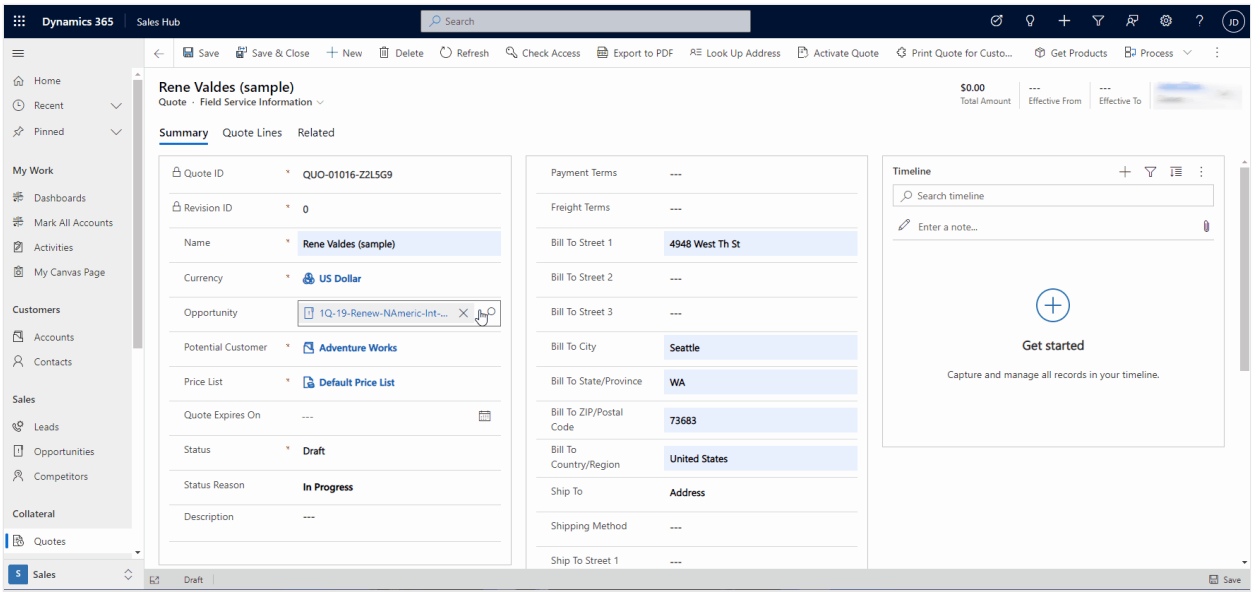


In this example, the quick create form is used to create an appointment for a contact from the timeline wall.



In this example, a user can quickly create an opportunity from a quote record form by using a lookup control.

> **Note**
>
> Opportunity and quote tables require a Dynamics 365 customer engagement app, such as Dynamics 365 Sales.

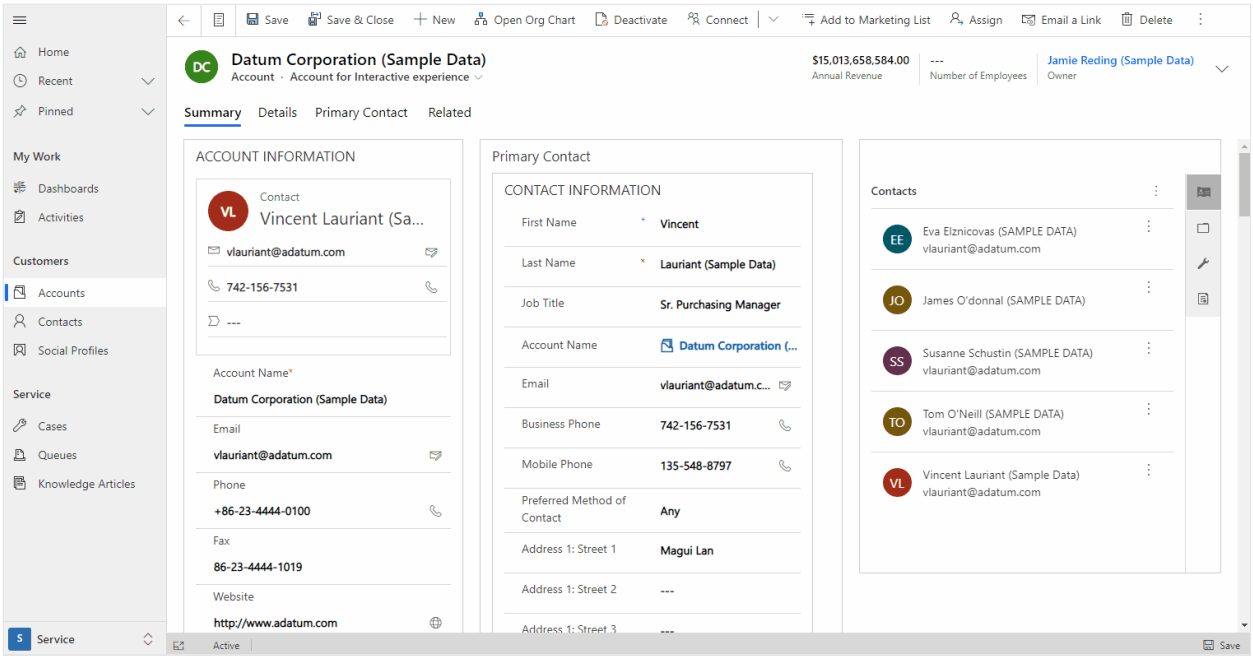


Using quick view forms to see data from related tables

In many scenarios, a user just needs to quickly view information from a related table without having to interact with it. To facilitate these scenarios, you can use quick view forms. An example of where a quick view form is used is in the reference panel of a main record. This demonstrates the power of accessing multiple related records without having to navigate away.

> **Note**
>
> While it is called a quick view form, it is in principle, a read only view of data. Users can't use this control to edit data.

More information: Create a model-driven app quick view form to view information about a related table



Using form display options to simplify forms

There are many times when you need to build an experience that focuses the user on the task at hand without additional distraction that might cause inefficiency. This is especially important when you're working with tables and records that have global components, which are created and automatically added to forms regardless of the task you're trying to build. Although this provides a shareable and easy-to-build infrastructure that drives consistency across an app, it does at times provide unnecessary distraction.

Form display options should be used when you want to lessen the number of actions, focus a user to complete a task, and reduce clutter by removing unnecessary components. Components that can be removed from a form include the command bar, the header body, and the form tabs.

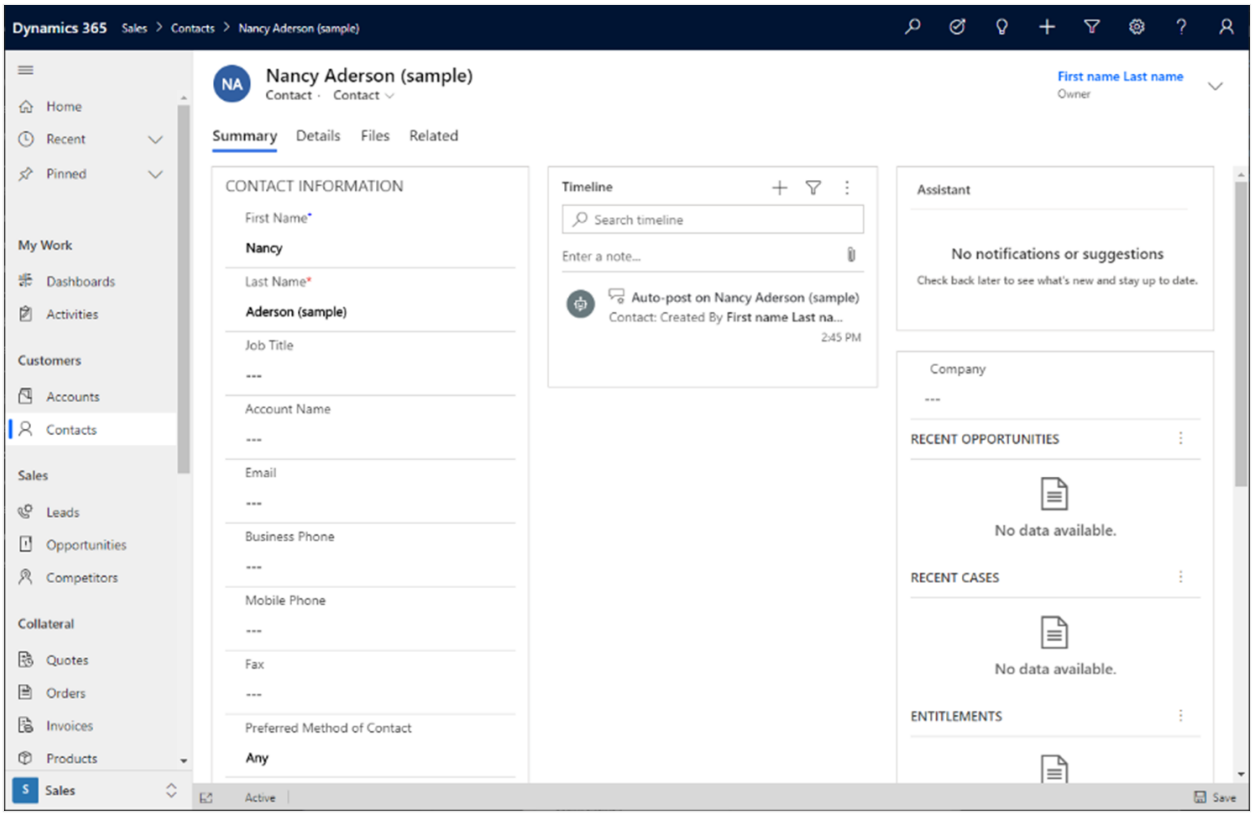
All these types of options are only available via the client API and manual formxml updates. Manual formxml manipulation can cause issues importing solutions if done incorrectly. Remove global form components carefully when designing your form.

Navigation considerations

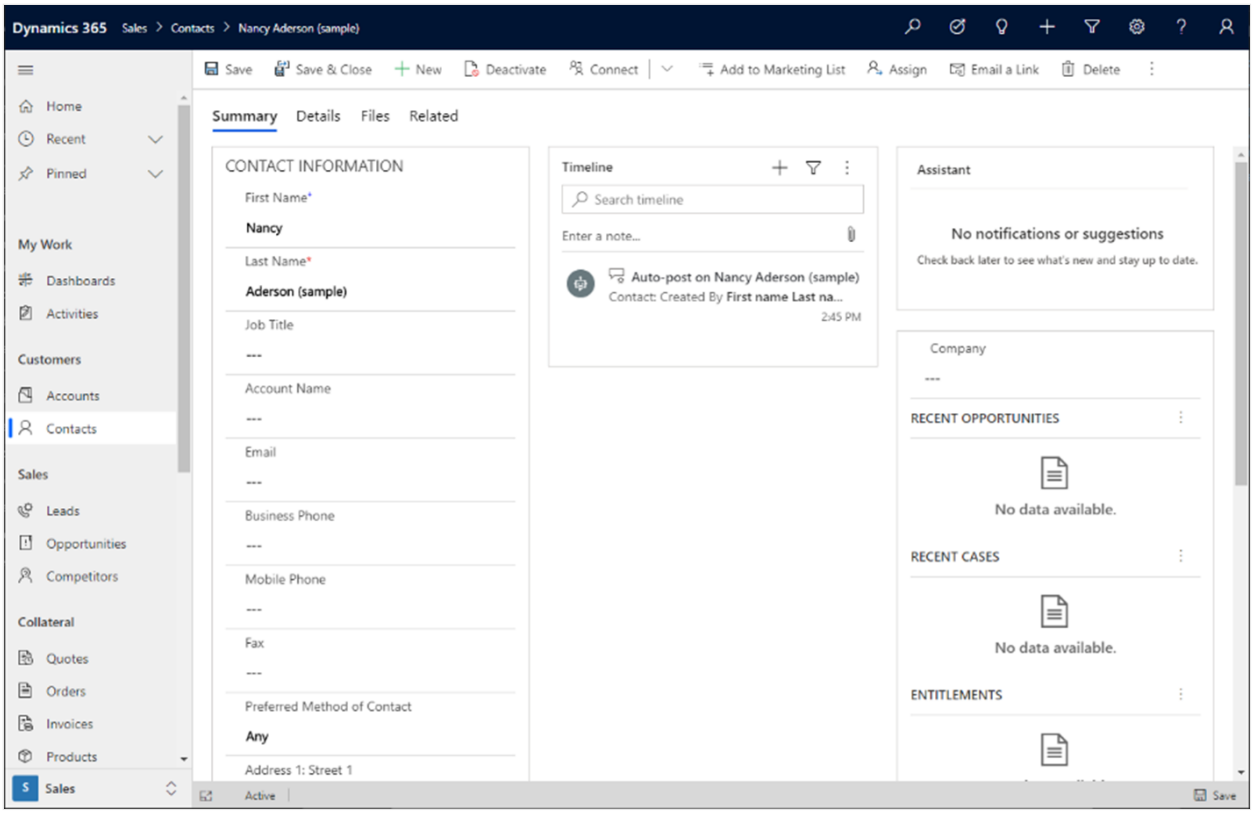
When certain components are hidden like the command bar or the tab list, this may remove navigation that might be necessary to complete a task. Be sure to account for those requirements in your form design by using additional controls created with the Power Apps component framework.

In this example, the **command bar** has been removed to reduce any unnecessary actions when working with an account. The command bar would ordinarily be shown as follows.

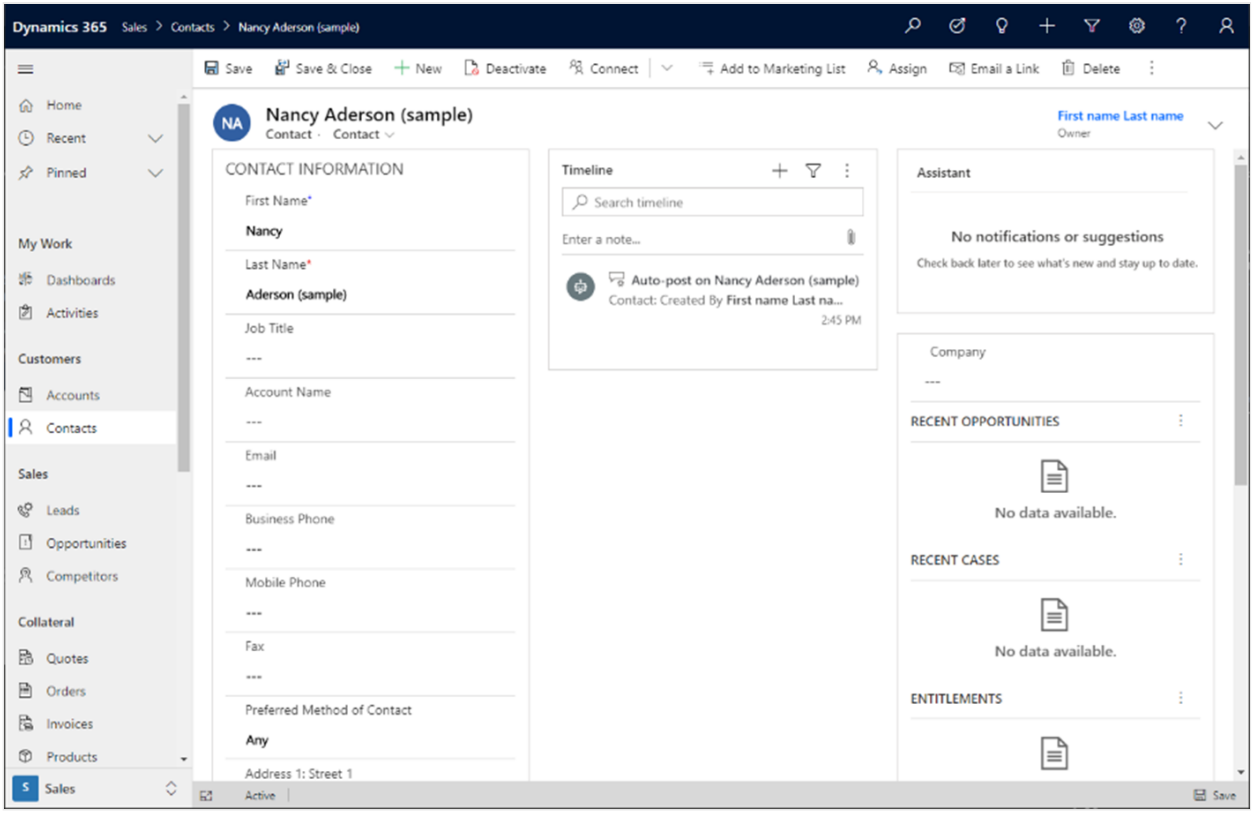
This form has been designed to not need the command bar, so the maker has removed it to keep the user on task. More information: setCommandBarVisible (Client API reference)



In this example, the header has been removed to promote a dense form that focuses the user on record details. This should only be used if the header doesn't provide additional value or displays information that doesn't always need to be available to a user. More information: setBodyVisible (Client API reference)



In this example, the tabs have been removed. This can be helpful when you build a form that only has a single tab or you want to focus the user on the first tab of a form without the distractions of additional tabs that can lead to loss in productivity for a specific task. More information: setTabNavigatorVisible (Client API reference)



Form display option to use the entire space of a tab

In many scenarios, a form might exist with a tab and a single control, and you want that control to take up the entire available space within the body of the form on that tab. This can be done by using the **form display option** that allows the first control on a page in a tab to expand the full height and width of the form. All existing reflow rendering across view port sizes from large to small is honored, and will behave like a regular form except that the control will use the entire space. In this example, the Dynamics 365 Marketing application supports a full tab layout for the customer journey experience. The command bar is removed to further reduce clutter and ensure that the user is focused on the task of managing customer journeys in the application. More information: setContentType (Client API reference)

Design forms for performance

Design forms for performance in model-driven apps

Article • 03/04/2022

Building experiences where tasks can be completed quickly and efficiently is crucial to user satisfaction. Model-driven apps can be highly customized to create experiences that meet the needs of your users, but it is important to know how to effectively code, build, and run model-driven apps that load quickly when a user opens and navigates in your app while working on daily tasks. Performance has been shown to be a key driver of dissatisfaction of an app when it is not optimized for performance.

Intelligent customizations and performant forms are important aspects to building highly efficient and productive forms. It's also important to make sure you're building highly productive forms with the best practices in user interface design and layout. For information about designing forms for efficiency and productivity, see Design productive main forms in model-driven apps.

It is also important to ensure users are on recommended and supported devices and minimum required specifications. More information: Supported web browsers and mobile devices

Working with data and tabs

This section covers how controls that display data and tabs impact form performance.

Significance of the default tab

The default tab is the first expanded tab on a form. It plays a special role in the loading of a form page. By design, the controls of the default tab are always rendered when opening a record. Specifically, the control initialization logic, such as data retrieval, is invoked for every control on the tab.

In contrast, a secondary tab does not perform this initialization on its controls when the form is initially loaded. Instead, the control initialization occurs at the time the secondary tab is opened either through user interaction or calling the `setFocus` client API method. This provides an opportunity to shelter the initial form load from excessive control processing by placing certain controls in secondary tabs instead of the default tab. Thus, the control placement strategy can have a significant effect on the responsiveness of the initial form load. A more responsive default tab provides a better

overall experience for modifying important fields, interacting with the command bar, and exploring other tabs and sections.

Always put controls that are used the most at the top of your default tab. Layout and information architecture is not only important for performance but also to improve productivity when users interact with data on the form. More information: Design productive main forms in model-driven apps

Data-driven controls

Controls that require extra data beyond the primary record produce the most strain on form responsiveness and loading speed. These controls fetch data over the network and often involve a waiting period (seen as progress indicators) because it can take time to transmit the data.

Some of the data-driven controls include:

- Quick view form
- Subgrid
- Timeline
- Assistant (requires Dynamics 365 Sales Insights)

Keep only the most frequently used of these controls on the default tab. The remaining data-driven controls should be distributed into secondary tabs to allow the default tab to load quickly. Furthermore, this layout strategy reduces the chance of fetching data that ends up being unused.

There are other controls that are less impactful than the data-driven controls but can still participate in the above layout strategy in order to achieve the best performance. These controls include:

- Lookup
- iFrame
- Web resource

Web browser

This section covers good practices to use with web browsers.

Don't open new windows

The `openForm` client API method allows a parameter option to display a form in a new window. Don't use this parameter or set it to false. Setting it to false will ensure the `openForm` method performs the default behavior of displaying the form using the existing window. It is also possible to directly call the `window.open` JavaScript function from a custom script or another application; however, this should also be avoided. Opening a new window means that all of the page resources need to be fetched and loaded from scratch since the page is unable to leverage the in-memory data caching capabilities between a previously loaded form and the form in a new window. As an alternative to opening new windows, consider using the multisession experience that allows records to be opened in multiple tabs while still maximizing the performance benefits of client caching.

Use modern browsers

Using the most up-to-date web browser is key to ensuring your model-driven app runs as fast as possible. The reason for this is that many of the performance improvements can only be used in the newer modern browsers.

For example, if your organization has older versions of Firefox, non-Chromium-based browsers, and so on, many of the performance gains that are built into a model-driven app will not be available in the older browser versions because they don't support features that the app depends on to run quickly and smoothly.

In most cases, you can expect to see page load improvements by just switching to Microsoft Edge, updating to the latest current browser version from an older version, or moving to a modern Chromium-based browser.

JavaScript customization

This section covers how to make intelligent customizations when you use JavaScript that help you build performant forms and pages in a model-driven app.

Using JavaScript with forms

The ability for forms to be customized by JavaScript provides professional developers great flexibility over how a form looks and behaves. The improper use of this flexibility can negatively impact form performance. Developers should use the following strategies to maximize form performance when implementing JavaScript customizations.

Use asynchronous network requests when requesting data

Request data asynchronously rather than synchronously when extra data is necessary for customizations. For events that support waiting for asynchronous code like the form `OnLoad` and form `OnSave` events, event handlers should return a `Promise` in order for the platform to wait until the `Promise` is settled. The platform will show an appropriate UI while the user waits for the event to complete.

For events that do not support waiting for asynchronous code, like the form `OnChange` event, you can use a workaround to stop interaction with a form while the code is doing an asynchronous request by using `showProgressIndicator`. This is better than using synchronous requests because users will still be able to interact with other parts of the application as a progress indicator is displayed.

Here's an example using asynchronous code in synchronous extension points.

JavaScript

```
//Only do this if an extension point does not yet support asynchronous code
try {
    await Xrm.WebApi.retrieveRecord("settings_entity", "7333e80e-9b0f-49b5-
92c8-9b48d621c37c");
    //do other logic with data here
} catch (error) {
    //do other logic with error here
} finally {
    Xrm.Utility.closeProgressIndicator();
}

// Or using .then/.finally
Xrm.Utility.showProgressIndicator("Checking settings...");
Xrm.WebApi.retrieveRecord("settings_entity", "7333e80e-9b0f-49b5-92c8-
9b48d621c37c")
    .then(
        (data) => {
            //do other logic with data here
        },
        (error) => {
            //do other logic with error here
        }
    )
    .finally(Xrm.Utility.closeProgressIndicator);
```

You should be careful when using asynchronous code in an event handler that does not support waiting for asynchronous code. This is particularly true for code that needs an action to be taken or handled on the resolution of the asynchronous code. Asynchronous code can cause issues if the resolution handler expects the application context to remain the same as it was when the asynchronous code was started. Your

code should check that the user is in the same context after each asynchronous continuation point.

For example, there may be code in an event handler to make a network request and change a control to be disabled based on the response data. Before the response from the request is received, the user may have interacted with the control or navigated to a different page. Because the user is on a different page, the form context may not be available, which might lead to errors, or there might be other undesired behavior.

Async support in form OnLoad and form OnSave events

The form `OnLoad` and `OnSave` events support handlers that return promises. The events will wait for any promises returned by a handler to resolve, up to a timeout period. This support can be enabled via app settings.

More information:

- Form OnLoad
- Form OnSave
- Interact with HTTP and HTTPS resources asynchronously

Limit the amount of data requested during form load

Only request the minimum amount of data that is necessary to perform business logic on a form. Cache the data that is requested as much as possible, especially for data that doesn't change often or doesn't need to be fresh. For example, imagine there is a form that requests data from a *setting* table. Based on data in the setting table, the form might choose to hide a section of the form. In this case, the JavaScript can cache data in `sessionStorage` so that data is only requested once per session (`onLoad1`). A stale-while-revalidate strategy might also be used where the JavaScript uses the data from `sessionStorage` while requesting data for the next navigation to the form (`onLoad2`). Finally, a deduplication strategy could be used in case a handler is called multiple times in a row (`onLoad3`).

JavaScript

```
const SETTING_ENTITY_NAME = "settings_entity";
const SETTING_FIELD_NAME = "settingField1";
const SETTING_VALUE_SESSION_STORAGE_KEY =
`${SETTING_ENTITY_NAME}_${SETTING_FIELD_NAME}`;

// Retrieve setting value once per session
async function onLoad1(executionContext) {
    let settingValue =
```

```
sessionStorage.getItem(SETTING_VALUE_SESSION_STORAGE_KEY);

    // Ensure there is a stored setting value to use
    if (settingValue === null || settingValue === undefined) {
        settingValue = await requestSettingValue();
    }

    // Do logic with setting value here
}

// Retrieve setting value with stale-while-revalidate strategy
async function onLoad2(executionContext) {
    let settingValue =
sessionStorage.getItem(SETTING_VALUE_SESSION_STORAGE_KEY);

    // Revalidate, but only await if session storage value is not present
    const requestPromise = requestSettingValue();

    // Ensure there is a stored setting value to use the first time in a
session
    if (settingValue === null || settingValue === undefined) {
        settingValue = await requestPromise;
    }

    // Do logic with setting value here
}

// Retrieve setting value with stale-while-revalidate and deduplication
strategy
let requestPromise;
async function onLoad3(executionContext) {
    let settingValue =
sessionStorage.getItem(SETTING_VALUE_SESSION_STORAGE_KEY);

    // Request setting value again but don't wait on it
    // In case this handler fires twice, don’t make the same request again
if it is already in flight
    // Additional logic can be added so that this is done less than once per
page
    if (!requestPromise) {
        requestPromise = requestSettingValue().finally(() => {
            requestPromise = undefined;
        });
    }

    // Ensure there is a stored setting value to use the first time in a
session
    if (settingValue === null || settingValue === undefined) {
        settingValue = await requestPromise;
    }

    // Do logic with setting value here
}

async function requestSettingValue() {
```

```
    try {
        const data = await Xrm.WebApi.retrieveRecord(
            SETTING_ENTITY_NAME,
            "7333e80e-9b0f-49b5-92c8-9b48d621c37c",
            `?$select=${SETTING_FIELD_NAME}`);
        try {
            sessionStorage.setItem(SETTING_VALUE_SESSION_STORAGE_KEY,
data[SETTING_FIELD_NAME]);
        } catch (error) {
            // Handle sessionStorage error
        } finally {
            return data[SETTING_FIELD_NAME];
        }
    } catch (error) {
        // Handle retrieveRecord error
    }
}
```

Use information available in the client API rather than make requests. For example, rather than request a user's security roles on form load, you can use getGlobalContext.userSettings.roles.

Load code only when it's needed

Load as much code as needed for events for a particular form. If you have code that is only for *form A* and *form B*, it shouldn't be included in a library that is loaded for *form C*. It should be in its own library.

Avoid loading libraries in the `OnLoad` event if they are only used for the `OnChange` or `OnSave` events. Instead, load them in those events. This way the platform can defer loading them until after the form loads. More information: Optimize form performance

Remove usage of console APIs in production code

Don't use the console API methods such as `console.log` in production code. Logging data to the console can significantly increase memory demand and might prevent data from being cleaned up in memory. This can lead to the app becoming slower over time and eventually crashing.

Avoid memory leaks

Memory leaks in your code can lead to slower performance over time and eventually cause your app to crash. Memory leaks occur when the application fails to release

memory when no longer needed. With all customizations and code components on your form, you should:

- Thoroughly consider and test scenarios for anything responsible for cleaning up memory, like classes responsible for managing lifecycle of objects.
- Cleanup all event listeners and subscriptions, especially if it's on the `window` object.
- Cleanup all timers like `setInterval`.
- Avoid, limit, and cleanup references to global or static objects.

For custom control components, cleanup can be done in the destroy method.

For more information on fixing memory problems, go to this Edge developer documentation.

Tools you can use to help make apps performant

This section describes the tools that can help you understand performance issues and offer recommendations about how to optimize your customizations in model-driven apps.

Performance insights

Performance insights is a self-service tool for enterprise app makers that analyzes runtime telemetry data and provides a prioritized list of recommendations to help improve the performance of model-driven apps. This feature provides a daily set of analytic insights related to the performance of a Power Apps model-driven or customer engagement app, such as Dynamics 365 Sales or Dynamics 365 Service, with recommendations and actionable items. Enterprise app makers can view detailed performance insights at an app-level in Power Apps. More information: What are performance insights? (preview)

Solution checker

Solution checker is a powerful tool that can analyze client and server customizations for performance or reliability issues. It can parse client-side JavaScript, form XML, and .NET server-side plug-ins and give targeted insights into what may slow end users down. We recommend that you run solution checker each time you publish changes in a development environment, so that any performance concerns are surfaced before

reaching end users. More information: Use solution checker to validate your model-driven apps in Power Apps

Some examples of performance-related issues found with solution checker:

- il-specify-column. Avoid selecting all columns via Dataverse query APIs.
- web-use-async. Interact with HTTP and HTTPS resources asynchronously.
- web-avoid-ui-refreshribbon. Avoid using `refreshRibbon` in form `OnLoad` and `EnableRule`.

Object checker

Object checker runs real-time diagnostics on component objects within your solution. If issues are detected, a recommendation is returned that describes how to fix the issue. More information: Use object checker to diagnose a solution component (preview)

Next steps

Design productive main forms in model-driven apps

Embed a Power BI report in a model-driven app main form

You can use Power BI reports in Power Apps model-driven apps to bring rich reporting and analytics to your main forms and empower your users to accomplish more. This unlocks the power to aggregate data across systems, and tailor it down to the context of a single record.

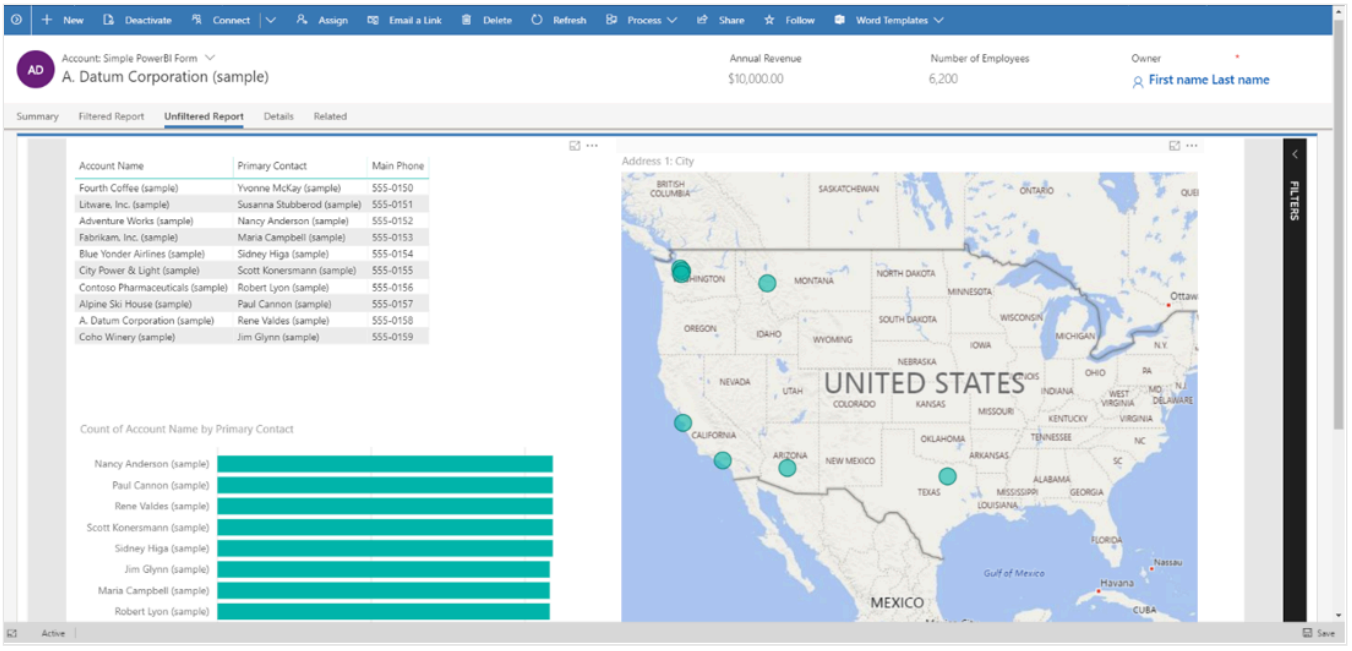
Prerequisites

Embedding Power BI content is an optional feature and is disabled on all environments by default. You must enable it before you can embed Power BI content. More information: Enable Power BI visualizations in the organization.

This feature requires exporting a solution, modifying it to replace the XML snippet, and then importing back into the environment. Be sure to import the changes on your development environment via an unmanaged solution only. Go to Import, update, and export solutions for guidance on installing an update to an existing unmanaged solution.

Embed without contextual filtering

You can use Power BI reports by embedding them, and get the exact same report. This doesn't involve contextualizing them to the current model-driven form, and hence you get the same report on all records of the table. For example, the following report shows the geographic location of all accounts at once, and is useful to show summary information.

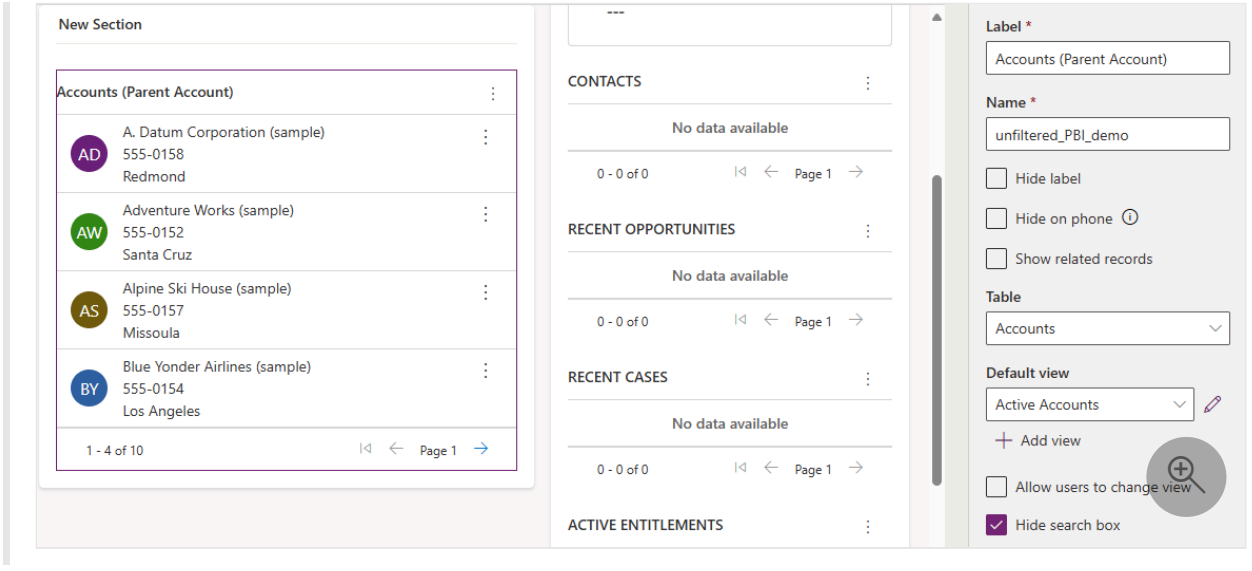


You can customize a main form XML `controls` node so that it can host an embedded Power BI report and tile by following these steps:

1. In your development environment, create a solution and add the table that contains the main form where you want the embedded Power BI report to display. Choose the **Select components** option when you add the table to the solution. Then, add just the table's main form.

2. Edit the table's main form in your solution and add a placeholder subgrid where you want to embed your Power BI report.

    - Update the label and name of your subgrid in the form designer.



3. Export the solution as unmanaged and extract all files in the solution package zip file. Then, edit the customizations.xml file and find the name of your subgrid. Replace the XML

code provided inside the `<control>` block in the customizations.xml file. The `rowspan` in the parent `cell` node can be adjusted to change the size of the embedded Power BI report.

XML

```
<cell id="{7d18b61c-c588-136c-aee7-03e5e74a09a1}" showlabel="true"
rowspan="20" colspan="1" auto="false" solutionaction="Added">
 <labels>
    <label languagecode="1033" description="Accounts (Parent Account)"/>
 </labels>
 <control id="unfilteredreport" classid="{8C54228C-1B25-4909-A12A-
F2B968BB0D62}">
    <parameters>
        <PowerBIGroupId>00000000-0000-0000-0000-000000000000</PowerBIGroupId>
        <PowerBIReportId>544c4162-6773-4944-900c-
abfd075f6081</PowerBIReportId>
        <TileUrl>https://app.powerbi.com/reportEmbed?reportId=544c4162-6773-
4944-900c-abfd075f6081</TileUrl>
    </parameters>
 </control>
</cell>
```

> **Important**
>
> Be sure to use the control `classid="{8C54228C-1B25-4909-A12A-F2B968BB0D62}"` as indicated in the XML sample.

- Make the following changes to the form XML that you copied into the customizations.xml file for your Power BI report. This table describes the values you need to change to the elements in the previous XML sample.

Expand table

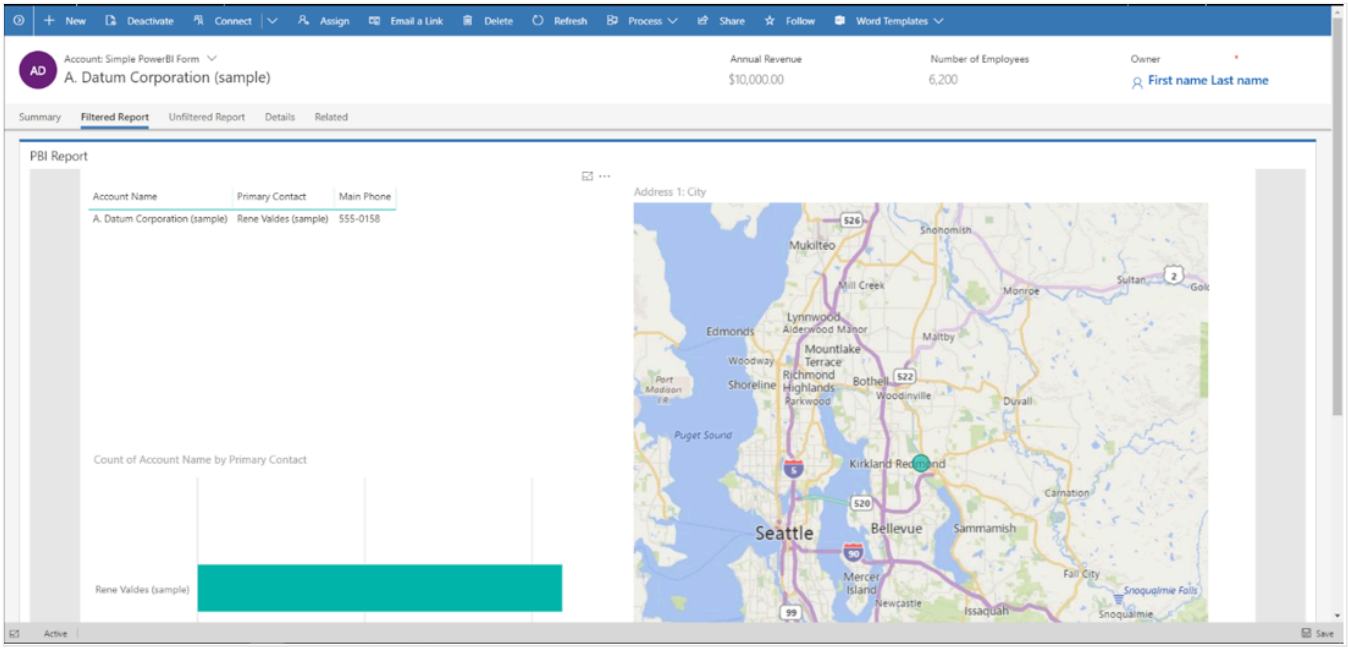
Property	Description
PowerBIGroupId	The Power BI workspace ID. If your report is in **My workspace**, then the workspace ID is 00000000-0000-0000-0000-000000000000. Otherwise, add the workspace ID. You can find the ID of the workspace in the Power BI service URL. More information: Find the Power BI workspace and report Ids.
PowerBIReportId	The Power BI report ID. Replace this with the report that you want to embed. You can find the ID of your report in the Power BI service URL. More information: Find the Power BI workspace and report Ids

Property	Description
TileUrl	The Power BI report URL that you want to embed. Be sure to use the correct Power BI subdomain name (you might need to replace app.powerbi.com with your own) and report ID (replace *reportId=544c4162-6773-4944-900c-abfd075f6081* with your own). For example, `https://app.powerbi.com/reportEmbed?reportId=544c4162-6773-4944-900c-abfd075f6081`.

4. Create a zip file out of all the solution files previously extracted. Then, import the solution into the development environment.

Embed with contextual filtering

You can make Power BI reports more meaningful by applying contextual filters to the current model-driven form, so that the report is filtered based on attributes of the current row. For example, the following report shows the geographic location of an account, by filtering the Power BI report using the account name. This allows a single report to show contextualized information for all rows of the table.



The filtering is done by adding a `<PowerBIFilter>` element in the `<parameter>` block as shown here. You can use any attribute of the form's table to construct the filter expression. More information: Constructing Filters to understand how to create your own filters.

XML

```
<control id="filteredreport" classid="{8C54228C-1B25-4909-A12A-F2B968BB0D62}">
    <parameters>
        <PowerBIGroupId>00000000-0000-0000-0000-000000000000</PowerBIGroupId>
```

```
        <PowerBIReportId>544c4162-6773-4944-900c-abfd075f6081</PowerBIReportId>
        <TileUrl>https://xyz.powerbi.com/reportEmbed?reportId=544c4162-6773-4944-
900c-abfd075f6081</TileUrl>
        <PowerBIFilter>{"Filter": "[{\"$schema\":\"basic\",\"target\":
{\"table\":\"table_name_of_power_bi_dataset\",\"column\":\"power_bi_field\"},\"oper
ator\":\"In\",\"values\":[$a],\"filterType\":1}]", "Alias": {"$a":
"field_name_in_powerapps_to_filter"}}</PowerBIFilter>
    </parameters>
</control>
```

Note that this uses the same control as the unfiltered report embedding, and hence the control class ID remains unchanged.

This table describes any additional properties used in the previous XML sample.

Expand table

Property	Description
PowerBIFilter	The filter expression that contextualizes the Power BI report by passing the form attributes as parameters. To make it more readable, the filter is constructed as shown here. The filter expression can't be a comma separated list of values.

JSON

```
{
        "Filter": "[{
                \"$schema\":\"basic\",
                \"target\":{
                        \"table\":\"table_name_of_power_bi_dataset\",
                        \"column\":\"power_bi_field\"
                },
                \"operator\":\"In\",
                \"values\":[$a, $b],
                \"filterType\":1
        }]",
        "Alias": {
                "$a": "field1_name_in_powerapps_to_filter",
                "$b":"field2_name_in_powerapps_to_filter"
        }
}
```

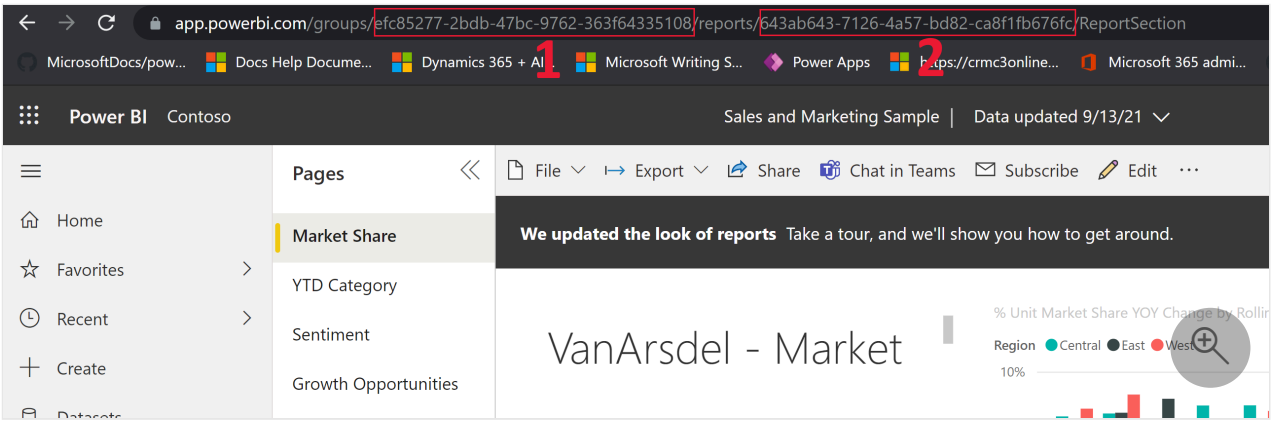
The target part of the previous expression identifies the table and the column to apply the filters on. The operator identifies the logic and values identify the data passed from the Power Apps model-driven app. To parameterize in a generic way, the values are constructed by aliasing. In the previous expression, the value of an account's **firstname** and **lastname** are passed, and either of them is searched in the **Account Name** column in the Power BI report.

Note that **firstname** and **lastname** are the unique names of attributes of the account table, whose value will be passed here.

You can create more complex filter expressions by looking at examples from Constructing Filters and providing the appropriate values for $schema and filterType. Be sure to escape every literal in the filter part using ", so that the JSON is generated correctly.

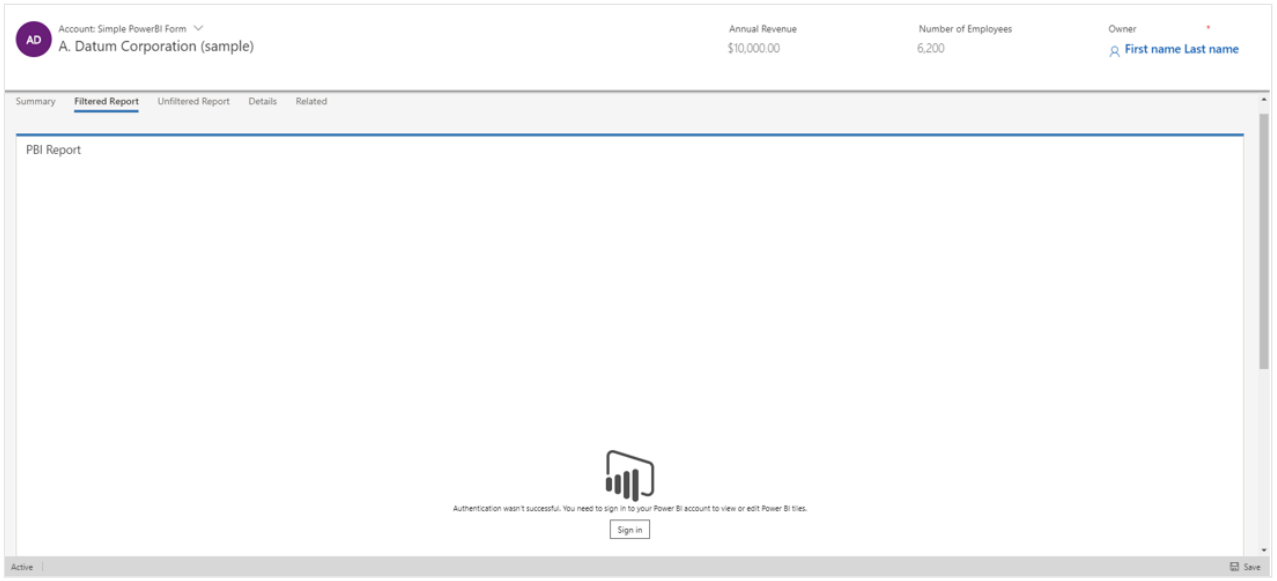
Find the Power BI workspace and report Ids

1. The workspace ID for this example is efc85277-2bdb-47bc-9762-363f64335108.
2. The report ID for this example is 643ab643-7126-4a57-bd82-ca8f1fb676fc.

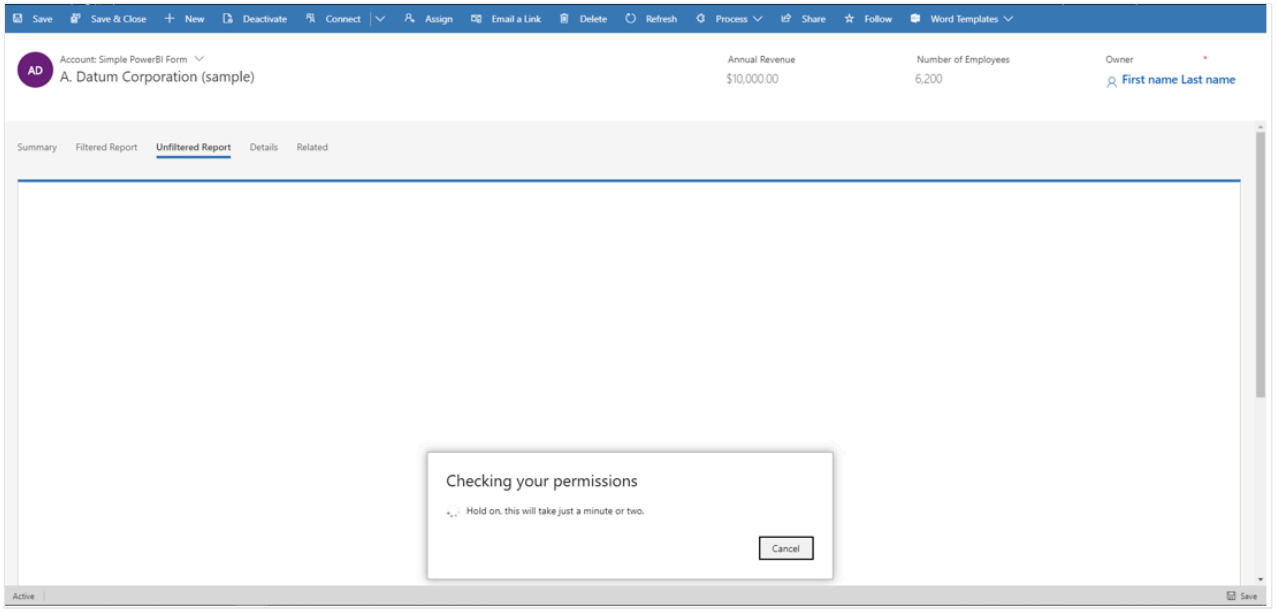


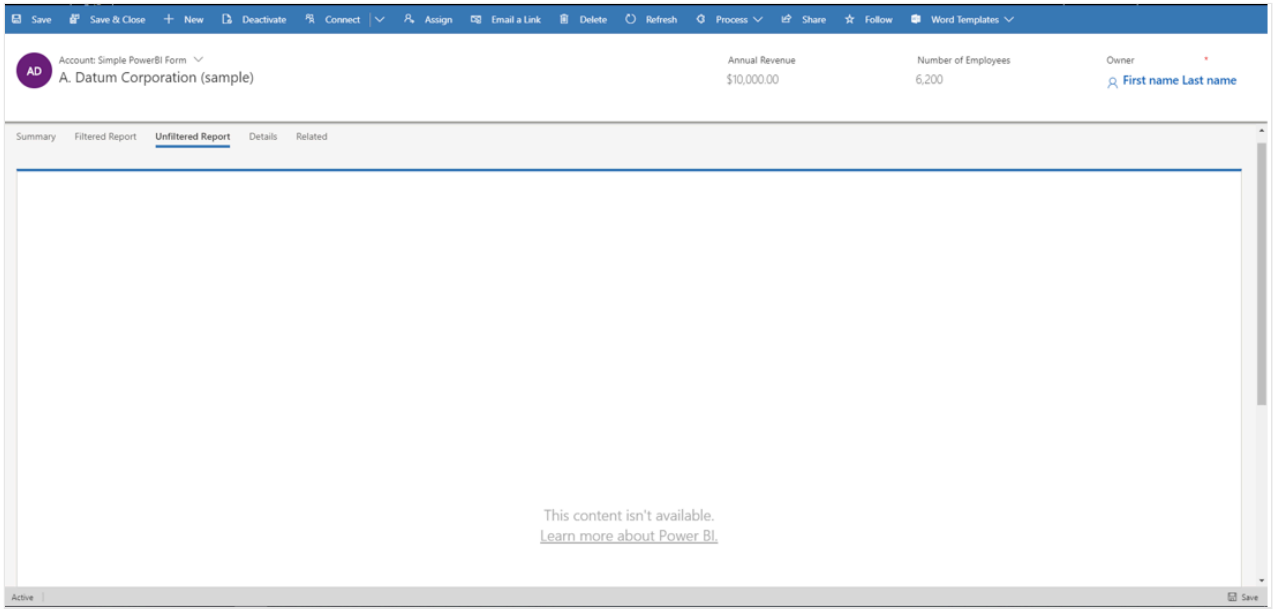
Known issues and limitations

- Opening this form in the Power Apps form designer doesn't show the control in a meaningful way. This is because the control is customized outside of the form designer.
- Users are authenticated into Power BI automatically with their Power Apps username and password. If a Power BI account with matching credentials doesn't exist, a sign-in prompt is displayed as illustrated here.



No data displays if an incorrect account is used to log into Power BI. To sign in with the correct credentials, sign out, and then sign in again.





- The view of the report data shown inside Power Apps is the same as Power BI, and Power Apps security roles and privileges don't affect the data that is displayed. Hence, the data is essentially the same as what the creator of the Power BI dataset would see. To apply data access restrictions similar to Power Apps security roles and teams, use Row-level security (RLS) with Power BI.
- If the form doesn’t show the Power BI report after importing the solution and publishing customizations, open it in the model-driven form designer and save it, so that the form JSON is regenerated.
- Embedding a Power BI tile on a form is only supported without contextual filtering.
- Embedding a Power BI report doesn't support cross-tenant references. For example, trying to embed a Power BI report belonging to the Contoso tenant in a model-driven app belonging to the Fabrikam tenant isn't currently supported, even if the report being embedded has been shared with users in the Fabrikam tenant via Power BI.
- Pinned reports as part of Power BI dashboards aren't meant to be interactive. If you want to have interactive Power BI reports, embed them directly instead of pinning them to a dashboard.

Common issues

- The group ID isn't specified in the `TileUrl` node of the control parameters when it might need to be. This example includes a group ID.

XML

```
<parameters>
    <PowerBIGroupId>fd266a4c-9a02-4553-9310-80e05ee844f3</PowerBIGroupId>
    <PowerBIReportId>544c4162-6773-4944-900c-abfd075f6081</PowerBIReportId>
    <TileUrl>https://xyz.powerbi.com/reportEmbed?reportId=544c4162-6773-4944-900c-
abfd075f6081&amp;groupId=fd266a4c-9a02-4553-9310-80e05ee844f3</TileUrl>
</parameters>
```

- Fields have different data types in Power BI and Dataverse. They need to be the same type, such as string in Power BI and string in Dataverse.
- String fields don't have escaped quotes in the Power BI filter. Notice `values` has `[\"$a\"]` rather than `[$a]`.

JSON

```
{
        "Filter": "[{
                \"$schema\":\"basic\",
                \"target\":{
                        \"table\":\"table_name_of_power_bi_dataset\",
                        \"column\":\"power_bi_field\"
                },
                \"operator\":\"In\",
                \"values\":[\"$a\"],
                \"filterType\":1
        }]",
        "Alias": {
                "$a": "field_name_in_powerapps_to_filter",
        }
}
```

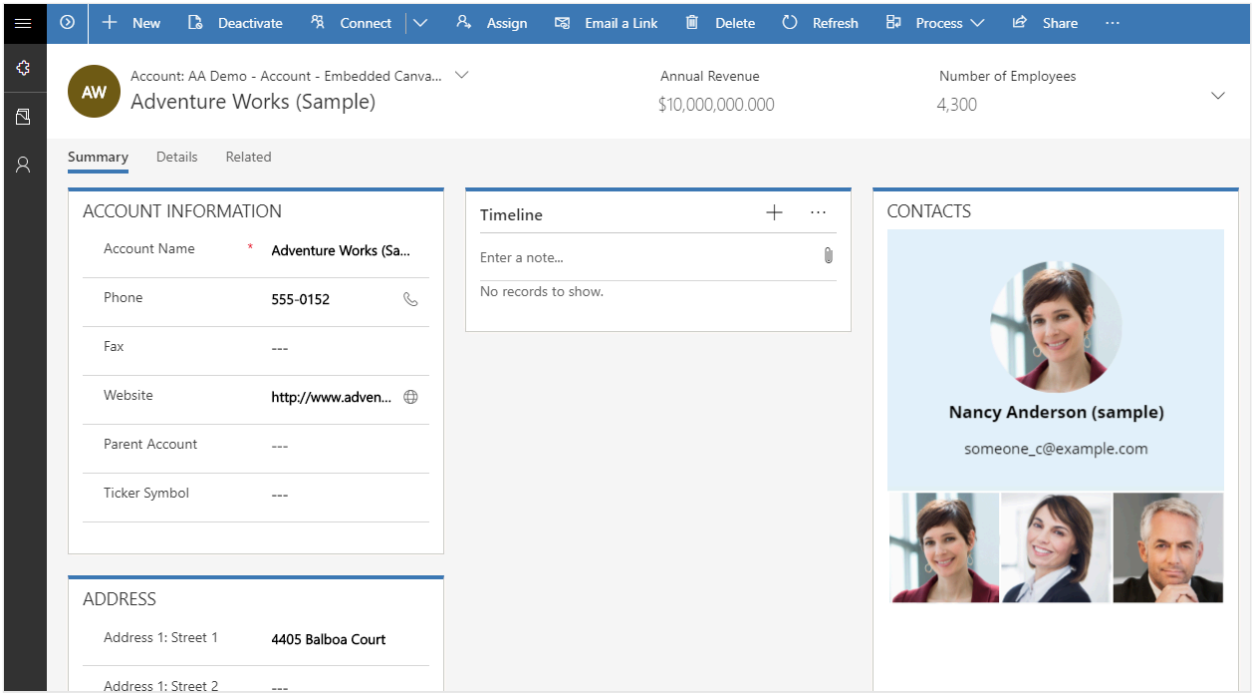
Embed a canvas app on a model-driven form

Article • 01/22/2025

Canvas apps enable makers to easily design and create custom layouts using the low-code, WYSIWYG canvas app designer. Canvas apps also enable makers to connect and display data from over 400 data sources.

Embedded canvas apps can help you build better solutions

With embedded canvas apps, makers can bring the power of canvas apps to their model-driven app forms. Using embedded canvas apps, it's possible to create rich visual areas on a form and display data from a variety of sources right next to data from Microsoft Dataverse.



Canvas apps are embedded in model-driven app forms in the same way other custom controls are added. An embedded canvas app includes rich data integration capabilities that bring in contextual data from the host model-driven form to the embedded canvas app.

Integrate canvas apps using custom pages in the modern app designer

With the modern app designer, canvas apps can be accessed through a model-driven app by using a custom page.

The modern app designer introduced the concept of pages, which can contain either canvas apps or Dataverse components, such as tables, dashboards, and web resources.

Embed using the modern designer

Select the **Canvas app** control to add a canvas app to a main form using the form designer. More information: Add an embedded canvas app on a model-driven form

Embed using the classic designer

Add canvas apps from an environment into a model-driven app that can either be contextually aware, or simply render the app within the model-driven experience. More information: Embed a canvas app using the classic experience.

Sharing embedded canvas apps

After an embedded canvas app is added to your model-driven form, learn how to share the embedded canvas app with other users. More information: Learn how to share an embedded canvas app.

For guidelines on working with embedded canvas apps as well as helpful tips to troubleshoot any issues, go to: Guidelines on working with embedded canvas apps.

Add an embedded canvas app on a model-driven form

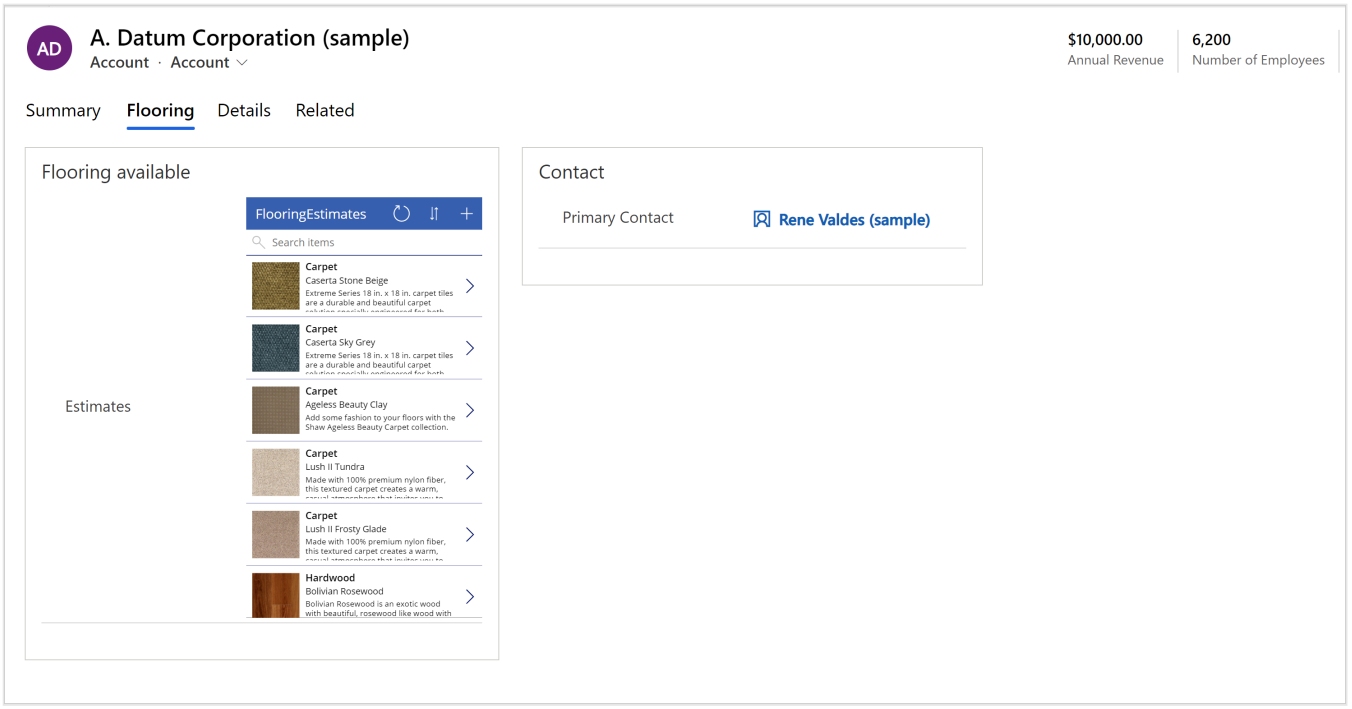
This article explains how to embed a canvas app on a model-driven form. Canvas apps can be connected to a wide range of data sources and offer designers greater control around the overall user experience.

Two methods of integration are described in this article. First, using the modern Unified Interface experience, and second, using the classic experience.

> **ⓘ Important**
>
> - There is a third and more recent method of embedding canvas apps inside a modern app, which uses custom pages for better integration with the canvas app. More information: Overview of custom pages for model-driven apps.
> - Both the modern form and classic form designers allow you to add an existing canvas app to embed in a model-driven form. However, currently only the classic form designer allows you to create a new canvas app to embed. More information: Embed a canvas app using the classic experience
> - To enable access to form data through the `ModelDrivenFormIntegration` control, the embedded canvas app *must be created using the classic form designer*. Apps *added* through the modern or classic experience don't currently support this integration. For more information about how to create a canvas app to embed on a model-driven form using the classic form designer go to Embed a canvas app using the classic experience. For more information about the `ModelDrivenFormIntegration` control go to ModelDrivenFormIntegration control properties and actions.



Embed a canvas app using the modern experience

To embed a canvas app on a model-driven app main form, such as the main form for the Accounts table, follow these steps:

1. Sign in to Power Apps.
2. Choose the environment, and then select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution that has the table where you want to add a canvas app to a main form.
4. Open the table, select **Forms**, and then open the **Main** form you want.

   > **Tip**
   >
   > By default, the canvas app component label is **New canvas app**. You might want to change the canvas app label name to something more meaningful, such as the name of the canvas app or a short description of the canvas app that you're embedding onto the form.

5. Select the area on the form where you want the canvas app to display or create a new tab to display the canvas app.
6. On the left navigation pane select **Components**, expand **Display**, and then select the **Canvas app** component.

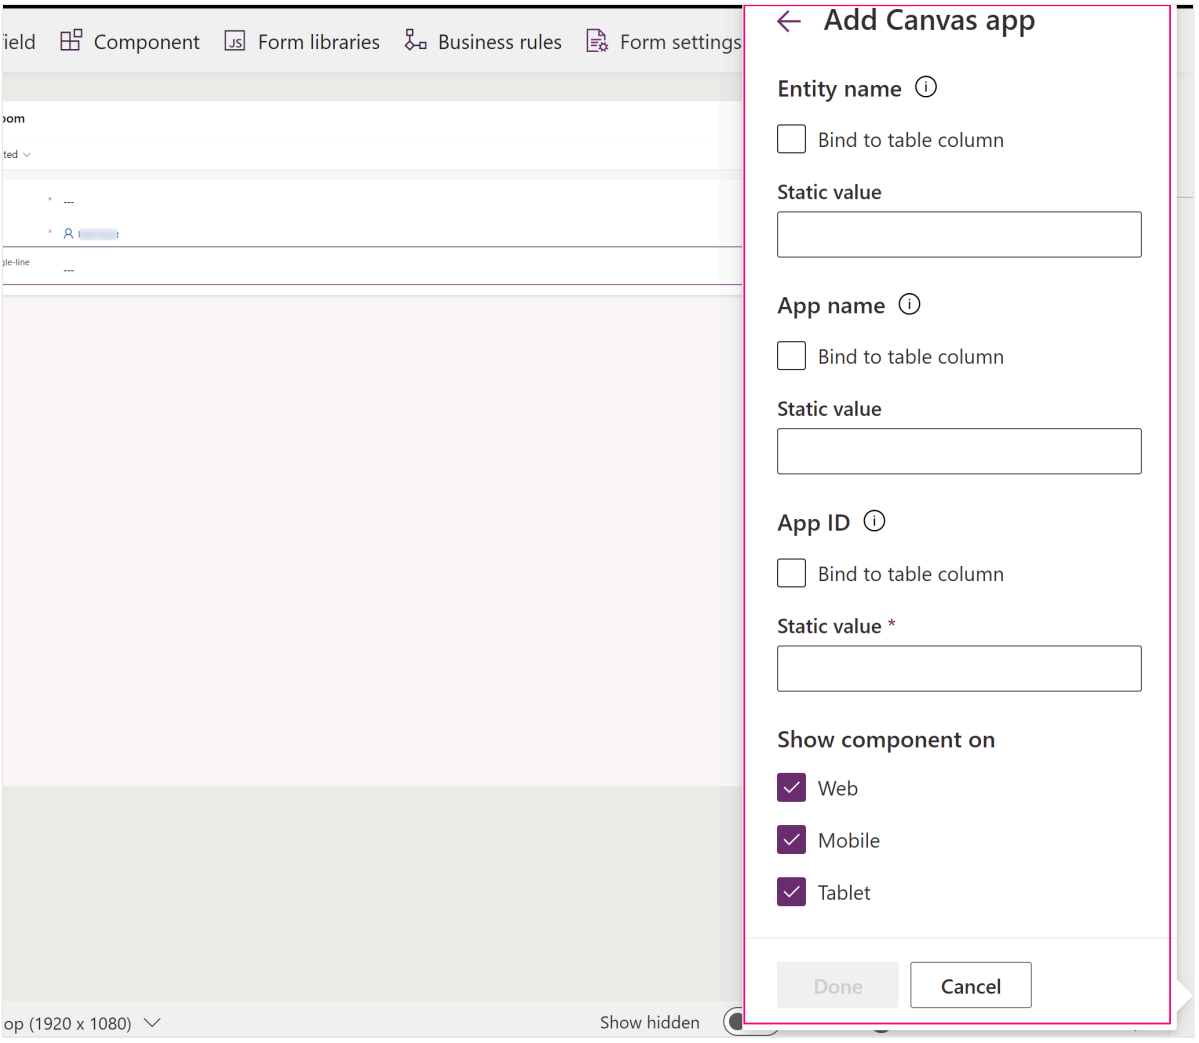
7. The following properties can be configured for the control.

- The **Entity name** area lets you specify the following properties:
  - **Bind to table column**: When the **Bind to table column** is selected, the **Static value** property changes to allow you to select what table column to bind to. When you choose to bind to a table column, the column will be defined by the table column value. For example, when **Bind to table column** is selected for the **Entity name**, at app runtime the value of the table name takes the value of the **Table column** specified.
  - **Static value**: Use this to add a name for you to refer to the canvas app. Notice that this value has no effect on the embedded canvas app. It's meant only to serve as a reference point.
- The **App name** area specifies the unique name of the canvas app.
  - **Bind to table column**: When you select the **Bind to table column**, the **Static value** property changes to allow you to select what table column to bind to. When you choose to bind to a table column, the column will be defined by the table column value. For example, when you select **Bind to table column** for the **App Name**, at app runtime the value of the app name takes the value of the Table column, such as the value from a custom text column.
  - **Static value**: Specifies the unique name of the canvas app to embed. Enter the canvas app's unique name for an existing canvas app. More information: How to find the unique name and app ID for a canvas app
- The required **App ID** area specifies the app ID for the canvas app.
  - **Bind to table column**: When you select **Bind to table column**, the list changes to allow you to select what table column to bind to. When you choose to bind to a table column, the column will be defined by the table column value. For example, when you select **Bind to table column** for the **App Name**, at app runtime the value of the app name takes the value of the column, such as the value from a custom text column.

    > **Important**
    >
    > For most situations, we don't recommend using the **Bind to table column** option for the App ID as this would require the correct app ID to be shown in a field within the record.

  - **Static value**: Enter the app ID for an existing canvas app. More information: How to find the unique name and app ID for a canvas app

- **Show component on**. Specifies the client type to display the embedded canvas app. Choose from **Web**, **Mobile**, and **Tablet**.



8. Select **Done**. Then, to publish your app to make it available to users, select **Save and publish**.

After you have published an embedded canvas app to your model-driven form, share your embedded canvas app with other users. More information: Share an embedded canvas app.

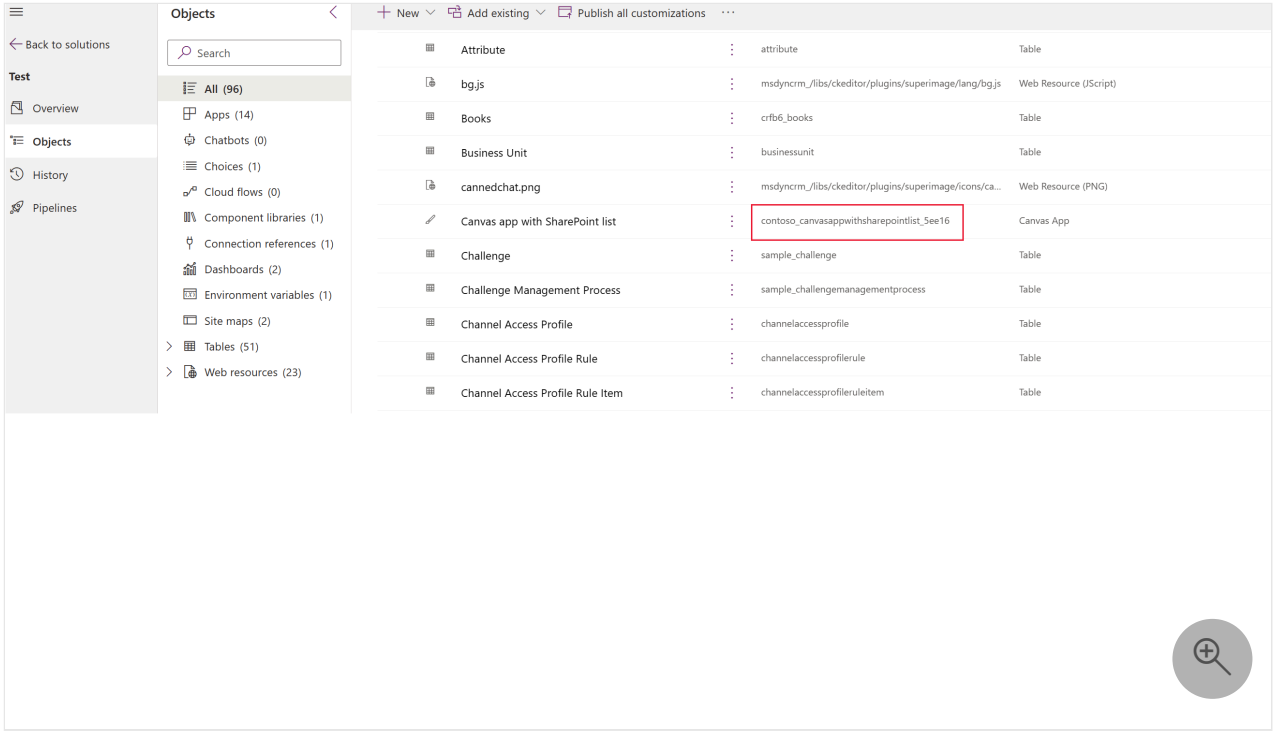
When users open a model-driven app that includes the form you have modified, they see the embedded canvas app on the form. Changing the record displayed on the main form changes the data context that is passed to the form, and the embedded app refreshes to show the relevant data.

This article showed you how to get started with embedding a canvas app in a model-driven form. You can further customize the embedded canvas app to connect and bring in data from various data sources. Use the `Filter`, `Search`, and `LookUp` functions and the context passed in from the host model-driven form to filter or find specific records in those data sources. Use the WYSIWYG canvas app editor to easily design the interface to match your requirements.

How to find the unique name and app ID for a canvas app

The canvas app control looks for the canvas app first by using the *unique* name found in the **App name** field. If a canvas app with that unique name can't be found in the environment, the canvas app control next uses the specified value in the **App ID** field to load the canvas app. Although you must enter values in both the App name and App ID fields, only one of the values needs to be accurate for the embedded canvas app to load in the control. Note that the canvas app must be in the current environment.

- The **App name** field is the unique name of the canvas app. To find the unique name, add the canvas app to a solution. The canvas app unique name is displayed in the **Name** column and appears in the form *solutionpublisherprefix_appnamenospaces_appendix*. For example, *contoso_canvasappwithsharepointlist_5ee16*.



- The **App ID** property specifies the ID of the embedded canvas app. Enter the App ID for an existing canvas app. The canvas App ID can be found on Power Apps, go to **Apps**, select the canvas app, and then select **Details** on the command bar.

Embed a canvas app using the classic experience

1. Sign in to Power Apps.
2. Create or edit the main form of a table, Accounts table in our example.
3. In the command bar, select **Switch to classic** to open the form in the classic form designer.

4. In the classic form designer, select the section on the form where you want the embedded canvas app to appear.

5. Using the column pane, add a required column, such as **Account Name**.

   > **Important**
   >
   > Always use a required column that is guaranteed to have a value. If your column doesn't have a value, your embedded canvas app won't refresh in response to any change in data on the host model-driven form.

6. With the column selected, on the **Home** tab in the **Edit** group, select **Change Properties**.

7. On the **Column Properties** dialog box, select the **Controls** tab.

8. On the **Controls** tab, select **Add Control**.

9. On the **Add Control** dialog box, in the list of available controls, select **Canvas app** and then select **Add**.

10. On the **Column Properties** dialog box, in the list of controls select **Canvas app**, and then select the **Web** option.

11. If you want to create a new canvas app, go to the next step. To add an existing canvas app, in the section below the controls list, the lists of properties available to the canvas app control are displayed.

    - The **Table name** property specifies the table that provides the data to your embedded canvas app. It is set to the table that contains the column you added in an earlier step.
      - Notice that, even though this property appears changeable, changing it has no effect on the embedded canvas app. It's meant only to serve as a reference for you.
    - The **App Name** property specifies the name of the canvas app to embed. The model-driven form looks for the canvas app with the specified name in the current environment. If a canvas app with that name can't be found in the environment, the canvas app control uses the App ID to load the canvas app. Enter the App Name for an existing canvas app.
    - The **App ID** property specifies the ID of the embedded canvas app. You can enter an App ID for an existing canvas app or an App ID will be automatically generated and filled-in for you when you create or edit a canvas app by selecting **Customize**. The canvas App ID can be found on Power Apps, go to **Apps**, select the canvas app, and then select **Details** on the command bar.

> ⓘ Note
>
> Notice that any change to the **App ID** value breaks the link from the model-driven form to the embedded canvas app.
>
> If neither the App Name or App ID matches an existing canvas app, the form displays the message "Sorry, we didn't find that app."

12. Go to step 20 if you're adding a completed canvas app. If you're creating a new or editing an existing canvas app, continue to follow these steps. Select **Customize** to create or edit a canvas app. This opens Power Apps Studio in a new tab.

> ⓘ Note
>
> If opening Power Apps Studio is blocked due to a web browser pop-up blocker you must enable the make.powerapps.com site or temporarily disable the pop-up blocker and then select **Customize** again. 13. Observe the following:

- In Power Apps Studio notice that there's a special `ModelDrivenFormIntegration` control in the left pane. This control is responsible for bringing contextual data from the host model-driven form to the embedded canvas app.
- Observe that a canvas app form control was automatically added to your embedded canvas app and displays the data being passed to it from the host model-driven form via the ModelDrivenFormIntegration control.
- Select the **View** tab, and then select **Data sources**. Notice that a data source for the parent table of your host model-driven form, Accounts in this case, was automatically added to your embedded canvas app. - Select the **Form1** control and observe that the **DataSource** property is set to **Accounts**.
  - With the **Form1** control still selected, observe that the **Item** property is set to **ModelDrivenFormIntegration.Item**.

> ⓘ Note
>
> The embedded canvas app has full access to read from the host model-driven form via ModelDrivenFormIntegration.Item. > As an example, to get the value of a column with the name **accountnumber** and display name **Account Number**, you can use **ModelDrivenFormIntegration.Item.accountnumber** or **ModelDrivenFormIntegration.Item.'Account Number'**. 14. In the property pane on the right, next to **Columns**, select **Edit columns**. 15. Select **+ Add column** to add another column to the canvas app form or reorder existing columns using drag and drop. Close

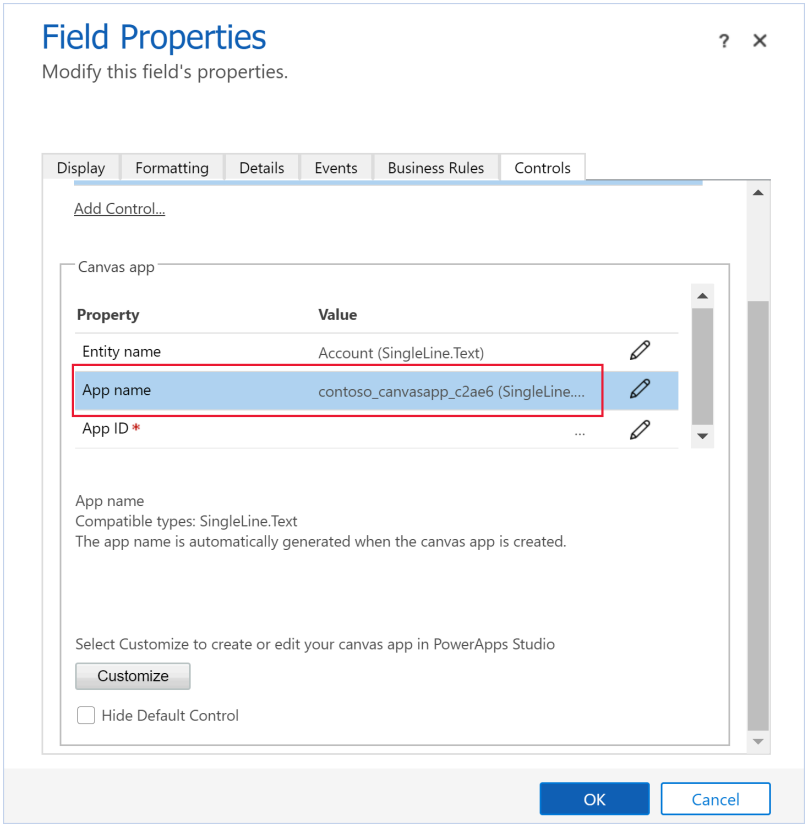
the data pane when you're done adding and reordering columns. 16. Select the **File** tab, and then select **Save**. 17. Select the **The cloud** tab. Provide a unique name for the app and then select **Save** located on the lower right. Note the following behavior:

- Saving an app for the first time automatically publishes the app.
- On subsequent saves, select **Publish** and then select **Publish this version** to make your changes available.

18. On the menu, select **Back**.
19. Select the browser tab that has the classic form designer open. Observe that the **App ID** and **App Name** properties of the canvas app control now have a value automatically filled in.

ⓘ Important

- The form designer has a direct link with Power Apps Studio that was opened in another browser tab in an earlier step.
- Make sure the App name has a value similar to the screenshot here. The App name property specifies the unique name that is used to reference the canvas app at runtime. If this name isn't set, the App ID property is used to reference the canvas app, which might cause issues when you import the canvas app as part of a solution. We recommend that you set this name to ensure proper canvas app referencing between environments. To set it, go back to step 12 and follow the steps to create the canvas app to embed.



20. On the **Column Properties** dialog box, select the **Display** tab.

21. Clear **Display label** on the form and then select **OK**. If you already have a canvas app embedded on this form, a message is displayed that "Only one canvas app can be enabled on a form." To add the new canvas app, you must first disable the current embedded canvas app. Then, enable the new embedded canvas app.

22. On the **Home** tab, select **Save**, and then select **Publish**.

Edit a canvas app embedded on a model-driven form

Summarize this article for me

This article explains how to edit a canvas app embedded on a model-driven form by using the classic designer.

Edit the canvas app directly

You can edit a canvas app embedded on a model-driven form just like any other canvas app. For steps on editing a canvas app go to: Edit a canvas app

Edit the canvas app via the host model-driven form

An alternate option is to edit the embedded canvas app via the host model-driven form.

Imagine that you want to edit a canvas app embedded on a form named Account Main Form for the Accounts table. To do this, follow these steps:

1. Sign in to Power Apps.
2. Edit the form named **Account Main Form** for the **Accounts** table.
3. In the command bar, select **Switch to classic** to open the form in the classic form designer.
4. In the classic form designer, select the column that is customized to display the embedded canvas app.
5. With the column selected, on the **Home** tab in the **Edit** group, select **Change Properties**.
6. On the **Column Properties** dialog box, select the **Controls** tab.
7. In the **Column Properties** dialog box, in the list of controls select **Canvas app**.
8. In the section below the controls list, select **Customize** to edit the canvas app. This opens the canvas app for editing, in Power Apps Studio, in a new tab.

> **Note**
>
> If opening Power Apps Studio is blocked due to a web browser pop-up blocker you must enable the make.powerapps.com site or temporarily disable the pop-up

blocker and then select **Customize** again.

9. When you finish making changes, select the **File** tab, and then select **Save**.
10. To make your changes available to users select **Publish** and then select **Publish this version**.

Customize the screen size and orientation of a canvas app embedded on a model-driven form

Article • 05/22/2025

You can customize the screen size (tablet layout only) and orientation of a canvas app embedded on a model-driven form.

1. Follow the steps to add or edit an embedded canvas app on a model-driven form.

    - Add an embedded canvas app on a model-driven form
    - Edit a canvas app embedded on a model-driven form

2. With the canvas app open in Power Apps Studio, select the **File** tab, select **Settings**, and then select the **Screen size + orientation** tab to set the orientation screen and orientation of the canvas app. More information: Change screen size and orientation of a canvas app in Power Apps

Perform predefined actions on the host model-driven form from within an embedded canvas app

Summarize this article for me

Embedded canvas apps provide the ability to perform predefined actions on the host model-driven form. These actions enable makers to navigate, refresh and save the host model-driven form. Using these actions, an embedded canvas app can act as a more integral part of the model-driven form and the model-driven app.

The **ModelDrivenFormIntegration** object includes the following new methods to enable makers to perform actions on the host model-driven form.

> **Important**
>
> To be able to interact with the `ModelDrivenFormIntegration` control, the canvas app must be *created* by selecting **Customize** on the **Canvas app** control properties for the model-driven form using the classic form designer. More information: Embed a canvas app using the classic experience

NavigateToMainForm(entityName, mainFormName, recordId)

Navigates the host model-driven form to a main form and displays the specified row.

- **entityName** - A required string parameter that specifies the parent table of the main form.
- **formName** - A required string parameter that specifies the name of the main form to navigate to.
- **recordId** - A required string parameter, that specifies the ID of the row to display in the main form.

Calling the NavigateToMainForm method can return the following error messages.

Expand table

Error message	Troubleshooting guidance
Table not found: *[EntityName]*	Please check the value of the *entityName* parameter and ensure it is a valid table name and that the user has access to it.

Error message	Troubleshooting guidance
Form not found: *[FormName]*	Please check the value of the *mainFormName* parameter and ensure it is a valid main form name and that the user has access to it.
There was a problem loading the row.	Please check the value of the *recordId* parameter and ensure it is a valid row ID and that the user has access to it.

NavigateToView(entityName, viewName)

Navigates the host model-driven form to a view.

- **entityName** - A required string parameter that specifies the parent table of the view.
- **viewName** - A required string parameter that specifies the name of the main form to navigate to.

Calling the NavigateToView method can return the following error messages.

Expand table

Error message	Troubleshooting guidance
Table not found: *[EntityName]*	Please check the value of the *entityName* parameter and ensure it is a valid table name and that the user has access to it.
View not found: *[ViewName]*	Please check the value of the *viewName* parameter and ensure it is a valid view name and that the user has access to it.

OpenQuickCreateForm(entityName)

Opens the default quick create form for a table.

- **entityName** - A required string parameter that specifies the parent table of the quick create form.

Calling the OpenQuickCreateForm method can return the following error messages.

Expand table

Error message	Troubleshooting guidance
Table not found: *[EntityName]*	Please check the value of the *entityName* parameter and ensure it is a valid table name and that the user has access to it.

RefreshForm(showPrompt)

Refreshes the data on the host model-driven form.

- **showPrompt** - A required boolean parameter that indicates if a confirmation prompt should be displayed to the user before saving any unsaved data on the host model-driven form. Values should be "true" or "false".

Calling the RefreshForm method can return the following error messages.

Expand table

Error message	Troubleshooting guidance
Please use "true" or "false" as the parameter value.	Please check the value of the *showPrompt* parameter and ensure that it is either "true" or "false".

SaveForm()

Saves the data on the host model-driven form.

> **Note**
>
> If you don't observe the IntelliSense for the methods to perform predefined actions in embedded canvas apps that were created prior to the functionality being made available; save, close and re-open the app.

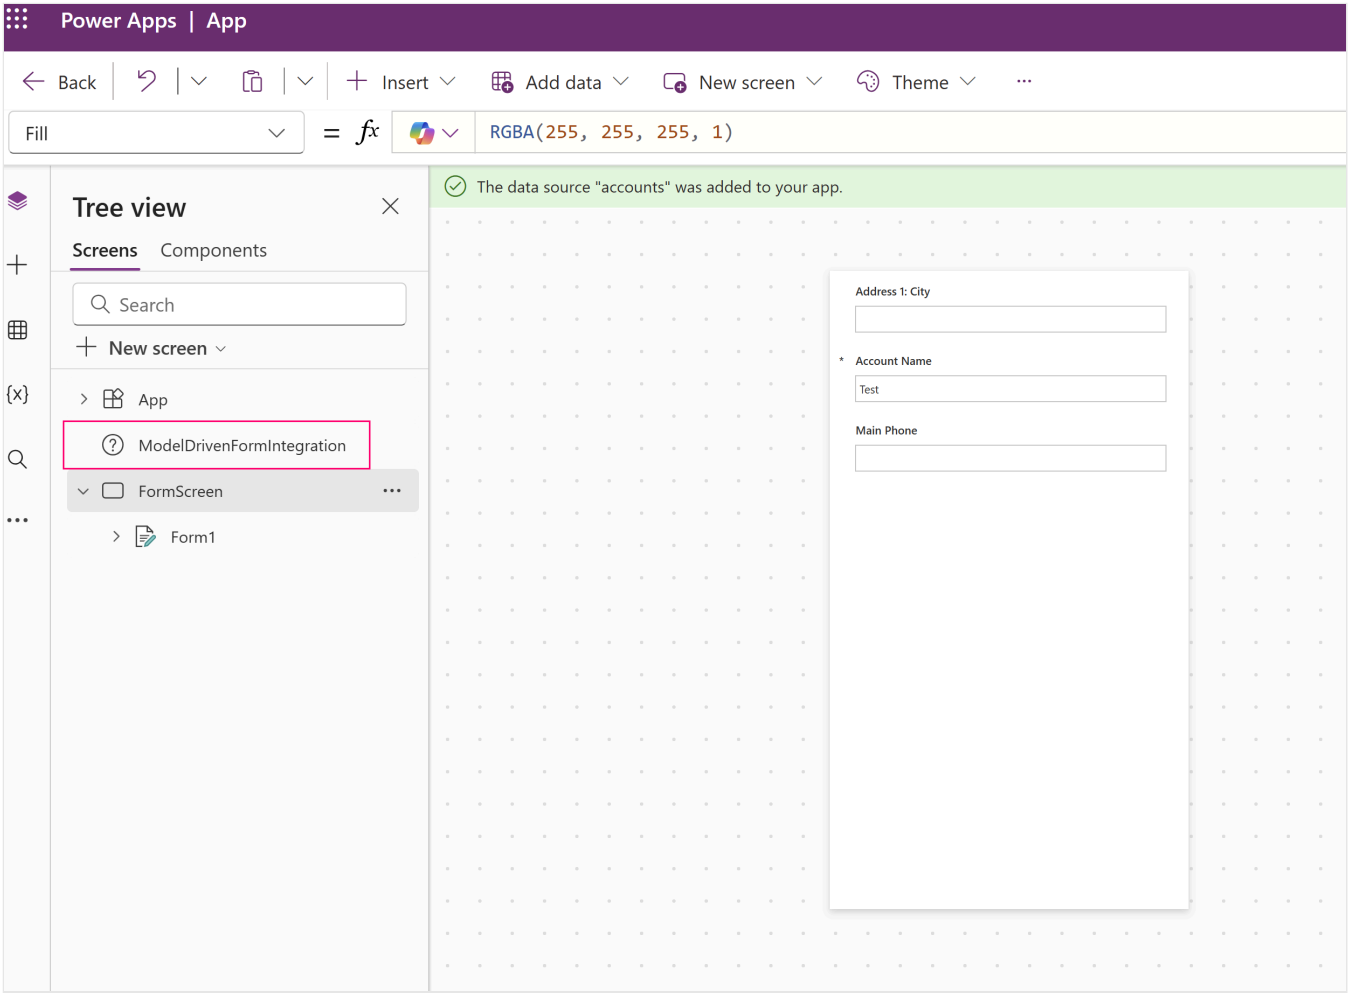
ModelDrivenFormIntegration control properties and actions

Canvas apps embedded on model-driven forms contain a special control named **ModelDrivenFormIntegration**. This control is responsible for bringing contextual data from the host model-driven form to the embedded canvas app.

> **Important**
>
> To be able to interact with the `ModelDrivenFormIntegration` control, the canvas app must be *created* by selecting **Customize** on the **Canvas app** control properties for the model-driven form using the classic form designer. More information: Embed a canvas app using the classic experience

This article explains the properties and actions available on the `ModelDrivenFormIntegration` control. This control is available to customize in Power Apps Studio when you create the canvas app using the Canvas app control properties UI in the classic form designer.

mod



Expand table

Property or action	Description
DataSource	Should be set to the data source connected to the parent table of the host model-driven form. Automatically set when embedding a new canvas app. When embedding an existing canvas app, ModelDrivenFormIntegration data source can be configured from the canvas app tree view. The value for DataSource should always refer to the table of the form the app is embedded in. The value shouldn't be filtered or modified in any way.
Item	Read-only property that enables the embedded canvas app to access the row from the host model-driven form. As an example, to get the value of a column with the name accountnumber and display name Account Number, you can use ModelDrivenFormIntegration.Item.accountnumber or ModelDrivenFormIntegration.Item.'Account Number'.
OnDataRefresh	The formula in this property is evaluated when the host model-driven form saves data. Use it to refresh the data source connected to the parent table of the host model-driven form and to perform other actions like setting or updating variables. As an example, setting it to the formula below will refresh the Accounts data source and set a variable named CurrentAccountNumber to the value of the Account Number column of the current row. Refresh(Accounts); Set(CurrentAccountNumber, ModelDrivenFormIntegration.Item.'Account Number') The OnDataRefresh action should only be used to refresh data within the embedded canvas app. We don't recommend that you use the OnDataRefresh action to save changes within the embedded canvas app. More information: Saving data in an embedded canvas app
RefreshForm	Refreshes the data on the host model-driven form. See Perform predefined actions on the host form for details.
SaveForm	Saves the data on the host model-driven form. See Perform predefined actions on the host form for details.
NavigateToMainForm	Navigates the host model-driven form to a main form and displays the specified row. See Perform predefined actions on the host form for details.
NavigateToView	Navigates the host model-driven form to a view. See Perform predefined actions on the host form for details.
OpenQuickCreateForm	Opens the default quick create form for an table. See Perform predefined actions on the host form for details.

Property or action	Description
Data	Read-only property used by the framework to send some key data from the host model-driven form to the embedded canvas app. Do not use this property. Use Item to access the row from the host model-driven form.

ModelDrivenFormIntegration control data is not available on app start

The `ModelDrivenFormIntegration.Item` property isn't guaranteed to be populated with data when the app starts. The app should either be designed to wait for this data using an expression like `!IsBlank(ModelDrivenFormIntegration.Item)`, or the app should explicitly retrieve the record using an expression like `LookUp(Accounts, Account = GUID(First(ModelDrivenFormIntegration.Data).ItemId))`.

Pass the current record as data context to an embedded canvas app

Summarize this article for me

> **Important**
>
> Canvas apps embedded on model-driven forms are generally available. The steps listed below are outdated and applicable only to the public preview release of canvas apps embedded on model-driven forms. For the updated list of steps for the latest release, go to: Add an embedded canvas app on a model-driven form

This article explains how to add an embedded canvas app and pass the current (main form) record as a data context to the embedded canvas app.

Imagine that you want to add an embedded canvas app on an account main form and pass the current account record to the embedded canvas app. To do this, follow these steps:

1. Sign in to Power Apps and open the form editor for a main form of a table, such as the account table.
2. Select the section on the form where you want the embedded canvas app to appear.
3. Using the column explorer pane, add a required column, such as **Account Name**.

   > **Important**
   >
   > Always use a required column that is guaranteed to have a value. If your column does not have a value, your embedded canvas app will not refresh in response to any change in data on the host model-driven form.

4. With the column selected, on the **Home** tab in the **Edit** group, select **Change Properties**.
5. On the **Column Properties** dialog box, select the **Controls** tab.
6. On the **Controls** tab, select **Add Control...**.
7. On the **Add Control** dialog box, in the list of available controls, select **Canvas app** and then select **Add**.
8. In the **Column Properties** dialog box, in the list of controls select **Canvas app**, and then select the **Web** option.
9. In the section below the controls list, the list of properties available to the canvas app control are displayed.

   - The **Table name** property specifies the table that will provide the data to your embedded canvas app. It will be set to the table that contains the column you

added in an earlier step.
    - Notice that, even though this property appears changeable, changing it has no effect on the embedded canvas app. It is meant only to serve as a reference for you.
- The **App ID** property specifies the ID of the embedded canvas app. It will be automatically generated and filled-in for you when the canvas app is created.
    - Notice that any change to the **App ID** value breaks the link from the model-driven form to the embedded canvas app.

10. Select **Customize** to create or edit the canvas app. This opens Power Apps Studio in a new tab.

    > ⓘ **Note**
    >
    > - The **Customize** option is currently only available by using the classic form designer.
    > - If opening Power Apps Studio is blocked due to a web browser pop-up blocker you must enable the make.powerapps.com site or temporarily disable the pop-up blocker and then select **Customize** again.

11. In Power Apps Studio notice that there is a special **ModelDrivenFormIntegration** control in the left pane. This control is responsible for bringing contextual data from the host model-driven form to the embedded canvas app.
12. Select the **Gallery1** control and observe that the **Items** property is set to **ModelDrivenFormIntegration.Data**.

    > ⓘ **Note**
    >
    > ModelDrivenFormIntegration.Data is a list of records. In this example it has only one record. To directly reference the record you can use the First function. For example, *First(ModelDrivenFormIntegration.Data).Name*.

13. In the property pane on the right, next to **Columns**, select **Edit**.
14. In the data pane, change the column mapped to the **Title1** control to **Name** or another column that has data.
15. Observe that the gallery displays the data being passed to it from the host model-driven form via the ModelDrivenFormIntegration control. Close the data pane.
16. Select the **File** tab, and then select **Settings**.
17. On the **Upcoming features** tab, in the **Experimental features** section, set **Optimize embedding appearance** to **On**.
18. Select the **General** tab. Provide a unique name for the app and then select **Save**. Note the following:

- Saving an app for the first time automatically publishes the app.
- On subsequent saves, select **Publish** and then select **Publish this version** to make your changes available.

19. Close the **Settings** dialog.
20. On the menu, select **Back** and then select the browser tab that has the form editor open. Observe that the **App ID** property of the canvas app control now has a value automatically filled in. Note the following:

    - The form editor has a direct link with Power Apps Studio that was opened in another browser tab in an earlier step.
    - The form editor "listens" for the **App ID** to be sent to it.
    - The **App ID** is sent to the form editor when the app is saved.

21. On the **Column Properties** dialog box, select the **Display** tab.
22. Clear **Display label** on the form and then select **OK**.

    - If you already have a canvas app embedded on this form, a message is displayed that “Only one canvas app can be enabled on a form.” To add the new canvas app you must first disable the current embedded canvas app. Then, enable the new embedded canvas app.

23. On the **Home** tab, select **Save**, and then select **Publish**.

After you have added an embedded canvas app to your model-driven form, share your embedded canvas app with other users. More information: Share an embedded canvas app.

When users open a model-driven app (Unified Interface only) that includes the form you have modified, they see the embedded canvas app on the form. Changing the row displayed on the main form changes the data context that is passed to the form, and the embedded app refreshes to show the relevant data.

This topic showed you how to get started with embedding a canvas app in a model-driven form. You can further customize the embedded canvas app to connect and bring in data from a variety of data sources. Use the Filter, Search, and LookUp functions and the context passed in from the host model-driven form to filter or find specific records in those data sources. Use the WYSIWYG canvas app editor to easily design the interface to match your requirements.

Pass a list of related records as data context to an embedded canvas app

Article • 02/15/2022

> **Important**
>
> Canvas apps embedded on model-driven forms are now out of preview and generally available. The steps listed below are outdated and applicable only to the public preview release of canvas apps embedded on model-driven forms. For the updated list of steps for the latest release, go to: **Add an embedded canvas app on a model-driven form**

Overview

This article explains how to add an embedded canvas app and pass a list of records related to the current (main form) record as a data context to the embedded canvas app.

Procedure

Let's say you want to add an embedded canvas app on an account main form and pass a list of contacts related to the current account record to the embedded canvas app. To do this, follow these steps:

1. Sign in to Power Apps and open the form editor for a main form of a table, such as the account table.
2. Select the section on the form where you want the embedded canvas app to appear.
3. With the section selected, on the **Insert** tab, in the **Control** group, select **Sub-Grid**.
4. In the **Set Properties** dialog box, select the **Display** tab, and then in the **Name** box enter a name for the grid control.
5. In the **Data Source** section, select an **Table** and **Default View** that corresponds to the list of records that you want to pass as data context to the embedded canvas app.

6. Select the **Controls** tab, and then select **Add Control...**

7. In the **Add Control** dialog box, in the list of available controls, select **Canvas app** and then select **Add**.

8. In the **Set Properties** dialog box, in the list of controls select **Canvas app** and then select the **Web** option.

9. In the section below the controls list, see the list of properties corresponding to the Canvas app control and note the following:

    - The **Table name** property specifies the table that will provide the data to your embedded canvas app. It will be set to the table that you selected earlier.
        - Even though this property appears changeable, changing it has no effect on the embedded canvas app. It is meant only to serve as a reference for you.
    - The **View name** property specifies the view of the table that will be used to filter the data provided to your embedded canvas app. It will be set to the **Default View** you selected earlier.
        - The data (fields and values) sent to the embedded canvas app at runtime are determined by this view. Only use columns in your canvas app that are included in the view or add them to the view if needed. Any columns that are not included in the view display as empty values at runtime.
        - The filter criteria for a view are not used at authoring time. Therefore, the data that you see when authoring embedded canvas apps is not filtered, it is simply a list of top few records that you have access to. At runtime, the filter criteria for the view are applied as expected so users only see relevant data.
    - The **App ID** property specifies the ID of the embedded canvas app. It is automatically generated and filled-in for you when the canvas app is created.
        - Notice that any change to the App ID value breaks the link from the model-driven form to the embedded canvas app.

10. Select the **Customize** button to create or edit the canvas app. This opens Power Apps Studio in a new browser tab.

    > **ⓘ Important**
    >
    > - The **Customize** option is currently only available by using the classic form designer.
    > - If opening Power Apps Studio is blocked due to a web browser pop-up blocker, you must enable the make.powerapps.com site or temporarily

disable the pop-up blocker and then select **Customize** again.

11. In Power Apps Studio, notice that there is a **ModelDrivenFormIntegration** control located in the left pane. This control is responsible for bringing contextual data from the host model-driven form to the embedded canvas app.

12. Select the **Gallery1** control and observe that the **Items** property is set to **ModelDrivenFormIntegration.Data**.

13. In the property pane on the right, next to **Columns**, select **Edit**.

14. In the data pane, change the column mapped to the **Title1** control to **FullName** or another column that has data.

15. Observe that the gallery displays the data being passed to it from the host model-driven form via the **ModelDrivenFormIntegration** control. Close the data pane.

16. Select the **File** tab, and select **Settings**.

17. On the **Upcoming features** tab, in the **Experimental features** section, set **Optimize embedding appearance** to **On**.

18. Select the **General** tab. Provide a unique name for the app and then select **Save**. Note the following:

    - Saving an app for the first time automatically publishes the app.
    - On subsequent saves, select **Publish** and then select **Publish this version** to make your changes available.

19. Close the **Settings** dialog.

20. Select **Back**, and then select the browser tab that has the form editor open.

21. Observe that the **App ID** property of the **Canvas app** control now has a value automatically filled in. Note the following:

    - The form editor has a direct link with Power Apps Studio that was opened in another browser tab in an earlier step.
    - The form editor has been listening for the App ID to be sent to it.
    - The App ID was sent to it when the app was saved.

22. In the **Set Properties** dialog box, select the **Display** tab, clear **Display label on the form**, and then select **OK**.

- If you already have a canvas app embedded on this form, a message is displayed that “Only one canvas app can be enabled on a form.” To add the new canvas app, you must first disable the current embedded canvas app. Then, enable the new embedded canvas app.

23. On the **Home** tab, select **Save**, and then select **Publish**.

After you have added an embedded canvas app to your model-driven form, share your embedded canvas app with other users. More information: Share an embedded canvas app.

When users open a model-driven app (Unified Interface only) that includes the form you have modified, they see the embedded canvas app on the form. Changing the record displayed on the main form changes the data context that is passed to the form and the embedded app refreshes to show the relevant data.

This article showed you how to get started with the embedding a canvas app in a model-driven form. You can further customize the embedded canvas app to connect and bring in data from various data sources. Use the Filter, Search, and LookUp functions and the context passed in from the host model-driven form to filter or find specific records in those data sources. Use the WYSIWYG canvas app editor to easily design the interface to match your requirements.

Share an embedded canvas app

Article • 10/14/2022

This article explains what's needed to share an embedded canvas app that you have already created.

After you have created and added an embedded canvas app to a model-driven form you will need to take steps to ensure that all users that have access to the model-driven form also have access to the canvas app and the data that it uses. Please refer to the following guidelines:

- Sharing an embedded canvas app with Everyone in your organization is not supported with Microsoft Dataverse. Doing so might cause issues when rendering the app. Instead, share your embedded canvas app with a security group or specific users. More information: Share an app
- Ensure that users have appropriate permissions for any Microsoft Dataverse tables that your embedded canvas app uses. Specifically add read privilege for the **Canvas App** table located on the **Customization** tab of the security role editor. More information: Manage table permissions
- Ensure that users have appropriate permission for data on any cloud services that your embedded canvas app uses, such as SharePoint or OneDrive. The steps to share are specific to each cloud service and beyond the scope of Power Apps.

> ⓘ **Note**
>
> Currently, you must explicitly share canvas apps through app sharing. The **Canvas App** privilege in a security role does not share the embedded or standalone application.

Embedded canvas apps are also solution aware. By default embedded canvas apps are created in the same solution as the host model-driven form. To move the embedded canvas app from one environment to another export and import embedded canvas apps as a part of a solution just like any other component.

Guidelines and troubleshooting for embedded canvas apps

Article • 01/10/2024

Guidance on embedding canvas apps

This article provides guidance on working with embedded canvas apps as well as helpful tips to troubleshoot any issues faced.

- Embedded canvas apps are only supported with Unified Interface model-driven apps.
- Only three embedded canvas apps can be enabled for each form with Web, and one for Tablet and Phone client types.
- Multiple embedded canvas apps can be added to the form, but can only enable three at a time for Web and one at a time for Tablet and Phone client types.
- If more than three embedded canvas apps are enabled with the Web client type on a model-driven app form the error message shows as follows "You have more than three canvas apps with Web form factor, the maximum is three for this form factor. The number of canvas apps are limited to three for Web and one for Tablet and Phone form factors."
- To enable or disable an embedded canvas app see Enable an embedded canvas app and Disable an embedded canvas app.
- We recommend that you have a single embedded canvas app for each form tab.
- When adding an embedded canvas app to a model-driven form always use a required column that is guaranteed to have a value. If your column doesn't have a value your embedded canvas app won't refresh in response to any change in data on the host model-driven form.
- Publishing a model-driven form doesn't also publish the embedded canvas app.
  - Embedded canvas apps must be published independent of the host model-driven form. More information: Publish an app.
- If opening Power Apps Studio to create or edit an embedded canvas app via the **Customize** button in the canvas app control properties is blocked due to a web browser pop-up blocker, you must enable the make.powerapps.com site or temporarily disable the pop-up blocker and then select **Customize** again.
- Embedded canvas apps aren't displayed when creating a new row since they need a row context to be passed to them.
- The ModelDrivenFormIntegration.Item object is read-only.

    - To write back data, you must use the Dataverse connector. More information: Microsoft Dataverse
- Embedded canvas apps can only be created via the host model-driven form.
- When viewing a model-driven form with an embedded canvas app, if an error message reads "It looks like you don't have access to this app" ask its owner to share it with you" make sure that the author has shared the embedded canvas app with you. More information: Share an embedded canvas app.
- Adding a canvas app on the subgrid control is no longer available.
    - In the preview release, makers were able to add a canvas app on a subgrid control. With canvas app embedding on model-driven forms now generally available, adding an embedded canvas app on a model-driven form is streamlined to the column.
    - This makes it easier for makers since they don't have to decide up front whether to pass the current (main form) row as data context or a list of rows related to the current (main form) row.
    - Makers always start with a column and can access both the current (main form) row or a list of rows related to the current (main form) row.
    - To access the list of related rows in the canvas app, makers can use the Dataverse connector and Filter function with the Improve data sources experience and Dataverse views capability enabled in the canvas app. For example, to access the *Active Contacts* view of the *Contacts* table, makers can use: *Filter(Contacts, 'Contacts (Views)'.'Active Contacts')*.
    - Existing canvas apps that use the subgrid control will continue to work. However, we recommend that you migrate these apps to use a column instead. More information: Migrating embedded canvas apps on model-driven forms that use a list of rows related to the current (main form) row for details.

Enable an embedded canvas app

1. Select the column that is customized to display as an embedded canvas app.
2. In the **Column Properties** dialog, select the **Controls** tab.
3. In the list of controls select **Canvas app** and then select the **Web** option.
4. Select **OK**.

Disable an embedded canvas app

1. Select the Column that is customized to display as an embedded canvas app.
2. In the **Column Properties** dialog, select the **Controls** tab.
3. In the list of controls, select the default control and then select the **Web** option.
4. Select **OK**.

Saving data in an embedded canvas app

- A save event made from a model-driven app, such as selecting the Save button on the main form command bar, doesn't save changes made in the embedded canvas app.
- To save changes made in an embedded canvas app, use the Dataverse connector.
- The ModelDrivenFormIntegration control OnDataRefresh action should only be used to refresh data within the embedded canvas app. We don't recommend that the OnDataRefresh action is used to save changes within the embedded canvas app.

Known issues and limitations with embedded canvas apps

Limitations

- The canvas app custom control is only supported for use with the **Web** client type. Currently, the **Phone** and **Tablet** client types aren't supported.
- The **Canvas App** privilege in a security role can't be used to grant app users access to either an embedded or standalone canvas app. For more information on sharing an embedded canvas app, go to: Share an embedded canvas app.
- If you write back the same data that is being displayed in the host model-driven form, the form will continue to display old data until it's refreshed. An easy way to do that is to use the RefreshForm method.
- Offline and device capability controls like barcode scanning, capturing photos from device, or attaching files aren't supported in embedded canvas apps.

The ModelDrivenFormIntegration control doesn't provide a value for columns of a related table

For example, when the ModelDrivenFormIntegration control is connected to the Accounts table, using *ModelDrivenFormIntegration.Item.'Primary Contact'.'Full Name'* won't return a value.

To access columns of a related table, makers can use either of the expressions listed here: - *LookUp(Accounts, Account = GUID(First(ModelDrivenFormIntegration.Data).ItemId)).'Primary Contact'.'Full Name'* - *ItemId* is empty at authoring time but will have a value at runtime. - *LookUp(Accounts,*

Account = ModelDrivenFormIntegration.Item.Account).'Primary Contact'.'Full Name' (This expression is easier to read, but the previous expression will perform slightly better.)

Embedded canvas app doesn’t render correctly

You can build your canvas app to be responsive, which refers to the ability of an app to automatically align to different screen sizes and form factors to use the available screen space sensibly. Depending on whether your app is built to be responsive or not, we recommend different settings to ensure that your canvas app might render correctly within the field on the model-driven app form. If you're experiencing additional whitespace or scroll bars around your canvas app, we recommend checking the following in your app.

For responsive apps:

- Disable the **Scale to fit** option. This allows your app to scale according to the dimensions and properties you have set for your app. An embedded canvas app might not render correctly within the field on the model-driven app form, such as additional whitespace or scroll bars around the canvas app.

For nonresponsive apps:

- We recommend that you enable the **Scale to fit** option. This helps the app to resize to fit the available space.

In both scenarios, ensure that the **App Name** property value is set and correctly defined in the embedded canvas app control.

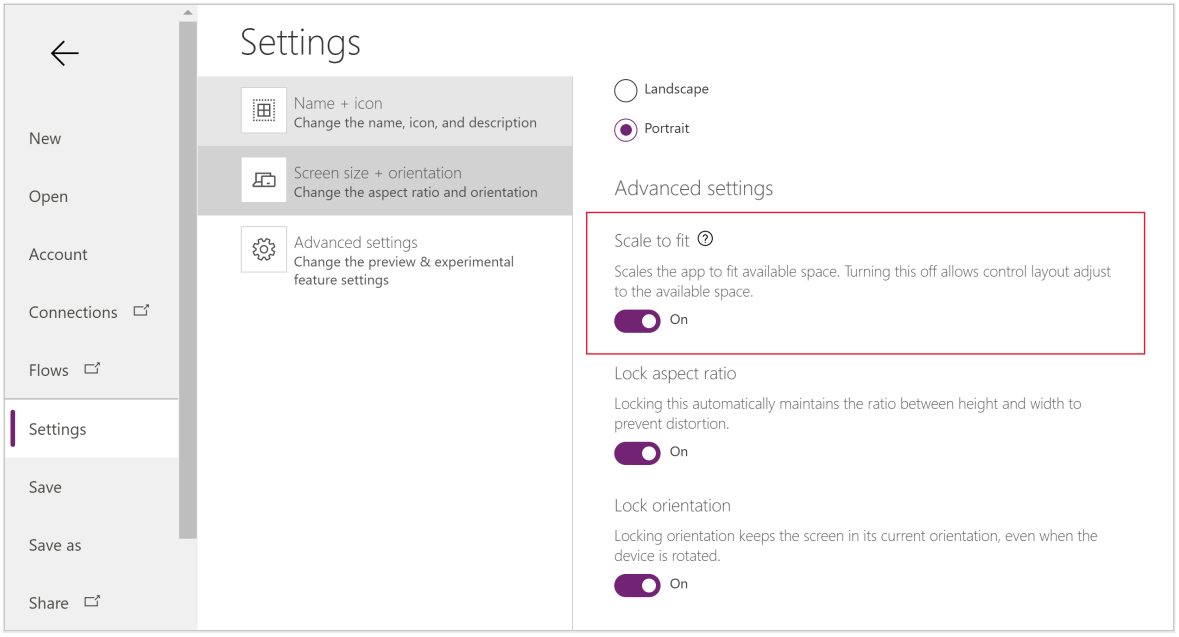
Embedded canvas app doesn't respect height

The **Form field height** property isn't respected by the canvas app component. When embedded, the dimensions of the canvas app component respect the aspect ratio set on the canvas app. Because the aspect ratio is fixed, the height of the canvas app component is calculated relative to the width of the app. The width of the app is determined based on the horizontal space available in the model-driven app. If you would like to make adjustments to the height of the canvas app component, we recommend customizing the aspect ratio on your canvas app. Note that to customize the aspect ratio, the app must be in tablet layout.

Enable scale to fit

By default, canvas apps have the scale to fit option enabled.

1. Open the canvas app that you're embedding on a model-driven app form for editing.
2. In Power Apps studio, select **File** > **Settings** > **Screen size + orientation**.
3. Under **Advanced Settings**, set **Scale to fit** to **On**.



The App Name property value is missing or is incorrectly defined

To resolve this issue, choose the correct option:

- Managed solutions: If the solution was imported into an environment as a managed solution, follow these steps:

    1. Sign into Power Apps and go to the development environment where you originally created your embedded canvas app. This is also the environment where the solution was exported.

    2. Open the unmanaged solution that includes the canvas app, and then find the canvas app in the list of solution components. Copy the canvas app **Name** exactly as it appears in the components list. For example, *contoso_flooringestimatesapp_624d7*.

    3. In the same solution, edit the model-driven app that has the embedded canvas app control, and then set the canvas **App Name** to the embedded

canvas app control using the value from the previous step. More information: Add an embedded canvas app on a model-driven form

4. Export the solution from the development environment and then import the solution into your target environment.

- Unmanaged solutions: If the solution was imported into an environment as an unmanaged solution, edit the model-driven app that has the embedded canvas app control, and then follow similar steps as described for a managed solution to set the canvas **App Name** property.

Embedded canvas app control loads the canvas app from a different environment

When a solution that contains a model-driven app with an embedded canvas app is imported into a target environment, the control loads the canvas app from the source environment (where the solution was exported). The control should load the canvas app from the target (current) environment.

This issue occurs because the app user doesn't have read access to the CanvasApp Extended Metadata table in the target (current) environment. To resolve this issue, add the user to a security role used for the app that has read access to the CanvasApp Extended Metadata table. More information: Grant read privileges for the CanvasApp Extended Metadata table

Error message: "You don’t have read privileges for the Canvas App entity. Please contact your administrator"

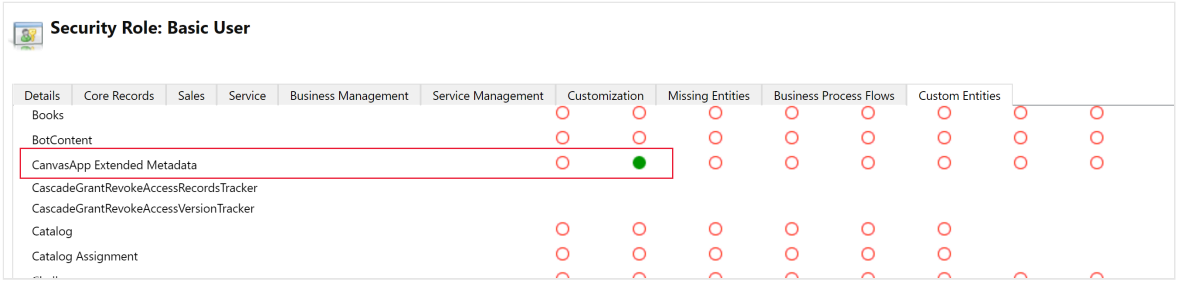
The error message is displayed on the model-driven app form where the embedded canvas app should appear.

This issue occurs because the app user doesn't have read access to the CanvasApp Extended Metadata table. To resolve this issue, add the user to a security role used for the app that has read access to the CanvasApp Extended Metadata table.

Grant read privileges for the CanvasApp Extended Metadata table

1. In Power Apps, select the environment, and then on the left navigation pane select **Apps**.
2. Select the app you want, select **...**, and then select **Share**.
3. On the left pane, select the app, and then select **Manage security roles**.
4. Open the security role assigned to the app, such as the Basic User security role.

5. Select the **Custom Entities** tab, and set organization scope read privileges for the **CanvasApp Extended Metadata** table.



6. Select **Save and Close** to close the security role window.

Migrate embedded canvas apps on model-driven forms

Summarize this article for me

> **Important**
>
> With the latest release, embedded canvas apps on model-driven forms are generally available. Any embedded canvas apps on model-driven forms created using the public preview release should be migrated to new embedded canvas apps created using the latest release. Support for embedded canvas apps on model-driven forms created using the public preview release will soon be deprecated.

To migrate an embedded canvas app on a model-driven form created using the public preview release to the latest, makers first need to create a new embedded canvas app using the latest release. Makers can then copy over the controls from the existing embedded canvas app to the new one, add required data sources and update broken references, if any. Detailed steps are provided below.

1. Sign in to Power Apps.
2. Open the embedded canvas app created using the public preview release for editing in Power Apps Studio. For steps on editing a canvas app, go to: Edit a canvas app.
3. In a new browser tab, follow the steps to add a new embedded canvas app on a model-driven form.
4. Copy the controls from the embedded canvas app created using the public preview release to the new embedded canvas app, one screen at a time using these steps:
   a. Select the browser tab from Step 2, that has the embedded canvas app, created using the public preview release, open in Power Apps Studio.
   b. Select a screen to copy controls from.
   c. Use **Ctrl + A** to select all controls on the screen.
   d. Use **Ctrl + C** to copy all selected controls.
   e. Select the browser tab from Step 3, that has the new embedded canvas app created using the latest release.
   f. Select a screen or add a new one.
   g. Use **Ctrl + V** to paste the controls on the selected screen.
   h. Repeat the steps to copy each screen.
5. When you finish copying all the screens, select the browser tab from Step 3, that has the new embedded canvas app created using the latest release.
6. Update all the places where the row from the host model-driven form is being accessed. Replace **First(ModelDrivenFormIntegration.Data)** with

ModelDrivenFormIntegration.Item.

7. Add any missing data sources in the new embedded canvas app.
8. Update all broken references in the new embedded canvas app.
9. When you finish making changes, select the **File** tab, and then select **Save**.
10. To make your changes available to users, select **Publish** and then select **Publish this version**.

Migrating embedded canvas apps on model-driven forms that use a list of rows related to the current (main form) row

In the preview release, to embed a canvas app on a model-driven form, makers had to decide up front if they wanted to pass the current (main form) row as data context or a list of rows related to the current (main form) row. They then had to add the canvas app control to either the column or sub-grid control.

With the latest release, adding an embedded canvas app on a model-driven form is simplified and streamlined to the column only. Makers can still easily access the list of related rows directly in the canvas app using the Common Data Service connector.

To migrate an embedded canvas app on a model-driven form that uses a list of rows related to the current (main form) row, follow these steps.

1. Follow the steps in the section above to migrate embedded canvas apps on model-driven forms created using the public preview release to the latest.
2. Using the Common Data Service connector, add a data source for the related table to the app. To learn how add a data source in a canvas app refer to Add a data connection to a canvas app in Power Apps.
3. When using the data source of the related table for a control such as Gallery or Data table, use the **Filter** function to filter the rows to the ones that are related to the current (main form) row. The current (main form) row is available via **ModelDrivenFormIntegration.Item**.

   > ⓘ **Note**
   >
   > The embedded canvas app has full access to row from the host model-driven form via `ModelDrivenFormIntegration.Item`. As an example, to get the value of a column with the name **accountnumber** and display name **Account Number**, you can use **ModelDrivenFormIntegration.Item.accountnumber** or **ModelDrivenFormIntegration.Item.'Account Number'**.

4. With recent updates Microsoft Dataverse now also provides support to use table views as a filter. Go to this blog post for details: Improved data source selection and Dataverse views.

List of controls available for model-driven apps

Controls allow app users to visualize data within table columns in addition to enabling interaction with them.

Most controls are configured for a table column, but some controls, like the grid control, can be configured for the table.

Using controls in the form designer

To use these controls in the form designer:

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane. If the item isn't in the side panel pane, select ... More and then select the item you want.
3. Select the required table and then select the **Forms** area.
4. Select the main form to be edited.
5. Select the column or section where you want to add the control.
6. In the right properties pane, select **+ Component** to display the available controls, and then select the control you want.

   > **Note**
   >
   > Different controls are available depending on the column or grid type. For example, star rating controls are only available for whole number columns.

7. Select the devices (web, tablet, and phone) you want the control to appear on.
8. Configure the values for each property.
9. Select **Done** when you're done configuring the control.

The following descriptions explain each control you can use on forms.

Grid controls

Grid controls can be configured at the following levels:

- Table. When you configure a grid control for a table, all views for the table use the grid control. For more information, see Configure a grid control for a table.
- Form. Subgrids added to a form use a grid control to control the behavior of the subgrid.

Subgrid

The read-only subgrid allows you to present a view of data related to the current record where users can view and open the record from within the grid. More information: Add and configure a subgrid component on a form

Editable grid

With editable grids, users can do rich in-line editing of records directly from views and subgrids whether they're using a web app, tablet, or phone. More information: Make model-driven app grids (lists) editable using the editable grid control

Power Apps grid control

The Power Apps grid control represents the next evolution of the Power Apps grid control, allowing users to view, open, and edit records from views and subgrids. By default, the Power Apps grid control is read-only but you can configure it to be editable.

More information: Power Apps grid control

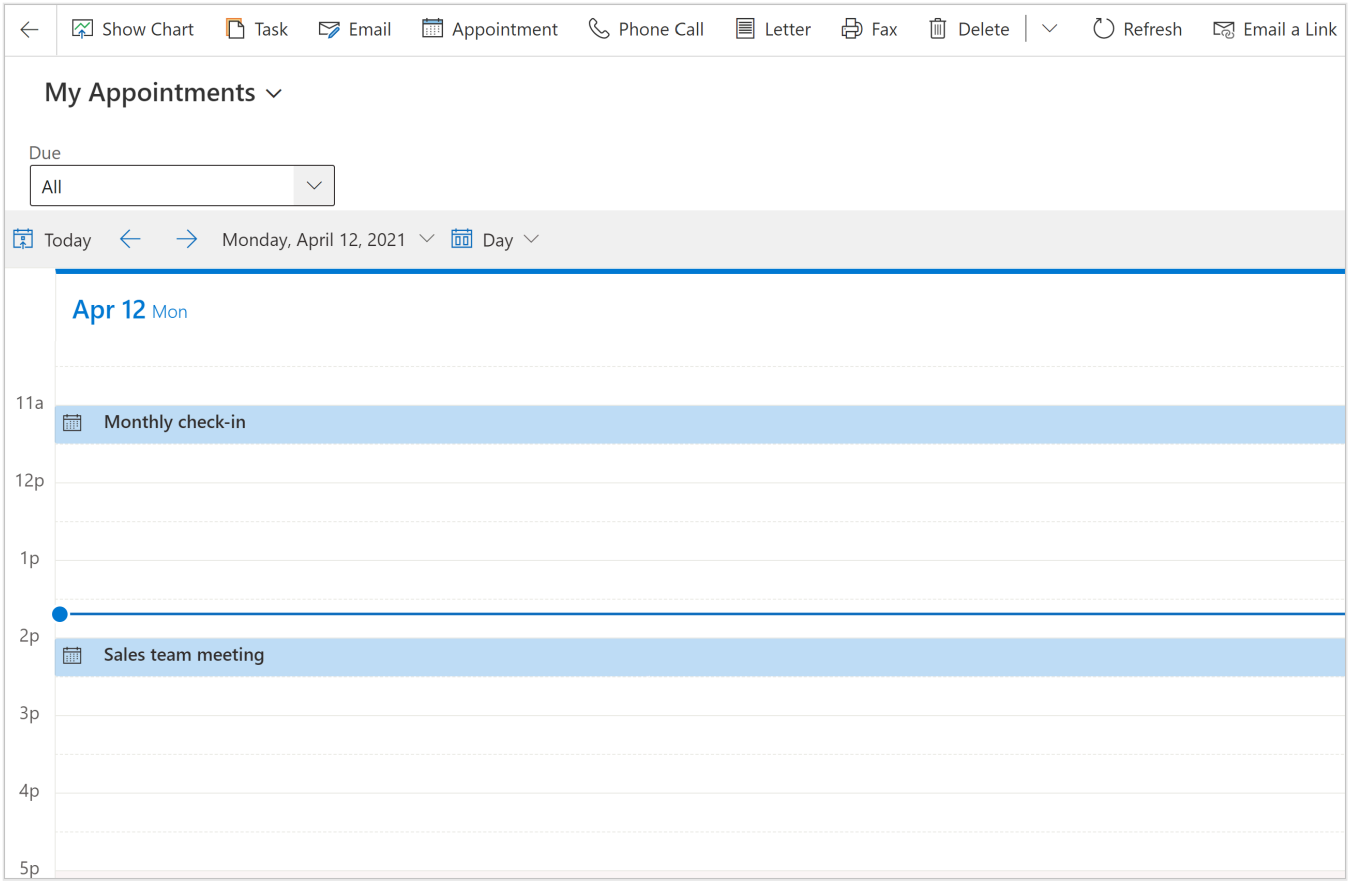
Configure a grid control for a table

1. Sign in to Power Apps.
2. Open solution explorer, expand **Entities**, and then select the table you want, such as the account table.
3. Select the **Controls** tab, and then select the grid you want for the table.
4. Depending on the grid control, specify the values you want, **Save** and then **Publish** the customization.

Display controls

Calendar

The Calendar control control displays scheduled activities and their associated details in a calendar. You can view, create, and delete your activities in a day, week, or month view. More information: Add the calendar control to tables



Canvas app

An embedded canvas app includes rich data integration capabilities that bring in contextual data from the host model-driven form to the embedded canvas app. Display the data you want from a variety of sources right next to data from Microsoft Dataverse. More information: Add an embedded canvas app on a model-driven form

External website

Add inline frames (iframes) to a form to integrate content from another website within the form. More information: Add an iframe to a model-driven app main form

HTML and image web resource

Display an HTML page or image file on a form via a web resource. More information: View and edit a web resource on a form

Knowledge search

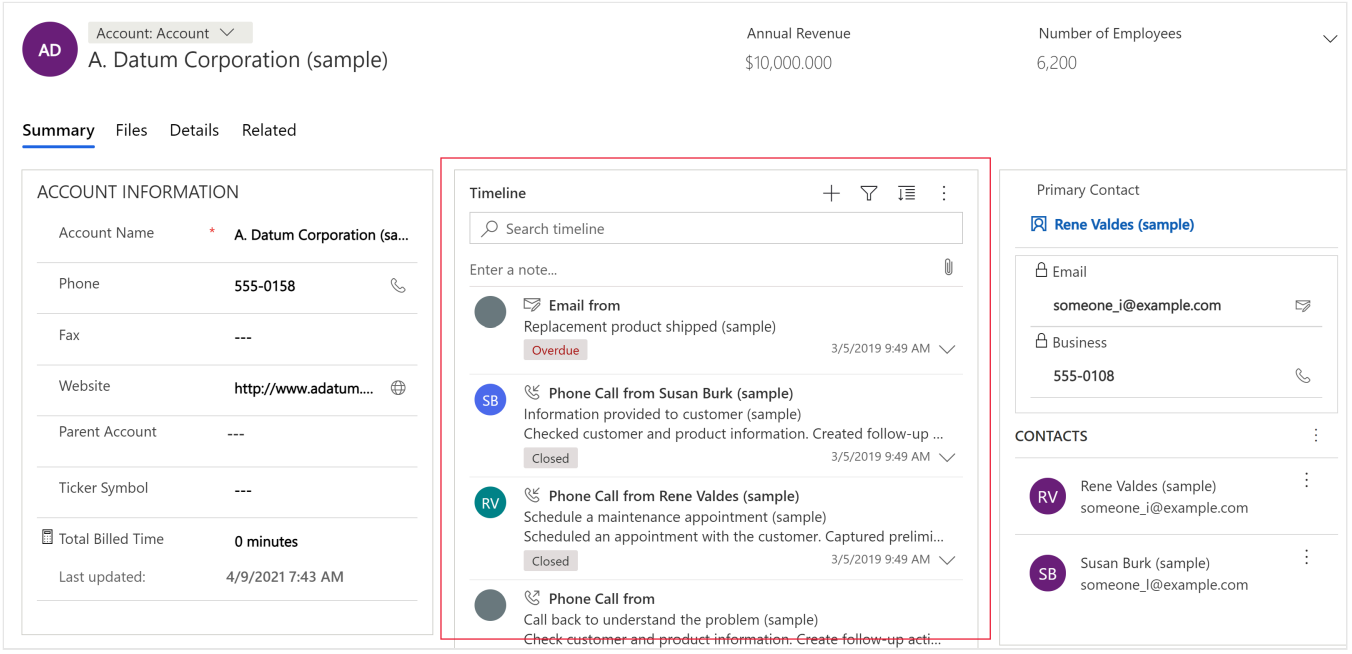
Requires Dynamics 365 Customer Service app. Add a Knowledge Base Search control to a form to make it easy for users in your organization to find knowledge articles so they can answer common customer questions and resolve their issues right from the records, without having to switch to a different application. More information: Add the Knowledge Base Search control to forms

Quick view

The quick view control displays data from a row that you select in a lookup on the form. You define the data displayed in the control by using a quick view form. The data displayed isn't editable, but when the primary column is included in the quick view form, it becomes a link to open the related row. For more information, see Model-driven app quick view control properties.

Timeline control

Provide a timeline of recent, relevant news articles and Twitter tweets for an account. More information: Set up the timeline control



Expand table

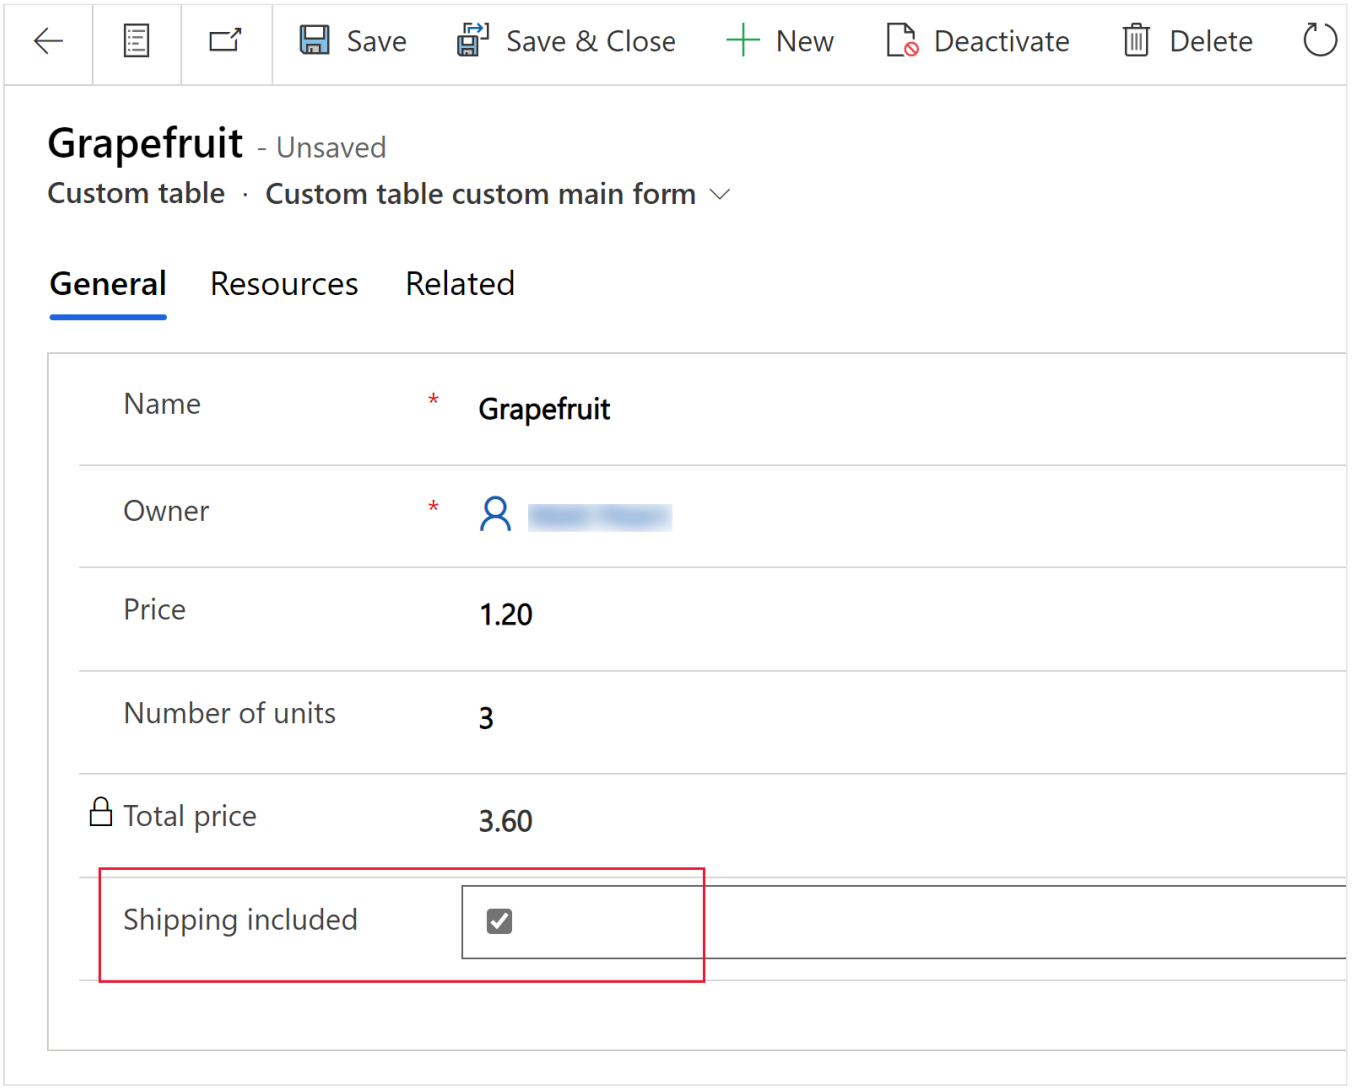
Property	Description
CC_Timeline_Title	Property to map for the title of each timeline item.
CC_Timeline_Title_Desc	Description for Title.
CC_Timeline_Label1	Column to be displayed below the title of timeline item.

Property	Description
CC_Timeline_Label1_Desc	Description for Label 1.
CC_Timeline_Label2	Column to be displayed after Label 1.
CC_Timeline_Label2_Desc	Description for Label 2.
CC_Timeline_Label3	Column to be displayed after Label 2.
CC_Timeline_Label3_Desc	Description for Label 3.
CC_Timeline_Label4	Column to be displayed after Label 3.
CC_Timeline_Label4_Desc	Description for Label 4.
CC_Timeline_Label5	Column to be displayed after Label 4.
CC_Timeline_Label5_Desc	Description for Label 5.
CC_Timeline_Timestamp	Column to use for sorting timeline in reverse chronological order.
CC_Timeline_Timestamp_Desc	Description for Timestamp.
CC_Timeline_Group	Column to map for grouping timeline.
CC_Timeline_Group_Desc	Description for Group column.
CC_Timeline_GroupOrder	Order of the group the item belongs to relative to other groups (assign values 1, 2, 3, and so on for groups to be displayed). The group will be displayed in ascending value of group values assigned.
CC_Timeline_GroupOrder_Desc	Description for Group Order column.
CC_Timeline_URL	URL column to map for displaying the URL of each timeline item.
CC_Timeline_URL_Desc	Description for URL column.
CC_Timeline_ThumbnailURL	Column to map for thumbnail of image/icon to display for each item.
CC_Timeline_ThumbnailURL_Desc	Description for the `ThumbnailURL` column.
CC_Timeline_Filter	Column to map for timeline filter.
CC_Timeline_Filter_Desc	Description for Filter.
CC_Timeline_Footer	Web resource to display as the footer of the timeline.
CC_Timeline_Footer_Desc	Description for Footer column.

Input controls

Checkbox

Use the checkbox control to let users choose between two values by checking or clearing a check box. Configure it by using yes/no choice columns.

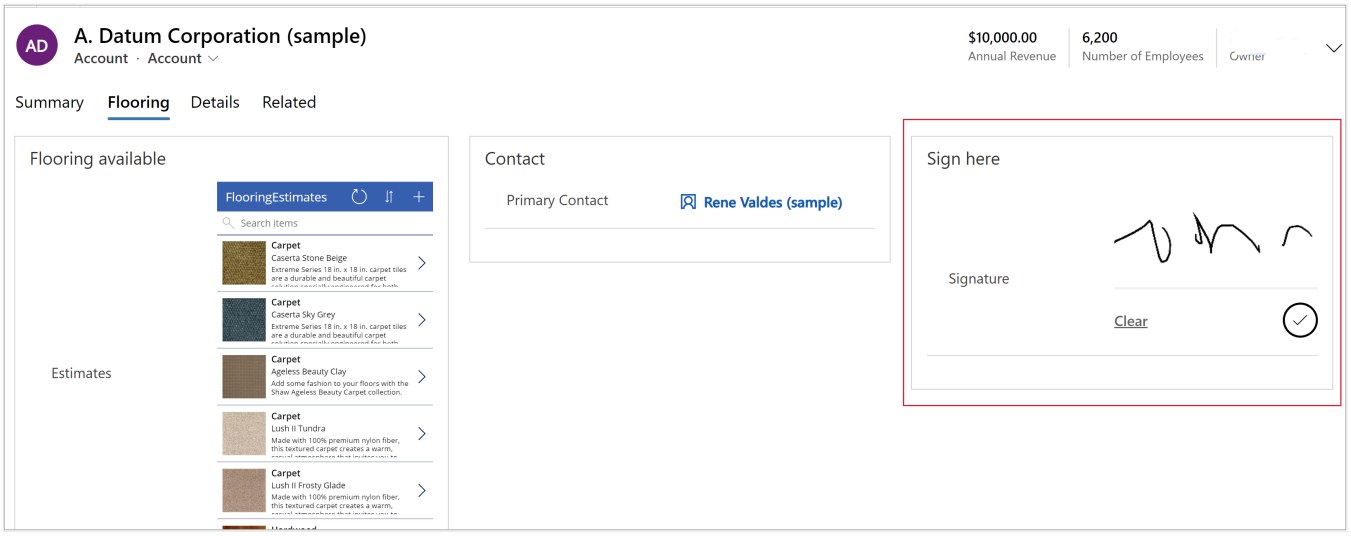


Option set

The option set control presents a set of choices for your users to choose from when entering data. It is made available by default when introducing a choice column into a form. More information: Choices

Pen input

Use the pen input control to capture written input such as signatures. The pen input control can be configured for multiline text columns for use with web, tablet, and phone clients.



> [!IMPORTANT]
> The minimum recommended **Maximum Length** specified for the column this control maps to is 15000.

Expand table

Property	Description
PenMode	Specify **PenMode!Draw**, **PenMode!Erase**, or **PenMode!Select** to determine what happens when a user drags a pointing device in a pen control.

Rich text editor

The rich text editor control provides the app user a WYSIWYG editing area for formatting text. The control's input and output format is HTML. The control allows copied rich text, such as from a web browser or Word, to be pasted into the control. It can be configured with text columns. More information: Add the rich text editor control to a model-driven app

Toggle

The toggle control allows users to choose between binary values, such as on/off and yes/no, by toggling the button. It can be configured with yes/no choice columns.

AI Builder

Business card reader

Use the AI Builder business card reader control to detect business cards and extract their information. You can take photos directly in the component or load images that you've taken. More information: Use the business card reader component in model-driven apps

Power BI

Power BI report

Embed a Power BI report in a model-driven app dashboard. More information: Create or edit a Power BI embedded system dashboard

More components controls

Some components aren't displayed in the default **Components** list in the form designer but can be added to the list by selecting Get more components.

Form component

The form component control lets users edit information of a related table record directly from another table's form. More information: Edit related table records directly from another table's main form

Collaboration controls

Collaboration controls give you the power to simplify your user's workflow collaboration. Build model-driven apps that allow users to work with approvals, files, meetings, notes, and tasks from Microsoft 365 and Microsoft Teams without switching the context from app to app. More information: Collaboration controls

Legacy controls

Timer control

The timer control shows your users how much time is available to complete an action in the resolution of an active row or how much time has passed since the time to complete the action has passed. More information: Model-driven app timer control overview

News control

Only available in classic.

Gain valuable insights from the latest news about your customers, competitors, and contacts. The news control delivers relevant news from Bing News. More information: Set up and use the news control

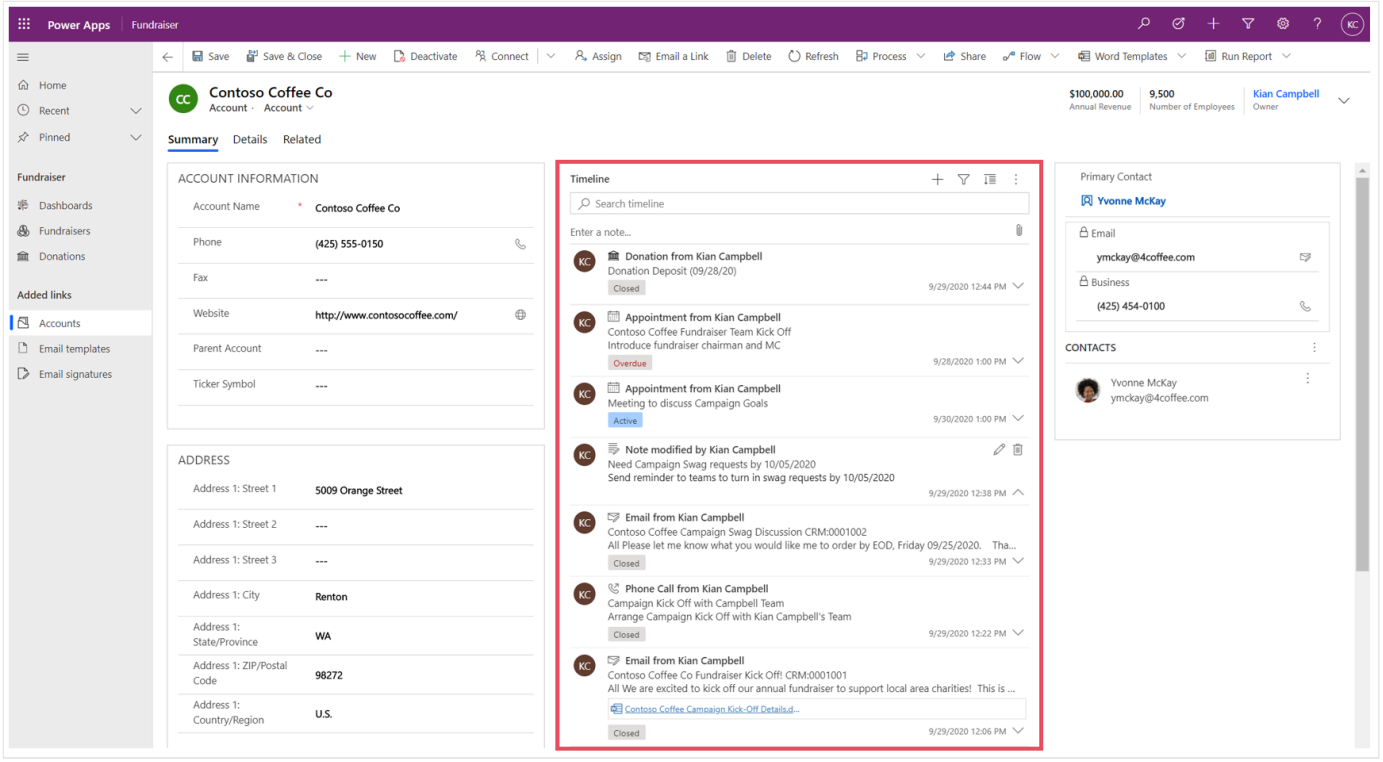
Next steps

Tutorial: Use custom controls for data visualizations

Last updated on 04/07/2026

Set up the timeline control

The timeline helps app users review all activity history. The Timeline control captures activities such as notes, appointments, emails, phone calls, and tasks. It tracks interactions for a related table over time. Use the timeline to quickly catch up on all of the latest activity details.



The timeline control provides an easy way to view information related to a table, such as accounts or contacts. This immersive experience helps give users a better understanding of their customer interactions, and helps them deliver more personalized service in an efficient and effective manner.

App makers can configure the information that appears on the timeline. Users can then access information and create activity records, such as emails and tasks, directly from the timeline.

Add a timeline

A timeline control is located on a form within a table. Any timeline control on a form can be configured. For example, an account table has three standard forms, and each of those forms can have a timeline that can be configured.

Display a custom table in a timeline

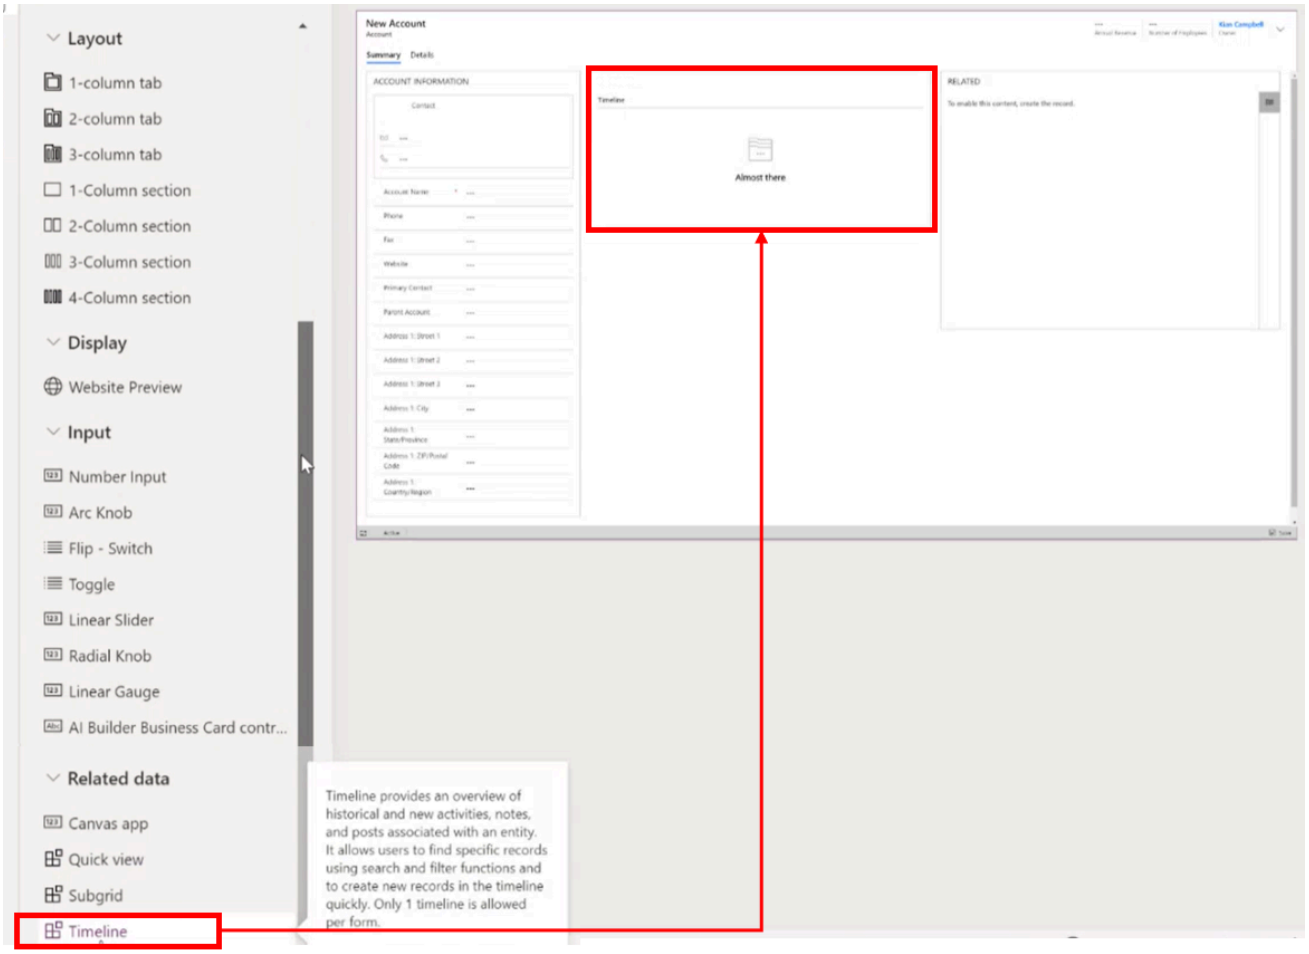
To add custom tables as activities in a timeline, configure the following settings when you create the table:

- Set the table **Type** as **Activity**.
- Check the **Enable attachments** setting if you want app users to be able to add attachments and notes to the custom activity record.

Learn more in Create a custom table.

Add the timeline component to a form

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane, and then open the table you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Forms** area, and then open the form where you want to add or configure a timeline.
4. In the form designer, select **Components** from the left navigation, and then scroll down to the **Timeline** component on the left side. Drag and drop it into a section on the form.



5. Make the changes you want to the timeline settings. Learn more in Configure the timeline component.

6. Before you can view any configuration changes on the table form, you must save and publish your updates on the timeline component. Select **Save**, and then select **Publish** to make your form changes available on the table form for the environment.

Note the following when you work with the timeline control in the form designer.

- You can add multiple timelines to a form.
- To remove the timeline component from a form, select the **Timeline** component area, and then press the Delete key.
- Since the timeline component relies exclusively on underlying related data, **Almost there** is displayed in the timeline section.
- Because you are in a create and/or edit state on the form, there's no underlying data, so the timeline section is blank in the form designer.

Configure the timeline component

The timeline component is rich in features and functionality that can be configured and tailored to support specific business needs. The timeline is composed of features and functionality that you configure in the timeline component, which is then displayed in the table form.

Display options

This section describes the settings available in the Display options area of the timeline control settings.

Timeline component name

The **Name** column under the **Properties** tab in **Display options** is the unique name of the timeline control and is only used by the app maker to reference.

> ⓘ Note
>
> - The **Name** column has limitations. For example, you can't use spaces between words. Instead, you must use an underscore (_)
> - You can't change the default heading label that is displayed as **Timeline** on the form during app runtime.

Records shown on page

This section allows you to control the number of records that appear before displaying **Load more** at the bottom of the section.

Expand table

Form designer configuration View	Form designer display View
	The default setting on the **Records shown on page** column is set to 10 records, but you can change it to display up to 50 records.	1. Per the default setting shown in this example, the form displays a maximum of 10 records. 2. Once records exceed 10, the **Load more** option appears at the bottom of the form.

Record types to show

There are three primary record types: Activities, notes, and posts. All record types are enabled by default.

- Activities. Activities can have a large number of customizable subactivity record types to support business needs. Depending on what you install, the administrator can create, add, and display many different customized subactivity record types under the **Activity** section of the dropdown menu on the timeline.
- Notes. Notes allow you to capture details related to the table record. For example, you can use notes to capture thoughts, summarize information, and provide feedback on a case, and then update the case details later.
- Posts There are two types of posts: auto and user:
  - **Auto Posts** are system-generated posts that notify you of account activity.

- **User Posts** allow you to leave a message for another user on a record.

> **Note**
>
> Posts require a Dynamics 365 app, such as an app for Dynamics 365 Customer Service.

Enable these record types to be displayed in the timeline

Expand table

Form designer configuration view	Form designer display view
	To enable **Record types shown** for **Activities**, **Notes**, and **Posts** on a form, check the box next to the record type.	1. To confirm that the record type is displaying on the form, select **Create a timeline record** + in the top-right nav in the timeline, and a dropdown menu that displays the list of enabled record types appears. 2. When **Activities** are enabled, the system displays **Activity** record types for appointments, email, phone calls, and tasks. 3. When **Notes** are enabled, the system displays the note record types on the form. 4. When **Posts** are enabled, the post record types display on the form.

> **Note**
>
> Activities and notes are standard entities. If additional solutions have been imported into the environment, other tables may also be displayed.

Activity, notes, post icons, and date / timestamp display on timelines

The timeline shows a simple icon before the activity, note, post, and custom table, making it easy for you to identify the record type.

Dates and timestamps always appear on each record on the bottom-right side of the preview, and are always viewable.

> **Note**
>
> When a custom table has a custom icon, activities related to the custom table are displayed using the default custom table icon not the custom icon.

Advanced

This section describes the settings available in the Advanced area of the timeline control settings. The **Advanced** settings apply to all record types.

When enabling and disabling **Advanced** features, you aren't able to view updates (even though it might appear that there's activity occurring on the timeline component) until you save and publish your configuration updates and refresh the table form.

Advanced covers common settings that span across an activity, note, or post, which are the three primary record types that appear in the timeline section.

Quick entry record type and sort order default

The following is a detailed overview of the **Advanced** configuration options, starting with selecting your **Quick entry record type**:

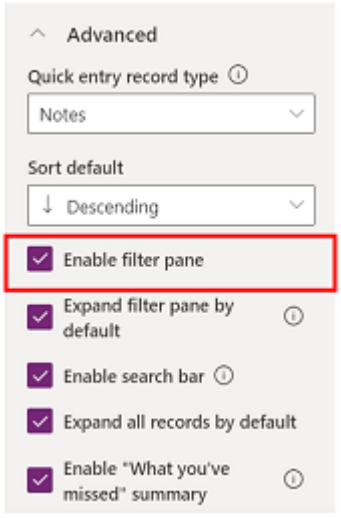
Expand table

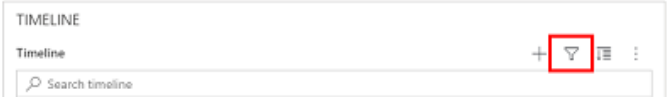
Form designer configuration View	Form designer display View
	1. Select **Advanced** to expand this area in the configuration view. The **Quick entry record** type provides you with quick access to create either a **Note** or a **Post**. The default setting for this setting is set to **Notes**. 2. The **Sort order default** setting controls the order of how all data is sorted on the timeline. The default setting for this setting is set to **Descending**.	1. When you select **Notes**, it displays under the **Search** bar in the timeline. Also, the system displays the paperclip icon that allows you to attach files. You can only attach files to notes. 2. If you select **Posts**, it also displays under the **Search** bar in the timeline.

Enable filter pane

Filters provide a quick option to sort and look for specific data quickly.

Expand table

Form designer configuration View	Form designer display View
	




Form designer configuration View	Form designer display View
The **filter pane** setting allows you to enable or disable filter functionality on timeline. It's enabled by default.	Enable the **filter pane** by checking the box next to the setting. This setting enables the filter icon to display on the timeline. To disable the **filter pane**, clear the box next to the setting and the filter icon no longer appears on the timeline.

Filter records on timeline

Filters are valuable for sorting data. You can quickly filter activities, notes, and posts with multiple options to display what matters to you. The filter is available for the activities, notes, posts, and custom tables that are present in the timeline. The timeline filters and displays the records and the count that are present in the timeline.

When you select filters based on an activity status then those activities, notes, and posts are displayed in your timeline. You can customize data using data filters and either choose to keep filters in place or clear them when you're done.

- When the **Filter** icon is transparent on the table form, it means no items were selected, so the filter pane is empty.
- When the **Filter** icon is dark, it means filters are set. To view which filters are set, select the **Filter** icon. The filter pane displays the selected filters.
- Choose how you want to filter data by selecting the box next to the filter.
- Clear filters by selecting the **Clear all filters** icon on the filter pane.

The following category and subcategory options are available on the filer menu:

Expand table

Category	Subcategory
Record type	• Notes • Activities • Posts
Activity type	• Appointment • Campaign Activity[1] • Campaign Response[1] • Email

Category	Subcategory
	• Fax • Case Resolution[1] • Letter • Opportunity Case[1] • Order Case[1] • Phone Call • Quote Close[1] • Recurring Appointment • Social Activity • Task • Project Service Approval[1] • Booking Alert[1] • Conversation • Session • Customer Voice survey invite[1] • Customer Voice survey response[1] • Custom activities (made available by imported solutions)
Activity status	• Active • Overdue • Closed
Activity status reason	Allows you to filter using specific status reasons. The values are a unique list of all of the status reasons from the activities in the timeline. The status reasons change depending on the activity. If multiple activities on the timeline have the same status reason, it appears once. The number next to it shows how many times the status reason occurs on the timeline.
Activity due date (active)	• Next 30 days • Next seven days • Next 24 hours • Last 24 hours • Last seven days • Last 30 days
Posts by	• Auto post • Users
Modified date	• Last 24 hours • Last seven days • Last 30 days

> **Note**
>
> By default, the fax and letter records are disabled on the timeline.

[1] Requires a Dynamics 365 app

Expand filter pane

The **Expand filter pane** setting provides quick access to sorting options within the timeline. It's enabled by default.

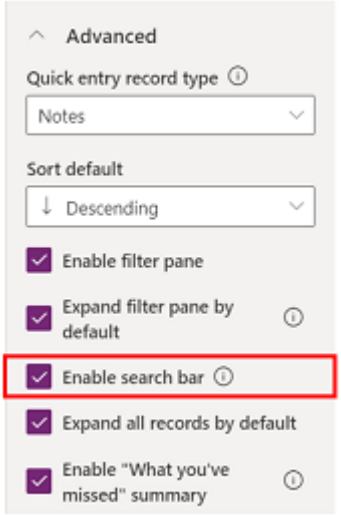
Expand table

Form designer configure view	Form designer display view
	The **Expand filter pane by default** setting displays an expanded filter pane at the top of the form each time the form opens or refreshes. It's disabled by default.	Enable the **Expand filter pane** by checking the box next to the setting. This setting enables the filter pane to appear at the top of the form anytime the form is opened and refreshed. To disable the **Expand filter pane**, clear the box next to the setting and the filter pane doesn't appear on the timeline.

Enable search bar

You can search for records in the timeline. When you search for a phrase in the timeline, it searches in the title of the record or body and description column of the record then displays the record for you.

Expand table

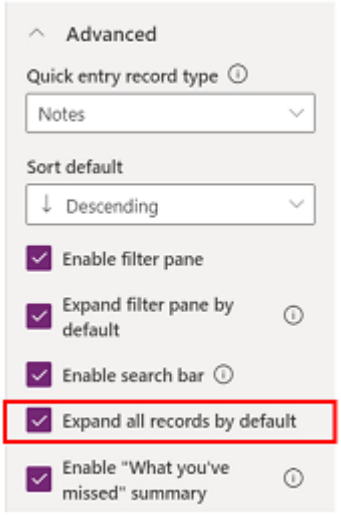
Form designer configure view	Form designer display view
	


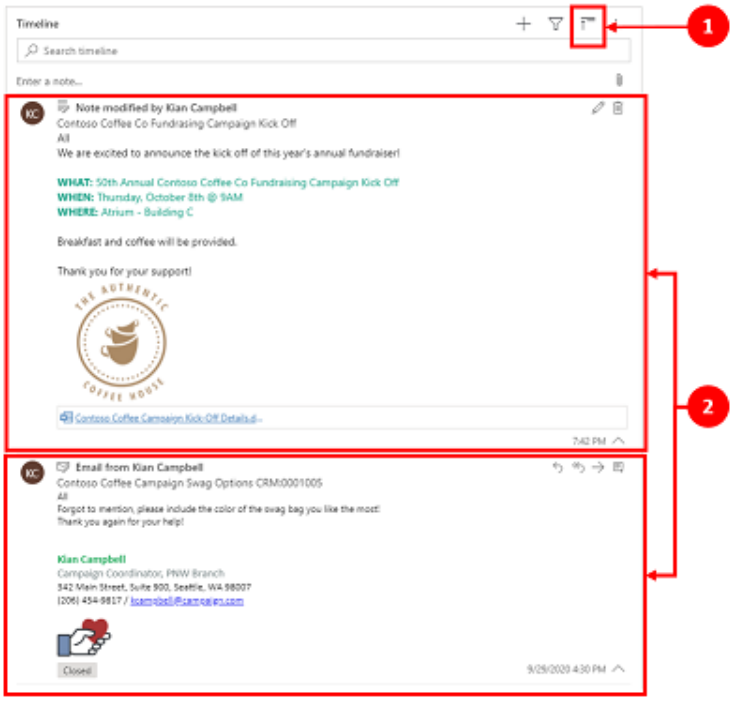
Select **Enable search bar** to enable the **Search timeline** bar functionality. It's enabled by default.	Enable the search bar setting to display a **search bar** at the top of the timeline. Disable the search bar by clearing the box next to the setting and the search bar doesn't appear on the timeline.

Expand all records in timeline

Expand all records by default displays all activities in an expanded view in timeline.

Expand table

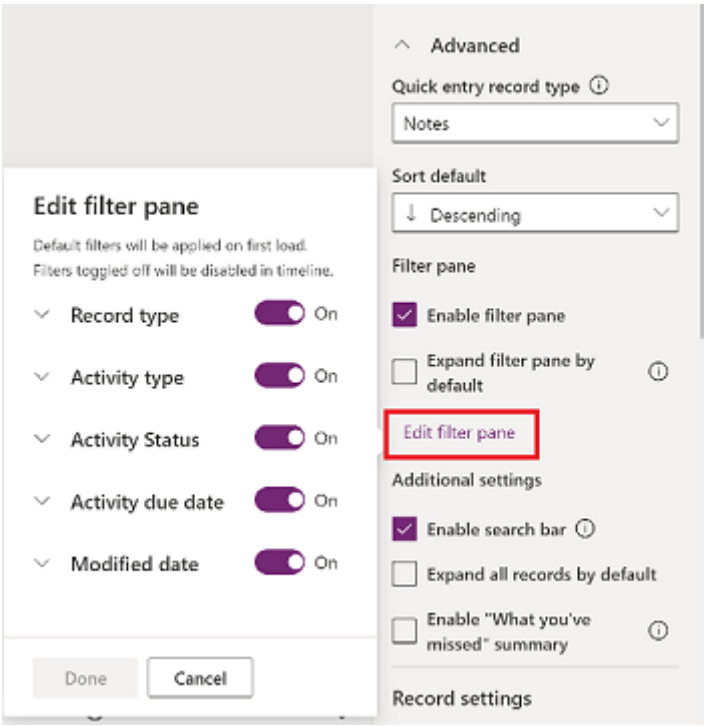
Form designer configure view	Form designer display view
	




Form designer configure view	Form designer display view
Select **Expand all records** to set the default view to display all records in the expanded view format in the form each time the timeline is opened. **Expand all records** is disabled by default.	1. When enabled, the **Expand all records** icon is displayed in the top-right corner of the timeline nav. 2. Records can be expanded or collapsed by using the **Expand all records** icon. When expanded, all records display in the expanded view each time the form opens. When you clear **Expand all records**, it no longer displays activities in an expanded view. When disabled, the **Expand all records** icon doesn't display in the top-right nav of the timeline. Records are always be displayed in a collapsed view.

Edit filter pane

You can configure the default filters that are applied when a form loads or is refreshed using **Edit filter pane**. Remove filter groups by turning the setting **Off**. Users can remove the default filters to display all the records unless **Enable filter pane** is disabled.

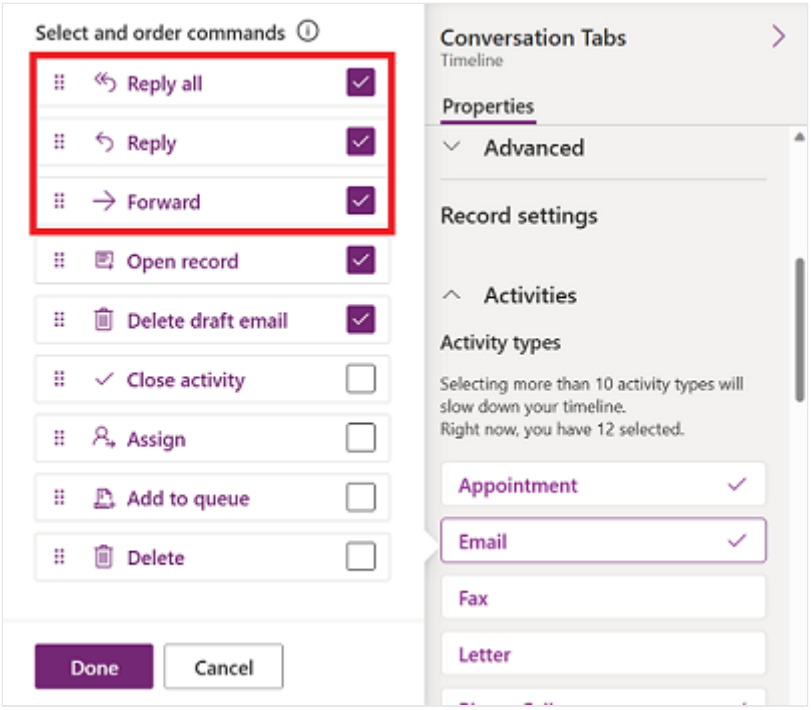


Configure email commands for timeline

You can configure email options for the timeline so that users can reply, reply-all, and forward messages. You can select the order in which the options are displayed for users, and exclude them if they're not needed. Reply-all is the default order setting.

1. Select the form for which you want to apply the email settings, and then in **Properties** in **Conversation Tabs**, select the **Email** activity type. The **Email** properties pane is displayed.

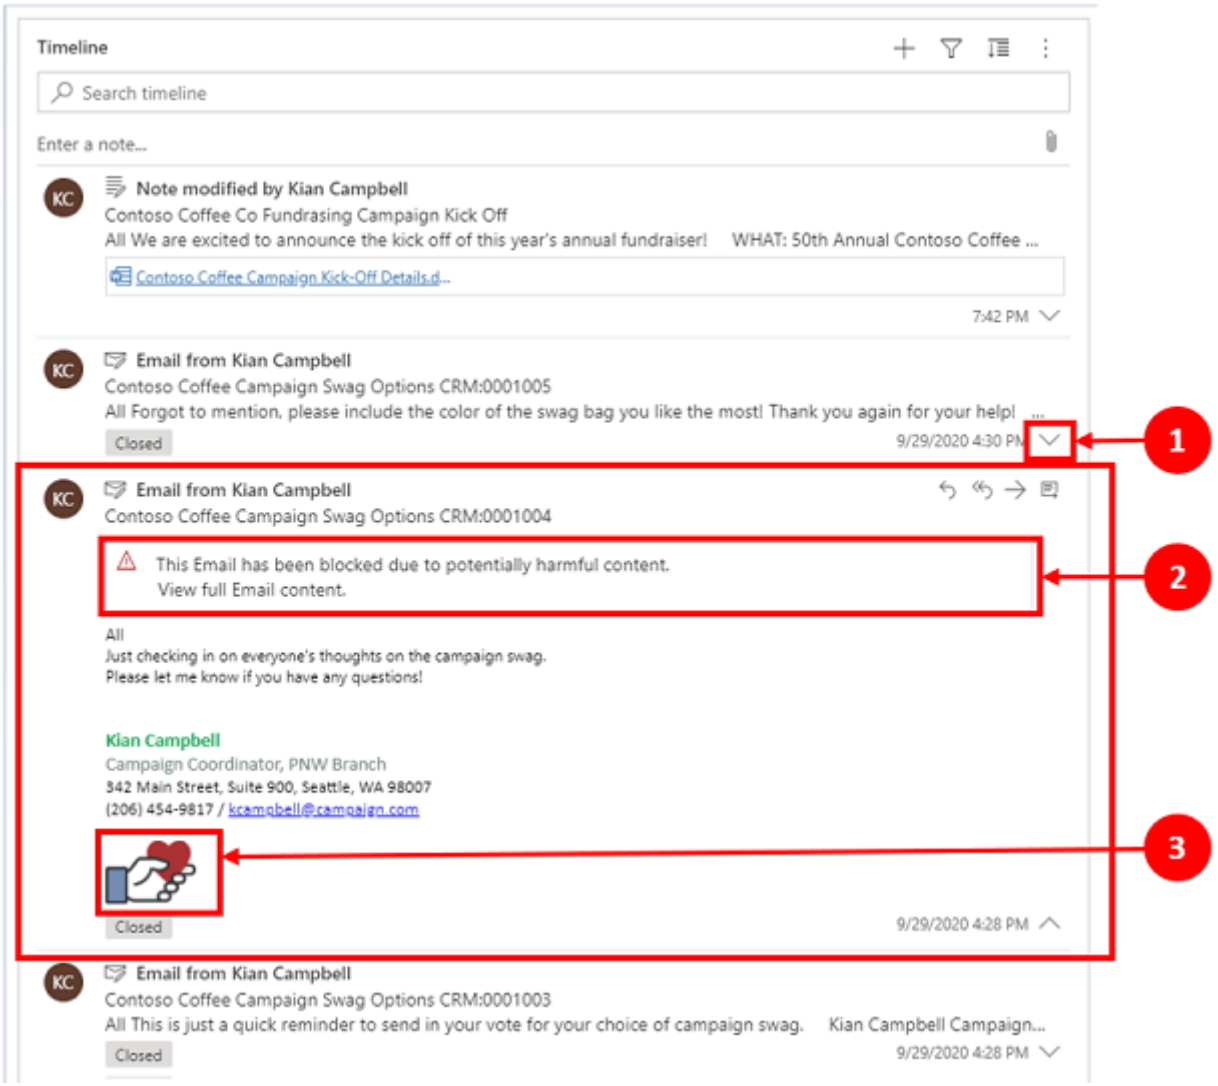
2. In **Select and order commands**, check the boxes for the email commands you want to configure for users. You can drag and drop the options to choose the order in which you want each option to display.



3. Select **Done**, and then save and publish your changes.

Expand records with images in timeline

You can send and receive records with images, but they don't display when the record is collapsed. To view the images, you must expand the records.



1. Records when collapsed provide a visual summary. To expand an individual record, select anywhere on the timeline record to expand and collapse a record view. In the bottom-right corner of the record, there's a caret:

    - When the caret is facing downward (v), the record is collapsed.
    - When the caret is facing upward (^), the record is expanded.

2. Records with images might display the following notice:
   This email has been blocked due to potentially harmful content. View full email content.

3. When you select the message, the warning goes away, and the image appears.

Enable "What you've missed" summary

The **What you've missed** summary helps you stay on top of updates and changes made to records by displaying updates at the top of the timeline when you access a record.

Expand table

Form designer configure view	Form designer display view
	The **What you've missed** setting displays new records that are available for review. It's enabled by default. To disable it, clear the box next to the setting.	When enabled, when you view an account record, the newest activities appear at the top of the list.

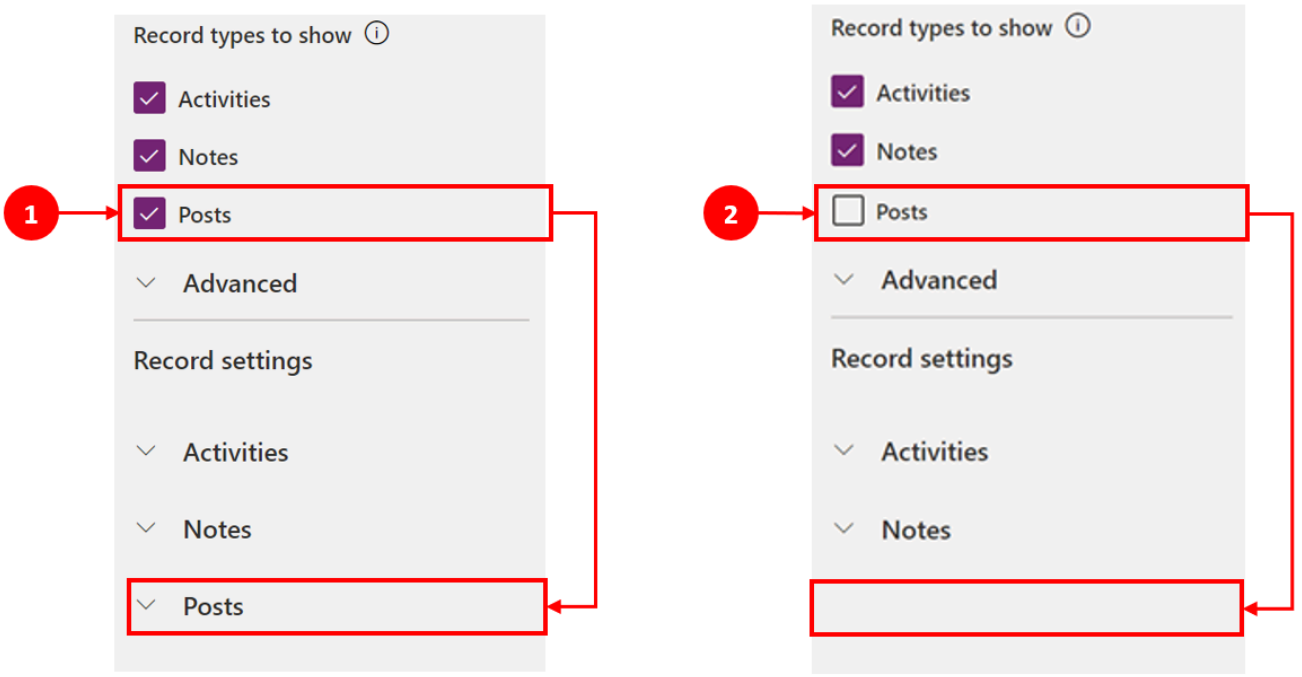
Record settings

This section describes the settings available in the Record settings area of the timeline control settings. The **Record types to show** setting determines the record types that are affected by the **Record settings** described here.

Record settings let you manage the settings within the record types.

- The **Activities** record type is tied to **Activities** in record settings.
- **Notes** record type is tied to **Notes** in record settings.
- **Posts** record type is tied to **Posts** in record settings.

To enable or disable a record type, select or clear the checkbox. Then, that record type either displays or no longer appears in the **Record settings** section.



1. When **Posts** is checked in the **Record types to show** section, it appears in the **Record settings** section.
2. When **Posts** is cleared in the **Record types to show** section, it no longer shows in the **Record settings** section.

Configure activity record types

When you expand the **Activities record settings** on the timeline component section, a list is displayed that shows all the activity types that can be either enabled or disabled on the table form.

Expand table

Form designer configuration view	Form designer display view
	1. Expand and view **Activities** under the **Record settings** section using the caret (^). 2. A list of **Activity types** is displayed in the expanded view. 3. You can enable or disable an activity by selecting an activity type. For example, enable **Email**. To enable an **Activity type**, check the box next to **Enable** and select **Done**. To disable an **Activity type**, clear the box next to **Enable**, and then select **Done**. This action disables all other items in the box and disables the activity type from displaying on the timeline. This action also disables the activity type from being created or viewed in the timeline.	1. When enabled, an **Activity type** appears under the **Create a timeline record** +. 2. The activity type is displayed as an option the user can choose from the dropdown menu. 3. Also, the **Activity type** record is displayed in the body of the timeline.

> **Note**
>
> A checkmark appears next to enabled **Activity types**. Other record type settings remain disabled until you enable them for that record type.

Show status tags on activity record types

Status tags match the status filters that display in the timeline to help you be able to quickly review whether the state of an activity record is **Active**, **Overdue**, or **Closed**, such as on a task,

appointment, or email. Makers enable or disable status tags for any **Activity type** in the default form configuration. Status tags are enabled by default.

Expand table

Form designer configuration view	Form designer display view
	To display email status tags, select **Default form** (pencil icon) > **Show** in the **Display option** dropdown list under **STATUS TAG**.	When enabled, status tags such as **Active**, **Overdue**, or **Closed** appear in the timeline next to that activity record.

Enable the ability to create directly from timeline

App makers have the ability to enable activity types so they can be created directly on the timeline. Having the ability to quickly select and create an activity, such as email, tasks, and appointments, helps to streamline productivity.

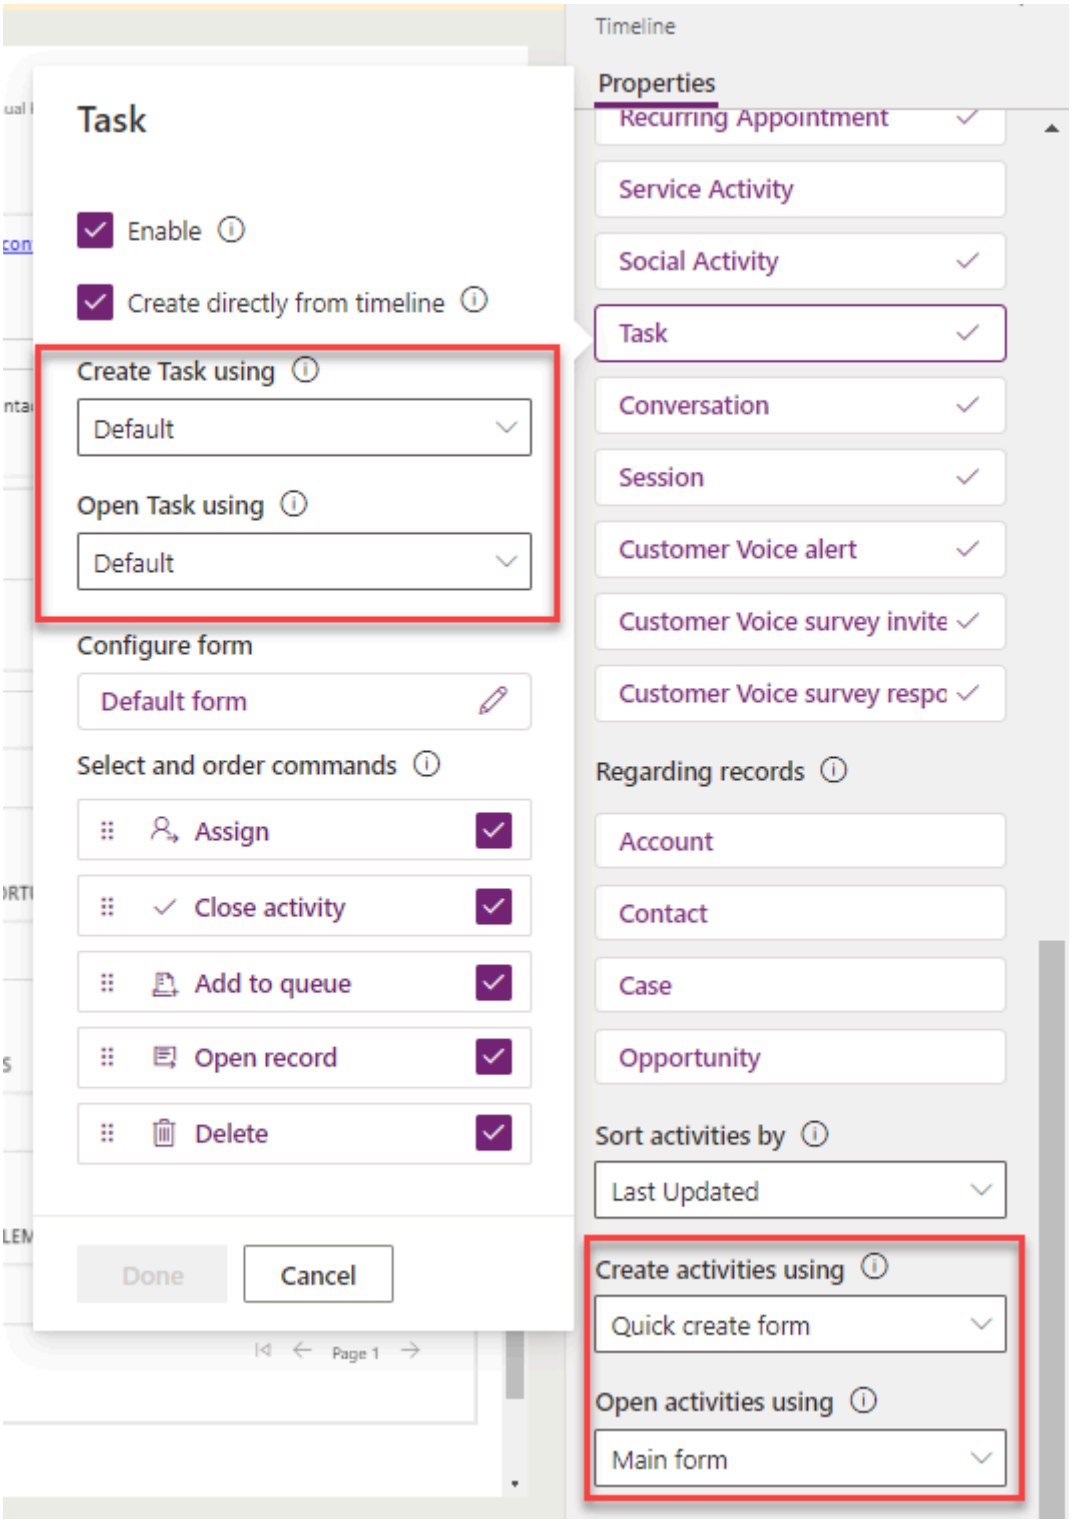
Expand table

Form designer configuration view	Form designer display view
	To allow users to create activity types directly from the timeline, check the box next to **Create directly from timeline**.	When enabled, the activity type appears in a dropdown box on the **Create a timeline record** icon in the top-right of the timeline.

Set form types to create and open activities

Set the **Create activities using** and **Open activities using** individually for an activity type or for all activity types to set the form type users use based on your business needs. You can set these fields as follows:

- Select an activity type in **Activities** and specify the values.
- Specify the value for these fields in the **Activities** pane.



If you set the following form type for a specific activity, the application considers the following settings:

- **Default**: The form type in the **Create activities using** or **Open activities using** in **Activities**.
- **Quick create form**, **Main form**, or **Main form dialog**: The activity specific setting irrespective of the form type set in **Create activities using** or **Open activities using** in **Activities**.

When a user creates or opens an activity from the timeline, it uses the selected form type.

Enable command actions on activity record types (Preview)

> **Note**
>
> These features are part of an early access release. You can opt in early to enable the features in your environment, which allows you to test them and then adopt them across your environments. For information about how to enable these features, refer to Opt in to early access updates.

Command actions allow users to assign, close, delete, open a record, or add a record to a queue for activities from the timeline. You can enable or disable the command actions for a specific activity type.

Based on the activity type, you can also enable other command actions. For example, for an email you can also enable actions such as Reply, Reply All, and Forward.

Expand table

Form designer configuration view	Form designer display view
	To allow users to enable command actions for an activity directly from the timeline, check the box next to command action in **Select and order commands**. You can only enable five command actions for an activity.	
You can also move the position of the command actions to change the order in which they're displayed on the timeline.	When enabled, the command action appears on the activity record in the timeline.

Display related records on the timeline

Accounts, contacts, cases, and opportunities linked to an activity are displayed on the timeline record. The administrator can enable or disable the records in **Regarding records**.

Expand table

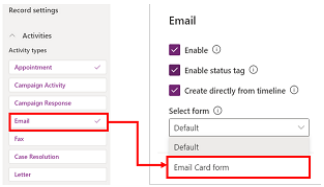
Form designer configuration view	Form designer display view
	1. Expand and view activities under the **Record settings** section using the caret (^). 2. A list of records are displayed in **Regarding records**. 3. To enable records, select the box next to **Enable** and select **Done**.	When the checkbox is enabled, users can view the linked records to an activity. The record linked to the activity is then displayed on the timeline. The linking of the record isn't manual and it occurs due to the rollup of the record. Learn more in Set the activity rollup type in timeline.

> **Note**
>
> A check mark appears next to the enabled record. Disabling the table type only disables the linked record for the Timeline records rolled up for that table.

Create and use card forms in timeline

Records are displayed using the default setting for each activity type. To display record information for an appointment or email, edit the existing card form, select a different card form in record settings, or customize a new card form.

Expand table

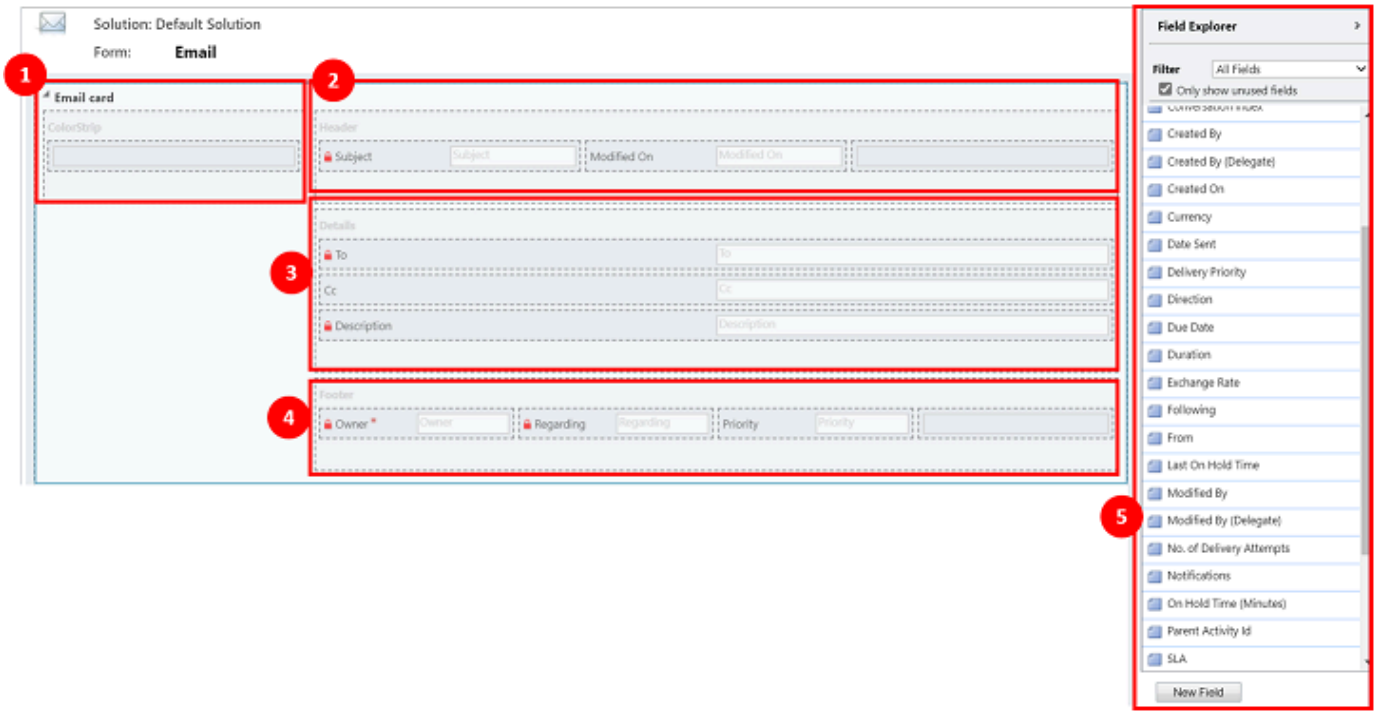
Form designer configure view	Form designer display view
	


You can change the default card settings to a different card form if one exists.	If you create a new card form, you must go to the parent table and add the new form of card type there before it appears in the timeline list for configuration. If **Default** is displayed, you aren't using the card form. You can't use the **Email card form** in a timeline unless you select and publish it first.

> **Note**
>
> Not all activity types allow you to create card types, so the default selection is your only option for those records.

Customize a card from within timeline

All card forms are separated into the following four sections:



Legend

1. **ColorStrip**: This section doesn't appear on the timeline record. The **ColorStrip** is located on the left of the card form.
2. **Header**: This section is displayed on the timeline record; however, only the first two columns are displayed on the timeline record. For this example, only the **Subject** and **Modified On** columns are visible.
3. **Details**: This section is displayed on timeline record; however, only the first three columns are displayed on the timeline record. For this example, only the **To**, **CC**, and **Description** columns are visible on the timeline record.
4. **Footer**: This section isn't displayed on the timeline record.
5. **Table columns**: You can select which columns you want to add to your card form from the column options listed. You can customize your card form by dragging and dropping the columns you want to use into the sections you want that column to appear in on the timeline record.

Each individual card form must be customized for each activity record, such as email, tasks, posts, and so forth.

Header section

The card **Header** displays the title/subject in your timeline email form. You can have up to six columns in the **Header** section, but only the first two columns display on the timeline record. The form ignores empty columns in all sections.

Expand table

Form designer configuration view	Form designer display view
	Column 1 1. Regardless of the column you choose for this section, it appears as a bold header at the top of your timeline record. For this example, we selected **Subject** for this column.	**Column 1** 1. Column 1 from the card header is always displayed in this section of the timeline record.

Form designer configuration view	Form designer display view
Column 2 2. Again, regardless of the column you choose for this section, this column always appears in the bottom-right corner of the timeline record. For this example, **Modified On** is selected for this column.	**Column 2** 2. Column 2 from the card header is always displayed in this section of the timeline record.

Details section

The card **Details** section displays in the body of your timeline email record. You can have up to four columns in the **Details** section, but only the first three columns are viewable on the timeline record.

Expand table

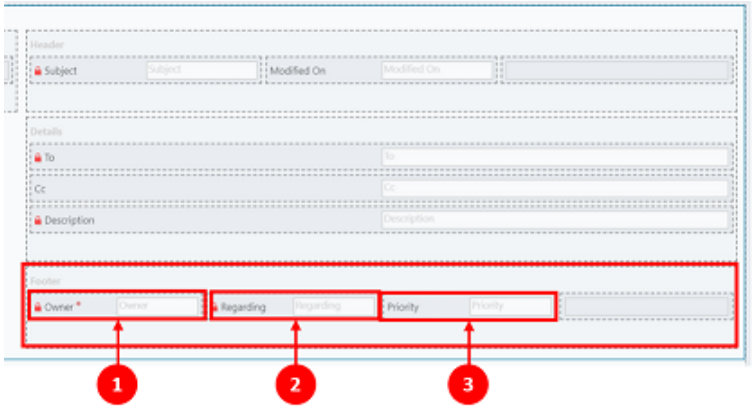
Form designer configuration view	Form designer display view
	The card details always appears below the header regardless of the column you choose. **Column 1** 1. In the card details, Column 1 acts as a subheader on the timeline record. For this example, **To** is selected for this column. **Column 2**	**Column 1** 1. This column always displays in this section and acts as a subheader on the timeline record. **Column 2** 2. This column always displays in this section and only displays one line of text

Form designer configuration view	Form designer display view
2. This column only displays one line of text in a summary view on the timeline record. When you expand your timeline record, content in this column is fully displayed and formatted. For this example, **CC** is selected for this column. **Column 3** 3. This column follows the content of **Column 2** and is part of the main body of your timeline record that is only viewable when you expand the record. For this example, **Description** is selected for this column.	in the summary view but when expanded, content is fully displayed. **Column 3** 3. This column always displays in this section and is only viewable when the record is expanded.

Footer section

This section isn't visible on the timeline record.

Expand table

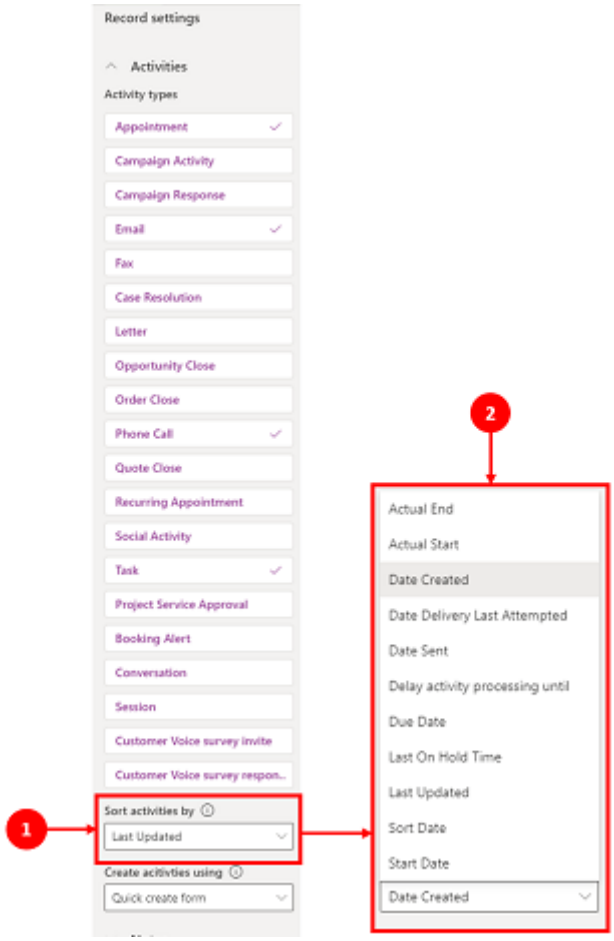
Form designer configuration view	Form designer display view
	


Column 1 1. For this example, we selected **Owner** for this column. **Column 2** 2. For this example, we selected **Regarding** for this column. **Column 3** 3. For this example, we selected **Priority** for this column.	These columns aren't visible on the timeline record

> **Note**
>
> The **Modified On** field updates to the time of the modification. The **Modified By** field assigns the record to a single user when the table is reassigned. This behavior occurs due to cascading relationships. Learn more in Configure table relationships cascading behavior.

Set the date to use when sorting activities in timeline

How users view data is important, and setting a default display view of the data varies based on the needs of your business. App makers can choose how data is sorted and create a default setting for **Activity types** in **Record settings**. **Last Updated** is on all activities. It's the default setting in ascending order.



Legend

1. The **Sort activity by** setting in the **Activities record settings** allows you to control how data is sorted in timeline.
2. The **Sort activities by** column displays a list when selected. You can select from this list how you want your data to be sorted and displayed on timeline in the form.

Sort date

Some dates can only exist on specific types of activities. For example, **Date sent** or **Date delivery last attempted** only apply to email. If you sort by such dates, then non-email activities end up grouped together without any ordering. You can't create a custom date column, but if you need more flexibility, you can use **Sort date**, which is empty by default and requires that you populate

it for each activity record with the date you want to use for sorting. Some of the ways you can populate the date are by using Microsoft Power Automate, business rules, or JavaScript.

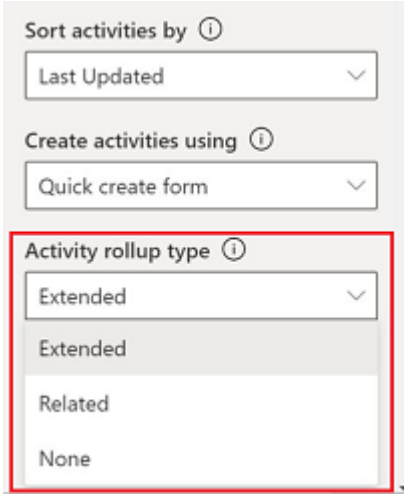
When using Sort date, keep in mind the following details:

- If you set a value in **Sort date**, you can use it for more customized sorting, but you have to populate it for every activity record or it doesn't work. The sort date has to be configured for each timeline instance, and must be set up for all three main forms in the account table.
- If the **DateTime** column is on the same calendar day, the date doesn't display if **DateTime** was earlier in the day compared to the current time.
- The sort date isn't based on a 24-hour period, but rather, compares the **DateTime** column value with the current date and time (based on the user's preferred time zone). If the value entered occurred earlier in the day, the date isn't displayed.

Set the activity rollup type in timeline

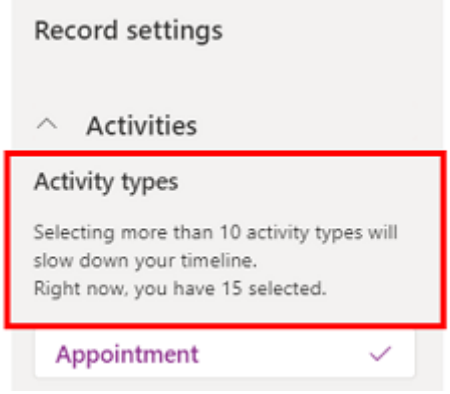
The activity rollup type can be configured for timelines on forms for the account and contact tables. The available types of rollups are **Extended**, **Related**, and **None**. Activity rollup only affects accounts and contacts in Dynamics 365 apps, such as Dynamics 365 Customer Service applications. To only show activities that are directly related to the table in timeline, select **None**.

Learn more in RollupType EnumType.



Timeline performance

If you select more than 10 **Activity types**, a warning message displays to indicate that the number of selected activity types impacts timeline performance. Limit activity types to 10 or fewer to improve performance.



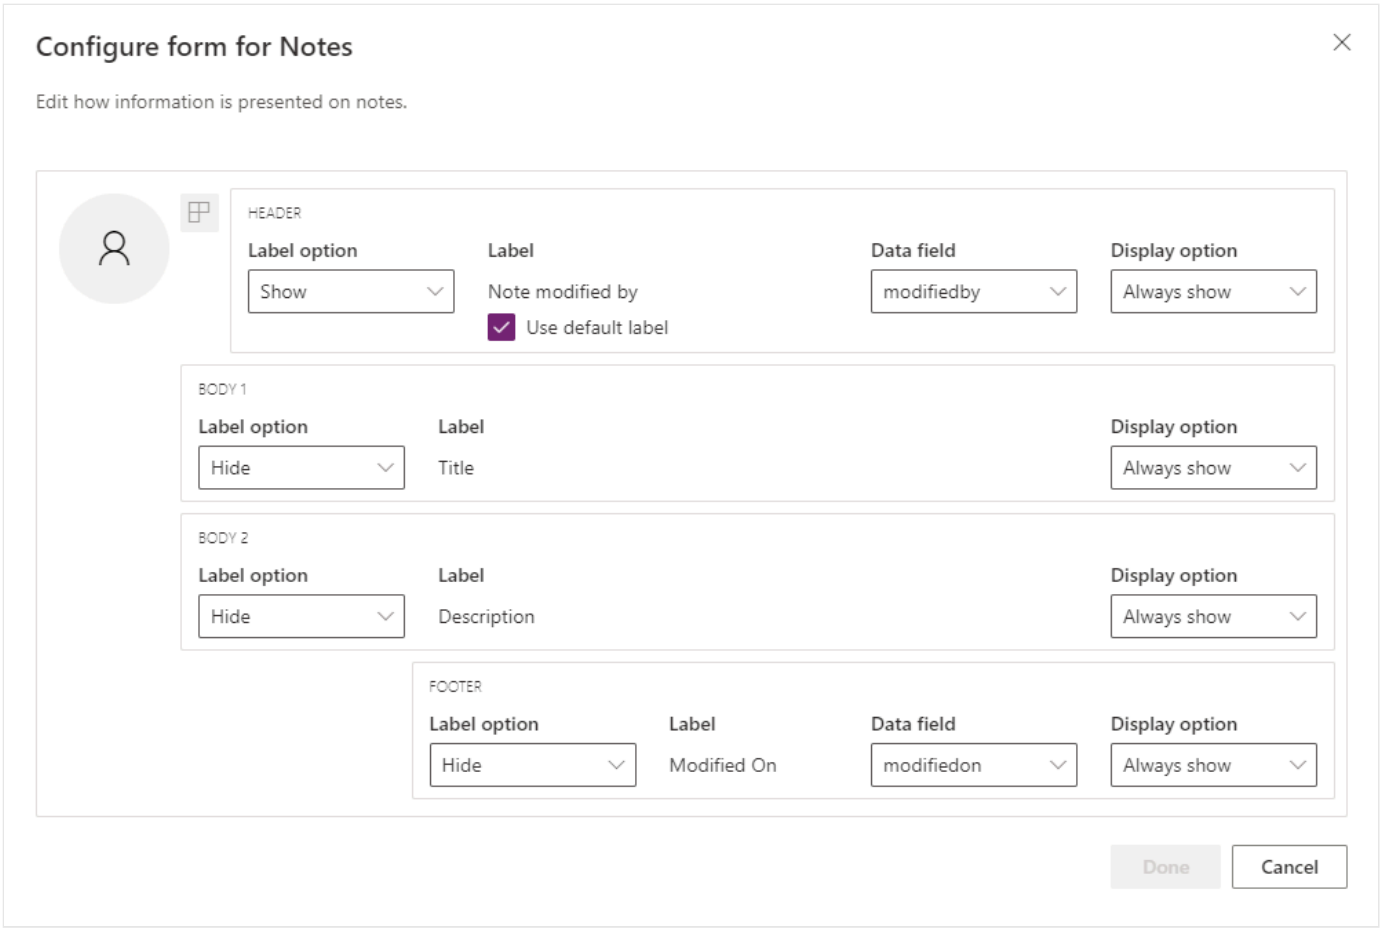
Notes on timeline

Expand table

Form designer configuration view	Form designer display view
	The **Notes** section expands when enabled and allows you to: 1. **Sort notes by** date created or date modified. The **Modified On** date is the default setting. 2. Add a relative web resource path in the **Rich text editor configuration URL** column for customized note capability. Learn more in Add the rich text editor control to a model-driven app.	1. When enabled, Notes can be access via the **Create a timeline record** + icon. 2. A dropdown list appears where you can access **Notes**. 3. Use **Notes** to create a note to add to a record using rich text editing. You can set the font and size for the notes from the timeline, without having to set it multiple times.

Configure the form for notes

In the **Notes** area, under **Configure form**, select **Default form** to configure how information is displayed in notes, such as relevant users and dates, and whether or not to include labels. This setting lets you increase or reduce the number of timeline records that display.



- Header
  - Label option: Hide, show, or show on hover the label, "Created by" or "Modified by".
  - Label: Select the **Use default label** checkbox label to display the label "Note modified by". Clear the checkbox to display the label "Modified by".
  - Data column: Select to show either the user who created the note or the user who modified the note. The label changes to match the data column you selected.
  - Display option: Always show, show on expand, or hide this header containing the user who created or modified the note.
- Body1
  - Label option: Show or hide the label of the note.
  - Display option: Always show, show on expand, or hide the body text.
- Body2
  - Label option: Show or hide the label of the note.
  - Display option: Always show, show on expand, or hide the body text.
- Footer
  - Label option: Show or hide the label, "Created on", "Modified on", or "Overridden on".
  - Data column: Select to show the createdon, modifiedon, or overridenon date.
  - Display option: Always show, show on expand, this footer containing the createdon, modifiedon, or overridenon date.

Set the notes rollup type in timeline

> **Note**
>
> This is an early access feature. You can opt in early to enable these features in your environment, which allows you to test these features and then adopt them across your environments.

The rollup type can be configured for timelines on forms for notes. The available types of rollups are **Extended**, **Related**, and **None**. To show those records only that are directly related to the notes in timeline, select **None**.

Learn more in RollupType EnumType.

Allow users to quickly save notes on timeline

You can enable **Quick save**, which allows users to save their notes using **Ctrl**+**S** while typing a note on the timeline. Quick save helps improve user efficiency by not requiring users to navigate to **Save** or **Save and close** on the command bar. When users save a note using **Ctrl**+**S**, a **Save successful** confirmation message appears in the note on the timeline.

To enable **Quick save**, in Power Apps, go to the timeline settings, and then select the **Enable Quick save** checkbox.

Posts on timeline

To enable rich text posts on the timeline, contact Microsoft Support.

> **Note**
>
> Posts are only available with certain Dynamics 365 apps, such as apps for Dynamics 365 Customer Service.

Expand table

Form designer configuration view	Form designer display view
	The **Posts** section expands when enabled and allows you to: - Select **Enable user posts** enabling users to leave a message on the record. **Note**: You can't enable user posts in the Dynamics 365 Field Service mobile app. - **Sort posts by** date created or date modified. The **Created On** date is the default setting. - The **Select and order commands (Preview)** section allows users to display the command actions that can be performed on posts displayed on the timeline. You can also move the position of the commands to change the order in which they're displayed on the timeline.	1. When enabled, posts can be accessed by selecting **Create a timeline record** +. 2. A dropdown menu displays, and you can access **Posts**. 3. Use **Posts** to create a post to add to a record. When date **Created On** is used to sort posts on the timeline, the location in the timeline remains constant even when there are responses to that post. When date **Modified On** is used to sort posts on the timeline, the location in the timeline adjusts to the top when there are responses to that post. **NOTE**: The timeline doesn't automatically refresh when post replies are added.

Form designer configuration view	Form designer display view
The **Enable simple auto posts (Preview)** allows auto posts to be displayed either in the existing card format or as a simple post. Clear the checkbox to display the posts in the existing card format. The checkbox is selected by default.		When the **Enable simple auto posts (Preview)** checkbox is enabled, the posts aren't displayed in card form. Command actions can't be performed on auto posts from the timeline.

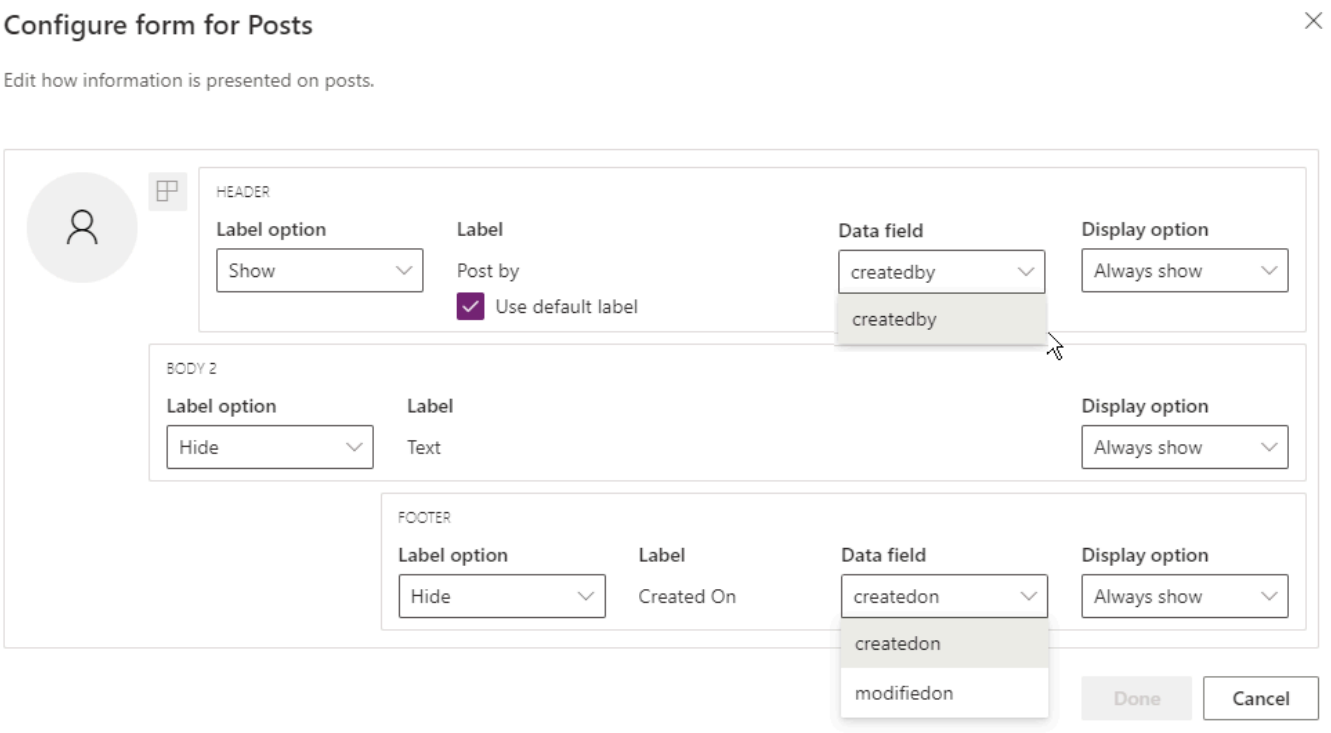
Configure the form for posts

You can configure how information is displayed in posts, such as relevant users and dates, and whether to include labels. This functionality enables you to increase or reduce the number of timeline records that appear onscreen.



Go to your timeline configuration in make.powerapps.com, scroll down to the **Posts** section containing the **Configure form** column, and edit the following column in the default form:

- Header
  - Label option: Hide, show, or show on hover the label, "Created by" or "Modified by".
  - Label: Select the **Use default label** checkbox label to display the label.
  - Data column: Select to show the user who created the post. The label changes to match the data column you selected.
  - Display option: Always show, show on expand, or hide this header containing the user who created the post.
- Body2
  - Label option: Show or hide the label of the post.
  - Display option: Always show, show on expand, or hide the body text.
- Footer
  - Label option: Show or hide the label, "Created on", "Modified on", or "Overridden on".
  - Data column: Select to show the createdon or modifiedon date.
  - Display option: Always show, show on expand, this footer containing the createdon or modifiedon date.

Configure @mentions in notes and posts on timeline

To enable @mentions in notes and posts, follow the instructions provided in this article: Use @mention for collaborating with your team using notes

> **Important**
>
> The @mentions feature doesn't work with Power Platform environments that were created with the **Enable Dynamics 365 apps** option set to **No**. Learn more in **Create an environment with a database**.
>
> Users must have the Read privilege for the **msdyn_postconfig** entity, and the Share privilege for the entity for which they use @mentions (for example, account, contact, case, and so forth).
>
> In-app notifications aren't supported for @mentions in posts on the timeline. Notifications are triggered only for @mentions in notes. If you need users to receive notifications, use @mentions in notes instead of posts.

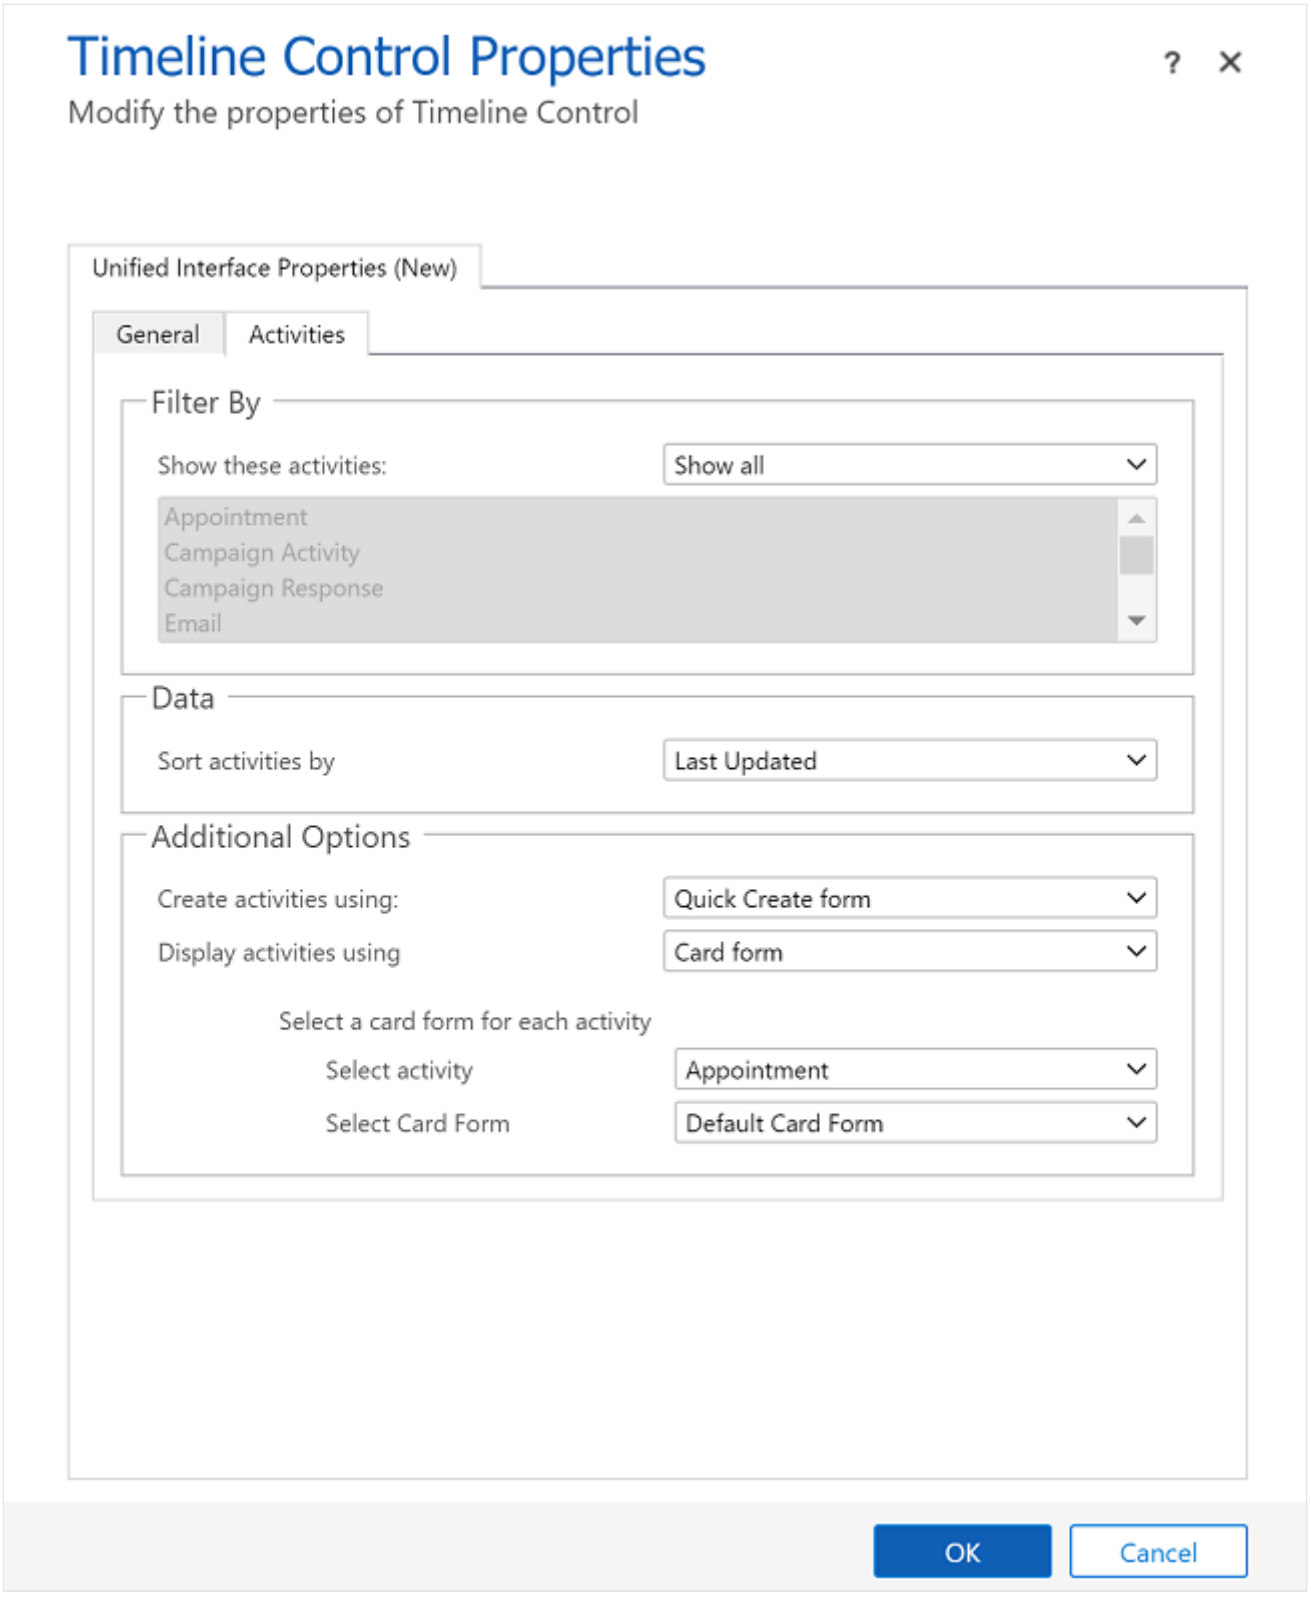
Configure dashboard timelines

Timelines can be configured and put on a dashboard. However, the configuration available for timeline applied to a dashboard is limited to the functionality provided by the legacy designer experience. The new form designer experience on dashboards isn't available.

> **Note**
>
> Capabilities on a dashboard timeline are different than those in an embedded dashboard timeline.
> Dashboard timelines contain records related to the current user. This means each user reviews a different set of information for the same dashboard timeline. Notes are not available on the dashboard.

This following image shows the General tab, where you can modify the timeline control properties:

The following image shows the Activities tab, where you can modify the Timeline Control properties:



-->

Configure autopost messages to display on the timeline

> **Note**
>
> - The autopost functionality is only available with environments that are configured for **Enable Dynamics 365 apps**.

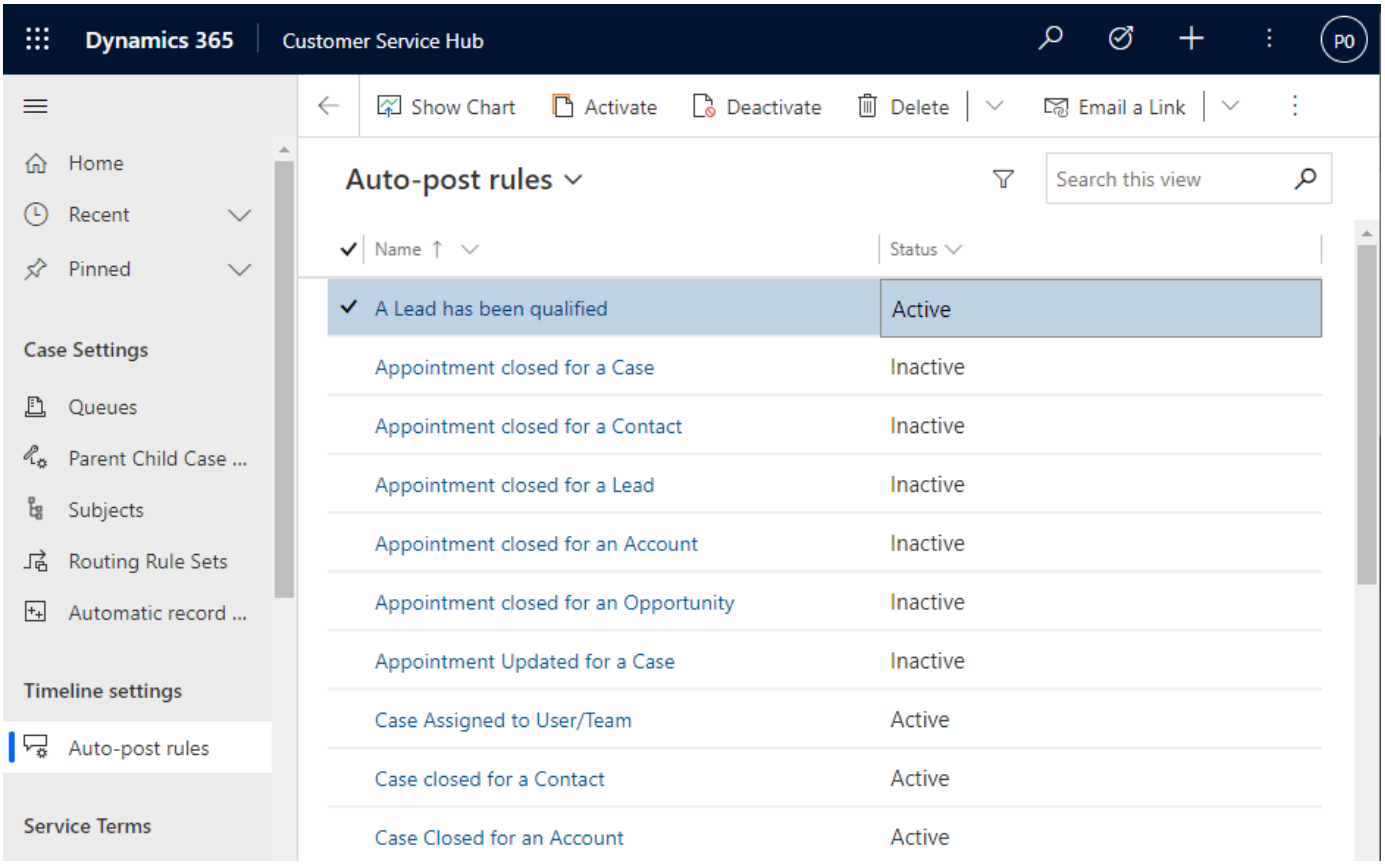
- Dynamics 365 includes autopost rules for some standard tables such as account, contact, lead, and case. It isn't possible to create new autopost rules. However, you can use other options such as Power Automate or a custom plug-in to create a post record based on the desired conditions.

You can configure which autopost messages appear on the timeline when a system event occurs. The autopost configuration replaces the legacy Activity Feed Configuration and Activity Feed Configuration Rules.

To configure the autopost messages that should be displayed:

1. In Customer Service Hub, go to **Service Management**, and under **Timeline settings**, select **Auto-post rules**.
2. Select which autopost rules to make active using the grid and **Activate** and **Deactivate** buttons at the top.

When a system event corresponding to an active rule occurs, an autopost message displays on the timeline.



If you're using a Dynamics 365 app other than Customer Service Hub or Customer Service workspace, you need to add your own sitemap. To add your own sitemap in your app:

1. Open your app in the app designer in **Power Apps**: make.powerapps.com

2. On the app designer command bar, select **Add page**, select **Table based view and form**, and then select **Next**.
3. In the **Table** list, select **Post Rule Configuration**, and then select **Add**.

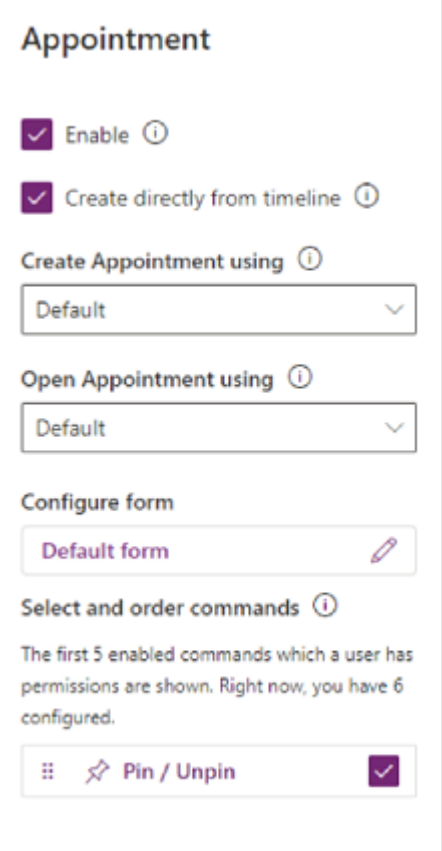
> **Note**
>
> If you don't have the Post Rule Configuration table, your environment doesn't have the required Dynamics 365 app installed.

4. Select **Save**, and then select **Publish**.

Let users pin and unpin activities to the top of timeline

You can configure the ability for users to pin or unpin activities, such as notes, to the top of the timeline so that they're easily accessible. Pinning activities helps users save time by not requiring them to scroll an entire timeline to find the information they need.

By default, notes are enabled for pinning. When you select an activity type such as a task, appointment, and so forth, the pin or unpin option appears in the list of commands. Select the **Pin / Unpin** checkbox for each activity you want users to be able to pin or unpin.



Enable modern Timeline control experience

The modern Timeline control experience provides a refreshed, visually consistent interface for activities and posts in model-driven apps. It improves readability and aligns with the latest Power Apps design patterns while preserving existing timeline functionality.

This feature is disabled by default and doesn't automatically replace the classic timeline experience.

Prerequisites

Before you enable the modern Timeline control experience, ensure that:

- You have the **System Administrator** or **System Customizer** security role.
- Your environment uses model-driven apps.

Enable the modern Timeline control experience

1. In Power Apps, select **Apps**.
2. Locate your model-driven app in the list.
3. Select **… (More commands)** next to the app, and then select **Edit**.
4. In the app designer command bar, select **Settings**.
5. In the **App settings** pane, select **Upcoming**.
6. Set the toggle to **Yes** for **Enable a modern Timeline control experience**.
7. Select **Save and Publish**.

After you enable the modern Timeline control experience, the updated experience appears the next time users open or refresh a form that includes a Timeline control.

Limitations

- Available only in model-driven apps.
- Some legacy customizations might not appear or behave exactly the same as in the classic timeline experience.

Create and add custom activities to timeline

You can create custom tables that display on a timeline. Learn more in Display a custom table in a timeline.

Configure blocked attachment file types

Power platform administrators can configure the file types that are blocked from being added as file attachments to records, including records in a timeline.

1. Find the **Set blocked file extensions for attachments** systems setting. Learn more in Open the System Settings dialog box General tab.
2. In the text box of blocked file attachments, type the file extension type you want to block for attachments (for example, ".pdf"). Separate file types with a semi-colon.
3. Select **OK**.

Set file size limits for attachments

Power platform administrators can restrict the file size of attachments users can upload in the rich text editor.

> **Note**
>
> File sizes for attachments generally can be any size under 90 MB, but for optimal system performance, smaller file sizes are recommended.

1. Go to **Advanced Settings**, and then on the Settings menu, select System > Administration.
2. On the **Administration page**, select **System Settings**.
3. On the **System Settings** dialog, select the **Email** tab, and then scroll down to find the **Set file size limit for attachments** value.
4. Enter the desired size limit for attachments, and then select **Save**. 131,072 KB is the maximum allowed value.

Enable and configure timeline highlights

Enable the timeline highlights widget to help users quickly get up to speed with the most important activities on a record. The widget uses Copilot to generate a list of significant activities on a record, summarized from notes, emails, tasks, appointments, phone calls, and conversations.

> **Important**
>
> This feature is only available for Power Platform environments with Dataverse that have the **Enable Dynamics 365 apps** setting enabled.

Before you set up copilot in your environment, review the FAQ about using AI responsibly in Power Apps.

Prerequisites

Copilot must be turned on in the settings of the model-driven app.

Enable timeline highlights

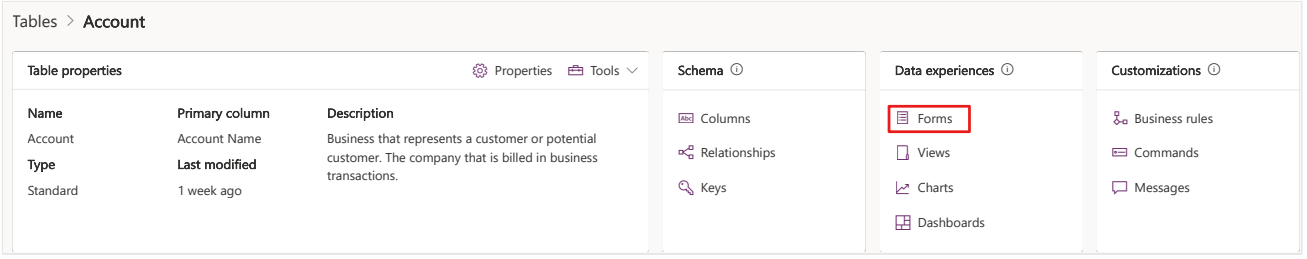
You can enable timeline highlights at the app level or form level, depending on whether you want to enable it for all entities/tables in an app or only for a specific form.

To enable timeline highlights at the app level, perform the following steps:

1. Go to Power Apps.
2. Select **Apps** and then select the app for which you want to enable the feature. For example, Sales Hub app.
3. Select **Settings** on the command bar and select **Upcoming**.
4. Turn on the **Enable Timeline Highlights** feature.
5. Save and publish the changes.

Enable timeline highlights at the form level

1. Go to Power Apps.
2. Select **Tables** and select the table that the form is based on. For example, select **Accounts** to enable timeline highlights for the account form.
3. Select **Forms** and then select the form for which you want to enable the feature.



4. Select **Enable Timeline Highlights powered by Generative AI**.
5. Save and publish the changes.

Known issues

Duplicate posts are shown when sorting records by older to newer

The API the timeline uses to fetch posts doesn't support sorting by older to newer posts. When you sort this way, the timeline receives the wrong posts to display. When sorting the timeline by older to newer, use notes instead.

Notes can only have one attachment added from the attachment button

This functionality is by design, with plans to allow more attachments soon. Multiple attachments can be added inline by dragging and dropping them into the note.

Timeline fails to load with error `code:"0x8004430d","message":"Number of link entity: <number> exceed limit 15`

There's a limit of 15 different tables that can be associated with a timeline. Either disable some of the activities associated with the timeline, or follow one of the workarounds described in this article: Timeline doesn't render and shows "Records couldn't be loaded"

When you create a note in a timeline, the character string "$&" is converted to "{3}amp;"

This issue is a configuration problem with the rich text editor control. To resolve this issue, add `"removePlugins": "stickystyles"` to your rich text editor config file. Learn more in Rich text editor properties.

Images in WebP format aren't displayed in the timeline

Images in WebP format don't display in timeline records. Use a supported image format such as JPEG or PNG.

Timeline records that contain unsupported image formats might not show inline images.

Use the timeline control

Last updated on 04/24/2026

Use custom connectors with the timeline control

Article • 01/14/2023

The custom connectors feature provides a way for developers to surface information such as Dataverse table rows, external data sources, and so forth, as records entries within the TimelineWallControl component. It allows for a broader set of scenarios in addition to the existing out-of-box notes, posts, and activities.

For information about configuring and using the timeline, see the following topics:

- Use timeline
- Configure timeline
- Timeline record card configuration

Records that are configured within custom connectors are a JavaScript web resource that conforms to the IRecordSource interface. The name of a web resource, along with the constructor (name including namespace), and optional JSON web resource path, can be added as a UClientRecordSourcesJSON parameter configuration within FormXML.

JSON

```
<UClientRecordSourcesJSON>
  {"recordSources": [{
    "name": "new_SecondaryRecordSource",
    "constructor": "SampleNamespace.SecondaryRecordSource"}]
  }
</UClientRecordSourcesJSON>
```

TimelineWallControl is expected to load the JavaScript web resource and then create the instance of IRecordSource from the configured constructor.

The IRecordSource is then initialized (init), with a request for pages of records (getRecordsData), request for filter details (getFilterDetails), and a request for the UX representation of a single record (getRecordUX).

The response from requesting records is persisted to minimize the number of record requests that occur within multi-session scenarios.

Configure the custom connector for the timeline control

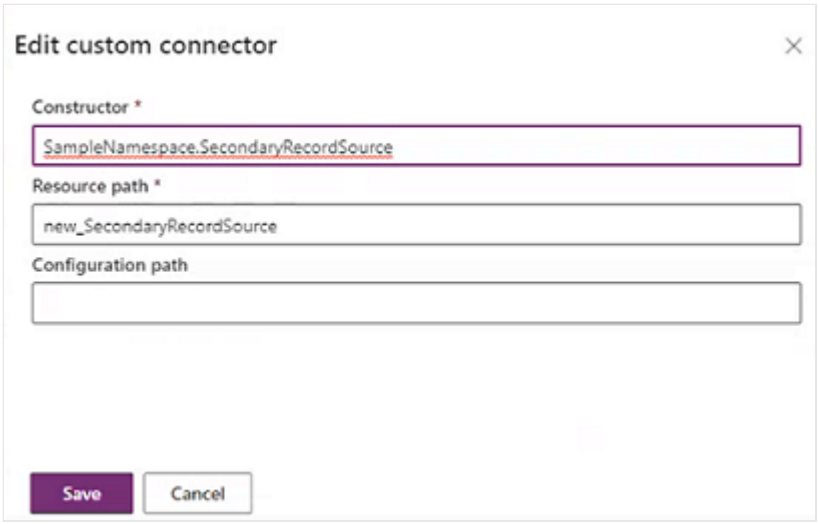
You can add or edit your custom connector for the timeline control by configuring it in the maker experience.

1. On the timeline control, select the form for which you want to add or edit the custom connector.

2. Complete one of the following options:

    - To add a new custom connector, in the **Properties** pane for the timeline table, in **Custom connectors**, select **Add connector**. The **New custom connector** pane is displayed.

    - To edit an existing custom connector you've already uploaded, in the **Properties** pane for the timeline entity, select the custom connector, and then select **Edit**. The **Edit custom connector pane** is displayed.



3. Edit the page, and then select **Save**.

Filter support

Custom connector filter support includes the following abilities.

- Add new filter type to existing filter group
- Add new filter group
- Update the existing filter type count
- Filter on search key

Custom connectors must use UserSettings Timezone information from context passed in init() to be consistent with timeline rendering.

Scope

The custom connectors feature is supported within single-session and multi-session table forms in Unified Interface client model apps.

Out of scope

The following functionality isn't available for the custom connectors feature:

- Offline and offline-by-default scenarios
- Dashboards
- Locations where TimelineWallControl isn't available (such as converged apps, canvas apps, Power Pages, custom pages, and so forth)

Known limitations

The configured web resources aren't formally declared as dependencies to the form. This means that exporting a form won't automatically export the web resources and they'd need to be added to that export manually. In addition, it can be easy to accidentally delete these web resources.

Develop a record source

When developing a record source, make sure to follow these practices:

- Ensure that you're retrieving data securely. The Unified Interface security model considers JS and JSON web resources as untrusted, and thus, such resources shouldn't contain tokens or secrets in them, as they'd be stored in plain text.
- If the data is within Dataverse, use the context object from init behavior to make requests into Dataverse. Calls into Dataverse from context have requests proxied through a secure iframe. This is how out-of-box record sources within TimelineWallControl retrieve data.
- If the data is outside of Dataverse, use existing mechanisms from the platform to retrieve external data.
- Locally test changes by using Fiddler: Improve the agility of development and debugging of JavaScript web resources by using Fiddler AutoResponder. More information: Script web resource development using Fiddler AutoResponder.
- Reduce the risk of XSS attacks: The risk of XSS attacks occurs when adding/binding HTML to the DOM. Use plain text whenever possible to reduce this risk. If HTML is required, you must sanitize this content before adding it to the record.
- Follow general best practices for client scripting. More information: Client scripting in model-driven apps
- Ensure inclusive design practices, including the usage of automated testing tools such as Accessibility Insights.

Solution sample

You can get started with a custom connectors solution sample that has the "SecondaryRecordSource" web resource, which is configured for "Account for Interactive Experiences" and "Account for Multisession Experiences" forms.

Configure timeline

FAQs for the timeline control

07/14/2025

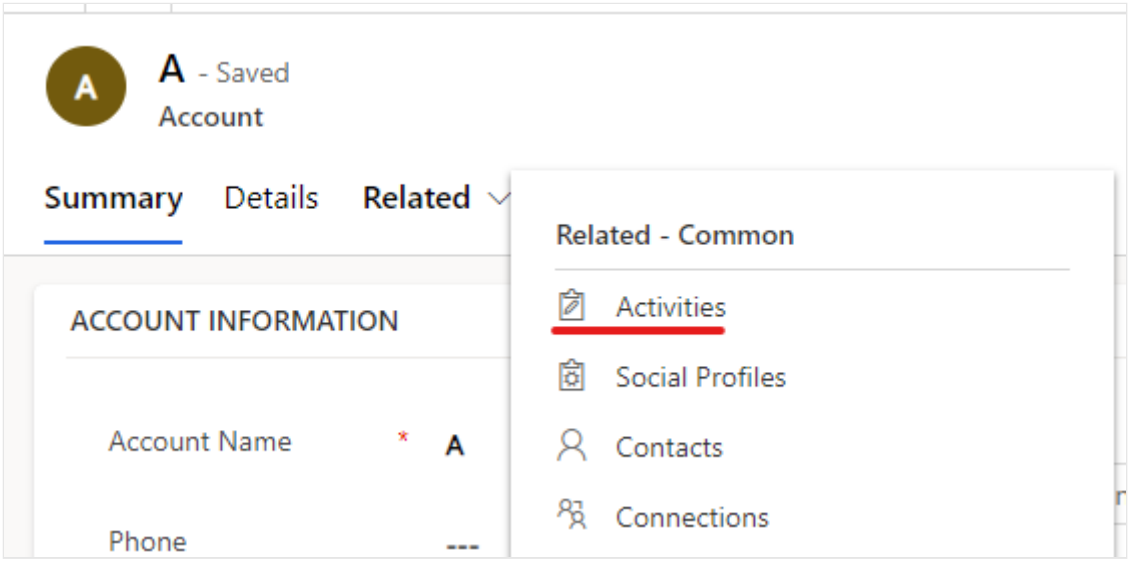
A command isn't working. How do I use the command checker tool for timeline?

For instructions about how to enable and use the command checker, go to Troubleshooting ribbon issues in Power Apps

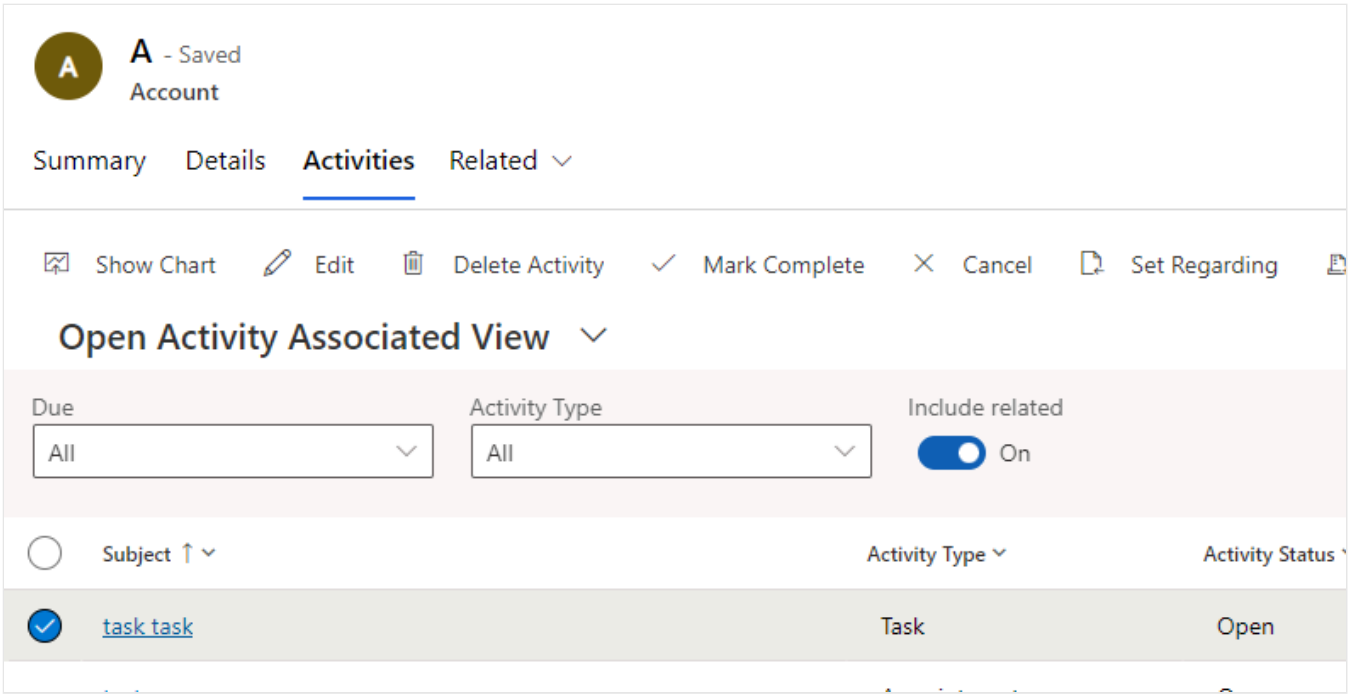
If you try to use the command action for activities on a timeline but the command action is hidden by custom rules, you might get the following error message:

"We can't compete the action you've selected."

You can check whether the action is hidden by navigating to **Related** > **Activities**.



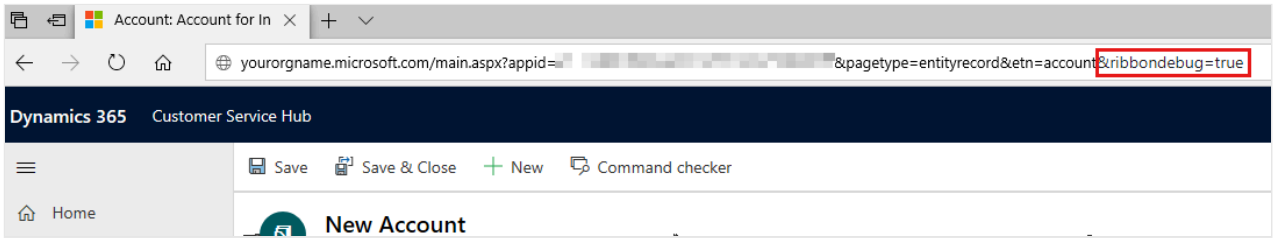
From the **Activities** tab, select the same activity that you want to perform the action on, and then check if you can perform the same command action from there.



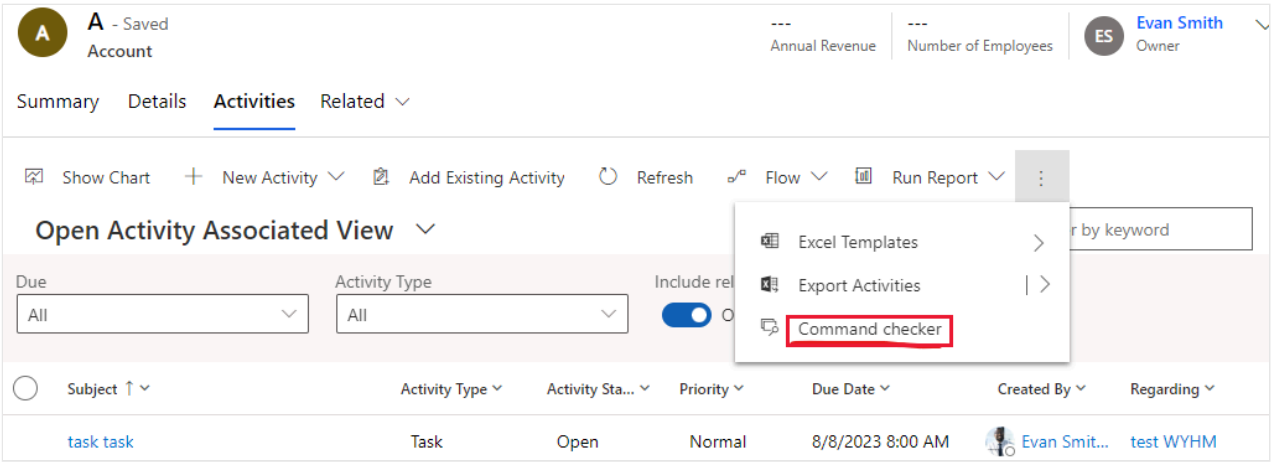
If the command action works here but not from the timeline, contact Microsoft Support.

If you can't find the command action from the related activity grid, you can further troubleshoot the issue with command checker to find out which custom rule hides the command.

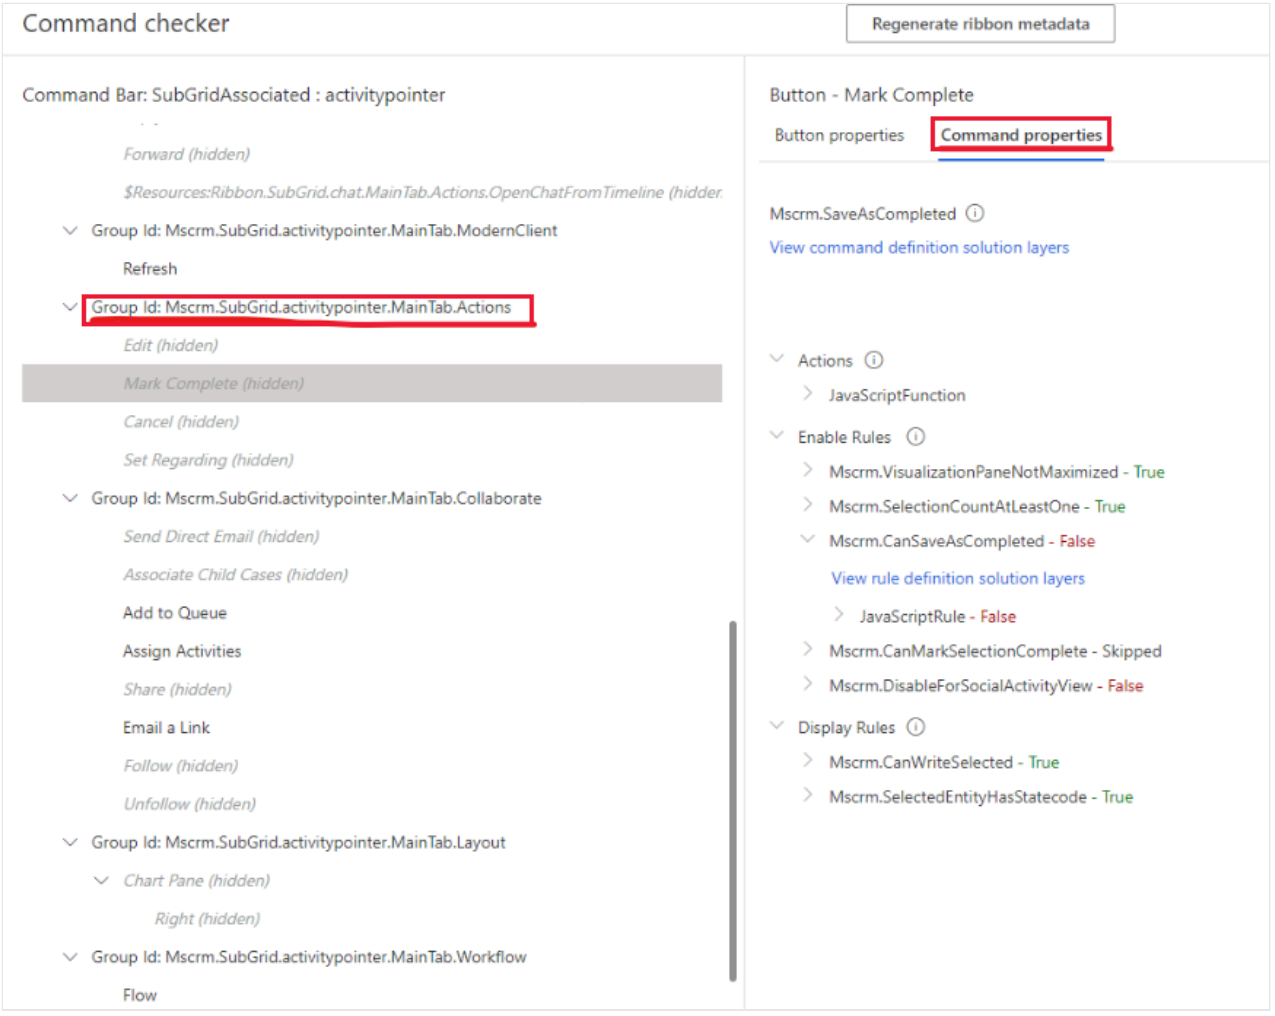
1. Play the model-driven app that has the timeline.
2. From a table record that displays the timeline, select **Related** > **Activities** to go to the **Open Activity Associated View**.
3. Enable the command checker tool by appending the `&ribbondebug=true` parameter to the app URL.



4. Select the **Command checker** command, which now appears on the app command bar. It might be listed on the **More** overflow flyout menu.



5. From the command checker page that is displayed, select **Group Id: Mscrm.SubGrid.activitypointer.MainTab.Actions**, select a hidden command such as **Mark Complete (hidden)**, and then select the **Command properties** tab to find out what custom rules are used to hide the command action.

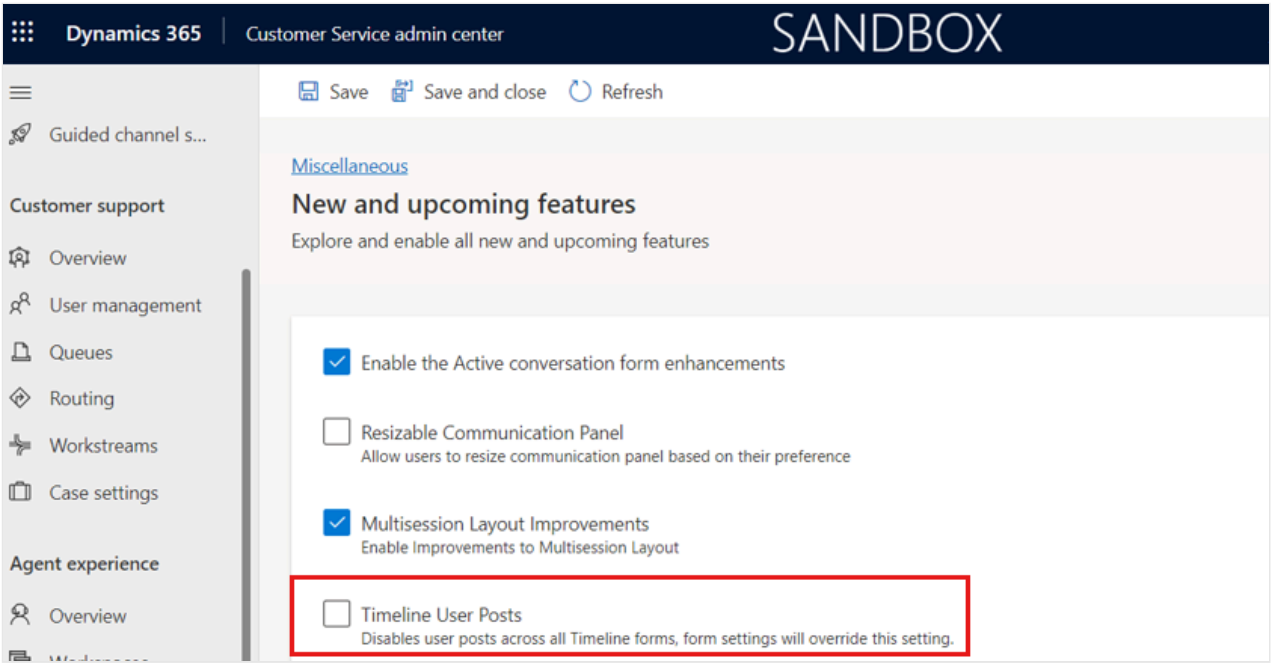


> **Note**
>
> The timeline always displays command actions without honoring the custom rules to hide or disable the command button for performance reasons.

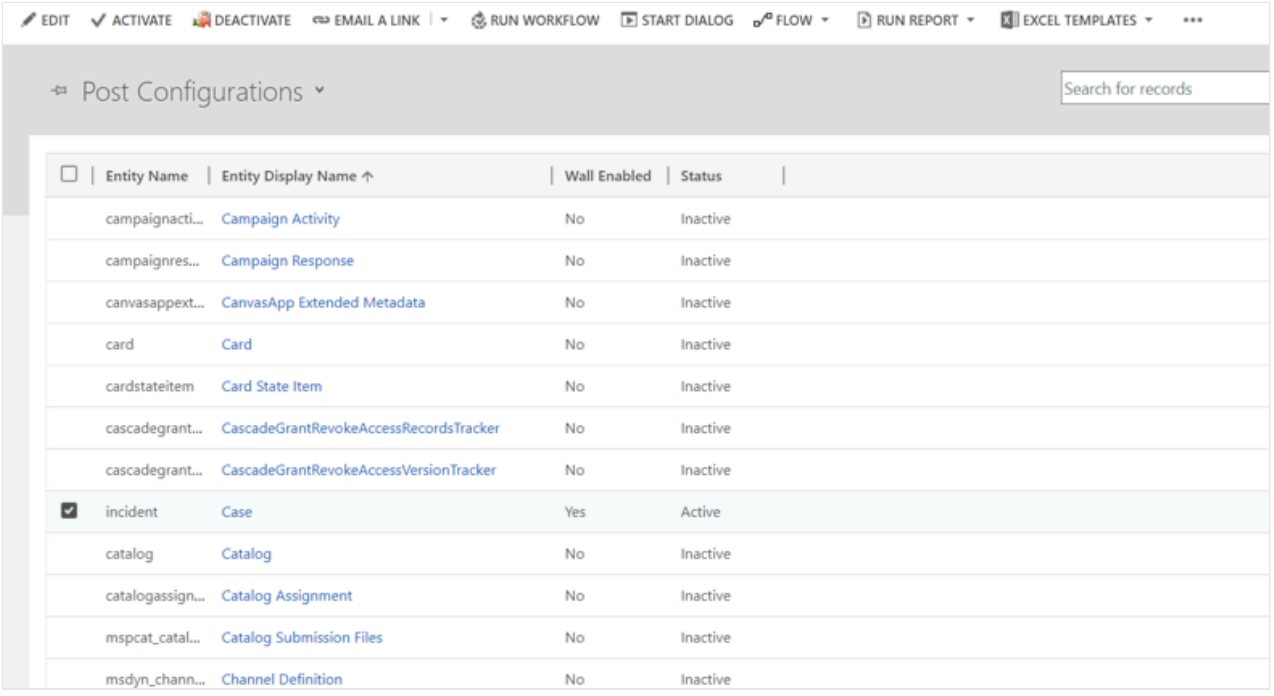
Why aren't posts appearing in timeline and why can't I create a new post?

Posts in the timeline are only available for Dynamics 365 app enabled Dataverse environments and posts are disabled with timelines by default for new environments. To enable, follow these steps:

1. Go to the Dynamics 365 Customer Service admin center > **Miscellaneous** > **New and upcoming features**, and then select **Timeline User Posts**.



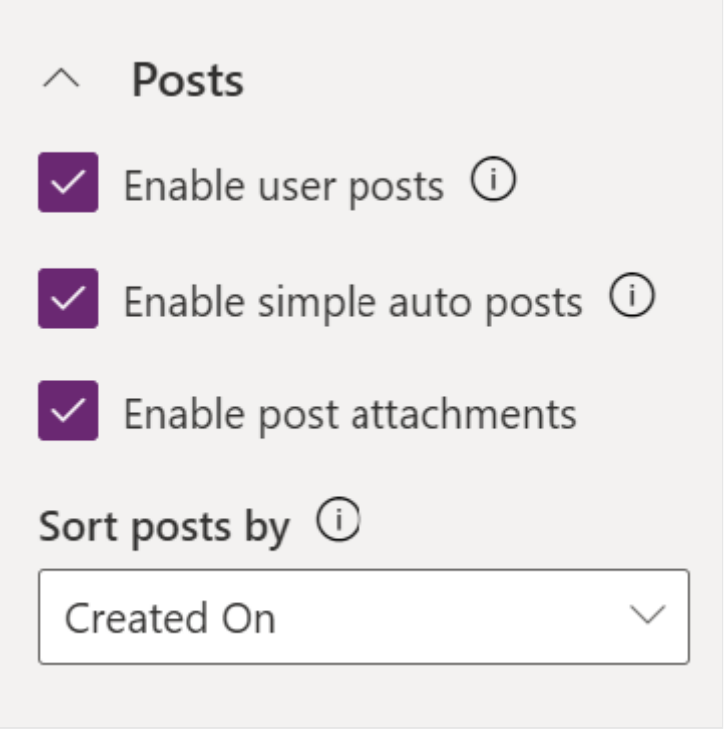
2. Check if the current table has the post configuration property activated. Go to **Settings** > **Activity Feeds configurations** > **Post Configurations**. In the following example, it's active for cases.



If the table isn't listed, look for it in the **Inactive Post Configurations** view. If the table you want isn't listed, select **Refresh** on the command bar. Select the table, and then select **Activate**.

3. Make sure posts are enabled from timeline configuration on the current form. More information: Record types to show

4. Verify the **Enable user posts** setting is enabled on the current form. If the checkbox is selected, clear it and select it again. Save and publish the changes from the form designer.



Do timeline records automatically refresh?

No. The timeline doesn't automatically refresh records. You must manually refresh the timeline to see updates made to a record. For example, if you update a record when you reply to an email, you must manually refresh the timeline to see the updated record.

Why do the "Modified On" columns of my records get changed when no changes are made to them?

The cascading behavior with the parent record can cause this scenario. For example, it can occur when a case is assigned to another user. Go to Table Relationships for information about how to configure this behavior.

Alternatively, you can configure timeline to sort notes by their **Created on** date. More information: Notes on timeline

What privileges do I need to use timeline?

- To open attachments, you need read privilege for the **Activity file attachment** table.
- For personal settings and bookmarks, you need read, write, and create privileges on the **Custom Control Extended Setting** table.

Power Platform admins can assign users these privileges. More information Security roles and privileges

How do I configure timeline for mobile offline?

For general guidance on enabling mobile offline for your app, go to Set up mobile offline.

> **Note**
>
> - The offline profile must have the **Note** and **User** tables in order for the timeline to work.
> - Only notes are available when offline.

How can I resolve issues with email tracking or auto capture?

Go to Auto Capture in Dynamics 365 sales for general information or go to the auto capture FAQ.

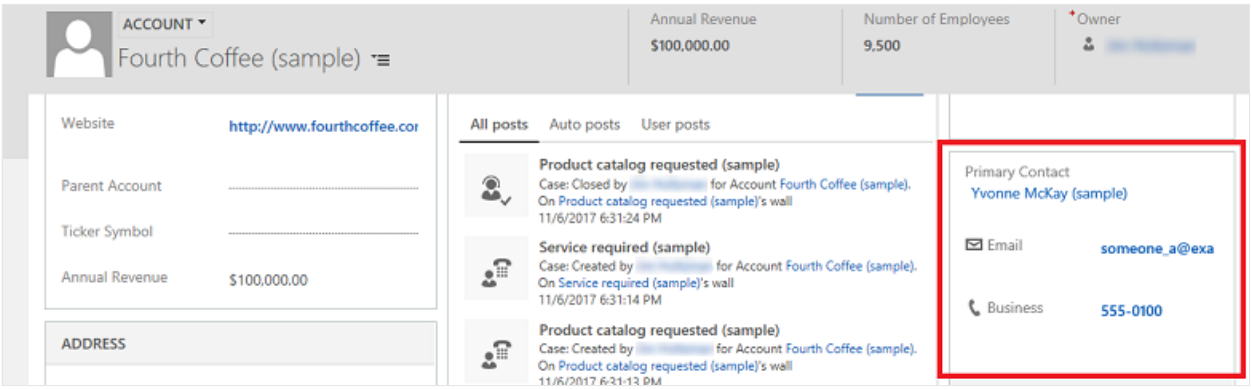
Model-driven app quick view control properties

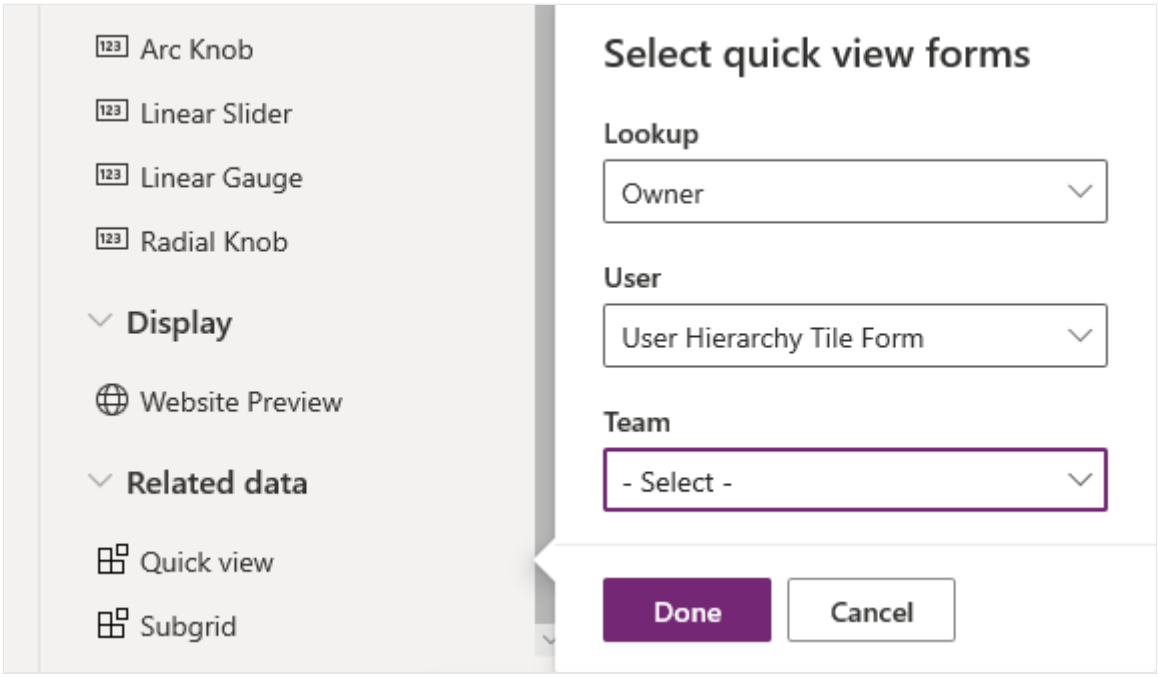
Article • 02/24/2023

A quick view control on a model-driven app form displays data from a row that is selected in a lookup on the form. The data displayed in the control is defined using a quick view form. The data displayed is not editable, but when the primary column is included in the quick view form, it becomes a link to open the related row. More information: Create and edit quick view forms



Add a quick view form

1. Sign in to Power Apps.
2. Select **Solution** from the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Open the solution you want, open the table you want, and then select the **Forms** area.
4. Select a form, which **Type** is **Main**.
5. In the form designer, select **+ Component**, and then in the left navigation pane, select **Quick view**.
6. In the **Select quick view forms** dialog box, select a **Lookup** column included in the form, and then select a quick view form for the related tables. The related tables shown depend on the **Lookup** column chosen.



7. Select **Done** to close the **Select quick view forms** dialog box. The quick view form appears on the form, and the properties of the quick view appear in the properties pane.

Quick view form properties

Property	Description
Label	**Required**: A label to display for the quick view form.
Name	**Required**: The unique name for the quick view form that is used when referencing it in scripts.
Hide label	Displays the label on the form.
Quick view forms	Lists the quick view forms selected for the related tables.
Select forms	Select or change the selected quick view forms for the related tables. The related tables shown depend on the **Lookup** column chosen.
Components	Properties to configure for the component. A quick view control component has no properties to configure, and by default is shown whether someone is using a web browser, Dynamics 365 for phones, or Dynamics 365 for tablets.

Quick view control properties in classic form designer

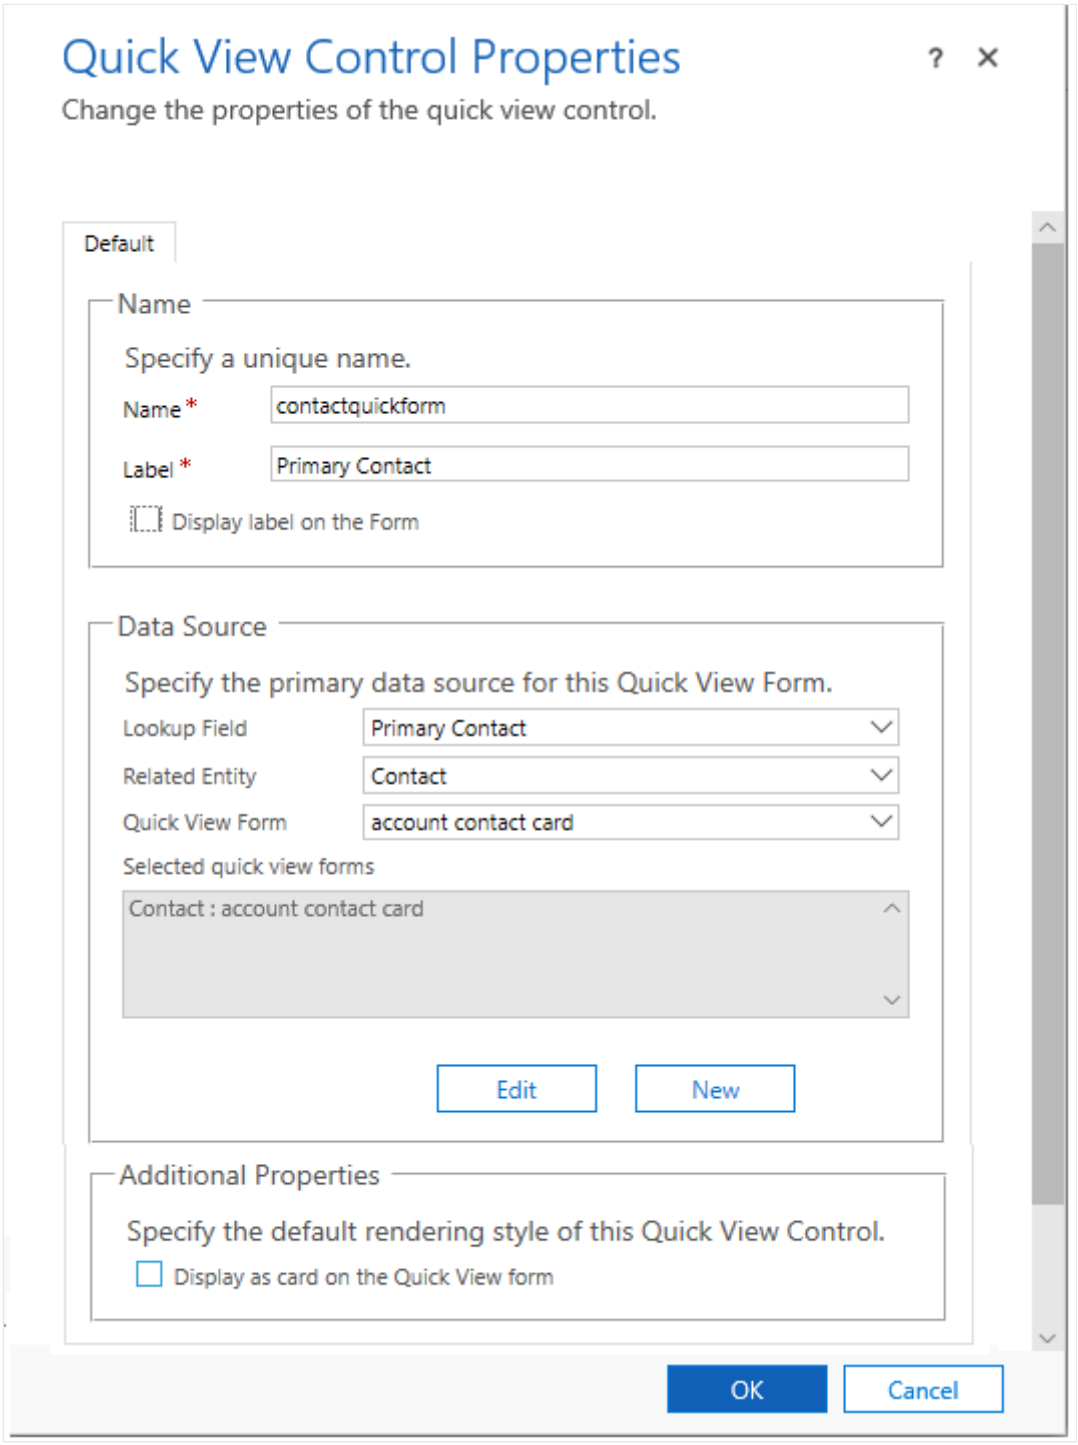
1. Sign in to Power Apps.

2. Expand **Data**, select **Tables**, select the table you want, and then select the **Forms** area.

3. In the list of forms, open the form of type **Main**.

4. On the command menu, select **Switch to classic**.

5. Then on the **Insert** tab, select **Quick View Form** to view quick view control properties.



Property	Description

Property	Description
Name	**Required**: The unique name for the quick view form that is used when referencing it in scripts.
Label	**Required**: A label to display for the quick view form.
Display label on the Form	Displays the label on the form.
Lookup Column	Choose one of the lookup columns included in the form.
Related table	This value depends on the **Lookup Column** chosen. It is usually the primary table for the 1:N table relationship for the lookup. If the table includes a **Potential Customer** lookup that can accept either an account or contact, in the **Quick View Form** column you can choose a quick view form for both account and contact by changing this value and then choosing another quick view form.
Quick View Form	If the **Related table** has any quick view forms these can be selected here. Otherwise, select **New** to create one. Select **Edit** to change the selected quick view form.
Additional Properties	The default rendering style can be specified by selecting the check box.

> **Note**
>
> When adding a multi-line text column to a quick view form, the form will have a height of one regardless of how the column control height is set. This ensures proper rendering of the form while maintaining density. Notice that multi-line text columns on other form types, such as main forms, work differently as the form automatically expands based on the amount of text.

Use the Main form and its components

Model-driven app timer control overview (Classic)

Article • 02/23/2023

Use a timer control with forms where rows need to meet a specific **time-based milestone**. A timer control shows people how much time is available to complete an action in the resolution of an active row or how much time has passed since the time to complete the action has passed.

> **Note**
>
> Currently, this control can only be added and configured using the classic experience.

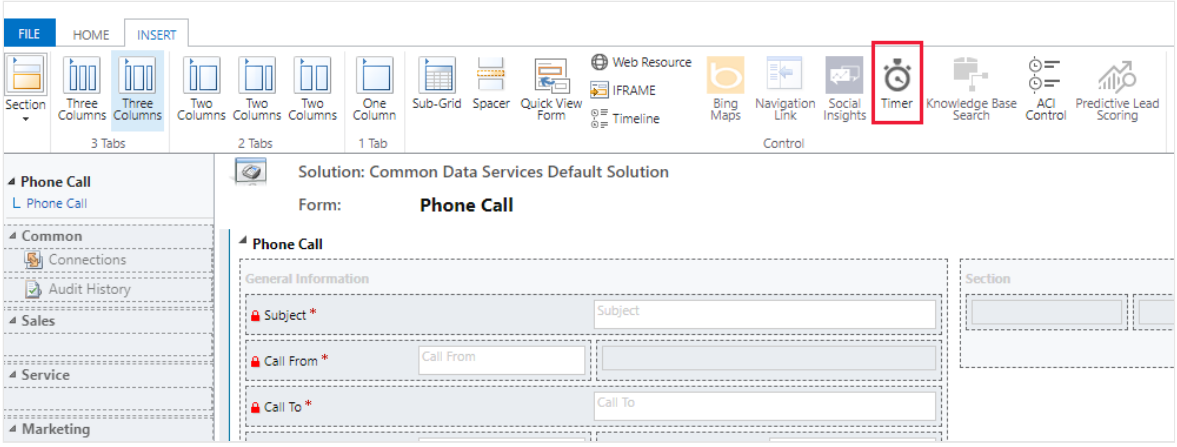
At a minimum, timer controls must be configured to show success or failure in completing the action. In addition, they can be configured to display warnings when the conditions are approaching failure.

How to add a timer control

A timer control can be added to a form for any table, but they are most frequently used for the case table, especially when linked to columns that track service level agreements. Multiple timer controls can be added in the body of a form. These cannot be added to the header.

To add a timer control to a form:

1. Sign in to Power Apps.
2. On the left navigation pane, select **Tables**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Select a table, such as the account table, and then select the **Forms** area.
4. Select the form that you want.
5. In the form designer, on the command menu, select **Switch to classic**.
6. In the classic form designer, select the **Insert** tab, and then on the toolbar select **Timer**.



7. On the **Timer Control** properties page, enter or select the properties that you want, and then select **OK**.

Timer control **Data Source** properties use columns for the table.

- The **Failure Time Column** uses a date-time column to set the time.
- The three condition columns use one of the **Choice**, **Two Options**, **Status**, or **Status Reason** columns for the table.

Timer control properties

The following table describes the properties of a timer control.

Group	Name	Description
Name	Name	**Required**. A unique name for the control.
	Label	**Required**. The label to display for the timer control.
Data Source	Failure Time Field	**Required**. Choose one of the date-time columns for the table to represent when a milestone should be successfully completed.
	Success Condition	**Required**. Select a column for the table to evaluate the success of the milestone, then choose which option indicates success.
	Warning Condition	Select a column for the table to evaluate whether the success of the milestone is at risk so that a warning should be displayed, then choose which option indicates that a warning should be displayed.
	Cancel Condition	Select a column for the table to evaluate whether the achievement of the milestone should be cancelled, then choose which option indicates that the milestone is cancelled.

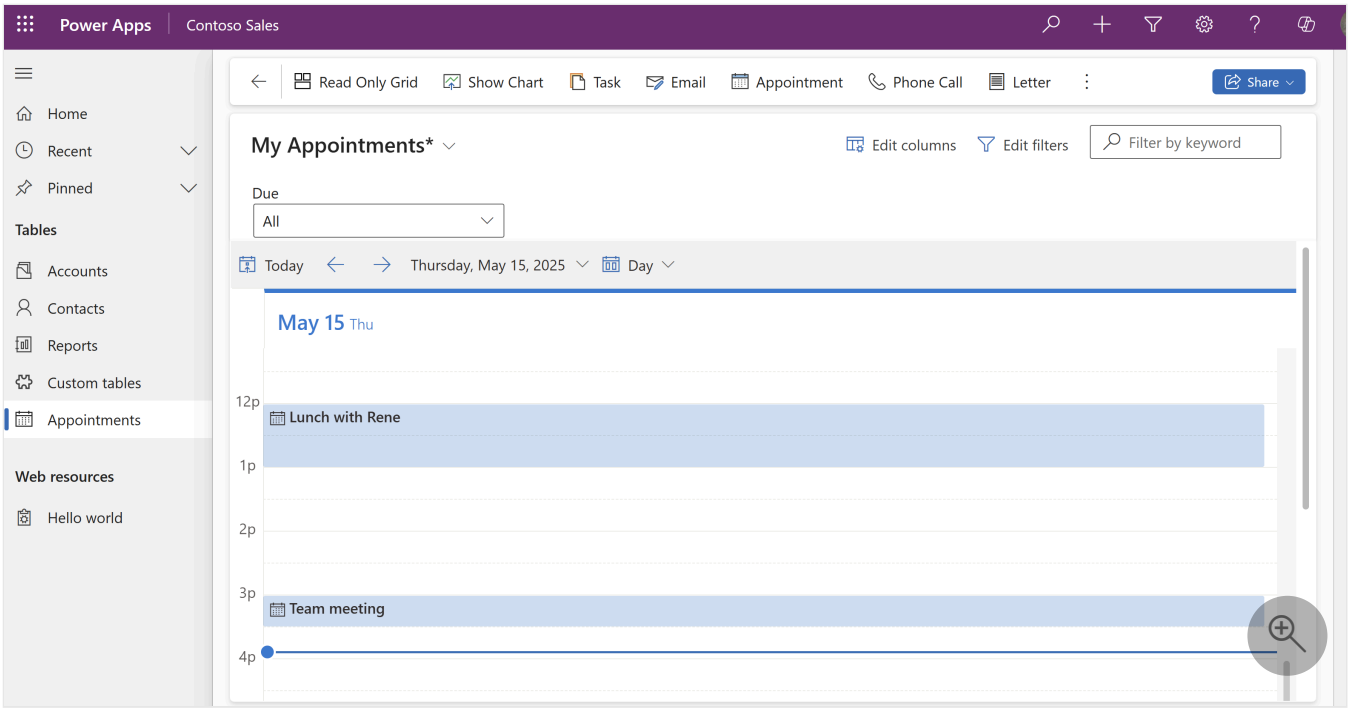
Overview of the form editor user interface

Add the calendar control to tables

Article • 05/16/2025

The calendar control displays scheduled activities and their associated details in a calendar layout. Activities can be viewed, created, and deleted in a day, week, or month view.



System customizer or system administrator privileges are needed to add the calendar control to a table.

Add the control using the modern app designer

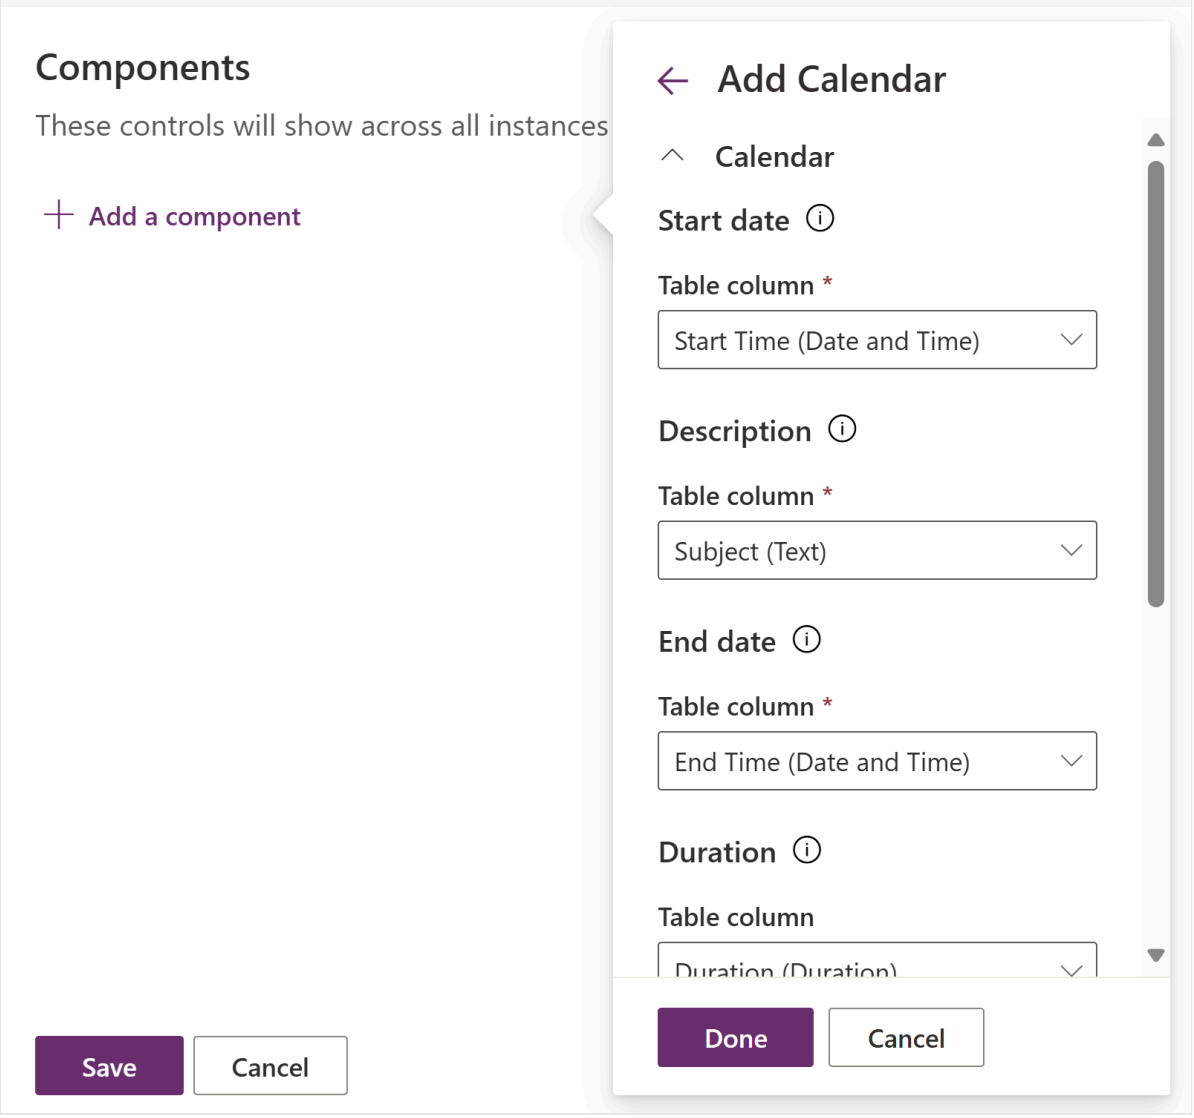
When you add the calendar control to a table, you can specify the columns that are used for the start date, end date, description, and duration. The calendar control is available in the modern app designer.

> **Note**
>
> When you add the control to a table view, it replaces the standard view for all views for that table.

1. While working in the app designer on the **Pages** tab, hover over the table view and then select **Edit view** (pencil icon).
2. Open the view where you want to replace the standard view with the calendar control. The view designer opens.
3. On the command bar select **Components**, and then select **Add a component**.
4. On the **Add a control** page, select **Calendar**.

5. On the **Add a calendar** properties page, select the table columns and clients to display the control. For example, with appointment table, you specify these columns.

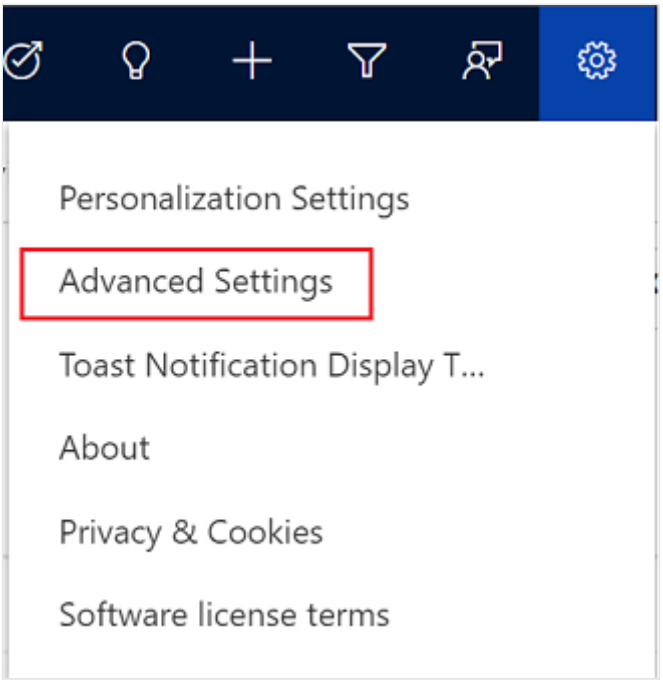
   - **Start date**. Select the column that is used for the start date on the calendar, such as **Start Time (Date and Time)**.
   - **Description**. Select the column that is used for the description, such as **Subject (Text)**.
   - **End date**. Select the column that is used for the end date on the calendar, such as **End Time (Date and Time)**.
   - **Duration**: Select the column that is used for the duration on the calendar, such as **Duration (Duration)**.



6. Select **Done**, and then select **Save**.
7. To make the updated view available in model-driven apps, select **Save and publish**.

Add the control using the classic solution explorer

1. In the app, select the **Settings** icon, and then select **Advanced Settings**.

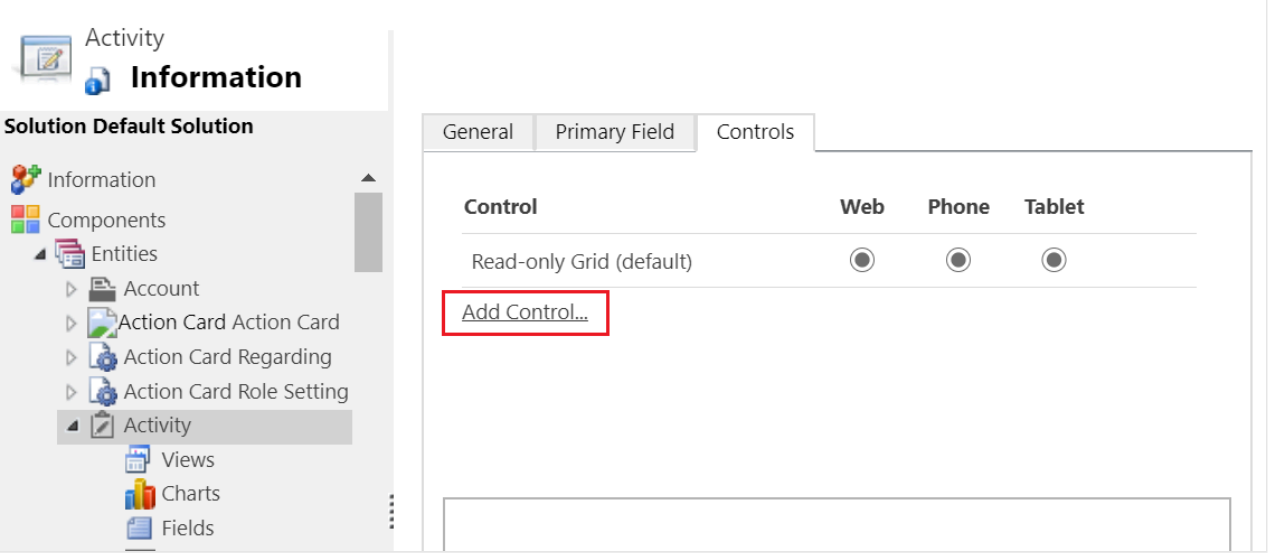


The **Business Management** page opens in a new browser tab.

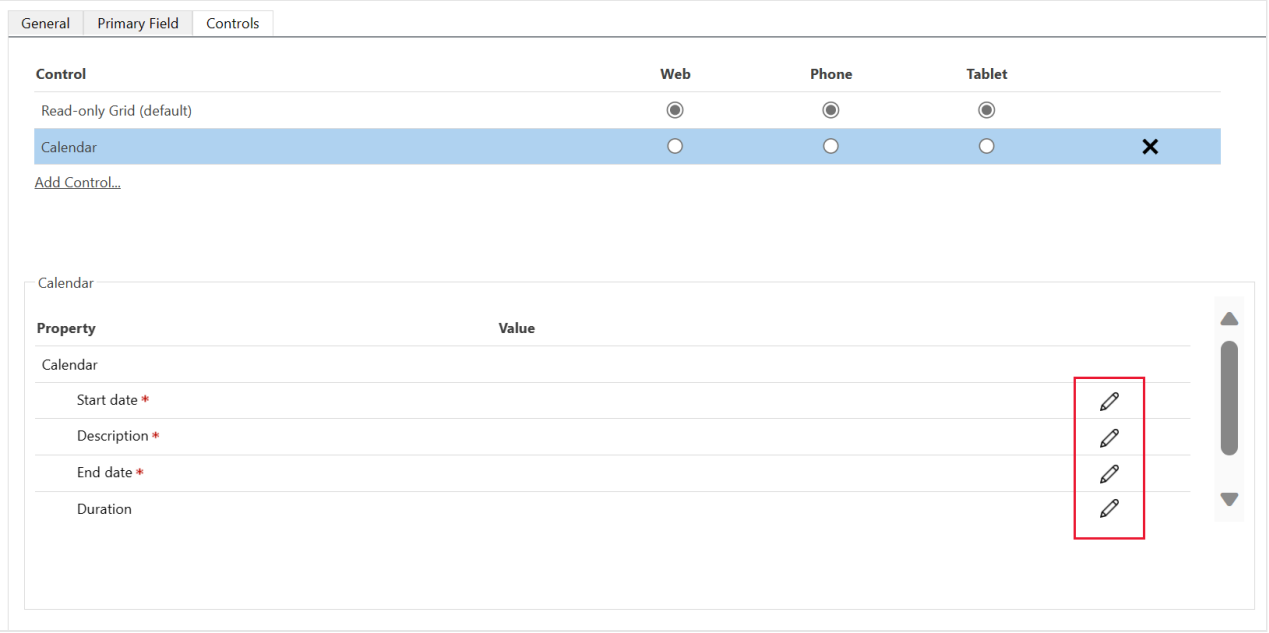
2. On the navigation bar, select **Settings**, and then under **Customization**, select **Customizations**.
3. Select **Customize the System**.
4. Under **Components** in the solution explorer, expand **Tables**, and then select a table. For example, **Activity**.

   > **Important**
   >
   > For **Description** and **Regarding** columns to be displayed in the Calendar Control, the table where the Calendar Control is configured must be created as an activity table. More information: Activity tables

5. On the **Controls** tab, select **Add Control**.



6. In the **Add Control** dialog box, select **Calendar**, and then select **Add**.
7. The calendar control is added to the list of controls.
8. **Read-only grid** is the default option, so when users select a table from the site map, they see a read-only grid of opportunities. To make the calendar view the default view instead, select the corresponding **Calendar** option buttons.
9. Select the edit icon for each of the mandatory columns indicated by a red asterisk, and then select the binding values.



10. Select **Save** to save changes.
11. To publish the changes, select **Publish**.

Mobile experience

The calendar* control is available when working on mobile devices with a different user experience that is optimized for mobile form factors. There's a scrollable day bar for selecting which date to view. The Day/Week/Month selection dropdown isn't available on mobile devices.

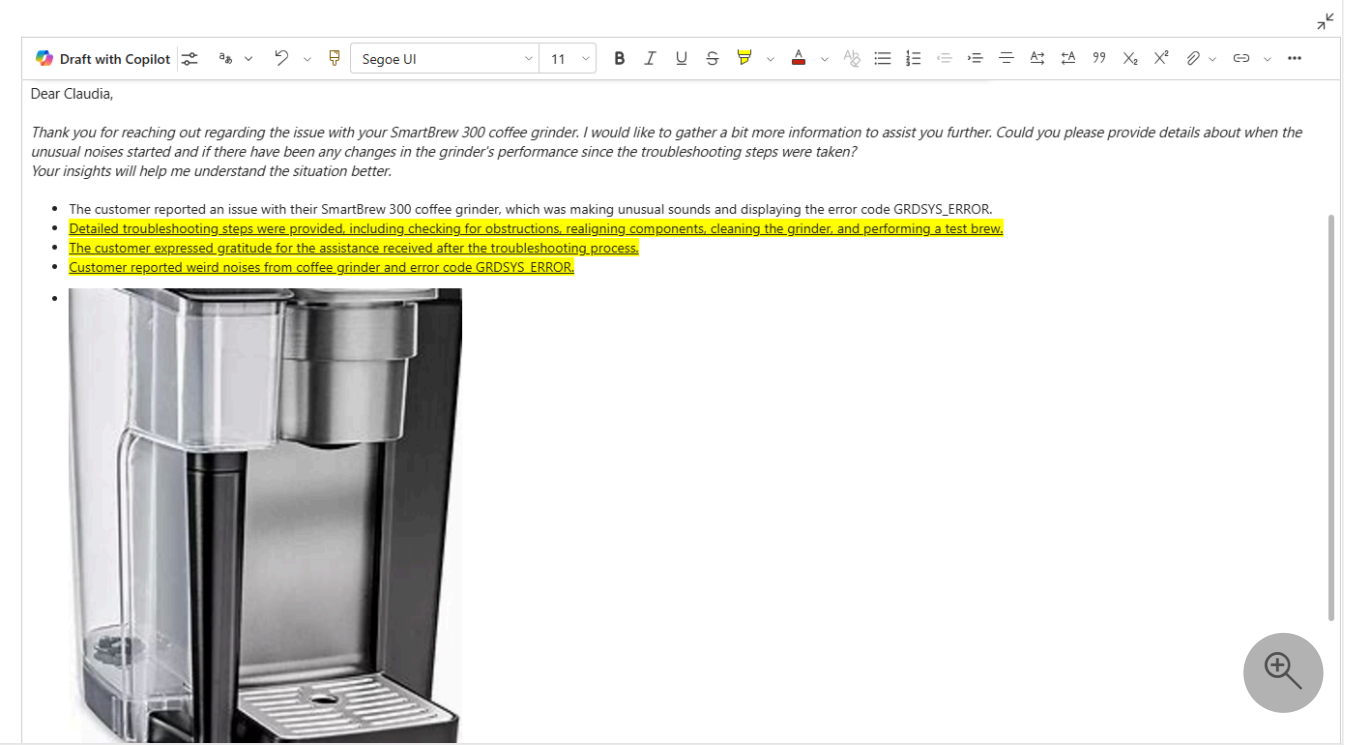
Add the rich text editor control to a model-driven app

The rich text editor control is a lightweight, HTML-based editor built on the popular CKEditor. It lets you create, paste, and edit formatted text in your model-driven apps. To format text in the editor, you can use the editor toolbar, insert HTML tags, or paste formatted text from other applications, like a web browser or Word.

You can customize the editor's appearance, features, and behavior.



Modern text editor enhancements

The modern text editor is designed to align with the familiar and intuitive interfaces of Microsoft applications such as Outlook, Word, and OneNote. This experience, set by default, introduces a modern design, dark mode, high contrast themes, and a new Copilot feature to enhance your text editing capabilities.

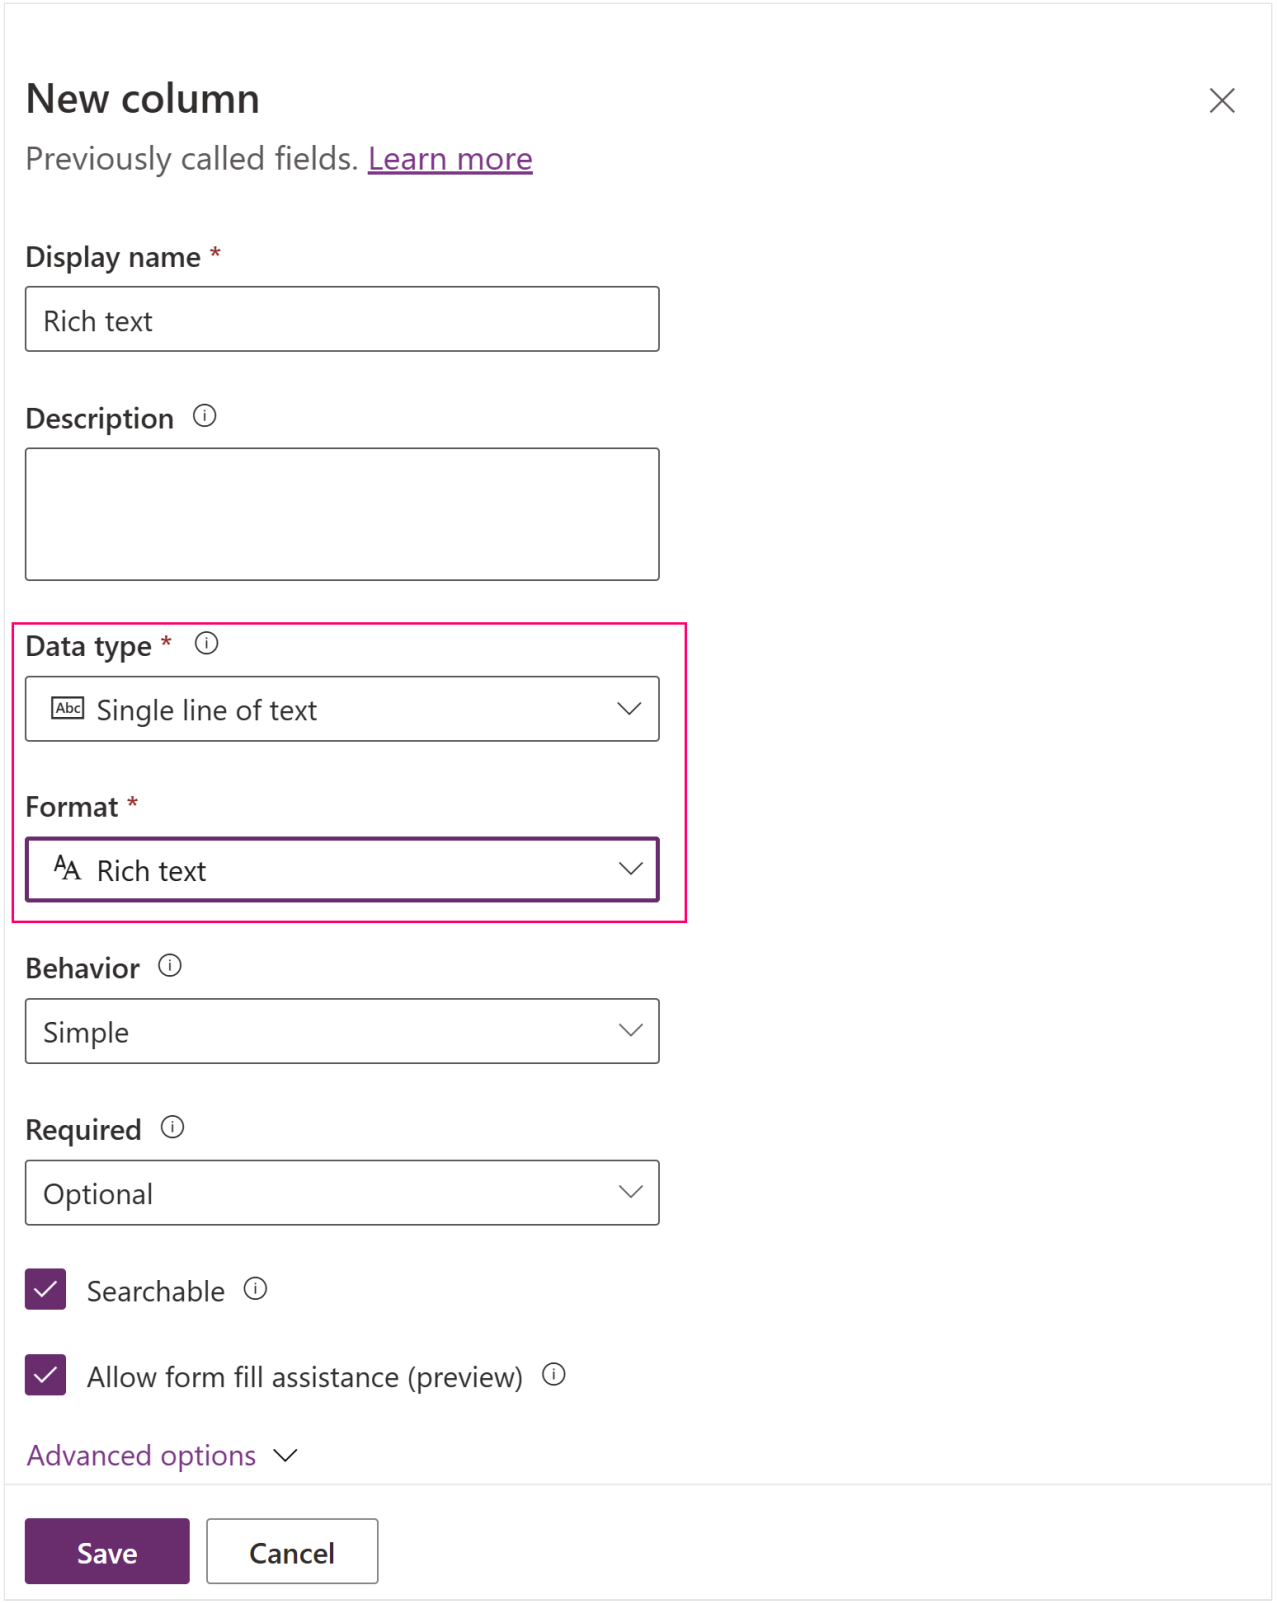
> **Note**
>
> - The classic version of the rich text editor was deprecated as of April 2025. If you have issues with upgrading or using the modern rich text editor, contact Microsoft Customer Support.

- If you customized the previous version of the rich text editor, you might need to recreate your customizations in the modern rich text editor.

Add the rich text editor control to a text column on a form

1. Sign in to Power Apps.
2. In the left navigation pane, select **Solutions**.
3. Open a solution and then open a table in the solution.
4. In the **Data experiences** area, select **Forms**, and then open the form that contains the text column you want to add the rich text editor to.
5. On the form designer canvas, select an existing text column. Alternatively, select **New table column** to create a new text column, enter a **Display name**, select **Text** > **Rich text**

for the **Data type**, and then select **Save**.



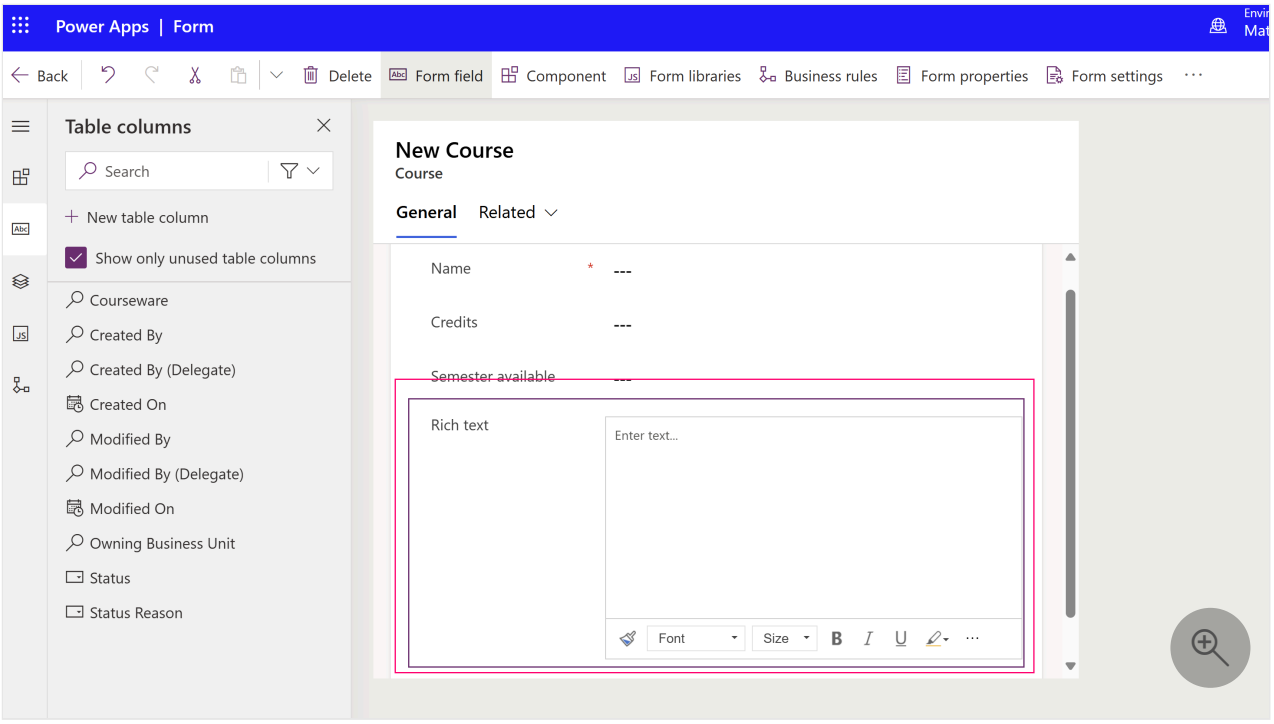
> **Note**
>
> If you want to add the rich text editor control to a column that already exists, you must first change the column's data type to **Text** (if not already a text column) and then select the **Format** using the **Rich text** option.

6. In the column **Properties** pane, expand the **Components** list, select **+ Component**, and then select **Rich Text Editor Control**.

7. In the **Add Rich Text Editor Control** pane, select **Web**, **Phone**, and **Tablet** to allow apps running on any device to use the editor.

   If you want to customize the editor, enter the relative URL of its configuration file, a JavaScript web resource that contains the properties you want to change, in the **Static value** box. If you leave this field empty, the editor uses its default configuration.

8. Select **Done**. The rich text column is added to the form.



9. Select **Save and publish** to apply your changes to the form.

Add the rich text editor control to a text column

You can also create a column for a table that uses the rich text editor control. The following steps show you how to create a text column that you can later add to a form for a model-driven app.

1. Sign in to Power Apps.

2. In the left navigation pane, select **Solutions**.

3. Open a solution and a table in the solution.

4. In the **Schema** area, select **Columns**, and then open a text column.

If the table doesn't contain a text column, select **New column** and enter a name for the column.

5. In the right pane, select **Format**, and then select **Rich text**.

6. **Save** the column.

Customize the rich text editor control

The following customizations are available in the classic rich text editor experience.

Power Apps allows you to change the properties of the rich text editor control to customize its appearance, features, and behavior. To customize a specific instance of the control, specify properties and their values in an individual JSON-formatted configuration file. To customize the control's global configuration, change the properties in the default configuration file.

Levels of customization

You can apply up to three levels, or layers, of configuration to customize the rich text editor:

1. At the most fundamental level, every instance of the control takes its configuration from the file `RTEGlobalConfiguration_Readonly.json`. The file is read-only, so you can't change these properties directly.

   > **Note**
   >
   > `RTEGlobalConfiguration.json` doesn't apply to email, knowledge articles, email templates, and signatures.

2. At the next level, every instance of the control takes its configuration from the properties in the file `RTEGlobalConfiguration.json`, if any are present. This configuration is layered on top of the previous one, so the properties in this file *replace* the same named properties in the read-only file.

3. Finally, at the highest level, a specific instance of the control takes its configuration from a specific configuration file, if one exists. This configuration is layered on top of the previous one, so the properties in this file *replace* the same named properties in the two lower-level files.

The system doesn't replace *all* properties with those in a higher-level configuration. The `extraPlugins` properties merge to allow the use of a wide range of external and out-of-the-box plug-ins in the default configuration. This merge operation lets you activate and deactivate plug-ins as needed in the configuration file for specific instances of the control.

Customize a specific instance of the rich text editor

1. In Visual Studio Code or other text editor, create a file and give it a meaningful name.

   The file `RTEGlobalConfiguration.json` contains the rich text editor's default, or global, configuration. If you're customizing the control in, say, a contact form, you might name the file something like `RTEContactFormConfiguration.json`.

2. Copy and paste the following code snippet into the file:

JSONCopy

```
{
"defaultSupportedProps": {
  "propertyName": "value",
  "propertyName": "value",
  "propertyName": "value"
},
"propertyName": "value",
"propertyName": "value",
}
```

The last *propertyName:value* pair doesn't end with a comma.

3. Replace *propertyName* and *value* with the rich text editor control properties you want to change. String values must be enclosed in quotation marks.

   We provided a few example configurations for you, but you can define others to suit your needs.

4. In Power Apps, create a **JavaScript (JS)** type web resource using the JSON file you created in step 1.

5. Add the rich text editor control to a text column on a form, and in the **Add Rich Text Editor Control** pane > **Static value**, enter the relative URL of the JavaScript web resource.

   Although you can enter the absolute URL of the web resource, we recommend that you enter the relative URL. That way, the web resource still works if you import it as a solution into a different environment, provided the relative path is the same.

For example, if the URL of the web resource is `https://yourorg.crm.dynamics.com/WebResources/rtecontactform`, the relative URL is */WebResources/rtecontactform*.

6. Select **Done**.

7. Select **Save and publish** to apply your changes to the form.

Customize the rich text editor globally

The editable global configuration file `RTEGlobalConfiguration.json` is the second level of customization you can apply. By default, the file is empty. That means that all instances of the rich text editor use the properties in the read-only file `RTEGlobalConfiguration_Readonly.json`, unless you create a configuration file for a specific instance of the control.

If your business needs require you to customize the control everywhere, specify the values you need in the `RTEGlobalConfiguration.json` file. Use the read-only file as an example to make sure you enter property-value pairs in the right format.

Use Copilot to refine text in the editor

Copilot uses natural language processing algorithms to help improve written content. You can add Copilot to the rich text editor and then get suggestions to improve the grammar, clarity, or overall quality of your text. Learn how to use Copilot in the rich text editor.

Rich text editor properties

The JSON file that determines the "look and feel" of an instance of the rich text editor contains two sets of properties:

- The defaultSupportedProps section contains properties of plug-ins that determine what the control can do. You're not limited to the properties of CKEditor and its plug-ins. You can also set values for properties of plug-ins that you add or create.
- The individual properties section contains properties that determine what the control looks like.

Example configuration file

The following code is an example of a JSON file that contains both defaultSupportedProps properties and individual configuration properties. If a property has a default value, the default

value is shown. If a property doesn't have a default value, a sample value is shown to illustrate the syntax. The properties are described in the two tables that follow.

JSON

```
{
    "defaultSupportedProps": {
        "height": 185,

    "showAsTabControl": false,
    "showHtml": false
}
```

defaultSupportedProps

The following table describes the most commonly used properties, but you can configure all the properties that CKEditor supports. The rich text editor control uses CKEditor 4.

Expand table

Property	Description	Default value
height	Sets the initial height of the content area, in pixels.	"185"
stickyStyle	Sets the editor font and size.	See defaultSupportedProps
stickyStyles_defaultTag	Creates a wrapper around the text in the editor content area. It's initially set to "div," but you can change it to "p" or any alternate tag.	"div"
font_defaultLabel	Sets the font label displayed in the toolbar. The label is for appearance only and isn't functional. The `stickyStyle` property determines the editor font and size.	"Segoe UI"
fontSize_defaultLabel	Sets the font size label displayed in the toolbar. The label is for appearance only and isn't functional. The `stickyStyle` property determines the editor font and size.	"9"
toolbarLocation	Sets the location of the toolbar in the editor content area. Supported values are "top" and "bottom."	"bottom"

Property	Description	Default value
toolbar	Lists the toolbar buttons to display.	See defaultSupportedProps
plugins	Lists preset plug-ins that the editor can use. The plug-ins in this list might be different from the plug-ins that are loaded, if `extraPlugins` and `removePlugins` are given a value. If you set this property to an empty string, the editor loads without the toolbar.	See defaultSupportedProps
extraPlugins	Appends plug-ins to the `plugins` list to load more plug-ins. Many plug-ins require other plug-ins to work. The rich text editor automatically adds them, and you can't use this property to override them. Use `removePlugins` instead.	See defaultSupportedProps
removePlugins	Lists plug-ins not to load. Use it to change which plug-ins are loaded without changing the `plugins` and `extraPlugins` lists.	See defaultSupportedProps
superimageImageMaxSize	Sets the maximum size in megabytes (MB) allowed for embedded images when using the superimage plug-in.	"5"
linkTargets	Allows you to configure which link target options are available for users when they create links: - "notSet": No target set - "frame": Opens the document in the specified frame - popupWindow": Opens the document in a popup window - "_blank": Opens the document in a new window or tab - "_top": Opens the document in the full body of the window - "_self": Opens the document in the same window or tab where the link is activated - "_parent": Opens the document in the parent frame	"notSet", "_blank"

Individual properties

The following table describes more properties you can use to customize the rich text editor control.

Expand table

Property	Description	Default value
attachmentEntity	To enforce more security on uploaded files by using a table other than the default, set this property and specify a different table. Syntax: "name": "*tableName*", "fileAttributeName": "*attributeNameofBlobReference*"	See defaultSupportedProps
disableContentSanitization	Content sanitization removes some custom attributes or tags from rich text content. It's disabled by default to allow copying and pasting of rich text content from external sources. This property applies only to edit mode. When the editor control is read-only or disabled, content is always sanitized.	true
disableDefaultImageProcessing	By default, images that are inserted in the editor are uploaded to the `attachmentEntity` defined in the configuration. External users might lack privileges to view the content in the table. Instead, set this property to true to store images as base64 strings directly in the column configured to use the rich text editor control.	false
disableImages	Determines whether images can be inserted in the editor. This property has highest priority. When this property is set to true, images are disabled, regardless of the value of the `imageEntity` property.	false
imageEntity	To enforce more security on images by using a table other than the default, set this property and specify a different table. Syntax: "imageEntityName": "*tableName*", "imageFileAttributeName": "*attributeNameofBlobReference*"	See defaultSupportedProps
readOnlySettings	These properties determine the behavior of the column when viewed in a read-only or disabled state. You can specify any supported property.	None; see defaultSupportedProps for an example
sanitizerAllowlist	Lists other kinds of content that can be displayed in the editor.	See defaultSupportedProps
showAsTabControl	Allows you to display more commands above the content area. Must be set to true	false

Property	Description	Default value
	to use the following properties: `showFullScreenExpander`, `showHtml`, `showPreview`, `showPreviewHeaderWarning`	
showFullScreenExpander	Determines whether the editor can be used in full-screen mode. `showAsTabControl` must be set to true.	false
showHtml	Allows users to display and edit the HTML content directly. `showAsTabControl` must be set to true.	false
showPreview	Allows users to preview the editor content rendered as HTML. `showAsTabControl` must be set to true.	false
showPreviewHeaderWarning	Allows you to show or hide the warning message displayed when previewing content. `showAsTabControl` and `showPreview` must be set to true.	false
allowSameOriginSandbox	Allows the content in the editor to be treated as from the same origin as the rendering app. **Use this property with caution.** Only use trusted external content. When this property is set to true, any external content could have access to internal resources.	false

Example configurations

The following sample configurations create specific customizations of the rich text editor in the classic experience. You can use them as-is or as a jumping-off point to customize a specific instance of the rich text editor or globally.

Set the default font to 11-point Calibri

Set these defaultSupportedProps properties in your configuration file. Each value except the last one must be followed by a comma (`,`).

JSON

```
"font_defaultLabel": "Calibri",
"fontSize_defaultLabel": "11",
```

```
"stickyStyle": {
  "font-size": "11pt",
  "font-family": "Calibri/Calibri, Helvetica, sans-serif;"
},
```

Make the Enter key insert a new line instead of a paragraph block

By default, pressing the Enter key creates a paragraph block with the **<p>** HTML tag. HTML uses paragraph blocks to group information, like paragraphs in a Word document. Browsers can format the **<p>** tag slightly differently, so for visual consistency, you might want to use the new line or line break tag **<br\>** tag instead.

Set this defaultSupportedProps property in your configuration file. Follow this value with a comma (`,`) unless it's the last property in the file.

JSON

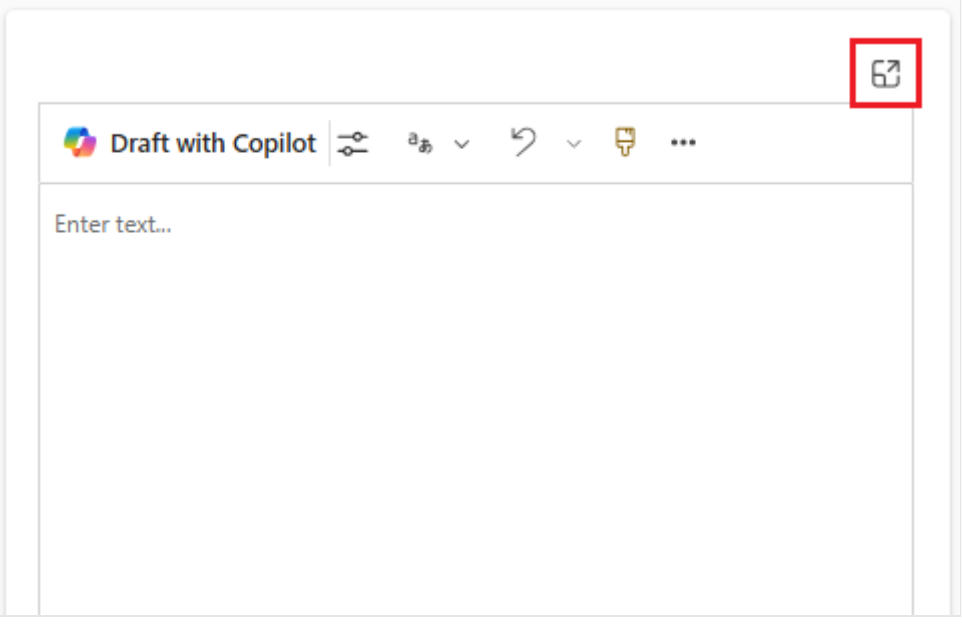
```
"enterMode": 2,
```

Allow the editor to use the full screen

Set these individual properties in your configuration file. Each value except the last one must be followed by a comma (`,`).

JSON

```
"showFullScreenExpander": true,
```



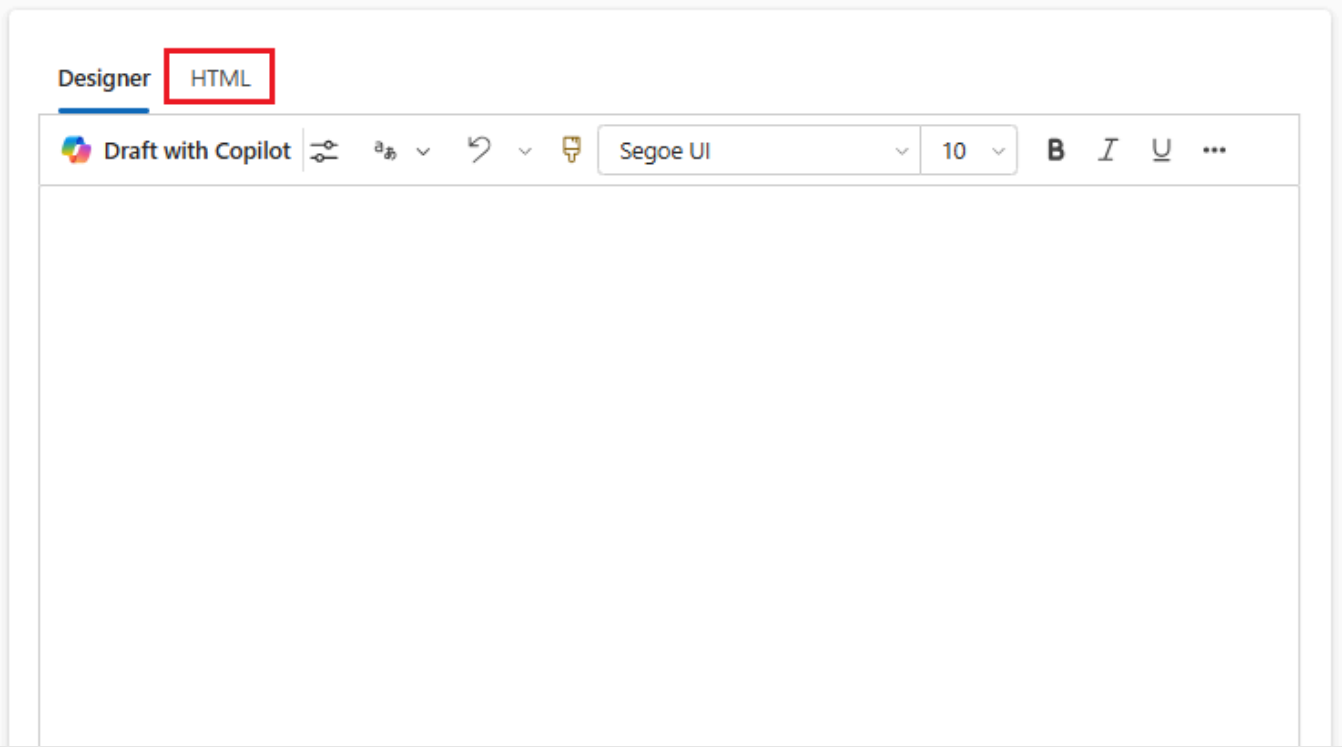
Allow viewing and editing HTML content

To allow users to view and edit the HTML of their content directly, show the **HTML** tab.

Set these individual properties in your configuration file. Each value except the last one must be followed by a comma (`,`).

JSON

```
"showAsTabControl": true,
"showHtml": true,
```



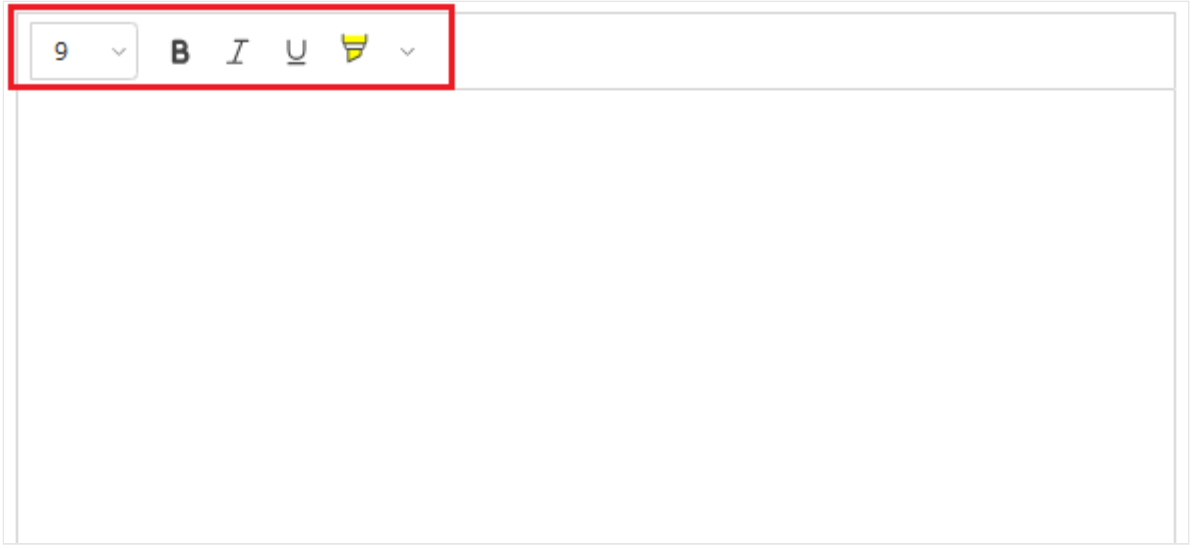
Show a simplified toolbar or remove it entirely

By default, the editor toolbar contains all the available formatting tools. To provide a simplified toolbar, use the `toolbar` property and specify the tools that users can use to format their content.

Set this defaultSupportedProps property in your configuration file. Follow this value with a comma (`,`) unless it's the last property in the file.

JSON

```
"toolbar": [ { "items": [ "FontSize", "Bold", "Italic", "Underline", "BGColor" ] }
],
```



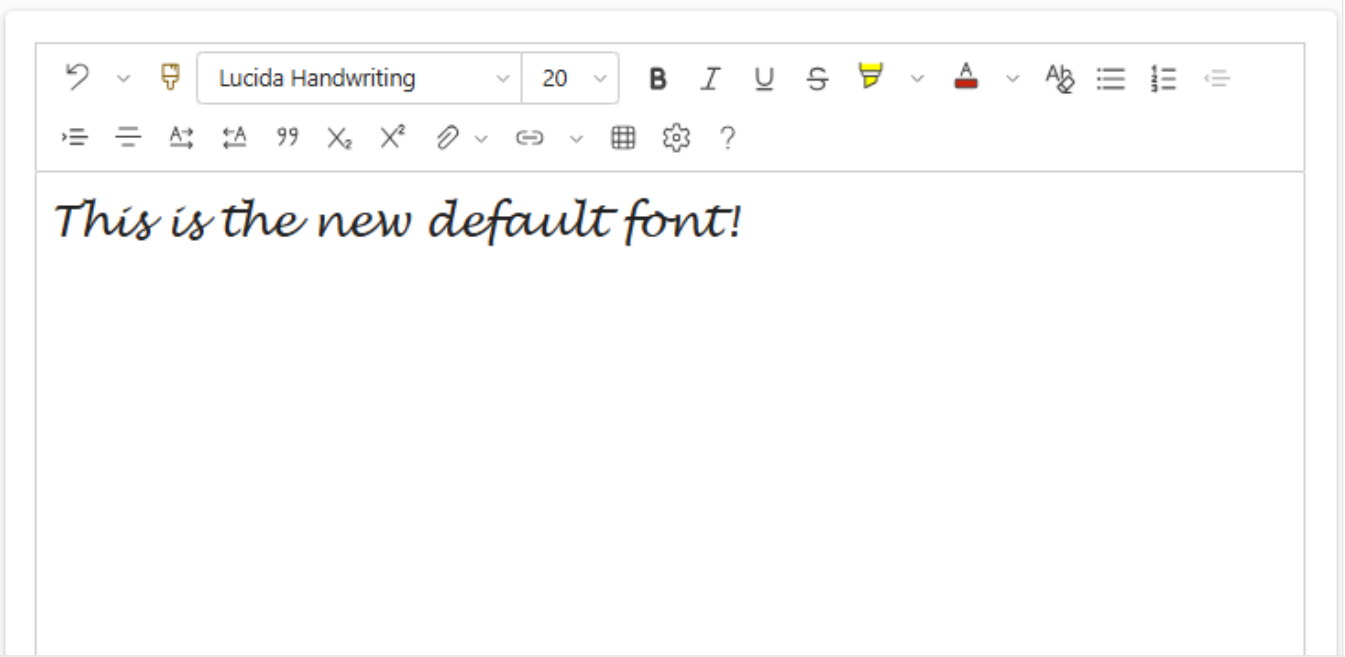
To remove the toolbar entirely, set the value of `toolbar` to '[]' (two square brackets).

Add a new font list and set 20-point Brush Script MT as the default font

Set these defaultSupportedProps properties in your configuration file. Each value except the last one must be followed by a comma (`,`).

JSON

```
"font_names": "Brush Script MT/'Brush Script MT', cursive;Calibri/Calibri,
Helvetica, sans-serif;Calibri Light/'Calibri Light', 'Helvetica Light', sans-
serif;"
"font_defaultLabel": "Brush Script MT"
"fontSize_sizes": "8/8pt;12/12pt;20/20pt;32/32pt"
"fontSize_defaultLabel": "20"
"stickyStyle": {
  "font-size": "20pt",
  "font-family": "'Brush Script MT', cursive"
},
```



Position the toolbar at the top of the rich text editor

Set this defaultSupportedProps property in your configuration file. Follow this value with a comma (`,`) unless it's the last property in the file.

JSON

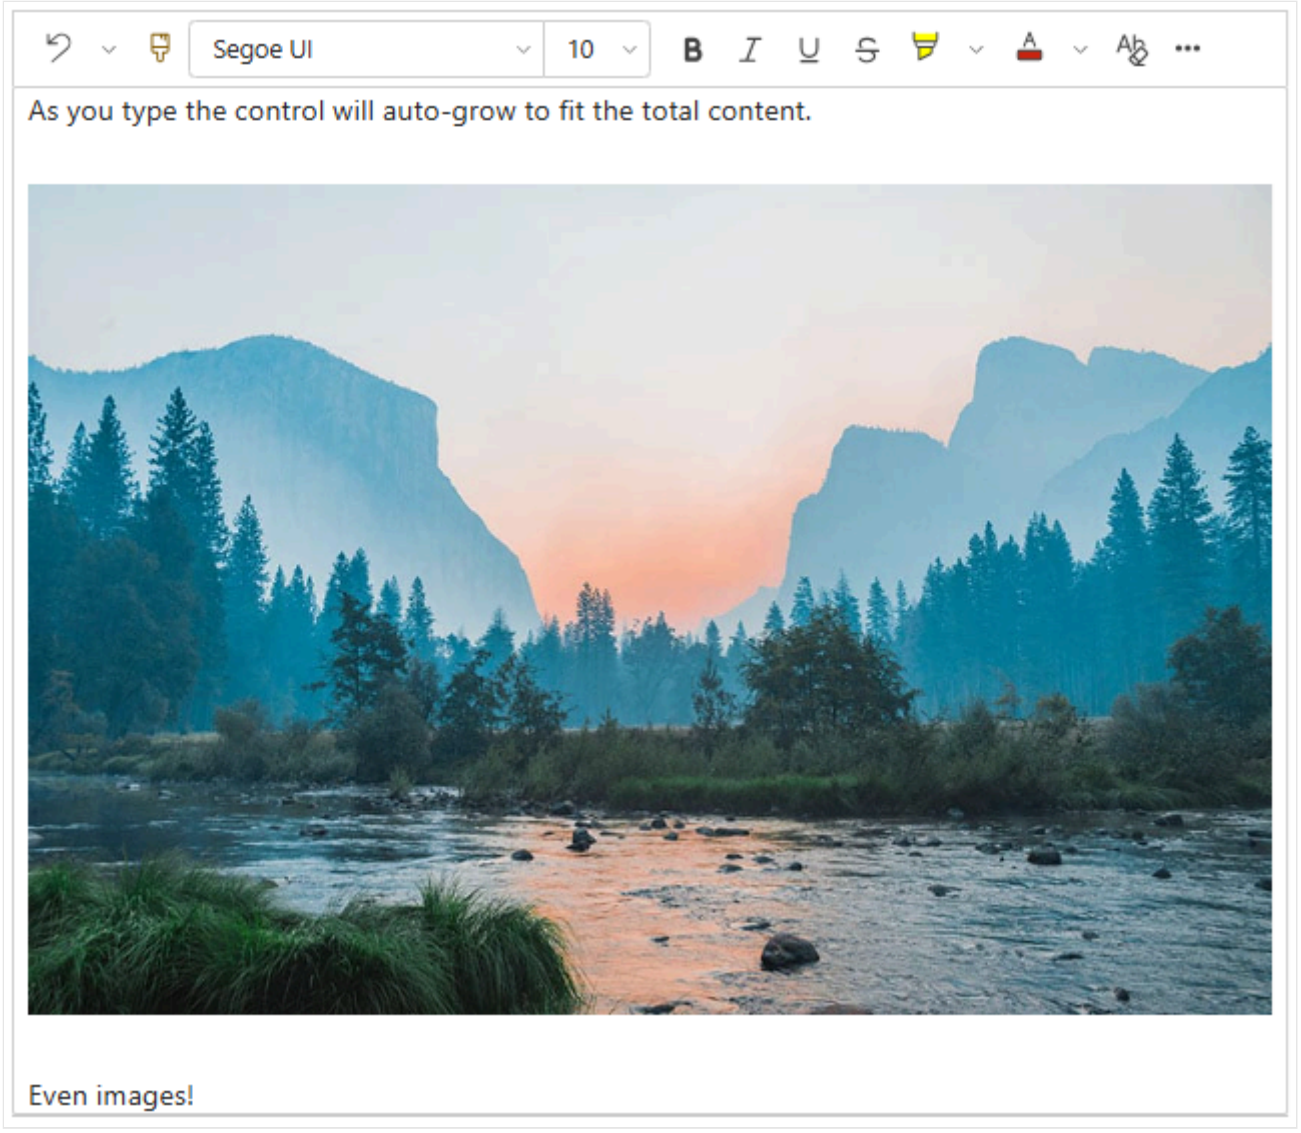
```
"toolbarLocation": "top",
```

Start the editor at 30 pixels high and grow to fit content

Set these defaultSupportedProps properties in your configuration file. Each value except the last one must be followed by a comma (`,`).

JSON

```
"autoGrow_onStartup": false,
"autoGrow_maxHeight": 8000,
"autoGrow_minHeight": 30,
"height": 30,
```

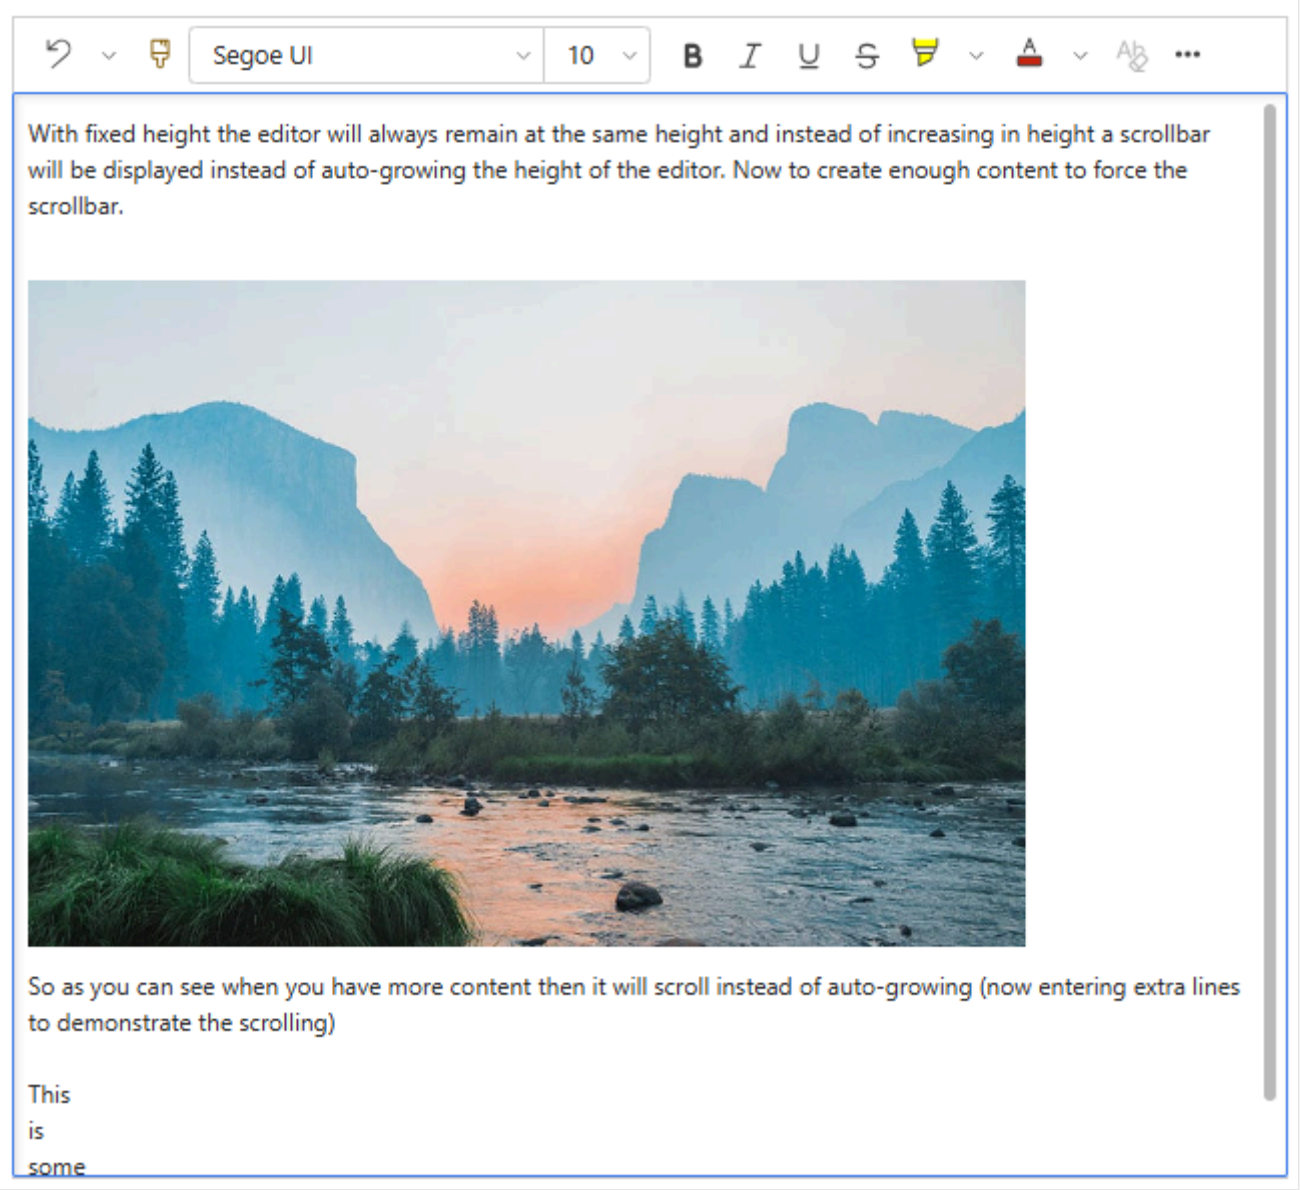


Fix the height of the editor at 500 pixels

Set these defaultSupportedProps properties in your configuration file. Each value, except the last one, must be followed by a comma.

JSON

```
"removePlugins": [ "autogrow" ],
"height": 500,
```



Make the context (right-click) menu use the browser's default context menu

To replace the editor control's context menu with the browser's default context menu, remove the contextmenu plug-in.

Set this defaultSupportedProps property in your configuration file. Follow this value with a comma (`,`) unless it's the last property in the file.

JSON

```
"removePlugins":
"contextmenu,liststyle,openlink,tableresize,tableselection,tabletools",
```

The rich text editor toolbar

The following table describes the formatting tools that are available in the rich text editor by default.

Expand table

Icon	Name	Shortcut key	Description
	Copy Formatting	Ctrl+Shift+C, Ctrl+Shift+V	Apply the look of a particular section to another section.
	Font Name	Ctrl+Shift+F	Select a font. The application considers the font that you select the default font. Segoe UI is the default font if you don't select one. When you select formatted content, the name of the font applied to it displays. If your selection contains multiple fonts, the first one applied to the selection displays.
	Font Size	Ctrl+Shift+P	Change the size of your text. The application considers the font size that you select the default size. 12 is the default size if you don't select one. When you select formatted content, the font size applied to it displays. If your selection contains multiple sizes, the first one applied to the selection displays.
	Bold	Ctrl+B	Make your text bold.
	Italic	Ctrl+I	Italicize your text.
	Underline	Ctrl+U	Underline your text.
	Background Color		Make your text stand out by highlighting it in a bright color.
	Text Color		Change the color of your text.
	Insert/Remove Bulleted List		Create a bulleted list.
	Insert/Remove Numbered List		Create a numbered list.
	Decrease Indent		Move your paragraph closer to the margin.
	Increase Indent		Move your paragraph farther away from the margin.

Icon	Name	Shortcut key	Description
	Block Quote		Apply a block-level quotation format to your content.
	Align Left	Ctrl+L	Align your content with the left margin.
	Align Center	Ctrl+E	Center your content on the page.
	Align Right	Ctrl+R	Align your content with the right margin.
	Link		Create a link in your document for quick access to web pages and other cloud resources. Enter or paste the anchor text in the **Display Text** box, and then enter or paste the URL in the **URL** box. Optionally, select a **Link Type** and protocol if the link is to something other than a web page. To specify where a URL-type link should open, select the **Target** tab and then select a **Target**. A pasted or typed URL is automatically converted into a link. For example, `http://myexample.com` becomes `<a href="http://myexample.com">http://myexample.com</a>`.
	Unlink		Remove the link from an anchor and make it plain text.
	Superscript		Type small letters just above the line of text.
	Subscript		Type small letters just below the line of text.
	Strikethrough		Cross out text by drawing a line through it.
	Image		To insert an image, paste it from your clipboard into the content area or drag an image file from a folder to the content area. Drag any corner of the image to resize it. The control supports .png, .jpg., and .gif images. To have more control over the image's source, appearance, and behavior, select the **Image** button. Browse to the image file in a local folder or enter its URL. If the image is stored on an external server, enter the absolute path. If it's on a local server, you can enter a relative path. Optionally, enter a specific height and width to resize the image, and select an alignment. You should also enter alt text to describe the image for people who use screen readers. If the image is also a link to a web page or other cloud resource, enter the URL of the resource in the **Target URL** box and, if needed, select the **Target** where the link should open.

Icon	Name	Shortcut key	Description
	Text direction from left to right		Change the text to left-to-right. This setting is the default.
	Text direction from right to left		Change the text to right-to-left for bi-directional language content.
	Undo		Reverse the last change you made to the content.
	Redo		Undo your last undo, or reapply the last change you made to the content.
	Remove Format		Remove all formatting from the select text.
	Table		Insert a table with the number of rows and columns you select. To have more control over the table's size and appearance, select the **Table** button > **More** and change its properties. You can also right-click a table to view and change its properties. To change the width of a column, drag its border. You can select one or more cells, rows, or columns and apply specific formatting, add a link to selected text, and cut, copy, and paste entire rows or columns.
	Personalization Settings		Set your default font and font size.
	Accessibility Help	Alt+0	Open the list of keyboard shortcuts you can use in the rich text editor.
···	Expand Toolbar		When the window is too narrow to show the entire toolbar, select to expand the toolbar to a second row.

Tip

To use your browser's built-in spell checker, press the Ctrl key as you right-click the text you want to check. Otherwise, the right-click (context) menu provides contextual formatting for the element you select.
An alternative to your browser's built-in spell checker is the Microsoft Editor browser extension. Microsoft Editor works seamlessly with the rich text editor control, and when enabled, provides fast and easy inline grammar and spell-check capabilities.

Use the rich text editor offline

The rich text editor control is available when you're working offline, although without some of the features and functionality you're used to. Images that you upload using the editor's default configuration aren't available when you're working offline.

The following plug-ins are available to the rich text editor when it's offline:

- ajax, autogrow, basicstyles, bidi, blockquote, button, confighelper, contextmenu, dialog, dialogui, editorplaceholder, enterkey, entities, fakeobjects, floatingspace, floatpanel, format, horizontalrule, htmlwriter, indent, indentblock, indentlist, justify, lineutils, list, listblock, maximize, menu, menubutton, notification, notificationaggregator, panel, panelbutton, popup, preview, removeformat, resize, richcombo, selectall, showborders, sourcearea, specialchar, stylescombo, tab, textmatch, textwatcher, toolbar, undo, widgetselection, wysiwygarea, xml

The following formatting tools are available in the rich text editor when it's offline:

- Bold, italic, underline, bulleted and numbered lists, decrease and increase indent, block quote, align left, align center, align right, strikethrough, bi-directional text, undo and redo, and remove formatting

Best practices for using the rich text editor

- Rich text fields store HTML tags for formatting along with user-entered data. When you set the maximum size of rich text fields, make sure to allow for both the HTML tags and the user's data.

- For the best performance, keep your HTML content to 1 MB or less. At larger sizes, you might notice slower response times for loading and editing.

- In the default configuration, images don't negatively affect performance because they're stored separately from the HTML content. However, images are stored as base64 content in the text column when the user who uploads them doesn't have permissions on the `msdyn_richtextfiles` table. Base64 content is large, so you generally don't want to store images as part of the column content.

- If you have a system administrator or basic user security role, the user personalization feature works by default. If you don't have these roles, you must have privileges to create,

read, and write on the `msdyn_customcontrolextendedsettings` table for the user personalization plug-in to work.

- In the default rich text editor configuration, if you drag and drop an image file into the rich text editor, it uploads the inline image to the `msdyn_richtextfiles` table. For appropriate users to be able to view the inline image, make sure you apply the correct permissions to `msdyn_richtextfiles`.

Rich text editor limitations

When using the rich text editor, consider the limitations listed in this section. For questions about feature availability, contact Microsoft Customer Support.

> **Important**
>
> The modern rich text editor is a new experience. For the functionality to work correctly, you must remove the classic version. Otherwise, your templates might not display correctly.

Rich text editor limitations include the following:

- You can't use rich text editor content from any external sources like Microsoft Word, Excel, and so forth.
- The rich text editor supports the following file types for attachments: .aac, .avi, .csv, .doc, .docx, .gif, .html, .jpeg, .mid, .midi, .mp3, .mp4, .mpeg, .msg, .pdf, .png, .ppt, .pptx, .svg, .txt, .vsd, .wav, .xls, .xlsm, and .xlsx. You can configure the allowed extensions for your environment in your advanced settings by going to **Administration** > **General** > **Set blocked file extensions for attachments** and removing the extensions you want to allow.
- The rich text editor doesn't support non-Microsoft plugins.

Email templates and signatures:

- If you experience an issue with the way an email template renders, we recommend that you recreate it in the modern editor.
- Nested HTML structures—such as deeply nested or <table> elements—can cause rendering problems in the rich text editor. We recommend that you simplify the HTML structure by removing unnecessary nested or <table> tags to ensure consistent rendering across clients.

HTML tags

The following HTML tags are either no longer supported or are replaced by a modern alternative in the rich text editor.

Expand table

Tag	Description	Modern rich text editor alternative
<acronym>	Defines an acronym	<abbr>
<applet>	Embeds Java applet	<object>
<basefont>	Sets default font size and color	CSS
<big>	Enlarges text	CSS font-size
<blink>	Makes text flash	CSS animations
	Centers content	CSS text-align
<dir>	Directory list	
<font>	Styles fonts	CSS
<frame>	Defines a frame	<iframe>
<frameset>	Groups frames	<iframe>
<isindex>	Single-line input	<form>
<marquee>	Scrolling text	CSS animations
<menu>	Menu list	
<noframes>	Fallback for no frame support	Not needed
<plaintext>	Displays plain text	<pre>
<s>	Strikethrough text	<del>, CSS
<strike>	Strikethrough text	<del>, <s>
<tt>	Teletype text	<code>, CSS
<u>	Underlined text	CSS text-decoration
<xmp>	Preformatted text	<pre>

HTML attributes

The following HTML attributes are either no longer supported or are replaced by a modern alternative in the rich text editor.

Expand table

Attribute	Affected tags	Modern rich text editor alternative
align	Many	CSS text-align, float
alink, vlink, link	<body>	CSS :link, :visited
background	<body>, <table>	CSS background-image
bgcolor	Many	CSS background-color
border	<img>, <table>	
height, width	<body>, <td>	CSS height, width
hspace, vspace	<img>	
language	<script>	type="text/JavaScript"
nowrap	<td>	CSS white-space: nowrap
type (on ,)	Lists	CSS list-style-type

Frequently asked questions

Why do typed characters display slowly?

If you have a lot of content in the editor, the response time can increase. Keep the content to 1 MB or less for the best performance. Spelling or grammar checks can also slow the typing performance.

Why doesn't my content render until the editor is refreshed?

This behavior occurs when custom code injects content into the rich text editor without triggering a re-render of the control. The rich text editor doesn’t automatically detect external updates unless it's explicitly notified.

To work around this issue, you can do either of the following actions:

- Use an event listener (for example, formContext.data.entity.addOnSave) to trigger a refresh after content is injected.

- Use formContext.ui.refreshRibbon() or a similar API to force an update.

Example:

```
window.top.addEventListener('rteEditorReady', (event) => {
    const { parentEntity } = event.detail;

    if (parentEntity?.typeName === 'email' &&
        parentEntity?.fieldName === 'description') {

        const descriptionAttr = Xrm.Page.getAttribute("description");
        if (descriptionAttr) {
            descriptionAttr.setValue(emailSignature);
        }
    }
}, { once: true });
```

In this example, the event listener is automatically removed after the `rteEditorReady` event triggers. This approach ensures the listener runs only once, helping to prevent memory leaks and unnecessary resource usage.

Why can't I upload an image? Why does the image preview fail to load?

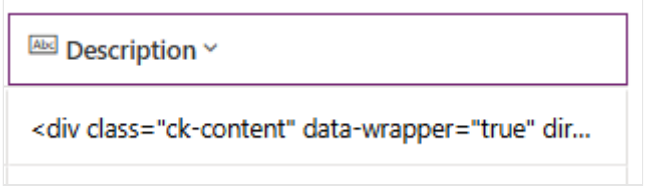
If the image file name, including the path, is long, the file might fail to upload, or the preview might not be displayed. Try shortening the file name or moving it to a location with a shorter path, and then upload it again.

Why do I see HTML in my text?

If you use the rich text editor control in a column that isn't formatted for rich text, the content appears in the underlying HTML instead of as formatted text.

What's the size limit of HTML content?

For the best performance, keep your HTML content to 1 MB or less. At larger sizes, you might notice slower response times for loading and editing.



To resolve this issue, make sure the format of the column is set to **Rich text**.

I exceeded the character limit but there are fewer characters than the limit. Why?

The database stores the entire HTML formatting, not just the characters, which takes up extra space.

Why don't I see the modern rich text editor?

The modern rich text editor control is part of the **New look for model-driven apps** and doesn't appear unless the app setting is turned on. Without the setting enabled, you might see an older version of the editor.

Add the Copilot control to the rich text editor

Article • 04/30/2025

The Copilot control is available in the email form's rich text editor toolbar by default. You can add the Copilot control to the rich text editor in other forms by changing the editor's properties in its advanced configuration file.

Prerequisites

Have a configuration file for the rich text editor in the form where you want to add the Copilot control.

Add the Copilot control

To add the Copilot control to the rich text editor toolbar in a form, you need to add a value that represents it to the `extraPlugins` and `toolbar` properties in the editor's advanced configuration file.

1. Open the editor's advanced configuration file.
2. Add the following values in the defaultSupportedProps section of the file:

   - In the `extraPlugins` property, add `copilotrefinement`.
   - In the `toolbar` property, add `CopilotRefinement`.

   It should look something like the following example, where "..." represents values that aren't shown to save space:

   ```text
   "defaultSupportedProps": {
       ...
       "extraPlugins": "computedfont,...,copilotrefinement",
       ...
       "toolbar":[{ "items": ["CopyFormatting", ... ,"CopilotRefinement"]}]
   },
   ```

3. Save the file, and then publish the changes.

Use Copilot in the email rich text editor

Use Copilot in the email rich text editor

When you draft customer emails in the rich text editor in a model-driven app, Copilot can offer suggestions to make them clearer, more concise, and more compelling.

> **Important**
>
> By using Copilot features powered by Azure OpenAI, you agree that data may be stored and/or processed outside of your geographic region, compliance boundary, or national cloud instance. Learn more: Data, privacy, and security for Azure OpenAI Service

Prerequisites

The generative AI feature in emails must be turned on in the model-driven app feature settings.

Draft and refine an email in the rich text editor

1. Select the **Copilot** icon in the rich text editor toolbar and then select **Draft with Copilot**.
2. In the **Draft with Copilot** dialog box, select a prompt as required.
3. To refine or update the generated content, select the following options as required:

Expand table

Option	Description
Keep it	Retains the current text and adds it to the email.
Start over	Removes the current suggestion and takes you back to the email prompt.
Discard	Removes the content suggestion and takes you back to email editor.
Adjust	Refines the text and tone of suggested content. - To adjust the length of the content, select **Short**, **Medium**, or **Long**. - To adjust the tone of the content, select **Friendly**, **Professional**, or **Formal**. Select **Update** and the content is updated according to your refinements.
Translate	Translates the content into the selected language. The languages listed here are those supported by your environment. To go back to the language that the content was originally generated, select **Show original**.

Adjust existing email content with Copilot

1. Select the text that you want to refine.
2. Select the **Copilot** icon in the rich text editor toolbar and then select **Adjust with Copilot**.
3. Refine the length and tone of the selected text:
    - Length: Select **Short**, **Medium**, or **Long** to condense or expand on your text.
    - Tone: Select **Friendly**, **Professional**, or **Formal** to adjust the tone of your text.
4. Select **Update** to apply Copilot's suggested refinements.

For example, Marina wants to send an email to a customer about a new product. Marina types a draft, selects **Adjust with Copilot**, and asks Copilot to rewrite the draft to be shorter and in a more formal tone.

- Before Copilot's assistance:

```text
Hi Samir,

My name is Marina; I'm a Sales executive at Contoso Inc. I was
recommended by Kevin to get in touch with you.

I noticed on your website that you don't have CRM application. I'd
love to connect with you to discuss the potential of partnering up.
When would you have time to chat about this?

If you want to learn more about the product first, here's a quick
link: www.contoso.com.

Kind regards,
Marina
```

- After Copilot's assistance:

```text
Dear Mr. Samir,

I am Marina, a Sales Executive at Contoso Inc. Kevin recommended that I
contact you. I noticed that your website does not have a CRM application.
I would like to discuss the possibility of a partnership. When would you
have time to talk about this? If you would like to learn more about our
product, please refer to this link: www.contoso.com.
```

```
Sincerely,
Marina
```

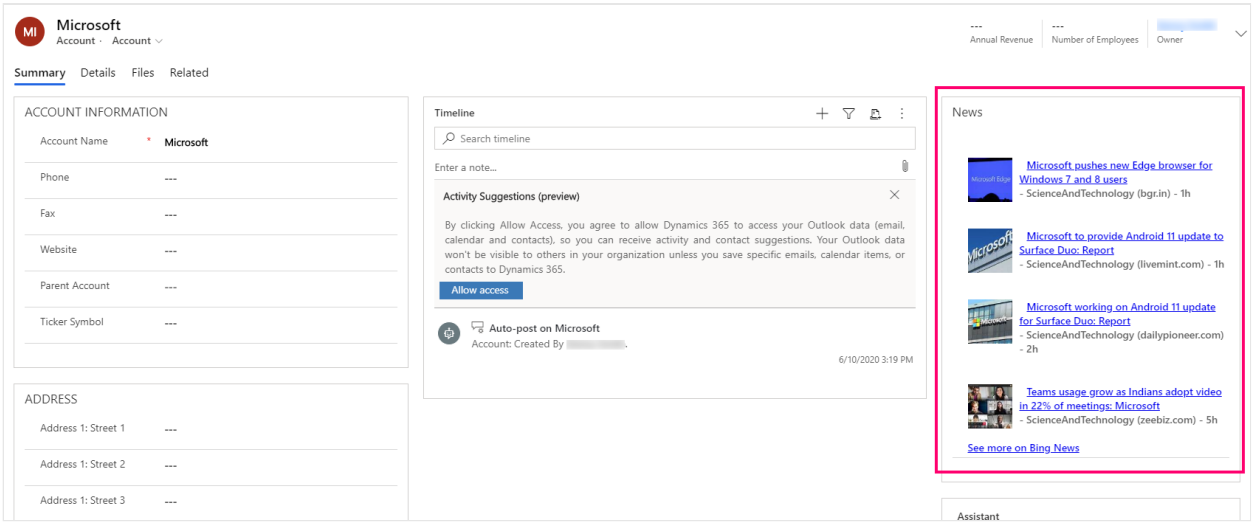
Set up and use the news control

Article • 03/13/2023

> **Note**
>
> This describes the process that currently uses the classic editor to introduce a control. In due course this will be migrated so that this can be performed within the modern form editor.

Gain valuable insights from the latest news about your customers, competitors, and contacts. Staying on top of the news helps you stay ahead of your competition by showing you real-time contextual information about your customers and competitors. Install the news Power Apps component framework control, which delivers relevant news from Bing News.



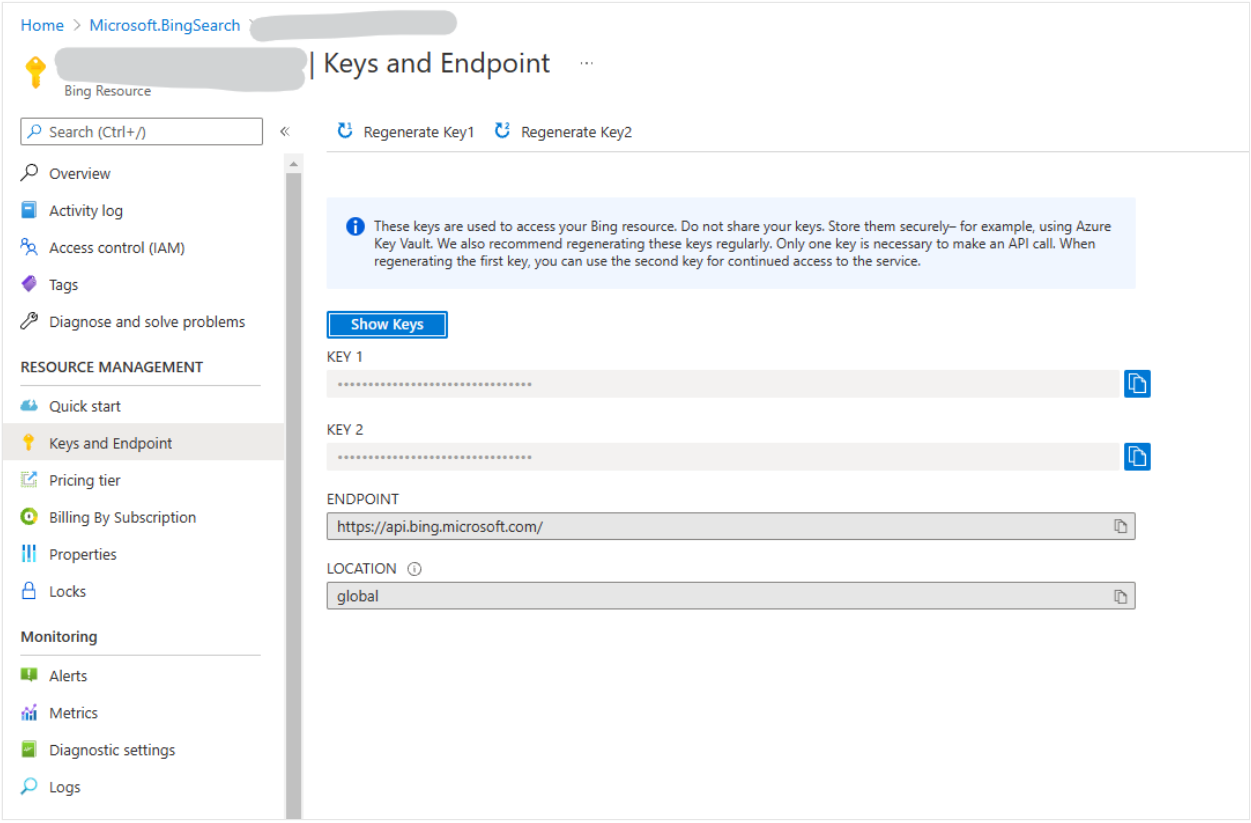
You can customize to support additional news sources, the look and feel and the behavior of the PCF control. For more information, see the readme in the news control GitHub repo.

Add the company news control to the account main form

The steps in this article add the company news control to the account main form already configured to query news topics collected from Bing News. You can use similar steps to add the control to the main form for other tables, such as contact and competitor.

Get the Bing News API key and URL

The news control requires a news API URL, API key, and more news URL. For Bing News, the more news URL is preconfigured in the control to use *https://www.bing.com/news/search*. For the News API URL, and API Key, you'll need to provide these by creating a Bing Search azure resource under your Azure account. Once created, you will get the API key and API URL under the **Keys and Endpoint** section.



Import the company news solution

1. Go to the news control GitHub repo.
2. Download Solutions.zip. To do this, open the **Solutions** folder, open **Solutions.zip**, and then select **Download**.
3. Sign-in to Power Apps, and then in the upper right select the environment where you want to install the company news control.
4. Select **Solutions** on the left pane, and then select **Import** on the command bar. If the item isn't in the left navigation pane, select ...More and then select the item you want.
5. In the Import solution wizard, select **Choose File**, browse to and select *Solutions.zip*, and then select **Open**.
6. Select **Next,** and then select **Next** again to complete the import.

Add the control to the account main form

1. In Power Apps select **Settings** (gear) on the upper right, and then select **Advanced settings**.

2. Go to **Settings** > **Customizations** > **Customize the System**.

3. In the left navigation tree, expand **Tables** > **Account**, select **Forms**, and then open the **Account Main** form.

4. In the form editor, add two new text columns, which will be used to pass the key and base URL to the news component.

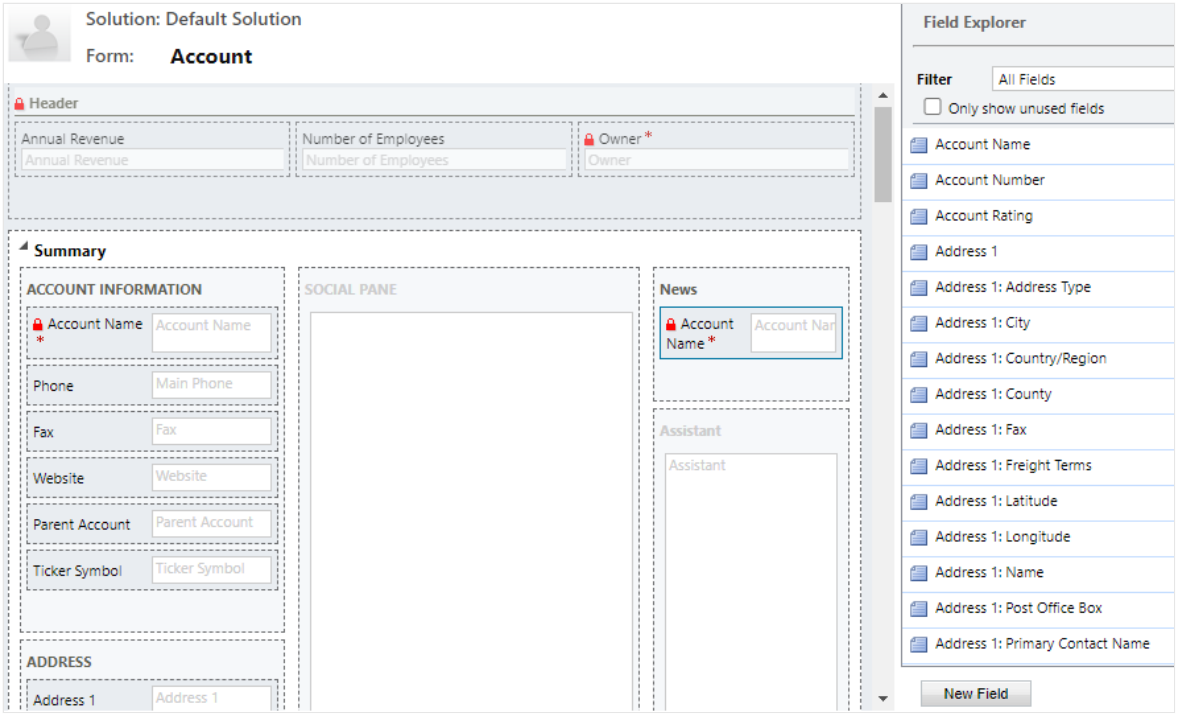
   a. Select **New Column** from the right navigation **Column Explorer**.

   b. For both **Display name** and **Name** enter *newsapikey*. Leave the rest of the settings as the default and then select **Save and Close**.

   c. Repeat the previous two steps to create another text column. For both the **Display name** and **Name** enter *newsurl*. Leave the rest of the settings as the default and then select **Save and Close**.

5. In the form editor, select a place on the form where you want the company news control, and then select **Insert** tab > **Section** > **One Column**.

6. To show news by account name, drag and drop the **Account Name** column from the right **Column Explorer** pane to the newly created section.

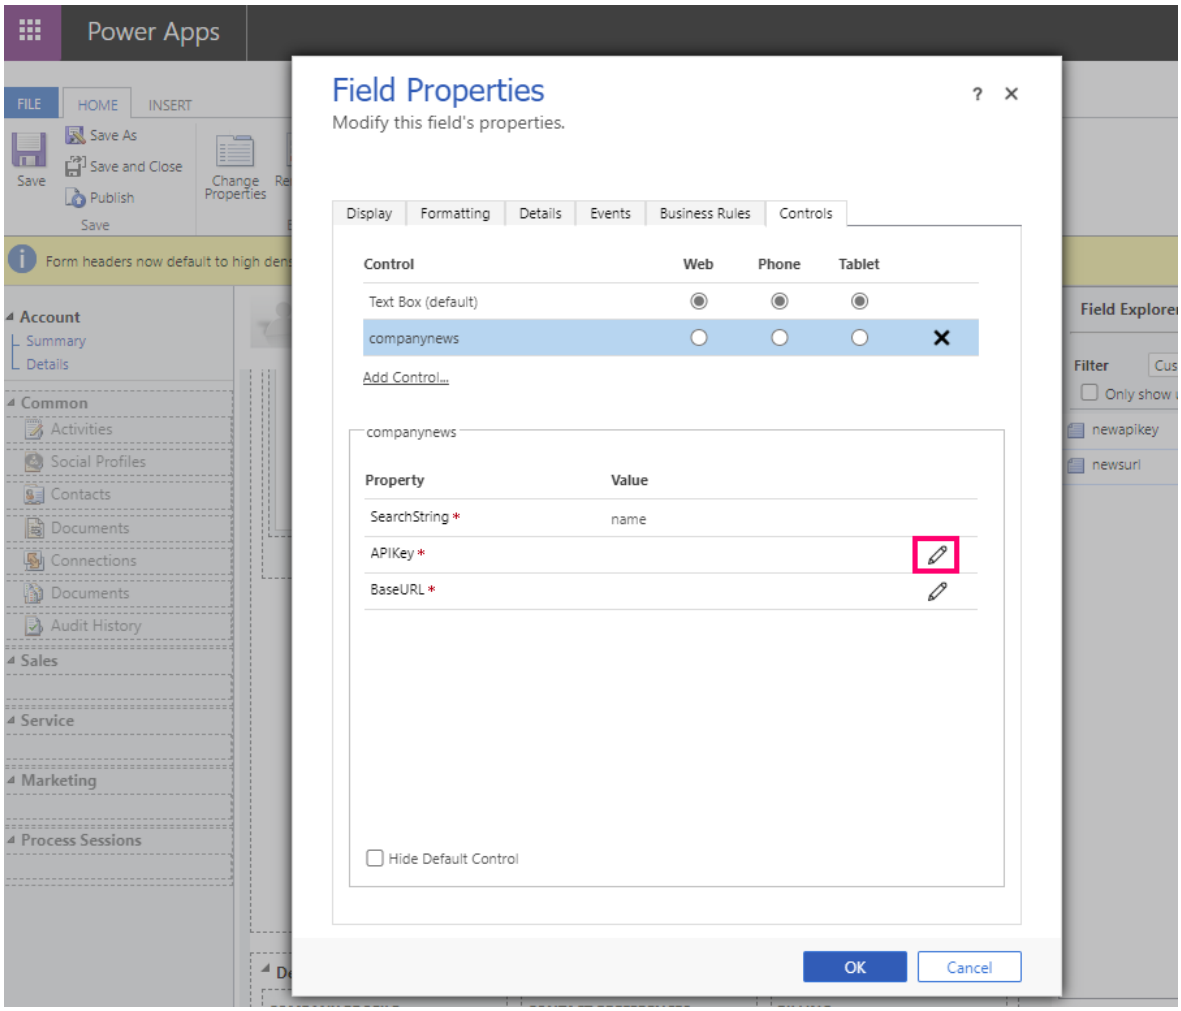


7. Select the section and then select **Change properties.** Enter a descriptive section a **Name**, such as *Company news*. You might want to check **Show the label of this section on the form** to provide heading to the section. Select **OK**.

8. Select the newly added **Account Name** column, and then select **Change properties** on the **Home** tab. On the **Column Properties** page, select the **Controls** tab, select **Add Control**, select the **companynews** control, and then select **Add**.

9. Configure the following bindings for the apikey and baseurl columns.

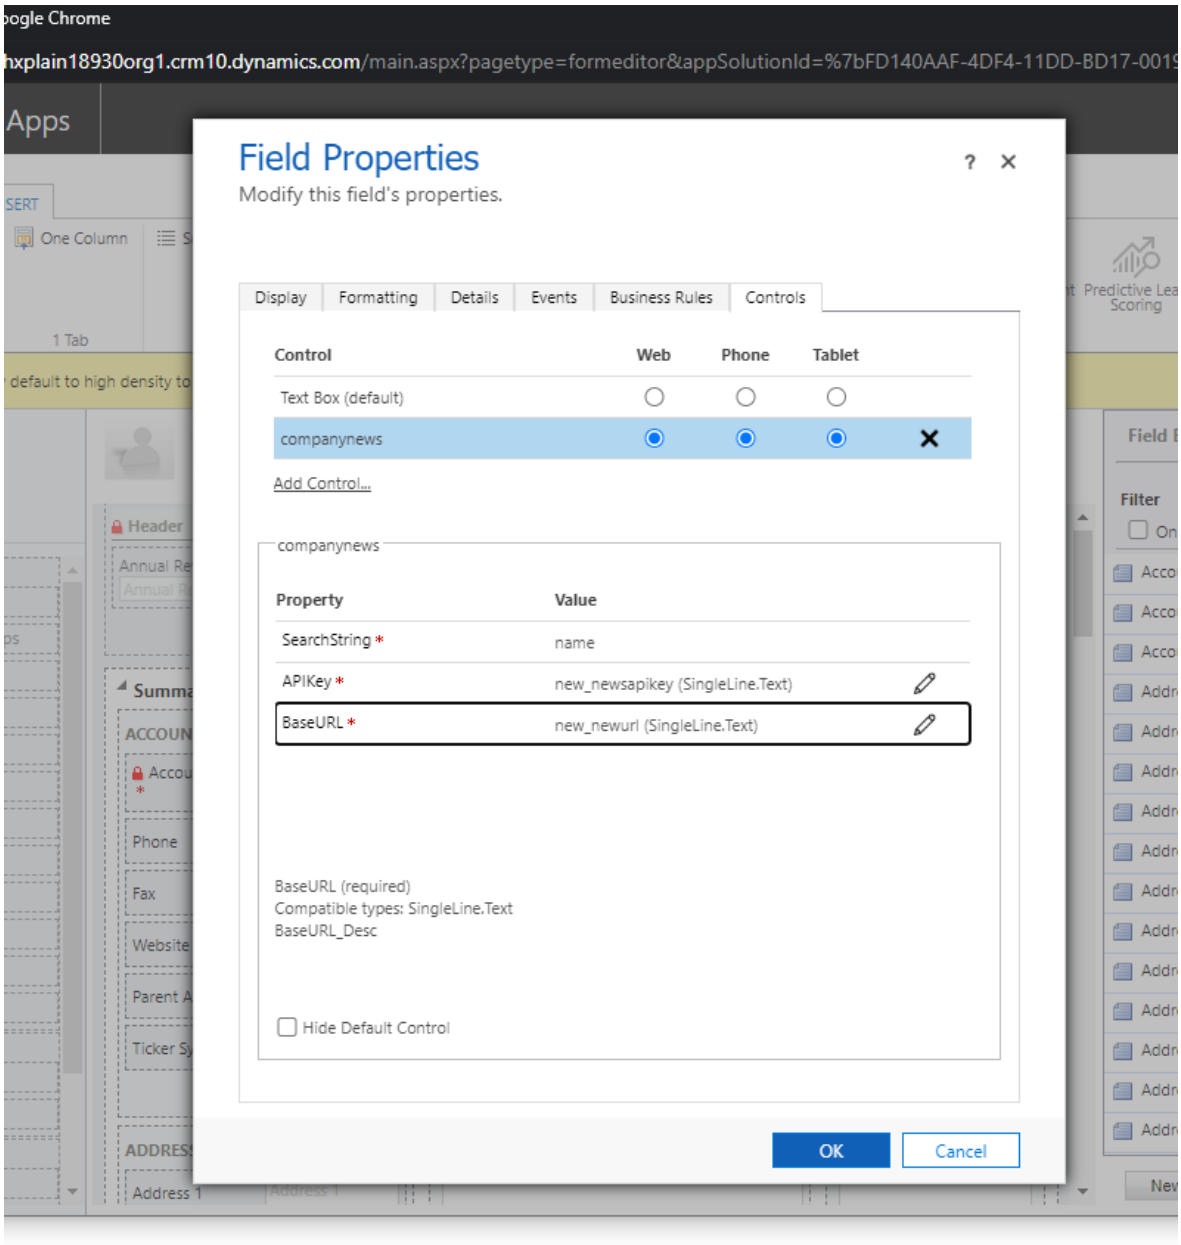
   a. Select **Configure property** (pencil icon) next to APIKey.



b. From **Bind to value on a column** the dropdown list, select **new_newsapikey (SingleLine.Text)**, and then select **OK**.

c. Select **Configure property** (pencil icon) next to **BaseURL**.

d. From **Bind to value on a column** the dropdown list, select **new_newsurl (SingleLine.Text)**, and then select **OK**.



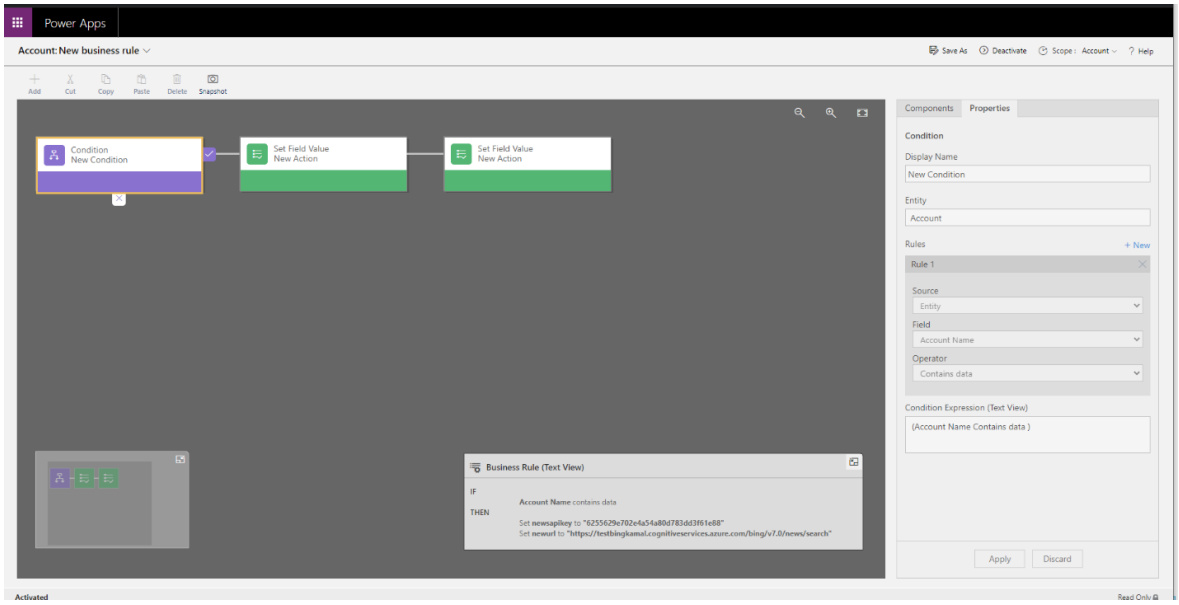
e. On the **Column Properties** page, select the **Web**, **Phone**, and **Tablet**, client options.

f. On the **Column Properties** page, select the **Display** tab, clear the **Display label on form** option, and then select **OK**.

10. To provide API Key and Base URL default values, use business rules. Select **Business Rules** from the form editor, and then select **New Business Rule** from the bottom of the right pane.

11. In the business rule designer, select **Condition** on the designer canvas, set **Column** to **Account Name** and **Operator** to **Contains data,** and then select **Apply**. Then, select the **Components** tab, drag a **Set Column Value** action, and provide a column value where **Column** is **newsapikey** and the value is the **Key** you copied from the Bing Search properties. Create another **Set Column Value** action where **Column** is **newsurl** and add the value as the **Endpoint** you copied from the Bing

Search properties. Make sure to append */v7.0/news/search* at the end of the news URL. The final URL should look like `https://api.bing.microsoft.com/v7.0/news/search`.



12. Save and activate the rule. Close the business rule designer.
13. Make sure you add the newly added columns, newsapikey and newsurl, to the account main form.
14. Clear **Visible by default** for the form tab properties where the newsapikey and newsurl columns are added.
15. In the form designer, select **Save** and then select **Publish**.

Use custom controls for model-driven app data visualizations

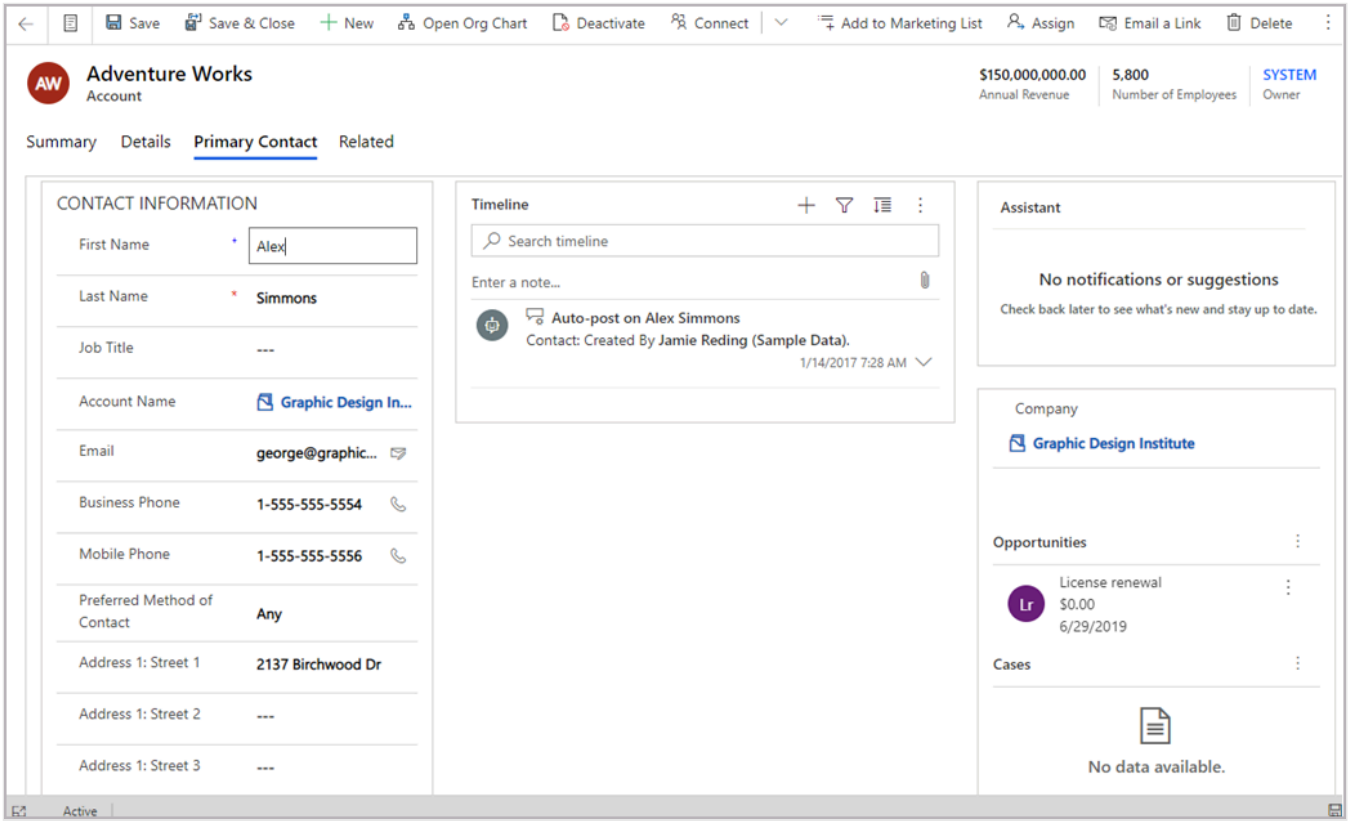
Edit related table records directly from another table's main form

Article • 04/28/2025

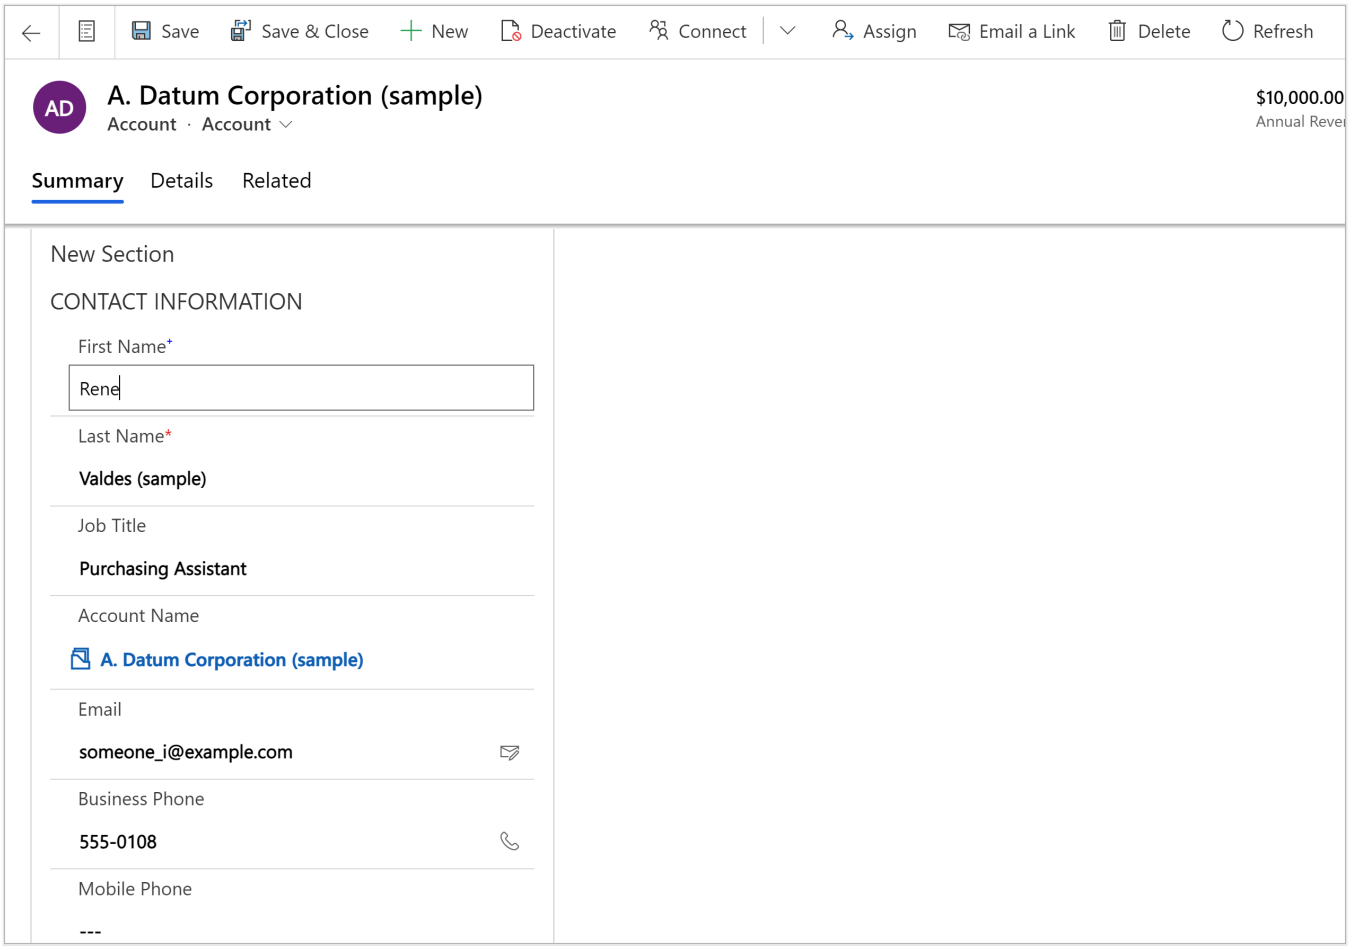
There are multiple ways that you can work with related table records on a table form within Power Apps. For example, you can include related tables in read-only mode with a quick view form and create or edit a record using a main form in a dialog.

Another way you can work with related table records is by adding a form component control to another table's main form. The form component control lets users edit information of a related table record directly from another table's form.

For example, here's the form component on a separate tab on the main account form, which lets the user edit a contact record without leaving the account form.



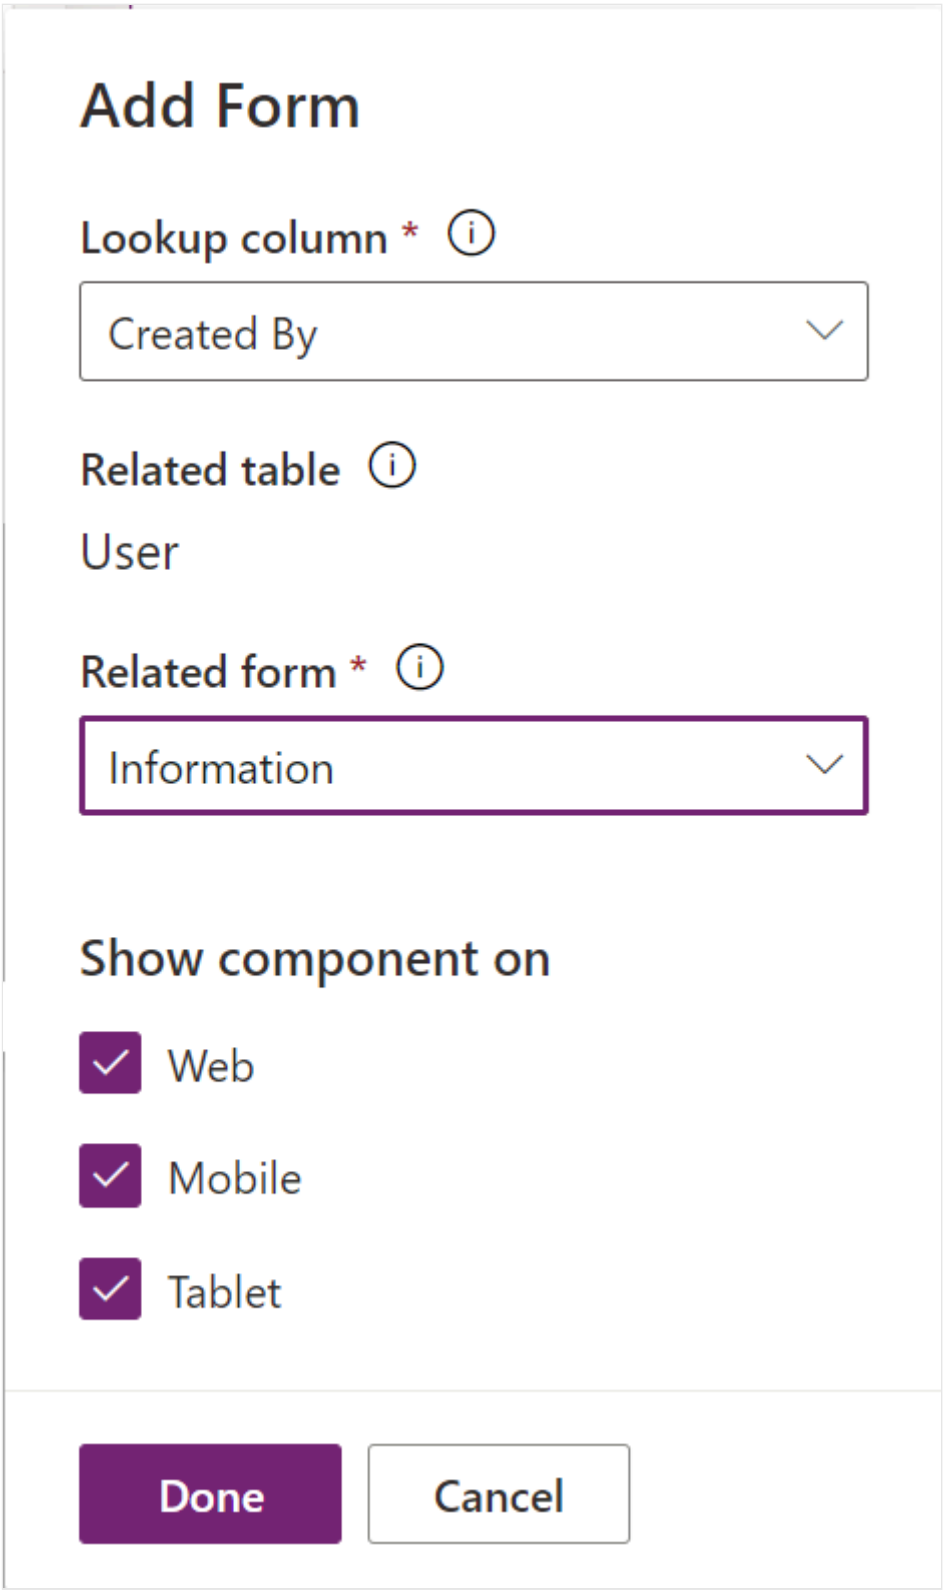
For example, here's the form component on an **existing tab** on the main account form, which also lets the user edit a contact record without leaving the account form **Summary** tab.



Add the form component to a table main form

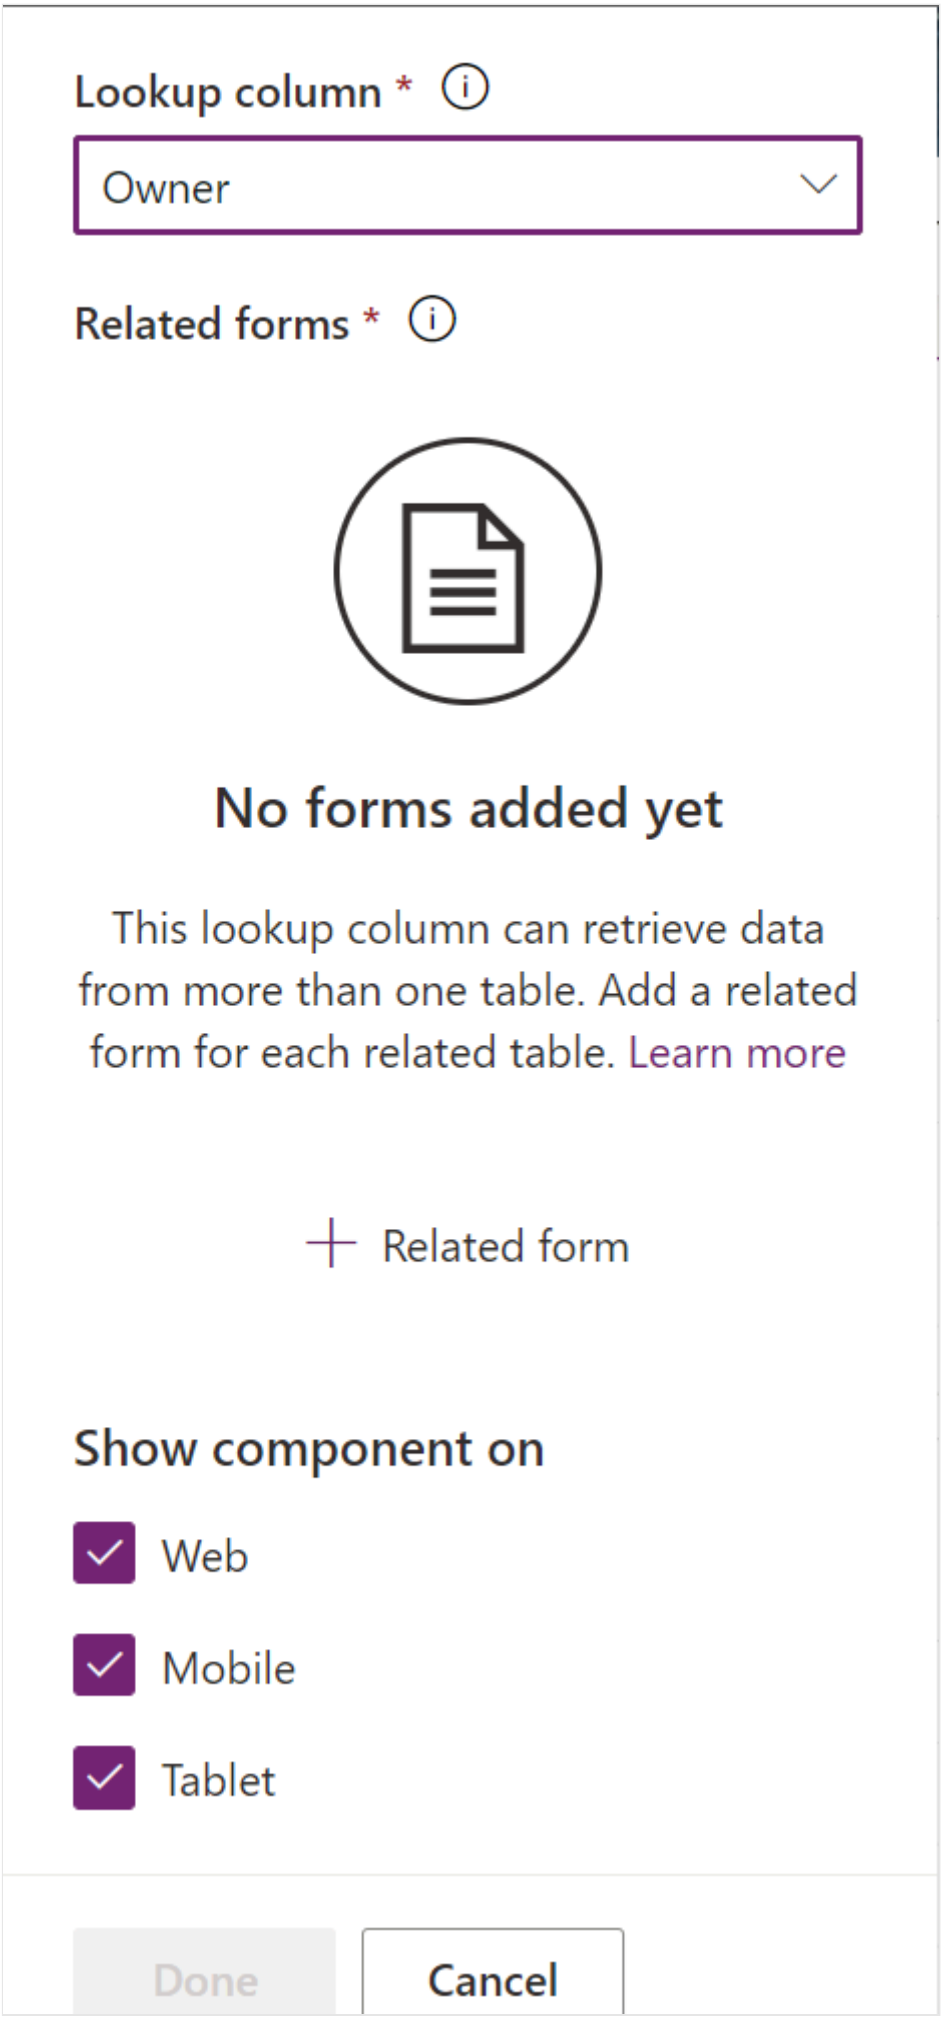
1. On the left navigation pane, select **Components**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Expand either **Input** or **Display**, and then select **Form**. On the form component control configuration page, select the properties for the control:

    - Select the **Lookup column** for the form.
    - Select the **Related form**. Depending on the related table configuration for the column:
        - If the column is connected to a single table (such as the Created By column), select the **Related form** to use.



- If the column is connected to multiple tables (polymorphic, such as the owner column), select **+ Related form** and then select **Add** to add the related form.

Continue to select + **Related form** > **Add** to add a related form for each related table.



- By default, all client app types **Web**, **Phone**, and **Tablet** are enabled to display the form. Clear the client types where you don't want the form displayed.

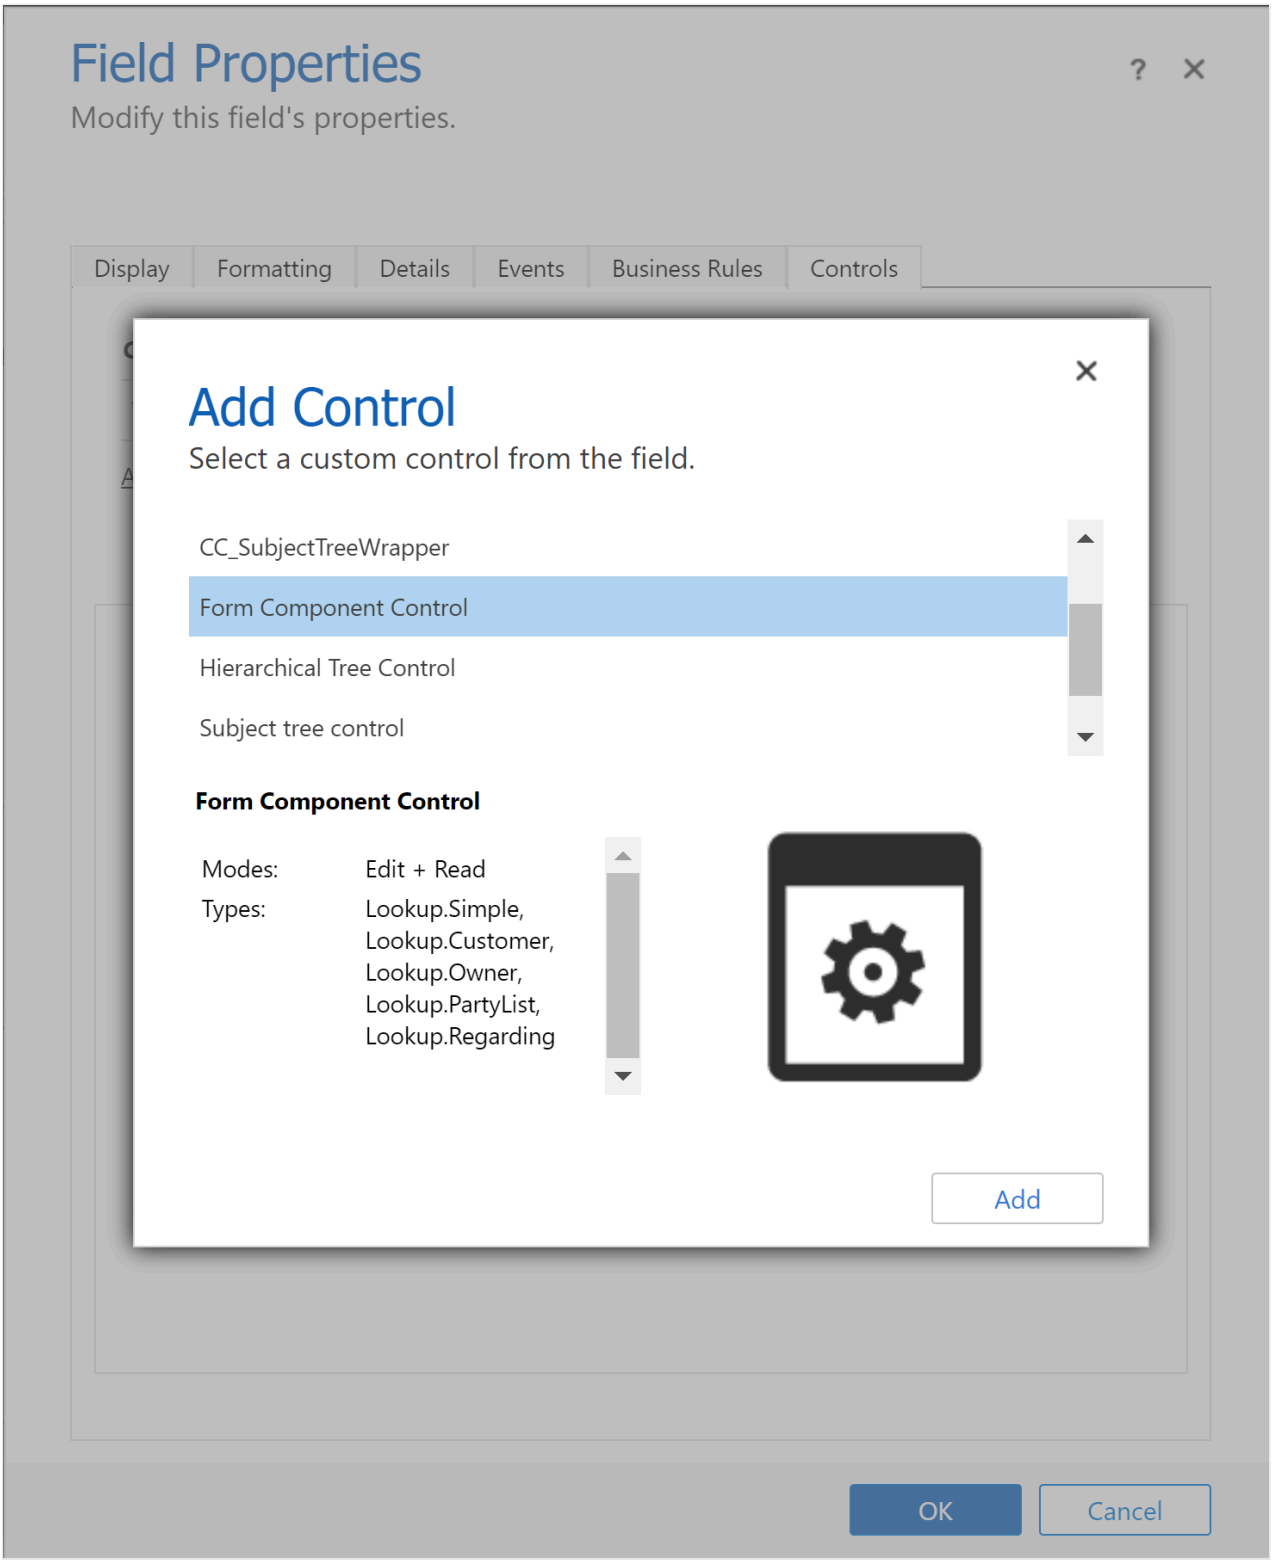
3. Select **Done**.
4. **Save** and then **Publish** the form.

Add the form component using the classic experience

In this example, the **Contact** standard main form is configured for the form component control that's added to the account main form.

> **Important**
>
> The way you add a form component control has changed. We recommend that you use the latest experience. More information: **Add the form component to a table main form**

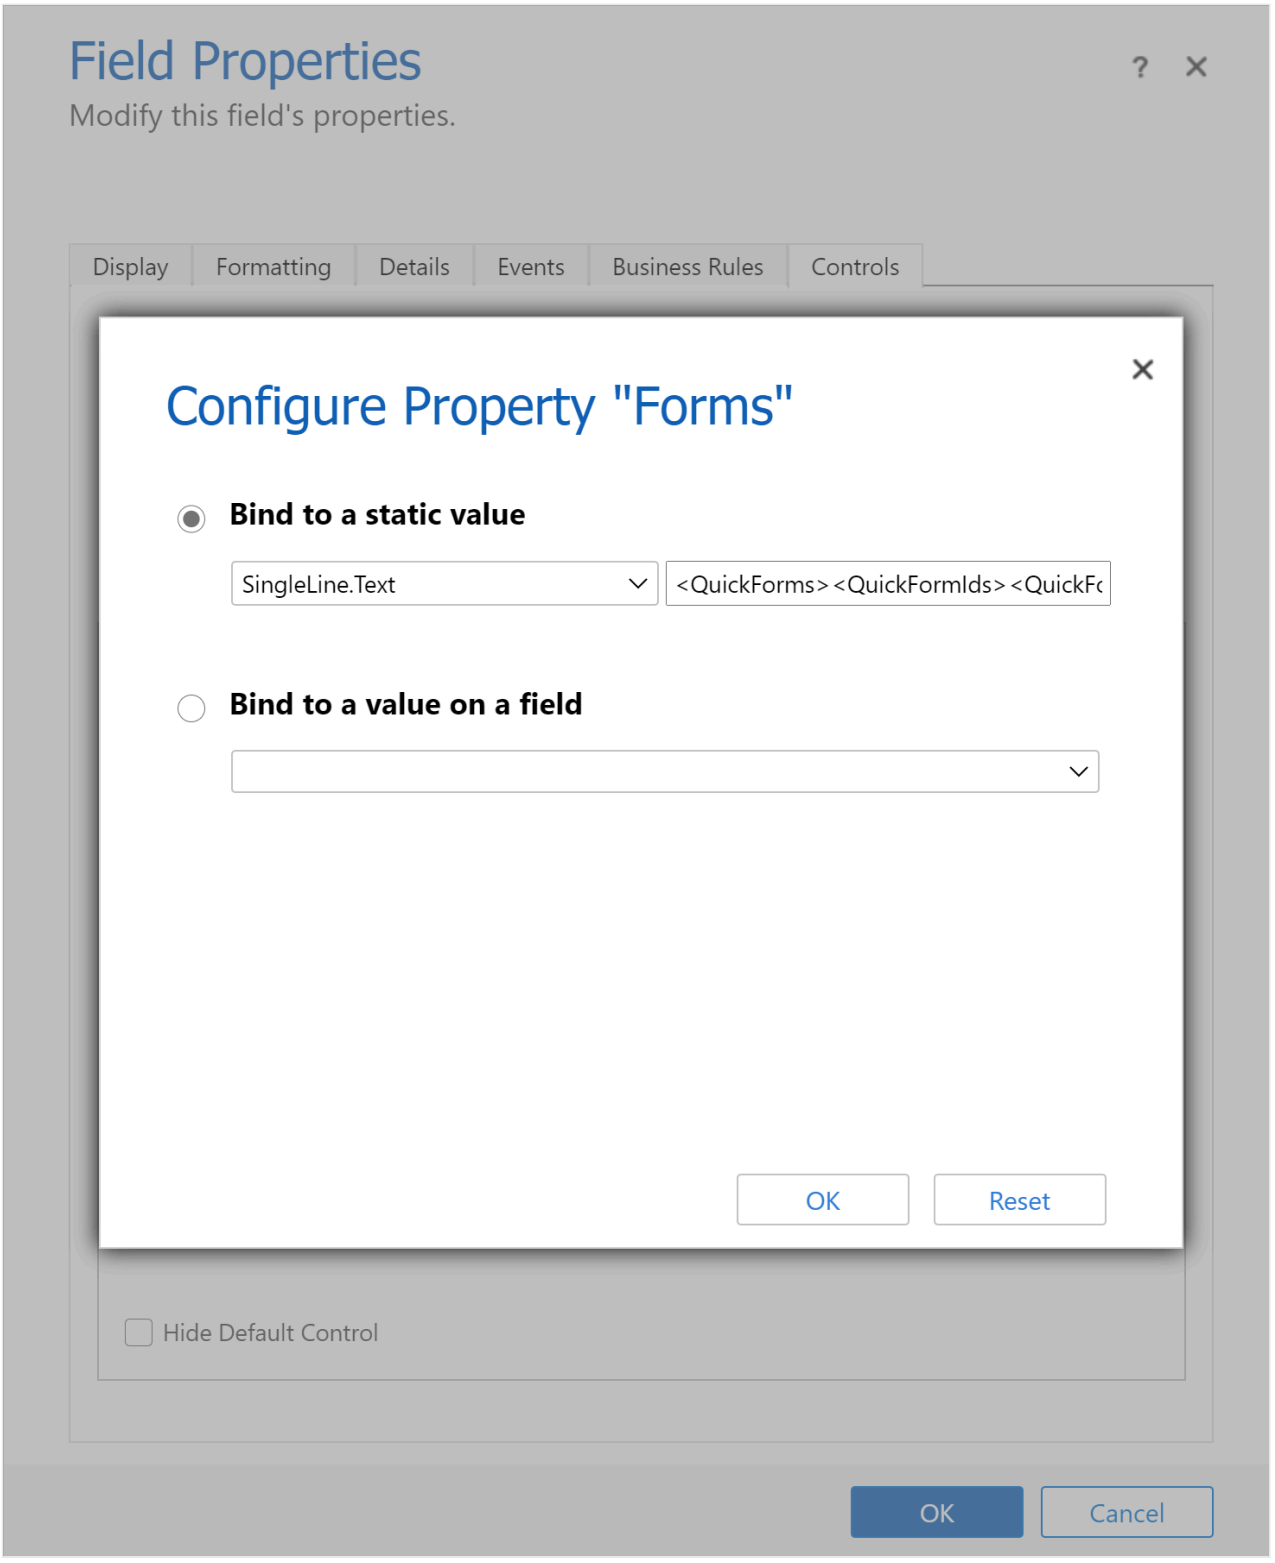
1. Sign in to Power Apps.
2. Select **Tables** in the left pane. Alternatively, open a solution, and then select a table, such as **Account**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Forms** from the components menu.
4. Select a form with a form type of **Main** from the forms available.
5. Select **Switch to classic**. The classic form editor interface opens as a tab in your browser.
6. Select the **Insert** tab. Then, create a new tab and add a new section or add a new section to an existing tab.
7. In the new section, add a lookup column, such as the **Primary Contact** lookup column.
8. Select the lookup column, and then on the **Home** tab, select **Change Properties**.
9. On the **Controls** tab, select **Add Control**, in the list of control types select **Form Component Control**, and then select **Add**.



10. Select **Web**, **Tablet**, and **Phone** for the component.

11. Select **Edit** (pencil icon) and on the **Configure Property** dialog box select **Bind to a static value** and then add an XML entry similar to this where *TableName* is the table unique name and *FormID* is the form ID for the main form: `<QuickForms><QuickFormIds><QuickFormId entityname="TableName">FormID</QuickFormId></QuickFormIds></QuickForms>`

    - For example, to render the **Contact** main form on the account form, use: `<QuickForms><QuickFormIds><QuickFormId entityname="contact">1fed44d1-ae68-4a41-bd2b-f13acac4acfa</QuickFormId></QuickFormIds></QuickForms>`



12. Select **OK**, and then select **OK** again.

13. **Save** and then **Publish** your form.

> **Tip**
>
> To find the unique name for a table, select the table in Power Apps and then select **Settings**. The **Name** appears on the **Edit** table pane. The form ID can be found in the

browser URL when you edit a form. The ID follows the **/edit/** portion of the URL.

In the classic form designer, the form ID follows the **formId%3d** portion of the URL.

Form component behavior

This section describes form component behavior when used in a model-driven app.

Record selection

In order for the form component control to show a form, the lookup column it's bound to needs to have a value. Otherwise, the control shows the message **Source record not selected**. One way to set the value is to add to the form a lookup control that is bound to the same lookup column as the form component control. When you use the lookup control to change the lookup column value, the form component control shows a form with the data for the new lookup column value.

Column validation

All columns, both in the main form and in the form component controls, must be valid for data to be sent to Microsoft Dataverse. This is true for both column validation errors, missing required columns, and so on.

`OnSave` handlers are run for the main form and its form component controls. Any handler can cancel the save for the main form and the form component controls by using preventDefault. This means no save operation can call `preventDefault` for data to be sent to Dataverse. The order of when the `OnSave` handlers are called isn't defined. More information: Form OnSave Event (Client API reference) in model-driven apps

Record save

Once the validation stage is passed, data is sent to Dataverse for each record. Currently, each record is updated independently with different requests. The saves aren't transactional, and the order of the saves isn't defined. An error saving one form component won't roll back changes to the main form or other form components. After each save is complete, data is refreshed for all the records on the form.

Notifications

Notifications on the form component are aggregated into the notifications of the main form. For instance, if there are invalid columns in the form component and you try to save, the invalid column notification appears at the top of the main form rather than in the form component.

Error handling

If there are multiple errors during save, only one error is shown to the user. If the user can make changes to fix the first error, and saves the next error will be visible. The user needs to continue saving until all errors are resolved.

Changing records with unsaved changes

If there are unsaved changes in a form for a form component and a user tries to change the lookup column the form component is bound to, the user is alerted about this change.

Client API

A form context is available for the form component control. It can be accessed via the main form's form context by accessing the control via an API, such as getControl. Before you access data for the related table in the form component control, event handlers should wait for the isLoaded API for the control to return true.

Limitations

Note the following limitations when you add the form component control to a table form:

- The form component control only supports rendering main forms. Similarly, support for adding a form component control is only supported with main forms. Other form types, such as quick create, quick view, and card aren't supported.
- Forms with a business process flow aren’t currently supported in either the main table form or the related table form. If you have a form with a business process flow, you might encounter unexpected behavior. We recommend that you don't use a form component with a form that uses a business process flow.
- The form component control doesn't support embedded form component controls, such as adding a form component control to a form that is used by a form component control.
- The form component control doesn't support embedded canvas apps. You might encounter unexpected behavior with these canvas apps.

- The form component control will only display the first tab of the form it uses if multiple tabs are included in that form.
- Using the same form for different form component controls on a single form isn't supported.
- The form that you use with a form component must be included in your app. If it isn't, or if the current user doesn't have access to the form, it falls back to the top-most main form that is included in the app and available to the user (based on form order).
- All components used by the form in a form component must be included in your app. These components include related tables, views, and business process flows. If they aren't, they won't be available in the form or there might be unexpected behavior.
- Form component controls have certain limitations when rendered in multi-session apps. Specifically, dynamically added handlers on the form component form such as `addOnSave` or `addOnChange` might not run after switching multisession tabs.
- You might notice that the timeline wall might not update when a column that is used to set the timeline wall has changed in the form component. When the page is refreshed the timeline wall updates as expected.
- On mobile, the timeline control doesn't currently appear in the form component control.
- For subgrids, the **See all records** and **See associated records** command buttons won't be available if they're rendered inside a form component.
- Form component controls aren't supported in bulk edit dialogs. They won't appear in the form in the bulk edit dialog by default and any changes made to related table records with them won't be saved.
- When duplicate records are detected when a form component control is saved, users might not be able to view the duplicates to resolve conflicts.
- Form validation only happens for the required fields that are rendered. Validation isn't possible for required fields that aren't visible or not rendered or present on another tab.

Use custom controls for model-driven app data visualizations

Use Live monitor to troubleshoot model-driven app behavior

Article • 11/19/2024

Live monitor is a tool that can help app makers debug and diagnose problems, which help them build faster, more reliable apps. Live monitor provides a deep view into how an app runs by providing a log of all activities in the app as it runs.

To help you isolate certain model-driven app features, you can filter on specific categories, such as forms or the Copilot control.

Create a Live monitor session

Sign in to Power Apps, select **Solutions** on the left navigation pane, open the solution that contains the app you want to monitor, select the app, and then select **Live monitor** on the command bar.

On the Live monitor page, select **Play model-driven** app on the command bar. For more information about creating a Live monitor session, go to Use Live monitor to troubleshoot page behavior in model-driven apps.

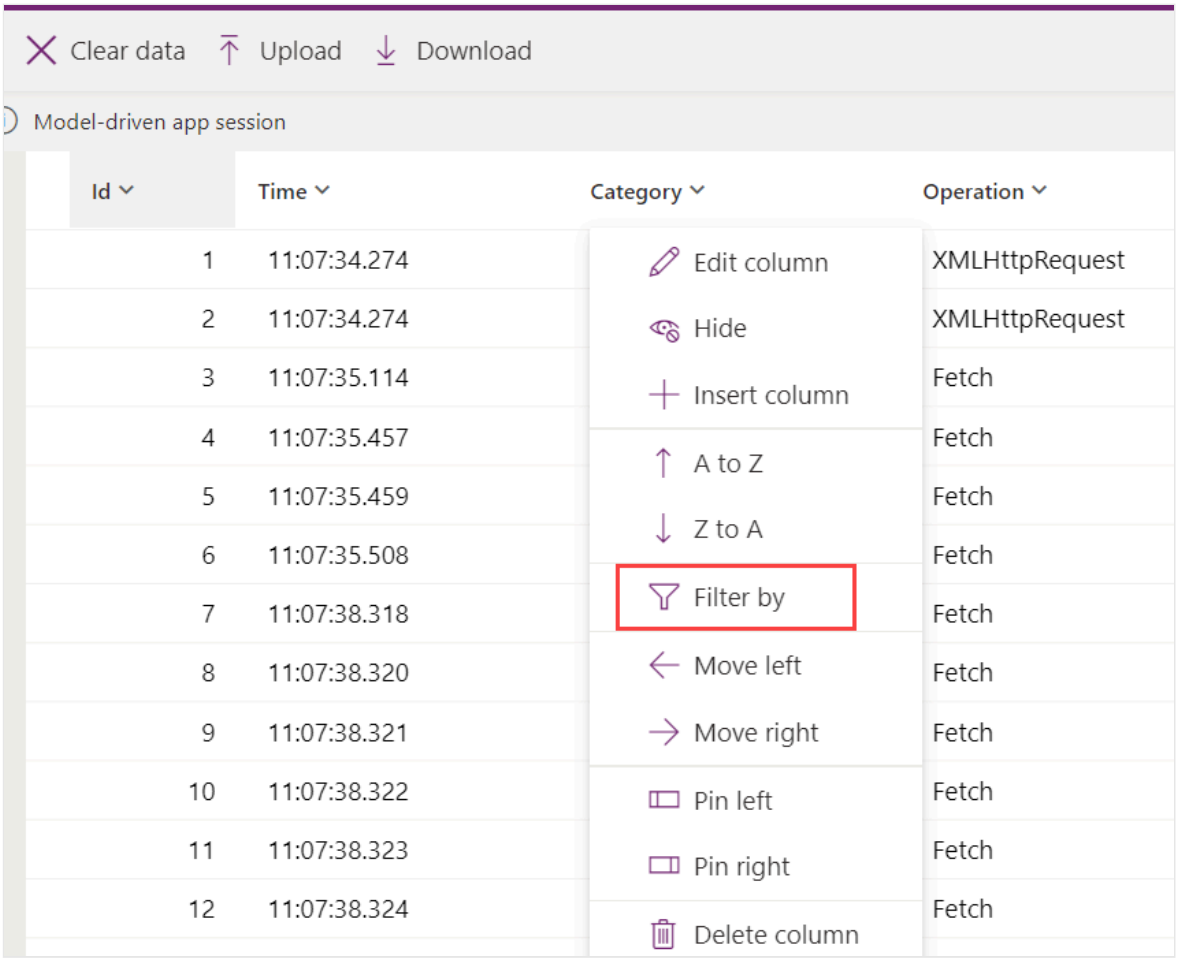
Filter Live monitor for form-related issues

Filtering on model-driven app form-related events in Live monitor can provide information about related tables, tables, controls, and components on a form in Live monitor as your app runs.

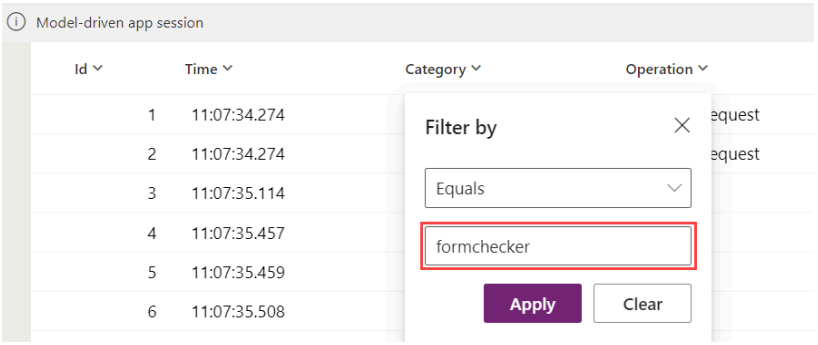
There are many situations where Live monitor can help makers understand why a form behaves a certain way. Many form issues are based on business rules, JavaScript, form events, or client API that admins and makers set. Live monitor can also help identify whether the issue experienced is designed out-of-the-box or is due to a customization. It provides details that can help answer the following questions:

- Why aren't rows showing in the related menu of a table?
- Why a control is disabled/enabled or visible/hidden
- Why is a row in a read-only state?

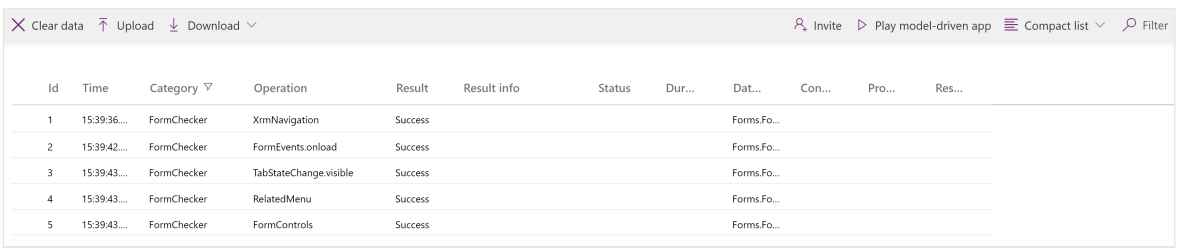
1. On the browser window running Live monitor, select the **Category** column, and then select **Filter by**.



2. Select **Equals** or **Contains** from the dropdown list, and then enter `formchecker` in the box. Select **Apply**.



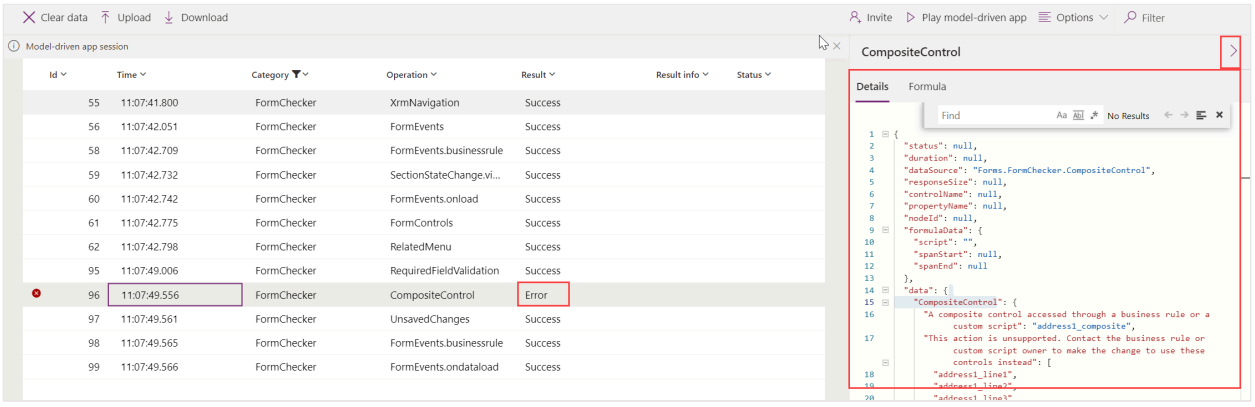
3. The categories are now filtered. The **Operation** column can be expanded to see the full name of the events that are tracked by selecting and holding the right side of the column and dragging to the right. As you use the app and open and use a form, Live monitor updates the list of events.



4. While the app is running in the monitored session, perform actions within the model-driven app consistent with normal use of the app. For example, open and change data using a table form.

Use Live monitor to understand form behavior

For each row with Live monitor, detailed information about the form event can be reviewed. For example, imagine you have a question about an error taking place within the form. You go to that form in the app and select the appropriate form component. Then return to the browser with Live monitor enabled and review the results either with or without filtering. In this case, there's an error on the composite control. By expanding areas of the **Details**, you can learn more about the event itself.



There are many types of events that are monitored, including the standard form events like `onload`, `onsave`, and `onclose`.

As you continue to use the app that's being monitored, Live monitor updates the information in the list of events. For forms, there are many different scenarios that you can troubleshoot and find additional information on the form, control, or table currently being worked on.

Form-checking areas and events

Areas for form monitoring include the following.

Expand table

App area	Description
Control state	Details about the state of the visible, enabled, and label source of a control when the form is loaded.
Related menu	Details about the state of related menu items. Examples: Why is a menu item not being displayed?

App area	Description
	Where does the menu item come from?
Tab / section / control state change	Details on who (via the callstack) has caused a form component—such as a tab, section, or control—to change the component's visibility and enabled state.
Navigation	Details about what's causing navigation or unexpected dialogs by tracing the callstack of these `Xrm.Navigation` client API methods: `openAlertDialog(), openConfirmDialog(), openDialog(), openErrorDialog(), navigateTo(), openForm(), openTaskFlow(), openUrl(), openWebResource()`
Unsupported customizations	Details about unsupported client API access before the form is ready. Examples: Accessing `parent.Xrm.Page` in iFrame before the form is fully loaded. Accessing `Xrm.Page` in a form web resource outside of form handler contexts using `window.setTimeout()` to periodically call the form client API. Accessing `Xrm.Page` in `updateView()` method of the Power Apps control framework control code.

Examples of the supported form-related events in Live monitor include:

- FormEvents.onsave
- XrmNavigation
- FormEvents.onload
- FormControls
- TabStateChange.visible
- RelatedMenu
- ControlStateChange.disabled
- ControlStateChange.visible
- SectionStateChange.visible
- UnsupportedClientApi

Filter Live monitor for Copilot control-related issues

1. On the browser window running Live monitor, select the **Category** column, and then select **Filter by**.
2. Select **Equals** or **Contains** from the dropdown list, and then enter `CopilotEvent` in the box. Select **Apply**.

Copilot control events

Events for Copilot control monitoring include the following.

Expand table

Event name	Description
AdaptiveCardActionData	Data sent to submit action for adaptive card
adaptiveCardContent	Content of adaptiveCard
AISummarize	This message is logged in case the summarize feature is off and logs the fcb status
AutoTriggerSummarizeHandler.isAutoTriggeredSummaryEnabled	Tells if auto trigger is enabled
ClientActionCalled	Logs the name of the client action and payload passed ot it
CopilotResponse	Response from the copilot
DVCopilotAction	isDVChatEnabled: if dv chat is enabled for the org or not
DynamicContextSentToBot	Dynamics context sent to bot
EnvironmentHostedBotSchemaName	Logs the environment bot schema name
ExecutingAction	Adaptive card action is getting executed
isSummaryEnabledForEntity	Tells if summarize is enabled for the entity
queryStructuredDataRequest	Request sent to query structure data
queryStructuredDataResponse	Response from query structure data
SessionContextSentToBot	Session context sent to bot
SummarizeResponse	Logs the response for the summarize
UserPrompt	Prompt entered by the User

Close a monitoring session

To close the monitoring session, close the browser tab where the monitored model-driven app is playing.

Overview of custom pages for model-driven apps

The custom page is a new page type within a model-driven app, which brings the power of canvas apps into model-driven apps. Custom pages increase the convergence of model-driven and canvas apps and can be used to add full pages, dialogs, or panes with the flexibility of Power Apps Studio. It also includes a low-code page authoring experience with expressions and custom Power Apps component framework controls.

A custom page is more flexible than a model-driven app form, view, or dashboard page. You can include one or more tables. Then, you define the data and component interactions. The custom page is a separate solution element, which means one maker can edit one custom page at a time. Like other model-driven app pages, the page state comes from the parameters passed or is retrieved from persisted tables.

> **Important**
>
> Custom pages are a feature with significant product changes and currently have a few known limitations outlined in Custom Page Known Issues.

Expand table

Capability	Status	Notes
Runtime for custom pages	General Availability	
Solution and ALM for custom pages	General Availability	
Connectors in custom pages	General Availability	List of all Power Apps connectors
Modern controls in custom pages	General Availability	List of supported controls
Code components in custom pages	General Availability	
Monitor support for custom pages	General Availability	
Authoring custom pages	General Availability	Use the modern app designer and Power Apps Studio to author custom pages that are supported at runtime.

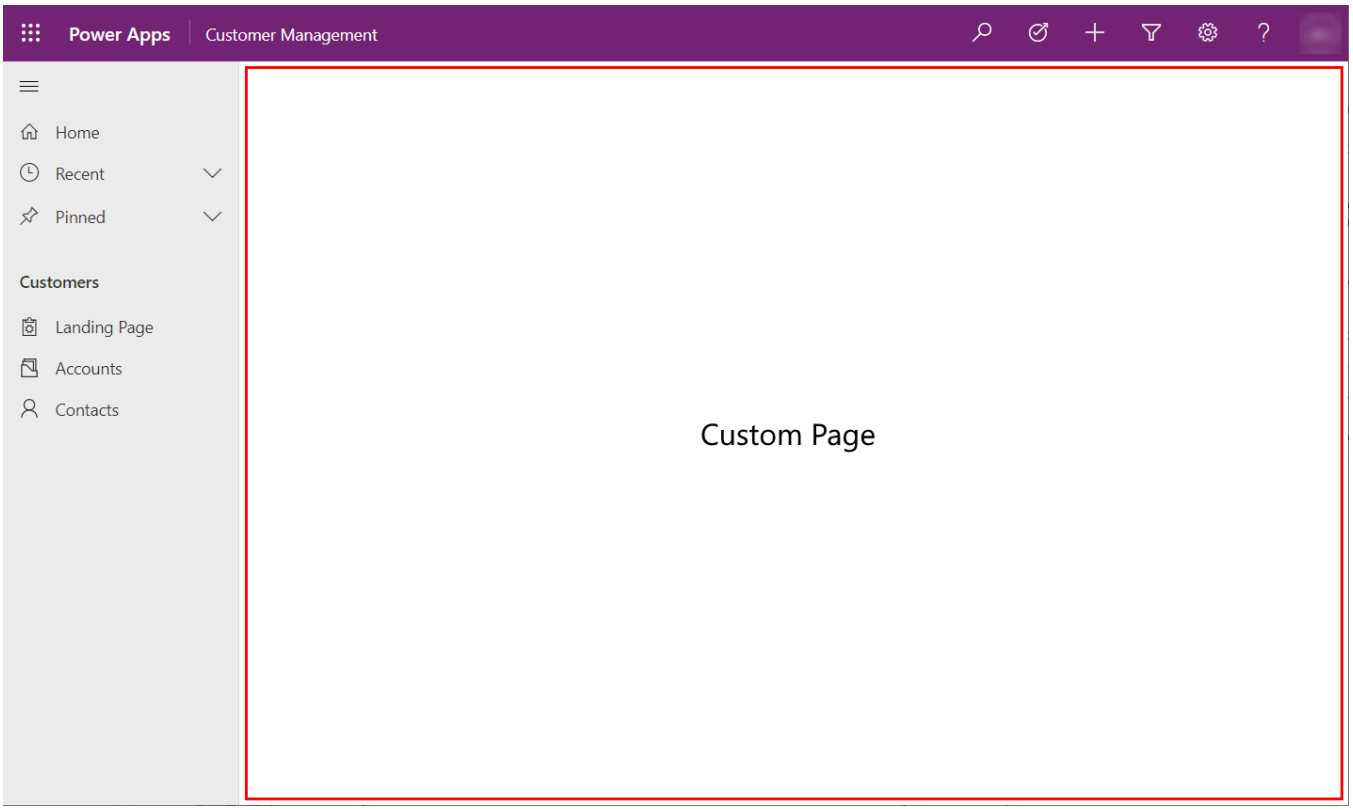
Capability	Status	Notes
Canvas components in custom pages	General Availability	
Custom page in Teams model-driven app	Public preview	
Custom page in mobile online	Public preview	iOS must allow enabling “Allow cross site tracking” that can be prevented by device management

Examples of custom pages

These images show the custom page inline within the model-driven app. The model-driven app has the full-page space in the images without the header and navigation.

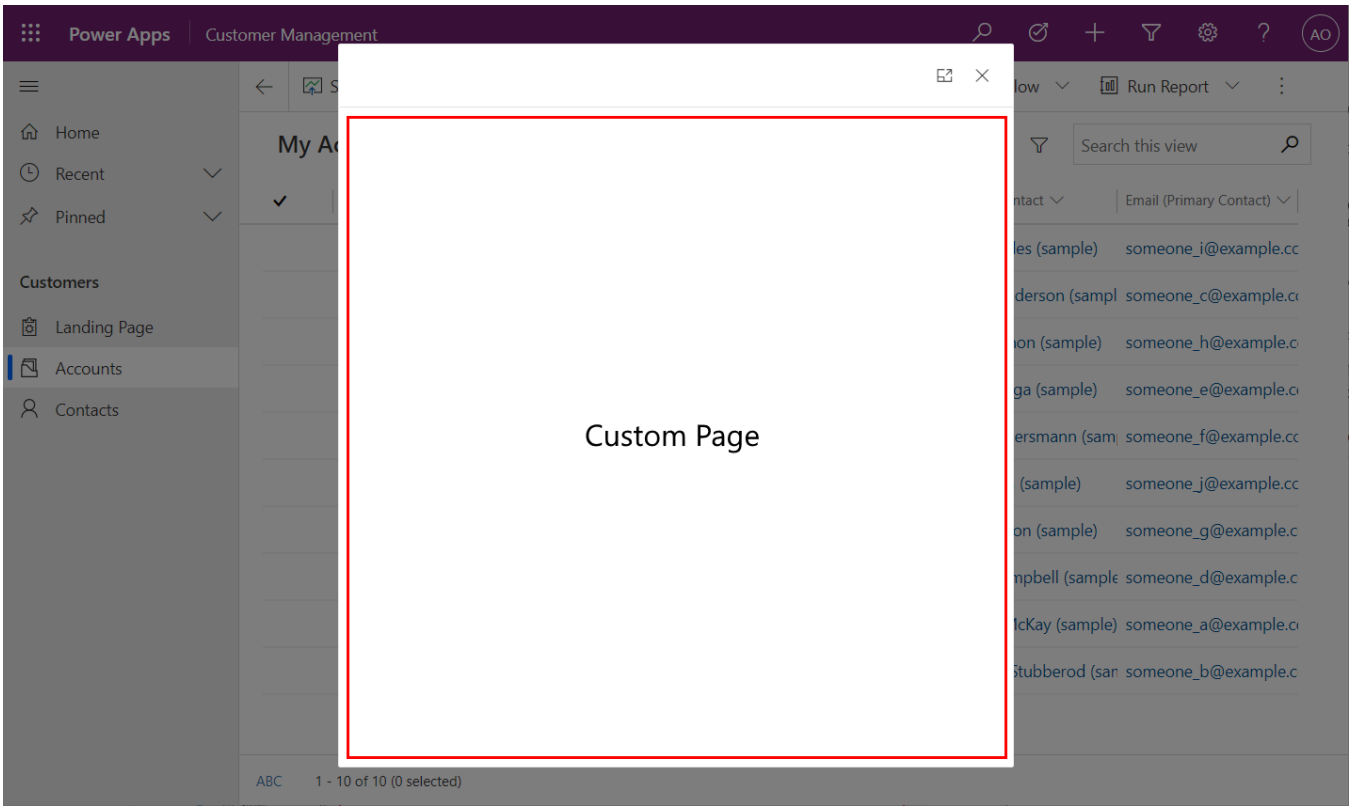
Custom page as main page.

[!div class="mx-imgBorder"]



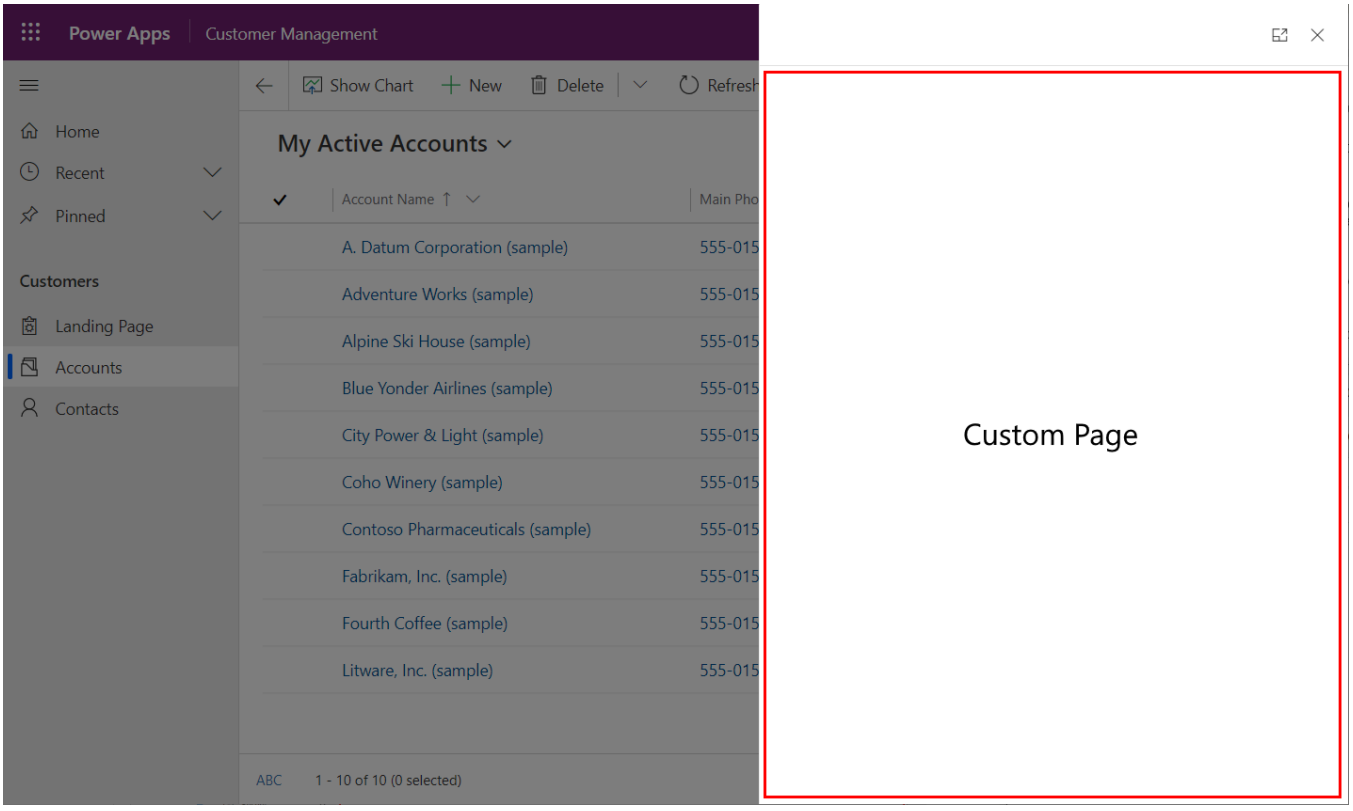
Custom page as a center dialog.

[!div class="mx-imgBorder"]



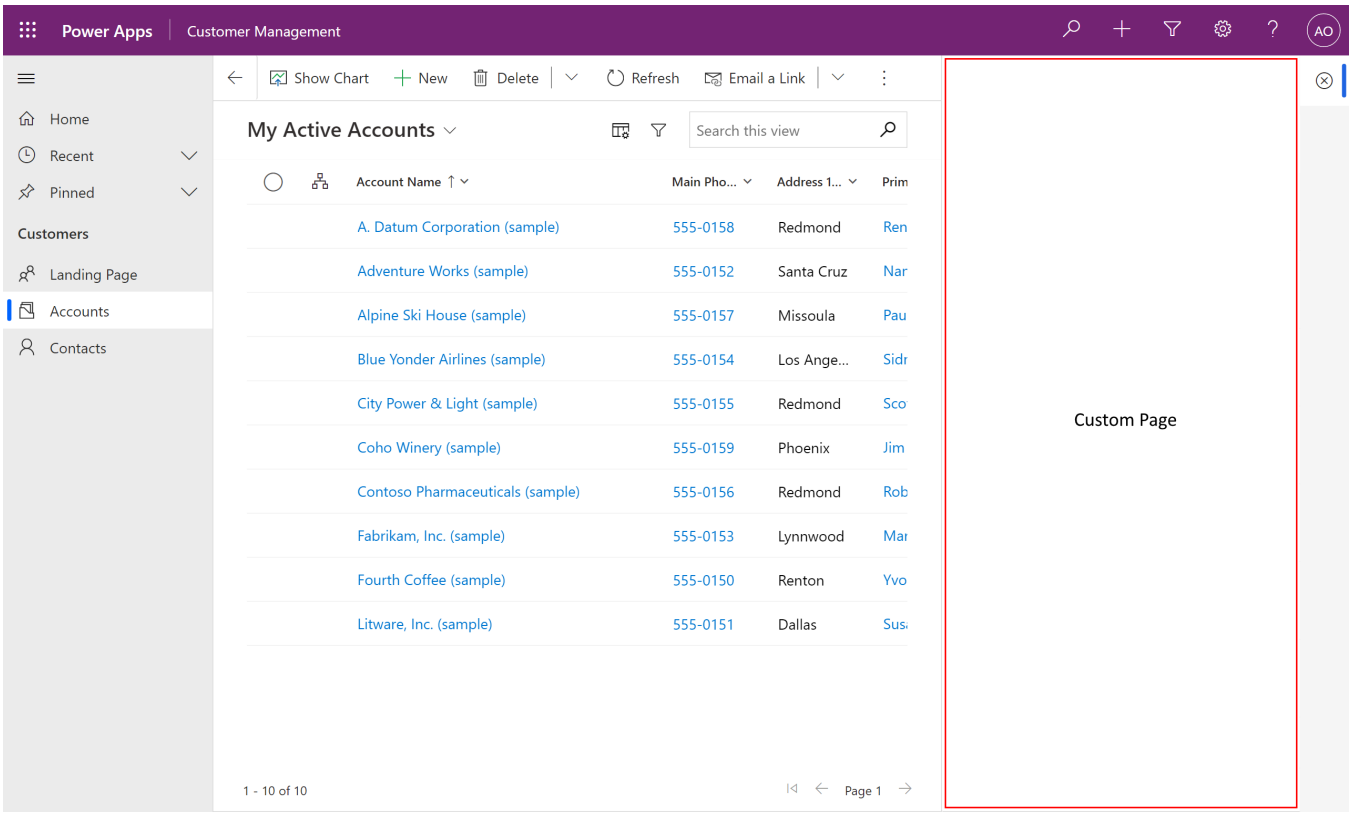
Custom page as a side dialog.

[!div class="mx-imgBorder"]



Custom page as an app side pane allows opening a custom page within the new app side pane on the right side of the app.

[!div class="mx-imgBorder"]



Custom pages must be created from a solution either from the modern app designer or the **Solution** area in Power Apps using **New** > **Page**. More information: Add a custom page to your model-driven app

Custom pages are different than embedded canvas apps

By using a custom page, you can create a new page experience by using the canvas app capabilities. This approach provides a low-code authoring experience with more flexible layouts, more control with styling options, the ability to add connector data, use expressions, and more. You create custom pages in Power Apps Studio with increasing context of the model-driven app that the page runs in.

Embedded canvas apps also use the canvas capabilities with a hosting approach that isn't as integrated as a custom page. The simpler integration of an embedded canvas app means the current limitation on number of embedded canvas apps hasn't changed. The advanced integration of the custom page addresses those limits. The embedded canvas app can only be placed on a model-driven form acting like a low-code component. More information: Embed a canvas app on a model-driven form.

In most cases, use custom pages instead of embedded canvas apps for tighter integration and better performance.

> **Note**
>
> Don't exceed 25 custom pages in a model-driven app. If you add more custom pages, it can increase the wait time that an app user experiences when they play an app with custom pages, after the last app publish. The increased user wait time affects only the first app launch, by the first user, after the last publish of the model-driven app.

Migrate standalone canvas app content to custom pages

Existing standalone canvas apps aren't supported for use as a custom page and the expected app structure is different. A standalone canvas app often has many screens with global access to all controls and variables. The custom page is expected to typically be a single screen with loose coupling to provide performance and co-development capabilities.

To migrate an existing standalone canvas app, start by identifying a mapping of screens to separate custom pages. For each separate custom page, complete these steps:

1. Create a blank custom page from the model-driven app designer. More information: Add a custom page to your model-driven app
2. Add a canvas app data source for data used by the screen.
3. Copy the screen from the original canvas app in Power Apps Studio.
4. Paste the screen into the blank custom page in Power Apps Studio.
5. Change the navigate calls to use the custom page name instead of the screen name.
6. Add the custom page into the model-driven app designer site map.

Frequently asked questions

- What data can the custom page use?

  A custom page can use Microsoft Dataverse and all of the connectors for Power Apps. More information: List of all Power Apps connectors.

- What interactions can the custom page have with the model-driven app?

  Custom pages can be added to the site map for direct navigation using Add custom page to sitemap. Model-driven app pages can open a custom page using the `navigateTo` Client API. Custom pages can navigate to other custom pages or to a model-driven app page such as a form, view, or dashboard with the Power Fx navigate function. More information: Navigating to a custom page

- How is the custom page made responsive?

  The responsive container controls enable building a responsive app page without formulas. More information: Building responsive pages. More custom page design guidance can also be found in Design a custom page for your model-driven app.

- How is the custom page managed in a solution?

  Each custom page is a separate component in the solution, which allows one maker to edit one custom page at a time. Most custom pages will have a single screen. Instead of multiple screens, they use the custom page's navigation functions to move to another custom page or model-driven app page. When a custom page has multiple screens, it's still a single solution component so only one maker can be working on the contained set of screens.

- What licenses are allowed to use a custom page and does a custom page impact app counts?

  The custom page uses a special canvas app type, which allows it to be managed differently. The custom page is considered part of the model-driven app infrastructure and can only be used within a model-driven app. So, it follows the license for the model-driven app. Also, custom pages don't count toward the app limits because they're treated as a page instead of an app.

- Do custom pages need to be shared like standalone canvas apps?

  The custom page aligns with the model-driven app page sharing, which relies on the model-driven app sharing without sharing individual pages for app users. Makers might need to share the custom page to allow editing.

Model-driven app custom page known issues

Last updated on 03/31/2026

Add a custom page to your model-driven app

This article shows you how to create and edit a custom page for a model-driven app by using the modern app designer.

This article walks you through opening a model-driven app in the app designer, which you use to add a custom page to a model-driven app. If you need to create a new model-driven app, go to Create a model-driven app with the app designer.

For information about the limitations and known issues with custom pages, see Custom page known issues.

Create or edit a custom page

Custom pages can be created from two places. The first is while authoring a model-driven app in the modern app designer. The other is from the **Solutions** area in Power Apps. Custom pages can be edited from the **Solutions** area but won't appear in the **Home** or **Apps** areas of make.powerapps.com.

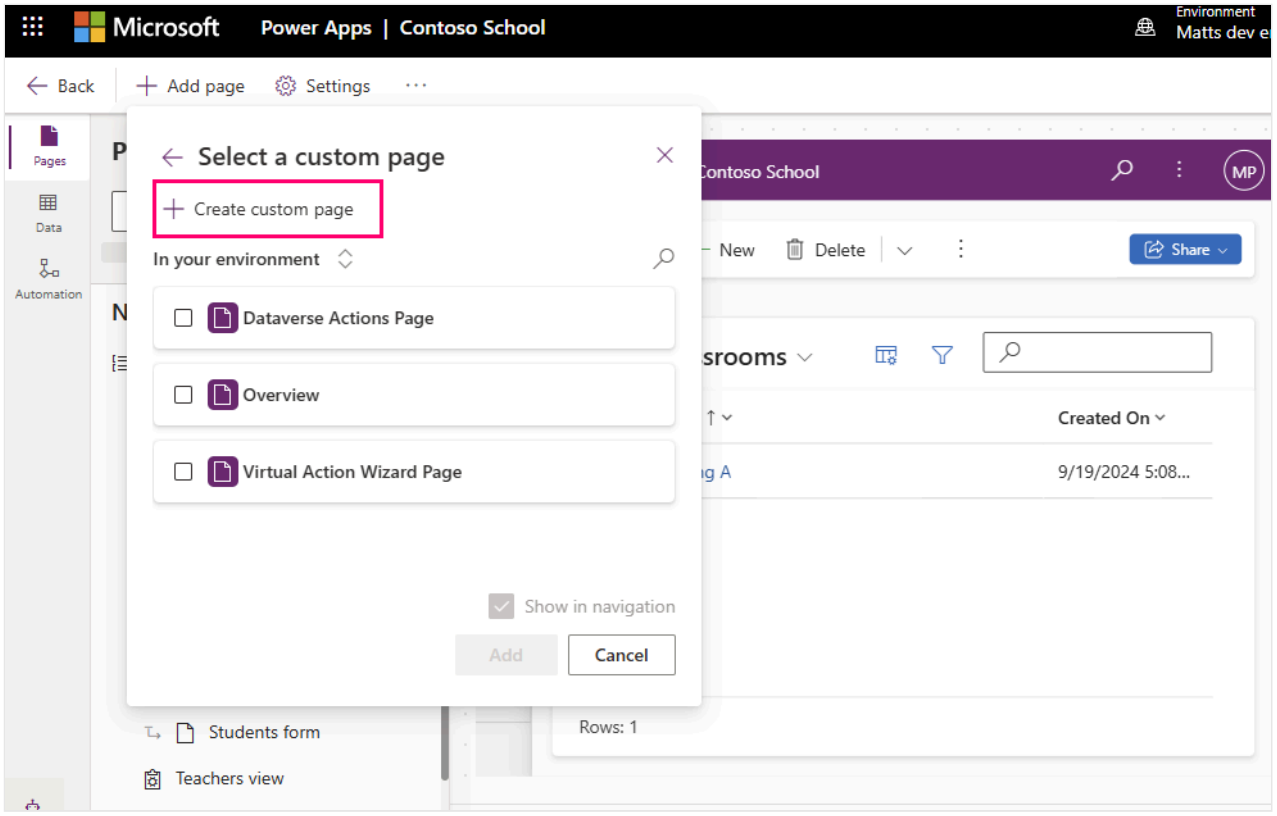
> **Note**
>
> Custom pages must be created from a solution either from the modern app designer or the **Solutions** area in Power Apps using **New** > **App** > **Page**. The custom page is a different canvas app type than the normal standalone canvas app.

Create new custom page from modern app designer

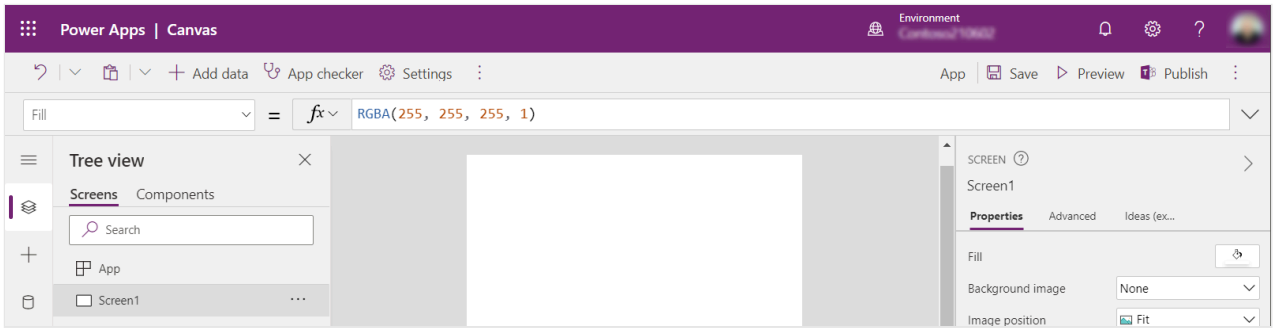
1. Open make.powerapps.com.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution containing the existing model-driven app.
4. Select the model-driven app where you want to add a custom page, and then select **Edit** on the command bar.

5. In the app designer, select **Add page** > **Custom page** on the command bar.

6. Select **Create custom page**.



7. Power Apps Studio opens for page authoring.



8. When you're finished creating your canvas app custom page, **Save**, **Publish**, and then close the Power Apps Studio browser tab to return to the model-driven app designer.

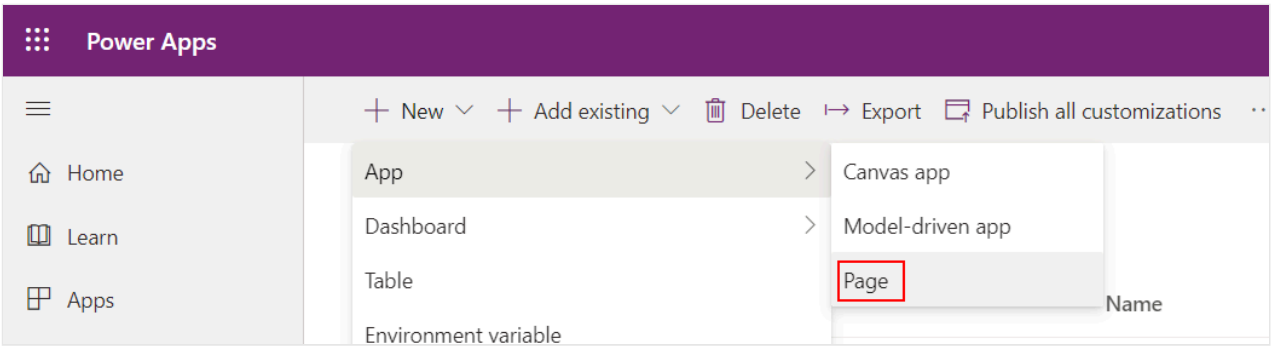
Create new custom page from the solutions area

1. Sign in to Power Apps.

2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Open or create a solution to contain the new custom page.

4. Select **New** > **App** > **Page**.



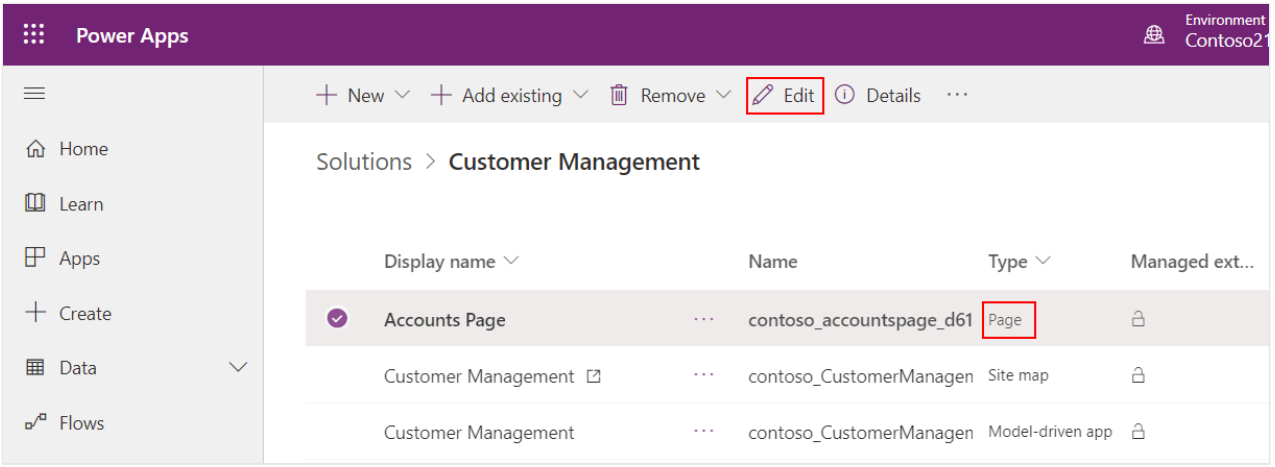
Edit an existing custom page

1. Open make.powerapps.com.

2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Open or create a solution to contain the new custom page.

4. Select the custom page with **Page** type, and then select **Edit**.



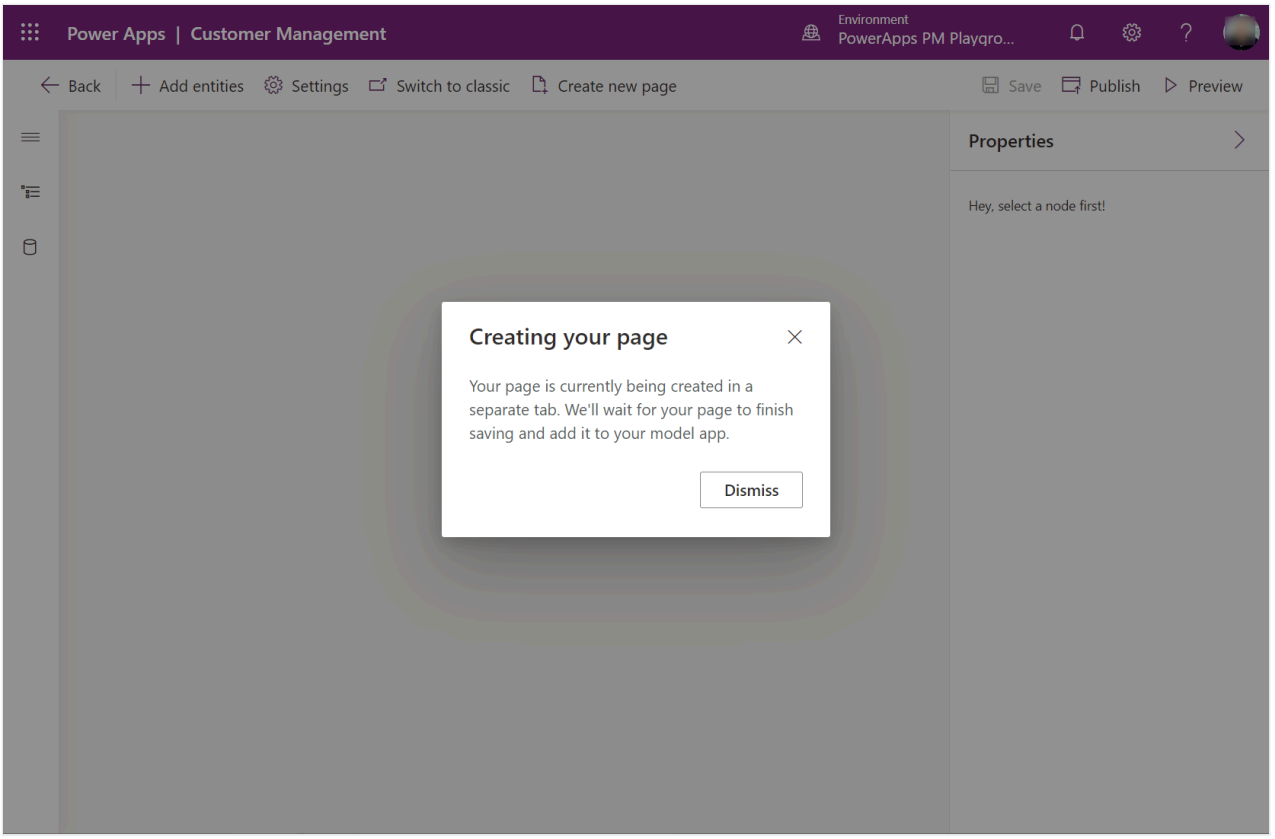
Author custom page content

1. Design the custom page content. More information: Design a custom page for your model-driven app

2. Save and publish the custom page.

3. Close Power Apps Studio.

4. Return to the app designer browser tab and refresh the app designer by selecting **Dismiss**.



5. Select **Publish** in the app designer to add the changed custom page into the model-driven app.

6. Select **Preview** to play the app in a new browser tab.

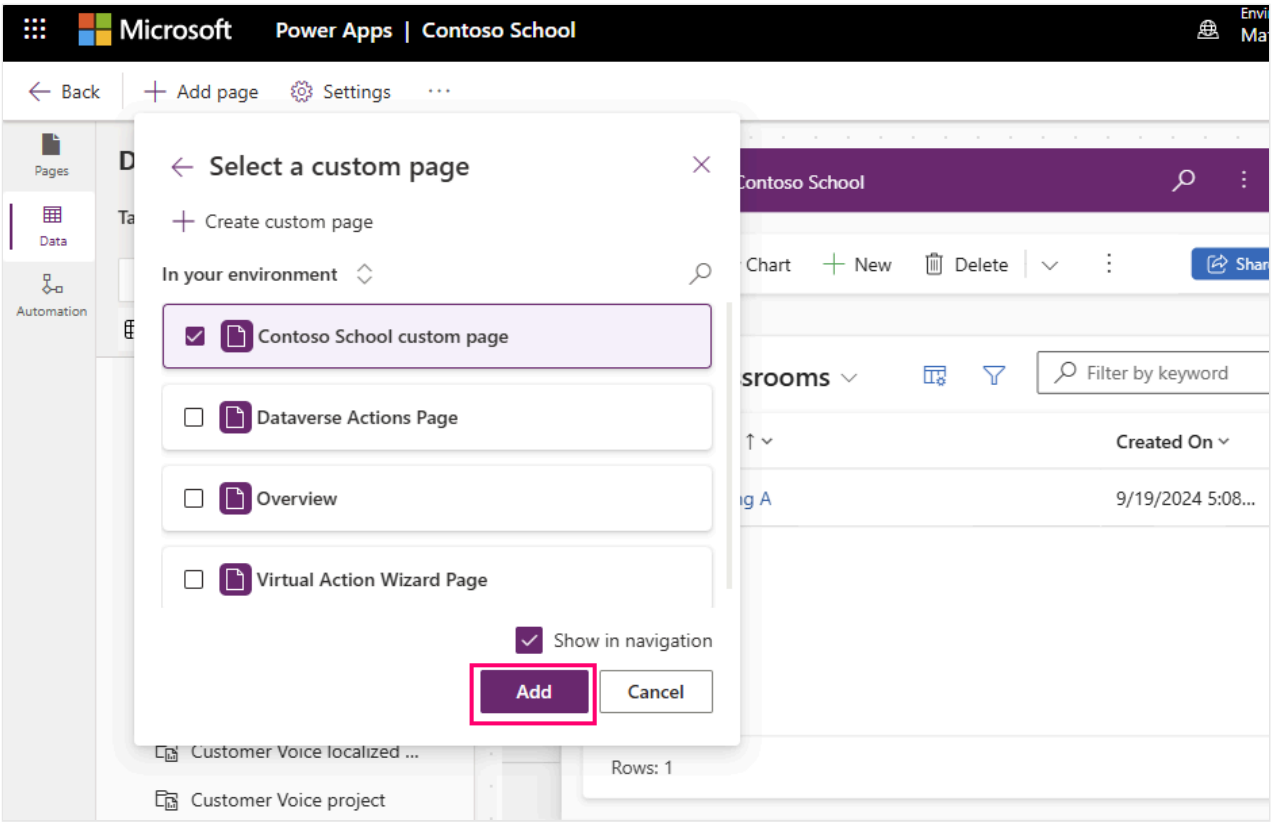
Add an existing custom page into a site map

1. Sign in to make.powerapps.com.

2. Open an existing model-driven app using modern app designer.

3. Select **Add page** > **Custom page** on the command bar.

4. Select the custom page in the list of custom pages available in the environment, and then select **Add**.



5. Select **Publish**, which also saves the app if there are changes.

6. Select **Play** to run the app in a new browser tab.

7. To close the app designer select **Back** and return to the solution.

Publishing a custom page

> **Important**
>
> Currently, model-driven apps must be re-published after a custom page is published. Otherwise the model-driven app continues to use the previous published custom page.

After saving changes to a custom page in Power Apps Studio, the custom page must be first published by Power Apps Studio. Then all model-driven apps referencing that custom page need to be published.

1. From Power Apps Studio, select **Publish**.

2. From app designer or solutions area, select **Publish** on each model-driven app referencing the custom page.

Design a custom page for your model-driven app

Article • 01/29/2025

This article provides tips for designing a custom page for use in a model-driven app. A custom page lets you create a page that's similar to a canvas app in your model-driven app.

> **Important**
>
> Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in Custom page known issues.

Supported controls in a custom page

Custom page authoring currently supports a subset of canvas app controls. The table here lists the currently supported controls.

Expand table

Control	Control Type	Notes
Label[1]	Display	
Text Box[1]	Input	
Date Picker[1]	Input	
Button[1]	Input	
Combo Box[1]	Input	
Check Box[1]	Input	
Toggle[1]	Input	
Radio Group[1]	Input	
Slider[1]	Input	
Rating[1]	Input	
Vertical Container	Layout	New responsive horizontal layout container

Control	Control Type	Notes
Horizontal Container	Layout	New responsive horizontal layout container
Rich Text Editor	Input	
Gallery	List	
Icon	Media	
Image	Media	
Edit Form	Input	
Display Form	Input	
Code components	Custom	Add code components to a custom page
Canvas components (preview)	Custom	Add canvas components to a custom page

[1] Control is a new modern control. The control was introduced for canvas apps in Teams. The control is based on Fluent UI library wrapped with Power Apps Component Framework.

Custom components support for custom page

You can add both low-code (canvas components) and pro-code (code components) custom UX components to your environment and make them available for all makers. For custom page specific UX extensibility articles, go to add canvas components to a custom page for your model-driven app and add code components to a custom page for your model-driven app.

In general, the low-code extensibility approach is simpler to build, test, and has a lower maintenance cost. We recommend evaluating canvas components first and then use code components only if there's a need for more complex and advanced customization.

More information:

- Canvas component gallery
- Code components samples
- Code components community resources

Enable responsive layout with container control

Responsive custom page layouts are defined by building a hierarchy of **Horizontal layout container** and **Vertical layout container** controls. These controls are found in the canvas app designer under **Layout** on the **Insert** tab.

Set the minimum screen height and width on the **App** object to prevent page level scroll bars and use a vertical body scroll bar.

PowerApps Formula

```
MinScreenHeight=200
MinScreenWidth=200
```

Optionally, the custom page design size can be adjusted in **Settings** > **Display** with **Size** set to **Custom**. Then set the **Width** and **Height** to a more typical desktop custom page size like width 1080 and height 768. Changing this setting after controls are added to the screen might cause some layout properties to reset.

Set the topmost container to fill the entire space and resize based on available space.

PowerApps Formula

```
X=0
Y=0
Width=Parent.Width
Height=Parent.Height
```

Horizontal wrapping of a flexible height container

To support pages adjusting from desktop down to a narrow width, enable these properties on a horizontal container with flexible height. Without these settings, the page clips the control when the page is narrow.

PowerApps Formula

```
Direction=Horizontal
FlexibleHeight=true
Justify=Stretch
Align=Stretch
VerticalOverflow=Scroll
Wrap=True
```

Child containers or controls directly under this container should be set to have a minimum width that allows the page to fit within a 300 pixel width. Consider the padding on the container or control as well as parent containers.

Vertical wrapping of a flexible width container

To support pages adjusting from desktop down to a narrow width, enable these properties on a vertical container with flexible width. Without these settings, the page clips the control when the page is narrow.

PowerApps Formula

```
Direction=Vertical
FlexibleWidth=true
Justify=Stretch
Align=Stretch
HorizontalOverflow=Scroll
Wrap=True
```

Child containers or controls directly under this container should be set to have a minimum height that allows the page to fit within a 300 pixel width. Consider the padding on the container or control as well as parent containers.

More information: Building responsive layout.

Vertical container with fixed header, flexible body, fixed footer

1. On the **Vertical Container**, set **Align (horizontal)** to **Stretch**
2. Insert three **Horizontal Container** controls within the parent **Vertical Container**.
3. On the first and third child horizontal container controls, set **Stretch height** off and reduce height to the amount of space needed, such as *Height=80*.

Horizontal container with two even child containers

1. On the parent horizontal container, set **Align (vertical)** to **Stretch**.
2. Insert two **Vertical Container** controls within the parent **Horizontal Container**.

Styling custom page controls to align to model-driven app controls

By creating the custom page from the modern app designer, these features use the default values.

- Theme for the custom page. Theme values for the controls used in a custom page are automatically set to match the default blue theme of the Unified Interface. This default theme is used both in the studio and at application runtime. Explicit theme selecting is removed from custom page authoring experience.
- Controls need to use a different font size, which is based on their position in the page hierarchy.

  > **Note**
  >
  > Custom page text has an upscaling of 1.33 so you need to divide the target **FontSize** by 1.33 to get the desired size.

  Expand table

Label Type	Target FontSize	FontSize to use
Page title	17	12.75
Normal labels	14	10.52
Small labels	12	9.02

- Primary and secondary button controls need the following styling changes:

  Primary buttons

  PowerApps Formula

  ```
  Color=RGBA(255, 255, 255, 1)
  Fill=RGBA(41,114,182,1)
  Height=35
  FontWeight=Normal
  ```

  Secondary buttons

  PowerApps Formula

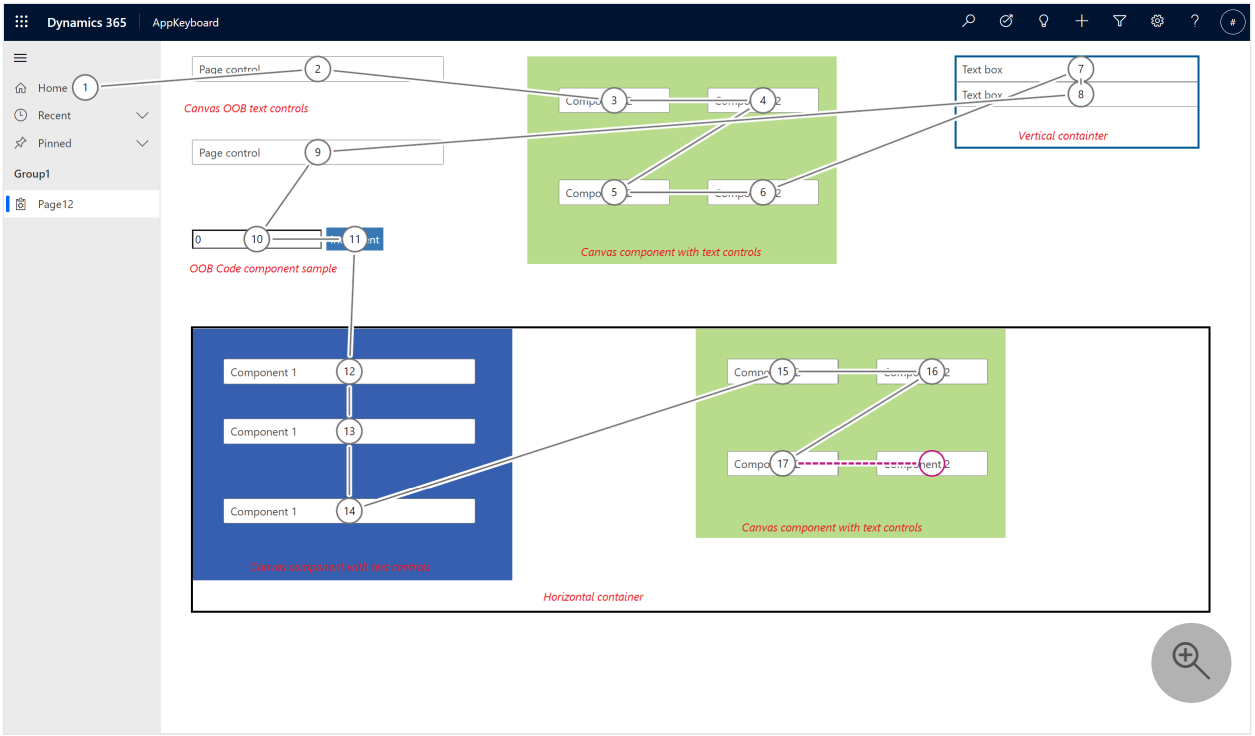
  ```
  Color=RGBA(41,114,182,1)
  Fill=RGBA(255, 255, 255, 1)
  BorderColor=RGBA(41,114,182,1)
  Height=35
  FontWeight=Normal
  ```

Tab navigation and keyboard accessibility for custom pages

Custom pages follow the same tab navigation design that's used by the hosting model-driven app. Visually aligned semantic HTML structure helps users navigate the custom pages seamlessly when using a keyboard or a screen reader. Unlike stand-alone canvas apps, custom page controls, and other UX elements don't need explicit tab numbers assignments. Modern controls don't have a `TabIndex` property and utilize the semantic HTML structure for navigation.

Various elements like controls, canvas and code components, containers, and so on, can be tabbed based on their position in the custom page layout. The tab navigation follows Z order navigation. Individual tab-stops inside larger grouping elements like components, containers are navigated first before the tab moves out to the next element in the document object model (DOM) tree.

Here's an example navigation with the page containing controls, code, and canvas components and containers.



> **Note**
>
> Overlapping controls and elements on the custom page don't have their DOM merged so tab stops can be out of sync from the visual layout. The same is true for the dynamic element positioning using formulas.

Feedback

Was this page helpful? Yes No

Provide product feedback

Navigate to a custom page using client API

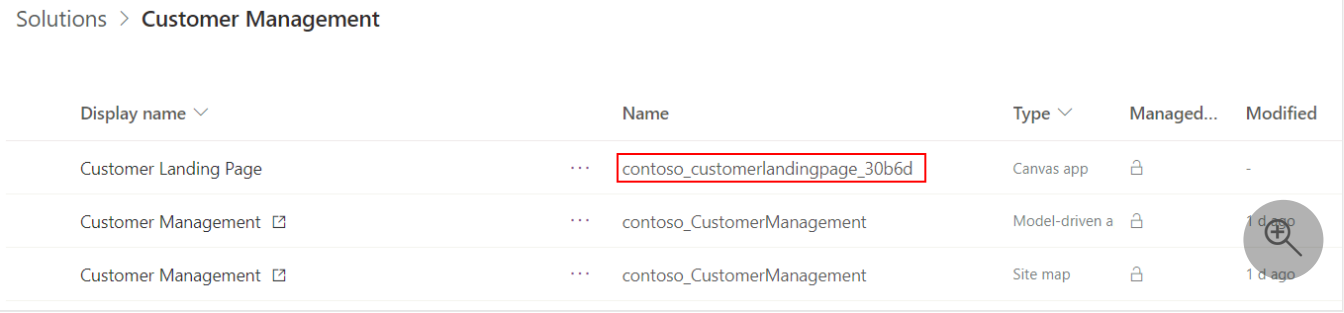
This article provides examples of navigating from a model-driven app page to a custom page using Client API. Learn how to open custom pages as full-page, dialog, or pane views in model-driven apps.

This article outlines the steps to use client API to open a custom page as a full-page, dialog, or pane. It provides examples of **custom** as a `pageType` value in navigateTo (Client API reference).

> **Important**
>
> Custom pages are a new feature with significant product changes. They currently have a number of known limitations outlined in Custom Page Known Issues.

Find the logical name

Each of the following client API examples takes the logical name of the custom page as the required parameter. The logical name is the **Name** value of the page in the solution explorer.



Open as an inline full page without context

Within a model-driven app client API event handler, call the following code and update the **name** parameter to be the logical name of the page.

JavaScript

```
// Inline Page
var pageInput = {
    pageType: "custom",
    name: "<logical name of the custom page>",
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
```

```
    .then(
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open as an inline full page with a record context

This example uses the `recordId` parameter within the NavigateTo function to provide the custom page with the record to use.

JavaScript

```
// Inline Page
var pageInput = {
    pageType: "custom",
    name: "<logical name of the custom page>",
    entityName: "<logical name of the table>",
    recordId: "<record id>",
};
var navigationOptions = {
    target: 1
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when page opens
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

The `Param` function within the custom page retrieves the value and uses the Lookup function to retrieve the record.

PowerApps Formula

```
App.OnStart=Set(RecordItem,
    If(IsBlank(Param("recordId")),
        First(<entity>),
        LookUp(<entity>, <entityIdField> = GUID(Param("recordId"))))
    )
```

> **ⓘ Important**
>
> The `recordId` parameter must be a GUID because it updates the URL and an app start from the URL validates the `recordId` is a GUID.

Open as a centered dialog

Within a model-driven app client API event handler, call the following code and update the **name** parameter to be the logical name of the custom page. This mode supports the sizing parameters similar to the Main form dialogs.

JavaScript

```
// Centered Dialog
var pageInput = {
    pageType: "custom",
    name: "<logical custom page name>",
};
var navigationOptions = {
    target: 2,
    position: 1,
    width: {value: 50, unit:"%"},
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open as a side dialog

Within a model-driven app client API event handler, call the following code and update the **name** parameter to be the logical name of the custom page.

JavaScript

```
// Side Dialog
var pageInput = {
    pageType: "custom",
```

```
    name: "<logical page name>",
};
var navigationOptions = {
    target: 2,
    position: 2,
    width: {value: 500, unit: "px"},
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
    );
```

Open from a grid primary field link as a full page with record ID

This example uses the `recordId` parameter within the navigateTo function to provide the custom page with the record to use. The `Param` function within the custom page retrieves the value and uses the `Lookup` function to retrieve the record.

You can find a more complete example at Override the default open behavior of data rows in an entity-bound grid.

1. Create a web resource of type **JScript** and update the **name** parameter to be the logical page name. Add the following code to the web resource.

   JavaScript

   ```
   function run(selectedItems)
   {
       let selectedItem = selectedItems[0];

       if (selectedItem) {
           let pageInput = {
               pageType: "custom",
               name: "<logical page name>",
               entityName: selectedItem.TypeName,
               recordId: selectedItem.Id,
           };
           let navigationOptions = {
               target: 1
           };
           Xrm.Navigation.navigateTo(pageInput, navigationOptions)
   ```

```
            .then(
                function () {
                    // Handle success
                }
            ).catch(
                function (error) {
                    // Handle error
                }
            );
    }
}
```

2. Customize the table ribbon **CommandDefinition** for **OpenRecordItem** to call the function earlier and include the **CrmParameter** with the value **SelectedControlSelectedItemReferences**.

XML

```
    <CommandDefinition Id="Mscrm.OpenRecordItem">
        <Actions>
            <JavaScriptFunction FunctionName="run"
Library="$webresource:cr62c_OpenCustomPage">
                <CrmParameter Value="SelectedControlSelectedItemReferences" />
            </JavaScriptFunction>
        </Actions>
    </CommandDefinition>
```

3. In the custom page, override the **App**'s **OnStart** property to use the `Param` function to get the `recordId` and `lookup` record.

PowerApps Formula

```
App.OnStart=Set(RecordItem,
    If(IsBlank(Param("recordId")),
        First(<entity>),
        LookUp(<entity>, <entityIdField> = GUID(Param("recordId"))))
    )
```

> **Note**
>
> After changing the `OnStart` property, you need to run `OnStart` from the App context menu. This function performs only once within a session.

4. Then, the custom page can use the **RecordItem** parameter as a record. The following example shows how to use it in an EditForm.

PowerApps Formula

```
EditForm.Datasource=<datasource name>
EditForm.Item=RecordItem
```

Open from a selected record in editable grid as a centered dialog with record ID

Use an editable grid to trigger the OnRecordSelect event when you want to perform an action after selecting a particular record in a view. This example uses the `recordId` parameter within the navigateTo function to provide the custom page with the record to use. The `getId` method in the GridEntity object retrieves the record ID. The `Param` function within the custom page retrieves the value and uses the `lookup` function to retrieve the record.

1. Enable editable grid control in the table.
2. Create a web resource of type **JScript** and update the **name** parameter to be the logical page name. Add the following code to the web resource.

JavaScript

```
function RunOnSelected(executionContext) {
// Retrieves the record selected in the editable grid
var selectedRecord = executionContext.getFormContext().data.entity;
var Id = selectedRecord.getId().replace(/[{}]/g, "");

// Centered Dialog
var pageInput = {
    pageType: "custom",
    name: "<logical page name>",
    recordId: Id,
};
var navigationOptions = {
    target: 2,
    position: 1,
    width: { value: 50, unit: "%" },
    title: "<dialog title>"
};
Xrm.Navigation.navigateTo(pageInput, navigationOptions)
    .then(
        function () {
            // Called when the dialog closes
        }
    ).catch(
        function (error) {
            // Handle error
        }
```

```
    );
}
```

3. In the custom page, override the **App**'s **OnStart** property to use the `Param` function to get the `recordId` and `lookup` record.

PowerApps Formula

```
App.OnStart=Set(RecordItem,
    If(IsBlank(Param("recordId")),
        First(<entity>),
        LookUp(<entity>, <entityIdField> = GUID(Param("recordId"))))
    )
```

> **Note**
>
> After changing the `OnStart` property, you need to run `OnStart` from the App context menu. This function performs only once within a session.

4. Then, the custom page can use the **RecordItem** parameter as a record. The following example shows how to use it in an EditForm.

PowerApps Formula

```
EditForm.Datasource=<datasource name>
EditForm.Item=RecordItem
```

Use Power Fx in a custom page for your model-driven app

Article • 01/23/2025

This article outlines how the common Microsoft Power Fx functions work differently between a standalone canvas apps and a custom page. Functions work differently because a custom page is a component within the model-driven app. Other Microsoft Power Fx formulas continue to behave in the same way.

> **Important**
>
> Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in Custom Page Known Issues.

Add notifications to a custom page

A notification can be shown to the user in a custom page by calling the Notify function. When the notification messages appear, they're docked above the default page to stay visible until disabled. If a time-out interval is provided, the notification message disappears after the time out interval. We recommend that you don't use a time-out interval of 10, as this is no longer considered as a time-out interval. More information: Notify function.

Power Fx

```
Notify( "Custom page notification message" )
```

Power Fx

```
Notify( "Custom page notify warning message", NotificationType.Warning )
```

Navigating to a custom page

This section provides examples of navigating from a model-driven app form to a custom page, navigating from a custom page to other custom pages or model-driven app form using Power Fx.

Navigating from a custom page

The Navigate function allows users to navigate either from model-driven app forms or custom pages. This function is only applicable when the custom page is running within a model-driven app. During custom page authoring or previewing in canvas designer, this function has no effect.

Navigate to another custom page

To navigate from one custom page to another, pass the display name of the custom page as the first parameter.

Power Fx

```
Navigate( CustomPage2  )
```

Navigate to the default view of the table

To navigate to the default view of the table, pass table name as the first parameter.

Power Fx

```
Navigate( Accounts )
```

> ⓘ **Important**
>
> Make sure you add the accounts Microsoft Dataverse table to the custom page before publishing and testing.

Navigate to specific system view of the table

To navigate to a specific system view of the table, pass the GUID of the view.

Power Fx

```
Navigate( 'Accounts (Views)'.'My Active Accounts' )
```

Navigate to the default form of the table

To navigate to the default form of the table, pass the record as the first parameter.

Power Fx

```
Navigate( Gallery1.Selected )
```

Navigate to a specific form of a table

To pass a Dataverse record to a specific form, pass the form name in the second parameter's `Page` attribute.

Power Fx

```
Navigate(
  AccountGallery.Selected,
  { Page: 'Accounts (Forms)'.Account  } )
```

Navigate to a specific custom page with a record input

To pass a Dataverse record to a specific custom page, pass the custom page name in the second parameter's `Page` attribute.

Power Fx

```
Navigate(
  AccountGallery.Selected,
  { Page: 'Account Record Page'  } )
```

In the target custom page, the record is retrieved using `Param` function to get the `etn` and `id` values.

Here's an example of loading the record into an `EditForm` control.

Power Fx

```
AccountEditForm.DataSource = Accounts
AccountEditForm.Item =
```

```
  LookUp( Accounts, accountid = GUID( Param("id") ) )
```

Navigate to the default form of the table in create mode

To navigate to the default form of the table in create mode, pass a Dataverse record created from the Defaults function. Defaults opens the default form with the record as a new record. The `Defaults` function takes the table name to create the record.

Power Fx

```
Navigate( Defaults( Accounts ) )
```

Navigate to the default form of the table in create mode with field defaulted

To navigate to a new record with some fields defaulted, use the `Patch` function to set fields on the default record for the table.

Power Fx

```
Navigate(
    Patch(
        Defaults(Accounts), { 'Account Name': "My company", Phone: "555-
3423" } )
  )
```

Navigate back to the prior page or close a dialog

To navigate back to the last page or to close a dialog, the Back function is called in a custom page. The `Back` function closes the current page and returns to the last model-driven app or custom page in the model-driven app. If the custom page has multiple screens, go to the article Navigating back when custom page has multiple screens.

Power Fx

```
Back()
```

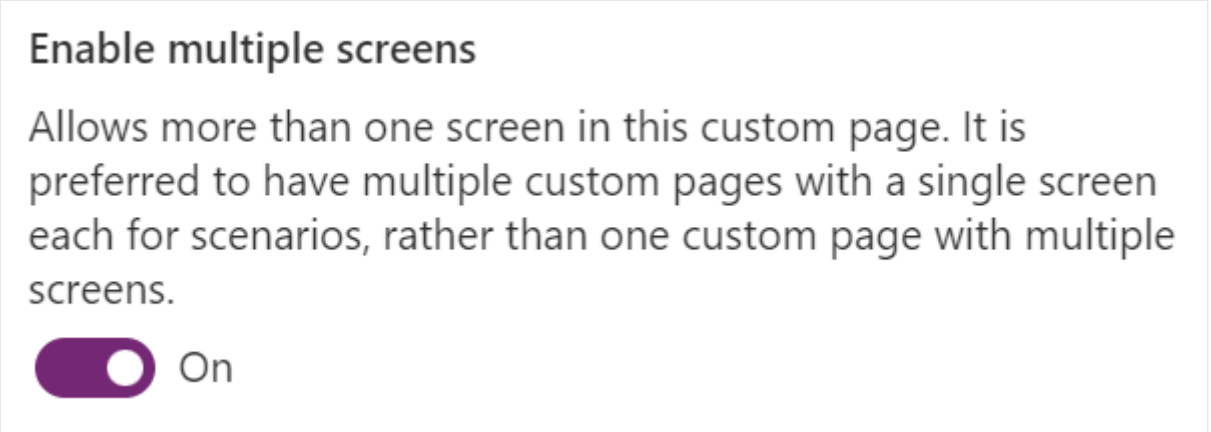
Navigating back when custom page has multiple screens

The default configuration for a custom page is to have one screen. In this case, the `Back` function call closes the custom page unless the custom page is the last in the page stack in model-driven app. The last page is kept open.

An app maker can enable multiple screens in a custom page. These should be considered like full page controls within the custom page that can be stacked. Opening a custom page has no means of specifying the screen to use. When a custom page contains multiple screens, the maker is responsible for managing the screen stacking. Calling the `Navigate` function to a screen adds to the screen stack with the custom page. Each `Back` function call removes a screen from the screen stack. When there's only one screen on the screen stack, the custom page is closed.

Enabling multiple screens

By default a custom page uses a single screen to encourage separation of the app into a screen per page. Single screen can be switched by enabling **Settings** > **Display** > **Enable multiple screens**.



Known issues

- The `Navigate` function doesn't have support for opening a model-driven app or custom page to a dialog. All navigation from a custom page opens inline.
- Navigate function doesn't support opening:
  - A dashboard collection or a specific dashboard.
  - A specific model-driven app form.
- A custom page can only open into the current session's current app tab in a multi-session model-driven app.

Add canvas components to a custom page for your model-driven app

Article • 06/01/2022

This article outlines the use of low-code canvas components to build custom UX for a custom page by utilizing shared canvas component library capability. For code first custom UX extensibility, see Add code components to a custom page for your model-driven app.

> **Important**
>
> Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in **Custom Page Known Issues**.

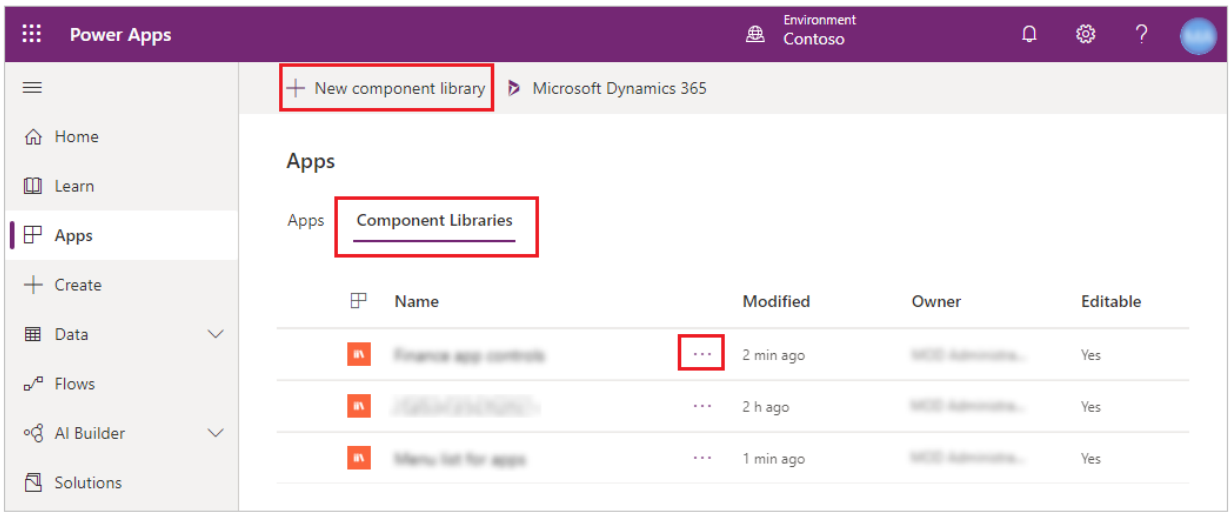
> **Note**
>
> - Custom page currently supports a **limited set of controls** and only the currently supported controls should be used to create canvas components for the custom page.
> - **Modern controls** are currently only supported with custom pages and not with standalone canvas apps. Make sure that the modern control experimental setting is used only for component libraries used with custom pages.

Canvas components provide app makers the ability to create custom components in a low-code fashion. These components cannot only then be reused across custom pages and applications, but also can be centrally updated, packaged, and moved using Microsoft Dataverse solutions. More information: Create a component for canvas apps

Since custom page authoring is limited to only one page, canvas components can only be authored inside a component library. This is different from the standalone canvas apps, which have the ability to create components at the app level.

Create a canvas component using the component library

You can create a new component library or edit an existing one either from the **Solutions** area or the **Component Libraries** tab in the **Apps** area.

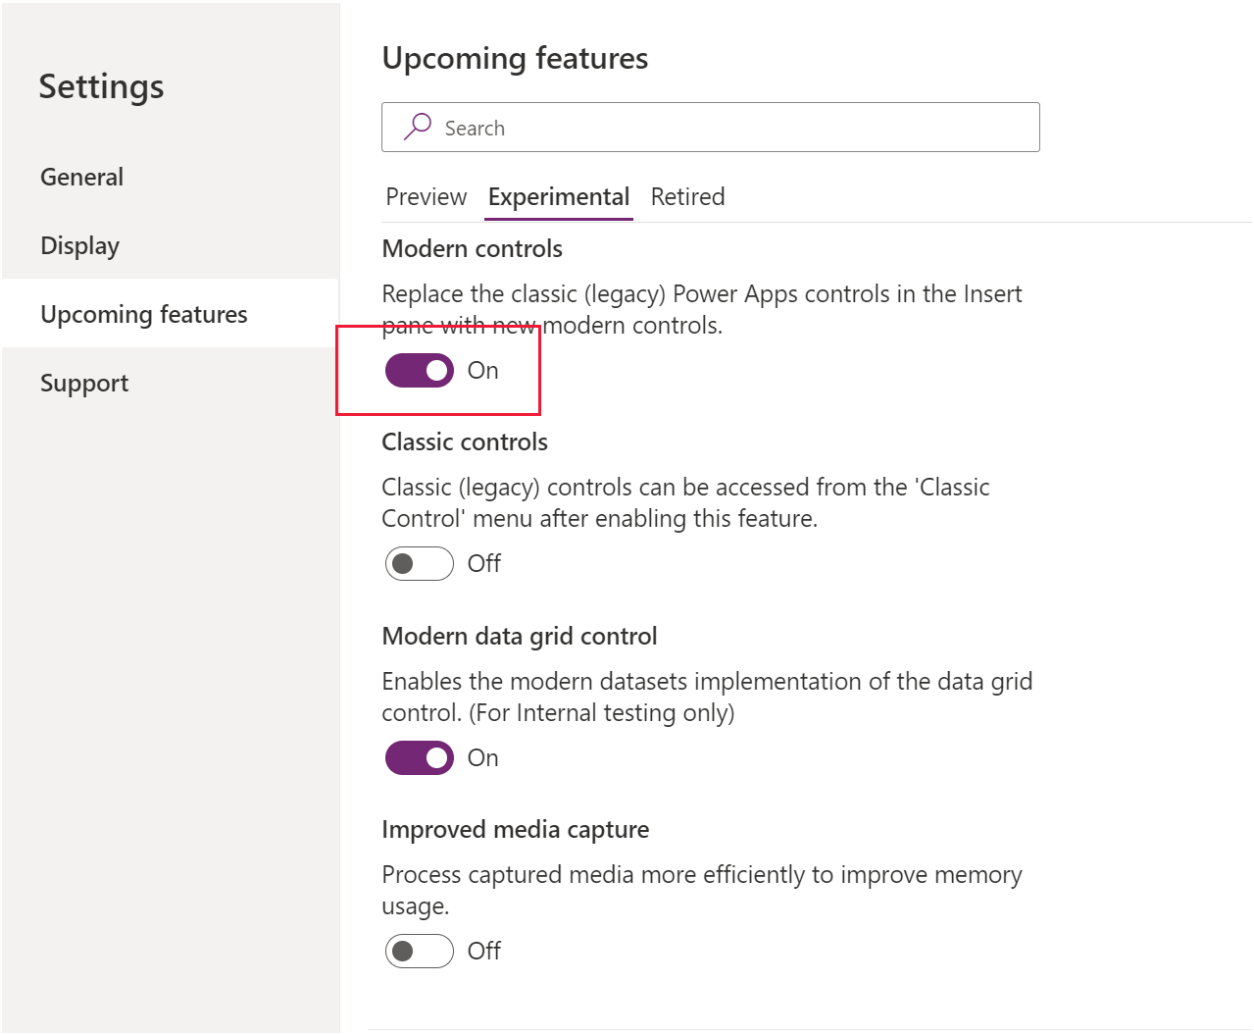


Create a canvas component for use in a custom page

This section explains how to create a canvas component that you can use in a custom page.

Enable modern controls for the component library

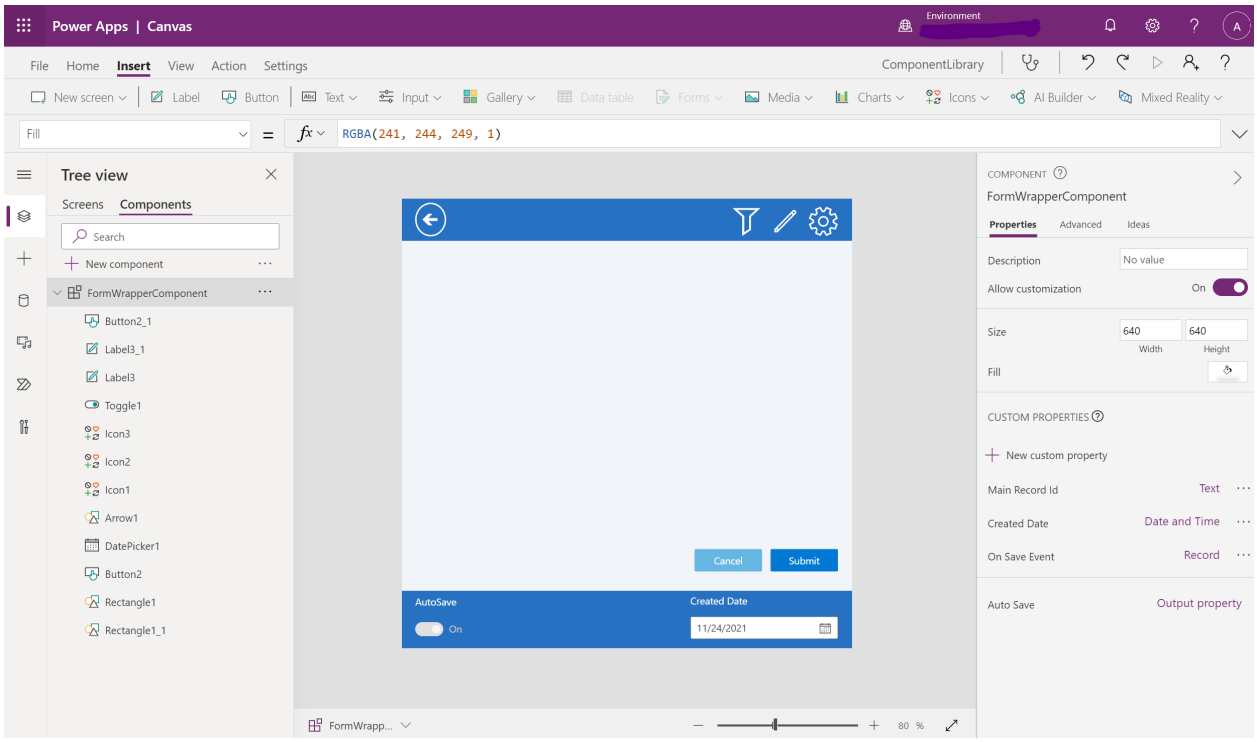
First, enable the **Modern controls** setting in the canvas app designer. To do this, go to **File** > **Settings** > **Upcoming features** > **Experimental**.



Make sure that only the supported set of controls are used to create components for custom page.

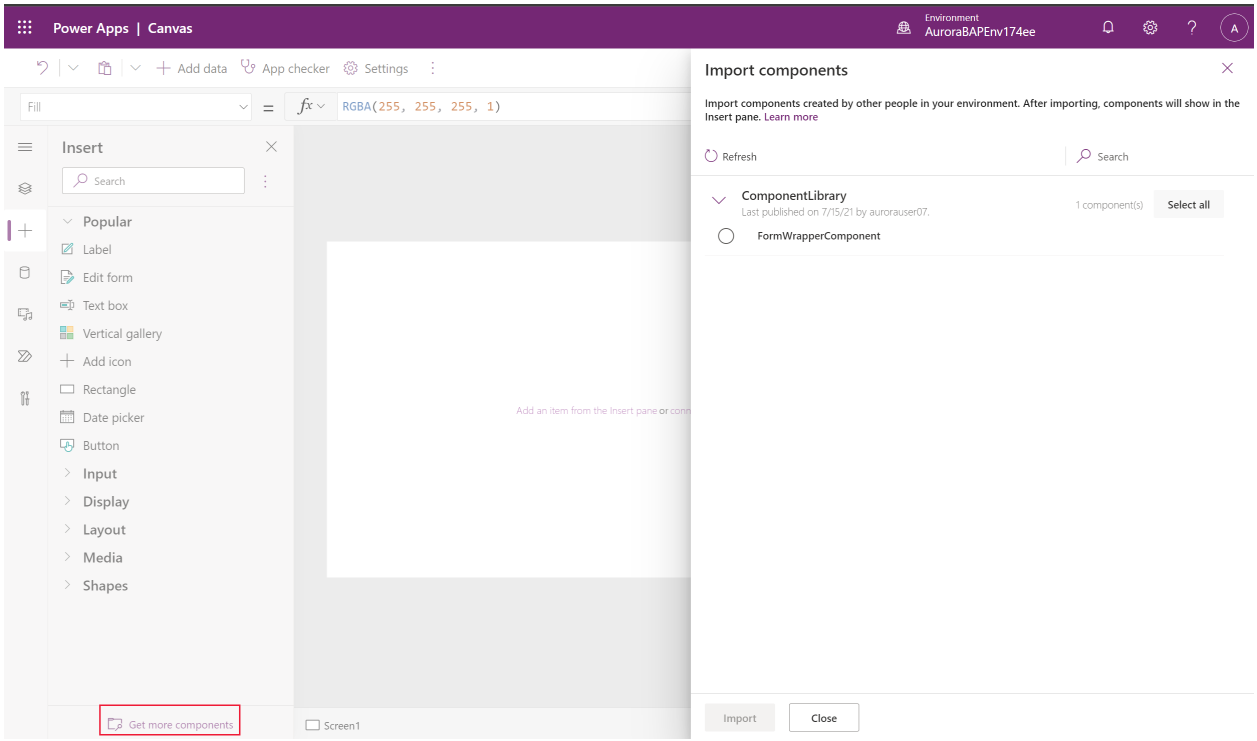
Create a canvas component

Once the modern controls are enabled, you can now create desired components inside the library and publish them once the components are ready.

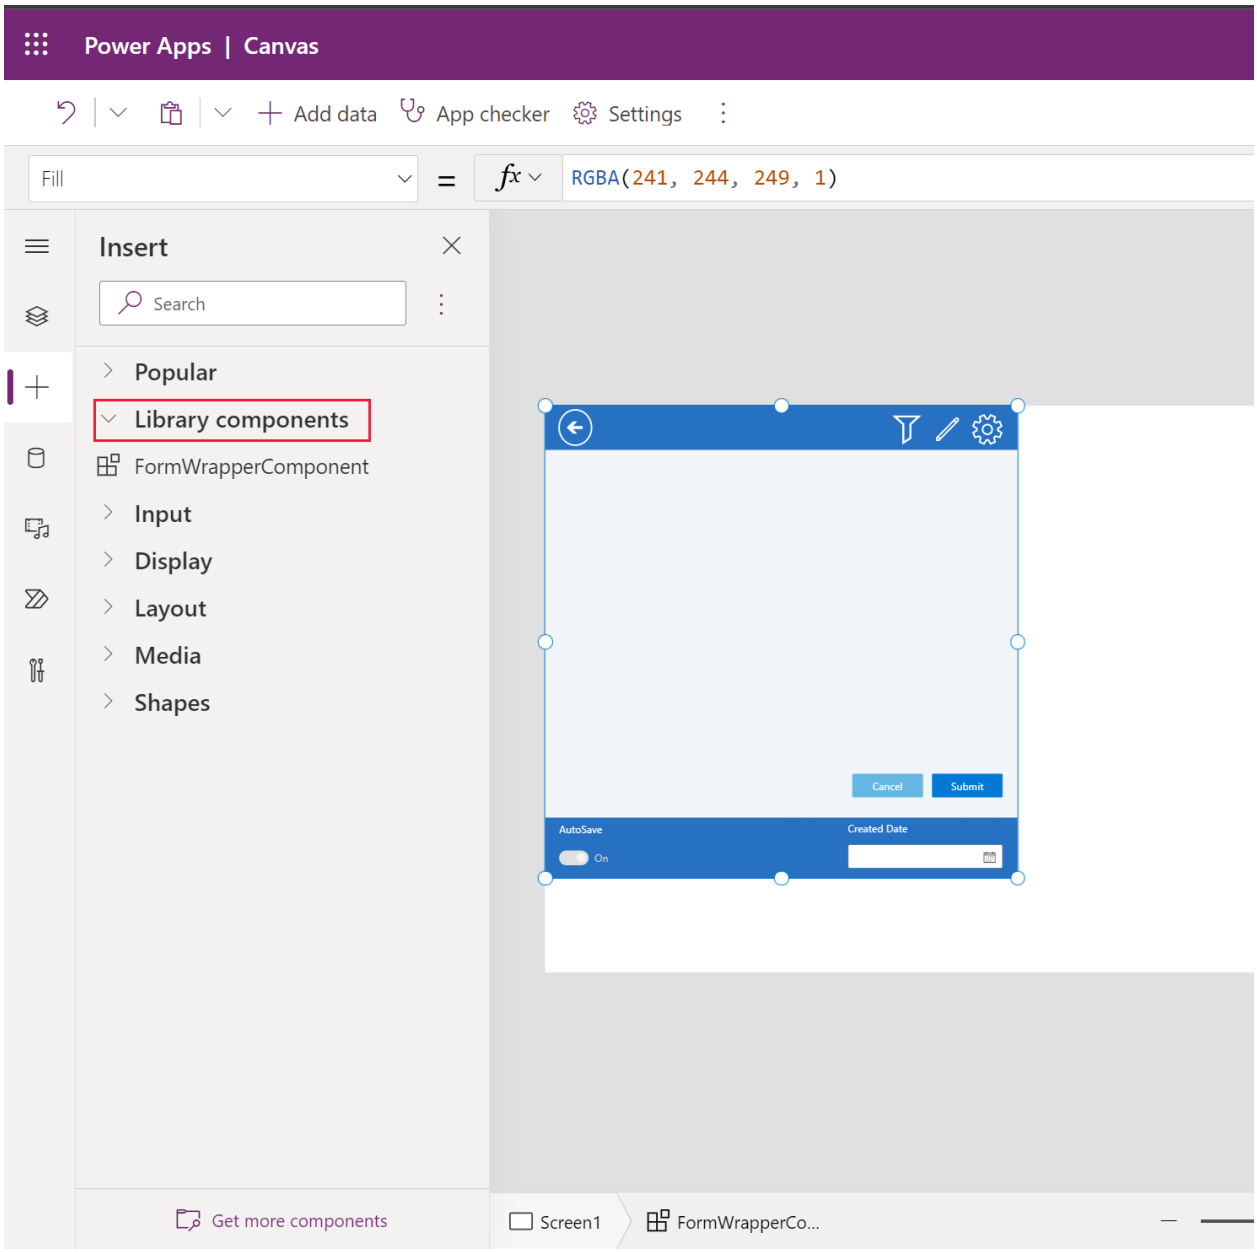


Import and use a canvas component in a custom page

Custom pages can use the components from the canvas component library created or imported in the current environment. You can select **Get more components** at the bottom of the add control left navigation area.

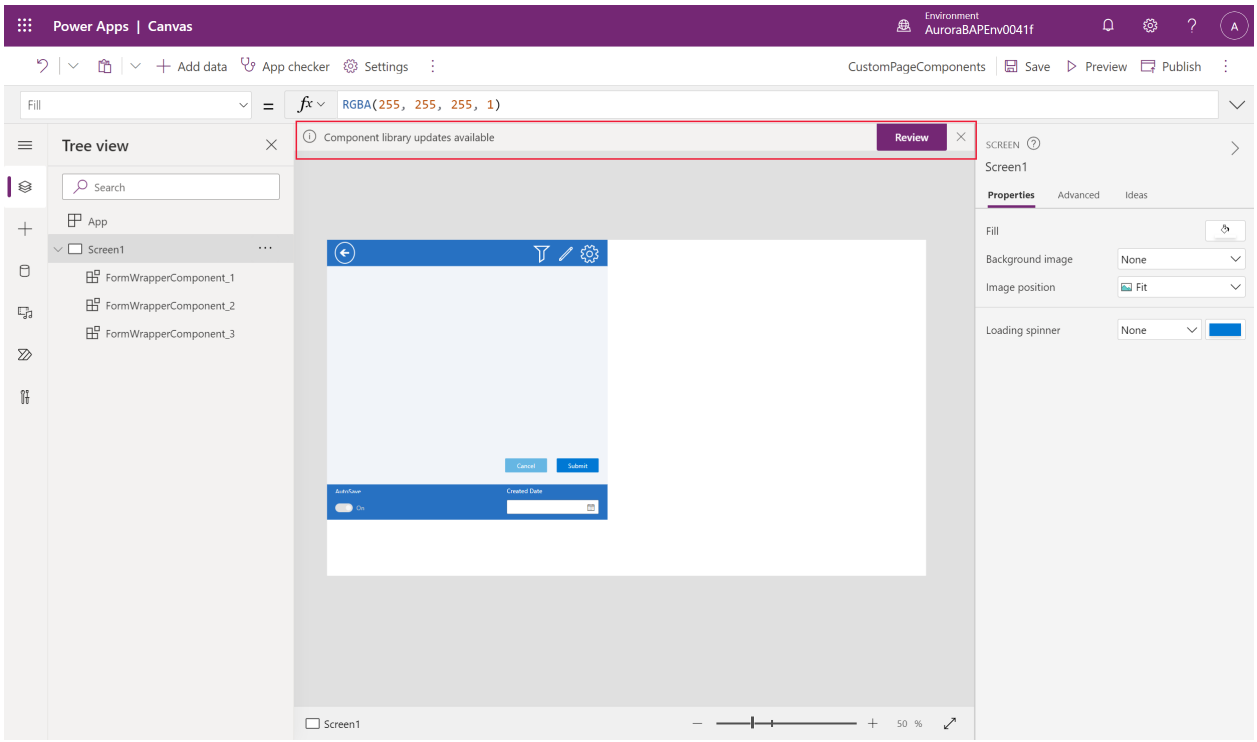


The canvas component is available under the **Library components** section and can be added to the custom page.



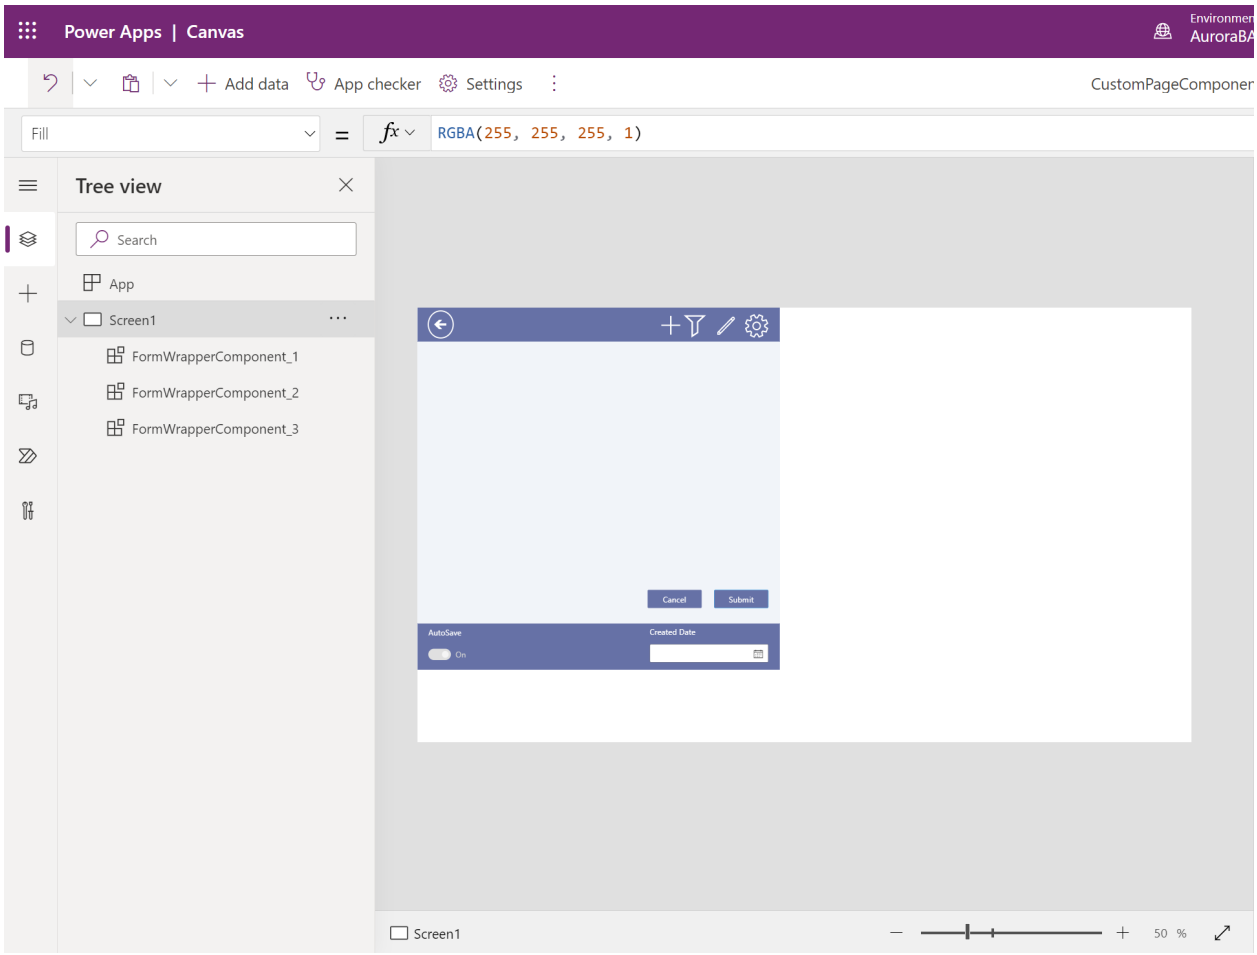
Component updates to the custom page

When the component is added to the custom page via the component library, it maintains the reference to the library. When the library owner publishes the newer library version with updated components, the custom page inline with the canvas app displays an update available message. This message is displayed when the custom page is opened for editing.



Select **Review** to review the updates, and then select **ok** to get the component refreshed with the latest changes from the canvas library.

> **Note**
>
> Individual custom pages present in a model-driven app should be opened individually for editing inside canvas app studio to get the latest updates from the shared component library.



You can now publish the custom page and model-driven app to get the latest changes reflected.

Additional canvas component resources

You can evaluate and use canvas component samples from Microsoft and other Power Apps community developers, which are hosted on the Canvas app components gallery.

Add code components to a custom page for your model-driven app

Article • 06/03/2022

This article outlines the use of code components built by professional developers using Power Apps component framework within a custom page. For low-code custom UX extensibility, see add canvas components to a custom page for your model-driven app.

Important

- Custom pages are a new feature with significant product changes and currently have a number of known limitations outlined in **Custom Page Known Issues**.

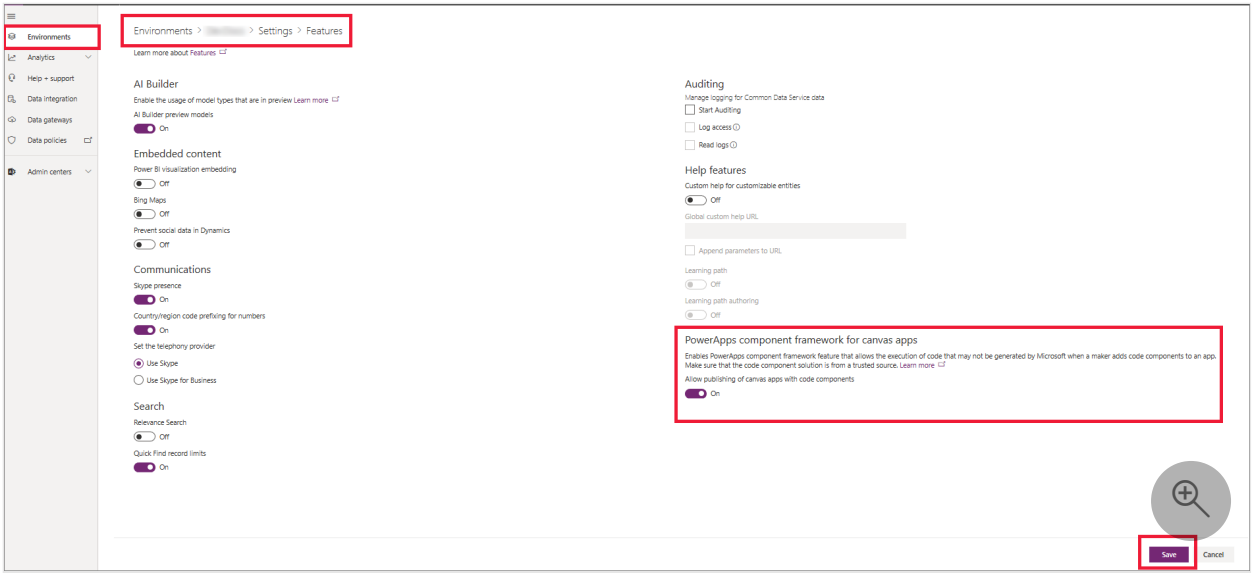
Note

- Custom pages support all the component framework APIs that are currently supported for canvas apps.
- Certain model-driven app specific APIs like **WebAPI** and **Navigation** have published app support for custom pages. These APIs can be used in the code component for custom pages and works on the final published app.
- For individual API support status on each platform, see **Power Apps component framework API reference**

Code components provide professional developers the ability to create custom code components for use within an app. This pro-code extensibility mechanism provides first-class application lifecycle management (ALM) to seamlessly extend the components available to all the app makers across the organization. Code components can be reused across custom pages, canvas, and model-driven apps. They can be centrally updated, packaged, and moved using standard Microsoft Dataverse solutions. More information: Power Apps component framework overview

Enabling Power Apps component framework for custom pages

To use code components inside a custom page, you need to enable Power Apps component framework feature. More information: Enable the Power Apps component framework feature



Create code components for use in a custom page

This section outlines how to create, import, and test code components.

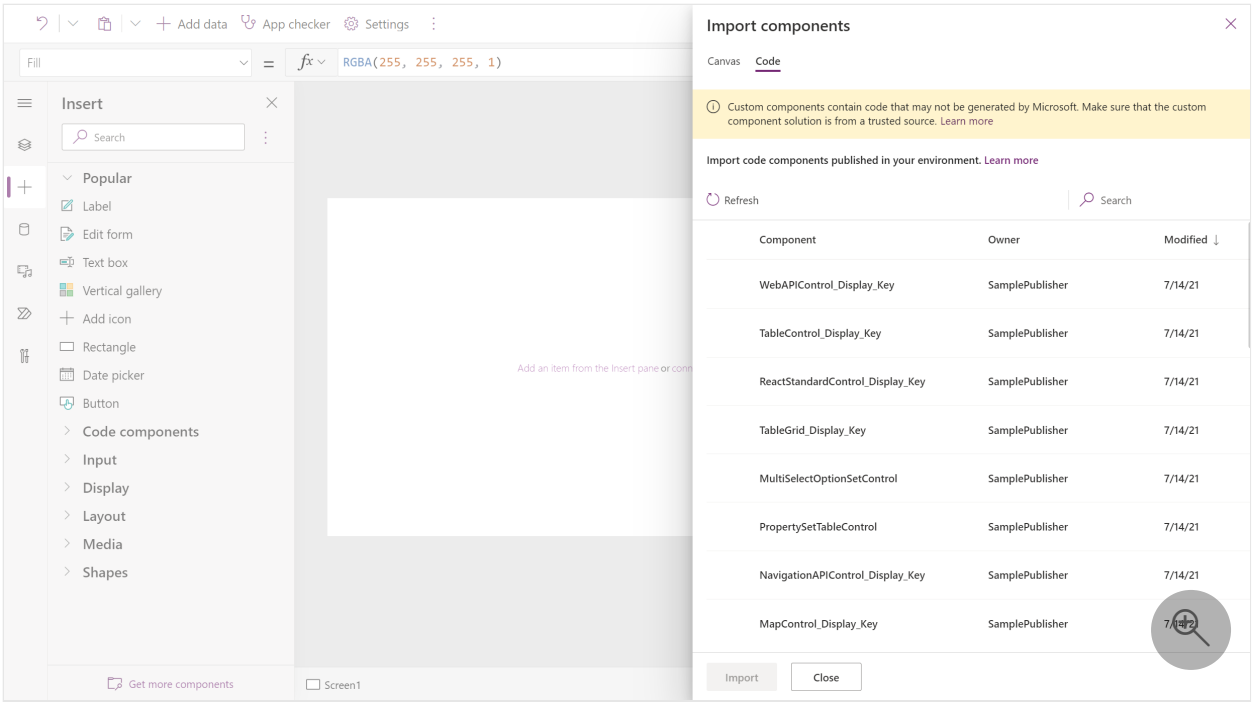
Creating and importing code components in Dataverse

Code components for custom pages follow the same pattern as they do with canvas app. Code components need to be implemented first before they can be added to a custom page. To create a code component, see Create your first component.

You can also try OOB sample components to jump-start. Once you are done implementing your code component, it can be packaged into a solution and added to Dataverse, making it available for use in all the custom pages in line with model-driven and canvas apps. More information: Code components application lifecycle management (ALM).

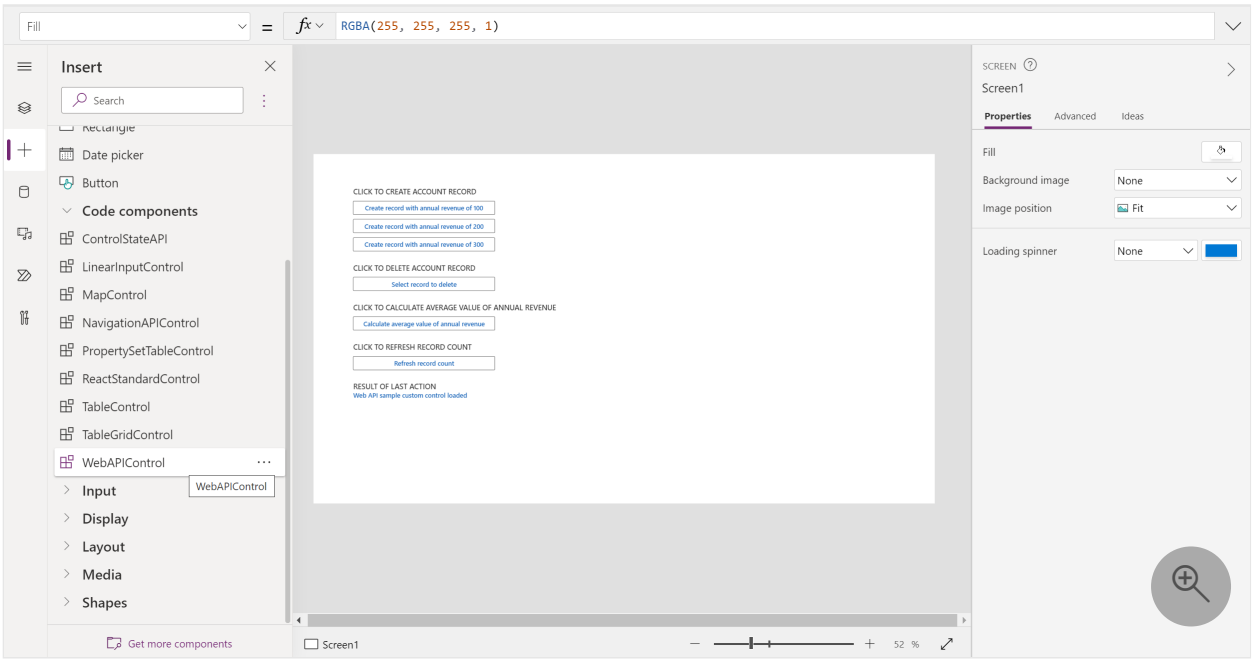
Importing and using code component in a custom page

In an environment, custom pages can use all the code components previously imported into Dataverse using solutions. On the left pane, select **Add (+)**, and then select **Get more components** at the bottom of the page. You will see a code tab on the **Import components** pane showing all code components present in the environment.



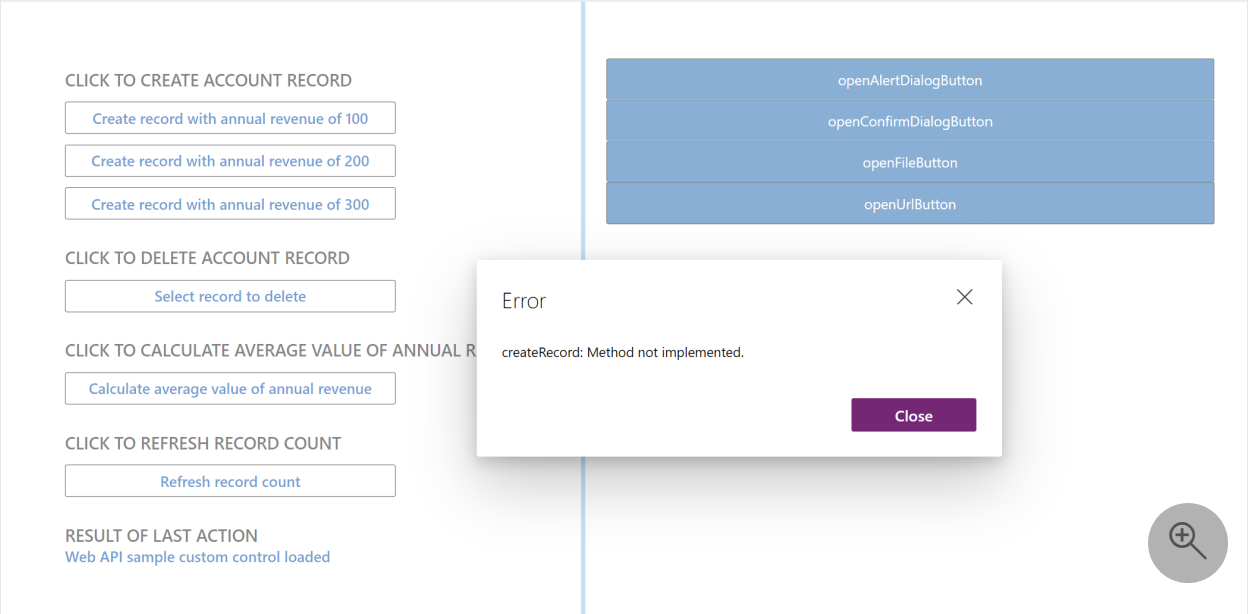
> **Note**
>
> - If the code tab doesn't show up in the **Import component** pane, verify that the Power Apps component framework feature setting for canvas apps is enabled. More information: **Enable Power Apps component framework feature**
> - Also, ensure that you are working on the latest canvas app studio authoring version.

The newly added code components are now available under the **Code components** section. It can be added to a custom page.



Testing the code component inside the studio and published app

Like canvas apps, code components are interactive and can be tested in the custom page studio authoring environment. However, specific APIs like `Web APIs` and `Navigation`, which only have the custom page runtime support when invoked, will show the error message "Method not implemented".

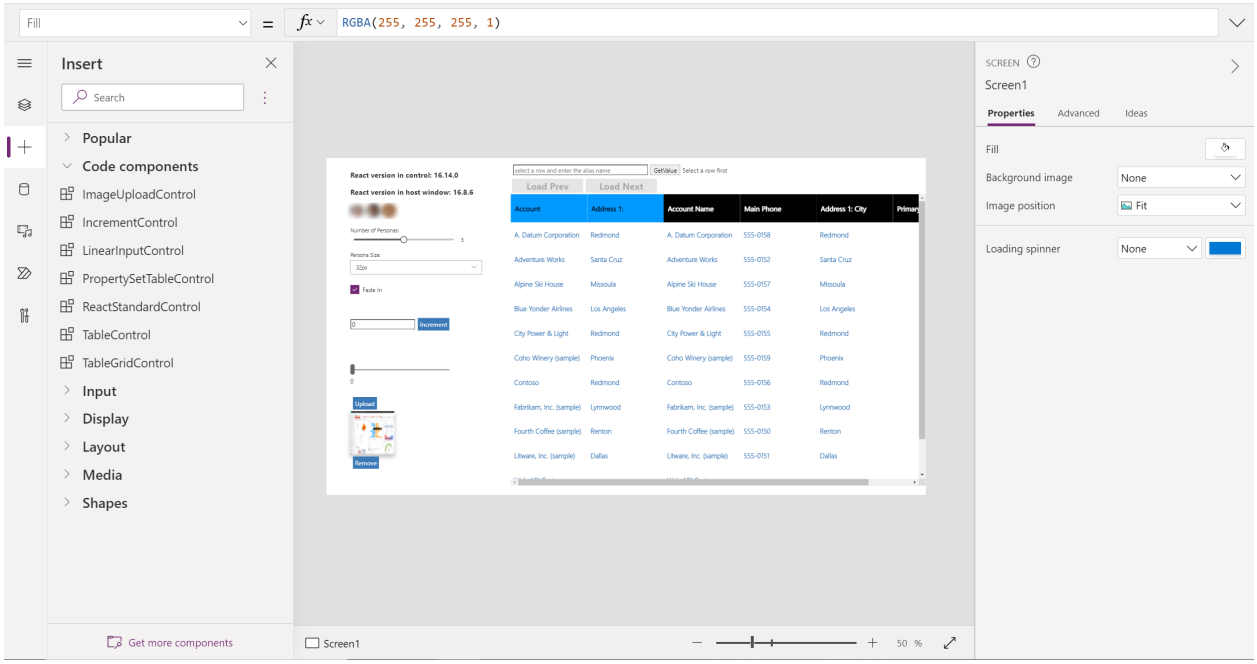


You can dismiss this error and publish the custom page. Then, add this custom page to the model-driven app and publish the app to see the custom page web API in action.

The image below shows the standard Web API sample control and Navigation API control added to custom page working inside a published model-driven app.

Additional code component resources

You can also use other sample components from Microsoft.



Or try some from the Power Apps community gallery.

Add data connection in canvas designer

Known issues with custom pages in a model-driven app

Article • 04/16/2025

The custom page is a new page type within model-driven apps. Custom pages bring the power of canvas apps into model-driven apps. Below are the known issues to be aware of.

> **Important**
>
> Using custom pages with mobile devices is currently in public preview. Offline and device capability controls like barcode scanning, capturing photos from device, or attaching files isn't supported.
>
> Custom pages aren't supported within **App for Outlook** and return an error on loading.

Maker-related issues

- When a custom page is modified, such as saved and published, the model-driven app isn't aware of the change. The model-driven app continues to use the last version of the custom page when the model-driven app was published. A model-driven app published through app designer, solution explorer, or **Publish all** updates all custom pages in the model-driven app.
- Images, icons, and shapes aren't currently supported with Right-To-Left (RTL) languages.
- The App.ConfirmExit property isn't supported in custom pages.
- The ability to get the current data formats from users settings including date, time, numbers, and currency isn't supported.
- Custom pages use a canvas app hosting session that can time out after 8 hours. However, the Unified Interface session has a longer timeout. When the timeout happens, an error message bar appears that prompts the user to refresh the browser.

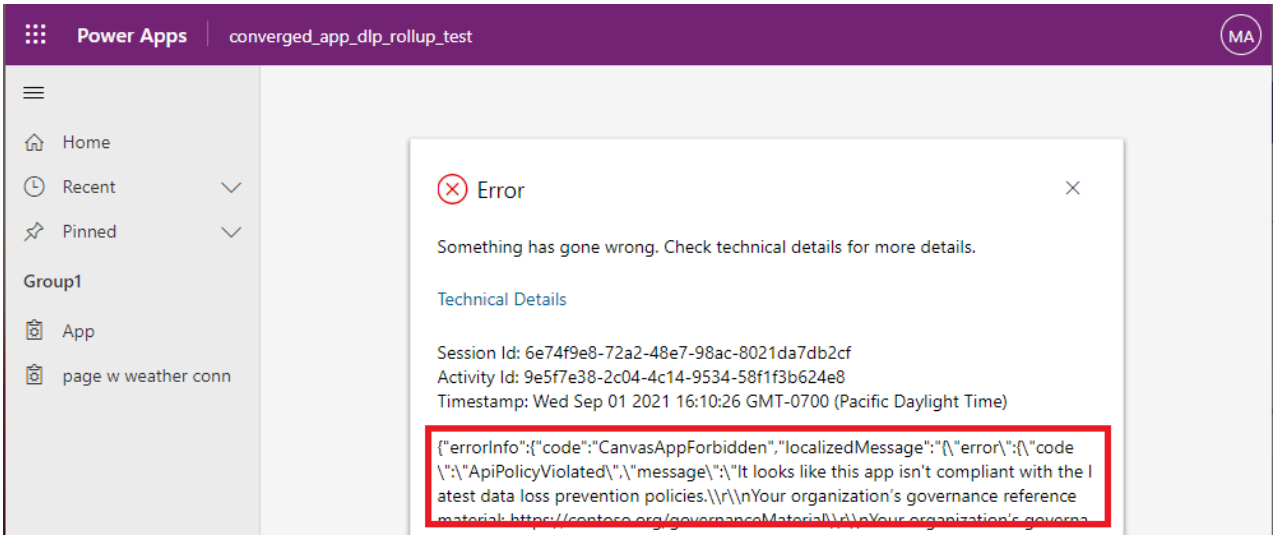
- When a custom page with code component is opened for editing, a security dialog is shown. Selecting **Go back** on the security dialog doesn't navigate back to the parent context. The user can close the browser tab to leave Power Apps Studio.

- Not all canvas app controls are available with custom pages. However, custom pages support the most common canvas app controls and custom pro-dev components. For more information about what is available, see Design a custom page for your model-driven app
- Makers need to share custom pages to allow another maker to make changes, which is a different behavior than the typical model-driven app components. If a custom page can't be shared from the **Solutions** area, open the environment in Power Platform admin center, and then open **Resources** > **Power Apps** > **Page** > **Share**. Similarly, to reuse the canvas app components inside the custom page, the corresponding canvas app component library also needs to be shared with the custom page makers.
- The maker experience for the custom page doesn't have support for certain Power Apps component framework APIs like `Navigation` and Web APIs, which is in line with the stand-alone canvas apps. However, these APIs are available in the published app where the custom page is added to model-driven apps. More information: Add code components to a custom page for your model-driven app.
- The maker experience for the custom page is currently not enabled in sovereign clouds. If you would like to enable it for a maker session, append "powerappsPortalApps.enableEditInShellAppDesigner=true" as a query parameter to the https://make.powerapps.com/ url.
- Makers can't use cross-environment Dataverse references in a custom page.

User-related issues

- When a user with no Power Apps user privileges opens a custom page in the model-driven app, they see an error mentioning no active entitlements to use Power Apps. More information: Licensing overview for Microsoft Power Platform and the associated licensing guide.
- Custom pages require third-party cookies to be enabled, which is required by the canvas app runtime.
- When a user is prompted for consent with connectors and selects **Don't allow**, the custom page renders but without data. The user doesn't get notified that data retrieval is skipped.
- After a model-driven app or custom page is changed and published, loading a custom page can take longer than normal, and no page loading spinner is shown.

- Native player support is available for iOS, Android, and Windows in online-only mode. Offline support currently isn't supported.
- When you go back to a custom page from another page, the page state isn't restored so the page appears like a new navigation. State is also not persisted when switching between multi-session tabs in multi-session apps. For more information about multi-session support with model-driven apps, go to Customer Service workspace sessions and tabs.
- While attempting to sign in, the current behavior caused by a user selecting anywhere away from the sign in box causes the pop out window for sign in to shift behind the app browser.
- When a user runs an app that isn't compliant with their organization's Data Loss Prevention (DLP) policies, they see an error dialog and the 'Technical details' reflects the app isn't DLP compliant.



- When there are multiple custom pages in an app, the consent dialog asks for data permissions for all of the connectors in all the custom pages even if they haven't yet been opened.

Connections

- All custom pages share the connection infrastructure, as if they were part of the same canvas app. For instance, if a model-driven app has two custom pages and one is connected to SQL Server while the other isn't, the consent dialog will still appear and require permission for SQL access even if the page being opened doesn't require it.
- Custom pages in model-driven apps don't support connection detection through the *Connected.connected* property.

- The number of connectors in a model-driven app, across all custom pages, shouldn't exceed 10. The number of connection references, across all custom pages, shouldn't exceed 20. The number of connectors and connection references can increase the wait time an app user experiences when the user plays an app with custom pages.
- The **App Permissions** dialog is not opened when a custom page is first opened by a user in the Power Apps mobile app. This behavior can cause the page to appear frozen, but is expected behavior. To resolve this issue, open the app in a browser to approve the permissions before playing it in the Power Apps mobile app. You can also run the AdminPowerAppApisToBypassConsent PowerShell command to bypass the need for the permissions dialog by a Power Platform administrator.

Model-driven app custom page overview

Use live monitor to troubleshoot page behavior in model-driven apps

07/19/2025

Live monitor can help you debug and diagnose problems, which help you build faster, more reliable model-driven apps. Live monitor provides a deep view into how an app runs by providing a log of all activities in your app as it runs.

> **Important**
>
> Live monitor must be run on the model-driven app and not directly on a custom page.

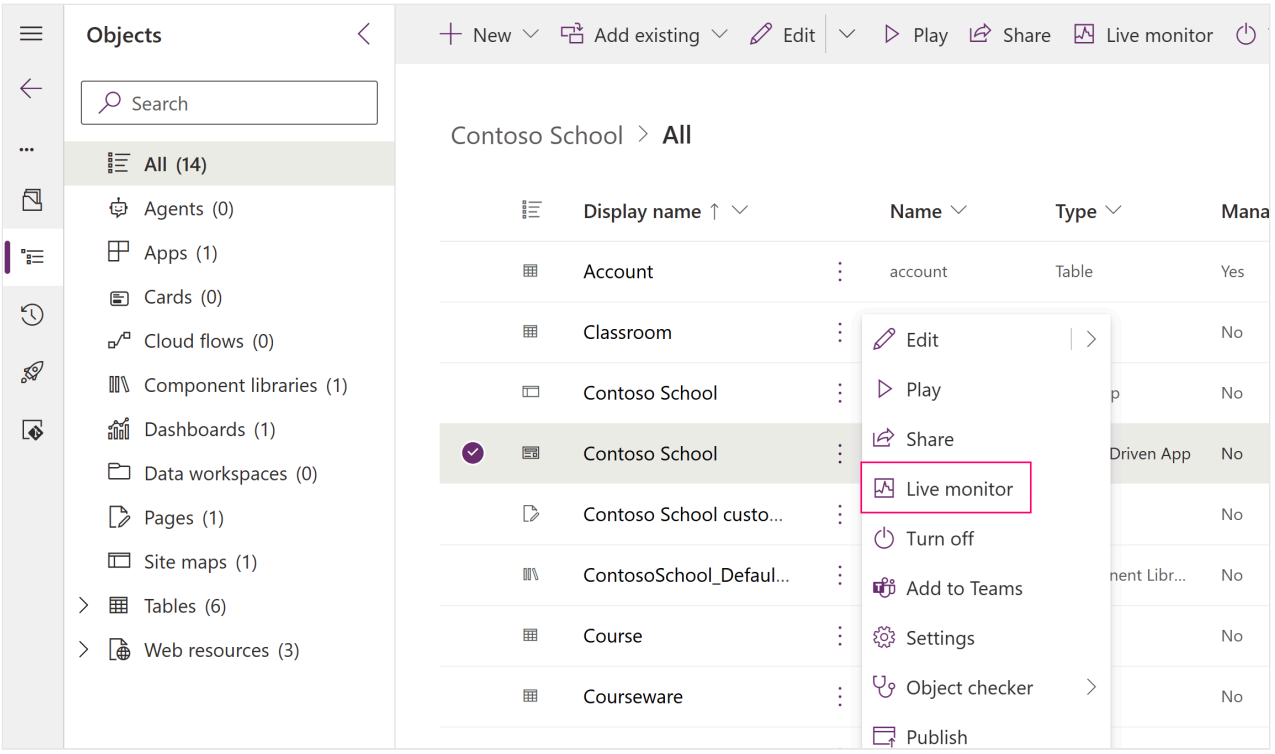
Start a live monitor session

There are two ways to open a live monitor session.

- From Power Apps
- From a model-driven app

From Power Apps

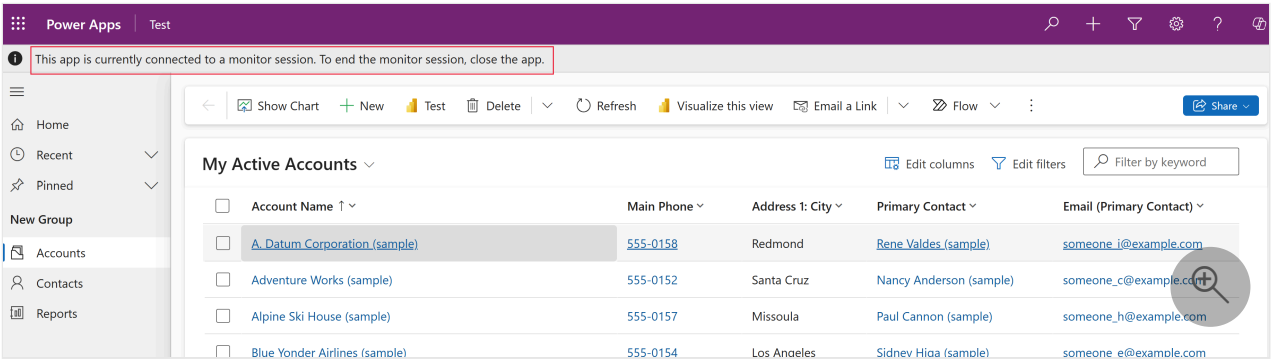
1. Sign in to Power Apps, select **Apps**.
2. Select **...** next to the model-driven app or on the global command bar, and then select **Live monitor**.



3. On the **Live monitor** browser tab that opens, select **Play model-driven app** on the command bar.

4. When prompted, select **Join**.

5. The app loads in a new browser tab with a message indicating the monitoring session. Switch back to the live monitor tab to view activity.

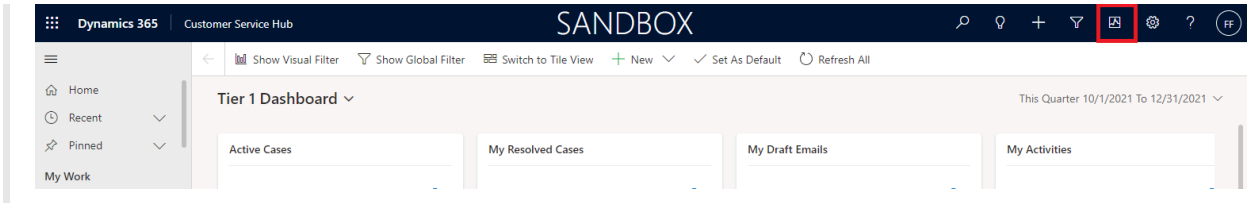


From a model-driven app

1. Play your model-driven app.

2. Add `&monitor=true` to the end of the URL in your web browser, and then refresh the page.

3. Select **Live monitor** on the command bar.



Filter monitored activity

When you filter on a model-driven app custom page-related events in live monitor, you can get information about related tables, tables, controls, and components, such as on a custom page, in live monitor as your app runs.

	Time	Cate...	Operation	Result	R	Status	Dura...	Data source	Control	Property	Resp...
1	10:40:11.9...	ScreenLoad	LoadScreen (Screen1)	Success			276				
2	10:40:12.1...	ScreenLoad	Navigate (Screen1)	Success			176				
3	10:40:12.1...	Network	getRows	Success		200	152	Contacts	Gallery1	Items	
4	10:40:07.3...	Network	XMLHttpRequest	Success			204	https://bugbash.cr...			
5	10:40:07.3...	Network	XMLHttpRequest	Success			6	https://bugbash.cr...			
6	10:40:07.8...	Network	Fetch	Success		200	193	https://bugbash.cr...			
7	10:40:07.9...	Network	Fetch	Success		200	190	https://bugbash.cr...			

For example, to filter on the custom page that uses the `Gallery1` control, select the **Control** column header > **Filter by**, enter *Gallery1*, and then select **Apply**.

For more information about model-driven app monitoring, go to Debug a model-driven app with live monitor

Close a live monitor session

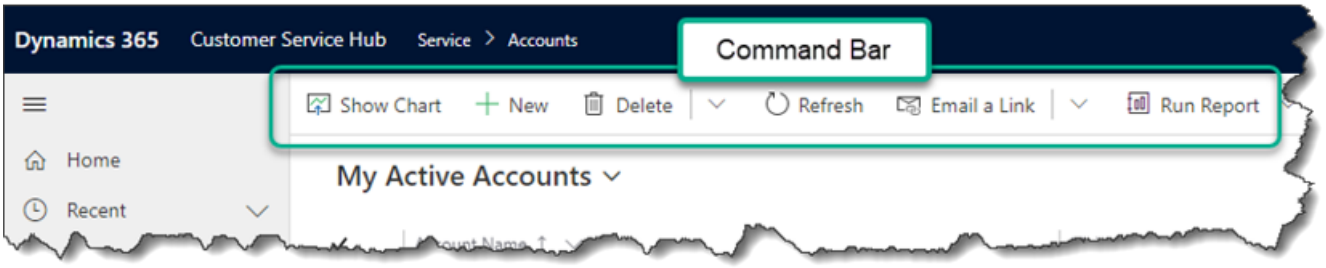
To close the monitoring session, close the browser tab where the monitored model-driven app is playing.

Next steps

Use live monitor to troubleshoot model-driven app form behavior

Modern commanding overview

Commands drive core application behavior for model-driven apps. They're the buttons users interact with when playing apps and the resulting actions performed when a button is selected. Each command is positioned in relation to other commands and bound to a command bar location within the app.

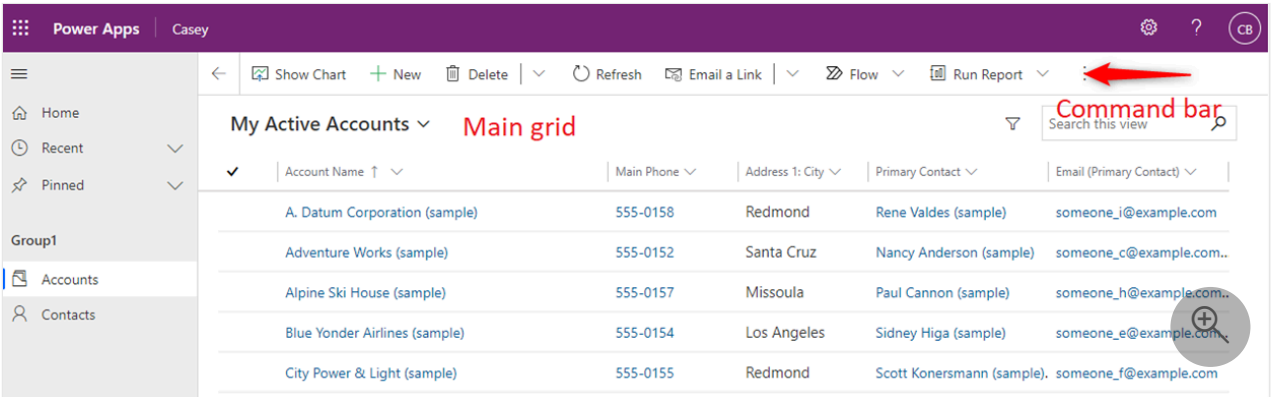


At a high level, command customization fits into three categories. Various capabilities exist within each category and are covered in more depth throughout the modern commanding documentation:

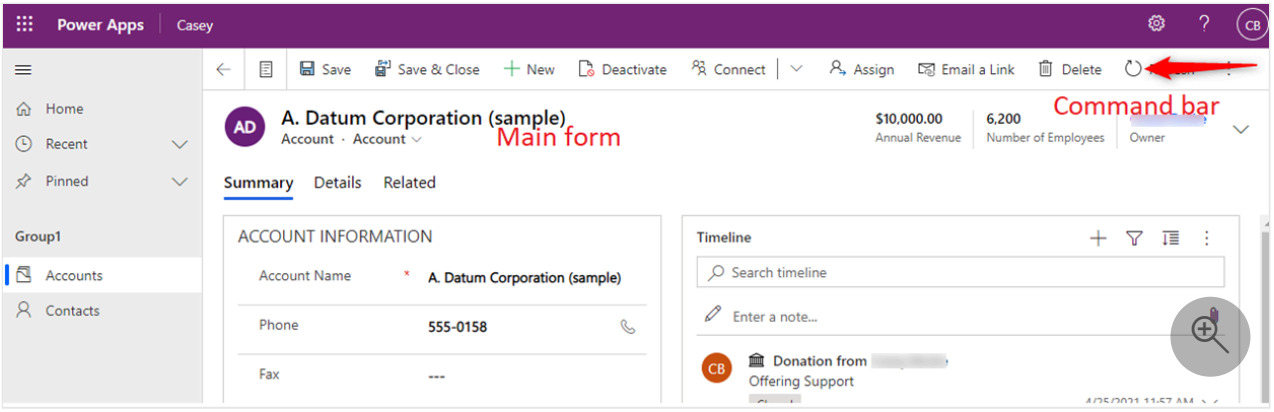
- **Display**. How the button appears and where it's located in an app. For example, the button's label, icon, and accessibility labels as well as the command bar location and position within a command bar.
- **Action**. The logic that runs when a user selects a button. For example, creating and updating data or interacting with various controls and pages inside the app.
- **Visibility**. Logical conditions that specify when a button is visible or hidden to a user. For example, you might want the button visible for some users and hidden for others. Or perhaps the button should only be visible when certain criteria of the data records are satisfied.

Command bar locations

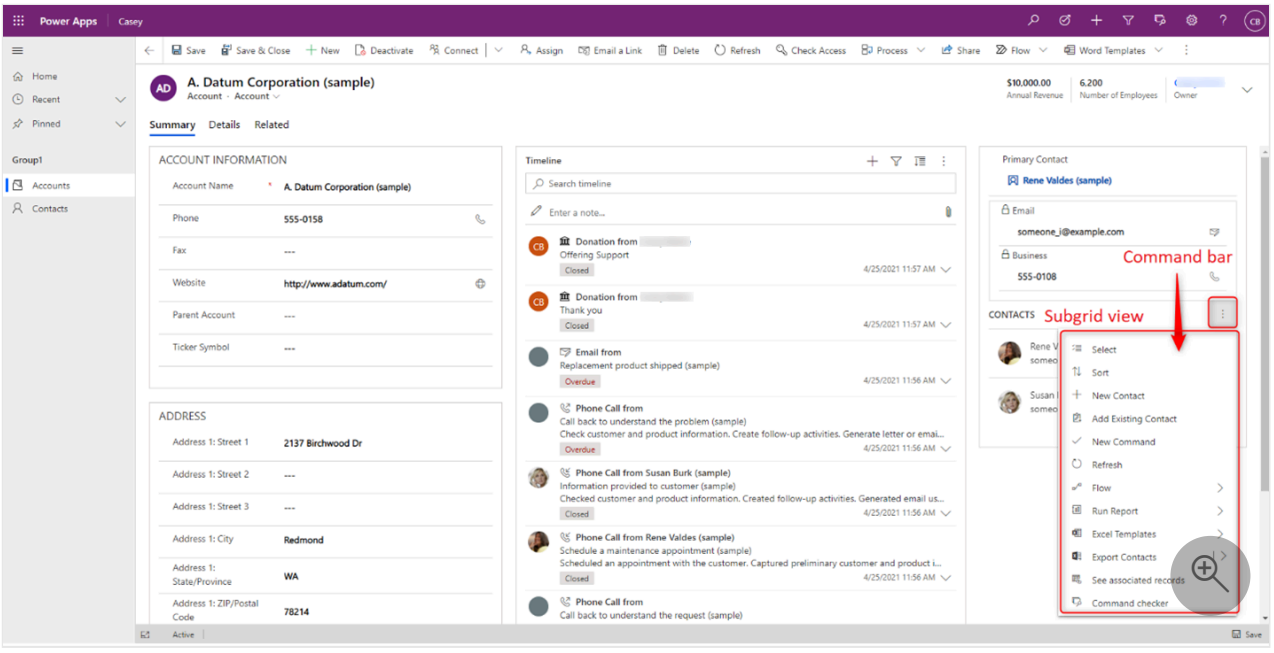
- **Main grid**. This command bar is displayed when using the left-hand navigation of an app to view a full page list of records in this table.



- **Main form**. This command bar is displayed on the table's main forms. This appears at the top of the form and isn't the same as the associated view or subgrid view that appears in different areas of the form.

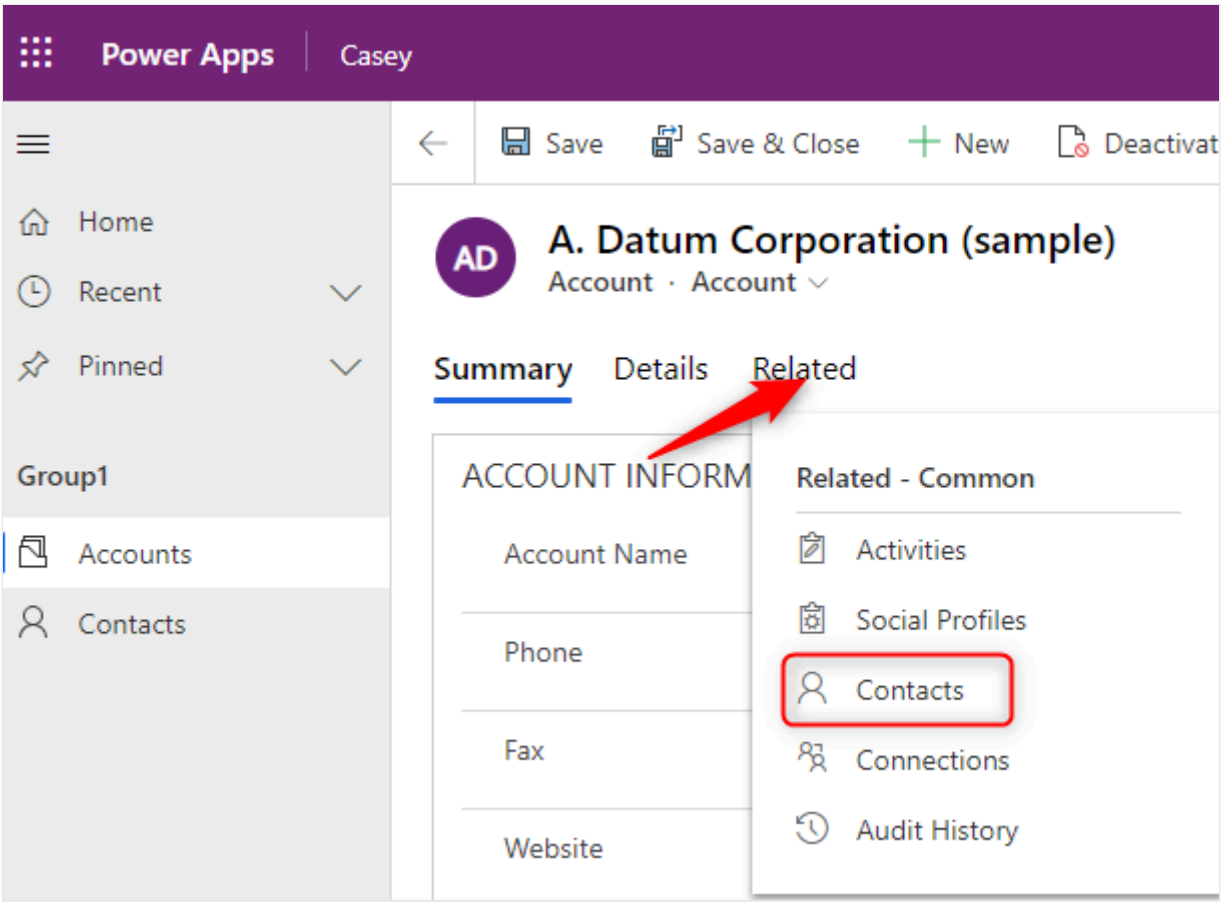


- **Subgrid view**. This command bar is displayed on forms of other tables that render this table's data within a subgrid. For example, the account main form has a subgrid control that lists contact records related to the account record. To edit the command bar shown here, edit the command bar for the contact table then subgrid view.

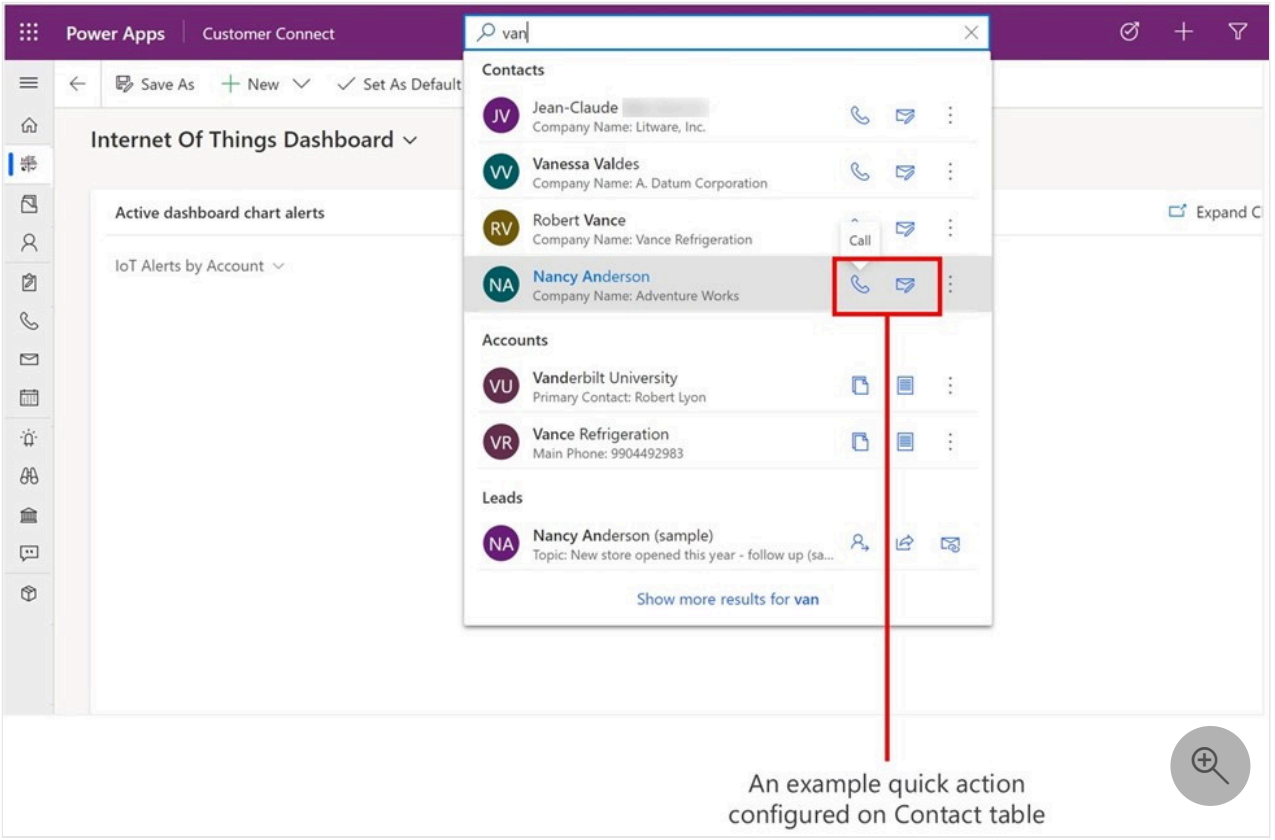


- **Associated view**. This command bar is displayed on the form of a parent table when viewing related data in this table. For example, from the main form of an account record

select the **Related** tab then select a related table like contacts.



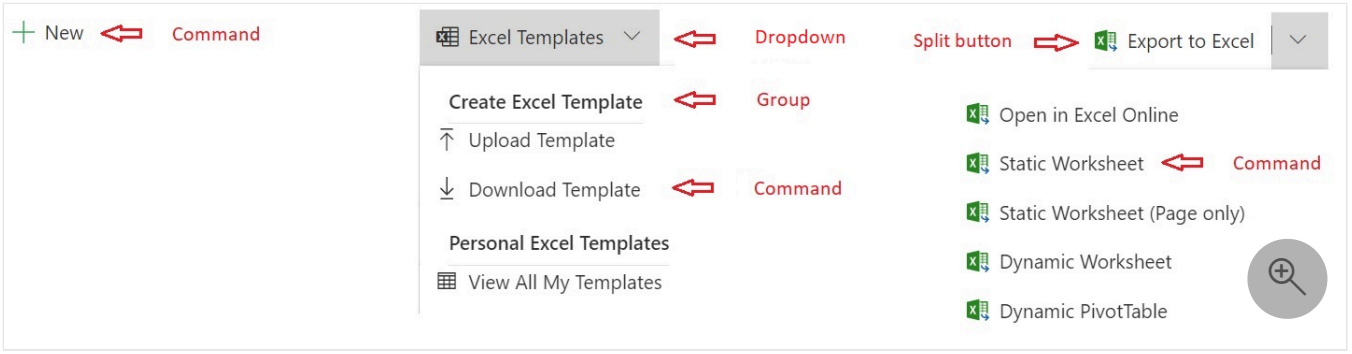
- **Quick actions**. Quick actions are associated with the main grid location. To add or edit commands for both quick actions and main grid locations, select the desired table from within the modern app designer, then edit the command bar and choose the main grid location. The first five commands, determined by order, are also shown as quick actions when playing the app.



> **Note**
>
> Less frequently customized command bar locations aren't supported in command designer. See the Global command bar and other ribbons sections for more information on customizing commands for these locations.

Types of commands

- **Command**. Standard button. Performs an action when selected. Can also be nested in groups within dropdowns and split buttons. These were called flyouts in classic commanding.
- **Dropdown**. Creates a menu where you can organize commands within a group.
- **Group**. Add titles to groups of commands nested within dropdowns and split buttons.
- **Split button**. Similar to a dropdown, but has a primary command. When the split button is selected, the action from the primary command is executed. If the expand chevron is selected, the primary command won't be executed. Instead a list expands to show additional groups, flyouts, and commands.



Key differences between classic and modern commands

Classic commands (formerly known as the ribbon) weren't customizable using low code. With code, command customizations were difficult, tedious, and error prone. In order to scale commanding to low code as well as use custom pages to converge canvas and model-driven apps, it was vital to reinvent and rebuild the command infrastructure.

Modern commanding offers many new capabilities and is much simpler to use.

Expand table

Capability	Classic	Modern
Supported in model-driven app runtime	Yes	Yes, Additionally supports Power Fx runtime.
Customized using	Hand editing XML within solution files or using non-Microsoft tools. Requires time-consuming solution export and import operations.	Command designer as well as Dataverse API support.
Supports Power Fx.	No	Yes. For actions and visibility.
Time required to customize	Slow, error prone.	Fast
Reliability and performance	Easy to make mistakes. Bad customization and lack of scoping often impact app performance.	Inline error handling prevents mistakes. Power Fx optimized for better runtime performance.
Sharing	Standard Dataverse role-based security.	Non-Power Fx commands use standard Dataverse role based security. Power Fx commands currently require the command component library to be shared in addition to having an appropriate security role.
Solution and application lifecycle management (ALM) behaviors	Inconsistent and problematic solution layering, no presence in solution interface. Many standard solution behaviors not supported such as patches, segmentation, solution upgrade, managed properties, and many more.	Standard solution layering centrally managed for multiple solution object types within Dataverse. Present in solution interface. All standard solution behaviors supported.
Localization	Nonstandard	Standardized using export and import translations for the entire solution.
Data model	Complex. Optimized for classic ribbons and contain many properties that are no longer needed.	Simple, optimized for today's model-driven app command bars.
Use JavaScript	Yes	Yes. Now simpler. The same JavaScript can be used for classic and modern commands.
Customize out of the box commands	Yes	Commands become editable in command designer once migrated to the modern framework.

Capability	Classic	Modern
App specific commands	No	Yes. Using modern command designer ensures commands are only visible within the selected app.
Table specific commands that display in all apps containing the table	Yes	Yes. Requires modifying the `appaction` definition within the solution file.
Global commands that display for all tables and apps for the specified command bar location	Yes	Yes. Requires modifying the `appaction` definition within the solution file.
Create split buttons, flyouts, and groups	Yes	Yes
Dynamically populate a flyout with code	Yes	No. Create commands declaratively.
Customize global application header commands	Yes	No
Customize commands for other, uncommon, or obsolete command bar locations	Yes	No.
Run a modern flow or workflow	Using JavaScript	Using JavaScript. Also supported using a custom page.

Classic versus modern visibility rule comparison

Classic visibility rules often had a specific rule for each scenario. With Power Fx, a declarative function replaces many classic rules. And it’s much simpler to use.

Classic visibility rules are also supported within modern commands. However, support for classic rules was needed for reliably migrating classic commands to modern commanding and classic rules customization within command designer isn't supported. We recommend you use Power Fx going forward.

Expand table

Use case	Classic Rule	Classic options	Power Fx visible property
Show or hide based on data values	CustomRule	Use JavaScript	!IsBlank(Self.Selected.Item.Email)
Show or hide based on table permission	EntityPrivilegeRule	Multiple	DataSourceInfo()
Show or hide based on record permission	RecordPrivilegeRule	Multiple	RecordInfo()
Reference the control context for primary and related tables	EntityRule	PrimaryEntity. SelectedEntity	Self.Selected
Reference the control context	EntityRule	Form. HomePageGrid. SubGridStandard. SubGridAssociated	Self.Selected
Table metadata properties	EntityPropertyRule		DataSourceInfo()
Show or hide based on form state. For example, show for the create form	FormStateRule	Create. Existing. ReadOnly. Disabled. BulkEdit	Self.Selected.State = FormMode.New
Show when > 1 records are selected in a grid	SelectionCountRule		CountRows(Self.Selected.Items) > 1
Show or hide for a related table in a polymorphic lookup. For example, check whether the lookup is a user or a team	CustomRule	PrimaryEntityTypeCode	IsType(), AsType
Reference environment properties (Org)	CustomRule	OrgName. OrgLcid. UserLcid	Not currently available

Frequently asked questions

- *Why do I see more commands in the designer than I see in my app?*

    - There are several reasons. Sometimes there's visibility logic that hides the command when running the app. Other times these commands are dynamically injected via custom JavaScript during runtime and aren't configurable.
- *Why do I see duplicate commands in the designer?*
    - This was a common pattern used with classic commands. Both commands wouldn't show up in runtime as they were controlled by visibility rules. The command designer shows all commands, regardless of their visibility rules.

Customize the command bar using command designer

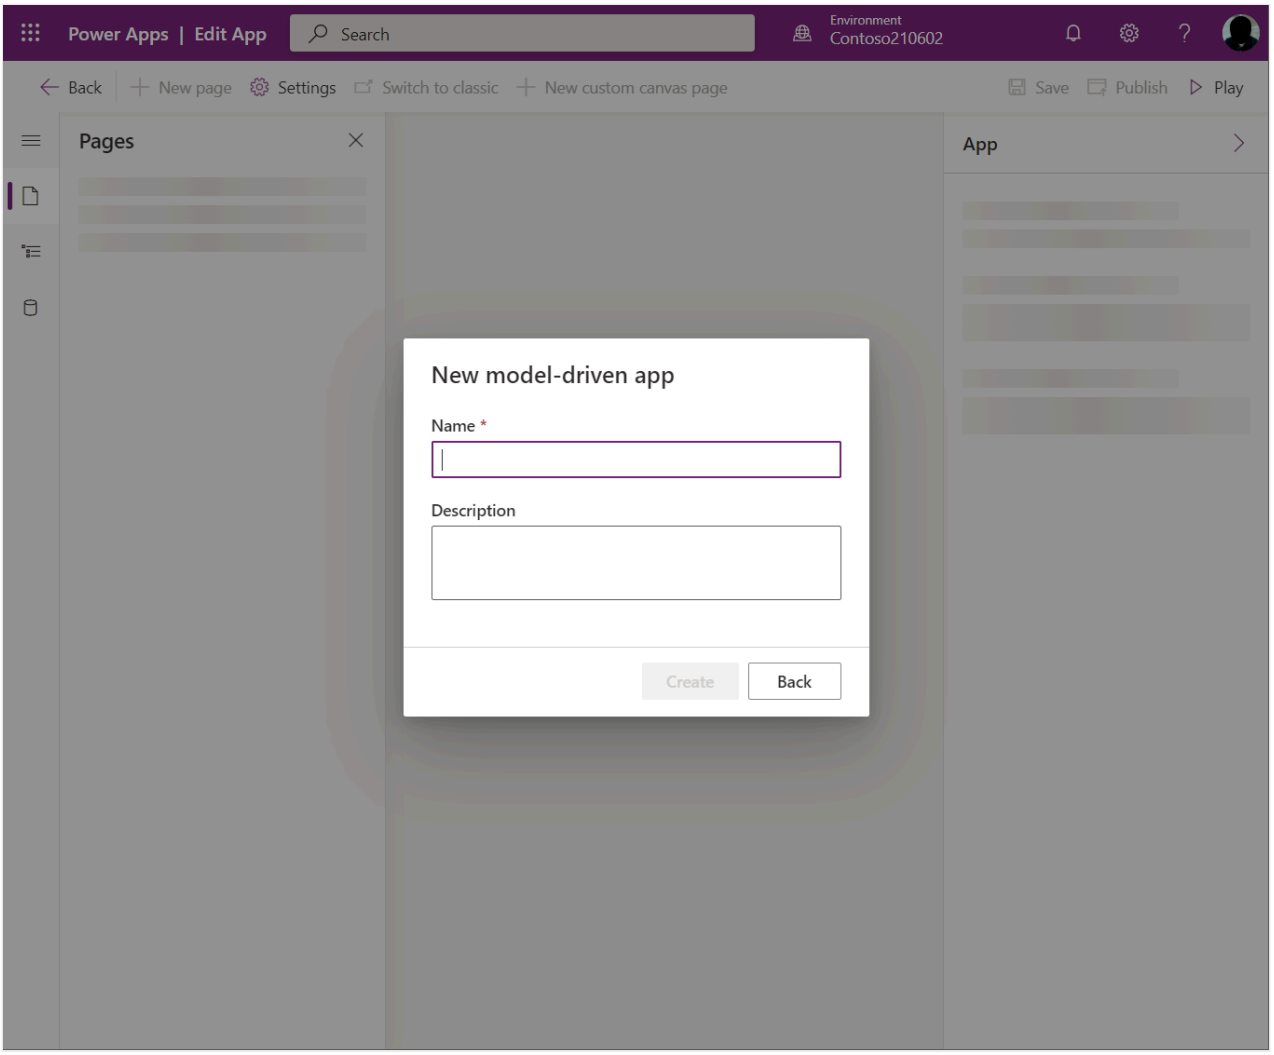
This article guides you through creating and editing modern commands using the command designer and Power Fx.

Open the app designer

Either Create a new model-driven app using modern app designer or Open an existing model-driven app using app designer.

Create a new model-driven app using modern app designer

1. Sign into Power Apps .
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open or create a solution to contain the new model-driven app.
4. Select **New** > **App** > **Model-driven app**.
5. Enter a **Name** for your app, and then select **Create**. More information: Build your first model-driven app



Open an existing model-driven app using app designer

1. Sign into Power Apps
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution containing the existing model-driven app.
4. Select the model-driven app, and then select **...** > **Edit** to open the modern app designer.

Create or edit modern commands

Once you are in the app designer, use the command designer to customize your command bars.

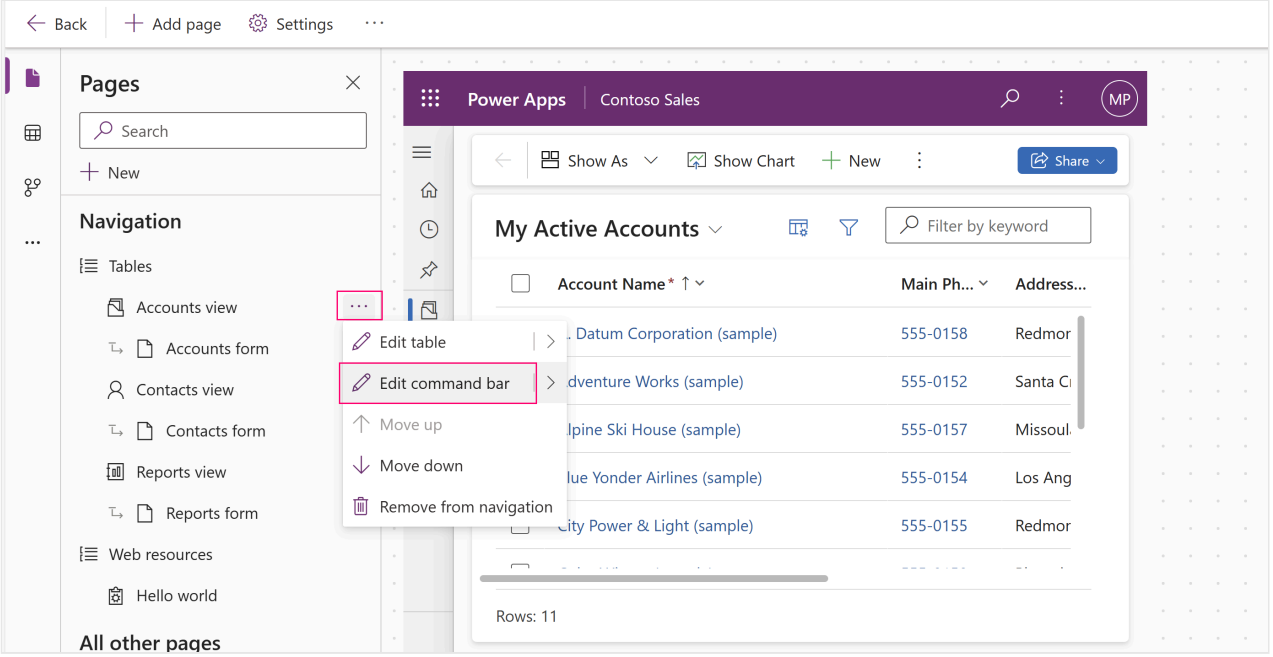
> **Note**
>
> - Currently, the command designer can only be accessed through the modern app designer or within solutions for existing commands.

- Currently, classic commands can't be edited within the command designer.

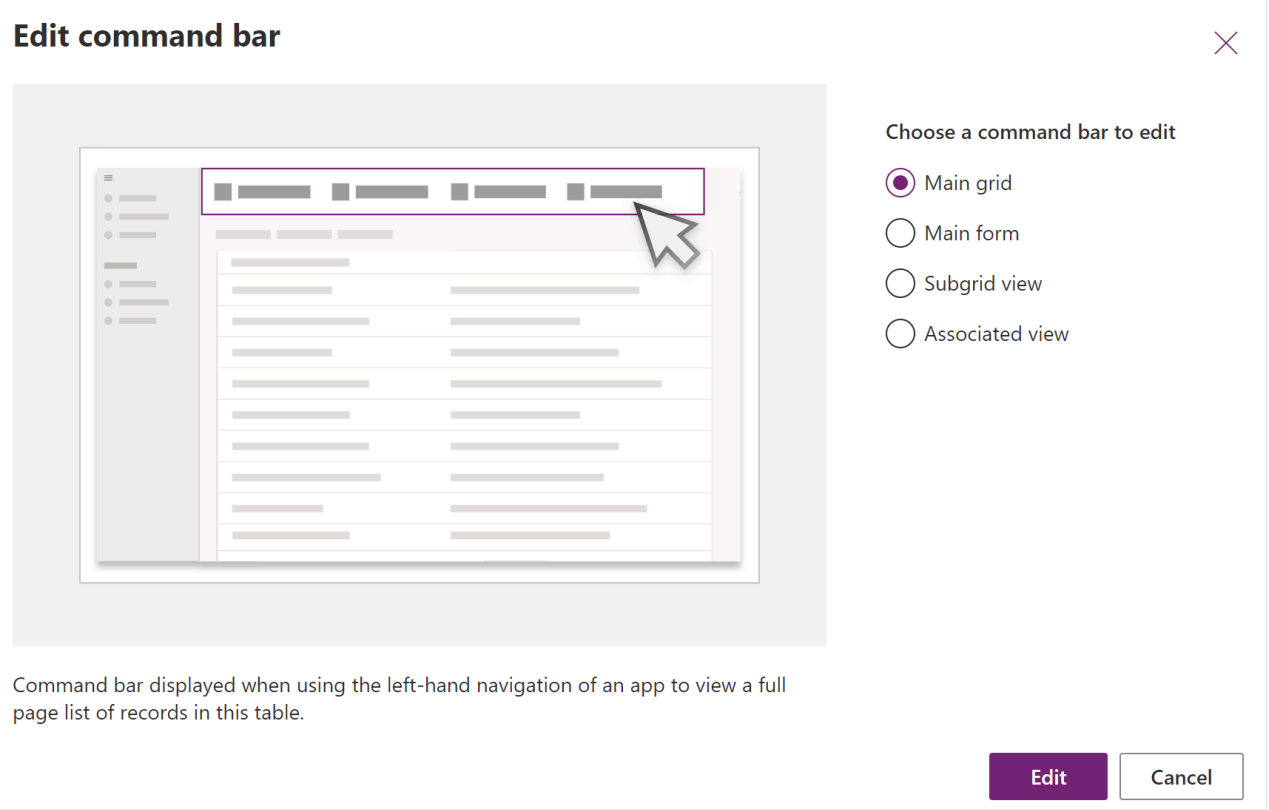
Edit the command bar

Open the command designer to edit a command bar

1. Next to any table view from the **Pages** area in the app designer, select **...**, and then select **Edit command bar**.



2. Select the location of the command bar you want, such as main grid (view) or main form, and then select **Edit**. More information: Command bar locations

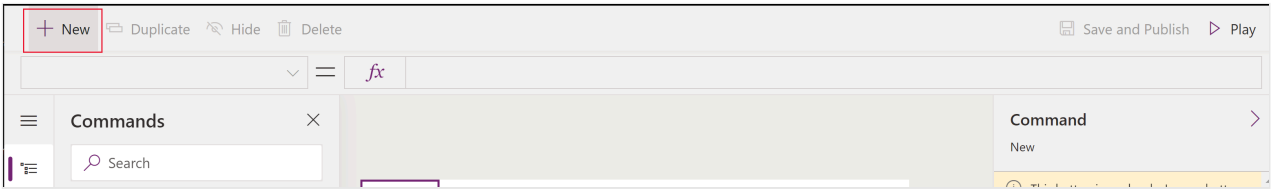


Create a new command

Unlike classic commands, modern commands are only displayed within the app you're editing. This prevents unwanted command transferring to other apps as well as better runtime performance.

The first time command designer is opened for an app, a prompt to either use **JavaScript** only or **Power Fx** is displayed. Selecting Power Fx also allows you to use JavaScript if desired. Selecting **Power Fx** in the dialog creates a command component library to store **Power Fx** formulas.

1. Open the command designer to edit a command bar, and then select **New** > **Command**.

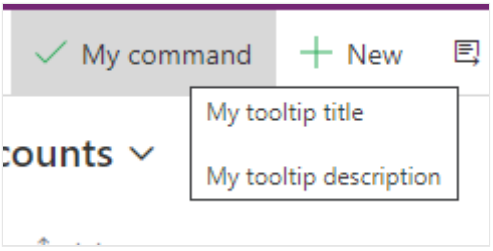


2. On the right pane, enter or select from the following options:

   - **Label (optional)**. Enter a label that displays on the command button.
   - **Icon**. Select an icon for the command button. You can choose from any system icons or web resource SVG files. To upload your own icon, choose **Web resource** then upload an **SVG** format file. Then, select **Save** and **Publish** the web resource. For

more information about how to create a web resource for the icon image you want, go to Create or edit model-driven app web resources to extend an app.

- **Action**. Select from the following:
  - **Run formula**. Enter the Power Fx formula to run the command action. More information: Use Power Fx for actions and visibility
  - **JavaScript**. Provide the JavaScript library and command to run the command action. More information: Use JavaScript for actions
- **Visibility**. Select whether to **Show** the command button or to **Show on condition from formula**.
- **Tooltip title**. Optionally, enter a tooltip title. The title appears to the user when they hover their mouse over the command.
- **Tooltip description**. Optionally, enter a tooltip description. The description appears for the user below the tooltip title when they hover their mouse over the command.



- **Accessibility text**. Optionally, enter the text that will be read by screen readers.
- **Order number**. The order the command displays in at runtime in relation to other commands within the same command bar.

3. Drag and drop the command to the desired location. You can arrange modern commands among classic commands.
4. Select **Save and Publish** to make the command available to app users.
5. Select **Play** to run the app and test your changes.

> **Note**
>
> Publishing Power Fx formulas can take a few minutes to publish the command component library. This background operation might still be in-progress after command designer has completed the request and unlocks the designer.

Use Power Fx for actions and visibility

You can use Power Fx for both actions (what happens when the command button is selected) as well as visibility (logic to control when the button is visible). Power Fx isn't supported in classic commands.

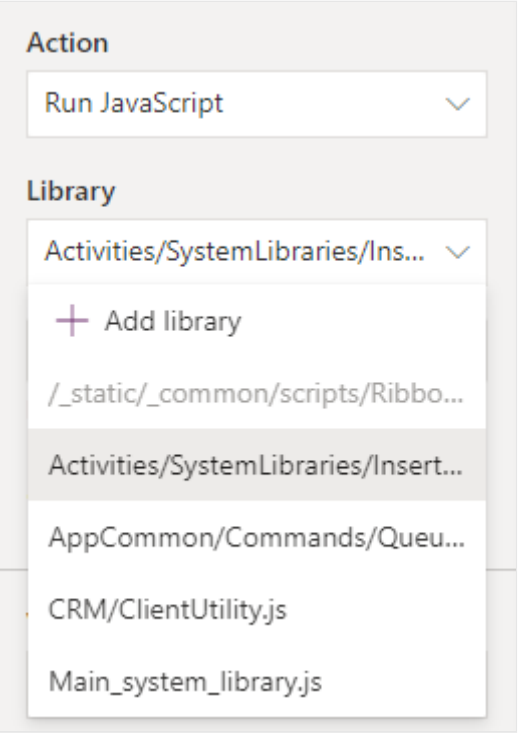
Notice the model-driven app command has a formula bar experience that is similar to canvas apps. For working with **Dataverse** data you can use Power Fx formulas just as you would in canvas apps. More information: Using Power Fx with commands

> ⓘ **Note**
>
> - Dataverse is currently the only data source supported with commands in model-driven apps.
> - You can't currently add additional tables as data sources directly from the command designer. However, you can open the command component library in canvas studio and add additional tables as data sources and then use them within the command designer.
> - Not all functions available within canvas apps are supported currently for model-driven app commands. Additionally, we've introduced some new functions specific to model-driven app commands.
> - For more limitations with modern commands, go to **Modern commanding known limitations**.

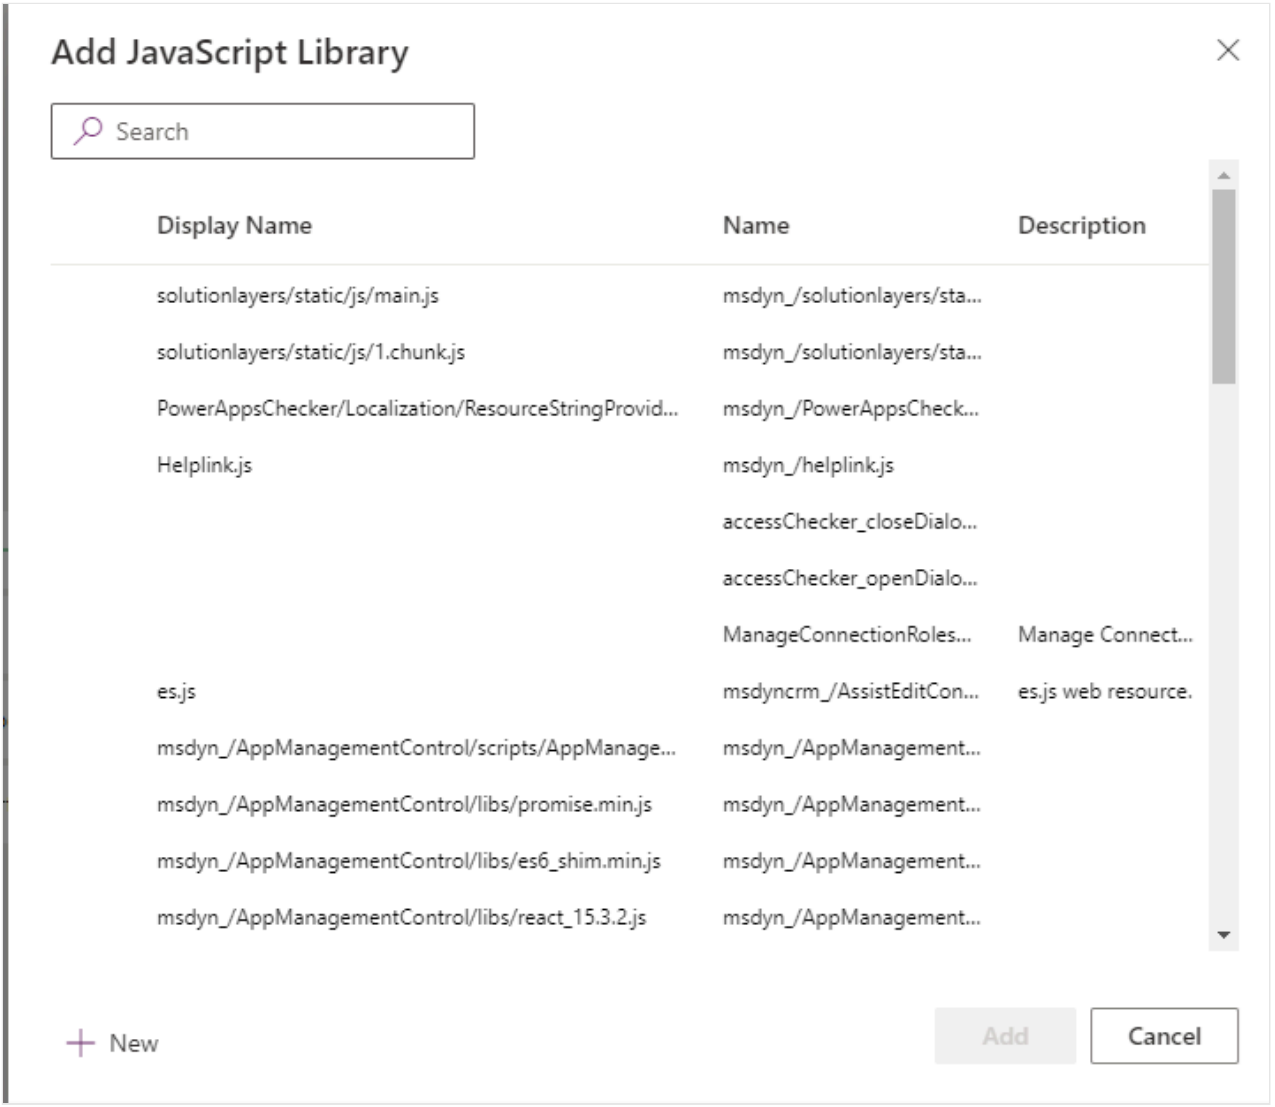
Use JavaScript for actions

JavaScript is supported with both classic and modern commands. However, it's simpler to create commands and associate your JavaScript using the modern command designer.

1. For the **Action** select **Run JavaScript**.
2. Select **Add library** or select another one from the list. The list is populated with any libraries in use by the current command bar.

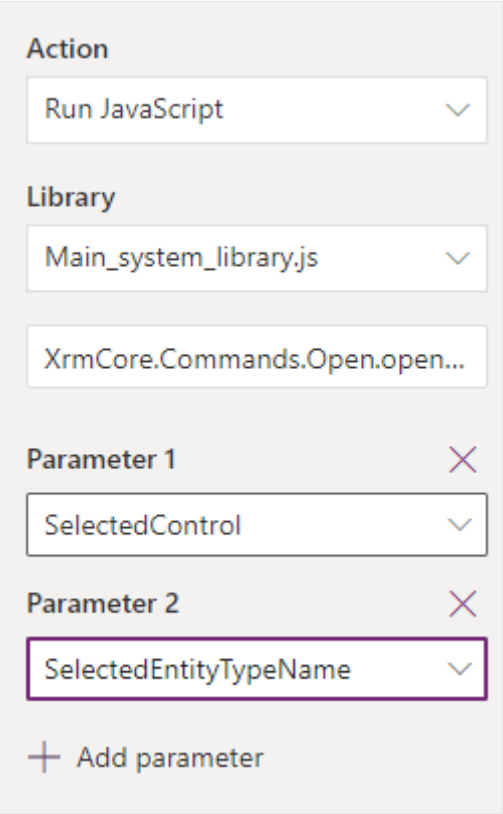


3. Select **Add** and search for existing JavaScript web resources or you can add your own.



4. Enter the **Function name**. For example, select the `Main_system_library.js` library then call this function: `XrmCore.Commands.Open.opennewrecord`.

5. Add parameters to pass to your function. For more information about the available parameters, go to Grid values.



> **Note**
>
> The use of calling multiple JavaScript libraries or calling multiple functions from a single command isn't supported.

Using Power Fx with commands

Article • 04/23/2025

This article covers aspects of Power Fx that are specific to commanding. Many other functions that are in use today within canvas apps can also be used. Keep in mind there are differences because commanding is for model-driven apps.

- All existing dataflow functions are supported. What are dataflows?
- Imperative functions that work with data are supported.
- Imperative functions for simple `Confirm` and `Notify` are supported.
- For a list of functions not supported, go to Functions not supported.

> **Note**
>
> Publishing Power Fx commands might take a few minutes. It might not be obvious that background operations are still running even after the publish operation appears to complete. You might need to wait a few minutes after publishing, then refresh the app to see your changes reflected. This operation typically takes longer the first time a Power Fx based command is published for an app.

OnSelect

Defines the logic that is executed when the button is selected within the app.

Visible

Defines logic for hiding or showing the button when running the app.

To define visibility logic, select the command. Then select **Visibility** on the right command properties pane and choose **Show on condition from formula**. You can select **Visible** on the left of the formula bar then write a Power Fx expression using the formula bar.

Selected property

Expand table

Field	Type	Description
Item	Record of DataSource	One of the records selected from the DataSource.

Field	Type	Description
AllItems	Table of records from the DataSource	All of the records selected from the DataSource.
State	Enum	State of the selected control. Edit (=0), New (=1), View (=2)
Unsaved	Boolean	Returns true if Selected or SelectedItems have unsaved changes. Otherwise returns false. Always returns false if AutoSave is set to true (default option) within the command component library.

- The **Selected** property is provided by the host of the command.
- **Item** and **AllItems** names are somewhat consistent with the ComboBox control and Gallery control, but this is a new pattern.
- If there's no record selected, **Item** returns Blank (IsBlank returns true) and **AllItems** returns an empty table (IsEmpty returns true).
- Null DataSource for record references (polymorphic record types). Generic functions can be called, such as Save or IsType/AsType can be used.
- **Item** is always blank if **SelectionMax** <> 1. This prevents writing formulas to just one item and not scaling to more than one.

AutoSave

- Many JavaScript commands start by saving the form buffer. This is because it makes the rest of the code easier to work with.
- By default, the form buffer is saved on behalf of the app maker.
  - The form is saved before the command is initiated.
  - Any problems that occur during the save operation are dealt with in the form's UI.

Patch function

Patch (update) the current selected record

Power Fx

```
Patch(Accounts, Self.Selected.Item, {'Account Name': "Changed Account name"})
```

Create a related record

> **Note**
>
> If the related table is not already in the command component library, you need to open it in canvas studio and add the data source there.

Power Fx

```
Patch(Tasks,Defaults(Tasks),{Regarding:Self.Selected.Item},{Subject:"Subject of the Task"})
```

Check and edit a date property

Power Fx

```
If(Self.Selected.Item.'Last Date Included in Campaign'>DateAdd(Now(),-3),
Patch(Accounts,Self.Selected.Item,{'Last Date Included in Campaign':Date(2021,10,19)}))
```

Visible property: Only show the command if one or more records is selected in a grid view

Power Fx

```
CountRows(Self.Selected.AllItems) > 0
```

Control visibility based on record data

Power Fx

```
//Button will be visible for accounts with Account Rating > 20
Self.Selected.Item.'Account Rating'>20
```

Navigate

> **Note**
>
> For additional options, see the client API reference to use JavaScript. More information: navigateTo (Client API reference)

Navigate to a custom page

To navigate to a custom canvas page within a model-driven app, pass the page name as the first argument.

Power Fx

```
Navigate( myCustomPage )
```

Navigate to the default view of the table

To navigate to the default view of the table, pass the table name as the first argument.

Power Fx

```
Navigate( Accounts )
```

Navigate to specific system view of the table

To navigate to a specific system view of the table, pass the table's `Views` enum.

Power Fx

```
Navigate( 'Accounts (Views)'.'My Active Accounts' )
```

Navigate to the default form of the table

To navigate to the default form of the table, pass the record as the first argument.

Power Fx

```
Navigate( Gallery1.Selected )
```

Navigate to the default form of the table in create mode

To navigate to the default form of the table, pass a Dataverse record created from the Defaults function. This opens the default form with the record as a new record. The **Defaults** function takes the table name to create the record.

Power Fx

```
Navigate( Defaults( Accounts ) )
```

Optimize the user experience with data source and record information

Use the **DataSourceInfo** function and **RecordInfo** function to optimize the user experience with information about the data being displayed and manipulated.

For example, use **RecordInfo** to determine if the current user has permission to modify a record and appropriately show or hide an "Edit" button using its **Visible** property:

Power Fx

```
EditButton.Visible =
   RecordInfo( Gallery1.Selected, RecordInfo.EditPermission )
```

For example, use **DataSourceInfo** to determine if the current user has permission to create a record and appropriately show or hide a "Create" button using its **Visible** property:

Power Fx

```
CreateButton.Visible =
   DataSourceInfo( Accounts, DataSourceInfo.CreatePermission )
```

Ask for confirmation before taking action

Use the **Confirm** function to display a dialog box on top of the current screen.

Power Fx

```
Notify( Confirm( "Are you sure?",
                 { ConfirmButton: "Yes", CancelButton: "No" }
        )
)
```

Displays a notification **true** if the **Yes** button is pressed, and a notification **false** if the **No** button is pressed.

Notify the user

A notification can be shown to app users by calling the Notify function.

> **Note**
>
> `NotificationType.Success` isn't currently supported and results in an informational notification type.

Power Fx

```
Notify( "Model-driven app notification message" )
```

Other examples

Launch a URL

PowerApps Formula

```
Launch("https://www.bing.com");
```

Access 1:N property

PowerApps Formula

```
Self.Selected.Item.'Recurring Appointments'
```

Check property of a related record

PowerApps Formula

```
Self.Selected.Item.'Parent Account'.'Account Name'="parent"
```

Functions available with commanding

For information about the formulas supported with commanding in model-driven apps, go to Formula reference - model-driven apps.

Functions not supported

The following Power Fx functions are *currently not supported* with commanding in model-driven apps.

- Back()
- Clear()
- Collect()
- Copy()
- Disable()
- Enable()
- Exit()
- InvokeControl()
- Language()
- LoadData()
- Param()
- Print()
- ReadNFC()
- RequestHide()
- ResetForm()
- Revert()
- SaveData()
- ScanBarcode()
- Set()
- SubmitForm()
- UpdateContext()
- User()
- ViewForm()

Enums not supported

- Align
- AlignInContainer
- BarcodeType
- BorderStyle
- Color
- Direction
- DisplayMode
- Font
- FontWeight
- FormPattern
- GridStyle
- ImagePosition

- ImageRotation
- LabelPosition
- Layout
- LayoutAlignItems
- LayoutDirection
- LayoutJustifyContent
- LayoutMode
- LayoutOverflow
- ListItemTemplate
- MapStyle
- Overflow
- PDFPasswordState
- PenMode
- RemoveFlags
- ScreenTransition
- TeamsTheme
- TextFormat
- TextMode
- TextPosition
- Themes
- Transition
- VerticalAlign
- VirtualKeyboardMode
- Zoom

Other unsupported areas

- Acceleration
- App
- Compass
- Connection
- Dataverse file type columns
- Environment
- Host
- Layout
- Location
- ScreenSize

Formula reference

Overview of Power Fx

Open custom pages as dialogs and use cloud flows

The sample in this article demonstrates how you can build simple custom pages that open as dialogs when a command is selected. You might also call a cloud flow from the custom page dialog.

Prerequisites

- Add a custom page to your model-driven app
- Optionally trigger a cloud flow from the custom page

Create a command

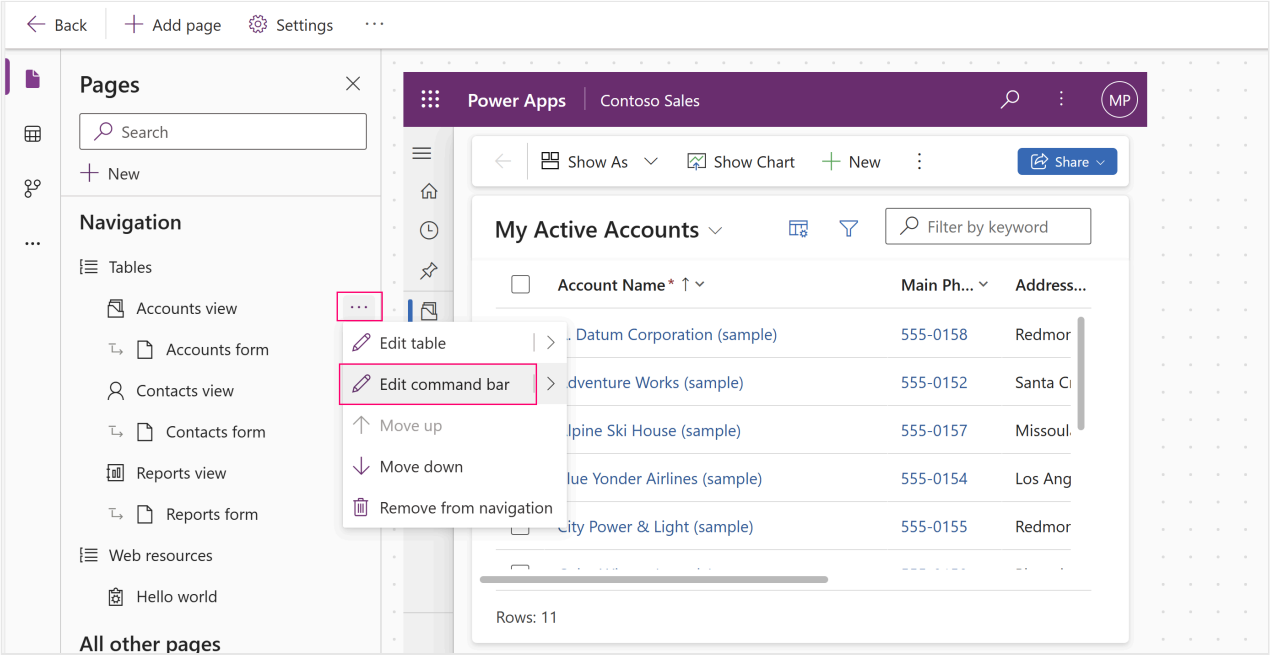
First, you need to determine the table and command bar location to place the command.

1. Open the app designer, and then add the desired table to your model-driven app. More information: Build your first model-driven app

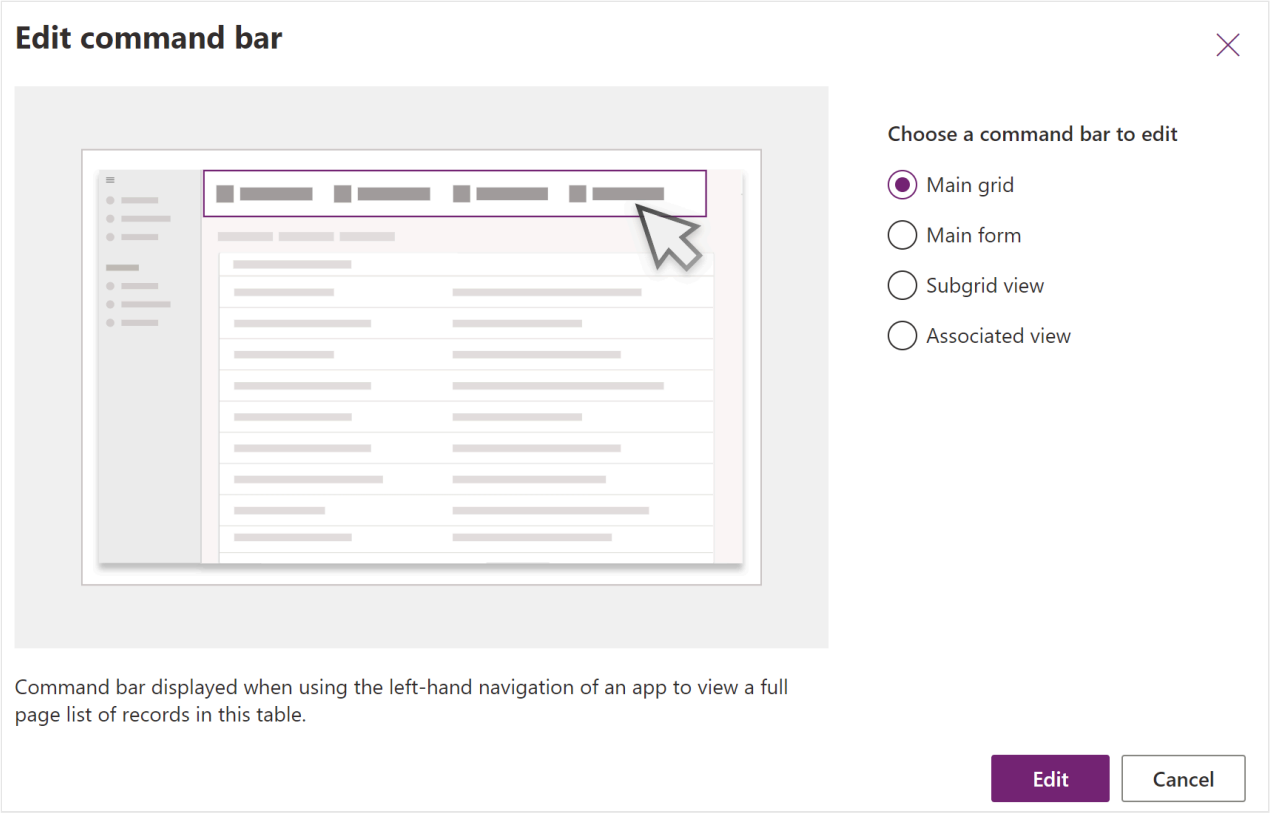
2. Publish the app.

3. Select the desired table view from the **Pages** area in the app designer.

4. Select **...** (ellipsis), and then select **Edit command bar**.



5. Select the location of the command bar you want, and then select **Edit**. More information: Command bar locations



6. Select + **New** on the command designer command bar, and then enter the command properties. More information:

   - Create a JavaScript web resource for your command.
   - For other properties, see Create a new command.

Create a JavaScript web resource for your command

> **Note**
>
> This commanding customization currently supports only JavaScript. Power Fx isn't supported.

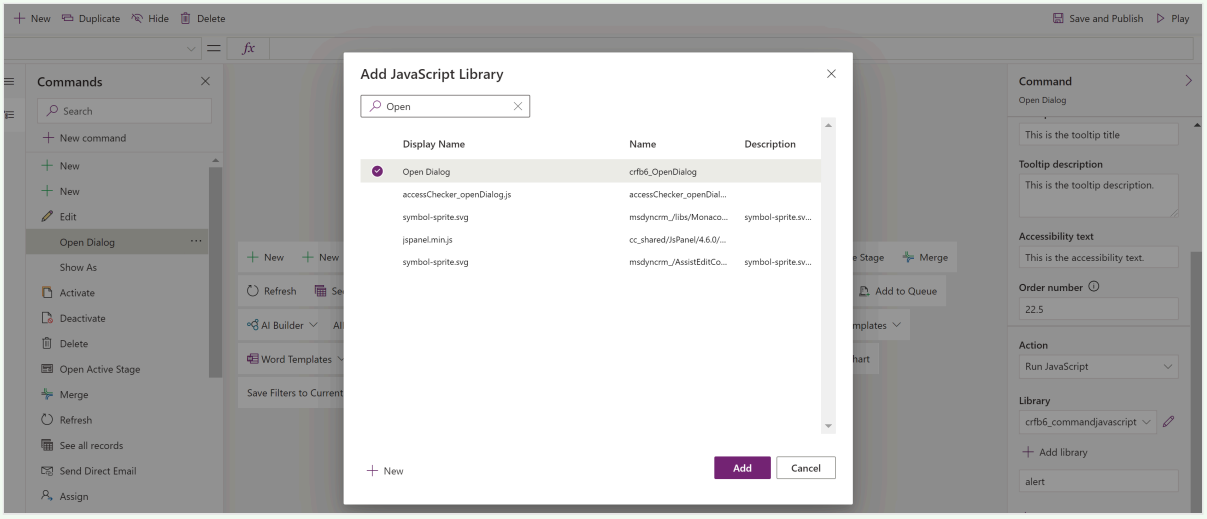
1. For the command properties **Action**, select **Run JavaScript**.
2. Select + **Add library**.
3. On the **Add JavaScript Library** list, select + **New web resource** to create a new JavaScript web resource.
4. On the **New web resource** pane, enter a **Name**, and optionally a **Display name** and **Description**.
5. For **Type**, select **JavaScript (JS)**.

6. In the **Code** box, paste your JavaScript. For example, depending on the type of dialog you want to use, copy and paste an example from the Navigate API reference .
7. Select **Save and publish** to save and publish the web resource.
8. Close the browser window tab to return to the command designer.

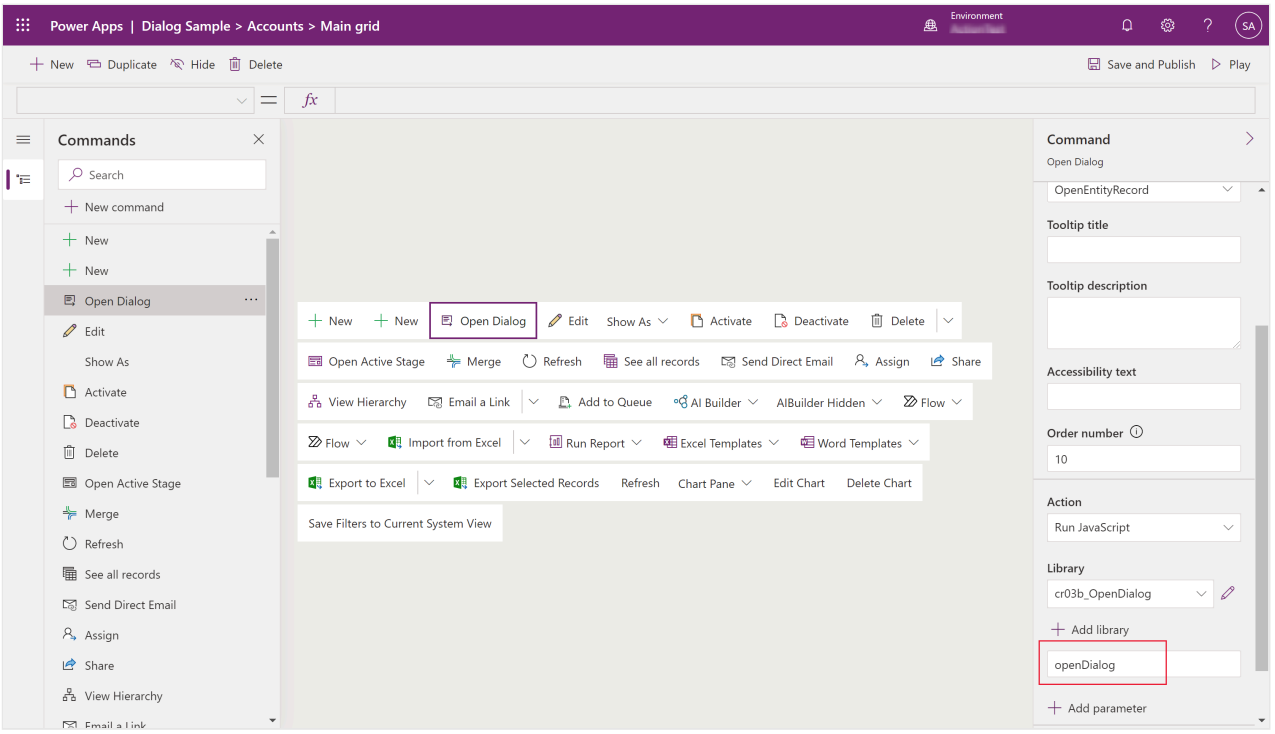
Call the JavaScript from your command

1. In the **Add JavaScript Library** dialog, select the library (web resource) you created in the previous steps, and then select **Add**.

> **Tip**
>
> If you can't find the web resource, enter the name in the **Search** box.



2. In the **Command** properties pane, if the name isn't specified, enter the name of the JavaScript **Function**. In this example, *openDialog* is entered.



3. Optionally, change the **Visibility** logic.

4. Select **Save and Publish**.

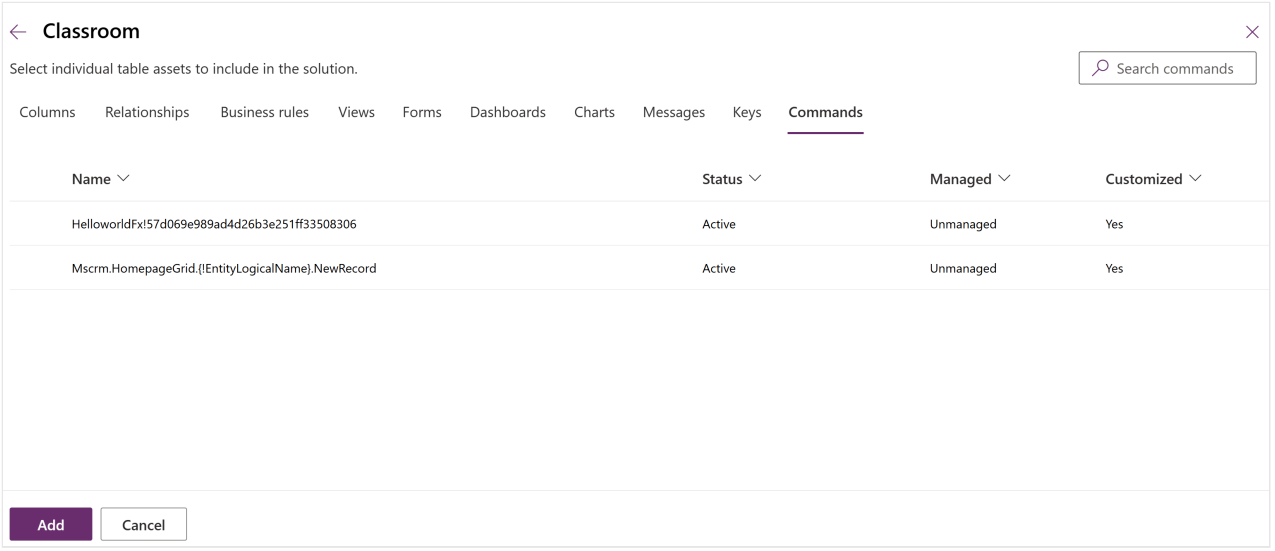
Manage commands in solutions

Article • 04/10/2025

Unlike classic commands, modern commands are treated the same as other solution objects and support core solution behaviors. You can also edit existing modern commands from within a solution.

To add commands to a solution, you add the solution objects that depend on your command actions:

- Modern commands are a table component. When you add a command to a solution, you must add the command component. In this screenshot there's one JavaScript and one Power Fx command for the custom Classroom table that can be added as a specific object to a solution for export.



- Power Fx commands use a Dataverse component library. Add the component library to your solution if you plan to export it.
- JavaScript commands use a web resource. Add the web resource that includes the underlying JavaScript to run your command to the solution if you plan to export it.

More information: Add an existing component to a solution

Modern commanding provides these benefits when you work with solutions:

- Block commands from being customized by using managed properties. Open the table, select **Commands**, select the command, and then on the command bar select **Advanced** > **Managed properties** to disable **Allow customizations**.
- View dependencies related to your modern command components. More information: View dependencies for a component in Power Apps
- Troubleshoot by viewing which solutions modified the component and when using solution layers. More information: Solution layers

- Remove any unmanaged customizations if in an unhealthy state. More information: Remove an unmanaged layer
- Segment solutions and build minor updates or patches that include your modern command components.
- Modern command components work with solution upgrade so you can delete components by importing a new version. Upgrade or update a solution
- Standardized localization via export/import translations. More information: Translate label text

Solutions overview

Scopes for modern commands

Article • 11/16/2022

Commands have one of three scopes. The scope determines whether a command (`schemaname = appaction`) will render for a table within a single app, for a table across all apps, or for all tables and all apps.

A command must be bound to a command bar location such as main grid or main form regardless of scope. Therefore, changing the scope will not render the command in different command bar locations such as main grid and main form.

- **App** This is the narrowest scope and **default behavior** when creating or editing commands using the modern command designer. Command designer is opened within the context of a model-driven app, table, and command bar location.
- **Table** Also known as entity scope. Bound to a specific table and command bar location. Not bound to any specific app. Therefore table scoped commands will render in all apps that use the table. For example, a table scope command for the account table and main form location will be present in all apps when viewing the main form for an account record.
- **Global** This is the broadest scope. Global scope commands are only bound to a command bar location, not an app or table. For example, a global scope command for the main form location is present in all apps within an environment when viewing the main form for every table.

> **ⓘ Important**
>
> Commands using Power Fx for the action and/or visibility can't be converted to table or global scope at this time.
>
> When commands are nested within dropdown lists, groups, and split buttons, all must be set to the same scope.

If a global or table scope command is edited within modern command designer, a copy (instance) is created with app scope and linked to the original command. For example, editing a global scope command in command designer overrides the original global scope command but only for the specific app and table chosen when opening command designer. All other apps and tables will will render the original command. The copy (instance) now has it's own lifecycle. Changes to the original global scope command will not effect the new app scope instance and vice versa.

Override table and global scoped commands

More narrow scopes can override a broader scope command at every level. The most narrow scope wins.

- A **table (entity) scoped** command overrides global scoped commands. You can define a command that will be the same across all tables, but modify the behavior only for specific tables.
- An **app scoped** command overrides all other scopes but only for a particular app and table.

How to create a table scope command

1. Create one or more commands within your solution using command designer. Alternatively, create a separate solution and select **Add existing** > **Table**.
2. Choose **Select objects**, and then add the desired commands.
3. Select **Export** to export your solution.

4. If you've made recent changes that haven't yet been published, select **Publish**. Then, select **Run** to check whether the solution has any issues or dependencies, and then select **Next**.
5. Select the **Unmanaged** option, and then select **Export**.
6. In the **Download** dialog box, select **Save**, and in the **Download complete** dialog box, select **Open Folder**.
7. Right-click to select the compressed .zip file that you downloaded, and then select **Extract All**.
8. Select a location to extract the files to, and then select **Extract**.
9. Open the folder to the extracted files, open the appaction.xml file, and find the desired command (appaction).
10. Delete the **appmoduleid** node from the xml.

```
XML
```

```
<appmoduleid>
  <uniquename>demo_DemoFestApp</uniquename>
</appmoduleid>
```

11. Change the value of the **appaction uniquename**. Changing any one of the last characters is sufficient, such as from 1 to 2, or you can use more descriptive naming conventions if desired.

Example XML.

XML

```
   <appaction
uniquename="crdff_NewCommand!a078463b5d7c473d8965f0f80469f412!crdff_CustomAp
p!crdff_entity1!1">
  <buttonlabeltext default="Show Alert">
    <label description="Show Alert" languagecode="1033" />
   </buttonlabeltext>
   <buttonsequencepriority>10.0000000000</buttonsequencepriority>
   <context>1</context>
   <contextentity>
    <logicalname>crdff_entity1</logicalname>
   </contextentity>
   <fonticon>AALinkedInLogo</fonticon>
   <contextvalue>crdff_entity1</contextvalue>
   <hidden>0</hidden>
   <iscustomizable>1</iscustomizable>
   <location>1</location>
   <name>EntityScoped!a078463b5d7c473d8965f0f80469f412</name>

<onclickeventjavascriptfunctionname>ShowAppAlert</onclickeventjavascriptfunc
tionname>
   <onclickeventjavascriptparameters>[]</onclickeventjavascriptparameters>
   <onclickeventjavascriptwebresourceid>
    <webresourceid>ac21ad24-3c11-ef11-b6u7-000d3a1d942c</webresourceid>
   </onclickeventjavascriptwebresourceid>
   <onclickeventtype>2</onclickeventtype>
   <statecode>0</statecode>
   <statuscode>1</statuscode>
   <type>0</type>
   </appaction>
```

After you've edited and saved the appaction.xml file, zip your solution in the same format it was exported in. Then **Import** the solution back into your environment and test the behavior.

How to create a global scope command

1. Follow the same steps above to edit the appaction.xml file.

2. **Delete** the **appmoduleid** node from the xml:

```
XML

 <appmoduleid>
   <uniquename>demo_DemoFestApp</uniquename>
 </appmoduleid>
```

3. Change the value of the **appaction uniquename**. Changing any one of the last characters is sufficient, such as from 1 to 2, or you can use more descriptive naming conventions if desired.

4. **Delete** the **contextentity** and **contextvalue** nodes from the xml:

```
XML

<contextentity>
 <logicalname>account</logicalname>
</contextentity>
<contextvalue>account</contextvalue>
```

5. Change the **context** value from 1 to 0.

```
XML

<appaction uniquename="crdff_NewCommand1!8fe72a85-1f84-431e-ac56-
854f1bfadc4e!1">
<buttonlabeltext default="Show Alert">
<label description="Show Alert" languagecode="1033" />
</buttonlabeltext>
<buttonsequencepriority>10.0000000000</buttonsequencepriority>
<context>0</context>
<hidden>0</hidden>
<iscustomizable>1</iscustomizable>
<fonticon>AALinkedInLogo</fonticon>
<location>1</location>
<name>EntityScoped!a078463b5d7c473d8965f0f80469f412</name>
<onclickeventjavascriptfunctionname>ShowGlobalAlert</onclickeventjavasc
riptfunctionname>
<onclickeventjavascriptparameters>[]</onclickeventjavascriptparameters>
<onclickeventjavascriptwebresourceid>
 <webresourceid>ac21ad24-3c01-ec11-b6e7-000d3a1d942c</webresourceid>
</onclickeventjavascriptwebresourceid>
<onclickeventtype>2</onclickeventtype>
<statecode>0</statecode>
<statuscode>1</statuscode>
<type>0</type>
</appaction>
```

After you've edited and saved the appaction.xml file, zip your solution in the same format it was exported in. Then **Import** the solution back into your environment and test the behavior.

How to override a global scope command with a table scope

This example is for when you want a global scope command to be the same everywhere *except* for a certain table.

- **Entity Scoped Action** will be visible on `crdff_entity1` grids in all apps except in `crdff_CustomApp`.
- **Global Scoped Action** will be visible on all the entity grids except `crdff_entity1`.

> ⓘ Note
>
> To override either global or table scope commands with an app scope command, simply edit the command using command designer.
>
> To override a global scoped command with a table scope command, modify the appactions.xml files so they have the same `XML <name>` .

Steps to override

1. Follow the steps in How to create a global scope command, but create two commands using command designer.
2. As described in the steps, export your solution and edit the appactions.xml files.
3. Continue following the steps to create one global and one entity scope command.
4. Set the **name** property to be the exact same for both the global and entity scope commands.

Example global scope command XML

XML

```
<appaction uniquename="crdff_NewCommand1!8fe72a85-1f84-431e-ac56-
854f1bfadc4e!1">
```

```
<buttonlabeltext default="Show Alert">
 <label description="Show Alert" languagecode="1033" />
</buttonlabeltext>
<buttonsequencepriority>10.0000000000</buttonsequencepriority>
<context>0</context>
<hidden>0</hidden>
<iscustomizable>1</iscustomizable>

Modern commanding known limitations

This article describes the known limitations with modern commanding for model-driven apps.

Power Fx and command component libraries limitations

Power Fx shares certain infrastructure with custom pages and canvas apps. Relevant limitations of custom pages also apply to commands.

- Not all Power Fx functions are currently supported for commands.
- Microsoft Dataverse is currently the only supported data source when using Power Fx with commands. However, custom pages can be used for connecting to external data.
- To add additional tables, open the command component library from command designer. Or you can reopen command designer by selecting a different table in app designer.
- When you write Power Fx formulas in the command designer, IntelliSense might sometimes provide recommendations for unsupported functions. It might not show an error for unsupported functions within command designer or the associated command component library.
- Commands and the command component library created from one app can't be added to different apps. However, you can copy the command and paste it within another app or command bar location.
- Not all out-of-the-box or custom visibility rules from classic commands are currently supported in Power Fx. Classic visibility is supported without using Power Fx. This is needed to migrate classic commands to modern and classic rule formats but won't be exposed in command designer. However, classic visibility is exposed within solution files and Dataverse.
- To delete command component libraries, you must delete the app. Alternatively, you can delete the associated record within the model-driven app element table, then delete the component library. The model-driven app element record exists in Dataverse but isn't exposed in solutions. More information: Delete a Model-Driven App Element record
- Power Fx based commands aren't supported and won't run within the Dynamics 365 app for Outlook or a model-driven app that's hosted within a Portal.
- Metadata changes for attributes might not reflect in the Power Fx expression. To update the metadata, open the component library using command bar actions in command

designer. In Power Apps Studio for canvas apps select **Data sources**, select the data source, and then refresh. This action updates the metadata for the component library.

Command designer limitations

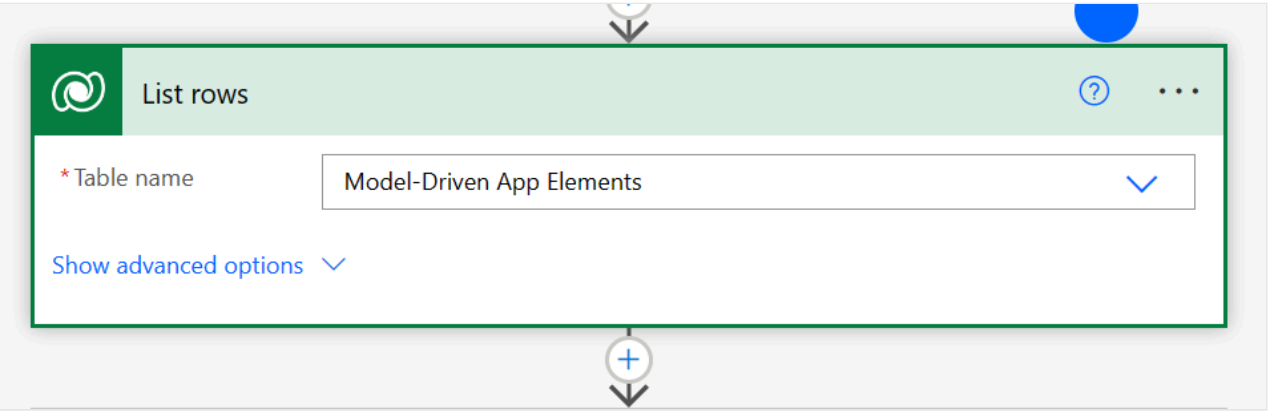
- Pre-existing classic commands can't be customized within the command designer until they're migrated to the modern infrastructure. This includes the out-of-the-box commands, which will be migrated incrementally over time. You can continue to use other mechanisms and third-party tools for customizing classic commands.
- Dynamically populated buttons aren't supported. We recommend creating them declaratively.
- Global application header and dashboard command bars aren't currently supported in command designer. These are customized infrequently. Share feedback if you find this valuable to prioritize.
- A single Power Fx component library is supported. The command designer might display the error message: "Unable to initialize component manager. There are multiple component libraries associated with your app." This error occurs when an app has multiple duplicate component libraries associated with it, which currently isn't supported with model-driven apps. To resolve this limitation, remove the additional `AppElement` entries for the app. Do this by removing the multiple library dependencies with the app, ensuring that only one `AppElement` entry exists.
- Editing commands on the commands page from the **Solutions** or **Tables** areas in Power Apps (make.powerapps.com) doesn't have the capability to set `Run formula` as the action or `Show on condition from formula` as the visibility rule. These capabilities are only available when editing commands from within the modern app designer.

Delete a model-driven app element record

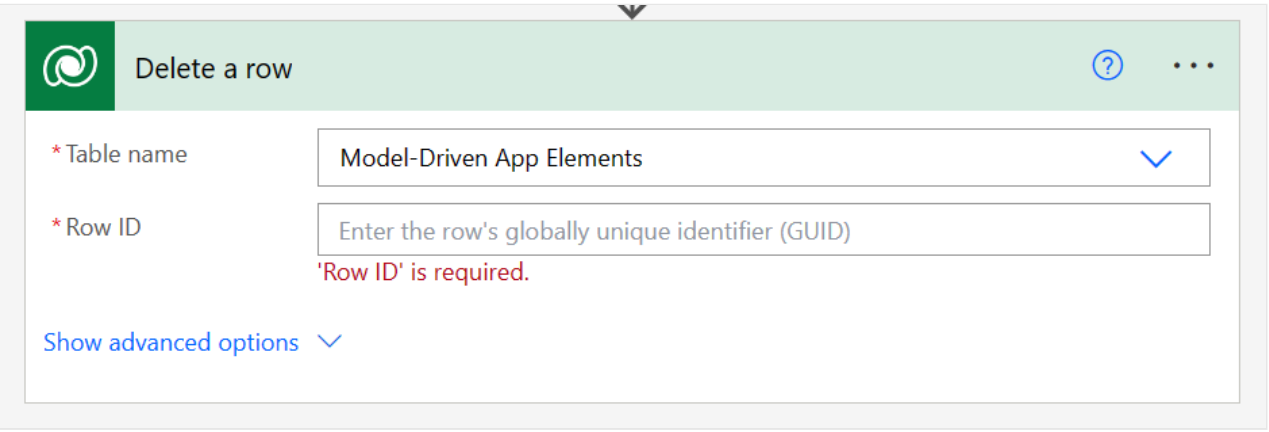
> **⚠ Warning**
>
> If the app includes Power Fx-based commands, they stop working after you delete the app's model-driven app element table record.

Using the **Model-driven App Elements** table, complete the following steps:

1. Create a flow to get a list of rows. More information: Get a list of rows



2. Then, run the flow to find the **Row id unique** value for the row you want to delete and copy it. You can also find this row value by viewing the table rows in the table hub for the Model-driven App Element table at make.powerapps.com.
3. Create a step to delete the row by using the unique ID value you copied in the previous step. More information: Delete a row.



4. Publish the model-driven app associated with the model-driven app element record.

Design model-driven apps using the classic app designer

Summarize this article for me

With Power Apps, model-driven apps are comprised of components such as tables, forms, views, dashboards, and business process flows.

As model-driven apps have evolved so too have the ways in which the various elements are edited. This article describes the method of creating an app using the classic app designer.

> **Important**
>
> This article describes how to use the classic app designer. Use the modern app designer to build your apps. More information: Create a model-driven app using the app designer

The app designer helps all these components to be brought together quickly. Its tile-based information structure and simplified interface make the process of building an app much easier, and apps that are specific to business roles and functions can be brought together without having to write any code.

Each app that you create can have its own site map with the integrated and easy-to-use site map designer. Just drag and drop areas, group, and subareas to the canvas. Components that you select in the site map are also added as tables in the app designer.

Tables can be added and removed as necessary, and also add other components.

Once components have been added, the app can be validated to confirm that all components have been added correctly.

The following table shows the steps required to create an app and assumes that all the necessary tables, forms, views, dashboards and relationships have been created within the environment in advance.

Expand table

Step	Description	Related topics
1	Define app properties.	Create or edit an app
2	Define navigation for an app using the site map designer.	Create a site map for an app

Step	Description	Related topics
3	Apps are composed of components like dashboards, tables, business process flows, forms, views, and charts. Include the required ones in your app by using the app designer.	Add or edit app components
4	Check the app for any required components that have not been added. After all required components are added make the app available for use.	Validate and publish an app
5	Give users access to the data within the apps created by using security roles.	Share a model-driven app

Supported web browsers

For information about the supported web browsers to use with the app designer and site map designer, see Supported web browsers and mobile devices.

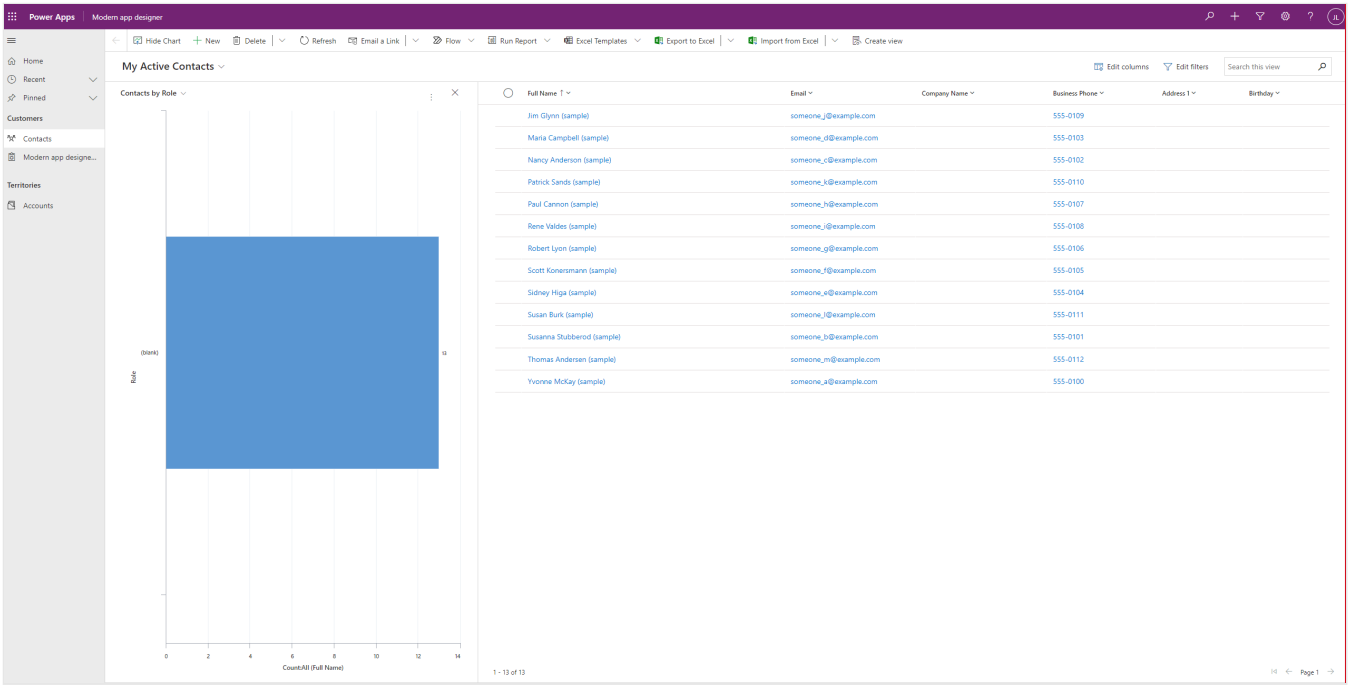
Build your first model-driven app from scratch

Last updated on 02/13/2026

Build your first model-driven app using the classic designer

> **Important**
>
> Starting in October 2023, the classic app, form, and view designers are deprecated and all model-driven apps, forms, and views will only open in the modern designers. By default, the **Switch to classic** command to revert back to the classic designer from the modern designer will no longer be available. More information: Classic app, form, and view designers are deprecated
>
> We recommend that you transition to use the modern designers to create and edit your model-driven apps and components.

In this article, you build a straightforward model-driven app that you can use to create, update, and delete account records as well as view data in one of the standard charts for the account table.

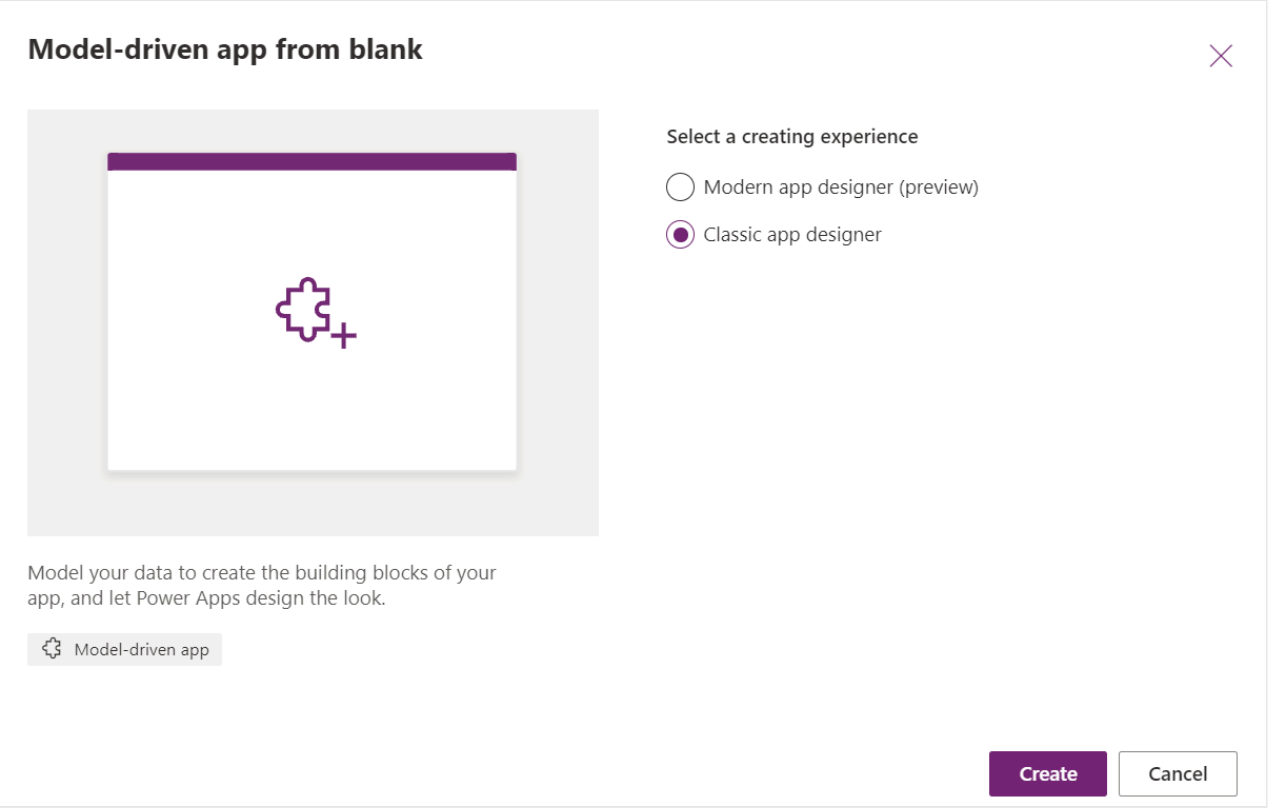


Create your model-driven app

> **Note**
>
> If you plan to share and distribute the app you create, see this article: Create a model-driven app by using the app designer

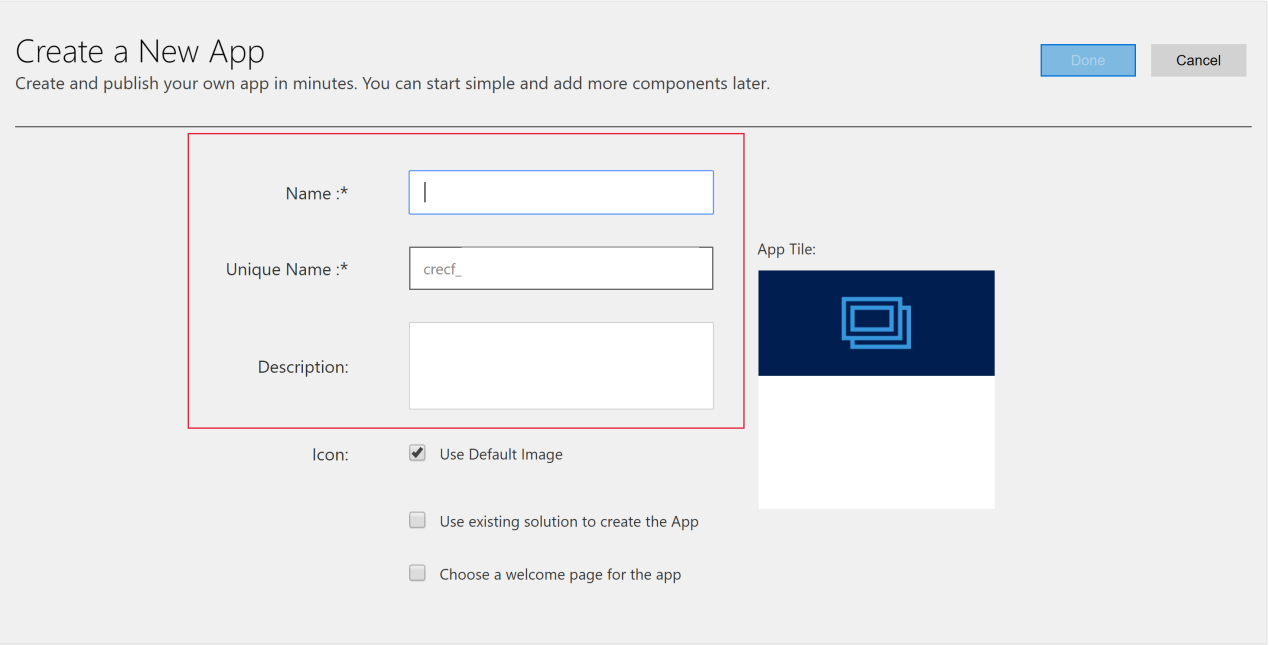
1. Sign in to Power Apps. If you don't already have a Power Apps account, you can get started free.

2. On the **Home** page, select **Blank app**, under **Blank app based on Dataverse** select **Create**. Select the **classic app designer** option and then **Create**.

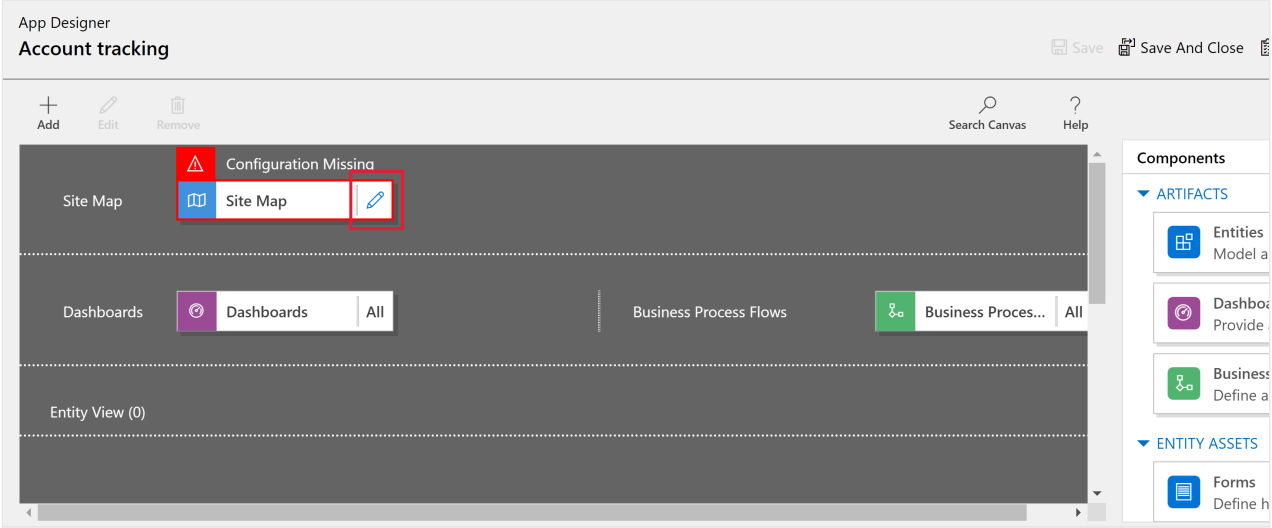


3. On the **Create a New App** page, enter the following details, and then select **Done**:

- **Name**: Enter a name for the app, such as *Account tracking*.
- **Unique Name**: By default, the unique name uses the name you specify in the **Name** box without spaces and preceded by the publisher prefix and an underscore (_). For example, *crecf_Accounttracking*.
- **Description**: Type a short description of what the app is or does, such as *This is my first app*.



4. Select the **Open the Site Map Designer** edit button (pencil icon) to open the sitemap designer.

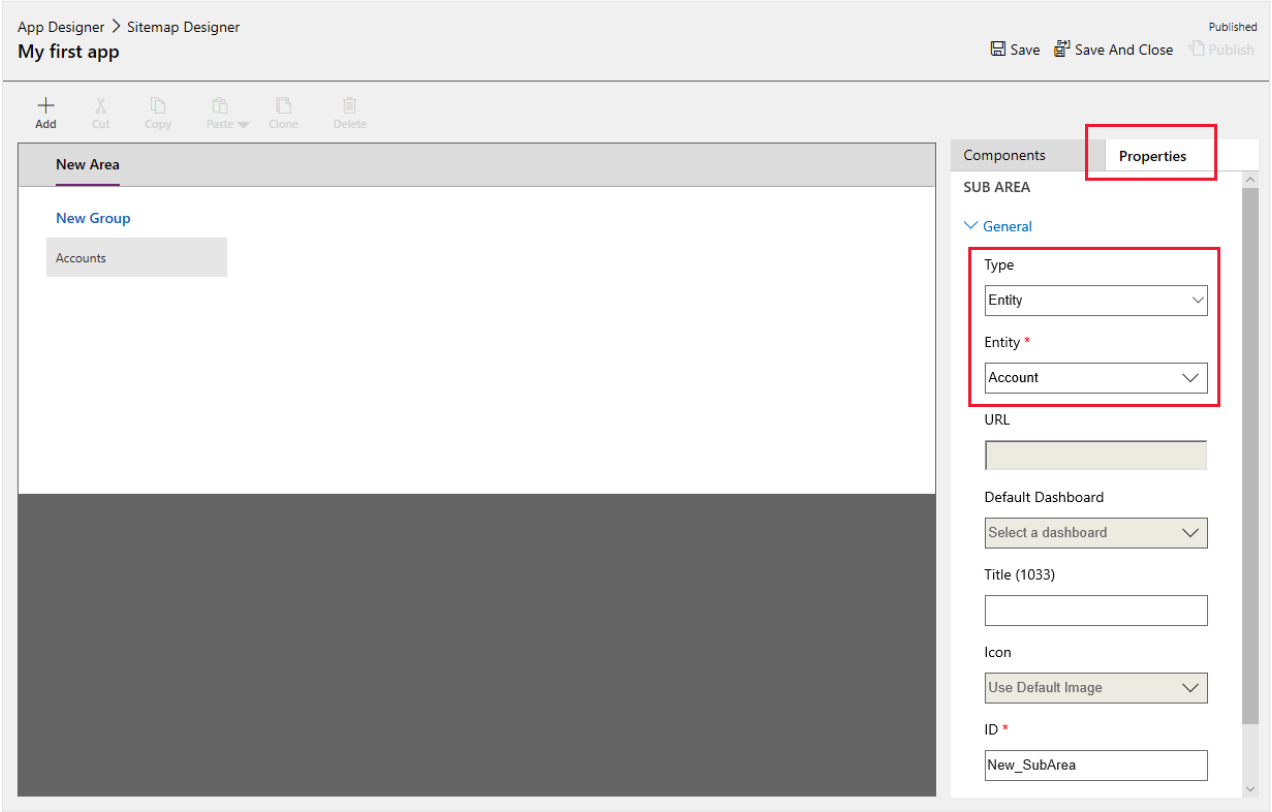


Notice that when you create a new app, you must first create the site map for it.

5. On the sitemap designer, select **New Subarea**.

6. In the right pane, select the **Properties** tab, and then select the following properties.

- **Type**: **Entity**
- **Entity**: **Account**



When you leave the **Title** property blank, the app uses the table name in the app's left navigation pane. For this app, **Accounts** will be displayed in the app at runtime.

7. Select **Save And Close** to close the sitemap designer.

   By default, all the account table's forms, views, charts, and dashboards are enabled for the app. From the app designer **Components** tab on the right pane, you can clear a component so it isn't available in the app at runtime. You can also create new components, such as a custom form. For this app, leave all components enabled.

8. On the app designer toolbar, select **Save**.

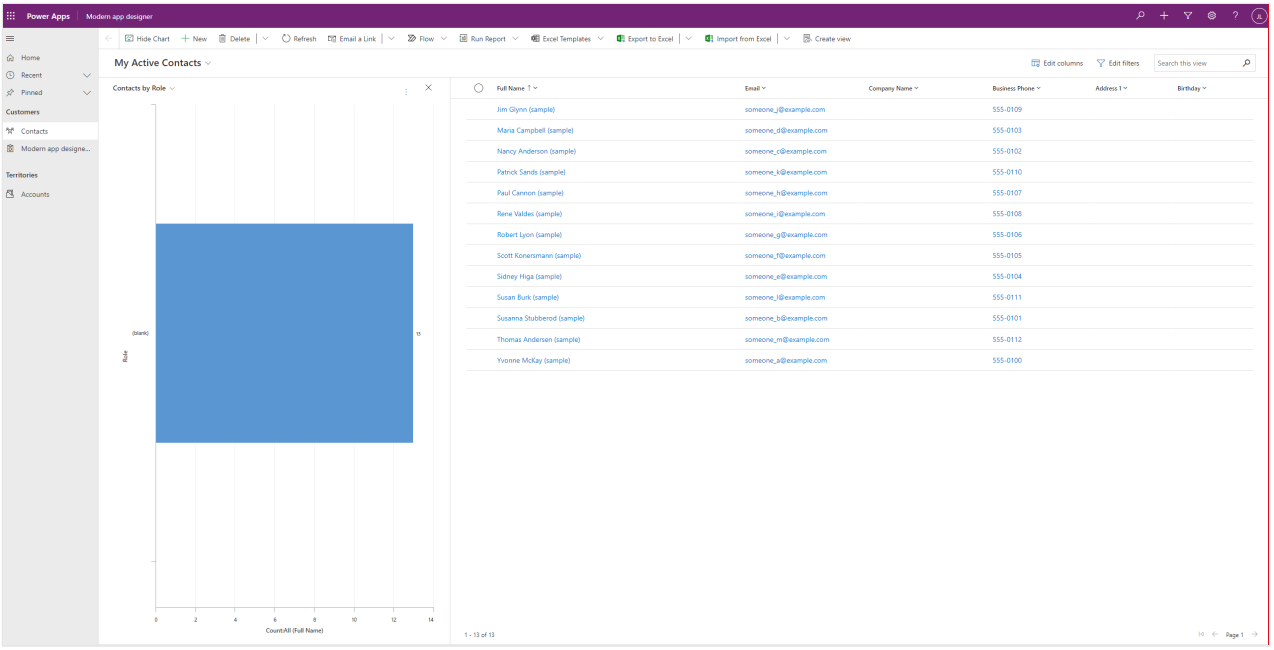
9. After your app is saved, on the app designer toolbar, select **Publish** to make it available to run and share.

Play your app

On the app designer toolbar, select **Play**.

- To create a record, select **+ New**.
- To view a chart, on the app command bar select **Show Chart**.

- To change the view, select the **My Active Accounts** view, and then select the view you want.



To learn more about how to use your app, see Basic navigation in a model-driven app.

> **Note**
>
> Don't see any of the data in your app like in the above screenshot? This is probably because your environment database doesn't have **Deploy sample apps and data** provisioned. More information: Create an environment with a database

Next steps

In this article, you built a simple model-driven app.

- To identify the URL of your model-driven app see Run a model-driven app in a browser
- To see how your app looks when you run it, see Run a model-driven app on a mobile device.
- To learn how to share your app, see Share a model-driven app.
- To get started and learn more about building model-driven apps, see Understand model-driven app components

Create a model-driven app using the classic app designer

Article • 11/06/2024

This article describes the basics of creating and editing a model-driven app that can be shared and distributed to other environments.

> **Important**
>
> Starting in October 2023, the classic app, form, and view designers are deprecated and all model-driven apps, forms, and views will only open in the modern designers. By default, the **Switch to classic** command to revert back to the classic designer from the modern designer will no longer be available. More information: Classic app, form, and view designers are deprecated

Prerequisites to creating model-driven apps

Verify the following prerequisites before creating an app:

- A Power Apps environment used for app development must exist within the tenant. More information Create an environment and Environment strategy for ALM.
- The environment used will need to have a Dataverse database associated with it. Dataverse environments can exist with or without a database and generally these are provisioned on creation of the environment. The database holds the tables and other components that will be used by the model-driven app. Create and manage environments in Dataverse
- Within the environment the app developer needs to have an environment maker, system administrator, or system customizer security role. More information: About predefined security roles

Create a model-driven app

1. Sign in to Power Apps.

2. Choose the environment by selecting the environment icon 

3. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

4. Open an unmanaged solution or create a new one. More information: Create a solution

5. Select **New** > **App** > **Model-driven app**.

6. There a two options. Modern app designer and Classic App designer. Select **Classic App Designer**.

7. On the **Create a New App** page, enter the following details:

    - **Name**: Enter a name for the app.

    - **Unique Name**: The unique name is automatically populated based on the app name that is specified. It's prefixed with a publisher prefix. It's possible to change the part of the unique name that's editable. The unique name can only contain English characters and numbers.

        > **Note**
        >
        > The publisher prefix is the text that's added to any table or column created for a solution that has this publisher.

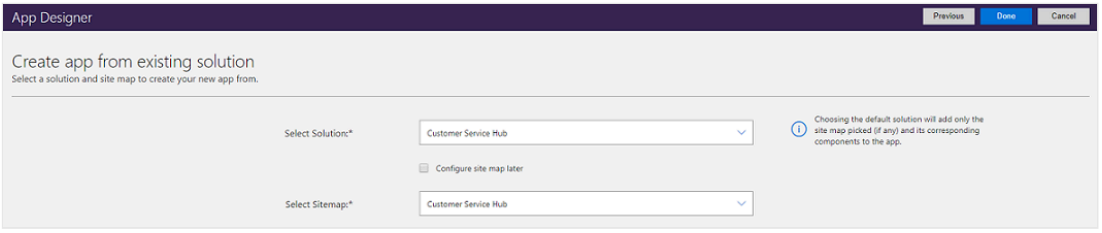
    - **Description**: Type a short description of what the app is or does.

    - **Icon**: By default, the **Use Default Image** check box is checked. To select a different web resource as an icon for the app, clear the check box, and then select an icon from the drop-down list. This icon is displayed on the preview

tile of the app. For more information about how to create a web resource, go to Create or edit model-driven app web resources to extend an app.

- **Use existing solution to create the App (Optional)**: Select this option to create the app from a list of installed solutions. When this option is selected, **Done** switches to **Next** on the header. If **Next** is selected, the **Create app from existing solution** page opens. From the **Select Solution** drop-down list, select a solution. If any site map is available for the selected solution, the **Select Sitemap** drop-down list will appear. Select the site map, and then select **Done**.

  > **Note**
  >
  > By selecting **Default Solution** when the site map is added, the components that are associated with that site map are automatically added to the app.



- **Choose a welcome page (Optional)**: This option allows a designer to select from the web resources available in your organization. The welcome pages created can contain information that's useful to users, such as links to videos, upgrade instructions, or getting started information. The welcome page is displayed when an app is opened. Users can select **Do not show this Welcome Screen next time** on the welcome page to disable the page so it doesn't appear the next time the app starts. Notice that the **Do not show this Welcome Screen next time** option is a user-level setting and can't be controlled by administrators or app makers. More information about how to create a web resource, such as an HTML file that can be used as a welcome page: Create and edit web resources to extend the web application

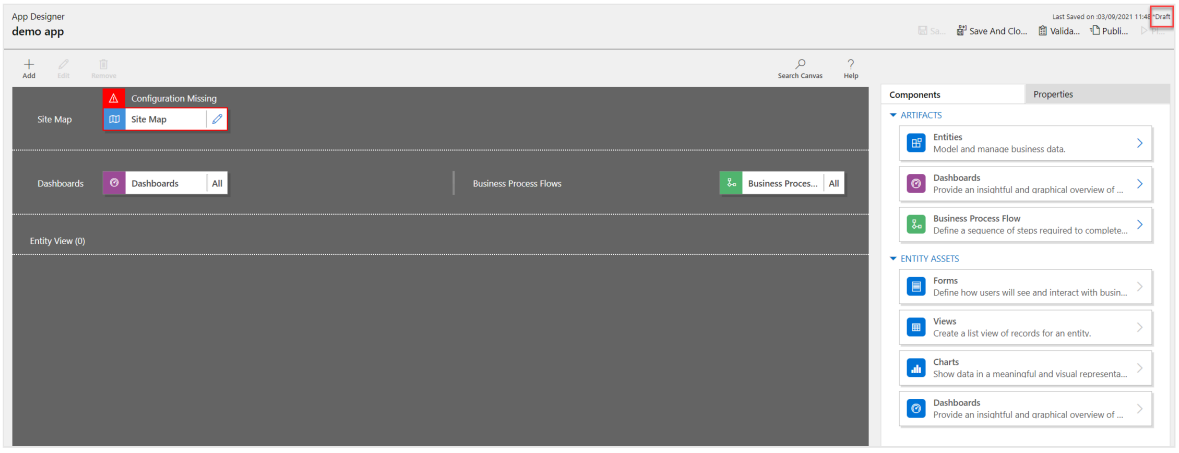
To edit app properties later, go to the **Properties** tab in the app designer. More information: Manage app properties

> **Note**

It is not possible to change the unique name and app URL suffix on the **Properties** tab.

8. Select **Done** or if **Use an existing solution to create the App** is selected, select **Next** to choose from the available solutions that were imported in the environment, then select **Done**.

9. A new app is created and is shown in **Draft** status. This is shown in the App designer.



> **Note**
>
> When opening the classic app designer, an error might appear similar to the image here. When this occurs, it doesn't impact the classic app designer functionality and you can close the error and continue editing the app. However, to avoid this issue, use the Modern app designer.
>
> >

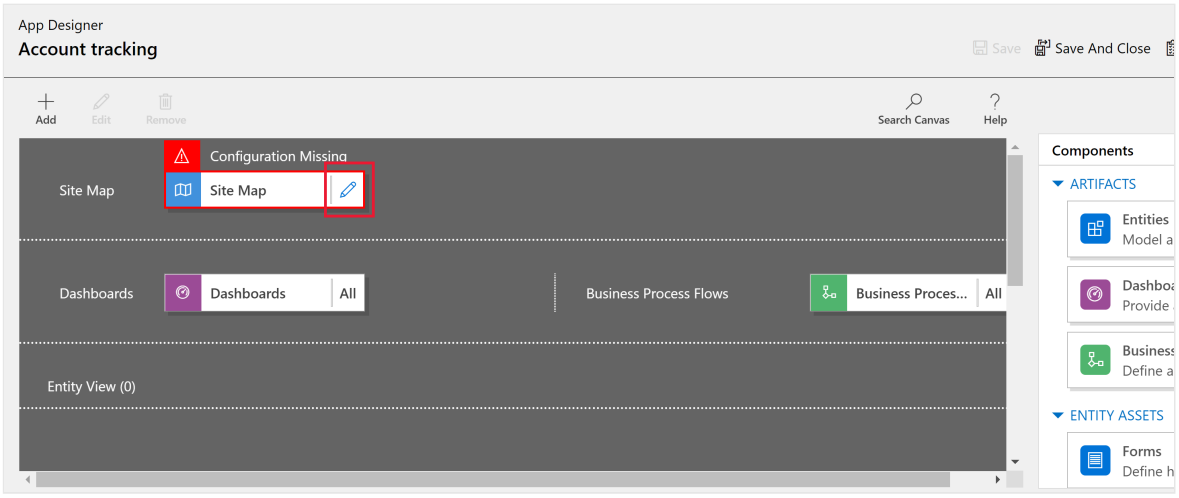
Configure the site map

The site map describes the components that make up a model driven app.

1. Select the **Open the Site Map Designer** edit button (pencil icon) to open the sitemap designer.

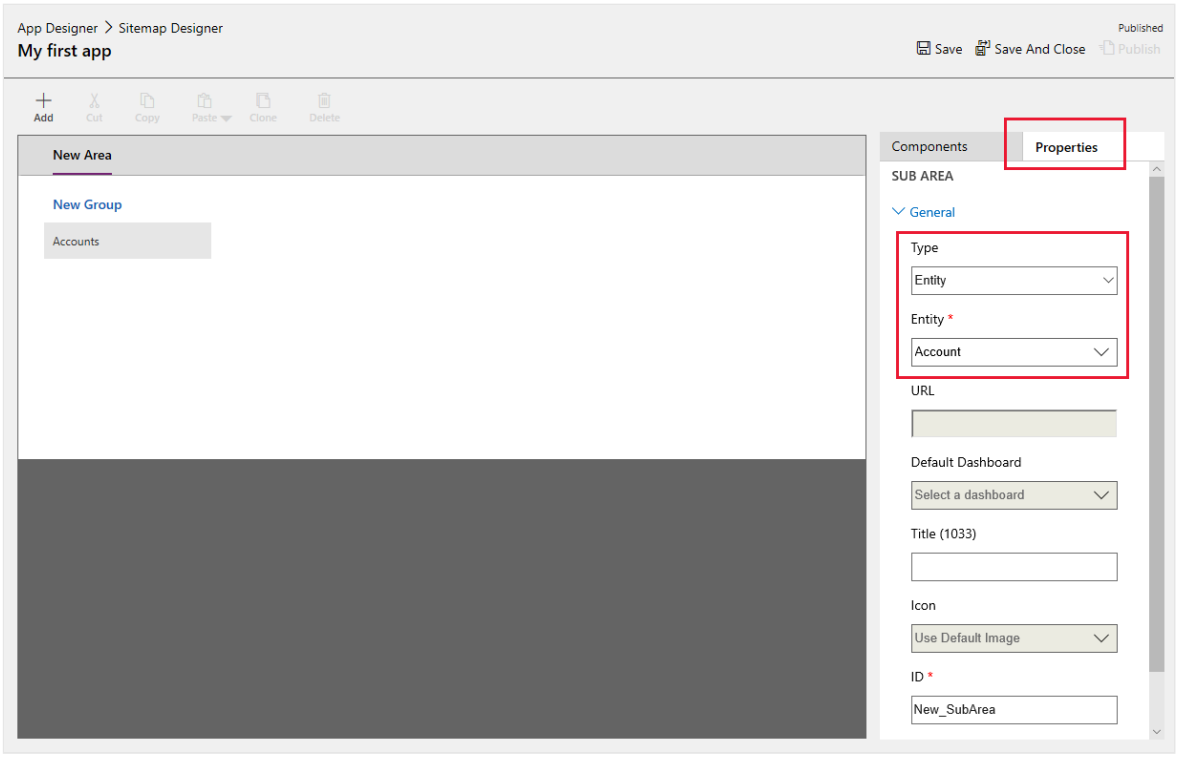


Notice that when an app is first created a site map must be configured for it.

2. On the sitemap designer, select **New Subarea**.

3. In the right pane, select the **Properties** tab, and then select the following properties.

- **Type**: **Entity**
- **Entity**: **Account**

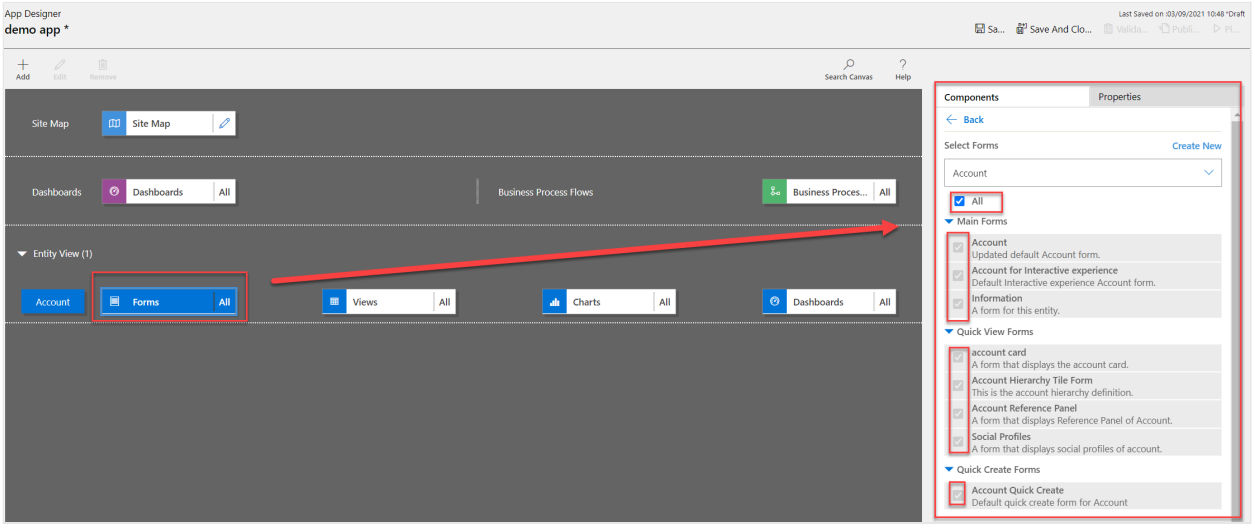


When the **Title** property is left blank, the app uses the table name in the app's left navigation pane. For this app, **Accounts** will be displayed in the app at runtime.

4. Select **Save And Close** to close the sitemap designer.

Finalizing the app

By default, all the account table's forms, views, charts, and dashboards are enabled for the app. From the app designer **Components** tab on the right pane, components can be cleared so that they aren't available in the app at runtime. It's also possible to create new components, such as a custom form. For this app, leave all components enabled.



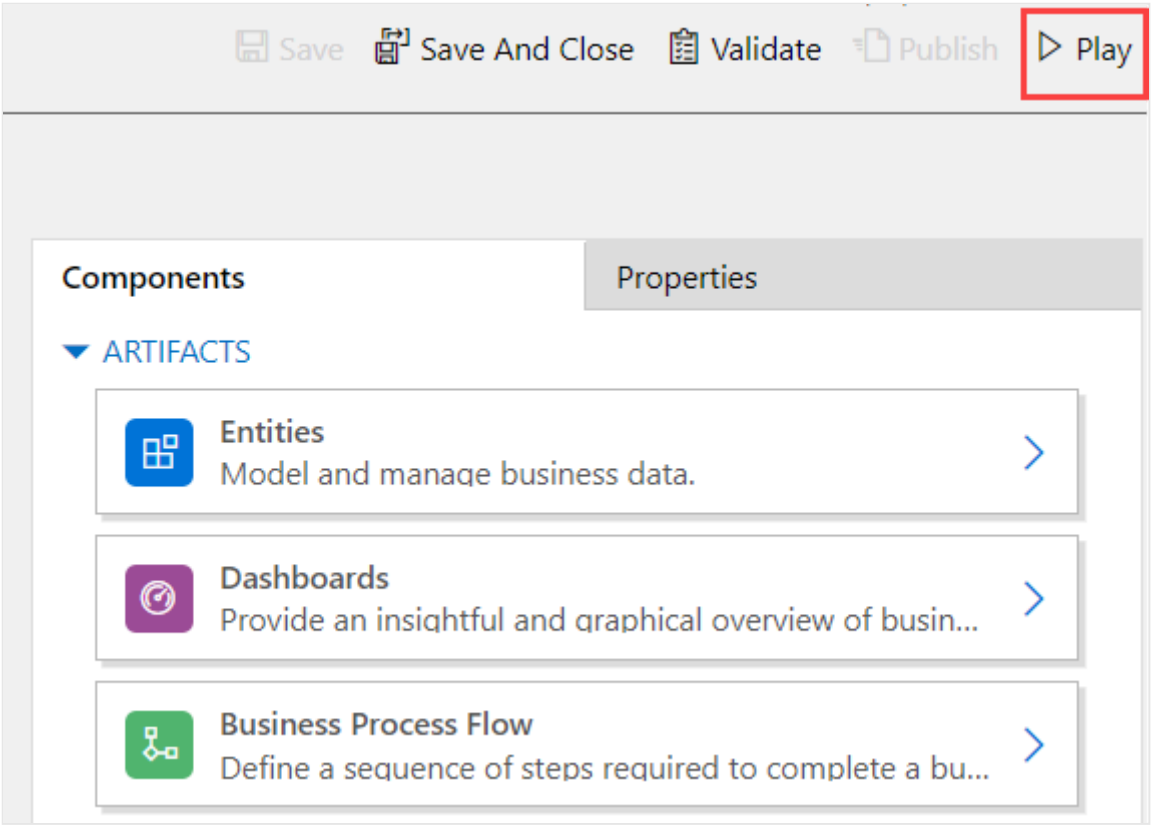
1. On the app designer toolbar, select **Save**.

2. After your app is saved, on the app designer toolbar, select **Publish** to make it available to run and share.

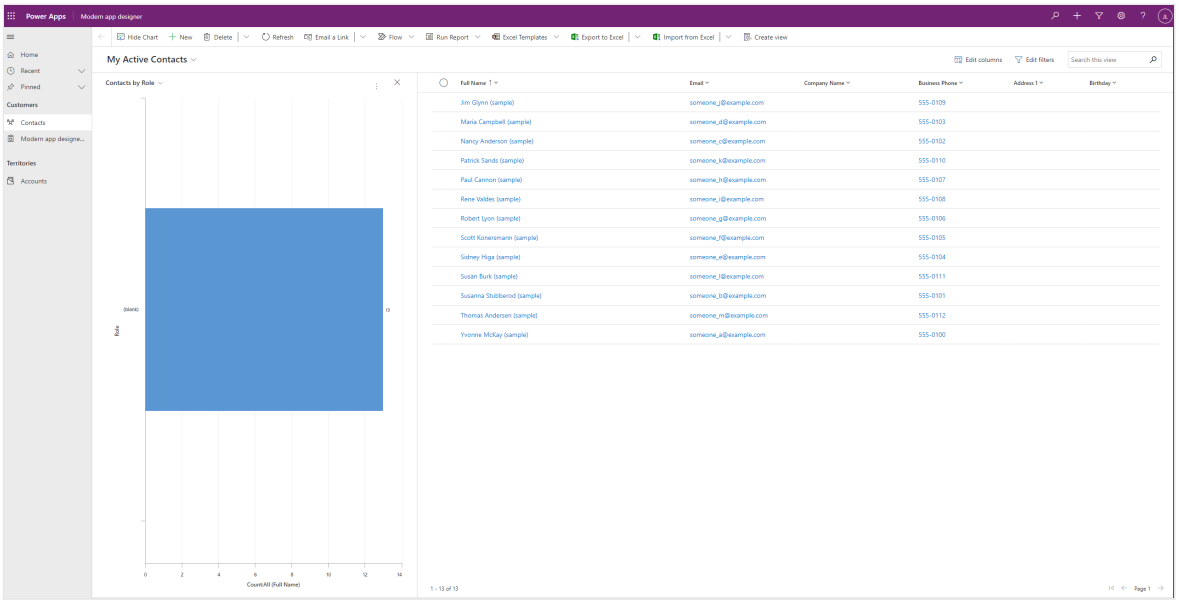
The rest of the design experience revolves around further developing the site map in addition to configuring the app through the app designer. More information: Add or edit app components

Play your app

On the app designer toolbar, select **Play**. This will only be available once the app is published.



- To create a record, select + **New**.
- To view a chart, on the app command bar select **Show Chart**.
- To change the view, select the **My Active Accounts** view, and then select the view required.



To learn more about how to use your app, see Basic navigation in a model-driven app.

Edit an app

1. Sign in to Power Apps.
2. Choose the environment by selecting the environment icon 
3. Select **Solutions**.
4. Choose the solution that contains the model-driven app where editing is required.
5. On the left navigation pane select **Apps**, select a model-driven app, and then on the toolbar select **Edit**.
6. As with creating an app editing experience will center around creating a strong site map
7. In the app designer, add or edit components to the app, as required. More information: Add or edit app components

Next steps

Share an app

Edit the site map

Add or edit app components

Create a model-driven app site map using the legacy site map designer

Article • 01/23/2025

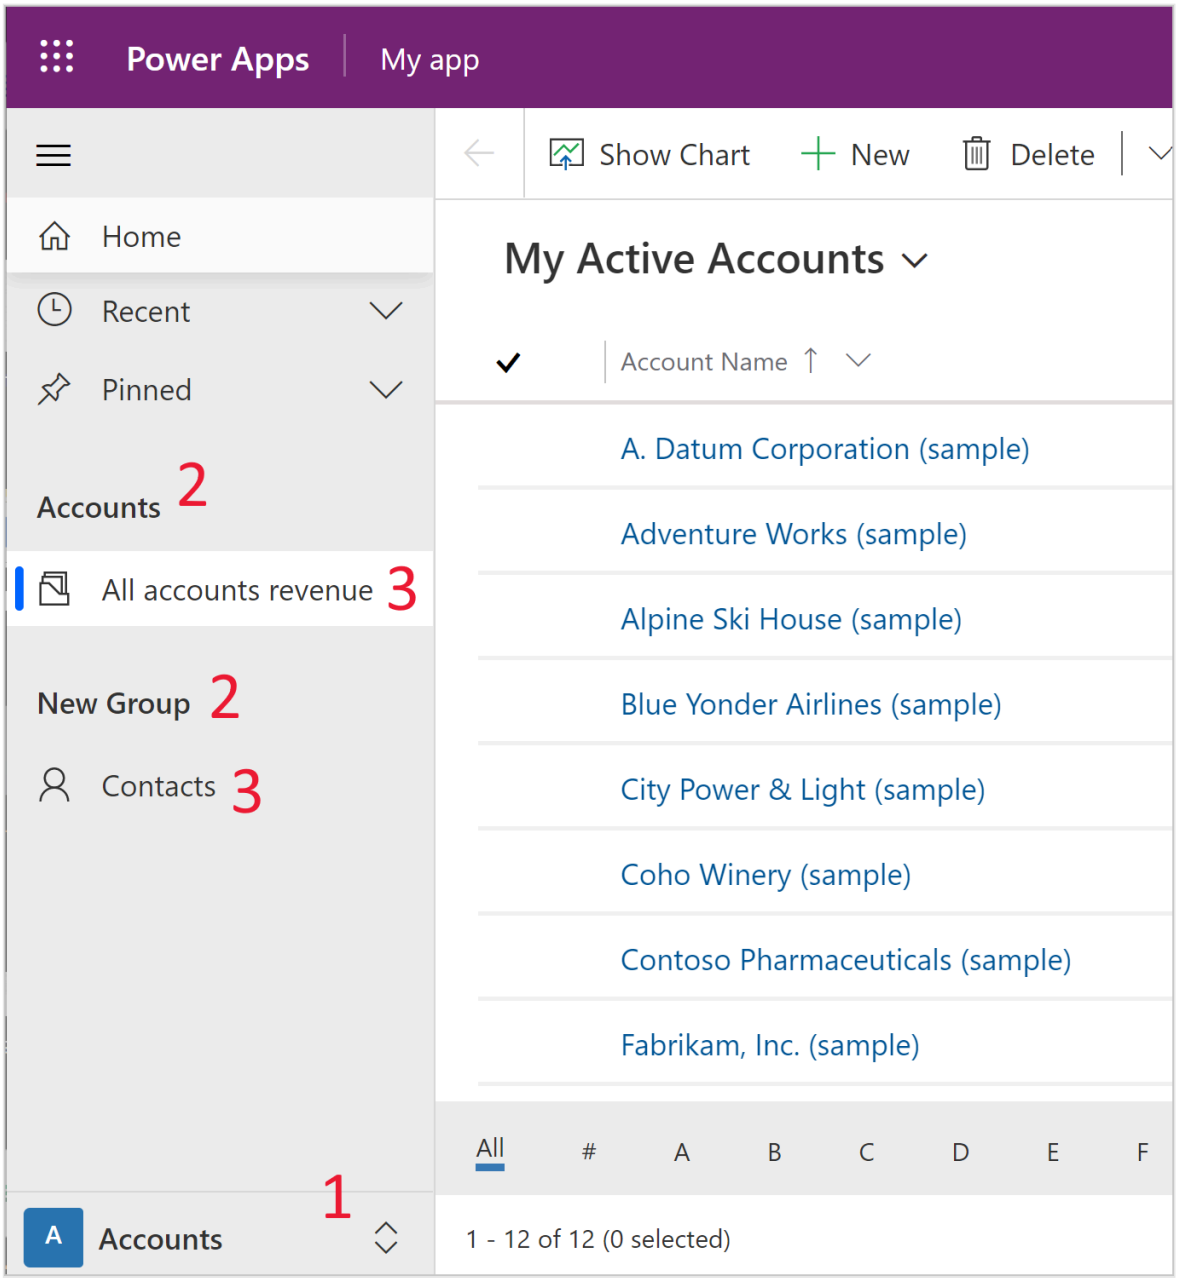
This article describes how to use the classic site map designer. For information about how to create site mapping in the modern app designer, go to App navigation in model-driven apps.

Site maps define the manner by which users move between tables in a model-driven app. This is called **navigation**. App navigation is a fundamental aspect of the user experience when performing tasks within the app.

To understand site maps it helps to introduce some concepts, so that you can understand the relationship between the site map designer and the way users intend to use the app.

The screenshot below illustrates a number of features.

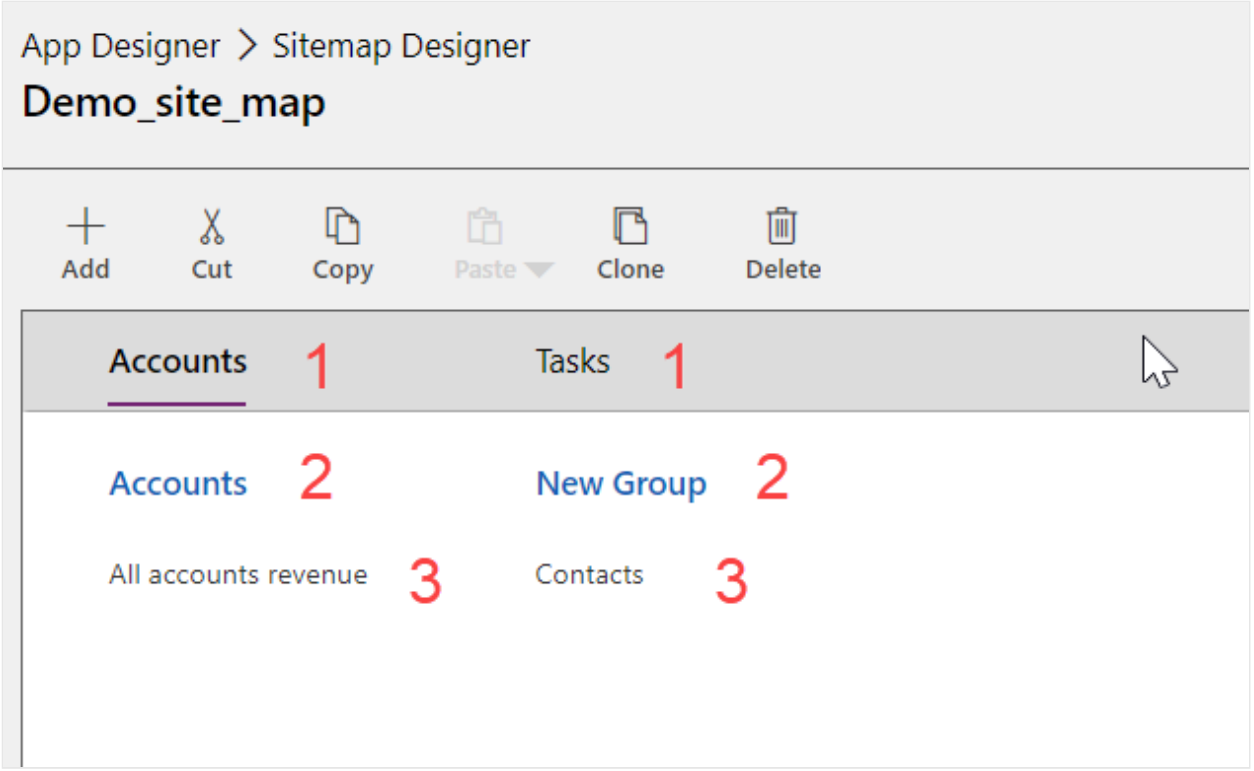
1. An **Area**. Model-driven apps can have multiple areas. Users toggle between these to access different groups.
2. A **Group**. Areas can have multiple groups. Essentially these allow you to group tables, custom pages, and other components, in a logical fashion.
3. A **Table (or entity)**. This allows users to see views of the tables that have been selected in the app designer.



This hierarchical structure is important to enable a good user experience, and the terminology used allows better understanding of the app designer.

Viewing an app from within the app designer

The same app viewed from within the site map designer shows the corresponding areas, groups, and tables. In this case you're viewing tables within the accounts **Group** and groups within the accounts **Area**. You can also notice there's another area called **Tasks** that also exists within the app designer.



Prerequisites for editing site maps

Users need to have the System Administrator or System Customizer security role or equivalent permissions. Specifically, any user with the following privileges can also create apps:

- Create, Read, and Write privileges for the App table.
- Read and Write privileges for the Customizations table.
- Read privileges for the Solution table.

These privileges can be viewed or set on the **Customization** tab of a security role.

How to build a site map

In this tutorial several site map tasks are carried out such as creating a new site map, and adding an area, group, and subarea.

The site map designer also lets an app designer define the area, subarea, or group titles in the languages supported by the environment.

A default site map is created automatically as part of the model-driven app creation process. This can be edited by using the site map designer.

Create a site map for an app

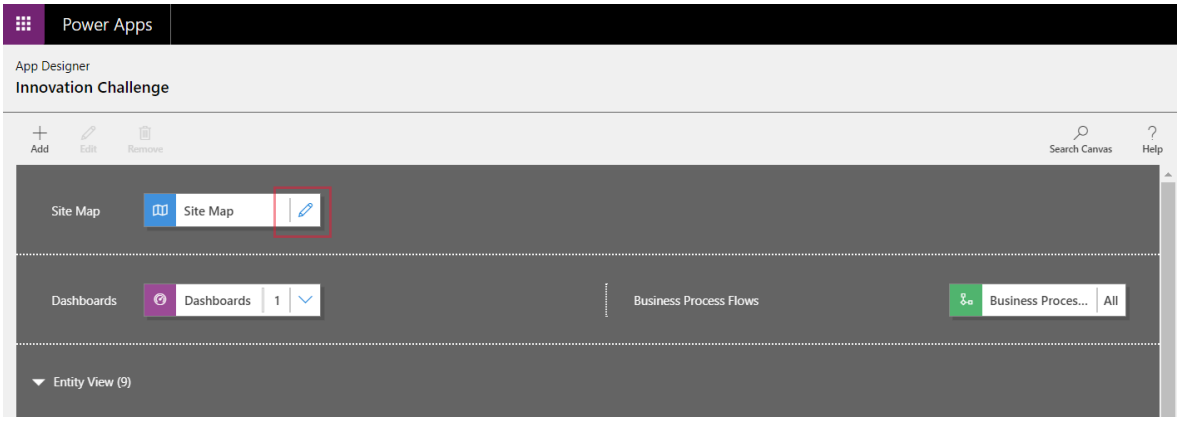
1. Sign in to Power Apps.

2. Select **Solutions**, open the solution you want.

3. Select **New** - **App** - **Model-driven app**.

4. From the two options available select **Classic App Designer**.

5. On the app designer canvas, in the **Site Map** area, select the pencil icon next to **Site Map** to **Open the Site Map Designer** .



The site map designer opens a canvas that is prepopulated with one area, one group, and one subarea. Select the area, group, or subarea tile to change its properties.

> **Note**
>
> Selecting **Open the Site Map Designer** from the app designer canvas automatically creates a new site map (if there's no existing site map), and gives the new site map the same name as the app name and the same unique name as the app unique name.

6. Add an area to the site map.

7. Add a group to the site map.

8. Add a subarea to a group in the site map.

9. Select **Save**.

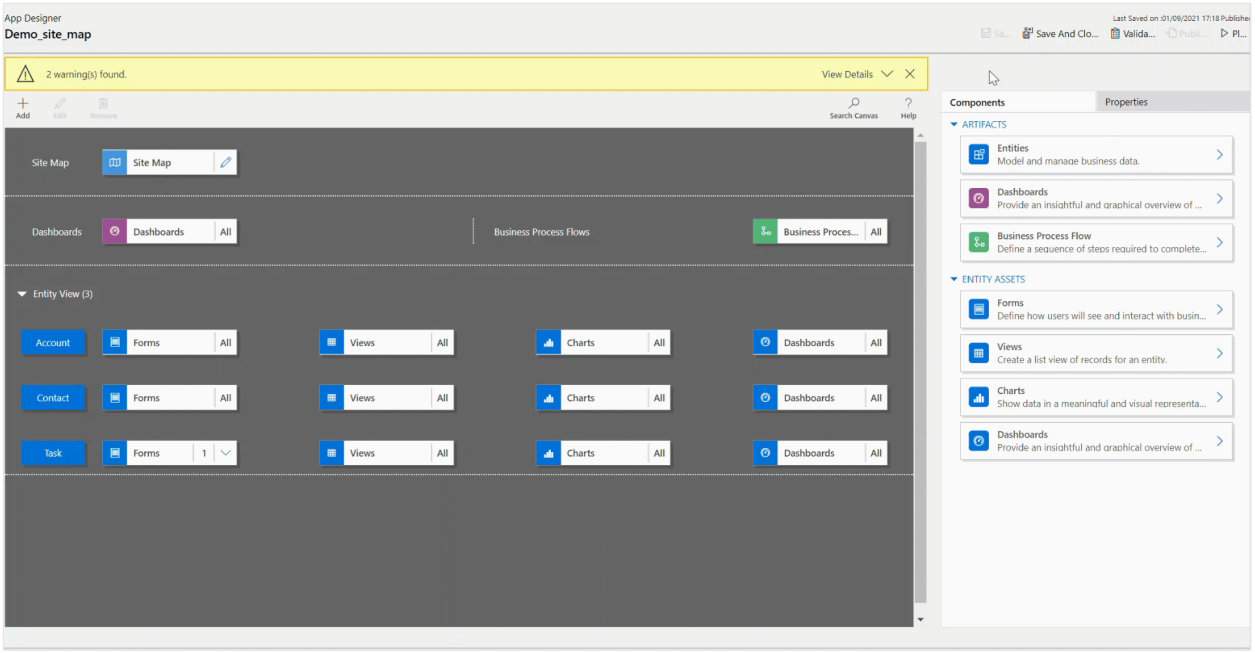
> **Note**
>
> The new site map is associated with the app when returning to the app designer and select **Save**. When a site map is configured, **Configured** appears

on the site map tile; otherwise **Not Configured** appears on the tile. If you open the site map designer from the app designer and configure a new site map, but close the browser before associating the site map with the app, the site map will be automatically associated with the app the next time the app designer is opened, based on the app unique name.

10. Select **Publish**.

Review the model-driven app

From that app designer select **Save** > **Validate** > **Play**. This runs the app with the latest changes and is an important part of the app building process.



Add an area to the site map

1. Select **Add** 

on the site map designer canvas, and then select **Area**.

   or

   From the **Components** tab, drag the **Area** tile to the empty box on the canvas. An empty box is visible you move the tile the correct place on the canvas.

2. Select the area that has been added. The **Properties** tab highlighted in the pane to the right of the canvas.

3. Add or edit the area properties.

Under **General**, do the following:

- **Title**: Enter the title for the area in the base language of the organization.
- **Icon**: A default application icon is selected. Select a different icon for the area from the list of web resources available in the solution. The icon only applies to the deprecated web client site map and not the modern model-driven app site map.
- **ID**: A unique ID is automatically generated, but different one can be entered if necessary. It's best practice to use the provided ID because if the ID entered isn't unique, users might get an error when they're using the app, or app designers might get an error when importing a solution that contains this site map.
- **Show Groups**: Select this check box to show groups of subareas in the navigation pane.

Under **Advanced**, do the following:

- **More Titles**: If your organization uses multiple languages, select a language (Locale) for the title, enter the title, and then select **Add**  . Titles can be created, edited, or deleted for as many languages as your organization uses. However, it's only possible to have one title per language.
- **More Description**: If an organization uses multiple languages, select a language for the description, enter the description, and then select **Add**  . Descriptions can be created, edited, or deleted for as many languages as your organization uses. However, it's only possible to have one description per language.
- **URL**: Enter the URL to render for the Dynamics 365 for Outlook folder that represents the area.

Creating and editing Groups, Subareas and Areas

The following sections provide instructions describing how to work with Groups, Subareas, and Areas in addition to reviewing their properties.

Add a group to the site map

1. On the site map designer canvas, select the area you want to add the group to.
2. Select **Add** 

, and then select **Group**.

   or

   From the **Components** tab, drag the **Group** tile to an empty box under the **Area** in the canvas. An empty box is visible when you move the tile to the correct place in the canvas.
3. Select the group just added.
4. On the **Properties** tab, add or edit the group properties:

   Under **General**, do the following:

   - **Title**: Enter the title for the group in the base language of the organization.
   - **ID**: A unique ID is automatically generated. Enter a different one if necessary. We recommend using the automatic ID because if the ID entered isn't unique, there might be an error when importing a solution containing this site map.

   Under **Advanced**, do the following:

   - **More Titles**: If your organization uses multiple languages, select a language (Locale) for the title, enter the title for the group, and then select **Add**  . Titles can be created, edited, or deleted for as many languages as your organization uses. However, it's only possible to have one title per language.
   - **More Descriptions**: If your organization uses multiple languages, select a language for the description, enter the description for the group, and then select **Add**  . Descriptions can be created, edited, or deleted for as many languages as your organization uses. However, it's only possible to have one description per language.
   - **URL**: Enter the URL to render for the Dynamics 365 for Outlook folder that represents the group.
   - **Set as Profile**: Select this check box to indicate whether this group represents a user-selectable profile for the workplace. The group set as a user-selectable profile is made available as options in your personal options. This only applies for groups within the **Workplace** area.

Add a subarea to a group in the site map

1. Select **Add**  on the site map designer canvas, and then select **Subarea**.

   or

   From the **Components** tab, drag the **Subarea** tile to an empty box under the **Group** section in the canvas. An empty box is visible the tile is moved to the correct place in the canvas.

2. Select the subarea that has been added.

3. On the **Properties** tab, add or edit the subarea properties:

   Under **General**, do the following:

   - **Type**: Select whether the subarea being adding is a dashboard, table, web resource, or URL.
   - **Entity**: Select the table that the subarea is for. This column is disabled if the subarea type is other than **Entity** in the **Type** drop-down list.
   - **URL**: Specify a URL to a web page. The URL text displays from this subarea and, when selected, a new browser window opens that displays the page. This column is disabled if **Entity** in the **Type** is selected in the drop-down list.

     > ⓘ **Important**
     >
     > Site map subarea URLs that link to an .aspx page aren't supported.

   - **Default Dashboard**: Select the default dashboard to be displayed for this subarea. This column is disabled if **Dashboard** hasn't been selected in the **Type** drop-down list.
   - **Title**: Enter the title for the subarea in the base language of the organization.
   - **Icon**: A default application icon is selected. Select a different icon for the subarea from the list of web resources available in the solution.
   - **ID**. A unique ID is automatically generated. Enter a different unique ID if necessary.
   - **Parameter Passing**. Select this check box to pass information about the organization and language context to the URL. This check box is checked only when the subarea type is a web resource or a URL-based subarea.

   Under **Advanced**, do the following:

- **Privileges**: This defines whether a subarea is displayed based on privileges available in any security roles that are assigned to the user. Select the name of the table to check privileges for, and then select the check boxes to assign privileges.
- **More Titles**: If your organization uses multiple languages, select a language for the title, enter the title for the subarea, and then select **Add**. Titles can be created, edited, or deleted for as many languages as your organization uses. However, it's only possible to have one title per language.
- **More Descriptions**: If your organization uses multiple languages, select a language for the description, enter the description for the subarea, and then select **Add**. Descriptions can be created, edited, or deleted for as many languages as your organization uses. However, it's only possible to have one description per language.
- **SKUs**: Select the versions of Dynamics 365 that display this subarea.
- **Client**: Select the type of client that displays this subarea.
- **Outlook Shortcut**: Select the icon to display in Dynamics 365 for Outlook.
- **Offline Availability**: Select this check box to make this subarea available to users when they're offline in Dynamics 365 for Outlook.

Organize areas, groups, and subareas

Organize areas, groups, and subareas by dragging them to new positions. A container box appears where you can drop the tiles. Here are some options:

- Move a subarea to a new position within the same group or a different group under the same area.
- Move a subarea to a new position within a group under a different area.
- Move a group to a new position within the same area.
- Move a group to a new position in a different area.
- Move an area to a new position.

Edit the default site map

Each environment comes with a default site map and this can be edited.

1. Open solution explorer.
2. In the solution window, under **Components**, select **Client Extensions**.
3. On the component toolbar, select **Add Existing** > **Site Map**.
4. In the list of solution components, select the site map named **Site Map**, and then select **OK**.
5. Double-click to select the site map added that has the display name **Site Map** and is in a **Managed** state. The site map can be selected, and then on the toolbar, select **Edit**.

   The site map opens in the site map designer.
6. Add an area to the site map.
7. Add a group to the site map.
8. Add a subarea to a group in the site map.
9. Organize areas, groups, and subareas.
10. Select **Save**.
11. Select **Publish**.
12. Select **Save and Close**.

Clone a component in a site map

To make a copy of an existing component, select the component, and then on the toolbar, select **Clone**. All details of the cloned component are same as the base component except the ID and title. The ID is generated randomly.

When an area is cloned, the cloned area is added to the right of the currently selected area. When a group is cloned, the cloned group is added to the right of the currently selected group. When a subarea is cloned, the cloned subarea is added below the currently selected subarea.

Delete an area, group, or subarea from a site map

To delete a site map component, select the component tile, and then on the toolbar, select **Delete**. When an area is deleted, all groups and subareas in the area are also deleted. Similarly, when a group is deleted, the group and subareas in it are deleted.

Clients supported

The following table explains the clients supported for different site maps.

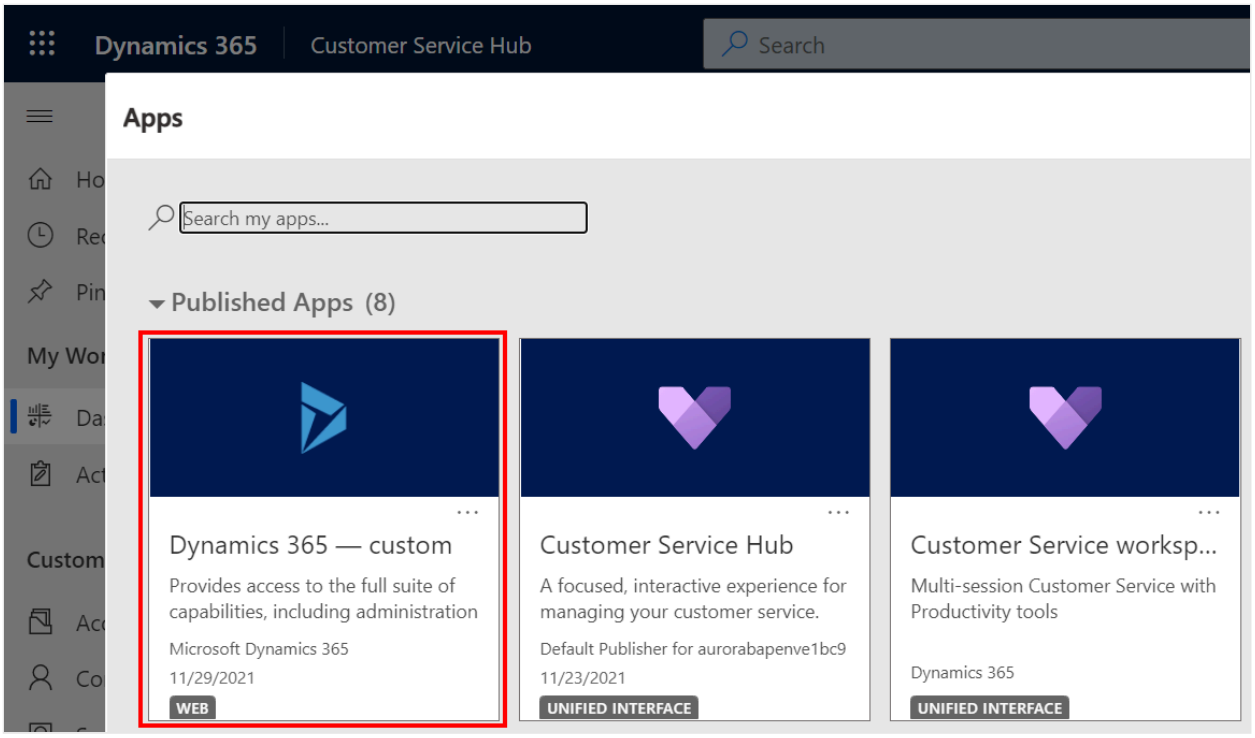
Expand table

Site maps	Supported clients
New apps	Unified Interface
Site map for the Dynamics 365 - custom app	Legacy web app and Dynamics 365 for Outlook
Model-driven apps (Sales, Sales Hub, Customer Service, Customer Service Hub, Field Service, Project Service Automation)	Legacy web app and Unified Interface

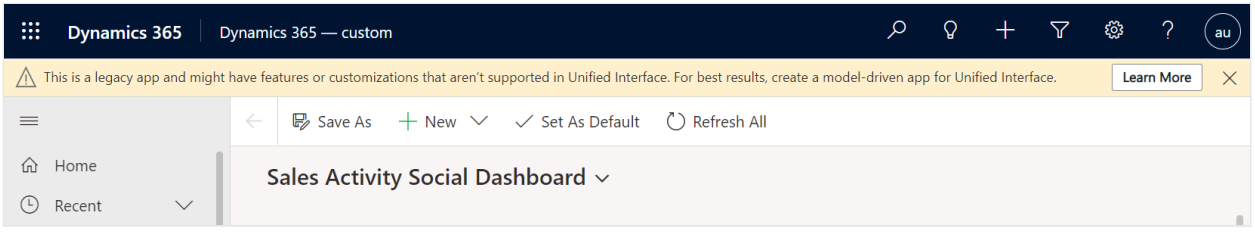
Replace the legacy app with a model-driven app

During the transition from web client to Unified Interface, a legacy app was provided which uses the web client site map. With the web client removed, we're deprecating the legacy app. Subsequently, makers might want to provide a replacement model-driven app for users. In a future release, the legacy app will be removed.

By default, the legacy app name is "Dynamics 365 - custom," but could have been renamed within the environment.



When the legacy app is run, a warning message is shown indicating that not all app features are supported.



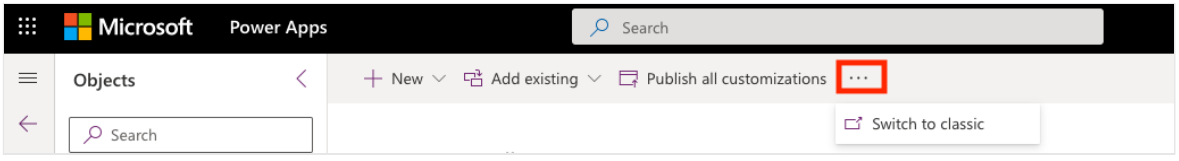
To create a model-driven app with the same site map items as the legacy app, the classic app designer can reuse the existing site map within a new app.

1. Open make.powerapps.com

2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Open or create a new solution.

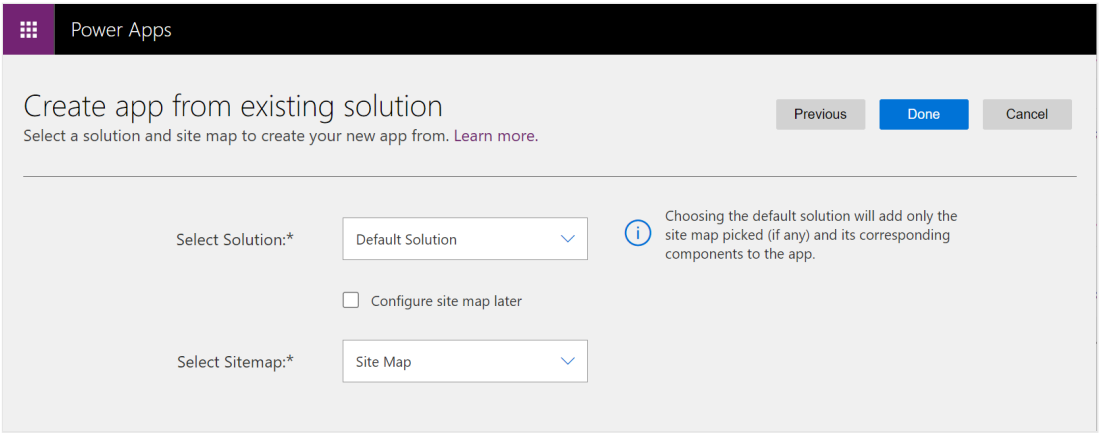
4. Select **...** on the top navigation bar, and then select **Switch to classic**, which opens the classic solution explorer.



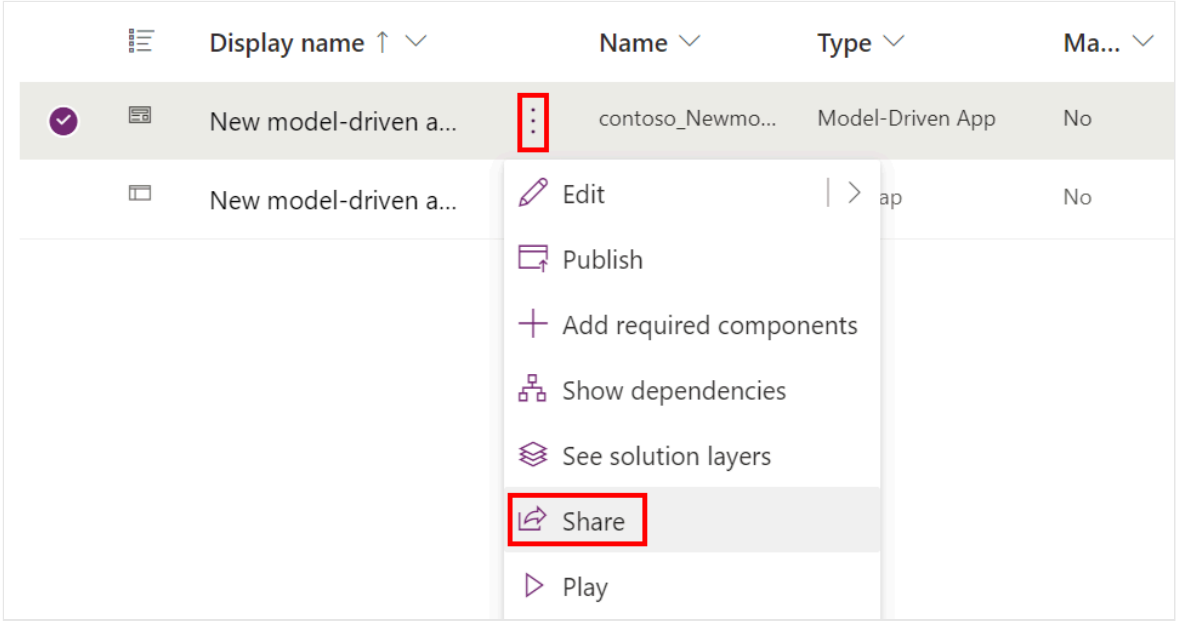
5. From the left pane, select **Model-driven Apps** > **New** .

6. In the **Create a New App** dialog:

- Enter the app name. The unique name and description can also be provided but aren't required.
- Select **Use existing solution to create the App**, and then select **Next**.
- Under **Select Solution** select **Default Solution**.
- Under **Select Sitemap** select **Site Map**, and then select **Done**.



7. Select **Publish**.
8. Close the classic app designer and open the solution containing the new model-driven app.
9. Select the new model-driven app, and then select **Share**.



10. Add people and assign security roles to allow them to use the app.

After the new model-driven app is available, the "Dynamics 365 - custom" app should be hidden for nonadmins in all environments.

1. Open Power Platform admin center and select the environment to hide the legacy app.
2. Select **Settings** > **Product** > **Behavior**.
3. Set **Show legacy app to everyone, not just admins** to **Off**.
4. Scroll to the bottom of the page and select **Save**.

Add or edit model-driven app components in the Power Apps app designer

Article • 10/17/2023

> **Important**
>
> Starting in October 2023, the classic app, form, and view designers are deprecated and all model-driven apps, forms, and views will only open in the modern designers. By default, the **Switch to classic** command to revert back to the classic designer from the modern designer will no longer be available. More information: **Classic app, form, and view designers are deprecated**
>
> We recommend that you transition to use the Modern Designers to create and edit your model-driven apps and components.

This tutorial describes how to add components to and remove components from a model-driven app.

A model-driven app is made up of various components. Two types of components can be added to an app:

- Artifacts
- Table assets

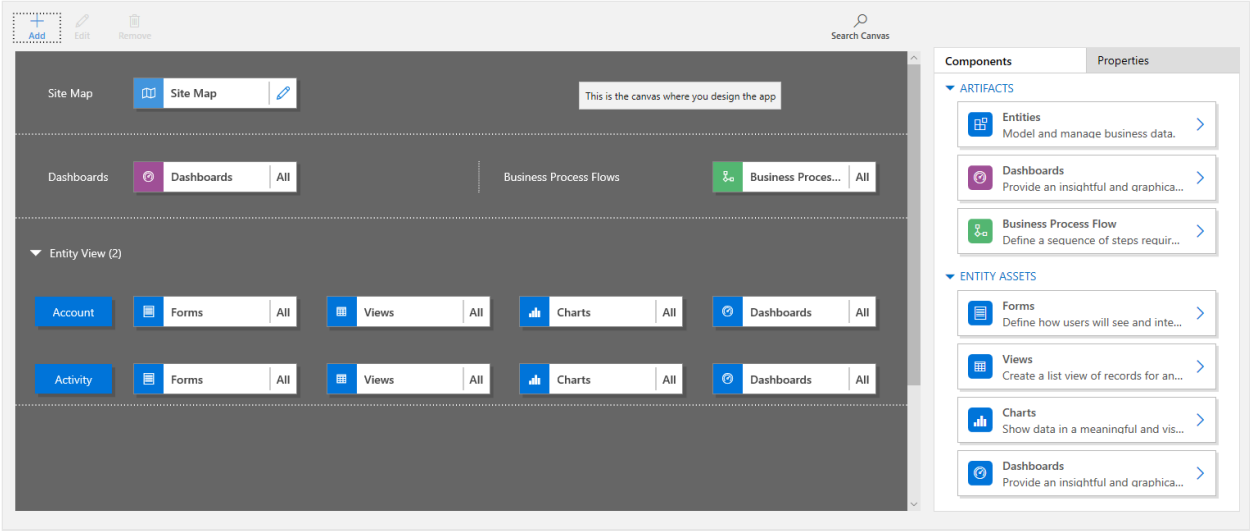
Tables, dashboards and business process flows are all artifacts of an app.

Table assets consist of forms, views, charts, and dashboards related to a specific table included in an app.

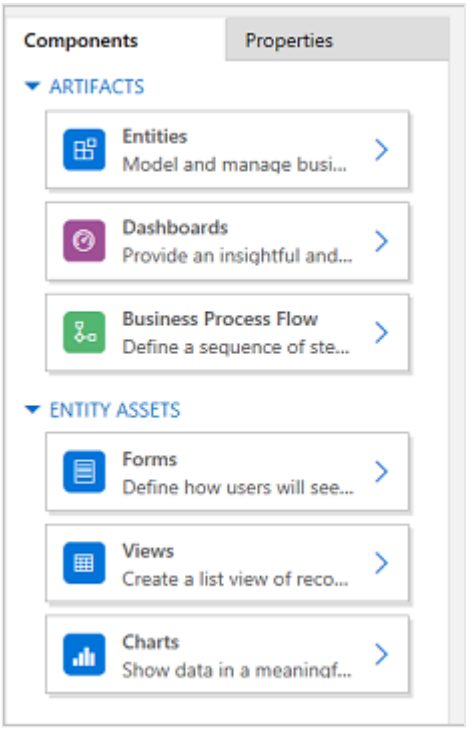
> **Note**
>
> Tables used to be called entities. The classic app designer uses the term entity in most places. For example, *Entity assets* rather than *Table assets*.

App designer layout

The app designer has two main areas. On the left side is the canvas, where app components can be added.



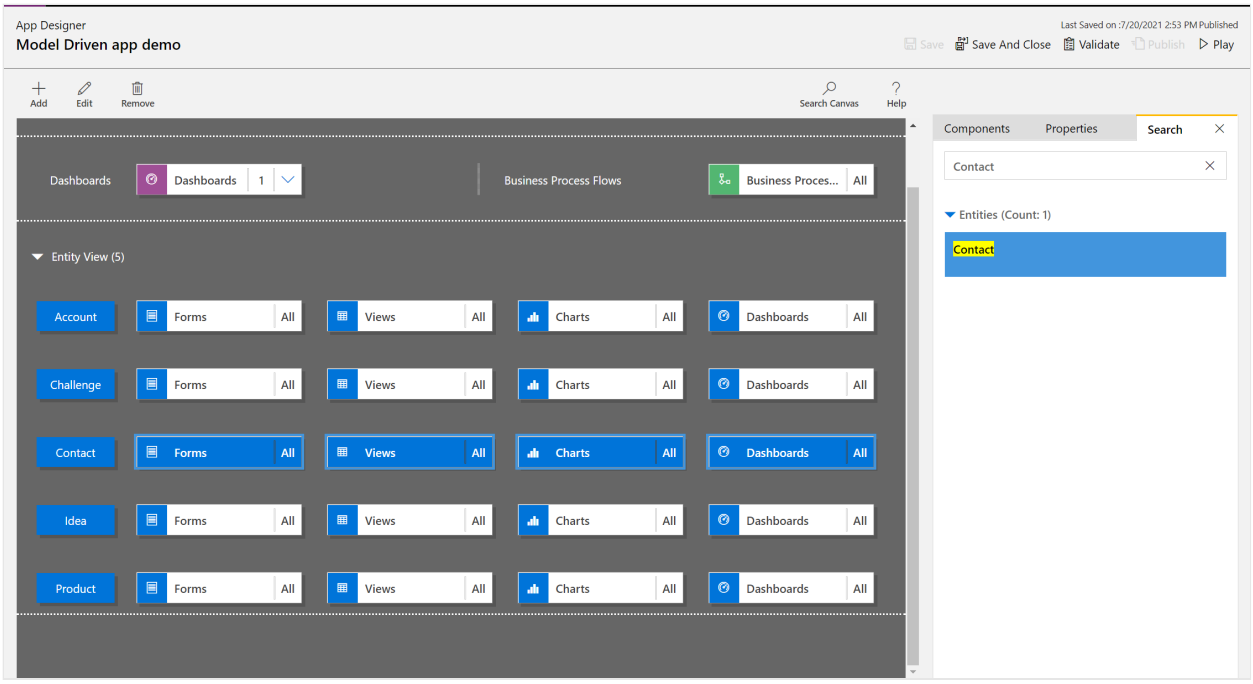
On the right side are tabs that are used to select components and set component properties.



The canvas includes areas for the **Site Map**, **Business Process Flow**, **Dashboards**, and **Tables**.

After the tables are in place, select each table and add the required table assets such as forms, views, and charts to it.

Use **Search Canvas** to search for components on the canvas. When **Search Canvas** is selected, a new search tab opens to the right of the tabs in the right pane.



Open an app

1. Sign in to Power Apps and optionally select an environment to work in.
2. Create a new model-driven app or select an existing one. For information about how to create an app, see Create or edit a model-driven app by using the app designer.

Add or edit a site map

You must define a site map before app components can be added to a newly created app. More information: Create a model-driven app site map using the site map designer.

Add a component

When a dashboard or a business process flow is added to an app, the related tables are automatically added to the app.

When a table is added to an app, the tiles for its assets are automatically added. There are two ways components can be added to the designer canvas:

- Use the **Add** button  on the command bar.
- Use the tiles on the **Components** tab.

Add a dashboard

To add a dashboard to an app, follow these steps:

1. On the app designer canvas, select the **Dashboards** tile.

   On the app designer canvas, the right pane shows dashboards that are available in the default solution.

2. In the **search** box, type keywords for the required dashboard.

   The dashboard list will be filtered to show results that match the keywords.

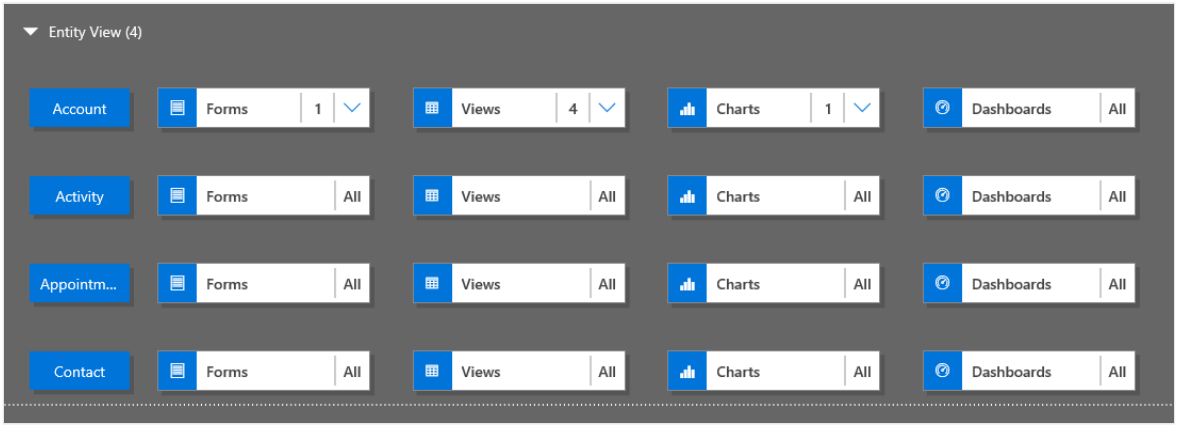
3. If users need to use only selected dashboard then select the check box for the component that needs to be added. The following types of dashboards are available:

   - **Classic Dashboards** appear on both the web app and the Unified Interface app.
   - **Interactive Dashboards** appear only on the Unified Interface app. If you have selected the client type for the app as web app, then the **Interactive Dashboards** option won't be displayed.

   Those dashboards will be added to the **Dashboard** tile on the app designer canvas. The **Dashboard** tile also shows a count of the number of dashboards added to the app. If no dashboard is selected, then **All** will appear instead of the dashboard count, and all dashboards will be available to users when they use the app.

   All tables the dashboard uses are also added to the **Entity View** area. For example, when the Customer Service Manager dashboard is added, the **Case**, **Entitlement**, and **Queue Item** tables are added to the **Entity View** area.

   For each table, tiles for its assets are also added. These tiles can be used to add forms, views, and charts. For more information, see: Add or edit app components in the Power Apps app designer



4. If the dashboard you want doesn't exist in the default solution, then create a dashboard by selecting **Create New** on the **Components** tab to the right of the canvas.

   The dashboard designer opens. For more information, see: Create and edit dashboards

5. Complete the above steps by selecting **Save**.

Add a business process flow

To add a business process flow to an app, follow these steps:

1. On the app designer canvas, select the **Business Process Flows** tile.

   On the app designer canvas, the right pane shows dashboards that are available in the default solution.

2. In the **Search** box, type one or more keywords that match the business process flow name you want.

   The business process flow list is filtered to show results that match keywords.

3. If the dashboard you want doesn't exist in the default solution, then create a dashboard by selecting **Create New** on the **Components** tab to the right of the canvas.

   > **Note**
   >
   > When adding a business process flow, the **Create New** option opens the **Create Process** dialog. To learn more about creating business process flows, go to **Create a business process flow**

4. Complete the above steps by selecting **Save**.

Add a table

To add a table to an app, follow these steps:

1. On the app designer canvas, select the **Tables** tile.

   On the app designer canvas, the right pane shows dashboards that are available in the default solution.

2. In the **Search** box, type one or more keywords matching the table name you want.

   The table list is filtered to show results that match the keywords.

   > **Note**
   >
   > When adding a table the **Create New** option opens the **New Table** dialog. To learn more about creating tables go to **Create a custom table**.

3. Complete the above steps by selecting **Save**.

Add table assets

With the components in place, table assets like forms, views, charts, and dashboards can be added to the app.

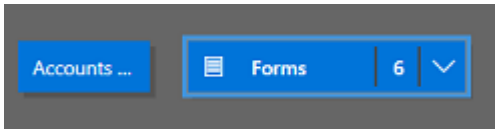
This section describes the steps for adding a form to the app. Use the same steps to add a view or chart to the app.

1. On the app designer canvas, select the **Forms** tile for the related table to add a form to.

   On the app designer canvas, the entire row for the table is selected. On the right side, all existing forms for the selected table will appear.

2. Select the check boxes for the forms that need to be available to users. The forms define how users will see and interact with data in the app.

   The form tile of the selected table will display the number of forms added.



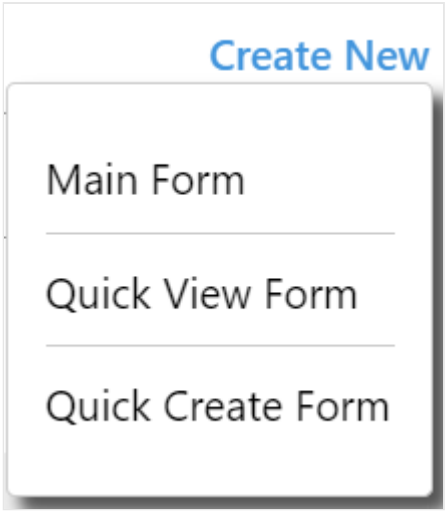
If none of the forms for a table are selected, then all the forms for that table will be displayed to the users while they use the app. This behavior is similar for views and charts also, if no view or chart is selected. This helps to create apps quickly when all available components are required. There's no need to select each component during app design.

If no dashboards or business process flows are selected, then all the dashboards and business process flows will be available for users while they use the app.

> **Note**
>
> For the app to run, each table that is added must have at least one active form. If multiple forms are selected then the first active form that appears in the default solution will be used when users run the app.

3. To add a new form that isn't available in the list, select **Create New**.

   In the drop-down list, select the type of form that is required.



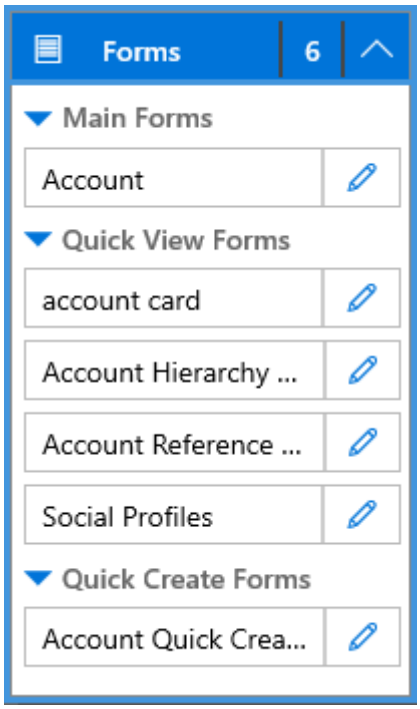
> **Note**
>
> The drop-down list is available only when adding forms. It isn't available for views and charts.

The form designer opens. More information: Create and design forms

When you add a view or a chart, the **Create New** option opens the corresponding designer. For more information go to: Understand views and Create or edit a system chart

> **Note**
>
> When you add a view, public views can be selected that are listed under the **Views** node in the solution explorer.

4. Select the down arrow to expand the tile and see a list of forms that have been added.



5. Repeat the previous steps to add table views and charts to the app.

6. Select **Save**.

Edit or remove components

- To edit a dashboard or a business process flow, select the down arrow to expand the tile, and then select the site map designer button corresponding to the dashboard or business process flow that needs to be updated.

  The designer for the selected artifact opens.

- To remove a dashboard or a business process flow, select the down arrow to expand the tile, and then select the dashboard or business process flow that needs to be removed. On the command bar, select **Remove**.

  Another way to remove a dashboard or business process flow is by clearing the corresponding check box on the **Components** tab.

- To edit or remove a table, select the table tile, and then on the command bar, select **Edit** or **Remove**. When editing a table, the solution explorer opens, where changes to the table can be made.

  Another way to remove a component is to select the dashboard, business process flow, or table tile. On the **Components** tab, clear the check boxes for the components that need to be removed from the designer.

  > **Note**
  >
  > When changes to a table are made, like changing a table display name or description, the changes do not appear in the app designer until the changes are published in the solution explorer.

Edit or remove table assets

Edit table assets

1. Select the down arrow  to expand the tile for forms, views, charts, or dashboards.
2. Select the form, view, chart, or dashboard that needs to be updated.
3. On the command bar, select **Edit**.

   or

   Select the site map designer button  corresponding to the form, view, chart, or dashboard.

Remove table assets

1. Select the down arrow  to expand the tile for forms, views, charts, or dashboards.
2. To edit an asset, select the relevant form, view, chart, or dashboard.
3. On the command bar, select **Remove**.

Alternatively, select the forms, views, charts, or dashboards tile and then on the **Components** tab, clear the check boxes for the assets that need to be removed.

Learn more about shortcuts for app users.

Keyboard shortcuts

Many users find that using an external keyboard with keyboard shortcuts for Power Apps helps them work more efficiently.

For users with mobility or vision disabilities, keyboard shortcuts can be easier than using the touchscreen and are an essential alternative to using a mouse.

This article itemizes the keyboard shortcuts for Power Apps.

App designer and site map designer

Expand table

To	Shortcut Keys (Windows)	Shortcut Keys (Mac)
Go to the next section or major component.	Ctrl + F6	Cmd + F6
Go to the previous section or major component.	Shift + Ctrl + F6	Shift + Cmd + F6
Save command.	Ctrl + S	Cmd + S
Save and Close command.	Ctrl + Alt + S	Cmd + Opt + S
Validate command.	Ctrl + Alt + V	Cmd + Op t+ V
Publish command.	Ctrl + Alt + P	Cmd + Opt + P

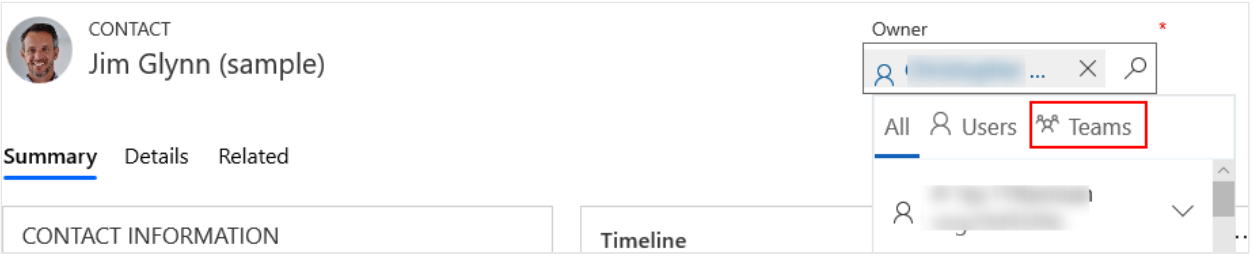
Add a table as a lookup option in your app

Article • 03/04/2025

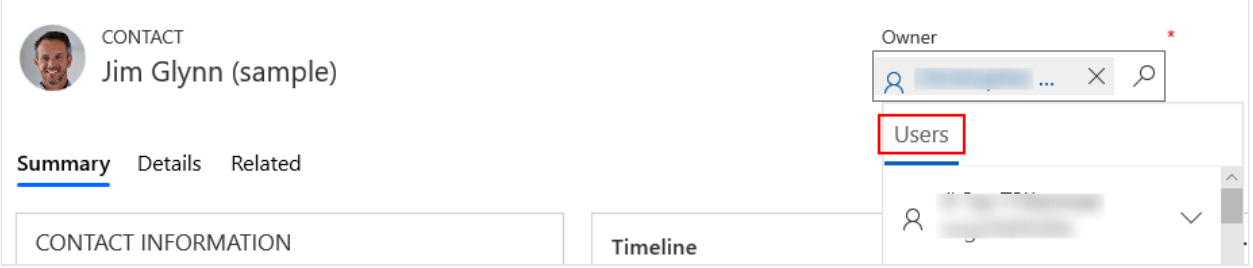
This article describes a feature that uses the classic app designer.

> **ⓘ Important**
>
> Starting in October 2023, the classic app, form, and view designers are deprecated and all model-driven apps, forms, and views only open in the modern designers. By default, the **Switch to classic** command to revert back to the classic designer from the modern designer is no longer available. More information: [Classic app, form, and view designers are deprecated]
>
> We recommend that you transition to use the modern designers to create and edit your model-driven apps and components.

With model-driven apps, for a table to be available in a lookup it must be added to the app. For example, contact records have the ability to be assigned to a user or a team. Both of these tables have a relationship with the contacts table.



However, if the **User** table is included in the app but the **Team** table isn't, only user rows appear in a lookup.



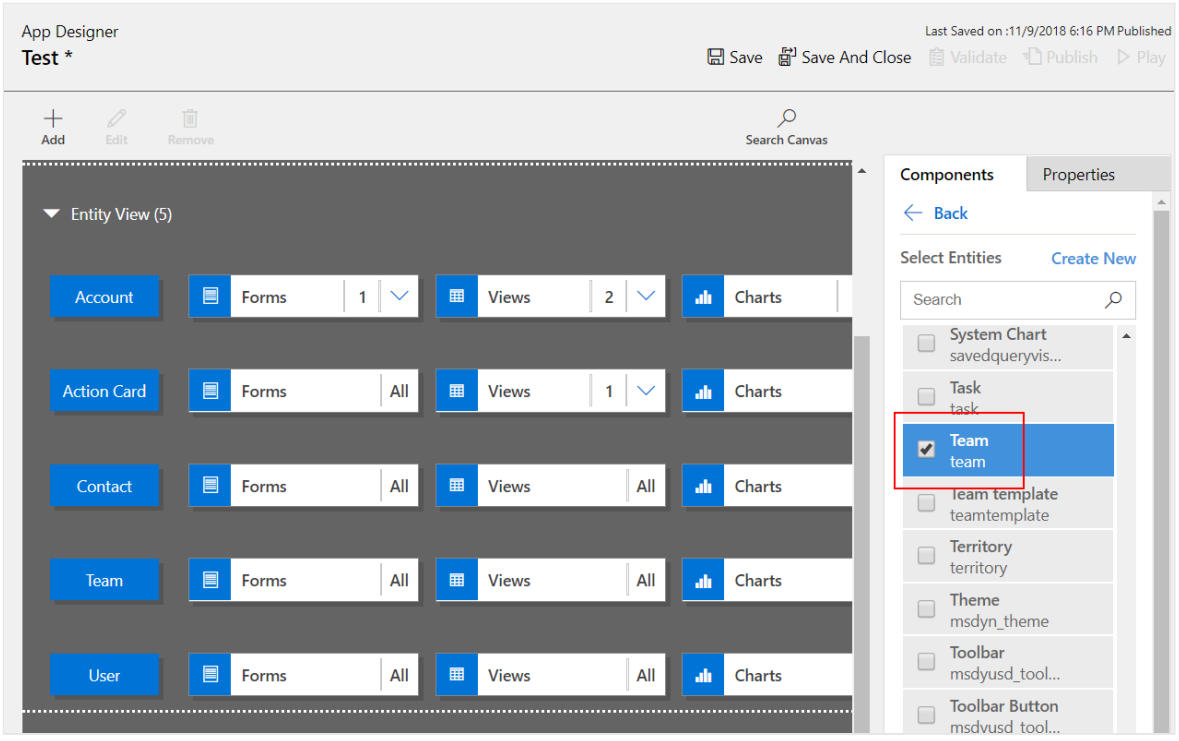
This can be resolved by adding the **Team** table to the app using the app designer.

Add a related table to an app to enable the lookup

1. Go to Power Apps, and then select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Open the solution you want, and then select the model-driven app. This opens the app in the app designer.

3. Select the **Components** tab, select **Entities** (tables), and then select **Team**.



4. Select **Save**, and then select **Publish** to make the change available to app users within the organization.

Classic form editor overview

Article • 10/21/2023

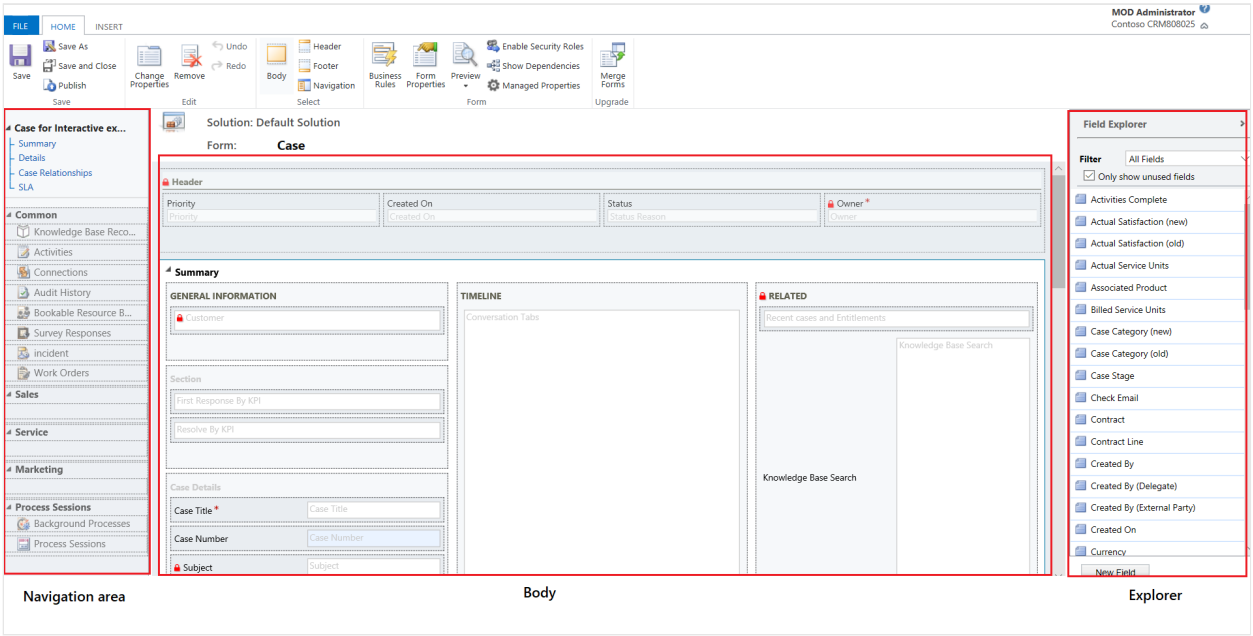
This article describes the classic form editor.

> **ⓘ Important**
>
> Starting in October 2023, the classic app, form, and view designers are deprecated and all model-driven apps, forms, and views will only open in the modern designers. By default, the **Switch to classic** command to revert back to the classic designer from the modern designer will no longer be available. More information: **Classic app, form, and view designers are deprecated**
>
> We recommend that you transition to using the modern form designer to create and edit your model-driven app forms. More information: **Overview of the model-driven form designer**

The form editor displays commands in three tabs: **File**, **Home**, and **Insert**.

- File tab
- Home tab
- Insert tab

The form editor is divided into three areas: **Navigation**, **Body**, and **Explorer**.



Navigation

Located on the left side, use the navigation area to control access to related tables or to

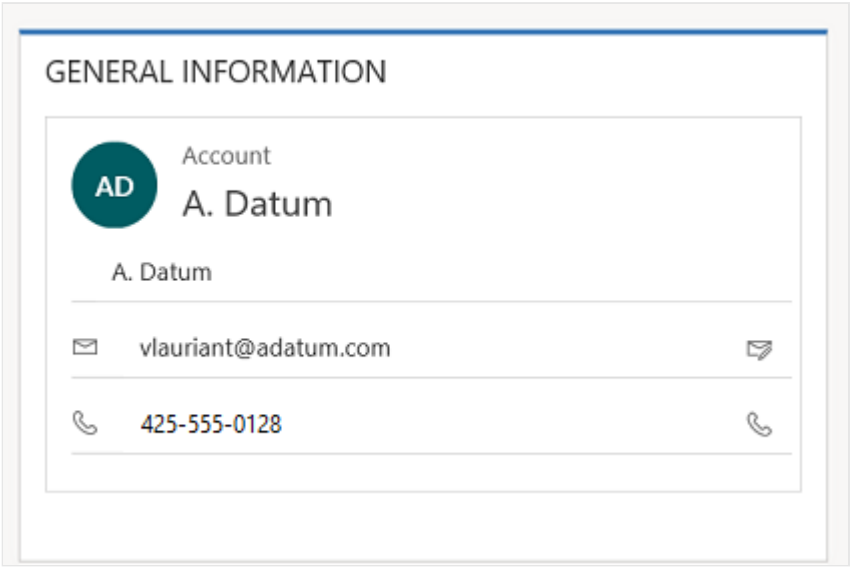
add links to URLs to be displayed in the main pane of the form. To edit navigation, you must first select the **Navigation** command in the **Select** group of the **Home** tab.

Main forms provide navigation options through the navigation bar, but use the same data in the navigation area to control what navigation options are available. More information: Edit Navigation

Body
Located in the center, use the body area to control the layout of the form. You can select and drag form elements to position them. Double-clicking on an element will open the properties for the element.

By default, for the Case, Contact, and Account Main forms, the first section under the **Summary** tab shows the account or contact card form of type **Quick View**. For custom tables, this section isn't available by default. You can insert a new section and a quick view form in it. The card form shows a maximum of five columns. Other than columns, it isn’t possible to show other controls in the Blue tile even if the quick view form contains it.

> **Note**
>
> To preserve the card format (as shown in the following image), we recommend that you do not move the quick view form to any other section on the form.



More information: Create and edit quick view forms

- To add a column, select it from the **Column Explorer** and drag it into a section.
    - To add an element that isn't a column, select where you want to place it and use the appropriate command from the **Insert** tab add it.

- To remove an element, select it and use the **Remove** command in the **Edit** group of the **Home** tab.
- To edit the **Header** or **Footer** for the form you must first select the corresponding command in the **Select** group of the **Home** tab.

Explorer
Located on the right side, the content of the explorer area depends on the context.

When you select **Body**, **Header**, or **Footer** in the **Select** group of the **Home** tab, you'll see the **Column Explorer**. Use the **Column Explorer** to drag columns you want to display into a section in the form or within the header or footer. You can include the same column multiple times in a form. Use the **New Column** button as a shortcut to create a new column.

When you select Navigation in the Select group of the Home tab, you'll see the **Relationship Explorer**. Drag any of the relationships into one of the groups within the navigation area. You can't add the same relationship twice. Relationships are available based on how they're configured. If you configure a relationship to not display, it won't display in the **Relationship Explorer**. For information about how to configure default display options for relationships, see Navigation pane item for primary table.

You can use the **New 1:N** and **New N:N buttons** as a shortcut to add new table relationships.

File tab

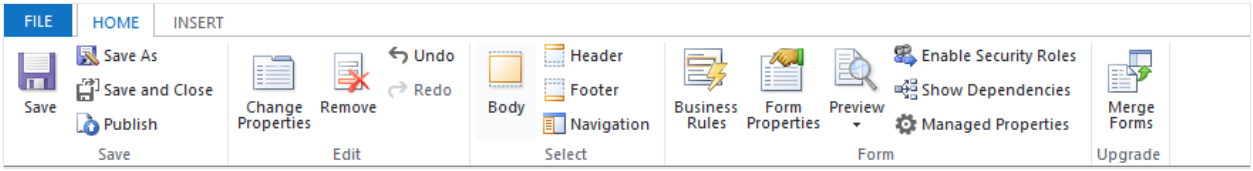
Select the **File** tab to add/view the following options:

- **New Activity** Add a new activity
- **New Row** Add a new row
- **Tools** Utilize options like Import data, Duplicate detection, and Bulk delete wizard
- **Options** Change the default display settings to personalize the default solution, and manage your email templates
  - General
  - Synchronization
  - Activities
  - Formats
  - Email Templates
  - Email Signatures
  - Email
  - Privacy

    - Languages
- Help
- Close

Home tab

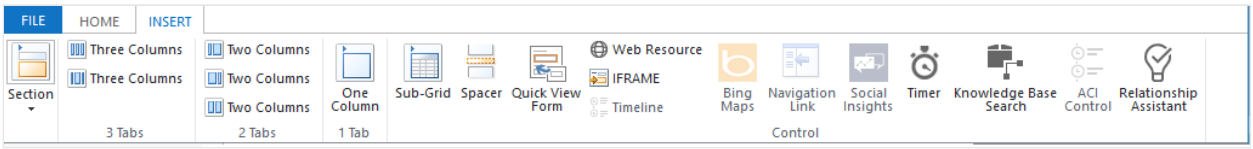
The **Home** tab displays the commands listed in the following table:



Group	Command	Description
Save	**Save (Ctrl+S)**	Save the form.
	Save As	Create a copy of this form with a different name.
	Save and Close	Save the form and close the form editor.
	Publish	Publish the form. More information: Publishing customizations
Edit	**Change properties**	Change properties of the selected item in the body. See the following sections depending on the selected item: - Tab Properties - Section properties - Common Column properties - Special column properties - Subgrid properties - Quick view control properties
	Remove	Remove the selected item.
	Undo (Ctrl+Z)	Undo the previous action.
	Redo (Ctrl+Y)	Redo the previous action.
Select	**Body**	Edit the main body of the form.
	Header	Edit the form header.
	Footer	Edit the form footer.
	Navigation	Edit the form navigation. More information: Edit Navigation

Group	Command	Description
Form	Business Rules	View, edit, or create new business rules with the Business Rules explorer. **Note:** For the interactive forms, only the "Entity" and "All Forms" scope is supported. More information: Create and edit business rules
	Form Properties	More information: Form Properties
	Preview	Use this to see how form looks after it's published. You can also preview to test scripts associated with from events.
	Enable Security Roles	Use this to set which security roles will have access to the forms. More information: Control access to forms **Important:** If you create a new form, only the System Administrator and System Customizer security roles will have access to the form. You must assign access to other security roles before people can use it.
	Show Dependencies	See which solution components depend on this form and which solution components are required by this form.
	Managed Properties	Managed properties command has two properties **Customizable** and **Can be Deleted**. Setting these properties to false means the form won't be customizable and can't be deleted after you included it in a solution, export that solution as a managed solution, and import that managed solution into a different environment. More information: Managed properties
Upgrade	Merge forms	If applicable, this option lets you merge this form with a form from a previous version of Dynamics 365 form

Insert tab



The Insert tab displays the commands in the following table:

Group	Command	Description
	Section	Add a section to a selected tab. You can include a section with one to four columns. You can also insert a Reference panel in the interactive forms. Reference panel is also added as a section to the Main - Interactive

Group	Command	Description
		experience form. By default the Reference panel section is added to the Case, Account, Contact and custom table forms. More information: Section properties
3 Tabs	Three Columns	Insert a three-column tab with equal widths. More information: Tab Properties
	Three Columns	Insert a three-column tab with a wider middle column.
2 Tabs	Two Columns	Insert a two-column tab with a wider right column.
	Two Columns	Insert a two-column tab with a wider left column.
	Two Columns	Insert a two-column tab with equal width columns.
1 Tab	One Column	Insert a one-column tab.
Control	Sub-Grid	Format a subgrid and insert it into the form. More information: Subgrid properties
	Spacer	Insert an empty space.
	Quick View Form	Insert a Quick View Form. More information: Quick view control properties
	Web Resource	Insert a web resource to embed content from other locations in one page. More information: Web Resource properties
	IFRAME	You can add an IFRAME to a form to integrate content from another website within a form.
	Timeline	Insert a timeline control in the form. This control shows the timeline of activities related to the table on a form.
	Navigation Link	Using this option, you can insert a link into a form navigation.
	Timer	Insert a timer control to a table form to track time against an SLA. More information: Add a timer control
	Knowledge Base Search	Insert a search control that users can use to search knowledge articles. More information: Knowledge Base Search control
	Relationship	Using this option, you can insert a relationship assistant control in the

Group	Command	Description
	Assistant	form.

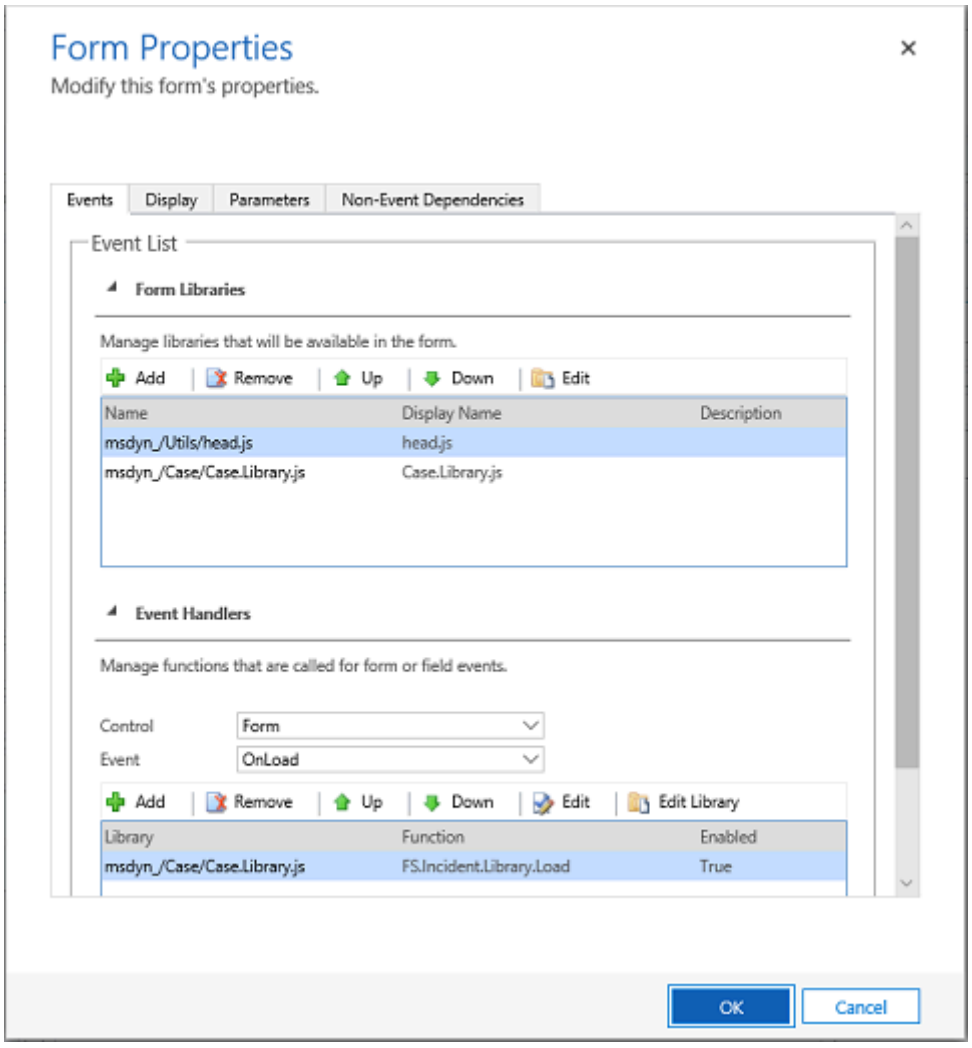
Model-driven app form properties

Article • 10/21/2023

> **Important**
>
> Starting in October 2023, the classic app, form, and view designers are deprecated and all model-driven apps, forms, and views will only open in the modern designers. By default, the **Switch to classic** command to revert back to the classic designer from the modern designer will no longer be available. More information: Classic app, form, and view designers are deprecated
>
> We recommend that you transition to use the modern designers to create and edit your model-driven apps and components.

This article describes the classic solution explorer. We recommend that you use the modern form designer to edit properties for your model-driven app forms. More information: Configure a form and Configure model-driven app form event handlers

You can access **Form properties** in solution explorer. Under **Components**, expand **Tables**, expand the table you want, and then select **Forms**. In the list of forms, open the form of type **Main**. Then on the **Home** tab, select **Form Properties**.



The following table lists the form properties:

Expand table

Tab	Property	Description
Events	**Form Libraries**	Manage which JavaScript web resources are available in the form and the order in which they'll be loaded.
	Event Handlers	Configure which JavaScript functions from the Form Libraries run for the `OnLoad` and `OnSave` form events and the order in which they'll be run.
Display	**Form Name**	Enter a name that will be meaningful to people. This name will be shown to people when they use the form. If they can use multiple forms configured for the table they'll use this name to differentiate between available forms.
	Description	Enter a description that explains how this form is different from other main forms. This description is only shown in the list of forms for a table in the solution explorer.
	Form Assistant	Select from the check box if you want to enable form assistant or view the form as expanded by default.

Tab	Property	Description
	Page Navigation	You can choose not to show navigation items. In forms for updated tables this means the primary name value for the row currently being viewed won't appear in the navigation bar to allow navigation to associated views. In forms using the classic presentation, the navigation options to choose associated views on the left side of the form won't be shown.
	Image	When a table has an image column and the entities' **Primary Image** option is set, this setting will enable showing the image column in the header of this form. See Enable or disable table options for more information about table options.
	Display	**Set a Max Width (in pixels)** to limit the width of the form. The default value is 1900.
	Display	Enter in pixels the max width that you want for the form here.
Parameters	**Parameters**	Each form can be opened with code using a URL. The URL might also contain data that can be passed to the form using a query string that is appended to the URL. Query strings look like this example: `?p_firstName=Jim&p_lastName=Daly` As a security measure, forms won't accept any unknown query string parameters. Use this parameters list to specify parameters this form should accept to support code that will pass data to the forms using a query string. The name and type of data will be checked and the form won't open if invalid query string parameters are passed to it. **Note:** The name can't start with an underscore (_) or crm_. It must start with alphanumeric characters followed by an underscore (_). For example, parameter_1 or 1_parameter. The name can't contain hyphens (-), colons (:), semicolons (;), commas (,) or periods (.).
Non-Event Dependencies	**Dependent Columns**	Each event handler has a similar **Dependent Columns** property so that any columns that are needed by the script can be registered. Anyone who tries to remove the dependent columns won't be able to.

Tab	Property	Description
		Some scripts operate on the form but aren't configured in an event handler. Scripts that are initiated from the command bar don't have a place where dependent columns can be registered. This form property provides a place for dependent columns for those scripts to be registered.

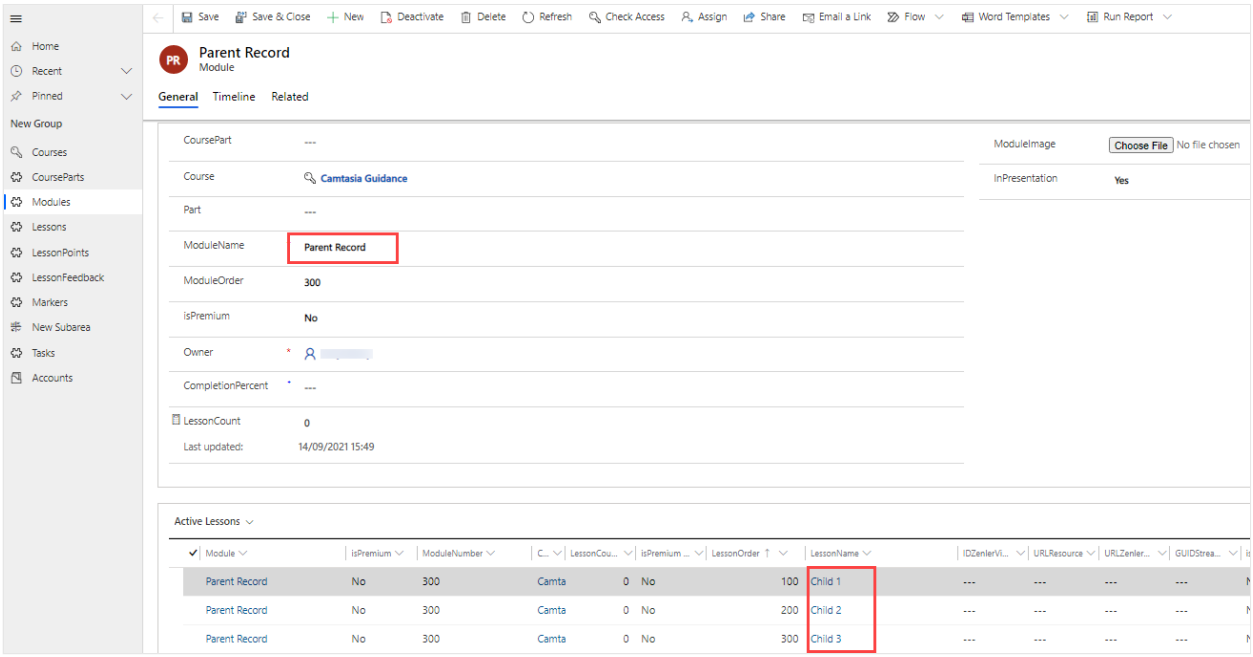
Subgrid properties for model-driven app main forms (classic)

Article • 09/26/2022

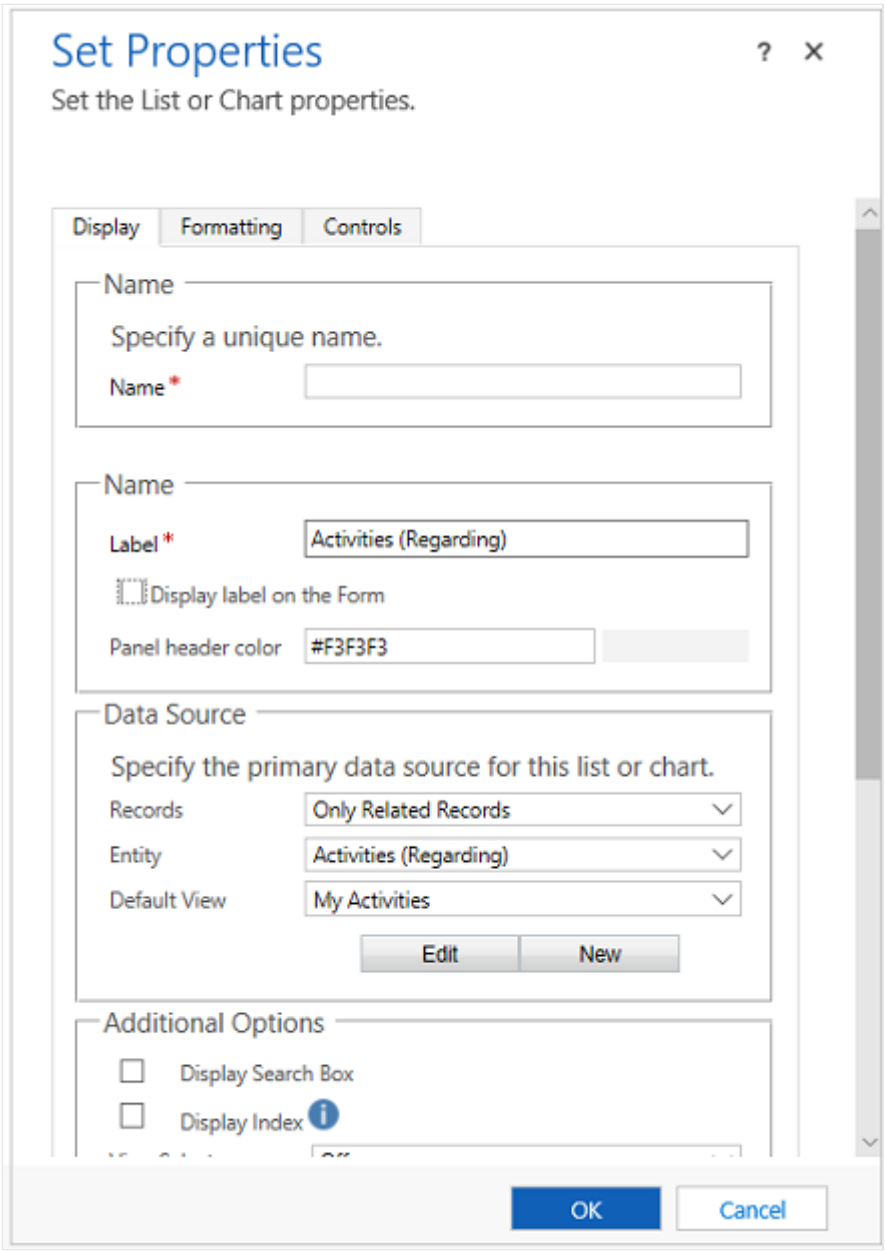
This article describes the classic form editor.

We recommend that you use the **modern form designer** to create and edit subgrids for model-driven app forms. More information: Add and configure a subgrid component on a form

A subgrid exists within a main form and let app users view data within a Dataverse table, typically related to the record currently being reviewed.



A subgrid on a form can be configured using the classic form designer to display a list of records or a chart. Select **Show Chart Only** on the **Display** tab to show a chart instead of a list.



These are the properties available to configure when using a subgrid component on a form using the classic form designer.

Tab	Property	Description
Display	**Name**	**Required**: The unique name for the subgrid that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores.
	Label	**Required**: The localizable label for the subgrid visible to users.
	Display label on the Form	Whether the label should be displayed on the form. This is required if you enable **Display Search Box**. You can also choose to have the panel header color.

Tab	Property	Description
	Records	Choose from two options: - **Only Related Records**: Subgrid will display only records related to the current record. - **All Record Types**: Subgrid will display records filtered only by the default view or, if the view selector is enabled, any views the user chooses. The option you choose will affect the behavior of the show list control. More information: Show list behavior
	Table	Depending on the option you choose for **Records**, this list displays either: - **Only Related Records**: A list of tables that are related to this table with the name of the lookup column on that table, which defines the relationship in parentheses. - **All Record Types**: A list of all tables.
	Default View	Choose the view that will be applied by default. If you do not enable any other views using the **View Selector** property. This will be the only view. Use the **Edit** button to open the default view for editing. Use the **New** button to create a new view to use for this subgrid.
	Display Search Box	Display the search box. When this option is chosen the **Display Label on the Form** option is required.
	Display Index	Only forms using the Classic forms support display index. Select this check box if you want the alphabetical index to be available with the list. This lets you jump to records starting with a particular letter or number.
	View Selector	You have three options: - **Off**: Only the default view can be used. - **Show All Views**: Allow people to choose any view. - **Show Selected Views**: Use the Ctrl key with your cursor to select which of the available views to show.
	Default Chart	Select which chart to show if **Show Chart Only** is selected.
	Show Chart Only	Rather than a list of records a chart will be displayed.

Tab	Property	Description
	Display Chart Selection	If **Show Chart Only** is selected, allow people to choose different charts.
	Availability	Specify whether the section should be available on phone.
Formatting	**Layout**	**Select the number of columns the control occupies**. When the section containing the subgrid has more than one column, you can set the column to occupy up to the number of columns that the section has.
	Number of rows	Determines how many records are shown on a page of a subgrid.
	Use available space	Note: This property only works with the legacy web client. It has no effect on Unified Interface. If **Automatically expand to use available space** is chosen, the form will allow space for two records and will expand the space as the number of records increases. If the number exceeds the **Number of Records**, users can navigate to additional pages to view the records. If **Automatically expand to use available space** is not chosen, the form will provide space for the number of records defined by **Number of rows** and users can navigate to additional pages to view any additional records.
Controls	**Controls**	Choose to add controls and select the radio button to have them for Web, Phone, or Tablet.

In forms using the classic forms, actions performed on a subgrid were available in the ribbon. Developers can customize the behavior of these actions or add additional actions by customizing the ribbon.

In forms using the current forms actions for subgrids are placed near the subgrid, making them easier to access. However the command bar does not allow for custom actions to be added. Developers can edit the ribbon to modify the actions for the remaining three actions: show list, add record, and delete record.

Show list behavior

When displaying a list in forms with the current forms, each subgrid displays the **Open View** button in the top-right when the table is also displayed as one of the tables included in the navigation area of the form editor. Choosing this button will open the

view. The behavior will change depending on the option chosen for the **Records** property.

When you select **Only Related Records** the view will open using one of the associated views in the same window. To return to the form, use the back button or choose the current record primary name value in the navigation bar.

When you select **All Record Types** the view will open in a new window.

Add record behavior

When displaying a list in forms with the current forms, each subgrid displays the **Add record** button ➕ in the top-right side of the subgrid. Choosing this button will allow you to add a record. This behavior will change depending on the option chosen for the **Records** property and if the lookup is for activity records.

When you select **Only Related Records** the default behavior is the behavior to add existing records. People see an in-line lookup to search for an existing record first. This helps prevent creating duplicate records. If they can't find an existing record, they can choose the **New** option. When a new record is created any of the column mappings defined in the relationship will be applied. More information: Map table columns

When you select **All Record Types** the default behavior is to add a new record. The quick create form will be shown if the target table has one. If not, the default table main form is shown.

If the subgrid displays activities, people will first need to choose the type of activity and then they will see the "add new record" behavior.

Delete record behavior

When you select a record in a subgrid the **Delete** button 🗑 appears on the right side of the record. The behavior of this delete action is different depending on the type of relationship with the current table.

When the subgrid uses a 1:N (one-to-many) relationship, the normal record delete behavior is to show a confirmation dialog before deleting the record.

When the subgrid uses a N:N (many-to-many) relationship, the record in the relationship (or intersect) table relating to two records is deleted without a confirmation and the record will no longer be displayed in the subgrid. But the record that was displayed is not deleted.

Use the Main form and its components

Tab properties for model-driven app forms overview

Article • 02/15/2022

This article describes the classic form editor. We recommend that you u se the modern form designer to add and edit tabs for your model-driven app forms. More information: Add, configure, move, or delete tabs on a form

These are the properties available to configure when using a tab on a form using the classic form designer. The following table shows properties that you can set for tabs on the form:

Tab	Property	Description
Display	**Name**	**Required**: The unique name for the tab that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores.
	Label	**Required**: The localizable label for the tab visible to users.
	Show the label of this tab on the Form	When the label is displayed people can select it to toggle whether the tab is expanded or collapsed. Choose whether you want to show the label.
	Expand this tab by default	The tab state can toggle between expanded or collapsed using form scripts or by people selecting the label. Choose the default state for the tab.
	Visible by default	Showing the tab is optional and can be controlled using scripts. Choose whether to make the tab visible. More information: Visibility options
	Availability	Choose if you want the tab to be available on the phone.
Formatting	**Layout**	Tabs may have up to three columns. Use these options to set the number of tabs and what percentage of the total width they should fill.
Events	**Form Libraries**	Specify any JavaScript web resources that will be used in the tab `TabStateChange` event handler.
	Event Handlers	Configure the functions from the libraries that should be called for the tab `TabStateChange` event. More information: Configure Event Handlers

Use controls for model-driven app data visualizations

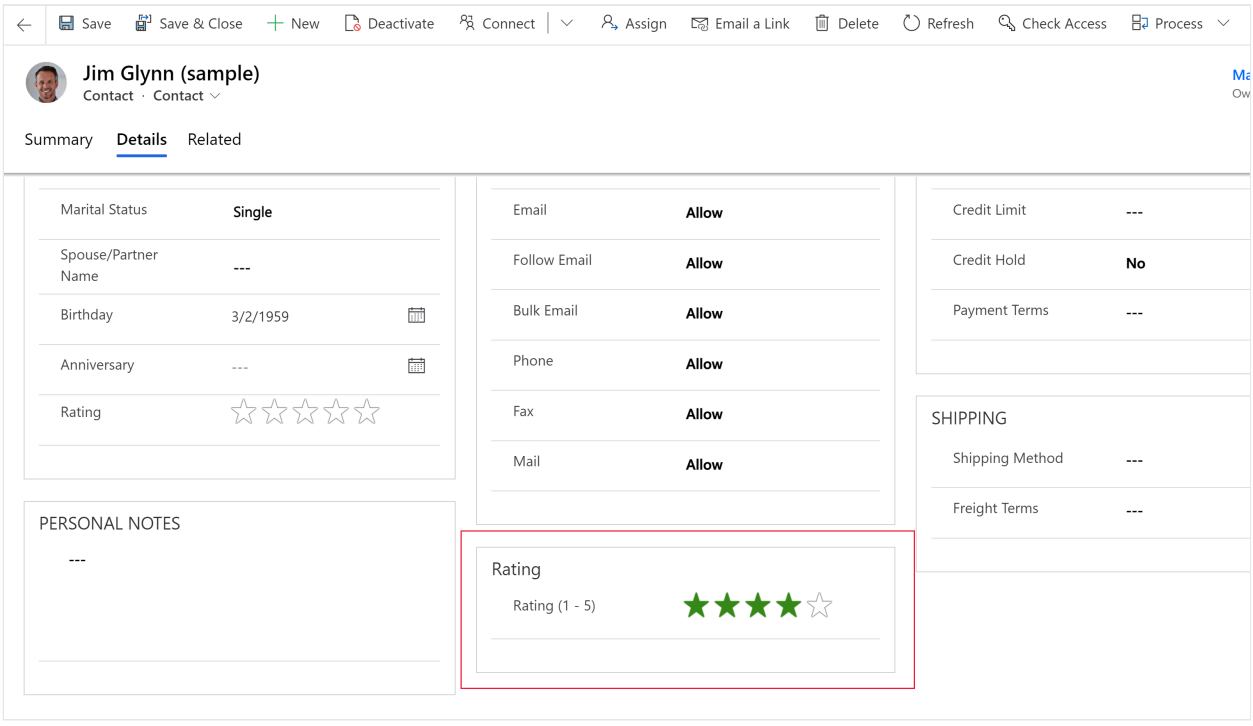
Article • 03/13/2023

In this article, you learn how to configure a control for a column using the classic form designer.

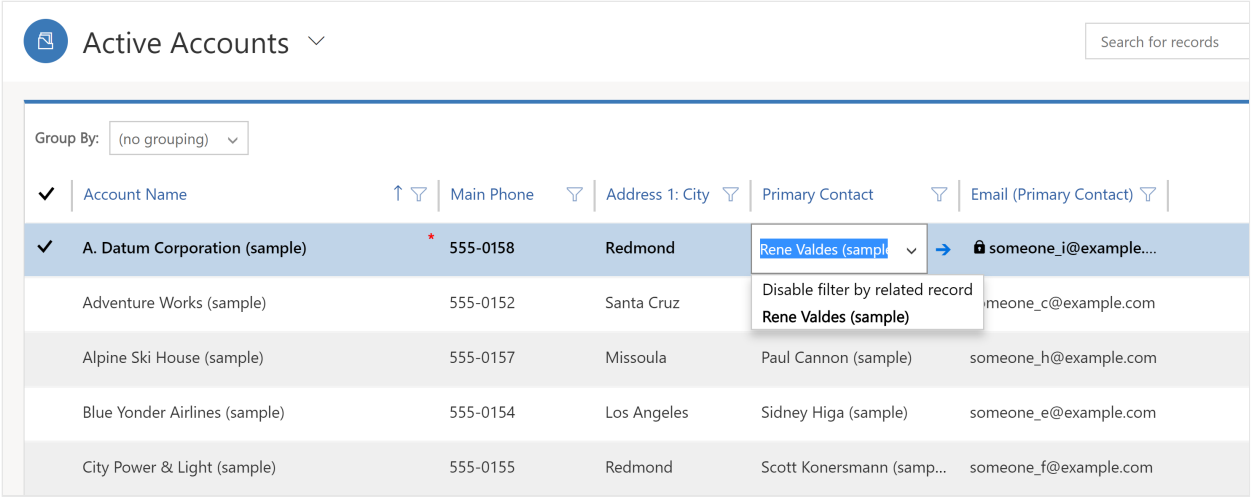
> **Important**
>
> This article describes classic controls many of which are now deprecated. For information about how to add modern controls using the modern Power Apps form designer, go to **Add components to a form**. For a list and descriptions of the current controls available for model-driven apps, go to **List of controls available for model-driven apps**.

Use a control using the classic form designer

Controls let you transform app user interface components, such as a column or view that traditionally contain text, into visualizations. Controls can be configured on columns, forms, dashboards, views, and grids. For example, a star rating can be configured on a whole number column.



Or the editable grid control can be configured on a view.



You can set one type of custom control to appear in the web browser client while having a different custom control appear in your Dynamics 365 phone or tablet mobile apps. For example, you could use a standard yes/no choice column in web browser clients and a toggle control for tablet and phone clients. After the customization is published, users can fully interact with the control to change the value, such as by tapping the control when using the toggle control. Changes are automatically saved when the form is closed just as they are when the user changes a traditional column on a form.

Use a custom control to add visualizations to a column

Following the steps in this procedure will change the default label and text box column of the **Budget Amount** column to the slider custom control on the opportunity table. You can use similar steps to replace an existing column with a custom control or configure a custom control for a custom column.

> **Note**
>
> Currently, this control can only be added and configured using the classic experience.

> The opportunity table requires a Dynamics 365 app, such as Dynamics 365 Sales.

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane, select the **Opportunity** table, and then select the **Forms** area. If the item isn't in the left navigation pane, select ...More and then select the item you want.

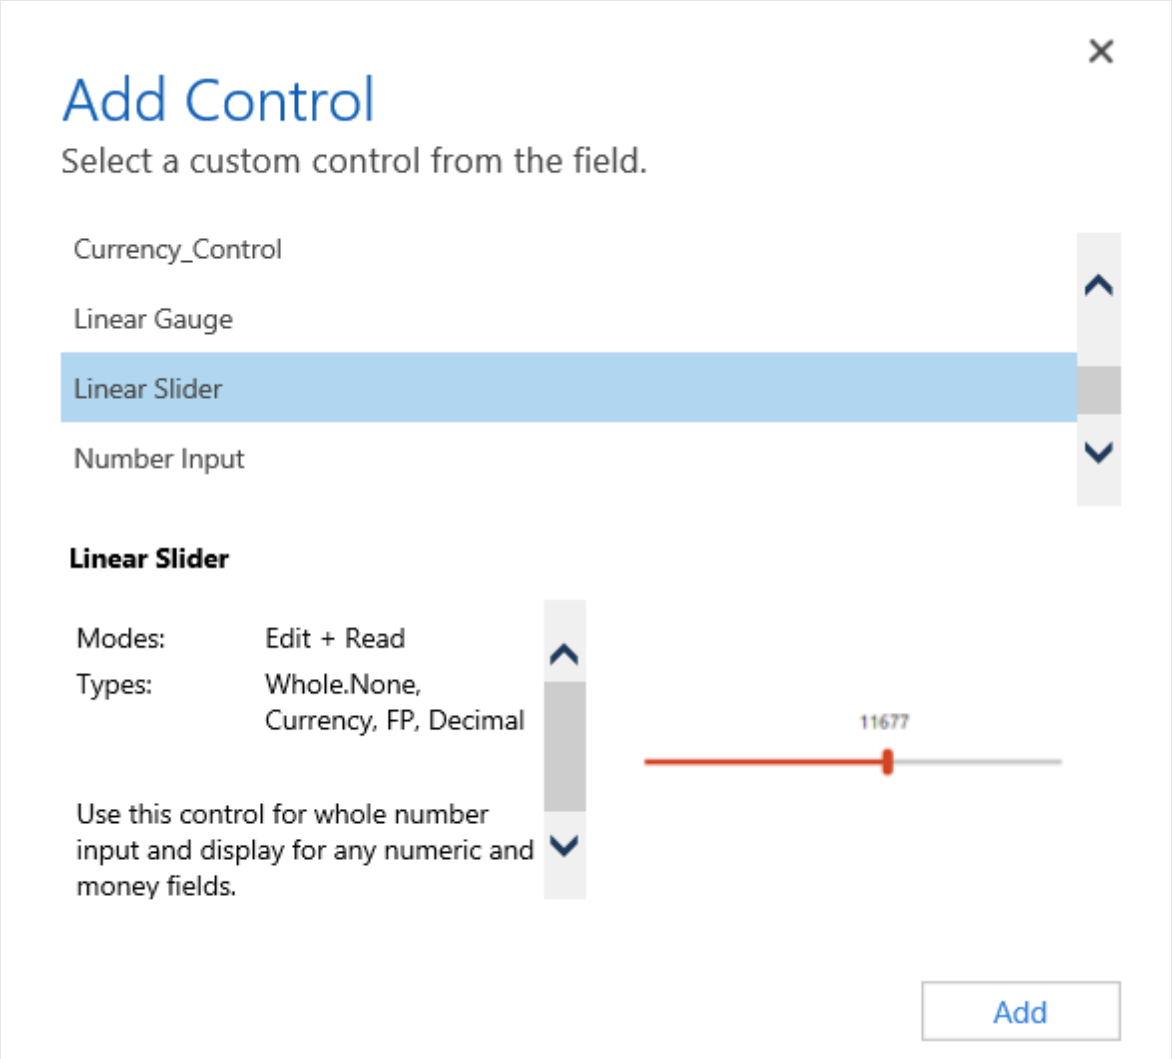
3. Open a form such as the **Main** form for the **Opportunity** table.

4. Once in the form, select **switch to classic**. This will open the classic editor in a separate tab.

5. In the form editor, double-click the column where you want to add a custom control, such as the **Budget Amount** column on the account main form. This is column of a number type. Alternatively, you can create a custom column.

6. On the **Column Properties** page, select the **Controls** tab, and then select **Add Control**.

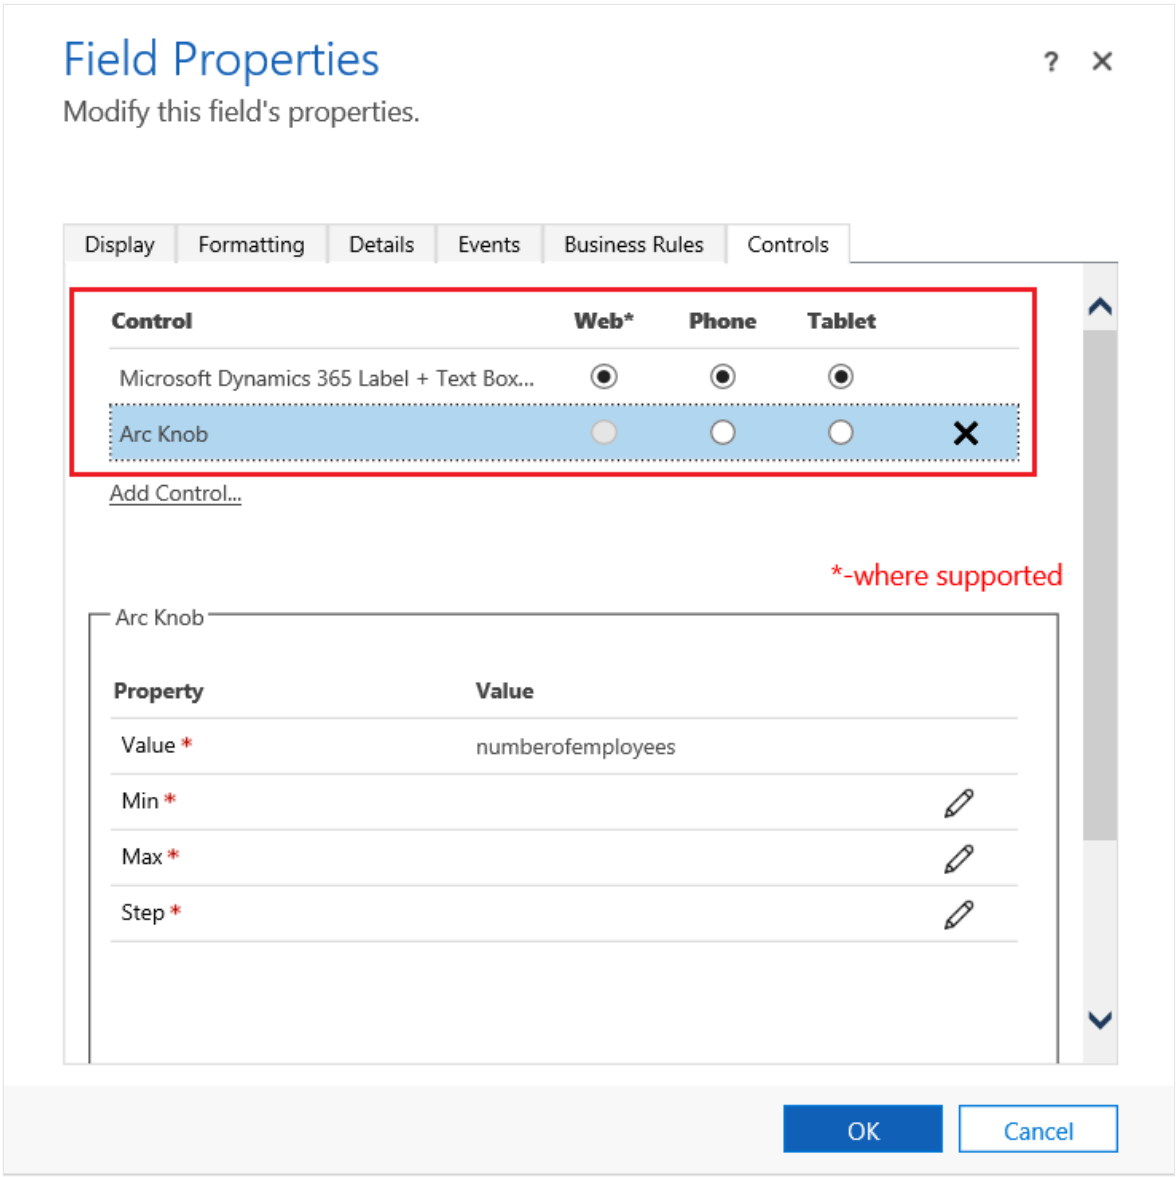
7. On the Add Control page, select the control that you want, such as the **Linear Slider** control shown here, and then select **Add**.



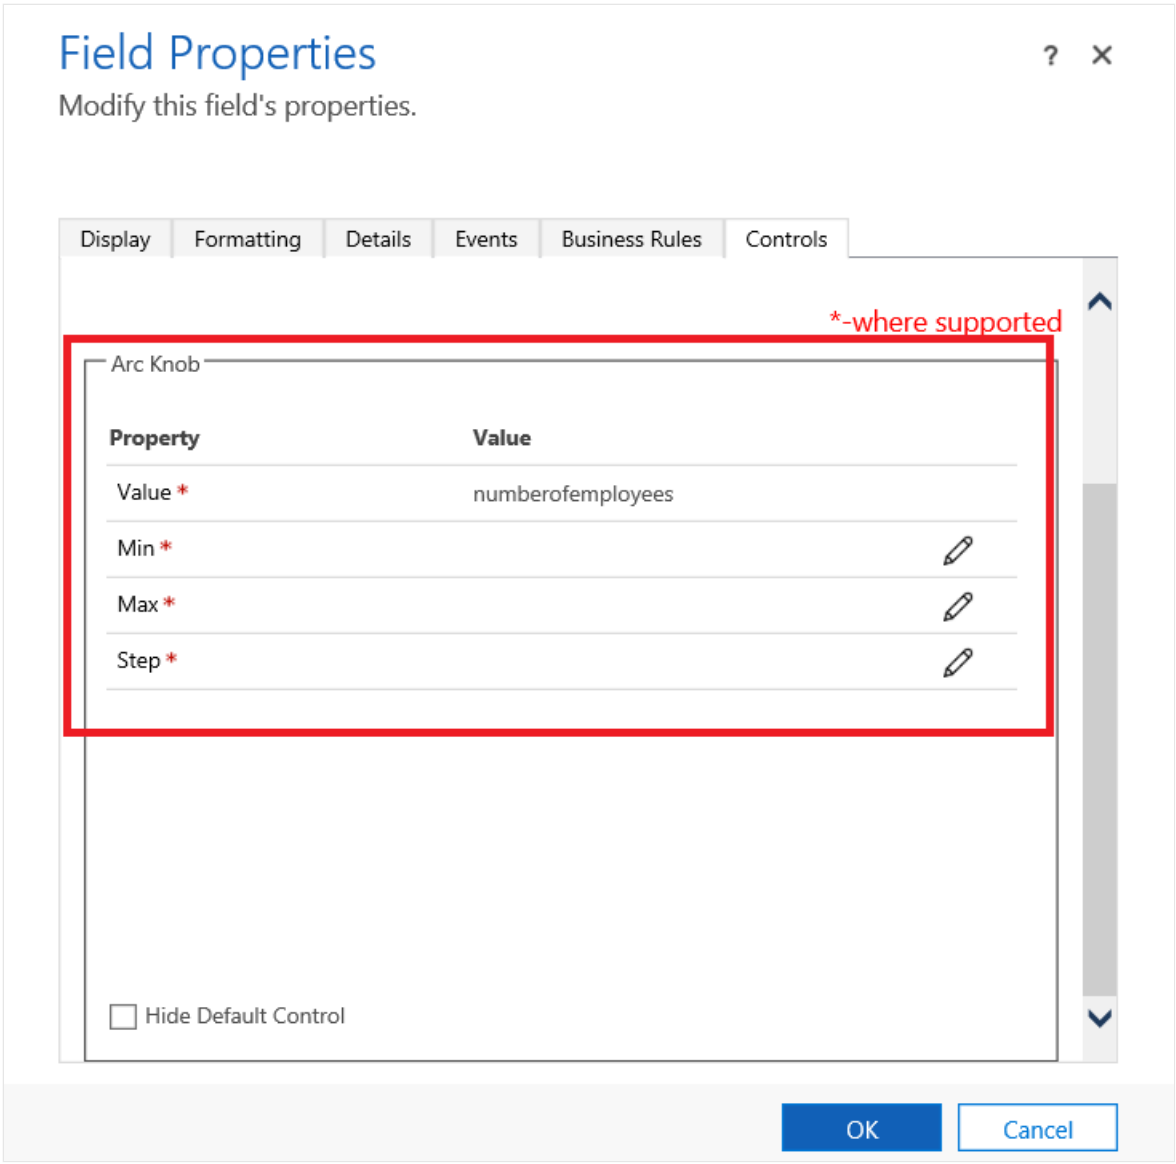
8. Choose the client where you want the control to appear.

   - **Web**. To make the custom control available from any web browser, select the **Web** option next to the control. Notice that setting the **Web** option includes rendering the control in web browsers on PCs, Macs, and mobile devices.

- **Phone**. To make the custom control available on phones running Dynamics 365 for phones, select the **Phone** option next to the control.
- **Tablet**. To make the custom control available on tablet devices running Dynamics 365 for tablets, select the **Tablet** option next to the control.



9. Select the pencil icon next to **Min**, **Max**, and **Step**, set the property option described below, and then select **OK**.

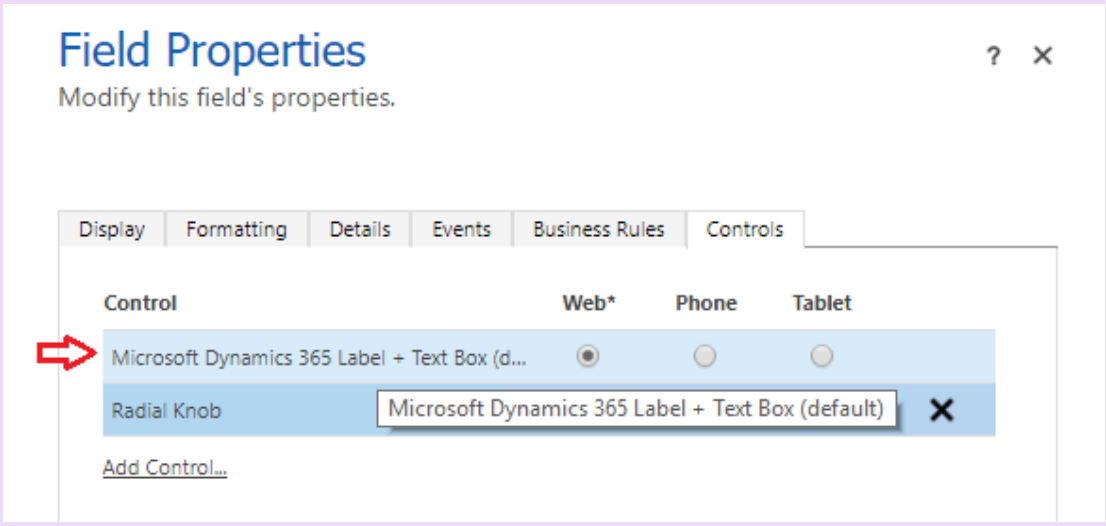


- **Min**. Set the minimum accepted value. You can bind a static value that you enter or bind the value to an existing column. In this example **Bind to static value** is **Currency** and the minimum value that can be entered is *zero*.
    - **Bind to a static value**. Select the data type, such as a whole number (Whole.None), currency, floating point (FP), or decimal. Next, enter a number that represents the minimum accepted value for the column.
    - **Bind to values on a column**. Select a column from the list that will be used as the minimum accepted value.
- **Max**. Set the maximum accepted value for the column. Similar to the Min value, you can bind a static value that you enter or bind the value to an existing column as described earlier. In this example, **Bind to static value** is **Currency** and the maximum value that can be entered is **1 billion**.
- **Step**. This represents the unit to increment or decrement when adding to or subtracting from the current value. For example, for budget amount you can select

100 dollar increments\decrements.

- **Hide Default Control**. Selecting this option hides the control so neither the control or the data is displayed in any of the clients that don't support the custom control. Notice that the classic Dynamics 365 web client doesn't support most custom controls. By default, this option is not selected and the classic Dynamics 365 web client displays the default, typically text based, control.

> ⓘ Note
>
> The default control is identified with **(default)** following the control name.



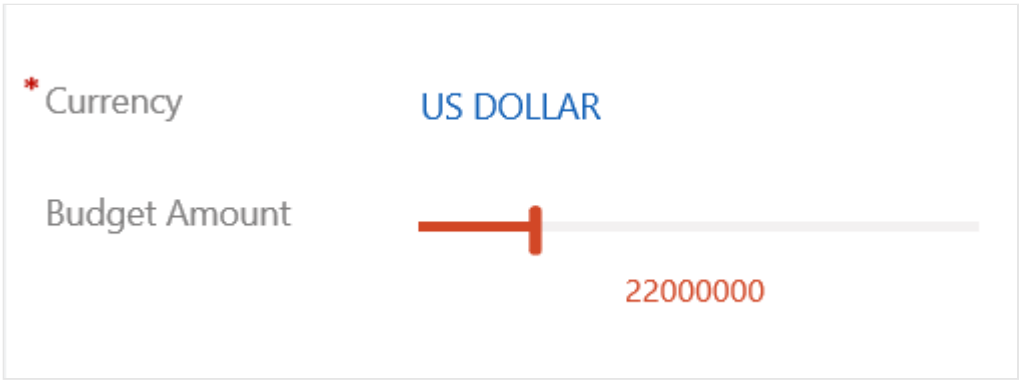
10. Select **OK**, to close the **Column Properties** page.

11. To activate the customization, on the table form select **Save**, and then select **Publish**.

12. Select **Save and Close** to close the form editor.

See the custom control in action

Open a record that includes the column with the custom control, such as the opportunity form from the previous example, and view how the column is changed.



The column is now rendered as a slider control instead of the text column.

Use the editable grid control on a view or subgrid

With editable grids, users can do rich in-line editing directly from views and subgrids whether they're using a web app, tablet, or phone. More information: Make grids (lists) editable using the Editable Grid custom control

Create and edit columns

Model-driven app form section properties (classic)

Article • 03/13/2023

A section in a form occupies the space available in a tab column. Sections have a label that can be displayed and a line might be shown below the label.

Sections can have up to four columns and includes options for displaying how labels for columns in the section are displayed.

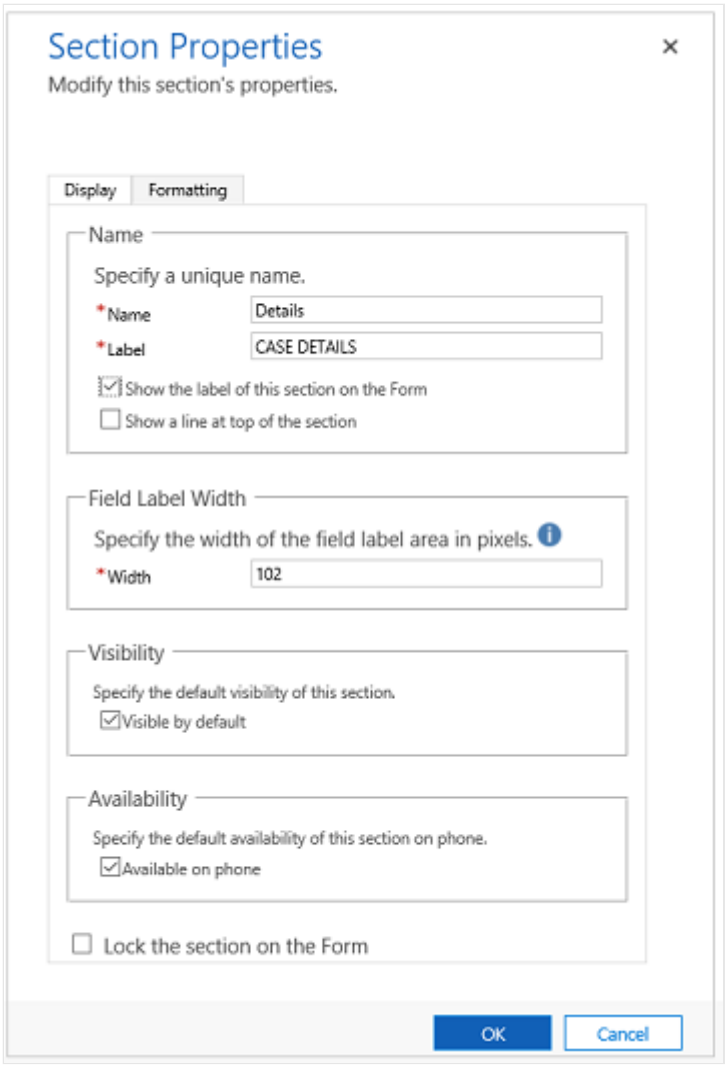
Headers and footers are similar to sections but cannot be removed. If they don't contain anything they will not be shown.

> ⓘ **Note**
>
> For the modern experience when working with sections on a form, see **Add, configure, move, or delete sections on a form**

Section properties in classic form designer

You can access **Section properties** in solution explorer from Power Apps (make.powerapps.com).

1. Sign in to Power Apps.
2. Select **Tables** on the left navigation pane, select the table that you want, and then select the **Forms** area. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. In the list of forms, open the form of type **Main**.
4. Select **Switch to classic** to edit the form in the classic form designer.
5. Double-click inside one of the sections to see the section properties.



Tab	Property	Description
Display	**Name**	**Required**: The unique name for the section that is used when referencing it in scripts. The name can contain only alphanumeric characters and underscores.
	Label	**Required**: The localizable label for the section visible to users.
	Show the label of this section on the form	Sections are frequently used without labels to control formatting of the columns within them.
	Show a line at top of the section	A line at the top of a section can help break up the form layout.
	Column Label Width	**Required**: Set a value between 50 and 250 to specify the space allowed for column labels. Header and footer elements also have this property.

Tab	Property	Description
	Visibility	Showing the section is optional and can be controlled using scripts. More information: Visibility options
	Availability	Choose if you want the tab to be available on the phone.
	Lock the section on the form	This will prevent the section from accidentally being removed and prevents people from removing the contents. Removing a section will not only remove the section, but also any columns within it. Someone wanting to remove this section would need to change this setting before removing it.
Formatting Header and footer components also have this property.	**Layout**	Specify up to four columns to be in the section.
	Column Label Alignment	Labels for columns within the section can be aligned left, right, or center.
	Column Label Position	Labels for columns within the section can be positions on the side or on top of the columns.

A new type of section called **Reference panel** can also be added. A Reference panel is a single column section. You can insert sub-grids, quick view control, or a Knowledge Base Search control inside a reference panel section. Each control that you added in the reference panel appears as a vertical tab within the panel at the runtime. You can drag and drop the various controls within the Reference panel section. The default tab at runtime is the first control added in the reference panel. The other tabs appear in the order in which they are added in the form editor. To delete a tab, use the delete key on your keyboard.

When you insert a reference panel, by default it's added as a last section in the tab. You can add only one reference panel per form.

> **ⓘ Important**
>
> - By default, the reference panel section is locked in these standard forms: Cases, Accounts, and Contacts. To remove it or change it, you must unlock it.

- Quick view forms are based on an organization and not at an app-level setting. So, any quick view form that is available, which may or may not be included in an app, will be used to render related information in a reference panel.

Use the Main form and its components

Configure model-driven app form event handlers

09/19/2025

Form event handlers for Power Apps forms can be configured for the following areas in a form:

Expand table

Element	Event	Description
Form	`OnLoad`	Occurs when the form loads.
	`OnSave`	Occurs when data is saved.
Tab	`TabStateChange`	Occurs when the tab is expanded or collapsed.
Column	`OnChange`	Occurs when data in the column changes and the control loses focus.
IFRAME	`OnReadyStateComplete`	Occurs when the content of an IFRAME loads.

An event handler consists of a reference to a JavaScript web resource and a function defined within that web resource that executes when the event occurs. Each element can have up to 50 separate event handlers configured.

> **Important**
>
> Configuring an event handler incorrectly can result in script errors that might cause the form to fail to load or function correctly. If you aren't the developer of the script, make sure you understand exactly what configuration options the script requires.
>
> Don't configure a script event handler using a library that doesn't come from a source you trust. Scripts can be used to perform any action a user might perform and a poorly written script can significantly damage the performance of a form.
>
> After you configure an event handler, always test it to verify it's working correctly.

Configure an event handler

The following procedure describes how to configure an event handler for a form. Use similar steps to configure an event handler for a tab, column, or IFrame.

1. Sign in to Power Apps, open the table that you want, and then open the form in the form designer where you want to configure an event handler.

2. Depending on the library state, choose from the following options:

   - If the library containing the function you want to set as the event handler is already available, on the right properties pane under **Account Main form**, select the **Events** tab, and then go to step 3.
   - If the library containing the function you want isn't already available, select **Form libraries** on the left navigation pane, and then select **Add library**:
     a. On the **Add JavaScript Library** page, select **New**.

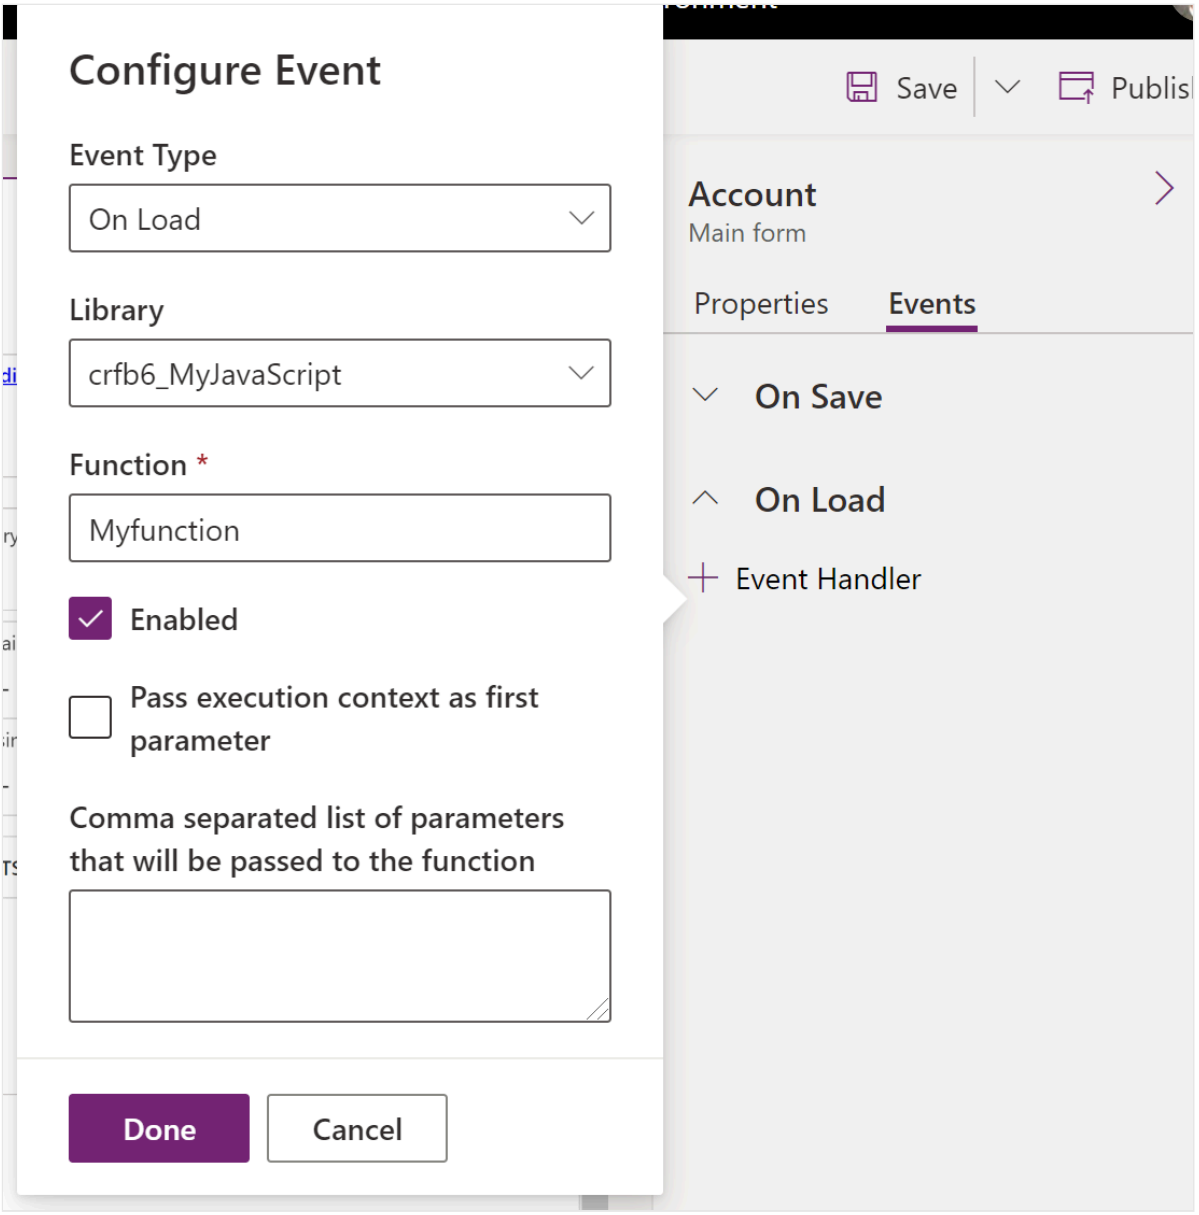
     b. In the new browser tab, complete the properties to create the JScript web resource, and then select **Save**, and then select **Publish**. More information: Create a JavaScript web resource
     c. Close the browser tab and go back to the **Add JavaScript Library** list.
     d. Select the JavaScript web resource from the list, select **Add**, and then select the **Events** tab.

> **Note**
>
> You might have to select **Cancel**, and then select **Add library** to refresh the list.

3. On the **Events** tab, select **Event Handler** and complete the following information to configure the form event, and then select **Done**:

   - **Event Type**:
     - **On Save**: When a record is saved after a form field change.
     - **On Load**: When the form opens.

- **Library**: The JavaScript web resource.
- **Function**: The name of the function within the JavaScript web resource that should be executed for the event.
- **Enabled**: By default, the event handler is enabled. Clear the **Enabled** checkbox if you don’t want to enable this event.
- **Pass execution context as the first parameter**: Some functions require an execution context to be passed to the function. Select **Pass execution context as the first parameter** if it's required.
- **Comma-separated list of parameters that will be passed to the function**: Some functions can accept a set of parameters to control the behavior of a function. The list of parameters can include variables or another function as accepted by the function parameters allowed by the JavaScript scripting language. If passing in parameters is required, enter them in the **Comma separated list of parameters that will be passed to the function**.
- **Table column dependencies**: For **On Save** events, select the columns where you want the event to be triggered after a record save.

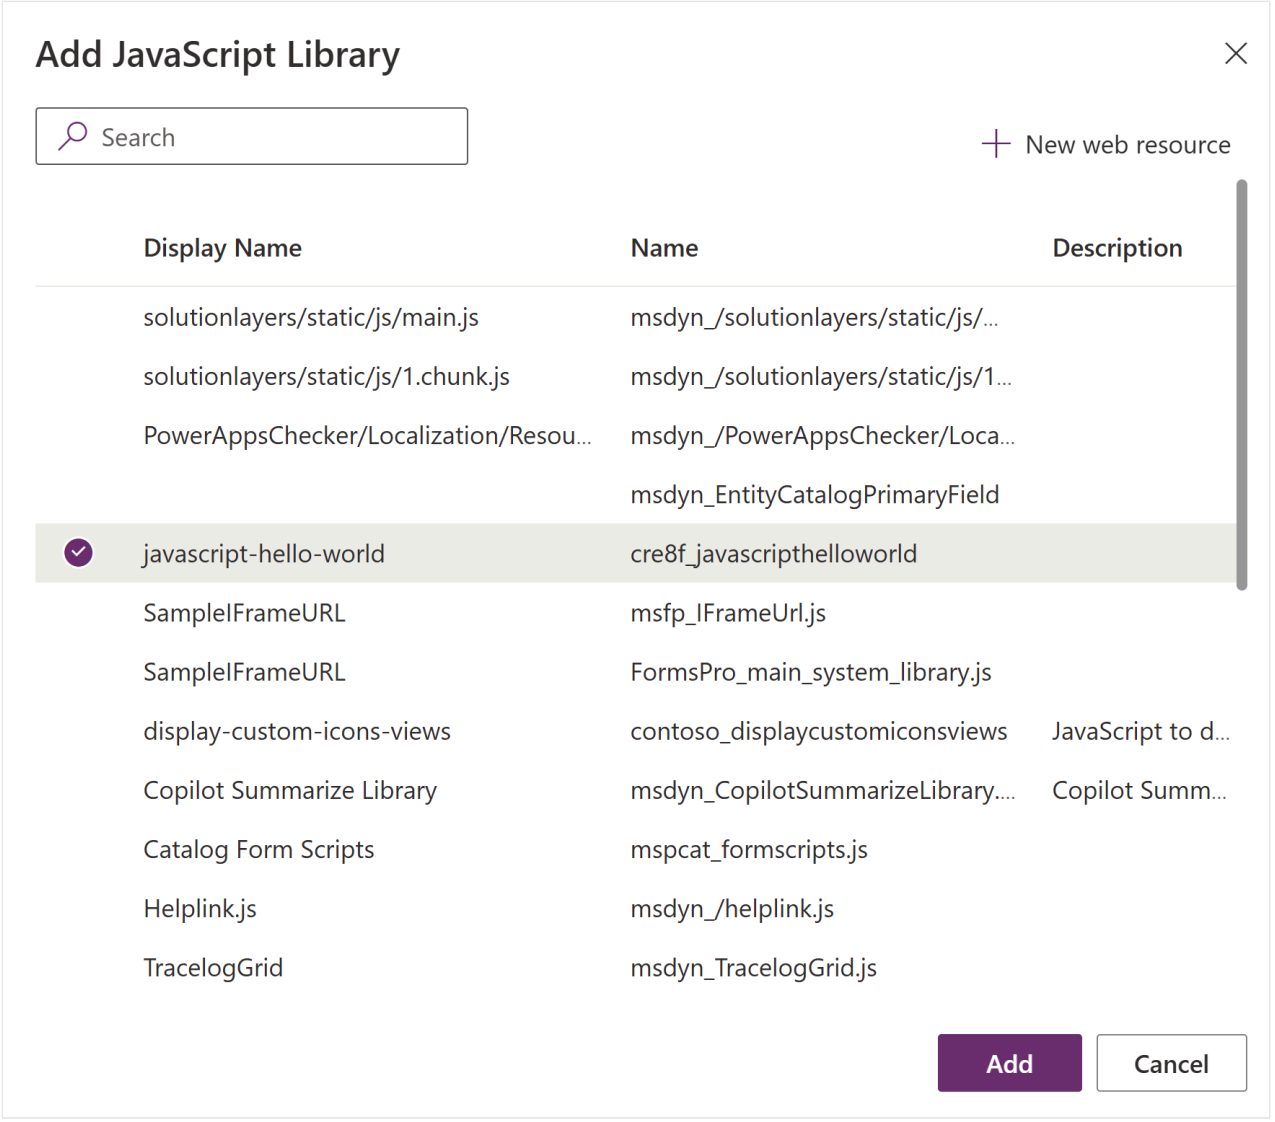


4. **Save**, and then **Publish** the form.

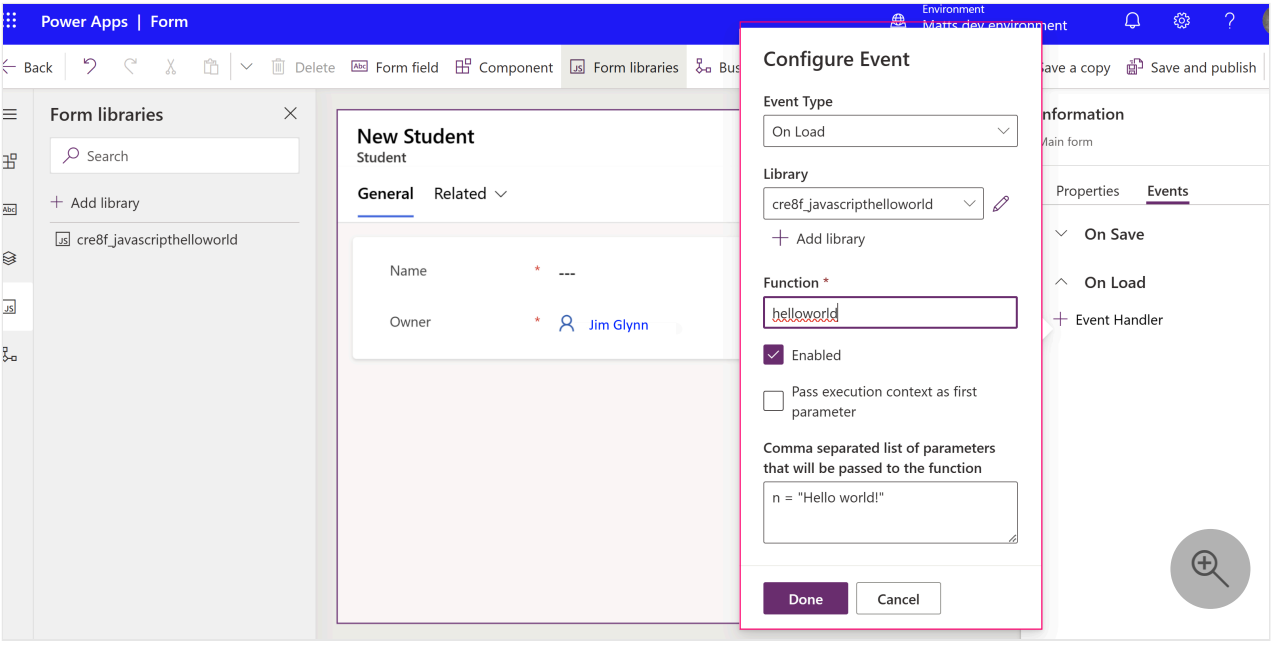
Example hello world for the onload event

This simple example demonstrates how to configure an onload form event using parameter passing of a single defined variable in the event handler, which displays an alert when the form loads.

1. Create the web resource using the Hello world JavaScript sample. More information: Create or edit model-driven app web resources to extend an app
2. Open the table Main form for editing in the form designer. This example uses the *Student* custom table main form.
3. On the left Information pane, select the **Events** tab.
4. Select **Add library**, select the web resource you created (in this example the resource is named *javascript-hello-world*), and then select **Add**.

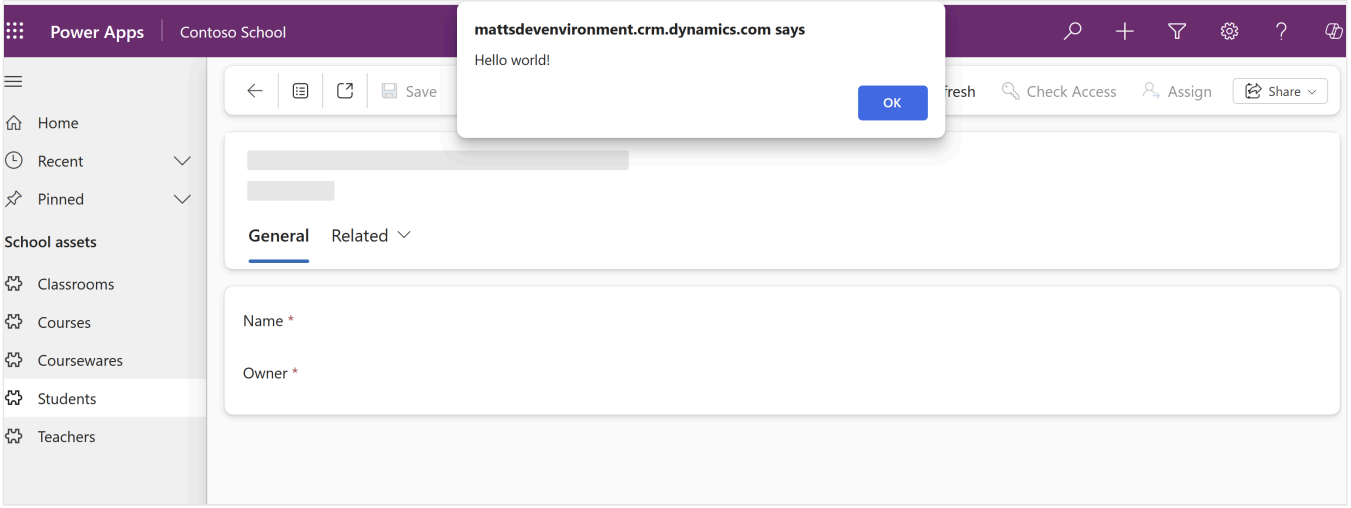


5. Select **On Load** to expand it, and then select **Event Handler**.
6. In the **Configure Event** pane, enter the **Function** name (in this example, *helloworld*), and then in the **Comma separated list of parameters that will be passed to the function** box enter a parameter such as `n = "Hello world!"`.



7. Select **Done**.
8. **Save and publish** the form.

Test the event by playing a model-driven app that includes the form. When the main form loads, an alert displays the modal dialog message "Hello world!" For this example, the user must select **OK** to dismiss the alert to continue using the form.



Hello world JavaScript sample

JavaScript

```
function helloworld(n) {
alert(n);
}
```

Configure an event handler using the classic experience

1. In the classic form editor, select the element with the event you want to configure a handler for.
2. On the Home tab, in the **Edit** group, select **Change Properties** or simply double-click the element.
3. In the element properties dialog, select the **Events** tab.
4. Expand the **Form Libraries** area. If the library containing the function you want to set as the event handler isn't already listed, add the library.
5. To add a form library to an event handler:
    a. In the **Form Libraries** section of the **Event List**, select **Add**.
    b. Locate the JavaScript web resource in the list of available web resources. Select it and then select **Add**.

If the JavaScript web resource you need doesn't exist, select **New** to open a new web resource form and create one.

c. To create a JavaScript web resource, see Create a JavaScript web resource.

d. The web resource you created is now selected in the **Look Up Row** dialog. Select **Add** to close the dialog.

6. In the **Event Handlers** section, select the event you want to set an event handler for.
7. Select **Add** to open the **Handler Properties** dialog.
8. On the **Details** tab, choose the appropriate library and type the name of the function that should be executed for the event.
9. By default the event handler is enabled. Clear the **Enabled** checkbox if you do not want to enable this event.

   Some functions require an execution context to be passed to the function. Select **Pass execution context as the first parameter** if it's required.

   Some functions can accept a set of parameters to control the behavior of a function. If these are required, enter them in the **Comma-separated list of parameters that will be passed to the function**.
10. On the **Dependencies** tab, add any columns that the script depends on into the **Dependent Columns** area.
11. Select **OK** to close the **Handler Properties** dialog.
12. When the event handler is entered, you can adjust the order in which the function is executed relative to any other functions by using the green arrows to move it up or down.
13. Select **OK** to close the element properties dialog.
14. Select **Save** to save your changes. Select **Publish** to publish the form.

> **Note**
>
> While the user interface (UI) lets you adjust the order in which the scripts are loaded by using the up and down green arrows, the scripts are actually not loaded sequentially.

Create a JavaScript web resource

1. In the web resource form set the following properties:

Expand table

Property	Value
Name	**Required**. Type the name of the web resource.
Display Name	**Required**. Type the name to be displayed in the list of web resources.
Description	Optional. Type a description of the web resource.
Type	**Required**. Select **Script (JScript)**.
Language	Optional. Choose one of the languages available for your organization.

2. If you have been provided with a script, we highly recommend that you use the **Browse** button to locate the file and upload it.

Alternatively, you can select the **Text Editor** button and paste or type the contents of the script in the **Edit Content** dialog.

> **Note**
>
> Because this simple text editor doesn't provide any features to check the correctness of the script, generally you should always try to use a separate application like Visual Studio to edit scripts, and then upload them.

3. Select **Save** and close the web resource page.

Use the Main form and its components

Disable AutoSave in a model-driven app

Article • 04/21/2025

AutoSave helps app users focus on their work without having to manage saving data in the form. Most people appreciate not having to explicitly save data each time they update a row, but some organizations might have customizations that were designed expecting an explicit save. For these organizations there are options to manage how AutoSave is applied.

How AutoSave works

By default all main forms for Updated tables and classic tables have AutoSave enabled. After a row is created (initially saved), any changes made to a form are automatically saved 30 seconds after the change is made. If no changes are made in the form, the automatic save doesn't occur while the form is open. After a change is made, the 30-second period before an AutoSave begins again. If someone else has updated the same row while you're editing it, those changes are retrieved and displayed in the form when AutoSave occurs.

With AutoSave enabled, the save button only appears for the initial save of the row. After the row is created, the save button in the command bar isn't shown, but you can see a 💾 button in the lower right corner that shows if there are any unsaved changes. This control is also displayed if AutoSave is disabled.

You can select this button to save the row and refresh data in the form immediately. When AutoSave is enabled the row is saved whenever you navigate away from a row or close a separate window displaying a row. There's no need for the **Save & Close** button that appears in forms for tables that aren't updated.

Should you disable AutoSave?

If you have plug-ins, workflows, or form scripts that execute when a row is saved, they run each time AutoSave occurs. This pattern might lead to undesirable behaviors if these extensions weren't designed to work with AutoSave. Whether AutoSave is enabled or not, plug-ins, workflows, and form scripts should be designed to look for specific changes, and shouldn't execute indiscriminately for each save event.

If you have auditing configured for a table, each save is treated like a separate update. If someone lingers on a form with unsaved changes for more than 30 seconds, you observe another entry only if they add more data after the AutoSave is performed. If you have reports that depend on auditing data and treat each save as an individual "touch" of a row, you might see an increase in the frequency of touches. If you're using this approach, you should consider that individual user behaviors make it an unreliable metric with or without AutoSave enabled.

Disable AutoSave for the organization

If you determine that AutoSave causes problems with extensions you're using, Power Platform admins can disable it for the environment. There's no setting to disable AutoSave for individual tables or forms.

1. Sign into the Power Platform admin center, go to **Manage** > **Environments**, and then open the environment you want.
2. Select **Settings** on the command bar.
3. Expand **Product**, and then select **Behavior**.
4. Under **Basic behavior**, for the **Auto save**, select **Off**.

Disable AutoSave for a form

If you want to disable AutoSave for specific table forms, you can add code to the `OnSave` event in a table.

> **Note**
>
> By using this method, auto-save is disabled for the form, but data is still saved when you select the button in the lower-right corner. If you attempt to navigate away from a form or close a form where data was changed, you get a prompt to save changes before you're allowed to navigate away or close the form.
>
> Using the procedure here causes the **Save and close** button on the form to not work, as it calls `preventDefault` on `saveMode` 2, which references **Save and Close**. You can remove the `getSaveMode() == 2` check to avoid this, but then the form autosaves when you attempt to navigate away from the form or close the form where data has changed. The **Save and Continue** button also doesn't work for this reason.

1. Sign in to Power Apps.

2. Select **Tables** on the left navigation pane, select the table that you want, and then select the **Forms** area. If the item isn't in the side panel pane, select ...More and then select the item you want.

   You can also make adjustments to the tables from within a solution. To do this, select **Solutions** on the left pane, select the table, and then select the **Forms** area. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Open the form you want to edit.

4. Select **Switch to classic** to edit the form in the classic form designer.

5. Create a JavaScript web resource and add it to the form:

   a. In the form editor, in the **Form** group, choose **Form Properties**.

   b. On the **Events** tab, below **Form Libraries** choose **Add**.

   c. In the **Look Up Row** dialog box, choose **New**.

   d. Enter the following information in the web resource form:

Expand table

Title	Reference
Name	preventAutoSave
Display Name	Prevent AutoSave
Type	Script (JScript)

   e. Next to the **Type** column, choose **Text Editor**.

   f. In the **Source** column, paste the following code:

```javascript
function preventAutoSave(econtext) {
    var eventArgs = econtext.getEventArgs();
    if (eventArgs.getSaveMode() == 70 || eventArgs.getSaveMode() == 2) {
        eventArgs.preventDefault();
    }
}
```

   g. Choose **OK** to close the text editor.

   h. Choose **Save** to save the web resource and then close the web resource window.

   i. In the **Look Up Row** dialog the new web resource you created is selected. Choose **Add** to close the dialog.

6. Configure the `OnSave` event:

   a. In the **Form Properties** window, in the **Event Handlers** section, set **Event** to **OnSave**.

   b. Select **Add**.

c. In the **Handler Properties** window, set **Library** to the web resource you added in the previous step.

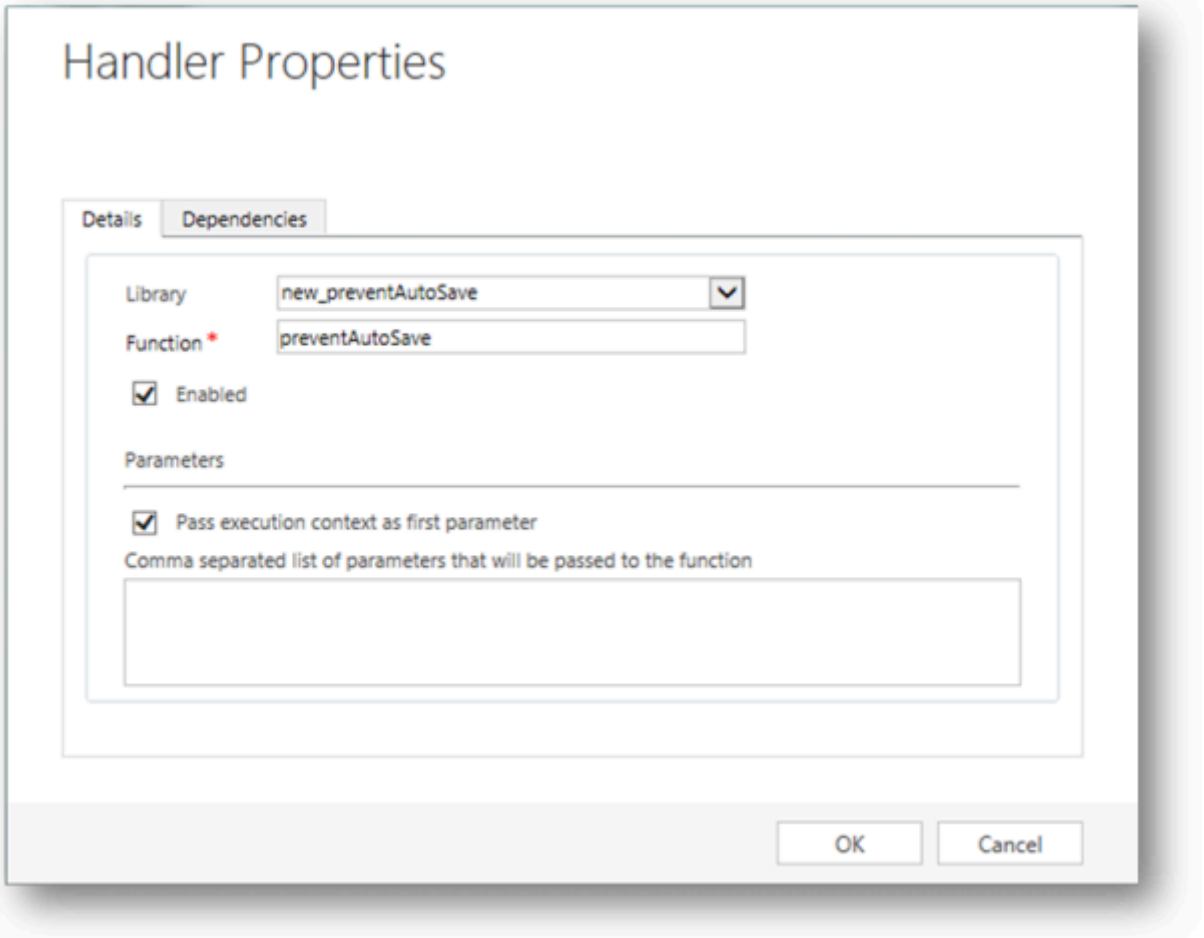
d. Type '`preventAutoSave`' in the **Function** column. This is case sensitive. Don't include quotation marks.

e. Make sure that **Enabled** is checked.

f. Check **Pass execution context as first parameter**.

> **ⓘ Important**
>
> If you don't do this the script won't work.

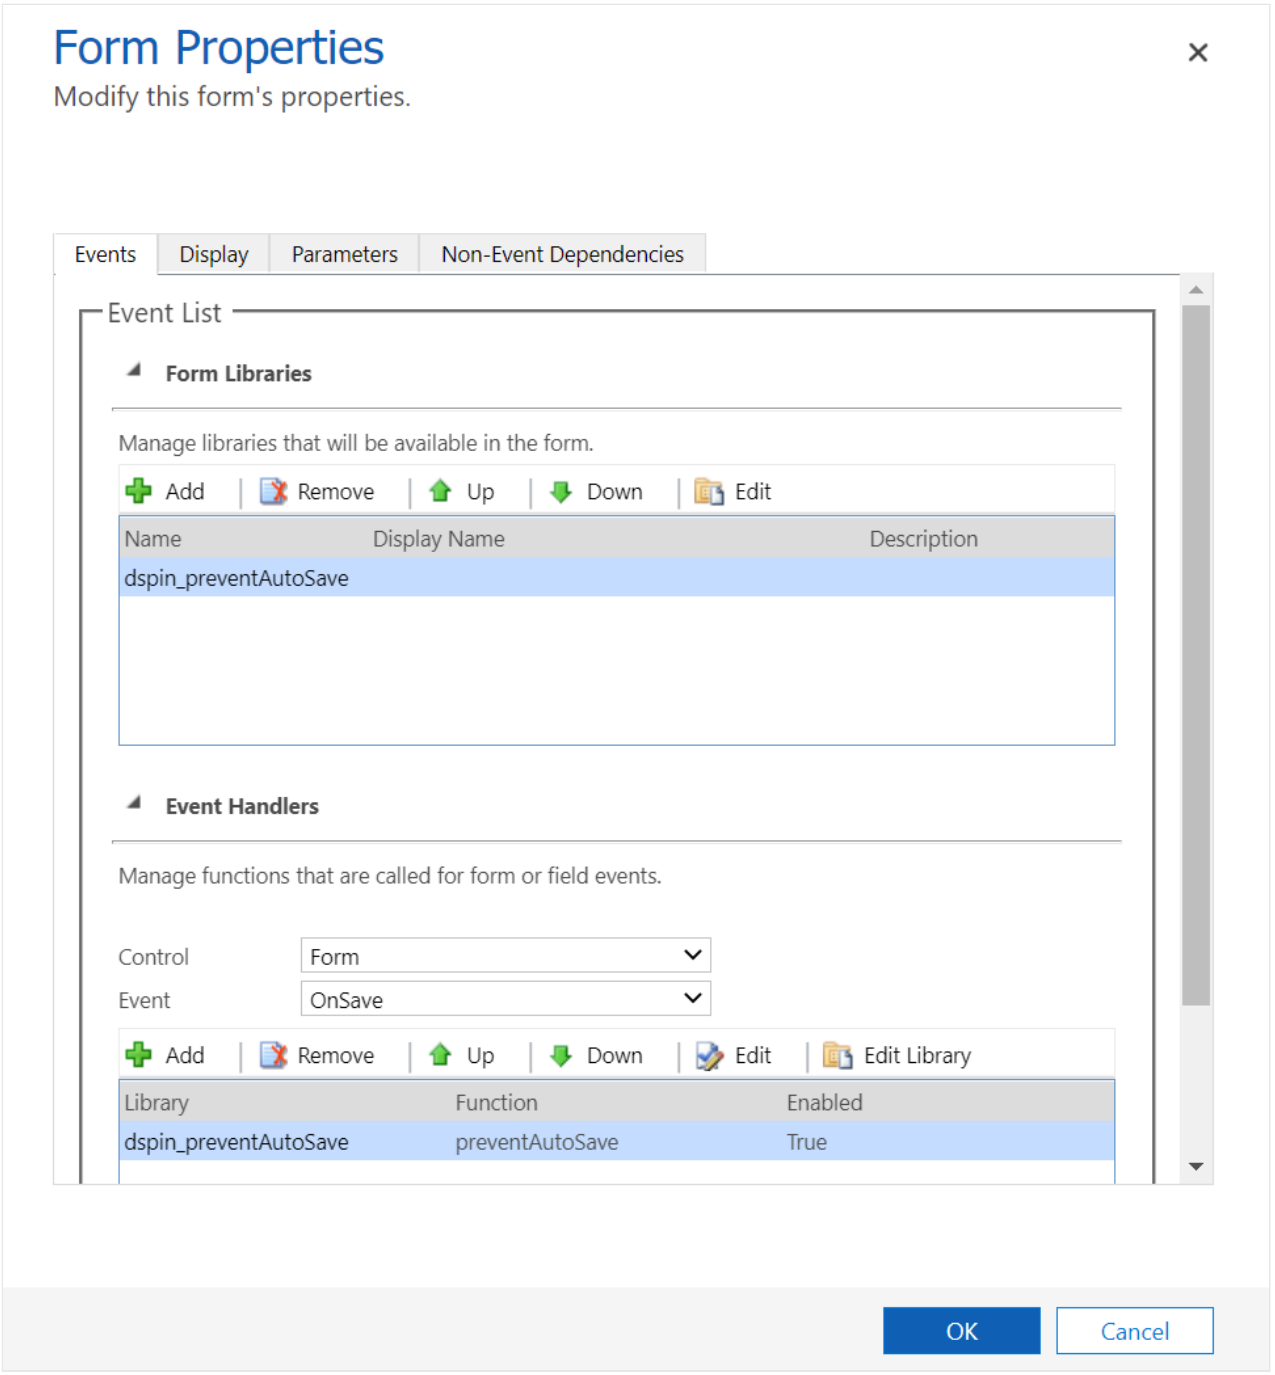
The **Handler Properties** dialog should look like this. The customization prefix: "new_" might vary based on the customization prefix set for the default publisher for your organization.



g. Select **OK** to close the **Handler Properties** dialog.

h. If there are any other event handlers for the `OnSave` event, use the green arrows to move this one to the top.

The **Form Properties** should display as follows. Note in the example shown here, the update has taken place from within a solution and as a result the publisher prefix (dspin_) isn't the same as the one provided by the default publisher (new_). This is because a different publisher is used for the solution.



7. Select **OK** to close the **Form Properties** dialog.

8. Select **Save and Close** to close the form.

9. In the solution explorer, select **Publish All Customizations**.

After you apply this script to the `OnSave` event, when users edit a row using this form the message **unsaved changes** appears in the bottom right corner of the form just as it would if

AutoSave wasn't disabled. But this message won't go away until people select the button next to it.

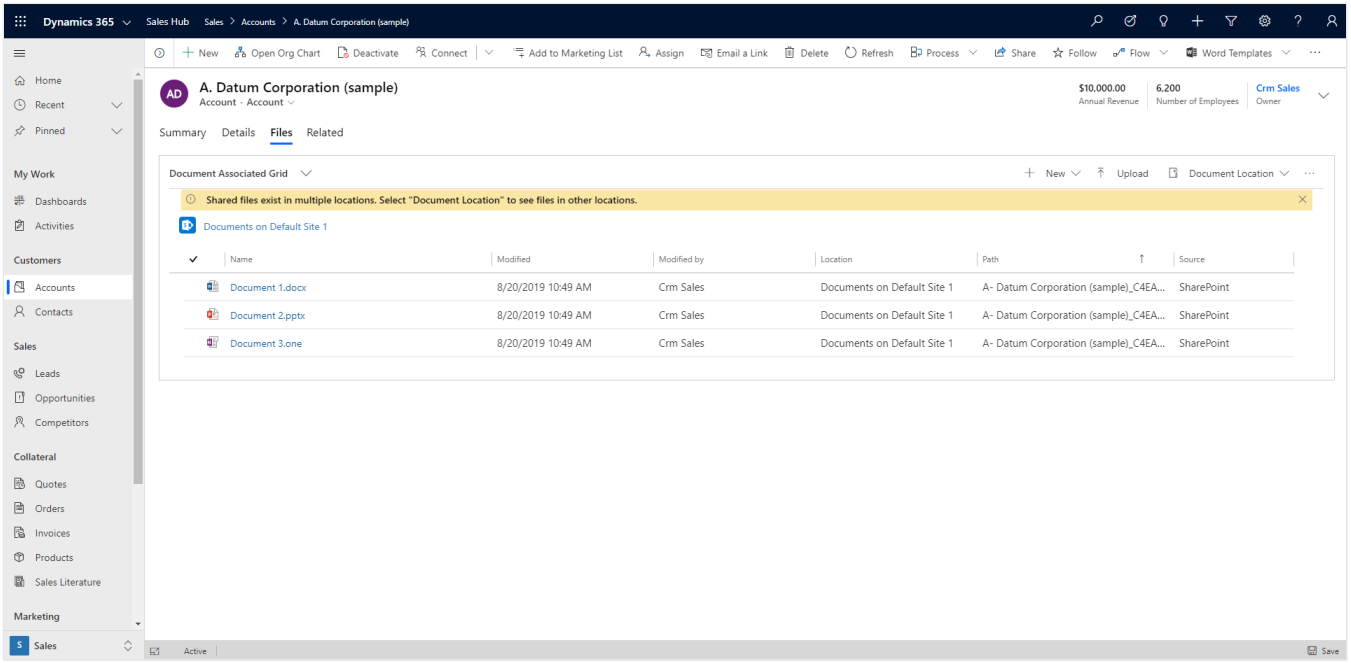
Create and design forms

Add or remove the SharePoint documents tab to the main form for any table

Summarize this article for me

[This topic is pre-release documentation and is subject to change.]

Adding a tab on a table main form to display SharePoint documents helps users discover and use the SharePoint integration features that are available in a model-driven app.



> **Important**
>
> To use this feature you must enable document management. More information: Manage documents using SharePoint

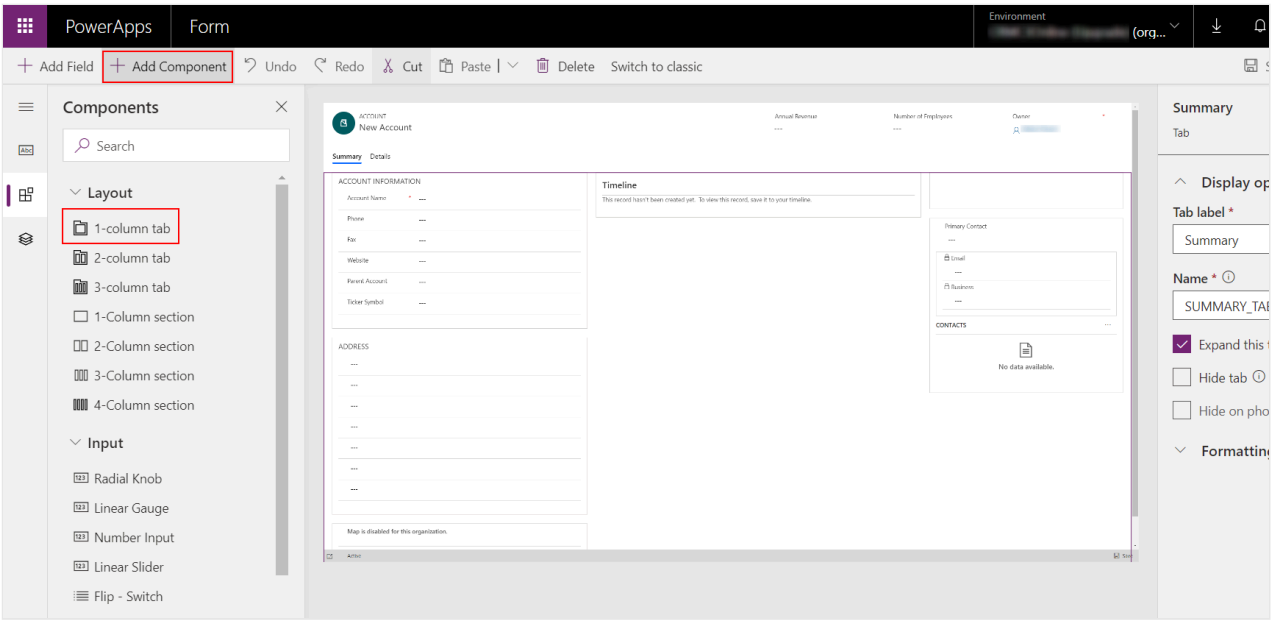
Add the documents tab in the FormXML

1. In your Power Platform development environment, create a new solution or open an existing solution. For more information about creating solutions, see: Create a solution.

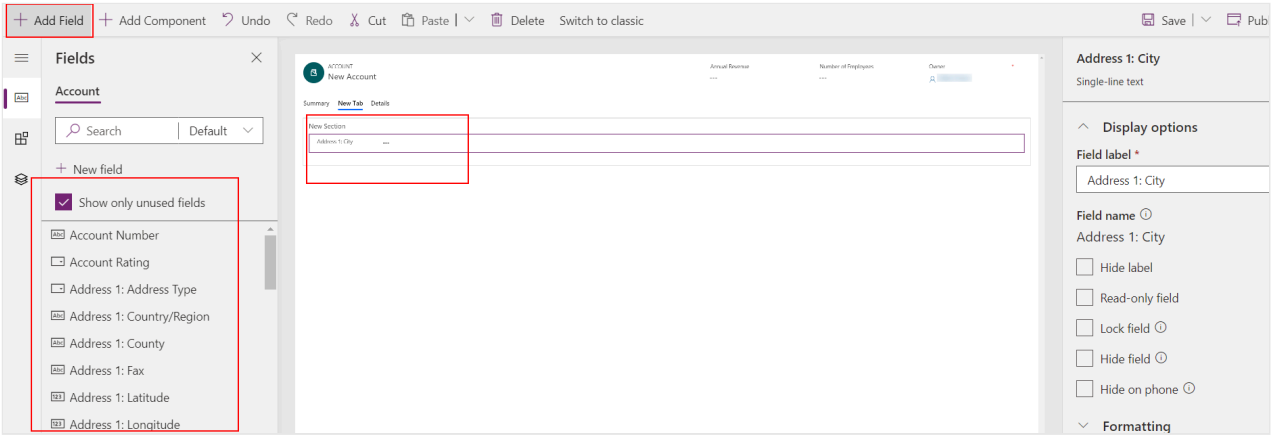
2. Add the table to the solution or select an existing table. All standard and custom tables are supported. For more information about tables in solutions, see: Add solution components

3. Include the form for the table in the solution, such as the main form for the account table. Next to the table, select ..., and then select **Edit**. Select the **Forms** area. If the required form is missing, add it.

4. Add a one-column tab to the main form. To do this, in the form designer select an area on the form canvas, select **Add Component**, and then select **1 Column Tab**.



5. In the form designer select the **New Tab** on the form designer canvas, select **Add Column**, and add a column such as *Address 1: City* from the left pane. Any text or numeric column can be used.



6. Rename the tab label. To do this, select **New Tab**, and in the right properties pane replace **New Tab** with something more descriptive, such as *Documents*.

7. Select **Save and Publish**, and then close the form designer.

8. From the Power Apps maker home page, select **Solutions**, select the solution, and the select **Export** to export the solution as an unmanaged solution. More information: Export solutions

9. Extract the solution and open the customization.xml file with an XML or text editor.

10. In the customization.xml search for **label description="Documents"** (or the name the tab was given in the previous step).

11. Scroll down to the control id="*field name*" element, such as **control id="address1_city"** and replace the entire element with the XML sample in this topic.

```
</tab>
<tab name="tab_8" id="{3283b8d3-26a9-aab9-b777-b5e5aacec3c9}" IsUserDefined="0" locklevel="0" showlabel="true" expanded="true">
  <labels>
    <label description="Documents" languagecode="1033" />
  </labels>
  <columns>
    <column width="100%">
      <sections>
        <section name="tab_8_section_1" showlabel="false" showbar="false" locklevel="0" id="{a29a4445-dd1e-335e-0075-91339b387110}" IsUserDefinec
          <labels>
            <label description="Documents" languagecode="1033" />
          </labels>
          <rows>
            <row>
              <cell id="{eb38c2ae-5ad7-6369-cbb2-6e6990e6c81d}" showlabel="true" locklevel="0">
                <labels>
                  <label description="Documents" languagecode="1033" />
                  <label description="Dirección 1: ciudad" languagecode="3082" />
                </labels>
                <control id="address1_city" classid="{4273EDBD-AC1D-40d3-9FB2-095C621B552D}" datafieldname="address1_city" disabled="false" uniqu
              </cell>
            </row>
          </rows>
        </section>
      </sections>
    </column>
  </columns>
</tab>
```

12. Make these modifications to the XML sample.

    a. Locate the **RelationshipName** element and replace it with the schema name that appears as *entityLogicalName*_SharePointDocument. For example, for the accounts table the schema name for the relationship is Account_SharePointDocument, which is the schema name for the XML sample in this topic. To find the name for a different table, go to **Settings** > **Customizations** > **Customize the System** > **Tables** > select the table > select **1:N Relationships**. Locate the **Related Table** of type **SharePointDocument**.

    ::image type="content" source="media/account-sharepointdocument.png" alt-text="Account relationship SharePoint document.":::

    b. Create a globally unique identifier (GUID) and replace the existing **uniqueid** GUID located in the **control** element pasted in the previous step while preserving the curly braces {}.
    ::image type="content" source="media/control-unique-id.png" alt-text="Control element unique id."::: c. Save the changes made to customizations.xml.

13. Open the solution.xml file and increment the **Version** element value. For example, change *1.1.0.0* to *1.2.0.0*.

14. Package all solution files into a compressed (zipped) folder and import it into the right environment. If an error appears then the previous solution should be removed. For more information on managing solutions see: Import, update, and upgrade a solution

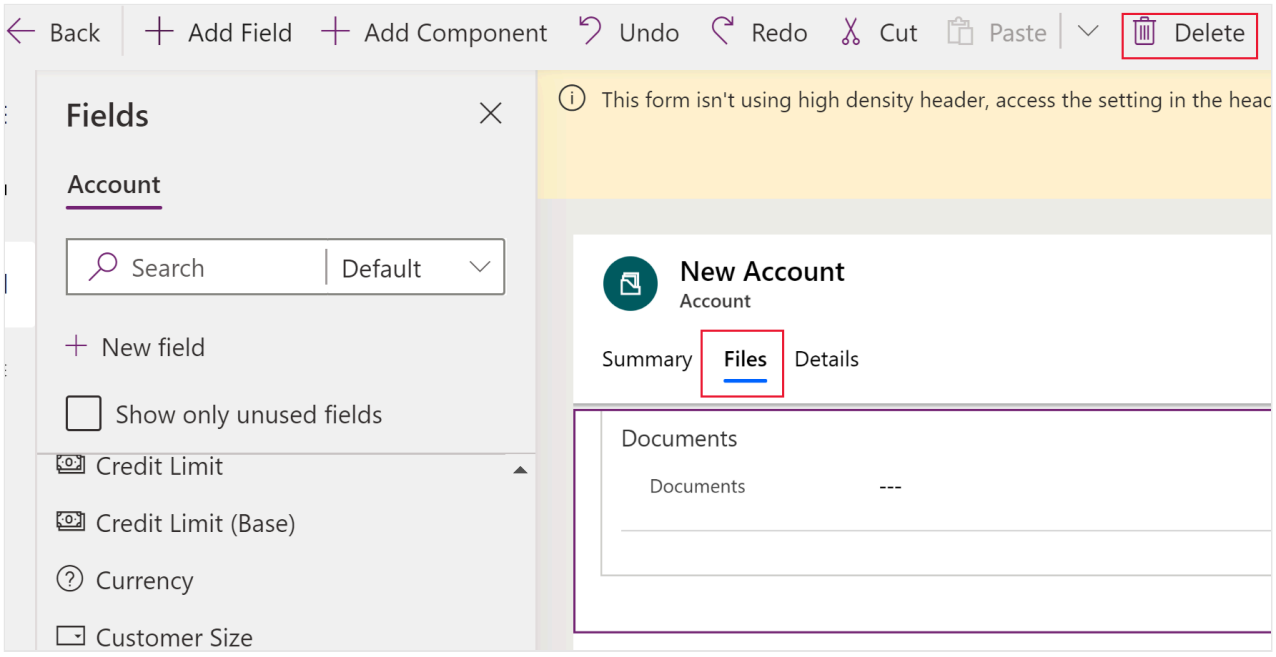
XML sample for adding the documents tab to a form

XML

```
  <control id="DocumentSubGrid" classid="{E7A81278-8635-4d9e-8D4D-59480B391C5B}"
indicationOfSubgrid="true" uniqueid="{9cd66b5c-8b7a-6433-c5a5-46a7245dd534}">
    <parameters>
      <ViewId>{0016F9F3-41CC-4276-9D11-04308D15858D}</ViewId>
      <IsUserView>false</IsUserView>
      <RelationshipName>Account_SharepointDocument</RelationshipName>
      <TargetEntityType>sharepointdocument</TargetEntityType>
      <AutoExpand>Fixed</AutoExpand>
      <EnableQuickFind>false</EnableQuickFind>
      <EnableViewPicker>true</EnableViewPicker>
      <ViewIds />
      <EnableJumpBar>false</EnableJumpBar>
      <ChartGridMode>Grid</ChartGridMode>
      <VisualizationId />
      <IsUserChart>false</IsUserChart>
      <EnableChartPicker>false</EnableChartPicker>
      <RecordsPerPage>10</RecordsPerPage>
      <HeaderColorCode>#F3F3F3</HeaderColorCode>
    </parameters>
  </control>
```

Remove the documents tab

1. Sign in to Power Apps, in the left pane expand **Data**, and then select **Tables**.
2. Select the required table and select the **Forms** area, and then open the form where the documents tab needs to be removed.
3. Select the **Documents** tab, and then on the form designer toolbar, select **Delete**.



4. On the form designer toolbar, select **Publish**.

Add model-driven app form navigation for related tables

Article • 03/13/2023

When an app user selects one of these links in a row, the associated view for the table is displayed. In this article, the form navigation pane is used to add links to related tables.

1. Sign in to Power Apps.

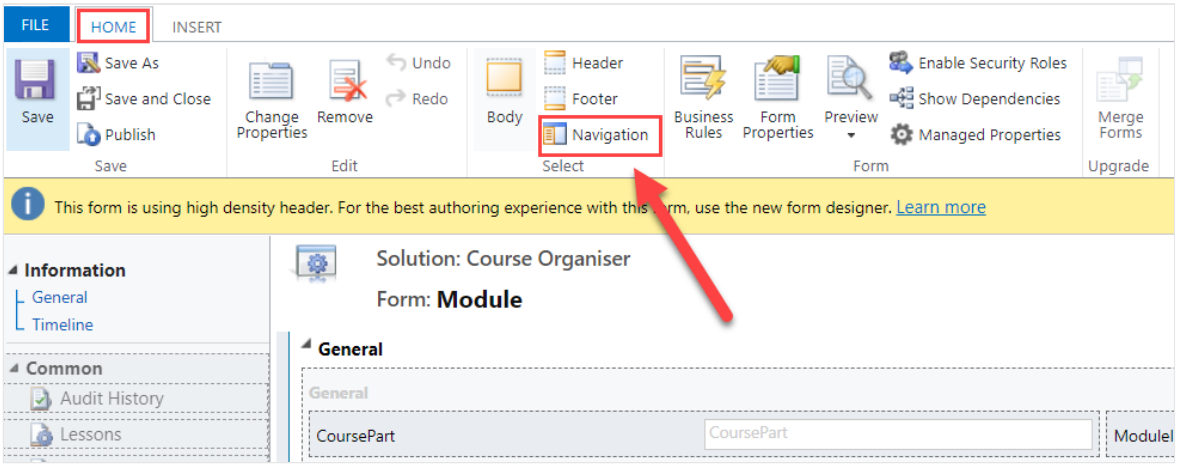
2. Select **Tables** on the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.

3. Select the table you want, and then select the **Forms** area.

4. In the list, open a form with the type of **Main** to edit it.

5. Select **Switch to classic** to edit the form in the classic form designer.

6. To add a link to a related table, on **Home** tab, in the **Select** group, choose **Navigation**.



The **Relationship Explorer** pane displays on the right side of the form editor.

7. In the **Relationship Explorer** pane, in the **Filter** list, select one of the following options:

   - **Available Relationships**. Lists all the tables that can be related to the table the form is associated with.

   - **1:N Relationships**. Lists tables that can be related in a 1:N relationship to the table the form is associated with.

- **N:N Relationships**. Lists tables that can be related in a N:N relationship to the table the form is associated with.

> **Note**
>
> If no related tables show up in the **Relationship Explorer** pane, you cannot create a link on this form to a related table.

8. Select the related table you want to link to, drag it to the Navigation Pane, and then drop it where you want it to be displayed.

> **Tip**
>
> You can also create a new relationship by choosing **New 1:N** or **New N:N** in the **Relationship Explorer** pane.

9. To edit the properties for this or any other related table link, in the Navigation Pane, select the link, and then on the **Home** tab, choose **Change Properties**.
10. In the **Relationship Properties** dialog, on the **Display** tab, type a new display label.
11. On the **Name** tab, choose **Edit** to view or edit the details associated with the relationship row.
12. Choose **OK**.
13. Preview how the main form will appear and how events will function:
    a. On the **Home** tab, choose **Preview**, and then select **Create Form**, **Update Form**, or **Read-Only Form**.
    b. To close the **Preview** form, on the **File** menu, choose **Close**.
14. When you finish editing the form, choose **Save and Close** to close the form.
15. When your customizations are complete, publish them:

    - To publish customizations for only the component that you are currently editing, in the Navigation Pane, choose the table you have been working on, and then choose **Publish**.
    - To publish customizations for all unpublished components at one time, in the Navigation Pane, choose **Tables**, and then on the command bar, choose **Publish All Customizations**.

> **Note**
>
> Installing a solution or publishing customizations can interfere with normal system operation. We recommend that you schedule a solution import when it's least disruptive to users.

Create and edit table relationships for Microsoft Dataverse

Collaboration in model-driven apps

Article • 12/18/2023

Collaboration features help fusion teams work together to build model-driven apps. The commenting feature introduces the best way to work asynchronously with other makers or leave notes for yourself within the app context. Copresence and coauthoring help you better work with other makers in the same app in real-time.

> **ⓘ Important**
>
> Commenting is available for all model-driven app makers. For real-time collaboration, you will have either the copresence or coauthoring experience as the copresence and coauthoring features are being deployed separately:
>
> - Most preview environments will have coauthoring available. More information: **Coauthoring in model-driven apps**
> - For preview environments that don't have coauthoring available, the environment will use copresence. More information: **Discover who's working on an app**

Coauthoring in model-driven apps (preview)
Discover who's working on an app (preview)

Add comments in the model-driven app designer

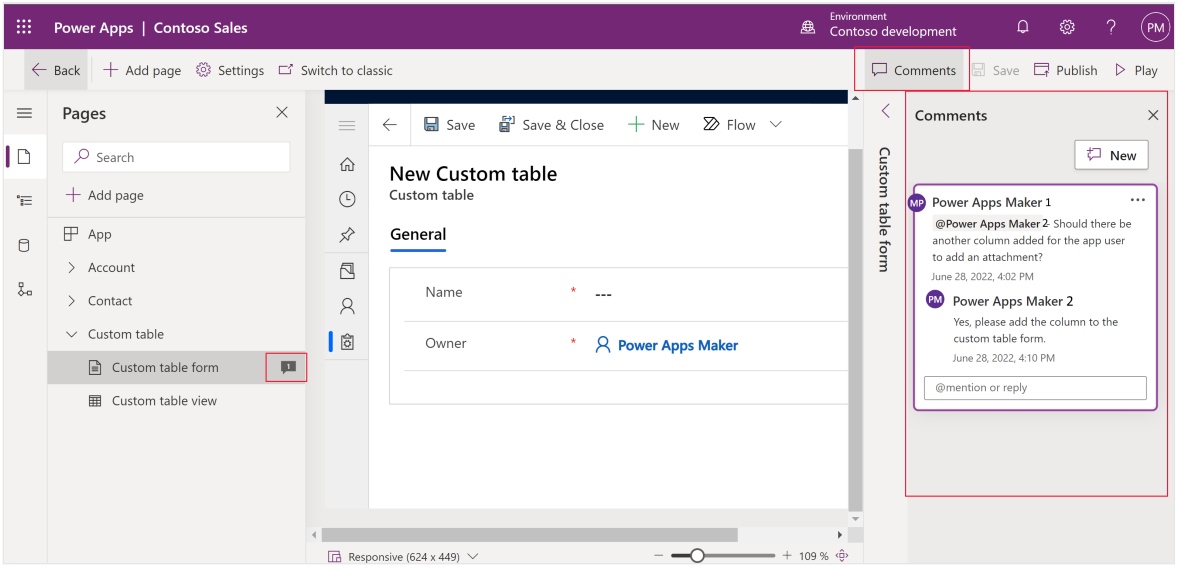
Article • 03/29/2023

Comments are notes that are associated with items in your app. Use comments to help your team review the app and provide feedback, or provide additional information on implementation details in your app.

In the app designer, the anchors, which are what comments attach to, are all of the pages in the pages pane, and any of the items in the **Navigation** pane. This lets you add comments to items such as areas, groups, pages, tables, and dashboards. Comments are stored in a table in Microsoft Dataverse in the default solution.

Add a comment to a page

1. Open a model-driven app for edit using the app designer.
2. Select an item in the **Pages** pane.
3. Select **Comments** on the command bar. This opens the comments pane for the selected component. You can also open the comments pane by selecting the comment count indicator for existing comments to an item in the left pane.



4. Select **New** to create a new comment and type the comment message in the box. Or, type into the **Reply** box to respond to an existing comment. Select **Post reply** or press Ctrl + Enter to post your comment.

Edit or delete a comment

You can edit your comments or remove existing comments from appearing in the app.

In the **Comments** pane, next to a comment, select **...**, and then select **Edit comment** or **Delete comment**.

Resolve a comment

Comments are commonly questions, feedback, or ideas that are important context to live alongside your app. But, they may not be active discussions anymore. You can resolve, or reopen a resolved, comment thread to better track the active comments.

1. In the **Comments** pane, next to a comment, select **...**, and then select **Resolve comment**.
2. The comment thread appears as **Resolved**.
3. To reopen select **Reopen thread** or **Delete thread** to remove the comment.

Moving comments between environments

Comments in model-driven apps can't be exported or imported as solution components because they contain user collaboration data. You can, however export the **Comment** table to Excel and then import the Excel file into the environment you want. More information: Export data

Discover who's working on an app
Coauthoring in model-driven apps (preview)

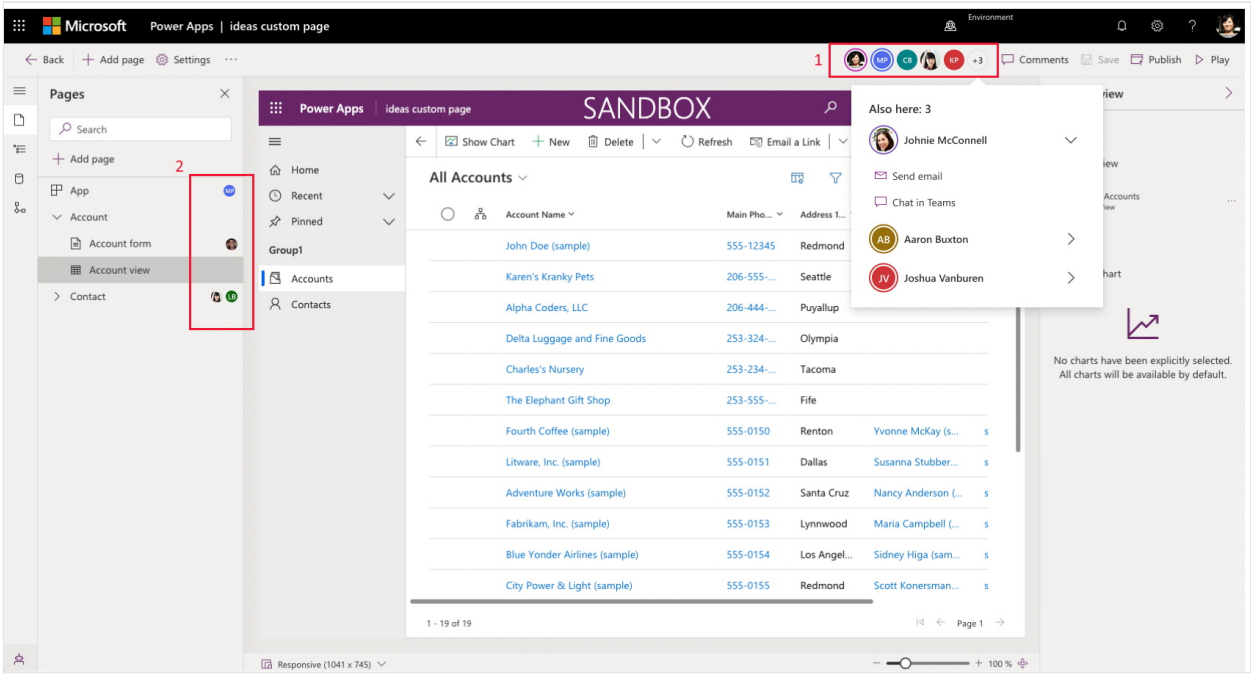
Discover who's working on an app

Article • 09/05/2023

Find who's working on an app at the same time as you with copresence. Copresence provides the following benefits:

- Icons and names of people who have the app open and might be making changes are displayed.
- Contact those people working on the app via email or Teams.
- On the left navigation pane, the structure of the app is displayed letting you know what part of the app is being worked on.
- Receive notification for saved changes made from other makers. Then, you'll be prompted to refresh the app to stay on the latest version so as not to lose your work or overwrite other's work later. More information: Notifications
- The name of the maker who made the first save or the last save is displayed.

> **Important**
>
> Most Power Platform environments have **coauthoring**. In case your tenant doesn't have coauthoring yet, you'll have the copresence experience that is described in this article.



1. Command bar displays makers currently working in the app and allows you to chat or email them.
2. Left navigation indicates what app component the maker is working on.

How copresence works

The first time someone joins your app in app designer while you working on it a notice appears that indicates other people are also working on the app. Advice is given to check with the other makers about the order you plan to make changes. Notice that it's possible that the other makers in the app might not want to save their changes.

Icons of copresent makers appear in both the toolbar area and the left navigation pane showing where other makers are working in the app.

When you have several tabs open, your icon is displayed in the left navigation pane as well. This way you'll always see if you have more than one tab open, which helps you find the one you want to continue working on.

On the right side of the app designer toolbar, all the makers that have this app open are displayed. If more than four makers are present, a +n, such as +1 or +30, is displayed that expands with all the makers' names. Select a name to display **Send email** and **Chat in Teams** links to contact that person.

Notifications

You may be working on the app, or you may be idle, but once someone else saves a change to the app, you'll receive a notification in the upper bar indicating that another maker made changes. When this occurs, you're advised to refresh to be at the latest version so as not to lose changes you make afterwards.

Tip

- If you weren't expecting anyone to make changes to the app, and spent a long time adding changes, we recommend you contact the person immediately. For example, it might happen that another maker saved something minor and you can agree that your changes may overwrite their changes. In this case, do not select refresh, instead select save to present the option to overwrite changes.
- We recommend that you to always stay at the latest version of the app and refresh when others save changes. If you were idle and didn't make changes and see this notification, select refresh.

If you've ignored or closed the refresh notification, you won't be at the latest version of the app. At the time when you select save, you're prompted with a choice: refresh (and

lose your changes) or overwrite (and lose other maker's changes).

> **Tip**
>
> We recommend you chat with the team or the person who made the last change. Copresence provides the name of the maker to alert you before you overwrite their changes.

Known copresence limitations and issues

- There may be a delay up to 20 seconds between when new members join the app and when you see their presence and location.
- There may also be a delay up to one minute between when someone saves a change and when you get a notification about the change. However, if there's a conflict, you'll always get the prompt to choose whether to refresh or overwrite when you try to save.
- Making a comment on a new page or area triggers a background save and if your app isn't on the latest version you'll be prompted to either refresh or overwrite.
- Instead of copresence, your environment may have coauthoring, which allows app change merges to occur in real-time with seamless collaboration. More information: Coauthoring in model-driven apps (preview)

Collaboration in model-driven apps

Coauthoring in model-driven apps

Article • 11/13/2024

Coauthoring allows multiple makers—whether pro or citizen developers—to make changes to the app at the same time and see those changes in real time. As a result, teams can innovate together and build stronger connections between professional developers and business domain experts, a critical ingredient to maximizing low-code development.

> **Important**
>
> - This feature is being gradually rolled out across regions and might not be available yet in your region.
> - This feature isn't currently available in Germany, China, and Government Cloud regions. Regions where coauthoring isn't available have copresence. More information: Discover who's working on an app

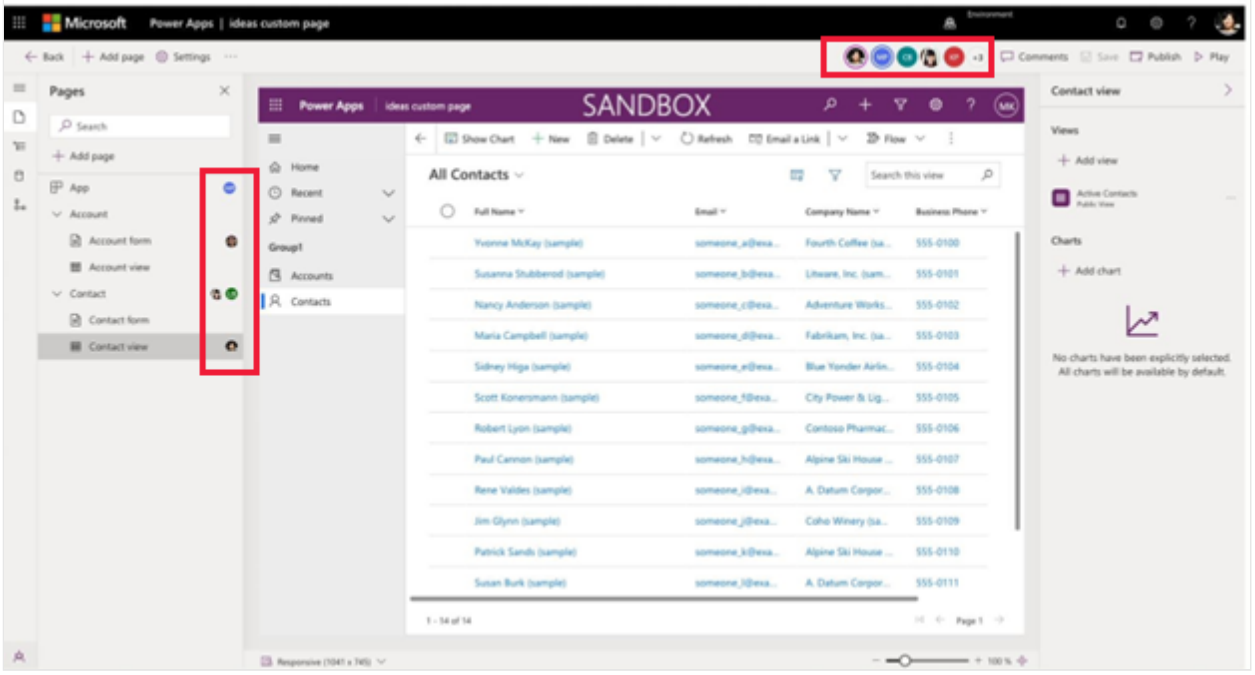
What you can coauthor in an app

Here's what multiple makers can do at the same time in the app while seeing each other's others changes in real-time.

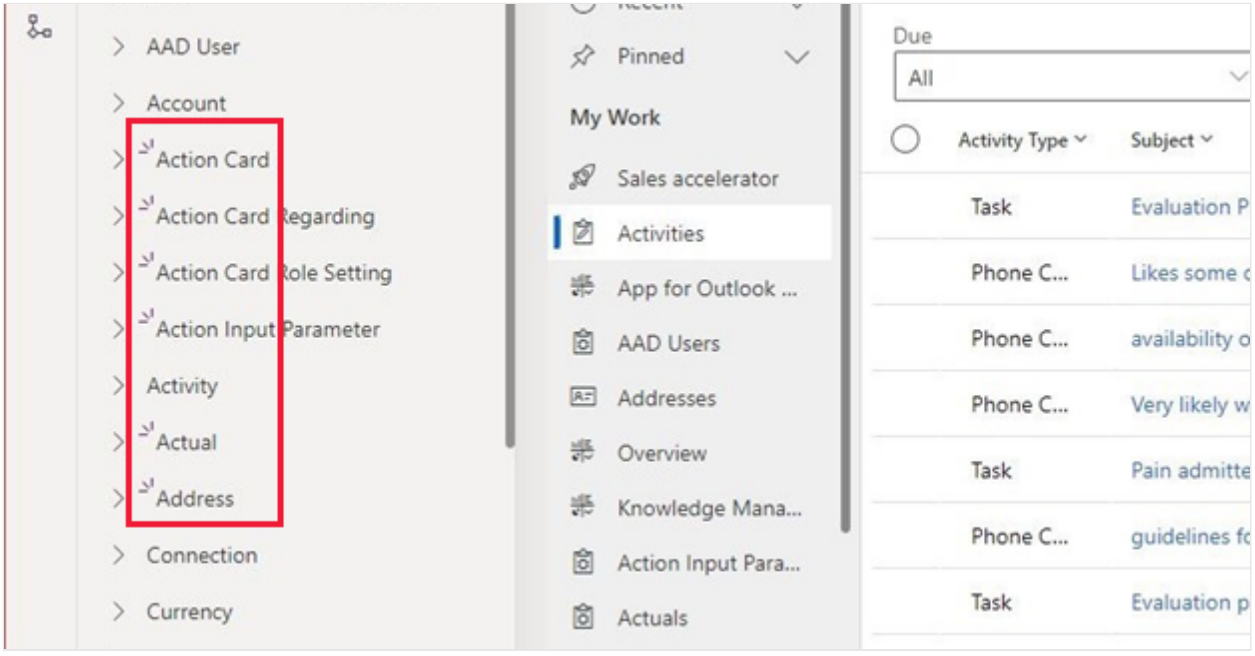
- Add and remove components, such as tables, dashboards, and custom pages, to and from the model-driven app.
- Add and remove subcomponents, such as views, forms, and charts, to and from the tables in the model-driven app.
- Add and remove areas, groups, and subareas to and from the navigation bar in the model-driven app.
- Change properties of the model-driven app.
- Change properties of the navigation pane.
- Change properties of areas, groups, and subareas in the navigation pane, including **Display Options** and **Advanced Settings**.
- Change order of the areas, groups, and subareas in the navigation pane.
- Change **General**, **Features** and **Upcoming** tabs in the **Settings** dialog.

How to know you're coauthoring

First, once there are other makers editing the app together with you, you see their presence in the top navigation bar and the left menu. You can see what components other makers are working on or what pages they have open. You'll also see them move through the components on the left navigation bar in real-time.



When someone is adding or removing a page, all other makers will see it appearing on the left navigation bar with a sparkle graphic indicator. The sparkle remains displayed until you select that page. You won't see a sparkle for the components and pages that you've added.



Once someone removes the page, it disappears for other makers in real-time.

Limitations

- Currently, there's no auto-save functionality, so you need to select the **Save** button to save changes. However, any maker that has access to the app can save the changes for others, as their changes are synced. Unsaved changes will be removed from the app in eight hours.
- Under **Settings**, changes to the **Features** and **Upcoming** sections must be saved from the settings dialog in order to be set. Users that don't see the changes immediately can close and open the settings dialog to see the most up-to-date settings.
- Changes made in other designers, such as the view and form designers, won't be synchronized in real-time in the modern app designer.

Apply custom business logic by using business rules and flows in model-driven apps

Summarize this article for me

Defining and enforcing consistent business processes is one of the main reasons to use model-driven apps. Consistent processes help ensure that people using a model-driven app can focus on their work and not on remembering how to perform a set of manual steps to reach their objectives.

Business logic falls into two major categories natively within model-driven apps: business rules and business process flows.

Business rules

Business rules provide a simple interface to implement and maintain fast-changing and commonly used rules. The *scope* of a business rule defines where the business rule runs:

Expand table

If you select this item...	The scope is set to...
Table	All forms and server
All Forms	All forms
Specific form (**Account** form, for example)	Just that form

For more information about defining business rules for a form in a model-driven app, go to Create business rules to apply logic in a model-driven app form.

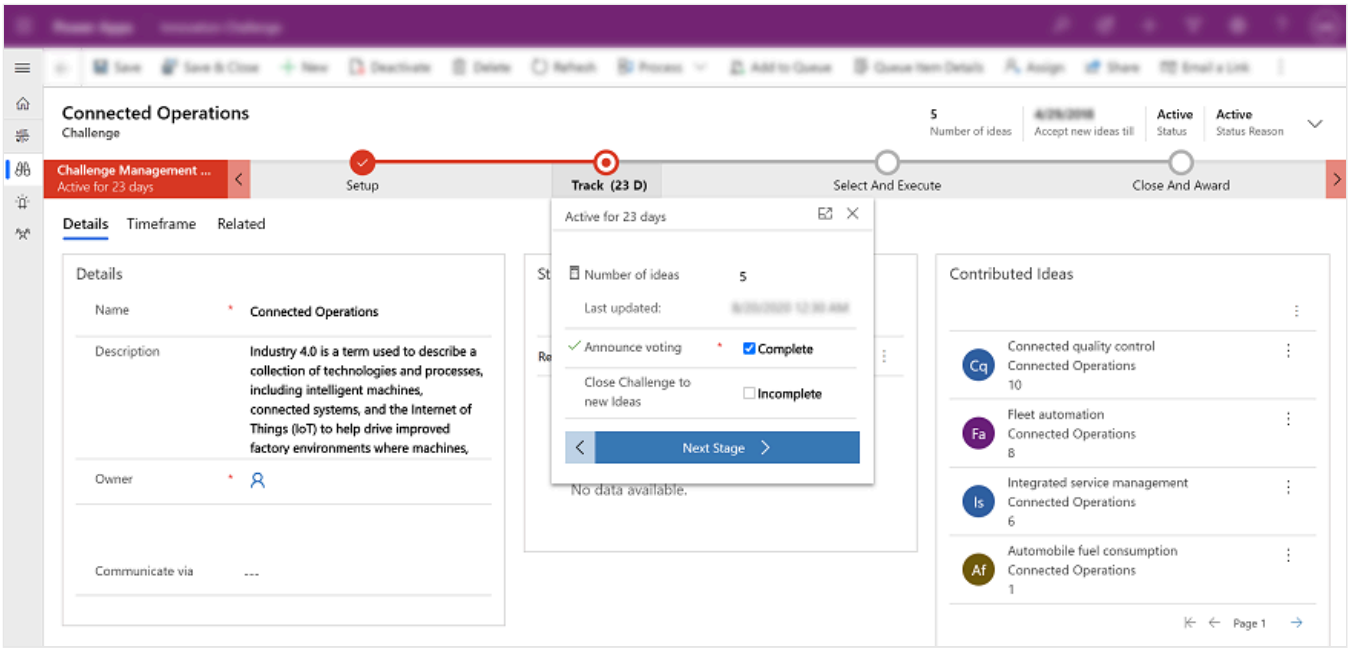
> **Note**
>
> To define a business rule for a table so that it applies at the server level to both *canvas apps* and *model-driven apps*, go to Create a business rule for a table.

Business process flows

By creating a business process flow, you ensure that people enter data consistently and follow the same steps every time they work in an app. These flows are authored by using the business process flow designer and only work with model-driven apps. For more information, go to Business process flows overview.

Power Automate flows

Power Automate includes several types of processes, each designed for a different purpose that can be designed to automate tasks in Dataverse or many other data sources to enhance model-driven apps:



- Workflows and actions. Dynamics 365 customizers might be familiar with the classic Microsoft Dataverse processes, which are workflows and actions. More information: Use Workflow processes and Actions overview

- Automated flows. Create a Power Automate cloud flow that performs one or more tasks automatically after it's triggered by an event. These flows have the added advantage of being able to reach into the connector framework within your environment and connect to other data sources, such as SQL, SharePoint, or any of the other 400 data sources and services. More information: Create a flow

- Button flows. Create a Power Automate cloud flow that performs repetitive tasks simply by tapping a button on your mobile device. More information: Introducing button flows

- Scheduled flows. Create a flow that performs one or more tasks on a schedule, such as once a day, on a specific date, or after a certain time. More information: Run flows on a schedule

Apply business logic with Dataverse

Last updated on 02/21/2026

Create business rules to apply logic in a model-driven app form

Often, you need to add business logic to ensure that columns in a model-driven app are shown, hidden, or set with the correct values.

This article shows how to create business rules and recommendations to apply form logic in a model-driven app without writing JavaScript code or creating plug-ins. Business rules provide a simple interface to implement and maintain fast-changing and commonly used rules. They can be applied to main and quick create forms. Business rules work in model-driven apps, legacy web apps, Dynamics 365 for tablets, and Dynamics 365 for Outlook (online or offline mode).

By combining conditions and actions, the following actions are possible with business rules:

Expand table

Action	Description	Applies to
Set Field Value	Sets a value of a table column. You can set the value to a hard-coded value, to the value of another column, or with a simple formula. You can also clear the value of the field.	All scopes
Set Default Value	Sets the value of a column but only when the column has no value (null).	All scopes
Show Error Message	Prevents the save of the row. In model-driven app form, the error message is displayed within the form; for server-side, the error message is passed back to the calling process.	All scopes
Lock/Unlock	Lock changes the column's property to read-only. Unlock enables the user to change the value of the column.	Model-driven app
Set Visibility	Setting to No hides the column on the form. Setting to Yes displays the column on the form	Model-driven app
Set Business Required	Sets the requirement level of the column on the form to Business Required or Not Business Required (Optional). Setting the column to Business Required shows a red asterisk next to the column's label and prevents the rows from being saved if the column's value is empty.	Model-driven app
Recommendation	Shows a light bulb icon next to the column's label. When the icon is selected, the user is prompted. If prompt is accepted, the rule can set field	Model-driven

Action	Description	Applies to
	values.	app

> **Note**
>
> To define a business rule for a table so that it applies to all forms, see Create a business rule for a table.
>
> Business rules don't work with multiselect choices.
>
> Actions that only apply to model-driven apps are ignored when the rule is run server-side.

View, edit, or create a business rule in Power Apps

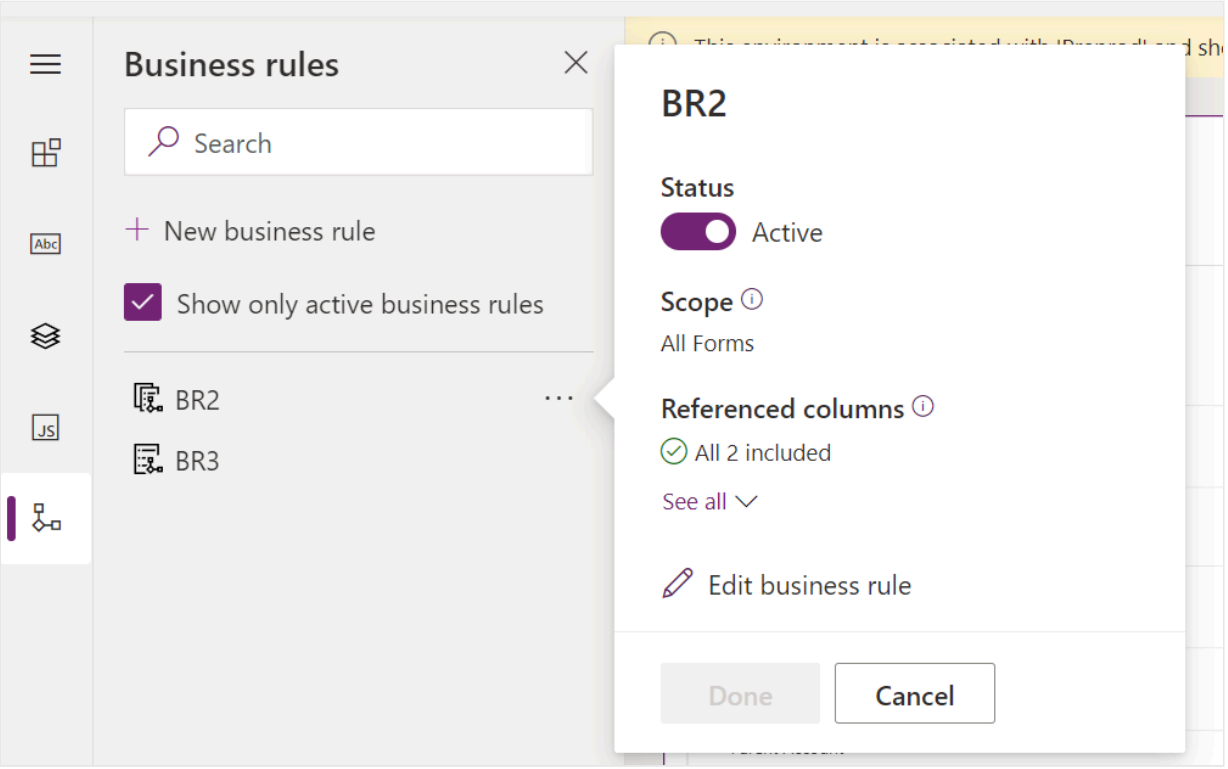
1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, open the solution you want, and then open or add the table you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **New**, and then under **Customizations**, select **Business rule**.

The business rules designer opens. Next step: Set the business rule properties

View, edit, or create a business rule in form designer

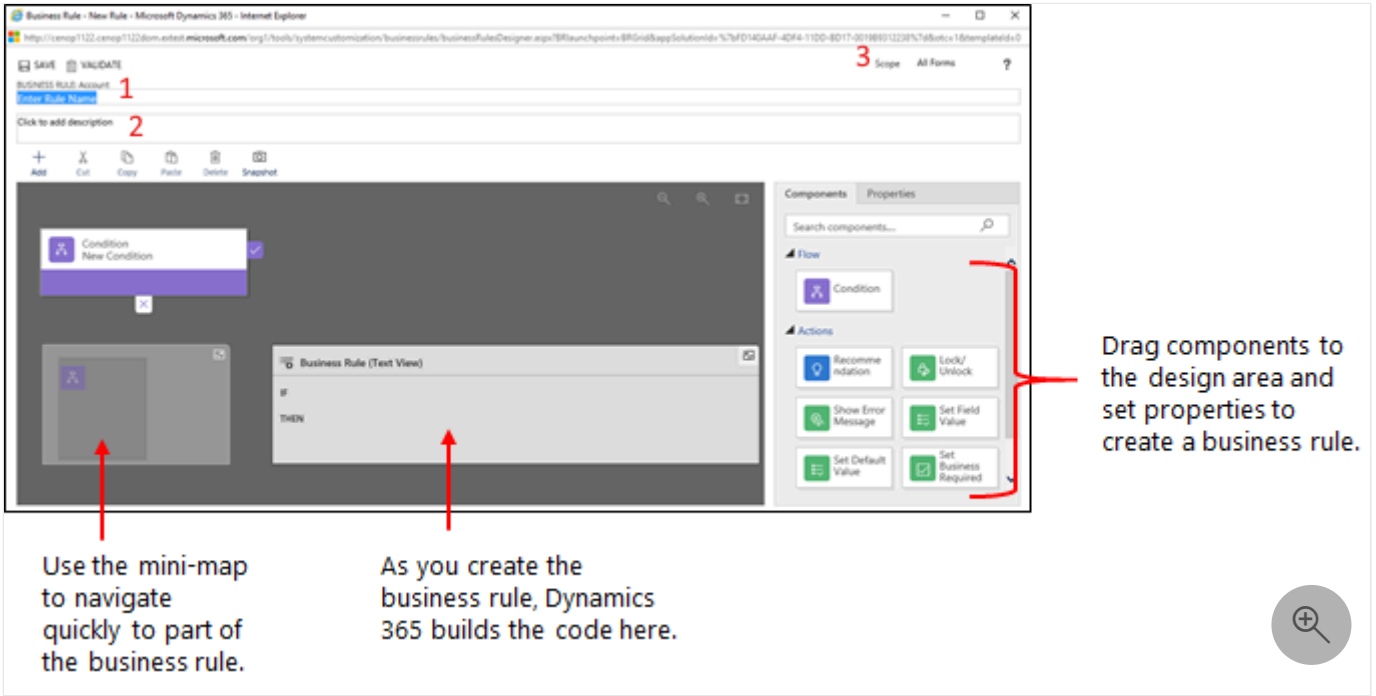
1. On the form designer left navigation pane, select **Business rules**.
2. Select from these options:
   - By default, only active business rules for the form are displayed. Clear **Show only active business rules** to view deactivated business rules for the form.
   - Select **New business rule** to create a business rule.

- Select the business rule to view properties and edit the business rule.



Set the business rule properties

When the business rule designer window opens for a new rule, a single condition is already created. Every rule starts with a condition. The business rule takes one or more actions based on that condition.



Enter or select the following properties from the business rule command bar.

1. **Business rule name**: By default, the rule is named *New business rule*. Enter a meaningful name for the business rule.
2. **Description**: Optionally, add a description.
3. **Scope**: The scope of the business rule determines which forms the business rule is applied. You set the scope, according to these options:

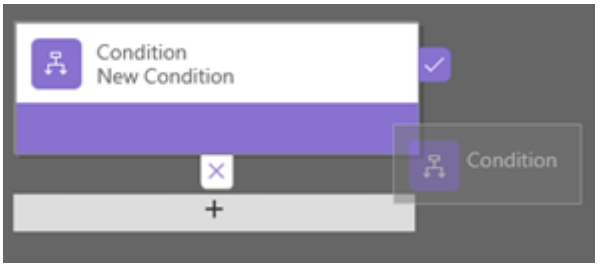
If you select this item...	The scope is set to...
Entity	The table and all forms for the table
All Forms	All forms for the table
Specific form (account **Main Form**, for example)	Just that form

> **Note**
>
> To modify an existing business rule, you must deactivate it before you can modify it.

Build the business rule

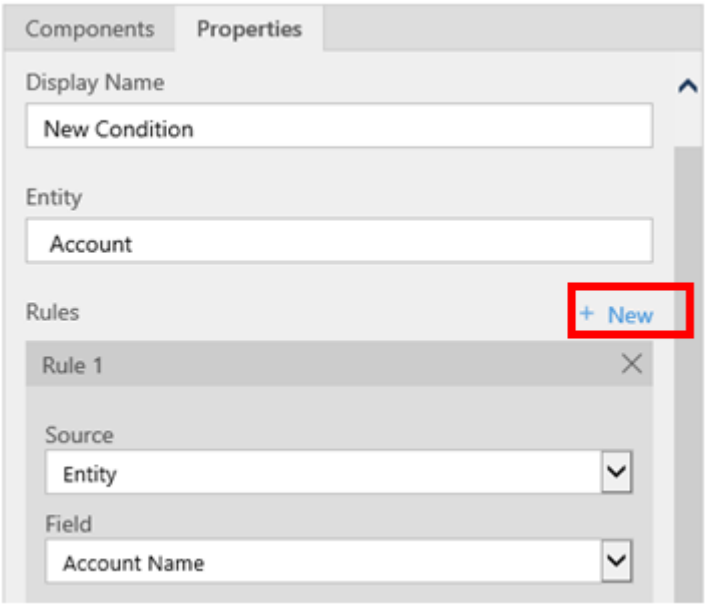
1. **Add conditions.** To add more conditions to your business rule:

   a. Drag the **Condition** component from the **Components** tab to a plus sign in the designer.



b. To set properties for the condition, select the **Condition** component in the designer window, and then set the properties in the **Properties** tab on the right side of the screen. As properties are set, an expression is created at the bottom of the **Properties** tab.

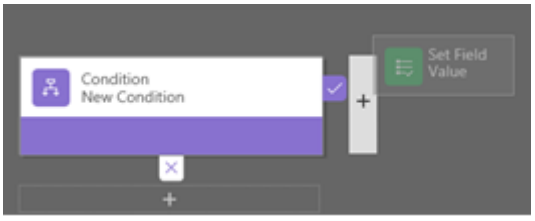
c. To add an additional clause (an AND or OR) to the condition, select **New** in the **Properties** tab to create a new rule, and then set the properties for that rule. In the **Rule Logic** column, you can specify whether to add the new rule as an AND or an OR.



d. When you finish setting properties for the condition, select **Apply**.

2. **Add actions.** To add an action:

a. Drag one of the action components from the **Components** tab to a plus sign next to **Condition** component. Drag the action to a plus sign next to a check mark if you want the business rule to take that action when the condition is met, or to a plus sign next to an x if you want the business rule to take that action if the condition isn't met.



b. To set properties for the action, select the **Action** component in the designer window, and then set the properties in the **Properties** tab.

c. When you finish setting properties, select **Apply**.

3. **Add a business recommendation.** To add a business recommendation:

a. Drag the **Recommendation** component from the **Components** tab to a plus sign next to a **Condition** component. Drag the **Recommendation** component to a plus sign next to a check mark if you want the business rule to take that action when the condition is met, or to a plus sign next to an x if you want the business rule to take that action if the condition isn't met.

b. To set properties for the recommendation, select the **Recommendation** component in the designer window, and then set the properties in the **Properties** tab.

c. To add more actions to the recommendation, drag them from the **Components** tab, and then set properties for each action in the **Properties** tab.

> **Note**
>
> When you create a recommendation, a single action is added by default. To see all the actions in a recommendation, select **Details** on the **Recommendation** component.

d. When you finish setting properties, select **Apply**.

4. To validate the business rule, select **Validate** on the action bar.

5. To save the business rule, select **Save** on the action bar.

6. To activate the business rule, select it in the Solution Explorer window, and then select **Activate**. You can't activate the business rule from the designer window.

> **Tip**
>
> Here are a few tips to keep in mind as you work on business rules in the designer window:
>
> - To take a snapshot of everything in the **Business Rule** window, select **Snapshot** on the action bar. This is useful, for example, when getting feedback from team members.
> - Use the mini-map to navigate quickly to different parts of the process. This is useful when working on a complicated process that scrolls off the screen.
> - As you add conditions, actions, and business recommendations to your business rule, code for the business rule is built and appears at the bottom of the designer window. This code is read-only.

Localize error messages used in business rules

If more than one language is provisioned for your environment, it's worth localizing any error messages that are set. Each time a message is set, a label is generated by the system. If the translations in your environment are set, localized versions of your messages can be added and then imported back into the system. This enables people using languages other than your base language to view the translated messages.

Common issues

This section describes common issues that might occur when you use business rules.

Full Name column and Address column not supported with Unified Interface apps

Actions or conditions that use a composite column like the **Full Name** `fullname` column or an **Address** column aren't supported in apps based on Unified Interface. Alternatively, you can use actions or conditions with the constituent columns. For example, for the **Full Name** column, you can use actions or conditions on the **First Name** (firstname) and **Last Name** (lastname) columns.

Business rules don't execute for some users

Make sure that users have a security role that includes, at a minimum, user scope read privileges on the Process table. By default, the Basic User security role has this privilege.

Business rules don't fire on editable grid on a dashboard

Entity scoped business rules won't fire on an editable grid when the editable grid is configured on a dashboard page.

Is the business rule not firing for a form?

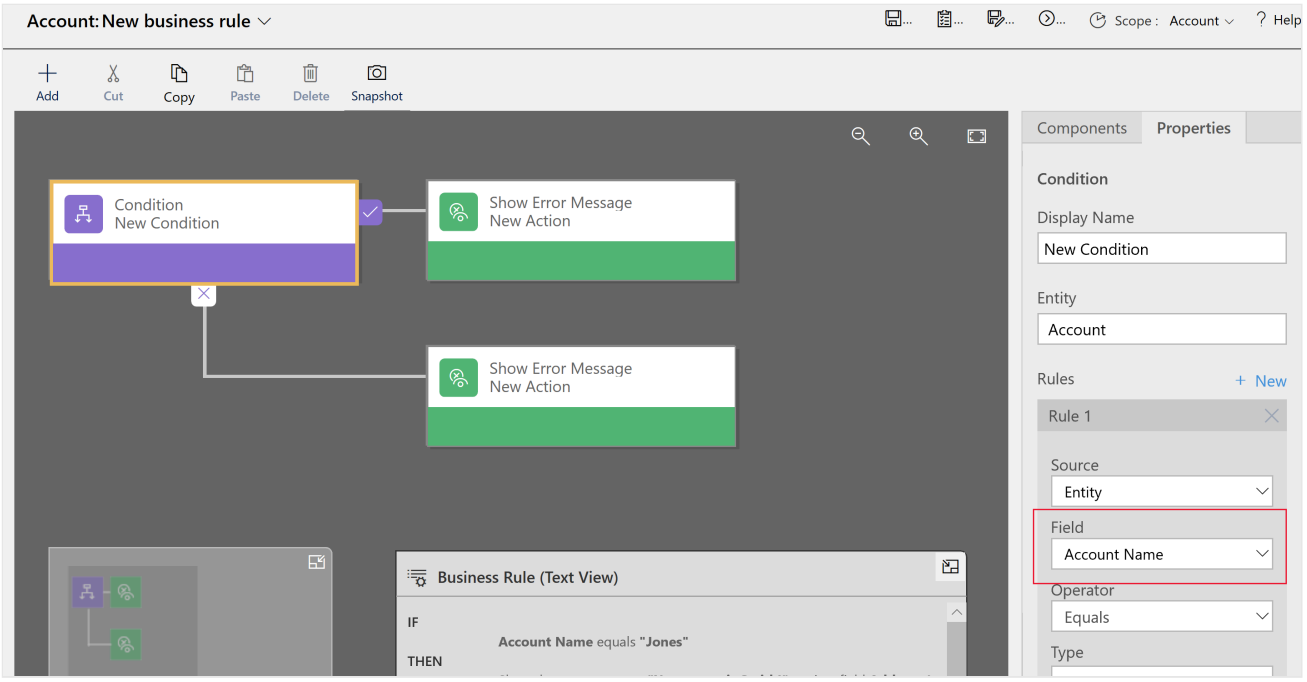
A business rule might not execute because the column referenced in the business rule isn't included with the form.

1. Go to the **Solutions** area in Power Apps and then open the solution you want. Expand the table that you want, and then select **Forms**.

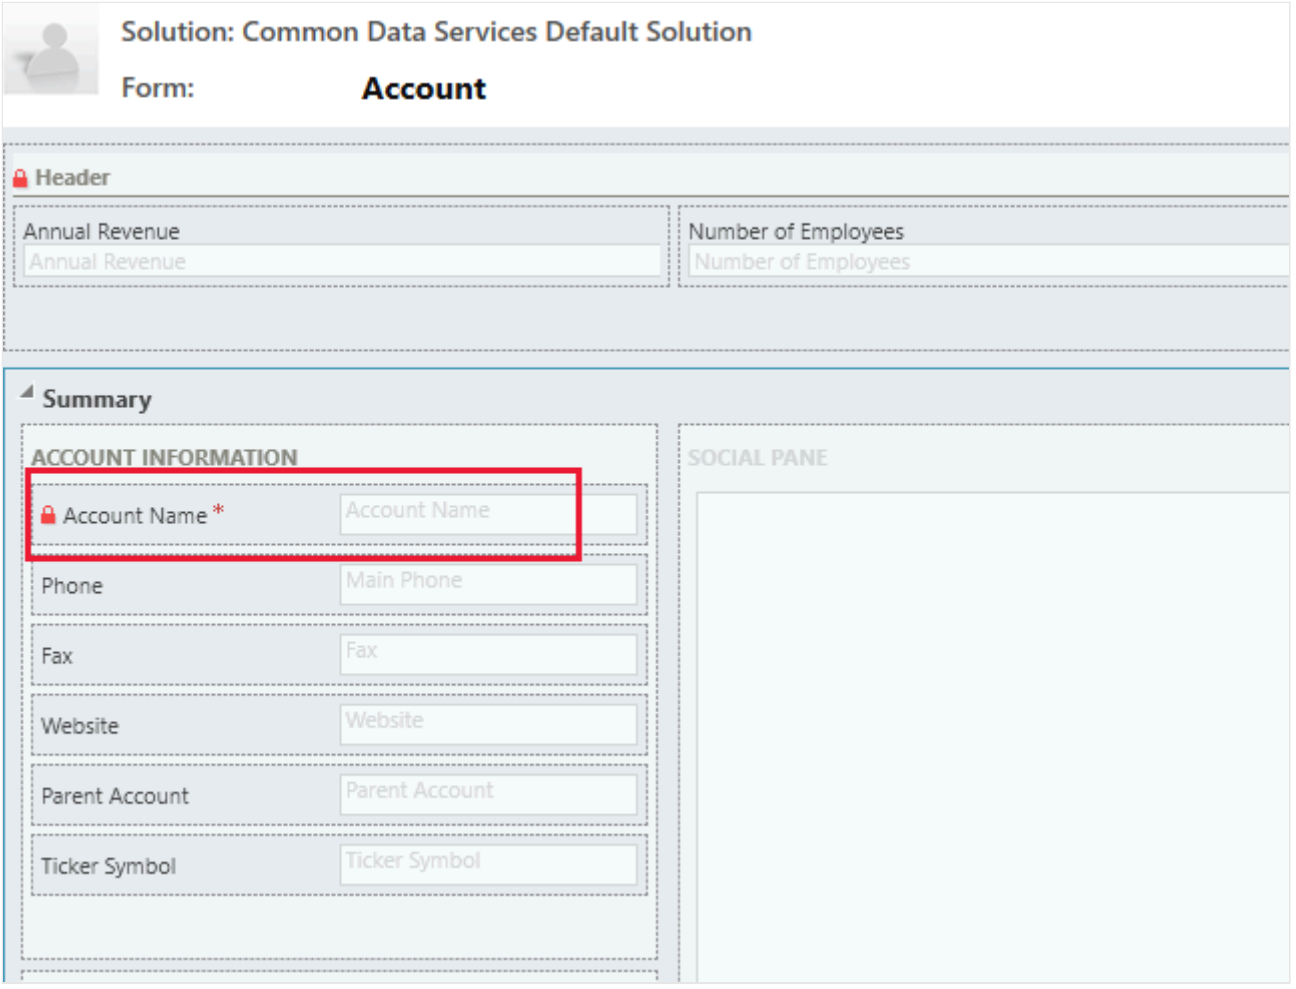
2. Open the form, and then on the form designer ribbon select **Business Rules**.

3. In the form designer, open the business rule.

4. In the business rule designer, select each condition and action to verify all the columns referenced in each condition and action.



5. Verify that each column referenced in the business rule is also included on the form. If not, add the missing column to the form.



A business rule might also not execute because a column referenced in the business rule is a composite column. Use the constituent columns of the composite column instead.

Unsupported column types

Columns of type unique identifier and rollup columns aren't supported with business rules.

A few special columns support localizable values, such as the **Name** column for the **Product** table that's included with Dynamics 365 for Sales apps. Columns that support localizable values aren't supported with business rules.

Frequently asked questions (FAQ)

Can business rules unlock columns on a read-only form?

- Yes, a business rule can unlock columns and edit actions on a read-only form.

How do I troubleshoot a business rule that isn't working?

- See Is your business rule not firing for a form? in this article.

What do recommendations look like within a form?

Recommendations show a light bulb next to the column label.

- 
Select the light bulb to expand the view and show the recommendation.

Reporting overview for model-driven apps

Article • 08/10/2023

Microsoft Dataverse as a platform supports interaction with many millions of records, filtered down to the relevant security roles. Dataverse presents data in a way that permits the correct record to be found in a reliable fashion.

Model-driven apps provide a range of reporting options to enable users to understand the data associated with their business area more easily.

Some types of reporting are straightforward to implement, and others require more advanced techniques.

Simple reporting techniques

All of the techniques described here are native to Dataverse. They provide a simple method by which application lifecycle management can be applied.

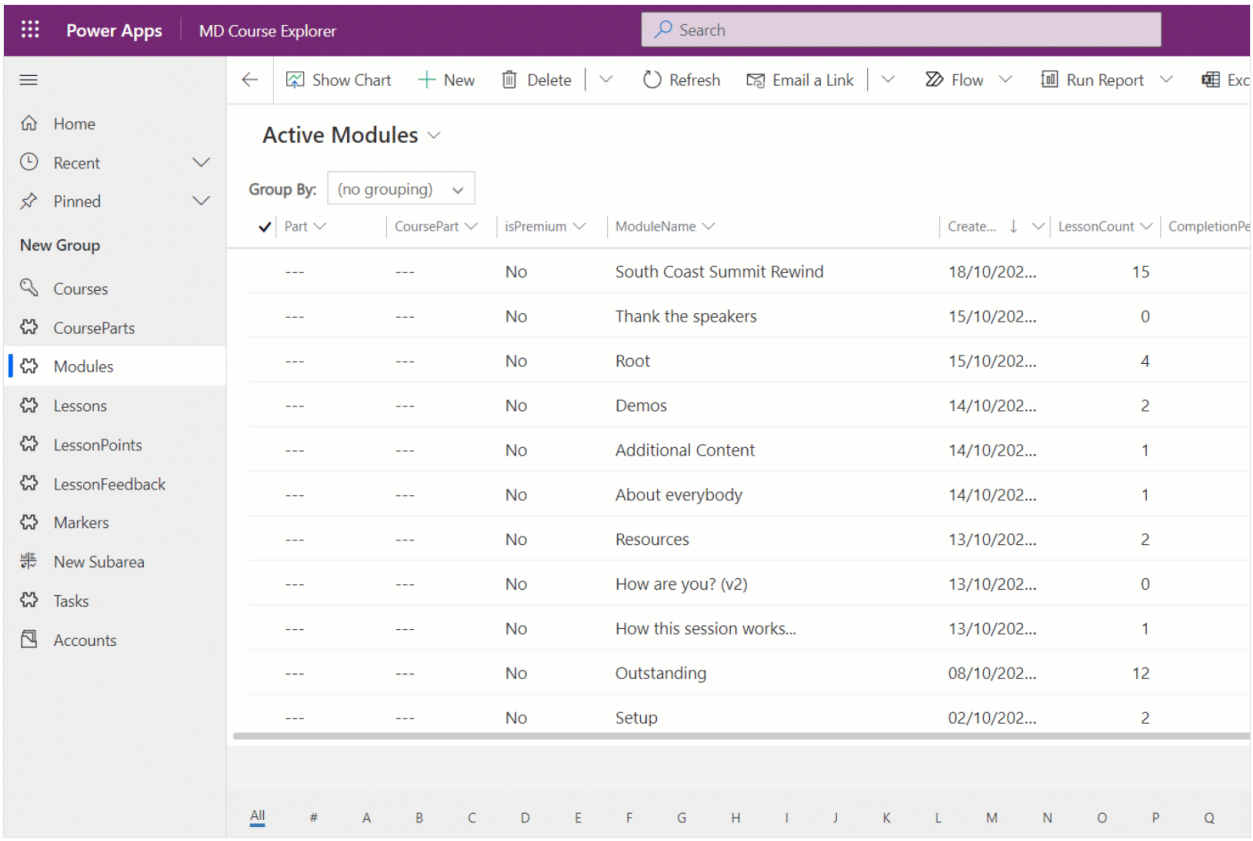
Table views

At the most basic level, table views offer a straightforward native experience in which records are presented in a tabular format. It's easy to overlook the power of views. A table can have multiple views, all of which have individual sorting and filtering applied to them, which offers a simple set of review options to the user.

Charts

Charts allow app users to view the data presented in a view in a range of ways, which include bar, pie, and line charts. Once again, a table can have multiple charts associated with it, and the charts themselves provide interactivity that enables a user to select a bar and the view filters accordingly.

The extract here shows views and charts used to create an efficient user experience.

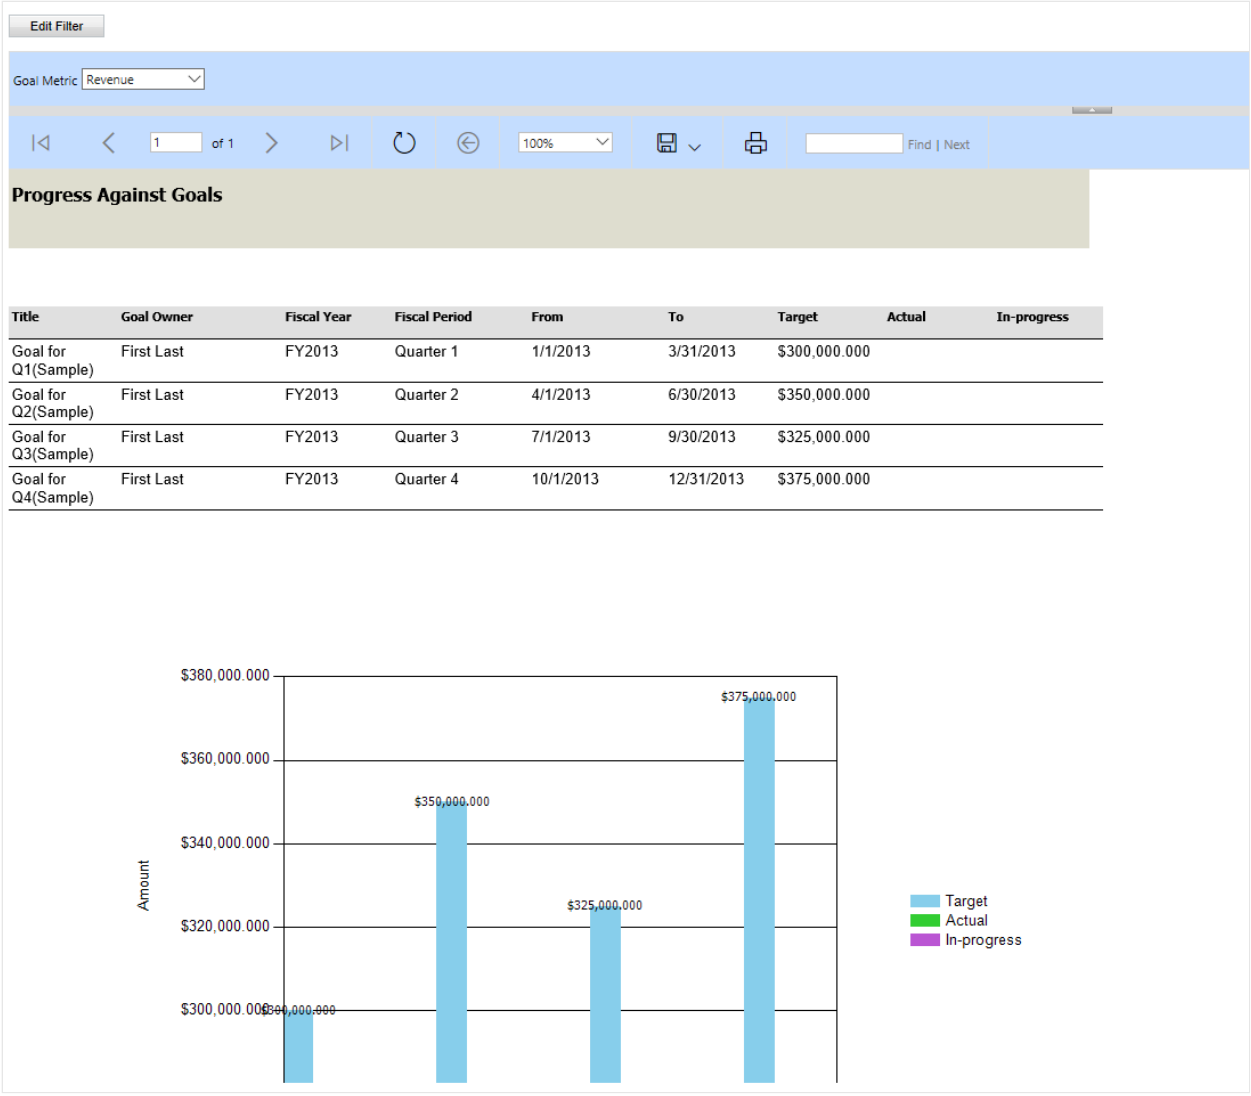


Forms

Forms can often be thought of as a method of entering data for a record. However, forms are an excellent way of providing the user columns of metadata associated with a record. Similar to views and charts, a table can have multiple forms. This permits forms to be developed that are most suited to the business needs of the individual.

Working with SQL Server Reporting style reports

SQL Server Reporting Services (SSRS) reports allow pixel perfect paginated reports to be created that can be rendered on screen and distributed in a range of ways such as PDF, CSV, Excel, and so on. The reports are created using the classic editor and are solution aware, which helps with application lifecycle management. Learn more about SSRS reports



Power BI Reporting

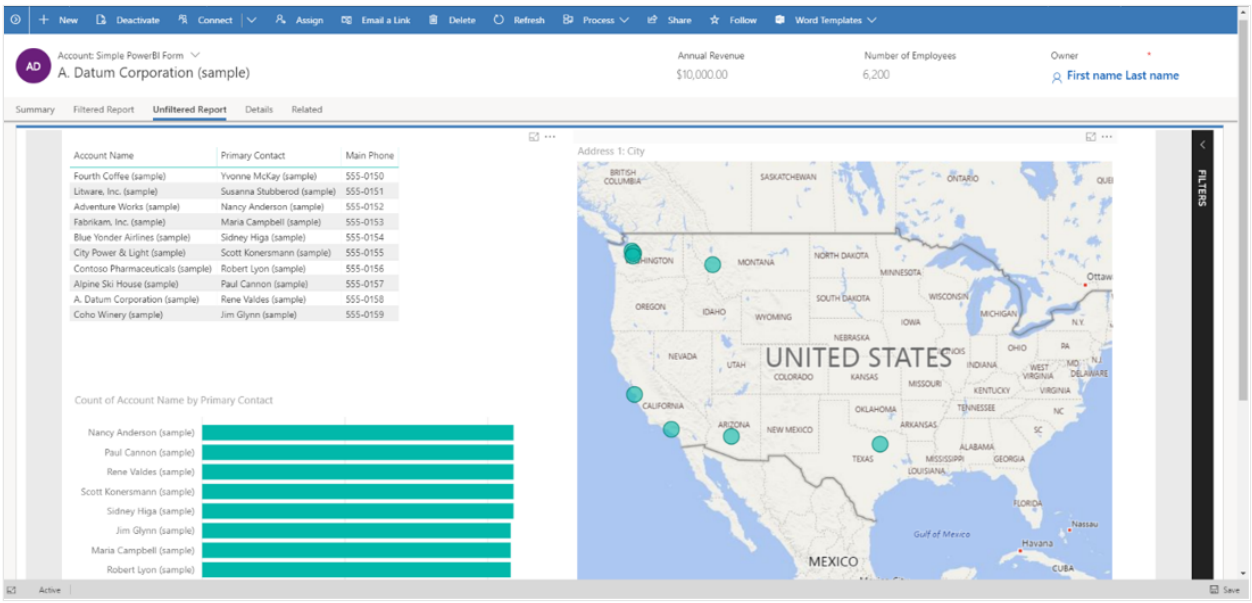
Power BI is a powerful and interactive reporting tool. Power BI dashboards and reports can be introduced into model-driven apps in a range of ways. You can also add Power BI reports and datasets as components in Power Apps solutions. Once you've added a Power BI report to a solution, it can be seamlessly managed as part of your application lifecycle management (ALM) process across environments and tenants.

Additionally, unless direct query techniques are used, record-level security must be reconfigured into the Power BI reports.

There are three techniques for adding Power BI into your model driven apps.

Technique	Notes	Power BI Object
Embed a Power BI report in a model-driven system form	This allows a Power BI report to be presented within a table form and this can be performed in the context of the current record.	Report

Technique	Notes	Power BI Object
Create or edit a Power BI embedded system dashboard	This is a technique that an administrator can use to introduce a Power BI dashboard	Dashboard
How app users can add or edit Power BI visualizations on their dashboards	This allows a full Power BI dashboard to be introduced, however it's introduced by the user, not an administrator.	Dashboard



Excel integration

Microsoft Excel integration lets users easily build self-service reports using, PowerView, PowerPivot, and PowerQuery.

Power BI Overview

Create a model-driven app system chart

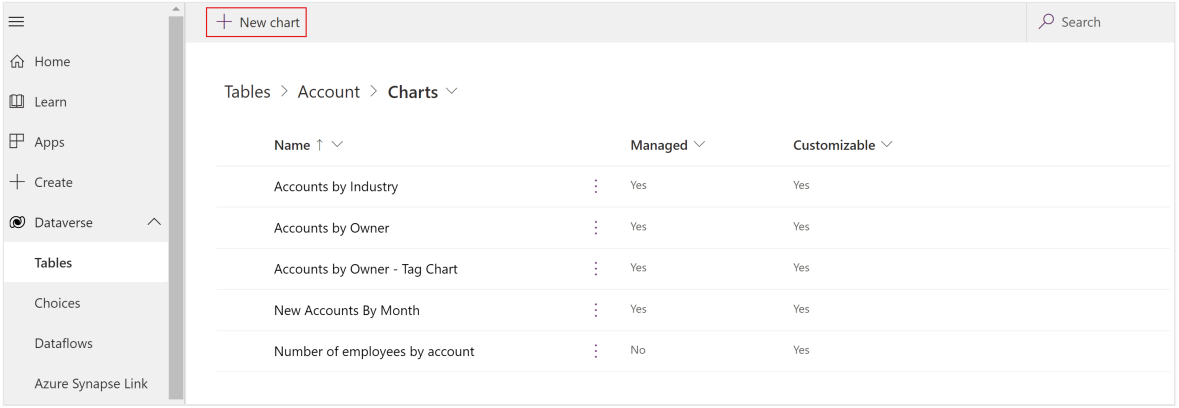
Article • 01/22/2025

In this article you learn how to create a system chart. System charts are organization-owned charts, which makes them available to anyone with access to read the data running the app. System charts can't be assigned or shared with specific app users.

> **Note**
>
> Model-driven apps not configured to display **All** charts for a table need newly created charts selected for the table within the app designer. More information: Add table assets

Create a new chart

1. Sign in to Power Apps.
2. On the left navigation pane, select the **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the table that requires a chart, and then select **Charts**.
4. Select **New chart**.

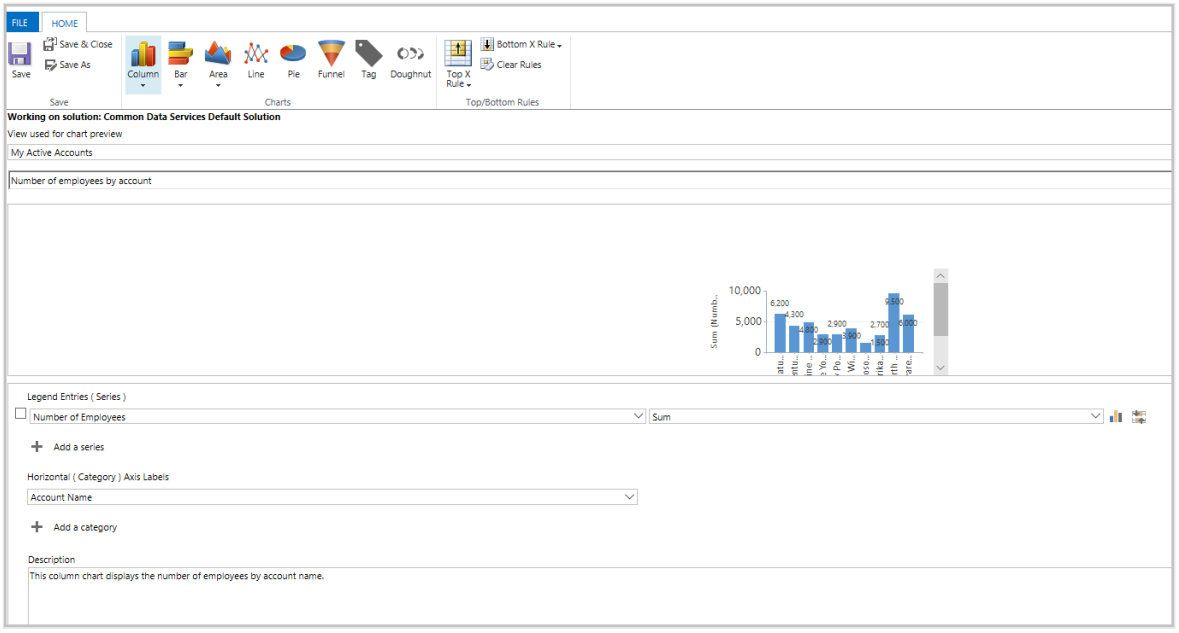


A new window opens where you can create a chart.

5. Specify the type of chart, and how the data is displayed in the chart.
   - Enter the chart name, such as *Number of employees by account*.
   - In the **Select Column** dropdowns:

- In the **Legend Entries (Series)** dropdown list select a column, such as **Number of Employees**.
- In the **Horizonal (Category) Axis** dropdown list select a column, such as **Account Name**.

- Add a description to identify the purpose of the chart, such as *This column chart displays the number of employees by account name*.



6. Select **Save and Close**.

The **Number of employees by account** chart is now displayed in the app designer list of charts available for the account table.

> **Note**
>
> When creating a chart, you can preview it with a selected view. The view isn't permanently associated with the chart. The next time you open the chart, the chart displays using the configured default view. You can change the view to display the chart for the data from a different view.

View your visualization in a model-driven app

Now that the chart is created, it can be used to visualize table data in the model-driven app. Follow these steps to view the chart:

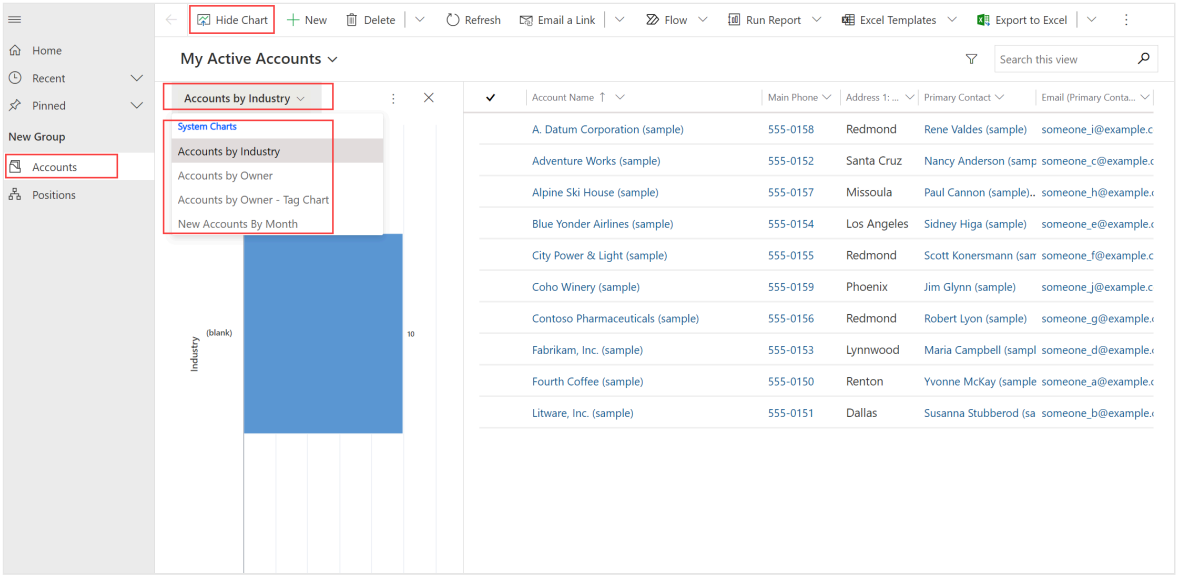
1. Open a model-driven app that contains your table via a solution or open the app directly from the **Apps** area.

2. Select … next to the app, and then select **Play**. The model-driven app opens in a separate browser tab.

3. On the left navigation pane, select a table such as **Accounts**.

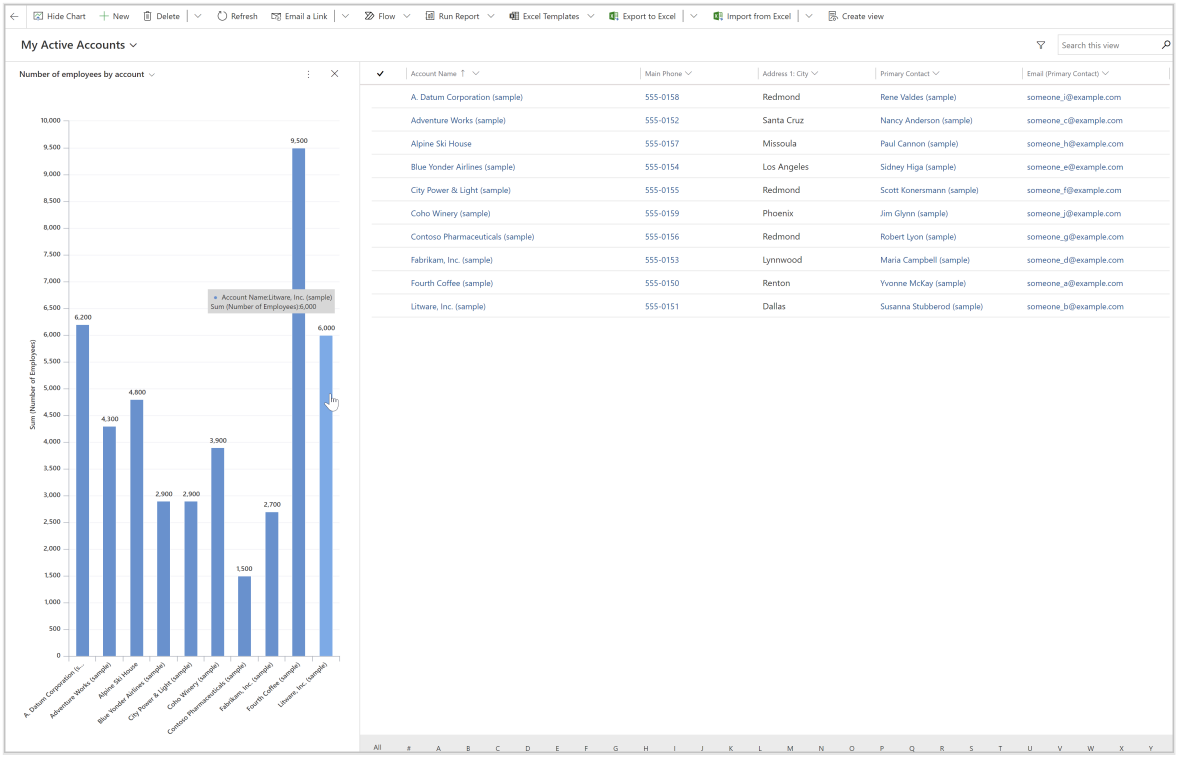
4. On the command bar, select **Show Chart**.

   The chart pane opens.



5. By selecting the dropdown chart list, any of the system charts in the app are available to select.

   The chart appears in-line with the data view.



Use your chart:

- Select a bar on the chart to filter the data in the view.
- Refresh the chart to display other data by changing the view.
- Add the chart to a model-driven app dashboard. More information: Create or edit model-driven app dashboards

> **Note**
>
> If the chart isn't visible in the dropdown chart list, then the model-driven app has been created with specific charts associated with it. To resolve this, open the model-driven app in design mode, select charts, and then select your newly created chart.
>
> 
>
>
> Then save and publish your app.

Maximum number of records displayed in a chart

Charts display views that return up to 50,000 records. Views that exceed 50,000 records display the message: The maximum record limit is exceeded. Reduce the number of records. More information: Reporting infrastructure

Known chart creation issues

In the chart designer, adding an order by on certain calculated columns isn't supported and cause an error. The calculated columns causing the issue are using another calculated column, a related table column, or a local column on the table.

Create or edit dashboards

Feedback

Was this page helpful? Yes No

Provide product feedback

Create or edit model-driven app dashboards

Dashboards are collections of charts relating to Microsoft Dataverse tables.

There are two types of dashboards, user dashboards and system dashboards. An app user can create a dashboard visible only to them in the app areas where they have privileges.

An admin or customizer creates or customizes system dashboards that, when published, are visible to all app users. A user can choose to set their user dashboard as their default dashboard and override the system dashboard.

Dashboard interactivity

Dashboards can be standard or interactive.

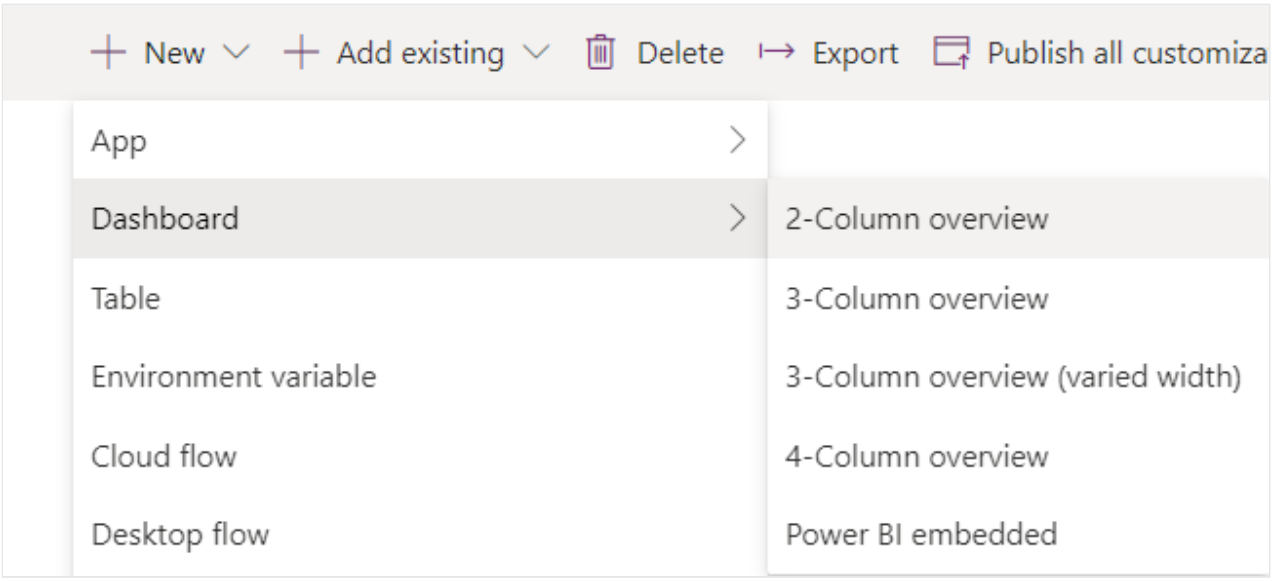
Standard dashboards support adding one or more unrelated components such as charts or lists.

Interactive dashboards provide the capability for users to act on a particular row directly from the dashboard. This article focuses on standard system dashboards. For information about interactive dashboards, see Configure model-driven app interactive experience dashboards.

Create a new standard dashboard

1. Sign in to Power Apps.
2. Select **Solutions** in the left navigation pane, and then open the unmanaged solution you want or create a new one. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. On the toolbar select **New**, select **Dashboard**, and then choose one of the following layouts:
    - 2-column overview
    - 3-column overview
    - 3-column overview (varied width)
    - 4-column overview

- Power BI embedded



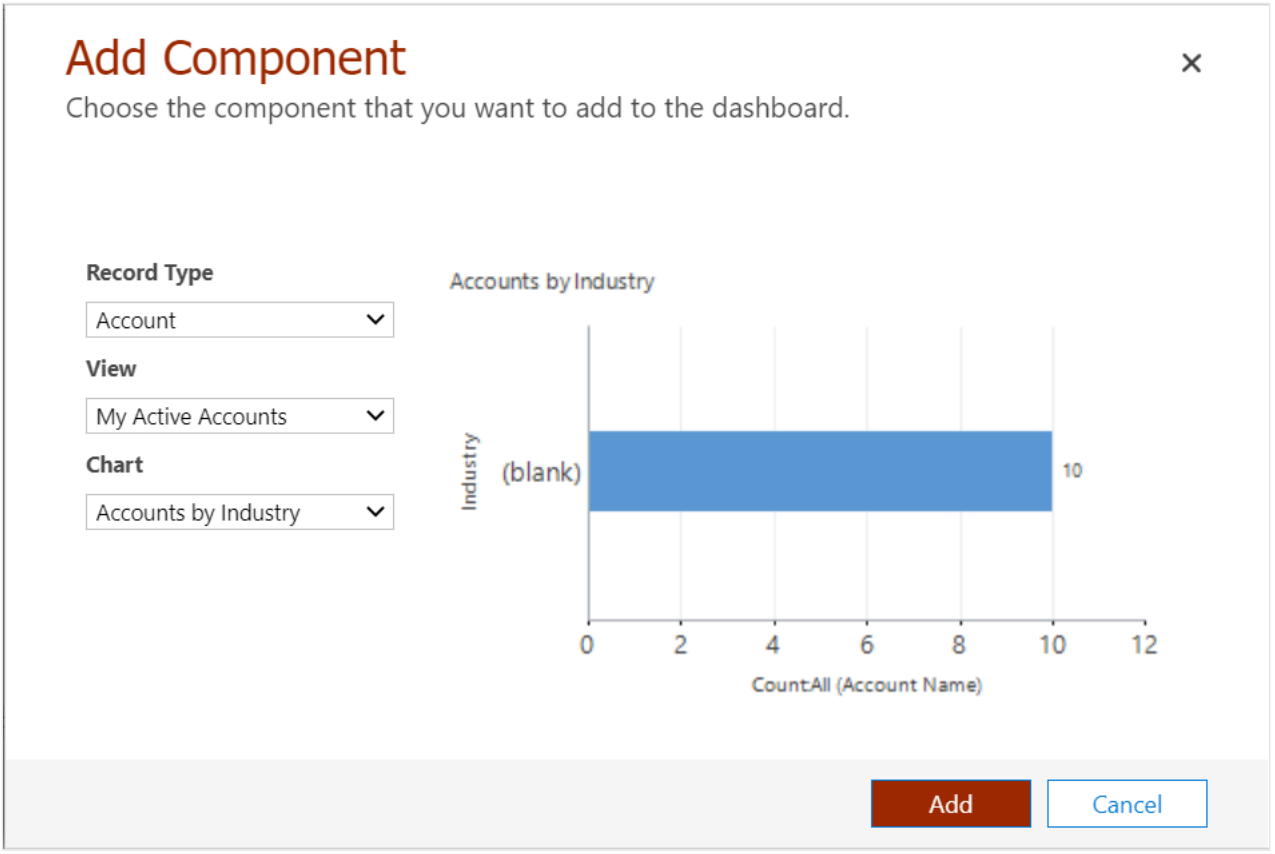
4. If you select Power BI embedded, go to Create or edit a Power BI embedded system dashboard. Otherwise, in the **Dashboard: New** page, enter a name for the dashboard.

5. In one of the component sections, select the icon for a chart or a list.

   Up to six components can be included in a dashboard.

6. For example, to add a chart, select the chart icon on the tile of the dashboard canvas where the chart needs to appear. Then, in the **Add Component** dialog, select values for **Record Type**, **View**, and **Chart**. Then select **Add** to add the chart to the dashboard. For

information about how to create a chart, see Create a model-driven app system chart.



7. When you finish adding components to the dashboard, select **Save** and then **Close**.

8. On the solution toolbar, select **Publish**.

Edit an existing dashboard

1. Sign in to Power Apps.

2. Select **Solutions** in the left navigation pane, and then open the solution you need. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. In the list of solution components, open the dashboard, select one of the component areas, and then on the toolbar select **Edit Component**.

4. In the **Set Properties** dialog box, make changes to a chart or list such as change the table, default view, or add a chart selector. When done, select **OK**.

   For more information about setting dashboard component properties, see Set properties for a chart or list included in a dashboard.

5. When the changes are complete, select **Save** and then select **Close**.

6. On the solution toolbar, select **Publish**.

> **Note**
>
> Lists in the dashboard designer don't display a data preview.

Next steps

Configure interactive experience dashboards

Last updated on 04/08/2026

Create and configure model-driven app interactive experience dashboards

Interactive experience dashboards can be a *one-stop workplace* for app users, such as service reps, to see workload information and take action. They're fully configurable, security-role based, and deliver workload information across multiple streams in **real time**. Interactive dashboard users don't need to page through the application looking for a particular row; they can act on it *directly* from the dashboard.

The interactive experience dashboards come in two forms: **multi-stream** and **single-stream**. In addition, multi-stream dashboards can be home page or table-specific dashboards. The table-specific dashboards are configured in a different part of the user interface and are partially preloaded with table-specific configuration information.

- Multi-stream dashboards. The multi-stream dashboards display data in real time over multiple data streams. There’s no limit on how many streams you can configure on the dashboard. The data in a stream can be based only on one table, but, each stream can be based on a different table.
- Single-stream dashboards. In the table-specific dashboards, all streams are based on the same table. The data flows from various views or queues, such as **My Activities**, **My Cases**, or **Cases in the Banking Queue**.

> ⓘ **Note**
>
> The examples described here use the Case table, which is available with the Dynamics 365 Customer Service app.

The single-stream dashboards display real-time data over one stream based on a table view or queue. The tiles are positioned on the right side of the dashboards and are always shown. The single-stream dashboards are typically helpful to tier two service leads or managers, who monitor fewer, but more complex or escalated cases.

Dashboard charts

Multi-stream and single-stream dashboards contain interactive charts that provide a count of relevant rows, such as cases by priority or by status. These charts also act as visual filters. The

visual filters (interactive charts) are based on multiple tables and in the single-stream dashboards, the table in the data stream defines the visual filter table.

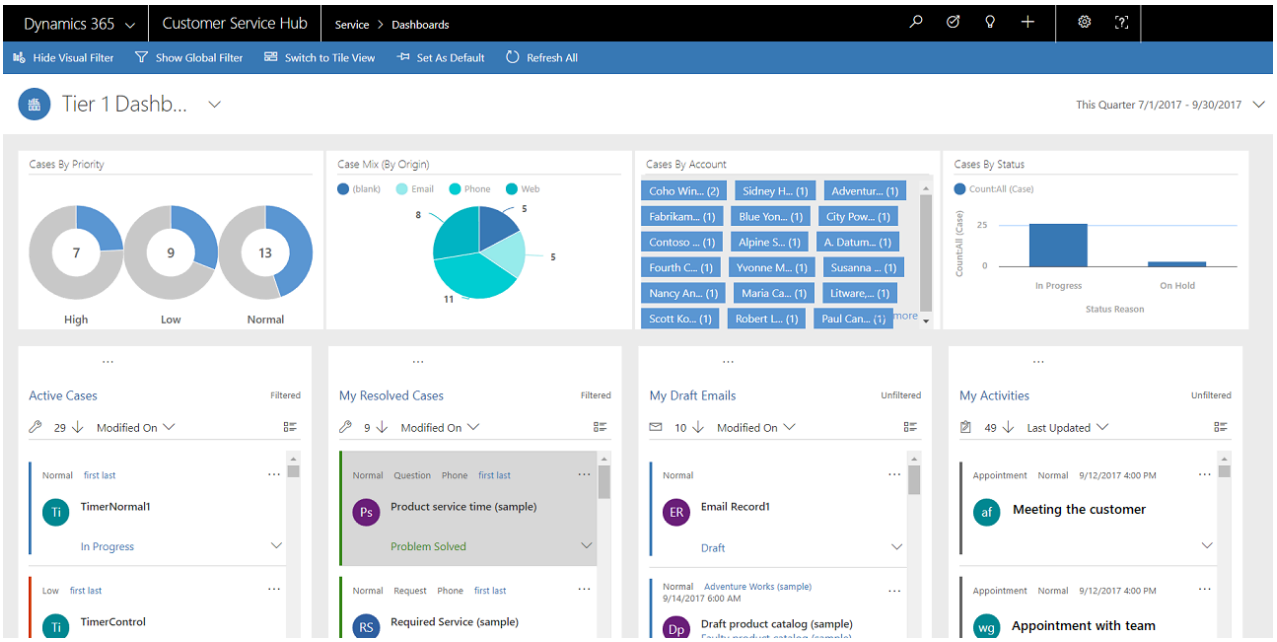
Users can apply additional filtering with `global filter` and `timeframe` filter. The global filter works at a column level on all charts, and also on streams and tiles that are based on the filter table (you specify the filter table when you configure the visual filters).

> **Note**
>
> The interactive dashboards are solution aware and can be exported and then imported into a different environment as a solution. However, the queues that the streams and tiles are based on aren't solution aware. Before you import the dashboard solution into the target system, the queues have to be manually created in the target system in **Settings** > **Service Management** > **Queues**. After you create the queues, import the dashboard solution to the target system, and then edit the streams or tiles that are based on the queues to assign the newly created queues appropriately.

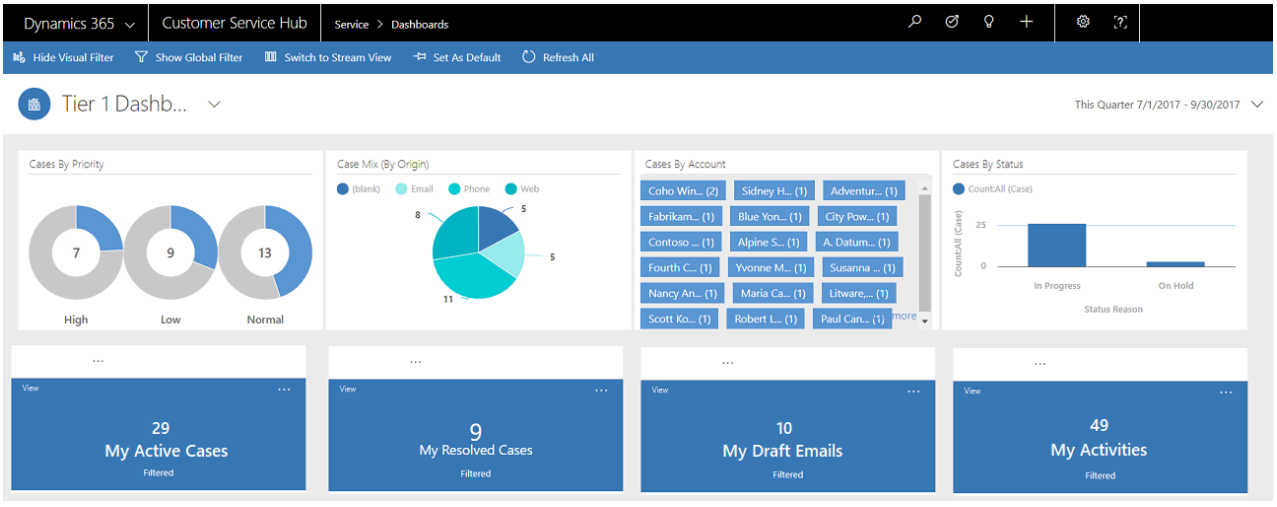
The illustrations in this article show multi-stream and single-stream dashboards with the header pane. Below the header you can view visual filters and streams. In the single-stream dashboard, you also view tiles. For each dashboard type, you can choose from several different layouts that are also shown. The dashboard header contains the following controls and selectable icons, from left to right: dashboard picker, refresh, visual filter icon, global filter icon, and time frame filter.

Dashboard layouts

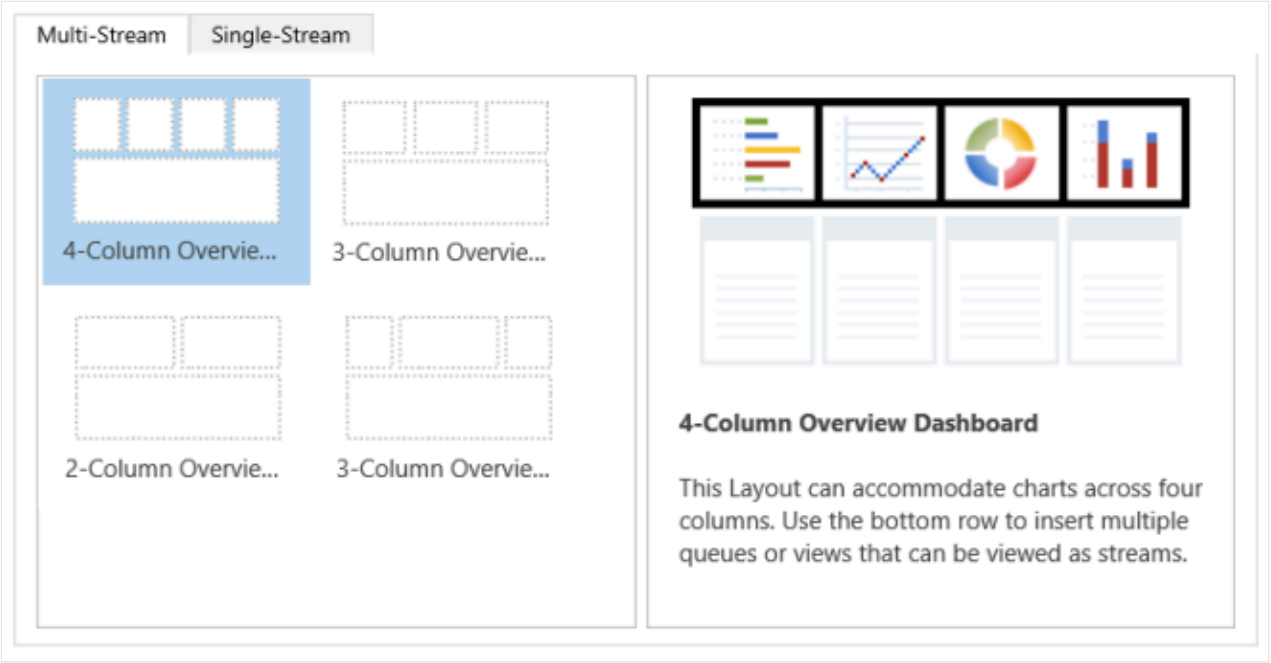
- Multi-stream dashboard standard view. In the multi-stream dashboard, you view a row of visual filters at the top with the data streams below them.



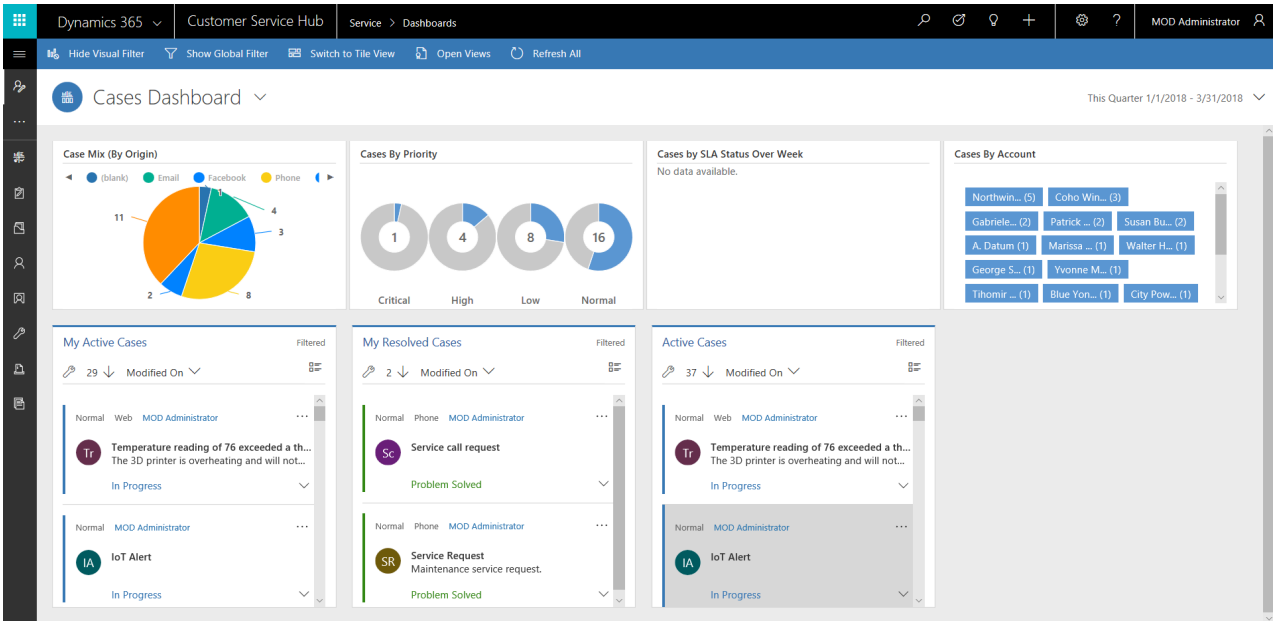
- Multi-stream dashboard tile view. The same dashboard, only in the tile view.



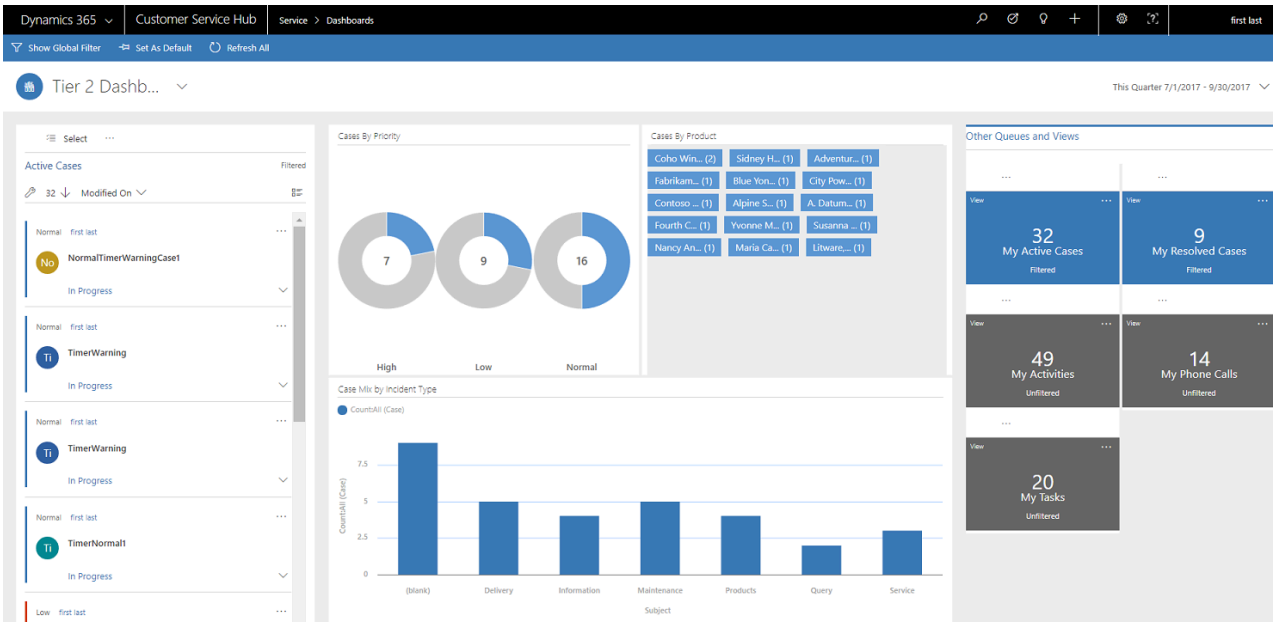
- Multi-stream dashboard layouts. For multi-stream dashboards, you can choose from four different layouts.



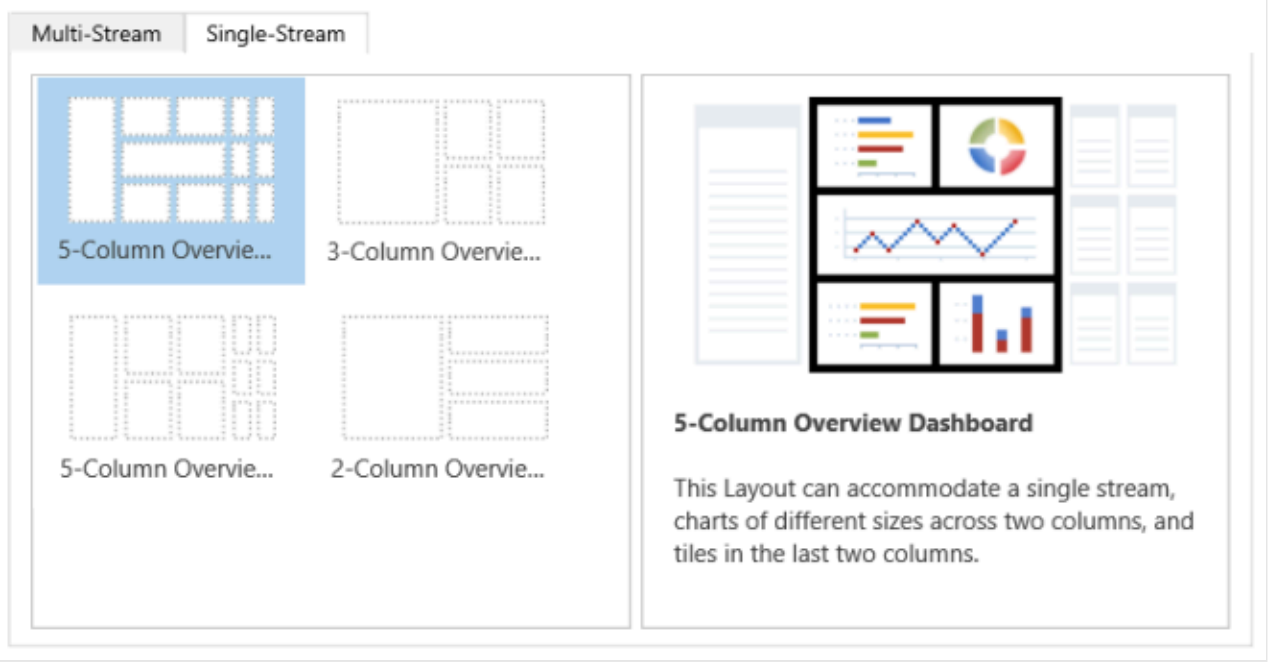
- Multi-stream table-specific dashboard. The table-specific dashboard for the case table is shown here.



- Single-stream dashboard. The single-stream dashboard contains the data stream on the left and visual filters and tiles on the right pane.



- Single-stream dashboard layouts. Four different layouts can be chosen for single-stream dashboards.



Configure filter columns, and security roles for interactive dashboards

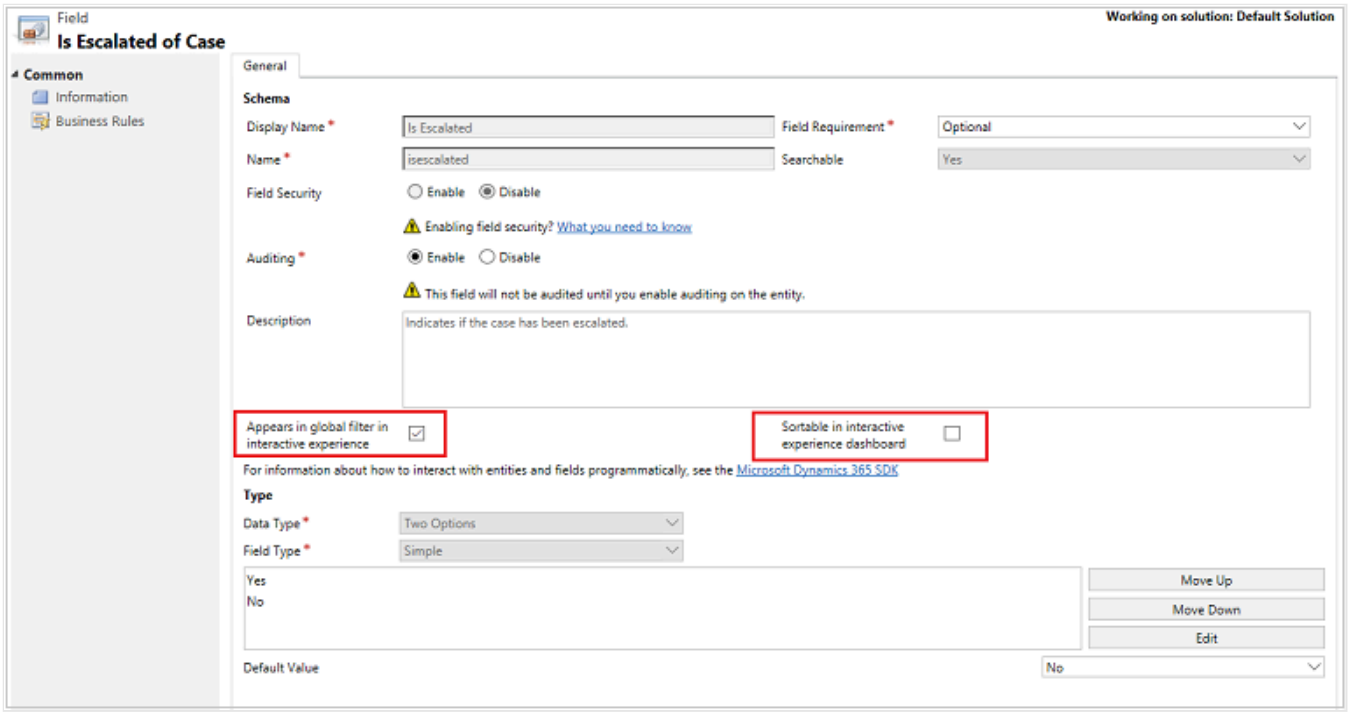
When interactive dashboards are configured, the first task is to enable filter columns and security roles so that interactive dashboards can be configured for them. Notice that interactive dashboards are enabled for all tables and custom tables by default.

Configure filter columns

For a column to appear in the global filter and be included in the data stream sort, two flags must be set:

- Appears in global filter in interactive experience.
- Sortable in interactive experience dashboard.

In this example there are two interactive dashboard options available in the Case table for the **IsEscalated** column.

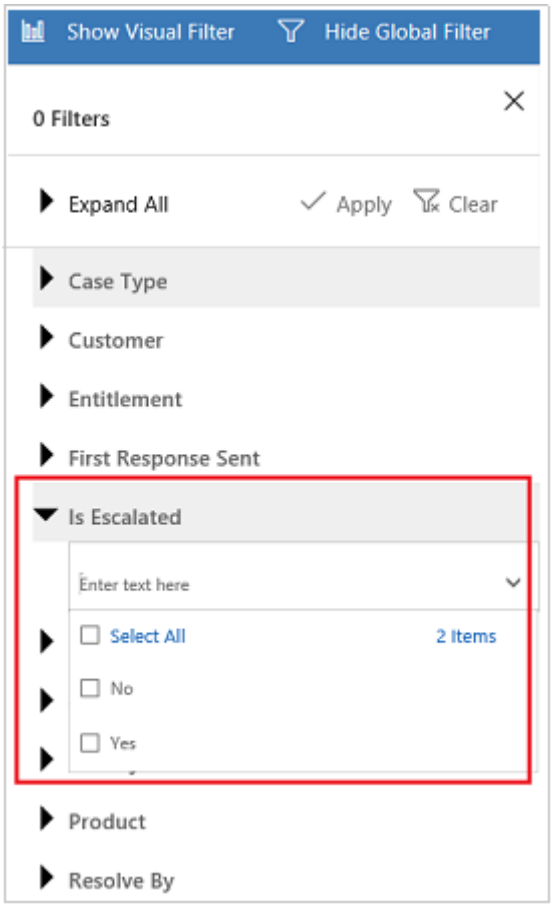


Configure the 'Appears in global filter in interactive experience' option

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution you want, and then on the toolbar select **Switch to classic**.
4. Under **Components**, expand **Entities** (which are effectively tables), and then expand the specific table.
5. In the navigation pane, select **Fields** and in the grid, double-click the column, or data field, required.
6. In the **General** tab, select the **Appears in global filter in interactive experience** check box. Select **Save and Close**.
7. Select **Publish All Customizations** for the changes to take effect.

The columns that are enabled for **Appears in global filter in interactive experience** appear in the global filter flyout window when the global filter icon is selected on the dashboard header. In the flyout window, the service reps can select the columns on which they want to filter globally, in charts, and also in streams and tiles that are based on the filter table.

The global filter flyout window is shown here:



> **Tip**
>
> When a visual filter is configured based on the columns like priority or status, a best practice is to also enable these columns (priority, status) to appear in the global filter.

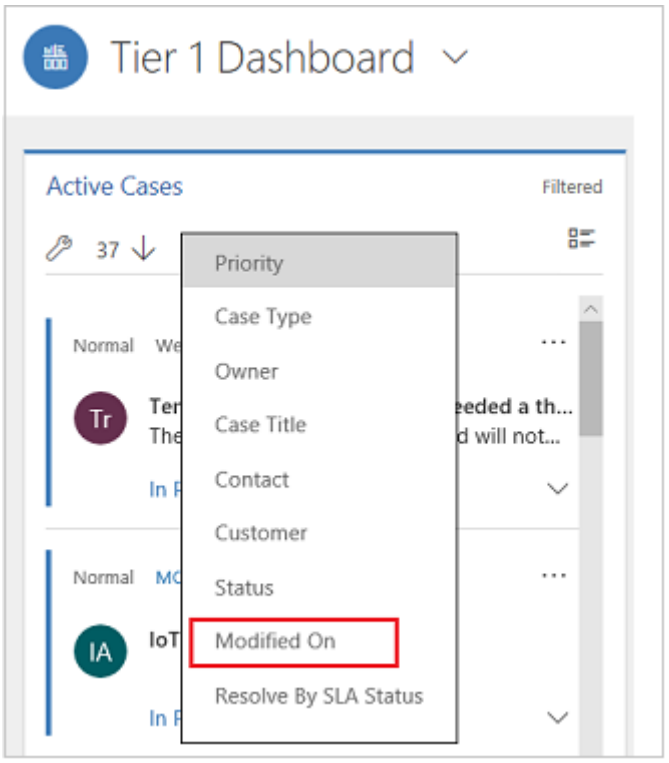
Configure the 'Sortable in interactive experience dashboard' option

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution you want, and then on the toolbar select **Switch to classic**.
4. Under **Components**, expand **Entities** (which are also known as tables), and then expand the specific table.

5. In the navigation pane, select **Columns** and in the grid, double-click the column for which sorting is required.
6. In the **General** tab, select the **Sortable in interactive experience dashboard** check box. Select **Save and Close**.
7. Select **Publish All Customizations** for the changes to take effect.

The columns that are configured for sorting appear in the drop-down list on the stream header.

The following screenshot shows the flyout dialog with the list of the available columns for sorting, in the drop-down list. The default sort is always set on the **Modified On** column.



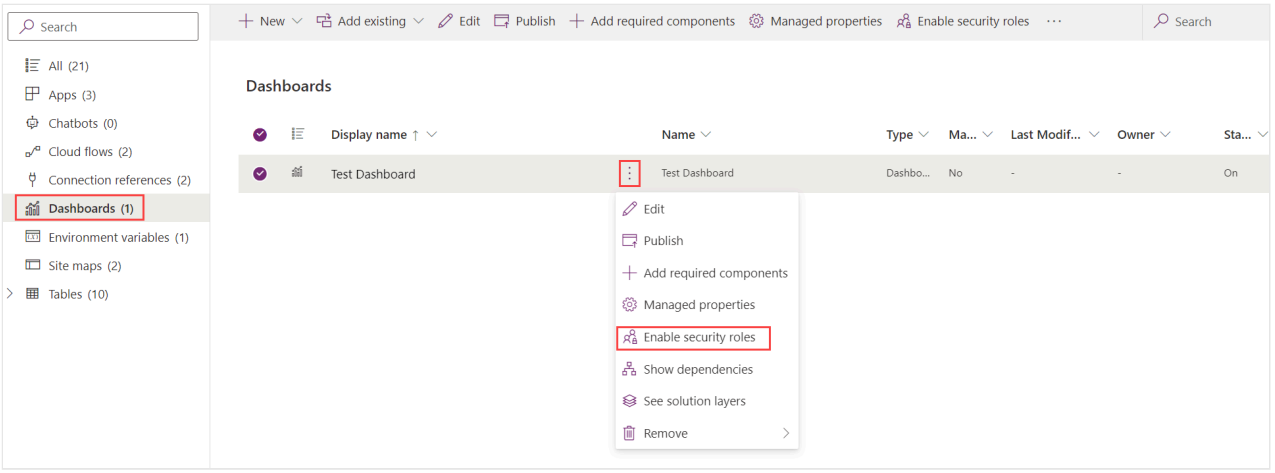
Enable security roles

Select and enable security roles that are able to view the interactive dashboards.

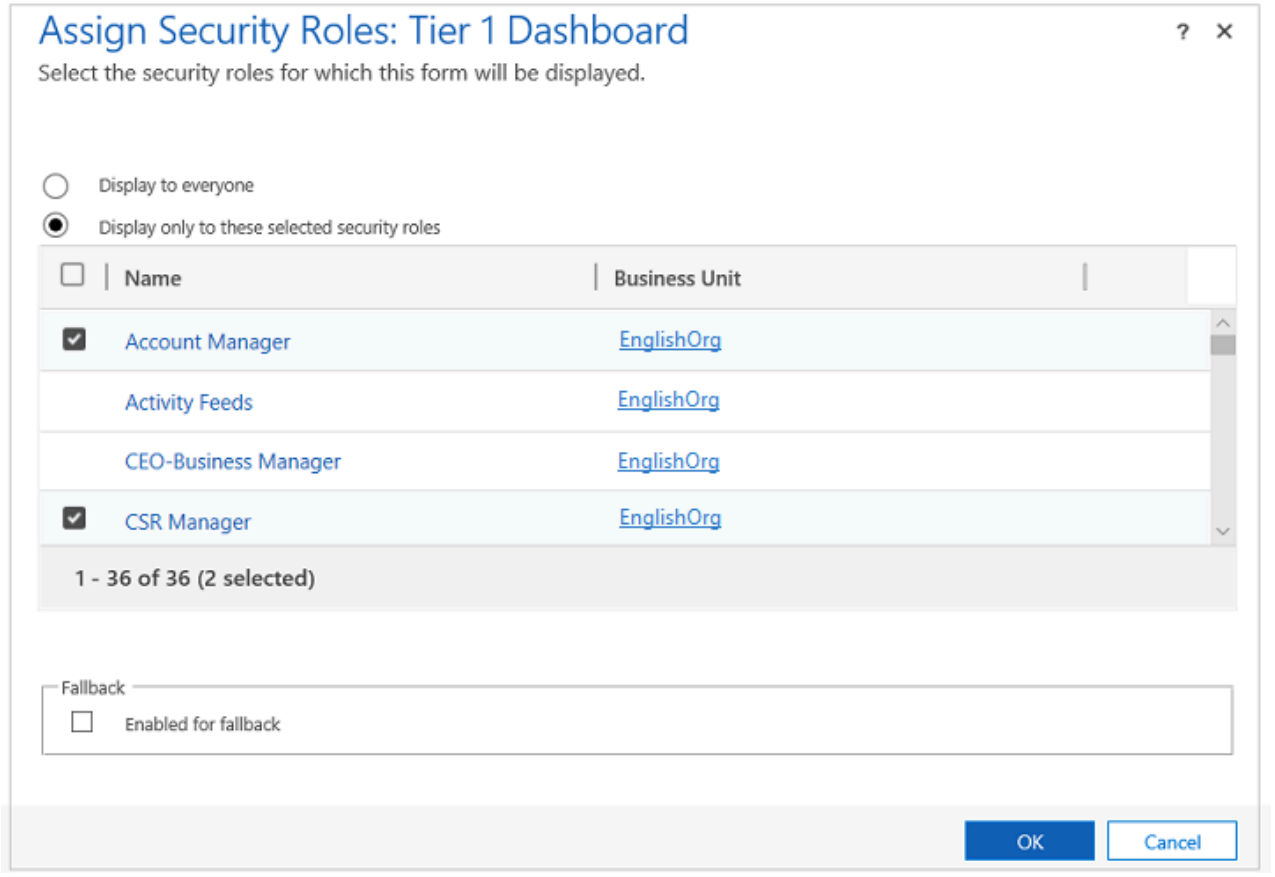
Enable security roles for interactive dashboards

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the required solution.

4. Select the dashboard and then on the toolbar select **Enable security roles**. This action opens a new tab with the classic interface.



5. In the **Assign Security Roles** dialog, select the **Display only to these selected security roles** option and select the roles that you want to enable. Select **OK**.



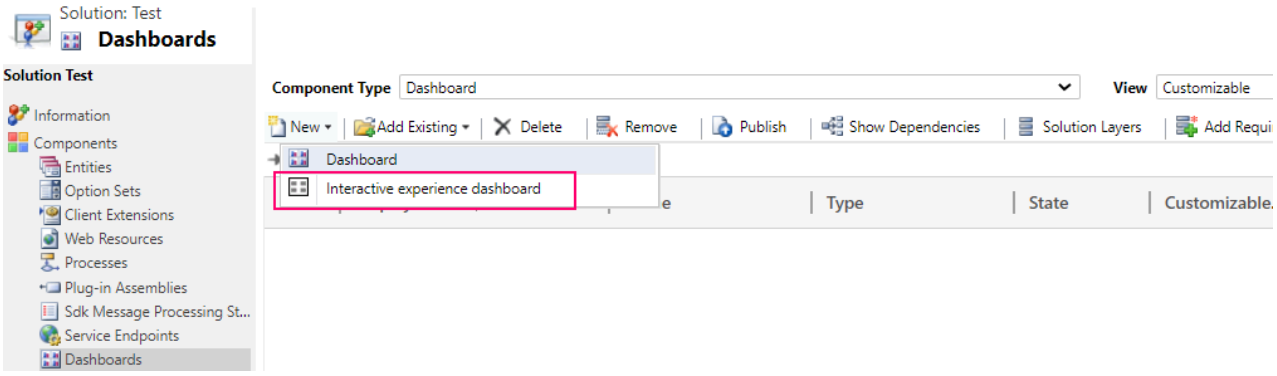
6. Select **Publish** for the changes to take effect.

Create interactive experience dashboards

The following sections describe how to create and then configure the various types of interactive dashboards.

Configure a multi-stream interactive dashboard using the 4-column layout

1. Sign in to Power Apps.
2. Select an environment with an unmanaged solution.
3. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Open the solution you want, and then on the toolbar select **Switch to classic**.
5. In the left navigation pane, select **Dashboards**, on the toolbar select **New**, and then select **Interactive experience dashboard**.

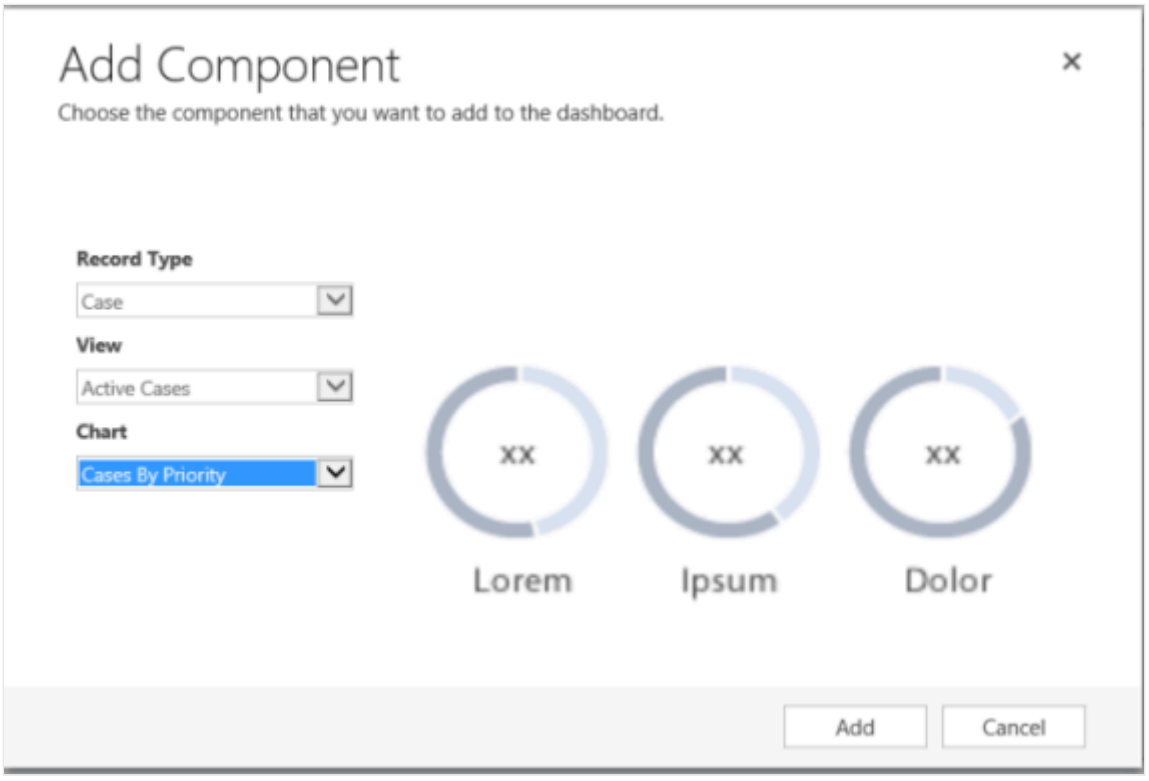


6. Choose the layout, either 2, 3, or 4 column width.
7. When the dashboard form opens, fill in the filtering information at the top of form, as shown here.

- **Filter Table**: The visual filters and global filter attributes are based on this table.
- **Table View**: The visual filters are based on this view.
- **Filter By**: The column that the time frame filter applies to.
- **Time Frame**: The default time frame filter value for the **Filter By** column.

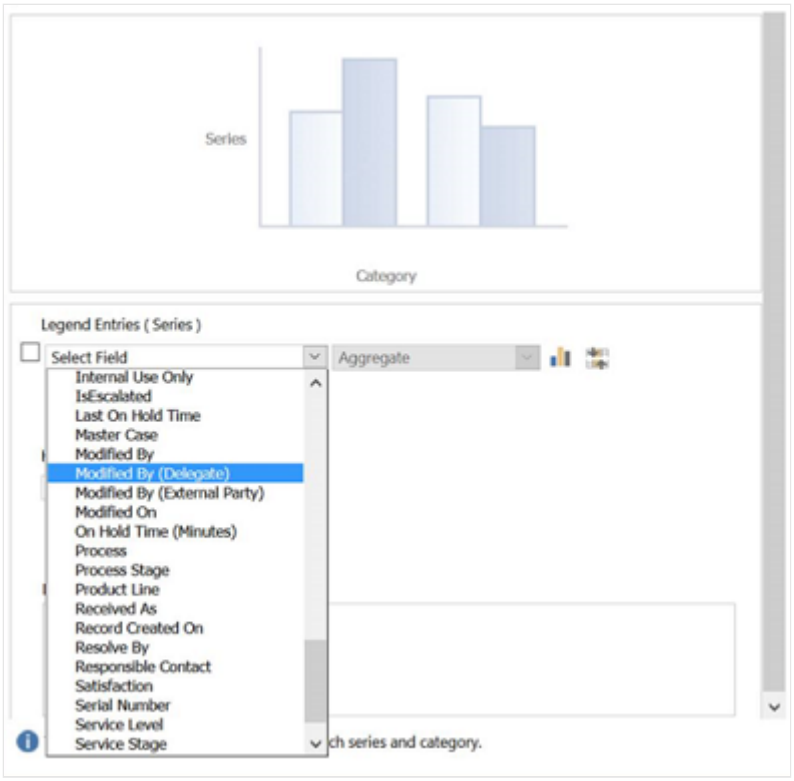
After filtering information is specified, start adding components for the charts and the data streams. To add a component, simply select the element in the center of the chart or stream, and when the dialog appears, select the required information from the drop-down list, as shown in these illustrations.

Add the **Cases By Priority** doughnut chart.



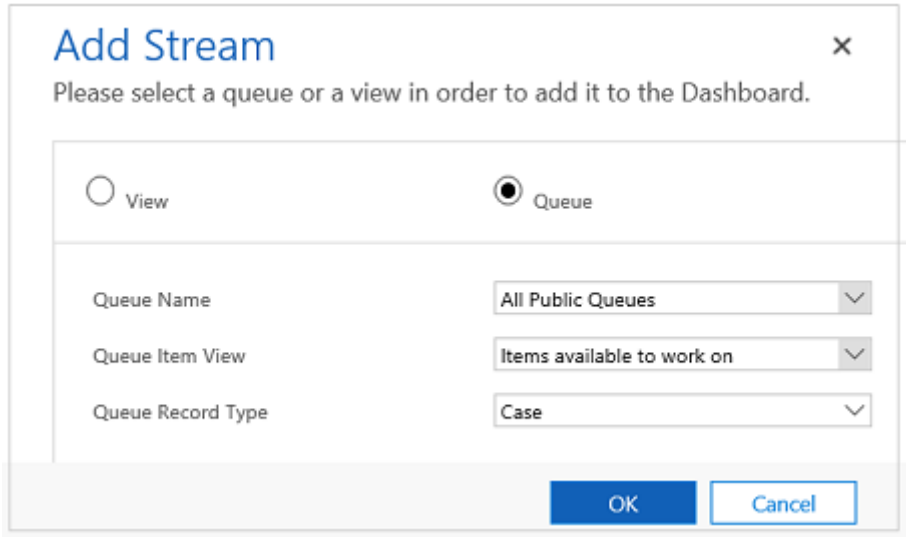
Some charts, such as bar charts or pie charts, render showing the data stored in the system. The doughnut charts and tag charts load as static images and don't show the preview of the actual data.

> ⓘ **Note**
>
> The charts configured for the visual filters can use the columns of the **Filter** table as well as related tables. When charts are based on related table columns, the customer service representatives can filter charts using these related table columns. The columns that are based on the related table usually have the following format in the chart configuration window: "field name (entity name)", such as the **Modified By (Delegate)** column. To create multi-entity charts, columns of a related table must be added to any of the views, and then use these columns while creating charts.



Next, configure the streams. Just like with adding components in the charts, select the element inside the stream panel. When the dialog appears, select **View** or **Queue** depending on what element you want the stream to use. Enter the required information, as shown in the following illustration.

Configure the stream for the **Items available to work on** as shown here:



> ⓘ **Note**
>
> The **Queue** option is available in the dialog box only for queue-enabled tables. For table dashboards, if the table isn't queue enabled, the **Queue** option won't be visible in the

dialog box. It's only possible to use the **View option** in the stream of dashboards for tables that aren't queue enabled.

The following illustration is an example of a fully configured chart panel and stream panel:
