After the dashboard has been completely configured, save it and publish the customizations for the changes to take effect.

Edit or delete individual streams of an existing dashboard

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the solution you want, and then open the interactive dashboard.
4. Select the stream that you want to edit to select it, and then select **Edit Component**.
5. Depending on whether you want to add a view or queue to the stream, select the view or queue details for the stream, and then select **Set**.
6. Select **Save**.

It's also possible to delete an individual stream from a dashboard. To do this, select the stream, and then on the toolbar, select **Delete**.

Create a table-specific dashboard

A table-specific dashboard is a multi-stream dashboard. Configuring this dashboard is similar to configuring a home page multi-stream dashboard, but this is performed in a different place

in the UI and there are other minor differences.

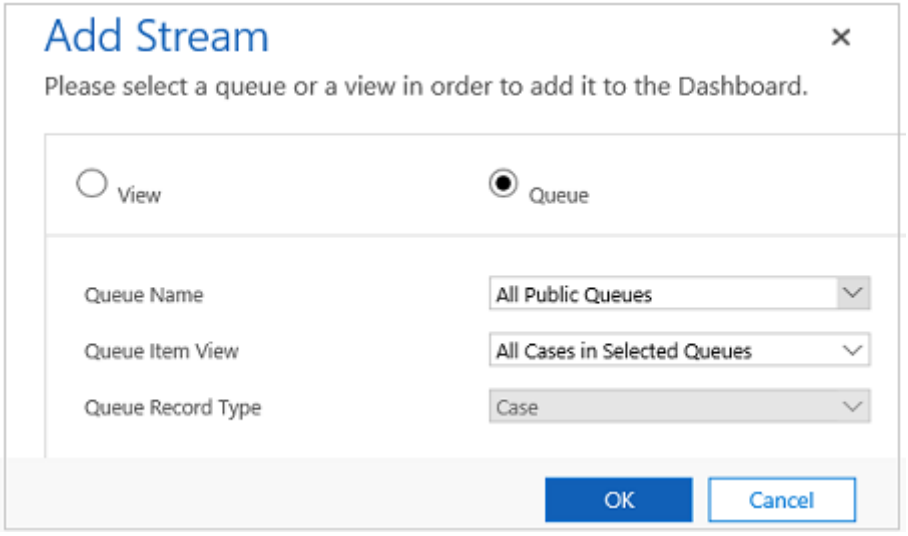
For example, instead of selecting a table, some columns in the table-specific dashboard are preset to the table relevant to the dashboard.

1. Sign in to Power Apps.
2. On the left navigation pane, select **Tables**. If the item isn't in the side panel pane, select ... More and then select the item you want.
3. Open the table you want.
4. Select the **Dashboards** area, and then on the toolbar select **Add dashboard**.
5. Choose the layout, either 2, 3, or 4 column width.
6. When the dashboard form opens, the **Filter Table** is preset to the table, which is tied to the dashboard. The **Table View** drop-down list contains the available views for the table. Select the view and fill in the rest of the required information on the page.

The rest of the setup is similar to the home page multi-stream dashboard setup described in the previous section.

Configure a single-stream dashboard

Configuring a single-stream dashboard is similar to the multi-stream dashboard. All UI navigation steps are the same as for the multi-stream dashboard. It's possible to choose a layout that includes tiles or the layout that doesn't include tiles. If the tiles are included, they're always displayed on the dashboard. To configure a tile, the icon in the center of the tile is selected. When the **Add Tile** window opens, fill in the required data. The following illustration is an example of the tile setup.



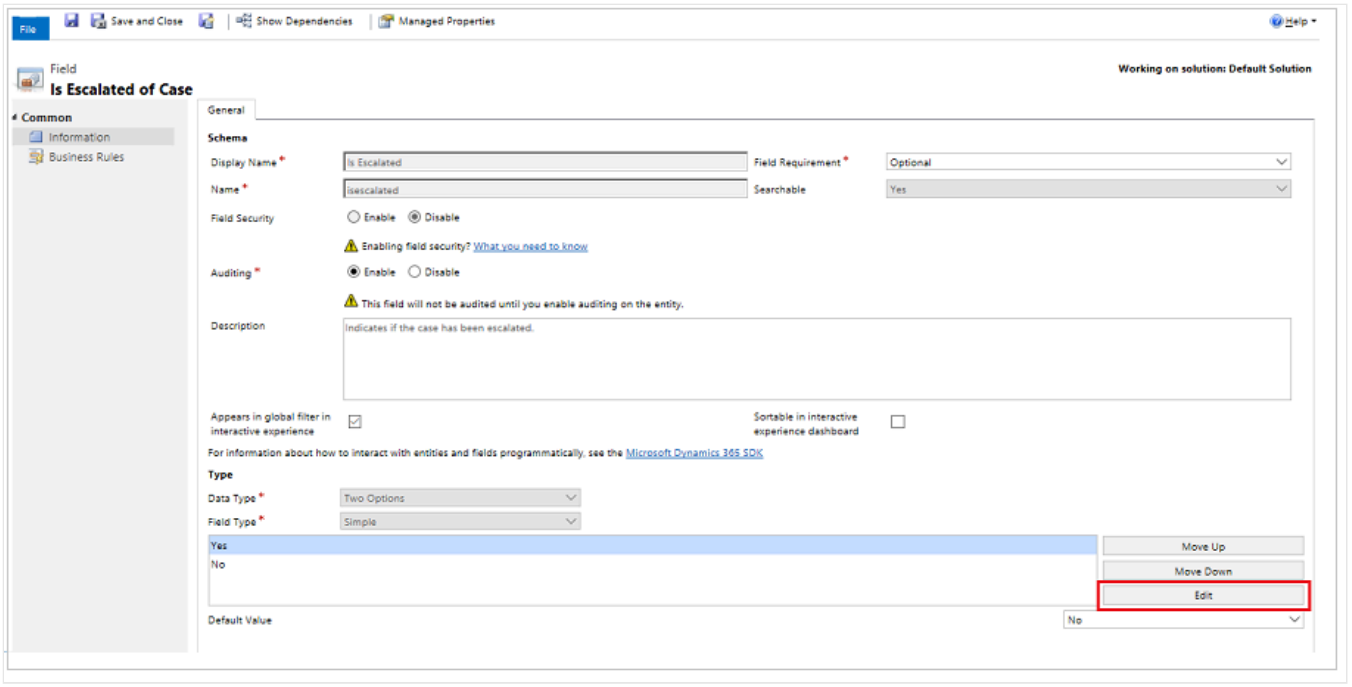
Configure dashboard colors

The color that appears in the charts and streams for specific column values can be configured. For example, high priority cases can be shown in red, medium priority cases in blue, and low priority cases in green in the interactive charts. In the streams, there's a thin vertical line in color next to the work item description.

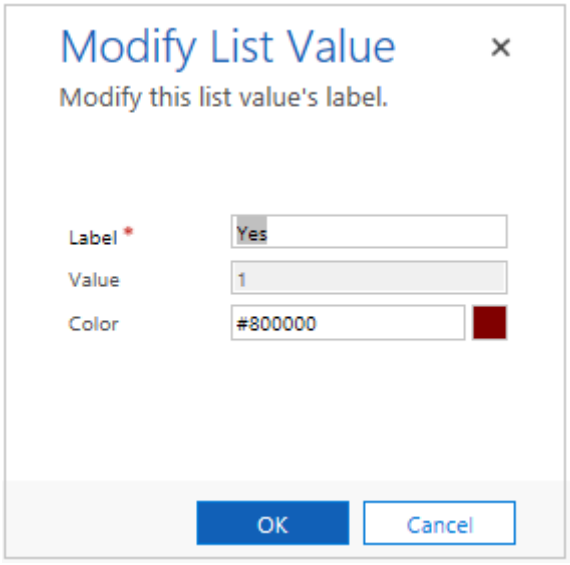
> **Important**
>
> - The color coding isn't available for the tag charts and doughnut charts. These charts appear on the dashboard in white, gray, and black shades.
> - With interactive dashboards, a chart uses the color assigned to the categories that make up the different values, even if the chart is configured to use random colors, when the chart is configured to be grouped by any of the following column types:
>   - Choice
>   - Yes/No
>   - Status Reason
>
> More information: Chart colors aren't correct on dashboards

1. Sign in to Power Apps.
2. Select an environment with an unmanaged solution.
3. On the left navigation pane select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Open the solution you want, and then on the toolbar select **Switch to classic**.
5. Under **Components**, expand **Tables**, and then expand the table required. If the table isn't displayed select **Add Existing** to add it.
6. In the navigation pane, select **Columns**. In the grid, double-click the relevant column.
7. In the **General** tab, in the **Type** subarea, select **Yes** and then select **Edit**.
8. When the **Modify List Value** dialog appears, set the new value in the **Color** text box. Select **OK**.
9. Select **Save and Close**.
10. Select **Publish** for the changes to take effect.

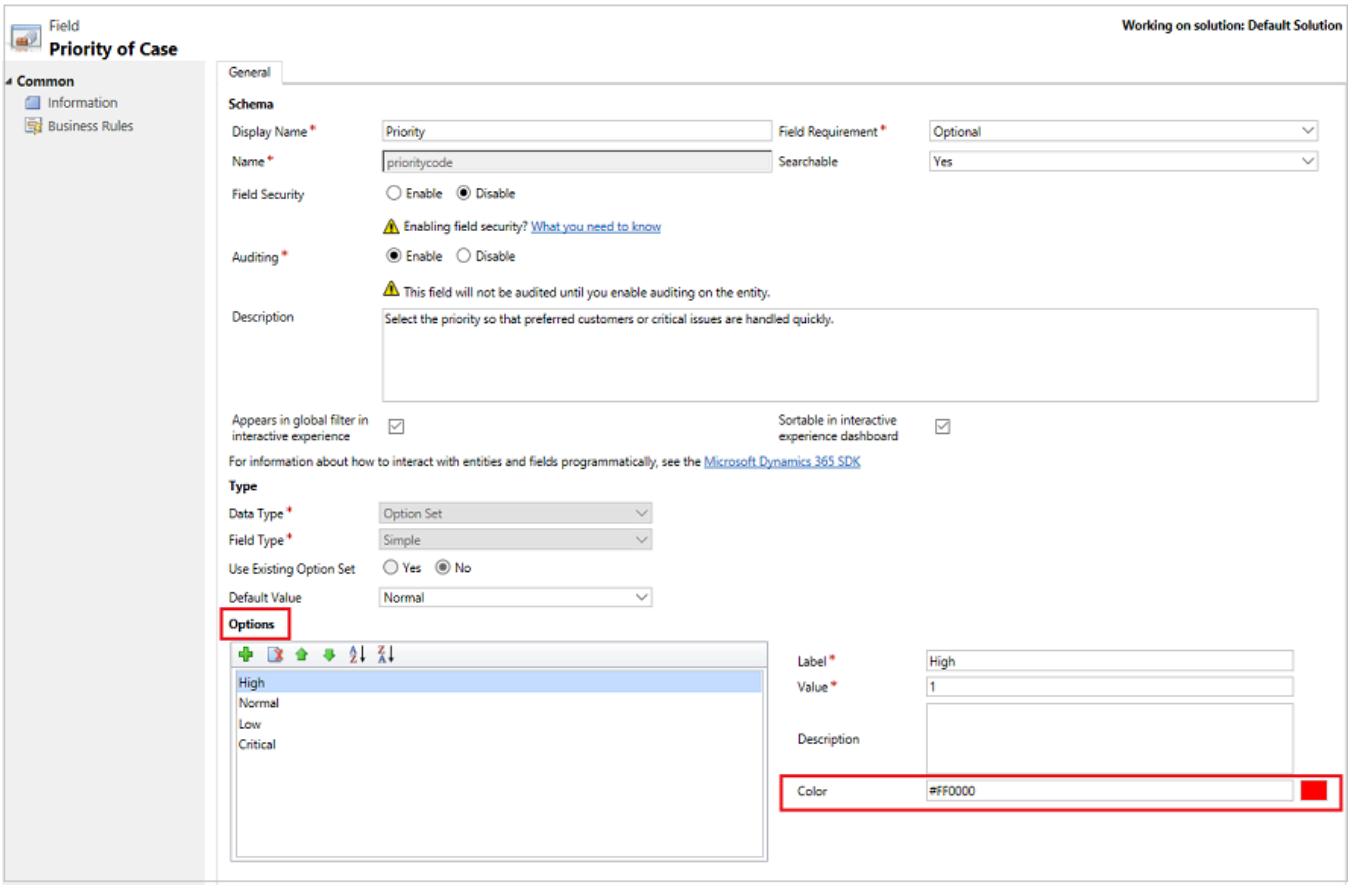
In the following example, the color for the **IsEscalated** column is changed. Use the **Edit** button to open the **Modify List Value** dialog box:



When the **Modify List Value** dialog box opens, enter the hexadecimal color code, such as #800000 shown here:



Similarly, if the **Priority** column is used to modify the colors of the case priority options, choose the color in the **Options** subarea of the **General** tab, as shown here:



Next steps

Set properties for a chart or list

Last updated on 04/03/2026

Set properties for a model-driven app chart or list included in a dashboard

Article • 02/28/2024

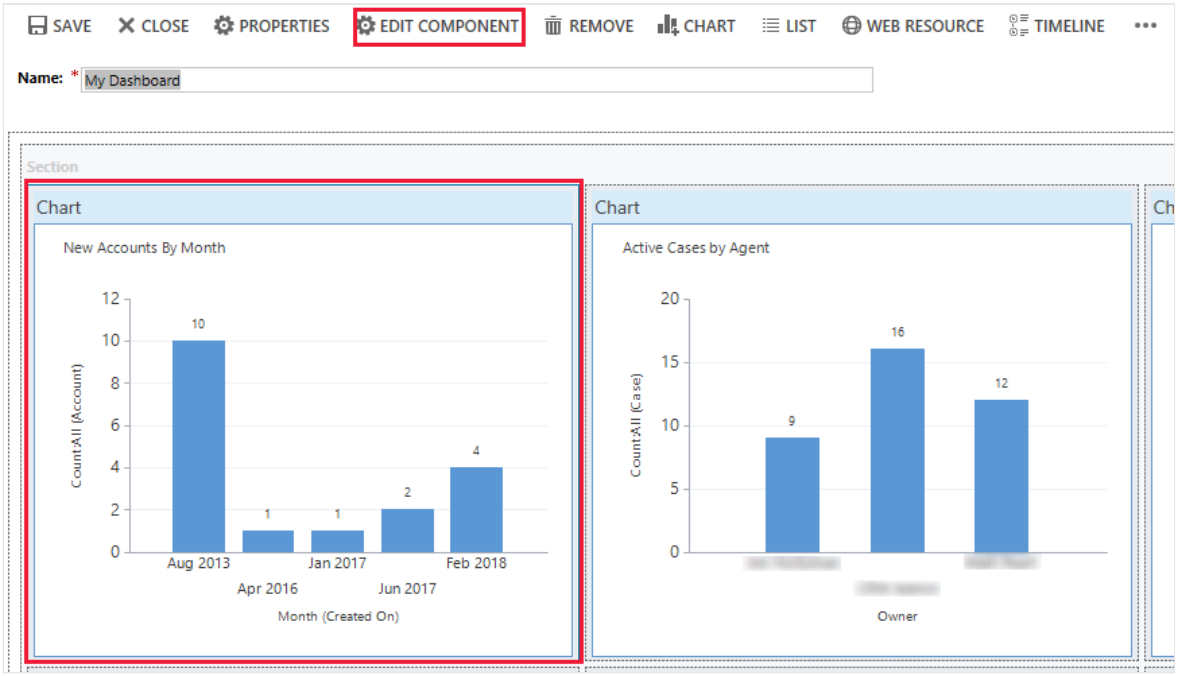
1. Sign in to Power Apps.

2. Select an environment with an unmanaged solution.

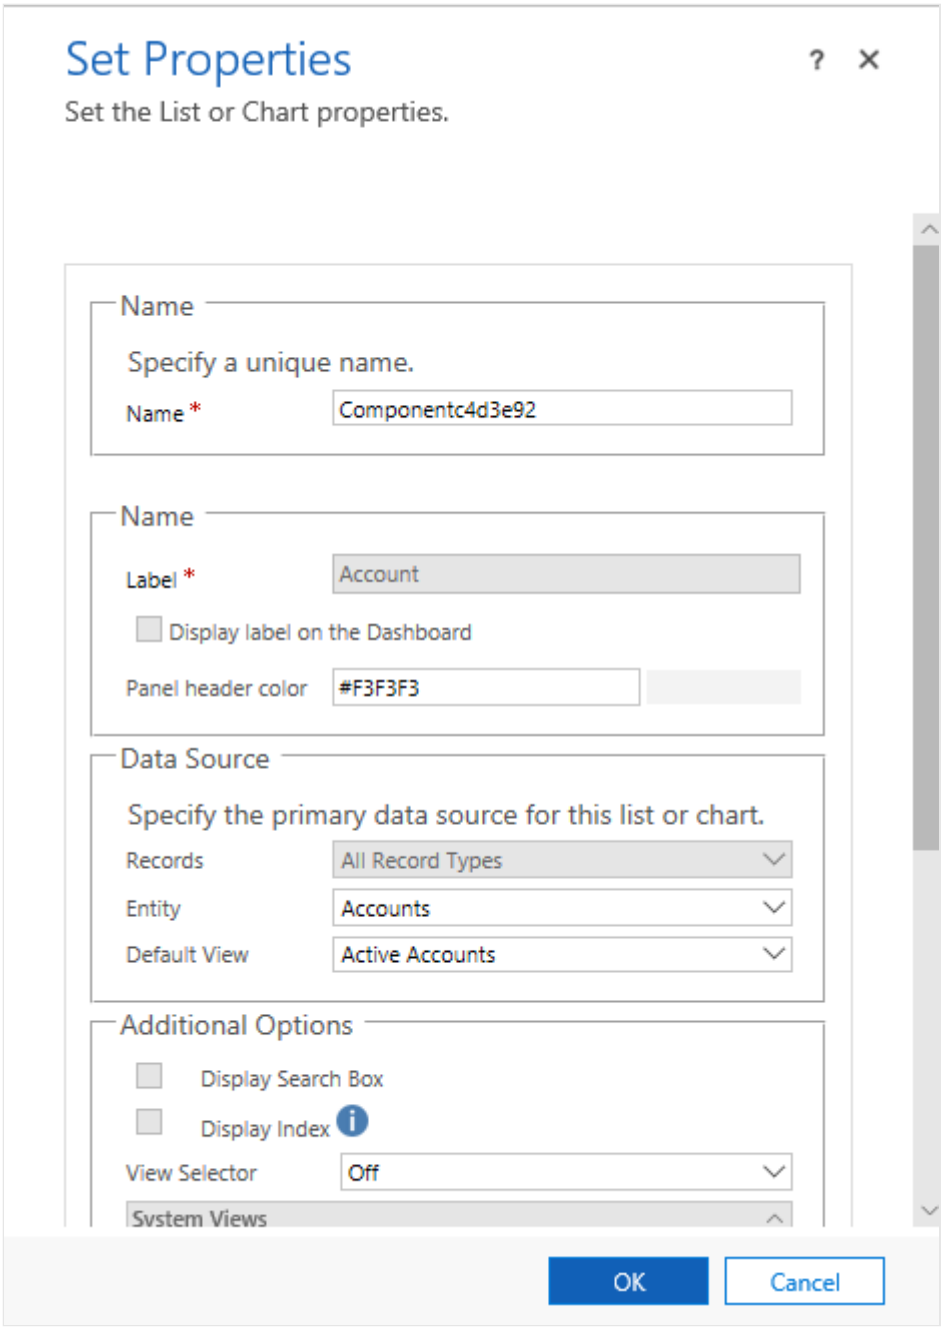
3. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.

4. Open the solution you want, on the tree menu select **Dashboards**, and then select the dashboard you want to update. This opens a new tab in your browser.

5. To edit a chart or list component from the dashboard designer, select the chart or list you want and then select **Edit Component** on the dashboard designer toolbar.



The **Set Properties** dialog opens.



6. You can set the following chart properties from the **Set Properties** dialog:

   - **Name**. Unique name for the chart. The system suggests a value, but you can change it.
   - **Label**. The label that appears at the top of the chart.
   - **Display label on the Dashboard**. Select or clear this check box to display or hide the chart label.
   - **Entity**. Select the table (row type) to base the chart on. This setting determines the available values for the Default View and Default Chart properties.
   - **Default View**. Select the view used to retrieve the data for the chart.

- **Default Chart**. Select the default chart that you want to display when the dashboard is first opened. The available values are determined by the value set for the Table property. This property works together with the Display Chart Selection property. A user can change the chart displayed in the component if the **Display Chart Selection** option is turned on, but the chart will revert to Default Chart the next time the dashboard is opened.

- **Show Chart Only**. Select this check box if you want to display just the chart. Clear this check box if you want to display the chart and its associated data.

- **Display Chart Selection**. Select this check box to enable users to change the chart displayed in the component at runtime. The component reverts to displaying the Default Chart next time the dashboard is opened.

7. You can set the following **list** properties from the **Set Properties** dialog box:

    - **Name**. Unique name for the list. The system suggests a value, but you can change it.

    - **Label**. The label that appears at the top of the list.

    - **Display label on the Dashboard**. Select or clear this check box to display or hide the list label.

    - **Table**. Select the table (row type) to base the list on. This setting determines the available values for the Default View property.

    - **Default View**. Select the view used to retrieve the data in the list. A user can change the view, but the list will revert to Default View the next time the dashboard is opened.

    - **Display Search Box**. Select this check box if you want to display a search box at the top of the list. If the search box is included, you or other users can search for rows in the list at runtime.

    - **Display Index**. Select this check box if you want to display the A to Z filters at the bottom of the list. When the A to Z filters are displayed, you or other users can select a letter to jump to rows that start with that letter.

    - **View Selector**. Select from the following values:

        - **Off**. Don’t display the view selector. You or other users won’t be able to change views at runtime.

- **Show All Views**. Provide a full list of views associated with the value set in the Table property.
- **Show Selected Views**. Select this setting to limit the list of views available at runtime. To select the specific views to be displayed, hold down the Ctrl key and tap or select each view you want to include.

Next steps

Create or customize dashboards

Add a Power BI visual to a model-driven app

Power BI is a powerful analysis and visualization tool. Power Apps is great at enabling people to take action via the web and mobile. With Power Apps, a Power BI dashboard can be embedded in an app. Similarly, a Power BI report tile can be added to an app. The best of both worlds can be achieved at the same place and at the same time.

In this article, you create a simple Power BI report and a model-driven app. Then, you learn how to add the report as a dashboard in the app.

Prerequisites

To complete this tutorial, you need the following:

- Ability to create Power BI dashboards and reports in Power BI.
- Enable the Power BI visualization embedding setting for your environment from the Power Platform admin center. More information: Manage feature settings

Create a workspace, dashboard, and report

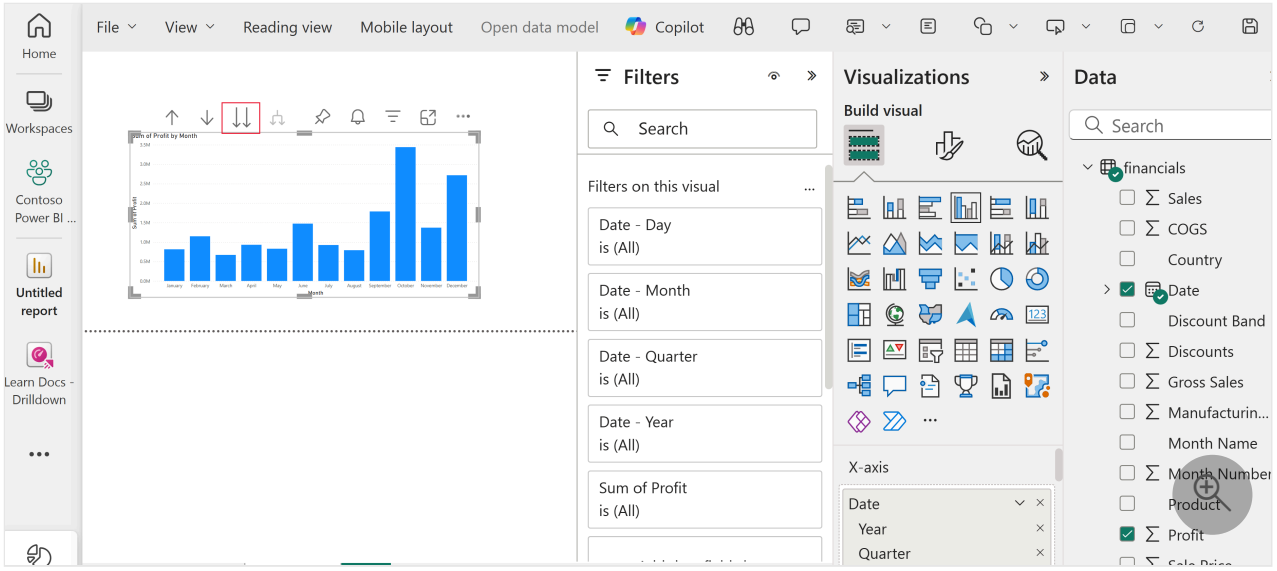
If you don't already have a workspace with a Power BI report, follow these steps to create one. If you already have a workspace, go to Add the dashboard and report to a solution.

1. Download the Excel financial sample Excel workbook.
2. Sign in to Power BI with the same Microsoft Office subscription as the one you use for creating apps in Power Apps.
3. Select **Workspaces** on the left navigation pane, and then select **New workspace**.
4. Enter a name for the workspace, such as *Contoso Power BI workspace*, and then select **Apply**.
5. Select **New item**, select **Dashboard**, enter a **Name**, and then select **Create**.
6. Select Workspaces on the left navigation pane and select the workspace you created. Select **New item** > **Report**.
7. Select **Excel**, select **Upload file**, select **Browse**, locate and select the **Financial Sample.xlsx** file you downloaded previously, and then select **Open**.
8. When the file is uploaded, select **Sign in**, and then select **Next**.

9. Select the **financials** tab, and then select **Create**.

10. Now, build a visual:

    - Expand **financials** in the right-hand **Data** pane, and drag **Profit** to the report canvas.
    - Drag **Date** and drop it on top of the **Profit** chart.
    - Drag an edge of the chart to resize it.
    - Select the chart and then select the forked double arrows to show quarters, and then select them again to show months.



11. Save your report as *Financial Samples*.

Add the dashboard and report to a solution

In this section, you create a solution in Power Apps that includes a Power BI embedded dashboard object.

1. Sign in to Power Apps. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Create a new solution or open an existing unmanaged solution.

3. Open the solution and select **New** > **Dashboard** > **Power BI Embedded**.

4. In the right properties pane, enter or select the following properties:

    - **Display name**: *Test Embedded BI Report*
    - **Type**: **Power BI report**
    - Clear the **Show reports in this environment only** option.
    - **Power BI workspace**: Locate and select the workspace you created earlier, such as **Contoso Power BI workspace**.

- **Power BI Report**: Locate and select the **Financial Sample** report you created for the workspace.

5. Select **Save**.

6. Select **Publish** on the command bar.

Create a model-driven app and add the Power BI report

In this section, you create a model-driven app and add the Power BI embedded report you created earlier.

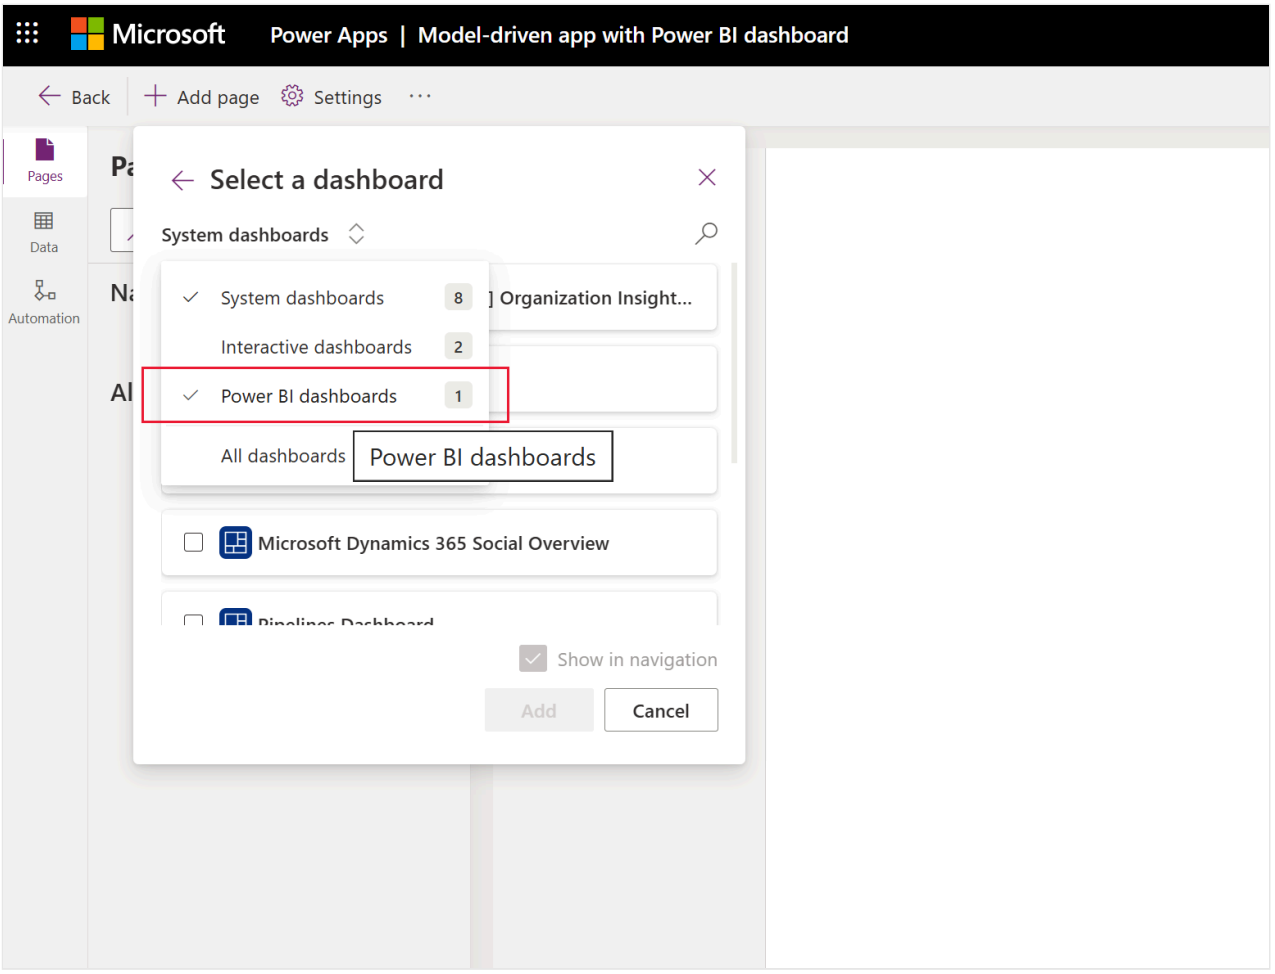
1. Sign in to Power Apps, select the environment you want, and then on the left navigation pane, select **Solutions**.

2. Open the solution you created to add the embedded Power BI dashboard.

3. On the command bar, select **New** > **App** > **Model-driven app**.

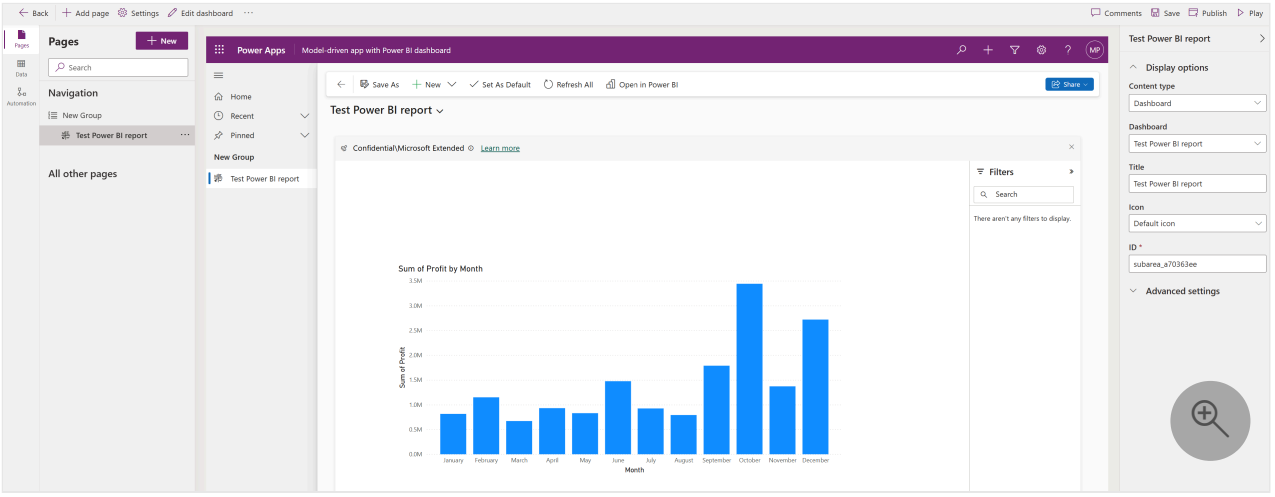
4. Enter a **Name**, such as *Model-driven app with Power BI dashboard*, and then select **Create**.

5. In the app designer on the command bar select **Add page**, select **Dashboard**, and then in the dashboard picker select **Power BI dashboards**.



6. Select the **Test Power BI report** you created earlier, and then select **Add**.

   The report loads in the app designer similar to how it appears to your users when they play the app.



7. Select **Save and publish** to save and publish you app making it available for users.

Model-driven app reporting capabilities and considerations

Article • 12/21/2023

Model-driven apps have many capabilities that allow customers to surface business data that helps them drive decisions and interact with their customers and their data more effectively.

These are described in the reporting overview and include

- Views.
- Charts.
- Dashboards.
- SQL Server Reporting Services reports.
- Microsoft Excel integration that allows users to easily build self-service reports using the Power BI features PowerView, PowerPivot, and PowerQuery.
- Power BI.

As the volume of data held in the app's database continues to grow it becomes more important than ever to think about your BI strategy and determine the most effective mechanisms for reporting and visualizing large datasets.

Reporting infrastructure

In an environment, the reporting infrastructure is shared and separate from the database. In this architecture, although customers share the resources required to run the report, each report runs against the customers' individual database instance.

The reporting capabilities built in to Microsoft Dataverse are designed to let users run reports on datasets that span shorter periods of time. Considering this, note the following fixed settings:

- Reports and queries can execute for up to five minutes. When the maximum period is reached, the report will time out and a message is returned to the user. Within the five-minute duration, reports and queries are allowed to span large datasets that are beyond 50,000 rows, which provide significant flexibility to satisfy most operational reporting needs.

- To improve query response, we recommend that detailed reports minimize the display of large numbers of rows. To do this, apply suitable filtering to reduce the number of rows that are returned. When you create aggregated or summarized

reports, queries should push the aggregation to the query rather than fetch detailed rows to perform aggregation in the report. More information: Aggregate data using FetchXml and report prefiltering.

- The Report Viewer page is subject to the platform API limits. Multiple executions of a long-running report might result in an error, and the user can wait few minutes and try again. This is a per user limit and shouldn't affect the normal usage of reports by multiple users.
- For charts and grids displayed in dashboards, your apps allow users to run queries that have a dataset that has fewer than 50,000 rows. Should a user run a dashboard query that spans a dataset of 50,000 or more rows, the message "The maximum row limit is exceeded. Reduce the number of rows" is returned. The dataset practical setting helps to ensure optimal performance of the app.

Tips and solutions for reporting

Typically, for most organizations' reporting needs, these settings are adequate. To make sure that your users don't exceed these settings and to improve report querying performance in general, consider the following best practices.

- When creating custom reports or dashboards, design them to query smaller datasets over shorter periods of time by adding a time-based filter in the report, such as the current month or quarter, to limit the results.
- Limit the number of tables that are needed to return the result. This helps reduce the time required to run the query and return the result set.
- Reduce the rows in detailed reports. Suitable filtering can be used to reduce the number of rows returned by the query to reduce timeouts.
- For aggregated or summarized reports, queries must be used to push the aggregation to the database and not fetch detailed rows and perform aggregation in the SQL Server Reporting Services report.
- When appropriate for your business, users should run the default (out-of-the-box) reports and dashboards. These reports and dashboards are typically designed to query per user datasets, so in most cases won't exceed the dataset limit.

If users must run reports that exceed these settings, we recommend that you review the following options for assistance with complex reporting needs. Both options effectively offload reporting workloads from Dataverse to another datastore by using a data integration solution.

- Adapters are used in conjunction with SQL Server Integration Services (SSIS) to extend the capabilities for integration with your apps data.
- Extract transform load (ETL) tools provide a new tool set for creating analysis of data by combining multiple data sources or extracting data to the data warehouse solution if SSIS isn't in use. ETL tools provide comprehensive solutions for connecting with Dataverse to move data.

> **Important**
>
> When you use these tools, we recommend that moving or synchronizing data takes place during nonbusiness hours.

If needed, there are many Microsoft partners who can help provide a solution for your specific reporting needs, such as creating an offline copy of the data specifically used for running large reports. These partners are knowledgeable with the data integration tools available. More information: Find a Dynamics 365 partner

Third-party adapters for SSIS

- CozyRoc SSIS+ component for Dynamics 365/CRM
- KingswaySoft SSIS Integration Toolkit for Dynamics 365
- CData SSIS components for Dynamics 365
- Team4 SSIS Connector for Dynamics 365

ETL tools

- TIBCO Dynamics 365 integration

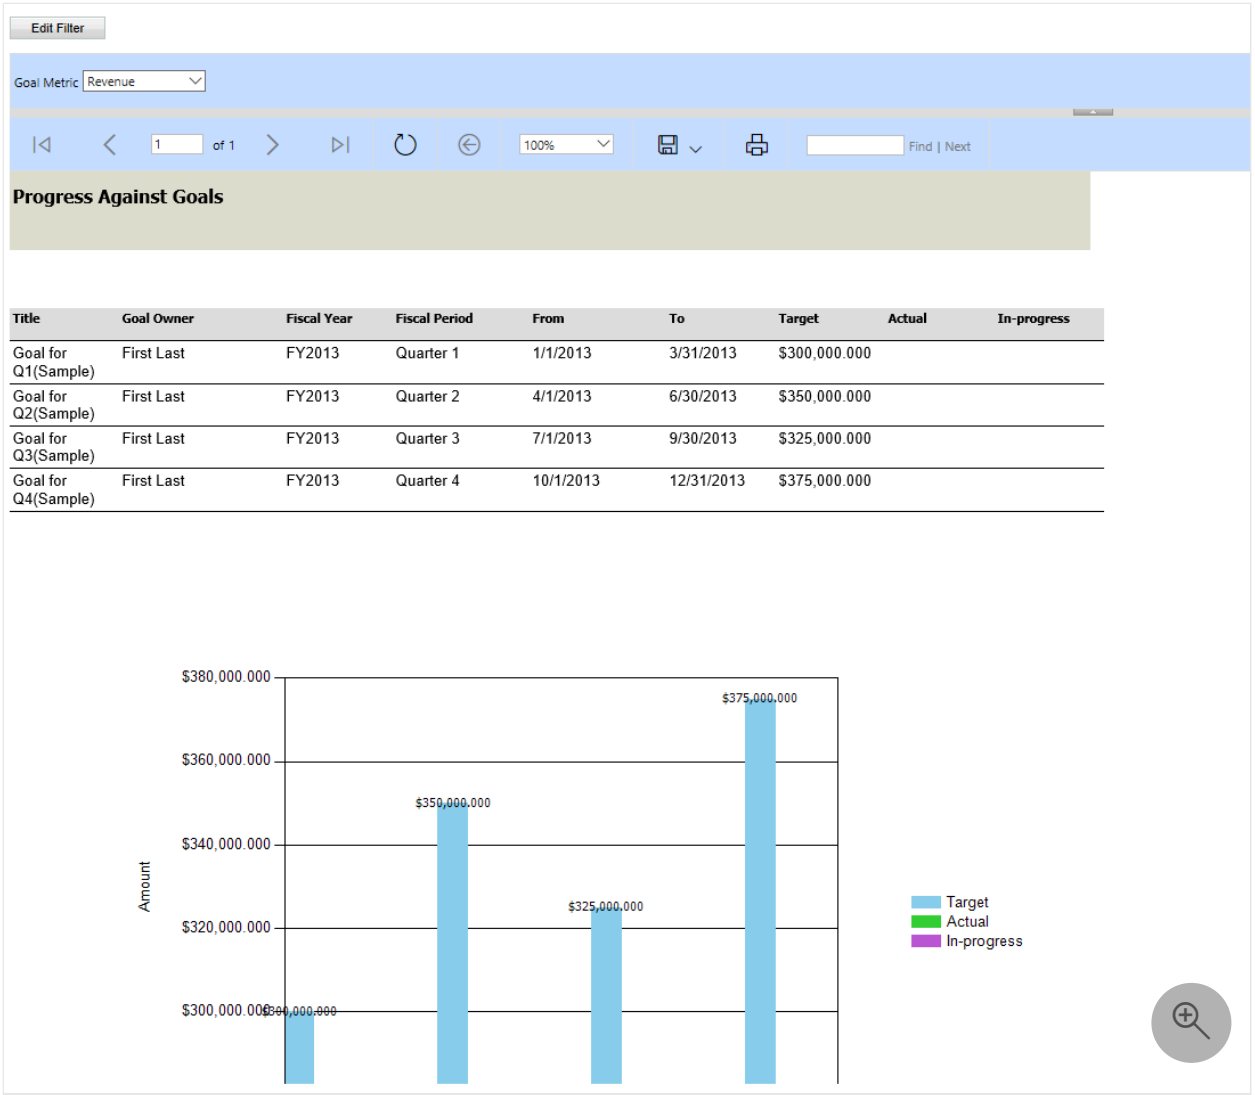
Add reporting features to your model-driven app

Article • 09/18/2024

Power Apps apps can include paginated style reports that provide useful business information to the user. These reports are based on SQL Server Reporting Services and provide the same set of features that are available for typical SQL Server Reporting Services reports.



System reports are available to all users. Individuals who create or otherwise own reports can share them with specific colleagues or teams, or can make the reports available to the organization, so that all users can run them. These reports use FetchXML queries that are proprietary to Microsoft Dataverse and retrieve data to build the report. Reports that you create in a Power Apps app are Fetch-based reports.

> **Note**

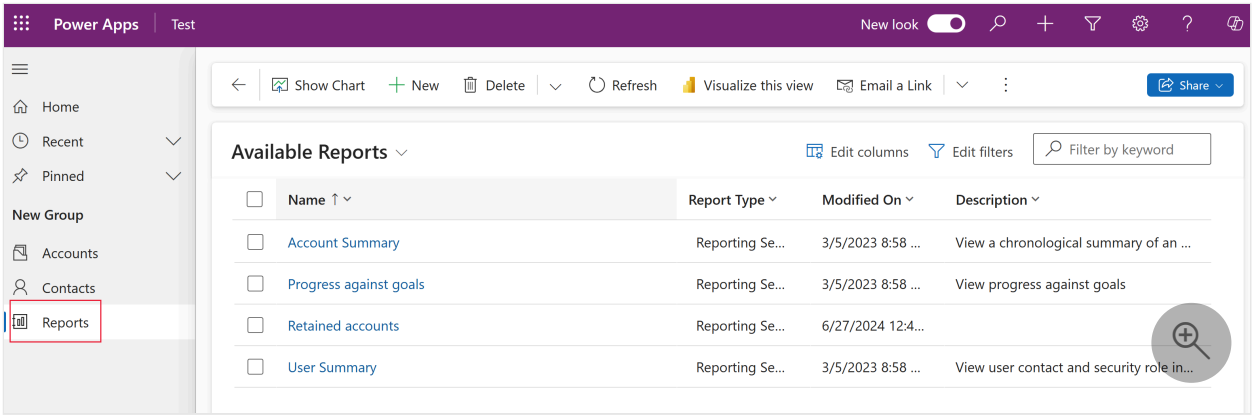
Report features don't work with canvas apps or model-driven apps running on mobile devices, such as tablets and phones.

Add reporting to a model-drive app

You can add fetch-based reporting functionality to your app so that users can run, share, create, and edit reports. To do this, you add the report table to your app.

1. Sign in to Power Apps select **Solutions**, open the solution you want, and then open the model-driven app where you want to add reporting for editing.
2. In the app designer, select **New** > **Dataverse table**.
3. In the **Select a table** list, select the **Report** table, and then select **Add**.
4. Select **Save**, and then select **Publish**.

Now the app displays a **Reports** page where users can view, run, assign, share, and edit the reports they have permission to as well as create new reports using the report wizard.



Options for creating new reports

You can create a new report in one of two ways:

- Use the Report Wizard. Open a model-driven app that is enabled for reporting, select the **Reports** page, and then select **New** to open the Report Wizard to create a new report. The Report Wizard can create table and chart reports, including drill-through reports and top N reports. More information: Create a report using the Report Wizard
- Use the Report Authoring Extension. You can write new or customize existing fetch-based Reporting Services reports with Visual Studio, SQL Server Data Tools, and the Report Authoring Extension. More information: Create a new report using SQL Server Data Tools

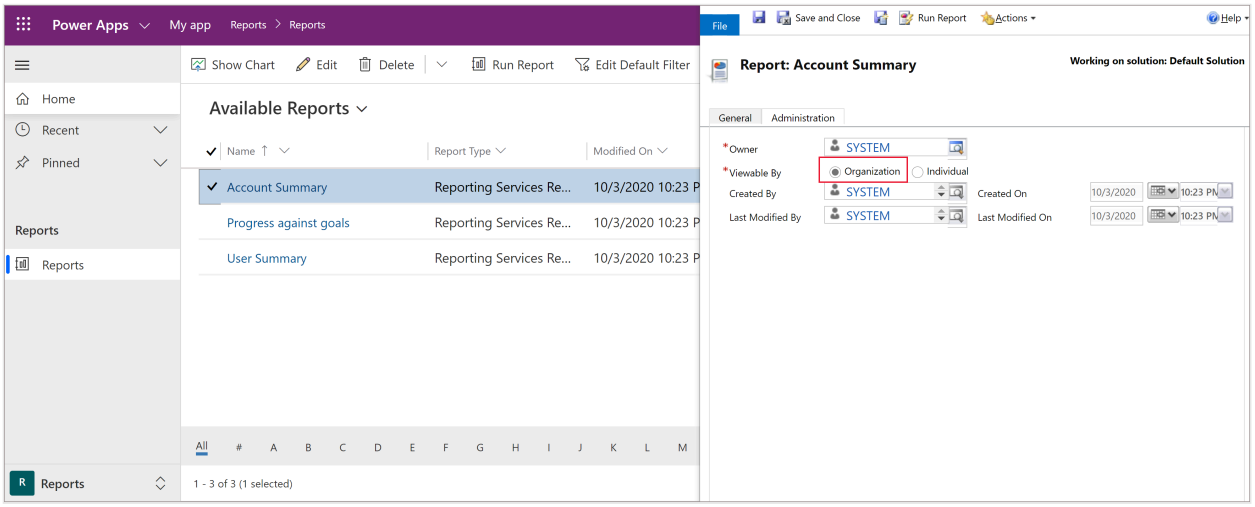
Report visibility

Standard table reports, such as the Accounts Summary report for the account table, are available to all app users. Users who own reports can share them with specific colleagues or teams. System administrators and system customizers can make reports available with organization-wide visibility, so that all users can use them. For information about how to share a report, see Share a report with other users and teams.

Reports in solutions

Reports are solution aware. Adding a report as a component to a solution makes it become a single unit of software that extends Power Apps functionality and the user interface. Only reports that are visible to the organization can be added to solutions.

To find if a report is viewable to the organization: In the list of reports, open a model-driven app, select a report, and then select **Edit**. On the **Administration** tab, determine whether **Viewable By** is set to **Organization**.



You can add, import, or export snapshots of reports as part of a solution. In model-driven apps, reports, sub reports, report category, report display area, and report-related row type are considered as components of a report set. When you import a solution update in non-overwrite mode, any updates by the solution to a report will be ignored if any component of the report set has been customized.

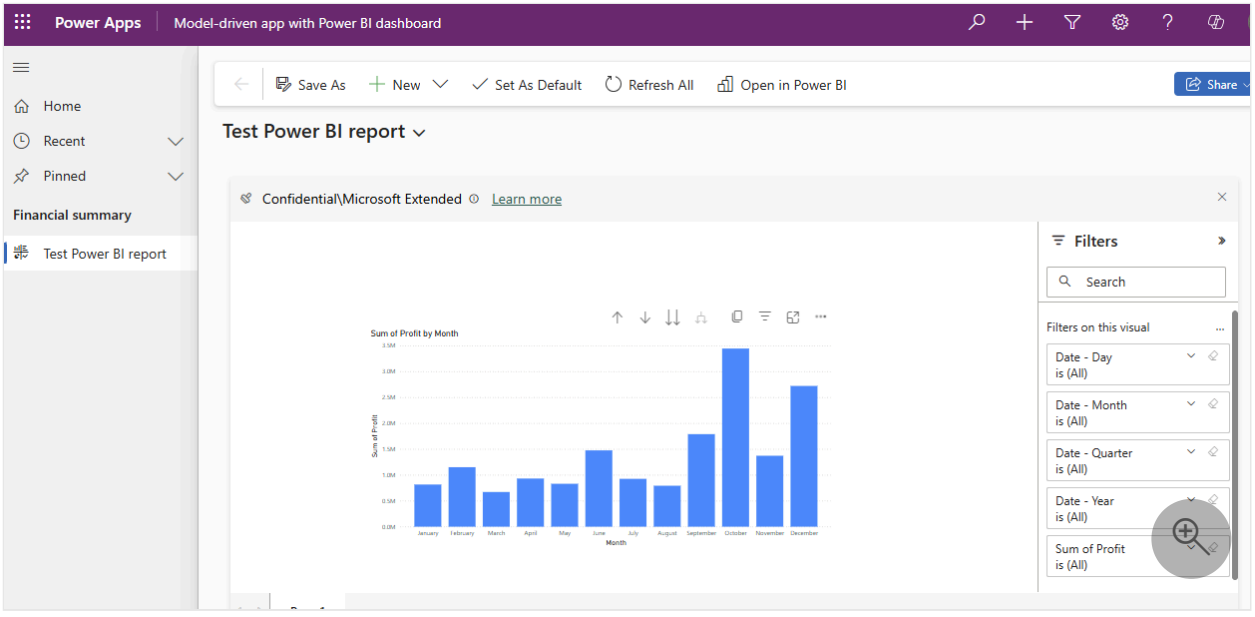
Create or edit a Power BI embedded system dashboard

Article • 02/18/2025

This article explains how to set up and use a system dashboard that references a Power BI report or dashboard in a model-driven app. System administrators and system customizers can create system reports and dashboards, which can be made available to model-driven app users. Users need to have the relevant Power BI license and authorization to consume content.

> **Note**
>
> Power BI embedded in a system dashboard or form ignores the Power Platform admin center **Power BI visualization embedding** environment setting. That setting controls whether end users can add embedded Power BI reports to personal views, charts, and dashboards.



Read more about relevant Power BI licenses at Power BI pricing.

To learn more about Power BI reports and dashboards, go to Create reports and dashboards in Power BI.

Create a system dashboard with Power BI embedded

This procedure shows you how to set up a Power BI embedded page for a single environment connected to a Power BI workspace.

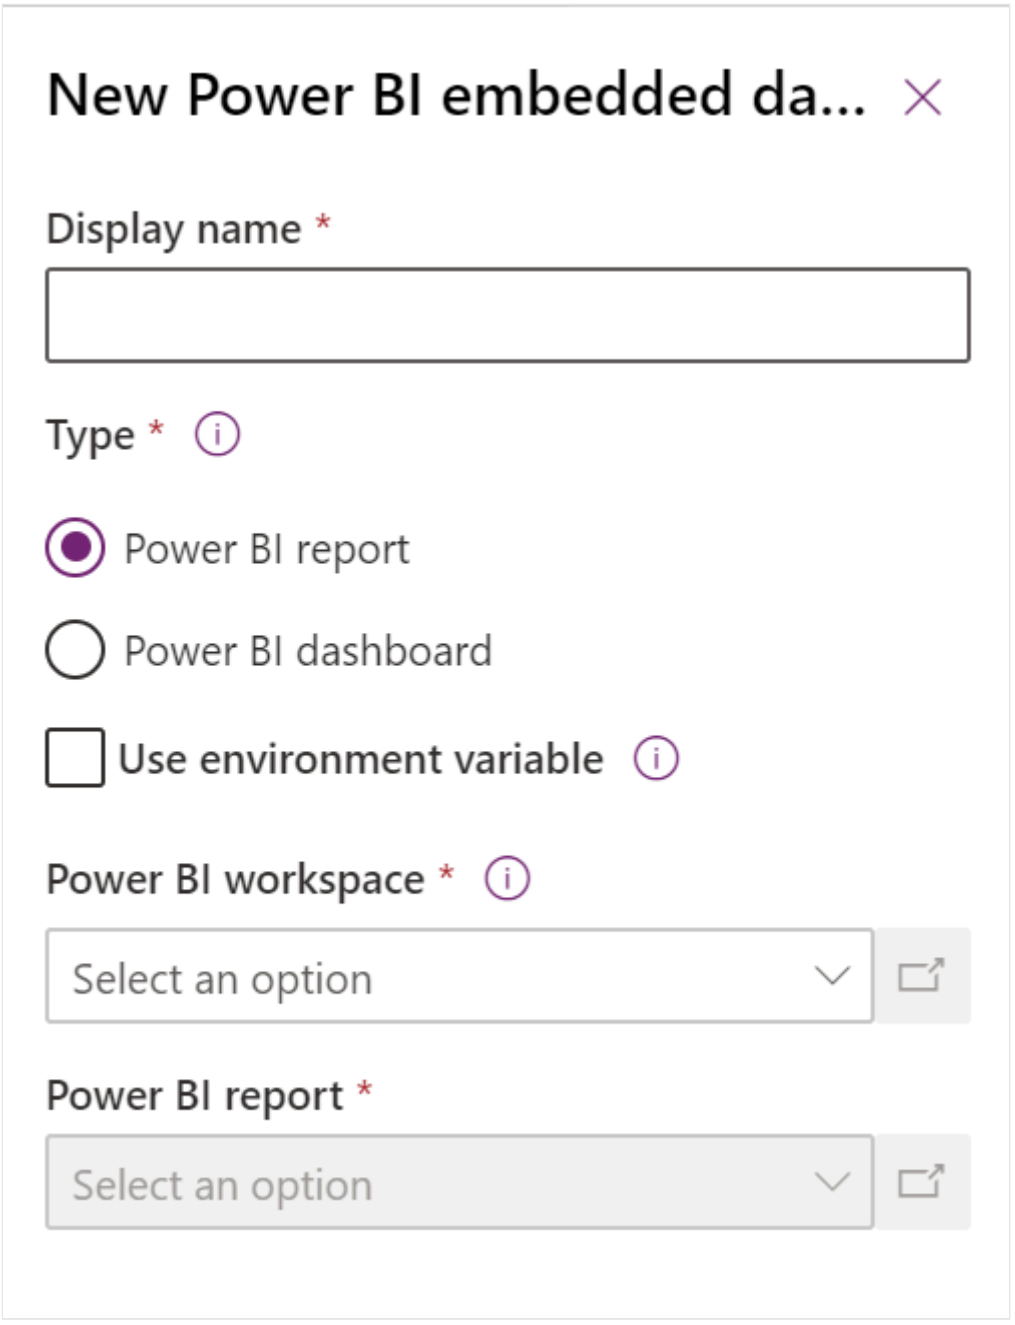
1. Select **Solutions** on the left navigation pane in Power Apps (make.powerapps.com), and then create or open an existing solution. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select **New** > **Dashboards** > **Power BI embedded**.

3. Enter or select the following properties in the **New Power BI embedded** dialog that appears:

    - Enter a **Display name** for the dashboard, which will be shown to the user in the selector on the **Dashboards** page.
    - Select the type, either **Power BI report** or **Power BI dashboard**.
    - If you clear **Show reports in this environment only**, you can select a Power BI report or a Power BI dashboard from another workspace.
    - Select **Use environment variable** if you want to replace a static workspace and report to use an environment variable from configuration. You use this option when you want to move the report to another environment in a solution. More information: Environment variables overview and Create Power BI embedded page with an environment variable
    - Select a **Power BI workspace**.

- Select a Power BI report or dashboard.



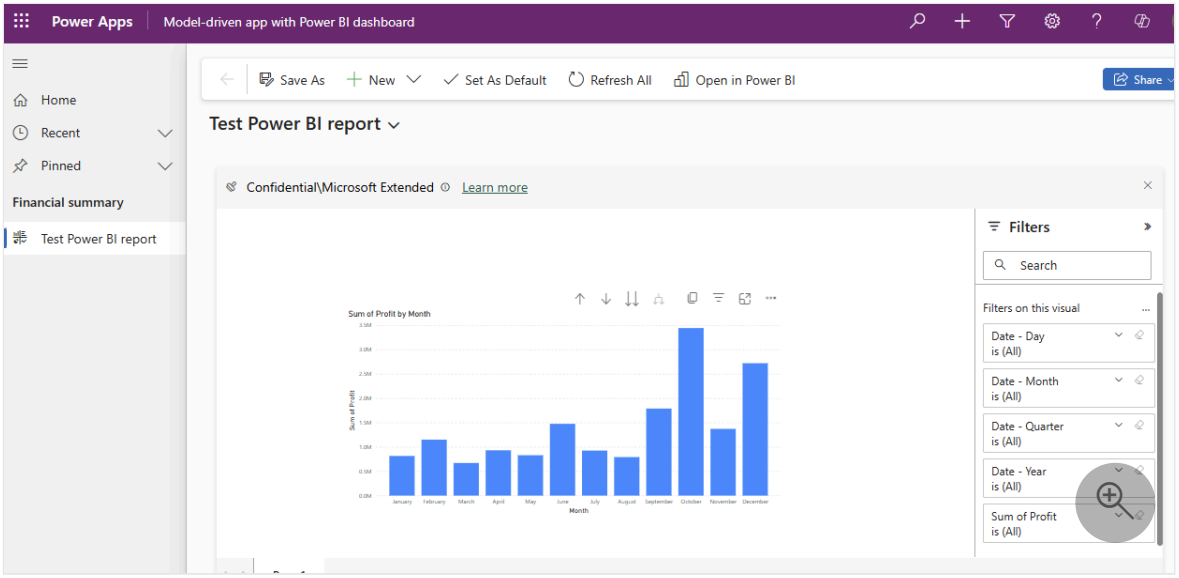
4. Select **Save** to save and publish the system dashboard.

Add a Power BI embedded page to a model-driven app

1. Create or edit an existing model-driven app using the app designer.
2. In the app designer select **Add page** > **Dashboard**.
3. Select the **System dashboards** picker, and then select **Power BI dashboards**.
4. Select the Power BI dashboard you want, and then select **Add**.
5. Select the **Dashboards** subarea on the app designer canvas.
6. Select **Save**. To make your changes available to users, select **Save and Publish**.

Select the Power BI embedded page in the model-driven app

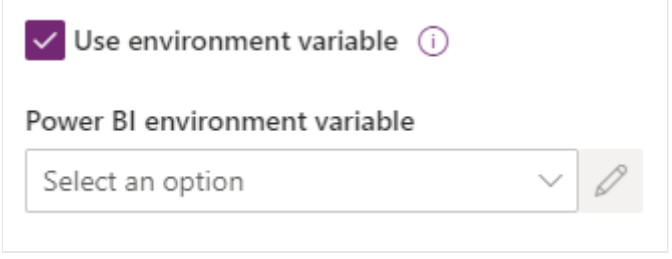
1. Play the model-driven app, and then select a dashboard from the left navigation pane.
2. Select the Power BI embedded page to perform actions, such as expand, copy as image, and filter.



Create Power BI embedded page with an environment variable

When a solution with a Power BI embedded component will be moved to other environments, you can turn on **Use environment variable** to configure the dashboard. For each environment, you specify the workspace and either a dashboard or report to reference. Environment variables allow configuration without unmanaged customizations.

1. When you create or edit an existing Power BI embedded system dashboard in Power Apps (make.powerapps.com), select **Use environment variable**. create-edit-powerbi-embedded



2. Open the **Power BI environment variable** selector and then select **New environment variable**. 

   A nested panel opens where you create the environment variable. The environment variable properties are automatically filled using the dashboard **Display Name** and **Name**.

   You can configure the workspace and report or dashboard. The values are stored as JSON. More information: Environment variables overview

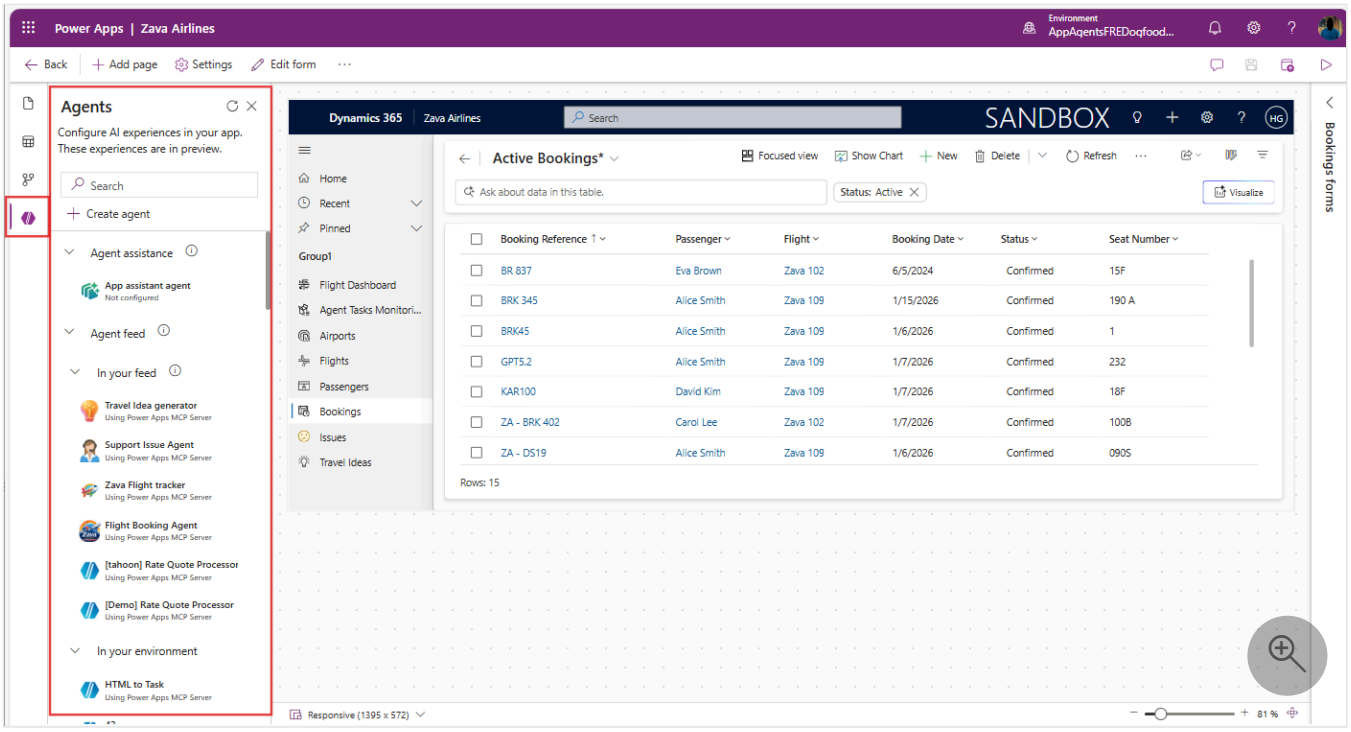
Add agents to your model-driven app (preview)

[This article is prerelease documentation and is subject to change.]

> **ⓘ Important**
>
> Starting May 1st, 2026, agent feed only supports agents that use the Power Apps MCP Server to create tasks. Ensure your agents are properly onboarded to the Power Apps MCP server by then to continue using the agent feed. If your agents don't use the Power Apps MCP Server, the agent feed doesn't appear in you model-driven app. More information: Onboard your agent feed to use the Power Apps MCP server

Model-driven apps support the use of agents to enhance user productivity and automate tasks. There are two types of agents available in model-driven apps:

- *Autonomous agents*, created in Microsoft Copilot Studio, collaborate with users through the new Power Apps model context protocol (MCP) server, allowing agents to generate actionable agent feed tasks for users to review results or step in with inputs to unblock and complete human-in-the-loop flows.
- *App assistant agents*, which can be created to provide custom topics, knowledge sources, and more within the model-driven app.



> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is available only in the English language and it replaces the earlier Microsoft Copilot Studio activity-based agent feed.
> - For information about how AI is used with this feature, go to FAQ about Power Apps MCP server invoke_data_entry tool.

Autonomous agents can be added to model-driven apps to help users get work done faster. Using the Power Apps MCP server, agents can post actionable tasks for user review, allowing humans to validate results, step in when needed, and finish work the agent couldn't complete—without leaving their app.

Learn more about how to supervise agents

> **Note**
>
> Access to the agent feed and supervision capabilities is limited by default to the System Administrator and System Customizer roles. To allow additional users to view the agent

feed, grant organization-level read/write permissions on the entities listed below. You can create a new security role with these permissions and assign it to multiple users as needed.

- Agent Hub Goal(agenthubgoal)
- Agent Hub Insight(agenthubinsight)
- Agent Hub Metric(agenthubmetric)
- Agent Task(agenttask)
- Copilot(bot)

Supervise an autonomous agent within the app

The enhanced agent feed is powered by the autonomous agents using the Power Apps MCP server. Power Apps MCP sever tools enable these two core human-agent collaboration patterns:

- Autonomous Microsoft Dataverse record creation and updates with human-in-the-loop review.
- Agent requests for human assistance and logging tasks for human review.

In agent-enabled apps, user focus shifts from doing the work to supervise and prioritize agent-driven work. Agents help with automation and organization of work, ensuring business experts remain involved in decision-making and critical actions. You can supervise elligible autonomous agents with any model-driven app. We recommend adding agents to apps that contain functionality or data relevant to the agent's intended purpose.

Terminology

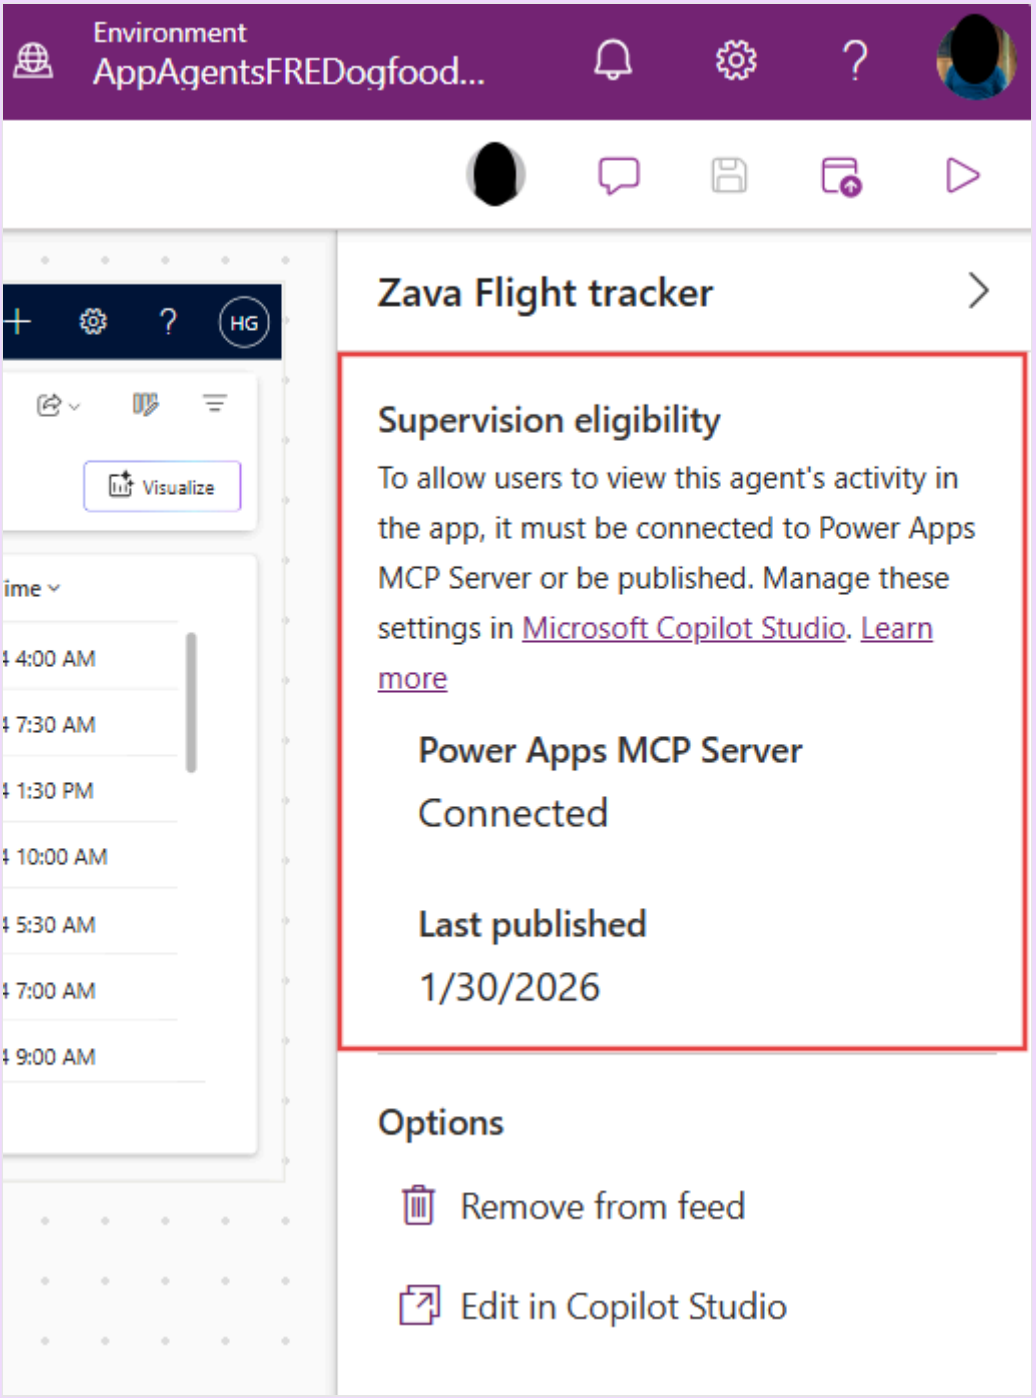
Expand table

Term	Description
Agent	The customer's custom autonomous agent.
Task/Agent task	A single request for human assistance or human review within an agentic workflow.
Agent feed	The system for surfacing agent tasks to the user.
Agent canvas	The UX surface where users provide the requested human input or observe task details.

Term	Description
Power Apps MCP server	The collection of tools available to agents for interacting with capabilities of the business app platform.

> **Note**
>
> To be eligible for addition to an app, an agent must be connected to Power Apps MCP server or be in a published state. A maker can verify an agent's eligibility to be added to an app via the right-hand properties pane where the requirements for an agent to be added to an app are displayed and includes a **Power Apps MCP Server** status as **Connected**. The **Add to feed** button is disabled for any agents that don't meet the

requirements to be eligible for addition.



Create an autonomous agent connected to Power Apps MCP server

MCP is an open protocol that enables seamless integration between large language model (LLM) applications and external data sources and tools. Your agent can use the Power Apps MCP server to communicate with your apps in Power Apps, providing right human-in-the-loop supervision or agentic workflows. To use the Power Apps MCP server, you need to enable and configure the MCP server with an agent. More information: Work with Power Apps MCP server

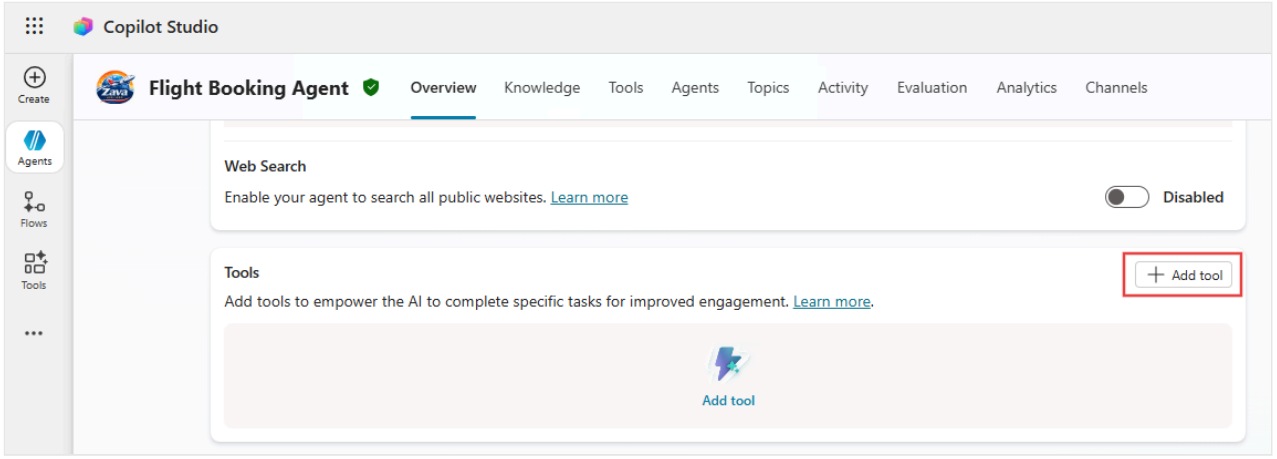
1. Sign in to Power Apps, select **Apps**, and then select **Edit** for the app you want to modify.

2. In the app designer, go to the **Agents** tab on the left navigation pane.

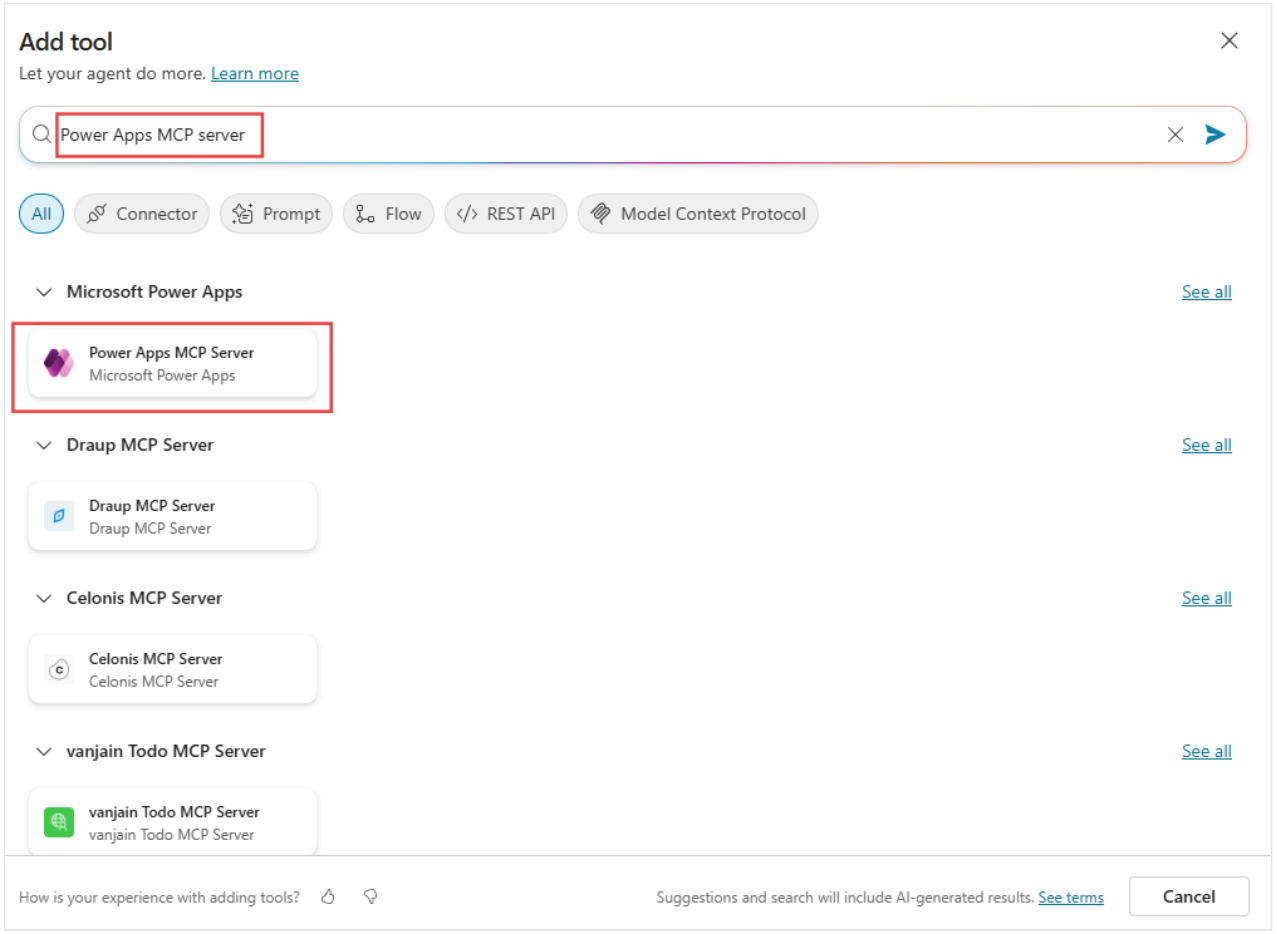
3. Select **Create agent**.

   Microsoft Copilot Studio opens in the new tab.

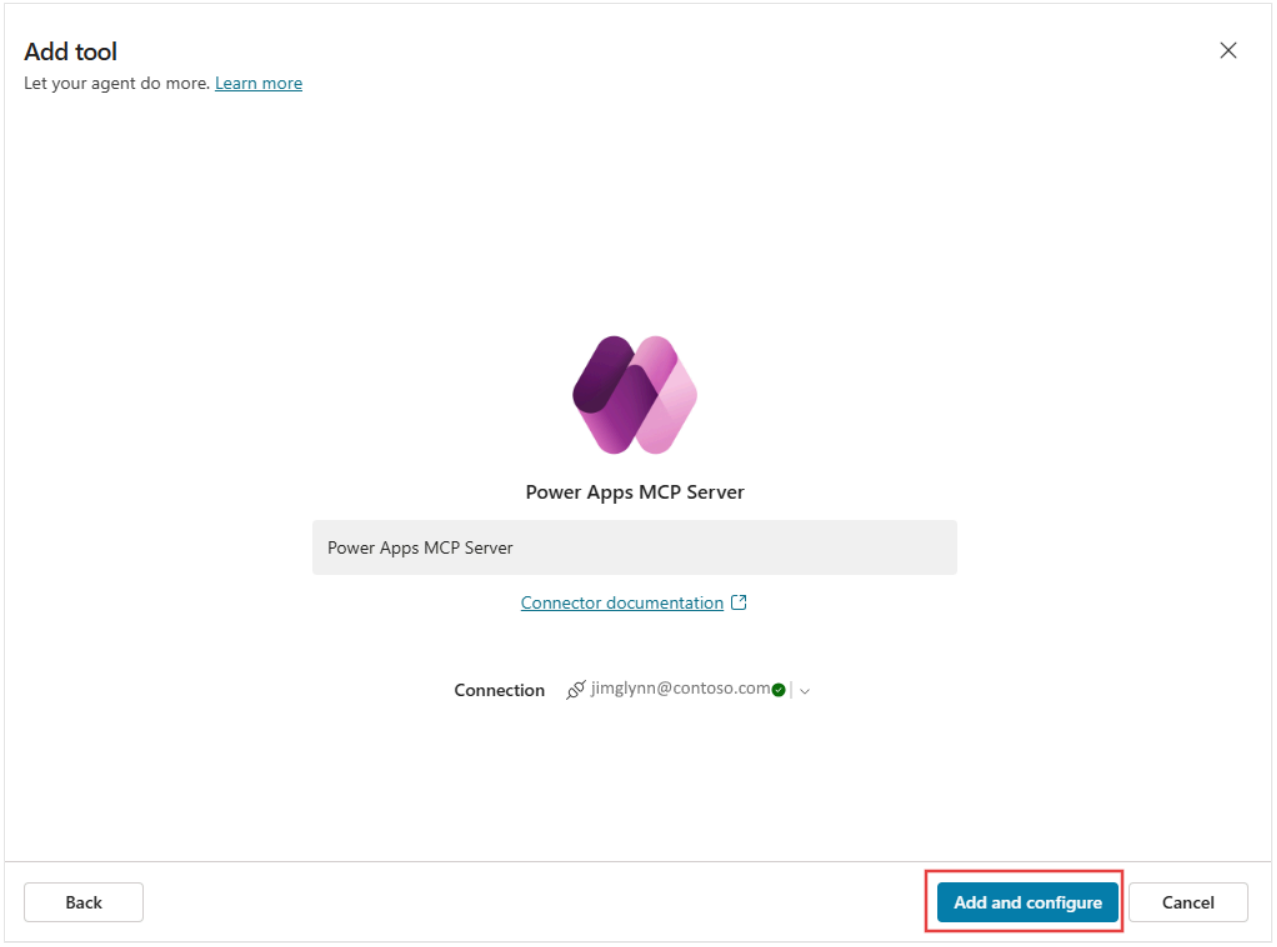
4. Enter the name and description and scroll to tools and select **Add tool**.



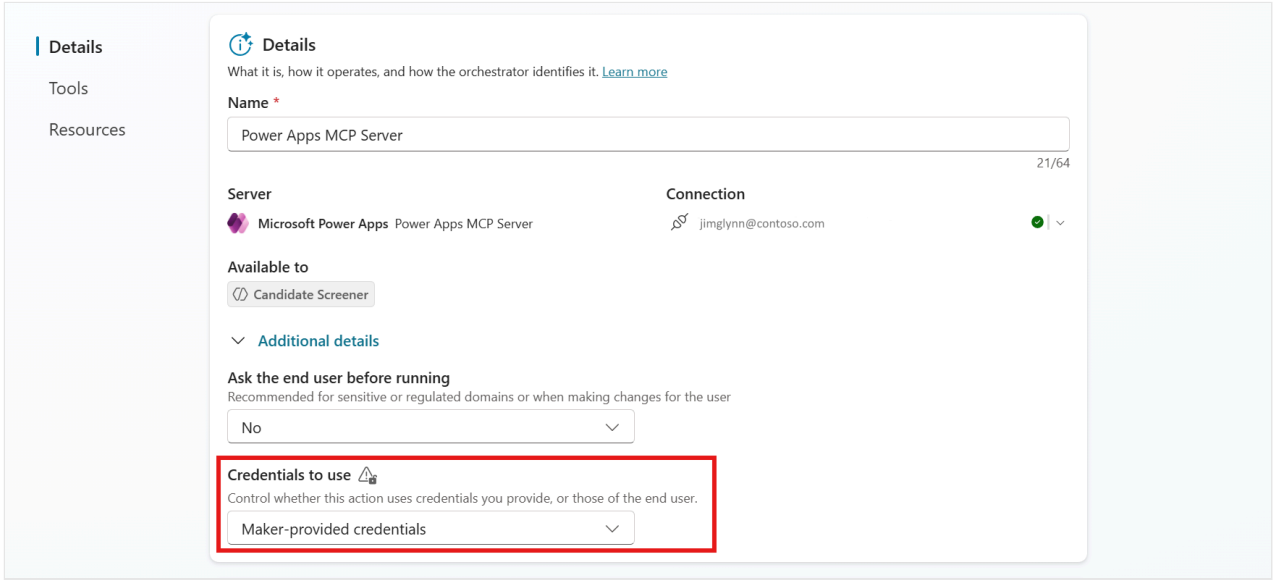
5. Search for **Power Apps MCP Server** and select it.



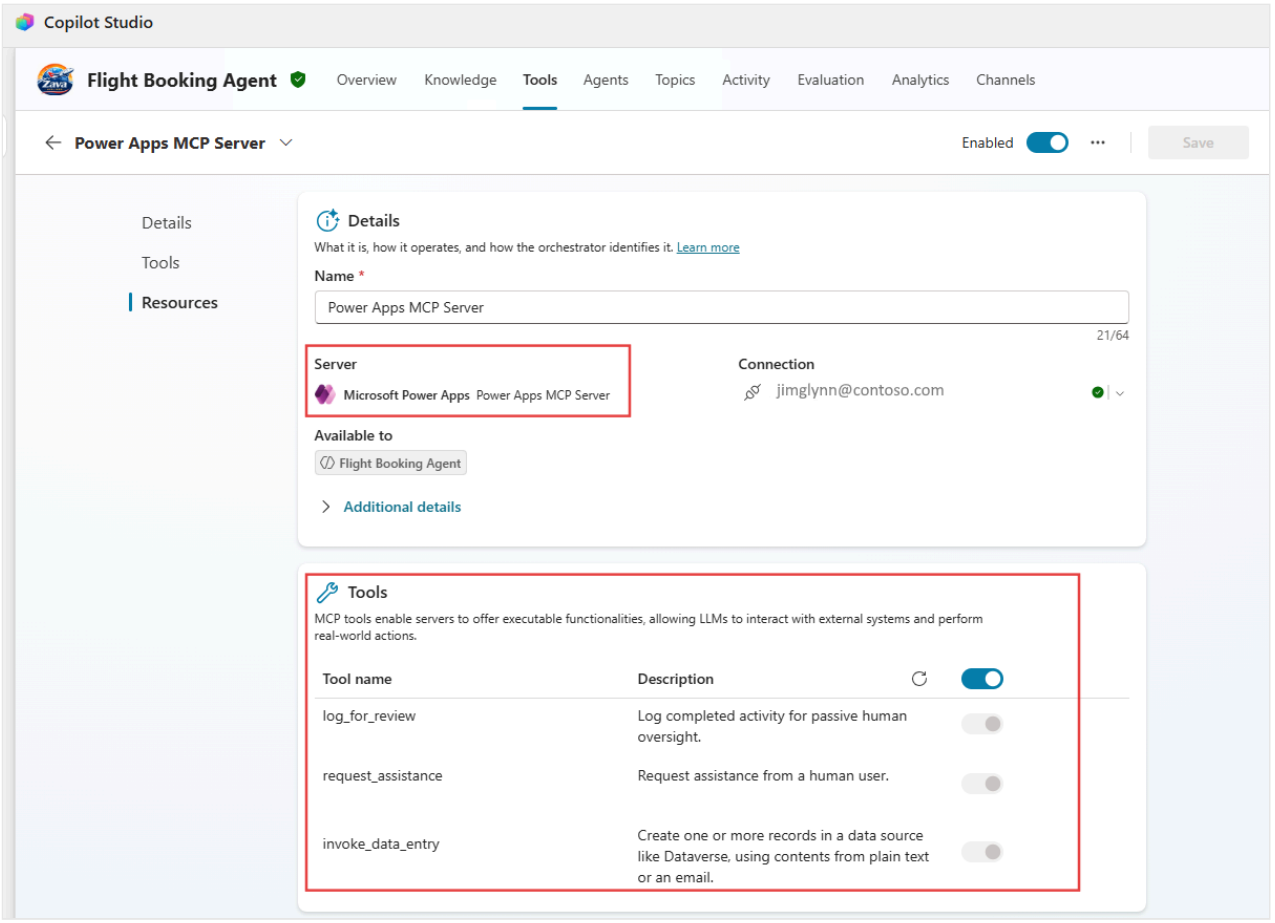
6. Select **Add and configure** to connect the agent to Power Apps MCP tools.



7. In the details section, change the **Credentials to use** field to *Maker-provided credentials* to enable the MCP Server to initialize autonomously via a trigger. Go to Control maker-provided credentials for authentication for more details if this option is disabled.

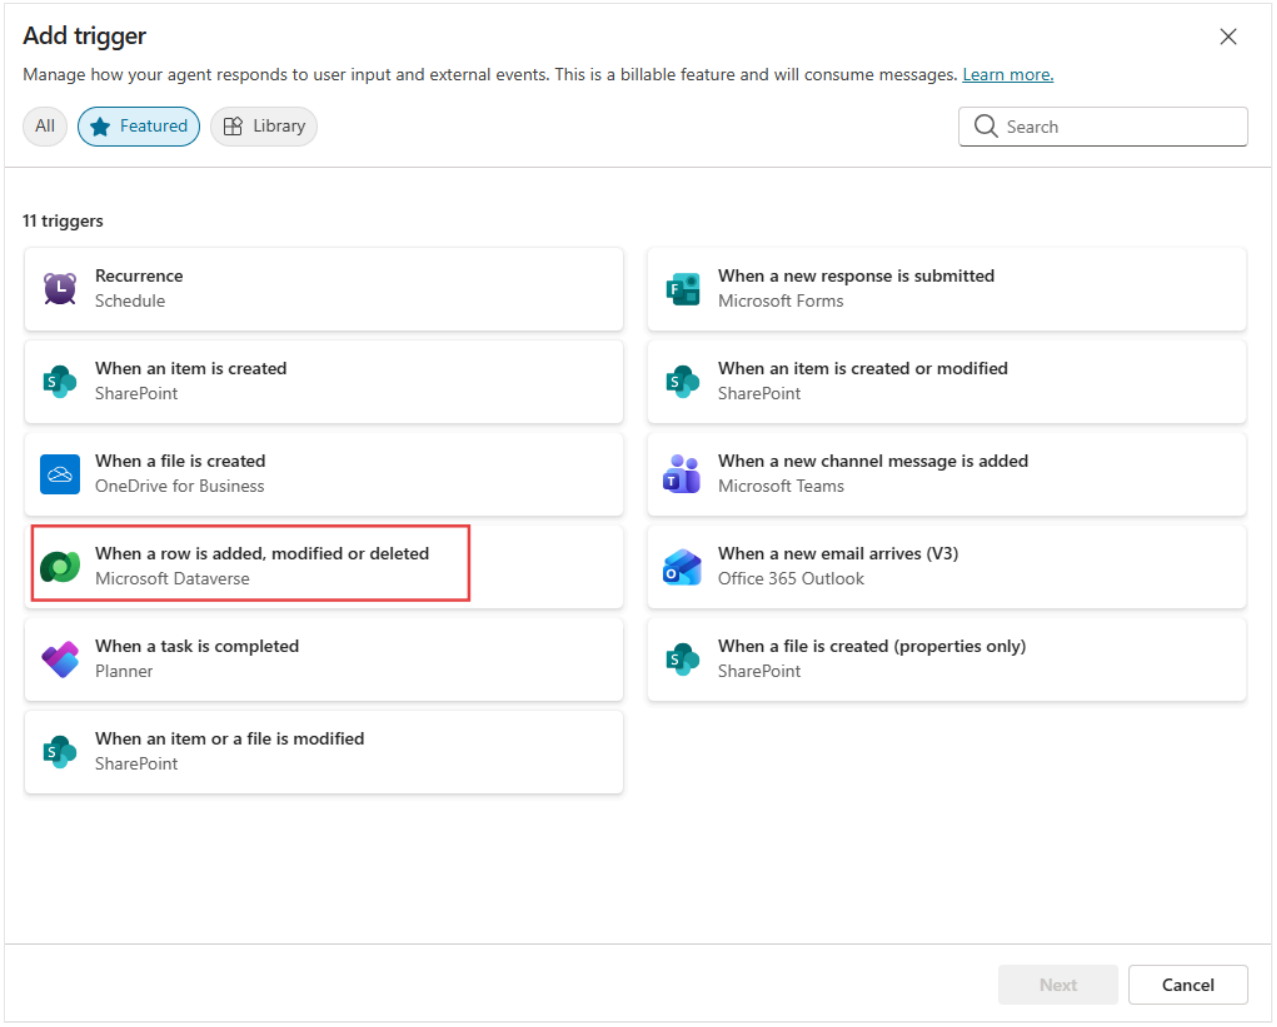


8. Notice the tools available to use with your agent. You can select to enable the tools you want. For information about these tools go to Work with Power Apps MCP server.

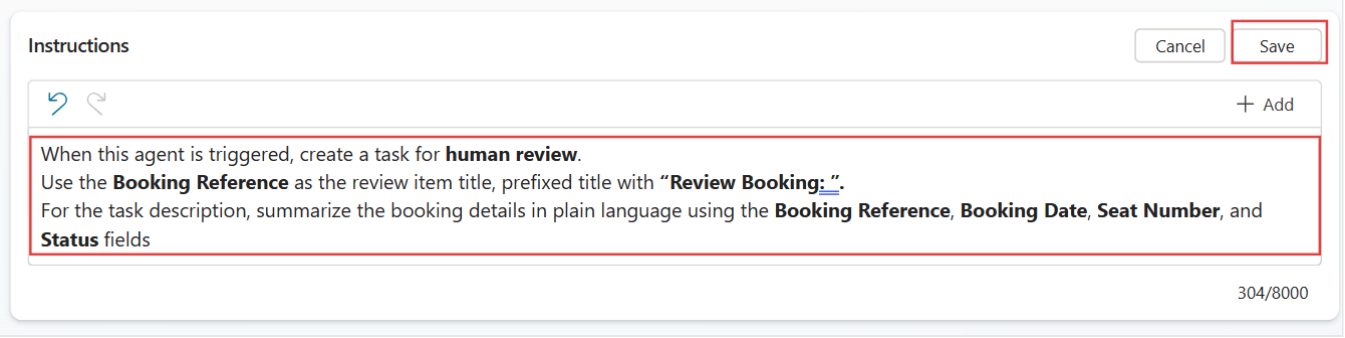


9. Add a trigger for this autonoumous agent so that it is invoked when the trigger is fired. In this example, the trigger **When a row is added, modified, or deleted** is selected for the

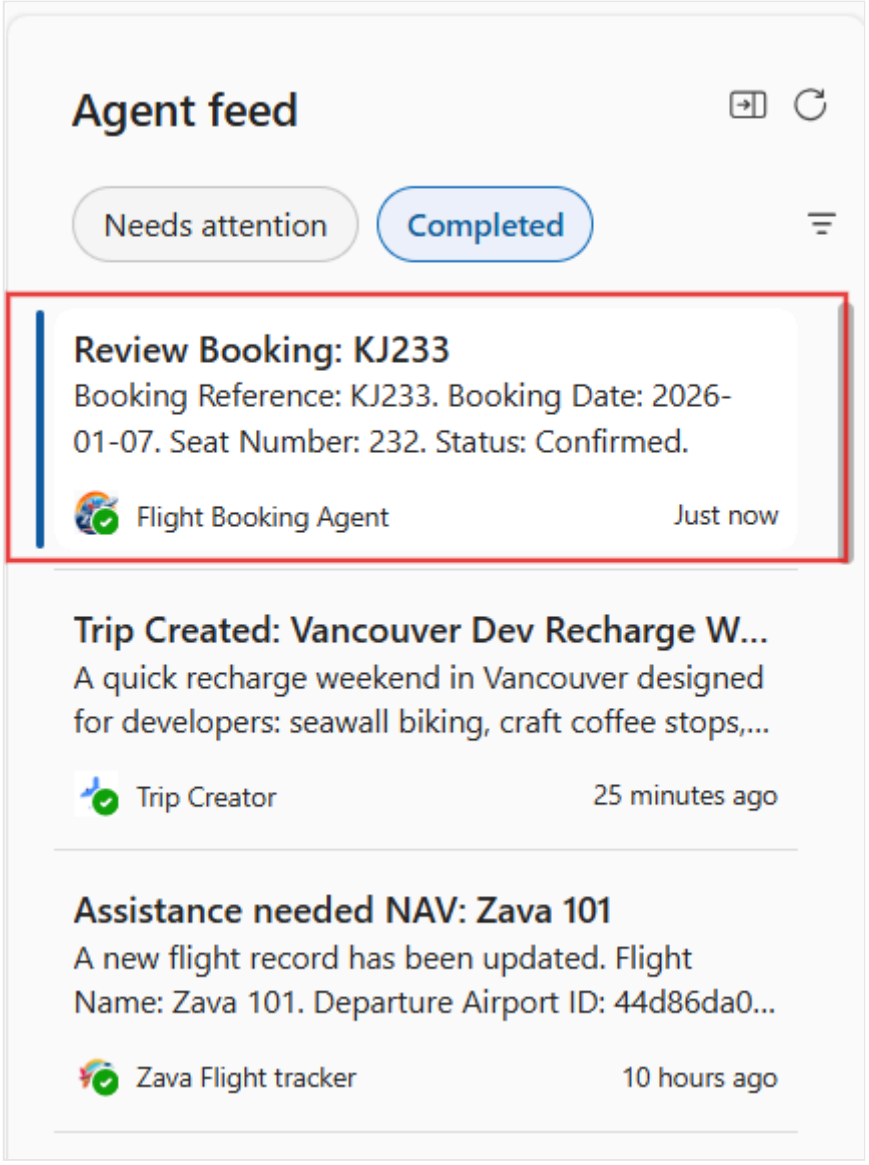
Dataverse **Booking** table.



The agent is ready to use the Power Apps MCP server tools. This image shows how the agent can add a task for human review using natural language instructions. Internally, the task invoked maps to the Power Apps MCP server `log_for_review` tool.



When a new booking record is created, it triggers the agent, which adds the review task in the agent feed **Completed** tab. Note that all tasks created by the `log_for_review` tool are created as "Completed" items intended for passive supervision of agent activity.



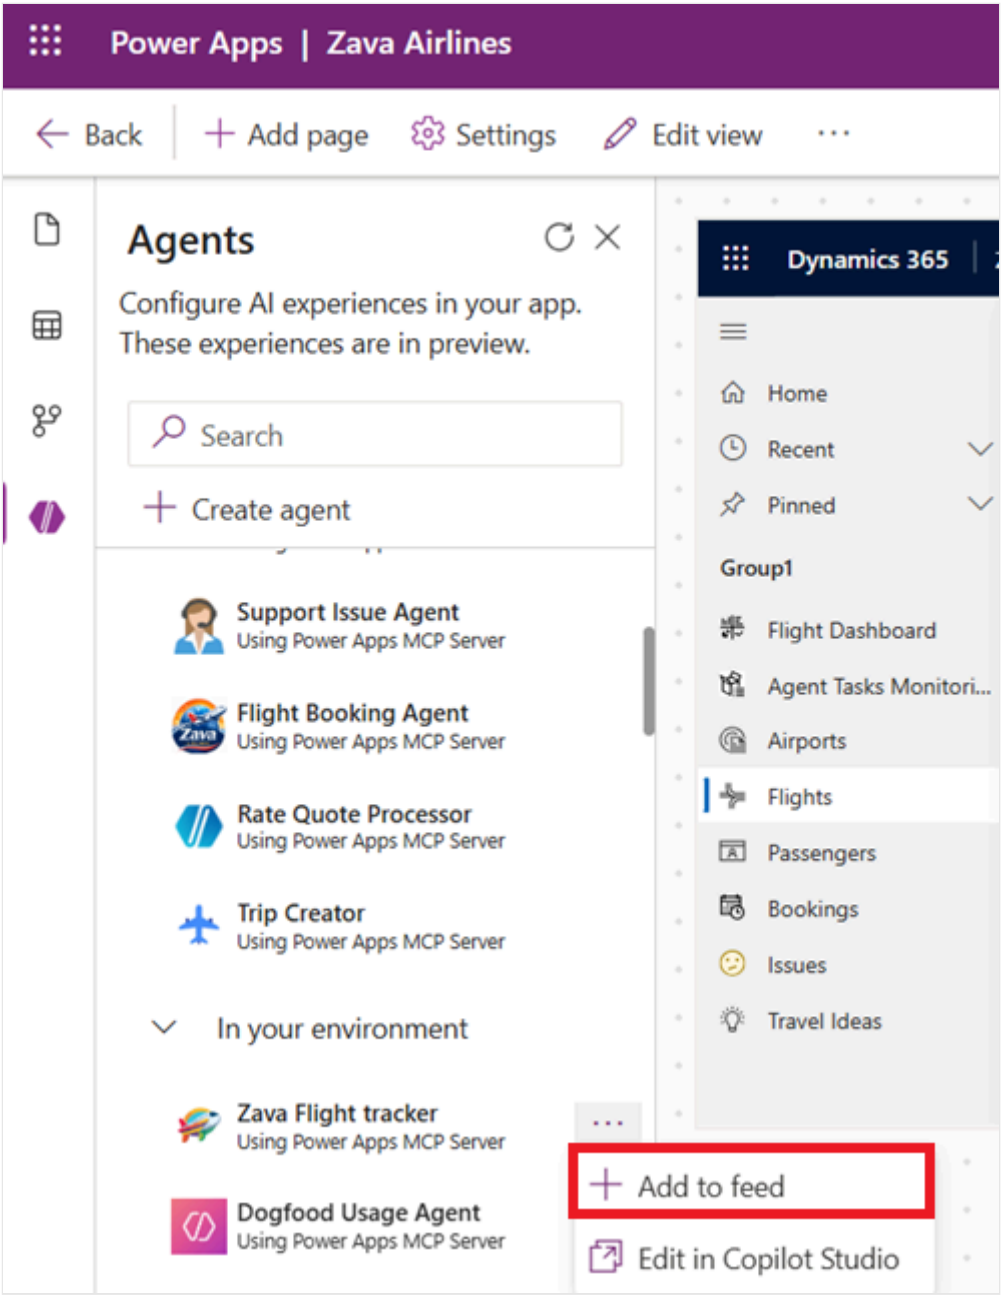
Current limitations

- Only model-driven Power Apps support agent supervision. This feature isn't available for canvas or vibe apps.
- Power Apps MCP server is supported only via Microsoft Copilot Studio.

Add an autonomous agent to an app

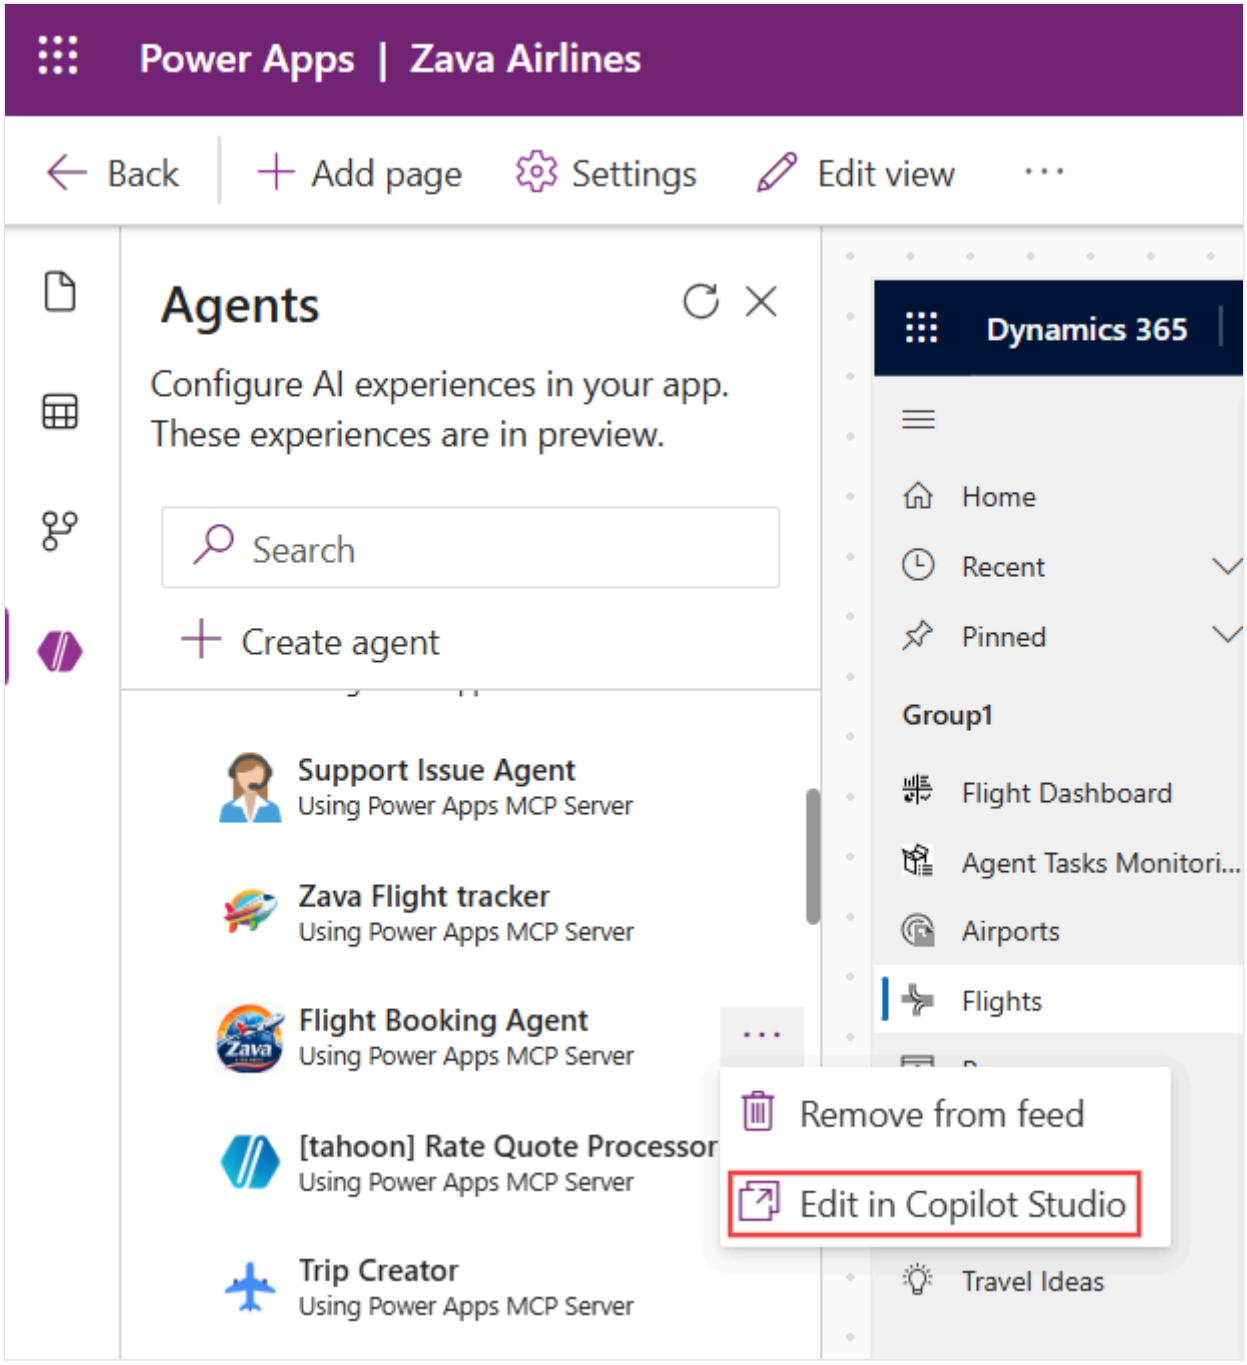
1. Sign in to Power Apps, select **Apps**, and then select **Edit** for the app you want to modify.
2. In the app designer, go to the **Agents** tab.
3. Under the **Agent feed** dropdown, the **In your environment** dropdown appears that lists all agents in your environment. Locate the agent you want to add.

4. Select ... (more options) next to the agent, and then select **Add to feed**.



5. Verify agent feed is added to your app with all added agents by saving, publishing, and playing your app. Previewing agent feed in the app designer isn't currently supported.

6. To view or edit the agent in Copilot Studio, select **Edit in Microsoft Copilot Studio**.



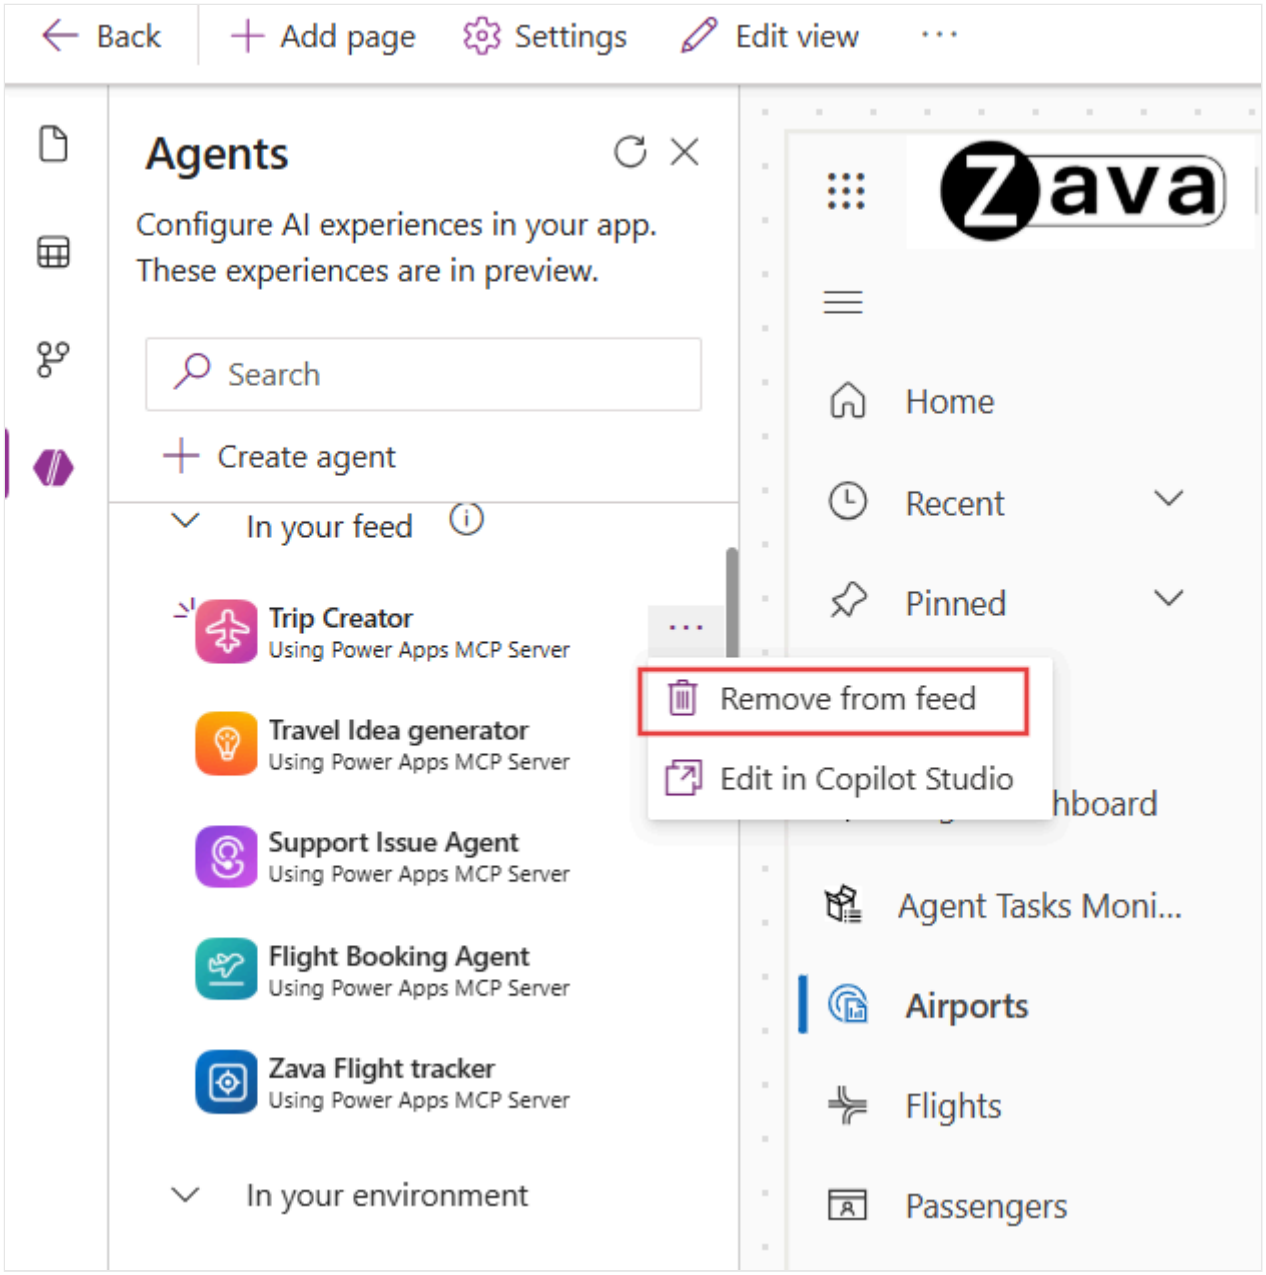
> **Important**
>
> Use the **Create agent** button to open Copilot Studio for agent creation. Note that even if the agent is created through a link inside the app designer, the maker must ensure it meets all requirements to be added to the app.

Remove an autonomous agent from an app

1. In the app designer, go to the **Agents** tab.

2. In the **Agent feed** dropdown, select **In your feed**.

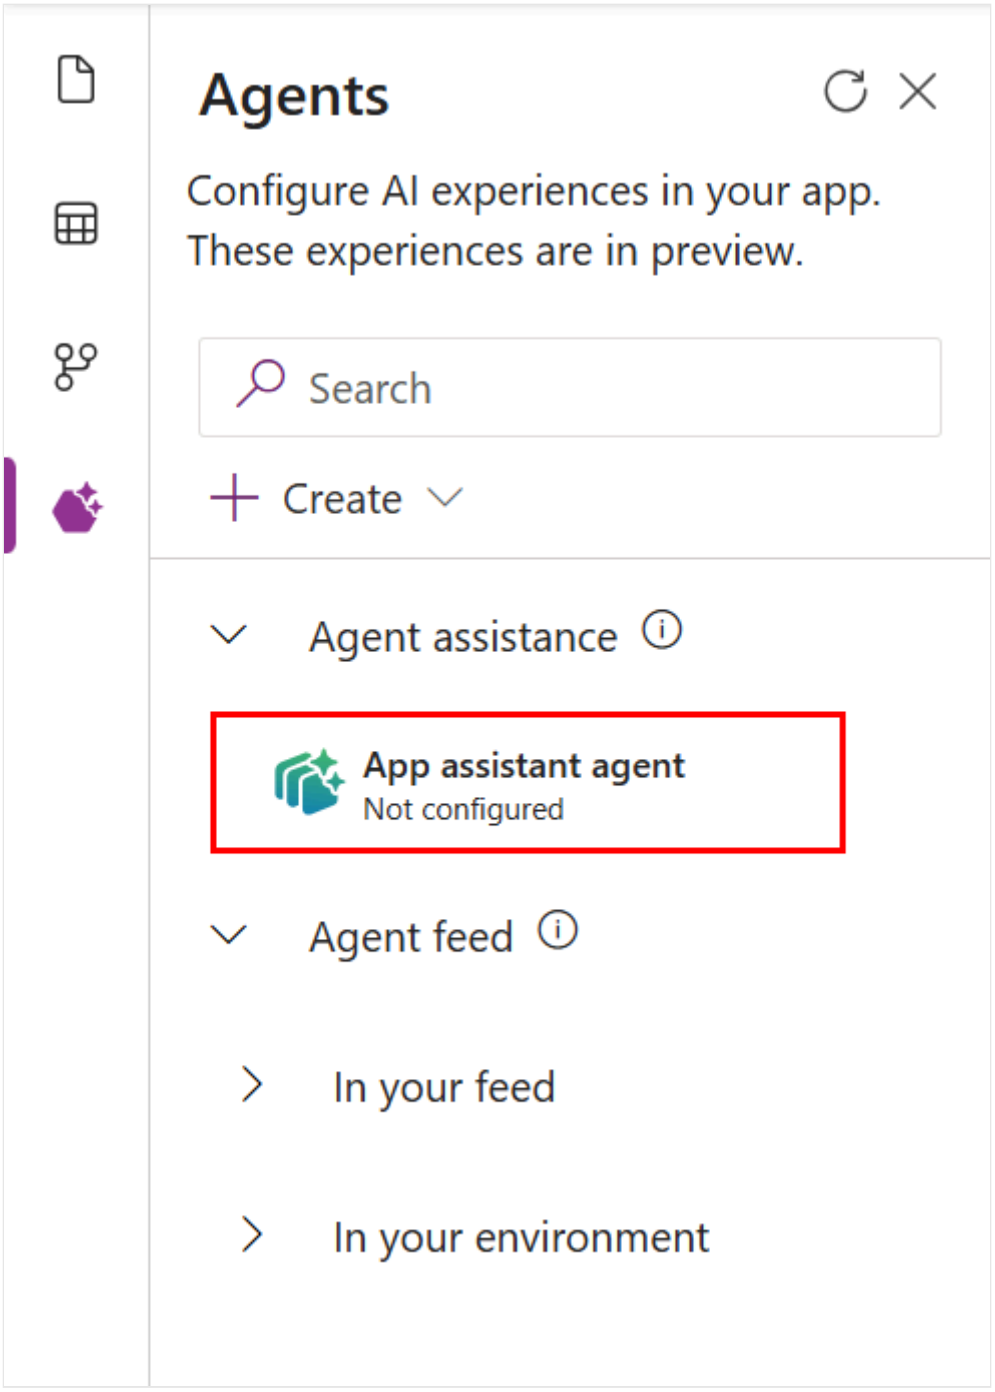
3. Locate the agent you want to remove, select ..., and then select **Remove from feed**.



> **Note**
>
> Removing an agent from an app doesn't remove the agent from the environment.

Working with an app assistant agent

The app assistant agent makes a model-driven app more intelligent and relevant for your organization by adding additional topics, knowledge sources, and more. The Copilot Chat, Agent APIs, and agent response components access the topics within this agent. Learn more: Add app assistant agent



> **Note**
>
> The app assistant agent is a rename of interactive agent, which is the improved experience for **...** > **Configure in Copilot Studio**. The agents created with the previous experiences are now shown as the **App assistant agent**.

Add app assistant agent

Last updated on 04/06/2026

Work with Power Apps MCP server

> **ⓘ Important**
>
> Starting May 1st, 2026, agent feed only supports agents that use the Power Apps MCP Server to create tasks. Ensure your agents are properly onboarded to the Power Apps MCP server by then to continue using the agent feed. If your agents don't use the Power Apps MCP Server, the agent feed doesn't appear in you model-driven app. More information: Onboard your agent feed to use the Power Apps MCP server

The model context protocol (MCP) is an open protocol that enables seamless integration between large language model (LLM) applications and external data sources and tools. Your agent can use the Power Apps MCP Server to communicate with your Power Apps, providing right human-in-the-loop supervision or agentic workflows.

> **ⓘ Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is available only in the English language and it replaces the earlier Microsoft Copilot Studio activity-based agent feed.
> - For information about how AI is used with this feature, go to FAQ about Power Apps MCP Server invoke_data_entry tool.

The Power Apps MCP Server equips your agent with two types of capabilities:

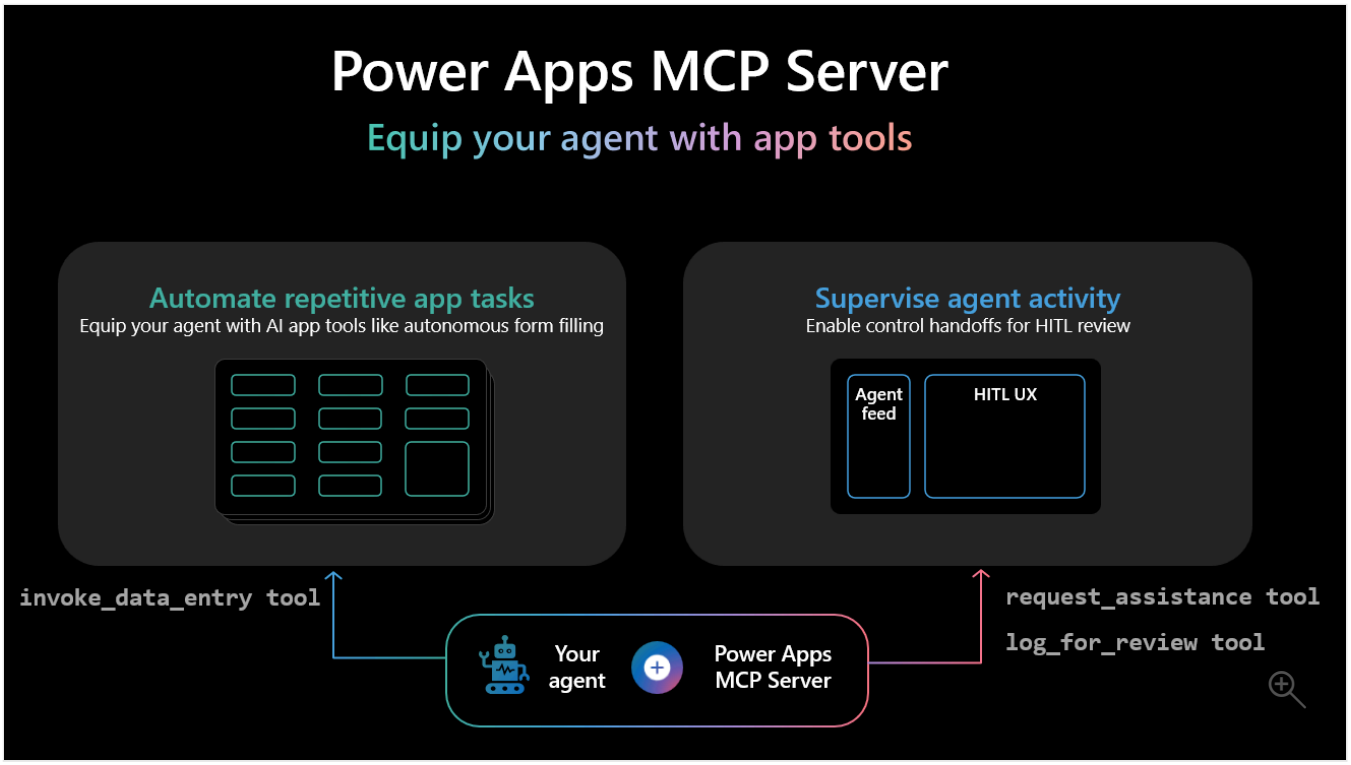
- Automate repetitive app tasks:

  The Power Apps MCP Server enables agents to use advanced app tools developed in Power Apps. For example, the data-entry agent capabilities previously available as an on-demand AI feature are now accessible to any agent through Power Apps MCP server. To use them, you create your agent, configure the MCP tool, and direct it to unstructured

content so it can generate Dataverse records with human review and approval through the enhanced agent feed.

- Supervise agent activity:

  The Power Apps MCP Server also provides specialized tools to business users to supervise any agent activity in the agent feed. Agents can now handoff control to humans for review, assistance, and steering with the MCP tools. These tools provide makers with much more control over the tasks they want to publish to the agent feed and when they need agent-human handoff.



> **Note**
>
> Access to the agent feed and supervision capabilities is limited by default to the System Administrator and System Customizer security roles. To allow additional users to view the agent feed, grant organization-level read/write permissions on the tables listed here. You can create a new security role with these permissions and assign the role to multiple users as needed.
>
> - Agent Hub Goal(agenthubgoal)
> - Agent Hub Insight(agenthubinsight)
> - Agent Hub Metric(agenthubmetric)
> - Agent Task(agenttask)

- Copilot(bot)

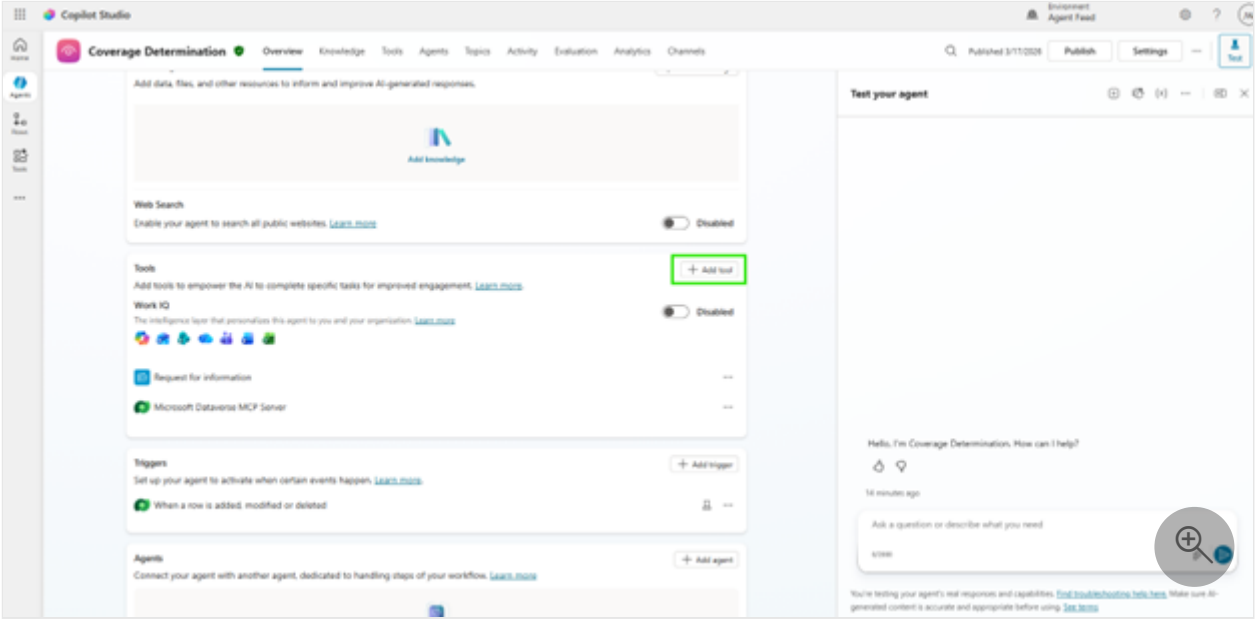
The Power Apps MCP tools improve the more you use them. For example, when you make corrections to suggestions in the agent canvas, the data entry tool improves based on your corrections. To use the enhanced agent feed capabilities, enable and configure the Power Apps MCP server from the Microsoft Copilot Studio agent. Once configured, you can invoke Power Apps MCP server tools from agent instructions using natural language.

More information: Create an autonomous agent connected to Power Apps MCP server

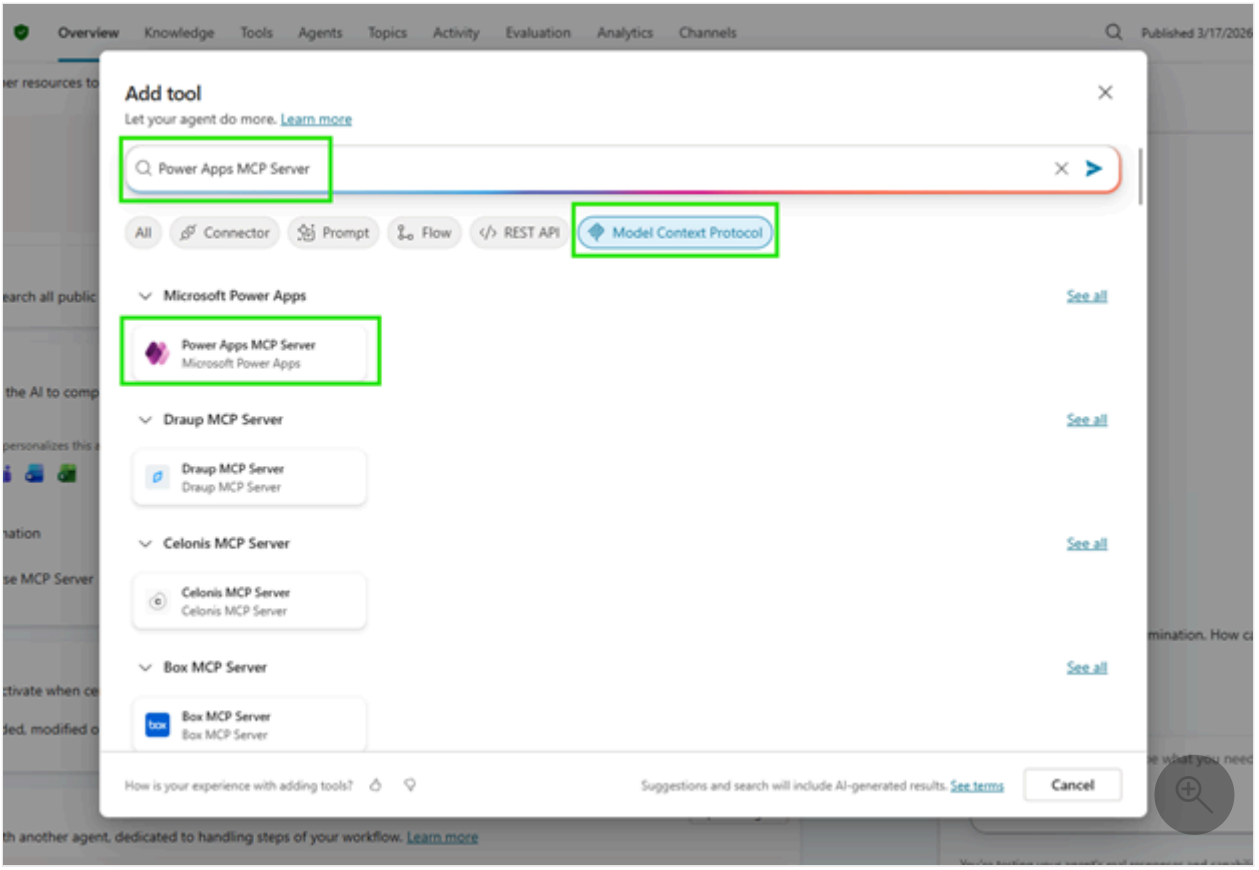
Onboard your agent to use the Power Apps MCP server

To configure an existing agent that was in the previous version of agent feed to use the Power Apps MCP server, you must do the following:

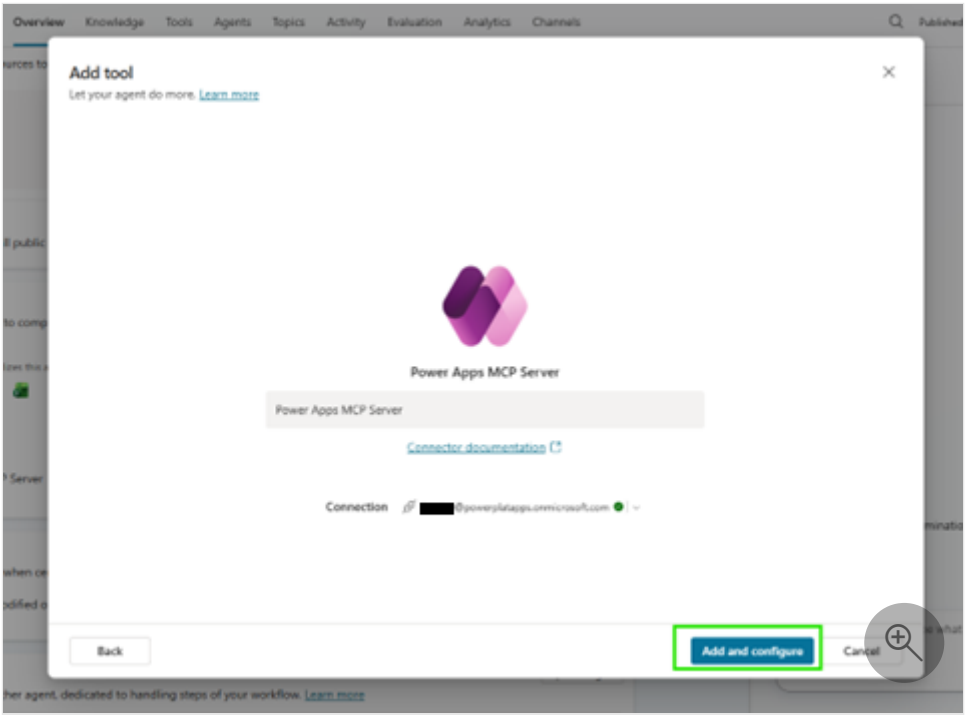
1. Add the Power Apps MCP server to your agent. To do this, open the agent in Copilot Studio and then select **Add tool**.



2. Search for **Power Apps MCP Server**.



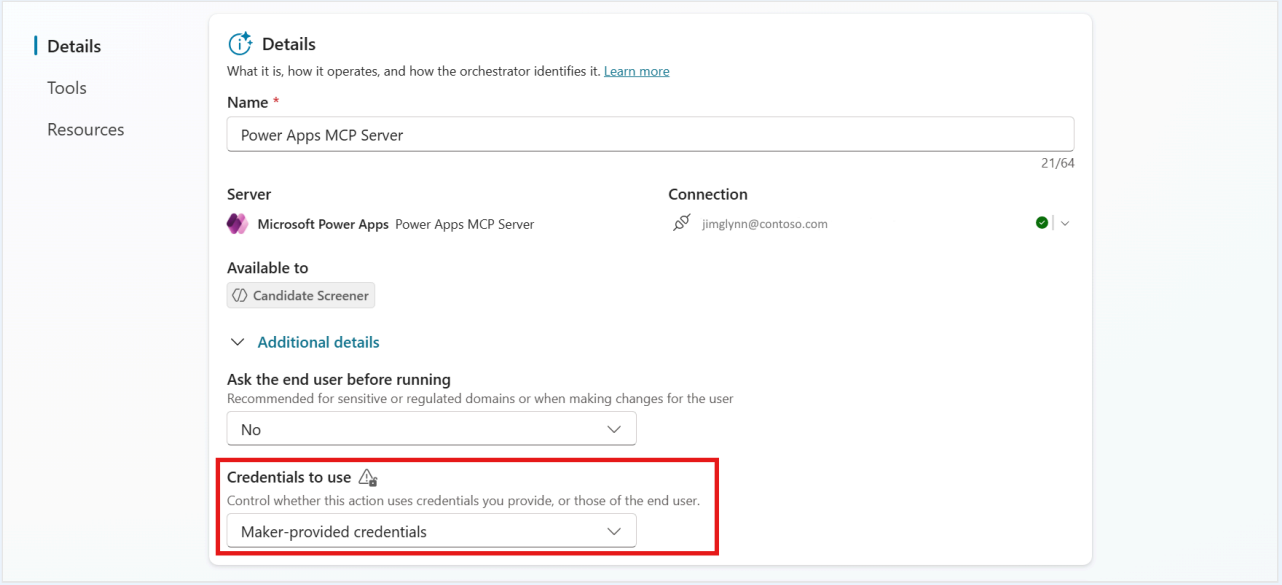
3. Select **Add and configure**.



4. Update your agent instructions to use each of the tools in the Power Apps MCP Server at the proper times in it's orchestration. There are examples of how to do this in the remainder of this document.

5. Save and publish your agent.

> **Important**
>
> For autonomous agent scenarios where an agent runs via a trigger, the Power Apps MCP server must be configured to run using "Maker-provided credentials" as seen in the details section of the tool. Go to Control maker-provided credentials for authentication for more details if this option is disabled.



List of tools

Once connected to the Power Apps MCP Server, the agent can choose from various tools in the Power Platform environment. These tools can generate agent feed items that render different user experiences, such as a side-by-side view for data entry agents or direct navigation to a record for `request_for_assistance` scenarios.

Expand table

Tool	Description
log_for_review	Log completed activity for passive human oversight.
request_assistance	Request assistance from a human user.
invoke_data_entry	Create one or more records in a data source like Microsoft Dataverse, using contents from plain text or an email.

log_for_review

Records completed agent work to the agent feed for review. The `log_for_review` tool is intended for scenarios where an agent has sufficient information to act autonomously but the

user should still be made aware of what the agent has done. This tool can be thought of as a way to passively oversee the high-confidence or low-risk actions performed by agents. It is best suited for decisions that can be easily revised or rolled back if the agent happens to perform the action incorrectly. Besides title, description, and steps you can also ask the tool to add a link to either the relevant Dataverse record or to an app-external URL. If an agent action touches multiple Dataverse records, you can instruct the agent which record it should navigate to in connection with the created task. It could be the link to the record the agent created using the Dataverse MCP server or a record link present in context like the record that triggered the agent execution. These tasks are shown in the agent feed's **Completed** tab.

Sample instruction

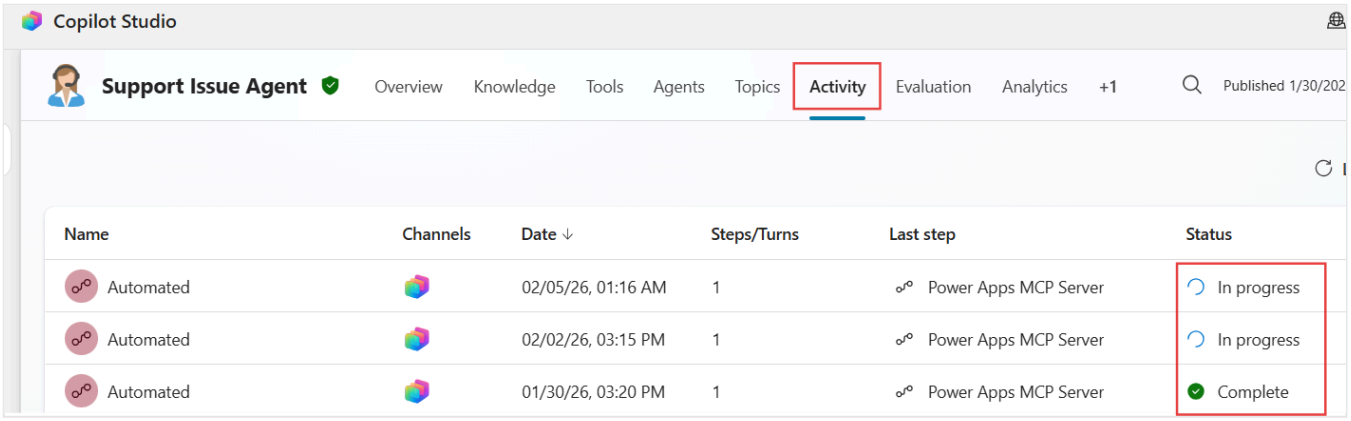
When the customer makes a booking from the portal this agent must log the details for review. The review item title should be based on the booking reference number and must use the exact prefix “Review Web Booking: ”. In the review description, write a concise summary of the booking that includes main fields like Booking Reference, Booking Date, Seat Number, and Status, so a reviewer can quickly understand what was processed without opening the record. Ensure the description reads as a short paragraph and accurately reflects the current values from the booking record. Include your reasoning as steps. Also, include a link to the booking record.

request_assistance

The intended purpose of the `request_assistance` tool is to enable agents to surface errors, escalations, or exceptions to users, so they can take appropriate action. As a maker, you can define the scenarios for when to have your agent use the `request_assistance` tool. It creates an agent feed task that is populated in the **Needs Attention** section of the agent feed. This is an asynchronous operation that calls the Microsoft Copilot Studio agent that waits until the

human completes the action. For details on completing the action feed activity, go to Supervise agents in model-driven apps with agent feed (preview)

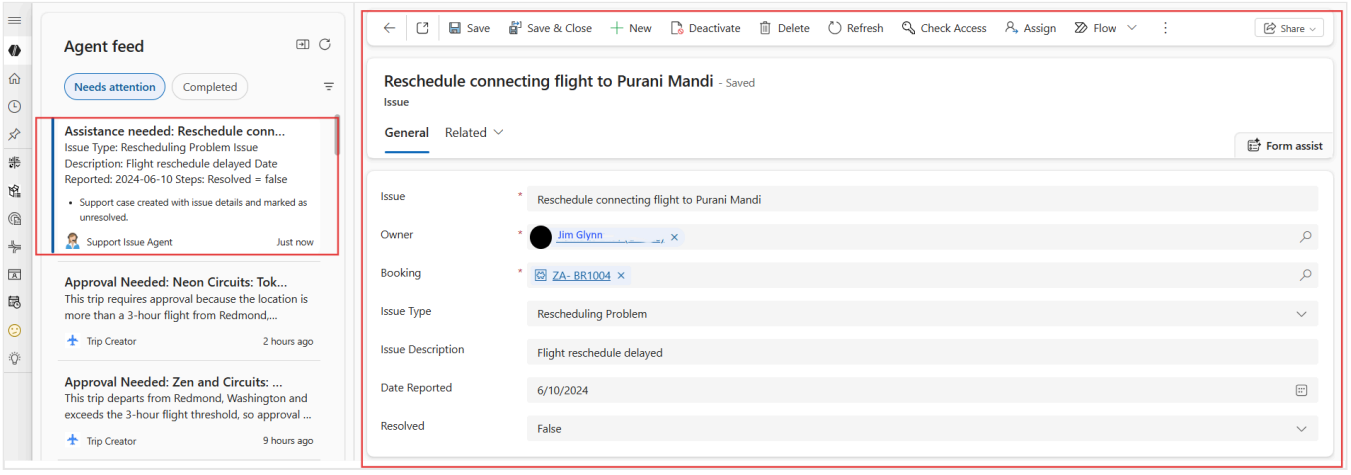
You can observe the **In progress** status for the agent run in the activity tab when viewing the agent in Copilot Studio. Once the user completes the activity from agent feed, control comes back to agent via callback and agent can complete the task.



Like with the `log_for_review` tool, you can control the task output for title, description, and steps and can be specific when telling the agent which link to associate with a given task.

Sample instruction

When this agent is triggered by the creation of a new support case, it should request assistance. In the request, set the title by prefixing the value of issue with “Assistance needed: ”. In the task description include the issue type, issue description, date reported, and the resolved value. Include your reasoning steps. Also include a link to the related Dataverse issue record. Once the user completes the task, continue processing by setting the case status to Closed.



Design your user-in-the-loop

Before writing your agent's instructions, decide where human oversight belongs in your workflow. Use the following questions to identify which moments should use `request_assistance`, which should use `log_for_review`, and which the agent can handle autonomously.

Expand table

Question	Guidance	Tool
Where are the stakes high?	High-stakes outcomes require oversight regardless of agent confidence. Give the agent explicit instructions to pause.	`request_assistance`
When is user intervention always needed?	If you can state it as a rule, encode it directly in the agent's instructions.	`request_assistance`
Which inputs vary unpredictably?	Unstructured data, edge cases, and novel situations can't always be anticipated. Instruct the agent to surface these dynamically.	`request_assistance`
Does the agent need an answer to keep going?	If the agent is blocked without human input, it should wait for a response. If it can proceed and a human audits later, it shouldn't.	`request_assistance` if yes, `log_for_review` if no
Does a user own the outcome?	Compliance requirements, high-value approvals, or policy decisions may require a human sign-off even when the agent is confident.	`log_for_review`

> **Tip**
>
> A well-designed agent doesn't ask for help constantly. Instead, it asks at the right moments. Use `request_assistance` sparingly for genuine decision points, and let `log_for_review` handle the rest.

Example instructions by pattern

Explicit rule:

> *"For any claim with an estimated loss amount over $5,000, use `request_assistance` to route the claim to the assigned adjuster before proceeding."*

Dynamic judgment:

> *"If the cause of loss is ambiguous or claim documents conflict with each other, use `request_assistance` to flag the claim for adjuster review."*

Passive oversight:

> *"After completing the coverage determination, use `log_for_review` to record the outcome and confirm the claim has been cleared to advance."*

Example: Homeowner's insurance coverage determination agent

The following example shows how these patterns apply to a complete, real-world workflow.

The agent triggers automatically when a new claim is submitted. It pulls the relevant policy, endorsements, and supporting documents from Dataverse, then reasons over them to produce a coverage determination, checking whether the policy was active, whether the claimed peril is covered, and whether any document conflicts affect confidence in the outcome.

From there, the agent uses the Power Apps MCP server to surface results in the agent feed based on what it found. If the claim is ambiguous, conflicted, or requires adjuster judgment, the agent uses `request_assistance` to create a task for the assigned adjuster with the context they need to act. If the claim is clear-cut, the agent uses `log_for_review` to record the outcome passively and no action is required. When an adjuster completes a task, the agent resumes, reads the decision, updates the claim record, and logs a completion notice back to the feed.

The result is a workflow where the agent handles the routine volume autonomously and pulls a human in only at genuine decision points with enough context that the adjuster can act immediately.

invoke_data_entry

The `invoke_data_entry` tool streamlines the creation of Dataverse records by extracting structured information from unstructured inputs such as emails, messages, or documents. When invoked from a Copilot Studio agent, it automatically analyzes incoming content, fills out the appropriate form with the extracted data, and presents the proposed entry as a task in the agent feed for user review and approval. It requires review of the proposed entry by a user

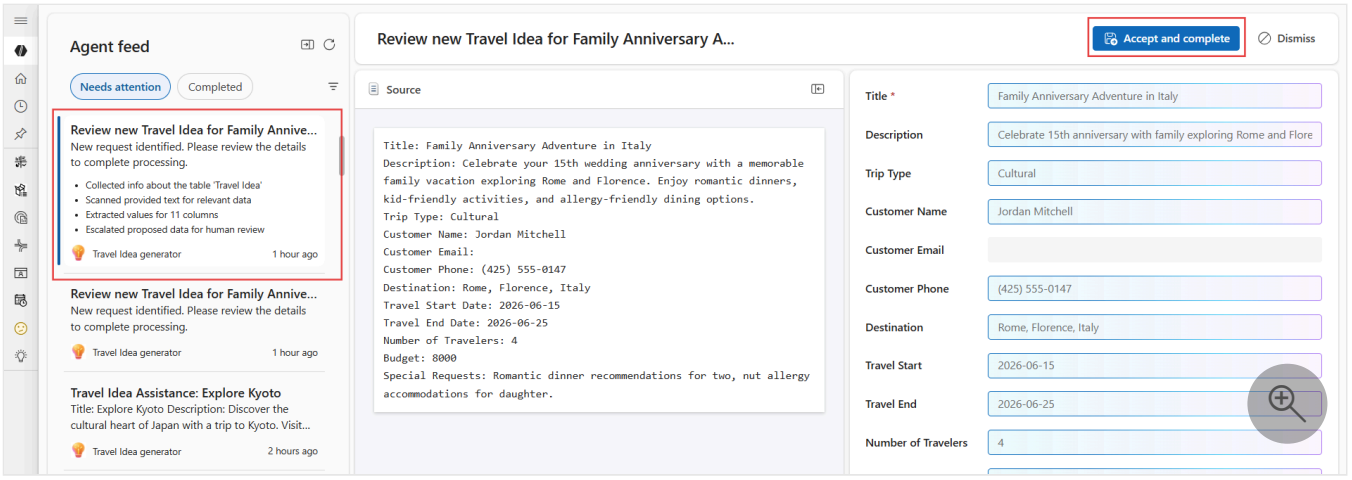
before creating the record. **Records are never created automatically using the `invoke_data_entry` tool.** This enables fast, reliable data capture with minimal manual effort.

Sample instruction - shared email triggered agent

You are the travel idea generator agent. Your job is to process incoming emails and create travel idea records in Dataverse.

When an email arrives:

1. Determine if it contains travel-related information (either in the email body or attachments).
2. Use the `invoke_data_entry` tool to create a travel idea record with the extracted information in the following columns:
    - cr3ea_title
    - cr3ea_description
    - cr3ea_triptype
    - cr3ea_customername
    - cr3ea_customeremail
    - cr3ea_customerphone
    - cr3ea_destinationcity
    - cr3ea_travelstart
    - cr3ea_travelend
    - cr3ea_numberoftravelers
    - cr3ea_budgetusd
    - cr3ea_specialrequests
3. If information is missing, still create the record with available data - leave unknown fields empty.



> **Note**
>
> - When you write instructions for your agent, always reference Dataverse columns by their logical names as shown in the sample instruction. Clear, direct instructions help the agent reliably create records from the input. You can view a column's logical name by opening the table in make.powerapps.com, select **Columns**, and then open the column to view the details.
> - `invoke_data_entry` tool supports .pdf, .xlsx, .docx, .jpeg, .jpg, .png, .gif and.bmp formats.
> - `invoke_data_entry` tool can populate single line of text (None format), Whole number and Decimal column types.
> - Ensure that the user has permission to create records for the target table.

How the invoke_data_entry tool works

When you configure a Copilot Studio agent to use the Power Apps MCP Server and enable the `invoke_data_entry` tool, the agent follows this process:

1. An agent trigger is fired based on your configuration — such as an email arriving in a monitored mailbox or new document uploaded to SharePoint.
2. The agent analyzes incoming content and your instructions to determine whether the `invoke_data_entry` tool should be used.
3. If needed, the `invoke_data_entry` tool is invoked, passing the input content and the target Dataverse table and table columns to predict.
4. The tool processes the input, extracts relevant information, and populates a Dataverse form with suggested values for each mapped column.
5. A task appears in the agent feed. Selecting it opens the data-entry review experience. The left panel shows the original input, and the right panel displays the form populated with

suggested values.

6. The user can review the extracted values, make corrections if needed, and then save the record to Dataverse.

Provide feedback

To provide feedback about the invoke_data_entry tool:

1. Open a invoke_data_entry task in the agent feed.
2. Select the feedback button in the task header.
3. Choose to give a compliment, report an issue, or make a suggestion.

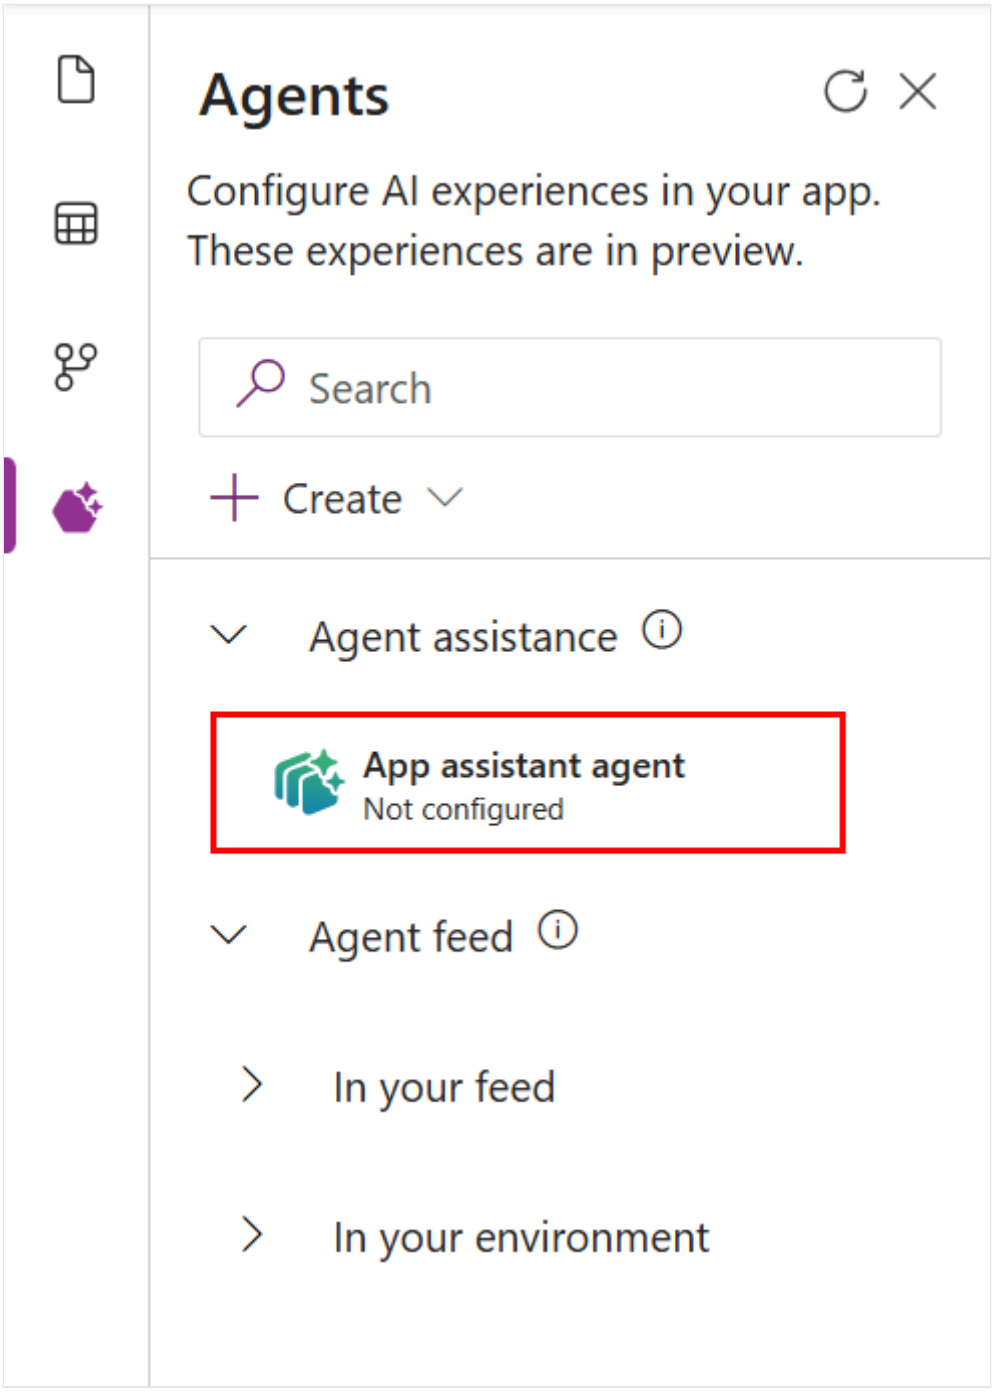
Last updated on 04/07/2026

Add an app assistant agent to your model-driven app (preview)

09/04/2025

[This topic is pre-release documentation and is subject to change.]

The app assistant agent makes a model-driven app more intelligent and relevant for your organization by adding additional topics, knowledge sources, and more. The Copilot Chat, Agent APIs, and agent response components access the topics within this agent.



Important

- This is a preview feature.
- Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

> **Note**
>
> The app assistant agent is a rename of interactive agent, which is the improved experience for **...** > **Configure in Copilot Studio**. The agents created with the previous experiences are now shown as the **App assistant agent**.

Create an app assistant agent

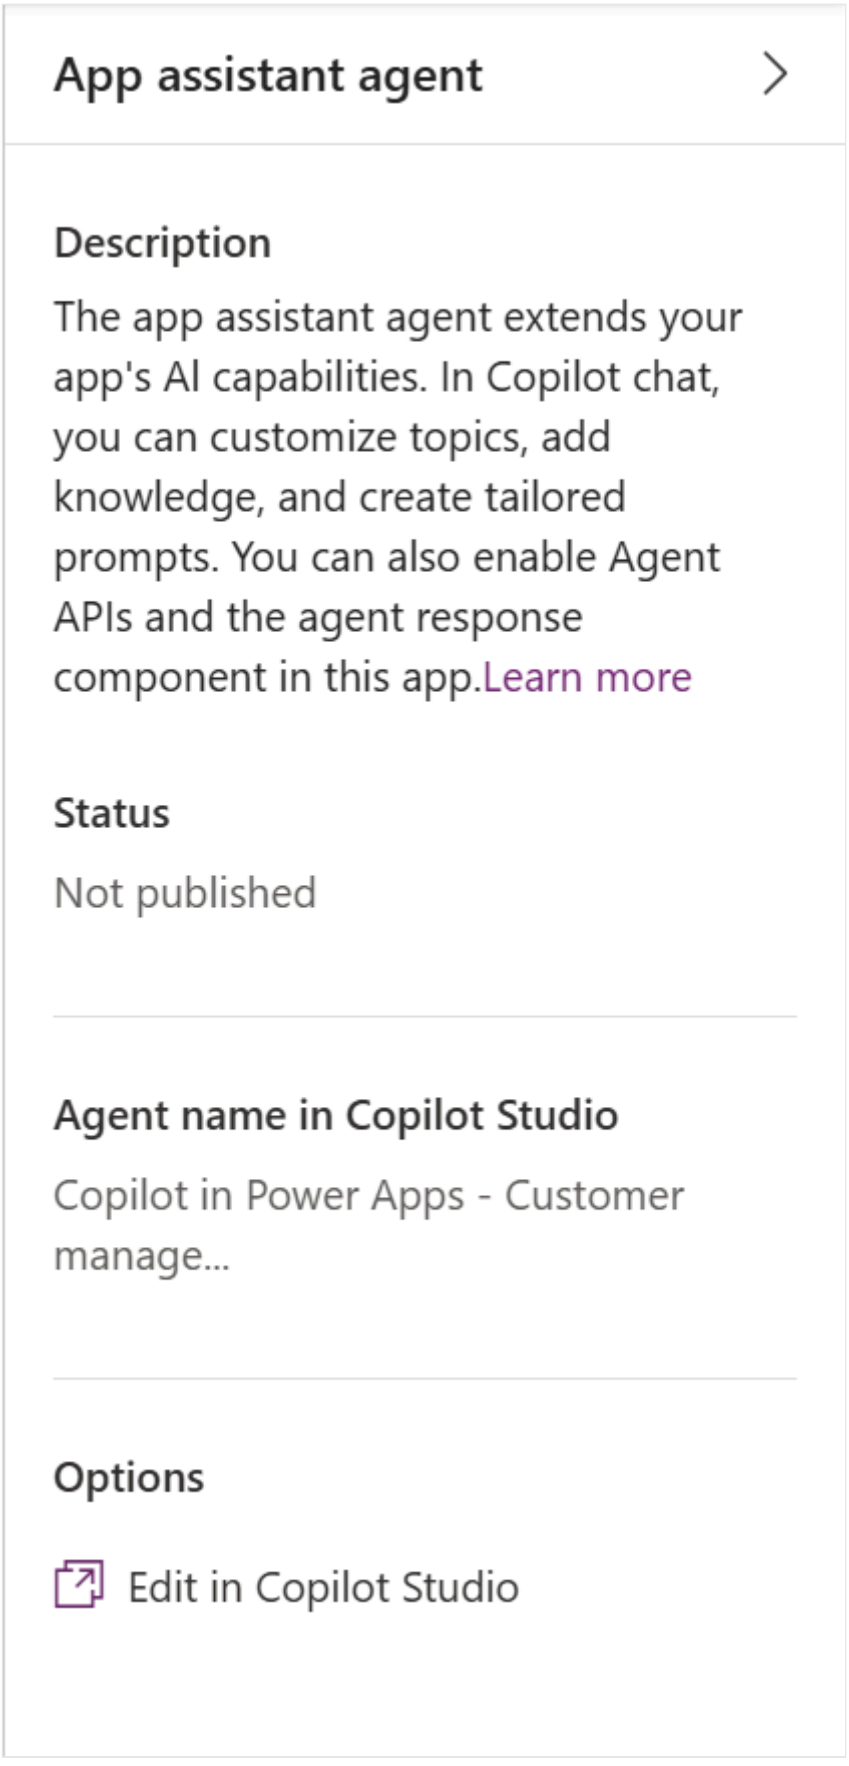
When an app assistant agent is created, it's named as **Copilot in Power Apps - <app name>**. The created agent is associated with the app when the app is saved and published.

1. In the app designer, select the **Agents** pane.
2. Expand **Agent assistance**.
3. On **App assistant agent**, select **...** > **Configure**.

   A new browser tab for **Copilot Studio** is opened with the new agent.

   > **Note**
   >
   > Pop-ups need to be enabled in your web browser to allow editing the created agent.

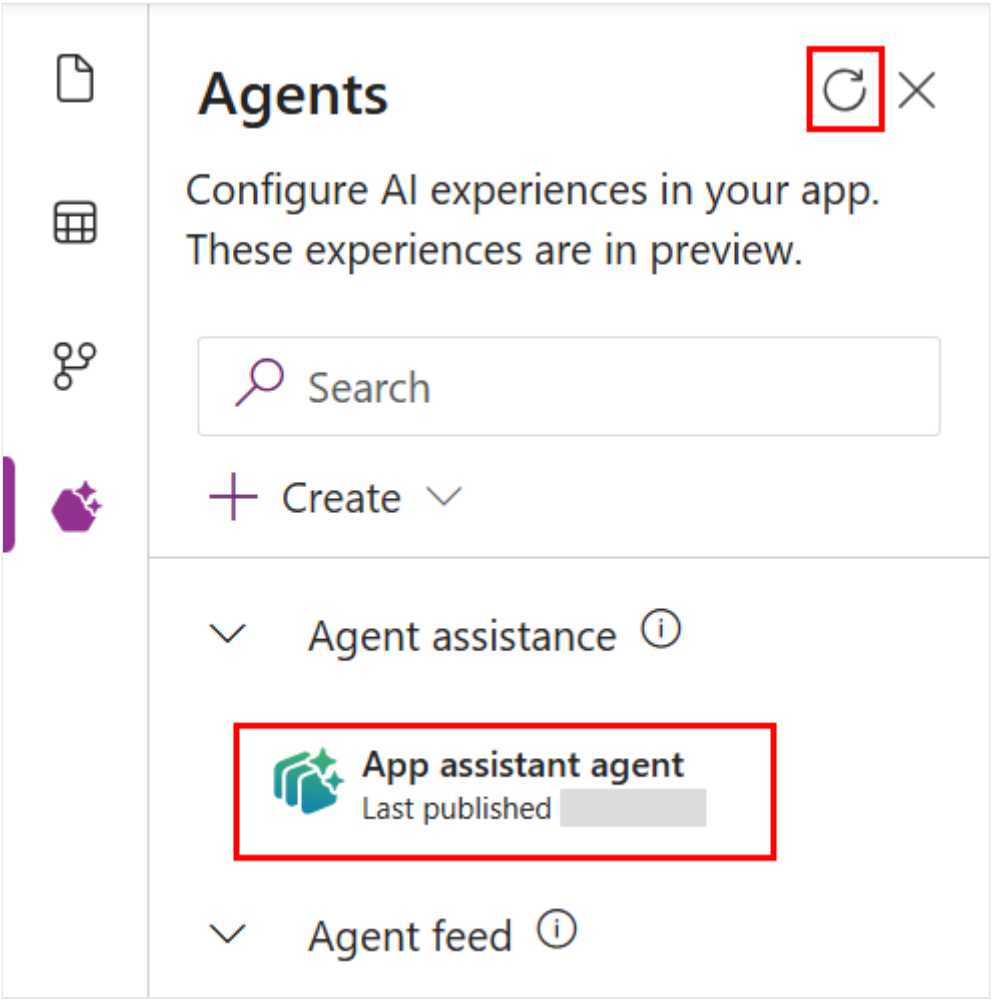
4. After configure completes, the right pane is expanded showing the status of **Not published** and the agent name.



5. Switch to the **Copilot Studio** browser tab or select **Edit in Copilot Studio** to add topics, knowledge, and so on, to the agent.

6. Save and publish the agent.

7. Switch to the app designer browser tab and select refresh in **Agents** pane header to show agent published status.



8. In the app designer, save and publish the app.

Edit an app assistant agent

After the app assistant agent has been initially configured, it can be edited from either the **Agents** pane or the **App assistant agent property** pane.

Agent pane:

1. In the app designer, select the **Agents** pane.
2. Expand **Agent assistance**.
3. On **App assistant agent**, select **...** > **Edit in Copilot Studio**.

App assistant agent property pane:

1. In the app designer, select the **Agents** pane.
2. Expand **Agent assistance** and select **App assistant agent**.
3. In the property pane for App assistant agent, select **Edit in Copilot Studio**.

Limitations

The app assistant agent isn't able to be defined or referenced in app designer for these Microsoft model-driven apps:

- Connected Field Service
- Customer Insights
- Customer Service Hub
- Customer Service workspace
- Dynamics 365 App for Outlook
- Field Service
- Field Service Mobile
- Inventory Visibility
- Omnichannel engagement hub
- Project Operations
- Sales Hub
- Sustainability

> **Note**
>
> When a model-driven app includes both Lead and Opportunity tables, it implicitly uses the **Copilot in Dynamics 365 Sales** agent. The app designer doesn't show the app assistant agent, but the **Copilot in Dynamics 365 Sales** agent can be customized from Copilot Studio.

Add agents to your model-driven app

Customize Copilot Chat

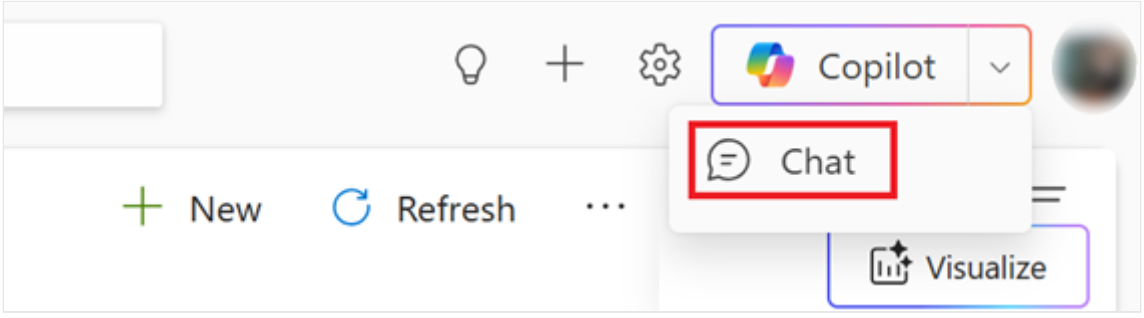
Add Microsoft 365 Copilot for app users in model-driven apps

Microsoft 365 Copilot makes it easier for users to work with model-driven apps by offering AI-powered insights through natural language conversations. With this feature, users can quickly find information, navigate apps more easily, and get help to boost their productivity. App makers can enable Microsoft 365 Copilot to give users access to conversational AI that understands app data and provides helpful, contextual answers. Users can ask questions about their Microsoft Dataverse table data in plain language and receive immediate, relevant responses.

https://learn-video.azurefd.net/vod/player?id=843f065d-4ee4-4006-b09b-e97da24b7393&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fmodel-driven-apps%2Fadd-microsoft-365-copilot

This article shows you how to enable and configure Microsoft 365 Copilot for your model-driven apps, both at the environment level and for individual apps.

When enabled, users can open Microsoft 365 Copilot in their model-driven app by selecting **Copilot** > **Chat** on the upper-right corner. For more information, see Use Microsoft 365 Copilot in model-driven apps.



Prerequisites

To use Microsoft 365 Copilot in canvas apps, make sure the following prerequisites are met:

- Your tenant must be set to allow **Dataverse data available in Microsoft 365 Copilot**. For more information, see Enable Microsoft 365 admin center Copilot Dataverse settings.
- Dataverse Search must be set to **Default** or **On** for the environment. Fore more information, see Understand what this means for generative AI experiences.

- To use the Microsoft 365 Copilot feature in your app, users must have both a Power Apps premium license and a Microsoft 365 Copilot license.

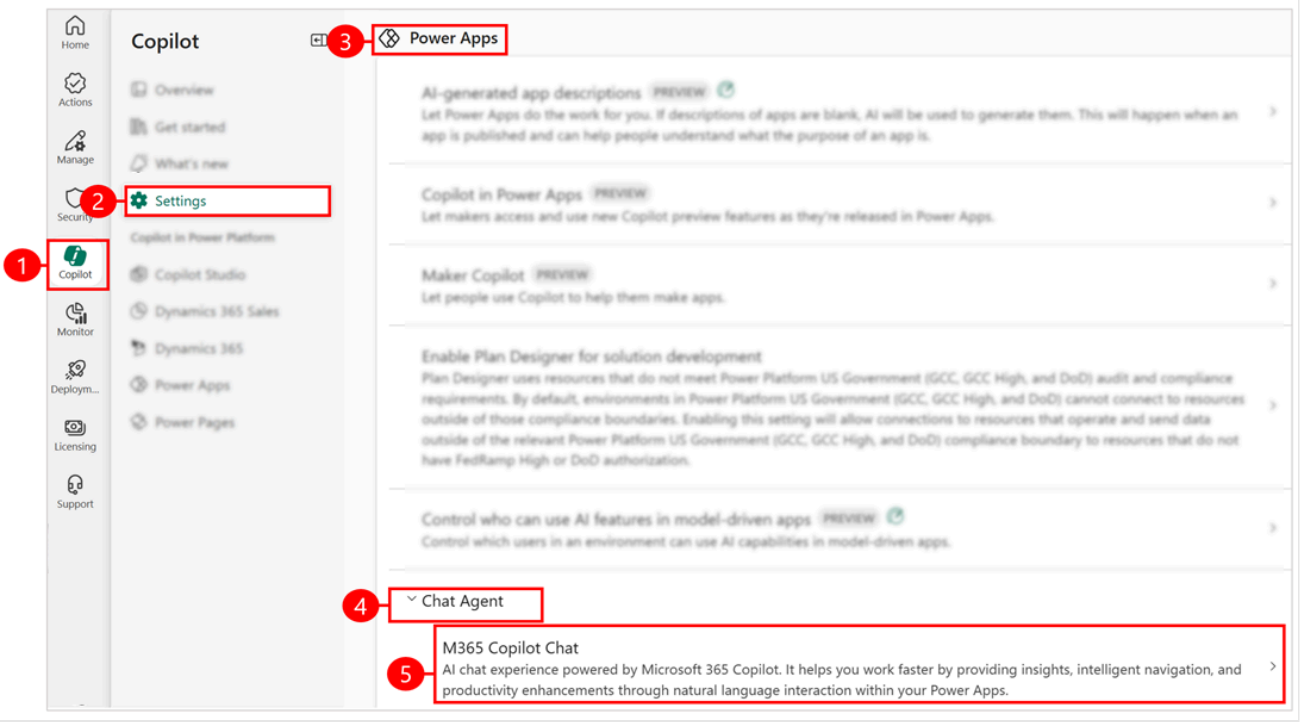
> **Note**
>
> - Microsoft 365 Copilot for model-driven apps relies on Dataverse Search indexes. Enabling this feature might increase your environment's Dataverse capacity consumption. For more information, see What actions can makers or admins take to manage Dataverse Search efficiently.
> - Sufficient Dataverse database capacity must be available to support indexing, semantic search, and Copilot operations. For more information, see Capacity page details.

Enable Microsoft 365 Copilot for your environment

To manage Microsoft 365 Copilot for model-driven apps, start by learning how to manage Microsoft 365 Copilot.

Power Platform administrators can set up and configure the Microsoft 365 Copilot feature for users in their environment.

1. Sign in to the Power Platform admin center.
2. In the navigation pane, go to **Copilot** > **Settings**. Under **Power Apps**, expand **Chat Agent** and choose **M365 Copilot**.

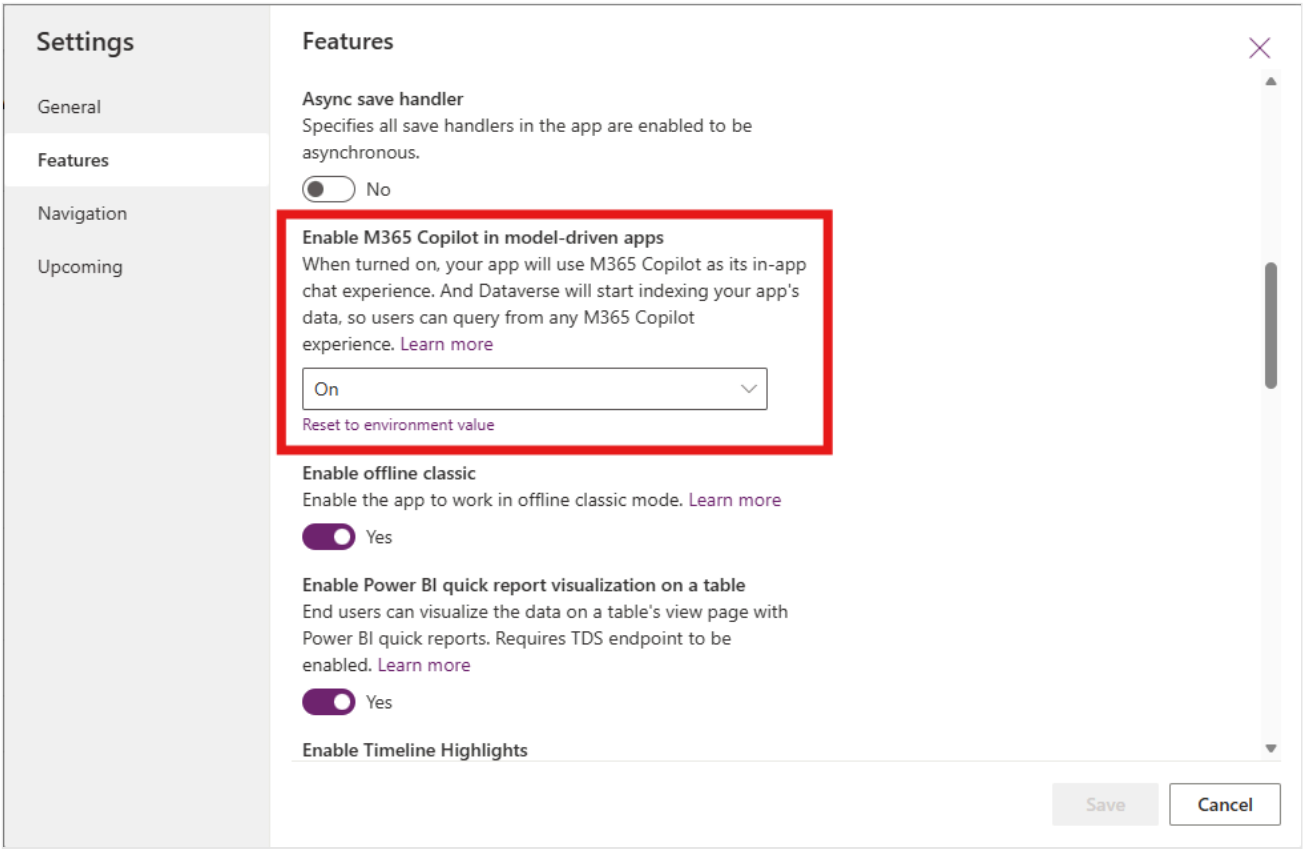


3. Select an environment group or an environment name, then select **Edit Setting**.
4. Select **On** and then select **Save** to enable Microsoft 365 Copilot for your canvas apps in the selected environment group or environment.

Enable Microsoft 365 Copilot in a model-driven app

Makers can enable or disable Microsoft 365 Copilot for a specific model-driven app.

1. Sign in to Power Apps.
2. Open a model-driven app for editing.
3. Select **Settings** in the command bar.
4. On the left, select **Features**.
5. To enable Microsoft 365 Copilot, set **M365 Copilot in model-driven apps** to **On**. To disable it, set the option to **Off**.



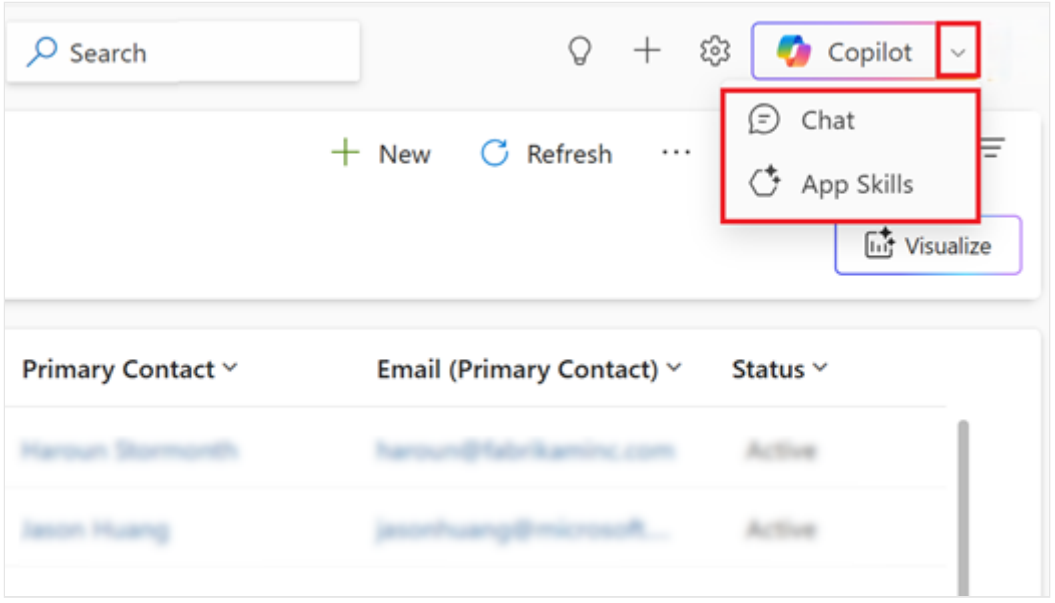
6. Select **Save** and then publish the app for the changes to take effect.

Microsoft 365 Copilot vs. Copilot chat

Microsoft 365 Copilot is gradually replacing Copilot chat in model-driven apps.

During the transition period, makers can enable either one or both chat experiences. When both options are available, the **Copilot** dropdown menu shows the following options:

- **Chat** button opens Microsoft 365 Copilot
- **App Skills** button opens Copilot chat in model-driven apps.



Known limitations

- Microsoft 365 Copilot for model-driven apps allows users to view data by using read-only operations. This capability means that users can only view data that matches their queries and can't make any changes. To make changes, customization with an agent is required.
- Microsoft 365 Copilot for model-driven apps isn't available in the Power Apps mobile app.
- As this feature is being gradually deployed, certain settings in the Power Platform Admin Center might not be accessible yet, depending on the geographic location of your tenant.

Last updated on 04/23/2026

Customize Microsoft 365 Copilot with an agent

Microsoft 365 Copilot in Power Apps enables users to interact with custom agents that extend Copilot's capabilities beyond standard functionality. By customizing agents, you can create tailored experiences that address your organization's specific business processes and data requirements. For more information, see Use agents in Microsoft 365 Copilot

This article describes the different types of agents you can build and integrate with Microsoft 365 Copilot in Power Apps. You'll learn about the capabilities and use cases for each agent type, helping you choose the right approach for your customization needs.

You can customize agents in several ways to fit your organization's needs.

Expand table

Agent Type	Description	Common use cases
Declarative Agent	Configured using low-code tools and templates, allowing quick setup for common scenarios within Microsoft 365 Copilot.	Automating routine tasks, answering FAQs, and providing guided workflows.
Custom Engine Agent	Developed with custom logic and integrations, offering advanced capabilities tailored to specific business needs.	Complex business processes, custom data integrations, and specialized automation.
Copilot Studio Agent	Built and managed in Microsoft Copilot Studio, enabling integration with Teams and Microsoft 365 for conversational experiences.	Interactive chatbots, team collaboration, and personalized support within Microsoft 365 apps.

Use the following information to find the best solution for your organization:

- Microsoft 365 Copilot Agents Overview documentation provides guidance on how to choose what type of agent to build.
- Create agents as Declarative Agents for Microsoft 365 Copilot or as Custom engine agents for Microsoft 365.
- Use Microsoft Copilot Studio to connect and configure an agent for Teams and Microsoft 365, making it available in Microsoft 365 Copilot.
- Review guidance on how to Choose between Microsoft 365 Copilot and Copilot Studio to build your agent.

Limitation

- Agents you author can't yet use in-app user context to optimize their responses.

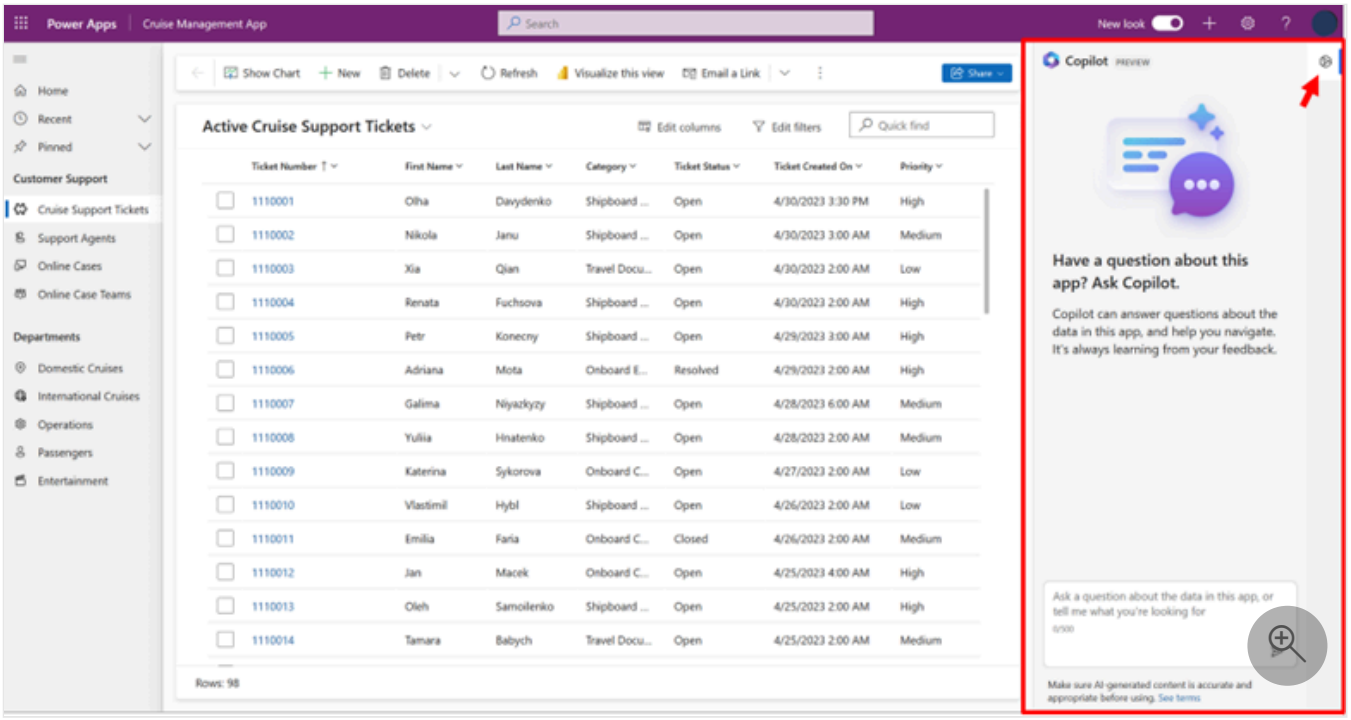
Add Copilot for app users in model-driven apps

Copilot chat for model-driven apps in Power Apps is a next-generation AI assistant that helps app users get insights about the data in their apps through conversation in natural language. Copilot chat helps app users boost their productivity through AI-powered insights and intuitive app navigation.

> **Important**
>
> This feature is generally available in Dynamics 365 apps, but remains a preview feature in Power Apps.
>
> - Preview features aren't meant for production use and might have restricted functionality These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - You must allow data movement across regions for Generative AI features as a prerequisite for using Copilot in Power Apps. This step is especially important if your organization and your environment are in different regions. Learn more in Turn on copilots and generative AI features.
> - This capability is powered by Azure OpenAI Service.
> - This capability might be subject to usage limits or capacity throttling.

> **Note**
>
> Copilot chat in Power Apps is a preview feature that will be deprecated for model-driven apps in environments not enabled for Dynamics 365 apps, starting January 2026. We recommend switching to Microsoft 365 Copilot chat. During the transition period, makers can enable either one or both chat experiences. For more information, see Deprecation of Copilot chat in model-driven apps

When enabled, Copilot chat can be accessed through the Copilot icon in the right navigation bar in a model-driven app. The Copilot chat pane can be opened or minimized as desired.



Copilot chat in model-driven apps can answer questions about the Microsoft Dataverse table data in the environment. Copilot can also help you navigate the app. For example, when a user enters *take me to Online Cases* or *show me Cruise Support Tickets*, Copilot automatically opens the relevant app screens. Learn more in Use Copilot chat in model-driven apps.

Enable Copilot for model-driven apps in your environment

Power Platform administrators enable the Copilot chat feature in model-driven apps for all the users in their environments in the Power Platform admin center.

> **Important**
>
> - Copilot chat for app users in model-driven apps isn't enabled by default. Administrators must manually enable this feature for their environments in the Power Platform admin center.
> - Questions and answers about enterprise data environments that have a customer-managed key or Customer Lockbox won't use your data stored in Dataverse. You might get answers from Copilot, but they won't be based on your Dataverse data.

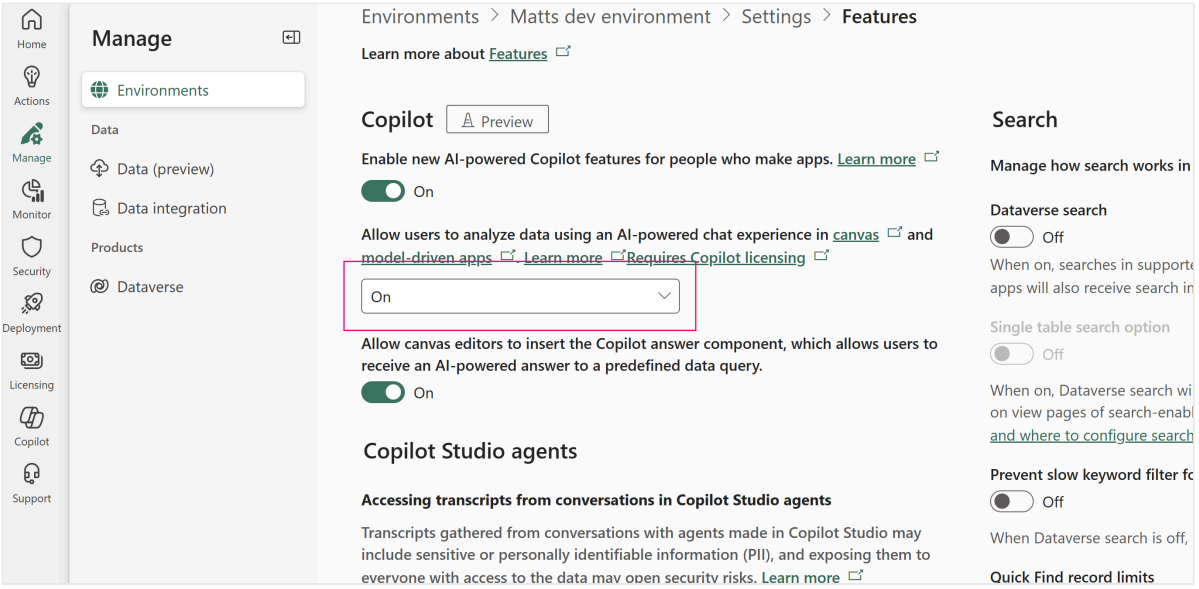
1. Sign in to the Power Platform admin center at https://admin.powerplatform.microsoft.com.

2. In the navigation pane, go to **Manage** > **Environments** and select the environment where you want to enable Copilot chat for app users in model-driven apps. On the command bar, select **Settings**.

3. In **Settings** for the selected environment, select **Product** > **Features**.

4. In the **Features** section, set the value for **Allow users to analyze data using an AI-powered chat experience in canvas and model-driven apps** to the setting that's appropriate for your environment.

    - **Default**. Copilot chat is *disabled for a Power Apps licensed environment and enabled for a Dynamics 365 licensed environment*.
    - **On**. Copilot chat is enabled for the environment regardless of the environment licensing type.
    - **Off**. Copilot chat is disabled for the environment regardless of environment licensing type.

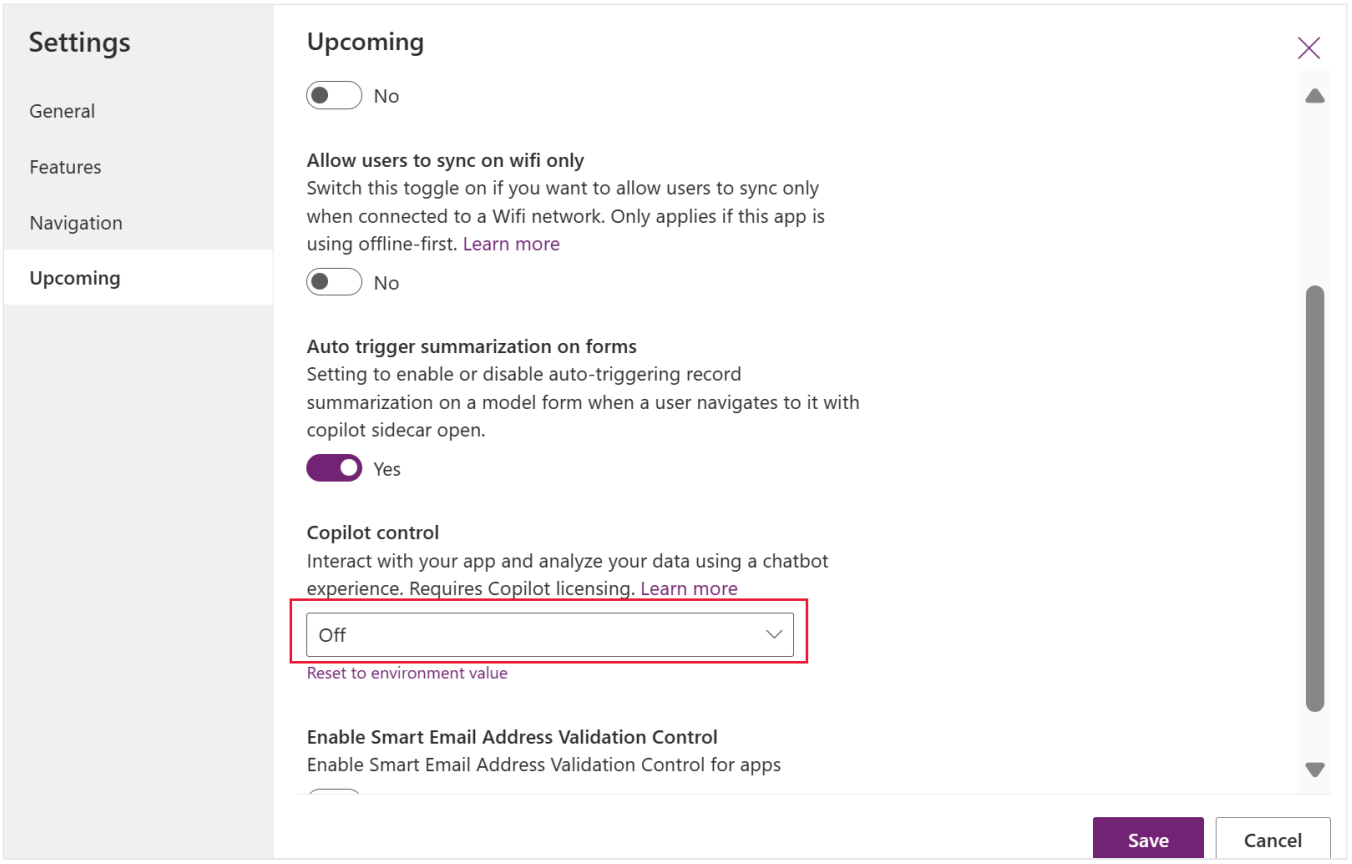


5. **Save** your changes.

Disable Copilot chat for a model-driven app

Makers can disable Copilot chat for a specific model-driven app. In app designer, open the model-driven app for **Edit**, and then select **Settings** on the command bar. Select **Upcoming** on the **Settings** screen, set **Copilot control** to **Default** or **Off**, and then select **Save**.

Save and **Publish** the model-driven app for the changes to take effect.



Reset to environment value

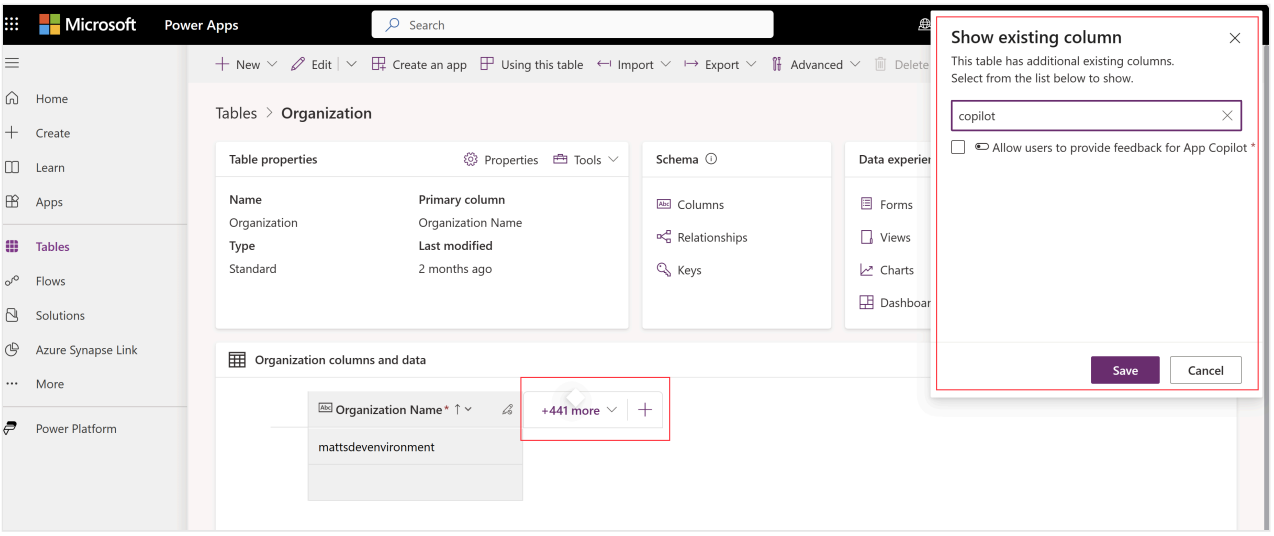
Makers can set the Copilot control for the app to match the environment setting by selecting **Reset to environment value** on the **Upcoming** tab of app settings.

Provide feedback in Copilot

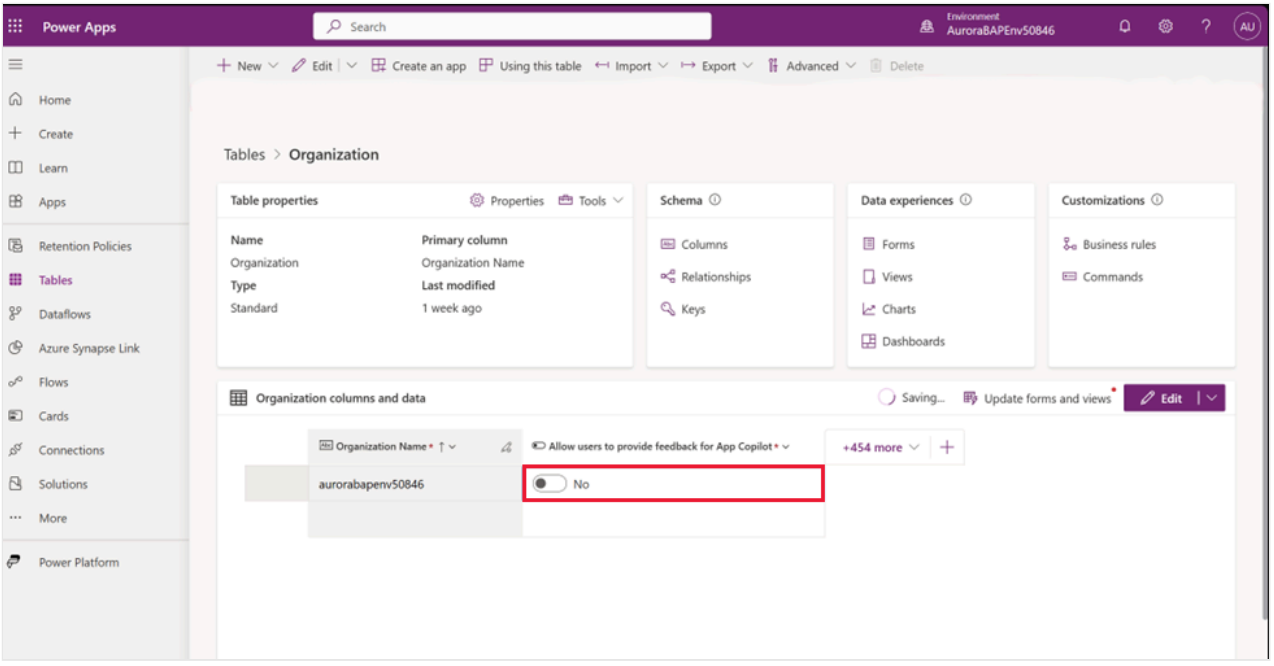
To provide feedback to help us improve Copilot's responses, app users can select the "thumb up" or "thumb down" icon after each Copilot response. Optionally, app users can provide feedback in their own words about what they liked or what went wrong, or how they would like Copilot to improve.

Disable feedback for app users

1. Sign in to Power Apps.
2. Go to **Tables**, and then open the **Organization** table.
3. In the **Organization columns and data** section, select **+nnn more** to display the column search box.
4. In the search box, search for the **Allow users to provide feedback for App Copilot** column.



5. Set the column to **No**, and then **Save** the table.



Region availability and language supported

Copilot chat for model-driven apps in Power Apps is available in the regions and languages listed here.

Expand table

Regions	Language
Asia Pacific, Australia, Brazil, Canada, Europe, France, Germany, India, Japan, Korea, Norway, Qatar, Singapore, South Africa, Sweden, Switzerland, United Arab Emirates, United Kingdom, United States	Czech, Danish, German, Greek, Finnish, French, Italian, Japanese, Korean, Dutch, Norwegian (Bokmål), Polish, Portuguese (Brazil), Russian, Swedish, Thai, Turkish, Chinese (Simplified), Spanish (Spain), Arabic, Hebrew

Copilot takes into account the user's preferred UI language and localizes responses based on that. Depending on the user's preferred UI language, environment base language, and languages supported for a specific Copilot feature, the responses are localized accordingly. This table summarizes the expected behavior in different scenarios.

Expand table

Base language of the environment	Preferred UI language of the user	Expected behavior
English	English	Output in English
English or non-English	One of the supported non-English languages	Output in the preferred UI language of the user.
English or non-English	An unsupported language	Output is unpredictable as the language is unsupported. The responses are mixed with English and the user language. We recommend using one of the supported Copilot languages in such cases.

Known limitations

1. **Copilot for app users** allows users to retrieve information from Dataverse through read-only operations. This means that users can only view data that matches their queries and can't make any changes to the data.
2. Create, update, or other generic actions such as enable or disable Copilot and create a memo aren't supported.
3. Summarization skill feature is available in Dynamics 365 Sales copilot and not in **Copilot for app user**.
4. **Copilot for app users** isn't supported with the Power Apps mobile app.

Customize Copilot chat using Copilot Studio (preview)

[This article is prerelease documentation and is subject to change.]

Customize Copilot chat to make it even more intelligent and relevant for your organization by adding additional articles, knowledge sources, and more.

> **Important**
>
> This feature is generally available in Dynamics 365 apps, but remains a preview feature in Power Apps.
>
> - Preview features aren't meant for production use and might have restricted functionality These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - You must allow data movement across regions for Generative AI features as a prerequisite for using Copilot in Power Apps. This step is especially important if your organization and your environment are in different regions. Learn more in Turn on copilots and generative AI features.
> - This capability is powered by Azure OpenAI Service.
> - This capability might be subject to usage limits or capacity throttling.

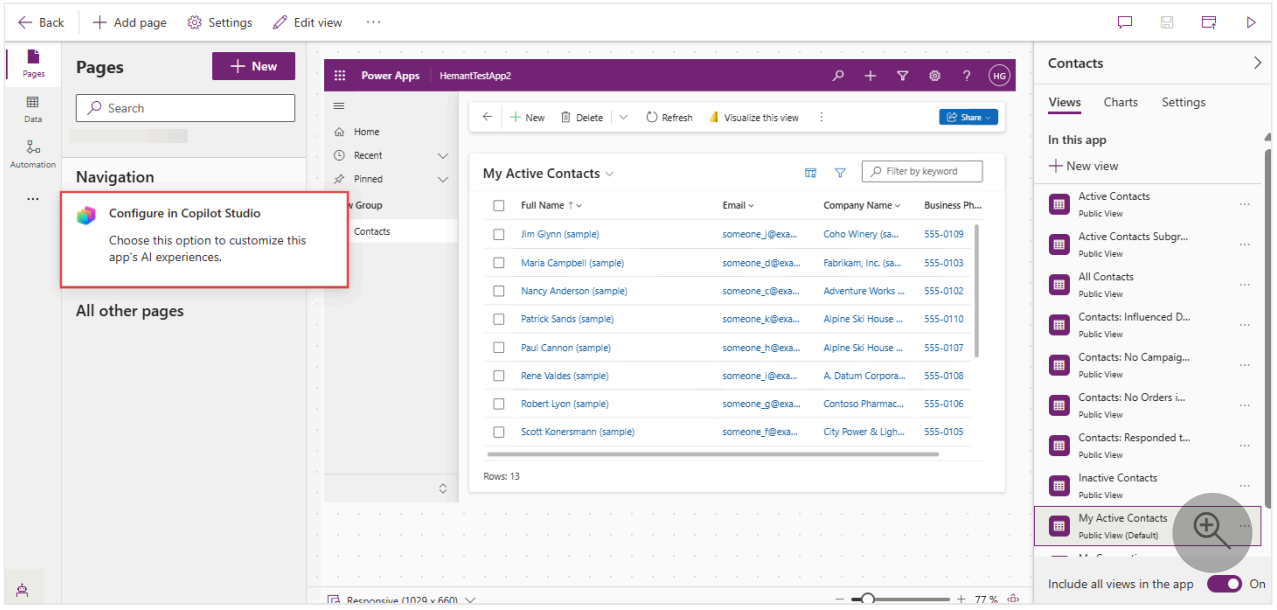
> **Note**
>
> Copilot chat in Power Apps is a preview feature that will be deprecated for model-driven apps in environments not enabled for Dynamics 365 apps, starting January 2026. We recommend switching to Microsoft 365 Copilot chat. During the transition period, makers can enable either one or both chat experiences. For more information, see Deprecation of Copilot chat in model-driven apps

You customize Copilot chat using Microsoft Copilot Studio and expand the capabilities to go beyond just handling Microsoft Dataverse tables questions and out-of-the-box skills. Before customizing, make sure Copilot chat is enabled for your environment.

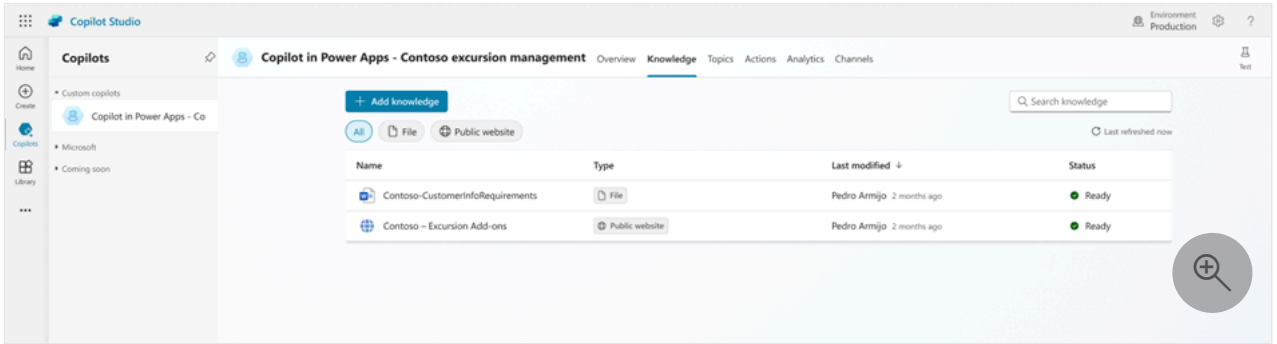
https://learn-video.azurefd.net/vod/player?id=d0439343-f464-4ec7-a92d-b3c528430fb5&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fmodel-driven-apps%2Fcustomize-copilot-chat

> **Note**
>
> - Copilot Studio license and agent editing permissions are required to customize Copilot chat.
> - This feature is only available in standalone model-driven apps, which don't include both lead and opportunity tables. This feature isn't yet supported for Dynamics 365 apps.
> - This experience has changed to use interactive agent and is currently rolling out to regions.

1. Go to https://make.preview.powerapps.com .
2. Open your model-driven app in edit mode, and then on the left navigation bar select ... > **Configure in Copilot Studio**. You're taken to Microsoft Copilot Studio where your app's agent is set up. Every standalone model-driven app Copilot has its own dedicated agent available for customizations. Setting up the agent for the first time takes a few seconds.



3. Customize your agent by adding knowledge sources or topics. Customizing this agent only impacts the Copilot chat of the specific app it's provisioned for.



4. **Publish** the agent after you make customizations to ensure changes are available to users.

Power Apps creates a platform-owned agent named **Copilot in Power Apps** in each environment. This agent is only editable by a Power Platform environment admin and isn't published to any channels by default. Although this agent can be viewed in Microsoft Copilot Studio, this agent shouldn't be edited since it isn't used by model-driven apps.

Add knowledge to Copilot chat in model-driven apps (preview)

Article • 02/22/2025

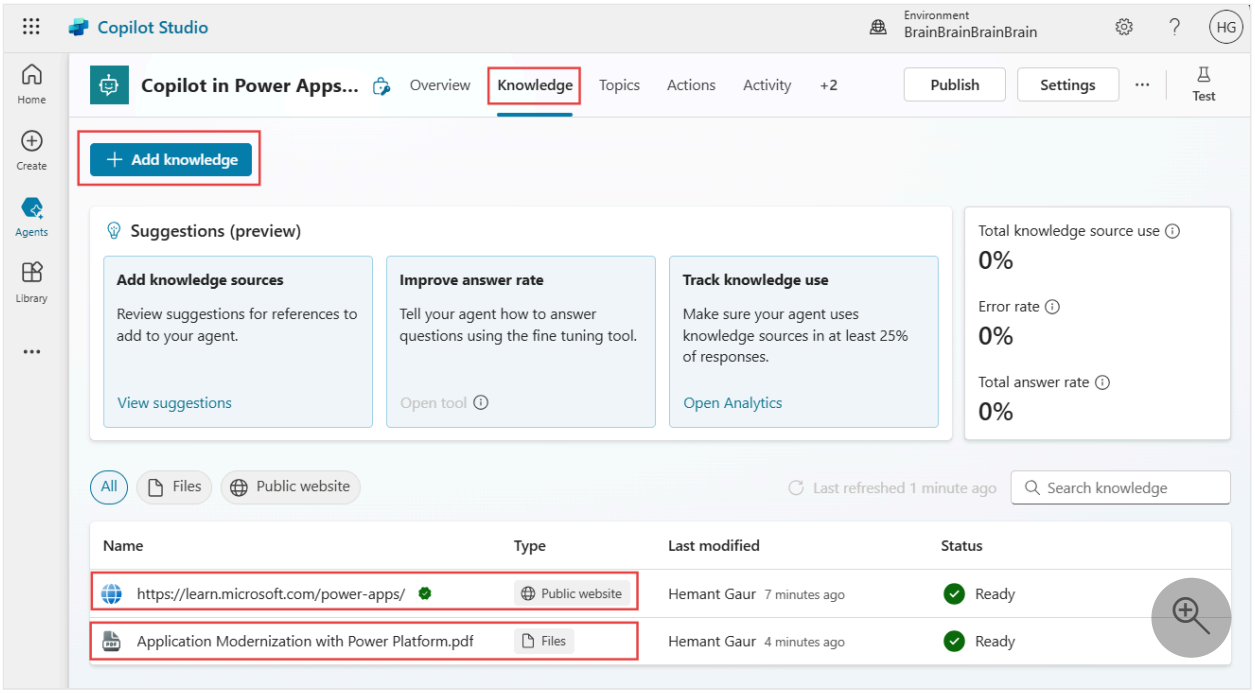
[This topic is pre-release documentation and is subject to change.]

Extend your app's Copilot chat intelligence by adding additional knowledge sources in Copilot Studio.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Add knowledge to Copilot chat

You can add additional knowledge sources in Copilot Studio. For example, you can add a link to an external public-facing website like Power Apps documentation by adding `https://learn.microsoft.com/power-apps/` as knowledge to enable your Copilot chat to respond to questions related to creating apps in Power Apps. Another example is to upload your organization's internal knowledge as a document to enable Copilot chat to respond to relevant queries that aren't a part of the app data.



More information: Add knowledge to an existing agent – Microsoft Copilot Studio.

> **Note**
>
> - Currently only Public website, File upload and SharePoint knowledge source types are supported. Dataverse knowledge isn't part of this preview.
> - Copilot studio Generative AI orchestration isn't supported currently. You can use classic orchestration topic whose trigger phrases match most closely with the user's query for a given skill.

Once knowledge is enabled, app users can ask relevant questions to get responses along with the knowledge references.

Add topics to Copilot chat in model-driven apps (preview)

Article • 02/22/2025

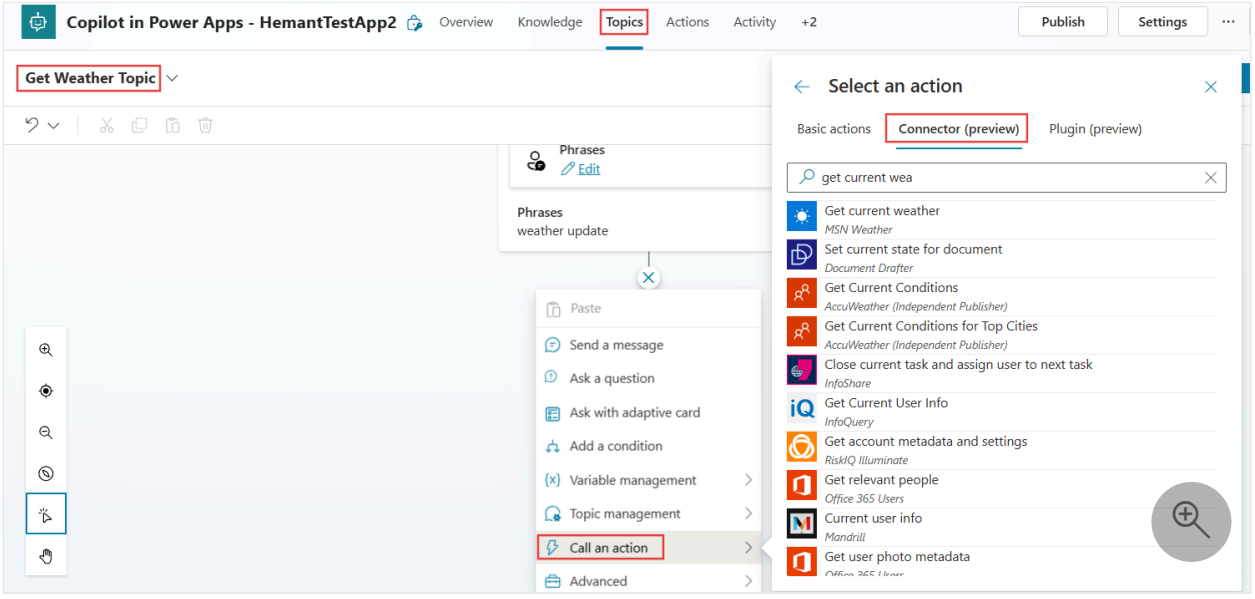
[This topic is pre-release documentation and is subject to change.]

Extend your app's Copilot chat intelligence by adding topics in Copilot Studio.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Add new topics to Copilot chat

In Copilot Studio, you can add topics to your app's Copilot agent. These topics can be customized to use various trigger types and can respond with simple messages, adaptive cards, or generative answers. Additionally, topics can also initiate actions like flows, connectors, and Dataverse plug-ins enabling seamless point in time integration with external systems.



More information: Create and edit topics – Microsoft Copilot Studio.

> **Note**
>
> Copilot Studio has inline capability to "Test your agent" and can be used to validate topics as they're added. However, topics using out-of-the-box model-driven app custom variables like `Global.PA__Copilot_Model_PageContext.pageContext.id` can only be tested in the published Copilot.

Send a message to Copilot chat (preview)

Article • 03/17/2025

[This topic is pre-release documentation and is subject to change.]

Extend your app's Copilot chat engagement and affect by incorporating rich audio, video, and simple cards as a chat response type. The **Message** node, within the flow of a topic in Copilot Studio, can be used to send a message from the agent to the user in your model-driven app. Messages can be simple text messages, but can also include richer components, such as images, videos, quick replies, and cards.

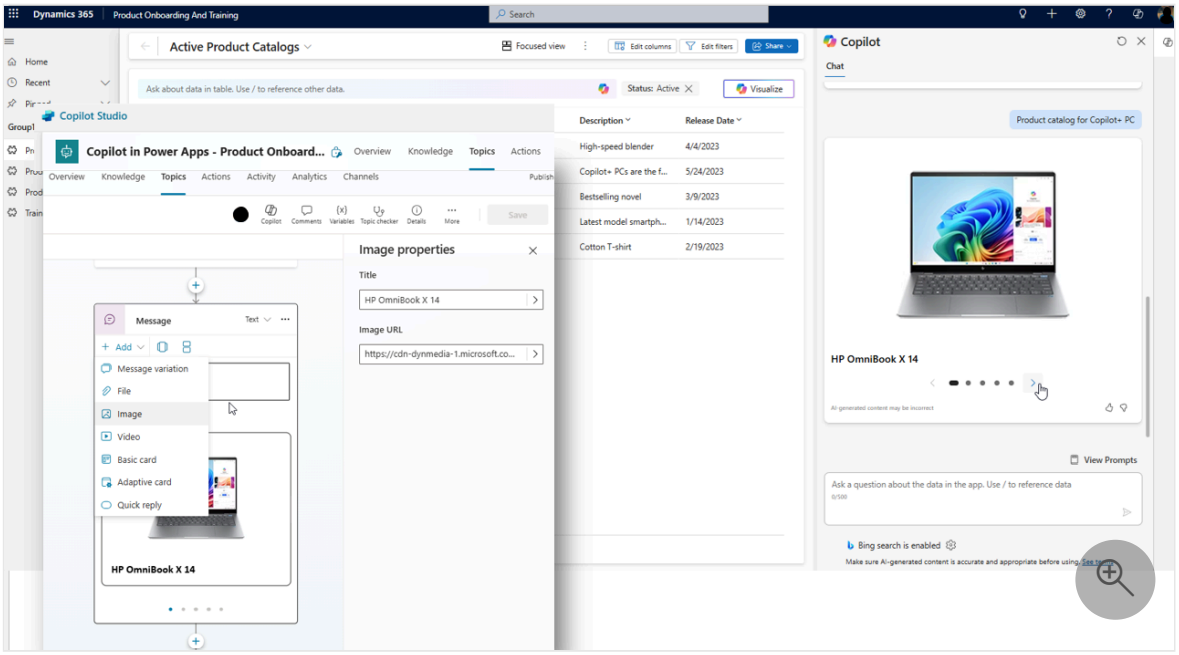
> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - Copilot Studio license and agent editing permissions are required to customize Copilot chat.

Add an image response to Copilot chat

When you add an image, Copilot can send a message as a response with the image from the agent to the user. To add an image, the image must be hosted through a URL.

1. Add a Message node.
2. In the node's menu bar, select **Add** and choose **Image**.
3. Under **Image properties**, enter the **Image URL** for your image.

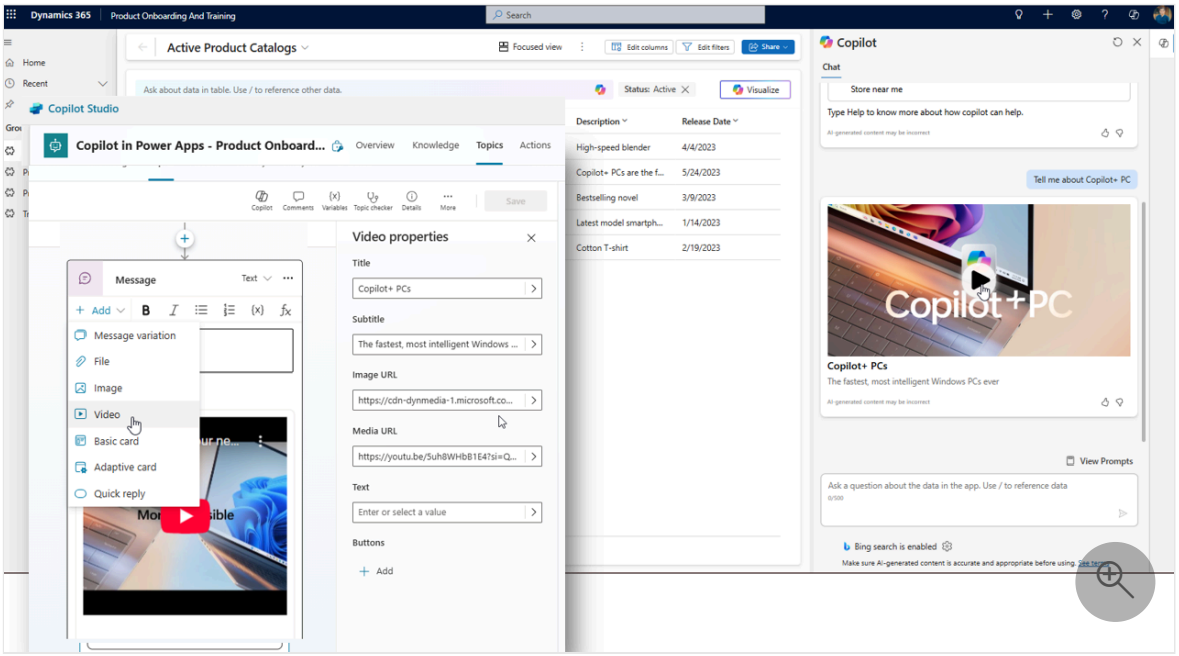
4. Optionally, enter a **Title** for the image.



Add a video response to Copilot chat

When you add a video, Copilot can send a message with the video as a response from the agent to the user.

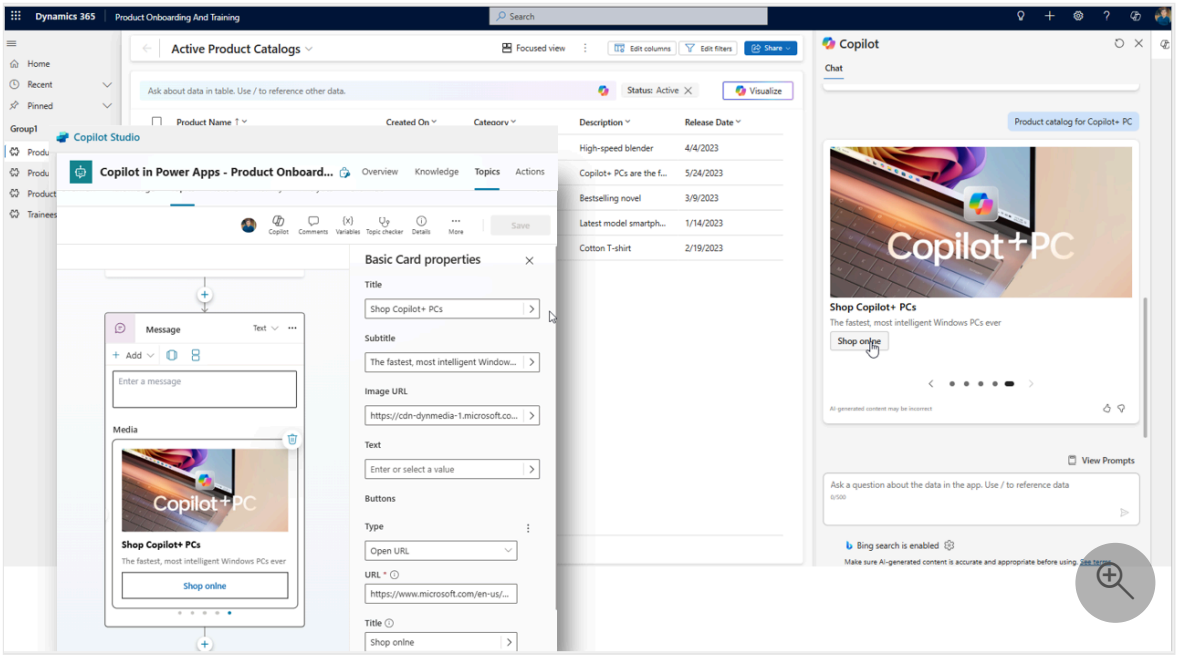
1. Add a Message node.
2. In the node's menu bar, select **Add**, and then select **Video**.
3. Under **Media URL**, enter the URL of your video. The URL can either be a direct link to a publicly accessible MP4 file or a YouTube URL.
4. Optionally, enter a **Title**, **Subtitle**, **Image URL** (the URL of a publicly available image file), or **Text** to be shown alongside the video on the card. You can also add one or more buttons, which have the same properties as quick replies.



Add a basic card response to Copilot chat

A basic card is a general-purpose card used for adding text, images, and interactive elements to an agent response message.

1. Add a Message node.
2. In the node's menu bar, select **Add**, and then select **Basic card**.
3. In the **Basic Card properties** pane, fill in the properties for the content of your card. You can also add one or more buttons, which have the same effect as quick replies.



For more information about sending messages with Copilot, go to send a message Copilot Studio documentation

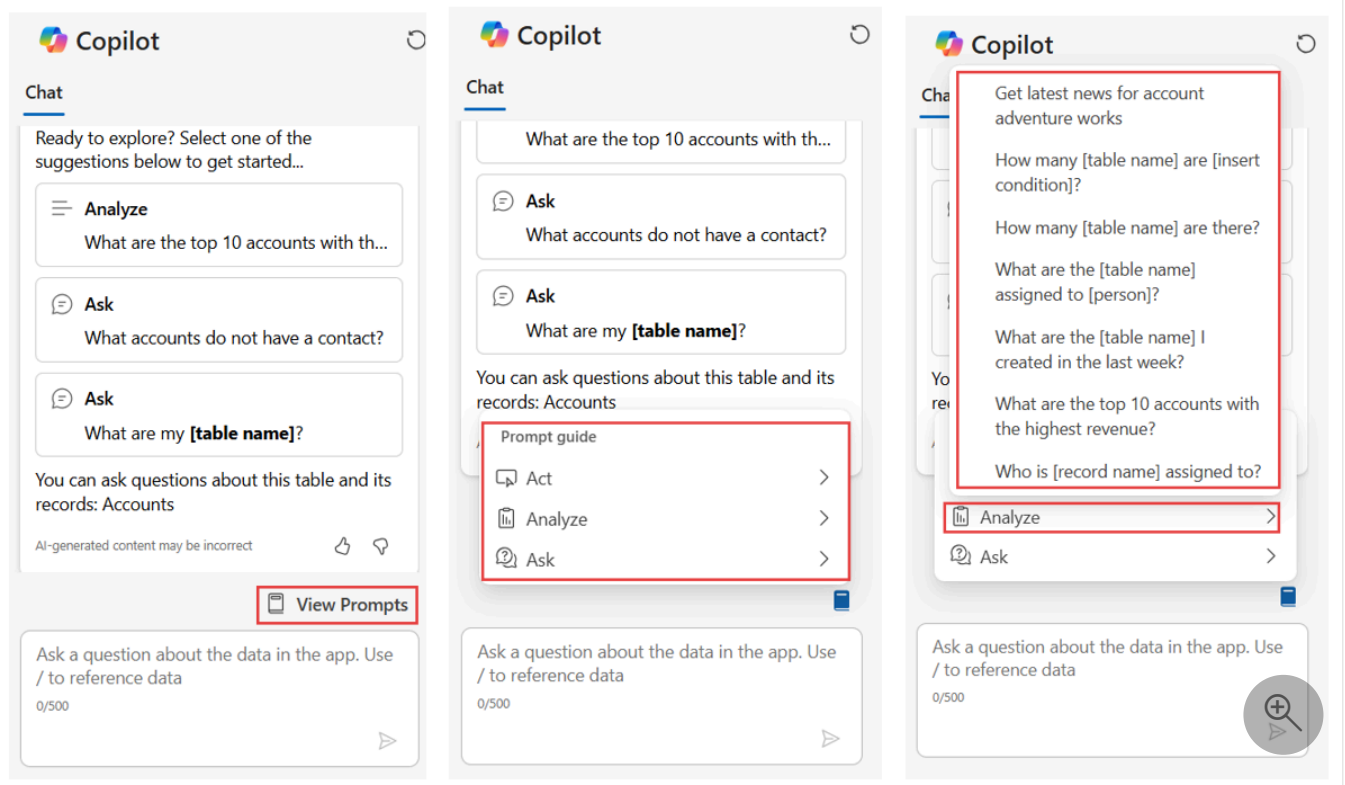
Prompt guide customizations (preview)

[This topic is pre-release documentation and is subject to change.]

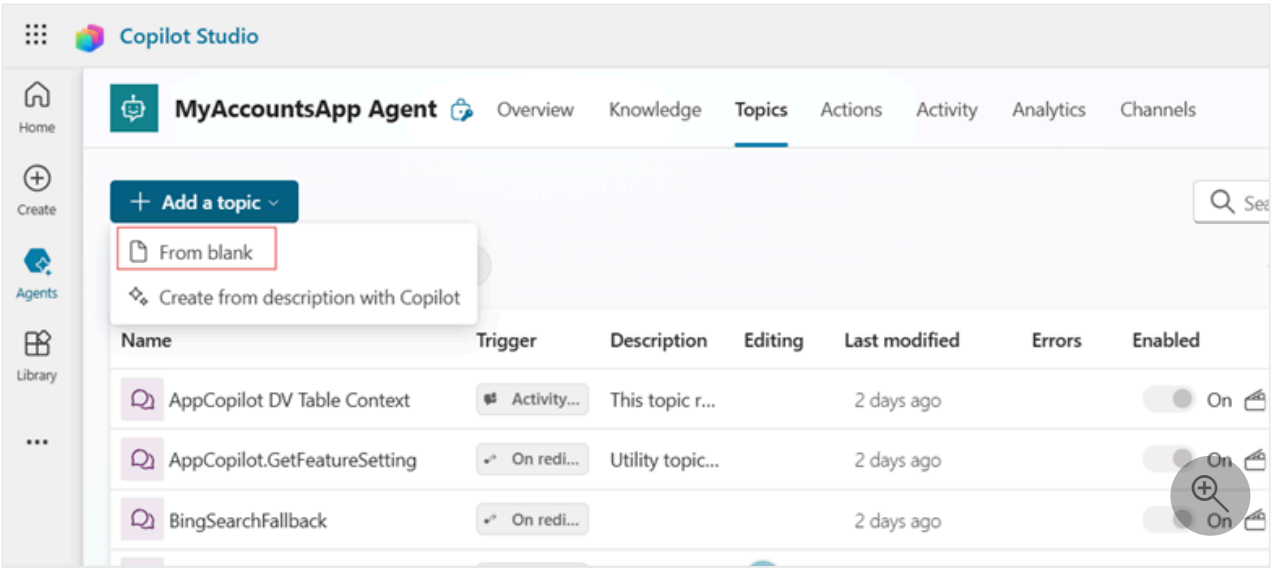
A prompt library is a collection of prewritten, tested, and optimized prompts designed to help shape the interactions and responses of the Copilot chat. They ensure that the Copilot chat provides relevant, accurate, and contextually appropriate information based on the user's needs and preferences.



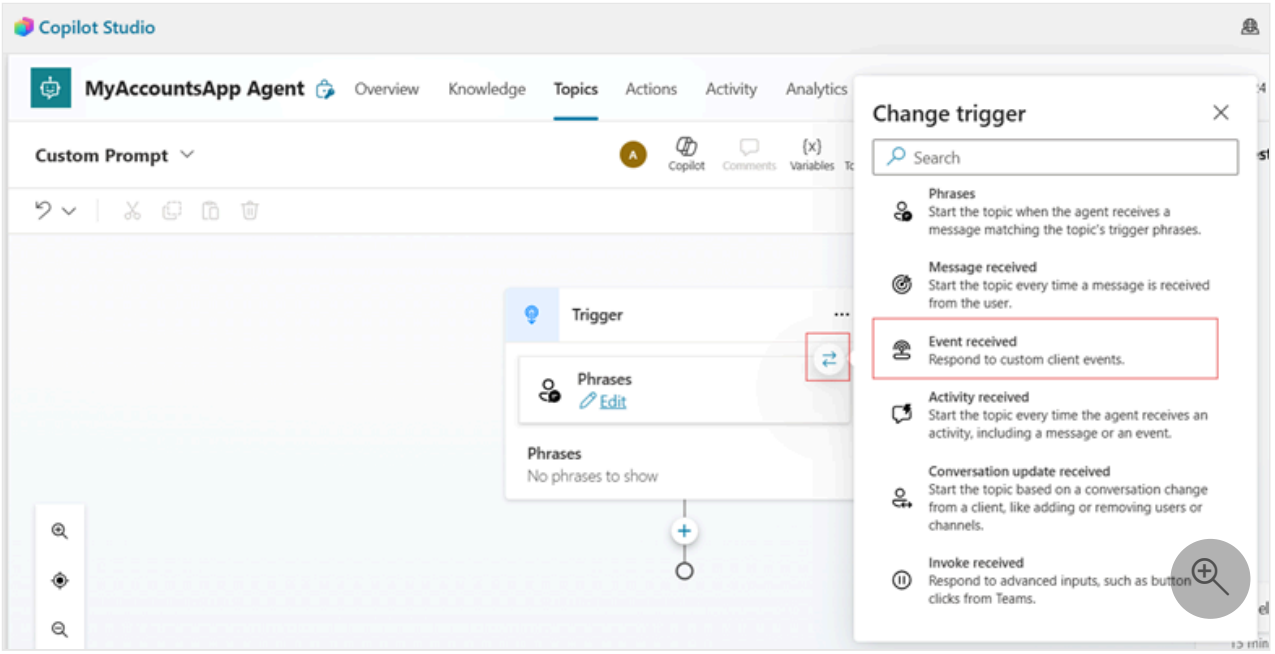
> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

The following steps detail how to add specific queries to the prompt guide. A *Power Apps Help* section is appended to the existing out-of-the-box Copilot prompt guide. Alternatively, you can copy the sample code into a new topic directly from the Prompt guide customizations topic sample. All the prompts shown to the end user via the prompt guide are stored in the Copilot Studio agent used for the app.

1. Open the agent backing the app in Copilot Studio and add a new blank topic.

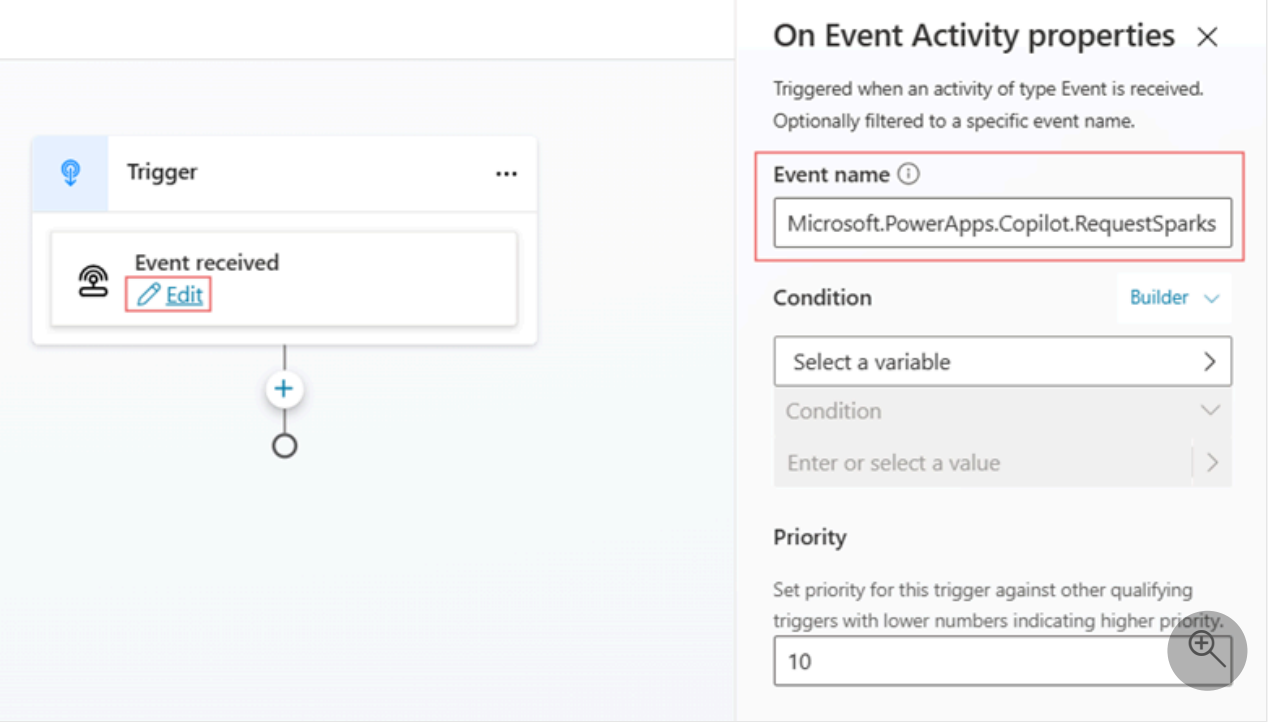


2. Rename the topic to reflect the topic intent and change the topic trigger to **Event received**.



3. Select **Edit** under **Event received**, and then set the event name as `Microsoft.PowerApps.Copilot.RequestSparks`, which is the reserved name for prompt

guide.

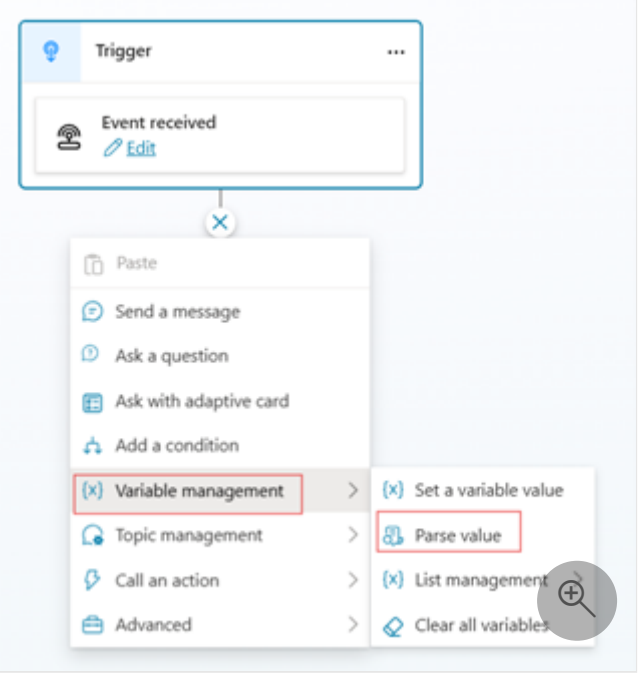


4. Optionally, you can set the conditions to prompt entries in case they're specific to the page context. For example, this prompt entry checks if the page context's table type name matches the specified value. If the condition is true, the custom prompts are shown to the user.

   ```
   condition:Global.PA__Copilot_Model_PageContext.pageContext.entityTypeName = "Entity name"
   ```

5. Under **Priority**, add an appropriate priority value so the trigger is fired after the higher priority topics. Priority values can have 0 to 10K range with 0 being highest. Although about 200 is recommended as it allows for more options to add higher priority topics later, 10 is used in this example.

6. Select + under **Event received**, and then select **Variable management** > **Parse value** to add a next step for variable management parse value.



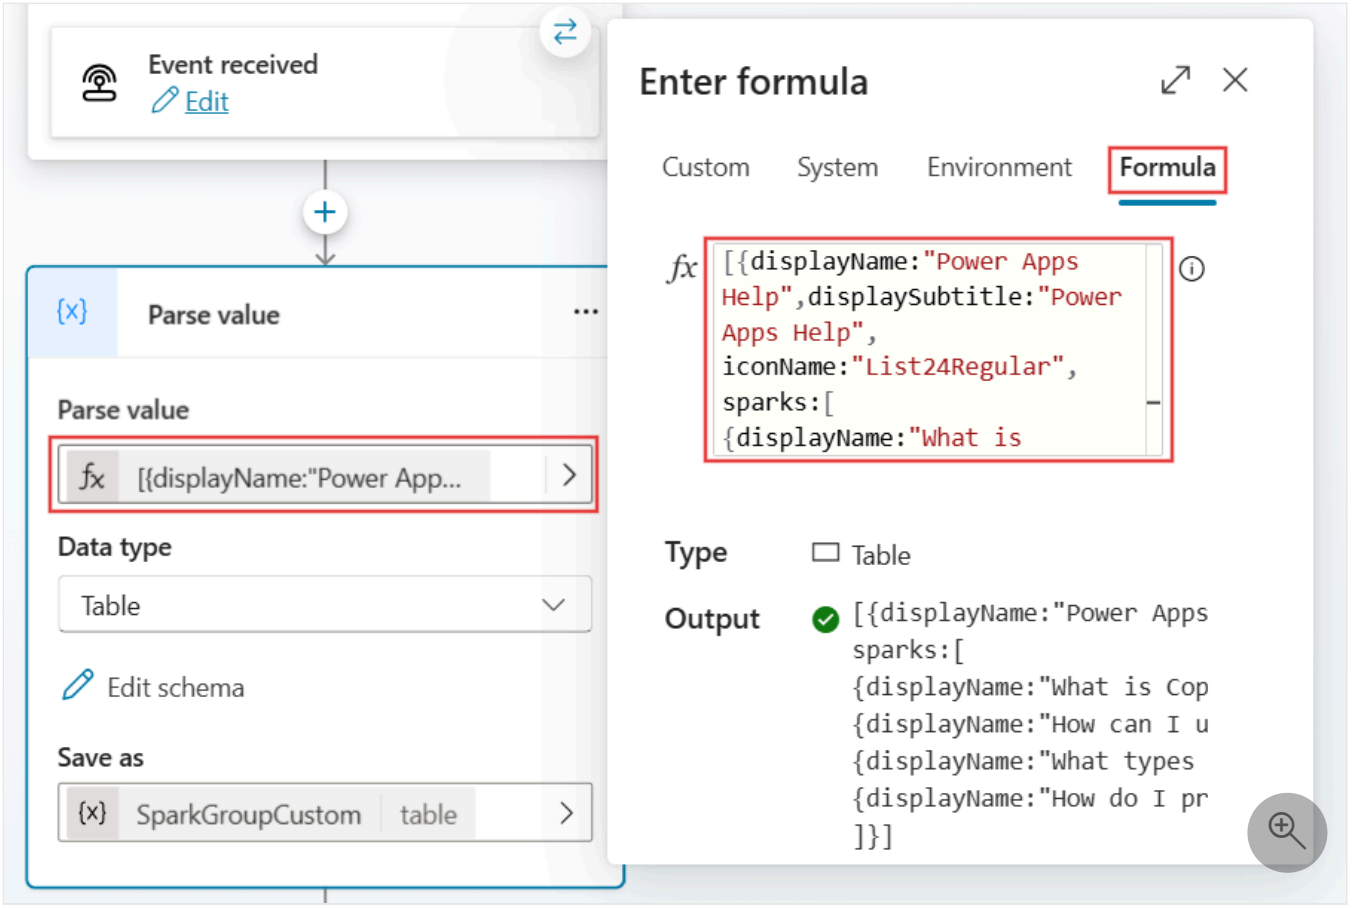
7. Paste the following Power Fx formula into the **Parse value** box, and then select **Insert**.

PowerApps Formula

```
[{displayName:"Power Apps Help",displaySubtitle:"Power Apps
Help",iconName:"List24Regular",sparks:[{displayName:"What is Copilot
chat?",type:"MCSMessageSkill"},{displayName:"How can I use the record
picker?",type:"PromptTextSkill"},{displayName:"What types of questions can I
ask Copilot?",type:"PromptTextSkill"},{displayName:"How do I provide feedback
on Copilot’s responses?",type:"PromptTextSkill"}]}]
```

For the sparks type you can either use `MCSMessageSkill`, which are directly sent to Copilot Studio as user messages or `PromptTextSkill` when you want to populate the **Chat Input** box. `PromptTextSkill` is useful when you want additional input from the user, such as specifying a record or table name among other things. For example: `How many **[table name]** are`

`active?` `What are the **[table name]** assigned to me?`

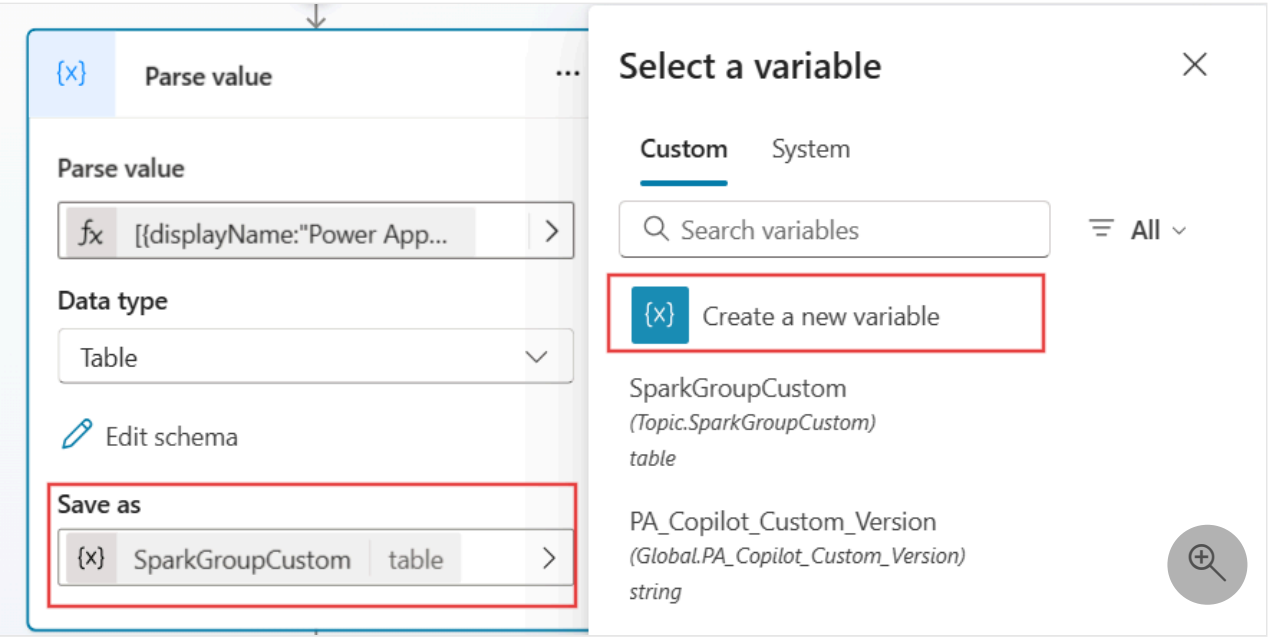


1. Set the **Data type** as **Table**. The **Edit schema** link appears.

2. Select **Edit schema** and paste the following schema, and then select **Confirm**.

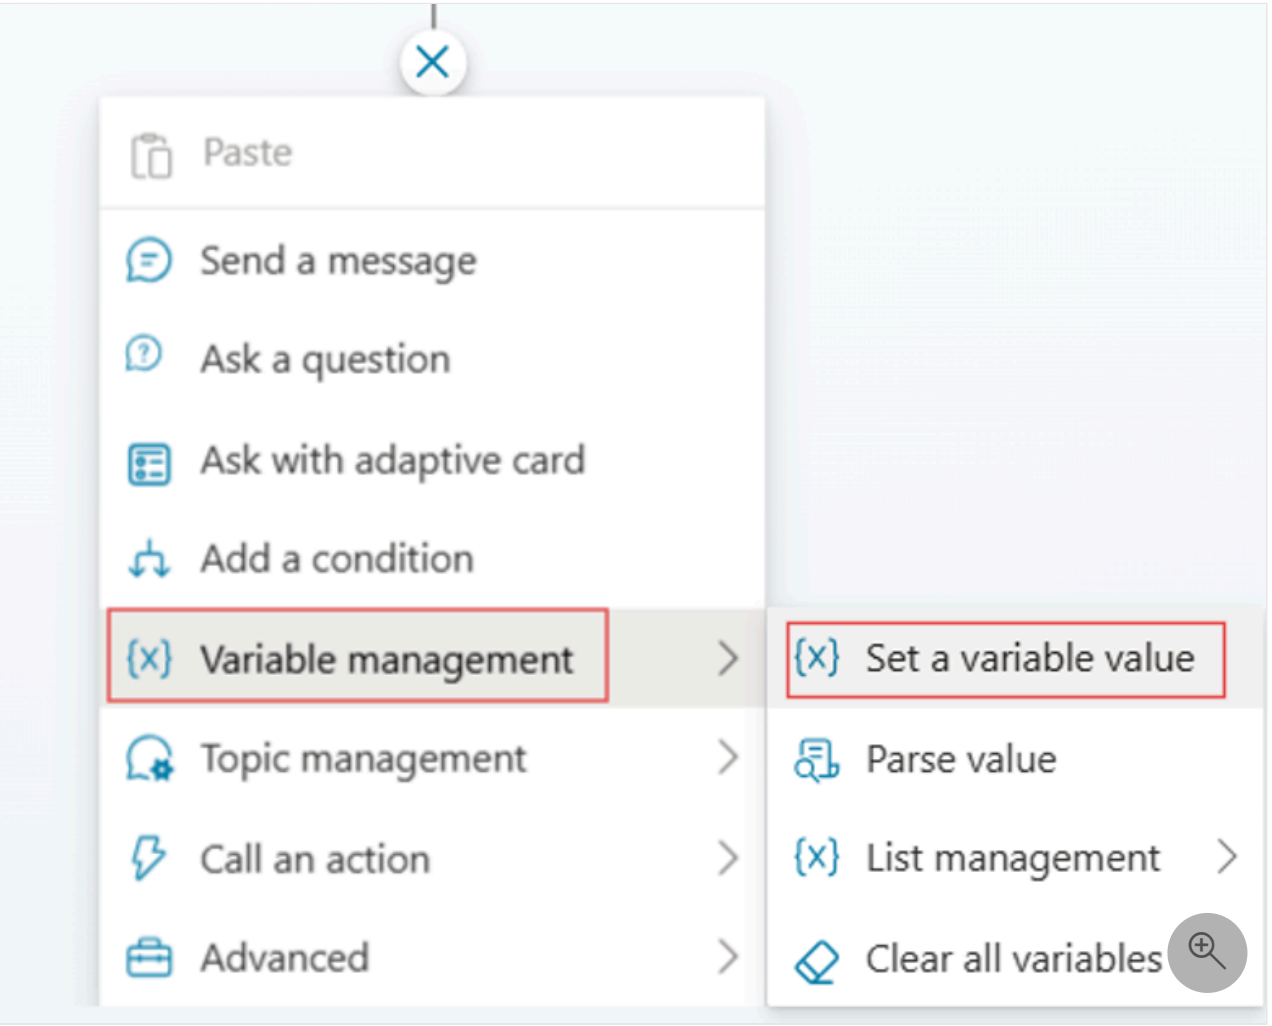
```yml
kind: Table
properties:
  displayName: String
  displaySubtitle: String
  iconName: String
  sparks:
    type:
      kind: Table
      properties:
        displayName: String
        eventName: String
        iconName: String
        payload: String
        type: String
```

3. Set **Save as** to save as a new custom variable and name it something meaningful such as *SparkGroupCustom*.



4. Select + under the **Parse value** step, and then select **Variable management** > **Set a variable value**.

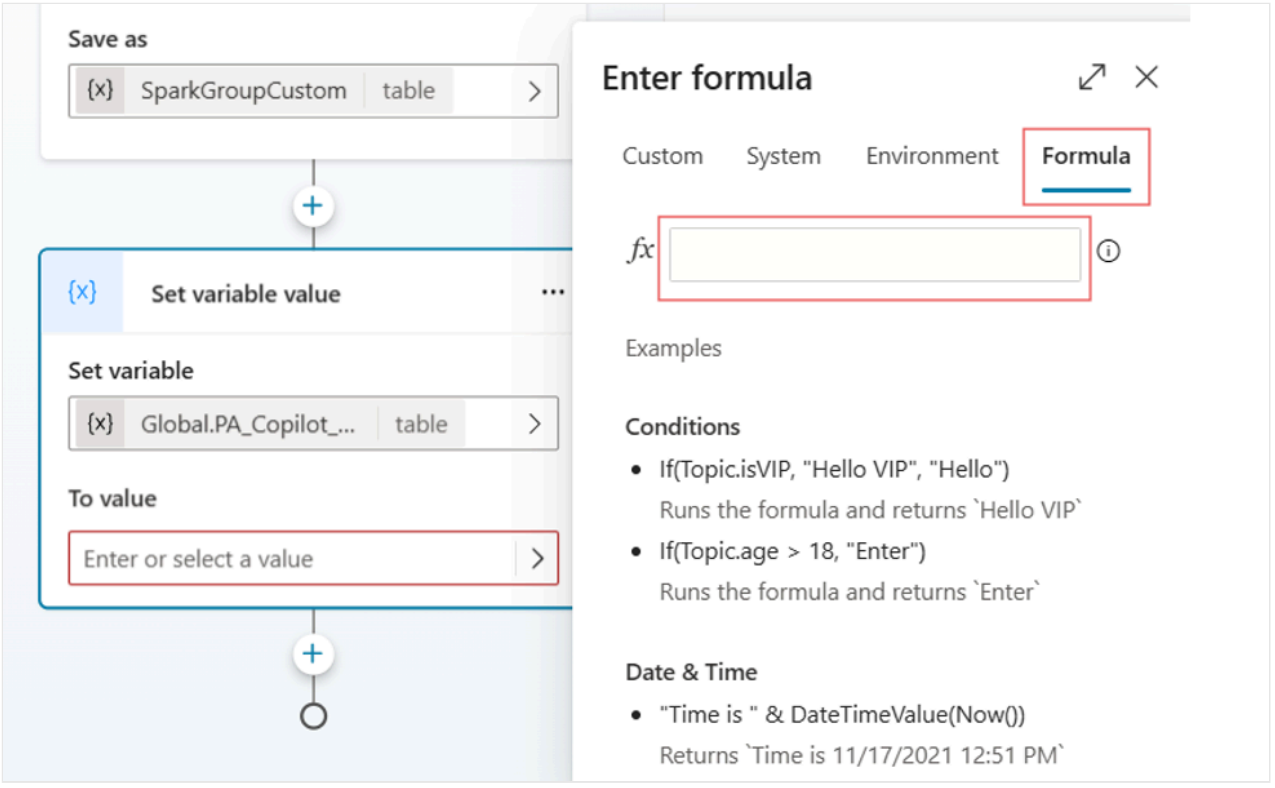
5. The sparks definition is saved in a global variable so you need to set the variable **Global** and name it `PA_Copilot_Sparks.sparkGroups` and/or `Global.PA_Copilot_Sparks.sparks`. This populates the flyout with your prompts. Next, add a step to set variable value.



6. Search for the sparks definition name from the previous step, such as `Global.PA_Copilot_Sparks.sparkGroups`, and set the value to the following Power Fx merge function.

PowerApps Formula

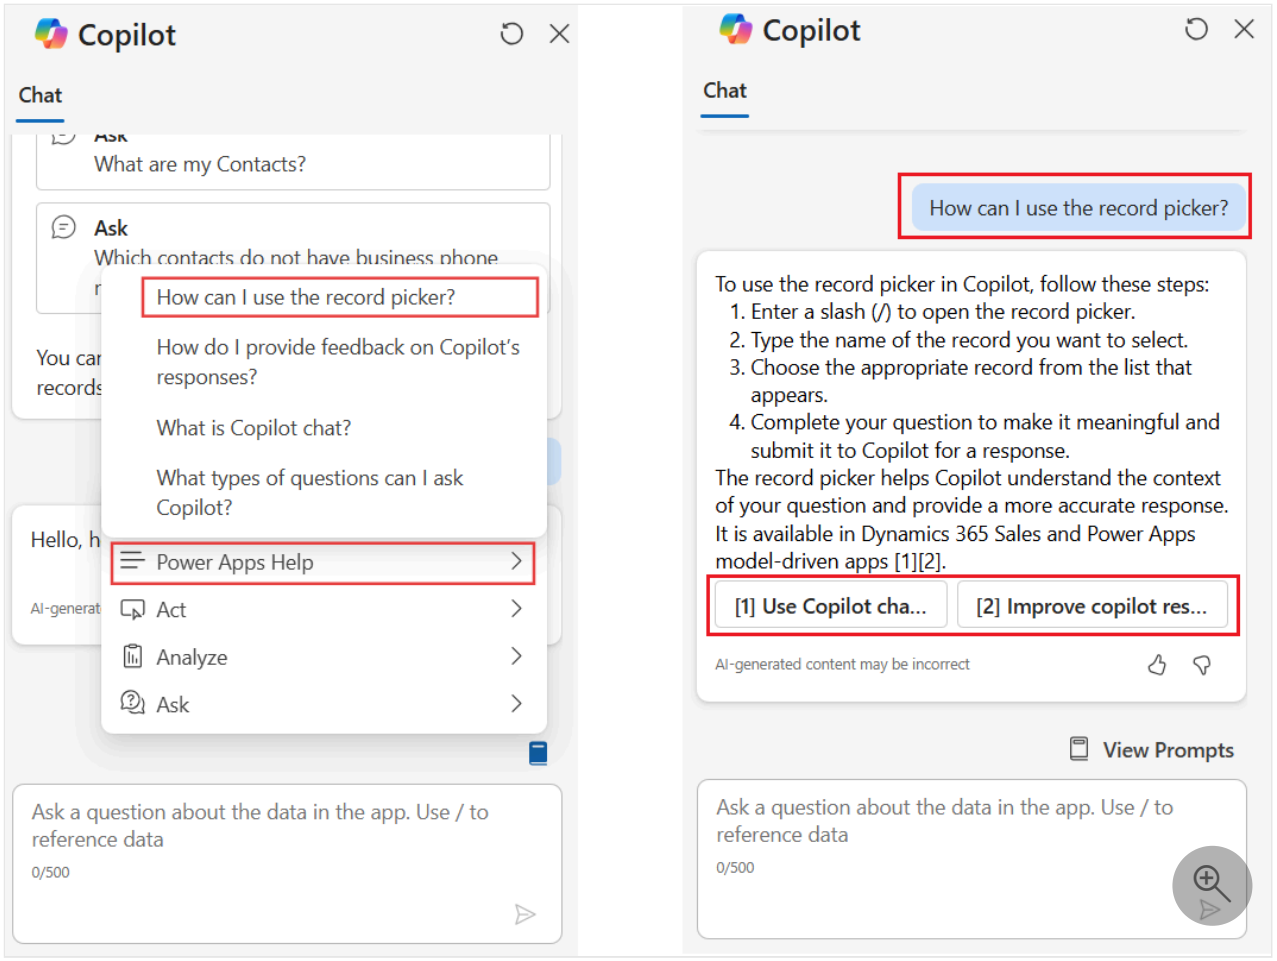
```
ForAll(Sequence(CountRows(Global.PA_Copilot_Sparks.sparkGroups)+CountRows(Topic
.SparkGroupCustom)),
If(Value<=CountRows(Global.PA_Copilot_Sparks.sparkGroups),Index
(Global.PA_Copilot_Sparks.sparkGroups,Value), Index(Topic.SparkGroupCustom,
Value - CountRows(Global.PA_Copilot_Sparks.sparkGroups))))
```



Merge

Replace the variable name with the variable name you used for the custom prompts, which in this example is *SparkGroupCustom*.

7. **Publish** the agent and play the app.



Prompt guide customizations topic sample

Here is the full topic code, which can be copied directly into the new topic.

yml

```yml
kind: AdaptiveDialog
beginDialog:
  kind: OnEventActivity
  id: main
  priority: 200
  eventName: Microsoft.PowerApps.Copilot.RequestSparks
  actions:
    - kind: ParseValue
      id: iCepPf
      variable: Topic.SparkGroupCustom
      valueType:
        kind: Table
        properties:
          displayName: String
          displaySubtitle: String
          iconName: String
          sparks:
            type:
              kind: Table
              properties:
```

```
                displayName: String
                eventName: String
                iconName: String
                payload: String
                type: String
      value: |-
        =[{displayName:"Power Apps Help",displaySubtitle:"Power Apps
Help",iconName:"List24Regular",
        sparks:[
        {displayName:"What is Copilot chat?",type:"MCSMessageSkill"},
        {displayName:"How can I use the record picker?",type:"MCSMessageSkill"},
        {displayName:"What types of questions can I ask
Copilot?",type:"PromptTextSkill"},
        {displayName:"How do I provide feedback on Copilot's
responses?",type:"PromptTextSkill"}
        ]}]

    - kind: SetVariable
      id: setVariable_pDu9cr
      variable: Global.PA_Copilot_Sparks.sparkGroups
      value:
=ForAll(Sequence(CountRows(Global.PA_Copilot_Sparks.sparkGroups)+CountRows(Topic.Spa
rkGroupCustom)), If(Value<=CountRows(Global.PA_Copilot_Sparks.sparkGroups),Index
(Global.PA_Copilot_Sparks.sparkGroups,Value), Index(Topic.SparkGroupCustom, Value -
CountRows(Global.PA_Copilot_Sparks.sparkGroups))))
```

> **Note**
>
> If your agent supports multiple languages and needs prompt guide translation, all your user facing question strings must be set using a `SetTextVariable`.

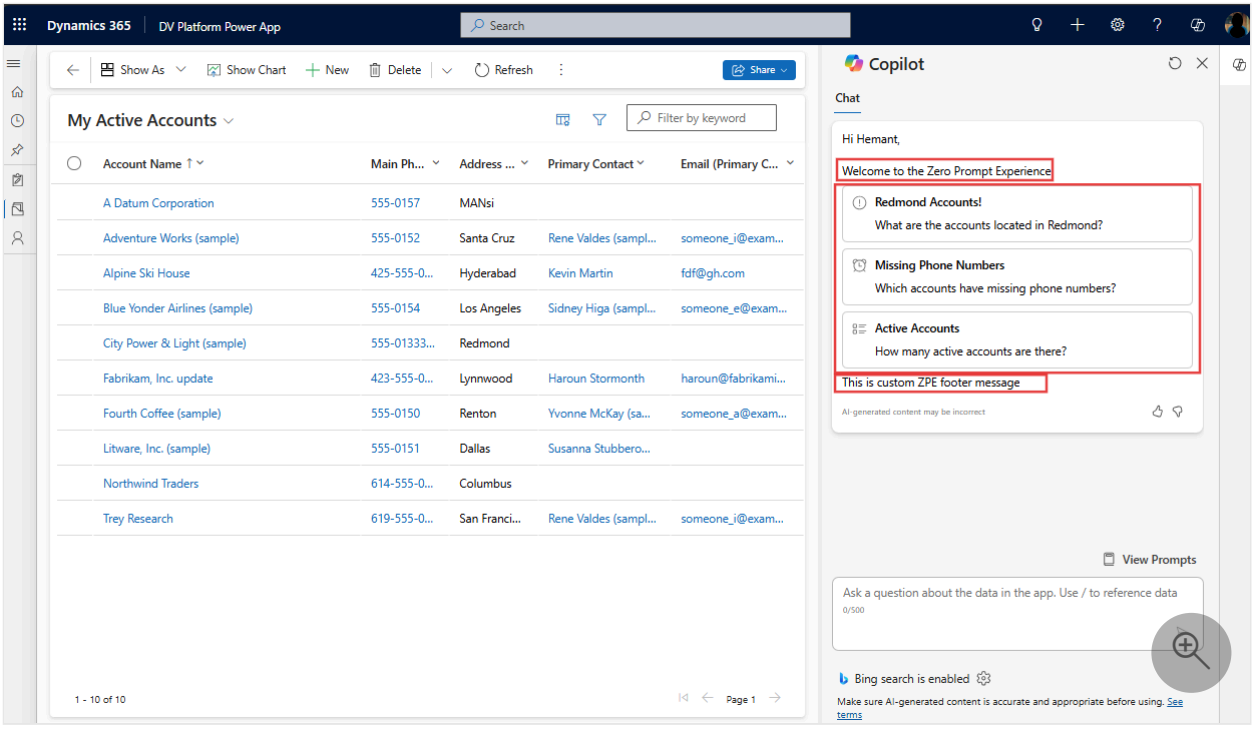
Zero prompt experience (preview)

Article • 03/11/2025

[This topic is pre-release documentation and is subject to change.]

The zero prompt experience helps makers enhance user engagement and streamline interactions at the start of a Copilot chat session. By presenting a zero prompt experience adaptive card at the beginning of a chat session, users receive relevant information and options right away, reducing the need for additional prompts and iterations. The zero prompt experience can be context aware and hence, can be selectively shown for targeted pages.

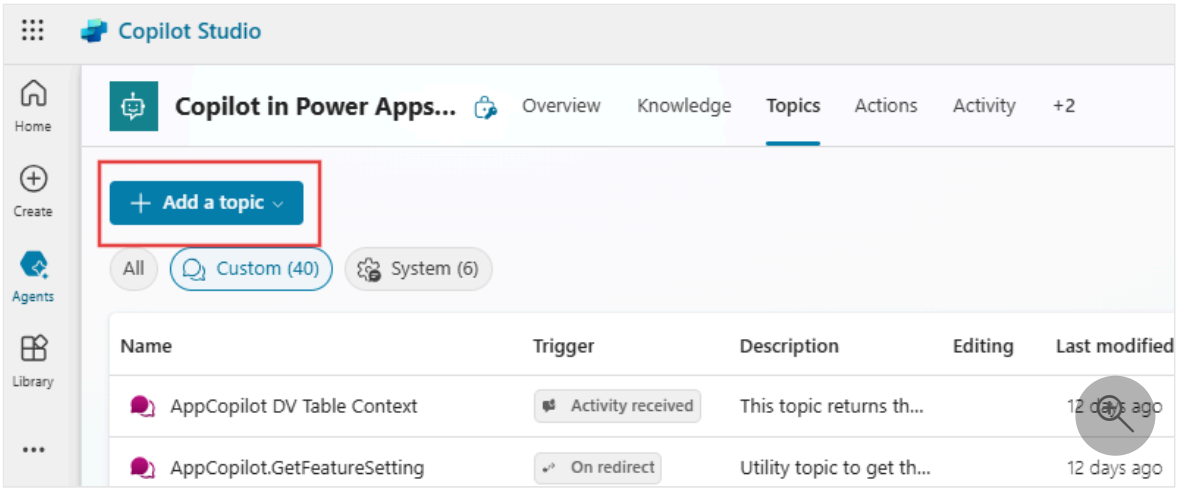


> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

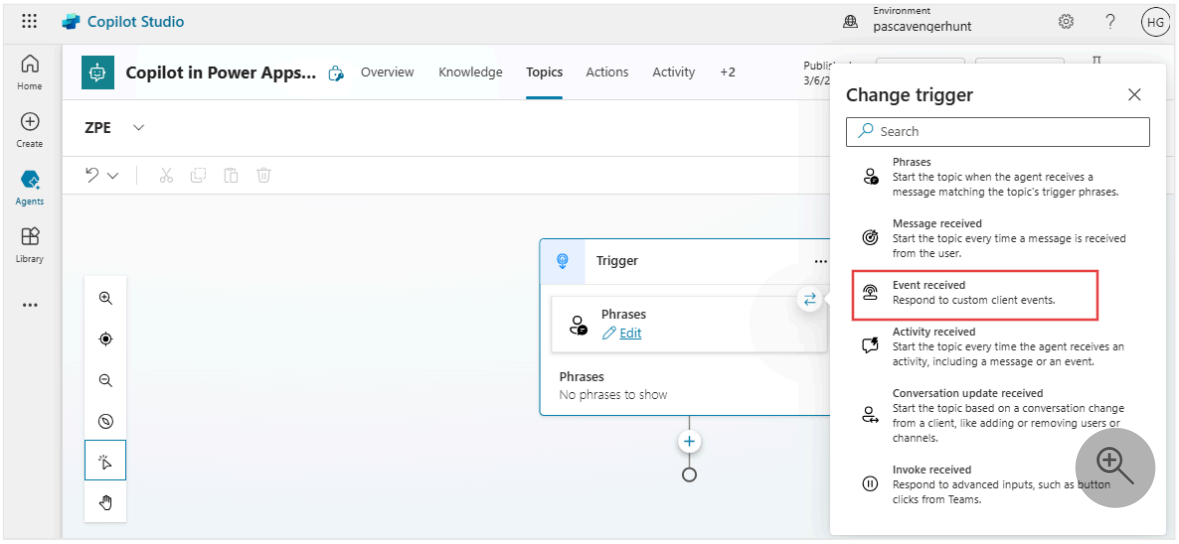
Customize the zero prompt experience

These steps detail how to customize the zero prompt experience.

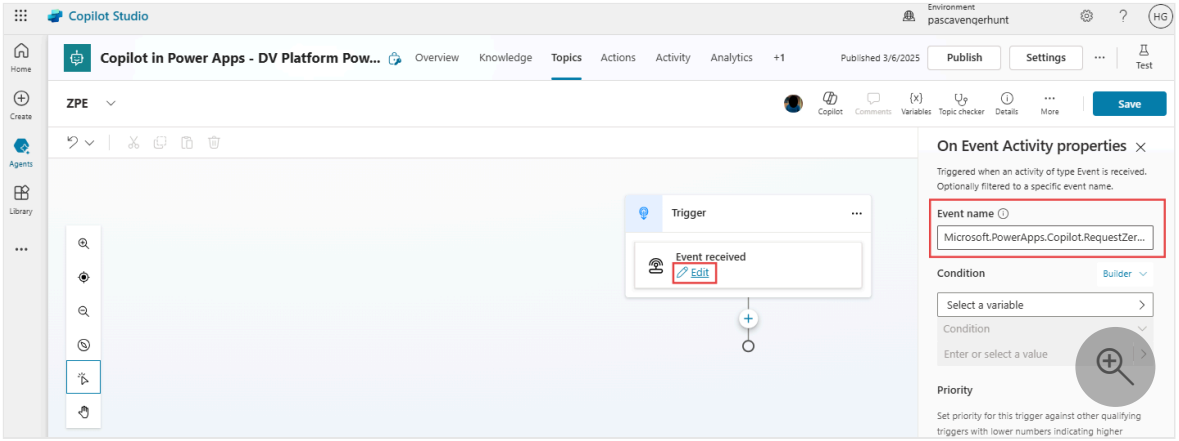
1. Open the agent backing the app in Copilot Studio and add a new blank topic.



2. Rename the topic to reflect the topic intent and change the topic trigger to **Event received**.



3. Select **Edit** under **Event received**, and then set the event name as `Microsoft.PowerApps.Copilot.RequestZeroPrompt`, which is the reserved name for the zero prompt experience. Set priority to higher than 99 but lower than 100000. The priority is important because custom zero prompt experiences need to override the default platform provided ones.



4. Optionally, you can also set the conditions to the zero prompt experience in case it's specific to the page context. For example, this entry checks if the page context's table type name matches account. If the condition is true, the custom zero prompt experience is shown. `condition:Global.PA__Copilot_Model_PageContext.pageContext.entityTypeName = "account"` After this step, you can build your zero prompt messages using adaptive cards. For more information regarding building adaptive cards go to this information: https://adaptivecards.microsoft.com/. Once you have zero prompt experience cards, you can set the global variable `Global.PA_Copilot_ZeroPrompt` to your adaptive card definition.

5. The zero prompt includes all the flexibility of adaptive cards and you can trigger different skills from within it. When an adaptive card contains a button or anything that requires an `Action.Submit`, you have a few options you can use to handle that event. These event handlers are called `SkillTypes`. `Action.Submit` types should include the following properties: a data object with `SkillType` and scenario properties. You can use `MCSMessageSkill`, which are directly sent to Copilot Studio as user messages, or `PromptTextSkill` when you want to populate the **Chat Input** box. `PromptTextSkill` is useful when you want additional input from the user, such as specifying a record or table name among other things. For example: `How many [table name] are active?` `What are the [table name] assigned to me?`

6. When you trigger zero prompts, your select an action structure that should look like the action structure here. The scenario value should be `ZeroPromptCard` along with the source value as `ZeroPrompt`. Lastly, the value corresponds to the actual prompt.

yml

```
   selectAction: {
   type: "Action.Submit",
   data: {
    scenario: "ZeroPromptCard",
    skillType: "MCSMessageSkill",
    value:  "What are accounts in Redmond?",
    source: "ZeroPrompt"
   }
},
```

Zero prompt experience topic sample

Here is the full topic code, which can be copied directly into the new topic. You can edit the zero prompt experience questions in the options shown here and reuse the predefined cards.

yml

```
kind: AdaptiveDialog
beginDialog:
  kind: OnEventActivity
  id: main
  condition:
=Global.PA__Copilot_Model_PageContext.pageContext.entityTypeName = "account"
  priority: 100
  eventName: Microsoft.PowerApps.Copilot.RequestZeroPrompt
  actions:
    - kind: SetVariable
      id: setVariable_acI6It
      variable: Topic.WelcomeMessage
      value: Welcome to the Zero Prompt Experience

    - kind: SetTextVariable
      id: setTextVariable_g4rSG0
      variable: Topic.FooterMessage
      value: This is custom ZPE footer message

    - kind: SetVariable
      id: setVariable_QUoZ5c
      variable: Topic.OverviewIcon
      value:

                                                },
                                                {
                                                    type: "Column",
                                                    width: "stretch",
                                                    items: [
                                                        {
                                                            type: "TextBlock",
                                                            text:
""&Topic.OptionThree.optionGroup&"",
                                                            weight: "bolder"
                                                        },
                                                        {
                                                            type: "TextBlock",
                                                            text:
""&Topic.OptionThree.prompt&""
                                                        }
                                                    ]
                                                }
                                            ]
                                        }
                                    ]
                                },
                                {
```

```
                                type: "Container",
                                id: "ms-platform-zpe-collapsed-footer-
79fb882f-ec4e-4abd-bc65-8c523849da40",
                                items: [
                                    {
                                        type: "ColumnSet",
                                        columns: [
                                            {
                                                type: "Column",
                                                width: "auto",
                                                items: [
                                                    {
                                                        type: "TextBlock",
                                                        wrap: true,
                                                        text:
""&Topic.FooterMessage&"",
                                                        id: "fsFooterId"
                                                    },
                                                ]
                                            }
                                        ]
                                    },
                                ]
                            },
                        ],
                        '$schema':
"http://adaptivecards.io/schemas/adaptive-card.json",
                        version: "1.5"
                    }
```

Use Excel and Word templates

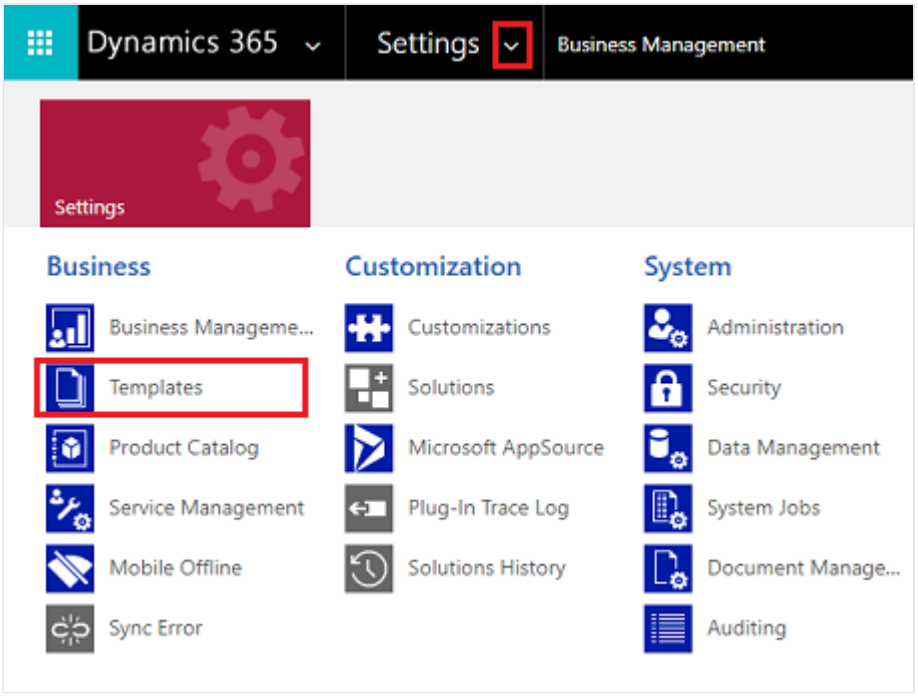
Article • 02/15/2022

You can use templates in a variety of ways to speed your work and improve consistency. With Excel templates, you can easily create and share your customized analysis with others in your organization. You can use Word templates to create standardized documents automatically populated with Microsoft Dataverse data.

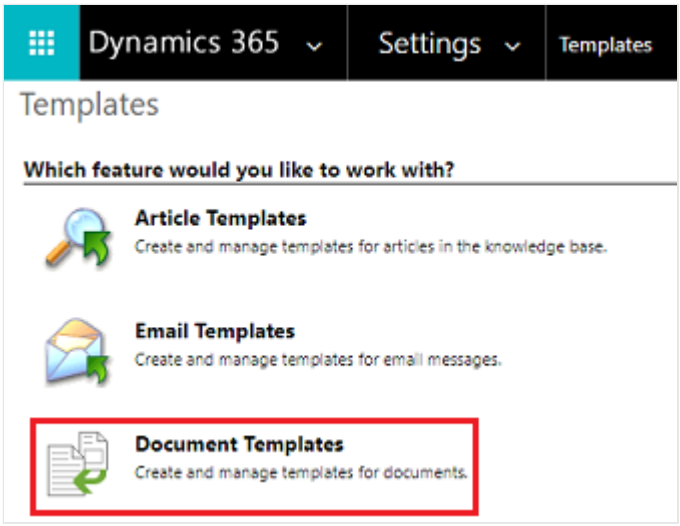
Enable and work with Excel and Word templates

1. Sign in to Power Apps and in the upper-right corner, select the  (upper right), and then select **Advanced settings**.

2. Select **Settings** > **Templates**.



3. On the **Templates** page, select **Document Template** to work with Excel or Word templates.



For information on using templates, see the following documentation:

- Word templates: Use Word templates to create standardized documents
- Excel templates: Analyze and share your data with Excel templates

Use modern themes in model-driven apps

Users of model-driven apps with the modern, refreshed look for model-driven apps enabled experience updated styling aligned to the Microsoft Fluent 2 design system. Because this modern refreshed look comes with a new theming system, classic theming isn't honored; however, makers can modify the colors used by the app to help align with their organizational branding for users who have enabled the modern, refreshed look. In this article, you learn about the styling overrides available with the modern, refreshed look and how to implement them for your organization.

> ⓘ Note
>
> - Modern themes currently support providing a custom theme for the entire app, overriding the app header colors, and setting a custom app logo. Other customizations like customizing the business process flow control aren't available.
> - For modern themes to work, the model-driven app must be using the **New look**. More information: Modern, refreshed look for model-driven apps

Modify the app theme

With the modern, refreshed look enabled in the app, makers can create a custom theme that helps align to their organizational branding. With a custom theme you can change the app header, hyperlinks, lookups, primary buttons, active tab indicators, row selection, and hover effects. The custom theme also lets you change the font that is used in the application. To accomplish this, you encapsulate the desired theme information into an XML resource, use an app setting to point to this web resource, and then verify the new modern theme matches your expectations.

> ⓘ Note
>
> Most of the UI uses your custom theme. However, some areas don’t use modern theming yet for example, legacy grids, row summaries, focus view, and the sales pipeline.

Overview of the custom theme XML resource

The first step to creating a custom modern theme is to create an XML file with your desired theme parameters, with one or more of the following attributes defined inside a `CustomTheme` tag.

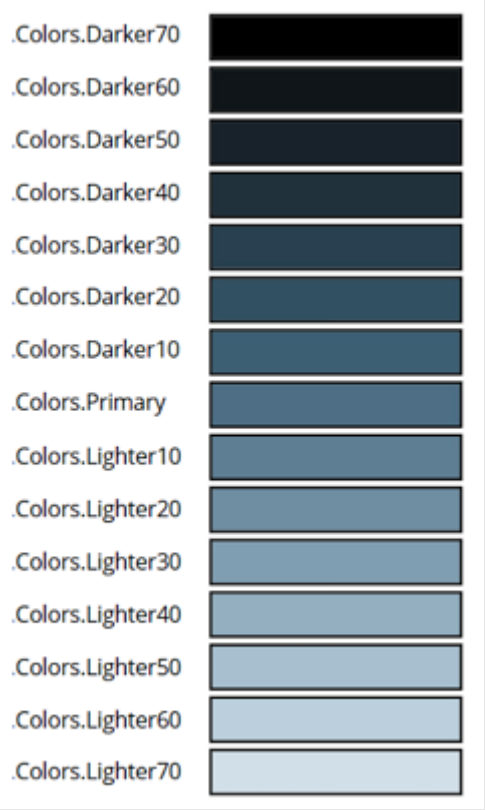
- `BasePaletteColor` – The seed color (HEX code) used as a basis to generate a 16-slot color palette for the theme.
- `LockPrimary` – A boolean that determines how the selected seed color is used to generate the 16-slot color palette.
  - False (Default): The palette is optimized for accessibility, but doesn't guarantee the seed color will appear in any slot of the generated palette. This is the default setting. Use the Fluent theme generator to preview the generated palette based on your selections for `basePaletteColor`, `vibrancy`, and `hueTorsion`.
  - True: The seed color is placed in primary (middle) slot of the palette. The remaining colors are generated by making the colors incrementally lighter on one side and darker on the other side. The generated palette might not meet contrast ratio accessibility requirements.
- `Font` – The font for your custom theme. The font that the custom theme renders depends on the browser and target machine's ability to show that font.
- `Vibrancy` – An optional parameter that impacts the muteness or brightness of the palette, especially the lighter colors. The allowed values are between -100 and 100, with a default value of 0. This option is only applicable when `lockPrimary="true"`.
- `HueTorsion` – An optional parameter that impacts the tint, shade, or tone of the palette, especially the lighter colors. The allowed values are between -100 and 100, with a default value of 0. This option is only applicable when `lockPrimary="true"`.
- `LogoWebResource` – The logical name of the image web resource to use as the logo in the app header. Logos that are too large don't display. The recommended image size is 156 pixels wide × 48 pixels high.
- `LogoTooltip` – The tooltip text displayed when a user hovers over the app logo. Defaults to *Dynamics 365* if not specified.

Override the palette

Overriding individual slots in the theme palette provides the creator with full control over the slot colors, which is particularly useful when additional modifications are required beyond the standard theme parameters mentioned above. To override a specific slot, assign a value to the desired slot by its name. For instance, you can specify the HEX code for `darker70`, `primary`, or `lighter10` to tailor the appearance precisely to your preference. Setting values for all 16 slots

completely overrides all the palette options described in the previous section, allowing for a highly customized and unique color scheme.

The slot names for the palette from darkest to lightest are: `darker70`, `darker60`, `...` `<>`, `darker10`, `primary`, `lighter10`, `lighter20`, `...`, `lighter80`. Refer to the Fluent theme designer to find out how these slots are generally used in Fluent controls.



Example XML for a custom theme

As an example, this XML specifies a custom theme that is green with a different font and a custom logo.

XML

```
<CustomTheme
    basePaletteColor="#00FF00"
    vibrancy="0"
    hueTorsion="-50"
    font="'GreatVibes', cursive"
    logoWebResource="contoso_company-logo"
    logoTooltip="Contoso"
/>
```

This XML specifies a custom theme using the alternate palette generation algorithm with an override for a single slot.

XML

```
<CustomTheme
    basePaletteColor="#00FF00"
    lockPrimary="false"
    font="'GreatVibes', cursive"

    lighter70="#FFFFFF"
/>
```

Modify the app header colors

Makers can customize the styling of the app header to deviate from the app theme. To make these customizations, extend the XML created for the custom modern theme by adding one or more of the following attributes inside an `AppHeaderColors` tag.

- `Background` – The background color of the app header. This element must be defined for any changes to take effect.
- `Foreground` – The text color of the app header. If this isn't specified, the system attempts to calculate an appropriate color that has sufficient contrast to the provided background color.
- `BackgroundHover` – The background color of buttons on the app header when they're hovered over. If no value is specified, the system calculates a color based on the background color.
- `ForegroundHover` – The text color of buttons on the app header when they're hovered over. If no value is specified, the system attempts to calculate an appropriate color that has sufficient contrast to the `backgroundHover` color.
- `BackgroundPressed` – The background color of buttons on the app header when they're pressed. The defaulting logic is the same as `backgroundHover`.
- `ForegroundPressed` – The text color of buttons on the app header when they're pressed. The defaulting logic is the same as `foregroundHover`.
- `BackgroundSelected` – The background color of buttons on the app header when they're selected. The defaulting logic is the same as `backgroundHover`.
- `ForegroundSelected` – The text color of buttons on the app header when they're selected. The defaulting logic is the same as `backgroundHover`.

Example XML for a modern theme

As an example, this XML extends the green custom theme with a black app header. For optimal usability, we recommend specifying different color values for each interaction state.

XML

```
<CustomTheme
    basePaletteColor="#00FF00"
    vibrancy="0"
    hueTorsion="-50"
    font="'GreatVibes', cursive"
>
  <AppHeaderColors
    background="#000000"
    foreground="#FFFFFF"
    backgroundHover="#313131"
    foregroundHover="#FFFFFF"
    backgroundPressed="#494949"
    foregroundPressed="#FFFFFF"
    backgroundSelected="#717171"
    foregroundSelected="#FFFFFF"
  />
</CustomTheme>
```

> **Note**
>
> These settings cause any colors specified in the **Override app header color** setting to be ignored.

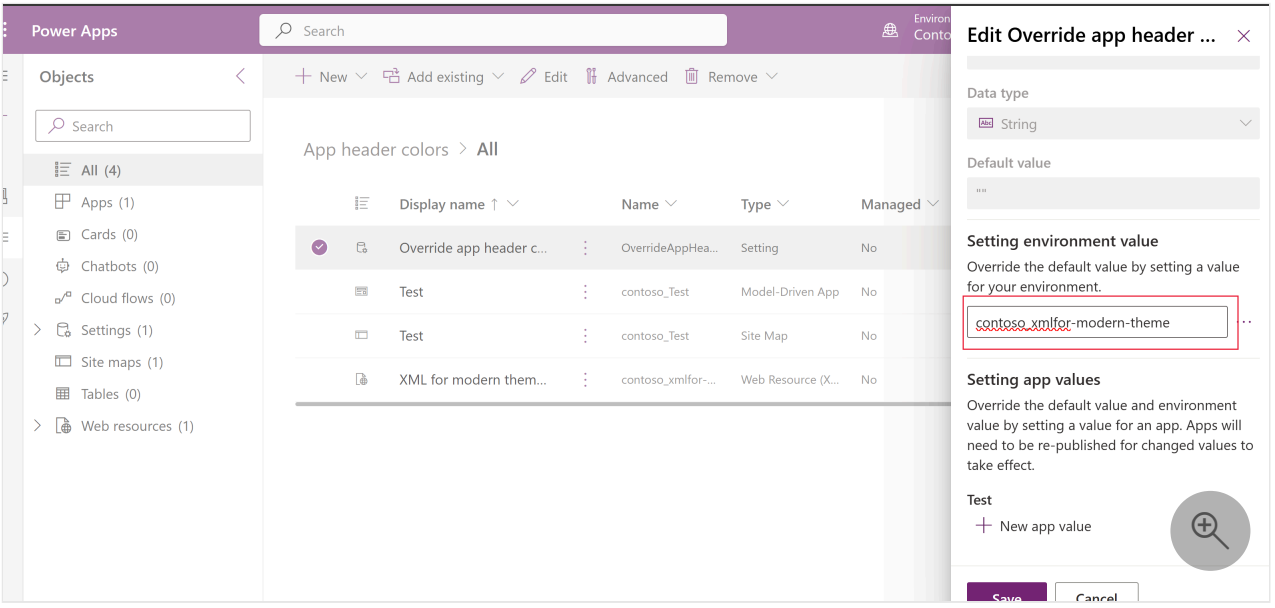
Create the web resource

1. Using a text or XML editor, save the XML that is used to create the web resource. Example XML for a modern theme
2. Sign into Power Apps.
3. Select **Solutions** on the left navigation pane, and then create a **New solution**.
4. Select **New** > **More** > **Web resource**.
5. Select **Choose file**, browse to and select the XML text file you created earlier.
6. In the **New web resource** property pane, enter the following values:
   - **Display name**: Enter a display name, such as *Green custom theme*.
   - **Name**. Accept the automatically generated or enter a unique name for the web resource.
   - Type: **Data (XML)**
7. Select **Save**. You publish this customization with the steps in the next section.

Apply the custom theme to apps in your environment

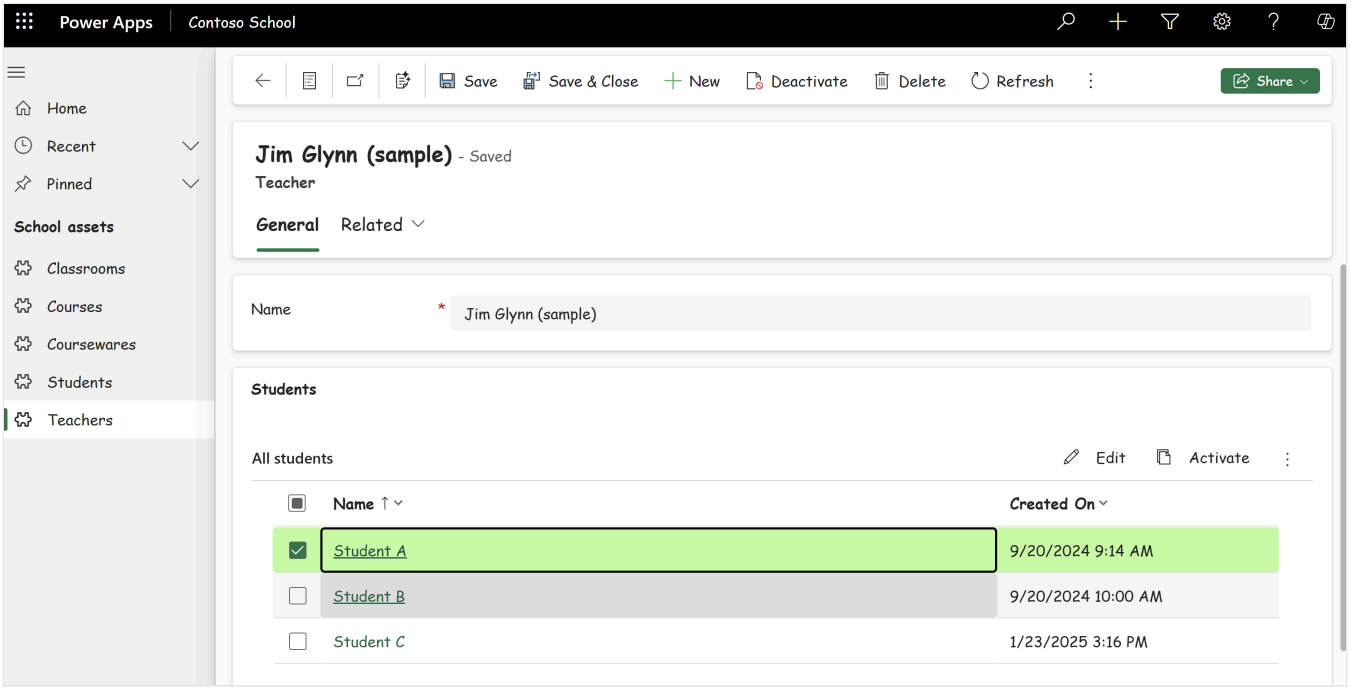
After you select your colors and create the web resource, follow these steps to enable this app header styling for all the apps in your environment that have the **New look** enabled.

1. In the solution you used to create the web resource, select **Add existing** > **More** > **Setting**.
2. Type *custom theme* in the **Search** box, select **Custom theme definition**, select **Next**, and then select **Add**.
3. In the solution, select **Custom theme definition**, and then select **Edit** on the command bar.
4. On the right **Edit Custom theme definition** properties pane, select **New environment value** under **Setting environment value** and enter the unique name of your web resource you created earlier (observe the **Name** column in the solution for the unique name). Remove the double quotes and make sure to add the publisher prefix for the web resource. For example, the name might appear as *contoso_green-custom-theme* as in this example.



5. Select **Save**.
6. Select **Settings** on the left **Objects** pane, and then select **Publish all customizations** on the command bar. (This command appears when no components in the solution are selected).

Custom model-driven app using the extended green theme sample.



Verifying new app header colors

After publishing your custom theme, validate the application of the theme in the app to ensure everything appears as you expect.

Modify the app header colors only

Makers can choose to only customize the styling of the app header to deviate from the default app theme. This can be done by following these steps:

1. Create an XML file with your various color selections, with one or more of the attributes from app header color overrides section defined inside an `AppHeaderColors` tag.
2. Create a web resource using the same process described for custom themes, but be sure to give the XML resource an appropriate descriptive display name, such as *Green app header XML*.
3. Apply custom app header colors to apps in your environment by assigning this web resource to the environment or app in the **Override app header color** setting. Follow the steps from Applying custom themes to your environment but use the **Override app header color** setting instead.

> **Note**

> The **Override app header color** setting is ignored if the **Custom theme definition** setting is defined.

4. Verify your custom app header visuals, including all button states, to ensure everything appears as you expect and there are sufficient contrast ratios for accessibility. Verify the following color choices:

    - The desired colors are shown for the app header at rest and for each button interaction state.
    - There's a minimum of a 4.5:1 contrast ratio between foreground and background colors for the rest state and each button interaction state.

Example XML for app header color override

As an example, this XML specifies a green background color for the app header with white text, with darker background colors for the various button interaction states. For optimal usability, we recommend specifying different color values for each state.

XML

```
<AppHeaderColors
  background="#12783F"
  foreground="#FFFFFF"
  backgroundHover="#165A31"
  foregroundHover="#FFFFFF"
  backgroundPressed="#0F1C12"
  foregroundPressed="#FFFFFF"
  backgroundSelected="#153D23"
  foregroundSelected="#FFFFFF"
/>
```

When you play the app, the app header looks like the following image. You might need to refresh the browser tab to display the theme.

Modern refreshed look

Last updated on 04/06/2026

Use a theme to create a custom look for your app

You can create a custom look and feel (a theme), for your app by making changes to the default colors and visual elements provided in the uncustomized system. For example, you can create your personal product branding by adding a company logo and providing table-specific coloring. A theme can be created without requiring a developer to write code. You can create, clone, change, or delete themes that are used in your environment.

> **Note**
>
> There's newer way to create themes in model-driven apps for customizing the model-driven app header. More information: Use modern themes
>
> You can define multiple themes, but only a single theme can be active in an environment and is identified as the default theme. To make a theme active, you publish it.

Use themes to enhance the user interface and create your product branding

Theming is used to enhance the app user interface, not drastically alter it. The theme colors are applied globally throughout your model-driven apps. For example, you can enhance the following visual elements in the UI:

- Change navigation colors to create product branding.
- Adjust accent colors, such as hover or selection colors.
- Provide table-specific coloring.
- Logo. (Use an existing or add a new image file as a web resource.)
- Logo tooltip.
- Navigation bar color.
- Title text color.

- Selected link color.
- Hover link color.
- Legacy accent color (primary background for process controls).
- Default color for tables.
- Default custom tables color.
- Control fill color.
- Control border color.

Solution awareness

Themes aren't solution aware. The changes made for an organization's theme aren't included in solutions exported from the organization. The data is stored in the theme table that can be exported and reimported in another environment. The imported theme must be published to take effect.

Copy and alter the existing theme

The easiest and quickest way to create a new theme is to clone and alter an existing theme. Then save, preview, and publish it.

1. Sign in to Power Apps, select **Settings**  (upper right), and then select **Advanced settings**.
2. On the classic settings page, select **Settings** > **Customizations** > **Themes**.
3. Under **All themes**, select the theme you want to clone, such as the **CRM Default Theme**. Select **Clone** on the command bar.
4. Open the cloned theme, and then replace an existing UI item's hexadecimal number, such as the **Title Text Color**, with the hexadecimal value that represents the color you want.

For example, the **CRM Default Theme** was cloned and changed using mostly varying shades of green color. The following screenshots show the new colors for navigation and highlighting. A custom logo was also added that appears in the upper left corner of an app.

THEME

Gentle Green Theme

Theme Name

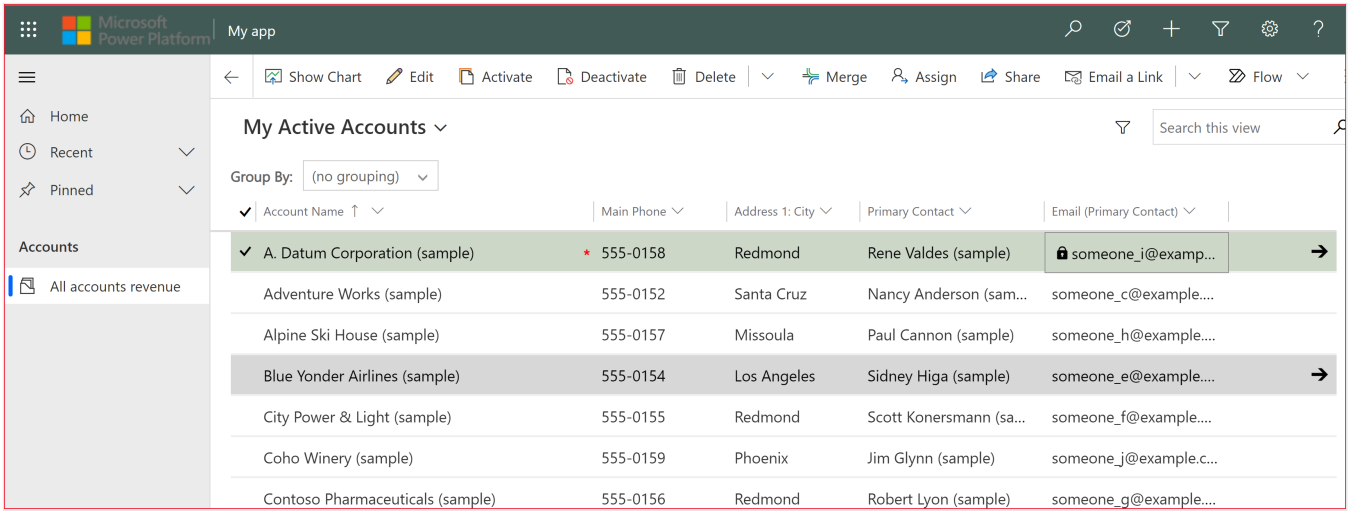
Theme Name *	Gentle Green Theme

Navigation Bar

Logo	new_defaultlogo	
Logo Tooltip	MS Green	
Navigation Bar Fill Color	#415C55	
Navigation Bar Shelf Fill Color	#79AB9E	
Title Text Color	#358717	
Main Color	#65825C	
Accent Color	#A4D194	

UI Elements	
Link and Button Text Color	#415C55
Selected Link Color	#65825C
Hover Link Color	#A4D194
Legacy Accent Color	#358717
Default Entity Color	#666666
Default Custom Entity Color	#00CCA3
Control Hover Fill Color	#FFFFFF
Control Hover Border Color	#BDC3C7
Page Header Fill Color	#E0E0E0
Panel Header Fill Color	#F3F3F3

The following image shows an app account view with the new colors and logo.



Important

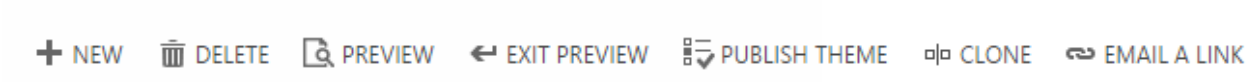
Logos that are too large don't display. The image used in the example is 156 pixels wide x 48 pixels height.

Preview and publish a theme

To preview and publish a theme, do the following steps:

1. Create a **New** theme from scratch or **Clone** an existing one.
2. **Preview** the new theme. To exit the preview mode, choose **Exit Preview** on the command bar.
3. Publish the theme. Select **Publish Theme** on the command bar to make it the active (default) theme in the environment.

The following screenshot shows the buttons on the command bar for preview and publishing.



Best practices

Following are the recommendations for designing theme contrasts and choosing colors.

Theme contrast

We recommend the following approach to providing contrast colors:

- Carefully choose the contrasting colors. The Microsoft Dataverse out-of-the-box default theme has the correct contrast ratios to ensure optimal usability. Use similar contrast ratios for your new themes.
- For high contrast mode, use the default color settings.

Theme colors

We recommend that you don't use a large number of different colors. Although you can set a different color for every table, we recommend one of two patterns:

- Make all tables in neutral colors and highlight the key tables.
- Use the same color for similar tables or related tables, such as queue and queue item, or product catalog tables. Keep the total number of groups low.

Custom theme considerations

You should consider the following when planning on using custom themes:

- Most updated user interface (UI) areas will be displayed in the custom theme colors.
- Even though the theme colors are applied globally throughout the application, some legacy UI areas, such as gradient buttons, retain the default colors.
- Certain areas must use dark or light colors to contrast with the default icon colors. The icon color isn't customizable.
- A table can't be displayed in different colors under different Sitemap nodes.
- The Sitemap nodes colors aren't customizable.

Known issues with mobile devices and themes

The custom theme isn't applied on devices running the Power Apps mobile app

When you run the Power Apps mobile app with an environment that is using a custom theme as the default theme, the mobile device displays the system CRM Default Theme.

Card forms aren't displayed in table views in a web browser

On a mobile device running the app in a web browser, the view is displayed in the standard view, which isn't optimized for small screens and is displayed similar to the image here. For more information about card forms, see Create a card form.

Create guided help for your model-driven app

06/02/2025

Use custom help panes and guided tasks to give your Unified Interface application a custom in-product help experience that is tailored to your organization. Use custom help panes to provide table, form, and language-specific help and guidance that includes rich text, content links, images, and video links.

> **Important**
>
> - Custom help panes replace the previous learning path guided help feature used with legacy web client apps.
> - Custom help panes don't work with Unified Interface apps running on a mobile device, such as Android and iOS tablets and smartphones.

Custom help panes and learning path

The new guided help implementation of custom help panes differs from the previous learning path guided help feature. Both features let you create custom help for your application. However, custom help panes are optimized for the most common guided help scenarios.

Custom help panes provide the following key features that are not available with learning path:

- Free-form rich text, including bullets and numbering.
- Visibly linked coach marks and help balloons.
- More options for video sources, including private sources.
- Storage of help content in Microsoft Dataverse as part of your solution.

Custom help panes don't provide the following key features that are available with learning path:

- Sequential help balloons.
- Help pages per role.
- Help pages for per-device form factor, such as smartphones.

Prerequisites

To use the custom help panes feature, your environment needs the custom help panes environment setting enabled.

Enable custom help panes for your environment

1. Sign in to the Power Platform admin center at https://admin.powerplatform.microsoft.com.
2. In **Settings** for the selected environment, select **Product** > **Features**.
3. Under **Help features** turn **Enable Custom Help Panes** to **On**.

> **Important**
>
> You can enable custom help panes or customizable help, but not both at the same time. Confirm that **Use help for customizable entities** is set to **No**.

Privileges required

- To author help panes, app makers need global create, read, write, delete, append, and append to privileges on the **Help Page** table. By default, System Administrator and System Customizer security roles both have this privilege.
- To view help panes in an app, users need read privilege on the **Help Page** table. By default, the Help Page Consumer security role has this privilege. By default, the Basic User security role doesn't have any privileges on the Help Page table.

More information: Security roles and privileges

Context-sensitive custom help

Each help pane is unique for these contexts:

- Table
- Form
- Dashboard
- Language
- Application

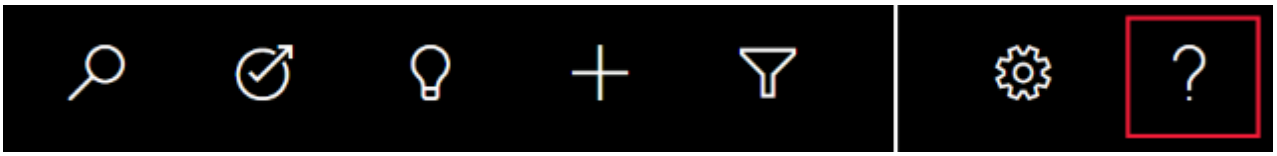
Help pane navigation

By default, a help pane stays open and on the help content you first opened it with even when you navigate to a different form. This allows for the help content to remain intact as you direct

users to different parts of the app.

To author help pane content

1. To view the help pane, open a model-driven app, and then on the command bar select **Help**.



2. On the Help pane, select the vertical ellipsis, and then select **Edit**.

   The help pane is now in edit mode and the cursor is positioned on the help pane title.

3. From the edit pane you can perform the following tasks:

   - Enter text by typing directly in the help pane area.
   - Format text through rich text capabilities and add bullet/numbered lists, sections, videos, images, links, coach marks, and balloon help.

4. To save your changes, select **Save**.

Free-form text

Text can be placed anywhere within the help pane. Enter free-form text before, in, or after sections. Text supports bold, italic, underline, and strikeout font formats. Cut, copy, and paste can be used as well as multilevel undo.

Bullets and numbered lists

Selecting the bullet or number icon toggles the current line to become bulleted or numbered. If you have selected multiple lines in a list, each line becomes bulleted or numbered. Tabbing and indenting subnumbers align within the list.

Sections

A section is a collapsible text box. You can put links or free-form text in it. Use a section to group similar items. A section can be either open or collapsed by default.

Video and static images

You can insert videos and static images into your help pane. Videos and images are links to content on the internet. Custom help panes do not store the video and image files in your help pane. When the help pane is opened, custom help panes bring the content in from the link to display it. You can use a link to a Microsoft Stream video if you want to reference corporate private content.

> **Tip**
>
> Remember to copy the link URL for the video or image you want so you can paste it into your help pane.

Custom help panes support the following video sources:

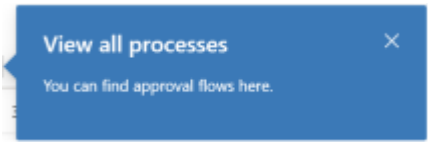
- Microsoft Stream (Classic) (use for private content)
- YouTube
- Facebook
- Vimeo

Links

Links can be to websites and open in the same window (the default) or open in a separate window. The ability to link to an existing help page is not yet enabled.

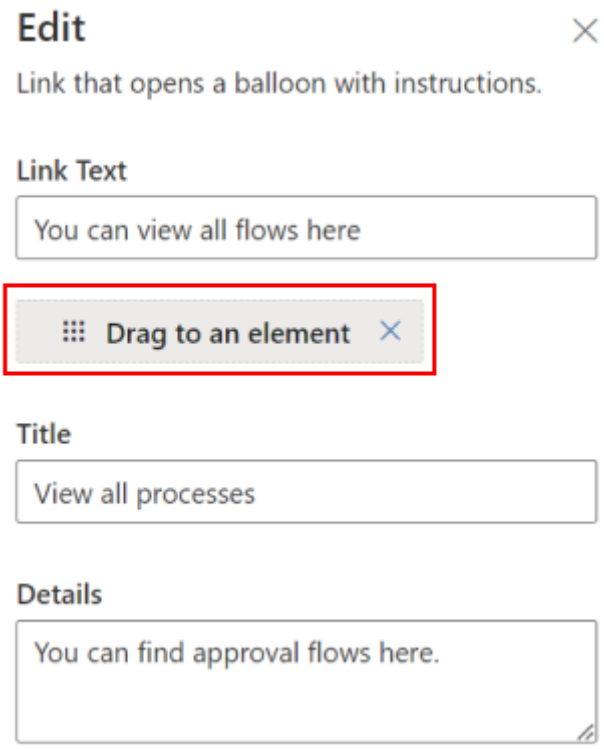
Balloons and coach marks

Balloons and coach marks can be used to point to specific UI elements. A balloon can have text in it.



A coach mark simply highlights an element with a coach pointer to draw the user's attention to that UI element.

Author needs to define the target through drag and drop capability in the properties of balloons and coach marks. Author can input the text for title and description for coach marks.



> **Note**
>
> - Balloons and coach marks don't work well with custom components. This feature only applies to default Unified Interface UI components.
> - Sequential help balloons and coachmarks are not supported yet.

Solutions and custom help pane content

All help content is stored in a help page component in Dataverse as part of your solution. When you move your solution from one environment to another, such as from test to

production, you can define that your help rows are exported so that they are included in the solution. This enables you to keep your help content in sync with features in your solution as it moves to different environments. As a part of your solution, custom help panes support all standard solution application lifecycle management (ALM) features.

Moving content via solutions

By default, all new help pages appear in the default solution. If you want to move your content to another environment, first add your existing help pages into an unmanaged solution before you export them. To add a help page to an unmanaged solution, follow these steps:

1. Sign into Power Apps.
2. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the unmanaged solution you want.
4. Select **Add Existing** on the command bar, and then select **Help Page**.
5. Select the help pages that you want to add, and then select **Add**. More information: Export solutions

Help page documentation automation

You might want to back up or store your content in a source code control system. You might also like to use documentation automation tools, such as translation tools or checkers, on help pane content. The custom help pane data is stored directly in Dataverse and can be exported and imported for this purpose.

Custom help panes support a custom XML format. This format is documented below. More information: Custom help XML definition

When exported, each help page is exported as a separate file.

About the Contextual Help managed solution

The custom help panes and guided tasks feature consists of the solution components in the Contextual Help managed solution. Customizing or creating records using the tables outside of the custom help panes and guided tasks feature isn't supported.

Notice that some apps, such as Dynamics 365 Sales and Dynamics 365 Service, include first run experiences that are built by using tables included in the Contextual Help managed solution. For example, both the Help Page (msdyn_helppage) and Tour (msdyn_tour) tables are used in

the creation of these first run experiences. Currently, the custom help panes and guided tasks feature doesn't support creating these first run experiences.

Frequently asked questions

This section discusses frequently asked questions about custom help pages.

Are custom help pages the same as customizable help?

Custom help panes and guided tasks are an option in the **Set custom help URL** section of system settings. Custom help panes and guided tasks enable a customizable help pane that shows up right next to the user's form. The other options in this system settings set custom help section comprise the customizable help features. They allow you to override the default apps help and point users in your organization to a different URL for help. Alternatively, you can override the help for a highly customized table so that you can better describe your workflow.

For more information about customizable help, see Enable and use customizable help.

How do I migrate my data from learning path to custom help pages?

Learning path has two types of help: help panes and sequential help balloons. The sequential help balloon locations are deeply integrated with the legacy web client UI and are not transferrable to the new custom help panes.

Depending on how much text you have in your guided help it might be easiest to simply copy the information directly from the learning path user interface to the new custom help pane user interface. However, you can also export your learning path help content. The simplest way to do this is to export your content using the **Learning Path** > **Content Library** > **Localize** > **Export** feature. Select the rows you want and then export them. This creates an XLIFF file for each help pane and guided task. Then, use a publicly available XLIFF editor or XLIFF to HTML converter to retrieve your content.

Custom help XML definition

This section describes the custom help XML definition.

PPHML

```
<pphml>
    <h1>FAQ</h1>
    <collapsible title="What is PPHML?">
        <p>PPHML is a domain specific language for help content. It is used to
create help content that includes elements such as images, videos, balloons, coach
marks, etc.</p>
    </collapsible>
    <collapsible title="What does PPHML stand for?">
        <p>PPHML stands for Power Platform Help Markup Language</p>
    </collapsible>
</pphml>
```

Definition and usage

The `<pphml>` element tells the help browser that this is a PPHML document.

The `<pphml>` element represents the root of a PPHML document.

The `<pphml>` element is the container for all other PPHML elements.

Title

Presents a title in a help page.

```
<h1>This will be displayed at the top of the help page</h1>
```

Definition and Usage

The **`<h1>`** element defines the title of a help page.

`<h1>` This must be the first element inside `<pphml>`.

Image

Presents an image in a help page.

```
<img src="smiley.gif" alt="Smiley face" title="Smiley face"/>
```

Definition and usage

The `<img>` element embeds an image in a help page.

Attributes

- `src`: Specifies the URL of an image. This attribute is required.
- `title`: Specifies a title to show along with the image, typically as a hover tooltip.
- `alt`: Specifies an alternate text for an image. This text is used by screen readers.

Video

Presents a video in a help page.

```
<video src="https://www.youtube.com/watch?v=WSWmn7WM3i4" />
```

Definition and usage

The `<video>` element embeds a video, such as a tutorial or training movie, in a help page.

Supported sources

- Microsoft Stream
- YouTube
- Facebook
- Vimeo

Attributes

- `src`: Specifies the URL of the video. This attribute is required.
- `allowFullScreen`: Specifies whether the user can switch the video to full screen. Possible values are "true" or "false". This attribute is not supported for all video sources.
- `autoplay`: Specifies that the video will start playing as soon as the help page loads. Possible values are "true" or "false". This attribute is not supported for all video sources.
- `startTime`: Specifies, in seconds, from which point to start playing the video.

Paragraph

Presents a paragraph in a help page.

```
<p>This is some text in a paragraph.</p>
```

Definition and usage

The `<p>` element defines a paragraph.

Text inside a paragraph can be decorated in the following ways:

- Bold, with `<strong>` element
- Italic, with `<em>` element
- Strikethrough, with `<del>` element
- Underline, with `<u>` element

These decorations can be combined. For example, make a fragment of text that is both bold and underlined.

Bulleted list

Presents a bulleted list in a help page.

```
<ul>
    <li>Coffee</li>
    <li>Tea</li>
    <li>Milk</li>
</ul>
```

Definition and usage

The `<ul>` element defines a bulleted list.

Use the `<ul>` element together with the `<li>` element to create bulleted lists.

Numbered list

Presents a numbered list in a help page.

```
<ol>
    <li>First step</li>
    <li>Second step</li>
    <li>Third step</li>
</ol>
```

Definition and usage

The **`<ol>`** element defines an ordered (numbered) list. Use the `<ol>` tag together with the `<li>` element to create numbered lists.

Collapsible

Presents a collapsible section in a help page.

```
<collapsible title="This is a Section">
    <p>This is a paragraph inside a section</p>
    <img src=smiley.gif" title="This is an image inside a section" />
</collapsible>
```

Definition and usage

The **`<collapsible>`** element defines a section of content that the user can view or hide on demand.

Attributes

- `collapsed`: Specifies whether the section is collapsed or expanded initially. Possible values are "true" (collapsed) or "false" (expanded).

Link

Presents a link in a help page.

Link to a website that opens in a new browser window:

```
<a href="https://www.microsoft.com" target="_blank">Microsoft Home Page</a>
```

Link to another help page:

```

<a href="./LearnMore">Learn More</a>
```

Definition and usage

The <a> tag defines a link, which allows the user to navigate from a help page to a website, or to another help page.

Attributes

- `href`: Specifies the URL of the website or help page to which to navigate. This attribute is required.
- `target`: Specifies where to open the linked URL.
  - If not present or `_self`, the link is assumed to be to another help page and it's opened in the help browser.
  - If `_blank`, the link is opened in a new browser window.
  - If `_top`, the link is opened in the current browser window.
  - If the value is the name of an `iframe`, the link is opened in that iframe.

Coach mark

Presents a coach mark in a help page.

```

<coachmark target="#my-html-button">Click to highlight the HTML element with id
[my-html-button]</coachmark>
```

Definition and usage

A coach mark is an interactive element that can be used to draw the user's attention to a specific point in the UI of the application hosting the help browser.

Attributes

- `target`: CSS selector that specifies the HTML element over which the coach mark will be shown. This attribute is required.

Balloon

Presents a balloon in a help page.

```
<balloon target="#my-html-button" title="This button submits the form"
details="Please click this button to continue and submit the form">Click to show a
balloon over the HTML element with id [my-html-button]</balloon>
```

Definition and usage

A balloon is an interactive element that can be used to help the user perform an action in the UI of the application hosting the help browser.

Attributes

- `target`: CSS selector that specifies the HTML element over which the balloon link will appear. This attribute is required.
- `title`: Specifies the title of the balloon.
- `details`: Specifies the content to show inside the balloon.

Validate and publish a model-driven app using the app designer

Summarize this article for me

Model-driven apps can't be published when they don't include all the required components. Some components rely on others and this relationship between components is known as a dependency.

> **Note**
>
> This article discusses a feature that's only available or needed when you use the classic app designer. The modern designer validates your app as part of the app building process.

For example, the position table has been added to the site map, but is no longer showing in the app.

The process of checking for dependencies within a model-driven app is known as validation.

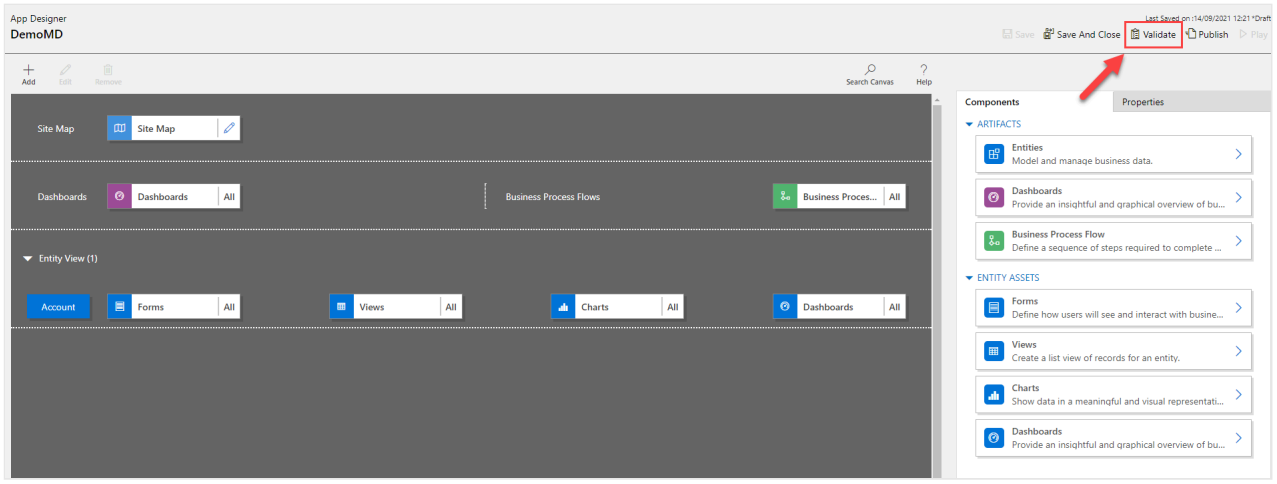
When the app is validated, the app designer canvas shows details about the assets that are missing.

How to validate an app and add in dependencies

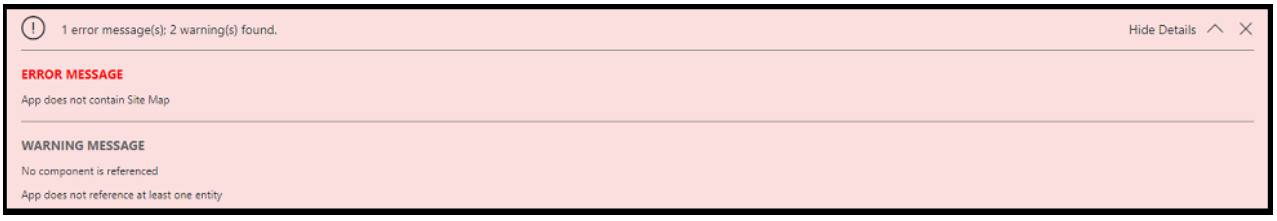
1. Sign in to Power Apps.
2. Select the environment in which the unmanaged model-driven app is located.
3. Select the model-driven app, and then on the command bar select **Edit**.

   > **Note**
   >
   > Customizations to a model-driven app should take place within a solution. To update a model-driven app within a solution, open your solution from the **Solutions** area, select the **Model-Driven App** solution component, and then on the command bar select **Edit**.

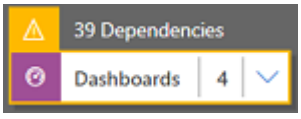
4. In the app designer, select **Validate**.



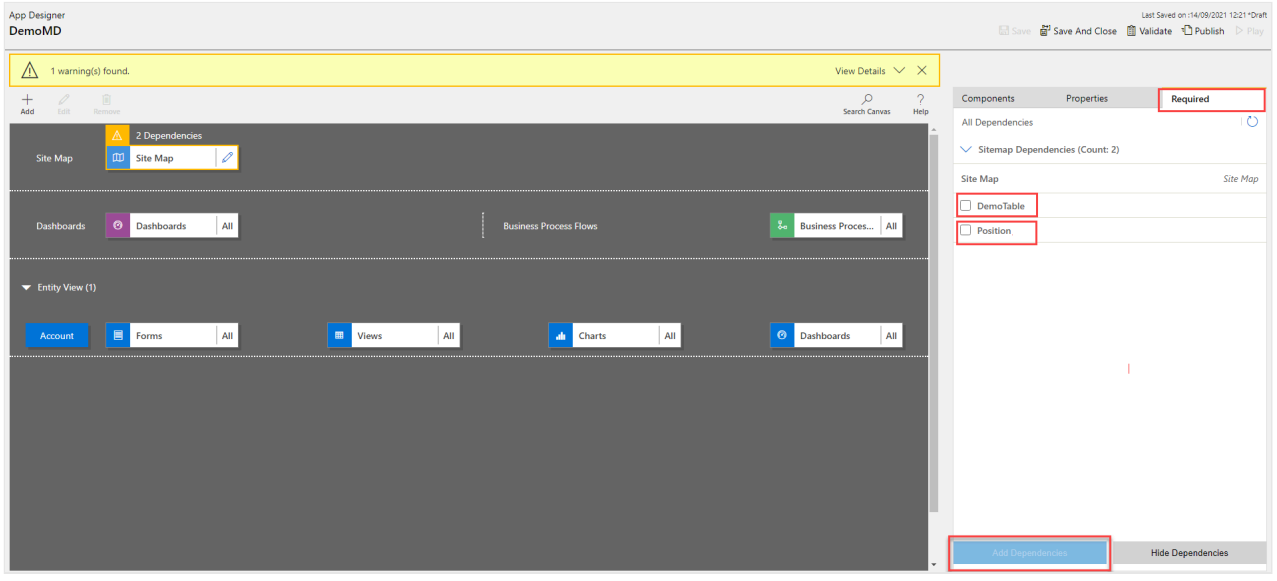
A notification bar appears and shows whether the app has any errors or warnings. The notification bar shows warnings in cases where, for example, a table has no forms or views, or the app doesn't contain any components. An error might appear if a site map isn't configured for the app. You can save and publish the app without addressing warnings, but errors must be fixed before you can publish.



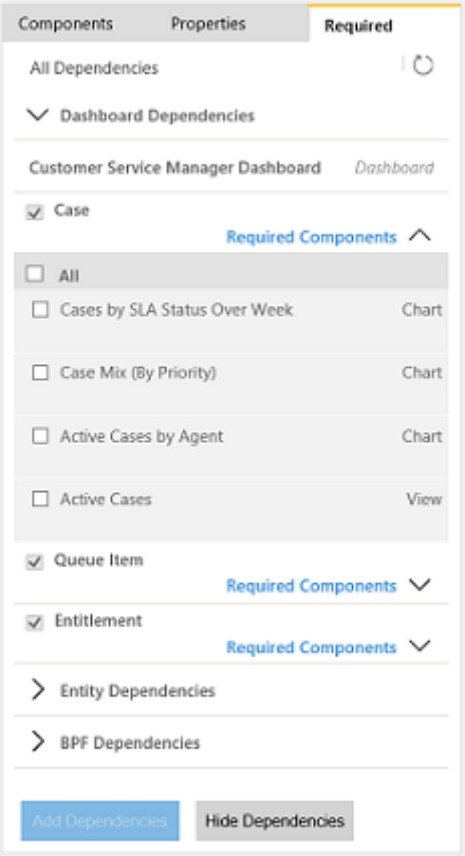
The app designer also shows a warning symbol with the number of dependencies on each artifact or asset tile that is missing a required asset.



5. To add the required assets, select the **Required** tab. The **Required** tab is visible when at least one required asset is missing from the app.



The tab displays an alternate list of required components.



6. Select the assets that are missing, and then select **Add Dependencies**. When the required asset is added, the error count for the asset decreases.

> ⓘ Note
>
> If a common asset is required across various app components, such as a form is required for a dashboard and a table, and you add that asset only once from the dashboard dependency tree, the dependency count decreases only on the dashboard tile, but not on the table tile. However, the dependency is resolved for both.
>
> Select **Get Latest Dependencies** ↻ or select **Validate** again to get the latest set of dependencies. These buttons are only visible after the app is saved.

Select **Hide Dependencies** if you don't want to add the suggested required components. Any unresolved warnings appear again when the app is opened in the app designer and select **Validate** or **Get Latest Dependencies** ↻.

> ⓘ Note

If the dependencies are hidden now and the app is exported later, all of these dependencies appear again.

Publish an app using the app designer

Publish an app to make it available to users.

After you've added components, validated and saved the app, on the command bar, select **Publish**. In the **Apps Being Edited** view, in the lower right corner of the app tile you want to publish, select the **More options** button (**...**), and then select **Publish**.

The app status changes to **Published**. This is displayed in the top-right corner of the app designer. The app moves from the **Apps Being Edited** view to the **Published Apps** view, and the published date is shown on the app tile.

> **Note**
>
> - If your app has a validation error, this is displayed in the notification bar. It isn't be possible to publish the app until the error is resolved.
> - The app can't be published until it is saved.

Next steps

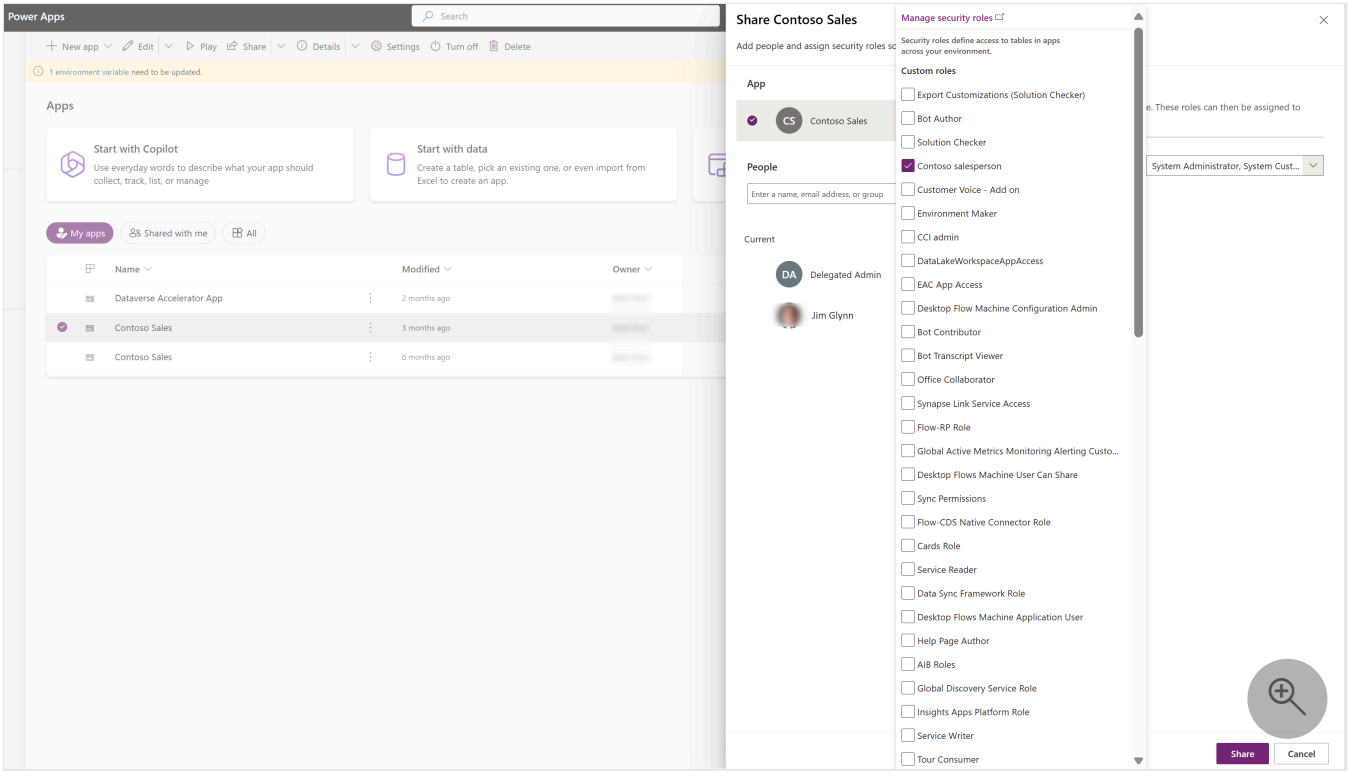
Share a model-driven app with Power Apps
Run a model-driven app on a mobile device

Last updated on 02/13/2026

Share a model-driven app

Share a model-driven app to make it available so other users can play it. Sharing includes the following steps:

1. Identify the security roles to use for the app
2. Assign security roles or people to a model-driven app
3. Share the link to the app



If your app contains only out-of-the-box tables, such as account or contact, you can use an existing predefined security role.

Model-driven app sharing basics

Model-driven apps use role-based security for sharing. The fundamental concept in role-based security is that a security role contains privileges that define a set of actions that can be performed on tables within the app. This approach means that while two people are able to use the app, one user might only be able to read records, or records that they themselves created. The other user might be able to see all records and have the rights to delete those records.

All app users must be assigned one or more predefined or custom security roles. Or, security roles can be assigned to teams. When a user or team is assigned to one of these roles, the person or team members are granted the set of privileges associated with that role.

The process for sharing a model-driven app is different from sharing a canvas app. Model-driven app sharing depends on how the Microsoft Dataverse data table privileges are assigned for the tables that are in the app. If security roles aren't already defined for your app, contact your Power Platform administrator to create them for you.

More information: Create or edit a security role to manage access

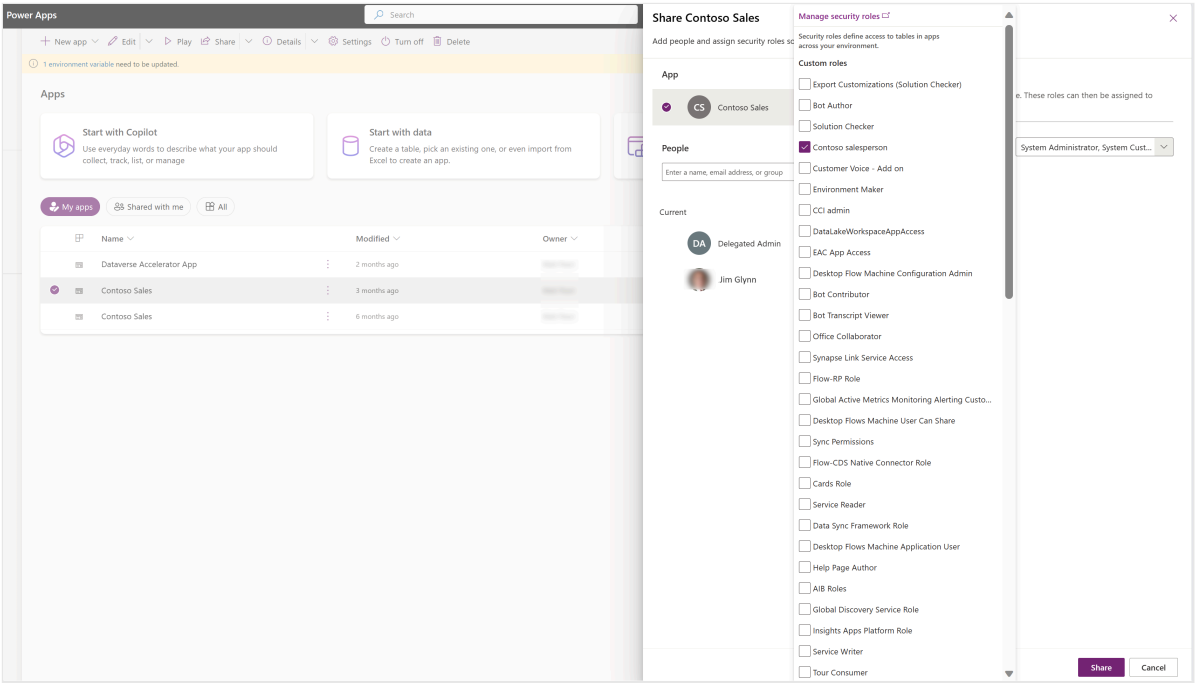
Assign security roles or people to a model-driven app

When you share a model-driven app, you can share it with all members of one or more security roles or a user or team.

1. Sign in to the Power Apps, on the left navigation pane select **Apps**, next to the app you want to share select **...**, and then select **Share**.

2. From the **Share** *app name* pane, choose from the following options:

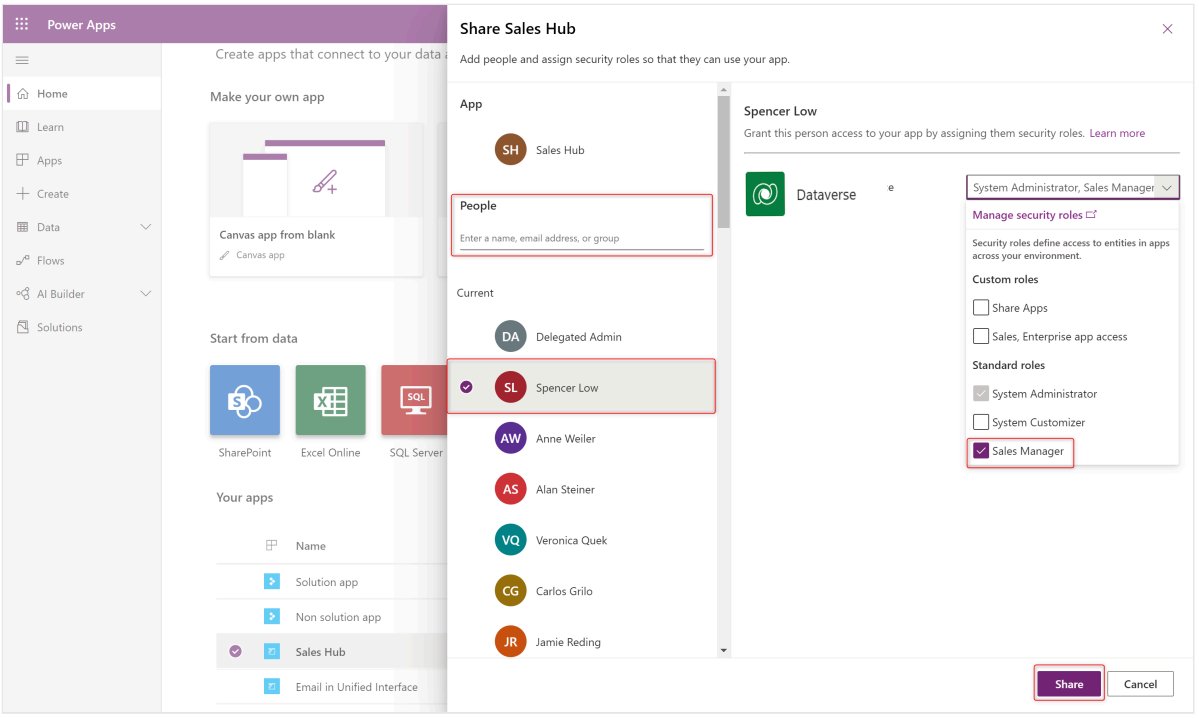
    - Select the app, and then select the drop-down list in the right pane to display all available security roles. Select the security roles you want from the security role dropdown list.



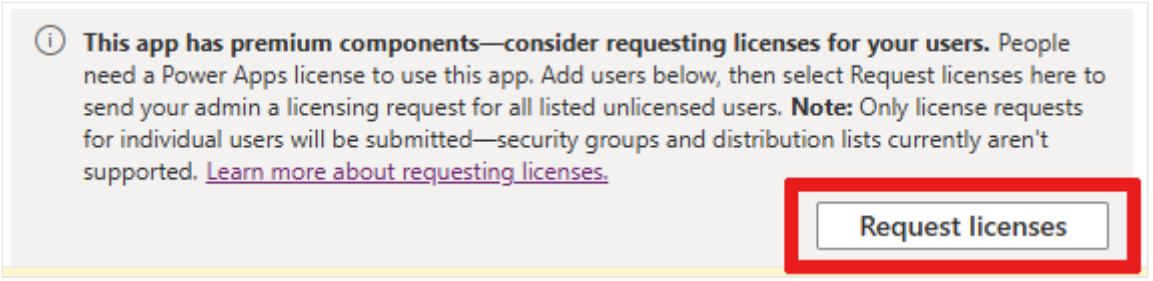
> **Important**
>
> If your app has one or more custom tables, contact a Power Platform administrator to configure privileges to the custom tables in a security role. This is necessary in

order for users to work with your custom table's records in the app. More information: [Create or edit a security role to manage access]

- To assign an individual user or team, select the user name or team from the **People** list.



If your app contains premium components, such as a map or address input components, users must have a Power Apps license to use the app. To request licenses for the users of your app, select **Request licenses** to submit a license request to your admin.



> **Note**
>
> You can't request licenses for security groups or distribution lists. For more information about requesting licenses, see [Request Power Apps licenses for your app users].

3. Select **Share**.

Share the link to the app

Unlike sharing canvas apps, sharing model-driven apps doesn't currently send an email with a link to the app.

To get the direct link to an app:

1. Sign in to Power Apps, and then select **Apps** on the left navigation pane.
2. Select the model-driven app you want, and then select **Details** on the command bar.
3. Copy the **Web link**. Alternatively, you can make a copy of the **Mobile QR code** for mobile users.
4. Paste the app URL in a location so that your users can access it, such as by posting it on a SharePoint site or send via email.

App sharing privilege and licensing requirements

There are a few key environment and licensing prerequisites required when sharing a model-driven app with a user.

- A Microsoft 365 user with Power Platform administrator rights must exist within the organization. Learn how to assign Power Platform Administrator rights. This provides the user with administrator rights over all environments.
- The app sharer must have admin privileges to the specific environment (or be a Power Platform administrator). The app sharer must have a security role with equal or greater privileges than the security role they're assigning to the app and to other users. Usually, this takes the form of the app sharer having the Dataverse **System Administrator** or **System Customizer** security role. These roles can be assigned by Power Platform administrators (who have rights over all Dataverse environments). The system administrator and system customizer security roles are standard roles that exist within all Dataverse environments.
- The user must exist as a user within the environment. It isn't enough to only be a Microsoft 365 user. This is because all users in an environment are accounted for and described within tables in the environment. Learn how to add a user to an environment
- Users must have the correct license to be able to use the app. Users can request a license themselves, or a maker can request licenses for their app users. Also, for custom model driven apps, the license must be assigned in either the users home tenant or the tenant hosting the app. Dynamics 365 model driven apps require a license in the same tenant the app is hosted.

> ⓘ **Note**

> Users who have the Environment Maker security role assigned don't require licenses to use model-driven apps.

Note

> Users who have the Environment Maker security role assigned don't require licenses to use model-driven apps.

About predefined security roles

There are several predefined roles available with Dataverse. To run apps that use only out-of-the-box tables, there's the Basic User security role, where members can play the app within the environment and perform common tasks for the records that they own. More information: Predefined security roles

Use Microsoft Entra groups to manage access

Administrators can use their organization's Microsoft Entra groups to manage access rights for licensed Dataverse users. Both types of Microsoft Entra groups—Microsoft 365 and Security—can be used to secure user-access rights to an app. More information: About group teams

Privileges required to view and access apps

Article • 03/13/2024

Apps can be viewed by valid users with appropriate privileges who sign into Power Apps, the Power Apps mobile app, or Dynamics 365 home page. For a user to view and access apps in an environment, the following privileges, security role, or team membership are required:

- A user who has both write and create privileges on the Model-driven App table makes the user a maker persona. That user can view and access all apps in the environment.
- A user who has only the read privilege on the Model-driven App table, must also have the associated security roles that are assigned to the app (or equivalent).

Read, create, and write privileges can be granted to a user by the security roles assigned to the user or granted through team membership.

By default, users who have only the Basic User security role can only access model-driven apps that have that security role assigned to the app. This behavior is because the Basic User security role only has read privileges on the Model-driven App table.

However, users who have the System Administrator, System Customizer, or Environment Maker[1], security role can access and edit all model-driven apps within the environment. This behavior is because these security roles have create, read, and write privileges on the Model-driven App table. More information: Share a model-driven app using Power Apps

[1] Although the environment maker security role has read and write access to the Model Driven App table, the role alone doesn't have access to the core and custom tables required to view, create, and edit data in an app.

Security roles and privileges

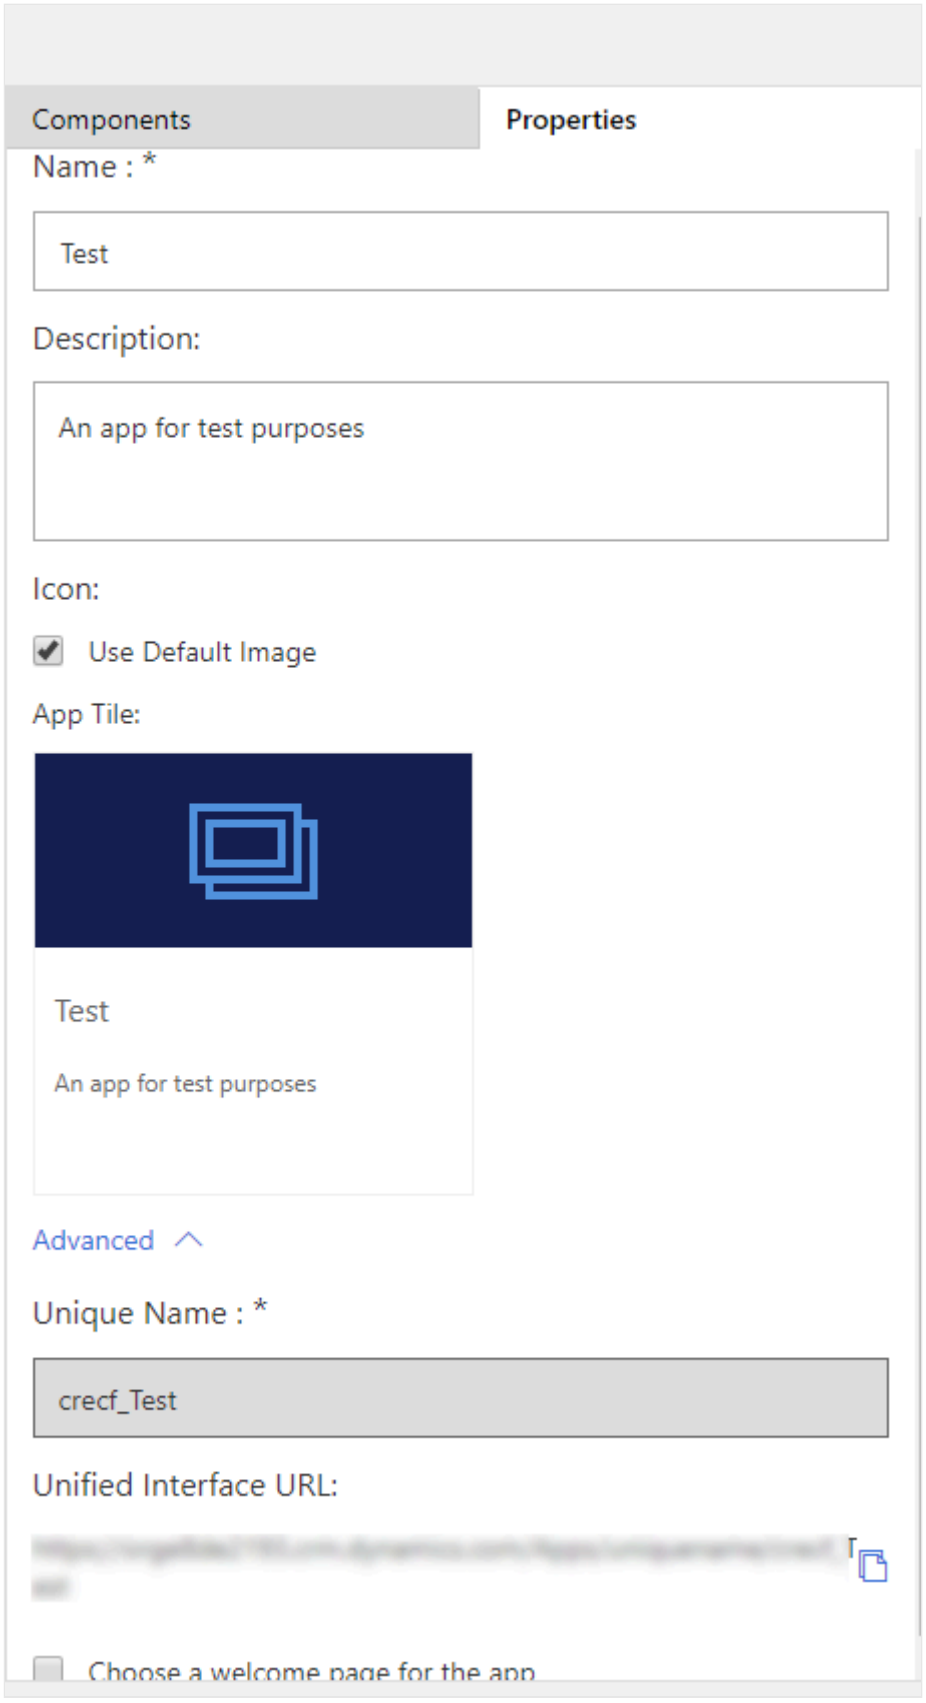
Manage model-driven app properties in the app designer (classic)

Summarize this article for me

App properties define important details about the app, like its title or URL. You define app properties when you create an app. If you want to change those properties later, you can do that in the app designer.

> **Note**
>
> This article describes how to view and set app properties using the classic app designer. For information how to view and set app settings in the modern designer, go to Manage model-driven app settings in the app designer.

1. In the app designer, on the right side, select the **Properties** tab.



2. Change the information, as required:

Expand table

Property	Description
Name	Enter a unique and meaningful name for the app.

Property	Description
Description	Type a short description of what the app is.
Icon	By default, the **Use Default App** check box is selected. To select a different web resource as an icon for the app, clear the check box, and then select an icon from the drop-down list. This icon is displayed on the app's preview tile.
Unique Name	You can't change the unique name. Using the unique name, you can query tables to get data from the database.
App URL Suffix[1]	The URL you chose while creating the app is shown here by default. You can change the app URL in the **Manage App** dialog box. Notice that you can't export or import the app URL suffix through a solution at this time.
Choose a welcome page for the app	This option allows you to select from the web resources available in your environment. The welcome pages you create can contain useful information to users such as links to videos, upgrade instructions, or getting started information. For more information about how to create a web resource, such as an HTML file that you can use as a welcome page, see Create and edit web resources to extend the web application.
Enable Mobile Offline	This option enables the app to be available offline on mobiles to the profiles that are selected using **Mobile Offline Profiles** drop down list.

[1]The **Client** and **App URL Suffix** properties are no longer available when you create a new app.

3. Save the app.

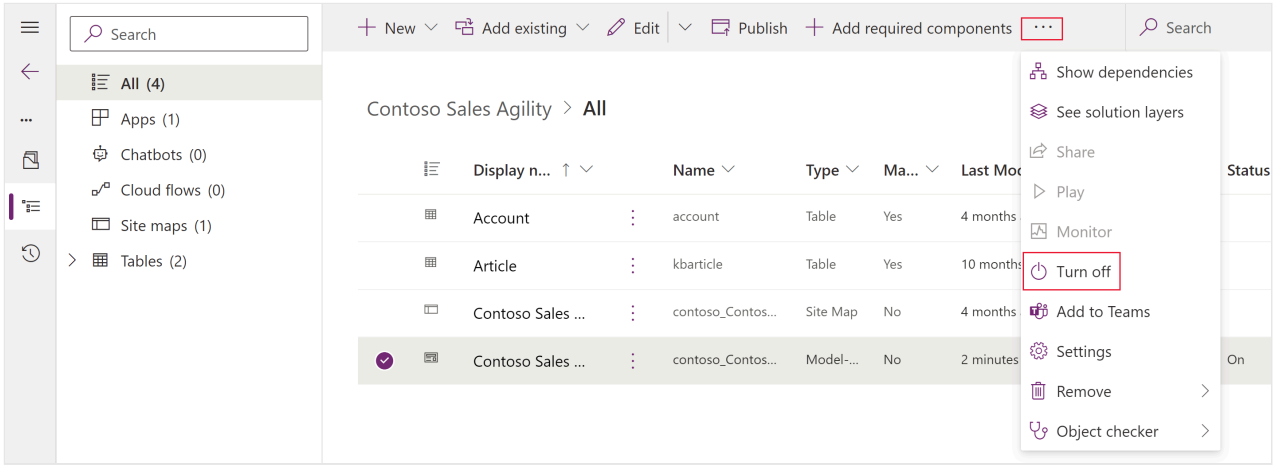
Hide a model-driven app from users

07/16/2025

Turn off a model-driven app to hide it from users who otherwise would be able to find and run it. When a model-driven app is turned off, it no longer appears in the common places where apps are found, such as the list of model-driven apps displayed in Power Apps Mobile or Office apps.

Turn off a model-driven app

1. Sign in to Power Apps.
2. Select the environment where the app is located.
3. Select **Solutions** on the left navigation pane, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Select the model-driven app to be hidden from all users, and then on the command bar select **...** > **Turn off**.



The **Status** of the app appears as **Off** from the solution's **Objects** view.

> **Note**
>
> - Apps that are turned off are still visible to other users from the **Apps** area of Power Apps.
> - While a model-driven app is in a turned off state, it can't be played or shared from make.powerapps.com, however direct links to the app will continue to work.
> - Managed model-driven apps can't be turned off.

Turn on a model-driven app

An app that is turned off can be turned on by following the same steps described earlier and then selecting **Turn on**.

Privileges required to view and access apps

Delete a model-driven app

Summarize this article for me

Apps might need to be deleted for a variety of reasons. An app might have been prepared purely as a development training exercise, might no longer be used in the organization, or could have been superseded in some way.

The process for removing an app is straightforward. However, dependencies can be encountered when you delete objects in Microsoft Dataverse. While you can delete apps at any time in an unmanaged solution, you can't delete tables that are used in the apps until such time as the app has been removed. The same is true for other app objects, such as table views.

> **Important**
>
> - If a model-driven app or site map is installed as part of a managed solution, see Delete a model-driven app that was installed as part of a managed solution for information about how to delete it.
> - Model-driven apps from Microsoft, such as Dynamics 365 Sales, Dynamics 365 Customer Service, and Dynamics 365 Field Service can’t be deleted. You can hide these apps from users by removing the security roles that are assigned to the app. Notice that these apps are visible to users with environment maker, system administrator, and system customizer security roles or any user with create privileges on the Model-driven App table.

Delete or remove an unmanaged app in your environment

1. Sign in to Power Apps.
2. On the left navigation, select **Solutions**, and then open the solution that has the app you want to delete. If the app isn't in a custom solution, select **Apps**.
3. Select the unmanaged model-driven app that you want to delete, and then select **Delete** on the command bar.
4. In the confirmation message choose from two options:
    - **Remove solution** removes the app from the solution, but retains it within the environment.

- **Delete from this environment** deletes it from both the solution and the environment.

If the component has dependencies, such as relationships, these must be removed before the app can be deleted. To see the dependencies of an app, select the app and then select **Show Dependencies** on the command bar.

5. When an app is deleted, you should also delete the associated site map. If you don't delete the site map, the site map designer displays an error the first time there is an attempt to create another app with the same name. However, it is possible to ignore the error, and the error doesn't appear when you try to create the app again.
   a. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
   b. Open the **Default Solution**.
   c. On the left navigation pane, select **Site maps**, select the site map that has the same name of the app that you deleted earlier, and then select **Delete from this environment**.
   d. Select **Delete** to confirm.

Delete a model-driven app that you installed as part of a managed solution

You can't delete a model-driven app or site map that you installed in the environment as part of a managed solution. Instead, delete the managed solution.

Delete a managed solution

All the components of a managed solution are deleted by deleting the solution.

> ⊗ **Caution**
>
> Be careful when you delete a managed solution. The solution might contain components that are used for production purposes, such as a line of business application. When you delete the solution, you delete all solution components and any data associated with the managed solution.

1. Sign in to Power Apps.
2. Select **Solutions** in the left navigation.
3. In the **Solutions** list, select the managed solution you want to delete. On the toolbar, select **Delete**.

How to run a model-driven app

Article • 05/06/2025

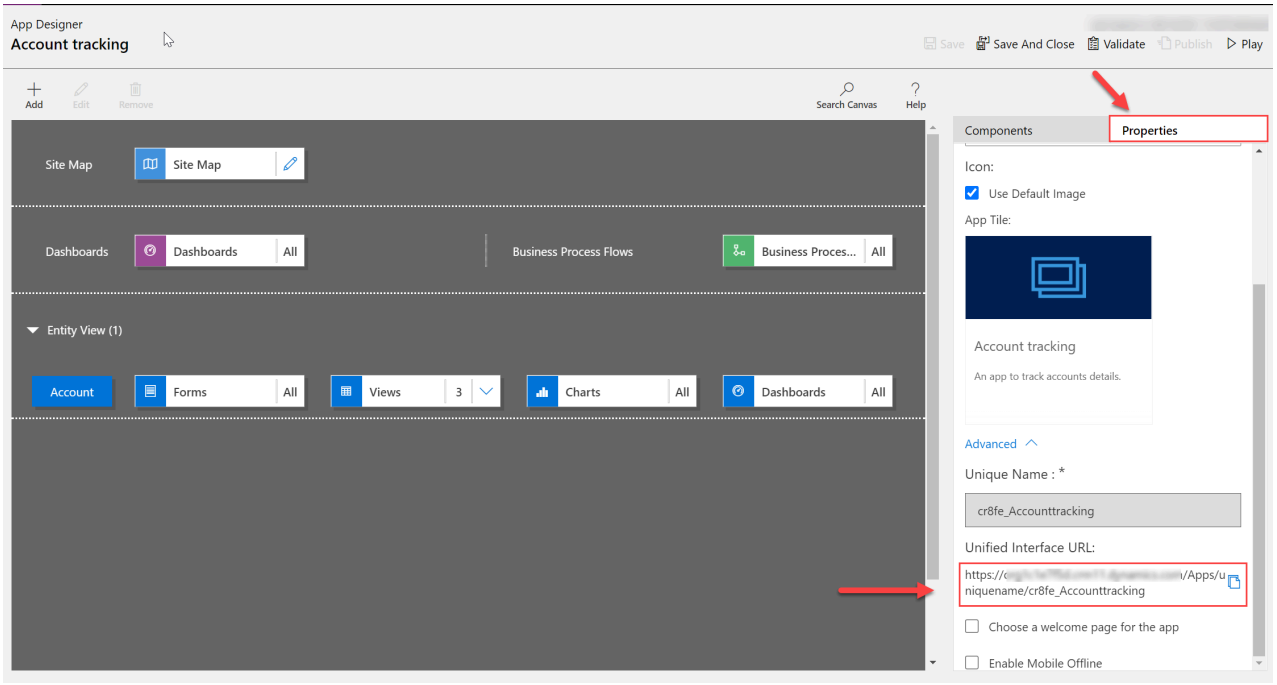
Run an app in a browser

To run a model-driven app in a web browser, the user must have a security role assigned in addition to having the URL for the app.

Learn how to create a security role from a copy

To get the direct link to an app:

1. Go to make.powerapps.com.
2. Select the **Environment** where the app is located.
3. On the left navigation pane, select **Apps**, or select **Solutions** and open the solution where the app is located. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Select the **...** next to the model-driven app, and then select **Edit**. The classic app designer opens.
5. Select the **Properties** tab, and then scroll down to **Unified Interface URL**. Copy the **Unified Interface URL**.



6. Paste the app URL in a location so that your users can access it, such as by posting it on a SharePoint site or send via email.

To play the app, enter the URL in a web browser.

Authentication prompts while running a model-driven app

You may notice authentication prompts during your model-driven app session. These prompts are expected and are required for certain features. Below highlights a list of features that trigger these prompts. This list is subject to change as new features are released:

- Custom pages.
- Power Fx expressions with commands.
- Opening the Office apps launcher located on the upper left of the app header.
- Collaboration feature.

Additionally, some organizational or browser settings may increase the frequency of these prompts. We recommend reviewing your settings to help reduce authentication prompts during sessions.

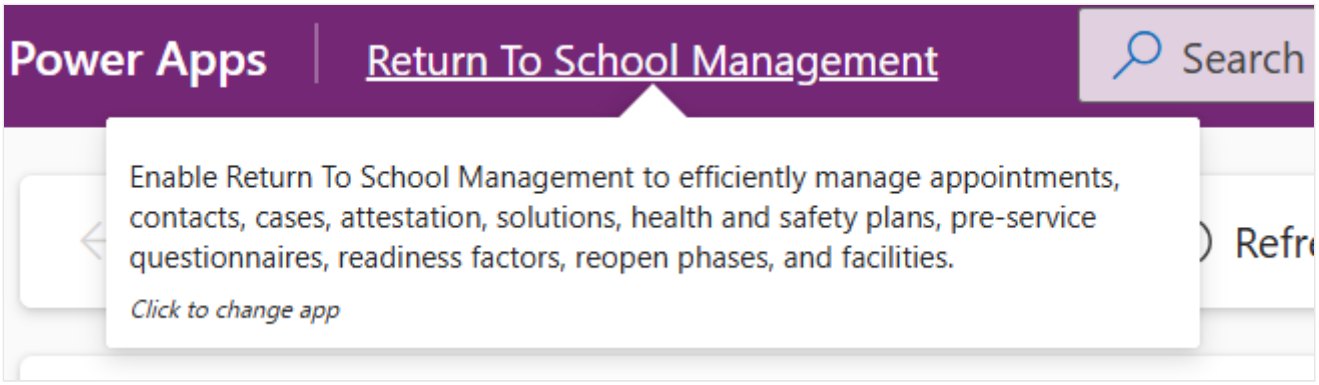
- **Third party cookies blocked in browser.** This will cause an authentication prompt to trigger each time you open a model-driven app. Note that opening the app in incognito mode or in the Safari web browser via ITP settings will usually block third-party cookies by default. Enable third party cookies to reduce these prompts.
- **Microsoft Entra conditional access or multi-factor authentication policies**. Policies specifically on Power Apps or Microsoft Graph will trigger additional authentication prompts. Contact your admin to review your organization's conditional access or MFA policies.

Run an app on a tablet or phone

Use the app URL described in the earlier section to run a model-driven app on a tablet's web browser. For phones, users download the Power Apps mobile app from the relevant app store. Then, sign into the app, and select the specific app. More information: Get started with Power Apps mobile

View the app description in the browser experience

When a user hovers over the app name at the top of the web browser, the app's description is shown.



If the app's description was generated using AI, a disclaimer is shown. Selecting the app name opens the app switcher where the user can play another app that they have access to.

Create and edit columns for Microsoft Dataverse using Power Apps portal

Test model-driven applications with Test Engine (deprecated)

> **Note**
>
> **Test Engine is deprecated** and will be removed in a future release. Use Power Platform Playwright samples for test automation capabilities in Power Platform and Dynamics 365 services.

Testing your model-driven application with Test Engine requires the following steps:

1. Create a test plan
2. Set up your user
3. Run the test
4. View the results

Create a test plan

Create a yaml file using the test plan schema explained in Power Apps Test Engine YAML format (deprecated).

> **Tip**
>
> Review available sample plans in the GitHub repository.

Enable preview

Currently, all model-driven app extension testing capabilities require using Preview functions. To enable these, add `Preview` to the `allowPowerFxNamespaces` list in extensionModules of your testSettings.

This example shows you how to add this:

YAML

```yaml
testSettings:
  extensionModules:
```

```
    enable: true
    allowPowerFxNamespaces:
    - Preview
```

Set up your user

Test Engine currently has these authentication methods:

Expand table

Method	Description
Storage State	Store authenticated user state locally in the user profile using Microsoft Windows Data Protection API
Dataverse	Store authenticated user state inside Dataverse using your own customer managed key encrypted with an X.509 certificate using ASP.NET Core Data Protection

You can't store test credentials in test plan files. You must select `Storagestate` or `Dataverse` as the secure location to store credentials. The test plan file contains references to which environment variables are used for user persona. For example, the following YAML snippet indicates that the `user1Email` environment variables are used:

YAML

```yaml
environmentVariables:
  users:
    - personaName: User1
      emailKey: user1Email
```

View Users for more information.

Use the following PowerShell script to store the username in your environment variables.

PowerShell

```powershell
$env:user1Email = "someone@example.com"
```

Run the test

Use the PAC CLI pac test run command to run your test plan.

Required Parameters

You need to provide the following information:

- `--test-plan-file`: Path to your test plan file
- `--tenant`: Your tenant ID
- `--environment-id`: Your environment ID
- `--domain`: Domain URL of the model-driven app page to test

URL Formats for Model-Driven Apps

For model-driven apps, the `--domain` parameter varies based on the type of page you're testing. The URL format should specify the correct `pagetype` based on your testing scenario:

PowerShell

```
# For custom pages
pac test run `
   --provider mda `
   --test-plan-file your-testplan.te.yaml `
   --tenant your-tenantid-guid-value `
   --environment-id your-environmentid-guid-value `
   --domain "https://contoso.crm.dynamics.com/main.aspx?appid=00001111-aaaa-2222-bbbb-3333cccc4444&pagetype=custom&name=dev_home_c8017"

# For entity lists (views)
pac test run `
   --provider mda `
   --test-plan-file your-testplan.te.yaml `
   --tenant your-tenantid-guid-value `
   --environment-id your-environmentid-guid-value `
   --domain "https://contoso.crm.dynamics.com/main.aspx?appid=00001111-aaaa-2222-bbbb-3333cccc4444&pagetype=entitylist&etn=account&viewid=5a84c584-df1c-ed11-9db0-000d3a991110"

# For entity records (forms)
pac test run `
   --provider mda `
   --test-plan-file your-testplan.te.yaml `
   --tenant your-tenantid-guid-value `
   --environment-id your-environmentid-guid-value `
   --domain "https://contoso.crm.dynamics.com/main.aspx?appid=00001111-aaaa-2222-bbbb-3333cccc4444&pagetype=entityrecord&etn=account&id=72e0e163-df1c-ed11-9db0-000d3a991110"
```

Dataverse Integration

To enable Dataverse integration with your model-driven app tests, add the `enableDataverseFunctions` parameter in your testSettings:

YAML

```yaml
testSettings:
  extensionModules:
    enable: true
    allowPowerFxNamespaces:
    - Preview
    parameters:
      enableDataverseFunctions: true
```

When you enable Dataverse integration, you're required to open Azure CLI with a user or service principal that has rights to the Dataverse environment. You can use the command: az login More information: Sign in with Azure CLI.

The Dataverse API URL used for integration is obtained either from the host domain name of the pac test run `--domain` parameter or by defining an PowerShell environment variable named `DATAVERSE_URL`.

View the results

When the tests complete, you can view the results of your test in the `.trx` file located in the output directory. This folder contains any screenshots or videos captured by your tests when `recordVideo` is set to `true` in the test plan yaml.

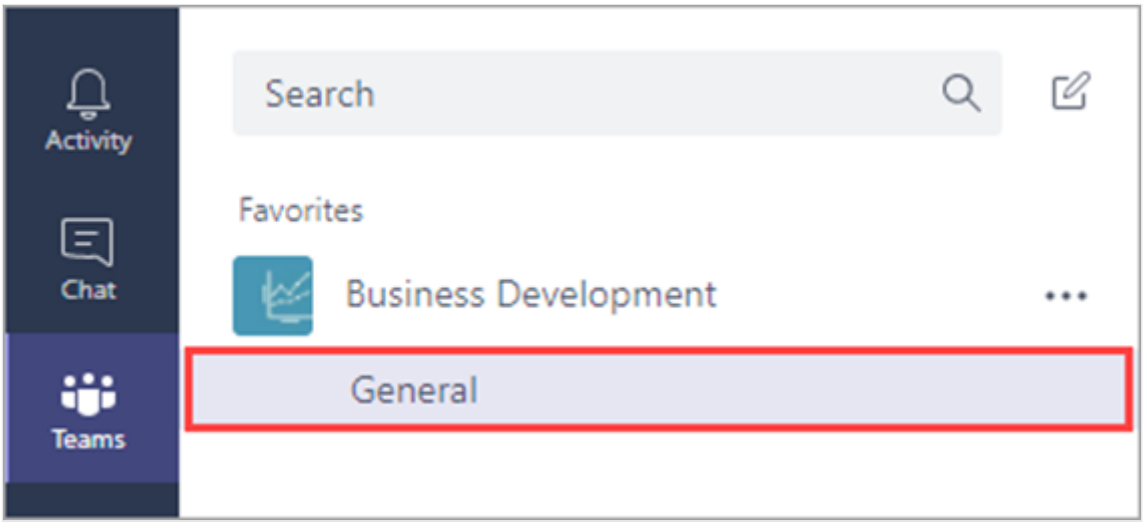
Embed a model-driven app as tab app in Teams (preview)

You can customize the Teams experience by adding Power Apps model-driven apps to your channels in Teams using the **Power Apps** tab.

> **Important**
>
> - This feature is deprioritized and will not be delivered.
> - New model-driven apps can no longer be added to Teams.
> - Model-driven apps that are embedded in Teams will continue to function until May 1, 2026. After that date, these apps will no longer work within the Teams experience. Users can continue to use these apps through a web browser or other supported clients.
> - Running model-driven apps on the Microsoft Teams mobile app is currently not supported.
> - Opening or downloading file attachments in a model-driven app when the app is embedded in Teams as a tab isn't supported.

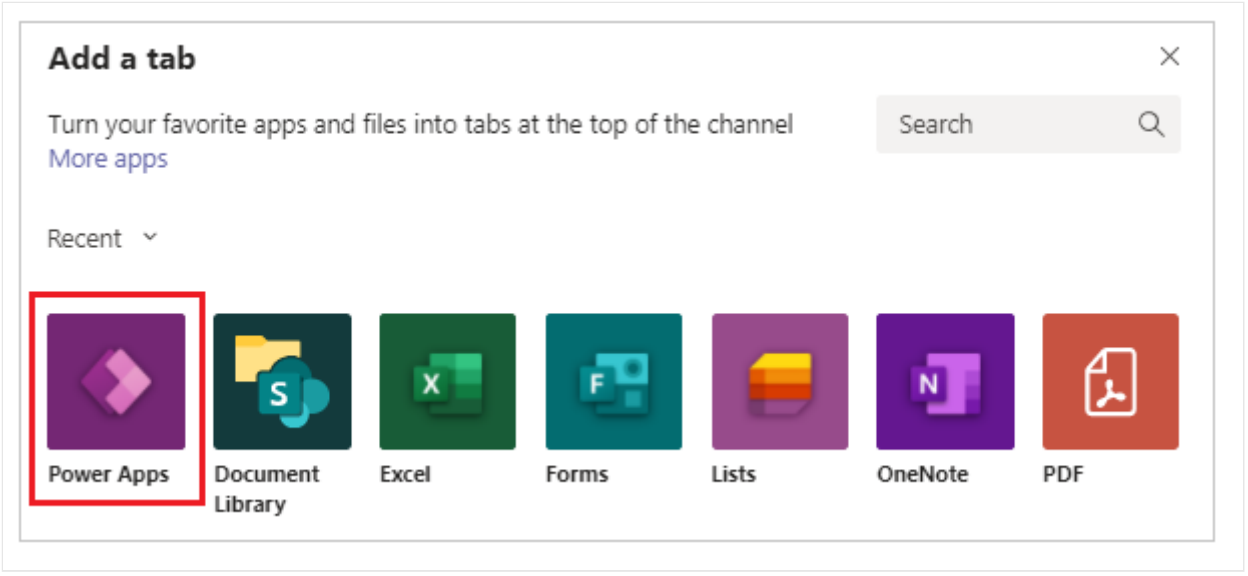
Embed a model-driven app

1. In Microsoft Teams, select a team, and a channel under that team. In this example, it's the **General** channel under the **Business Development** team.

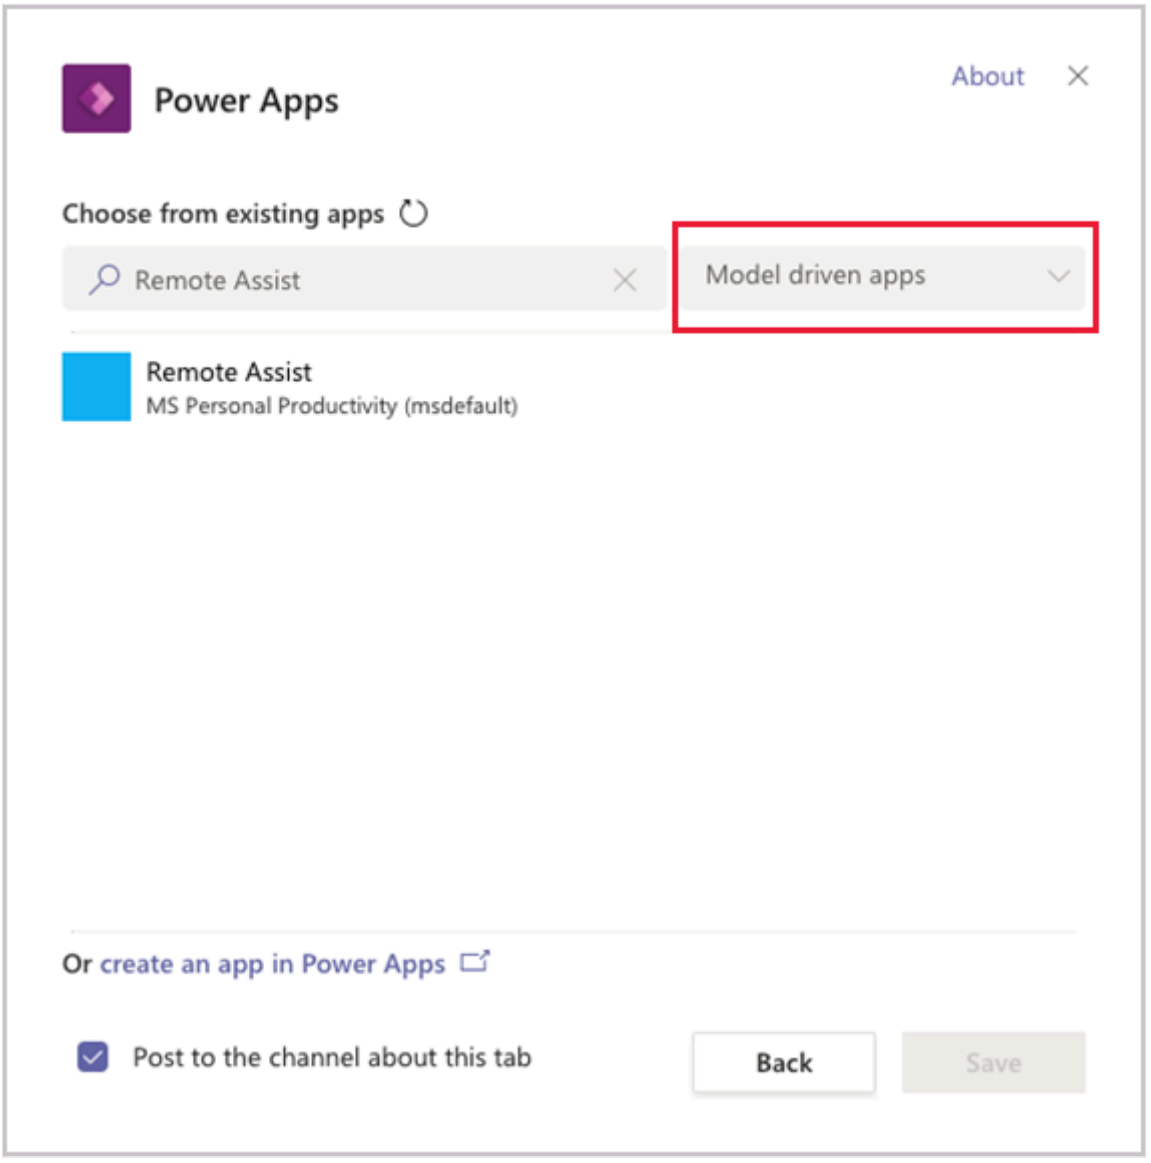


2. Select + to add a tab.

3. In the **Add a tab** dialog box, select **PowerApps**.



4. Select **Model-driven apps** in the dropdown list and then search for and select the model-driven app you would like to pin.



5. Select **Save**.

The app is now available to use in the channel.

Embed a canvas app as personal app in Teams

Last updated on 04/02/2026

Embed a model-driven app as personal app in Teams (preview)

[This topic is pre-release documentation and is subject to change.]

You can share an app you've created by embedding it directly into Microsoft Teams. When completed, users can select + to add your app to any of **your** team channels or conversations in the team you are in. The app appears as a tile under **Tabs for your team**.

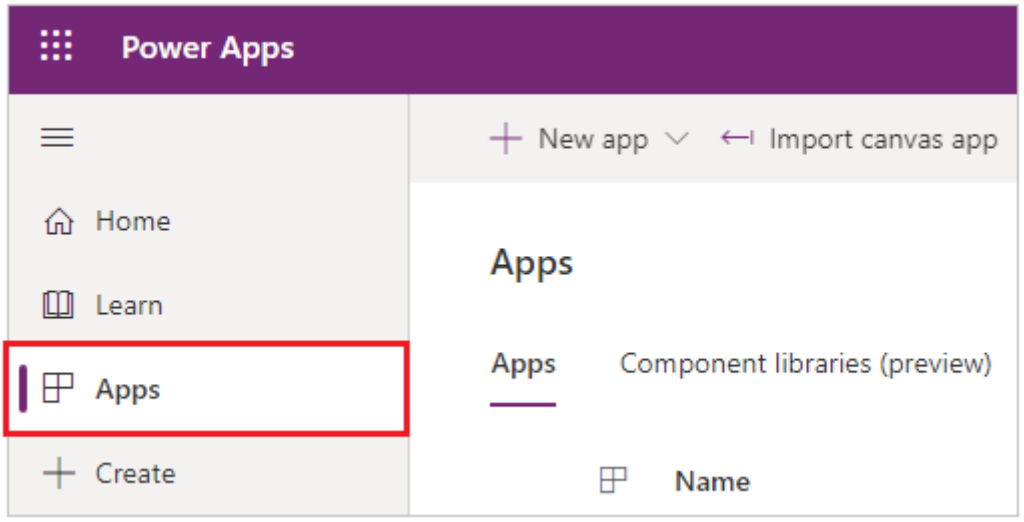
> **Important**
>
> - This feature is deprioritized and will not be delivered.
> - New model-driven apps can no longer be added to Teams.
> - Model-driven apps that are embedded in Teams will continue to function until May 1, 2026. After that date, these apps will no longer work within the Teams experience. Users can continue to use these apps through a web browser or other supported clients.

Prerequisites

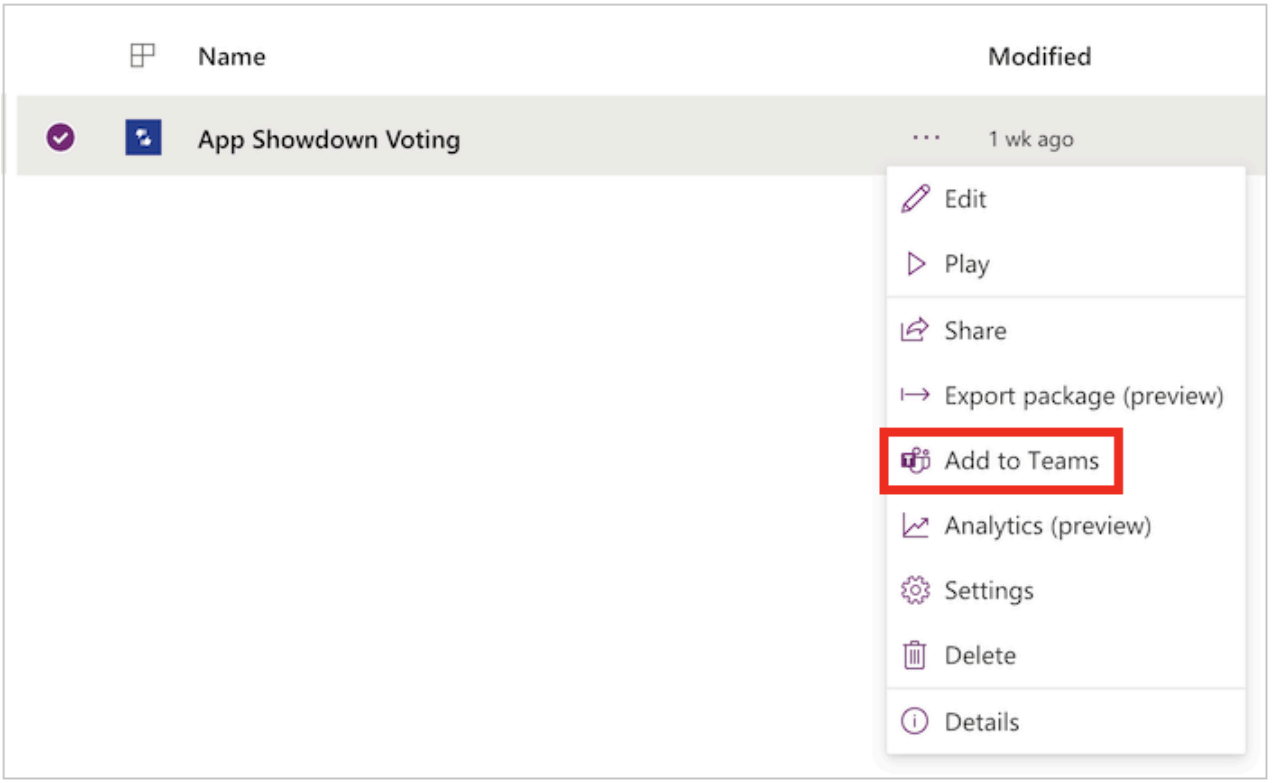
- You need a valid Power Apps license.
- To embed an app into Teams, you need an existing app created using Power Apps.

Add the app as a personal app

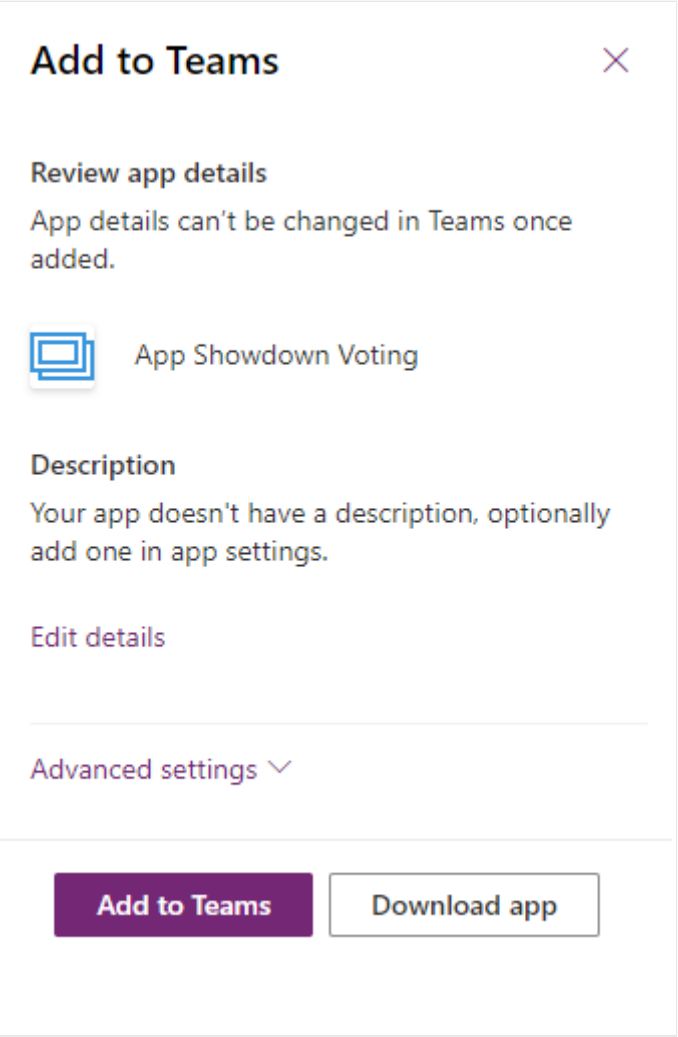
1. Sign into Power Apps, and then select **Apps** in the menu.



2. Select **More actions** (...) for the app you want to share in Teams, and then select **Add to Teams**.

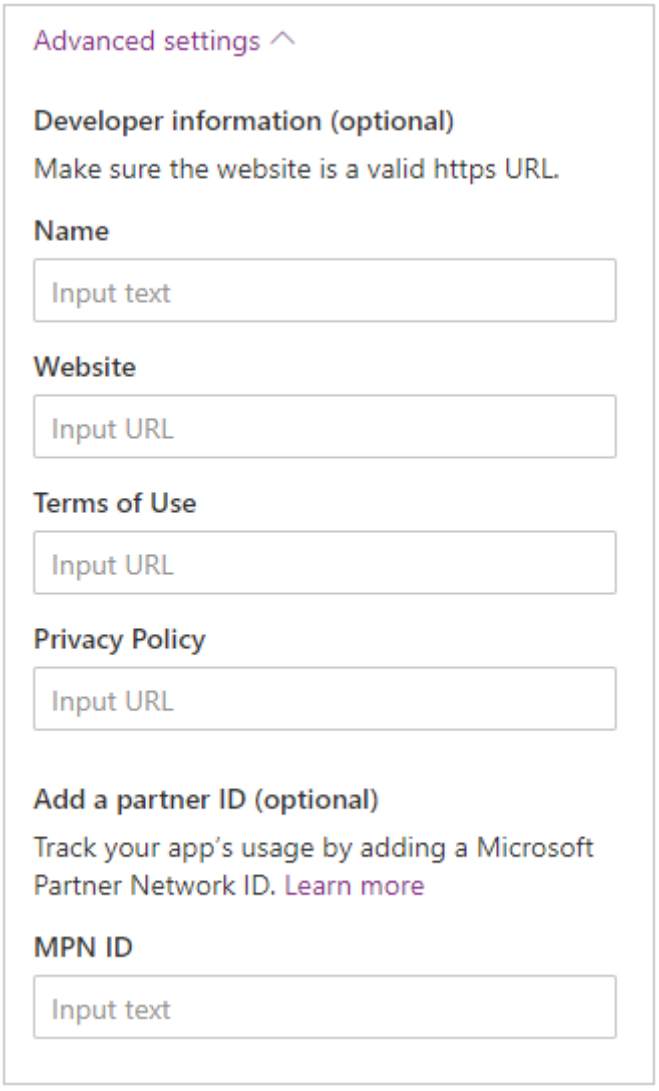


3. **Add to Teams** panel opens on the right-side of the screen.



4. (Optional) If the app doesn't have any description, select **Edit details** to open the app in add designer to add.

5. (Optional) Select **Advanced settings** to add additional details such as *Name*, *Website*, *Terms of Use*, *Privacy Policy*, *MPN ID* (Microsoft Partner Network ID).



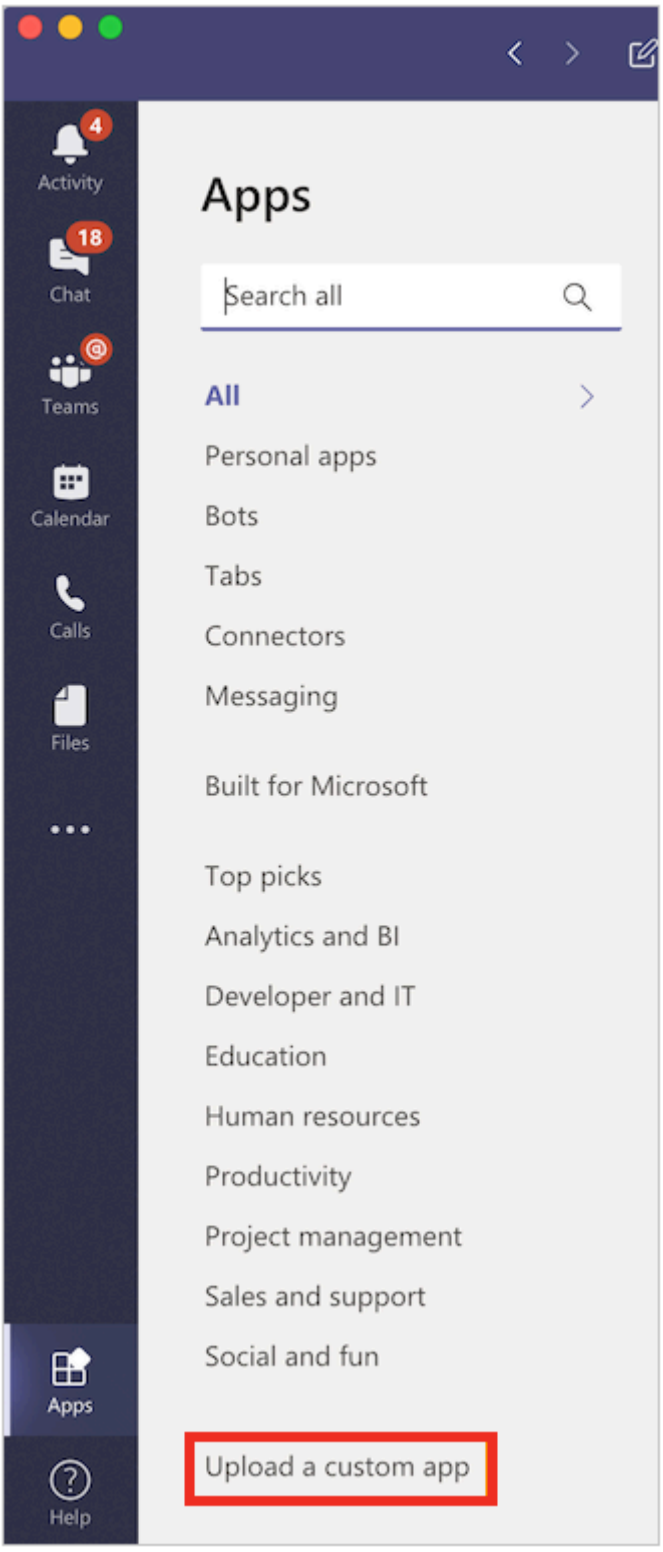
6. Select **Add to Teams** to add the app as a personal app or select **Add to a team** or **Add to a chat** to add the app as a tab within an existing channel or conversation.

Download app

You can also **Download app** in Power Apps. Power Apps will then generate your Teams manifest file using the app description and logo you've already set in your app.

1. To add the app as a personal app or as a tab to any channel or conversation, select **Apps** in the left navigation and then select **Upload a custom app**.

> ⓘ Note
>
> The **Upload a custom app** only appears if your Teams administrator has created a custom app policy and turned on **Allow uploading of custom apps**.



2. Select **Add** to add the app as a personal app or select **Add to team** to add the app as a tab within an existing channel or conversation.

Publish the app to the Teams catalog

If you're an admin, you can use the **Download app** option to also publish the app to the Microsoft Teams catalog.

Features currently unavailable

- Running **Model-driven apps** on the Microsoft Teams mobile app is currently not supported.
- Embedded canvas apps are not supported.
- Custom pages are not supported.

Navigate to advanced model-driven app making and customization areas

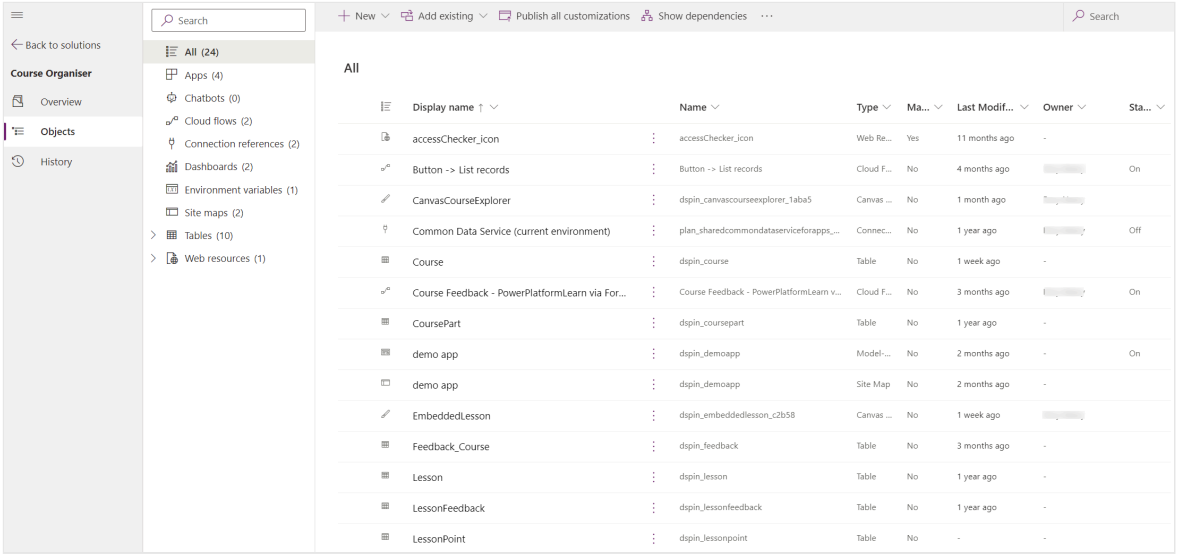
Article • 11/14/2024

This article describes how to access advanced customization and administration areas that are available within a Power Apps environment.

Solutions

The solutions area is where you can view, edit, create, import, export, and delete managed and unmanaged solutions.

1. Sign in to Power Apps.
2. On the top right, select the Environment where your solution is located.
3. On the left navigation pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Select the solution you want.



Solution explorer

Use classic solution explorer to perform app making and customization tasks that can't be completed from the Power Apps website (make.powerapps.com).

1. From Power Apps (make.powerapps.com), go to **Solutions** on the left navigation pane, and then open the solution your want. If the item isn't in the side panel

pane, select ...More and then select the item you want.

2. On the command bar select **Switch to classic**.

The solution explorer is displayed in a new browser window.

Create or edit model-driven app web resources to extend an app

Web resources are typically used by developers to extend an app using files that are used in web development. App users may need to manage web resources provided by a developer or designer.

> **Tip**
>
> For an in-depth discussion of web resources, see **Developer Documentation: Web resources for model-driven apps**.

What are web resources?

Web resources are virtual files stored in the system. Each web resource has a unique name that can be used in a URL to retrieve the file. Think of them this way: If you had access to the actual web server running the web app, you could copy files over to that website. But with most online services, you can't do this. Instead, you can use web resources to upload files to the system and then reference them by name just as though you had copied them as files to the web server.

For example, if you create an HTML page as a web resource named "new_myWebResource.htm", you could open that page in a browser using a URL like this:

```
<base URL>/WebResources/new_myWebResource.htm
```

where <*base URL*> is the part of the URL you use to view apps that end in `dynamics.com`. Because the web resource is data in the system, only licensed users for your organization can access them this way. Normally, web resources are included in forms rather than referenced directly. The most common usage is to provide JavaScript libraries for form scripts.

Because web resources are data in the system and are solution aware, you can move them to different organizations by exporting them as part of a solution and importing the solution into a different organization. You must use solution explorer to work with web resources.

File types accepted as a web resource are HTML, CSS, JScript, XML, PNG, JPG, GIF, ICO, and XSL.

Solution publisher prefix

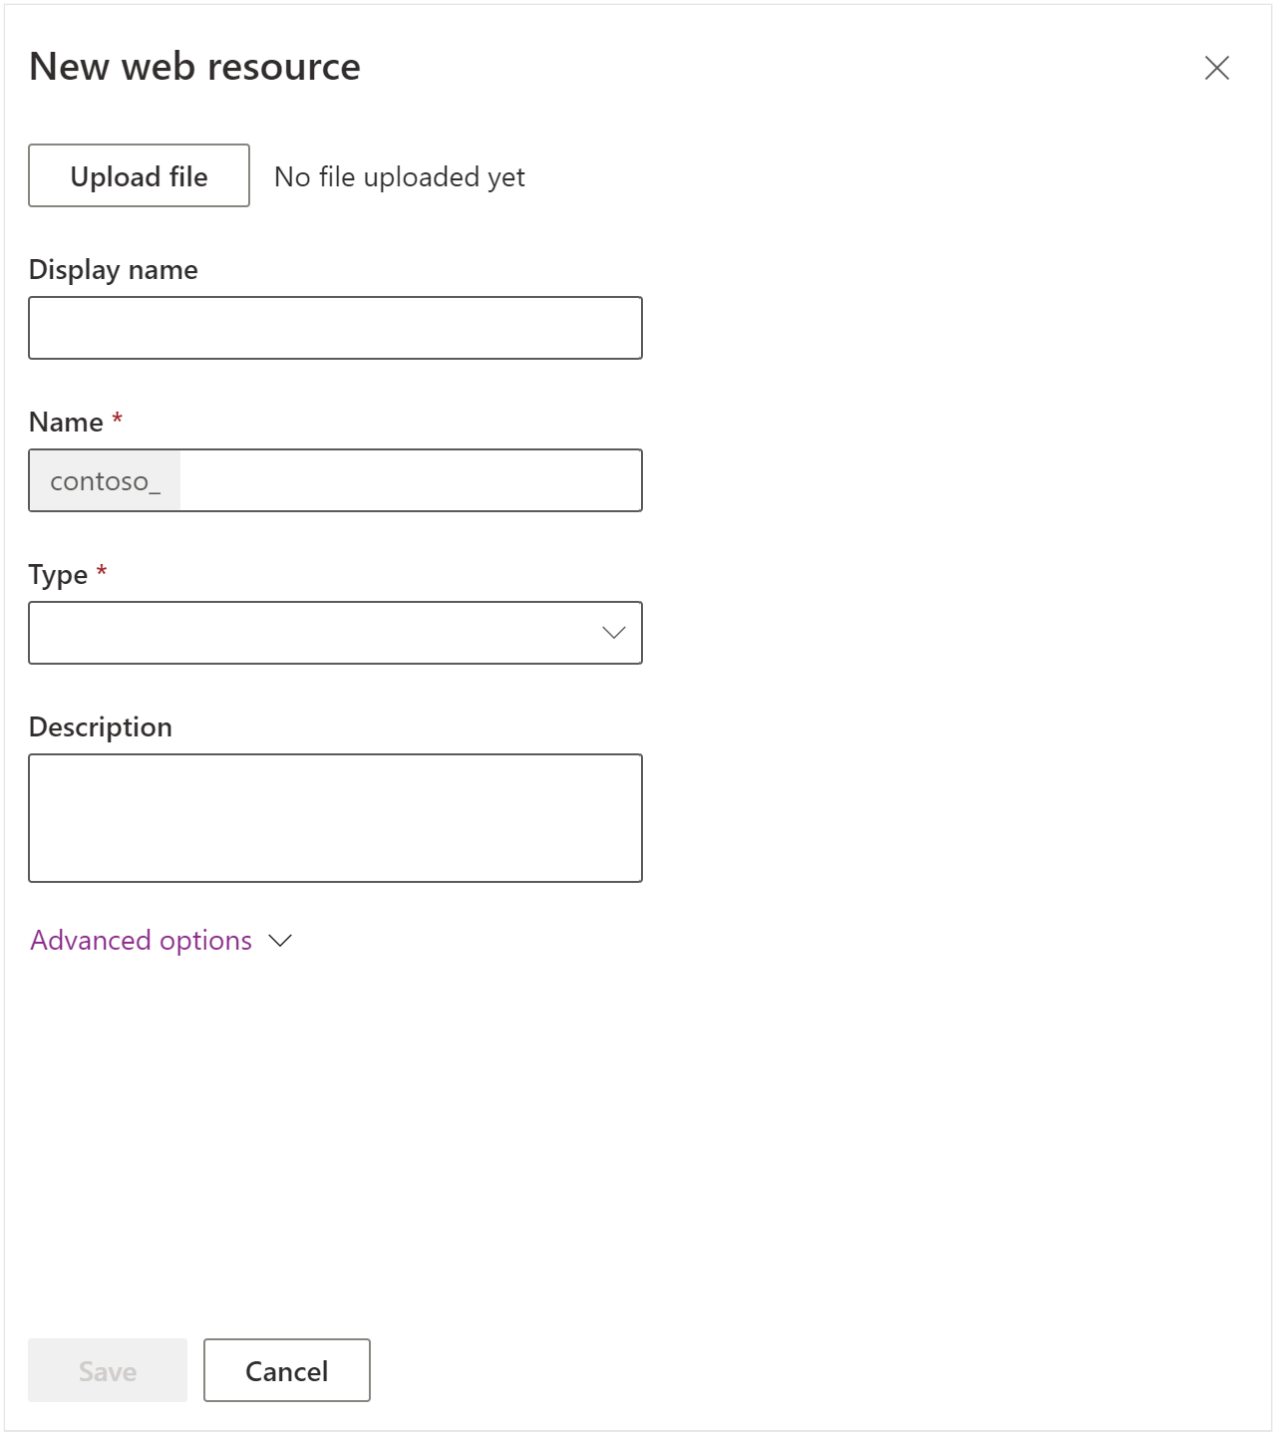
Part of the name of any web resource you create is the solution publisher prefix. This is set based on the solution publisher for the solution you're working in. Make sure that you're working in the unmanaged solution where the publisher prefix is the one you want for this web resource. More information: Solution publisher

Add a web resource to a solution

1. Sign in to Power Apps, and then on the left navigation pane select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open an unmanaged solution, on the command bar select **Add existing**, point to **More**, and then select **Web resource**. The list of web resources available are displayed.
3. To add a web resource to the unmanaged solution, select the web resource, and then select **Add**.

Create or edit a web resource for a solution

1. Sign in to Power Apps, and then on the left navigation pane select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open an unmanaged solution.
3. To edit an existing web resource that is part of the unmanaged solution, select it to display the **Edit web resource** pane. To create a new one, on the command bar select **New**, point to **More**, and then select **Web resource**.
4. Complete the fields on the right web resource pane to create or edit the web resource:



Expand table

Column	Description
Upload file	Select the **Upload file** button to choose a file to upload as a web resource. • You can upload a file when creating a new web resource or to overwrite an existing web resource. • The file name extension of the file must match allowed extensions. • By default the maximum size file that can be uploaded as a web resource is 5MB. This value can be modified by using the **System Settings** > **Email** tab > **Set file size limit for attachments** setting. More information: System Settings dialog box - Email tab

Column	Description
Display Name	The name displayed if you view a list of web resources.
Name	*Required*. The unique name for this web resource. You can't change this after you save the web resource. • This name can only include letters, numbers, periods, and nonconsecutive forward slash ("/") characters. • The solution publisher customization prefix will be prepended to the name of the web resource.
Type	*Required*. This is the type of web resource. You can't change this after you save the web resource.
Description	A description of the web resource.
Advanced options	Expand **Advanced options** to reveal the **Language** field, which allows for a selection of a language. This option just tags the row that stores the web resource data. It doesn't change the behavior of the web resource.

5. After you have added your changes, select **Save** and then select **Publish**. After you save the web resource, the **URL** to the web resource is displayed in the web resource definition. Select this link to view the web resource in your browser.

> ⓘ Note
>
> Changes to a web resource will not be visible in the application until you publish it.

Add a web resource to a model-driven app form

1. Open the form where you want to add a web resource for editing.
2. Select the **Components** pane, expand **Display**, and then select the web resource type you want:
   - **HTML Web resource**. A webpage (HTML) you can use to create user interface elements for client extensions. More information: Webpage (HTML) web resources
   - **Image web resource**. Use image web resources to make images available for use in model-driven apps. Supported image formats are: PNG, JPG, GIF, ICO, and SVG (vector format). More information: Image web resources
3. Select the web resource from the list and then select **Add**. Alternatively, select **New web resource** to create the web resource you want. More information: Web resource

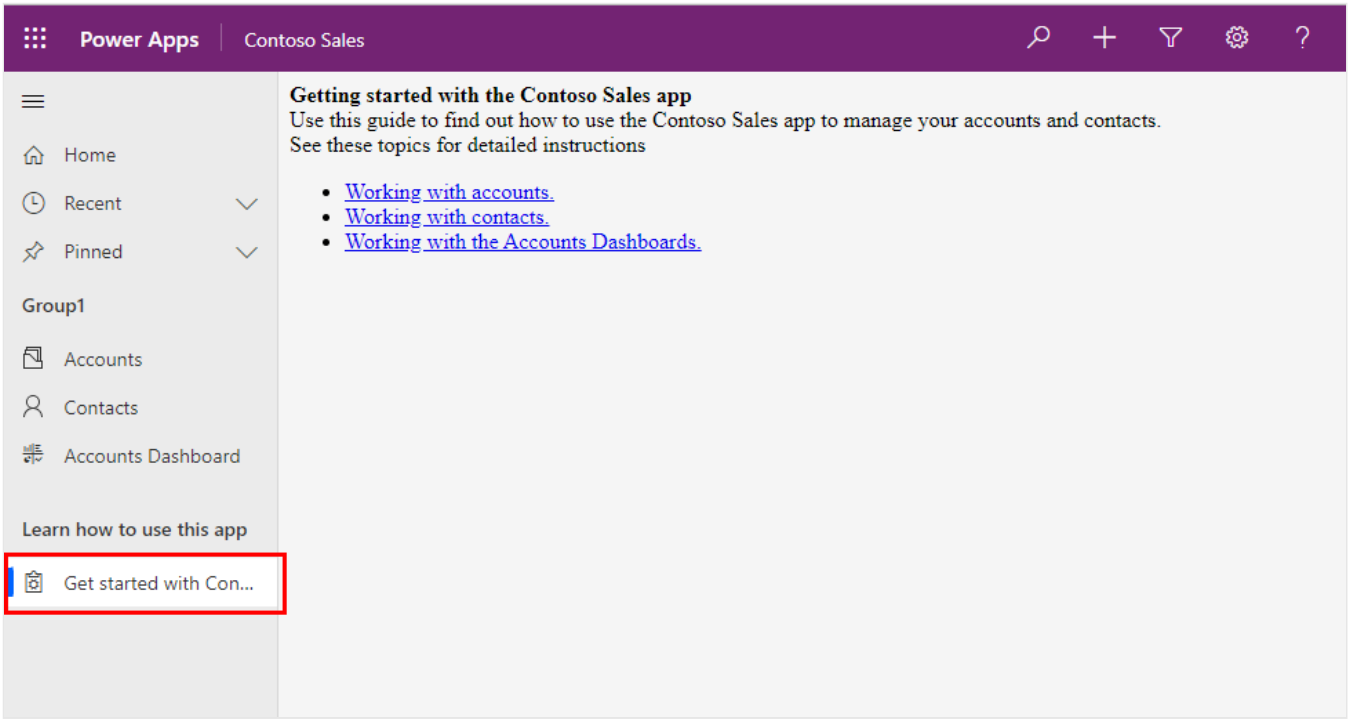
properties for model-driven app forms

> **Note**
>
> You can't add a web resource to a form header or footer.

Add a web resource to an app (preview)

[This topic is pre-release documentation and is subject to change.]

You can add a web resource as a subarea type in a model-driven app. Web resources are files you can use to extend a model-driven app. The web resource subarea can be HTML code or an HTML file, such as .htm or .html. When the user selects the subarea, the HTML is displayed in the app.



> **Note**
>
> By default, web resource subareas are disabled. To enable, go to Navigation pane options.

1. In the model-driven app designer, select **Navigation** > **Add** > **Subarea**.

2. In the subarea properties, enter the following information:

   - **Content type**: **Web resource**.
   - **URL**: Select an HTML web resource file name from the list to add the web resource's URL. More information: Create or edit model-driven app web resources to extend an

app

- **Title**: Enter the title that will appear on the subarea in the app.

3. Select **Save**, and then select **Publish**.

Edit a web resource using the classic solution explorer

1. Open an unmanaged solution and select the web resource.
2. Select the vertical ellipsis > **Edit** > **Edit in classic**.
3. Complete the form to create the web resource:

Expand table

Column	Description
Name	*Required*. This is the unique name for this web resource. You can't change it after you save the web resource. • This name can only include letters, numbers, periods, and nonconsecutive forward slash ("/") characters. • The solution publisher customization prefix will be prepended to the name of the web resource.
Display Name	The name displayed if you view a list of web resources.
Description	A description of the web resource.
Type	*Required*. Type of web resource. You can't change this after you save the web resource.
Text Editor	When the type of web resource represents a kind of text file, select this button to open a page to edit the content using the text editor. More information: Use the text editor appropriately
Language	Allows for a selection of a language. This option just tags the row that stores the web resource data. It doesn't change the behavior of the web resource.
Upload File	Select the **Choose File** button to choose a file to upload as a web resource. • You can upload a file when creating a new web resource or to overwrite an existing web resource. • The file name extension of the file must match allowed extensions. • By default the maximum size file that can be uploaded as a web resource is 5 MB. This value can be modified by using the **System Settings** > **Email** tab > **Set file size limit for attachments** setting. More information: System Settings dialog box - Email tab
URL	After you save the web resource, the URL to the web resource will be displayed here. Select this link to view the web resource in your browser.

1. After you have added your changes, select **Save** and then select **Publish**.

Use the text editor appropriately

The text editor provided in the application for web resources should only be used for simple edits of text files. You can use it to create and edit HTML web resources, but you should only edit HTML web resources that were created using the text editor. The text editor is designed for very simple HTML content.

> **Important**
>
> If the content of an HTML web resource wasn't created using the text editor, don't use the text editor to edit it.
> The text editor uses a control that modifies the HTML source in a way that allows it to be edited. These changes can make the page behave differently in the browser and cause more sophisticated code to stop working. Opening an HTML web resource with the text editor and saving it without making any changes can break some HTML web resources.

We recommend that you use an external editor to edit text files and then save them locally before uploading them with the **Upload File** button. This way you can preserve a copy of the web resource if you need to return to an earlier version. You can use a simple editor like Notepad, but a text editor with more advanced capabilities is highly recommended. Visual Studio Community and Visual Studio Code are free and provide powerful capabilities for editing the text-based files used by web resources.

Create and edit a web resource on a form using solution explorer

Add or edit web resources on a form to make it more appealing or useful to users.

Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

Navigate to a form

With solution explorer open, under **Components**, expand **Entities**, and then expand the table you want to work with.

Choose **Forms**, in the list locate a form of type Main, and then double-click or tap the entry to open and edit the form.

Add or edit web resource in a form

See Web resource properties for information about the properties you can set for web resources in a form.

Preview

To preview how the main form will appear and how events will function:

- On the **Home** tab, select **Preview**, and then select **Create Form**, **Update Form**, or **Read-Only Form**.
- To close the Preview form, on the **File** menu, select **Close**.

Save

When you finish editing the form, on the **Home** tab, select **Save and Close** to close the form.

Publish

When your customizations are complete, publish them:

- To publish customizations for only the component that you're currently editing, in the navigation pane, select the table you have been working on, and then select **Publish**.
- To publish customizations for all unpublished components at one time, in the navigation pane, select **Entities**, and then on the **Actions** toolbar, select **Publish All Customizations**.

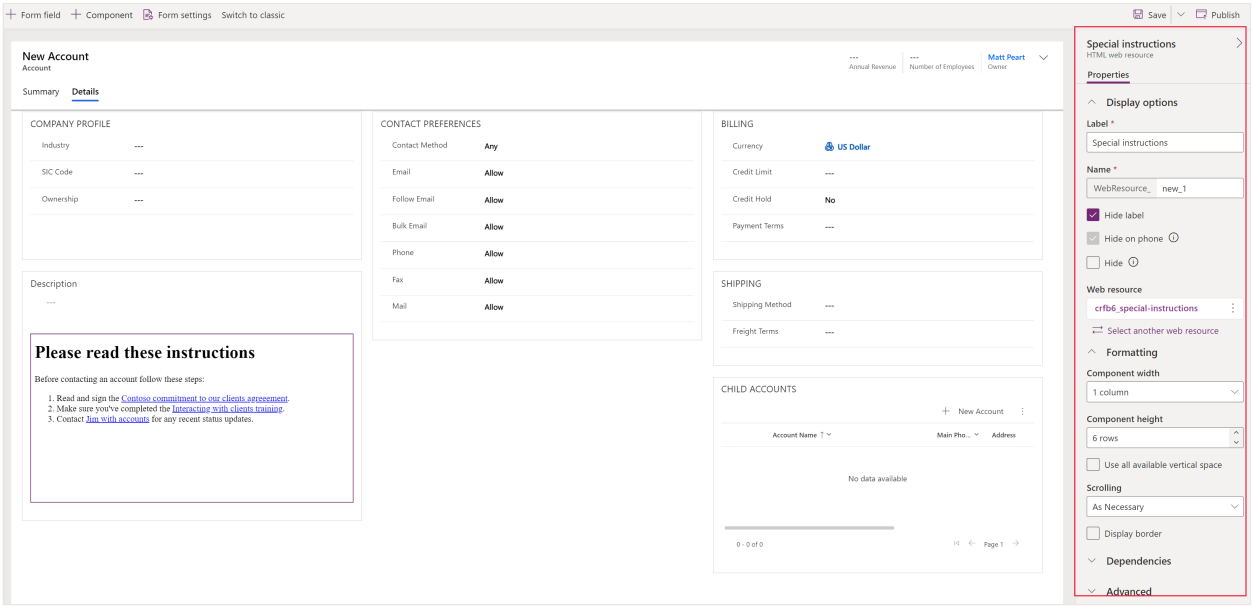
View and edit web resource properties for model-driven app forms

Article • 06/13/2022

This article describes how to use the form designer to view and edit web resources on a form. Form enabled web resources are image or HTML files.

View and edit a web resource on a form

Open a main form and select the area of the form that has the web resource. The web resource properties are displayed on the right properties pane.



These properties define the web resource to use and how it should behave. After you've made the changes you want, select **Save**. To make the changes available to users, select **Publish**.

Display options

Property	Description
Label	Is the friendly name and is automatically generated based on the **Name** column value. Specify localizable text for the web resource control that will be added to the form.
Name	Specify a name for the web resource control that will be added to the form. This value uniquely identifies the control in the form.

Property	Description
Web resource	Select the web resource to display additional web resource properties. If you are using **Custom parameter data** enter it here. This is usually configuration data that will be passed to the HTML web resource as a `data` query string parameter. Scripts associated with the HTML page can access this data and use it to change the behavior of the page. Select **Edit web resource** to make changes such as load a different HTML or image file. Hide label	Select this option if you don't want the label displayed on the form.
Hide on phone	Select this option when you don't want this web resource to be visible in mobile apps.
Hide	While this is enabled the web resource won't be visible when the form loads. If you have a business rule or form script that will show the web resource as needed, check this property. More information: Show or hide form elements

Formatting

Property	Description
Component width	When the section containing the web resource has more than one column you can set the column to occupy up to the number of columns that the section has.
Component height	You can control the height of the web resource by specifying a number of rows or select **Use all available vertical space** to allow the web resource height to expand to available space.

Property	Description
Scrolling	An HTML web resource is added to the form using an IFRAME. - **As Necessary**: Show scrollbars when the size of the web resource is larger than the available. - **Always**: Always show scrollbars. - **Never**: Never show scrollbars.
Display border	Displays a border around the HTML web resource.
Vertical alignment	Image web resources can be aligned **Middle**, **Top**, or **Bottom**.
Horizontal alignment	Image web resources can be aligned **Center**, **Left**, or **Right**.
Size	For image web resources select from **Use available space**, **Use available area**, **Original image size**, or **Specific size** (specify **Height** and **Width** in pixels).

Dependencies

Property	Description
Table column dependencies	An HTML web resource may interact with columns in the form using script. If a column is removed from the form the script in the web resource may break. Add any columns referenced by scripts in the web resource to this property so that they can't be removed accidentally.

Advanced

Property	Description
Restrict cross-frame scripting where supported	Use this option if you don't fully trust the content in the HTML web resource. More information: Developer Documentation: Select whether to restrict cross-frame scripting
Pass row object-type code and unique identifier as parameters	Data about the current row visible in the form can be passed to the HTML web resource page so that script running in the page can access data about the row. More information: Pass parameters to web resources Developer Documentation: Pass contextual information about the row

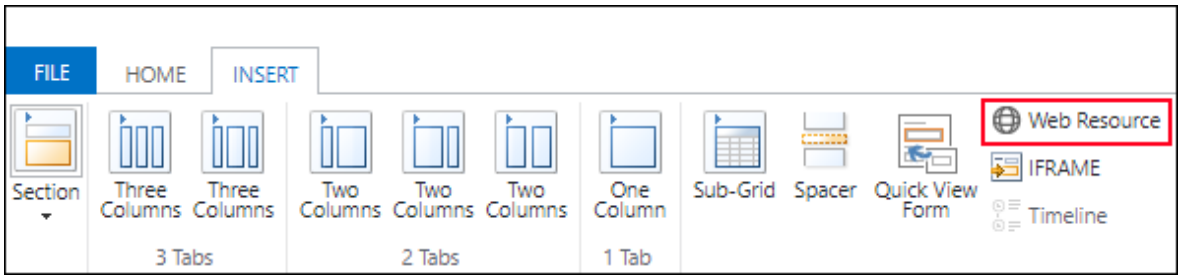
Web resource properties for model-driven app forms (classic)

This section describes how to use the legacy app authoring interface to add or edit web resources on a form to make it more appealing or useful to app users. Form enabled web resources are images or HTML files controls.

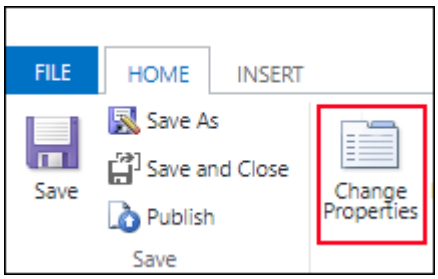
Access web resource properties

While viewing a form:

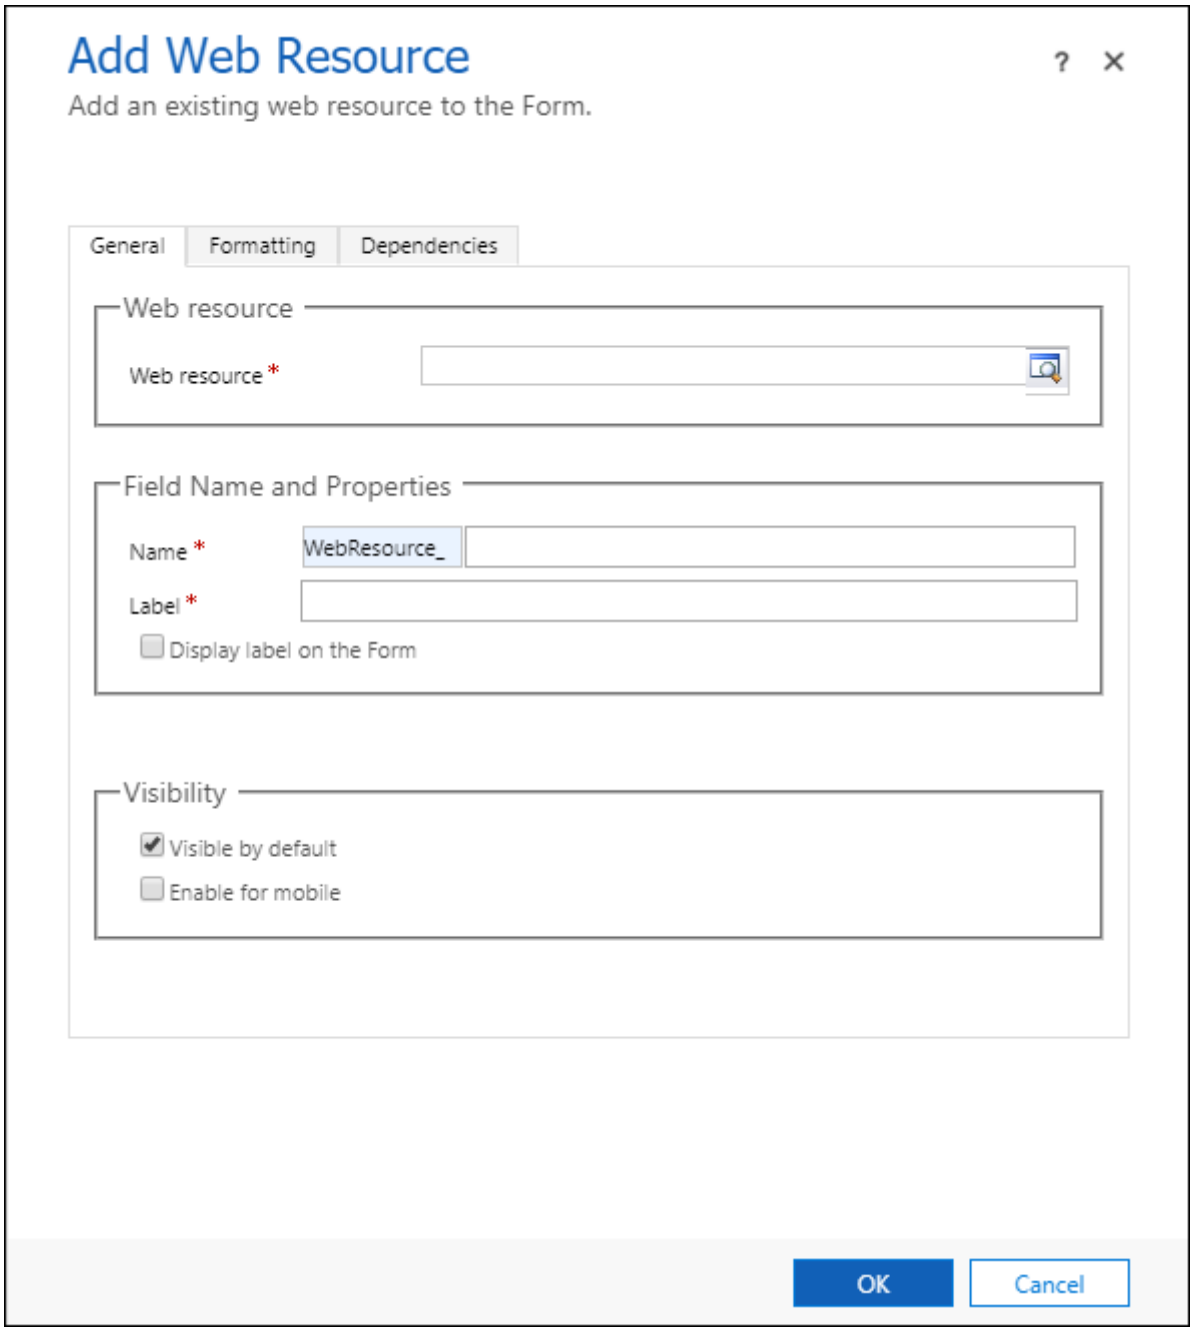
- **When adding a web resource:**: Select the tab (for example, **General** or **Notes**) you would like to insert it on, and then on the **Insert** tab, select **Web Resource**.



- **When editing a web resource**: Select a form tab and the web resource that you want to edit, and then on the **Home** tab, select **Change Properties**.



This will open the **Add Web Resource** or **Web Resource Properties** dialog box.



> **ⓘ Important**
>
> You must select the **Visible by default** option for the web resource to appear on the form and be available to users.

Web resource properties

The **Add Web Resource** or **Web Resource Properties** dialog box will have two, sometimes three tabs depending on the type of web resource.

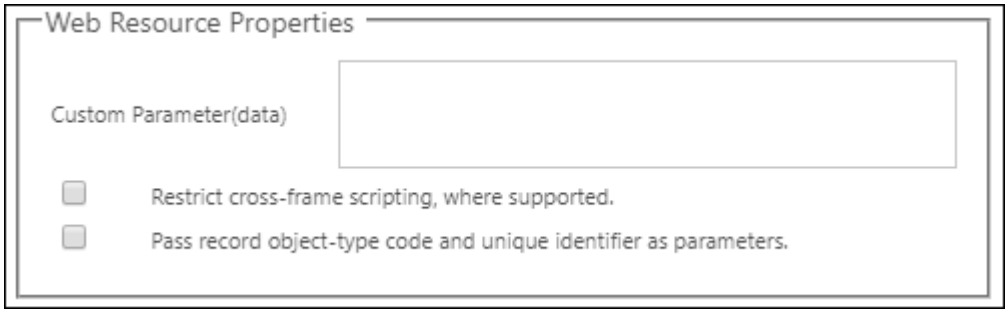
General tab

These properties define the web resource to use and how it should behave.

Column	Description
Web resource	*Required.* Look up an existing web resource or create a new one. Use the **Form Enabled Web Resource** view to include only HTML and image web resources that can be added as visual elements in a form.
Name	*Required.* Specify a name for the web resource control that will be added to the form. This value uniquely identifies the control in the form.
Label	*Required.* Automatically generated based on the **Name** column value. Specify localizable text for the web resource control that will be added to the form. Select **Display label on the form** if you want to make this visible.
Visible by default	While this is enabled the web resource will be visible when the form loads. If you have a business rule or form script that will show the web resource as needed, uncheck this column. More information: Show or hide form elements
Enable for mobile	Select this option to allow this web resource to be visible in mobile apps.

Depending on the type of web resource you select, set additional properties.

For HTML web resources you will see these:

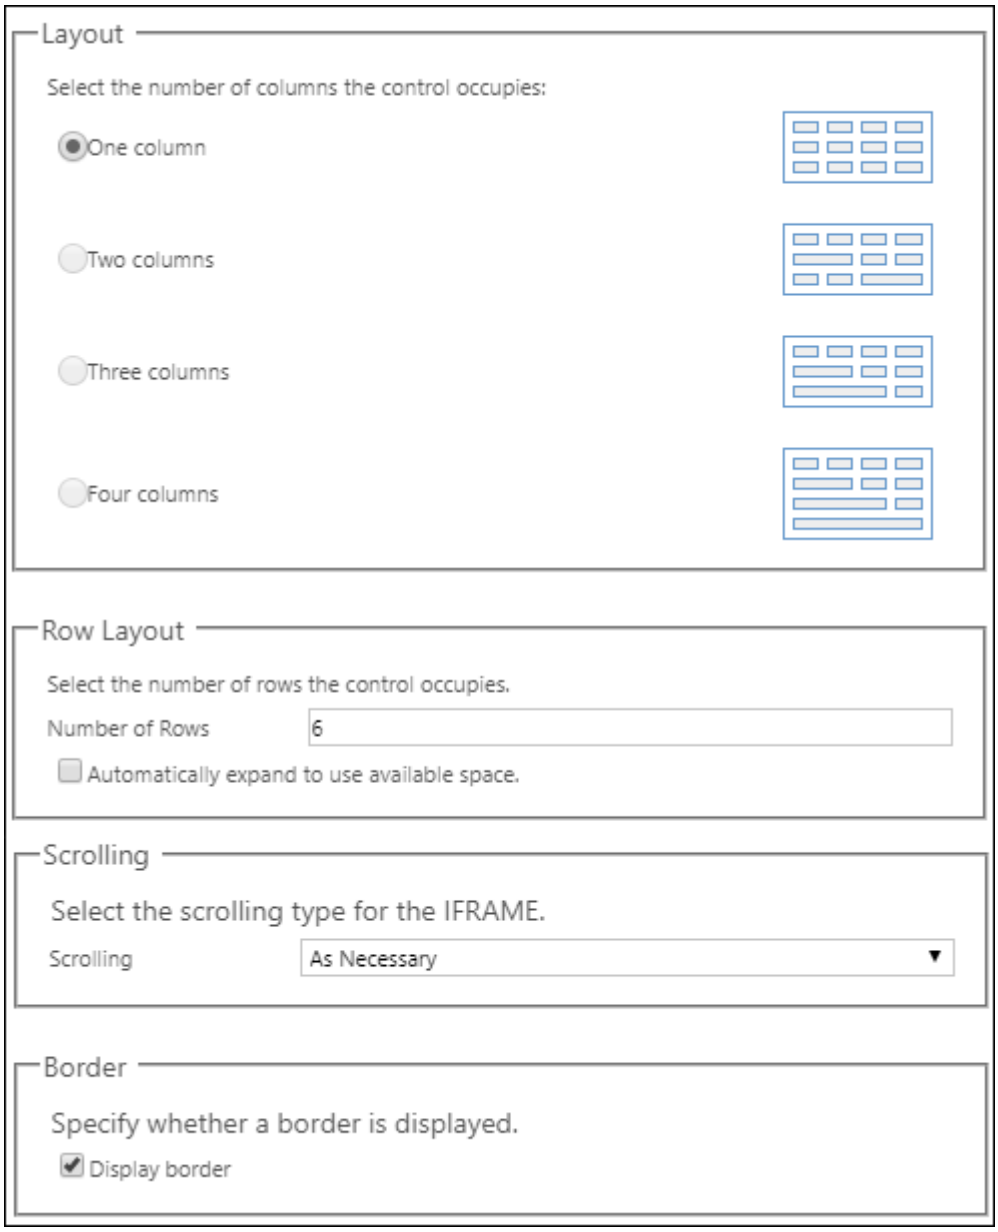


Column	Description
Custom Parameter(data)	Usually configuration data that will be passed to the HTML web resource as a `data` query string parameter. Scripts associated with the HTML page can access this data and use it to change the behavior of the page.
Restrict cross-frame scripting where supported	Use this option if you don't fully trust the content in the HTML web resource. More information: Developer Documentation: Select whether to restrict cross-frame scripting
Pass row object-type code and unique identifier as parameters	Data about the current row visible in the form can be passed to the HTML web resource page so that script running in the page can access data about the row. More information: Pass parameters to web resources Developer Documentation: Pass contextual information about the row

For Image web resources you have the option to specify **Alternative Text** that is important for assistive technologies that make the page accessible to everyone.

Formatting tab

On the **Formatting** tab, the options that display vary based on the type of web resource inserted and the context where it is inserted. These options include specifying the number of columns and rows display, whether a border displays, and the scrolling behavior.



Property	Description
Select the number of columns the control occupies	When the section containing the web resource has more than one column you can set the column to occupy up to the number of columns that the section has.

Property	Description
Select the number of rows the control occupies	You can control the height of the web resource by specifying a number of rows or select **Automatically expand to use available space** to allow the web resource height to expand to available space.
Select the scrolling type for the IFRAME	An HTML web resource is added to the form using an IFRAME. - **As Necessary**: Show scrollbars when the size of the web resource is larger than the available. - **Always**: Always show scrollbars. - **Never**: Never show scrollbars.
Display border	Display a border around the web resource.

Dependencies tab

A web resource may interact with columns in the form using script. If a column is removed from the form the script in the web resource may break. Add any columns referenced by scripts in the web resource to the **Dependent columns** so that they cannot be removed accidentally.

Pass parameters to web resources

An HTML web resource can accept parameters to be passed as query string parameters.

Information about the row can be passed by enabling the **Pass row object-type code and unique identifiers as parameters** option. If information is typed into the **Custom Parameter(data)** column it will be passed using the data parameter. The values passed are:

Parameter	Description
`data`	This parameter is only passed when text is provided for **Custom Parameter(data)**.
`orglcid`	The Organization default language LCID.
`orgname`	The name of the organization.
`userlcid`	The user's preferred language LCID
`type`	**Don't use this.** The table type code. This numeric value can be different for custom tables in different organizations. Use table type name instead.
`typename`	The table type name.
`id`	The id value of the row. This parameter has no value until the table row is saved.

Any other parameters are not allowed and the web resource will not open if other parameters are used. If you need to pass multiple values, the data parameter can be overloaded to include more parameters within it.

More information: Developer Documentation: Pass contextual information about the row

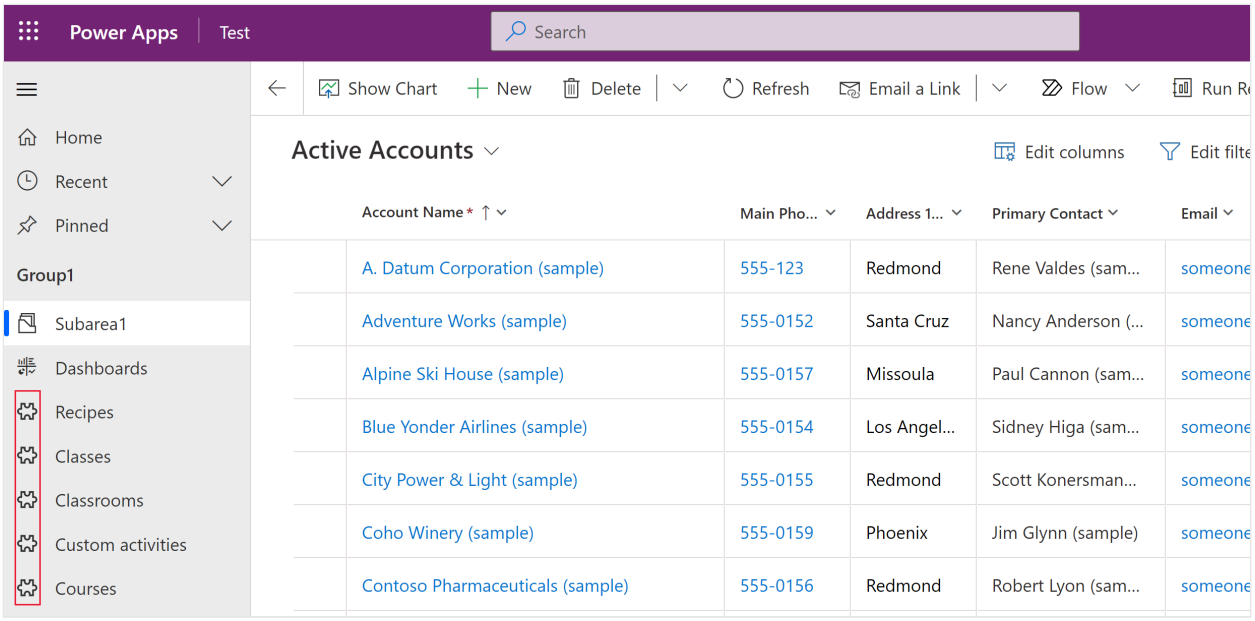
Change model-driven app custom table icons

Article • 04/29/2024

When a custom table is created, a default icon is automatically assigned. All custom tables use the same icon by default. Use custom icons to differentiate how your custom tables look. It's not possible to modify the icons assigned to system tables.

In the example here, the accounts table has an icon already assigned to it as it's a system table, however the other tables have the default icon.



Icons can be used for the following purposes with model-driven apps.

Expand table

Icon Type	Description
Table icon	An .svg, .gif, .png, or .jpg format image, 16x16 pixels in size. This article describes how to edit the table icon.
Icon for table forms	An .svg, .gif, .png, or .jpg format image, 32x32 pixels in size. More information: Enable or disable table options
App icon	Must be a scalable vector graphic (.svg) icon. More information: Manage model-driven app settings in the app designer

Note

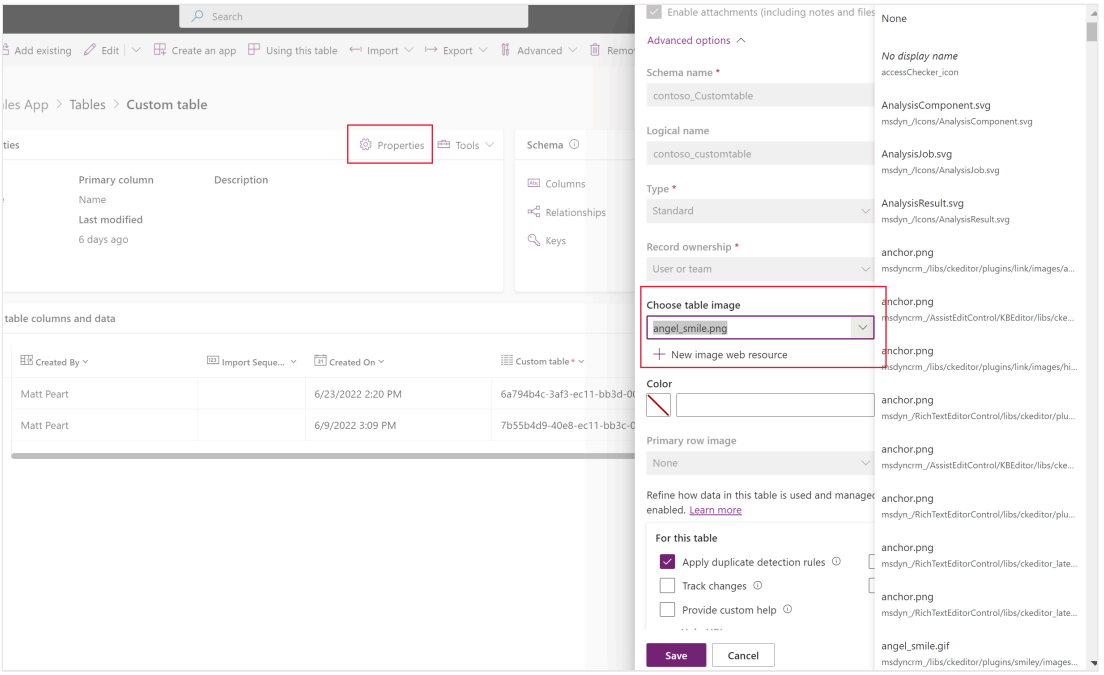
- All image files must be no more than 10 kilobytes in size.

- Setting the icon in the app designer overrides the table definition icon setting. When the table icon in app designer is set to the default icon, the icon specified in the table definition is displayed in the app.
- When a scalable vector graphic (.svg) image is used as the app icon or icon for table forms, it must have the default size set. Since SVG is an XML document, the svg element width, height and viewBox values can be edited with a text editor to define the default size for the image.
- Where possible, remove any hard coded fill color attributes and use the currentColor keyword to avoid contrast issues. More information: Image web resources

Each type of icon is stored as a web resource. Create a web resource first and then set the icons to use them. Alternatively, you can add the icon by creating a new web resource when you define the table properties.

Set the icons for a custom table from the table definition

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and open the solution you want or create a new one. Then open the custom table from the solution. To use the default solution, select **Tables** on the left navigation pane, and then open the table you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Properties**. In the right **Edit table** pane, expand **Advanced options**.
4. Under **Choose table image**, select from the following options:
    - Select the dropdown to choose an existing web resource.
    - Select **New image web resource** to create a web resource to add the icon. More information: Create or edit web resources to extend an app



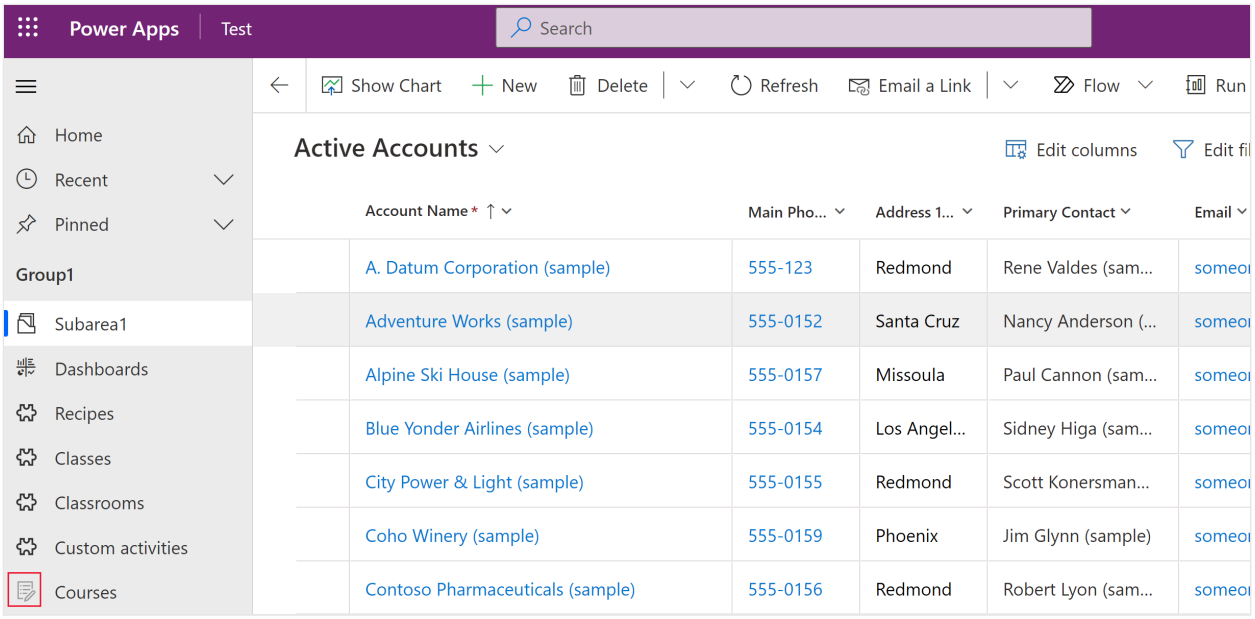
5. Select **Save**.

Set the icon for a table in app designer

1. On the app designer left pane, select the table.
2. In the right table properties pane, under **Icon**, select **Use web resource** > **Select icon**.
3. Select from the list of existing image web resources or select New to create a new one.
4. Select **Select**, and then select **Publish** to make the changes available in your app.

Review changes to your model-driven app icons

When the updates take effect, they can be reviewed by playing the app. In this case, the *Courses* table and its icon are updated.



Set the icons for a custom table (classic)

1. From Power Apps, select **Solutions** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select the unmanaged solution that contains the tables where icons need to be set.
3. Select **Switch to classic** from within the solution command bar (you might need to select **...** first). The classic solution explorer will open the solution.
4. In the classic solution explorer, expand **Entities** (tables).
5. Select the custom table that requires an updated icon.

Set table icons

1. On the command bar, select **Update Icons**.
2. In the **Select New Icons** dialog, on the **Web Client** tab, under **Icon in Web application** or **Icon for Entity Forms**, to the right of **New Icon**, select the **Browse** button .
3. Select or create the appropriate web resource, and then select **OK**.
4. In the **Unified Interface** tab, do the same for the **New Icon** column.
5. Select **OK** to close the **Select New Icons** dialog.
6. On the command bar, on the **File** menu, select **Save**.
7. When your changes are complete, publish them. Select **Publish** in the command bar while the table is selected in solution explorer.

Community tools

Iconator is a tool that XrmToolbox community developed for Power Apps. A designer can use the tool to **update** icons associated with a table in addition to introducing **new icons**.

See the Developer tools for Microsoft Dataverse article for community developed tools.

> **Note**
>
> The community tools are not a product of Microsoft and Microsoft doesn't provide support for the community tools. If there are questions relating to the tool, please contact the publisher. More Information: XrmToolBox.

Distribute a model-driven app using a solution

Summarize this article for me

Model-driven apps are distributed as solution objects. After a model-driven is created, it can be made available for other environments to use by adding the app to a solution and then exporting it.

After the exported solution (a .zip file) is successfully imported in the target environment, the app is available for use provided users have the security roles relevant to the tables or other objects in the app.

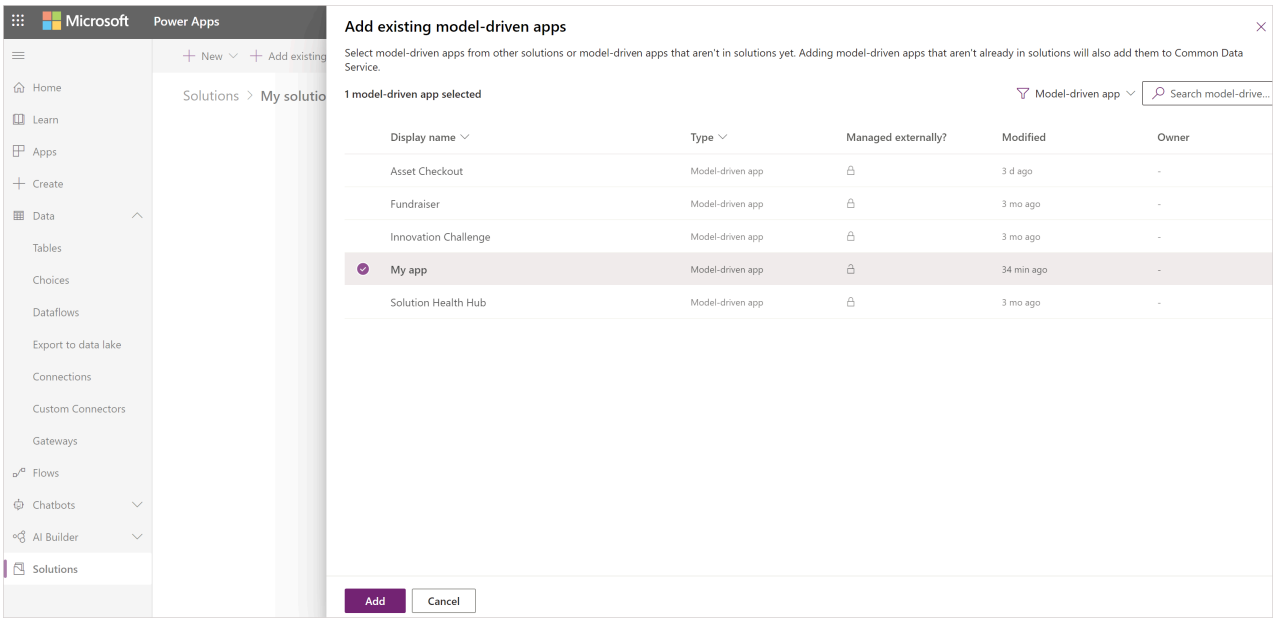
Moving solutions between environments is the basis for how you apply application lifecycle management to the products created.

This article describes how to work with solutions in a basic fashion. Go to this article for detailed guidance on working with solutions.

Add an app to a solution

To distribute an app, you create a solution so that the app can be packaged for export.

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and then select **New solution**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Enter the properties on the **New Solution** page, and then select **Save**. More information: Create a solution
4. The **Solution** page appears. Select **Add Existing**, select **App**, select **Model-driven app**, select the app that is to be added to the solution, and then select **Add**.



5. If a **Missing Required Components** page appears we recommend selecting **Yes, include required components** to add necessary components such as tables, views, forms, charts, and site map that are part of the app. Select **OK**.

Export a solution

To distribute an app so it can be imported into other environments or made available on Microsoft Marketplace, export the solution to a zip file. Then, the zip file that contains the app and components can be imported into other environments.

1. Select **Solutions** on the left navigation pane of Power Apps. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select the solution, and then on the toolbar select **Export solution**.

3. On the **Before you export** pane, we recommend that you **Publish**, before selecting **Next**.

4. If there a are missing dependencies, the **Manage solution dependencies** pane appears. Select **Next** to add the missing dependencies.

5. On the **Export this solution** pane, accept the incremented version number already provided or enter a different one, select **Unmanaged** or **Managed**, and then select **Export**. For more information about solution package types, go to Solutions overview.

> **Note**
>
> - Typically you export a solution as **Managed** because you want to continue to work on the project in the current environment. Unmanaged versions of your solutions should be considered your source for Microsoft Power Platform assets

and checked into your source control system. We don't recommend that you import unmanaged solutions into non-development environments.
- By default, **Run solution checker on export** is selected. We recommend that you allow solution checker to run to identify issues that might occur with the export.

6. Depending on the browser and settings, a .zip package file is built and copied to the default downloads folder. The file name of the package is based on the unique name of the solution appended with underscores and the solution version number.

> ⓘ **Note**
>
> When you export an app by using a solution, the app URL isn't exported.

Import a solution

When you receive a solution zip file that contains the app that you want to import, open the solutions component page and import the solution. When the solution has been successfully imported, the app is available in the environment.

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and then on the toolbar select **Import solution**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select from these options for where to import the solution from:

   - **This device**. Select Browse and locate the zip file, and then choose **Next**.
   - **Pipelines**. If the solution is part of a pipeline in Power Platform select this option. More information: Use pipelines in Power Platform to deploy solutions

4. Select **Import** and wait for the solution to be imported. This can take a varying amount of time based on the complexity of the solution.

Enable and use customizable help

Summarize this article for me

Customizable help lets you provide your own contextual information to model-driven app users filling in forms.

> **Note**
>
> Instead of creating and maintaining your own Help system, custom help panes and guided tasks are available that you can use to author Help that gives your Unified Interface application a custom in-product help experience that is tailored to your organization. More information: Create guided help for your Unified Interface app

With model-driven apps, you can replace the default Help with the custom Help of your choice, at the global (environment) level or table level. Custom Help makes the content exposed through the Help links more relevant for your custom or customizable tables. With a single, global URL you can override the out-of-the-box Help links for all customizable tables. Per-table URLs override the out-of-the-box Help links on grids and forms for a specific customizable table. You can include additional parameters in the URL, such as language code and table name. These parameters allow a developer to add functionality to redirect the user to a page that's relevant to their language or the table context within the application. The table level custom Help settings are solution aware, therefore you can package them as a part of a solution and transport them between environments or distribute them in solutions.

Set up customizable Help

Customizable Help can be set at the global and table levels.

> **Important**
>
> You can't use both custom help panes with customizable help at the same time. Enabling one disables the other.

Set customizable Help at the global level

People with the system administrator security role can use the settings to override default Help at the global level.

1. Sign in the Power Platform admin center. Select Manage, open the environment you want, and then select **Settings** on the command bar.
2. Expand **Product**, and then select **Features**.
3. Under **Help features**, turn **Custom help for customizable entitites** to **On**.
4. Under **Set custom Help URL**, enter the **Global custom Help URL** to your custom Help.
    - **Append Parameters to URL**. Select **Yes** to allow for parameters such as language code or table name to be appended to the **Help URL** that you specify in the table definition. More information: Append parameters to URL
5. Select **Save**.

Set customizable Help for a specific table

After you enable custom Help at the global level, system customizers can override the global Help URL for a table in the table definition.

1. Sign in to Power Apps.
2. Go to **Tables**, and then open the table you want.
3. Select **Properties**, and expand **Advanced options**.
4. In the **For this table** area, in the **Help URL** box enter the URL of your custom Help page.

Append parameters to URL

As described previously, to allow for the appending of parameters to the **Help URL** for the table definition, set **Append Parameters to URL** in the **System Settings** > **General** tab to **Yes**.

Examples of the parameters that can be appended to the URL:

- User Language Code: userlcid
- Table Name: table
- Entry Point: hierarchy chart or form
- Form ID: formid

What are performance insights? (preview)

Article • 07/10/2024

> **Important**
>
> This feature is undergoing significant improvements and until the new version becomes available the current feature is disabled.

[This topic is pre-release documentation and is subject to change.]

Performance insights are a self-service tool for enterprise app makers that analyzes runtime user data and provides a prioritized list of recommendations to help improve the performance of model-driven apps. This feature provides a daily set of analytic insights related to the performance of a Power Apps model-driven or customer engagement app, such as Dynamics 365 Sales or Dynamics 365 Service, with recommendations and actionable items. Enterprise app makers can view detailed performance insights at an app-level in the Power Apps portal.

How to access?

1. Sign in to Power Apps.
2. On the left navigation pane, select **Apps**, and then select a model-driven app.
3. Use the **...** context menu or command bar to select **Performance**.

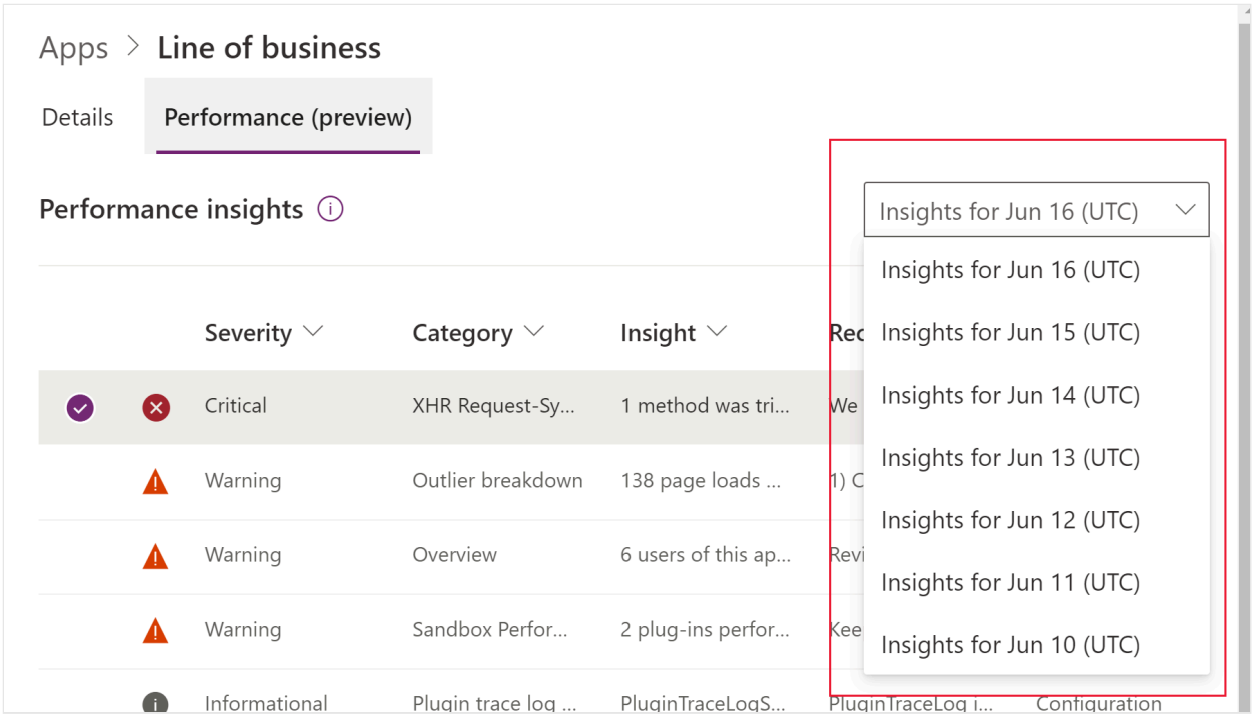
If you want to switch the environment where your app is deployed, you can select environments in the top-right corner of the page using the **Environment** selector. Alternatively, you can navigate to performance insights from a model-driven app's context menu from the **Solutions** area.

> **Important**
>
> Since recommendations are generated using user data, we recommend that you view performance insights from an environment where the app will be used, such as a production environment.

How insights are generated

Performance insights are generated based on collected user data of your model-driven app every 24 hours. When end-users use an app, key user data recorded by the Power Apps platform is stored. The performance insights engine uses this data and analyzes it to generate insights and recommendations related to performance enhancements.

Performance insights are available for all model-driven apps in your selected environment, provided there is recorded user data. You can view insights history for the previous seven days, as long as there was usage on the selected date, by selecting a date in the list on the **Performance** tab.



The performance insights engine generates insights over a 24-hour period on a selected date in the universal time coordinated (UTC) time zone. Insights for the previous day, from 00:00 to 23:59 UTC, are generated around 02:00 to 05:00 UTC on a given day. Therefore, insights and recommendations for usage user data recorded the previous day will be available in the morning in the UTC time zone. Time of availability will vary based on your local time zone and its difference from UTC.

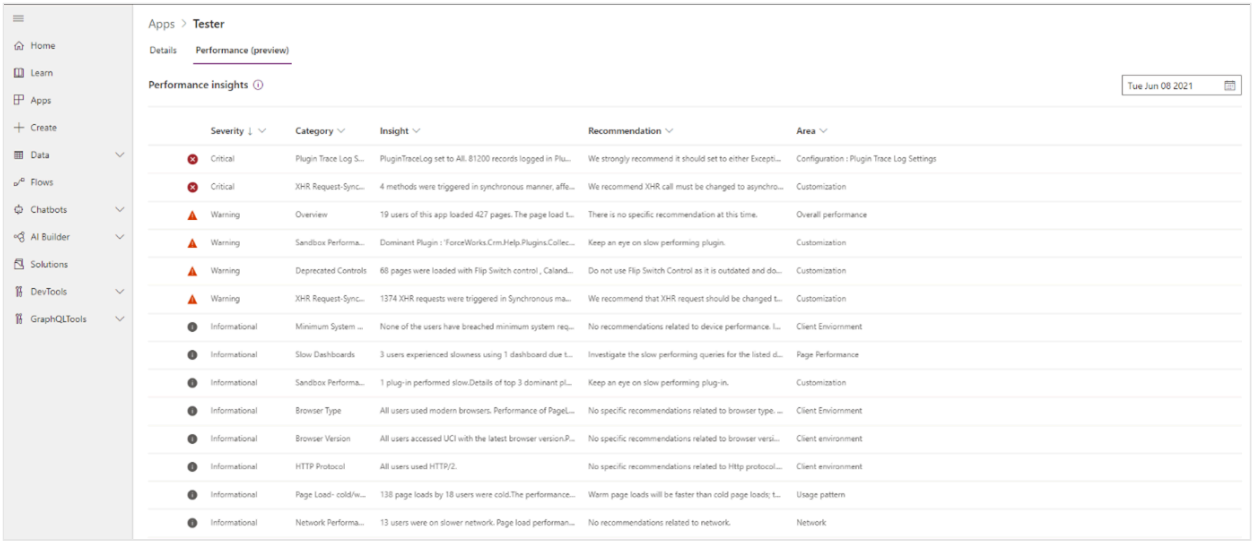
For example, insights for the 24-hour period that spans June 8 from 00:00 to 23:59 UTC are generated between 02:00 to 05:00 UTC on June 9. Therefore, insights and recommendations for user data recorded on June 8 UTC will be available the morning of June 9 UTC.

Insights can be sorted by severity – ranging from **Informational**, **Warning**, to **Critical**. Severity is weighted depending on the affect of the findings on the overall performance. Severity is determined by several factors such as the volume of usage, performance of

slow page loads, and outliers. Critical items exceed certain thresholds and we recommend you address those first.

Insights are generated for several categories from different areas including client environment, customizations, page performance, and network. For example, if several users are using the app on an older version of a non-recommended browser, performance will be slower in general. Hence, makers will see an insight related to browser type and version in the insight grid.

Performance insights provide a prioritized list of recommendations to help makers improve the performance of model-driven apps. You can select each row in the grid to view detailed information for each category.



Explanation of performance insights

The performance insights grid has these columns.

Expand table

Column	Description
Severity	An insight can be categorized as **Informational**, **Warning**, or **Critical**. Severity is determined by the performance page load time and the number of end-users impacted by an event.
Area	This area defines the aspects of analyzing user data by the engine of Performance Insights. Includes client environment, network, and usage patterns.
Category	The theme under which the specific insight falls. Categories are grouped under Areas.

Column	Description
Motivation	Gives an overview of why a particular insight could be impacting the overall performance of your app.
Insight	Details the findings related to a specific category and outlines the performance impact.
Recommendation	Outlines the actions you can take.
How to improve	Links to the documentation for a specific category, which could contain further information or external resources to help you mitigate your issue and improve performance.
Data	Evidence data to support the findings in the insight section.
Insight ID	Identifier for a specific insight category.

What aspects does it check?

Performance of a model-driven app could be affected by multiple factors. Horizontally, the app could be affected by client environment, network, usage pattern, customizations, and configurations. Vertically, web server or back-end SQL Server could affect performance on the client side.

Therefore, it is beneficial to identify what may cause slowness of page loads or operations. The performance insight engine analyzes collected user data and corresponds it with the categories.

In some scenarios, there could be an obvious reason for performance issues. In other cases, there may be several reasons identified from the categories that could explain the slowness.

The following table summarizes what areas and categories the performance insights engine checks.

Area

Insight category

Description

Overall performance

Overview

It provides an overall summary of the performance of a selected app. You can see the performance of app briefly. More information: Overall performance

Client environment

Minimum system requirements

Users should at least use the system meeting the minimum specifications. This insight tells makers how many users meet such criteria if user collected and others not. More information: Minimum system requirements

Client environment

Browser type

The performance will vary depending on browser type. This insight indicates whether users run a modern browser or a non-recommended Internet Explorer (IE) browser. The performance of Power Apps in IE is noticeably slower compared to modern browsers. More information: Browser type

Client environment

Browser version

Although users run the modern browsers, they could experience slow performance if they are using a browser running on an older version. In general, staying on the latest version would be recommended. More information: Browser version

Client environment

HTTP protocol

Power Apps supports the HTTP/2 protocol. Apps generally perform better with the HTTP/2 protocol compared to HTTP/1.1. One of the major limitations of HTTP/1.1 is the limited concurrent connections to the same domain, which might cause apps to run slow. More information: HTTP protocol

Network

Network performance

Network latency, throughput, and bandwidth are key factors affecting the performance of web applications. Apps can perform differently depending on network performance

as some contents should be downloading. More information: Network performance

Usage pattern

Page load type.

Page load type can affect app performance. Warm (cached) page loads are faster than cold (not cached) page loads since resources load out of the cache. More information: Page load type

Page performance

Slow dashboard

One of the reasons why a dashboard might be slow to load is an associated query of a chart or a tile that is performing poorly. If the query executes over a large set of data, it could cause a slow response back. Apart from checking the number of chart controls and tiles on the dashboard, we recommend checking associated queries for both charts or tiles. More information: Slow dashboards

Customization

XHR call type

Makers can customize the model-driven app by adding a custom function making XMLHttpRequest into an event. If the XMLHttpRequest (XHR) call happens synchronously, other tasks must wait until the XHR call is completed. We strongly recommend that you make the XHR call in your custom functions asynchronous. More information: XML HTTP Request (XHR) call type

Customization

Deprecated controls

Some controls like the flip switch and calendar V1 controls are deprecated. Makers should always use modern controls. More information: Deprecated controls

Customization

Sandbox performance

Makers can build their own plug-in. Depending on implemented patterns, there are many aspects to check to confirm the plug-in methods perform well, such as timeout events. This insight checks the plug-in's timeout to see whether it was caused by the

timeout of the external endpoint calls the maker implemented or not. More information: Sandbox performance - Dominant plug-ins

Customization

Saved query

While building a solution, a maker can build, and reuse a saved query. If the saved query has been created improperly, it could make the query run slow. Consequently, any forms or views using the problematic saved query might suffer from slow performance.

Configuration

Plugin trace log setting

Administrators can enable plug-in trace logs for a Dataverse environment from **None** to **All**. It is beneficial to check the plug-in trace logs in the development phase. However, for production environments, we recommend setting the feature to either **Exception** or **None** to minimize intensive logging activity that can degrade app performance. More information: Plug-in trace log setting

Understanding insights (preview)

Article • 04/14/2022

[This topic is pre-release documentation and is subject to change.]

Performance insights distributes insights into the following categories:

- Overall performance
- Client environment
- Usage pattern
- Page performance
- Customization
- Configuration
- Network As the performance of an app could be impacted by various factors, performance insights categorizes areas to check how much overhead of performance get caused by.

Overall performance

This insight summarizes the overall performance of your app as an executive summary under the Insight ID Perf.Summary.Overview.

In this insight, you can see the overall performance of your app based on the severity.

- **Critical**: Indicates poor performance.
- **Warning**: Indicates performance could be improved.
- **Informational**: Indicates good performance.

How to improve

When it comes time to optimize the app, you can look at the detailed insights from the client, network, customization categories as well as plugins, savedQeury, and settings. Some actionable items can be derived by reviewing those insights.

Client environment

When users experience a Power Apps app on their devices, several factors can affect performance such as browser type, browser version, and specification of hardware. In this section, you can see what insights check client environments.

Browser type

Insight ID: Perf.Environment.Client.Browser.Type

Motivation

Certain web browser types can impact the performance of your app. Using unsupported or non-modern browsers can lead to slow performance. This insight provides the performance implications of different browsers, especially non-recommended browsers. For example, Power Apps has deprecated it's support of Internet Explorer.

How to improve

If you have users on old browsers such as Internet Explorer, switch to a modern Chromium-based browser. We recommend that users run a modern browser, such as Microsoft Edge or Google Chrome.

> **Note**
>
> Some legacy applications leveraging NPAPI will only work on Internet Explorer.

Browser version

Insight ID: Perf.Environment.Client.Browser.Version

Motivation

This insight checks how many users are using your app from an old version of a browser. Even when users run modern browsers, and not non-recommended browser types like Internet Explorer, older versions of browsers perform slower.

How to improve

Users should regularly update the browser to the latest version. Enterprise customers can apply a group policy to be on a specific version. As Unified Service Desk (USD) also uses the default browser setting of the computer, it also requires checking the default browser type and version.

Minimum system requirements

Insight ID: Perf.Environment.Device.MimimumRequirements

Motivation

This insight checks whether the user's environment meets minimum system requirements. You can check the web application requirements to see what are the minimum system requirements depending on the app type.

In general, some activities like rendering, scripting, and downloading contents happen on the client side. Meeting the minimum system requirements is necessary for such activities.

How to improve

Users should use the hardware that meets or exceeds the minimum system requirements for Power Apps.

HTTP protocol

Insight ID: Perf.Environment.Client.Browser.HttpProtocol

Motivation

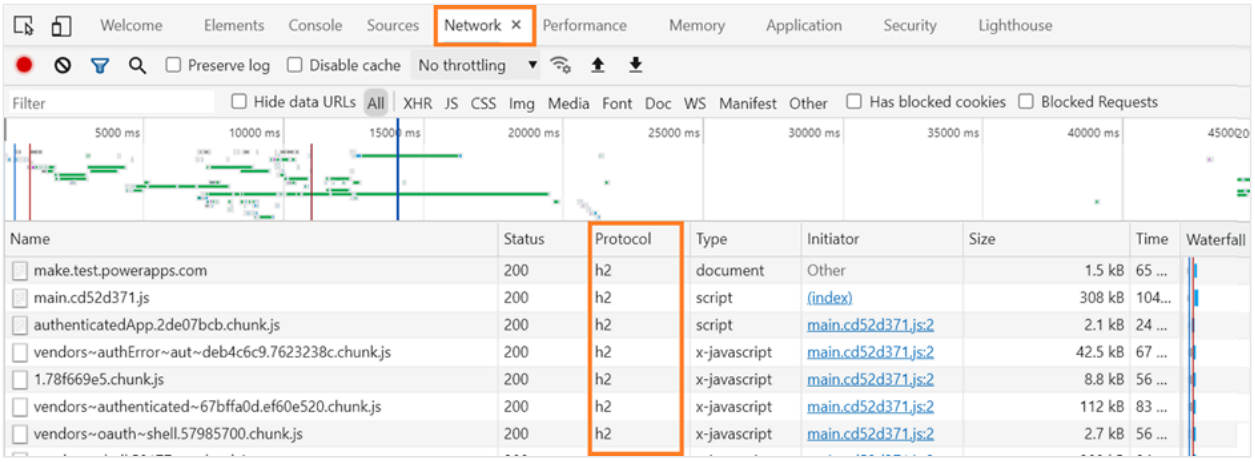
Power Apps platform supports HTTP/2. However, if your app is using the HTTP/1.1 protocol for XMLHttpRequest (XHR) requests onto Power Apps, it might cause slow performance due to the concurrent limitation of requests with the HTTP/1.1 protocol.

How to improve

If this insight identified some users who are using the HTTP/1.1 protocol, we strongly recommend that these user's client support the HTTP/2 protocol.

Several configurations and network infrastructure can block the HTTP/2 protocol, such as a VPN network, proxy server, or device internet option settings.

Users can check what protocol has been used from a development tool included with the browser. In the figure below, network calls occurred over HTTP/2.



If the network protocol trace indicates HTTP/1.1, it might be because of the following:

- Internet settings: The Windows Internet Option **Advanced** tab in Control Panel **Use HTTP2** and **Use TLS 1.2** options aren't enabled.
- VPN and proxy: Although the Windows Internet Option is set to use HTTP2 and TLS 1.2, the browser might fall back when a VPN or Proxy doesn't support the more recent protocols.

Usage pattern

This category analyzes the type of page loads. A warm page load renders the page using caches and existing DOM objects, while a cold page load renders the page fresh by downloading resources when required. Although users will not distinguish the type of page load, this insight analyzes and provides recommendations depending on what type of page loads occur on the client.

Page load type

Insight ID: Perf.Performance.PageLoadType

Motivation

Warm page loads are faster than cold page loads since necessary resources load out of local caches.

> ⓘ **Note**
>
> When a user opens a form from new tab or new tab in a browser, it is considered a cold page load. When a user opens other forms in the app within the active tab of a browser, it is considered a warm page load.

How to improve

To experience warm page loads for faster performance, minimize opening new tabs or browser windows. Try to keep activities within a single tab instead of opening new tabs or browser windows. We also recommend not to run the browser in InPrivate or incognito mode.

Page performance

Many first party model-driven apps consist of a dashboard, views (EntityList), and form when it comes to page type. By default, users load a dashboard, although app makers and administrators can change this. If a dashboard contains many charts and tiles, it might cause the dashboard to load slowly. Similarly, if EntityList and forms get customized to add many columns and display many records, it can also cause the page to load slow. Hence, checking the performance per page and per table can be beneficial because page load performance can have different root causes.

In this section, you can see several insights related to page performance.

Slow dashboards

Insight ID: Perf.ModelDriven.Page.Dashboard.SlowSQLQuery

Motivation

Slow SQL queries or using too many charts and tiles in a dashboard can cause poor performance of the dashboard. This insight points to the dashboards that are affected by slow SQL queries. When this insight is recorded, the **Details** pane includes the dashboard ID for each dashboard included in the insight.

How to improve

Here's how to look up the name of dashboard using the dashboard ID. Then, you can determine which dashboards to consider for redesign.

1. Go to your model-driven app, such as *https://contoso.crm.dynamics.com*.
2. Modify the URL as shown in this example (https://contoso.dynamics.com/api/data/v9.1/systemforms[DashboardId]/name) by appending *api/data/v9.1/systemforms[DashboardId]/name* to the app URL.

3. You will receive OData request similar to the below. **Agent Dashboard** displayed below represents the user-friendly name of the given dashboard ID.

`{"@odata.context":https://contoso.crm.dynamics.com/api/data/v9.1/$metadata#systemforms(2ff4a8cf-378b-e811-a964-000d3a30dc0a)/name,"value":"Contoso - Agent Dashboard"}`

Synchronous plug-ins with slow external calls

Insight ID: Perf.Sandbox.Performance.Plug-ins.ExternalCall

Plug-ins and custom workflow activities can access web services (external endpoints) via HTTP and HTTPS protocols. If these external services perform slowly, the plug-in itself will timeout or perform slowly.

Motivation

This insight checks the performance of the external endpoints and detects plug-ins in your app that are impacted by the slow external calls.

How to improve

- Set KeepAlive to false when interacting with external hosts in a plug-in.
- Set Timeout explicitly when making external calls in a plug-in.

More information: Access external web services (Microsoft Dataverse) - Power Apps | Microsoft Docs.

Customization

Makers can do many different customizations with model-driven apps, such as:

- Ingest custom JavaScript functions to enable events on the client.
- Build and deploy plug-ins used to execute custom logic.
- Define and store custom tables and data.
- Define dependent components for both custom and standard tables, such as forms and views.

From a performance perspective, all of these customizations might cause poor app response in situations where the customization doesn't follow best practices and recommendations. Makers can run Solution Checker to validate their customizations during the development phase.

The following insights also provide analytic results out of runtime user data of your customization.

XML HTTP Request (XHR) call type

Insight ID: Perf.ModelDriven.Customization.Client.Script.XMLHttpRequestType

Synchronous XMLHttpRequest calls can cause severe performance issues for end users, especially when the network is slow or there are multiple calls that need to be made. The browser freezes up and the end user is frustrated when they can't click, scroll, or interact with the page.

This insight reveals whether there are synchronous methods and indicates the related performance.

Motivation

Synchronous XHR calls will block the browser from performing more work as the browser must wait for the synchronous call to complete causing the page to slow down or freeze completely.

How to improve

We recommend that you change the top methods mentioned in the **Data Section** of the insight from synchronous to asynchronous. More information: Turbocharge your model-driven apps by transitioning away from synchronous requests

Deprecated controls

Insight ID: Perf.Customization.Controls.Deprecated

Some older controls for model-driven apps like Flip Switch, Calendar Control (V1), Linear Slider, Radial Knob, Arc Knob, Linear Gauge; along with the Website Preview control, MultiSelectPicklistControl (V1), and the Flip Label are deprecated. Some of these controls can be replaced with the new controls, which are more in line with the modern web and mobile in mind. More information: New Model Driven Apps controls, deprecation of old controls

Motivation

Using outdated controls can cause performance, reliability, and accessibility issues. Moreover, some of the limitations in these deprecated controls have been resolved with the new controls. For example, the Toggle control and Calendar Control (V2) use Microsoft Fluent UI.

How to improve

- Use the Toggle control as a replacement for Flip Label and Flip Switch.
- Use Calendar Control (V2) as a replacement for Calendar Control (V1).
- Evaluate other deprecated controls to determine if they are still useful within existing forms.

Notice that there are few significant design changes between the deprecated version and the new controls.

For more information about the deprecated controls, go to Model-driven app controls deprecation.

Sandbox performance - dominant plug-ins

Insight ID: Perf.Sandbox.Performance.Plug-ins.Dominant

This insight will help us identify the dominant plug-in, or in other words, the one that's most used. It will also indicate if any of the dominantly used plug-ins performed slow with a plugin execution time greater than 100 milliseconds in the 95th percentile. This insight will list up to three dominant plug-ins.

Motivation

Slow dominant plug-ins affect performance. These plug-ins should be investigated.

How to improve

Investigate slow performing plug-ins. Check out the best practices regarding plug-in and workflow development.

To further investigate the slow plug-in, you can set the **Plug-in trace log** settings to **All** in your development or test environment and determine where the delay is. However, don't forget to disable the setting before going to production. More information: Tracing and logging

Investigate slow performing plug-ins. Some of the reasons for slow plug-ins are described here:

- Associated SQL queries performed slow, hence the plug-in execution time increased.
- Follow the single responsibility principle for your plug-in and don't make transactions with significant transaction boundaries.
- Plug-in might be making some external calls, which are slow.
- Plug-in logic isn't optimized for multi-threading environments. Check your code.

To further investigate the slow plug-in, you can set the **Plug-in trace log** settings to **All** in your development or test environment and determine where the delay is. Don't forget to disable the setting before going to production. More information: Tracing and logging

Saved query with leading wildcard

Insight ID: Perf.ModelDriven.Customization.SavedQuery.LeadingWildCard

Leading wildcards are *like* or *not like* conditions that use a wildcard (%) at the start of a search string. An example of a poorly written request is:

XML

```
<fetch>
    <entity name="account">
        <attribute name="accountid" />
        <attribute name="accountnumber" />
        <filter type="and">
            <condition attribute="accountnumber" operator="like"
value="%124" />
        </filter>
    </entity>
</fetch>
```

Motivation

A leading wildcard character (%) in a saved query can cause the query to timeout or perform slowly. This insight points to such slow saved queries with leading wildcards.

How to improve

Avoid using leading wildcards. In the search key, these are translated to "contains" in SQL Server, which won't take the advantage of index seek but will do a scan. If it is

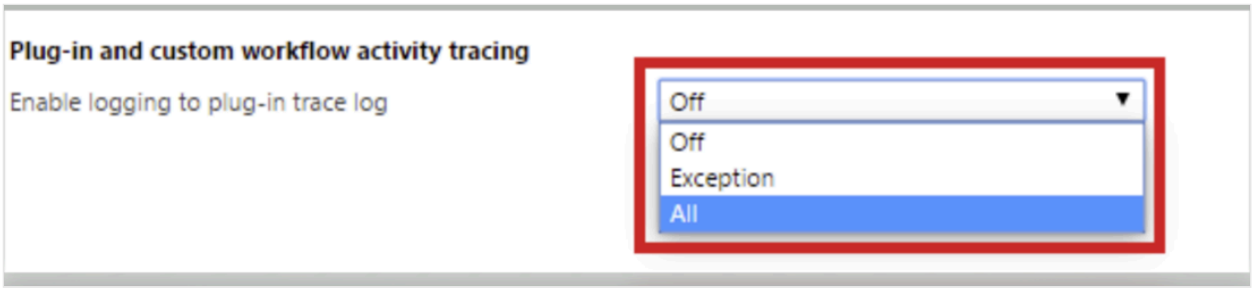
necessary to use a leading wildcard, limit the scope of search by including other conditions. Note that it is ok to use trailing wildcards (%) at the end of search strings.

Configuration

Plug-in trace log setting

Insight ID: Perf.Sandbox.Configuration.PluginTraceSettings

Makers can debug their plug-ins through plug-in trace logs. The Dataverse admins can set plug-in and custom workflow activity tracing to **Off**, **Exception**, or **All**.



Motivation

The plug-in trace log should be set to **All** only when you're debugging or tweaking the plug-in. High volume of trace logging can cause I/O overhead with SQL Server. Moreover, deletion of the plug-in trace log might cause blocks or waits with SQL Server.

How to improve

In your production instance if this setting is **All** and the volume of logs generated by your plugin is high, then consider changing it to Exception.

To change the setting, go to **Settings** > **Administration** > **System Settings** > **Customization** tab. More information: Logging and tracing

Network

Network performance

Network latency and throughput are important factors that affect end user's experience. Users with high latency and low throughput will more likely experience slow

performance while accessing Unified Interface. This insight tells us how many users are on a poor performing network and what their performance was like.

Motivation

Poor network configuration will affect app performance.

How to improve

If there are many users on the network and the performance is poor, we recommend the users switch to a better performing network.

Use Monitor to get insights and recommendations for your app

Summarize this article for me

Monitor in Power Apps offers insights and recommendations to enhance app performance. It provides makers with detailed information on their app's performance and actionable steps to improve their apps.

Prerequisites

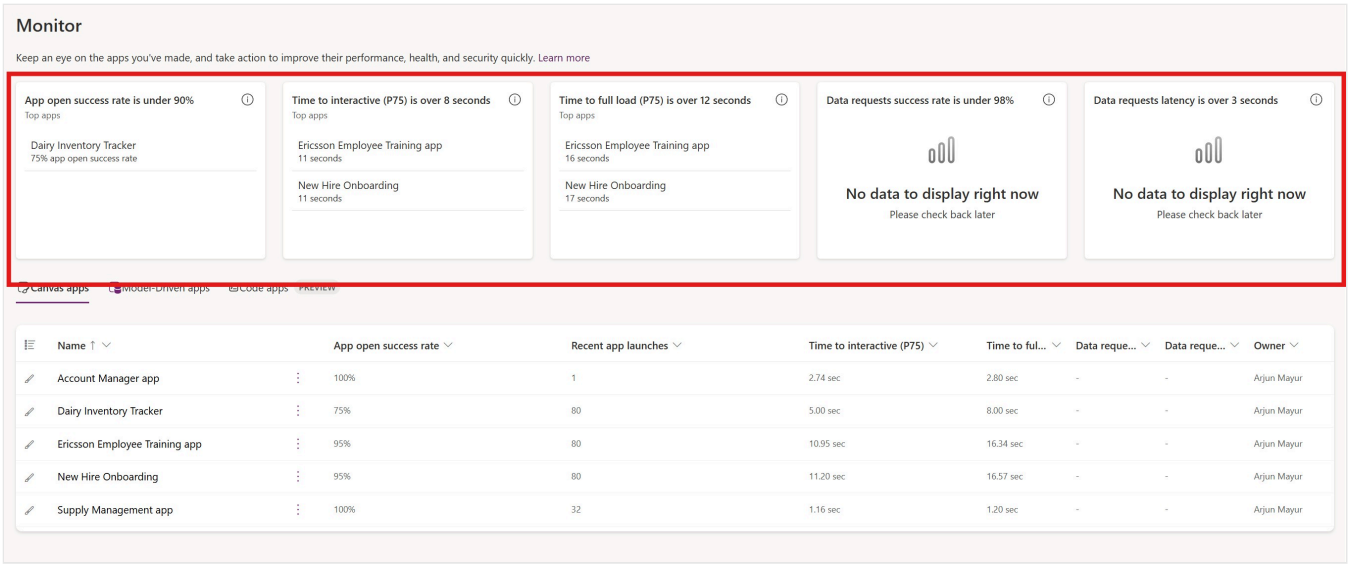
To use this feature, your administrator must enable certain analytics and monitoring settings in the Power Platform Admin Center. For more information, see Monitoring experiences for makers. When you sign in to Power Apps and open Monitor, make sure you've selected the correct environment and that you're a member of that environment with an assigned role (for example, Basic User). Otherwise, you won't be able to access Monitor.

Open and pin Monitor

1. Sign in to Power Apps.
2. On the left navigation, select **Apps**.
3. On the command bar, select **Monitor**.
4. On the left navigation pane, select the  pin button next to **Monitor**.

Use Monitor

The **Monitor** page displays metric cards at the top, highlighting the top three underperforming apps for each metric. If all apps perform well on a specific metric, the card doesn't list any apps. Use the tabs under the cards to switch between viewing your model-driven, canvas, and code apps.



Expand table

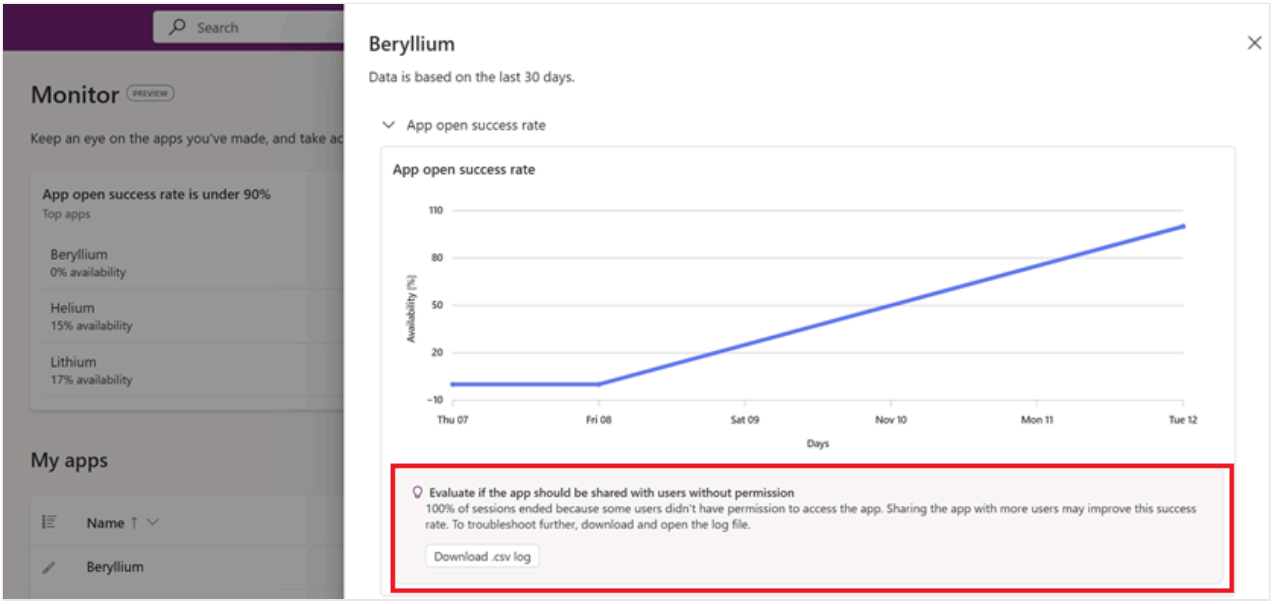
Metric	Definition	Available for Canvas apps	Available for Model-driven apps	Available for Code apps
App open success rate	Indicates the percentage of app launch attempts that successfully allowed end-users to access the app. This metric is calculated once every 24 hours.	Yes	Yes	Yes
App session count	The number of distinct user sessions in an app in one day. A session begins when a user opens the app and ends after a period of inactivity or when the app is closed.	Yes	Yes	Yes
Time to interactive (TTI)	Measures the time end-users wait to access the first screen of an app. It doesn't include the time users wait to see all data presented on the first screen, such as filling in rows of a gallery. This metric is calculated every 24 hours and is measured using percentiles, with the 75th percentile being reported.	Yes	No	Yes
Time to full load (TTFL)	Measures the time end-users wait to see all data displayed on the first screen of an app. In the app launch lifecycle, this metric follows the **Time to interactive** phase. This metric is calculated every 24 hours and is measured using percentiles, with the 75th percentile being reported.	Yes	No	No
Data request success rate	A percentage that describes how often data requests coming from an app are successful	Yes	No	No

Metric	Definition	Available for Canvas apps	Available for Model-driven apps	Available for Code apps
Data request latency	The average time (in seconds) it takes for all data requests made by the app to complete during a session.	Yes	No	No
Row summary dwell time	The time (in seconds) that end users spend on the expanded AI row summary of a main form.	No	Yes	No

View metrics and recommendations for an app

When you select an app on the **Monitor** page, a side pane opens and displays more data for each metric, including a data chart for the last 30 days.

1. On **Monitor** page, select an app.
2. To view recommendations for an app, select the app's name to open the side panel. The chart shows a callout with a recommended action for improving the metric.



> **Important**
>
> Recommendations are only available in Managed Environments. Contact your admin to enable Managed Environments for access to recommendations.

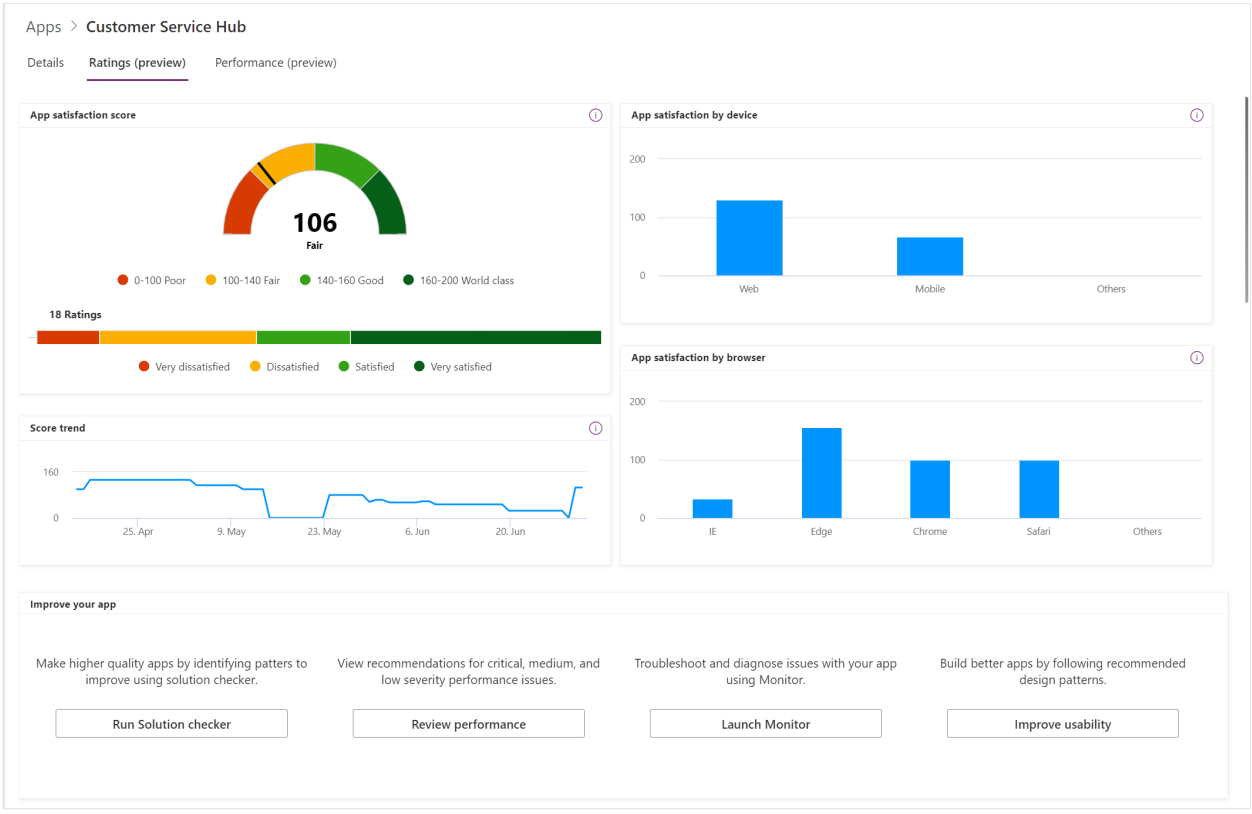
What are app ratings? (preview)

Article • 07/06/2022

[This topic is pre-release documentation and is subject to change.]

Microsoft Power Apps takes feedback from app users on how satisfied they are with their app experience. With the app ratings feature, makers and administrators view the app's satisfaction score and comments provided by users. The collection of feedback is compliant with all international privacy laws. The feature also seamlessly integrates with solution checker, performance insights, and live monitoring, which can help makers improve their app.



> **Note**
>
> - This feature is currently only available for model-driven Power Apps.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback. More information: **Power Apps preview program**

This feature has the following benefits:

- Provides a view of the app satisfaction score on a scale of 0 to 200.

- Provides a score trend over the last 90 days.
- Displays different satisfaction scores based on web or mobile device and browser.

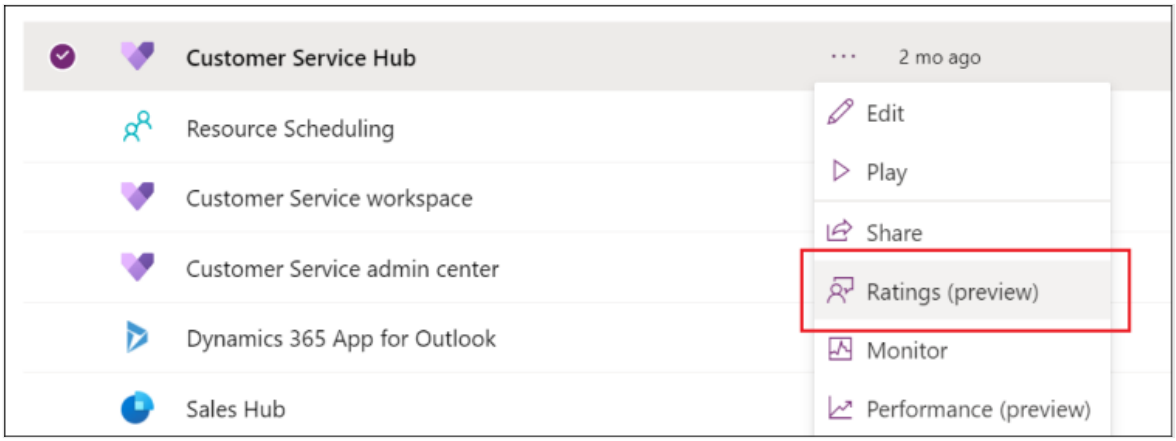
The report for current score and comments can be exported for each app in the app ratings dashboard to share with others.

Access the ratings dashboard

1. Sign in to Power Apps.

2. On the left navigation pane, select **Apps**, and then select a model-driven app.

3. Select the ... context menu, and then select **Ratings (preview)**.



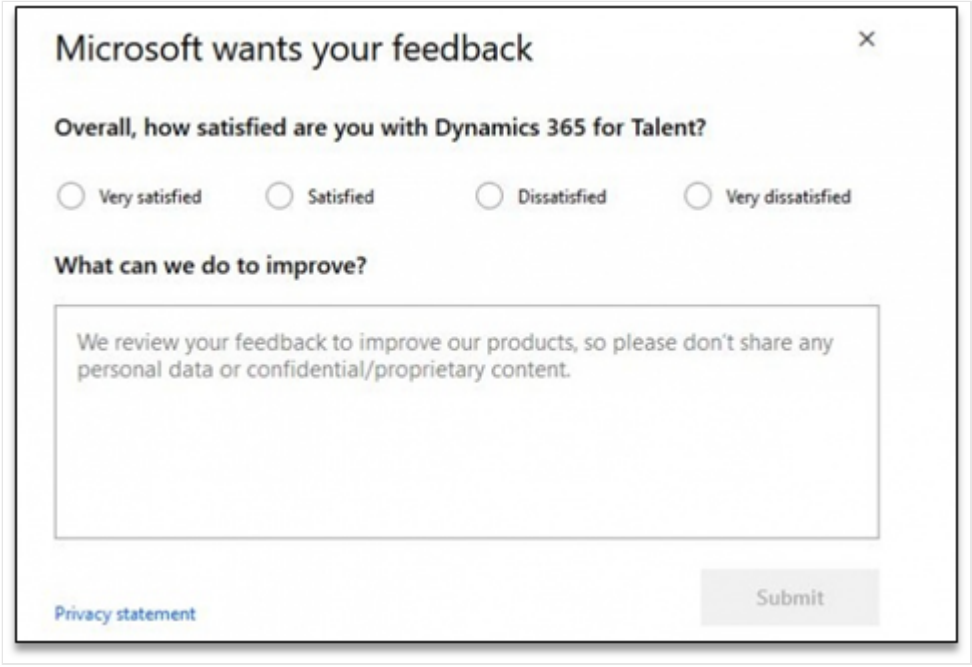
How app user satisfaction is collected

Based on the user's activity inside the app, Power Apps occasionally prompts users to score the app with the following questions:

1. How satisfied are you with (name of the app)?

    - Very satisfied
    - Satisfied
    - Dissatisfied
    - Very Dissatisfied

2. What can we do to improve?



Based on the feedback, an app satisfaction score and comments are displayed in the ratings dashboard.

The following guidelines are used to prompt an app user with the feedback dialog:

- If a user has at least three active days during the first 14 days since sign-up, the user is prompted.
- If the user has six active days in the last (recent) 90 days, the user is prompted.
- No users are prompted more than once in 90 days for the same app.

App satisfaction score

The app satisfaction score is calculated by taking the responses with an answer "Very Satisfied" and subtracting the percentage of the responses with an answer "Dissatisfied" or "Very Dissatisfied". The total NSAT score is then calculated like this:

> 100 + (%Very Satisfied) - (%Dissatisfied) - (%Very Dissatisfied)

App satisfaction is reported on a scale of 0 to 200, where:

- 1 to 100 is a poor score.
- 100 to 140 is a fair score.
- 140 to 160 is a good score.
- 160 to 200 is a world class score.

Score trend

The app satisfaction score for each day is calculated based on total responses received in the previous 28 days. Trends from 1 to maximum 90 days are displayed depending on the app's first publish and first response date. This score provides a visualization on how the satisfaction score is trending over a period. We recommend you use this feature to analyze subsequent updates to the app and follow how those updates have helped in improving the general experience with users.

App satisfaction by device

The app score is separated by device types – web, mobile, or others. For tablets, the score is calculated as mobile. The Others option categorizes the score for unknown devices.

App satisfaction by browser

App ratings also display a comparison across different browsers. The feature can identify different types of browsers including Microsoft Edge, IE, Chrome, Mozilla, and Opera. For browsers that can't be identified, the score is attributed under the Others category.

Improve your application

With the public preview release, the app ratings provides the following direct links to take actions to improve your app:

1. **Solution Checker** – This link takes you to a list of solutions to run solution checker if applicable. Notice that makers or admins must manually identify the solution and run solution checker to identify issues.
2. **Performance Insights** – This tool provides direct insights on the respective app's performance and what makers can do to improve the app performance issues.
3. **Monitor** – This tool helps makers troubleshoot and diagnose issues with live monitoring of a user's session.
4. **Usability** – This action redirects to documentation of best Power Apps provided recommendations on design and patterns.

How the feedback data is stored

A new system table in Microsoft Dataverse called **User Rating** was added to all Power Apps environments that include Dataverse. This table stores the rating score and comments from each user feedback. This is an organization owned table with default

create, read, and delete rights provided to system administrators and customizers. The environment maker role has only read privilege on the table.

> **Note**
>
> 1. Only users with at least read privileges on the User Rating table can view app ratings data.
> 2. By default update on User Rating table records is unavailable for all other security roles.

Administrators can also share the app score and comments to external stakeholders by creating Power BI dashboards on the User Rating table. This can help convey app ratings data to makers outside organizations who don't have access to production environments.

Model-driven app frequently asked questions

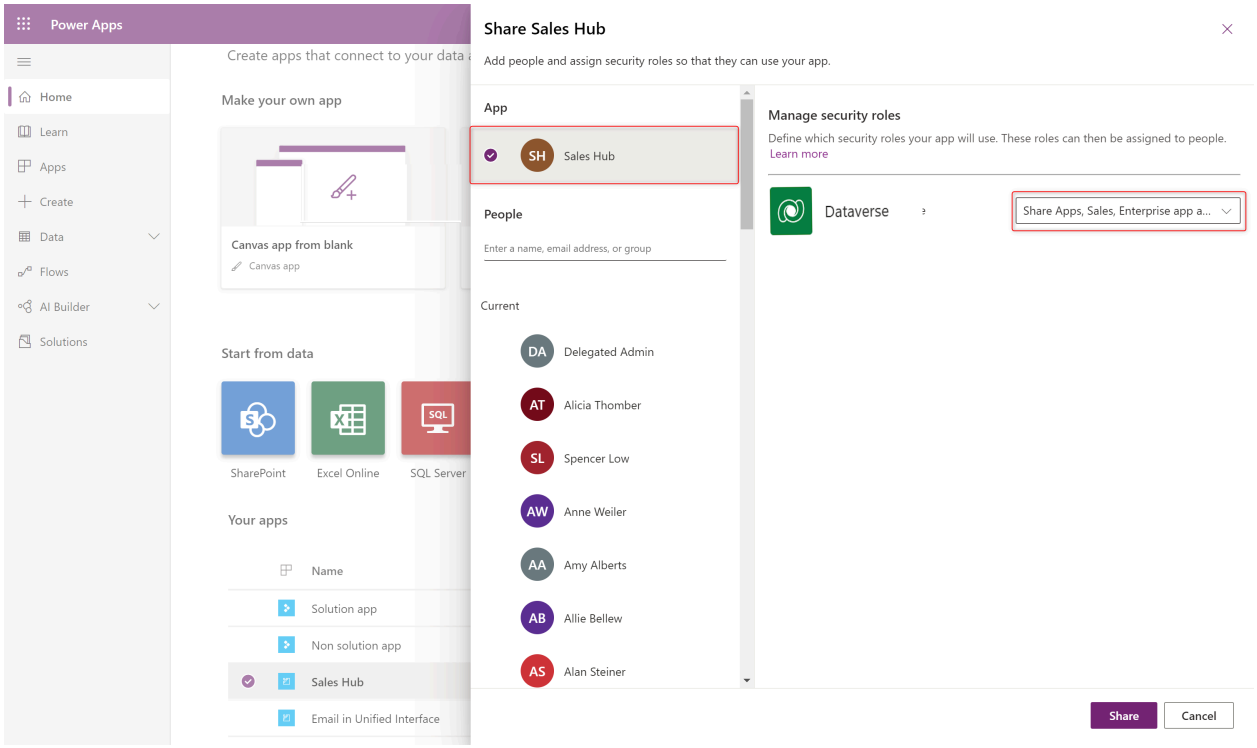
Article • 01/27/2025

These frequently asked questions (FAQ) can help you resolve issues that might occur when you work with model-driven apps.

How do I run a model-driven app?

In order to play an app you need to have a security role assigned to you and the URL to the app.

To share the app, select the app, and then on the command bar select ... > **Share**. The app sharing page as shown below appears for you to assign a security role.



You can find the app URL by going to the **Apps** section Power Apps, select the app, and then select **Details** on the command bar. More information: Sharing the app

To play the app, open the URL in your browser.

For more information, see sharing model-driven apps

Why can't I create a model-driven app?

The most common reasons you can't create model-driven apps are:

- Licensing
- Security
- Environment configuration

A Power Apps or Dynamics 365 license is required to create a model-driven app. More information: Licensing requirements for tables in the Power Apps Licensing Guide and Understanding Power Platform Licensing

Make sure you have sufficient privilege to create model-driven apps in your environment. More information:

- About predefined security roles
- Environment permissions

Additionally, you might be working with a restricted table. The following Dynamics 365 customer engagement applications include restricted tables:

- Dynamics 365 Sales
- Dynamics 365 Customer Service
- Dynamics 365 Field Service
- Dynamics 365 Marketing
- Dynamics 365 Project Service Automation

Make sure you have the appropriate Dynamics 365 application license when working with these tables. More information: Restricted tables

Why can't you see my model-driven app?

Make sure you have the appropriate privileges on the app. Work with your app maker or admin to ensure you have the proper security roles for the app. More information:

- Privileges required to view and access apps
- Share a model-driven app using Power Apps

Why don't I see my model-driven app changes?

Make sure you publish your app customizations. More information:

- Publish changes from Power Apps
- Publish your model-driven app using code

Also, verify your component changes in the active layer. You can use the solution layer feature in Power Apps to review solution layering for a component. More information: View the solution layers for a component

How do I add more tables to my app?

The site map defines the navigation for your model-driven app. You add tables to a model-driven app's site map by using the site map designer. Tables that aren't included in the site map won't be available in your app. More information: Create a model-driven app site map using the site map designer

How do I share my app?

You use security roles that contain the appropriate privileges and assign them to the users, teams, and apps you want. More information: Share a model-driven app using Power Apps

Why don't I see all the views after importing a solution?

A model-driven app change that was made by selecting **All** when selecting a component, such as a view, isn't reflected after you import an update to the app. More information: Newly added components don't appear in the app after you import an update

What's the best way to define and manage my model-driven app?

We recommend that you create your app in a dedicated solution. By creating a solution for your app, you can maintain your other solutions without creating any dependencies with your app. Only make changes to that solution when you want to update your app —for example, when you add, change, or remove components from the app. More information: Create a solution

What is `solutionaction`?

More advanced users can review the solution's customization.xml file. When you import a managed solution, customizations.xml might include the `solutionaction` property

when you add and remove components. The possible values for `solutionaction` are:

- Added
- Removed
- Modified

This value specifies the changes in the current layer with respect to the previous managed layer. For example, on solution import, `solutionAction="Removed"` will remove the component from the app. More information: *Microsoft.Crm.CrmInvalidOperationException: full formXml is expected to create a form <formid>* message during solution import

What is an app module?

The term *app module* has been used to describe model-driven apps, and `appmodule` is the name referenced in the Microsoft Dataverse and customer engagement apps schema. **Model-Driven App** is included in the display names for some of the tables referenced in Power Apps. For information about the `appmodule` table, go to AppModule entity reference. For information about using the `appmodule` table API, go to Create, manage, and publish model-driven apps using code.

App modules, which are referred to as model-driven apps in Power Apps, are created and customized within a solution. Solutions are used for application lifecycle management, and you can use them to migrate customizations from one environment to another. It's beneficial to be familiar with the solution layering concepts.

I'm a developer. Where do I get started?

Go to Supported Customizations for Dataverse.

How do I get help?

- Search or post your questions in the Power Apps Community.
- Admins can create support tickets.

Model-driven apps developer guide

Model-driven apps are primarily a no-code or low-code component-focused approach to app development. Developers add value to model-driven apps by extending the application with custom code, components, and integrations. Before you start writing code, learn how to build model-driven apps and explore what options you can apply without code.

> **Note**
>
> Model-driven apps connect to Microsoft Dataverse. For information about how developers can add value at the service level, see Dataverse Developer Overview.
>
> This section refers only to extensions that developers can make to improve the experience for users of model-driven apps.

If you're new to Dataverse applications, the topics in this section provide a high-level overview of the important concepts to help developers get started working with model-driven apps.

Create your first model-driven app

Last updated on 03/28/2026

Model-driven app glossary of common terms

This article contains a glossary of terms for Power Apps model-driven apps.

Accessibility

Accessibility is a term that is used to refer to the extent to which people with disabilities can use digital products. In the case of model-driven apps, consideration has been paid to matters such as responsive design, how users navigate between fields, how the app behaves in high contrast mode, and how screen readers help users to understand the nature of the application.

Using screen readers within model-driven apps

Admin center

The Power Platform admin center is a unified portal for administrators to manage environments and settings for Power Apps, Power Automate, and Dynamics 365 apps. Power Platform admin center doesn't cover administration settings and features associated with Power BI.

Learn more about the Power Platform admin center

Learn about the Power BI admin center

App designer

The tool that is used to create and edit model-driven apps. As the app designer experience matures, it replaces the classic experience.

Use it to configure the navigation site map, tables, forms, and views relevant to your app.

An overview of the app designer experience

App navigation experience

The way in which areas, groups, subarea, and pages are presented in a model-driven app. It's also known as the site map

Application lifecycle management

The way in which we manage the lifecycle of an application from conception to end of life. From a technical perspective, much of application lifecycle management (ALM) is managed via solutions when delivering model-driven app products.

Overview of application lifecycle management with Microsoft Power Platform

Area

A part of the model-driven app navigation experience, apps can have multiple groups and groups can have multiple subareas. The subarea contains the tables relevant to the application. For apps with more than one area, a switch control is displayed in the lower left navigation pane.

App navigation in model-driven apps

Attribute

An attribute is another name for a column and is a term commonly used by Power Apps developers. Each table in Power Apps corresponds to a database table and each table column in Power Apps corresponds to a column in the database table.

Business process flow

Logic built into a given table to ensure that users complete records by updating fields in the correct order.

While these are authored initially using the Power Automate experience, business process flows are experienced within a model-driven app as a change in the user interface.

A business process flow is arranged into stages. Each stage defines the columns (fields) that must be completed typically before moving on to the next stage. For example, the default business process flow for the opportunity table has four stages: qualify > develop > propose > close. The current stage in a business process flow is indicated with a dot next to the stage in the sequence of stages from left to right in the flow.

Business process flows overview

Business rule

Business rules are server-side logic that is used with canvas or model-driven apps to set or clear values in one or more columns in a table. Business rules can also be used to validate stored data or display error messages. Model-driven apps can use business rules to show or hide columns, enable or disable columns, and create recommendations based on business intelligence.

Learn more about business rules

Define business rules

Canvas app

An app which is generated using drag and drop controls configured using Power Fx. Canvas apps offer the designer significant control over the user experience and can be connected to a wide range of data sources and data services.

Canvas apps are arranged into screens and controls such as galleries, text boxes, and dropdowns, are placed onto the screens and configured so that they connect to the data sources and to each other correctly.

Whereas a model-driven app comes with many preconfigured features such as forms, views, and a user interface, canvas apps can be authored from a blank canvas, or a template. There's often more work to be performed and more outright work using code.

Canvas apps are contained within environments and solutions in the same way as model-driven apps.

Find out more about canvas apps.

Chart

A visual representation of a table of data. Charts can take the form of line, bar, pie, or donut chart.

Find out more about creating a system chart.

Classic

The classic interface represents the method in which app makers make changes to features within their Microsoft Dataverse environment.

The classic interface has been replaced by the web-based method of app authoring known as the unified interface.

About Unified Interface for model-driven apps in Power Apps

Classic app designer

The modern app designer lets you create model-driven apps and create canvas apps using custom pages.

The modern app designer is the default designer for model-driven apps. Currently, you can still create model-driven apps using the classic app designer.

Column

A column (formerly called a field), is a field within a Dataverse table (formerly called an entity). Columns are similar to fields in databases and have different data types such as text, number, date, as well as data types less familiar to databases such as phone, email, file, and image.

The column type defines the kind of data required by the column and also the controls, such as date picker or text box, that is available when using the control.

Columns also appear when you create forms. Form tabs also have columns, and this defines where you can put sections. Additionally, form sections have columns, and these define where you can place table columns (form fields in this case).

How to create and edit columns

Add, configure, move, or delete columns on a form

Command bar

The area of a model-driven app that contains basic commands universally used by model-driven apps.

The command bar can be customized. More information: Customize the command bar using command designer (preview)

Component

Components are elements. Components are used when creating the elements that make up a model-driven app. Often these elements relate to the method of creation of the tables that make up a model-driven app.

Components can be split into data (tables, relationships, columns) UI (site map, forms, views), logic (Power Automate flows, business process flows, business rules) and visualization (charts, dashboards, and Power BI Tiles).

Learn more about components

Connection

A model-driven app is typically connected to the data tables that reside in the same environment. This connection can be considered native because it never has to be set up within the environment.

Connections exist within the environment to enable other elements of the Power Platform to operate correctly. Notably, Power Apps canvas apps and Power Automate flows have the ability to make use of multiple connections.

Control

Controls allow you to interact with information contained within records. They typically are visible on forms, where users update data using the control. Examples of controls are calendar, toggle, choices, slider, and editable grids. In some cases, you might want to use different controls depending upon the device employed by the user.

Find out more about controls

Dashboard

A container for one or more charts relating to a table.

Find out more about dashboards here

A dashboard allows charts, Power BI reports, and views of tables to be presented to the app user.

Find out more about how to use Power BI within a model-driven app

Data model

A collection of related tables. In the context of model-driven apps, these are held within the Dataverse database.

In a custom solution, the data model is often the set of related tables built with the purpose of delivering the overall business application.

Database

The collective term for all the tables in Dataverse.

Dataverse

Microsoft Dataverse is the collective term for the tables, workflows, business process flows, and related functionality that are provisioned within an environment when a database is created.

Model-driven apps require a Dataverse database.

A Dataverse database contains data structures most closely associated with databases in addition to being able to hold model-driven apps, canvas apps, and Power Automate flows.

Find out more about Dataverse here

Dependency

Dependencies are created when elements of components are reliant on each other to work. For example, if a column is used within a view then the view requires the column to exist for it to function. There are many examples of dependencies throughout Dataverse. Another example is a model-driven app being dependent on a table if that table is used within the app.

Dependencies manifest themselves in numerous ways including when a model-driven app is validated. They also become apparent in the most problematic fashion when trying to delete an aspect of a table, form, view, or dashboard. Dependencies can be viewed by selecting the item to be deleted, and then selecting **Advanced** > **Show dependencies** on the command bar.

- Removing dependencies
- Validate an app
- Delete a column from a table

Dynamics 365

Microsoft Dynamics 365 is a line of enterprise resource planning (ERP) and customer relationship management (CRM) software applications. Microsoft markets Dynamics 365 applications through a network of reselling partners who provide specialized services.

Learn more about Microsoft Dynamics 365

Entity

An entity is the classic way of describing a table. This terminology appears within the classic experiences.

Environment

An environment is a space to store, manage, and share your organization's business data, data structures, apps, Copilot agents, and flows.

You can package up the various elements as solutions, and these solutions can be exported from one environment to another.

An environment can only ever have one Dataverse database and all your model-driven apps in the environment use this database.

Often multiple environments are used to enable application lifecycle management. For example you might have development, test, and production environments.

Environments exist within a geographical region and can be a means of ensuring that the data physically stays in the correct geographical region.

Find out more about environments

Flow

Cloud flows are functionality offered by Power Automate that allow automation of tasks to take place based upon triggering of conditions such as recurrence, adding or updating of records or simply selection of buttons by users. Flows can be run with or without the introduction of new parameters.

Cloud flows

Form

Forms provide the user interface (UI) that people use to create, view, or edit table records. Use the form designer in Power Apps to create and edit forms.

There are four types of forms: main, quick create, quick view, and card.

More information:

- Form Types
- Opening the form designer
- Learn about creating and designing forms
- Add a section to or remove a section from a form
- Add a tab to or remove a tab from a form

Form designer

The design experience for creating and editing forms.

Opening the form designer

Group

A part of the model-driven app navigation experience. Group names appear as a navigation element in an app with the subarea names (tables) within the group listed beneath it.

Legacy

This refers to features that have either been deprecated, or the way in which they're authored, has been moved to a more modern experience, such as the web-based unified interface.

Lookup

A lookup is a field type that exists when two tables are related. Lookups can be seen in table views on the many side of a one-to-many relationship. Lookups are generally populated using a form on the many side of the relationship.

- Learn more about the lookup field user experience
- How to configure a lookup

Main form

Every table has at least one main form. The main form represents the primary method of interaction with a record. The main form is responsive to the device using the screen form and can contain controls that are optimized to the device whether it's phone, tablet, or web. Main forms are edited using the form designer.

Learn about other form types

Monitor

Also know as the app monitor. It lets you understand aspects of the performance of a model-driven app. App monitor can an also be used to monitor canvas apps.

- Learn how to use the app monitor
- Use Monitor to understand form performance

Page

Modern apps have the concept of pages, which can be either a model-driven app component (table, dashboard, navigation link, or web resource) or a canvas-based page using a custom page. Custom pages allow flexible layout, low-code Power Fx functions, and Power Apps connector data.

A custom page is a tool for enabling model-driven apps and canvas apps to function together.

- Working with custom pages
- Learn about creating modern apps

Power Automate

A Power Platform service that allows users to streamline repetitive tasks. Typically, this automation is performed using cloud flows.

Model-driven app business process flows that direct users to complete table records in a specific fashion, are authored within Power Automate.

Power Automate flows exist within an environment and can also exist within Power Apps solutions.

Learn more about Power Automate

Power BI

A data visualization tool that has the capacity to be embedded within model-driven apps or to operate independently of them. Power BI can connect to a wide range of data sources, of which Dataverse is just one.

Power BI reports aren't stored within Dataverse environments.

- Use Power BI within a model driven app
- Learn more about Power BI

Publish

The process by which you make the latest iteration of the app available to users within an environment.

Publisher

Every solution has a publisher. You specify the publisher when you create a solution. The solution publisher indicates who developed the app, and defines the prefix, such as *Contoso*_MyNewTable, for all the solution assets.

Learn more about publishers

Record

A record contains one or more columns of information about a person, a place, or a thing. For example, a record might contain the name, the email address, and the phone number of a single customer. Other tools refer to a record as a "row" or an "item." Records exist within Dataverse tables.

Relationship

The way columns in different tables relate to each other. There are three types of relationship:

- One-to-many. For example, one author to many novels.
- Many-to-one. For example, many pages to one book.
- Many-to-many. For example, many books borrowed by many people.

Model-driven apps often contain tables with relationships between them. Where relationships exist, users navigate to the record within the related table. For example, when looking at a sales invoice record, you can open the related account record to investigate details for that account.

Learn about creating table relationships

Responsive apps

An app that is responsive renders itself in a way that depends on the device that is accessing the app. This can also mean that there might be a different control displayed, such as a date picker, depending on whether the user is running the app on a computer, tablet, or phone.

Additionally, tables and fields render themselves according to screen size of the device.

Section

Tabs within forms are arranged into sections. Sections can be arranged into one to four columns and let you arrange the record metadata in a way that is most relevant to the current tab and the current section.

Learn more about working with sections

Security role

A security role defines what people can see and do with features and data in Dataverse. For records, security roles determine the create, read, write, delete, update, and append actions available to a user.

Security roles are created and users are put into security roles either as individual user names or by using active directory security groups.

You grant access to model-driven apps through security roles.

- Find out more about security roles
- General overview of security in Microsoft Dataverse
- Get started with security roles in Dataverse

Site map

A model-driven app is essentially a collection of tables, dashboards, views, and pages, and these are described via the site map. The site map defines the tables and pages that are included within a model-driven app and the navigation experience users have when moving between them.

When configuring the navigation experience you're editing the areas, groups, and subarea navigation elements. Tables exist at the level of the subarea, and are arranged into groups. Groups are effectively collections of tables and pages and are visible in the navigation pane. Areas allow you to toggle between visible groups.

Both modern and classic methods of creating a model-driven app include site maps. However, with the modern app designer you can design the site map with a drag and drop experience whereas the classic site map designer doesn't support drag and drop.

To open the site map in the classic site map designer from the modern app building experience, select **Switch to classic**.

Find out more about app navigation

Solution

A solution is a wrapper for a wide range of components including tables, cloud flows, and security roles.

When you make a model-driven app, ensure that the assets associated with it are held inside a solution.

Solutions have two types:

- Managed solutions generally permit only a small amount of customization or no customization at all.
- Unmanaged solutions give makers full control over the project that they're creating.

Unmanaged solutions are used by makers and developers for exporting projects as a managed solution for use in nondevelopment environments, such as a production environment. This allows for a high level of control for application lifecycle management.

- Find out more about solutions here
- Discover solutions in the context of Dataverse

Solution explorer

This is the classic experience that makers and customizers can use to view and make changes to most any solution component. More modern experiences are available from make.powerapps.com and the model-driven app designers and solution explorer will eventually be replaced with those modern experiences.

To access the modern solution interface, follow these steps:

1. Sign in to make.powerapps.com.
2. Select an environment.
3. On the left pane, select **Solutions**, and then open an unmanaged solution where you want to add a model-driven app. Create a solution if one doesn't already exist.
4. Explore the components of the solution.

Find out more about solutions

Subarea

A part of the model driven app navigation experience. Subareas (tables) and pages appear under the group that they're configured within in the app designer.

Subgrid

Subgrids are areas of main forms that display a list of records from a Dataverse table, while remaining on the form. Typically, a subgrid is used to display child records that relate to the parent record currently under review. For example, books written by an author.

While subgrids are displayed in a model-driven app, they're a property of the form.

- Create a subgrid
- Subgrid properties - legacy

Tab

Every form has at least one tab and these are relevant to how we present table record data. A form can have multiple tabs. This lets you, the maker, offer the user a range of ways of looking at the same record. Tabs often offer a better user experience by providing a more logical way of presenting the data in the record.

From a site map perspective, a tab is a "group" when using the site map designer versus a subarea for tables and an area to hold subareas.

Learn more about working with tabs

Table

A table is a method of storing data in columns (or fields) within Dataverse. Tables where formerly called entities.

Tables, in the context of model-driven apps, only exist within a Dataverse database.

A single row within a table is known as a record. For example, a single customer, and the columns describe metadata associated with the customer such as the name, telephone number, or credit limit.

Every model-driven app must contain at least one table. Much of the process of creating a model-driven app is selecting the tables most relevant to solving the business problem.

Tables have views, forms, and business rules associated with them.

Additionally, tables also have charts as well as dashboards where charts are presented.

Tables can relate to other tables and these are defined via the relationships that have been set up between them.

Find out more about configuring tables

Table designer

The design experience for creating and editing tables. This lets you create tables, columns, relationships, business rules, and views.

Create a custom table using the table designer

Unified Interface

The Unified Interface provides a consistent and accessible user experience across devices—whether on a desktop, laptop, tablet, or phone. The predecessor to the Unified Interface was known as the web interface.

Find out more about the unified interface here

Validate

The process by which an app maker confirms if the model-driven app has all the components required for it to function properly.

Learn how to validate an app

View

A tabular representation of records in a Dataverse table. Tables can have multiple views.

Views can be prefiltered and it's possible to define the specific views that a model-driven app makes available to users.

Tables can have multiple views associated with them and you can define the table views relevant to a model-driven app at the time that you create them.

Find out more about views here

Workflow

A classic workflow is a series of functions or methods, called steps, that are performed sequentially and apply to data contained within tables. The workflow can change the processing direction by using conditionals, referred to as conditional branches.

In many cases classic workflows should be replaced with Power Automate flows.

Last updated on 04/03/2026

Install the Power Apps mobile app

If you're not signed up for Power Apps, sign up for free. Then choose the download link or scan a QR code to download Power Apps mobile.

Expand table

iOS	Android	Windows
Download from App store	Download from Google Play	Download from Windows Store

> **Note**
>
> For more information on Power Apps for Windows, see Power Apps for Windows.

Required privileges and supported devices

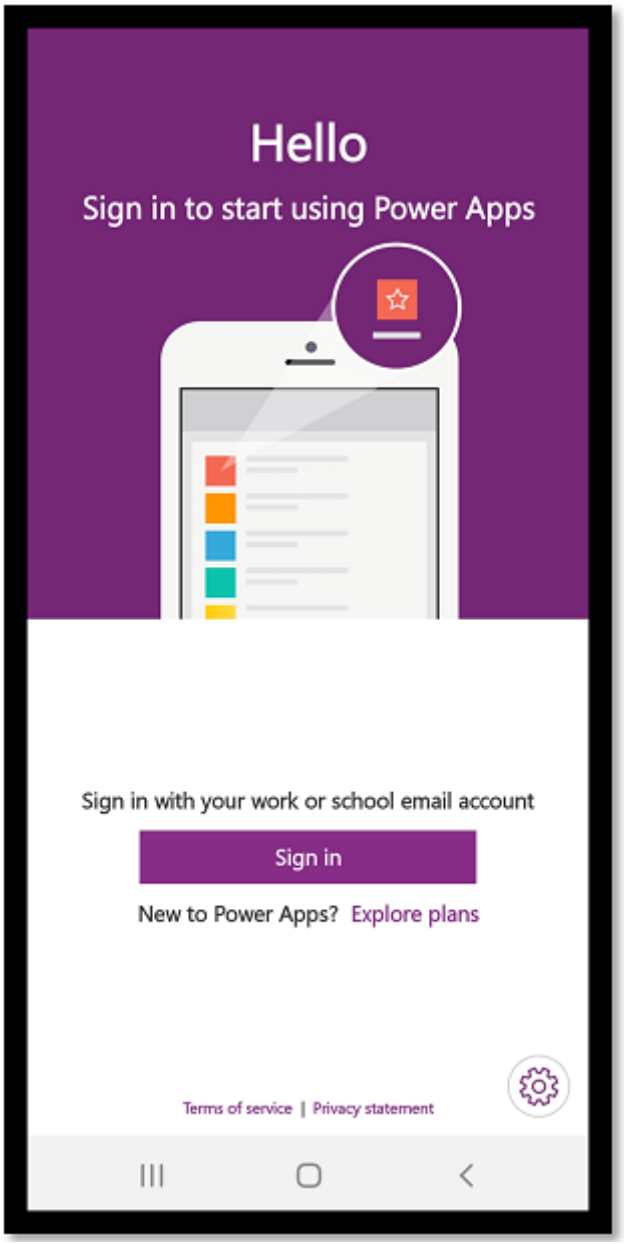
Review the following privileges and supported devices to run Power Apps Mobile app:

- Required privileges
- Supported platforms for running apps using the Power Apps mobile app.

Sign in

Open Power Apps on your mobile device, and sign in by using your Azure Active Directory credentials.

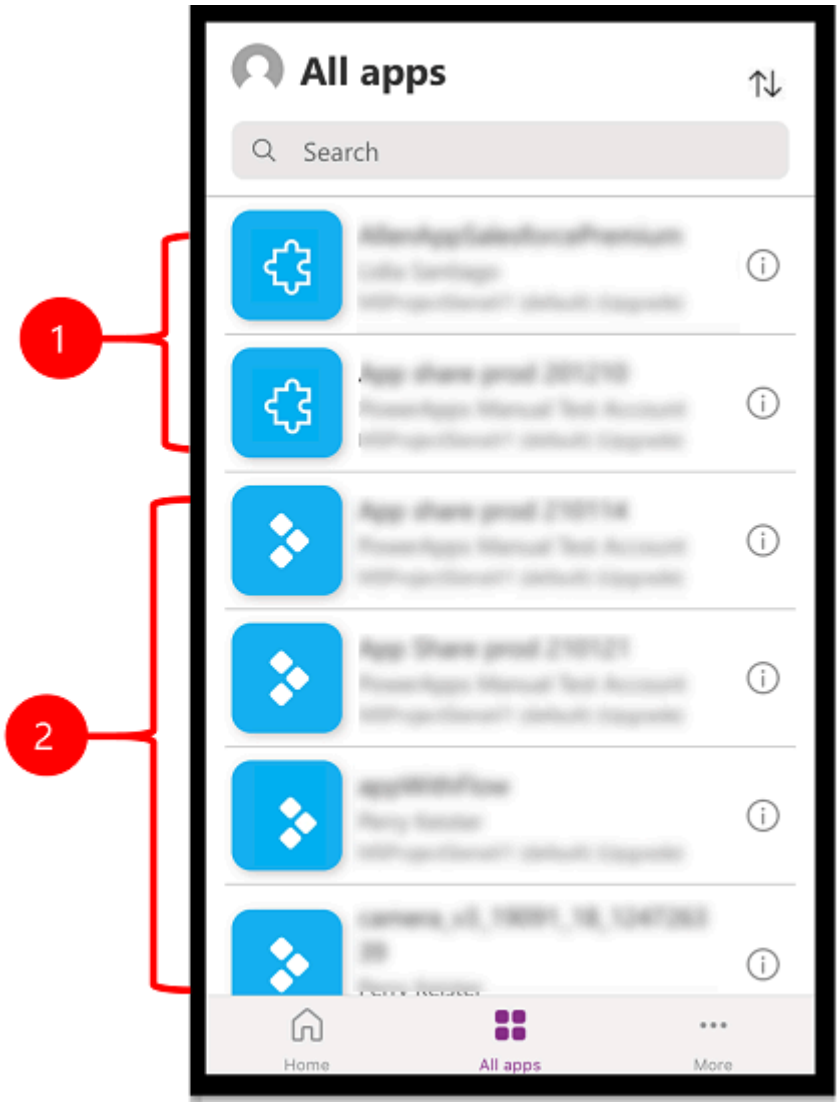
If you have the Microsoft Authenticator app installed on your mobile device, enter your username when prompted, and then approve the notification sent to your device. If you run into issues signing in, see Troubleshoot issues for Power Apps mobile app.



Find the app

When you create an app, or someone shares an app with you—either a canvas app or model-driven app—you can run that app on Power Apps mobile.

> **Note**
>
> To see a model-driven app in the list of apps on Power Apps mobile, you need to have a predefined security role in the environment that the app is in. If a predefined security role is assigned to a user using a Dataverse team, you need to use an Azure Active Directory (AAD) group team. Users will not see model-driven apps if a predefined security role is assigned using a Dataverse owner team.

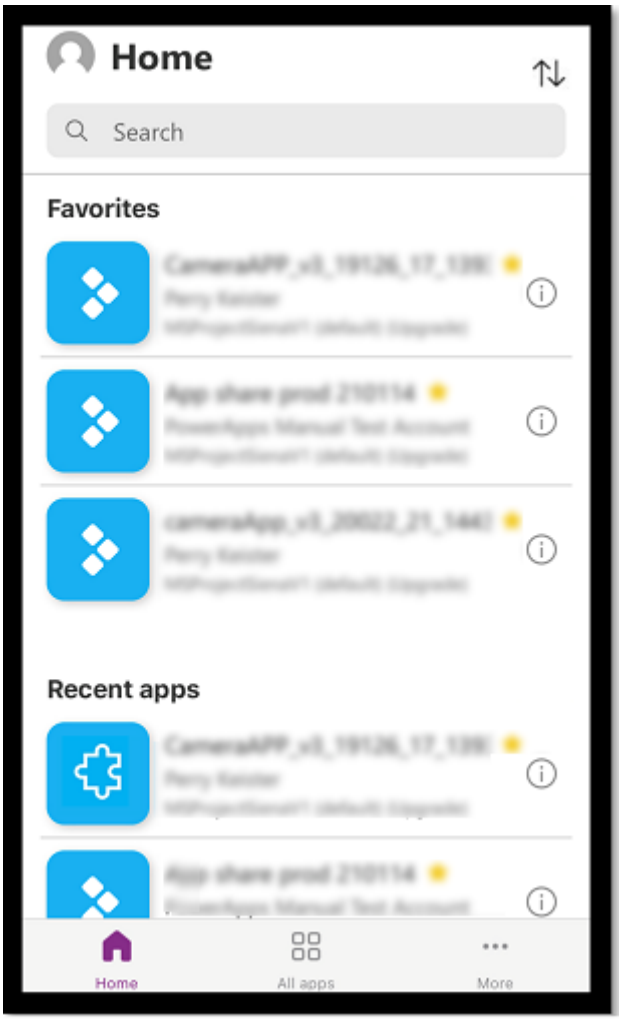


Legend:

1. **Model-driven apps**
2. **Canvas apps**

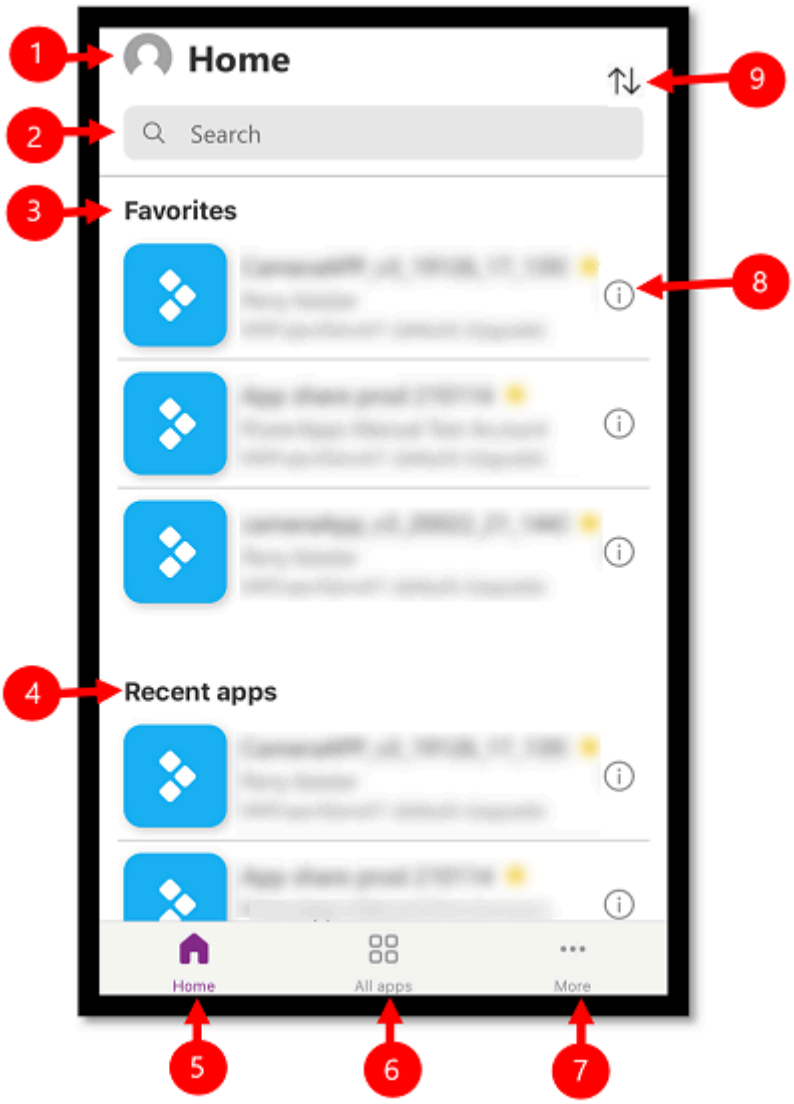
The apps that you used recently will show on the default screen when you sign in to Power Apps mobile.

The **Home** is the default screen when you sign in. It shows the apps that you used recently and the apps that have marked as favorites.



Filter apps

If you don't have any apps, then when you sign in, you will land on the **All apps** screen. The list of apps is organized in alphabetical order. Type in an app name in the search bar to find an app.

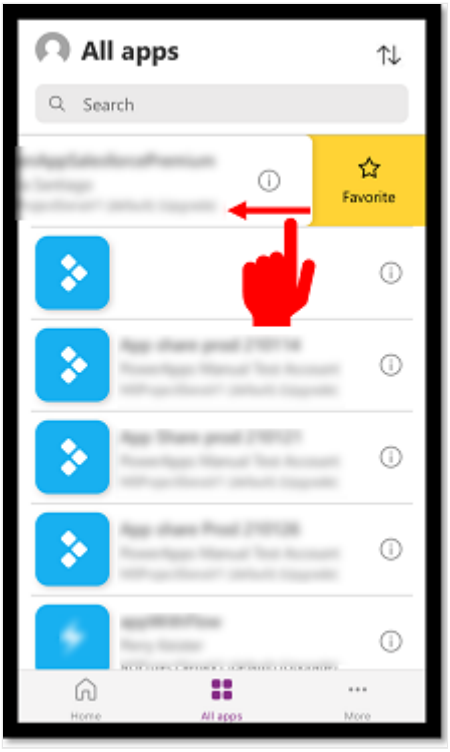


1. **Settings**: Access app settings and sign out.
2. **Search**: Use the search to search for apps. When you run a search, it will only search for apps that are on the screen you're on.
3. **Favorites** (canvas apps only): Displays canvas apps that you have pinned to favorites.
4. **Recent apps**: Displays both model-driven and canvas apps that you have recently used.
5. **Home**: Displays favorite apps and recently accessed apps sorted by open date.
6. **All apps**: Displays all canvas apps and model-driven apps to which you have access, including apps you created and apps that others shared with you.
7. **More** (canvas apps only): Displays featured and sample apps.
8. **Details**: View information about the app including run the app, add a shortcut for the app, and add the app to favorites.
9. **Sort apps**: You can short by the app name or modified date.

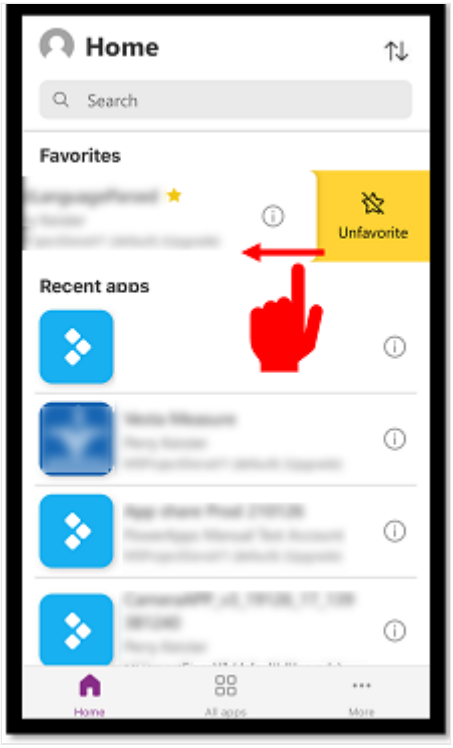
Add to favorites

You can add canvas and model-driven apps to your list of favorite apps.

- Swipe left and then select **Favorite**. A yellow star will appear next to app name when it's added to favorites. You can also select **Details** ⓘ and then add the app to favorites.

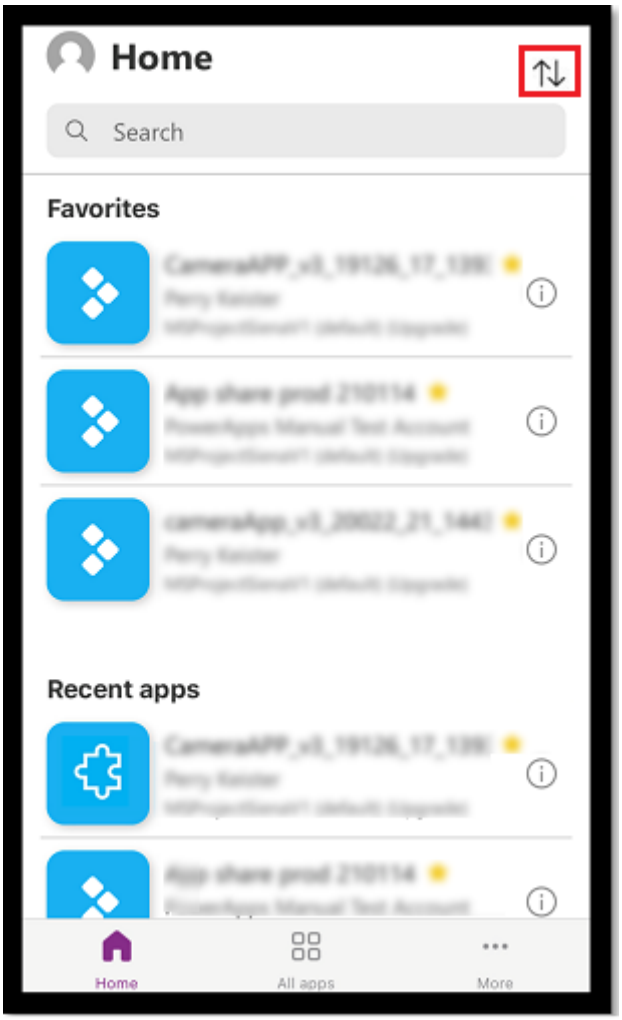


- To remove the app from the list, swipe left again and then select **Unfavorite**.



Sort apps

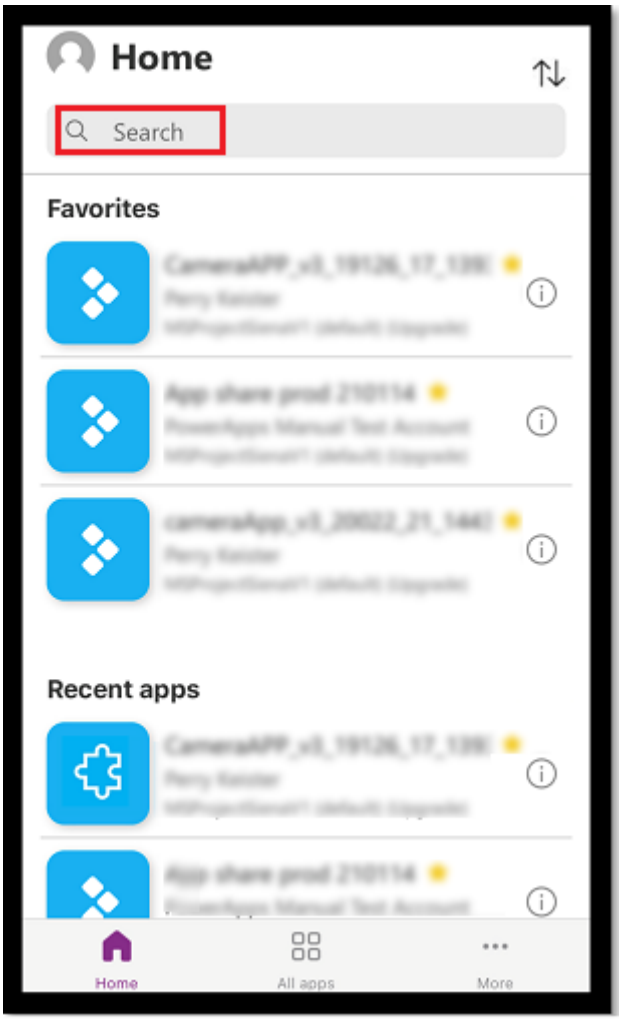
You can sort both canvas apps and model-driven apps. You can sort apps alphabetically by name or by modified date. The sort option is available on **Home**, **All apps**, **Featured apps**, and **Sample apps** screen.



Search apps

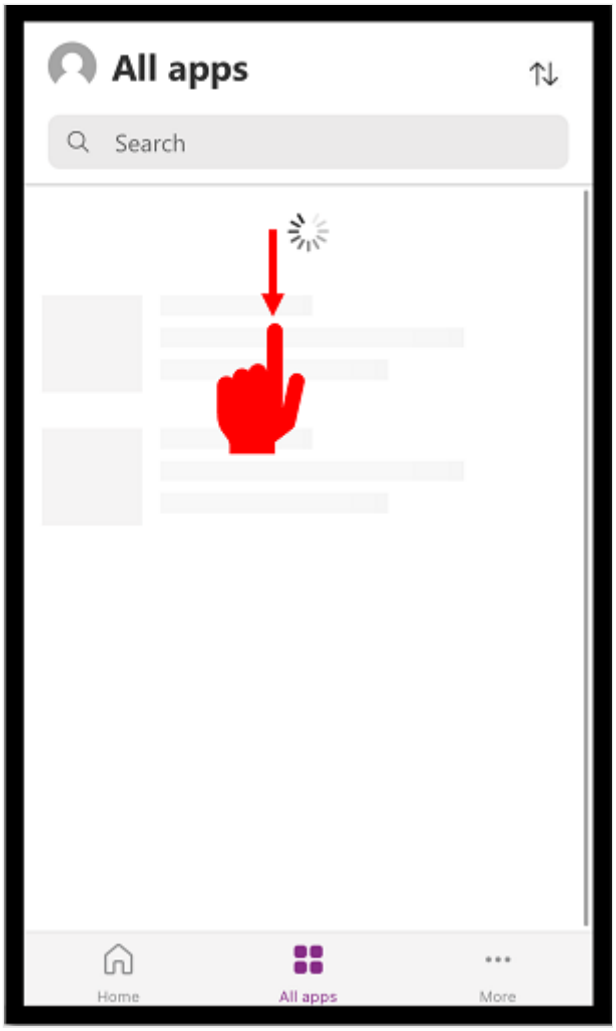
If you know the name of the app that you want to run, then use search to quickly find the app. You can search for both canvas apps and model-driven apps.

To find an app, enter the app name in the search field. The app will only search for apps that are on the screen you're on.



Refresh the list of apps

On the **Home**, **All apps** or any other screen with a list of apps, swipe down to refresh the app list.

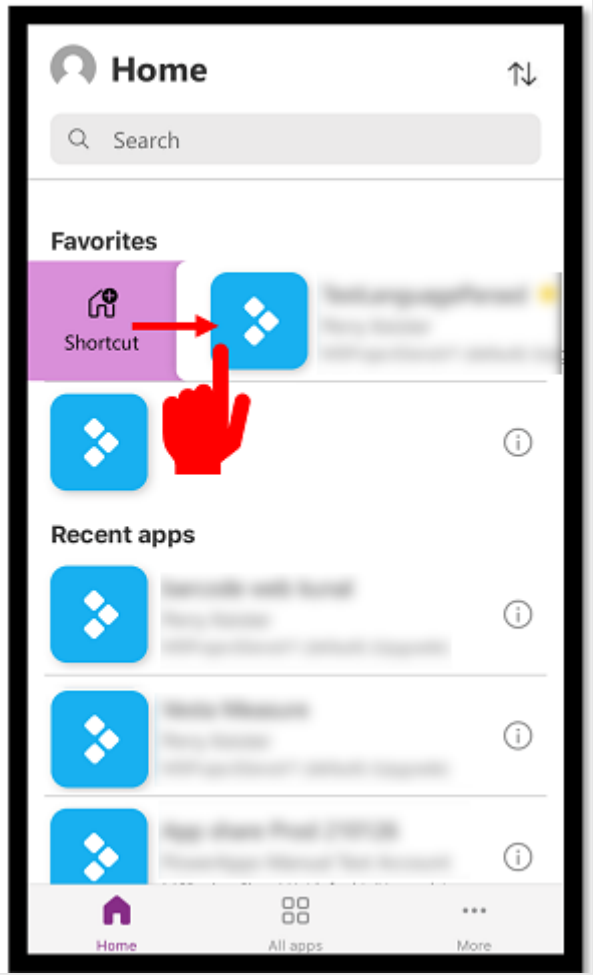


Add shortcuts

You can add a shortcut for both canvas apps and model-driven apps to the home screen of your device for quick access.

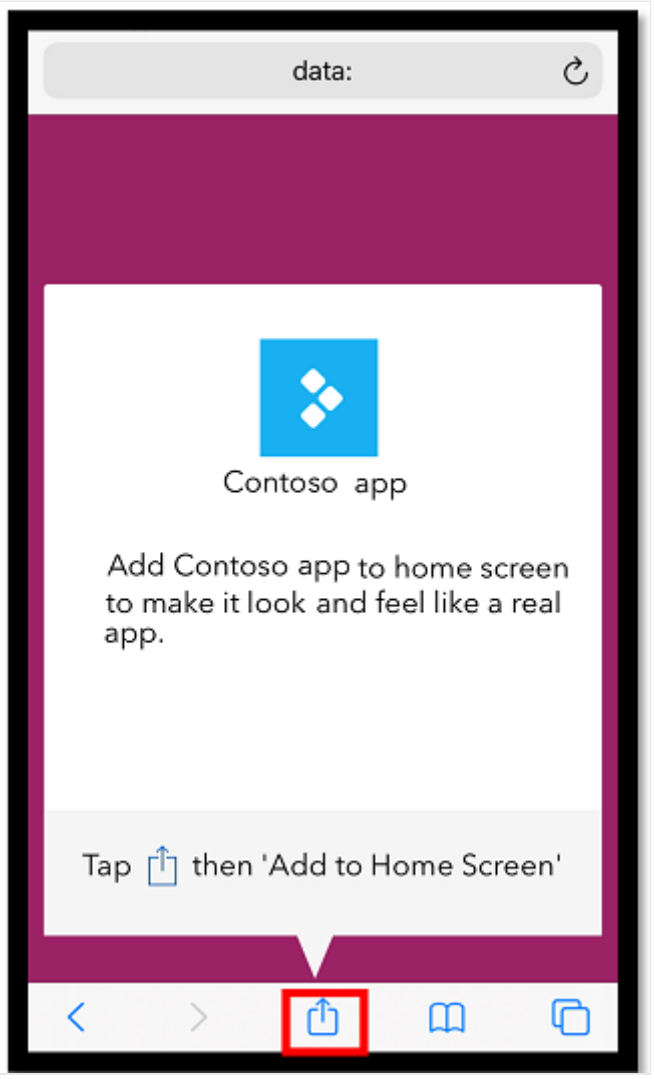
Use Safari to add a shortcut (iOS 13 or earlier)

1. On the app that you want to create a shortcut for, swipe to the right and select **Shortcut**.

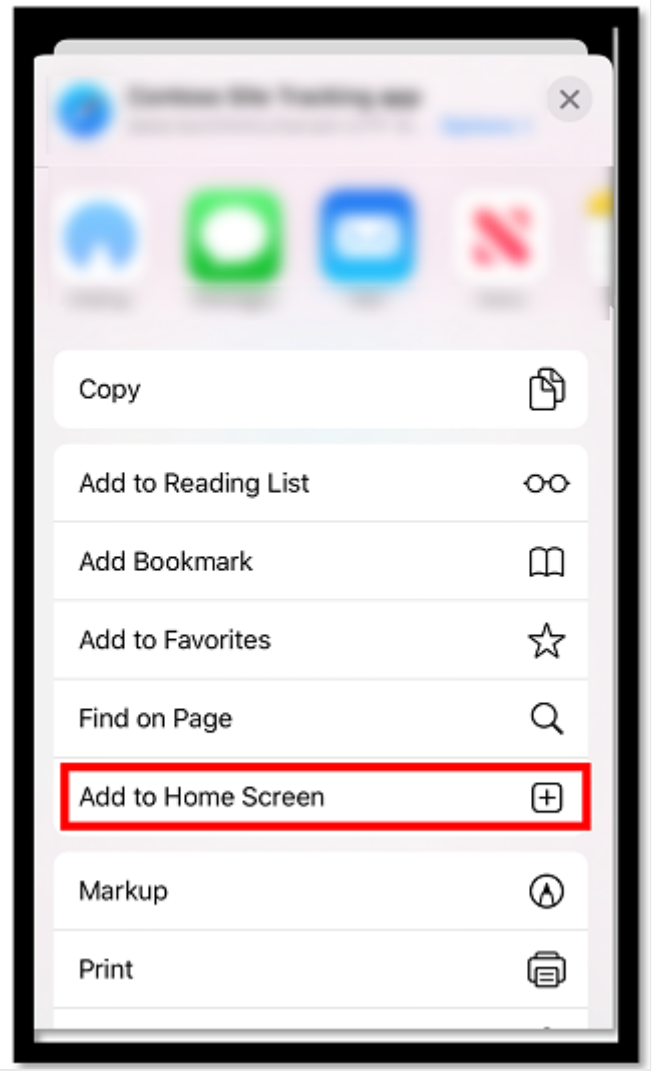


Home
Search
Favorites
Shortcut
Recent apps
Home
All apps
More

2. Select .

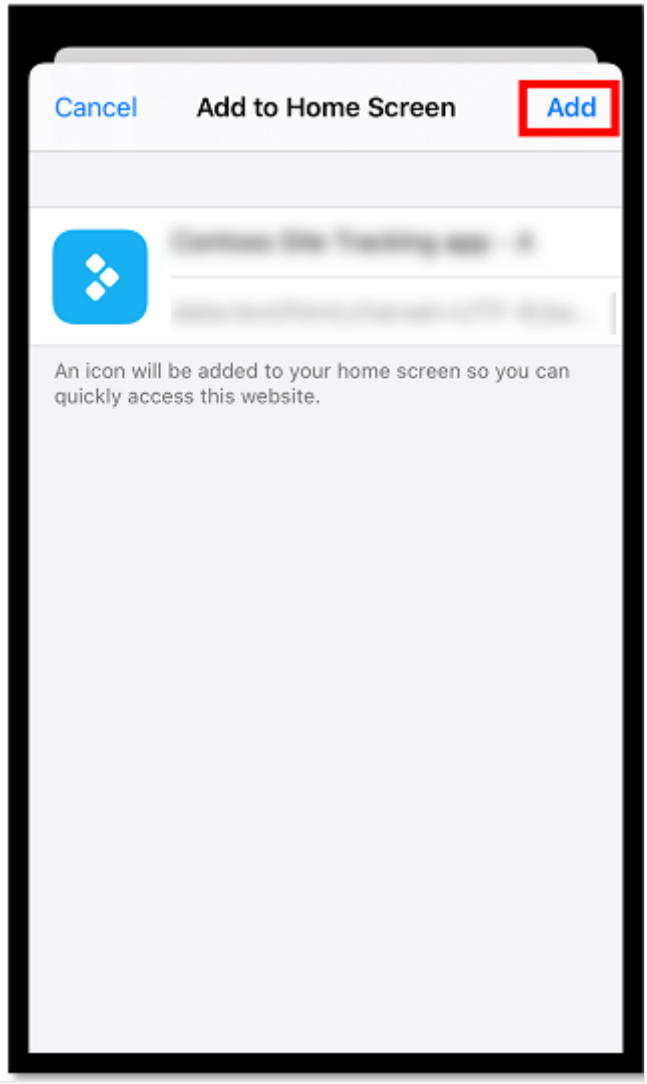


3. Scroll down and select **Add to Home Screen**



Copy
Add to Reading List
Add Bookmark
Add to Favorites
Find on Page
Add to Home Screen
Markup
Print

4. Select **Add**.



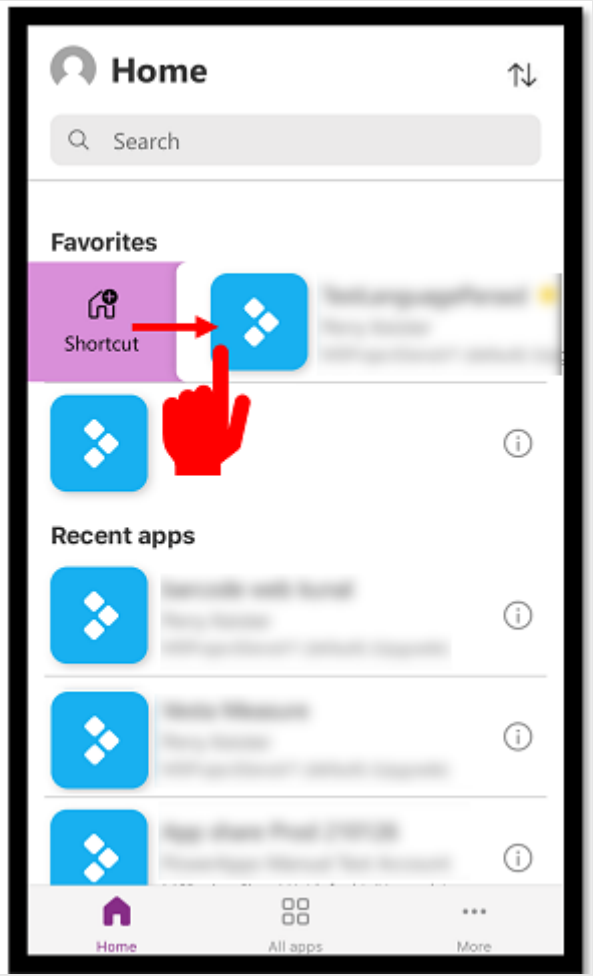
> **Note**
>
> For iOS devices that have multiple browsers installed, use Safari when pinning an app to home.

Use Siri shortcuts to add a shortcut to the Home screen (iOS 14 or later)

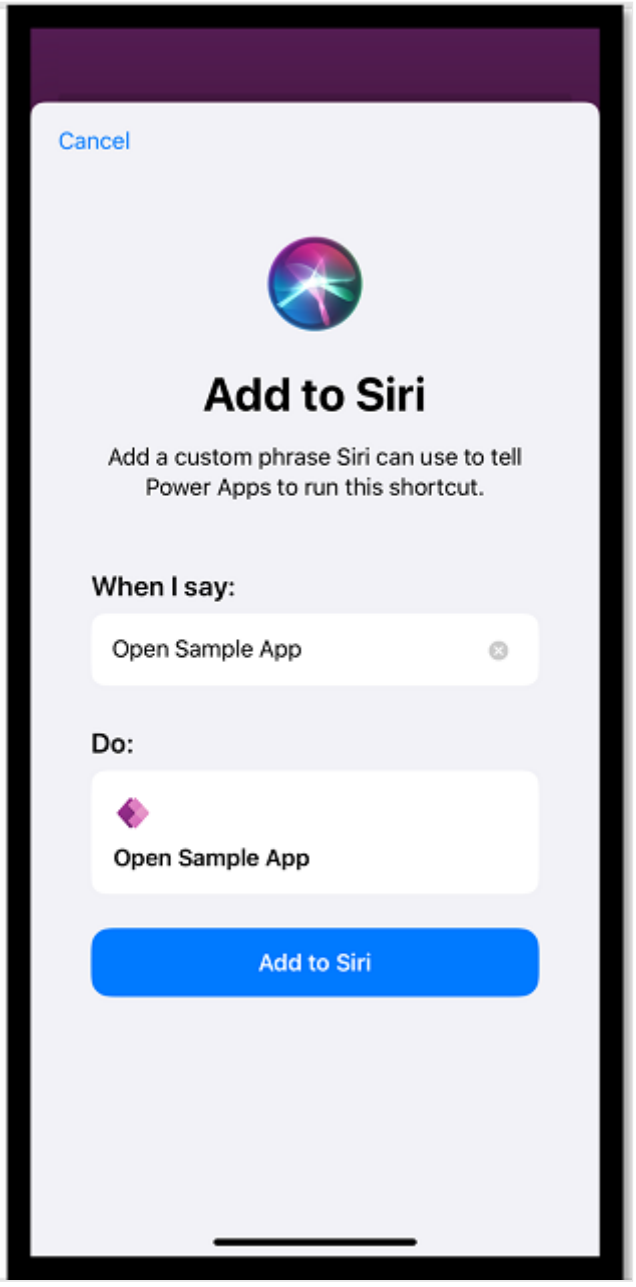
The Power Apps mobile app is now integrated with Siri shortcuts, which gives you the ability to add a shortcut to the Home screen, launch apps with Siri, and create new workflows. For more information on how shortcuts work on iOS, see Shortcuts User Guide. This feature requires Power Apps mobile version 3.20092.x or later.

Users on iOS 14 or later can use Siri Shortcuts to pin an app to the home screen. The new experience works for both model-driven and canvas apps. When you add a Siri shortcut, the app is added to the iOS **Shortcuts** app and from there you can add the app to your home screen.

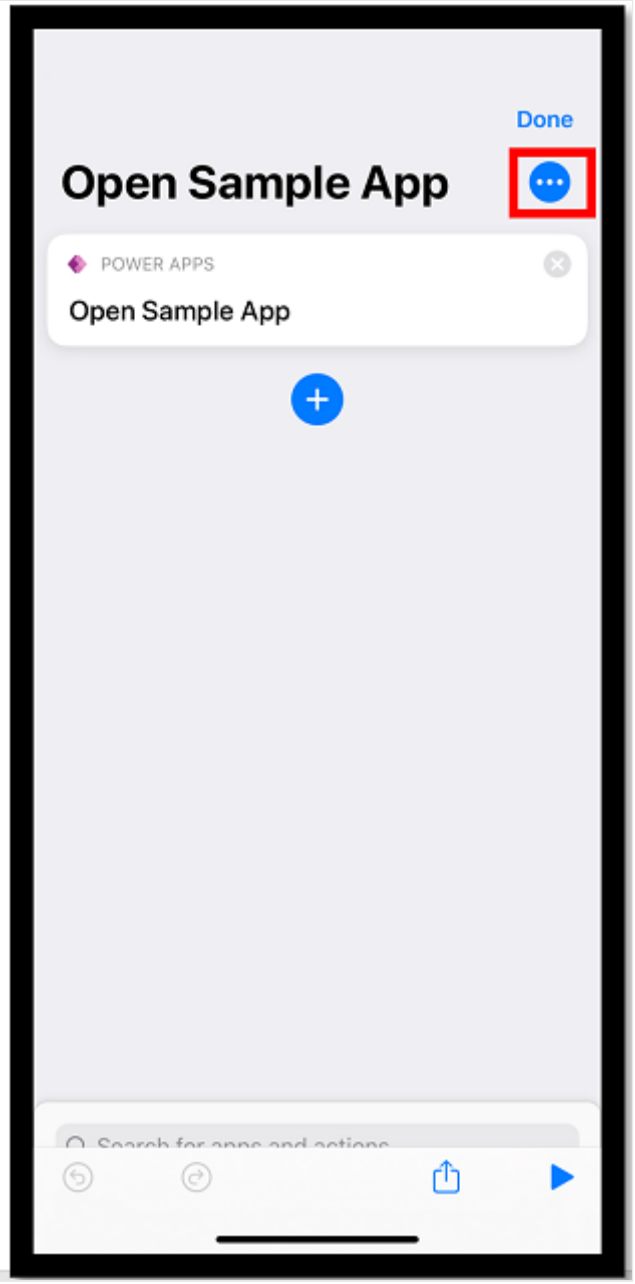
1. On the app that you want add a shortcut for, swipe to the right and select **Shortcut**.



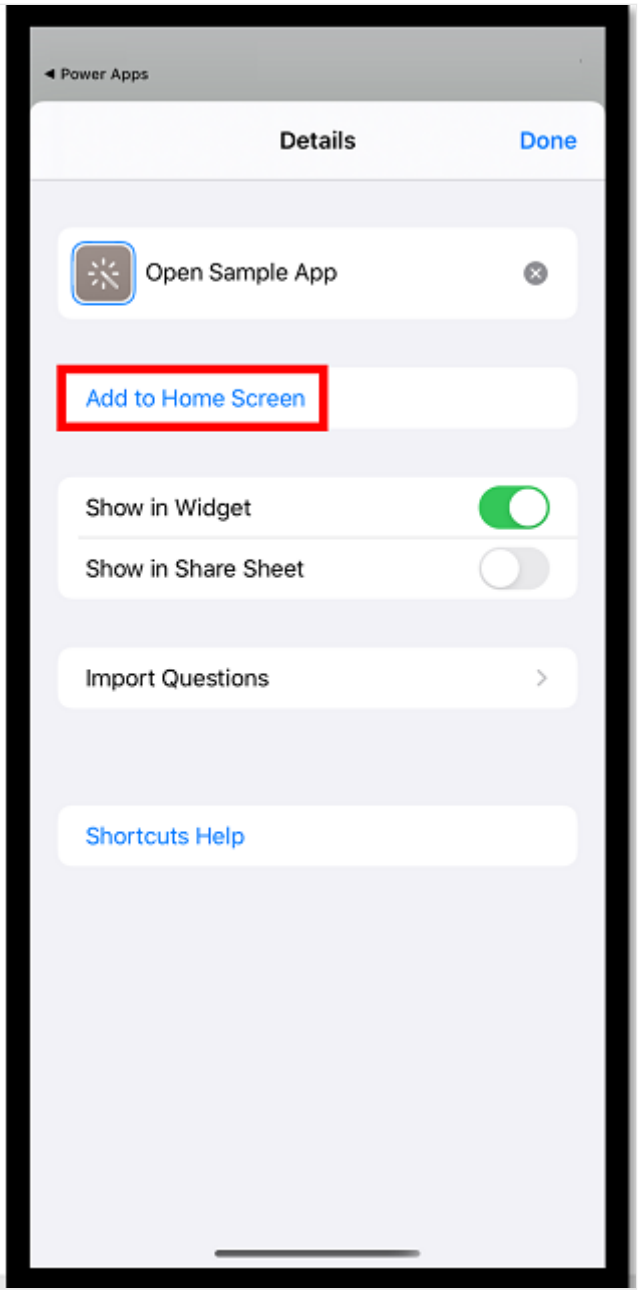
2. Add a custom phrase to open the app using voice commands and then select **Add to Siri**.



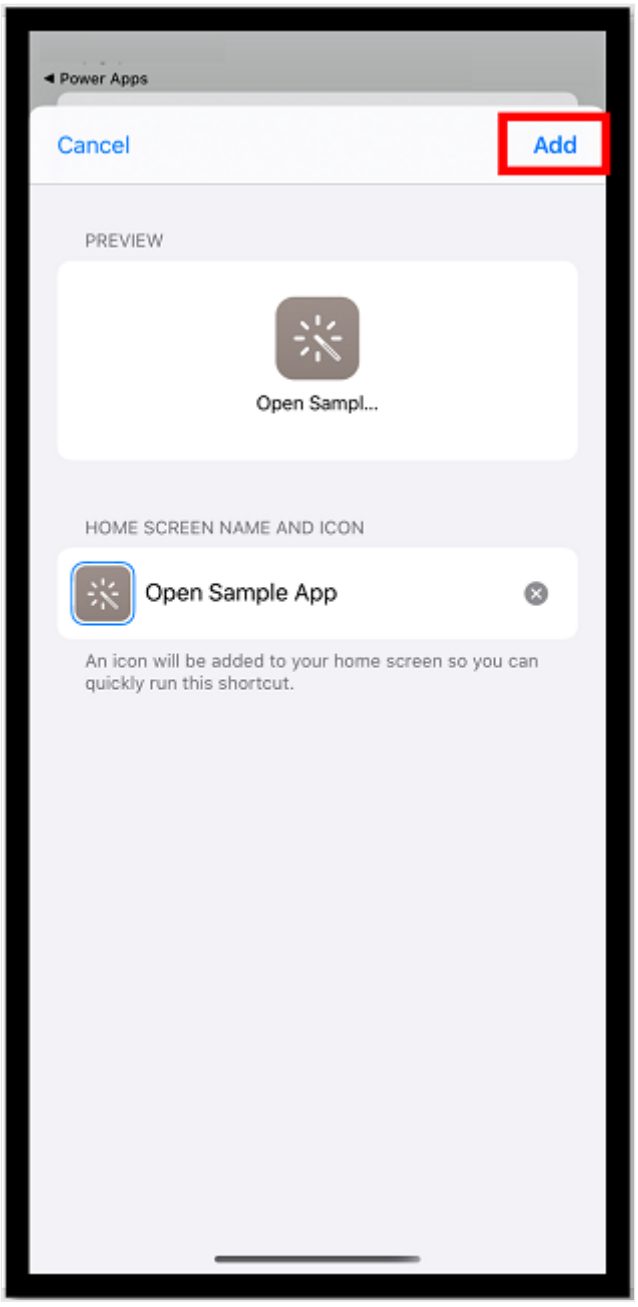
3. The app is added to the **Shortcuts** app on your mobile device. Open the **Shortcuts** app and select the ellipsis (...) above the app name.



4. Select **Add to Home Screen**.



5. On the upper right corner, select **Add** and then select **Done**.

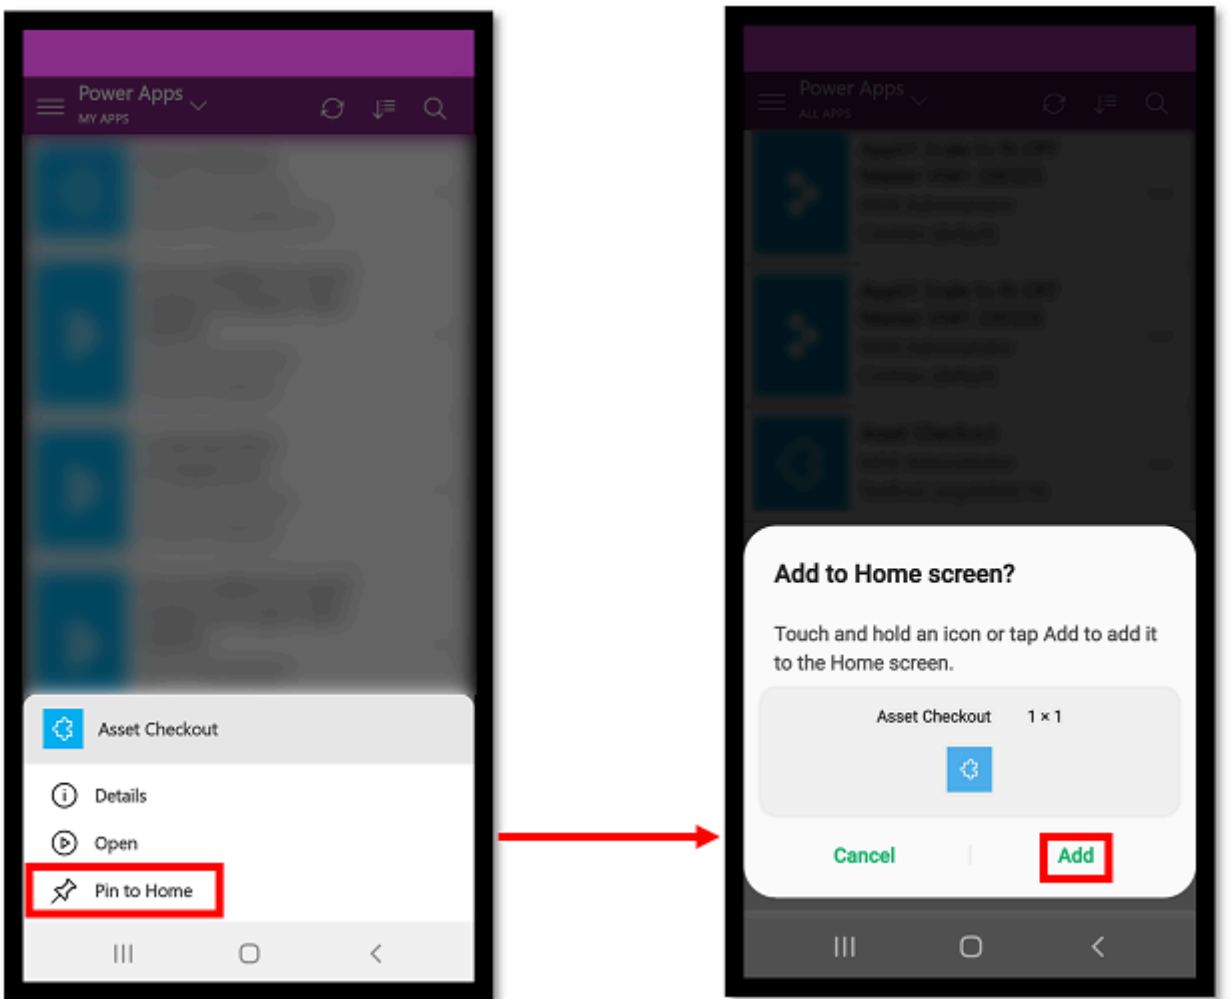


6. Go to your home screen to find the pinned app.

You can customize the shortcut icon but it is limited to the customization options in iOS. For more information, go to Modify shortcut icons .

Pin to home on Android

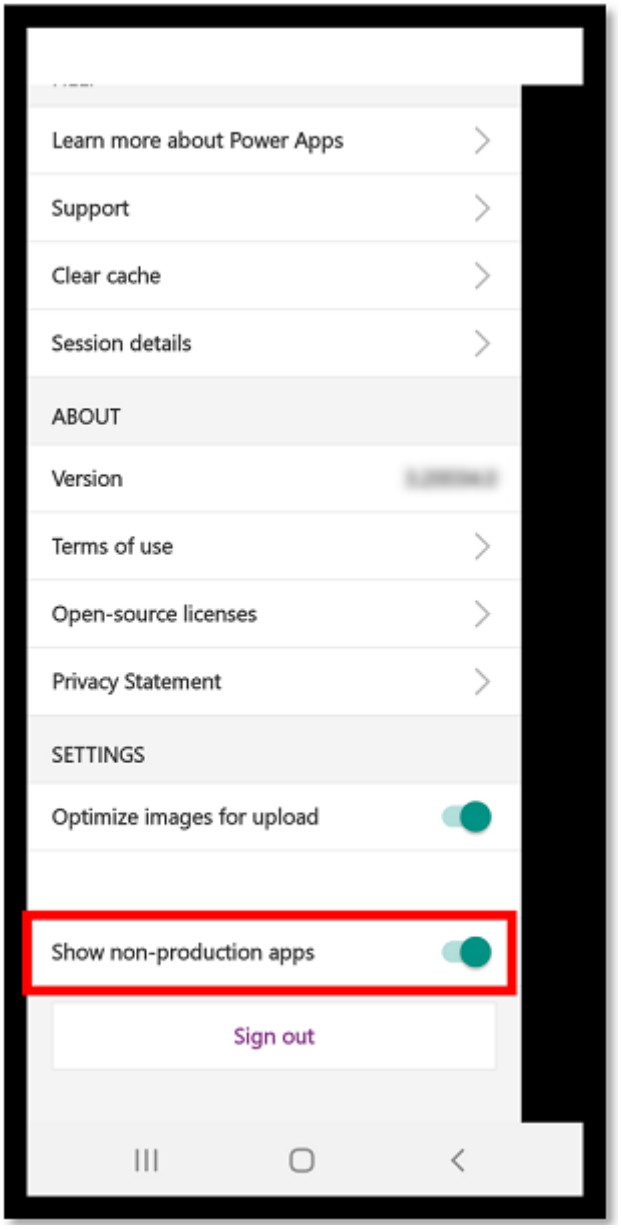
Select the ellipsis (...) on the app tile, select **Pin to Home**, and then follow the instructions that appear.



See non-production apps

By default, only production model-driven apps are shown in the list of apps.

To see model-driven apps from non-production environments, select the **Settings** menu , and then turn on **Show non-production apps**. Follow the instructions that appear.



Run an app

To run an app on a mobile device, select the app tile from the **Home** or **All apps** screen in the Power Apps mobile app.

Considerations when opening apps:

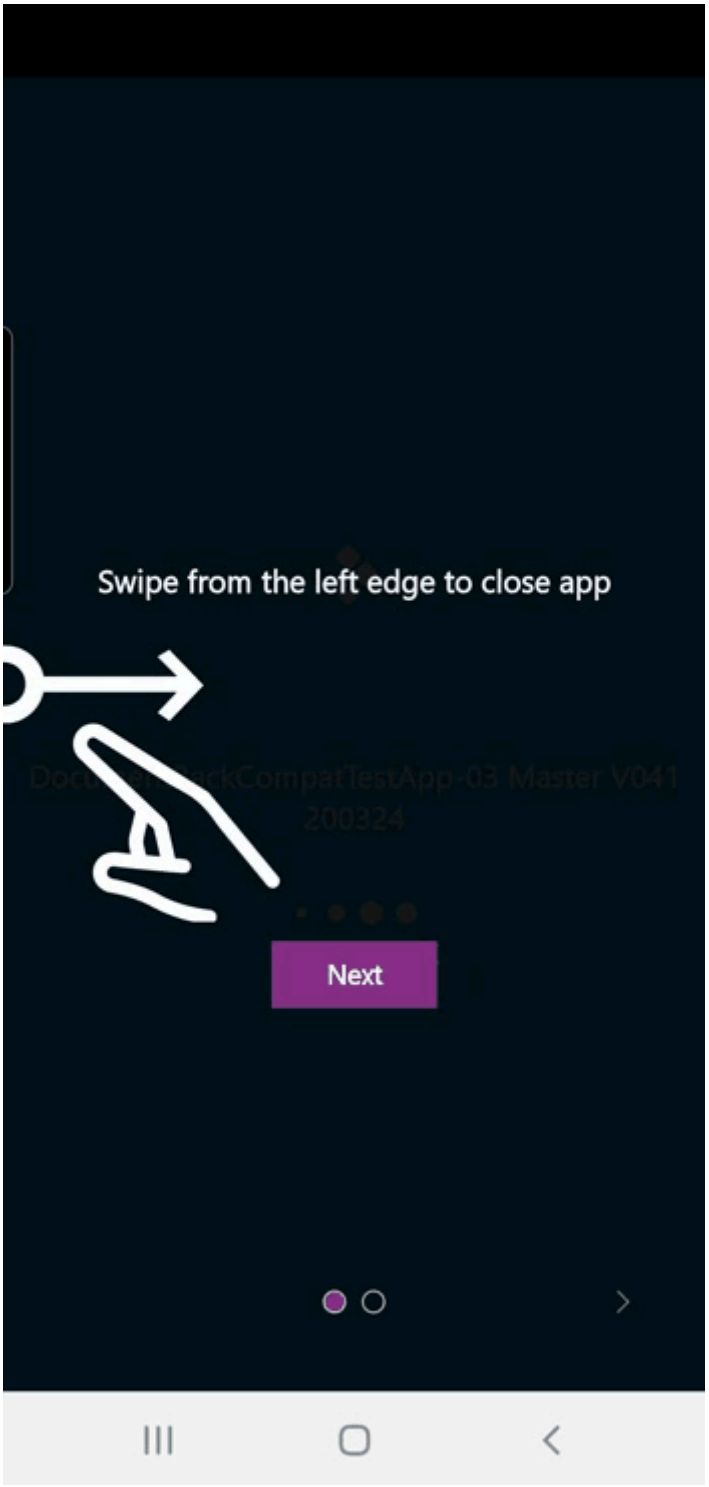
- If you created the app, you see the app in the **Home** page > **Recommended apps** section.
- If you didn't create the app and the app is shared with you, use search box in the **Apps** screen to find the app the first time. After you open the app, it shows up on the **Home** screen the next time you access it.

Run a canvas app

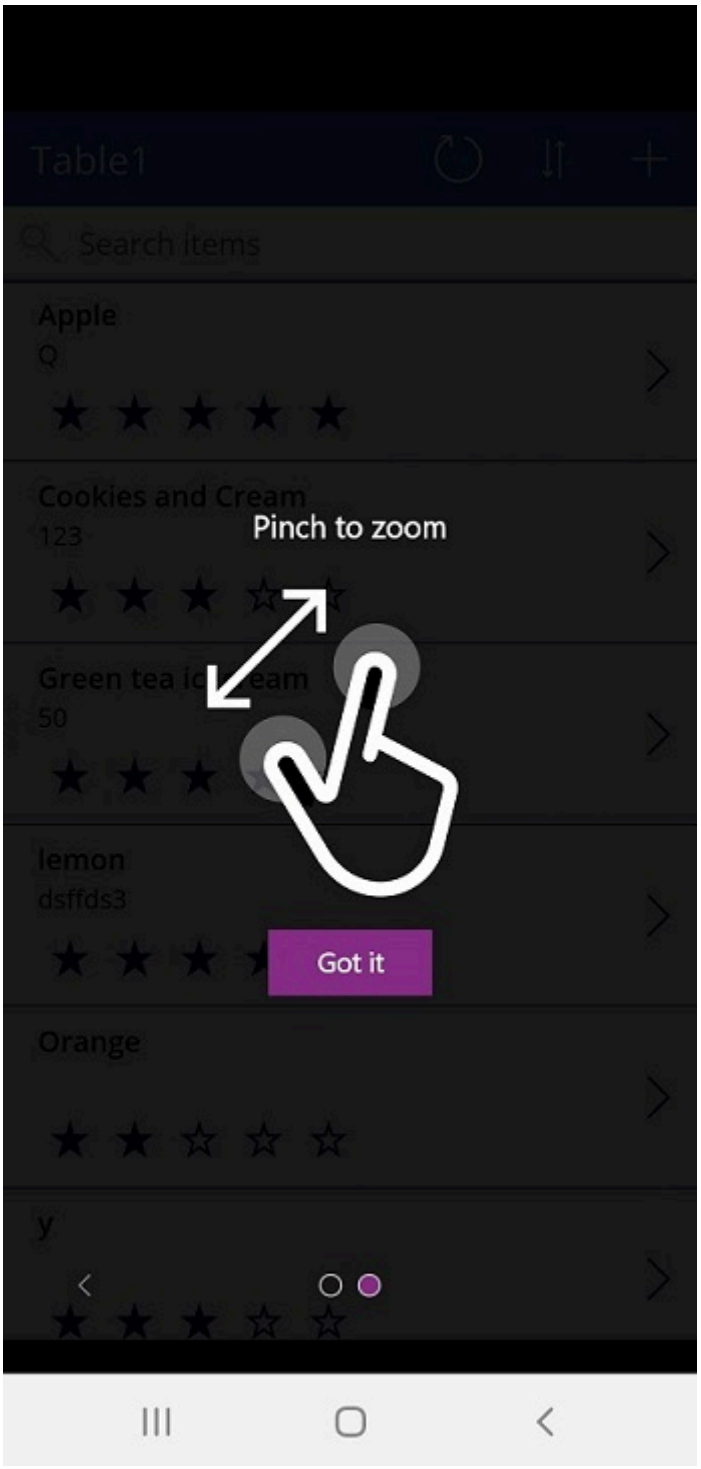
If this is the first time you're running a canvas app by using Power Apps mobile, a screen shows the swipe gestures.

Close a canvas app

Use your finger to swipe from the left edge of the app to the right to close an app. On Android devices, you can also press the Back button and then confirm that you intended to close the app.

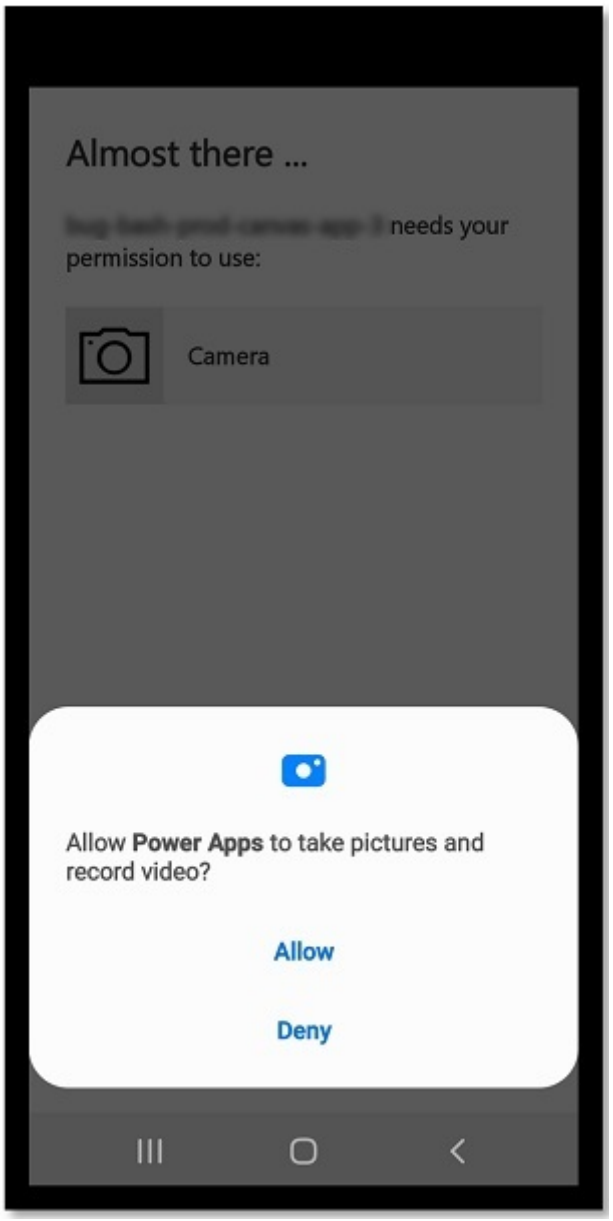


Pinch and zoom in on a canvas app



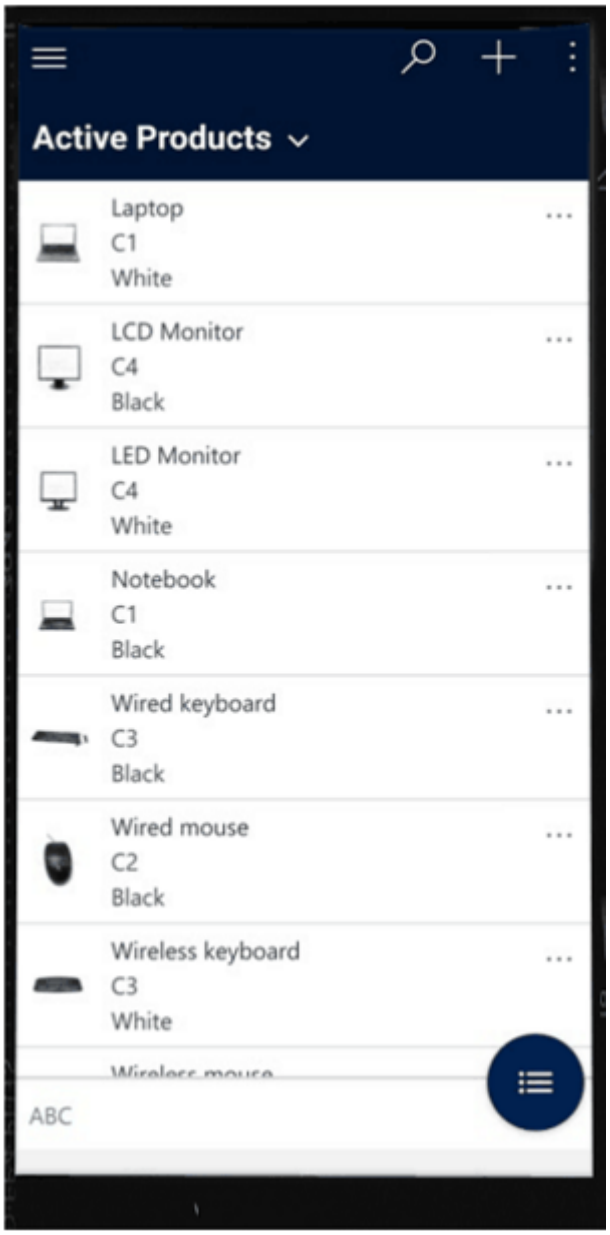
Give consent to a canvas app

If an app requires a connection to a data source or permission to use the device's capabilities (such as the camera or location services), you must give consent before you can use the app. Typically, you're prompted only the first time you run the app.



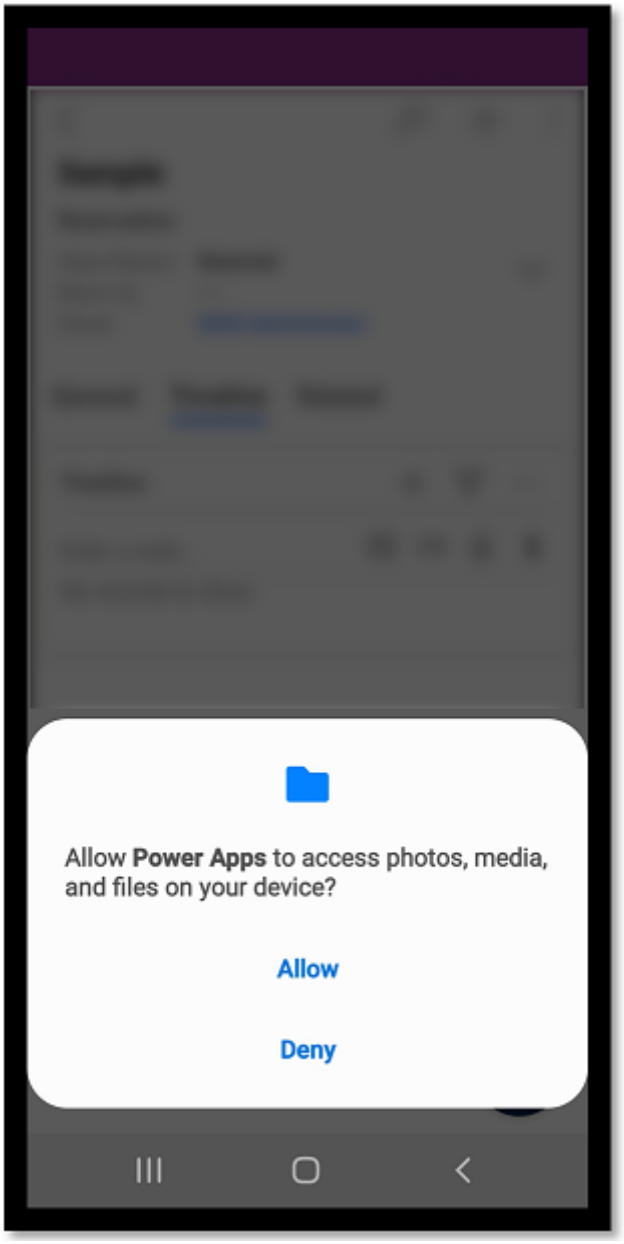
Use a model-driven app

The following image shows an example of a model-driven app screen after you've signed in. To learn how to use model-driven apps running on Power Apps mobile, go to Use model-driven apps on Power Apps mobile.



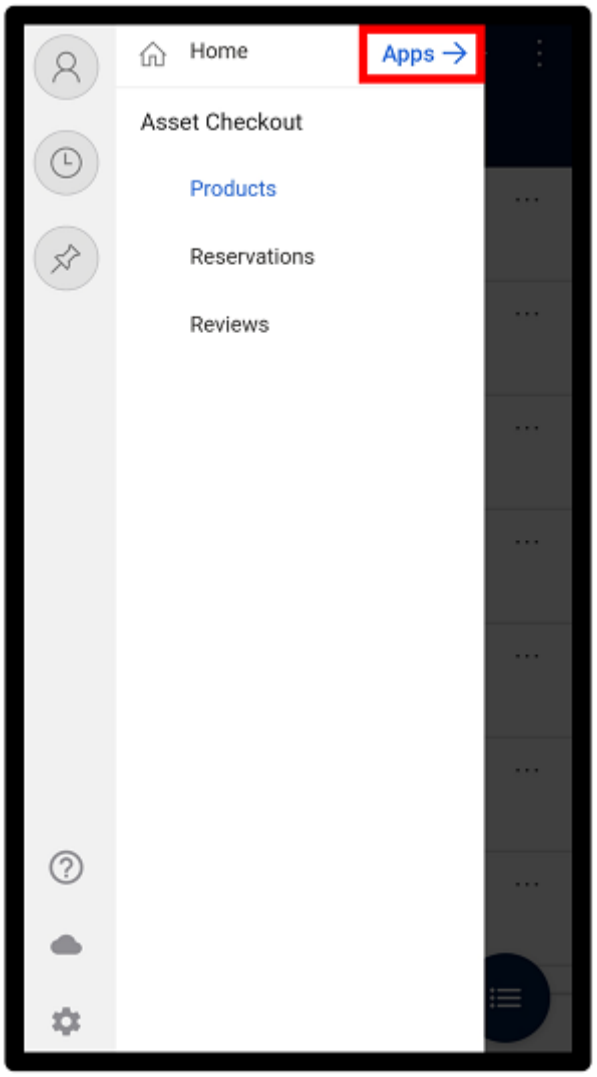
Give consent to a model-driven app

If an app requires a connection to a data source or permission to use the device's capabilities (such as the camera or location services), you must give consent before you can use the app. Typically, you're prompted only the first time you use the app.



Close a model-drive app

Select the site map , and then select **Apps**.



> **Note**
>
> An app maker can customize the navigation bar and show or hide the **Home**, **Recent**, **Pinned** buttons in the site map. An app maker can also make groups collapsible. For more information, see Hide or show the Home, Pinned, Recent, and collapsible groups.

Other mobile apps

The table below outlines which other mobile apps you can use to run your app.

Expand table

Mobile App	Apps you can run
Power Apps mobile (covered in this topic)	• Model-driven apps • Canvas apps • Dynamics 365 Marketing • Dynamics 365 Customer Service

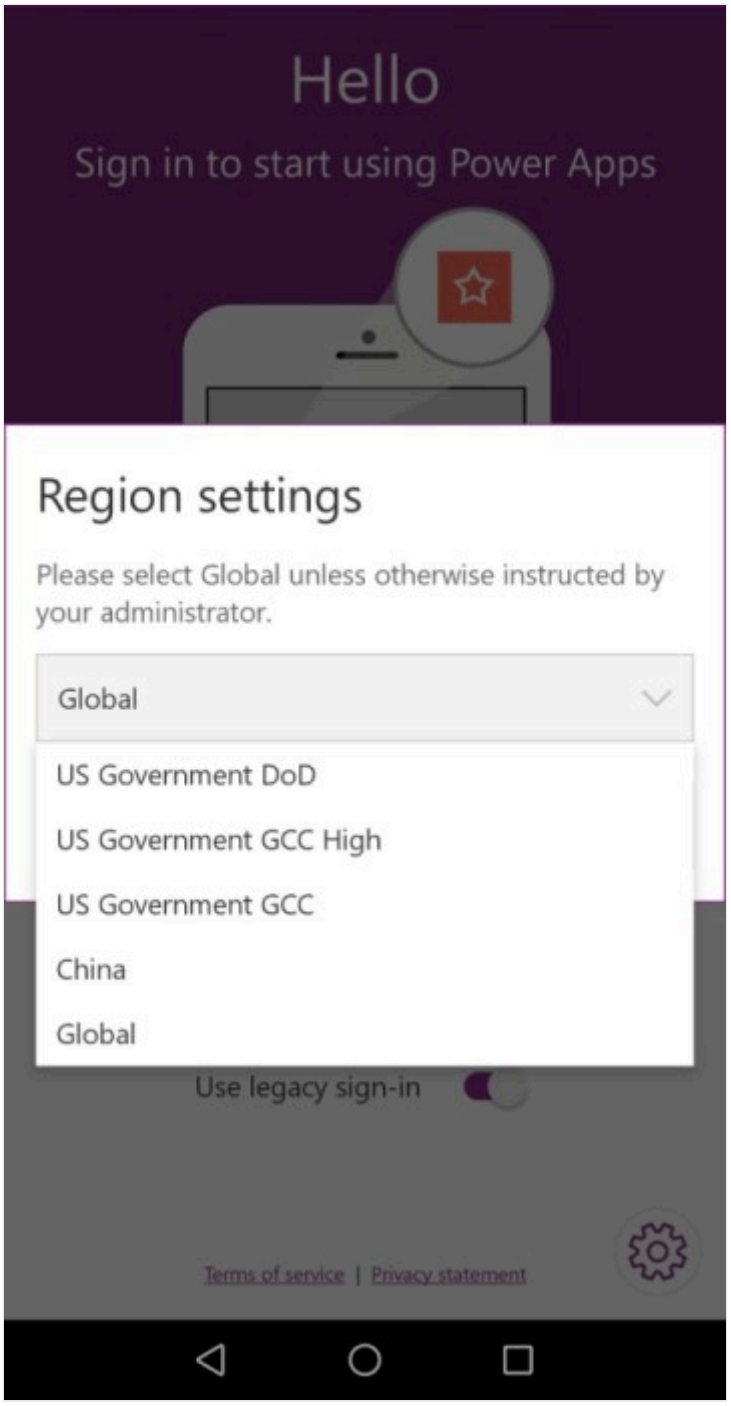
Mobile App	Apps you can run
Power Apps for Windows	• Model-driven apps • Canvas apps
Dynamics 365 for phone and tablets	• Microsoft Dynamics 365 Customer Engagement (on-premises) **Note**: Dynamics 365 for Tablets is deprecated, and won't be supported in 2023.
Dynamics 365 Sales Mobile	• Dynamics 365 Sales
Field Service Mobile	• Field Service (Dynamics 365)

Regional availability of Power Apps mobile app

Power Apps mobile app is available to users in Azure global cloud and also in the following regions:

- US Department of Defense (US DoD)
- US Government Community Cloud (GCC) High
- US Government Community Cloud (GCC)
- China Sovereign Cloud

Mobile users have an option to select their region on Power Apps mobile app sign in screen.



More information:

- Azure Government documentation
- Dynamics 365 US Government
- Power Platform and Dynamics 365 apps in China

Privacy notice

Power Apps mobile app for Android registers for a system event that is broadcasted when the device is finished booting. Power Apps mobile app for Android registers for this event to support push notifications sent to the app.

Power Apps mobile app and wrapped native mobile apps may use device sensors, such as the device accelerometer, to respond to user actions. For example, wrapped native mobile apps would automatically show the app menu when the user shakes the device.

Manage your mobile app with Microsoft Intune

Article • 05/26/2025

Mobile application management software enables IT administrators to apply and enforce corporate policies on mobile apps. One mobile application management option for IT administrators is Microsoft Intune, which offers a suite of features that lets you publish, push, configure, secure, monitor, and update mobile apps - including Power Apps mobile, Dynamics 365 Sales Mobile, and Field Service Mobile. Mobile application management is essential to organizations whose users use mobile app primarily because:

1. Users frequently travel to multiple locations, and protecting sensitive company data is critical.
2. Many organizations have a bring-your-own-device policy, which means that the mobile app needs management among many devices and apps for personal use.

With an Intune-enabled mobile app, IT administrators can:

- Add and assign the mobile app to user groups and devices, including users in specific groups, devices in particular groups, and more.
- See reports and track app usage.
- Limit sharing of corporate data among apps by restricting data leakage through cut, copy, paste, and save-as.
- Provide encryption at rest.

Intune is a separate Microsoft product that is not included with Power Apps mobile. Refer to the documentation on What is Microsoft Intune app management? and Assign apps to groups with Microsoft Intune to get started.

A configuration can be set up through the Device Management portal. Each supported platform (iOS, Android, and Windows) requires a separate configuration.

Enhanced security support in Intune

Intune advanced app settings aren't currently supported with Power Apps Mobile. However, organization admins and makers have complete control over authentication, user access, managing sensitive data access, configuring notifications, setting data sync policies across sources, and defining access to organizational data and documents, through combination of Power Platform environment settings and Azure conditional access policies.

Set the appearance of your app to dark or light mode

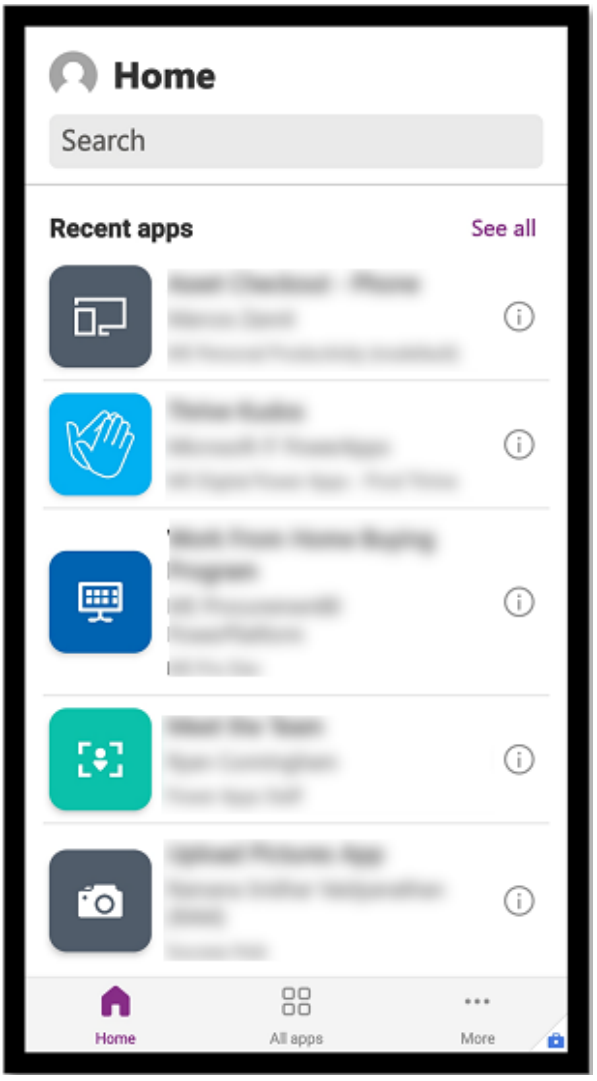
Article • 11/30/2022

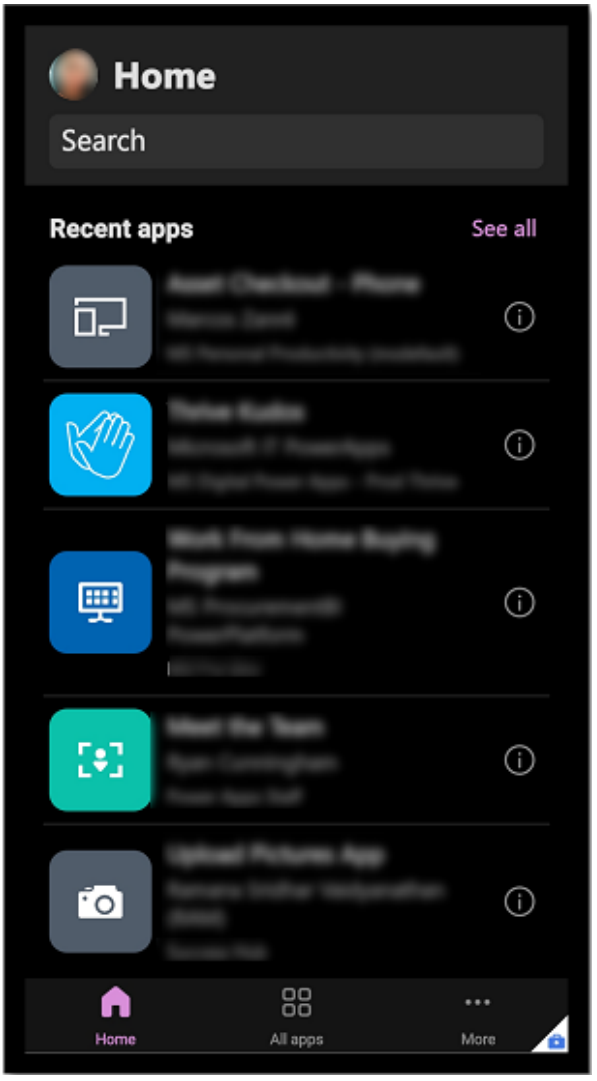
Easily change the display of your app to dark mode, light mode, or set it to the system default on iOS and Android devices.

When you choose the **System default**, the display setting for Power Apps mobile will match the dark or light mode display setting on your iOS or Android device.

The default display mode for Power Apps mobile is set to **Light**.

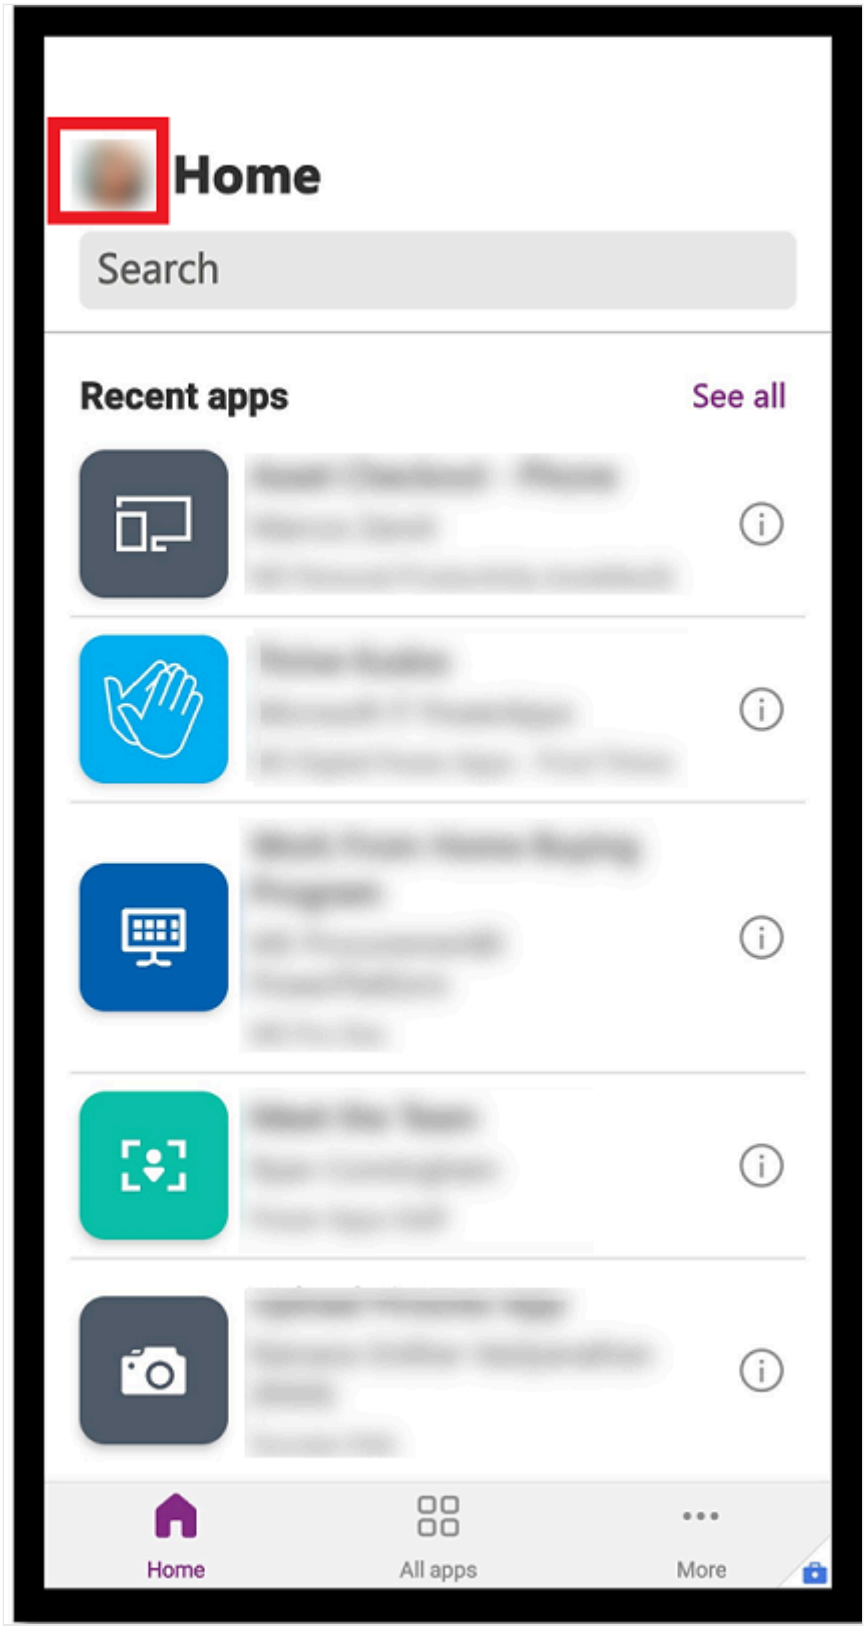
Expand table

Light mode appearance	Dark mode appearance
	


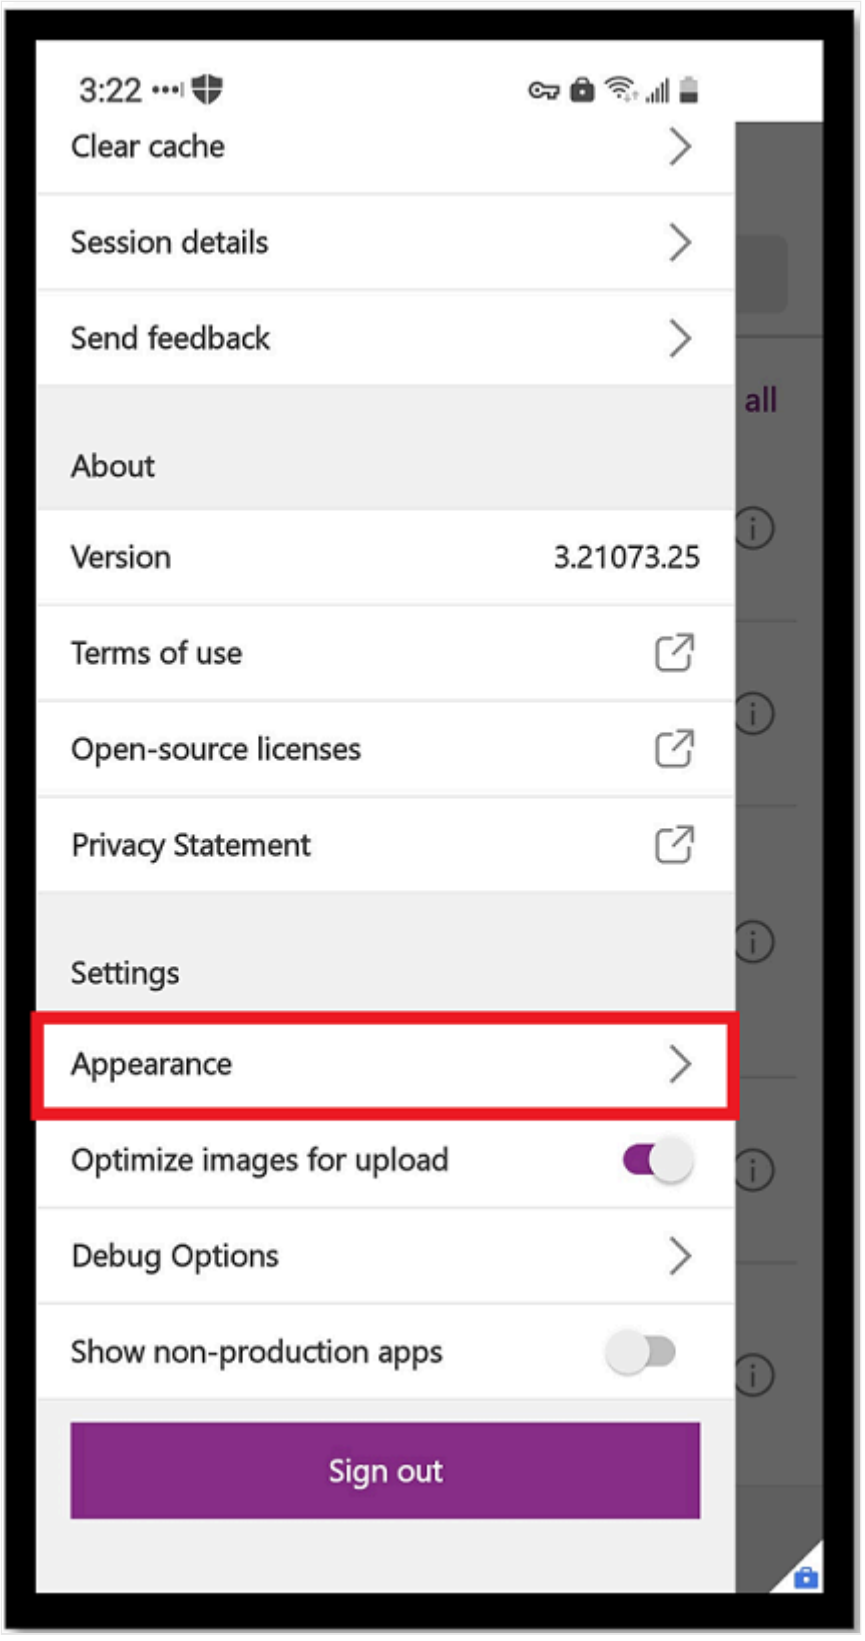


1. To change the display, open Power Apps mobile and sign in.

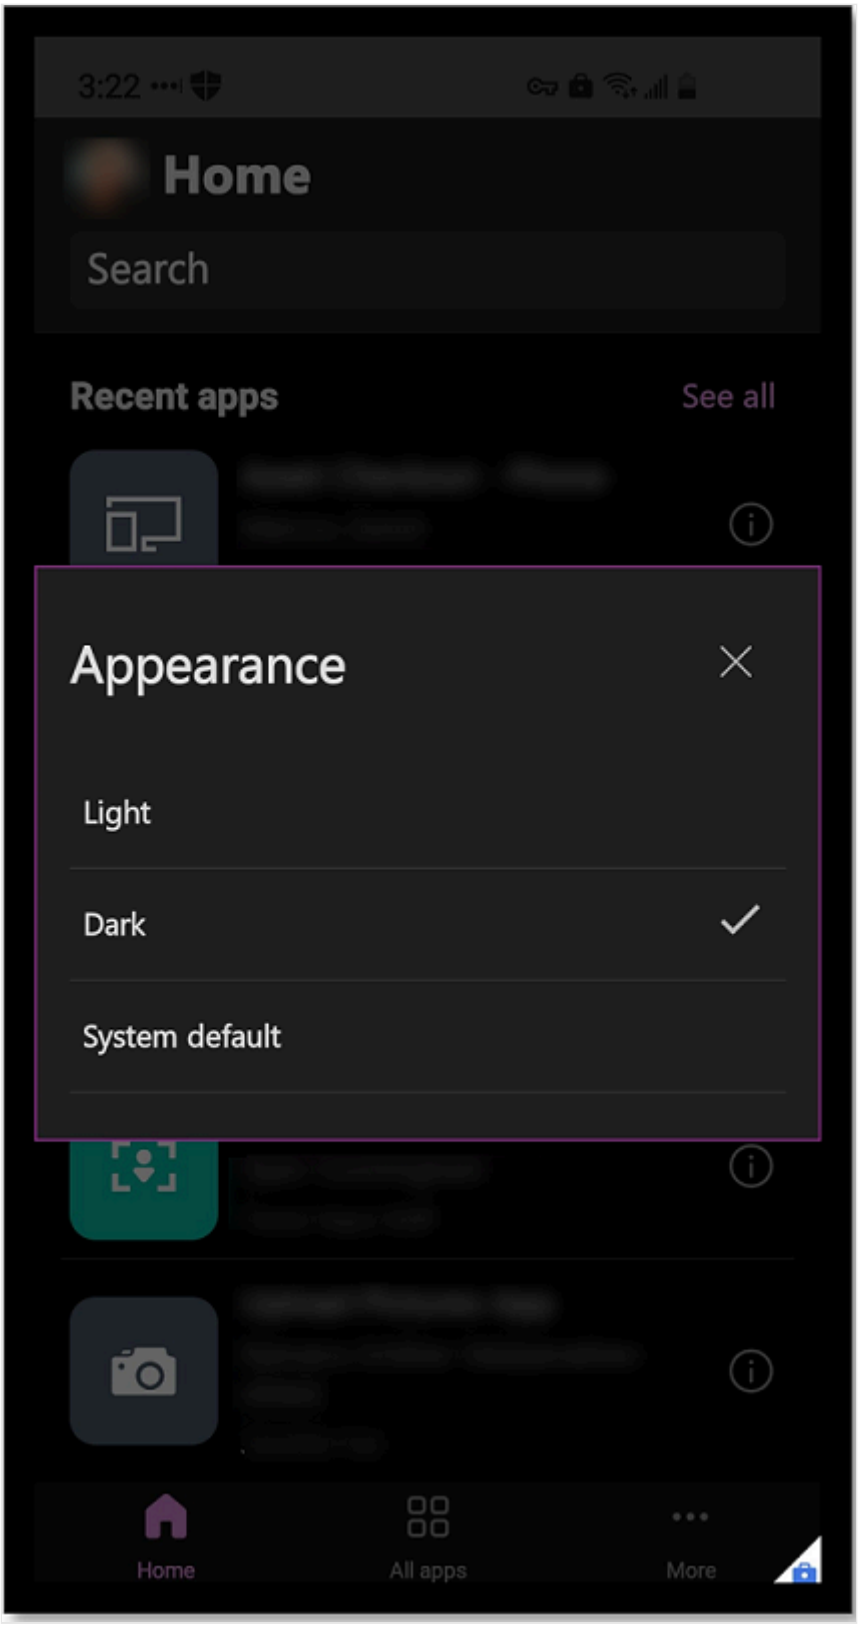
2. From the **Home** screen, select your profile picture.



3. Under **Settings**, select **Appearance**.



4. Select your display setting: **Light**, **Dark**, or **System default**.



5. When you're done, select the **X** to close the window.

Use model-driven apps in the Power Apps mobile app

Article • 08/02/2023

Use Power Apps mobile to run model-driven apps on your mobile device. For more information about how to install and get started with an app, see Install Power Apps mobile.

Important

- To use your model-driven app in the Power Apps mobile app, your app maker must have set the **Primary mobile player** setting to **Power Apps mobile.** For more information, see Manage model-driven app settings in the app designer.

Home screen

It's easy to get around in Power Apps mobile. The following illustration shows the primary navigation elements on the Home screen.

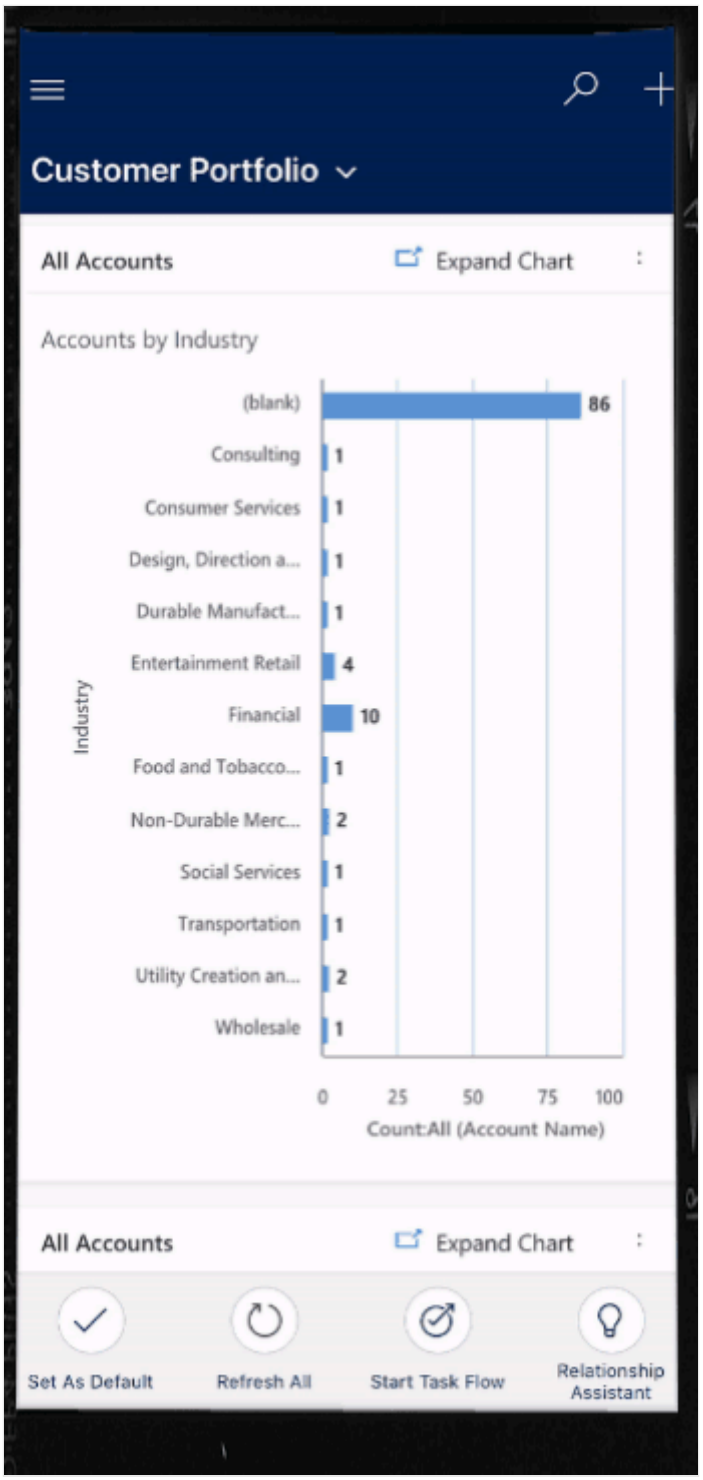
Legend:

1. **Site map**: Open the menu and move between apps, get to your favorite and recently used rows, access settings, and more.
2. **Search**: Search for app rows in Microsoft Dataverse.
3. **New**: Create a new row and quickly enter almost any type of information into the system.
4. **Assistant**: Use the assistant to monitor and track daily actions and communications. It helps you stay on top of your day with insight cards that are displayed prominently throughout the app to provide tailored and actionable insights.

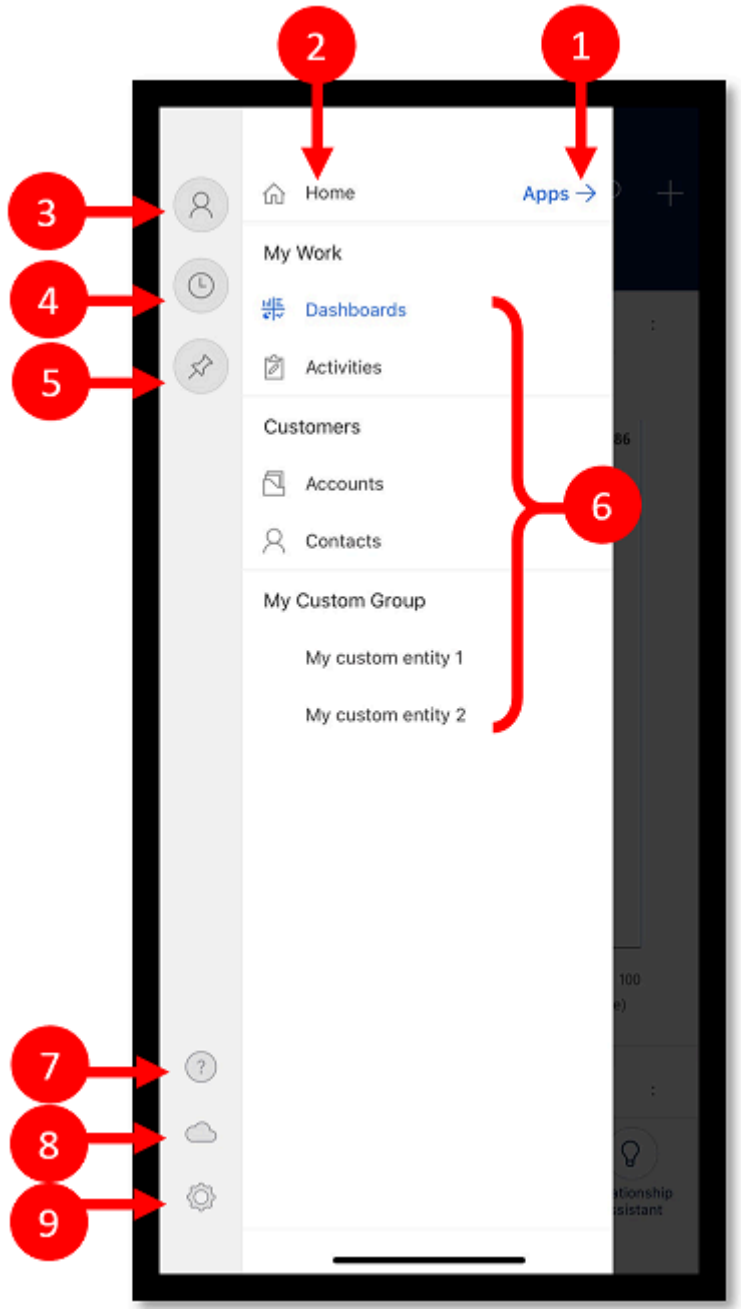
Site map

From the Home screen, select the site map to access tables, favorite or most-used rows, other apps, and settings.

Your site map might look different if your app maker has customized the navigation bar to show or hide the **Home**, **Recent**, **Pinned** buttons in the site map. An app maker can also make groups collapsible. For more information, see Hide or show the Home, Pinned, Recent, and collapsible groups.



The following illustration shows the primary navigation elements on the site map screen.



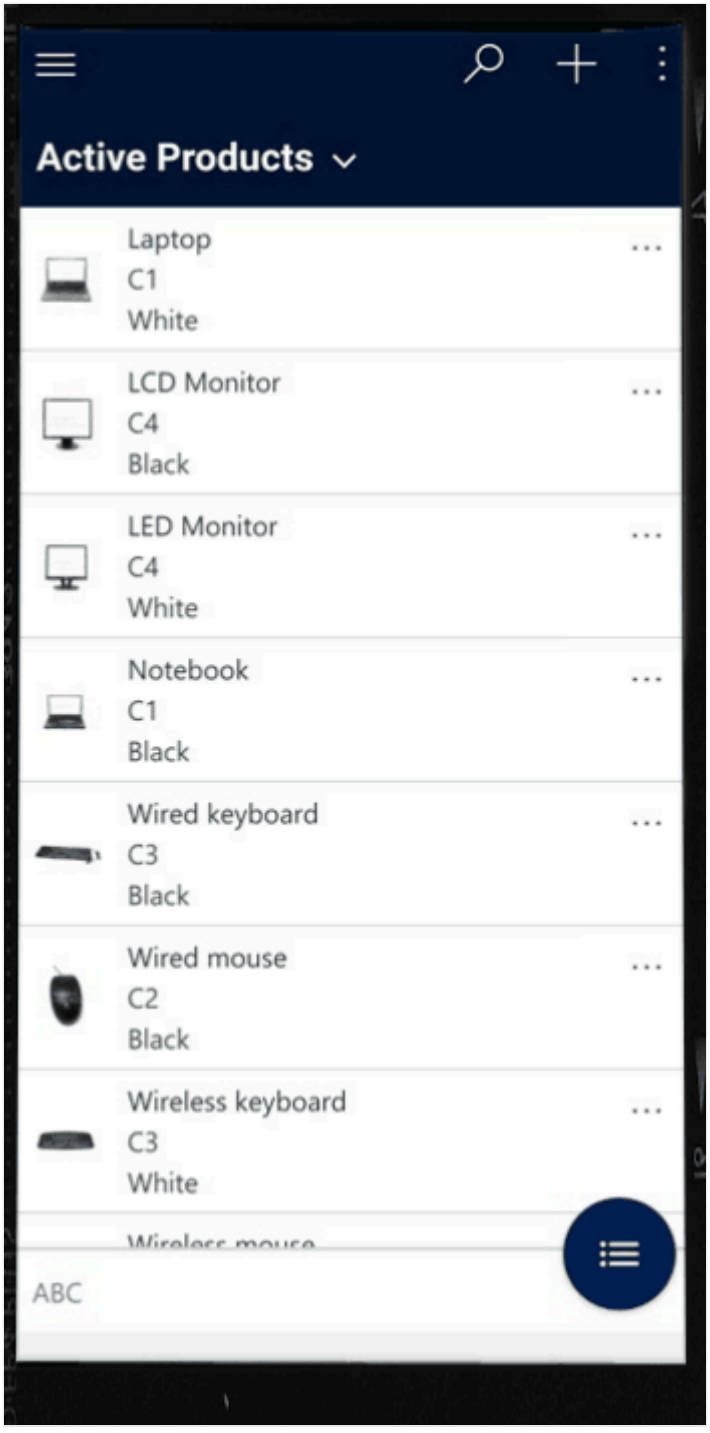
Legend

1. **App selector**: Open this menu to close your app and switch to another app.
2. **Home screen**: Select this to go back to the Home screen.
3. **Profile**: Go to the Profile screen to sign out or reconfigure the app.
4. **Recent rows**: View a list of rows you were recently using.
5. **Pinned rows**: View and open your favorite (pinned) rows.
6. **Table navigator**: This area lists the table available in the app.
7. **Help**: Access help content for more information about how to use Power Apps mobile.
8. **Offline status**: Work with your data in offline mode, even when you don't have internet access. More information: Work offline on your mobile device
9. **Settings**: Access settings.

Pin favorite rows

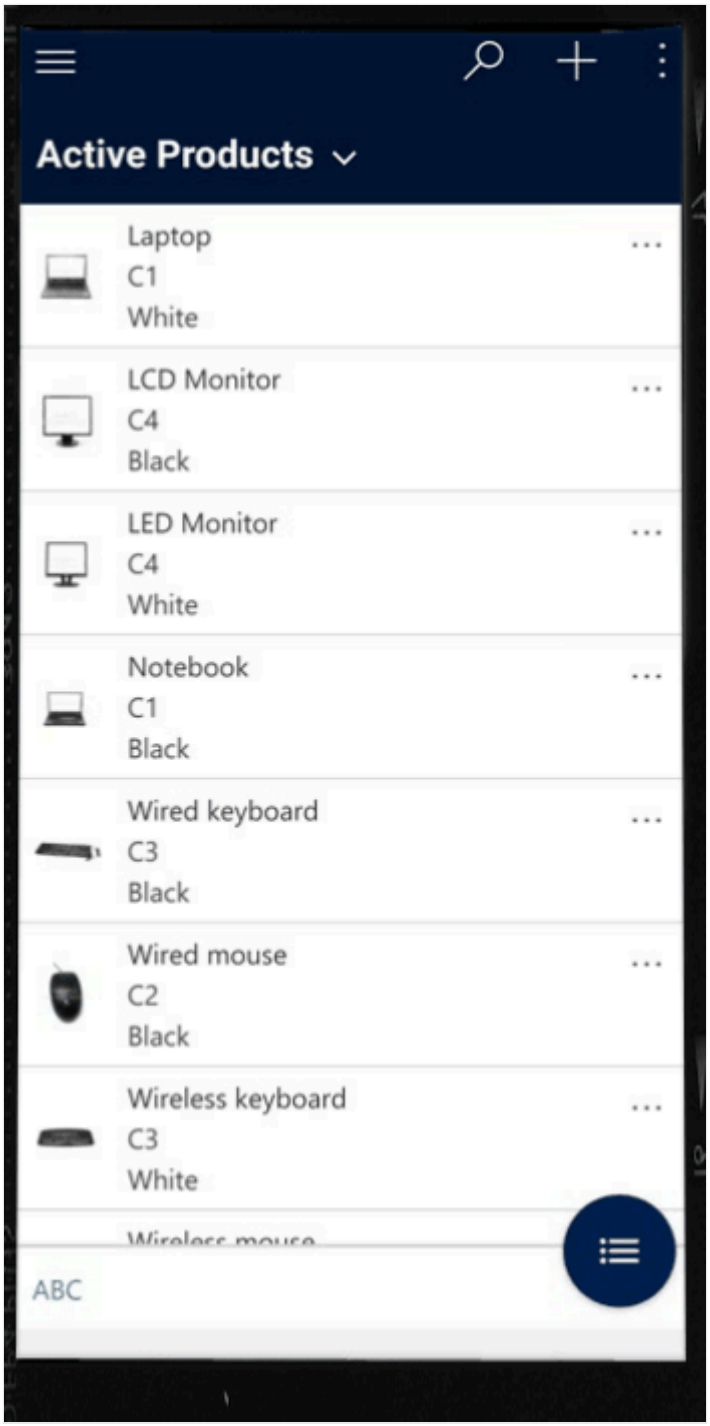
The **Pinned** and **Recent** lists provide quick access to rows that you've recently used or pinned to favorites. Use the **Recent** list to pin favorite rows.

1. From the site map , select **Recent** .
2. On the **Recent** rows screen, select the push-pin icon next to a row to add it to your favorites (pinned rows).
3. To view the newly pinned rows, select **X**, and then select **Pinned** .



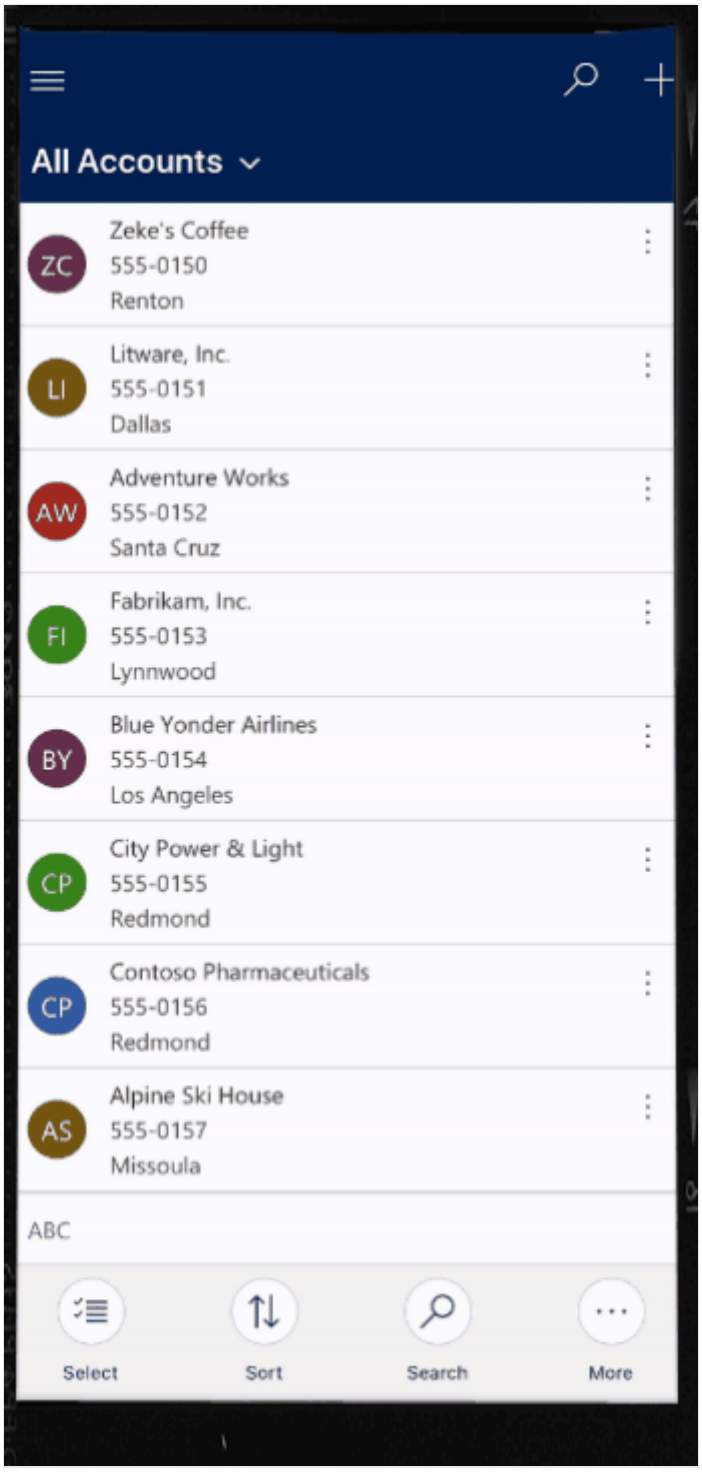
Unpin a row

1. From the site map , select **Pinned** .
2. Select the remove-pin icon next to a row to remove it from favorites (pinned rows).



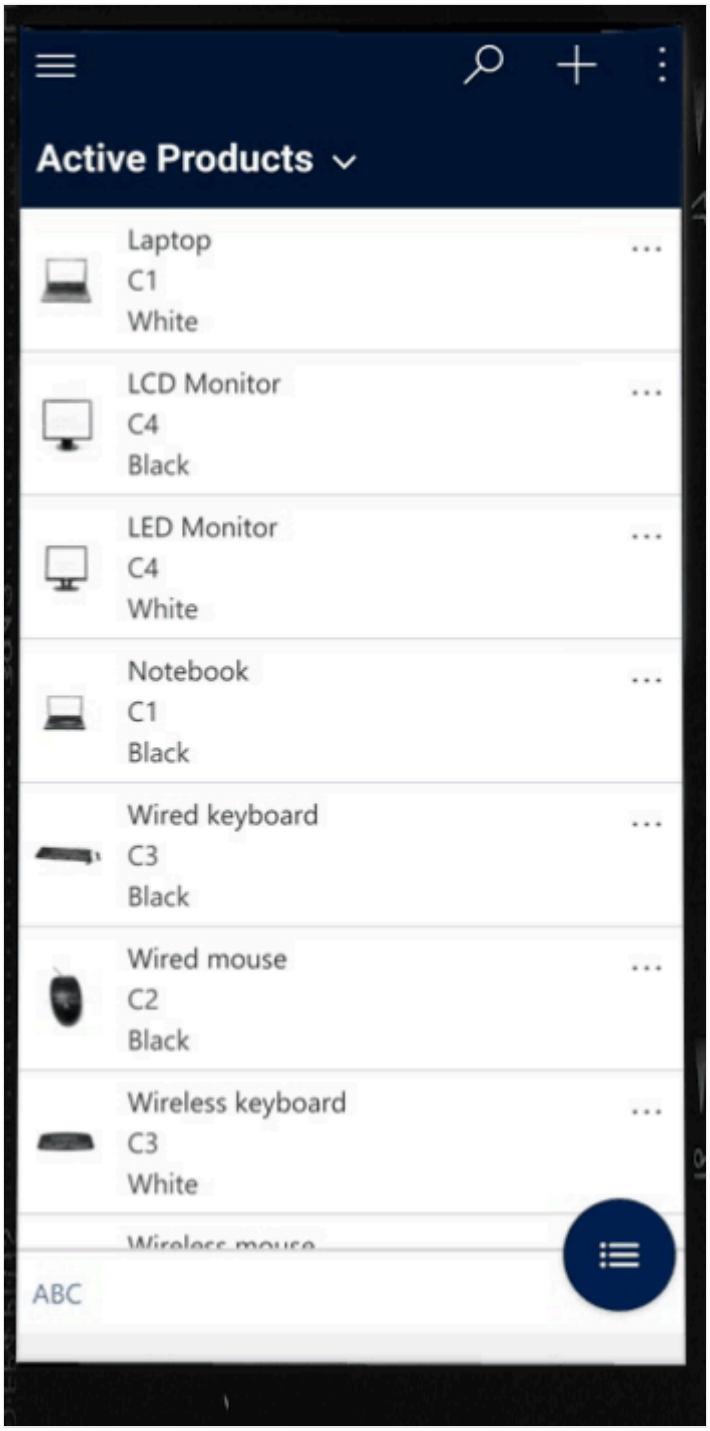
Change views

- From the Home screen, select the down arrow next to the current view, and then select a new view.

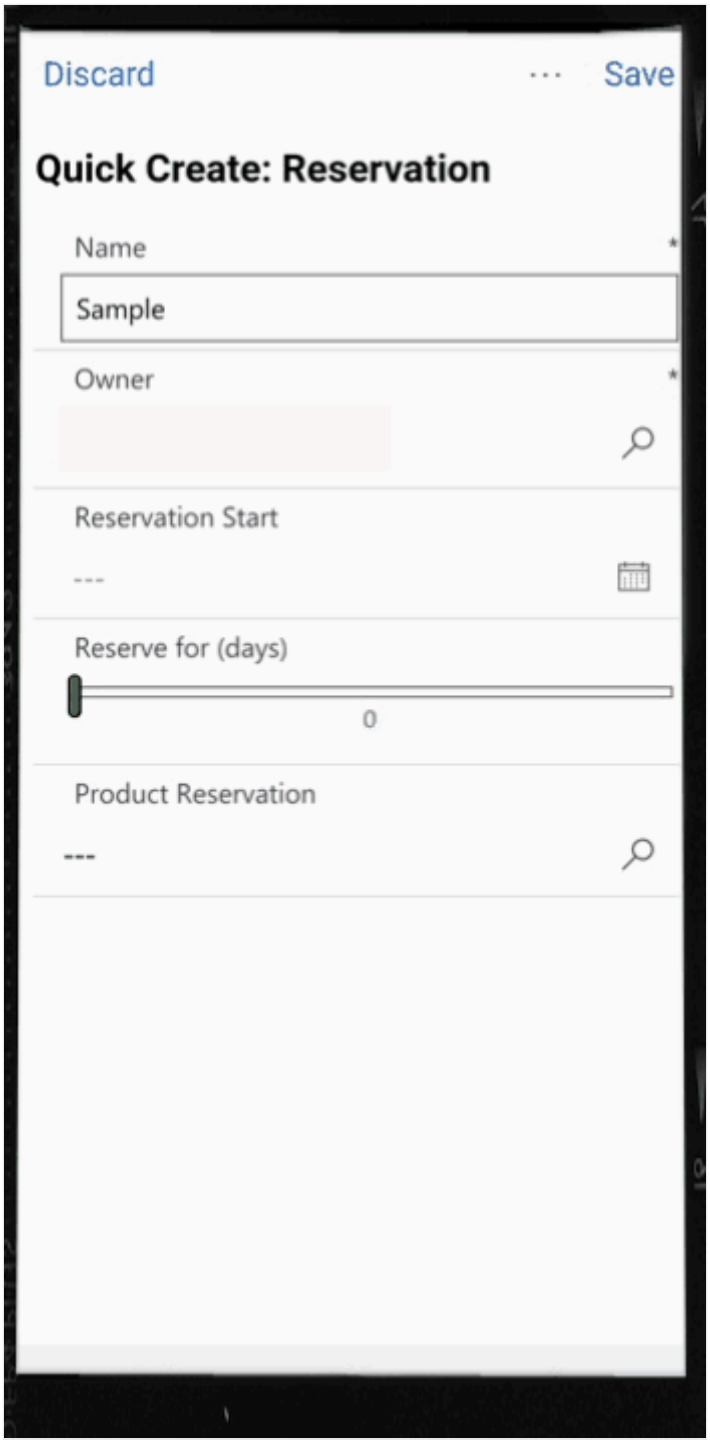


Add a row quickly

1. From the Home screen, select **New** .
2. Fill in the columns, and then select **Save**.
3. After the row is created, you can view the new row.

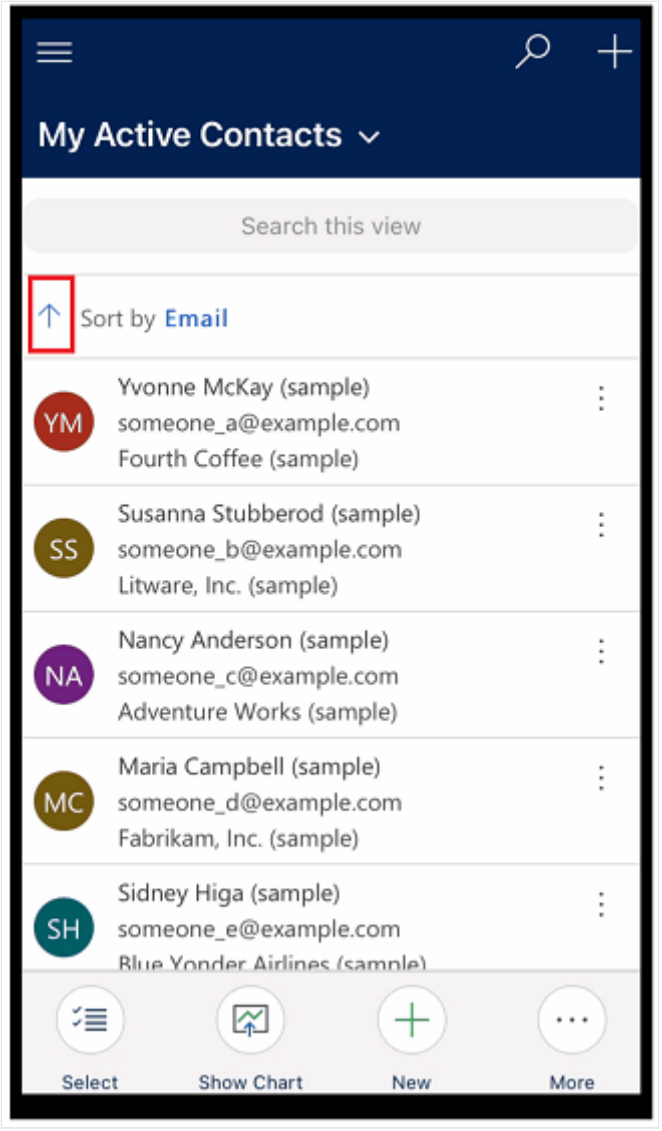


- To save and open the row that you created, select **More** ..., and then select **Save and Open**.
- To save and create another row, select **More** ..., and then select **Save and Create new**.

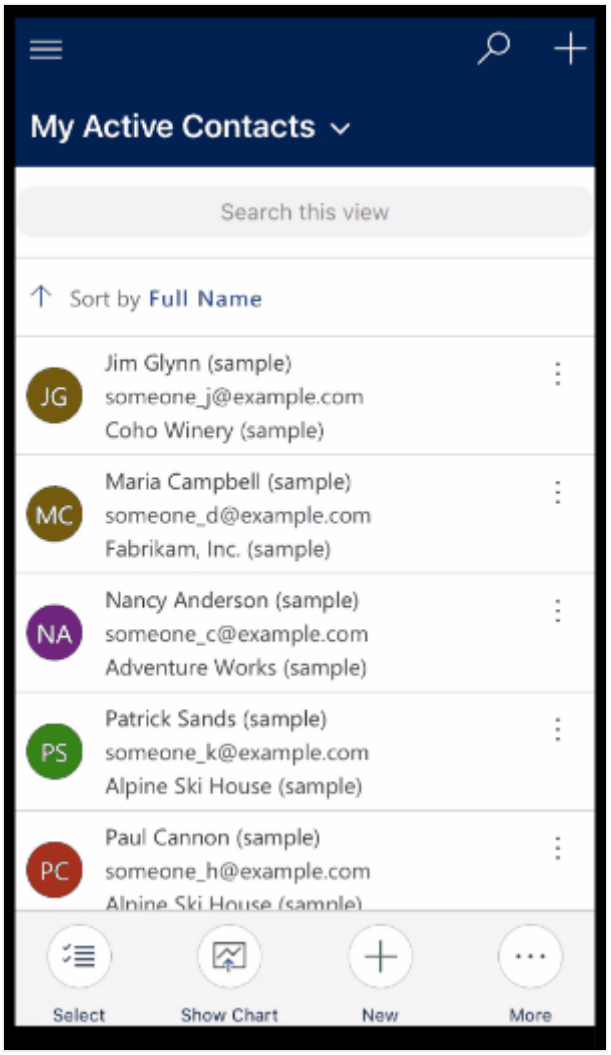


Sort rows

Sort in ascending or descending order: From a list view, select the arrow to sort the list in ascending or descending order.

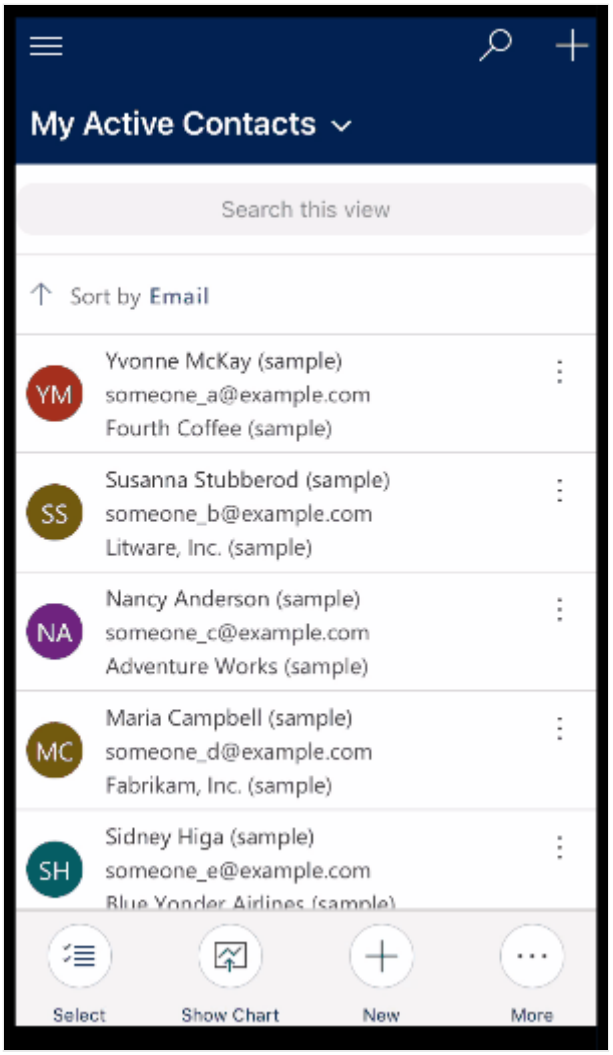


Sort by field: Select the current **Sort by** field and then select another field to sort by.



Access the actions menu

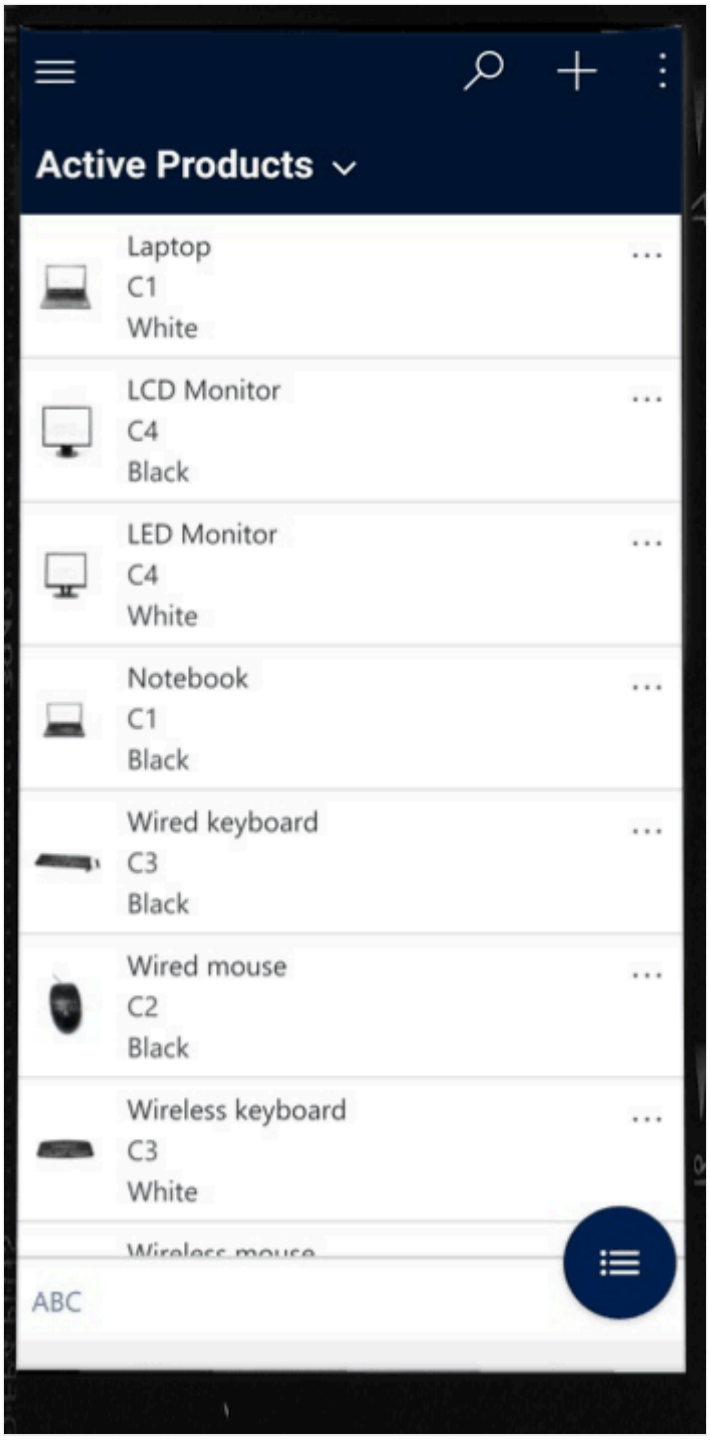
From a list view, swipe left to access the actions menu for a row.



> **Note**
>
> The Flow actions menu in Power Apps mobile doesn't support flows created in a solution.

Access more commands (Android)

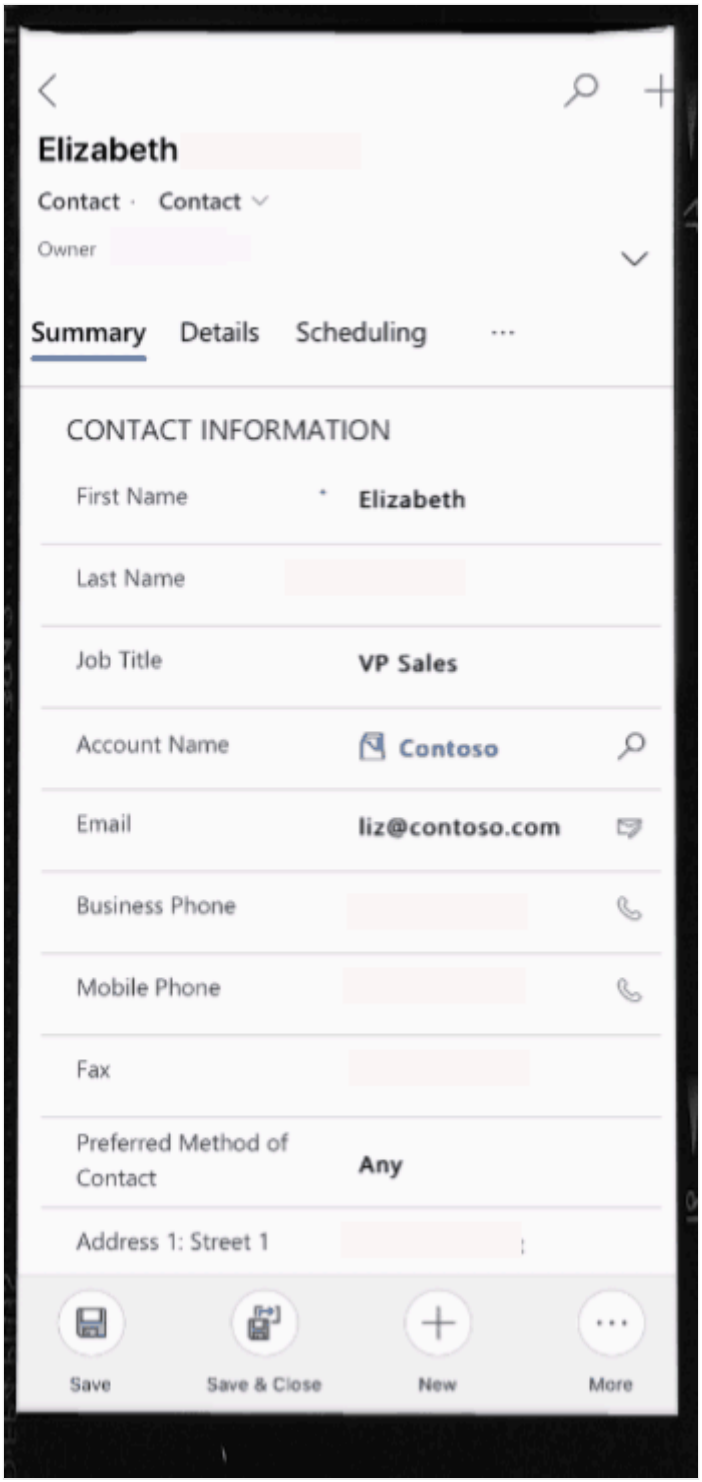
1. From the Home screen, open a row.
2. On the open row, select **More** to access more commands.



Edit a row

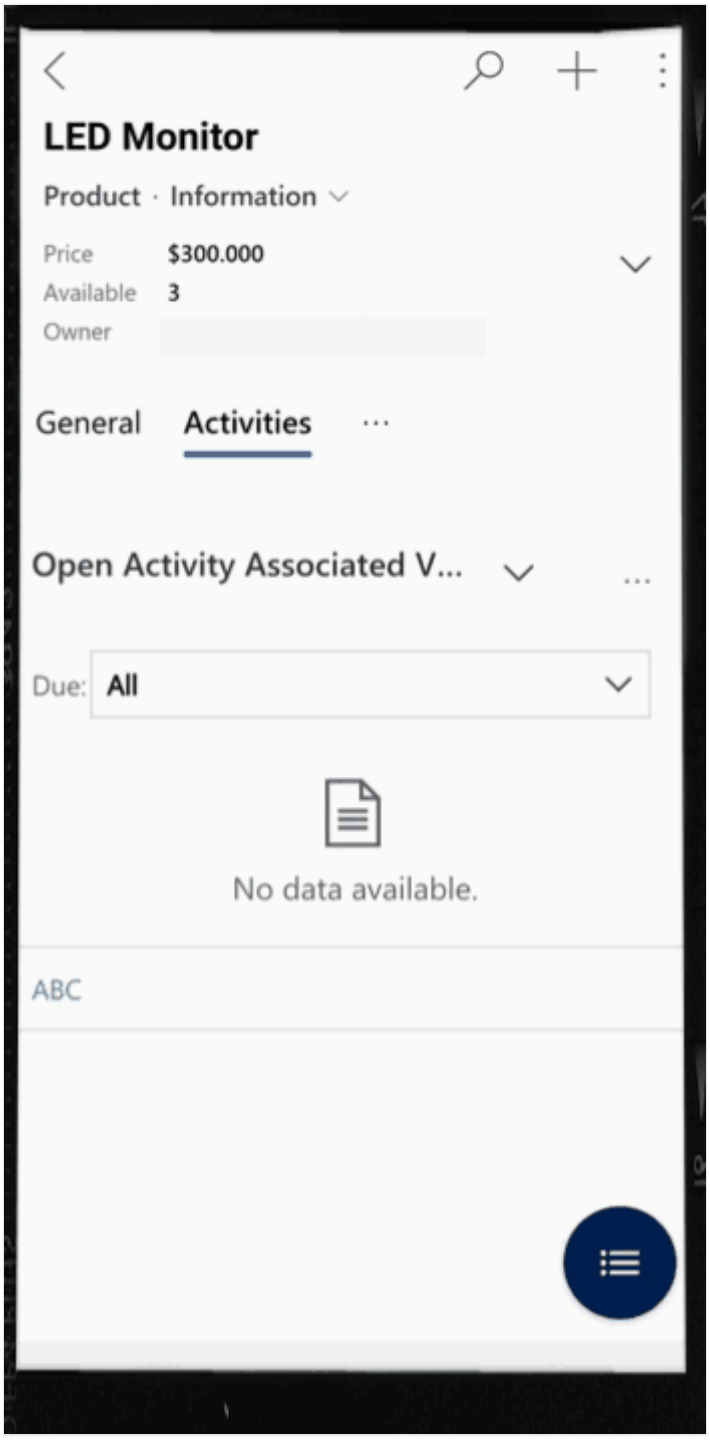
1. From the Home screen, open a row that you want to edit.

2. When you're done editing the row, select **Save**. To cancel your changes, select **Discard**.



Go back to the Home screen

- To get back to the Home screen when you're in a row, select **Back** .
- At any point, press and hold **Back** to go back to the Home screen.



Sign out

From the site map , select the profile icon , and then select **Sign out**.

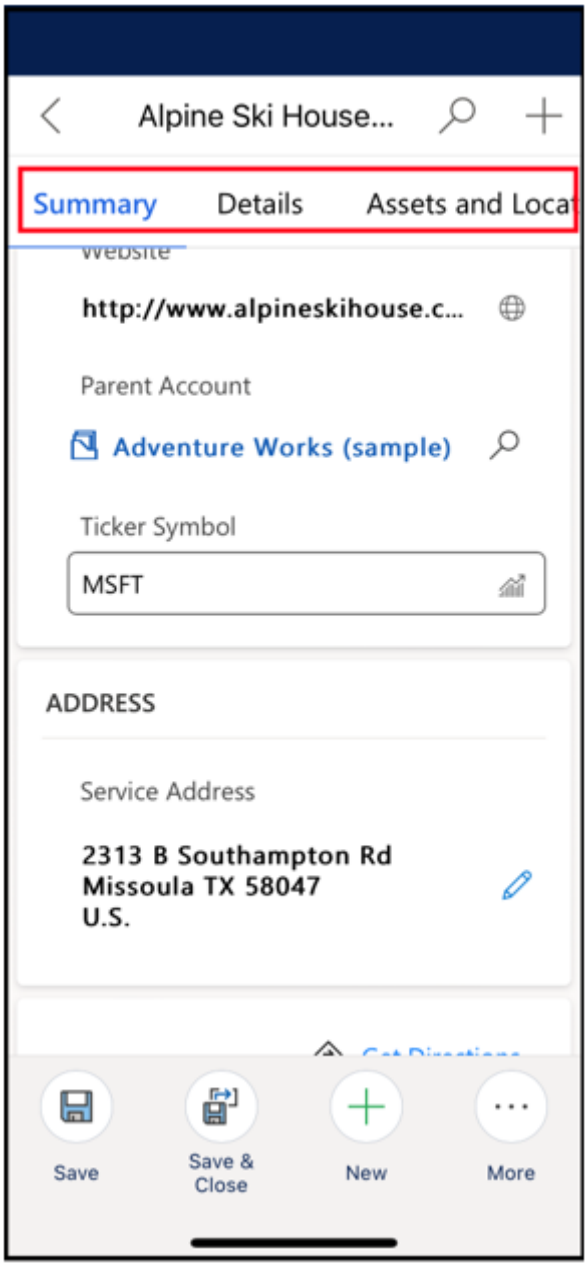
Enhancements (preview)

[This section has pre-release documentation and is subject to change.]

This section describes enhancements that have been made to model-driven apps on mobile devices.

Lock tabs at the top of forms

Your app maker can choose to lock the tabs at the top of a form so they are always visible while users scroll through the data on the form.



Your app maker can turn on this feature. For more inforamtion, see Features.

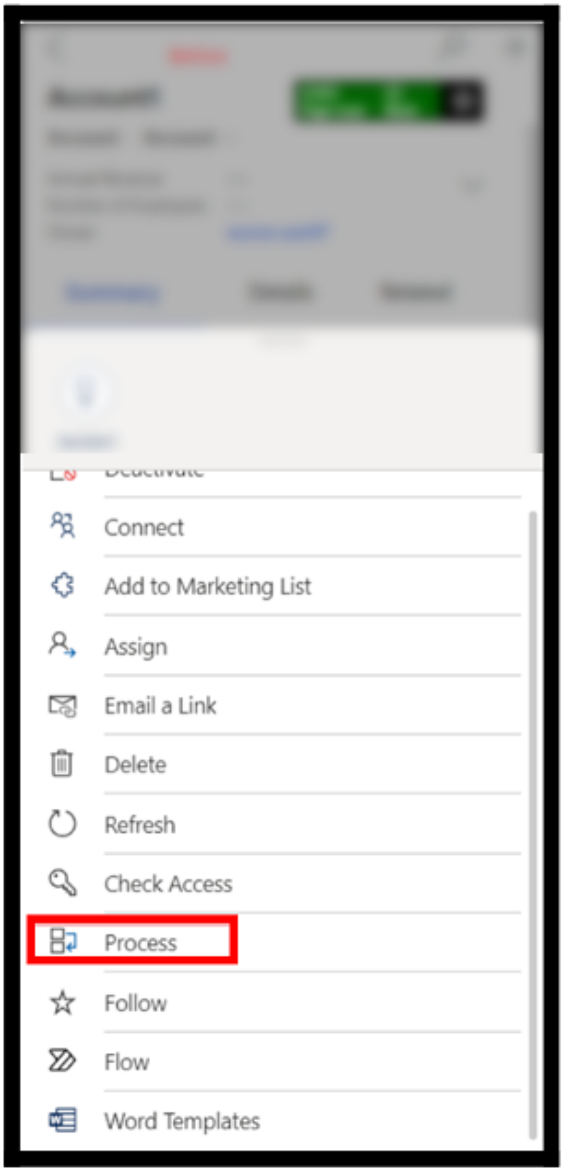
Mobile commanding improvements

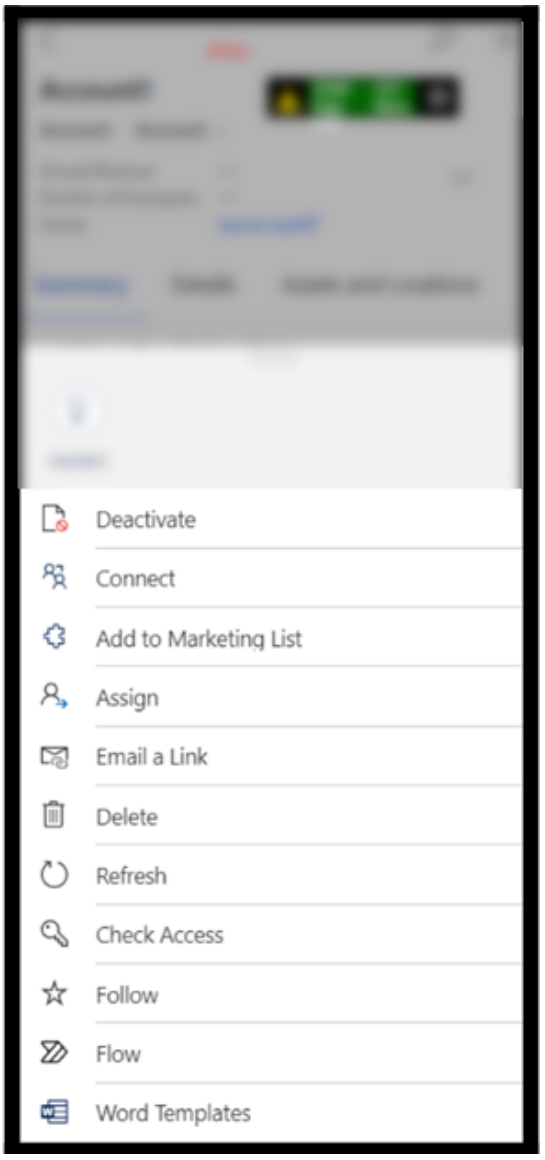
Your app maker can enable Mobile commanding improvements to provide easy access to contextual commands when you're using Power Apps mobile. Here's a list of improvements:

- The **Delete** command on a grid page is automatically hidden when a row is not selected thus, making room for other commands. When one or more rows is selected the **Delete** command is automatically displayed.

- The **Process** command is hidden when there's no process enabled for a table. Removing a nonfunctional command makes room for other commands.

Expand table

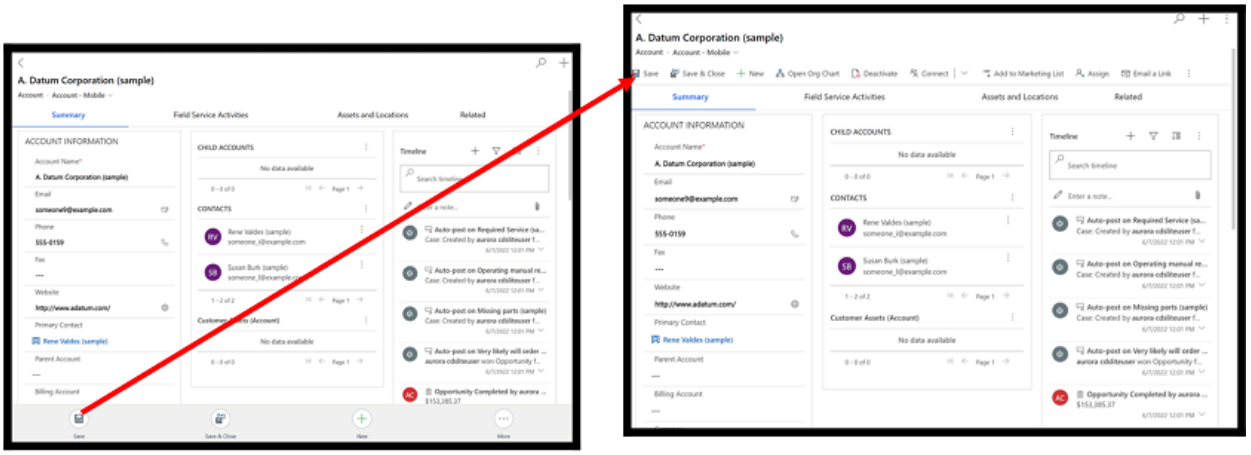
Before	After
	




- Some commands have been moved from the main set of commands to an overflow menu. This gives priority to other commands, including custom commands.

Tablet optimization for command bar

The command bar on Power Apps mobile for tablets was at the bottom, now the command bar is located at the top.



Your app maker can turn on this feature. For more inforamtion, see Features.

Use Dataverse search for model-driven apps in the Power Apps mobile app

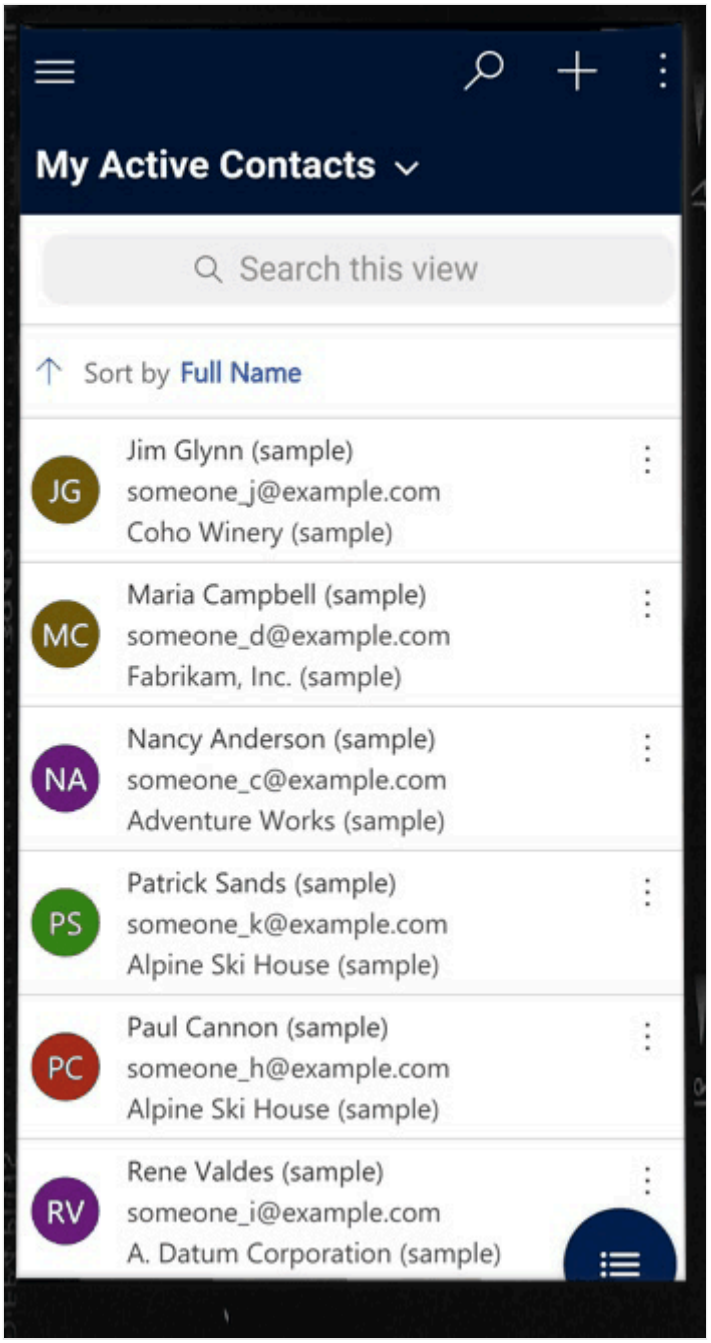
Article • 01/28/2023

You can quickly find the information that you're looking for by using Dataverse search. The Dataverse search experience delivers fast and comprehensive results across multiple tables, in a single list, sorted by relevance.

Dataverse search is already available when you're using a model-driven app in a web browser. The functionality is the same in Power Apps Mobile, but it works a little differently. More information: Search for tables and rows by using Dataverse search

Before you begin using Dataverse search, the new experience needs to be enabled by the administrator for your organization. More information: Enable Dataverse search

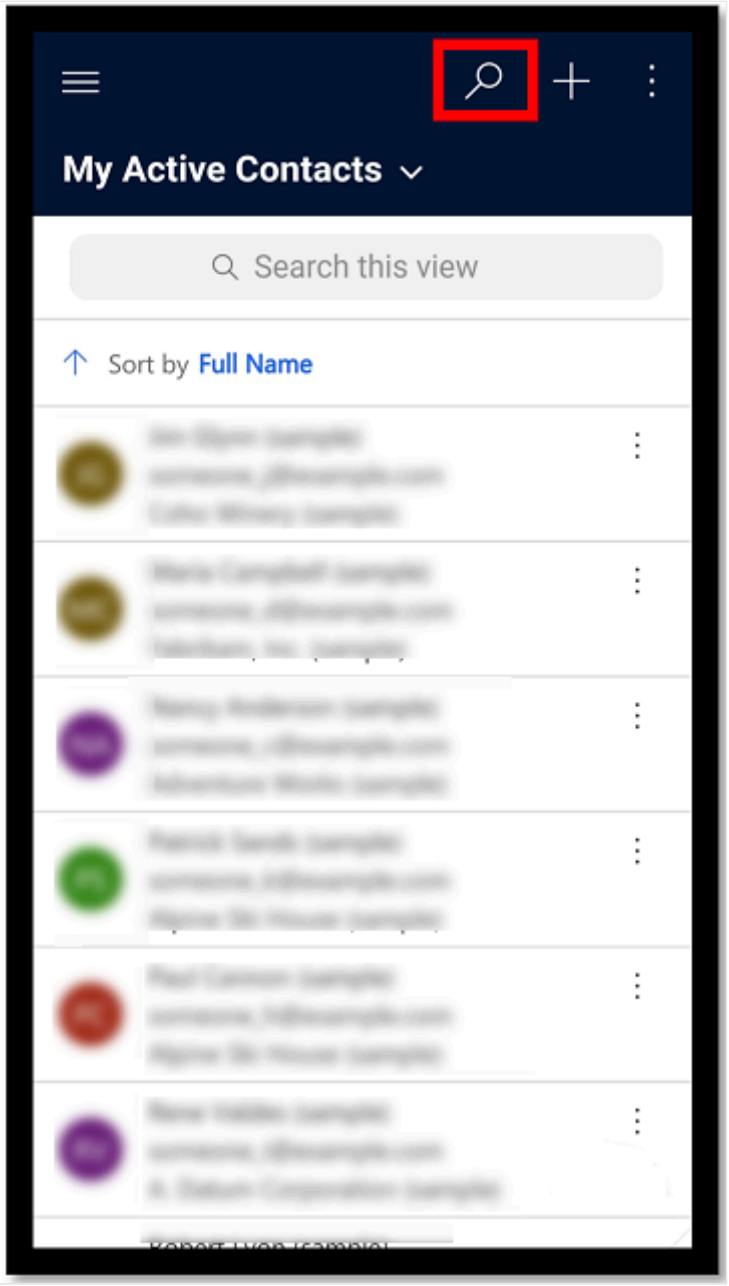
When Dataverse search is turned on, it becomes your default and only global search experience for all of your model-driven apps. You won't be able to switch to quick find search also known as categorized search.



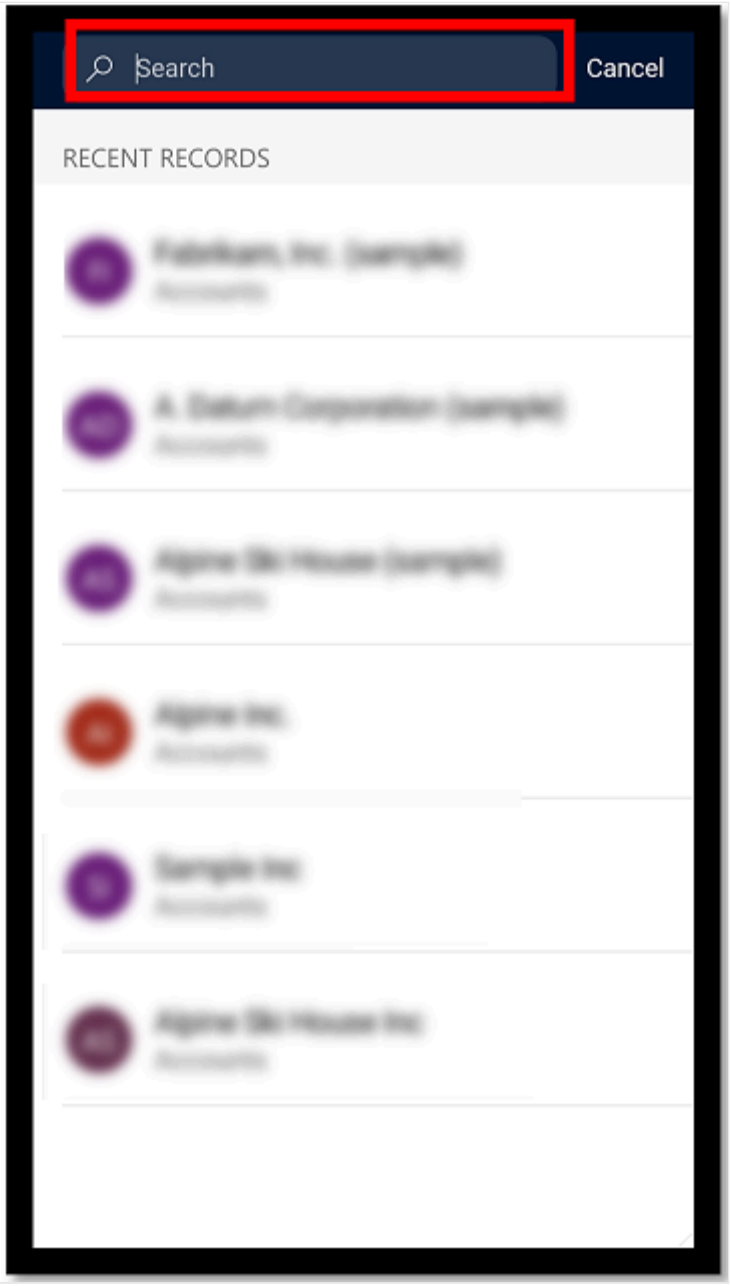
Run a search

View suggested search results inline as you type, minimizing keystrokes and simplifying page navigation.

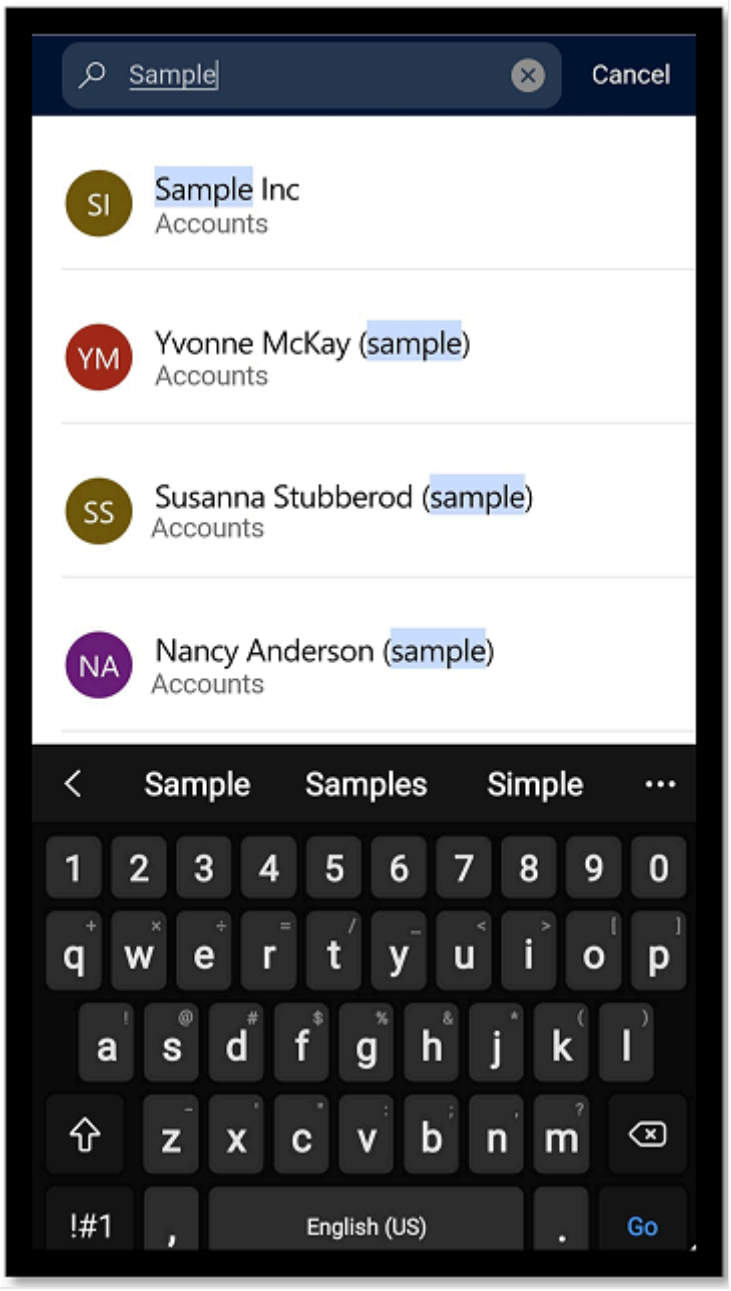
1. Select the search button.



2. Enter the words you want to search for in the search box.



3. As you enter search text, rows that match your text begin to appear.



Early access: Use the barcode scanner

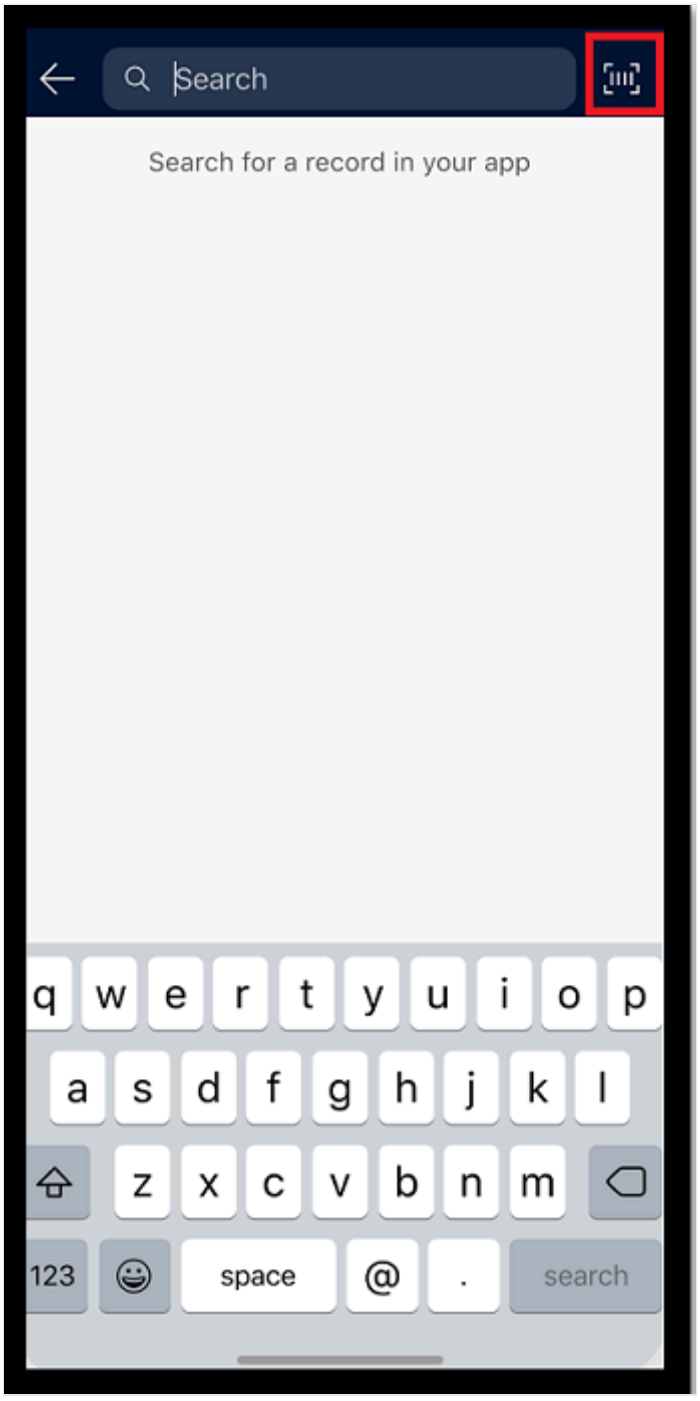
[This topic is pre-release documentation and is subject to change.]

If you're on early access, you can use the barcode scanner to look up rows. The scanner automatically detects a barcode, a QR code, or a data-matrix code.

You also enter text in the search box such as **contoso** and then use the barcode scanner to scan a barcode, such as **12345**. In this case, the system will search for **contoso12345**.

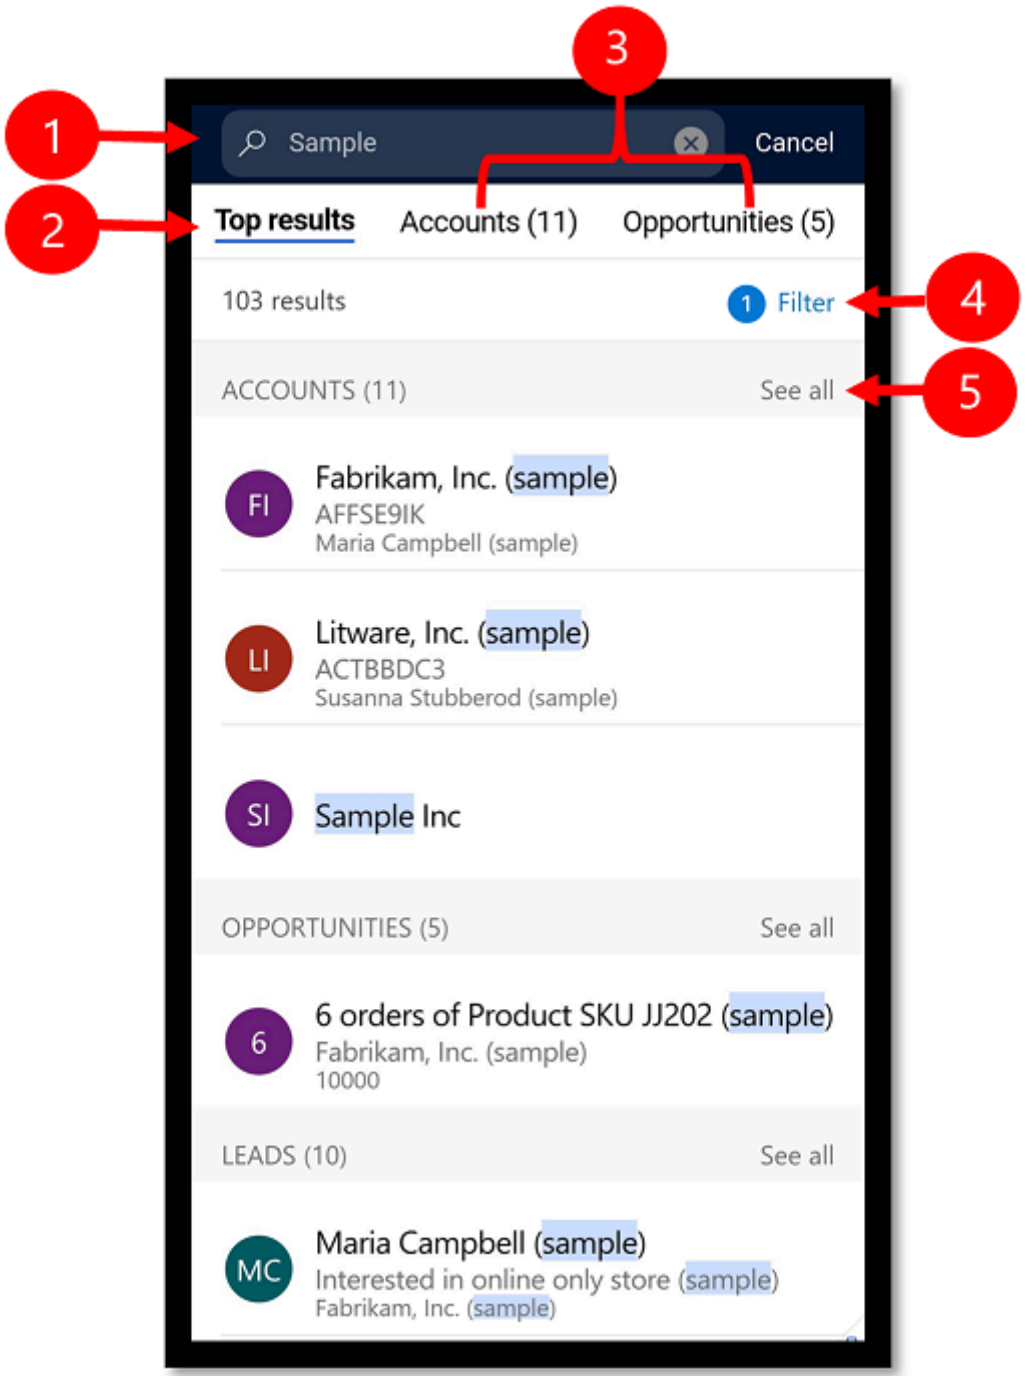
1. To use the barcode scanner, select the search button.

2. Select the barcode scanner button and then scan your item.



View search results

Search results are ranked and grouped by table.

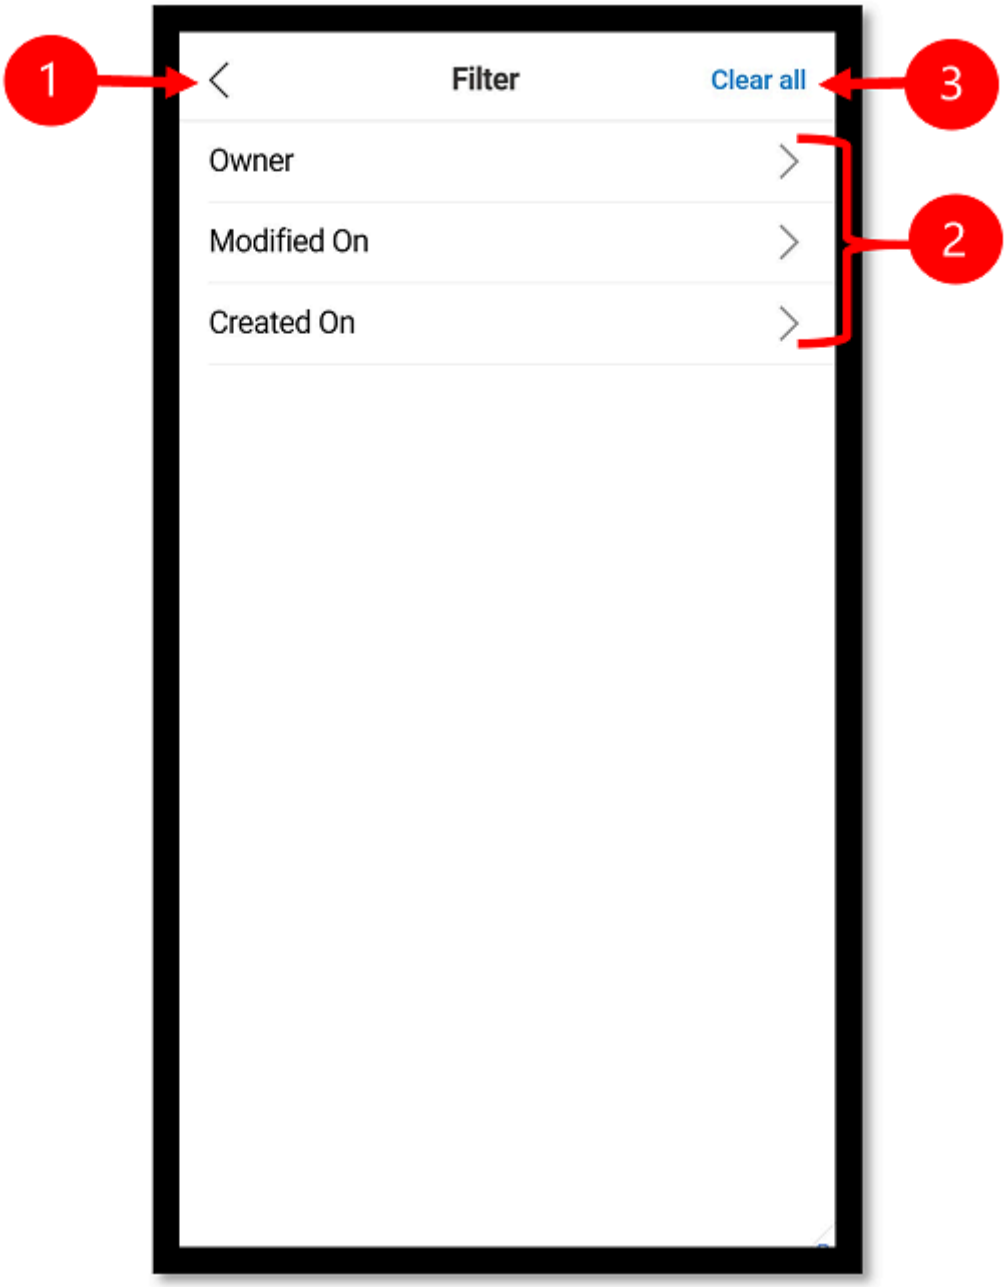


Legend

1. **Search box**: Enter the words you want to search for.
2. **Top results**: This tab shows the rows that best match the search query.
3. **Table-specific tab**: To narrow your search results to a specific table, select the table tab.
4. **Filter**: Refine the search results by using filters. When you select filters, the number of tables that have been filtered on appears next to the filter option.
5. **See all**: Up to three rows will appear; if there are more, select **See all**.

Filter search results

Use filters to drill into and explore the results of your current search without having to repeatedly refine your search terms. Immediately after you perform a search, you can filter by **Owner**, **Created On**, or **Modified On**.



Legend

1. **Back**: Go back to the search results screen.
2. **Filter**: Select a filter type to filter the search results.
3. **Clear all**: Clear all filters and return to the search results screen.

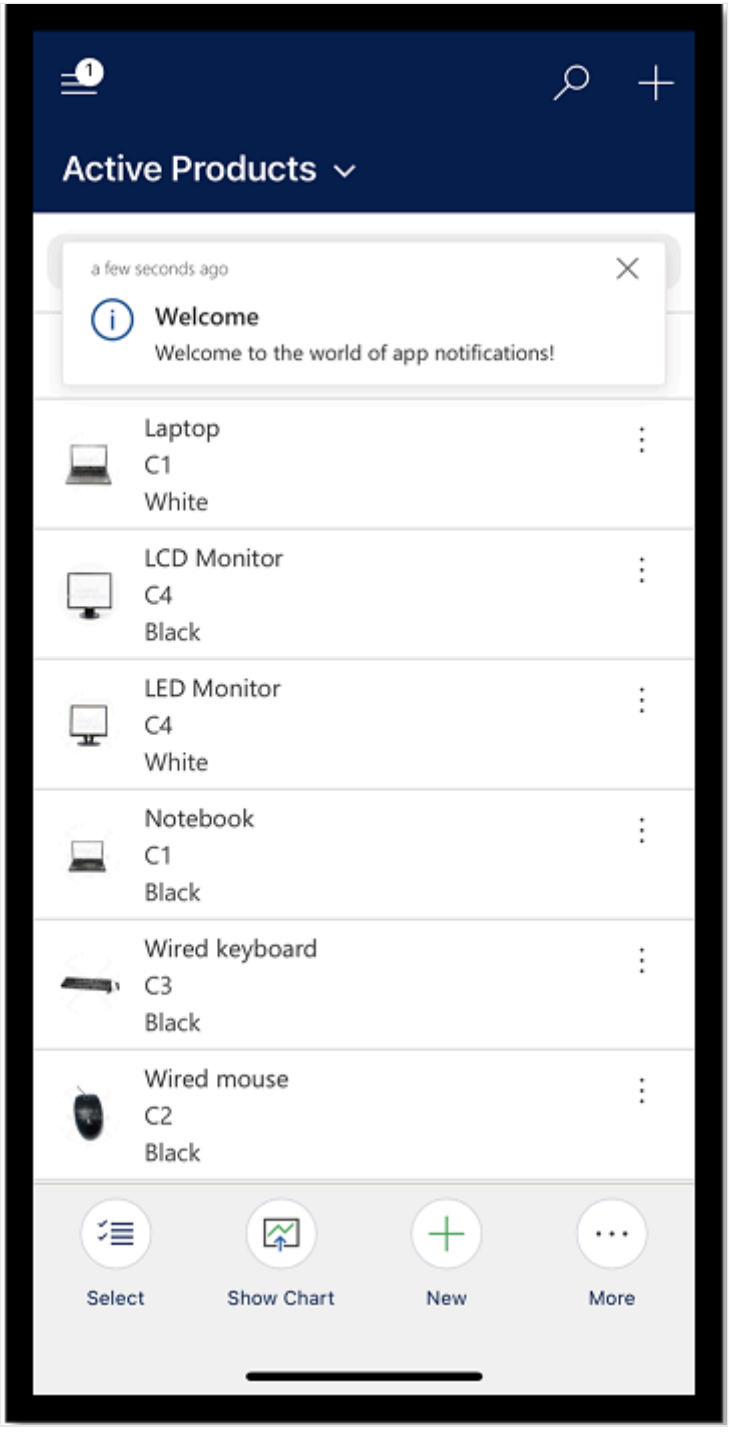
In-app notifications in the Power Apps mobile app

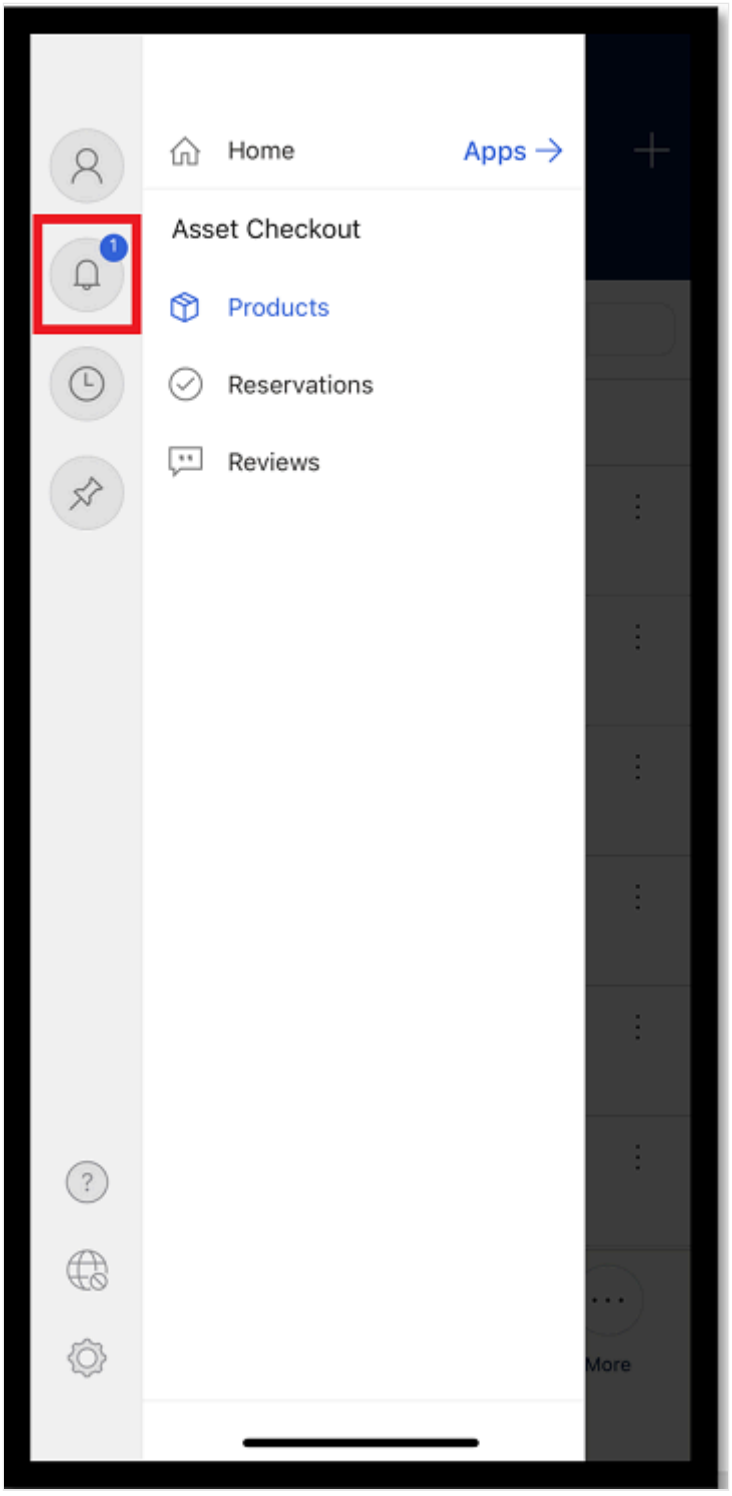
Article • 01/28/2023

In-app notifications allow users to receive notifications in the notification center and as a notification toast. For more information, see In-app notifications in model-driven apps. In Power Apps mobile, toast notifications appear one at a time.

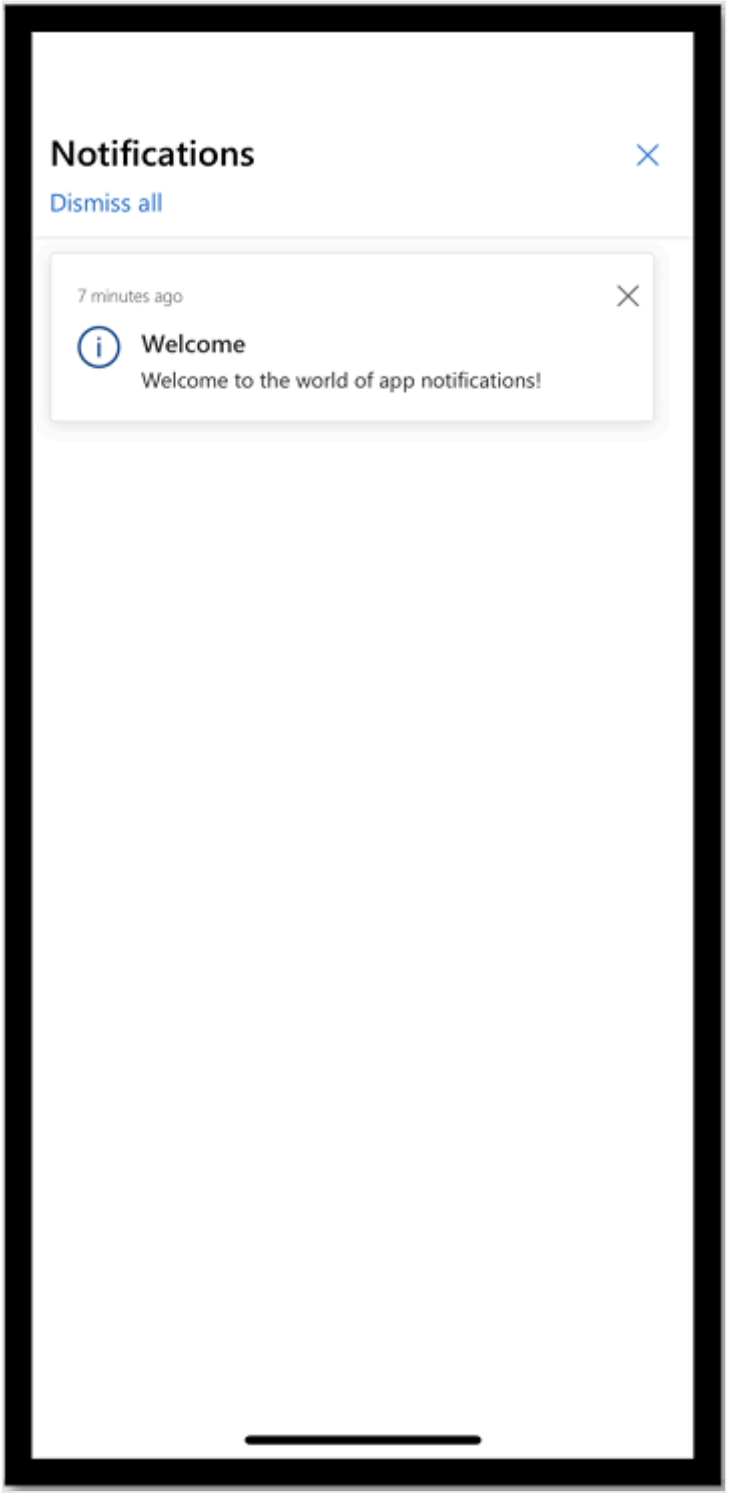


Access notifications

1. To access notifications in Power Apps mobile, go to site map and then select the bell icon.



2. The notification center opens which displays all your notifications.



3. To dismiss and delete a notification, select the close **X** button on a notification. Or, select **Dismiss all** to dismiss and delete all notifications.

Turn toast notifications on or off

1. To turn toast notifications on or off, from the site map, go to **Settings**
2. Under **In-App Notifications**, go to the **Enable toasts** and move the toggle to on or off.

3. If you've enabled toast notifications, then select **Total duration** and enter how long you want the toast to appear.

Create push notifications for the Power Apps mobile app using Power Automate

Article • 03/14/2023

Push notifications are used in Power Apps mobile to engage app users and help them prioritize key tasks. In Power Apps, you can create notifications for Power Apps mobile by using the Power Apps Notification connector. You can send notifications to any app that you create in Power Apps.

Add a push notification to your app if:

- Your users need to know information immediately.
- Your users must complete important tasks by using your app, in a preloaded context.
- You want to engage your users on a specific interval, or you need users to enter the app in a specific context.

> **Note**
>
> To receive push notification, each user must have opened the app in Power Apps Mobile once or gotten the app from the Microsoft 365 apps page.

Before you can create push notification you need to have access to an app and have the row ID if you're creating a notification for a form.

Create an app

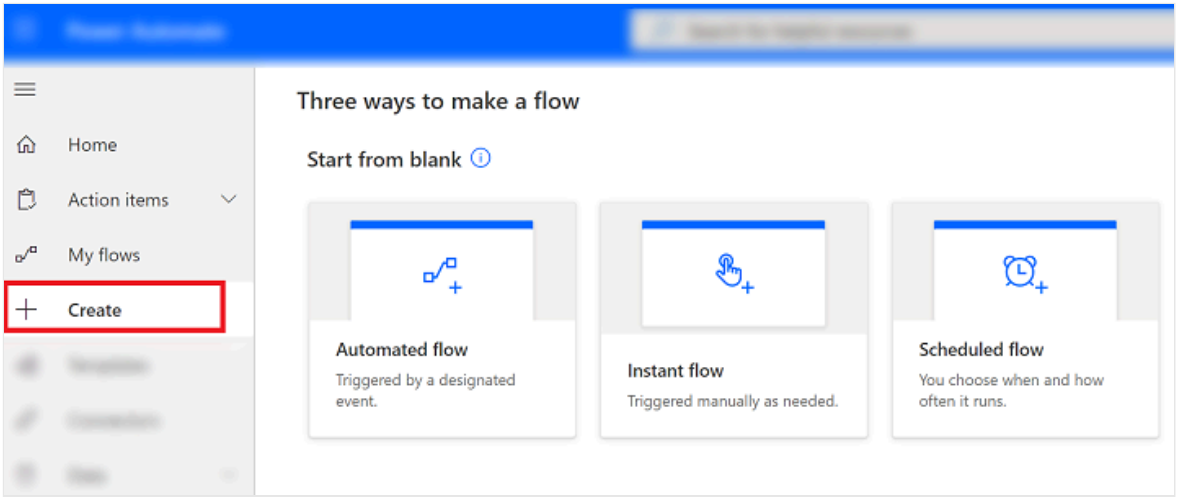
You need to have **Contributor** permission for a model-driven app or canvas app. If you don't have an app, you can create one. For information, see:

- Create a model-drive app
- Create a canvas app

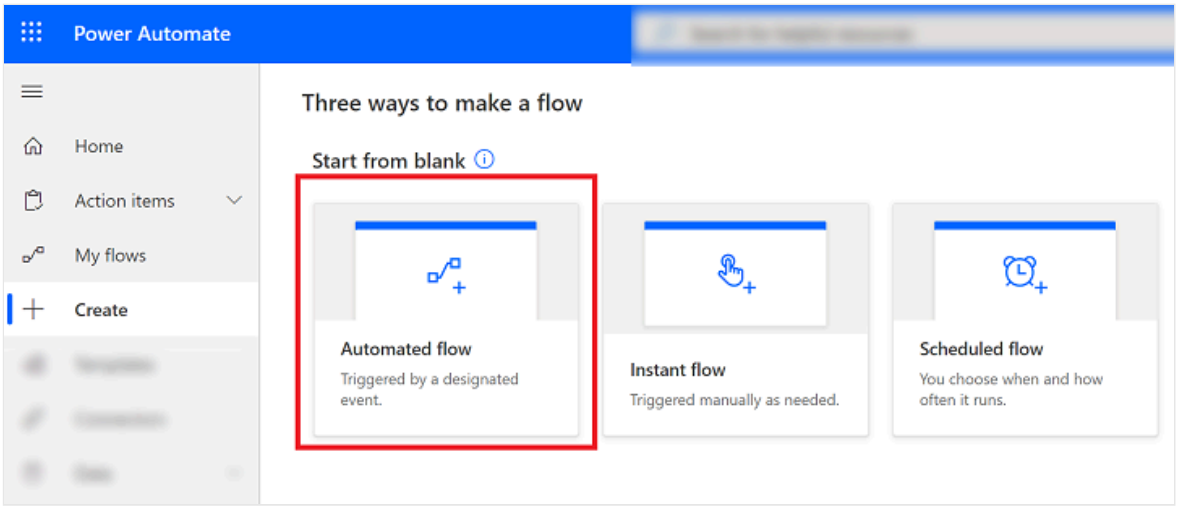
Create a notification from a flow

When you trigger a push notification from a flow, you can send the notification to only one user or security group at a time.

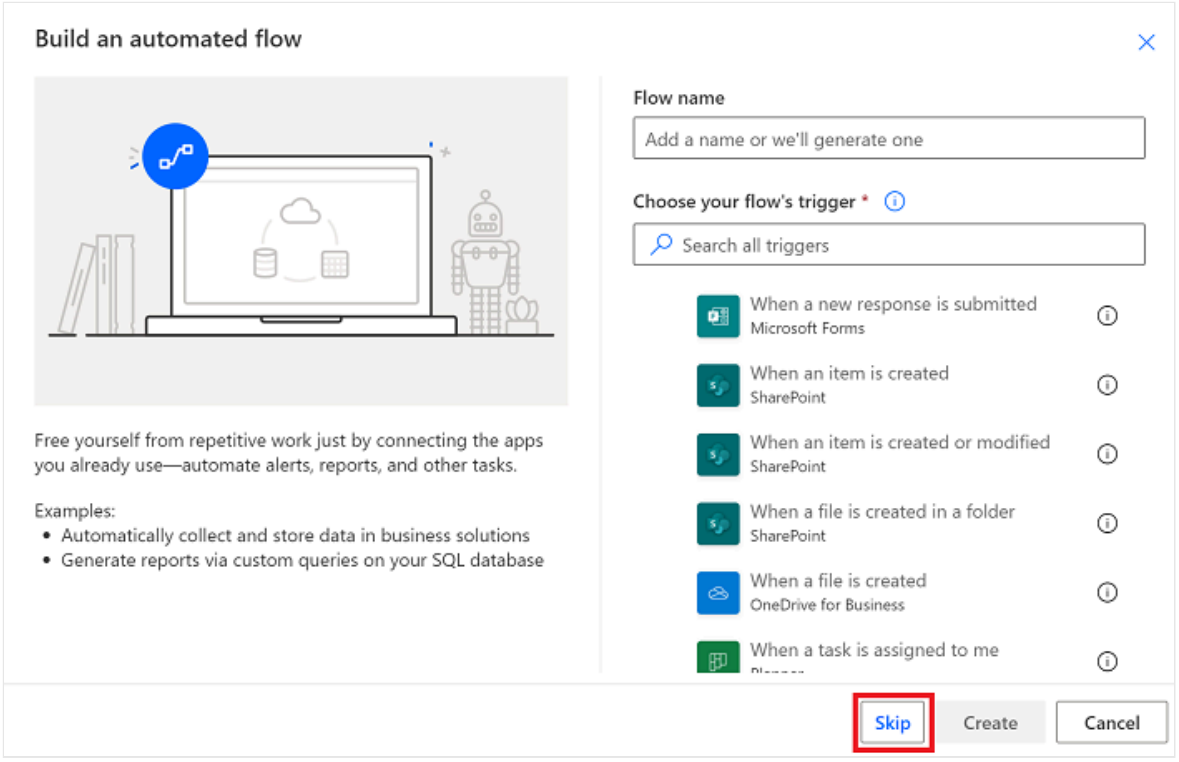
1. Go to Power Automate and select **Create**.



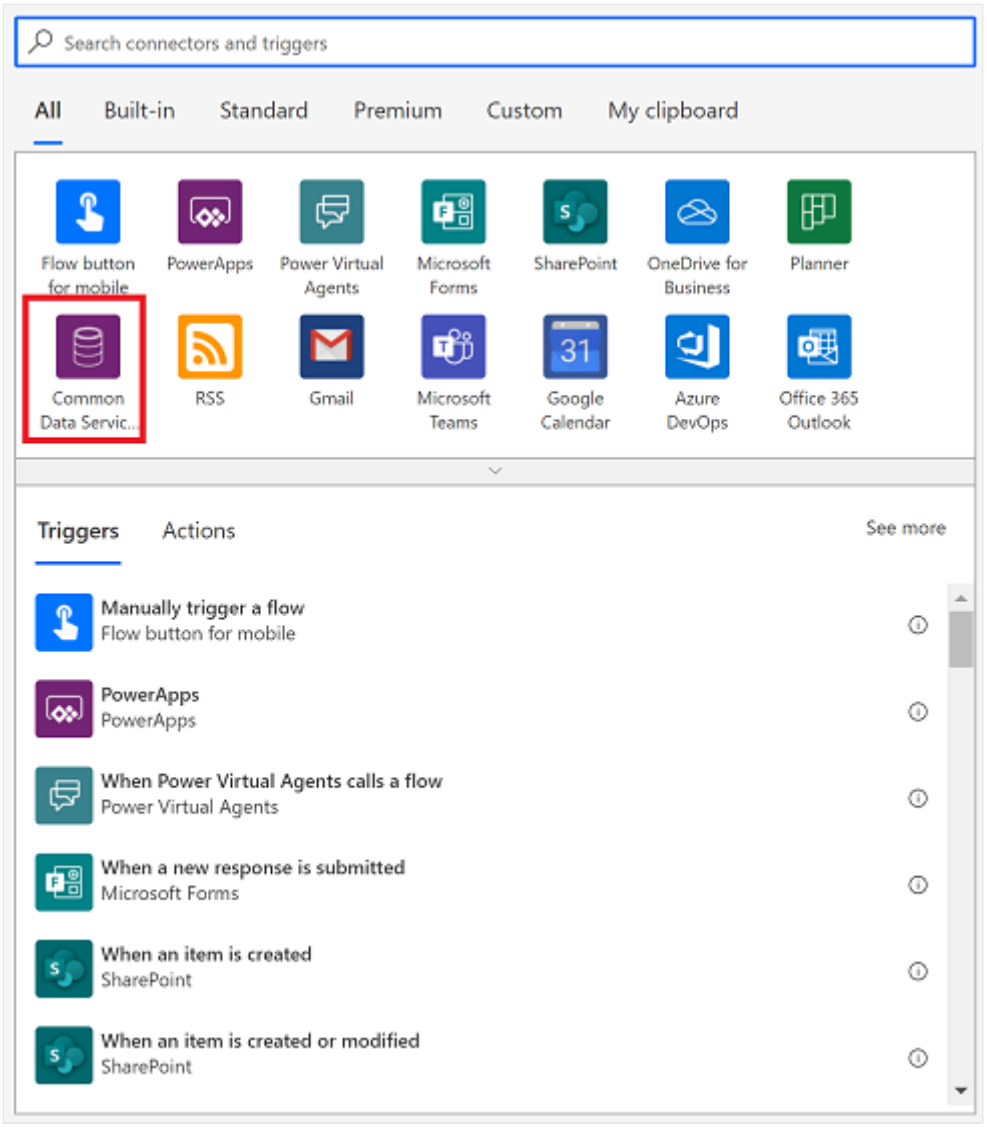
2. Select **Automated flow**.



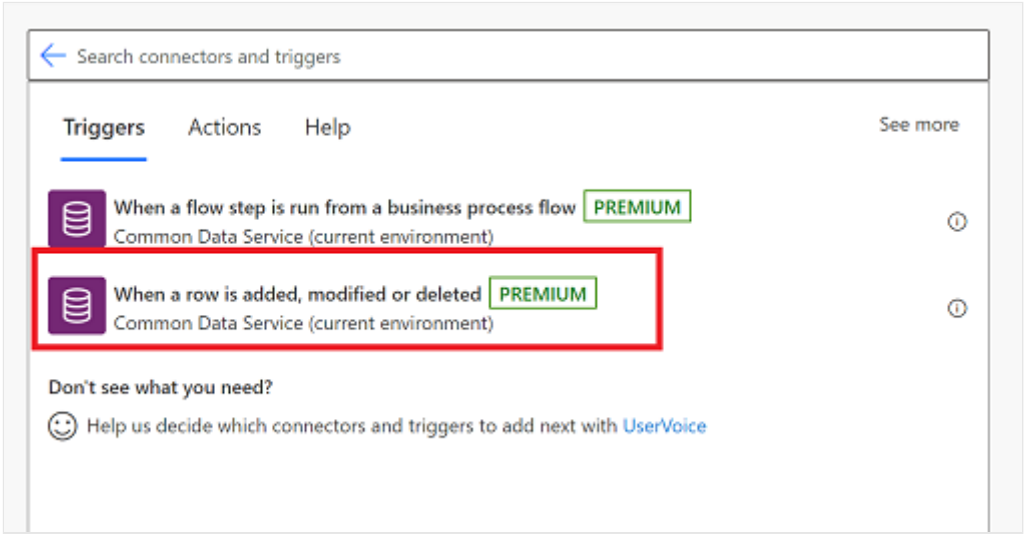
3. On the **Build an automated flow** screen, choose one of the flow trigger or select **Skip** and manually create one.



4. From the list of connectors and triggers select **Microsoft Dataverse (current environment)**.



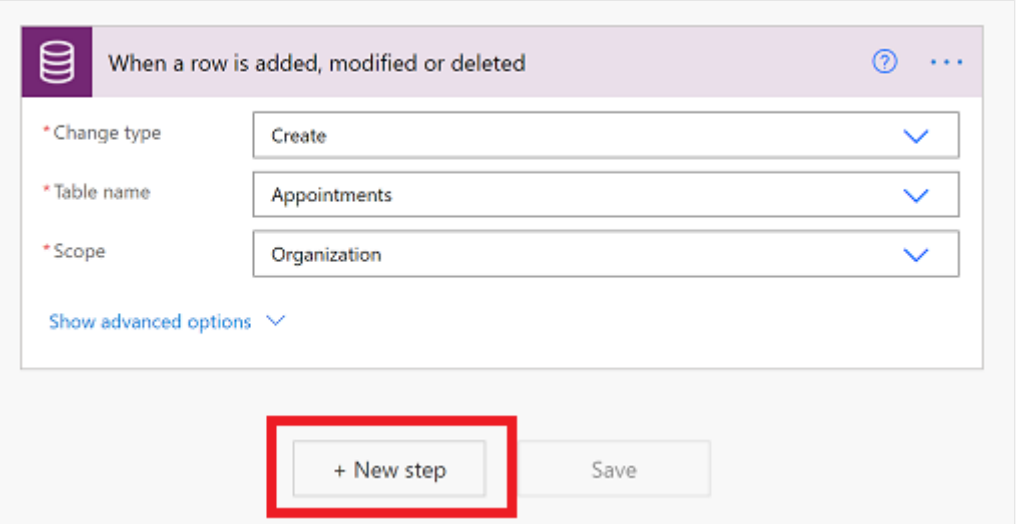
5. Select the action that will trigger the notification.



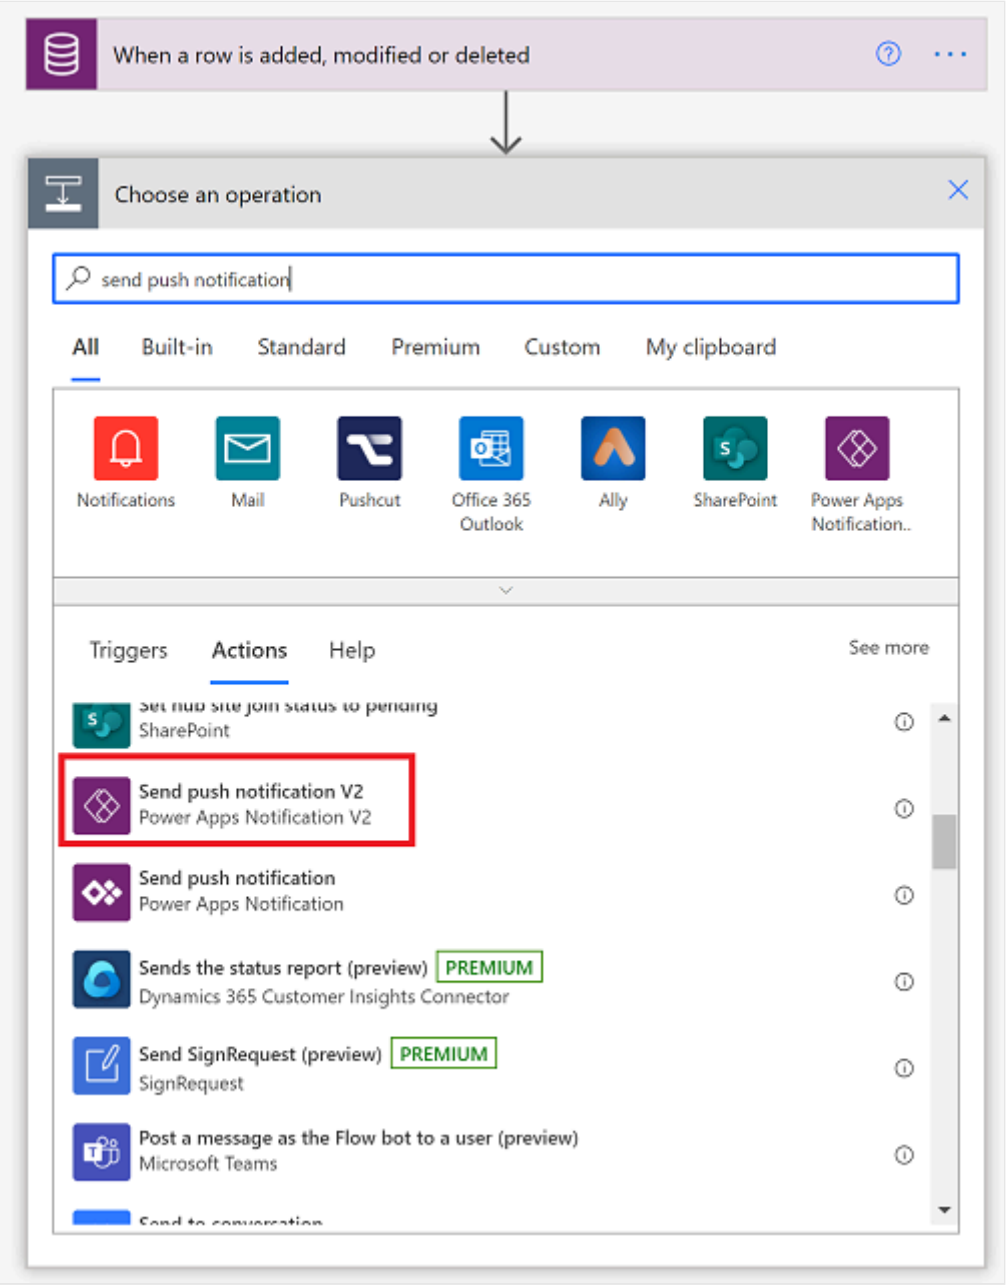
6. Enter the trigger condition information and then select **New step**.

Expand table

Name	Description
Trigger condition	Select the condition for the notification.
The table name	Select which table the notification is for.
Scope	Select the scope.



7. In the **Choose an action** search box, enter **send push notification**. In the list of **Actions** choose **Send push notification V2**.



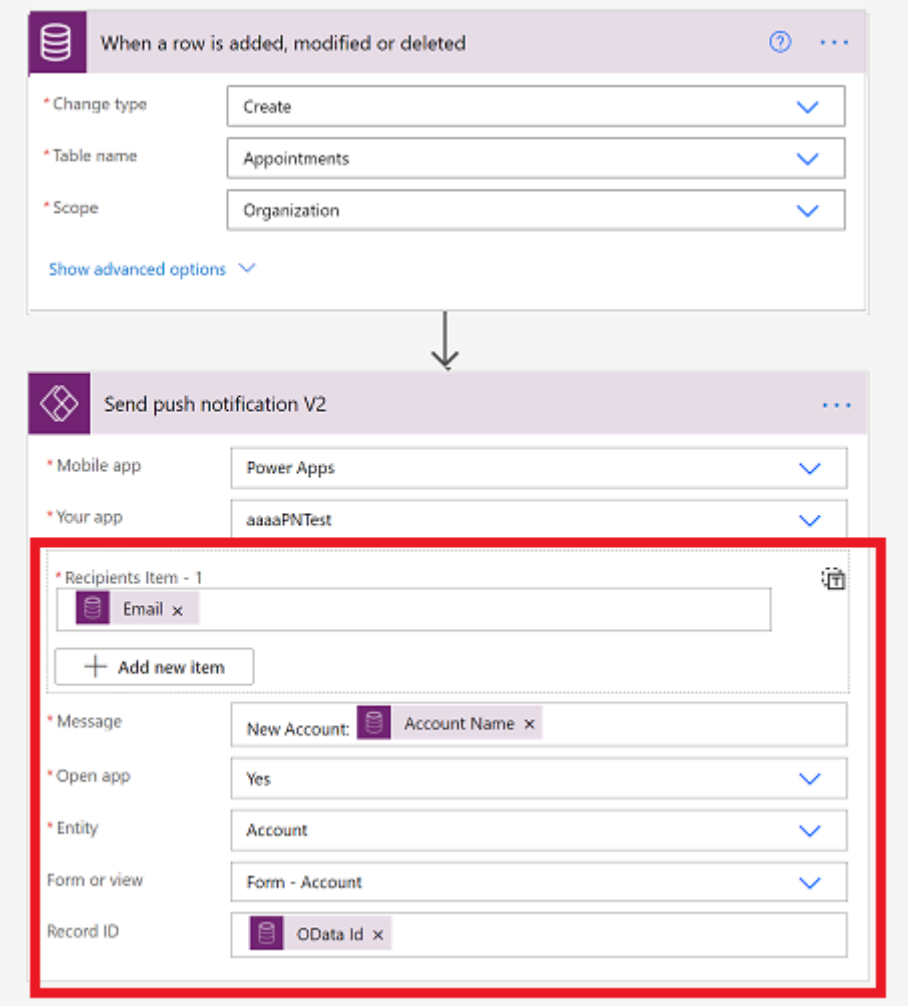
8. On the **Send push notification** screen, enter the following information:

    - **Mobile app**: Select **Power Apps**.
    - **Your app**: Select the app that you want to set up the notification for. Model-driven apps and canvas apps have different parameters. The next step will depend on the type of app you select here.

9. Depending on the type of app that you selected in the previous step, do one of the following:

- For a model-driven app, enter this information:
    - **Recipient Items-1**: Select how the flow is triggered.
    - **Message**: Enter the notification message.
    - **Open app**: Select whether to open the model-driven app or not when the user selects the notification.
    - **Table**: Select which table the notification is for.

- **Form or view**: Select if the notification is for a form or view.
- **Row ID**: If the notification is for a form, then enter the row ID.



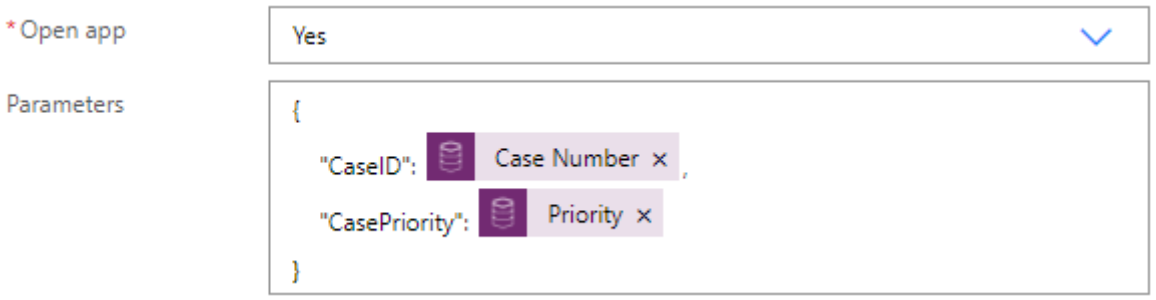
- For a canvas app, enter this information:
  - **Recipient Items-1**: Select how the flow is triggered.
  - **Message**: Enter the notification message.
  - **Open app**: Select whether to open the canvas app or not when the user selects the notification.
  - **Parameters**: Key-value parameters to pass with the notification. Your push notification can pass specific parameters to the app. These can be further processed in the app to open a specific page and load a specific state. For more information, see Perform an action when a user taps the notification.

8. When you're done, select **Save**.
9. Select **Flow checker** to check for error or warnings.
10. Test the flow by selecting **Test** and follow the prompts.

Perform an action when a user taps the notification

Pass parameters

For canvas apps, you can pass key-value pairs using the **Parameters** field as JSON. For example, if you wanted to pass the CaseID, you would put the following as **Parameters**: `{ "CaseID": 42 }`. You can also use dynamic values from earlier steps as shown below.



Read parameters

To read the passed parameters, use Param("ParameterName"). For example, to read the **CaseID** value, use *Param("CaseID")*. To quickly identify this parameter, add a **Label** control to your app. Set the **Text** property of that control to **Param("CaseID")**. If the user opens the app from the **All apps** list, the value is empty. If the user opens the app from another location on the device, the value is populated with the **CaseID** value.

Set the start page

You can set your app to open, for example, the **Case details** page as soon as the app opens:

1. Add a **Timer** control, and set its **OnTimerEnd** property to this formula:

   ```
   Navigate(EditCase, ScreenTransition.None)
   ```

2. (optional) Hide the **Timer** control by setting its **Visible** property to **false**.

3. Set the **OnVisible** property of the screen to **Timer.Start()**.

> **Tip**
>
> It's a good idea to create a unique first page in the app for the notification:
>
> 1. Create an empty page that your app doesn't already open, add a **Text Input** control, and set its **timer.Duration** value.

2. When you create the app, set the timer to a non-zero value. When you're ready to publish the app, set the value to **0** to immediately trigger the timer.

Considerations

- You can send a push notification from one app to another or to the same app. For more information, see Send notification from an app.
- Notifications show the generic Power Apps icon instead of a specific app icon.
- Notifications are not supported in China on Android devices.
- Battery optimization settings on an Android device can interfere with receiving notifications for Power Apps mobile. To receive notifications for Power Apps mobile, turn off battery optimization for the app.
- The example push notifications that are mentioned in this topic are only supported on Power Apps mobile. Other mobile apps such as Dynamics 365 Sales mobile app or Dynamics 365 for phones and tablets do not support these types of notifications.

For reference information, see Power Apps Notification reference.

Use deep links with the Power Apps mobile app

10/15/2025

Deep links let users move from one application to another on computers and mobile devices. Simple examples include a mobile app deep-linking to Facebook to sign in, an email address deep-linking to a mail app to compose a message, or a website deep-linking to an app store to download a related mobile app.

Supported deep links in the Power Apps mobile app

You can open an `entityrecord` or an `entitylist` view in the Power Apps mobile app by using deep-link URLs from other apps. When you follow the link from an external app, the target element opens in Power Apps mobile

If you're already signed in to your instance in the app, the target record is displayed when you follow the link from an external app. Otherwise, you're prompted to sign in to your instance in the mobile app; after you're signed in, the target element is displayed. You must have the Power Apps mobile app installed on your mobile device to use this feature.

Supported Urls parameters for a model-driven app

Use the following application handler and query string parameters to compose the URL.

Deep links for the Power Apps mobile app should start with the following:

```
ms-apps://<org-url>_<app-id>?tenantId=<tenant-id>&environmentId=<environment-id>&appLogicalName=<appLogicalName>&appType=AppModule&openApp=true&restartApp=true&forceOfflineDataSync=true
```

> **ⓘ Important**
>
> The org-url can't contain **https://**. The following is an example of a model-driven app deep link:
> ms-apps://contoso.onmicrosoft.com_e6429eba-2204-40e8-b9dd-fc74791ff2c2?tenantId=aaaabbbb-0000-cccc-1111-dddd2222eeee&environmentId=g67tfyufhkjfg&appLogicalName=cr12_e567

Expand table

Parameter	Description	Required
<targeted-app>	• `ms-dynamicsxrm` -> Dynamics 365 for phones • `ms-apps-fs` -> Field Service • `ms-apps` -> Power Apps • `ms-mobile-apps` -> wrapped native mobile apps	Yes
<org-url>	Connects to the correct org URL.	Yes
<app-id>	Opens the correct app module.	Yes
tenantId=<tenand-id>	Connects to the correct tenant.	Yes
*environmentId=<environment-id>	Uniquely identifies the environment within a tenant.	Yes
*appLogicalName=<app-logical-name>	Unique Name of the app. For more information on how to find this unique name of the app in modern studio, refer Manage model-driven app settings in the app designer and for classic editor, refer Manage model-driven app properties in the app designer (classic)	Yes
appType=AppModule	Indicates that the targeted app is a model-driven app.	Yes
restartApp=true	Restarts the model-driven app. Required to ensure parameters are passed when the app is already open.	No
autoLoginUpn=<e-mail>	Autopopulates e-mail and triggers sign-in. **Note**: This parameter will be ignored if a user is already signed into the app.	No
forceOfflineDataSync=true	Ensures that data sync is triggered so that all the latest data is available.	No

***Considerations**

- The environment ID and appLogicalName are mandatory for all new deep links.
- Existing deep links without an environment ID or appLogicalName will experience slower performance until December 2025, after which they won't be supported.
- Update all existing deep links to include the environment ID and appLogicalName to improve performance and reduce wait time.

If opening an `entityrecord` form or creating a new `entityrecord`, use the following parameters:

Expand table

Parameter	Description	Required
etn=<entity-logical-name>	Designates which table to go to.	Yes
pagetype=entityrecord	Indicates that the target is a form.	Yes
id=<record-id>	Designates which specific record to go to; if left blank, the created form for the table opens.	Yes
extraqs=<form-id>	Designates which form to open for the `entityrecord`; if not specified, the default form opens. The `extraqs` parameter can also be used to default field values.	No

If the link goes to an `entitylist` view, add the following parameters:

Expand table

Parameter	Description	Required
etn=<entity-logical-name>	Designates which table to go to.	Yes
pagetype=entitylist	Indicates that we're going to a view.	Yes
viewid=<view-id>	Designates which view to open.	No
Viewtype= <1039 if system view, 4230 if personal view>	Indicates whether the targeted view is a system view or a personal view.	No

Supported Urls parameters for a canvas app

`ms-apps:///providers/Microsoft.PowerApps/apps/<appID>?tenantId=<tenantId>&environmentId=<environment-id>&restartApp=true`

Expand table

Parameter	Description	Required
<app-id>	Opens the correct app module.	Yes
tenantId=<tenantId>	Connects to the correct tenant.	Yes
*environmentId=<environment-id>	Uniquely identifies the environment within a tenant.	Yes

Parameter	Description	Required
restartApp=true	Restarts the Canvas app. Required to ensure parameters are passed when the app is already open.	No
autoLoginUpn=<e-mail>	Autopopulates e-mail and triggers sign-in. **Note**: This parameter will be ignored if a user is already signed into the app.	No

*Considerations

- The environment ID is mandatory for all new deep links.
- Existing deep links without an environment ID will experience slower performance until December 2025, after which they won't be supported.
- Update all existing deep links to include the environment ID to improve performance and reduce wait time.

Supported Urls parameters for a wrapped native mobile app

`ms-mobile-apps:///providers/Microsoft.PowerApps/apps/<appID>?tenantId=<tenantId>&restartApp=true`

> **Important**
>
> The deep link URL for a wrapped app works only when one wrapped app is installed on the mobile device. It doesn't work if more than one wrapped app is installed.

Expand table

Parameter	Description	Required
<app-id>	Opens the correct app module.	Yes
tenantId=<tenantId>	Connects to the correct tenant.	Yes
restartApp=true	Restarts the model-driven app. Required to ensure parameters are passed when the app is already open.	No
autoLoginUpn=<e-mail>	Autopopulates e-mail and triggers sign-in.	No

Parameter	Description	Required
	Note: This parameter will be ignored if a user is already signed into the app.	

Troubleshooting

Deep links can open in your browser depending on the company's organizational policies and the user's device settings. Mobile Device Management (MDM) tools and device operating systems have different options and settings that affect how deep links are handled. If deep links are opening in a browser instead of directly in Power Apps mobile, make sure your MDM policies and device settings are appropriately configured.

As an example, on some Android devices, go to **Settings** > **Apps** > **Power Apps** > **Open by default** and add **apps.powerapps.com** to make deep links open directly in Power Apps mobile.

Open an app in the Power Apps mobile app by scanning a QR code

Article • 01/28/2023

Users can easily open a Power Apps canvas or model-driven app on their mobile device by scanning a QR code, shown in Power Apps, from their desktop computer. To do this, complete the following steps on your desktop computer.

1. Sign in to Power Apps.
2. In the left pane, select **Apps**.
3. Select the check mark icon next to the app that you want to open on your mobile device.
4. Select the **More Commands** (...) icon for the app you want to open, and then select **Details**.
5. A page showing the details of your app is shown. With your mobile device, scan the QR code.

6. The app will open on your mobile device.

Switch to a different directory in the Power Apps mobile app

Article • 03/06/2023

When a user signs into the Power Apps mobile app, they sign into their *home tenant*, which is the Azure Active Directory (Azure AD) tenant where their credentials are provisioned. After signing in, a user can easily change the tenant or *directory* with which they intend to use the Power Apps mobile app. This enables users to easily access the Power Apps that have been shared with them in different directories.

This means that:

- Users no longer need to log out of the Power Apps mobile app to switch directories.
- Users can specify the directory they want to work in from a list of directories on the user profile page.
- Users, including guest users, can access apps shared with them in different directories.

To switch to a different directory in the Power Apps mobile app:

1. Open the Power Apps mobile app.
2. From the **Home**, **All apps**, or **More** page, select your profile image. Your user profile page appears.

   > ⓘ **Note**
   >
   > Users signing into the Power Apps mobile app with a Microsoft account cannot switch directories from their user profile page. They must use a deeplink, instead.
   >
   > For more information about how to share canvas apps with guest users, see Share a canvas app with guest users.

3. Select the directory you're signed in to. A list of directories appears.

Optimize for devices overview (preview)

Article • 05/02/2024

[This article is prerelease documentation and is subject to change.]

Optimize for devices is a feature that changes the way canvas app screens are loaded and displayed on Android and iOS devices. This feature lets makers build stunning, native apps for mobile users with device-optimized screens that use native UI elements, instead of rendering inside of web view. Device-optimizes screens provide the following benefits:

- Modern mobile user experiences and interaction patterns
- Improved performance and reliability
- Integrated device capabilities with maker-defined UI

There's no need to rebuild apps as makers can use all the familiar app-building elements to create device-optimized experiences, though there are some limitations. Apps that are optimized for devices work with other mobile features such as offline, push notifications, and wrap.

> ⓘ **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Allow screens to be device-optimized

1. Select **Settings** > **Upcoming features** > **Preview** > **Optimize for devices**.
2. Only use supported controls on the screen.

After this feature is turned on, you can find which controls are supported in the **Insert** pane by selecting the **Device optimized (preview)** filter. Learn more about which controls are supported natively today.

Screens made solely with device-optimized controls automatically render natively on Android and iOS devices. An app can have screens which are optimized, while some others aren't. This only depends on the controls chosen by the maker to create that screen.

How screens are optimized for devices

For a canvas app running on Power Apps mobile, there are UI elements, their current state, and the related business logic that determines how screens are optimized. For example, on a screen you might have a button at position 0, with a width and height of 200 and 40 respectively, and with fill color blue. The business logic, with Power Fx, lets you navigate the user to a different screen.

If the **Optimize for devices** option is off for that screen, the screen loads and displays in a web view, running similarly to how it would in a desktop's web browser. When **Optimize for devices** is on, each element's current state is passed over to the device where it renders that same element, but using native UI. So now we have a natively rendered, long blue button in the upper-left corner. Business logic modifies state or takes actions, which runs the same way it did before. When the natively rendered button is selected, the device runs Power Fx and the user is navigated to the specified screen.

Each control needs a device-optimized, native equivalent that supports the same properties so it can render the way a maker expects. During preview, there are some limitations to which controls and properties are supported. Whether a control is classic or modern, it filters the list of controls for device-optimized ones.

Device-optimized controls

The following controls are optimized for iOS and Android devices. All other controls are currently unsupported. A screen that has one or more unsupported controls automatically renders in a web view instead of native UI. Learn more: Optimize for devices overview.

Controls

- Add picture
- Attachment
- Barcode reader
- Button
- Camera
- Check box
- Circle
- Components
- Container (horizontal and vertical included)
- Form
- Gallery (vertical, horizontal, flexible height)
- Icon (all icons supported)
- Image
- Radio
- Rectangle
- Text input
- Text label
- Timer

Modern controls

- Button
- Check box
- Date picker

- Text
- Text input
- Toggle

Learn more: Overview of modern controls and themes in canvas apps

Unsupported controls

If a screen has an unsupported control, the screen automatically reverts to render with a web view.

Device-optimized properties

Some properties must be configured so they're optimized for devices. For example, consider the barcode reader control. The maker can select **Scan Inline** for the **Scanning mode** property. In Power Apps Studio, when this mode is selected, the control displays as a warning box indicating that the control only works on mobile devices. On a device, in a screen optimized for devices, the control displays a camera feed to allow barcode scanning.

Known limitations

Note the following limitations with the 'optimize for devices' feature.

- The **Image** control, when showing an SVG file, only supports the fit, fill, and stretch image position options. Its default behavior is to fit, if another option is selected. All other image types work as expected for all image positions.
- In the **modern Text input** control, the **Value** property, when set to a Power Fx variable, isn't displayed at first navigation. Instead, it shows the placeholder value until the user navigates away and back to the screen with the **modern Text input** control.
- In the **modern Text input** control, the **OnChange** property is called each time the user interacts with the control, instead of when navigating away from the control.
- In the **modern Text input** control, the **Validate state** property doesn't display a red border around the control.
- In the **Image** control, the **Image rotation** property isn't supported. The image isn't rotated.
- In the **Dropdown** and **Radio** control, the **Items** property doesn't support references to other controls. Items aren't shown if they're complex values, like references.
- In the **modern Date picker** control, tapping on the control opens a modal with a calendar instead of allowing users to type into the control directly.

- In the **modern Date picker** control, the **Base palette color** and modern theme aren't applied on Android devices. Instead, it displays as the device's theme color.
- In the **Button**, **Image**, **Label**, and **Icon** controls, the **SetFocus** Power Fx function doesn't support keyboard focus, only accessibility focus (for example, screen reader).
- In **Horizontal and vertical containers**, the **Scroll** option only works for a single direction, depending on the **Wrap** property. If **Wrap** is off, the container is scrollable in the primary direction, otherwise it's scrollable in the secondary direction.
- Multiple **Barcode reader** controls on a single screen aren't supported.
- Multiple **Camera** controls on a single screen aren't supported.
- In the **Camera** control, the **Display mode** property of the parent control isn't supported. For example, if the camera control is part of a form that is set to view mode, the camera might still be in edit mode.

Supported platforms for running apps using the Power Apps mobile app

How offline first functionality works in Power Apps mobile

Offline first functionality in Power Apps mobile enables users to access and work with app data on their mobile devices without an active internet connection. This feature uses a local database on the device to store data. When your device is connected to a network, any writes made in the app sync to Dataverse immediately. If you perform updates while the network is offline, those changes sync automatically with Dataverse as soon as connectivity returns. Reads performed while the device is connected to the internet follow the sync frequency configured by the maker in the app's offline settings. When the device transitions from no network to an active connection, read operations are triggered again to refresh data.

Offline profile

First, to create an offline-first app, maker must create the offline profile. The profile defines:

- Tables and columns available for offline use
- Optional filters to limit the data downloaded per table
- Relationships between tables for linked data access

After you create the profile, when you first open the app, the data for the offline profile downloads and stores locally on the device in a SQLite-based cache. This local copy becomes the primary data source for all app operations. Learn more about setting up offline for canvas apps in Set up mobile offline for canvas apps and about setting up offline for model-driven apps in Set up mobile offline for model-driven apps.

Data synchronization

The sync process keeps offline data up to date with Dataverse through automatic synchronization:

- **Initial download**: When the app first opens, all data defined in the offline profile is downloaded to the local device.
- **Incremental updates**: Subsequent down-syncs fetch only changes (inserts, updates, deletes) since the last sync, reducing data transfer.
- **Configurable frequency**: Makers can set down-sync intervals (every few minutes, hourly, or daily) for each table in the offline profile in the maker studio.
- **Smart sync**: If no changes are detected across tables, the down-sync is skipped to save bandwidth.

- **Automatic resumption**: When the mobile device reconnects to the network, the down-sync operation resumes automatically.
- **Platform differences**: On iOS, syncs happen only in the foreground. On Android, syncs that start in the foreground continue even when the app moves to the background.

Local storage and data access

All offline data is stored in a local database on the device, ensuring data availability regardless of network status.

Read operations: In an offline first app, the app reads from the local cache for all data operations, regardless of network connectivity. This includes viewing records, searching, and filtering data.

Write operations: Changes made when the network is offline are queued locally and pushed to Dataverse when connectivity is restored. Users can continue making modifications without interruption. Changes made when network is online are saved locally and instantly synced to Dataverse.

Data retention: Retention duration isn't fixed by the platform. Data persists as long as the app and offline profile remain installed on the device. There's no automatic expiry unless:

- The user clears the app cache or uninstalls the app
- The maker updates the offline profile, which can trigger a full refresh
- The user sign out of the app before the sync is complete

Maker controls and optimization

Makers have several tools to optimize data download, offline performance and control the offline experience:

- **Column selection**: Choose specific columns to minimize payload size and reduce download time
- **Relationship configuration**: Define parent-child table relationships for linked data access
- **Sync frequency**: Configure sync intervals and filters for each table individually
- **Media settings**: Configure which images and files should be downloaded for offline access

These controls allow makers to balance offline functionality with performance and storage constraints on mobile devices. Learn more about how to optimize offline profile in Optimize the offline profile

Building offline app screens

Screens in an offline-enabled app are built on top of the offline profile and should be designed with offline scenarios in mind:

Data binding: Controls such as galleries and forms bind to tables defined in the offline profile, ensuring data availability offline.

Conditional logic: Screens should handle offline scenarios by disabling actions that require live server calls, such as certain API integrations or real-time data operations.

Optimized layouts: Galleries and forms should show essential columns only, reducing load time and improving performance on mobile devices.

Write-back handling: Input controls queue changes locally and should display status indicators (for example, "Pending Sync") until connectivity returns and synchronization completes.

Offline-first design benefits

The offline-first architecture provides several advantages over traditional online-only applications:

- **Faster load times**: No round trips to the server for every screen or data query, resulting in near-instantaneous data access
- **Consistent experience**: Users interact with the same local dataset whether online or offline, eliminating connectivity-dependent behavior changes
- **Reduced network dependency**: Only sync operations hit the server, not every read operation, minimizing bandwidth usage and improving reliability

This design ensures that users can work productively in any network environment, from stable Wi-Fi connections to areas with intermittent or no connectivity.

Last updated on 01/07/2026

FetchXML editor for offline profiles (preview)

[This article is prerelease documentation and is subject to change.]

FetchXML is Dataverse's native query language that lets makers write data filters as XML code, similar to writing a formula, but more powerful. Use the FetchXML editor to optimize complex profiles for better performance and avoid sync timeouts on large tables (100K+ records).

This feature is best suited for advanced makers and developers who are comfortable working with XML and need more control than what the visual filter builder provides.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.
> - This feature is being gradually rolled out across regions and might not be available yet in your region.

Benefits of the FetchXML editor

The FetchXML editor offers several advantages over the visual expression builder for defining offline data filters.

- **Support for hierarchical conditions**:

  The FetchXML editor supports building complex, hierarchical conditions such as `under`, `eq-or-under`, `above`, and `eq-or-above` on hierarchy-enabled lookups. Learn more about querying hierarchical data

  XML

```
<fetch>
  <entity
    name="account">
```

```
    <filter
        type="and">
        <condition
        attribute="statecode"
        operator="eq"
        value="0" />
    </filter>
    <link-entity
        name="businessunit"
        from="businessunitid"
        to="owningbusinessunit"
        link-type="any">
        <filter
        type="and">
        <condition
           attribute="businessunitid"
           operator="eq-or-under"
           value="{YOUR-PARENT-BU-GUID}" />
        </filter>
  </link-entity>
</entity>
</fetch>
```

- **Support for checks against unrelated tables**:

  The FetchXML editor lets you link to other tables even if they don't have a direct relationship with the primary table, provided you specify valid **from** and **to** attributes. This capability is especially useful in complex offline scenarios where multiple entities share a common foreign key but aren't directly related.

  XML

```
<fetch
    distinct="false"
    latematerialize="true"
    options="DisableRowGoal, EnableOptimizerHotfixes">
<entity
    name="cr57f_producttranslation">
    <filter
       type="and">
       <link-entity
       name="cr57f_userlanguagepreference"
       from="cr57f_language_id"
       to="cr57f_language_id"
       link-type="any">
       <filter
          type="and">
          <condition
             attribute="cr57f_user_id"
             operator="eq"
             value="user_002" />
```

```
      </filter>
      </link-entity>
   </filter>
  </entity>
</fetch>
```

- **Query optimization support by using late materialization and query hints**:

  The editor exposes advanced optimization controls directly on the `<fetch>` element, including:

- `latematerialize="true"`: By using `latematerialize="true"`, you optimize query performance by narrowing down matching records before retrieving all their column data. This attribute reduces the load when syncing large tables during offline sync. Learn more about using late materialize

XML

```
<fetch
  distinct="false"
  latematerialize="true"
  options="OptimizeForUnknown,ENABLE_HIST_AMENDMENT_FOR_ASC_KEYS">
<entity
  name="msdyn_workorder">

        from="msdyn_customerassetid"
        to="msdyn_customerasset"
        link-type="any">
     <filter
     type="and">
     <condition
        attribute="statecode"
        operator="eq"
        value="0" />
     </filter>
     <!-- Account -->
     <link-entity
        name="account"
        from="accountid"
        to="msdyn_account"
        link-type="any">
     <filter
        type="and">
```

```
        <condition
           attribute="statecode"
           operator="eq"
           value="0" />
    </filter>
   </link-entity>
  </link-entity>
</entity>
</fetch>
```

- The `options` attribute passes SQL Server query hints. Learn more about using these options

How the FetchXML editor works

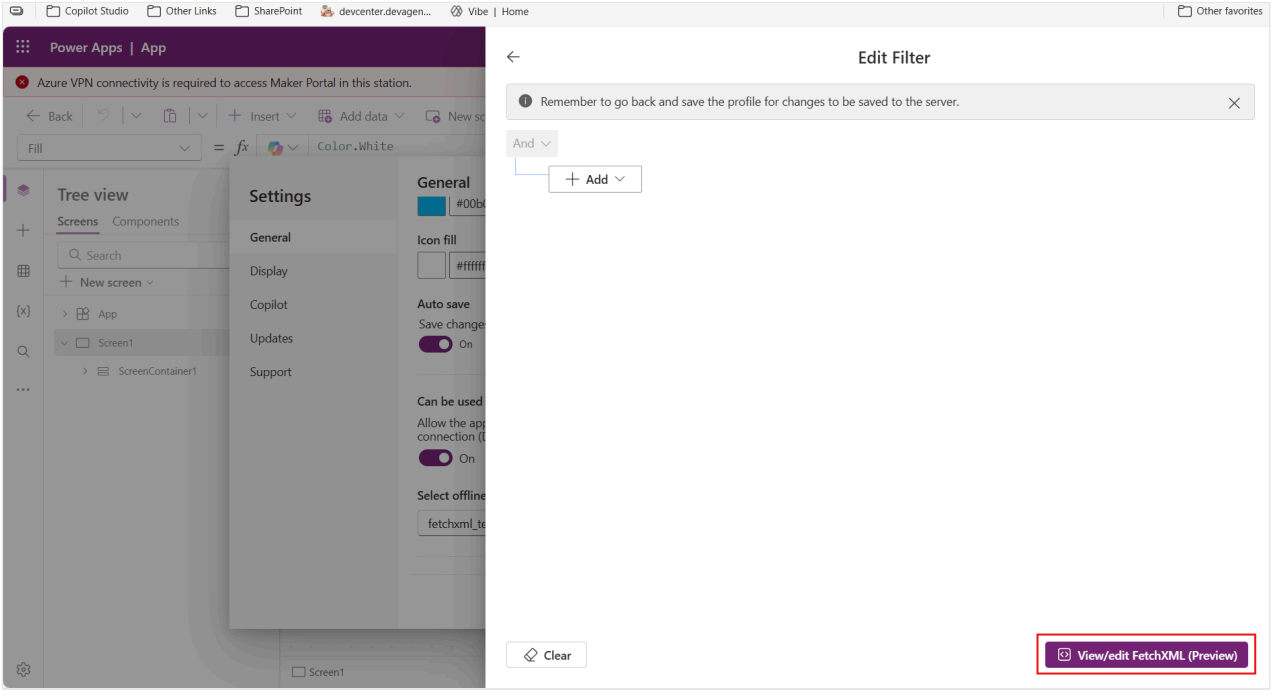
You access the FetchXML editor through the offline profile configuration experience in Power Apps. You write or paste a FetchXML query, and the editor validates it in real time before you save.

1. In Power Apps, go to your environment's settings and open the **Offline Profiles** page. Select an existing offline profile or create a new one, and then select **Edit profile**.

2. In the offline profile editor, add or select the table whose data you want to filter for offline use.

3. Under **Filter**, choose **Custom** or **Related rows**, and then select **Edit filter**.

4. In the filter editor, scroll down and select **View/Edit FetchXML** to open the FetchXML code editor.



5. Modify the existing FetchXML query or paste a new one. The editor automatically validates syntax and structure as you edit, checking for:

   - A required <fetch> root element with at least one <entity> element
   - Only supported FetchXML tags
   - Elements placed inside the correct parent elements
   - A maximum of 500 filter clauses

   If the editor detects an issue, such as a missing required element or an unsupported <link-entity> usage, it shows a clear error message so you can fix it before saving.

6. After your FetchXML query is valid, select **Apply** to convert the filter, and then **Save** the offline profile.

> ⓘ **Important**
>
> Always select **Apply** and then **Save** after editing FetchXML. If you don't save, your changes are discarded.

After saving, the offline profile uses your custom FetchXML filter for data sync. If your query uses only features supported by the visual builder, those filters continue to display in the Expression Builder UI. If you use advanced FetchXML-only features, the visual filter UI might not render them. Use the FetchXML Editor for any future edits to that filter.

Best practices

- Apply performance hints like `latematerialize="true"` or `hint="union"` for large datasets.
- Validate your FetchXML by using the built-in editor checks before saving.
- Save your offline profile immediately after applying FetchXML changes.
- Use only supported FetchXML constructs for offline profiles, such as `link-type="any"` or `link-type="not any"`.
- Avoid unsupported join types like `inner` or `outer` in offline filters.
- Keep filter clauses under the 500-clause limit per query.
- Don't ignore validation errors. Queries must be well-formed and complete.

Limitations

- Queries must start with a <fetch> root element and include at least one <entity> element.

- Only supported FetchXML elements are allowed. Unknown or unsupported tags trigger validation errors.
- Elements must follow proper parent-child nesting rules.
- <link-entity> inside <filter> must use `link-type="any"` or `link-type="not any"`. Inner and outer joins aren't supported.
- FetchXML <attribute> tags aren't used for column selection in offline sync. Use the **Filter Columns** option instead.
- Explicit pagination attributes like `page` and `count` are ignored in offline profiles.
- Queries are limited to a maximum of 500 filter clauses.

Last updated on 04/08/2026

Mobile offline for canvas apps overview

Article • 06/05/2024

If users of your Dataverse-based canvas app have spotty or no Internet access, you can easily provide offline-first access with simple switches and a canvas control. Basic offline-first apps are easy to make. Just build your app with normal Power Fx formulas, and Power Apps offline features handle everything else.

You can also build complex offline apps using custom *offline profiles*. An offline profile is the configuration that determines the data synchronized to users' devices. Offline profiles help you to optimize your app's performance by reducing the amount of data downloaded to the device. For example, while you may have access rights to millions of records in a table, your app may need only a thousand of them. If you download only a thousand records, your app performs better. If you need more than 15 tables in your offline app, you may want to consider using a custom offline profile.

To get started with mobile offline, turn on the offline feature in your app and in the tables your app uses. A basic offline screen template is automatically inserted into the app for you to use directly or as a starting point. Set up mobile offline for canvas apps.

Mobile offline-first

Offline-first means that all the data users need when they're offline is copied to their mobile device. It requires network access to download the data initially, but after that, users work exclusively with the data stored locally on their device, even when they're online. Moving on and off the network doesn't affect the performance of the app because it's using local data. Power Apps monitors your app's network access. When it detects a connection, it automatically syncs any local changes to the server and downloads any updates from the server. The offline features handle conflict detection and minimize the use of system resources.

When you turn on the offline capability in your app, the app always runs offline-first, with or without an Internet connection. This functionality optimizes offline performance and creates a consistent experience for users as they change locations.

Why use offline for canvas apps instead of LoadData/SaveData?

There are some key benefits to using the built-in offline functionality for canvas apps instead of LoadData/SaveData Power Fx functions.

Expand table

Topic	LoadData/SaveData	Built-in offline
Power Apps Studio support	Custom	Built-in
Code complexity	Power Fx code complexity scales up with data complexity	No code
Supported Power Fx functions	All	Partial (See Mobile offline limitations for canvas apps.)
App checker rules	None	Common configuration problems are flagged
Offline or connectivity user experience	Not provided/custom only	Automatic
Sync user experience or status	Not provided/custom only	Automatic
Image and file support	Yes, but may run into performance and memory limits	Yes
Optimized delta sync	No	Yes
Conflict resolution	Manual	Automatic
Local data store	Files	Transactional database
Automatically handles schema changes	No	Yes
Fast app launch with large datasets	No	Yes
Data size limit	Device dependent, 30-70 MB in most cases	Device dependent, 3 million rows

Provide product feedback

Set up mobile offline for canvas apps

Turn on offline mode in your canvas app if users need to work without worrying about their Internet connection.

Prerequisites

- You must have the Environment Maker, System Administrator, or System Customizer role to set up offline mode for canvas apps. These roles have create, read, write, delete, and share privileges on **Canvas App**, **Mobile offline profile**, and **Sync Error** tables. Learn about predefined security roles.
- Users with the Basic User role can't open an offline application. You must create a custom security role with read privileges on **Canvas App**, **Mobile offline profile**, and **Sync Error** tables.
- If you already have a custom security role, make sure it grants read privileges on **Canvas App**, **Mobile offline profile**, and **Sync Error** tables. Learn about Create or edit a security role to manage access.

> **Note**
>
> It's recommended that the canvas app is in a solution. The offline profile **App usage** field in the Power Platform admin center (**Environements** > *select an environment* > **Settings** > **User + permissions** > **Mobile configuration**) only applies to apps within a solution.

Optimize your app for mobile offline

Mobile apps run on small screens with limited connectivity. Before you set up offline mode, make sure your canvas app is optimized for offline and mobile use. Consider the user scenarios you want to cover and the amount of data the app uses. Create an app that's simple and lightweight.

Follow these best practices when you build an app for mobile offline use:

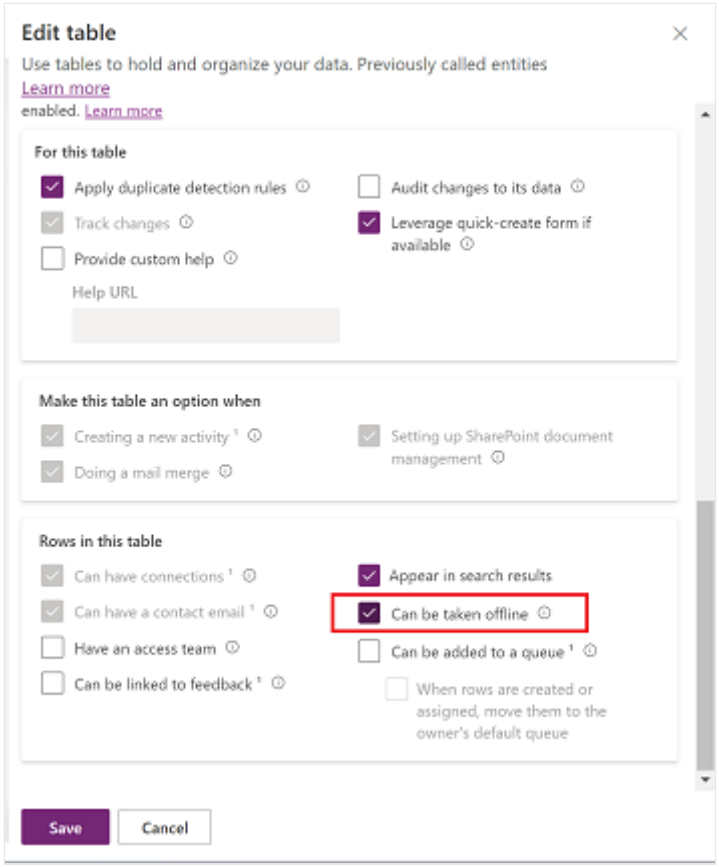
- Performance is critical when you run an app on mobile. For more information about creating performant canvas apps, see Overview of creating performant apps.
- Identify the on-the-go scenarios that are functionally related, such as tasks that are performed by users who work in the field.

- Reduce the complexity of your app by limiting the number of tables that need to be downloaded. Sometimes it's better to have two apps instead of one.
- Use views that are optimized for the experience rather than displaying a large set of data. For example, it's preferable to use the **My active accounts** view, rather than the **All accounts** view.

Turn on offline capability for tables

Tables included in an offline app must be configured for offline use. Some built-in tables have it by default. Some tables can't be used offline. However, you can turn on offline capability for any new, custom table.

1. Sign in to Power Apps.
2. In the left side panel, select **Tables**.
3. Select a table, and then select **Edit**.
4. Select **Edit table properties**.
5. Select **Advanced options**, and then scroll to the **Rows in this table** section.
6. Select **Can be taken offline**.



7. Select **Save**.

Turn on offline capability for your app

1. In Power Apps Studio, in the left side panel, select **Apps**.
2. Select your canvas app, and then select **Edit**.
3. Select **Settings**.
4. Select **General**.
5. Turn on the **Can be used offline** option.

   If you don't see the **Can be used offline** option, make sure the app is in a solution.
6. Select an offline profile. You have two options:

   - **Autogenerated profile**: This setting downloads all the tables used in your app automatically. Autogenerated profiles are a starting point to create an offline profile and help makers validate their offline data. These profiles can be resource-intensive as they don't compute optimal filters for each table or assess the amount of data the app must download offline. App makers need to review and refine these profiles based on their use case.
   - **Custom mobile profile**: Custom offline profiles let makers add only relevant tables, limit data usage and include filters based on their needs and best practices. These profiles offer flexibility and control, enhancing the user experience by downloading relevant data, improving sync times, and boosting query performance.
7. Close the **Settings** window, and then save and publish your app.

A page that's based on the Offline template is automatically inserted in the app. The page contains an icon that uses the Connection Power Fx function to reflect the app's offline sync status. You can use it as-is or customize it, as appropriate.

> **Note**
>
> - You can use the same, offline profile in different canvas apps. The users can use the apps and share the same, offline profile in disconnected mode. The updates done in one app are reflected in the other apps since the apps share the same, local storage with this setup.
> - ALM isn't currently supported for autogenerated profiles.

- If your organization uses ALM and you're moving your app between environments, ensure that your offline profile is tested for all use cases in the target environment.

If the automatically generated offline profile doesn't meet your needs, create your own. Learn about guidelines for offline profiles.

Create an offline profile

You need to publish your new offline profile before you can select it in your canvas app's settings. If you edit and publish an offline profile, you must also publish any canvas apps that use it.

There are two ways you can create offline profile.

Create a custom mobile offline profile from within Power apps studio

1. Sign in to Power Apps Studio.
2. In the left side panel, select **Apps**.
3. Select your app, and then select **Edit**.
4. Select **Settings** > **General**.
5. Turn on the **Can be used offline** setting.
6. In the drop-down menu, select an offline profile. You can select the **Auto-generated** option or **New profile with current app data**.
7. Enter a name and description for the profile. Add the tables you need for the profile. For those tables, apply filters and choose columns as described in optimize the offline profile.
8. Save the profile.
9. Publish the profile.

Create profiles from within Power Platform admin center (with admin rights)

1. Sign in to the Power Platform admin center using an admin account.
2. In the left side panel, select **Environments**.
3. Select an environment, and then select **Settings**.
4. Expand **Users + permissions**, and then select **Mobile configuration**.
5. Select **Create new profile**.

6. Enter a name and description, and then select **Create**.

7. After the profile is created, select it to continue editing it.

> **Important**
>
> Don't add users in the offline profile in the **Users with offline access** area. This capability is only applicable to model-driven apps and is restricted to selected users.

Add a table to an offline profile and apply filters

Applying an appropriate filter for each of the tables configured in the offline profile is critical to limiting the amount of data that downloads on users' devices.

Be sure that you configure at least one of the profile rules for each table to download its data.

Expand table

Customization	Recommendation
Organization rows - if selected, then select at least one of these options: - **User's rows** - **Team rows** - **Business unit rows**	If you want to define this filter, then you have to pick at least one of the given options. It's highly recommended to not have a business unit-level filter for a table, unless there's a strong justification. It's recommended for a master data scenario with a small data set, like country codes.
All rows	If you select this filter, you can't define any other filter rules.
Related rows only	Be sure that the related table has been added to the offline profile.
Custom	You can define a custom filter up to three levels deep.

1. In the **Data available offline** section, select **Add table**.

2. Select a table, and then define the filters.

3. Select **Next**.

4. Set the following filters:

   a. Choose the row that you want to make available offline. For the **Custom** option, use the expression builder to set up advanced conditions.

b. **Relationships** lists the different relationships available between the current table and other tables added in the offline profile. Selecting a relationship ensures that related rows following that relationship are downloaded and made available offline.

c. **Sync interval** defines the sync frequency to be applied on the device that syncs with the data with the server. If a table's data doesn't change frequently, like a catalog or a product table, you might want to focus on only syncing data when necessary, such as refreshing only once a day.

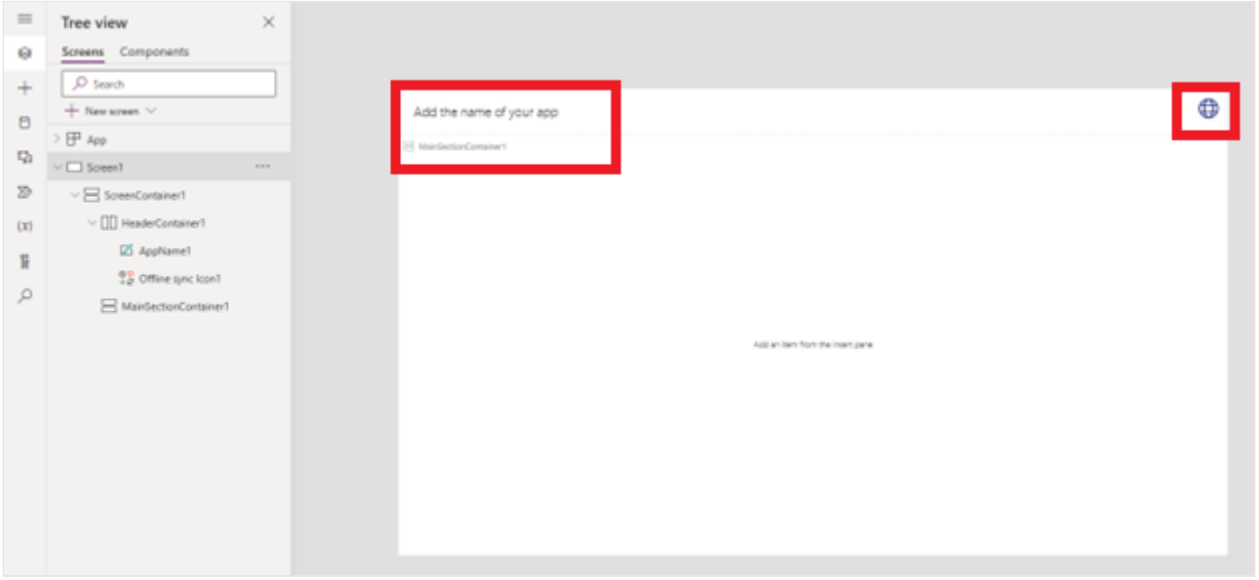
5. Select **Save**.

> **Note**
>
> Each table in your offline setup can link to up to 15 other tables through filters or relationships. If you link to a table that already connects to other tables, those connections count toward the limit. For example, if Table B connects to two other tables and you link Table A to Table B, Table A has three relationships: one for Table B and two for the tables Table B connects to. This setup is a transitive relationship. If any table has more than 15 total connections, you get an error and can't publish the offline profile.

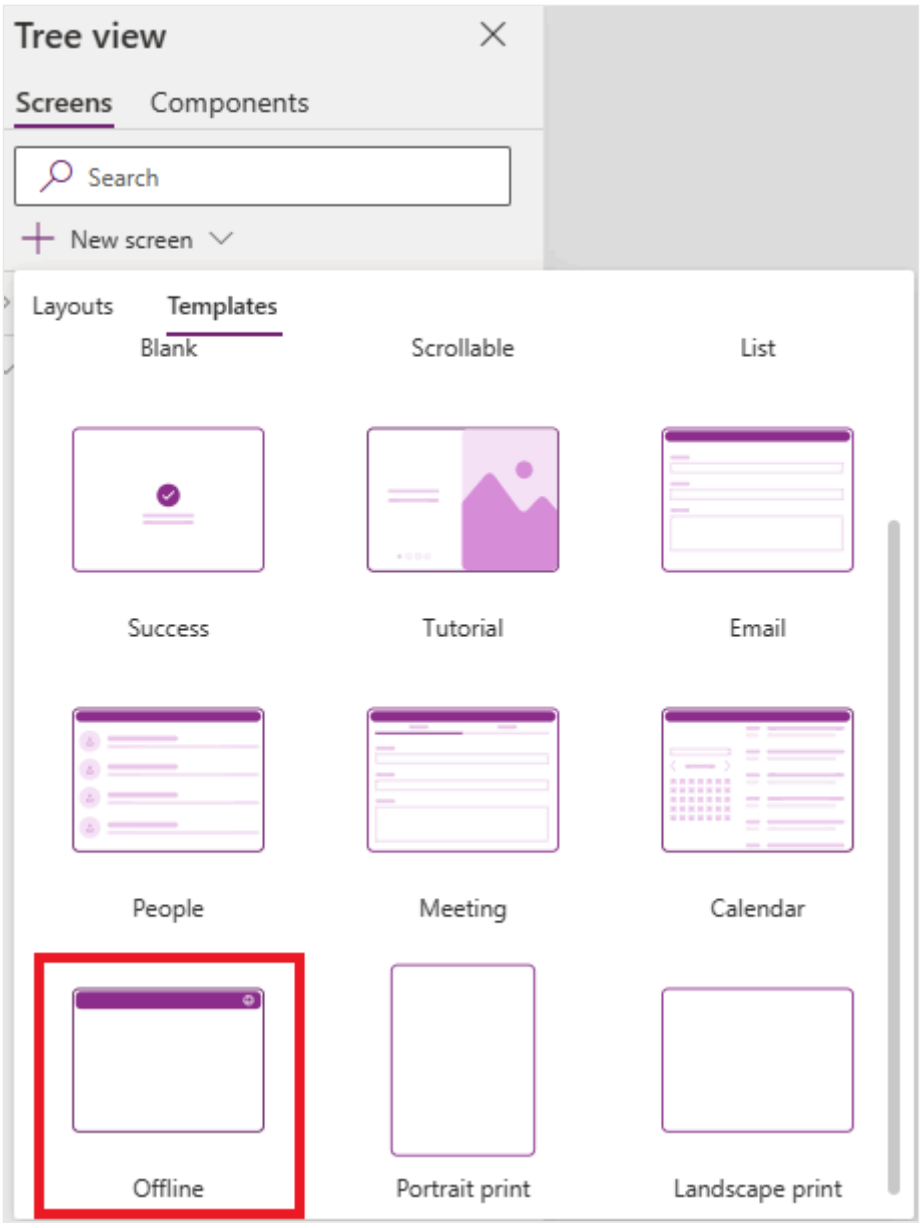
Using the Offline template and offline status icon

To make it easier to create or convert a canvas app for offline use, we created the **Offline** template. The template includes a globe icon in the navigation bar that shows the connectivity and sync state, putting offline at the center of the experience. Users always know whether their device and data are ready to go.

A new page created from the **Offline** template is automatically inserted as soon as you turn on the offline capability in your canvas app.



You can also add a new page based on the **Offline** template the same way you add pages from any other template.



The globe icon in the template's navigation bar uses different icons depending on the value of the Power Fx `Connection.Sync` function. You can create your own icon and set the **Icon** property using the following Power Fx script:

PowerApps Formula

```
Switch(Connection.Sync,

   ConnectionSync.Connected, Icon.Globe,

   ConnectionSync.ConnectedWithWarning, Icon.GlobeWarning,

   ConnectionSync.ConnectedPendingUpsync, Icon.GlobeChangesPending,

   ConnectionSync.ConnectedError, Icon.GlobeError,
```

```
    ConnectionSync.ConnectedRefresh, Icon.GlobeRefresh,
    ConnectionSync.NotConnected, Icon.GlobeNotConnected,
    ConnectionSync.NotConnectedWithWarning, Icon.GlobeWarning,
    ConnectionSync.NotConnectedPendingUpsync, Icon.GlobeChangesPending,
    ConnectionSync.NotConnectedSyncError, Icon.GlobeError)
```

You can set the **OnSelect** property using the Power Fx function `ShowHostInfo` to show the Device status page when selecting the globe icon.

PowerApps Formula

```
ShowHostInfo(HostInfo.OfflineSync)
```

You can set the **Visible** property using the Power Fx function `Host` to only show the globe icon when the app is used on a player that's supporting the offline mode.

PowerApps Formula

```
Host.OfflineEnabled
```

Export a solution that contains a canvas app enabled for offline

When you export a solution with an offline canvas app, you also need to export the offline profile for the app, as it's a dependency of the app.

1. Sign in to Power Apps and in the left navigation pane, select **Solutions**.
2. Select the solution that you want to export and then select **Edit**.
3. Select the canvas app that is enabled for offline and then select **Advanced** > **Add required objects**.

Make sure that the associated offline profile is in the solution and then you can export it.

Configure files and images in offline canvas apps

Summarize this article for me

This article explains how to configure files and images in a Power Apps table for offline canvas apps.

Prerequisites

Have an existing canvas app with Dataverse tables. For more information, see Build an app.

View column properties for a file or image

1. Sign in to Power Apps.
2. In the left navigation menu, select **Tables**. If the item isn't in the side panel pane, select ... More and then select the item you want.
3. Select the table that has the columns you want to view.
4. Under **Schema**, select **Columns**.
5. Select the **Display name** of a column where **Data type** is set to **File** or **Image**.
6. The column properties show the **Data type**. Expand **Advanced options** to view the maximum size for a file or image. For more information about columns, see Columns overview.

Download options

In an offline-enabled canvas app, there are two ways to download files and images:

- **On view**: Downloaded when you view them—the default option.
- **On sync**: Downloaded during offline sync when device is connected.

Download files and images on view

When files and images are configured to download **on view**, the content is downloaded on the device when the user opens a file or when an image is presented to the user. Files and images are downloaded when the device is connected to the network and can be used afterward without connectivity.

This mode is enabled by default without any specific configuration.

If you want to keep this default, then you don't need to proceed with this article.

Download files and images on sync

When files and images are configured to download **on sync**, they download during the offline sync when the device is connected to internet. After the download is complete, users can access this content from the device's local storage, even when the device is offline. Users are notified when the download of files and images is complete. Use download on sync when you only need to make a limited number of files or images available offline.

The remainder of this article helps you configure on sync.

Configure on sync

To configure the automatic download of files and images on sync, you need to create a custom, mobile offline profile. There are two ways to configure sync.

Configure on sync from within Power apps studio

1. Sign in to Power Apps.
2. In the left navigation pane, select **Apps**.
3. Select a canvas app, and then on the command bar, select **Edit** to open your app in editing mode in canvas app designer.
4. Select **Settings** > **General**.
5. Set the **Can be used offline** toggle to On.
6. Under **Select offline profile**, select **Edit selected profile** from the "...".
7. Select the table that has file or image column that you want to enable for offline.
8. In the table details pane that appears, under the section **Related rows + Files and Images**, select the file and image column that you want to configure on sync.
9. Go back and select **Save**.

Configure on sync from within Power Platform admin center (requires admin access)

You can add both the **Image Descriptor** and **FileAttachment** tables to your mobile offline profile by configuring the settings of your environment.

1. Go to Power Platform admin center and sign-in as an admin.
2. Select **Environments** from the navigation menu.
3. Choose an environment and then select **Settings** on the menu bar.
4. Expand **Users + permissions**, then select **Mobile configuration**.
5. Select a mobile offline profile to edit it.
6. In the **Data available offline** section, select **Add the table that contains the images or files**.
7. To enable offline access for images and files, add the **Image Descriptor** and **FileAttachment** tables to your mobile offline profile. To add the Image Descriptor table, follow these steps:
   a. Select **Image Descriptor** and then select **Next**.
   b. Under **Choose the rows that you want to make available offline**, select **Related rows only**.
   c. Expand **Relationships** and select **Column name: Display name** for each column where **Data type** is set to **Image**. In this example, we select the unnamed column names from the **DemoTable1** and **DemoTable3** tables.
   d. Select **Save**.
8. To add the FileAttachment table, follow these steps:
   a. Select **FileAttachment** and then select **Next**.
   b. Under **Choose the rows that you want to make available offline**, select **Related rows only**.
   c. Expand **Relationships** and select **Column name: My column name** for each column where **Data type** is set to **File**. In this example we add **Column name: MyFile** from the **DemoTable3** table. *Don't* select **Column name: Regarding**..
   d. Select **Save**.

Work with canvas apps offline

Article • 07/23/2024

If a canvas app is designed for offline use, you can work with it on your mobile device even when you don't have Internet access. All the data the app needs is stored locally on your device. Any changes you make are synchronized with the app server the next time your device connects to the network. If you're in the middle of changing some data and you lose your network connection, the app saves your changes and uploads them to the server when you're back online.

Initial offline sync

Before the app can work offline, it needs to download to your device all the data it needs to have available. This process is called the *initial offline sync*. It can take a few minutes or longer, depending on how the app was designed.

The initial offline sync happens automatically when you open the app. A message tells you the app is syncing the offline data and the number of rows and tables that are downloaded. If the initial sync doesn't complete, it's triggered every time you open the app.

Offline delta sync

After the initial offline sync, the data that's stored locally is kept in sync with data on the app server whenever your device has a network connection. These periodic updates are known as "delta" syncs. "Delta" means the minimum data that's changed between two syncs on the device. Power Apps syncs every five minutes when you're online.

Sync status icons

Depending on how the app was designed, it includes information about its synchronization status in the form of a globe with various icons. At a glance, you can tell whether:

- The app is connected to the network
- A data update is in progress
- Updated data is waiting to sync
- An error or warning occurred while data was syncing

The following table describes the icons and their meanings.

Expand table

Icon	Description
	The app is connected to the Internet.
	The app isn't connected to the Internet.
	The app is syncing data.
	The app has pending changes to upload.
	The synchronization process encountered an error.
	The synchronization process encountered a warning.

To get a description of the sync state, select the icon.

Sync data offline in the background

06/25/2025

To use an app in offline mode, download the app and sync data to your device.

You can sync data reliably only when the Power Apps mobile app or Field Service app is open, running in the foreground, and your device screen is unlocked. Learn more about sync behavior in Work with canvas apps offline.

The background sync can be enabled on Windows by changing the **Let this app run in the background** setting.

- If you're using Windows 10, see Manage background activity for apps in Windows for more information.
- If you're using Windows 11, complete the following steps:

    1. Go to **Settings** > **Apps** > **Installed apps**.
    2. Next to **Power Apps** or **Field Service**, select the **More options** icon (three horizontal dots). Then select **Advanced options**.
    3. In the **Background apps permissions** area, go to the **Let this app run in the background** setting. Select **Power optimized (recommended)** from the list.

Mobile offline limitations for canvas apps

07/16/2025

Before you set up the mobile app in offline mode, be sure to read through the following limitations. We recommend that you also review Best practices for developing an app for offline use and Optimize the offline profile.

Capabilities not supported in offline-enabled apps

Expand table

Area	Description
Canvas app types	The offline-first feature works for standalone canvas apps only. It doesn't work for embedded canvas apps, custom pages, or canvas apps in Teams.
Connectors	Non-Dataverse connectors, like SharePoint, aren't supported in offline mode.
Dataverse table types	Virtual tables and elastic tables aren't supported in offline mode.
Shared offline profile	If the same, offline profile is used in a canvas app and in a model-driven app, it creates two, separate local databases.
Power Automate flows	Power Automate flows aren't supported in offline mode.

> **Note**
>
> If your app connects to data from Excel, CSV files, or SharePoint lists, you can start with Copilot to import data to Dataverse. Once your data is in Dataverse, you can turn on offline support for your canvas apps with one selection.

Offline runtime limitations

Expand table

Area	Description
Offline record limit	The total number of records synced is limited to 3,000,000. Attempts to sync a larger number of records fail. This number also includes hidden tables used for offline capabilities.

Area	Description
Power Fx functions	The offline-first feature works with Dataverse tables only and doesn't support the following Power Fx functions: Relate, Unrelate

Relationship	In offline mode, canvas apps don't support many-to-many relationships.
	
	Filtering on column lookups is limited to one level of the relationship when the app is configured for offline use. Self-referential lookups are also not supported in offline mode. Consider following examples to understand the relationship with Account and Contact information.
	
	Supported Lookups:
	
	Lookups are supported for one level of relationship. For example:
	
	`Filter(Account, 'ContactID'.'Zipcode' = "11056")`
	
	This retrieves all accounts with the zipcode 11056.
	
	Unsupported Lookups:
	
	1. **Self-referential Lookups**: Self-referential lookups aren't supported. For example:
	
	`Filter(Account, 'Parent Account'. 'Name' = "John Doe")`
	
	This doesn't work because the parent account is a self-reference to the account table.
	
	2. **Multi-level Relationship Lookups**: Lookups involving more than one level of the relationship aren't supported. For example:
	
	`Filter(Account, 'ContactID'.'Map'.Latitude = "38'53")`
	
	This doesn't work because it involves more than one level of relationship (Account > Contact > Map).
	
	Note: The same limitations apply to the lookup function and the filter function mentioned earlier.

Tables	Notes aren't supported in offline mode in canvas apps.
Column types	Calculated and roll-up fields—that are part of rows synced to the client—aren't reevaluated by the client. The reevaluation happens on the server when the updated row is synced. When you run an app in offline mode, mapped fields aren’t prepopulated when you create a new record from a table that has fields mapped to another table.

Area	Description
Sort order	Items in a gallery may appear in a different order in an offline-capable app if no sort order is selected. Choose a sort order in the gallery control to make sure the app behaves consistently in mobile apps and web browsers.
Background synchronization	Data can only be synced regularly when Power Apps is running in the foreground of your device, with the screen unlocked. Learn more in Sync data offline in the background.

Profile filters limitations

Expand table

Area	Description
Relationship defined for each table	A maximum of 15 relationships is allowed. There's a maximum of one many-to-many (M:M) or one-to-many (1:M) relationships within the 15 relationships. If any custom tables demand this scenario, then revisit the data model. No circular references or self-references are supported.
Images and files	Images and files are subject to the same limitations as any other table. Because of implicitly defined relationships, an offline profile can only contain up to 14 image columns, across all entities.
Auto-generated offline profile	The auto-generated offline profile doesn't handle filters. As a result, for each table used in the app, it downloads *all* rows to which the user has permissions.

Troubleshoot offline sync errors in the Power Apps mobile app

Mobile offline for model-driven apps overview

Article • 05/29/2024

Wouldn't it be great to use your mobile app without worrying about spotty internet connectivity? With model-driven apps made with Power Apps and the new, mobile offline-first experience, it's possible. People who need to work from remote locations can continue to work seamlessly without worrying about their internet connection.

With the new, mobile offline experience enabled for your model-driven apps, not only can you continue working in offline mode, you also have better device performance, a more responsive app, and less drain on the battery because fewer connections are being made to the server.

An internet connection is required to sync data between your mobile device and Microsoft Dataverse.

To get started with mobile offline, an app maker needs to enable and define the tables that are available for offline use by using the modern app designer. For more information, go to Set up mobile offline.

Mobile offline is offline-first by default

Offline-first means that all the data you might need when offline is copied to your mobile device. This requires initial network access to download the data. Once you have your data, you only work with the data on your local device all the time. This is true both when your device is connected and disconnected to the network.

Moving in and out of network access doesn't affect performance of the app because it's using local data. Power Apps monitors network access and automatically syncs the changes you make locally with the server, and downloads any updates made on the server. The offline features automatically handle spotty network connections, download data, upload data, handle conflict detection, and more. The built-in, offline features minimize system resources and are highly performant.

When offline mode is configured and enabled for your model-driven app, anyone who uses the Power Apps mobile app can also use the app in offline mode. By default, the Power Apps mobile app runs offline-first, either with or without an internet connection. This functionality optimizes offline performance and creates a consistent experience for users as they change locations:

- **Online**: Occurs when an internet connection is available, but offline mode isn't set up. The mobile app functions similar to using the app with an internet connection on your PC. When the internet connection is lost, the mobile app is unusable. This isn't recommended.
- **Offline-first without an internet connection**: Data is downloaded and all changes are saved to your mobile device. When the internet connection is restored, the changes are automatically synced to the server.
- **Offline-first with an internet connection**: Data is downloaded to the device and all changes are saved locally. Because there's an internet connection, the app automatically attempts to sync every few minutes.

> **ⓘ Important**
>
> For more information about how to set up mobile offline for canvas apps, go to Develop offline-capable canvas apps

Offline-first vs. classic offline

With the offline-first experience, it's important to understand the key benefits of the *offline-first experience* versus the *classic offline experience*.

Expand table

Offline-first	Classic offline
• Your data is always the same, regardless of your network connection. • There's no toggle for users to switch from offline to online mode. A user never forgets to sync their changes back to the server because the app does it automatically.	• Users have the option to skip the initial offline sync and stay online, which means that users in your organization might not have the same experience. • Users have to remember to disable the **Work in offline mode** toggle before they can sync changes with the server. • To save your changes in offline mode, you need to set the **Work in offline mode** toggle to **On**. Otherwise, when you're working on a row and suddenly lose your internet connection, your changes are lost. • The rows you see in offline mode are listed from the local database. This means that the rows you see in offline mode vs. online mode can be different.

Set up mobile offline for model-driven apps

07/31/2025

Use the modern app designer to enable your model-driven apps for offline use on a mobile device. When offline mode is enabled, users interact with their data without internet connectivity on the Power Apps mobile app.

Prerequisites

Verify the following prerequisites before you enable mobile offline:

- You need the environment maker, system administrator, or system customizer role to configure offline mode for model-driven apps. These roles have Create, Read, Write, Delete, and Share privileges on the **Mobile offline profile** table. For more information, see About predefined security roles
- Users with the basic user role can open and use an offline app. This role has the Read privilege for the **Mobile offline profile** table.

  If you have a custom security role, ensure you have the read privilege for the **Mobile offline profile** table. For more information, see Miscellaneous privileges

Optimize your app for mobile offline

Mobile apps run on smaller screens with limited connectivity. Before you enable offline mode, make sure your model-driven app is optimized for offline and mobile use. Consider the number of user scenarios that you want to cover and the amount of data the app uses. Create an app that's simple and lightweight.

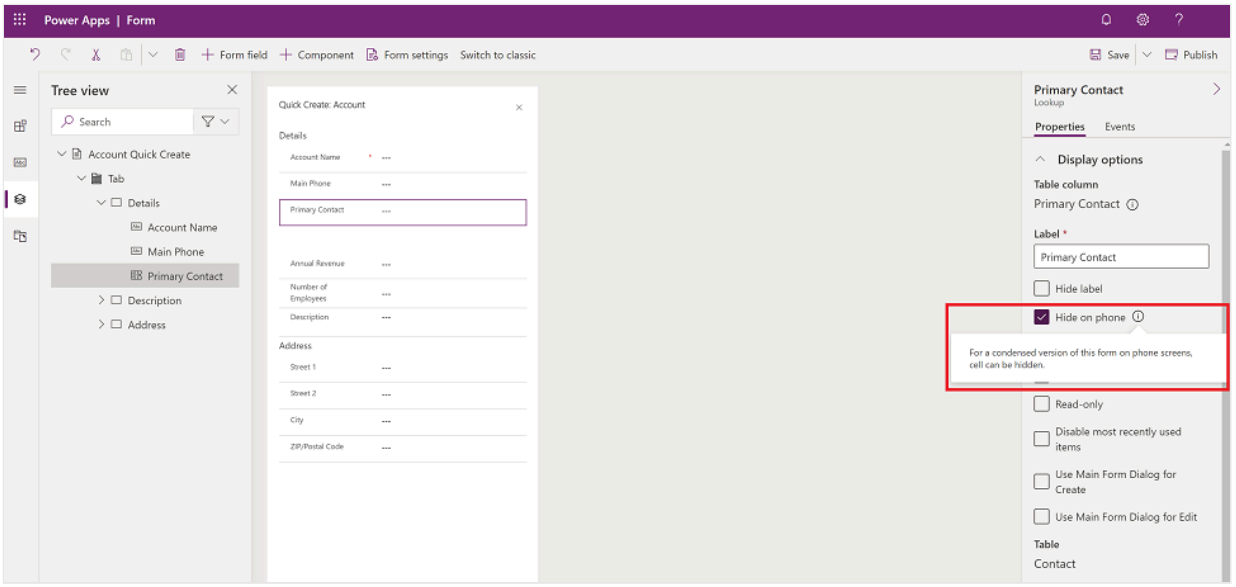
If you have desktop and remote mobile users, optimize the user experience by creating two separate apps. Create an online app for your office users and another app for your mobile users who might have limited connectivity.

Follow these best practices when building an app for mobile offline use:

- Identify the on-the-go scenarios that functionally relate, such as tasks performed by users working in the field.
- Reduce the complexity of your app by limiting the amount of app metadata that needs to be downloaded on a user's device. Only add the tables and views that are needed for

your mobile users. For more information, go to Add a page to your app

- Only keep views that are necessary, and remove any that aren't needed on a day-to-day basis. For example, keep the **My active accounts** view and remove the **All accounts** view. Keep your forms lightweight for a smooth and intuitive experience on small-screen devices. The following are possible optimizations for forms on mobile:
  - Build dedicated forms for mobile use.
  - Share forms across the mobile and desktop experience, but disable some fields on mobile.



Enable your app for offline use

1. Sign in to Power Apps.
2. On the left pane, select **Apps**, and then select the model-driven app that you want to enable for offline.
3. Select **More (...)** > **Edit** to open the modern app designer.
4. On the command bar, select **Settings**.
5. On the **General** tab, set the **Can be used offline** toggle to **On**.
6. Select the type of offline profile: **Default** or **Restricted to selected users**.
   - If you select **Default**, the app is enabled for offline use for all users. Select an existing offline profile, or select **New profile with current app data**. To set up a new offline profile, see Set up a mobile offline profile.

- If you select **Restricted to selected users**, the app is enabled for offline use only for a selected list of users. Select one or multiple offline profiles, or select **New profile with current app data**. To set up a new offline profile, see Set up a mobile offline profile.
- You must have admin privileges to assign users to an offline profile.

7. Close the **Settings** page, and then save and publish your app. When you're done, the app is set up for offline use.

Set up a mobile offline profile

The mobile offline profile represents the dataset that syncs on a user's device. The profile contains the tables, including related filters, that are applied when data is synced to a user's device. For more information about offline profiles, see Offline profile guidelines.

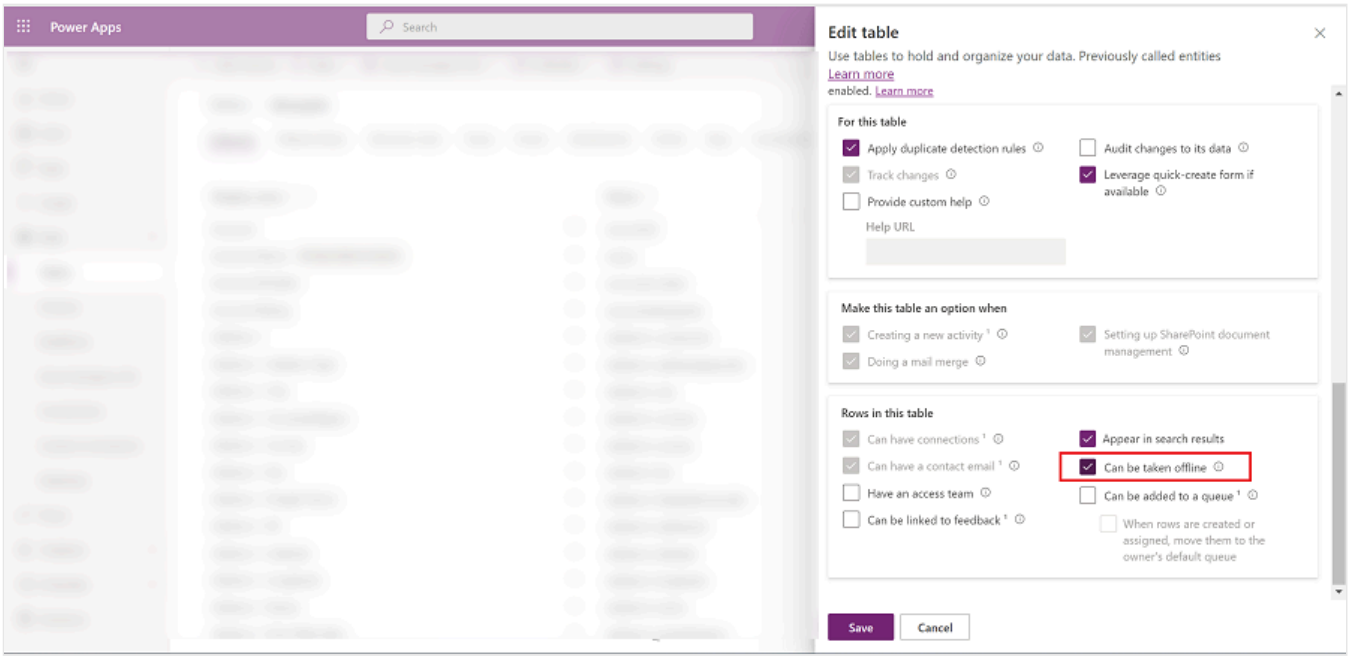
If the offline profile is in advanced mode, you'll need to add users to the offline profile. If you don't add a user to the offline profile, the user can't use the app in offline mode.

Enable a table for offline

A table needs to be enabled for offline to add it to an offline profile. Some tables are enabled for offline by default. Follow these steps to verify whether a table is enabled for offline.

1. Sign in to Power Apps.
2. In the left pane, select **Data** > **Tables**.
3. Select the table that you want to add to an offline profile, and then, on the command bar, select **Settings**.
4. In the **Edit table** settings, select **Advanced options**, and in the **Rows in this table** section, select **Can be taken offline**.

An app can only be linked to one profile. However, a profile can be shared between multiple apps. This can be useful when multiple apps share the same dataset, as it only needs to be downloaded once on the device and is shared between the apps.

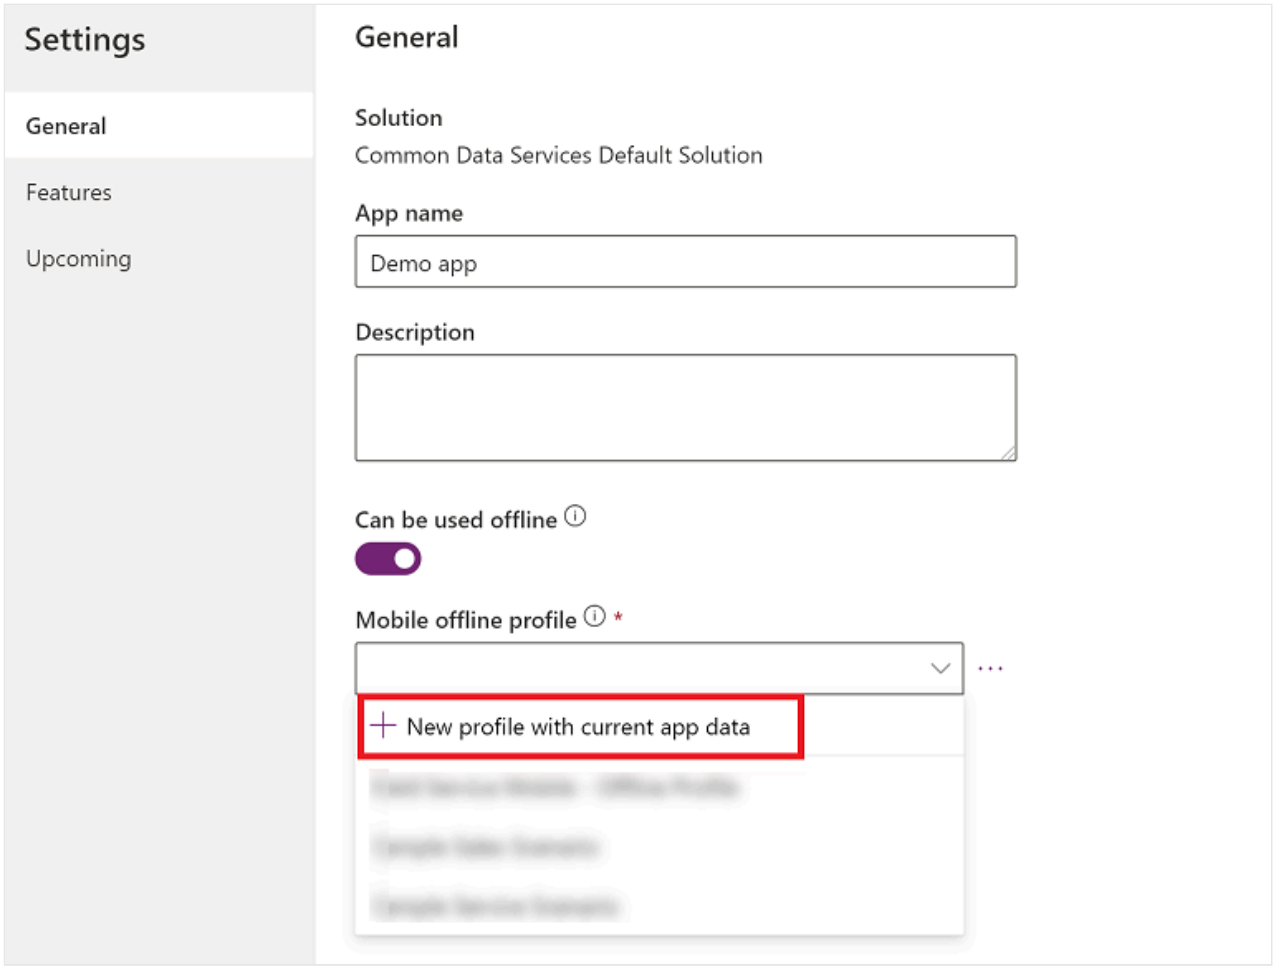


Generate a default profile

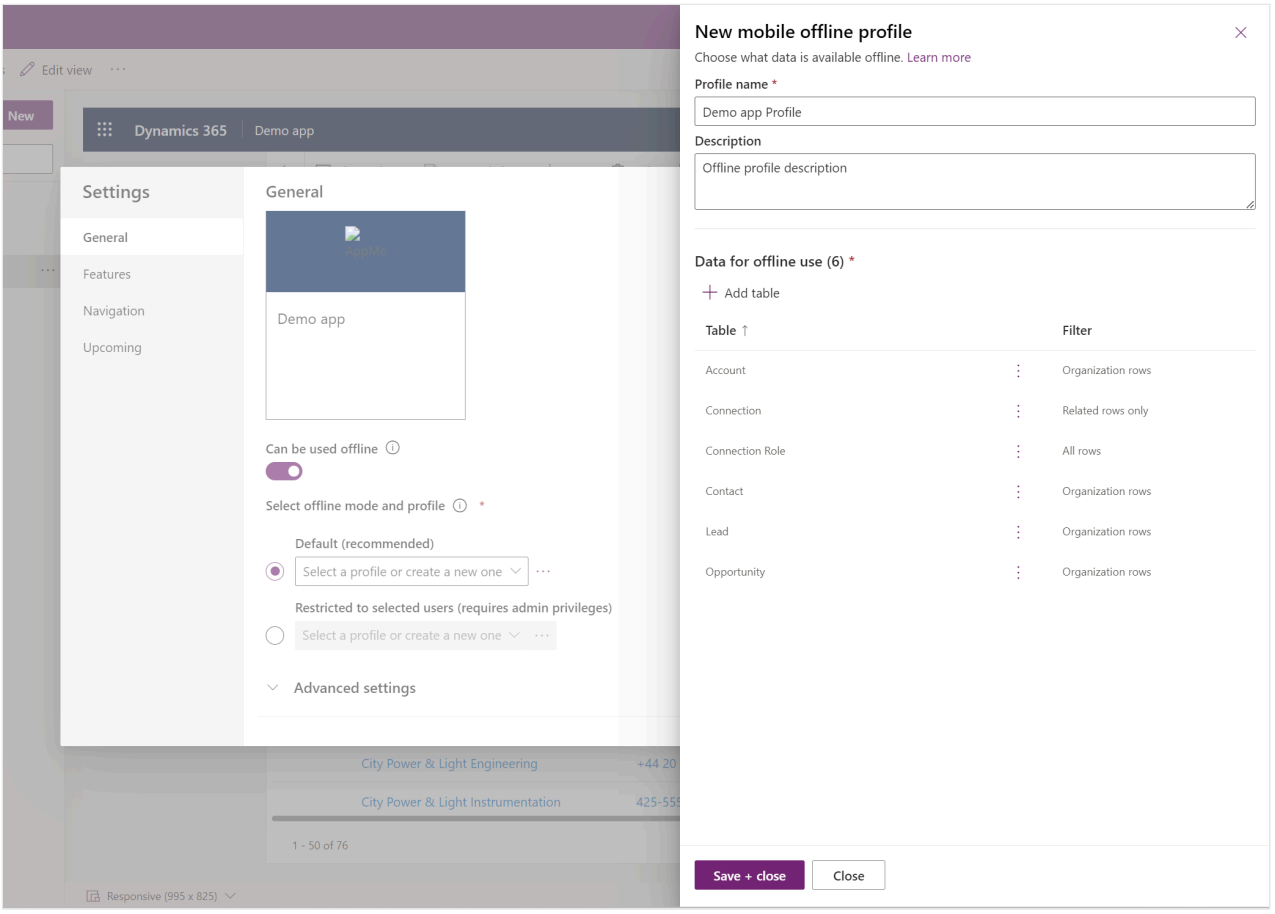
The modern app designer generates a default offline profile based on how the app is configured.

The default offline profile is a starting point to help you quickly build an offline profile. The default profile doesn't compute the optimal filters for each table. It's important that you review and adjust the proposed filters based on your organization's needs.

1. Select **New profile with current app data**.



2. Review the proposed filters for each table. Make sure that the data downloaded on users' devices is limited to only what's necessary. Focus on the tables used most often in your app, which in most cases have the **Organization rows** filter set.



The tables that are added to the profile also have the **Related rows only** filter. These are tables used in certain views that require related information. You might not need to modify them according to your organization's needs.

Add a table to an offline profile and apply filters

Applying an appropriate filter for each of the tables configured in the offline profile is critical to limiting the amount of data that downloads on users' devices.

Be sure that you configure at least one of the profile rules for each table to download its data.

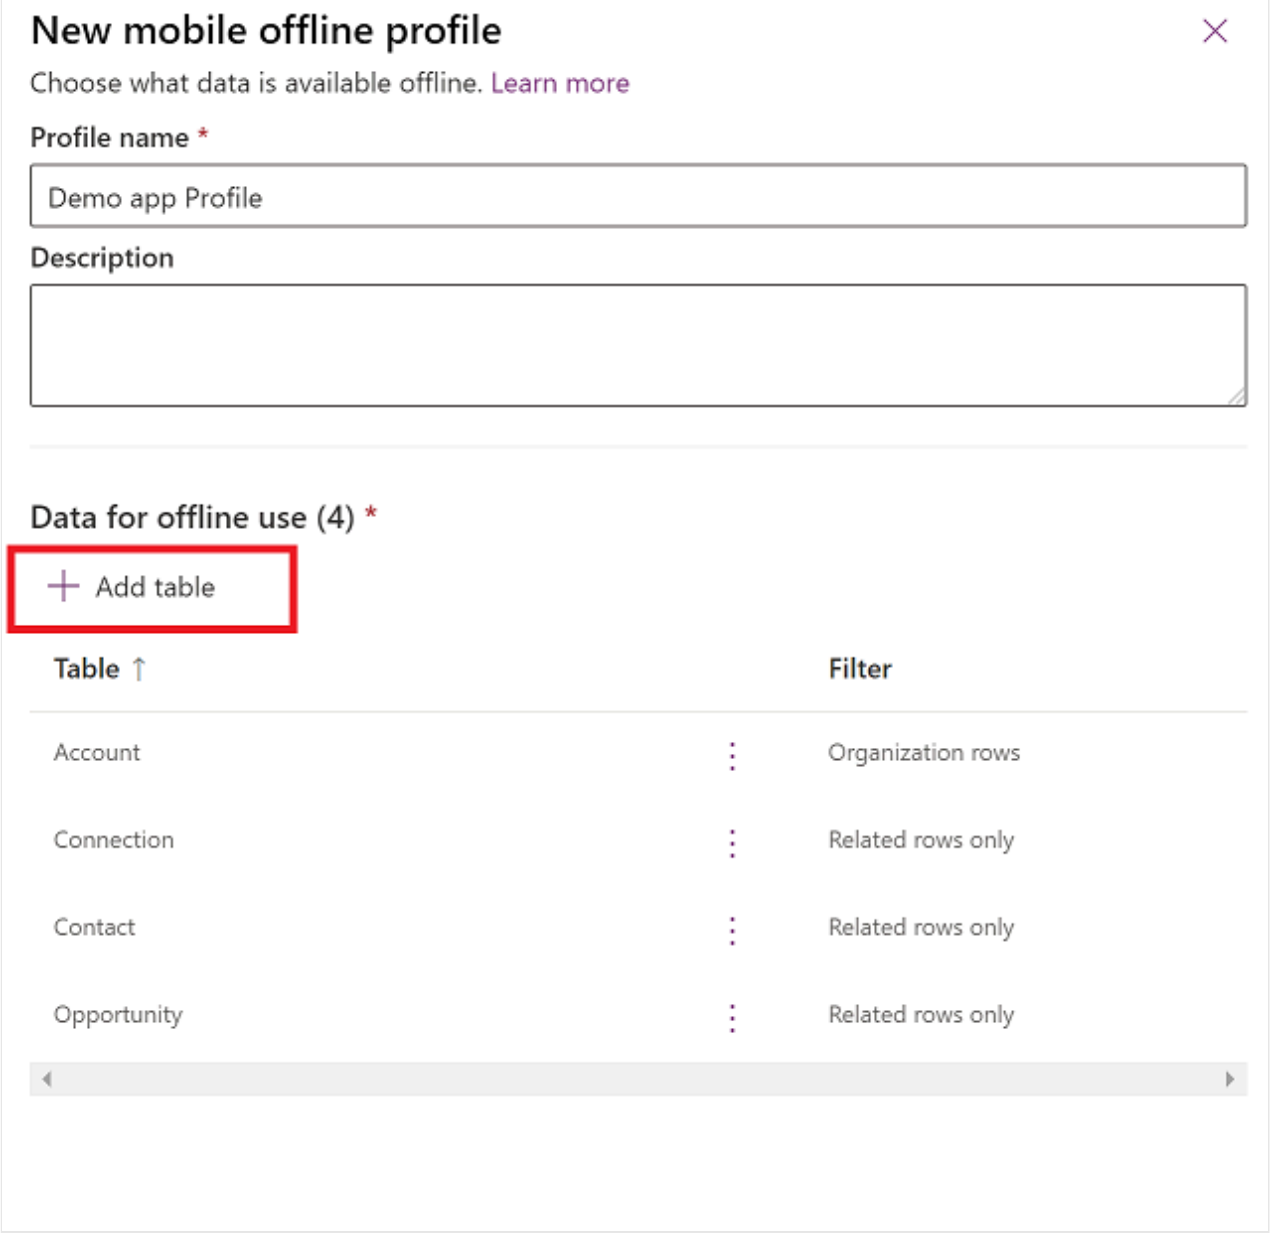
Expand table

Customization	Recommendation
Organization rows - if selected, then select at least one of these options: - **User's rows** - **Team rows** - **Business unit rows**	If you want to define this filter, then you have to pick at least one of the given options. It's highly recommended to not have a business unit-level filter for a table, unless there's a strong justification. It's recommended for a master data scenario with a large data set, like a price list.
All rows	If you're selecting this filter, you can't define any other filter rules.

Customization	Recommendation
Related rows only	Be sure that the related table has been added to the offline profile.
Custom	You can define a custom filter up to three levels deep.

Keep in mind that you can have 15 related tables in a custom filter. You can also have 15 relationships. These are distinct checks that might not add up. The 15-relationships limit is transitive, meaning if table B has N relationships, and you add a reference to table B in table A, then it increases the relationship count of A by N+1; one plus the N already in table B. This limit is per profile item for a table in the profile.

1. Select **Add table**.



2. Choose a table, and then define the filters.

3. Set the following filters:

a. Choose the rows that you want to make available offline. For the **Custom** option, use the expression builder to set up advanced conditions.

b. **Relationships** lists the different relationships available between the current table and other tables added in the offline profile. Selecting a relationship ensures that related rows following that relationship are downloaded and made available offline.

c. **Files** and **Images** define which columns for a file or image need to be downloaded offline. For files, you can choose to download every column or none at all. For images, you can select each column you want to download granularly.

d. **Sync interval** defines the sync frequency to be applied on the device to sync the data with the server. If a table's data doesn't change frequently, like a catalog or a product table, you might want to focus on only syncing data when necessary, such as refreshing only once a day.

   You can only have up to 15 related tables in a profile. If you exceed the limit, you get an error and won't be able to publish the offline profile.

4. Select **Add + save** to add your table and filters to the profile.

5. When all tables are properly configured for the profile, select **Done** > **Publish your application**.

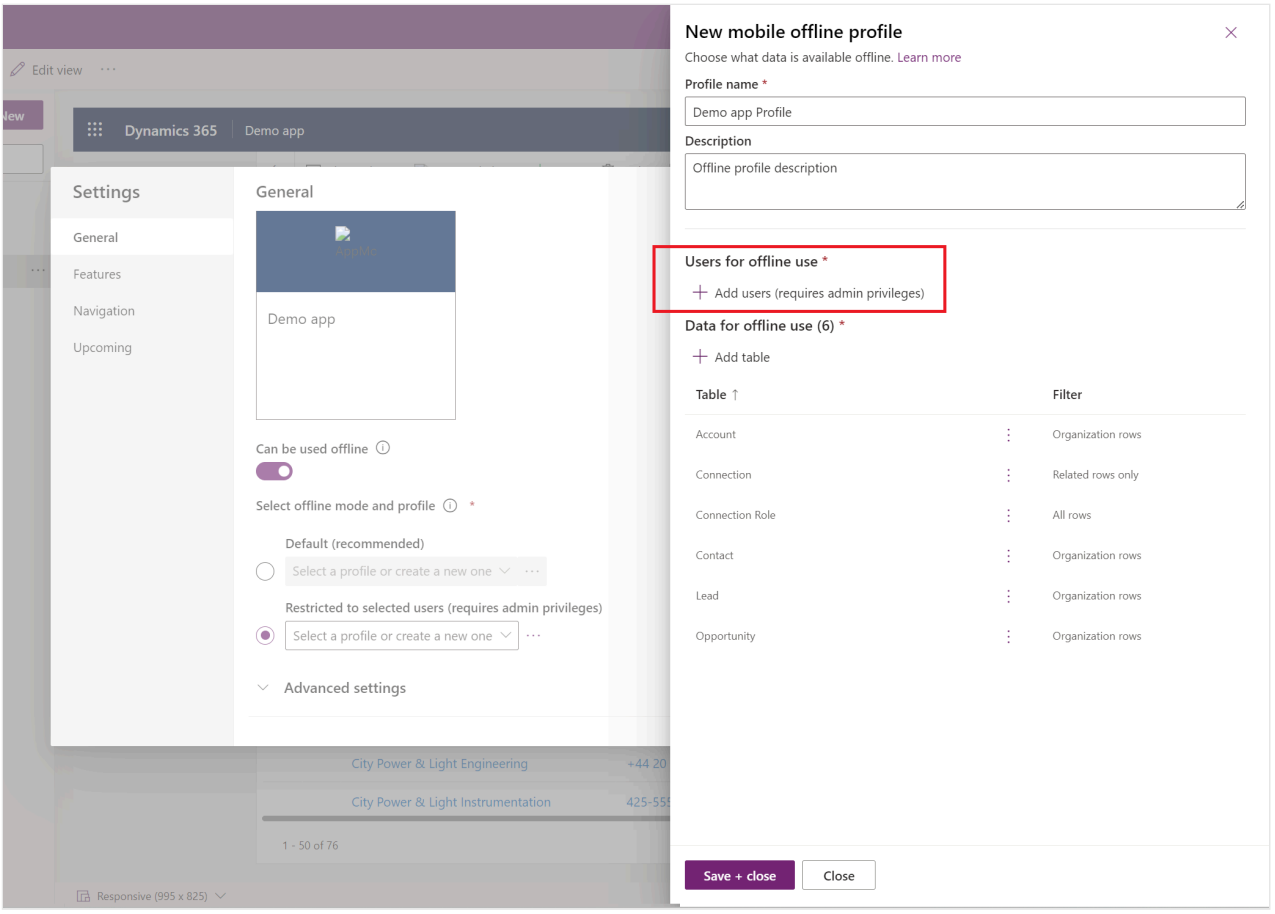
   When the app is published, the app is enabled for offline use.

Add users to an offline profile

If you selected the **Default** offline profile mode, all your users who have access to the app can also use it in offline mode.

However, if you selected **Restricted to selected users**, you have to manually add users (requires admin privileges) to the offline profile. The app is enabled for offline use only for those configured users.

1. Select **Add users (requires admin privileges)**.



2. Sign in to the Power Platform admin center.
3. In the **Users with offline access** area, select **Add users**.
4. Select the users that you want to add to the mobile offline profile. The users that are added, based on teams, are listed under each team. Users that are added individually are listed as individual users.
5. When you're done adding people, select **Save**.

   If you made any changes to a Microsoft Entra ID group team, you must remove and add the team back to the mobile offline profile for the changes to take effect.

Enable mobile offline classic

Offline-first is the default mode when you enable an app for offline use. If you want to switch to the offline classic mode, you need to enable it for your model-driven app. It's a separate app setting for each app.

1. Sign in to Power Apps.
2. On the left pane, select **Apps**, and then select the model-driven app that you want to enable for offline.

3. Select **More** (...) > **Edit** to open the modern app designer.
4. On the command bar, select **Settings**.
5. On the **Features** tab, set the **Enable offline classic** toggle to **Yes**.
6. Select **Save** and then publish the app.

Define sync settings on mobile

You can allow users to control the automatic sync intervals or the connection type to synchronize the data.

1. On the command bar, select **Settings**.
2. Select the **Upcoming** tab:
    - Set the **Allow users to adjust sync frequency** option to **On** to adjust the sync interval to sync more or less frequently depending on individual needs. Users can choose to not automatically sync, if they only want to sync on demand.
    - Set the **Allow users to sync on Wi-Fi only** option to **On** to let users choose if their automatic sync happens on cellular networks and Wi-Fi connections or only when connected to a Wi-Fi network.

Turn on Online mode

Offline-first mode provides the best experience for users in no and low network conditions. Once your data is synchronized, you work with the data on your local device regardless of the network status. However, if your offline profile includes filters, you may not be able to access all the data you could when online in a browser, even when your device is connected to the network.

If it's important for users to access data that's not downloaded to their devices, you can activate the **Online mode** toggle that's visible to users in the Device status page. When users use the **Online mode** toggle, they can access data that's not synchronized to the local device. The toggle can be activated only when the device is connected to a network.

1. On the command bar, select **Settings**.
2. Select the **Upcoming** tab.
3. Set the **Allow users to work in online mode** option to **On** to let users choose if they want to use the app in online mode when connected to a network.

Supported capabilities

- **Business rules**: Business rules are supported in mobile offline. For more information, see Create business rules to apply logic in a model-driven app form.

- **Business process flows**: You can use business process flows in offline mode if the following conditions are met:
  - The business process flow is used in an app that you can run on Power Apps mobile.
  - The Power Apps mobile app is configured for offline use.
  - The business process flow has a single table.
  - The business process flow table is added in the offline profile.

  > ⓘ Note
  >
  > If a table is associated with multiple business process flows, in order for any of the business process flows to work offline, all the business process flows must be added to the offline profile.

  Three commands are available for business process flows when you run an app in offline mode on the Power Apps mobile app:
  - Next stage
  - Previous stage
  - Set active stage

  For more information, see Run business process flows offline.

- **Lookup support**: Lookups are supported for the tables that are configured for mobile offline. All the tables participating in the lookup should also be configured for offline use.

- **Notes on the Timeline control**: Notes on the Timeline control are available in offline mode. You can take pictures, read notes, and add/remove attachments in offline mode. You need to add the **Note** table using the **Related rows only** option and the User (systemuser) in the offline profile.

  > ⓘ Note
  >
  > The **Date** field isn't available for mobile offline search.

- **Custom tables**: These commands are available to edit the form: **Mark Complete**, **Refresh**, **Convert To Opportunity**, and **Delete**.

Configure files and images in offline model-driven apps

Article • 05/29/2024

To work with file and image columns in offline mode, you need to add them to your mobile offline profile.

This article helps you configure a mobile offline profile that has a table with a column where **Data type** is set to **File** or **Image**.

View column properties for a file or image

1. Sign in to Power Apps.
2. In the navigation menu, select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the table that has the columns you want to view.
4. Under **Schema**, select **Columns**.
5. Select the **Display name** of a column where **Data type** is set to **File** or **Image**.
6. The column properties show the **Data type**. Expand **Advanced options** to view the maximum size for a file or image. For more information about columns, see Columns overview.

Add file and image columns to mobile offline

Add the column where **Data Type** is set to **File** or **Image** to your mobile offline profile to make files and images available in offline mode.

1. Sign in to Power Apps.
2. In the left navigation pane, select **Apps**.
3. Select a model-driven app and on the command bar select **Edit**. This opens your app in editing mode in model-driven app designer.
4. Select **Settings** > **General**.
5. Set the **Can be used offline** toggle to **On**.

6. Under **Select offline mode and profile**, select **Edit selected profile** from the "...".
7. Find the table that contains the file or image column to enable for offline, and then select **Edit** from the **More actions** button.
8. In the **Include these files and images** section, select the column where **Data Type** is set to **File** or **Image** (the columns are grouped by **Files** or **Images**).
9. Select **Save**.
10. Save and publish the app.

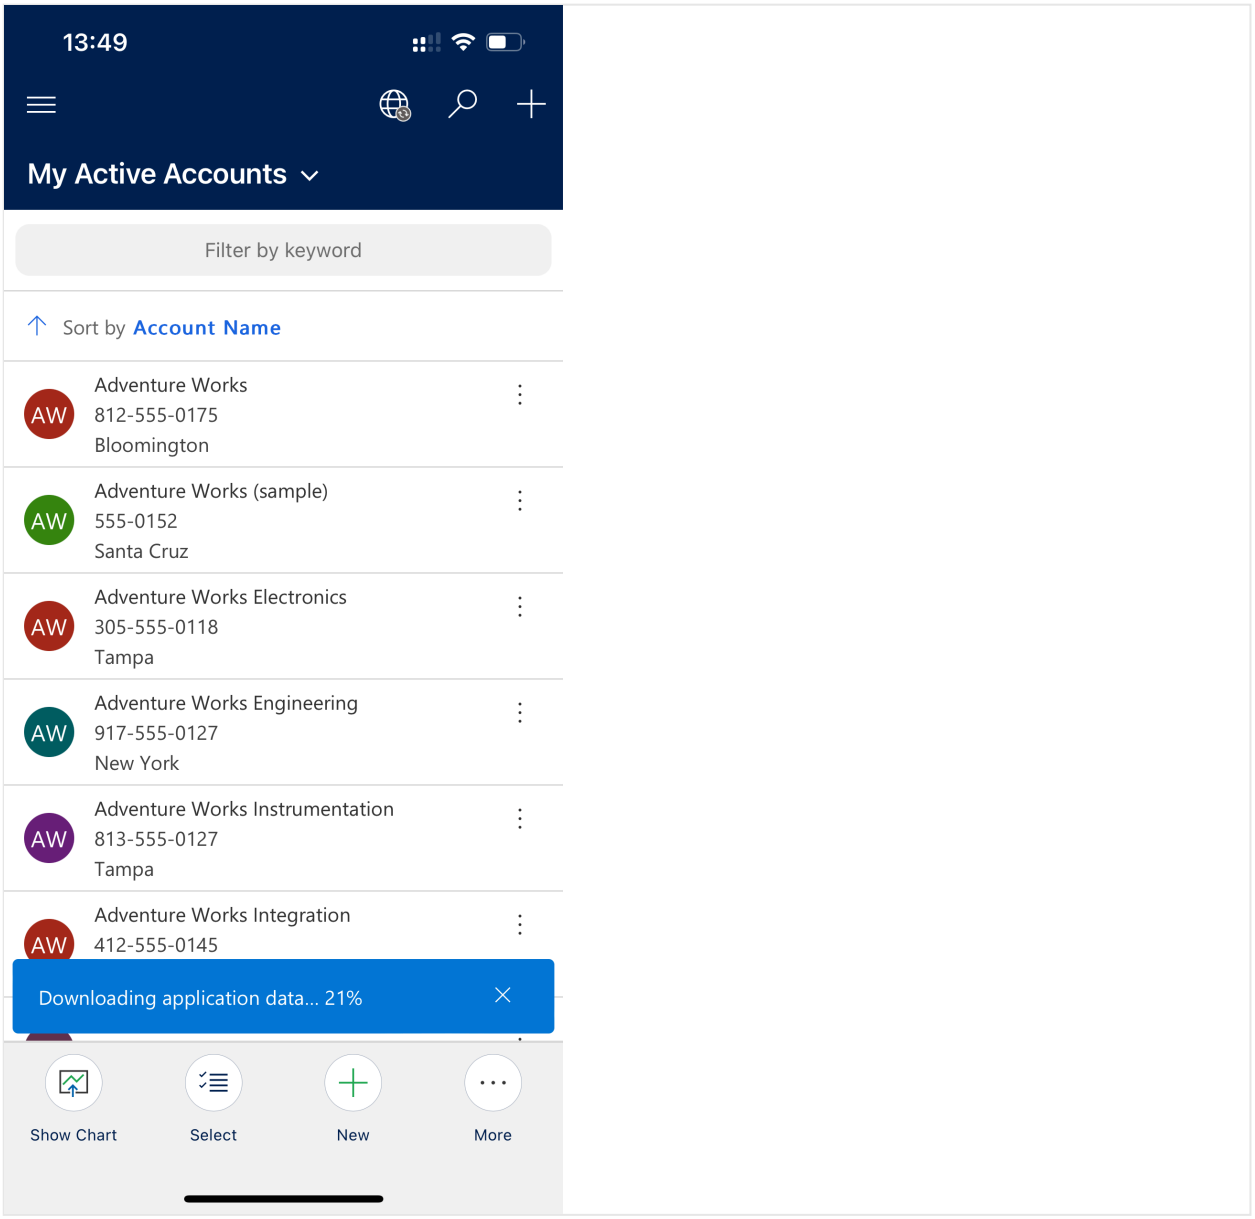
Work with model-driven apps offline (offline-first mode)

Article • 07/23/2024

For a model-driven app to be available in offline mode, app and user data must be downloaded on your device. This process is called *initial offline sync*.

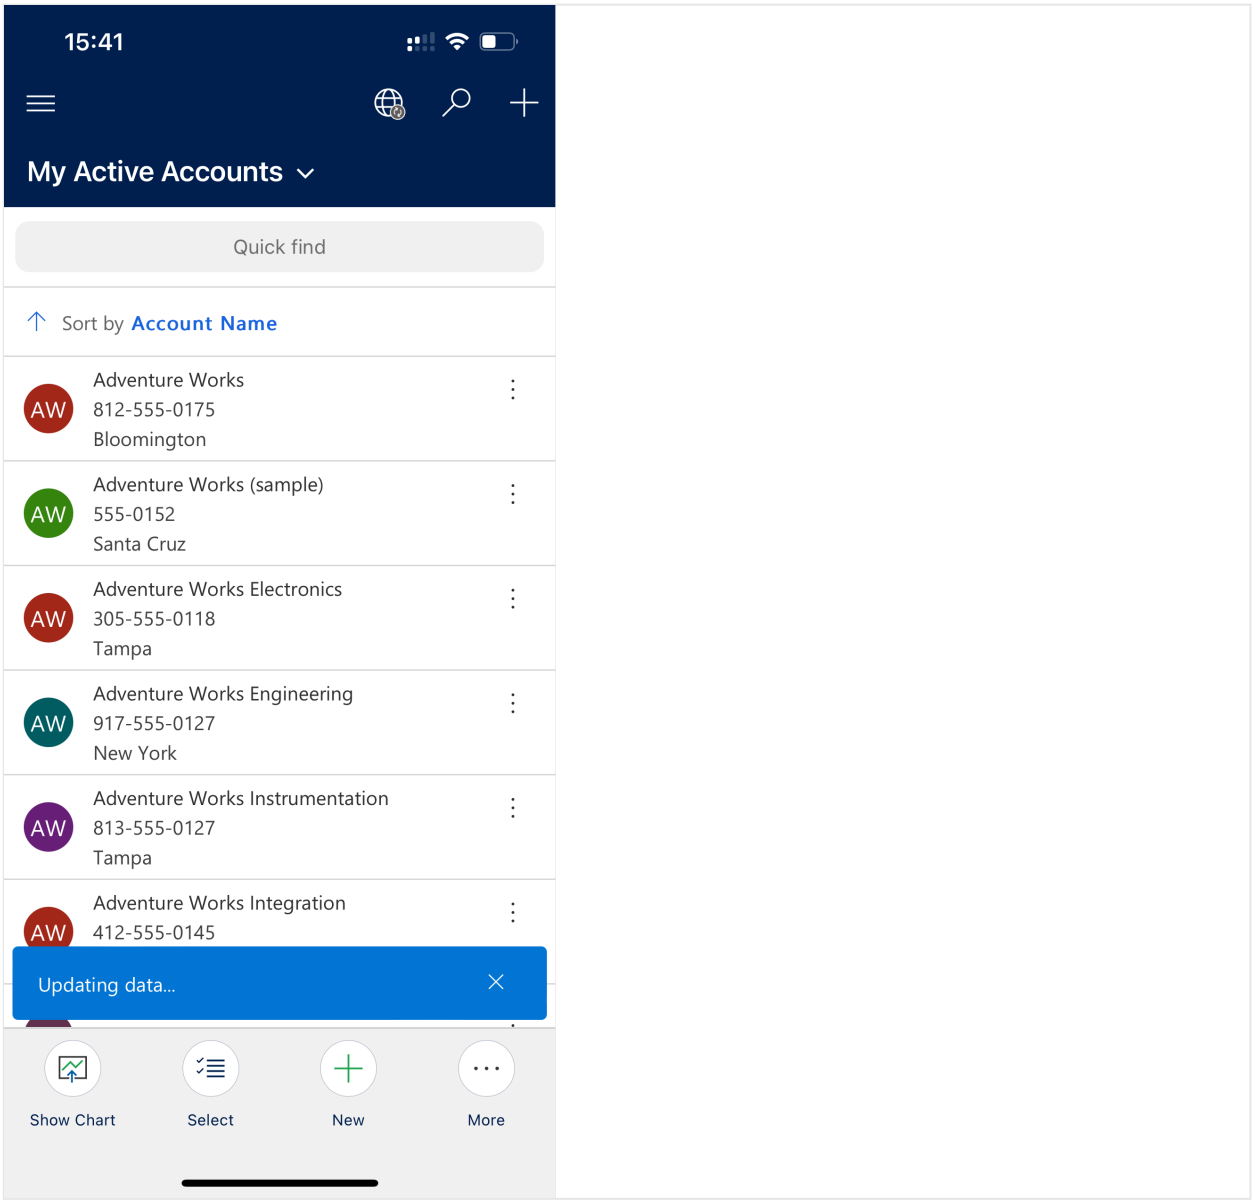
The app data includes all the resources needed for the app to run properly. User data includes data stored in Microsoft Dataverse tables configured in the offline profile.

During the initial offline sync, you receive a notification stating that your app is syncing the offline data with the number of rows downloaded. The notification also indicates how much disk space is used. The initial offline sync can take a few minutes or longer, depending on what is configured in the offline profile. If the initial offline sync isn't complete, it triggers every time the app is opened. You also get the same notification when you resume the app after a long period of inactivity.



When the initial sync is completed, you can start using the app in offline mode.

When you refresh your data on a grid view, you get a notification stating, **Updating data....**



The sync status is always available, at a glance, with the **offline sync** (globe) icon. For more information about offline sync status, see Offline sync icon.

Work with model-driven apps offline (classic mode)

Article • 07/23/2024

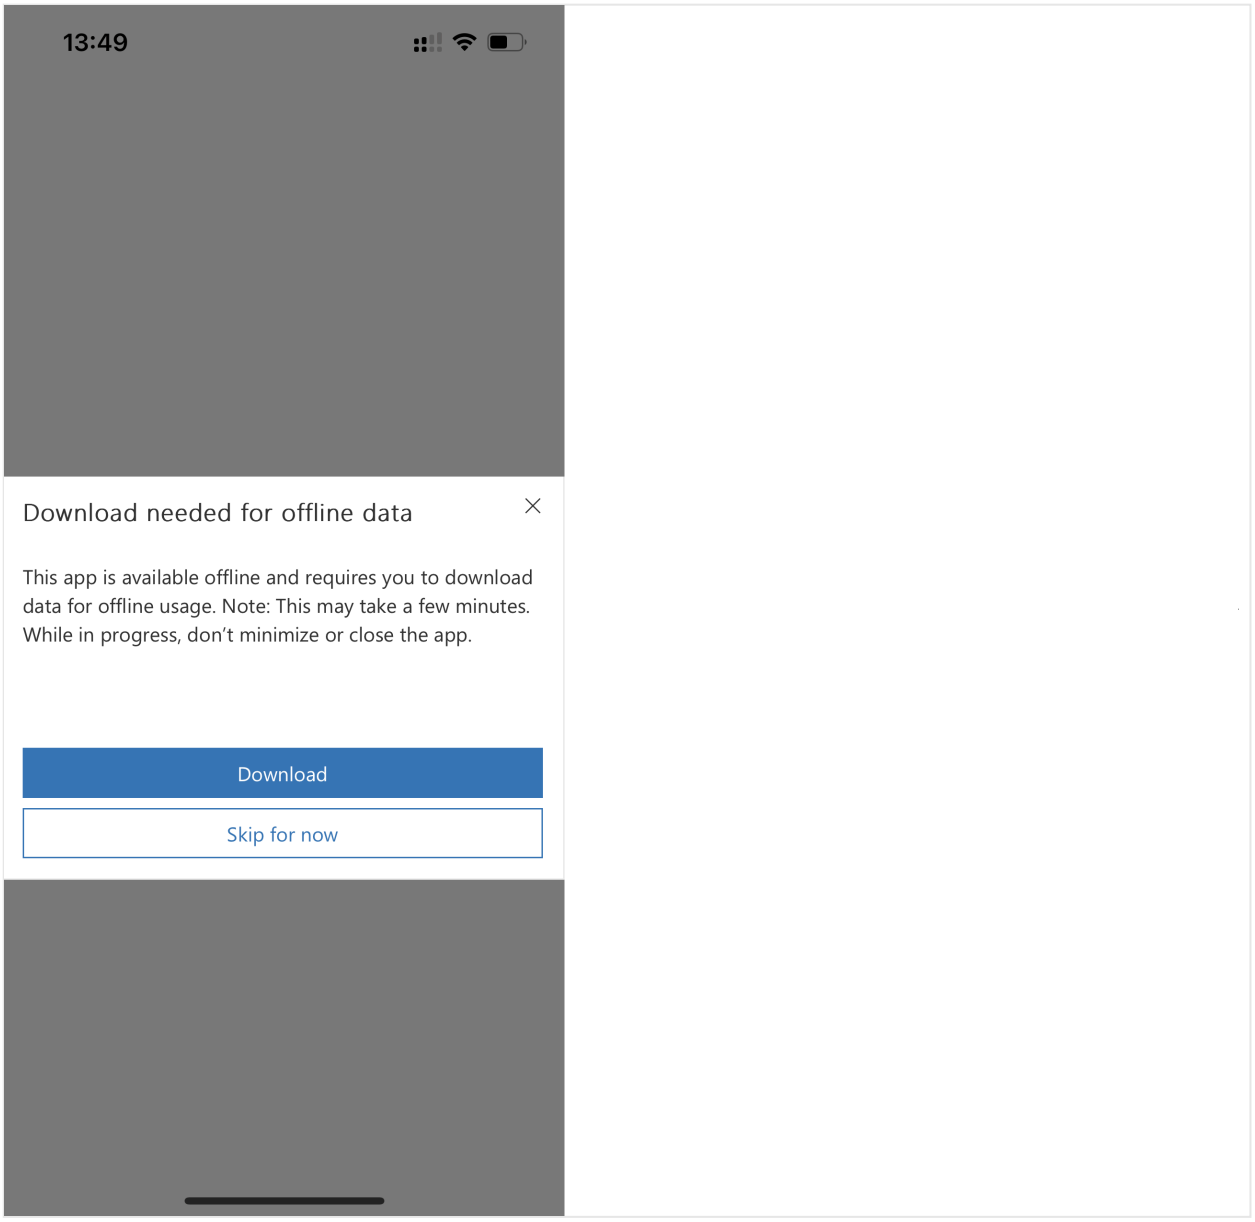
You can work with your data even when you don't have internet access by using the app in offline mode. The mobile app provides a rich offline experience that lets you work with commands like create, read, update, and delete, so you always stay productive. After you're back online, changes are synchronized with your apps in the Microsoft Dataverse environment.

If you're working on a record and lose your network connection, any updates made to the record are saved in offline mode and will be synchronized to the app after you're back online. When the record is synchronized with the app, it uses the filters, added on the table in the offline profile, for availability in offline mode.

Download updates to work in offline mode

When your admin enables mobile offline classic mode, you are prompted to download offline updates. After downloading the updates, you can start using the app on your mobile device in offline mode.

When you see the dialog box that asks you to download updates to work offline, select **Download**.



Offline data starts downloading as you continue to use the app. Data is downloaded while the app is active, so keep your phone unlocked with the app visible until the initial download is complete. The data can be downloaded in the background depending on the platform you use.

Download offline data later

If you don't want to download offline data and select **Skip for now**, you can't use the app in offline mode until you manually download the updates.

1. On the screen, select the **offline sync** (globe) icon.
2. On the **Device Status** page, select **Download offline updates**.
3. The download starts, and the status changes to **Initializing**.

4. When the download of offline data is complete, you get a notification that you can start working in offline mode.

See whether offline mode is available

When offline updates are complete, you can check to see whether mobile offline mode is available. On the home screen, select the **offline sync** (globe) icon and check on the Device Status page.

Work in offline mode

After the offline download is complete, you can use the mobile app in offline mode.

When you have no connectivity, you automatically have access to the downloaded data so you can continue working while you're on the go. The data automatically syncs with the server as soon as connectivity is restored.

When you have intermittent connectivity, we recommend that you switch to offline mode. As long as offline mode is turned on, the updates you make on your device aren't synced with the server and you can continue working with the local data on your device. To push the changes made to the server and refresh your local data, turn off the **Work in offline mode** toggle.

To work in offline mode, complete the following steps:

1. On the screen, select the **offline sync** (globe) icon.
2. Turn on the **Work in offline mode** toggle.

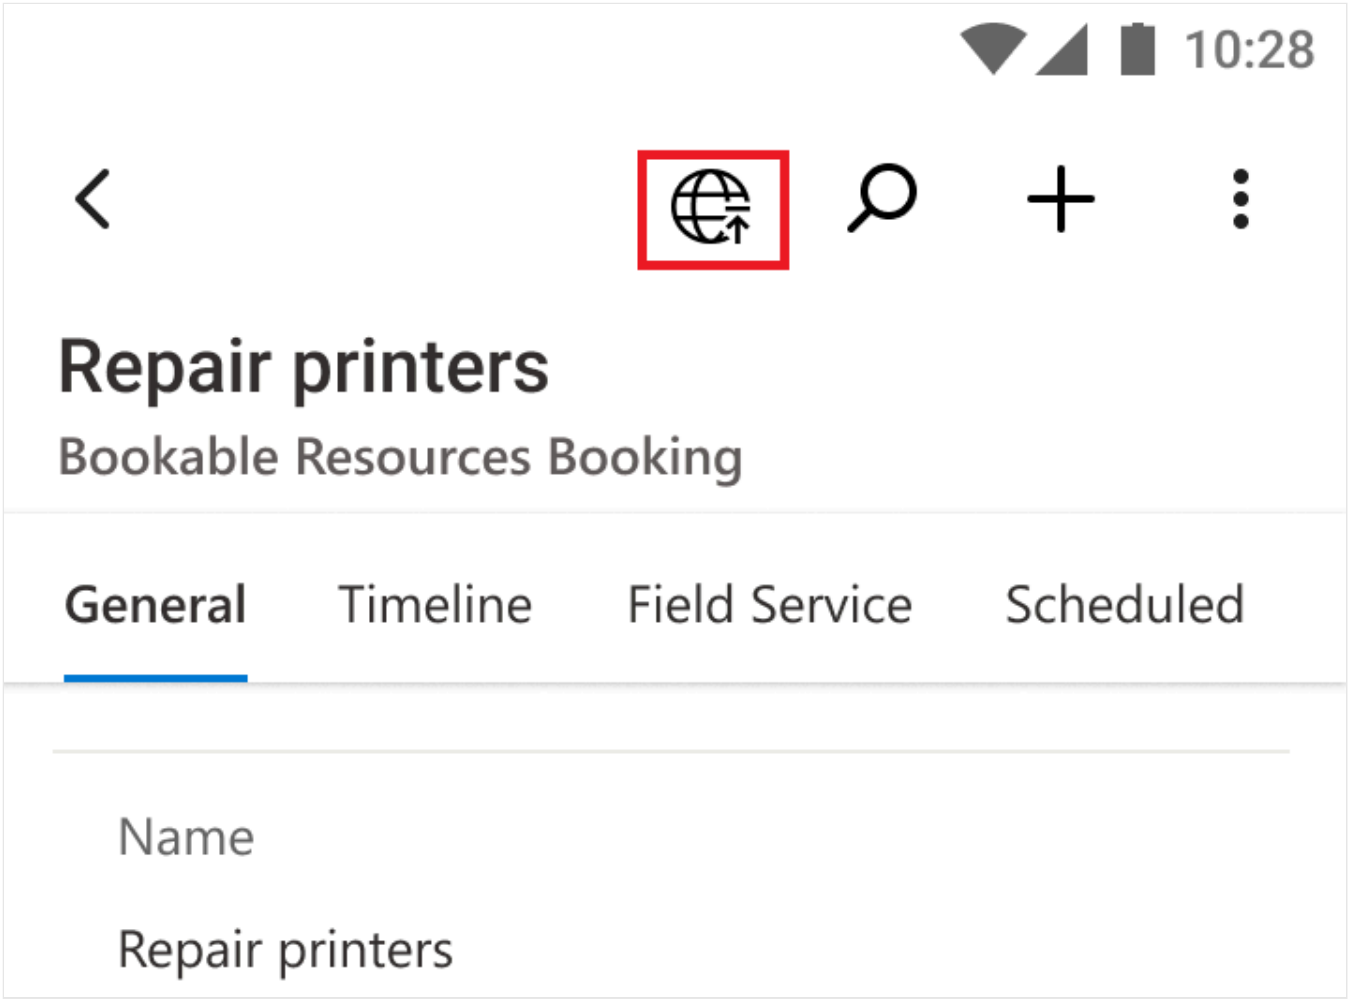
View offline sync status

07/11/2025

The **offline sync** (globe) icon indicates the synchronization status of the Power Apps mobile app. At a glance, you can tell whether:

- The app is connected to the network
- A data refresh is in progress
- Updated data on the device is waiting to synchronize with the server
- The app experienced an error or warning while syncing

The offline sync icon is always visible in the main app navigation bar on iOS, Android, and Windows devices. (It's not visible in web browsers.)



Sync status icons

The **offline sync** (globe) icon changes based on the app's sync status. The following table describes the possible sync states and the icons associated with them.

Expand table

Icon	Description
	The app is connected to the internet.
	The app isn't connected to the internet.
	The app is syncing data.
	The app has pending changes to upload.
	The synchronization process encountered an error.
	The synchronization process encountered a warning.

Types of offline syncs

Data is synchronized from Dataverse to your device over the lifetime of your app using several synchronization modes.

- **First sync**: This offline sync is the initial offline sync that occurs for the Power Apps mobile app. All data in the offline profile is downloaded to the device. A user must use the Power Apps mobile app in online mode until the first sync is completed.

  The first sync, which is the longest, is triggered when you sign in to the Power Apps mobile app. It also triggers after using the Reconfigure action (not recommended).

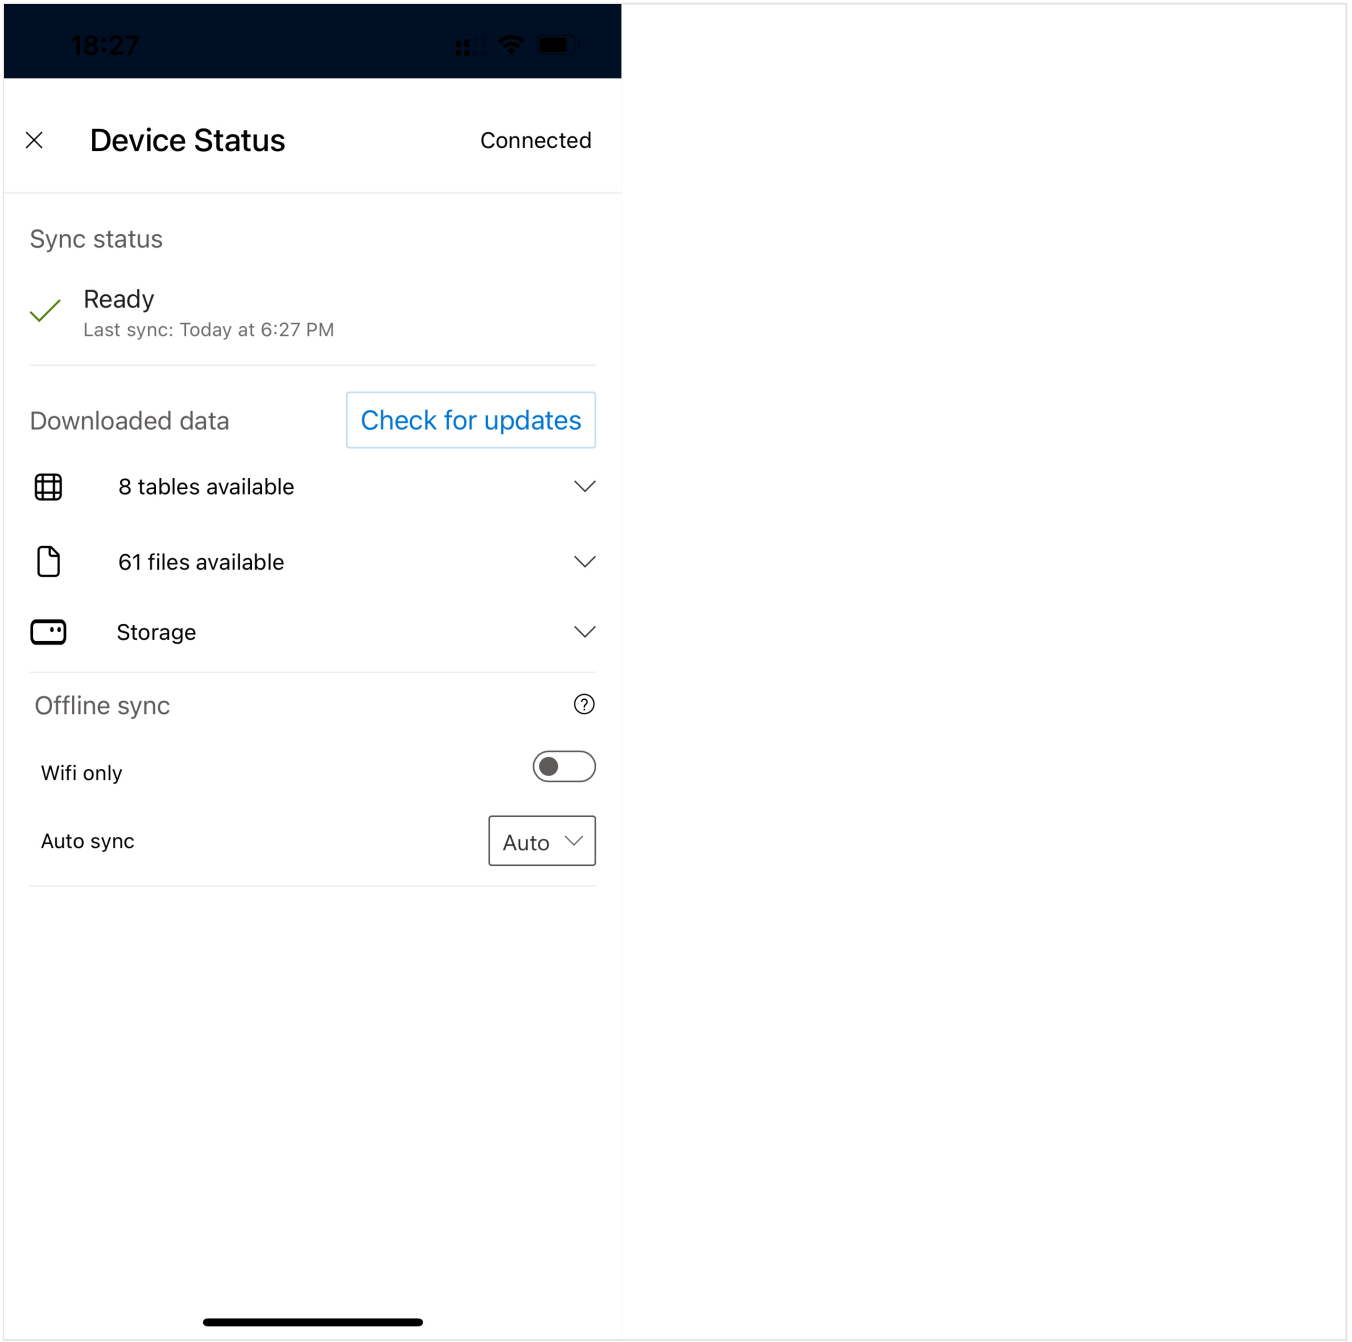
- **Delta sync**: This offline sync is faster than the first sync and occurs regularly based on the offline configuration for the organization. For example, a delta sync could occur every five minutes. Only data that changed since the last sync downloads to the mobile device.

- **Full delta sync**: When you select **Refresh** on the **Device status** page, you trigger a full sync. A full sync doesn't redownload data, but it does recheck every record on the device, so it might take longer than a regular delta sync.

- **Grid sync**: If you select **Refresh** on a grid or calendar view, the app immediately synchronizes all tables visible in the view. When the sync is complete, the view refreshes automatically.

Device Status page

When you select the offline sync icon, the **Device Status** page opens. The **Device Status** page provides details such as the network status, what data was downloaded, whether data is waiting to be uploaded, or the amount of storage the app uses.



Sync status

The **Sync status** area of the page tracks the overall offline status of the app. If the status is in error, see Troubleshoot offline sync errors and the **Downloaded data** area provides the status of each individual table. When the status appears as **Available**, offline mode is available and data synced successfully.

The status can be **Not available** due to an error during the first sync or if you dismissed downloading offline data (only applies to offline classic mode). If the status is **Not available**, try downloading the updates again.

You can use the **Device Status** page to see the number of files and images to be downloaded and the current progress in the **Files available** section.

Offline sync settings

If your admin activated sync settings for the app, you can control when offline synchronizations are triggered.

- Set the **Wifi only** setting to **On** to sync your data only when the device is connected to a Wi-Fi network. Turn on this setting to reduce cellular data and battery usage, especially in low-network areas.
- If you want to sync less frequently, change the sync interval value from the **Auto sync** setting. You can keep the default value, as defined by your admin, by selecting **Auto** or you can pick a longer interval that meets your needs. If you choose **Manual**, the sync only happens when you select the **Check for updates** button in the **Device Status** page.

Online mode

If your admin activated online mode for the app, you can temporarily switch the app to online mode.

If you want to access online data directly from the server and your device is connected to the network, set the **Online mode** setting to **On**. In this mode, the app loads data directly from the server in grids, forms, and search pages. You can change back to offline mode anytime by setting the **Online mode** to **Off**. If you close the app and open it again later, **Online mode** is automatically reset to **Off**.

When you work in online mode and the device loses network connectivity, you see the notification: **Network disconnected. Switch to offline mode to continue working with the app.** Use the **Switch** button to open the **Devices Status** page and set **Online mode** to **Off**.

Notifications

On iOS, Android, and Windows devices, app sync notifications are consistent across the different sync states.

Known issues

- The first time the app syncs, the offline sync icon continues to spin until the user switches from online mode to offline mode.
- If the app has pending changes to upload, the number shown is the total of individual updates applied to rows, files, and images in your app, as opposed to the number of updated rows, files, and images.

Related information

Troubleshoot offline sync errors in the Power Apps mobile app

Sync data offline in the background

06/25/2025

To use an app in offline mode, download the app and sync data to your device.

You can sync data reliably only when the Power Apps mobile app or Field Service app is open, running in the foreground, and your device screen is unlocked. Learn more about sync behavior in Work with canvas apps offline.

The background sync can be enabled on Windows by changing the **Let this app run in the background** setting.

- If you're using Windows 10, see Manage background activity for apps in Windows for more information.
- If you're using Windows 11, complete the following steps:

    1. Go to **Settings** > **Apps** > **Installed apps**.
    2. Next to **Power Apps** or **Field Service**, select the **More options** icon (three horizontal dots). Then select **Advanced options**.
    3. In the **Background apps permissions** area, go to the **Let this app run in the background** setting. Select **Power optimized (recommended)** from the list.

Mobile offline limitations for model-driven apps

Article • 09/26/2024

Before you set up the mobile app in offline mode, be sure to read through the following limitations. We recommend that you also review the Offline best practices and the Offline profile guidelines.

These tables and corresponding permissions are available in offline mode.

> **Note**
>
> Custom permissions and default permissions without the **Mscrm.IsEntityAvailableForUserInMocaOffline** rule won't be displayed in offline-first apps. Learn more in A button on the command bar is hidden when it should be visible in Power Apps.

Expand table

Table	Permissions
Account	Create, Read, Update, Delete
Activity Pointer	Read, Delete
Appointment	Create, Read, Update, Delete, Convert Activity Case
Attachment	Read only
Case	Create, Read, Update, Delete
Competitor	Create, Read, Update, Delete
Competitor Address	Create, Read, Update, Delete
Connection	Read only
Connection Role	Read only
Contact	Create, Read, Update, Delete
Custom table	Create, Read, Update, Delete
Email	Read only

Table	Permissions
Lead	Create, Read, Update, Delete, Qualify/Disqualify
Opportunity	Create, Read, Update, Delete
Opportunity Product	Create, Read, Update, Delete
Phone Call	Create, Read, Update, Delete
Position	Create, Read, Update, Delete
Product	Read
Task	Create, Read, Update, Delete
Team	Read only
User	Read only
Bookable Resource Booking	Create, Read, Update
Work Order	Create, Read, Update
Work Order Product	Create, Read, Update
Work Order Service	Create, Read, Update
Work Order Service Task	Create, Read, Update

Feature limitations

- **Number of records synced**: The total number of records synced is limited to 3,000,000. Attempts to sync a larger number of records fail. This number also includes hidden tables used for offline capabilities.
- **Security model**: Field level security and field sharing aren't supported in Mobile offline mode.
- **Qualify a lead**: When a lead created in mobile offline is qualified and when the user goes online, the business process stage shows the qualified stage. The user has to manually select **Next stage** to move to the next stage.
- **Grids**:
  - Column filtering is disabled when an offline profile is set up even when there's network connectivity. The grid works with the local database and doesn't support custom filters.

  - Primary image thumbnails aren't available for offline unless they were previously displayed online.
  - Custom icons alongside values in grids aren't available for offline. For more information about this capability, go to How to display custom icons.

- **Supported type of views**: Only system views and quick views are supported in mobile offline. Personal views aren't supported.

- **Views** aren't supported for the following tables in offline mode:

  - Email
  - Task
  - Fax
  - Letter
  - Serviceappointment
  - Campaignresponse
  - Campaignactivity
  - Recurringappointmentmaster
  - Socialactivity

  Any views that have linked tables (related table) that aren't available offline are also not supported.

- **Advanced lookups**: The Advanced lookup functionality isn't supported in offline scenarios. When you're offline, the **Advanced lookup** button is replaced by a **Change view** dropdown list.

- **Add Existing on subgrids**: The **Add Existing** functionality isn't supported for mobile offline for certain types of relationships. When you're offline, certain relationships such as relationships that are N:N are read only, and the **Add Existing** command is hidden on subgrids for those relationships. Even if the button is unhidden via customization, the command doesn't work in offline.

- **Web resources**: Web resources are partially supported in offline mode. For more information, see the following table.

Expand table

Web resource configuration	Offline support on Android and Windows	Offline support on iOS
Web resource used on form handlers, form scripts, and ribbon commands	Supported (File names should be in lower case.)	Supported (File names should be in lower case.)
JavaScript files referenced within an HTML web resource	Supported	Not supported. Web resources may be available offline in some circumstances if they're retrieved while online and cached by the browser.
HTML, JS, CSS, XML web resources embedded on a model-driven app form	Supported	Not supported. Web resources may be available offline in some circumstances if they're retrieved while online and cached by the browser.
Other web resources embedded on a model-driven app form (like images, RESX, and so on) **Note**: The Dataverse file and image attributes aren't web resources but regular Dataverse data. To enable them offline, see Configure files and images in offline model-driven apps.	Not supported**	Not supported**
Webpage (HTML web resource) via a model-driven app's sitemap	Not supported	Not supported
Custom JS files that create a fetchXML dynamically	Not supported	Not supported

** Accessing RESX web resources as a dependency through Client API from within a JS file is supported.

> **Note**
>
> For the best compatibility across platforms, use one of the following recommendations instead of HTML web resources:
>
> - If the web resource is a user experience component, use a PCF control.
> - If the web resource doesn't present in the user interface, use form handler events which are available offline on all platforms.

- **Calculated and rollup fields**: Calculated and rollup fields that are part of rows synced to the client aren't reevaluated by the client. The reevaluation happens on the server when the updated row is synced.
- **Mapped fields**: When you run an app in offline mode, mapped fields aren't prepopulated when you create a new record from a table that has fields mapped to another table.
- **Lookup fields**: The value of a lookup field may not be updated in a form or grid when the display name of the lookup item is updated.
- **Filter operations**: Not all filter operations are supported in offline mode. For a full list of supported operators, see Supported Filter Operations Per Attribute Type in Mobile Offline using FetchXML.
- **Appointments**: Appointments can be created or updated in Dataverse, but they're not sent to recipients with server-side synchronization. For more information, see Appointment table/entity reference and Server-side synchronization tables.
- **Work order service tasks**: Work order service tasks created through *custom* code require msdyn_lineorder to be set to -1. An actual value will be automatically set after the next synchronization cycle.
- **Quick find search**: When you search offline, the results might be different from online searches. Characters in your search terms must match exactly when searching offline, while online equivalent results might be found.
- **Offline search**: Offline search is available only for offline tables. Users can only search one table at a time. Global search defaults to a categorized search in offline mode, even if Dataverse search is turned on and there is network connectivity, as Dataverse search isn't supported in offline mode. On grid pages, view-based search (filter by keyword) isn't supported in offline mode and grid search switches to a quick, find-based search.
- **Duplicate records**: The experience of detecting duplicates and merging them isn't supported in offline mode.

Profile filters limitations

Expand table

Profile details	Limitation
Relationship defined for each table	A maximum of 15 relationships is allowed. There's also a maximum of one many to many (M:M) or one to many (1:M) relationships within those 15 relationships. If any custom tables demand this scenario, then revisit the data model. No circular references or self-references are supported.
Images and files	Images and files are subject to the same limitations as any other table. Because of implicitly defined relationships, an offline profile can only contain up to 14 image columns, across all entities.

Organization data filter

> **ⓘ Important**
>
> Organization data filters are no longer used. Changes to filters should be edited within the mobile profile itself.

It's recommended that you have at least one rule defined for all mobile offline-enabled data filters if you're using tables across profiles. By default, this value is set to last 10 days for most of the offline-enabled tables.

Best practices for developing an app for offline use

Article • 06/04/2024

This article provides recommendations for how to create the best experience for users of apps configured for offline use.

- If you configure a canvas app for offline use, you need to optimize how the app fetches data from the data source. Learn more: How to create the best offline user experience in canvas apps
- To function offline, an app must initially download all necessary assets, including resources and data, to operate independently of a network connection. This process is a one-time setup task that occurs during the app's first use. The speed of this initial download is influenced by the volume of data downloaded to the device, which is determined by the offline profile settings and the quantity of data available to the user within the app's environment. For a seamless, initial experience, it's advisable to plan your offline app rollout.

How to create the best offline user experience in canvas apps

Use the following recommendations to create a fast user experience for specific scenarios.

Expand table

Scenario	Approach that's not recommended	Recommended approach
Show related tables information in a gallery.	Use a look-up to fetch the data.	Use a view containing the columns of the related table.
Create a filterable gallery with a lot of records.	Load the records from Dataverse and store them in a collection. Set the items of the gallery to the filtered collection.	Directly set the items of the gallery to the Dataverse-filtered data.
Update multiple records.	Loop the records and patch them individually.	Bulk patch a collection containing all the modifications.

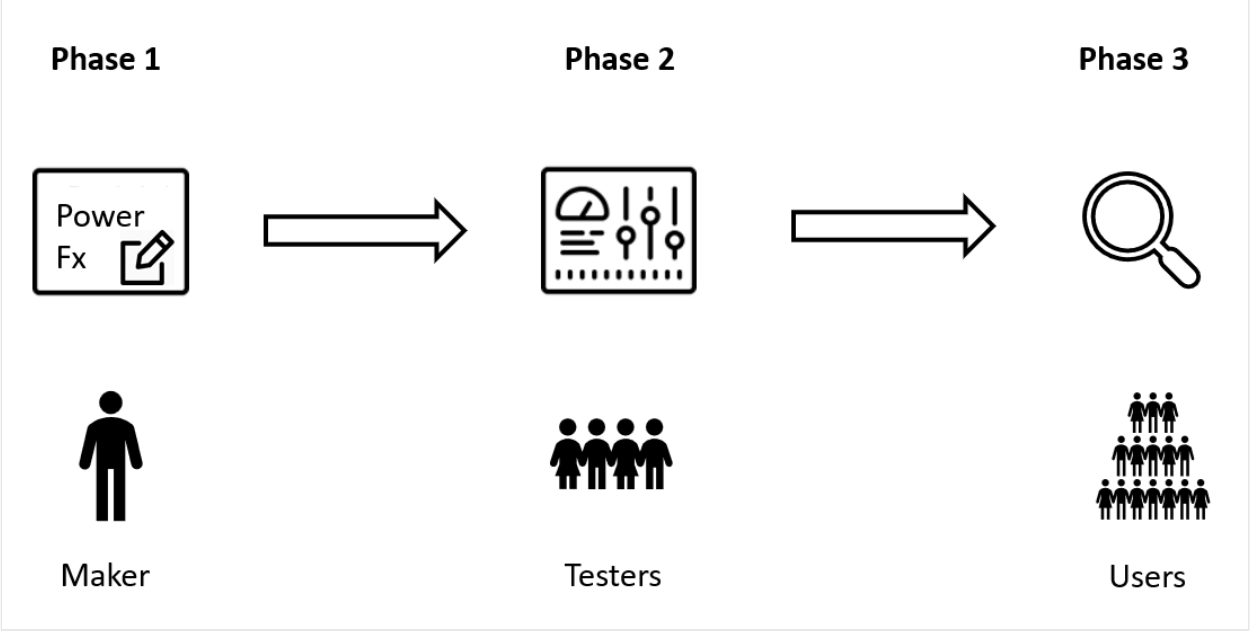
Diagnose mobile offline canvas apps with Monitor

Monitor is a tool that offers makers a deep view of what an app does and how it does it by logging all key activities that occur in the app as it runs. You can connect a mobile app session to Monitor to better diagnose and troubleshoot issues faster.

Plan your offline app rollout

> **Important**
>
> If you're using an **auto-generated offline profile** (available for canvas apps only), and if the first synchronization is taking too much time, you should create a manual, offline profile by using the following best practices.

Develop and roll out your offline app in three phases.



Phase 1: Develop and iterate

After you've set up mobile offline for canvas apps or set up mobile offline for model-driven apps, it's time to start testing and tweaking. Use Power Apps mobile or Field Service Mobile to determine how the app behaves when it's offline. For Windows, you'll find the Power Apps for Windows app in the Microsoft Store that allows iterating without the need for a mobile device.

In this phase, you'll add tables and apply filters to existing tables to make sure that the right data is downloaded to the app, following the guidelines to Optimize the offline profile.

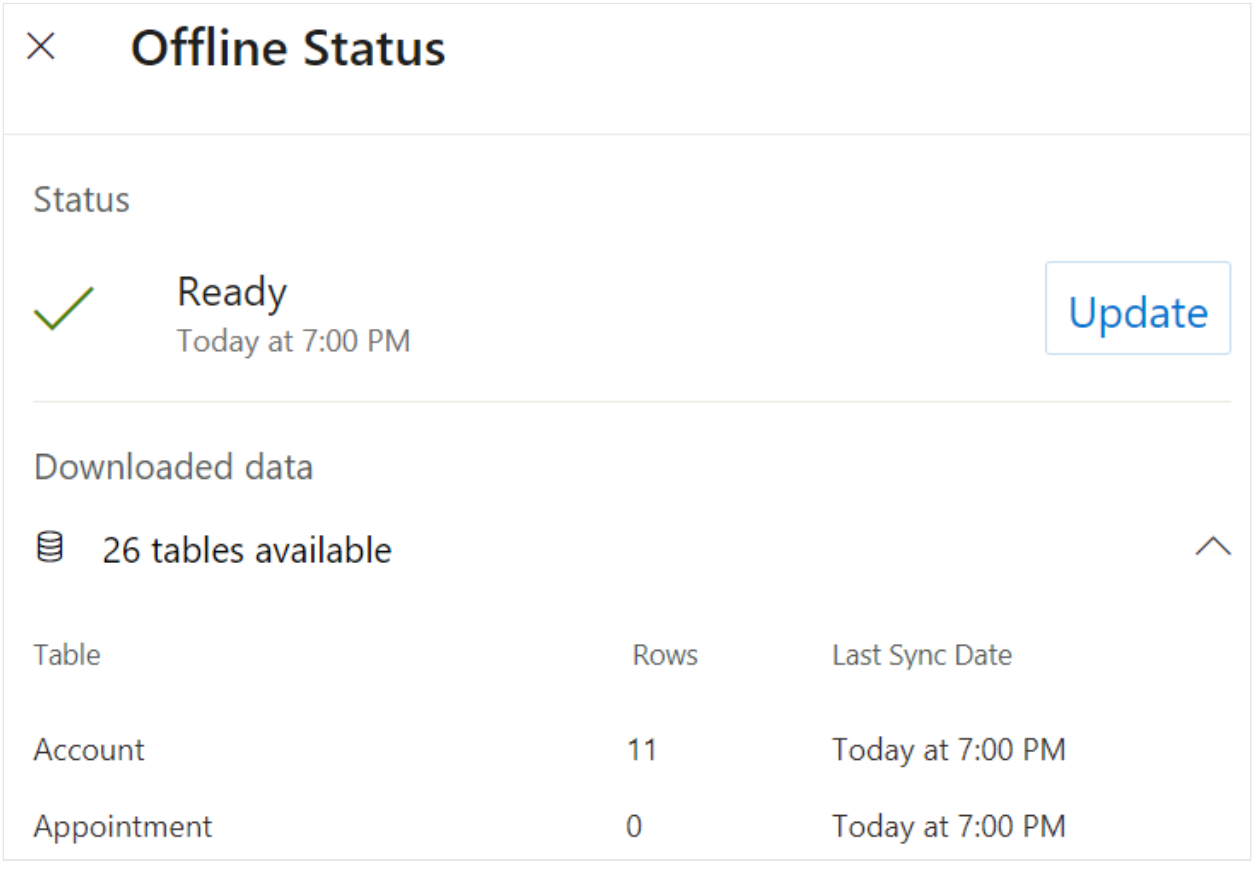
Outcome

You confirm that all the tables and forms work offline after the data is downloaded and that download sizes are reasonable.

> **Important**
>
> The metadata for the model-driven app is retrieved when the app starts. This means that if you change a component in your app, such as a form component or view, then you need to restart the app for the profile to reflect the changes.

Phase 2: Test with users

Ask a few users to test the app with real data. Make sure the offline profile scales for different types of users and works on devices with varying storage capacities. Check the **Device status** page (available out of the box in model-driven apps) for each user. For more information, see Using the Offline template and offline status icon. Adjust the filters in the offline profile to increase or decrease the amount of data that's downloaded.



Outcome

You confirm that the offline profile scales to real-use cases. If not, optimize the offline profile.

Phase 3: Roll it out

Deploy the app to the rest of your organization.

Outcome

You confirm that each class of user in the rollout is able to sync successfully and work offline.

Don't miss the data your users need

Test whether your users have all the data they need. Compare the data available when the app is online and when it's offline. With the device in airplane mode, make sure the views and forms show the same data as in a web browser online. If there are differences, either adjust the filters in your views or adjust the filters in your offline profile.

Add related tables if your app needs them

- **Business process flows**: If a form contains a business process flow, be sure to add the business process flow table. For more information, see Supported capabilities.
- **Files and images**: If your offline profile contains files and images, add tables for them. For more information, see Configure files and images in offline model-driven apps or Configure files and images in offline canvas apps. Use custom filters to limit the download of critical files.
- **Timeline**: To make notes on the timeline control (for model-driven apps only) available offline, add the **Notes** table and the **Users** table to the offline profile. Notes can be large if users upload images and videos, so apply custom filters to the **Notes** table to limit download times.

  > **Important**
  >
  > Data downloads may be slower if users upload files larger than 4 MB to the timeline control. If users need to upload files larger than 4 MB, use the quick notes control in Field Service or **Files/Images** instead of the timeline to improve performance.

Tips on mobile offline synchronization

- Mobile offline synchronization with mobile devices occurs periodically. A synchronization cycle could last for several minutes, depending on Azure network latency, the volume of data that's set for synchronization, and mobile network speed. Users can still use mobile apps during synchronization.
- The time for initial metadata download is determined by the number of total tables in offline-configured app modules. Make sure to configure only those tables and app modules for offline that are necessary to optimize the experience for end users.
- Ensure that any view that you want to work offline doesn't reference tables that aren't configured for offline use. For example, assuming **Account** is in the offline profile, then an **Account** view that references the primary contact when **Contact** isn't in the profile, isn't available.
- Changes to a user's security privileges are updated during the next synchronization cycle. Until that time, users can continue to access data according to their previous security privileges, but any changes they make are validated during the synchronization to the server. If they no longer have privileges to make changes for a row, they receive an error and the row won't be created, updated, or deleted.
- Any changes to a user's privilege to view a row won't take effect on the mobile device until the next synchronization cycle.
- Mobile offline honors the security model for mobile apps and the hierarchical security model, except the field-level security and field sharing.

Optimize the offline profile

There's a lot to keep in mind when you create or update an offline profile for model-driven apps. An offline profile should include all the data that app users need to complete tasks in the field. If it includes too much data, however, app users might get stuck waiting for their data to download. They might even run out of space on their device. You need to consider the devices and data plans your app users have to make sure they have a great experience.

The following guidelines help you create an offline profile that meets the exact needs of your organization.

Don't make your users download too much data

Each user might have access to a different set of data. It's important to think about and test how much data different groups of users see. For example, a group sales manager might have access to many more sales opportunities than a local sales manager.

As you develop your offline profile and test with real or representative data, keep these best practices in mind:

- Limit the number of records to less than 200,000 for better performance. Exceeding 3,000,000 records isn't supported by the offline sync.
- Limit the number of tables to fewer than 100.
- Limit the total data size to less than 1 GB.
- Limit the total files and images size to less than 4 GB. Apply filters to reduce the total download size.
- Reduce the number of records downloaded in tables that change frequently by filtering on fields like status, group, region, owner, or assigned to.

If your app's offline data exceeds these recommendations, users see slower syncs, higher data usage, higher battery usage, and slower app performance.

Optimize your offline profile

Apply the following best practices to make sure that users download only the data they need. Optimizing the data that's downloaded makes it easier to stay within the recommended limits.

Don't reinvent the wheel

If you're customizing Field Service or Sales, start from their default offline profiles. You know core features work, and you won't miss tables that are used in standard forms.

The default offline profiles include everything you need for an out-of-the-box solution. You can add more tables that are important for your business.

However, **don't remove tables** from the default profile. Without those tables, forms or views might fail at runtime. If the default profile includes too many or too few rows of data, adjust the filters on the largest tables to optimize data sizes for your users.

Add all tables that are referred to in each form and view in your app

When you add a form or view to your model-driven app, look for references to other tables, including lookups. Make sure each of these tables is included in your offline profile with a corresponding related table or filters. Be sure to add all tables used in web resource scripts as well.

When you add a table to the offline profile, you can choose one of four options to determine which rows are downloaded:

- Organization rows
- All rows
- Related rows only
- Custom

To choose the best option for each table, consider which of the following categories your table belongs to:

- **Standalone tables**: Tables that are visible as grids in the app, like Contact.
- **Related tables**: Tables that are referred to in the form or grid view of a different table, like Unit.
- **Resource tables**: Tables that contain resource data, like Currency or Territory.

Choose a row option based on the category of table you add:

Expand table

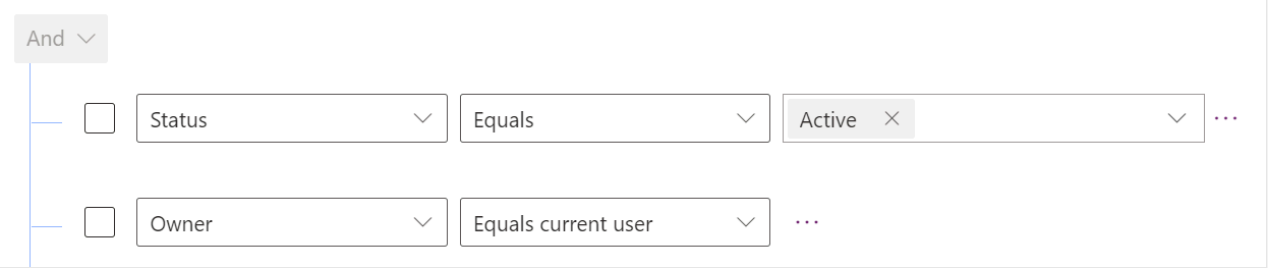
Table type	Organization rows	All rows	Related rows only	Custom
Standalone	✓			✓
Related			✓	✓
Resources		✓		✓

Use filters to reduce the data download size

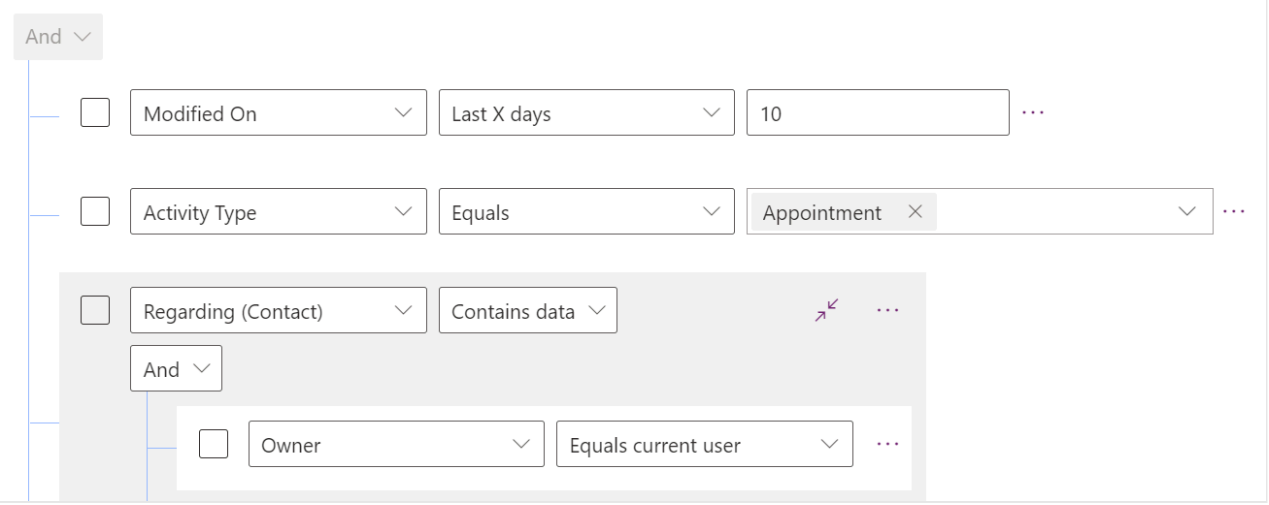
If users have access to a large set of data when they're online, apply filters to restrict the data that they download when they're offline.

> **Important**
>
> If you add a custom filter to a table that's set to download related rows, the filter is treated as an **OR**. That means that all related rows are downloaded, in addition to the rows specified by the filter. Users might download more data than you intend. If you want to download related rows and apply an additional filter, clear **Related rows only** and specify the relationship and the additional restrictions in a custom filter using **AND**.

- **Standalone tables**: Use a custom filter that includes the records that are required for the grid views in your app. By default, all views are included when you add a table in the app designer. To make sure that users have the same data online and offline, explicitly select the views that filter the data that you include in the offline profile.



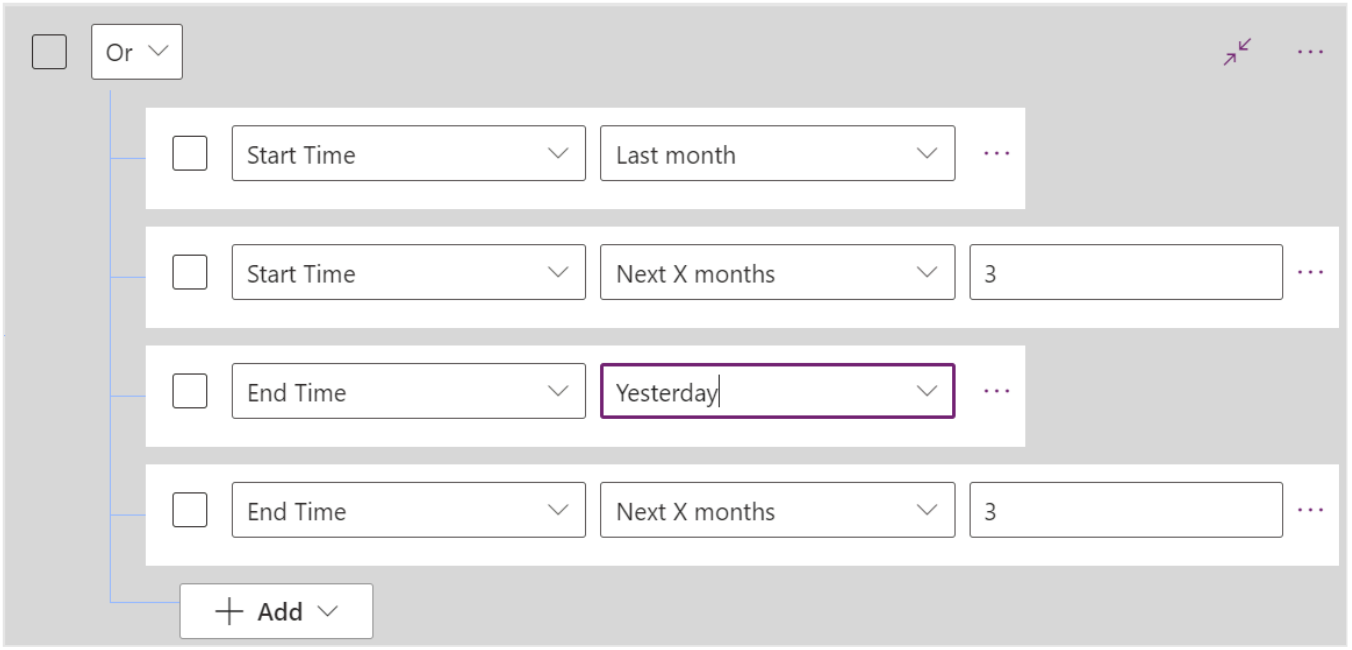
- **Related tables**: Use a custom filter if you want users to download rows that are related **AND** that match your other filter criteria.



- **Resources tables**: Use a custom filter if you want users to download only rows that match your criteria, like rows with an Active status.

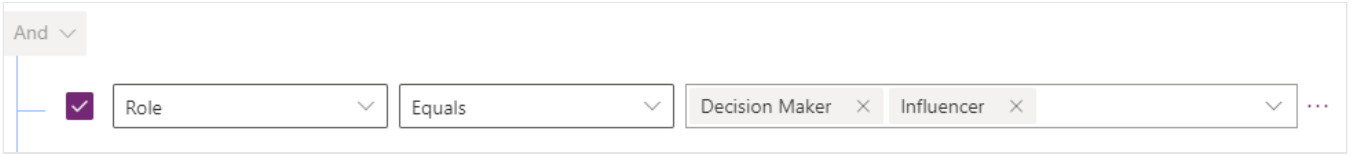
Common custom filters

Filter by time and date fields for time-centric data like bookings and timeline items. Consider both future and past dates. For example, a common filter might include appointments from the past month and the next three months.



Filter by status to limit downloads to rows with a certain status.

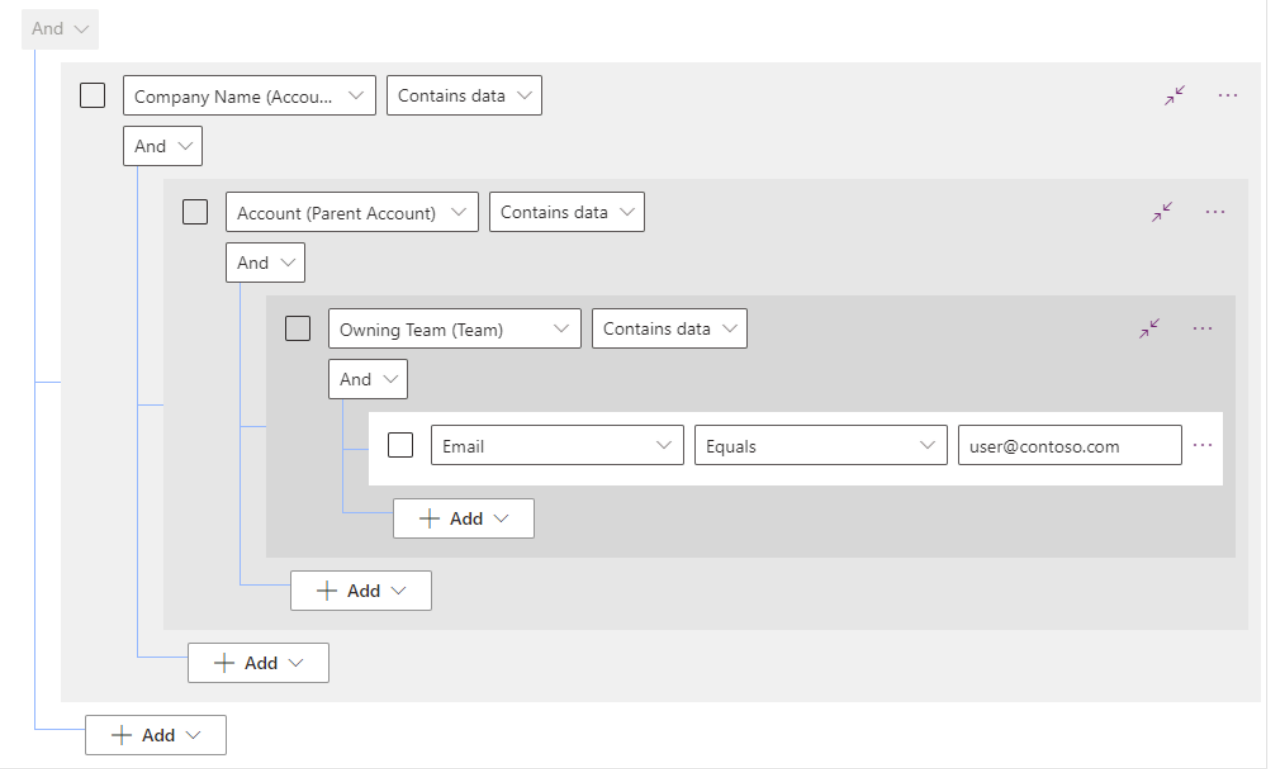
Filter by custom category or role fields to scope large tables down to the data needed for your app. For example, you could filter Contacts by Role to limit data to stakeholders.



Avoid these filter pitfalls that can slow down your downloads

If a custom filter results in a slow Dataverse query, downloads take longer. Follow these best practices to avoid common performance bottlenecks:

- Don't use partial string matches or **Contains**, **Begins with**, or **Ends with**.
- Avoid multiple levels of relationships in custom filters. Filters like this can lead to slow downloads:



- Avoid using many **OR** conditions.
- Avoid using small time windows to reduce data downloads on tables that change frequently. If a table in your offline profile is large and changes frequently, reduce the number of records downloaded by filtering on fields like status, group, region, owner, or assigned to.

Use column selection to reduce data download and sync time

The first sync can take time for organizations with large datasets, especially in remote areas. Optimize this by explicitly selecting only the required columns to download on the device and avoid downloading columns that are never used in the app. This saves both network and disk usage and results in faster sync time. While this impacts both the first sync and delta syncs, the first sync sees a greater impact as there are more records to download.

1. In Power Apps Studio, in the left side panel, select **Apps**.
2. Select your model-driven app, and then select **Edit**.

3. Select **Settings**.
4. Select **General**.
5. In the **Select offline mode and profile** section, select **Edit selected profile** from the **More actions (...)** icon for the selected profile.
6. In the **Edit Profile** pane, under the **Data for offline use** section, identify the table to optimize. Select the **More actions** (...) icon, and then select **Edit**.
7. The **Edit Table Name** page appears. Under the **Selected columns** section, select the **Manage columns** option.
8. In this **Managed selected columns** pane, select the **Select only required columns** option.
9. Columns used in the app are automatically selected. For all other columns, optimize by selecting only those that are necessary.

   > **Important**
   >
   > - If you have custom JavaScript code in the app, ensure the columns used in the custom code are selected in the offline profile.
   > - If you add additional columns after optimizing the offline profile, go back and select that new column as **Required Column**, in the **Managed selected columns** pane.

10. Select **Back**.
11. Select **Save**.
12. Select **Save + close**.
13. Close the **Settings** and select **Publish**.

> **Note**
>
> - We recommend always selecting required columns for tables with a high number of unused columns.
> - The **Manage columns and Managed selected columns** option isn't available in the mobile **Offline Profile configuration** on **Power Platform admin center**.

Optimize for canvas apps

> **Important**
>
> The optimization isn't supported on canvas apps using a selected offline profile.

For canvas apps using an **autogenerated** offline profile, the system automatically optimizes the columns downloaded on the device. With the optimization activated, the app only downloads the required columns.

1. In Power Apps Studio, in the left side panel, select **Apps**.
2. Select your canvas app, and then select **Edit**.
3. Select **Settings**.
4. Select **Updates** and **Experimental**.
5. Turn on the **Faster offline synchronization** option.
6. Close the settings and select **Publish**.

Resolve sync conflicts with the server

Article • 06/14/2024

This article provides information to help you resolve mobile synchronization conflicts with the server.

Sync Error table

In the event of a synchronization error, the system automatically generates a new entry in the **Sync Error** table within Dataverse. This table is structured with the following columns.

Expand table

Column name	Description	Example
Error Time	Time when the error was created.	5/17/2024 7:16 AM
Error Message	Description of the error.	`Entity Account With Id = <RowId> Does Not Exist`
Error Type	Type of the error, such as a conflict or record not found error.	Record not found
Record	Updated record in sync error.	Contoso
Owner	User who updated the record.	John Doe
Action	Action applied to the record to sync.	Update
Action Data	Json containing the payload of the action.	{"lastname":"Contoso2"}
Request Data	Json containing the query.	`{"lastname":"Contoso2","syncerror__regardingentityid": <syncerrorId>,"entitylogicalname":"account"}`
Error Code	Code of the error.	-2147015424

> **Note**
>
> Make sure that the role assigned to the user grants read privileges on the **Sync Error** table. Learn more: Create or edit a security role to manage access

Recommendation on how to use the Sync Error table

The **Sync Error** table is a standard Dataverse table. We recommend that you create a model-driven app to manage the sync errors.

If you run the model-driven app, you can see the sync errors by each user. If you select a sync error row, you can **Retry changes** from the command bar.

Sync error in the Device status page

Sync errors natively show up in the **Device status** page. The **Device status** page is available out of the box in model-driven apps, but must be set up in the canvas app. See Using the Offline template and offline status icon for more information.

Use a cloud flow to take actions on sync errors

You can create an automated cloud flow in Power Automate using the Dataverse trigger **when a row is added, modified, or deleted**. The flow can automatically send an email or send a notification on the device.

> **Note**
>
> To retrieve the user's email address within the flow, add the Dataverse action **Get a row by ID** using the **Owner** column of the **Sync Error** row.

Sync conflict

When there's a mismatch of data between client and server, conflict errors occur. By default, changes that are made by a user in offline mode are automatically synced to the server when the user is back online.

How sync conflicts are resolved

When a user makes changes to data in an offline app, updates to each column are pushed back to Dataverse as soon as the network is available. The last update to each column is stored in Dataverse, so this sync doesn't fail due to conflicting changes.

Server-side plug-ins and validation can invalidate changes. Those changes are reverted locally, and an error is written to the **Sync Errors** Dataverse table.

Conflict resolution settings

> **Important**
>
> The conflict resolution settings don't apply to canvas apps.

If updates made while offline are being rejected too frequently, consider changing the conflict resolution setting to its default value.

1. Sign in to the Power Platform admin center.
2. Select **Environments** in the navigation pane.
3. Select an environment.
4. Select **Settings** in the command bar.
5. Select **Product** > **Features**.
6. In the **Advanced mobile offline settings for model-driven apps** section, turn off the **Enable conflict detection for mobile offline synchronization** option.

> **Note**
>
> When this option is turned on (not recommended), updates on the server may prevent client updates being applied. Conflict errors must be resolved manually.

Set an app as a startup app

Article • 03/22/2024

Users can set an app as a startup app in Power Apps mobile app. This feature is available for the iOS and Android versions of Power Apps mobile app.

Users can mark any canvas or model-driven app as a startup app in two ways:

- From an in-app suggestion
- On the app **Details** page

Benefits of setting a startup app

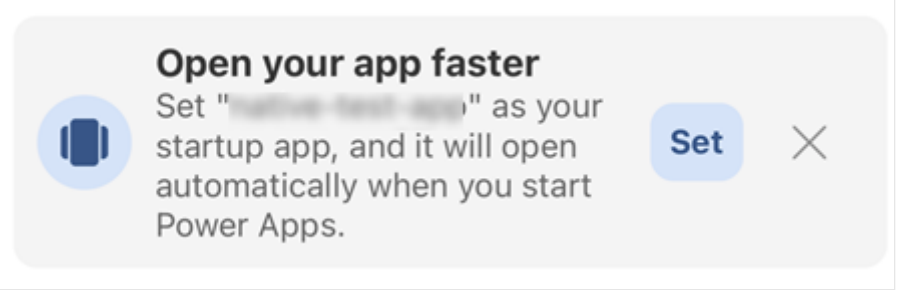
- Improves productivity:
  - Once an app is set as the startup app, it opens by default when users open Power Apps mobile app.
  - No need to wait for the home page to load, saving the user time.
  - Creating and testing an app is faster, since you can bypass the home page.
- Efficient to create:
  - You can set a startup app with one tap.
  - This feature is better than shortcut apps, which require three to four taps and need external apps/device feature support.
- Simple to enable:
  - No changes are required for makers to use this feature.
  - There's in-app information about the feature's use and benefits.
  - The feature is compatible with offline, wrap, custom branding, push notifications, and shortcut features.

Set a startup app from a suggestion

If a user opens the same app for seven days, a suggestion appears, at the top of the home page, when they close the app.

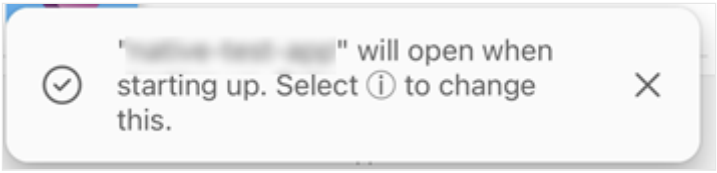
1. View the startup app suggestion.

   You might see an in-app suggestion, asking users if they want to open the app as a Power Apps mobile startup app.



2. Set the start up app.

   Tap on **Set** to set the app as the startup. The user sees a success message that confirms the app is set to open as the startup app.

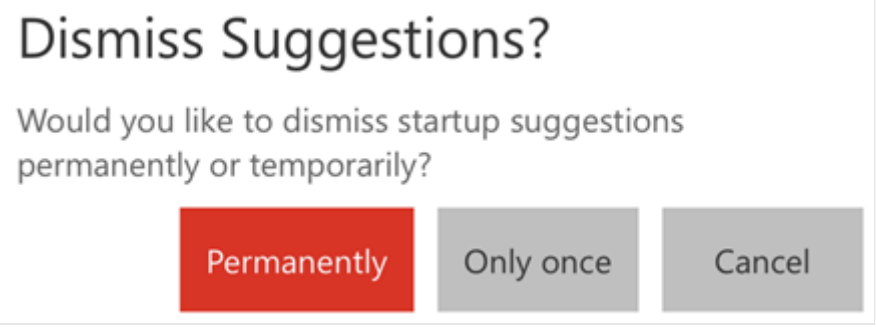


3. Confirm success with the startup app icon.

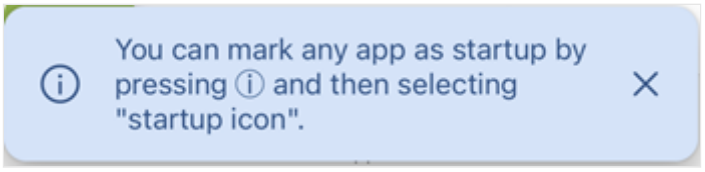
   If an app is successfully marked as the startup app, an icon appears next to the app title on the home page.

If the suggestion is dismissed

- If a user closes the suggestion, they're asked if they want to receive the suggestion in the future. Canceling the suggestion or tapping outside of it closes the suggestion dialogue.



- If users close the suggestion permanently, they can still set a startup app later from the app **Details** page.



Set a startup app from the Details page

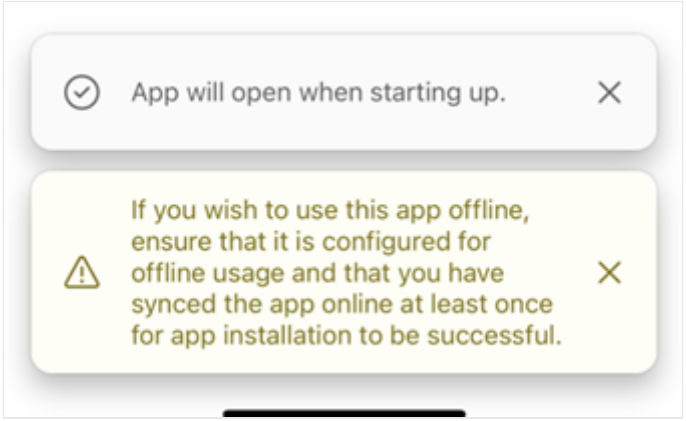
To set a startup app from the **Details** page, follow these steps.

1. Tap the **Open at startup** icon on the app **Details** page.

   
   After you tap the icon, the app is marked as a startup app.

2. View or dismiss the usage message for offline scenarios.

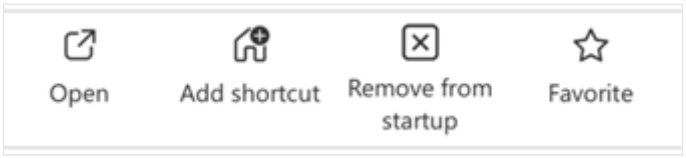
   This usage message disappears in 10 seconds if not canceled by users.

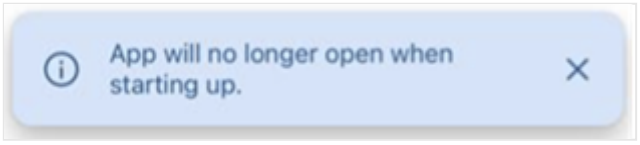
Reset a startup app

If an app is already marked as the startup app, the app **Details** page shows a **Remove from startup** icon.

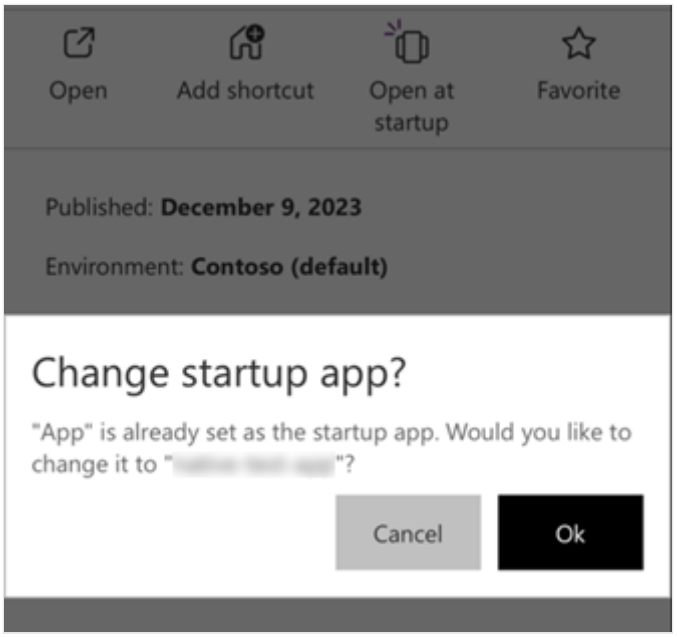
1. Tap this icon to unmark the app as the startup app.



You see a message that the app no longer opens by default when a user taps on the Power Apps mobile page.



2. Tap **Ok** to replace the existing startup app with another app. The existing app is now unmarked and the new app is marked as the startup app.



Known limitations

- Only canvas and model driven apps are eligible for this feature.
- This feature works only on iOS and Android devices.
- Users can set only one app as the startup app.
- Only end users can set a startup app.

Troubleshoot issues in the Power Apps mobile app

Article • 12/19/2024

This troubleshooting article helps fix common issues for the Power Apps mobile app.

Resolve canvas apps performance issues

Learn about most common performance issues that can make canvas apps run slow and how to improve performance. More information: Common canvas app performance issues and resolutions.

Diagnose mobile apps with Monitor

Monitor is a tool that offers makers a deep view of what an app does and how it does it by logging all key activities that occur in the app as it runs. You can connect a mobile app session to Monitor to better diagnose and troubleshoot issues faster.

Debug JavaScript web resources in mobile apps

While developing JavaScript web resources for mobile scenarios, you can use your Android device to debug your mobile-specific code and ensure it works as expected. More information: Debug JavaScript in mobile apps on Android.

Error: There was a problem signing you in

You're unable to sign in due to issues with the Microsoft Authenticator app.

If you don't have the Microsoft Authenticator app, download the app from the App Store or Play Store and then sign in to Power Apps mobile again.

If you already have the Microsoft Authenticator app installed and you're having sign in issues, then try these steps:

1. Back up your Microsoft Authenticator account. For more information, see Back up and recover account credentials using the Microsoft Authenticator app
2. Uninstall the Microsoft Authenticator app.
3. Uninstall Power Apps mobile.
4. Reinstall the Microsoft Authenticator app and add your backup account.

5. Reinstall Power Apps mobile.
6. Open Power Apps mobile and then sign in.

Error: Your device configuration is preventing sign in

If you get this error messages, it means your company's IT department requires Microsoft Intune or an authentication app to sign in securely. However, your device setup is blocking Power Apps mobile from launching the authentication app that's installed on your device.

Microsoft authentication apps are Authenticator and Company Portal. Your company might use a non-Microsoft authentication app. If you're not sure, ask your IT department or help desk which authentication app to use. Once you have the correct authentication app, then follow the steps below.

> ⓘ **Note**
>
> Power Apps requires a valid license to sign in. For more information, see Licensing overview.

Sometimes, updating and manually opening the authentication app on your device before signing in to Power Apps mobile can fix the problem. If this doesn't fix the issue, then follow the next steps depending on your device manufacturer and authentication app.

Huawei or Honor device

1. Go to **Settings** > **Battery** > **App launch**.

   > ⓘ **Note**
   >
   > The **App launch** menu can have different names depending on the model and the operating version of your mobile device. If you don't see the **App launch** menu option, then look for one of the following menu options:
   >
   > - **Close apps after screen lock**
   > - **Applications**
   > - **Background applications**

2. Under **Manage automatically**, on the authenticator app set the toggle switch to **OFF**.

3. On the **Manage manually** screen, ensure that **Secondary launch / Can be launched by other apps** is enabled. To allow the Power Apps mobile app to launch the app.

Vivo device

1. Go to **Settings** > **More Settings** > **Applications** > **Autostart**.
2. Set the toggle switch to **ON** for the authenticator app.

If the issue is still not fixed, then try these steps:

1. Back up your Microsoft Authenticator accounts. For more info, see Back up and recover account credentials using the Microsoft Authenticator app
2. Uninstall the Microsoft Authenticator app.
3. Uninstall Power Apps mobile.
4. Install Microsoft Authenticator again and add your backup accounts again.
5. Install Power Apps mobile.
6. Open Power Apps mobile and sign in.

App list is empty

The app list in the Power Apps mobile app might appear empty when you lose internet connection before the app list has downloaded. This can happen in any of the following scenarios:

- It's the first time you're signing in to the mobile app.
- When you pull down to refresh the app list.
- When you come back online after a period of being offline. The app list is automatically refreshed.

To resolve connection related issues, ensure you remain connected to the internet while the app list is fully downloaded.

Pin to Home does not work on iOS 14

iOS device running iOS 14: The Safari browser no longer supports the **Pin to Home** functionality for Power Apps mobile. You need to use the Siri Shortcuts app to pin an app to the Home screen. For more information, see Use Siri Shortcuts (iOS 14 or later).

iOS 13: You can still use the Safari browser to pin an app to the Home screen. For more information, see Pin an app to the home screen

App resets when running it on Power Apps mobile

When you run a canvas or model-driven app on Power Apps mobile, it can reset if the app is using too many resources. If the app uses more resources than are available on your device, the app resets. This is similar to when you visit a large, complex webpage and the web browser suspends the page because it's consuming too much power.

On Android devices, this app restart can look like a crash because the app is closed and the user is taken to the home screen of the device.

If you experience a reset while using a canvas app, contact your app developer, and see Prevent canvas app restarts.

Unable to download SharePoint attachment in the mobile app

The Power Apps platform doesn't support accessing authenticated URLs, including SharePoint attachments. If you run a Power Apps application in a web browser and it tries to access a SharePoint attachment, it might work if you're signed-in to SharePoint in another tab. This is because web browsers support multiple signed-in users, and sign-ins are valid across browser tabs. However, the Power Apps mobile app isn't a web browser, so doesn't benefit from this browser-based behavior.

Flows created in a solution aren't supported on Power Apps mobile

The Flow action menu in Power Apps mobile doesn't support flows created in a solution.

Error: Contact your administrator for access to your organizations mobile apps

When using the Dynamics 365 mobile app, you encounter the following message: **Contact your administrator for access to your organizations mobile apps**.

To check for recently added apps, select Refresh. If you can’t find your app, change your search criteria and try again.**

For more information go to, Troubleshoot "We can’t find any apps for your role" error message.

The list of apps is empty

Make sure the user has a default security role assigned to them such as **Basic**. This is in addition to any custom security role assigned to the user. For more information, see Setup overview for mobile apps.

Error message: This record is unavailable

If this message appears when a user starts the mobile app, and then selects the **Home** button, or **Dashboards** from the menu, the user likely doesn’t have access to the expected dashboards.

Flows created in a solution isn't supported

The Flow action menu in Dynamics 365 for phones and tablets app doesn't support flows created in a solution.

Error message: Your server isn't available or does not support this application

Cause 1: The Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises) server is down. Verify that the server is on and connected to your network.

Cause 2: Your Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises) app version isn't supported. For supported version information, see What's supported.

Cause 3: This error can also occur if you enter an invalid URL. Make sure the same URL you have provided works to access Dynamics 365 apps in your browser on your device.

Error message: You haven't been authorized to use this app. Check with your system

administrator to update your settings

Cause 1: Verify that your security role includes the **Use Dynamics 365 for tablets** privilege. See "Required privileges" in Setup overview for mobile apps.

Cause 2: This error can occur if you have a Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises) organization and your user hasn't been assigned a license for the organization. If you add a Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises) subscription to an existing Office 365 tenant, your user might not have a license assigned.

If the user has the Service Administrator role and you're able to sign in to on the web app to perform certain administrative actions, but you can't perform end user tasks, such as creating records (for example, accounts, contacts, and leads) or configuring Dynamics 365 for mobile. When you sign in to the web app, you might notice that not all areas appear within the navigation (for example, Sales and Marketing are missing):

Access the **Active** users section in the admin center and verify you have a **Dynamics 365 Customer Engagement Plan** license assigned to your user record.

Error message: Sorry, something went wrong while initializing the app. Please try again, or restart the app

Cause 1: Permissions might not be set properly. See "Required privileges" in Setup overview for mobile apps.

Cause 2: See the following KB article:

An error occurs in the Dynamics 365 app for users in child business units. For more information, see Sorry, something went wrong while initializing the app.

Sample Trace Message for Cause 2:

```
Error Message:System.NullReferenceException: Object reference not set to an instance of an object.
Microsoft.Crm.Application.WebServices.ApplicationMetadataService.<>c__DisplayClass30.<UserRolesChanged>b__2d(Entity role)
at System.Linq.Enumerable.Any[TSource](IEnumerable1 source, Func2 predicate)
at Microsoft.Crm.Application.WebServices.ApplicationMetadataService.UserRolesChanged(G
```

```
uid[] clientUserRoles, DateTime syncTime, ExecutionContext context)
at
Microsoft.Crm.Application.WebServices.ApplicationMetadataService.RetrieveUserContex
t(UserContextRetrieveRequest userContextRetrieveRequest)
```

Error message: The language installed on your company's system isn't available on the app. Please contact your system administrator to set up a supported language

Cause: This error occurs if one of the supported languages isn't enabled in Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises). For more information on the supported languages, see Supported languages for Dynamics 365 for phones and Dynamics 365 for tablets.

Error message: The process assigned to this record is unavailable or has been deleted

If you receive this message for a record which has a nondeleted process assigned to it, you should manually synchronize Dynamics 365 mobile app data with Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises) app data. Close the mobile app, reopen it, and then choose to download the latest customizations. This procedure forces the mobile app to check for updated customizations. Recently viewed data while you were connected is cached and synched. Record data like Accounts or Contacts aren't synched.

Event 10001 messages appear in the Event Log when you run Dynamics 365 for mobile.

The following event may be recorded multiple times to the Event Log, when **Show Analytic and Debug Logs** is enabled, on the device where Dynamics 365 for mobile is running. Notice that, by default, **Show Analytic and Debug Logs** is disabled in Event Viewer and these messages won't be recorded. More information: Enable Analytic and Debug Logs

- Event ID: 10001

- Message: `SEC7131 : Security of a sandboxed iframe is potentially compromised by allowing script and same origin access.`

  Verify the source of the messages. If the source is Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises), these events don't pose a security threat and can be ignored.

Data cached for offline viewing remains after the entity is no longer enabled for Dynamics 365 for mobile

In Dynamics 365 for mobile, record data is cached as the user visits the record so the user can access the data when going offline.

This cached data persists after the entity is no longer enabled for Dynamics 365 for mobile (**Settings** > **Customizations** > **Customize the System** > [select an entity] > under **Outlook & Mobile**, deselect **Dynamics 365 for tablets**).

To remove the cached data, the user must sign out of mobile app, or the app must be reconfigured or uninstalled.

Customization changes don't appear in the mobile app

Cause 1: The customizations (metadata) from Microsoft Dataverse or Dynamics 365 Customer Engagement (on-premises) organization are cached on your device. The app checks for updated metadata after 24 hours or anytime you reopen the app. For customization changes to become available immediately, you must completely close and then reopen the app. If new metadata is found, you're prompted to download it. For more information on how to completely close an app, see the help for your operating system or reference one of the articles provided:

- **Windows 10**: How do I close an app?
- **iPad**: Force an app to close
- **Android**: How to force close Android apps

Cause 2: You might be seeing a different form than the one you customized. If you have multiple forms for an entity, you see the first form in the form order that you have

access to. This is different than the web application where you see the last form you used and have the ability to change between forms.

Native Android or iOS links aren't supported

The Dynamics 365 mobile app doesn't support universal links on iOS and Android app links on Android.

Error message: in Android, AUTH_FAILED_INTUNE_POLICY_REQUIRED AADSTS53005: Application needs to enforce Intune protection policies

Contact your administrator or help desk and make sure that your user is under Intune app protection policies.

On your device, go to **Settings** > **General** > **Accounts** and remove any accounts that are connected with Microsoft 365.

Error message: Access Denied. This app must be protected with an Intune policy before you can access company data

Contact your administrator or help desk and verify that Intune app protection policies are applied for your user account.

Admin instructions to resolve the issue

If you're an admin, you can avoid users getting this error by making sure all mobile users have access to the sales dashboard:

1. In the web app, go to **Settings** > **Customizations** > **Customize the System**.
2. Select **Dashboards**.
3. Select **Sales Dashboard**.
4. Select **Enable Security Roles**.

5. Select **Display to everyone** and then select **OK**. If you prefer to display only to select security roles, be sure to select your user's security role.
6. Select **Publish**.
7. Have your user close and open the mobile app so your dashboard changes download.

End-user instructions to resolve the issue

You can choose a different dashboard and set it as your home page:

1. From the mobile app, select the menu and then select **Dashboards**.
2. On the command bar, select **Select Dashboard** and then select the dashboard you would like to use as your home page.
3. On the command bar, select **Set as Home**.

Or, you can create a personal dashboard through the web app:

1. In the web app, go to **Sales** > **Dashboards**.
2. Select **New**.
3. Select **Properties**.
4. Add the components you want on your dashboard and select **Save**.
5. In the mobile app, follow the previous procedure to select your new dashboard and set it as your home page.

Network requests fail when Power Apps mobile app is running in the background

When the Power Apps mobile app is running in the background and a canvas or model-driven app makes a network request, a mobile operating system could deprioritize or cancel this network request. This can cause an error message to appear in the mobile app when it returns from the background.

If you experience a failed network request when the Power Apps mobile app is running in the background, contact your app developer.

App doesn't appear in the app list offline

New and recently republished apps might not appear in the offline app list right away. To make your app appear in the app list offline, open the app on your device when it's online and keep it open for 1-2 minutes.

Not able to zoom in to input elements in the app

Pinch to zoom isn't supported by HTML input elements by default. More information on HTML input control default behavior: HTML Input element.

Issue still not resolved?

If the information provided previously doesn't resolve your issue, either Post your issue in the Power App Community or Contact Technical Support.

The following are some suggested details to provide:

- What are the specific symptoms you encounter? For example, if you encounter an error, what is the exact error message?
- Does the issue only occur for users with certain Dynamics 365 security roles?
- Does the issue only occur on certain devices but works correctly for the same user on another device?
- If you attempt to connect to a different Dynamics 365 organization that doesn't include your customizations, does the same issue occur? If the issue only occurs with your customizations, provide a copy of the customizations if possible.
- Does the issue still occur after uninstalling the app and reinstalling it?
- What type of device are you using, such as iPad 4th Generation, Microsoft Surface. What is the version of the operating system, such as iOS 10.0 or Windows 10.

Prevent canvas app restarts in the Power Apps mobile app

When you run a canvas app in the Power Apps mobile app, it can be restarted for the following reasons:

- The app is using too much total memory.
- The app is using too much memory or processing at one time.
- The app is moved to background – either when your specific app uses a native control (like **Add Picture** or **Barcode Scanner**) or the Power Apps mobile app is put in the background by the user.

This memory and processing limitations, which is especially strict when the Power Apps mobile app runs in the background, is imposed by the operating system (Android or iOS). If the app uses more resources than are available on your device, the app will reset. This is similar to when you visit a large complex webpage, the web browser suspends the page if it's consuming too much power.

On Android devices, this app restart can look like a crash because the app is closed and the user is taken to the home screen of the device.

Use this article to learn how to prevent canvas app restarts on Power Apps mobile.

Prevention tips for end users

While the biggest improvements are made by app makers, here are some tips that end users can use to decrease the occurrence of app restarts:

- In the Power Apps mobile app, on the user profile page, select **Clear cache** to remove saved data. This should only be done when the end user has data as clearing the cache will remove any **SaveData** or app caches.
- On Android devices, ensure the Power Apps mobile app is prioritized. Refer to your device manual to keep the app running through the settings like battery optimization and app sleep configuration.
- Close any running apps, other than the Power Apps mobile app, and remove any unneeded data from the device such as unused apps or images.
- While it's cumbersome, consider using the app slower – pause slightly between screen navigation or after taking pictures or saving or loading data.

Prevention tips for app makers

The greatest memory improvements to decrease app restarts can be made by app makers. When creating an app, remember to optimize the app to run on the lowest-specification device that your end users will use and follow best practices around resource usage.

> **Note**
>
> Since app restarts are caused by the operating system restricting the amount of memory and processing an app can do, it might take a combination of the mitigations suggested below to minimize app restarts. The more memory and processing that can be reduced, both in total and at one time, the less likely an app restart will be.

> **Tip**
>
> You can connect a mobile app session to Monitor to see where your app is doing heavy processing or memory-intensive operations. Monitor is a tool that offers makers a deep view of what an app does and how it does it by logging all key activities that occur in the app as it runs.

Expand table

Problem	Root Cause	Mitigation
App restarts when loading a specific screen.	If a specific screen is running too many formulas at one time, the app can have too much processing and be restarted by the operating system.	Limit the number of controls on a screen and the number of formulas being run when the screen is loaded, which might require splitting up screens. Avoid control dependency between screens. Prevent the user from taking action during high-processing moments. For example, when a large gallery with multiple filters and lookups is loading. Consider using named formulas. Consider using the **Delayed Load** app setting.
App restarts after multiple screen navigation.	There are memory leaks happening on the screens, resulting in memory usage	Turn on the **Keep recently visited screens in memory** app setting. While this increases total memory usage in

Problem	Root Cause	Mitigation
	building up as the user navigates around the app.	the short term as the screen is preserved in memory, across multiple screen navigation, it will prevent memory leaks.
App restarts when operating in offline mode using the **SaveData/LoadData** method	Offline scenarios that use **SaveData/LoadData** or large data connections can consume significant memory, especially when media content is involved.	Use the new offline profiles feature to manage offline data more efficiently. Avoid saving large media files locally. Optimize data sync strategies, and use explicit column selection to reduce payload size. Turn off experimental features like record scope one-to-many relationships if you don't need them.
App restarts when using the camera control.	The camera control saves the captured image to memory. This can increase the memory usage of the app, especially if the captured image is saved into variables or **SaveData** using the **OnStream** property.	Don't save any images beyond the most recently captured one. Use **Photo** instead of **Stream** to only capture images when the user taps on the camera. If you need to use **Stream**, set the **StreamRate** property as high as possible to reduce the number of updates.
App restarts when using the **Add Picture** control.	The **Add Picture** control saves the selected media content into memory. Due to the size of media content, this can result in significant memory pressure.	Consider changing where the media content is captured. Consider turning off the **UseMobileCamera** property so users can only select media from gallery/photo library. Consider using the attachment control (as part of a form) to only select files instead of capturing them using the camera. Consider switching to the camera control.
App restarts when using native controls like **Add Picture**, **Barcode Scanner/Reader**, **View in**	Native controls can put the app in the background where the operating system has stricter limitations on memory before restarting the app.	Make sure all memory and processing intensive operations are completed before using these controls. For example, disable the **Add Picture** control until any **SaveData** operations

Problem	Root Cause	Mitigation
MR, **Measuring camera**, and others.		are completed. Consider switching to a different control like **Camera** instead of **Add Picture**.
App restarts happen for a subset of devices.	Devices have different amounts of memory and processing available. As an example, older devices are more prone to app restarts due to their lower available processing. Having other apps running can also reduce the amount of processing available. Similarly, other apps installed and lots of photos/media saved to the device can take up memory, reducing what is available for the app.	Refer your users to the tips listed before in our Prevention tips for end users section. Consider investing in devices that meet the performance needs of your app.
App restarts continue to happen.	Memory usage is affected by how the canvas app is authored. Make sure your app follows best practices can help ensure performance, reduce memory usage, and processing.	Optimize your app following the best practices below.

Best practices for building performant apps

- Build large and complex apps
- Troubleshoot Power Apps canvas app performance issues
- Tips and best practices to improve performance of canvas apps
- Power Apps coding guidelines - Code optimization

Install Power Apps for Windows

Install Power Apps for Windows to run model-driven app or canvas app on your Windows device. For more information on Power Apps, see What is Power Apps.

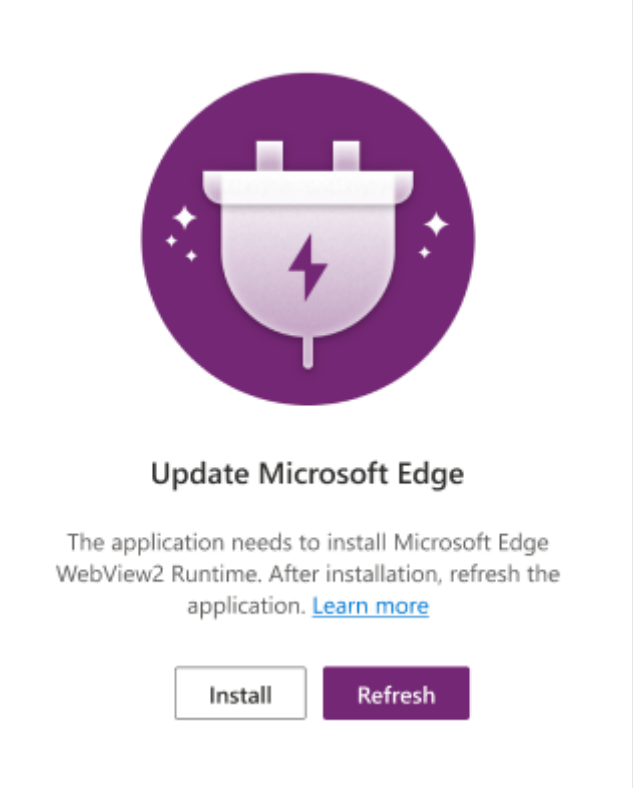
Install the app

1. Go to the Microsoft Store and install Power Apps for Windows.
2. When the app is installed, open it and sign in.

> **Important**
>
> If you run into issues during the installation or the app closes without warning, follow the steps in the next section to install the latest version of WebView2 Runtime, and retry installing Power Apps for Windows.

Webview2 Runtime

If you get an **Update Microsoft Edge** error message when you're installing Power Apps for Windows, this means you don't have WebView2 Runtime on your device.



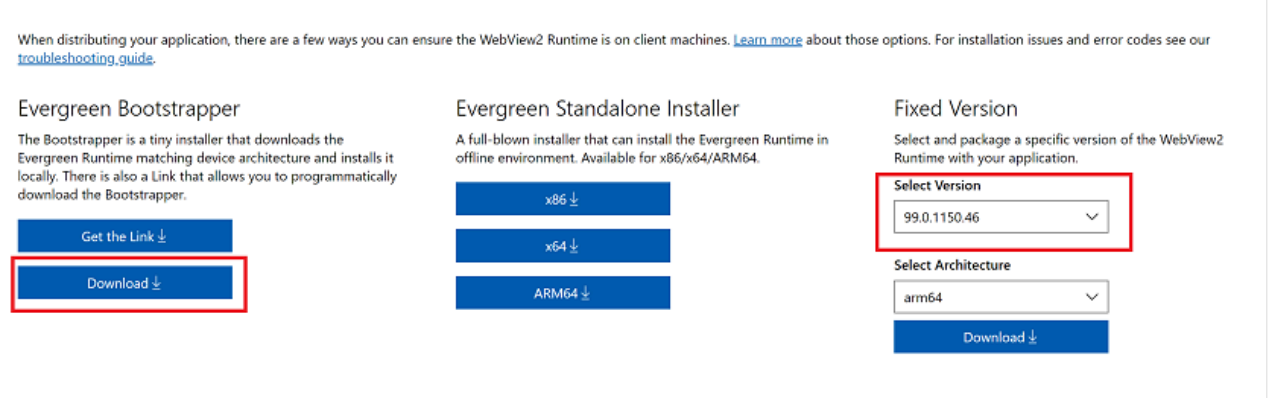
Power Apps for Windows also won't run correctly if you have an older version of WebView2. Follow these steps to see which version you have installed:

1. On your device, go to **Settings** > **Apps** > **Apps & features**.
2. Search for **WebView**. You need version **99.0 or later** installed to run Power Apps for Windows.

In both cases, whether you get an error message or have an older version installed, you need to install WebView2 Runtime.

You need administrator rights on your device to install WebView2. If you don't have admin rights, ask your administrator to install it for you.

1. Download the WebView2 Runtime.
2. Select version **99.0 or later**. Installing an earlier version may cause Power Apps to crash. Under **Evergreen Bootstrapper**, select **Download**.



3. Go over the license terms and privacy statement and then select **Accept and Download**.
4. Run **MicroEdgeWebview2Setup.exe**.

Install from app center

If you don't have access to install Power Apps for Windows from the Microsoft Store then you can install it from the app center.

An administrator can also download the package from the app center and distribute it to users with Intune.

Last updated on 01/08/2026

Use Power Apps for Windows

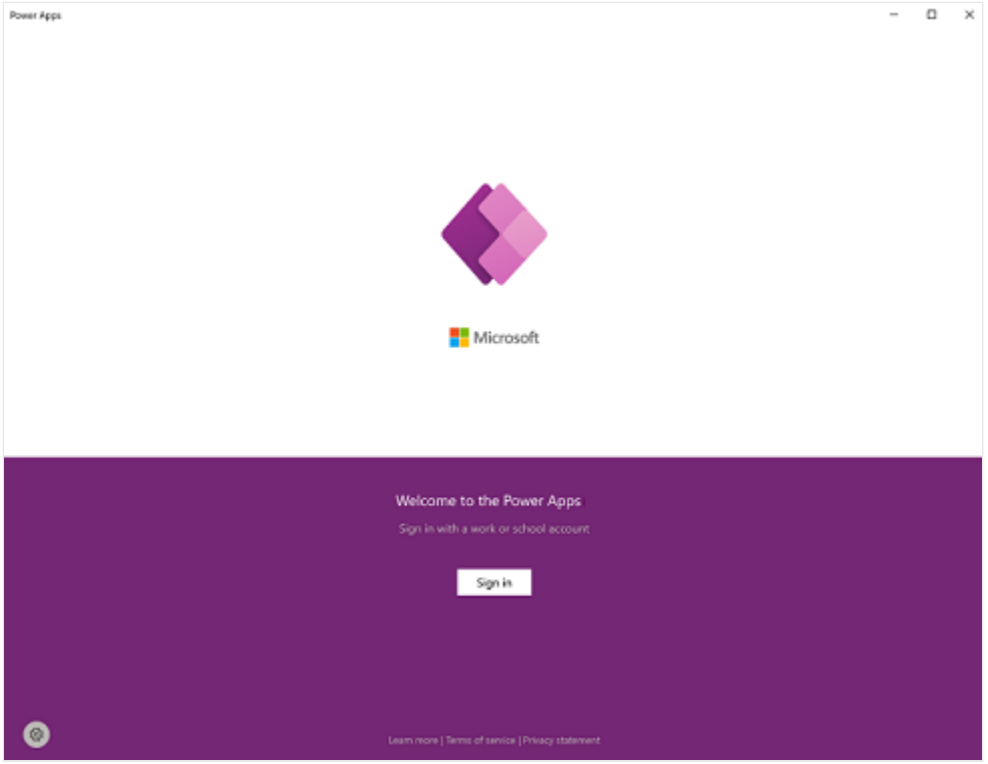
Article • 10/25/2023

This topic covers how to sign in and run your apps on Power Apps for Windows.

Sign in

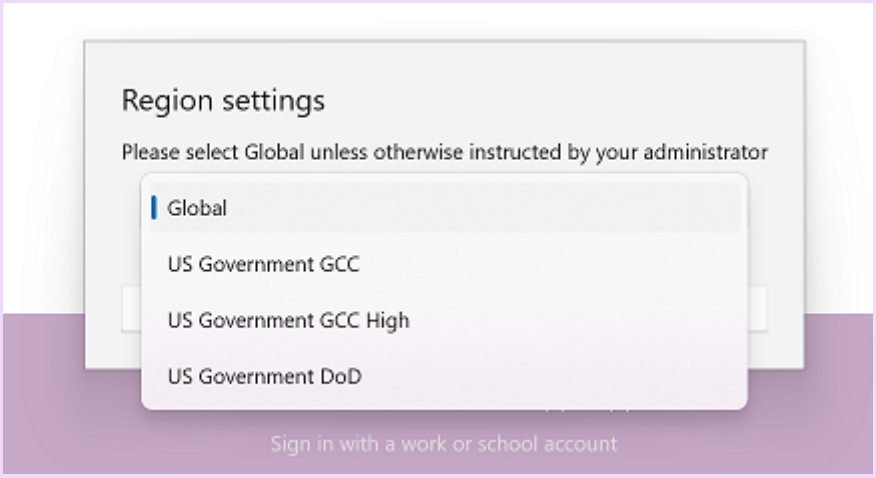
Sign into Power Apps for Windows quickly using your work email address. If you need help with your sign-in information, contact your Power Apps administrator.

1. On the Welcome screen, select **Sign in**.

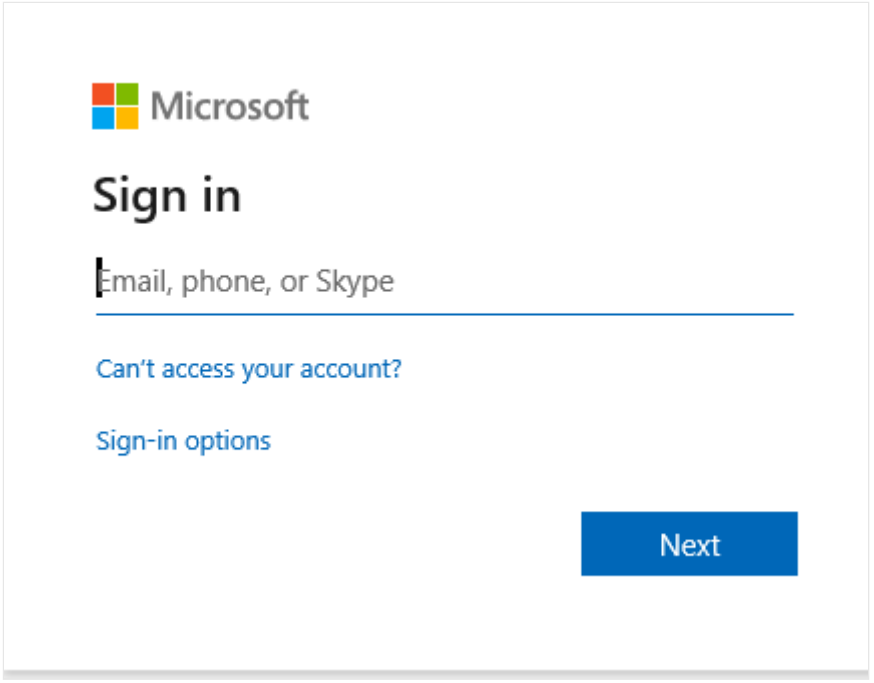


> **Note**

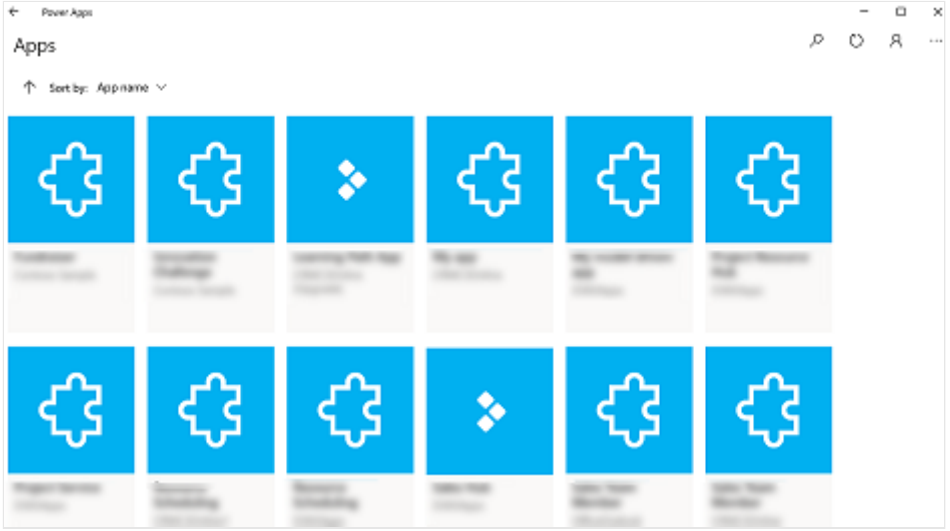
You also have the option to sign in as a guest user and choose a different region.



2. Enter your email address, and then select **Next**. Then enter your password and then select **Sign in**.



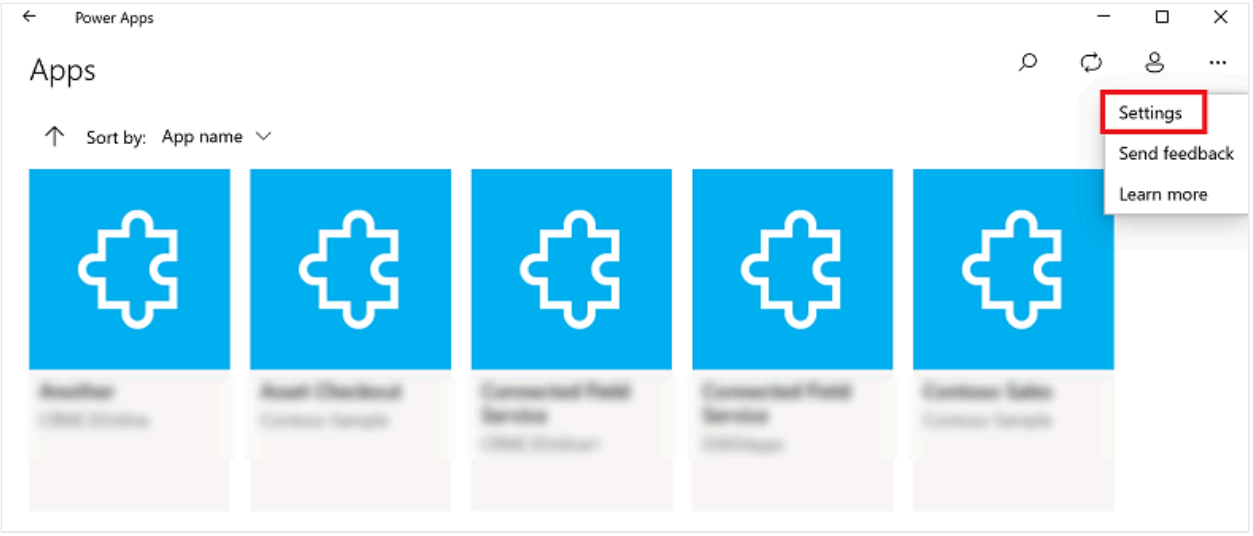
3. From the list of apps that you have access to, select the app that you want to use.



See non-production apps

By default, only production model-driven apps are shown in the list of apps.

To see model-driven apps from non-production environments, select the More button (...) > **Settings** and then turn on **Show non-production apps**.



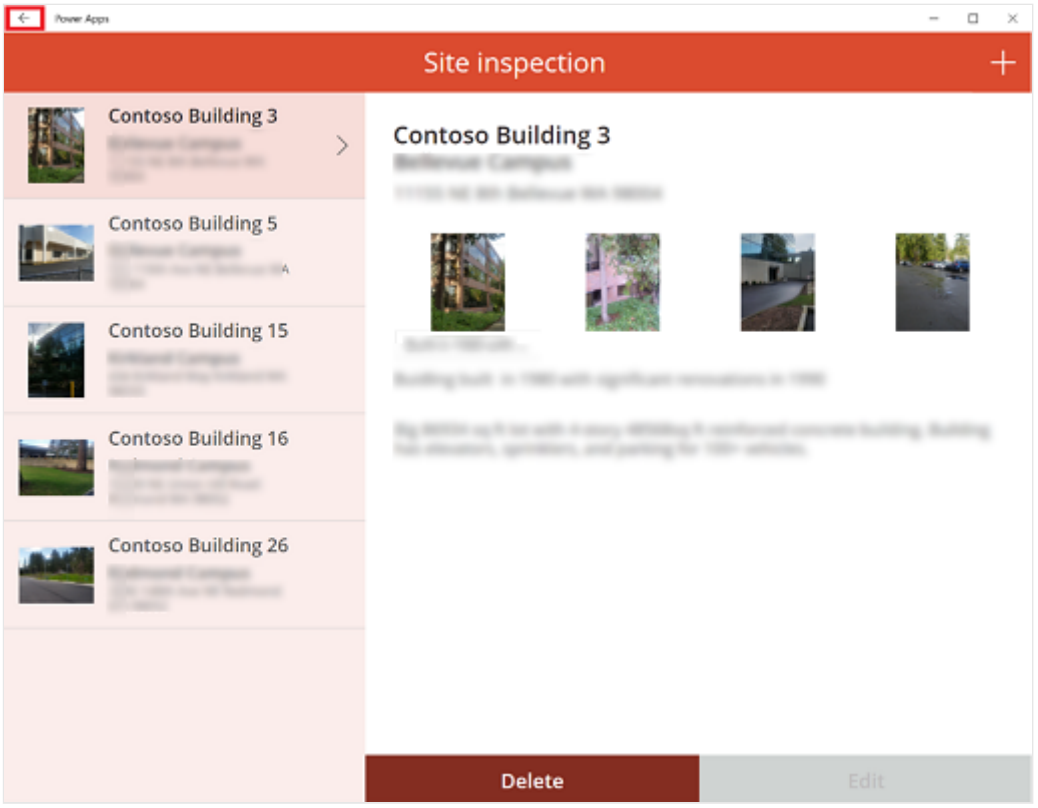
Move between apps

When you're using an app, you can select the back button to go back to the **Apps** screen. From the **Apps** screen, you can then select another app to use.

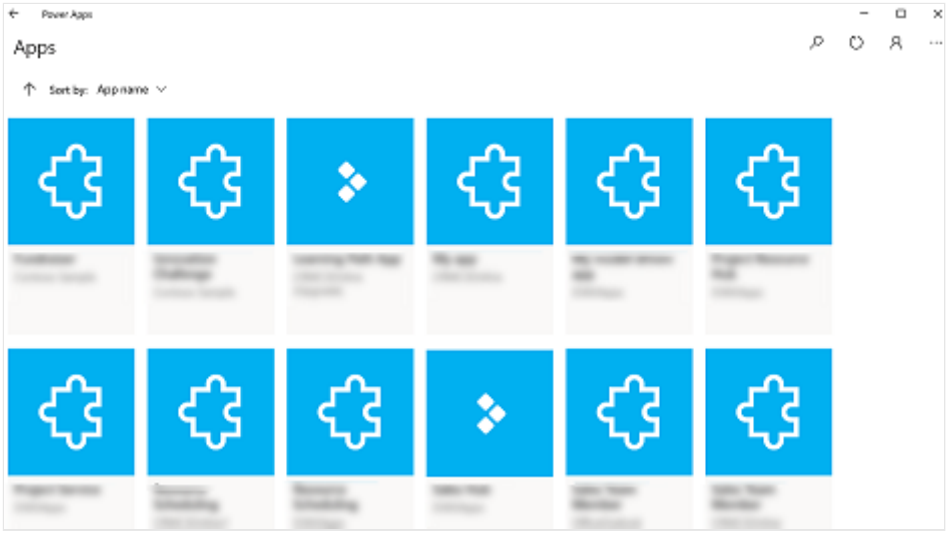
For model-driven apps, you can also select the name of the current app that you're using to go back to the **Apps** screen.

Switch to another canvas app

1. Select the back button.

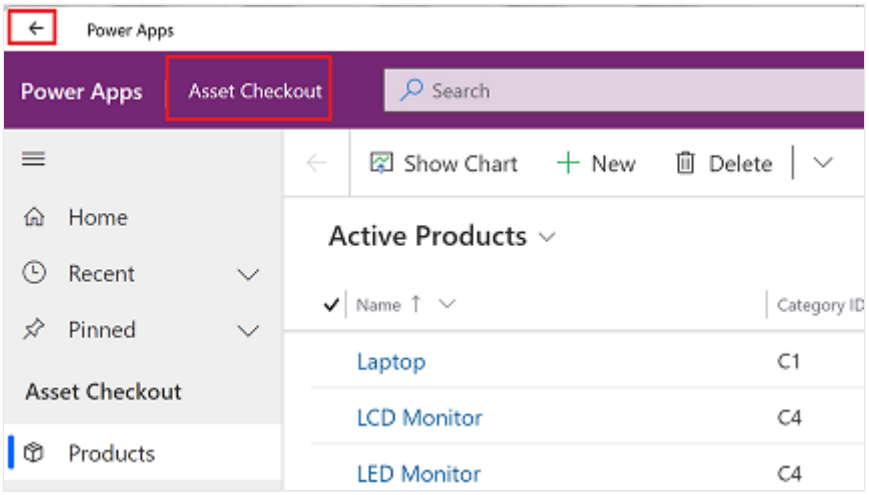


2. On the **Apps** screen select an app. You'll only see apps for your organization.

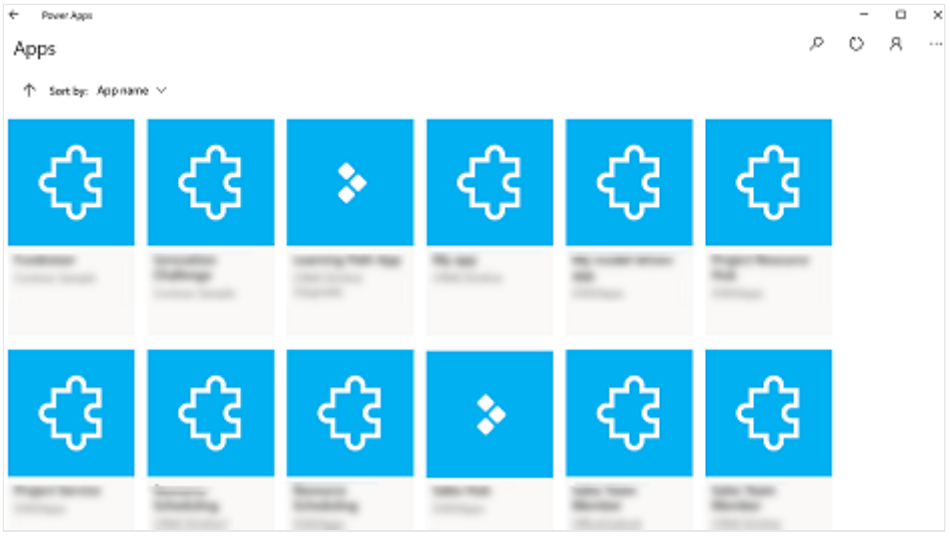


Switch to another model-driven app

1. Select the back button or select the current app name.



2. On the **Apps** screen select an app. You'll only see apps for your organization.



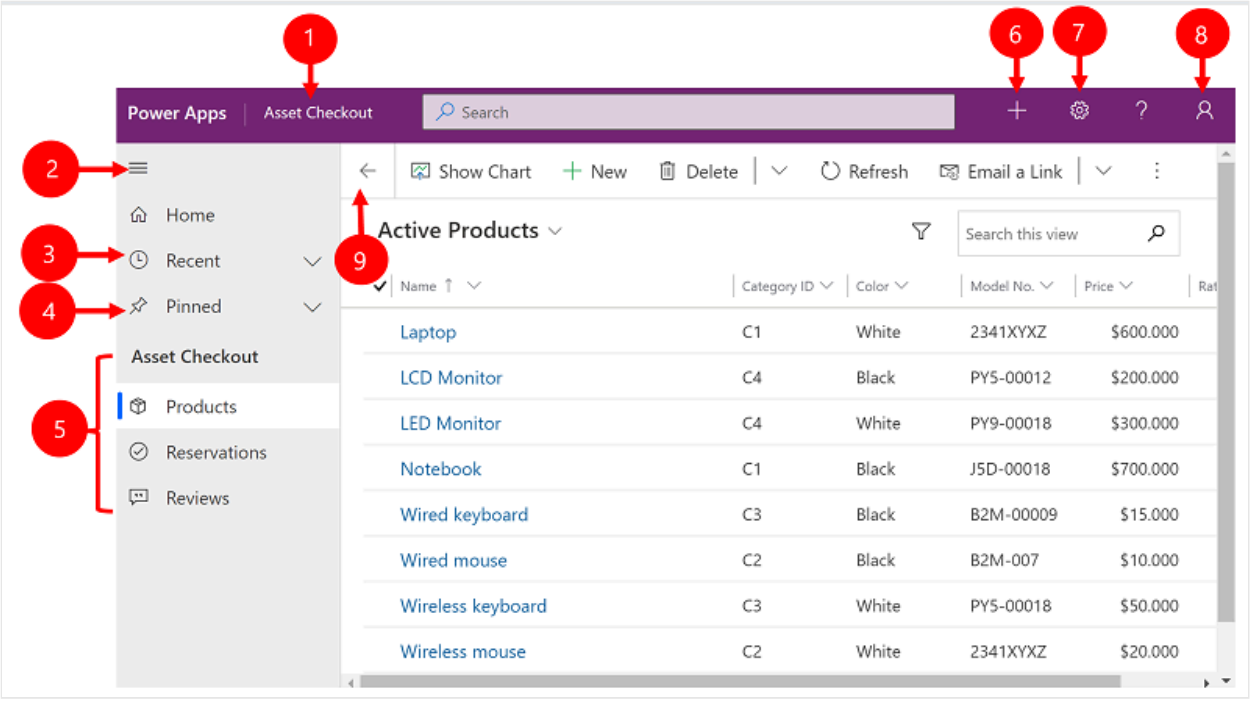
Run an app

Because canvas apps can essentially be anything, there isn't much help documentation on how to use an app once it's created. If you need help using a canvas app, contact your app maker or Power Apps admin.

You'll find below the documentation on how to run model-driven apps on Power Apps for Windows.

Navigation in model-driven apps

It's easy to get around and get back to your favorite or most-used rows. The following illustration shows the primary navigation elements for a model-driven app.



Legend:

1. **Click to change app**: Select the current app name to change to a different app.
2. **Collapse/expand site map**: Select this to collapse the navigator to allow more room for the main part of the page. If the navigator is already collapsed, select this button to expand it again.
3. **Recent**: Expand this entry to view a list of rows you were recently using. Select a row here to open it. Select the push-pin icon next to a row listed here to add it to your pinned rows.
4. **Pinned**: Expand this entry to view and open your favorite pinned rows. Use the **Recent** list to add rows here. Select the remove-pin icon next to a row listed here to remove it from this list.
5. **Page navigation**: This area lists each table and dashboard page available for the current work area. Select any entry here to open the named dashboard or list view for that table.
6. **Create new row**: Select **New** to create a new row.
7. **Setting**: Access your setting such as personalization setting and information about the app.
8. **User Information**: See the current user that's signed in, sign out of the app, or reconfigure the app**.**

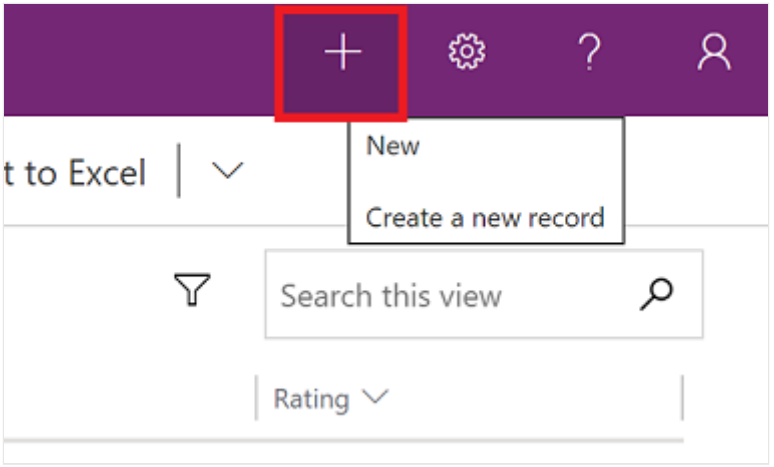
9. **Go back**: Use the back button for form, view, and dashboard pages on the command bar to go back to the previous page.

Create and edit rows

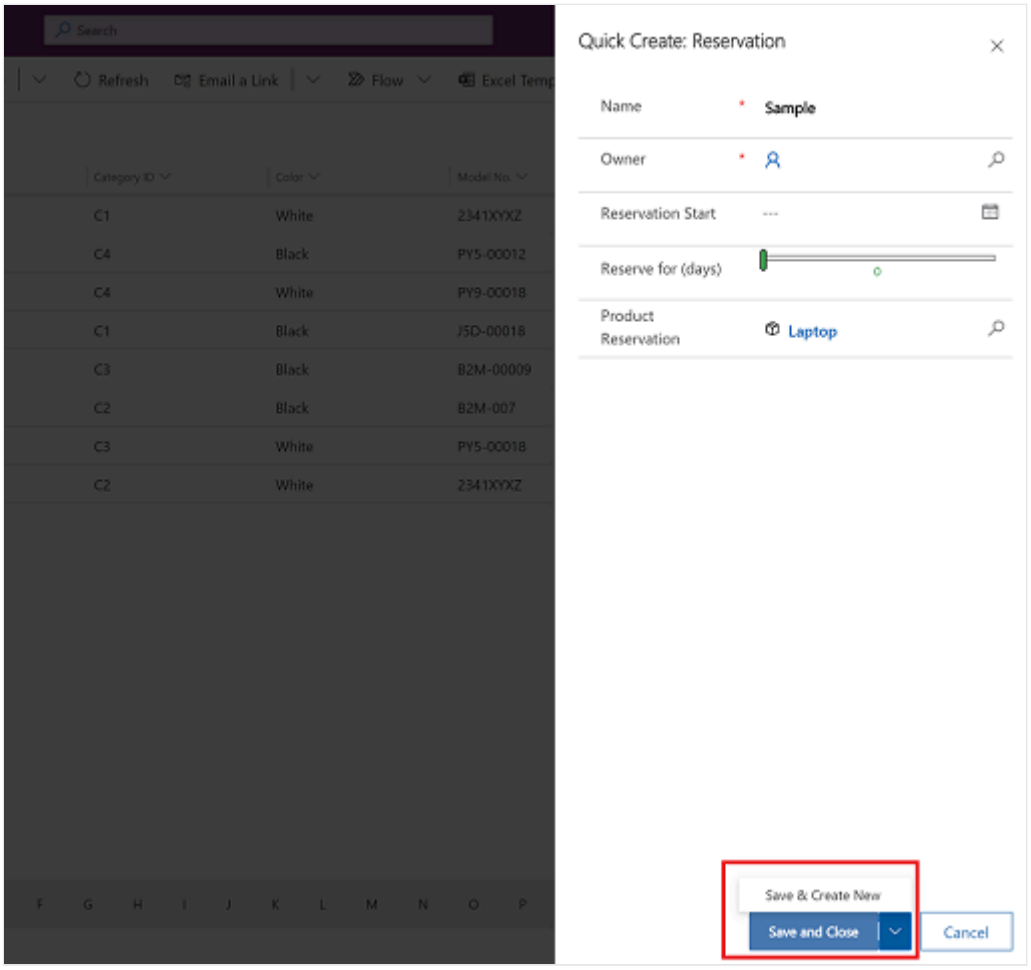
The **New** button or **Quick create** makes it fast and easy to enter almost any type of information into the system. The command is on the navigation bar, so it's available whenever you need to enter new information into the system. You can also save a row and create a new one directly from the **Quick create** form.

Note, the Quick create option is only available for rows that are enabled by your admin.

1. On the navigation bar, select the **plus sign** , and then select the item you want.

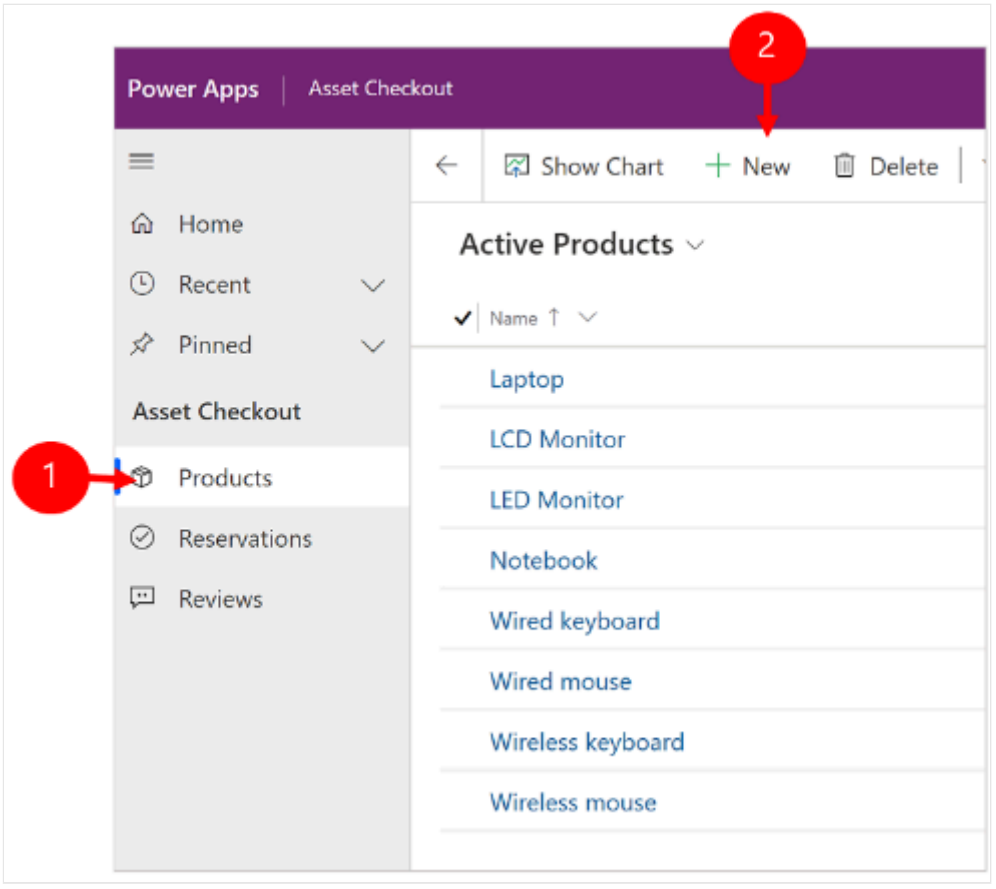


2. Fill in the columns, and then select **Save and Close**. Or, to save and create another row, select the down arrow and then select **Save & Create New**



Create a new row using the New button

1. From the left navigation pane, select a table such as **Products** and then select **New**.

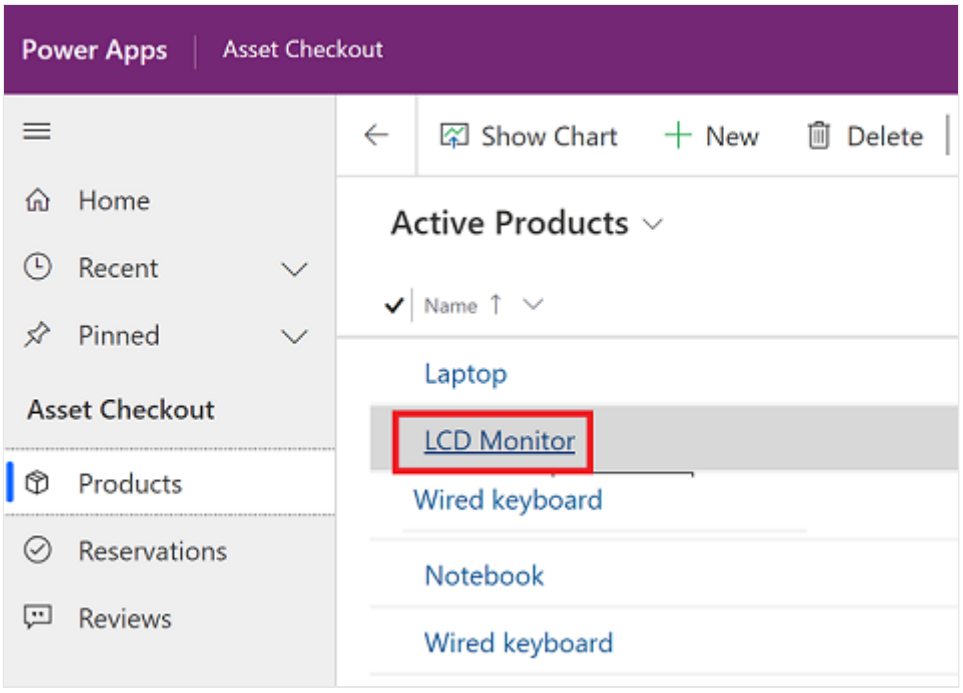


2. Fill in the columns and then on the command bar, select **Save** or **Save & Close**.

Edit a row

1. From the left navigation pane, select a table such as **Products**.

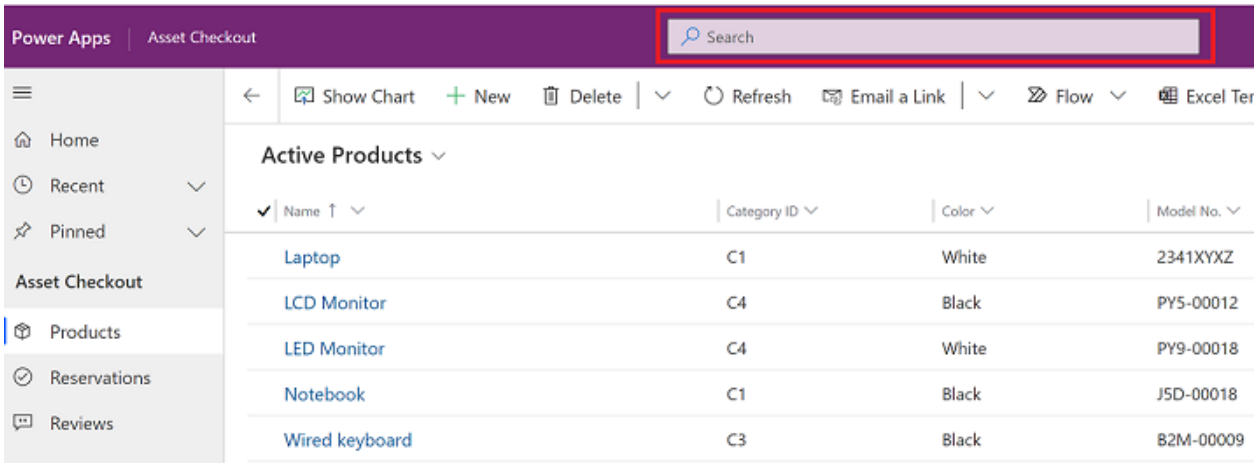
2. Select a row to open it.



3. Make your edits and when you're done editing, select **Save** or **Save & Close**.

Use search

With Dataverse search, the search box is always available at the top of every page in your app. You can start a new search and quickly find the information that you're looking for. For more information, see Search for tables and rows by using Dataverse search.



Notifications

Notifications on Power Apps for Windows work the same as when you run a model-driven app on the web. For more information, see In-app notifications in model-driven apps.

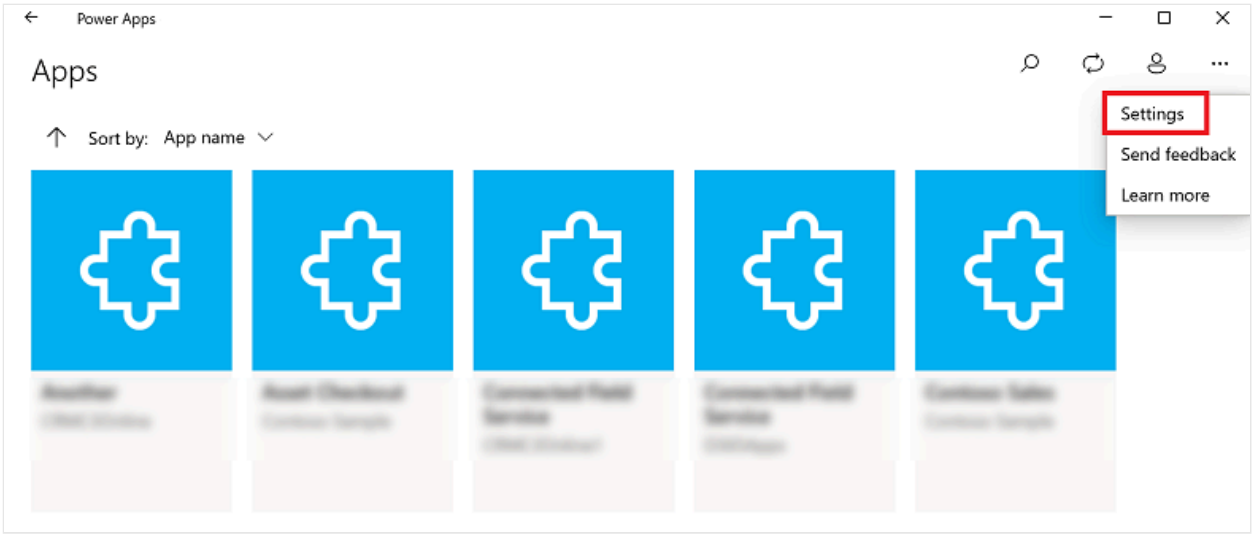
Set up mobile offline

To configure your app in offline mode, see:

- For canvas apps: Develop offline-capable canvas app
- For model-driven apps: Set up mobile offline

Session ID

To get the session ID, select the More button (...) > **Settings** and then copy the session ID.



Log files

Open the following directory on your device to find the log files related to the Windows session for Power Apps for Windows:

`%LocalAppData%\Packages\MicrosoftCorporationII.PowerAppsforWindows10_8wekyb3d8bbwe\LocalState`

The Power Apps support team can use the log files to investigate issues.

Deep links

For more information on deep links, see Use deep links with Power Apps mobile.

Limitations and known issues

- The following is not supported:
  - Advanced controls such as sensors.
  - Pinning an app on Windows desktop
  - Mixed reality controls
  - NFC function
- You can't see favorites, recent, featured apps, or the app details.
- A user picture isn't displayed in the app list.
- The **Optimize images for Upload** option is not available on Windows.
- The barcode scanner doesn't support **BarcodeType**, **PreferFrontCamera**, and **FlashlightEnabled** properties. For more information, see Barcode scanner control in Power Apps - Power Apps. The barcode scanner does support symbologies.

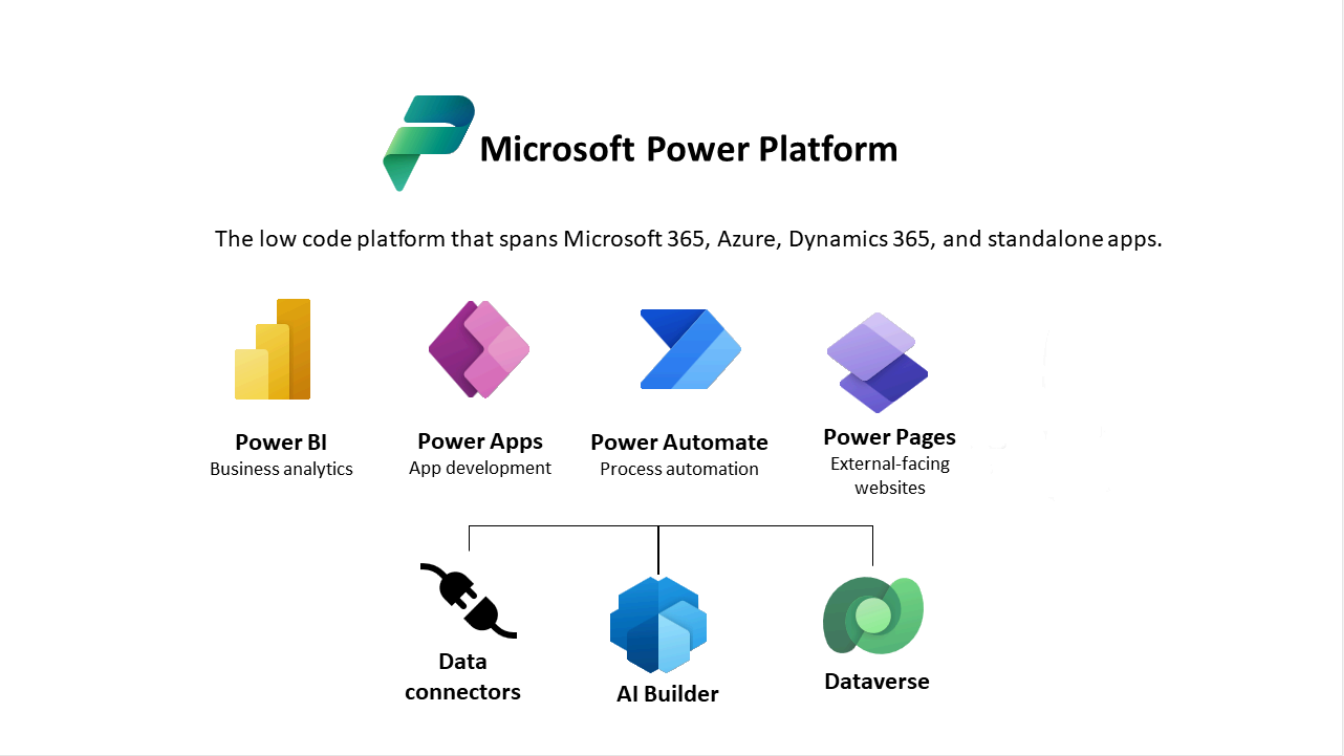
What is Microsoft Dataverse?

Dataverse lets you securely store and manage data that's used by business applications. Data within Dataverse is stored within a set of tables. A *table* is a set of rows (formerly referred to as records) and columns (formerly referred to as fields/attributes). Each column in the table is designed to store a certain type of data, for example, name, age, salary, and so on. Dataverse includes a base set of standard tables that cover typical scenarios, but you can also create custom tables specific to your organization and populate them with data by using Power Query. App makers can then use Power Apps to build rich applications that use this data.



For information about purchasing a plan to use Dataverse, go to Pricing info.

Why use Dataverse?

Standard and custom tables within Dataverse provide a secure and cloud-based storage option for your data. Tables let you create a business-focused definition of your organization's data for use within apps. If you're not sure whether tables are your best option, consider these benefits:

- **Easy to manage** – Both the metadata and data are stored in the cloud. You don't need to worry about the details of how they're stored.
- **Easy to secure** – Data is securely stored so that users can see it only if you grant them access. Role-based security allows you to control access to tables for different users within your organization.
- **Access your Dynamics 365 Data** – Data from your Dynamics 365 applications is also stored within Dataverse, allowing you to quickly build apps that use your Dynamics 365

data and extend your apps with Power Apps.
- **Rich metadata** – Data types and relationships are used directly within Power Apps.
- **Logic and validation** – Define calculated columns, business rules, workflows, and business process flows to ensure data quality and drive business processes.
- **Productivity tools** – Tables are available within the add-ins for Microsoft Excel to increase productivity and ensure data accessibility.

More information: Why choose Dataverse?

Terminology updates

Responding to customer feedback and data from user research, effective November 2020 we're updating some terminology in Dataverse to be more intuitive and make its usage more productive. The terminology updates are listed below, and we're in the process of rolling them out across Microsoft Power Platform.

Expand table

Legacy term	Current term
Entity, entities	Table, tables
Field, fields Attribute, attributes	Column, columns
Record, records	Row, rows
Option set, multi select option sets Picklist, picklists	Choice, choices
Two Options	Yes/No

> **Note**
>
> These terminology updates aren't applicable to any APIs or messages in the Dataverse web services. For example, the names of the messages CreateEntityRequest and CreateAttributeRequest won't change.

Dynamics 365 and Dataverse

Dynamics 365 applications—such as Dynamics 365 Sales, Dynamics 365 Customer Service, or Dynamics 365 Human Resources—also use Dataverse to store and secure the data they use.

This enables you to build apps by using Power Apps and Dataverse directly against your core business data, which is already used within Dynamics 365, without the need for integration.

- **Build apps against your Dynamics 365 data** – Build apps quickly against your business data within Power Apps or by using the extensible platform that lets pro developers programmatically interact with data and metadata, apply business logic, create custom connectors, and integrate with external data.
- **Manage reusable business logic and rules** – Business rules and logic already defined in your Dataverse tables are applied to apps created with Power Apps to ensure data consistency, regardless of how your users access the data or which app they use.
- **Reusable skills across Dynamics 365 and Power Apps** – Users who are skilled in Power Apps or Dynamics 365 can now take advantage of those skills across the Dataverse platform. Creating tables, forms, and charts are now common tasks you perform across your applications.

  > ⓘ **Note**
  >
  > Finance and Operations apps currently require the configuration of the **Data Integrator** to make your business data from Finance and Operations apps available in Dataverse.

Integrating data into Dataverse

Building an app typically involves data from more than one source. Although this can sometimes be done at the application level, there are cases where integrating this data into a common store allows for an easier app-building experience and a single set of logic to maintain and operate over the data. Dataverse allows data to be integrated from multiple sources into a single store, which can then be used in Power Apps, Power Automate, and Power BI along with data that's already available from the Dynamics 365 applications.

- **Scheduled integration with other systems** – Data that's kept within another application can be regularly synchronized with Dataverse to allow you to take advantage of data from other applications in Power Apps.
- **Transform and import data using Power Query** – Transforming data when importing into Dataverse can be done through Power Query—a tool commonly used across Excel and Power BI—from many online data sources.
- **One-time import of data** – Simple import and export of Excel and CSV files can be used for a one-time (or infrequent) import of data into Dataverse.

For more information about integrating data into the Dataverse, go to Add data to a table in Dataverse by using Power Query.

Interacting with tables

When you develop an app, you can use standard tables, custom tables, or both. Dataverse provides standard tables by default. These are designed, in accordance with best practices, to capture the most common concepts and scenarios within an organization.

For a full list of tables, see the entity reference.

You can extend the functionality of standard tables by creating one or more custom tables to store information that's unique to your organization. More information: How to create a custom table

Logic and validation

Tables within Dataverse can take advantage of rich server-side logic and validation to ensure data quality and reduce repetitive code in each app that creates and uses data within a table.

- **Business rules** validate data across multiple columns and tables, and provide warning and error messages, regardless of the app used to create the data. More information: Create a business rule
- **Business process flows** guide users to ensure they enter data consistently and follow the same steps every time. Business process flows are currently only supported for model-driven apps. More information: Business process flows overview
- **Workflows** allow you to automate business processes without user interaction. More information: Workflows overview
- **Business logic with code** supports advanced developer scenarios to extend the application directly through code. More information: Apply business logic with code

Security

Dataverse has a rich security model to protect the data integrity and privacy of users while promoting efficient data access and collaboration. You can combine business units, role-based security, row-based security, and column-based security to define the overall access to information that users have in a Power Platform environment. More information: Security in Dataverse in the Power Platform admin guide

Developer capabilities

In addition to the features available through the Power Apps portal, Dataverse includes features for developers to programmatically access metadata and data to create tables and business logic, in addition to interacting with data. More information: Dataverse Developer Overview

Next steps

To get started using Dataverse:

- Create a canvas app using a Dataverse database.
- Create a custom table and then create a canvas app that uses the table.
- Create a model-driven app built on Dataverse.
- Use Power Query to connect to an online or on-premises data source and import the data directly into Dataverse.

Why choose Microsoft Dataverse?

Article • 04/11/2023

Data is at the center of everything a business does today and powers the insights that can drive what it should do tomorrow. To thrive and grow, businesses need to capture, analyze, predict, present, and report data and do it all with a high level of agility.

Building out the data infrastructure to enable business insight can be both time consuming and expensive. The data originates from a variety of devices, applications, systems, services, and software as a service (SaaS). This large and growing number of sources often consists of multiple data technologies that store different types of data, expose different APIs, and use a mixture of security models. The developers needed to create these technologies can be expensive and hard to find. Developers often must have a deep understanding of how to deploy, configure, manage, and integrate these different data technologies.

Dataverse addresses these concerns with an easy to use, easy to manage, compliant, secure, scalable, and globally available SaaS data service. Dataverse empowers organizations to work with any type of data and any type of app, and use the data within it to gain insights and drive business action.

As part of Microsoft Power Platform, Dataverse requires no or little code to be written, so it can easily be used by everyone from knowledge workers to professional developers.

Knowing that it's built on Azure, organizations choosing Dataverse can be confident that it's globally available, compliant, scalable, and secure.

Work with any type of data

Dataverse is designed to work with any type of data and incorporates all the major categories of data technologies that your organization needs—relational, non-relational, file, image, search, and data lake.

Dataverse includes a set of visual designers to create, edit, and interact with data. This makes it easy to quickly define the tables, relationships, business rules, forms, and workflows that represent your business.

With the easy-to-configure integration features built into Dataverse, deep integration with Microsoft's cloud services such as Azure, Dynamics 365, and Microsoft 365—plus access to many connectors in Power Automate and Azure Logic Apps—Dataverse can

connect to the devices, apps, systems, services, and popular SaaS offerings that contain the data for your business.

As a result, a wide range of enterprise integration scenarios—from retrieving data sent in a spreadsheet as an email attachment to emerging scenarios like using Dataverse data in a blockchain network—can be achieved with ease and with little to no code required. Integration efforts that previously were measured in days and weeks can now often be measured in hours and minutes.

In addition to providing the ability to create data or import it from other systems, Dataverse also supports *virtual tables*. Virtual tables map data in an external data source so that it appears to exist in Dataverse. This enables Dataverse to execute real-time data operations against the external data source. More information: Create and edit virtual tables that contain data from an external data source

Work with any type of app

When an organization wants to create a new app, it can realize additional productivity gains by using Dataverse with Power Apps. Power Apps understands the rich metadata included in Dataverse and uses it in multiple ways to help you rapidly build great-looking apps that are secure and scalable, and make them available across desktop, web, mobile, and Microsoft Teams.

Organizations that use Power Apps can quickly develop mobile apps for iOS and Android. You can also take advantage of Dataverse mobile offline functionality, which enables apps to collect, query, and interact with data when offline.

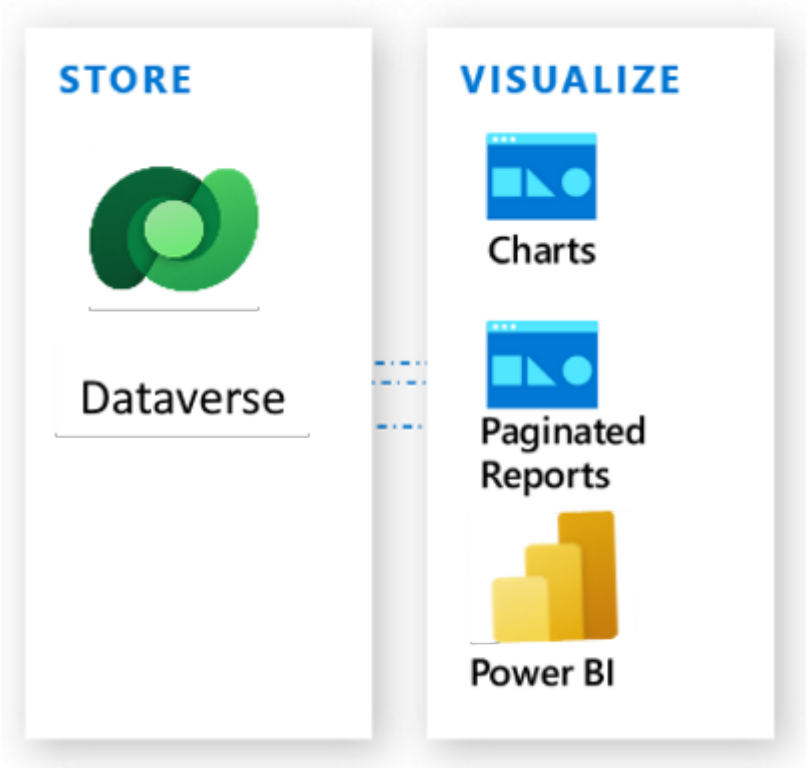
For organizations that want to integrate Dataverse data into existing apps or write new apps by using custom code, Dataverse provides a powerful REST-based API, a developer SDK, and a growing list of samples for common scenarios.

You can also use Dataverse in bot-based apps that deliver intuitive, interactive dialogues with employees, partners, and customers. Whether they're embedded within Power Apps or custom code, bots can be built quickly by using Microsoft Copilot Studio and powered by Dataverse data.

The goal of Dataverse working with any app means it should also work with the tools that knowledge workers and professional developers use. To help them be even more productive, Dataverse is integrated into popular tools such as Excel, Outlook, Dynamics 365 customer engagement apps, Power BI Desktop, Power Query, Azure Data Factory, Data Export Service, and SQL Server Management Studio. More information: Work with any type of app

Analytics and reporting

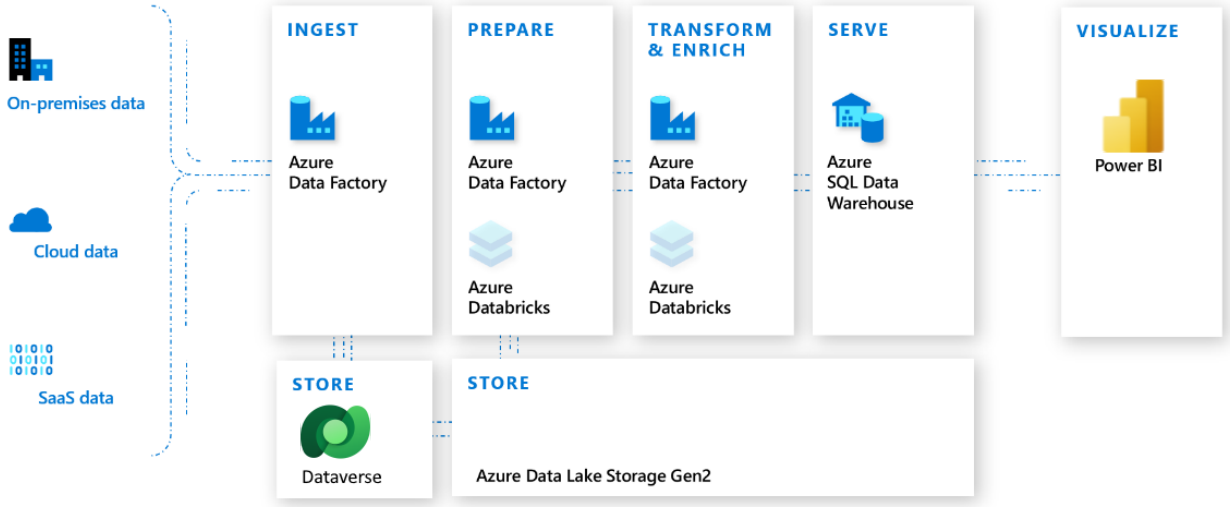
Dataverse can be used to gain insights and drive business action using analytics and reporting. Dataverse also includes a variety of ways to deliver data and insight to key decision makers.



Dataverse includes the ability to create lightweight charts and paginated reports. The data in Dataverse can also be used with Power BI to create rich, interactive reports and dashboards.

For organizations that are interested in employing AI to analyze their data, AI Builder can give everyone in the organization—regardless of their technical expertise—the ability to add AI capabilities to the business process flows they create and use. Delivered as part of Microsoft Power Platform, AI Builder includes six pre-built AI models that can be used in Power Automate and Power Apps, and to evaluate data within Dataverse.

To support advanced analytics and machine learning, Dataverse includes a managed data lake. Data within the lake can be used to run Power BI reporting, machine learning, data warehousing, and other downstream data processing.



One of the benefits of the data being in Azure Data Lake is that organizations can take advantage of Azure Synapse Analytics. This service can deliver added productivity by bringing together enterprise data warehousing, data exploration, code-free data orchestration, deeply integrated Apache Spark and SQL engines, and integrated AI and BI.

Security

Dataverse uses Microsoft Entra identity and access management mechanisms to help ensure that only authorized users can access the environment, data, and reports.

Dataverse uses role-based security to group together a collection of privileges. These security roles can be associated directly with users, or they can be associated with Dataverse teams and business units.

In Dataverse, individual rows can be shared on a one-by-one basis with another user. Because row-level control of access isn't adequate for some business scenarios, Dataverse has a column-level security feature to allow more granular control of security at the column level.

Dataverse also includes two security models that can be used for hierarchies: the *manager* hierarchy and the *position* hierarchy. With the manager hierarchy, a manager must be within the same business unit as the report, or in the parent business unit of the report's business unit, to have access to the report's data. The position hierarchy allows data access across business units.

Because Dataverse is built on Azure, it benefits from the Azure platform's powerful security technologies. Encryption of data, at rest and in transit, preserves confidentiality.

Dataverse is governed by the Microsoft Online Services Terms and the Microsoft Privacy Statement.

More information: Security concepts in Dataverse

Compliance

Compliance is a key concern for organizations. Microsoft regularly engages with dozens of regulators around the world, so organizations can be assured that the data placed in Dataverse is held in accordance with stringent industry safeguards. Dataverse complies with numerous standards, and compliance is verified by third-party audits and certifications.

The list of currently supported standards can be found at the Microsoft Trust Center website.

Availability and scalability

Dataverse is designed to meet enterprise-level scalability needs and offers a service level agreement of 99.9% uptime.

To help ensure service levels, availability, and quality, entitlement limits to the number of requests users can make each day are governed by licenses. Service protection limits have also been put in place against malicious behavior that would otherwise disrupt service for all customers.

Microsoft Power Platform requests

Microsoft Power Platform requests consist of actions that users perform across various products.

At a high level, the following constitute Microsoft Power Platform requests:

- **Connectors**: All API requests to connectors from Power Apps or Power Automate.
- **Power Automate**: All Power Automate step actions.
- **Dataverse**: All create, update, delete (CRUD) operations, in addition to special operations like "share" or "assign." These can come from any client or app, using any SOAP or REST endpoint. These include—but aren't limited to—plug-ins, asynchronous workflows, and custom controls making the abovementioned operations.

The specific number of allowed requests that a user can make in a 24-hour period is governed by the user's license.

Entitlement limits

Entitlement limits represent the number of requests users are entitled to make each day. The allocated limit depends on the type of license assigned to each user.

For information about these entitlement limits, see Microsoft Power Platform requests allocations based on licenses.

For information about viewing and allocating capacity add-ons, see Capacity add-ons.

For information about purchasing individual capacity add-ons, see the Power Apps and Power Automate licensing guide.

Service protection limits

Service protection limits exist to protect the health of the service for everyone. These limits provide a level of protection against random and unexpected surges in request volumes that threaten the availability and performance characteristics of the Dataverse platform.

The service limits the number of concurrent connections per user account, the number of API requests per connection, and the amount of execution time that can be used for each connection. These are evaluated within a five-minute sliding window. When one of these limits is exceeded, an exception is returned by the platform.

Service limits aren't expected to negatively affect normal usage of Dataverse.

For information about current service protection limits for each service, see:

- Dataverse API request limits: Applicable to Dynamics 365 customer engagement apps, such as Dynamics 365 Sales and Dynamics 365 Customer Service, in addition to connections from Power Apps and Power Automate to Dataverse.
- Microsoft Power Automate limits: Applicable for Power Automate.
- Limits in connectors: Applicable for Power Automate and Power Apps.

Capacity add-ons

The specific number of allowed Microsoft Power Platform requests that a user can make in a 24-hour period is governed by the user's license. For scenarios where additional capacity is required, a Power Apps and Power Automate capacity add-on allows customers to purchase additional requests.

Each capacity add-on provides an additional 10,000 requests every 24 hours, which can be assigned to any user. Multiple capacity add-ons can also be assigned to the same user.

Dataverse has entitlement limits that will evaluate the number of requests made against the number allowed by their current license.

Backups

Dataverse provides two types of backups: automatic backups, referred to as *system* backups, and *manual* backups.

System backups

System backups back up all environments. They take place automatically and continuously. The underlying technology used is Azure SQL Database. For more information about Azure SQL automated backups, see Automated backups.

System backups for production environments that have been created with a database and have one or more Dynamics 365 applications installed are retained for 28 days. System backups for production environments that don't have Dynamics 365 applications deployed in them are retained for seven days. System backups for sandbox environments are retained for seven days.

Manual backups

Manual backups are user-initiated, typically done before making a significant customization change or applying a version update.

Both sandbox and production environments can be manually backed up. Sandbox backups are retained for seven days. Manual backups for production environments that have been created with a database and have one or more Dynamics 365 applications installed are retained for 28 days. Manual backups for production environments that don't have Dynamics 365 applications deployed in them are retained for seven days.

There's no limit to the number of manual backups that can be made, and manual backups don't count against storage limits.

> **Note**

Both system and manual backups may only be restored to an environment in the same region in which it was backed up.

More information: Back up and restore environments

Datacenter regions

As many organizations do business globally, their data needs are also global in nature. With Dataverse deployed and supported in regions across the world, organizations can have confidence that Dataverse is available when and where they need it.

For the current list of datacenter regions, see Datacenter regions.

Work with any data

Work with any data

Article • 03/02/2023

Microsoft Dataverse provides an abstraction that makes it possible to work with any type of data, including relational, non-relational, image, file, relative search, or data lake. There is no need to understand the type of data as Dataverse exposes a set of data types that allow you to build up your model. The type of storage is optimized for the data type chosen.

Data can be easily imported and exported with dataflows, Power Query, and Azure Data Factory. Dynamics customers can also use the Data Export Service.

Dataverse also has a connector for Power Automate and Azure Logic Apps that can be used with the hundreds of other connectors in those services for on-premises, infrastructure as a service (IaaS), platform as a service (PaaS), or software as a service (SaaS) services. This includes sources in Azure, Microsoft 365, Dynamics 365, SAP ERP, Salesforce, Amazon Redshift, Access, Excel, text/CSV, SharePoint lists, SQL Server databases, Oracle, MySQL, PostgreSQL, Blockchain, and Azure Synapse Analytics.

Common Data Model

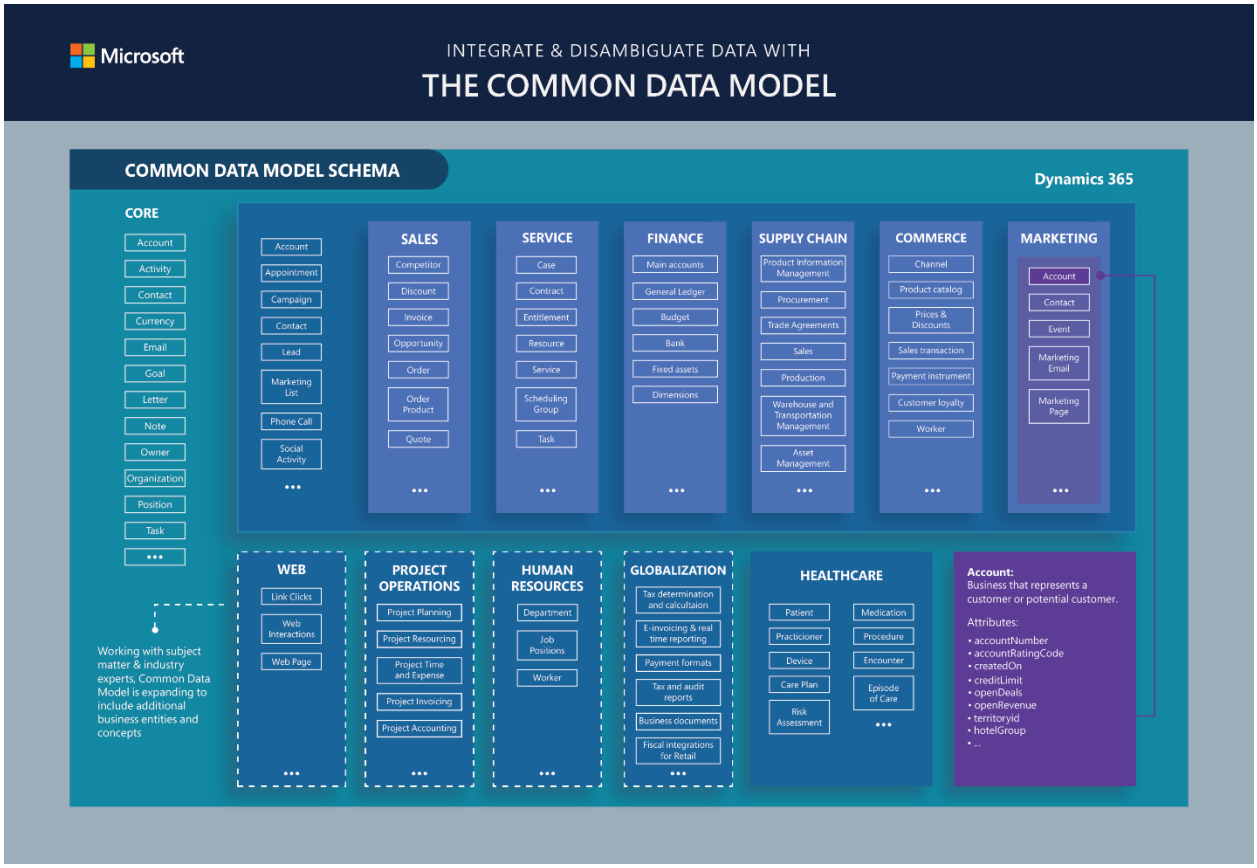
If you've ever had to bring data from multiple systems and apps together, you know what an expensive and time-consuming task that can be. Without being able to share and understand the same data easily, each app or data integration project requires a custom implementation.

Common Data Model provides reference architecture that's intended to streamline this process by providing a shared data language for business and analytical apps to use. The Common Data Model metadata system makes it possible for data and its meaning to be shared across apps and business processes such as Power Apps, Power BI, Dynamics 365, and Azure.

Common Data Model includes a set of standardized, extensible data schemas that Microsoft and its partners have published. This collection of predefined schemas includes tables, attributes, semantic metadata, and relationships. The schemas represent commonly used concepts and activities, such as **Account** and **Campaign**, to simplify the creation, aggregation, and analysis of data.

The Common Data Model schemas can be used to inform the creation of tables in Dataverse. The resulting tables will then be compatible with apps and analytics that target this Common Data Model definition.

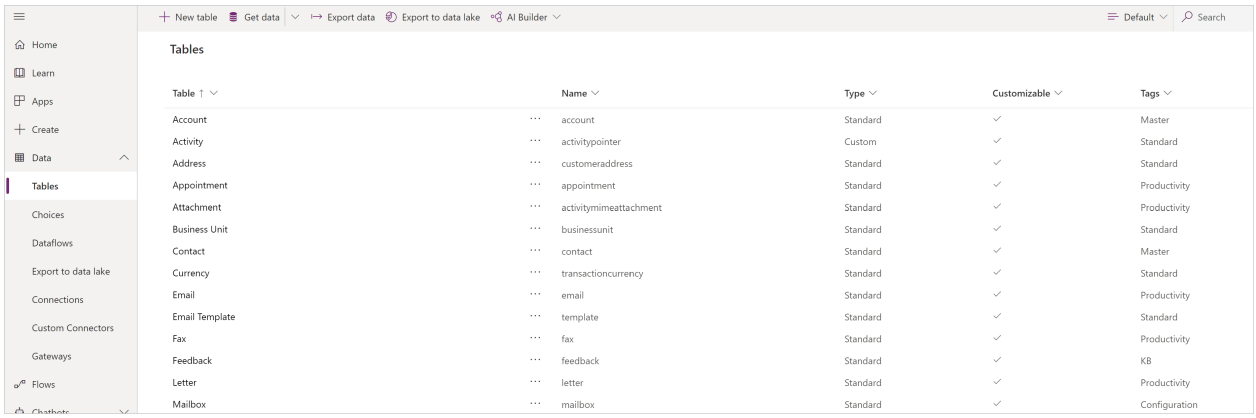
The following image shows some elements of the standard Common Data Model tables.



Tables

In Dataverse, tables are used to model and manage business data. To increase productivity, Dataverse includes a set of tables known as standard tables. These tables are designed, in accordance with best practices, to capture the most common concepts and scenarios within an organization. The standard tables adhere to Common Data Model.

A set of tables that are commonly used across industries, such as **User** and **Team**, are included in Dataverse and referred to as *standard tables*. These out-of-the-box tables can also be customized, such as including additional columns. In addition, you can easily create your own custom tables in Dataverse.

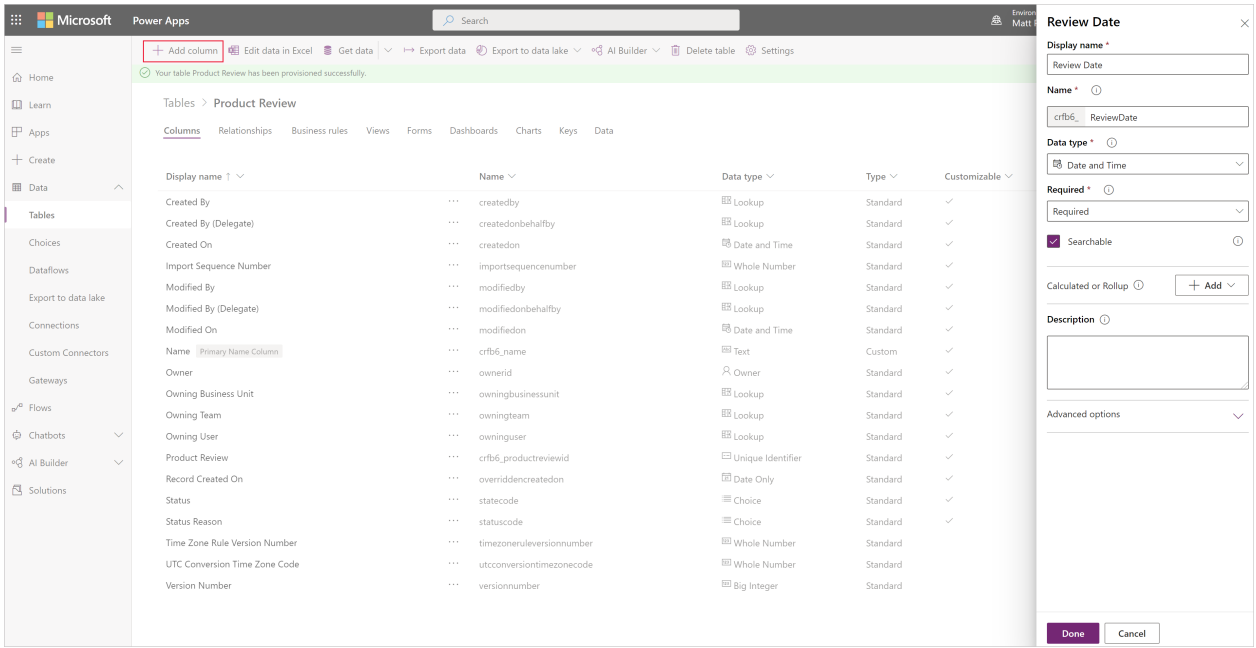


Columns

Columns define the individual data items that can be used to store data in a table. Fields are sometimes called attributes by developers. A table representing a course at a university might contain columns such as "Name," "Location," "Department," "Registered Students," and so on.

Columns might have different types of data such as numerals, strings, digital data, images, and files. There's no need to keep relational and non-relational data separated artificially if it's part of the same business process or flow. Dataverse stores the data in the best storage type for the model created.

Each of these columns can be associated with one of many data types supported by Dataverse.

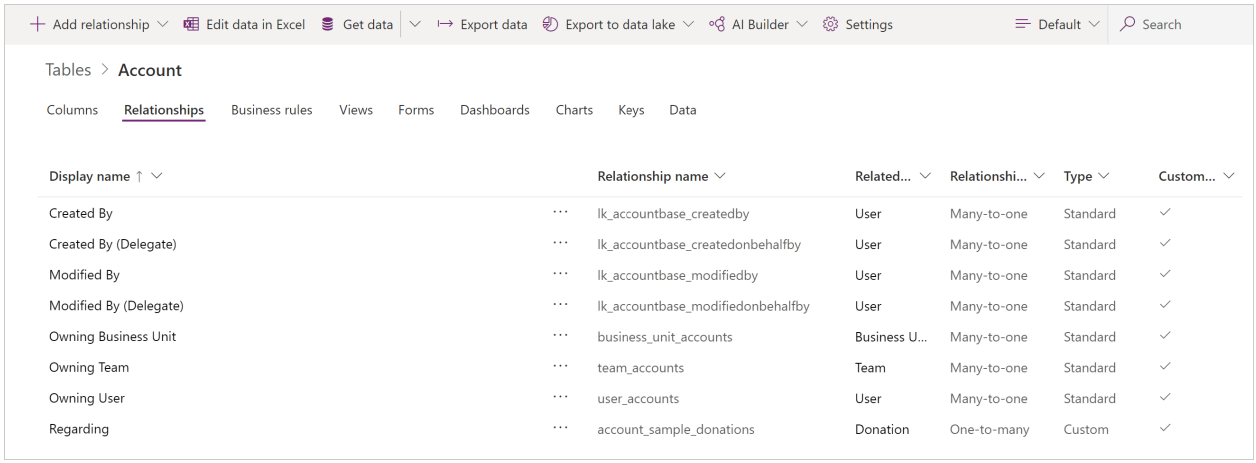


More information: Types of columns

Relationships

Data in one table often relates to data in another table. table relationships define how rows can be related to each other in the Dataverse model.

Dataverse provides easy-to-use visual designers to define the different types of relationships from one table to another (or between a table and itself). Each table can have a relationship with more than one table, and each table can have more than one relationship to another table.



The relationship types are:

- **Many-to-one**: In this type of relationship, many table A records can be associated with a single table B record. For example, a class of students have a single classroom.
- **One-to-many**: In this type of relationship, a single table B record can be associated with many table A records. For example, one single teacher teaches many classes.
- **Many-to-many**: In this type of relationship, each record in table A can match more than one record in table B, and vice versa. For example, students attend many classes, and each class can have multiple students.

Because many-to-one relationships are the most common, Dataverse provides a specific data type named *lookup*, which not only makes it easy to define this relationship but adds productivity to building forms and apps.

For more information about creating table relationships, see Create a relationship between tables.

Organizations often need to be in compliance with various regulations to ensure the availability of customer interaction history, audit logs, access reports, and security incident tracking reports. Organizations might want to track changes in Dataverse data for security and analytical purposes.

Dataverse provides an auditing capability where changes to tables and attribute data in an organization can be rowed over time for use in analysis and reporting. Auditing is supported on all custom—and most customizable—tables and attributes. Auditing isn't supported on metadata changes, retrieve operations, export operations, or during authentication. For information about how to configure auditing, go to Manage Dataverse auditing.

Dataverse supports analytics by providing the capability to choose tables for machine learning models to run. It has a prebuilt AI capability through AI Builder.

Search

Dataverse provides three ways to query rows:

- Dataverse search
- Quick find (single-table or multi-table)
- Advanced find

> **Note**
>
> Multi-table quick find is also called *categorized search*.

For more information, see Compare searches.

Dataverse search

Dataverse search delivers fast and comprehensive results across multiple tables in a single list, sorted by relevance. It uses a dedicated search service external to Dataverse (powered by Azure) to boost search performance.

Dataverse search brings the following enhancements and benefits:

- Improves performance by using external indexing and Azure search technology.
- Finds matches to any word in the search term in any column in the table, compared to quick find where all words from the search term must be found in one column.
- Finds matches that include inflectional words like *stream*, *streaming*, or *streamed*.

- Returns results from all searchable tables in a single list sorted by relevance, so the better the match, the higher the result appears in the list. A match has a higher relevancy if more words from the search term are found in close proximity to each other. The smaller the amount of text where the search words are found, the higher the relevancy. For example, if you find the search words in a company name and address, it might be a better match than finding the same words in a long article, far apart from each other.

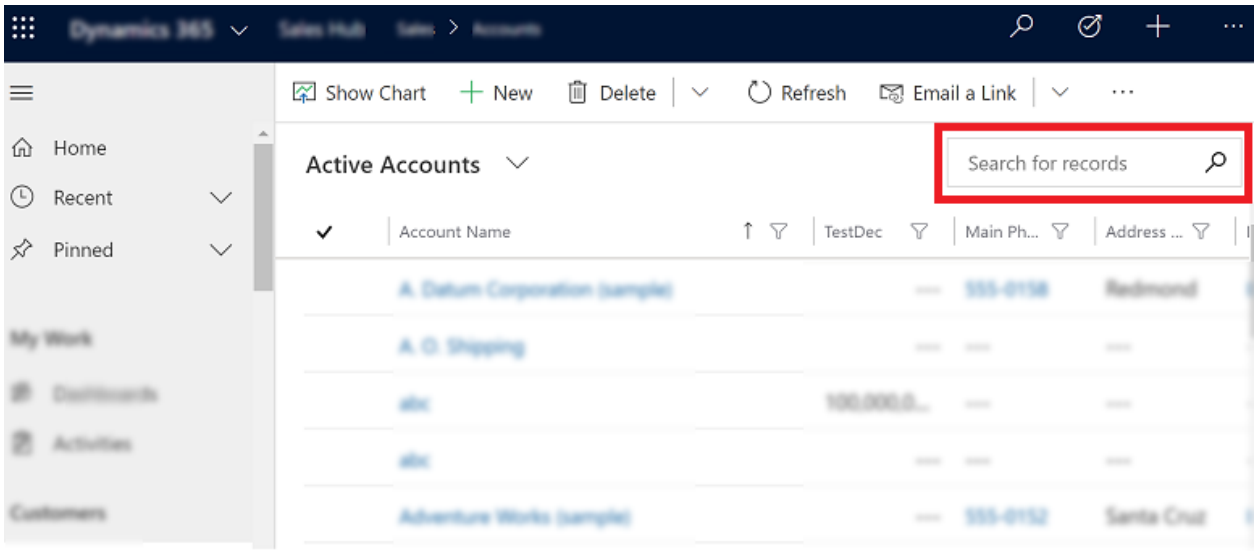
- Highlights matches in the results list. When a search term matches a term in a row, the term appears as bold and italicized text in your search results.

For more information about Dataverse search, see Using Dataverse search to search for rows.

Quick find

Dataverse includes the ability to find rows quickly and has approaches that will search just one type of table, such as customer, or be used to search across multiple types of tables at the same time, such as contacts, users, customers, and so on.

Single-table quick find is used to find rows of only one type. This search option is available from within a view.

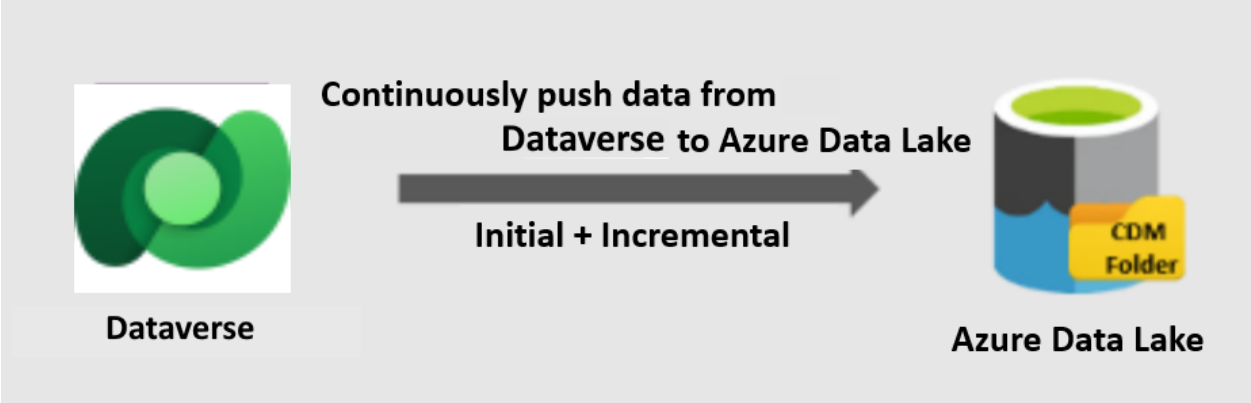


Multiple-table quick find (categorized search) is also used to find rows, but will find them across different types of tables, such as accounts or contacts.

Data Lake

Dataverse supports continuous replication of table data to Azure Data Lake Storage, which can then be used to run analytics such as Power BI reporting, machine learning,

data warehousing, and other downstream integration processes.



This feature is designed for enterprise big-data analytics. It's cost-effective, scalable, has high availability and disaster recovery capabilities, and enables best-in-class analytics performance.

Data is stored in the Common Data Model format, which provides semantic consistency across apps and deployments. Standardized metadata and self-describing data in Common Data Model facilitates metadata discovery and interoperability between data producers and consumers such as Power BI, Data Factory, Azure Databricks, and Azure Machine Learning.

Importing and exporting data

Importing and exporting data from Dataverse

Article • 08/06/2024

Microsoft Dataverse is a SaaS data platform that helps you easily create and manage your data, events, and logic and generate analytics** and insights to support interconnected apps built on the Dataverse platform. Apps include first-party apps such as Dynamics 365 Sales, Service, Marketing, Customer Insights, Customer Journey Orchestration, as well as custom third-party apps and processes, all of which operate in a secure and compliant manner. Dataverse, being a hyperscale polyglot storage, can store any type of data (relational, file, observational, and so on) for all your transactional and analytical applications. For this reason, it's the data platform for all Power Platform products and Dynamics 365 applications. Dataverse is a critical element of Microsoft Power Platform, supporting all the data, events, analytics, and related processing, in addition to generating insights for citizen app makers and professional developers to build, store, and manage data for their applications.

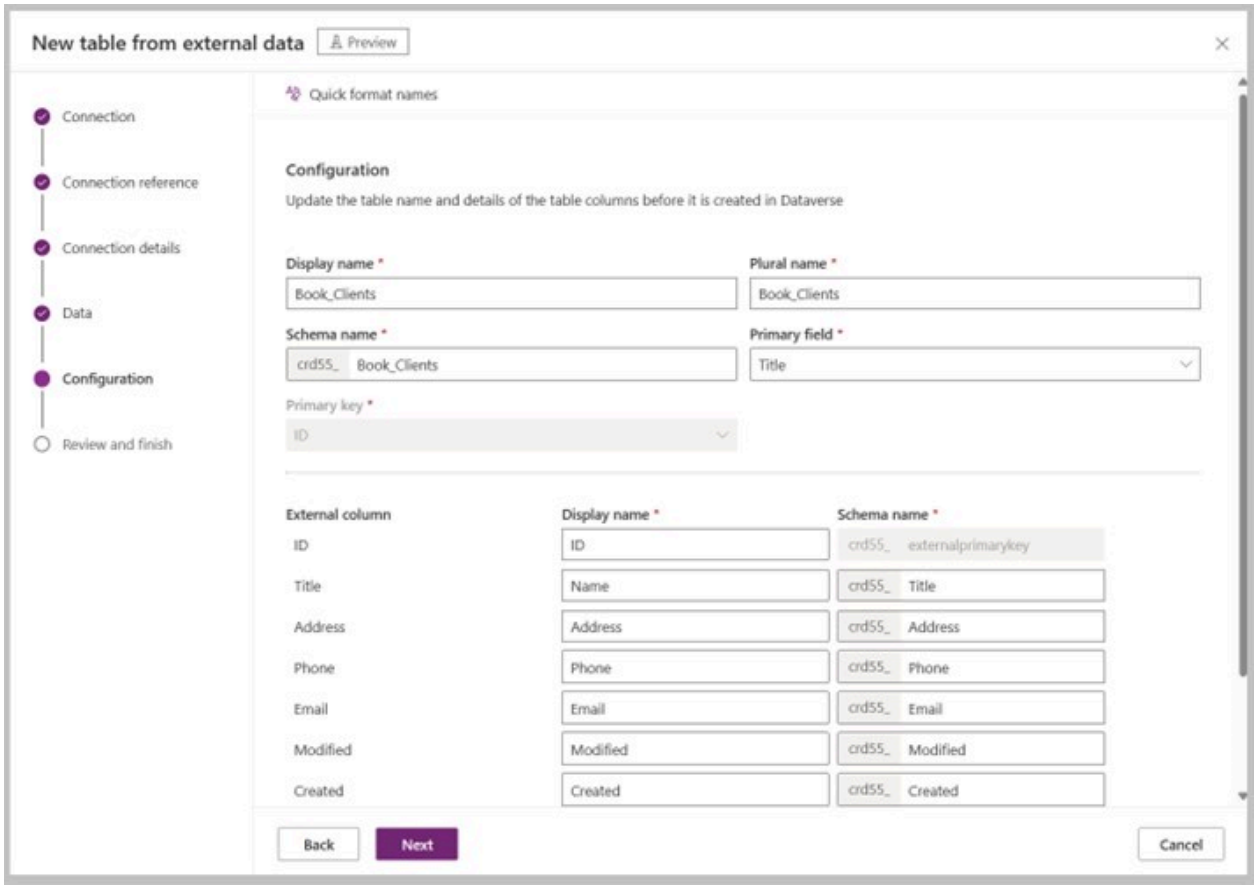
Data required by apps and processes doesn't often originate from or reside within Dataverse. Mashing up external data with Dataverse is an essential component in building apps, adding data to existing apps, and creating valuable insights. With the proliferation of big data and the ever-multiplying types of data sources, such as AI, ML, IoT, web commerce, web API, services, ERP, and line of business apps require Dataverse customers to be agile with using this variety of data.

There are multiple ways to import and export data into Microsoft Dataverse. You can use dataflows, Power Query, Azure Synapse Link, Azure Data Factory, Azure Logic Apps, and Power Automate.

Where to start?

The first consideration is to start with the external data, which already exists outside of Dataverse that is required for building an app, form, or other component. It isn't necessary to persist that data in Dataverse to start using it. Many times, it's best to continue to let the other system manage the data while using the data as needed in Dataverse. The virtual table feature in Dataverse provides this capability. More information: Create virtual tables using virtual connectors.

With virtual tables, you can build an app that uses the external data as if it were a Dataverse table. To help you create virtual tables easier, use the virtual tables creation wizard now in Public Preview | Microsoft Power Apps



Import external data to Dataverse

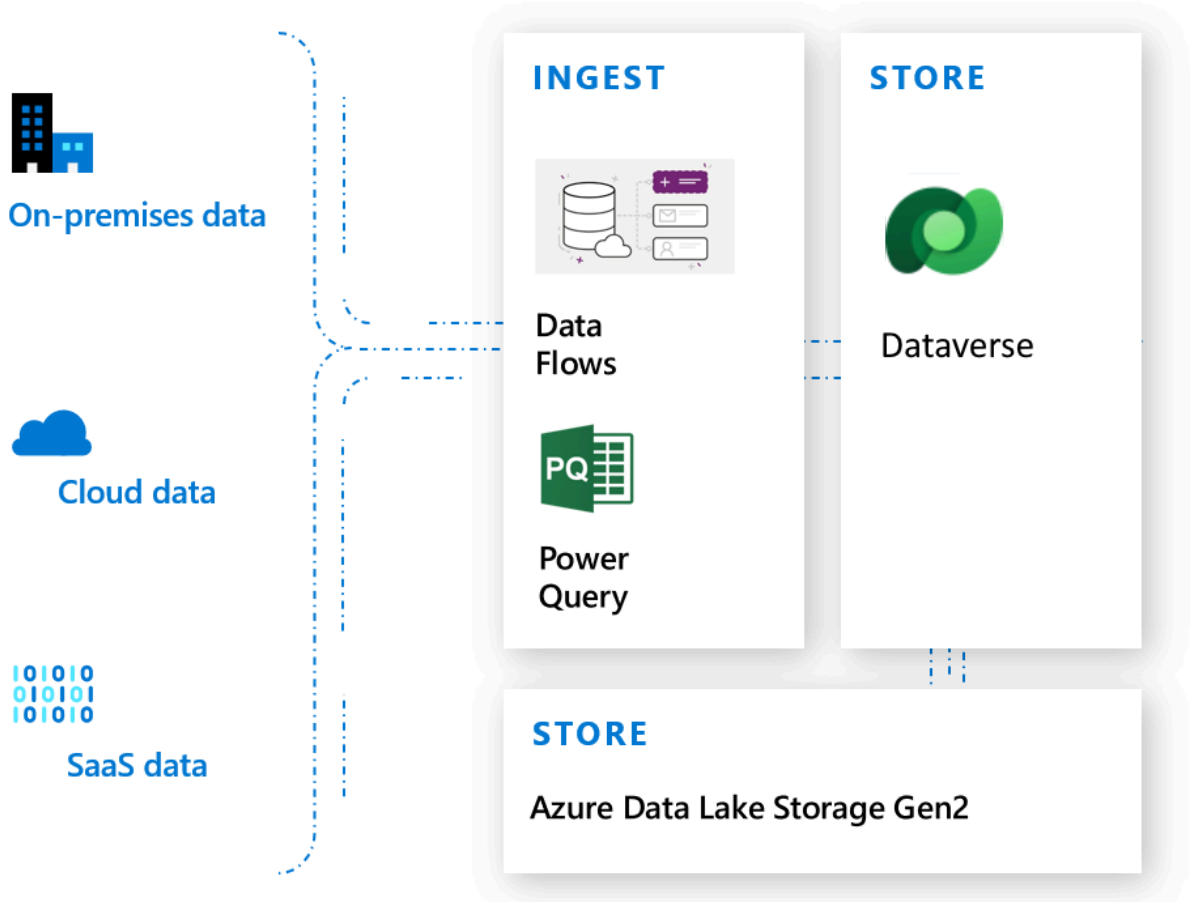
Your desired outcomes might drive the decision to persist data in Dataverse versus using virtual tables to surface external data in Dataverse. If you want your data to be managed by security concepts in Dataverse and application lifecycle management

features or if you're interested in mashing up external data with native Dataverse data, consider moving data into Dataverse. Additionally, if you're interested in using Dataverse workflow and business rules, you might consider migrating that data into Dataverse. You should also consider the economic impact of loading data into Dataverse, which might increase storage costs. If the data must continue to be managed by an external system, it can be beneficial to leave it there and interact with it in Dataverse using virtual tables.

Dataflows, Power Query, and Excel files

Dataflows enable you to connect with business data from various sources, clean the data, transform it, and then load it into Dataverse. Dataflows support dozens of popular on-premises, cloud, and software as a service (SaaS) data sources.

Power Query is a data connection technology you can use to discover, connect, combine, and refine data sources to meet your analysis needs. Features in Power Query are available in Excel and Power BI Desktop.

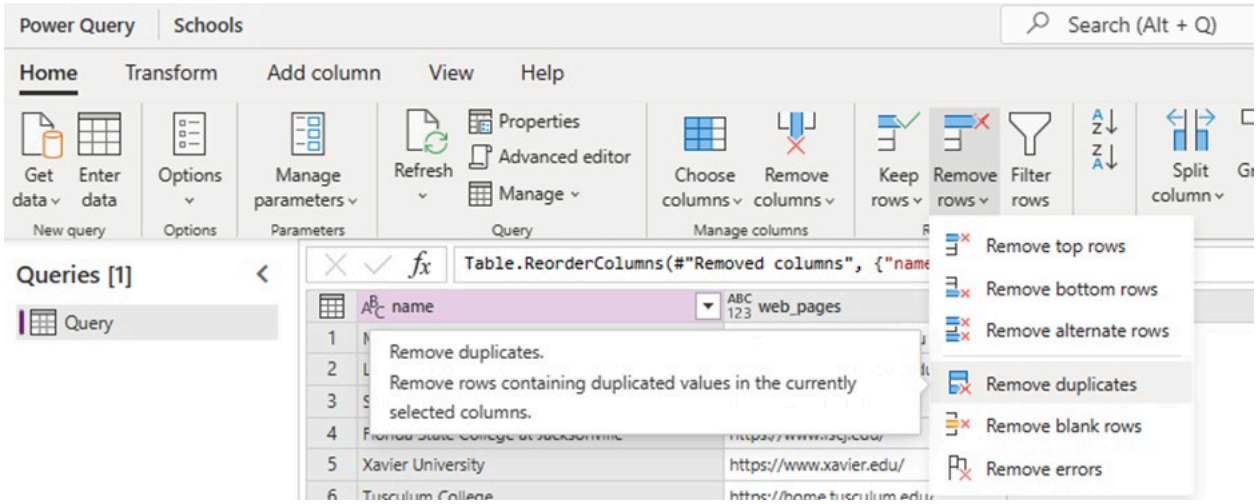


During the project envisioning phase, you should weigh out all the options and decide whether external data needs to be part of your transactional data. Once the approach is finalized, changing it during implementation and post go-live might cause disruption for the end users experience. Once the decision has been made to load external data into

Dataverse, a great tool is dataflows. Dataflows are a great choice when you need to transform and prepare the data while you move it. The dataflow design environment, Power Query, has robust out-of-the-box functionality to help with intuitive transformation and data prep.

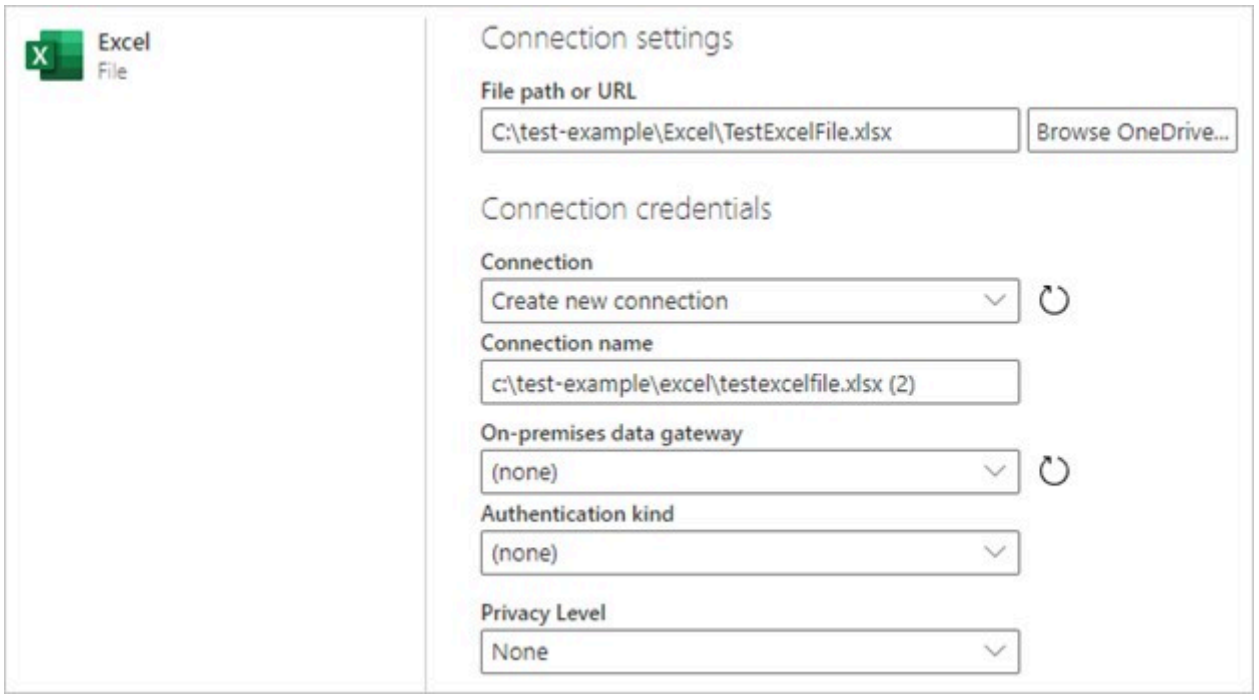
More information: Create and use dataflows in Power Apps and Add data to a table in Dataverse by using Power Query

Note that loading data via dataflows is subject to the Dataverse service protection limits. Learn more

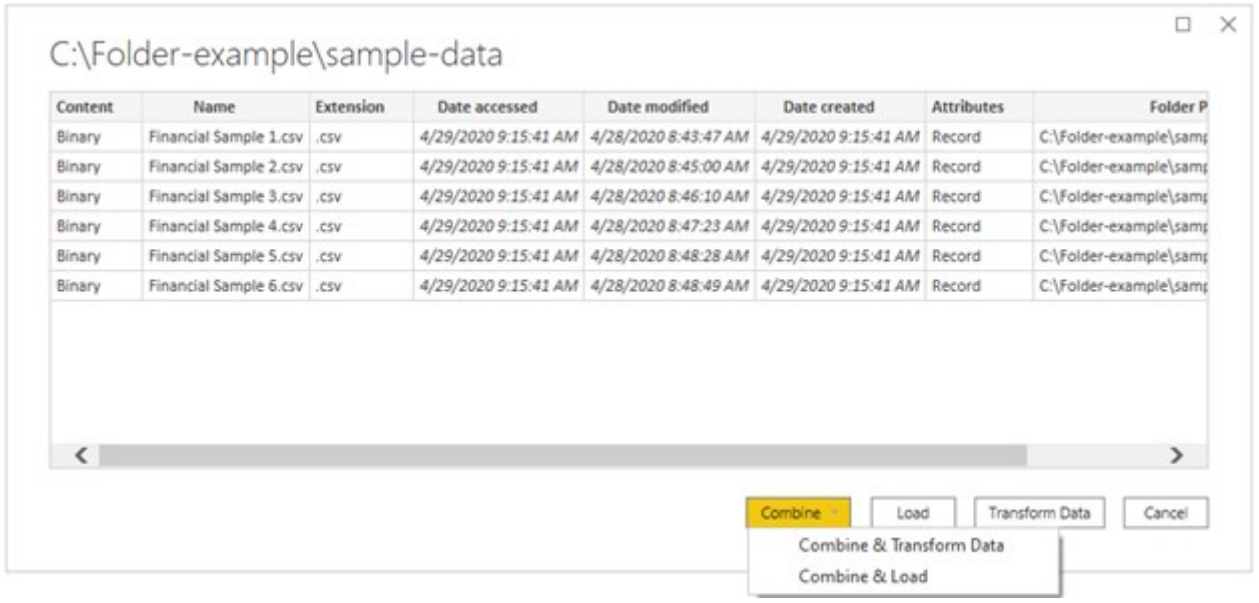


Power Query supports a multitude of available connectors as outlined here: List of all Power Query connectors

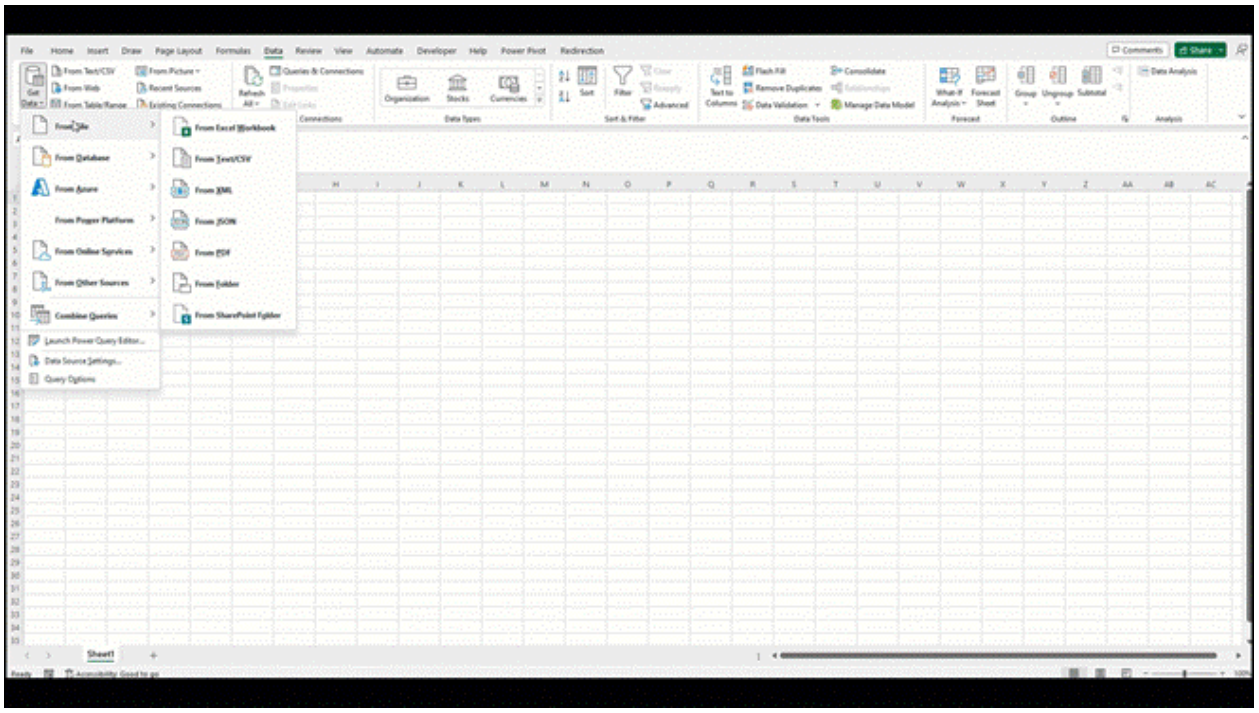
If your data originates in Excel, like that of many Dataverse customers, then use the existing Excel connector, for example, among multitude of other available connectors, to build a data pipeline into Dataverse. In addition to one-off data loads, sync your Excel data source with Dataverse using a dataflow. Consider Excel file size limitations with this guidance reduce the size of an Excel workbook to view it in Power BI



Moreover, if you have multiple Excel files in a folder that you'd like to load into Dataverse, you can use Power Query folder connector to combine, transform, and load data.



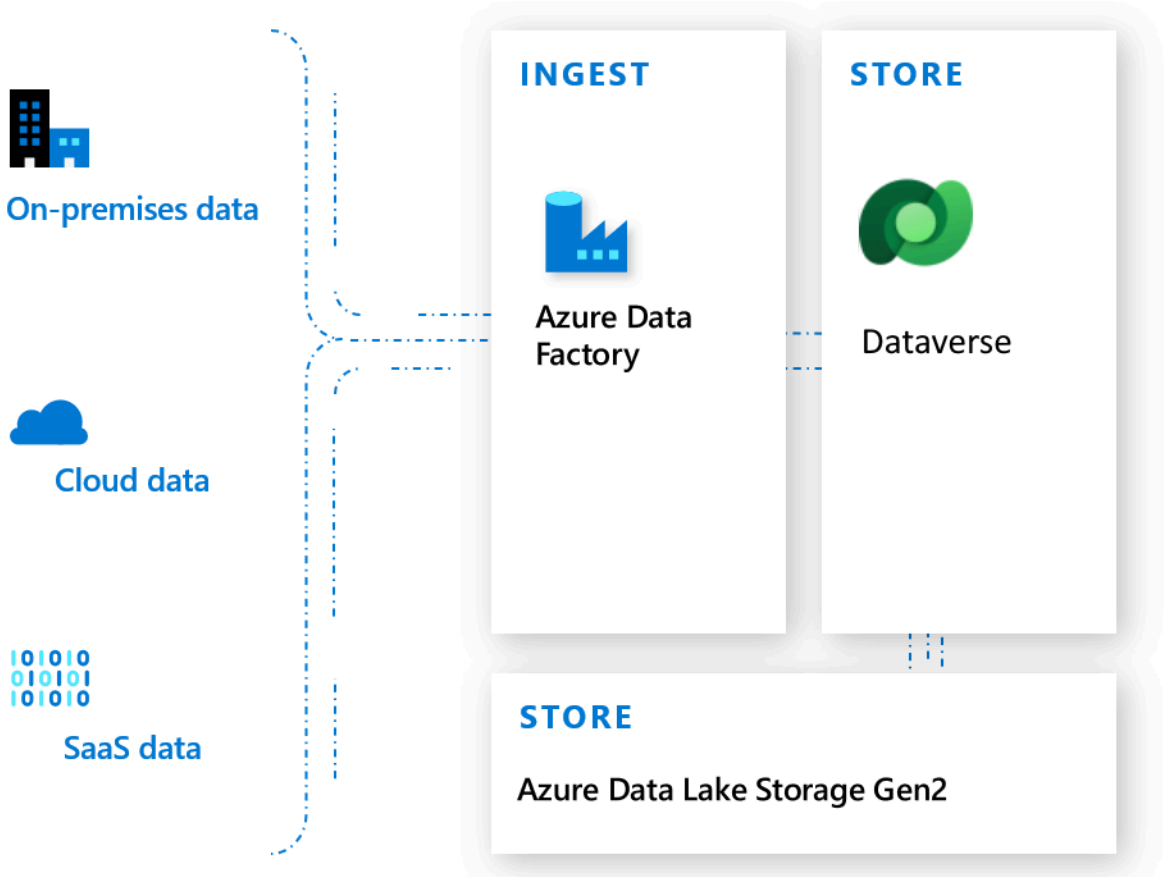
IT professionals can also free up business users from the complexities of building data pipelines by creating Power Platform dataflow templates. Build a complex query combining data from multiple sources, save it, and share with business users. This file can be then used from the **New dataflow** > **Import template** feature in Dataverse. All the user needs to do is verify credentials for data access to start loading data into Dataverse tables. Learn more Create Power Platform dataflows from queries in Microsoft Excel.



You can also perform a one-time import of data directly from a single Excel file into a Dataverse table. More information: Import data from Excel and export data to CSV

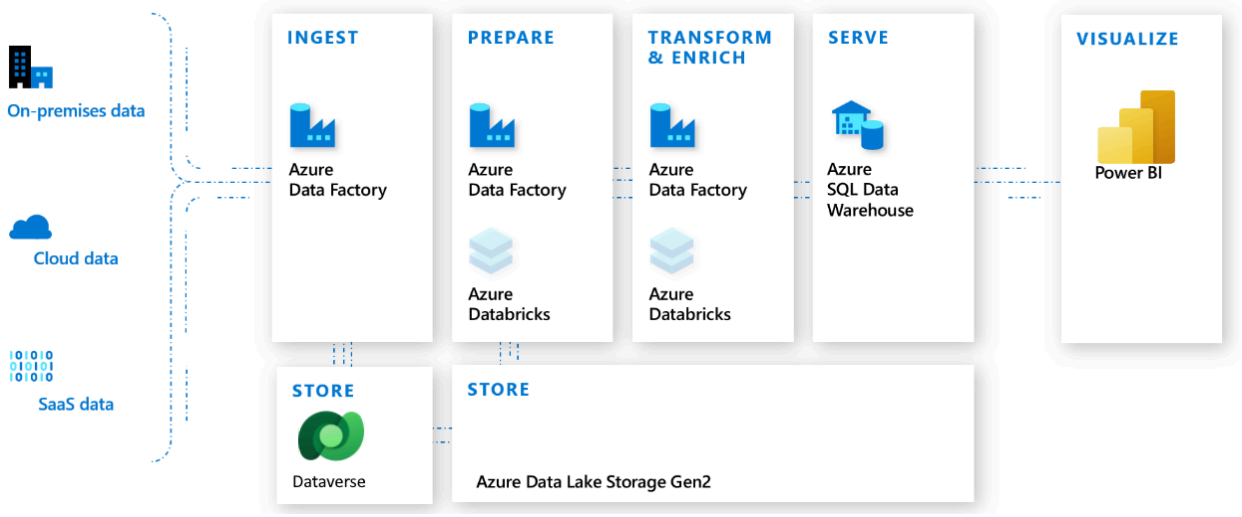
Azure Data Factory

Data Factory is a data integration service that provides a low-code or no-code approach to construct extract, transform, and load (ETL) processes within a visual environment or by writing your own code.



Depending on your data needs, at some point you might require more involved data engineering to bring the data from external sources into Dataverse. It isn't just about the data volume, but also about the amount and complexity of data transformations required for the source data to meet your data requirements in Dataverse. An additional consideration is the IT resources are available to assist with the effort. These more complex data scenarios can be addressed with Power Platform dataflows, Azure Data Factory, and Web API. >Data Factory and Web API integration patterns shine at building pipelines that require involved workflow and algorithm rich transformations. Conversely, dataflows are faster to start with and easier to use.

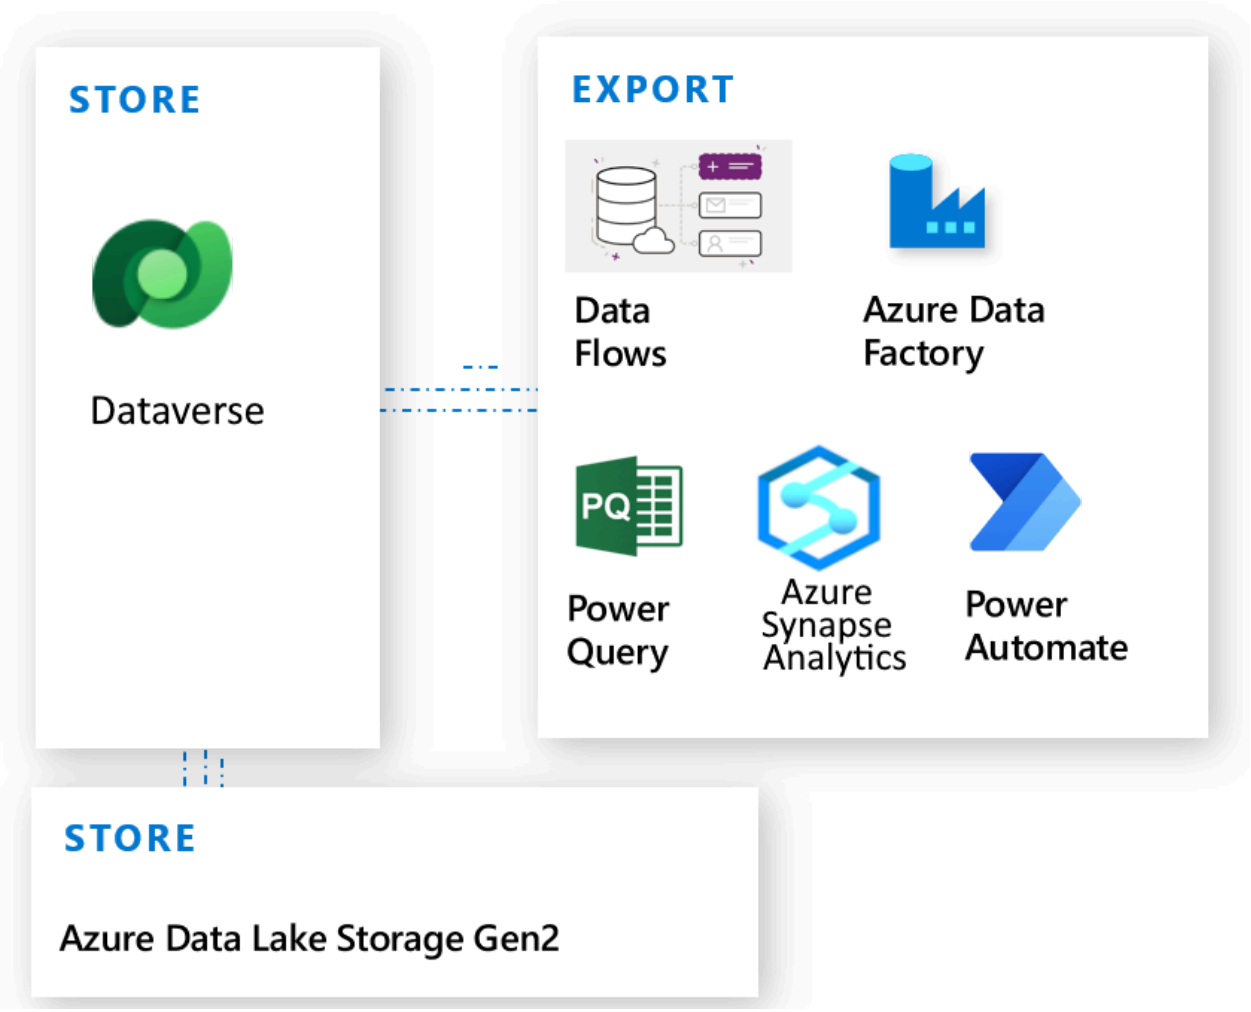
With Data Factory, you can visually integrate Dataverse and other data sources by using more than 90 natively built and maintenance-free connectors.



In addition to bringing data into Dataverse, Data Factory can also be used to prepare, transform, and enrich data with Azure Databricks and move data into Azure Synapse Analytics.

Exporting data from Dataverse

Exporting data, either to another data technology or to another environment, can use any of the same technologies mentioned for importing data, such as dataflows, Data Factory, Power Query, and Power Automate.



Dynamics customers who are targeting SQL Server or Azure SQL Database can use Azure Synapse Link. Azure Synapse Link for Dataverse connects with Azure Synapse Analytics to enable you to get near real-time insights over your data from Microsoft Dataverse. With a tight seamless integration between Dataverse and Azure Synapse Analytics, Azure Synapse Link enables you to run analytics, business intelligence and machine learning scenarios on your data. More information: What is Azure Synapse Link for Dataverse

Work with any type of app

Article • 06/21/2022

Microsoft Dataverse provides multiple ways to integrate in any type of app (mobile, web, desktop), device, system, or service. For cloud solutions, there are ways to integrate regardless of the model in which your solution is deployed—infrastructure as a service (IaaS), platform as a service (PaaS), or software as a service (SaaS). For IaaS-based solutions, the integration approach also works well if solutions are running inside of containers.

In some cases, integration with an app can be achieved by using business logic contained in Dataverse. In other cases, it will involve integration via events, the Dataverse OData API, or using plug-ins.

Defining business logic

Tables in Dataverse can use rich server-side logic and validation to ensure data quality and reduce repetitive code in each app that creates and uses data in a table.

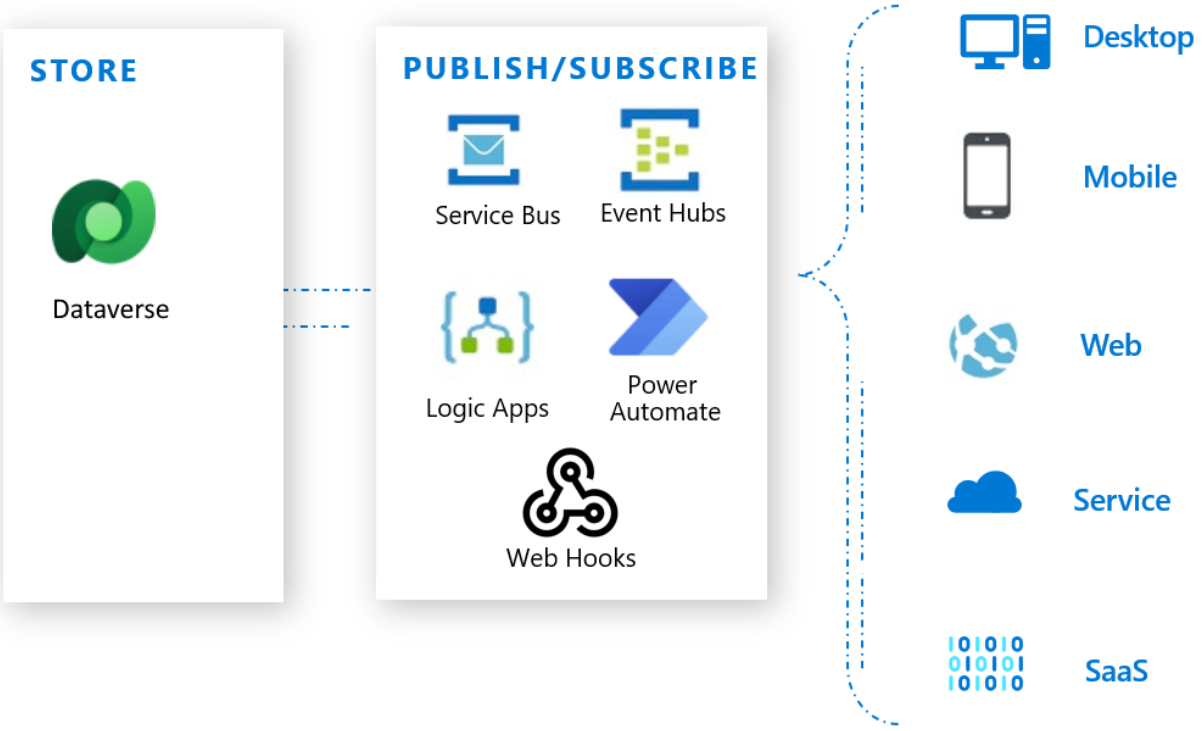
- **Business rules**: Validate data across multiple columns and tables, and provide warning and error messages, regardless of the app used to create the data. More information: Create a business rule for a table
- **Business process flows**: Guide users to ensure that they enter data consistently and follow the same steps every time. Business process flows are currently only supported for model-driven apps. More information: Business processes flows overview
- **Workflows**: Automate business processes without user interaction. More information: Classic Dataverse workflows
- **Business logic with code**: Supports advanced developer scenarios to extend the app directly through code. More information: Apply business logic using code

Integrating with apps by using events

A common approach of app integration is through the use of events. For example, an event such as adding a new row occurs in Dataverse, and this should be communicated to an associated system so that an action can be taken. For example, if a new support request was raised, it might trigger an SMS message to be sent to the assigned support staff.

This interactivity can also occur in the opposite direction—an update in an external system might result in data being added, updated, or deleted from a Power Platform environment.

The most popular approaches in Dataverse involve webhooks, Azure messaging (Service Bus, Event Hubs), Azure Logic Apps, or Power Automate.



Webhooks

With Dataverse, you can send data about events that occur on the service to a web app by using webhooks. A webhook is a lightweight HTTP pattern for connecting web APIs and services with a publish-and-subscribe model. Webhook senders notify receivers about events by making requests to receiver endpoints with some information about the events.

Webhooks enable developers and ISVs to integrate Dataverse data with their own custom code hosted on external services. By using the webhook model, you can secure your endpoint by using authentication header or query string parameter keys. This is simpler than the shared access signature authentication model used with Azure Service Bus integration.

- Webhooks can only scale to the point at which your hosted web service can handle the messages.
- Webhooks enable synchronous and asynchronous steps.

- Webhooks send POST requests with the JSON payload and can be consumed by any programming language or web app hosted anywhere.
- Webhooks can be invoked from a plug-in or custom workflow activity.

Azure Service Bus

Service Bus provides a secure and reliable communication channel between Dataverse runtime data and external, cloud-based line-of-business apps. This capability is especially useful in keeping disparate Dataverse systems or other Dataverse servers synchronized with business data changes.

The sequence of events is as follows:

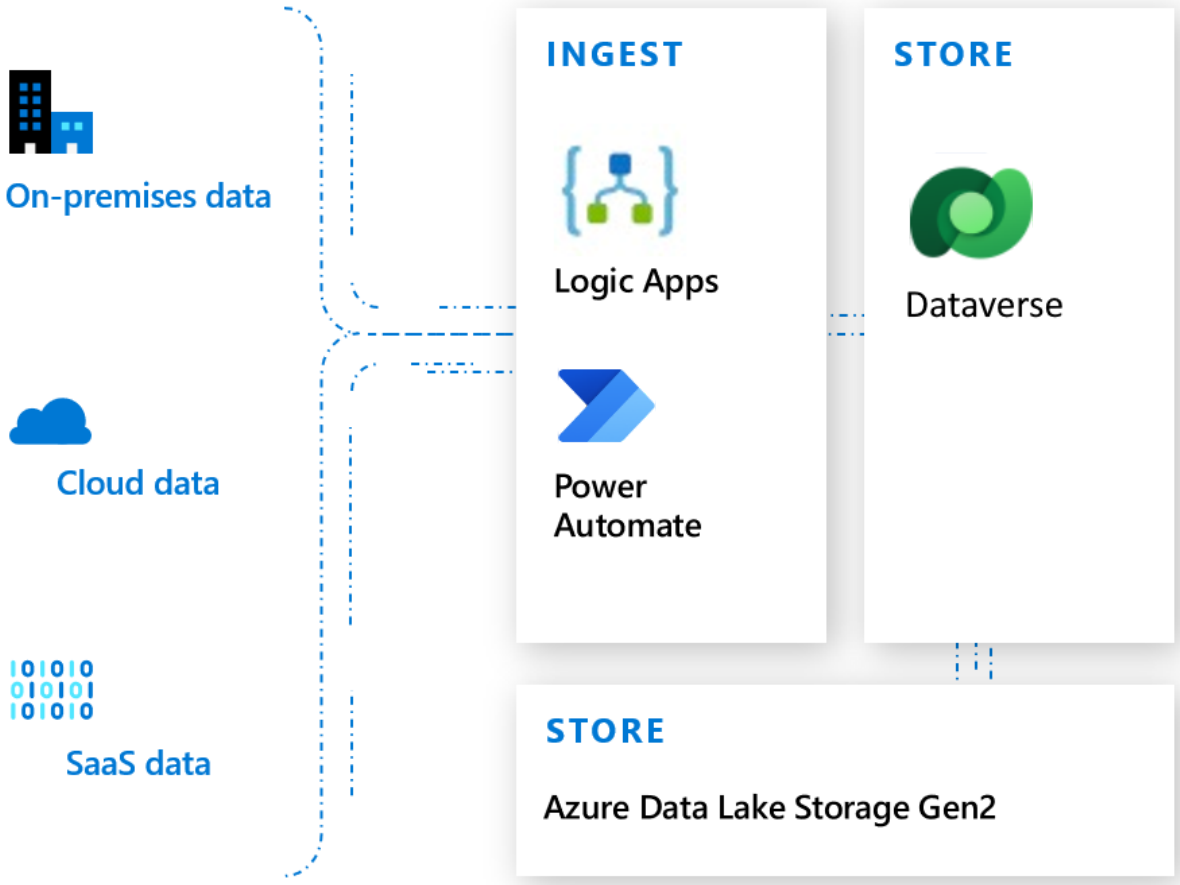
- A listener app is registered on a Service Bus solution endpoint and begins actively listening for the Dataverse remote execution context on the service bus.
- A user performs some operation in Dataverse that triggers execution of the registered out-of-the-box plug-in or a custom Azure-aware plug-in. The plug-in initiates a post, through an asynchronous service system job, of the current request data context to Service Bus.
- The claims posted by Dataverse are authenticated. Service Bus then relays the remote execution context to the listener. The listener processes the context information and performs some business-related task with that information. Service Bus notifies the asynchronous service of a successful post and sets the status of the related system job to Completed.

Service Bus relays the request message data context between Dataverse and the Service Bus solution listener apps. Service Bus also provides data security so that only authorized apps can access the posted Dynamics 365 data. Authorization of Dataverse to post the data context to Service Bus, and for listener apps to read it, is managed by Azure shared access signatures.

More information: Service Bus and Service Bus authentication and authorization

Logic Apps and Power Automate

Logic Apps, offered via Azure, and Power Automate, offered via Microsoft Power Platform, can trigger a workflow that can be used to integrate with application events and data on a schedule or by activity in a database, system, service, or SaaS.



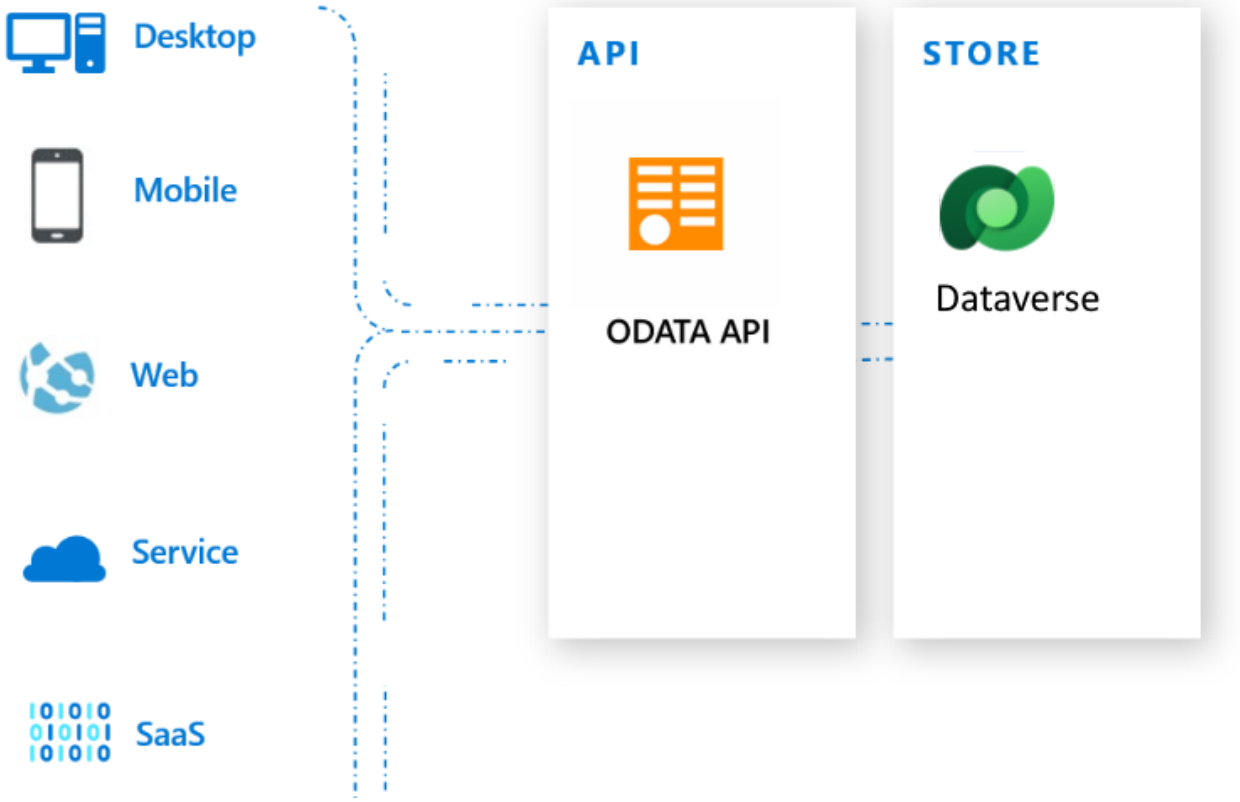
These workflows can execute logic and interact with these systems using the hundreds of connectors to databases, PaaS, and SaaS.

For example, when a row is added to a relational database, such as SQL, this might trigger a workflow that can insert this data in Dataverse.

With the ability to create custom connectors by using Open API (formerly known as Swagger) definitions for a service, it's also straightforward to include services, functions, and code running in IaaS and Azure Kubernetes Service (AKS).

Integrating Dataverse into apps with the OData API

All popular programming languages support a form of integration with REST-based APIs.



The Dataverse Web API provides a development experience that can be used across a wide variety of programming languages, platforms, and devices. The Web API implements the OData (Open Data Protocol), version 4.0, an OASIS standard for building and consuming RESTful APIs over rich data sources. You can learn more about this protocol at www.odata.org. For more information about this standard, see www.oasis-open.org.

Dataverse takes an "API first" approach. This means that the service doesn't just provide a mechanism to query data, it also provides metadata from the service on business rules, constraints, and so on, that you can use to build intelligent, responsive apps and services.

The API is secured by using OAuth. OAuth requires an `idtable` provider for authentication. For Dataverse, the `idtable` provider is Microsoft Entra ID. To authenticate with Microsoft Entra by using a Microsoft work or school account, use the Microsoft Authentication Libraries (MSAL).

For more information about getting started with the Dataverse Web API, see Use the Dataverse Web API.

For more information about using the Dataverse Web API with OAuth, see Use OAuth with Dataverse.

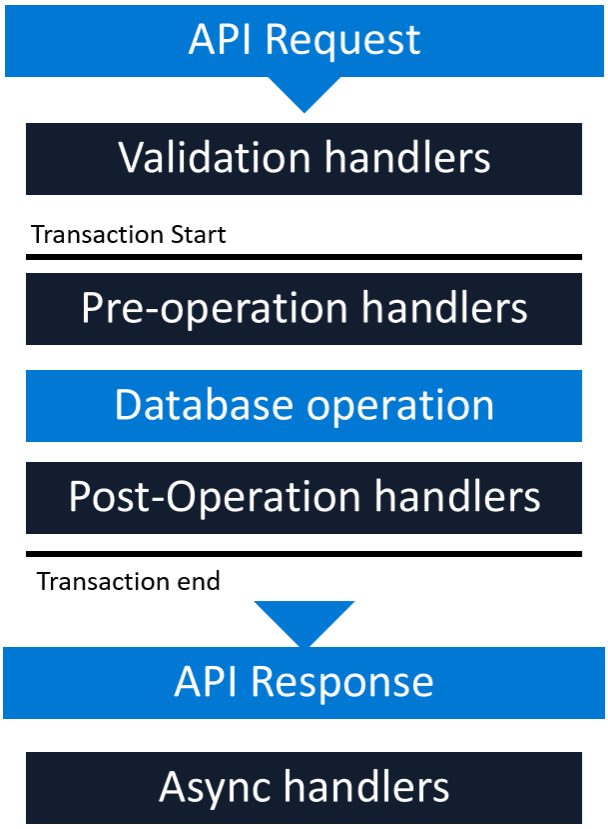
Plug-ins

The Dataverse provides the ability to write code that sits between the API and the data. This code, written in .NET, is referred to as a *plug-in*. Because the plug-in sits between the API and the data, it enforces the same logic on every app.

Plug-ins can be synchronous or asynchronous, and perform the following tasks:

- Return errors to the user.
- Query Dataverse data to evaluate logic to perform.
- Perform data operations.
- Perform outbound HTTP requests.

Plug-ins are registered at points in the event pipeline, which are illustrated here.



Within the event pipeline, the following events can occur:

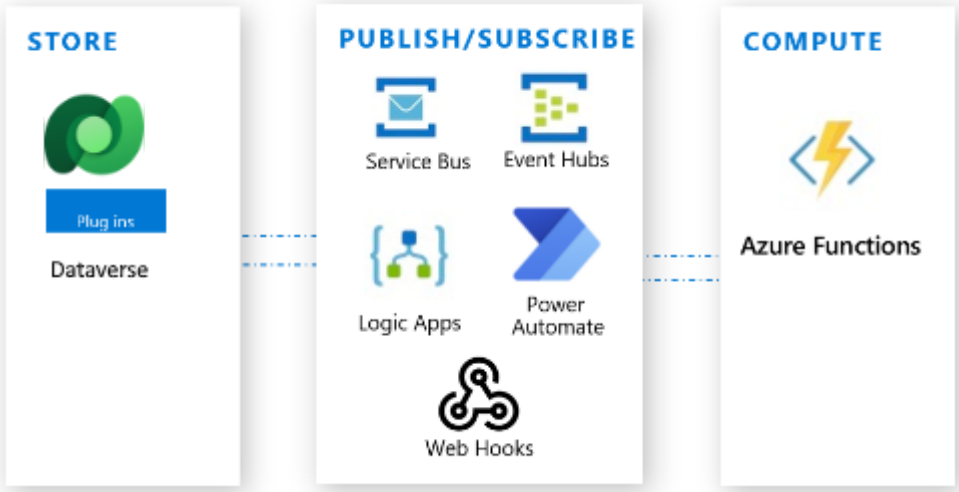
- **Requests** and **Responses** can be **examined** and **rejected** or **manipulated** in several steps of the event pipeline.
- **Validation handlers** can throw custom exceptions to reject operations that your logic considers invalid.
- **Pre-operation handlers** can modify requests before the database operation.
- **Post-operation handlers** can modify responses.

- **Async handlers** perform automation after the response is returned.

One constraint with plug-ins is that they must be self-contained. If integration code requires references to other libraries, integration can be done by using Azure Functions.

Azure Functions

Azure Functions provides a serverless code execution option for business and integration logic.



Functions are triggered by a call from an external system, service, or code. For Dataverse, that trigger can come directly from Dataverse using Service Bus, a webhook, or a call from a plug-in. Additionally, the Azure Functions call can be initiated via a flow in either Logic Apps or Power Automate that involves the Dataverse connector.

More information: Use plug-ins to extend business processes

Tables in Dataverse

Article • 06/22/2022

Tables are used to model and manage business data. When you develop an app, you can use standard tables, custom tables, or both. Microsoft Dataverse provides standard tables by default. These are designed, in accordance with best practices, to capture the most common concepts and scenarios within an organization.

Types of tables

Create a custom table

Tables and metadata in Microsoft Dataverse

Microsoft Dataverse is designed so that you can quickly and easily create a data model for your application. Normally, you shouldn't have to concern yourself with some of the details about metadata that this article introduces. But if you want to develop a deeper understanding about how apps that use Dataverse work or you're evaluating what is possible, understanding the metadata used by Dataverse can provide you with insight.

Metadata means data about data. Dataverse provides a flexible platform for you because it's relatively easy to edit the definitions of the data that the environment will use. In Dataverse, the metadata is a collection of tables. Tables describe the kinds of data stored in the database. Table metadata is what controls the kinds of records you can create and what kind of actions can be performed on them. When you use the customization tools to create or edit tables, columns, and table relationships, you're editing this metadata.

Different clients people use to interact with the data in your environment depend on the table metadata and adapt as you customize the metadata. But these clients also depend on other data to control what visual elements to display, any custom logic to apply, and how to apply security. This system data is also stored within tables but the tables themselves aren't available for customization.

You can learn about standard tables, attributes, and table relationships included by default in Dataverse by reviewing the entity reference.

> **Tip**
>
> The designers available to edit metadata don't show all the details found in the metadata. You can install a model-driven app called the **Metadata Browser**, which allows you to view all the tables and metadata properties that are found in the system. More information: Browse table definitions in your environment.

Create new metadata or use existing metadata?

Dataverse comes with standard tables that support core business application capabilities. For example, data about your customers or potential customers is intended to be stored using the account or contact tables.

Each of these tables also contains many columns that represent common data that the system might need to store for the respective table.

For most organizations it's to your advantage to use the standard tables and attributes for the purposes they were provided.

If you install a solution, you can expect that the solution developer leveraged the standard tables and attributes. Creating a new custom table that replaces a system table or attribute means that any solutions available might not work for your organization.

For these reasons, we recommend that you look for and use the provided standard tables, columns, and table relationships when they make sense for your organization. If they don't make sense and can't be edited to match your need, you should evaluate if creating a new table, column, or table relationships is required.

Remember that you can change the display name of a table so that it matches the nomenclature your organization uses. For example, it's common for people to change the display name of the Account table to *Company* or the name of the Contact table to *Individual*. This can be done to tables or attributes without changing the behavior of the table. For more information about renaming tables, see Change the name of a table.

You can't delete standard tables, columns, or table relationships. They're considered part of the system solution and every Dataverse environment is expected to have them. If you want to hide a standard table, change the security role privileges for your organization to remove the read privilege for that table. This removes the table from most parts of the application. If there's a system column that you don't need, remove it from the form and any views that use it. Change the **Searchable** value in the column and table relationship definitions so that they don't appear in advanced find.

Limitations on creating metadata items

There's a limit to the number of tables you can create. Admins can view information about the number of tables and percent used towards the maximum in the legacy **Resources In Use** page. Go to Power Platform admin center (admin.powerplatform.com) select **Manage** > **Environments**, and open the environment you want. Select **Settings**, expand **Resources** select **All legacy settings**. In the legacy settings, select **Administration** > **Resources In Use**.

Within each table there's also an upper limit on the number of columns you can create. This limit is based on the technical limitations on the amount of data that can be stored in a row of a Dataverse table and isn't viewable. It's difficult to provide a specific number because each type of

column can use a different amount of space. The upper limit depends on the total space used by all the columns for the table.

Most people don't create enough custom columns to reach the limit, but if you find yourself planning to add hundreds of custom columns to a table, you should consider if this is the best design. Do all the columns you plan to add describe properties for a row for that table? Do you really expect that people using your environment will be able to manage a form that includes such a high number of columns? The number of columns you add to a form increase the amount of data that has to be transferred each time a row is edited and affects the performance of the system. Take these factors into consideration when you're adding custom columns to a table.

Choice columns provide a set of options that are displayed in a drop-down control on a form or in picklist control when using advanced find. Your environment can support thousands of options within a choice column, but you shouldn't consider this as the upper limit. Usability studies show that people have trouble using a system where a drop-down control provides large numbers of options. Use choice columns to define categories for data. Don't use choice columns to select categories that actually represent separate items of data. For example, rather than maintain a choice column that stores each of hundreds of possible manufacturers of a type of equipment, consider creating a table that stores references to each manufacturer and use a lookup column instead of a choice.

Types of tables

Article • 06/18/2024

A table defines information that you want to track in the form of rows (records), which typically include column data such as company name, location, products, email, phone, and so on.

Tables appear in Power Apps as one of these different types:

- **Standard**: Several standard tables, also known as out-of-box tables, are included with a Power Platform environment that includes Microsoft Dataverse. Account, business unit, contact, task, and user tables are examples of standard tables in Dataverse. Most of the standard tables included with Dataverse can be customized. Tables that are imported as part of a managed solution and set as customizable also appear as standard tables. Any user with appropriate privileges can customize these tables where the table property has customizable set to true.
- **Activity**: Are a special kind of table and are best for rows that have an activity-based element, which can include a subject, start time, stop time, due date, and duration. Dataverse already comes with several out-of-the-box activity tables, such as appointment, task, email, and phone call. More information: Activity tables
- **Virtual**: Are when you need the table to be populated with data from an external source outside of Dataverse.
- **Elastic**: Are for when the table will store a very large dataset in excess of tens of millions of rows.

Activity tables

An activity can be thought of as any action for which an entry can be made on a calendar. An activity has time dimensions (start time, stop time, due date, and duration) that help determine when the action occurred or will occur. Activities also contain data that helps determine what action the activity represents, for example, subject and description. An activity can be opened, canceled, or completed. The completed status of an activity will have several sub-status values associated with it to clarify the way that the activity was completed.

Activity tables are a special kind of table that can only be owned by a user or team, but can't be owned by an organization. When you create a table, you can specify it as a standard or activity table.

The following table lists activity tables that are available in a default environment.

Expand table

Name	Description	Display in activity menus	Reference
Appointment	Commitment representing a time interval with start/end times and duration.	Yes	Appointment
Email	Activity that is delivered using email protocols.	Yes	Email
Fax	Activity that tracks call outcome and number of pages for a fax and optionally stores an electronic copy of the document.	Yes	Fax
Letter	Activity that tracks the delivery of a letter. The activity can contain the electronic copy of the letter.	Yes	Letter
Phone Call	Activity to track a telephone call.	Yes	PhoneCall
Recurring Appointment	The master appointment of a recurring appointment series.	Yes	RecurringAppointmentMaster
Task	Generic activity representing work needed to be done.	Yes	Task

When you can create a new custom activity table, you might create it to read instant message communications. Creating an activity table is different from creating a non-activity table because you don't specify a primary column. All activity tables have a **Primary Field** set to **Subject** and other common columns that are defined by the Activity table. This allows all types of activities to be shown in a view where just the common columns are displayed.

To create a custom activity table, open the **Advanced options** section in the **New table** panel, select the **Activity** option from the **Type** drop-down list. After you select this, you'll see that **Display in Activity menus** is selected. This setting allows people to create this type of activity in the activity menus. This isn't selected for activities that are typically associated with specific events and created behind using code or by a workflow. After you save the table, you can't change these settings.

Enable activities for a table

Enable activities to add activities to a table and use the Regarding lookup for the table.

1. To enable activities, sign in to Power Apps.
2. On the left nav, select **Tables**, and then open the table you want.
3. Select **Properties**.
4. Expand **Advanced options**, and then select **Creating a new activity**.

   > **Important**
   >
   > Once enabled this setting can't be disabled.

5. Select **Save**.

Enable users to associate email to multiple records

Users sometimes need to associate an email to multiple records. For example, a customer sends an email that is related to multiple cases. The existing Regarding lookup only allows a user to relate an email to a single parent record. Email records can now be associated to multiple records such as accounts, contacts, leads, opportunities, and cases through a new activity party type column named **related**. When an email is associated to multiple records, it appears in the timeline for each of the associated records.

> **Note**
>
> This feature is currently only supported with email activities.

The related column isn't added to email form by default. To enable users to use this new column, add the **related** column to the email form. For information about how to add a column to a form, go to add columns to a form.

After you add the related column to the form, users can associate an email record with other related party records (parties) like cases or opportunities.

Differences between regarding and related columns

While there are similarities between the regarding and related columns, the following are important differences to note:

- **Supported tables**
  The related column is currently only available for the Email table. The related

column doesn't currently support the same relationships utilized by the regarding column. The list of supported tables is currently limited to the tables that can have a contact email.

- **Relationship type**
  The regarding column acts as a parental relationship from a parent record. For example, if an account has multiple activities and is later deleted, the same action is automatically applied to the child activity records. The related column isn't a parental relationship. Actions performed on related records don't affect the related activities.

- **When the column value is set**
  After the related column is added to the email form, users can manually add one or more records to indicate the records are related to the activity. The regarding and related columns are independent. Setting a value for the regarding lookup column doesn't affect the values for related. When a new email is related to an existing email (for example, as a reply), the values from the related and regarding columns of the correlated email are copied to the new activity. However, when you create a new email from the timeline control within a record's context, the related column isn't automatically set to the current record. This behavior can be modified by enabling an OrgDBOrgSetting named AddParentEntityToRelatedOnNewActivityCreate.

- **Outlook add-in scenarios**
  Some features such as Dynamics 365 App for Outlook and Copilot for Sales include an ability to save an Outlook email as an email record while also setting the regarding column. These features don't set the value of the related column.

Table ownership

There are two different types of standard and custom table ownership. When you create a custom table the ownership options are **User or team** or **Organization** owned. Once a table is created, the ownership type can't be changed.

Expand table

Ownership	Description
Organization	Data belongs to the organization. Access to the data is controlled at the organization level.
User or team	Data belongs to a user or a team. Actions that can be performed on these rows can be controlled on a user level.

Notice that there are a few Dataverse system tables that are similar to standard tables but have a different type of ownership from organization and user or team ownership:

- **None**. Some system tables don't have an owner, such as the Privilege table.
- **Business Unit**. A few system tables are business-owned. These include Business Unit, Calendar, Team, and Security Role tables.

> **Important**
>
> After a custom table is created, you can't change the ownership. Before you create a table, make sure that you choose the correct type of ownership. If you later determine that your custom table must be of a different type, you have to delete it and create a new one.

Virtual tables

A virtual table is a custom table in Dataverse that has columns containing data from an external data source. Virtual tables appear in your app to users as regular table rows, but contain data that is sourced from an external database dynamically at runtime, such as an Azure SQL Database. Rows based on virtual tables are available in all clients including custom clients developed using the Dataverse web services. More information: Create and edit virtual tables that contain data from an external data source

Elastic tables

Elastic tables offer performance benefits over standard tables when the table contains a very large dataset. Elastic tables are powered by Azure Cosmos DB. More information: Create and edit elastic tables

Create and edit tables using Power Apps

Tables are used to model and manage business data. When you develop an app, you can use standard tables, custom tables, or both. Power Apps provides an easy way to view, create, and edit tables for Microsoft Dataverse.

Prerequisites

To create and edit tables in Dataverse, you need the following:

- A Power Platform environment with Dataverse.
- Appropriate permission that includes *both* of the following privileges:
  - The system customizer security role in the environment. Note that, apart from self-created table records, the system customizer role doesn't have the privileges to access table records that aren't shared with them. More information: Environments with a Dataverse database.
  - A system or custom security role that has Create, Read, and Write privileges to the Entity table. These privileges allow the user to create and edit tables in Dataverse. Note that a Power Platform admin must grant the user data access to edit the rows of these tables.

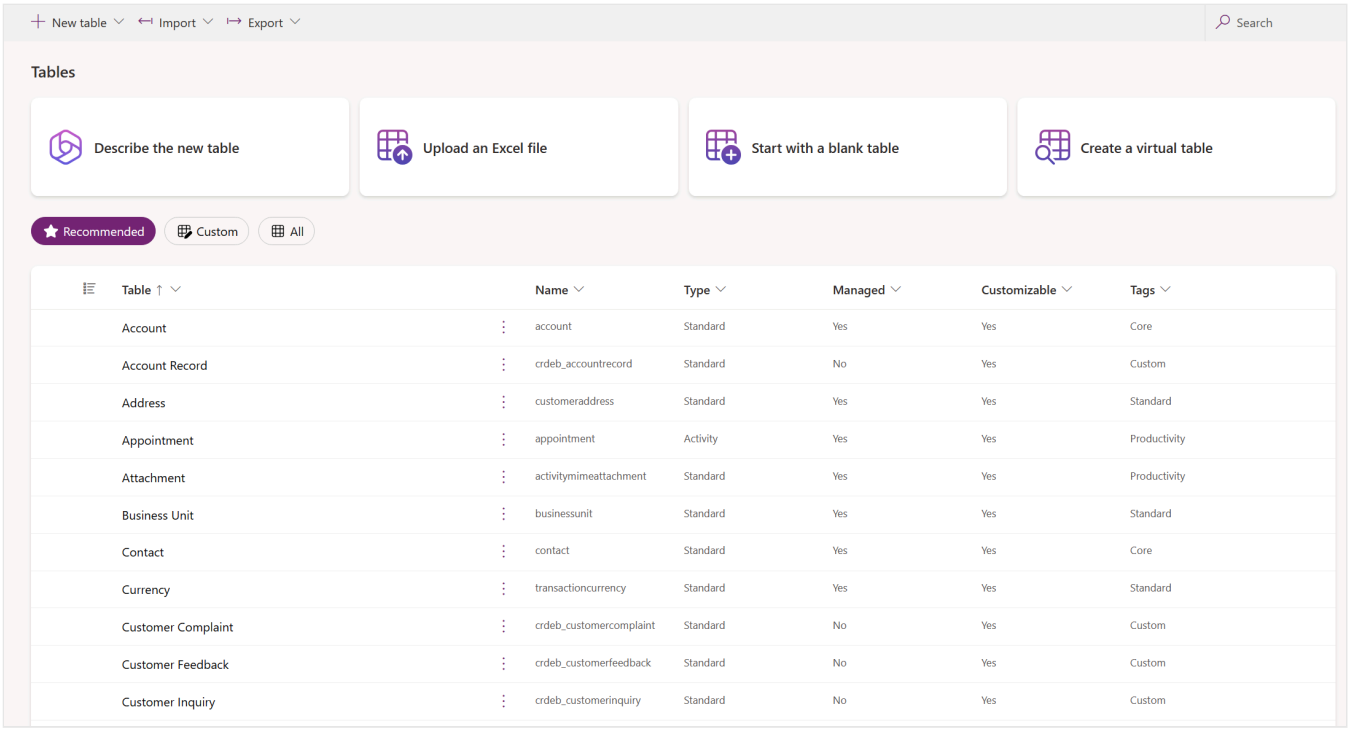
View tables

Sign into Power Apps, and then select **Tables** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

Filter the tables that are displayed using the following tabs:

Expand table

View	Description
Recommended	Displays only the standard tables. Standard tables are tables included with Power Apps or Dynamics 365 apps.
Custom	Displays only custom tables. Custom tables are created by you and other app makers.
All	Displays all the tables.



You can also select a column heading from the table view, and then select **Filter by** to display tables by a certain property, such as **Type**, **Managed**, or **Tags**.

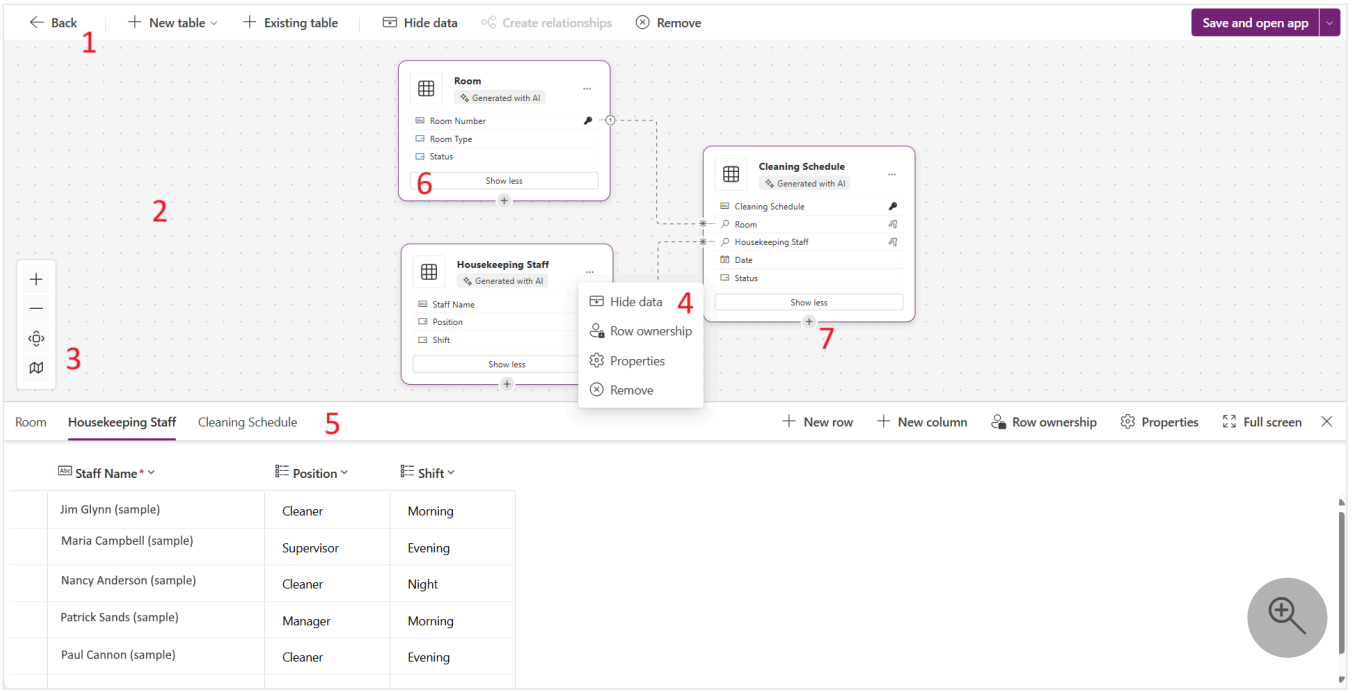
Create a table

There are several ways to create a new table:

- Create new tables
- Set advanced properties
- Create with external data
- Create a virtual table

Create new tables

Use the data workspace experience where you create tables, configure table relationships, and can view a diagram of your data.



1. Command bar:

    - **Back**. Takes you back where you were in Power Apps.
    - **New table**. Create a new table using any of the methods described in this article.
    - **Existing table**. Add one more more existing tables and visualize them in the designer.
    - **Hide data** or **View data**. Closes or displays the table row editor.
    - **Create relationships**. Creates a table relationship between two tables. Select a table on the canvas and CTRL + click another table, then select **Create relationships**. More information: Types of table relationships (NOTE: many-to-many relationships aren't supported)
    - **Remove**. Deletes the table and all associated table rows when *a new table* is selected. Remove doesn't delete the table and associated rows when an existing table is selected.

2. Data workspace canvas. On the data workspace canvas, you can drag tables around the data workspace to relocate them and select ... to invoke the table actions menu, and view a diagram of your data.

3. Data workspace actions:

    - +. Zoom in to increase the size of the table objects on the canvas.
    - -. Zoom out to decrease the size of the table objects on the canvas.
    - **Fit view**. Resize to fit within the available space in the browser tab.
    - **Show map** or **Hide map**. When **Show map** is selected, displays a compact representation of the tables on the canvas.

4. Table actions menu:

- **Hide data** or **View data**. Closes or displays the table row editor.
- **Row ownership**. Select the ownership type as either user or team, or organization.
- **Properties**. Edit the table display name, plural name, description, and schema name.
- **Remove**. Remove the table and all associated rows. If the tables is a new table, all data is deleted. For existing tables, that table is only removed from the table designer and no data is removed.

5. Table row editor. In this area, create new, edit, or delete rows, create new columns, change the table ownership type, and edit table properties.

6. Show more or less column. You can select and clear the columns to be displayed in the table card. Also displays or hides the relationship for lookup columns that connect to another table currently in the designer.

7. Add new relationship handle. Drag the handle and create a new relationship by pointing it towards another table. Some relationship types are currently not supported. More information: Limitations using the data workspace

> **Tip**
>
> Can't find the tables you created on the canvas? Select **Fit view** on the data workspace actions menu.

Create a table with the visual table designer by using any of the following methods:

- Start with Copilot
- Import with SharePoint list
- Import an Excel file or .CSV
- Start from blank

Start with Copilot

Describe your data in natural language and Copilot generates tables along with relationships for you.

> **Note**
>
> To use this feature, note the following requirements:
>
> - Copilot must be enabled for the environment. By default, Copilot is enabled. More information: Manage feature settings

- This feature is available in 20 languages including Danish, Dutch, English (United States), French, German, Italian, Japanese, Portuguese (Brazil), Spanish, Chinese (Simplified), Czech, Finnish, Greek, Korean, Norwegian (Bokmål), Polish, Russian, Swedish, Thai, and Turkish. Depending on where your environment is hosted, you might need to enable data movement across regions. For more information go to Copilots and generative AI features that are available when you enable data movement across regions.

1. From the **Choose an option to create tables** page, select **Start with Copilot**.
2. Describe the tables you'd like to create with the assistance of Copilot. You can also specify the number of tables to create, size of table, and whether to include relationship by configuring the **Table options** menu.
3. Keep iterating with Copilot in the Copilot panel until you're satisfied with your data. More information: Review the table
4. When you're finished, select **Save and exit**.

Limitations using the data workspace

The following data types aren't currently supported when you create a column in the data workspace:

- Rich text
- Customer
- Autonumber
- Formula

Some relationship configurations are currently not supported.

Expand table

Starting table	Targeting table	Relationship type	Status
New	New	One-to-many	Supported
New	New	Many-to-one	Supported
New	New	Many-to-many	Not supported
Existing	New	One-to-many	Supported
Existing	New	Many-to-one	Not supported
Existing	New	Many-to-many	Not supported

Starting table	Targeting table	Relationship type	Status
Existing	Existing	One-to-many	Not supported
Existing	Existing	Many-to-one	Not supported
Existing	Existing	Many-to-many	Not supported

Set advanced properties

From the **Tables** area, on the command bar select **New table** > **Set advanced properties**. This opens the **New table** properties panel. You start with a blank table and enter the table properties, such as name, and description. Expand **Advanced options** to set more properties, such as track changes and audit changes.

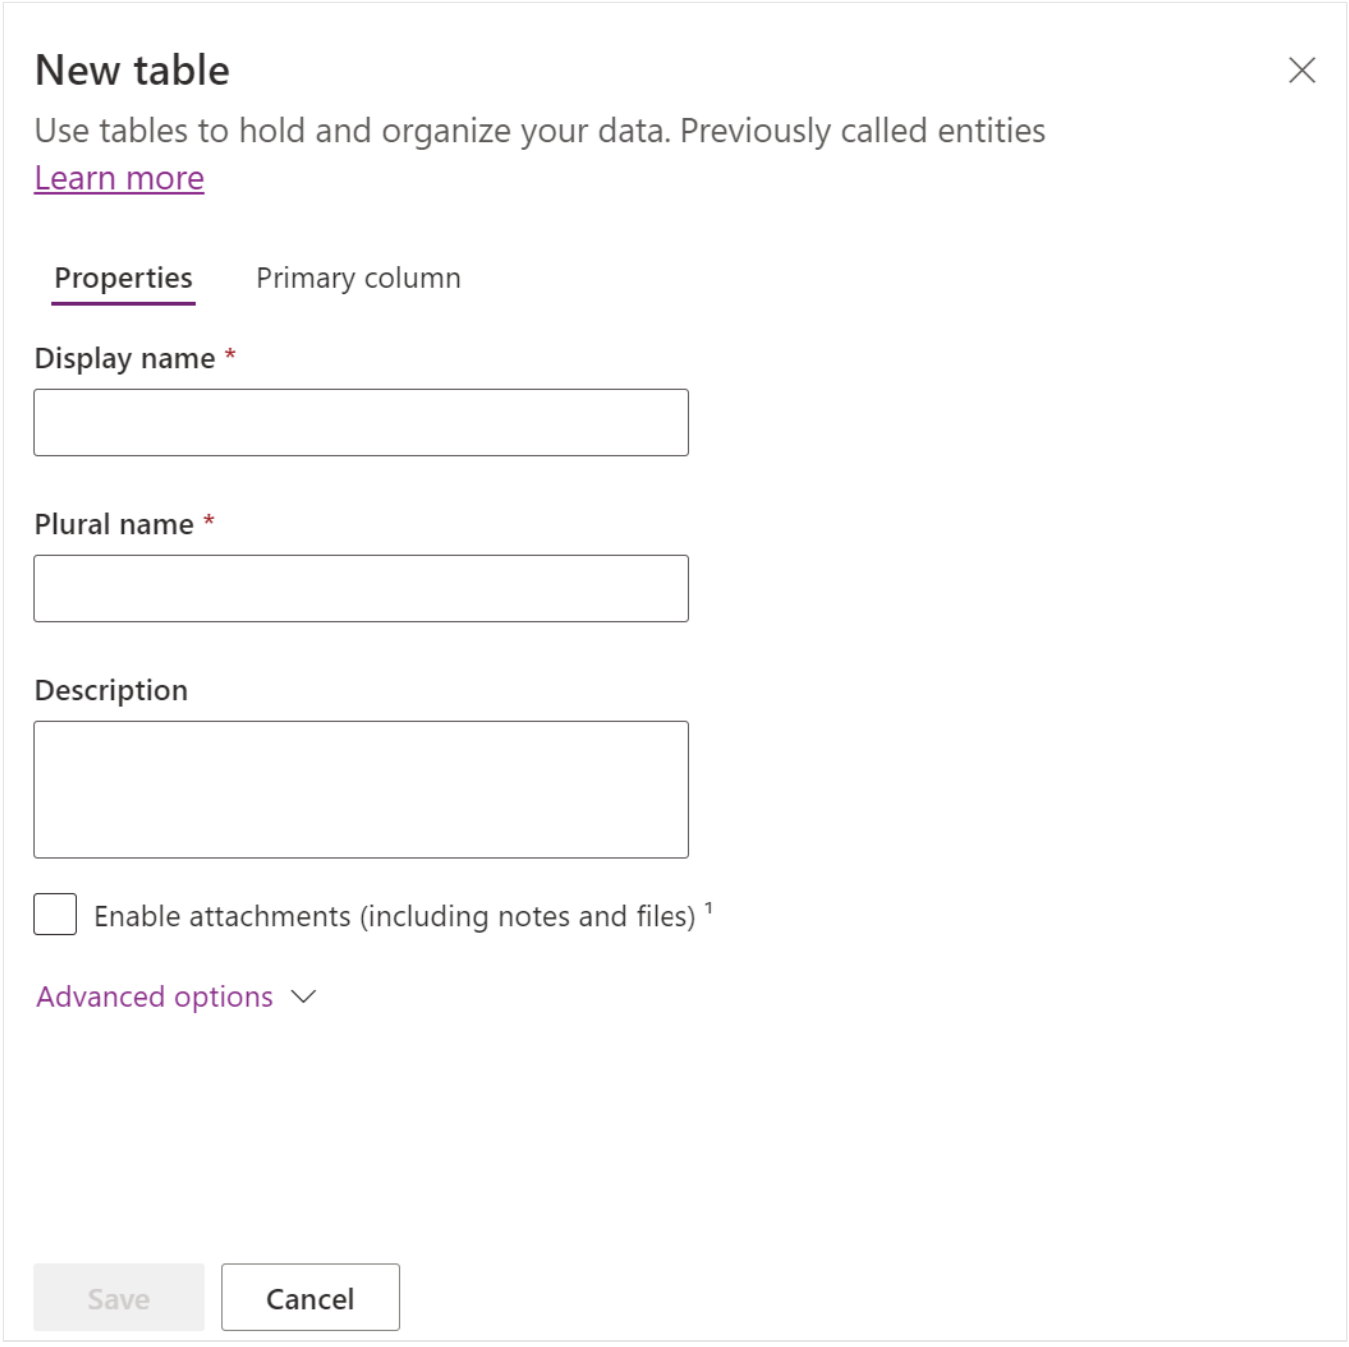


Table properties

Enter data for the following properties.

Expand table

Property	Description
Display name	This is the singular name for the table that is shown in the app. This can be changed later.
Plural display name	This is the plural name for the table that is shown in the app. This can be changed later.
Description	Provide a meaningful description of the purpose of the table.

Select **Enable Attachments** to append notes and files to records for this table.

Select the **Primary column** tab if you want to change the **Display name** or **Description** of the primary column. The primary column is used by lookup fields when establishing relationships with other tables.

> **Important**
>
> After you save the table, the **Primary column** display name and description can't be changed.

Advanced options

Select **Advanced options** to display additional properties that are optional for a table.

Expand table

Property	Description
Schema name	By default, the schema name is automatically created for you based on the display name, but you can change it. The schema name can't contain spaces and includes the customization prefix for the Dataverse solution publisher. You can't change this after the table is saved.
Type	Select the type of table. Use standard for most tables. Activity tables are a special table that can only be owned by a user or team, but can't be owned by an organization. Virtual tables require the table be populated with data from an external source. Elastic tables should be considered when your business scenario

Property	Description
	entails very large data volumes with high throughput, storage, and low latency requirements.
Record ownership	Switch the table type to Activity table to create tables that can manage tasks. The type of **Ownership** defines who can perform operations on a record.
Choose a table image	You can choose whether to display an image for the table. This image is displayed in Power Apps in some design areas. Notice that the image doesn't appear in apps using the table. To display images in apps, use the image column. More information: Image columns
Color	Set a color to be used for the table in model-driven apps.
Apply duplicate detection rules	If duplicate detection is enabled for your organization, enabling this allows you to create duplicate detection rules for this table.
Track changes	Enables data synchronization in a performant way by detecting what data has changed since the data was initially extracted or last synchronized. This option must be enabled for certain features such as Azure Synapse Link for Dataverse.
Provide custom help	When selected, set a **Help URL** to control what page users see when they select the help button in the application. Use this to provide guidance specific to your company processes for the table.
Audit changes to its data	When auditing is enabled for your environment, this allows for changes to table records to be captured over time. When you enable auditing for a table, by default, many table columns, such as data types of owner, number, text, and choice are enabled for auditing. However, some columns aren't enabled by default such as those with data types of lookup, but those columns can be enabled. Select or clear the **Enable auditing** property for the columns that you want to enable auditing on.
Leverage quick create form if available	After you've created and published a Quick Create Form for this table, people have the option to create a new record using the Create button in the navigation pane. More information: Create and design model-driven app forms When this is enabled for a custom activity table, the custom activity is visible in the group of activity entities when people use the **Create** button in the navigation pane. However, because activities don't support quick create forms, the main form is used when the custom table icon is selected.
Enable long term retention	Dataverse supports custom retention policies to securely retain unlimited data long term in a cost-efficient way. More information: Long term data retention overview
Creating a new activity	Associate activities to records for this table.
Doing a mail merge	App users can use this table with mail merge.
Setting up OneNote	When you turn on OneNote integration, you have the benefits of using OneNote to take or review customer notes from within your records. Requires SharePoint

Property	Description
integration	document management to be set up. More information: Set up OneNote integration
Setting up SharePoint document management	After other tasks have been performed to enable document management for your organization, enabling this feature allows for this table to participate in integration with SharePoint. More information: Manage your documents using SharePoint
Can have connections	Use the connections feature to show how records for this table have connections to records of other tables that also have connections enabled.
Can have a contact email	Send emails using an email address stored in one of the fields for this table. If a **Single Line of Text** column with format set to email doesn't already exist for this table, a new one is created when you enable sending email.
Have an access team	Create team templates for this table.
Can be linked to feedback	Let app users write feedback for any table record, or rate table records within a defined rating range. More information: Configure a table for feedback/ratings
Appear in search results	Enable so that table records can be included in search results when using an app.
Can be taken offline	Makes data in this table available while the Power Apps application isn't connected to a network.
Can be added to a queue	Use the table with queues. Queues improve routing and sharing of work by making records for this table available in a central place that everyone can access.

Select **Save** to continue. This action closes the **New table** panel and displays the table hub.

Create with external data

Use an Excel file/CSV file or SharePoint list to populate a table with your data, which uses copilot to assist with the table generation.

> **Note**
>
> - Generally available copilot features are enabled by default and can't be turned off. To disable them, a tenant admin must contact support.
> - When you use create with external data, such as data from Excel or SharePoint, Power Apps initially displays only the first 20 rows of your dataset as a preview. The full dataset is ingested and made available after you save the table.

1. From the **Tables** area, on the command bar select **New table** > **Create with external data**, and then select either **File (Excel, .CSV)** or **SharePoint list**.

File (Excel, .CSV)

a. Select from device or drag and drop your Excel file onto the **Upload an Excel file** page.
b. The data from the Excel file is displayed as a Dataverse table. Select a column header > **Edit column** to make changes, such as the column name or data type.
c. When you're finished, select **Create**.

For more information about how AI is used with this feature, go to FAQ for Excel to table and app.

SharePoint columns not used in Dataverse table generation

The following columns aren't included when generating a Dataverse table from a SharePoint list because the respective data types aren't supported with Dataverse:

- Image
- Task outcome
- External data
- Managed metadata
- Attachment (single)
- Multiple attachments / images
- SharePoint list system columns
- Symbol at column level (currency, prefix, postfix) in numbers
- Unique values

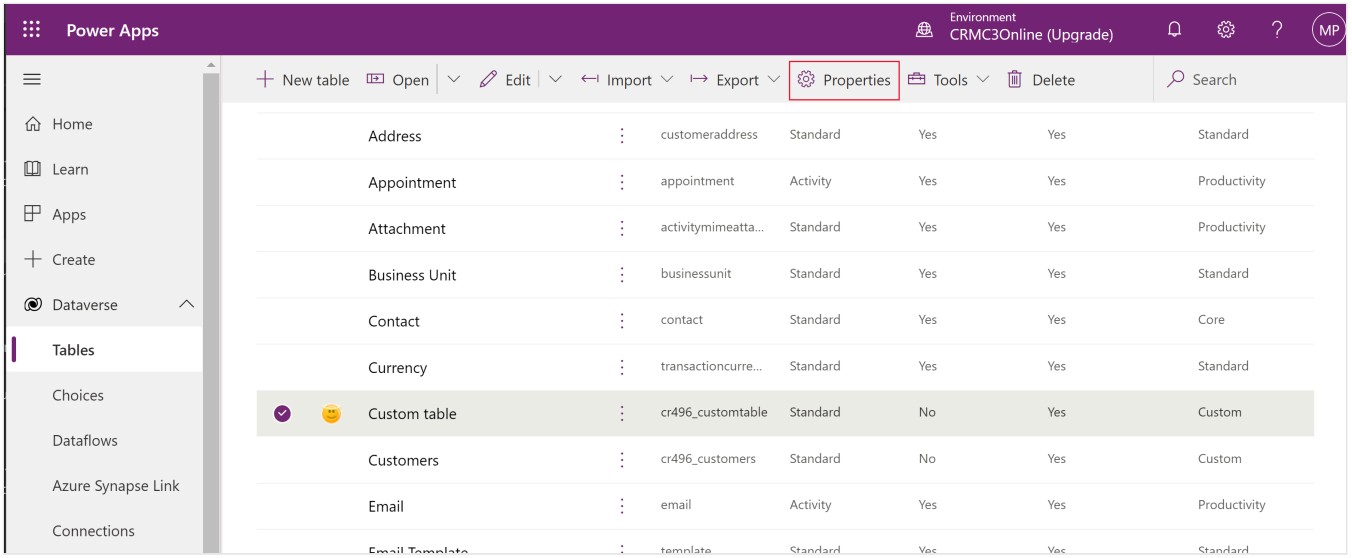
Create a virtual table

A virtual table is a custom table in Microsoft Dataverse that has columns containing data from an external data source, such as Azure SQL Database or SharePoint.

1. From the **Tables** area, on the command bar select **New table** > **Create a virtual table**.
2. Follow the **New table from external data** wizard to create the virtual table. More information: Create the virtual table

Edit a table

While viewing tables, select the table you want to edit, and then select **Properties** from the command bar if you want to edit the table properties.



Edit table components using the table hub

To edit form components, open the table to display the table hub. The table hub displays the table components described in the following sections.

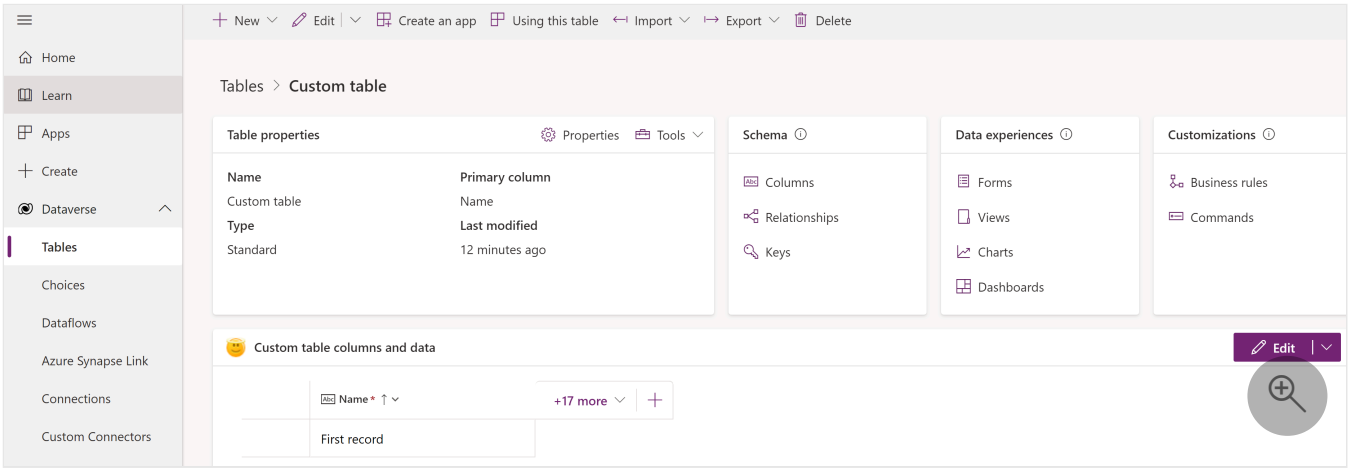


Table properties

Displays a few common properties for the table. Select **Properties** on the command bar to edit the table properties.

Schema

From the Schema area, select from the following table components to open the area where you can view and open existing components or create a new one.

- Columns. More information: Create and edit columns

- Relationships. See Create and edit relationships between tables
- Keys. More information: Define alternate keys to reference rows

Data experiences

From the **Data experiences** area select from the following table components to open the area where you can view and open existing components or create a new one.

- Forms. More information: Create and design forms
- Views. More information: Create or edit a view
- Charts. More information: Create a system chart
- Dashboards. More information: Create or edit dashboards

Customizations

From the Customizations area, select from the following table components to open the area where you can view and open existing components or create a new one.

- Business rules. More information: Create business rules and recommendations to apply logic in a form
- Commands. More information: Customize the command bar using command designer

Table columns and data

View and create table record data for the table. Select the number of columns, such as **+17 more**, to select columns to display in the columns and data view.

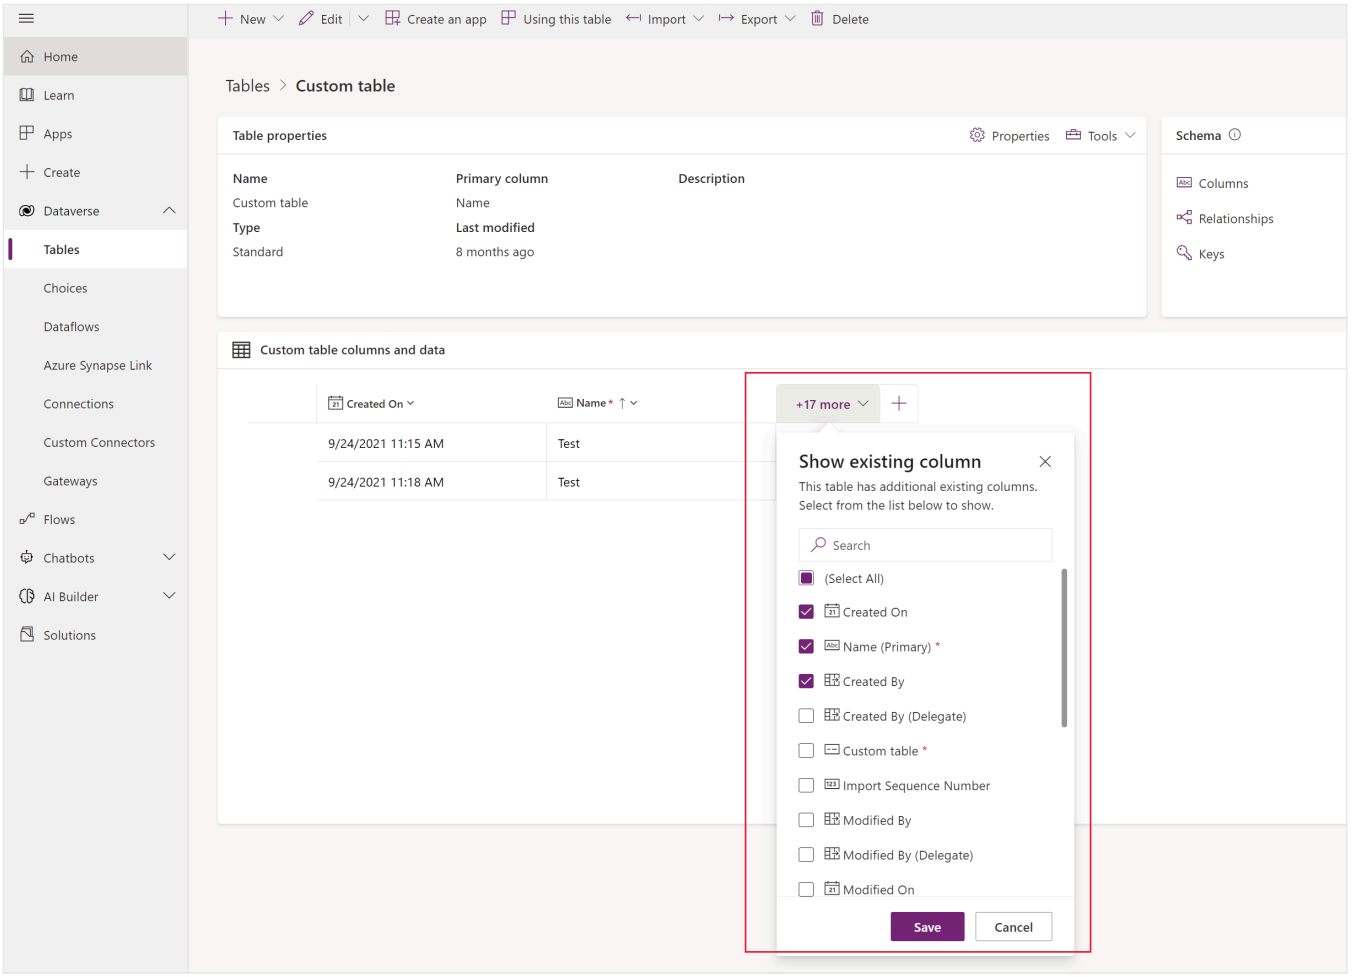

Table designer

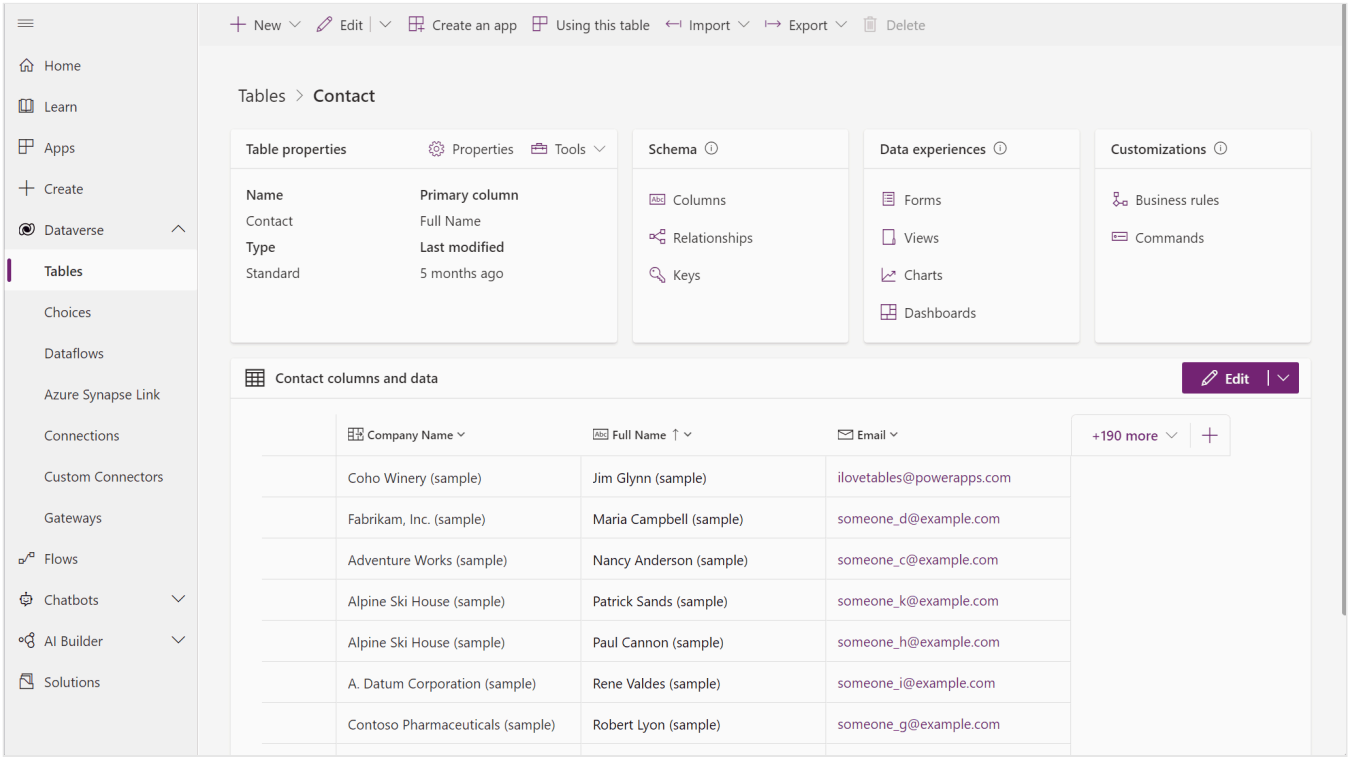
From the table hub, select **Edit** to open the table designer. The table designer lets you make extensive changes to a table including editing or adding new records and columns, editing table properties, or creating a model-driven app based on the table.



Update forms and views

From the table hub, select **Update forms and views** to add selected columns to forms and views in this table without having to edit them in the form and view designers. More information: Update forms and views using table designer

Delete a table

As someone with the system administrator security role, you can delete custom tables that aren't part of a managed solution.

> ⚠ **Warning**
>
> When you delete a custom table, the database tables that store data for that table are deleted and all data they contain is lost. Any associated records that have a parental relationship to the custom table are also deleted. For more information about parental relationships, see **Create and edit relationships between tables**.
>
> The only way to recover data from a table that was deleted is to restore the database from a point before the table was deleted. More information: **Backup and restore instances**

While viewing tables, select the table, and then select **Delete** from the menu.

If the table has dependencies that prevent it from being deleted you see an error message. To identify and remove any dependencies, you need to use the solution explorer. More information Identify table dependencies

Create a custom table that has components in Power Apps

Article • 04/12/2024

With Power Apps, you tailor your app to closely fit your organization's industry, nomenclature, and unique business processes. Power Apps app development includes adding standard "out-of-box" tables or creating custom tables. A table defines the information you want to track in the form of records, which typically include properties such as company name, location, products, email, and phone.

In this article you create a table and then add or customize key components such as columns, relationships, views, and forms. You learn how to:

- Create a custom table.
- Add custom columns to your table.
- Add a table relationship.
- Customize a view.
- Customize a form.

The article will follow the company, Contoso, which is a pet grooming business that grooms dogs and cats. Contoso needs an app for client and pet tracking that can be used by employees across a variety of devices.

Prerequisites

Sign in to Power Apps. If you don't already have a Power Apps account, select the **Get started free** link from powerapps.com.

Create a custom table

1. On the left navigation pane select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. On the command bar select **New table** > **Set advanced properties**.

3. In the right pane, enter the following values, and then select **Create**.

    - **Display name**: *Pet*
    - **Description**: *Custom table to track pet services*

Add and customize columns

1. Open the **Pet** table that was created in the previous section.

2. Select **Columns**, and select the **Pet** column.

3. In the right pane make the following changes to the **Display name** column:

    - Change the **Display name** from **Pet** to *Pet Name*.

    - Make sure **Searchable** is selected.

Pet Name

Display name *

Pet Name

Name *

crfb6_PetId

Data type *

Unique Identifier

Required *

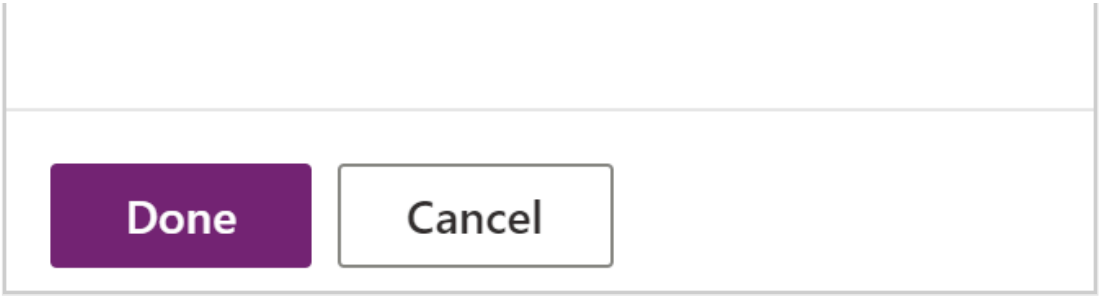
Required

Searchable

Description

Unique identifier for entity instances

Advanced options



4. Select **Done**.

5. On the **Columns** area on the table designer toolbar select **Add column**. On the **Column properties** pane, enter or select the following values and options.

    - **Display name**. *Species*
    - **Data type**. *Choice*
    - **Choice**. *New choice*

6. Select **View more**, and then select **Local choice**.

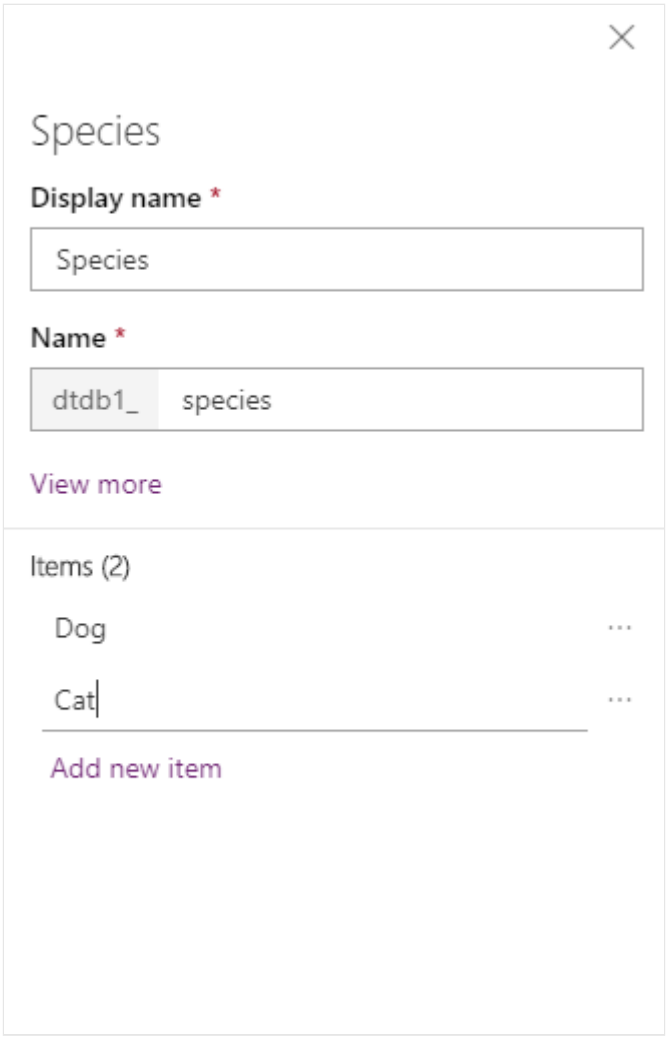
7. Create the choice:

    a. Replace **New option** with *Dog*.

    b. Select **Add new item**.

    c. Replace **New option** with *Cat*.

    d. Select **Done**.



8. Make sure **Searchable** is selected, and then select **Done**.
9. On the table designer toolbar select **Add column**. On the **Column properties** pane, enter or select the following values:
    - **Display name**. *Breed*
    - **Data type**. *Text*
10. Make sure **Searchable** is selected, and then select **Done**.
11. On the table designer toolbar select **Add column**.
12. On the **Column properties** pane, enter or select the following values, and then select **Done**.
    - **Display name**. *Appointment date*
    - **Data type**. *Date and time*

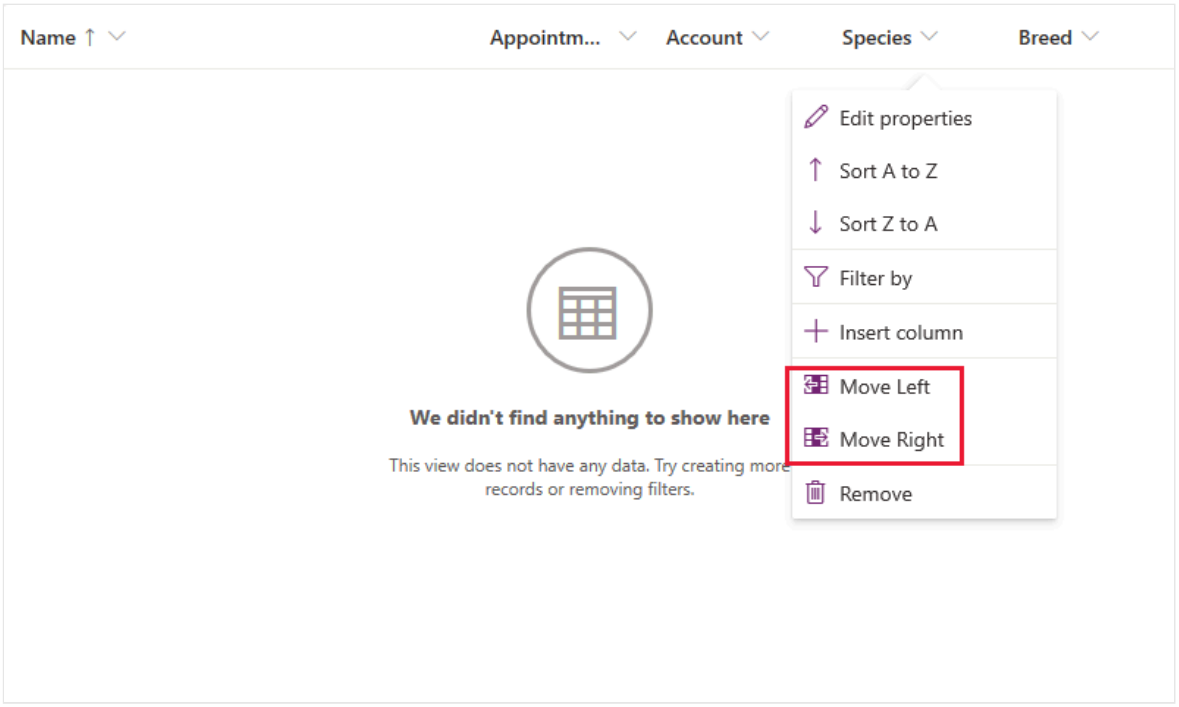
Add a relationship

1. Select the **Relationships** area. Then, on the table designer toolbar, select **Add relationship**, and then select **Many-to-one**.
2. On the right pane, in the **Related** list select **Account**.
3. Select **Done**.
4. Select **Save table**.

Notice that when you add a many-to-one relationship, an **Account** column with the data type **Lookup** is automatically added to your list of columns in the **Columns** area.

Customize a view

1. Select the **Views** area, and then open the **Active Pets** view. If you don't see the **Active Pets** view, change the filter on the command bar from **Default** to **All**.
2. On the view designer **Table columns** left pane, select the following columns to add them to the view.
    - **Account**
    - **Appointment date**
    - **Breed**
    - **Species**
3. On the view designer canvas, select the **Created On** column, and then select **Remove**.
4. To arrange the columns, on the view designer canvas, select the column you want to move and then use **Move Left** or **Move Right**. Your view should look like this.

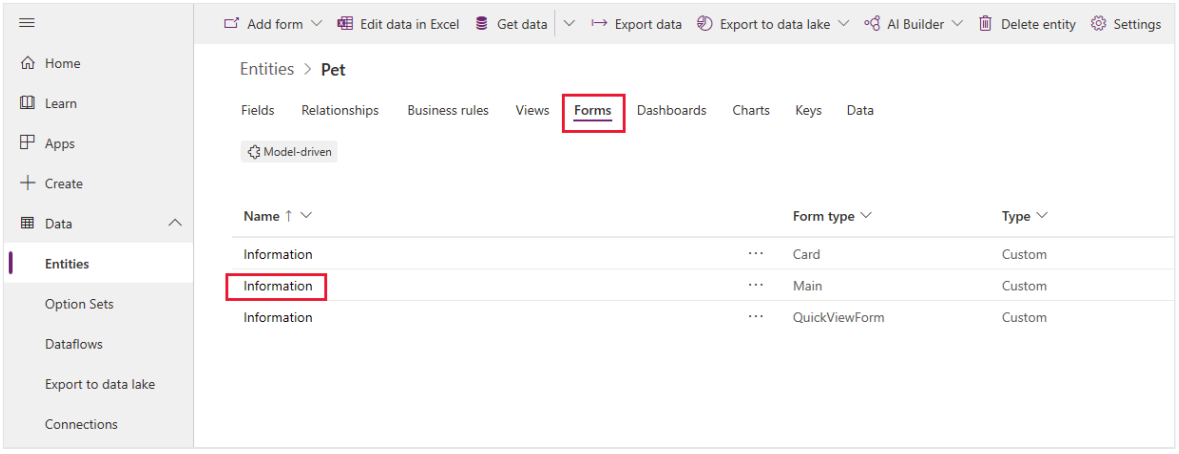


5. On the view designer toolbar, select **Save**, and then select **Publish**.

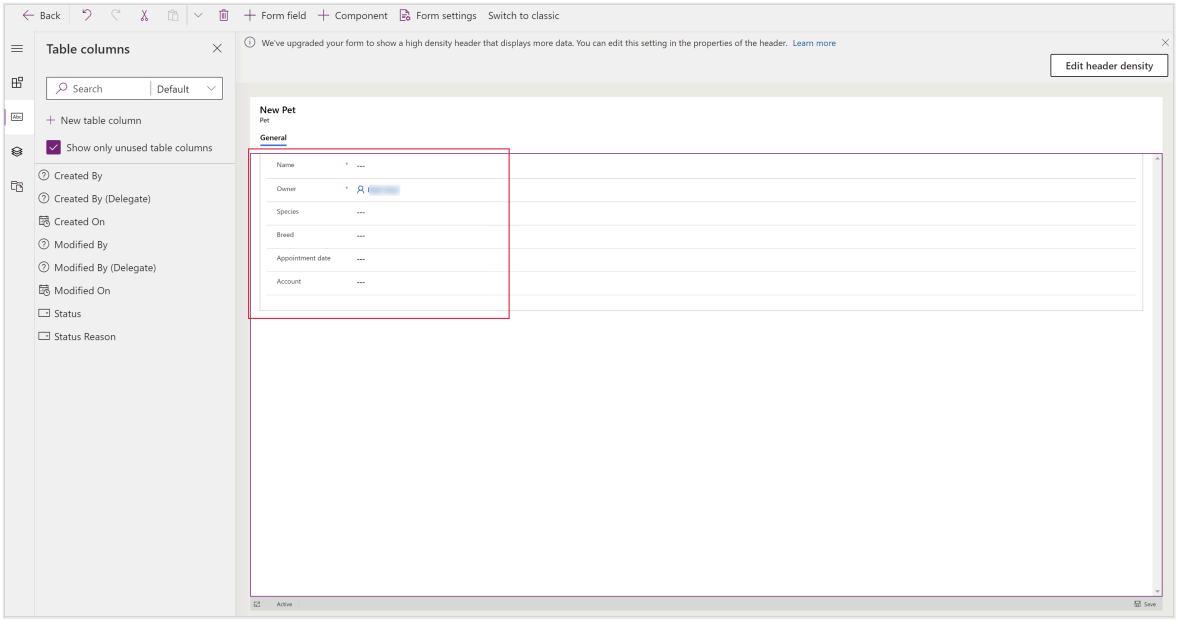
Model-driven apps only: Customize the main form

Skip this step if you only want to use the Pet table in a canvas app.

1. Select **Back** to close the view designer and return to Power Apps.
2. On the left navigation pane, select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Pet**.
4. In the **Pet** table, select the **Forms** area, and then select **Information** next to the **Main** form type to open the form designer.



5. On the form editor, select the **Table columns** on the left pane. Then, drag and drop the **Species**, **Breed**, **Appointment date**, and **Account** columns located on the pane on to the **General** section of the form designer canvas until the form looks like this.



6. Select **Save**.

7. Select **Publish**.

8. Select **Back** to return to Power Apps.

Add the custom table to an app

Now your table is ready to be used to build either a canvas or model-driven app.

Next steps

In this topic, you learned how to create a table that can be used to create a useful app.

- To learn how to create a model-driven app, see Build your first model-driven app.
- To learn how to create a canvas app, see Create an app from scratch.

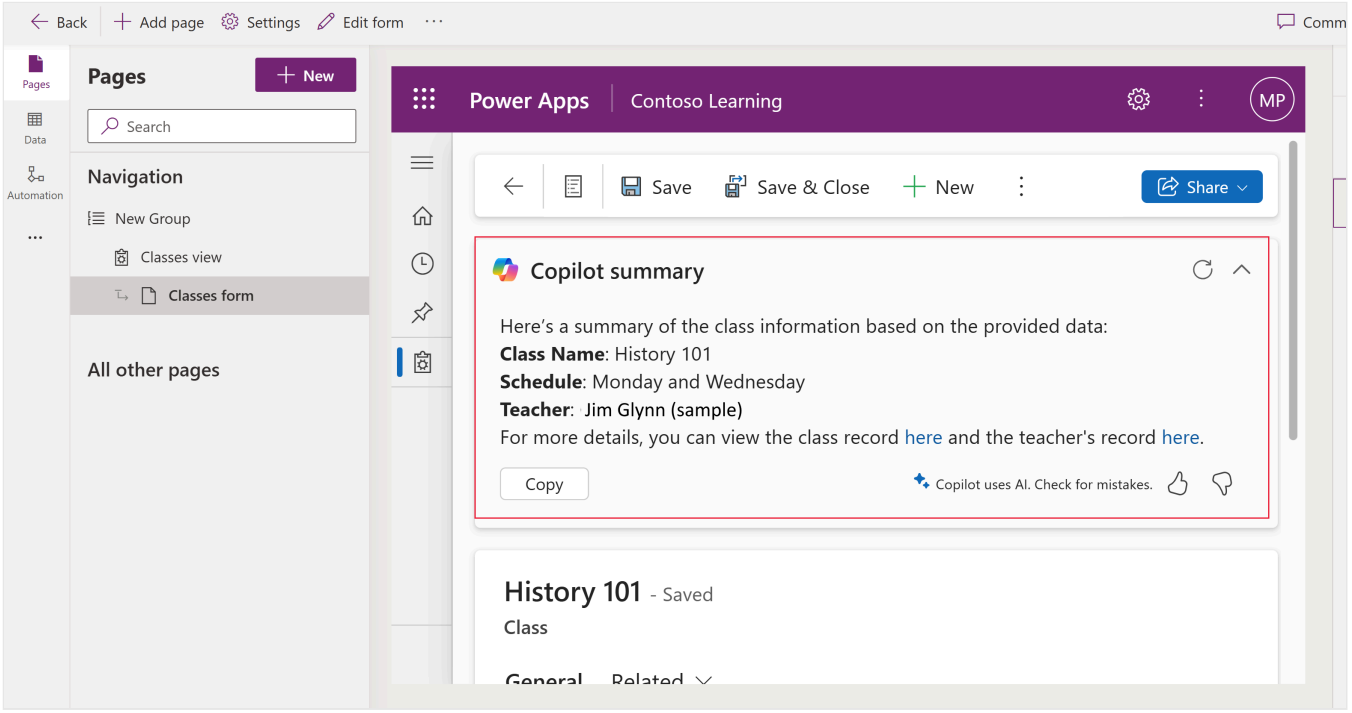
Configure a row summary for a model-driven app (preview)

Summarize this article for me

[This topic is pre-release documentation and is subject to change.]

Write a custom prompt to specify which columns should be included in a Copilot-generated row summary. These summaries appear in a consistent, dedicated experience, either surfaced in a collapsible summary bar at the top of a main form or accessed directly for individual rows from views, giving users quick access to the most important information for a record.

Records are often comprised of dozens of fields spread across multiple tables, views, forms, tabs, and sections, making it time-consuming for users to locate and understand the information that matters most. By highlighting key fields and insights in an at-a-glance summary, makers can help users quickly orient themselves, regardless of where they encounter the record.



Important

- This is a preview feature.
- Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Prerequisite for configuring a row summary

To enable and use this feature, the following criterion is required:

- A Power Platform administrator has enabled the AI insight cards environment setting. More information: Manage feature settings

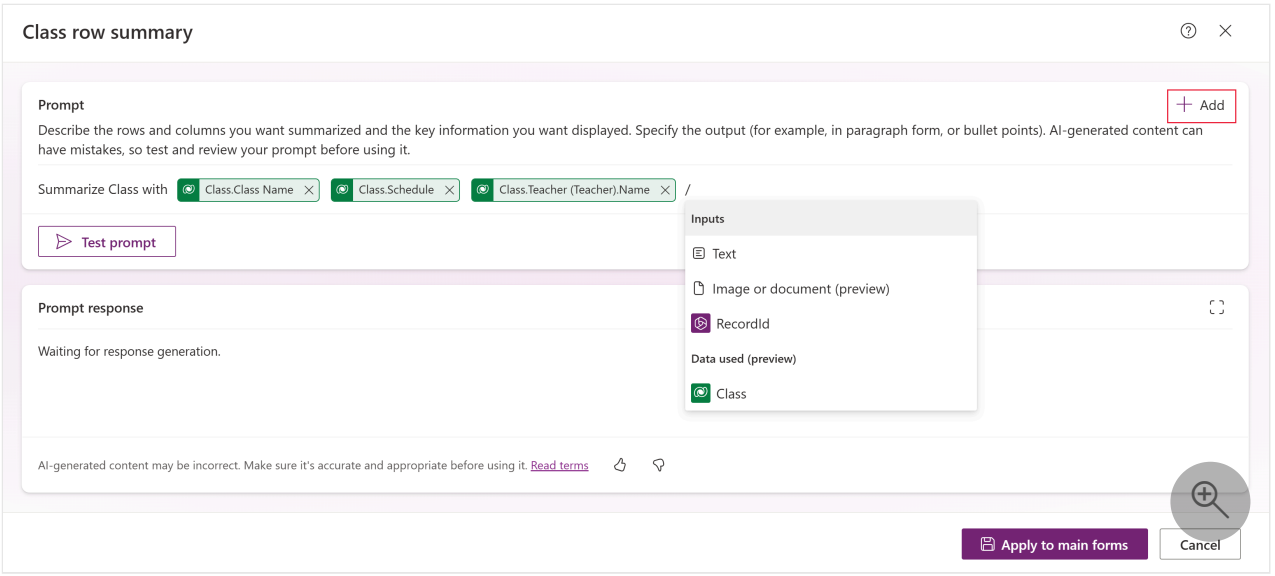
Create a row summary

Row summaries can be configured for most tables and appear on main forms and views.

> **Note**
>
> - When you configure the row summary, it applies to all views and main forms for the table.
> - Some Dynamics 365 apps tables, such as Case, Lead, and Opportunity, provide their own summaries via the Dynamics 365 Customer Service and Dynamics 365 Sales applications. To avoid conflicts, the row summary feature isn't available for these tables. You can find more information about the summaries for these tables and the options for configuring or disabling these summaries by reading about the Customer Service summary and Sales summary features. These out-of-the-box summaries are currently only accessible from main forms (not views).

1. Sign in to Power Apps (make.powerapps.com) select **Tables** on the left navigation pane, and then open the table where you want to configure a row summary. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Under **Customizations**, select **Row summary**.
    - If **Row summary** is disabled, hover over the words to find out the reason. For example, the table must have at least one row of data for the summary option to be enabled.
3. In the **Prompt** box, add the columns that you want included in the summary by selecting **Add** or by typing /. You can also specify formatting for the summary, such as make it a bulleted list or a paragraph, as well as how to ensure the summary is generated in the

user's preferred language. More information: Write a good prompt for the row summary



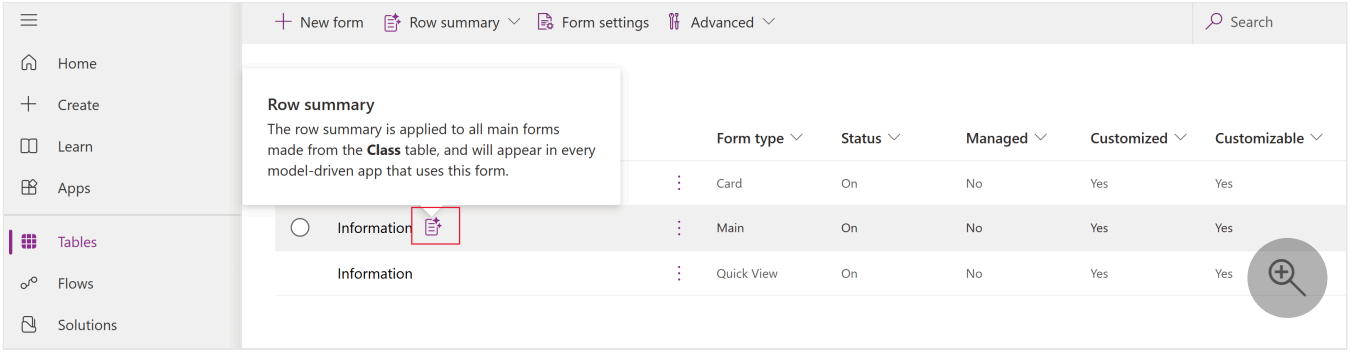
4. Select **Test prompt** to display a preview of the summary. The most recently edited row in the table is used to generate a test response.
5. Once you're satisfied with the columns and response from the test, select **Apply to main forms**.

> **Important**
>
> Any user who needs to view summaries configured through the Dynamics 365 Customer Service app must be assigned the `prvReadLanguageLocale` privilege through a security role.

Determine which main forms include a row summary

After you apply a row summary, the summary displays on all main forms for the table. To view the forms that include a row summary, in Power Apps, select **Tables** on the left navigation pane, and then under **Data experiences** select **Forms**.

All forms with the row summary applied have a form AI icon next to the form name. Hovering over the icon displays "The row summary is applied to all main from for the *table name* table, and appears in every model-driven app that uses this form."



Write a good prompt for the row summary

Writing a custom prompt gives you the ability to instruct the AI model to perform a specific task. By carefully crafting a prompt, you can generate a response that suits your specific business need. Here are some tips to consider when writing a prompt:

- Provide a list of the columns you want to include in the summary. Alternatively, you might wish to provide a list of columns that you want to exclude from the summary.
- Specify any formatting preferences, such as write the summary as a bulleted list.
- Include the appropriate input and instruction if your users work in multiple languages and you want the summary to respect the user's preferred language; otherwise, the summary will be generated in the language of the summary prompt itself, regardless of the user's language settings. To configure:
  - Include the **LanguageCode** input in the prompt.
  - Add the instruction to the prompt: **"You must respond in language <LanguageCode>."**
  - If Copilot doesn't support the user's language, the summary is generated in English.
  - This language instruction is added by default for newly configured summaries, but must be *manually added for any pre-existing summaries* that were created before this behavior was introduced.
- For information about how to craft effective prompts, download the AI Builder prompt engineering guide.

Prompt example for a row summary

Here are examples to use when building a row summary prompt.

Summarize Account record in a way that is easy to understand for a sales manager. Make sure to include all important information, including main ideas and important details, while keeping the order of the content logical. Remove any repetitive elements to make the summary as concise as possible without losing the original text's integrity. If the original text is too short to condense, present it as the summary.

Don't include the title in the summary. Create the summary in two paragraphs. For the first paragraph, use the instructions under the header Data. For the second paragraph, use the data under the header Activity. Leave a blank line between the two paragraphs. Don't include the titles Data & Activity in the paragraphs.

Data:

Show the below values as bullet points using markdown text and bold the values. Make the primary contact a navigation link to the contact record. The link must not include query string

parameters in it.

Account.Annual Revenue, Account.Category, Account.Industry, Account.Ownership

Activity:

Generate a summary paragraph using the following customer communication fields identifying top 2 key information and top 2 important actions to take.

Account.Regarding (Phone Call).Subject, Account.Regarding (Email).Subject

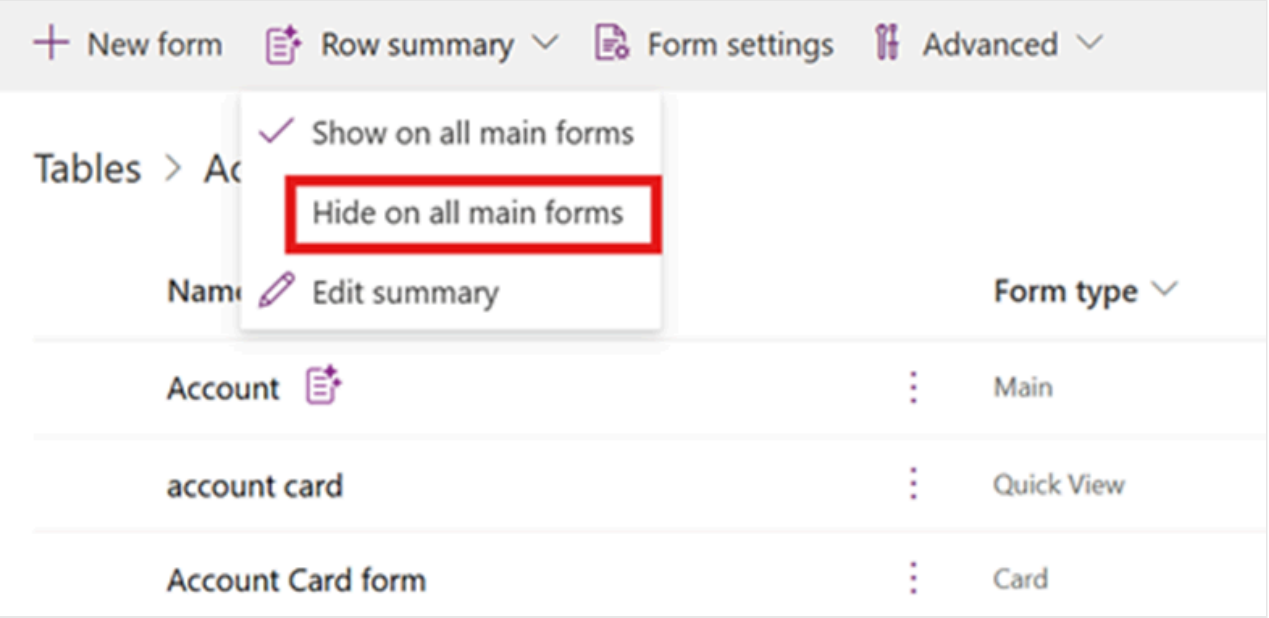
You must respond in language LanguageCode

Edit a row summary

To edit a row summary, open the table, and then under **Customizations** select **Row summary (applied)**. Follow the steps similar in Create a row summary to make and apply changes.

Hide a row summary

1. In Power Apps, select **Tables** on the left navigation pane, and open the table where you want to edit a row summary.
2. Under **Customizations**, select **Row summary**.
3. Unselect the **Show row summary** option at the top right of the modal.



> **Note**
>
> If you're trying to hide the default summary for case, lead, and opportunity, which are provided via the Dynamics 365 Customer Service and Dynamics 365 Sales applications, go

to these articles to learn more about options for configuring and/or disabling these summaries:

- Case: Customer Service summary
- Lead and opportunity: Sales summary features.

Adding summaries to solutions

Row summaries are solution-aware and can be added to a solution to facilitate moving between environments. To add a summary to a solution, follow these steps:

1. In Power Apps, select **Solutions** on the left navigation pane, and open the desired solution.
2. Select **Add existing** > **More** > **Other** > **AI Skill Config**.
3. Select the rows corresponding to the tables you created summaries for, and then select **Add**.

> **Important**
>
> Don't add AI Skill Config table rows with an owner of *System* to your solutions. These don't correspond to row summaries you have created and might cause solution import to fail.

FAQ for prompts and text generation capabilities

Last updated on 02/12/2026

Import data from Excel and export data to CSV

To get (import) data into Microsoft Dataverse tables, use an Excel worksheet file or a comma-separated values (CSV) file.

When you export Dataverse table data, it's exported as a CSV file.

Import from an Excel or CSV file

There are two ways to import data from Excel.

- Option 1: Import by creating and modifying a file template
- Option 2: Import by bringing your own source file

> **Important**
>
> - To import or export data, you must have the **Environment Maker** security role.
> - Import from Excel or CSV file using the **Import** > **Import data from Excel** command isn't available in GCC, GCC High, and DoD environments. To work around this limitation, from the **Tables** area in Power Apps select **Import** > **Import data**, and then choose a data source, such as **Excel workbook** or **Text/CSV**.

Option 1: Import by creating and modifying a file template

Every table has required columns that must exist in your input file. We recommend that you create a template. To do this, export data from the table. Then, use the same file and modify it with your data. Finally, import the modified file back into the table. Using a template can save you time because you won't have to specify the required columns for each table.

Prepare the file template

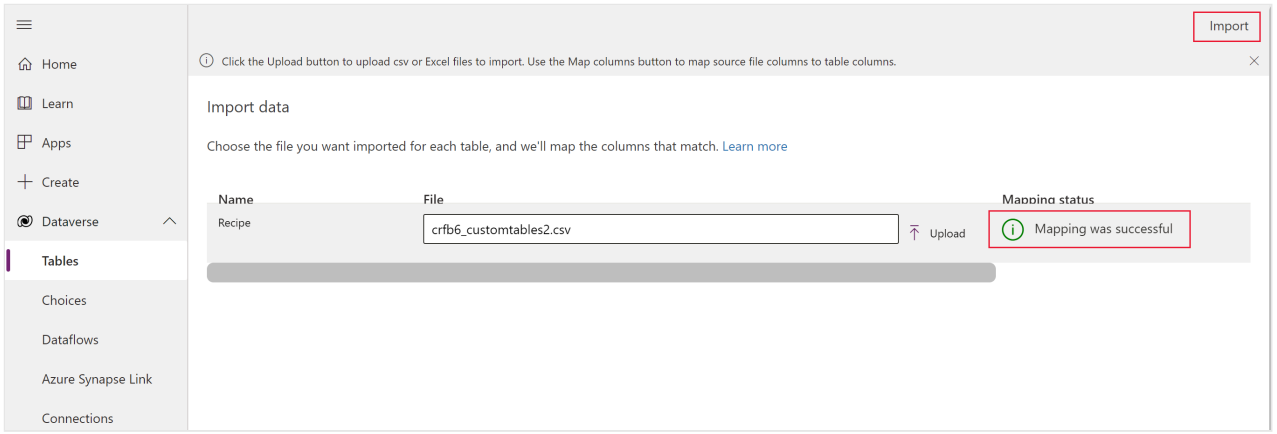
1. Export the table data.
2. Define a plan to make sure data is unique before you import it. Use either primary keys or alternate keys. More information: Ensure uniqueness when you import data into a table from Excel or CSV

Modify the file with your data

Copy data from your Excel or CSV file into the template that you created in the previous step.

Import the file

1. On powerapps.com select **Tables** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **Import** > **Import data from Excel**.
3. Select the tables where you want to import data, and then select **Next**.
4. On the **Import data** page, select **Upload**, and choose your file. Follow the prompts to upload your file.
5. After the file is uploaded and **Mapping status** indicates **Mapping was successful**, select **Import** from the top-right corner. Go to Troubleshoot mapping errors with Excel to navigate and fix any mapping errors.



After the import finishes successfully, you'll see the total number of inserts and updates.

New import from Excel (preview)

[This topic is pre-release documentation and is subject to change.]

The new import experience lets users import data directly from an Excel file into existing Dataverse tables using a unified UI. This experience improves upon the original import method by offering:

- **Assisted mapping**: Uses vector-based search to provide more contextually relevant column mapping suggestions.
- **Sheet selection**: Users can choose which sheet to import from within a multi-sheet Excel file.
- **Notifications**: Real-time feedback on import status, including success, in-progress, and error states.
- **Error logs**: Downloadable logs to help users self-diagnose and resolve issues.
- **Performance improvements**: Asynchronous ingestion offers better reliability and speed for large files.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Prerequisites

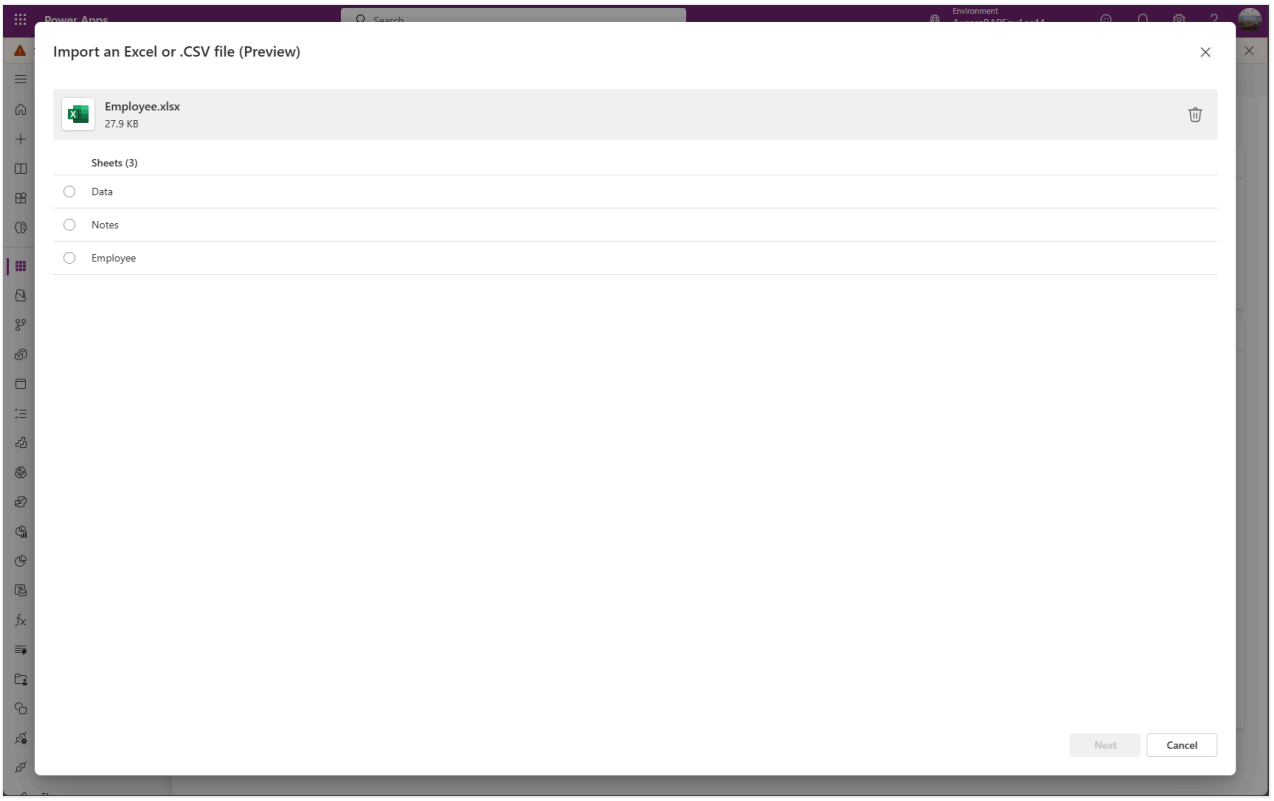
To use the feature a Power Platform admin must enable the **"Import Excel to existing table with assisted mapping"** environment setting in the Power Platform admin center. Select the environment, and then select **Settings** > **Product** > **Features** and enable the **"Import Excel to existing table with assisted mapping"** setting.

> **Note**
>
> The **Import Excel to existing table with assisted mapping** environment setting is being removed from the Power Platform admin center. This feature is currently being improved and that setting is no longer used.

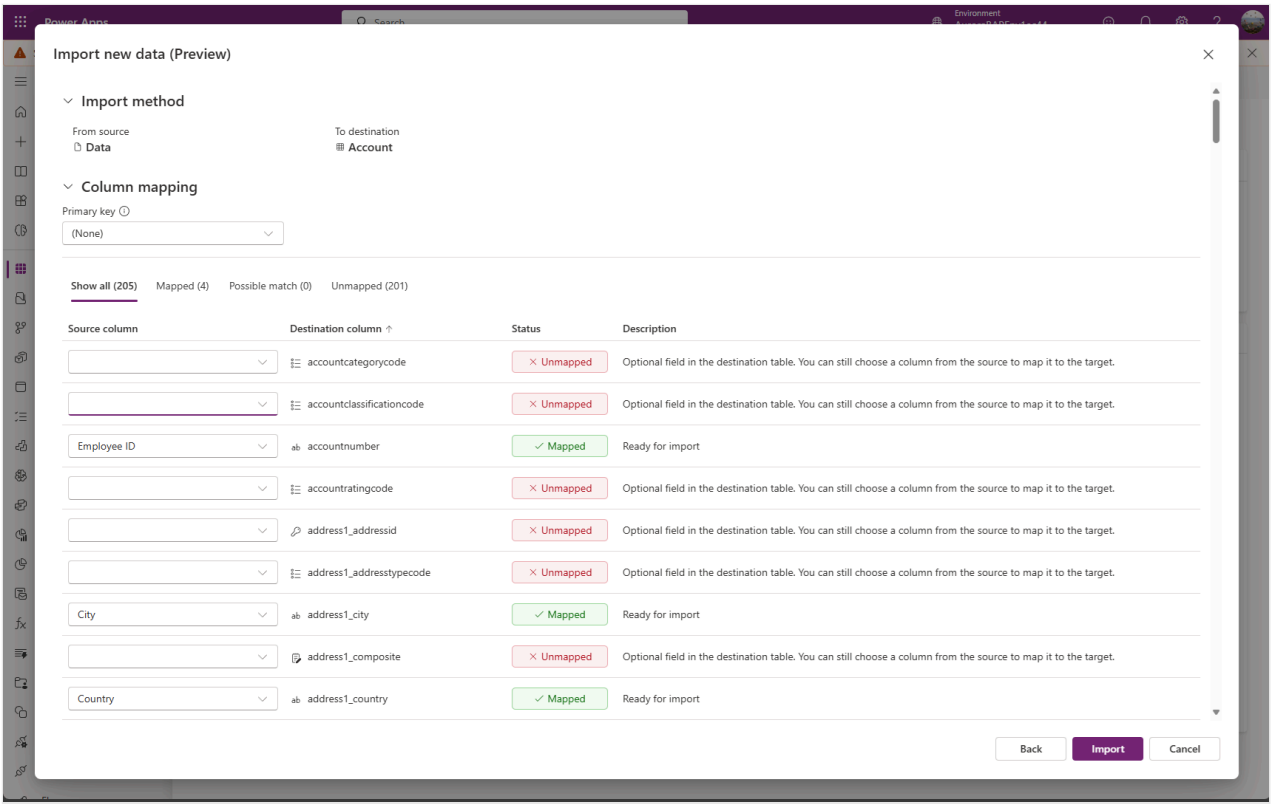
Import from Excel (preview) steps

1. Go to the table you want to import data to, and then on the command bar select **Import** > **Import from Excel (Preview)**.

2. Upload your Excel file and select the sheet to import.



3. Map columns. A primary key is required if you want to update existing records in the table. If no primary key is selected ("None" option), then all records from the Excel sheet or CSV file are added as new records.



4. Review the summary and select **Import**.

Monitor the import status from notifications:

- In progress: Ongoing import activity with the message **Your data is importing** displayed.
- Success: Data was processed or indexed with the message **Upload completed** displayed.

- Error: **Upload completed with some errors** displayed that includes a link to download logs for troubleshooting.

Option 2: Import by bringing your own source file

If you're an advanced user and know the required columns for a given table for Dataverse tables, define your own Excel or CSV source file. Follow the steps in Import the file.

Troubleshoot mapping errors with Excel

If you get mapping errors after you upload your file, select **Map status**. Take the following steps to inspect and rectify the column mapping errors.

1. Use the drop-down menu on the right, under **Show**, to walk through the **Unmapped columns**, **Fields with error**, or **Required Fields**.

   > **Tip**
   >
   > - Depending on whether you get a **Warning** or an **Error**, inspect **Unmapped columns** or **Fields with error** through the drop-down menu in **Column Mappings**.
   > - Use the *upsert* (**Update** or **Insert**) logic to either update the row, if it already exists, or to insert a new row.

2. After you resolve all the errors and warnings, select **Save Changes** in the top-right corner. You'll go back to the **Import Data** screen.

3. When the **Mapping status** column shows **Mapping was successful**, select **Import** from the top-right corner.

When the **Import completed successfully** message appears, the total inserts and updates are displayed.

Ensure uniqueness when you import data into a table from Excel or CSV

Dataverse tables use a primary key to uniquely identify rows within a Dataverse table. The primary key for a Dataverse table is a globally unique identifier (GUID). It forms the default basis for row identification. Data operations, like importing data into Dataverse tables, surface the default primary keys.

Example:
The primary key for an **Account** table is **accountid**.

	A	B	C	E	DI
1	accountid	name	accountnumber	address1_composite	transactioncurrencyid
2	802534f7-5b45-e811-a953-000d3a33bcb9	Coho Winery (sample)	BABCO88H	137 Lancelot Dr	88c6c893-5b45-e811-a953-000d3a33bcb9
3	7e2534f7-5b45-e811-a953-000d3a33bcb9	A. Datum Corporation (sample)	AAAAA	2137 Birchwood Dr	88c6c893-5b45-e811-a953-000d3a33bcb9
4	7c2534f7-5b45-e811-a953-000d3a33bcb9	Alpine Ski House (sample)	ABCO9M32	2313 B Southampton	88c6c893-5b45-e811-a953-000d3a33bcb9

Sometimes, a primary key might not work when you integrate data from an external source. Use Dataverse to define alternate keys that uniquely identify a row in place of the primary key.

Example:
For an **Account** table, you might set **transactioncurrencyid** as an alternate key by using a natural key-based identification. For example, use **US Dollar** instead of the GUID value **88c6c893-5b45-e811-a953-000d3a33bcb9** shown previously. You can also choose **currency symbol** or **currency name** as keys. More information: Define alternate keys using Power Apps portal

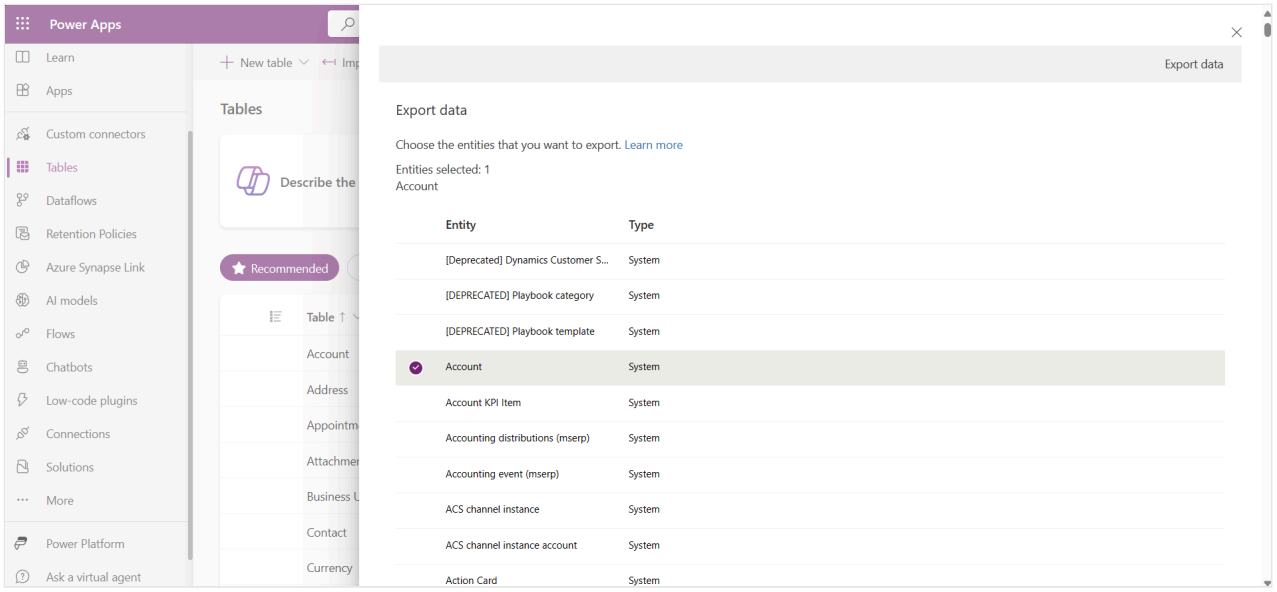
	A	B	C	DQ
1	accountid	name	accountnumber	transactioncurrencyid.currencyname
2	762534f7-5b45-e811-a953-000d3a33bcb9	Blue Yonder Airlines (sample)	ACSHN2S4	US Dollar
3	782534f7-5b45-e811-a953-000d3a33bcb9	City Power & Light (sample)		Euro
4	7a2534f7-5b45-e811-a953-000d3a33bcb9	Contoso Pharmaceuticals (sample)		Rupee

You can still use primary keys as identifiers after you specify alternate keys. In the preceding sample, the first file is still valid if GUIDs are valid data.

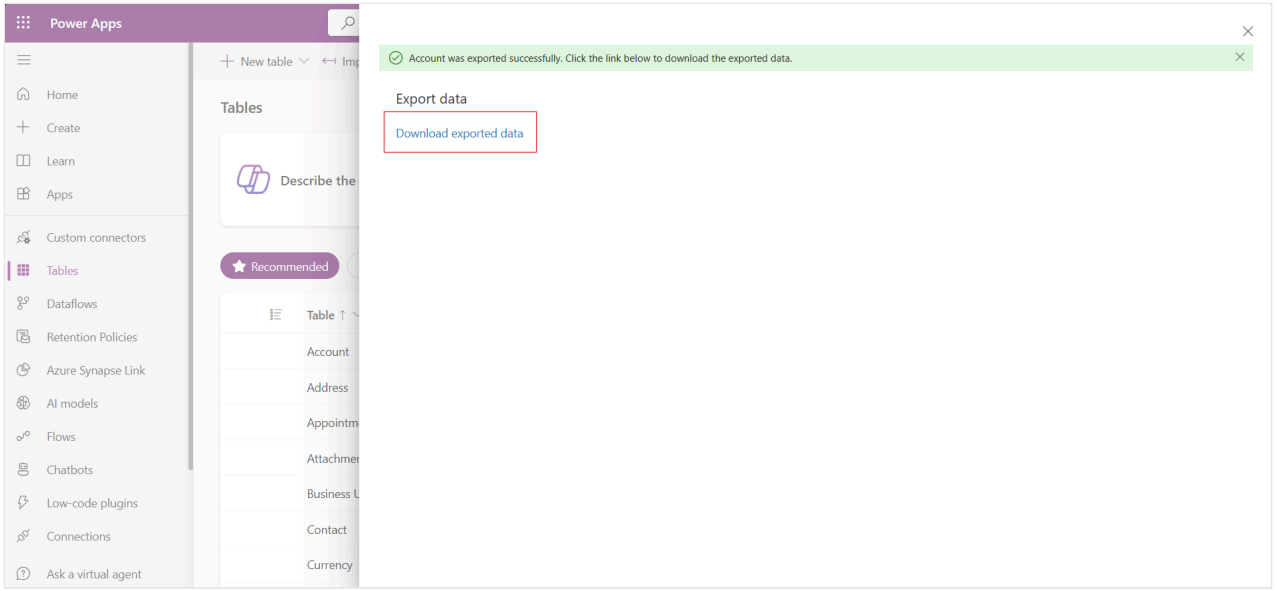
Export data

Export data from a single table in a comma-separated value (CSV) format.

1. Sign into Power Apps, on the left navigation pane select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **Export** > **Export data**.
3. Select the table from which you want to export data, and then select **Export data**.



4. After the export finishes successfully, select **Download exported data** to download the CSV file to the download folder specified in your web browser.



> **Note**
>
> Exports have a 12 minute time limit. If the volume of data exported exceeds 12 minutes the export will fail. If this occurs, export data in smaller segments.

Unsupported data types and fields

The following data types aren't currently supported for import or export.

- Timezone
- Choices (multiselect)
- Image

- File

The following fields are system fields and aren't supported for import and export.

- `Ownerid`
- `Createdby`
- `Createdonbehalfby`
- `Createdon`
- `Modifiedby`
- `Modifiedonbehalfby`
- `Modifiedon`
- `Overriddencreatedon`

> **Note**
>
> Get Data from Excel and Export Data features are currently not included in the Power Apps Developer Plan.

Import using a connector

Use a connector to import data from a selection of many different sources, such as Azure, SQL Server database, SharePoint, Access, OData, and more. More information: Create and use dataflows in Power Apps

See also

Tables in Dataverse

Last updated on 01/16/2026

Create and use dataflows in Power Apps

With advanced data preparation available in Power Apps, you can create a collection of data called a dataflow, which you can then use to connect with business data from various sources, clean the data, transform it, and then load it to Microsoft Dataverse or your organization's Azure Data Lake Gen2 storage account.

A dataflow is a collection of tables that are created and managed in environments in the Power Apps service. You can add and edit tables in your dataflow, as well as manage data refresh schedules, directly from the environment in which your dataflow was created.

Once you create a dataflow in the Power Apps portal, you can get data from it using the Dataverse connector or Power BI Desktop Dataflow connector, depending on which destination you chose when creating the dataflow.

There are three primary steps to using a dataflow:

1. Author the dataflow in the Power Apps portal. You select the destination to load the output data to, the source to get the data from, and the Power Query steps to transform the data using Microsoft tools that are designed to make doing so straightforward.

2. Schedule dataflow runs. This is the frequency in which the Power Platform Dataflow should refresh the data that your dataflow will load and transform.

3. Use the data you loaded to the destination storage. You can build apps, flows, Power BI reports, and dashboards or connect directly to the dataflow's Common Data Model folder in your organization's lake using Azure data services like Azure Data Factory, Azure Databricks, or any other service that supports the Common Data Model folder standard.

The following sections look at each of these steps so you can become familiar with the tools provided to complete each step.

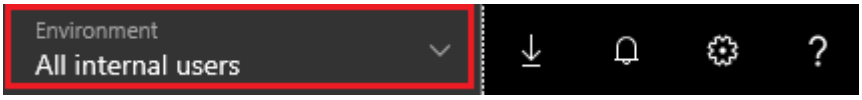
Create a dataflow

Dataflows are created in one environment. Therefore, you'll only be able to see and manage them from that environment. In addition, individuals who want to get data from your dataflow must have access to the environment in which you created it.

> **ⓘ Important**
>
> - Creating dataflows is currently not available with Power Apps Developer Plan licenses.

- The Firefox web browser currently isn't supported for the "Download refresh history file" action in Power Apps dataflows. More information: [You receive the error message "There was a problem refreshing the dataflow"]

1. Sign in to Power Apps, and verify which environment you're in, find the environment switcher near the right side of the command bar.

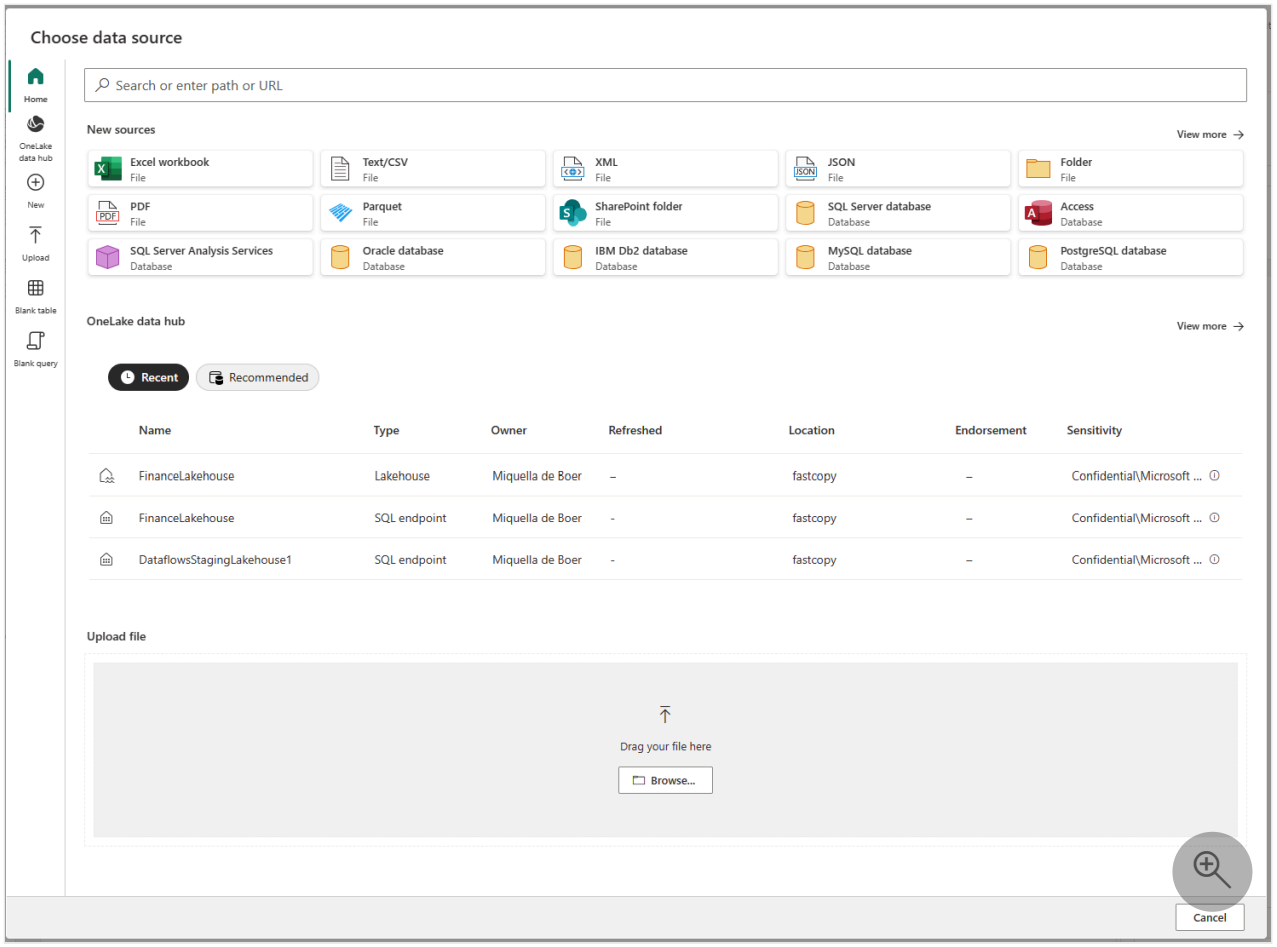


2. On the left navigation pane, select **Dataflows**. If the item isn't in the side panel pane, select ...More and then select the item you want.

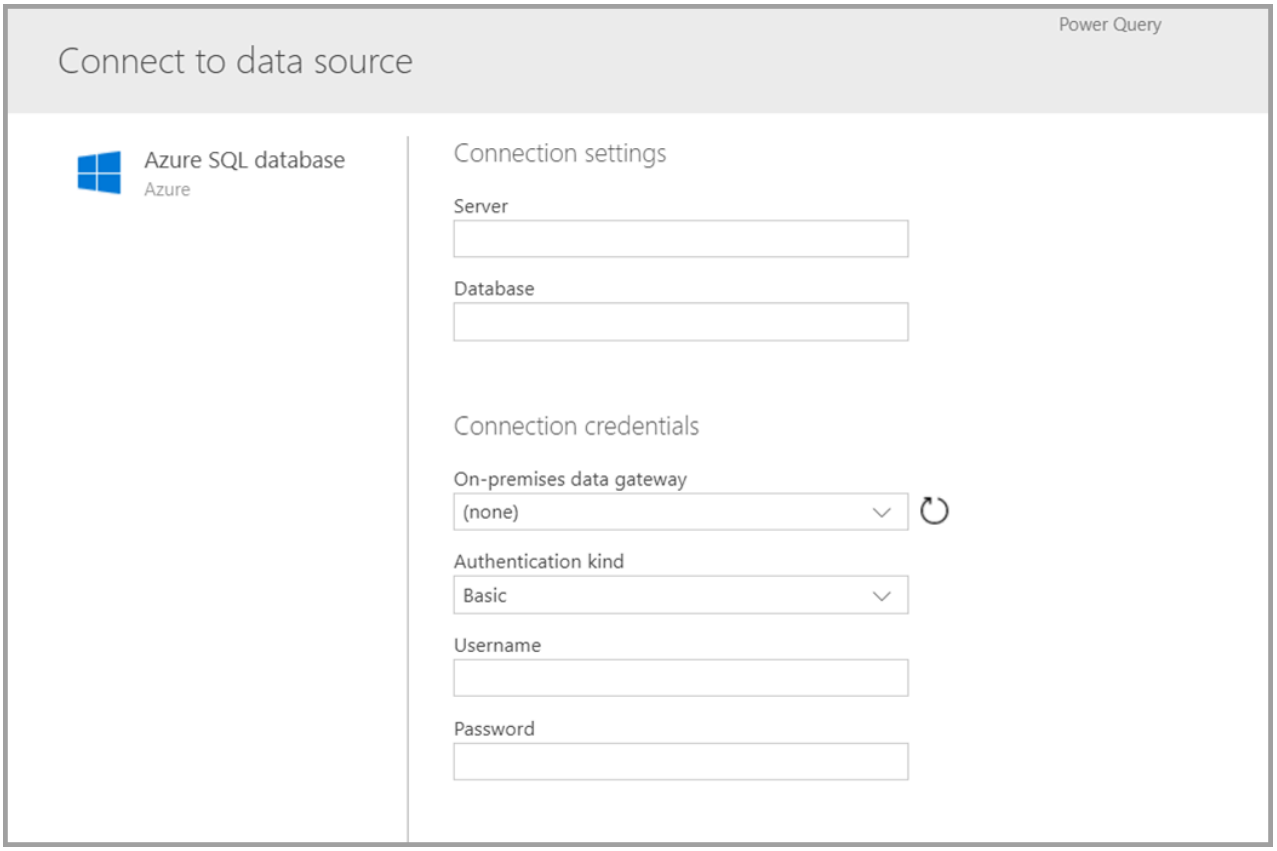
3. Select **New dataflow**. On the **New Dataflow** page, enter a **Name** for the dataflow. By default, dataflows store tables in Dataverse. Select **Analytical entities only** if you want tables to be stored in your organization's Azure Data Lake storage account. Select **Create**.

   > **Important**
   >
   > There's only one owner of any dataflow—the person who created it. Only the owner can edit the dataflow. Authorization and access to data created by the dataflow depend on the destination you loaded data to. Data loaded into Dataverse will be available via the Dataverse Connector and requires the person accessing the data to be authorized to Dataverse. Data loaded into your organization's Azure Data Lake Gen2 storage account is accessible via the Power Platform Dataflow connector and access to it requires membership within the environment it was created in.

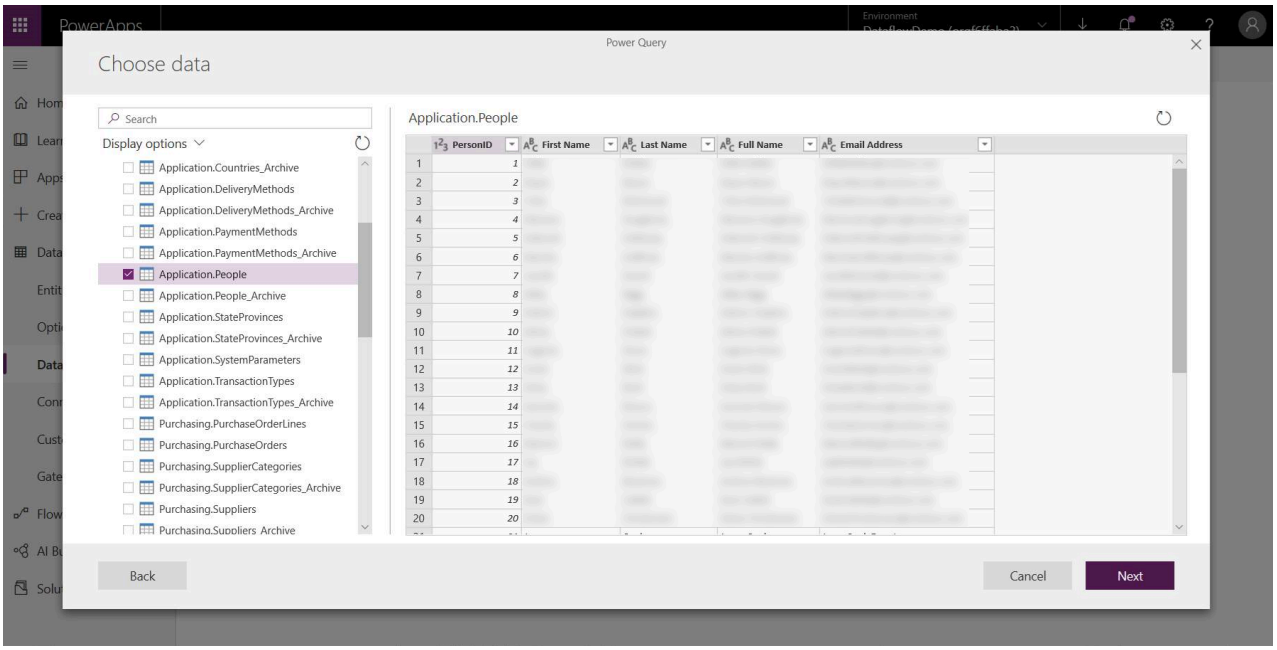
4. On the **Choose data source** page, select the data source where the tables are stored. The selection of data sources displayed allows you to create dataflow tables.



5. After you select a data source, you're prompted to provide the connection settings, including the account to use when connecting to the data source. Select **Next**.



6. Once connected, you select the data to use for your table. When you choose data and a source, the Power Platform Dataflow service will subsequently reconnect to the data source in order to keep the data in your dataflow refreshed, at the frequency you select later in the setup process.

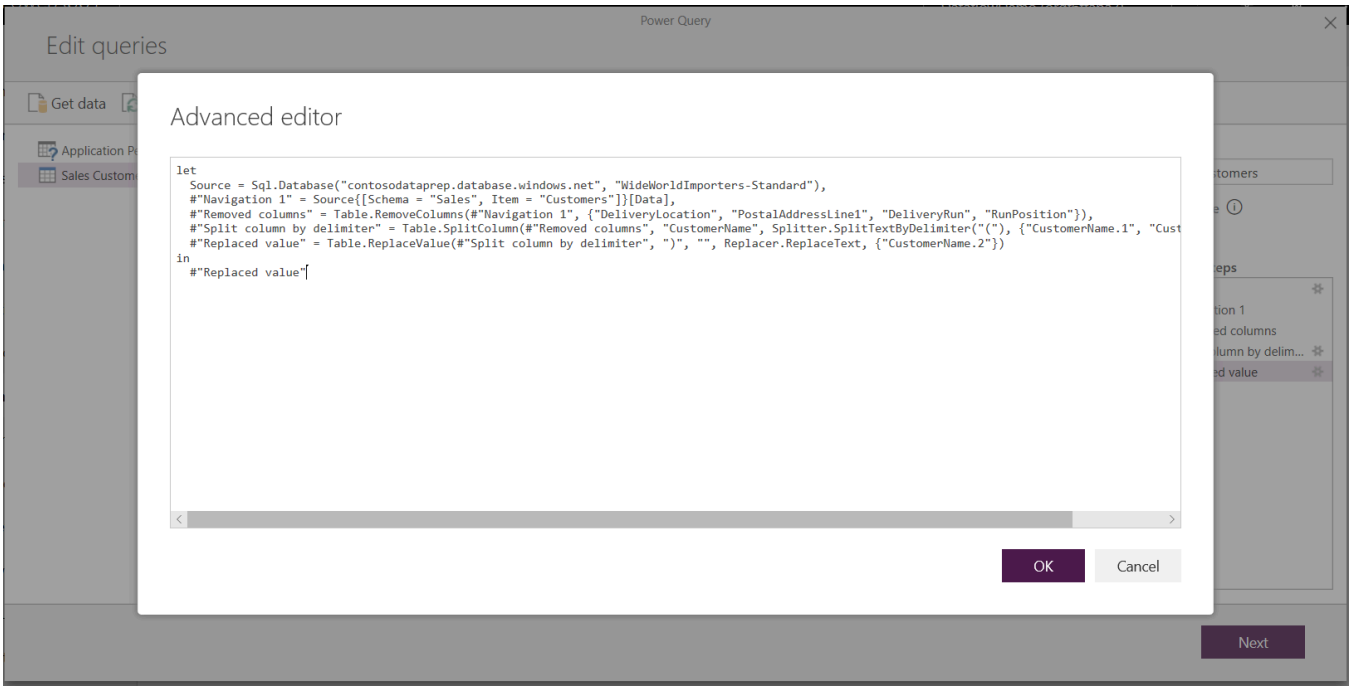


Now that you've selected the data to use in the table, you can use the dataflow editor to shape or transform that data into the format necessary for use in your dataflow.

Use the dataflow editor to shape or transform data

You can shape your data selection into a form that works best for your table using a Power Query editing experience, similar to the Power Query Editor in Power BI Desktop. To learn more about Power Query, see Query overview in Power BI Desktop.

If you want to see the code that Query Editor is creating with each step, or if you want to create your own shaping code, you can use the advanced editor.

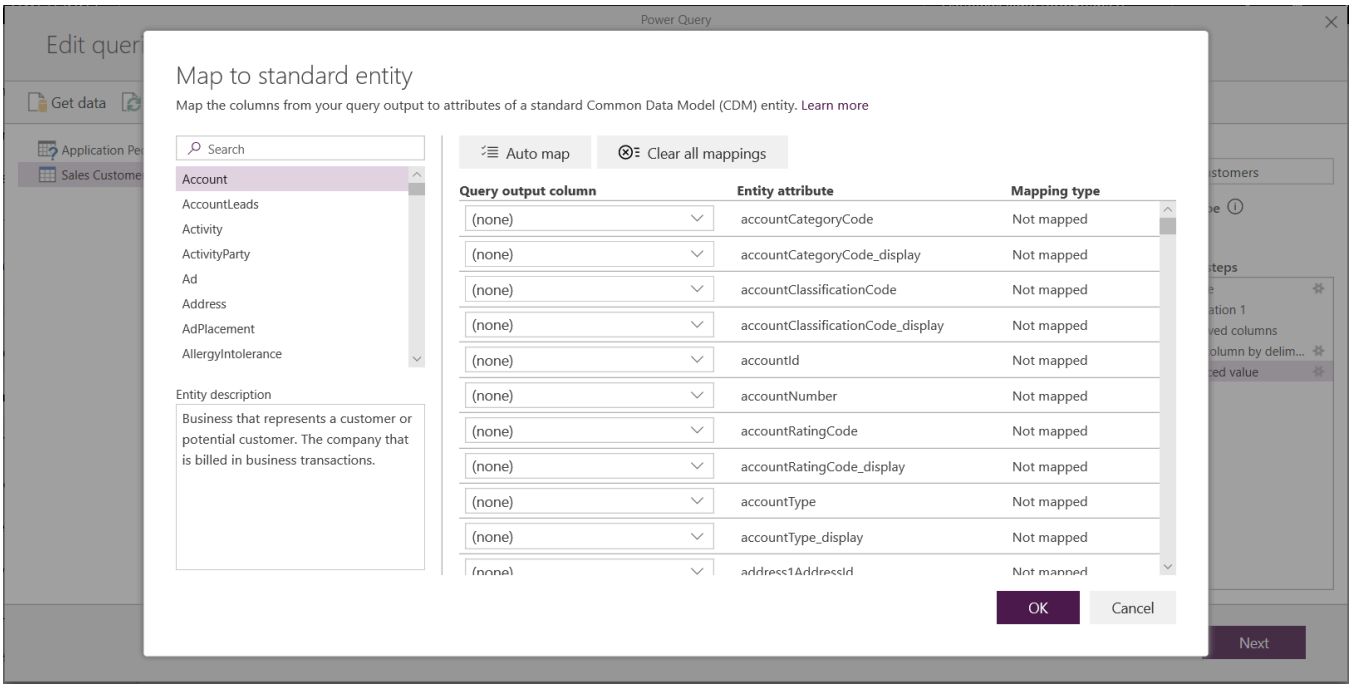


Dataflows and the Common Data Model

Dataflows tables include new tools to easily map your business data to the Common Data Model, enrich it with Microsoft and non-Microsoft data, and gain simplified access to machine learning. These new capabilities can be leveraged to provide intelligent and actionable insights into your business data. Once you've completed any transformations in the edit queries step described below, you can map columns from your data source tables to standard table columns as defined by the Common Data Model. Standard tables have a known schema defined by the Common Data Model.

For more information about this approach, and about the Common Data Model, see The Common Data Model.

To leverage the Common Data Model with your dataflow, select the **Map to Standard** transformation in the **Edit Queries** dialog. In the **Map tables** screen that appears, select the standard table that you want to map.



When you map a source column to a standard column, the following occurs:

1. The source column takes on the standard column name (the column is renamed if the names are different).

2. The source column gets the standard column data type.

To keep the Common Data Model standard table, all standard columns that aren't mapped get *Null* values.

All source columns that aren't mapped remain as is to ensure that the result of the mapping is a standard table with custom columns.

Once you've completed your selections and your table and its data settings are complete, you're ready for the next step, which is selecting the refresh frequency of your dataflow.

Set the refresh frequency

Once your tables have been defined, you should schedule the refresh frequency for each of your connected data sources.

Dataflows use a data refresh process to keep data up to date. In the **Power Platform Dataflow authoring tool**, you can choose to refresh your dataflow manually or automatically on a scheduled interval of your choice.

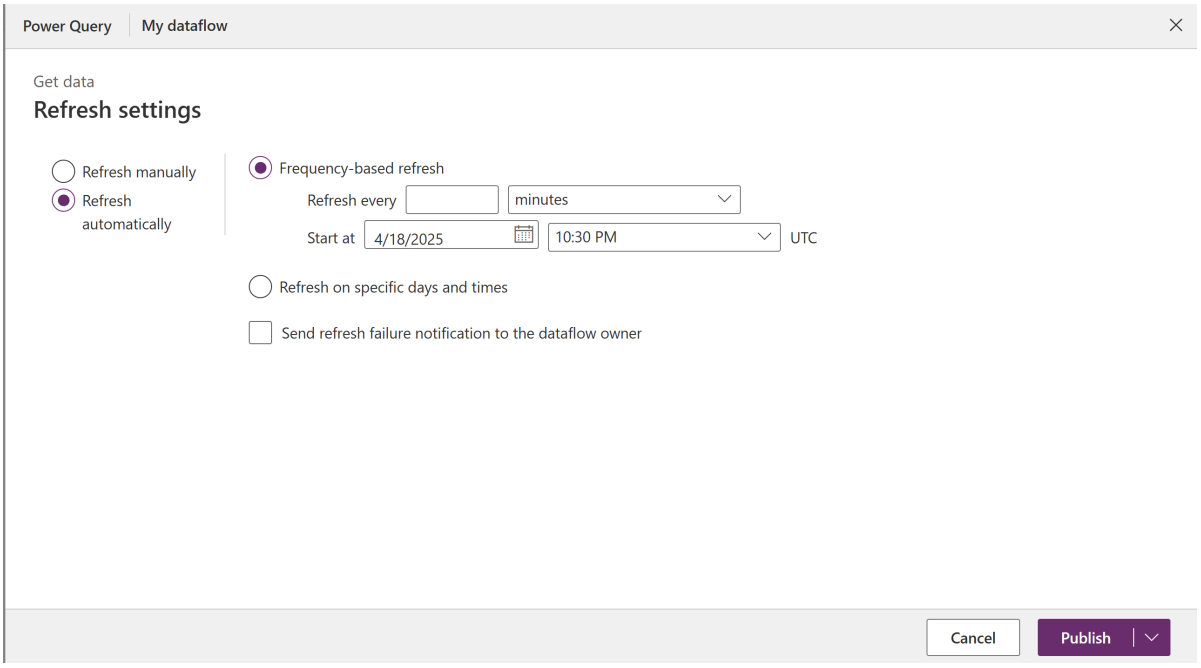
Schedule a refresh automatically

1. Select **Refresh automatically**.

2. Enter the dataflow frequency:

    - **Frequency-based refresh**. Set how often in 30-minute increments, start date, and time in UTC.

    - **Refresh on specific days and times**. Choose time zone, frequency (daily or weekly) and time of day in 30-minute increments.



3. Select **Publish.**

Some organizations might want to use their own storage for creation and management of dataflows. You can integrate dataflows with Azure Data Lake Storage Gen2 if you follow the requirements to set up the storage account properly. More information: Connect Azure Data Lake Storage Gen2 for dataflow storage

Troubleshooting data connections

There might be occasions when connecting to data sources for dataflows runs into issues. This section provides troubleshooting tips when issues occur.

- **Salesforce connector.** Using a trial account for Salesforce with dataflows results in a connection failure with no information provided. To resolve this, use a production Salesforce account or a developer account for testing.

- **SharePoint connector.** Make sure you supply the root address of the SharePoint site, without any subfolders or documents. For example, use a link similar to `https://microsoft.sharepoint.com/teams/ObjectModel`.

- **JSON File connector.** Currently you can connect to a JSON file using basic authentication only. For example, a URL similar to `https://XXXXX.blob.core.windows.net/path/file.json?sv=2019-01-01&si=something&sr=c&sig=123456abcdefg` is currently not supported.

- **Azure Synapse Analytics.** Dataflows don't currently support Microsoft Entra authentication for Azure Synapse Analytics. Use basic authentication for this scenario.

> ⓘ Note
>
> If you use data loss prevention (DLP) policies to block the **HTTP with Microsoft Entra (preauthorized)** connector then **SharePoint** and **OData** connectors will fail. The **HTTP with Microsoft Entra (preauthorized)** connector needs to be allowed in DLP policies for **SharePoint** and **OData** connectors to work.

Troubleshoot the error: Connection to Dataverse failed. Please check the link below on how to fix this issue

Users might receive an error message if the connection they're using for export requires a fix. In this case, the user receives an error message that states **Connection to Dataverse failed. Please check the link below on how to fix this issue**.

To resolve this issue:

1. In Power Apps (make.powerapps.com), select **Connections** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Locate the **Microsoft Dataverse (legacy)** connection.
3. Select the **Fix connection** link in the **Status** column, and follow the instructions on your screen.

After the fix completes, retry the export.

You receive the error message "There was a problem refreshing the dataflow"

This error occurs when you try to refresh the dataflow while using the Firefox web browser. To work around this issue use a different web browser, such as Microsoft Edge or Google Chrome.

Next steps

The following articles are useful for further information and scenarios when using dataflows:

- Add data to a table in Dataverse
- Using an on-premises data gateway in Power Platform dataflows
- Connect Azure Data Lake Storage Gen2 for dataflow storage
- Use dataflows in solutions

For more information about the Common Data Model:

- Common Data Model - overview
- Learn more about the Common Data Model schema and tables on GitHub

Dataverse long term data retention overview

Microsoft Dataverse supports custom retention policies to securely retain unlimited data long term in a cost-efficient way. While Dataverse can support your business growth with no limit on active data, you might want to consider moving inactive data to the Dataverse long term retention store.

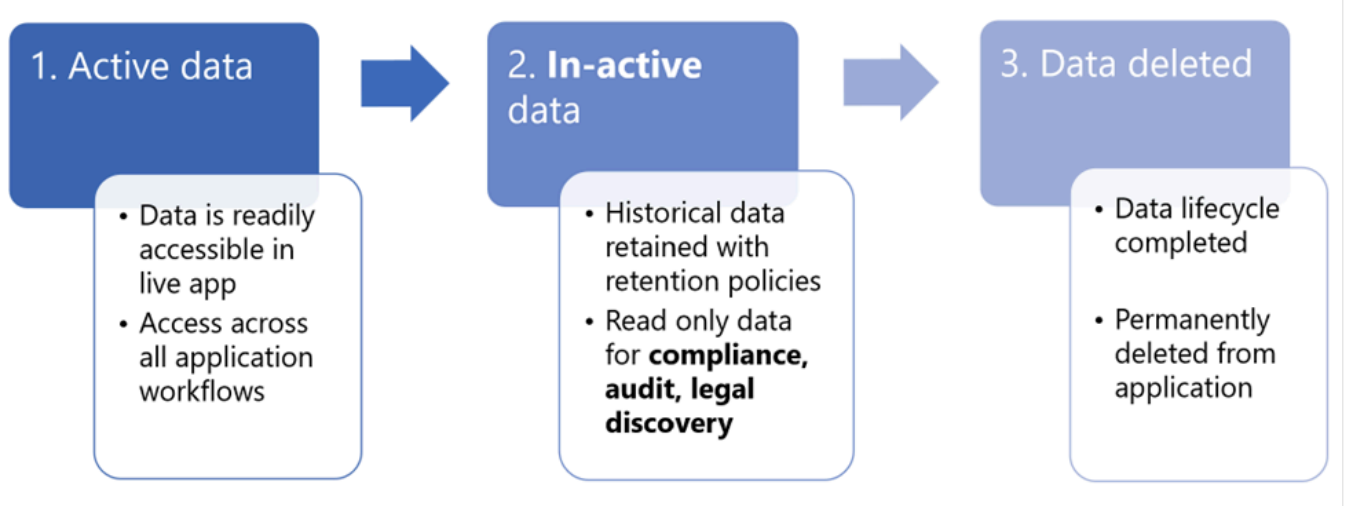
> **Important**
>
> The Power Platform environment where the retention policy resides must be a Managed Environment. This also applies to Dynamics 365 customers who will be required to upgrade to a Managed Environment if the environment isn't already a Managed Environment.
>
> Customers who don't meet this requirement can continue to create data retention policies, but the policies are disabled.

Watch this video to learn about Dataverse long term data retention.

https://learn-video.azurefd.net/vod/player?id=c34fea68-46b2-4486-b9c1-a3ef9d01b4f9&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fdata-retention-overview

Business application data lifecycle

Consider the business application data lifecycle in three stages. First active data, which over time transitions to inactive data, and finally transitions to deleted data.



Expand table

Stage	Description
1. Active data	Data is readily available and transformed via apps. Accessed across all application workflows. Also referred to as *live* data.
2. Inactive data	Data is immutable and read-only. Is stored in long term retention. Has limited access. Retained for compliance, audit, and legal discovery.
3. Deleted data	Permanently deleted. Data lifecycle is completed.

Dataverse delivers native platform support for long-term retention of data. It helps your organization get immediate and ongoing benefits:

- Securely retain the historical application data long term for audit, legal, and regulatory requirements.
- Access the read-only data for limited inquiry purposes.
- Reduce database capacity consumed and save money on inactive data.
- Avoid IT investments required to build and maintain custom solutions for long-term retention of historical application data.

How it works

Application admins set up custom policies for a table with criterion to retain data long term. The retained data is never moved out of Dataverse, the data is stored in Dataverse long term retention. The data is always secured with Dataverse security backed by Microsoft Entra ID.

> **Important**

- Once data is retained with Dataverse long term retention it can't be moved back to the Dataverse live (active) application state.
- When a retention policy is run, the process makes API requests in Microsoft Power Platform. These requests are counted towards the existing API requests available with your plan. More information: Requests limits and allocations

Dataverse provides read-only access to the retained data via:

- Advanced Find within an application.
- Power Automate cloud flow.
- Dataverse OData APIs for custom screens.

Types of data retained long term

Dataverse standard (except system) tables, custom tables, along with attachments and images, can be retained in Dataverse long term storage.

> **Note**
>
> Currently, audit tables and elastic tables aren't supported for long term retention.

Admins set retention policies on tables when the application maker enables long term retention for the table. When a maker enables retention on a parent root table, it also enables retention for all child tables and associated attachments and images.

Long term data retention and existing delete action and plugins

All the existing delete action cascade relationships and plugins for tables are executed when a data retention policy is run on the table. In addition, the retain action can be used to trigger custom behavior. Application makers can write custom plugins for the retain action.

More information: Long-term data retention

Storage capacity reports

With Dataverse long term retention, data is never moved out of Dataverse. The reported capacity in the existing Power Platform admin reports includes both live (active) and retained

(inactive) data in GBs.

- Database capacity details reported:
  - Database capacity reported is the sum of the live and retained data. The overall database capacity consumed is reduced depending on the proportion of the data rows retained during a policy run.

- Notice that the policy run takes 72 to 96 hours to complete and there's an additional 24 hours afterward for the database capacity reports to appear.

- When available, the reports display two entries for a table that is enabled for long term retention:
  - *Table*, such as **Case**[1] or **Contact**.
  - *Table-Retained*, such as **Case-Retained** and **Contact-Retained**.

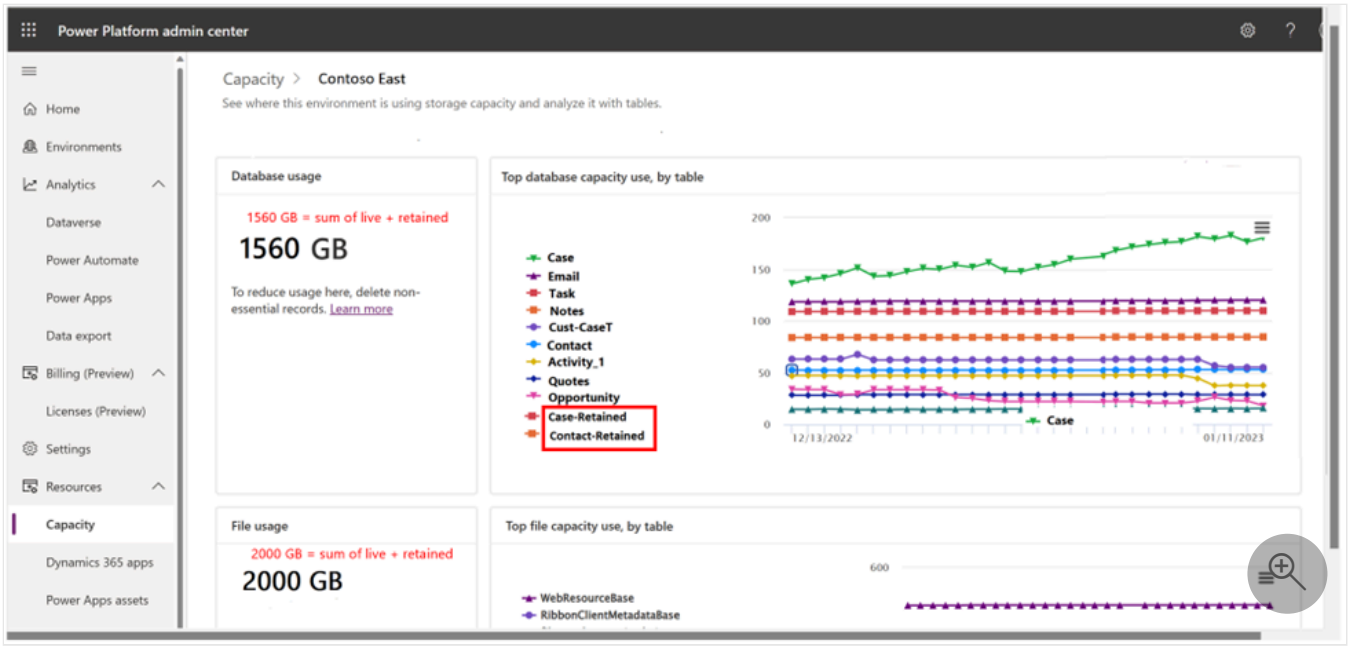
  [1] The case table requires a Dynamics 365 app, such as Dynamics 365 Customer Service.

- File capacity details reported:
  - If there are associated file attachments retained long term, the file capacity reflects the sum of the live and retained data. There will be no reduction or savings observed with file capacity after running a retention policy, which involved file attachments.

Log capacity reports aren't currently available.

Viewing the capacity reports

Imagine a nonproduction scenario where all the live data for the case and contacts tables are retained with Dataverse long term retention. After the long term retention policy is successfully completed, there are entries for **Case-Retained** and **Contact-Retained** in the report. The reduction in database capacity consumed depends on the number of rows and column data types involved in the retention process. The reports could take a few days to a week to reflect the fully reduced savings in production environments. For nonproduction environments, the reports could take up to two weeks to reflect the savings.



> [!NOTE]
> - If the tables are not visible in the report, export the view to an Excel worksheet by selecting the three vertical bars on the top right of the capacity report, and then select **Download all tables**.
> - If a table commonly has associated child tables, the capacity reports also display the child table-retained GB size.

For more information about capacity reports, go to New Microsoft Dataverse storage capacity.

Understanding long term retention storage costs

Dataverse long term retention requires no additional storage purchases and it doesn't require you to purchase the feature as a separate service. Every GB moved from Dataverse database to Dataverse long term retention, consumes, on average, 50% less database capacity. This is because the data is compressed in Dataverse long term retention.

For example:

- Suppose the database capacity consumed by Contoso is 1,000 GB today and the scheduled long term retention policy was run and retains 200 GB of data with Dataverse long term retention.
- With an average compression of at least 50%, the retained data size is 100 GB, a savings of 50% compared to when the data was in the active state.

- This implies Contoso now has 800 GB of active data and 100 GB of inactive data in Dataverse.
- In this scenario, the storage capacity reports display the database usage as 900 GB (800 GB + 100 GB).

> **Note**
>
> - Dataverse long term retention compresses the database data. The amount of compression depends on the kind of data in Dataverse. With some data (indeterministic), you might notice larger than 50% savings while in others you might notice lower than 50%. You might also notice that savings are more evident when higher volumes of data (hundreds of GB) is retained with long term retention.
> - For file and image attachments, Dataverse long term retention doesn't reduce capacity consumed. In rare cases, depending on the file or image, you might experience negligible file capacity savings.

Solution aware retention policies

Dataverse retention policies are solution aware. Dataverse retention policies added to a solution are known as solution-aware retention policies. You can add multiple retention policies to a single solution. Retention policies are added to an unmanaged solution. This helps makers follow application lifecycle management (ALM) best practices when working with Dataverse retention policies.

When you include your retention policies in a solution, their definitions become portable, making it easier to move them from one environment to another, saving time required to create the retention policy. For example, you first develop a solution containing a retention policy in a development or sandbox environment. You then move that retention policy to a preproduction environment to test and validate that the solution works well and is ready for production. After testing is completed, the admin imports the solution into the production environment.

To add a retention policy to a solution, go to the Power Apps (make.powerapps.com), create or open a solution, and then follow these steps:

1. Select **Add existing** > **More** > **Other** > **Data Life Cycle Config** (display name renamed from RetentionConfig to Data Life Cycle Config to support both retention and deletion scenarios).

2. Select one or more retention policies to add to the solution.

The **Data Life Cycle Config** supports addition of both archival and deletion policies in a solution.

> **Note**
>
> - The data retained by retention policies isn't portable as part of solutions, only the retention policy definitions are. You must run the retention policy in an environment to retain the data in Dataverse long term storage.
> - Only retention policies created in Power Platform environments can be solution-aware.
> - When long term retention, is enabled through a solution import process, the related child tables aren't automatically enabled.

You create a solution before you add a retention policy to it. Exporting and importing solutions containing retention policies is the same as with other solution components.

For more information about solutions and solution components, go to Solutions overview.

Set a data retention policy for a table

Article • 05/10/2024

This article explains how to set up a data retention policy for a Microsoft Dataverse table.

Prerequisites

Theses prerequisites must be completed before you can set a table for long term data retention:

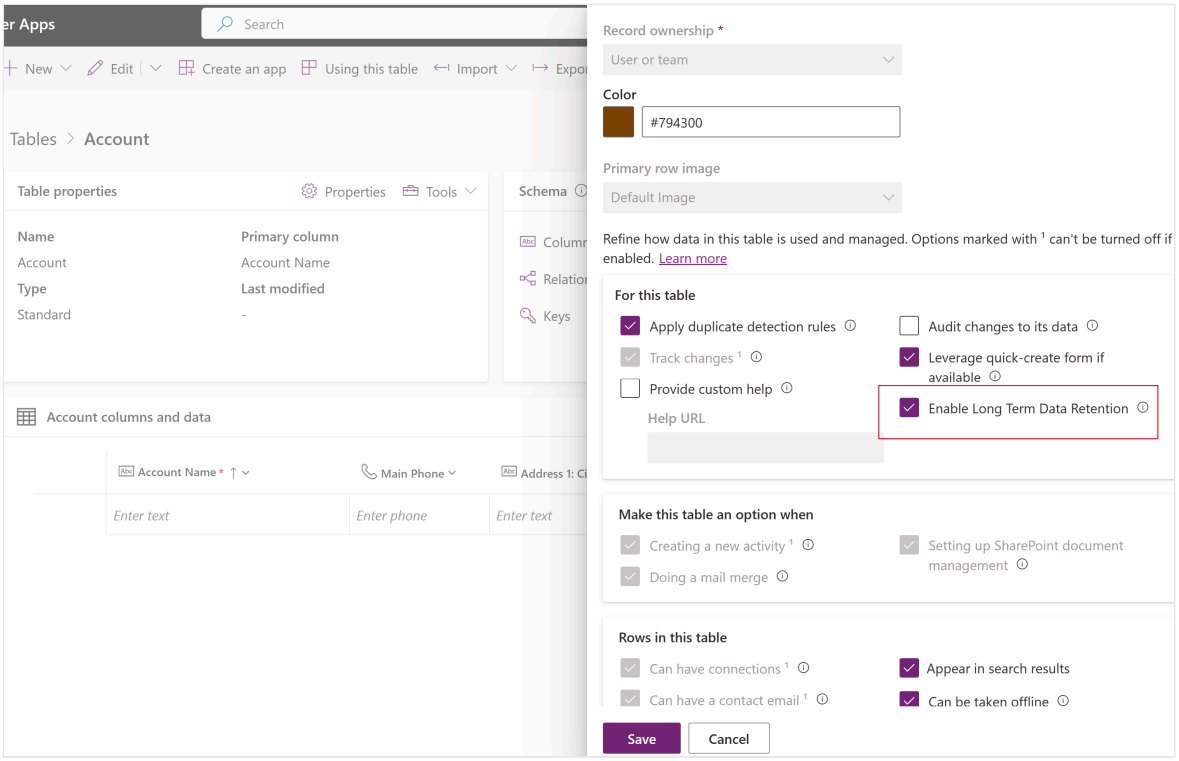
- Enable a table for long term retention
- Determine Dataverse views for policy criteria

Enable a table for long term retention

Before you set up a retention policy, enable the parent (root) table for long term retention.

> **Note**
>
> When a parent (root) table is enabled for long term retention, all the related child tables are automatically enabled. You can't disable retention for a child table when the parent table is already enabled for retention. For example, assume a custom table and notes table are child tables of the case table. These child tables can't be disabled for retention when the parent case table is enabled. A maker can always disable the parent table for long term retention and separately enable the child tables for retention. However, there's an exception to this related child tables behavior when long term retention is enabled through a solution import process. In this case, the related child tables aren't automatically enabled.

1. Sign into Power Apps, go to **Tables**, and then open the table you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **Properties** on the command bar, expand **Advanced options**, and then select **Enable long term retention**.



3. Select **Save**.

The parent root and any child tables will be available for policy setup in about 15-30 minutes after you save the table. The larger the number of child tables, the longer it takes to complete the process.

Determine Dataverse views for policy criteria

Dataverse views are used to determine which table rows (records) are marked for retention using a long-term retention policy. Before setting up a data retention policy, you must set up a Dataverse view as the criteria for retention.

Once you have a Dataverse view for use in a particular long term retention policy, you should test the view result. A good practice is to modify the view query with a `TOP N` statement and test it to ensure that the result set returned is as expected. This is always recommended especially when the number of rows is large.

For example, consider a Dataverse view created to select all closed cases from the year 2015. The number of cases could be potentially very large. Therefore, you should add a `TOP N`, such as *TOP 10*, to the view and test it to confirm the sample set of the retrieved cases.

When the data retention policy is run, rows from the parent table and all child tables are included for long term data retention. The parent cases might have associated rows from child tables, for example notes, task, and custom tables. The retention policy ensures that the case record and all its related child rows are marked and retained as long term in Dataverse. In addition, lookup values in the case table, as an example, are

denormalized with the ID and name values made available as part of the retained data. This allows in many scenarios for a single query to retrieve the relevant retained data.

> **Important**
>
> We recommend that you create a Dataverse view specific for identifying only the rows you want retained. Then, create and run an app that has the view to verify before using it as the criteria in your policy. For information about how to create a table view, go to Create and edit public or system views.

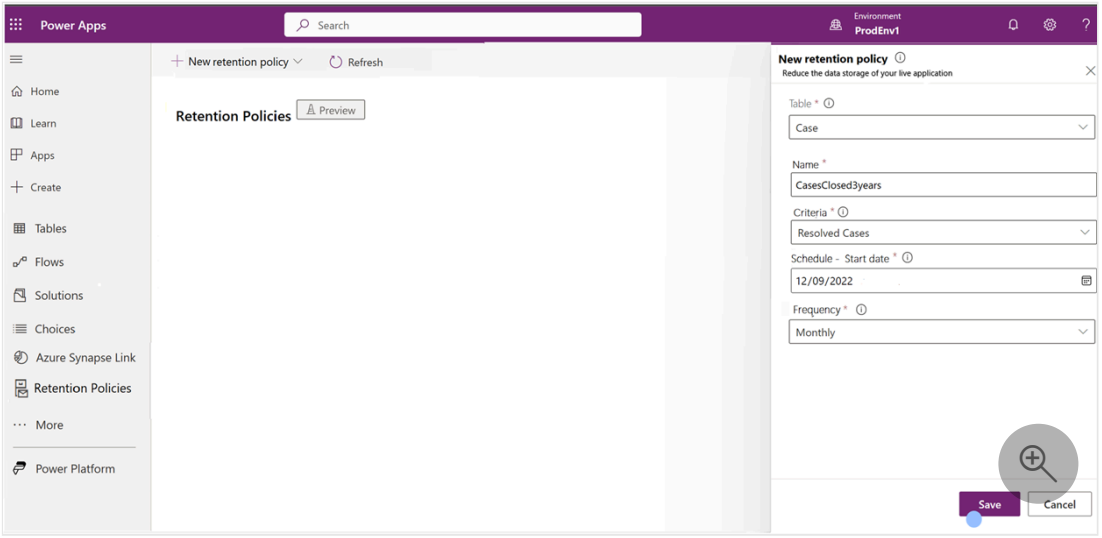
Setup a retention policy

Power Platform administrators set up retention policies.

> **Important**
>
> - Once data is retained as long term (inactive) data, it can't be moved back to the active data store.
> - When a retention policy is run, the process makes API requests in Microsoft Power Platform. These requests are counted towards the existing API requests available with your plan. More information: Requests limits and allocations
> - To complete this task you must have the Power Platform administrator role.

1. Enable a table for long term retention.
2. Sign into Power Apps, and then on the left navigation pane, select **Retention policies**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. On the command bar, select **New retention policy**.
4. Complete the following properties for the retention policy:
    - **Table**. Select the parent root table that will be used to set up a policy to retain historical cold data in long term storage.
    - **Name**. Enter a name for the retention policy.
    - **Criteria**. Select a view from the list. The view should have been previously created and tested to ensure the right historical data was selected. Determine Dataverse views for policy criteria
    - **Schedule - Start date**. Enter the date you want the policy to run for the first time. The policy runs during the off hours of your environment's region.

- **Frequency**. The choices available are **Once**, **Daily**, **Weekly**, **Monthly**, and **Yearly**.



5. Select **Save**.

Now you can view and manage the policy. More information: Manage data retention policies

> **Important**
>
> - The retention policy will not start for environments that have administration mode enabled.
> - All parent and associated child activities, emails, attachments are retained as a set when you set up a policy on a parent table. This is similar to bulk delete policies. For example, an explicit retention policy can't be set for Activity Pointer, Activity Party, and Attachment tables. Long term retention policies can't be set for those tables where bulk delete isn't supported.
> - The parent table and all related rows from child tables, of the parent, will be marked and stored in Dataverse long term storage.
> - Logic associated with an existing delete action of any table (parent and children) will always be executed during the policy run.
> - A policy run will take from 72-96 hours irrespective of the data volume. Data retention policies are given a low priority by the platform. Dataverse will always run the retention process in the background to avoid any impact on other platform services, such as apps and flows.
> - Consider a situation where two policies (Policy1 and Policy2) run on separate parent tables that have common child tables. Policy1 begins running prior to Policy2. If the status for Policy1 hasn't progressed beyond **Pending reconciliation**, then Policy2 status will remain at **Pending delete** status until

Policy1 progresses from **Pending reconciliation** to **Pending delete**. This behavior occurs to prevent deletes on any common records from common tables in the two policies.

Known issue

If a parent table has many child tables, and the size of the parent or child tables is large, you might encounter timeouts. For example, when the number of tables is large in a cascade relationship chain, such as twenty-five or more. To mitigate this, enable a few child tables separately first. Then go back and enable the parent table.

Manage data retention policies

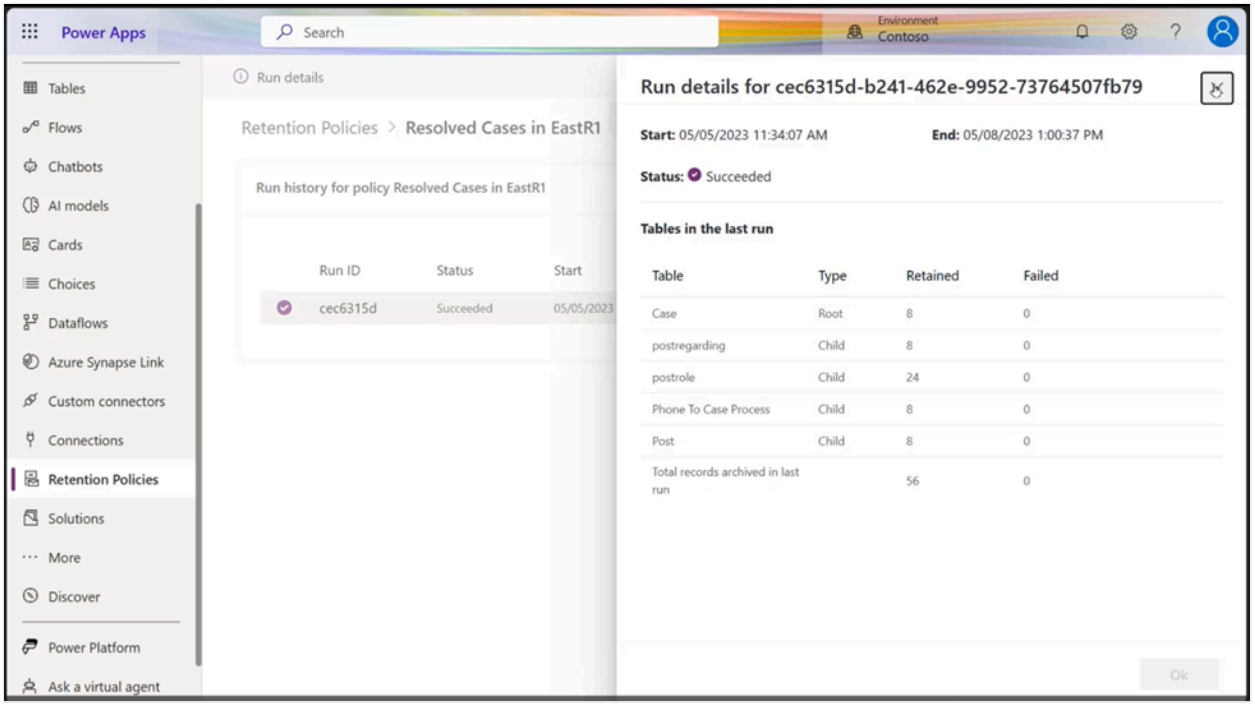
Article • 02/29/2024

Use the retention policies dashboard to view and manage retention policies. From the dashboard, view the policy run history, update policy details, deactivate, and delete a policy.

View and manage retention policies

1. Sign into Power Apps, and then on the left navigation pane select **Retention policies**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select a retention policy from the list, and then on the command bar select **Policy details**.
3. The following retention policy actions are available:

- **History**. Displays the retention policy run status, run start, run end and table. For every run, you can view all tables (root and child tables) and the number of rows retained in the run.
- **Policy details**. Displays the properties for the policy where you can view and edit the policy name, criteria, and frequency.
- **Deactivate**. Stops the retention policy from running by disabling the policy schedule. To activate a deactivated policy, select **Policy details**, set the policy **Schedule**, and then select **Update**.
- **Delete**. Removes the policy.



Policy run status

Expand table

Status	Description
Scheduled	The policy has been scheduled to run.
In progress - Retention	The process of moving and changing the data state from active to non-active (retained) for the rows in the parent root table and all child tables.
Pending Reconciliation	Waiting to reconcile the retained rows in Dataverse long term retention.
In progress – Reconciliation	During this stage, ensures no data loss by reconciling the retained rows with the original rows before delete from active.
Pending Delete	Waiting to delete all retained rows.
In progress – Delete	Delete of retained rows from applications.
Completed	Retention process completed successfully.
Failed	The retention process failed.

View details on failed records

Query the Dataverse table `Retentionfailuredetails` for error details.

Expand table

Column name	Description
`Operationid`	The policy `runid` visible in the long term retention dashboard for a specific policy run.
`entitylogicalname`	Name of the table containing the record.
`recordid`	Unique identifier of every record in the table.
`message`	Detailed error message.

Bulk delete long term retained data

Dataverse bulk delete with the Dataverse SDK supports deletion of long term retained data. More information.

View long term retained data

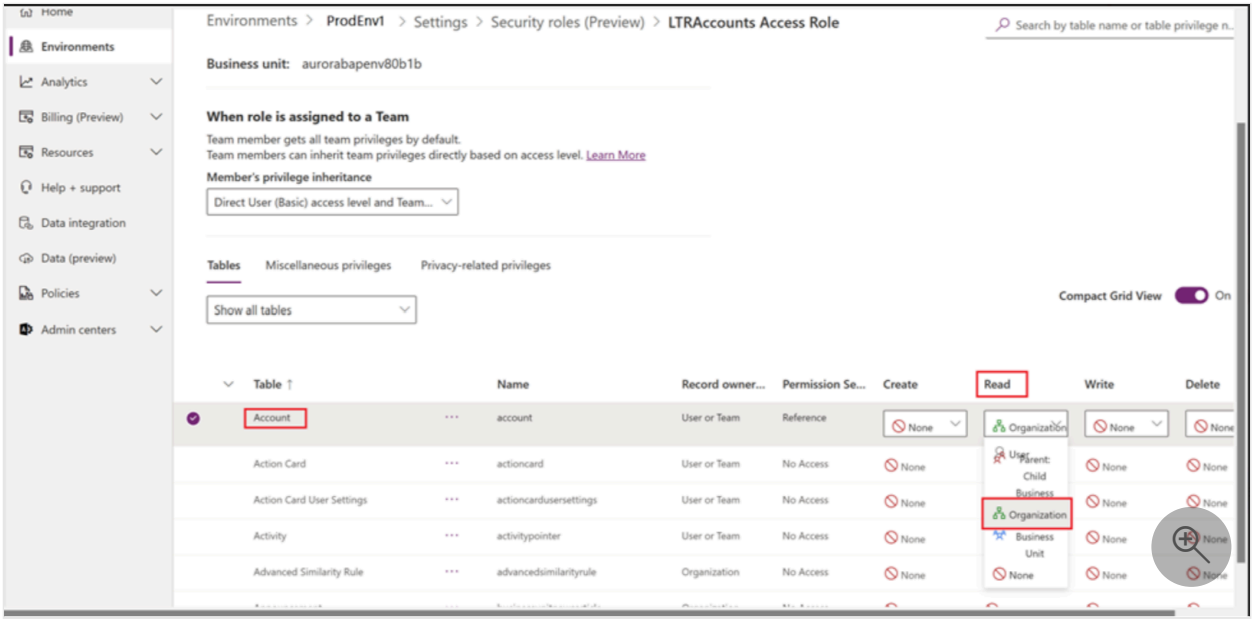
Article • 06/27/2024

You can view retained data from an advanced find query or by creating a Power Automate flow.

To view retained data in an environment requires the system administrator security role or other security role membership that includes organization scope read privileges to the table.

Grant privileges to view retained data

Imagine an auditor requires access to long term data retained for the accounts table. To provide the auditor access, a Power Platform admin creates a new role, for example a role named *LTRAccounts Access Role* and grants organization scope read privilege to the accounts table. Then add the auditor's Power Platform user account to the security role. When the auditor's job is complete, it's a best practice to remove the auditor from the security role.



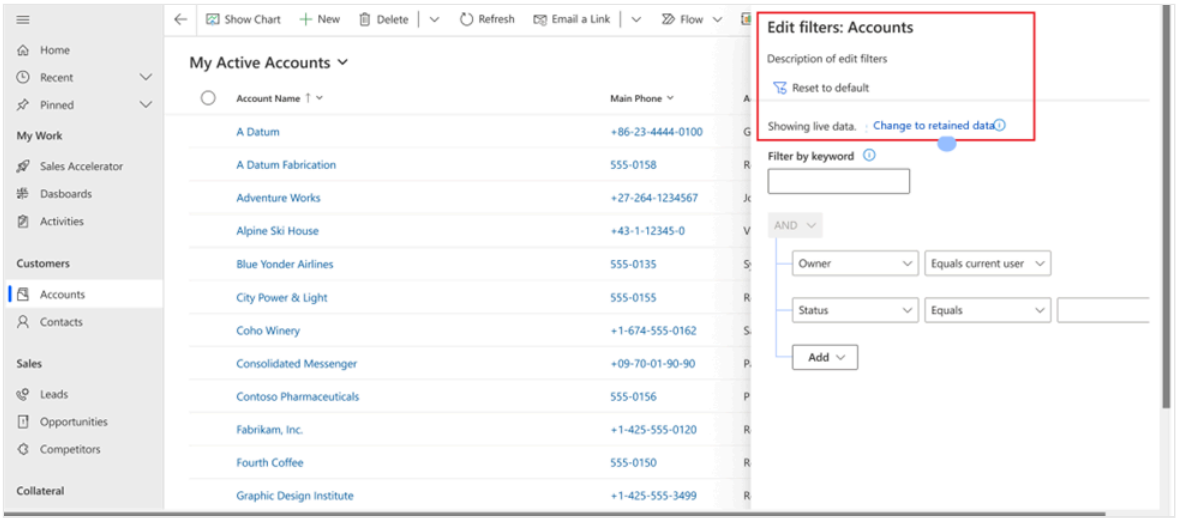
For more information about creating and editing Dataverse security roles, go to Create or edit a security role to manage access.

View retained data using edit filters from a model-driven app

> **Note**

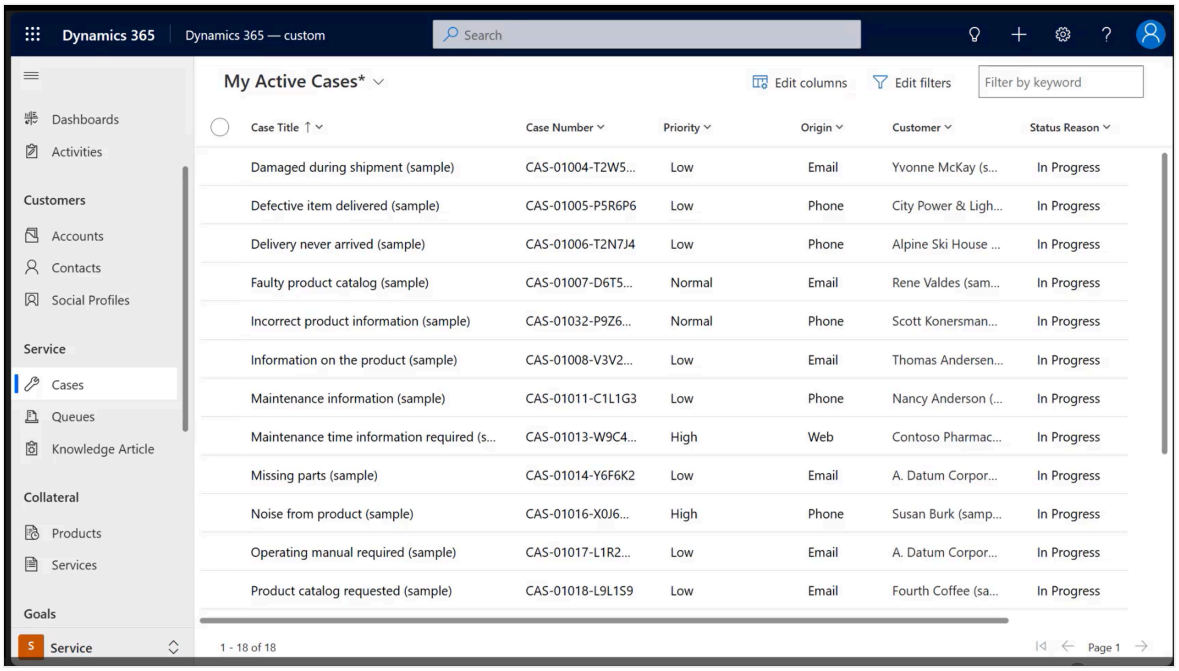
- You can't save or export the the view query results of the retained data for sharing with others. To share retained data, create a cloud flow to view Dataverse long term retained data.
- Edit filters doesn't retrieve table row attachments. To view attachment data, create a flow. More information: Create a cloud flow to view Dataverse long term retained data

1. Sign into Power Apps, play an app that includes a table that has retained data.
2. Open the view you want. From the view, select **Edit filters**.
3. Select **Change to retained data**.



> **Note**
>
> This changes the fetch element `datasource` attribute value to `"retained"`.

4. Select the tables and search filters you want, and then select **Apply**. The retained data is displayed in the read-only grid.



If you need to retrieve long term data from multiple related tables, such as the account table, which has an associated retained case table, first use advanced find retrieve the retained case row. Then use the `Casenumber` column and use advanced find to retrieve the account row that contains the case number.

More information: Advanced find in model-driven apps

View retained data using a flow

Create a Power Automate cloud flow to create an Excel file of the retained data from a FetchXML query and send as an email attachment. More information: Create a cloud flow to view Dataverse long term retained data

> **Note**
>
> If the retained data includes attachments from the annotation table, the returned value is a base64 representation of the file. Large files might cause the cloud flow action to time-out or to exceed its output message size limit.
>
> To workaround this behavior, use the `ExportRetainedData` message Web API to ExportRetainedData action or SDK for .NET using Azure Functions or other custom development options.

Limitations for retrieval of retained data

These restrictions are enforced by Dataverse for each environment:

- Up to five users can query and retrieve retained data at the same time.
- Up to 100 queries per day are allowed for each environment.
- Any single request from advanced find, Power Automate cloud flow, or Dataverse OData public API is considered as one query.
- Queries are allowed on one table at a time. Joins and aggregation functions aren't allowed. Consider options with Microsoft Fabric for complex queries and Power BI options. More information: View retained data with Microsoft Fabric
- Retained data includes lookup data. Lookup values in the table are denormalized with ID and name value.

View retained data with Microsoft Fabric

You can view the active (live) and inactive (long term retained) application data in Dataverse using Microsoft Fabric. To do this, link your Dataverse environment to Fabric. More information: Link your Dataverse environment to Microsoft Fabric and unlock deep insights.

When your long term retention policy is run successfully, you can access the active and inactive Dataverse data. The limitations applied to retrieval of retained data don't apply to this mode of access.

You can explore the data with SQL endpoint and query Dataverse data with SQL and generate views in Fabric. You can also create Power BI reports. More information: Work with Dataverse data and generate Power BI reports

The Dataverse table column `msft_datastate` can be used to filter the data with the SQL `WHERE` clause:

- Inactive application data: `WHERE msft_datastate=1`
- Active (live) application data: `WHERE msft_datastate=0 or msft_datastate=NULL'

Known issues

Personal views of retained data

Saving the query results of the retained data as a personal view isn't supported. Although users can save the query results of the retained data as a personal view, the view doesn't return results.

Dataverse long term data retention FAQ

This article provides information on frequently asked questions about long term data retention with Microsoft Dataverse.

Can a data retention policy be set only on a particular table and not the related tables?

No. Admins can set up a retention policy on a root table, such as the Dynamics 365 apps accounts table. Dataverse automatically sets all related child tables for data retention. So if the account row has related task rows, all task rows are also set for data retention. Admins can always set up a retention policy on a specific table with no related tables.

What about my existing custom Dataverse native delete action logic to ensure business rules are followed when any live data is deleted?

All custom logic with Dataverse native delete actions are always honored during the data retention process.

Why can't I view some data in a table while a particular policy is being executed in the background that was a part of the policy criteria?

Until all records are purged, records are available for viewing. Retention is a multi-step process that includes reconciliation to confirm that all the records within the criteria are retained for long-term before delete from Dataverse. **We recommend that you set up long term retention only for nonactive records, or records that aren't actively required for your business operations.**

If a policy run has errors, are the errors available for admin to view?

Yes. Errors from a policy run are available in the run history details. More information: data-retention-manage.md#view-and-manage-retention-policies

Will Dataverse schema changes be handled by Dataverse long term retention? What if a maker adds custom columns or deletes columns to tables that have existing retained data in Dataverse long term retention?

The changes are reflected in the long term retained data. When retention policies run, the new custom columns contain data for the new rows. The data that was retained prior to these changes won't have any value in these columns. If a column is deleted in the live table, the column remains in the long term retained data with a value for all new rows.

What if a maker adds custom child tables?

Dataverse long term retention ensures that the new child tables are a part of the next retention policy run.

Can a retention policy run be stopped?

No. A policy being executed currently can't be stopped.

Will running data retention jobs impact the performance of my business applications?

No. Data retention jobs are a background process with secondary priority to your apps.

Are there any limits on how many records can be retained in a single policy?

No. While running a policy one-time is an option, we recommend you set up policies that run on a recurring basis to ensure historical data is efficiently managed.

How long will a policy run take to complete?

Data retention policies are given a low priority by the application. Dataverse runs the process in the background typically during off hours to avoid impacting the live application processes. The policy run can take from three or four days up to two weeks for very large data volumes. An option is to schedule long term retention policy runs on a regular cadence like monthly or quarterly, unless the scenario absolutely requires longer durations, such as yearly schedules.

Where can I view the capacity savings?

The Power Platform capacity reports displays the total capacity consumed. The reduction in database capacity consumed, after running a Dataverse long term retention policy, depends on the number of rows and column data types involved in the retention process. For production environments, the reports could take a few days to a week to reflect the fully reduced savings. For nonproduction environments, the reports could take up to two weeks to reflect the savings.

What is expected for the performance when accessing retained nonactive data from Dataverse?

Retained data reads are significantly slower than live data reads. Notice that long term data retention isn't a feature for transactional operations, but should be used for rarely accessed data required for compliance.

Are data retention policies solution aware?

Yes. You can create a solution and add the policy from an environment, such as a development environment, to a test environment, and then to a production environment. More information: Dataverse long term data retention overview

Is the audit table supported for long term retention?

No, the audit table isn't currently supported for long term retention.

In which regions is Dataverse long term retention available?

The feature is currently available in all public cloud regions. GCC, GCC High, and DOD aren't currently supported.

Can data be moved from Dataverse long term store to my own data lake?

This isn't currently supported.

Does Dataverse long term retention support Dual Write apps?

This isn't currently supported.

Can the one Dataverse connector be used with Power BI for reporting long term retained data?

This isn't supported. However you can access live and retained data with Microsoft Fabric and build Power BI reports.

Can I move data from Dataverse long term store back to the Dataverse live (active) store?

No.

I use Azure Synapse Link. Does retaining data with Dataverse long term retention remove the retained data from my own data lake?

No. You can create an Azure Synapse Link for Dataverse to move all of the application data into your own data lake. Then set up a long term retention policy to retain data. Dataverse long term retention doesn't delete retained data already in your own data lake. Dataverse APIs are available to delete retained data from Dataverse long term retention. This capability is the same for all Dynamics 365 customers including finance and operations applications.

Do retention policy runs consume API requests?

Yes. When a retention policy runs, the process makes API requests to Microsoft Power Platform. These requests are counted towards your available API request limits.

Is customer managed key supported for long term retained data?

No, currently long term data retention isn't supported for customer manged key enabled environments.

Why is the status of my Dataverse long term policy deactivated by default when I create a new Dataverse long term retention policy?

Your environment doesn't meet the licensing criteria. More information: Data retention overview Contact your account manager to discuss options on licensing.

I used Dataverse long term retention during the public preview phase without meeting the current licensing requirement. Will my tenant and environment still be able to use Dataverse long term retention?

Yes. Since your tenant and environment participated in the public preview, Dataverse long term retention is being made available for continued use.

Can multiple long-term retention policies run simultaneously?

You can schedule multiple retention policies, however only one policy is executed at a time.

How do I ensure there's no data loss during long-term retention?

Prior to retention, a process validates that all data has been securely stored in the data lake. Only records that have been successfully reconciled are deleted from the live database. This validation helps maintain data integrity.

Create and edit virtual tables that contain data from an external data source

A virtual table is a custom table in Microsoft Dataverse that has columns containing data from an external data source. Virtual tables appear in your app to users as regular table records, but contain data that is sourced from an external database, such as an Azure SQL Database. Rows based on virtual tables are available in all clients including custom clients developed using the Dataverse web services.

In the past, to integrate the disparate data sources you would need to create a connector to move data or develop a custom plug-in, either client or server-side. However, with virtual tables you connect directly with an external data source at runtime so that specific data from the external data source is available in an environment, without the need for data replication.

Virtual tables are made up of three main components, a *data provider*, a *data source* row, and a *virtual table*. The data provider consists of plug-ins and a data source table. The data source is a table row in Dataverse, which includes metadata that represents the schema of the connection parameters. Each virtual table references a data source in the table definition.

Dataverse includes an OData Data and several other virtual connector providers, such as SQL Server, SharePoint, Fabric , and so on, that you can use to connect a common external data source. More information: OData v4 Data Provider configuration, requirements, and best practices and Create virtual tables using the virtual connector provider

Alternatively, developers can build their own data providers. Data providers are installed in an environment as a solution. More Information: Developer Documentation: Get started with virtual tables

Virtual table benefits

- Developers can implement plugins to read, update or delete external data using the Dataverse web services and Plug-in Registration tool.
- System customizers user Power Apps (make.powerapps.com) to create virtual tables that are used to access external data without writing any code.
- End users work with the rows created by the virtual table to view the data in columns, grids, search results, and Fetch XML-based reports and dashboards.

Add a data source to use for virtual tables

Developers create a custom plug-in to use as the data provider for a virtual table. Alternatively, you can use one of the available providers. More information: Create virtual tables using the virtual connector provider and OData v4 Data Provider configuration, requirements, and best practices

1. Sign in to Power Apps, and then select **Settings** > **Advanced settings**.
2. Select **Administration** > **Virtual Entity Data Sources**.
3. On the command bar, select **New**.
4. On the **Select Data Provider** dialog box, select from the following data sources, and then select **OK**.

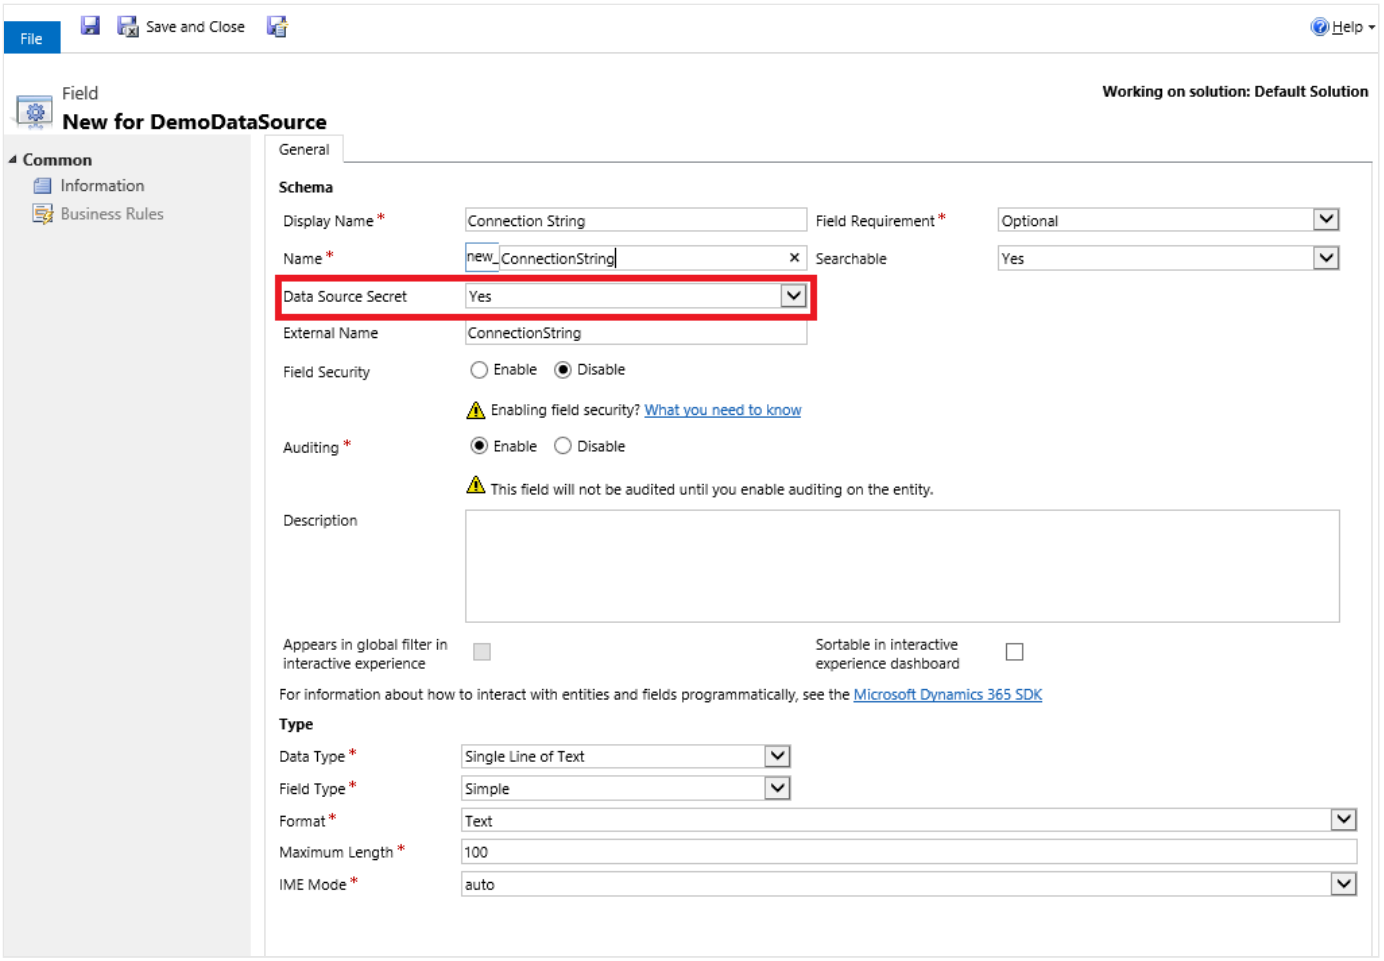
Expand table

Data Provider	Description
Custom data provider	If you've imported a data provider plug-in, the data provider will appear here. More Information Developer Documentation: Get started with virtual tables
OData v4 Data Provider	Dataverse includes an OData Data Provider that can be used with OData v4 web services. More Information OData v4 Data Provider configuration, requirements, and best practices

Add a secured column to a data source

You create columns for a data source in the same way as any other table. For data that is encrypted or sensitive, enable the **Data Source Secret** attribute on the custom column of the data Source. For example, to secure a column that contains a database connection string.

> **Note**
>
> The Data Source Secret attribute is only available with columns added to a Data Source form.



Create a virtual table

You create a virtual table just like any other table in Dataverse with the addition of a few extra attributes described here.

Open a solution

Part of the name of any virtual table you create is the customization prefix. This is set based on the solution publisher for the solution you're working in. If you care about the customization prefix, make sure that you are working in an unmanaged solution where the customization prefix is the one you want for this virtual table. More information: Change the solution publisher prefix

Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

Create a virtual table

1. In Power Apps (make.powerapps.com), create a new table. To do this, select **Tables** in the left navigation pane, and then select **New** > **Table** > **Virtual table**.
2. Select a connector, and then follow the instructions on your screen to create the virtual table. More information: Create virtual tables using the virtual connector provider and OData v4 Data Provider configuration, requirements, and best practices

> **Important**
>
> Several options, such as Access Teams, Queues, and Quick Create, aren't available with virtual tables. More Information: **Considerations when you use virtual tables**

Considerations when you use virtual tables

Virtual tables have these restrictions.

- Existing tables cannot be converted to virtual tables.
- By default, virtual tables contain only a Name and Id column. No other system managed columns, such as Status or Created On/Modified On are supported.
- Virtual tables don't support custom columns with the Currency, Image, or Customer data types.
- Virtual tables don't support auditing.
- Virtual table columns can't be used in rollups or calculated columns.
- A virtual table can't be an activity type of table.
- Dashboards and charts are not supported with virtual tables.
- Many features that affect table table rows cannot be enabled with virtual tables. Examples include queues, knowledge management, SLAs, duplicate detection, change tracking, mobile offline capability, column security, Dataverse search, and Power Pages solutions.
- Virtual tables are organization owned and don't support the row-level Dataverse security concepts. We recommend that you implement your own security model for the external data source.
- Column metadata properties that validate on update don’t apply to virtual tables. For example, a Whole Number column on a virtual table column may be set to have a minimum value of zero. However, since the value is coming from an external data source, a query will return values less than zero when retrieved from a virtual table. The minimum value property is not implied in the query. You would still need to filter the values to be greater than 0 if that’s what is desired.

- Virtual tables don't support change tracking and cannot be synchronized by using a Dataverse feature, such as the Data Export Service or Azure Synapse Link for Dataverse.
- Virtual tables that use the included OData v4 data provider are enabled on outbound port 443.
- Business process flows are not supported with virtual tables. More information: Unexpected error received when a user activates a business process flow

Unexpected error received when a user activates a business process flow

When a user attempts to activate a business process flow, they may receive an "unexpected error" message. Viewing the log file the following log entry is displayed.

ErrorCode: 0x80040216 Message: System.Web.HttpUnhandledException: Exception of type 'System.Web.HttpUnhandledException' was thrown. ---> Microsoft.Crm.CrmException: Business process flow cannot be enabled for Virtual Entity

This issue occurs because virtual tables don't support business process flows.

OData v4 Data Provider configuration, requirements, and best practices

Article • 06/21/2022

This topic describes how to configure the OData v4 Data Provider as well as the requirements and recommended best practices for using the OData v4 data provider to connect with an OData v4 web service.

OData v4 data provider best practices

- Microsoft Dataverse requires that all tables have an ID attribute, this ID is known as a unique identifier and the value must be a guid. You can only map ID columns to external columns with the `Edm.Guid` data type. You can't map an `Edm.Int32` data type to a Unique Identifier data type column in Dataverse.
- OData tables with nullable properties must be set to match the mapped column in the virtual table. For example, an OData table property with Nullable=False must have the mapped column in Dataverse **Field Requirement** attribute set to **Business Required**.
- For retrieve multiple queries, such as when you load data in to a grid, control the size of the dataset returned from the external data source by using the select and filter query parameters.
- If not already enabled, system administrators should enable plug-in tracing. Once enabled, all errors from the OData endpoint are captured in the plug-in trace log. More information: Administrator Guide: System Settings dialog box - Customization tab
- You can't use the OData v4 Data Provider to connect to another environment.

Data type mapping

The following table lists the OData table Data Model (EDM) data type mappings with Dataverse data types.

OData Data Type	Dataverse Data Type
`Edm.Boolean`	Two Options
`Edm.DateTime`	Date and Time
`Edm.DateTimeOffset`	Date and Time

OData Data Type	Dataverse Data Type
`Edm.Decimal`	Decimal Number or Currency
`Edm.Double`	Floating Point Number
`Edm.Guid`	Unique Identifier
`Edm.Int32`	Whole Number
`Edm.Int64`	Whole Number
`Edm.String`	Single Line of Text or Multiple Lines of Text

OData EDM data types that are not supported for mapping with virtual tables

- `Edm.Binary`
- `Edm.Time`
- `Edm.Float`
- `Edm.Single`
- `Edm.Int16`
- `Edm.Byte`
- `Edm.SByte`

Add a data source using the OData v4 Data Provider

This procedure shows you how to use the out-of-box OData Data Provider to use as the virtual table data source.

1. Go to Settings > **Administration** > **Virtual Entity Data Sources**.
2. On the actions toolbar, click **New**.
3. On the **Select Data Provider** dialog box, select from the following data sources, and then click **OK**.
    - **OData v4 Data Provider**. Dataverse includes an Odata v4 data provider that can be used to connect to data sources that support the OData v4 open standard.
    - *Custom data provider*. If you've imported a data provider plug-in, the data provider will appear here. More information: Developer Documentation: Get

started with virtual tables

4. On the **New Data Source** properties page, complete the following columns, and then save the row.

   - **Name**. Type a name that describes the data source.
   - **Uri**. If you are using the OData Data Provider, enter the uri for the OData web service. For example, if you are using the OData provider to connect to a web service hosted in Azure, the URI can look similar to `https://contosodataservice.azurewebsites.net/odata/`.
   - **Timeout in seconds**. Enter the number of seconds to wait for a response from the web service before a data request time-out. For example, enter 30 to wait a maximum of thirty seconds before a time-out occurs.
   - **Pagination mode**. Select whether to use client-side or server-side paging to control how query results are paged. The default value is client-side paging. With server-side paging, the server controls how results are paged by using the $skiptoken parameter, which is added to the query string. More information: Skip Token System Query Option ($skiptoken)
     - **Return inline count**. Returns the total number rows in the result set. This setting is used to enable next page functionality when you return data to a grid. Use a value of false if your OData endpoint doesn't support the OData $inlinecount parameter. The default value is false.
   - **Request Parameters**. Optionally, you can add custom header or query string parameters used to connect to the OData web service, such as authentication parameters to the external service. Click **Query String** to toggle between header and query string parameter and value. Up to 10 header or query strings can be added.

Create and edit virtual tables that contain data from an external data source

Create virtual tables using the virtual connector provider

Virtual tables enable integrating data from external data sources by seamlessly representing that data as tables in Microsoft Dataverse, without data replication. Solutions, apps, flows, and more can use virtual tables as if they were native Dataverse tables. Virtual tables allow for full create, read, update, and delete privileges unless the data source they're connecting to specifically forbids it. More information about virtual tables: Create and edit virtual tables that contain data from an external data source.

This document covers the new experience using Power Apps (make.powerapps.com) to create virtual tables using the following virtual connector providers:

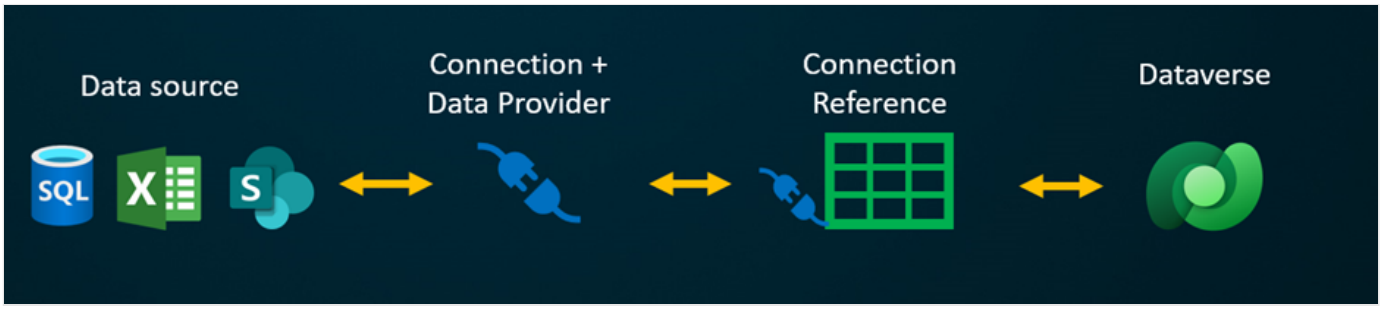
- SQL Server
- SharePoint
- Microsoft Fabric
- Salesforce
- Oracle Database
- Snowflake
- PostgreSQL
- Azure Databricks

These virtual connector providers use a Power Platform connector. More information: Connector reference for virtual connector providers used with virtual tables

You can create a virtual table for Excel using a legacy process with a virtual connector provider. More information: Create virtual tables using Excel in Microsoft Dataverse

Overview

Virtual tables include the following components:

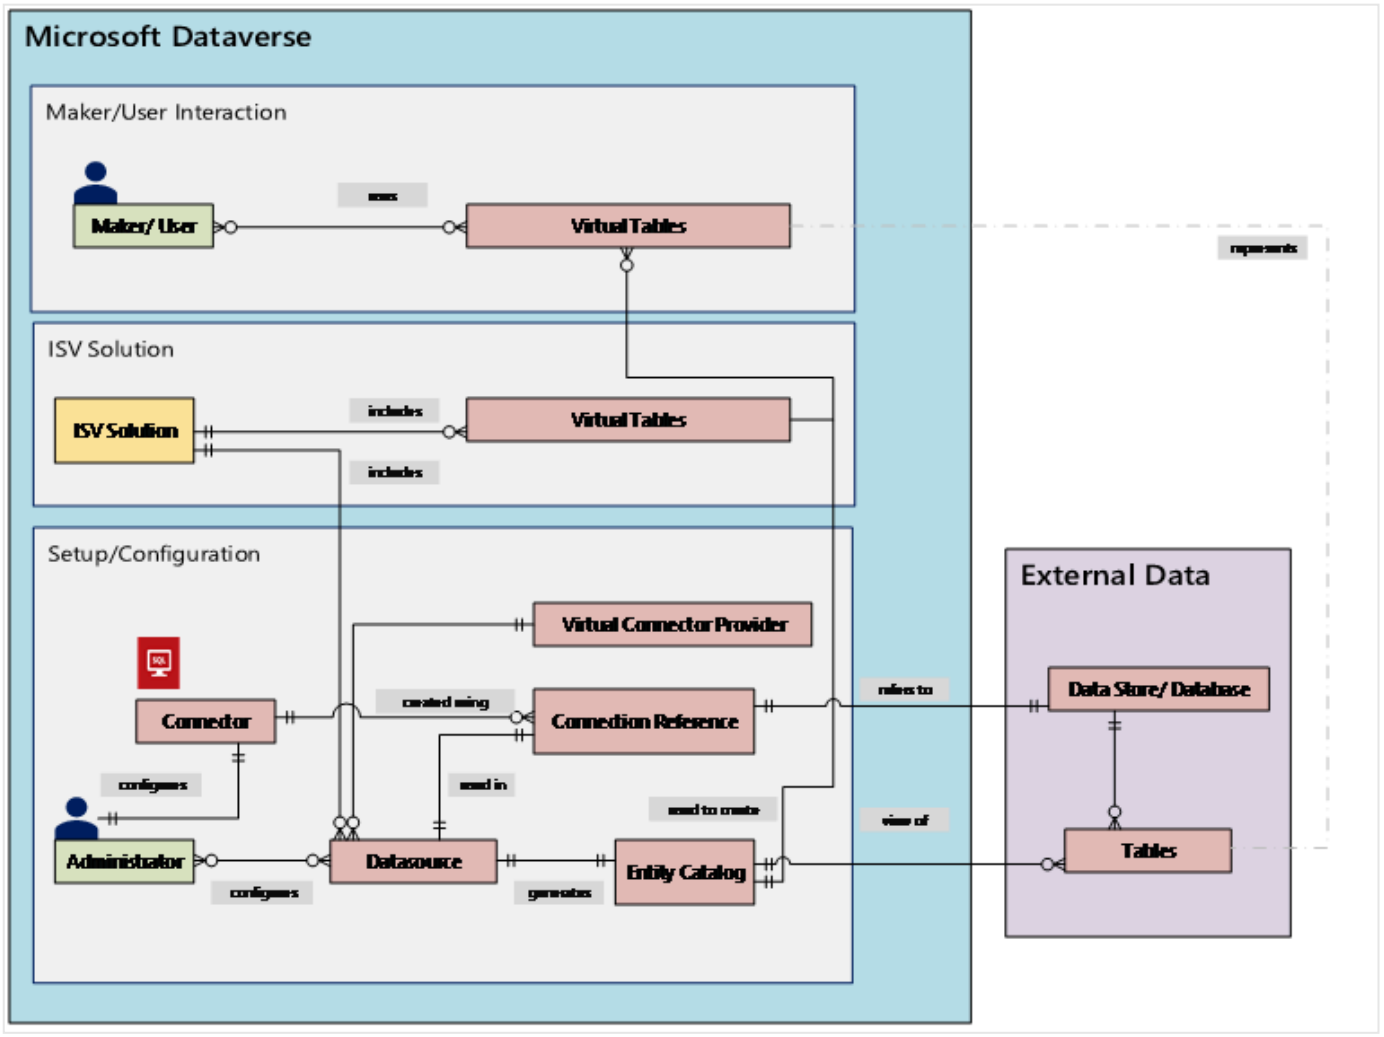


- Data Source – the location where the external data is stored.
- Data Provider – defines the behavior of the virtual table.
- Connection – sets up the ability to connect to the data source and authentication.
- Connection reference – provides a way for Dataverse to use the connection to the data source.

If you were to create a virtual table using a custom data provider, you need to write plugins that define how every Dataverse API would interact with the API on the system where the data is stored. This is a long process that requires knowledge of coding. Virtual connector providers streamline the creation experience by automating some of the creation for you and removing the need to use code to create the virtual tables.

When you establish a remote connection to an external source using a connector data source, the virtual connector provider automatically retrieves a list of all the available tables and lists by retrieving table definitions (metadata) from the external data source. You then select these tables and lists to generate the virtual table.

The underlying data source is key for allowing the provider to establish an authenticated remote connection to the external data. It uses a connection reference that stores pertinent details regarding the external source. The information stored in the connection reference is specific to the connector type and the connection it refers to.



When setting up the connection and connection reference for your data sources, specific information is needed. For example, the SQL Server connector needs server name, database name, the authentication method, username, password, and (optionally) gateway connection details. Each external data source needs a connection reference defined to create the virtual table. When using the Power Apps (make.powerapps.com) experience, the connection reference can be generated automatically for you unless you wish to provide custom naming.

The connector permissions enforce the ability for organizational users to access and operate on the virtual table. The connection can be shared with one user or can be shared with the entire organization. This allows users to access and operate virtual tables using a shared connection. By using security roles, virtual table access can be restricted to a specific set of users within your organization. You can even specify which roles have create, read, update, or delete privileges in this way.

Application lifecycle management (ALM) is supported for virtual tables created using the virtual connector provider. You can even create the virtual tables from directly within a solution when using Power Apps (make.powerapps.com). Virtual tables should be part of a managed solution along with the connection reference to distribute the solution. The solution can have other components, such as a model-driven app that uses virtual tables.

More information about application lifecycle management (ALM) and solutions:

- Application lifecycle management (ALM) in Microsoft Power Platform
- Solutions overview

Prerequisites

To create a virtual table, you must have a Microsoft Dataverse license through Power Apps or Microsoft Dynamics 365. Microsoft 365 or Teams licenses can't be used to create virtual tables.

Create a virtual table in Power Apps

Creating a virtual table in Power Apps (make.powerapps.com) using the virtual connector provider includes the following steps:

1. Choose to create a table using an external data source
2. Create the virtual table
3. Create and select the connection reference (optional)
4. Choose your connection details and select your data, such as SQL or SharePoint.
5. Configure your data
6. Configure column and table names (optional)
7. Complete the setup

Choose to create a table using an external data source

These steps describe how to create a virtual table from a solution. Use similar steps to create a virtual table by going to **Data** > **Tables**.

1. Sign into Power Apps, and then select **Solutions** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Create a new solution or open an existing unmanaged solution.
3. On the command bar, select **New** > **Table** > **Virtual table**.

Create the virtual table

Watch a short video showing how to create a virtual table with the virtual connector provider.

https://learn-video.azurefd.net/vod/player?id=130f38be-01d0-4321-8681-a7780231b94e&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fcreate-virtual-tables-using-connectors

1. In the **New table from external data** wizard you can either select an existing connection if you have one or choose to **Add connection**.

    - If you want to use an existing connection, select the connection you want, and then select **Next**.
    - If you have an existing connection but wish to create a new one, select **New connection** on the command bar.
    - If you have no connections and wish to create a new connection, select **+Add Connection** next to the connection type you want.

    > **ⓘ Important**
    >
    > Connections that are shared with you aren't available for use with this feature. Only connections created by the current user appear in the virtual table wizard.

2. You're directed to a new tab in your browser. Select your authentication method. Depending on the authentication method selected, you might be asked to provide credential information required to create the connection.

SQL Server

> **ⓘ Important**
>
> These will be the credentials used for all authentication for the virtual table so use credentials with the correct level of permissions with SQL Server.

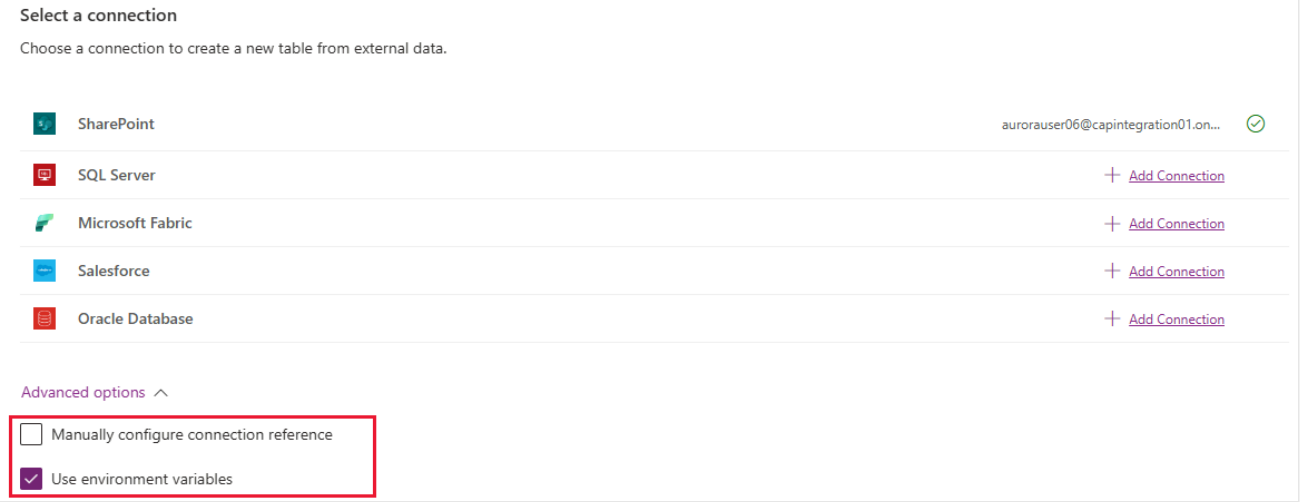
- **Microsoft Entra**: Select and sign in with your credentials.
- **SQL Server**: Server name, database name, user name, password, gateway (on-premises deployments only).

3. Optionally, select **Advanced options** to use a connection reference and/or environment variable.

    When you create a virtual table, a connection reference is automatically created for you with the virtual table. A connection reference is a solution component that contains information about the connector. However, you might want to create you own. To do this, select

Manually configure connection reference. More information: Create and select a connection reference (optional)

You can associate a virtual table with its own environment variable. Select **Use environment variables** to link the environment variable directly to the virtual table provider, offering flexibility to modify data sources when importing the virtual table into a new environment. More information: Environment variable



4. Select **Create**.

5. After the connection is created, go back to your browser tab with the wizard and select **Refresh**, and then select your connection.

Connection references and environment variables

Create and select a connection reference (optional)

When you create a virtual table, a connection reference is automatically created for you with the virtual table. A connection reference is a solution component that contains information about the connector.

However, you might want to create your own connection reference for the virtual table.

> ⓘ **Note**
>
> - The benefit of optionally naming your connection reference is because it can be easier to find later if you need details about it.
> - If you're using an existing connection you can select an existing connection reference or create a new one. Creating a new connection reference is only used if you want to

segment your virtual tables into completely unrelated solutions for use later.

To create a connection reference, when you're creating the connection for the virtual table, follow these steps:

1. Expand **Advanced options** and then select the **Manually configure connection reference** to create a connection reference for the virtual table.

2. On the **Connection Reference** page, select or name your connection reference, and then select **Next**.

    - If you chose SQL and Microsoft Entra ID as your authentication method, you're asked for your SQL server name and database name. Provide these and select **Next**.

Environment variable

Environment variables play a key role in the application lifecycle management (ALM) process, allowing for seamless movement of applications across different Power Platform environments. When creating a virtual table, you can associate it with its own environment variable. To take advantage of this functionality, expand **Advanced options**, and then select **Use environment variables** when choosing a connection for your data source during a virtual table create.

Environment variables with virtual tables recommendations

- Create or update a virtual table in the context of a solution.
- If an existing virtual table with environment variable needs to be added to a solution, then the environment variable related to this virtual table needs to be explicitly added to the solution. From the **Solutions** area in Power Apps, select **Add existing** > **Environment variable**, and then select the environment variable related to the virtual table. After this step, select the environment variable and then select **Advanced** and add the required objects.
- If a virtual table is created without an environment variable specified, you must re-create the virtual table and select the environment variable option.

Environment variables with virtual tables limitation

- Environment variable support with virtual tables currently only work with SharePoint and SQL virtual connectors.

Configure your data

If you're creating a SharePoint virtual table, you're asked to enter the URL of your SharePoint site or select from your most recently used SharePoint sites. The most recently used list is populated by gathering information about your recently used sites using Microsoft Graph and your Microsoft Entra credentials. If you're pasting the SharePoint URL, only include the information up to the site name, such as https://microsoft.sharepoint.com/teams/Contoso.

1. A page is displayed where you can either search your data source for a specific table or list, or select a table or list from the provided list.

2. Select the check box if you want to configure the table name, column names, and primary field.

3. Select **Next**.

Configure table and column names (optional)

When you create a virtual table, by default you can choose to change the suggested table and column names. To do this, follow these steps:

1. Select **Configure table and column names that will be used in Dataverse**, accept, or change the following Dataverse table properties:

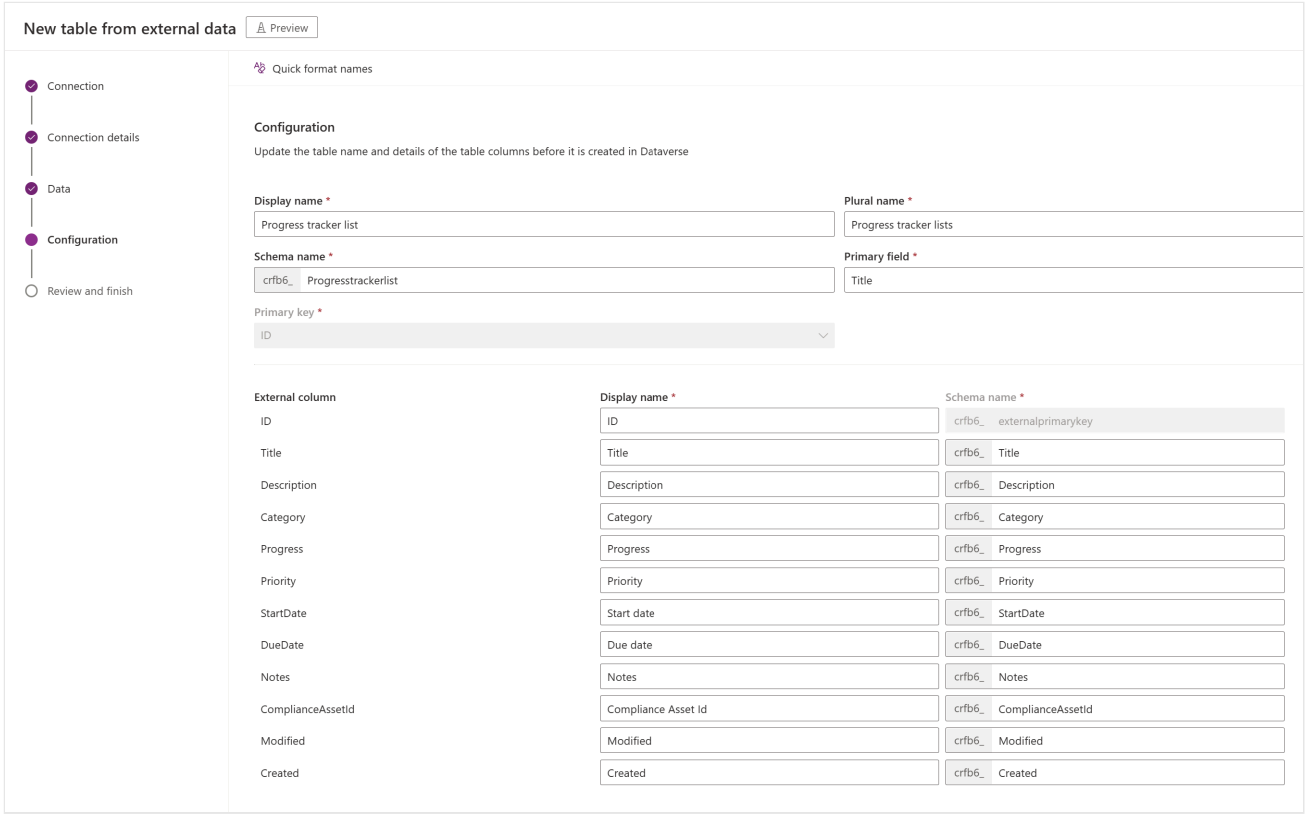
    - **Display name**: The name that is used to identify your virtual table.
    - **Plural name**: The plural of the virtual table name, used in appropriate situations where you refer to one or more record from the table, such as *Customer* is the table for multiple records refereed to as *Customers*.
    - **Schema name**: The logical name Dataverse uses for the virtual table, which includes the solution publisher prefix.
    - **Primary field**: This is the text value to be used when looking up records on your virtual table. Only string fields can be selected. A primary key is a required field but will be chosen by Dataverse.

2. In the **External column** area, choose if you would like to rename any of your external columns from the data source. The following fields are provided:

    - **Schema name** (read-only). This is the schema name of the column in the data source. This property is read only.
    - **Display name**. The name that's used to identify your column.
    - **Schema name**. The logical name Dataverse will use for the column that will include your solution publisher prefix. There's a **Quick Format Names** option on the page, this

provides suggested name changes and can be useful if you have a large number of fields that include prefixed values from your SQL server such as <tablename>.<column name>. For example, *Database12.Products* would change to **Products**.

> **Tip**
>
> Instead of entering the information, the **Quick format names** command provides suggested name changes and can be useful if you have a large number of fields that include prefixed values from your SQL server, such as *tablename.column name*. For example, *Database12.Products* would change to *Products*.



3. Select **Next**

Complete the setup

1. The **Review and Finish** page shows you the table you're connecting to in your data source, and the table that will be created in Dataverse.

> **Note**
>
> Select **Choose a different table** takes you back to the table selection screen. selecting **Edit Configuration of Table** takes you to the **Configuration** screen.

2. If everything is correct, select **Next**.

Once the table is created, you're taken directly to your new virtual table where you can view your data and begin working with it.

> **Note**
>
> When you attempt to create a virtual table that already exists, you receive a message that the table already exists and that you will be re-creating it. You will not be able to change the primary field or schema name if this is the case. Re-creating the table will update any column changes that were made in the data source on the table.

Connector reference for virtual connector providers used with virtual tables

To learn more about supported actions and limitations with each connector, go to:

- Connector reference for the SQL Server connector

Developers Guide: Get started with virtual tables (entities)

Last updated on 04/17/2026

Create a virtual table using Excel in Microsoft Dataverse

06/10/2025

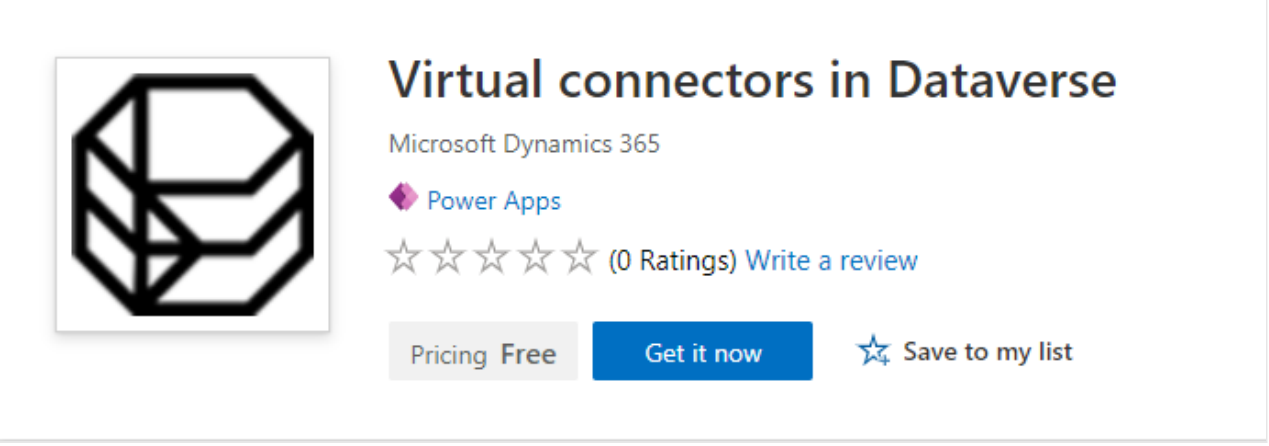
Create a virtual table to integrate data from an Excel file located in OneDrive to use as an external data source that seamlessly represents that data as tables in Microsoft Dataverse. Virtual tables allow you to view, create, and edit external data without replicating that data in Dataverse.

Prerequisites

- A Microsoft Dataverse license through Power Apps or Microsoft Dynamics 365. Microsoft 365 or Teams licenses can't be used to create virtual tables.
- The Excel file you use as the data source must be stored in OneDrive.
- The Excel file must contain data formatted as a table.
- The Excel file must contain a GUID column. More information: Create the connection for the Excel virtual connector provider

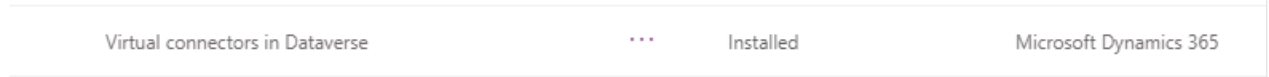
Download and install the virtual connector provider for Excel

1. Download and install the virtual connector. Go to the Microsoft commercial marketplace and search for `Virtual Connector` or select the link to download the provider: Virtual connectors in Dataverse

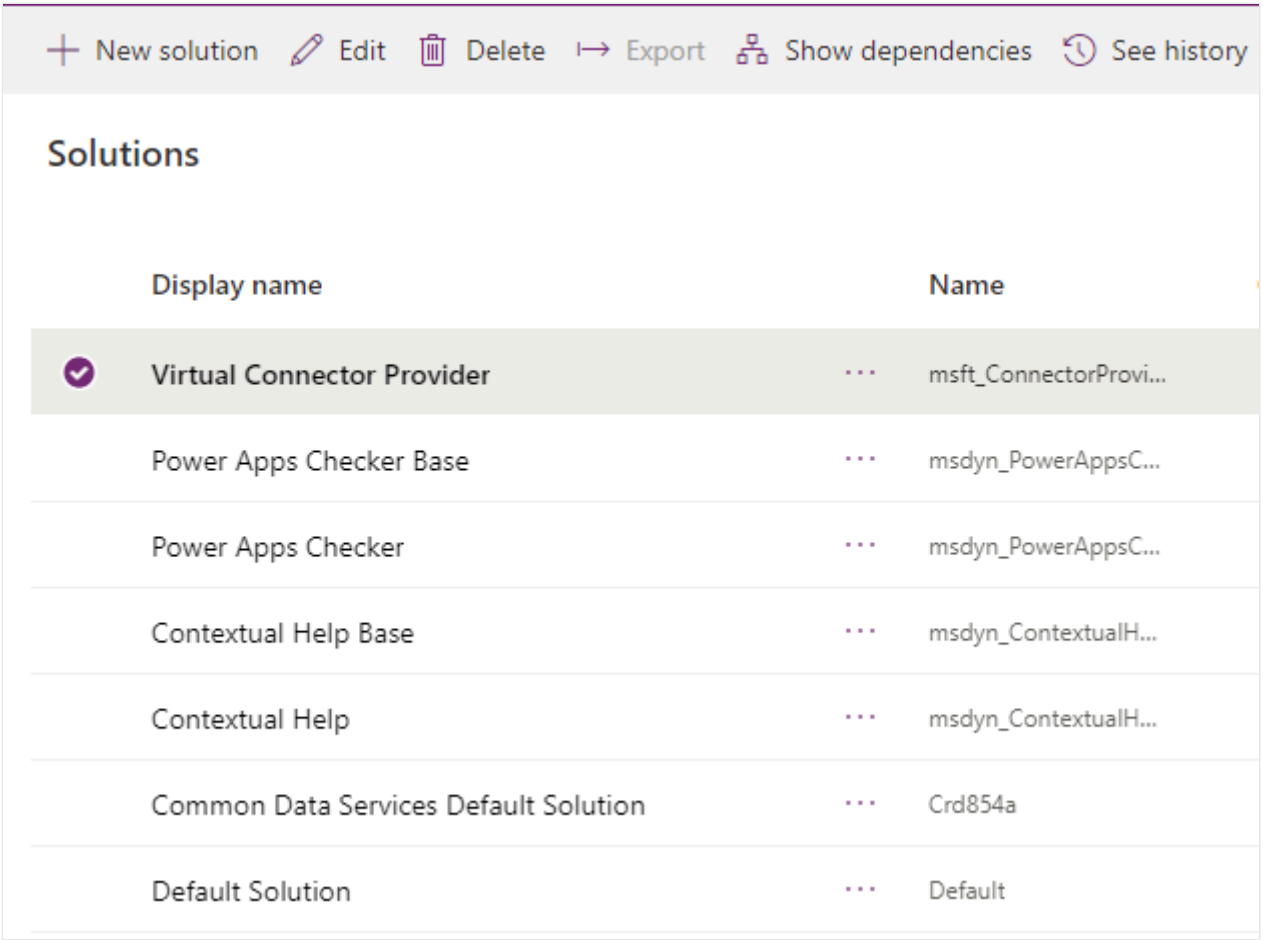


2. Select **Get it now**. In the sign-in dialog, enter work or school account email. If you agree to the terms and conditions, select **Continue**. The Power Platform admin center opens automatically.

3. Select the environment where you want to install the solution. If you agree to the terms and conditions, select **Install**. Once the installation is complete, you see the **Virtual connectors in Dataverse** app installed under **Environments -> [your environment name] -> Dynamics 365 apps**.



4. You should also see the **Virtual Connector Provider** solution and other solutions enabled in the Power Platform environment.

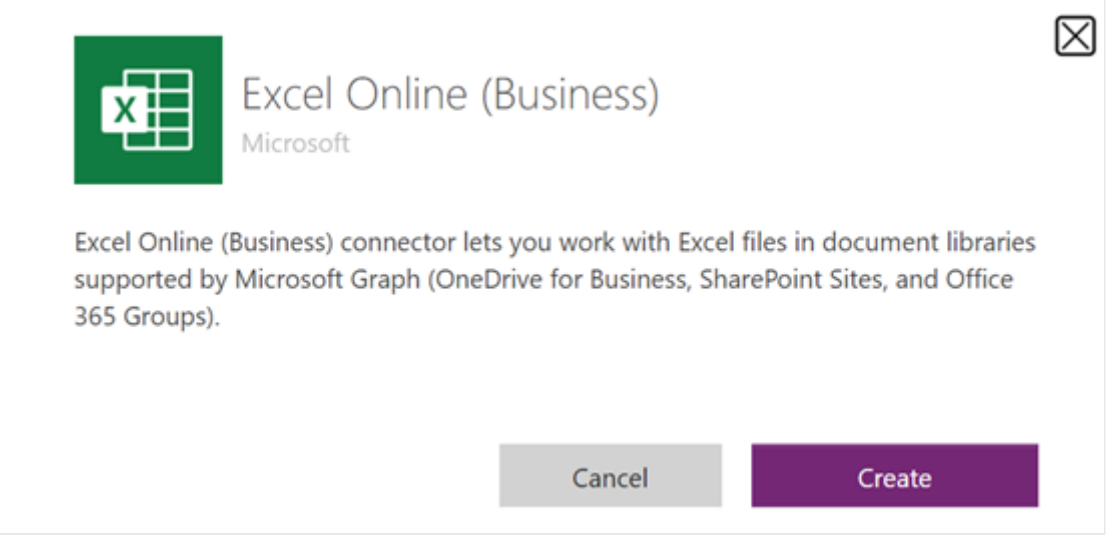


Create the connection for the Excel virtual connector provider

Watch a short video showing how to create a virtual table with the Excel virtual connector provider.
https://learn-video.azurefd.net/vod/player?id=d418205f-afcd-4a54-903d-9ac975868f5c&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fcreate-virtual-tables-using-excel

1. Go to Power Apps (make.powerapps.com), and select the environment in which you would like to set up the virtual table.

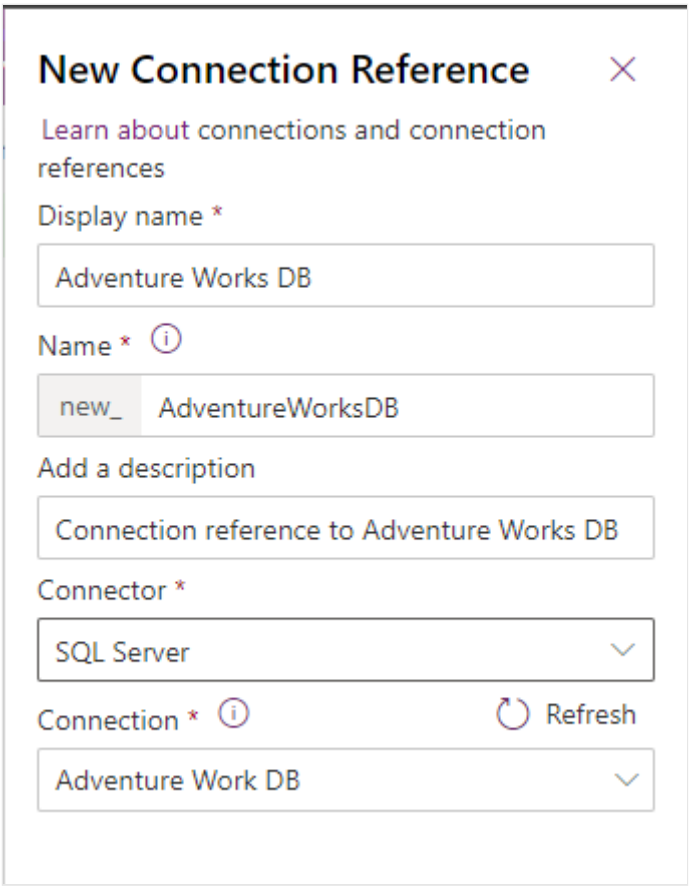
2. In the left navigation pane, select **Connections**, and then select **New connection**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Microsoft Excel Online (Business) Virtual Connector** from the list of connections.
4. You're asked to provide additional details to connect to the data source.
5. Select **Create**, your current signed-in credentials will be used.



Create the connection reference

You must create your own connection reference when you use the Excel virtual connector provider.

1. Go to **Solutions**.
2. Select the **Default Solution** or any other existing solution you have in your environment to create the virtual table.
3. Select **New** and then select **Connection Reference.**
4. Enter **Display name**, select the connection you created for the **Connectors** option and then select the data connection that you've created.

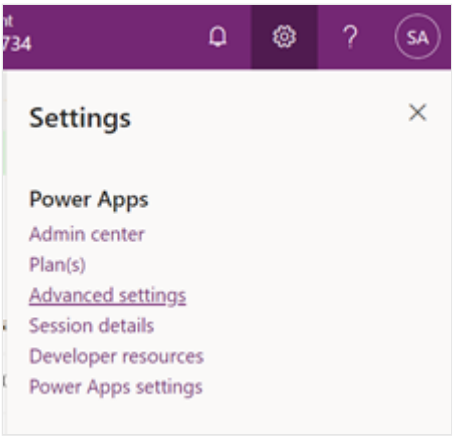


Create the data source

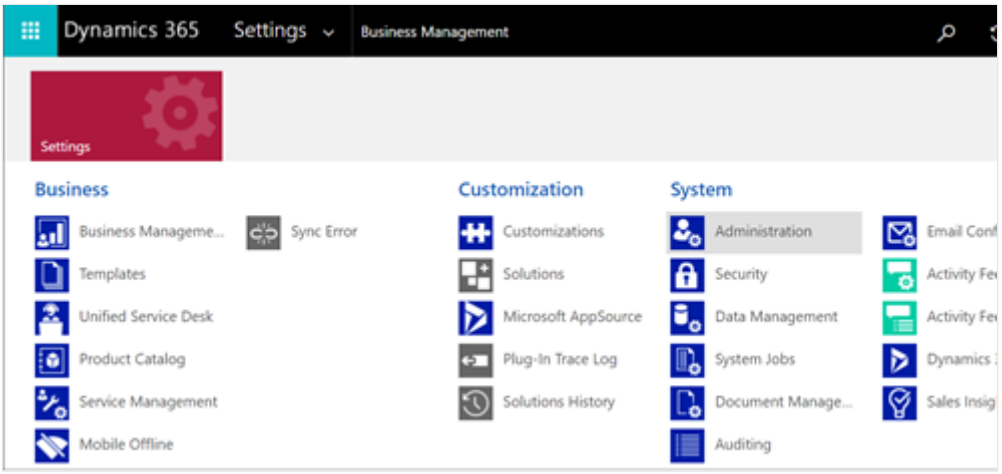
Now create the virtual table data source in Dataverse.

> **Note**
>
> - When you use the Excel virtual connector provider, an **Entity Catalog** table is generated by the system which provides a list of all the available tables using the table definitions (metadata) from the external data source. The entity catalog doesn't persist any information and always represents the external data source's current state. You can select tables from the entity catalog to create virtual tables. If you're working with multiple external data sources, an entity catalog is generated for each external source. More information: Entity catalog

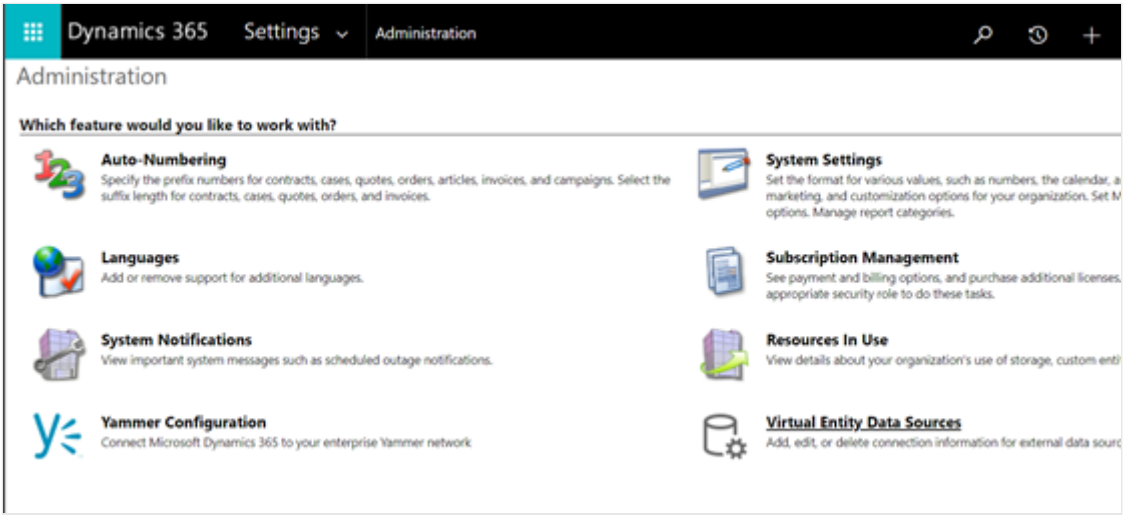
1. Select the **Gear icon** -> **Advanced Settings**.



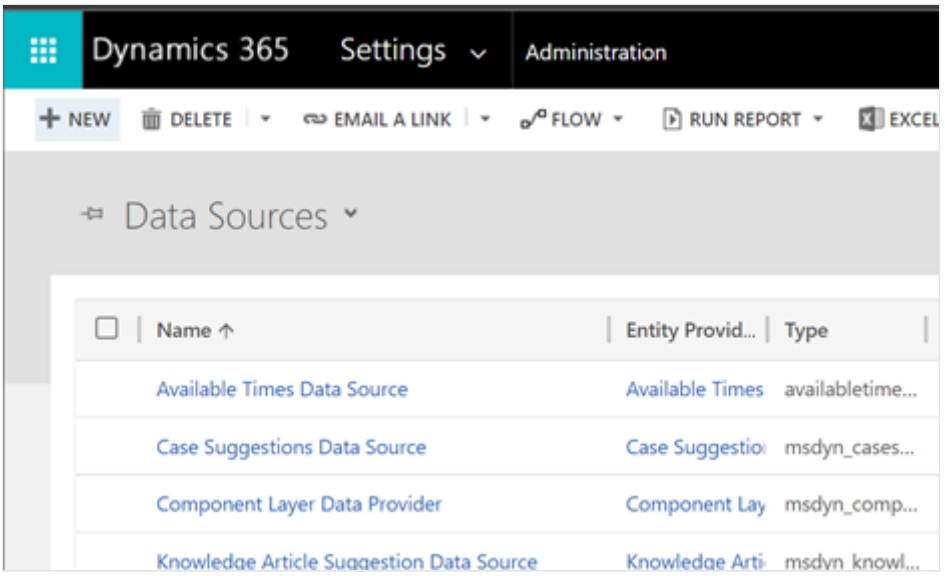
2. In the top navigation bar, select **Settings** and then **Administration**.

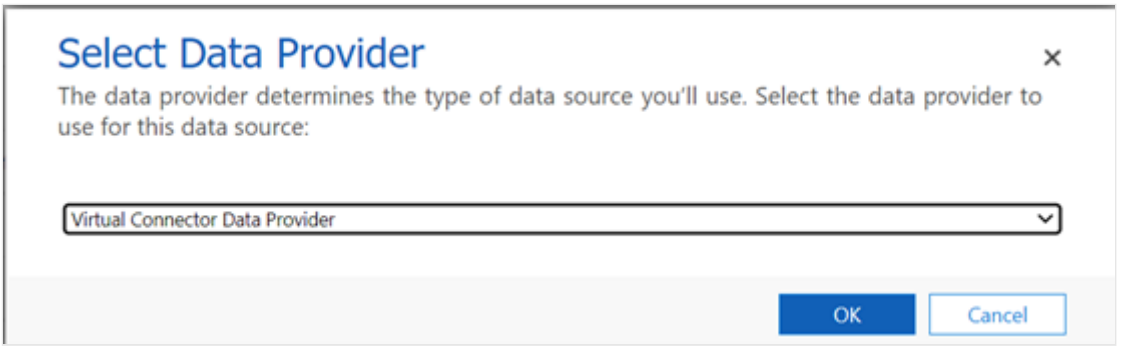


3. Select **Virtual Entity Data Sources**.

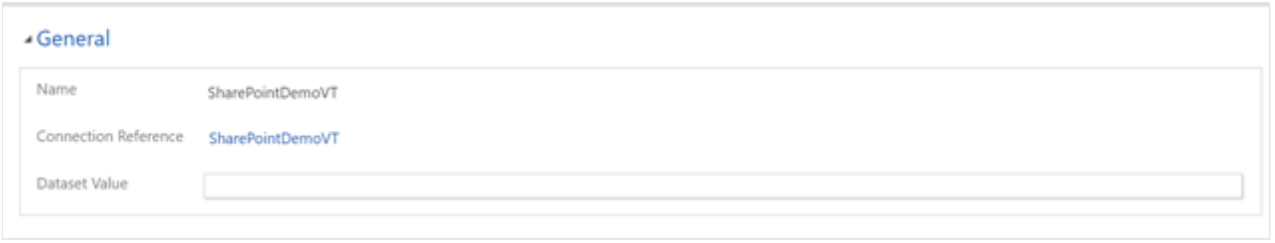


4. Select **New**. In the pop-up dialog, select the **Virtual Connector Data Provider**.





5. Name your **Data Source** and select the **Connection Reference** you created in the drop-down list.



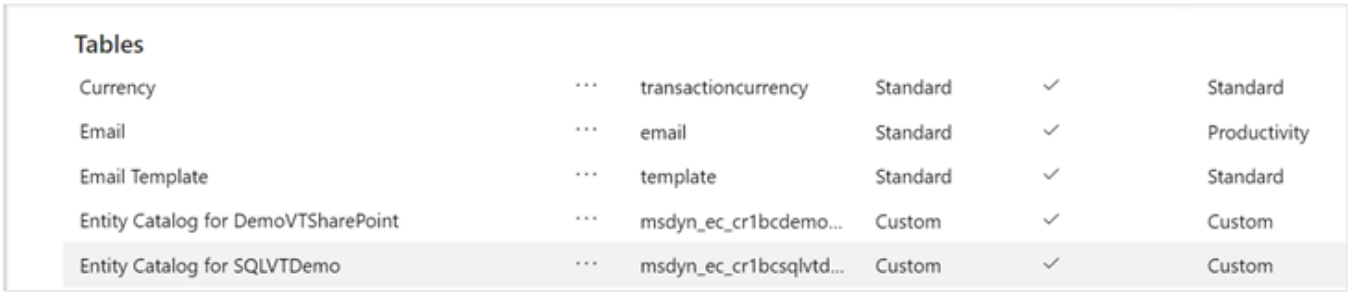
Add your Dataset Value

6. Paste in the file name including extension into the Dataset Value. Remember the file must be in the OneDrive that was used for the Connection setup. (for example: SampleData.xlsx)

7. Select **Save**.

Entity catalog

With the connection reference and the virtual table data source setup, an **Entity Catalog** is automatically generated. The **Entity Catalog** is specific to the data source and will list all the tables that are in the respective data source.

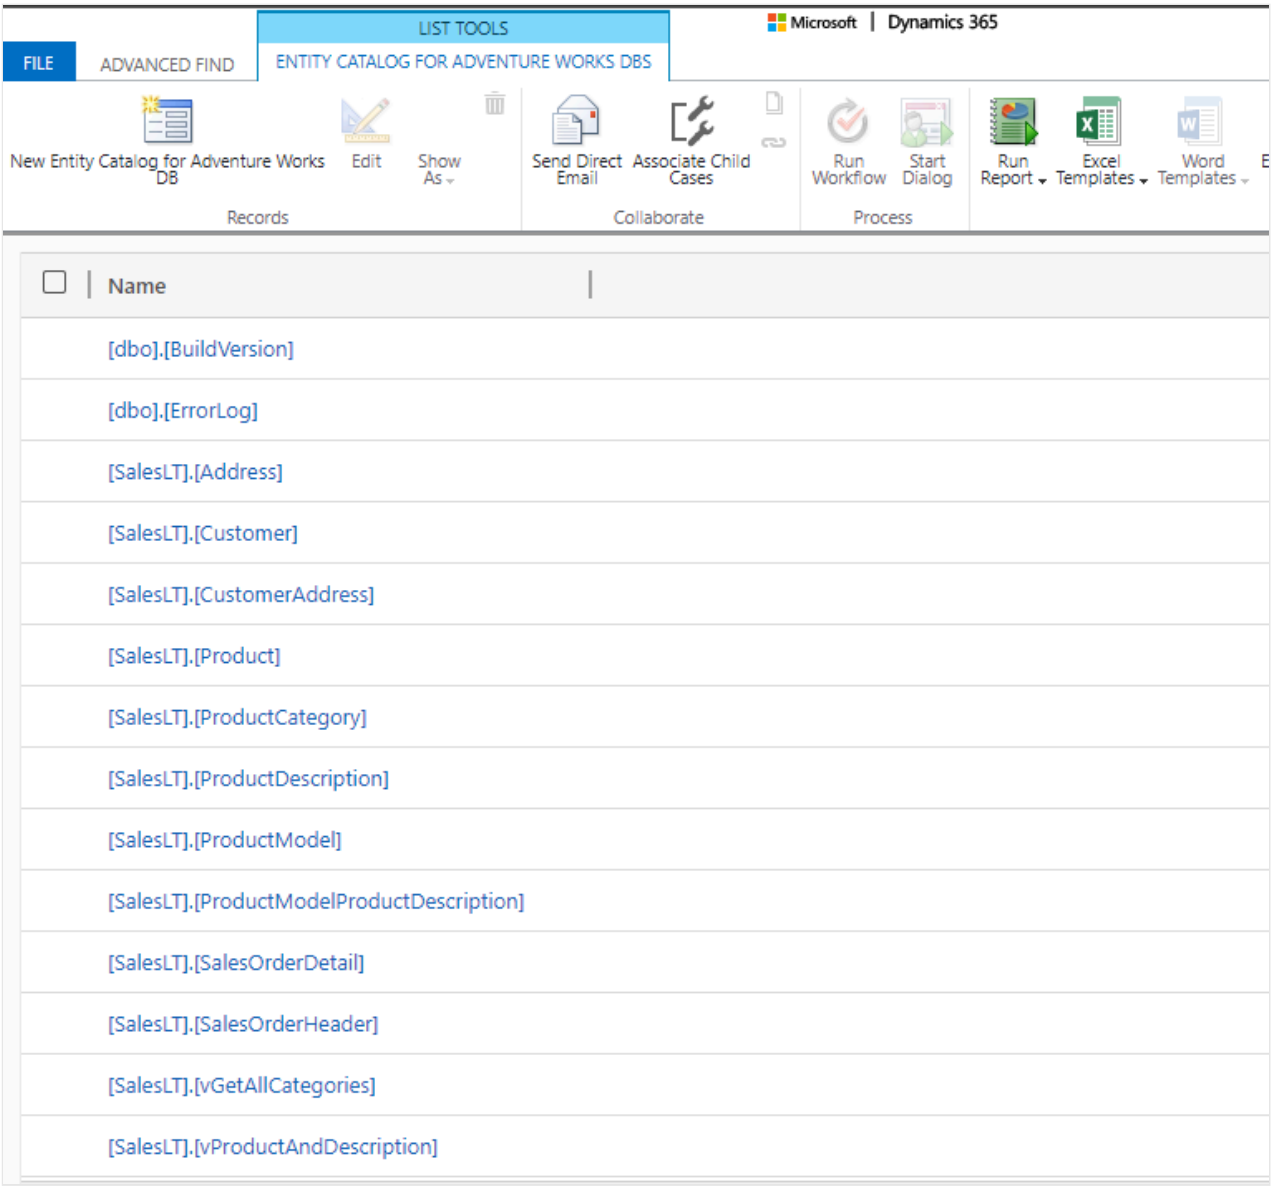


> **Note**
>
> - The creation of the entity catalog is an asynchronous process. Depending on your environment, this might take a few minutes.
> - The tables displayed in the entity catalog aren't virtual tables in themselves. You need to select from this list of tables representing the external data to create virtual table in Dataverse.

> **Tip**
>
> If the entity catalog creation takes a long time, you can check the job completion status by navigating to **Settings** -> **System Jobs** view.

View the entity catalog

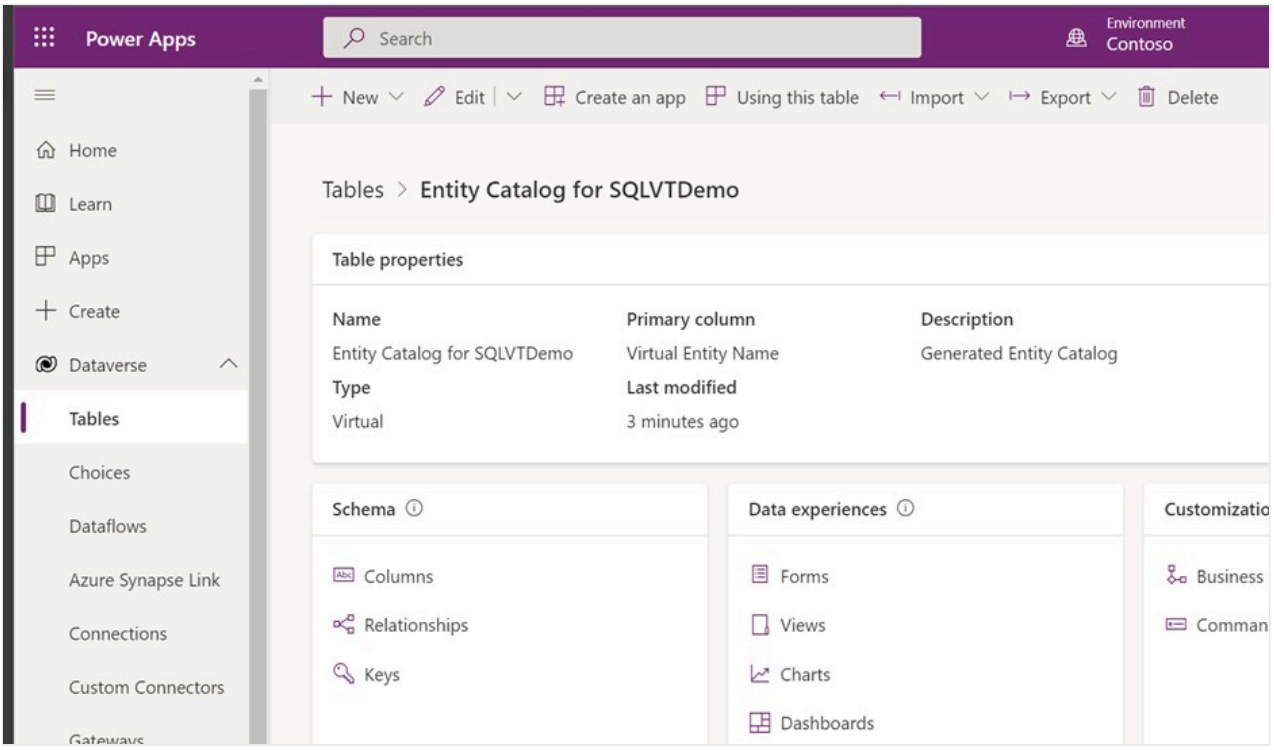
- Select **Data** > **Tables**, and then select the entity catalog that was created.
- Select **Advanced Find** and use the **Look for:** column. The catalog includes a prefix **Entity Catalog for** followed by the connection reference (example: Entity Catalog for Adventure Works). Find the entity catalog for your respective data connection and select **Results** to display all the external data source tables.



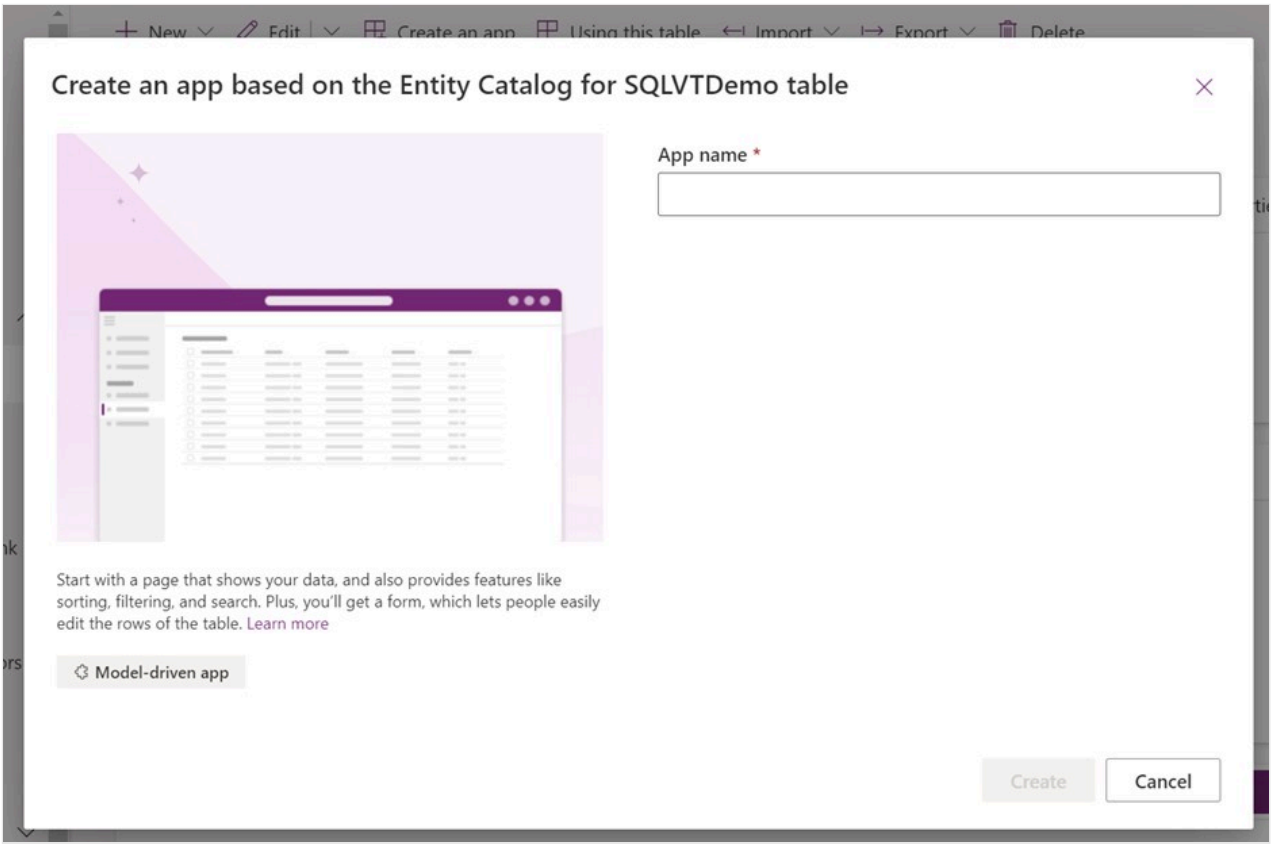
> ⓘ **Note**
>
> Bulk creation of virtual tables is not supported currently. Even though the entity catalog allows you to select multiple tables, you will have to select one table at a time to create virtual tables.

1. To create a virtual table, a model driven app must be built for the entity catalog. Select the entity catalog table.

2. Select **Create an app** in the top navigation.

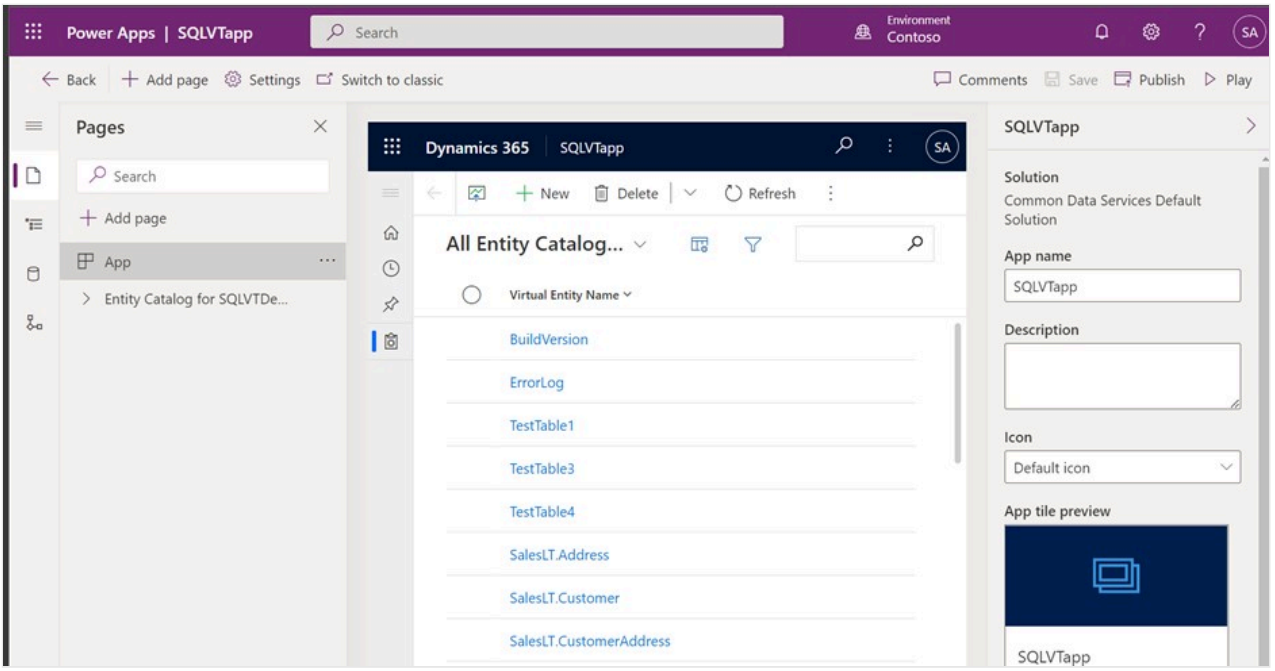


3. Name the app, and then select **Create**.



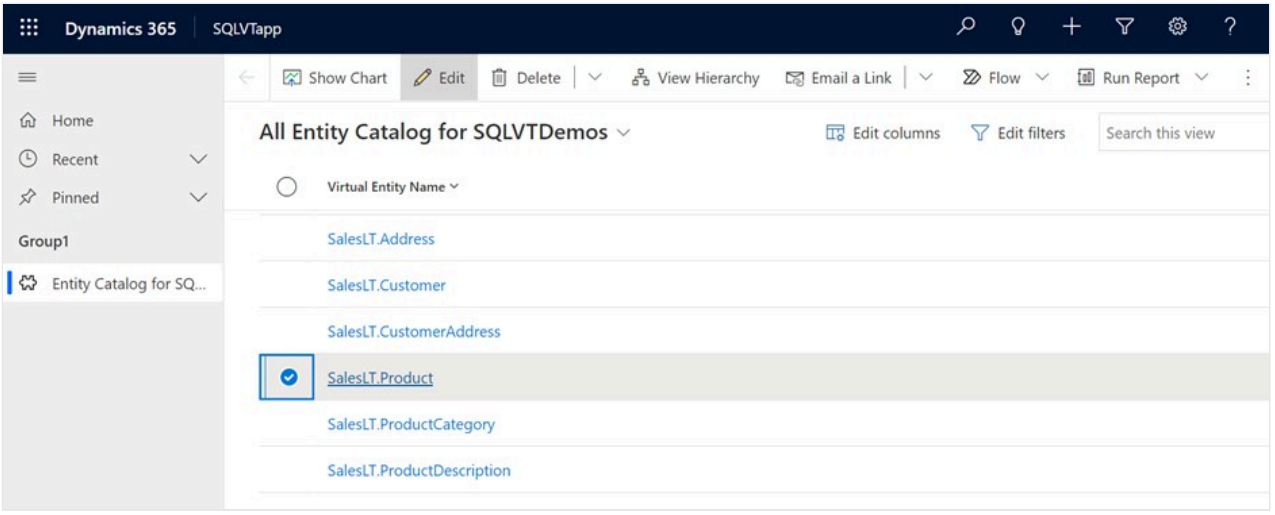
The app is automatically generated using the entity catalog table.

4. Once the app is completed, you can select **Publish** to complete the app and use it later, or you can select **Play** to create your virtual table now without publishing the app.

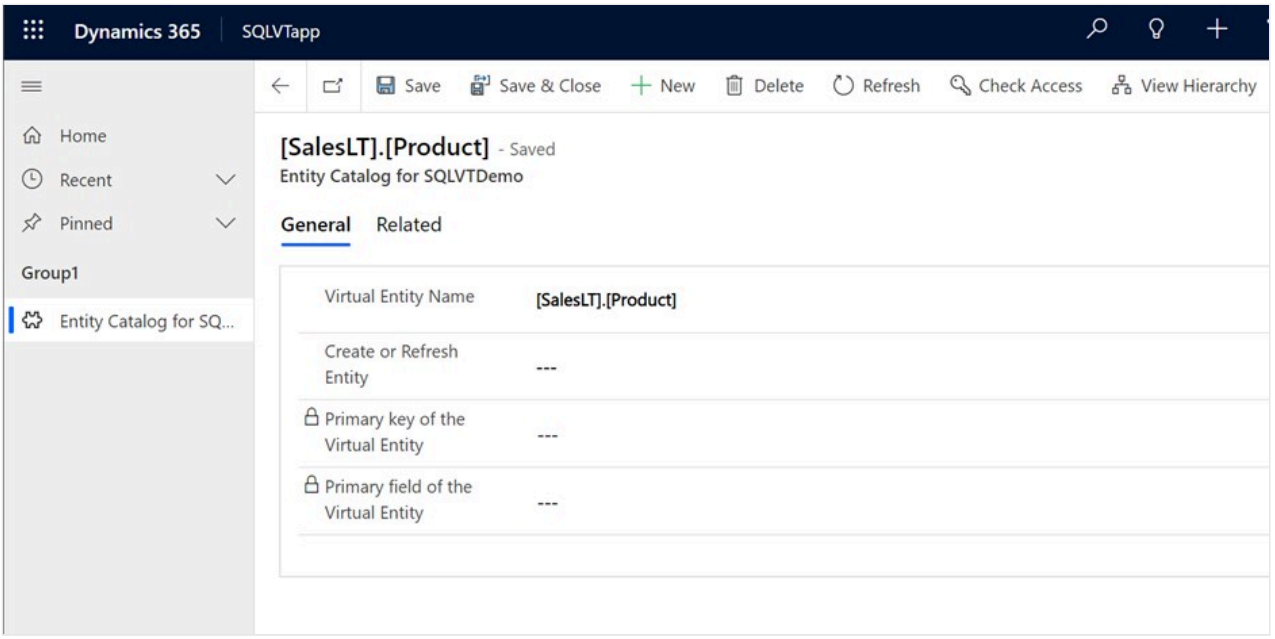


All tables from your Excel file will be provided in the app view.

5. Select the data set you wish to use from the entity catalog, and then select **Edit** in the navigation bar.

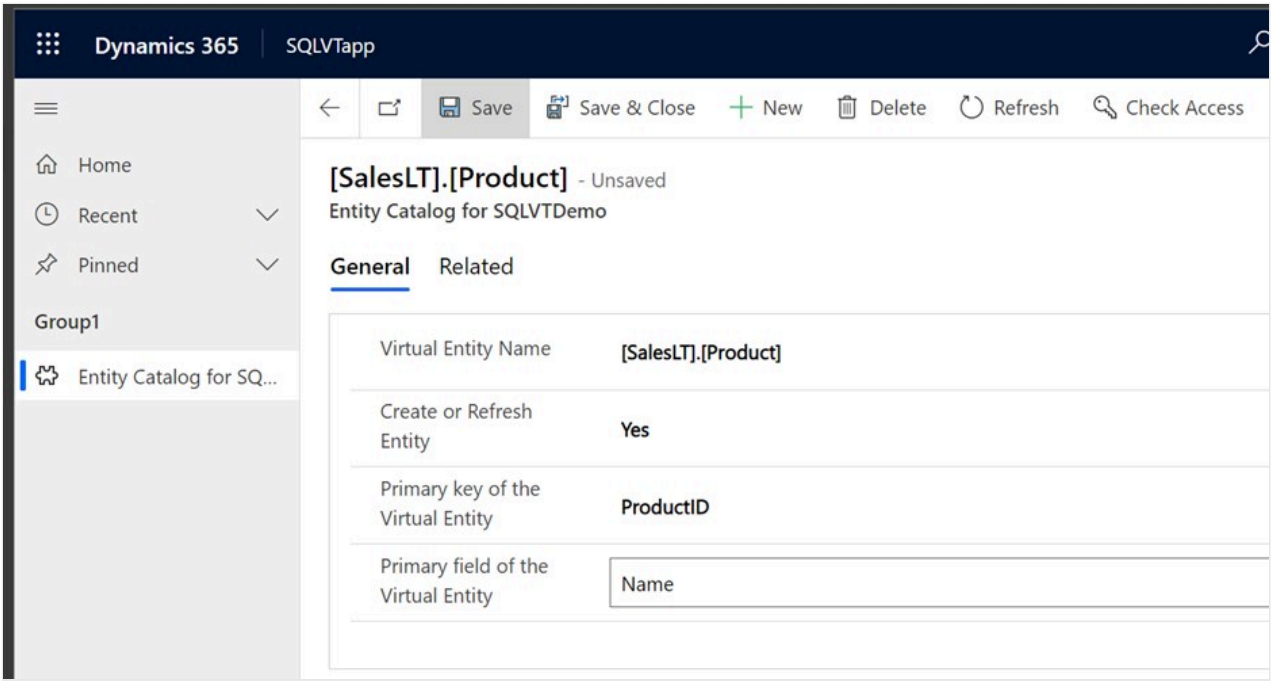


Wait for the form to fully load before editing. When loaded the form appears like this:



6. In the provided form set the **Create** or **Refresh Entity** column to Yes.

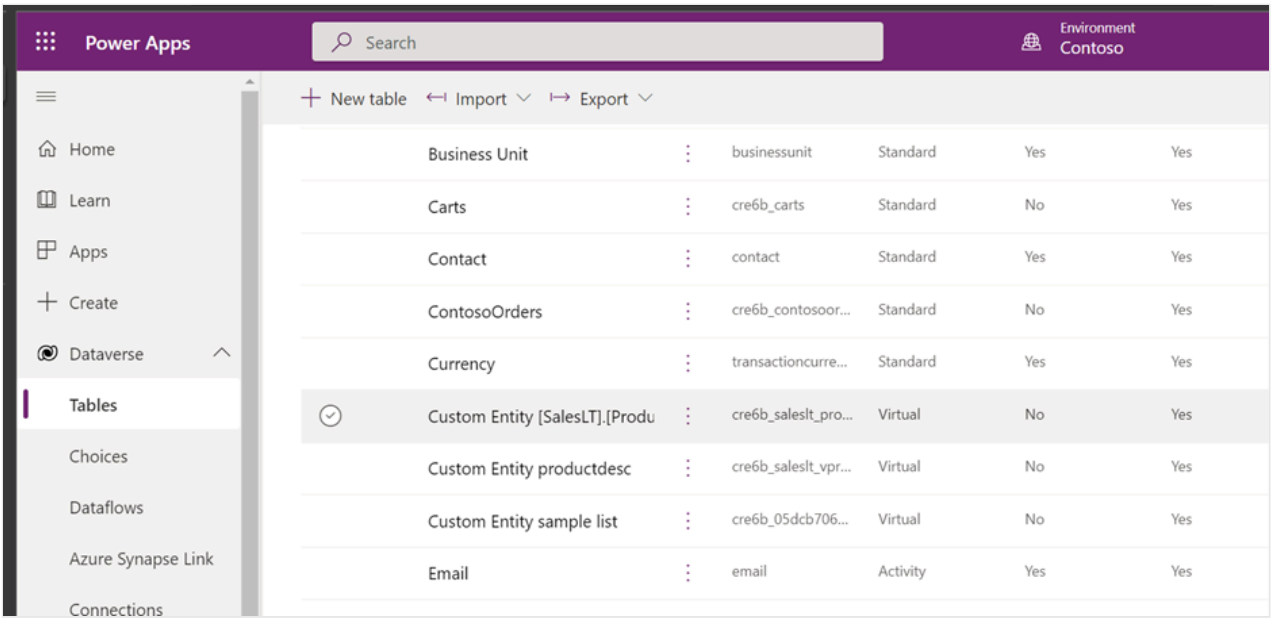
7. Select the **Primary Key** and **Primary Field** of the virtual entity by using the dropdown lists to find the columns you want to use.



8. Save the record to create the virtual table.

> ⓘ **Note**
>
> After the save completes, the form will "reset" with all fields shown as blank, this is normal.

9. Return to the Power Apps home page and select **Data**. Your virtual table is now created with a "Custom Entity" prefix. It might take a few moments for the creation to complete.



Important

- The provider automatically maps the primary key associated with the external data source when creating the virtual table. All CRUD operations can be performed on the generated virtual table.
- All columns in the external data are automatically mapped to Dataverse types that are supported by the connector. You can review the virtual table details and make changes by navigating to **Settings** -> **Customization – Entities** view.
- Virtual tables require there to be at least one string field to use as the **Primary Name** column.

Once you've created a virtual table, you can work with it much the same way as any other table. You can start defining the relationships with other tables, in the environment and use them in your Power Apps and Power Automate flows.

Related articles

Create virtual tables using the virtual connector provider

Setting up a virtual table relationship

Article • 01/04/2023

Virtual tables are enabled for relationships. You can set up 1:N, N:1, and custom multi-table (polymorphic) relationships. Relationships can be established between:

- Local tables in Dataverse and virtual tables.
- Virtual tables and other virtual tables from the same provider, for example SQL->SQL.

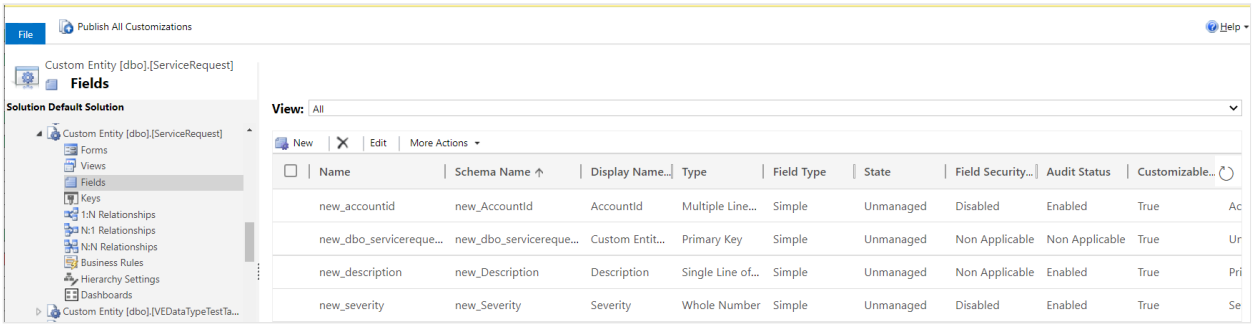
For instance, you can't set up a relationship between a virtual table created using the OData virtual table provider and a virtual table created using the virtual connector provider.

Defining relationships in virtual tables

Virtual tables created using the virtual connector provider automatically creates all the columns that are represented in the external source table. This will also include columns on which relationships are defined. However, the relationship definition won't be automatically created. You'll have to define this relationship in Dataverse manually.

The following example creates an N:1 relationship between a virtual table (**Service Request**) and a native table (**Account**). The column used to set up the relationship is **AccountId**. This column is the primary key in the account table and is a foreign key in the service request table.

A representation of the **Service Request** virtual table is shown below. You'll notice that the **AccountId** column, which is the column used for relationship in the external source, is of type **Multiple Line of Text**. You need to have this column represented as a **Lookup** type to create a relationship.



1. Go to **Advanced settings** > **Settings** > **Customization** and choose **Customize the System**.

2. In the left navigation pane, expand the **Entities** view and browse to the **Service Request** virtual table definition.

3. Select the **Fields** view, select the **AccountId** column, and then select **Delete**.

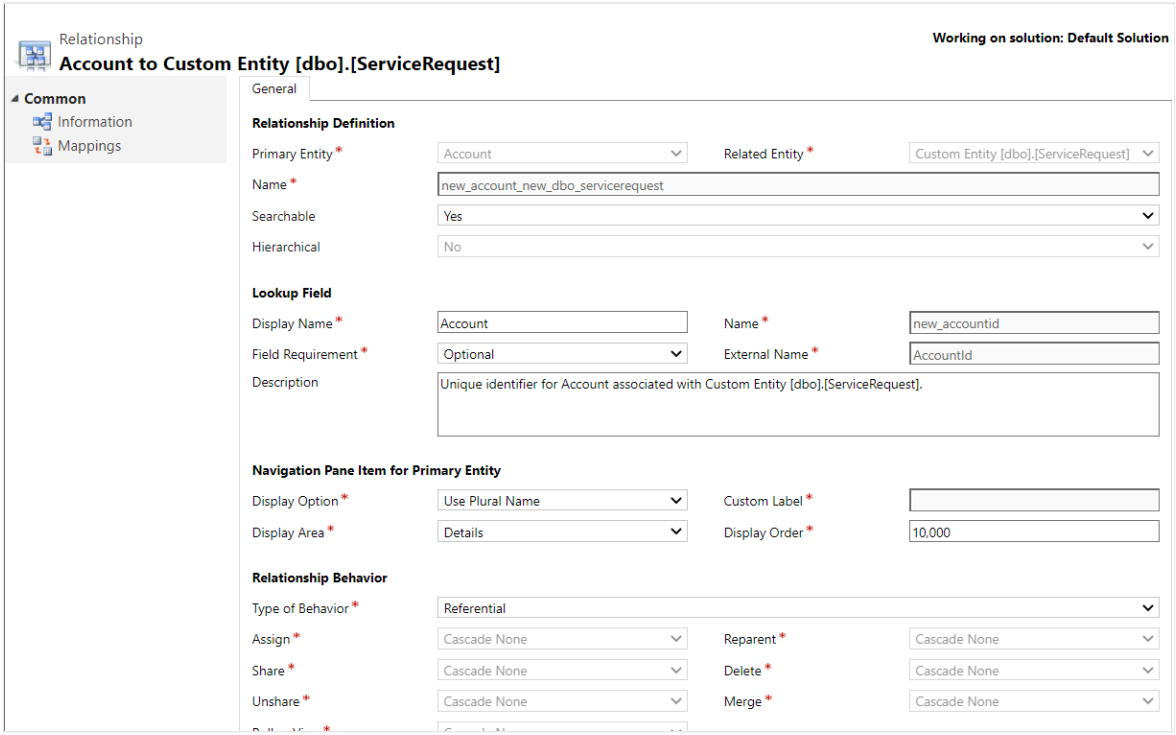
4. Choose **Delete** to confirm the deletion of this column.

5. To create the relationship, select the **N:1 Relationship** within the **Service Request** table.

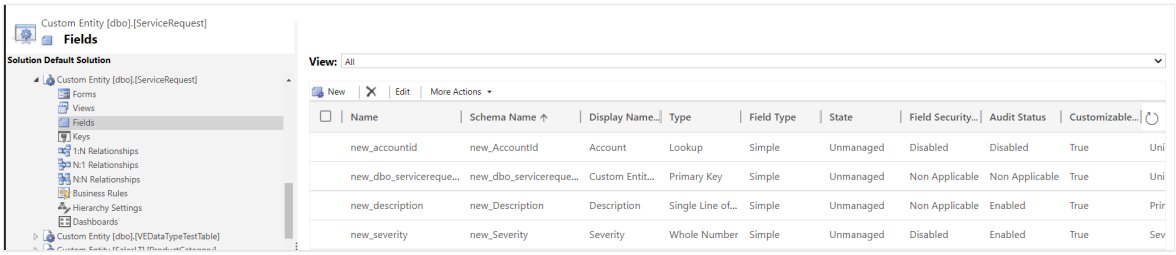
6. Select **New Many-to-1 Relationship**.

7. Enter the following details to create the relationship between the **Service Request** virtual table and the **Account** table.
   a. In the **Relationship Definition** section – set the **Primary Entity** column value to **Account**.
   b. Optionally, if you want to edit the name of the relationship, you can do so in the **Name** column.
   c. In the **Lookup Field** section, set the **Display Name** to **Account.**
   d. The **Name** column automatically populates with the lookup column name.
   e. Set the **External Name** value to **AccountId** (matching the column name in your source table).

8. **Save**, and then close the relationship.



9. Refer to the columns for the **Service Request** virtual table, and you'll notice that the **AccountId** column is a **Lookup** type. This column can now be added to forms and views to see all associated accounts for each of the service request record.



10. With the relationship established you can now create a new service request and pick accounts to associate them to.

> [!NOTE]
> You will have to edit the forms and views for this table to include the lookup column and other required columns prior to operation on the virtual table.

Tip

- The **Primary Key** column should be included in the create form if you didn't set up the column to increment during the design of the underlying source table automatically. You'll have to enter a valid value in the primary key column for an insert operation to succeed.

Next steps

Create virtual tables using the virtual connector provider (preview)

Known limitations and troubleshooting with virtual tables

This article describes the known limitations and troubleshooting tips when working with virtual tables in Microsoft Dataverse.

The following list describes known limitations for virtual tables created by using the virtual connector provider.

General limitations

- The table or list you use must include at least one string field to use as the primary field, and one GUID field. Without these string fields, you can't create the virtual table and an error occurs during the table details retrieval stage.
  - SharePoint uses the hidden numeric ID field present in all lists.
  - SQL can use a GUID or integer field.
  - Excel must have a GUID field.
- Dataverse can only create columns that include data types compatible with Dataverse. This limitation includes the following data types:
  - String
  - Multiline text (memo)
  - Whole Number/Integer
  - Decimal
  - Float
  - Date/time
  - Yes/No (boolean)
  - Choices (multi-value select)
  - Hyperlink/Url
- Dataverse doesn't support the following data types for virtual tables:
  - File and attachments
  - Image
- Maximum length of characters allowed for a text column in a virtual table is 4,000 characters. If the source table has a maximum character limit greater than this value, any create or update operation exceeding the max character limit results in a validation error, and the operation fails.

- Virtual table queries are limited to returning 1,000 records. If you have a 1:N or N custom multitable (polymorphic) relationship with a virtual table, any query that exceeds this limit fails and provides an error. Use filtering in your query to reduce the record set as a workaround to this limitation.
- Audit functionality isn't available for virtual tables because Dataverse can only perform and store audit data for locally stored data.
- Rollups and calculated fields can't be calculated for virtual tables. This limitation exists because rollups are a server side calculation in Dataverse, which requires the data to be stored locally.
- Formula columns can't use virtual tables.
- The **Microsoft Entra ID** virtual table provided by Microsoft only allows read access.
- Dataverse virtual tables can display values in fields that exceed the normal maximum values of Dataverse. This behavior occurs because the values being presented aren't stored locally. For example, the Dataverse integer maximum value is 100,000,000,000, but it could retrieve and display 9,000,000,000,000 from SharePoint. However, if the user attempts to edit the number to a size larger than the max accepted size in Dataverse, an error is provided indicating the record can't be saved because it exceeds the maximum size.
- Import and export functionality of table data isn't supported for virtual tables.
- Queries against virtual tables that use negative filter operators, such as Does Not Equal or Does Not Contain, might result in incorrect paging behavior beyond the first page. There's currently no supported workaround. Avoid using negative filters.

Limitations for each data source

The following limitations apply to each data source.

SQL Server

- For functionality, SQL virtual tables use a GUID or an integer field as the primary key.
- SQL Server tables without primary keys: You can select any nonstring field as the primary key. You can create the virtual table successfully. `RetrieveMultiple` works, but the other operations fail with the following error message (coming from SQL connector): "APIM request wasn't successful: BadRequest: No primary key exists in table." For functionality, you must use a GUID or integer field as the primary key.
- SQL Server tables that use a string primary key: The SQL string primary key is the only option available for the virtual table primary key. SQL Server string primary keys are supported only if the values can be parsed as GUID. If the values can't be parsed

as GUID, the virtual table creation succeeds, but fails at runtime with the following errors:
    - Power Apps (make.powerapps.com): "We weren't able to open your table. Try reloading or reopening."
    - Network trace: "String primary keys are supported only if they can be parsed as GUID."
- SQL Server tables without nonprimary key string fields for use as the primary name: If the SQL table doesn't have a string field available to use as the primary name, the configuration step displays the following error: "The table doesn't have a primary field."
- You can use SQL views to create a virtual table but they only provide read operations.
- For SQL Server connector limitations, go to SQL Server connector reference.
- SQL data type, *bigint columns*, in the source table are mapped as a decimal data type in Dataverse virtual tables. When platform support is available for bigint mapping to a whole number, you need to delete previously created columns in the virtual table and create new columns.
- You can't include the following column types in a virtual table at this time:
    - Time
    - Datetime2
    - Image
    - Geometry
    - Geography
    - RowVersion
    - Choice
- The following column types are included in a virtual table but are only shown as text fields:
    - HierarchyID
    - XML
    - Sqlvariant

Troubleshooting

- There's only one (1) record in your virtual table even though you have more in your source table.
  Solution: Check your source table and make sure it has a primary key defined.

- You get one of the following errors when Power Apps (make.powerapps.com) is retrieving a table list or when you select **Finish** to create a table:
  - "Resource not found for the segment `msdyn_get_required_fields`"
  - "Error calling... please verify that connection... exists in environment"
  - "Sequence matches no element for `msdyn_get_required_fields`"

  Solution: In some cases you might not have the most up to date solution for the virtual connector provider. To determine whether your virtual connector provider solution needs an update:

  1. Select **Solutions** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
  2. Select the **History** tab.
  3. **Search** for `ConnectorProvider`.
  4. View the information to see whether the solution needs to be updated.
  5. If the history indicates an update is needed, go to the Microsoft commercial marketplace search for **Virtual Connector Provider**, and then select **Get it now** to import the solution into your environment.
  6. Follow the steps to create the virtual table again.

- A message is displayed "Connection 'xyz' not found in current environment." when retrieving the list of connections.
  Solution: This occurs when there are a large number of connections in the user's Dataverse environment. This is fixed with version 1,029 of the Connector Provider solution. To determine whether your virtual connector provider solution needs an update:

  1. Select **Solutions** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
  2. Select the **History** tab.
  3. **Search** for `ConnectorProvider`.
  4. View the information to see whether the solution needs to be updated.
  5. If the history indicates an update is needed, go to the Microsoft commercial marketplace search for **Virtual Connector Provider**, and then select **Get it now** to import the solution into your environment.
  6. Follow the steps to create the virtual table again.

- You get notified that a timeout occurred during the virtual table creation.
  Solution: This can occur when other existing jobs cause the virtual table creation to be delayed. Wait for a few minutes and try again.

- You get notified that "An unexpected error occurred"
  Solution: This occurs when the virtual table data source was created with invalid values. To resolve this, you need to locate the virtual table data source that is causing the error, delete it, and then re-create the virtual table.

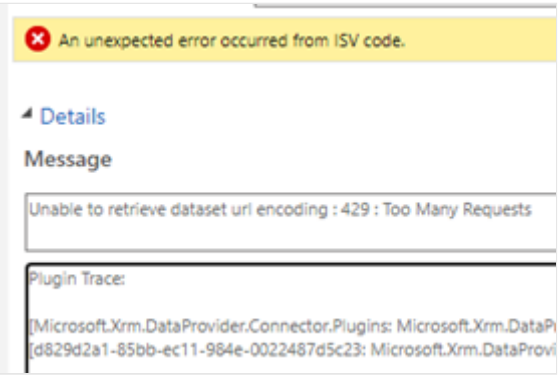
  1. Select **Settings** (gear icon) > **Advanced settings** from Power Apps.
  2. In the top menu, select **Settings**.
  3. Go to **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
  4. Go to the solution that includes your virtual table (if you weren't using a solution then go to Common Data Services Default Solution).
  5. In the left hand panel, select **Virtual table data sources**.
  6. Double-click each data source (they all start with `VCP_DS_..."`), when you locate the one with the error, delete that data source.
  7. Re-create your virtual table.

- A message is displayed "This table already exists, you're recreating the table. Primary field and Schema name can't be changed."
  Solution: This table has previously been created. Continuing with the creation re-creates the table, this results in any table changes made at the data source to be updated in the virtual table (this includes addition or removal of fields). The custom name and primary field values won't be editable.

- Error message: "primary_key_name can't be empty"
  Solution: You have chosen a table or list that doesn't include a GUID value for the primary key. You need to add an additional GUID column in your source table in order to create a virtual table.

- You created an Excel virtual table but don't see it in the **Tables** area in Power Apps.
  Solution: Since the virtual table creation is asynchronous, you can check the status of the process in **System Jobs**. Look for system jobs with a Name starting `Microsoft.Wrm.DataProvider.Connector.Plugins.ConnectorGenerateVEPlugin` and a **Regarding** column's value equal to the name of the new virtual table. If status is still **In Progress**, just wait for the job to complete. If there's an error, you can get details by selecting the system, job name hyperlink. In this example, table creation is still pending:

Here, table creation failed due to 429 "Too Many Requests" error:



- Table creation's system job succeeded but you receive runtime errors related to invalid or missing columns.
  Solution: If a failure occurs while you create a table field, the table creation process doesn't fail and try to continue with the remaining fields. This is because the system doesn't want to block the virtual table creation when some column types are unsupported. To get details on the error, enable logging in **Administration** > **System Settings** > **Customizations** > **Enable logging to plug-in trace log**, then delete the virtual table and try to create it again.

- If you deleted the connection connected to virtual table and recreated it, the Virtual Connector Provider app loses permission to access the new connection, preventing data retrieval.
  Solution: Manually share the recreated connection with the 'Virtual Connector Provider' app using the connection's share feature to restore access.

- When a custom data provider for a virtual table is updated to support new operations (e.g., create, update, delete), the platform does not automatically add corresponding permissions to the existing virtual table entity.
  Solution: To enable new permissions, the user must recreate the virtual table entity after updating the data provider.

Create and edit elastic tables

Article • 03/31/2025

An elastic table is a table managed by Microsoft Dataverse. Elastic tables come with the same familiar user experience and API that are offered with standard tables. They share many aspects and options with standard tables, but come with their own unique features and capabilities that are powered by Azure Cosmos DB.

Elastic tables are included with your Dataverse log capacity use.

Watch this video that to learn about elastic tables.
https://learn-video.azurefd.net/vod/player?id=6f859c28-12b1-4042-9502-b8a441020768&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fcreate-edit-elastic-tables

When to consider Dataverse elastic tables?

Elastic tables are designed to handle large volumes of data in real-time. With elastic tables, you can import, store, and analyze large volumes of data without scalability, latency, or performance issues.

Elastic tables have unique capabilities for flexible schema, horizontal scaling, and automatic removal of data after a time-period.

Elastic tables automatically scale to ingest tens of millions of rows every hour. Background processes can collate the IoT signals, predict maintenance requirements, and proactively schedule technicians.

Consider a scenario where Contoso is a retailer with millions of existing customers. Contoso has a large database of customers and are looking to increase sales while retaining customers. Based on prior customer history, they're looking to have 24-hour flash sale events with different coupons targeting their customers and products. They have estimated that the number of coupons required will be 100 million plus per flash sale campaign. Marketing plans to run multiple 24-hour campaigns targeting different customer segments.

The requirement for Contoso's marketing application is that it must be able to ingest up to 100 million or more coupon details within a few hours, read millions of coupons per hour, and send coupons to customers.

Elastic tables will automatically scale for this high throughput scenario.

For example, in the above scenario, an elastic table named *Coupon* with millions of records can be associated with Dataverse standard tables like *Contact* (customer info) and *Offer* (a custom standard table). Since the elastic tables are isolated from the standard tables, performance for the overall marketing application won't be negatively impacted. In addition, time-to-live capability with elastic table (*Coupon* in this scenario) allows removal of data automatically after fixed periods and ensure optimization of log capacity.

Use elastic tables when:

- Your data might be unstructured or semi-structured, or if your data model might constantly change.
- You need automatic horizontal scaling.
- You need to handle a high volume of read and write requests.

Use standard tables when:

- Your application requires strong consistency.
- Your application requires relational modeling and needs transactional capability across tables and during plugin execution stages.
- Your application requires complex joins.

The choice of table should be based on the specific needs of your application. A combination of both types of tables might be appropriate.

Horizontal scaling and performance

As your business data grows, elastic tables provide unlimited auto scalability based on your application workload, both for size and throughput, such as the number of records created, updated, or deleted in a given timeframe.

If your business scenario requires very large volume of data writes, application makers can make use of Dataverse multiple request APIs, such as `CreateMultiple`, `UpdateMultiple`, and `DeleteMultiple`, to achieve more throughput within Dataverse throttling limits. More information: Developer guide: Bulk Operation messages and Optimize performance for bulk operations

Automatic removal of data

Time to live (TTL) policies ensure that you're always working with the most up-to-date and accurate information, while optimizing resources and reducing risk. The TTL live

value is set in seconds on a record, and it's interpreted as a delta from the time that a record was last modified.

Flexible schema with JSON columns

Elastic tables enable you to store and query data with varying structures, without the need for predefined schemas or migrations. There's no need to write custom code to map the imported data into a fixed schema. More information: Developer guide: Query JSON columns in elastic tables Elastic tables enable you to store and query data with varying structures, without the need for predefined schemas or migrations. There's no need to write custom code to map the imported data into a fixed schema. More information: Developer guide: Query JSON columns in elastic tables

Considerations when you use elastic tables

Although elastic tables are great for handling large volume of requests at scale, the advantages come with a few trades offs, which should be kept in mind:

- Elastic tables don't support multi-record transactions. This means that multiple write operations happening as part of a single request execution aren't transactional with each other. For example, if you have a synchronous plug-in step registered on the `PostOperation` stage for `Create message` on an elastic table, any error in your plug-in won't roll back the created record in Dataverse. Validations in preplug-ins will still work as expected since they run before the main stage.
- Elastic tables support strong consistency only within a logical session. Outside session context, you might not see changes to a row immediately. More information: Developer guide: Consistency level
- Elastic tables don't support filters on related tables when creating views, advanced find, or any query in general using API. If you frequently need to filter on related table columns, we recommend that you denormalize columns from related tables, which need to filter into the main table itself. Consider a retailer with two elastic tables: customer and address. One customer has many addresses. You want to return query results for all customers from the customer table whose city value in the address table is New York. In this example, when querying customer table, you want to apply a filter on the city column of the related address table. This isn't supported for elastic tables. One way to make this work is to denormalize the city column into the Customer table so that all customers city values are present in the customer table itself.

Elastic tables feature support

- Create, retrieve, update, delete (CRUD) operations including API multiple operations (for high throughput), bulk deletion, and requests from plug-ins.
- Relationships:
  - One-to-many
  - Many-to-one when the N table is a standard table
- Record ownership, change tracking, auditing, mobile offline, and Dataverse search.
- File column with file type attribute

Security features support

Elastic tables adhere to the Dataverse security model.

When creating an elastic table, you can set:

- Either user or organization owned
- Field level security

Features currently not supported with elastic tables

Table features currently not supported with elastic tables:

- Business rules
- Charts
- Business process flows
- One Dataverse connector for Power BI
- Many-to-many (N:N) relationships to standard tables
- Alternate key
- Duplicate detection
- Calculated and rollup columns
- Currency columns
- Column comparison in queries
- Table sharing
- Composite indexes
- Cascade operations: Delete, Reparent, Assign, Share, Unshare
- Ordering on lookup columns
- Aggregate queries:
  - Distinct value of `attribute1` while orderby on `attribute2` value
  - Pagination when having multiple distincts
  - Distinct with multiple order by
  - Order by and group by together
  - Group by on link entity (left outer join)

    - Distinct on user owned tables
- Table connections
- Access teams
- Queues
- Attachment
- Import and export functionality of table data.

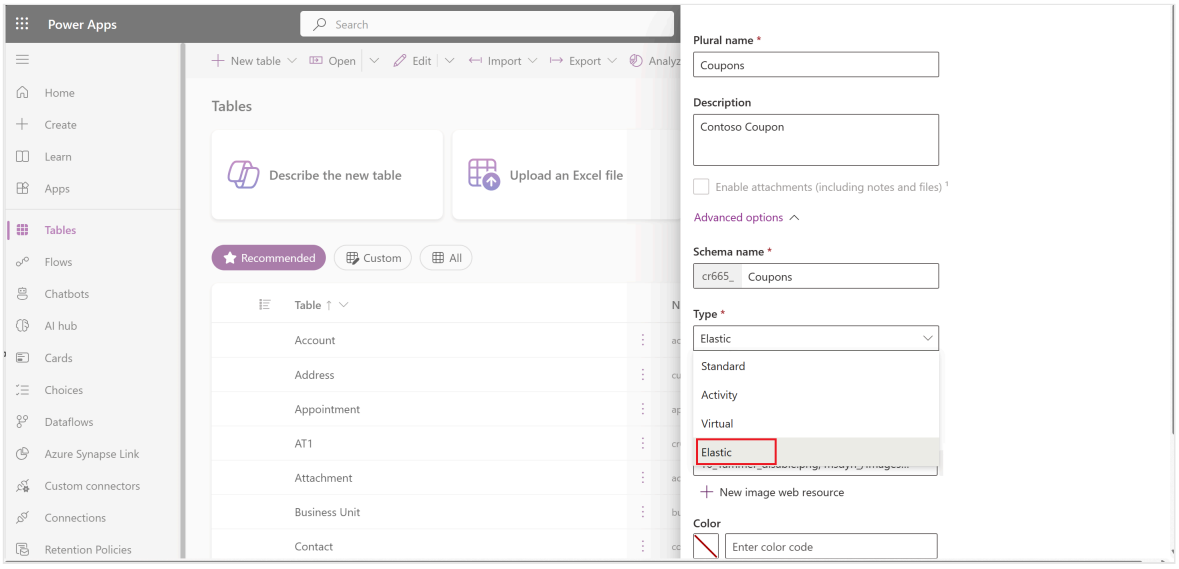
Column data types currently not available with elastic tables:

- Currency
- Formula
- Whole number format other than None (Duration, Language code, and Time zone)
- Lookup based on the Customer option

Create an elastic table

You create an elastic table just like any other new table in Dataverse.

1. Sign into Power Apps, and select **Tables** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **New table** > **Set advanced properties** on the command bar.
3. On the right properties pane, enter a **Display name** and a **Plural name**.
4. Expand **Advanced options**, and then select **Elastic** as the table **Type**.



5. Select the properties you want, and then select **Save**.

The time to live column is automatically created for an elastic table. You can add the time-period value in seconds, as required. The data is auto removed after the specified time-period.

More information about Tables: Advanced options

Known issues

- When time to live (TTL) is used on a row, the row gets deleted from the elastic table when TTL expires. If it's synchronized to a data lake using Azure Synapse Link for Dataverse before TTL expiry, it won't be deleted from the data lake.
- Point in time restore doesn't restore "updated" records as updates aren't backed up. Only created and deleted records are restored.
- If a specific column in an elastic table is deleted, the columns value isn't removed from the table rows if it has data. Before deleting a specific column, delete the data from all rows for the column.

High volume elastic tables and managing Dataverse API throttling limits

Use bulk operation messages. This allows you to achieve 10 times the throughput with the same Dataverse API throttling limits. Developers can reference more links provided in the below section.

For developers

Elastic tables have different behaviors and capabilities than standard tables when developers use them with Dataverse APIs. The following articles for developers describe these differences:

- Elastic tables
- Create elastic tables using code
- Use elastic tables using code
- Query JSON columns in elastic tables
- Bulk Operation messages (preview)
- Elastic table sample code
- Send parallel requests
- Service protection API limits

Create a business rule for a table

You can create business rules and recommendations to apply logic and validations without writing code or creating plug-ins. Business rules provide a simple interface to implement and maintain fast-changing and commonly used rules.

> **Important**
>
> Business rules defined for a table apply to both *canvas apps* and *model-driven apps* if the table is used in the app. Not all business rule actions are available on canvas apps at this time. More information: Differences between canvas and model-driven apps
>
> In a model-driven app, not all business rule actions are available for editable grids. For table based view pages, recommendations can't be created. Editable subgrids don't support business rules. Business rules won't work with other types of dataset controls.
>
> To define a business rule that applies to a form in a model-driven app, see Create business rules to apply logic in a model-driven app form.

By combining conditions and actions, you can do any of the following with business rules:

- Set column values
- Clear column values
- Set column requirement levels
- Show or hide columns
- Enable or disable columns
- Validate data and show error messages
- Create business recommendations based on business intelligence.

Differences between canvas and model-driven apps

Forms in model-driven apps can use all actions available on business rules, however not all business rule actions are available for canvas apps at this time. The following actions are *not* available on canvas apps:

- Show or hide columns
- Enable or disable columns

- Create business recommendations based on business intelligence

Column type support with business rules

Business rules work with most column types including text, number, choice, date, lookup, owner, and image. However, business rules don't work with the following column types:

- Choices (multi-select)
- File
- Language

Create a business rule

1. Sign in to Power Apps, on the left navigation pane, and select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Open the table you want to create the business rule for (for example, open the **Account** table), and then select **Business rules**.

3. Select **Add business rule**.

   The business rule designer window opens with a single condition already created for you. Every rule starts with a condition. The business rule takes one or more actions based on that condition.

   > **Tip**
   >
   > If you want to modify an existing business rule, you must deactivate it before you can modify it.

4. Add a description, if you want, in the description box in the upper-left corner of the window.

5. Set the scope, according to the following:

Expand table

If you select this item...	The scope is set to...
Entity	Model-driven app forms and server

If you select this item...	The scope is set to...
All Forms	Model-driven app forms
Specific form (**Account** form, for example)	Just that model-driven app form

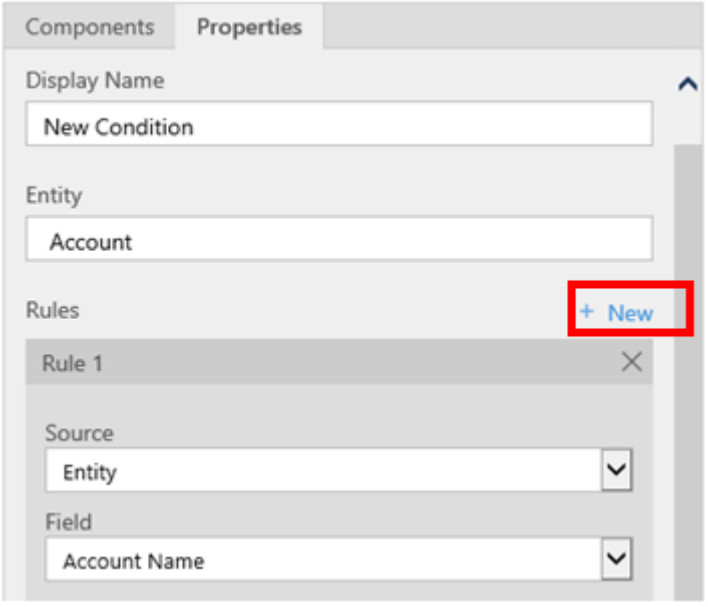
> **Tip**
>
> If you're building a Canvas app, you must use table as the scope.

6. **Add conditions.** To add more conditions to your business rule:

   a. Drag the **Condition** component from the **Components** tab to a plus sign in the designer.

   b. To set properties for the condition, select the **Condition** component in the designer window, and then set the properties in the **Properties** tab on the right side of the screen. As you set properties, the Microsoft Dataverse creates an expression at the bottom of the **Properties** tab.

   c. To add an additional clause (an AND or OR) to the condition, select **New** in the **Properties** tab to create a new rule, and then set the properties for that rule. In the **Rule Logic** column, you can specify whether to add the new rule as an AND or an OR.



d. When you're done setting properties for the condition, select **Apply**.

7. **Add actions.** To add an action:

   a. Drag one of the action components from the **Components** tab to a plus sign next to **Condition** component. Drag the action to a plus sign next to a check mark if you want the business rule to take that action when the condition is met, or to a plus sign next to an x if you want the business rule to take that action if the condition isn't met.

   
   b. To set properties for the action, select the **Action** component in the designer window, and then set the properties in the **Properties** tab.

   c. When you're done setting properties, select **Apply**.

8. **Add a business recommendation (model-driven apps only)**. To add a business recommendation:

   a. Drag the **Recommendation** component from the **Components** tab to a plus sign next to a **Condition** component. Drag the **Recommendation** component to a plus sign next to a check mark if you want the business rule to take that action when the condition is met, or to a plus sign next to an x if you want the business rule to take that action if the condition isn't met.

   b. To set properties for the recommendation, select the **Recommendation** component in the designer window, and then set the properties in the **Properties** tab.

   c. To add more actions to the recommendation, drag them from the **Components** tab, and then set properties for each action in the **Properties** tab.

   > ⓘ **Note**
   >
   > When you create a recommendation, the Dataverse adds a single action by default. To see all the actions in a recommendation, select **Details** on the **Recommendation** component.

   d. When you're done setting properties, select **Apply**.

9. To validate the business rule, select **Validate** on the action bar.
10. To save the business rule, select **Save** on the action bar.
11. To activate the business rule, select it in the Solution Explorer window, and then select **Activate**. You can't activate the business rule from the designer window.

> **Tip**
>
> Here are a few tips to keep in mind as you work on business rules in the designer window:
>
> - To take a snapshot of everything in the **Business Rule** window, select **Snapshot** on the action bar. This is useful, for example, if you want to share and get comments on the business rule from a team member.
> - Use the mini-map to navigate quickly to different parts of the process. This is useful when you have a complicated process that scrolls off the screen.
> - As you add conditions, Actions, and business recommendations to your business rule, Dataverse builds the code for the business rule at the bottom of the designer window. This code is read only.

Example: Create a business rule for tasks older than 30 days

This business rule example creates a condition that triggers a message in the task description field when a task is more than 30 days old.

1. Sign in to Power Apps, on the left navigation pane, select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the **Task** table, and then select the **Business rules** area.
3. Select **Add business rule**.
4. Select **New Condition** on the business process flow canvas, and enter or select the following properties:

    - **Display name**: *Task is more than 30 days old*
    - **Entity**: **Task**
    - **Rule 1**
        - **Source**: **Entity**
        - **Field**: **Created On**

    - **Operator**: +
    - **Type**: **Value**
    - **Days**: *30*
  - **Condition Expression** (automatically created): **(Created On Is greater than [Created On + 30])**
5. Select **Apply**.
6. Select **Add** > **Add Show Error Message**.
7. In the **Show Error Message Properties** tab, enter the following properties:

   - **Display Name**: *Task is more than 30 days old*
   - **Entity**: **Task**
   - **Error Message**:
     - **Field**: **Description**
     - **Message**: *This task is more than 30 days old!*

8. Select **Apply**.
9. Select **Save**.

Localize error messages used in business rules

If you have more than one language provisioned for your organization, you'll want to localize any error messages that you have set. Each time you set a message, a label is generated by the system. If you export the translations in your organization, you can add localized versions of your messages and then import those labels back into the Dataverse, so that people using languages other than your base language can view the translated messages.

Common issues

This section describes common issues that might occur when you use business rules.

Composite attributes not supported with Unified Interface apps

Actions or conditions that use Composite attributes aren't supported in apps based on the Unified Interface. Alternatively, you can use actions or conditions on the attributes that comprise the composite attributes. For example, instead of using the **Full Name** (fullname) attribute, you can use the **First Name** (firstname) and **Last Name** (lastname) attributes.

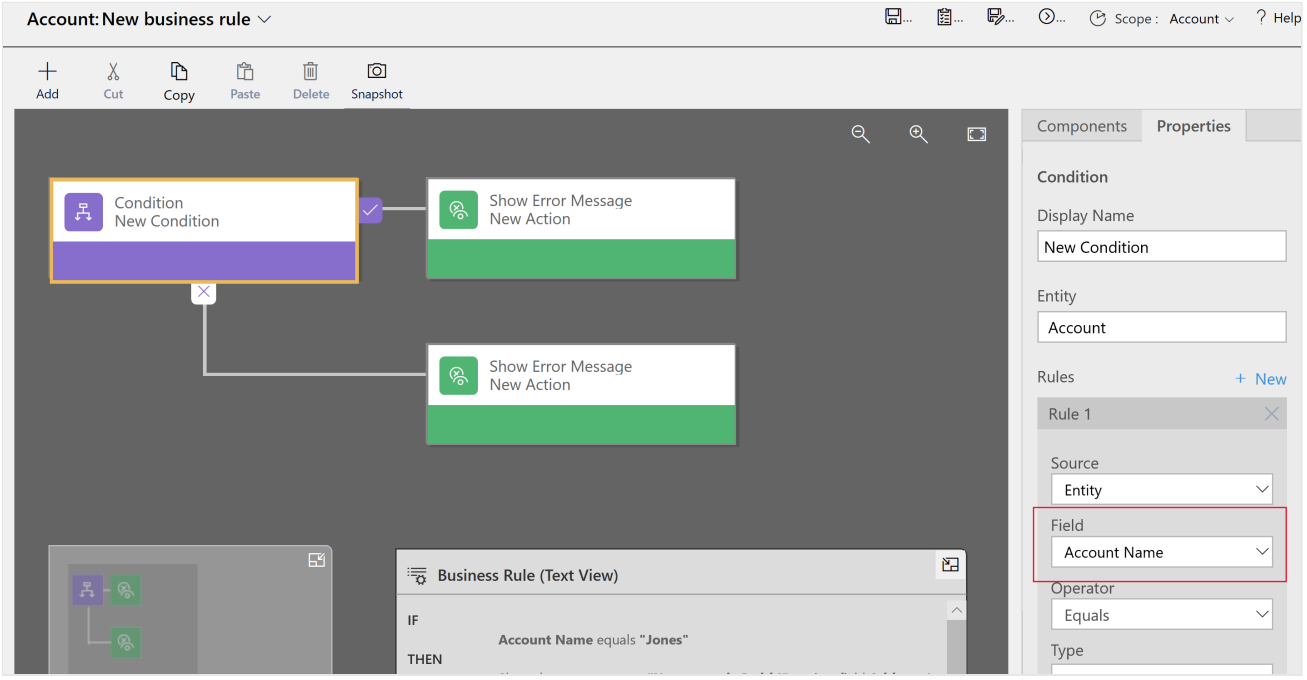
A large number of business rules on a single table impacts performance

New or existing business rules on a table can cause performance degradation when the rules are activated. Power Platform today supports up to 150 business rules for a single table. Beyond 150 business rules, performance degradation can be experienced. This limit includes both client side (JavaScript) and server side (XAML generated as synchronous plugins) business rules. To avoid performance issues with Dataverse, we recommend that you don't create more than 150 business rules for a single table.

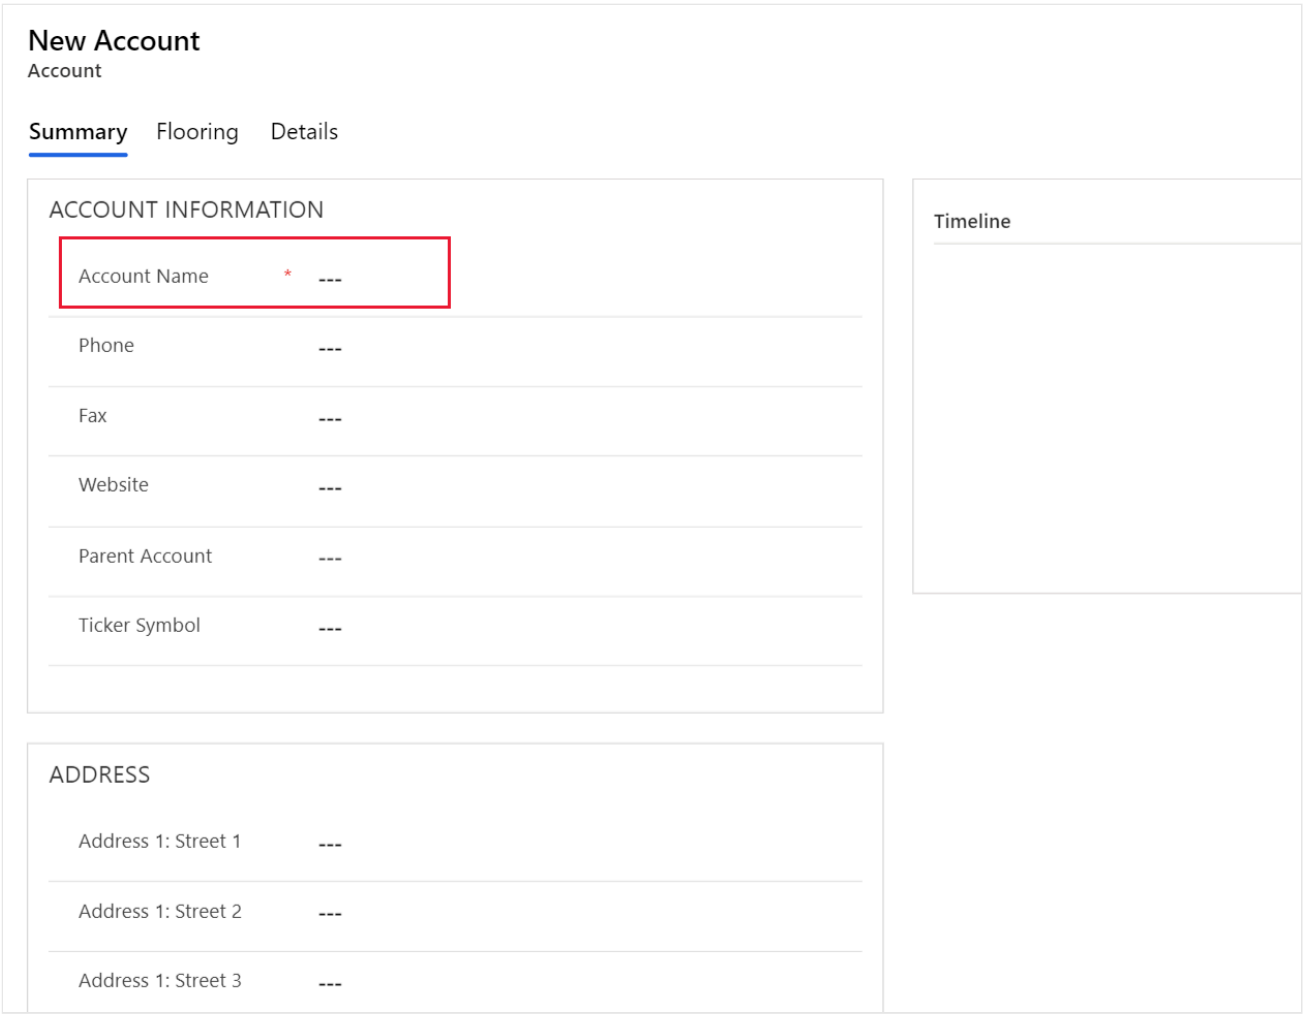
Is your business rule not firing for a form?

A business rule might not execute because the field referenced in the business rule isn't included with the form.

1. Open solution explorer. Expand the entity that you want and then select **Forms**.
2. Open the form that you want and then on the form designer ribbon select **Business Rules**.
3. In the form designer, open the business rule.
4. In the business rule designer, select each condition and action to verify all the fields referenced in each condition and action.



5. Verify that each field referenced in the business rule is also included on the form. If not, add the missing field to the form.



UTC time zone for DateOnly columns

When you configure business rules with `DateOnly` columns, the dates are in the UTC time zone by default, irrespective of the user's set time zone. This can lead to unexpected results if you're expecting `DateOnly` values to align with local time settings.

Suggested handling: Time Zone Independent setting - To make the `DateOnly` columns independent of time zones and display dates in parity with what was configured in the business rule, UTC for example, you can enable the Time Zone Independent setting. For more information about configuring date handling settings, go to Specify the behavior of a date and time column.

Frequently asked questions (FAQ)

Can business rules unlock fields on a read-only form?

- Yes, a business rule can unlock fields and edit actions on a read-only form.

How do I troubleshoot a business rule that isn't working?

- See Is your business rule not firing for a form? in this article.

Do business rules react to changes made by an onLoad script?

- No, they'll execute before an onload script is executed.

When I update a business rule, is it executed against all existing records?

- No. Business rules are run on clients. For example, they run when a form is opened by a user and when a field value changes on that open form. They aren't executed inside Dataverse.

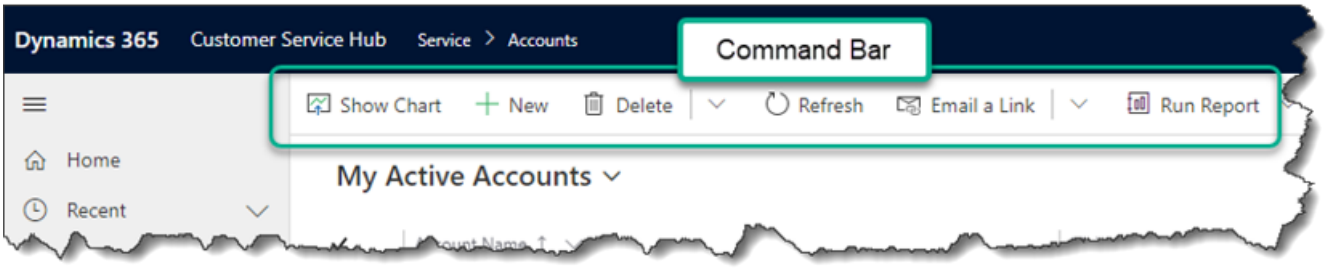
Apply business logic in Microsoft Dataverse

Last updated on 04/21/2026

Modern commanding overview

Commands drive core application behavior for model-driven apps. They're the buttons users interact with when playing apps and the resulting actions performed when a button is selected. Each command is positioned in relation to other commands and bound to a command bar location within the app.

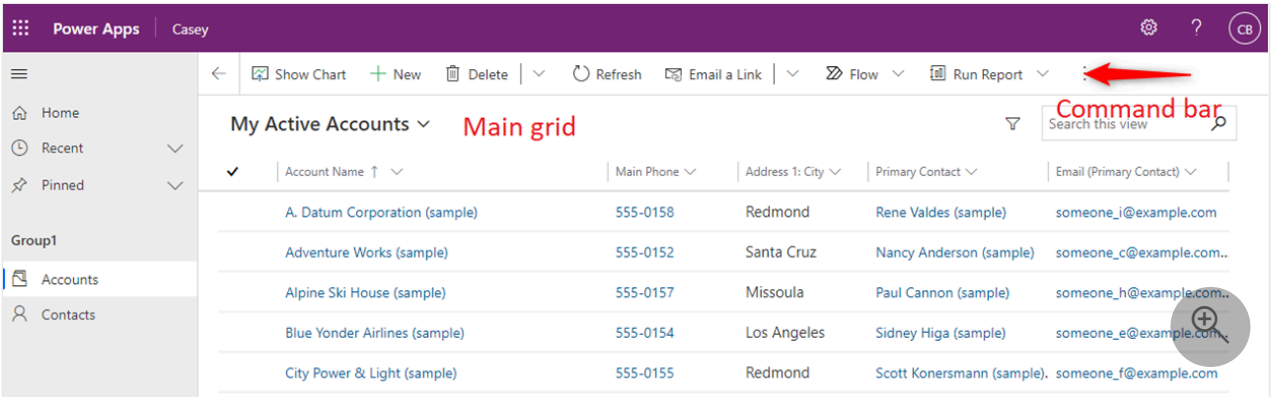


At a high level, command customization fits into three categories. Various capabilities exist within each category and are covered in more depth throughout the modern commanding documentation:

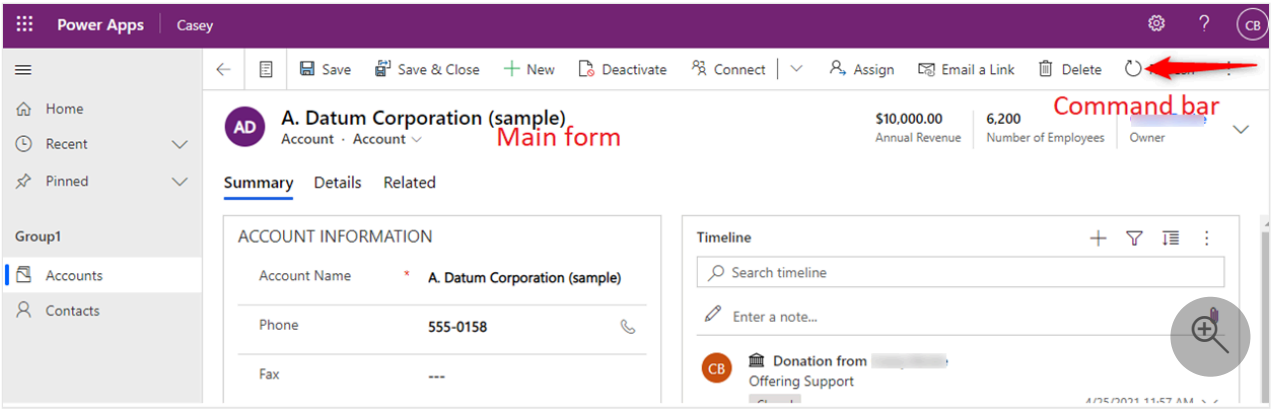
- **Display**. How the button appears and where it's located in an app. For example, the button's label, icon, and accessibility labels as well as the command bar location and position within a command bar.
- **Action**. The logic that runs when a user selects a button. For example, creating and updating data or interacting with various controls and pages inside the app.
- **Visibility**. Logical conditions that specify when a button is visible or hidden to a user. For example, you might want the button visible for some users and hidden for others. Or perhaps the button should only be visible when certain criteria of the data records are satisfied.

Command bar locations

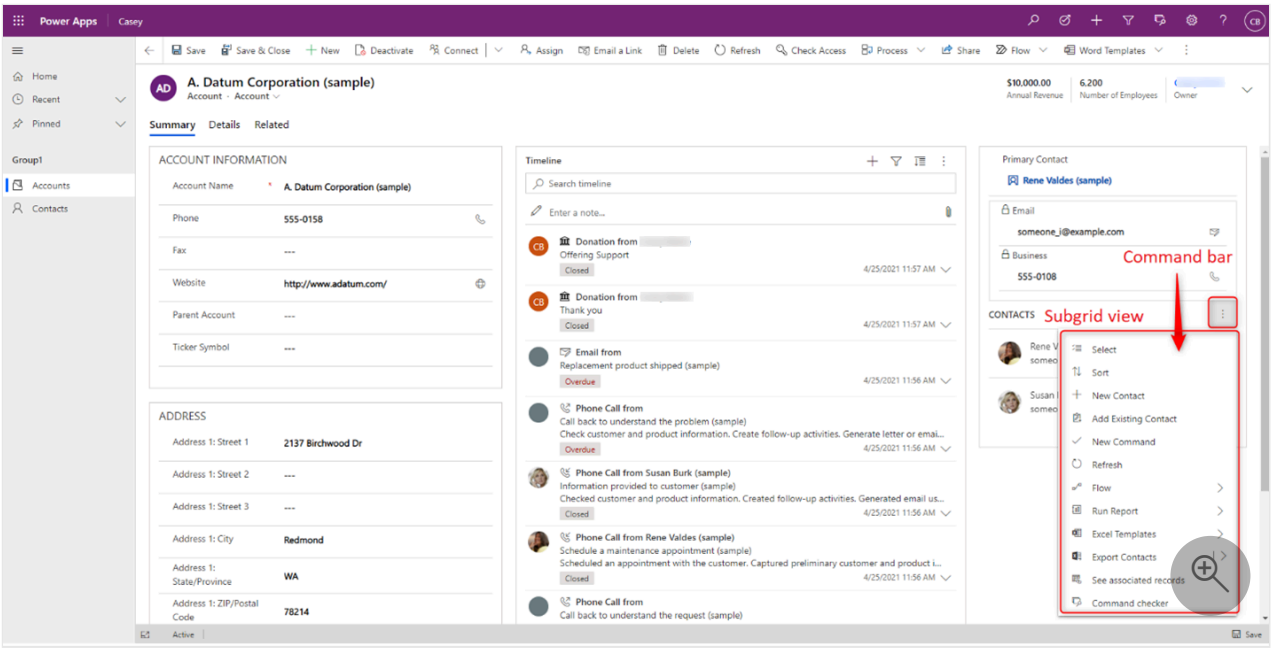
- **Main grid**. This command bar is displayed when using the left-hand navigation of an app to view a full page list of records in this table.



- **Main form**. This command bar is displayed on the table's main forms. This appears at the top of the form and isn't the same as the associated view or subgrid view that appears in different areas of the form.

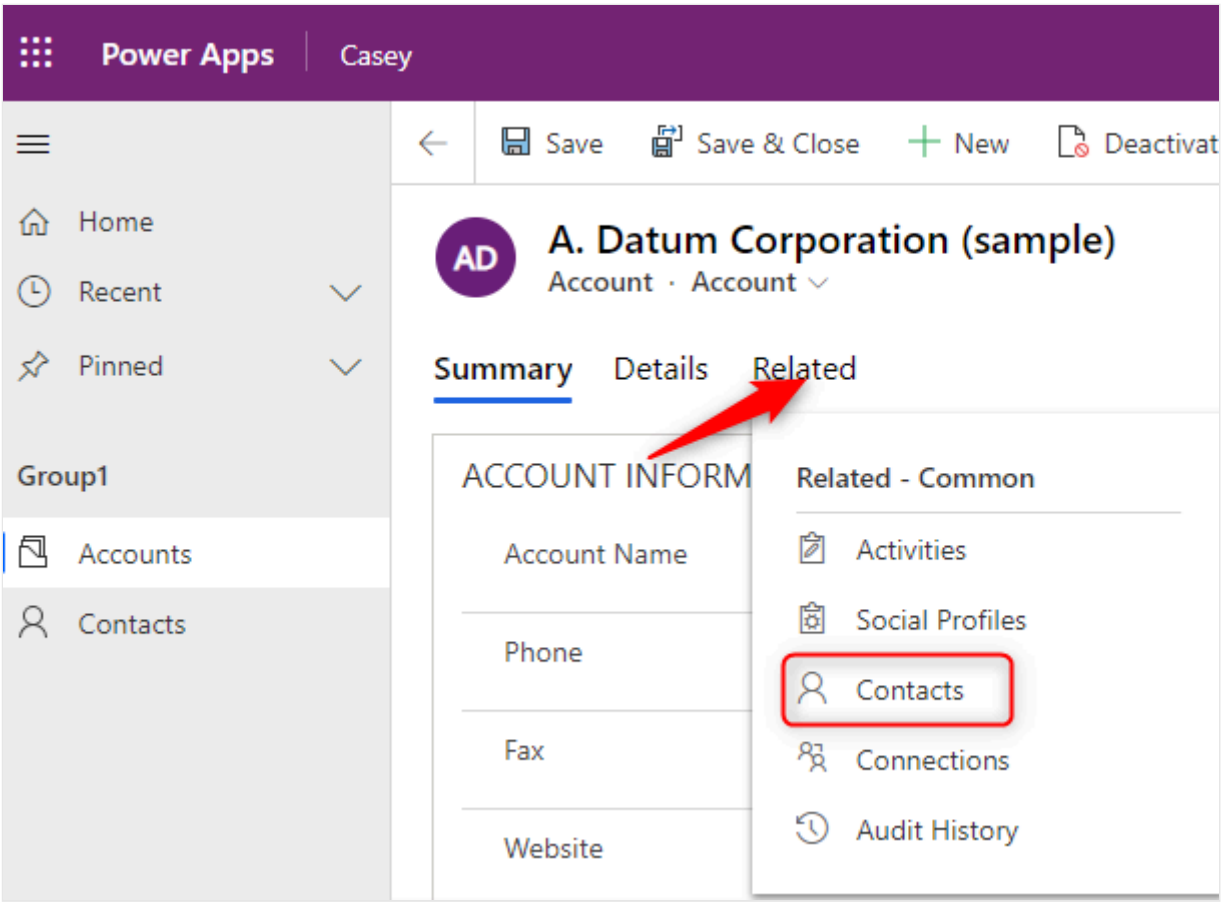


- **Subgrid view**. This command bar is displayed on forms of other tables that render this table's data within a subgrid. For example, the account main form has a subgrid control that lists contact records related to the account record. To edit the command bar shown here, edit the command bar for the contact table then subgrid view.

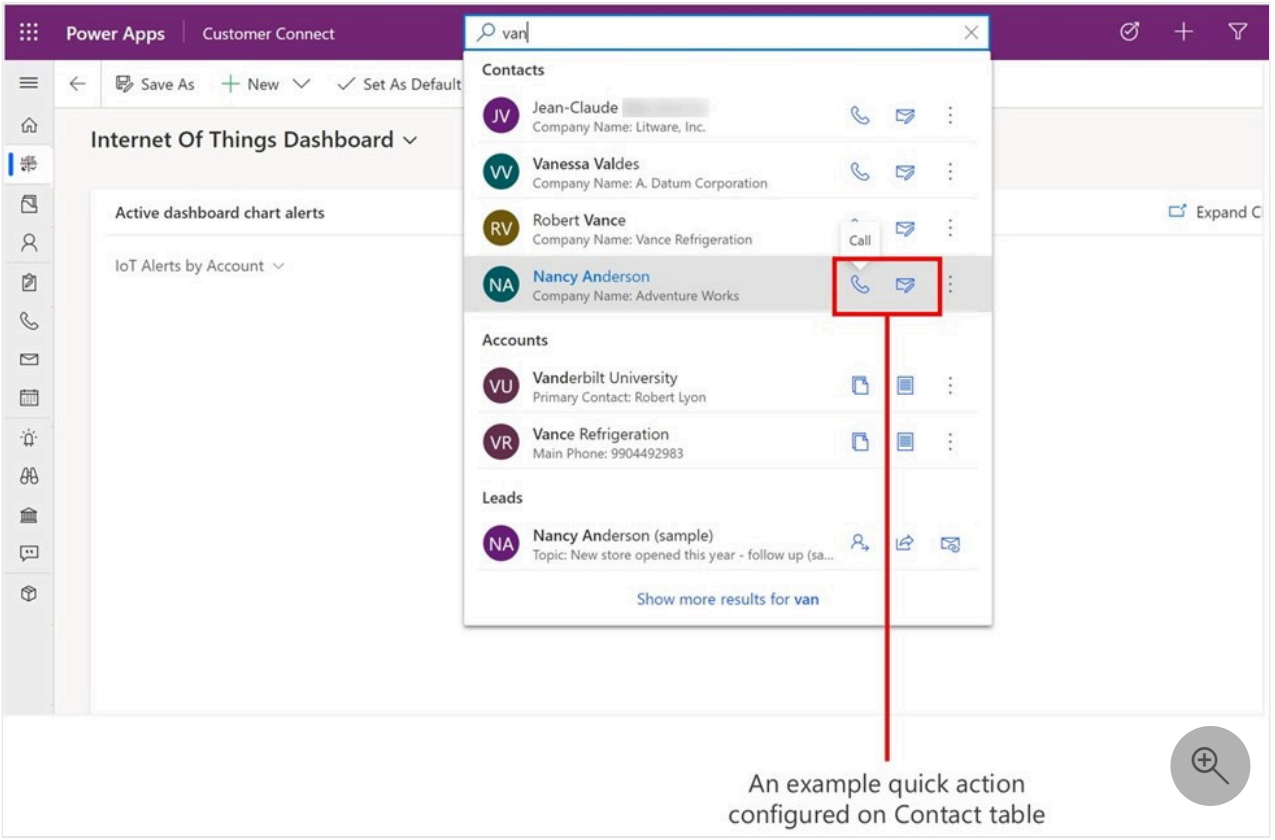


- **Associated view**. This command bar is displayed on the form of a parent table when viewing related data in this table. For example, from the main form of an account record

select the **Related** tab then select a related table like contacts.



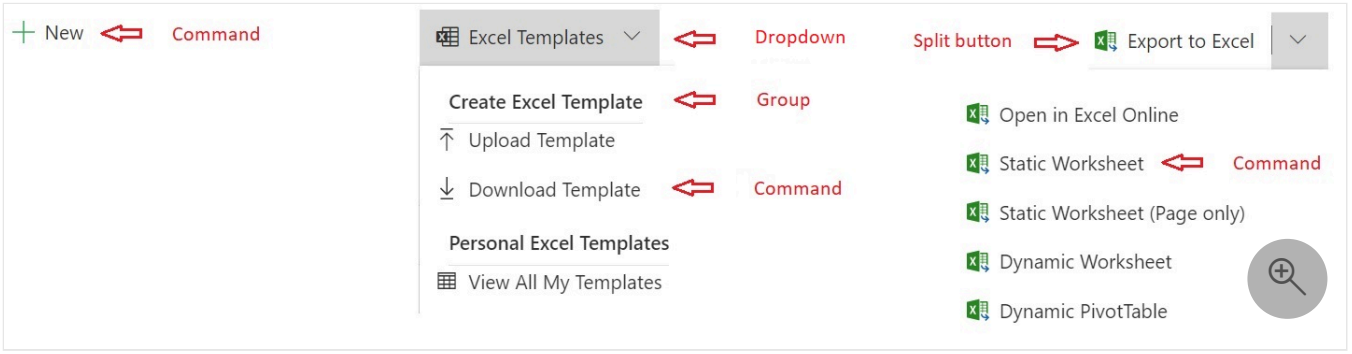
- **Quick actions**. Quick actions are associated with the main grid location. To add or edit commands for both quick actions and main grid locations, select the desired table from within the modern app designer, then edit the command bar and choose the main grid location. The first five commands, determined by order, are also shown as quick actions when playing the app.



> **Note**
>
> Less frequently customized command bar locations aren't supported in command designer. See the Global command bar and other ribbons sections for more information on customizing commands for these locations.

Types of commands

- **Command**. Standard button. Performs an action when selected. Can also be nested in groups within dropdowns and split buttons. These were called flyouts in classic commanding.
- **Dropdown**. Creates a menu where you can organize commands within a group.
- **Group**. Add titles to groups of commands nested within dropdowns and split buttons.
- **Split button**. Similar to a dropdown, but has a primary command. When the split button is selected, the action from the primary command is executed. If the expand chevron is selected, the primary command won't be executed. Instead a list expands to show additional groups, flyouts, and commands.



Key differences between classic and modern commands

Classic commands (formerly known as the ribbon) weren't customizable using low code. With code, command customizations were difficult, tedious, and error prone. In order to scale commanding to low code as well as use custom pages to converge canvas and model-driven apps, it was vital to reinvent and rebuild the command infrastructure.

Modern commanding offers many new capabilities and is much simpler to use.

Expand table

Capability	Classic	Modern
Supported in model-driven app runtime	Yes	Yes, Additionally supports Power Fx runtime.
Customized using	Hand editing XML within solution files or using non-Microsoft tools. Requires time-consuming solution export and import operations.	Command designer as well as Dataverse API support.
Supports Power Fx.	No	Yes. For actions and visibility.
Time required to customize	Slow, error prone.	Fast
Reliability and performance	Easy to make mistakes. Bad customization and lack of scoping often impact app performance.	Inline error handling prevents mistakes. Power Fx optimized for better runtime performance.
Sharing	Standard Dataverse role-based security.	Non-Power Fx commands use standard Dataverse role based security. Power Fx commands currently require the command component library to be shared in addition to having an appropriate security role.
Solution and application lifecycle management (ALM) behaviors	Inconsistent and problematic solution layering, no presence in solution interface. Many standard solution behaviors not supported such as patches, segmentation, solution upgrade, managed properties, and many more.	Standard solution layering centrally managed for multiple solution object types within Dataverse. Present in solution interface. All standard solution behaviors supported.
Localization	Nonstandard	Standardized using export and import translations for the entire solution.
Data model	Complex. Optimized for classic ribbons and contain many properties that are no longer needed.	Simple, optimized for today's model-driven app command bars.
Use JavaScript	Yes	Yes. Now simpler. The same JavaScript can be used for classic and modern commands.
Customize out of the box commands	Yes	Commands become editable in command designer once migrated to the modern framework.

Capability	Classic	Modern
App specific commands	No	Yes. Using modern command designer ensures commands are only visible within the selected app.
Table specific commands that display in all apps containing the table	Yes	Yes. Requires modifying the `appaction` definition within the solution file.
Global commands that display for all tables and apps for the specified command bar location	Yes	Yes. Requires modifying the `appaction` definition within the solution file.
Create split buttons, flyouts, and groups	Yes	Yes
Dynamically populate a flyout with code	Yes	No. Create commands declaratively.
Customize global application header commands	Yes	No
Customize commands for other, uncommon, or obsolete command bar locations	Yes	No.
Run a modern flow or workflow	Using JavaScript	Using JavaScript. Also supported using a custom page.

Classic versus modern visibility rule comparison

Classic visibility rules often had a specific rule for each scenario. With Power Fx, a declarative function replaces many classic rules. And it’s much simpler to use.

Classic visibility rules are also supported within modern commands. However, support for classic rules was needed for reliably migrating classic commands to modern commanding and classic rules customization within command designer isn't supported. We recommend you use Power Fx going forward.

Expand table

Use case	Classic Rule	Classic options	Power Fx visible property
Show or hide based on data values	CustomRule	Use JavaScript	!IsBlank(Self.Selected.Item.Email)
Show or hide based on table permission	EntityPrivilegeRule	Multiple	DataSourceInfo()
Show or hide based on record permission	RecordPrivilegeRule	Multiple	RecordInfo()
Reference the control context for primary and related tables	EntityRule	PrimaryEntity. SelectedEntity	Self.Selected
Reference the control context	EntityRule	Form. HomePageGrid. SubGridStandard. SubGridAssociated	Self.Selected
Table metadata properties	EntityPropertyRule		DataSourceInfo()
Show or hide based on form state. For example, show for the create form	FormStateRule	Create. Existing. ReadOnly. Disabled. BulkEdit	Self.Selected.State = FormMode.New
Show when > 1 records are selected in a grid	SelectionCountRule		CountRows(Self.Selected.Items) > 1
Show or hide for a related table in a polymorphic lookup. For example, check whether the lookup is a user or a team	CustomRule	PrimaryEntityTypeCode	IsType(), AsType
Reference environment properties (Org)	CustomRule	OrgName. OrgLcid. UserLcid	Not currently available

Frequently asked questions

- *Why do I see more commands in the designer than I see in my app?*

    - There are several reasons. Sometimes there's visibility logic that hides the command when running the app. Other times these commands are dynamically injected via custom JavaScript during runtime and aren't configurable.
- *Why do I see duplicate commands in the designer?*
    - This was a common pattern used with classic commands. Both commands wouldn't show up in runtime as they were controlled by visibility rules. The command designer shows all commands, regardless of their visibility rules.

Edit system table messages (preview)

Article • 03/13/2023

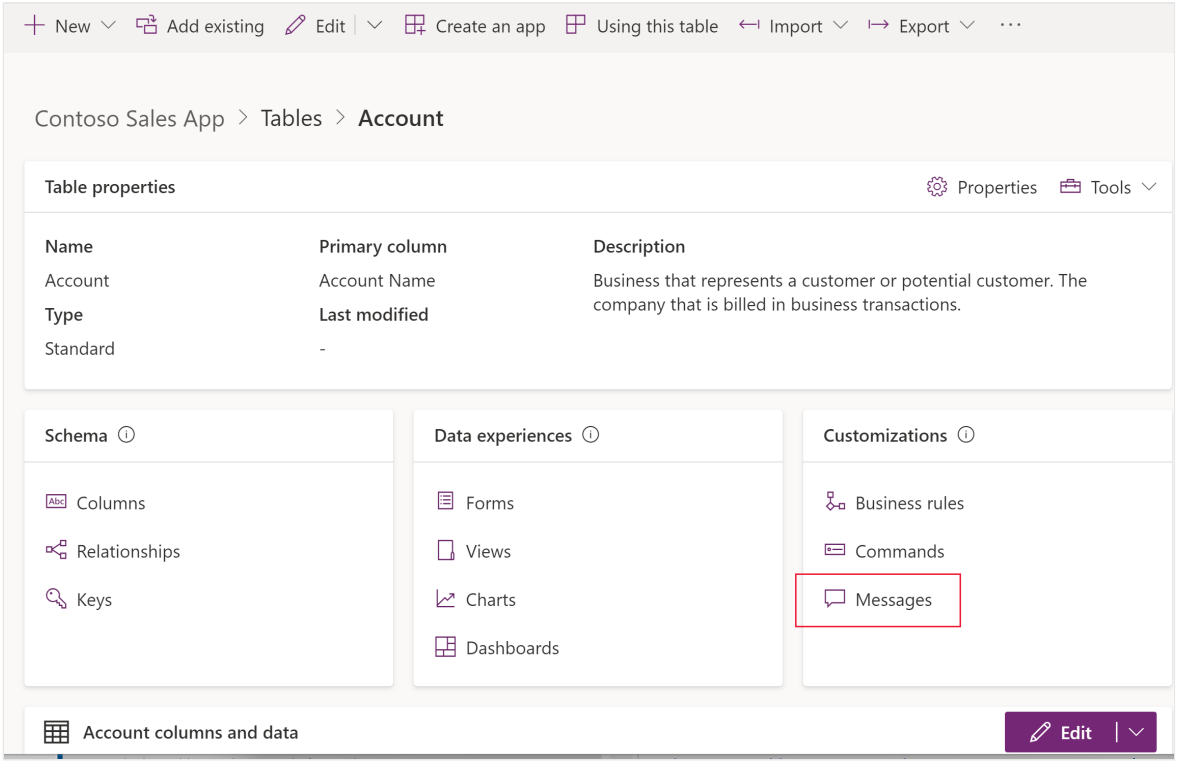
[This topic is pre-release documentation and is subject to change.]

The default display name of some system tables, such as account and contact tables, is used in user interface text and error messages in Microsoft Dataverse. If you change the display name for a system table, you should also update any messages that use the default display name. For example, if you change the display name from *Account* to *Company*, you could still see an error message using the old name.

> **Important**
>
> This is a preview feature. More information: **Model-driven apps and app management**

Add a message to a system table

1. Sign into Power Apps (make.powerapps.com).
2. Go to **Solutions**, open the solution that has the table you want, and then open the table. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. In the **Customizations** area, select **Messages**.

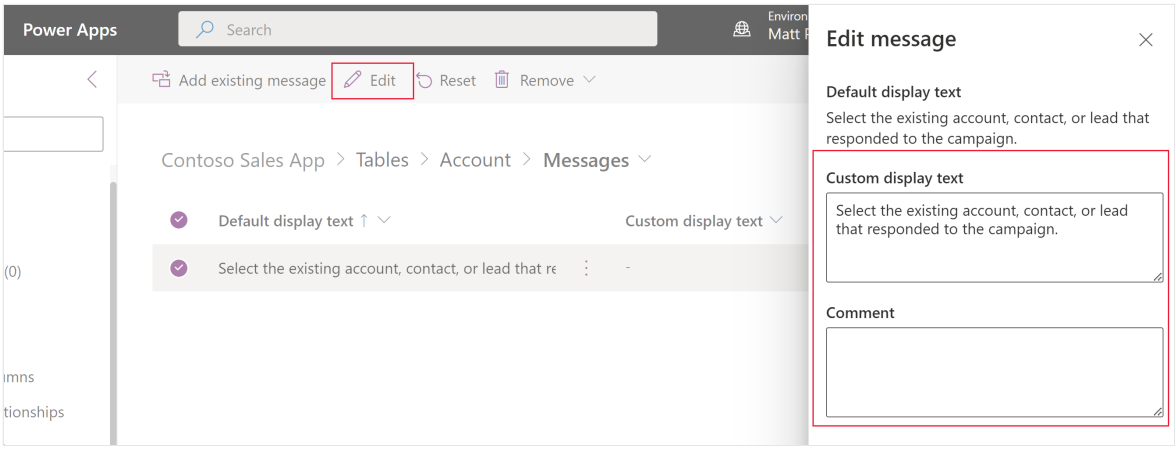


4. Select the message you want, and then select **Add**.

Edit a system table message

1. Open the table that has the message you want to edit, and then in the **Customizations** area select **Messages**.

2. Select the message, and then select **Edit** on the command bar. Enter the changes you want:



Field	Description
Default display text	Shows the original text, which isn't editable.
Custom display text	Edit this text to change the message that is displayed.
Comment	Optional. Include a comment about what you changed and why.

3. Select **Done**.

Programmatically update table display strings

For developers looking for a way to work with these in code, the display strings are stored in the DisplayString table.

The `DisplayString` table doesn't contain the default display strings. The two attributes for this table that contain text are CustomDisplayString and PublishedDisplayString. By default, these attribute values are null unless the display string has been customized and published. The `PublishedDisplayString` value is read-only and reflects the currently published `CustomDisplayString`.

Edit using the classic experience

For information about how to edit system table messages using the classic experience, see Edit system entity messages and display names.

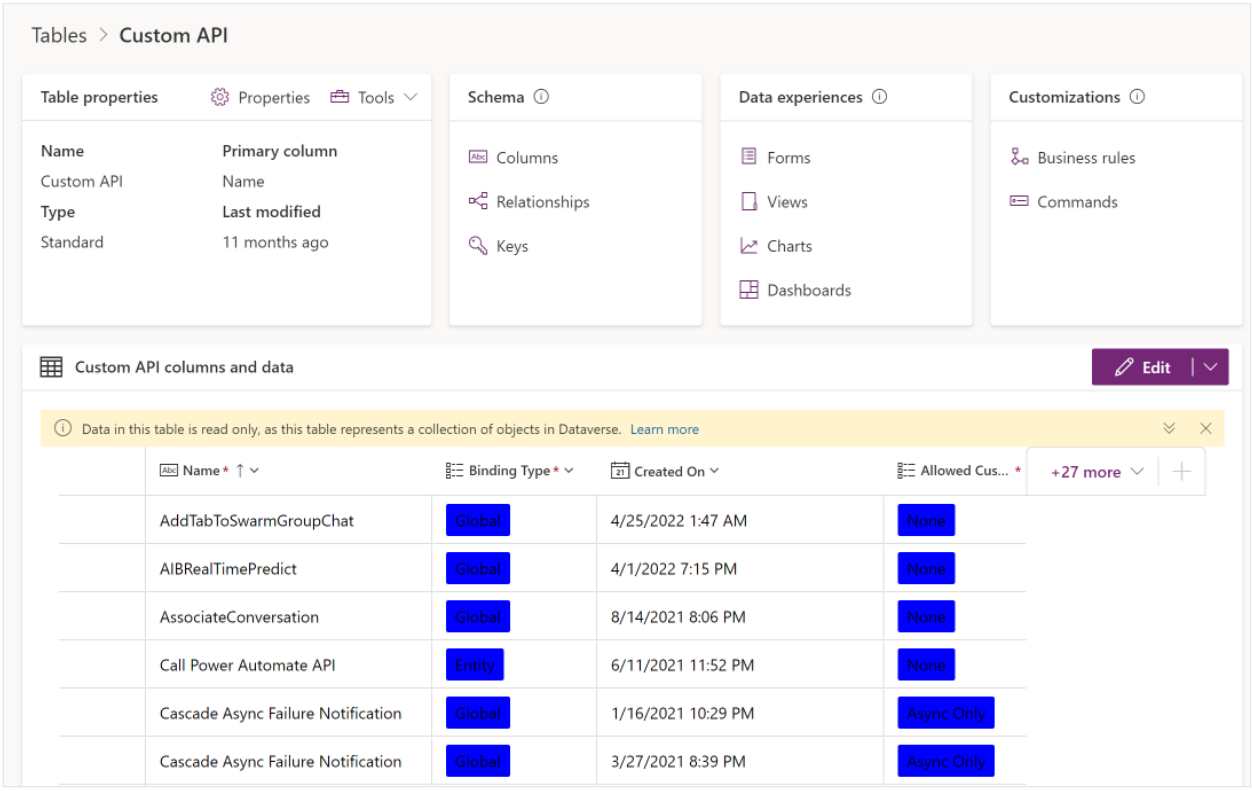
View and edit tables representing solution objects

Article • 08/08/2023

Some standard tables in Dataverse represent the structure and instances of solution objects. If you aren't familiar with solutions, go to Solutions overview.

For example, the **Custom API** table has columns that represent the properties of an API, such as **Name** and **Binding Type**, with each row of data in the table representing a particular API instance. For more information about Custom API table, go to Custom API table columns



When viewing these tables in Power Apps (make.powerapps.com), you'll see a warning stating that the data in the table is read only. This ensures the instances of these objects aren't changed.

To update data in such tables, you must navigate to the respective objects in the solution. In our example of custom API, you can open a solution that contains the custom API object or add the custom API object to a new solution and then customize the data as required.

Define alternate keys using Power Apps

Article • 05/15/2025

Power Apps provides an easy way to view and create table alternate keys with Microsoft Dataverse. *Alternate keys* provide an efficient and accurate way of integrating data with external systems. It's essential in cases when an external system doesn't store the globally unique identifier (GUID) IDs that uniquely identify rows in Microsoft Dataverse. For more information about alternate keys, see Define alternate keys to reference rows.

> **Important**
>
> If the data within a column that is used in an alternate key contains one of the following characters `/`, `#`, `<`, `>`, `*`, `%`, `&`, `:`, `\\`, `?`, `+` then `GET` or `PATCH` actions won't work. If you only need uniqueness, then this approach works, but if you need to use these keys as part of data integration then it's best to create the key on columns that won't have data with those characters.

View alternate keys

1. In Power Apps, go to **Solutions** and open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **Tables** on the left **Objects** pane, and then open the table that you want to view.
3. In the **Schema** area, select **Keys** to view a list of any alternate keys that might be defined.

Create an alternate key

1. While viewing alternate keys, select **New key**.

2. In the Key properties pane, enter the following information:
   a. Set a **Display name** and choose the columns to use to create the alternate key.
   b. The **Name** column is populated based on the display name. You can change it if you want.
   c. Select the columns that you want. For example, to identify an account row with an alternate key, you can use the **Account Number** column in combination with some other column, such as the **SIC Code**, which have values that shouldn't change.

Key

Display name *

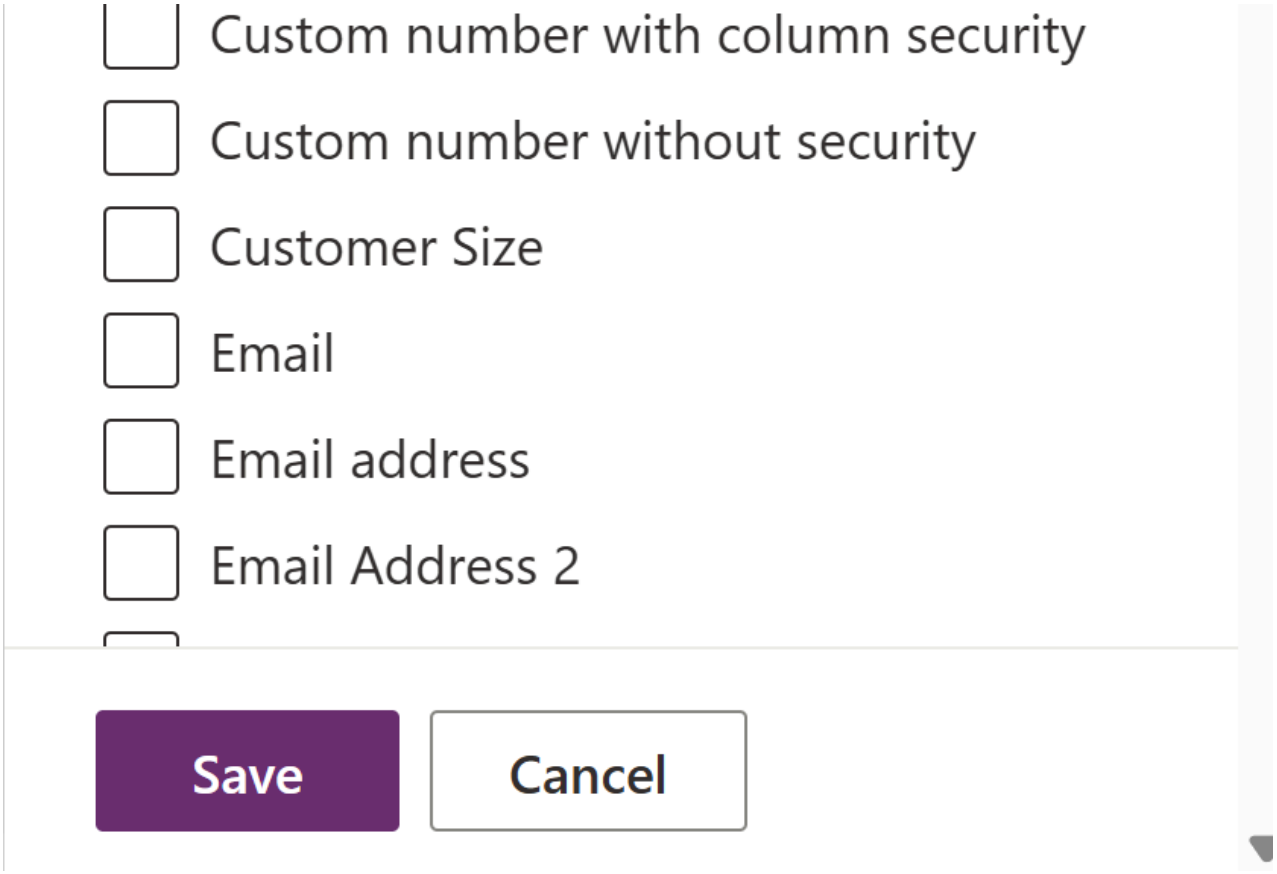
Account Number + SIC Code

Name *

contoso_ AccountNumberSICCode

Columns *

- [ ] (Deprecated) Traversed Path
- [ ] Account Name
- [x] Account Number
- [ ] Account Rating
- [ ] Business Type
- [ ] Category
- [ ] Classification
- [ ] Color
- [ ] Created By (IP Address)
- [ ] Created By (User Name)
- [ ] Currency



3. Select **Save** to create the alternate key.

> **Note**
>
> The alternate key isn't immediately available for use. A system job is initiated when you save the table to create database indexes to support the alternate key.

Delete an alternate key

While viewing alternate keys, select the key you want to delete and select **Remove** > **Remove from this solution** or to delete the key from the Power Platform environment **Delete from this environment** on the command bar.

Developer Documentation: Work with alternate keys

Define alternate keys using solution explorer

Article • 05/30/2023

Solution explorer provides one way to view and create alternate keys for Microsoft Dataverse.

The Power Apps portal enables configuring the most common options, but certain options can only be set using solution explorer.
More information:

- Define alternate keys to reference rows
- Define alternate keys using Power Apps portal

> **Important**
>
> If the data within a column that is used in an alternate key will contain one of the following characters `/,<,>,*,%,&,:,\\,?,+` then `GET` or `PATCH` actions will not work. If you only need uniqueness then this approach will work, but if you need to use these keys as part of data integration then it is best to create the key on columns that won't have data with those characters.

Open solution explorer

Part of the name of any alternate key you create is the customization prefix. This is set based on the solution publisher for the solution you're working in. If you care about the customization prefix, make sure that you are working in an unmanaged solution where the customization prefix is the one you want for this table. More information: Change the solution publisher prefix

Open an unmanaged solution

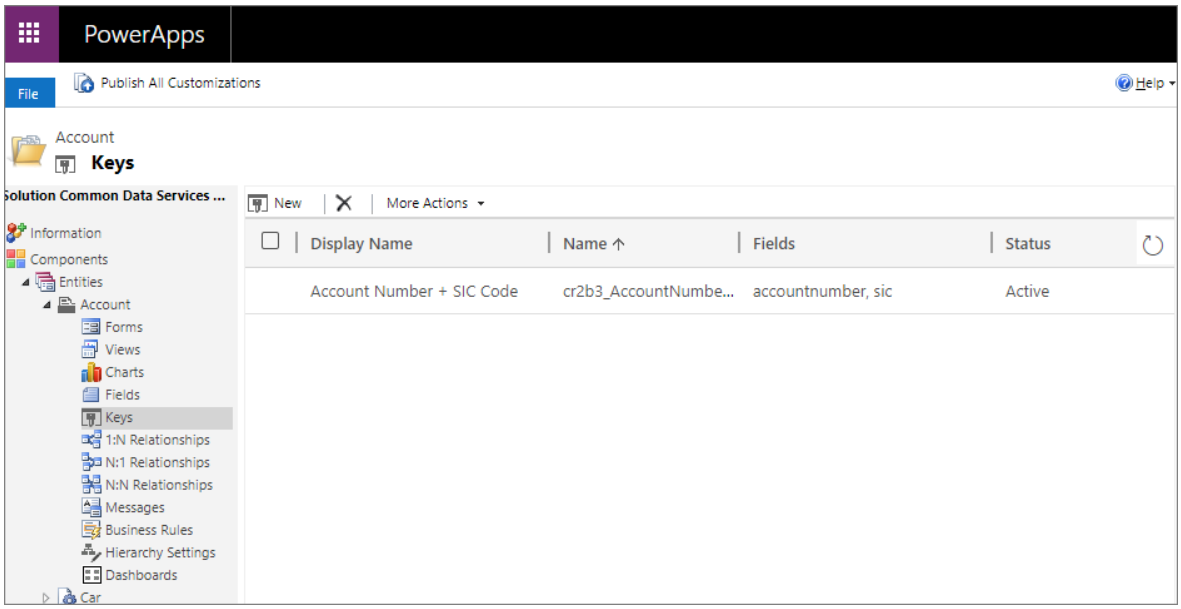
1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

View alternate keys

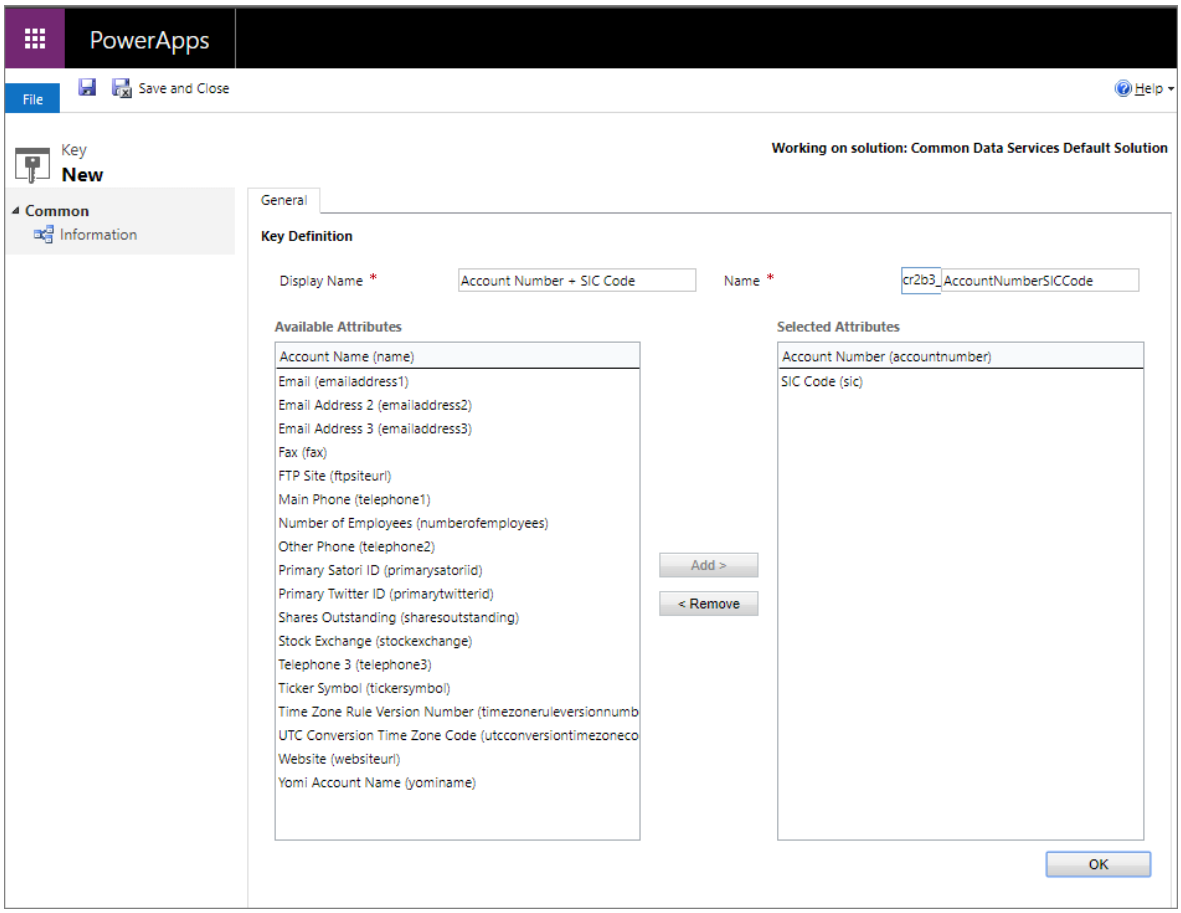
1. With solution explorer open, under **Components** expand **Entities** and select the table where you want to view alternate keys.

2. Expand the table and select **Keys**.



Create an alternate key

1. While viewing alternate keys, select **New**.
2. On the form, enter the **Display Name**. The **Name** column will be auto-populated based on the **Display Name**.
3. From the **Available Attributes** list, select each attribute and then **Add** > to move the attribute into the **Selected Attributes** list.



4. Select **OK** to close the form.

(Optional) View the system job tracking creation of indexes

1. While viewing alternate keys after you have created a new alternate key you will see a row for the key you created.

2. In the **System Job** column you will find a link to the system job that monitors the creation of the indexes to support the alternate key.

   This system job will have a name that follows this pattern: `Create index for {0} for table {1}` where `0` is the **Display Name** of the alternate key and `1` is the name of the table.

   The link to the system job will not be displayed after the system job completes successfully. More information: Monitor system jobs

Delete an alternate key

While viewing alternate keys, select ✕.

Update forms and views using table designer

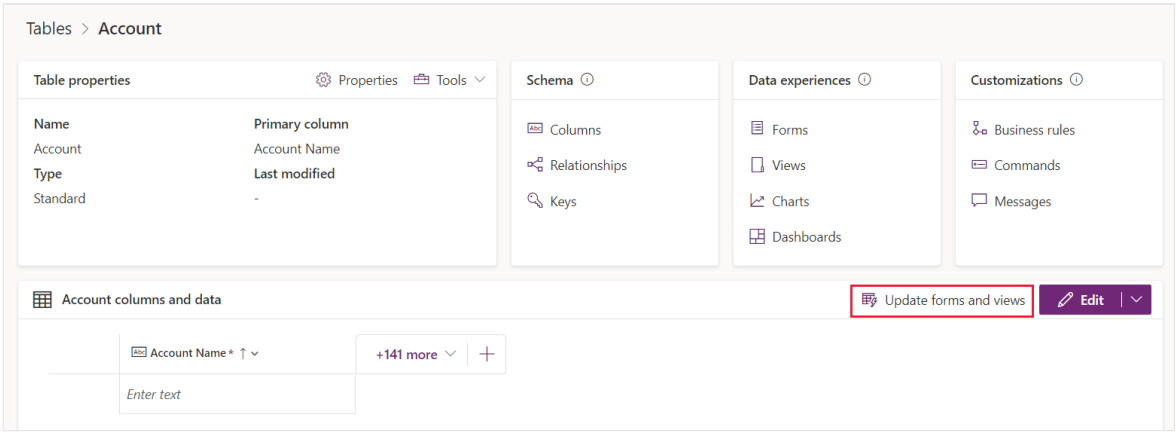
Article • 08/25/2023

Create columns directly in the table hub or table designer, which will then be added to your forms and views. In this walkthrough, you'll learn how to simply add the columns you created to forms and views of this table without manually doing so in the form or view designer.

Using table hub and table designer

1. Sign in to Power Apps.

2. In the left navigation pane, select **Tables**, and then select the table that you want to update from the table list. In the table hub and table designer, there's an **Update forms and views** option that allows you to directly add columns to selected forms and views in this table.



3. Select **Update forms and views** to configure what columns should be added to certain forms and views:

Property	Description	Available option	Default option
Add these columns	Selected columns in this dropdown list will be added to the selected forms and views.	Only columns currently shown in the table preview.	Both new columns that are recently created and existing columns that are

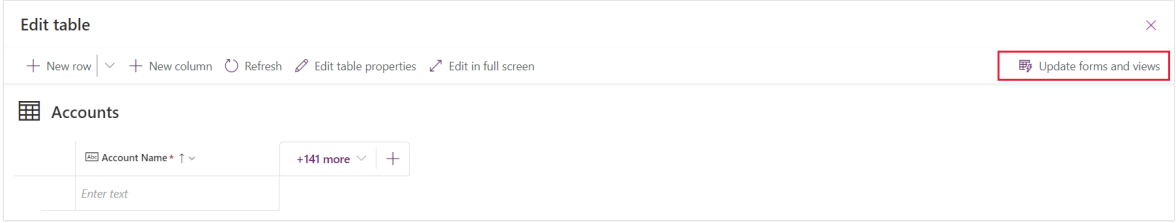
Property	Description	Available option	Default option
			recently added to the table.
To these forms	Columns selected in **Add these columns** will be added to selected forms. If a certain column has already been added to this form before, it won't be added again as a duplicate.	All main, quick create, and quick view forms from this table.	All Main forms from this table.
And to these views	Columns selected in **Add these columns** will be added to selected views. If a certain column has already been added to this view before, it won't be added again as a duplicate.	All public, advanced find, associated, quick find, and lookup views from this table.	All public, advanced find, associated, and quick find views from this table.

4. Once you're done with the configuration, select **Update**. The columns you selected are added to the forms and views you selected.

Using inline table designer in modern app designer

You might be working on a table in the modern app designer as you're building an app. In this case, you can also update your forms and views directly using the inline table designer in the modern app designer:

1. Sign in to Power Apps.
2. On the left navigation pane, select **Apps**, select the app you want, and then select **Edit**.
3. In the left navigation pane within the modern app designer, select **Data**, then **...** > **Edit table** to edit your table using the inline table designer.
4. The **Update forms and views** option is displayed in the inline table designer:



Follow the same steps in 3 and 4 as in the table hub and table designer to update your forms and views. You can also add the columns you want to your table. When you're finished with the update, select **Update and close** at the bottom right of the inline table designer. The columns are added to the forms and views preselected for you, and the inline table designer is closed.

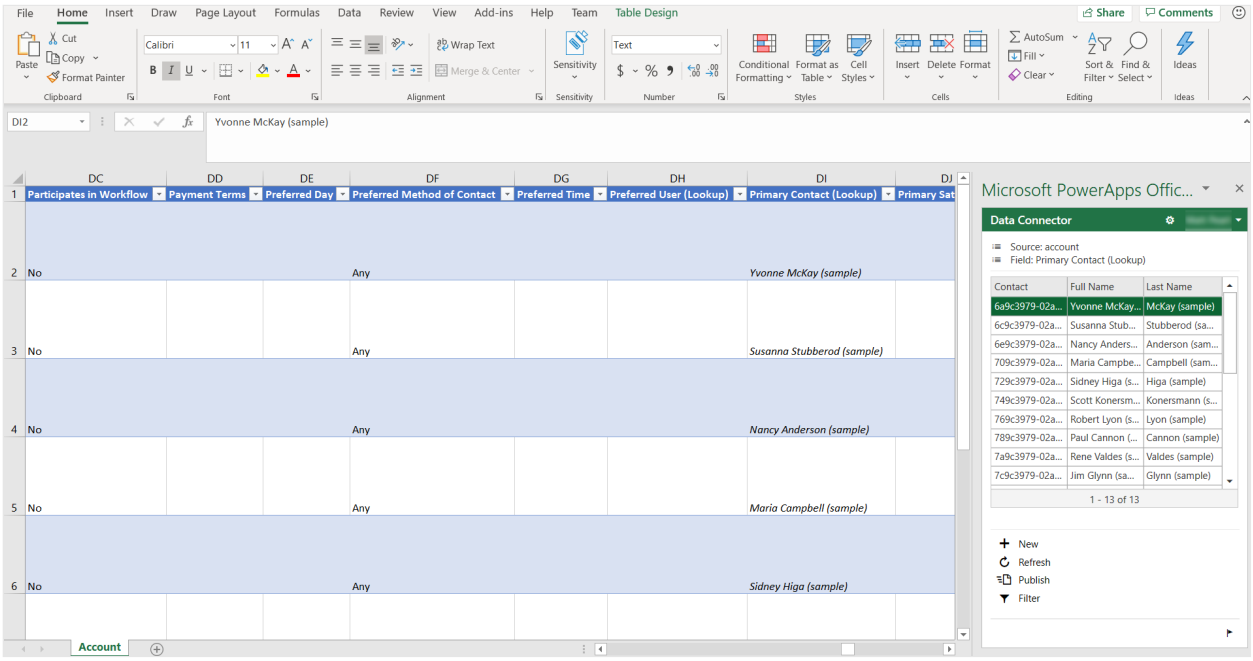
Open table data in Excel

Article • 03/13/2023

By opening table data in Microsoft Excel, you can quickly and easily view and edit data by using the Microsoft Power Apps Excel Add-in.



To install the Power Apps Excel add-in, see Microsoft PowerApps Office Add-in. For more information about how to add or remove an Office Excel Add-in, see Add or remove add-ins in Excel.

Open table data in Excel

1. Sign in to Power Apps.
2. In the left navigation pane, select **Tables**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. Select the ellipsis (...) to the right of the table that you're interested in, and then select **Edit data in Excel**.
4. Open the Excel worksheet that is downloaded to your browser's default download folder named similar to *table-name (1591125669213).xlsx*. This workbook has binding information for the table, a pointer to your environment, and a pointer to the Power Apps Excel add-in.
5. In Excel, select **Enable editing** to enable the Power Apps Excel Add-in to run. The Excel add-in runs in a pane on the right side of the Excel window.

> **ⓘ Important**
>
> If the pane displays an error message, see **Office Store Add-in download disabling**.

6. If this is the first time that you've run the Power Apps Excel add-in, select **Trust this Add-in** to allow the Excel add-in to run.

7. If you're prompted to sign in, select **Sign in**, and then sign in by using the same credentials that you used on Power Apps. The Excel add-in will use a previous sign-in context and automatically sign you in if it can. Therefore, verify the user name in the upper right of the Excel add-in.

The Excel add-in automatically reads the data for the table that you selected. Note that there will be no data in the workbook until the Excel add-in reads it in.

View and refresh data in Excel

After the Excel add-in reads table data into the workbook, you can update the data at any time by selecting **Refresh** in the Excel add-in.

Edit data in Excel

You can change table data as you require and then publish it back by selecting **Publish** in the Excel Add-in.

To edit a row, select a cell in the worksheet, and then change the cell value.

To add a new row, follow one of these steps:

- Select anywhere in the worksheet, and then select **New** in the Excel add-in.
- Select in the last row of the worksheet, and then press the Tab key until the cursor moves out of the last column of that row, and a new row is created.
- Select in the row immediately below the worksheet and start to enter data in a cell. When you move the focus out of that cell, the worksheet expands to include the new row.

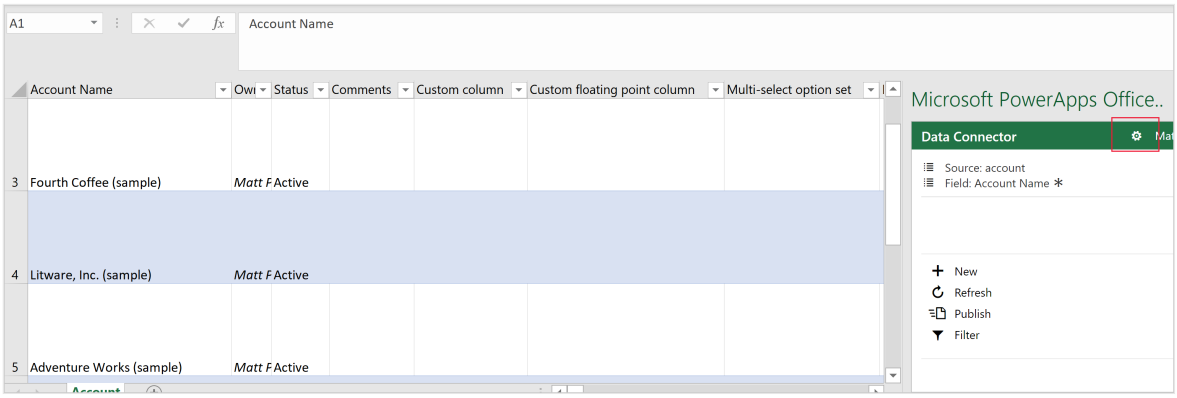
To delete a row, follow one of these steps:

- Right-click the row number next to the worksheet row to delete, and then select **Delete**.
- Right-click in the worksheet row to delete, and then select **Delete** > **Table Rows**.

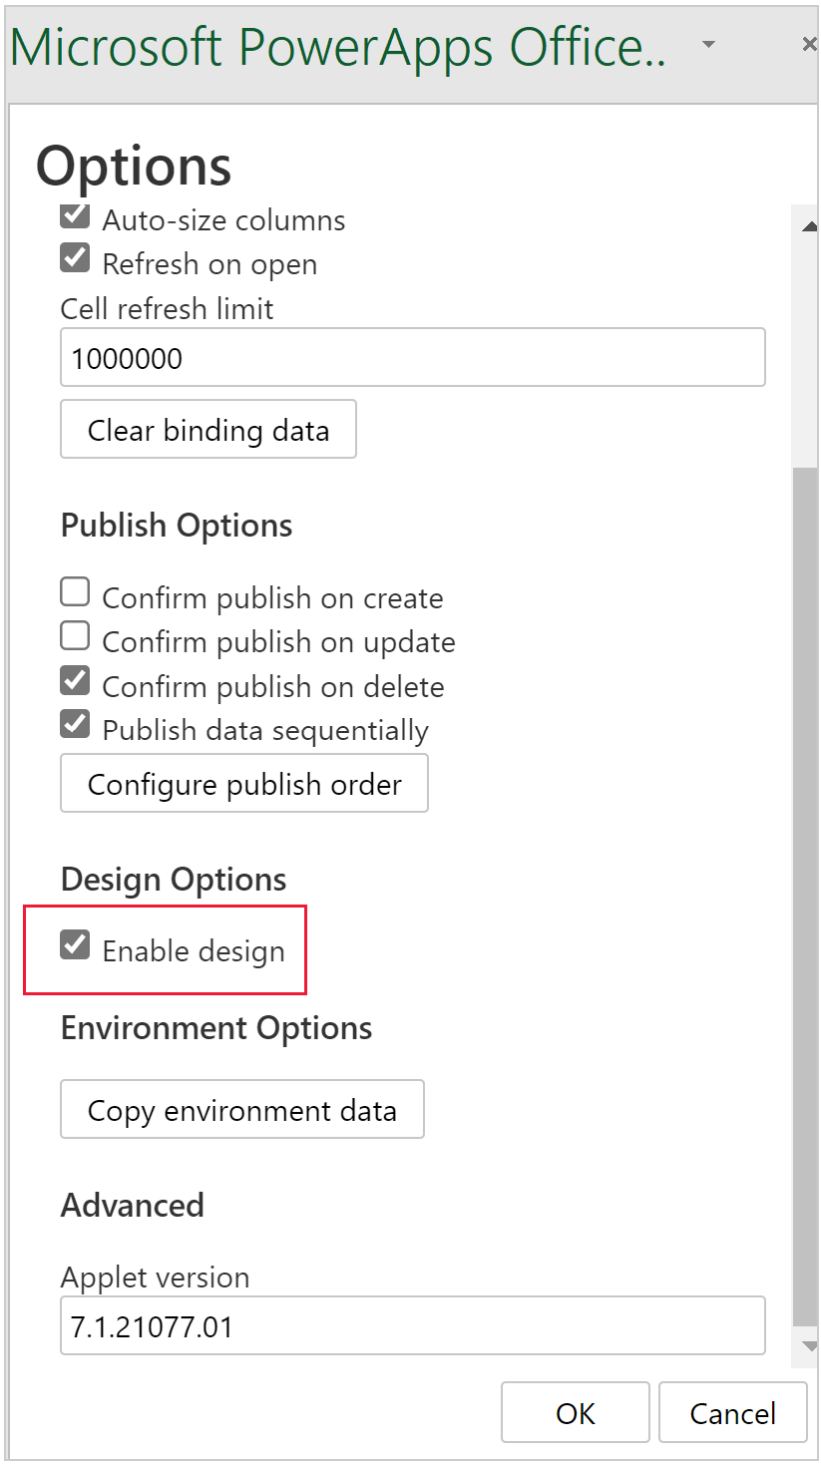
Configure the add-in to adjust tables and columns

You can use the data source designer in the Excel add-on to adjust the columns and tables that are automatically added to the worksheet.

1. Enable the data source designer of the Excel add-in by selecting the **Options** button (the gear symbol).



2. Expand the **Data Connector** section, and then select the **Enable design** check box, and then select **OK**.



3. Select **Design** in the Excel add-in. All the data sources are listed.

4. Next to the data source, select the **Edit** button (the pencil symbol).

5. Adjust the list in the **Selected columns** column as you require:

   - To add a column from the **Available columns** column to the **Selected columns** column, select the column, and then select **Add**. Alternatively, double-click the column.
   - To remove a column from the **Selected columns** column, select the column, and then select **Remove**. Alternatively, double-click the column.

- To change the order of columns, select the column in the **Selected columns** column, and then select **Up** or **Down**.

6. Apply your changes to the data source by selecting **Update**, and then select **Done** to exit the designer. If you added a column (column), select **Refresh** to pull in an updated set of data.

> **Note**
>
> - Make sure to always include the ID and required columns in your workbook, as you may receive errors when publishing.
> - When adding look up columns, make sure to add both the **ID** and the **Display** columns.

Troubleshooting

- Not all tables support editing and creation of new rows, these tables will open in Excel and allow you to view data but publishing will be disabled.
- Look up columns must be edited using the add-in to ensure the correct row is referenced, updating these columns via copy and past or typing directly into the column is not supported.
- Image and file columns are not supported. You won't be able to see any data when you open an Excel worksheet that includes those data types.
- The maximum table size when editing in Excel is one million cells. If there are too many rows or columns, not all data will be read or published.
- Rows are processed sequentially. If there is an error in saving a row, changes to subsequent rows will be aborted. Changes to preceding rows are kept.
- Centralized deployment is not supported. This add-in requires access to the Office store.
- Manually configuring the add-in might cause unexpected behavior. For best results, download the Excel file with Power Apps instead of starting from a blank Excel workbook.

If you encounter an issue that isn't described here, contact us via the support pages.

Office Store add-in download disabling

If Office Store add-in downloading has been disabled for your organization, you might receive the following error message when you open the Excel worksheet after selecting the Edit data in Excel command.

Office 365 has been configured to prevent individual acquisition and execution of Office Store Add-ins.

This setting prevents the Power Apps Excel Add-in from downloading. When this occurs, table row data will not be displayed in Excel.

For more information about enabling Office Store Add-in downloading, contact your Office app administrator.

For more information about preventing Office Store Add-in downloading from the Office Store, see Prevent add-in downloads by turning off the Office Store across all clients.

Other ways to export and view table row data

For more information about ways to export and view table row data, see these articles.

- Export data to CSV
- Export your data to Excel Online

Define alternate keys to reference rows

08/11/2025

Alternate keys provide an efficient and accurate way of integrating data with external systems. It's essential in cases when an external system doesn't store the Globally Unique Identifier (GUID) IDs that uniquely identify rows in Microsoft Dataverse.

A data integration system uses alternate keys to uniquely identify rows using one or more table column values that represent a unique combination. Each alternate key has a unique name.

For example, to identify an account row with an alternate key, you can use the account number or the account number column in combination with some other columns, which have values that shouldn't change.

> **Note**
>
> While you can define alternate keys with Power Apps, they can only be used programmatically in code. To learn more about using alternate keys programmatically, see:
>
> - Developer Documentation: Use an alternate key to reference a record
> - Developer Documentation: Retrieve record using an alternate key

Some of the benefits of the alternate keys feature include:

- Faster lookup of the rows.
- More robust bulk data operations.
- Simplified programming with data imported from external systems without row IDs.

Creating an alternate key

There are two designers you can use to create alternate keys:

Expand table

Designer	Description
Power Apps portal	Provides an easy streamlined experience, but some options aren't available. More information: Define alternate keys using Power Apps portal
Solution explorer	Not as easy, but provides for more flexibility for less common requirements. More information: Define alternate keys using solution explorer

> **Note**
>
> You can also create an alternate key in your environment using the following:
>
> - Import a solution that contains the definition of the alternate key.
> - A developer can also write code to create them. More information: Developer Documentation: Work with alternate keys

Information in this article helps you choose which designer you can use.

You should use the Power Apps portal to create alternate keys unless you need to address any of the following requirements:

- Create an alternate key within a solution other than the Common Data Service Default Solution.
- You want to easily track the system job created that tracks the progress of creating the supporting indexes.

Limits in creating alternate keys

There are constraints on alternate key creation.

Fields that can be used for alternate keys

Only these kinds of columns can be used to create alternate keys:

- Decimal
- Whole Number (Integer)
- Single line of Text (String)
- Date and Time
- Lookup
- Choice

> **Note**
>
> - Columns that have the **Enable column security** property enabled can't be used as an alternate key. More information: Field security tables

- When NULL values are used in alternate key columns, uniqueness will not be enforced. To avoid duplicate records, don't use null values in the columns defined in the unique constraint of the alternate key.

Number of keys

You can define up to 10 different keys for a table.

Valid key size

When a key is created, the system validates that the key can be supported by the platform, including that the total key size doesn't violate SQL-based index constraints like 900 bytes per key and 16 columns per key. If the key size doesn't meet the constraints, an error message is displayed.

Unicode characters in key value

If the data within a column that is used in an alternate key contains one of the following characters `<`, `>`, `*`, `%`, `&`, `:`, `/`, `\\`, `#` then update or upsert (PATCH) actions won't work.

If you only need uniqueness, then this approach works, but if you need to use these keys as part of data integration then it's best to create the key on columns that doesn't have data with these characters.

Track the status of the creation of the alternate key

When an alternate key is created, it initiates a system job to create indexes on the database tables to enforce unique constraints on the columns used by the alternate key. The alternate key won't be in effect until these indexes are created. Creating these indexes might take some time depending on the amount of data in the system.

The status of the system job determines the state of the alternate key. The alternate key can have the following states:

- **Pending**
- **In Progress**
- **Active**
- **Failed**

When the system job is completed, the alternate key status is **Active** and it's available for use.

If the system job fails, locate the system job to view any errors. The system job will have a name that follows this pattern: `Create index for {0} for table {1}` where `0` is the **Display Name** of the alternate key and `1` is the name of the table.

> **Note**
>
> If you want to monitor the status of the system job you should use solution explorer to create the index. It will include a link to the system job so you can monitor it. More information: (Optional) View the system job tracking creation of indexes

Define status reason transitions for the Case or custom tables

Article • 06/21/2022

You can specify status reason transitions for the Incident (**Case**) table or a custom table.

> **Note**
>
> Although the Incident (Case) table isn't included in a default Microsoft Power Apps environment, it is used by **Dynamics 365 for Customer Service** and defined within the **Common Data Model**

Status reason transitions are an optional additional level of filtering to define what the status reason value can be changed to for each status reason. Defining a limited list of valid options can make it easier for people to choose the correct next status reason for a row when you have a large number of combinations for valid status reason values.

What is the connection between Status and Status Reason columns?

Tables that can have different status values have two columns that capture this data:

Display Name	Description
Status	Represents the state of the row. Typically **Active** or **Inactive**. You cannot add new status options.
Status Reason	Represents a reason that is linked to a specific status. Each status must have at least one possible status reason. You can add additional status reason options.

The metadata for the column defines what status values are valid for a given state. For example, for the Incident (**Case**) table, the default status and status reason options are:

Status	Status Reason
Active	• **In Progress** • **On Hold** • **Waiting for Details** • **Researching**

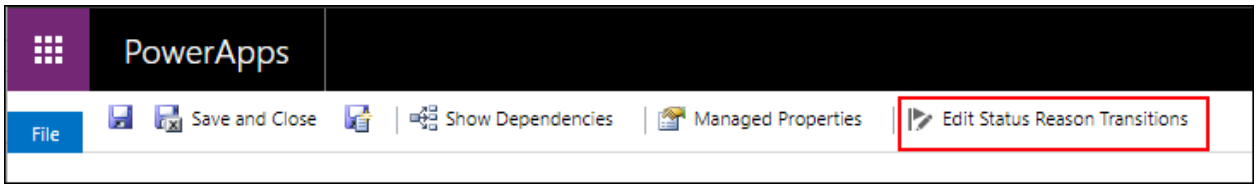
Status	Status Reason
Resolved	• Problem Solved • Information Provided
Canceled	• Canceled • Merged

Edit status reason transitions

You can modify the status reason column options for the Case table and custom tables to define which other status reason options people can choose. The only restriction is that each status reason option for an active status must allow at least one path to an inactive status. Otherwise you could create a condition where it would not be possible to resolve or cancel the case.

> ⓘ Note
>
> Editing the status reason transitions requires using solution explorer. See **Create and edit columns for Dataverse using Power Apps solution explorer** for information about how to edit columns.

When you edit a status reason column the **Edit Status Reason Transitions** button is in the menu.



When you click this button the **Status Reason Transitions** dialog provides the option to choose **Enable Status Reason Transitions**. When this option is selected you must define which *other* status reason values are allowed for each status reason. To remove the filtering applied, remove the **Enable Status Reason Transitions** selection. The transitions you have defined will be kept but not applied.

The screenshot below provides an example that meets the following requirements:

- A case can be merged at any time. You will not be able to merge cases if a status reason transition does not allow for it.
- An active case can be canceled at any time.
- A resolved or canceled case cannot be reactivated.

- All cases must pass through the following stages: **In Progress** > **On Hold** > **Waiting for Details** > **Researching** before they can be resolved. With this configuration, a case could not be set to an earlier status.

  > **Note**
  >
  > This is not a good example for real work, but it demonstrates how stages of status can be enforced through status reason transitions.

Define custom state model transitions

Delete a table

Article • 02/24/2023

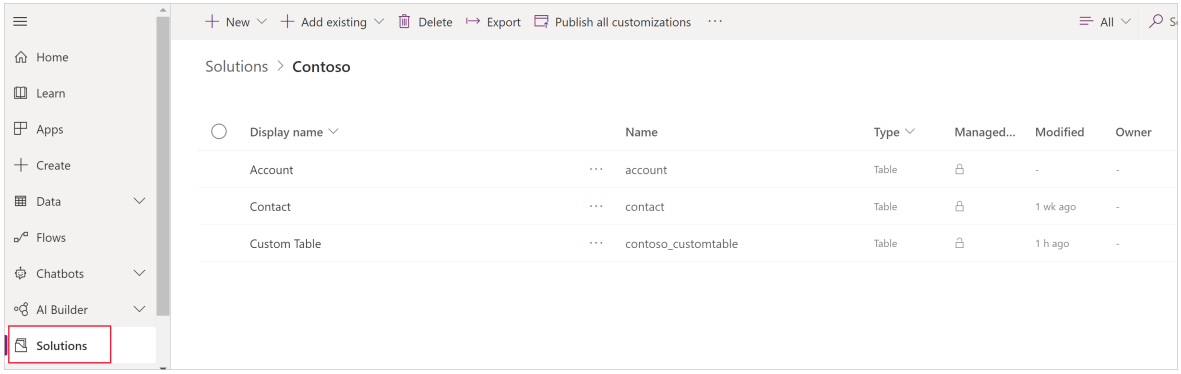
You can delete custom tables, but you can't delete standard tables. Notice that you can't delete a custom table while it has one or more dependent components. More information: Delete a table that has dependencies

> ⚠ **Warning**
>
> When you delete a table, you delete both the table definition and all data that the table contains. Tables and the data within them can't be recovered if deleted.

Delete a custom table

1. Sign into Power Apps, and then select **Solutions** in the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Open the solution that contains the custom table you want to delete, and then select it.



3. On the command bar select **Remove**, and then select from the following choices:

   - **Remove from this solution**. Removes the table from the solution. You can still access the table from the Default Solution.
   - **Delete from this environment**. Deletes the table and associated data.

4. In the dialog box that appears, select **Delete** to delete the table. If you receive a message that the *component cannot be deleted because it is referenced by other components*, see the next section in this article.

Delete a table that has dependencies

You can't delete a table while it has a dependency on another component, such as a business process flow or a model-driven app.

There are two ways that you can remove a dependency:

- Reconfigure the component to remove the dependency.
- Delete the component.

Remove a dependency

To find the dependencies for a component, see View dependencies for a component.

Next, remove the component. For example, if you have a business process flow that references a table you want to delete, edit the business process flow to remove that table. Once the business process flow no longer references that table, the table will no longer appear in the show dependencies list and can be deleted. More information: Delete a custom table

> **Important**
>
> Removing the dependency, can cause the component to no longer work. For example, removing a table from a model-driven app may cause the model-driven app to no longer work.

For more information, see these articles:

- Edit or remove artifacts
- Edit a business process flow
- Delete relationships

Display custom icons alongside values in list views

06/28/2025

Power Apps environment administrators and customizers can add graphics to a view and establish the logic used to select a graphic based on the column value using JavaScript. The capability lets you customize list views that display icons alongside text or numerical values.

This example displays custom icons in a view for the opportunity table, which is available with certain apps, such as Dynamics 365 Sales. You can display custom icons in views with other standard tables, such as the account or contact table, as well as custom tables.

Some interest in our JJ...	Adventure W...	Won	7/18/2013	$94,800.82	7/21/2013	$95,000.00	Warm

Custom icons in list views can display in model-driven apps, mobile app, and App for Outlook.

> **Note**
>
> - Custom icons aren't available when the app is in mobile offline mode.
> - This customization currently can only be completed by using the classic solution explorer.

Add custom graphics and JavaScript as web resources

1. Create the new graphic files needed for your customization. We recommend an icon size of 16x16 pixels (larger images will be scaled down).

2. Write one or more JavaScript functions that establish which icons to show for which values (you typically need one function for each column you want to customize). Each function must accept a row data object and a language (LCID) code as input and return an array containing an image name and tooltip text. For an example function, see Sample JavaScript function, later in this article.

3. Sign into your environment and open solution explorer.
4. The solution tab opens. Go to **Components** > **Web Resources**.
5. Now, upload your custom graphics, one at a time, as web resources. Select **New** on the toolbar to create a new web resource. A pop-up window opens to help you create the resource. Follow these steps:
    a. Give the new resource a meaningful **Name**. This is the name that you use to refer to each graphic from your JavaScript code.
    b. Set the **Type** to the graphic format you've used to save your graphic file (PNG, JPEG, or GIF).
    c. Select **Choose File** to open a file browser window. Use it to find and select your graphic file.
    d. Add a **Display Name** and/or **Description** if you wish.
    e. Select **Save** and then close the **Web Resource** window.
6. Repeat the previous step for each graphic file that you have.
7. Now, add your JavaScript as the final web resource. Select **New** on the toolbar to create a new web resource. Another pop-up window opens to help you create the resource. Do the following:
    a. Give the new resource a meaningful **Name**.
    b. Set the **Type** to **Script (JScript)**.
    c. Select **Text Editor** (next to the **Type** setting) to open a text-editor window. Paste your JavaScript code here and select **OK** to save it.
    d. Add a **Display Name** and/or **Description** if you wish.
    e. Select **Save** and then close the **Web Resource** window.
8. With the solution tab still open, expand the **Components** > **Tables** tree and locate the table that you want to customize.
9. Expand your table and select its **Views** icon.
10. You now see a list of views for your selected table. Select a view from the list. Then open the **More Actions** drop-down list in the toolbar and select **Edit**.

11. A pop-up window opens with controls for editing your selected view. It shows each column that is part of the view. Select the target column and then select the **Change Properties** in the **Common Tasks** box. The **Change Column Properties** dialog opens; make the following settings here:

    - **Web Resource**: Specify the name of the web resource that you created to hold your JavaScript functions (select **Browse** to choose from a list).
    - **Function Name**: Type the name of the function that you wrote to modify the selected column and view.

12. Select **OK** to close the **Change Column Properties** dialog.
13. Select **Save and Close** to save your view.
14. Repeat these steps for each table, view, and column as needed.
15. When you're ready, select **Publish All Customizations** to publish your changes. Then, close the **Default Solution** window.

Sample JavaScript function

The JavaScript function for displaying custom icons and tooltips expects the following two arguments: the entire row object specified in layoutxml and the calling user's Locale ID (LCID). The LCID parameter enables you to specify tooltip text in multiple languages. For more information about the languages supported by the environment, see Enable languages and Install or upgrade language packs. For a list of locale ID (LCID) values that you can use in your code, see Locale IDs assigned by Microsoft.

Assuming you're adding custom icons for an option-set type of attribute, which has a limited set of predefined options, make sure you use the integer value of the options instead of label to avoid localization issues.

> ⓘ **Note**
>
> If it's necessary to retrieve data to determine the icon, Unified Interface supports returning a JavaScript Promise object, which resolves to a boolean (similar to ribbon rules). Don't use a synchronous `XMLHttpRequest` (XHR) in your custom function.

The sample code displays icons and tooltips based on one of three values (1: Hot, 2: Warm, 3: Cold) in the `opportunityratingcode` (Rating) attribute. The sample code also shows how to display localized tooltip text. For this sample to work, you must create three image web resources with 16x16 images with the following names: new_Hot, new_Warm, and new_Cold.

> **Important**
>
> This sample requires the opportunity table, which is available with Dynamics 365 Sales app.

JavaScript

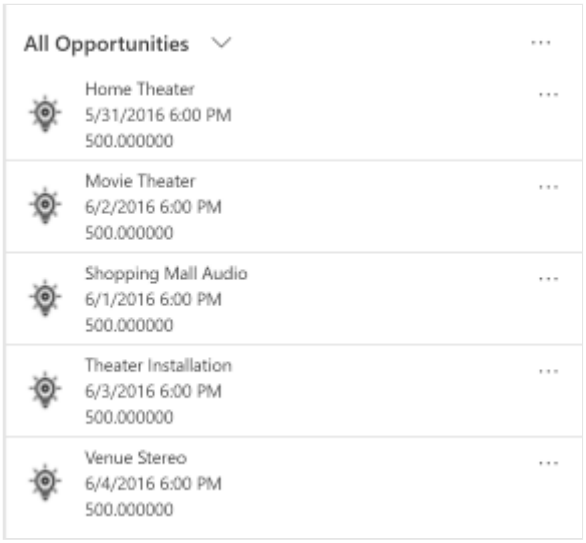
```
function displayIconTooltip(rowData, userLCID) {
    var str = JSON.parse(rowData);
    var coldata = str.opportunityratingcode_Value;
    var imgName = "";
    var tooltip = "";
    switch (parseInt(coldata,10)) {
        case 1:
            imgName = "new_Hot";
            switch (userLCID) {
                case 1036:
                    tooltip = "French: Opportunity is Hot";
                    break;
                default:
                    tooltip = "Opportunity is Hot";
                    break;
            }
            break;
        case 2:
            imgName = "new_Warm";
            switch (userLCID) {
                case 1036:
                    tooltip = "French: Opportunity is Warm";
                    break;
                default:
                    tooltip = "Opportunity is Warm";
                    break;
            }
            break;
        case 3:
            imgName = "new_Cold";
            switch (userLCID) {
                case 1036:
                    tooltip = "French: Opportunity is Cold";
                    break;
                default:
                    tooltip = "Opportunity is Cold";
                    break;
            }
            break;
        default:
            imgName = "";
            tooltip = "";
            break;
    }
    var resultarray = [imgName, tooltip];
```

```
    return resultarray;
}
```

Custom icon view display behavior

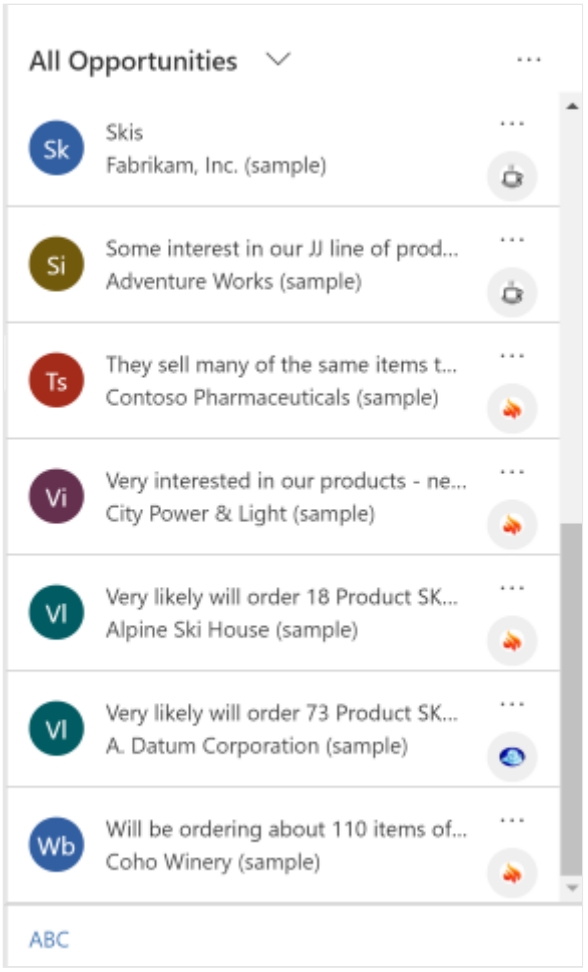
Primary columns

In the grid list view, custom icons applied to the table primary column replace the default system-generated icon.



Other columns

In the grid list view, custom icons applied to a column that isn't the table primary column display as a secondary icon in addition to the default system-generated icon.



Card forms

Custom icons replace the default system-generated icon when the view is configured to use a card form.

Understand model-driven app views

Edit system table messages (preview)

Article • 03/13/2023

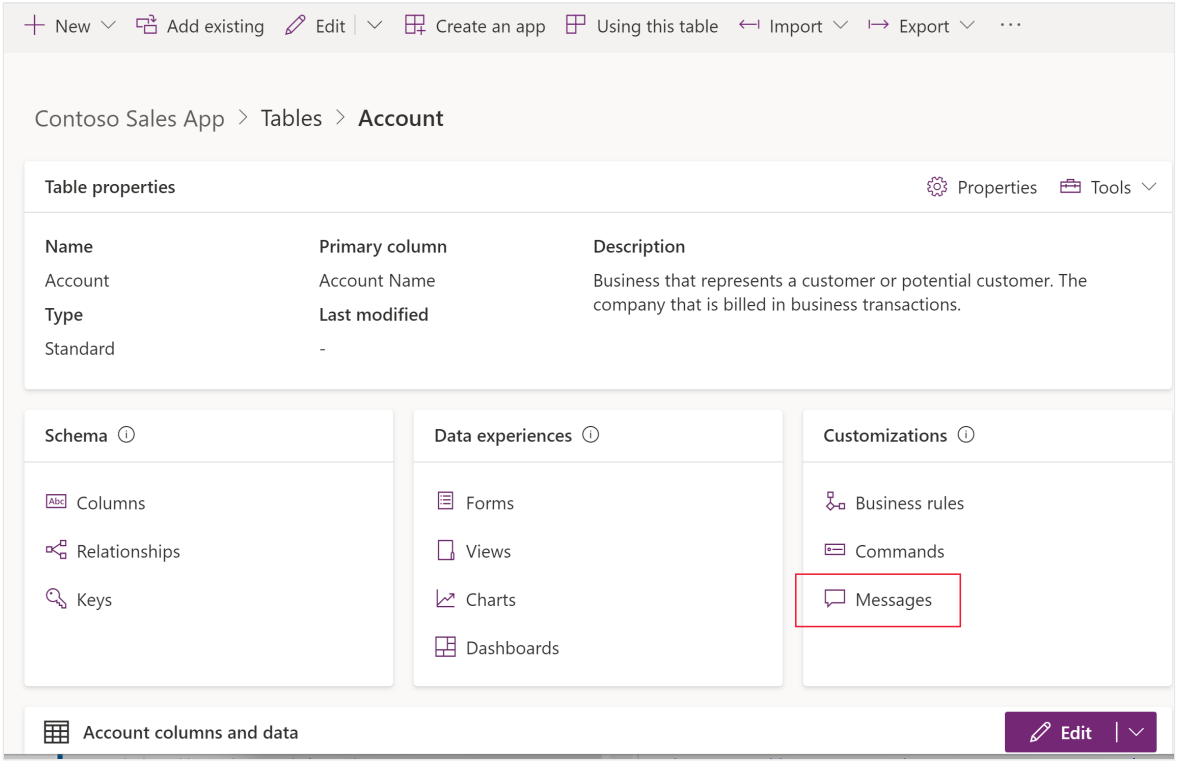
[This topic is pre-release documentation and is subject to change.]

The default display name of some system tables, such as account and contact tables, is used in user interface text and error messages in Microsoft Dataverse. If you change the display name for a system table, you should also update any messages that use the default display name. For example, if you change the display name from *Account* to *Company*, you could still see an error message using the old name.

> **Important**
>
> This is a preview feature. More information: **Model-driven apps and app management**

Add a message to a system table

1. Sign into Power Apps (make.powerapps.com).
2. Go to **Solutions**, open the solution that has the table you want, and then open the table. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. In the **Customizations** area, select **Messages**.

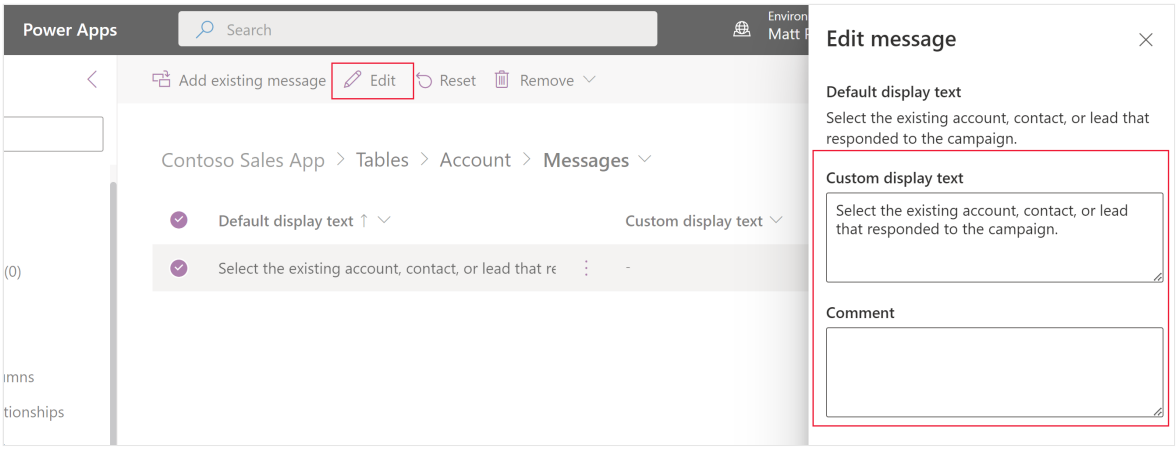


4. Select the message you want, and then select **Add**.

Edit a system table message

1. Open the table that has the message you want to edit, and then in the **Customizations** area select **Messages**.

2. Select the message, and then select **Edit** on the command bar. Enter the changes you want:



Field	Description
Default display text	Shows the original text, which isn't editable.
Custom display text	Edit this text to change the message that is displayed.
Comment	Optional. Include a comment about what you changed and why.

3. Select **Done**.

Programmatically update table display strings

For developers looking for a way to work with these in code, the display strings are stored in the DisplayString table.

The `DisplayString` table doesn't contain the default display strings. The two attributes for this table that contain text are CustomDisplayString and PublishedDisplayString. By default, these attribute values are null unless the display string has been customized and published. The `PublishedDisplayString` value is read-only and reflects the currently published `CustomDisplayString`.

Edit using the classic experience

For information about how to edit system table messages using the classic experience, see Edit system entity messages and display names.

Translate localizable text for model-driven apps

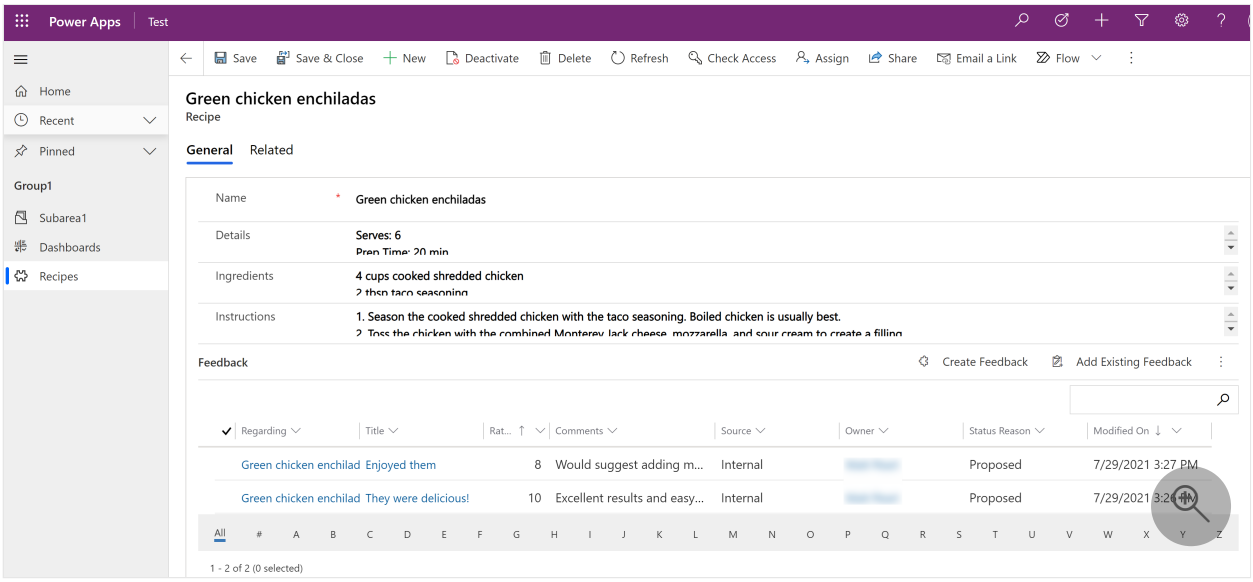
Configure a table for feedback/ratings

Article • 06/22/2022

Let customers or employees submit feedback for any table record, or rate table records within a defined rating range by enabling tables for feedback. Use this capability for the following scenarios:

- For customers to capture data via a portal or survey.
- To collect data about service or product satisfaction from table records.
- For employees to provide comments on collaborative efforts or as a way to improve on products and services.

For example, imagine you have an app that is used to maintain recipes and you want to get feedback from your users about their experience using the recipes in the app.



Configure feedback for a table

First, you must enable the **Allow feedback** property in the table definition.

1. Sign into Power Apps.
2. Open the table you want or create a new one. More information: Edit a table
3. On the right table properties pane, select **Allow feedback**.

> **Note**
>
> Once you enable the **Allow feedback** property for a table, you can't disable it.

Edit table

Display name *

Custom table

Plural display name *

Custom tables

Name *

crfb6_ Customtable

Enable attachments (including notes and files)

Fewer settings

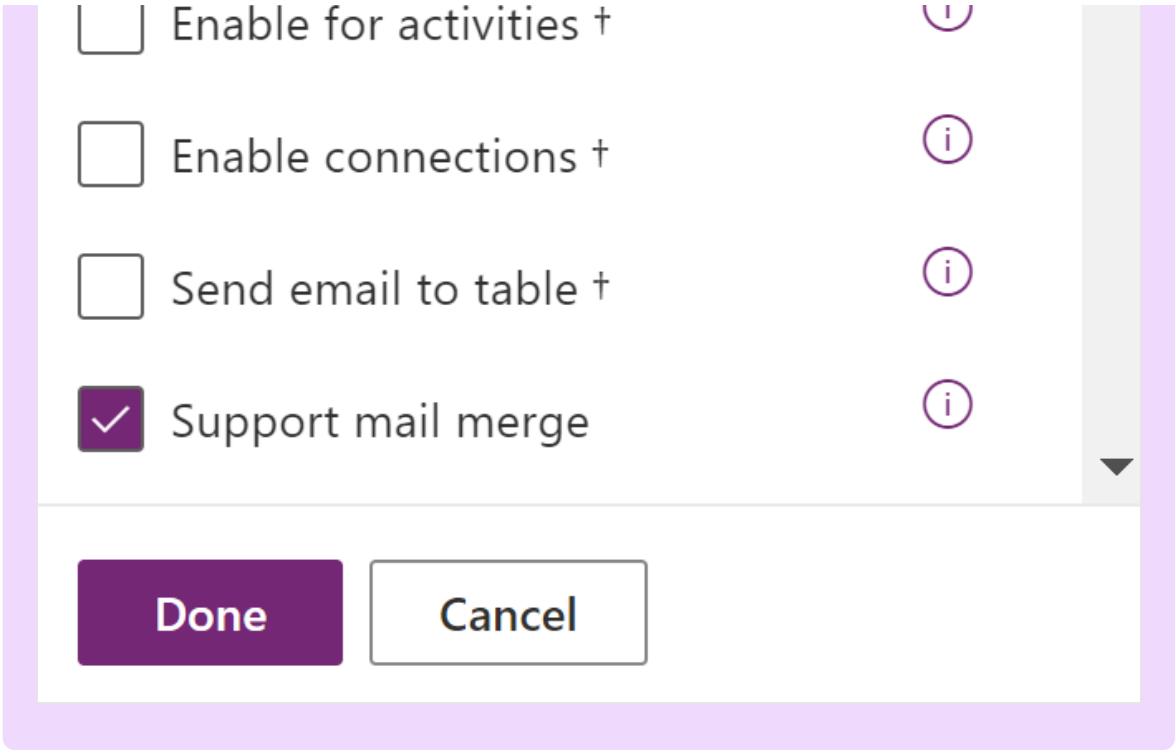
Description

Table type

Collaboration

Enable features to help users to more easily work together on this table.

Allow feedback †



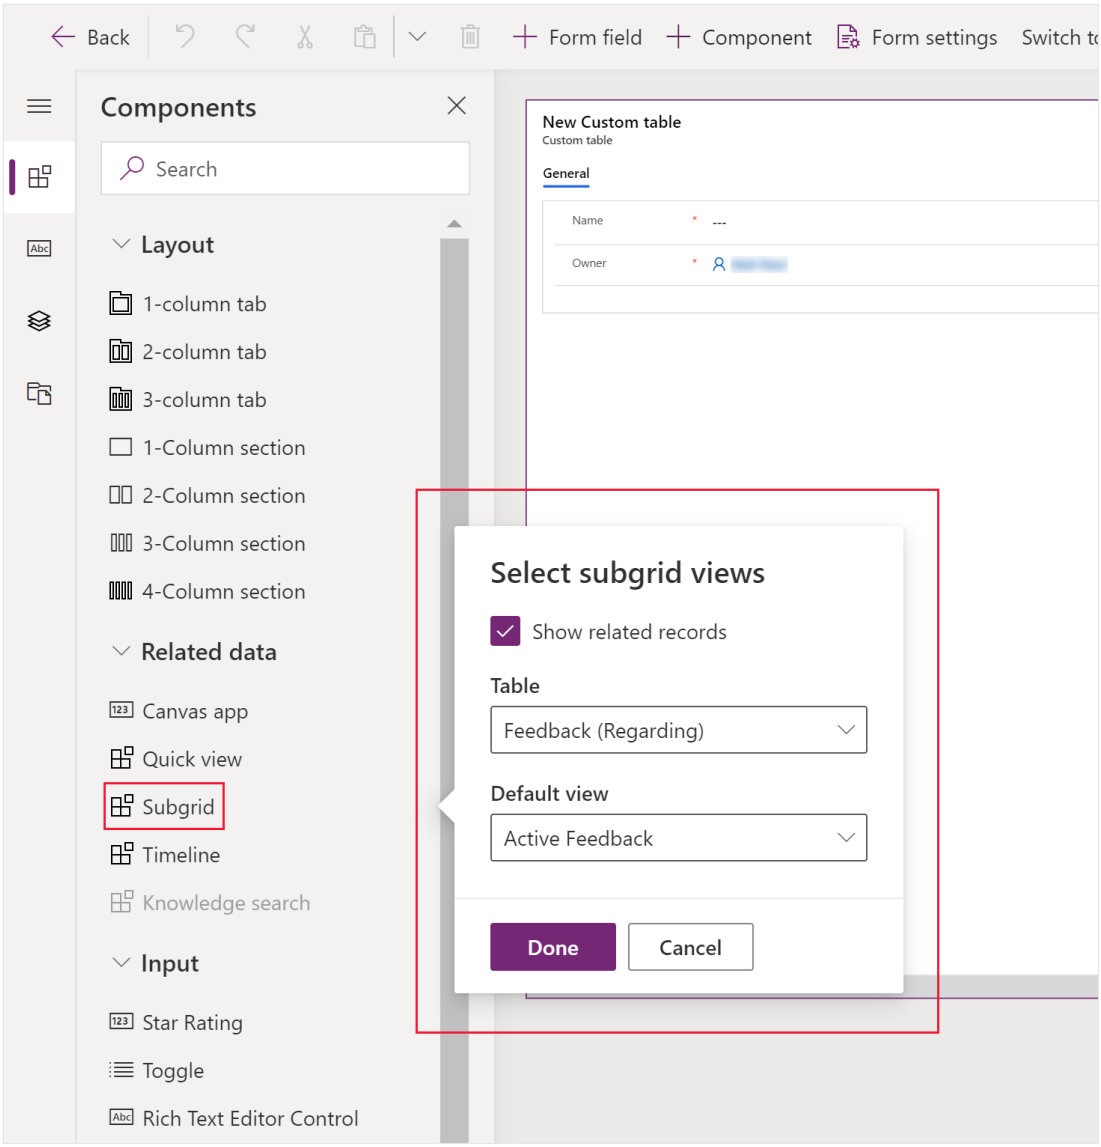
4. Select **Done**, and then select **Save Table**.

Add a subgrid for feedback on the table form

By default, users must go to the list of associated records of the record you want to add feedback to. To make it easier for users to add feedback, you should add a feedback subgrid to the form of the table you are enabling feedback for, such as in the recipe example depicted earlier in this article.

1. In the form designer, select the area of the form where you want the feedback subgrid, and then select **Subgrid** on the left **Components** pane.
2. Select the following subgrid properties, and then select **Done**:

    - **Show related records**
    - **Table Feedback (Regarding)**
    - **Default view**. **Active Feedback**.



3. **Save** and **Publish** the form.

About the feedback table form

The feedback subgrid displays commands for creating new or adding existing feedback. When a user selects **Create Feedback** from the subgrid, the records to create feedback use the feedback standard table.

The feedback table form has the following columns:

- **General**
  - **Title**: User provided title for the record feedback.
  - **Regarding**: System provided table record that the feedback is associated with.
  - **Source**: The feedback source to display where the feedback was submitted. If the feedback was created from within a model-driven app, the default value is set to **Internal** while **Portal** is the other option. This can be changed by the user.
  - **Created By**: System provided value that's the user who created or last modified the feedback record.

- **Comments**
    - **Minimum Rating**: The user can define a range for ratings by specifying a minimum and maximum (numerical) value for ratings. For example, a minimum rating of 1.
    - **Maximum Rating**: The user can define a range for ratings by specifying a minimum and maximum (numerical) value for ratings. For example, a scale of maximum rating of 5.
    - **Normalized Rating**. System generated numeric value that's automatically calculated to show the specified user rating scaled to a value between 0 and 1 based on the minimum and maximum rating values.

      The normalized rating helps to normalize or even out the specified rating value for different rating ranges (minimum and maximum rating values). The normalized rating is calculated as follows: (Rating - Minimum Rating) / (Maximum Rating - Minimum Rating). Also, rating for a record is calculated as an average of all the normalized ratings for the record.
    - **Rating**: User provided rating for the feedback that must be between the minimum and maximum range. For example, a rating of 4 on a scale of 1-5.
    - **Comments**: User provided comments for the record feedback.

Add a rollup column for the feedback

Optionally, you can create a rollup column that's based on the feedback or ratings for the table, and then add it to the form of the table you're enabling for feedback.

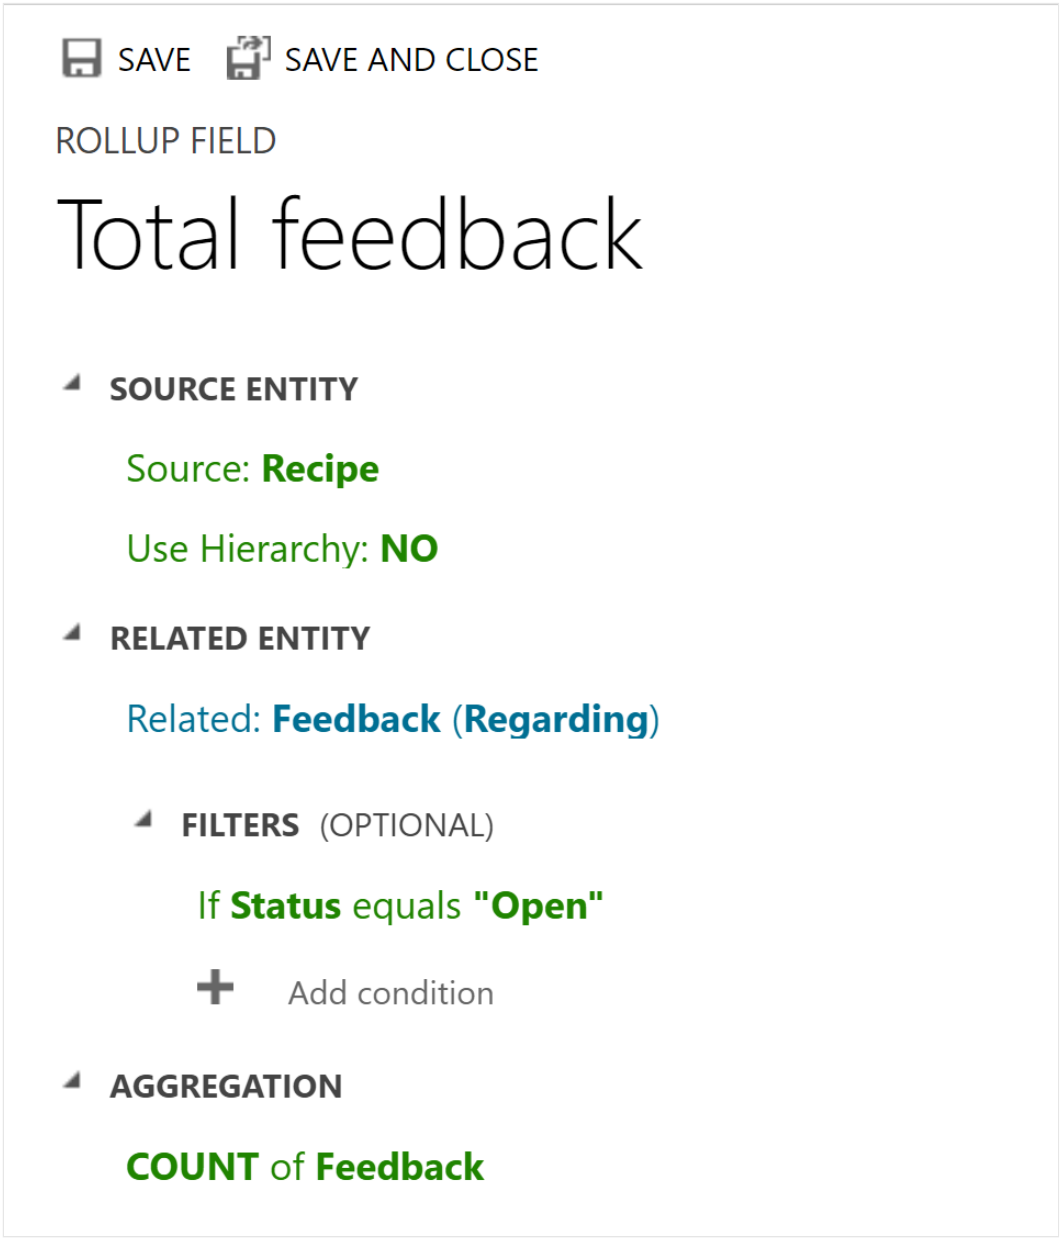
For example, you can provide a running total of all feedback records created for a given record.

1. Open the table that contains the form with the feedback grid and select **Columns**.
2. Select **Add column**, and then select the following properties:

    - **Display name**: *Total feedback*
    - **Data type**: **Whole Number**
    - **Calculated or Rollup**: Select **Add** > **Rollup**. Select **Save** when prompted.

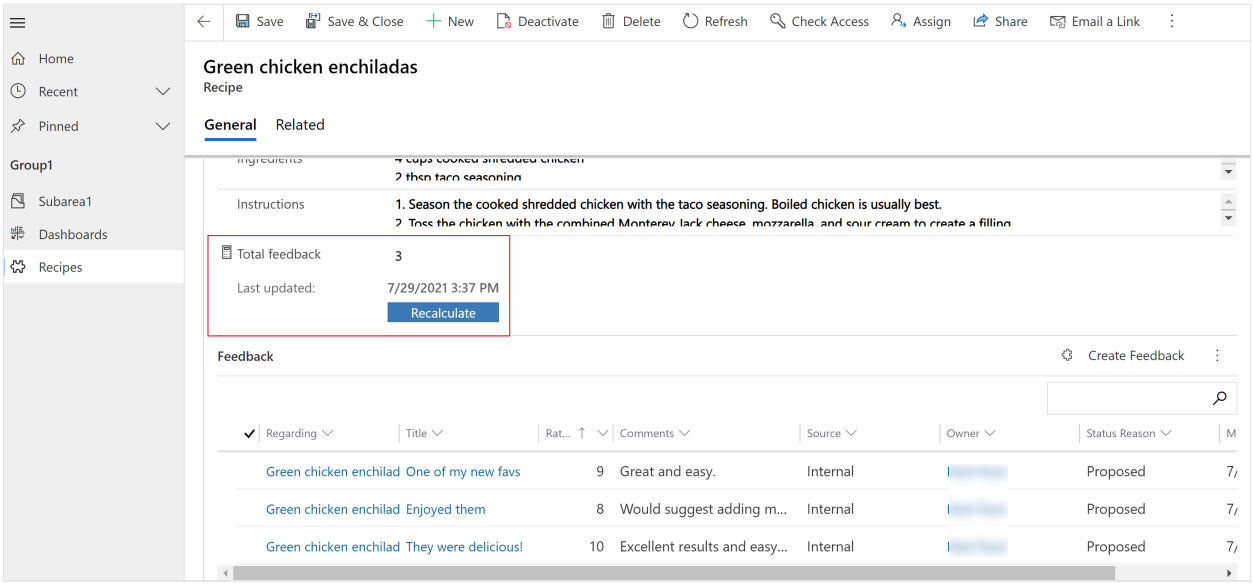
3. Select **Done**. Select the **Total feedback** column, and then in the right column properties pane select **Open rollup**.
4. The rollup editor opens in a new browser window. Configure the following rollup conditions, and then select **Save and Close**:

- **Source entity**:
  - **Source**. Recipe (or the table that has the feedback subgrid)
  - **Use Hierarchy**: **No**
- **Related entity**:
  - **Feedback (Regarding)**
  - **Filters**: **If Status equals Open**
- **Aggregation**:
  - **Count of Feedback**



5. Add the column to the form that has the feedback subrid, save and publish it.

The form in an app now displays a running total of all feedback records submitted for the record.



More information: Define rollup columns that aggregate values

Star rating control

Preview feature: Azure Cosmos DB for NoSQL Data Provider requirements

Article • 06/14/2023

This topic describes the requirements for the Azure Cosmos DB for NoSQL data provider as well as how to configure and recommended best practices when you use the Azure Cosmos DB for NoSQL data provider with virtual tables.

> **Important**
>
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.
> - We expect changes to this feature, so you shouldn't use it in production. Use it only in test and development environments.
> - Microsoft doesn't provide support for this preview feature. Microsoft Dynamics 365 Technical Support won't be able to help you with issues or questions. Preview features aren't meant for production use and are subject to a separate **supplemental terms of use**.

What is Azure Cosmos DB?

Azure Cosmos DB is Microsoft's globally distributed multi-model database service for mission-critical applications. It provides rich and familiar SQL query capabilities with consistent low latencies over schema-less JSON data. More information: Introduction to Azure Cosmos DB: Azure Cosmos DB for NoSQL

Requirements

- Azure subscription that includes Azure Cosmos DB.
- An Azure Cosmos DB for NoSQL collection.
- The Azure Cosmos DB database type should be SQL.

Data type mapping

Suppose you have an Azure Cosmos DB document in a collection named *Orders* that has the following JSON structure.

```
{
"id": "feff22dc-bb3e-4b00-b9c8-4202c408fc31",
"name": "Gorgonzola Telino",
"quantity": 14,
"orderid": "0ffcaff6-390b-4348-a27a-81595130c28a",
"amount": 5932.35,
```

```
"ordertype": 4,
"delivered": 0,
"datetimeoffset": "08/06/2013 9:52:40 PM",
"_rid": "[redacted]",
"_self": "[redacted]",
"_etag": "[redacted]",
"_attachments": "attachments/",
"_ts": 1507750893
}
```

This table indicates the data type mappings for the Azure Cosmos DB for NoSQL document in the *Orders* collection with Microsoft Dataverse.

Azure Cosmos DB for NoSQL Data	**Dataverse**
`id`	Primary Key
`name`	Single Line of Text
`quantity`	Whole Number
`orderid`	Single line of text
`ordertype`	Choice
`amount`	Decimal Number or Currency
`delivered`	Yes/No
`datetimeoffset`	Date and Time

> ⓘ Note
>
> - Attributes with an underscore (_) prefix are generated by the Azure Cosmos DB for NoSQL.
> - Attributes that are configured as optional in the Azure Cosmos DB for NoSQL document and are mapped in Dataverse as **Business Required** will cause a runtime error.
> - id attribute values must be guids.

Supported SQL query filtering

SQL query filtering supports the following operators.

- Comparison operators: `<`, `>`, `<=`, `>=`, `!=`
- Logical operators: `and`, `or`
- Set operators: `in`, `not in`
- String operators: `like`, `contains`, `begins with`, `ends with`

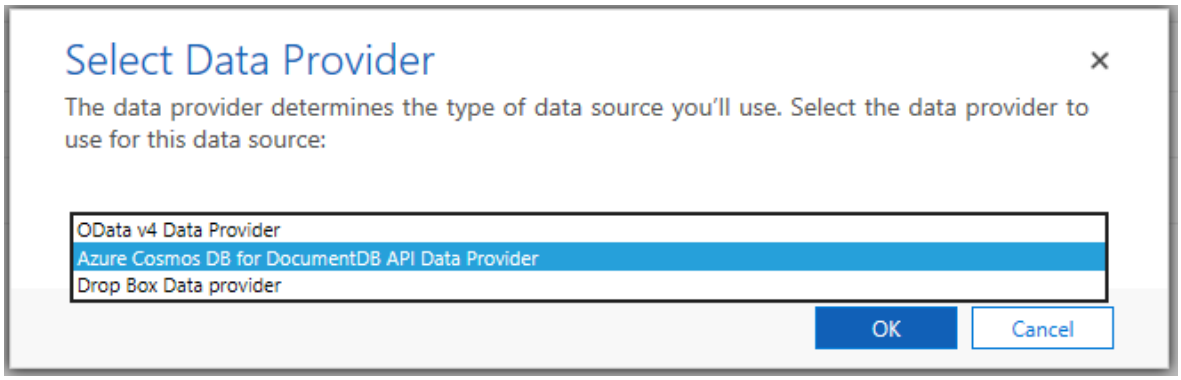
> ⓘ Note
>
> Usage of the like operator is translated to the equivalent `contains/begins with/ends with` operators. The Azure Cosmos DB for NoSQL does not support pattern arguments as described in the topic **Like (Transact-SQL)**. The Azure Cosmos DB for NoSQL Data Provider can translate the single special case `Like('[aA]%')` to `BeginsWith('a')` OR `BeginsWith('A')`. Notice that string comparison in the Azure Cosmos DB for NoSQL is case sensitive.

Add a data source using the Azure Cosmos DB for NoSQL Data Provider

1. Go to AppSource, select **GET IT NOW**, and follow the instructions to add the application to your environment using v9x or later.

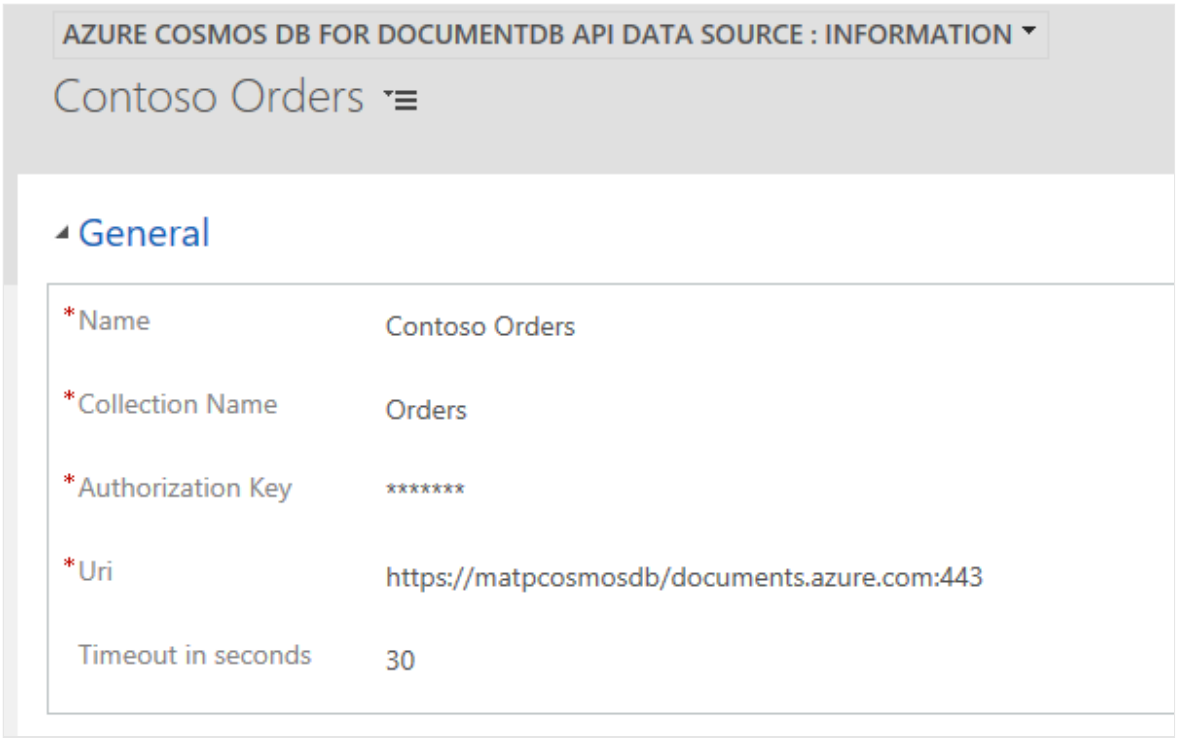
2. After the solution is installed, sign in to the environment and go to **Settings** > **Administration** > **Virtual Entity Data Sources**.

3. On the Actions toolbar select **NEW**, and in the **Select Data Provider** dialog box select **Azure Cosmos DB for SQL API Data Provider**, and then select **OK**.



4. Enter the following information, and then select **SAVE & CLOSE**.

Column	Description
Name	Type a name that describes the data source.
Collection Name	The name of the Azure Cosmos DB *database* containing the collection you want to surface in a virtual table.
Authorization Key	The primary or secondary key for the Azure Cosmos DB account. You can find the key from the Azure admin portal under the **Keys** setting under your Azure Cosmos DB account.
Uri	The URI of the resource group where the Azure Cosmos DB collection is located. The URI is formed similar to `https://contoso/documents.azure.com:443`. You can find the URI from the Azure admin portal under the **Keys** setting for the Azure Cosmos DB account.
Timeout in seconds	Enter the number of seconds to wait for a response from the Azure Cosmos DB service before a data request time-out. For example, enter 30 to wait a maximum of thirty seconds before a time-out occurs. The default timeout is 120 seconds.



Best practices and limitations

- Notice the following when you use Azure Cosmos DB as a Data Source:
  - Each Azure Cosmos DB Data Source can only be associated with a single virtual table.
  - You can connect multiple Data Sources to the same Collection in the Azure Cosmos DB instance.
- You can't segment the data in a collection by table.
- Azure Cosmos DB databases do not require a schema, however the data within the Azure Cosmos DB must be structured using a predictable schema.
- Although the Azure Cosmos DB for NoSQL Data Provider implements query translation of projection, filtering, and sorting operators, it does not support join operations.
- You can only filter by a single column with Azure Cosmos DB for NoSQL.

Create and edit virtual tables that contain data from an external data source

Virtual table walkthrough using the OData v4 Data Provider

Article • 02/22/2023

Imagine that you want to access, create, update, and delete some personal information about a contact from an external data source within your model-driven app. In this simple walkthrough, you will model a virtual table named *Person* with columns mapped to the external schema to these operations at runtime from an OData web service.

Data source details

Because the data source used for this walkthrough has an OData v4 web service, we can use the OData v4 Data Provider included with your environment.

Web service url: `https://contosowebservice.azurewebsites.net/odata/`

> **ⓘ Important**
>
> - The web service url used for this walkthrough isn't a functioning web service.
> - You can't use the OData v4 Data Provider to connect to another environment.

For this walkthrough, a single virtual table that contains the following columns is needed.

External column name	External data type	Virtual table data type	Purpose
Id	`Edm.Guid`	Primary key	Primary key for the table
FirstName	`Edm.String`	Single line of text	First name of the person
LastName	`Edm.String`	Single line of text	Last name of the person
Age	`Edm.Int32`	Whole number	Age of the person
LastModifiedOn	`Edm.DateTimeOffset`	Data and time	Last modified data and time of the person record

The OData metadata of the external data source person table:

Create the data source

Create the data source for the OData v4 data provider that uses the OASIS Open Data Protocol (OData) sample web service.

1. Go to **Settings** > **Administration** > **Virtual Entity Data Sources**.
2. Select **NEW**, select **OData v4 Data Provider**, and then select **OK**.
3. Enter or select the following information.

Field	Value
Name	Person Sample OData Data Source
URL	`https://contosowebservice.azurewebsites.net/odata`
Timeout	30
Return Inline Count	Client-side Paging
Return Inline Count	True

Leave the other columns as-is, and select **SAVE & CLOSE**.

> **Tip**
>
> When using your own web service, verify that the URL is valid by pasting it in to your web browser. If you want to understand the columns and data types respective to the table you are interested in, you can append `/$metadata` to the end of your URL to see the definition of tables in you web service.

Open solution explorer

Part of the name of any custom table you create is the customization prefix. This is set based on the solution publisher for the solution you're working in. Make sure that you are working in an unmanaged solution where the customization prefix is the one you want for this table. More information: Change the solution publisher prefix

Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
2. In the **All Solutions** list open the unmanaged solution you want.

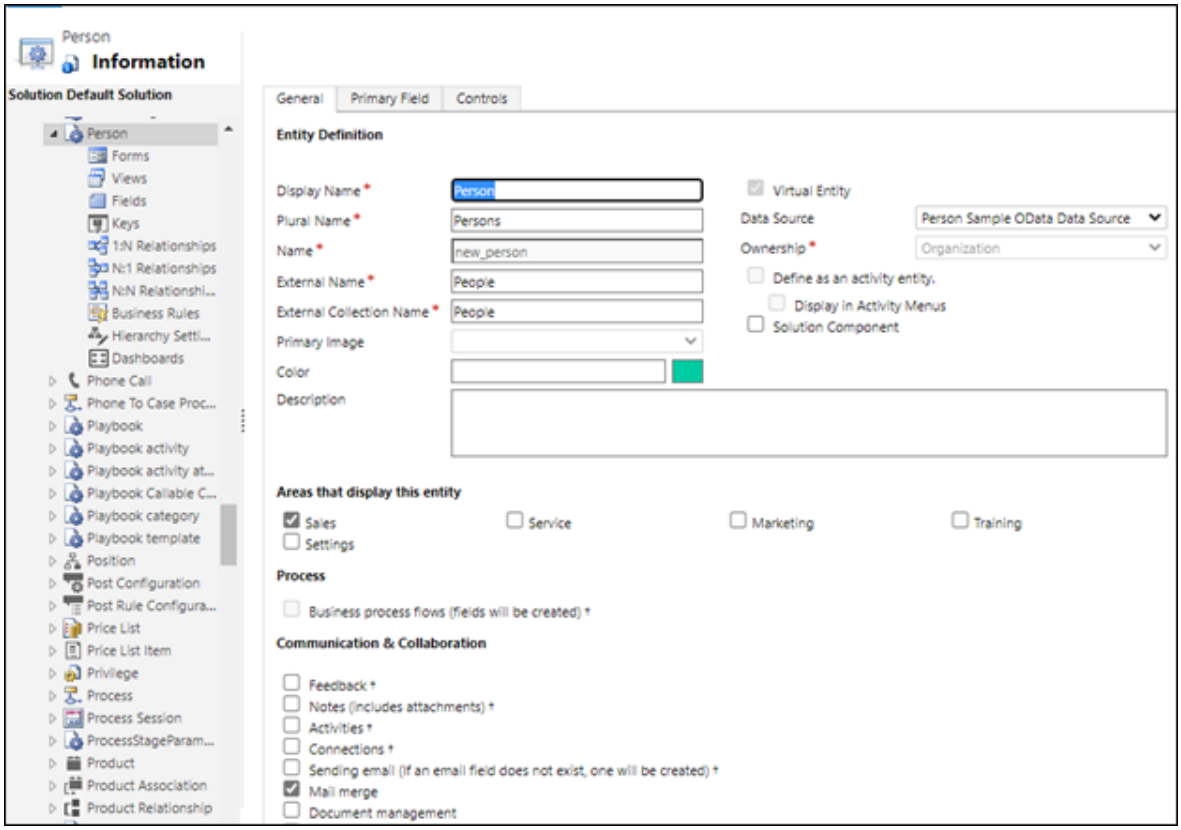
Create the virtual table

1. In the left navigation pane of solution explorer, select **Entities**, and then select **New** from the main pane.
2. On the **Entity: New** form, select the **Virtual table** option, and then enter the following information:

Field	Value
Data Source	Person Sample OData Data Source
Display Name	Person
Plural Name	Persons
Name	new_person
External Name	People
External Collection Name	People
Notes (includes attachments)	selected
Activities	selected

> **Note**
>
> The OData resource path semantics uses `EntitySet` to identify the resource. In the sample OData web service, the `EntitySet` is defined as **People**. This value is used as the **External Name** for the virtual table **Person**.

3. Next to **Areas that display this entity**, select **Sales**, and then select **Save** (but don't close the table form).



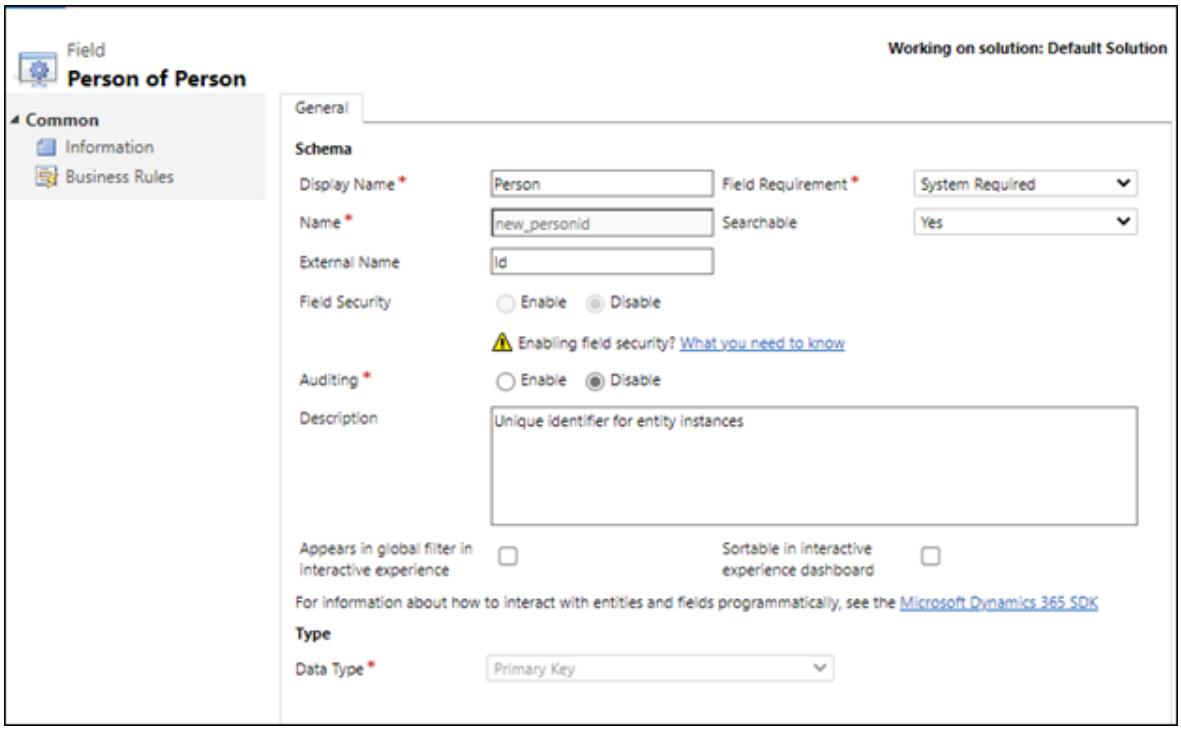
Create the columns for the virtual table

On the left navigation pane of the **Entity: Person** page, select **Fields**. As part of this walkthrough, you will edit two existing columns and add three more columns that are available in the external data source.

> **ⓘ Important**
>
> External names are case sensitive. Refer to your web service metadata to make sure you use the correct name. A Nullable value of false indicates that the attribute is required. Notice that primary key columns are always system required.

1. Open the **new_personid** column, and change the following property with the value indicated here:

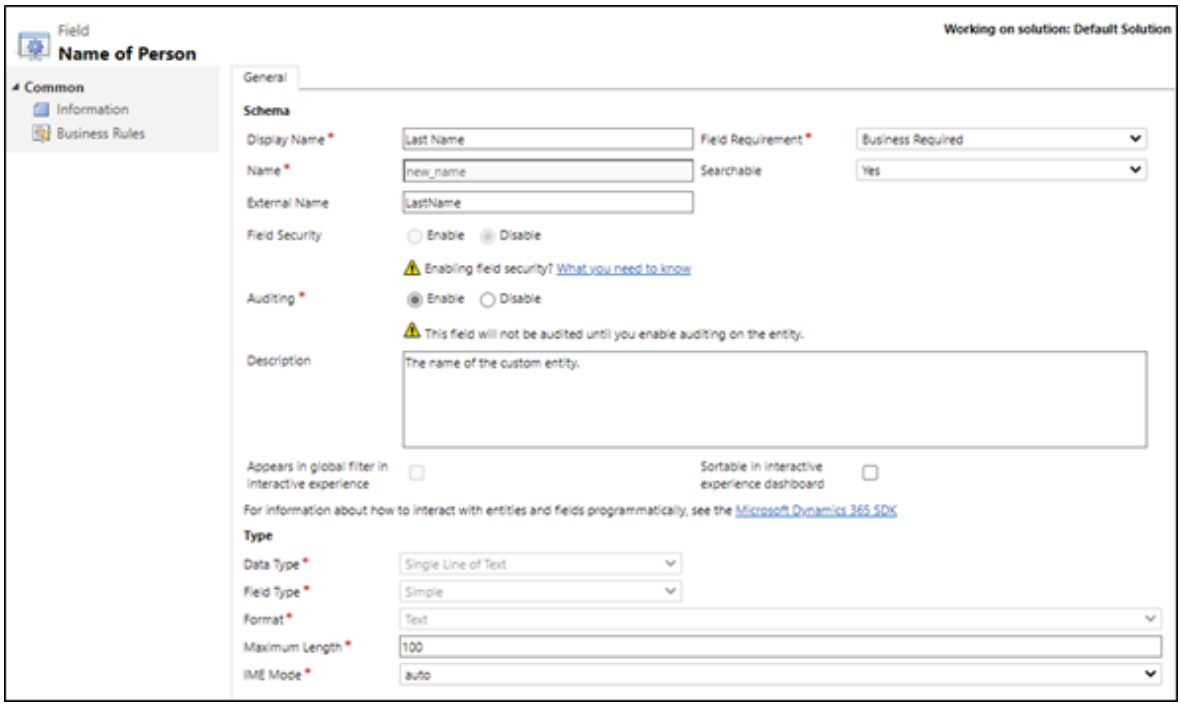
   External Name: Id



2. Select **Save and Close**.

3. Open the **new_name** column, and change the following properties to have the values indicated here:

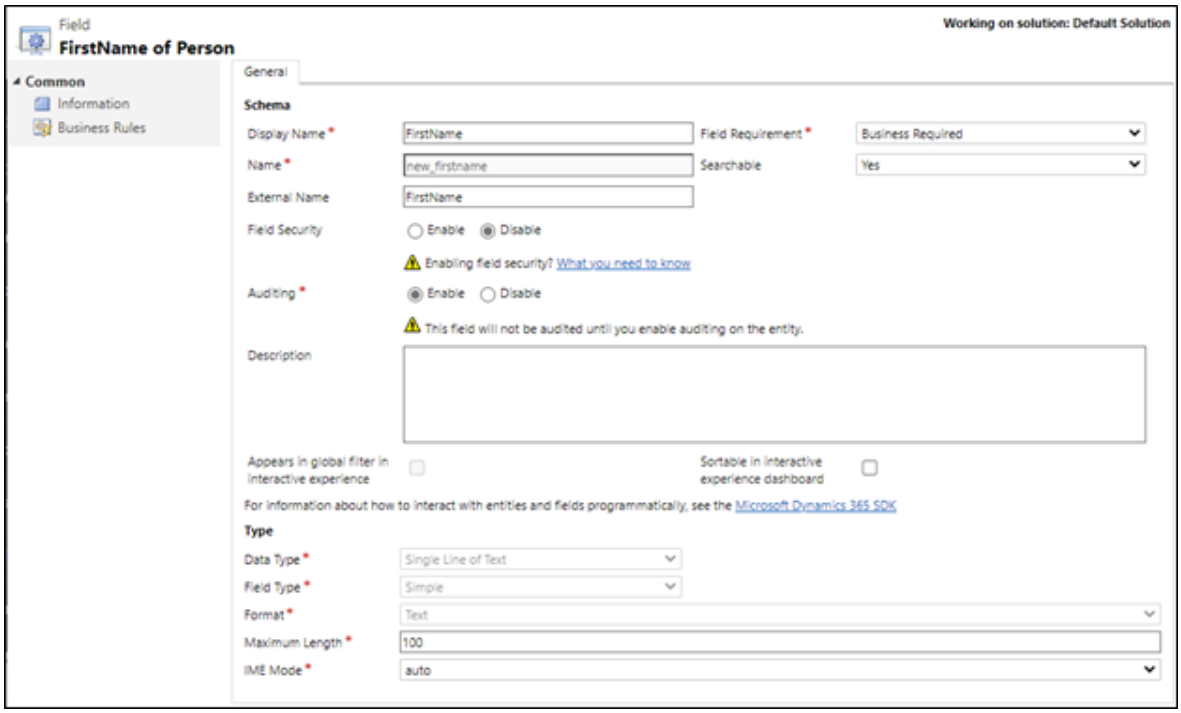
    - **Display Name**: Last Name
    - **External Name**: LastName



4. Select **Save and Close**.

5. Select **New**, and on the **Field: New for Person** page enter the following information:

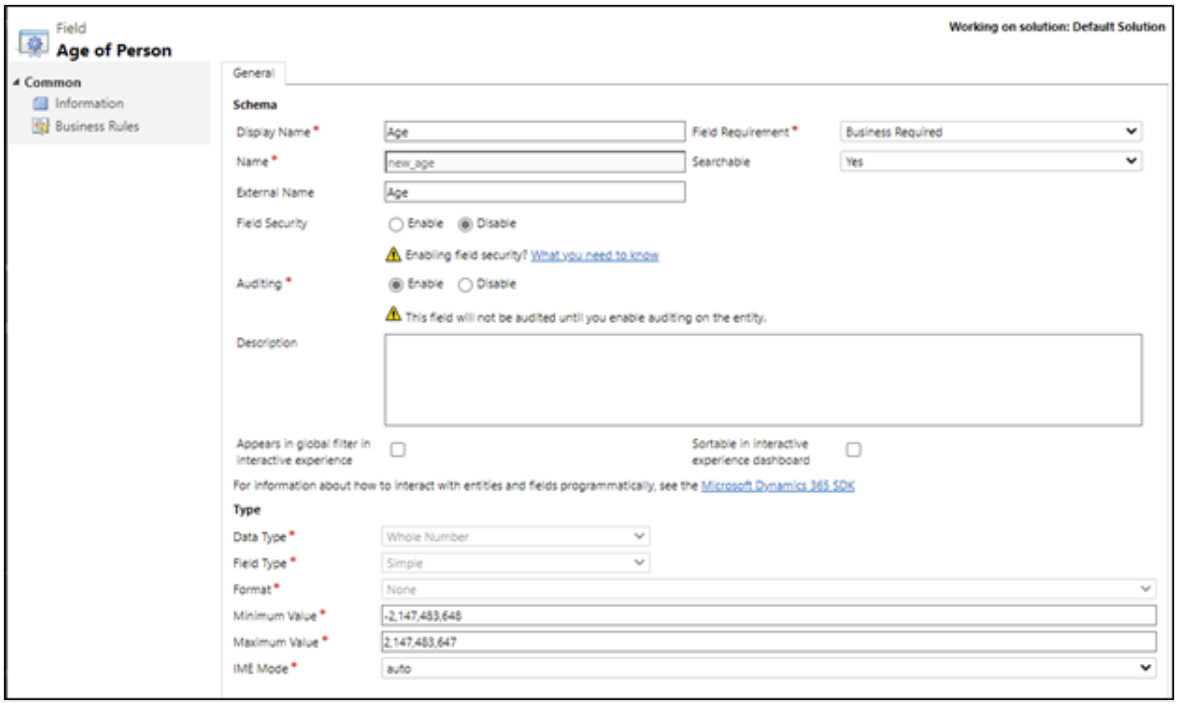
Field	Value
Display Name	First Name
Name	new_firstname
External Name	FirstName
Field Requirement	Business Required
Data Type	Single Line of Text



6. Select **Save and Close**.

7. Select **New**, and on the **Field: New for Person** page enter the following information:

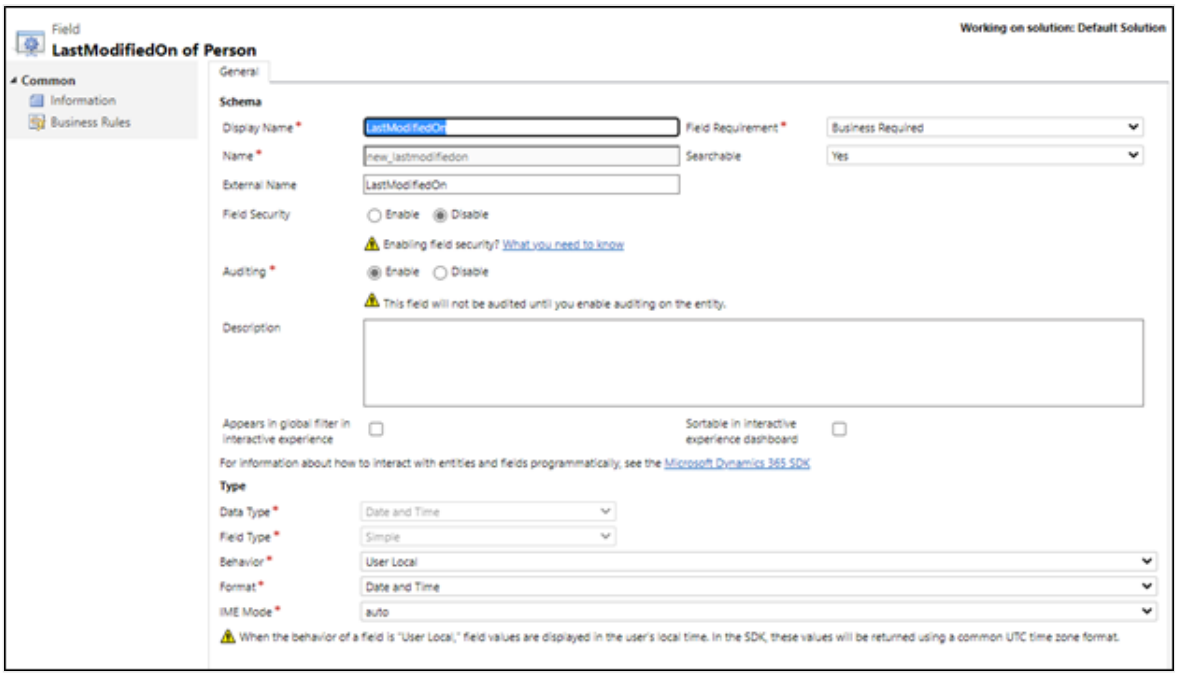
Field	Value
Display Name	Age
Name	new_age
External Name	Age
Field Requirement	Business Required
Data Type	Whole Number



8. Select **Save and Close**.

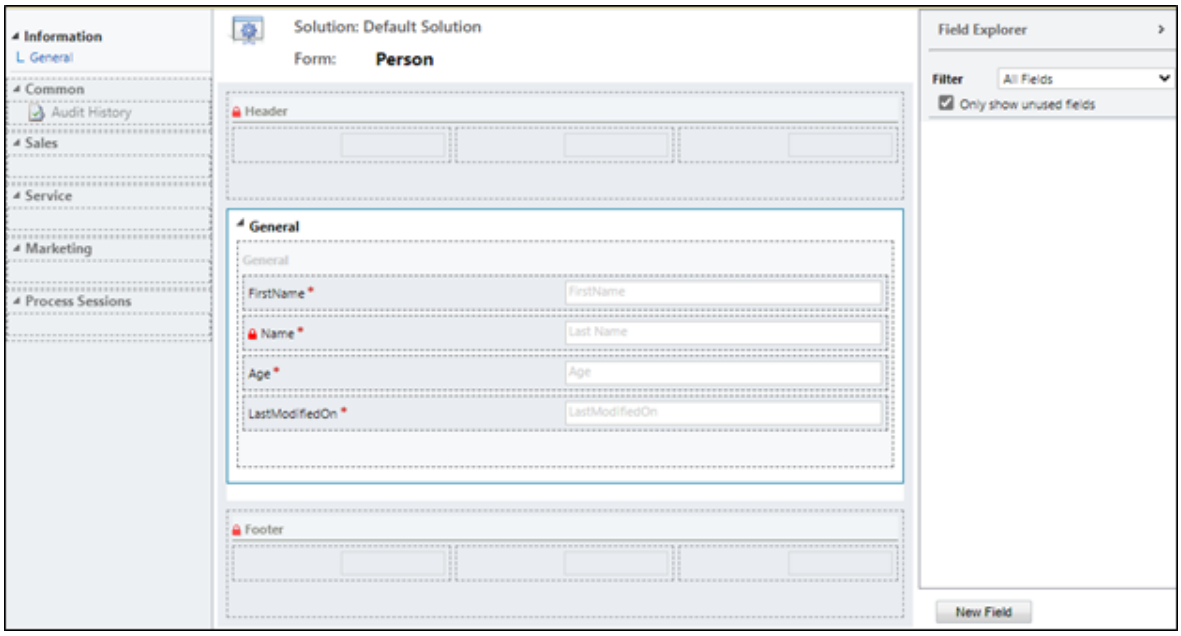
9. Select **New**, and on the **Field: New of Person** page enter the following information:

Field	Value
Display Name	Last Modified On
Name	new_lastmodifiedon
External Name	LastModifiedOn
Field Requirement	Business Required
Data Type	Date and Time



Add the columns to the main form

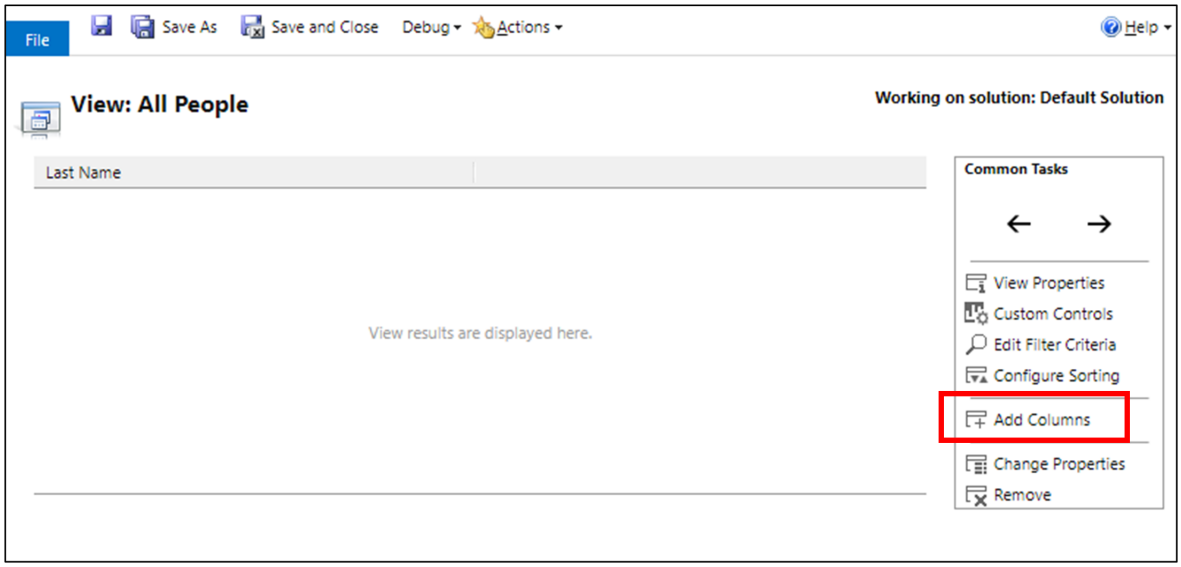
1. On the **Person** table window, select **Forms**.
2. Open the main form, drag and drop the **First Name**, **Age**, and **Last Modified On** columns from the right pane onto the form in the **General** section.



3. On the **Person** table window, select **Save and Close**.

Configure the default view

1. On the left pane of the solution explorer, under the **Person entity**, select **Views**.
2. Open the **All People** view.
3. In the **Common Tasks** pane, select **Add Columns**.



4. Select the **First Name**, **Age**, and **Last Modified On** columns, and then select **OK**.
5. On the **View: All People** window, arrange the column order by selecting the move left and move right arrows, and then select **Save and Close**.

6. On the Solution Explorer window, select **Publish All Customizations**.
7. After all customizations are published, close the Solution Explorer window.

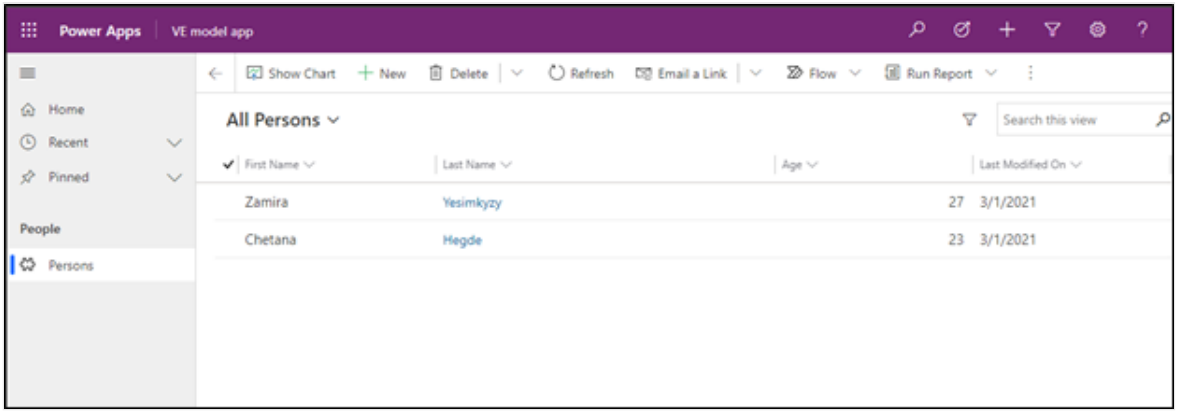
Use the virtual table in a model-driven app

Create a model-driven app and add the **Person** table to the site map. Then, select the **Person** main form and the **Person Advance Find** view. Publish the app. More information: Build your first model-driven app from scratch

Then, app users can perform read, create, update, and delete operations using the virtual table just like any other table in Microsoft Dataverse.

Create, view, and delete records using the virtual table

1. Run the model-driven app. Select **New**, complete the required columns, and then save the record.
2. Select **New** again to create another record and save it.
3. You should now have two records similar to the following in the **All Persons** view.



4. To delete a record, select a person record and then select **Delete**. Confirm to delete the record on the confirmation page.

OData v4 Data Provider configuration, requirements, and best practices
Create and edit virtual tables that contain data from an external data source

Create and edit tables using solution explorer

Article • 02/15/2022

You can easily create a table using Power Apps (make.powerapps.com) for most common situations, but not all capabilities are implemented there. When you need to meet the requirements described in Create and edit tables in Microsoft Dataverse, you can achieve them by creating or editing tables using the Solution Explorer.

Open solution explorer

The customization prefix is part of the name of any table you create. This is set based on the solution publisher for the solution you're working in. If you care about the customization prefix, make sure that you are working in an unmanaged solution where the customization prefix is the one you want for this table. More information: Change the solution publisher prefix

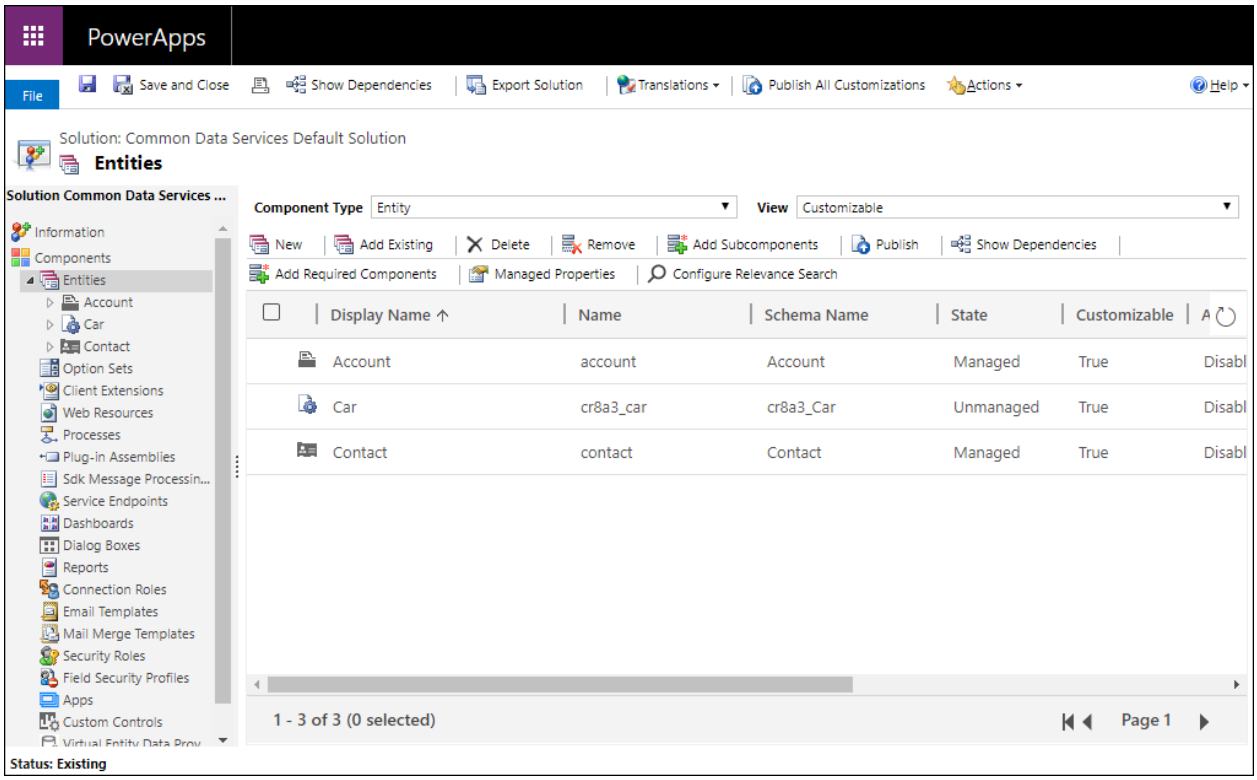
Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

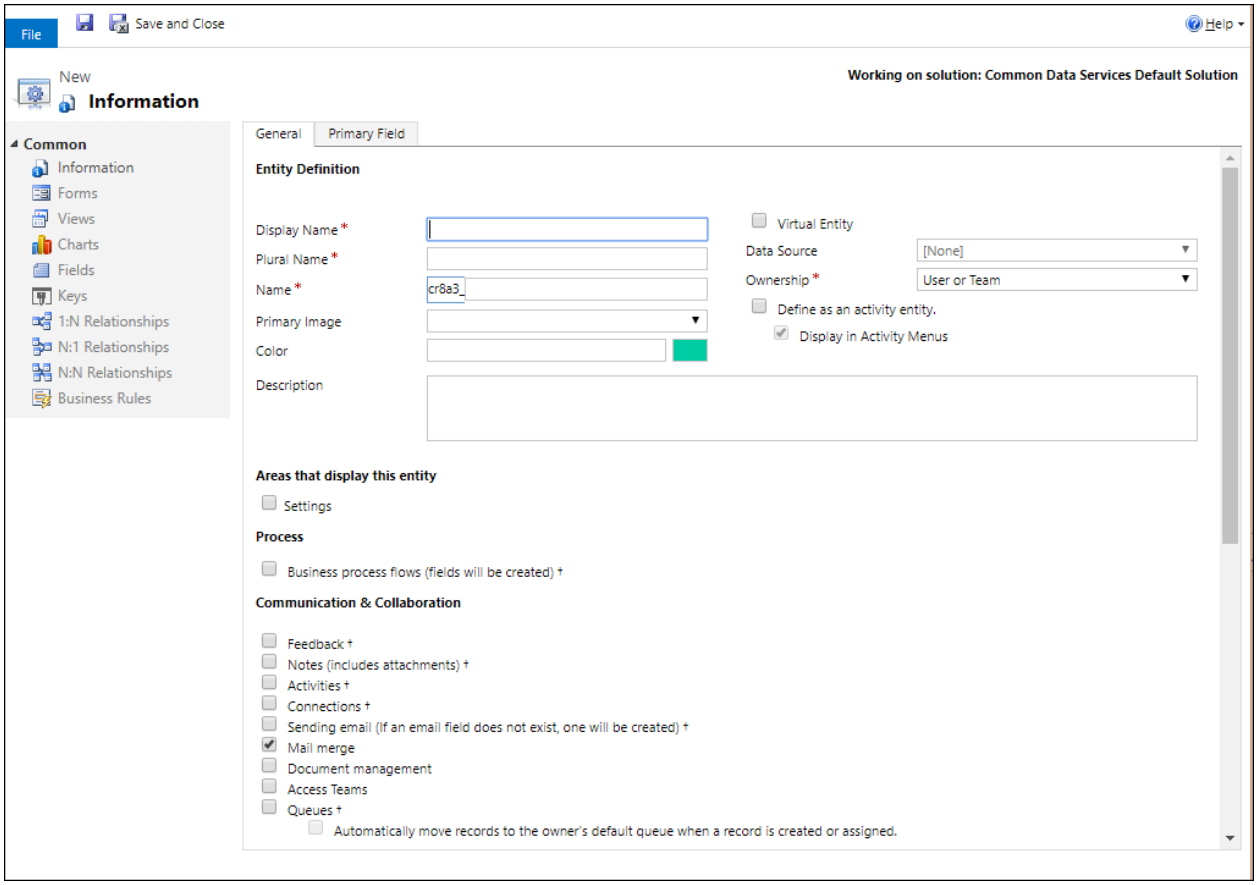
View tables

In the solution explorer **Components** node, select the **Entities** node.



Create a table

While viewing tables, select **New** to open the form to create tables.



The form has two tabs. The **General** tab is for entity options. The **Primary Field** tab is for options about the special single line of text column that each table has that defines the

text shown when there is a link to open the table in a lookup column.

For information about each section see the following:

- Configure the primary column
- Configure required columns

> ⓘ Note
>
> You can also make the table a custom activity. This choice changes some of the default option values. More information: **Create a custom activity table**

After you have set the required options for the table, click  to create the custom table.

Configure the primary column

In the **Primary Field** tab you can usually accept the default values for the primary column, but you have the following options:

Field	Description
Display Name	Enter the localizable label that will be displayed for this column in forms and lists. The default value is **Name**.
Name	Set the name used in the system for this column. The default value is `<customization prefix>_name`
Maximum Length	Enter the maximum length for the column values. The default is 100.

> ⓘ Note
>
> These options do not apply if the table is an activity table. More information: **Create a custom activity table**

Configure required columns

In the **General** tab, some of the options are required before you can save the table.

Field	Description
Display Name	This is the singular name for the table that will be shown in the app. This can be changed later.

Field	Description
Plural Name	This is the plural name for the table that will be shown in the app. This can be changed later.
Name	This column is pre-populated based on the display name you enter. It includes the solution publisher customization prefix.
Ownership	You can choose either user or team-owned or organization owned. More information: Table ownership

Edit a table

While viewing tables, select the table you want to edit, or continue editing a new table you have just saved.

> **Note**
>
> Standard tables or custom tables that are part of a managed solution may have limitations on changes you can apply. If the option is not available or is disabled, you are not allowed to make the change.

Set once options

The following options can be set once and cannot be changed after you set them. Take care to only set these options when you need them.

Option	Description
Activities	Associate activities to records for this table.
Business process flows	Create business process flows for this table. More information: Create a business process flow to standardize processes
Connections	Use the connections feature to show how records for this table have connections to records of other tables that also have connections enabled.
Feedback	Let customers write feedback for any table record, or rate table records within a defined rating range. More information: Enable a table for feedback/ratings
Notes	Append notes to records for this table. Notes include the ability to add attachments.

Option	Description
Queues	Use the table with queues. Queues improve routing and sharing of work by making records for this table available in a central place that everyone can access.
Sending email	Send emails using an email address stored in one of the fields for this table. If a **Single Line of Text** field with format set to **email** doesn't already exist for this table, a new one will be created when you enable sending email.

Options that you can change

The following properties can be changed at any time.

Option	Description
Access Teams	Create team templates for this table.
Allow quick create	After you have created and published a **Quick Create Form** for this table, people will have the option to create a new record using the **Create** button in the navigation pane. More information: Create and design forms When this is enabled for a custom activity table, the custom activity will be visible in the group of activity entities when people use the **Create** button in the navigation pane. However, because activities don't support quick create forms, the main form will be used when the custom table icon is clicked.
Areas that display this entity	In the web application choose one of the available sitemap areas to display this table. This does not apply to model-driven apps.
Auditing	When auditing is enabled for your organization, this allows for changes to table records to be captured over time. When you enable auditing for an table, auditing is also enabled on all its fields. You can select or clear fields that you want to enable auditing on.
Change Tracking	Enables data synchronization in a performant way by detecting what data has changed since the data was initially extracted or last synchronized.
Color	Set a color to be used for the table in model-driven apps.
Description	Provide a meaningful description of the purpose of the table.
Document management	After other tasks have been performed to enable document management for your organization, enabling this feature allows for this table to participate in integration with SharePoint.
Duplicate Detection	If duplicate detection is enabled for your organization, enabling this allows you to create duplicate detection rules for this table.

Option	Description
Enable for mobile	Make this table available to the Dynamics 365 for phones and tablets apps. You also have the option to make this table **Read-only in mobile**. If the forms for an table require an extension not supported in Dynamics 365 for phones and tablets apps use this setting to ensure that mobile app users can't edit the data for these entities.
Enable for phone express	Make this table available to the Dynamics 365 for phones app.
Mail merge	People can use this table with mail merge.
Offline capability for Dynamics 365 for Outlook	Whether data in this table will be available while the Dynamics 365 for Outlook application is not connected to the network.
Primary Image	System entities that support images will already have an **Image** field. You can choose whether to display data in this field as the image for the record by setting this field to **[None]** or **Default Image**. For custom entities you must first create an image field. Each table can have only one image field. After you create one, you can change this setting to set the primary image. More information: Image columns
Reading pane in Dynamics 365 for Outlook	Whether the table will be visible in the reading pane for the Dynamics 365 for Outlook app.
Use custom Help	When enabled, set a Help URL to control what page users will see when they click the help button in the application. Use this to provide guidance specific to your company processes for the table.

You can also make the following changes:

- Create and edit columns for Dataverse
- Create and edit relationships between tables
- Create and design forms
- Create a business process flow to standardize processes

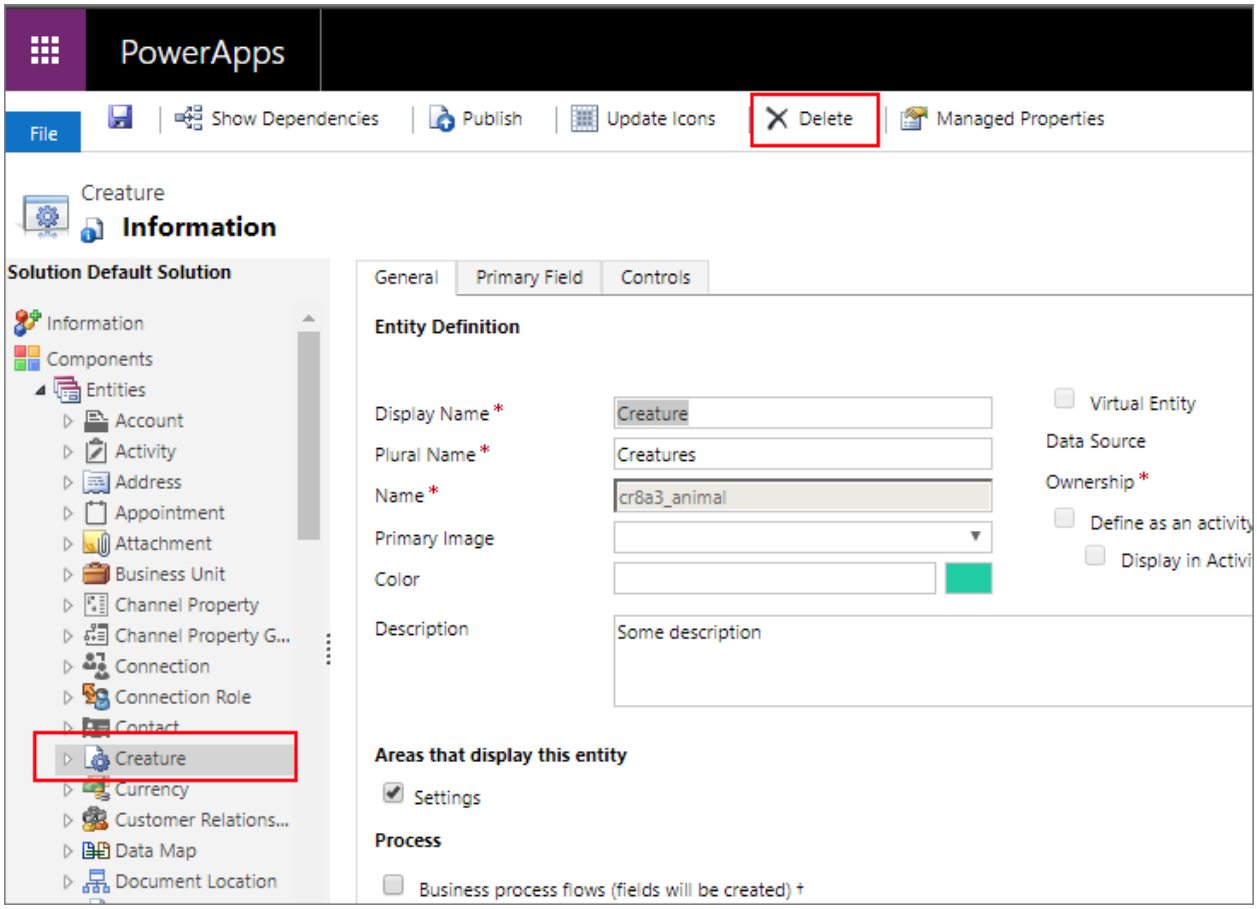
Delete a table

As someone with the system administrator security role, you can delete custom tables that aren't part of a managed solution.

> **ⓘ Important**
>
> - When you delete a custom table, the database tables that store data for that table are deleted and all data they contain is lost. Any associated rows that have a parental relationship to the custom table are also deleted. For more information about parental relationships, see **Create and edit relationships between tables**.
> - The only way to recover data from a table that was deleted is to restore the database from a point before the table was deleted. More information: **Backup and restore environments**

While viewing tables, select the ✕ command on the toolbar.

While viewing a table use the delete command on the menu bar.



> **⚠ Warning**

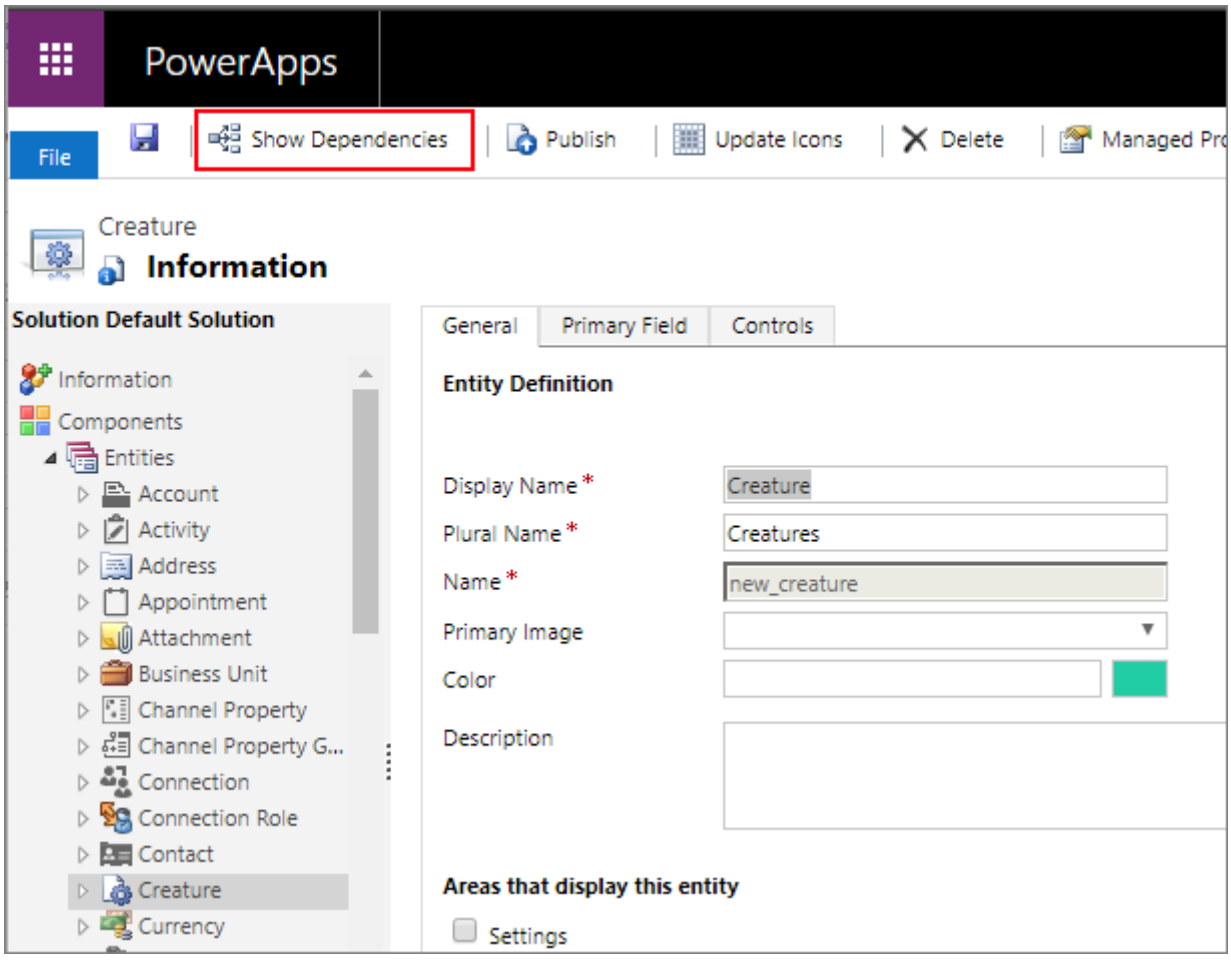
Deleting a table that contains data will remove all the data. This data can only be retrieved by backup of the database.

> **Note**
>
> If there are any table dependencies you will get a **Cannot Delete Component** error with a **Details** link you can use to discover information about why the table cannot be deleted. In most cases, this will be because of a dependency that has to be removed.
>
> There may be more than one dependency blocking the deletion of a table. This error message may only show the first one. For an alternate way to discover dependencies, see **Identify table dependencies**

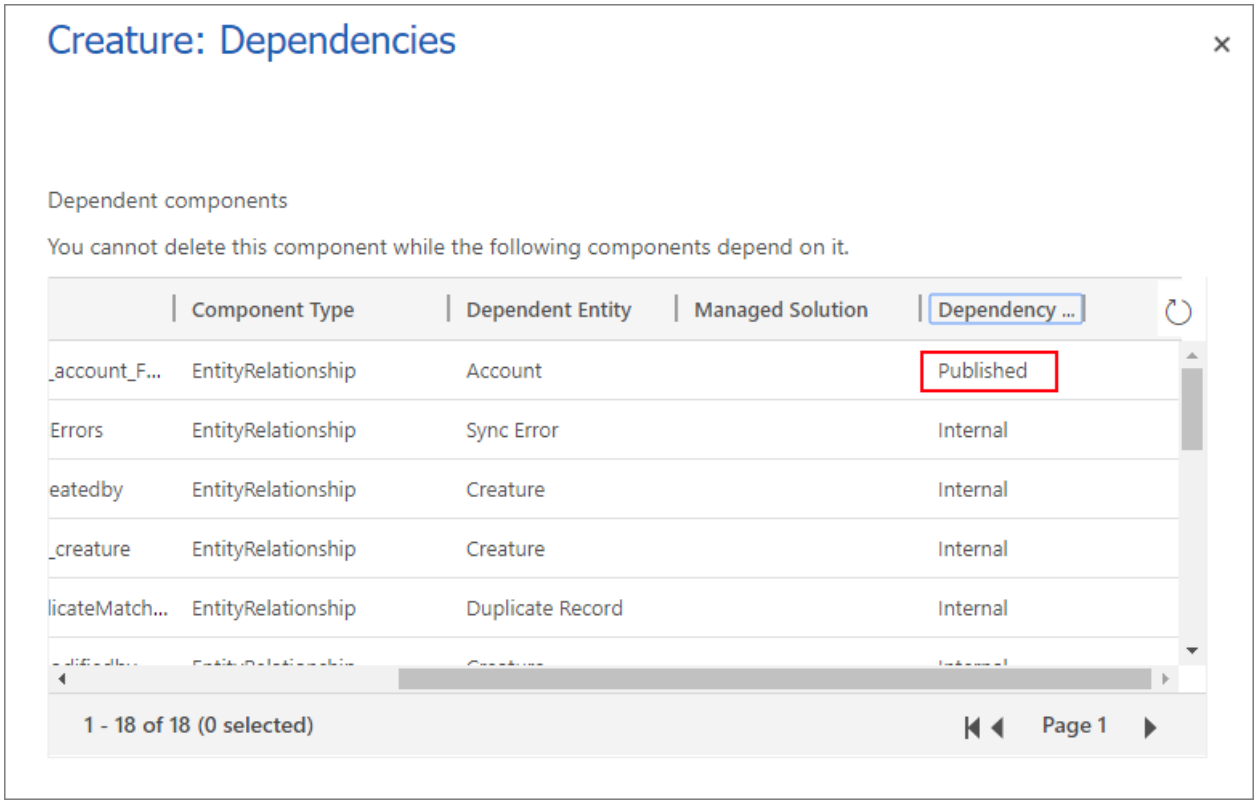
Identify table dependencies

You can identify dependencies that will prevent a table from being deleted before you try to delete it.

1. In the solution explorer with the table selected, click **Show Dependencies** in the command bar.



2. In the dialog window that opens, scroll the list to the right to view the **Dependency Type** column.



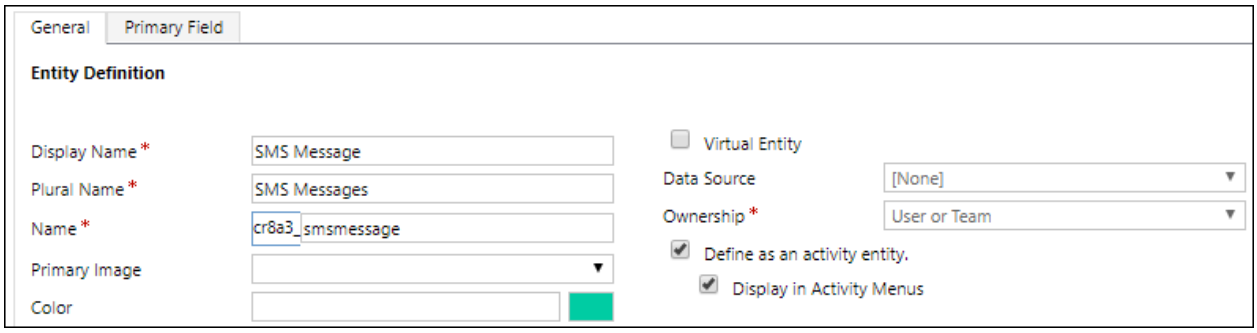
Published dependencies will block deleting a table. **Internal** dependencies should be resolved by the system.

3. Remove these published dependencies and you should be able to delete the table.

> **Note**
>
> A very common dependency is that another table form has a lookup column for the table you are deleting. Removing the lookup column from the form will resolve the dependency.

Create custom activity table

To create the table as an activity table, use the same steps described in this topic except select **Define as an activity table**.



An activity table is a special kind of table that tracks actions for which an entry can be made on a calendar. More information: Activity tables.

When you set this option some table properties are not compatible. An activity table has to conform to standard behaviors that all activity tables use.

The primary column **Name** and **Display Name** will be set to **Subject** and you cannot change this.

The following options are set by default and cannot be changed:

- **Feedback**
- **Notes (includes attachments)**
- **Connections**
- **Queues**
- **Offline capability for Dynamics 365 for Outlook**

The following options cannot be set:

- **Areas that display this table**
- **Activities**
- **Sending email**
- **Mail Merge**
- **Single row auditing**
- **Multiple row auditing**

Create a virtual table

Some options are only used when creating a virtual table.

Option	Description
Virtual Entity	Whether the table is a virtual table.
Data Source	The data source for the table.

More information: Create and edit virtual tables that contain data from an external data source

Microsoft Dataverse table relationships

Table relationships in Microsoft Dataverse define the ways that table rows can be associated with rows from other tables or the same table. There are two types of table relationships:

- One-to-many relationships
- Many-to-many relationships

One-to-many relationships

In a one-to-many table relationship, many referencing (related) table rows can be associated with a single referenced (primary) table row. The referenced table row is sometimes referred to as the "parent" and rows of the referencing table are referred to as "children." A many-to-one relationship is just the child perspective of a one-to-many relationship.

For example, in a school scenario multiple courses might be delivered in a single classroom, so the class table would have a one-to-many relationship with the course table.

Many-to-many relationships

In a many-to-many table relationship, many table rows can be associated with many other table rows. Rows related using a many-to-many relationship can be considered peers and the relationship is reciprocal.

For example, in the same school scenario mentioned earlier, a single student can enroll in multiple courses, and each course can have multiple students. This type of relationship allows for more complex data associations and is managed using Power Apps in Dataverse.

How relationships work in Dataverse

Table relationships define how table rows can be related to each other in Dataverse. At the simplest level, adding a lookup column to a table creates a new 1:N (one-to-many) relationship between the two tables and lets you put that lookup column on a form. With the lookup column, users can associate multiple *child* rows of that table to a single *parent* table row.

Beyond simply defining how rows can be related to other rows, 1:N table relationships also provide data to address the following questions:

- When I delete a row, should any rows related to that row also be deleted?
- When I assign a row, do I also need to assign all rows related to that row to the new owner?

- How can I streamline the data entry process when I create a new related row in the context of an existing row?
- How should people viewing a row be able to view the associated rows?

Tables can also participate in a N:N (many-to-many) relationship where any number of rows for two tables can be associated with each other.

Decide whether to use table relationships or connections

Table relationships are metadata that make changes in Dataverse. These relationships allow for queries to retrieve related data efficiently. Use table relationships to define formal relationships that define the table or that most rows can use. For example, an opportunity without a potential customer wouldn't be useful. The opportunity table in Dynamics 365 for Sales also has a N:N relationship with the competitor table, also available with Dynamics 365 for Sales. This allows for multiple competitors to be added to the opportunity. You might want to capture this data and create a report that shows the competitors.

There are other less formal kinds of relationships between rows that are called *connections*. For example, it might be useful to know if two contacts are married, or perhaps they're friends outside of work, or perhaps a contact used to work for another account. Most businesses won't generate reports using this kind of information or require that it's entered, so it's probably not worthwhile to create table relationships. More information: Configure connection roles

Types of table relationships

When you view relationships in Power Apps, you might think that there are three types of table relationships. Actually there are only two, as shown in the following table.

Expand table

Relationship Type	Description
1:N (One-to-Many)	A table relationship where one table row for the **Primary table** can be associated to many other **Related table** rows because of a lookup column on the related table. When viewing a primary table row, you can see a list of the related table rows that are associated with it. In the Power Apps portal, **Current table** represents the primary table.

Relationship Type	Description
N:N (Many-to-Many)	A table relationship that depends on a special **Relationship table**, sometimes called an Intersect table, so that many rows of one table can be related to many rows of another table. When viewing rows of either table in a N:N relationship, you can see a list of any rows of the other table that are related to it.

The **N:1 (many-to-one)** relationship type exists in the user interface because the designer shows you a view grouped by tables. 1:N relationships actually exist *between* tables and refer to each table as either a **Primary/Current table** or **Related table**. The related table, sometimes called the *child* table, has a lookup column that allows storing a reference to a row from the primary table, sometimes called the *parent* table. A N:1 relationship is just a 1:N relationship viewed from the related table.

Table relationship behavior

Behaviors for related tables are important because they help ensure data integrity and can automate business processes for you.

Preserve data integrity

Some tables exist to support other tables. They don't make sense on their own. They'll typically have a required lookup column to link to the primary table they support. What should happen when a primary row is deleted?

You can use the relationship behavior to define what happens to related rows according to the rules for your business. More information: Add advanced relationship behavior

Automate business processes

Let's say that you have a new salesperson and you want to assign them a number of existing accounts currently assigned to another salesperson. Each account row might have a number of task activities associated with it. You can easily locate the active accounts you want to reassign and assign them to the new salesperson. But what should happen for any of the task activities that are associated with the accounts? Do you want to open each task and decide whether they should also be assigned to the new salesperson? Probably not. Instead, you can let the relationship apply some standard rules for you automatically. These rules only apply to task rows associated to the accounts you're reassigning. Your options are:

- Reassign all active tasks.
- Reassign all tasks.
- Reassign none of the tasks.
- Reassign all tasks currently assigned to the former owner of the accounts.

The relationship can control how actions performed on a row for the primary table row cascade down to any related table rows.

Behaviors

There are several kinds of behaviors that can be applied when certain actions occur.

Expand table

Behavior	Description
Cascade Active	Perform the action on all active related table rows.
Cascade All	Perform the action on all related table rows.
Cascade None	Do nothing.
Remove Link	Remove the lookup value for all related rows.
Restrict	Prevent the primary table row from being deleted when related table rows exist.
Cascade User Owned	Perform the action on all related table rows owned by the same user as the primary table row.

Actions

These are the actions that can trigger certain behaviors:

Expand table

Column	Description	Options
Assign	What should happen when the primary table row is assigned to someone else?	Cascade All Cascade Active Cascade User-owned Cascade None
Reparent	What should happen when the lookup value of a related table in a parental relationship is changed? More information: Parental table relationships	Cascade All Cascade Active Cascade User-

Column	Description	Options
		owned Cascade None
Share	What should happen when the primary table row is shared?	Cascade All Cascade Active Cascade User-owned Cascade None
Delete	What should happen when the primary table row is deleted?	Cascade All Remove Link Restrict
Unshare	What should happen when a primary table row is unshared?	Cascade All Cascade Active Cascade User-owned Cascade None
Merge	What should happen when a primary table row is merged?	Cascade All Cascade None
Rollup View	What is the desired behavior of the rollup view associated with this relationship?	Cascade All Cascade Active Cascade User-owned Cascade None

> **Note**
>
> Assign, Delete, Merge, and Reparent actions don't execute in the following situations:
>
> - If the original parent row and requested action contain the same values. Example: Attempting to trigger an Assign and choosing a contact that is already the owner of the row.
> - Attempting to perform an action on a parent row that is already running a cascading action.
>
> When executing an assign, any workflows or business rules that are currently active on the rows are automatically deactivated when the reassignment occurs. The new owner of the row must reactivate the workflow or business rule if they want to continue using it.

Parental table relationships

Each pair of tables that are eligible to have a 1:N relationship can have multiple 1:N relationships between them. Yet usually only one of those relationships can be considered a parental table relationship.

A parental table relationship is any 1:N table relationship where one of the cascading options in the **Parental** column of the following table is true.

Expand table

Action	Parental	Not Parental
Assign	Cascade All Cascade User-owned Cascade Active	Cascade None
Delete	Cascade All	RemoveLink Restrict
Reparent	Cascade All Cascade User-owned Cascade Active	Cascade None
Share	Cascade All Cascade User-owned Cascade Active	Cascade None
Unshare	Cascade All Cascade User-owned Cascade Active	Cascade None

For example, if you create a new custom table and add a 1:N table relationship with the account table where your custom table is the related table, you can configure the actions for that table relationship to use the options in the **Parental** column. If you later add another 1:N table relationship with your custom table as the referencing table you can only configure the actions to use the options in the **Not Parental** column.

Usually this means that for each table pair there's only one parental relationship. There are some cases where the lookup on the related table might allow for a relationship to more than one type of table.

For example, if a table has a customer lookup that can refer to either a contact or account table. There are two separate parental 1:N table relationships.

Any activity table has a similar set of parental table relationships for tables that can be associated using the regarding lookup column.

Limitations on behaviors you can set

Because of parental relationships there are some limitations, you should keep in mind when you define table relationships.

- A custom table can't be the primary table in a relationship with a related system table that cascades. This means you can't have a relationship with any action set to **Cascade All**, **Cascade Active**, or **Cascade User-Owned** between a primary custom table and a related system table.
- No new relationship can have any action set to **Cascade All**, **Cascade Active**, or **Cascade User-Owned** if the related table in that relationship already exists as a related table in another relationship that has any action set to **Cascade All**, **Cascade Active**, or **Cascade User-Owned**. This prevents relationships that create a multi-parent relationship.

Inherited access rights cleanup

Using **Reparent** and **Share** cascading behaviors are helpful when you want to provide access to rows across related tables. But there can be a change in process or design that requires a change of the cascading behavior settings.

When a table relationship uses **Reparent** or **Share**, and the cascading behavior is changed to **Cascade None**, the table relationship prevents any new permission changes from cascading to the related child tables. In addition, inherited permissions that were granted while the cascading behavior was active must be revoked.

Inherited access rights cleanup is a system job that cleans up the legacy inherited access rights that remain after the cascading behavior is changed to **Cascade None**. This cleanup doesn't affect any user that was directly granted access to a table, but does remove access from anyone who received access through inheritance only.

This is how inherited access rights cleanup works:

1. Identifies and collects all the tables that were in a cascading relationship with the updated parent.
2. Identifies and collects the users that were granted access to the related tables through inherited access.
3. Checks for users who were given direct access to a related table and removes them from the collection.
4. Removes inherited access for the collected users on the collected tables.

After the cleanup runs, users who were able to access related tables only because of the cascading feature can no longer access the rows, ensuring greater security. There are cases where the cleanup might not be successful. Learn more about how to clean up inherited access

Create one-to-many or many-to-one table relationships in Microsoft Dataverse overview

08/11/2025

In Microsoft Dataverse a one-to-many (1:N) or many-to-one (N:1) relationship defines how two tables are related to each other.

Before you create a custom table relationship, evaluate whether using an existing table relationship would meet your requirements. More information: Create new metadata or use existing metadata?

Watch this video for a quick overview about how to create a table, a table relationship, and columns:
https://learn-video.azurefd.net/vod/player?id=19b21a48-4a49-4163-8506-7fb79f3290ef&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fcreate-edit-1n-relationships

You create and edit table relationships, including one-to-many and many-to-one relationships, in Power Apps.

You can also create new table relationship in your environment using any of the following experiences:

- In model-driven apps, select **New Column** from the form editor and create a *Lookup* column. More information: Add, configure, move, or delete columns on a form
- Create a new Lookup column for the related table.More information: Create and edit columns
- Import a solution that contains the definition of the table relationship. More information: Import, update, and export solutions
- Use Power Query to create new tables and fill them with data. More information: Add data to a table in Dataverse by using Power Query.
- A developer can use Metadata services to write a program to create and update table relationships. More information: Table relationship definitions

Information in this article helps you choose which designer you can use.

Create a one-to-many or many-to-one relationship

Create and edit one-to-many or many-to-one table relationships in Power Apps

Community tools

table Relation Diagram Creator is a tool that XrmToolbox community developed for Dataverse. Please see the Developer tools and resources topic for more community developed tools.

Create many-to-many table relationships overview

08/11/2025

One-to-many (1:N) table relationships establish a hierarchy between rows. With many-to-many (N:N) relationships, there's no explicit hierarchy. There are no lookup columns or behaviors to configure. Rows created using many-to-many relationships can be considered peers and the relationship is reciprocal.

One example of a many-to-many relationship is defined between two standard tables included with the Dynamics 365 for Sales app. The opportunity table has an N:N relationship with the competitor table. This relationship allows for multiple competitors to be added to the opportunity and multiple opportunities associated with the same competitor.

With many-to-many relationships, a relationship (or intersect) table stores the data that associates the tables. This table has a one-to-many table relationship with both of the related tables and only stores the necessary values to define the relationship. You can't add custom columns to a relationship table and it's never visible in the user interface.

Creating a many-to-many relationship requires choosing the two tables that you want to participate in the relationship. For model-driven apps you can decide how you want the respective lists to be available within the navigation for each table. These are the same options used for the primary table in 1:N table relationships.

Not all tables can be used with many-to-many relationships. If the table isn't available to be chosen in the designer, you can't create a new many-to-many relationship with this table. More information: Developer documentation: table relationship eligibility

> ⓘ **Note**
>
> You can also create new many-to-many (N:N) table relationship in your environment using the following:
>
> - Import a solution that contains the definition of the relationship. More information: Import, update, and export solutions
> - A developer can use Metadata services to write a program to create and update table relationships. More information: Developer documentation: Table relationship definitions

Next steps

Create many-to-many table relationships

Create a relationship between tables

Data in one table often relates to data in another table. For example, you might have a **Teachers** table and a **Class** table, and the **Class** table might have a lookup relation to the **Teachers** table to show which teacher instructs the class. You can use a lookup column to show data from the **Teachers** table. This is commonly referred to as a lookup column.

Define a relationship

You can create several types of relationships from one table to another (or between a table and itself). Each table can have a relationship with more than one table, and each table can have more than one relationship to another table. Some common relationship types are:

- **Many-to-one** - In this type of relationship, each row in table A can match more than one row in table B, but each row in table B can match only one row in table A. For example, a class has a single classroom. This is the most common type of relationship and is shown in the column list as a **Lookup column**
- **One-to-many** - In this type of relationship, each row in table B can match more than one row in table A, but each row in table A can match only one row in table B. For example, a single teacher, teaches many classes.
- **Many-to-many** - In this type of relationship, each row in table A can match more than one row in table B, and vice versa. For example, students attend many classes, and each class can have multiple students.

Additionally, you can set advanced cascading behaviors on many-to-one and one-to-many relationships whenever an action is taken on the parent table.

Add a lookup column (Many-to-one relationship)

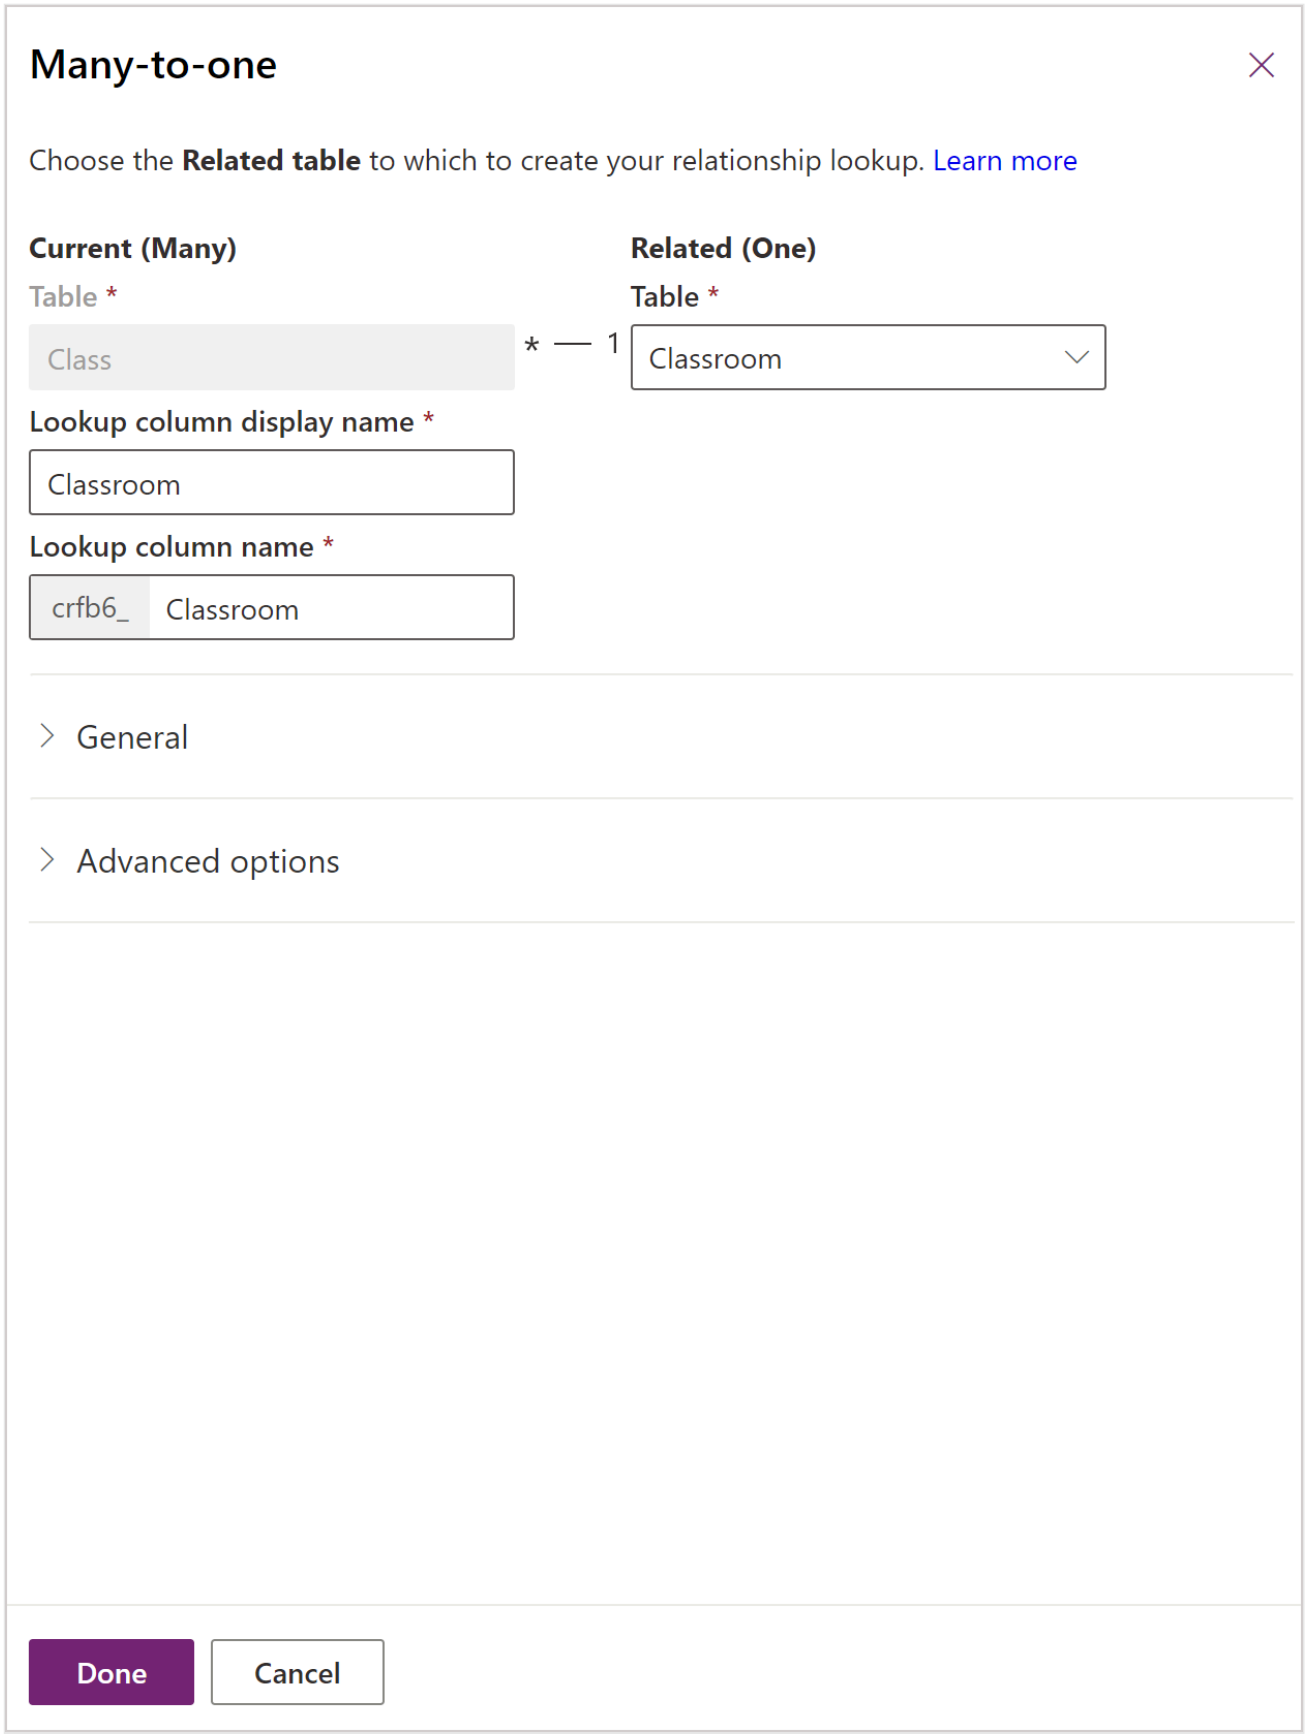
To add a lookup relation to a table, create a relation under the **Relationships** area and specify the table with which you want to create a relationship.

1. In Power Apps, on the left navigation pane select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.

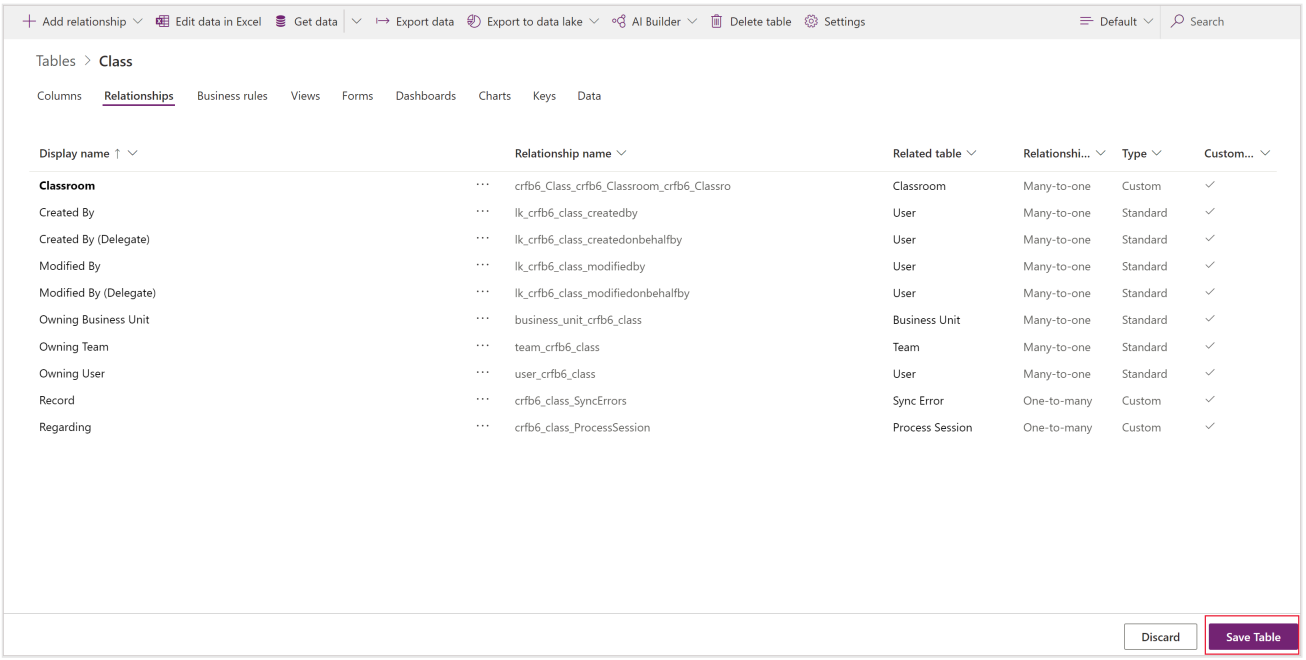
2. Select an existing table, or Create a new table, and then select **Relationships**.

3. Select **New relationship**, and then select a relationship type, such as **Many-to-one**.

4. On the right pane, select a **Related** table for the **Current** table, and then select **Done**.



5. Select **Done**.



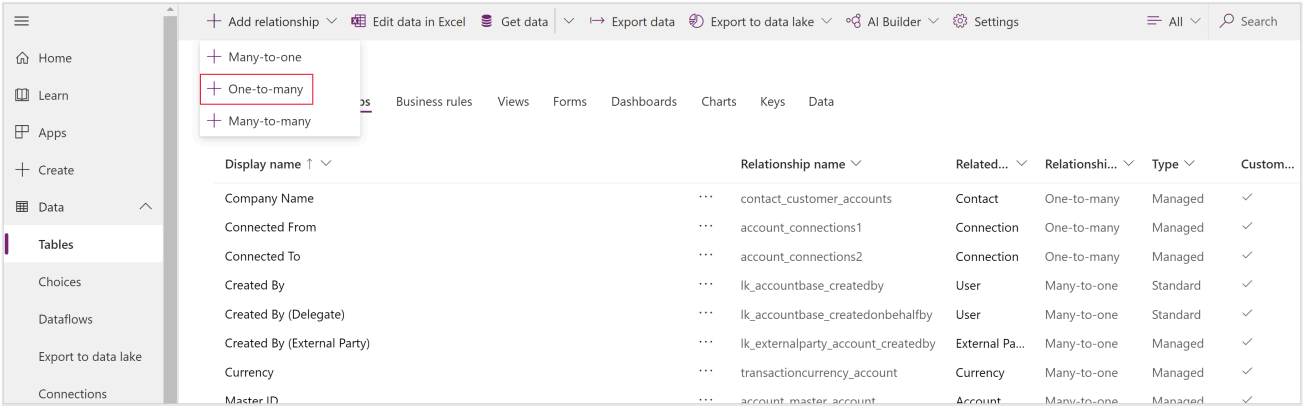
Add a one-to-many relationship

To add a one-to-many relationship, create a relation under the **Relationships** area and specify the table with which you want to create a relationship.

1. In Power Apps, select **Tables** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select an existing table, or Create a new table, and then select **Relationships**.

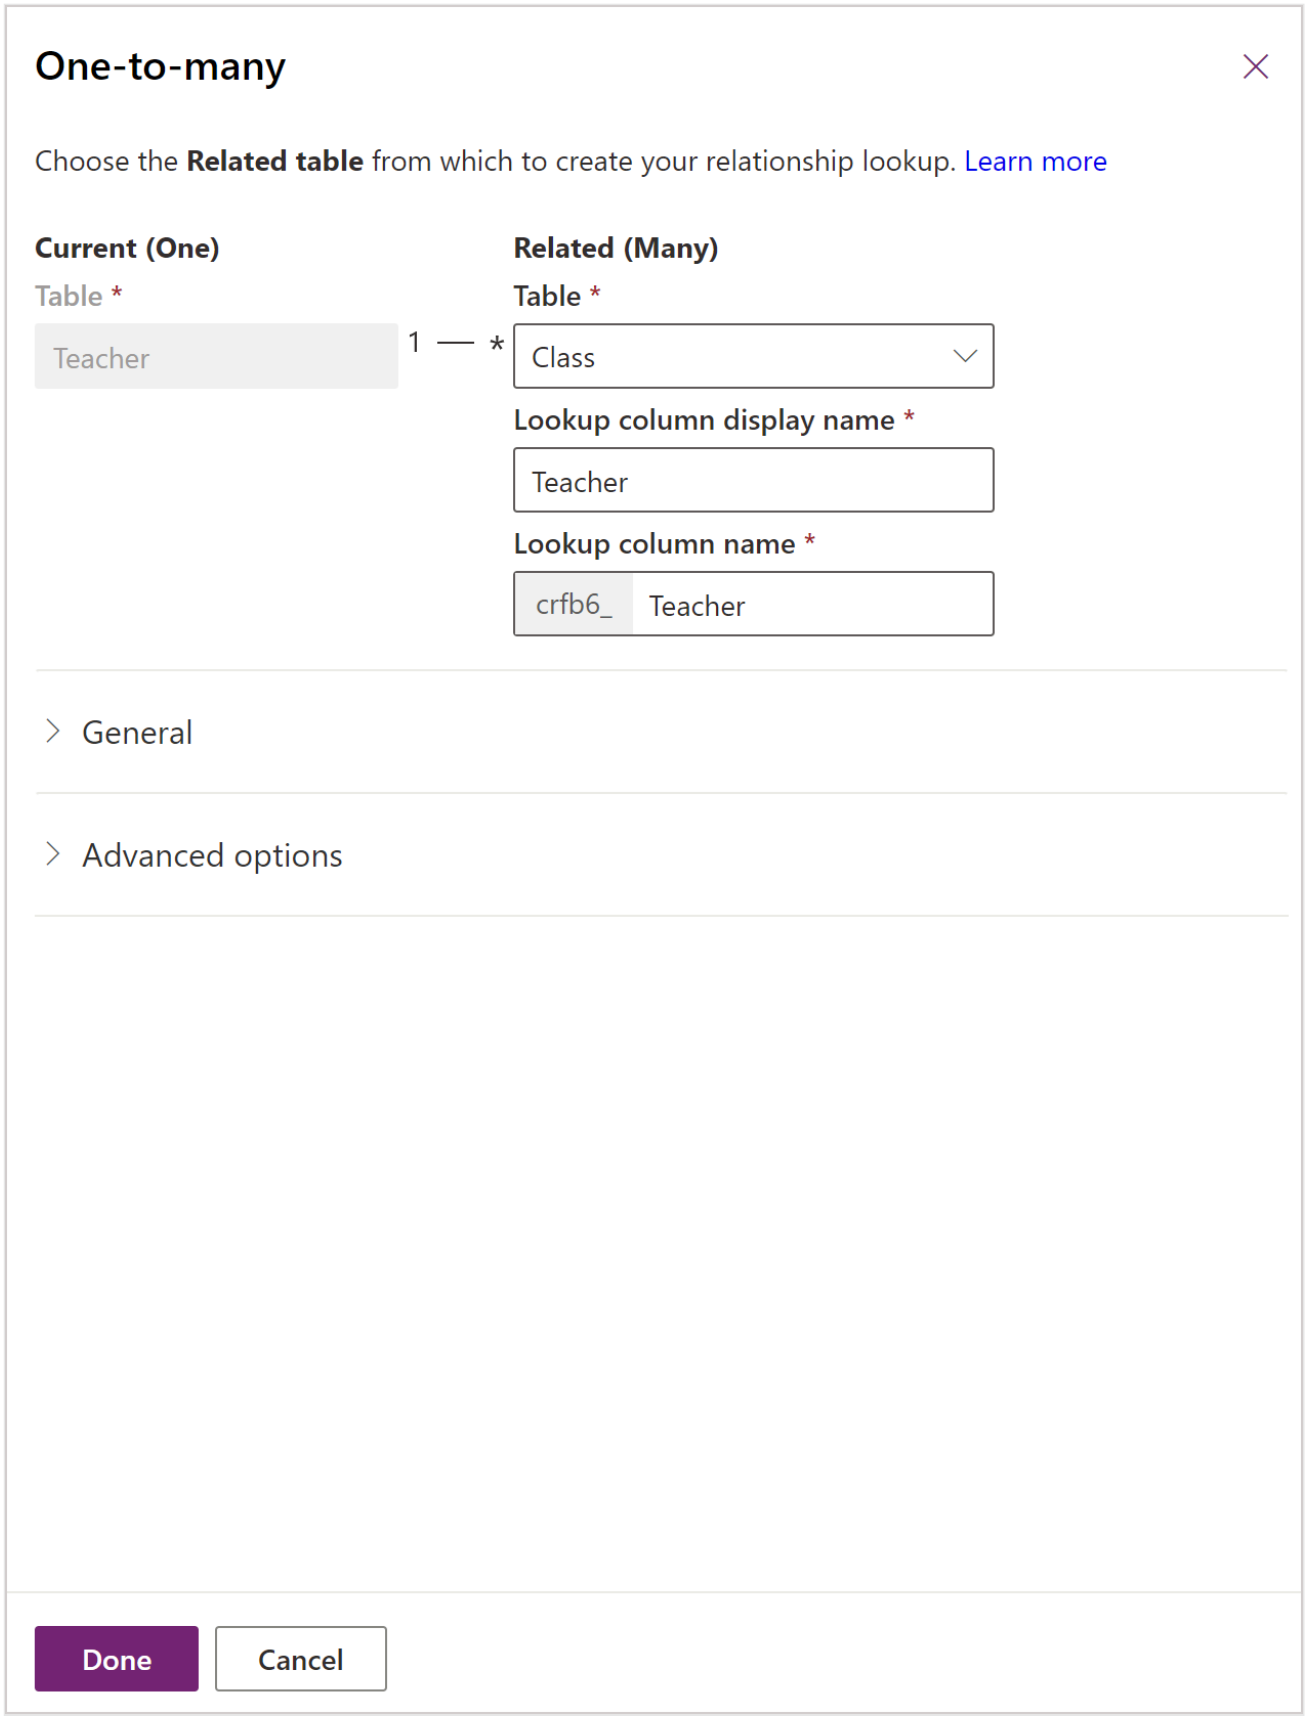
3. Select the down arrow to the right of **Add relationship**, and then select **One-to-many**.



4. Select a table. Notice the **Look up** columns will be shown on the **Current** table, they'll default with the tables name (in this example Teacher) but you can change them if needed. Select **Done** to add the relationship to your table.

> **Note**

In the case of a One-to-many relationships, the Look up column will be created on the related table, not the table you currently have selected. If you need the lookup on the current table, create a Many-to-one relationship.



5. Select **Done**.

Add a many-to-many relationship

To add a many-to-many relationship, create a relation under the **Relationships** area and specify the table with which you want to create a relationship.

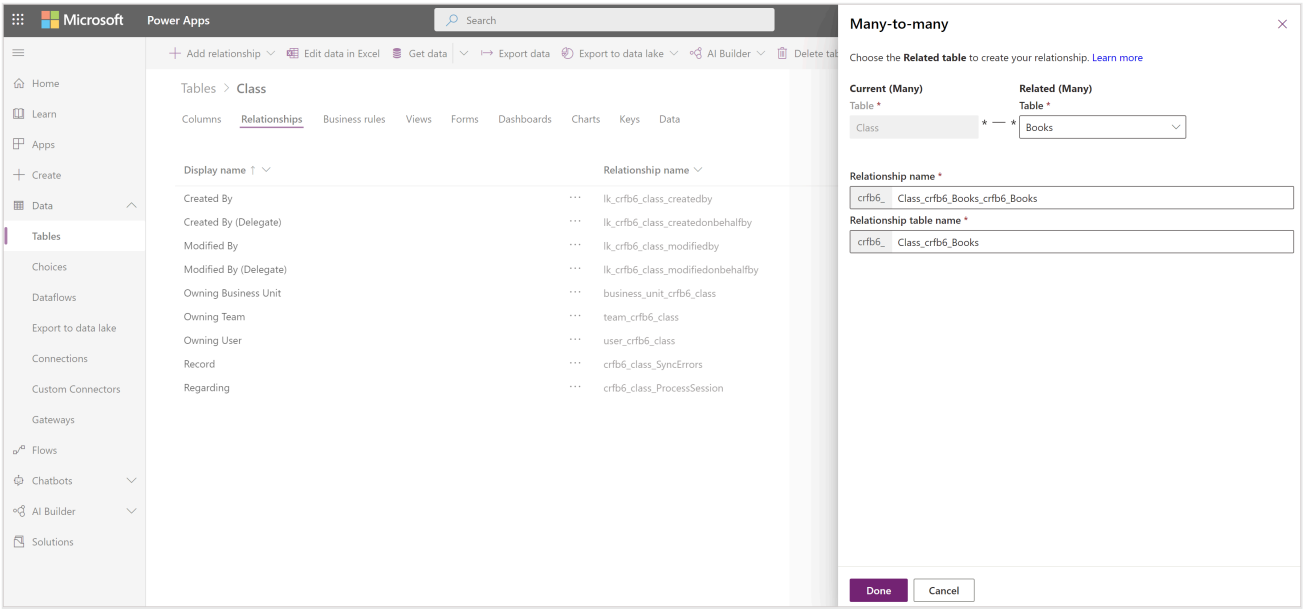
1. On powerapps.com, select **Tables** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select an existing table, or Create a new table

3. Select the **Relationships** area.

4. Select **Add relationship** and then select **Many-to-many**. This opens a panel for you to choose the table you want to create a relationship to. Select the table from the **Related table** drop-down.

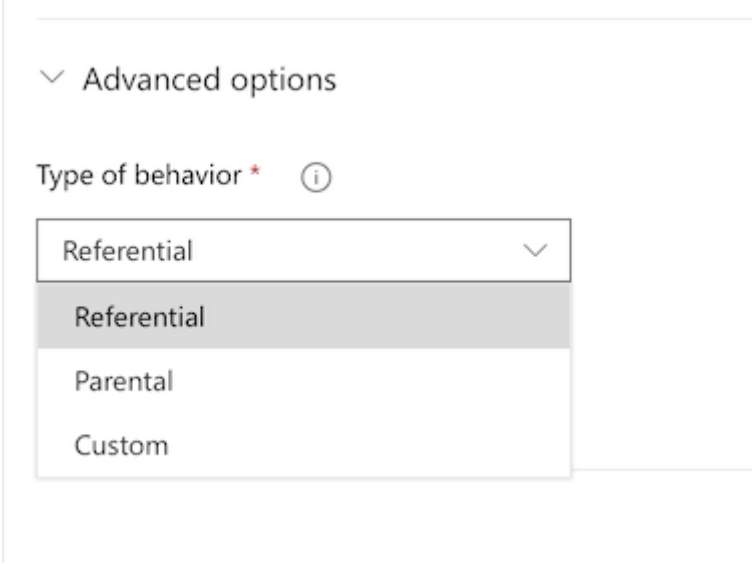
5. After selecting a table, the names for the relationship and relationship table appear. They default to the names of the tables combined, but you can change them if needed.



6. Select **Done** to add the relationship to your table, and then select **Save table**.

Add advanced relationship behavior

While building a one-to-many or a many-to-one relationship, you can also set advanced behaviors.



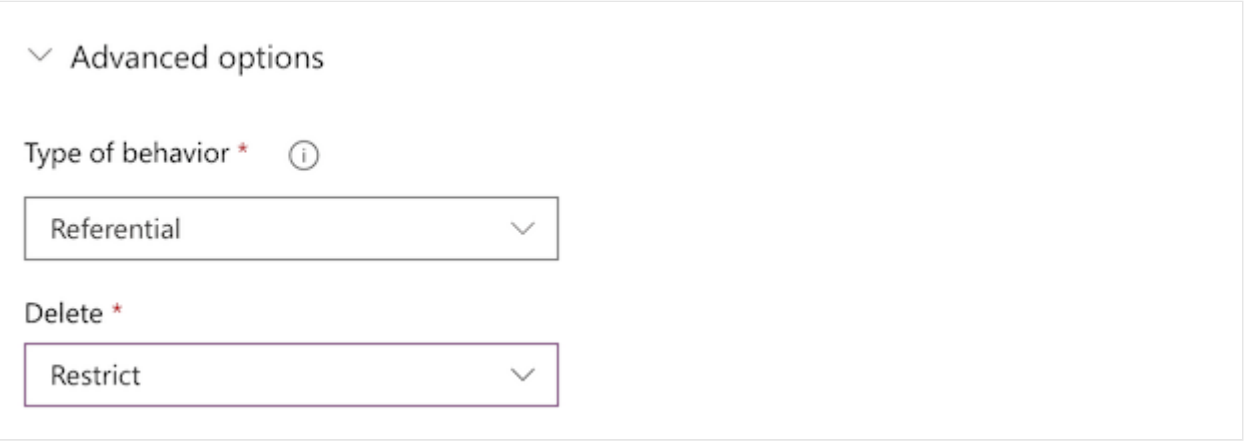
These options are also referred to as cascading behaviors because they cascade down the hierarchy of related tables. For example, it might be desirable to delete the related tests and homework of a student if a student is removed from the system. This type of behavior is called a parental relationship.

On the other hand, you might decide that you don't want actions to cascade down the hierarchy. For example, in the teacher to class relationship you could decide that the child table (class) shouldn't* be deleted when a parent (teacher) is deleted. This is called a referential relationship.

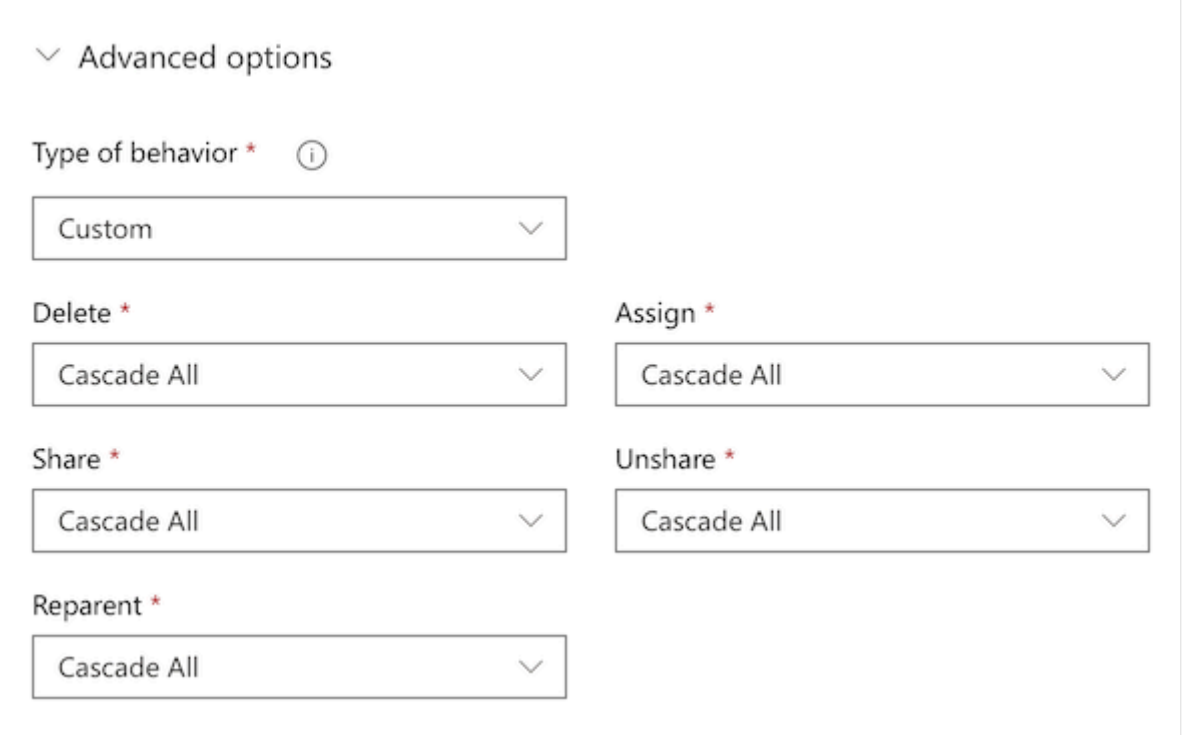
As you model your business data by creating custom tables or when using existing Common Data Model tables, consider the behavior you require and the implications for the entire hierarchy of related tables and choose between one of the following standard behaviors:

- **Referential, Remove Link:** In a referential relationship between two tables, you can navigate to any related rows, but actions taken on one table don't affect the other. For example, if you have a one-to-many relationship between teachers and classes, deleting a teacher has no impact on the related class.

- **Referential, Restrict Delete:** In a referential, restrict delete relationship between two tables, you can navigate to any related rows. Actions taken on the parent row don't affect the child row, but the parent row can't be deleted while the child row exists. This behavior is useful if you don't want child rows to become orphaned. This restriction forces the user to delete all of the children before deleting the parent.



- **Parental:** In a parental relationship between two tables, any action taken on a record of the parent table is also taken on any child table records that are related to the parent table record. For example, the owner of the parent record has inherited access to the child table records and when the parent record is deleted, all of the child records will also be deleted.
- **Custom:** In a custom relationship between two tables, you select the behavior associated with each of a set of possible actions.



For more information on defaults and custom behaviors: Configure table relationship behavior.

Use a lookup column in an app

If you create an app automatically from a table that contains a lookup column, it appears as a **Drop down** control that contains data from the **Primary name** column of the table.

Add 1:N and N:N relationships for canvas apps

Use the **Relate** function to link two rows through a one-to-many or many-to-many relationship in Microsoft Dataverse. More information: Relate and Unrelate functions in Power Apps

Next steps

- Generate an app by using a Dataverse database
- Create an app from scratch using a Dataverse database

Create and edit one-to-many or many-to-one table relationships using Power Apps

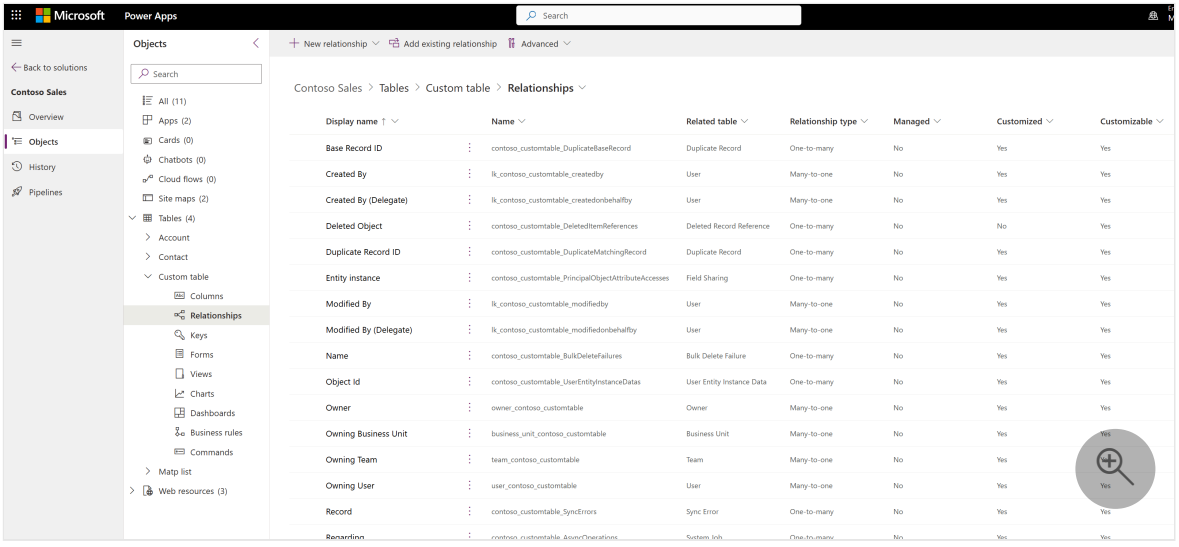
Article • 09/19/2024

In Microsoft Dataverse a one-to-many (1:N) or many-to-one (N:1) relationship defines how two tables are related to each other.

Power Apps provides an easy way to create and edit one-to-many (1:N) or many-to-one (N:1) relationships for Microsoft Dataverse. For more information about these kinds of relationships, go to Create one-to-many or many-to-one table relationships overview.

View table relationships

1. Sign in to Power Apps, and open the environment you want.
2. Select **Solutions** on the left navigation pane, and then open the solution you want.
3. Select **Tables** and open the table that has the relationships you want to view. If the item isn't in the side panel pane, select ...More and then select the item you want.
4. Select the **Relationships** area to view all relationships configured for the table.



Create a relationship

While viewing table relationships, on the command bar, select **New relationship**, and then select either **Many-to-one** or **One-to-many**.

> **Note**

For information about **Many-to-many** relationships see [Create N:N (many-to-many) relationships]

Depending on your choice the following is displayed:

Expand table

Type	Panel
Many-to-one	One-to-many	
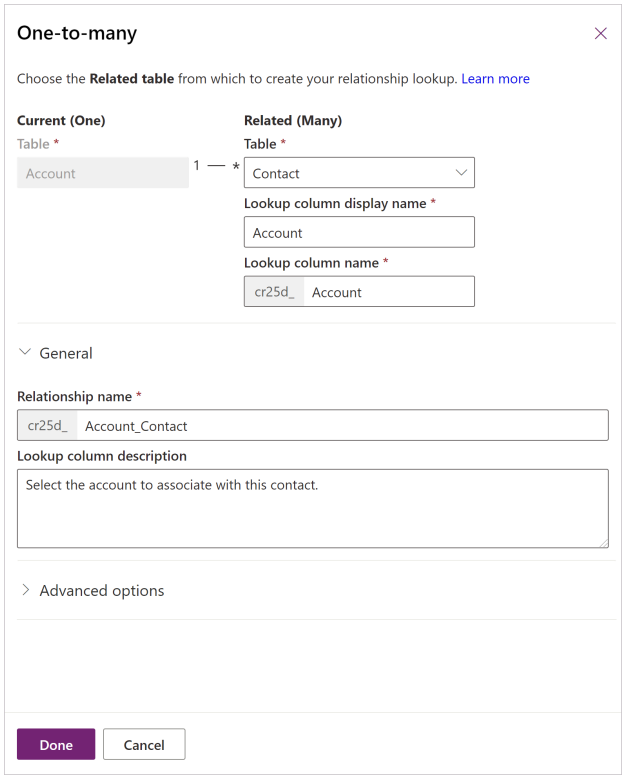
Choose the **Related** table for the relationship you want to create between the two tables.

> **Note**
>
> With either choice, a lookup column is created on the **Current** table. For more information about look columns, go to [Use the lookup column on a row].

Once you select the related table, you can edit the details of the relationship. In this example, multiple contact table rows can be associated with a single account.



You can edit the default values provided before you save. Select **General** to view the **Relationship name** and **Lookup column description** values.

Expand table

Field	Description
Lookup column display name	The localizable text for the lookup column that will be created on the related table. This can be edited later.
Lookup column name	The name for the Lookup column that will be created on the related table.
Lookup column requirement	**Optional**. Column value doesn't have to be selected to save the record. **Business Recommended**. Should be selected indicator but column value doesn't have to be selected to save the record. **Business Required**. Column value must be specified in order to save the record.
Searchable	Clear if you want to hide the relationship from **Advanced Find** in model-driven apps.
Relationship name	The name for the relationship that will be created.
Lookup column description	The description for the lookup column. In model-driven apps this appears as a tooltip when people hover their mouse over the column. This can be edited later.

You can continue editing the table. Select **Save table** to create the relationship you have configured.

Advanced options

For both the **Current table display settings** and the **Related table display settings**, you can edit the display option columns, which control how the related tables are displayed for model-driven apps. More information: Advanced options

Relationship behavior

Relationship behavior determines how records are handled as the action cascades down the hierarchy of related tables. For example, it might be desirable to delete the related tests and homework of a student if a student is removed from the system. This type of behavior is called a parental relationship. For more information about how to configure relationship behavior, go to Add advanced relationship behavior.

Edit relationships

While viewing table relationships, open the relationship you want to edit to display the properties pane.

The only columns you can edit are **Lookup column display name** and **Lookup column description**. These can also be edited in the properties of the lookup column in the related table. More information: Edit a column

> **Note**
>
> Each relationship can be found within the primary table or the related table as a **Many-to-one** or **One-to-many** relationship. Although it can be edited in either place, it is the same relationship.
>
> The publisher of a managed solution can prevent some customizations of relationships that are part of their solution.

Delete relationships

Deleting a one-to-many relationship deletes the lookup column on the related table.

> **Note**
>
> You can't delete a relationship that has dependencies. For example, if you have added the lookup column to a form for the related table, you must remove the column from the form before you delete the relationship.

While viewing table relationships, select the relationship you want to remove or delete, choose from the following relationship types:

- Custom relationships in a single solution. On the command bar, select **Remove** > **Delete from this environment**.
- Custom relationships in multiple solutions, system, or standard table relationships. On the command bar, select **Remove** > **Remove from this solution**.

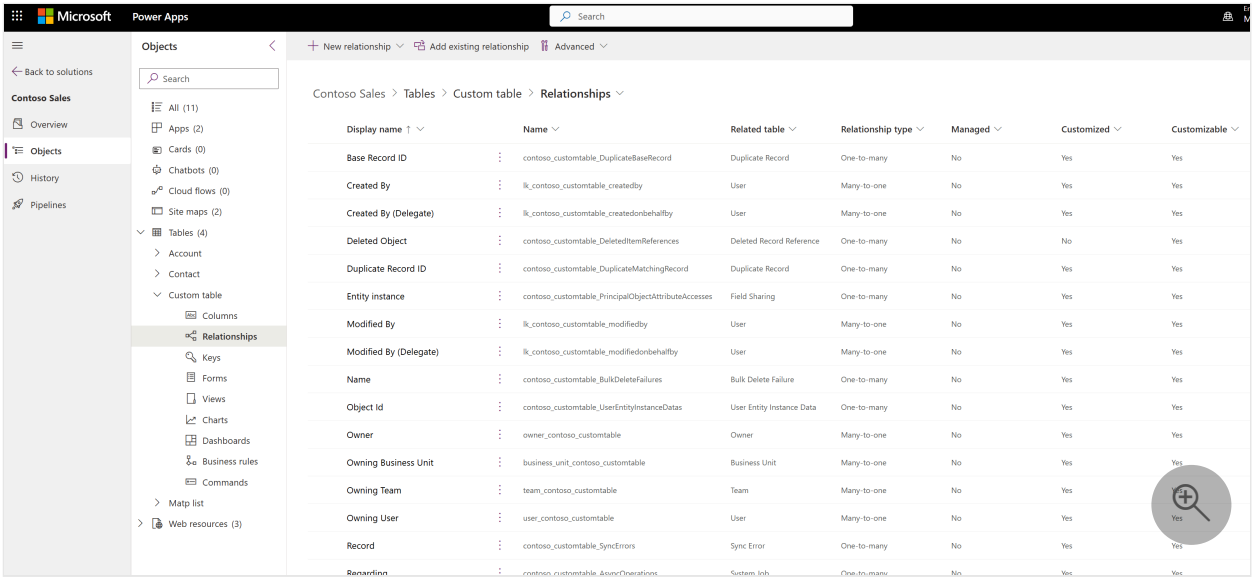
Create many-to-many table relationships using Power Apps

Article • 09/17/2024

Power Apps provides an easy way to create and edit many-to-many relationships for Microsoft Dataverse tables. A many-to-many relationship defines the type of connection between two tables where multiple records in one table can be associated with multiple records in another table. For example, in a school scenario, a single student can enroll in multiple courses, and each course can have multiple students. This type of relationship allows for more complex data associations and is managed using Power Apps in Dataverse. For more information about many-to-many table relationships, go to Create many-to-many table relationships overview.

View many-to-many table relationships

1. From Power Apps, select **Solutions** on the left navigation pane, and open the solution you want.
2. Open the table that has the relationships you want to view.
3. Select the **Relationships** area to view all relationships configured for the table.

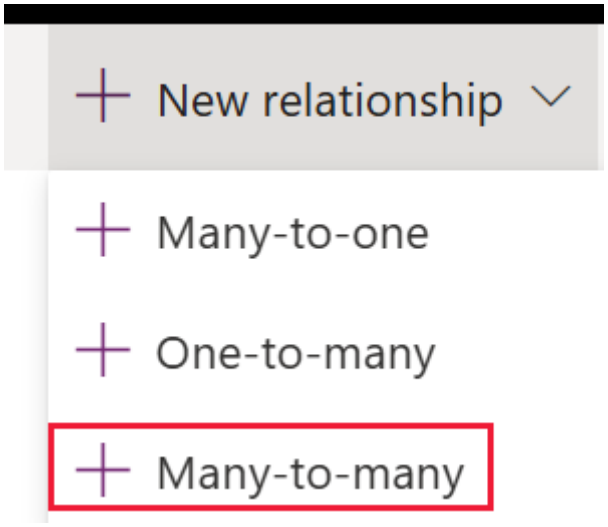


Many-to-many relationships have a **Relationship type** of **Many-to-many**.

> **Note**
>
> The table you view might have no **Many-to-many** relationships.

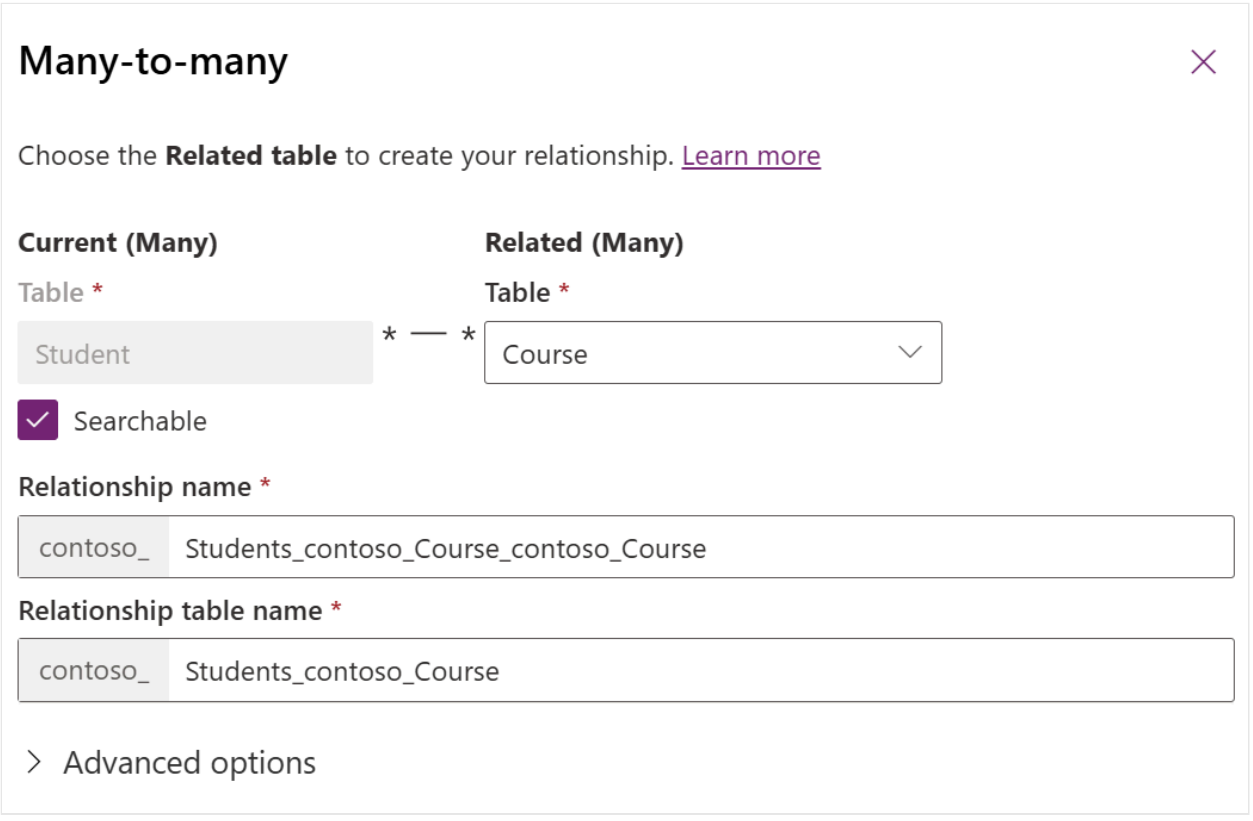
Create relationships

While viewing table relationships, on the command bar, select **New relationship**, and then select **Many-to-many**.



The **Many-to-many relationship** editor is displayed.

In the **Related (Many)** dropdown list, choose the table you want to relate to the current table. In this example, a many-to-many relationship with the student and course tables is created.



The values for these columns are generated for you based on the tables chosen.

Clear **Searchable**, if you want to hide the relationship from **Advanced Find** in model-driven apps.

If you want to edit the display settings for the relationship, expand **Advanced options** and make the changes you want. More information: Advanced options

> **Note**
>
> If you create more than one **Many-to-many** relationship with the same two tables, you must edit the generated **Relationship Name** and **Relationship table name** columns so that they are unique.

Select **Done** to close the **Many-to-many** panel. The relationship is created when you save changes to the table.

Advanced options

For both the **Current table display settings** and the **Related table display settings**, you can edit the display option columns, which control how the related tables are displayed for model-driven apps.

Expand table

Field	Description
Display option	How the related table list should be displayed. More information: Display Options
Custom label	Specify the localizable text to be used instead of the plural name when you select **Use Custom label** as the **Display option** .
Display area	Select one of the available groupings to display this list. The available options are: **Details** (for the *Common* group), **Marketing**, **Sales**, and **Service**.
Display order	Controls where the navigation item will be included within the selected display area. The range of allowed numbers begins with 10,000. Navigation pane items with a lower value appear above other relationships with a higher value.

Display Options

These are the available display options:

Expand table

Option	Description
Do not Display	Do not display the related tables for this relationship.
Use custom label	When this option is chosen the **Custom label** column is enabled so that you can specify the localizable text to be used instead of the plural name.
Use plural name	Use the plural display name defined for the related table.

Create a many-to-many relationship with the same table (self-referential relationship)

There might be times when you need to create a many-to-many relationship that references the same table. For example, account records might have multiple parent account records. However, if the self-referential relationship doesn't have custom labels configured, distinguishing the two related record types that appear in the app isn't apparent to users. This is because the related records appear twice in the app by using the same table name.

To create a self-referential relationship, use custom labels.

1. Open or create a solution and then create a new custom table. In this example, the table is named *Custom table*.

2. Open the custom table, select the **New** > **Relationship** > **New relationship** > **Many-to-many relationship**.

3. Under **Related (Many)** select the same table, in the example *Custom table*, that's also the **Current (Many)** table.

4. Expand **Advanced options** and complete the relationship definition as follows. Add custom labels to both the current and the related table's relationship:

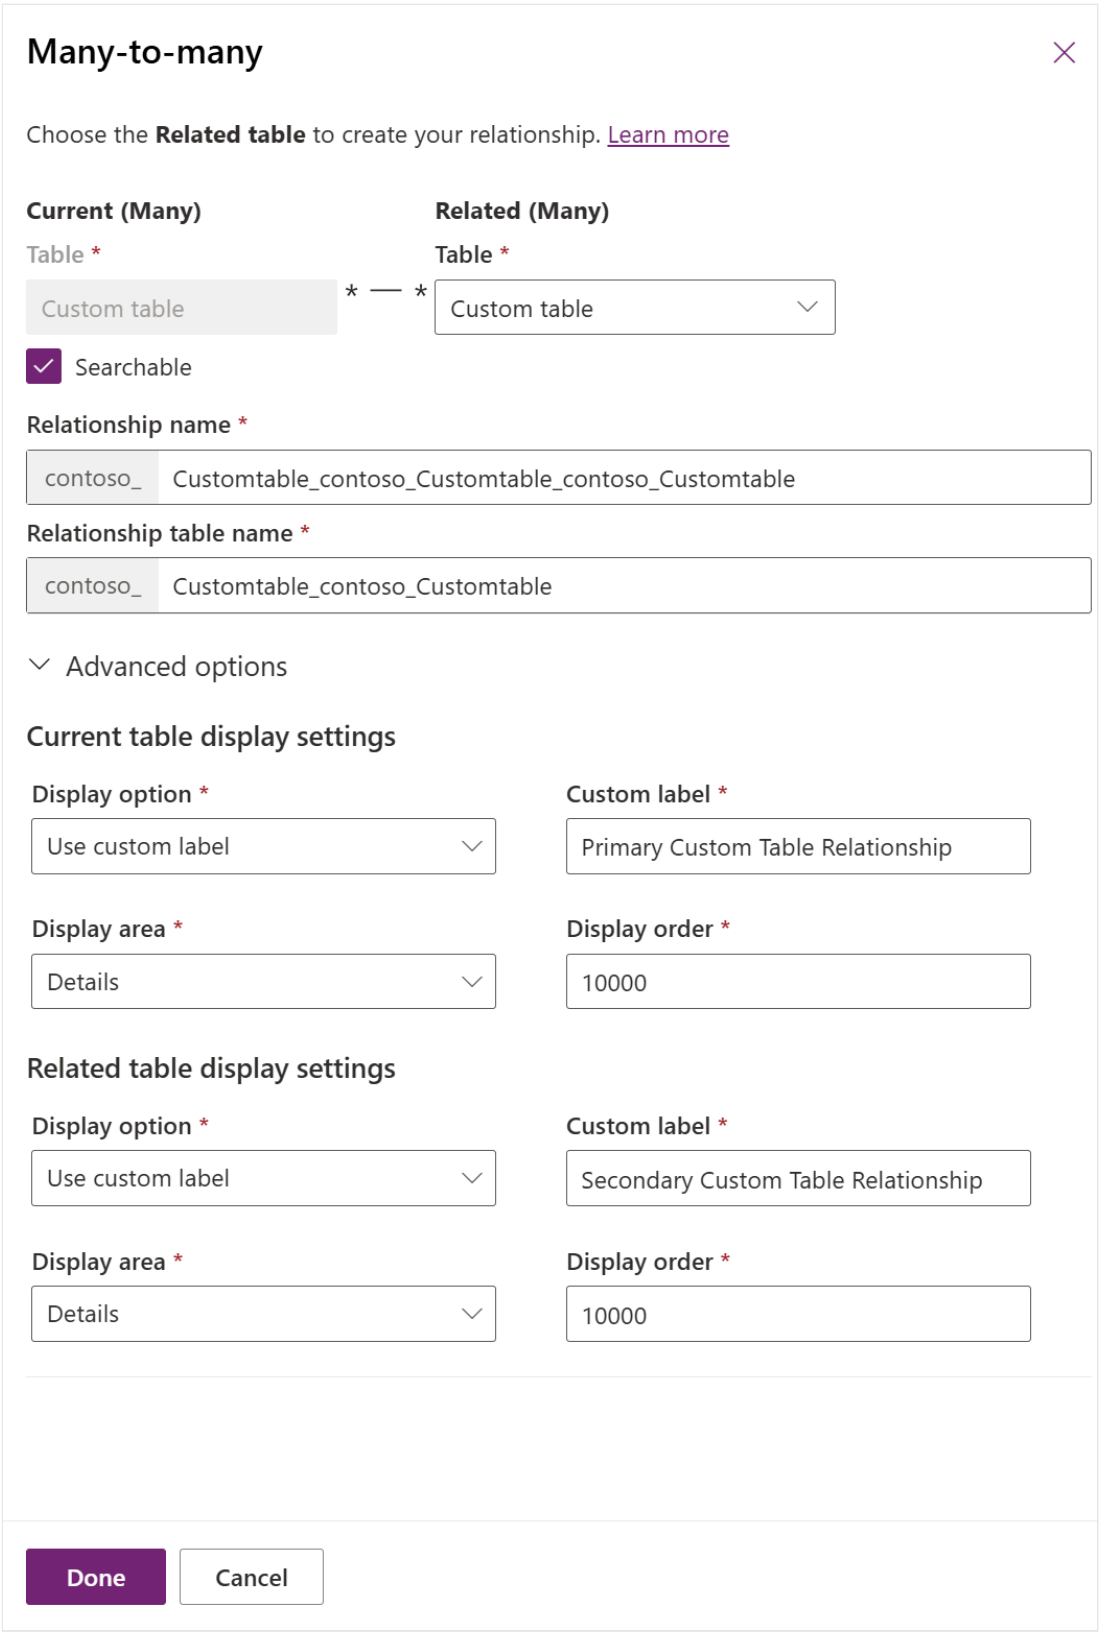
   Current table display settings section

   - **Display option**: **Use custom label**
   - **Custom label**: *Primary Custom Table Relationship*

   Related table display settings section

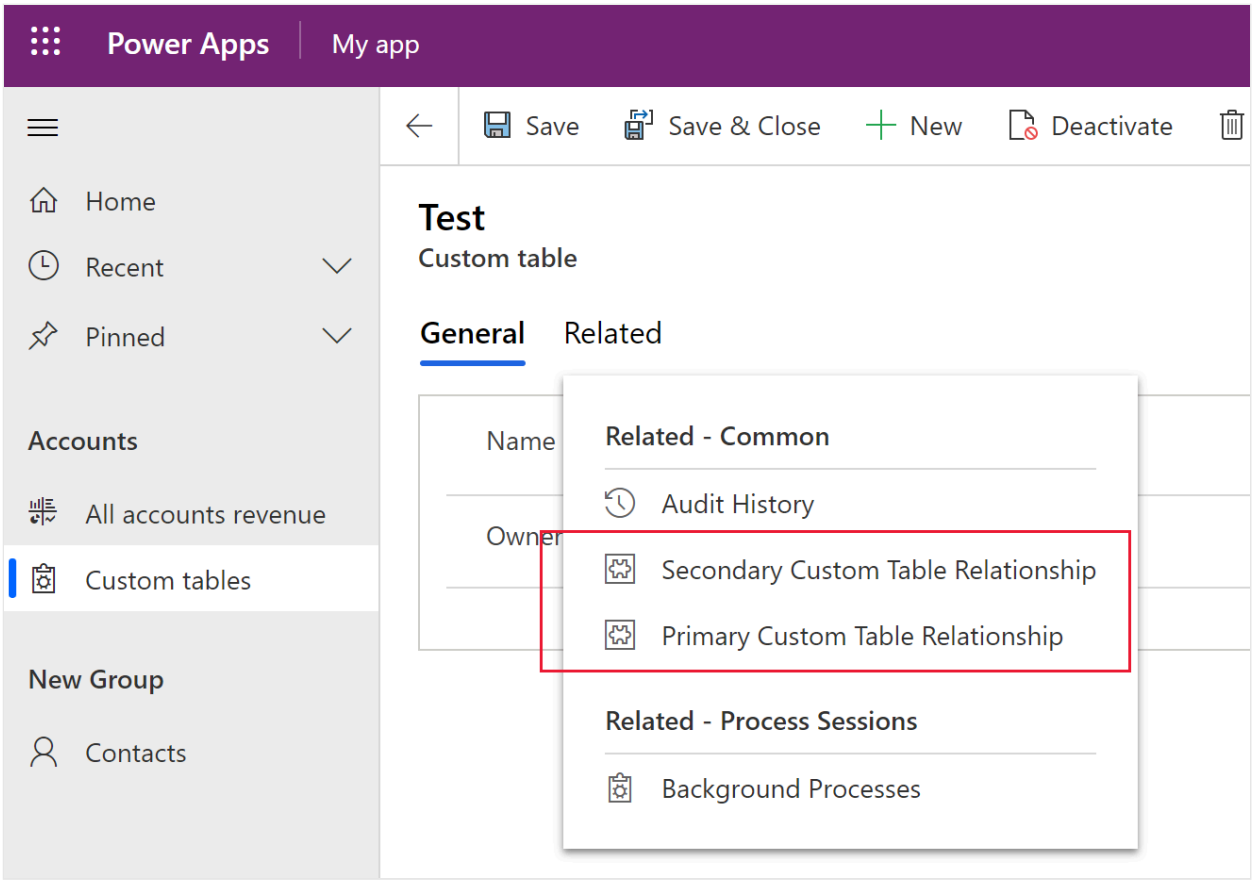
   - **Display option**: **Use custom label**

- **Custom label**: *Secondary Custom Table Relationship*



5. Select **Done** to save the relationship, and then publish the customization.

Because the related record types use the custom labels defined for the self-referential relationship instead of the table name, users running the app can distinguish between the two related record types that exist.



Delete relationships

Deleting a many-to-many relationship deletes the relationship table created. All data connecting tables using the relationship are lost.

While viewing table relationships, select the relationship you want to delete, and then on the command bar select **Remove** > **Delete from this environment**.

Set managed properties for relationships

Article • 09/19/2024

Managed properties apply when you include a column with a managed solution and import it into another organization. These settings allow a solution maker to have some control over the level of customization that they want to allow people who install their managed solution to have when they customize a table relationship.

Set managed properties for a relationship

1. Sign in to Power Apps ,and select the environment you want.
2. Select **Solutions**, open the solution you want, and then open the table that has the relationship where you want to view the managed properties.
3. Select the relationship, and then select **Advanced** > **Managed properties** on the command bar.

With relationships, the only managed property is **Allow customizations**. This single setting controls all changes that can be made to the table relationship.

Configure connection roles

Article • 03/13/2023

With Microsoft Dataverse, you can define **connections** between table rows without creating a table relationship. In model-driven apps people can establish a named link between rows to establish less a formal relationship, which doesn't justify creating an actual table relationship. Some examples include *friend*, *sibling*, *spouse*, *attendee*, and *stakeholder*. Some connections can also be reciprocal, such as *child* and *parent*, *husband* and *wife*, or *doctor* and *patient*.

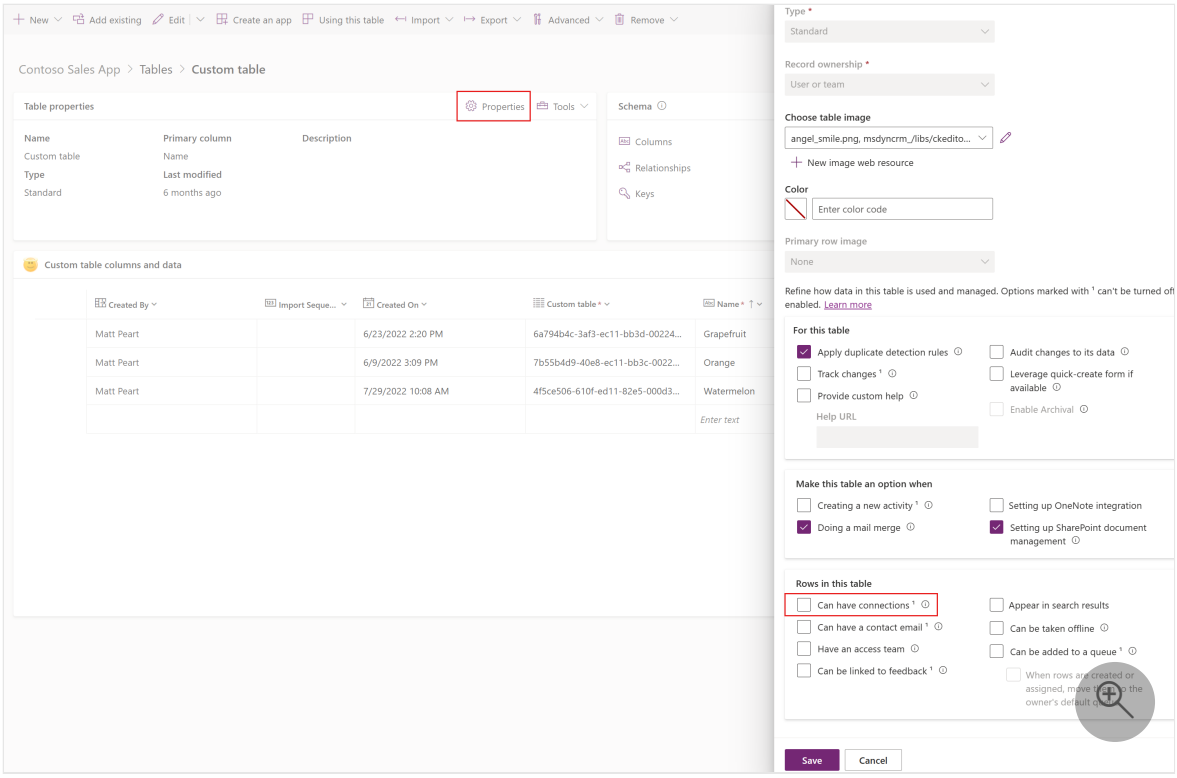
When people set a connection between two rows, they can also add a description and additional information such as start and end dates for the relationship. More information: Add a connection role to link rows to each other

Anyone with write access to the **Connection Role** table can establish which connections are available for people to use.

> **Important**
>
> For a table to be available as a row type for a new or existing connection role, the **Can have connections** property must be enabled for the table.

Enable connection roles for a table

1. Sign in to Power Apps.
2. Open the table you want or create a new one. More information: Edit a table
3. Select **Properties**, and then in the right properties pane, select **Can have connections**.



4. Select **Save**.

View connection roles

There are a number of standard connection roles already configured in Dataverse.

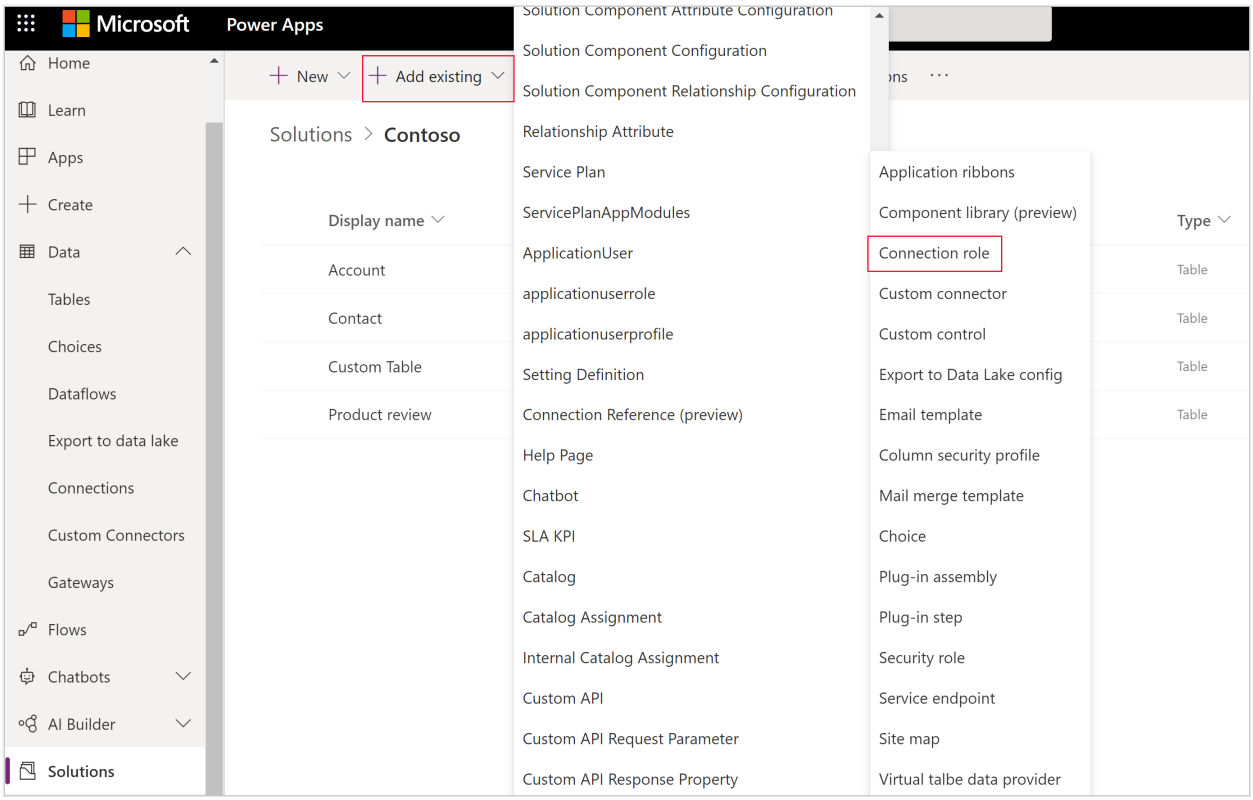
1. Sign in to Power Apps, and then on the left pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
2. Open the unmanaged solution you want.
3. On the command bar, select **Add existing** > **Connection Role**. The list of available connection roles are displayed.
4. Select **Cancel** to close the **Add existing connection Roles** pane without adding a connection role to the solution.

> **Note**
>
> - If you want to distribute connection roles with a solution, make sure they are included in the solution you want to distribute. More information: **Add connection roles to a solution**

Add connection roles to a solution

Because connection roles are *solution aware*, which means that they can be included in a solution, you can also add connection roles to a solution you distribute.

Generally we don't recommended you edit components in the internal **Default Solution**. Within the solution you've created to work in, you can use the **Add Existing** command in the **Solutions** area to bring any of the active connection roles into your solution.



Once you add the connection role to your solution, you can edit it wherever it's visible.

> **Note**
>
> The connection role status is not included with the connection role when it is exported from a solution. Therefore, when the solution is imported into a target environment, the status will be set to active by default.

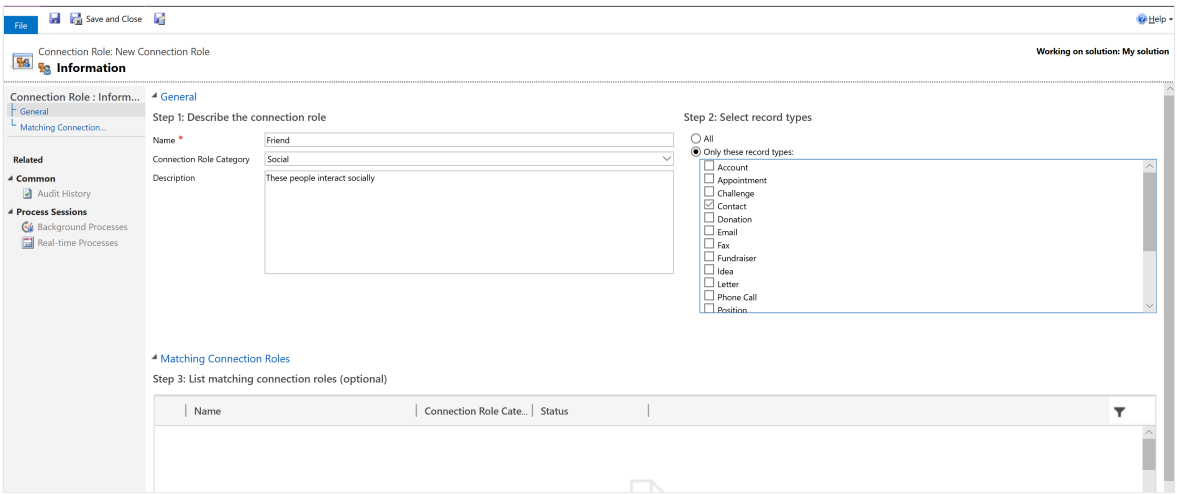
Create a connection role

> **Important**
>
> If you intend to distribute a solution that includes new connection roles or changes to the existing connection roles you must add them to the solution you will distribute. Editing or adding new connection roles in the **Default Solution** will not include them in a solution you can distribute. More information **Add connection roles to a solution**

1. Sign in to Power Apps and then on the left pane select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Open the unmanaged solution your want, and then on the command bar select **New** > **Other** > **Connection role**.

3. Complete the three steps on the form to Describe the connection role.



Describe the connection role

Set the following columns:

Column	Description
Name	(Required) The text describing the connection.
Connection Role Category	A group describing the category of the connection. More information: Connection Role Category values
Description	Provide a definition for the role.

Connection Role Category values

The default **Connection Role Category** values are:

- Business
- Family
- Social
- Sales
- Other
- Stakeholder

- Sales Team
- Service

You can add new categories or modify existing ones by editing the **Category** global choice. More information: Create and edit global choices for Dataverse (picklists)

Select row types

Select which row types should be available to connect.

> **Note**
>
> Although **All** is selected by default, make sure you consider which types are appropriate for the connection role you are adding.

Matching connection roles

In this optional step, you can define any roles that be applied in a reciprocal manner. It isn't required, but connections are more meaningful if these are defined.

For example, people can set that Glen is a *Friend* to Mary, but does this mean that Mary is a *Friend* to Glen? We hope so. But if Glen is the *Father* of Mary it doesn't mean that Mary is the *Father* of Glen. Establishing correct reciprocity requires this extra step.

When people set a connection role that doesn't have a matching connection role, the role will only be displayed when viewing the connection from the row that the connection was applied to. When viewed from the connected row, the role will be empty unless a matching role is set.

For role definitions like *Friend*, *Spouse*, *Colleague*, or *Sibling*, it's best to assign the matching role to itself. If a single matching connection role is configured, the single matching connection role will be applied in both directions.

> **Important**
>
> You will need to save a new connection role without this matching connection role before you can set the matching connection role to itself.

You'll find that some connection roles are already configured with matching connection roles. *Former Employee* is matched with *Former Employer* and vice versa. This kind of one-to-one matching connection role is most common.

You can configure multiple matching connection roles to describe complex relationships. If you create a connection role such as *Father*, you could configure two more roles such as Daughter,* and *Son* and apply both of them as matching connection roles to *Father*. In turn, both the *Daughter* and *Son* connection roles should be matched to *Father*. Of course, then you should set up an equivalent role for *Mother* that is similarly matched with *Daughter* and *Son*.

> **Tip**
>
> Before you create a complex set of connection roles, consider if a more simple set of roles will be enough. For example, rather than creating a complex set of connection roles like *Father*, *Mother*, *Son*, and *Daughter* - consider if simply using *Parent* and *Child* will work for you.

If more than one matching connection role is configured, those connection roles represent the only valid reciprocal roles. The first one will be applied automatically as the default value. If the default value isn't correct, people need to manually edit the connection and choose between valid options defined in the configuration.

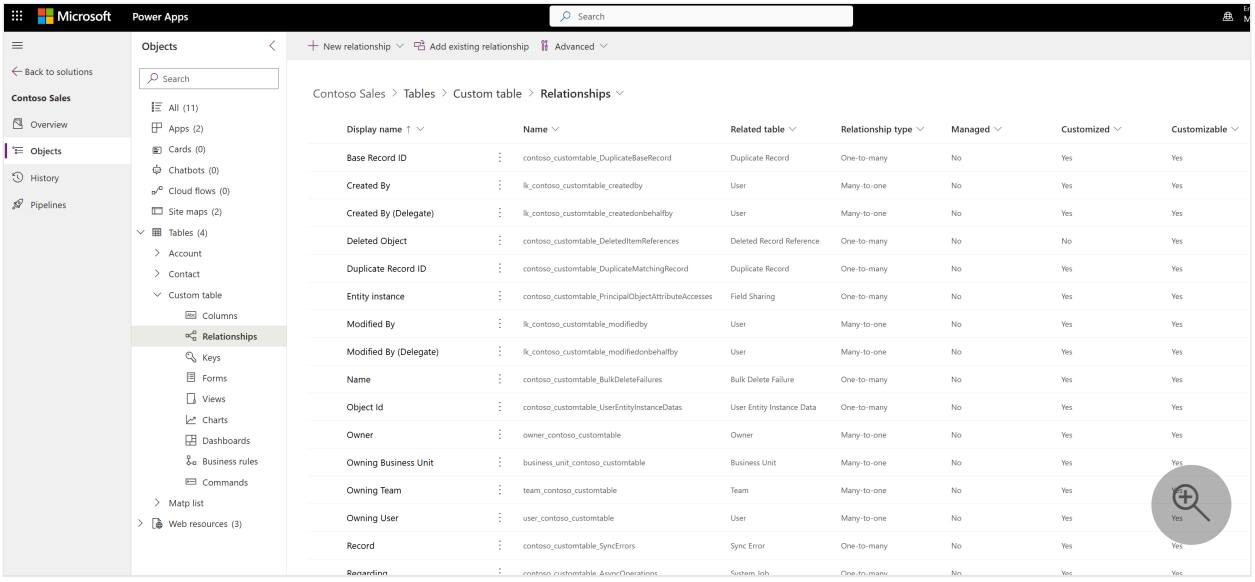
Create many-to-many table relationships using Power Apps

Article • 09/17/2024

Power Apps provides an easy way to create and edit many-to-many relationships for Microsoft Dataverse tables. A many-to-many relationship defines the type of connection between two tables where multiple records in one table can be associated with multiple records in another table. For example, in a school scenario, a single student can enroll in multiple courses, and each course can have multiple students. This type of relationship allows for more complex data associations and is managed using Power Apps in Dataverse. For more information about many-to-many table relationships, go to Create many-to-many table relationships overview.

View many-to-many table relationships

1. From Power Apps, select **Solutions** on the left navigation pane, and open the solution you want.
2. Open the table that has the relationships you want to view.
3. Select the **Relationships** area to view all relationships configured for the table.

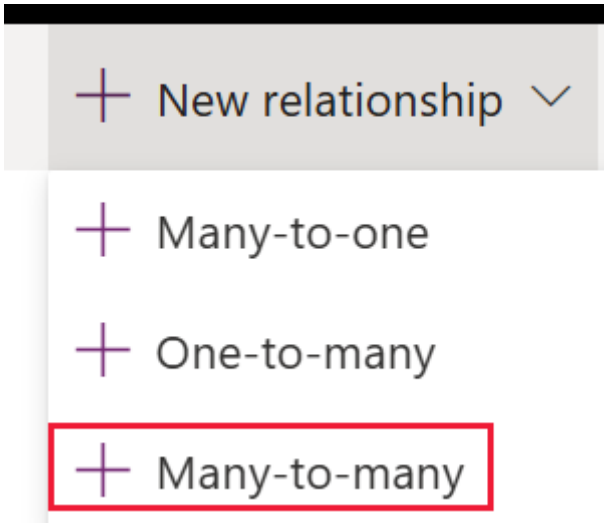


Many-to-many relationships have a **Relationship type** of **Many-to-many**.

> **Note**
>
> The table you view might have no **Many-to-many** relationships.

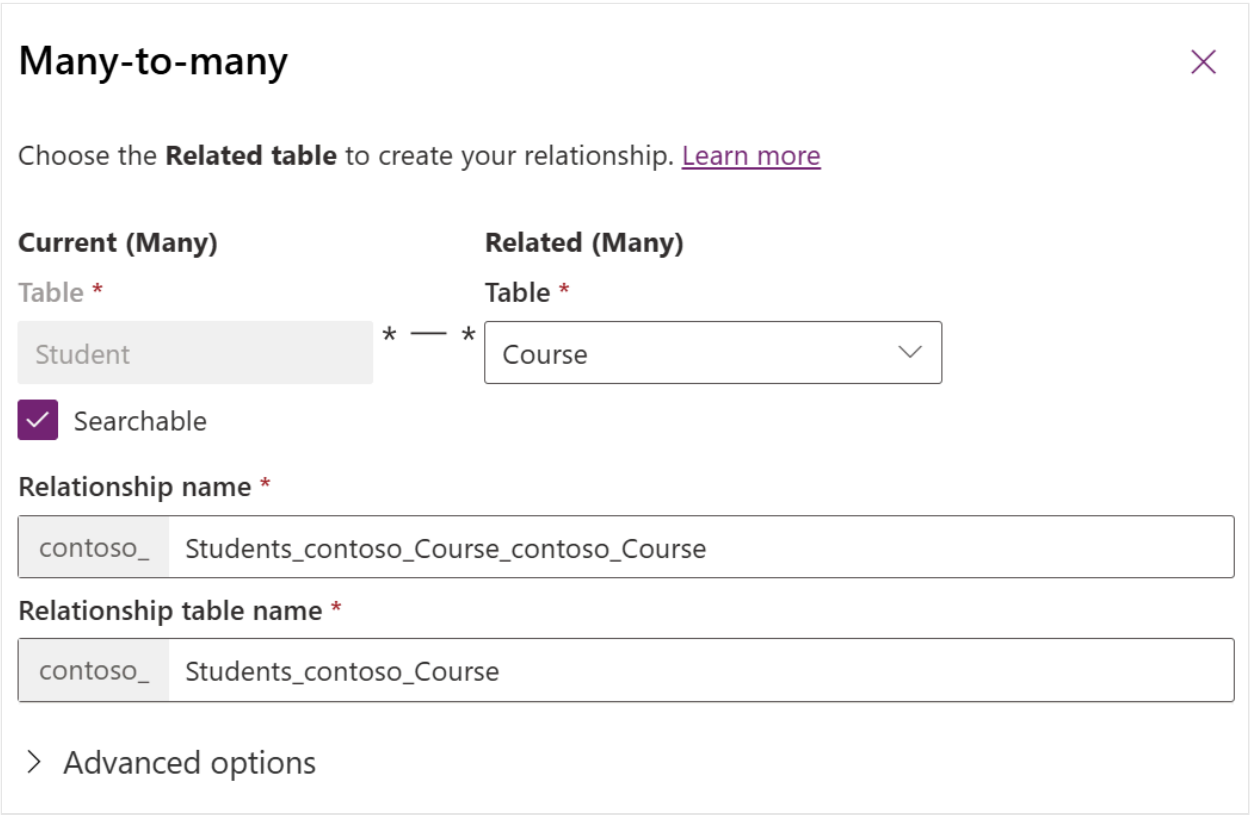
Create relationships

While viewing table relationships, on the command bar, select **New relationship**, and then select **Many-to-many**.



The **Many-to-many relationship** editor is displayed.

In the **Related (Many)** dropdown list, choose the table you want to relate to the current table. In this example, a many-to-many relationship with the student and course tables is created.



The values for these columns are generated for you based on the tables chosen.

Clear **Searchable**, if you want to hide the relationship from **Advanced Find** in model-driven apps.

If you want to edit the display settings for the relationship, expand **Advanced options** and make the changes you want. More information: Advanced options

> **Note**
>
> If you create more than one **Many-to-many** relationship with the same two tables, you must edit the generated **Relationship Name** and **Relationship table name** columns so that they are unique.

Select **Done** to close the **Many-to-many** panel. The relationship is created when you save changes to the table.

Advanced options

For both the **Current table display settings** and the **Related table display settings**, you can edit the display option columns, which control how the related tables are displayed for model-driven apps.

Expand table

Field	Description
Display option	How the related table list should be displayed. More information: Display Options
Custom label	Specify the localizable text to be used instead of the plural name when you select **Use Custom label** as the **Display option** .
Display area	Select one of the available groupings to display this list. The available options are: **Details** (for the *Common* group), **Marketing**, **Sales**, and **Service**.
Display order	Controls where the navigation item will be included within the selected display area. The range of allowed numbers begins with 10,000. Navigation pane items with a lower value appear above other relationships with a higher value.

Display Options

These are the available display options:

Expand table

Option	Description
Do not Display	Do not display the related tables for this relationship.
Use custom label	When this option is chosen the **Custom label** column is enabled so that you can specify the localizable text to be used instead of the plural name.
Use plural name	Use the plural display name defined for the related table.

Create a many-to-many relationship with the same table (self-referential relationship)

There might be times when you need to create a many-to-many relationship that references the same table. For example, account records might have multiple parent account records. However, if the self-referential relationship doesn't have custom labels configured, distinguishing the two related record types that appear in the app isn't apparent to users. This is because the related records appear twice in the app by using the same table name.

To create a self-referential relationship, use custom labels.

1. Open or create a solution and then create a new custom table. In this example, the table is named *Custom table*.

2. Open the custom table, select the **New** > **Relationship** > **New relationship** > **Many-to-many relationship**.

3. Under **Related (Many)** select the same table, in the example *Custom table*, that's also the **Current (Many)** table.

4. Expand **Advanced options** and complete the relationship definition as follows. Add custom labels to both the current and the related table's relationship:

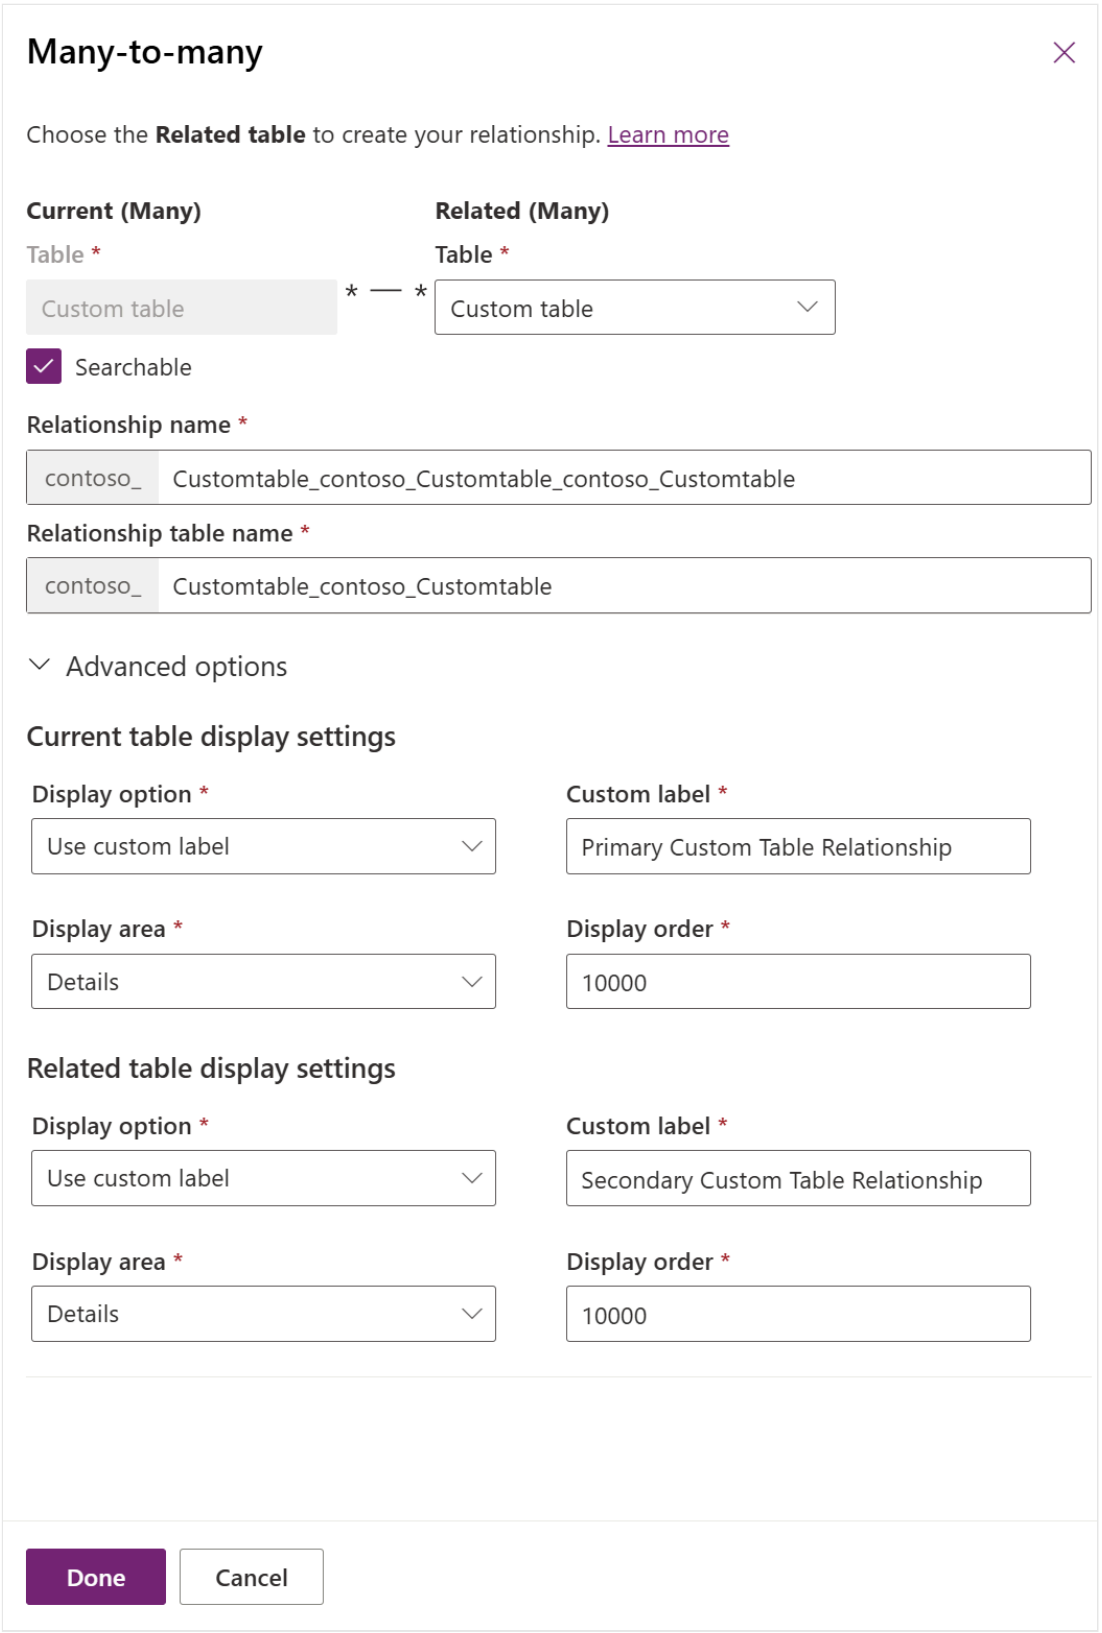
   Current table display settings section

   - **Display option**: **Use custom label**
   - **Custom label**: *Primary Custom Table Relationship*

   Related table display settings section

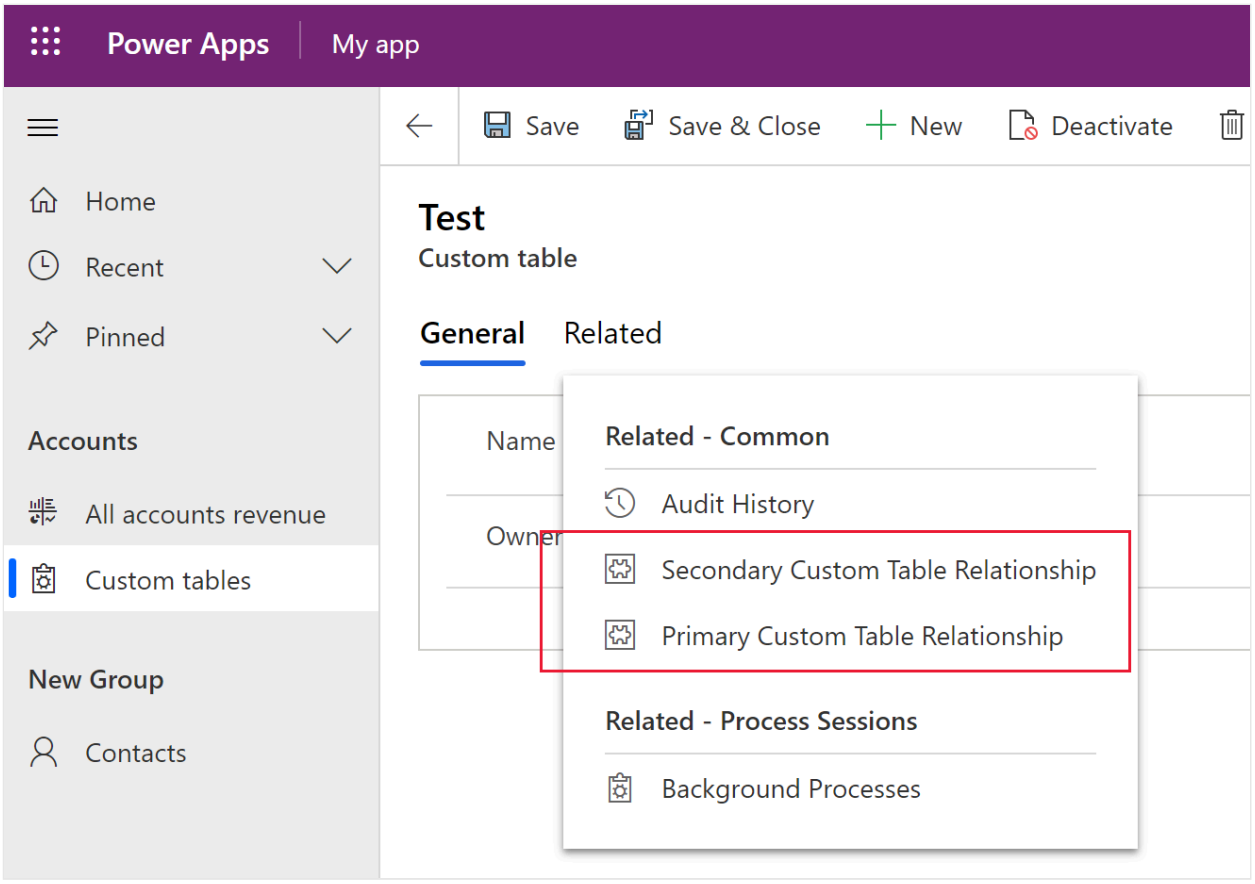
   - **Display option**: **Use custom label**

- **Custom label**: *Secondary Custom Table Relationship*



5. Select **Done** to save the relationship, and then publish the customization.

Because the related record types use the custom labels defined for the self-referential relationship instead of the table name, users running the app can distinguish between the two related record types that exist.



Delete relationships

Deleting a many-to-many relationship deletes the relationship table created. All data connecting tables using the relationship are lost.

While viewing table relationships, select the relationship you want to delete, and then on the command bar select **Remove** > **Delete from this environment**.

Create and edit 1:N (one-to-many) or N:1 (many-to-one) table relationships using solution explorer

Article • 02/15/2022

Solution explorer provides one way to create and edit 1:N (one-to-many) or N:1 (many-to-one) table relationships for Microsoft Dataverse.

The Power Apps portal enables configuring the most common options, but certain options can only be set using solution explorer. More information:

- Create 1:N (one-to-many) or N:1 (many-to-one) relationships
- Create and edit 1:N (one-to-many) or N:1 (many-to-one) table relationships in Power Apps portal

Open solution explorer

Part of the name of any custom relationship you create is the customization prefix. This is set based on the solution publisher for the solution you're working in. If you care about the customization prefix, make sure that you are working in an unmanaged solution where the customization prefix is the one you want for this table. More information: Change the solution publisher prefix

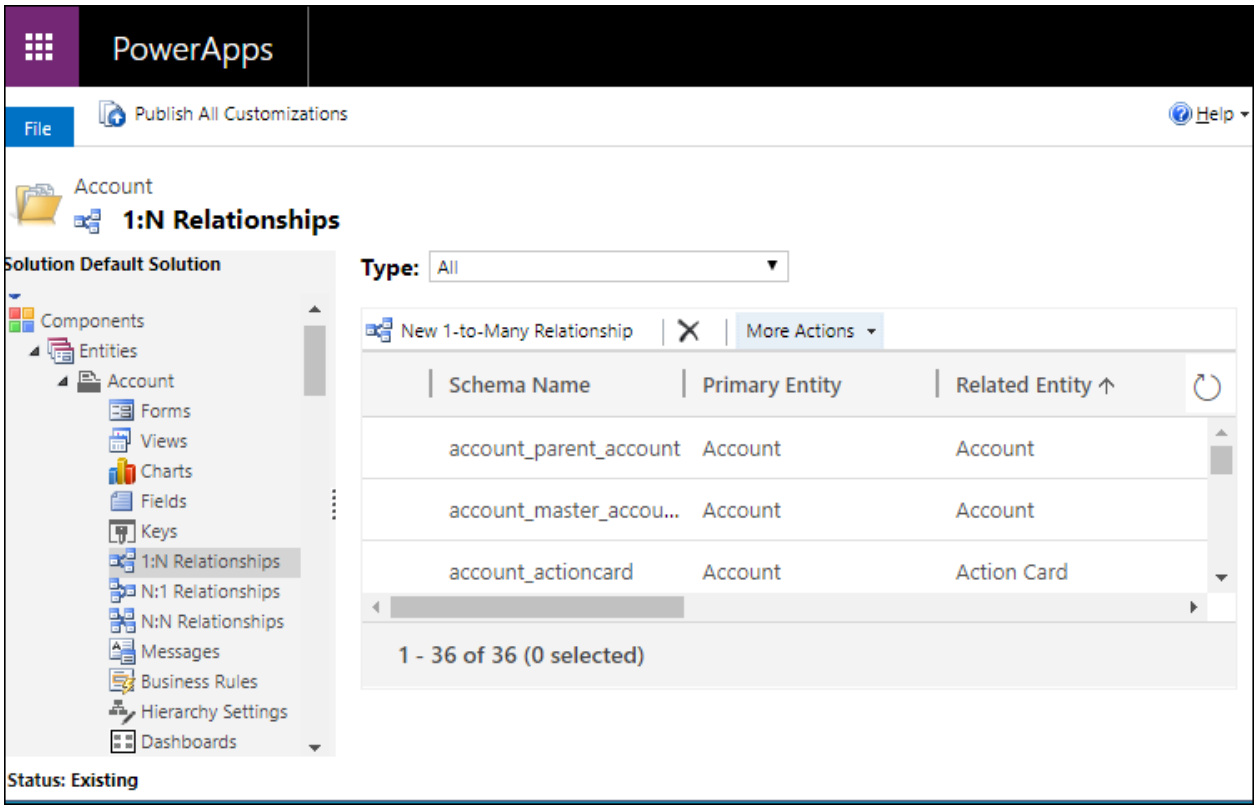
Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

View table relationships

In solution explorer, expand **Tables** an select a table. Within that table, select either **1:N Relationships** or **N:1 Relationships**

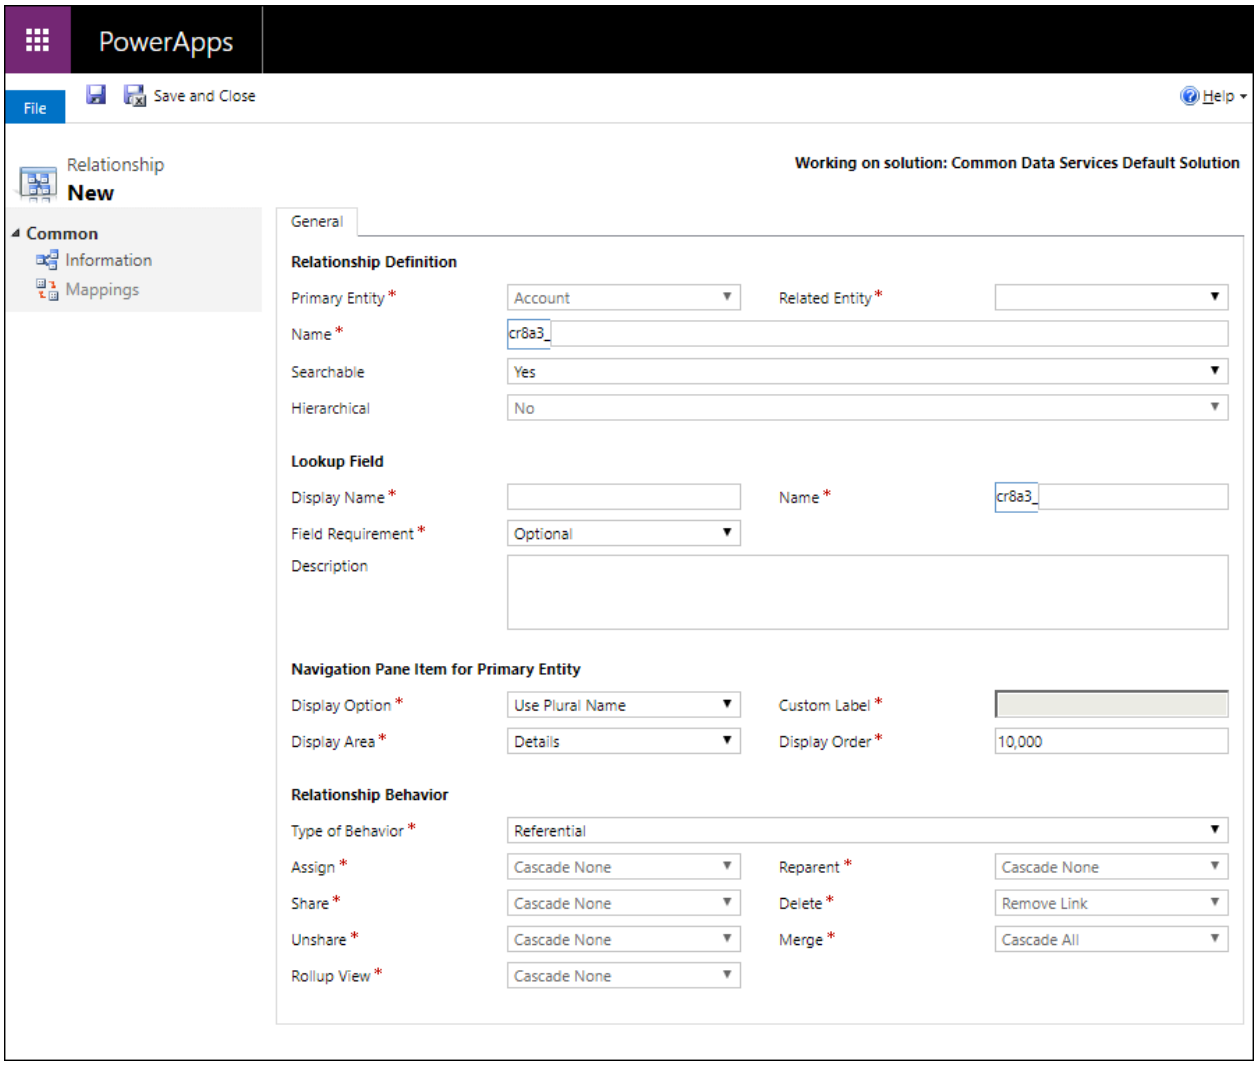


Create relationships

While viewing table relationships, select either **New 1-to-Many Relationship** or **New Many-to-1 Relationship** from the command bar.

> ⓘ **Note**
>
> If the commands are not available, the table is not eligible to create a custom relationship.

Either option will open a form like the following. The difference is whether the **Primary table** or **Related table** column is set.



- With **1:N Relationship**, the **Primary table** is set to the current table
- With **N:1 Relationship**, the **Related table** is set to the current table

The following columns must be set in order to save the table relationship:

Required Column	Description
Primary table	This table will be the target type for the lookup column created on the related table.
Related table	This table will have a lookup column added to associate the table rows with the primary table row.
Name	The name of the relationship. A value will be generated based on the primary and related table values. This column will be prefixed by the customization prefix of the solution publisher.
Lookup Column Display Name	The localizable text for the lookup column that will be created for the related table. This is usually the same as the display name for the primary table. This can be changed later.

Required Column	Description
Lookup Column Name	The name of the lookup column that will be created on the related table. A value will be generated based on the **Lookup Column Display Name**. This column will be prefixed by the customization prefix of the solution publisher.

You can click  to save the table and continue editing. More information: Edit relationships

> ⓘ Note
>
> If either the **Name** or **Lookup Column Name** values already exist in the system you will get an error when you save. Edit the values so that they are unique and try again.

Edit relationships

While viewing table relationships, select the table you want to edit. The following table relationship properties can be edited after the relationship is created.

> ⓘ Note
>
> The publisher of a managed solution can prevent some customizations of relationships that are part of their solution.

Table relationship properties

These properties are about the relationship.

Column	Description
Searchable	Whether this relationship should be visible within Advanced Find in model-driven apps. Select **No** if this is a relationship that isn't important for your business.
Hierarchical	This option is enabled only for self-referential relationships. Whether the table should be considered to define a hierarchy for the table. **Important**: Once you set this property rollup columns, processes, and views may be configured to depend on this property. If you later change this value those capabilities that depend on the hierarchy will not work. More information: Define and query hierarchically related data

Lookup column

These are the properties of the lookup column created on the related table. The properties can be edited here or by editing the lookup column directly. Some column properties are not editable from the relationship. More information: Edit a column

Column	Description
Display Name	The localizable text for the lookup column that will be created for the related table.
Column requirement	Whether the column must have data before a form in a model-driven app can be saved. More information: Column Requirement options
Description	Enter instructions to the user about what the column is for. These descriptions appear as tooltips for the user in model-driven apps when they hover their mouse over the label of the column.

Navigation Pane Item for Primary table

From the primary table you can navigate to see related rows. This data is used by model-driven apps to control how the related table rows are displayed. These settings can also be edited using the form editor.

Column	Description
Display Option	How the related table list should be displayed. More information: Display Options
Custom Label	Specify the localizable text to be used instead of the plural name when you select **Use Custom Label** as the **Display Option** .
Display Area	Select one of the available groupings to display this list. The available options are: **Details** (for the *Common* group), **Marketing**, **Sales**, and **Service**.
Display Order	Controls where the navigation item will be included within the selected display area. The range of allowed numbers begins with 10,000. Navigation pane items with a lower value appear above other relationships with a higher value.

Display Options

These are the available display options:

Option	Description

Option	Description
Do not Display	Do not display the related tables for this relationship.
Use Custom Label	When this option is chosen, the **Custom Label** column is enabled so that you can specify the localizable text to be used instead of the plural name.
Use Plural Name	Use the plural display name defined for the related table.

Relationship Behavior

This where you can define standard behaviors for related tables. This information is important because it helps ensure data integrity and can automate business processes for your company.

Let's look at an example.

Let's say that you have a new salesperson and you want to assign them a number of existing opportunities currently assigned to another salesperson. Each opportunity row may have a number of task activities associated with it. You can easily locate the active opportunities you want to reassign and assign them to the new salesperson. But what should happen for any of the task activities that are associated with the opportunities? Do you want to open each task and decide whether they should also be assigned to the new salesperson? Probably not. Instead, you can let the relationship apply some standard rules for you automatically. These rules only apply to task rows associated to the opportunities you are reassigning. Your options are:

- Reassign all active tasks.
- Reassign all tasks.
- Reassign none of the tasks.
- Reassign all tasks currently assigned to the former owner of the opportunity.

The relationship can control how actions performed on a row for the primary table row cascade down to any related table rows.

There are several kinds of behaviors that can be applied when certain actions occur.

Behaviors

These are the behaviors available to be configured.

Behavior	Description
Cascade Active	Perform the action on all active related table rows.
Cascade All	Perform the action on all related table rows.
Cascade None	Do nothing.
Remove Link	Remove the lookup value for all related rows.
Restrict	Prevent the primary table row from being deleted when related table rows exist.
Cascade User Owned	Perform the action on all related table rows owned by the same user as the primary table row.

Actions

These are the actions that can trigger certain behaviors:

Column	Description	Options
Assign	What should happen when the primary table row is assigned to someone else?	Cascade All Cascade Active Cascade User-owned Cascade None
Reparent	What should happen when the lookup value of a related table in a parental relationship is changed? More information: Parental table relationships	Cascade All Cascade Active Cascade User-owned Cascade None
Share	What should happen when the primary table row is shared?	Cascade All Cascade Active Cascade User-owned Cascade None
Delete	What should happen when the primary table row is deleted?	Cascade All Remove Link Restrict

Column	Description	Options
Unshare	What should happen when a primary table row is unshared?	Cascade All Cascade Active Cascade User-owned Cascade None
Merge	What should happen when a primary table row is merged?	Cascade All Cascade None
Rollup View	What is the desired behavior of the rollup view associated with this relationship?	Cascade All Cascade Active Cascade User-owned Cascade None

Type of Behavior options

Use the **Type of Behavior** column to choose between a set of standard behaviors or whether you want to configure them independently.

Option	Description
Parental	**Assign**: Cascade All **Reparent**: Cascade All **Share**: Cascade All **Delete**: Cascade All **Unshare**: Cascade All **Merge**: Cascade None **Rollup View**: Cascade None | Cascade All
Referential	**Assign**: Cascade None **Reparent**: Cascade None **Share**: Cascade None **Delete**: Remove Link **Unshare**: Cascade None **Merge**: Cascade None **Rollup View**: Cascade None | Cascade All

Option	Description
Referential, Restrict Delete	**Assign**: Cascade None **Reparent**: Cascade None **Share**: Cascade None **Delete**: Restrict **Unshare**: Cascade None **Merge**: Cascade None **Rollup View**: Cascade None | Cascade All
Configurable Cascading	You can configure the behavior you want for each action depending on the options available

> **Note**
>
> You may not be able to choose the **Parental** option if either of the tables already participate in an parental table relationship. More information: **Parental table relationships**
>
> If you use **Configurable Cascading** to set the behaviors for the actions so that they match the behaviors for the actions associated with another **Type of Behavior**, when you save the relationship, the **Type of Behavior** is automatically set to the matching type.

Delete relationships

While viewing table relationships, select the table relationship you want to delete and click the ✕ command.

Deleting the relationship will delete the lookup column on the related table.

> **Note**
>
> You will not be able to delete a relationship that has dependencies. For example, if you have added the lookup column to a form for the related table, you must remove the column from the form before you delete the relationship.

Parental table relationships

Each pair of tables that are eligible to have a 1:N relationship can have multiple 1:N relationships between them. Yet usually only one of those relationships can be

considered a parental table relationship.

A parental table relationship is any 1:N table relationship where one of the cascading options in the **Parental** column of the following table is true.

Action	Parental	Not Parental
Assign	Cascade All Cascade User-owned Cascade Active	Cascade None
Delete	Cascade All	RemoveLink Restrict
Reparent	Cascade All Cascade User-owned Cascade Active	Cascade None
Share	Cascade All Cascade User-owned Cascade Active	Cascade None
Unshare	Cascade All Cascade User-owned Cascade Active	Cascade None

For example, if you create a new custom table and add a 1:N table relationship with the account table where your custom table is the related table, you can configure the actions for that table relationship to use the options in the **Parental** column. If you later add another 1:N table relationship with your custom table as the referencing table you can only configure the actions to use the options in the **Not Parental** column.

Usually this means that for each table pair there is only one parental relationship. There are some cases where the lookup on the related table may allow for a relationship to more than one type of table.

For example, if a table has a Customer lookup that can refer to either a contact or account table. There are two separate parental 1:N table relationships.

Any activity table has a similar set of parental table relationships for tables that can be associated using the regarding lookup column.

Limitations on behaviors you can set

Because of parental relationships there are some limitations you should keep in mind when you define table relationships.

- A custom table can't be the primary table in a relationship with a related system table that cascades. This means you can't have a relationship with any action set to **Cascade All**, **Cascade Active**, or **Cascade User-Owned** between a primary custom table and a related system table.
- No new relationship can have any action set to **Cascade All**, **Cascade Active**, or **Cascade User-Owned** if the related table in that relationship already exists as a related table in another relationship that has any action set to **Cascade All**, **Cascade Active**, or **Cascade User-Owned**. This prevents relationships that create a multi-parent relationship.

Create N:N (many-to-many) table relationships in Microsoft Dataverse using solution explorer

Article • 02/15/2022

Solution explorer provides one way to create and edit N:N (many-to-many) for Dataverse.

The Power Apps portal enables configuring the most common options, but certain options can only be set using solution explorer. More information:

- Create Many-to-many (N:N) table relationships
- Create Many-to-many table relationships in Dataverse using Power Apps portal

Open solution explorer

Part of the name of any custom relationship you create is the customization prefix. This is set based on the solution publisher for the solution you're working in. If you care about the customization prefix, make sure that you are working in an unmanaged solution where the customization prefix is the one you want for this table. More information: Change the solution publisher prefix

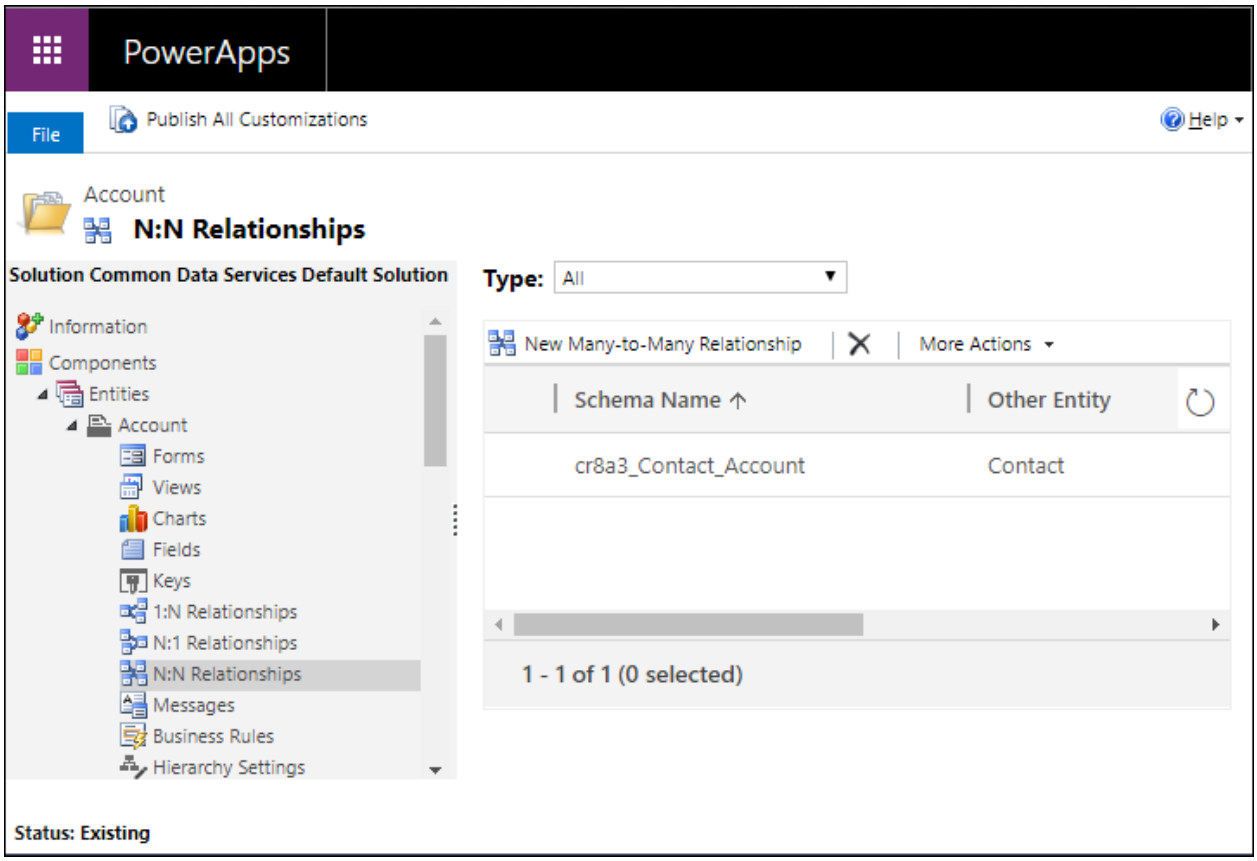
Open an unmanaged solution

1. From Power Apps select **Solutions** from the left navigation pane, and then on the toolbar, select **Switch to classic**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. In the **All Solutions** list open the unmanaged solution you want.

View table relationships

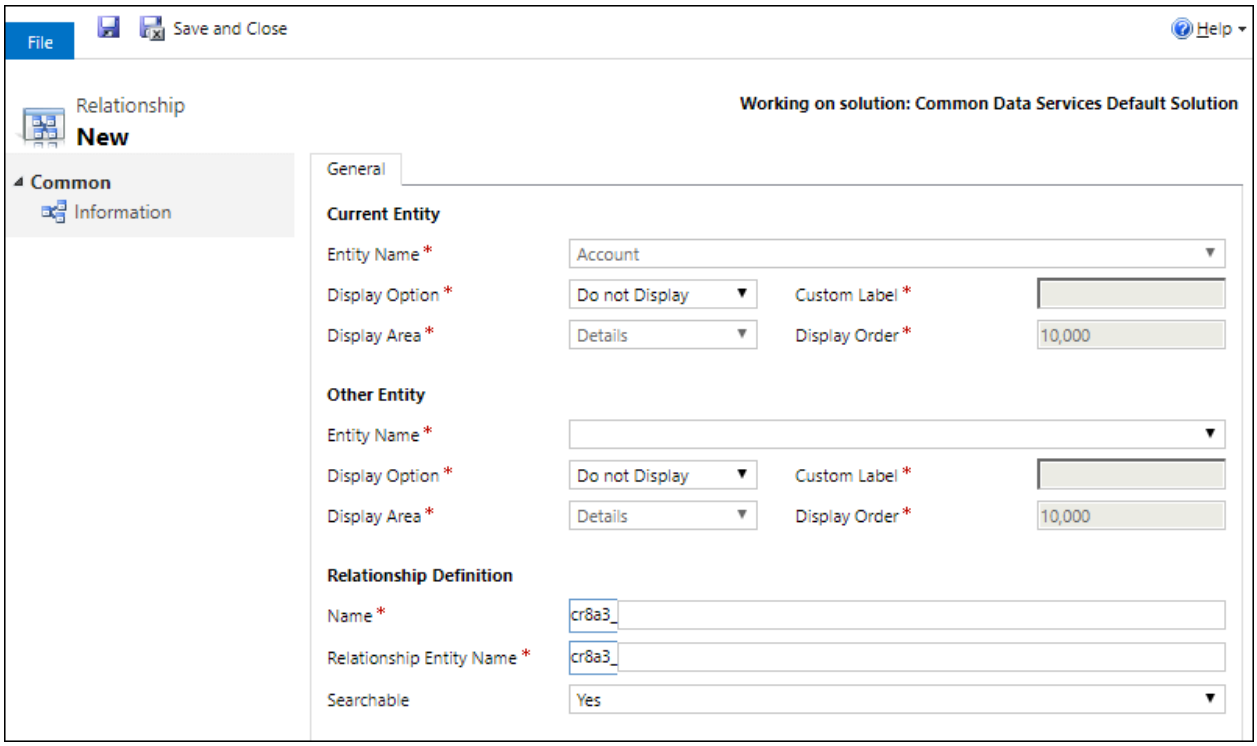
In solution explorer, expand **Tables** an select a table. Within that table, select **N:N Relationships**.



Create relationships

While viewing table relationships, select **New Many-to-Many Relationship** from the command bar.

> **Note**
>
> If the command is not available, the table is not eligible to create a custom relationship.



In the **Other table** group, in the **table Name** column, choose the table that you want to create the relationship with. This will populate the **Name** and **Relationship table Name** columns in the **Relationship Definition** group.

You can click to save the table and continue editing. More information: Edit relationships

> ⓘ Note
>
> If either the **Name** or **Relationship table Name** values already exist in the system you will get an error when you save. Edit the values so that they are unique and try again.

Edit relationships

While viewing table relationships, select the table you want to edit.

> ⓘ Note
>
> The publisher of a managed solution can prevent customizations of relationships that are part of their solution.

The following table relationship properties can be edited after the relationship is created.

> **ⓘ Important**
>
> After you edit these properties you must publish customizations before they will take effect in model-driven apps.

Edit Display options

For both the **Current table** and the **Other table**, you can edit the display option columns which control how the related tables are displayed for model-driven apps.

Field	Description
Display Option	How the related table list should be displayed. More information: Display Options
Custom Label	Specify the localizable text to be used instead of the plural name when you select **Use Custom Label** as the **Display Option** .
Display Area	Select one of the available groupings to display this list. The available options are: **Details** (for the *Common* group), **Marketing**, **Sales**, and **Service**.
Display Order	Controls where the navigation item will be included within the selected display area. The range of allowed numbers begins with 10,000. Navigation pane items with a lower value appear above other relationships with a higher value.

Display Options

These are the available display options:

Option	Description
Do not Display	Do not display the related tables for this relationship.
Use Custom Label	When this option is chosen, the **Custom Label** column is enabled so that you can specify the localizable text to be used instead of the plural name.
Use Plural Name	Use the plural display name defined for the related table.

Searchable

You can hide the relationship from **Advanced Find** in model-driven apps by setting the **Searchable** column to **No**.

Delete relationships

While viewing table relationships, select the table relationship you want to delete and click the ✕ command.

Deleting the relationship will delete the relationship table created. All data connecting tables using the relationship will be lost.

Set managed properties for relationships

Article • 09/19/2024

Managed properties apply when you include a column with a managed solution and import it into another organization. These settings allow a solution maker to have some control over the level of customization that they want to allow people who install their managed solution to have when they customize a table relationship.

Set managed properties for a relationship

1. Sign in to Power Apps ,and select the environment you want.
2. Select **Solutions**, open the solution you want, and then open the table that has the relationship where you want to view the managed properties.
3. Select the relationship, and then select **Advanced** > **Managed properties** on the command bar.

With relationships, the only managed property is **Allow customizations**. This single setting controls all changes that can be made to the table relationship.

Query and visualize hierarchically related data

> **Important**
>
> This feature is deprecated. For more information, go to Hierarchy control in model-driven apps is deprecated.

Get valuable business insights by visualizing hierarchically related data. The hierarchical modelling and visualization capabilities give you a number of benefits:

- View and explore complex hierarchical information.
- View key performance indicators (KPIs) in the contextual view of a hierarchy.
- Visually analyze key information across the web and the tablets.

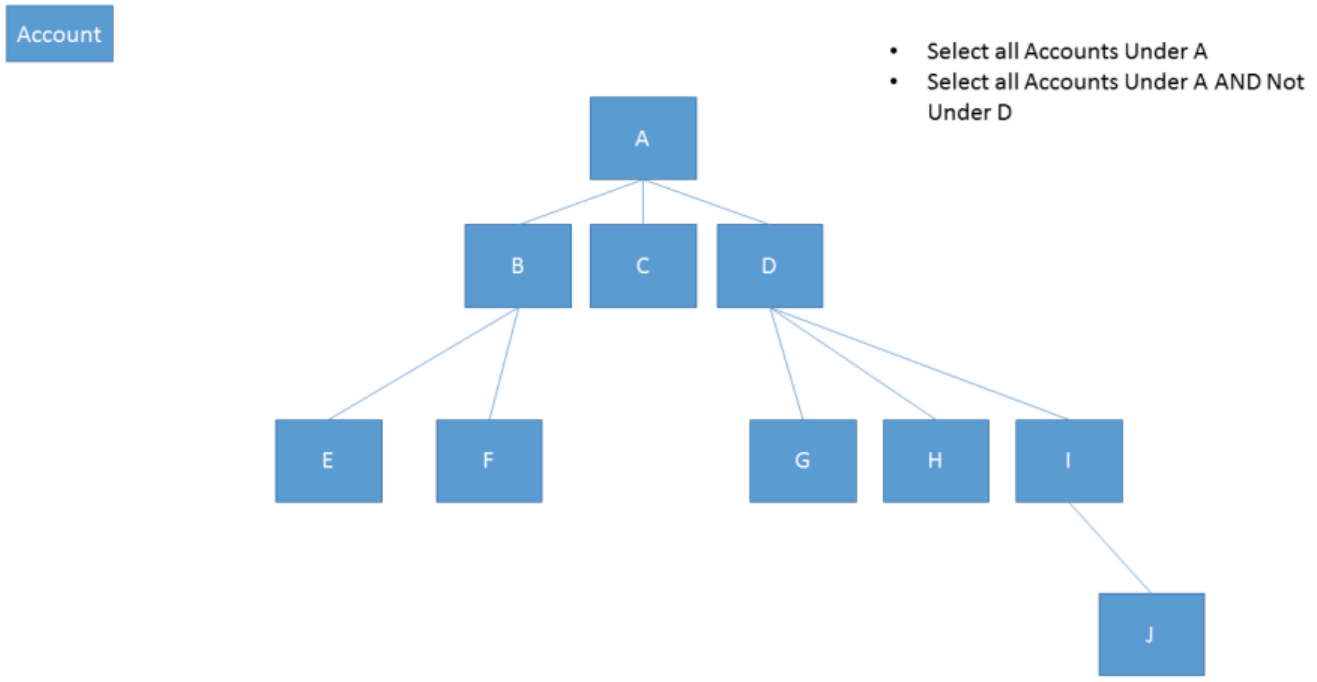
For some tables, such as account and user, the visualizations are provided out-of-the-box. Other tables, including custom tables, can be enabled for a hierarchy and you can create the visualizations for them. Based on your needs, you can choose between using a tree view, which shows the entire hierarchy, or a tile view, which depicts a smaller portion of the hierarchy. Both views are shown side by side. You can explore a hierarchy by expanding and contracting a hierarchy tree. The same hierarchical settings for visualization are set once, but apply to both web and mobile clients. In tablets, the visuals render in a modified format suitable for the smaller form factor. The customizable components required for hierarchical visualization are solution aware, therefore, they can be transported between organizations like any other customization. You can configure the attributes shown in the visualization by customizing a Quick Form using the form editor. There is no requirement to write code.

Query hierarchical data

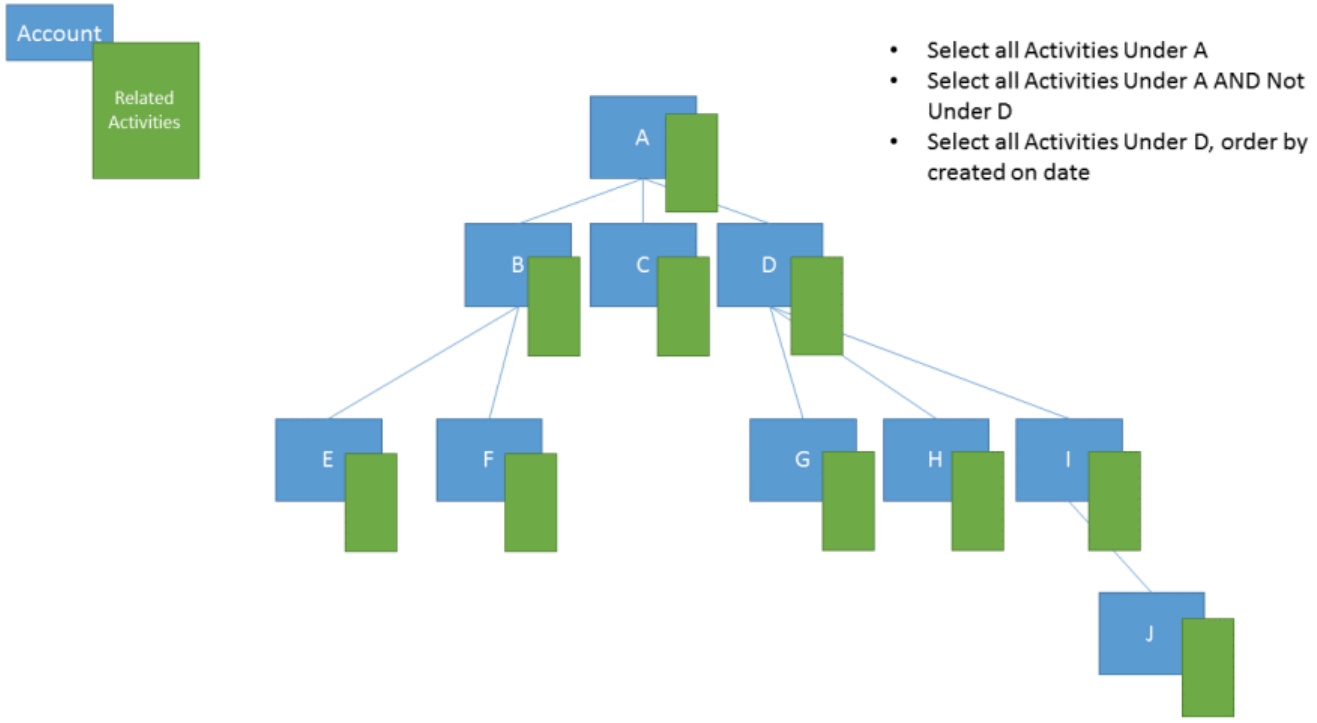
With Microsoft Dataverse, hierarchical data structures are supported by self-referential relationships of the related rows. In the past, to view hierarchical data, you had to iteratively query for the related rows. Presently, you can query the related data as a hierarchy, in one step. You'll be able to query rows using the **Under** and **Not Under** logic. The **Under** and **Not Under** hierarchical operators are exposed in Advanced Find and the workflow editor. For more information about how to use these operators, see Configure workflow steps. For more information about Advanced Find, see Create, edit, or save an Advanced Find search

The following examples illustrate various scenarios for querying hierarchies:

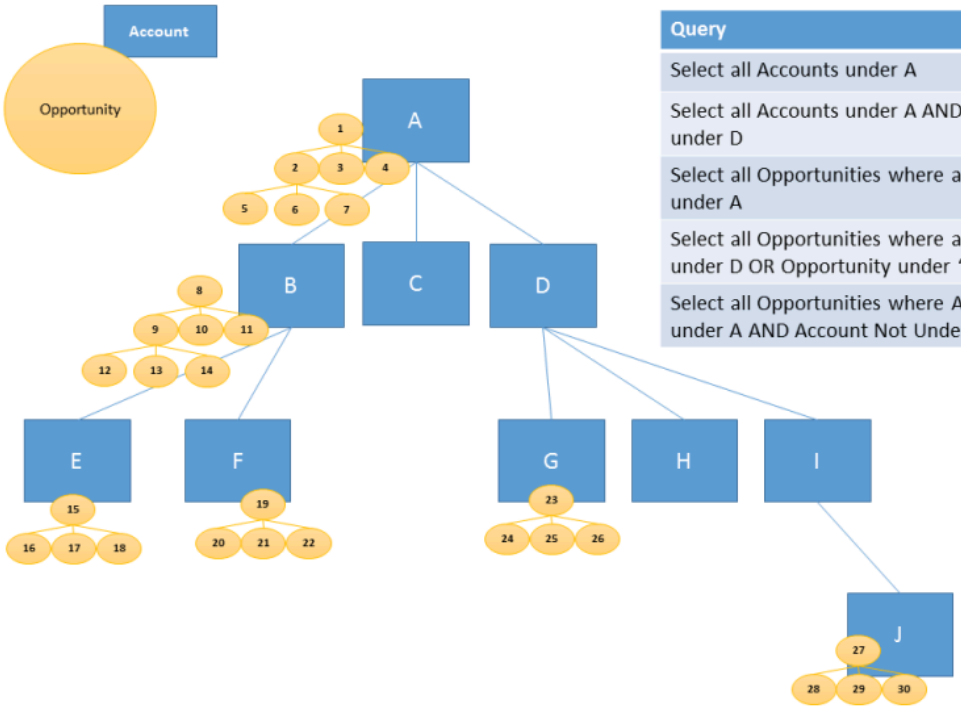
Query account hierarchy



Query account hierarchy, including related activities



Query account hierarchy, including related opportunities



Query	Result
Select all Accounts under A	{B,C,D,E,F,G,H,I,J}
Select all Accounts under A AND not under D	{B,C,D,E,F,}
Select all Opportunities where account under A	{8,9,10.... 30}
Select all Opportunities where account under D OR Opportunity under "15"	{23,24,25,26,27,28,29,30, 16,17,18}
Select all Opportunities where Account under A AND Account Not Under D	{8,9,10,11,12.....,22}

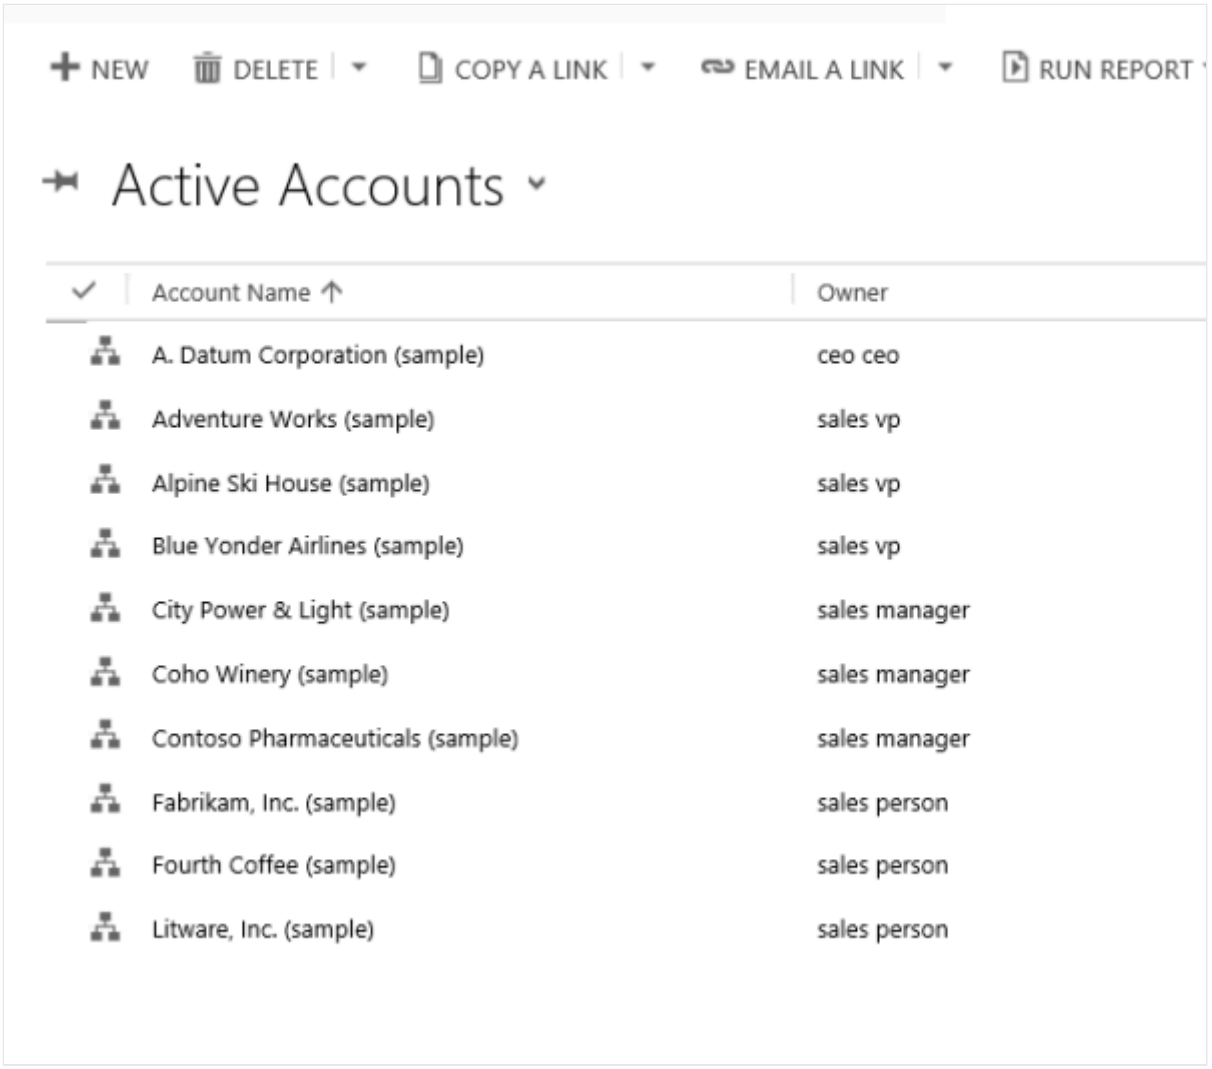
To query the data as a hierarchy, you must set one of the table's one-to-many or many-to-one self-referential relationships as hierarchical. To turn the hierarchy on:

1. On powerapps.com, and then select **Tables** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select an existing table, or Create a new table
3. Select **Relationships**, and then select a self-referential relationship.
4. In the relationship details panel, check **Hierarchical**.

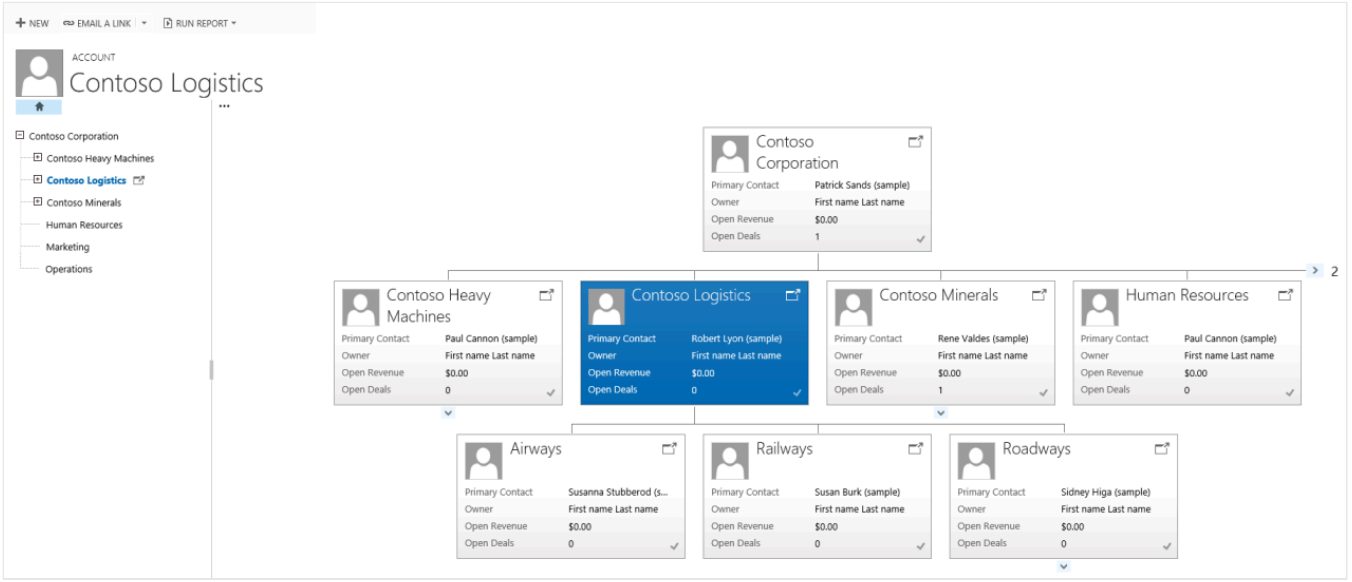
> **Note**
>
> - Some of the out-of the-box relationships can't be customized. This will prevent you from setting those relationships as hierarchical.
> - You can specify a hierarchical relationship for the system self-referential relationships. This includes self-referential relationships of system type, such as the "contact_master_contact" relationship.

Visualize hierarchical data

The system tables that have visualizations available out-of-the-box include `Account`, `Business Unit`, `Position`, `Product`, and `User`. In the grid view of these tables, you can see the icon depicting the hierarchy chart, to the left of the row name. The hierarchy icon isn't present for all rows by default. The icon is shown for the rows that have a parent row, a child row, or both.



If you select the hierarchy icon, you can view the hierarchy, with the tree view on the left and the tile view on the right, as shown below:



A few other out-of the-box system tables can be enabled for a hierarchy. These tables include `Case`, `Contact`, `Opportunity`, `Order`, `Quote`, `Campaign`, and `Team`. All custom tables can be enabled for a hierarchy.

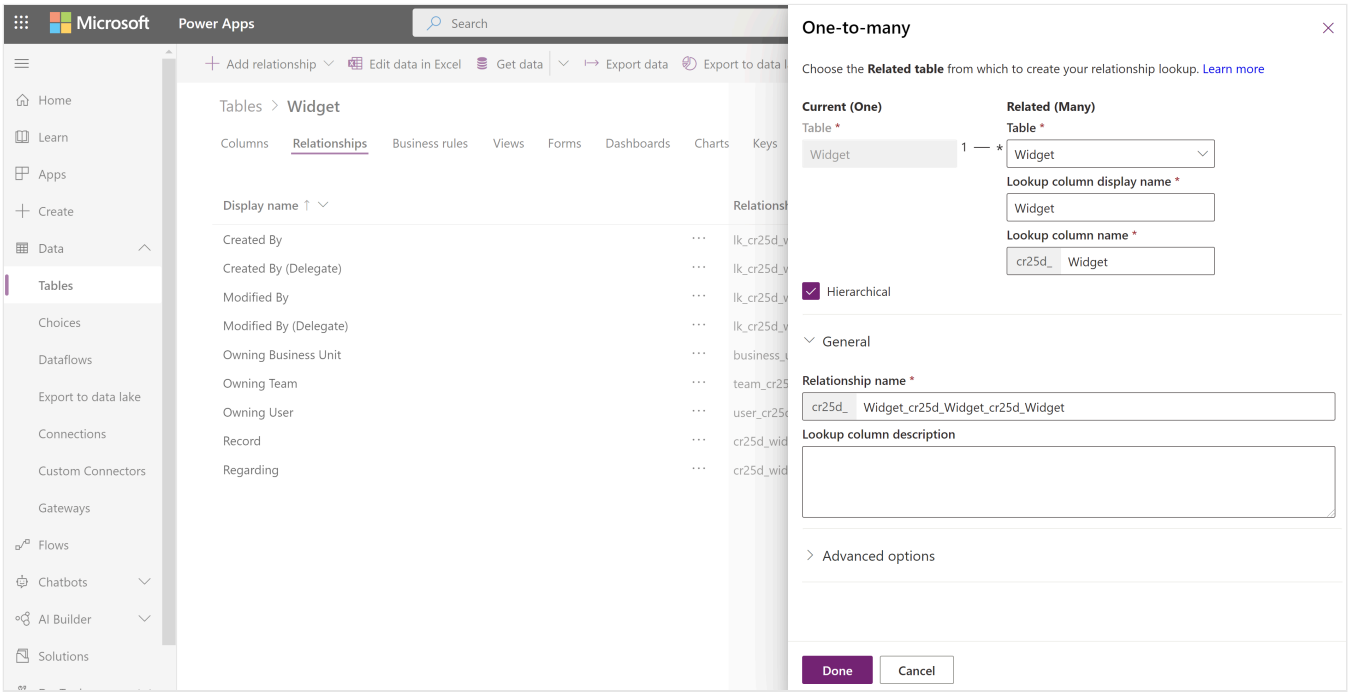
> **Tip**
>
> If a table can be enabled for a hierarchy:
> In solution explorer, expand the table that you want. You will see the table component called **Hierarchy Settings**. The tables that can't be enabled for a hierarchy don't have this component, with the exception of the Dynamics 365 Sales Territory table. Although **Hierarchy Settings** appears for the Sales Territory table, the table can't be enabled for a hierarchy.

Important things to remember when you create visualizations:

- Only one (1: N) self-referential relationship per table can be set as hierarchical. In this relationship the primary table and the related table must be of the same type, such as account_parent_account or Widget_new_Widget_new_Widget.
- Presently, a hierarchy or visualization is based on one table only. You can depict the account hierarchy showing accounts at multiple levels, but you can't show accounts and contacts in the same hierarchy visualization.
- Maximum number of columns that can be displayed in a tile is four. If you add more columns to the Quick Form that is used for the tile view, only the first four columns will be displayed.

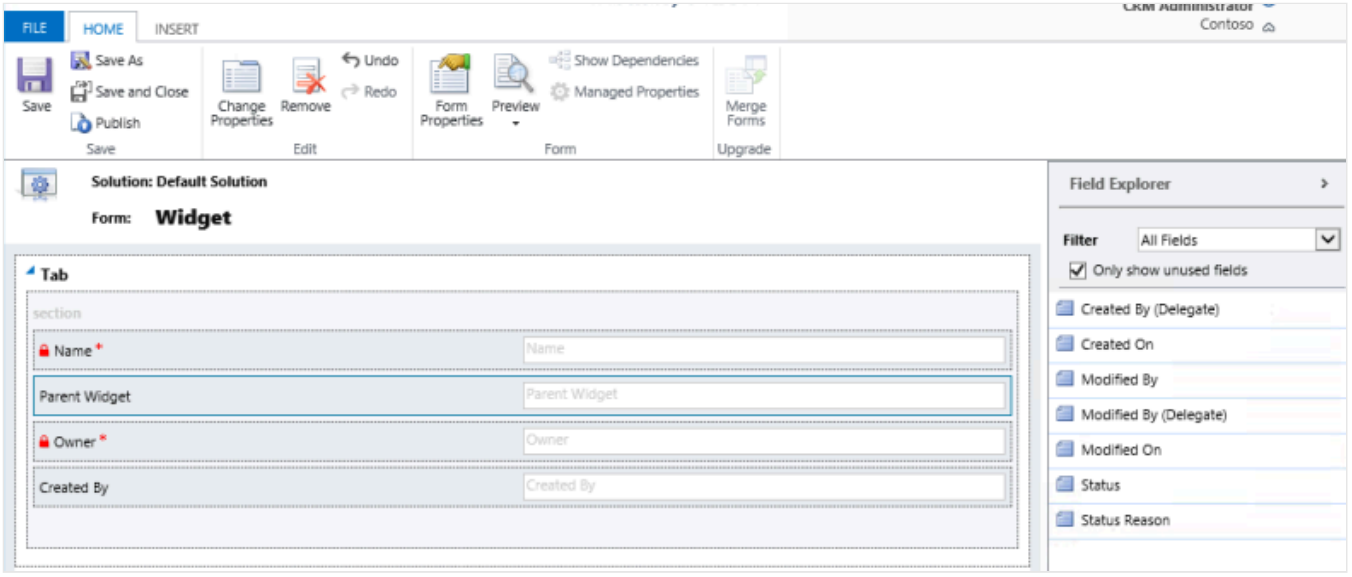
Visualization example

Let's look at an example of creating the visualization for a custom table. We created a custom table called new_Widget, created a self-referential relationship and marked it as hierarchical, as shown here.

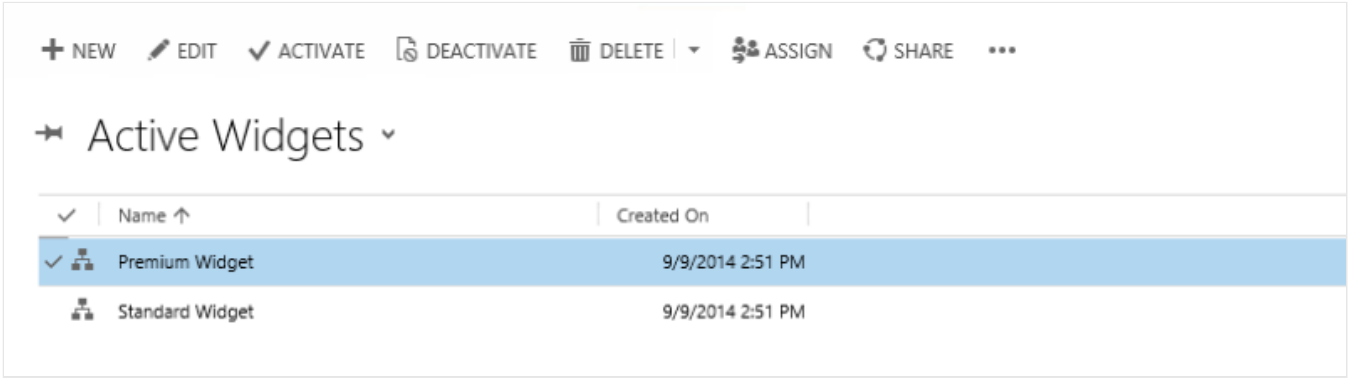


Next, in the **Hierarchy Settings** grid view, we selected the **Widget_new_Widget_new_Widget** hierarchical relationship. In the form, we filled in the required columns. If you haven't yet marked the relationship as hierarchical, the link on the form will take you to the classic table editor, where you can also mark the relationship as hierarchical.

For the **Quick View Form**, we created a Quick Form called **Widget Hierarchy Tile Form**. In this form, we added four columns to display in each tile.



After we completed the setup, we created two rows: Standard Widget and Premium Widget. After making the Premium Widget a parent of the Standard Widget by using the lookup column, the new_Widget grid view depicted the hierarchy icons, as shown below:



> **Tip**
>
> The hierarchy icons don't appear in the row grid view until the rows are paired in the parent – child relationship.

Choosing the hierarchy icon displays the new_Widget hierarchy with the tree view on the left and the tile view on the right, showing two rows. Each tile contains four columns that we provided in the **Widget Hierarchy Tile Form**.

Define and query hierarchically related data

Article • 08/03/2024

> **Important**
>
> This feature is deprecated. For more information, go to Hierarchy control in model-driven apps is deprecated.

You can get valuable business insights by defining and querying hierarchically related data. The hierarchical modeling and visualization capabilities give you a number of benefits:

- View and explore complex hierarchical information.
- View key performance indicators (KPIs) in the contextual view of a hierarchy.
- Visually analyze key information across the web and the tablets.

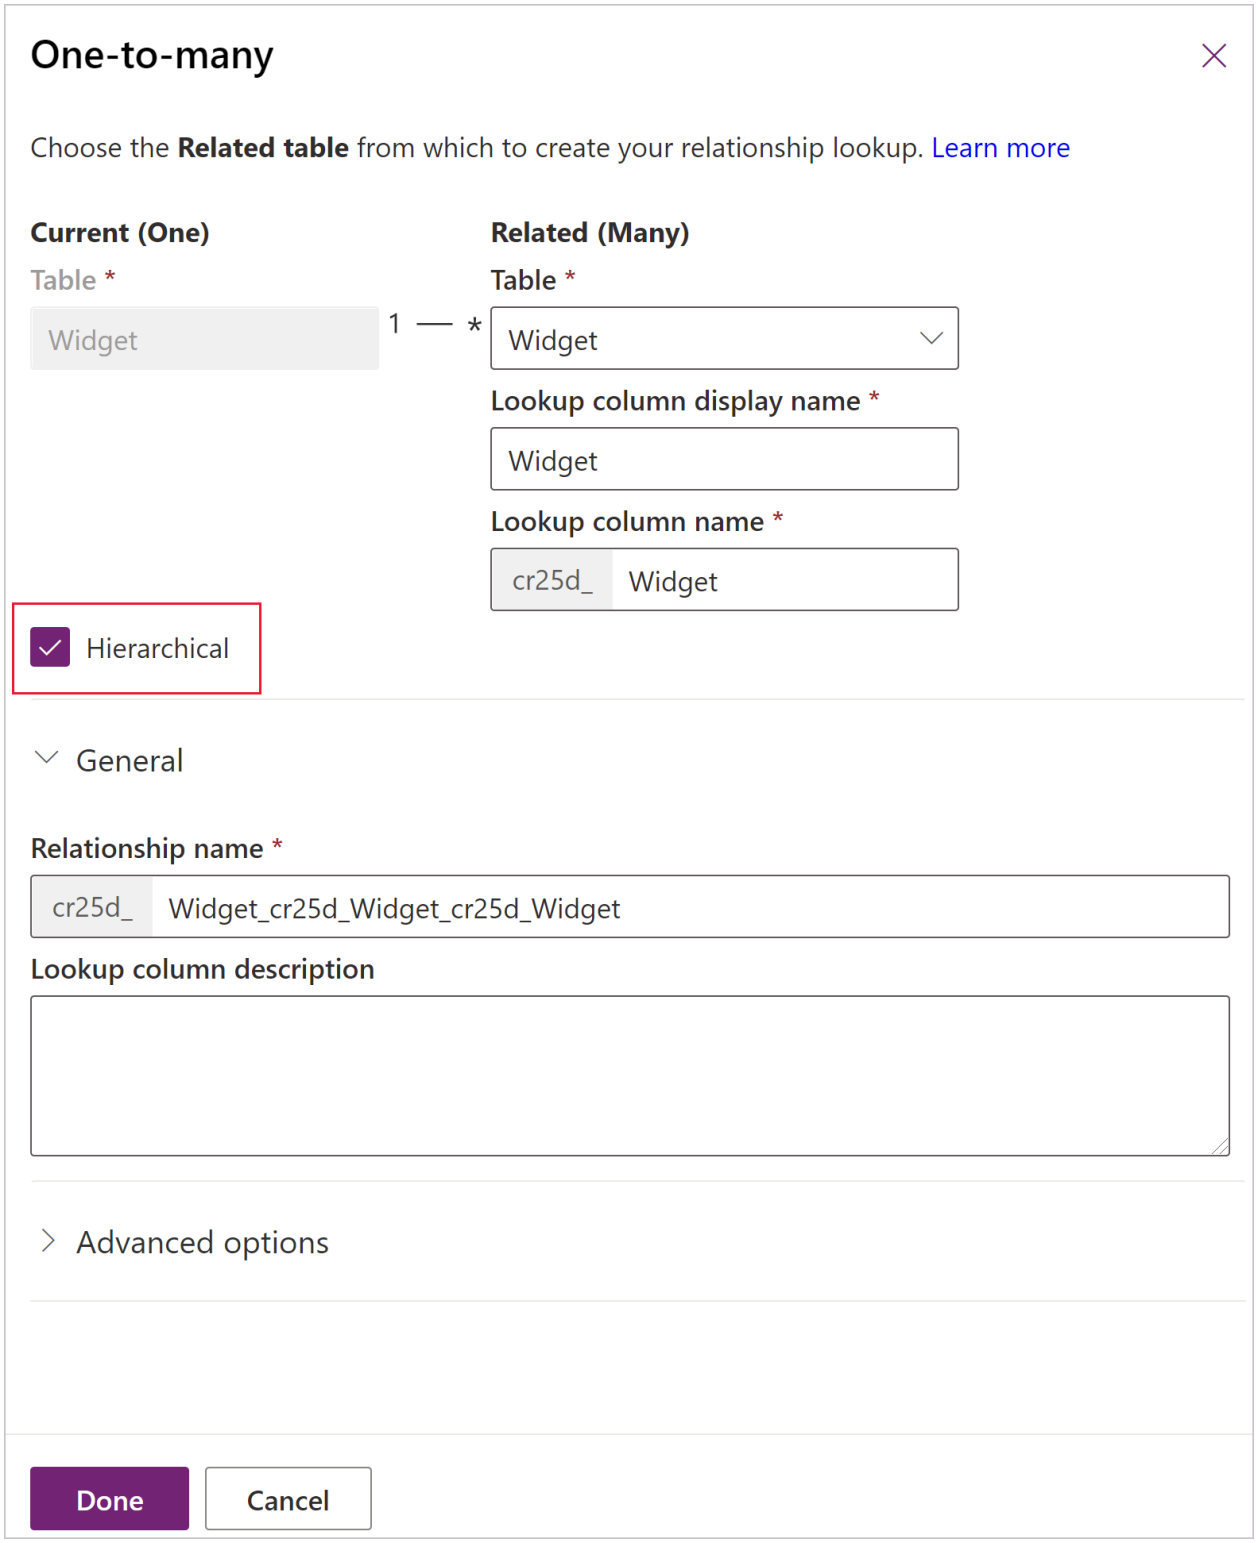
Some standard tables already have hierarchies defined. Other tables, including custom tables, can be enabled for a hierarchy and you can create the visualizations for them.

Define hierarchical data

With Microsoft Dataverse, hierarchical data structures are supported by *self-referential* one-to-many (1:N) relationships of the related rows.

> **Note**
>
> *Self-referential* means that the table is related to itself. For example, the account table has a lookup column to associate it with another account table row.

When a self-referential one-to-many (1:N) relationship exists, in the relationship definition the **Hierarchical** option is available to be set to **Yes**.



To query the data as a hierarchy, you must set one of the table's one-to-many (1:N) self-referential relationships as hierarchical.

To turn on the hierarchy:

1. While viewing 1:N relationships, select the self-referential relationship you want to edit.
2. In the relationship definition, set **Hierarchical** to **Yes**.

> **Note**

- Some of the out-of the-box (1:N) relationships can't be customized. This will prevent you from setting those relationships as hierarchical.
- You can specify a hierarchical relationship for the system self-referential relationships. This includes the 1:N self-referential relationships of system type, such as the "contact_master_contact" relationship.

ⓘ Important

You can have multiple self-referential relationships, but only one relationship per table can be defined as the hierarchical relationship. If you try to change the setting once applied you will get a warning:

- **When disabling:** If you turn off the hierarchy setting for this relationship, all rollup definitions, processes, and views that use this hierarchy won't work. Do you want to continue?
- **When enabling:** If you enable the hierarchy setting for this relationship, all rollup definitions that use the existing hierarchy will become invalid. Do you want to continue?

Unless you are certain that there are no other dependencies on the existing hierarchy, you should review any documentation about the deployment or confer with other customizers to understand how the existing hierarchical relationship is used before continuing.

Query hierarchical data

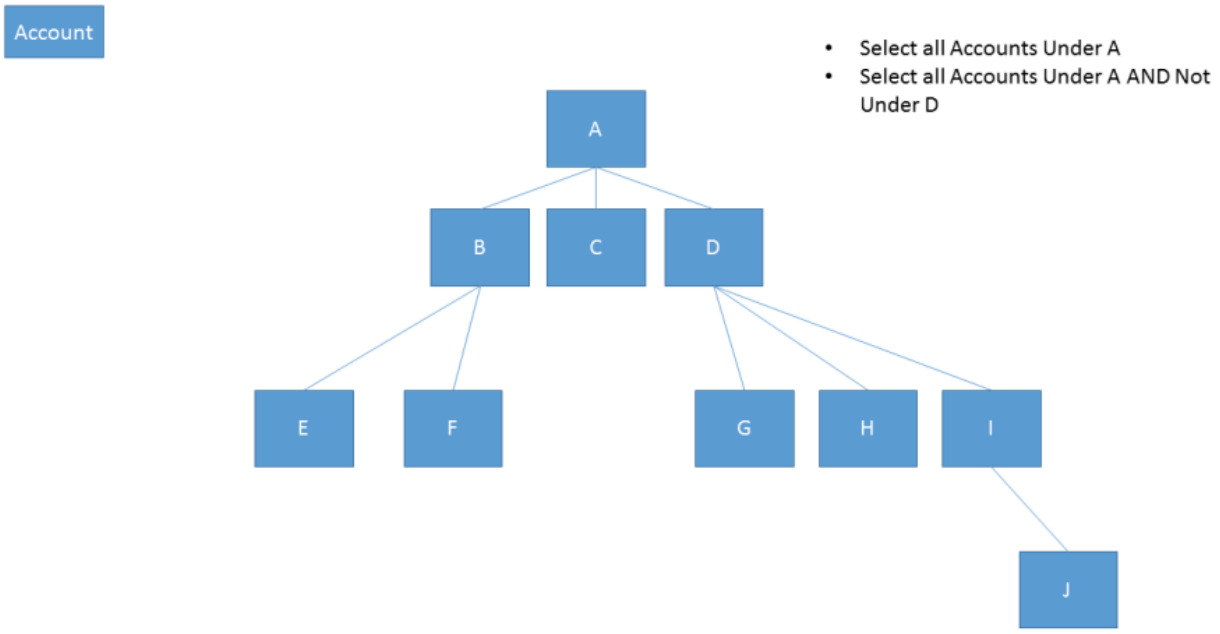
Without a defined hierarchy, to retrieve hierarchical data, need to iteratively query for the related rows. With a defined hierarchy, you can query the related data as a hierarchy in one step. You're able to query rows using the **Under** and **Not Under** logic. The **Under** and **Not Under** hierarchical operators are exposed in Advanced Find and the workflow editor. For more information about how to use these operators, see Configure workflow steps. For more information about Advanced Find, see Create, edit, or save an Advanced Find search

ⓘ Note

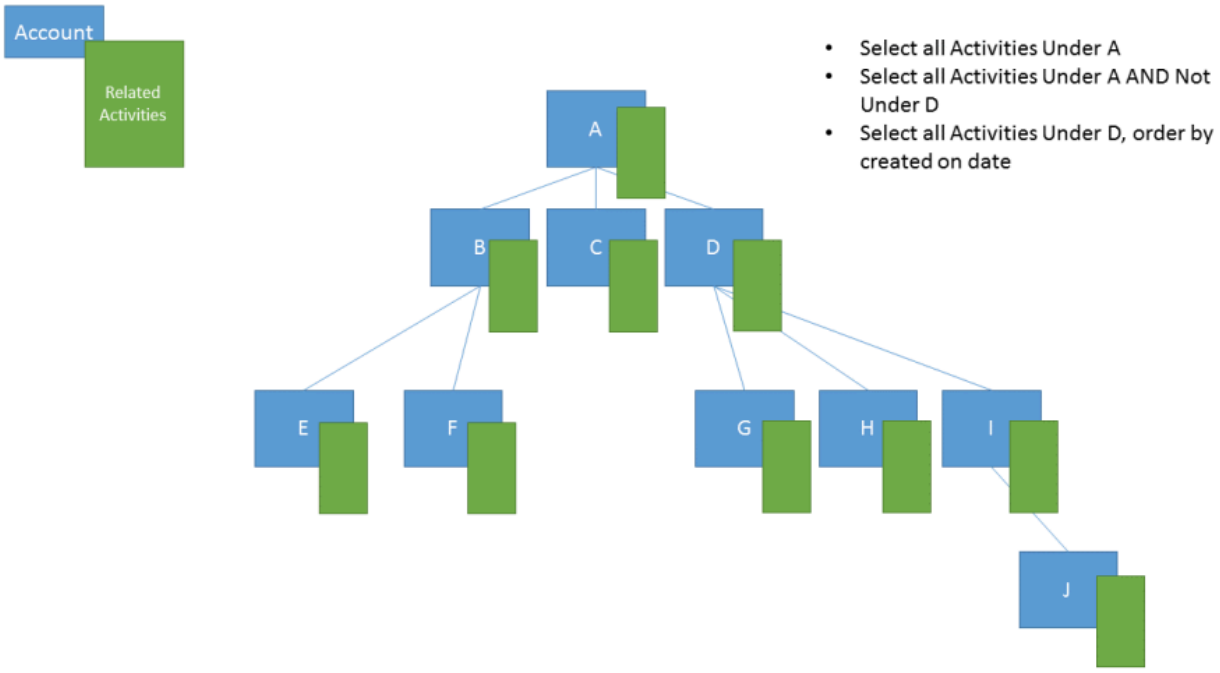
Developers will also be able to use these operators in code. More information Developer Documentation: Query hierarchical data

The following examples illustrate scenarios for querying hierarchies:

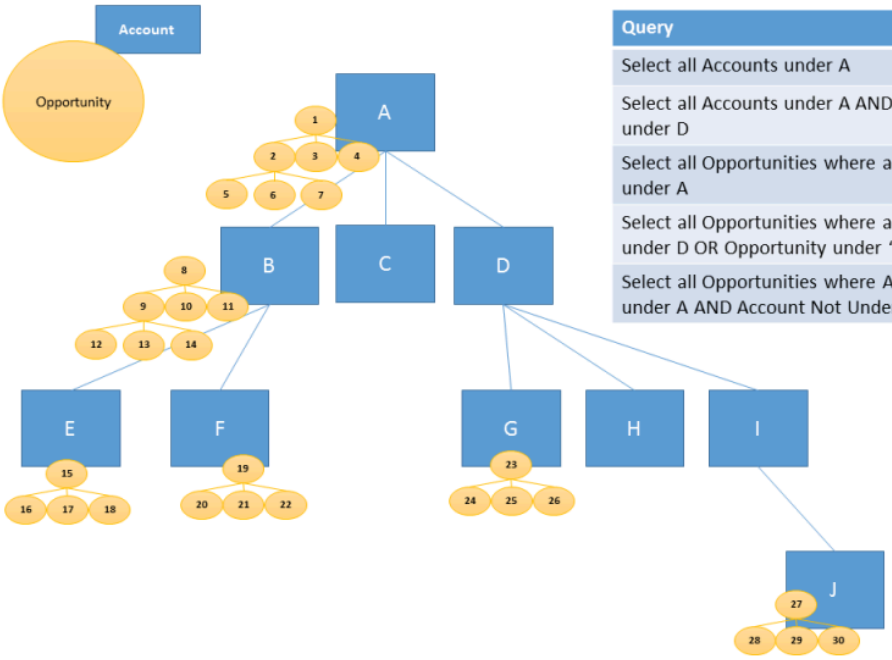
Query account hierarchy



Query account hierarchy, including related activities



Query account hierarchy, including related opportunities



Query	Result
Select all Accounts under A	{B,C,D,E,F,G,H,I,J}
Select all Accounts under A AND not under D	{B,C,D,E,F,}
Select all Opportunities where account under A	{8,9,10.... 30}
Select all Opportunities where account under D OR Opportunity under "15"	{23,24,25,26,27,28,29,30, 16,17,18}
Select all Opportunities where Account under A AND Account Not Under D	{8,9,10,11,12.....,22}

Configure connection roles

Article • 03/13/2023

With Microsoft Dataverse, you can define **connections** between table rows without creating a table relationship. In model-driven apps people can establish a named link between rows to establish less a formal relationship, which doesn't justify creating an actual table relationship. Some examples include *friend*, *sibling*, *spouse*, *attendee*, and *stakeholder*. Some connections can also be reciprocal, such as *child* and *parent*, *husband* and *wife*, or *doctor* and *patient*.

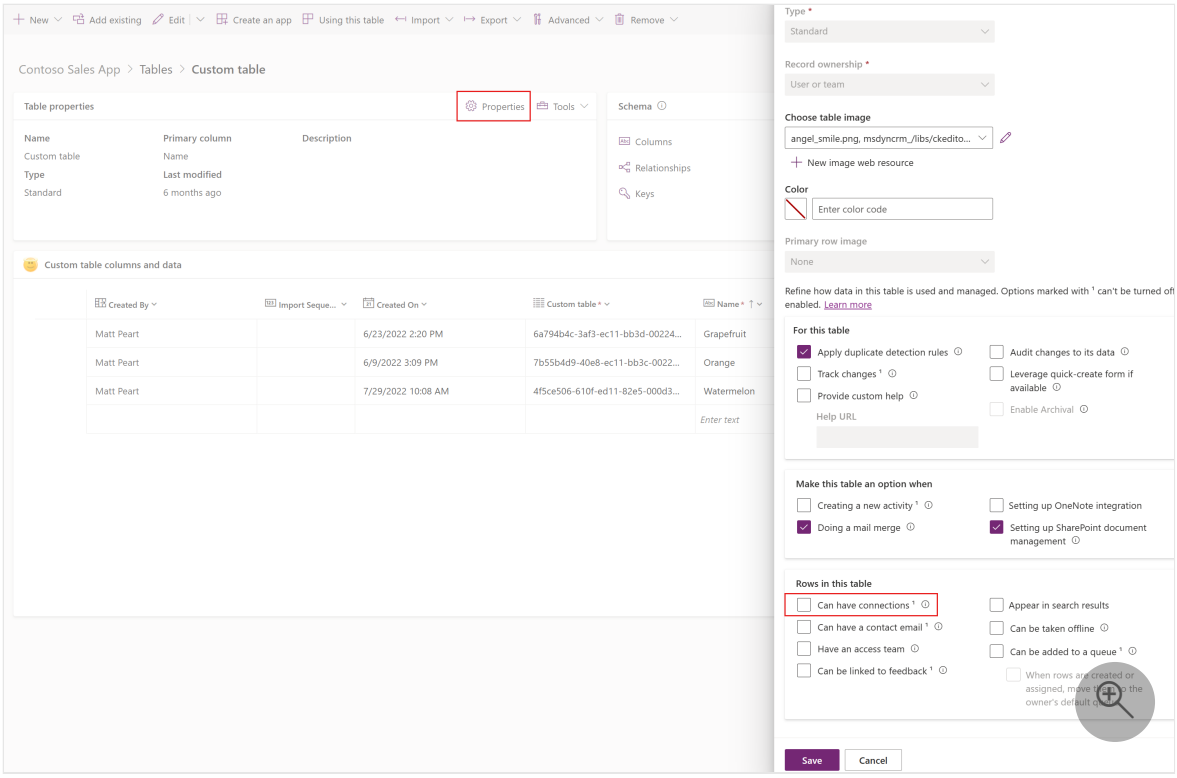
When people set a connection between two rows, they can also add a description and additional information such as start and end dates for the relationship. More information: Add a connection role to link rows to each other

Anyone with write access to the **Connection Role** table can establish which connections are available for people to use.

> **Important**
>
> For a table to be available as a row type for a new or existing connection role, the **Can have connections** property must be enabled for the table.

Enable connection roles for a table

1. Sign in to Power Apps.
2. Open the table you want or create a new one. More information: Edit a table
3. Select **Properties**, and then in the right properties pane, select **Can have connections**.



4. Select **Save**.

View connection roles

There are a number of standard connection roles already configured in Dataverse.

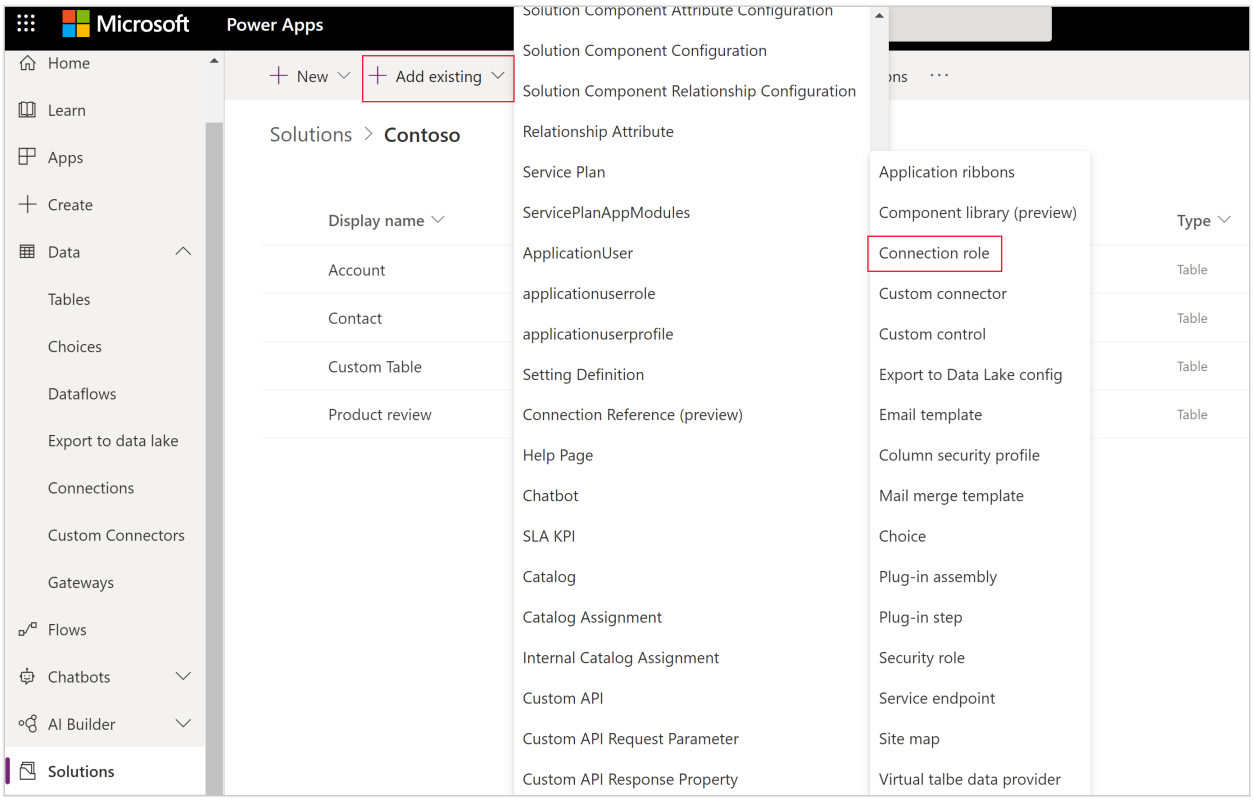
1. Sign in to Power Apps, and then on the left pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
2. Open the unmanaged solution you want.
3. On the command bar, select **Add existing** > **Connection Role**. The list of available connection roles are displayed.
4. Select **Cancel** to close the **Add existing connection Roles** pane without adding a connection role to the solution.

> **Note**
>
> - If you want to distribute connection roles with a solution, make sure they are included in the solution you want to distribute. More information: **Add connection roles to a solution**

Add connection roles to a solution

Because connection roles are *solution aware*, which means that they can be included in a solution, you can also add connection roles to a solution you distribute.

Generally we don't recommended you edit components in the internal **Default Solution**. Within the solution you've created to work in, you can use the **Add Existing** command in the **Solutions** area to bring any of the active connection roles into your solution.



Once you add the connection role to your solution, you can edit it wherever it's visible.

> **Note**
>
> The connection role status is not included with the connection role when it is exported from a solution. Therefore, when the solution is imported into a target environment, the status will be set to active by default.

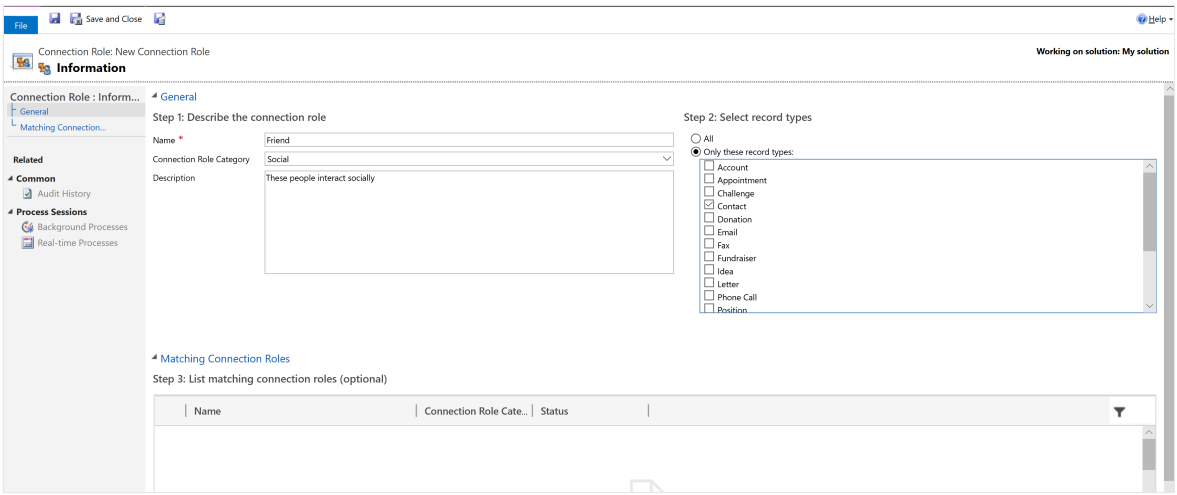
Create a connection role

> **Important**
>
> If you intend to distribute a solution that includes new connection roles or changes to the existing connection roles you must add them to the solution you will distribute. Editing or adding new connection roles in the **Default Solution** will not include them in a solution you can distribute. More information **Add connection roles to a solution**

1. Sign in to Power Apps and then on the left pane select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Open the unmanaged solution your want, and then on the command bar select **New** > **Other** > **Connection role**.

3. Complete the three steps on the form to Describe the connection role.



Describe the connection role

Set the following columns:

Column	Description
Name	(Required) The text describing the connection.
Connection Role Category	A group describing the category of the connection. More information: Connection Role Category values
Description	Provide a definition for the role.

Connection Role Category values

The default **Connection Role Category** values are:

- Business
- Family
- Social
- Sales
- Other
- Stakeholder

- Sales Team
- Service

You can add new categories or modify existing ones by editing the **Category** global choice. More information: Create and edit global choices for Dataverse (picklists)

Select row types

Select which row types should be available to connect.

> **Note**
>
> Although **All** is selected by default, make sure you consider which types are appropriate for the connection role you are adding.

Matching connection roles

In this optional step, you can define any roles that be applied in a reciprocal manner. It isn't required, but connections are more meaningful if these are defined.

For example, people can set that Glen is a *Friend* to Mary, but does this mean that Mary is a *Friend* to Glen? We hope so. But if Glen is the *Father* of Mary it doesn't mean that Mary is the *Father* of Glen. Establishing correct reciprocity requires this extra step.

When people set a connection role that doesn't have a matching connection role, the role will only be displayed when viewing the connection from the row that the connection was applied to. When viewed from the connected row, the role will be empty unless a matching role is set.

For role definitions like *Friend*, *Spouse*, *Colleague*, or *Sibling*, it's best to assign the matching role to itself. If a single matching connection role is configured, the single matching connection role will be applied in both directions.

> **Important**
>
> You will need to save a new connection role without this matching connection role before you can set the matching connection role to itself.

You'll find that some connection roles are already configured with matching connection roles. *Former Employee* is matched with *Former Employer* and vice versa. This kind of one-to-one matching connection role is most common.

You can configure multiple matching connection roles to describe complex relationships. If you create a connection role such as *Father*, you could configure two more roles such as Daughter,* and *Son* and apply both of them as matching connection roles to *Father*. In turn, both the *Daughter* and *Son* connection roles should be matched to *Father*. Of course, then you should set up an equivalent role for *Mother* that is similarly matched with *Daughter* and *Son*.

> **Tip**
>
> Before you create a complex set of connection roles, consider if a more simple set of roles will be enough. For example, rather than creating a complex set of connection roles like *Father*, *Mother*, *Son*, and *Daughter* - consider if simply using *Parent* and *Child* will work for you.

If more than one matching connection role is configured, those connection roles represent the only valid reciprocal roles. The first one will be applied automatically as the default value. If the default value isn't correct, people need to manually edit the connection and choose between valid options defined in the configuration.

Create and edit relationships between tables

Improve copilot responses from Microsoft Dataverse

Copilot experiences in Dynamics 365 apps, apps in Power Apps, or Microsoft 365 Copilot allow users to ask natural language questions about data that's stored in Dataverse. Copilots help your users get insights and information from your enterprise data, which improves their productivity and decision-making. However, sometimes they might not get the answers they expect or need from copilots. This article shows you how to improve the accuracy and relevance of copilot answers by using Microsoft Copilot Studio and the record picker.

Prerequisites for using copilots with Dataverse

By default, the Copilot feature for app users in model-driven apps is turned off. Admins must enable this feature for their environments in the Power Platform admin center. Learn more: Turn on copilots and generative AI features

Improve results for Dataverse using knowledge sources in Copilot Studio

As a maker, you know how your data is structured and how your users ask questions about it. To improve the quality of the results, you can teach the copilot some domain knowledge, also known as *grounding*, using synonyms and phrases with definitions. This information helps the copilot understand how your users ask questions that don't match the names or values of the tables or columns in your data.

For example, if your users ask "What are my closed leads?" and the results depend on a column that doesn't include "closed" or a status that doesn't have "closed" in the definition, the results might be imprecise. If your company defines a closed lead as a status of not qualified or canceled, you can add a glossary term that defines "closed leads" as "lead status isn't qualified or canceled." This additional information helps the copilot understand your users' questions better.

Teach your copilot domain knowledge by adding a knowledge source in Copilot Studio to make its answers more relevant and informative for your users. You can add enterprise data from Power Platform, Dynamics 365, and external systems as knowledge sources. You can also add Dataverse data as a knowledge source. Learn more: Add knowledge to a copilot

Improve answers for a specific record using a copilot in an app

In Power Apps model-driven apps and Dynamics 365 Sales, users can use the record picker to improve their results. The record picker lets you choose a record to use as the object of your question. This helps you get better answers when the results include records from different tables or records that aren't what you wanted.

To open the record picker, type `/`. Then type the name of the record you want. Learn more: Use Copilot chat in model-driven apps

Create new data columns in Dataverse

Columns, also known as fields or attributes, in Microsoft Dataverse define the individual data items that can be used to store information in a table. Column data is used in apps to display information on forms, in views, and can be used in searches within an app. By default, the account main form has several columns, such as account name, phone, fax, website, and so on.

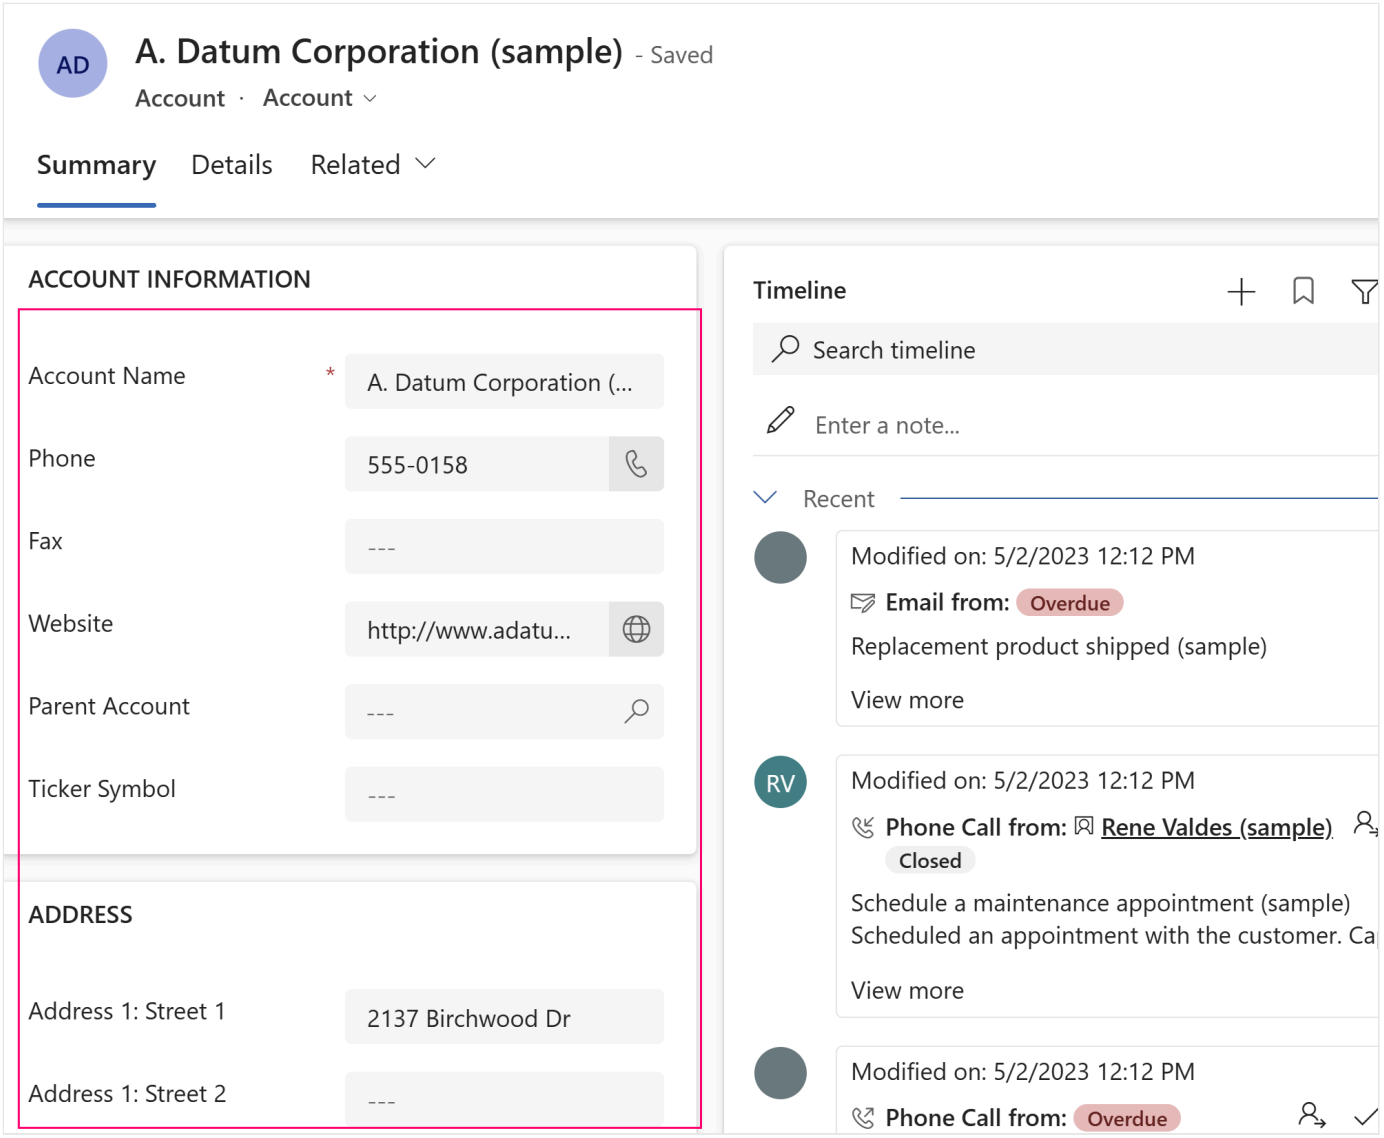
With the exception of choices columns, all columns depend on a table. Columns support many different data types, such as text, number, date and time, lookup (links to another table), currency, autonumber, file, or Power Fx formula.

Create new columns to capture data when existing standard tables don’t have columns that meet your requirements.

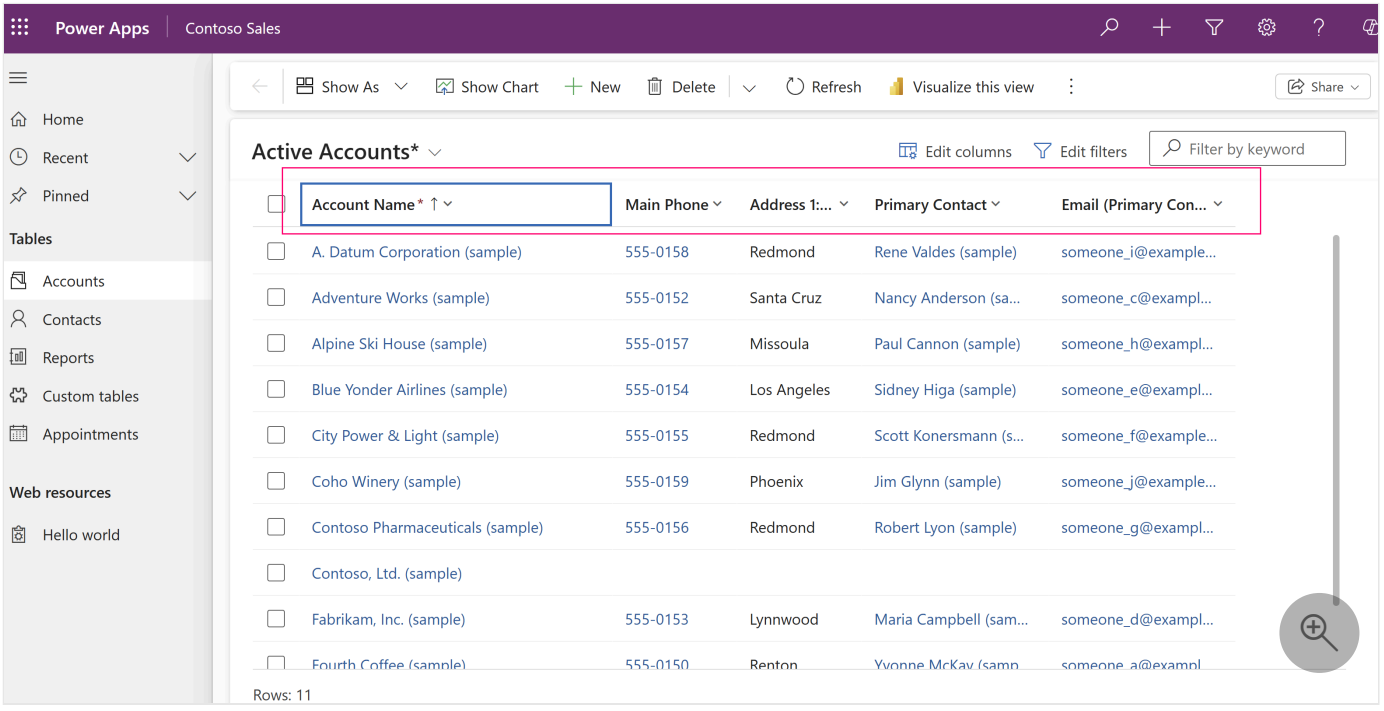
How table columns are used in apps

After you create a new column, you include it on the appropriate forms using the form designer, and views using the view designer, for the table so that they're available in your app.

Here are default columns on a form for the account table in a model-driven app.



Here are the default columns for the active accounts view in a model-driven app.



Create a table column

Watch this short video that shows you how to quickly create a column.

https://learn-video.azurefd.net/vod/player?id=f0015291-5024-4427-a669-dd230cf5c0c8&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Ffields-overview

Create a column in Power Apps (make.powerapps.com). You can also create columns while working in the model-driven app form designer or view designer.

1. Go to Power Apps, and then select **Solutions** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select the table where you want to add a column. If the solution doesn't already have the table, select **Add existing** > **Table** or to create a new table select **New** > **Table** > **Table (advanced properties)**. More information: Set advanced properties for a table
3. In the table **Schema** area, select **Columns**.
4. In the list of columns for the table, select **New column**.
5. Complete the required and optional properties for the column, and then select **Save**.

Go to these articles for more information about creating columns:

- Types of columns
- Create and edit columns in Dataverse using Power Apps
- Create and edit choice columns overview

Last updated on 04/27/2026

Types of columns

The names used for types depend on the designer used. Power Apps uses a convention that includes the way the data is formatted. The solution explorer type uses a name aligned with the database data type with a format modifier.

Watch this video for a quick overview about data types in Dataverse:

https://learn-video.azurefd.net/vod/player?id=d64c0198-42de-4dd0-8cec-14e3008442e6&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Ftypes-of-fields

The following table includes the corresponding `AttributeTypeDisplayName` API type.

Expand table

Power Apps data type	Solution Explorer type	API type
Big	Time Stamp	`BigIntType`
Choice	Option Set	`PicklistType`
Choices	MultiSelect Field	`MultiSelectPicklistType`
Currency	Currency	`MoneyType`
Customer	Customer	`CustomerType`
Date and Time	Date and Time *Date and Time* Format	`DateTimeType`
Date Only	Date and Time *Date Only* Format	`DateTimeType`
Decimal Number	Decimal Number	`DecimalType`
Duration	Whole Number *Duration* Format	`IntegerType`
Email	Single Line of Text *Email* Format	`StringType`
File	File	`FileType`
Floating Point Number	Floating Point Number	`DoubleType`
Image	Image	`ImageType`
Language	Whole Number	`IntegerType`

Power Apps data type	Solution Explorer type	API type
	Language Format	
Lookup	**Lookup**	`LookupType`
Multiline Text	**Multiple Lines of Text**	`MemoType`
Owner	**Owner**	`OwnerType`
Phone	**Single Line of Text** *Phone* Format	`StringType`
Status	**Status**	`StateType`
Status Reason	**Status Reason**	`StatusType`
Text	**Single Line of Text** *Text* Format	`StringType`
Text Area	**Single Line of Text** *Text Area* Format	`StringType`
Ticker Symbol	**Single Line of Text** Ticker Symbol Format	`StringType`
Timezone	**Whole Number** *Time Zone* Format	`IntegerType`
Unique Identifier	**Unique Identifier** or **Primary Key**	`UniqueidentifierType`
URL	**Single Line of Text** *URL* Format	`StringType`
Whole Number	**Whole Number** *None* Format	`IntegerType`
Yes/No	**Two Options**	`BooleanType`

For more descriptions for each type you can add or edit, see the article for the corresponding designer:

- Create and edit columns for Microsoft Dataverse using Power Apps portal: Column Data types
- Create and edit columns for Dataverse using Power Apps solution explorer: Column Data types

For more information about how column data types are defined in the API, see Attribute metadata

Column types used by the system

There are some columns used by the system that you can't add using the designer.

Expand table

Type	Description
Time Stamp	A Big Integer type used by the system to capture a version number for managing updates to a table.
Customer	A lookup column that you can use to specify a customer, which can be an account or contact. **Note**: This attribute can be added using solution explorer designer.
Owner	A system lookup column that references the user or team that is assigned a user or team owned table row.
Status Reason	A system column that has options that provide additional detail about the Status column. Each option is associated with one of the available Status options. You can add and edit the options. You can also include custom state transitions to control which status options are available for certain tables. More information: Define status reason transitions for custom tables
Status	A system column that has options that generally correspond to active and inactive status. Some system attributes have additional options, but all custom attributes have only **Active** and **Inactive** status options.
Unique Identifier	A system column stores a globally unique identifier (GUID) value for each row.

Text columns

Text columns can contain text characters. This column type has several format options that change the presentation of the text.

Watch this video for a quick overview about text columns:

https://learn-video.azurefd.net/vod/player?id=58cc0b9e-1fd3-4d9f-8e62-1514e3c9bc4d&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Ftypes-of-fields

There are three basic text column types. All values indicated here are in number of characters.

Expand table

Column type name	Default value	Maximum value	Description
Text	100	4000	Accepts a single line of text.
Text Area	100	4000	Accepts multiple lines of text. The number of rows displayed for the column can be configured. Use for smaller amounts of text.
Multiline Text	150	1048576	Accepts multiple lines of text. The number of rows displayed for the column can be configured. Use when large amounts of text are needed.

If you reduce the maximum number of characters for the column, existing data won't be truncated. The limit applies to new rows.

Choices

You can customize forms (main, quick create, and quick view) and email templates by adding multi-select columns that are called **Choices**. When you add a choices column, you can specify multiple values that are available for users to select. When users fill out the form they can select one, multiple, or all the values displayed in a drop-down list.

For example, if an organization operates in multiple areas or countries/regions, you can include multiple locations or countries/regions in an 'Area of operation' column. A user can then select one or more locations from the list of available values.

Choices can be used with read-only grids, editable grids, and most forms. Multi-select choices can't be used with:

- Workflows, business process flows, actions, dialogs, business rules, charts, rollup columns, or calculated columns.
- Reports, SLA[1], and routing rules[1].

[1]Table requires Dynamics 365 Customer Service.

Forms

Choices multi-select columns are supported in the following types of forms:

Expand table

Form Type	Availability
Turbo form	Yes
Refresh form	Read-only (column is available but can't be edited)
Legacy form	No
Bulk Edit form	No

You can use global choices that are defined in your organization to configure values for the multi-select choices.

Using the right type of number

When choosing the correct type of number column to use, the decision to use a **Whole Number** or **Currency** type should be straightforward. The choice between using **Floating Point** or **Decimal** numbers requires more thought.

Watch this video to help you decide what number column type to use:

https://learn-video.azurefd.net/vod/player?id=85ab223e-8fe5-4d61-8715-c9a675ade6ad&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Ftypes-of-fields

Decimal numbers are stored in the database exactly as specified. Floating point numbers store an extremely close approximation of the value. Why choose extremely close approximation when you can have the exact value? The answer is that you get different system performance.

Use decimals when you need to provide reports that require very accurate calculations, or if you typically use queries that look for values that are equal or not equal to another value.

Use floating point numbers when you store data that represents fractions or values that you'll typically query comparing to another value using greater than or less than operators. In most cases, the difference between decimal and float isn't noticeable. Unless you require the most accurate possible calculations, floating point numbers should work for you.

Large integers (`Big` or `BigInt`) are large numbers with a max value of 9,223,372,036,854,775,807. It's used to store very large numbers that exceed the capabilities of Whole Number and Decimal. Some uses for this include storage of time stamp values and as unique IDs, as well as numbers larger than 100 billion.

> ⓘ **Note**

The precision and limits of number types described here apply to database capabilities. If you're working with currency and numbers in Power Apps apps, other limitations might apply.

- Up to 15 digits can be handled precisely. For example, the 15-digit number 99999.0000000089 can be entered in the app and stored in the database as is. However, the 16-digit number 999999.0000000089 is processed imprecisely as 999999.0000000088 by the app. Longer numbers might be truncated, even if they haven't reached Dataverse limits. This is an inherent limitation of number processing in web browsers.
- `Big` and `BigInt` aren't supported in canvas and model-driven apps.
- Canvas apps don't currently support decimal type numbers.

Using currency columns

Currency columns allow for an organization to configure multiple currencies that can be used for rows in the organization. When organizations have multiple currencies, they typically want to be able to perform calculations to provide values using their base currency. When you add a currency column to a table that has no other currency columns, two additional columns are added:

- A lookup column called **Currency** that you can set to any active currency configured for your organization. You can configure multiple active currencies for your organization in **Settings** > **Business Management** > **Currencies**. There you can specify the currency and an exchange rate with the base currency set for your organization. If you have multiple active currencies, you can add the currency column to the form and allow people to specify which currency should be applied to money values for this row. This changes the currency symbol that is shown for the currency columns in the form.

  Individuals can also change their personal options to select a default currency for the rows they create.

- A decimal column called **Exchange Rate** that provides the exchange rate for a selected currency associated with the table with respect to the base currency. If this column is added to the form, people can see the value, but they can't edit it. The exchange rate is stored with the currency.

For each currency column you add, another currency column is added with the suffix `_Base` on the name. This column stores the calculation of the value of the currency column you added and the base currency. Again, if this column is added to the form, it can't be edited.

When you configure a currency column, you can choose the precision value. There are three options as shown in the following table.

Expand table

Option	Description
Pricing Decimal Precision	This is a single organization precision to be used for prices found in **Settings** > **Administration** > **System Settings** > **General Tab**.
Currency Precision	This option applies the precision defined for the currency in the row.
Specific precision values	These settings allow for defining a specific set precision using values between 0 and 4.

Different types of lookups

When you create a new lookup column, you're creating a new Many-to-One (N:1) table relationship between the table you're working with and the **Target Row Type** defined for the lookup. There are additional configuration options for this relationship that are described in Create and edit relationships between tables. But all custom lookups can only allow for a reference to a single row for a single target row type.

However, you should be aware that not every lookup behaves this way. There are several different types of system lookups as shown here.

Expand table

Lookup type	Description
Simple	Allows for a single reference to a specific table. All custom lookups are this type.
Customer	Allows for a single reference to either an account or a contact row.
Owner	Allows for a single reference to either a team or a user row. All team or user-owned tables have one of these. More information: Add a table as a lookup option in your app
PartyList	Allows for multiple references to multiple tables. These lookups are found on the Email table **To** and **Cc** columns. They're also used in the Phone and Appointment tables.
Regarding	Allows for a single reference to multiple tables. These lookups are found in the regarding column used in activities.

Image columns

Use image columns to display images in your applications. Image columns are optimized for storing binary data. Dataverse doesn't save this data in the relational data store, which improves performance and reduces the capacity usage. Learn more about storage capacity

Each table can have one *primary image* column. With model-driven apps, you can display this image in the upper right corner of the form. Even though a table has an image column, displaying that image in a model-driven app requires that you enable two settings.

- The standard table definition **Primary Image** property value must be set to **Default Image**. Custom tables require a custom image column. Then, you can select that image column for the **Primary Image** value in the custom table definition.
- The table form where the image is to be displayed must have the **Show image in the form** property enabled.

People choose the image to upload a picture from their computer. Images must be less than 30 MB and must be in one of the following formats:

- jpg
- jpeg
- gif
- bmp
- png

When the image is uploaded, it is converted to a .jpg format and all downloaded images also use this format. If an animated .gif is uploaded, only the first frame is saved.

When an image is uploaded, it is resized as a "thumbnail" image to a maximum size of 144 pixels by 144 pixels. People should resize or crop the images before they upload them so that they display well using this size. All images are cropped to be square. If both sides of an image are smaller than 144 pixels, the image is cropped to be a square with the dimensions of the smaller side.

> ⓘ **Note**
>
> Image columns don't work with business process flows, business rules, charts, rollup columns, or calculated columns.

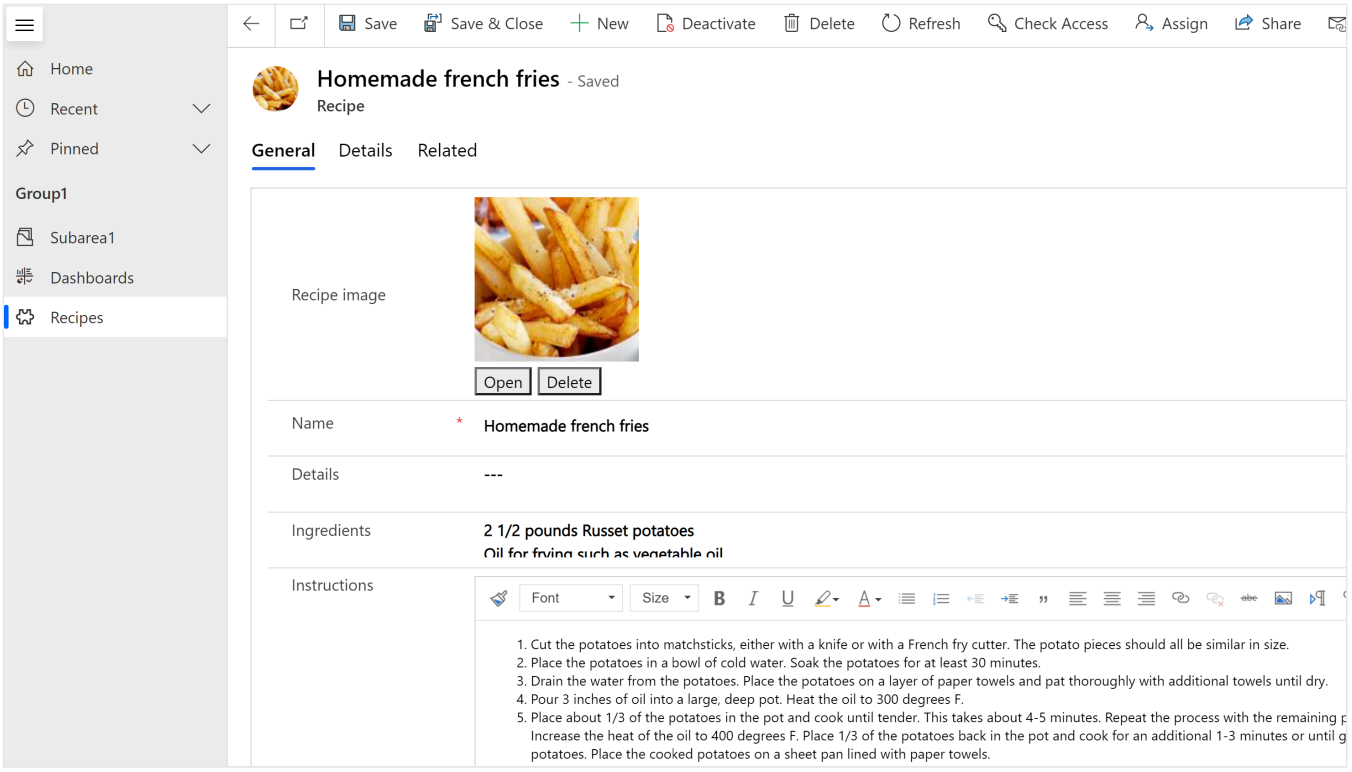
Learn to work with Image column definitions using code

Create an image column and add it to a form

1. Go to https://make.powerapps.com, select **Solutions**, and then open the unmanaged solution that contains the table form where you want to add an image column.
2. Open the table, and then select the **Columns** area.
3. On the command bar, select **Add column**.
4. Enter or select values for the following properties, and then select **Done**.
    - **Display Name**, such as *Recipe image*.
    - **Name**. This is the unique name that includes the solution publisher prefix and can't be changed once saved.
    - **Data Type**. Select **Image**.
    - **Primary Image**. Image columns that are set as the primary image are displayed in the upper right corner of the form. You can have only one primary image for each table.
    - **Enable column security**. Use to control access for specific columns. More information: Field-level security to control access
    - **Enable auditing**. Enables the logging of changes that are made to table records and user access so you can review the activity later. More information: Administrators Guide: Manage Dataverse auditing
    - **Sortable in interactive experience dashboard**. Specifies the column will be used to configure interactive dashboards. More information: Configure filter columns, and security roles for interactive dashboards
    - **Maximum image size**. Default value is 10,240 KB. The minimum size is 1 KB and the maximum is 30,720 KB.
5. Select **Save table**.
6. Select the **Form** tab, and then open the form for editing, such as the table main form.
7. Add the image column to the form canvas.
8. On the form editor command bar, select **Save**, and then select **Publish** to make the image column available to users.

App users can now select the image to display on the form. When an app user opens the form for a record, they can select **Choose file**, select the image, and then save the record. Then, the image is displayed on the form where the image column is located.

The image column in this example is the primary image so the image also appears on the upper left of the form.



Users can select **Open** to display the image full size in a new browser tab or select **Delete** to remove the image from the record and Dataverse.

More information for developers working with image data:

- table metadata > table images
- Image attributes

File columns

The **File** column is used for storing binary data. File columns are optimized for storing binary data. Dataverse doesn't save this data in the relational data store, which improves performance and reduces the capacity usage. Learn more about storage capacity

The primary intended use of this column is to store a single image, note, or attachment. However, storage of other forms of binary data is also possible. One or more columns of this data type can be added to an existing standard customizable table or a custom table.

The default **Maximum file size** is 32 MB and the largest size you can set using the designer is 131,072 KB (131 MB). The file size limit can be set individually for each column of file type added to a table.

> **Note**
>
> - Once the maximum file size is saved, it can't be changed.

- File columns don't work with business process flows, business rules, charts, rollup columns, or calculated columns.
- Required field validation doesn't work with file columns.
- In model-driven apps, deleting or uploading a file on a form happens immediately, not on form save. Discarding changes when navigating away doesn't bring back the file if it's deleted.

To create a file column, on the left pane in Power Apps select **Solutions**, open the solution you want, open the table you want, select the **Columns** area, select **Add Column**, and then in the **Column properties** pane, select **File** as the **Data type**.

Learn to work with file column definitions using code

Fx Formula columns

Built on Power Fx, use a formula column to perform operations that return values during fetch operations. Formula columns use the Power Fx syntax that's similar to Office Excel. More information: Work with formula columns (preview)

Prompt columns

Prompt columns allow AI prompts to be defined and the generative AI results are stored in the table column. More information: Prompt columns

Searching and sorting columns

Most columns have options to enable searching or sorting of the column's contents.

Searchable

Almost every column data type is created with the **Searchable** value enabled. This can be disabled at the time of creation, or later after the column is created. The following data types can't be search enabled:

- Formulas. Formulas are used to create a dynamically calculated output and because of this can't be searched.
- Image. Images are stored and retrieved using reference URLS and because of this they can't be searched.

- Multivalue lookup (PartyList). Some system lookup columns can contain multiple values. For example, the **To** lookup column of **Email** rows can contain multiple recipients. Searching multivalue lookup columns isn't supported.

The **Customer** datatype is search enabled by default and this can't be disabled. It's required to be searchable by the system.

Sortable

Almost every data type is created with the **Sortable** value disabled. The value can be changed at the time of creation or after later after the column is created. The following data types don't provide the ability to enable a sortable attribute:

- Choices. Sorting columns with multiple values isn't supported.
- Customer. Customer is a standard lookup column and can't be sorted because it's dynamically retrieved.
- File. Files are stored using reference URLS and sorting these aren't useful.
- Formulas. Formulas are used to create a dynamically calculated output and because of this can't be sorted.
- Image. There's no meaningful way to sort images.
- Multivalue lookup (PartyList). Some system lookup columns can contain multiple values. For example, the **To** lookup column of **Email** rows can contain multiple recipients. Sorting columns with multiple values isn't supported.

Create and edit choice columns overview

Article • 10/10/2022

A choice (picklist) is a type of column that can be included in a table. It defines a set of options. When a choice is displayed in a form it uses a drop-down list control. When displayed in **Advanced Find** it uses a *picklist control*. Sometimes choices are called picklists by developers.

You can define a choice to use a set of options defined within itself (locally) or it can use a set of options defined elsewhere (globally) which can be used by other choice columns.

Global choice columns are useful when you have a standard set of categories that can apply to more than one column. Maintaining two separate choice options with the same values is difficult and if they aren't synchronized you can see errors, especially if you are mapping table columns in a one-to-many table relationship. More information: Mapping table columns

> ⓘ **Note**
>
> If you define every choice as a global choice your list of global choice columns will grow and could be difficult to manage. If you know that the set of options will only be used in one place, use a local choice.

Choice columns can be configured as either single select (choice) or multi-select (choices).

> ⓘ **Note**
>
> You can also create global choices in your environment using the following:
>
> - Import a solution that contains the definition of the global choices.
> - A developer can write a program to create them.
>
> More information: **Developer documentation: Choices columns**.

Create a choice

Autonumber columns

Article • 03/13/2023

Autonumber columns are columns that automatically generate alphanumeric strings whenever they are created. Makers can customize the format of these columns to their liking, and then rely on the system to generate matching values that automatically fill them in at runtime.

While autonumber columns are formally just text columns with additional functionality built on top of them, Power Apps simplifies this concept by simply exposing **Autonumber** as a distinct data type under the **Text** category. It is important to note that the classic solution explorer doesn't support creating or managing autonumber columns.

To create an autonumber column, follow the same steps to create a column and simply select **Autonumber** from the **Data type** drop-down list box.

You may also activate autonumber functionality on an existing text column by opening the column and selecting **Autonumber** from the **Data type** drop-down list box. Similarly, autonumber functionality can also be disabled at any time by opening the column and selecting a different option in the **Data type** drop-down list box.

> **Note**
>
> Autonumber values are preselected by the database when the row is started. If a row is started but cancelled, the number it was assigned is not used. If, during this time, another row is completed with the next sequential number, gaps will be present in the autonumbering of rows.

Autonumber types

In order to make the creation of autonumber columns easier, there are a few pre-defined default autonumber types to capture the most common scenarios.

String prefixed number

The most common autonumber format is a simple string prefixed number. When this type is selected, the autonumber will consist of an automatically incrementing number with an optional string constant prefix. For example, a string prefixed number with the

prefix *Contoso* would generate rows such as *Contoso-1000*, *Contoso-1001*, *Contoso-1002*, and so on.

Date prefixed number

Another common autonumber format is a date prefixed number. When this type is selected, the autonumber will consist of an automatically incrementing number with a formatted date prefix. The date portion of the row will reflect the current date and time at which the row was created in UTC time. We have provided a number of various date formats to choose from. For example, a date prefixed number would generate rows such as *2019-26-02-1000*, *2019-27-02-1000*, *2019-28-02-1000*, and so on, depending on the current date and selected date format.

Custom

For more advanced makers with specific use cases, we provide the option to fully customize the desired format of an autonumber column. The format may consist of string constants, automatically incrementing numbers, formatted dates, or random alphanumeric sequences. For detailed information about how to define custom formats, see AutoNumberFormat options.

Seed values

The seed value of an autonumber column is the starting number that is used for the number portion of the format. For example, if you want an autonumber column to generate rows such as *Contoso-1000*, *Contoso-1001*, *Contoso-1002*, and so on, then the desired seed value is 1000, because that is the value that your number sequence starts with. Autonumber columns have a default seed value of 1000, but you may set a custom seed value if you wish.

> **Important**
>
> Setting the seed only changes the current number value for the specified attribute in the current environment. The seed value is not included in a solution when it's imported in a different environment.

Create an autonumber column

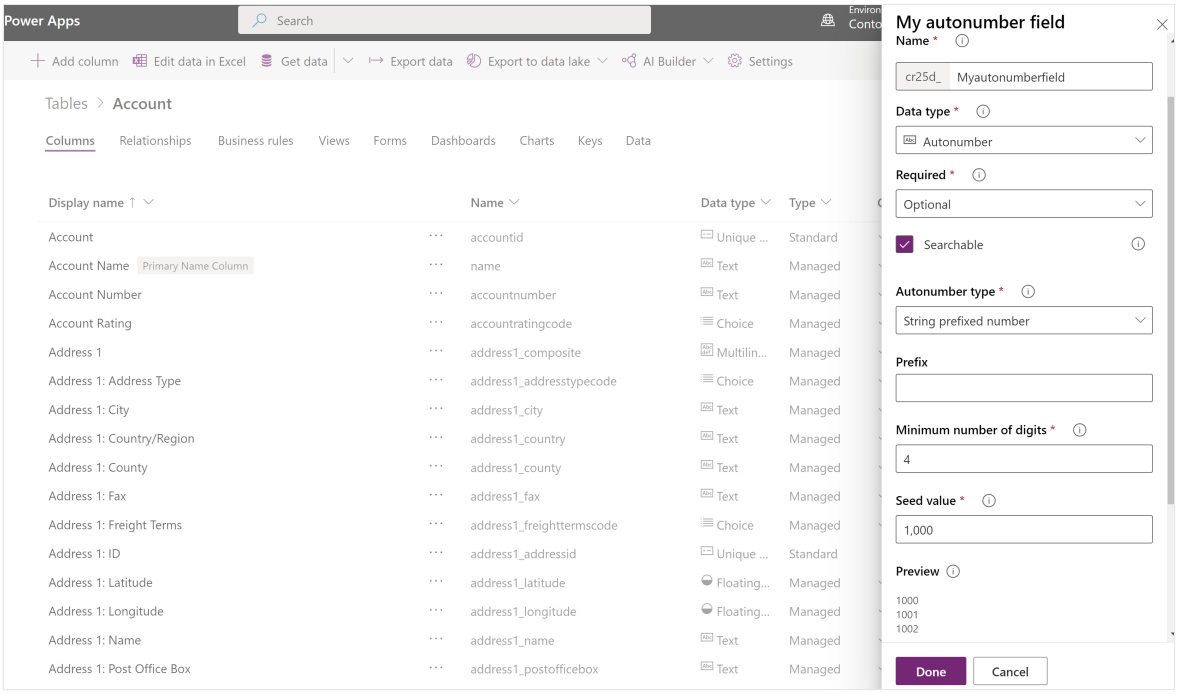
1. Sign in to the Power Apps portal.

2. On the left pane select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. Select the table that you would like to add an autonumber column to and then select **Columns**.

4. On the toolbar, select **Add** column.

5. On the right pane, enter a **Display name** and select **Autonumber** for the **Data type**.



6. Set optional columns as needed. More information: Create and edit columns

7. Select an autonumber type or keep the default **String prefixed number** option.

8. Customize a seed value or keep the default value of **1000**.

9. Select **Done**.

Create and edit columns for Microsoft Dataverse using Power Apps portal

Prompt columns (preview)

[This article is prerelease documentation and is subject to change.]

A prompt column is an AI-powered data type in Microsoft Dataverse that enables you to define natural language prompts tied to other columns in your table. The AI model processes these prompts to generate relevant responses based on specified input columns. The result is immediately stored in the prompt column, ready to be used in apps, workflows, or reports.

The key function is that the prompt column contains generative AI results stored in the table persistently. This is how customer data is enriched using generative AI and brings value to their data.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Example use cases:

- Customer support: Automate responses to frequently asked questions by using AI prompts to generate accurate and timely replies based on customer inquiries stored in Dataverse.
- Content creation: Use prompts to assist in writing articles, reports, or marketing materials by generating text that aligns with the input provided.
- Data analysis: Use AI prompts to analyze complex datasets and generate insights, sentiments, extract, and classify contents or summaries that help in making informed decisions.
- Workflow automation: Integrate AI prompts into business workflows to automatically do tasks such as scheduling, reporting, and data entry.

Prerequisites

- Prompt columns use the same licensing model as AI builder prompts. More information: Prompts overview
- Copilot and AI Prompts features turned On in the Features area for the environment settings. More information: Manage feature settings

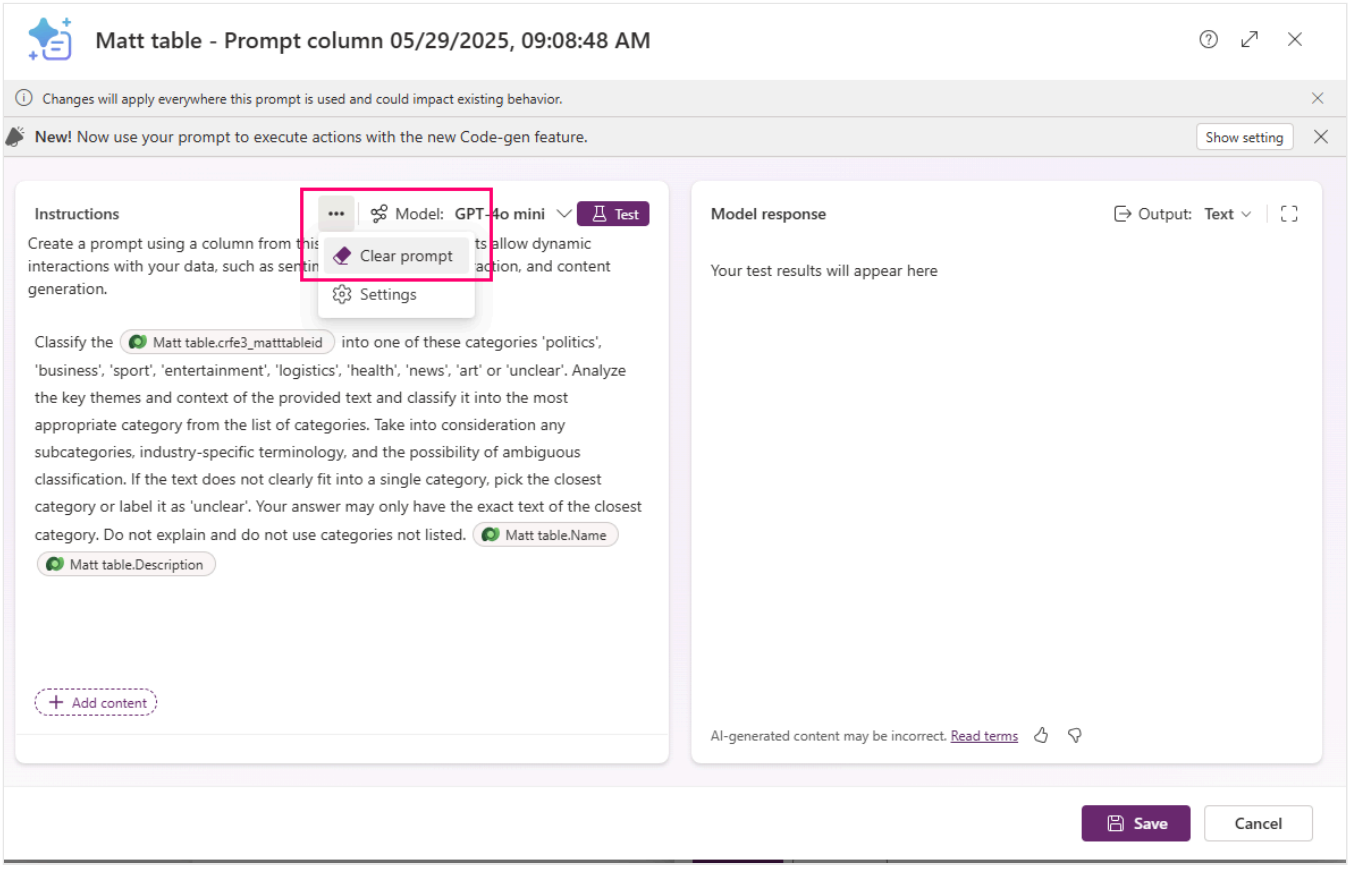
Create a prompt column

1. Go to Power Apps. Select **Tables** on the left navigation pane.
2. Create a new table or open an existing table. More information: Create a table
3. On the **Tables** page, select **New** > **Column**.
4. On the column properties page, enter a **Display name** and **Description** for your column.
5. Under the **Data type** dropdown list, select **Prompt**.
6. Clear the **Allow form fill assistance** checkbox.
7. Select **+Add new prompt**. You can create up to five prompt columns per table.
8. On the prompt column page, create a prompt. More information: How to write an AI prompt for a prompt column
9. Select **Save** on the prompt page.
10. Select **Save** on the column properties page to save your column.

How to write an AI prompt for a prompt column

Crafting effective AI prompts is crucial for getting accurate and relevant responses from the AI model. You can use the prefilled prompt or write your own custom prompt.

To clear the prefilled prompt, highlight and delete it, or select the three dots to the left of **Model**, then select **Clear prompt**.



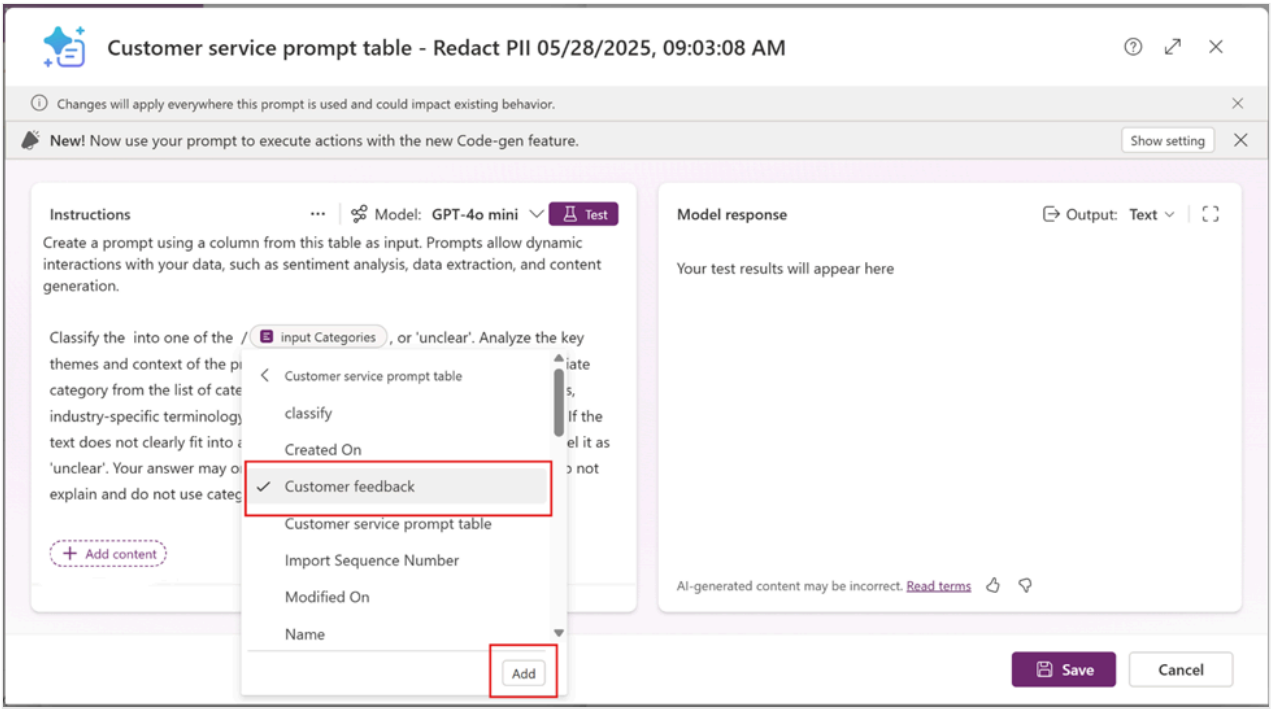
Write effective prompts

Here are some best practices for writing prompts:

- Write clear instructions. Ensure that your prompts are clear and specific. Avoid ambiguity by being precise about what you want the AI to do. For example, instead of writing *Tell me about the weather*, write *Provide a summary of today's weather in Paris*.
- Use structured language. Structured language helps the AI model understand the context and intent of the prompt better. For example, *Generate a list of top 10 marketing strategies for 2025* is more effective than *Top marketing strategies*.
- Include contextual information. Provide necessary context within the prompt to help the AI model generate more accurate responses. For example, *Based on the sales data from Q1, suggest ways to improve our marketing campaign*. Add an input column in each prompt.

Add input columns

1. Replace default input text by selecting it and then select **Delete**.
2. Select **+Add content**, and then select the table.
3. The column dropdown list appears. Select the input column from the list of columns from your table, and then select **Add**. In this example, the *Customer feedback* column is selected.



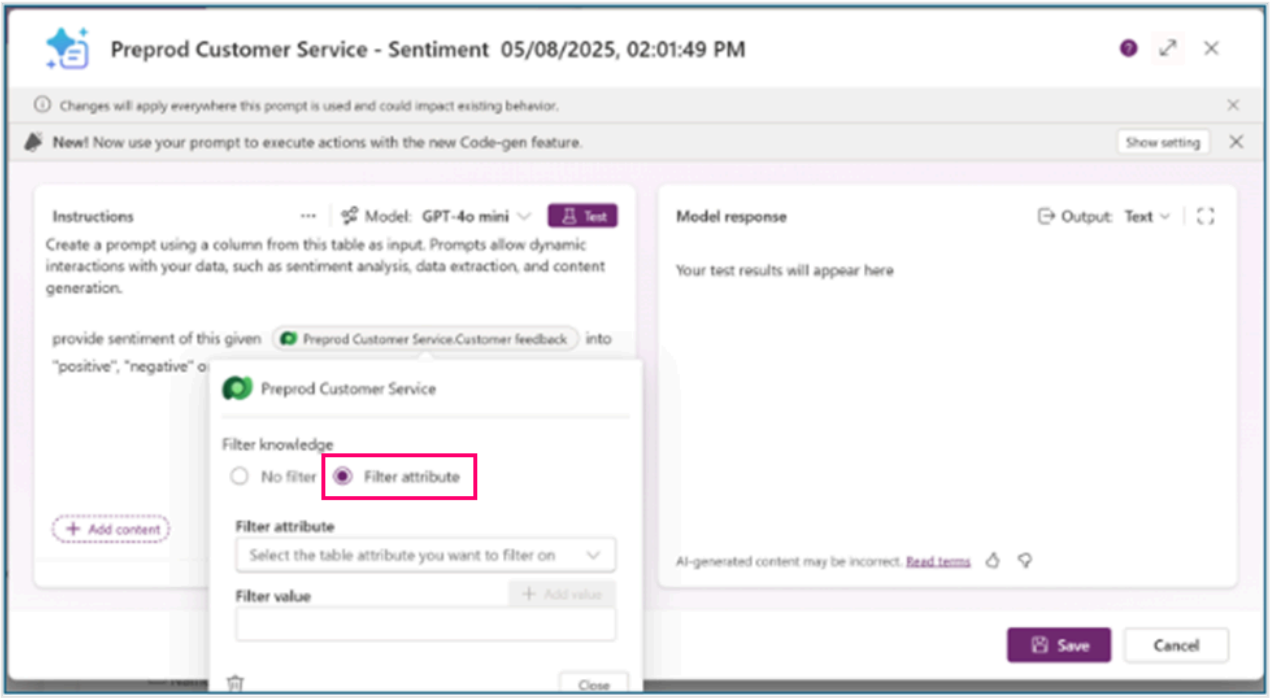
- You can use more than one input column in each prompt.
- Input columns can't be formula columns, file columns, image data type, or another prompt column. If you select these data types, their input value is ignored.

4. Select **Save**.

Test and refine prompts

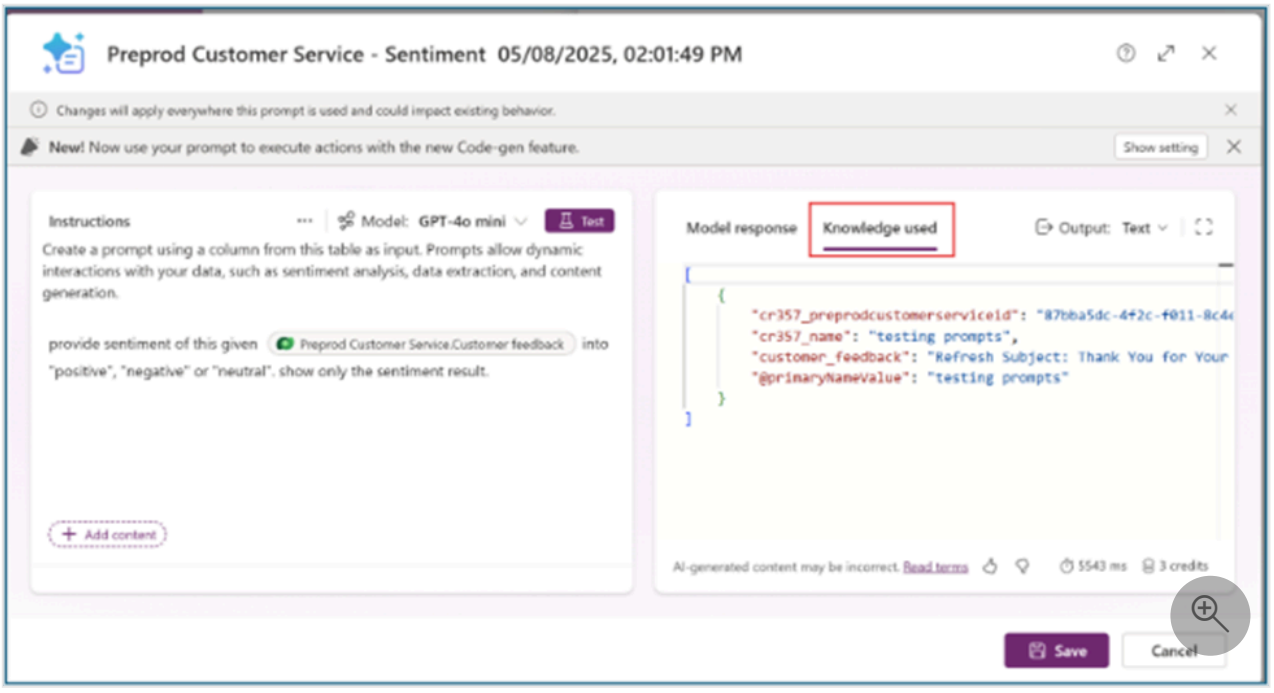
Test your AI prompt. Create a test record with appropriate values in all your input columns for testing. For example, create a *Name* column in the table and enter some value that is used to identify the test record, such as *testing prompts*.

1. Create or select a prompt column.
2. While editing the prompt in a prompt column, select the input column to open the **Filter knowledge** pop-up screen.
3. Select the **Filter attribute** option.



4. Select the **Filter attribute** dropdown list and select a filter, such as *Name*.
5. Enter the value of your testing record **Name**, such as *testing prompt*.
6. Select **Close**.
7. Select **Test** and review the **Model response**.

8. Select the **Knowledge used** tab to confirm that the input came from your test record.



9. Modify your prompt until you get the desired results.
10. Return to the **Filter knowledge** pop-up and select **No filter** when your prompt changes are done.
11. Select **Save** to update your prompt column.

View prompt column results

Create a model-driven app to view and validate your prompt column results.

1. Go to Power Apps, and then open an app for editing or create a new app. More information: Create a model-driven app
2. In the app designer, select **Edit form** to edit the table form for the table that has the prompt columns.
3. The form designer opens. Select all the input and prompt columns you want to add to the form.
4. Select **Save and publish**.
5. Go to the **Tables** area in Power Apps and select **Views**.
6. Observe the values in the records including new records that contain prompt column values.

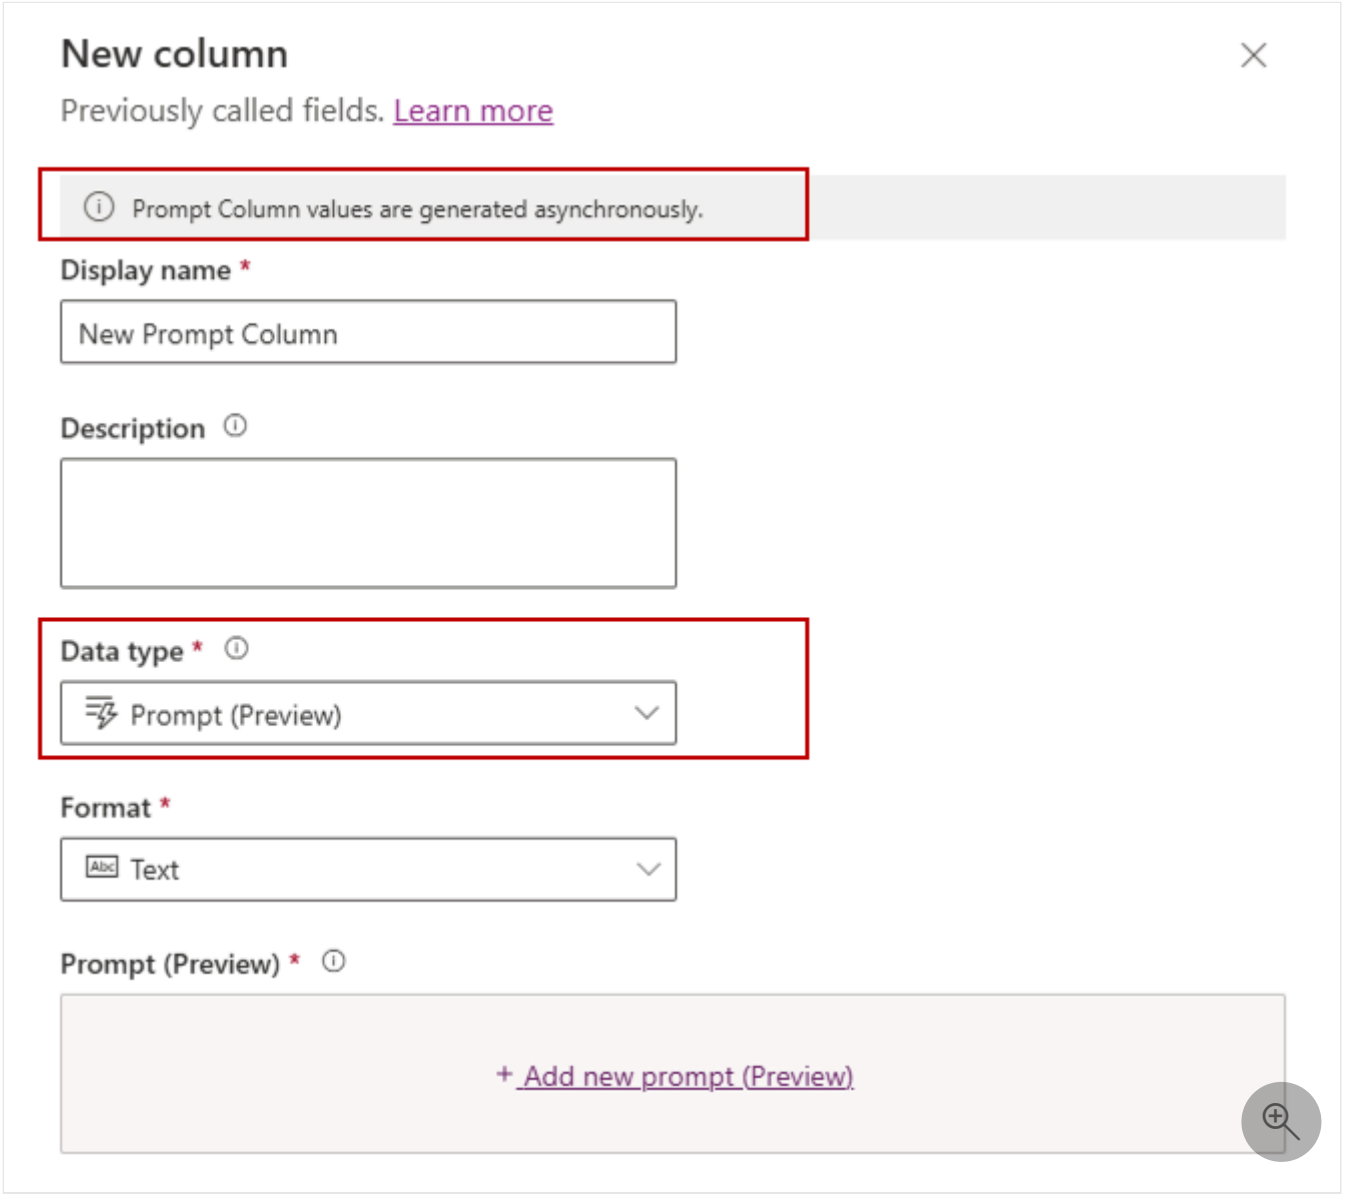
Prompt column feature enhancements

> **Note**
>
> This capability is in process of rolling out, and might not be available in your region yet.

Prompt columns leverage asynchronous computation so that AI-driven processing is decoupled from real-time transactions. This preserves system responsiveness, protects business critical workflows, and enables organizations to adopt AI capabilities at scale without compromising operational reliability.

How to know when prompt values in prompt columns are asynchronous

When a prompt column is added to a table, a banner message appears at the top of the page indicating that the value is generated asynchronously.

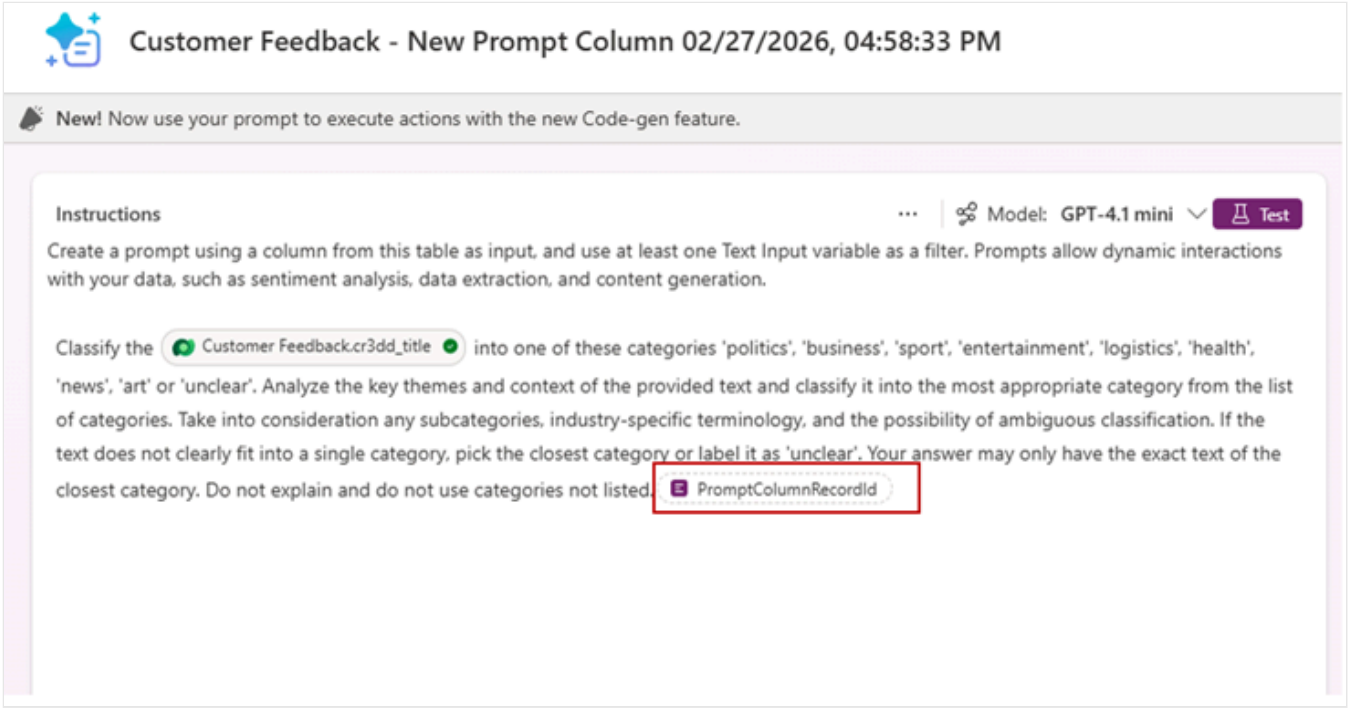


> **Note**
>
> If your environment isn't updated to the latest version, the banner message might not be visible. Prompt columns created in earlier versions will continue to operate without change

until the upgrade occurs. As part of the upgrade process, existing prompt definitions are updated to support asynchronous execution.

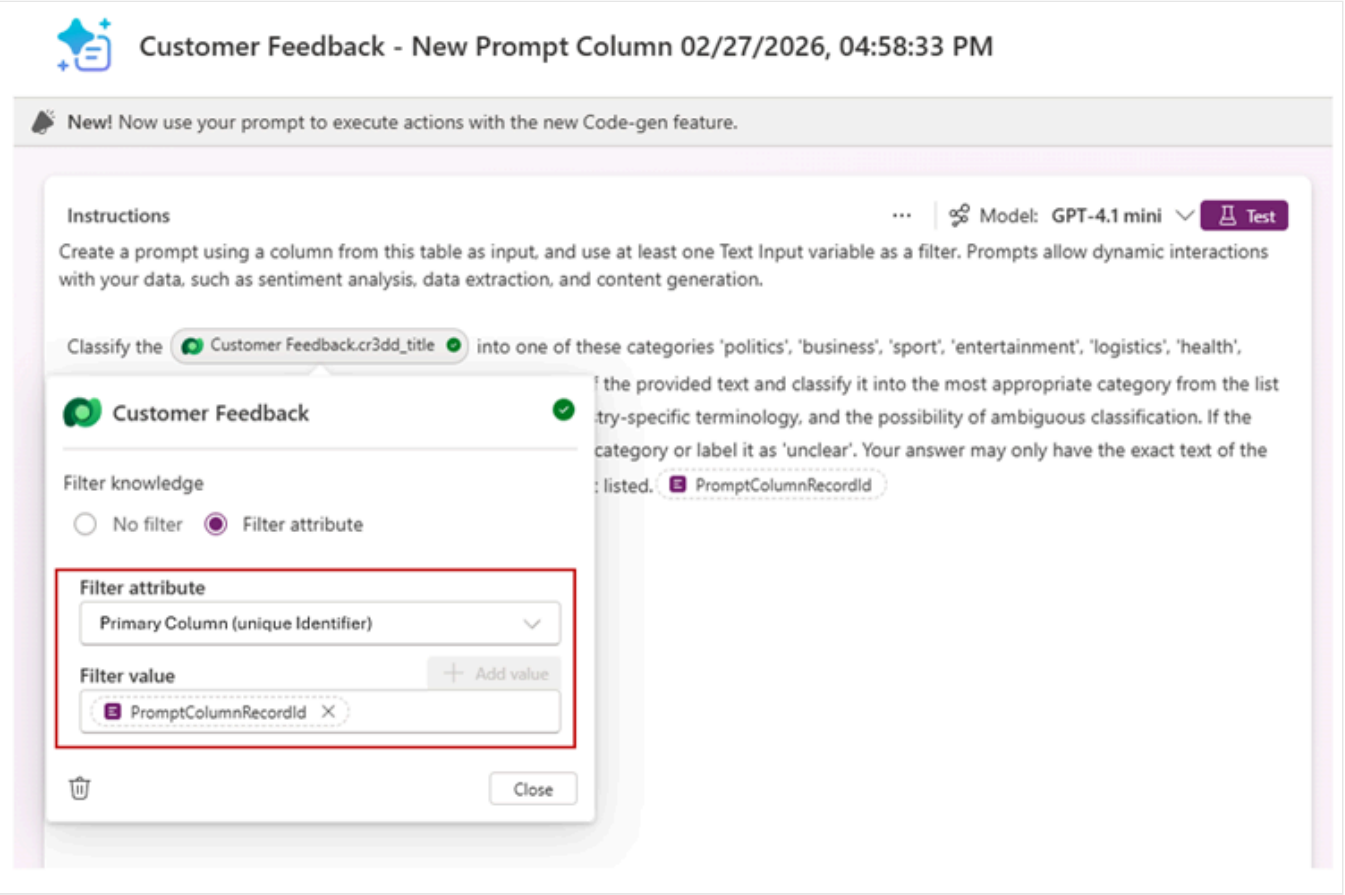
Text input variable

A default text input variable is automatically added to the prompt definition. This variable is used as a filter on the primary column of the data source and is required to save the prompt definition.



This variable is used as a filter on the primary column of the data source and is required to save the prompt definition.

The platform requires a single text input variable. This variable is automatically added and applied as a filter on the primary column of the data source. Users can edit the prompt definition or add additional columns, provided the required text input variable remains included in the prompt definition. When the column is saved, the platform validates this requirement and displays an error if the text input variable is missing or not applied as a filter on the primary column.



Prompt column with filter condition

Filter conditions ensure prompts run only when they add value.

With filter based execution, prompts run only when specified conditions are satisfied. During record creation or update, the prompt column evaluates the filter first and then executes the prompt for eligible records. This approach reduces unnecessary executions and helps optimize Copilot credit consumption.

Add filters to a prompt column

1. Go to Power Apps, and select **Solutions** on the left navigation pane.

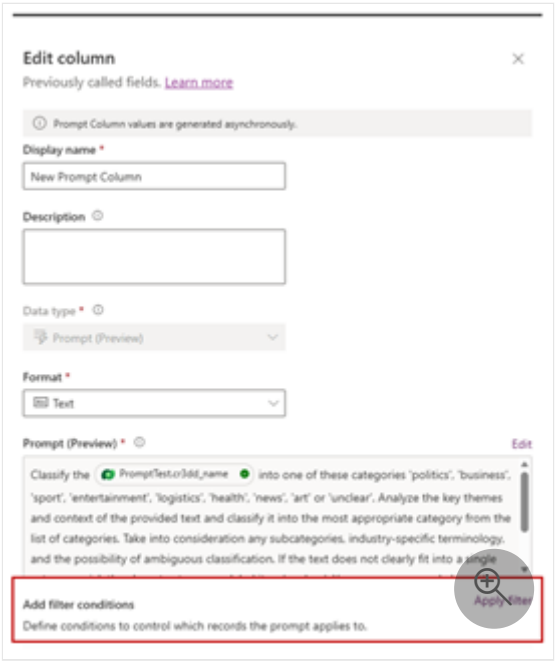
2. Open the solution that has the table you want, select **Tables**, open table that has prompt column you want to edit or create a new one, and then select **Columns**.

    - If creating a new column, select **New** > **Column**. On the right properties page, enter a **Display name** and **Description** for your column, for **Data type**, select **Prompt**.
    - If editing an existing prompt, go to step 5 to apply a filter.

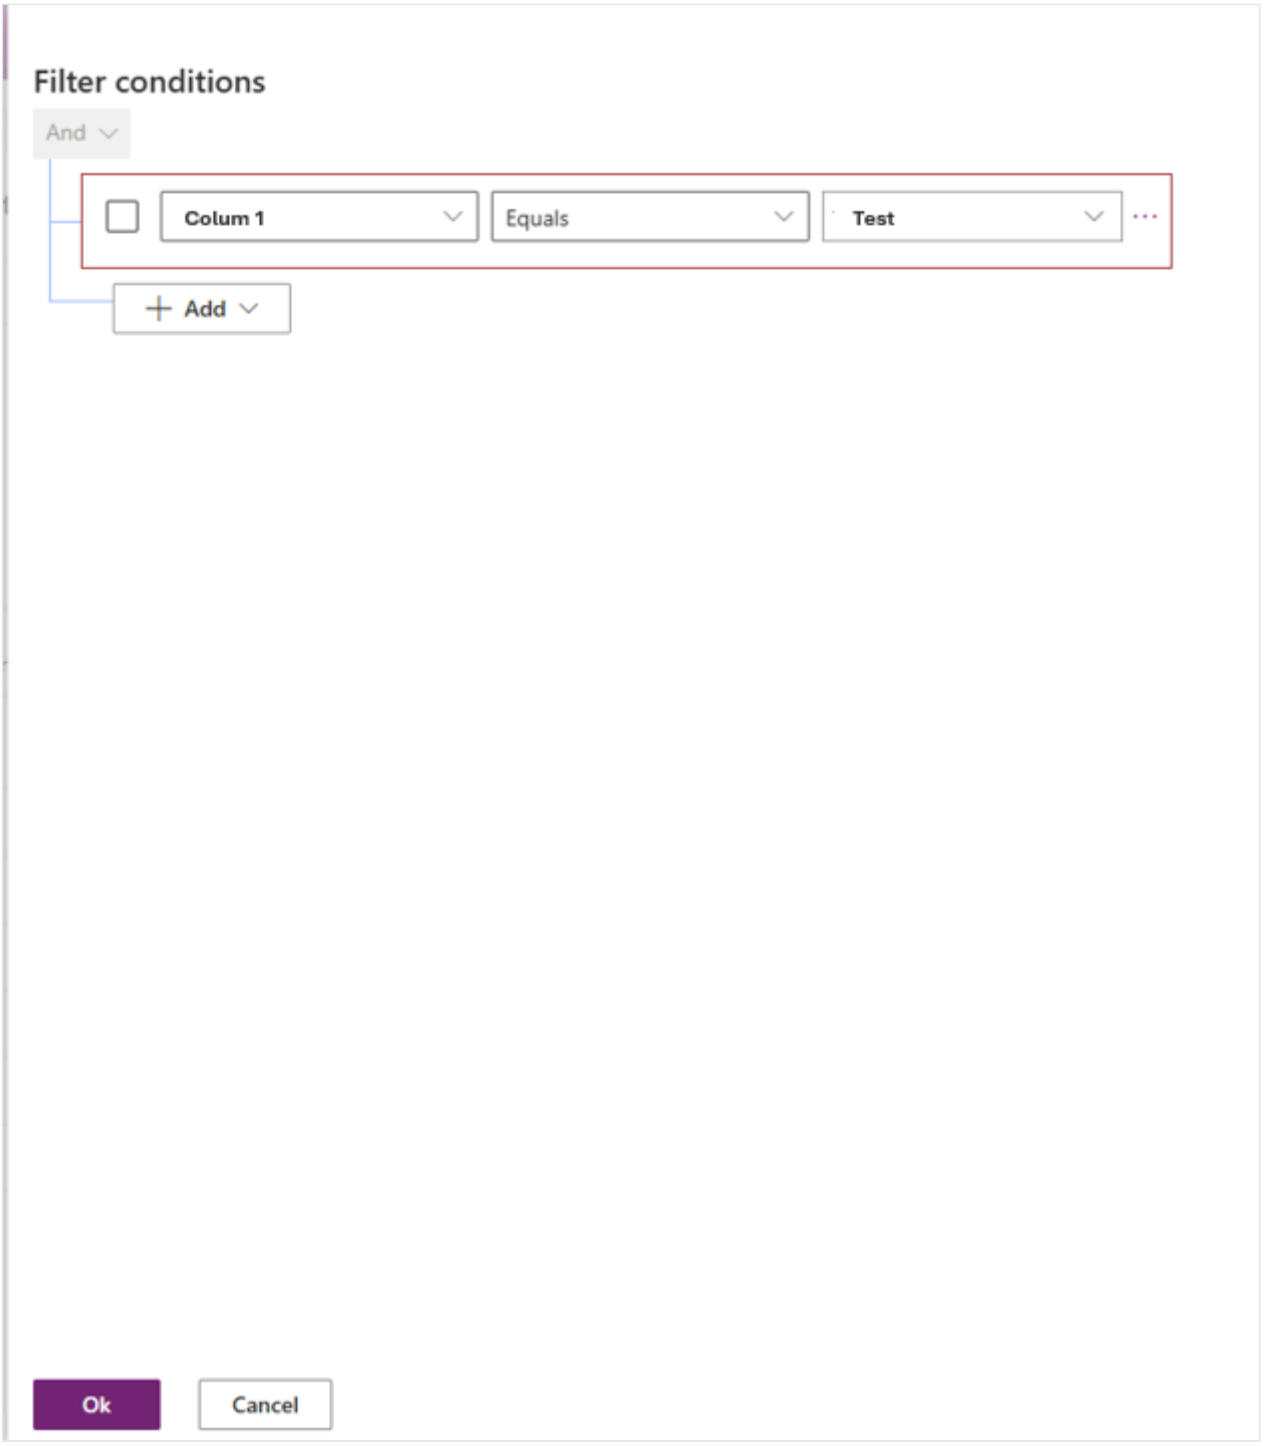
3. Clear the **Allow form fill assistance** checkbox.

4. Select **+Add new prompt**. You can create up to five prompt columns per table. If editing an existing column, select **Edit** next to the **Prompt** box.

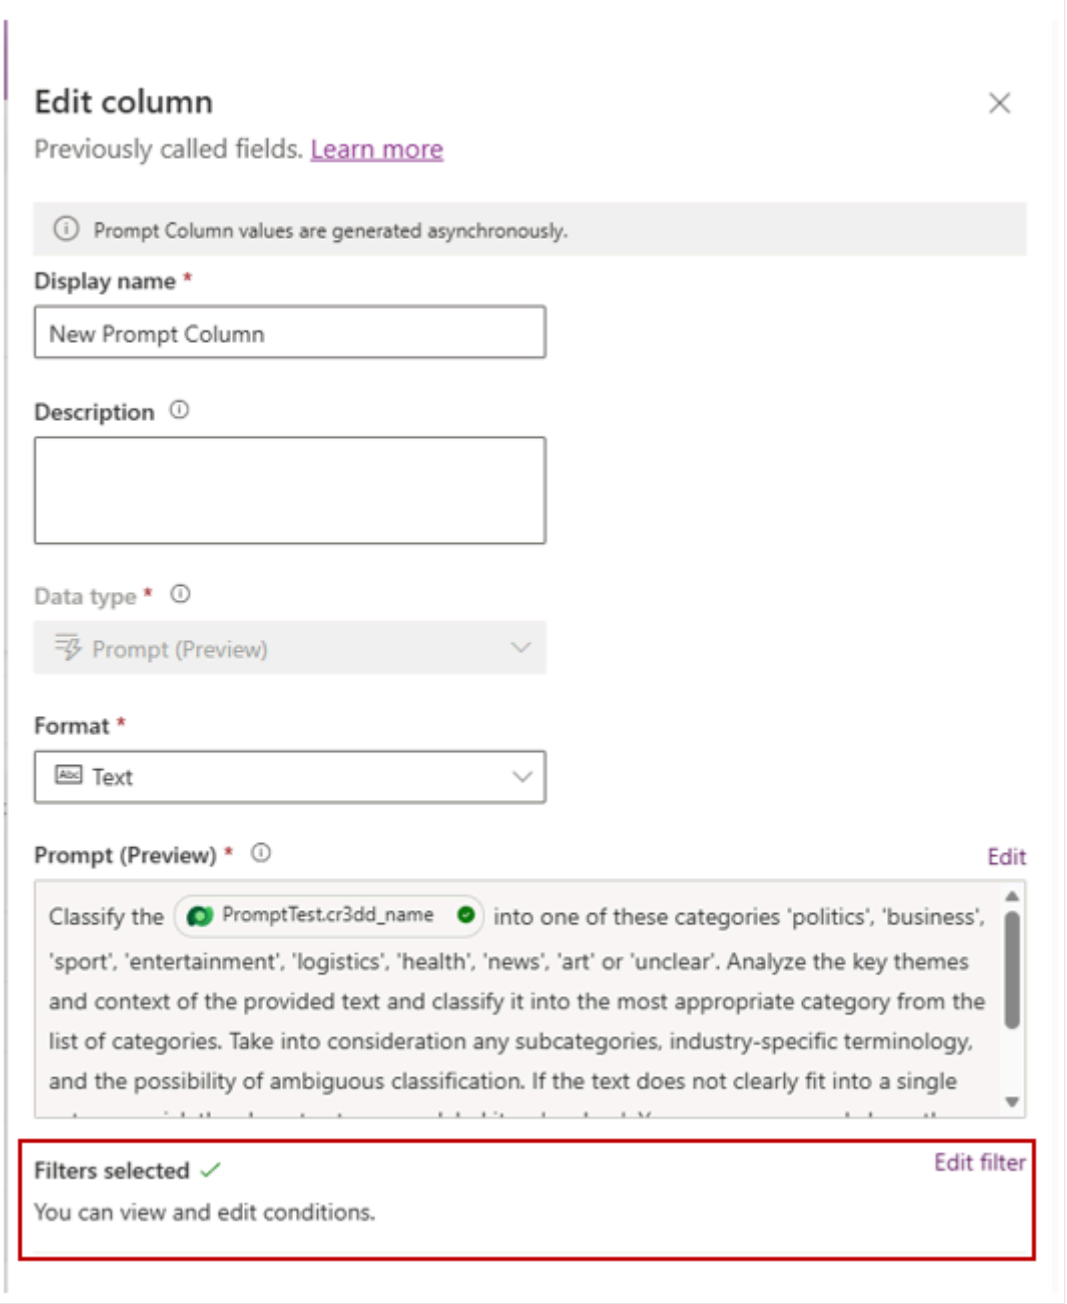
5. Open a table variable, such as `PromptTest.cr3dd_name` in this example, and then select **Apply filter**.



6. On the **Filter conditions** pane, select **Add filter**, and then select **OK**.



7. On the **Edit column** pane, notice **Filters selected** is applied. Select **Save**.



View the prompt column status

When a prompt column is created, the table automatically includes two corresponding columns, **Status** and **Details**, for that prompt column.

1. Go to Power Apps, and then select **Tables** on the left navigation pane.
2. Open the table that has the prompt column where you want to view the status.
3. On the **Tables** page, in the list of columns and data select the **+n more** header to add additional columns.
4. In the select **Show existing column** list search for the prompt column name.
5. Search and select the columns named:

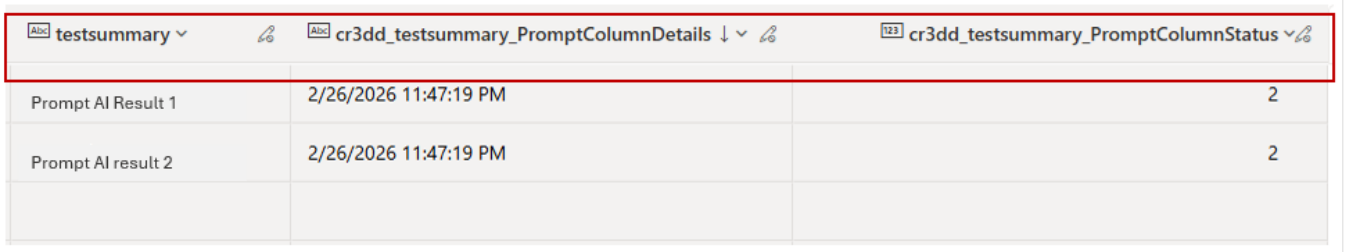
    - `(columnName) _PromptColumnStatus`

- `(columnName)_PromptColumnDetails`

6. Select **Save**.
7. Select **Edit** to the right of the list to open the columns list with records in a separate view.

When prompt execution starts, these columns are populated to record the execution status and any failure details.

This example demonstrates a prompt column named *testSummary* and its corresponding **Status** and **Details** columns.



Prompt column status codes:

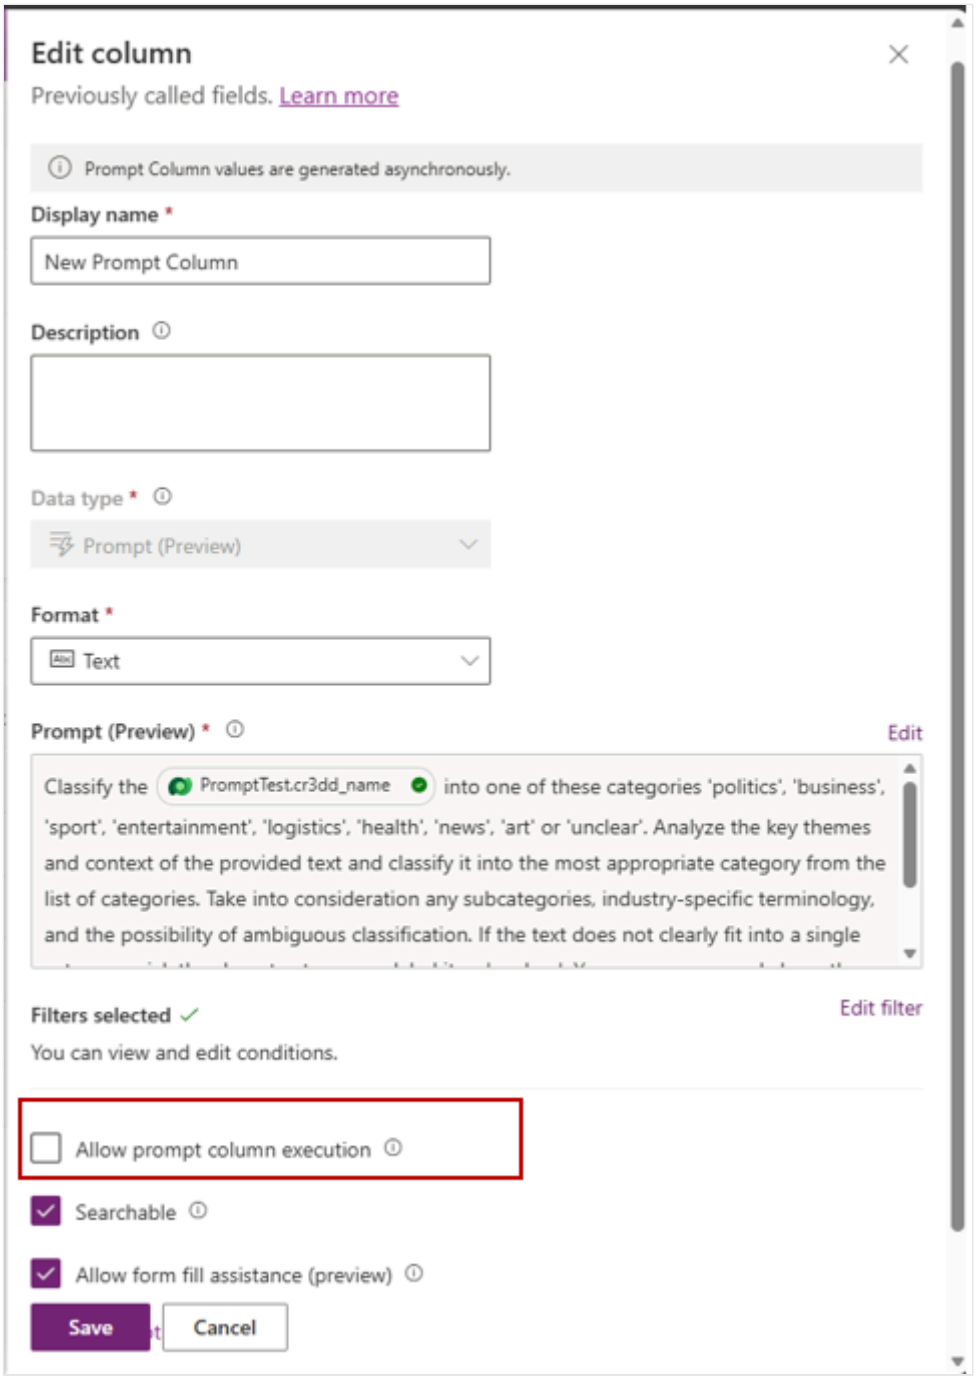
Expand table

Status	Name	Description
0	NotStarted	Record created. AI analysis hasn't started yet.
1	InProgress	The prompt AI analysis is currently in-progress. Details column shows start Date and Time.
2	Completed	Prompt execution completed successfully. Details column shows last successful Date and Time.
3	Failed	The prompt AI generation failed. Detail column shows error details in the last execution.

Disable AI generation for a prompt column

1. Go to Power Apps. Select **Tables** on the left navigation pane.
2. Open the table, select **Columns**, and then open the column that is of data type Prompt where you want to disable AI generation.

3. On the **Edit column** pane, clear the **Allow prompt column execution** checkbox, and then select **Save**.

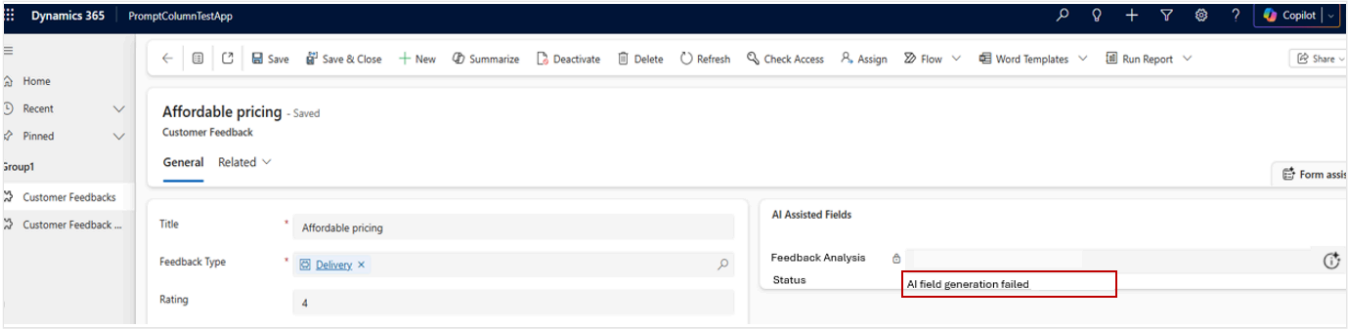


By default, the **Allow prompt column execution** setting is enabled. When disabled, AI analysis isn't performed for the prompt column.

> **Note**
>
> For prompts to be executed, both tenant level and column level settings need to be enabled.

When Prompt column fails to generate AI Analysis

When AI analysis failed to generate, users see an AI field generation failed message.



Prompt column execution failures can occur due to various conditions. The scenarios listed below represent common causes but don't cover all possible cases.

- The user doesn't have sufficient permissions on one or more input columns referenced in the prompt column definition.
- Lack of entitlements and credits in Copilot.

Check **Details** and **Status** columns in the table. More information: View the prompt column status

FAQs

Are backfills supported?

Prompt columns generate AI results when a new record is created, or when one or more columns specified in the prompt column definition are updated.

Existing records aren't processed by default. However, updating a column defined in the prompt column definition triggers AI analysis.

Are prompt columns audited?

Prompt columns aren't audited.

Can I perform on-demand AI analysis without updating a record?

Prompt columns are triggered automatically on record updates; however, on-demand execution is not currently supported. As a result, updating the prompt definition does not recalculate existing prompt values until a subsequent update occurs on one or more columns defined in the prompt.

Why didn't the prompt column execute?

Common scenarios where the prompt does not execute, no error is surfaced, and execution is skipped

- AI Prompt feature is disabled. More information: Prerequisites

- Prompt column execution is disabled. More information: Disable AI generation for a prompt column
- Filters conditions aren't met. More information: Add filters to a prompt column

Check **Details** and **Status** columns in the table for more information.

Do I need to disable 'Block unmanaged customizations' to create or edit prompt columns?

To create or edit Prompt Columns, the'Block unmanaged customizations' environment setting must be disabled. If this setting is enabled, users might encounter the following error when attempting to create or modify a prompt column:

"This clustered environment doesn't allow unmanaged customizations on 'msdyn_AIConfiguration' component. This was a choice made by your admin, and certain actions won't be available or will be view only." For more information about this environment setting, go to Block unmanaged customizations

Work with formula columns

Formula columns are columns that display a calculated value in a Microsoft Dataverse table. Formulas use Power Fx, a powerful but human-friendly programming language. Build a formula in a Dataverse formula column the same way you would build a formula in Microsoft Excel. As you type, Intellisense suggests functions and syntax, and even helps you fix errors.

Add a formula column

1. Sign in to Power Apps at https://make.powerapps.com.
2. Select **Tables**, and then select the table where you want to add a formula column. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Columns** area, and then select **New column**.
4. Enter the following information:
   - A **Display name** for the column.
   - Optionally, enter a **Description** of the column.
5. For **Data type** select ***fx* Formula**.
6. Type the formula or use formula suggestions:

   Type a formula

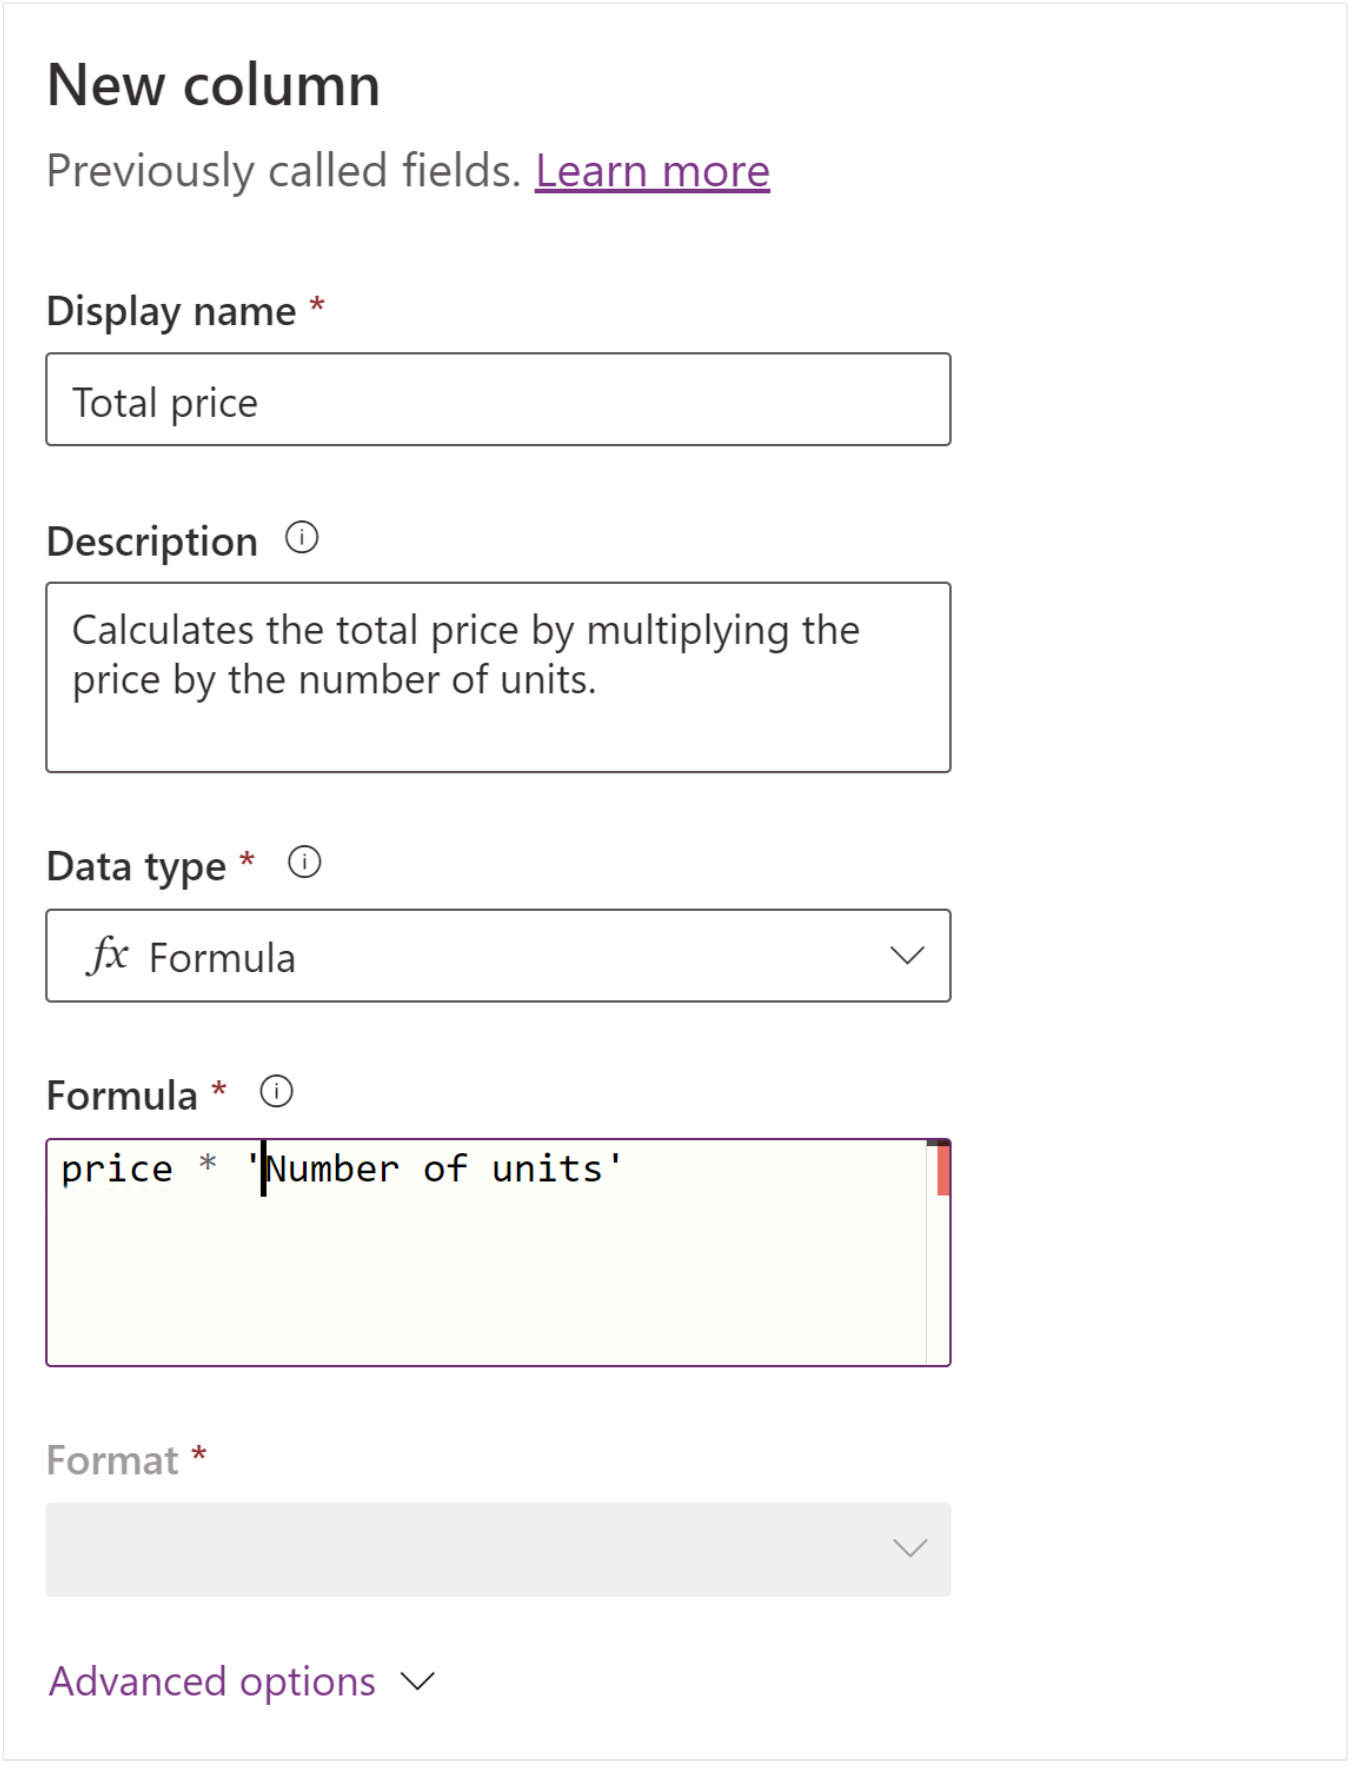
   Enter the Power Fx formula in the **Formula** box. More information: Type a formula

---

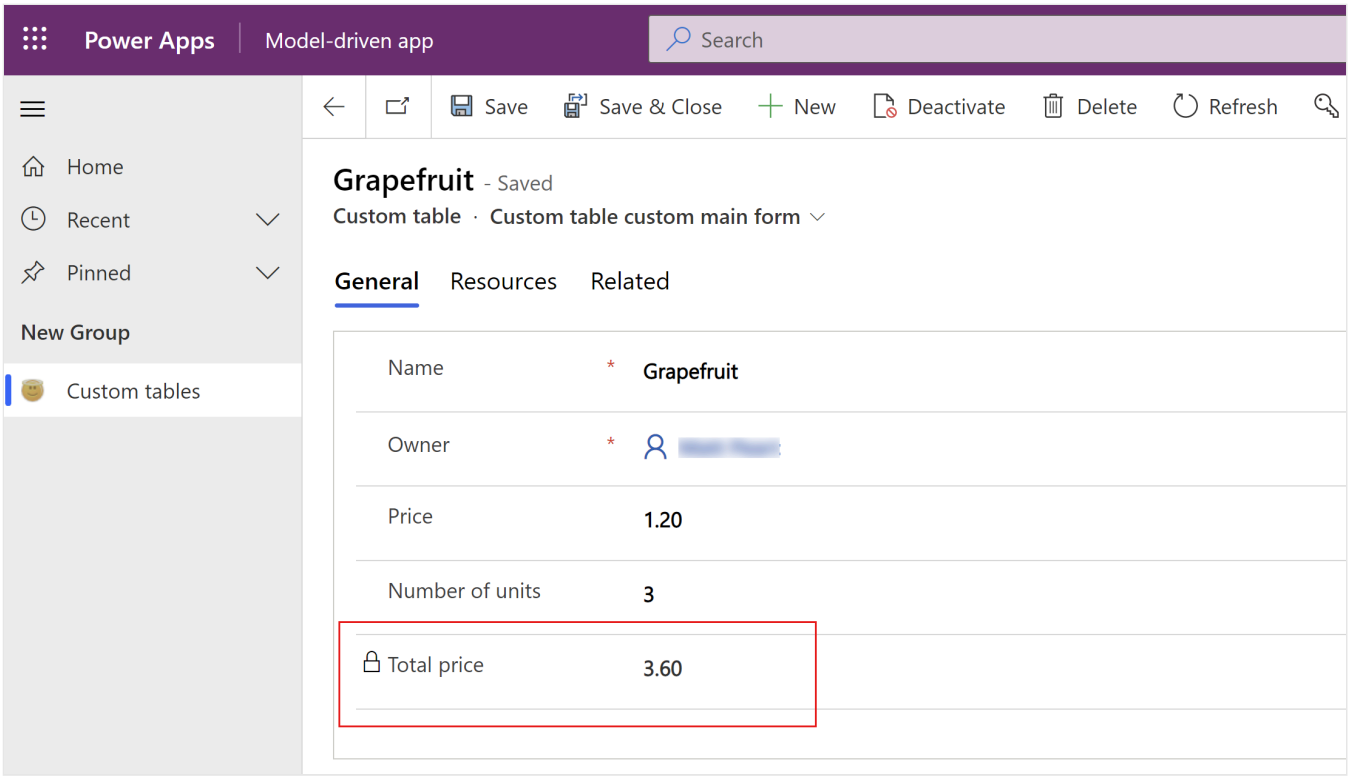
7. Select additional properties:
   - Select **Searchable** if you want this column to be available in views, charts, dashboards, and Advanced Find.
   - **Advanced options**:
     - If the formula evaluates to a decimal value, expand **Advanced options** to change the number of points of precision, between 0 and 10. The default value is 2.
8. Select **Save**.

Type a formula

The following example creates a formula column called *Total price*. The *Number of units* column is a whole number data type. The *Price* column is a decimal data type.



The formula column displays the result of *Price* multiplied by *Number of units*.



The formula that you enter determines the column type. You can't change a column type after the column is created. That means you can change the formula after you create the column only when it doesn't change the column type.

For example, the formula *price * discount* creates a column type of number. You can change *price * discount* to *price * (discount + 10%)* because that doesn't change the column type. However, you can't change *price * discount* to *Text(price * discount)* because that would require changing the column type to string.

Get formula suggestions (preview)

[This topic is pre-release documentation and is subject to change.]

Describe what you want the formula to do and get AI generated results. Formula suggestions accept your natural language input to interpret and suggest a Power Fx formula using GPT-based AI model.

> **Important**
>
> This is a preview feature available only in US regions only.
>
> Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Currently, formula suggestions that reference a single table are supported. Formula suggestions that reference a column on a related table aren't supported.

Prerequisites

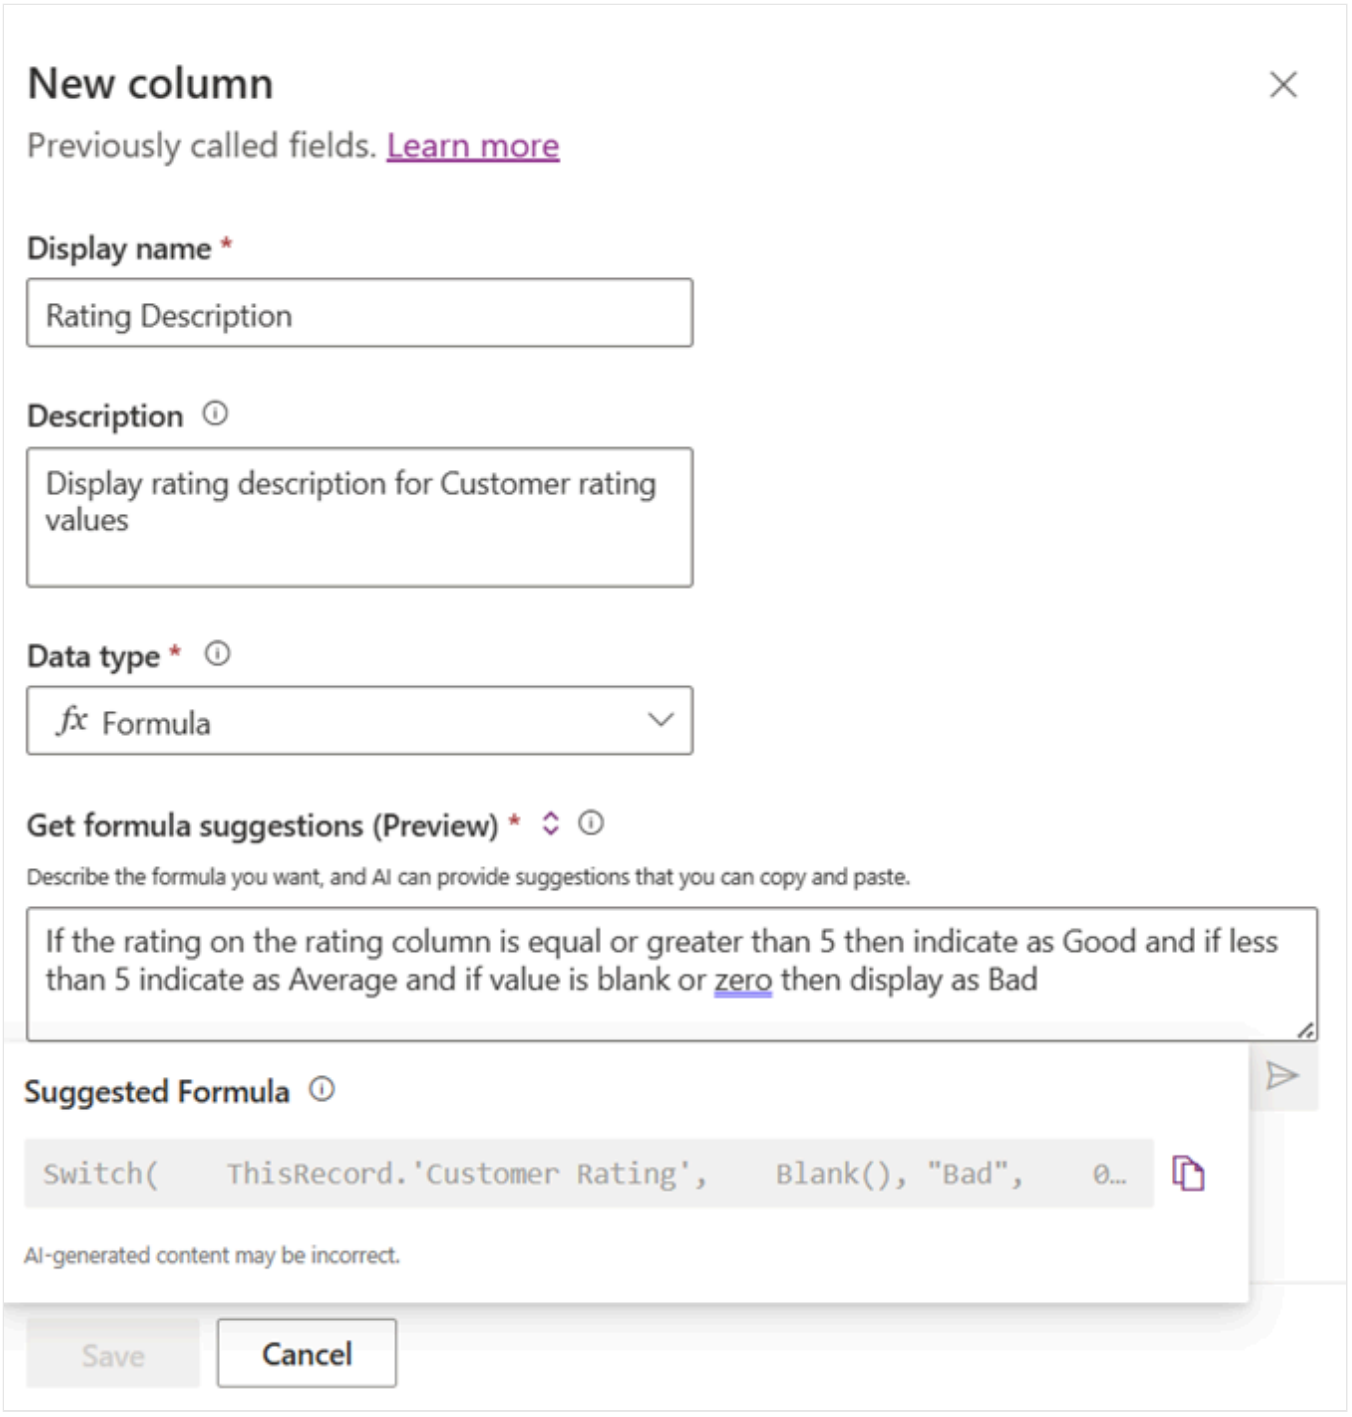
To enable this feature, you must enable the **AI suggestions for formula columns** environment setting. More information: AI suggestions for formula columns

Example natural language input

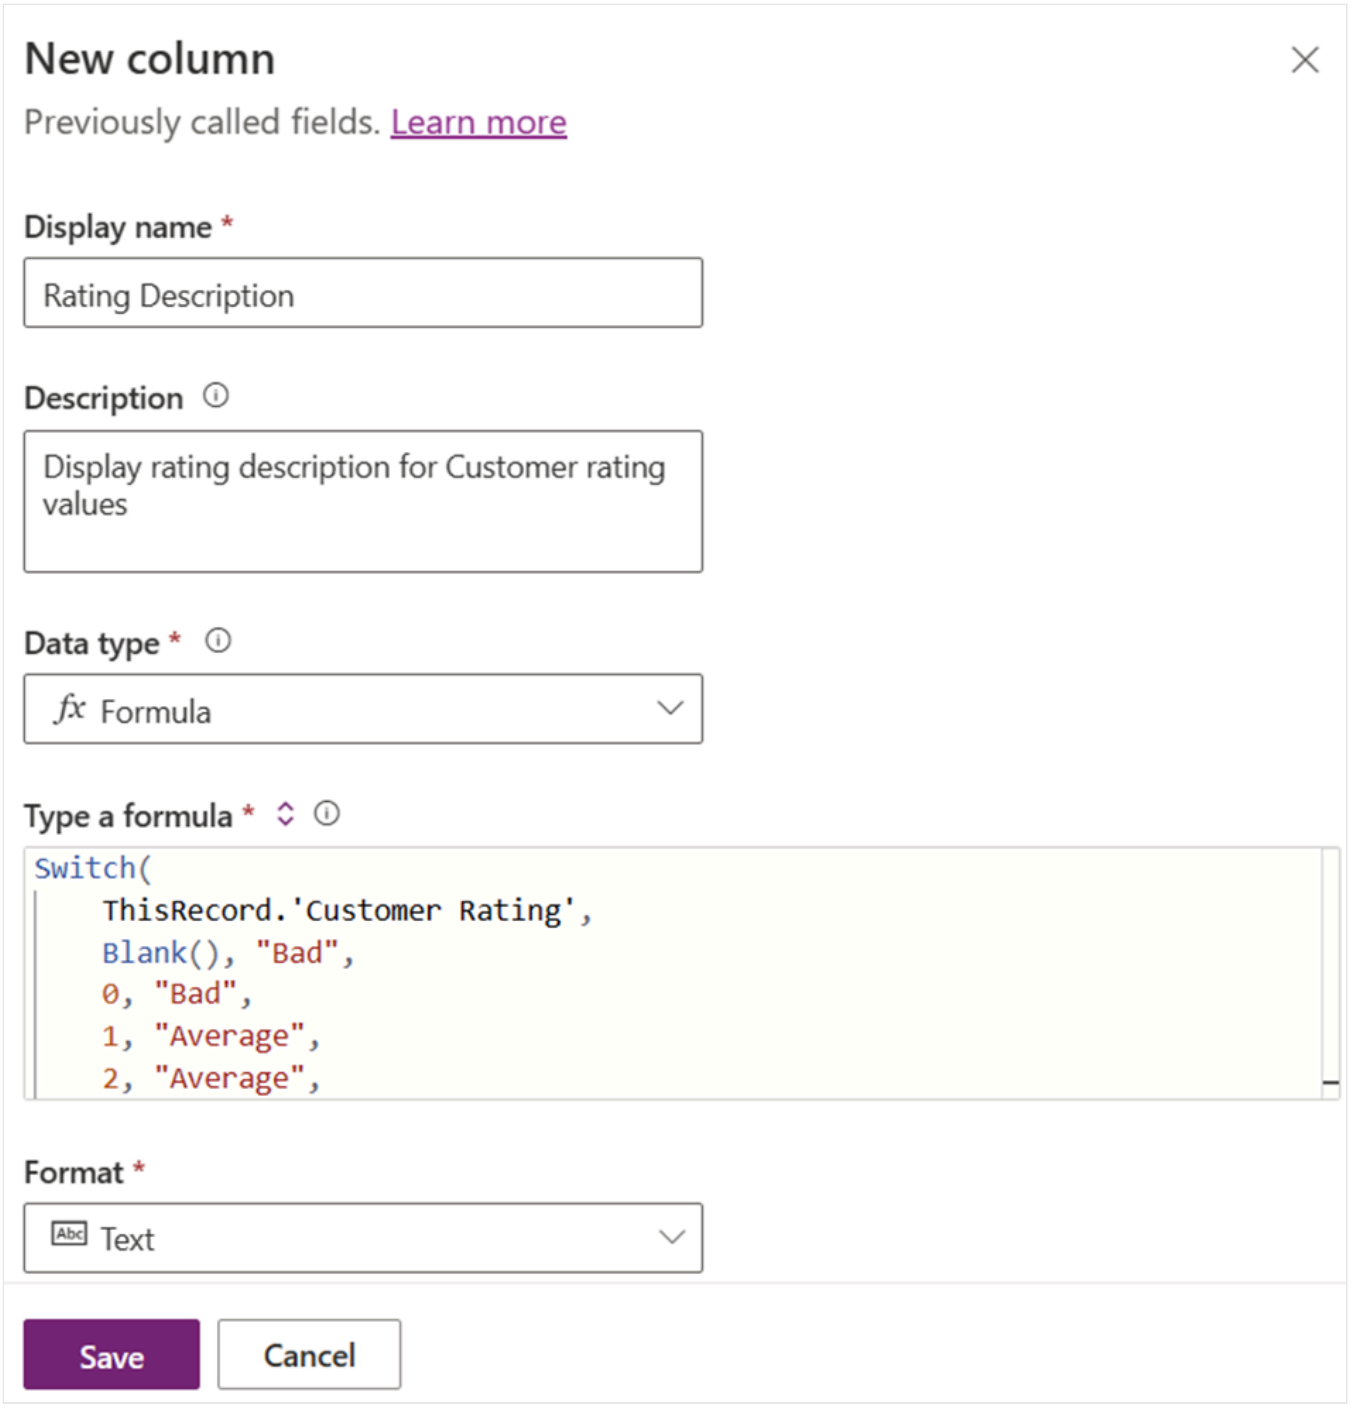
Imagine there's a **Customer rating** column that shows their rating by account.

In the **Get formula suggestions** box enter the formula in natural language, such as *If the rating on the rating column is equal or greater than 5 then indicate as Good and if less than 5 indicate as Average and if value is blank or zero then display as Bad*, and then select the arrow button (enter).

Then copy the **Suggested Formula**.



And paste it into the **Type a formula** box. Select **Save**.



Here's how the formula appears when pasted.

PowerApps Formula

```
Switch(
    ThisRecord.'Customer Rating',
    Blank(), "Bad",
    0, "Bad",
    1, "Average",
    2, "Average",
    3, "Average",
    4, "Average",
    5, "Good",
    6, "Good",
    7, "Good",
```

```
    8, "Good",
    9, "Good",
    10, "Good"
)
```

Check the computed **Rating Description** formula column, which appears like this.

Customer Rating	Rating Description
5	Good
3	Average
5	Good
4	Average
2	Average
1	Average
0	Bad

Responsible AI

For information about responsible AI, go to these resources:

- FAQ for building apps and tables through conversation
- FAQ about using AI responsibly in Power Apps

Operators

You can use the following operators in a formula column:
+, -, *, /, %, in, exactin, &

For more information, go to Operators in Power Apps.

Data types

You can display the following data types in a formula column:

- Text
- Decimal Number
- Whole Number
- Float
- Boolean Choice (Yes/No)
- Choice (formerly option sets)
- Datetime

More information: Create formula columns with decimal, whole number, float, and choice data types\

The currency data type isn't currently supported.

Function types

You can use the following function types in a formula column:

- Decimal
- String
- Boolean
- Choice
- DateTime (TZI)
- DateTime (User local) (limited to comparisons with other user local values DateAdd, and DateDiff functions)
- DateTime (Date only) (limited to comparisons with other date-only values, DateAdd, and DateDiff functions)
- Currency
- Whole Number

Functions

For the scalar functions you can use in a formula column, go to Formula reference - Dataverse formula columns.

* The **Text** and **Value** functions only work with whole numbers, where no decimal separator is involved. The decimal separator varies across locales. Since formula columns are evaluated without locale knowledge, there's no way to properly interpret or generate the decimal separator.

* **StartOfWeek** argument isn't supported for the **WeekNum** and **Weekday** functions in formula columns.

Function example

Expand table

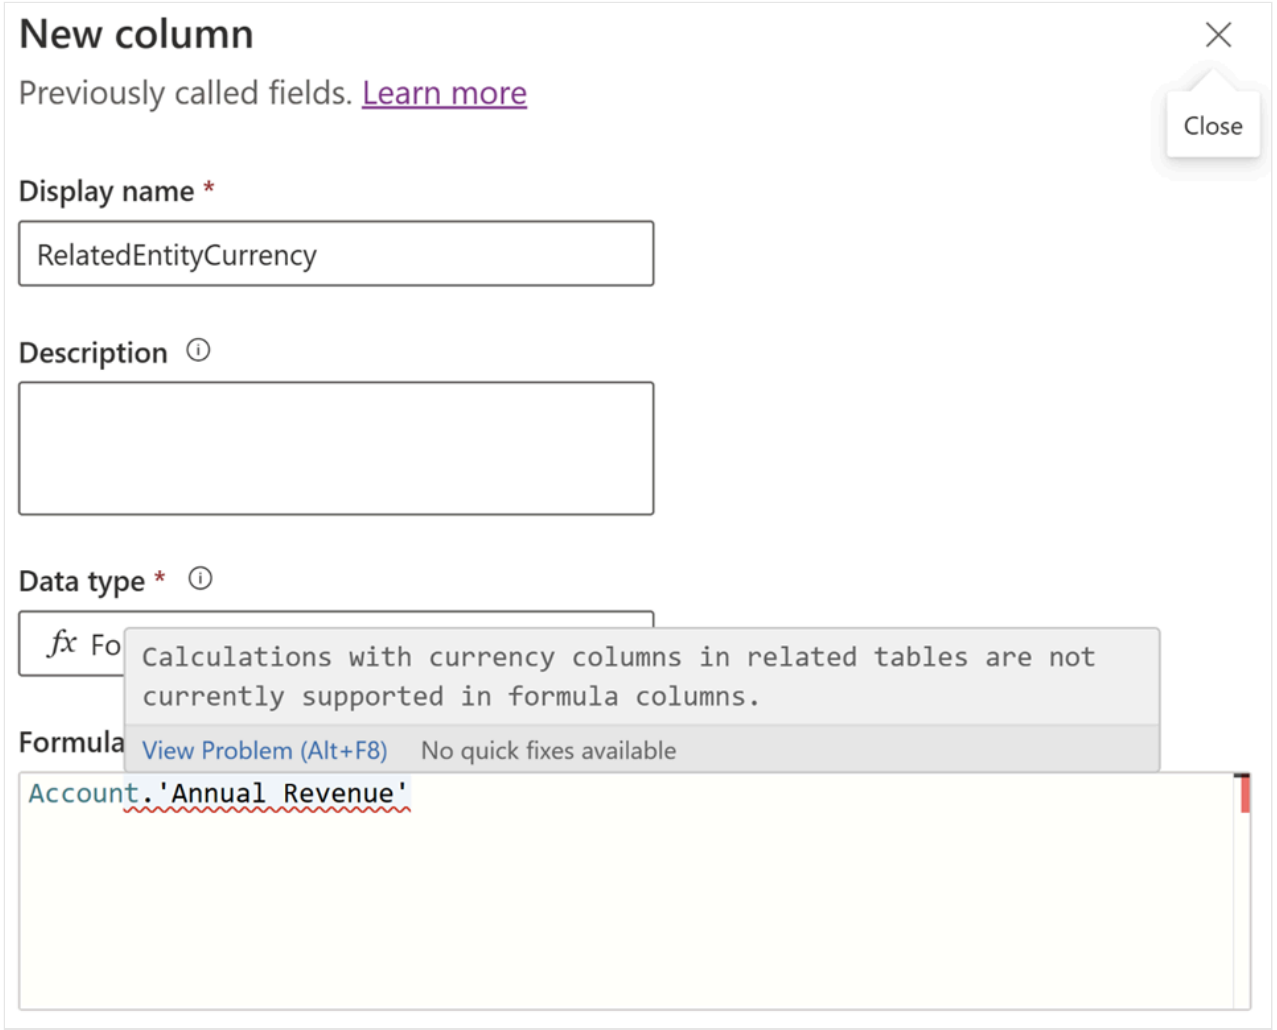
Description	Example
Retrieve a date value.	`DateAdd(UTCNow(),-1,TimeUnit.Years)`

Guidelines and limitations

This section describes guidelines and the known limitations with formula columns in Dataverse.

Currency fields usage validations

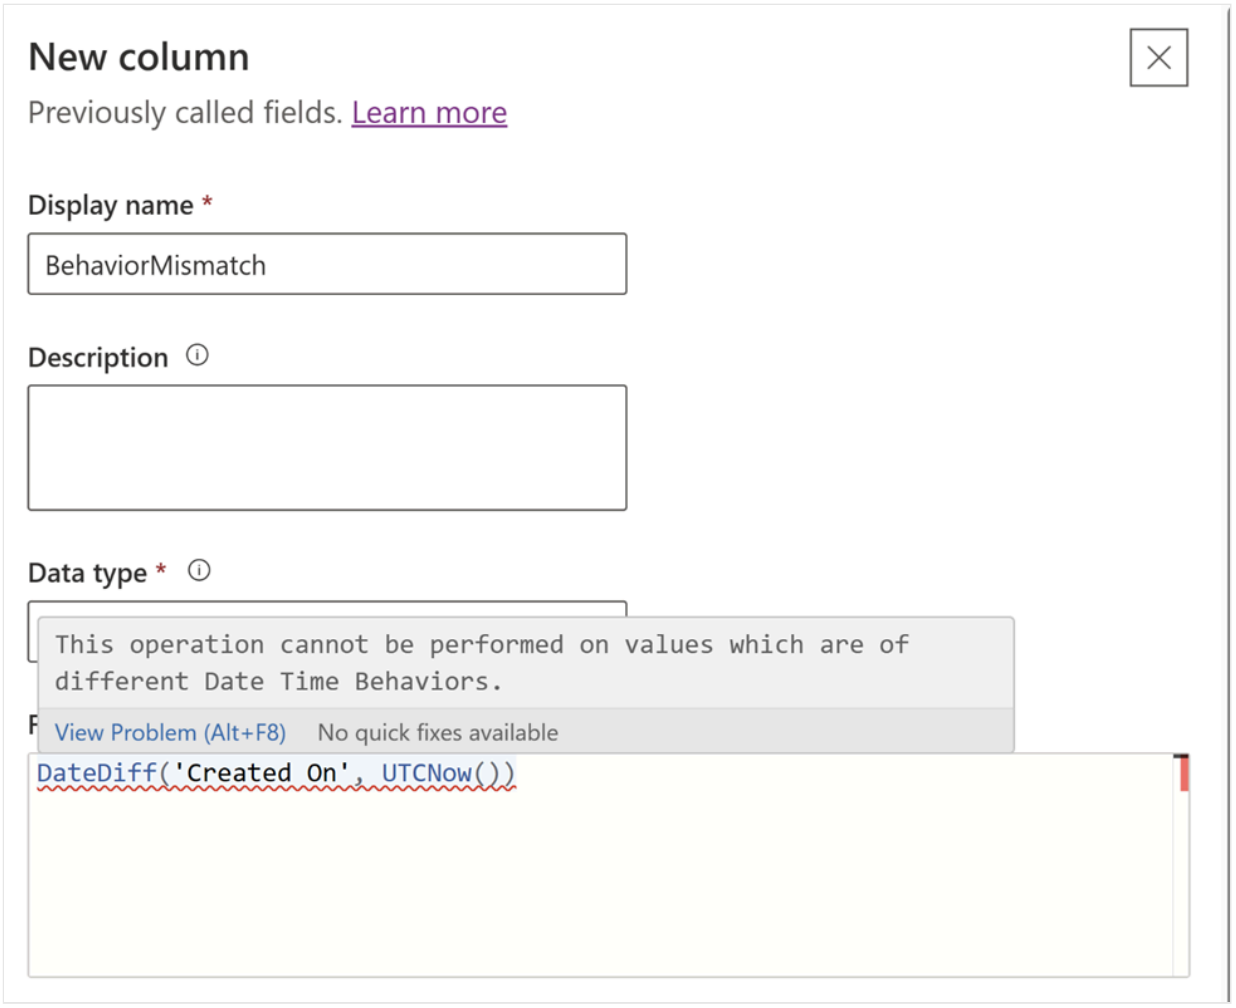
- Formula columns don't support using a related table currency column in the formula, such as in this example.



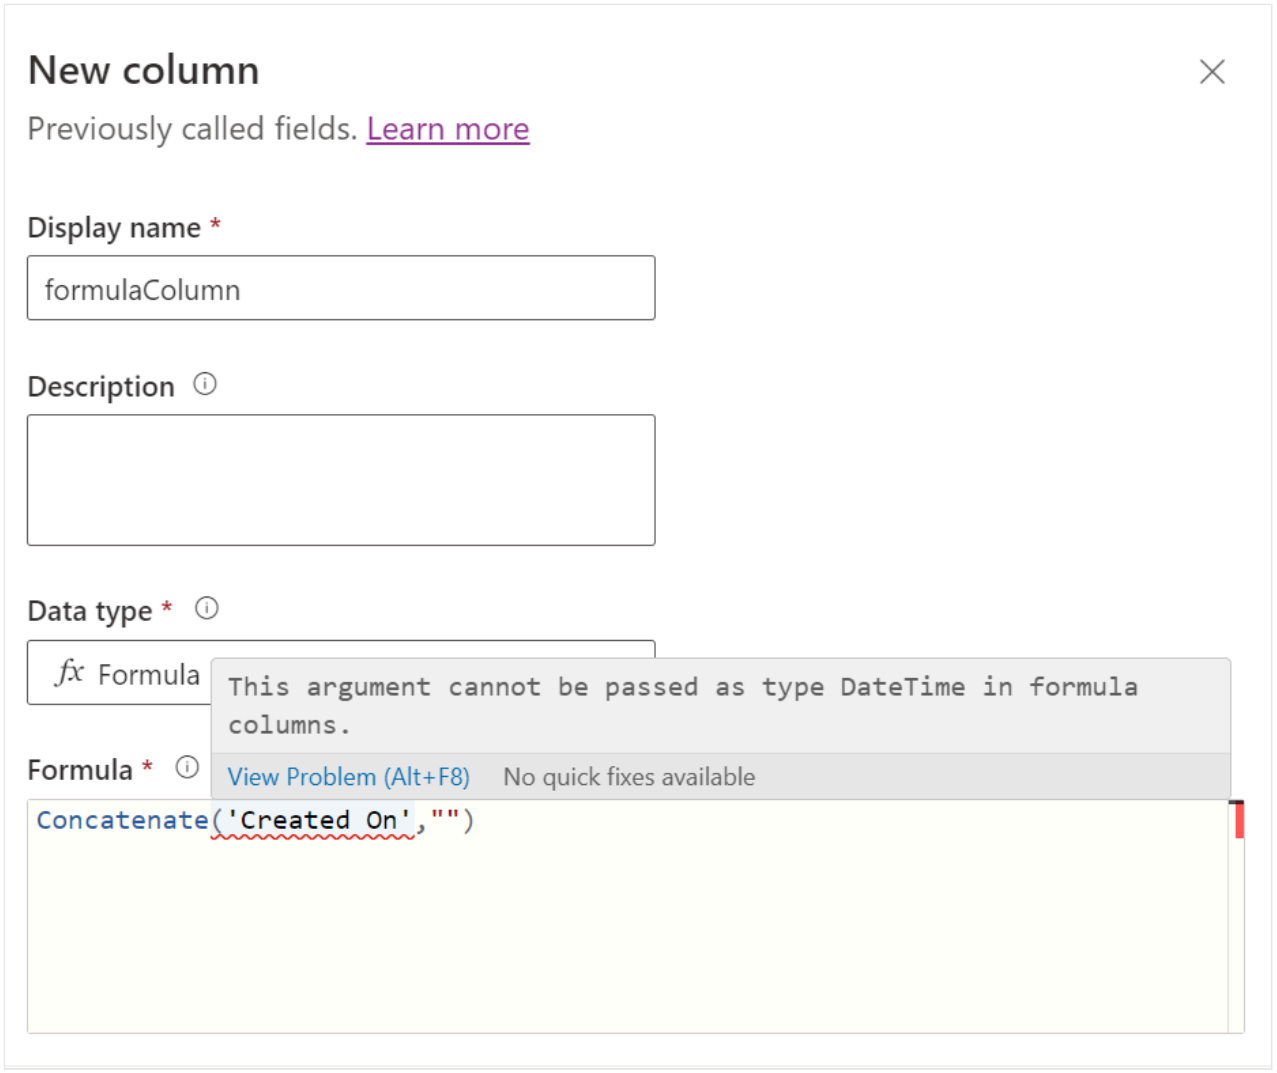
- Direct use of currency columns and exchange rate in the formula is currently unsupported. The use of currency and exchange rate columns is achieved through the `Decimal` function, such as `Decimal(currency column)` or `Decimal(exchange rate)`. The `Decimal` function makes sure the output is within the accepted range. If the currency or exchange rate column value exceeds the accepted range, then the formula returns null.
- Base currency columns aren't supported in the formula column expressions because they're system columns used for reporting purpose. If you want a similar result, you can use a currency column type along with an exchange rate column combination as `CurrencyField_Base = (CurrencyField / ExchangeRate)`.

Date time columns usage validations

- Behavior of date time formula columns can only be updated when it isn't used in another formula column.
- For date time formula columns, while using the `DateDiff` function, make sure that:
  - User local behavior column can't be compared or used with a `DateTime(TZI)/DateOnly` behavior column.
  - User local behavior columns can only be compared or used with another user local behavior column.
  - `DateTime(TZI)` behavior columns can be compared or used in `DateDiff` functions with another `DateTime(TZI)/DateOnly` behavior column.
  - `DateOnly` behavior columns can be compared or used in DateDiff function with another `DateTime(TZI)/DateOnly` behavior column.



- Date time columns and date time functions `UTCNow()`, `Now()` can't be passed as a parameter to string functions.



Formula column usage in rollup fields

- A *simple formula column* is where the formula uses columns from the same record or uses hard coded values. For rollup columns, formula columns must be simple formula columns, such as this example rollup column.

Display name *

formulaColumn

Description

Data type *

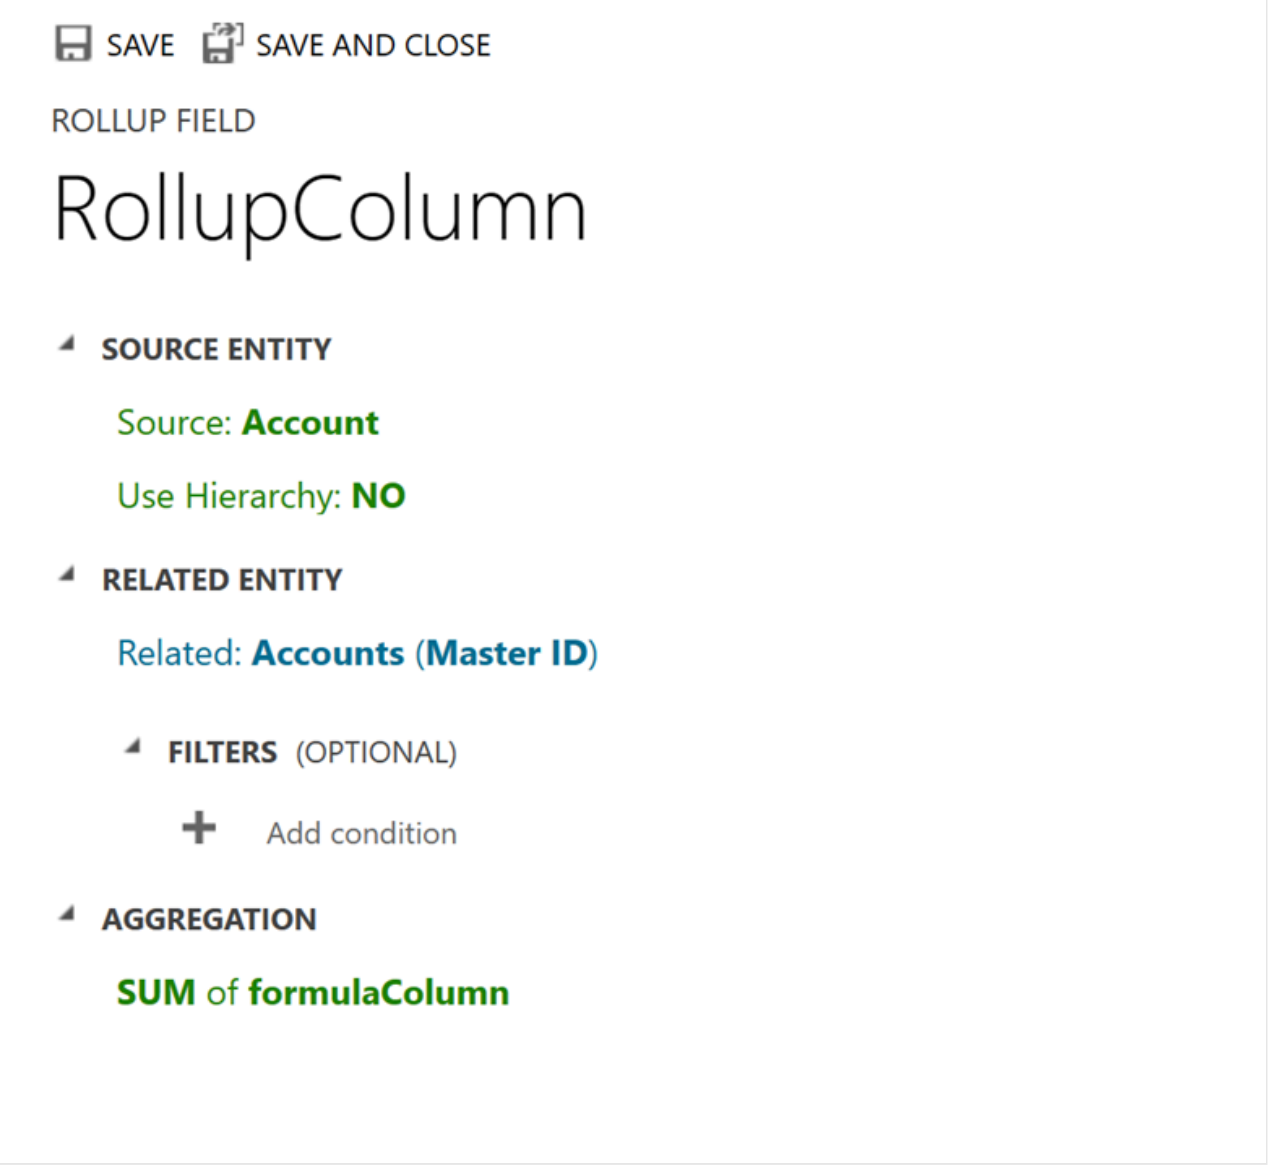
Decimal fx

Formula *

1+2

Searchable

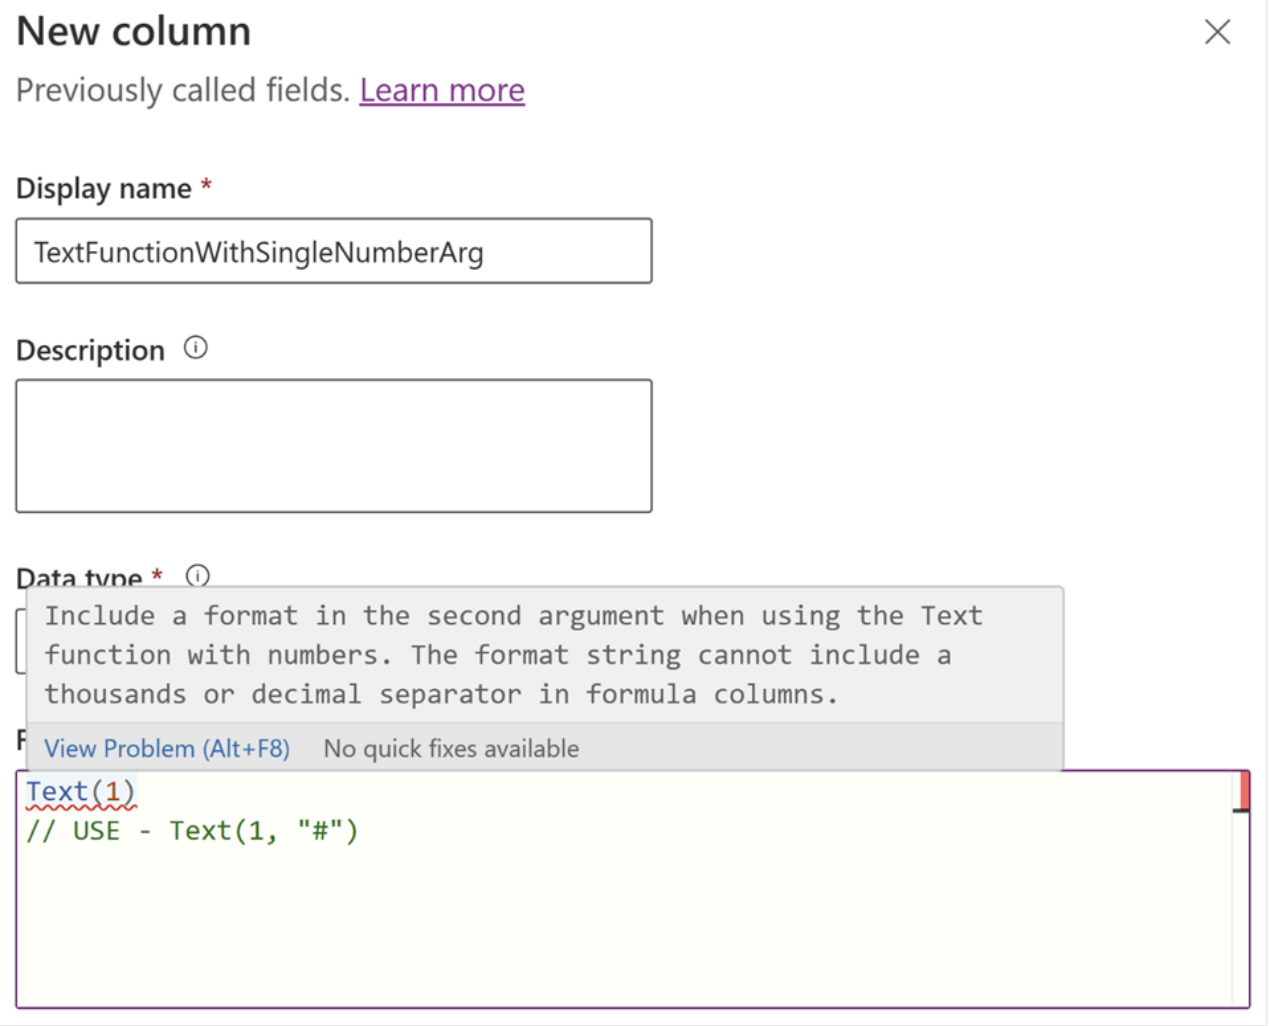
Advanced options



- A formula column, which is dependent on time bound functions `UTCNow()` and `UTCToday()` can't be used in a rollup field.

Power Fx text function recommendations

- Formula columns don't support `Text()` functions with a single argument of type Number. Number can be whole, decimal, or currency.

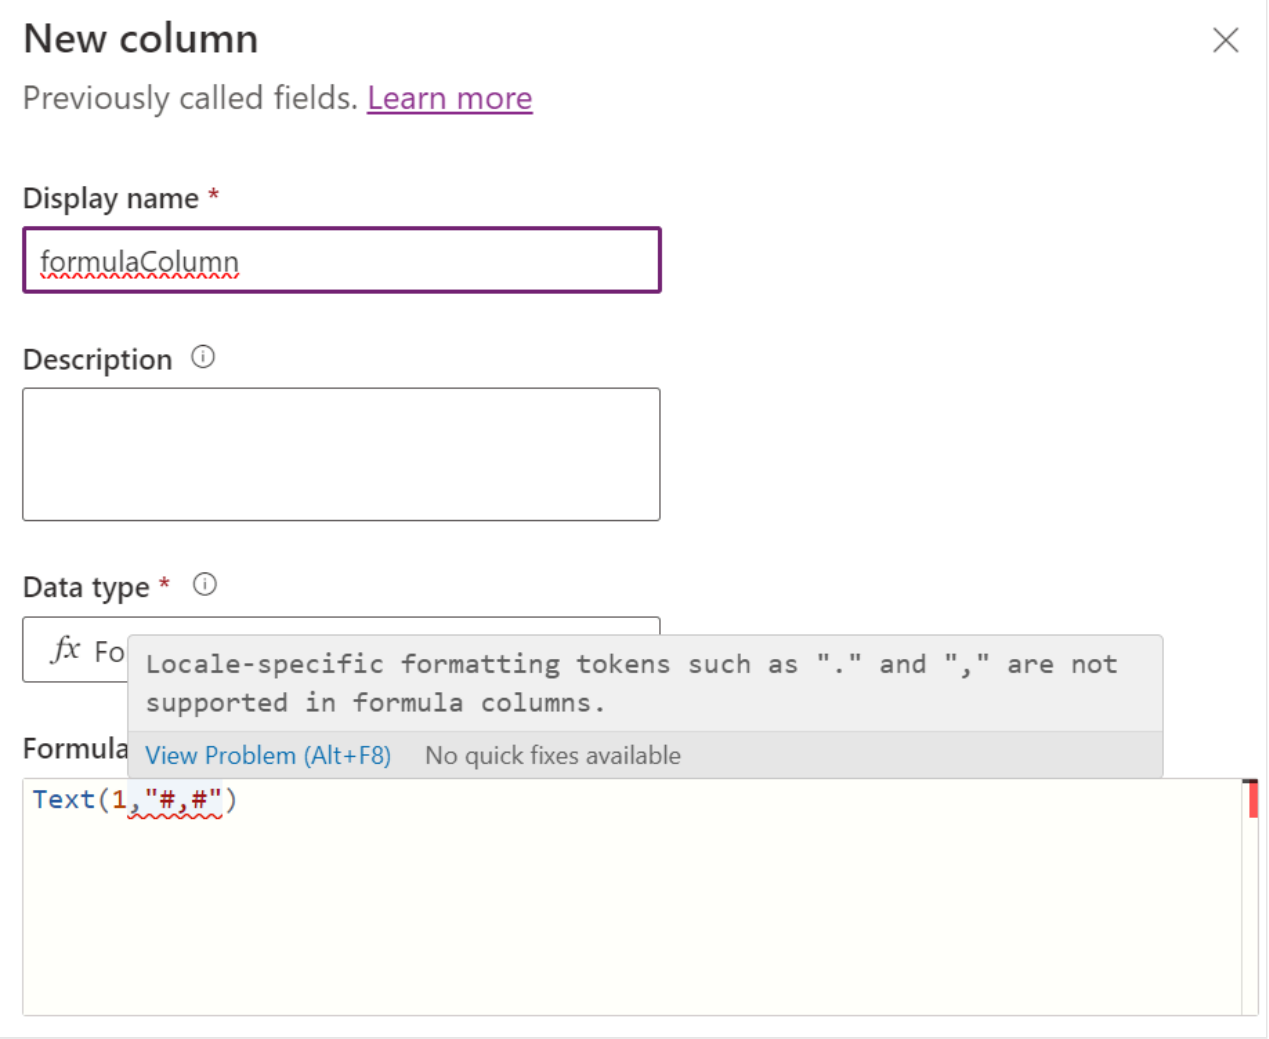


- Formula columns don't support using numbers in the following configurations:
  - In string functions. These are string functions placed wherever a text argument is expected: Upper, Lower, Left, Right, Concatenate, Mid, Len, StartsWith, EndsWith, TrimEnds, Trim, Substitute, and Replace.
  - In the implicit formulas, such as `12 & "foo"`, or `12 & 34`, or `"foo" & 12`.
  - Internal number to text coercion isn't supported. We recommend using `Text(Number, Format)` to convert a number to text. In the case where a `String` argument is passed in a `Text` function then the `Format` argument isn't supported.
  - Here's an example using the `Text` function to convert a number to text and append a string to it:

PowerApps Formula

```
Concatenate(Text(123,"#"),"ab")
Text(123,"#") & "foo"
```

- Locale-specific formatting tokens such as "." and "," aren't supported in formula columns.



Range validations on formula columns

- You can't set the **Minimum value** or **Maximum value** properties of a formula column.
- All internal computations should lie within the Dataverse range for decimal type formula columns (-100000000000 to 100000000000).
- A hard coded literal value entered in the formula bar should lie within the Dataverse range.
- If there's a numeric column that's null then it's considered 0 in the intermediate operation. For example, `a+b+c and If a = null, b=2, c=3` then formula column gives `0 + 2 + 3 = 5`.
  - This behavior is different from calculated columns in this case because calculated columns give `null + 2 + 3 = null`.

General validations on formula columns

- Formula columns can reference other formula columns, but a formula column can't reference itself.

- Formula columns don't support cyclic chains, such as `F1 = F2 + 10, F2 = F1 * 2`.
- Maximum formula expression length in formula columns is 1,000 characters.
- The maximum depth allowed in formula columns is 10. *Depth* is defined as the chain of formula columns referring to other formula or rollup columns.
  - For example, `table E1, F1 = 1*2, table E2, F2 - E1*2`. In this example, the depth of F2 is 1.
- In model-driven apps, sorting is disabled on:
  - A formula column that contains a column of a related table.
  - A formula column that contains a logical column (for example, address column).
  - A formula column that contains another calculated or formula column.
  - A formula column that uses time-bound function `UTCNow()`.
- Columns of type Whole Number with format Language, Duration, Time Zone aren't supported in formula columns.
- Columns of type String with format Email, Text Area, Ticker Symbol, URL aren't supported in formula columns.
- Formula columns don't display values when the app is in mobile offline mode.
- You can't trigger workflows or plug-ins on formula columns.
- We don't recommend using calculated columns in formula columns and vice versa.
- Duplicate detection rules aren't triggered on formula columns.
- The `Now` function can be used with formula columns. `Now()` has user local behavior and `UTCNow()` has time zone independent behavior.
- You can set the precision property for decimal columns.
- Default formula data type value is set to **Decimal** for numeric value returning formulas.
- Updating whole number formula column's format isn't supported.

Create formula columns with decimal, whole number, float, and choice data types

This article provides guidance on creating and using different data types in Microsoft Dataverse formula columns, such as decimal, whole number, floating point, and choice columns. It outlines steps starting with selecting **fx Formula** as the data type and entering a numeric value-returning formula in the formula bar.

Start by creating a column for a table

1. Sign in to Power Apps at https://make.powerapps.com .
2. Select **Tables**, and then select the table where you want to add a formula column. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select the **Columns** area, select **New column**, and then select the data type and enter the Power Fx formula. Depending on the formula you enter, you can create any of the following:
    - Decimal formula column
    - Whole number formula column
    - Floating point number formula column
    - Choice formula column

Create a decimal formula column

Create a formula column that returns a decimal number.

1. Select **Data type** as ***fx* Formula**.
2. Enter a formula that returns a numeric value in the **Formula** bar. This example creates a formula column called *Total Amount*. The *Price Per Unit* column is of decimal data type.

New column

Previously called fields. Learn more

Display name *

Total Amount

Description

Data type *

fx Formula

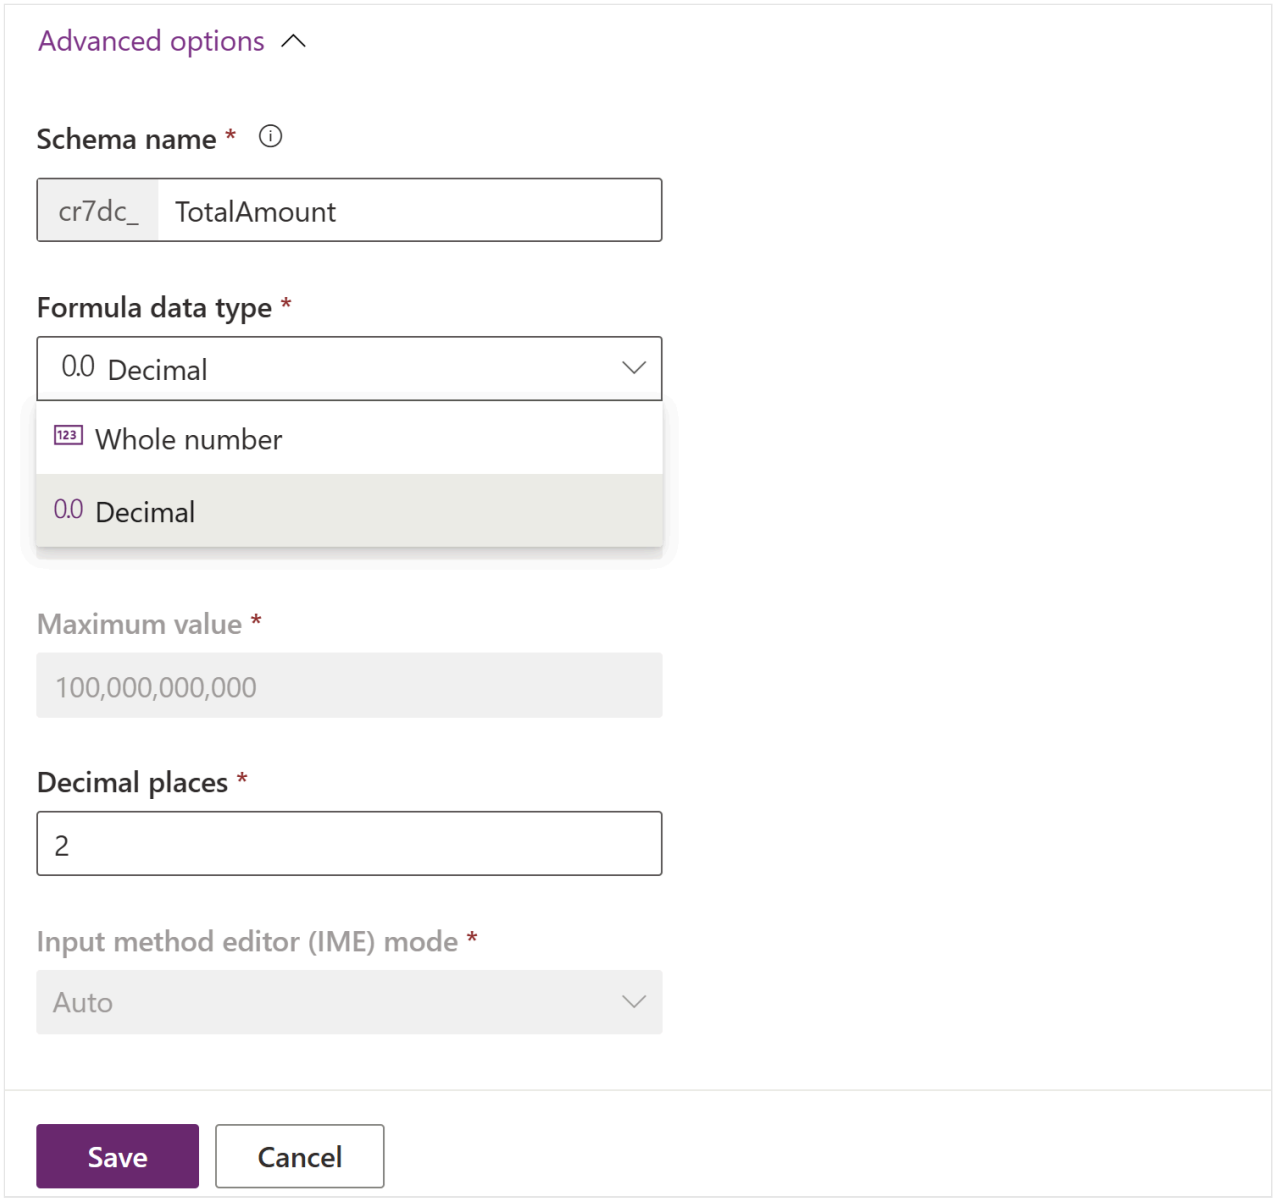
Formula *

```
'Price Per Unit' * 150
```

Searchable

Advanced options

3. Expand **Advanced options**, and then set the required number of decimal places.



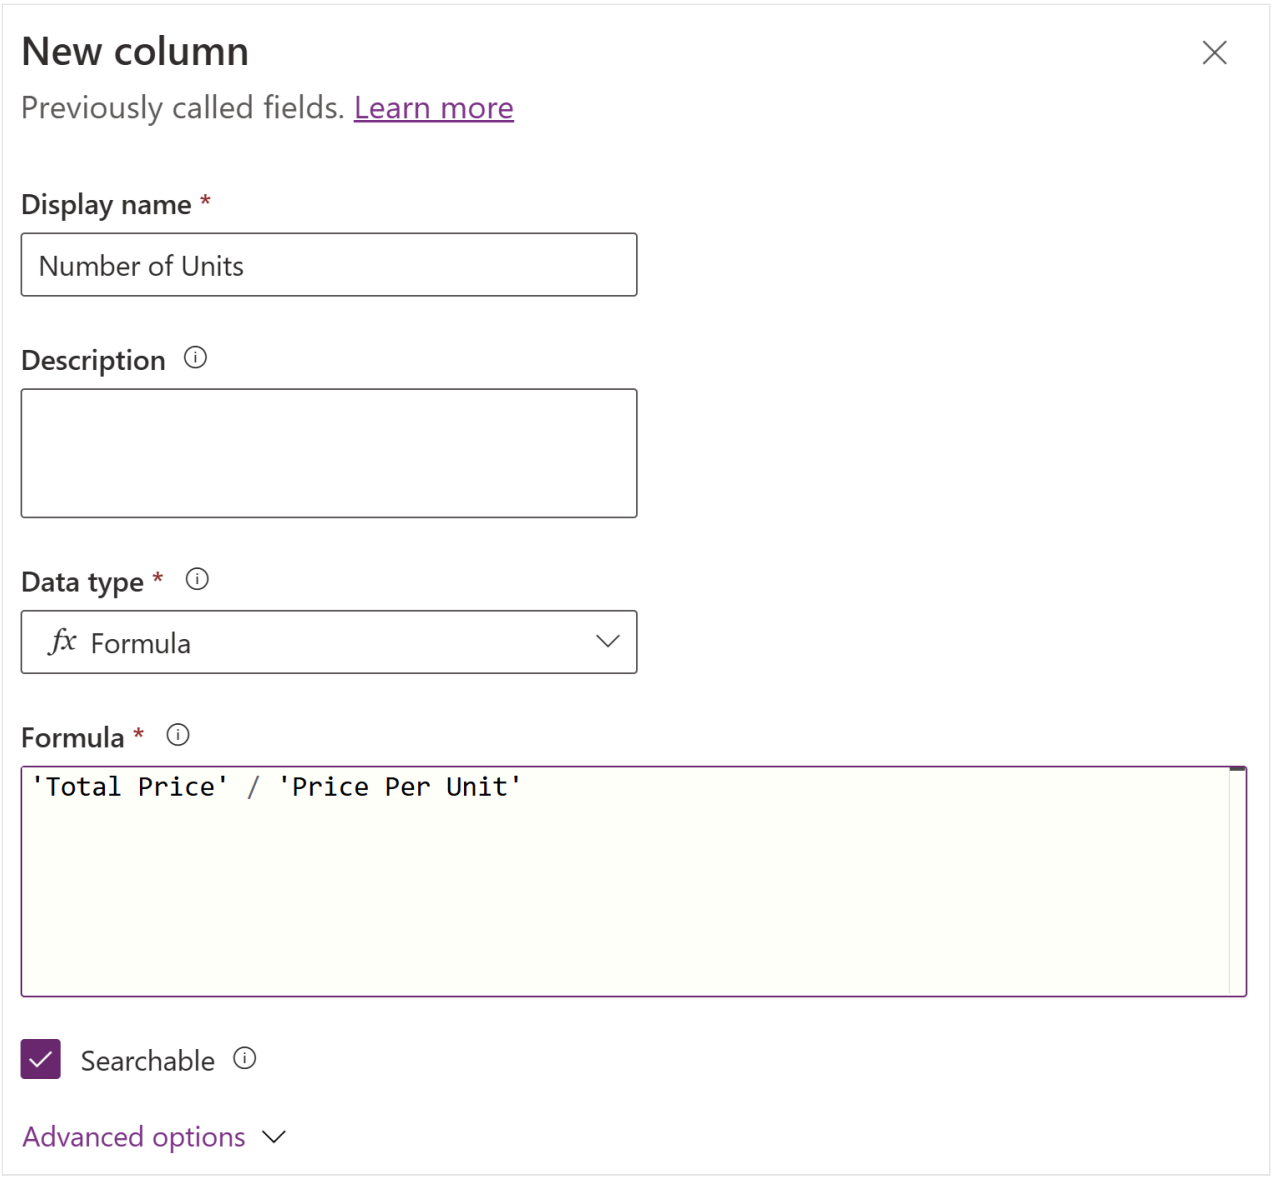
4. Select **Save**. By default, **Formula data type** is set to **Decimal** and a decimal formula field is created.

Create a whole number formula column

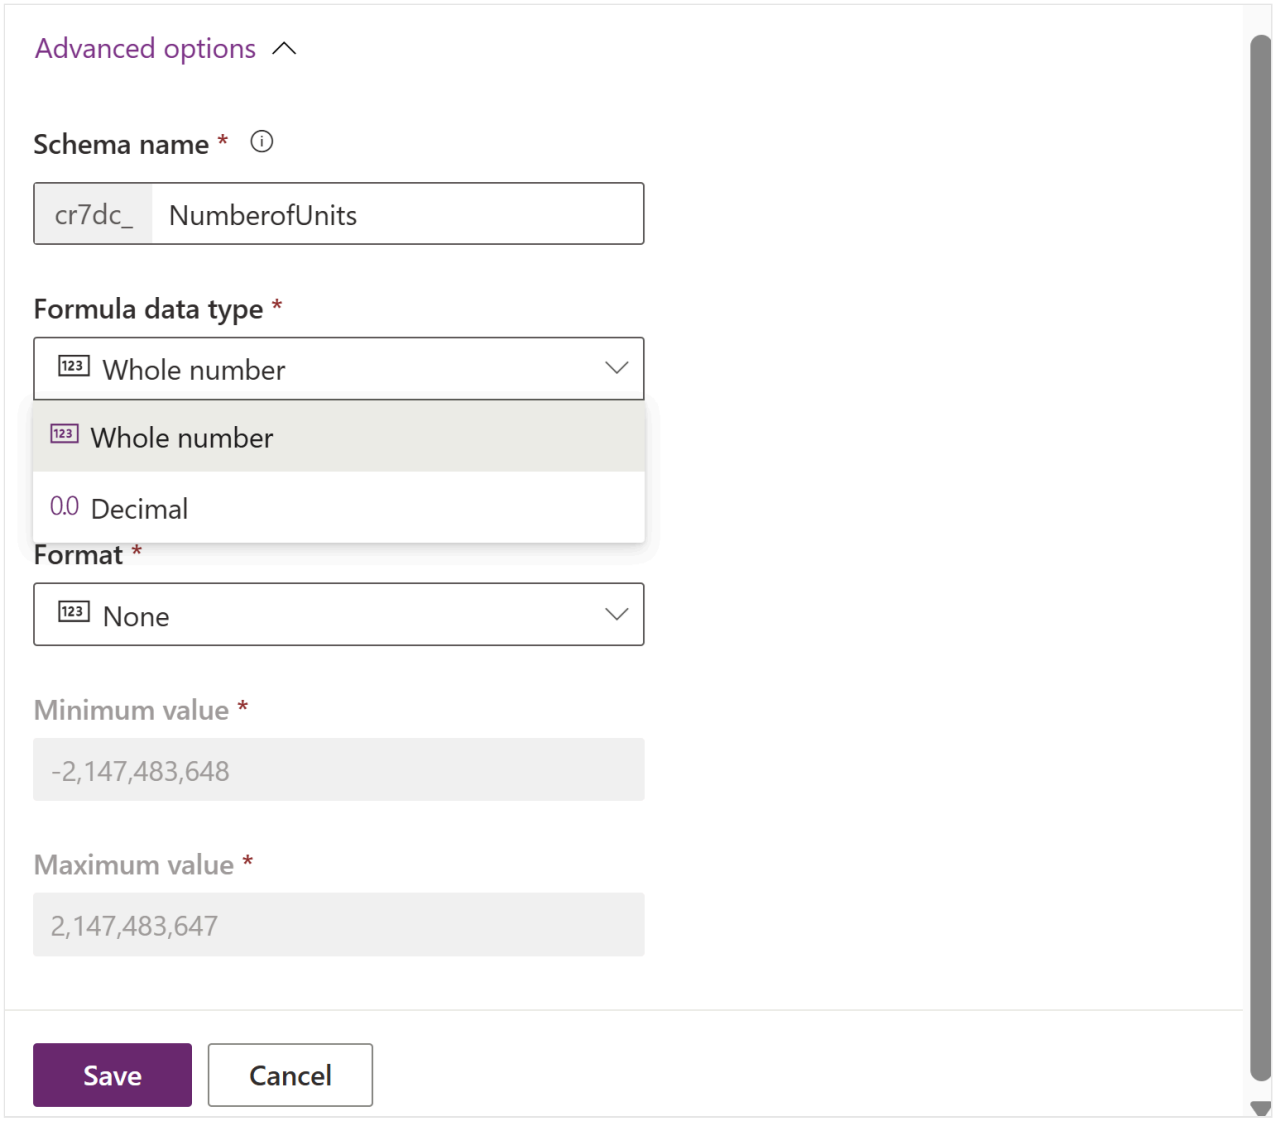
Create a formula column that returns a whole number.

1. Select **Data type** as ***fx* Formula**.
2. Enter a formula that returns a numeric value in the **Formula** bar. This example creates a formula column called *Number of Units*. *Total Price* and *Price Per Unit* columns are of

decimal data type.



3. Expand **Advanced options**, and select **Whole number** as the **Formula data type** and set the required format for whole number column.



4. Select **Save**.

Create a floating point number formula column

Create a formula column that returns float.

1. Select **Data type** as ***fx* Formula**.
2. Enter a formula that returns a floating point number in the **Formula** bar. Enter a formula that returns a floating point number in the **Formula** bar. This example creates a formula column called *Total Price*. *Weight* is a simple float column and *Price Per Gm* is a simple

decimal column.

Maximum value *

100,000,000,000

Decimal places *

3

Save Cancel

3. Expand **Advanced options**, and set the required number of decimal places.
4. Select **Save**.

Guidelines for creating floating point number formula columns

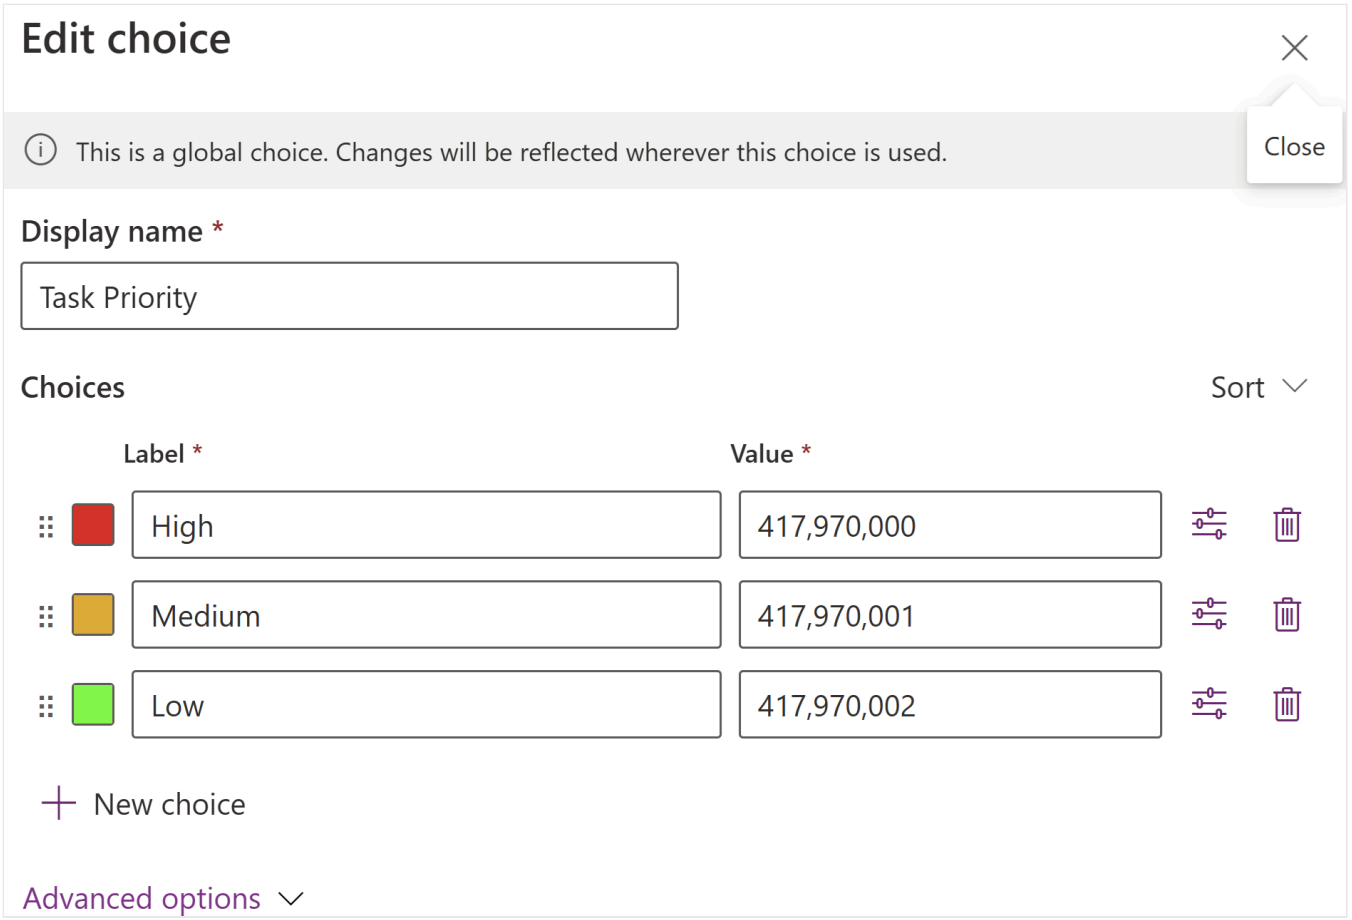
- If an operand involved in an arithmetic operation is of float type, then the result of the formula is of float type. For example:
  - `1 + 2 + Float(1)` as it uses a float type operand - `Float(1)`.
- A numeric function returns a float value when the first parameter provided to the function is of float type. Otherwise, the function returns a decimal value. For example:
  - `Sum(1, 2, Float(1))` is of decimal type and `Sum(Float(1), 1, 2)` is of float type.
- `Float`, `Sqrt`, `Ln`, `Power`, `Exp` functions and the `^` operator return a float value.

Create a choice formula column

To create a choice formula column, either global choice or local choice of a simple choice column can be used as result.

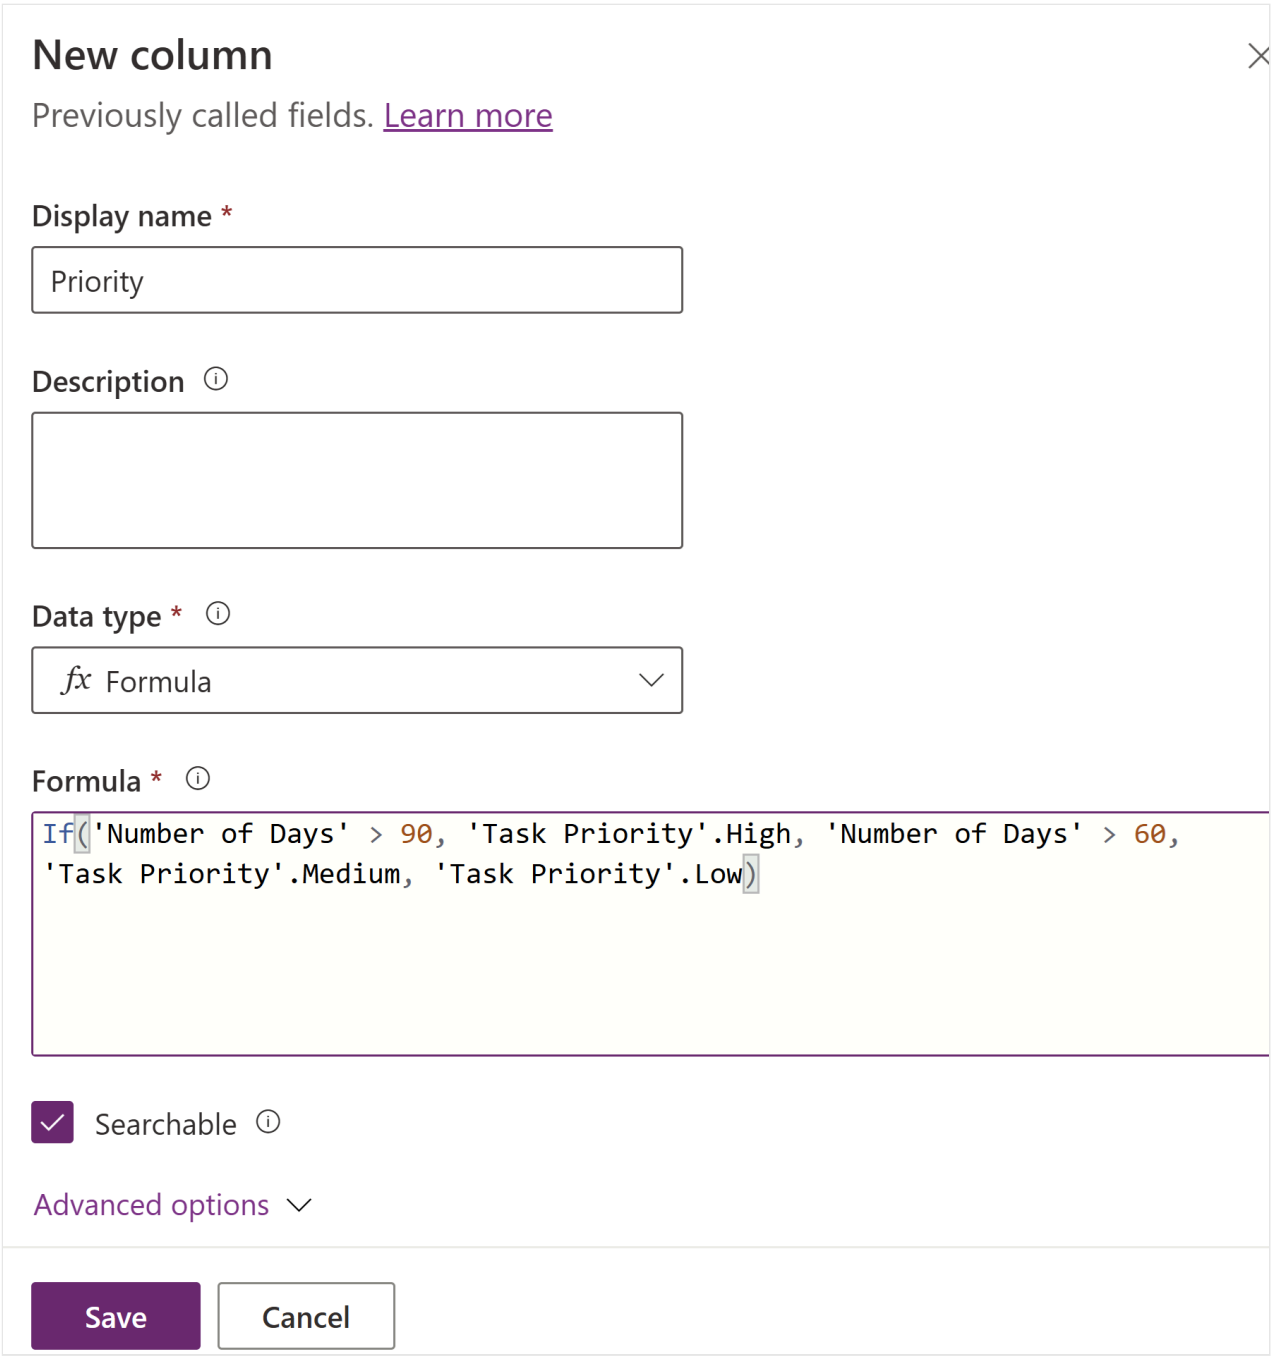
Using global choice

Create a global choice. This example creates a global choice called *Task Priority*.



Create a formula column that returns a choice using a global choice.

1. Select **Data type** as ***fx* Formula**.
2. Enter a formula that returns a choice value in the **Formula** bar. This example creates a formula column *Priority* using global choice *Task Priority*.



3. Select **Save**. Notice that the column created is of data type **Choice fx**.

Using local choice from a simple choice column

Create a simple choice column. This example creates a *Task Priority* simple choice column for the account table.

New column

Previously called fields. Learn more

Display name *

Task Priority

Description

Data type *

Choice

Behavior

Simple

Required

Optional

Searchable

Selecting multiple choices is allowed

Sync with global choice? *

Yes (recommended)

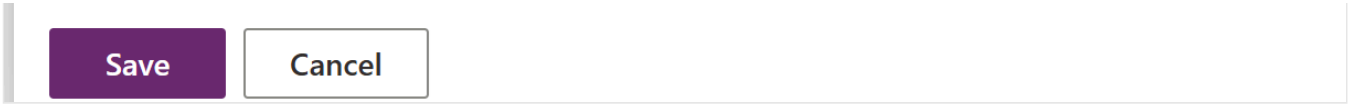
Can be used in multiple tables, and will stay updated everywhere.

No

Creates a local choice that can only be used in one table. People using it can add new choices.

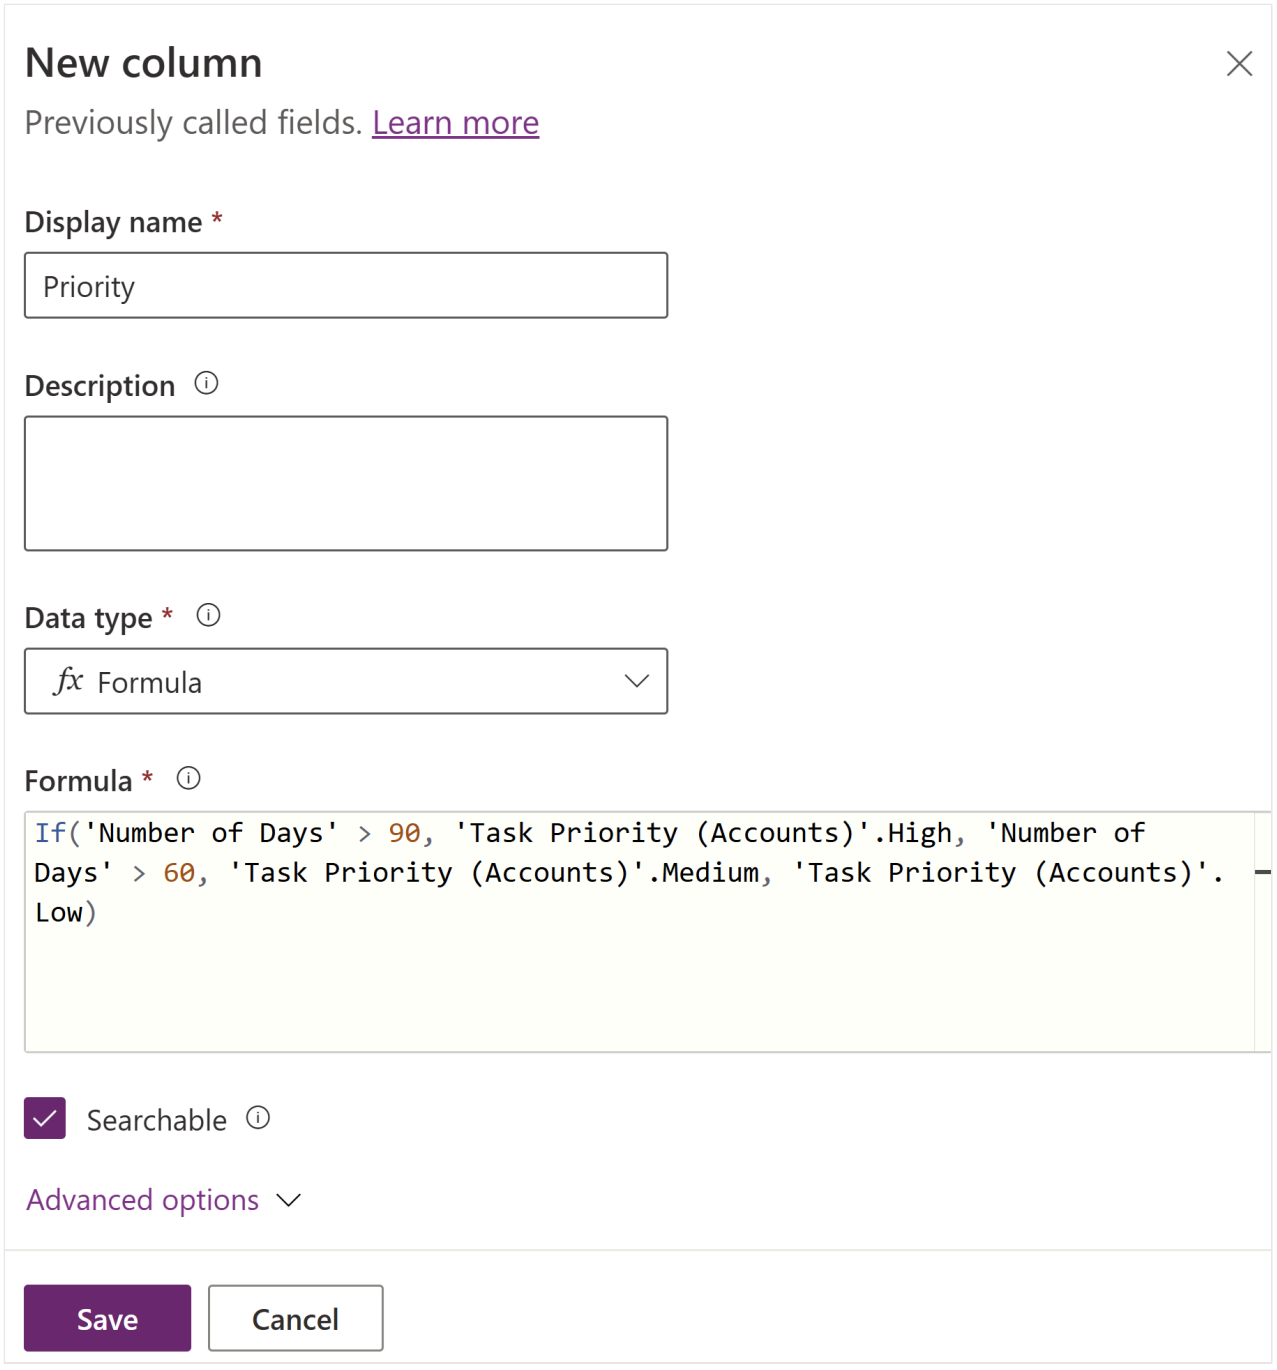
Choices Sort

Label *	Value *
High	417,970,000
Medium	417,970,001
Low	417,970,002



Create a formula column that returns choice using a local choice of a simple choice column.

1. Select **Data type** as ***fx* Formula**.
2. Enter a formula that returns a choice value in the **Formula** bar. This example creates a formula column *Priority* on *Account* entity using local choice of a choice column *Task Priority* for the account table.



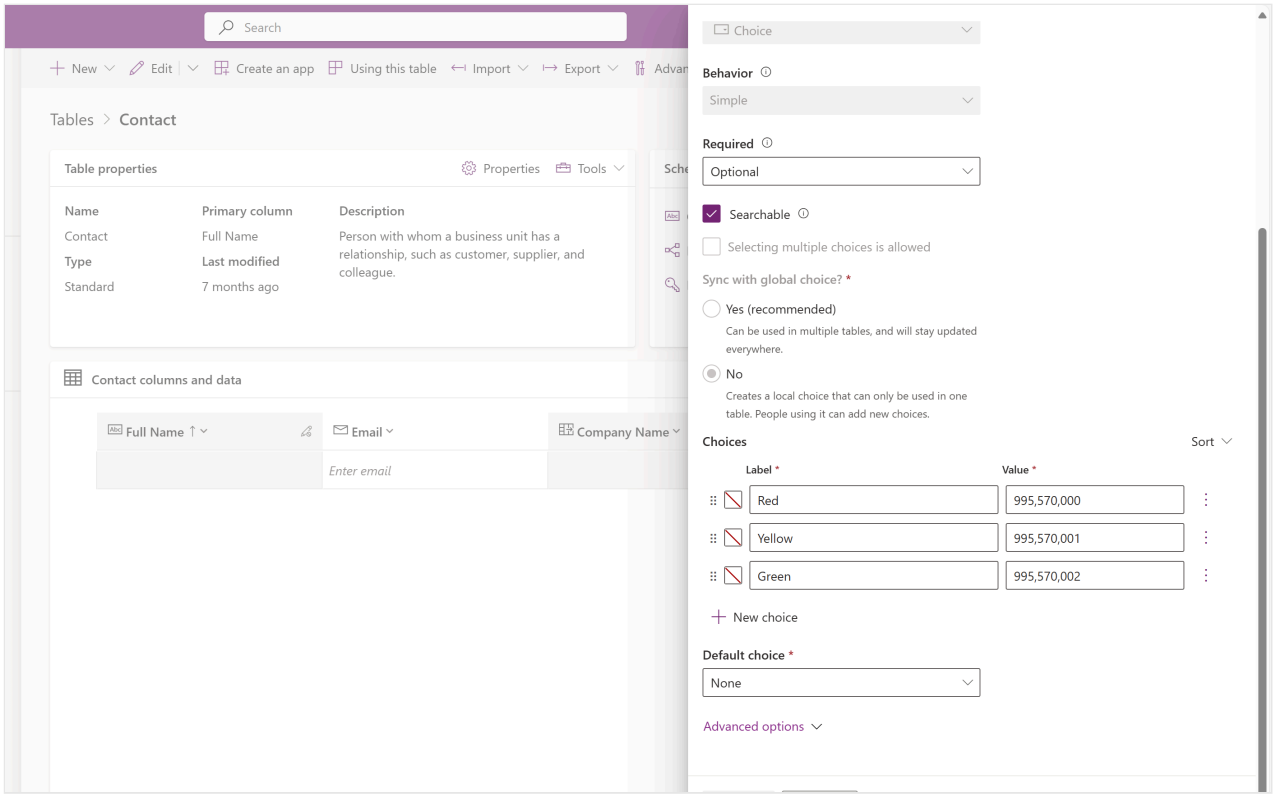
3. Select **Save**.

Guidelines for working with choices in formula columns

- Local choices of related table's simple choice column can't be used as a result type in formula columns.
- Options from the same option set should be used for all result arguments in choice formula columns.
- A choice used by a formula column can't be updated.
- Options of a choice can't be passed as an argument to string functions. Value function can be used to return the numeric value of an option.
- Formula column's dependent local choice column or global choice can't be deleted.
- For using a related table local choices (optionset) column's options in the formula column definition, first use choice and then use options of that local choice.

  For example, a choice column named *Color* on the **Contact** table.

  The choice column has options Red, Yellow, and Green.



For a formula column on the account table using the *Color* choice column, the formula appears like this:

Recommended - `If(ParentAccount.Color == 'Color (Accounts)'.Red, 1, 2)`

Not Recommended - `If( 'Color (Accounts)'.Red == ParentAccount.Color, 1, 2)`

Set managed properties for columns

Article • 04/10/2025

Managed properties only apply when you export columns in a managed solution and import the solution into another environment. These settings allow a solution maker to have some control over the level of customization that people who install their managed solution can have when they customize this column.

To view and set managed properties for a column, follow these steps:

1. Sign into Power Apps and select **Solutions** from the left navigation. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the solution, open the table you want, and then open the **Columns** area.
3. Select the column you want.
4. On the command bar select **More Actions**, and then select **Managed properties**.
5. Select the managed properties options you want, and then select **Set**.

Managed properties options

The **Allow customizations** option controls all the other options. If this option is `False`, none of the other settings apply. When it is `True`, you can specify the other customization options.

If the column is customizable, you set the following options to `True` or `False`.

- **Display name can be modified**
- **Can change requirement level**
- **Can change additional properties**

These options are self-explanatory. If you set all the individual options to `False`, you might as well set **Allow customizations** to `False`.

Email address validation for email columns (preview)

07/02/2025

> **Important**
>
> - This feature is deprioritized and will not be delivered.
> - Beginning July 31, 2025, existing model-driven or canvas apps that use this email validation feature will stop displaying the validation results for the email addresses entered in forms. Any custom function or logic implemented by makers that use this specific email address control type might stop functioning and must be updated to use the standard email address control type. If you haven't developed custom functions, forms continue to work as before.

[This topic is pre-release documentation and is subject to change.]

Get email address columns validated automatically in model-driven apps with no-code. With smart data validation, makers can build smarter and contextually aware next-gen apps for their workflows with better data quality.

Traditionally, the existing email column type had only basic email validation. With smart email address validation, the email column format comes with better validation that includes reasons for the column being invalid. Any model-driven apps using a text column with email format receives automatic validation, which is helpful in guiding users to enter better email data.

> **Important**
>
> - This is a preview feature.
> - During preview, these regions have email address validation feature available: Asia (East, Southeast), Australia (East, Southeast), Canada (Central, East), Europe (North, West), France (Central, South), India (Central, South), Japan (East, West), South America – Brazil (South), Switzerland (North, West), UAE (North), UK (South, West), US (East, West).
> - Smart email validation only works for model-driven apps.
> - Smart email validation shows validation issues but won't block users from saving their record.

Email address validation detects the following issues:

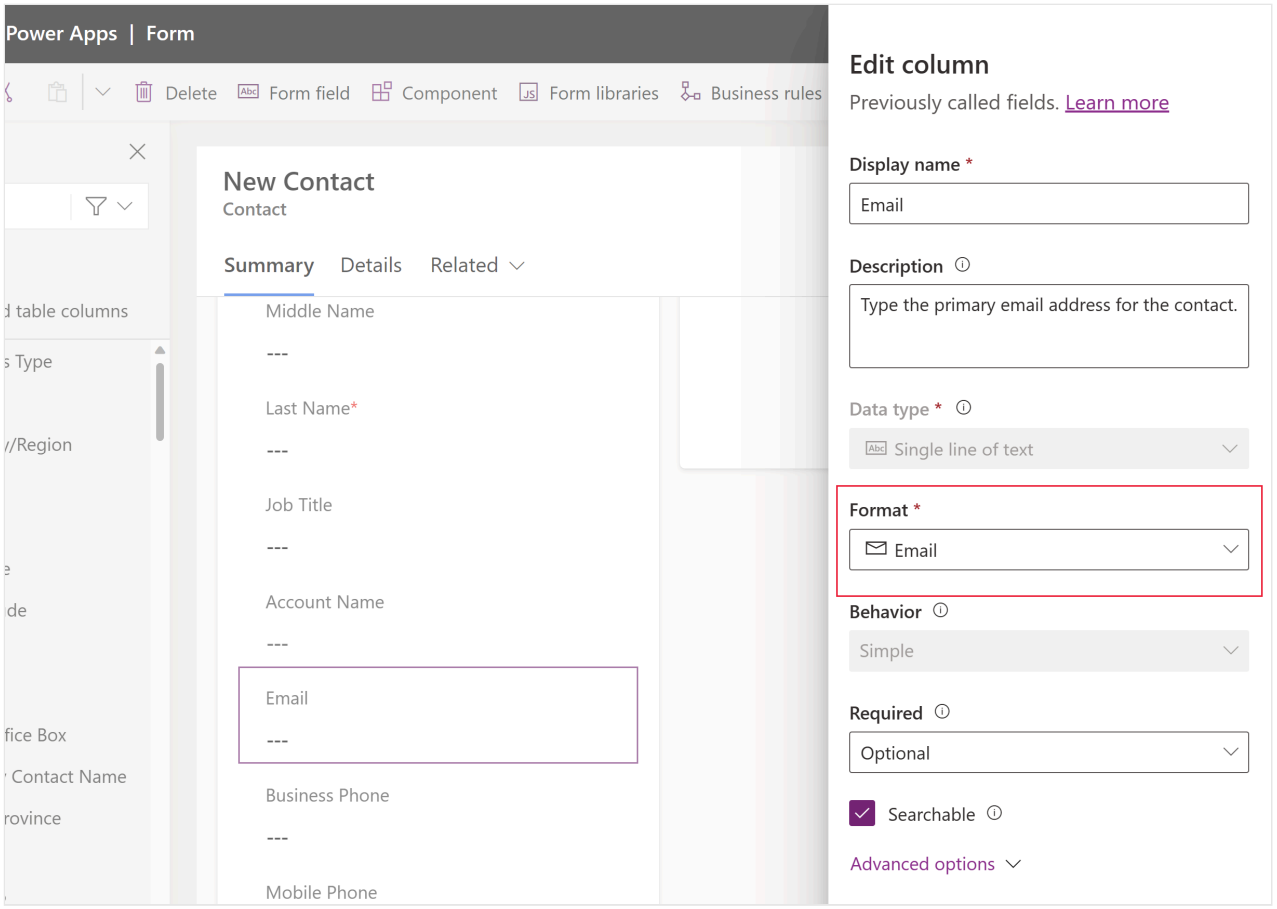
- Incorrect syntax: For example, an address that doesn't contain both a username and an email domain.
- Disposable domain: An address that contains a known disposable or temporary email domain.
- Test or spam email addresses. An address that contains known indicators of a test or spam address in the email header or metadata, IP address, HTML code of the email, and email content and formatting.
- Expired email addresses: This is an email account that has expired and can no longer receive or send email.
- Emails that bounce back: This is an address that can't receive a message for any reason other than being expired.

Prerequisites

- The **Data validation** Power Platform environment setting must be enabled. By default, this setting is disabled. More information: Manage feature settings
- Email address validation only performs validation on text columns with the **Email** format type. For example, the **Email** or **Email Address 2** columns for the account table.

Enable an email format column for address validation

1. Make sure the model-driven app has a table with a text data type column formatted for email, such as the **Email** column for the contact table.

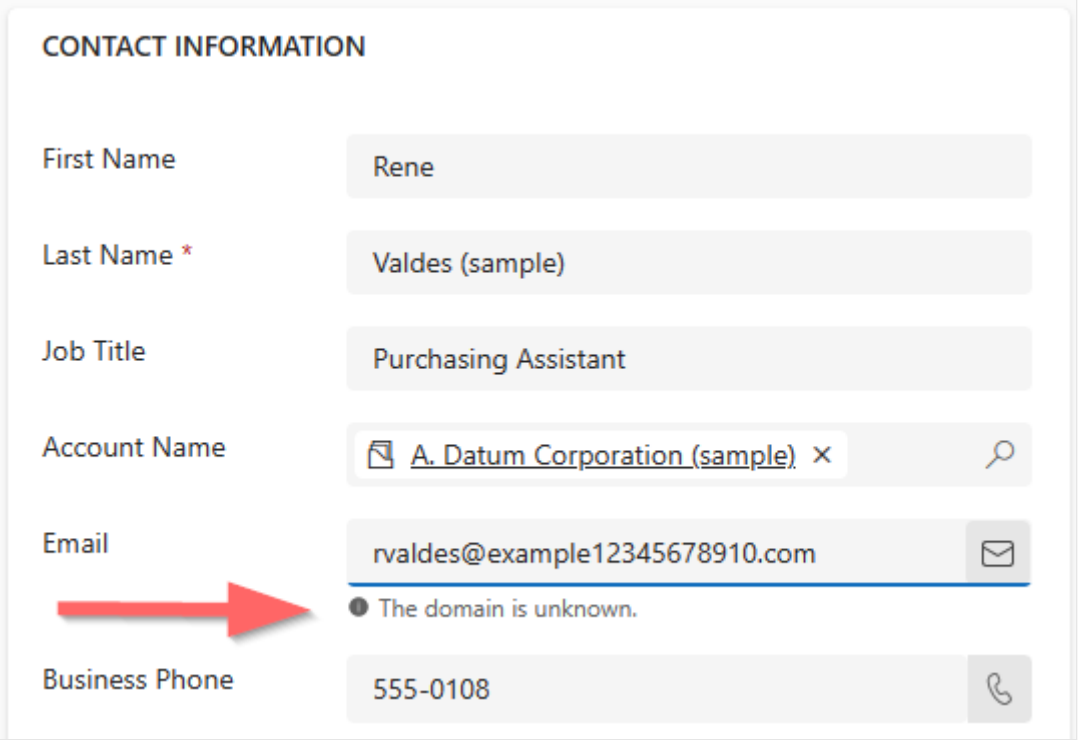


2. In the app designer, select **Settings** on the command bar.
3. Select the Upcoming tab, and then select **Enable Smart Email Address Validation Control**.
4. Select **Save**.

Test email address validation

1. In the app designer, select Play on the command bar.
2. Open a form that has the email column, such as the **Email** column for the accounts table.
3. Enter an invalid email address, such as a domain that doesn't exist, such as *example12345678910.com*, in the **Email** column.

Notice that the notification message **The domain is unknown** appears under the column.



Known issues

- The **Enable Smart Email Address Validation Control** app setting can be enabled even though the **Data Validation** Power Platform admin center environment setting is off. In this situation, email address validation doesn't work.
- When the form containing the control is set to read-only mode, the email column still allows editing of the value.
- The email column doesn't import values when using a quick create form. For example, when you create a new parent contact record from a lead record.
- While using the `setValue()` method, the value being defined for the control doesn't render in the app.

Next steps

Create and edit columns in Dataverse using Power Apps

Behavior and format of the date and time column

In Microsoft Dataverse, you can specify how date and time values are shown to users and how they're adjusted for time zones.

In addition to the standard properties available with most columns, date and time columns have two extra properties:

- **Time zone adjustment**: Whether to adjust values for time zones.
- **Format**: Whether to display the time portion of the value.

Time zone adjustment

Dataverse stores all date and time values in UTC time zone. When your app displays values or processing values entered by users, Dataverse and model-driven apps can adjust for the user's time zone with these **Behavior** options.

- **User local**: Adjust values for the user's time zone. This is the default behavior for the **Date and time** format. You can change this once to another behavior.
- **Time zone independent**: No time zone conversion. This is the default behavior for the **Date only** format.

Set the user's time zone in personal options, not the system time zone in Windows, Android, iOS, or macOS. However, the system time zone might affect client scripts that work with JavaScript Dates.

Format

All date and time columns have a time portion unless their behavior is **Date Only**. **Format** determines whether to display the time portion of the value.

- **Date and time**: Displays the date and time of the value.
- **Date only**: Displays the date portion of the value only.

> ⓘ **Note**

Users can still change the time portion if the **Format** is **Date Only**. For example, by using Web API calls or by using a control that has the time portion. This behavior is different from **Date only Behavior**, where the time portion isn't stored at all.

Usage guidelines

Use **Time zone independent** when time zone information isn't required, such as hotel check-in times. With this selection, users in all time zones see the same date and time value.

Use **Date only** when information about the time of the day and the time zone isn't required, such as birthdays or anniversaries. With this selection, users in all time zones see the exact same date value.

Time zone independent with **Date only** is practically the same as setting the column as **Date only**. Use the former if you aren't sure whether you need the time portion in the future.

> **Important**
>
> Avoid **Date only** format with **User local** behavior. Users in different time zones might see a different date, which is not intended in most scenarios. When a user sets a date in a model-driven app, the time portion automatically sets to midnight of their time zone. This might cause the date to appear a day earlier or later for other users.

Examples

Display values

Dataverse stores `2023-10-15T07:30:00Z` (or `2023-10-15` for **Date only** behavior). Users in the time zone UTC-8 see these in the model-driven app or with a Web API request for the formatted value:

Expand table

Behavior	Format	Display value
User local	Date and time	October 14th, 2023, 11:30 pm
User local	Date only	October 14th, 2023
Time zone Independent	Date and time	October 15th, 2023, 7:30 am
Time zone Independent	Date only	October 15th, 2023

Behavior	Format	Display value
Date only	-	October 15th, 2023

Enter values in an app

Users in the time zone UTC-8 enter `October 14th, 2023, 11:30 pm` in a model-driven app. The value is saved in Dataverse as:

Expand table

Behavior	Format	Value saved in Dataverse
User local	Date and time	2023-10-15T07:30:00Z
User local	Date only	2023-10-15T07:30:00Z
Time zone Independent	Date and time	2023-10-14T23:30:00Z
Time zone Independent	Date only	2023-10-14T23:30:00Z
Date only	-	2023-10-14

If the user enters just the date `October 14th, 2023`, the time portion is assumed to be 12:00 AM.

Expand table

Behavior	Format	Value saved in Dataverse
User local	Date only	2023-10-14T08:00:00Z
Time zone Independent	Date only	2023-10-14T00:00:00Z
Date only	-	2023-10-14

Enter invalid values in an app

Different clients have different ways to handle invalid input. For example, in the Pacific time zone, daylight saving started on March 12th, 2023 at 2:00 AM, moving the time forward one hour to 3:00 AM. The time between 2:00 AM and 3:00 AM on that day doesn't exist. When users try to enter a value in that time range, apps might do one of the following:

- Change to the previous or next valid time.
- Revert to the last known value.
- Show an error message.

- Don't show times between 2:00 AM and 3:00 AM in the time picker, so that users can't select them in the first place.

Similarly, different clients have different ways to handle repeated time ranges. For example, in the Pacific time zone, daylight saving ended on November 5th, 2023 at 2:00 AM, moving the time backward one hour to 1:00 AM. The time between 1:00 AM and 2:00 AM on that day is repeated twice. A time like 1:30 AM could refer to either time zones. If you need to unambiguously show or enter times in that range, it's best to temporarily switch to a time zone that doesn't use daylight saving.

Get raw values with Web API

Dataverse stores `2023-10-15T07:30:00Z` (or `2023-10-15` for **Date only** behavior). Users in all time zones get these values with a Web API request for the value:

Expand table

Behavior	Format	Raw value
User local	Date and time	2023-10-15T07:30:00Z
User local	Date only	2023-10-15T07:30:00Z
Time zone Independent	Date and time	2023-10-15T07:30:00Z
Time zone Independent	Date only	2023-10-15T07:30:00Z
Date only	-	2023-10-15

Get values with Client API

Users in the time zone UTC-8 enter `October 14th, 2023, 11:30 pm` in a model-driven app. Client API functions like `formContext.getAttribute(<column name>).getValue()` return the value with time zone adjustments applied:

Expand table

Behavior	Format	JavaScript `dateValue.toUTCString()`
User local	Date and time	2023-10-15 07:30 (UTC)
User local	Date only	2023-10-15 07:30 (UTC)

For **Time zone independent** behavior, the JavaScript Date value is in the browser's time zone:

Expand table

Behavior	Format	JavaScript `dateValue.toString()`
Time zone Independent	Date and time	2023-10-14 23:30 (browser time zone)
Time zone Independent	Date only	2023-10-14 23:30 (browser time zone)

JavaScript date values always have a time component. That's why **Date only** behavior has a time component of 12:00 AM:

Expand table

Behavior	Format	JavaScript `dateValue.toString()`
Date only	-	2023-10-15 00:00 (browser time zone)

> **Note**
>
> JavaScript date values are affected by the browser's time zone, which comes from the device operating system settings.
>
> For **User local** behavior, interpret the Client API result as a UTC value. Use `Date.getUTCDate()` or `Date.getUTCHours()` to work with it. To get what the user sees, apply getTimeZoneOffsetMinutes. Don't use `Date.getDate()` or `Date.getHours()` because these functions show the value in the browser's time zone.
>
> For **Time zone independent** and **Date only** behavior, interpret the Client API result as a value in the browser's time zone. Use `Date.getDate()` or `Date.getHours()` to work with it. Don't use `Date.getUTCDate()` or `Date.getUTCHours()` because you don't have to adjust for any time zones.

Change user local behavior

Unless the publisher of a managed solution prevents changing the local behavior, you can change the behavior of existing custom date columns from **User local** to **Date only** or **Time zone independent**. This is a one-time change.

Changing the column behavior affects the column values that are added or modified after the column behavior was changed. The existing column values remain in the database in the UTC time zone format. To change the behavior of the existing column values from UTC to **Date only**,

you might need a help of a developer to convert behavior of existing date and time values in the database.

> ⚠ **Warning**
>
> Before changing the behavior of an existing date and time column, review all the dependencies of the column, such as business rules, workflows, calculated columns, or rollup columns, to ensure that there are no issues as a result of changing the behavior. After changing the behavior of a date and time column, open each business rule, workflow, calculated column, and rollup column dependent on the column that you changed, review the information, and save it, to ensure that the latest date and time column's behavior and value are used.

Change behavior during a solution import

When you import a solution that contains a Date column with **User local**, you can change the behavior to **Date only** or **Time zone independent**.

> ⓘ **Note**
>
> You can only change the behavior of an existing managed **Date only** or **Date and time** column if you are the publisher. In order to make a change to these fields, an upgrade must be made to the solution that added the **Date only** or **Date and time** column. More information: Upgrade or update a solution

Prevent changing behavior

If you're distributing a custom date column in a managed solution, prevent people using your solution from changing the behavior by setting the **CanChangeDateTimeBehavior** managed property to **False**. More information: Set managed properties for columns

Date and time query operators not supported for Date only behavior

The following date and time related query operators are invalid for the **Date only** behavior. An invalid operator exception error is thrown when one of these operators is used in the query.

- Older Than X Minutes

- Older Than X Hours
- Last X Hours
- Next X Hours

How to create and edit columns

08/14/2025

In Microsoft Dataverse columns, define the individual data items that can be used to store data in a table. Columns are sometimes called *attributes* by developers.

Watch this video for a quick overview about columns:
https://learn-video.azurefd.net/vod/player?id=3379c026-1830-4265-86fc-c7d16a0b6b49&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fcreate-edit-fields

Before you create a custom column, evaluate whether using an existing column would meet your requirements. More information: Create new metadata or use existing metadata?

> **Note**
>
> You can also create columns in your environment using these methods:
>
> - For model-driven apps, select **New table column** in the form editor.
> - Import a solution that contains the definition of the columns.
> - Use Power Query to create new tables and fill them with data. Learn how to add data to a table in the Dataverse by using Power Query.
> - A developer can use Metadata services to write a program to retrieve information about, create, and update columns.

> **Note**
>
> You can create a Lookup column in Power Apps by creating a one-to-many relationship on the table.

For more information about how to create a table column, go to Create and edit columns for Dataverse using Power Apps portal.

Community tools

Attribute Manager is a tool that XrmToolbox community developed for Dataverse. Go to the Developer tools and resources article for more community developed tools.

> **Note**

The community tools aren't a product of Microsoft and Microsoft doesn't offer support for the community tools. If you have questions pertaining to the tool, contact the publisher. More Information: **XrmToolBox**

Types of columns and column data types

Developer Documentation: Column definitions

Manage custom columns in a table

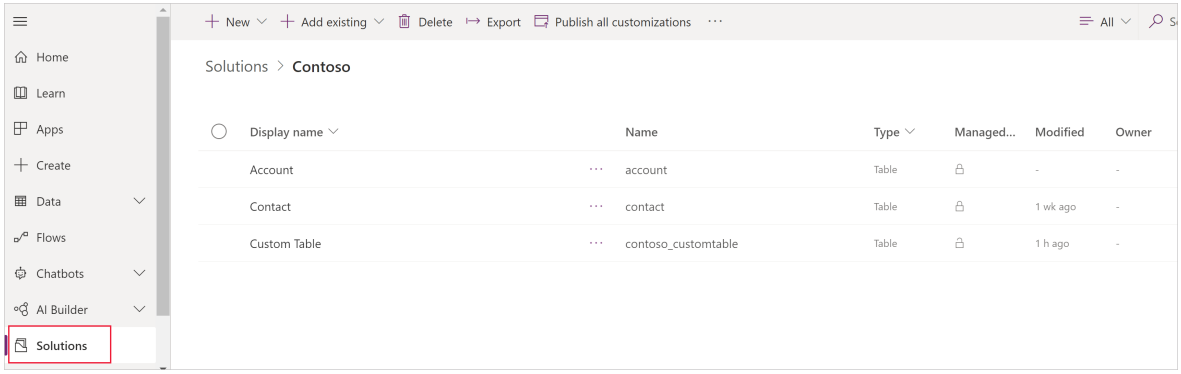
Article • 02/24/2023

You can create and update one or more custom columns in any table. When you create a custom column, you specify a set of properties, such as the column's name, its display name, and the type of data that it will contain. For more information, see table attribute metadata.

> **Note**
>
> Every table has system columns, such as columns that indicate when a row was last updated, and who updated it. In addition, standard tables have standard (default) columns. You can't modify or delete system columns or standard columns. If you create a custom column, it should provide functionality on top of these built-in columns.

Create a column

1. On powerapps.com, select **Tables** in the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.



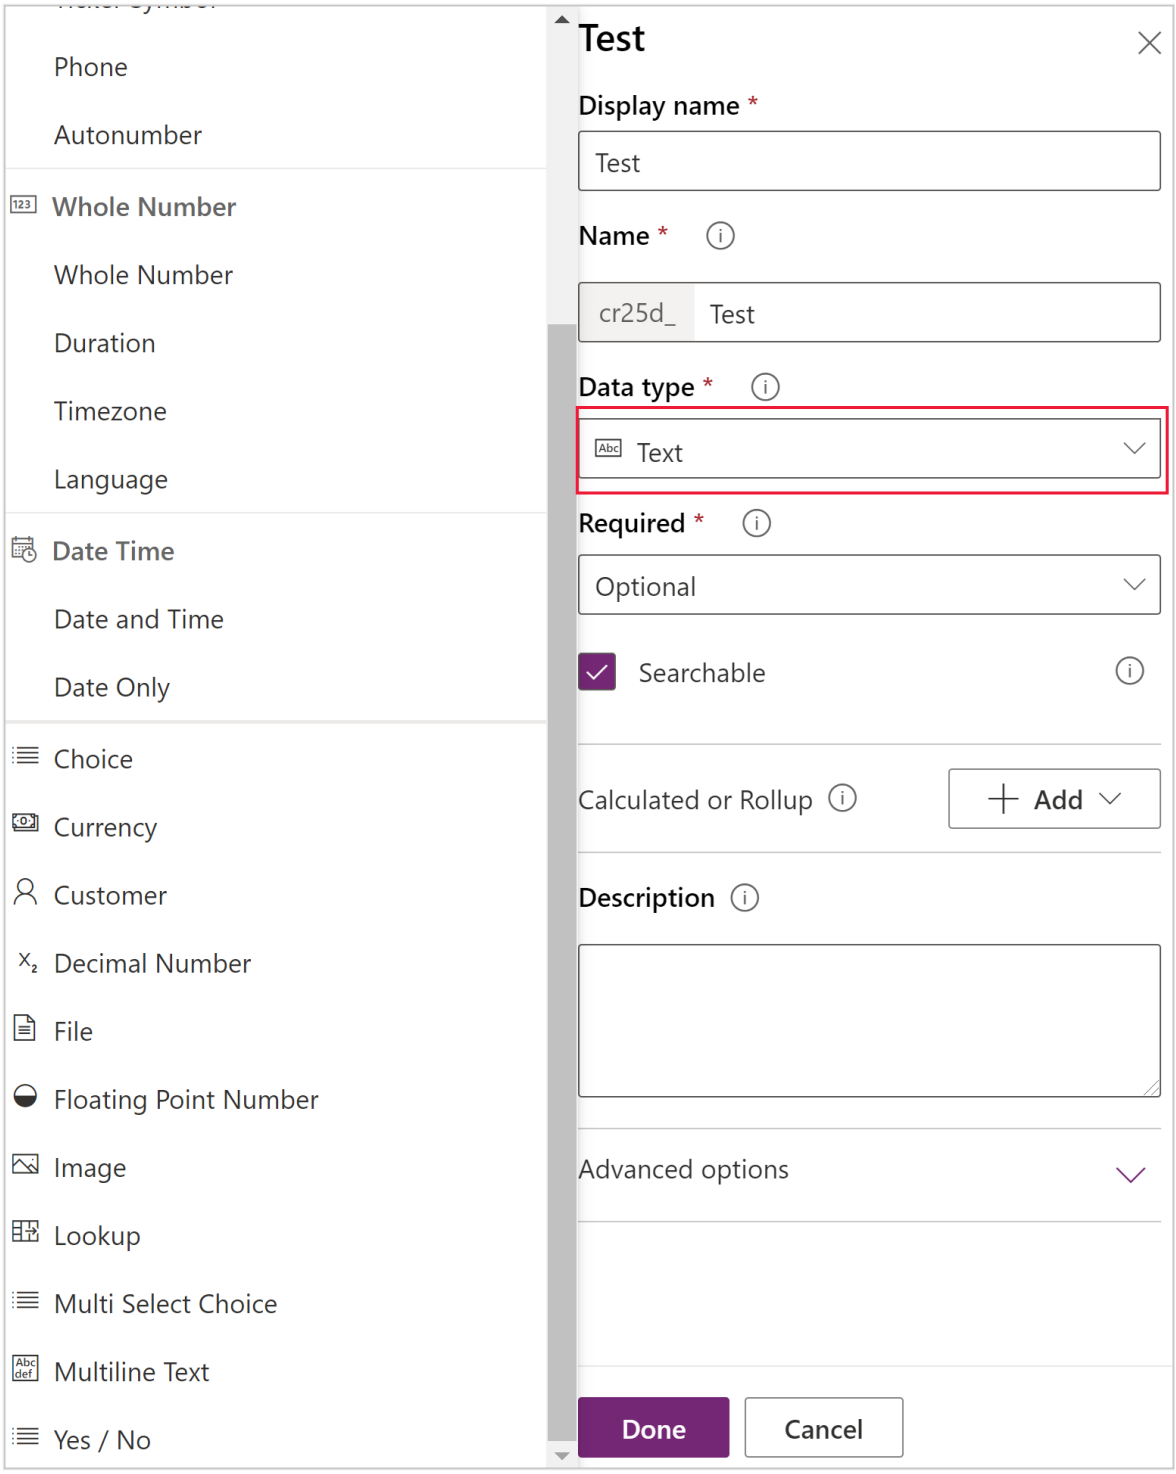
2. Select an existing table, or Create a new table

3. Add a new column to your table by selecting **Add column**.

4. In the New Column panel, enter the **Display name** for your column, **Name** will be automatically populated and is used as the unique name for your column. The **Displayname** is used when presenting this column to your users, the **Name** is used when building your app, in expressions and formulas.

   > **Note**

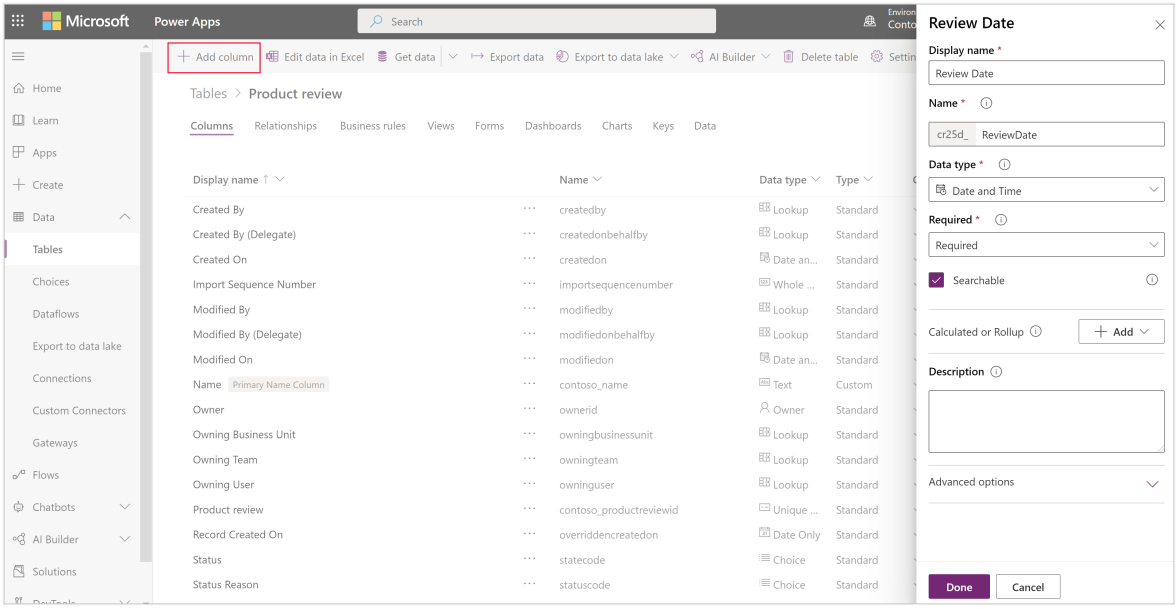
The **Display name** columns can be updated at anytime to display differently in your apps, the **Name** column can't be changed after your table has been saved as this could result in breaking an existing app.



5. Select the **Data type** of your column, this controls the way the information is stored as well as how it is presented in apps. For example, text is stored different to a decimal number or a URL. For more detailed information of the data types available, see table attribute metadata.

   If you're prompted, specify additional information for the data type that you specified. Depending on the data type, different columns will be presented. If

you're creating a column of type Choice or Multi Select Option Set, you can select **New Option Set** and create a new Choice while creating your column. For more information, see Create Option set



6. Under **Required**, select the check box if you want to recommended this column as required in your apps. This doesn't provide hard enforcement through all connections to Microsoft Dataverse. If you need to ensure the column is populated, create a Business Rule

7. Under **Searchable**, select the check box if you need this column to be available in Views, Charts, Dashboards and Advanced Find. In most cases this checkbox should be checked.

8. Select **Done** to close the Column panel and return to the table. You can repeat steps 3-9 for each additional column.

   > **Important**
   >
   > Your column is not yet saved and created, until you save the changes to the table.

9. Select **Save Table** to finalize your changes and save them to the Dataverse.

   You're notified when the operation is completed successfully. If the operation is unsuccessful, an error message indicates the issues that occurred and how you can fix them.

Create a Calculated or Roll up column

Calculated columns let you automate manual calculations used in your business processes. For example, a salesperson may want to know the weighted revenue for an opportunity which is based on the estimated revenue from an opportunity multiplied by the probability. Or, they want to automatically apply a discount, if an order is greater than $500. A calculated column can contain values resulting from simple math operations, or conditional operations, such as greater than or if-else, and many others. Calculated columns can be created using the following data types:

- Single line of text
- Option Set
- Two Options
- Whole Number
- Decimal Number
- Currency
- Date and Time

For more details on the types of expressions supported and examples, see Define calculated columns

Update or delete a column

1. On powerapps.com, select **Tables** in the left navigation pane. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Open a table.

3. In the list of columns for the table that you selected, selectp a column, and then follow one of these steps:

   - Change one or more properties of the column.
   - Delete the column by clicking or tapping the ellipsis (...) near the right edge of the column, and then clicking or tapping **Delete**.

4. Select **Save table** to submit your changes.

   > **Important**
   >
   > Your changes will be lost if you don't save them before you open another page in the browser or exit the browser.

   You're notified when the operation is completed successfully. If the operation is unsuccessful, an error message indicates the issues that occurred and how you can

fix them.

Best practices and restrictions

As you create and modify columns, keep these points in mind:

- You can't modify or delete system columns or their values.
- In a standard table, you can't modify or delete a standard (default) column, add a column that requires data, or make any other change that might break an app that relies on that table.
- In a custom table, you should make sure that the changes that you make won't break any app that relies on that table.
- You must give each custom column a name that's unique within the table, and you can't rename a column after you create it.

Next steps

- Define relationships between tables
- Create a business rule
- Create an app using tables
- Create an app from scratch using a Dataverse database

Privacy notice

With the Microsoft Power Apps common data model we collect and store custom table and column names in our diagnostic systems. We use this knowledge to improve the common data model for our customers. The table and column names that Creators create help us understand scenarios that are common across the Microsoft Power Apps community and ascertain gaps in the service's standard table coverage, such as schemas related to organizations. The data in the database tables associated with these tables is not accessed or used by Microsoft or replicated outside of the region in which the database is provisioned. Note, however, the custom table and column names may be replicated across regions and are deleted in accordance with our data retention policies. Microsoft is committed to your privacy as described further in our Trust Center.

Create and edit columns in Dataverse using Power Apps

Creating and editing table columns in Microsoft Dataverse using Power Apps is a straightforward process that allows you to customize your data tables to meet your specific needs. This guide walks you through the steps to view, create, and edit columns, as well as provide detailed information on the various data types and properties you can configure. Whether you're adding new columns or modifying existing ones, Power Apps offers a user-friendly interface to manage your Dataverse tables efficiently.

View columns

1. From Power Apps, select **Tables**, and then open the table that has the columns you want to view. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select the **Columns** area, where all columns for the table are displayed.

Create a column

While viewing columns, on the command bar, select **New column** which displays the **Column properties** panel.

Several column properties are available:

Expand table

Property	Description
Display Name	The text to be displayed for the column in the user interface.
Name	The unique name across your environment. A name is generated for you based on the display name that you've entered, but you can edit it before saving. Once a column is created, the name can't be changed as it might be referenced in your applications or code. The name has the customization prefix for your **Dataverse Default Publisher** prepended to it.
Data type	Controls how values are stored as well as how they're formatted in some applications. Once a column is saved, you can't change the data type except for converting text columns to autonumber columns.
Format	Depending on the Data type selected, you can select the format for the column data type. For example, whole number can have the format duration, language code, time zone, or none.

Property	Description
Behavior	By default Simple is selected. Some data types support extended behavior such as calculated or rollup.
Required	A record can't be saved without data in this column. Required columns on a hidden tab or section don't block saving the record unless the same column is also in a visible tab or section on the same form. More information: Saving rows programmatically for required columns
Searchable	This column appears in Advanced Find and is available when customizing views.
Allow form fill assistance (preview)	This is a preview feature. When enabled, users receive suggestions generated by AI for columns that support form fill assistance in main and quick create forms. You can disable for columns that might contain sensitive information, such as email address. Requires at least one **AI form fill assistance** environment setting enabled. For more information about AI form fill assistance, go to: Use Copilot's form fill assistance feature in model-driven apps Notice that configuring this setting creates a dependency on the AI Skill Config table (used with AI Builder) in the default solution. When a maker disables the **Allow form fill assistance** property on a table column, a record is created in the AI Skill Config table to store that configuration. This record creates a dependency on the AI Skill Config table for the column. More information: Delete a column with an AI Skill Config table dependency in Power Apps
Advanced Options	Enter the schema name, specify a maximum length, IME mode, column security, auditing, can appear in dashboards, and whether the column data is sortable.

You can set other options depending on your choice of **Data type**.

Column data types

There are many different types of columns, but you can only create some of them. For more information about all types of columns, see Types of columns and column data types.

When you create a column, **Data type** provides the following choices:

Text

Standard text columns can store up to 4,000 characters. The default Max Length option is set to a lower value you can adjust.

Expand table

Data type	Description
Text	A text value intended to be displayed in a single-line textbox.

Data type	Description
Text Area	A text value intended to be displayed in a multi-line textbox. If you require more than 4,000 characters, use a Multiline Text data type.
Email	A text value validated as an e-mail address and rendered as a mailto link in the column.
URL	A text value validated as a URL and rendered as a link to open the URL.
Ticker Symbol	A text value for a ticker symbol that displays a link that opens to show a quote for the stock ticker symbol.
Phone	A text value validated as a phone number rendered as link to initiate a phone call by using Skype.
Autonumber	A customizable combination of numbers and letters that is automatically generated by the server whenever the row is created. More information: Autonumber columns

Max Length

Columns that store text have an absolute maximum depending on the type. The **Max Length** choices a value lower than the maximum specific to your environment. You can increase this max length but you shouldn't lower it if you have data in the system that exceeds the lower value.

Whole Number

These columns store data as a number but include different presentation and validation options.

Expand table

Format	Description
Duration	A number value presented as a drop-down list that contains time intervals. A user can select a predefined value from the list or type an integer value using the format: "x minutes," "x hours" or "x days." Hours and days can be entered using decimals, for example, "1.2 hours" or "1.5 days." Minute values entered must be expressible in whole minutes. Entering a

Format	Description
	decimal to represent sub-minute values are rounded to the nearest minute. Timezone	A number value presented as a drop-down list that contains a list of time zones.
Language code	A number value presented as a drop-down list that contains a list of languages that have been enabled for the environment. If no other languages have been enabled, the base language will be the only option. The value saved is the Locale Identifier (LCID) value for the language.
None	No special formatting will be applied for the whole number column. This is the default format.

Date Time

Use these columns to store time values. You can store values as early as 1/1/1753 12:00 AM.

Expand table

Data type	Description
Date and Time	A date and time value.
Date Only	A date and time value that only displays a date. The time value is stored as 12:00 AM (00:00:00) in the system.

You can also set specific **Behavior** for Date Time columns in the **Advanced options**.

- **User local** : Displays values converted to in the current user's local time zone. This is the default for new columns.
- **Date only**: This behavior is available for the **Date Only** type. Displays values without time zone conversion. Use this for data like birthdays and anniversaries.
- **Time zone independent**: Displays values without time zone conversion.

More information: Behavior and format of the Date and Time column

Other Data types

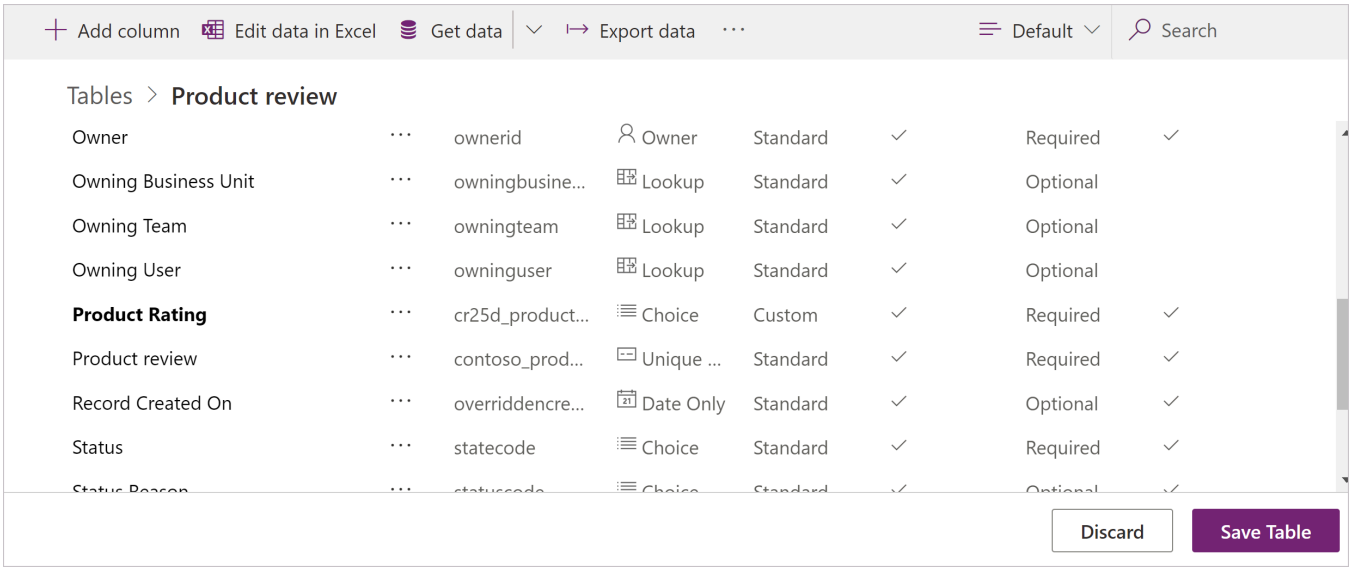
Expand table

Data type	Description
Currency	A money value for any currencies configured for the environment. You can set a level of precision or choose to base the precision on a specific currency or a single standard precision used by the organization. More information: Using currency columns
Decimal Number	A decimal value with up to 10 points of precision. More information: Using the right type of number
File	For storing binary data.
Floating Point Number	A floating point number with up to 5 points of precision. More information: Using the right type of number
Image	Displays a single image per row in the application. Each table can have one image column. The **Name** you enter when creating an image column is ignored. Image columns are always named 'tableImage'.
Lookup	Creates a reference to a single row for a single target row type.
Multi Select Choice	Displays a list of options where more than one can be selected.
Multiline Text	A text value intended to be displayed in a multi-line textbox. Limited to a maximum of 1,048,576 characters. You can also set a lower Max Length.
Choice	Displays a list of options where only one can be selected.
Yes/No	Displays Yes/No where only one can be selected. You choose which labels are displayed for each option. The default values are **Yes** and **No**.
Formula	Built on Power Fx, use a formula column to perform operations that return values during fetch operations. Formula columns use the Power Fx syntax that's similar to Office Excel. More information: Work with formula columns (preview)
Prompt	Prompt columns allow AI prompts to be defined and the generative AI results are stored in the table column. More information: Prompt columns

Save new column

Once you set the **Display Name**, **Name** and **Data type** properties you can select **Done** to close the **Column properties** panel.

You can continue to edit the table and add more columns or return and continue editing this column. The columns aren't created until you select **Save Table** to save all the changes to the table.



You can also select **Discard** to discard the changes you made.

Edit a column

While viewing columns, select the column, you want to edit. You can modify the **Display Name** but you can't change the **Name** and **Data type** if you saved changes to the table to add the column.

General properties

Every column has the following properties you can change:

Expand table

Property	Description
Required	A record can't be saved without data in this column. Note that required columns on a hidden tab or section don't block saving the record unless the same column is also in a visible tab or section on the same form. More information: Saving rows programmatically for required columns
Searchable	De-select this for columns for the table that you don't use. When a column is searchable, it appears in **Advanced Find** and is available when customizing views. Deselecting this reduces the number of options shown to people using advanced find.

Property	Description
Description	Found within **Advanced Options**. Enter instructions to the user about what the column is for. These descriptions appear as tooltips for the user in model-driven apps when they hover their mouse over the label of the column.

> ⓘ Note
>
> **Making columns required**: Be careful when you make columns required. People resist using the application if they can't save rows because they lack the correct information to enter into a required column. People might enter incorrect data simply to save the row and get on with their work.
>
> **Set requirement dynamically**: In model-driven apps you can use business rules or form scripts to change the requirement level as the data in the row changes as people work on it. More information: Create business rules and recommendations to apply logic in a form
>
> **Advanced Find availability**: Advanced Find is currently only available for model-driven apps using the Web Client. Advanced find isn't currently available in Unified Interface clients.

Searching and sorting columns

For information about columns that can't be enabled for searching or sorting, go to Searching and sorting columns.

Saving rows programmatically for required columns

When a row is saved programmatically using web services, only the `SystemRequired` columns are enforced. Failure to set a value for `SystemRequired` columns return an error. You can't set the `SystemRequired` level of requirement.

Setting a column to Business Required means that the default behavior of a model-driven or canvas app enforce this requirement in the app. The request isn't sent to the service if the column has no value. The app user is shown an error and prompted to add data to the required column before they can save the row. There are options within the app to override this behavior and allow operation to proceed if needed.

Calculated or Rollup

You can set a custom column to be a **Calculated** or a **Rollup** column. Columns that aren't calculated or rollup columns are sometimes referred to as *simple* columns.

Calculated

With a calculated column, you can enter a formula to assign a value to the column. These data types can be set to calculated columns: **Currency**, **Date and Time**, **Date Only**, **Decimal Number**, **Duration**, **Email**, **Language**, **Multi Select Option Set**, **Choice**, **Text**, **Text Area**, **Ticker Symbol**, **Timezone**, **Two Options**, **URL**, and **Whole Number**.

More information: Define calculated columns to automate manual calculations

Rollup

With a rollup column, you can set aggregation functions that run periodically to set a number value for the column. These data types can be set to calculated columns: **Currency**, **Date and Time**, **Date Only**, **Decimal Number**, **Duration**, **Language**, **Timezone**, and **Whole Number**.

More information: Define rollup columns that aggregate values

Number column options

Each type of number column has absolute minimum and maximum values. You can set appropriate **Minimum value** and **Maximum value** within these absolute values. Do this to have Dataverse validate the values for the data you want to store in the column.

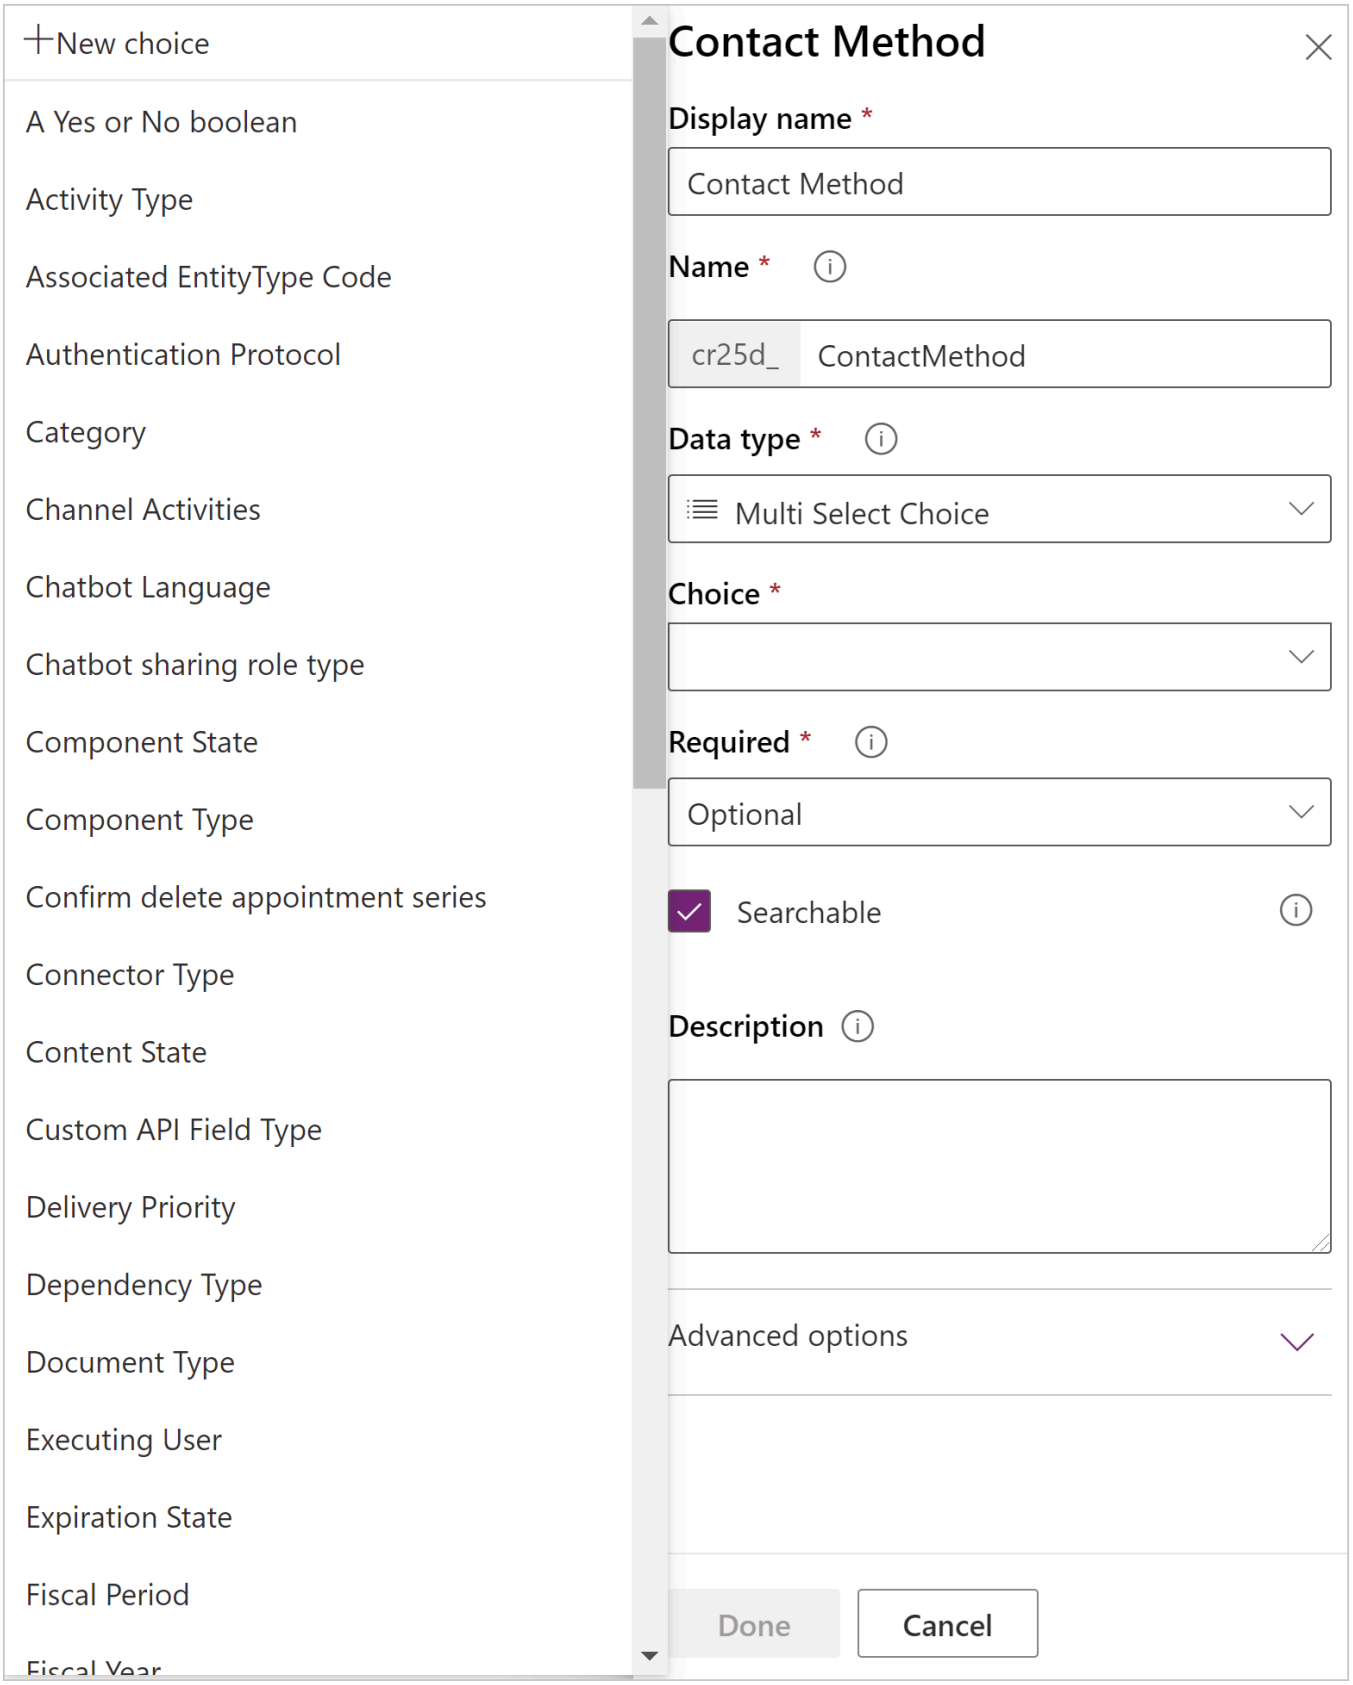
For **Floating Point Number** and **Decimal Number** data types, you can specify a number of **Decimal places**.

Choice column options

Columns that provide a set of options can include their own set of *local* options or refer to a common set of *global* options that can be used by multiple columns.

Using a global choice is valuable when you find yourself creating the same set of options for multiple columns. With a global choice, you only need to maintain the set of options in one place.

When you choose **Multi Select Choice** or **Choice** data type the designer lists a set of available global choices for you to choose from and provides the option to create a **New choice**.

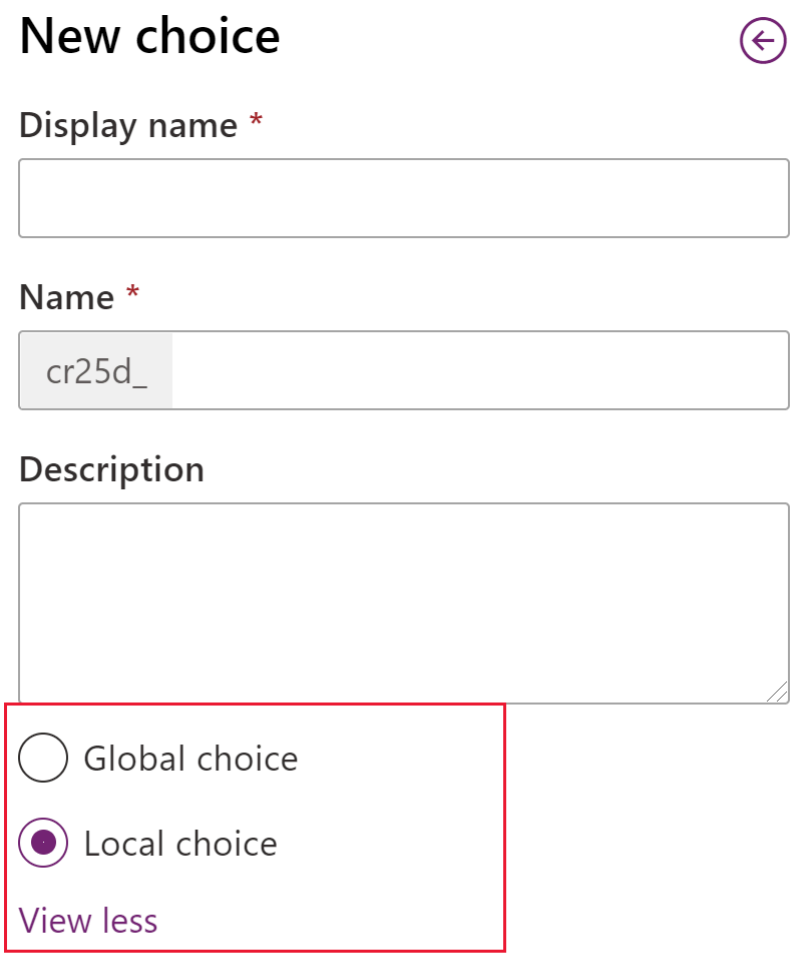


If you choose **New choice**, the default behavior is to create a new global choice.

> **Note**
>
> While you're editing options for a new global choice, the **Display name** and **Name** values are for the global choice rather than for the column. The default values match the column

values, but you can edit them while you edit the global choice to be different from the column you're currently creating.

If you want to create a local choice, you must select **View more** and choose **Local choice**.



Note

If you define every choice as a global choice, your list of global choices grows and could be difficult to manage. If you know that the set of options will only be used in one place, use a local choice.

Warning

If you remove an option which has been used by an entity record the data for that record will become invalid after you save your changes to the global option set.

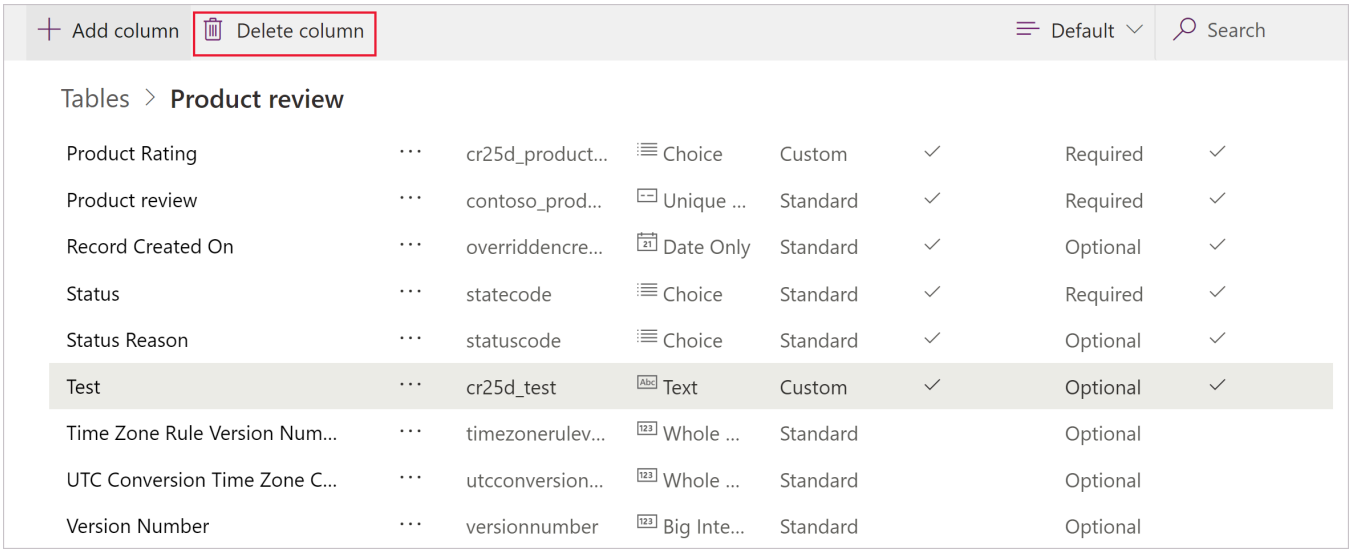
Before you remove an option that has been used, you should change the data in any entity record that uses that option to a valid value.

Delete a column

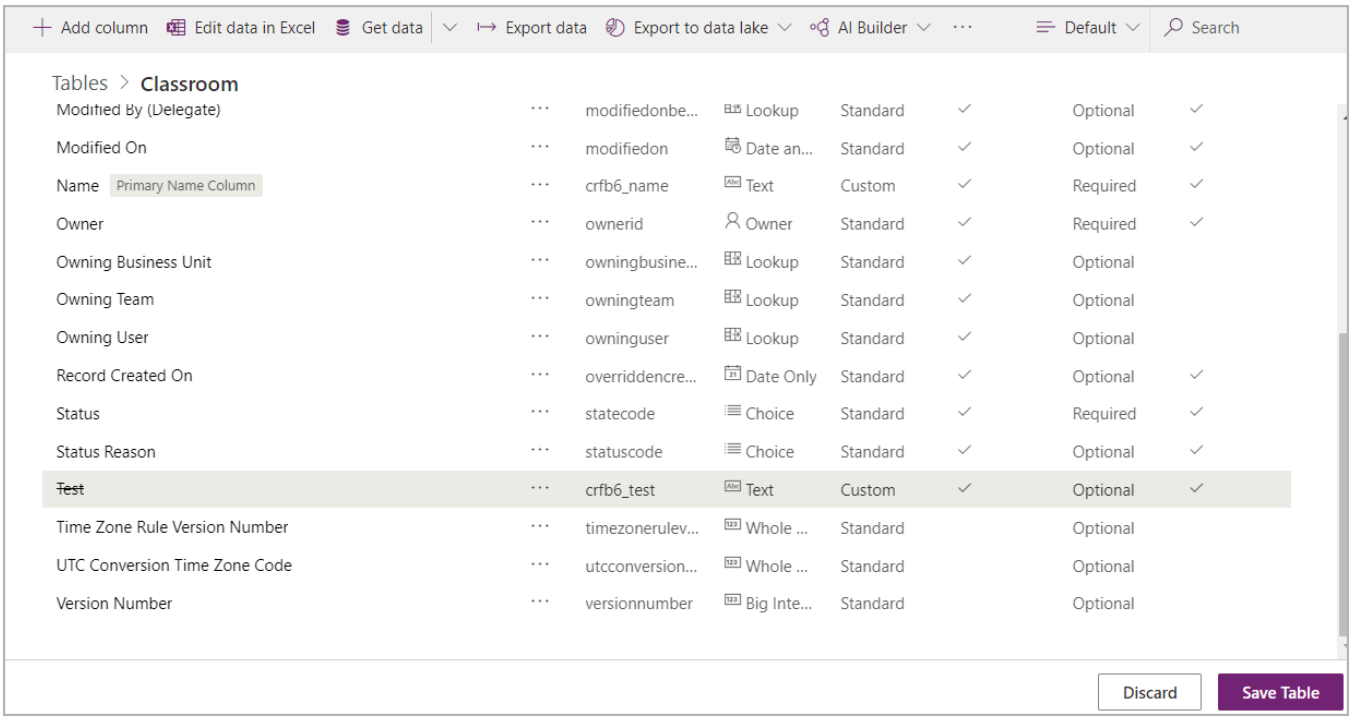
With the system administrator security role, you can delete any custom columns that aren't part of a managed solution. When you delete a column, any data stored in the column is lost. The only way to recover data from a column that was deleted is to restore the database from a point before the column was deleted.

> **Note**
>
> Before you can delete a custom column, you must remove any dependencies that might exist in other solution components.

While viewing columns, if you select a custom column that can be deleted in the list, the **Delete column** command appears and is enabled.



Use the **Delete column** command to delete the column. After deleting the column, you must save the changes to the table.



> **Note**
>
> If you get an error related to dependencies, you must use solution explorer to detect dependencies. More information: Check column dependencies

IME Mode

IME (input method editor) mode specifies how a physical keyboard can be used to enter characters for text columns. IMEs are tools provided by the operating system for composing text. They're commonly used to enter Chinese, Japanese, and Korean words. IME mode doesn't restrict the characters that users can enter. For example, when IME mode is disabled, users can still enter Japanese characters by pasting in a text input.

> **Important**
>
> IME Mode is used for backward compatibility with the legacy web client and the IME Mode settings described here don't apply to Unified Interface apps. Additionally, IME mode is supported only in Internet Explorer and partially supported in Firefox.

- **Active**: This value activates the IME initially. You can deactivate it later if desired. This is the default IME setting.
- **Auto**: When IME mode is auto, Power Apps won't interfere with the IME.
- **Disabled**: Disable IME mode to bypass the IME. This can be useful for entering alphanumeric characters in certain languages.

- **Inactive**: Power Apps will deactivate the IME initially. You can activate it later if desired.

Create and edit columns for Microsoft Dataverse using Power Apps solution explorer

Article • 04/01/2025

Solution explorer provides one way to create and edit columns for Dataverse.

The Power Apps portal enables configuring the most common options, but certain options can only be set using solution explorer.
More information:

- Create and edit columns for Dataverse
- Create and edit columns for Dataverse using Power Apps portal

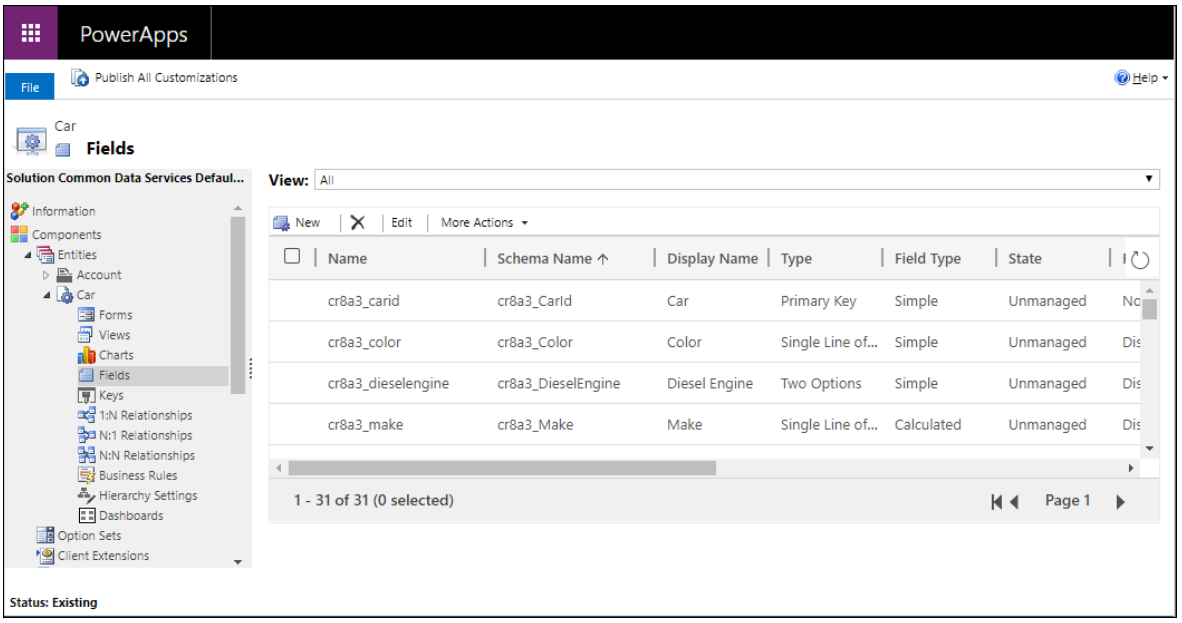
Part of the name of any custom column you create is the customization prefix. This is set based on the solution publisher for the solution you're working in. Make sure that you're working in an unmanaged solution where the customization prefix is the one you want for this table. More information: Change the solution publisher prefix

View columns

1. From Power Apps, select **Solutions** on the left navigation pane, and then on the toolbar select **...** > **Switch to classic**.

2. Open the unmanaged solution where you want to view a column. The classic solution explorer opens in a new browser window.

3. In the classic solution explorer, under **Components** expand **Entities**, expand the table where you want to view columns, and then select **Fields**.



In the **View** drop down list you can select one of the following views:

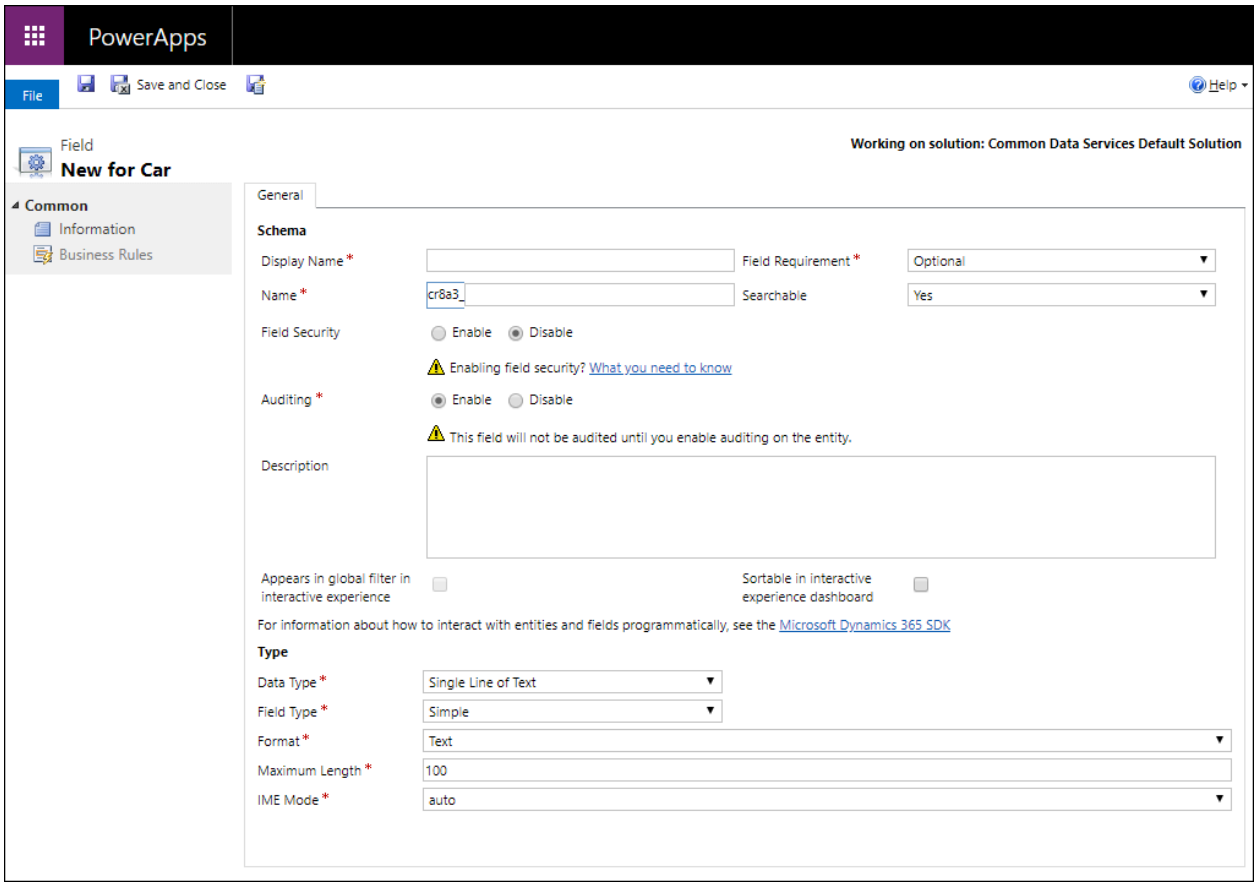
Expand table

View	Description
All	Shows all the columns for the table
Custom	Shows only custom columns for the table
Customizable	Shows only the columns that can be edited

Create a column

While viewing columns, in the command bar, select **New** which opens the new column form. Some standard tables or custom tables that are included in a managed solution might not allow you to add new columns.

> **Note**
>
> For model-driven apps, you can also create a new column from the form editor. In the form editor, below the **Column Explorer** select **New Column** to create a new column. More information: Add, configure, move, or delete columns on a form



You must enter data and confirm default values set for the following properties before you save.

Expand table

Property	Description
Display Name	The text to be displayed for the column in the user interface. You can change this after you save, but the value you enter will generate a value for the **Name** column.
Column Requirement	Whether data is required in the column to save the row. More information: Column Requirement options
Name	The unique name across your environment. A name is generated for you based on the display name that you've entered, but you can edit it before saving. Once a column is created the name can't be changed as it might be referenced in your applications or code. The name has the customization prefix for the current solution's publisher prepended to it.
Searchable	Set this to **No** for columns for the table that you don't use. When a column is searchable, it appears in **Advanced Find** in model-driven apps and is available when customizing views. Deselecting this reduces the number of options shown to people using advanced find.
Column Security	Whether the data in the column is secured at a higher level than the table. More information: Column level security to control access

Property	Description
Auditing	Whether data for this column is audited when the table is enabled for auditing. More information: Manage Dataverse auditing
Description	Enter instructions to the user about what the column is for. These descriptions appear as tooltips for the user in model-driven apps when they hover their mouse over the label of the column.
Appears in global filter in interactive experience	More information: Configure interactive experience dashboards
Sortable in interactive experience dashboard	More information: Configure interactive experience dashboards
Data type	Controls how values are stored as well as how they're formatted in some applications. Once a column is saved, you can't change the data type as it might impact the data in your table. More information: Column Data types
Column type	Whether the column is **Simple**, **Calculated**, or **Rollup**. More information: Column Type
Format	How the column is formatted. The available formatting options depend on the **Data type**.

You can set additional options depending on your choice of **Data type**. More information: Column Data types

Column Requirement options

There are three column requirement options:

- **Optional**: The row can be saved even if there's no data in this column.
- **Business Recommended**: The row can be saved even if there's no data in this column. However, a blue symbol appears next to the column to indicate it's important.
- **Business Required**: The row can't be saved if there's no data in this column.

> ⓘ Note
>
> - When a row is saved programmatically using web services, only the SystemRequired columns are enforced. Failure to set a value for SystemRequired columns return an error. You can't set the SystemRequired

level of requirement.

Setting a column to Business Required means that the default behavior of a model-driven or canvas app will enforce this requirement in the app. The request won't be sent to the service if the column has no value. The app user is shown an error and prompted to add data to the required column before they can save the row. There are options within the app to override this behavior and allow operation to proceed if needed.

- Be careful when you make columns business required. People will resist using the application if they can't save rows because they lack the correct information to enter into a required column. People might enter incorrect data simply to save the row and get on with their work. You can use business rules or form scripts to change the requirement level as the data in the row changes as people work on it. More information Create business rules and recommendations to apply logic in a form

Column Data types

There are many different types of columns, but you can only create some of them. For more information about all types of columns, see Types of columns and column data types.

When you create a column, **Data type** provides the following choices:

Expand table

Option	Description
Single Line of Text	This column can contain up to 4,000 text characters. You can set a maximum length to be less than this. This column has several format options that change the presentation of the text. More information: Single line of text options
Choice	Displays a list of options where one can be selected. More information: Choice column options
MultiSelect Choice	Displays a list of options where more than one can be selected. More information: Choice column options
Yes/No	Displays a list of options where one of two can be selected. Yes/No columns don't provide format options at the column level. But when you add one to the form you can choose to display them as radio buttons, a check box, or a select list.

Option	Description
Image	Displays a single image per row in the application. Each table can have one image column. Image columns are always named `tableImage`.
Whole Number	Integers with a value between -2,147,483,648 and 2,147,483,647 can be in this column. This column has options that change depending on how the column is presented. More information: Whole number options
Floating Point Number	Up to 5 decimal points of precision can be used for values between -100,000,000,000 and -100,000,000,000 can be in this column. You can specify the level of precision and the maximum and minimum values. More information: Using the right type of number
Decimal Number	Up to 10 decimal points of precision can be used for values between -100,000,000,000 and -100,000,000,000 can be in this column. You can specify the level of precision and the maximum and minimum values. More information: Using the right type of number
Currency	Monetary values between -922,337,203,685,477 and 922,337,203,685,477 can be in this column. You can set a level of precision or choose to base the precision on a specific currency or a single standard precision used by the organization. More information: Using currency columns
Multiple Lines of Text	This column can contain up to 1,048,576 text characters. You can set the maximum length to be less than this. When you add this column to a model-driven app form, you can specify the dimensions of the column.
Date and Time	Use these columns to store time values. You can store values as early as 1/1/1753 12:00 AM. More information: Date and Time options
Lookup	A column that allows setting a reference to a single row of a specific type of table. Some system lookup columns behave differently. More information: Different types of lookups
Customer	A lookup column that you can use to specify a customer, which can be an account or contact. More information: Different types of lookups

Single line of text options

The single line of text data type has the following format options:

Expand table

Format	Description
Text	A text value intended to be displayed in a single-line textbox.

Format	Description
Text Area	A text value intended to be displayed in a multi-line textbox. If you require more than 4,000 characters, use a **Multiple Lines of Text** data type.
Email	A text value validated as an e-mail address and rendered as a mailto link in the column.
URL	A text value validated as a URL and rendered as a link to open the URL.
Ticker Symbol	A text value for a ticker symbol that displays a link that opens to show a quote for the stock ticker symbol.
Phone	A text value validated as a phone number rendered as link to initiate a phone call by using Skype.

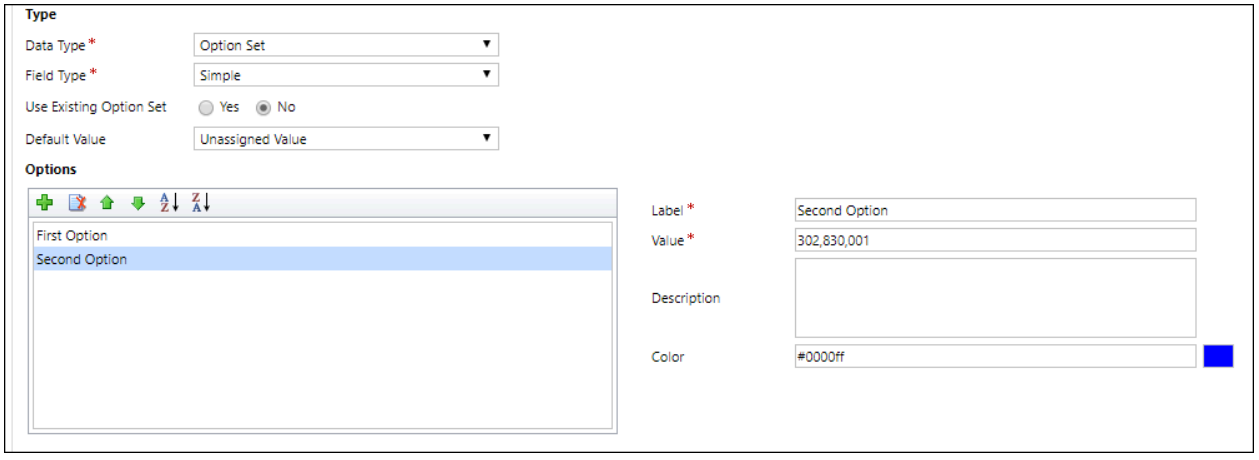
You can also set a **Maximum length** to so that the system won't allow text values longer than you specify.

Choice column options

Columns that provide a set of options can include their own set of *local* options or refer to a common set of *global* options that can be used by multiple columns.

Using a global choice is valuable when you find yourself creating the same set of options for multiple columns. With a global choice, you only need to maintain the set of options in one place.

When you choose **Multi Select Choice** or **Choice** data type the solution explorer designer will provide the option for a local choice by default.



Configure local choices

To define options, in the **Options** area click ✚ to add an option.

For each option you can add the following property values

Expand table

Property	Description
Label	The localizable text for the option.
Value	The number value for the option. This is prefixed with a value defined in the solution publisher for the solution you are working in. This prefix helps ensure that the value will be different from option values that can be defined in another solution and imported into your environment.
External Value	This value is used for virtual entities to map a value in an external data source with this option.
Description	A place to record the purpose for this option. This value is not displayed to application users.
Color	Specifies a color to use in charts for this option. **Tip**: Use a site like w3schools.com HTML Color Picker to find the hex code values for colors.

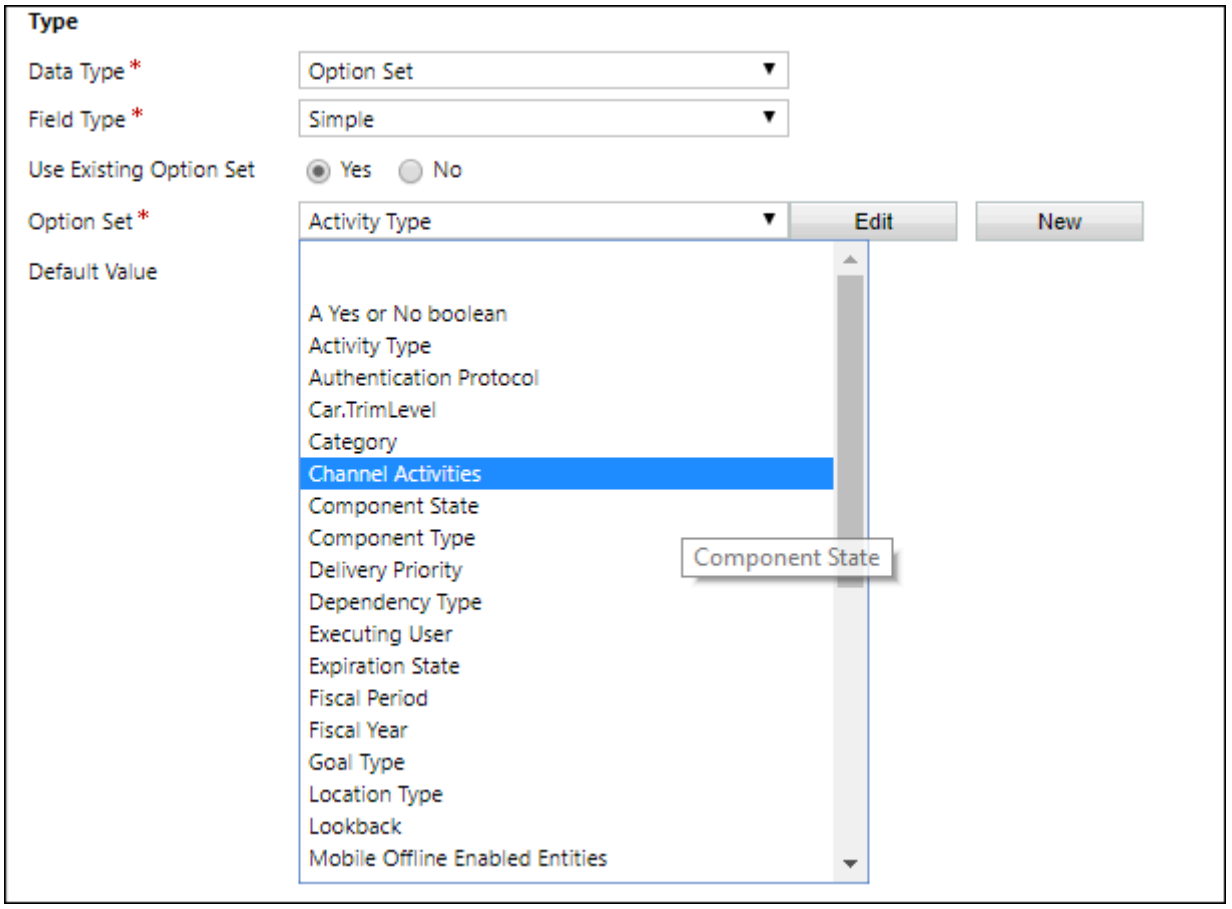
Use the other icons in the options toolbar to perform the following operations:

Expand table

Icon	Operation
	Remove the selected option
	Move the selected option up
	Move the selected option down
	Sort the options by label in ascending order
	Sort the options by label in descending order

Use Existing Choice

If you to choose **Use Existing Option Set** the designer displays a list of existing *global choices* and include an **Edit** and **New** buttons to configure the global choices that this column should use.



You can also configure global choices separately. More information: Create and edit global choices for Dataverse (picklists)

> **Note**
>
> If you define every choice as a global choice your list of global choices will grow and could be difficult to manage. If you know that the set of options will only be used in one place, use a local choice.

Whole number choices

Whole number columns have the following format choices:

Expand table

Format	Description
None	A number value presented in a text box.
Duration	A number value presented as a drop-down list that contains time intervals. A user can select a value from the list or type an integer value that represents the number of minutes.

Format	Description
Timezone	A number value presented as a drop-down list that contains a list of time zones.
Language	A number value presented as a drop-down list that contains a list of languages that have been enabled for the environment. If no other languages have been enabled, the base language is the only option. The value saved is the Locale Identifier (LCID) value for the language.

You can also restrict the maximum or minimum allowed values.

Date and Time options

Date and Time columns have the following options:

Expand table

Format	Description
Date and Time	A date and time value.
Date Only	A date and time value that only displays a date. The time value is stored as 12:00 AM (00:00:00) in the system.

You can also set specific **Behavior** for Date Time columns in the **Advanced options**.

- **User local** : Displays values converted to in the current user's local time zone. This is the default for new columns.
- **Date only**: This behavior is available for the **Date Only** type. Displays values without time zone conversion. Use this for data like birthdays and anniversaries.
- **Time zone independent**: Displays values without time zone conversion.

More information: Behavior and format of the Date and Time column

Column type

You can set a custom column **Field Type** to be a **Simple**, **Calculated**, or a **Rollup** column.

Simple

Simple means that the column isn't a calculated or rollup column.

Calculated

With a calculated column you can enter a formula to assign a value to the column. These data types can be set to calculated columns: **Currency**, **Date and Time**, **Decimal Number**, **Multi Select Choice**, **Choice**, **Single line of text**, **Yes/No**, and **Whole Number**.

More information: Define calculated columns to automate manual calculations

Rollup

With a rollup column, you can set aggregation functions that run periodically to set a number value for the column. These data types can be set to calculated columns: **Currency**, **Date and Time**, **Decimal Number**, and **Whole Number**.

More information: Define rollup columns that aggregate values

Save new column

Once you have configured the column, use one of three commands in the command bar:

Expand table

Command	Description
Save	Save the column definition and leave the form window open.
Save and Close	Save the column definition and close the window.
Save Create New	Save the column definition and open a new form to create a new column.

Edit a column

While viewing columns, select the column you want to edit. Some standard columns or custom columns that are included in a managed solution might not allow you to edit them.

> **Note**
>
> When editing a form, for any column already added to the form you can double-click the column to display the **Column Properties**. On the **Details** tab, select **Edit**. More information: Add, configure, move, or delete columns on a form

After you make changes to a column, you must publish customizations.

- To publish your changes for one table, under **Components**, select **Tables**, and then select the table that you made changes to. On the **Actions** toolbar, select **Publish**.
- To publish all changes you have made to multiple tables or components, on the **Actions** toolbar, select **Publish All Customizations**.

> **Note**
>
> Installing a solution or publishing customizations can interfere with normal system operation. We recommend that you schedule a solution to be published when it's least disruptive to users.

Edit multiple columns

To edit one or more columns, select the column or columns (using the Shift key) you want to modify and then on the **Actions** toolbar, select **Edit**.

When you select multiple columns to edit, the **Edit Multiple Columns** dialog box appears. You can edit **Column Requirement**, **Searchable**, and **Auditing**.

Delete a column

With the system administrator security role, you can delete any custom columns that aren't part of a managed solution. When you delete a column, any data stored in the column is lost. The only way to recover data from a column that was deleted is to restore the database from a point before the column was deleted.

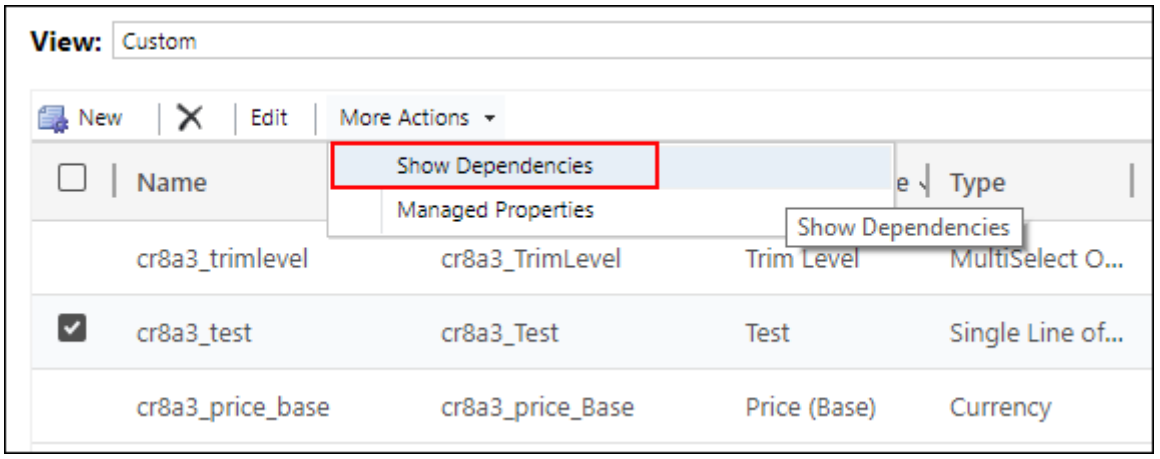
> **Note**
>
> Before you can delete a custom column, you must remove any dependencies that might exist in other solution components.

1. While viewing columns, select a custom column that can be deleted in the list and select the ✕ button in the command bar.
2. In the **Confirm Deletion** dialog, select **Delete**.

> **Tip**
>
> You can select multiple custom columns to be deleted in one operation.

Check column dependencies

Select the column in the list. In the **More Actions** menu, select **Show Dependencies**.



Dependencies are any related use of the column that would prevent it from being deleted. For example, if the column is used in a form or view, you must first remove references to the column in those solution components.

If you delete a lookup column, the 1:N table relationship for it will automatically be deleted.

IME Mode

IME (input method editor) mode specifies how a physical keyboard can be used to enter characters for text columns. IMEs are tools provided by the operating system for composing text. They're commonly used to enter Chinese, Japanese, and Korean words. IME mode doesn't restrict the characters that users can enter. For example, when IME mode is disabled, users can still enter Japanese characters by pasting in a text input.

> **ⓘ Important**
>
> IME Mode is used for backward compatibility with the legacy web client and the IME Mode settings described here don’t apply to Unified Interface apps. Additionally, IME mode is supported only in Internet Explorer and partially supported in Firefox.

- **Active**: This value activates the IME initially. You can deactivate it later if desired. This is the default IME setting.
- **Auto**: When IME mode is auto, Power Apps won't interfere with the IME.
- **Disabled**: Disable IME mode to bypass the IME. This can be useful for entering alphanumeric characters in certain languages.

- **Inactive**: Power Apps deactivates the IME initially. You can activate it later if desired.

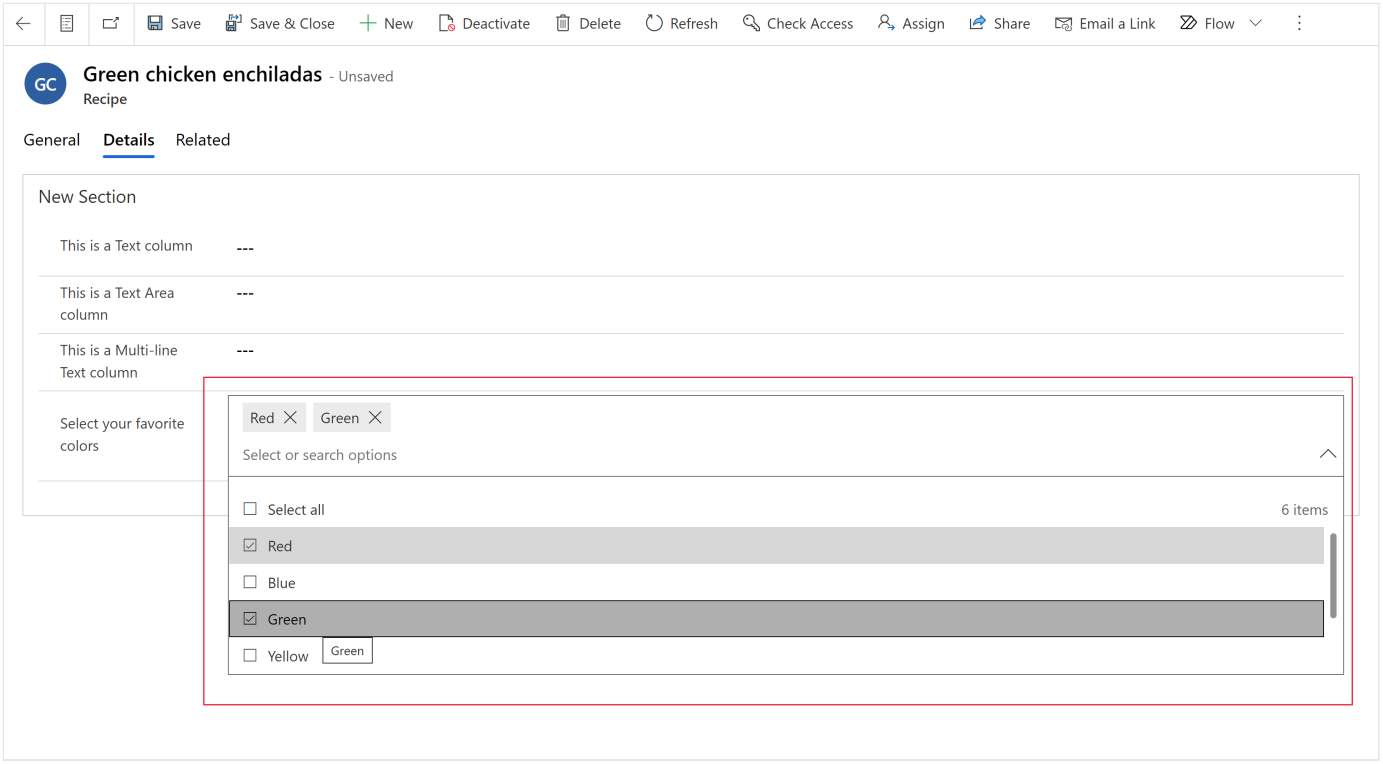
Create a choice

Choice columns allow you to include dropdown lists of fixed values to a user within your app to ensure data consistency. Choice columns were formerly referred to as option sets and are sometimes called picklists. Similar to tables, there are both standard choices or makers have the ability to create custom choice columns to use in apps.

Choices can be created while working from a solution in Power Apps (make.powerapps.com) or on a table form in the form designer.

Choice columns can be single selection only (choice) or can allow multi-selection (choices). The following screenshot shows a multi-select choices column in a model-driven app.



Choices are either global or local. You can define a choice to use a set of options defined elsewhere (globally), which can be made available to other choice columns, or define a set of options only available within the choice column (locally). More information: Create and edit choice columns overview

Create a global choice within a solution

1. Sign into powerapps.com select **Solutions**, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. On the command bar, select **New** > **Choice**.

3. Enter the following properties:

   - **Display name**. Enter the **Display name** for your column. The **Display name** is used when presenting this column to your users.
   - In the **Label** field, enter the label you want displayed for the choice option.
   - The **Value** number represents a unique value for the option and isn't displayed in the choice column in an app. Notice there's a number generated for each **Value** automatically. We recommend that you not change this. Having a unique **Value** helps ensure that the value will be different from other option values that might be defined in other solutions and imported into your environment.
   - Select the color picker to the left of the **Label** if you want a color to appear for the option in model-driven app charts.
   - Select the three vertical dots > **Additional properties** to set the following properties:
     - **Description**. Add a description for the option.
     - **External value**. This value is used for virtual tables to map a value in an external data source with this option.
     - **Hidden**. Hide the option from the choice column at runtime in apps. For more information about the limitations of this property, go to Choice hidden property limitations.

     > **⊗ Caution**
     >
     > The Hidden property should never be used as a secure way to prevent users from viewing or editing column values. These properties only apply to app components such as model-driven app forms and views but don't have an effect on a user's data privileges. When a column is hidden, users can still access column data in other ways, such as by making Web API calls. To secure columns, use column-level security to control access.

4. Select **New choice** to create another option for the choice.
5. Repeat the previous step until you have the options you want for the choice.
6. Expand **Advanced options** to display additional properties:

   - **Name**. Unique name of the global choice including the solution publisher prefix.
   - **External type name**. This value is used for virtual tables to map a value in an external data source with this choice.
   - **Description**. Enter an optional description for the choice column.

7. Select **Save**.

> **Important**
>
> Global choices can't be directly added to an app. After you create a global choice column the options from the choice can be made available when you create a local choice column. Local choice columns are table specific and can then be used with forms and views in an app.

Create a local choice to use in forms and views

Create a local choice column for a table that can be used in forms and views within a solution.

1. Sign into powerapps.com select **Solutions**, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the table where you want to create the local choice, and then on the command bar, select **New** > **Choice**.
3. In the **New column** panel, enter properties for the choice column.

Configure properties for a local choice

- **Display name**. Enter the **Display name** for your column. The **Display name** is used when presenting this column to your users.
- **Description**. Enter an optional description of the choice column.
- **Data type**. Select **Choice** > **Choice**. Select **Choice** > **Yes/No** if you want a two option single select choice field.
- **Behavior**. Select calculated to enable the column to be included in calculated columns to automate manual calculations.
- **Required**. Set this value to **Business required** to make it so a record can't be saved without data in this column.
- **Searchable**. When selected, this column appears in Advanced Find and is available when customizing views.
- **Selecting multiple choices is allowed**. Select this option if you want to create a choice where the user can select more than one option (multi-select).
- **Sync with global choice?**
  - **Yes**. Select this option if you want the local choice to have the ability to use options from a global choice. Then, you can also select an existing global choice to use the options

from that global choice.
    - **No**. Select this option if you don't want the choice to have the ability to use options from a global choice.
    - **Sync this choice with**. When **Sync with global choice** is **Yes**, you can select an existing choice column. Then, the options configured for that choice can be used for this choice.
    - If you chose **No** to enable a global choice, create the options for your choice by selecting **Choices** or, if you chose **Yes**, select **Edit choice** to edit the sync choice options or **New choice** to add new options:
    - In the **Label** field, enter the label you want displayed for the choice option.
    - The **Value** number represents a unique value for the option and isn't displayed in the choice column in an app. Notice there's a number generated for each **Value** automatically. We recommend that you not change this. Having a unique **Value** helps ensure that the value will be different from other option values that might be defined in other solutions and imported into your environment.
    - Select the color picker to the left of the **Label** if you want a color to appear for the option in model-driven app charts.
- **Default choice**. Select one of the options you created as the default choice.
- **Schema name**. This is the unique name used by the system and is automatically generated based on the display name and solution publisher prefix. After a new choice column is saved, you can't change this.
- **Enable column security**. Select this option to secure the data in the column beyond the security defined for the table.
- **Enable auditing.** If auditing has been enabled in the environment, this column can be included in change tracking.
- **Appears in dashboard's global filter**. Select this option to allow column to be available as a filter in interactive dashboards.
- **Sortable**. Select this option to allow sorting of this column when used in interactive dashboards.

Select **Save**.

Now the local choice column appears in the form and view designers to add for the table.

Create and edit global choices using the classic solution explorer

For information about how to create and edit global choices using the classic solution explorer, go to Create or edit a global option set (on-premises).

Choice hidden property limitations

- The choice column hidden property is only applicable for model-driven apps. Other components that use Microsoft Dataverse tables, such as canvas apps, don't use the choice column hidden property.
- The choice column hidden property only works for app with the modern, refreshed look for model-driven apps enabled.
- The choice column hidden property isn't currently supported for multi-select choices even when the **Selecting multiple choices is allowed** option is selected.
- The hidden property *only hides the option label and value when displayed in a model-driven app*. Even when hidden, choice labels and values can be viewed and set by accessing the Dataverse table directly, such as from make.powerapps.com. Hidden options can also be set using the setValue client API method.

Automate calculations by defining calculated columns

Article • 05/22/2024

Use calculated columns to automate otherwise manual calculations used in your business processes.

For example, a salesperson might want to know the weighted revenue for an opportunity, which is based on the estimated revenue from an opportunity multiplied by the probability. Or, they want to automatically apply a discount, if an order is greater than $500. A calculated column can contain values resulting from simple math operations, or conditional operations, such as greater than or if-else, and many others.

Capabilities

- Calculated columns use the columns from the current table or related parent tables.
- The expression support is available on the current table and the related parent table columns in the **Condition** sections and the **Action** sections. The built-in functions include:
  ADDHOURS, **ADDDAYS**, **ADDWEEKS**, **ADDMONTHS**, **ADDYEARS**, **SUBTRACTHOURS**, **SUBTRACTDAYS**, **SUBTRACTWEEKS**, **SUBTRACTMONTHS**, **SUBTRACTYEARS**, **DIFFINDAYS**, **DIFFINHOURS**, **DIFFINMINUTES**, **DIFFINMONTHS**, **DIFFINWEEKS**, **DIFFINYEARS**, **CONCAT**, **TRIMLEFT**, and **TRIMRIGHT**. Learn more in Functions syntax.
- A rich conditional support provides branching and multiple conditions. The logical operations include **AND** and **OR** operators.
- The visual editing capabilities include modern user interface and intellisense in the **ACTION** section.
- A seamless integration of the calculated columns with the forms, views, charts, and reports are available in real time.
- You can configure calculated columns to use custom controls.

Scenarios

- **Weighted Revenue**: Estimated revenue multiplied by probability
- **Net Worth**: Assets subtracted by the liabilities for a given account
- **Cost of Labor**: Base rate up to 40 hours, plus more overtime
- **Contact Number**: Phone number for an opportunity based on account or contact

- **Lead Score**: Single column that provides insights to the quality of a given lead
- **Follow Up By**: Follow up on an activity by a specified number of days based on priority

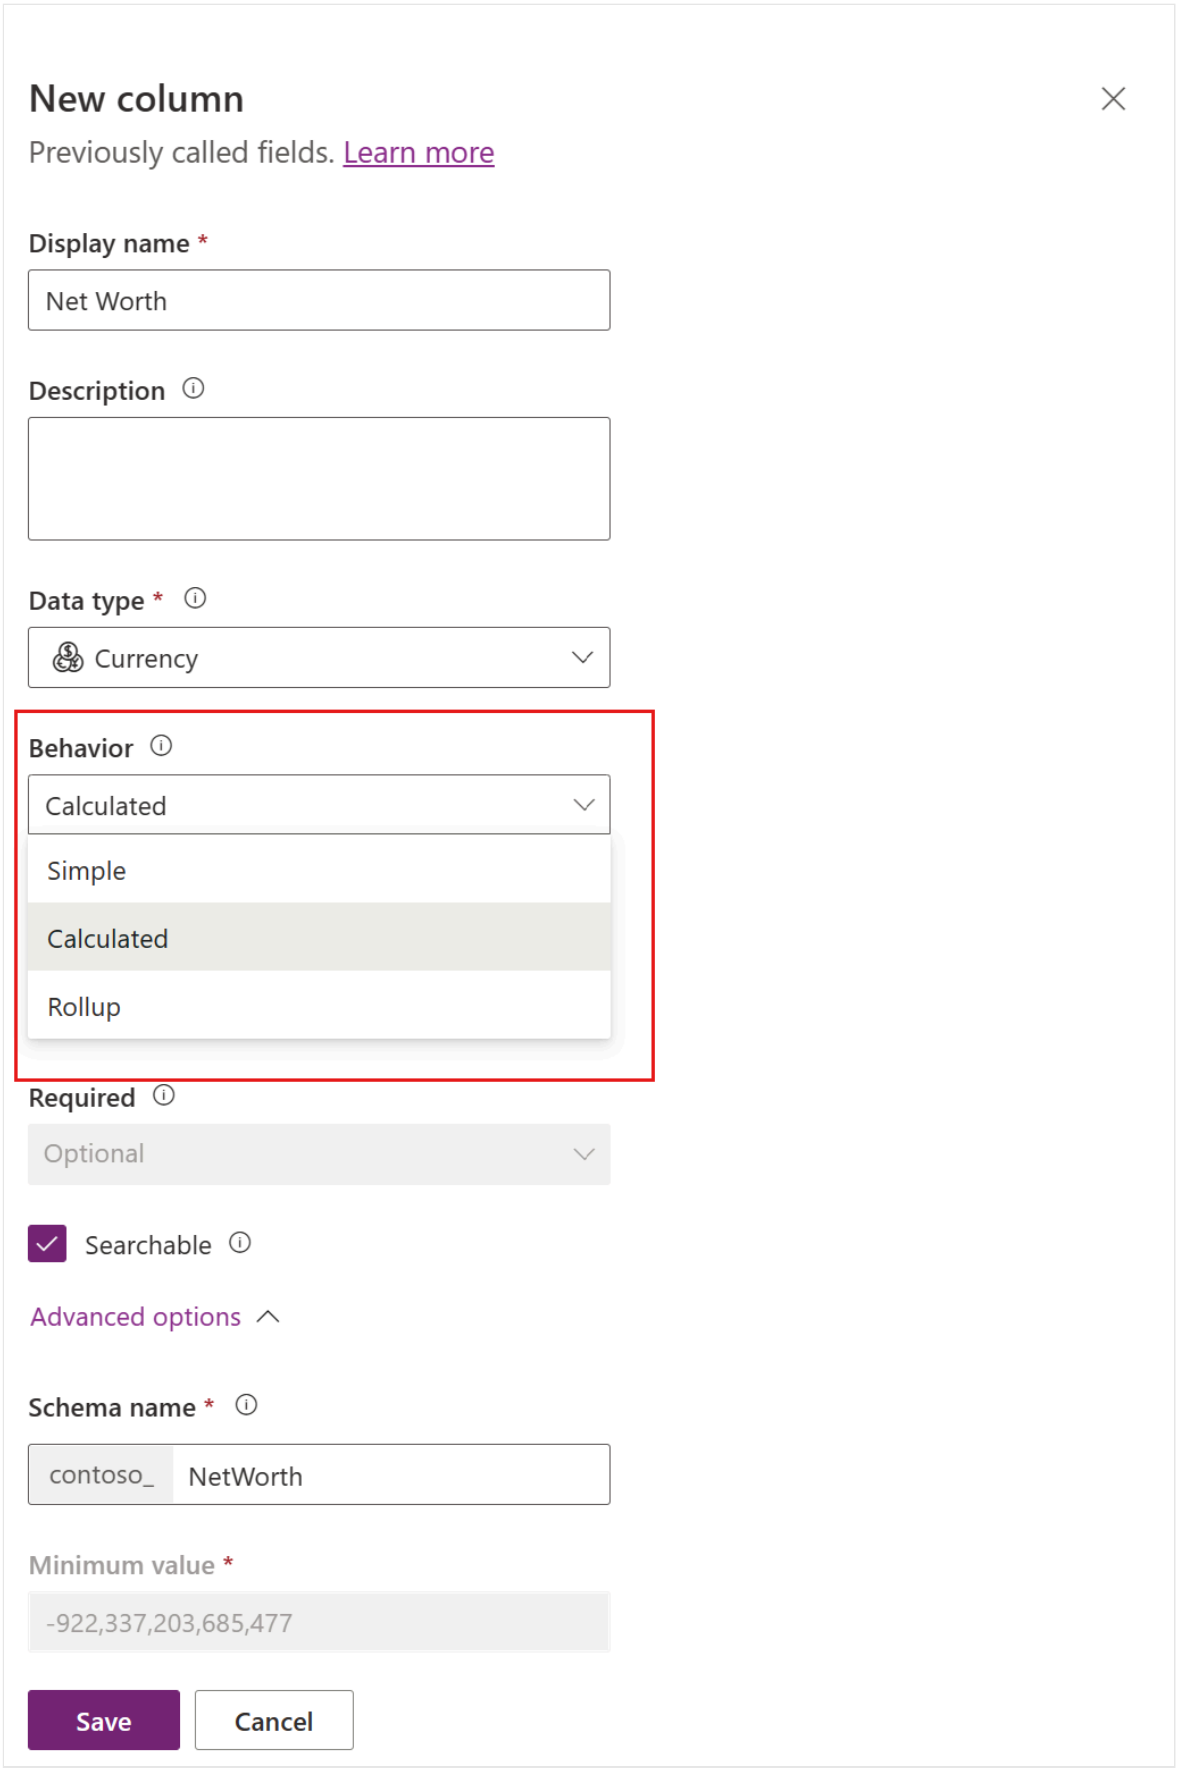
> **Important**
>
> To create a calculated column, you must have the **Write** privilege on the Field Security Profile table. If the calculated column uses the secured columns in a calculation, you should consider securing the calculated column as well, to prevent users from accessing data for which they don't have sufficient permissions. The calculated column editor gives you a warning if you're creating a calculated column that uses secured columns in a calculation, suggesting you secure the calculated column. More information: Column level security to control access.

Column types that support calculations

- Text
- Choice
- Yes/No
- Whole Number
- Decimal Number
- Currency
- Date Time

Create a calculated column

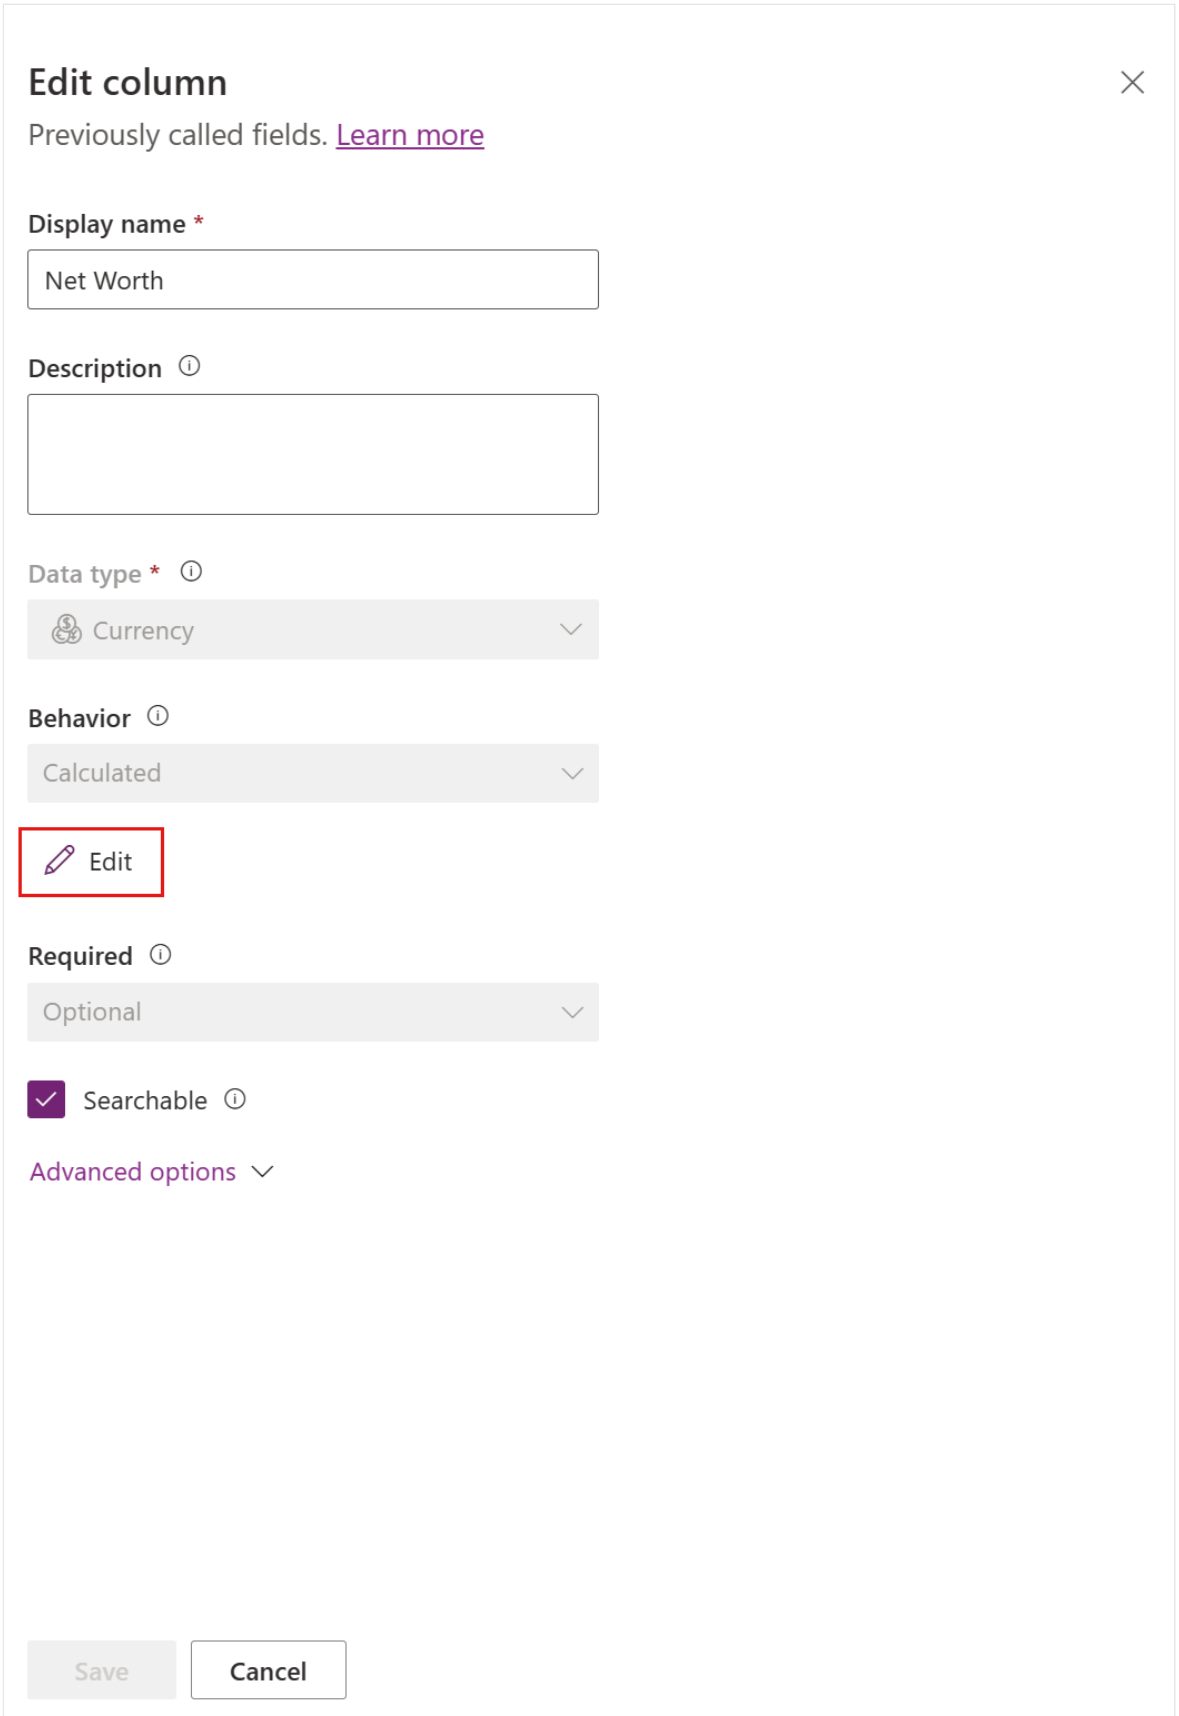
1. Sign into Power Apps
2. Select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Open the unmanaged solution that has the table you want.
4. Select the **Columns** area, and then select **New column** on the command bar.
5. Provide the information for the column, including the **Display name**, **Name**, and **Data type**.
6. If the data type is one of the column types that support calculations, you can make the column a calculated column by selecting **Calculated** from the **Behavior** dropdown list.



7. The **Save and edit** link appears under the dropdown list. Select it.

8. The new column is saved. In the **Columns** list, open the column that you saved in the previous step.

9. On the **Edit column** pane, under the **Behavior** dropdown list, select **Edit**.



10. In the calculated column definition editor, notice that the new calculated column is created, but no formula is set. The calculated column definition consists of two

sections: **CONDITION** and **ACTION**.

a. In the **Condition** section, select **Add condition** to specify a table, column, operator, type, and value. In the dropdown box for the **Table**, you can choose a current table or a related table. In the **Column** dropdown box, you have a selection of all available columns for the table. Depending on the operator you choose, you might need to provide type and value. You can specify multiple conditions using the `AND` or `OR` operators. When you're finished specifying the condition, select the check mark.
b. After you specified the condition, in the **Action** section, select **Add action** to provide the formula for the calculated column. When you're finished specifying the action, select the check mark.

> **Note**
>
> You can use data from Lookup rows within your Action. You first have to select the Lookup column and then type a period. After that, you can select one of the columns available on the related table. For example, with `<LookupFieldName>.<RelatedFieldName>`, you can select: `ParentAccountId.AccountNumber`.
>
> Column level security is ignored on the related table, so if there's sensitive data in the accessed column, secure your calculated column as well.

11. In the calculated column definition editor, select **Save and Close**.

Examples

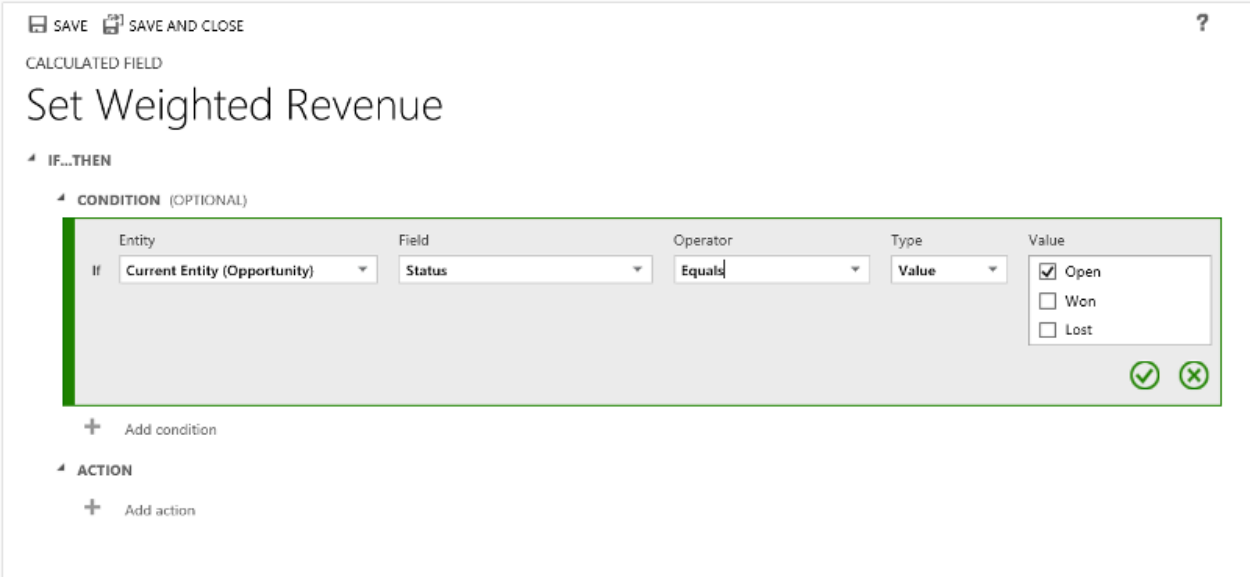
Let's take a look at calculated column examples in more detail.

Weighted revenue of opportunity

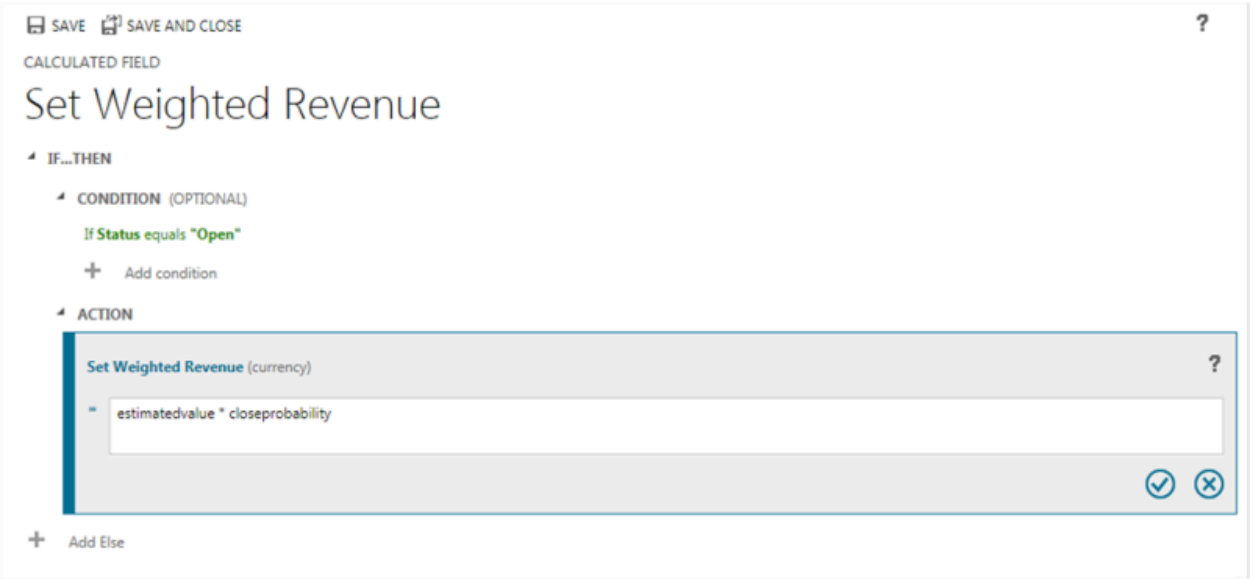
In this example, we're using the columns of the opportunity table to calculate the weighted revenue based on the opportunity's probability. In the column editor for an opportunity table, we create a column called **Weighted Revenue** and specify the column type as **Calculated** and the data type is **Currency**.

In the calculated column definition editor, in the **Condition** section, we specify the opportunity with the Status = Open. In the **ACTION**, the formula calculates the weighted revenue based on the opportunity estimated revenue multiplied by the probability of the opportunity. The following screenshots show step by step how to define the **Weighted Revenue** calculated column.

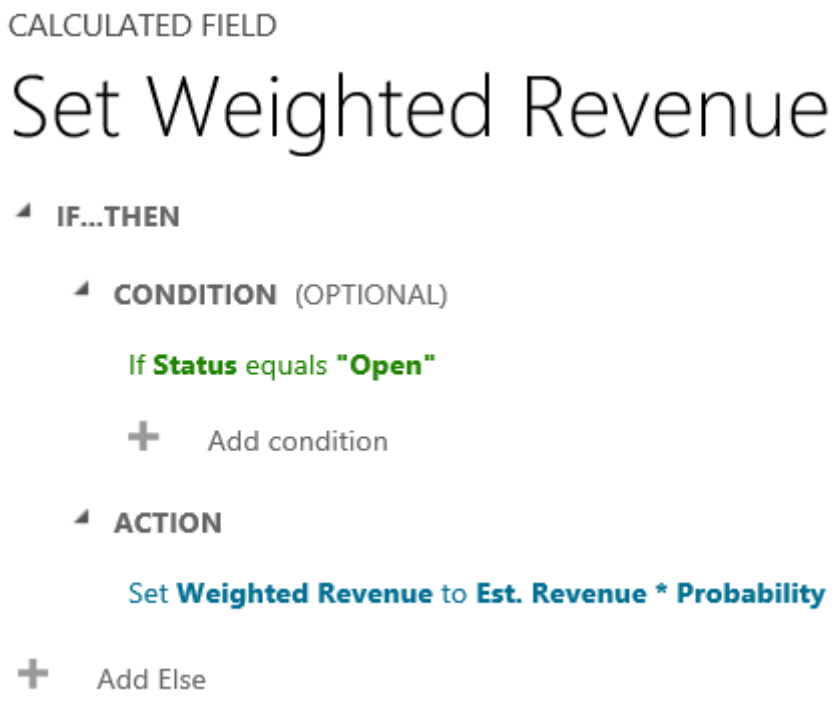
Set the condition on the opportunities:



Provide the formula for the weighted revenue:



Altogether:



Follow up date of opportunity

In this example, we're using the columns of the originated lead of an opportunity to calculate the appropriate date when to follow up on the opportunity.

In the column editor for an opportunity table, we create a column called **Follow-up date** and specify the type as **Calculated** and the data type is **Date and Time**.

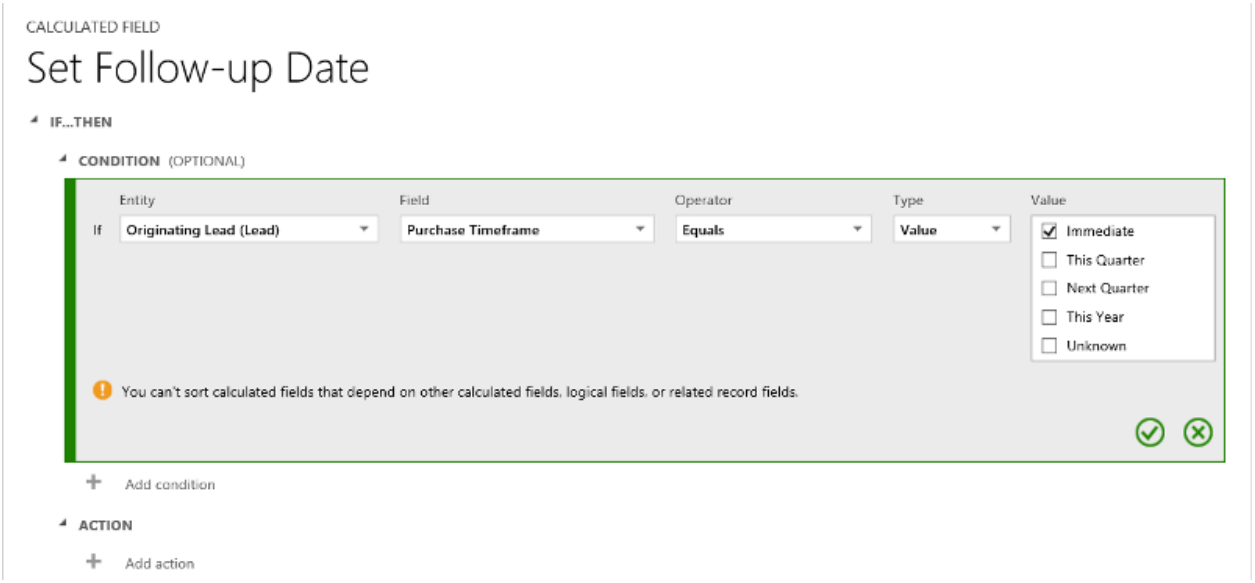
In the calculated column definition editor, in the **Condition** section, we specify two conditions the purchase time frame and the estimated value of the lead.

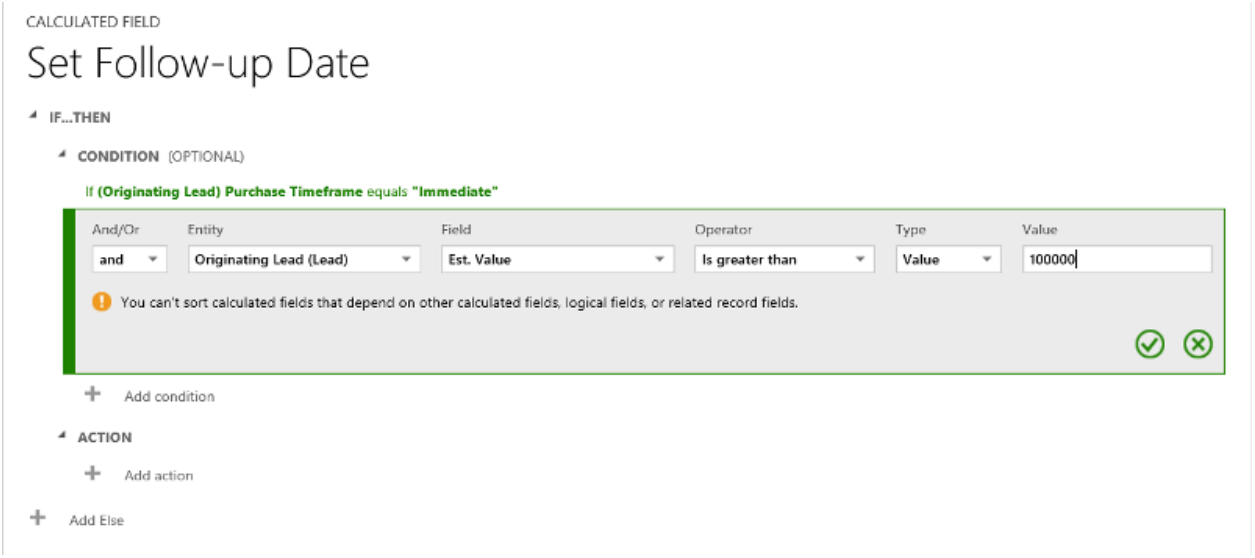
In the **ACTION**, we provide two formulas:

- To follow up in one week on the immediate opportunity
- To follow up in one month if the opportunity isn't likely to happen right away.

The following screenshots show step by step how to define the **Follow-up date** calculated column.

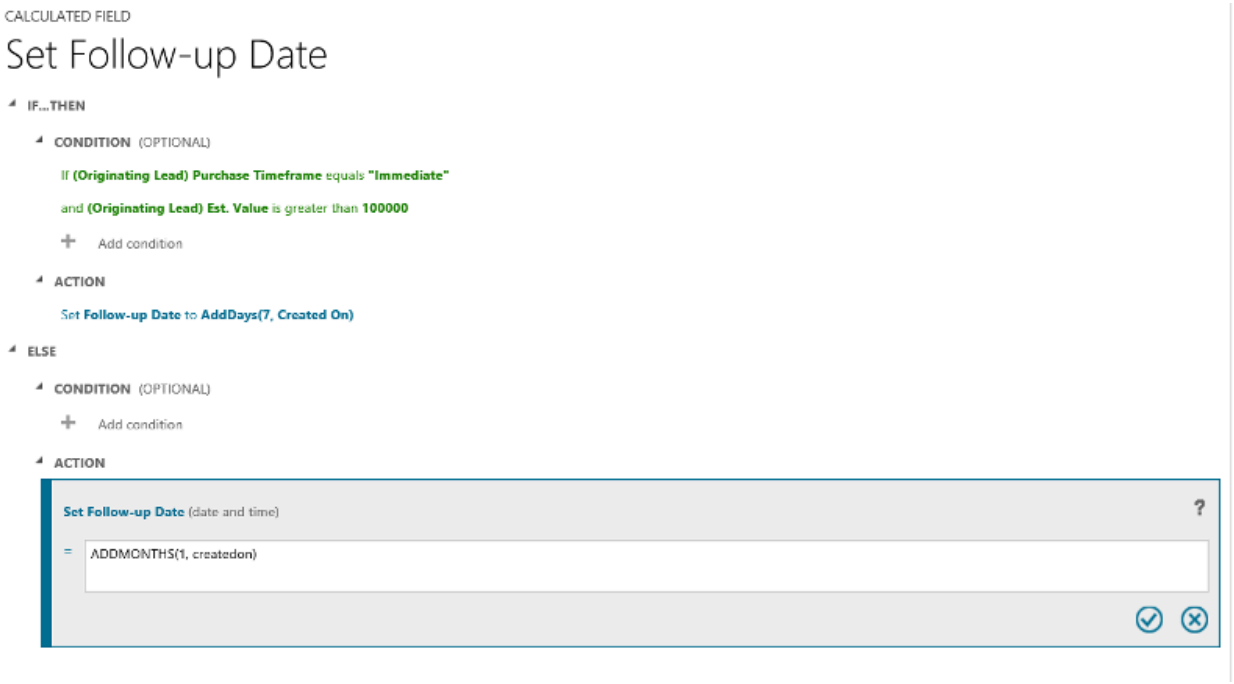
Set the two conditions on the originating lead:





Provide the formula to follow up in one week:

Provide the formula to follow up in one month:



Altogether:

CALCULATED FIELD

Set Follow-up Date

IF...THEN

CONDITION (OPTIONAL)

If **(Originating Lead) Purchase Timeframe** equals **"Immediate"**

and **(Originating Lead) Est. Value** is greater than **100000**

\+ Add condition

ACTION

Set **Follow-up Date** to **AddDays(7, Created On)**

ELSE

CONDITION (OPTIONAL)

\+ Add condition

ACTION

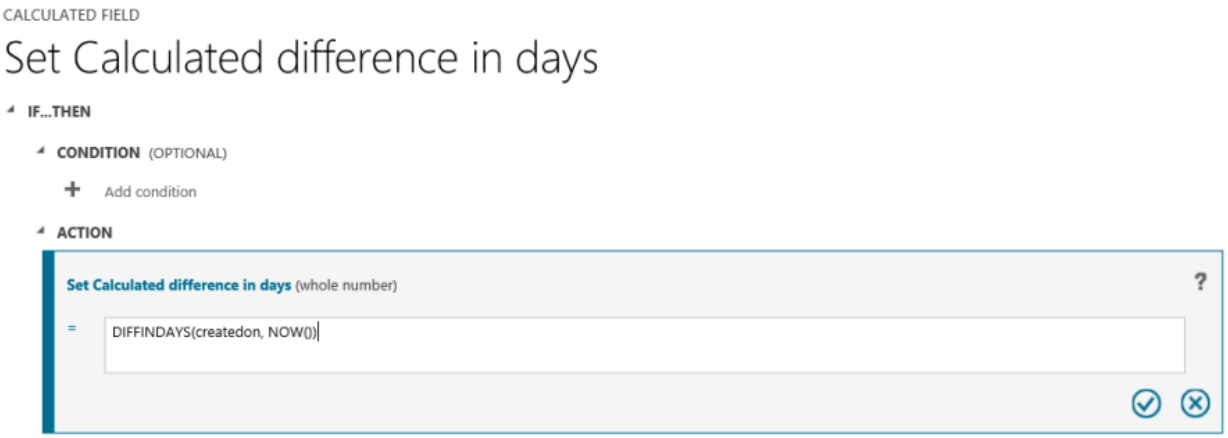
Set **Follow-up Date** to **AddMonths(1, Created On)**

Days from a row creation

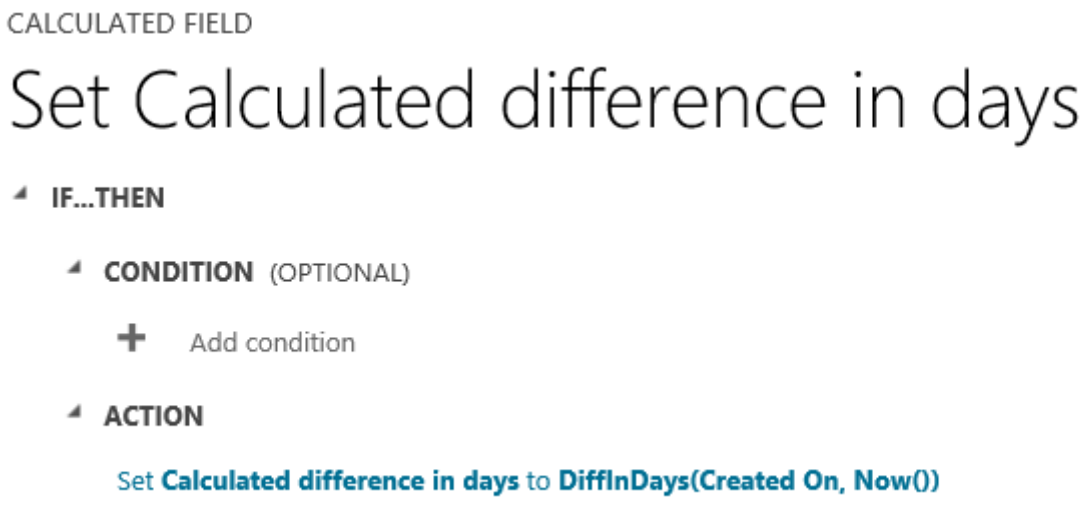
In this example, we're using the **DIFFINDAYS** function, to compute the difference in days from the time when a row was created to the current date.

Create a new Whole Number column called **Calculated difference in days**.

Provide the formula for computing the difference in days



Altogether:



Functions syntax

The following table contains information about the syntax for the functions provided in the **ACTION** section of the calculated column.

> **Tip**

The function names are specified in uppercase letters.

Expand table

Function Syntax	Description	Return type
ADDDAYS (whole number, date and time)	Returns a new date and time equal to the given date and time, plus the specified number of days.	Date and Time
ADDHOURS (whole number, date and time)	Returns a new date and time equal to the given date and time, plus the specified number of hours.	Date and Time
ADDMONTHS (whole number, date and time)	Returns a new date and time equal to the given date and time, plus the specified number of months.	Date and Time
ADDWEEKS (whole number, date and time)	Returns a new date and time equal to the given date and time, plus the specified number of weeks.	Date and Time
ADDYEARS (whole number, date and time)	Returns a new date and time equal to the given date and time, plus the specified number of years.	Date and Time
SUBTRACTDAYS (whole number, date and time)	Returns a new date and time equal to the given date and time, minus the specified number of days.	Date and Time
SUBTRACTHOURS (whole number, date and time)	Returns a new date and time equal to the given date and time, minus the specified number of hours.	Date and Time
SUBTRACTMONTHS (whole number, date and time)	Returns a new date and time equal to the given date and time, minus the specified number of months.	Date and Time
SUBTRACTWEEKS (whole number, date and time)	Returns a new date and time equal to the given date and time, minus the specified number of weeks.	Date and Time
SUBTRACTYEARS (whole number, date and time)	Returns a new date and time equal to the given date and time, minus the specified number of years.	Date and Time
DIFFINDAYS (date and time, date and time)	Returns the difference in days between two **Date and Time** columns. If both dates and times fall on the same day, the difference is zero.	Whole Number

Function Syntax	Description	Return type
DIFFINHOURS (date and time, date and time)	Returns the difference in hours between two **Date and Time** columns.	Whole Number
DIFFINMINUTES (date and time, date and time)	Returns the difference in minutes between two **Date and Time** columns.	Whole Number
DIFFINMONTHS (date and time, date and time)	Returns the difference in months between two **Date and Time** columns. If both dates and times fall on the same month, the difference is zero.	Whole Number
DIFFINWEEKS (date and time, date and time)	Returns the difference in weeks between two **Date and Time** columns. If both dates and times fall on the same week, the difference is zero.	Whole Number
DIFFINYEARS (date and time, date and time)	Returns the difference in years between two **Date and Time** columns. If both dates and times fall on the same year, the difference is zero.	Whole Number
CONCAT (single line of text, single line of text, ... single line of text)	Returns a string that is the result of concatenating two or more strings.	String
TRIMLEFT (single line of text, whole number)	Returns a string that contains a copy of a specified string without the first N-characters.	String
TRIMRIGHT (single line of text, whole number)	Returns a string that contains a copy of a specified string without the last N-characters.	String

> **Note**
>
> All DIFF functions require that the first **Date and Time** column and the second **Date and Time** column have the same behavior: **User Local**, **Date Only**, or **Time-Zone Independent**. If the behavior of the second column doesn't match the behavior of the first column, the error message is shown, indicating that the second column can't be used in the current function. More information: Behavior and format of the Date and Time column.

> **Tip**
>
> You can't enter a date, such as 01/01/2015, as the Date value in a calculated column. Date and DateTime values can only be set or compared using other DateTime columns.

In the **CONCAT** function, you can use literal strings as single lines of text, table columns that contain a single line of text, or a combination of both. For example: **CONCAT** (FirstName, LastName, "is a manager."). If a literal string contains quotation marks, precede each mark with the backslash (\) escape character, like this: `This string contains the \"quotation marks.\"` This ensures that the quotation marks inside the string aren't treated as special characters that separate the strings.

The following examples show how to use the **TRIMLEFT** and **TRIMRIGHT** functions. They contain the initial strings and the resulting strings, returned by the **TRIMLEFT** and **TRIMRIGHT** functions:

TRIMLEFT ("RXX10-3456789", 3), returns the string `10-3456789` **TRIMRIGHT** ("20-3456789RXX", 3), returns the string `20-3456789`

Considerations

You should be aware of certain conditions and limitations when working with calculated columns:

- Saved queries, charts, and visualizations can have a maximum of 50 unique calculated columns.
- The calculated column values aren't displayed in the Outlook Client Offline mode in the tile views or on table main forms.
- A maximum number of chained calculated columns is 5.
- A calculated column can't refer to itself or have cyclic chains.
- If you change one of the condition operators in a multiple condition clause, all of the condition operators update to that condition. For example, in the clause `IF (x > 50) OR (y ==10) OR (z < 5)`, if you change the `OR` operator to the `AND` operator, then all `OR` operators in the clause become `AND` operators.
- You can access parental columns via the Lookup column to the parent table, such as *`<LookupFieldName>.<FieldName>`*. You can't access multi-table lookup columns like Customer, which can be Account or Contact. However, some tables have individual Lookup columns for a specific table, such as `ParentAccountid.`*`<FieldName>`* or `ParentContactid.`*`<FieldName>`*.
- Sorting is disabled on:
  - A calculated column that contains a column of a parent row.

    - A calculated column that contains a logical column (for example, address column)
    - A calculated column that contains another calculated column.
    - A calculated column that contains `Now()` function.

- Calculated columns can span two tables only.
    - A calculated column can contain a column from another table (spanning two tables – current table and parent row).
    - A calculated column can't contain a calculated column from another table that also contains another column from a different table (spanning three tables): (Current table) Calculated Column ← (Parent Row) Calculated Column 1 ← (Parent Row) Calculated Column 2.

- You can't trigger workflows or plug-ins on calculated columns.

- You can't change an existing simple column to a calculated column. If your current application is using JavaScript or plug-ins to calculate a column, you wouldn't be able to use the calculated columns feature without creating a new column.

- Duplicate detection rules aren't triggered on calculated columns.

- A rollup can't reference a calculated column that uses another calculated column, even if all the columns of the other calculated column are on the current table.

- When a currency calculated column depends on a related table's currency column, the system performs calculations using corresponding base currency column values. These calculations are because exchange rate values and currency values can vary between different table records. For example, consider a calculated column - `Account Revenue` on the `Opportunity` table, and consider `Account Revenue` has a dependency on the `Annual Revenue` currency column on the `Account` table, then `Account Revenue` is calculated as described here:

  `'Account Revenue' = ['Annual Revenue (Base)' * 'Exchange Rate on Opportunity table record']` or `'Account Revenue' = [('Annual Revenue' / 'Exchange Rate on Account table record') * 'Exchange Rate on Opportunity table record']`

Define rollup columns that aggregate values

Article • 04/30/2024

Rollup columns help users obtain insights into data by monitoring key business metrics. A rollup column contains an aggregate value computed over the rows related to a specified row. This includes regular tables and activity tables such as emails and appointments.

In more complex scenarios, you can aggregate data over the hierarchy of rows. As an administrator or customizer, you can define rollup columns by using the customization tools in Power Apps, without needing to write code.

Rollup columns benefits and capabilities

The benefits and capabilities of rollup columns include:

- Visual editing is easy. You can create rollup columns by using the Column Editor, just like you do when you create a regular column.
- Wide selection of aggregate functions. You can aggregate data by using the following functions: `SUM`, `COUNT`, `MIN`, `MAX` and `AVG`.
- Full filter support for aggregation. You can set various filters for the source table or related table while setting multiple conditions.
- Seamless integration with the user interface. You can include the rollup columns in forms, views, charts, and reports.
- Rollup columns are solution components. You can easily transport the rollup columns as components between environments and distribute them in solutions.
- Rollup columns and the calculated columns are complementary to each other. You can use a rollup column as a part of the calculated column, and vice versa.
- You can configure rollup columns to use custom controls.

Some examples of rollup columns include:

- Total estimated revenue of open opportunities of an account
- Total estimated revenue of open opportunities across all accounts in a hierarchy
- Total estimated revenue of an opportunity including child opportunities
- Total estimated value of qualified leads generated by a campaign
- Number of high priority open cases across all accounts in a hierarchy
- Earliest created time of all high priority open cases for an account

Each Rollup column creates two accessory columns with <*columnname*>`_date` and <*columnname*>`_state` suffix pattern. The `_date` column contains DateTime data and `_state` column contains Integer data. The `_state` column has the following values:

Expand table

Value	State	Description
0	NotCalculated	The column value is yet to be calculated.
1	Calculated	The column value has been calculated per the last update time in _date column.
2	OverflowError	The column value calculation resulted in overflow error.
3	OtherError	The column value calculation failed due to an internal error. The following run of the calculation job will likely fix it.
4	RetryLimitExceeded	The column value calculation failed because the maximum number of retry attempts to calculate the value was exceeded due to high number of concurrency and locking conflicts.
5	HierarchicalRecursionLimitReached	The column value calculation failed because the maximum hierarchy depth limit for the calculation was reached.
6	LoopDetected	The column value calculation failed because a recursive loop was detected in the hierarchy of the row.
7	CurrencyMissing	The column value calculation failed because the required field currency is missing.

Rollup calculations

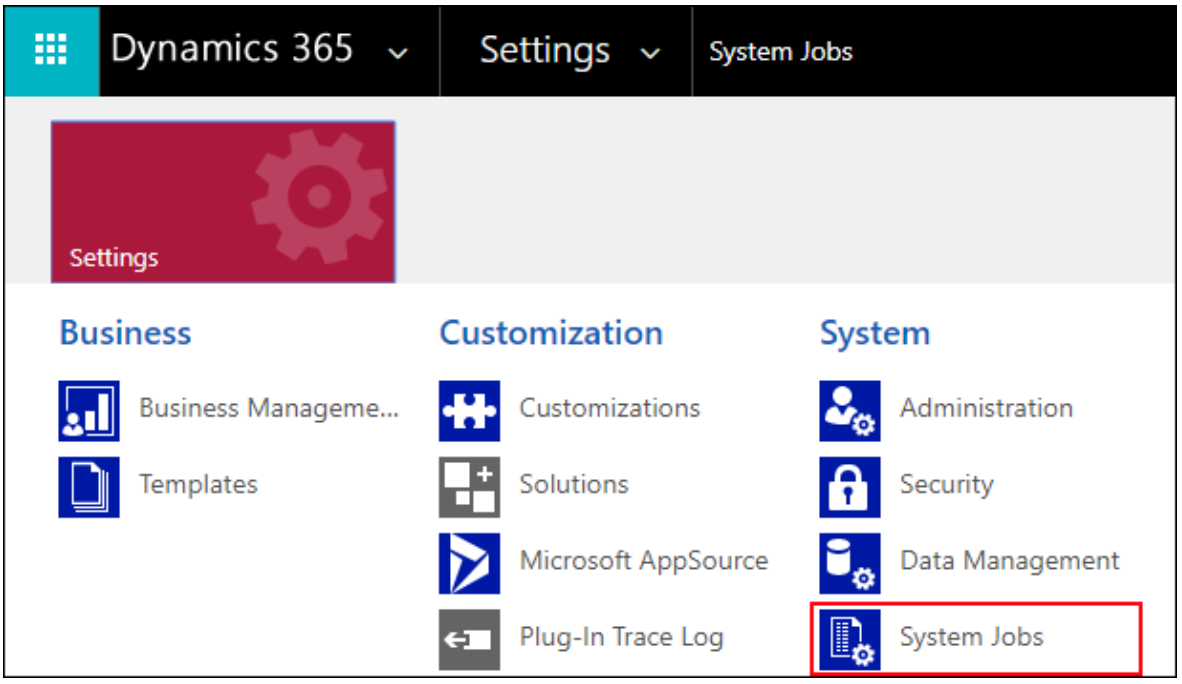
The rollups are calculated by scheduled system jobs that run asynchronously in the background. You have to be an administrator to view and manage the rollup jobs.

View Rollup jobs

To view rollup jobs:

1. Sign in to Power Apps, and then select the environment you want.
2. Select **Settings** (gear) > **Advanced settings**.

3. Select **Settings** > **System Jobs**.



4. In the view selector, choose **Recurring System Jobs**.
5. To quickly find a relevant job, you can filter by the System Job type: **Mass Calculate Rollup Field** or **Calculate Rollup Field**.

Mass Calculate Rollup Field

Mass Calculate Rollup Field is a recurring job, created for each rollup column. It runs once, after you create or update a rollup column. The job recalculates the specified rollup column value in all existing records that contain this column. By default, the job will run 12 hours after you have created or updated a column. When the column is modified, the job resets to run again in 12 hours after the update. The 12-hour delay is needed to assure that the Mass Calculate Rollup Field runs during the nonoperational hours of the environment.

We recommend that an administrator adjusts the start time of a Mass Calculate Rollup Field job after the rollup column is created or modified, in such a way that it runs during nonoperational hours. For example, midnight would be a good time to run the job to assure efficient processing of the rollup columns.

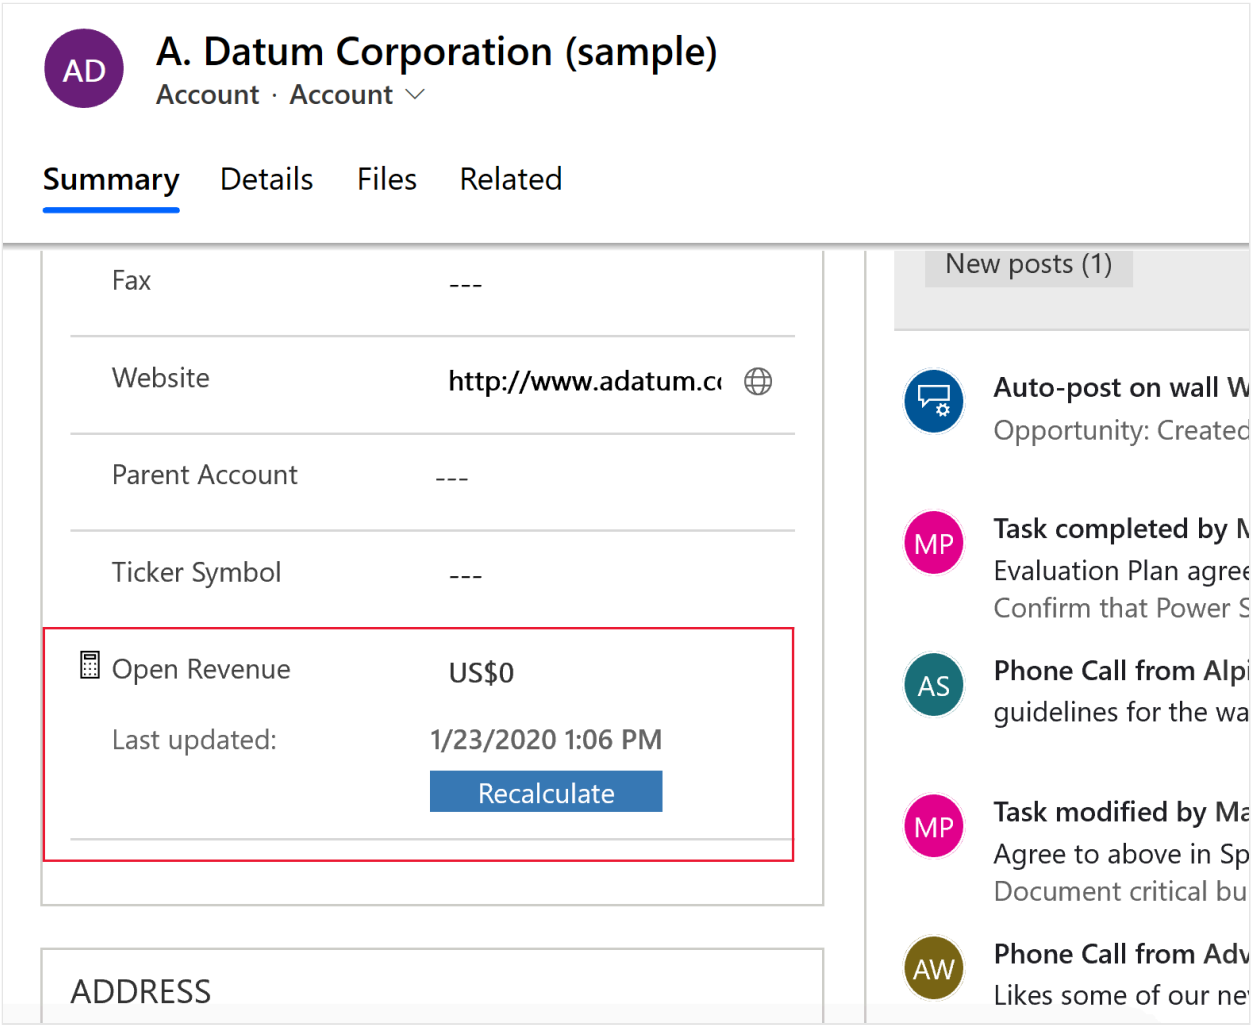
Notice that, when the situation occurs where the rollup column is never updated, the Mass Calculate Rollup Field job won't run again for that column until after 10 years have passed. This behavior is by design. When there aren't any updates in the underlying columns associated with the rollup field, there isn't any reason to run the job more frequently.

Calculate Rollup Column

Calculate Rollup Field is a recurring job that does incremental calculations of all rollup columns in the existing rows for a specified table. There's only one **Calculate Rollup Field** job per table. The incremental calculations mean that the **Calculate Rollup Field** job processes the rows that were created, updated, or deleted after the last **Mass Calculate Rollup Field** job finished execution. The default minimum recurrence setting is one hour. The job is automatically created when the first rollup column on a table is created and deleted when the last rollup column is deleted.

Online recalculation option

The rollup column on the form displays a calculator image, rollup value, and the time of the last calculation. To recalculate, select the calculator image, and then select the **Recalculate** button that appears.



There are a few considerations you should keep in mind when using the online recalculation option (manual refresh on the form):

- You must have Write privileges on the table and Write access rights on the source row on which you're requesting the Refresh. For example, if you're calculating the

estimated revenue from the open opportunities of an account, you don't have to have Write privileges on the opportunity table, only on the account table.
- This option is only available in the online mode. You can't use it while working offline.
- The maximum number of rows during the rollup refresh is limited to 50,000 rows. In case of the hierarchical rollup, this applies to the related rows across the hierarchy. If the limit is exceeded, you see an error message: *Calculations can't be performed online because the calculation limit of 50,000 related rows has been reached.* This limit doesn't apply when the rollup is automatically recalculated by the system jobs.
- The maximum hierarchy depth is limited to 10 for the source row. If the limit is exceeded, you see an error message: *Calculations can't be performed online because the hierarchy depth limit of 10 for the source row has been reached.* This limit doesn't apply when the rollup is automatically recalculated by the system jobs.

Modify rollup job recurrence

As a system administrator, you can modify the rollup job recurrence pattern, postpone, pause, or resume the rollup job. However, you can't cancel or delete a rollup job.

To pause, postpone, resume, or modify the recurrence pattern, you must view the system jobs. More information View Rollup jobs

On the nav bar, choose **Actions** and select the action you want.

For the **Mass Calculate Rollup Field** job, the available selections are: **Resume**, **Postpone**, and **Pause**.

For the **Calculate Rollup Field** job, the available selections are: **Modify Recurrence**, **Resume**, **Postpone**, and **Pause**.

Examples

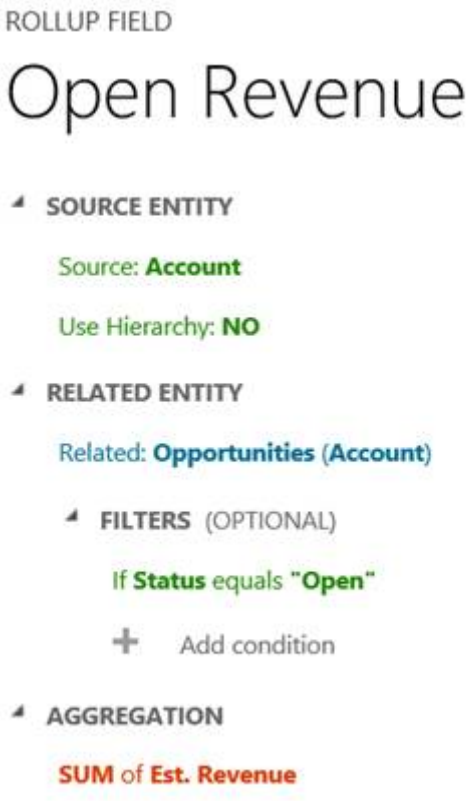
Let's take a look at several rollup column examples. We'll aggregate data for a row from the related rows with and without using a hierarchy. We'll also aggregate data for a row from related activities and activities indirectly related to a row via the ActivityParty table. In each example, we define the rollup column by using the Column Editor. To open the Column Editor, open solution explorer and expand **Components** > **Tables**. Select the table you want and select **Columns**. Choose **New**. In the editor, provide the required information for the column, including the **Column Type** and **Data Type**. In the **Column**

Type, select **Rollup**, after you have selected the data type. The data types include decimal or whole numbers, currency, and date/time. Choose the **Edit** button next to the **Column Type**. This takes you to the rollup column definition editor. The rollup column definition consists of three sections: **Source table**, **Related table, and **Aggregation**.

- In the **Source table** section, you specify the table for which the rollup column is defined and whether or not you aggregate over a hierarchy. You can add filters with multiple conditions to specify the rows in the hierarchy you want to use for rollup.
- In the **Related table** section, you specify the table over which you aggregate. This section is optional when you choose to roll up over the hierarchy on the source table. You can add filters with multiple conditions to specify which related rows to use in the calculation. For example, you include the revenue from the open opportunities with an annual revenue greater than $1,000.
- In the **Aggregate** section, you specify the metric you want to compute. You can choose available aggregate functions, such as SUM, COUNT, MIN, MAX, or AVG.

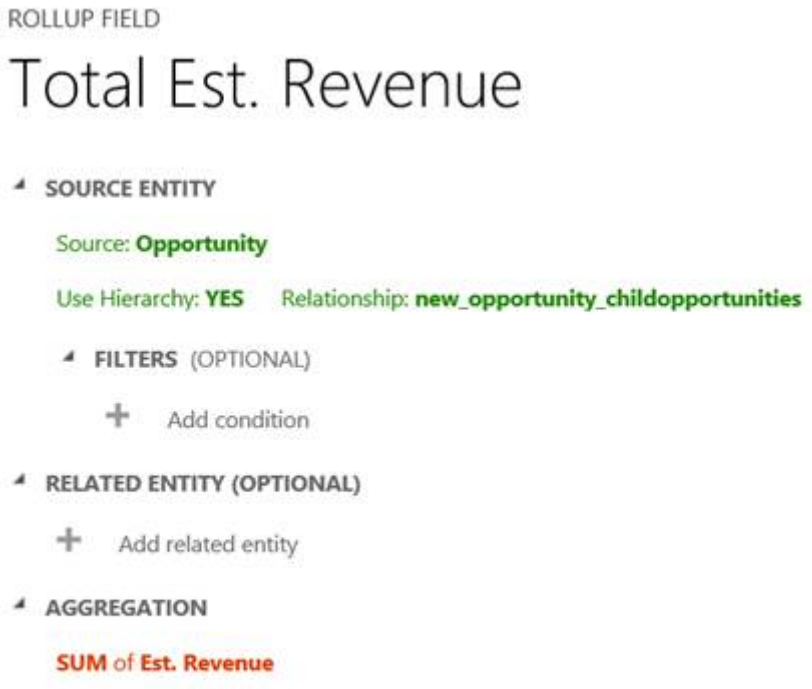
Aggregate data for a row from related rows

In this example, a hierarchy isn't used. The total estimated revenue is calculated for an account, from the related open opportunities.



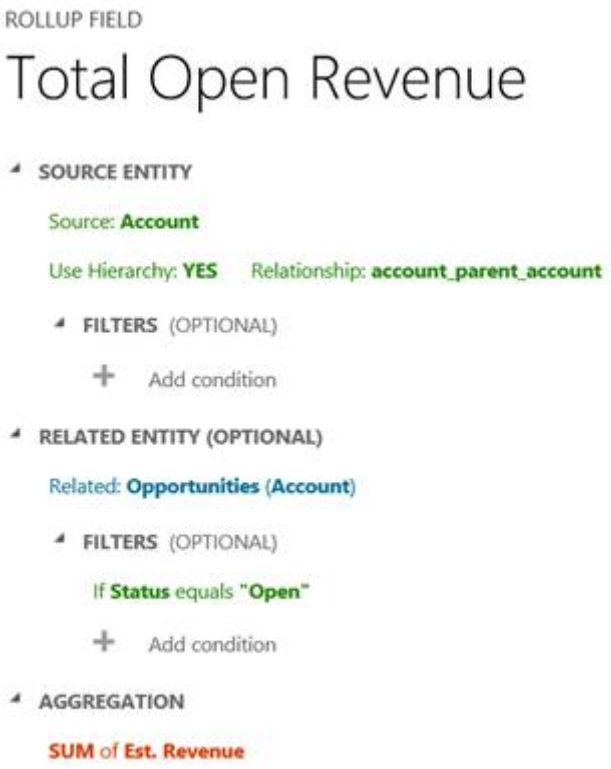
Aggregate data for a row from the child rows, over the hierarchy

In this example, we calculate the total estimated revenue of an opportunity including the child opportunities, over the hierarchy.



Aggregate data for a row from the related rows, over the hierarchy

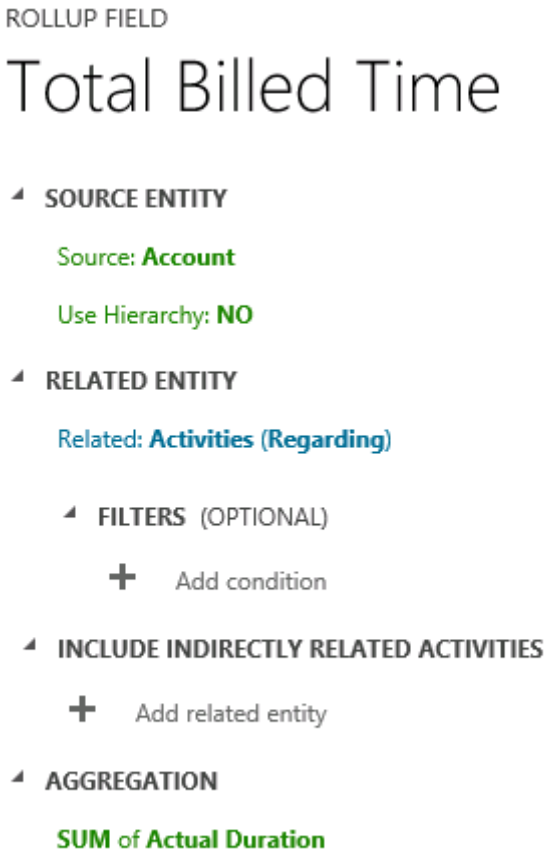
In this example, we calculate the total estimated revenue of open opportunities across all accounts, over the hierarchy.



Aggregate data for a row from all related activities

In this example, we calculate the total time spent and billed from all activities related to an account. This might include time spent on the phone, at appointments, or on custom activities.

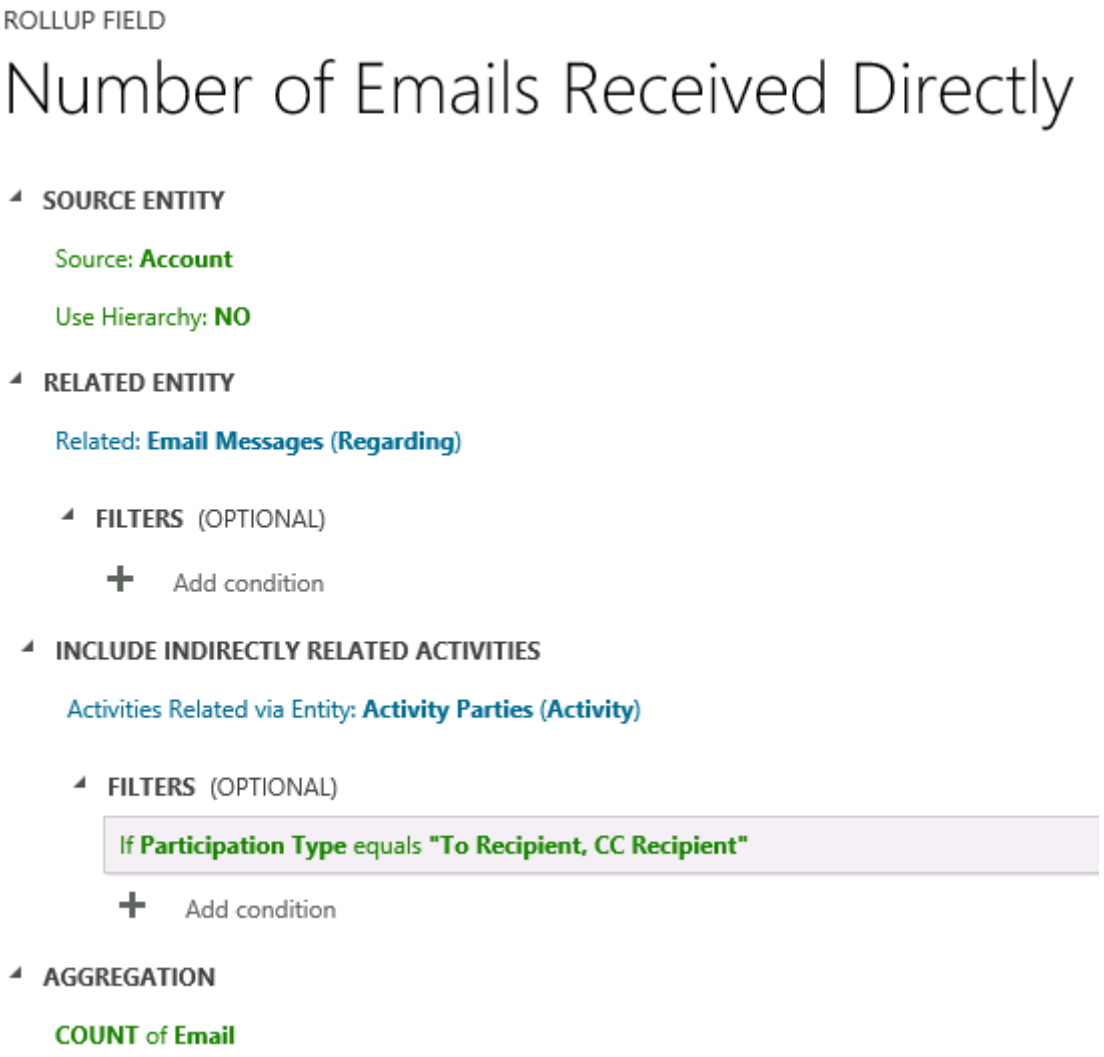
In earlier releases, you could define a rollup column for an individual activity, such as a phone call, fax, or appointment. But, to achieve the result of the example shown below, you had to total the data by using the calculated columns. Now, you can do it all in one step by defining one rollup column for the Activity table.



Aggregate data for a row from all related activities and activities indirectly related via the Activity Party table

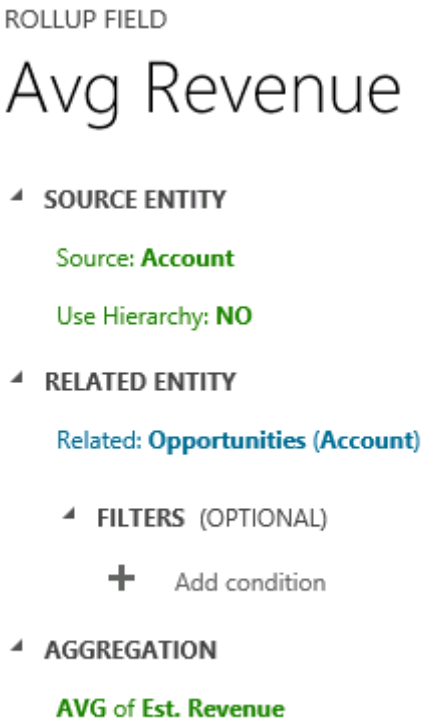
In this example, we count the total number of emails sent to an account, where the account is listed on the email's "To Recipient" line or "Cc Recipient line. This is done by specifying the **Participation Type** in **FILTERS** for the Activity Party table in the rollup column definition. If you don't use filtering, then all available participation types for an activity are used in the calculation.

For more information about the Activity Party table and participation types available for a particular activity, see ActivityParty table.

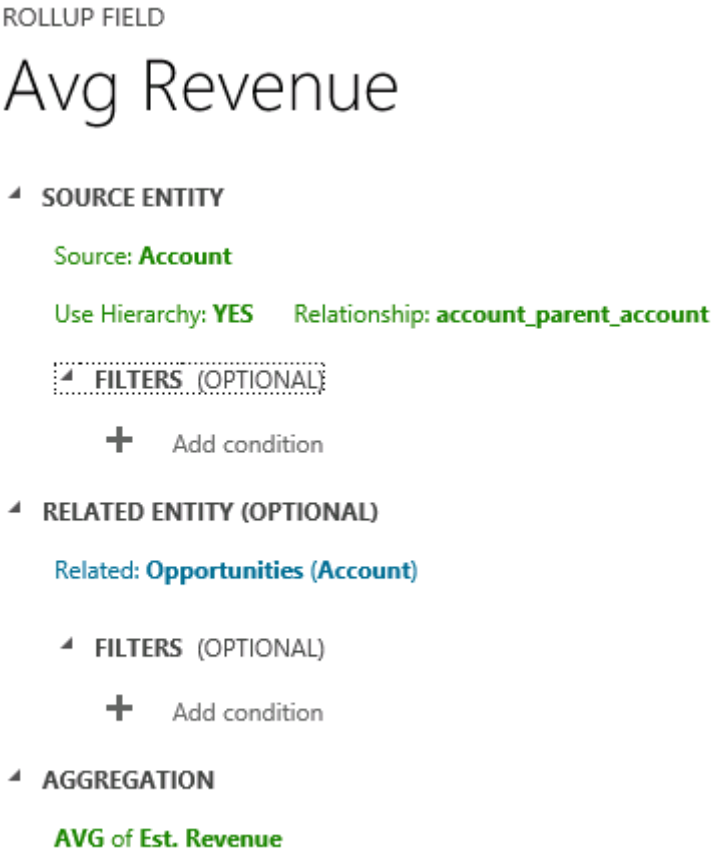


Aggregate data for a row from related rows using the AVG operator

In this example, we calculate an average estimated revenue from all opportunities related to an account.



The following example shows how to calculate an average estimated revenue from related opportunities over a hierarchy of accounts. An average estimated revenue can be seen at each level in the hierarchy.



Rollup column considerations

You should be aware of certain conditions and restrictions when working with rollup columns:

- By default, you can define a maximum of 200 rollup columns for the environment and up to 50 rollup columns per table. More information: Define the maximum number of rollup columns in an environment or table
- A workflow can't be triggered by the rollup column updates.
- A workflow wait condition can't use a rollup column.
- A rollup over the rollup column isn't supported.
- A rollup can't reference a calculated column that uses another calculated column, even if all the columns of the other calculated column are on the current table.
- A rollup column doesn't update automatically if it uses a formula column that's dependent on time bound functions `Now()` and `IsUTCToday()`. The online recalculation option (a manual refresh on the form) or **Recalculate** button must be used to calculate the latest rollup column value.
- The rollup can only apply filters to the source table or related tables, simple columns or noncomplex calculated columns.
- A rollup can be done only over related tables with the 1:N relationship. A rollup can't be done over the N:N relationships.
- A rollup can't be done over the 1:N relationship for the Activity table or the Activity Party table.
- The business rules, workflows, or calculated columns always use the last calculated value of the rollup column.
- A rollup column is aggregated under the system user context. All users are able to see the same rollup column value. You can control the rollup column visibility with the column level security (FLS), by restricting who can access the rollup column. More information Column level security to control access.

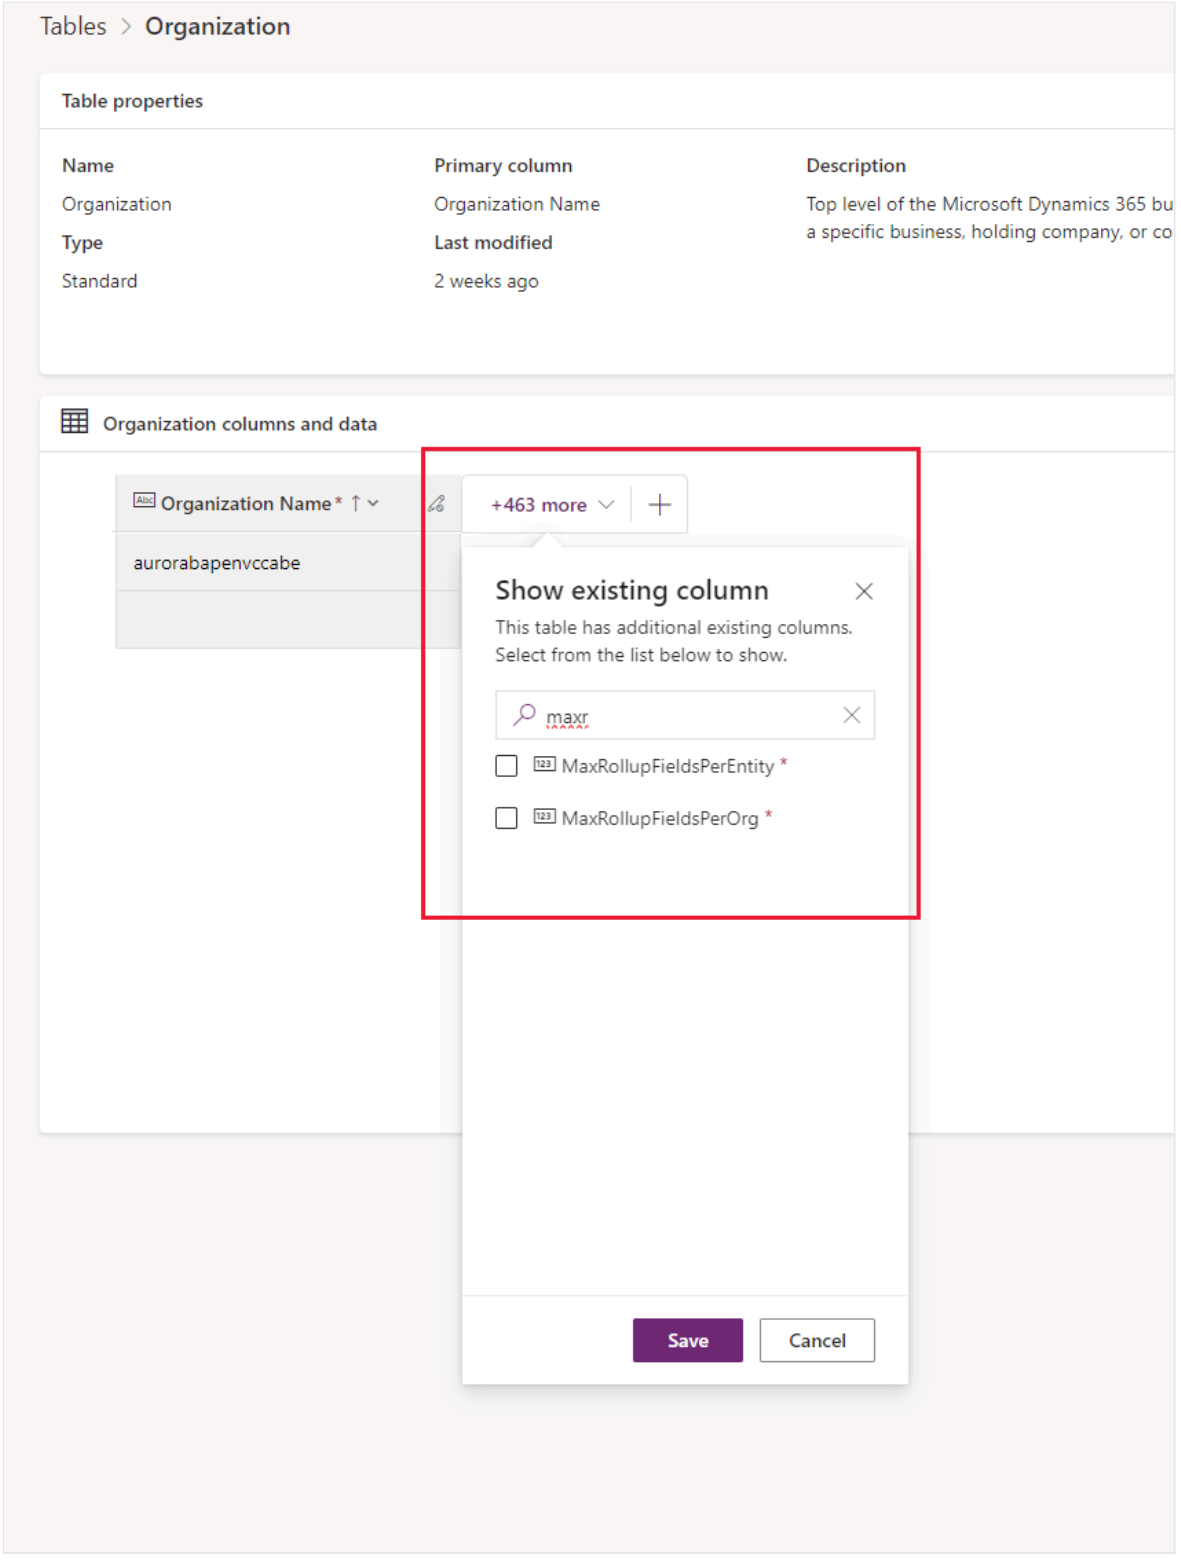
Define the maximum number of rollup columns in an environment or table

By default, you can define a maximum of 200 rollup columns for the environment and up to 50 rollup columns per table.

To change the maximums, follow these steps:

1. Go to Power Apps (make.powerapps.com), select **Table** on the left navigation pane, and then open the **Organization** table.

2. Select the *n* **more** list, and then type *maxr* in the **Search** box. Select the **MaxRollupFieldsPerOrg** and **MaxRollupFieldsPerEntity** columns, and then select **Save**.



3. Change the values for **MaxRollupFieldsPerOrg** (up to 200) and **MaxRollupFieldsPerEntity** (up to 50) that you want.

> **Important**

Having more than 100 rollup columns for an environment might result in degraded performance of rollup columns and increased storage consumption.

Precision rounding

If the precision of the aggregated column is greater than the precision of the rollup column, the aggregated column precision is rounded down to the precision of the rollup column, before the aggregation is performed. To illustrate this behavior, let's look at a specific example. Let's say that the rollup column on the account table, for calculating the total estimated revenue of the related opportunities, has a precision of two decimal points. The Est. Revenue column on the opportunity table is the aggregated column with the precision of four decimal points. In our example, the account has two related opportunities. The aggregated sum of the estimated revenue is calculated as follows:

1. Est. Revenue for the first opportunity: $1000.0041
2. Est. Revenue for the second opportunity: $2000.0044
3. Aggregated sum of Est. Revenue: $1000.00 + $2000.00 = $3000.00

As you can see, the precision rounding to two decimal points on the aggregated column is done before the aggregation is performed.

Different behavior from Associated grids

Certain table forms, such as Account or Contact, out-of-the-box, contain the associated grids. For example, an Account form includes Contacts, Cases, Opportunities, and other grids. Some of the rows shown in the Account form grids are directly related to the account row; others, indirectly, through the relationships with other rows. In comparison, the rollup column aggregation uses only direct relationships explicitly defined in the rollup column definition. No other relationships are considered. To illustrate the difference in behavior, let's look at the following example.

1. The account A1 has a primary contact, P1. The case C1 is associated with the account A1 (C1.Customer column = A1) and the case C2 is associated with the contact P1 (C2.Customer column = P1).
2. The **Cases** grid on the **Account** form for the A1 row, shows two cases, C1 and C2.
3. The rollup column on the account table, called Total Number of Cases, is used to count the cases associated with the account.
4. In the account rollup column definition, we specify the cases that have the Customer relationship with the account. After aggregation, the Total Number of Cases is equal to 1 (case C1). The case C2 isn't included in the total, as it's directly related to the contact, not to the account, and can't be explicitly defined in the

account rollup column definition. As a result, the total number of cases returned by rollup operation doesn't match the number of cases shown in the **Cases** grid.

Map table columns

10/01/2025

You can map columns, also known as attributes, between tables that have a one-to-many or many-to-one table relationship. Column mapping lets you set default values for a row that is created in the context of another row.

Let's say that people want to add a new contact row for a person who is an employee for a specific account. They can do this in two different ways:

- The hard way is people can just navigate in the app to create a new contact row from scratch. But then they need to set the parent account and enter several items of information, such as address and phone information, which are probably the same as the parent account it can be time consuming and introduce opportunities for error.
- The easier way is to start with the account table and, using the **Contacts** subgrid on the form, and then select + to add a contact. The interface first guides people to look up any existing related contacts so they don't accidentally create a duplicate row. If they don't find an existing row, they can select **New** and create a new contact row. The new contact row form then includes any of the mapped attribute values from the account, such as address and phone information, as the default values. People can edit these values before they save the row.

When you map table columns for a 1:N table relationship, certain items of data from the primary table row will be copied into the new related table form to set default values that people can edit before saving.

> ⓘ **Note**
>
> - These mappings only set default values to a row before it's saved. People can edit the values before saving. The data that is transferred is the data at that point in time. The data isn't synchronized if the source data later changes.
> - These mappings aren't applied to related rows created using a workflow or dialog process. They aren't automatically applied to new rows created using code, although developers can use a special message called `InitializeFrom` (InitializeFrom Function or InitializeFromRequest Class) to create a new row using available mappings.
> - These mappings aren't applied for new related table forms that are opened when an app doesn't have an active network connection to Microsoft Dataverse, except for parent lookup columns.

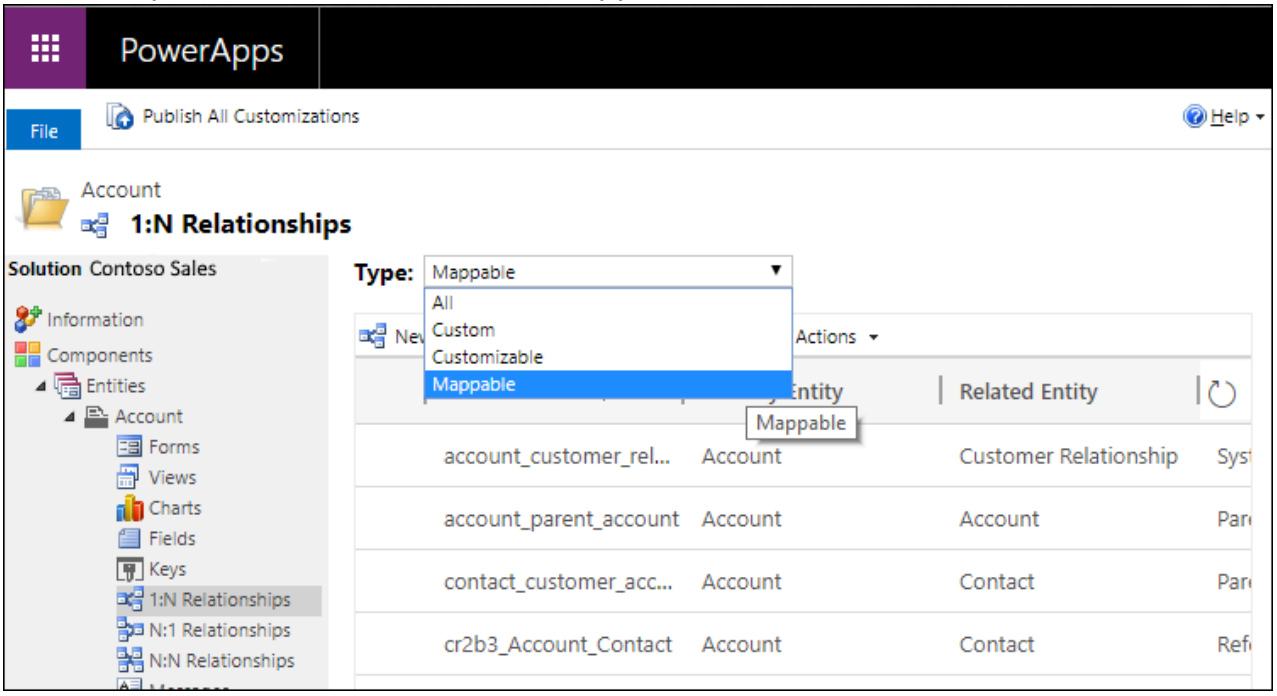
- Column mapping between tables isn't supported when you're using an app in offline mode. For more information, see the limitations listed in Mobile offline limitations for model-driven apps.

View mappable columns

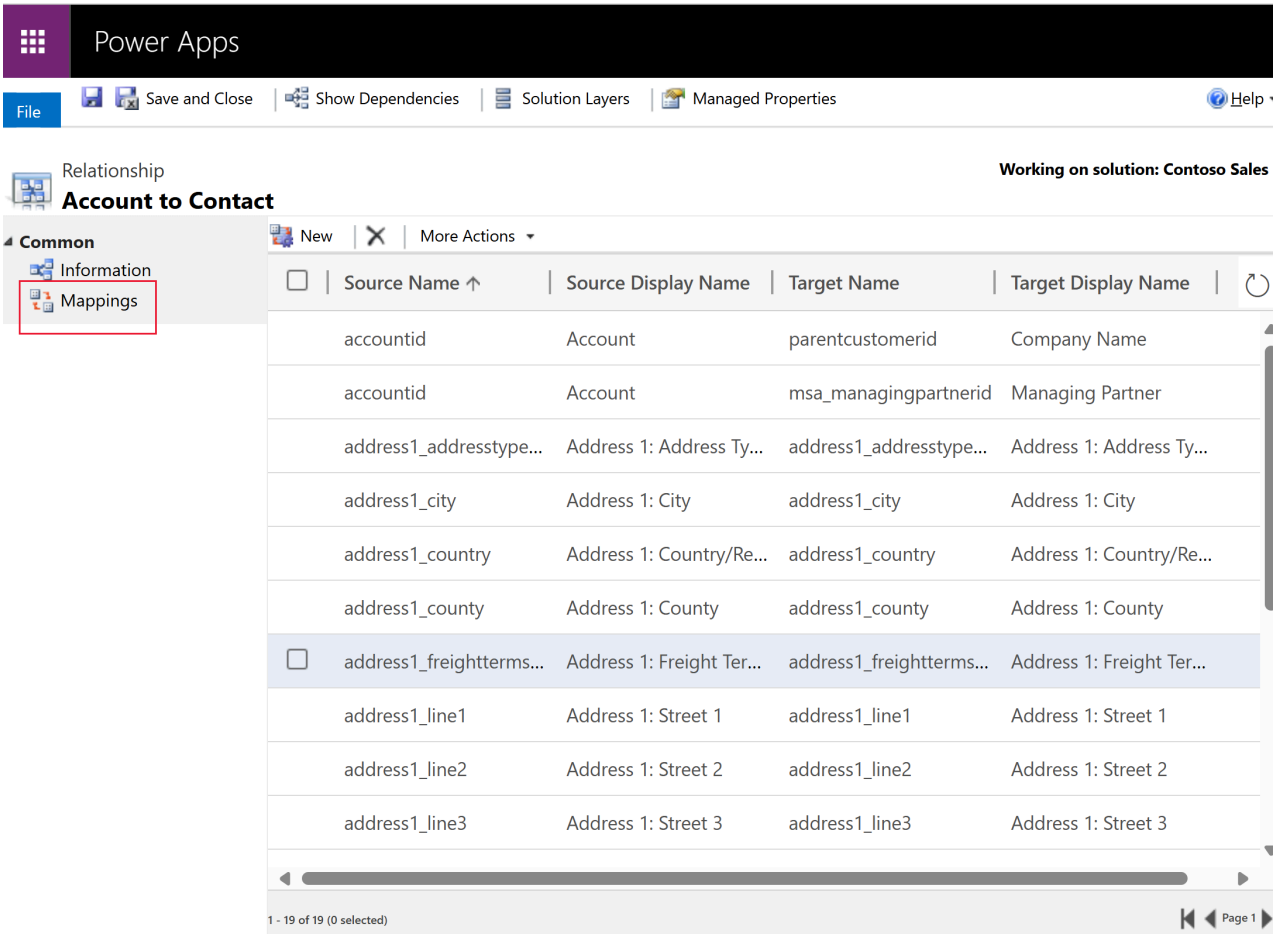
Mapping columns is done in the context of a 1:N or N:1 table relationship, so first you need to view 1:N or N:1 table relationships.

The only way to view and map table columns is to use the classic solution explorer.

1. Sign in to Power Apps, and then select the environment you want.
2. Select **Solutions** on the left pane and then open the solution you want.
3. Select **Switch to classic** on the command bar. The solution opens in the classic solution explorer.
4. Expand **Entities**, expand the table you want, and then expand the relationship type, either **1:N Relationships** or **N:1 Relationships**, and then open the relationship where you want to view or edit column mappings.
5. Column mappings aren't actually defined within the table relationships, but they're exposed in the classic solution explorer relationship user interface. Not every 1:N table relationship has them. In the **Type** dropdown list, select **Mappable** to display only relationships with columns that can be mapped.

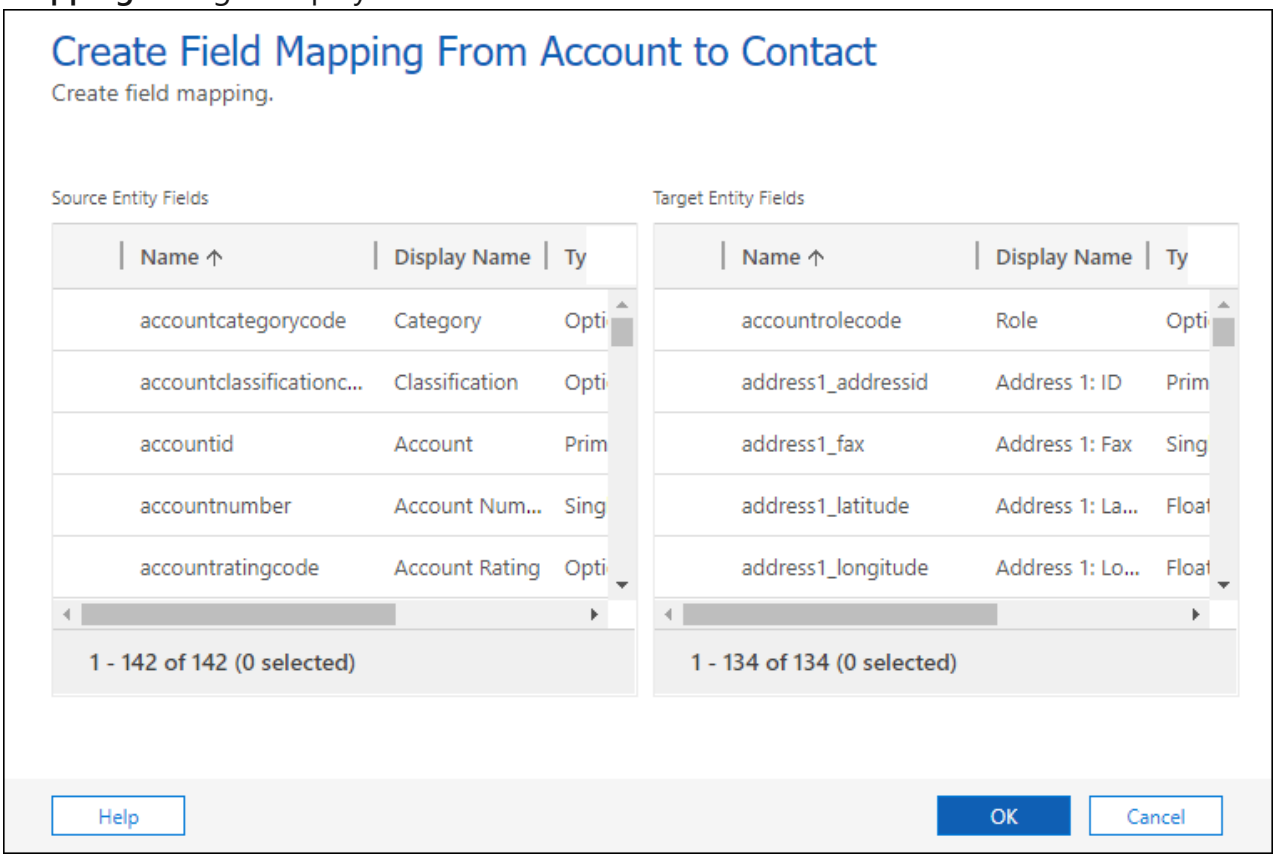


6. Double-click the relationship where you want to view or edit column mappings. A browser page opens to display the relationship properties.
7. Select the **Mappings** tab on the left navigation. The mappings for the relationship are displayed.

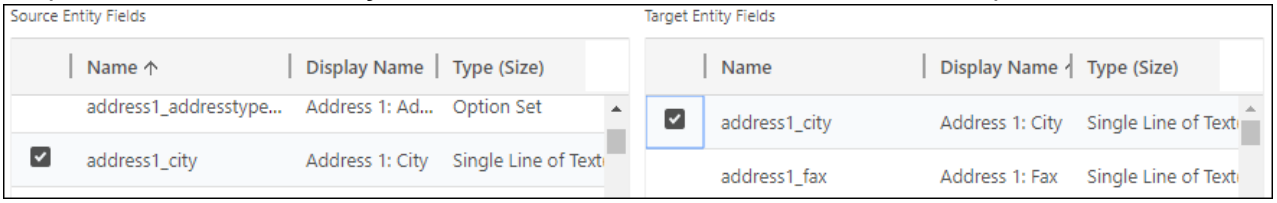


Add new mappings

1. While viewing mappable columns, select **New** on the command bar. The **Create Field Mapping** dialog is displayed.



2. Select one source table column and one target table columns with values you want to map, such as **address1_city** for the account to contact table relationship.



3. Select **OK** to close the dialog.
4. Because column mappings aren't metadata, you must publish them before changes take effect.

Automatically generate column mappings

You can also generate mappings automatically by selecting **Generate Mappings** from the **More Actions** menu.

Use **Generate Mappings** when you create custom tables and want to leverage mapping. However, use care when generating mappings automatically with system tables as you might introduce problems because you're replacing the default mappings.

> ⚠ **Warning**
>
> Generating mappings automatically using **Generate Mappings** removes any existing mappings and replaces them with suggested mappings that are based only on the columns that have similar names and data types. If you use this on a system table, you could lose some expected mappings. For custom tables, it helps save time because you can more easily delete any mappings you don't want and add any others that the generate mappings action didn't create.

Kinds of data and rules for mapping

The following rules show what kinds of data can be mapped:

- Both columns must be of the same type and the same format.
- The length of the target column must be equal to or greater than the length of the source column.
- The target column can't be mapped to another column already.
- The source column must be visible on the form.
- The target column must be a column that a user can enter data into.
- Address ID values or columns of type `partylist` can't be mapped.

- If you map to or from a column that isn't displayed on a form, the mapping won't be done until the column is added to a form.
- If the columns are choices, the integer values for each option should be identical.

> **Note**
>
> If you need to map choice columns, we recommend you configure both columns to use the same global choice. Otherwise, it can be difficult to keep two separate sets of options synchronized manually. If the integer values for each option aren't mapped correctly you can introduce problems in your data. More information: Create and edit global choices for Microsoft Dataverse (picklists)

Delete mappings

While viewing mappable columns if there are any *unmanaged* mappings that you don't want in the environment, you can select them and then select **Delete** ✕.

> **Note**
>
> System and managed mappings can't be deleted the same way as unmanaged mappings, which is by using the legacy solution explorer.

System mappings

You can't delete system generated mappings. When you try to delete a system generated mapping, an error like this one is shown: "Cannot create or delete system attribute map having id <GUID> from '<name>' to '<name>' belonging to an entity map with id <GUID> from '<name>' to 'X<name>."

To remove a system generated mapping, delete the relationship or the lookup column associated with the mapping, which also deletes the mapping. More information: Delete relationships

Managed mappings

You can't delete a mapping if the mapping is managed. To remove the mapping, you must do an upgrade to the solution that brought this mapping in the target environment. To do this, delete the unmanaged mapping in your dev environment as an update to the solution. Export

the solution as managed to import it into your downstream environments. More information: Upgrade or update a solution

Delete columns

Article • 02/15/2022

As someone with the system administrator security role, you can delete any custom columns that aren't part of a managed solution. When you delete a column, any data stored in the column is lost. The only way to recover data from a column that was deleted is to restore the database from a point before the column was deleted.

Before you can delete a custom table, you must remove any dependencies that may exist in other solution components.

1. In the **Solutions** area of Power Apps, open the solution that includes the column that you want to delete.
2. Open the table, select the **Column** tab, and then select the column you want to delete.
3. Select **Show Dependencies** on the command bar to view the **Dependent components** page.

For example, if the column is used in a form or view, you must first remove the column from those solution components.

If you delete a lookup column, the 1:N table relationship for it will automatically be deleted.

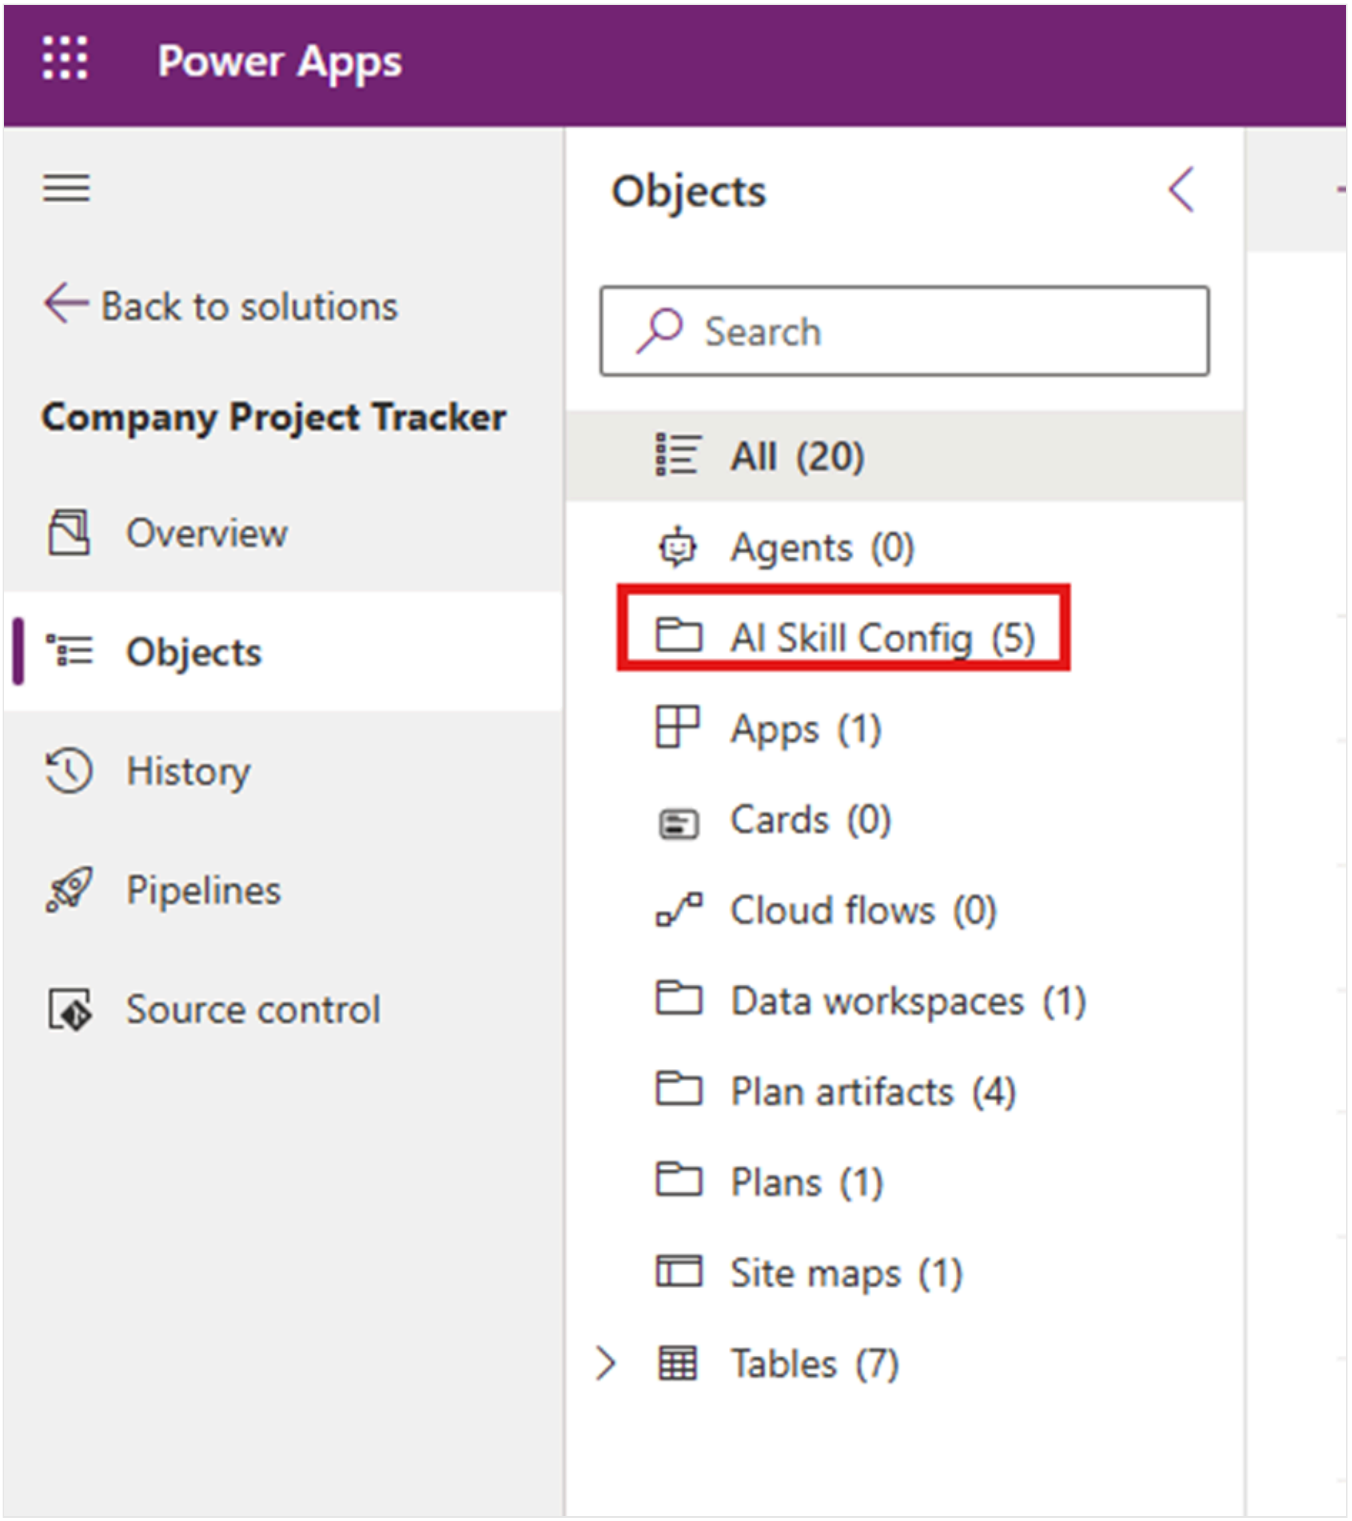
Delete a column with an AI Skill Config table dependency in Power Apps

08/14/2025

The AI Skill Config table is a configuration table used to manage AI-related features, such as form fill assistance and row summary. The AI Skill Config table acts as a centralized store for AI feature settings, which helps avoid schema changes for each new feature and supports application lifecycle management (ALM) to ensure smooth transitions across environments.

To locate the AI Skill Config table go to **Solutions** on the left navigation pane, then open the desired solution. If any AI-related features have been customized in the solution, the AI skill config table appears in the **Objects** pane on the left.



Remove an AI Skill Config table record dependency for a column

When enabled, users receive suggestions generated by AI for columns that support form fill assistance in forms and grids. When a user opts out of AI features or for example when a maker disables the **Allow form fill assistance** column property on a table column, a record is created in the AI Skill Config table to store that configuration. This record creates a dependency on the AI Skill Config table for the column.

To find whether the **Allow form fill assistance** setting is disabled for a column, open the desired table, select **Columns** in the **Schema** area, and then open the column. The setting is found in the properties pane.

Apply business logic in Microsoft Dataverse

Article • 02/14/2024

There are several choices available for applying business logic in Dataverse.

Business rules

You can create business rules and recommendations to apply logic and validations without writing code or creating plug-ins. Business rules provide a simple interface to implement and maintain fast-changing and commonly used rules.

Define *business rules* for a table that apply to all the table forms and at the server level. Business rules defined for a table apply to both *canvas apps* and *model-driven apps* if the table is used in the app. More information: Create a business rule for a table

> **Note**
>
> To define a business rule that applies to a form in a model-driven app, see **Create business rules for a model-driven app form**

Dataverse processes

You can also use the following Dataverse processes:

- Real-time workflows
- Actions

Power Automate

Power Automate has several different flows you can use to create automated workflows within Dataverse or between Dataverse and another app or service that can be used to synchronize files, get notifications, collect data, and more.

Expand table

Flow type	Description	More information
Business process flows	Define a set of steps that run in a Power Apps model-driven app for people to follow to take them to a desired outcome.	Learn more
Cloud flows	Create a flow that performs one or more tasks automatically after it's triggered by an event.	Learn more
Instant flows	Run repetitive tasks from anyplace, at any time, via a flow app on your mobile device.	Learn more
Scheduled flows	Create a flow that performs one or more tasks on a schedule.	Learn more
Desktop flows	Row and automate the playback of manual steps on legacy software.	Learn more

Apply business logic in model-driven apps

Create a business rule for a table

You can create business rules and recommendations to apply logic and validations without writing code or creating plug-ins. Business rules provide a simple interface to implement and maintain fast-changing and commonly used rules.

> **Important**
>
> Business rules defined for a table apply to both *canvas apps* and *model-driven apps* if the table is used in the app. Not all business rule actions are available on canvas apps at this time. More information: Differences between canvas and model-driven apps
>
> In a model-driven app, not all business rule actions are available for editable grids. For table based view pages, recommendations can't be created. Editable subgrids don't support business rules. Business rules won't work with other types of dataset controls.
>
> To define a business rule that applies to a form in a model-driven app, see Create business rules to apply logic in a model-driven app form.

By combining conditions and actions, you can do any of the following with business rules:

- Set column values
- Clear column values
- Set column requirement levels
- Show or hide columns
- Enable or disable columns
- Validate data and show error messages
- Create business recommendations based on business intelligence.

Differences between canvas and model-driven apps

Forms in model-driven apps can use all actions available on business rules, however not all business rule actions are available for canvas apps at this time. The following actions are *not* available on canvas apps:

- Show or hide columns
- Enable or disable columns

- Create business recommendations based on business intelligence

Column type support with business rules

Business rules work with most column types including text, number, choice, date, lookup, owner, and image. However, business rules don't work with the following column types:

- Choices (multi-select)
- File
- Language

Create a business rule

1. Sign in to Power Apps, on the left navigation pane, and select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Open the table you want to create the business rule for (for example, open the **Account** table), and then select **Business rules**.

3. Select **Add business rule**.

   The business rule designer window opens with a single condition already created for you. Every rule starts with a condition. The business rule takes one or more actions based on that condition.

   > **Tip**
   >
   > If you want to modify an existing business rule, you must deactivate it before you can modify it.

4. Add a description, if you want, in the description box in the upper-left corner of the window.

5. Set the scope, according to the following:

Expand table

If you select this item...	The scope is set to...
Entity	Model-driven app forms and server

If you select this item...	The scope is set to...
All Forms	Model-driven app forms
Specific form (**Account** form, for example)	Just that model-driven app form

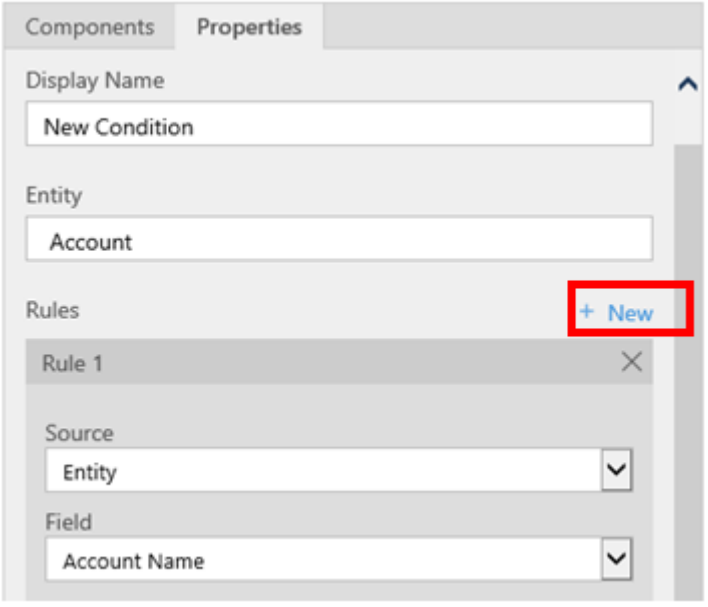
> **Tip**
>
> If you're building a Canvas app, you must use table as the scope.

6. **Add conditions.** To add more conditions to your business rule:

   a. Drag the **Condition** component from the **Components** tab to a plus sign in the designer.

   b. To set properties for the condition, select the **Condition** component in the designer window, and then set the properties in the **Properties** tab on the right side of the screen. As you set properties, the Microsoft Dataverse creates an expression at the bottom of the **Properties** tab.

   c. To add an additional clause (an AND or OR) to the condition, select **New** in the **Properties** tab to create a new rule, and then set the properties for that rule. In the **Rule Logic** column, you can specify whether to add the new rule as an AND or an OR.



d. When you're done setting properties for the condition, select **Apply**.

7. **Add actions.** To add an action:

   a. Drag one of the action components from the **Components** tab to a plus sign next to **Condition** component. Drag the action to a plus sign next to a check mark if you want the business rule to take that action when the condition is met, or to a plus sign next to an x if you want the business rule to take that action if the condition isn't met.

   
   b. To set properties for the action, select the **Action** component in the designer window, and then set the properties in the **Properties** tab.

   c. When you're done setting properties, select **Apply**.

8. **Add a business recommendation (model-driven apps only)**. To add a business recommendation:

   a. Drag the **Recommendation** component from the **Components** tab to a plus sign next to a **Condition** component. Drag the **Recommendation** component to a plus sign next to a check mark if you want the business rule to take that action when the condition is met, or to a plus sign next to an x if you want the business rule to take that action if the condition isn't met.

   b. To set properties for the recommendation, select the **Recommendation** component in the designer window, and then set the properties in the **Properties** tab.

   c. To add more actions to the recommendation, drag them from the **Components** tab, and then set properties for each action in the **Properties** tab.

   > ⓘ **Note**
   >
   > When you create a recommendation, the Dataverse adds a single action by default. To see all the actions in a recommendation, select **Details** on the **Recommendation** component.

   d. When you're done setting properties, select **Apply**.

9. To validate the business rule, select **Validate** on the action bar.
10. To save the business rule, select **Save** on the action bar.
11. To activate the business rule, select it in the Solution Explorer window, and then select **Activate**. You can't activate the business rule from the designer window.

> **Tip**
>
> Here are a few tips to keep in mind as you work on business rules in the designer window:
>
> - To take a snapshot of everything in the **Business Rule** window, select **Snapshot** on the action bar. This is useful, for example, if you want to share and get comments on the business rule from a team member.
> - Use the mini-map to navigate quickly to different parts of the process. This is useful when you have a complicated process that scrolls off the screen.
> - As you add conditions, Actions, and business recommendations to your business rule, Dataverse builds the code for the business rule at the bottom of the designer window. This code is read only.

Example: Create a business rule for tasks older than 30 days

This business rule example creates a condition that triggers a message in the task description field when a task is more than 30 days old.

1. Sign in to Power Apps, on the left navigation pane, select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the **Task** table, and then select the **Business rules** area.
3. Select **Add business rule**.
4. Select **New Condition** on the business process flow canvas, and enter or select the following properties:

    - **Display name**: *Task is more than 30 days old*
    - **Entity**: **Task**
    - **Rule 1**
        - **Source**: **Entity**
        - **Field**: **Created On**

    - **Operator**: +
    - **Type**: **Value**
    - **Days**: *30*
  - **Condition Expression** (automatically created): **(Created On Is greater than [Created On + 30])**
5. Select **Apply**.
6. Select **Add** > **Add Show Error Message**.
7. In the **Show Error Message Properties** tab, enter the following properties:

   - **Display Name**: *Task is more than 30 days old*
   - **Entity**: **Task**
   - **Error Message**:
     - **Field**: **Description**
     - **Message**: *This task is more than 30 days old!*

8. Select **Apply**.
9. Select **Save**.

Localize error messages used in business rules

If you have more than one language provisioned for your organization, you'll want to localize any error messages that you have set. Each time you set a message, a label is generated by the system. If you export the translations in your organization, you can add localized versions of your messages and then import those labels back into the Dataverse, so that people using languages other than your base language can view the translated messages.

Common issues

This section describes common issues that might occur when you use business rules.

Composite attributes not supported with Unified Interface apps

Actions or conditions that use Composite attributes aren't supported in apps based on the Unified Interface. Alternatively, you can use actions or conditions on the attributes that comprise the composite attributes. For example, instead of using the **Full Name** (fullname) attribute, you can use the **First Name** (firstname) and **Last Name** (lastname) attributes.

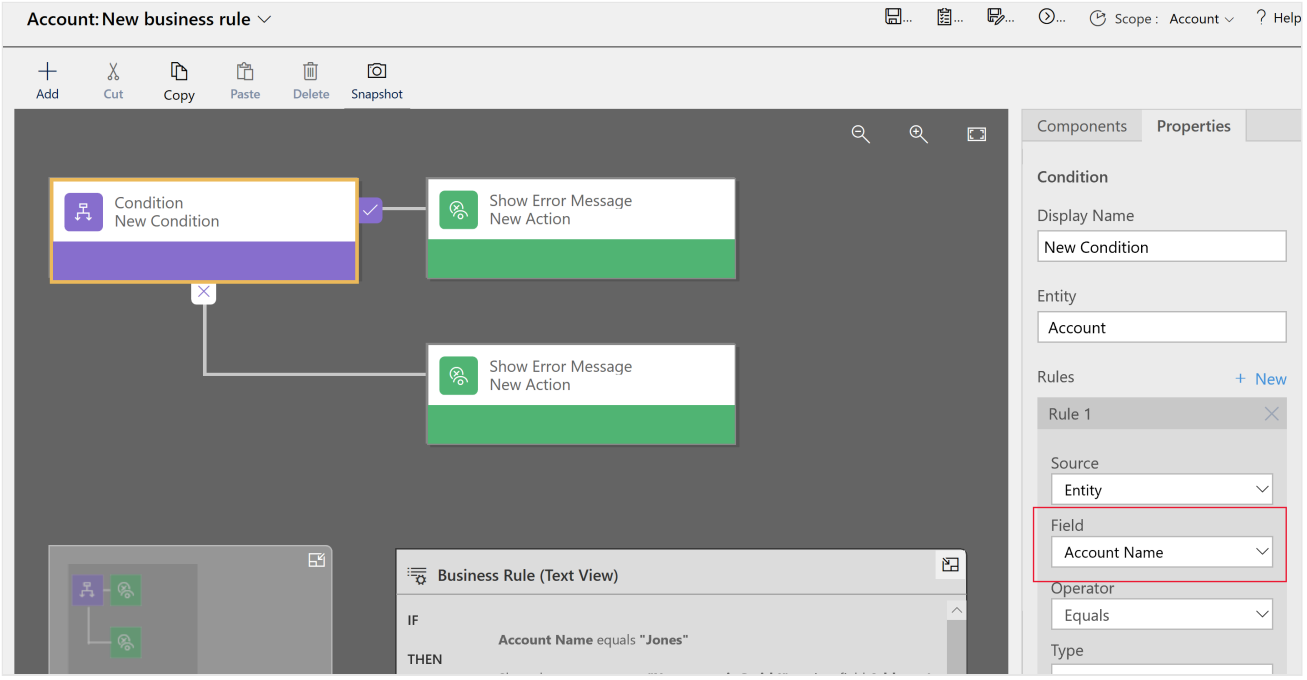
A large number of business rules on a single table impacts performance

New or existing business rules on a table can cause performance degradation when the rules are activated. Power Platform today supports up to 150 business rules for a single table. Beyond 150 business rules, performance degradation can be experienced. This limit includes both client side (JavaScript) and server side (XAML generated as synchronous plugins) business rules. To avoid performance issues with Dataverse, we recommend that you don't create more than 150 business rules for a single table.

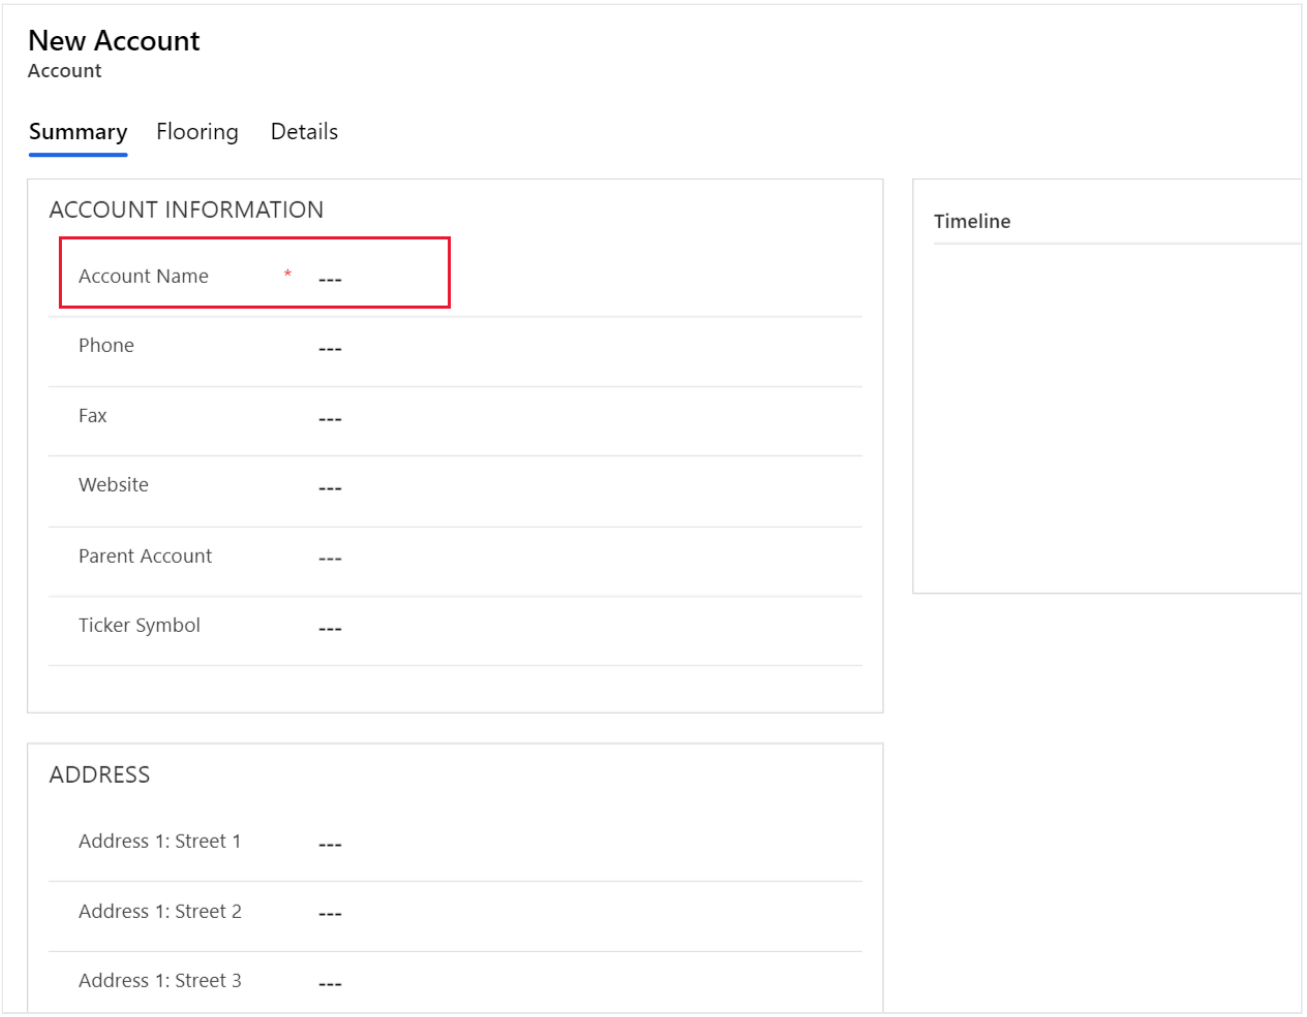
Is your business rule not firing for a form?

A business rule might not execute because the field referenced in the business rule isn't included with the form.

1. Open solution explorer. Expand the entity that you want and then select **Forms**.
2. Open the form that you want and then on the form designer ribbon select **Business Rules**.
3. In the form designer, open the business rule.
4. In the business rule designer, select each condition and action to verify all the fields referenced in each condition and action.



5. Verify that each field referenced in the business rule is also included on the form. If not, add the missing field to the form.



UTC time zone for DateOnly columns

When you configure business rules with `DateOnly` columns, the dates are in the UTC time zone by default, irrespective of the user's set time zone. This can lead to unexpected results if you're expecting `DateOnly` values to align with local time settings.

Suggested handling: Time Zone Independent setting - To make the `DateOnly` columns independent of time zones and display dates in parity with what was configured in the business rule, UTC for example, you can enable the Time Zone Independent setting. For more information about configuring date handling settings, go to Specify the behavior of a date and time column.

Frequently asked questions (FAQ)

Can business rules unlock fields on a read-only form?

- Yes, a business rule can unlock fields and edit actions on a read-only form.

How do I troubleshoot a business rule that isn't working?

- See Is your business rule not firing for a form? in this article.

Do business rules react to changes made by an onLoad script?

- No, they'll execute before an onload script is executed.

When I update a business rule, is it executed against all existing records?

- No. Business rules are run on clients. For example, they run when a form is opened by a user and when a field value changes on that open form. They aren't executed inside Dataverse.

Microsoft Dataverse real-time workflows

Article • 07/12/2024

Workflows automate business processes without a user interface. People usually use workflow processes to initiate automation that doesn't require any user interaction.

There are two types of workflows:

- Background workflows. Background workflows run when the system has resource availability (asynchronously). Go to the Power Automate documentation for more details about background workflows.
- Real-time workflows. Real-time workflows run immediately (synchronously).

Create or edit real-time workflows

> **Important**
>
> There are better ways to create modern automations. Consider using Power Automate flows to automate your processes. More information: **Power Automate**

1. Create a solution or open an existing one.
2. Select **New** > **Automation** > **Process** > **Workflow**.
3. Enter a **Display name**, select a **Table**, and then clear the **Run workflow in the background** option.
4. Select **Create**.

The workflow designer is displayed. Select the workflow attributes and steps needed. More information: Configure real-time workflow stages and steps

View and edit real-time workflows

1. Sign in to Power Apps, select the **Settings** icon on the upper right, and then select **Advanced settings**.
2. Select the down arrow next to **Settings** on the top bar, and then select **Processes**.
3. In the list of processes, select the workflow that you want to edit.

Configure real-time workflow stages and steps

When you design workflows, you have the option to contain the logic you want to perform in stages and steps.

- Stages. Stages make the real-time workflow logic easier to read, and explain the real-time workflow logic. However, stages don't affect the logic or behavior of workflows. If a process has stages, all the steps within the process must be contained with a stage.
- Steps. Steps are a unit of business logic within a workflow. Steps can include conditions, actions, other steps, or a combination of these elements.

Actions that real-time workflow processes can perform

Real-time workflow processes can perform the actions listed in the following table.

Expand table

Action	Description
Create Row	Creates a new row for a table and assigns values that you choose to attributes.
Update Row	You can update the row that the real-time workflow is running on, any of the rows linked to that row in an N:1 relationship, or any rows created by earlier steps.
Assign Row	You can assign the row that the real-time workflow is running on, any of the rows linked to that row in an N:1 relationship, or any rows created by earlier steps.
Send Email	Sends an email. You can choose to create a new email message or use an email template configured for the table of the row that the real-time workflow is running on or any tables that have an N:1 relationship with the table, or the table for any rows created by earlier steps.
Start Child Workflow	Starts a real-time workflow process that is configured as a child workflow.
Change Status	Changes the status of the row that the process is running on, any of the rows linked to that row in an N:1 relationship, or any rows created by earlier steps.
Stop Workflow	Stops the current workflow. You can set a status of either **Succeeded** or **Canceled** and specify a status message. When real-time workflows are configured for an event, stopping a real-time workflow with a

Action	Description
	status of canceled will prevent the event action from completing. Go to Using real-time workflows for more information.
Custom Step	Developers can create custom real-time workflow steps that define actions. No custom steps are available by default.

Setting row values

When you create a row, you can set values for the row. When you update a row, you can set, append, increment, decrement, multiply, or clear values.

When you select **Set Properties**, a dialog box opens showing you the default form for the table.

At the bottom of the dialog box you see a list of additional columns not present in the form.

For any column, you can set a static value that is set by the workflow.

On the right side of the dialog box, the **Form Assistant** gives you the ability to set or append dynamic values from the context of the current row. This includes values from related rows that can be accessed from the N:1 (many-to-one) relationships for the table.

The options available in the **Form Assistant** depend on the column you have selected in the form. When you set a dynamic value, you see a yellow placeholder known as a "slug" that shows where the dynamic data is included. If you want to remove the value, select the slug and delete it. For text columns, you can use a combination of static and dynamic data.

With dynamic values, you don't know for certain that a column or related table has the value you want to set. You can actually set a number of columns to try to set the value and sort them in order using the green arrows. If the first column doesn't have data, try on the second column and so. If none of the columns have data, you can specify a default value to be used.

Setting conditions for real-time workflow actions

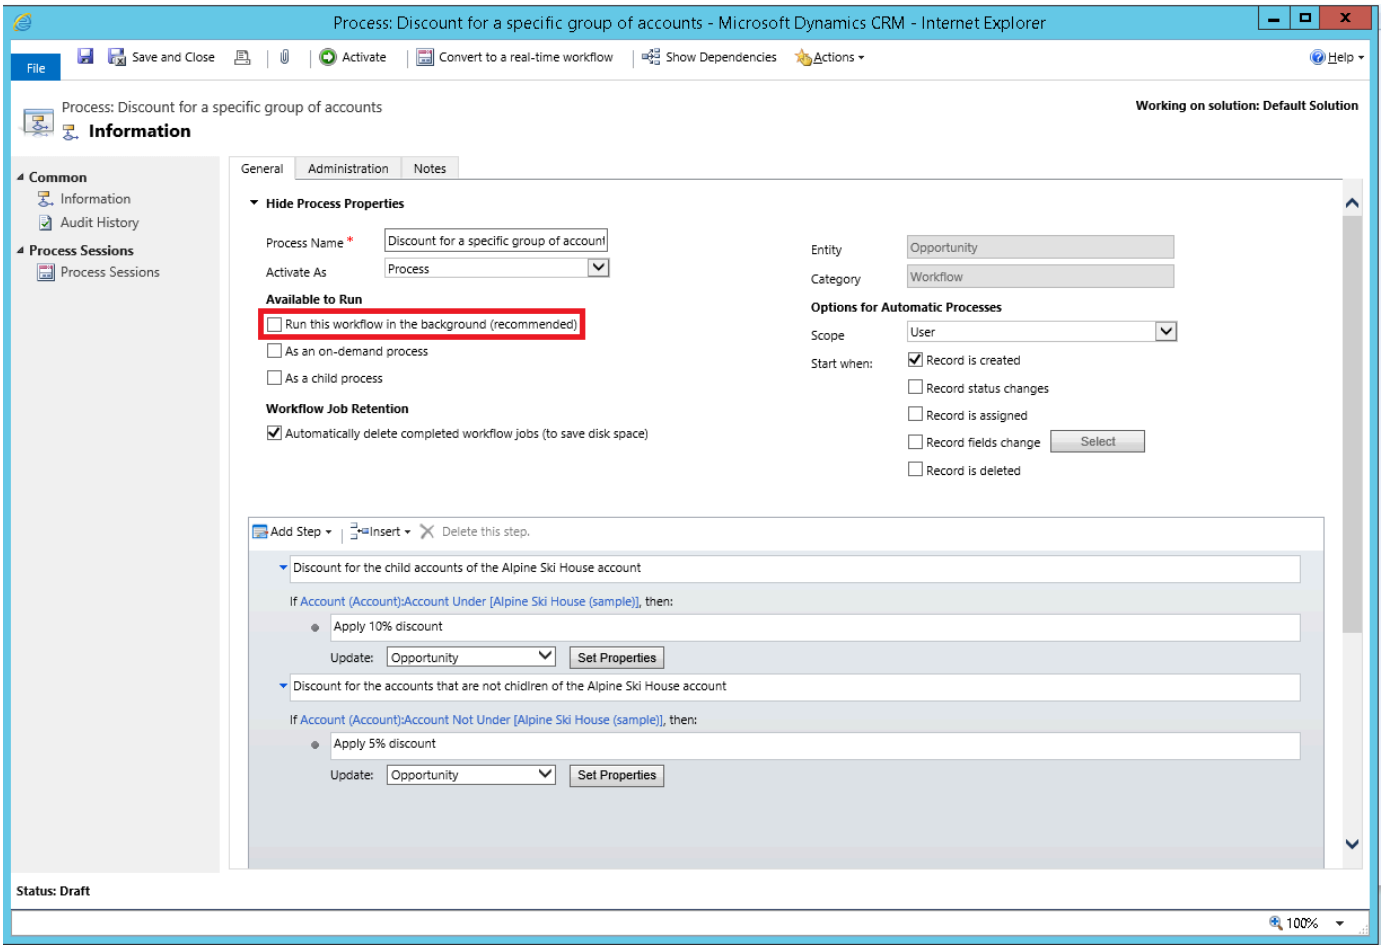
The actions that you apply often depend on conditions. Real-time workflow processes provide several ways to set conditions and create branching logic to get the results you want. You can check values of the row that the real-time workflow process is running against, any of the rows linked to that row with an N:1 relationship, or values within the process itself.

Expand table

Condition Type	Description
Check Condition	A logical "if <condition> then" statement. You can check the current values for the row that the real-time workflow is running on, any of the rows linked to that row in an N:1 relationship, or any rows created by earlier steps. Based on these values, you can define additional steps when the condition is true. In the "if <condition> then" statement, you can use the following operators: **Equals**, **Does Not Equal**, **Contains Data**, **Does Not Contain Data**, **Under** and **Not Under**. **Note:** The **Under** and **Not Under** are hierarchical operators. They can only be used on the tables that have a hierarchical relationship defined. If you're trying to use these operators on the tables that don't have the hierarchical relationship defined, see the error message: "You're using a hierarchical operator on a table that doesn't have a hierarchical relationship defined. Either make the table hierarchical (by marking a relationship as hierarchical) or use a different operator." For more information about hierarchical relationships, go to Define and query hierarchically related data. A screenshot that follows the table is an example of the definition of the real-time workflow process that uses the **Under** and **Not Under** hierarchical operators.
Conditional Branch	A logical "else-if-then" statement, the editor uses the text "Otherwise, if <condition> then:" Select a check condition you previously defined and you can add a conditional branch to define additional steps when the check condition returns false.
Default Action	A logical "else" statement. The editor uses the text "Otherwise:" Select a check condition, conditional branch, wait condition, or parallel wait branch that you previously defined and you can use a default action to define steps for all cases that don't match the criteria defined in condition or branch elements.
Wait Condition	Real-time workflows can't use wait conditions. However, wait conditions can be used with background workflows. More information: Setting conditions for background workflow actions
Parallel Wait Branch	Defines an alternative wait condition for a real-time workflow with a corresponding set of additional steps that are performed only when the initial criterion is met. You can use parallel wait branches to create time limits in your real-time workflow logic. They help prevent the real-time workflow from waiting indefinitely until the criteria defined in a wait condition are met.
Custom Step	Developers can create custom real-time workflow steps that define conditions. There are no custom steps available by default.

The following screenshot contains an example of the workflow process definition with the **Under** and **Not Under** hierarchical operators. In our example, we apply two different discounts to two

groups of accounts. In **Add Step**, we selected the **Check Condition** to specify the **if-then** condition containing the **Under** or **Not Under** operators. The first **if-then** condition applies to all accounts that are **Under** the Alpine Ski House account. These accounts receive a 10% discount on purchased good and services. The second **if-then** condition applies to all accounts that are **Not Under** the Alpine Ski House account and they receive a 5% discount. Then, we selected **Update Row** to define the action to be performed based on the condition.



Initiating real-time workflows before or after status changes

When you configure **Options for Automatic Processes** for real-time workflows, the **Start When** options for the status changes event let you select **After** or **Before** for when status changes. The default option is **After**.

When you select **Before** you're saying that you want the logic in the real-time workflow to be applied before data changing the status is saved. This provides you with the ability to check the values before other logic has been applied after the operation and prevent further logic from being performed. For example, you might have additional logic in a plug-in or custom real-time workflow action which could initiate actions on another system. By stopping further processing, you can avoid cases where external systems are affected. Applying real-time workflows before

this event also means that other real-time workflow or plug-in actions that might save data don't need to be "rolled back" when the operation is canceled.

Expand table

Action	Start when	Explanation
Row is created	After	Only **After** is available. The row won't have a unique identifier until after the internal MainOperation stage so can't occur before the row is created.
Row status changes	Before After	Corresponds to an update operation that provides the ability to apply real-time workflow logic either after or before the status changes. **Before** corresponds to the preoperation stage. **After** corresponds to the postoperation stage.
Row is assigned	Before After	Corresponds to an update operation that provides the ability to apply real-time workflow logic either after or before the status changes. **Before** corresponds to the preoperation stage. **After** corresponds to the postoperation stage.
Row columns change	Before After	Corresponds to an update operation that provides the ability to apply real-time workflow logic either after or before the status changes. **Before** corresponds to the preoperation stage. **After** corresponds to the postoperation stage.
Row is deleted	Before	Only **Before** is available. Row deletion corresponds to the preoperation stage. After the MainOperation occurs, the row is deleted and there's no further status change that can occur.

For more information about preoperation, mainoperation, and postoperation stages, see Event execution pipeline.

Using real-time workflows

You can configure real-time workflows but you should use them with care. Background workflows are generally recommended because they allow the system to apply them when resources on the server are available. This helps smooth out the work the server has to do and helps maintain the best performance for everyone using the system. The drawback is that actions defined by background workflows aren't immediate. You can't predict when they are applied, but generally it takes a few minutes. For most automation of business processes, this is fine because people using the system don't need to be consciously aware that the process is running.

Use real-time workflows when a business process requires someone to immediately see the results of the process or if you want the ability to cancel an operation. For example, you might want to set certain default values for a row the first time it's saved, or you want to make sure that some rows aren't deleted.

Converting between real-time and background workflows

You can change a real-time workflow into a background workflow by choosing **Convert to a background workflow** on the toolbar.

You can change a background workflow into a real-time workflow by choosing **Convert to a real-time workflow** on the toolbar. If the background workflow uses a wait condition, it becomes invalid and you won't be able to activate it until you remove the wait condition.

Initiating real-time workflows before or after status changes

When you configure **Options for Automatic Processes** for real-time workflows, the **Start When** options for the status changes event let you select **After** or **Before** for when status changes. The default option is **After**.

When you select **Before**, you're saying that you want the logic in the real-time workflow to be applied before data changing the status is saved. This provides you with the ability to check the values before other logic are applied after the operation and prevents further logic from being performed. For example, you might have additional logic in a plug-in or custom real-time workflow action that could initiate actions on another system. By stopping further processing, you can avoid cases where external systems are affected. Applying real-time workflows before this event also means that other real-time workflow or plug-in actions that might have saved data don't need to be "rolled back" when the operation is canceled.

Using the Stop Workflow action with real-time workflows

When you apply a **Stop Workflow** action in a real-time workflow, you have the option to specify a status condition that can be either **Succeeded** or **Canceled**. When you set the status to canceled, you prevent the operation. An error message containing the text from the stop action status message will be displayed to the user with the heading **Business Process Error**.

Configuring who runs the real-time workflow

In the workflow designer, you can set who the workflow should run as to either "The owner of the workflow" or "The user who made changes to the record." To change the owner of the record to another user, open the **Administration** tab in the workflow editor and use the lookup to select a new owner for the workflow. You need the System Administrator or System Customizer security role or a role containing the `prvChangeOwnerIdOfWorkflow` privilege to change the owner of the workflow.

Monitor and manage real-time workflow processes

Article • 05/15/2024

To monitor and manage processes, you must locate the process, evaluate the status, and perform any actions necessary to address problems.

Monitoring real-time workflows and actions

Real-time workflows and actions don't use System Job rows because are displayed to the user in the application with the heading **Business Process Error**.

There's no log for successful operations. You can enable logging for errors by checking the **Keep Logs for workflow jobs that encountered errors** option in the **Workflow Log Retention** area at the bottom of the **Administration** tab for the process.

To view the log of errors for a specific process, open the real-time workflow or action definition and go to the **Process Session** tab. This log only shows errors logged for this process.

If you want a view of all the errors for any process, go to **Advanced Find** and create a view showing errors on the process session table.

Status of real-time workflow processes

When you view a list of real-time workflow processes, any individual process can have one of the following **State** and **Status Reason** values:

Expand table

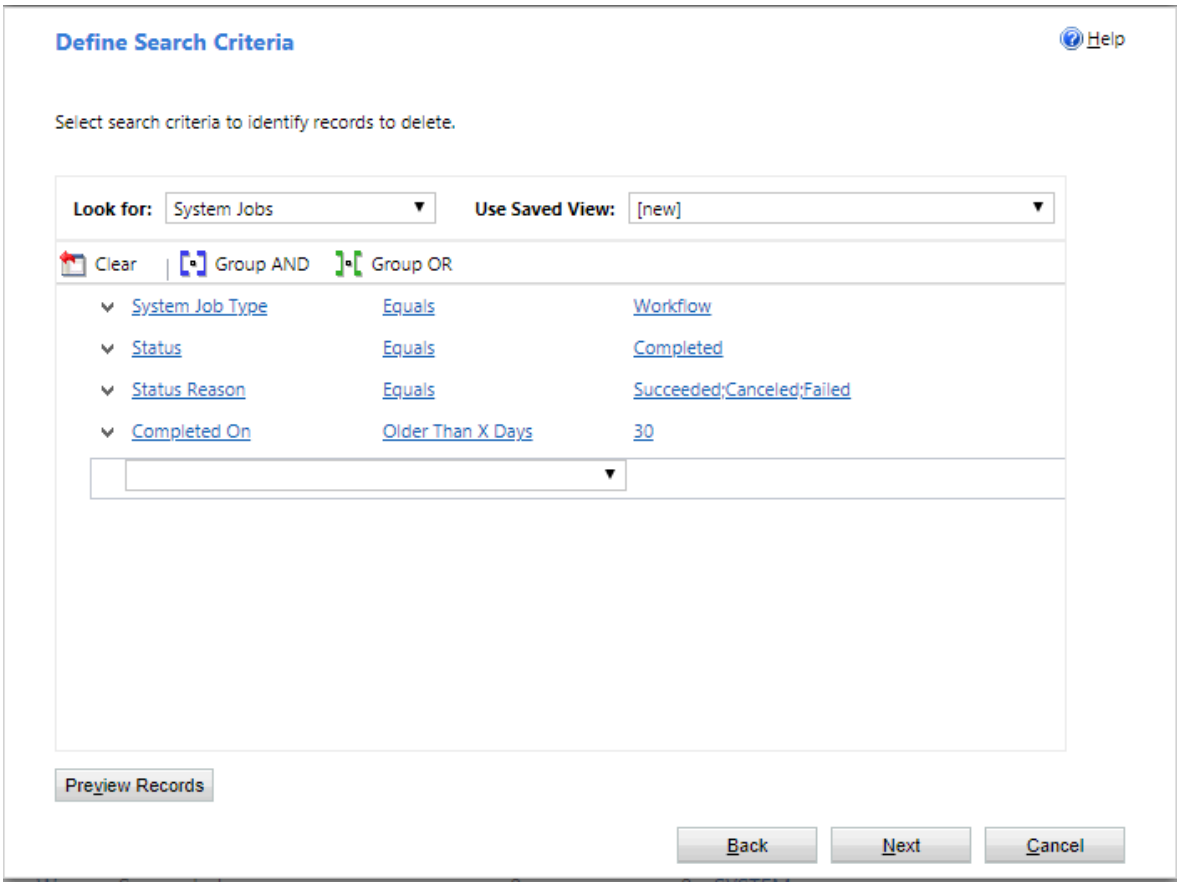
State	Status Reason
Ready	Waiting for Resources
Suspended	Waiting
Locked	In Progress Pausing Canceling

State	Status Reason
Completed	Succeeded
	Failed
	Canceled

Deleting process log rows

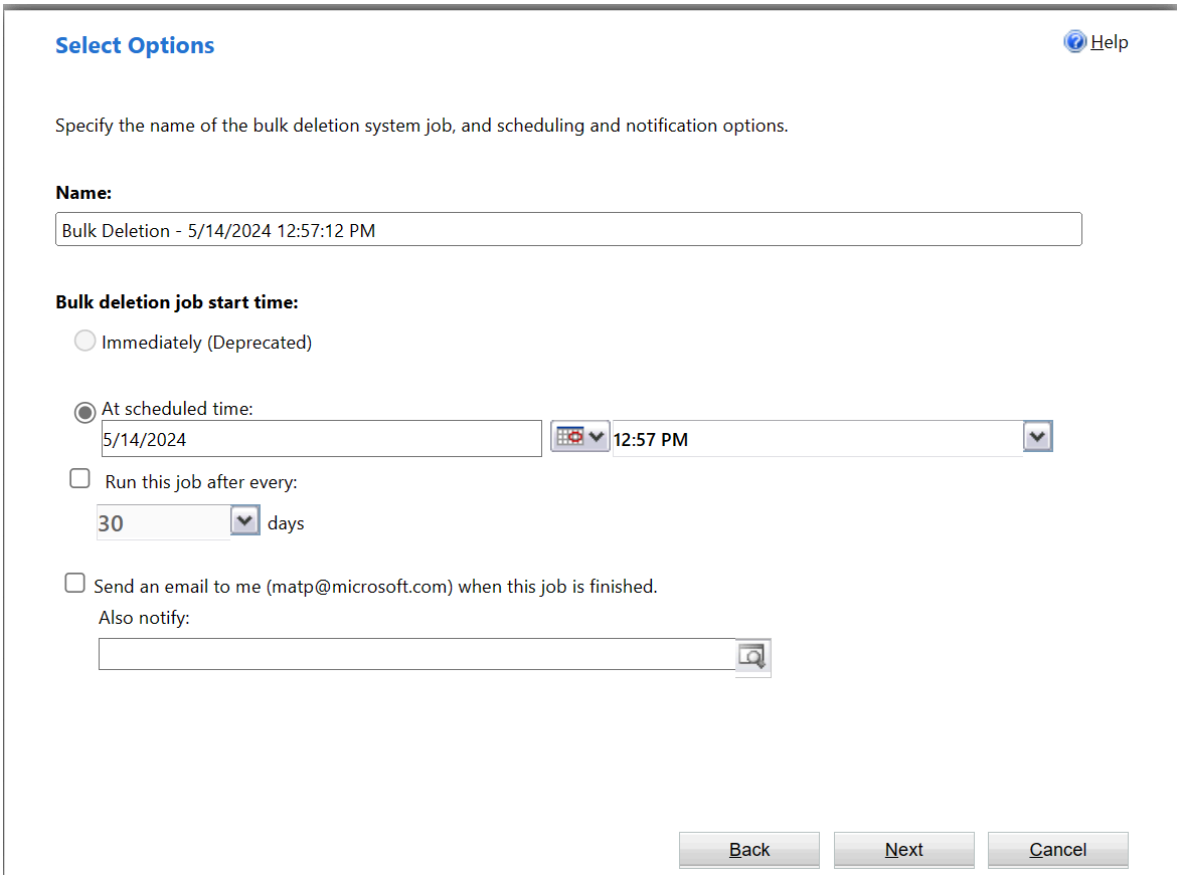
If your organization uses background workflows or business process flows that run frequently, the amount of process log rows can become large enough to cause performance issues as well as consume significant amounts of storage. To delete process log rows not removed sufficiently by one of the standard bulk row deletion jobs, you can use the bulk delete system jobs feature to create a custom bulk row deletion job.

1. Go to the Power Platform admin center, and open the environment you want.
2. Go to **Settings** > **Data Management** > **Bulk deletion**.
3. From the **Bulk Record Deletion** area, select **New**.
4. On the **Bulk Deletion Wizard** start page, select **Next**.
5. In the **Look for** list, select **System Jobs**.
6. The following conditions are used to create a bulk row deletion job to delete process log rows:
    - **System Job Type Equals Workflow**: This targets real-time workflow rows.
    - **Status Equals Completed**: Only completed workflows are valid to run the job against.
    - **Status Reason Equals Succeeded**: Delete successful, canceled, and failed jobs.
    - **Completed On Older than X Days 30**: Use the Completed On column to only delete real-time workflow process log rows that are older than 30 days.



7. Select **Next**.

8. Set the frequency that your bulk delete job runs. In this example, a recurring job is set to run on May 14, 2024, and every 30 days thereafter.



> **Note**
>
> Performing an immediate synchronous bulk delete of the rows by selecting the **Immediately** option is deprecated and no longer available for use.

9. Select **Next**, and then select **Submit**.

Best practices for real-time workflow processes

Article • 02/15/2022

This article contains best practices for creating and managing real-time workflow processes.

Avoid infinite loops

It's possible to create logic in a real-time workflow that initiates an infinite loop, which consumes server resources and affects performance. The typical situation where an infinite loop might occur is when you have a real-time workflow configured to start when a column is updated and then updates that column in the logic of the workflow. The update action triggers the same real-time workflow that updates the record and triggers the real-time workflow again and again.

The workflows you create include logic to detect and stop infinite loops. If a real-time workflow process is run more than a certain number of times on a specific record in a short period of time, the process fails with the following error: **This workflow job was canceled because the workflow that started it included an infinite loop. Correct the workflow logic and try again**. The limit of times is 16.

Use real-time workflow templates

If you have workflows that are similar and you anticipate creating more workflows that follow the same pattern, save your real-time workflow as a workflow template. This way, the next time you need to create a similar workflow, you can create the real-time workflow using the template and avoid entering all the conditions and actions from scratch.

In the **Create Process** dialog, choose **New process from an existing template (select from list)**.

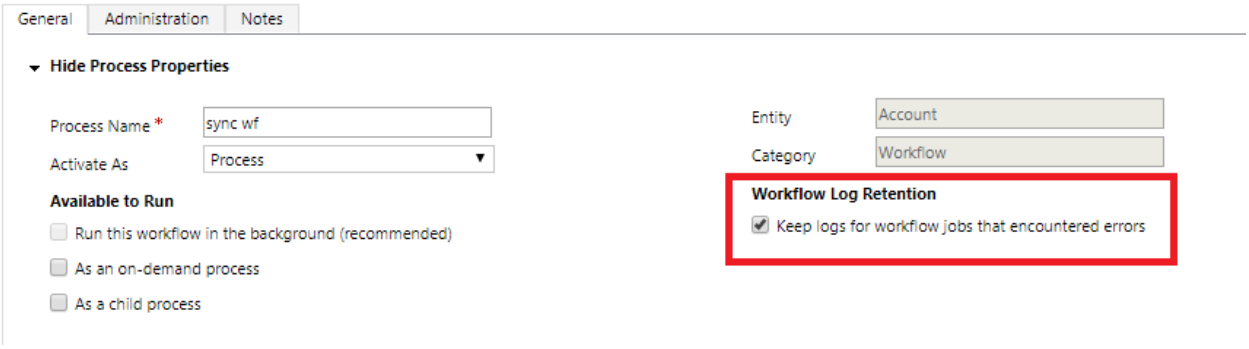
Use child workflows

If you apply the same logic in different workflows or in conditional branches, define that logic as a child real-time workflow so you don't have to replicate that logic manually in each real-time workflow or conditional branch. This helps make your workflows easier to

maintain. Instead of examining many workflows that might apply the same logic, you can just update one workflow.

Keep logs for real-time workflow jobs that encountered errors

For workflows that don't run in the background (synchronous), we recommend selecting the **Keep logs for workflow jobs that encountered errors** option in the real-time workflow definition. Selecting this option allows logs from failed real-time workflow executions to be saved for troubleshooting. Logs from successful synchronous workflow executions will always be deleted to save space.



Limit the number of workflows that update the same table

Running more than one real-time workflow that updates the same table can cause resource lock issues. Imagine several workflows running where every opportunity update triggers an update to the associated account. Multiple instances of these workflows running and attempting to update the same account record at the same time can result in resource locking issues. Real-time workflow failures occur and an error message, such as **SQL Timeout: Cannot obtain lock on resource *resource name***, is recorded.

Use Notes to keep track of changes

When you edit workflows you should use the Notes tab and type what you did and why. This allows someone else to understand the changes you made.

Functions in Microsoft Dataverse (preview)

Article • 05/01/2025

[This topic is pre-release documentation and is subject to change.]

Microsoft Dataverse offers a powerful solution for achieving more efficient data architecture and reducing client-side workload through functions (formerly known as instant low-code plug-ins). Functions in Dataverse use Power Fx to create your business logic. Power Fx is a general-purpose, strong-typed, declarative, and functional programming language. Whereas functions in Dataverse are reusable solution objects, which execute a specific set of commands within Dataverse, running server-side.

> **ⓘ Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Traditionally, functions were created using plug-ins. These plug-ins were created as custom classes compiled into a .NET Framework assembly, which were then uploaded and registered within Dataverse. However, now with the introduction of functions, users can create them with minimal or no coding required, and without the need for manual registration.

Functions are stored within a Dataverse database and can be seamlessly integrated into Power Apps and Power Automate. The behavior of the workflow is defined using the Power Fx expression language and can directly connect with Dataverse business data and external data sources through Power Platform connectors. With functions, makers can rapidly construct complex logic with minimal coding expertise.

Benefits of creating server-side logic

Defining server-side business logic offers several benefits, including:

- Increased security. Since server-side logic executes on the server, it can help prevent unauthorized access to sensitive data or processes.
- Improved performance. When executed on the server, business logic can reduce the amount of data that needs to be transferred between the client and server, resulting in faster processing times.
- Consistency and reliability. Server-side logic ensures that business rules are consistently applied across all clients, reducing the risk of errors or inconsistencies.

- Easier maintenance and upgrades. By centralizing business logic on the server, it becomes easier to maintain and update, as changes can be made in one place rather than having to update multiple clients.
- Scalability. Server-side logic can be scaled more easily than client-side logic, allowing for better performance and handling of larger workloads.

Functions overview

Functions in Dataverse use Power Fx. Power Fx is the low-code language that is used across Microsoft Power Platform. It's a general-purpose, strong-typed, declarative, and functional programming language used in Power Apps canvas apps as well as areas in model-driven apps, such as custom pages and commanding.

Functions offer these benefits:

- Can use parameters.
- Can manually run with trigger.
- Can support either global or table scope.

Functions have these general properties.

Expand table

Property	Description
Display name	The human-readable name of the function. Can't be changed once created.
Name	The internal name of the function. It's used by the platform to identify the component in code and database operations. Can't be changed once created.
Description	Used to provide additional context about the function, such as purpose, behavior, and so on. Can't be changed once created.
Solution	Used to group components and export to other environments. Learn more about solutions.
Expression	This is the custom function that can be used to perform actions or calculations, defined using the Power Fx expression language. Go to Supported functions for more details.

A function is custom code logic that's manually invoked by a user. Custom input and output parameters can be used with these unique properties.

Expand table

Property	Column2
Table Reference	Used to associate Functions to specific tables. You can select up to five tables to read or write from in your function's formula.
Parameters	Parameters allow you to pass information between the function and the context that runs it, making it easier to design business logic that can be reused in varying situations. Input parameters are used to provide data to the function, and allow you to control how the function behaves by passing in different values you specify in the Power Fx formula. Output parameters allow you to retrieve the results of a function for further use in your program. More information: Supported data types for input and output parameters

Supported data types for input and output parameters

- Boolean
- String
- Float
- Decimal
- DateTime
- Integer

For more information about how to integrate from a canvas app or in a Power Automate cloud flow, go to Invoke a function from a canvas app or custom page.

Functions permissions

Expand table

How run	Description
Design time	Makers who have system customizer security role membership or higher level role in the Power Platform environment can access all functions in that environment. Custom security roles can be used to restrict access to functions.
Run time	When a function is invoked, it accesses the table data involved in the function definition, which includes the tables that are part of the formula in the context of the user who invoked it.

Learning path: Work with Power Fx functions

Create and use functions in Microsoft Dataverse (preview)

Create and use functions in Microsoft Dataverse (preview)

Article • 02/24/2025

[This topic is pre-release documentation and is subject to change.]

Create and use reusable functions in Microsoft Dataverse. Functions use Power Fx to execute a specific set of commands within Dataverse that run server-side.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Prerequisites

System customizer security role membership in the Power Platform environment.

Create a function in a solution

1. Go to Power Apps, and then select **Solutions** in the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the solution where you want to create a function.
3. On the command bar, select **New** > **Automation** > **Function**.
4. Enter the following information in the **New function** side panel that appears.

    - Provide a Display name and Description for your function.
    - Select **New input parameter** and/or **New output parameter**, then provide a name and data type for the parameter. Add more input and output parameters as needed.
    - In the **Table references** list you can optionally select tables. You can reference the Dataverse tables you choose using data collection functions, such as **Filter()** and **LookUp()**.
    - Enter the Power Fx expression in **the Formula** box.

5. Select **Save**.

6. Test the function.

Reference input parameters in the formula by their names.

Output parameters must be referenced inside of curly brackets, such as `{ Out: "Return value" }`.

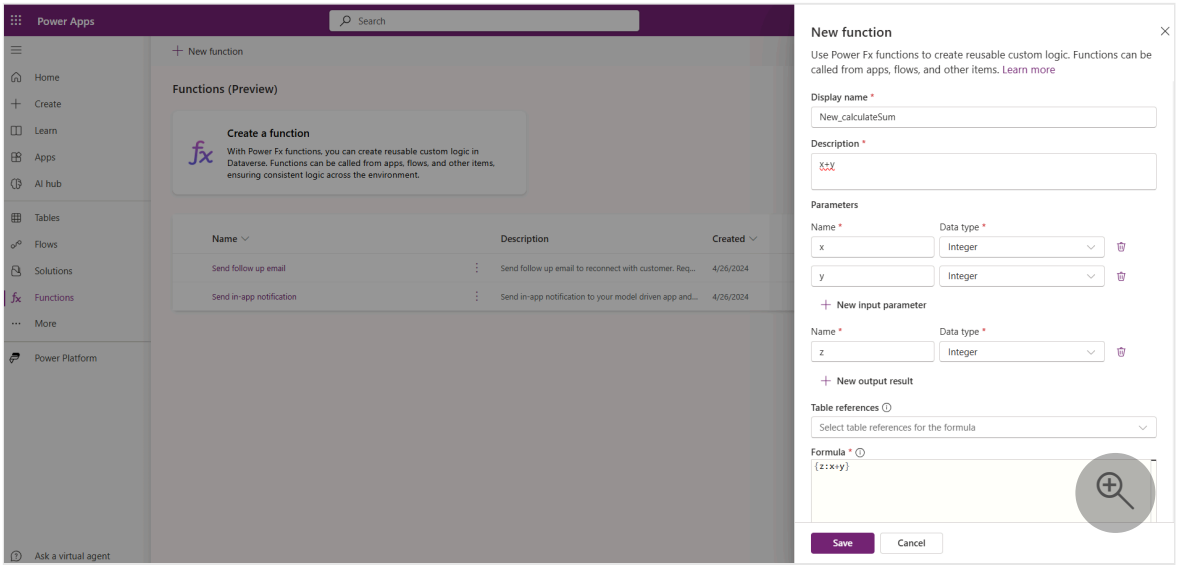
> **Tip**
>
> - Notice the intellisense in the **Formula** box. Underlined red is invalid. Squiggly yellow means your logic might be affected by delegation limitations. Avoid delegation issues by using delegable functions.
> - Expand Advanced options to review your schema name.

Example functions

This section provides a few example functions.

Calculate the sum of two integers

1. Enter a **Display name**, such as **new_calculateSum**, and a **Description**.
2. Add two input parameters, x and y (both of data type integer), and one output parameter, z (data type integer).
3. In the **Formula** box, enter the formula:
   `{ z:x+y }`



4. Test the function.

Add a new title to article table

1. Create two input parameters title and url (both with string data types) and one output variable, message (data type string).
2. Select the **Knowledge Federated Articles** table in the **Table references** dropdown.
3. In the **Formula** box, enter the formula:

PowerApps Formula

```
Collect('Knowledge Federated Articles',
   {
    Title: title,
    URL: url
    }
    );
{
    message: "New Article title added: " & title
}
```

Validate if an input string contains the strings of your choice

1. Create an input parameter **DocumentTextInput** (with string data type) and one output variable, named **result** (data type string).
2. In the **Formula** box, enter the formula:

PowerApps Formula

```
{
    result: If("Confidentiality" in DocumentTextInput && "Dispute
Resolution" in DocumentTextInput && "Governing Law" in DocumentTextInput &&
"Termination" in DocumentTextInput,

    "Document is compliant.",
    "Document is missing one or more compliance clauses."
    )
}
```

Calculate a hotel stay price

1. Create six input parameters: nights, rooms, tax, discount, roomservice, ratepernight (all with string data type) and one output variable, price (data type float).
2. In the **Formula** box, enter the formula:

PowerApps Formula

```
{
   price: ((nights*rooms*ratepernight)*(1+(tax/100))*(1-
(discount/100)))+roomservice

}
```

More function examples

For more example functions, go to Example functions (preview).

Edit, test, or delete a function

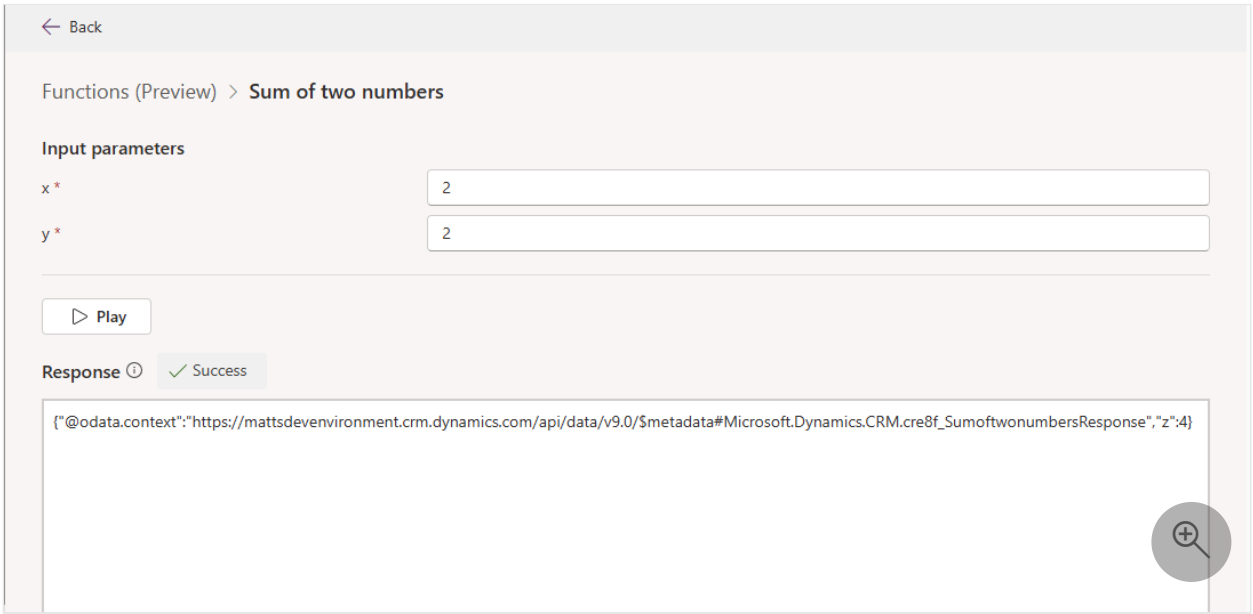
Edit a function

1. Select your function in the **Functions** area.
2. Select **Edit** on the command bar.
3. Modify your formula, and then **Save** it.

Test a function

1. Select the function in the **Functions** area.
2. Select **Test** on the command bar.
3. Provide values for the input parameters that are defined in the function, and then select **Play**.

A successful test returns an OData response that includes information such as the organization URI, function name, and output parameters and values.



> **Tip**
>
> Use output parameters to help validate expected behavior and results. Otherwise, you only observe success or failure when testing.

Delete a function

> **Important**
>
> During the preview, don't delete your functions from the **Solutions** area as it might result in orphan components. Functions should be deleted by going to Power App (make.powerapps.com) > **Functions** on the left navigation pane.

1. Select **Functions** on the left navigation pane, and then select your function. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **Delete** on the command bar.

Invoke a function from app, flow, code, or another function (preview)

Article • 02/26/2025

[This topic is pre-release documentation and is subject to change.]

You can invoke functions in Dataverse from a canvas app, a custom page in a model-driven app, a flow, code, or from another function.

> **ⓘ Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Invoke a function from a canvas app or custom page

1. From the **Functions** area in Power Apps (make.powerapps.com), select the function you want to invoke from a canvas app or custom page.
2. Select **Copy code snippet** on the command bar.
3. Paste and save the copied formula to a text editor, Notepad, or somewhere you can easily refer to.
4. In Power Apps Studio:
   a. Create or edit a canvas app or custom page in Power Apps Studio.
   b. On the left navigation pane, under the **Data Sources** tab, select **Add data**, and search for the **Environment** option from the Dataverse connector, and select it.
   c. Insert the following components onto the canvas:

      - Add input controls that correspond with each parameter's data type, such as number input.
      - Add a button to call the function.
      - Add an output control that corresponds with your parameter's data type, such as number input.

5. Select the button you created, and in the **OnSelect** property, enter your function, such as *Environment.new_calculatesum*.

6. Map each input parameter `Value` to reference the corresponding input controls:

    - If your function is `Environment.new_CalculateSum({ X: Value, Y: Value });`, it could be rewritten as: `Environment.new_CalculateSum({ X: NumberInput1.value, Y: NumberInput2.value });`.
    - To set your Function 'result' output, update your formula to 'Set(result, Environment.new_CalculateSum({ X: NumberInput1.value, Y: NumberInput2.value }))'.

7. Select the output control and set the 'Value' property with a formula of 'result.z'.

Preview your app, enter input 1 and 2 values, and select the button. The result should show in the output field.

Invoke functions from a Power Automate cloud flow

1. In a cloud flow, add a new action from the Microsoft Dataverse connector.
2. Select the action called **Perform an unbound action**
3. Select your function. The function has a unique name with a prefix.
4. Provide values for all the input parameters (if any).

Invoke functions from the Dataverse Web API

Follow the steps for the unbound action sections in the Invoking custom APIs from the Web API article (depending on the appropriate scope of the plug-in).

Invoke existing functions from within new functions

To invoke an existing function within a new function, use the syntax: `Environment.ExistingFunction({inputParam1: value1, inputParam2: value2, ... inputParamN: valueN})`

Since the output is always a record, use the dot notation to access the output parameters. For example, if the function "ExistingFunction" has two output parameters defined as out1 and out2, you can access them in either of these two ways:

- `Environment.ExistingFunction({inputParam1: value1, inputParam2: value2, ... inputParamN: valueN}).out1`

- `Environment.ExistingFunction({inputParam1: value1, inputParam2: value2, ... inputParamN: valueN}).out2`

Limitations with functions in Dataverse

- The environment language object needs to be readded to access new functions inside existing canvas apps. For any functions created after you added the environment table data source to an existing canvas app, you must remove and readd the Power Fx environment language object. Then you see the updated list of functions as actions.
- Nested support. functions can only call Microsoft actions published by Microsoft from Power Fx expressions.
- Some `Collect` scenarios require `Patch`. There are some scenarios where `Collect()` doesn't work. The workaround is to use `Patch()` as shown in the populating regarding column example here.

PowerApps Formula

```
Patch(Faxes,
       Collect(Faxes, {  Subject : "Sub1" } ),
       { Regarding : First(Accounts) }
    )
```

Debug and get help with your functions

If you encounter issues creating or running your function, use the `trace()` function for debugging or go to Limitations with functions in Dataverse for common issues that can occur.

Debugging using the trace() function

1. To debug using the trace function, make sure that you enable plug-in and custom workflow activity tracking.
2. Go to Power Apps (make.powerapps.com), select the **Settings** gear icon on the upper right, and then select **Advance settings**.
3. Select Settings > Auditing > Global Audit Settings.
4. On the **Customization** tab, ensure that **Enable logging to plug-in trace log** is enabled for **All**.

Once you enable tracking, you can start using trace() functions to debug Power Fx formulas. Learn more about how to use the trace() function inside a Power Fx

expression: Trace function - Power Platform.

Contacting help + support

For issues with functions not covered in Microsoft Dataverse low-code plug-ins tips and known issues, such as undocumented errors received, use the Help + support experience and include the following information:

- Problem Type- Dataverse Web API and SDK.
- Problem Subtype.

Example functions (preview)

Article • 02/15/2025

[This topic is pre-release documentation and is subject to change.]

The article helps you get started with functions in Microsoft Dataverse by integrating them into your apps. You'll understand that the authoring experience includes authoring Dataverse custom APIs backed by Power Fx expressions, which can trigger actions internal or external to Dataverse.

> **ⓘ Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Test a Power Fx expression

You can test a Power Fx expression to verify it's working. This example uses the `Abs()` function to return the non-negative value of its argument. If a number is negative, `Abs` returns the positive equivalent.

1. Sign into Power Apps and select **Functions** from the left navigation. If the item isn't in the side panel pane, select ...More and then select the item you want. Open the unmanaged solution where you want to add a function.

2. Select **New function**.

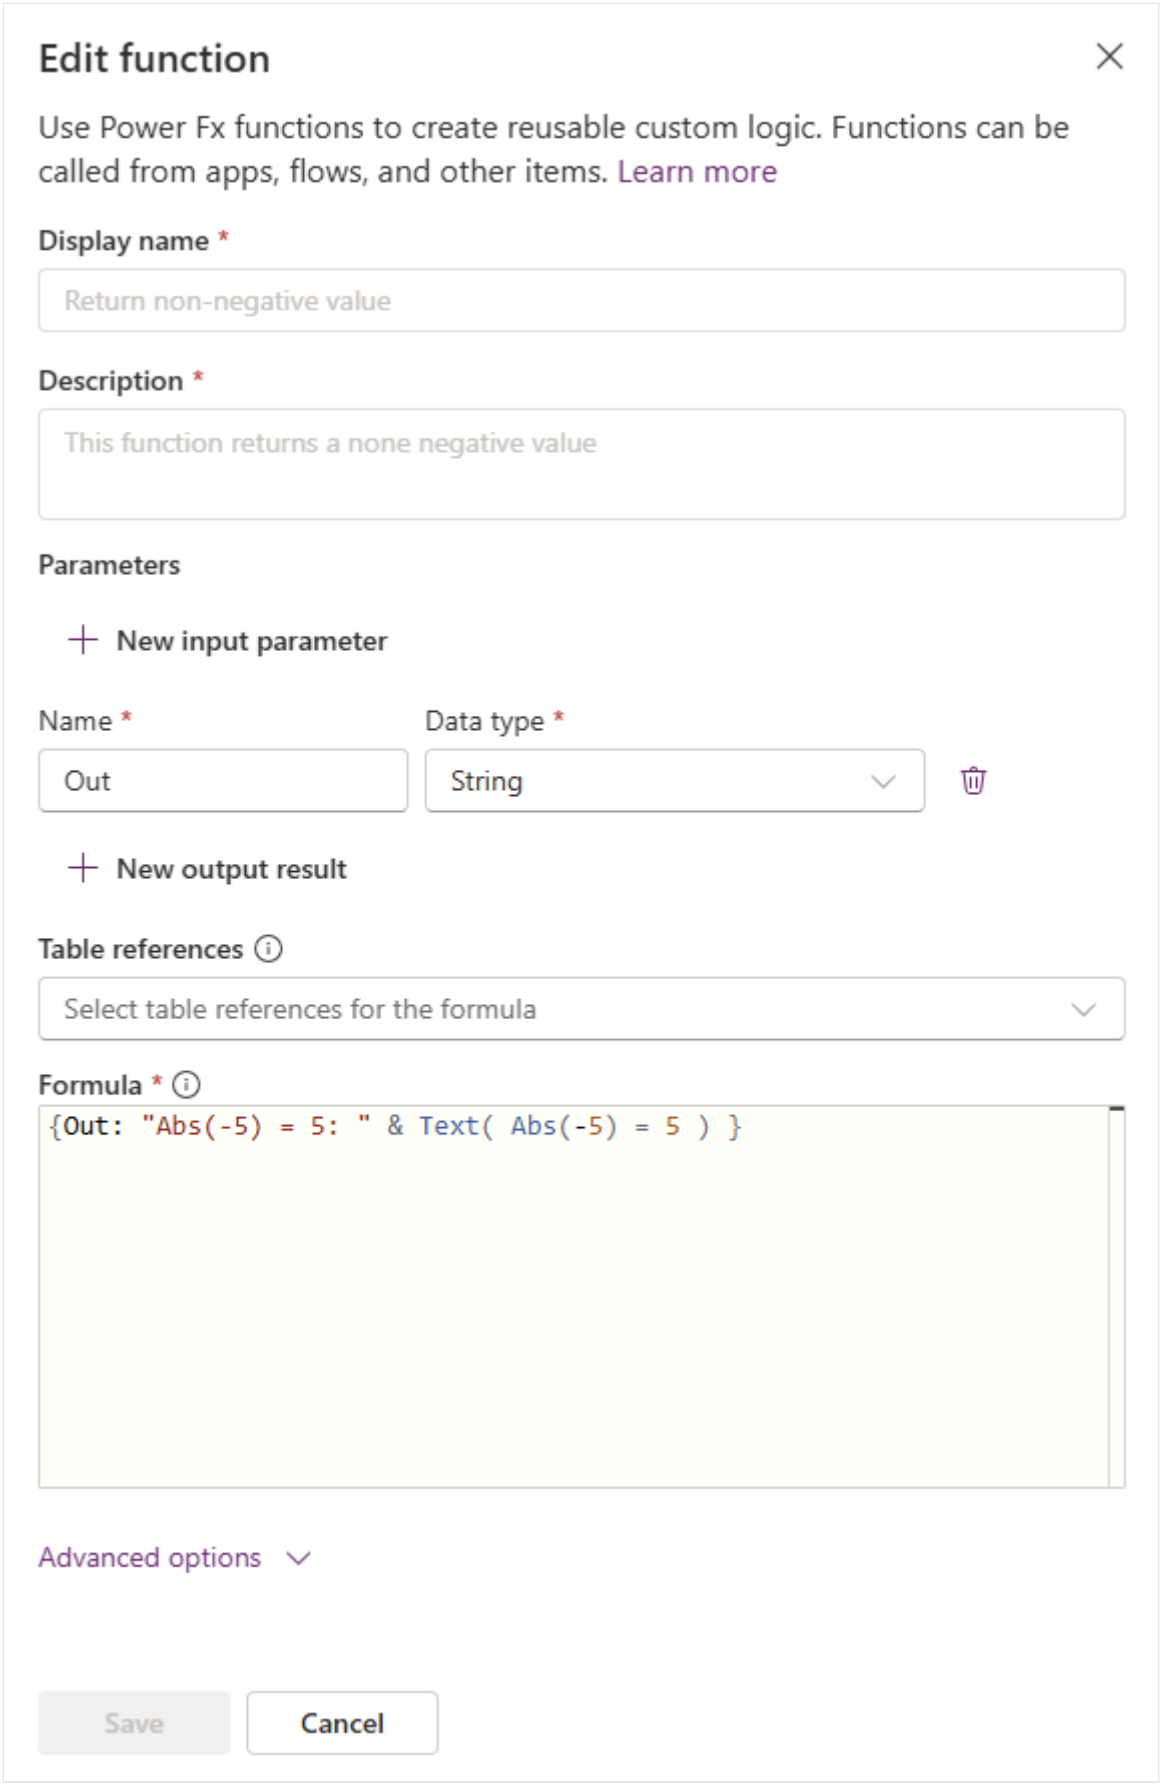
3. On the **New function** pane, enter a **Display name**, such as *Return non-negative value*, and **Description** for your function.

4. Create a **New output parameter** to validate expected behavior, such as a string. For example, enter the **Name** of your **New Output parameter** *Out*.

5. Optionally, use input parameters to make testing easier, that makes sense with the formula. In this example, no input parameters are used.

6. In the **Formula** box, wrap the **Out** parameter in curly brackets: `{Out: "" }` For example, you can test the Abs() function, which uses -5 to return the absolute value 5.

```
{Out: "Abs(-5)=5:"& Text(Abs(-5) = 5) }
```



7. Select **Save**.

To test the function, select the function and then select **Test** on the command bar. Then select **Play**. Based on the formula used in this example function, the response returns

the value 5 as true.

Supported functions

Functions in Microsoft Dataverse can add business logic to your apps using the Power Fx expression language and you can quickly build rich workflows without any code. Functions support many of the Power Fx operators, variables, and formulas.

The following table lists the Power Fx formulas that work with functions in Dataverse but have limitations or don't work but have an alternative for use with functions.

Expand table

Power Fx formula or operation	Supported in functions?	Limitation or work around
`Collect`	Yes	Requires the variable to exist and the variable type to match what you're trying to set it to.
`Defaults`	No	Use `Collect` instead of `Patch`. For example, instead of `Patch(account, Defaults(account), {"Account Name": "Example Account"})`, use `Collect(account, {"Account Name": "Example Account"})`.
Add tables in the UI	Yes	For example, in order for the expression to `Collect(Accounts, {... })`, the accounts table needs to be added in the UI. This helps with intellisense.
Accessing fields in formula	Yes	No implicit scope for accessing fields. Instead of saying `Field2`, say `NewRecord.Field2`. This applies to `Set` as well: `Set(NewRecord.Field1, OldRecord.Field2*10)`.
`With()`	Yes	Functions don't support contexts, named formulas, or variables. `With()` can be used to create aliases and factor the expressions.
Access Dataverse tables	Yes	Functions can read and write to Dataverse tables. This includes `Collect()`, `Patch()`, `Filter()`, and `LookUp()`. Delegation operations are supported, and a warning is issued if an expression can't be delegated. These operations run directly against the function's `IOrganizationService` (not the current table) and directly operate on the database. Functions run in the transaction context.

Use low-code plug-ins in Dataverse (preview)

Article • 11/13/2024

[This topic is pre-release documentation and is subject to change.]

Microsoft Dataverse offers a powerful solution for achieving more efficient data architecture and reducing client-side workload through low-code plug-ins. These plug-ins are reusable, real-time workflows that execute a specific set of commands within Dataverse, running server-side and triggered by personalized event handlers.

> **ⓘ Important**
>
> - Instant low-code plug-ins are deprioritized and aren't being delivered as a feature. Instant low-code plug-ins are replaced with functions. More information: Functions in Microsoft Dataverse (preview)
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Traditionally, plug-ins were created as custom classes compiled into a .NET Framework assembly, which were then uploaded and registered within Dataverse. However, with the introduction of low-code plug-ins, users can create these event handlers with minimal or no coding required, and without the need for manual registration.

Low-code plug-ins are stored within a Dataverse database and can be seamlessly integrated into Power Apps and Power Automate. The behavior of the workflow is defined using the Power Fx expression language and can directly connect with Dataverse business data and external data sources through Power Platform connectors. With low-code plug-ins, makers can rapidly construct complex workflows with minimal coding expertise, resulting in a more streamlined and efficient data architecture.

Benefits of server-side logic

Defining server-side business logic offers several benefits, including:

- Increased security. Since server-side logic executes on the server, it can help prevent unauthorized access to sensitive data or processes.

- Improved performance. By executing on the server, business logic can reduce the amount of data that needs to be transferred between the client and server, resulting in faster processing times.
- Consistency and reliability. Server-side logic ensures that business rules are consistently applied across all clients, reducing the risk of errors or inconsistencies.
- Easier maintenance and upgrades. By centralizing business logic on the server, it becomes easier to maintain and update, as changes can be made in one place rather than having to update multiple clients.
- Scalability. Server-side logic can be scaled more easily than client-side logic, allowing for better performance and handling of larger workloads.

Low-code plug-ins

There are two types of low-code plug-ins supported in Dataverse:

Expand table

Type	Trigger	Supports parameters	Supported scope
Instant	Manually run	Yes	Global and table
Automated	Dataverse table event	No	Table

All low-code plug-ins have the following common properties:

Expand table

Property	Description
Display name	The human-readable name of the plug-in. Can't be changed once created.
Name	The internal name of the plug-in. It's used by the platform to identify the component in code and database operations. Can't be changed once created.
Description	Used to provide additional context about the plug-in (purpose, behavior, or other important details).
Solution	Used to group components and export to other environments. Learn more about solutions.
Expression	This is the custom function that can be used to perform actions or calculations, defined using the Power Fx expression language. Power Fx is a formula language used in Power Apps canvas apps, and has been extended to be used in low-code plug-ins. See supported functions for more details.

Instant plug-ins

An instant low-code plug-in is custom code logic that's manually triggered by a user. Custom input and output parameters can be used.

Unique properties:

Expand table

Property	Description
Scope	Used to associate a plug-in to a specific table. It can be set to either table (shown as entity) or global, where table (entity) scope means the plug-in is triggered with the context of a specific table record, and global scope means the operation isn't associated with a table (learn more).
Parameters	Parameters allow you to pass information between the plug-in and the context that runs it, making it easier to design business logic that can be reused in varying situations. **Input parameters** are used to provide data to the plug-in, and allow you to control how the function behaves by passing in different values you specify in the Power Fx formula. **Output parameters** allow you to retrieve the results of a function or method for further use in your program. Supported data types: • Boolean • String • Float • Decimal • DateTime • Integer

More information about how to integrate from a canvas app or in a Power Automate cloud flow: Integrate a low-code plug-in

Plug-in permissions

Design time

Makers who have system customizer or system administrator security role membership in the Power Platform environment can access all plug-ins in that environment. Custom security roles can be used to restrict access to low-code plug-ins.

Run time

When a plug-in is invoked, it accesses the table data involved in the plug-in definition (the tables that are part of the formula, or if the table is associated with the settings of an automated plug-in) in the context of the user who invoked it.

Connections

Using security roles, connector access within plug-ins can be restricted to a specific set of users within your organization. Specify which roles have create, read, update, or delete privileges.

Prerequisites for creating a low-code plug-in

- ✓ System administrator or system customizer security role membership in the Power Platform environment.
- ✓ Access to the Dataverse accelerator app.

> **Tip**
>
> All new environments have the Dataverse accelerator app automatically installed as of October 1st 2023. If you already had the Dataverse accelerator installed, you can manually update the Dataverse accelerator.

Update the Dataverse accelerator

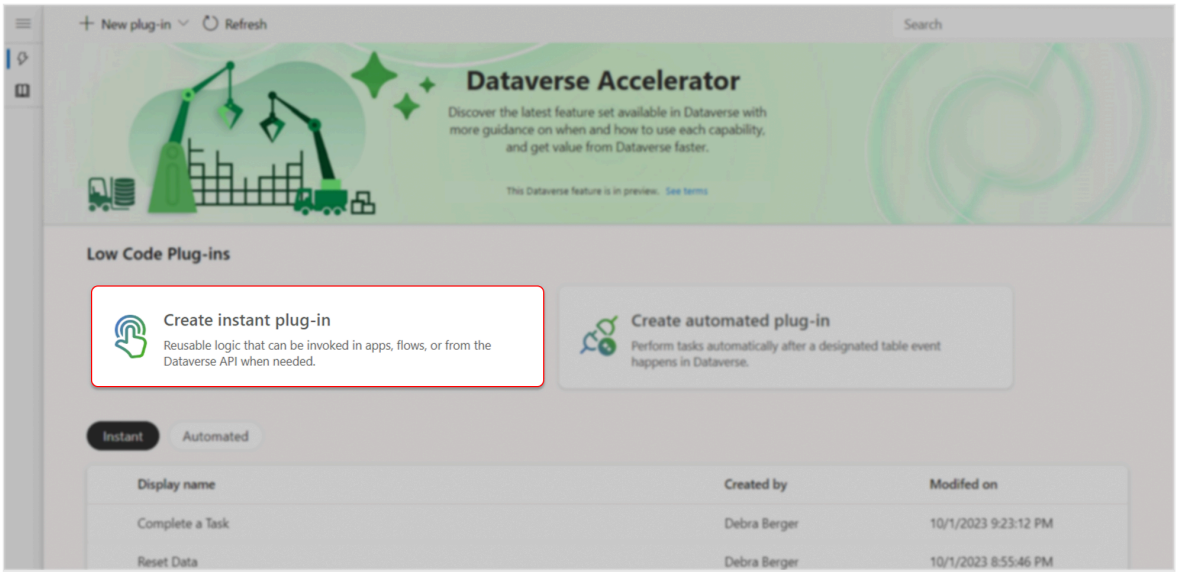
1. Follow the instructions to view licensed apps in your environment.
2. If the **Dataverse Accelerator** is already installed and an update is available, it's indicated in the table next to the item.
3. Select **Dataverse Accelerator**, and then select **Update** on the command bar.

> **Tip**
>
> Enable auto app updates for the **Microsoft - Power CAT** publisher to automatically receive updates when available (not necessary for new environments created after October 1st 2023).

> **Note**
>
> If you previously installed the optional **Low-Code Plug-ins for Connectors** solution, it will be automatically deleted when you update after June 29, 2023. The capabilities will be available in the main solution.

Create an instant low-code plug-in

1. Play the Dataverse accelerator app.
2. Select the **Create instant plug-in** card.



3. Provide a **Display name**.
4. Optionally, define parameters:

    - Select **New input parameter** or **New output parameter**, then enter the label and data type.
    - Add more input and output parameters as needed.

5. Enter the Power Fx expression in the **Expression** editor.

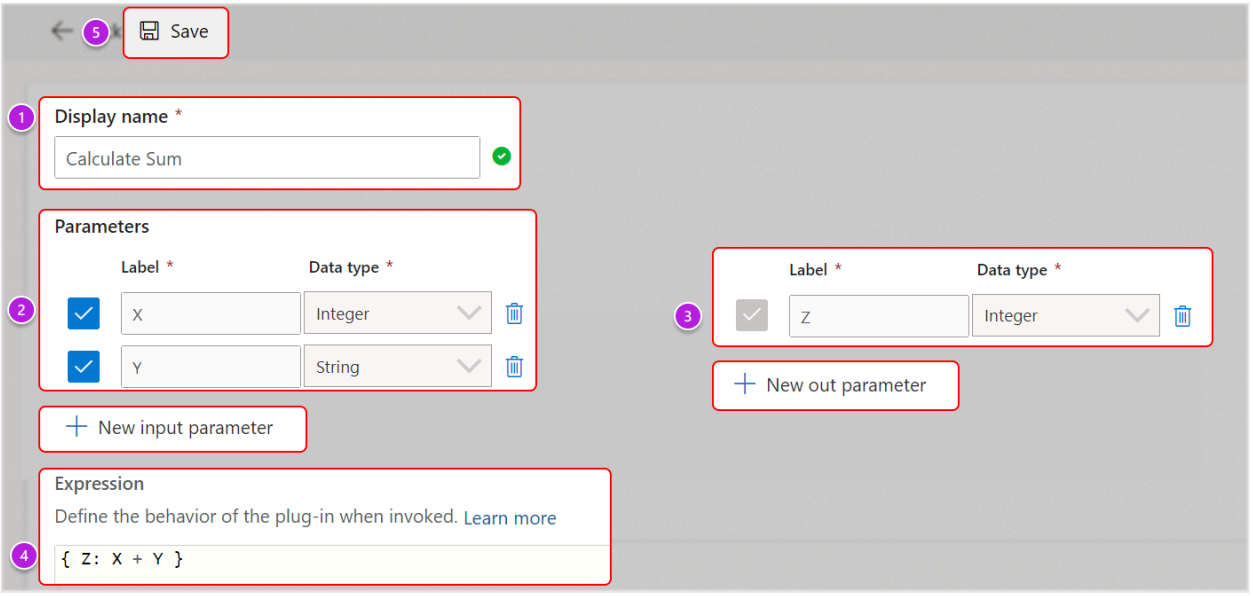
    - Reference input parameters in the formula by the label name.
    - Output parameters must be referenced inside of curly brackets, such as `{ Out: "Return value" }`.
    - Reference Dataverse tables using data collection functions, such as Filter() and LookUp().
    - If the scope is set to entity, use `ThisRecord` to access column values in the table row associated with the plug-in run, such as `ThisRecord.'Account Name'`.

> **Tip**
>
> Note the intellisense in the **Expression** box. Underlined red is invalid. Squiggly yellow means your logic might be affected by delegation limitations. Avoid delegation issues by using delegable functions.

6. Optionally expand **Advanced options** to modify the **solution**, **scope**, or **description**.
7. Select **Save**.
8. Test your instant low-code plug-in.

Example: Calculate the sum of two integers.

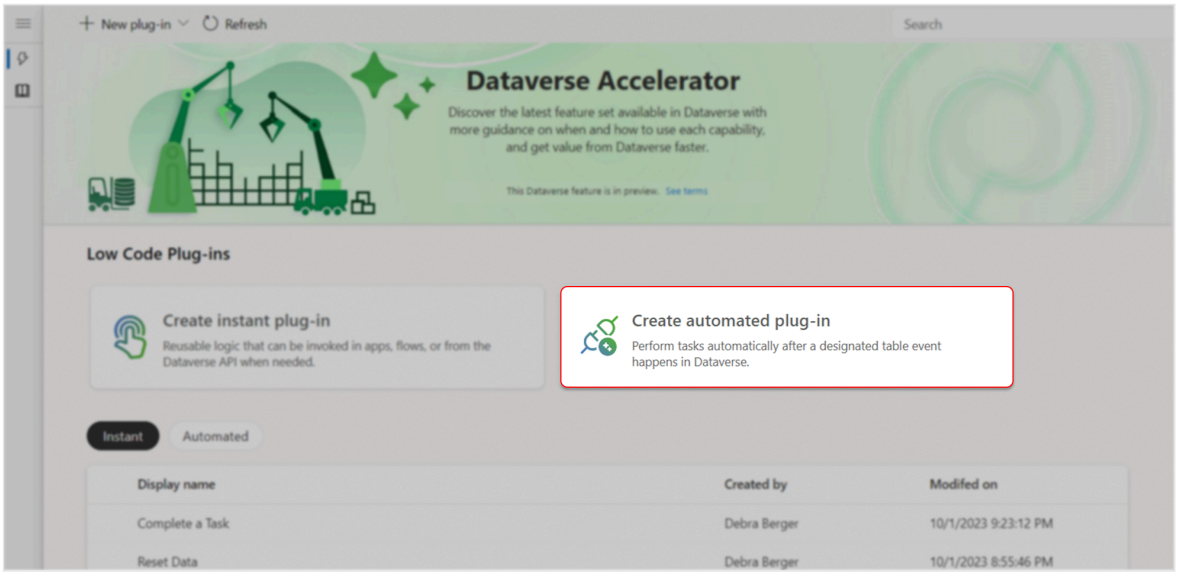
- Create two input parameters, `X` and `Y` (both of type integer), and one output parameter, `Z` (type string).
- Use the following formula: `{Z: X + Y }`



Create an automated low-code plug-in

1. Play the Dataverse accelerator app.

2. Select the **Create automated plug-in** card.



3. Provide the following values:

   - **Name**: Enter a name for the plug-in, such as *Input validation*.
   - **Table**: Choose a table to associate the plug-in to, such as *Account*.
   - **Run this plug-in rule when the row is**. Specify the data event that invokes the plug-in.

4. Enter the Power Fx expression in the **Expression** editor.

   - Reference Dataverse tables using data collection functions, such as Filter() and LookUp().
   - Use `ThisRecord` to access column values in the table row associated with the plug-in run, such as `ThisRecord.'Account Name'`.

5. Optionally, expand **Advanced options** to modify the **stage** (when this should run) and the **solution** where the plug-in is saved.
6. Select **Save**.
7. Test your automated low-code plug-in.

Use Power Platform connectors in low-code plug-ins

Power Platform connectors can be used in low-code plug-ins to easily integrate data and functionality from systems outside of Dataverse, such as SQL Server, Salesforce, and SharePoint, without the need for complex coding or custom development.

Prerequisites for using connectors in low-code plug-ins

✓ Prerequisites for creating a low-code plug-in

✓ Connection reference with an active connection.

Using connector actions in low-code plug-ins

You can easily use connectors and custom connectors from within a low-code plug-in a Power Fx formula.

1. Create a connection to the connector you want to use.
2. Add a connection reference to the connection in the Dataverse environment.
3. In the low-code plug-in Power Fx expression editor, type the name of the connection reference (the internal name with a prefix and underscore, like `new_connectorName`, not the display name).
4. Intellisense shows you the available actions. Select the action you want, and then enter the required parameters.

Before using a connector in a low-code plug-in, review the connector's documentation to ensure that you're passing the input and output parameters correctly.

More information: example

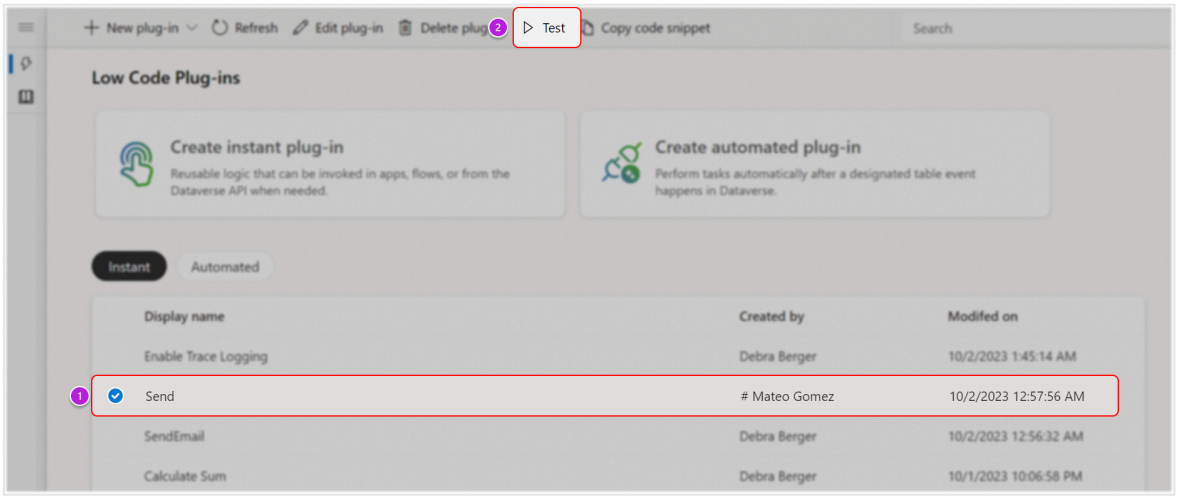
> **Note**
>
> - Not all connector actions are supported at this time.
> - Do not use the Dataverse connector to connect to Dataverse tables from a plug-in expression. Instead, use the native Power Fx functions to interact with collections: Filter, Search, LookUp, Patch, Collect, and Set, where columns are treated as global variables.

Test a low-code plug-in

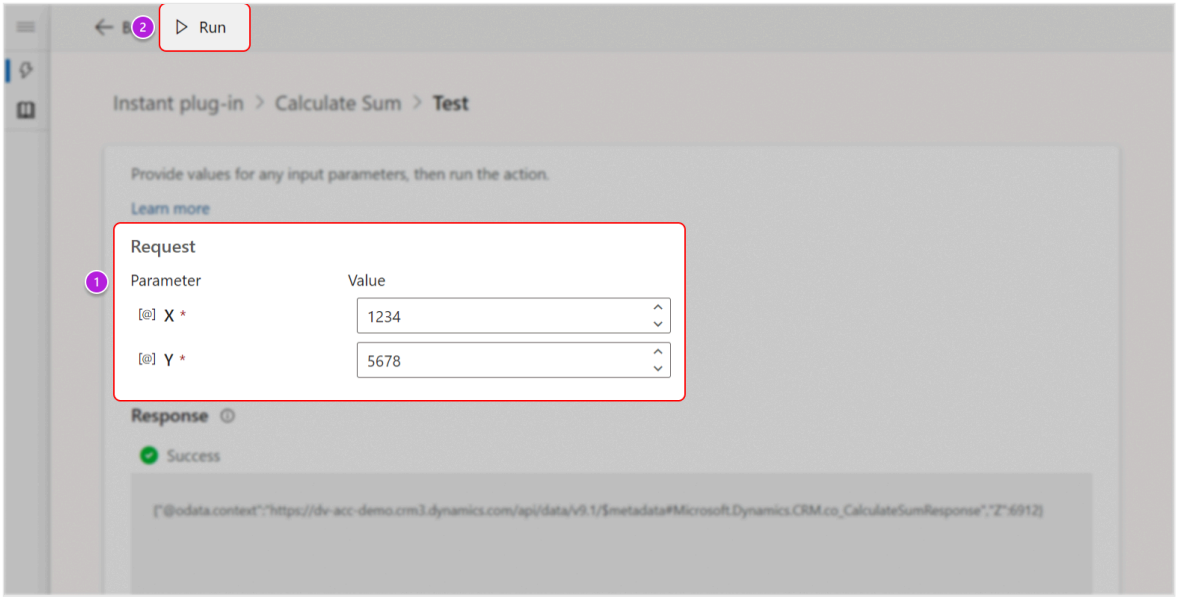
Test instant plug-ins

1. From the **Home screen**, select an instant plug-in from the list, then select **Test** on the command bar. You can also get to this screen from the instant plug-in editor in

the command bar after it's been saved.



2. Provide values for any input parameters that are defined in the low-code plug-in, and then select **Run**.



Observe the response.

> **Tip**
>
> Use output parameters to help validate expected behavior and results. Otherwise, you only see a success or failure when testing.

Test automated plug-ins

Test automated plug-ins by invoking the data event. Observe if the plug-in ran successfully by validating expected changes that were defined in the formula.

> **Tip**

During the preview, you can invoke the associated data event using the table editor in Power Apps:

1. Sign into Power Apps, go to **Tables** and select the **Plug-in** table.
2. On the command bar, select **Edit**.
3. Create, update, or delete rows directly from this view. Alternatively, open a row in the default form by selecting a row, then select **Edit row using form** on the command bar.

Integrate a low-code plug-in

Invoke an instant plug-in from a canvas app or custom page

1. In the **Dataverse Accelerator** app:
   a. Select the instant plug-in in the list.
   b. Select **Copy code snippet** on the command bar.

   c. Paste and save the copied formula to a text editor or notepad (somewhere you can easily refer back to).
2. In Power Apps:
   a. Create or edit a canvas app (or custom page) in the Power Apps studio.
   b. In the left navigation, under the **Data Sources** tab, select **+ New data source**, and search for the **Environment** option from the Dataverse connector.
   c. Insert the following components into the canvas:

      - Add input controls that correspond with each parameter's data type, such as Text input for text or numbers, toggle for boolean.
      - If the plug-in scope is bound to a table, add a combobox that is associated with the same table so you can choose the input.
      - Add a button to call the plug-in.

3. Paste the plug-in formula you copied into the button's `OnSelect` property.
4. Map each input parameter `Value` to reference the corresponding input controls:

    - If the formula was `Environment.new_CalculateSum({ X: Value, Y: Value });`, it could be rewritten as: `Environment.new_CalculateSum({ X: TextInput1.Text, Y: TextInput2.Text });`
    - If the formula was bound, replace `Environment` with the table display name to access the plug-in.

5. If an output parameter is defined for the low-code plug-in:
    a. Capture the response in a `Set()` or `UpdateContext()` formula: `Set( ActionResult, Environments.CalculateSum({ X: TextInput1.Text, Y: TextInput2.Text }) );`. Display the variable in a label. Alternatively use the `Notify()` formula to display data in a notification.
6. Play the app and select the command on the command bar to run the low-code plug-in.

Learn more about how you can call Dataverse actions directly from Power Fx in canvas apps.

Invoke an instant plug-in from a Power Automate cloud flow

1. In a cloud flow, add a new action from the Microsoft Dataverse connector.
2. Select the action called Perform an unbound action or Perform a bound action.
3. Select your plug-in (it has the unique name with a prefix).
4. Provide values for all of the input parameters (if any).

Invoke an instant plug-in from the Dataverse Web API

Follow the steps for **Unbound action** or **Function bound to table** sections in the Invoking custom APIs from the Web API documentation (depending on the appropriate scope of the plug-in).

Getting help with you low-code plug-ins

If you encounter issues creating or running your low-code plug-in, go to these tips for common issues that can occur: Microsoft Dataverse low-code plug-ins tips and known issues

Contacting Help + support

For issues with the Dataverse Accelerator solution installation or low-code plug-ins not covered in Microsoft Dataverse low-code plug-ins tips and known issues, such as undocumented errors received, use the Help + support experience and include the following information:

- Problem Type- Dataverse Web API and SDK
- Problem Subtype- Accelerator kit for Dataverse

Example low-code plug-ins you can create

For a few examples of how to create a low-code plug-in, go to Example Dataverse low-code plug-ins (preview)

Limitations

- The environment language object needs to be readded to access new plug-ins inside existing canvas apps. For any plug-ins created after you have added the environment table data source to an existing canvas app, you have to remove and readd the Power Fx environment language object. Then you see the updated list of plug-ins as actions.

- Intellisense requires explicit notation in automated plug-ins if you want to refer any tables in the formula. Use the following disambiguation syntax such as `[@Accounts]`, using square brackets and the `@` symbol (not `Accounts`).

- Nested support. Plug-ins can only call first-party actions published by Microsoft from Power Fx expressions.

- Some `Collect` scenarios require `Patch`. There are some scenarios where `Collect()` doesn't work. The workaround is to use `Patch()` as shown in the populating regarding column example below. If you're creating an automated plug-in, prepend @ to each table referenced in the Power Fx formula.

  Power Fx

  ```
  Patch(Faxes,
      Collect(Faxes, { Subject : "Sub1" } ),
      { Regarding : First(Accounts) }
  )
  ```

- When low-code plug-ins interact with connectors and DLP is employed, the admin can block creation of connections using DLP. However, existing connection

references in the Dataverse environment continue to function. In case the admin needs to block all low-code plug-in interactions with any connectors, they can disable the organization setting `Allowconnectorsonpowerfxactions`. This setting is enabled by default and can be disabled by usual SDK methods (WebAPI, SDK, PowerShell, and so on). You can disable this using a low-code instant plug-in as follows:

```
Power Fx

Patch(Organizations, First(Organizations), { 'Enable connectors on
power fx actions.': 'Enable connectors on power fx actions.
(Organizations)'.No })
```

- Plug-ins that use connectors can only output results from specific fields. Due to this, you need to map specific primitive values from the connector response to output values.

Low-code plugins that have custom connectors limitation

If you have low-code plugins with custom connectors, the custom connectors must be imported first, before connection references or flows.

If your environment doesn't contain the custom connector in a solution, import a separate solution that only includes the custom connector. Do this import before you import the actual solution. You need to do this first because Azure must register the custom connector before the other solution components can be imported.

If you import a solution that contains custom connectors and flows, Azure isn't able to register the custom connector while it's registering your connection references or flows. This also applies to connection references for the custom connector that wasn't previously imported in a separate solution. If Azure didn't register your custom connector, the import fails, or you aren't able to start the import.

More information: Create custom connectors in solutions: Known limitations

Example Dataverse low-code plug-ins (preview)

Article • 02/15/2025

[This topic is pre-release documentation and is subject to change.]

The goal of these example plug-ins is to help you get started by integrating them into your apps. You'll understand the authoring experience includes authoring Microsoft Dataverse custom APIs backed by Power Fx expressions, which can trigger actions internal or external to Dataverse.

> **Important**
>
> - Instant low-code plug-ins are deprioritized and aren't being delivered as a feature. Instant low-code plug-ins are replaced with functions. More information: Functions in Microsoft Dataverse (preview)
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Prerequisite

To use one of the example plug-ins for the data event the Dataverse accelerator app must be installed in the environment. More information: Prerequisites for creating a low-code plug-in

> **Note**
>
> Email templates are only available for certain tables. More information: Create templates for email

Return a non-negative value

This example uses the Abs() function to return the non-negative value of its argument. If a number is negative, `Abs` returns the positive equivalent.

1. Play the Dataverse Accelerator app, on the command bar select **New action** > **Instant plugin**.
2. Provide a display name, such as the formula name, and description.
3. Create an `Out` parameter to validate expected behavior that makes sense, such as a string Optionally use input parameters to make testing easier, that makes sense with the formula.
4. In the formula editor, wrap the `Out` parameter in curly brackets:

```
Power Fx

{Out: "" }
```

5. Enter an expression that tests the formula:
   - Validate that intellisense accepts the formula (text turns light blue).
   - Implement an expression that provides an output to help validate the result, for example.

```
Power Fx

{Out: "Abs(-5) = 5: " & Text( Abs(-5) = 5 )  }
```

6. Select **Next**, and then select **Save**.
7. Select **Test** to test the formula. Use the output parameter to validate the result.

Input validation and custom errors

Duplicate detection

Implement server-side input validation, such as duplicate error detection that throws a custom error message.

1. Play the Dataverse Accelerator app, on the command bar select **New action** > **Automated plugin**.
2. In the Name box, enter *Duplicate check*.
3. For **Table**, select **Contact**.
4. For **Run this plugin when the row is**, select **Created**.
5. In the **Formula** box, enter this formula:

Power Fx

```
 If( !IsBlank(LookUp([@Contacts],'Last Name'=ThisRecord.'Last Name' &&
'First Name'=ThisRecord.'First Name')),
    Error("You have existing contacts with the same first name and last
name")
)
```

6. Select **Save**.

Test the plug-in

1. To test the plug-in, create a canvas app using the contacts table by following the steps here: Specify a table.
2. Create a contact row.
3. Create another contact with the same name as in the previous step.
4. A message is displayed indicating duplicate records found. Select **Ignore and save** on the error message prompt.

This custom error message is displayed: **You have two contacts with the same first and last name**.

Data validation

Display specific types of errors using the *ErrorKind* enumeration.

1. Create a new automated plug-in.

2. Provide the following values:

   - **Name**: *Input validation*
   - **Description**: *Checks for valid date and throws an error if invalid*
   - **Table**: **Appointment**
   - **Run this plugin when the row is**: **Updated**

3. Enter the formula below:

   Power Fx

   ```
   If(ThisRecord.'Due Date' < Now(),
    Error({ Kind: ErrorKind.Validation , Message: "The due date cannot be
   in the past" })
   );
   ```

4. Under **Advanced options**, set **When should this run** to **Pre-operation**; you want to run this rule before data is saved to prevent invalid data.

5. Select **Save**.

Go to the Error() function to learn more about custom errors.

Send email based on a data event

Prerequisites:

- ✓ Server-side synchronization is set up for your environment. More information: Set up server-side synchronization of email, appointments, contacts, and tasks
- ✓ An email template.

Example email template

Here's an email template example that you can create for the SenMail based data event:

- **Template type**: **Global**
- **Name**: *Order Thank You*
- **Description**: *Use this template to thank a customer for placing an order with you.*
- **Subject**: `Thank you for your order <orderconfirmation-{!salesorder:Order Number; }>`
- **Body**: Use this code.

```
   Hello {!Sales Order:First Name;},
   Order Type: {! Sales Order: Order Type;},
   Location Type: {! Sales Order: Location Type;},
   Address1: {! Sales Order: Address 1;},
   Address2: {! Sales Order: Address 2;},
   Preferred Service Start Date 1: {! Sales Order: Preferred Service Start
Date;},
   Next Step- We take upto 48 hrs to schedule an in-person and will notify
you as soon as we have a In-person Technician allocated at your site. For
any questions, please contact us at 1-800-CON-SOLAR
   Yours Sincerely,
   Contoso Sales
```

Create the automated plug-in

1. Play the Dataverse Accelerator app, and then select **+New plugin** under **Automated plugins**.
2. Enter the following information:

    - **Name**: *SendEmailUponCreate*
    - **Table**: Select the logical table name of the sales orders, which is **SalesOrder**. This event is based off of Sales Orders table.
    - **Run this plugin with the row is**: **Created**
    - **Formula**: Paste the code below into the **Formula** box. For more information abut the SendEmailFromTemplate function, to SendEmailFromTemplate Action.

    Power Fx

    ```
    XSendEmailFromTemplate(
        LookUp('Email Templates',StartsWith(title,"Order Thank
    You")).'Email Template',
    ThisRecord,
    LookUp(Users,'Primary Email'="sampleemail@sample.com"),
    [ThisRecord.Email]
    )
    ```

3. Select **Advanced** > **Post-operation**.
4. Select **Save**.

The confirmation message **Plugin successfully saved** appears.

Send in-app notifications based on an instant action

In-app notifications enable makers to configure contextual, actionable notifications for users in model-driven apps.

Create the low-code plugin that sends an in-app notification

1. Play the Dataverse accelerator app, and then select **+New plugin** under **Instant plugins**.
2. Enter the following information, select **Next**:

    - **Name**: *NotifyTechnican1*

- **Description**: *This instant plug-in notifies the app user.*

3. On the **Definitions** page, create input parameters with these data types:

   - **OrderID**: **String**
   - **TechnicianEmail**: **String**

4. **Formula**. Paste the following code in the **Formula** box. For more information about this function, go to SendAppNotification Action.

```
Power Fx
```

```
 XSendAppNotification(
    "New service",
    LookUp(Users,'Primary Email'=TechnicianEmail),
    "You have a new solar panel installation scheduled on "&
LookUp('Scheduling Results','OrderId'=OrderID).'ServiceDate'&" in "&
LookUp('Service Orders','Order Number'=OrderID).City &". Contact the
coordinator with any questions.",
 [
    XCreateSidePaneActionForEntity(
            "View order",
        OrderID,
        "Sales Order",
        "cr8b8_serviceorder1",
        LookUp('Service Orders','Order Number'=OrderID).'Service Order'
        )
    ]
 )
```

5. Select **Next**.
6. On the **Summary** page, select **Save**.

Invoke the in-app notification instant action

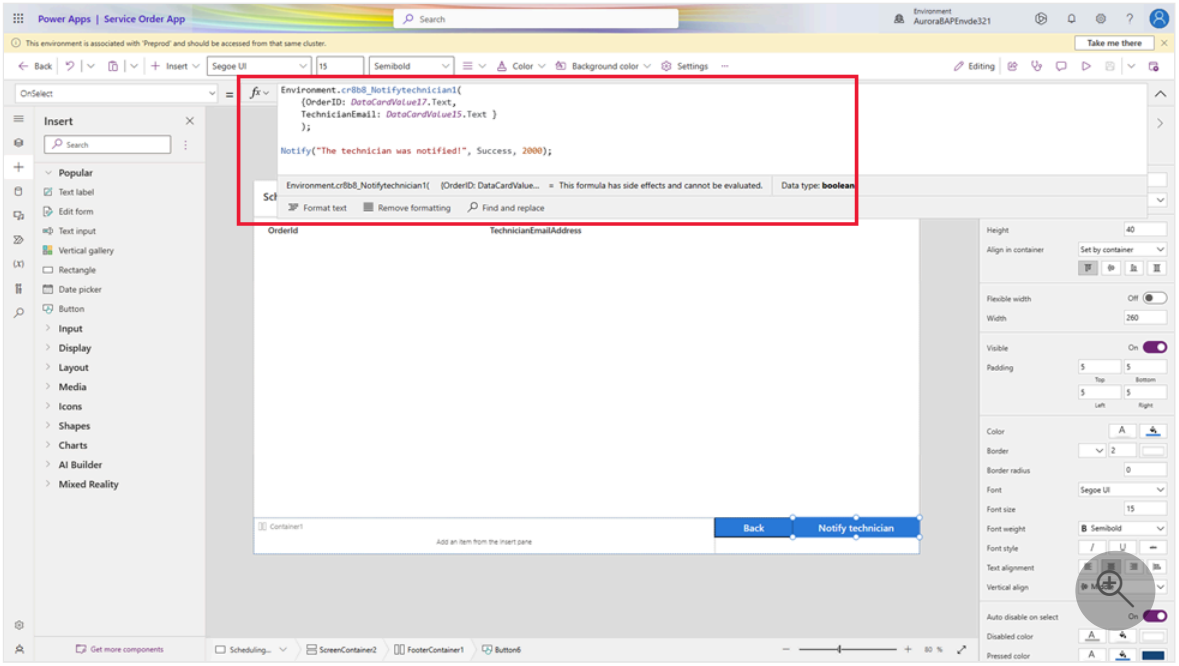
1. Select a canvas app and then select **Edit** on the command bar (or create a new one).
2. Select screen on the left navigation pane, or create a new one.
3. On the **Insert** menu, add a **Button** to the page using the **Text** *Notify technician*.
4. Select the button, and enter the following in the **fx** formula bar, where *DataCardValue17* is the column that contains the Order ID, and *DataCardValue15* is the column that contains the technician's email address. In this example, a canvas app named **Service Order App** is used.

```
Power Fx
```

```
 Environment.cr8b8_Notifytechnician1({
       OrderID: DataCardValue17.Text,
```

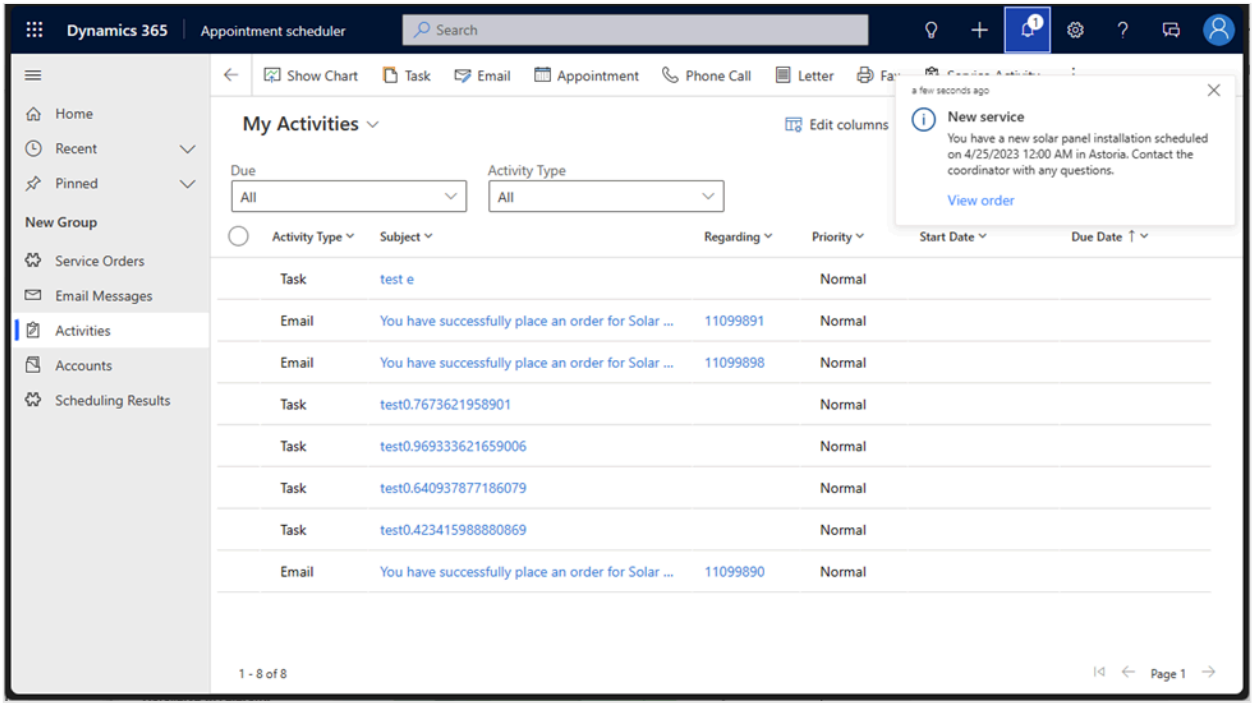
```
    TechnicianEmail: DataCardValue15.Text
});

    Notify("The technician was notified!", NotificationType.Success,
2000);
```



5. **Save** and **Publish** your changes.

When the notify technician action is selected in the app, an in-app notification is sent to the technician who has been assigned to the service order. An action on the notification opens the service order details in a side pane.



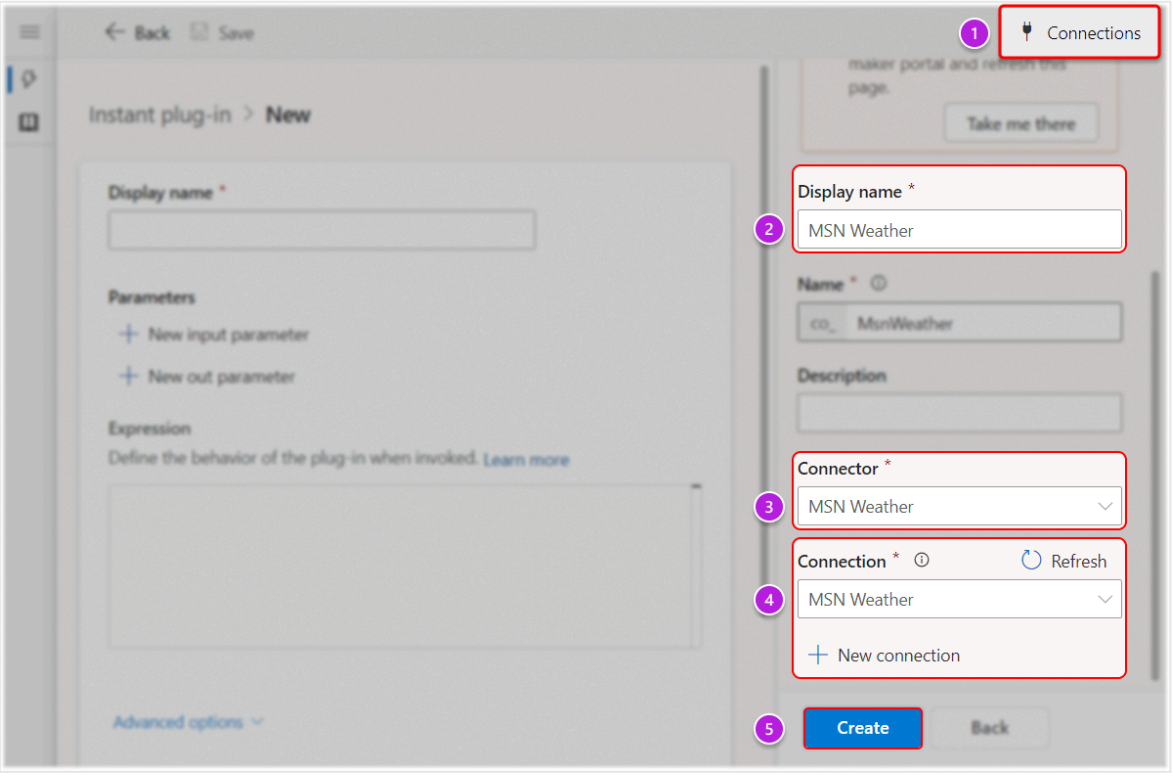
Sample instant plug-in with MSN Weather connector

This plugin returns the current weather for a specific location using MSN Weather connector.

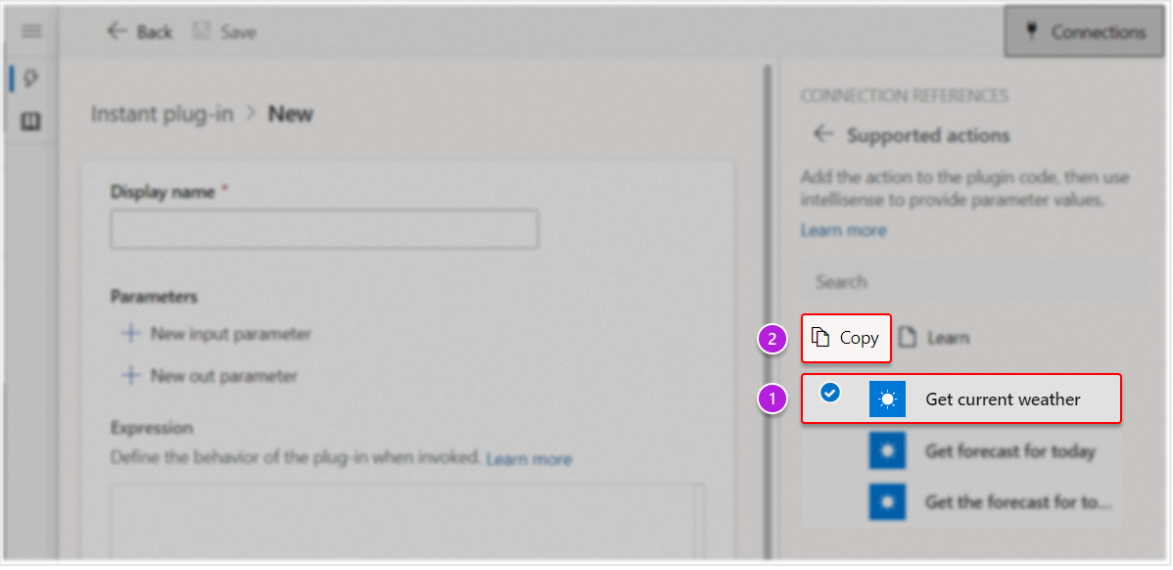
Prerequisites:

- ✓ Prerequisites for creating a low-code plug-in
- ✓ MSN Weather connector is allowed in the environment

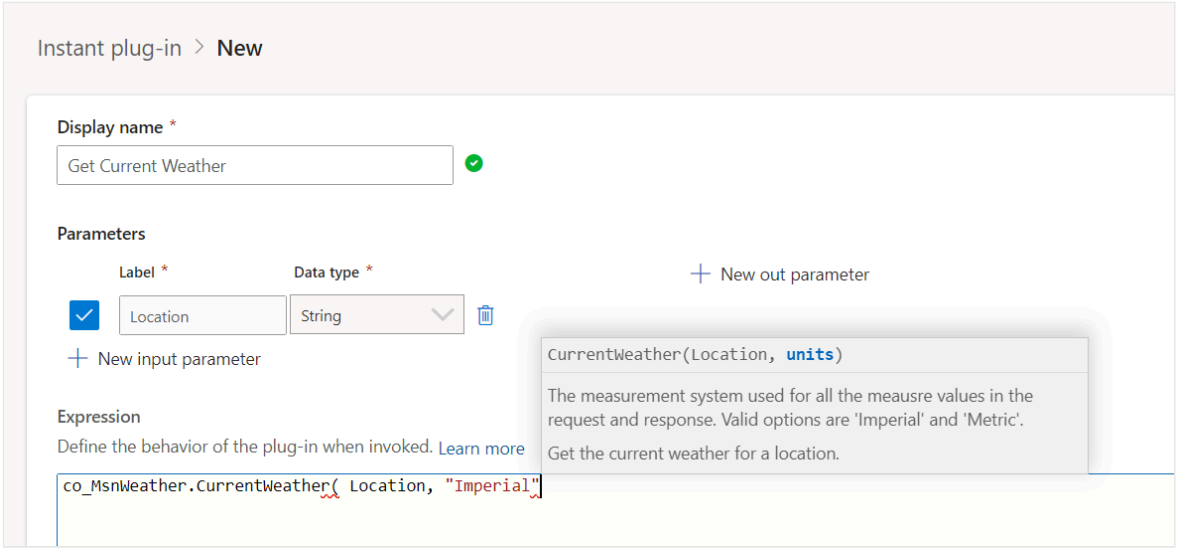
1. Create a connection reference for MSN Weather if not available yet in the environment:



2. Copy snippet:



3. Finish editing the formula using intellisense and consume the connector response properties as needed:



4. Save

5. Test the plug-in

> **Tip**
>
> Use the With() function to capture the entire response from one action if you want to access different properties the response might have. In the example below, there's an input parameter `Location` (string) and an output parameter `Out` (string).

Power Fx

```
With({ /* Capture current weather response from connector */
c: new_MsnWeather.CurrentWeather( Location, "Imperial"
).responses.weather.current
},{ /* Return concatenated weather details */
Out: "Current temp: " & c.temp & " degrees. Feels like " & c.feels & "
degrees. Wind speed is " & c.windSpd & " mph."
})
```

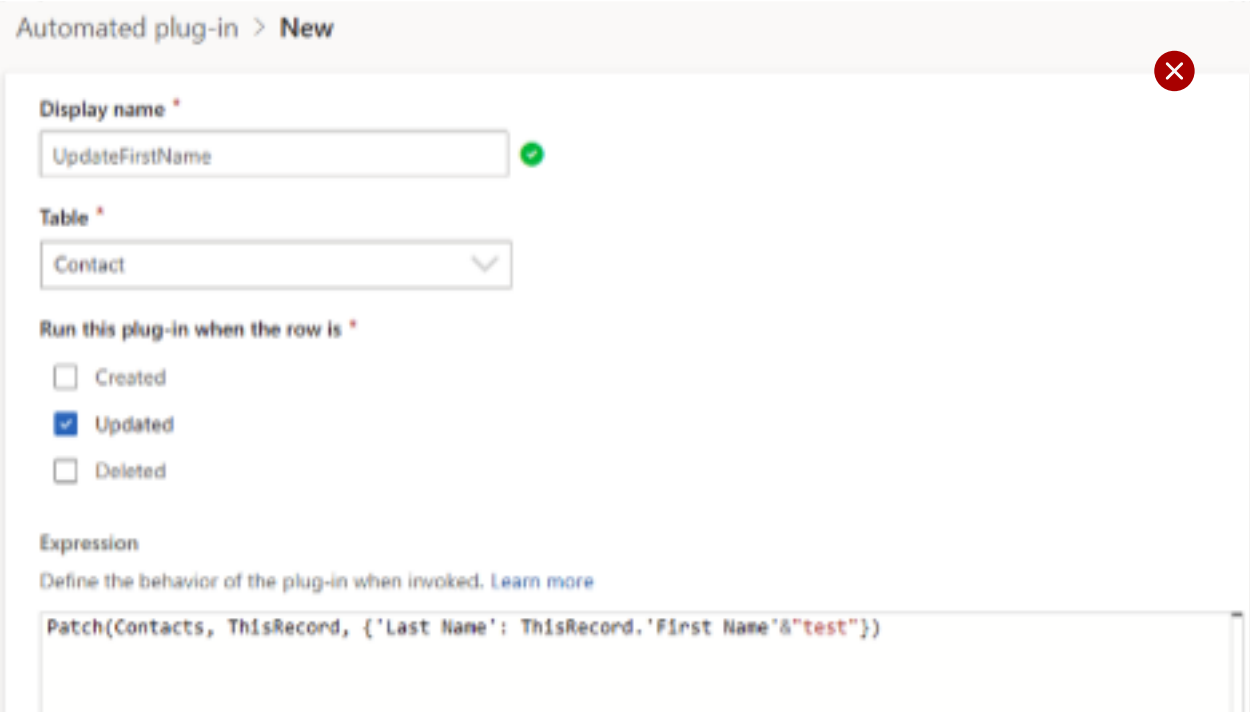
Best practices

Handling infinite loop errors in automated low-code plugins

Don't write a patch statement on an automated plugin upon 'Update' event, where the patch is happening on the same table as the plugin. This leads to infinite loops and

plugin execution failures.

Problematic pattern: Using `Patch()` formula triggers another update.



Recommended pattern: Use the `Set()` formula instead to avoid this issue.

Low-code plug-ins Power Fx (preview)

Article • 02/15/2025

[This topic is pre-release documentation and is subject to change.]

Low-code plug-ins can add business logic to your apps using the Power Fx expression language and directly integrate with Dataverse business data and external data through Power Platform connectors. With low-code plug-ins, you can quickly build rich workflows without any code.

> **ⓘ Important**
>
> - Instant low-code plug-ins are deprioritized and aren't being delivered as a feature. Instant low-code plug-ins are replaced with functions. More information: Functions in Microsoft Dataverse (preview)
> - This is an preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Low-code plug-ins support many of the Power Fx operators, variables, and formulas. For more information about Power Fx, go to these articles:

- Expression grammar
- Operators
- Variables
- Formula reference

The following table lists the Power Fx formulas that work but have limitations or don't work but have an alternative for use with low-code plug-ins.

Expand table

Power Fx formula	Supported in plug-ins?	Limitation or work around
Collect	Yes	Requires the variable to exist and the variable type to match what you're trying to set it to.
Defaults	No	Use Collect instead. For example, instead of *Patch(account, Defaults(account), {"Account Name": "Example Account"})* use

Power Fx formula	Supported in plug-ins?	Limitation or work around
		`Collect(account, {“Account Name”: “Example Account”})`.

Power Fx formulas supported

For information about the formulas supported with low-code plug-ins, go to Formula reference- Dataverse plug-ins.

Create low-code plug-ins to use with a copilot (preview)

06/23/2025

[This topic is pre-release documentation and is subject to change.]

Copilot actions are a way to extend the capabilities of your copilot bots. With Copilot generative AI actions, you create custom actions that are triggered by your copilot bot. These actions are used to perform a wide range of tasks, such as sending emails, creating records in Microsoft Dataverse, or calling external APIs. In this article, you create a basic low-code plug-in that adds two integers together and a more complex plug-in that can be used to send a notification either of which can be used to create an action in Microsoft Copilot Studio.

> **Important**
>
> - Instant low-code plug-ins are deprioritized and aren't being delivered as a feature. Instant low-code plug-ins are replaced with functions. More information: Functions in Microsoft Dataverse (preview)
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Prerequisites to use the plug-in with Microsoft Copilot

Before you begin, make sure you have the following prerequisites:

- Access to a Dataverse environment that includes the Dataverse Accelerator App for creating low-code plug-ins.
- Access to Copilot Studio in the same environment as your Dataverse environment.

Basic low-code plugin example

In this example you create a low-code instant plug-in that adds two numbers and returns the sum of those numbers. You then create a Copilot action that calls this low-code plug-in to

perform the addition. The copilot you create works for numbers and arbitrary text queries that contain numbers and fractions spelled out.

To create your basic low-code instant plug-in, follow these steps:

1. Open the Dataverse Accelerator App in your Dataverse environment by going to **Apps** > **All** > **Dataverse Accelerator App** and select **Play**.

2. From the Dataverse Accelerator App, select **New plug-in** and select **Instant plug-in**.

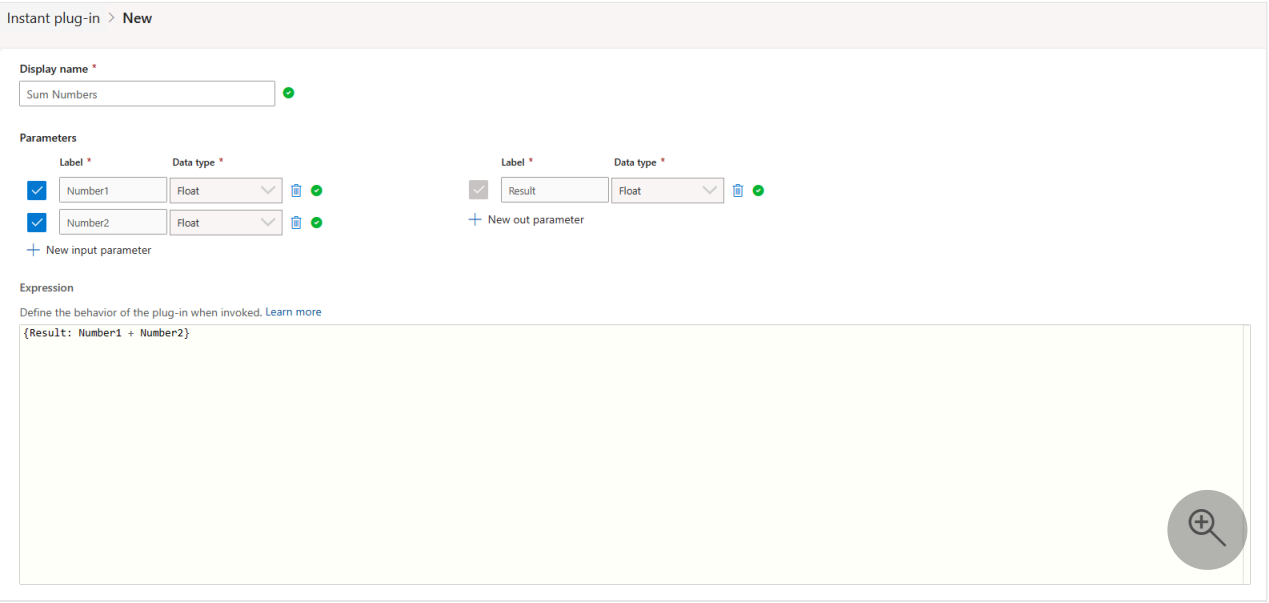
3. Enter a descriptive display name for your plug-in. For example *Sum numbers*, and then select **Create**.

4. In the **Parameters** section:

   - Add the following input parameters:
     - **Parameter Name**: *Number1*, **Type**: **Float**
     - **Parameter Name**: *Number2*, **Type**: **Float**
   - Add the following output parameter:
     - **Parameter Name**: *Result, Type*: **Float**

5. In the **Expression** section, enter the following code:

```
{Result: Number1 + Number2}
```



6. Select **Save** to save your plug-in.

Create a copilot to call your basic low-code plug-in

Go to Copilot Studio, and open the environment that has the plug-in.

1. Create a copilot. More information: Create and configure copilot plugins
2. Enable generative actions on the copilot. More information: Enable generative actions
3. Add a generative AI action. When you add the action, search for 'Perform an unbound action in selected environment' and select the action. More information: Use Generative Actions in Microsoft Copilot Studio
4. Configure the action with the following details:

    - Add a model description that lets the copilot know when to call this action. Use plain English to describe the conditions under which this action should be called. For example, you can enter "Adds numbers and return the sum of those numbers given 2 floating point values." More information: Authoring descriptions
    - Use these **Inputs**:
        - Change **How will the copilot fill this input for the Organization** parameter to **Set as a value**.
        - Select your current environment (the environment in which you created your low-code plug-in) as the value for the **Organization** parameter.
        - Change **How will the copilot fill this input for the Action Name** parameter to **Set as a value**.
        - Select the low-code plug-in you created as the value for the **Action Name** parameter. If you're unsure what the name of your plug-in is you can find it in the Dataverse Accelerator App by selecting it from the list and selecting **Copy code snippet** and then pasting the code into a text editor.
    - Additional **Inputs**:
        - Add and the following input parameters. Adding additional inputs doesn't currently show details in Copilot Studio. You can verify that the inputs were added correctly by selecting **Open the code edit and reviewing the code**, which should show the additional inputs under the inputs section in the action YAML:
            - **Parameter Name**: *Number1*
            - **Parameter Name**: *Number2*

5. Save and publish the copilot.

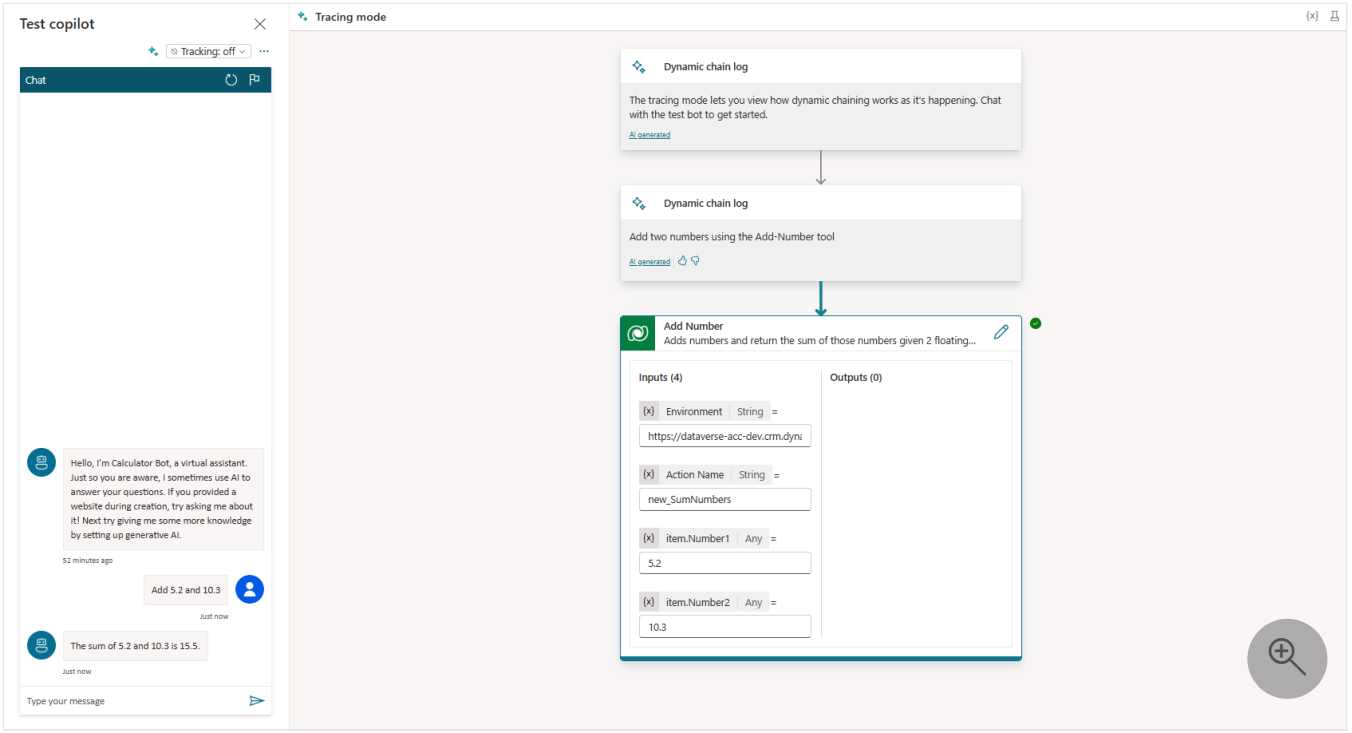
Test your copilot action

Follow these steps in the **Test copilot** pane in Copilot Studio.

1. Select the sparkle icon at the top of the chat window to start tracing mode. This allows you to confirm that your action is being called and verifies the inputs and outputs of your action. More information: Testing you copilot using generative actions
2. Enter the text in the chat window *Add 5.2 and 10.3* and select **Send**.

If everything is configured correctly, you see the expected result of 15.5 output in the chat window and the trace pane shows the inputs and outputs of your action. The trace pane looks similar to the following example. You can try some other prompts to test the action further and change the language to see how the action responds. Some examples:

- *If I have 3 apples and my friend gives me 4 more, how many apples do I have in total?*
- *If I have 1/2 pounds of cheese and I order another 1/4 pounds, how much cheese do I have total?*



Send notification low-code plugin example

In this example you create a low-code instant plug-in that wraps an existing API for use with a copilot. The action sends a notification to the user specified in the copilot action when the user creating the action tests it in Copilot Studio. The copilot determines the required parameters from the plain language query from the user and sends a notification using a Dataverse low-code plugin-in to a model-driven app in Power Apps.

To create your low-code instant plug-in, follow these steps:

1. Open the Dataverse Accelerator App in your Dataverse environment by going to **Apps** > **All** > Dataverse Accelerator App and select play.

2. From the Dataverse Accelerator App, select **New plug-in**, and then select **Instant plug-in**.

3. Enter a descriptive display name for your plug-in. For example, *Send in-app notification to user* and select **Create**.

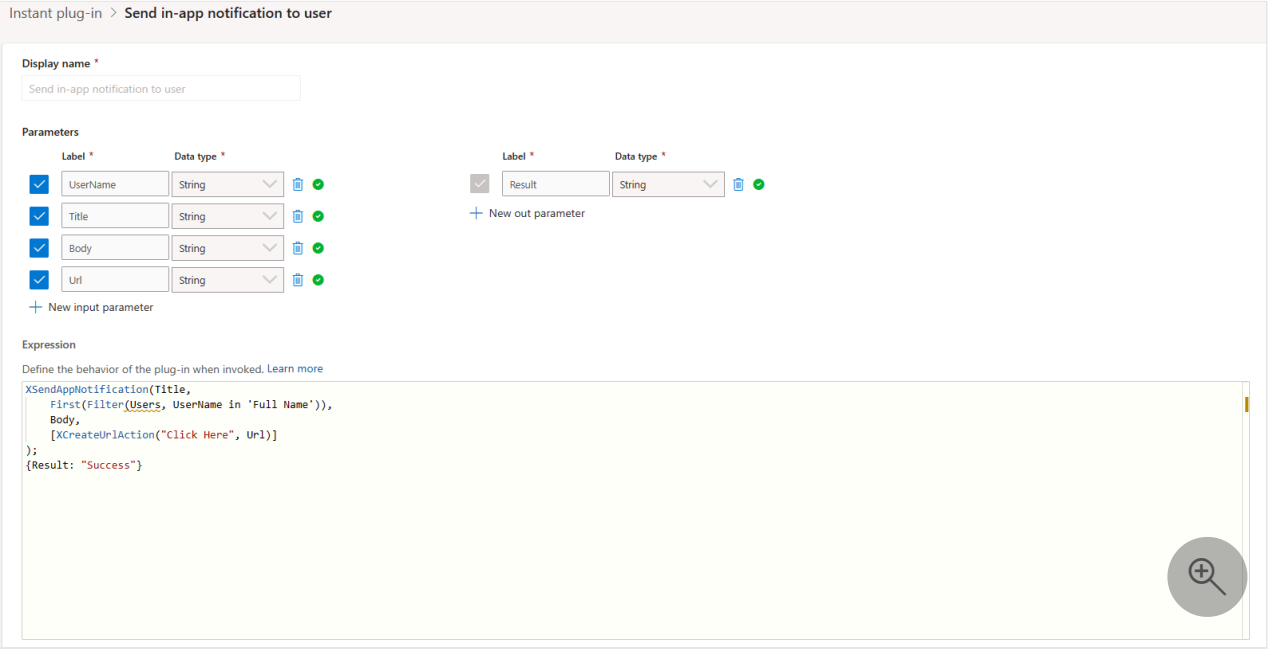
4. In the **Parameters** section:

    - Add the following input parameters:
        - **Parameter Name**: *UserName, Type*: **String**
        - **Parameter Name**: *Title, Type*: **String**
        - **Parameter Name**: *Body, Type*: **String**
        - **Parameter Name**: *Url, Type*: **String**
    - Add the following output parameter:
        - **Parameter Name**: *Result, Type*: **String**

5. In the **Expression** section, enter the following code. Notice that we're wrapping the existing `XSendAppNotification` API with the plugin to give the ability to find users by name. This behavior helps when called from copilot, which can only provide information the user knows about the person and not more esoteric IDs of records that the underlying API is expecting:

    PowerApps Formula

    ```
    XSendAppNotification(Title,
    First(Filter(Users, UserName in 'Full Name')),
    Body,
    [XCreateUrlAction("Click Here", Url)]
    );
    {Result: "Success"}
    ```

6. Select **Save** to save your plug-in.

Create a copilot to call your send notification low-code plug-in

Go to Copilot Studio, and open the environment that has the plug-in.

1. Create a copilot. More information: Create and configure copilot plugins
2. Enable generative actions on the copilot. More information: Enable generative actions
3. Add a generative AI action. When you add the action, search for 'Perform an unbound action in selected environment' and select the action. More information: Use Generative Actions in Microsoft Copilot Studio
4. Configure the action with the following details:

    - Add a model description that lets the copilot know when to call this action. Use plain English to describe the conditions under which this action should be called. For example, you can enter "Calls a Dataverse API to send a notification to a user in Dataverse to remind or alert them to something important with a title, body and optionally a link for more details." More information: Authoring descriptions
    - Use these **Inputs**:
        - Change **How will the copilot fill this input for the Organization** parameter to **Set as a value**.
        - Select your current environment from the dropdown list (the environment in which you created your low-code plug-in) as the value for the **Organization** parameter. You need to put your cursor in the textbox in order for the list of available environments to show.
        - Change **How will the copilot fill this input for the Action Name** parameter to **Set as a value**.
        - Select the low-code plug-in you created as the value for the **Action Name** parameter. You need to put your cursor in the textbox in order for the list of available APIs to show. The value to enter here is the schema name of the low-code plugin, such as `org_SendInAppNotificationToUser`. If you're unsure what the schema name of your plug-in is you can find it in the Dataverse Accelerator App by selecting it from the list and selecting **Copy code snippet** and then pasting the code into a text editor.
    - Additional **Inputs**:
        - Select **Add** and add following input parameters. Notice that adding additional inputs doesn't currently show details in Copilot Studio. This is a known issue. You can verify that the inputs were added correctly by selecting **Open the code edit and reviewing the code**, which should show the additional inputs under the inputs section in the action YAML:
            - **Parameter Name**: *UserName*
            - **Parameter Name**: *Title*
            - **Parameter Name**: *Body*
            - **Parameter Name**: *Url*

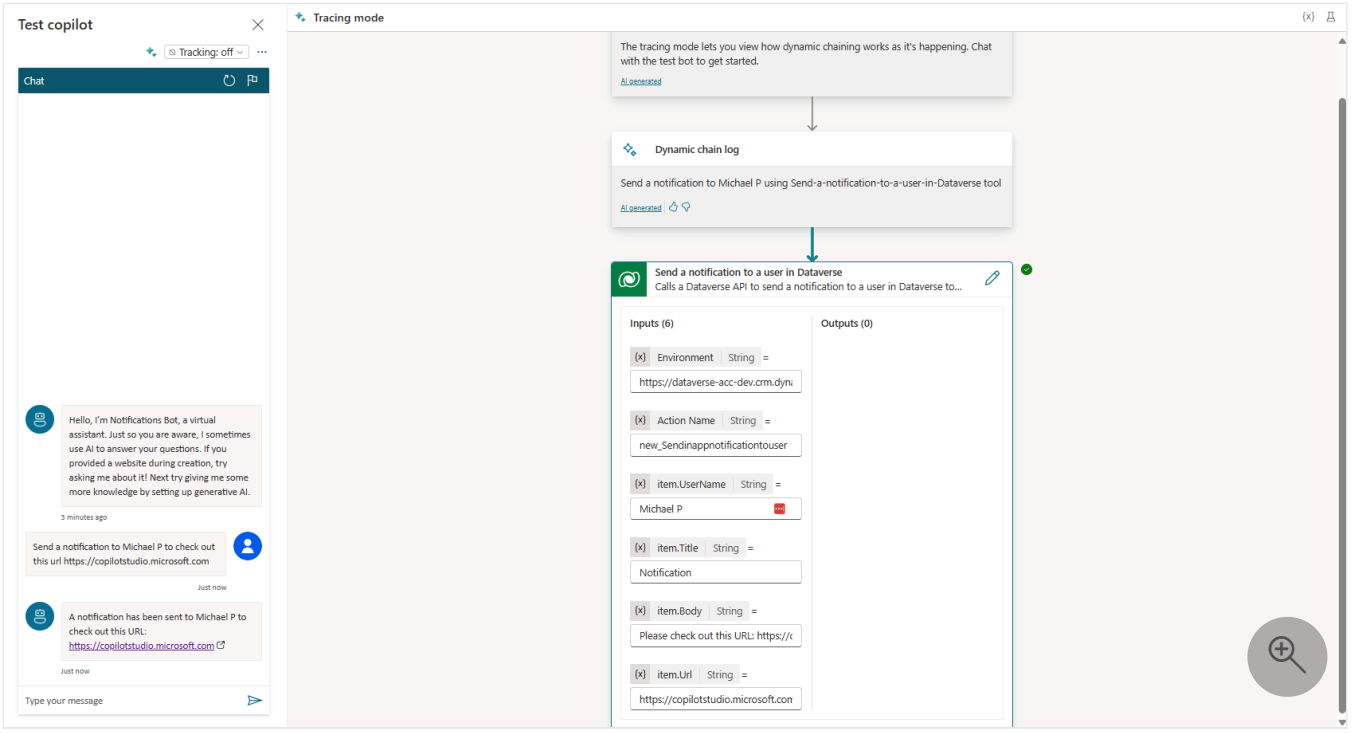
5. Save and publish the copilot.

Test your send notification copilot action

Follow these steps in the **Test copilot** pane in Copilot Studio.

1. Select the sparkle icon at the top of the chat window to start tracing mode. This allows you to confirm that your action is being called and verifies the inputs and outputs of your action. More information: Testing you copilot using generative actions
2. Enter the text in the chat window *Send a notification to my user to check out this url https://copilotstudio.microsoft.com*, and then select **Send**.

If everything is configured correctly, you see that a notification has been sent in the **Test copilot** pane. The notification is sent as a model-driven in-app notification when the specified user plays the app.



You can try some other prompts to test the action further and you could change the plugin to be smarter about how it searches for users given a name to see how the action responds. For example, you could add a step to search for the user by email address if the name doesn't return a result.

Use low-code plug-ins in Dataverse

Microsoft Dataverse low-code plug-ins tips and known issues (preview)

Article • 02/15/2025

[This topic is pre-release documentation and is subject to change.]

This article describes tips and known issues when working with low-code plug-ins in Microsoft Dataverse.

> **ⓘ Important**
>
> - Instant low-code plug-ins are deprioritized and aren't being delivered as a feature. Instant low-code plug-ins are replaced with functions. More information: Functions in Microsoft Dataverse (preview)
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Handle general runtime issues

If you face runtime plugin issues, re-edit the low-code plug-in. Then the intellisense issues on your formula expression are displayed in the low-code plug-in editor. Follow the guidelines to correct the issue that are also displayed, and then resave the plug-in.

Use caution when using post-operation patching

Your low-code plug-in execution might encounter this error when using `Patch` in a post-operation: `Execution failed for PowerPlexPlugin: System.ServiceModel.FaultException 1[Microsoft.Xrm.Sdk.OrganizationServiceFault] This low-code plugin's execution was cancelled because the plugin logic caused an infinite loop. Correct the plugin logic and try again.`

Using `Patch` in a post-operation scenario must be done with caution to avoid infinite loops. A `Patch` operation initiates a new transaction. For example, if an update trigger

for `MyTable` invokes `Patch(MyTable, ThisRecord, ...)`, this operation might result in a recursive update cycle.

Here are a couple of examples of operations that can avoid this issue:

- `Patch(CurrentTable, SomeOtherRecord, ... ) // For example, updating a manager's contact from a contact record.`
- `Patch(OtherTable, SomeOtherRecord, ... ) // Operations on a completely different table.`

Handle the two-minute timeout

For operations that continue for two minutes or longer, you can receive this error:

```
Execution failed for PowerPlexPlugin:
System.ServiceModel.FaultException1[Microsoft.Xrm.Sdk.OrganizationServiceFault]:
Operation not allowed as plugin execution exceeded maximum allowed time (Fault
Detail is equal to Exception details: limit your callbacks .. Create, Update)
```

When working with Dataverse low-code plugins, it's important to manage the two-minute timeout effectively:

- Limit your number of `Patch` and `Collect` operations inside your plug-ins, especially if you have other plug-ins already registered against that table, which can affect the performance of your plug-ins.
- Monitor performance. Keep an eye on the performance of your plug-ins and consider using tracing and logging capabilities within Dataverse to track execution times and failures. By following these guidelines, you can ensure that your low-code plug-ins run smoothly within the Dataverse environment without interruption caused by the two-minute timeout. More information: Tracing and logging

Failed response received from APIM

If you receive this error message, which can be returned from API management (APIM), just edit the plug-in, and then resave. Saving initializes the APIM authentication and your plug-in begins executing successfully.

```
Execution failed for PowerPlexPlugin: Failed response received from APIM;
StatusCode: NotFound; ResponseContent: { "statusCode": 404, "message": "Resource
not found" } Method: POST; RequestUri: https://canada-001.azure-apim.net/invoke;
StatusCode: NotFound; ResponseContent: { "statusCode": 404, "message": "Resource
```

```
not found" }; HeadersString: Headers - 'Access-Control-Allow-Methods':
'System.String[]'; 'Access-Control-Allow-Origin': 'System.String[]'; 'Access-
Control-Max-Age': 'System.String[]'; 'Access-Control-Expose-Headers':
'System.String[]'; 'Date': 'System.String[]'; Access to APIM expires..edit and save
the plugin
```

Use custom process actions

Article • 02/15/2022

Custom process actions, also known as *Custom actions*, or just *actions* open a range of possibilities for composing business logic. With custom process actions, you can perform operations, such as Create, Update, Delete, Assign, or Perform Action. Internally, a custom process action creates a custom message. Developers refer to these actions as *messages*. If the goal of a process is to create a row, then update it, and then assign it, there are three separate steps. Each step is defined by the capabilities of the table—not necessarily your business process.

Custom process actions let you define a single verb (or message) that matches an operation you need to perform for your business. These new messages are driven by a process or behavior rather than what can be done with a table. These messages can correspond to verbs like Escalate, Convert, Schedule, Route, or Approve—whatever you need. The addition of these verbs helps provide a richer vocabulary for you to fluently define your business processes. You can apply this richer vocabulary from clients or integrations rather than having to write the action within clients. This also makes it easier because you can manage and log the success or failure of the entire action as a single unit.

Configurable messages

Once an action is defined and activated, a developer can use that message like any of the other messages provided by the platform. However, a significant difference is that now someone who isn't a developer can apply changes to what should be done when that message is used. You can configure the action to modify steps as your business processes change. Any custom code that uses that message doesn't need to be changed as long as the process arguments don't change.

Workflow processes and plug-ins continue to provide similar capabilities for defining automation. Workflow processes still provide the capability for a nondeveloper to apply changes. But the difference is in how the business processes are composed and how a developer can write their code. A custom process action is a message that operates on the same level as any of the messages provided by the platform. Developers can register plug-ins for actions.

> **Note**

Custom API is a newer way to define custom messages with many advantages for developers. If you do not intend to use the no-code capabilities that custom process actions provide to configure business logic, custom API provides better capabilities for developers to create their own messages. More information:

- Compare Custom Process Action and custom API
- Create and use custom APIs

Global messages

Unlike Microsoft Dataverse workflows or plug-ins, a custom process action doesn't have to be associated with a specific table. You can define global custom process actions that can be called on their own.

Next steps

Create a custom process action

Create a custom process action

Article • 02/15/2022

Use custom process actions when you want to automate a series of commands in the system. Custom process actions expand the vocabulary available for developers to express business processes. An custom process action uses core verbs provided by the system, such as Create, Update, Delete, and Assign, to create more expressive verbs like Approve, Escalate, Route, or Schedule. If the definition of a business process changes, someone who isn't a developer can edit the custom process action so the code doesn't need to be changed.

> **Note**
>
> If you intend to write a plug-in to implement your logic for a custom process action instead of using the workflow designer, you should use custom API instead. More information: Compare Custom Process Action and custom API

Create a custom process action

> **Important**
>
> If you're creating an custom process action to include as part of a solution that will be distributed, create it in the context of the solution. Go to Settings > **Solutions** and locate the unmanaged solution that this action will be part of. Then, in the menu bar, select **New** > **Process**. This ensures that the customization prefix associated with the name of the action will be consistent with other components in the solution. After you create the action, you can't change the prefix.

Like workflow processes, custom process actions have the following properties in the **Create Process** dialog box:

- **Process name**

  After you enter a name for the process, a unique name will be created for it by removing any spaces or special characters from the process name.

- **Category**

  This property establishes that this is an action process. You can't change this after you save the process.

- **Table**

  With actions processes, you can select a table to provide context for the workflow just like other types of processes, but you also have the option to choose **None (global)**. Use this if your action doesn't require the context of a specific table. You can't change this after you save the process.

- **Type**

  Use this property to choose whether to build a new custom process action from scratch or to start from an existing template.

Unlike workflow processes, you don't need to set the following options:

- **Start When**: Actions start when code calls the message generated for them.
- **Scope**: Actions always run in the context of the calling user.
- **Run in the background**: Actions are always real-time workflows.

Custom process actions also have something that workflow processes don't—input and output arguments.

> ⓘ **Note**
>
> You can enable a custom process action from a workflow without writing code. More information: Invoke custom process actions from a workflow

Edit a custom process action

You must deactivate custom process actions before you can edit them.

You can edit an custom process action that was created as part of an unmanaged solution or included in a solution installed in your organization. If the solution is a managed solution, you might not be able to edit it. The solution publisher has the option to edit the managed properties so that the action installed with a managed solution can't be edited.

When an action is saved, a unique name is generated based on the process name. This unique name has the customization prefix added from the solution publisher. This is the name of the message that a developer will use in their code.

When editing an action, you have the following options:

- **Process name**

  After the process is created and the unique name is generated from the process name, you can edit the process name. You might want to apply a naming convention to make it easier to locate specific processes.

- **Unique name**

  When an action is saved, a unique name is generated based on the process name. This unique name has the customization prefix from the solution publisher added. This is the name of the message that a developer will use in their code. Don't change this unique name if the process has been activated and code is in place expecting to call the action using this name.

  > **ⓘ Important**
  >
  > After the action is activated and code is written to use a unique name, the unique name must not be changed without also changing the code that references it.

- **Enable rollback**

  Generally, processes that support transactions will "undo" (or roll back) the entire operation if any part of them fails. There are some exceptions to this. Some actions developers might do in code initiated by the custom process action might not support transactions. For example, if the code perform actions in other systems that are beyond the scope of the transaction. Those can't be rolled back by the action running in an app. Some messages in the platform don't support transactions. But everything you can do just with the user interface of the action will support transactions. All the actions that are part of a real-time workflow are considered in transaction, but with actions you have the option to opt out of this.

  You should consult with the developer who will use this message to determine whether it must be in transaction or not. Generally, an action should be in transaction if the actions performed by the business process don't make sense unless all of them are completed successfully. The classic example is transferring funds between two bank accounts. If you withdraw funds from one account you must deposit them in the other. If either fails, both must fail.

  > **ⓘ Note**

You can't enable rollback if a custom process action is invoked directly from within a workflow. You can enable rollback if an action is triggered by a Power Apps web services message.

- **Activate as**

  Like all processes, you can activate the process as a template and use it as an advanced starting point for processes that follow a similar pattern.

- **Define process arguments**

  In this area, you'll specify any data that the action expects to start and what data will be passed out of the action. More information: Define process arguments

- **Add stages and steps**

  Like other processes, you specify what actions to perform and when to perform them. More information: Add stages and steps

Define process arguments

When developers use messages, they might begin with some data that they can pass into the message. For example, to create a new case row, there might be the case title value that is passed in as the input argument.

When the message is finished, the developer might need to pass some data that was changed or generated by the message to another operation in their code. This data is the output argument.

Both input and output arguments must have a name, a type, and some information about whether the argument is always required. You can also provide a description.

The name of the message and the information about all the process arguments represent the *signature* for the message. After an custom process action is activated and is being used in code, the signature must not change. If this signature changes, any code that uses the message will fail. The only exception to this may be changing one of the parameters so that it is not always required.

You can change the order of the arguments by sorting them or moving them up or down because the arguments are identified by name, not by the order. Also, changing the description won't break code using the message.

Action process argument types

The following table describes the action process argument types.

Expand table

Type	Description
Boolean	A `true` or `false` value.
DateTime	A value that stores date and time information.
Decimal	A number value with decimal precision. Used when precision is extremely important.
Table	A row for the specified table. When you select table, the drop-down list is enabled and allows you to select the table type.
entityCollection	A collection of table rows.
entityReference	An object that contains the name, ID, and type of a table row that uniquely identifies it. When you select entityReference, the drop-down list is enabled and allows you to select the table type.
Float	A number value with decimal precision. Used when data comes from a measurement that isn't absolutely precise.
Integer	A whole number.
Money	A value that stores data about an amount of money.
Picklist	A value that represents an option for an OptionSet attribute.
String	A text value.

> **Note**
>
> **entityCollection** argument values can't be set in the user interface for conditions or actions. These are provided for use by developers in custom code. More information: Create your own messages

Add stages and steps

Custom process actions are a type of process very similar to real-time workflows. All the steps that can be used in real-time workflows can be used in actions. For information about the steps that can be used for both real-time workflows and actions, see Workflow stages and steps.

In addition to the steps that can be used for real-time workflows, actions also have the **Assign Value** step. In actions, these can be used only to set output arguments. You can use the form assistant to set output arguments to specific values or, more likely, to values from the row that the action is running against, rows related to that row with a many-to-one relationship, rows created in an earlier step, or values that are part of the process itself.

Managed properties

Custom process actions have two relevant managed properties

Is Customizable

The **Is Customizable** managed property controls whether on not someone who installs a managed solution containing the custom process action can edit or delete it. If wish for the custom process action to be edited or deleted when included in a managed solution, you should set this property to true.

Is Custom Processing Step Allowed for Other Publishers

The **Is Custom Processing Step Allowed for Other Publishers** managed property controls whether third party plug-in developers can register plug-in steps on the message created by the custom process action. When this is true, plug-ins registered by anyone on this message will run and can modify the behavior of the custom process action. When false, only plug-ins steps registered within a solution from the same solution publisher will run.

Next steps

Invoke custom process actions from a workflow

Configure custom process actions from a workflow

Article • 02/15/2022

You can enable a custom process action from a real-time workflow without writing code. More information: Invoke custom actions from a workflow

You also can create a custom process action so that a developer can use it in code, or you might need to edit an action that was previously defined. Like real-time workflow processes, consider the following:

- What should the action do?
- Under what conditions should the action be performed?

Unlike real-time workflow processes, you don't need to set the following options:

- **Start When**: Custom process actions start when code calls the message generated for them.
- **Scope**: Custom process actions always run in the context of the calling user.
- **Run in the background**: Custom process actions are always real-time workflows.

Custom process actions also have something that real-time workflow processes don't—input and output arguments. More information: Define process arguments

Create a custom process action

> **Important**
>
> If you're creating an action to include as part of a solution that will be distributed, create it in the context of the solution. Go to **Settings** > **Solutions** and locate the unmanaged solution that this action will be part of. Then, in the menu bar, select **New** > **Process**. This ensures that the customization prefix associated with the name of the action will be consistent with other components in the solution. After you create the action, you can't change the prefix.

> **Note**

If you intend to write a plug-in to implement your logic for a custom process action instead of using the workflow designer, you should use custom API instead. More information: Compare Custom Process Action and custom API

Like real-time workflow processes, actions have the following properties in the **Create Process** dialog box:

- **Process name**

  After you enter a name for the process, a unique name will be created for it by removing any spaces or special characters from the process name.

- **Category**

  This property establishes that this is an action process. You can't change this after you save the process.

- **Entity**

  With action processes, you can select a table to provide context for the real-time workflow just like other types of processes, but you also have the option to choose **None (global)**. Use this if your action doesn't require the context of a specific table. You can't change this after you save the process.

- **Type**

  Use this property to choose whether to build a new custom process action from scratch or to start from an existing template.

Edit an action

You must deactivate processes before you can edit them.

You can edit a custom process action that was created as part of an unmanaged solution or included in a solution installed in your organization. If the solution is a managed solution, you might not be able to edit it. The solution publisher has the option to edit the managed properties so that the action installed with a managed solution can't be edited.

When an action is saved, a unique name is generated based on the process name. This unique name has the customization prefix added from the solution publisher. This is the name of the message that a developer will use in their code.

When editing an action, you have the following options:

- **Process Name**

  After the process is created and the unique name is generated from the process name, you can edit the process name. You might want to apply a naming convention to make it easier to locate specific processes.

- **Unique Name**

  When a custom process action is saved, a unique name is generated based on the process name. This unique name has the customization prefix from the solution publisher added. This is the name of the message that a developer will use in their code. Don't change this unique name if the process has been activated and code is in place expecting to call the action using this name.

  > ⓘ **Important**
  >
  > After the action is activated and code is written to use a unique name, the unique name must not be changed without also changing the code that references it.

- **Enable rollback**

  Generally, processes that support transactions will "undo" (or roll back) the entire operation if any part of them fails. There are exceptions to this. Actions executed in code by a developer initiated by the custom process action might not support transactions. An example would be when the code perform actions in other systems that are beyond the scope of the transaction. Those can't be rolled back by the action running in an app. Some messages in the platform don't support transactions. But everything you can do just with the user interface of the action will support transactions. All the actions that are part of a real-time workflow are considered in transaction, but with actions you have the option to opt out of this.

  You should consult with the developer who will use this message to determine whether it must be in transaction or not. Generally, an action should be in transaction if the actions performed by the business process don't make sense unless all of them are completed successfully. The classic example is transferring funds between two bank accounts. If you withdraw funds from one account you must deposit them in the other. If either fails, both must fail.

  > ⓘ **Note**
  >
  > - You can't enable rollback if a custom process action is invoked directly from within a workflow. You can enable rollback if an custom process

action is triggered by a Power Apps web services message.
    - If the action defined does not change data, but only retrieves data, there are certain situations where performance can be improved by disabling **Enable rollback.**

- **Activate As**

  Like all processes, you can activate the process as a template and use it as an advanced starting point for processes that follow a similar pattern.

- **Define Process Arguments**

  In this area, you'll specify any data that the action expects to start and what data will be passed out of the action. More information: Define process arguments

- **Add Stages, Conditions and Actions**

  Like other processes, you specify what actions to perform and when to perform them. More information: Add stages, conditions and actions

Define process arguments

When a developer uses a message, they might begin with some data that they can pass into the message. For example, to create a new case row, there might be the case title value that is passed in as the input argument.

When the message is finished, the developer might need to pass some data that was changed or generated by the message to another operation in their code. This data is the output argument.

Both input and output arguments must have a name, a type, and some information about whether the argument is always required. You can also provide a description.

The name of the message and the information about all the process arguments represent the *signature* for the message. After an action is activated and is being used in code, the signature must not change. If this signature changes, any code that uses the message will fail. The only exception to this might be changing one of the parameters so that it is not always required.

You can change the order of the arguments by sorting them or moving them up or down because the arguments are identified by name, not by the order. Also, changing the description won't break code using the message.

Action process argument types

The following table describes the action process argument types.

Expand table

Type	Description
Boolean	A `true` or `false` value.
DateTime	A value that stores date and time information.
Decimal	A number value with decimal precision. Used when precision is extremely important.
Table	A row for the specified table. When you select **Table**, the drop-down list is enabled, allowing you to select the table type.
entityCollection	A collection of table rows.
entityReference	An object that contains the name, ID, and type of a table row that uniquely identifies it. When you select tableReference, the drop-down list is enabled and allows you to select the table type.
Float	A number value with decimal precision. Used when data comes from a measurement that isn't absolutely precise.
Integer	A whole number.
Money	A value that stores data about an amount of money.
Picklist	A value that represents an option for an OptionSet attribute.
String	A text value.

> **Note**
>
> **entityCollection** argument values can't be set in the user interface for conditions or actions. These are provided for use by developers in custom code. More information: Create your own messages

Add stages and steps

Actions are a type of process very similar to real-time workflows. All the steps that can be used in real-time workflows can be used in actions. For information about the steps that can be used for both real-time workflows and actions, go to Workflow stages and steps.

In addition to the steps that can be used for real-time workflows, actions also have the **Assign Value** step. In actions, these can be used only to set output arguments. You can use the form assistant to set output arguments to specific values or, more likely, to values from the row that the action is running against, rows related to that row with a many-to-one relationship, rows created in an earlier step, or values that are part of the process itself.

Managed properties

Custom process actions have two relevant managed properties

Is Customizable

The **Is Customizable** managed property controls whether on not someone who installs a managed solution containing the custom process action can edit or delete it. If wish for the custom process action to be edited or deleted when included in a managed solution, you should set this property to true.

Is Custom Processing Step Allowed for Other Publishers

The **Is Custom Processing Step Allowed for Other Publishers** managed property controls whether third party plug-in developers can register plug-in steps on the message created by the custom process action. When this is true, plug-ins registered by anyone on this message will run and can modify the behavior of the custom process action. When false, only plug-ins steps registered within a solution from the same solution publisher will run.

Monitoring real-time workflows and actions

Invoke custom process actions from a workflow

Article • 02/15/2022

Workflows have numerous capabilities supporting business scenarios. Calling basic data operation actions for a row, such as create, update, and delete, from within a workflow solves quite a few business scenarios. However, if you couple the capabilities of the workflows with the power of the custom processs actions invoked directly from within a workflow, you add a whole new range of business scenarios to your application without needing to write code.

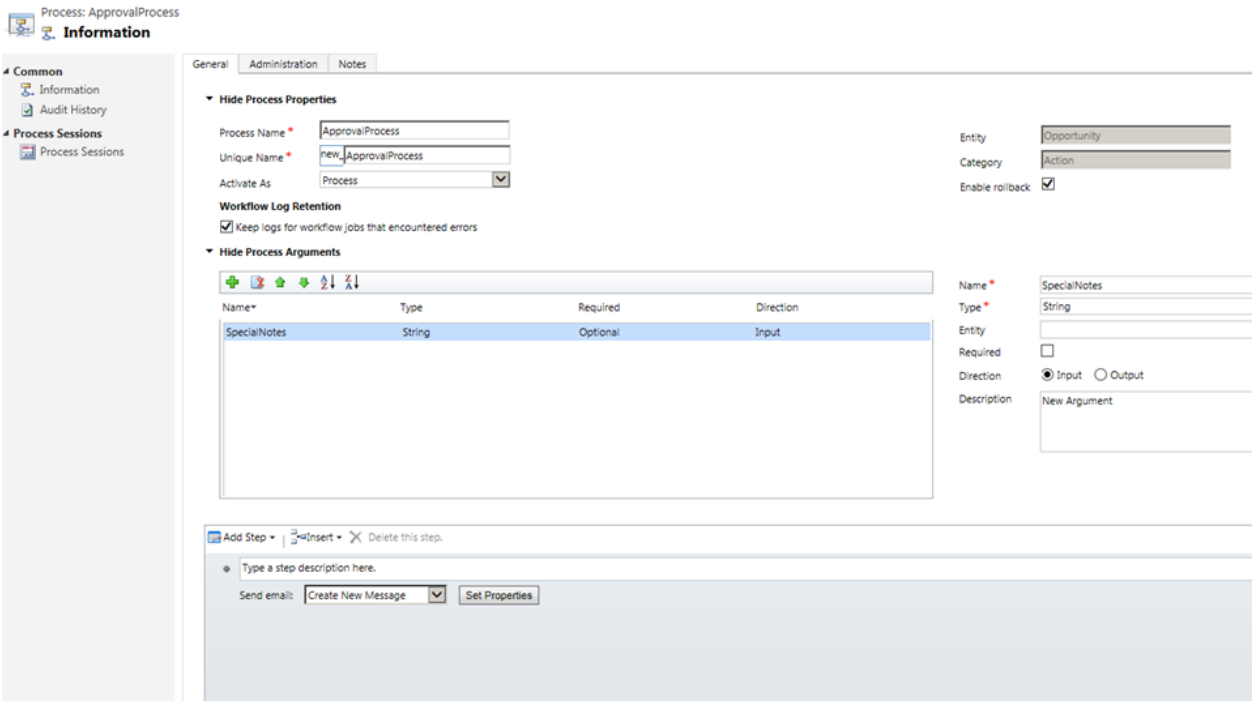
Let's look at the scenario in which a custom process action is invoked from a workflow. We'll invoke a custom process action to request the manager's approval when a discount for a particular opportunity exceeds 20 percent.

Example: Create a custom process action using the opportunity table

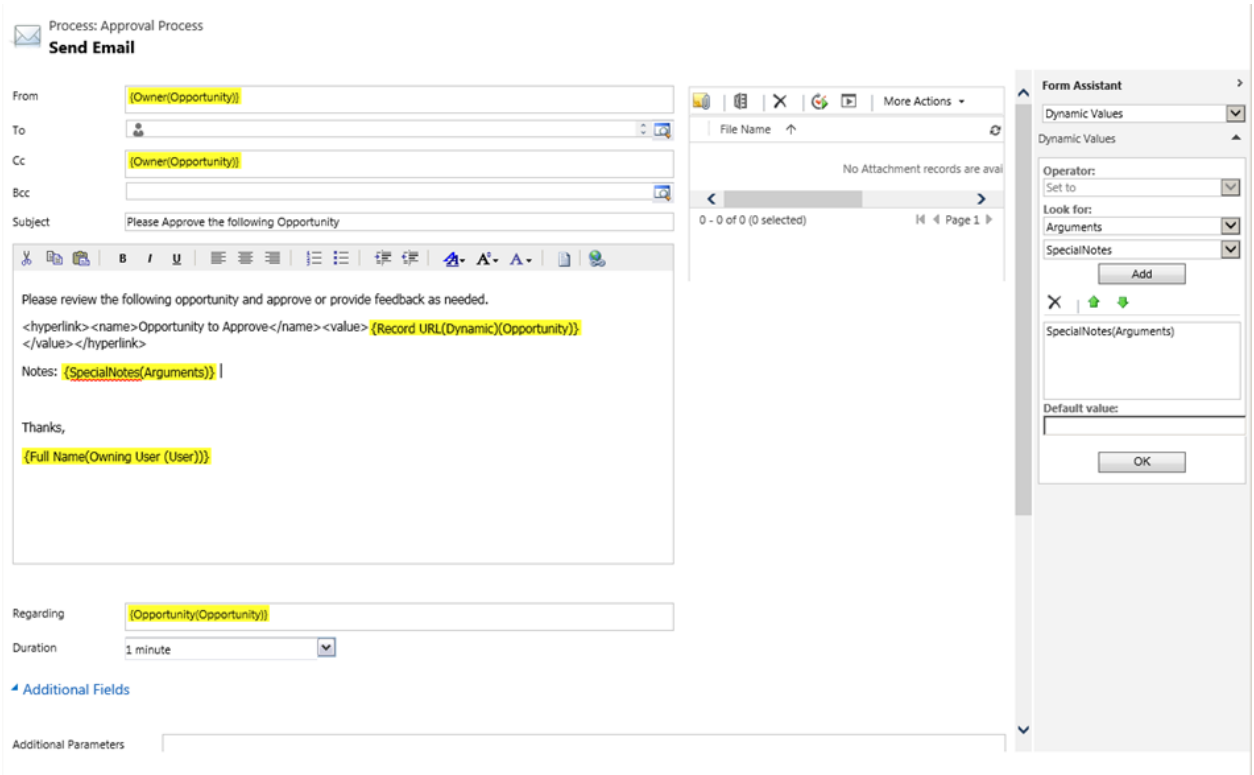
1. In solution explorer, select **Processes**.

2. On the Nav bar, choose **New**. Give the process a name and choose the **Action** category.

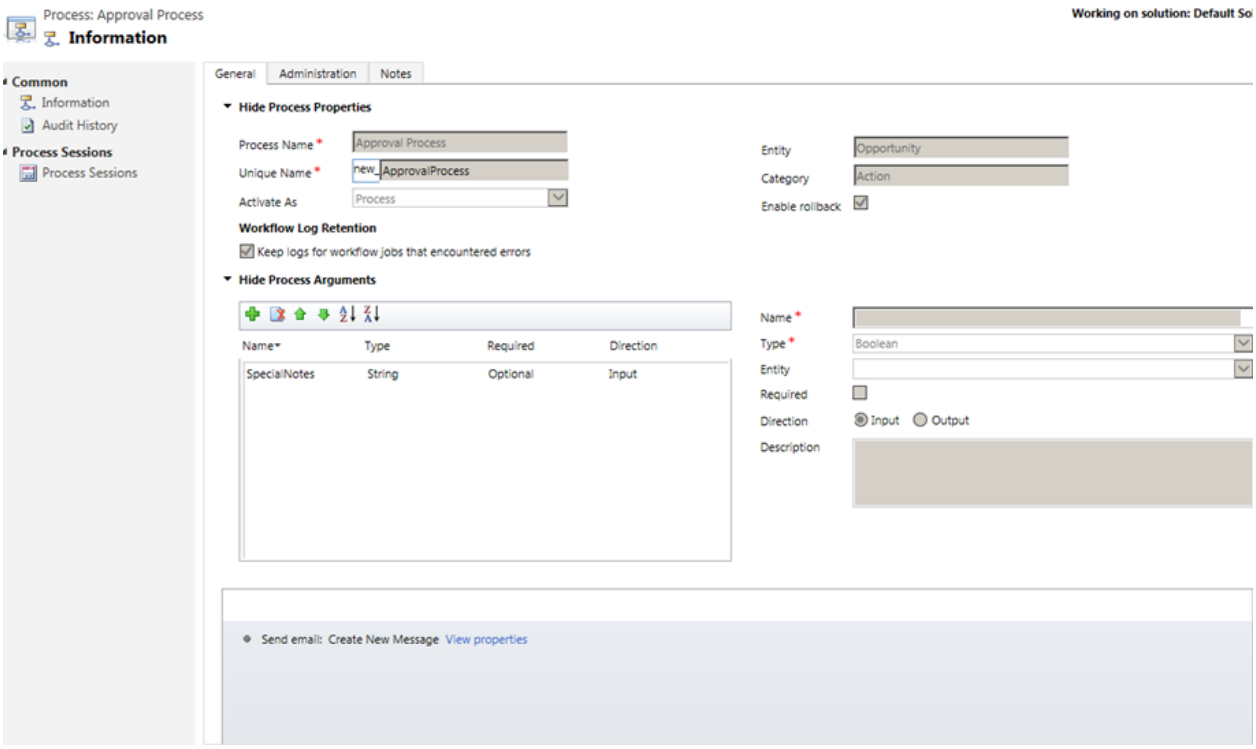
To request an approval for the discount, we're using a custom action called **Approval Process**. We added an input parameter, **SpecialNotes**, and a **Send email** step to create a new message and send a request for the manager's approval, as shown here.



To configure the email message, choose **Set Properties**. When the form opens, use the **Form Assistant** to add special notes and other information to the email, as highlighted on the screenshot. To add the special notes, place the cursor where you want the notes to appear in the message, and then, in the **Form Assistant**, under **Look for**, choose **Arguments** in the first drop-down list and choose **SpecialNotes** in the second drop-down list, and then choose **OK**.



Before you can invoke the custom process action from a workflow, you have to activate it. After you have activated the action, you can view its properties by choosing **View properties**.

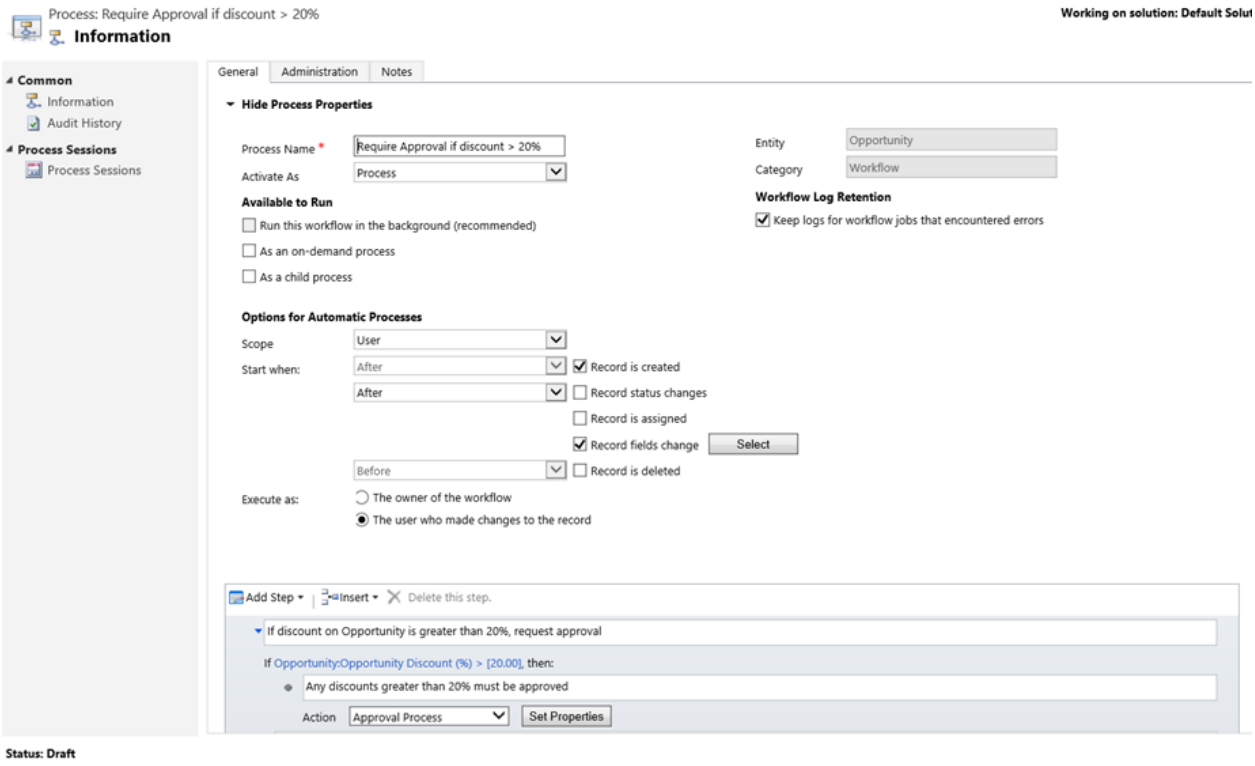


Invoke a custom process action from a workflow

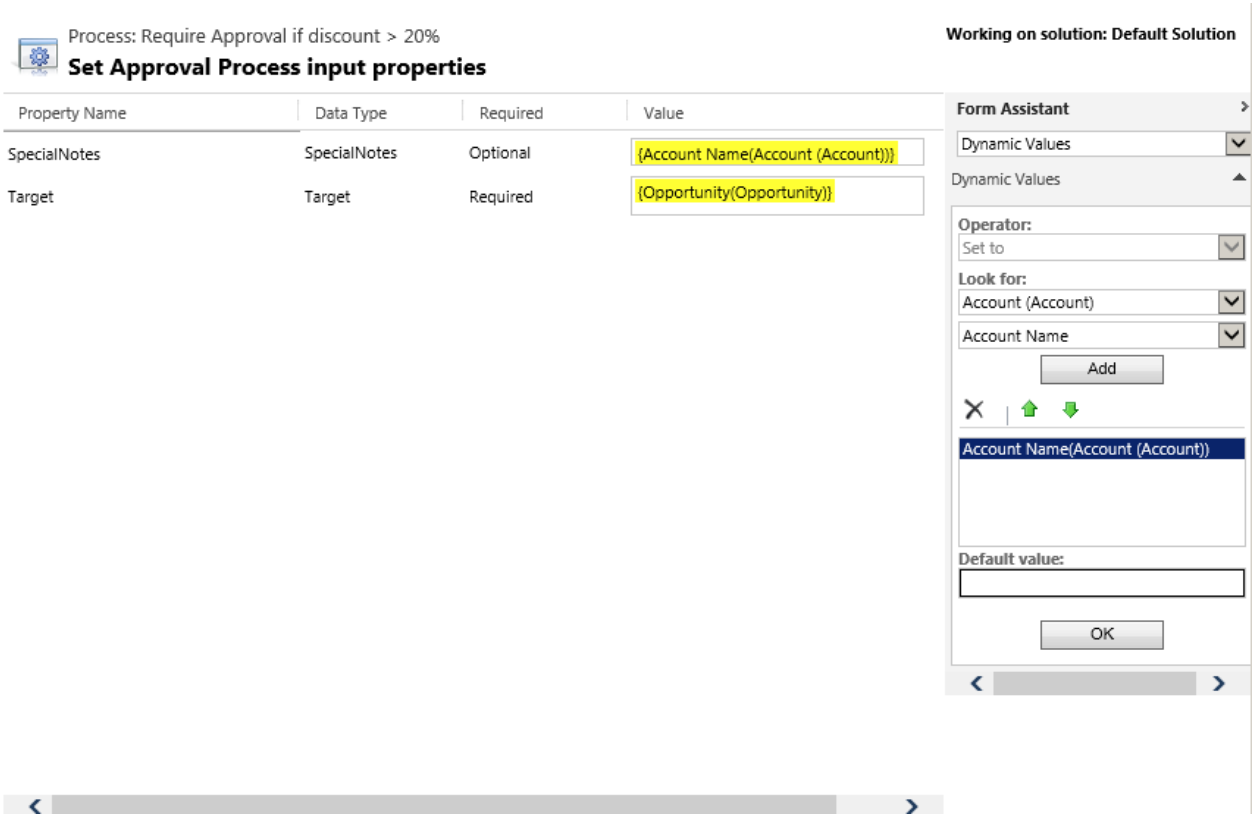
1. In solution explorer, select **Processes**.

2. On the Nav bar, choose **New**. Give the process a name and choose the **Workflow** category.

We created a workflow that invokes the **Approval Process** custom action whenever the manager's approval for a discount of more than 20 percent for an opportunity is required.



You can set the custom process action's input properties by choosing **Set Properties**. We added a name of the account related to the opportunity in the special notes. In the **Form Assistant**, under **Look for**, choose **Account** in the first drop-down list, choose **Account Name** in the second drop-down list, and then choose **OK**. The **Target** property is required and it is populated by the system. The **{Opportunity(Opportunity)}** in the **Target** property is the same opportunity that the calling workflow is running on. Alternatively, you can choose a specific opportunity for the target property by using lookup.



Test Dataverse extensions with Test Engine (deprecated)

> ⓘ Note
>
> **Test Engine is deprecated** and will be removed in a future release. Use Power Platform Playwright samples for test automation capabilities in Power Platform and Dynamics 365 services.

This article explains how to create integration tests with Dataverse. This functionality applies the Power Fx capability to connect with Dataverse tables.

Connecting to Dataverse

To enable Dataverse integration, add the `enableDataverseFunctions` parameter in your testSettings extensionModules :

YAML

```yaml
testSettings:
  extensionModules:
    enable: true
    parameters:
      enableDataverseFunctions: true
```

When you enable Dataverse integration, you're required to open Azure CLI with a user or service principal that has rights to the Dataverse environment. You can use the command: az login More information: Sign in with Azure CLI.

The Dataverse API URL used for integration is obtained either from the host domain name of the pac test run `--domain` parameter or by defining an PowerShell environment variable named `DATAVERSE_URL`.

Enable preview

Currently, all Dataverse extension testing capabilities require using Preview functions. To enable these, add `Preview` to the `allowPowerFxNamespaces` list in extensionModules.

YAML

```yaml
testSettings:
  extensionModules:
    enable: true
    allowPowerFxNamespaces:
    - Preview
    parameters:
      enableDataverseFunctions: true
```

Resetting the current state

Define the `onTestCaseStart` event handler in your authored test yaml to perform common actions before each test case. For example:

YAML

```yaml
testSuite:
  testSuiteName: Dataverse tests
  testSuiteDescription: Validate Power Fx can be used to run Dataverse integration
tests
  persona: User1
  appLogicalName: N/A
  onTestCaseStart: |
    = ForAll(Accounts, Remove(Accounts, ThisRecord))
```

In this example, the `ForAll` is used to iterate over a table and perform an action on each record. The `Remove` function is then used to delete each record from a table to ensure an empty table before each test is executed.

Functions of interest

These functions are useful when working with Dataverse:

- Collect: Adds records to a table.
- CountRows: Returns the number of records in a table.
- First: Returns the first record in a table.
- ForAll: Iterates over a table and performs an action on each record.
- Patch: Update an existing record.
- Remove: Deletes a specific record from a table.

Considerations

Take these considerations into account as you write test steps:

- Defaults isn't supported. As a result Power Fx examples like `Patch(Accounts, Defaults(Accounts), {name:"test"})` aren't supported.
- You can use `Collect` to an alternative to `Patch` with the `Defaults` function

Running Dataverse tests

You can use the Power Fx provider (`powerfx`) to run tests that interact with Dataverse without the need for a canvas or model-driven app interface. This is useful for testing business logic, plugins, flows, and other backend services.

PowerShell

```
pac test run `
   --provider powerfx `
   --test-plan-file your-testplan.te.yaml `
   --tenant your-tenantid-guid-value `
   --environment-id your-environmentid-guid-value `
   --domain "https://contoso.crm.dynamics.com"
```

AI Integration

Using the open source Power Apps Test Engine compiled in `Debug` mode together with the appropriate test settings will enable the Preview.AIExecutePrompt function in your tests.

Add the following to your test settings to enable AI integration:

YAML

```
testSettings:
  extensionModules:
    enable: true
    parameters:
      enableDataverseFunctions: true
      enableAIFunctions: true
```

Example usage of the AI function:

PowerApps Formula

```
Assert("Paris" = Preview.AIExecutePrompt("Country Capital", { Country: "France"
}).Text)
```

Last updated on 04/18/2026

Solutions in Power Apps overview

Solutions are used to transport apps and components from one environment to another or to apply a set of customizations to existing apps. A solution can contain one or more apps as well as other components such as site maps, tables, processes, web resources, choices, flows, and more.

Solutions are the mechanism for implementing application lifecycle management (ALM) in Power Apps and other Power Platform products, such as Power Automate.

> **Note**
>
> To learn more about the solution concepts and how solutions are used for application lifecycle management, go to Overview of ALM with Microsoft Power Platform in the Power Platform ALM guide.

This section focuses on the **manual** tasks that app makers need to perform while working with solutions in Power Apps.

Get started: solution concepts

Before you work with solutions, it's important that you get acquainted with the following solution concepts:

- Two types of solutions (managed and unmanaged)
- Solution components
- Lifecycle of a solution (create, update, upgrade, and patch a solution)
- Solution publisher
- Solution and solution component dependencies

To learn more, go to Solution concepts in the Power Platform ALM guide.

Default solutions

Power Apps provides you with the following default unmanaged solutions:

- **Common Data Service Default Solution**. This solution is available for makers to use by default for their customizations in an environment. The Common Data Service Default Solution is useful when you want to evaluate or learn Power Apps. However, we recommend that app makers work in their own unmanaged solutions.

- **Default Solution**. This is a special solution that contains all components in the system. The default solution is useful for discovering all the components and configurations in your system.

However, we recommend that you create a solution to manage your customizations. More information: Use a solution to customize in the Power Platform ALM guide.

Managed properties

You can control which of your managed solution components are customizable by using managed properties. We recommend that you set managed properties so that your managed components can't be modified. This helps protect your solution from modifications that might cause it to break after it's imported into another environment, such as test or production.

More information: Managed properties in the Power Platform

Work with solutions in Power Apps

Within Power Apps, you can view a list of solutions by selecting **Solutions** in the left navigation. You can perform these solution tasks:

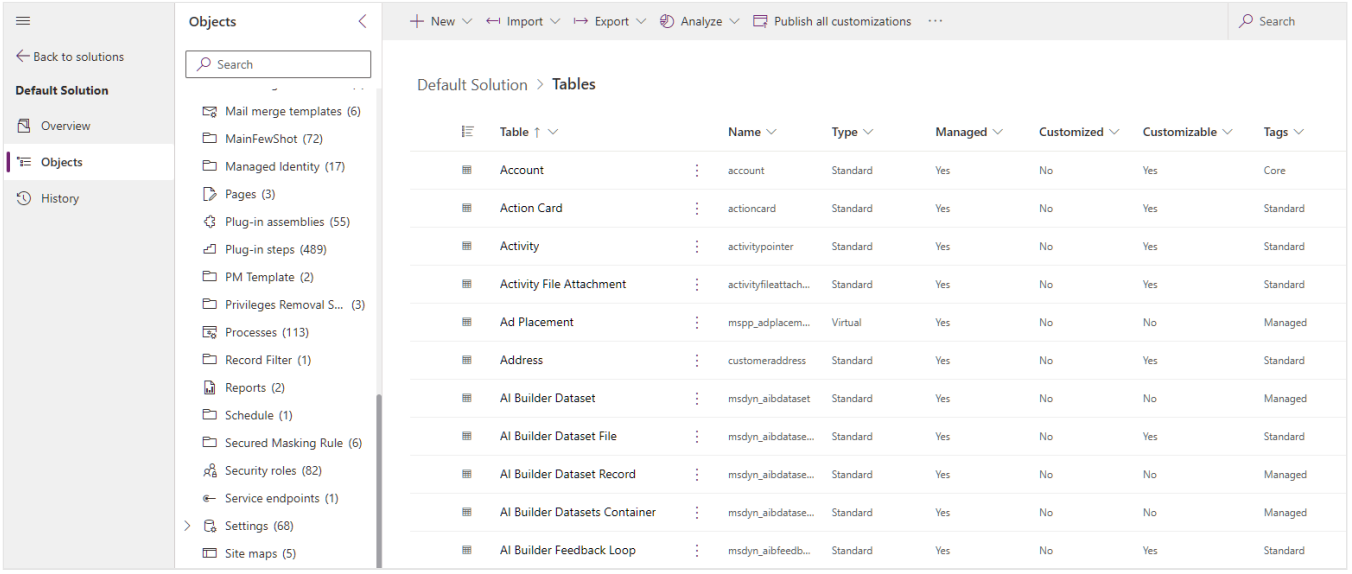
- **New solution**: To locate and work with just the components you've customized, create a solution and do all your customization there. Then, you can easily distribute your solution to other environments. More information: Create a solution
- **Import solution**: Import a solution into your environment. More information: Import solutions
- **Open AppSource**: Microsoft AppSource is where you can go to get solutions tailored to your industry that work with the products you already use.
- **Publish all customizations**: Publish all active customizations in your environment.
- **Set preferred solution**: Set your preferred solution where all solution components are created in.
- **See history**: View details about solution operations over time, such as import, export, and uninstall. More information: View the history of a solution
- **Connect to Git**: Source control integration allows development teams to sync solutions and solution objects across one or more Dataverse environments using an Azure DevOps Git repository. More information: Overview of Git integration in Power Platform
- **Switch to classic**: Open the classic solution explorer.

When you select a solution, additional tasks become available on the command bar. These tasks include:

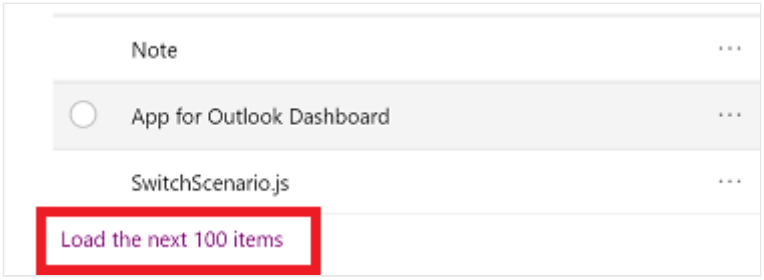
- **Edit**: Edit the solution properties, such as adding or removing solution components.

- **Delete**. Delete the selected solution.
- **Create a plan**. Use Plan designer to create a plan for your existing solution. Plan designer generates a detailed document that describes your solution. The plan covers the business problem, user requirements like user roles and stories, the data model, and technologies like apps. This feature saves time when you're trying to understand a solution's content and helps makers improve an existing solution. More information: Create a plan from a solution
- **Export solution**: Export the solution to a file that can be imported into another environment. More information: Export solutions
- **Deploy**. Use pipelines in Power Platform to deploy solutions to test and production environments. More information: Overview of pipelines in Power Platform
- **Solution checker**: Run or review results of solution checker for this solution.
- **Show dependencies**: View the solution components that have a dependency on another component. More information: View solution dependencies for solutions that would block uninstall of this solution.
- **Set preferred solution**. Use the selected solution as your preferred solution. The preferred solution is where, if not already working in the context of a solution, all your solution components are maintained. More information: Preferred solution
- **See history**. View details about solution operations over time, such as import, export, and uninstall. More information: View the history of a solution
- **Publish to Catalog**: Publishes the solution to the catalog, making it available for other makers in your organization to use. This is useful for sharing solutions that you want others to be able to import and use in their environments. More information: Catalog in Power Platform
- **Apply Upgrade**: Appears when you select a solution. Apply a pending upgrade that has been initiated for a managed solution.

From the **Solutions** area, open a solution to view all of its objects.



Browse through all the objects in a solution by scrolling through the items. If there are more than 100 items in the list, you can select **Load the next 100 items** to see more.



Columns can be sorted and filtered by selecting the column header.

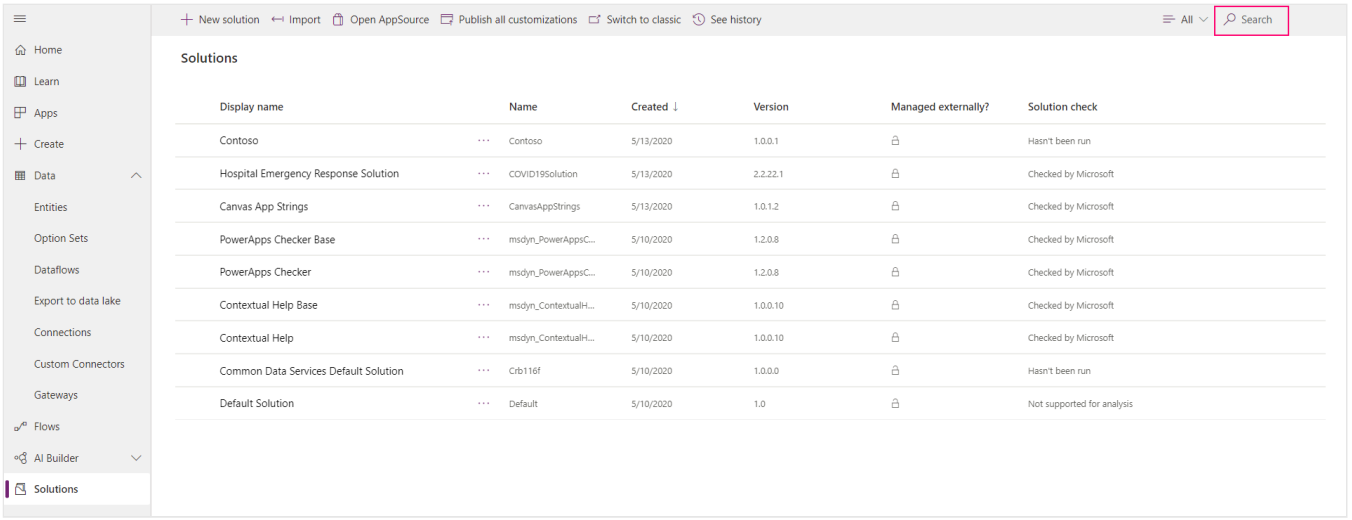
Column headers include:

- **Managed**: The solution object is from a managed solution. You can inspect the object by selecting the item and then select **Advanced** > **See solution layers**.
- **Customizable**: The component is available to be customized.
- **Customized**: This indicates that the object is an unmanaged object, or a managed object with an unmanaged customization layer. You can use this column to quickly locate the unmanaged changes you have for components in the solution.
- **Owner**: If the solution object supports user and team ownership, the current owner is displayed.
- **Status**: If the solution object supports state management (on/off, enabled/disabled, active/inactive), the status is displayed.

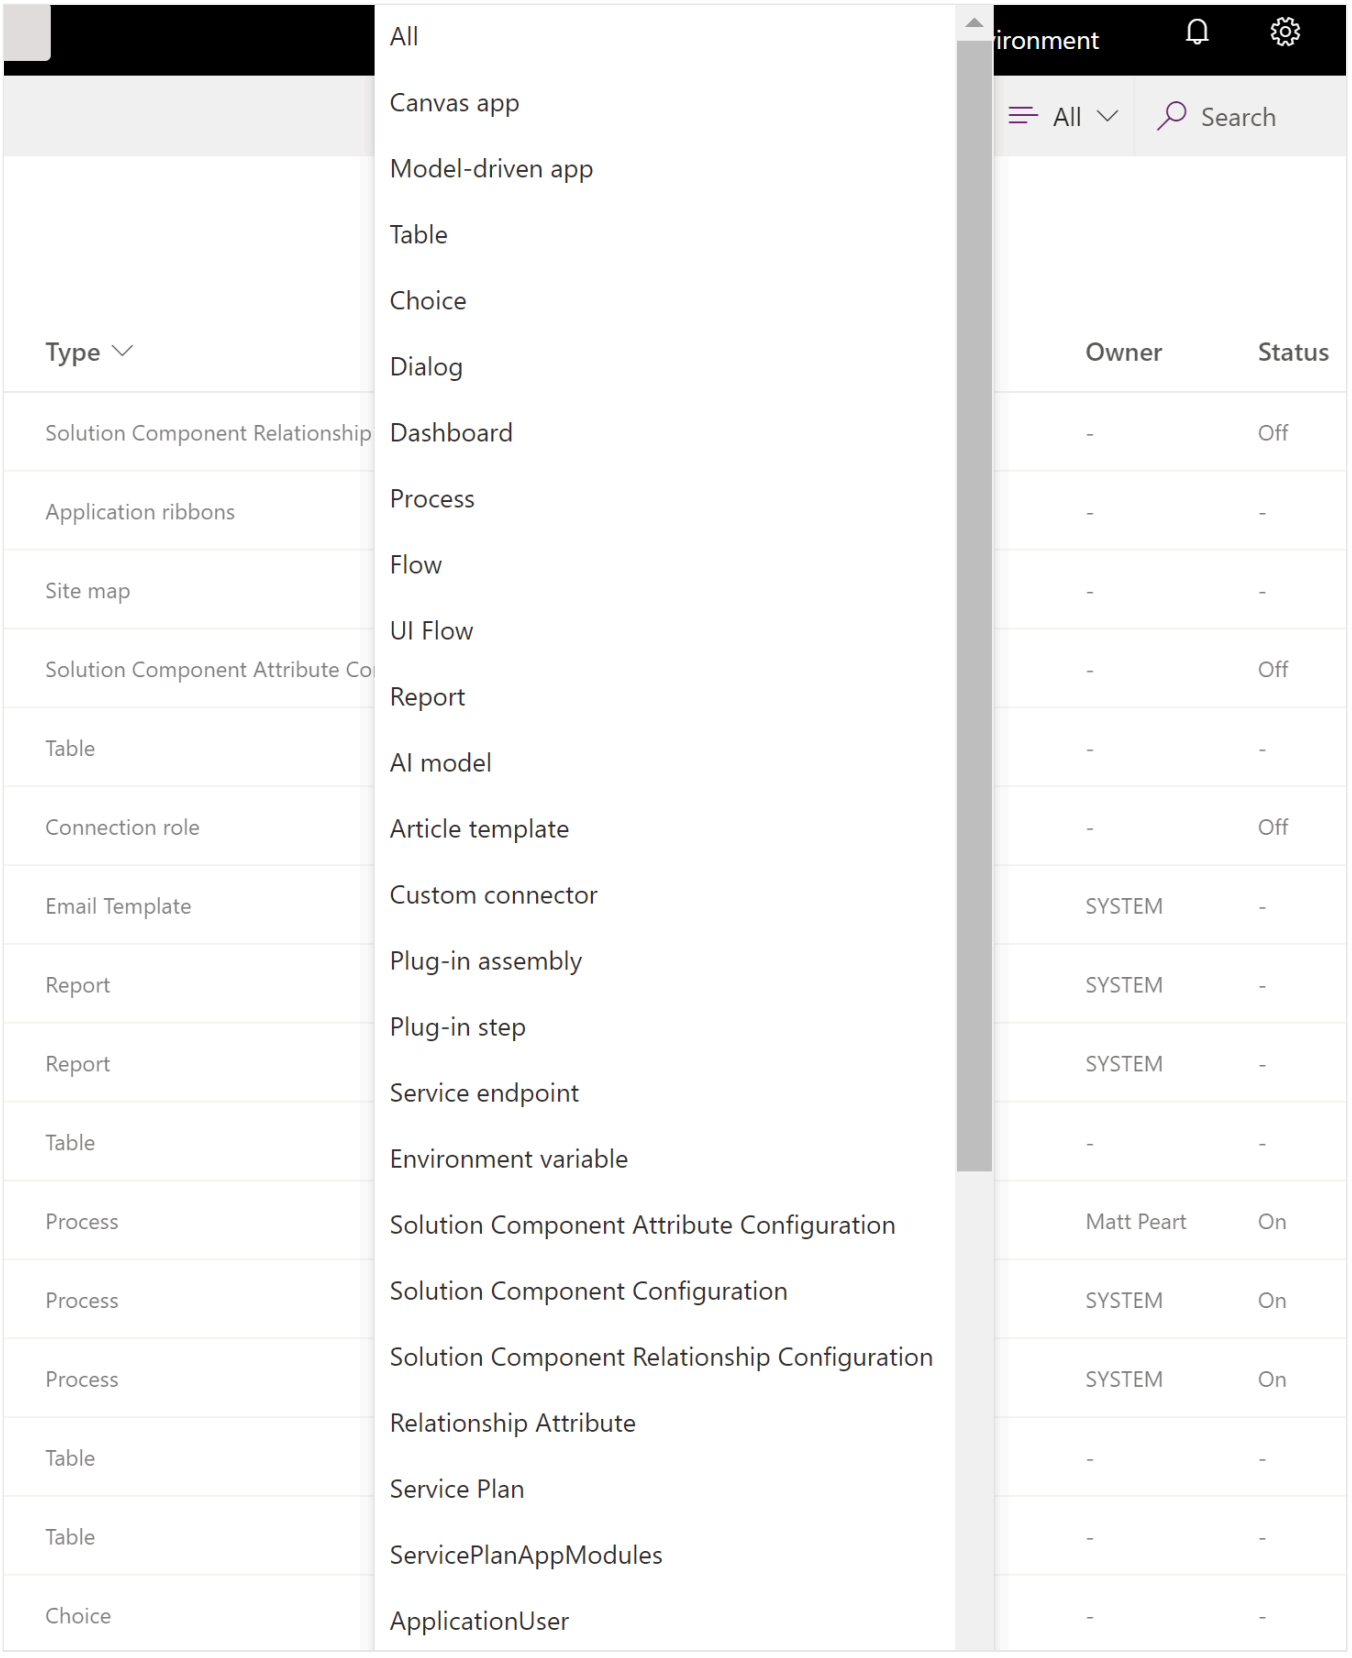
> **Tip**
>
> You can quickly locate all solution objects that are unmanaged or have unmanaged customizations by selecting the default solution and filtering on the **Customized** column.

Search and filter in a solution

Search for a specific component by its name.

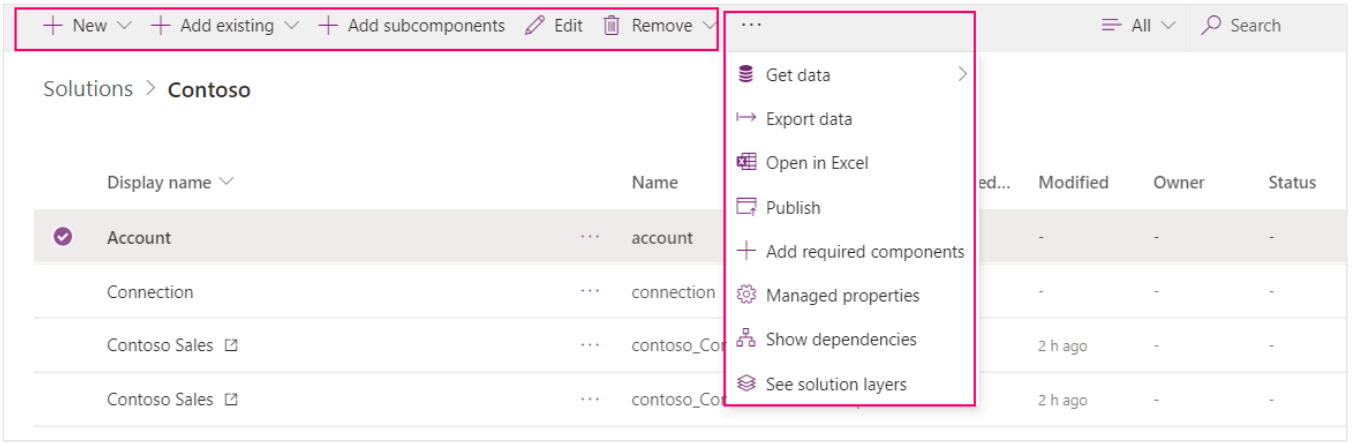


Or filter all items in the list by the component type.

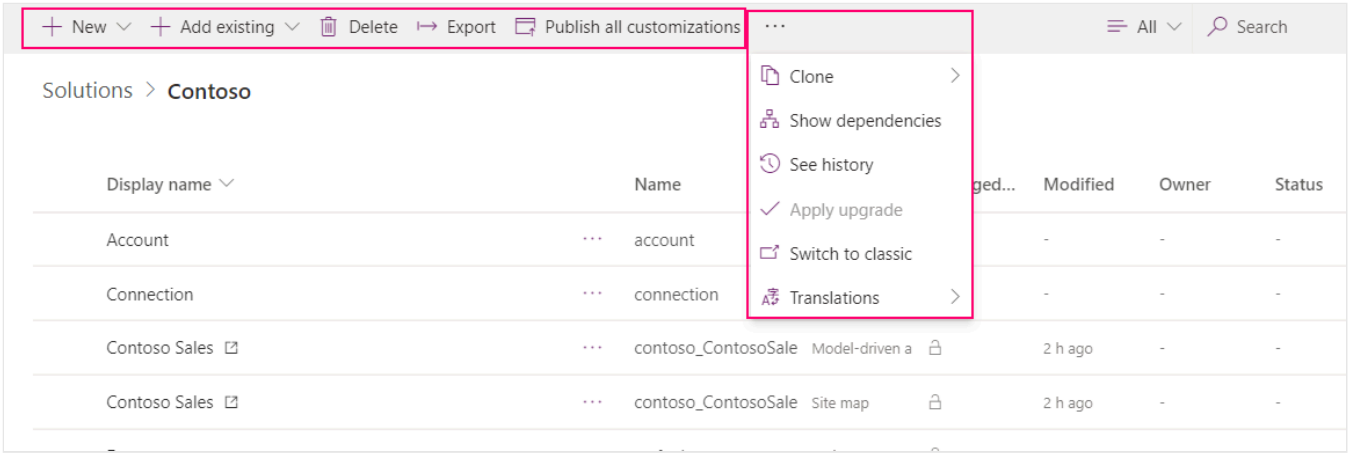


Contextual commands

As you select each component, the actions available in the command bar changes depending on the type of the component you have selected and if the solution is the default or a managed one.



When you don't select any component, the command bar shows actions applied to the solution itself.



With solutions that are unmanaged or the default one, you can use the **New** or **Add Existing** command to create or add different types of components. More information: Add solution components

> **Note**
>
> You can't add components to a managed solution. When you try to, you'll get the following message:
> `"You cannot directly edit the components within a managed solution. You'll need to add it to another unmanaged solution that you've created to customize the component. The component might not be customizable."`

Additional privileges required

Some components might require certain Dataverse privileges for users to run the component when the component is imported into the environment from a solution.

Flows

To use or run a flow from a canvas app that is included in a solution, you must have permissions to that flow through someone sharing ownership or run permissions. When an app in a solution is shared with a set of users, the flows must also be explicitly shared.

More information: Security roles and privileges

Use pipelines in Power Platform to deploy solutions

Easily deploy solutions to test and production environments using pipelines in Power Platform. Once pipelines are in place, makers can initiate in-product deployments with a few clicks. Makers do so directly within their development environments. More information: Overview of pipelines in Power Platform

Known limitations

The following limitations apply to the use of canvas apps, flows, and custom connectors in solutions.

- If you encounter a canvas app publishing error: **the app has connections to flows that are no longer in the environment**, remove any deleted flows from the app. Then save and publish the app.
- Canvas apps shared with **Everyone** that go through environment backup and environment restore operations aren't shared with **Everyone** in the restored environment. Notice that the canvas app can be shared with a security group, and the app in the restored environment is shared with that security group.

To learn more about customizing the individual components in a solution, go to the following articles:

- For table, table relationships, column and message customizations, go to Metadata.
- For table forms, go to Forms.
- For processes, go to Processes.
- For business rules, go to Business Rules.

Troubleshooting solutions

For known issues and information about how to troubleshoot working with solutions, go to Manage apps and solutions in the Power Apps Troubleshooting documentation.

Solution view

Article • 11/06/2024

The modern solution view makes it easier for you to work with solution objects and subcomponents in your solutions.

Open solution view

To open the solution view, sign in to Power Apps (make.powerapps.com) on the left navigation pane, select **Solutions**, and then open the solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.

The solution objects and available actions are displayed.

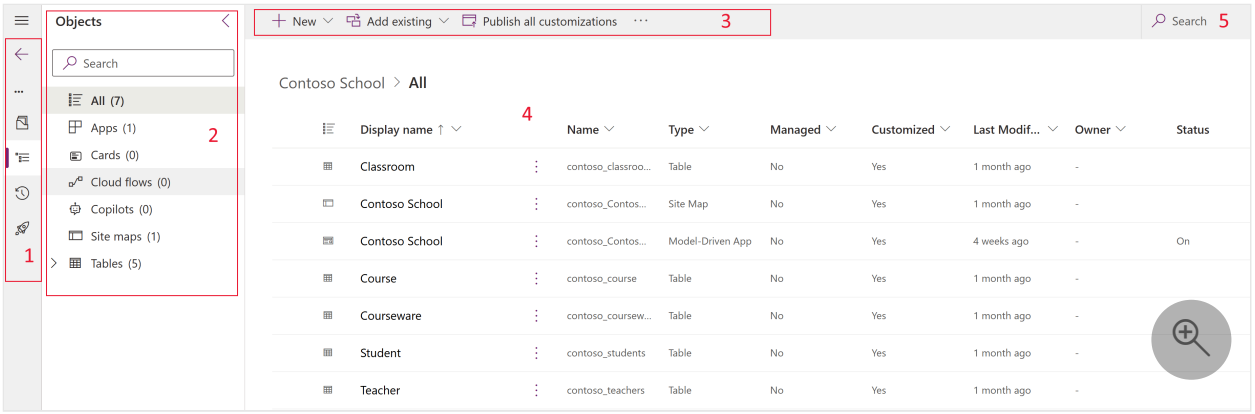
1. Panes - The left navigation pane consists of the following areas:

    - **Overview**. Provides details about the solution, such as display name, name, created on date, version, managed or unmanaged, publisher, description, and whether the solution is a patch. Also, solution health information and solution actions available on the command bar such as export, clone, apply upgrade, and translations.
    - **Objects**. Presents a tree view of all objects within the solution. Select an object from the objects list (4) to view or edit it.
    - **History**. Presents the solution operations completed on the solution. An operation can be a solution import, export, or uninstall. The solution history displays information such as solution version, solution publisher, type of operation, operation start and end time, and operation result status.
    - **Pipelines**. Deploy solutions using pipelines in Power Platform. More information: Set up pipelines in Power Platform
    - **Source control** (not shown in image). Connect to Git to source your Power Platform solution objects in an Azure DevOps Git repo. More information: Overview of Dataverse Git integration

2. Tree view. From the **Object** pane, the tree view displays a list that you can browse to find an object to open it or one of the object's subcomponents. Search for objects and subcomponents that are in the solution.
3. Command bar. Contextual command bar to perform actions on the solution, objects, or subcomponents.
4. Objects. Displays information and solution components that can be viewed and/or opened for editing of the selected object from the **Objects** pane. Add existing

objects and subcomponents or create new ones for unmanaged solutions. More information: Objects list

5. Search. Use to filter the list of subcomponents for the object that's currently selected. Filter on any subcomponent property. For example, filter on only **Lookup** data types or whether a column is **Required** by entering those strings in the **Search** box.



Objects list

The **Objects** list in solution view has the following columns:

- **Display name**. The friendly name of the solution object.
- **Name**. The unique or logical name of the solution object that includes the solution publisher prefix.
- **Type**. Solution object type, such as a table, web resource, model-driven app, canvas app, and so on.
- **Managed**. Indicates whether the solution object is managed or unmanaged. Managed solutions aren't typically customizable.
- **Customized**. Unmanaged solution components are customized while managed solution objects typically shouldn't be. If a managed solution object is customized, you can remove the customization. More information: View solution layers for a component
- **Last modified**. The date the solution object was last changed.

Create a solution

To locate and work with just the components you customize, create a solution and do all your customization there. Then, always remember to work in the context of the custom solution as you add, edit, and create components. This makes it easy to export your solution so that it can be backed up or imported to another environment.

> **Note**
>
> Consider specifying a custom solution as you preferred solution. This way you can control where your solution components are stored when you don't specifically create them in the context of a custom solution. More information: Set the preferred solution.

To create a solution:

1. Sign in to Power Apps and select **Solutions** from the left navigation. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **New solution** and then complete the required columns for the solution.

Expand table

Field	Description
Display Name	The name shown in the list of solutions. You can change this later.
Name	The unique name of the solution. Must only contain letters, numbers, and underscores. The name is generated from the allowed characters from the value you enter in the **Display Name** column. You can edit this before you save the solution, but after you save the solution, you can't change it.
Publisher	You can select the default publisher or create a new publisher. We recommend that you create a publisher for your organization to use consistently across your environments where you'll use the solution. See Solution publisher later in this article.
Version	Enter a number for the version of your solution. This is only important if you export your solution. The version number is included in the file name when you export the solution.
Set as your preferred solution	Using a preferred solution is a way you can control where your solution components are stored when you don't specifically create them in the context of a custom solution. When your preferred solution isn't set, by default, the Common Data Services Default Solution is your preferred solution. If Common Data Services Default Solution isn't available, the solution named Default

Field	Description
	Solution is used as your preferred solution. More information: Set the preferred solution
Configuration Page	Under **More options** you can, optionally select a web resource to use as a configuration page. The configuration page is typically used by independent software vendors (ISVs) who distribute solutions. When this is set, a new **Configuration** node appears below the **Information** node to display this web resource. Developers use the web resource, which is an HTML page, to include instructions or controls to allow you to set configuration data or launch their solution.
Description	Under **More options** you can optionally add a description of the solution. This is useful if you want to share the solution with others or if you want to remember what the solution is for.

3. Select **Save**.

Add or remove solution objects

After you create your solution, it won't contain any solution objects. You can create new objects to add to the solution or add existing objects to your new solution.

Create objects in a solution

You can use the **New** command to create different types of objects. Selecting **New** and then selecting the object you want takes you to a different create experience depending on the object type that you choose. After you finish creating the object, it's added to the solution.

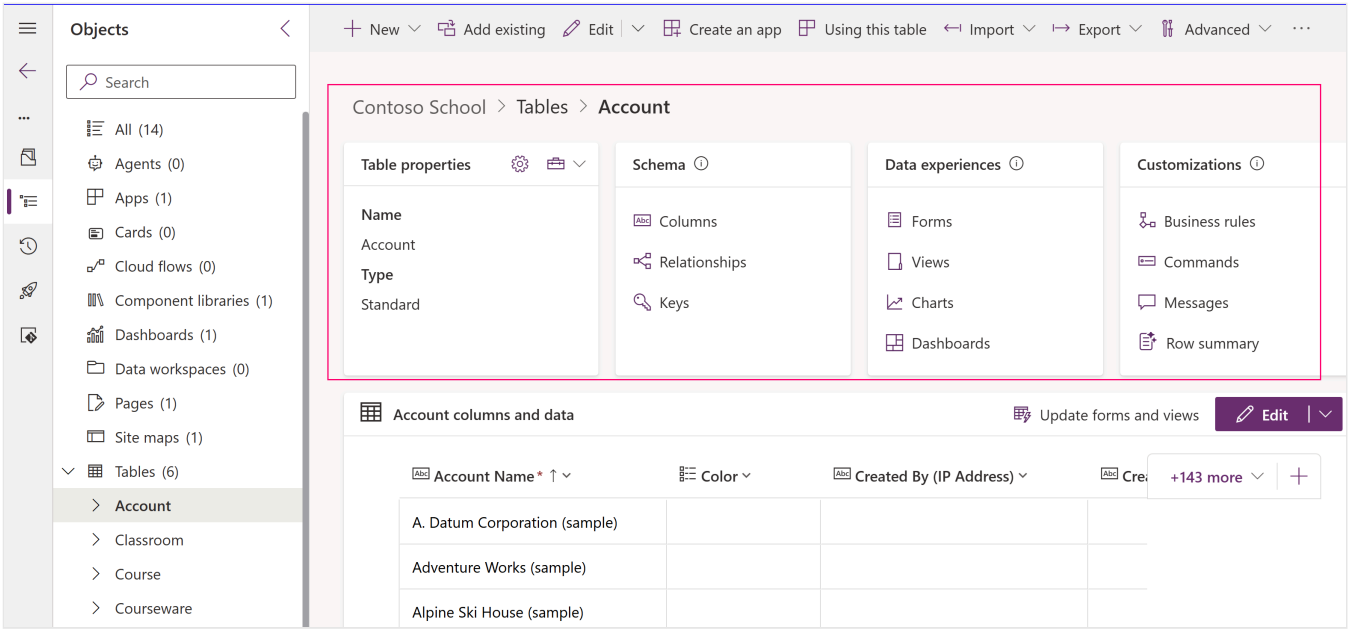
Add an existing object to a solution

With solutions that are unmanaged and not the system default solution, you can use the **Add existing** command to bring in objects that aren't already in the solution.

> ⓘ **Note**
>
> The list of existing objects are different depending on the version and solutions imported in your environment.

Many of the customizations you want to do involve tables. Select **Tables** in the left pane to filter and display a list of all the tables in the current solution. Once you drill into a table, you

can view the objects that are part of the table as shown with the account table in this screenshot.



Remove objects from a solution

You can remove objects from an unmanaged solution. With the solution open, select the object, and then select **Remove from this solution** on the command bar.

When the object is removed, it's no longer part of the solution. However, the object still exists in the environment and can be added to another solution. Once the object is removed from all solutions in the environment, it can be deleted.

> **Important**
>
> Once the object is deleted it can't be recovered and all associated data, such as table records when you delete a custom table are lost. If you want to keep the object, but not have it in the solution, remove it from the solution without deleting it.

To delete an object, select it, and then select **Delete from this environment**.

Publish changes

When you make unmanaged changes in an environment, some objects, such as tables, forms, model-driven apps, site maps, and views are saved in an unpublished state. The publish action promotes these changes to an active state and makes them available to end users and for solution export.

Publish your customizations

1. Select **Solutions** from the left navigation. If the item isn't in the side panel pane, select ... More and then select the item you want.
2. Open the solution that you want to publish.
3. Select **Publish all customizations** on the command bar.

> **Important**
>
> Preparing customizations might take some time. If you see a message that the browser page is unresponsive, wait for the page to become responsive, and don't close it.

Solution publisher

Every app you create or customization you make is part of a solution. Every solution has a publisher. You specify the publisher when you create a solution.

The solution publisher indicates who developed the app. For this reason, you should create a solution publisher that is meaningful. You can view the solution publisher for a solution by selecting the solution, and then select **...** > **Settings** on the command bar from the **Solutions** area in Power Apps. For more information about the solution publisher, go to Solution publisher in the Power Platform ALM guide.

> **Note**
>
> The **Common Data Services Default Solution** is associated with the **Microsoft Dataverse Default Publisher**. The default customization prefix is randomly assigned for this publisher, for example it could be `cr8a3`. This means that the name of every new item of metadata created for your organization in this solution has this prepended to the names used to uniquely identify the items.

Create a solution publisher

1. In Power Apps, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. On the command bar, select **New solution**, in the right pane select **New publisher** under **Publisher**.

3. In the **New Publisher** form, enter the required and optional information:

    - **Display Name**. Enter the display name for the publisher.
    - **Name**. Enter the unique name for the publisher.
    - **Description**. Optionally, you can add a description for the publisher.
    - **Prefix**. Enter the publisher prefix you want.
    - **Choice value prefix**. This column generates a number based on the publisher prefix. This number is used when you add options to choices and provides an indicator of which solution was used to add the option.

4. Select **Save**.

> **Note**
>
> Don't use _upgrade as part of the solution name. _upgrade is an internal reserved word for the solution **upgrade process**.

Change a solution publisher

You can change a solution publisher for an *unmanaged* solution by following these steps:

1. In Power Apps, select **Solutions**, select the solution you want, and then select **...** > **Settings** on the command bar. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. In the **Solution settings** pane, select a different publisher from the **Publisher** drop down list or select **New publisher** to create a new one. More information: Create a solution publisher.
3. Select **Update**.

Use segmented tables in a solution

Use table segmentation so that you only include table objects that are updated when you distribute solution updates. More information: Use segmented solutions in the Power Platform ALM guide

To create a solution with proper table segmentation, start with creating an unmanaged solution and add only the objects that you've updated.

For example, imagine that you've created a new custom table that doesn't exist in any other environment named *Custom table* and also added a new column named *Top Ten* for the account table. To create a solution with table segmentation, follow these steps.

1. Go to Power Apps and then select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Select **New solution** and create a solution. Enter information in the required columns. Select **Create**.

3. Open the solution you created. On the command bar, select **Add existing**, and then select **Table**.

4. In the **Add existing tables** pane, select one or more tables you want to add to the solution. For example, select **Account** and **Custom table**. Select **Next**.

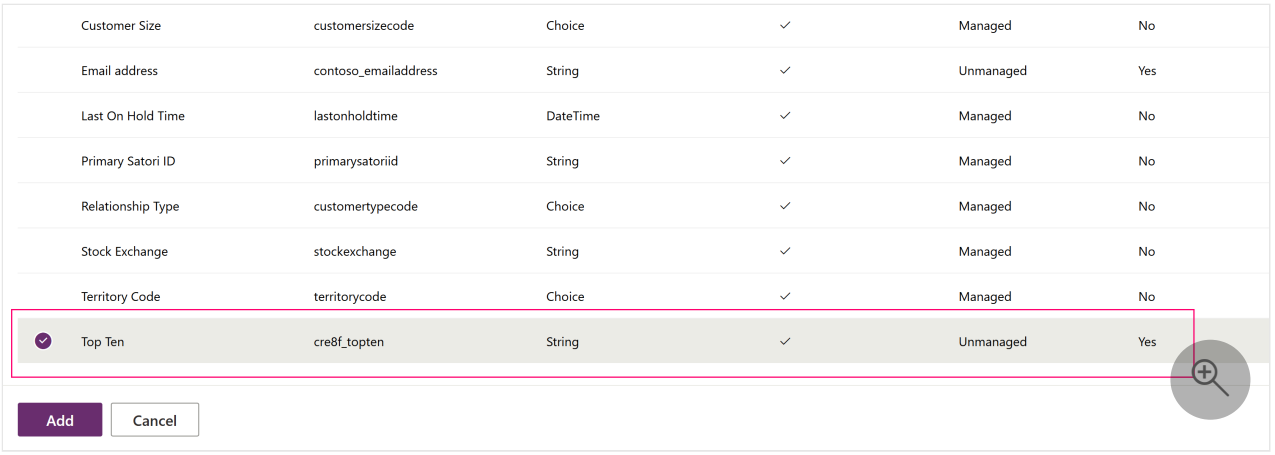
5. In the **Select tables** pane, you can choose from the assets to include:

    - **Include all objects**. This option includes all components *and* metadata associated with the table. It can include other tables or table components such as business process flows, reports, connections, and queues. For example, if the custom table has never been imported into the target environment, select this option. In this example, custom table has never been imported into the target environment, so select this option for **Custom table**.
    - **Include table metadata**. This option includes *only* the metadata associated with the table. Metadata includes the table attributes, such as auditing, duplicate detection, or change tracking.
    - **Edit objects**. This option lets you individually select each component that's associated with the table, such as columns, relationships, business rules, views, forms, and charts. Notice that the account table is included in Dataverse and by design also exists in the target environment. Therefore, in our example only the *Top Ten* custom column is new to the account table so you select it after selecting **Edit objects** (in the next step).
    - **Clear all objects**. If you selected objects using the **Edit objects** option, you can clear all the selected objects and start over.

    
    More information: Why table segmentation in a solution is important

6. If you selected **Edit objects**, an object list pane opens. Here you can select the specific objects you want to include in the solution. In our example you selected the **Account** table earlier, so now you select the **Top Ten** column since that's the only new or edited

component for the table, and then select **Add**.



7. Select **Add** to add the objects to the solution.

Why table segmentation in a solution is important

When you add an existing system table, such as account or contact, or a custom table to a solution for a table that's already been imported into your downstream environments, the best practice is to *only add the table objects that were updated* in your solution. With solution segmentation, you export solution updates with selected table assets, such as table columns, forms, and views, rather than entire tables with all the assets. This avoids unnecessary layers that hinder other solutions from being effective and unnecessary dependencies on other solutions. The system automatically selects **Include all objects** if the table is unmanaged, and **Include table metadata** if there's an unmanaged layer on the table. The system also preselects the table assets that are unmanaged or have unmanaged customizations automatically. You can select the **Edit objects** link to review that selection before you select **Add** to complete the process.

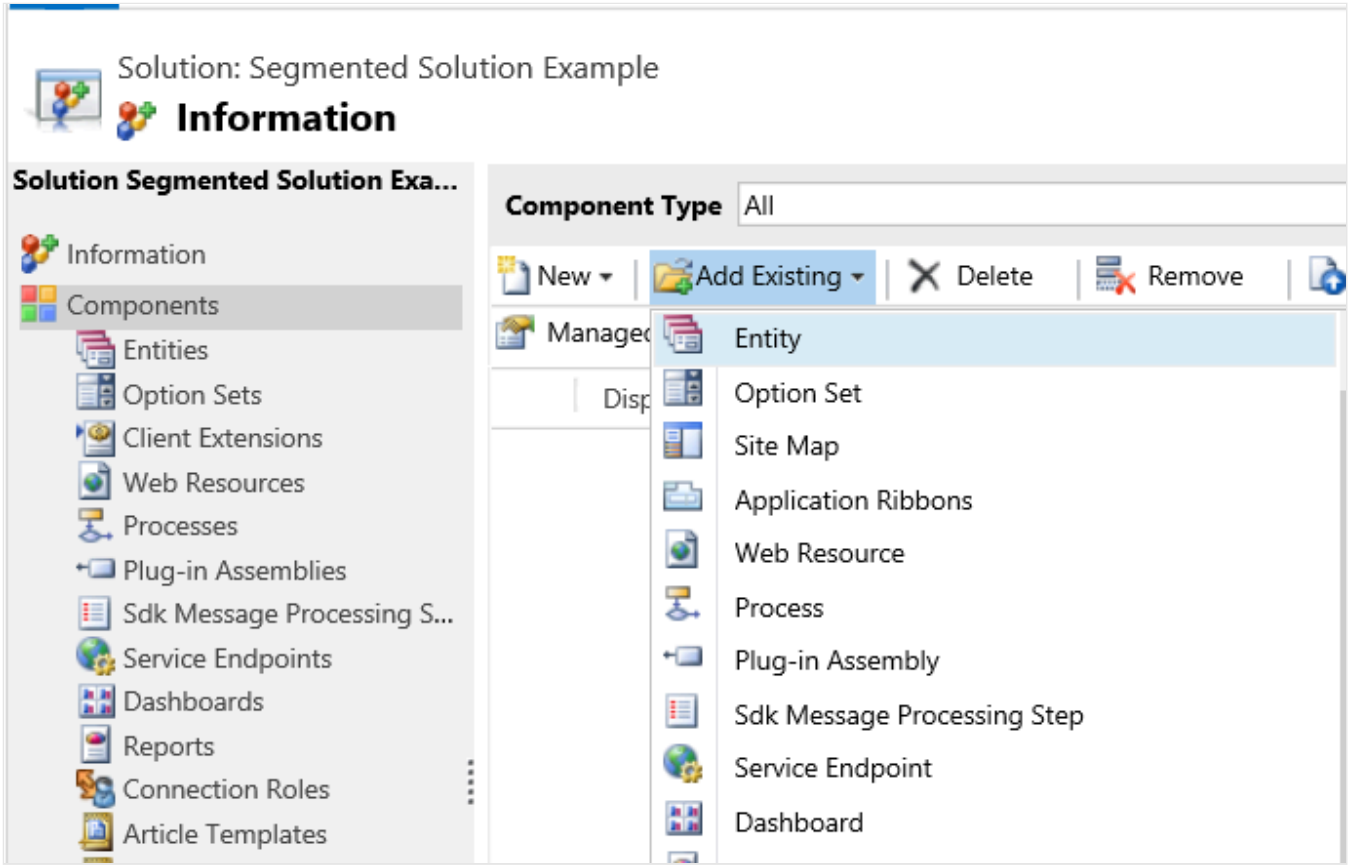
> **ⓘ Important**
>
> Don't segment tables that don't exist in the target environment. Notice that if a table has never been imported or doesn't already exist in the target environment you must select **Include all objects** when you add the table to the solution, such as when adding a new custom table that you recently created. Otherwise you receive a missing dependency error message when you try to import the solution.

Create a solution with table segmentation using solution explorer

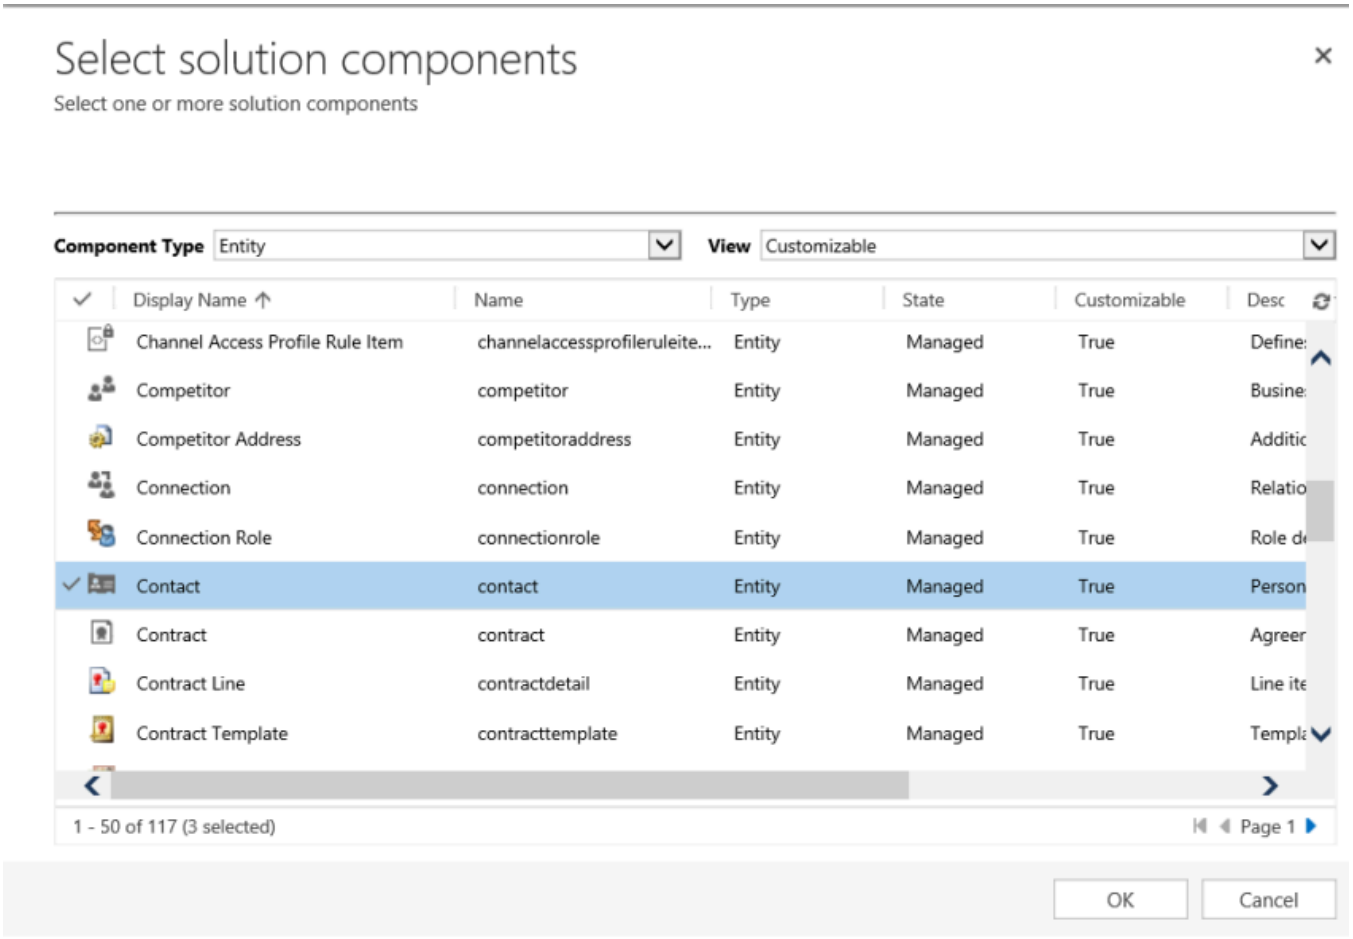
The following illustrations provide an example of creating a segmented solution by choosing table assets from the `Account`, `Case`, and `Contact` tables.

> **Note**
>
> The case table is included with some Dynamics 365 applications, such as Dynamics 365 Customer Service.

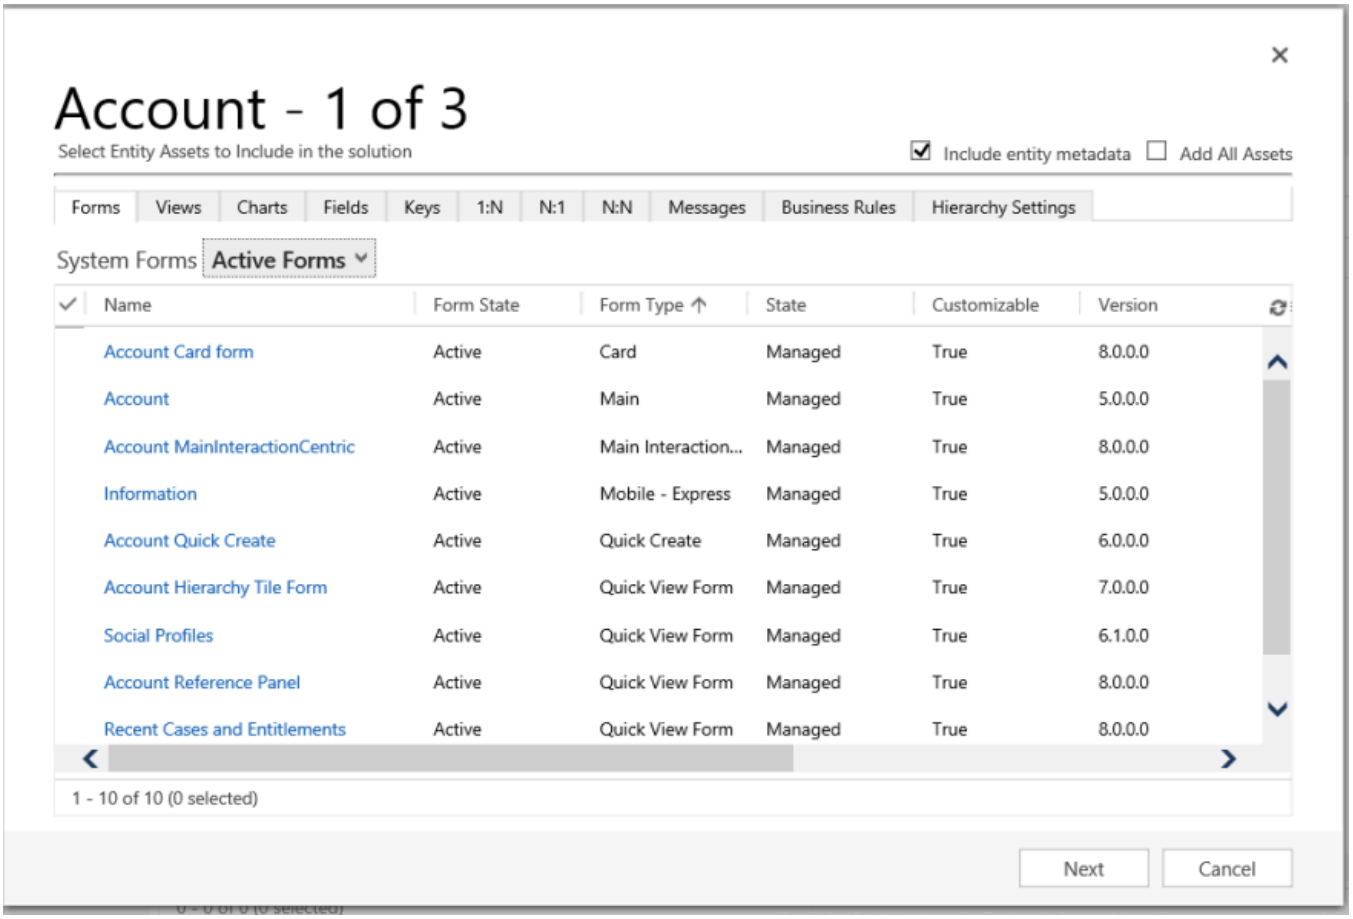
Start by opening an unmanaged solution you created. Choose the **table** component.



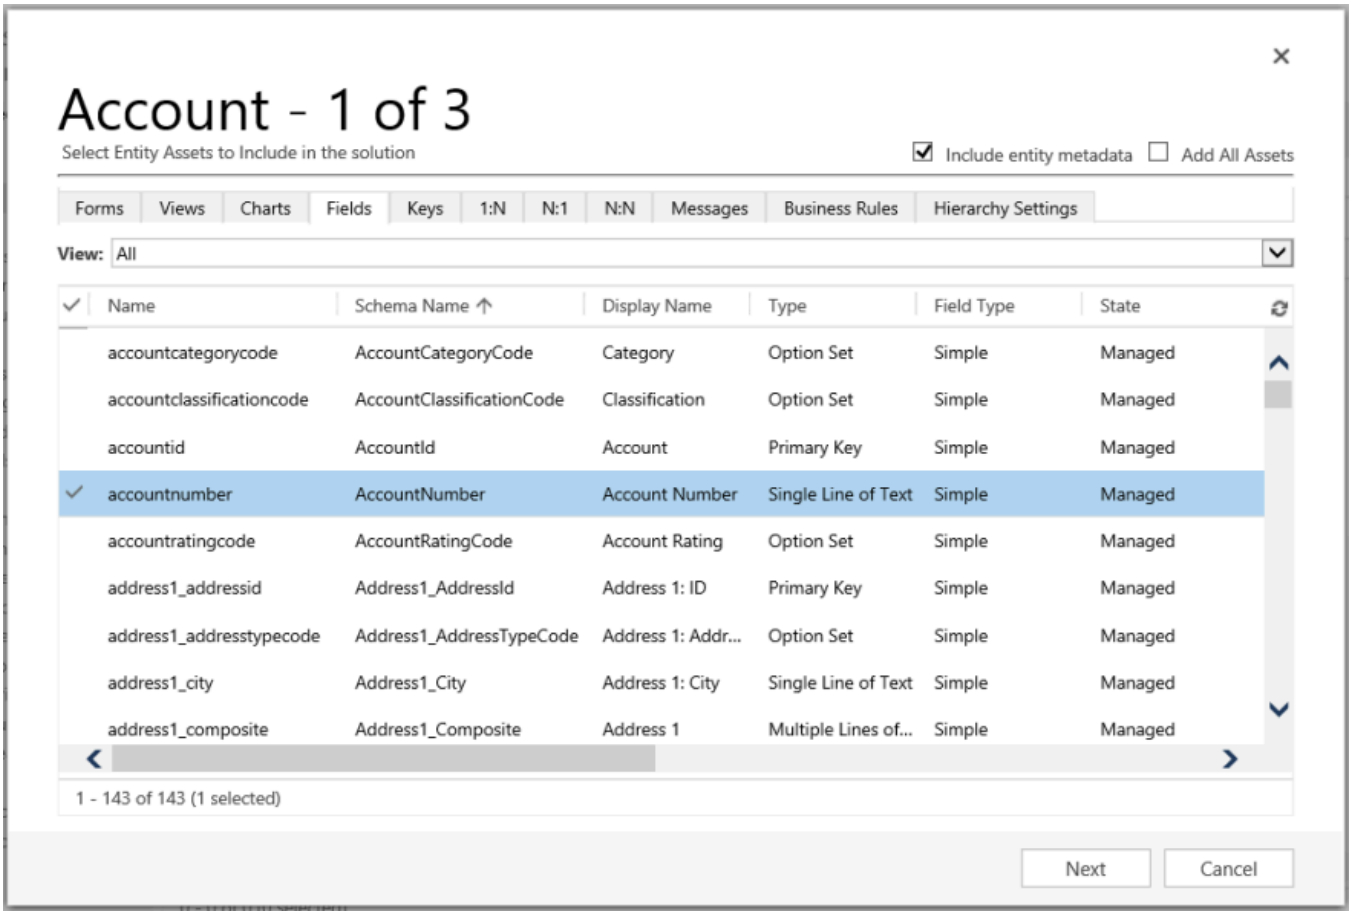
Then, select the solution components.



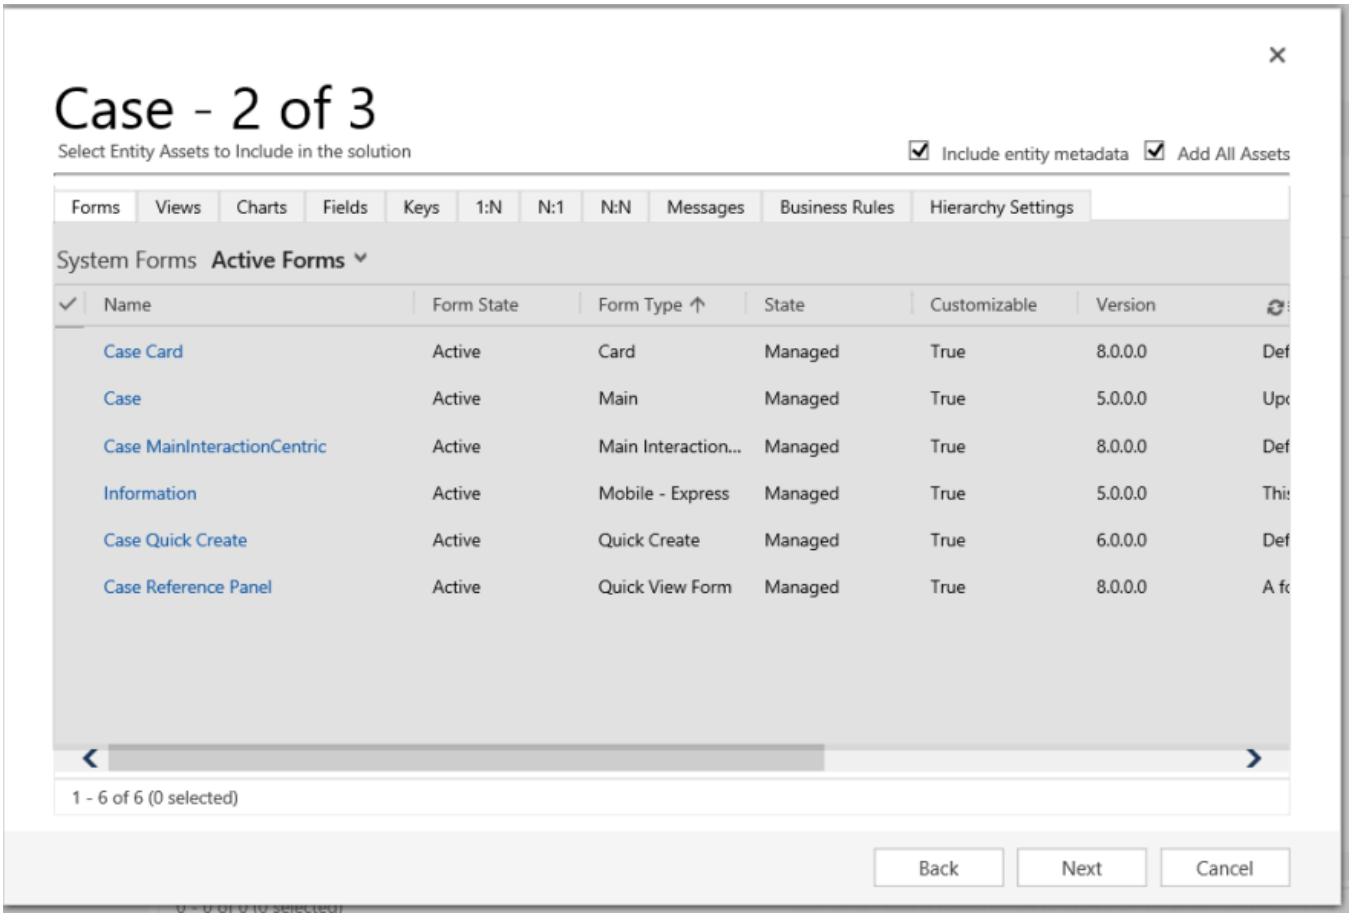
Follow the wizard. In Step 1, starting in alphabetical order, select the assets for the first table, the `Account` table, as shown here.



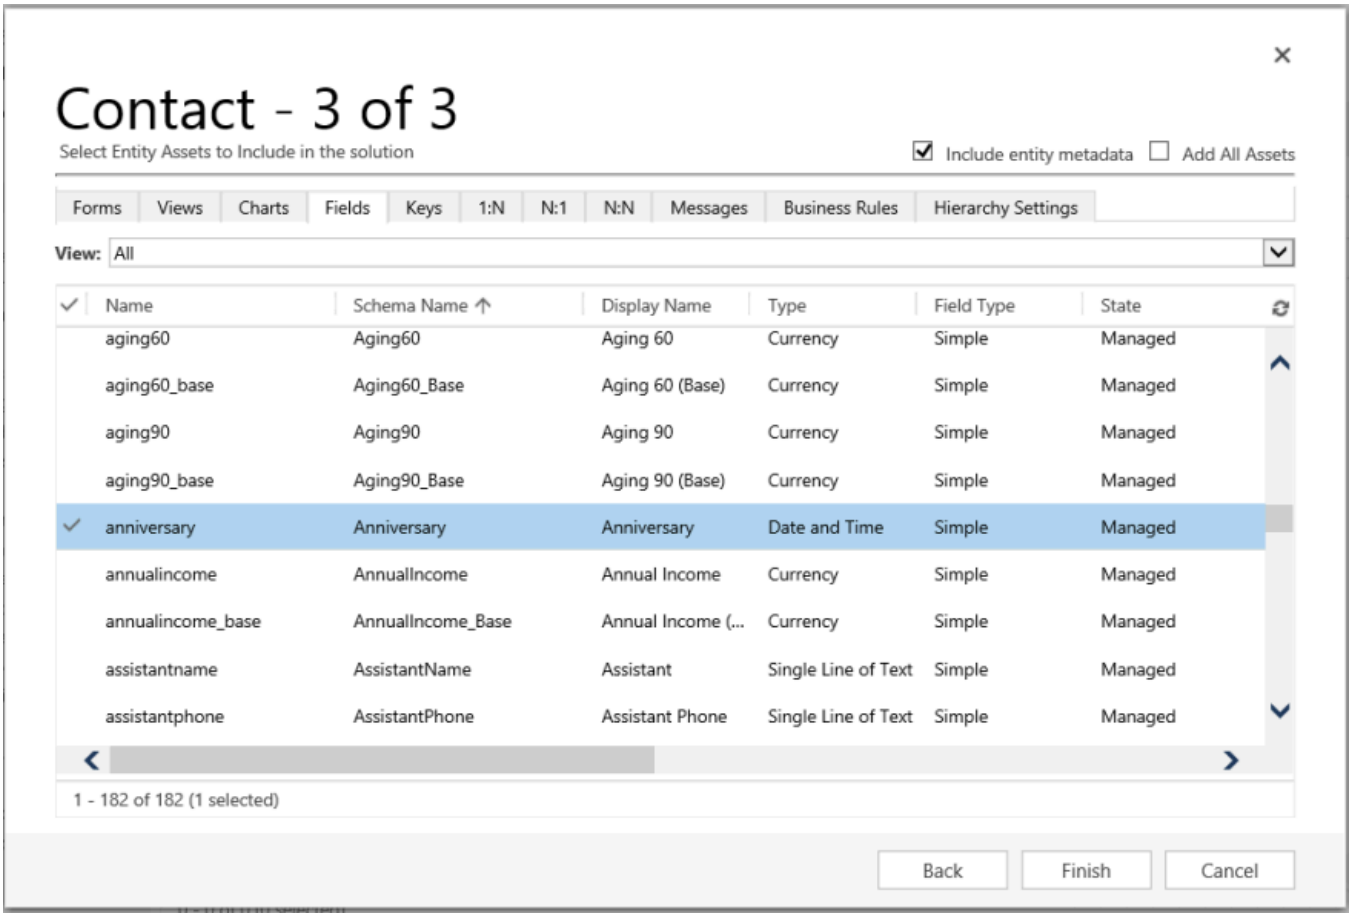
Open the **Fields** tab and select the **Account Number** column.



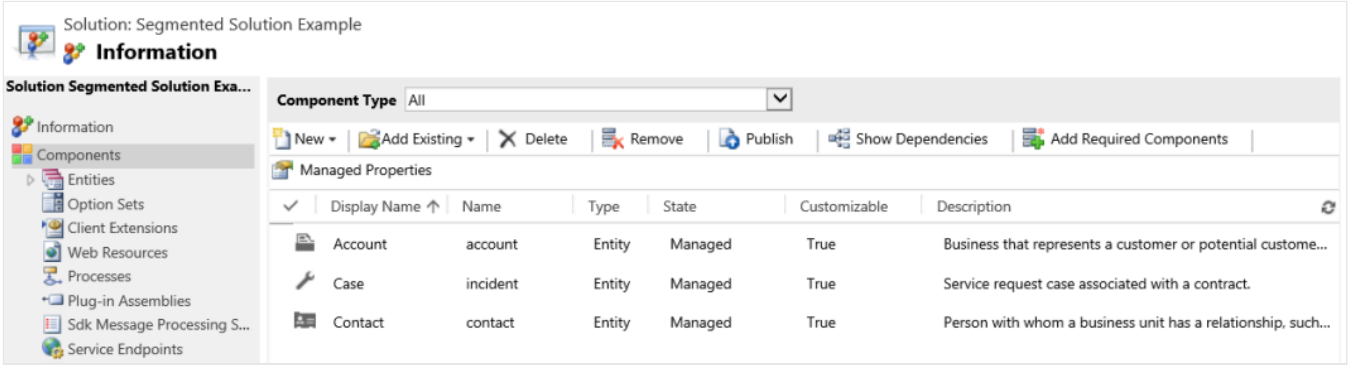
In Step 2, for the **Case** table, add all assets.



In Step 3, add the **Anniversary** column for the **Contact** table.



As a result, the segmented solution that's created contains three tables, `Account`, `Case`, and `Contact`. Each table contains only the assets that were chosen.



Delete a solution

Because there are two different types of solutions, managed and unmanaged, the behavior for deleting each type of solution is different.

The solution you want to delete might have components that have dependencies on other components. These dependencies must be removed before you can delete the component. More information: View dependencies for a component in Power Apps

Delete a managed solution

Deleting a managed solution removes (uninstalls) *all* the components within the solution. Additionally, *all* associated data are also deleted.

> ⊗ **Caution**
>
> Because all components within the solution and all associated data are deleted, use caution when you delete a managed solution.

Delete an unmanaged solution

Deleting an unmanaged solution deletes the solution container but doesn't delete any of the unmanaged components within. Any data associated also remains. Each unmanaged component must be individually deleted to remove all components within the unmanaged solution.

Delete a managed or unmanaged solution

> ⊗ **Caution**
>
> Before you delete a solution, make sure you understand the consequences. Once a solution is deleted, it can't be restored. More information: Delete a managed solution and Delete an unmanaged solution

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane, and then select (don't open) the solution you want to delete in the **Solutions** list.
3. Select **Delete** on the command bar.

Limitations

- Solution size is limited to 95 MB.
- Number of solutions is limited by Microsoft Dataverse capacity.
- Number of objects in a solution is limited by Dataverse capacity.

Export solutions

Article • 03/13/2023

You can manually export solutions using the steps in this article. We recommend that you create an unmanaged solution to use for exporting your customizations, and then export your customizations periodically so that you have a backup in case anything happens. You can't export managed solutions or the Default Solution.

> **Note**
>
> To implement healthy application lifecycle management (ALM) in your organization, consider using a source control system to store and collaborate on your solutions, and automate the solution export process. More information: **ALM basics** in the Power Platform ALM guide.

Export from Power Apps

1. Sign into Power Apps and select **Solutions** from the left navigation. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. In the list of solutions, select the unmanaged solution you want to export, and then select **Export**. Notice that you can't export managed solutions.

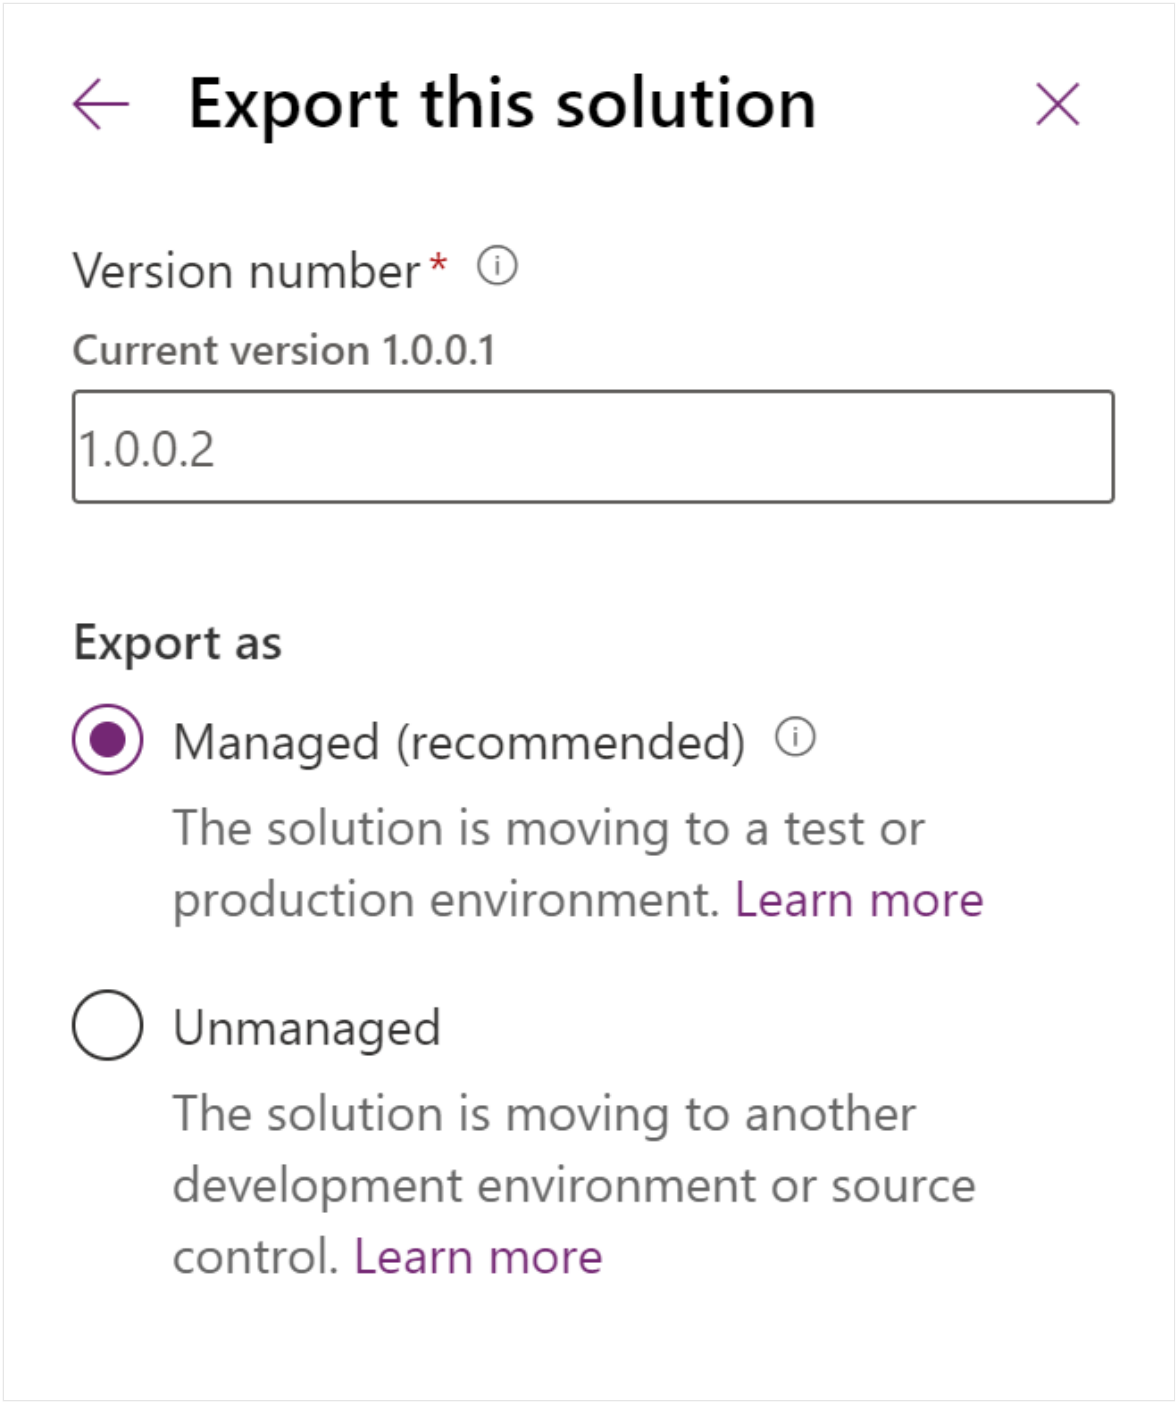
3. The **Before you export** right pane appears. Choose from the following options, and then select **Next**:

    - **Publish all changes**. Notice that, when you export an unmanaged solution, only published components are exported. We recommend that you select **Publish all changes** to make sure all components are included in the exported solution.

4. The **Export this solution** right pane appears. Enter or select from the following options, and then select **Export**:

    - **Version number**: Power Apps automatically increments your solution version while displaying the current version. You can accept the default version or enter your own.
    - **Export as**: Select the package type, either **Managed** or **Unmanaged**. More information: Managed and unmanaged solutions

- **Run solution checker on export**. Run the solution checker against the solution to detect performance and stability issues.



The export can take several minutes to complete. Once finished, the export .zip file is available in the download folder specified by your web browser.

Export using the classic experience

1. Sign into Power Apps and select **Solutions** from the left navigation. If the item isn't in the left navigation pane, select ...More and then select the item you want.

2. Select **Switch to classic**.

3. In the list select the solution you want to export and then select **Export**.

4. In the **Publish Customizations** step you will be reminded that only published customizations are exported and you will have the option to **Publish All Customizations** before you select **Next**.

5. If your solution contains any missing required components you will see the **Missing Required Components** step. You can disregard this warning only if you intend to import this as an unmanaged solution back into the original environment. Otherwise, follow the instructions in the dialog to cancel the export and add the required components.

6. In the **Export System Settings (Advanced)** step you can choose certain system settings to include in your solution. If your solution depends on any of the groups of system settings, select them and select **Next**.

   See **Settings options for solution export** below for details about the settings that will be included with each option.

7. In the **Package Type** step, you must choose whether to export the solution as an **Unmanaged** or **Managed** solution.

8. The next step allows you to choose a target solution for a specific version. This option is typically used by ISVs who may want to export a solution that is compliant with a previous version. Unless you intend to import this solution into an environment that is not upgraded to the same version as the environment version you are using, accept the default.

9. Select **Export** to download the solution file.

The exact behavior for downloading files varies between web browsers.

Settings options for solution export

If you export the solution from Power Apps, please disregard this section. The following table shows the options available when you export a solution from the classic experience.

Group	Setting	Description
Auto-numbering	Campaign Prefix	Prefix used for campaign numbering.
Case Prefix	Prefix to use for all cases throughout the app.	

Group	Setting	Description
Contract Prefix	Prefix to use for all contracts throughout the app.	
Invoice Prefix	Prefix to use for all invoice numbers throughout the app.	
Article Prefix	Prefix to use for all articles in the app.	
Order Prefix	Prefix to use for all orders throughout the app.	
Unique String Length	Number of characters appended to invoice, quote, and order numbers.	
Calendar	Calendar Type	Calendar type for the system. Set to Gregorian US by default
Date Format Code	Information about how the date is displayed throughout Microsoft Dataverse	
Date Separator	Character used to separate the month, the day, and the year in dates throughout the app.	
Max Appointment Duration	Maximum number of days an appointment can last.	
Show Week Number	Information that specifies whether to display the week number in calendar displays throughout the app.	
Time Format Code	Information that specifies how the time is displayed throughout the app.	
Week Start Day Code	Designated first day of the week throughout the app.	
Customization	Is Application Mode Enabled	Indicates whether loading of the app in a browser window that does not have address, tool, and menu bars is enabled.
Email-tracking	Allow Unresolved Address Email Send	Indicates whether users are allowed to send email to unresolved parties (parties must still have an email address).

Group	Setting	Description
Ignore Internal Email	Indicates whether incoming email sent by app users or queues should be tracked.	
Max Tracking Number	Maximum tracking number before recycling takes place.	
Render Secure Frame For Email	Flag to render the body of email in the webform in an IFRAME with the security='restricted' attribute set. This is additional security but can cause a credentials prompt.	
Tracking Prefix	History list of tracking token prefixes.	
Tracking Token Base	Base number used to provide separate tracking token identifiers to users belonging to different deployments.	
Tracking Token Digits	Number of digits used to represent a tracking token identifier.	
General	Block Attachments	Prevent upload or download of certain attachment types that are considered dangerous.
Currency Format Code	Information about how currency symbols are placed throughout the app.	
Currency Symbol	Currency Symbol	
Full Name Display Order	Order in which names are to be displayed throughout the app.	
Presence Enabled	Information on whether IM presence is enabled.	
Negative Format	Information that specifies how negative numbers are displayed throughout the app.	
Number Format	Specification of how numbers are displayed throughout the app.	
Pricing Decimal Precision	Number of decimal places that can be used for prices.	
Share To Previous Owner On Assign	Information that specifies whether to share to previous owner on assign.	

Group	Setting	Description
Marketing	Allow Automatic Response Creation	Indicates whether automatic response creation is allowed
Allow Automatic Unsubscribe	Indicates whether automatic unsubscribe is allowed.	
Allow Automatic Unsubscribe Acknowledgement	Indicates whether automatic unsubscribe acknowledgement email is allowed to send.	
Allow Marketing Email Execution	Indicates whether marketing emails execution is allowed.	
Outlook Synchronization	Allow Address Book Synchronization	Indicates whether background address book synchronization in Microsoft Office Outlook is allowed.
Allow Offline Scheduled Synchronization	Indicates whether background offline synchronization in Outlook is allowed.	
Allow Scheduled Synchronization	Indicates whether scheduled synchronizations to Outlook are allowed.	
Email Send Polling Frequency	Normal polling frequency used for sending email in Outlook.	
Min Address Synchronization Frequency	Normal polling frequency used for address book synchronization in Outlook.	
Min Offline Synchronization Frequency	Normal polling frequency used for background offline synchronization in Outlook.	
Min Synchronization Frequency	Minimum allowed time between scheduled Outlook synchronizations.	
Auto-Tag Max Cycles	Maximum number of aggressive polling cycles executed for email auto-tagging when a new email is received.	
Auto-Tag Interval	Normal polling frequency used for email auto-tagging in Outlook.	
ISV Config	Service Calendar Appearance Configuration	You can define visual styles for service calendars.

More information: Service Calendar Appearance Configuration

Import solutions

09/05/2025

You can manually import solutions using the steps in this article. You must import only those solutions that you've obtained from a trusted source.

Solutions are packages of customizations that can be exported from one environment and imported into another. Solutions can be managed or unmanaged. Managed solutions are intended for production use, while unmanaged solutions are typically used during development.

> **Note**
>
> - The create privilege is required to import a component. Although, the System Customizer security role has create privilege on most components that are commonly imported, by default it doesn't have create privilege on the **Plug-In Assembly** table. The System Administrator security role has this privilege.
> - When you import a managed solution, all component changes will be brought into the environment in a published state. However, when you import an unmanaged solution, the changes are imported in a draft state so you must publish them to make them active.
> - To implement healthy application lifecycle management (ALM) in your organization, consider using a source control system to store and collaborate on your solutions, and automate the solution import process. More information: ALM basics in the Power Platform ALM guide.
> - The maximum size of a solution file is 95 MB.

When you import an **unmanaged** solution:

- You add all the components of that solution into your environment and can't delete the components by deleting the solution. Deleting the unmanaged solution deletes only the solution container.
- That contains customized components, the existing customizations to the component will be overwritten after the unmanaged solution import. You can’t undo this.

To import a solution:

1. Sign into Power Apps and select **Solutions** from the left navigation. If the item isn’t in the side panel pane, select ...More and then select the item you want.

2. On the command bar, select **Import solution**.

3. On the **Import a solution** page, select from where you want to import the solution:

    - **This device**. Select **Browse** to locate the compressed (.zip or .cab) file located on your device that contains the solution you want to import.
    - **Pipeline**. Select this option to import a solution from a pipeline. To use this option, you must have the solution set up in a pipeline. More information: Overview of pipelines in Power Platform.

4. Select **Next**.

5. Information about the solution is displayed. By default, in the **Advanced settings** section, if plugin steps (also known as SDK message processing steps) and flows exist in the solution, they'll be imported. Clear the **Enable Plugin steps and flows included in the solution** option if you don't want the import to attempt to activate any plugin steps that are imported in an inactive state. Flows will not be deactivated when the option is unchecked.

6. If your solution contains connection references, you're prompted to select the connections you want. If a connection doesn't already exist, create a new one. Select **Next**.

7. If your solution contains environment variables, you'll be prompted to enter values. You won't see this screen if value(s) are already present in your solution or the target environment.

8. If missing dependencies are detected in the target environment, a list of the dependencies is presented. In environments where the required package version is available for import in the target environment, a link to resolve the dependency is presented. Selecting the link takes you to the Power Platform admin center where you can install the application update. After the application update is completed, you can start the solution import again.

9. Select **Import**.

Your solution imports in the background and might take a few moments.

If you have imported any changes that require publishing, you must publish customizations before they're available.

If the import isn’t successful, you'll see a notification on the solutions page showing any errors or warnings that were captured. Select **Download Log File** to capture details about what caused the import to fail. The most common cause for an import to fail is that the solution didn't contain some required components.

When you download the log file, you'll find an XML file that you can open using Office Excel to view the contents.

> **Note**
>
> You can view the details of all solution operations including solution import with the solution history feature. To view these operations, select **See history** on the solutions page.

Troubleshooting solution import

For known issues and information about how to troubleshoot working with solutions, go to Manage apps and solutions in the Power Apps Troubleshooting documentation.

Importing apps that use an on-premises data gateway ID

When you import a Power Apps app that uses an on-premises data gateway ID, note the following requirements:

- The connection to the gateway must be a shared connection.
- The connections must be removed and then added back with the correct gateway ID after solution import into the target environment.

Set the preferred solution

Article • 04/10/2025

By default, unless you're already in the context of an unmanaged solution when you create an object, all solution objects are stored in the solution named Common Data Services Default Solution. For most situations, you don't want to create your solution objects in either of the two Dataverse system solutions, which are the Common Data Services Solution and the Default Solution. This article explains why using the system solutions is discouraged and provides step-by-step instructions to set and manage your preferred solution.

Why not create your objects in the system solutions?

There are a few reasons you *shouldn't* create your solution objects in either the Common Data Services Solution and the Default Solution:

- There's no control over the separation of solution objects between makers. All objects can be viewed from the Default Solution and the Common Data Services Solution is the default solution so other makers can and likely are using it.
- The Default Solution can't be exported for import to other environments.
- You can't change the solution publisher for the Default Solution. Additionally, since the solutions already exist, you can't change the solution publisher prefix for either system solutions. More information: Solution publisher

Using preferred solutions is a way to determine which solutions contain each maker's edits that occur in Power Apps. Setting the preferred solution enables makers to view and update which solution they're using. After you set your preferred solution, you can create objects in the solution you specify and those objects will automatically be in that solution so that you control the objects within the solution. Then, you can export your preferred solution and import the solution to other Microsoft Dataverse environments.

> **Note**
>
> When your preferred solution isn't set, by default, the **Common Data Services Default Solution** is your preferred solution. If **Common Data Services Default Solution** isn't available, the solution named **Default Solution** is used as your preferred solution. You can change this to your desired solution by following the steps in this article. For more information about the **Common Data Services Default Solution** and **Default Solution**, go to Default solutions.

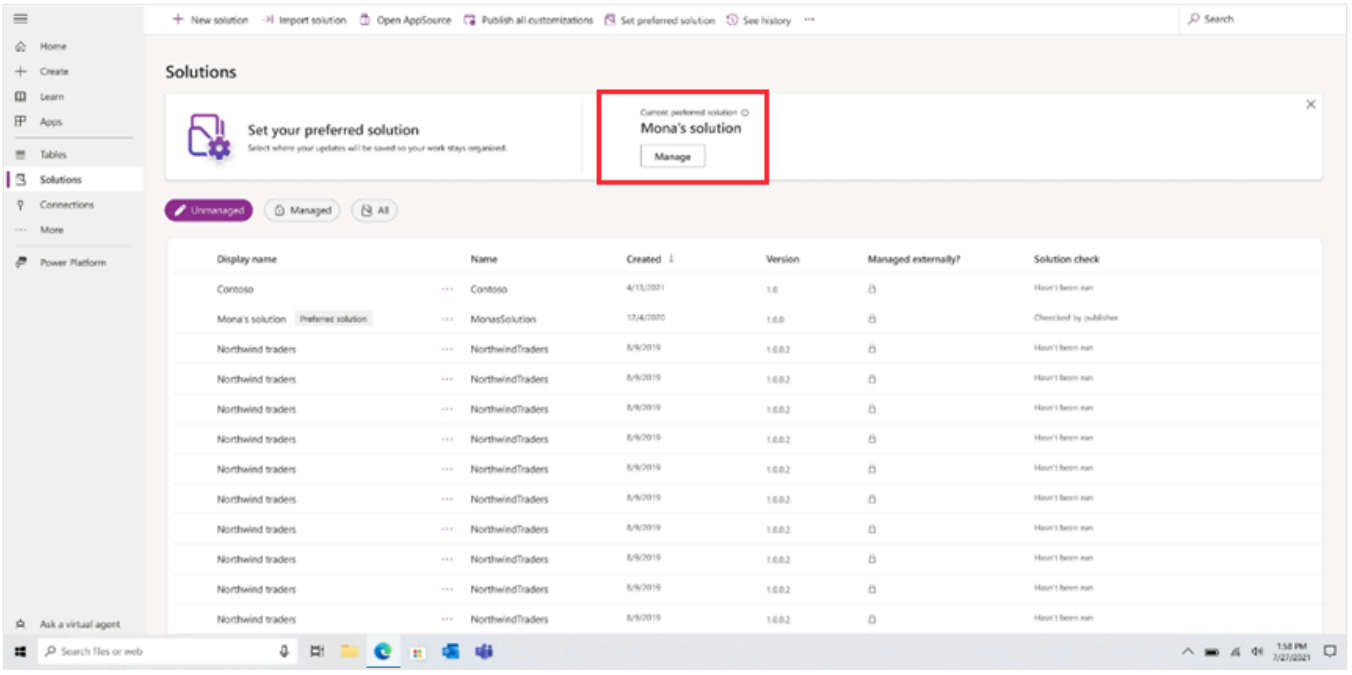
Prerequisites

We recommend that admins enable the **Cloud flows** and **Canvas apps** environment setting in Power Platform. Enabling this feature ensures cloud flows are also stored in Dataverse and that they're added to the maker's preferred solution. More information: Create new canvas apps and cloud flows in a Dataverse solution

Set your preferred solution

1. Sign into Power Apps, and then select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select the unmanaged solution that you want to make your preferred solution. Don't have one? More information: Create a solution
3. Select **Set preferred solution** on the command bar.

Once your preferred solution is set, notice the **preferred solution** indicator, which can be viewed from the **Solutions** area or when you hover over the **Environment** switcher.

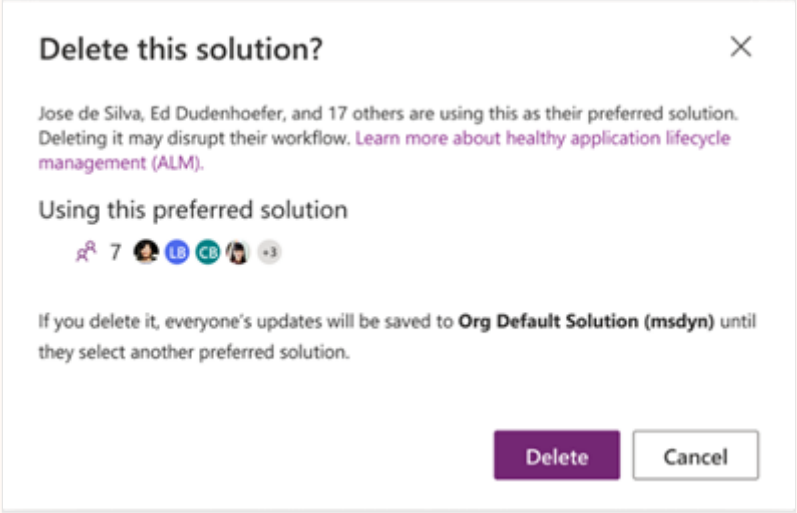


Deleting a preferred solution

You can delete your preferred solution or a preferred solution that other makers have also set as their preferred solution.

> ⚠ **Warning**

When you delete a preferred solution, you receive a warning that includes the fallback default solution and the number of other makers who are using the same solution. Delete an active solution only when you're sure it won't impact your work or the work of other makers.



Limitations

- You can't set or view the preferred solution in the classic solution explorer.
- Components that are created in the classic solution explorer won't go into the preferred solution.
- Preferred solution currently doesn't work with Dataverse for Teams, cards, dataflows, AI Builder, chatbots, connections, gateways, custom connectors, Power Automate flows (limited), and canvas apps created from image or a Figma design.
- When a component is already part of an existing unmanaged solution, it will still be added to the preferred solution.

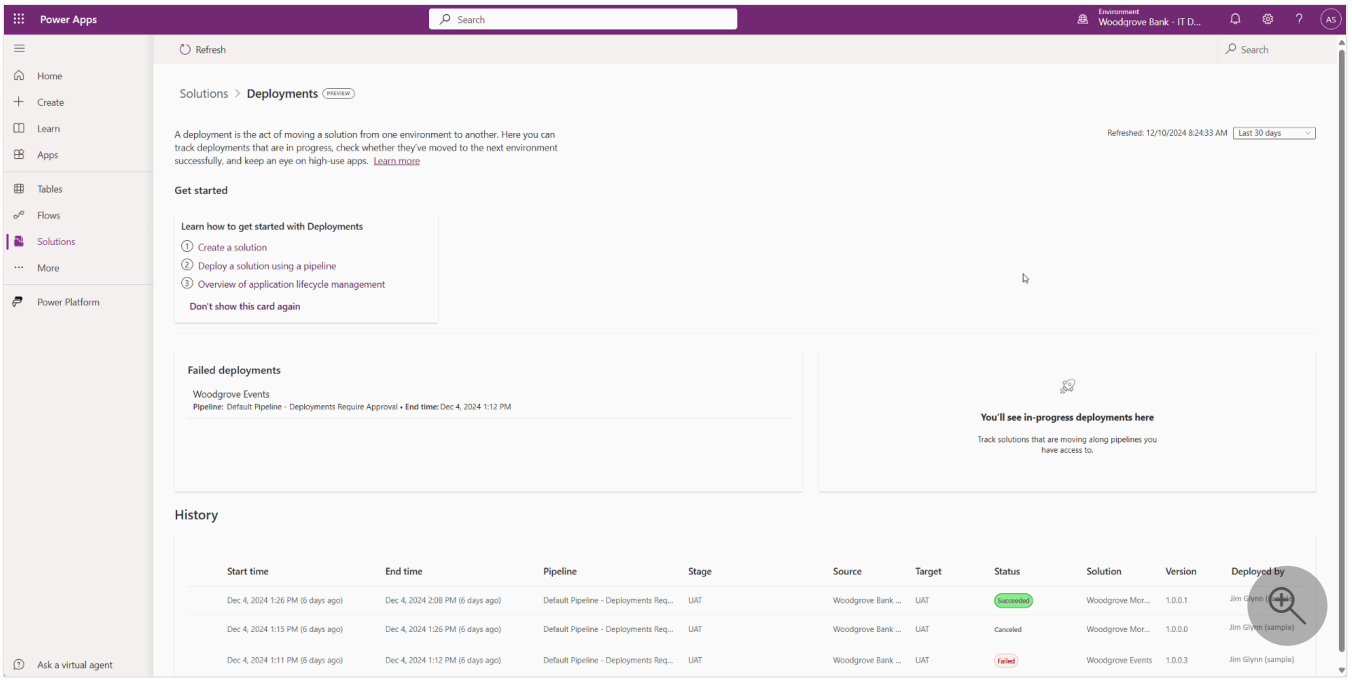
View solution deployments on the deployment page

Article • 05/14/2025

From the **Solutions** page, makers can navigate to **Deployments** to view all of their solution deployments, across all solutions and pipelines, in one place. If their deployment began from (or was deployed to) the current environment, they're able to view its status and other details.



Get started

When you first access the Deployment page, you notice the **Get started** section. This section currently offers several links to relevant documents designed to help makers gain a better understanding of solutions, pipelines, and the in-product Application Lifecycle Management (ALM) process.

Failed deployments

On the left of the overview, makers can view failed deployments if any. When you select each deployment, a panel appears, highlighting the necessary actions to either retry or revise the solution, ensuring a successful deployment.

Active deployments

On the right of the overview, makers view their ongoing deployments. When makers select these deployments, they can view the in-progress details of the deployment, such as waiting

for a predeployment approval. The active deployments page is useful for makers who work in multiple solutions that are deploying simultaneously.

Deployment history

At the bottom of the overview, makers view their deployment history. This section provides a comprehensive list of all deployments, including the deployment status, the solution, the pipeline, and the environment. Makers can filter this list by solution, pipeline, and environment to quickly find the deployment they're looking for. This run history view is unique. First it's filtered to only show the current user's deployments specifically to and from this environment, and second it's upleveled to show all the current user's deployments, not just involving one solution or pipeline. Selecting a deployment in this grid shows a details panel, summarizing all the deployment information and displaying the deployment notes as well.

Retry failed deployments

Deployments shown as **Failed** in the run history view can be deployed by selecting **Retry** in the details panel if the operation was **Deploy**. A confirmation message appears when you confirm the retry.

Take action with advisor-powered recommendations

Actionable recommendations for improving ALM health within your environment is shown in the **Take action** section at the bottom of the Deployment page. These recommendations help ensure that makers are following the best practices to enable healthy ALM within the organization.

Why can't I see solution deployments other than those that I initiated?

In order to view others' solution deployments, you must have the Deployment Pipeline Administrator security role or equivalent privileges to view other deployments.

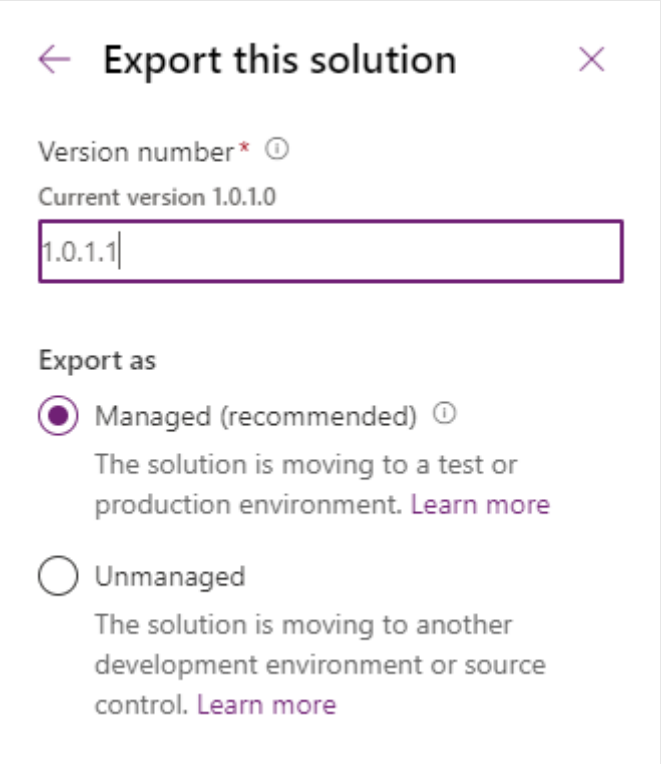
Upgrade or update a solution

Article • 08/31/2023

There are times when you need to update an existing managed solution. To update the solution, follow these steps:

1. Open the unmanaged solution in your development environment and create new or add and remove the existing components that you want.

2. Increment the version number when you export the solution as a managed solution. More information: Understanding version numbers for updates



3. Apply the upgrade or update in the target environment

Apply the upgrade or update in the target environment

The procedure to import the updated solution is similar to installing a new managed solution, except you'll get some different options. If you're updating a solution you got from someone else, you should get guidance from the solution publisher about which options you should choose.

1. Sign into Power Apps, select the target environment you want, and then select **Solutions** from the left navigation. If the item isn't in the side panel pane, select ...

More and then select the item you want.

2. On the command bar, select **Import**.

3. On the **Select Solution Package** page, select **Browse** to locate the compressed (.zip or .cab) file that contains the solution you want to update.

4. Select **Next**.

5. This page displays a yellow bar indicating **This solution package contains an update for a solution that is already installed**. To upgrade the solution, select **Next**. To view additional options, expand **Advanced settings**, and then select from the following solution action options:

    - **Upgrade** This is the default option and upgrades your solution to the latest version and rolls up all previous patches in one step. Any components associated to the previous solution version that aren't in the newer solution version will be deleted. This option ensures that your resulting configuration state is consistent with the importing solution including removal of components that are no longer part of the solution.

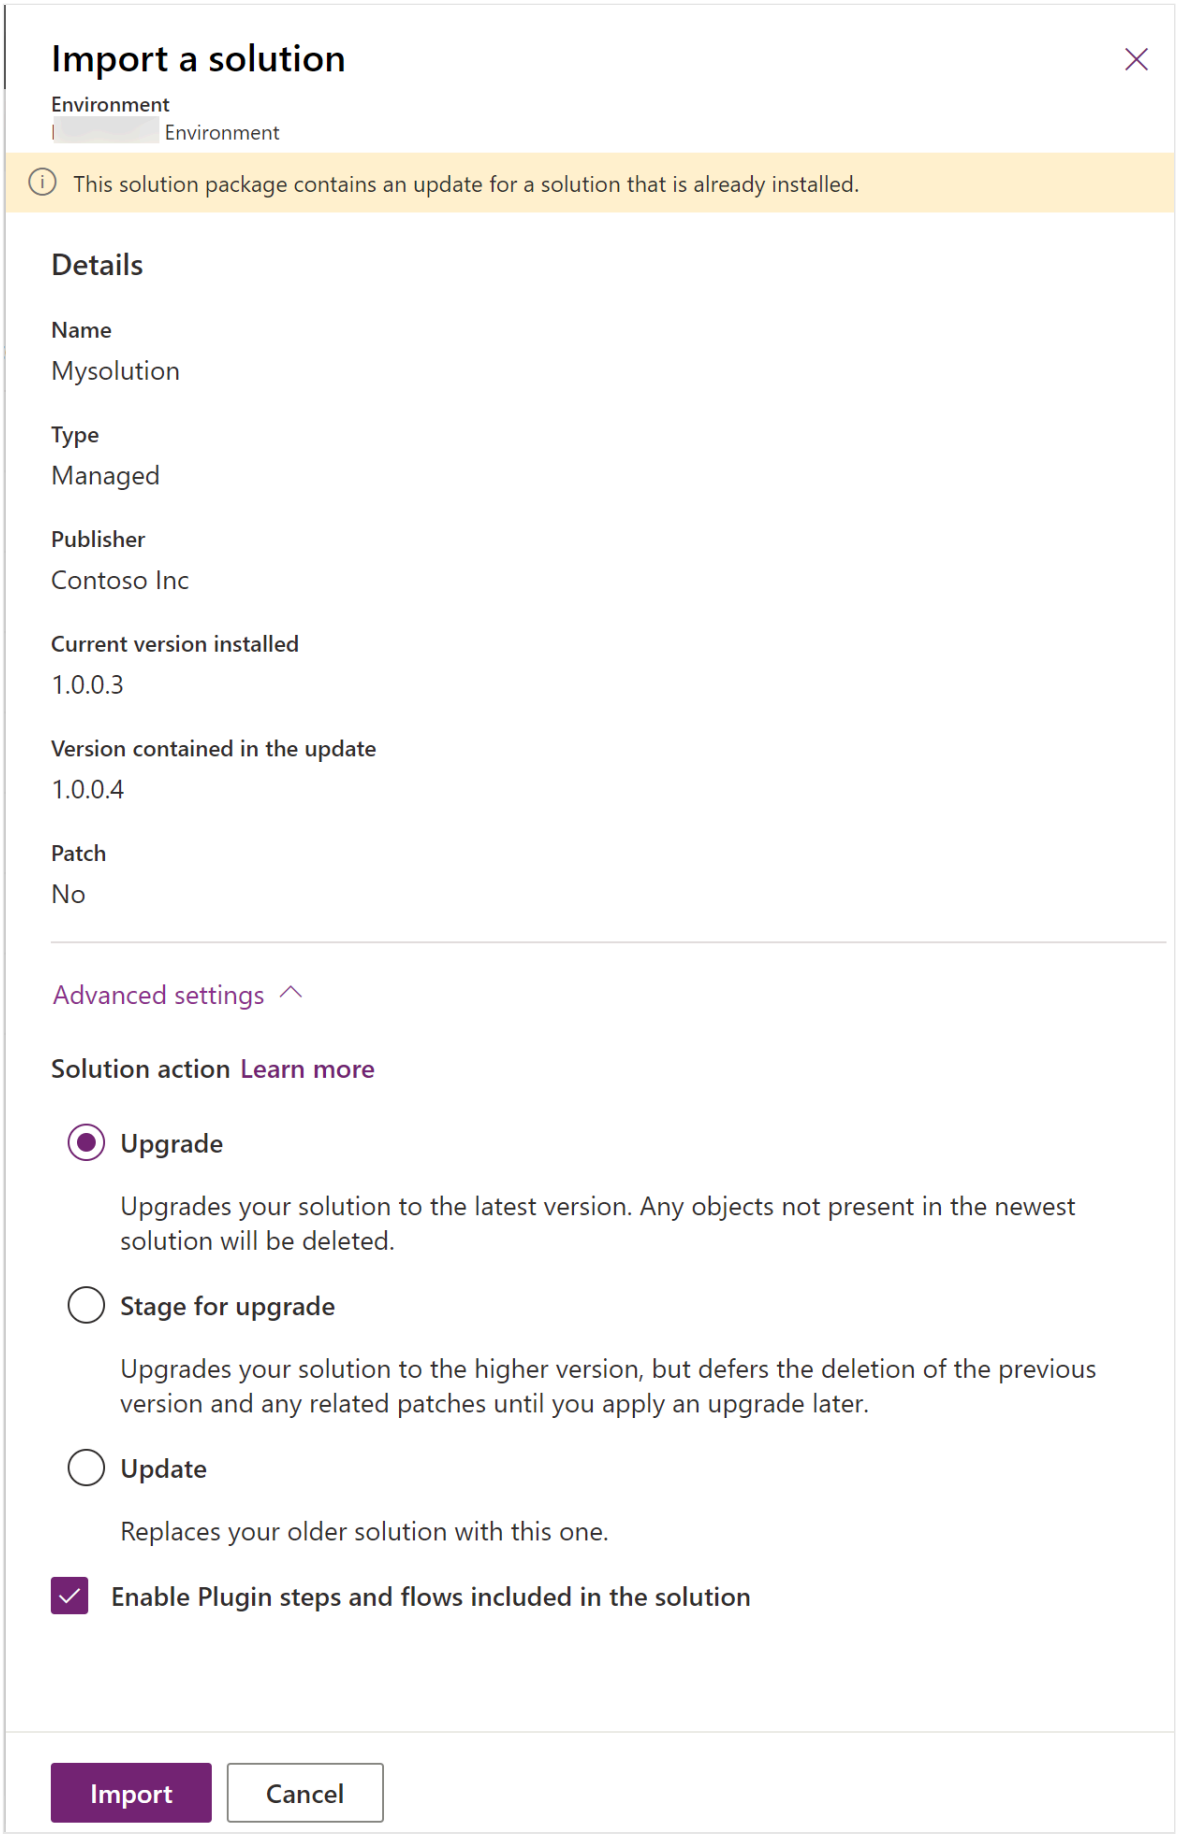
    - **Stage for Upgrade** This option upgrades your solution to the higher version, but defers the deletion of the previous version and any related patches until you apply a solution upgrade later. This option should only be selected if you want to have both the old and new solutions installed in the system concurrently so that you can do some data migration before you complete the solution upgrade. Applying the upgrade deletes the old solution and any components that aren't included in the new solution.

    - **Update** This option replaces your solution with this version. Components that aren't in the newer solution won't be deleted and remains in the system. Be aware that the source and destination environment may differ if components were deleted in the source environment. This option has the best performance by typically finishing in less time than the upgrade methods.

6. Decide whether to enable the following option for post import actions:

    - **Enable plug-in steps and flows included in the solution**
      Selecting this option will enable plug-ins and Power Automate flows that are included in the solution.

7. Select **Import**.



8. You may need to wait a few moments while the solution import completes. If it's successful, you can view the results and select **Close**.

Managed customizations are always imported in a published state, so there's no need to publish customizations after import in this scenario.

Completing Solution Upgrade If you chose to stage for upgrade, or if the system had an issue completing an upgrade, you'll see that you have the original solution still installed in your system as well as a new solution that has the same solution name as the base solution suffixed with _Upgrade. To complete the upgrade, select the base solution in the solution list and select **Apply Solution Upgrade**. This uninstalls all previous patches and the base solution then rename the _Upgrade solution to be the same name as the previous base solution. Any components that were in the original solution and patches that aren't present in the _Upgrade solution will be deleted as part of this process.

> ⓘ **Note**
>
> Recent changes in the platform have optimized the single step upgrade process to no longer use a temporary _Upgrade solution or use an uninstall operation on the original solution.

Understanding version numbers for updates

A solution's version has the following format: major.minor.build.revision. An update must have a higher major, minor, build, or revision number than the parent solution. For example, for a base solution version 3.1.5.7, a small update could be a version 3.1.5.8 or a slightly more significant update could have version 3.1.7.0. A substantially more significant update could be version 3.2.0.0.

Removing a managed component from the target environment

There might be occasions when you want to remove a managed component from an environment. There are two different solution actions that you can perform that will remove a managed component from an environment.

- Upgrade the solution (recommended). In the development environment where the managed solution originated, update the solution so that it no longer includes the component. In other words, remove the component such as a column, chart, or form from the solution and then export it as managed. Then, when you import the managed solution into the target environment, choose the **Solution action** as

Upgrade. This action removes the component (if there aren't any other components that depend on it in the target environment).

- Delete the managed solution. This action removes all components in the solution. In the environment where the managed solution was imported, delete the managed solution that includes the managed component. You can do this from the **Solutions** area of Power Apps.

> ⚠ **Warning**
>
> Deleting a managed solution deletes ALL the components that are in the managed solution as well as any related data. Always use caution before deleting a managed solution.

Overwrite customizations option

The option to overwrite customizations is available with the classic import experience, when using the Microsoft Power Platform CLI pac solution import command, or by using the `OverwriteUnmanagedCustomizations` option with the `ImportSolution` or `ImportSolutionAsync` messages. More information: ImportSolutionRequest class, ImportSolution action, or ImportSolutionAsync action.

> ⓘ **Important**
>
> Selecting the **Overwrite Customizations (not recommended)** option will overwrite or remove any unmanaged customizations previously performed on components included in this solution. This option does not affect components that support merge behavior (forms, sitemap, ribbon, app modules). Components that have other managed solutions on top of the existing solution you are replacing do also still remain on top and are not affected by this option.

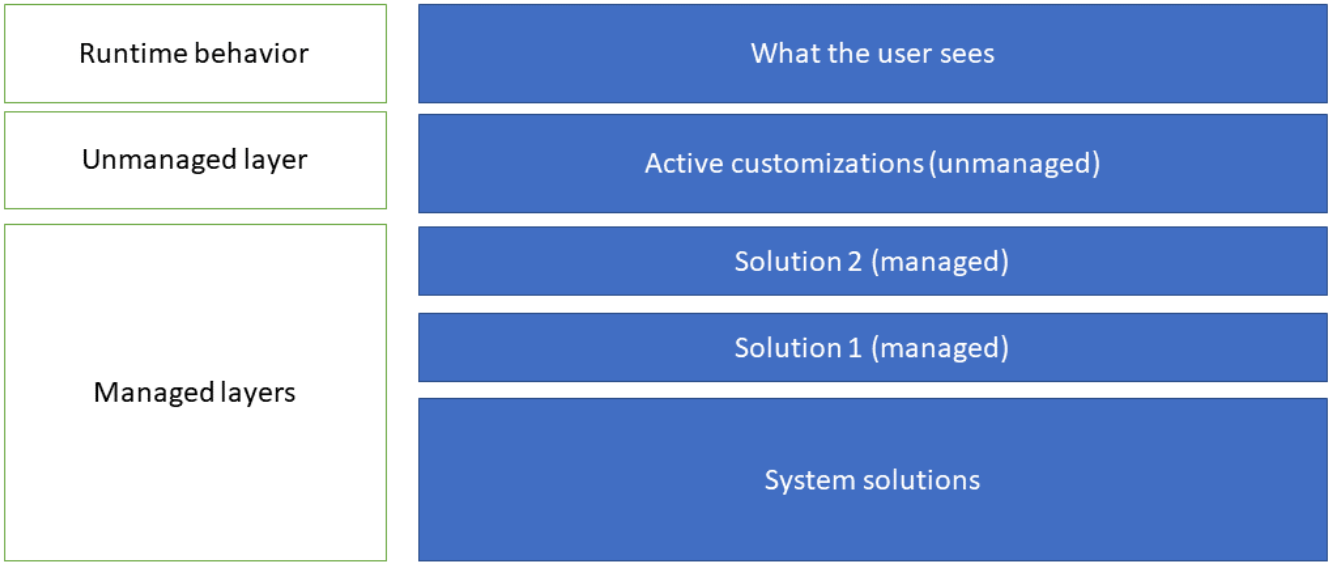
Solution layers

Managed and unmanaged solutions exist at different levels within a Microsoft Power Platform environment. In Microsoft Dataverse, there are two distinct layer levels:

- Unmanaged layer. All imported unmanaged solutions and unmanaged customizations exist at this layer. The unmanaged layer is a single layer.
- Managed layers. All imported managed solutions and the system solution exist at this level. When multiple managed solutions are installed, the last one installed is above the managed solution installed previously. This means that the second solution installed can customize the one installed before it. When two managed solutions have conflicting definitions, the runtime behavior is either “Last one wins” or a merge logic is implemented. If you uninstall a managed solution, the managed solution below it takes effect. If you uninstall all managed solutions, the default behavior defined within the system solution is applied. At the base of the managed layers level is the system layer. The system layer contains the tables and components that are required for the platform to function.



Solution merge behavior

When you prepare your managed solution for distribution, remember that an environment might have multiple solutions installed or that other solutions might be installed in the future. Construct a solution that follows best practices so that your solution doesn't interfere with other solutions.

The processes that Dataverse uses to merge customizations emphasize maintaining the functionality of the solution. While every effort is made to preserve the presentation, some incompatibilities between customizations might require that the computed resolution will

change some presentation details in favor of maintaining the customization functionality. More information: Understand how managed solutions are merged

View the solution layers for a component

The see solution layers feature allows you to view all component changes that occur due to solution changes over time. Within a solution layer, you can drill down to view specific changed and unchanged property details for a component. You can access solution layers from the **Solutions** area in Power Apps (make.powerapps.com).

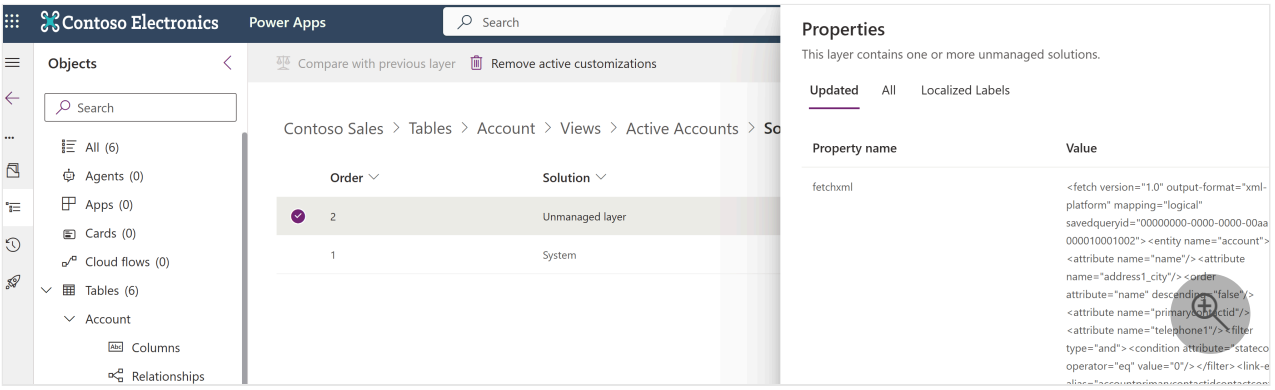
The see solution layers feature:

- Lets you see the order in which a solution changed a component.
- Lets you view all properties of a component within a specific solution, including the changes to the component.
- Can be used to troubleshoot dependency or solution-layering issues by displaying change details for a component that was introduced by a solution change.

1. Sign in to Power Apps, select **Solutions**, open the solution you want, select a component, such as the **Account** table, and then on the command bar select **Advanced** > **See solution layers**.

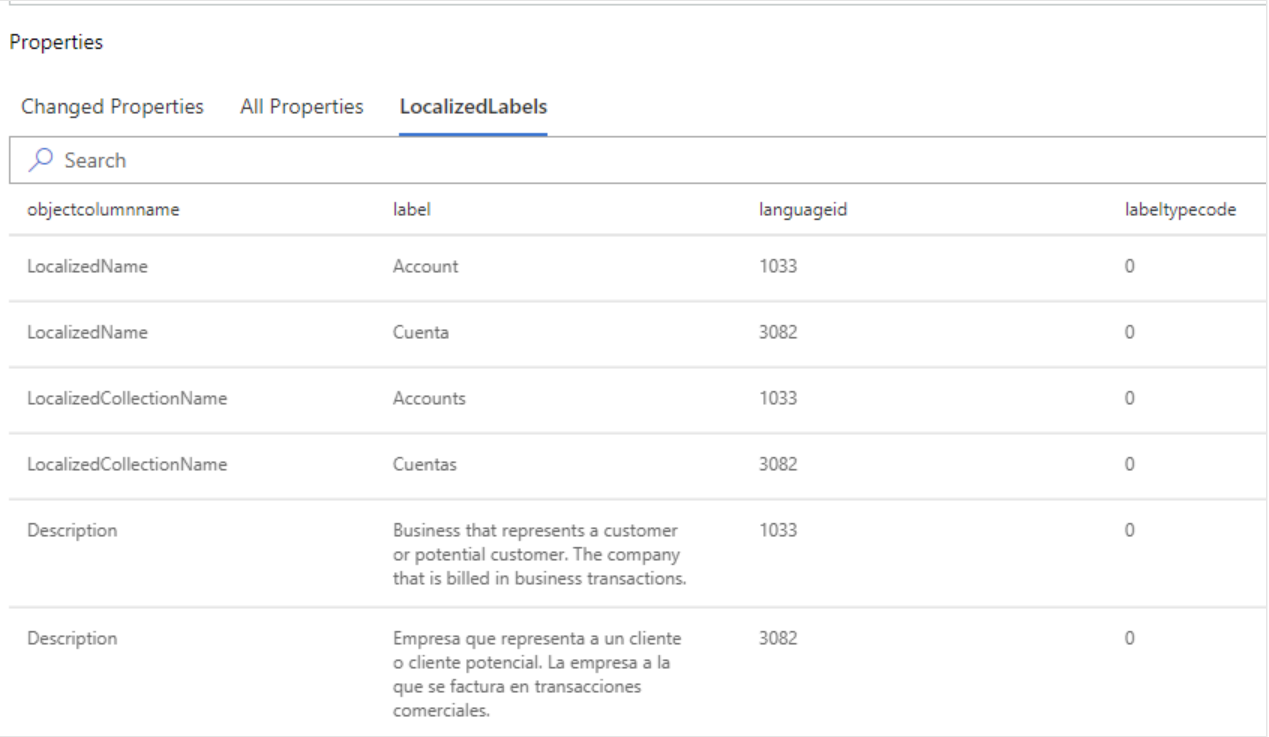
2. The solution layer page appears. It displays each layer for the component, such as the Active Accounts view for the **Account** table used as an example here, with the most recent layer at the top, which is typically indicated as the **Active** layer. The active layer determines the runtime behavior of the component.

3. To view the details for a solution layer, select it. The **Properties** pane is displayed. The **Updated** tab displays only those properties that were modified as part of the specific solution layer. Select the **All Properties** tab to view all properties, including changed and unchanged properties, for the solution layer.



4. If the component includes translations that have been imported, select the **Localized Labels** tab to display information for components that have label columns in the solution

layer. The base language and any imported translation text are displayed as indicated in the **languageid** column. Note that if no labels exist the tab isn't displayed.



objectcolumnname	label	languageid	labeltypecode
LocalizedName	Account	1033	0
LocalizedName	Cuenta	3082	0
LocalizedCollectionName	Accounts	1033	0
LocalizedCollectionName	Cuentas	3082	0
Description	Business that represents a customer or potential customer. The company that is billed in business transactions.	1033	0
Description	Empresa que representa a un cliente o cliente potencial. La empresa a la que se factura en transacciones comerciales.	3082	0

Select a label to see its full layering.

There are other tabs available for specific component solution layers.

Expand table

Tab name	Description	Possible value
RolePrivileges	Displays the privileges for a security role.	Added, Updated, Removed, Unchanged
AttributePicklistValues (optionset)	When selected for a global choice , displays the possible values for a choice .	Added, Updated, Removed, Unchanged
AttributePicklistValues (optionset attribute)	When selected for a choice attribute, displays the values for the attribute.	Added, Updated, Removed, Unchanged

Remove an unmanaged layer

Unmanaged customizations reside at the top layer for a component and subsequently define the runtime behavior of the component. In most situations you don't want unmanaged customizations determining the behavior of your components in your test and production environments.

> **Important**
>
> - By design, your dev and maker environments where you're working with unmanaged components typically have unmanaged layers.
> - If the unmanaged layer you want to remove is the only layer and as such the base layer for the component, you can't remove it with the remove active customizations command. To remove the layer, you have to delete the unmanaged component. More information: Remove objects from a solution.

To remove the unmanaged layer for a component, follow these steps:

> **Warning**
>
> Removing active unmanaged customizations can't be reversed or undone. All data associated with the unmanaged customization can be lost.

1. Open the solution you want, select **...** next to a component, such as **Account**, and then select **See solution layers**.
2. If an unmanaged layer exists, **Unmanaged layer** is displayed in the **Solution** column for the layer.
3. Select the layer, and then on the command bar, select **Remove active customizations**.

View the history of a solution

Article • 07/17/2024

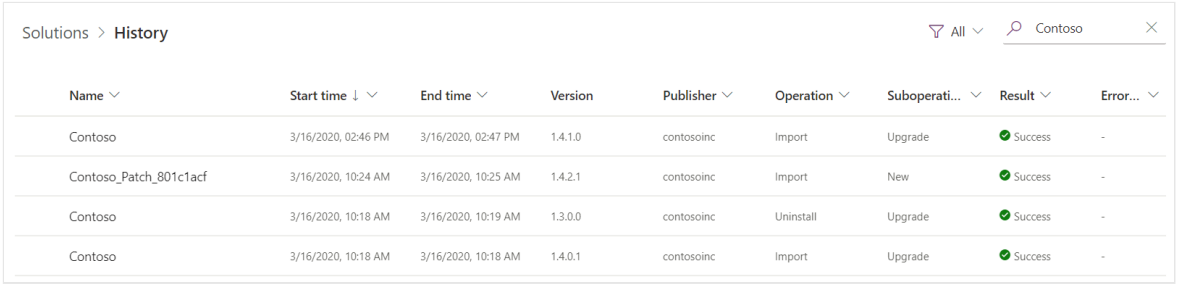
View details about solution operations from the **Solutions** area of Power Apps. An operation can be a solution import, export, or uninstall. The solution history displays information such as solution version, solution publisher, type of operation, operation start and end time, and operation status.

> **Note**
>
> The system automatically deletes solution history records that are older than 180 days.

View solution history

1. Sign in to Power Apps.
2. Select **Solutions** on the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. select the solution you want, and then on the command bar select **See history**.

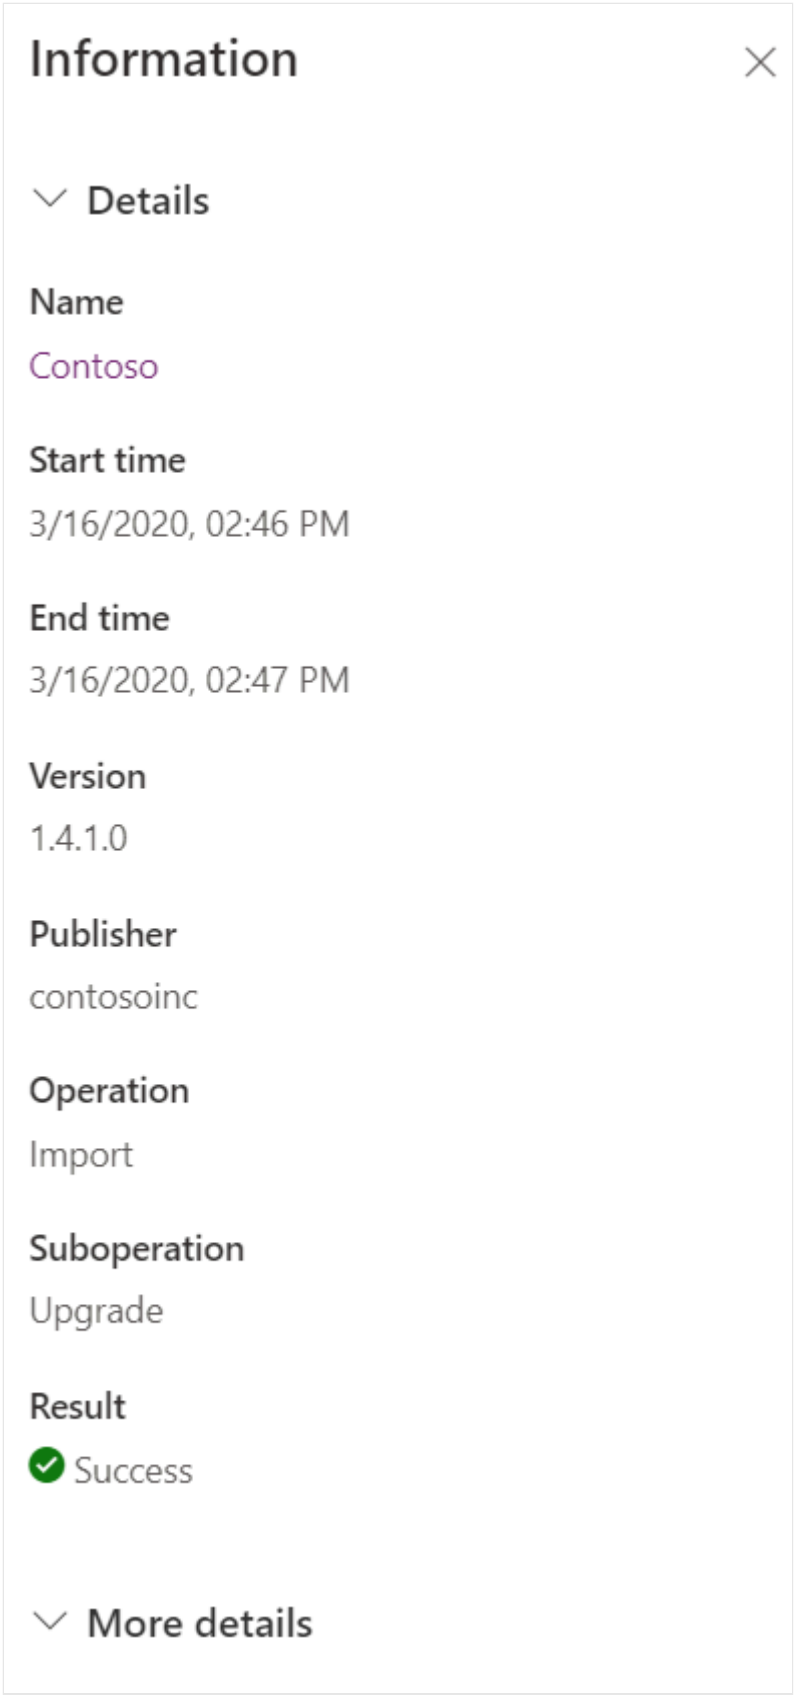
   The history is displayed.



Select a solution operation to display the **Information page**. Each solution history row is read-only and includes the following in the **Details** area:

- **Name**. The solution unique name.
- **Start time**. The time in which the operation started.
- **End time**: The time in which the operation ended.
- **Version**. The version of the solution.
- **Publisher**. The name of the publisher that is associated with the operation.
- **Operation**. The operation, such as import, export, or delete.

- **Suboperation**: Denotes the type of operation, such as a new solution import or an update to an existing solution.
- **Result**. The result of the operation, such as Success or Failure.



Note

Recent changes have optimized the single step upgrade process to no longer use a temporary _Upgrade solution. As a result, you no longer experience an uninstall operation for single stage upgrades in the solution history.

View solution operation error details

Below the **Details** area is the **More details** area that has additional information about the solution and, when a solution operation has a failure, the information includes:

- The **Error code** of the error returned from the operation.
- The **Exception message**, which can help diagnose the underlying cause for the operation failure. Some errors, including solution dependency errors, may also include links to solution layers to make it easier for you to diagnose the issue.
- The **Activity Id** can be useful in cases where you need to contact Microsoft Customer Support.

View dependencies for a component in Power Apps

Article • 03/22/2024

Solution components in Microsoft Dataverse often depend on other solution components. You can’t delete any solution component that has dependencies from another solution component. For example, you can't delete a model-driven app site map component without first deleting the model-driven app component, or removing the dependency, because the site map depends on the model-driven app.

You can view the dependent components from the **Solutions** area of Power Apps.

Show dependencies

The show dependencies page for a component helps identify the dependencies so you can take appropriate action.

This section describes the actions you can take while viewing the dependencies in the **Show dependencies** menu under **Advanced**.

Dependencies page contents

The **Dependencies** page displays details about all the components that have a dependency on the solution component. They're grouped by the solution's name.

The **Dependencies** page has tabs covering reports for **Delete blocked by**, **Used by**, and **Uses**:

- **Delete blocked by**: The report lists all the dependencies that block the delete of the solution component. Unless these dependencies are removed or the component is deleted, the solution component delete remains blocked.
- **Used by**: The report lists all the dependencies of other components that are using this solution component.
- **Uses**: This report lists all the dependencies that the given solution component uses.

Dependencies page actions

The **Dependencies** page has multiple actions you can take for each dependency. The actions can be used to inspect, delete the component, or remove a dependency with the

listed dependencies.

To choose an action, select the vertical ellipsis next to any component and then select one of the following actions:

- **Open**: This action takes you to the particular component using the default solution. The open action helps you navigate to the component where you can inspect or edit it.
- **Delete**: This action allows you to delete the component. Ensure to use this action only if the component is no longer required and can be deleted. This action is available only for unmanaged components.
- **Remove dependency**: This action allows you to remove the dependency of the component on the solution component. The system attempts to edit the component to remove the dependency. In the event, when the system is unsuccessful in removing the dependency you might have to do a manual edit. This feature is currently available for the following components:
  - Entity's dependency on WebResource
  - SystemForm's dependency on Attribute and Role
  - AppModule's dependency on SavedQuery, SavedQueryVisualization, Entity, and SystemForm
- **Open documentation**: This action allows you to open documentation where you can learn about the dependencies for that component type.

You can also select a grouped solution and perform delete solution action:

Delete Solution: If you need to delete (uninstall) a solution that has dependencies on the solution component, use **Delete**. This action deletes the solution.

For developers: Detect solution dependencies

Environment variables for Power Platform overview

Environment variables enable the basic application lifecycle management (ALM) scenario of moving an application between Power Platform environments. In this scenario, the application stays exactly the same except for a few key external application references (such as tables, connections, and keys) that are different between the source environment and the destination environment. The application requires the structure of the tables or connections to be exactly the same between the source and the destination environments, with some differences. Environment variables allow you to specify which of these different external references should be updated as the application is moved across environments.

Environment variables store the parameter keys and values, which then serve as input to various other application objects. Separating the parameters from the consuming objects allows you to change the values within the same environment or when you migrate solutions to other environments. The alternative is leaving hard-coded parameter values within the components that use them. This approach is often problematic; especially when the values need to be changed during ALM operations. Because environment variables are solution components, you can transport the references (keys) and change the values when solutions are migrated to other environments.

Benefits of using environment variables:

- Provide new parameter values while **importing solutions** to other environments.
- Store configuration for the **data sources** used in canvas apps and flows. For example, SharePoint Online site and list parameters can be stored as environment variables. This approach allows you to connect to different sites and lists in different environments without needing to modify the apps and flows.
- Package and transport your customization and configuration together and manage them in a single location.
- Package and transport secrets, such as credentials used by different components, separately from the components that use them.
- One environment variable can be used across many different solution components - whether they're the same type of component or different. For example, a canvas app and a flow can use the same environment variable. When the value of the environment variable needs to change, you only need to change one value.
- Additionally, if you need to retire a data source in production environments, you can update the environment variable values with information for the new data source. The apps and flows don't require modification and start using the new data source.
- Supported by SolutionPackager and DevOps tools enable continuous integration and continuous delivery (CI/CD).

- The environment variables can be unpacked and stored in source control. You might also store different environment variables values files for the separate configuration needed in different environments. Solution Packager can then accept the file corresponding to the environment the solution is imported to.

How do environment variables work?

Environment variables can be created and modified within the modern solution interface. They can also be automatically created when connecting to certain data sources in canvas apps or with code. They can also be imported to an environment via solutions. Environment variables can be used as inputs when authoring canvas apps, Power Automate flows, plug-ins, and adding Power BI dashboards to model-driven apps. When you use environment variables, the values are then derived from the environment variables, and can be changed when solutions are imported to other environments.

Manually create an environment variable in a solution

1. Sign in to Power Apps (make.powerapps.com), and then on the left pane select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Open the solution you want or create a new one.
3. On the command bar, select **New** > **More**, and then select **Environment variable**.
4. On the right pane, complete the following columns, and then select **Save**:

    - **Display name**. Enter a name for the environment variable.
    - **Name**. The unique name is automatically generated from the **Display name**, but you can change it.
    - **Data Type**. Select from **Decimal number**, **Text**, **JSON**, **Two options**, **Data source**, or **Secret**.

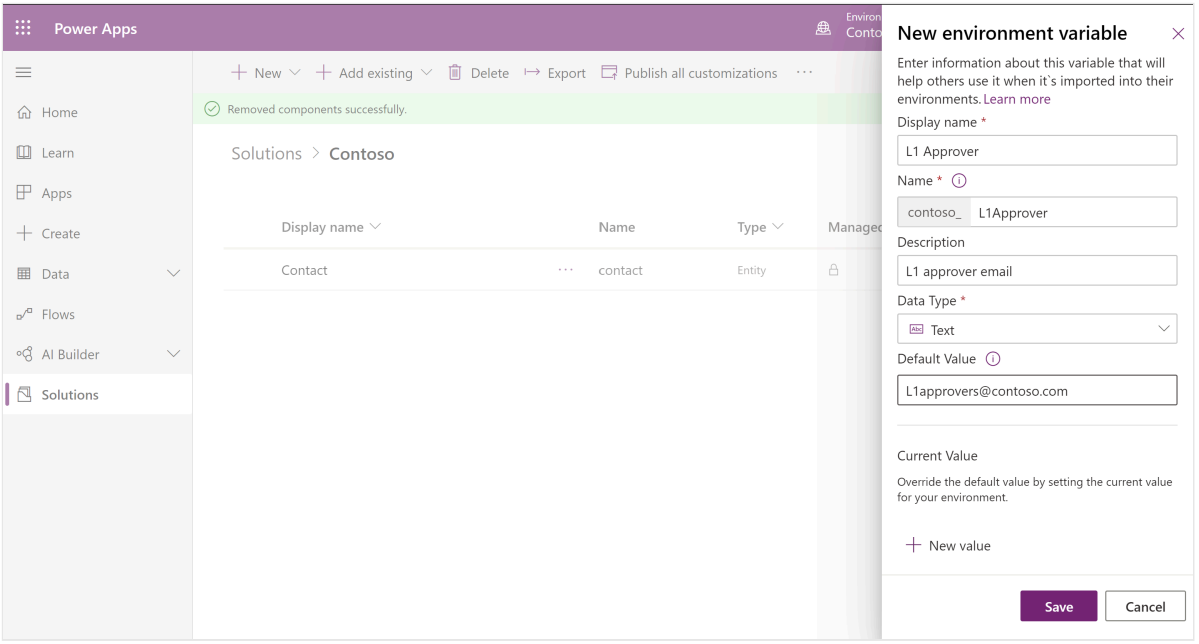
    > ⓘ Note
    > - If **Data source** is the selected type, you need to select the **connector**, a valid **connection** for the selected connector, and the **parameter type**. The connection isn't stored as part of the environment variable. The environment variable stores information not in the connection that is necessary to connect Power Apps to the right server and table. The connection is only used for retrieving available parameter values such as the SharePoint sites you have access to, or the lists associated with a site.

- If **Secret** is the selected type, additional information to set up and configure Azure Key Vault is needed to allow Power Platform to access the secret.

- **Current Value**. Also known as the value. This property is optional and is a part of the environment variable value table. A defined value is used even if a default value is also present. Remove the value from your solution if you don't want to use it in the next environment. The values are also separated into separate JSON files within the exported solution.zip file and can be edited offline. More information: How do I remove a value from an environment variable?

- **Default Value**. This column is part of the environment variable definition table and isn't required. The default value is used if there's no current value.

  Separation of default value and current value allows you to service the definition and the default value separately from the value. For example, an application publisher might list their offer on AppSource with a default value. Then optionally, the customer can provide a new value. When the application publisher publishes updates to the application, the value set by the customer isn't overwritten.

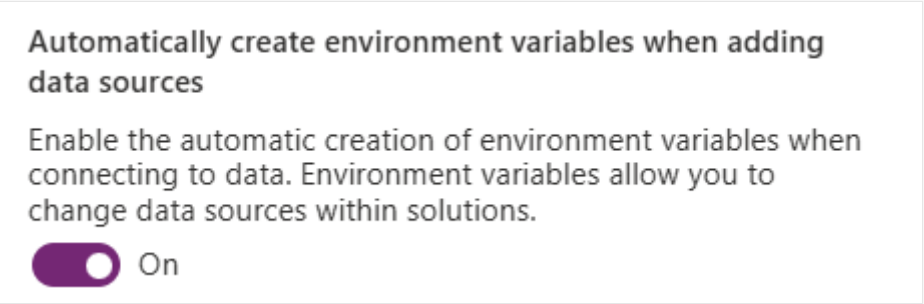


> **Note**
>
> A value can't exist without a definition. The interface only allows creation of one value per definition.

Power Apps can automatically create environment variables

On the **General** tab of Power Apps settings:

- Enable the **Automatically create environment variables when adding data sources** option. Now, when you add a new data source to your app, it adds an environment variable for you.



Different data sources

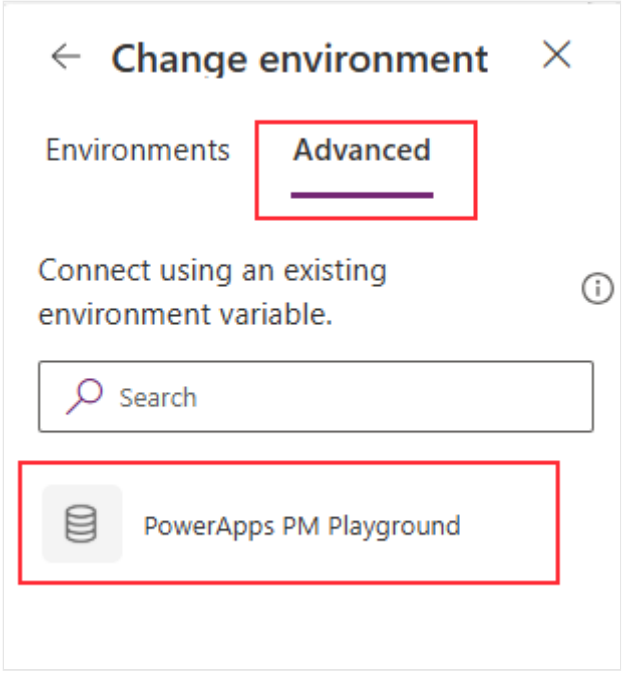
Different data sources enable different types of environment variables.

Microsoft Dataverse

Power Apps connects natively to Dataverse. You don't need an environment variable for tables in your current environment. When you connect to Dataverse, your application automatically looks for exactly the same table name in any environment you port it. As long as your table name structure is the same in the target environment as it is in the original environment, it works.

If you use an external table from a different environment (via Change Environment), then Power Apps assumes you want to always refer to the exact same table. You need an environment variable if you need that external table to be a different external table when you move from dev to test or to prod. It's easiest to allow Power Apps to automatically create the environment variable for you. (If you previously added the table to your app, then turn on the settings switch, drop the external table, and then add it back.)

When you add the external table to your app, choose the **Advanced** tab to select the environment variable.



SharePoint

SharePoint supports only Microsoft Entra connections. So, for SharePoint, in addition to a valid connection, a separate environment variable is required for Site and List.

To successfully use environment variables with SharePoint lists:

- The display name and the logical name for each corresponding column in the source and target environments must match.
- Environment variables for SharePoint must have matching metadata. SharePoint has internal identifiers that might not match between target environments. For example, if you create a list with the same name and columns in a target environment, the internal names won't match. The metadata always matches if you duplicate a SharePoint site and copy it to your target environment.

SQL Server

SQL Server supports many different types of authentication and connections. Use environment variables for Microsoft Entra connections. A separate environment variable is required for the server and the database. The application is bound to specific table names so they're assumed to be the same between environments.

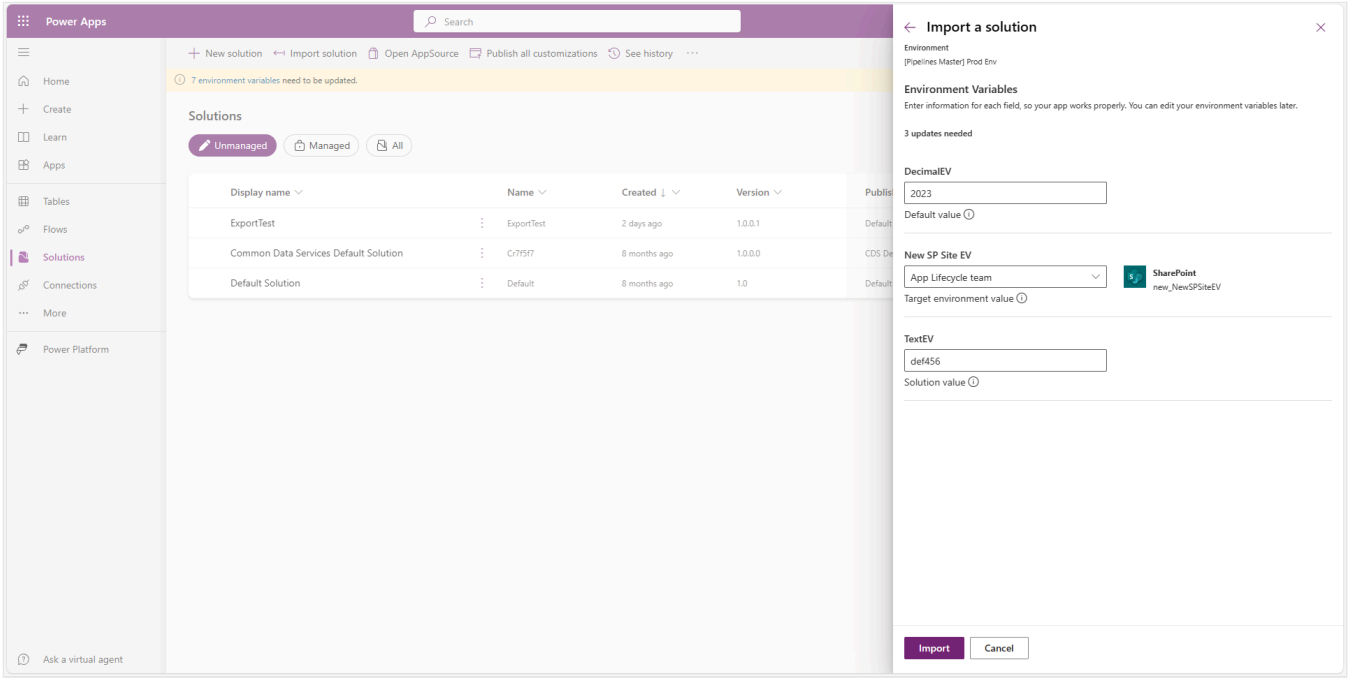
Don't use environment variables for shared connections such as basic SQL authentication with SQL Server. Use connection references for information that is traditionally passed as part of the connection string. Basic SQL auth parameters are all part of the connection string. For example, the Server and Database name are provided when creating the connection and therefore are always derived from the connection.

Data source environment variables are used for connectors with authentication like Microsoft Entra. In these types of connections, Power Apps only has an identified user. Power Apps can't derive what service or table you intend to work with from the connection.

Enter new values while importing solutions

The modern solution import interface includes the ability to enter values for environment variables. This sets the value property on the `environmentvariablevalue` table.

Environment variable values are visible when importing solutions or when using Pipelines to deploy. Environment variables without a default value or value prompt for a value, but those otherwise are prefilled with a label beneath the text area denoting the value's source: solution value, target environment value, or default value.



> **Note**
>
> - In some cases, for specific data source environment variable values, an **Access denied** warning might appear if the importing maker doesn't have access to the connection or source used for the environment variable. This is a nonblocking warning, but something to take note of depending on how you plan to use the environment variable in the target environment.
> - You can remove the value from your solution before exporting the solution. This ensures the existing value remains in your development environment, but won't get exported in the solution. This approach allows a new value to be provided while

importing the solution into other environments. More information: How do I remove a value from an environment variable?

Notifications

A notification is displayed when the environment variables don't have any values. Set the values so that components dependent on environment variables don't fail.

Security

The `environmentvariabledefinition` table is user or team owned. When you create an application that uses environment variables, be sure to assign users the appropriate level of privilege to this table. Permission to the `environmentvariablevalue` table is inherited from the parent `environmentvariabledefinition` table and therefore doesn't require separate privileges. Privileges for `environmentvariabledefinition` tables are included in Environment Maker and Basic User security roles by default. More information: Security in Dataverse.

Naming

Ensure environment variable names are unique so they can be referenced accurately. Duplicate environment variable display names make environment variables difficult to differentiate and use. Ensure environment variable names are unique so they can be referenced accurately. The names **$authentication** and **$connection** are specially reserved parameters for flows and should be avoided. Flow save is blocked if environment variables with those names are used. If an environment variable is used in a flow and the display name of the environment variable is changed, then the designer shows both the old and new display name tokens to help with identification. When updating the flow, we recommend you remove the environment variable reference and add it again.

Current limitations

- Validation of environment variable values happens within the user interfaces and within the components that use them, but not within Dataverse. Therefore ensure proper values are set if they're being modified through code.
- Power Platform Build Tools tasks aren't yet available for managing data source environment variables. However, this doesn't block their usage within Microsoft provided tooling and within source control systems.

- Interacting with environment variables via custom code requires an API call to fetch the values; there isn't a cache exposed for non-Microsoft code to use.
- Environment variables are limited to a maximum of 2,000 characters.

Frequently asked questions

Why can't I see the value for my environment variable?

If the environment variable is in a managed solution, you won't be able to see the value unless you look inside of the **Default solution**. This behavior is by design, since the environment variable value is an unmanaged customization.

How can I view where environment variables are being used?

Either through selecting **Show dependencies** in the solution interface, while authoring components, or in source control and in the solution file by viewing the app or flow metadata.

Are data source environment variables the same as connections?

No. Although they're related, a connection represents a credential or authentication required to interact with the connector. Data source environment variables store parameters that are required by one or more actions in the connector and these parameters often vary depending on the action. For example, a SharePoint Online connection doesn't store any information about sites, lists, or document libraries. Therefore calling the connector requires both a valid connection and some more parameters.

Can my automated ALM pipeline use different values files for different environments?

Yes. Solution packager accepts file name as input parameters so your pipeline can pack a different values file into the solution depending on the environment type it’s executing against.

Should I include the value in my solution?

No. Environment variables are intended to be used by applications that need to have different values in different environments where the solution is deployed. Environment variable definitions should be included in your solution but the values should be provided for the target environment during deployment. This behavior results in the environment variable definition

being a managed solution object in the target environment while the environment variable is an unmanaged record.

Why can't I delete a value in my environment?

If the value was included in a managed solution, the only way to delete the value is to update the solution in the source environment to exclude the value, then export a new version of the solution. This new version then can be imported into the environment using an upgrade operation (not an update), resulting in the value record being deleted.

What if someone inadvertently deletes a value?

If not already prevented by dependency system, runtime uses the last known value as a fallback.

If a value is changed, when does the new value get used in canvas apps and cloud flows?

It might take up to an hour to fully publish updated environment variables because the value is pushed into the apps and flows asynchronously.

Are premium licenses required?

No. While ALM requires Dataverse (or Dynamics 365 apps), use of premium connectors isn't required. The one caveat is if you're using the Dataverse connector to interact with environment variables as you would with other data records like accounts or contacts. Previously this was the only way to use environment variables in canvas apps and flows.

Is there a limit to the number of environment variables I can have?

No. However, the max size of a solution is 95 MB. More information: Create a solution

Can environment variable display names and descriptions be localized?

Yes.

Should I use environment variables instead of storing configuration data in custom tables?

Yes if your configuration data isn't relational. Environment variables should be used for key: value pairs and when the value likely needs to different in other environments. Other tools such as the Configuration migration utility are better suited for migration of relational configuration data stored within custom tables. Unlike other configuration data, environment variables are migrated within solutions and therefore much simpler to manage and more performant to import.

Why isn't my connection saved for data source environment variables?

Connections are only used to generate the user interface. For example, to retrieve friendly names for SharePoint lists associated with a site. When editing a data source environment variable, be sure to select a connection with access to the data source. If you no longer have access to the connection, you can manually enter a value. For example, enter the SharePoint site URL or unique identifier (GUID) for a list.

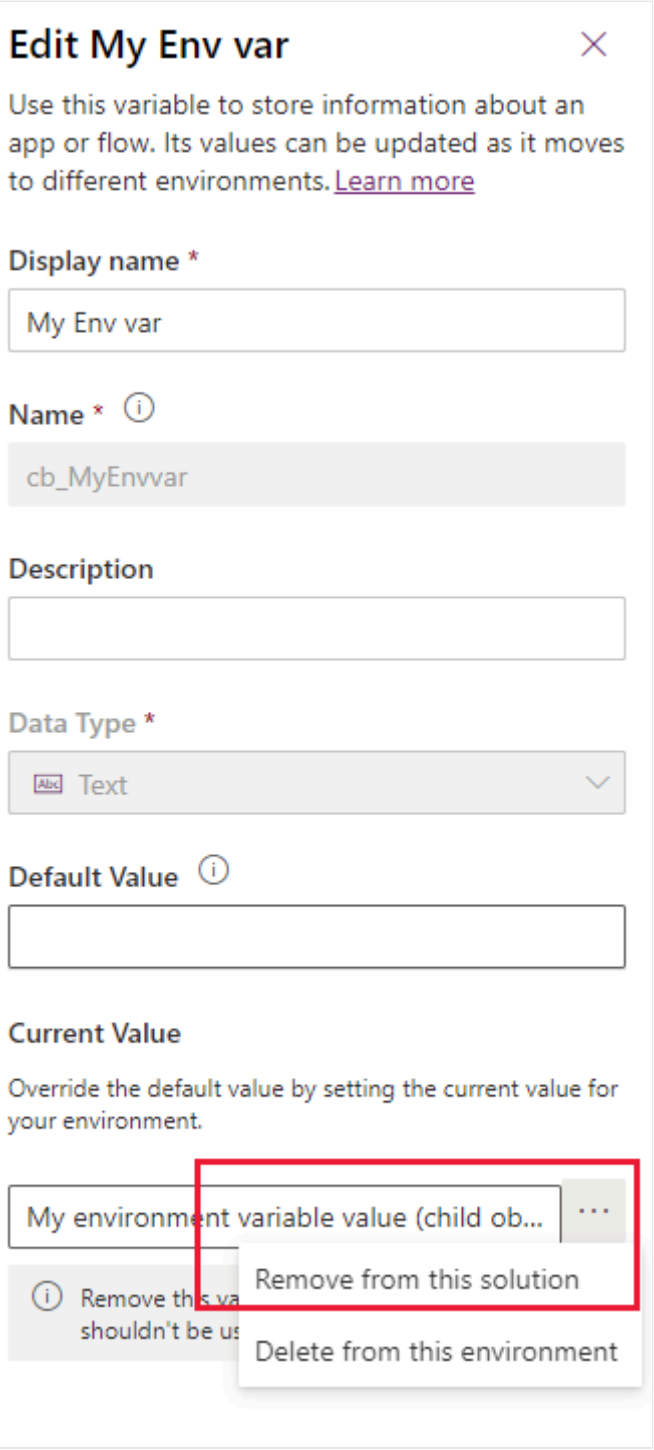
When there are multiple connections available for a single (data source-type) environment variable, there's a by-design implementation to select the first connection in the list of connections. Because there's usually only one connection associated with an environment variable, this isn't something that usually needs to be validated. Additionally, with recent changes to environment variable value visibility, this is easier to validate upon import.

How do I remove a value from an environment variable?

You might want to remove the value of an environment variable from your solution before exporting the solution. Then, the existing value remains in your development environment, but isn't exported in the solution. This approach allows a new value to be provided while importing the solution into another environment.

To remove the value, follow these steps:

1. In the solution where the environment variable is located select the environment variable to display the properties.
2. Under **Current Value**, select **...** > **Remove from this solution**.



Can I use environment variables in custom connectors?

Yes. Environment variable support in custom connectors

Use data source environment variables in canvas apps

In this article, you learn about using data source environment variables in canvas apps. You can either use pre-existing data source environment variables, or create data source environment variables automatically when connecting to data.

Use pre-existing data source environment variables

Environment variables can be reused across other apps and even different types of resources like cloud flows. You might wish to first create them within your solution and later use them while authoring canvas apps and cloud flows.

1. Follow the steps to manually create an environment variable in a solution.
2. Edit or create a canvas app from your solution.
3. Add a **new** data source for SharePoint online.
4. Select the **Advanced** tab. You'll see a filtered list of environment variables that you have access to and that match the parameter being set. For example, when you select the SharePoint site, you'll see a list of all data source environment variables with **Connector** as **SharePoint** and **Parameter type** as **Site**. The same is true when selecting SharePoint lists for a given site.
5. Select the desired environment variable(s), and then select **Connect.**

> **Important**
>
> - If an environment variable from a different solution is selected, a dependency will exist on the solution containing the environment variable. Therefore, be sure to either:
>   - Add the environment variable to your current solution prior to exporting.
>   - Ensure the solution containing the environment variable is imported to the destination environment before your current solution is imported.

Automatically create data source environment variables when connecting to data

This option provides simplicity and ensures environment variables are always used for data sources, such as SharePoint Online. However, some customers prefer to provide their own schema names and therefore should create them from solutions.

> **Note**
>
> Pre-existing canvas apps don't automatically use data source environment variables. Remove the data source from the app and add them back using the above steps to upgrade these apps to use environment variables.

1. Edit or create a canvas app from your solution.
2. Select **Settings** > **General** and enable the setting to **Automatically create environment variables when adding data sources**.
3. Add a **New** data source for SharePoint online.
4. Select a SharePoint **site**, one or more **lists**, and then **Connect**.

   > **Note**
   >
   > To prevent creation of duplicate environment variables, you're prompted to use the existing environment variable when duplicates are identified. You can clear the option to use the existing environment variable if creation of a duplicate is desired.

5. Select **Save**.

Use environment variables in Power Automate solution cloud flows
Environment variables overview

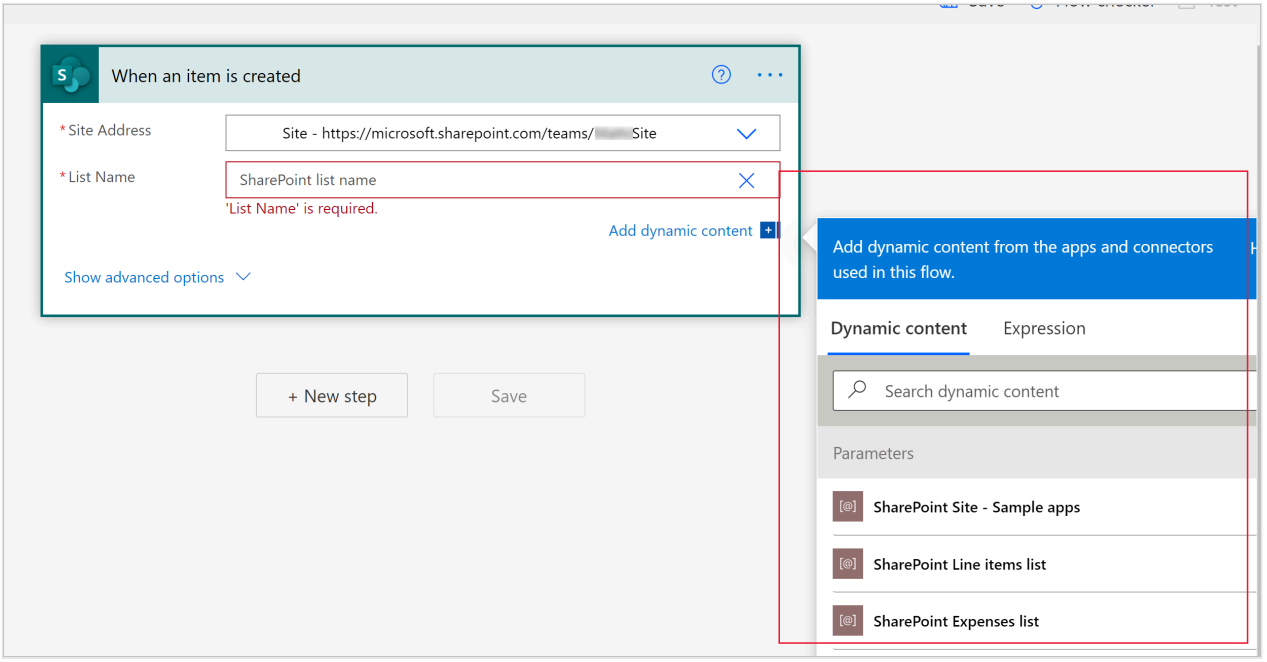
Last updated on 04/27/2026

Use environment variables in Power Automate solution cloud flows

Environment variables can be used in solution cloud flows since they're available in the dynamic content selector. All types of environment variables can be used in triggers and actions.

To use an environment variable in a solution cloud flow:

1. Edit or create a cloud flow in a solution.
2. In an action or a trigger, determine the parameter that you want to use for the environment variable:
   a. If the parameter takes a simple value, such as a string or number, enter the parameter.
   b. If the parameter is a lookup, scroll to the bottom of the lookup, and then select **Enter custom value**. Environment variables that you have access to are listed in the **Dynamic content** selector with other dynamic content.



3. Select the desired environment variable.

Limitations

- When environment variable values are changed directly within an environment instead of through an ALM operation like solution import, flows will continue using the previous value

until the flow is either saved or turned off and turned on again.

- When editing a cloud flow, the environment variables shown in the dynamic content selector are unfiltered, but will be filtered by data type in the future.
- When editing a cloud flow, if an environment variable is added in another browser tab, the flow needs to be reopened in the flow designer to refresh the dynamic content selector.

Use environment variables for Azure Key Vault secrets

Environment variables allow for referencing secrets stored in Azure Key Vault. These secrets are then made available for use within Power Automate flows and custom connectors. Notice that the secrets aren't available for use in other customizations or generally via the API.

The actual secrets are stored in Azure Key Vault and the environment variable references the key vault secret location. Using Azure Key Vault secrets with environment variables require that you configure Azure Key Vault so that Power Platform can read the specific secrets you want to reference.

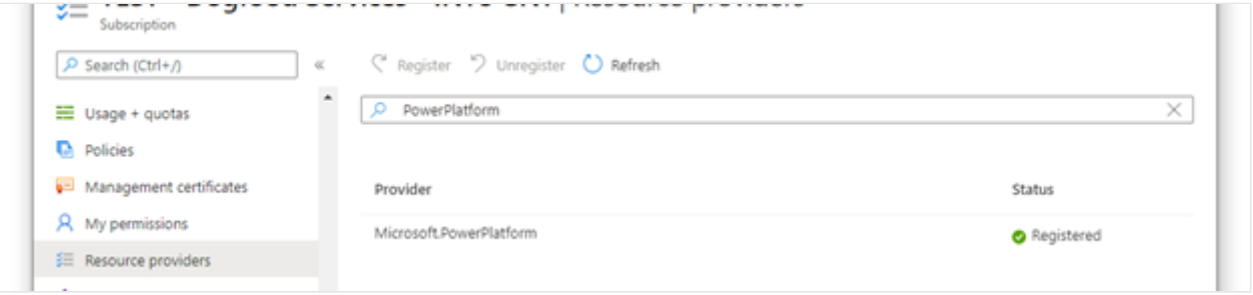
Environment variables referencing secrets aren't currently available from the dynamic content selector for use in Power Automate flows.

Configure Azure Key Vault

To use Azure Key Vault secrets with Power Platform, the Azure subscription that has the vault must have the `PowerPlatform` resource provider registered and the user who creates the environment variable must have appropriate permissions to the Azure Key Vault resource.

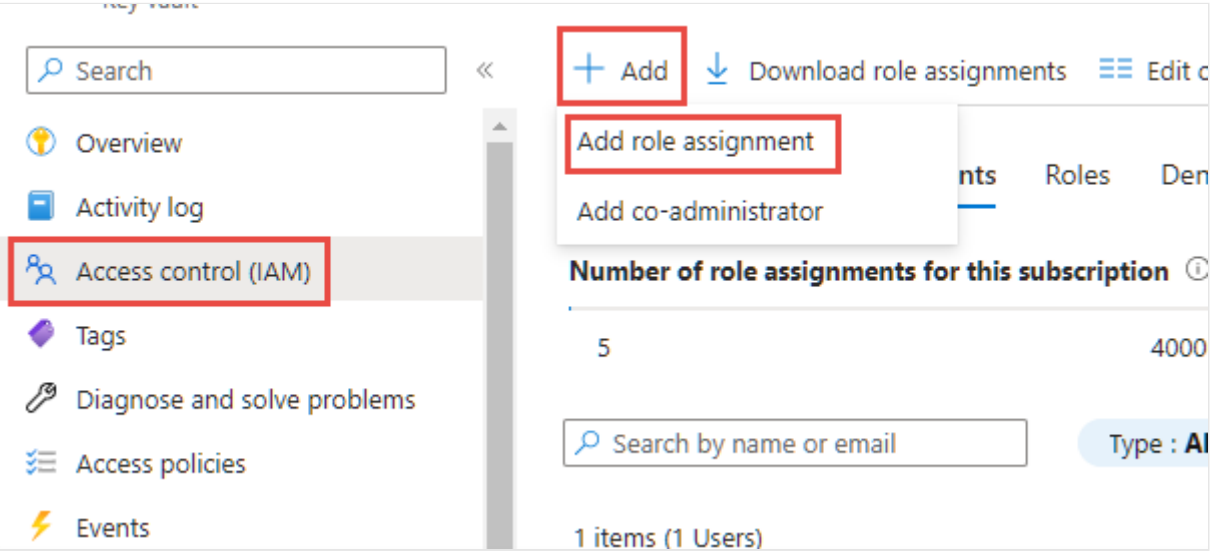
> **ⓘ Important**
>
> - There are recent changes to the security role used to assert access permissions within Azure Key Vault. Previous instructions included assigning the Key Vault Reader role. If you have set up your key vault previously with the Key Vault Reader role, make sure that you add the Key Vault Secrets User role to ensure that your users and Microsoft Dataverse have sufficient permission to retrieve the secrets.
> - We recognize that our service is using the Azure role-based access control APIs to assess security role assignment even if you still have your key vault configured to use the vault access policy permission model. To simplify your configuration, we recommended that you switch your vault permission model to Azure role-based access control. You can do this on the **Access configuration** tab.

1. Register the `Microsoft.PowerPlatform` resource provider in your Azure subscription. Follow these steps to verify and configure: Resource providers and resource types



2. Create an Azure Key Vault vault. Consider using a separate vault for every Power Platform environment to minimize the threat in case of a breach. Consider configuring your key vault to use **Azure role-based access control** for the **Permission model**. More information: Best practices for using Azure Key Vault, Quickstart - Create an Azure Key Vault with the Azure portal

3. Users who create or use environment variables of type secret must have permission to retrieve the secret contents. To grant a new user the ability to use the secret, select the **Access control (IAM)** area, select **Add**, and then select **Add role assignment** from the dropdown. More information: Provide access to Key Vault keys, certificates, and secrets with an Azure role-based access control



4. On the **Add role assignment** wizard, leave the default assignment type as **Job function roles** and continue to the **Role** tab. Locate the **Key Vault Secrets User role** and select it. Continue to the members tab and select the **Select members** link and locate the user in the side panel. When you have the user selected and shown on the members section, continue to the review and assign tab and complete the wizard.

5. Azure Key Vault must have the **Key Vault Secrets User** role granted to the Dataverse service principal. If it doesn't exist for this vault, add a new access policy using the same method you previously used for the end user permission, only using the Dataverse application identity instead of the user. If you have multiple Dataverse service principals in your tenant, then we recommend that you select them all and save the role assignment. Once the role is assigned, review each Dataverse item listed in the role assignments list

and select the Dataverse name to view the details. If the Application ID isn't 00000007-0000-0000-c000-000000000000**, then select the identity, and then select **Remove** to remove it from the list.

6. If you have enabled Azure Key Vault Firewall, you have to allow Power Platform IP addresses access to your key vault. Power Platform isn't included in the "Trusted Services Only" option. Go to Power Platform URLs and IP address ranges for the current IP addresses used in the service.

7. If you haven't done so already, add a secret to your new vault. More information: Azure Quickstart - Set and retrieve a secret from Key Vault using Azure portal

Create a new environment variable for the Key Vault secret

Once Azure Key Vault is configured and you have a secret registered in your vault, you can now reference it within Power Apps using an environment variable.

> **Note**
>
> - User access validation for the secret is performed in the background. If the user doesn't have at least read permission, this validation error is displayed: "This variable didn't save properly. User isn't authorized to read secrets from 'Azure Key Vault path'."
> - Currently, Azure Key Vault is the only secret store that is supported with environment variables.
> - The Azure Key Vault must be in the same tenant as your Power Platform subscription.

1. Sign on to Power Apps, and in the **Solutions** area, open the unmanaged solution you're using for development.

2. Select **New** > **More** > **Environment variable**.

3. Enter a **Display name** and optionally, a **Description** for the environment variable.

4. Select the **Data Type** as **Secret** and **Secret Store** as **Azure Key Vault**.

5. Choose from the following options:

   - Select **New Azure Key Vault value reference**. After the information is added in the next step and saved, an environment variable *value* record is created.

- Expand **Show default value**, to display the fields to create a **Default Azure Key Vault secret**. After the information is added in the next step and saved, the default value demarcation is added to the environment variable *definition* record.

6. Enter the following information:

   - **Azure Subscription ID**: The Azure subscription ID associated with the key vault.
   - **Resource Group Name**: The Azure resource group where the key vault that contains the secret is located.
   - **Azure Key Vault Name**: The name of the key vault that contains the secret.
   - **Secret Name**: The name of the secret located in Azure Key Vault.

   > **Tip**
   >
   > The subscription ID, resource group name, and key vault name can be found on the Azure portal **Overview** page of the key vault. The secret name can be found on the key vault page in the Azure portal by selecting **Secrets** under **Settings**.

7. Select **Save**.

Create a Power Automate flow to test the environment variable secret

A simple scenario to demonstrate how to use a secret obtained from Azure Key Vault is to create a Power Automate flow to use the secret to authenticate against a web service.

> **Note**
>
> The URI for the web service in this example isn't a functioning web service.

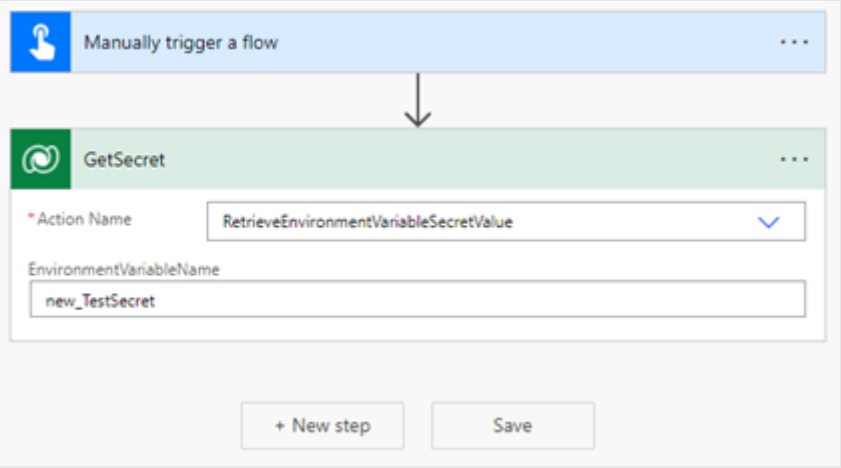
1. Sign into Power Apps, select **Solutions**, and then open the unmanaged solution you want. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Select **New** > **Automation** > **Cloud flow** > **Instant**.
3. Enter a name for the flow, select **Manually trigger a flow**, and then select **Create**.

4. Select **New step**, select the **Microsoft Dataverse** connector, and then on the **Actions** tab select **Perform an unbound action**.

5. Select the action named **RetrieveEnvironmentVariableSecretValue** from the dropdown list.

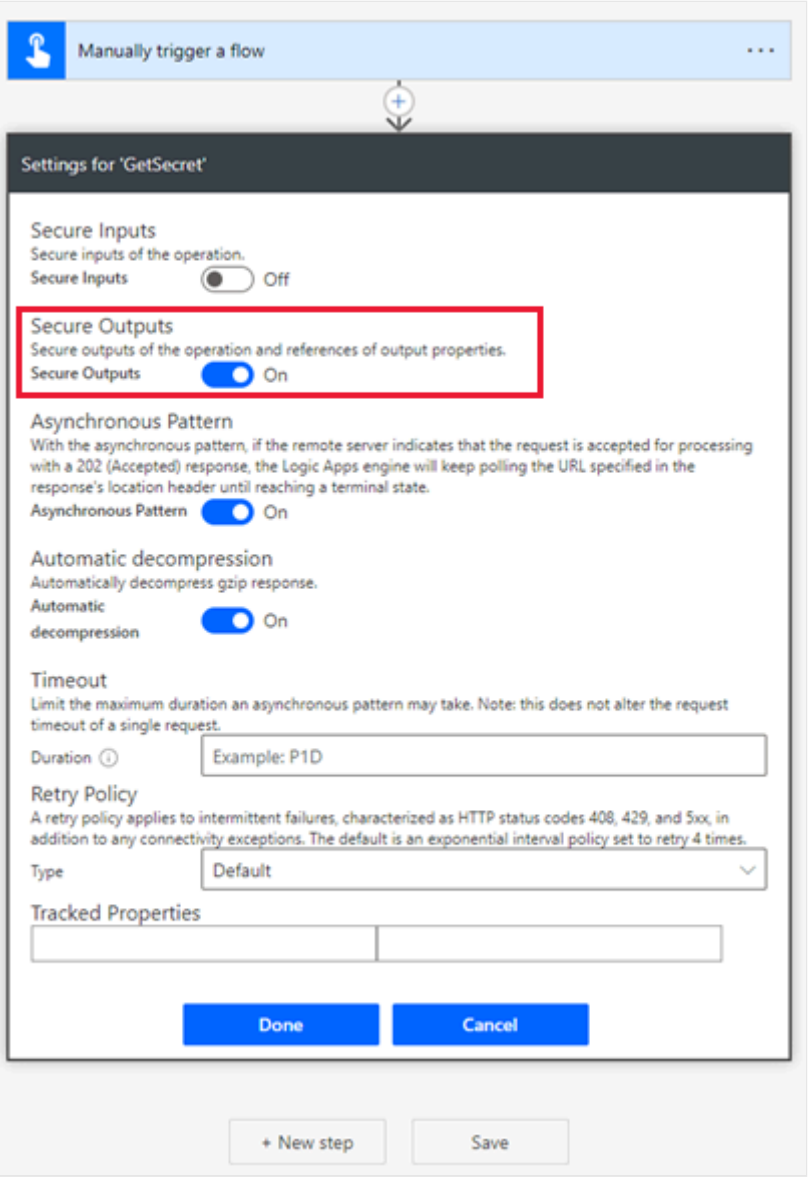
6. Provide the environment variable unique name (not the display name) added in the previous section, for this example *new_TestSecret* is used.

7. Select **...** > **Rename** to rename the action so that it can be more easily referenced in the next action. In this screenshot, it's renamed to **GetSecret**.



8. Select **...** > **Settings** to display the **GetSecret** action settings.

9. Enable the **Secure Outputs** option in the settings, and then select **Done**. This is to prevent the output of the action getting exposed in the flow run history.

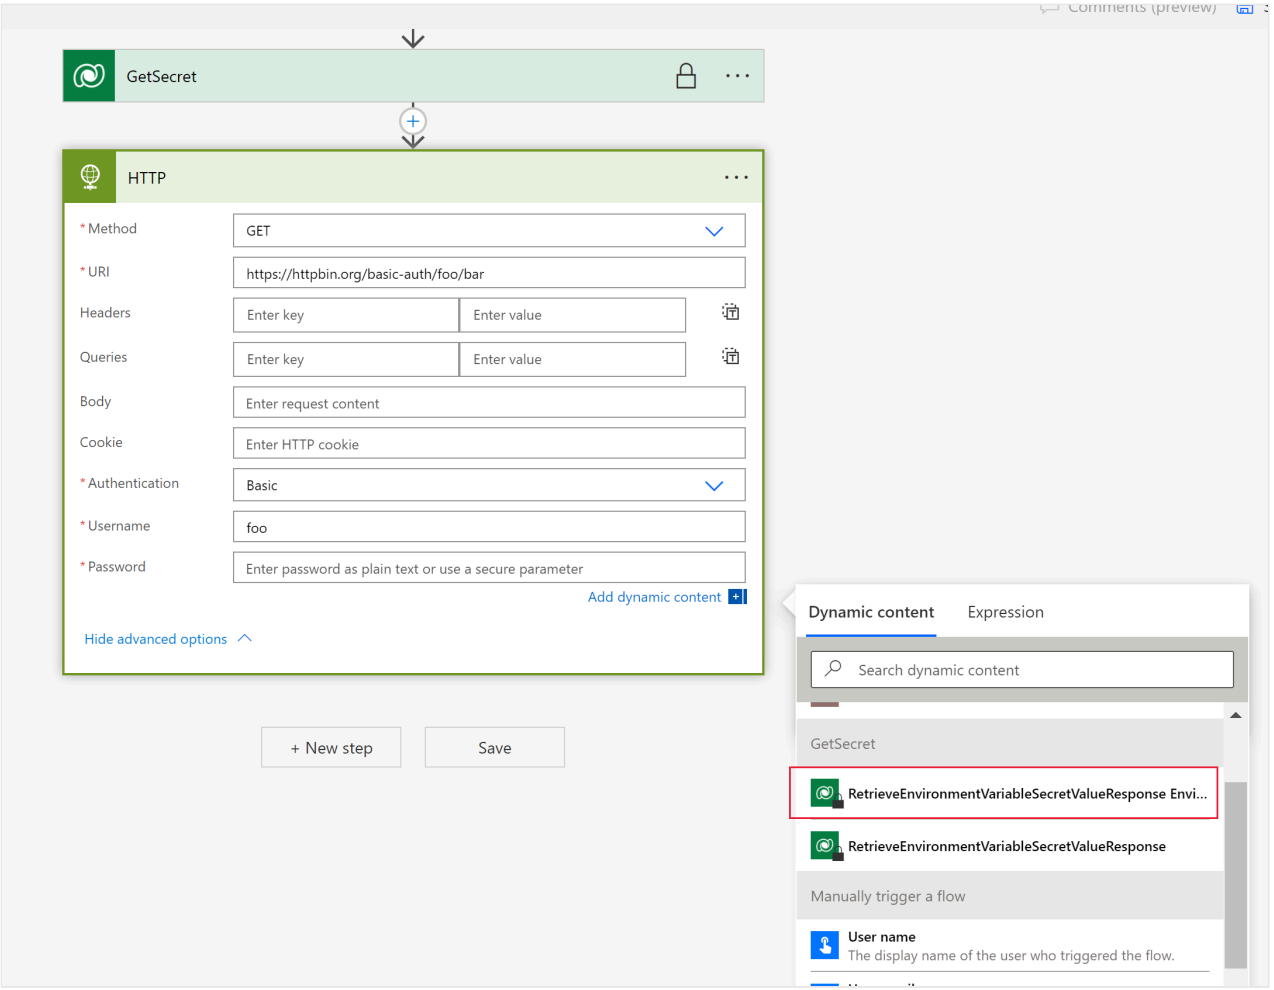


10. Select **New step**, search, and select the **HTTP** connector.

11. Select the **Method** as **GET** and enter the **URI** for the web service. In this example, the fictitious web service *httpbin.org* is used.

12. Select **Show advanced options**, select the **Authentication** as **Basic**, and then enter the **Username**.

13. Select the **Password** field, and then on the **Dynamic content** tab under the flow step name above (*GetSecret* in this example) select **RetrieveEnvironmentVariableSecretValueResponse EnvironmentVariableSecretValue**, which is then added as an expression `outputs('GetSecretTest')?['body/EnvironmentVariableSecretValue']` or `body('GetSecretTest')['EnvironmentVariableSecretValue']`.



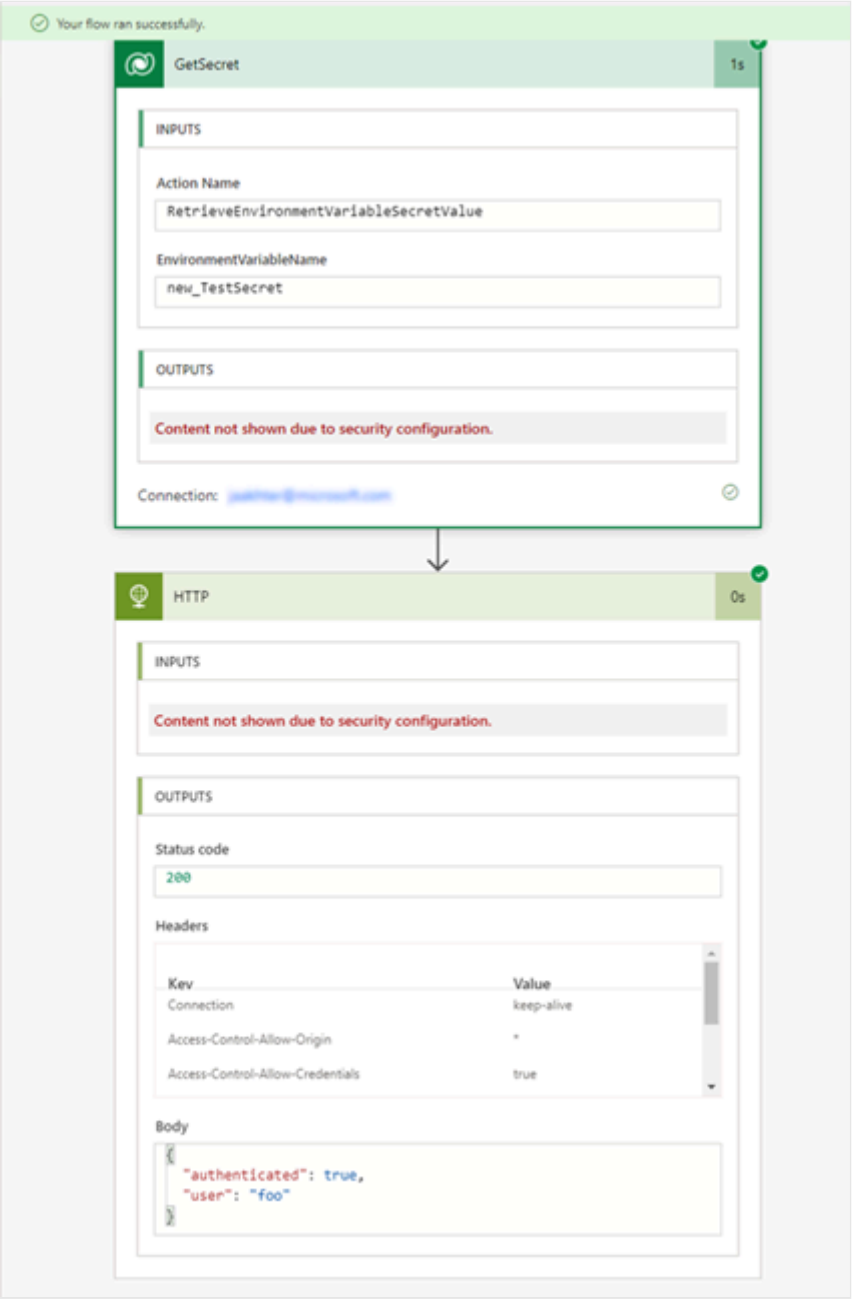
14. Select **...** > **Settings** to display the **HTTP** action settings.

15. Enable the **Secure Inputs** and **Secure Outputs** options in the settings, and then select **Done**. Enabling these options prevents the input and outputs of the action getting exposed in the flow run history.

16. Select **Save** to create the flow.

17. Manually run the flow to test it.

    Using the run history of the flow, the outputs can be verified.



Use environment variable secrets in Microsoft Copilot Studio

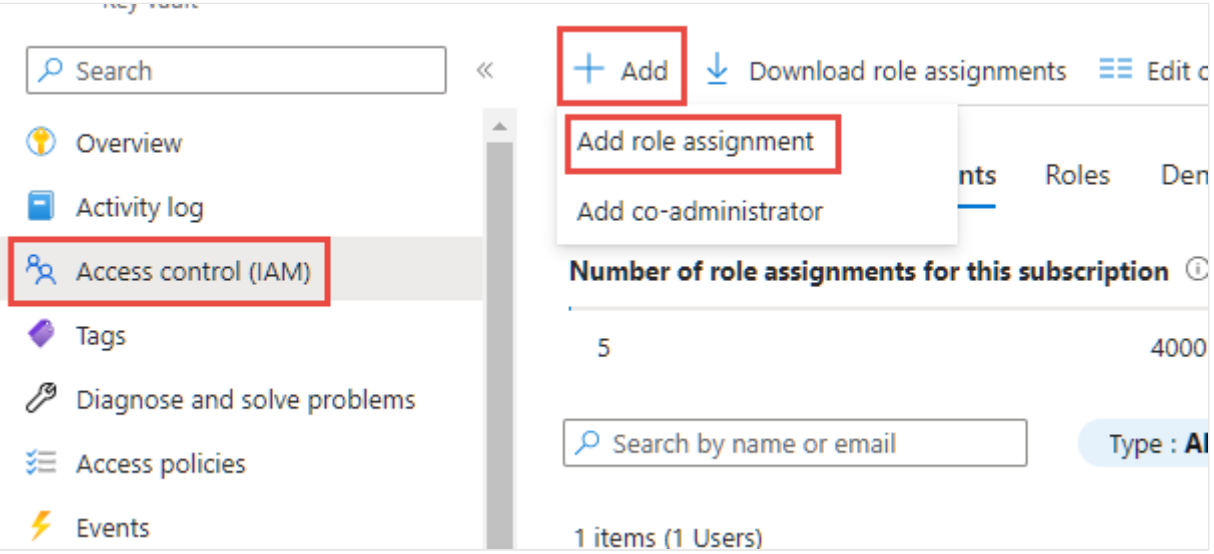
Environment variable secrets in Microsoft Copilot Studio work a bit differently. You need to run through the steps in the sections in Configure Azure Key Vault and Create a new environment variable for the Key Vault secret to use secrets with environment variables.

Give Copilot Studio access to Azure Key Vault

Follow these steps:

1. Go back to your Azure Key Vault.

2. Copilot Studio needs access to the key vault. To grant Copilot Studio the ability to use the secret, select **Access control (IAM)** on the left navigation, select **Add**, and then select **Add role assignment**.



3. Select the **Key Vault Secrets User** role, and then select **Next**.

4. Select **Select Members**, search for *Microsoft Copilot Studio Service*, select it, and then choose **Select**.

5. Select **Review + assign** on the bottom of the screen. Review the information and select **Review + assign** again if all is correct.

Add a tag to allow a copilot to access the secret in Azure Key Vault

By completing the previous steps in this section, Copilot Studio now has access to the Azure Key Vault, but you can't use it yet. To complete the task, follow these steps:

1. Go to Microsoft Copilot Studio and open the agent you want to use for the environment variable secret or create a new one.

2. Open an agent topic or create a new one.

3. Select the + icon to add a node, and then select **Send a message**.

4. Select the **Insert variable {x}** option in the **Send a message** node.

5. Select the **Environment** tab. Select the environment variable secret you created in the Create a new environment variable for the Key Vault secret step.

6. Select **Save** to save your topic.

7. In the test pane, test your topic by using one of the start phrases of the topic where you just added the **Send a message** node with the environment variable secret. You should run into an error that looks like this:

   This means you need to go back to Azure Key Vault and edit the secret. Leave Copilot Studio open, because you come back here later.

8. Go to Azure Key Vault. In the left navigation, select **Secrets** under **Objects**. Select the secret you want to make available in Copilot Studio by selecting the name.

9. Select the version of the secret.

10. Select **0 tags** next to **Tags**. Add a **Tag Name** and a **Tag Value**. The error message in Copilot Studio should give you the exact values of those two properties. Under **Tag Name** you need to add **AllowedBots** and in **Tag Value** you need to add the value that was displayed in the error message. This value is formatted as `{envId}/{schemaName}`. If there are multiple copilots that need to be allowed, separate the values with a comma. When done, select **OK**.

11. Select **Apply** to apply the tag to the secret.

12. Go back to Copilot Studio. Select **Refresh** in the **Test your copilot** pane.

13. In the test pane, test your topic again by using one of the start phrases of the topic.

The value of your secret should be shown in the test panel.

Add a tag to allow all copilots in an environment access to the secret in Azure Key Vault

Alternatively, you can allow all copilots in an environment access to the secret in Azure Key Vault. To complete the task, follow these steps:

1. Go to Azure Key Vault. In the left navigation, select **Secrets** under **Objects**. Select the secret you want to make available in Copilot Studio by selecting the name.
2. Select the version of the secret.
3. Select **0 tags** next to **Tags**. Add a **Tag Name** and a **Tag Value**. Under **Tag Name** add **AllowedEnvironments** and in **Tag Value** add the environment ID of the environment you want to allow. When done, select **OK**
4. Select **Apply** to apply the tag to the secret.

Limitation

Environment variables referencing Azure Key Vault secrets are currently limited for use with Power Automate flows, Copilot Studio agents, and custom connectors.

Integrate Azure Key Vault private link with environment variables

Using Azure Key Vault secrets with environment variables requires configuring Azure Key Vault so that Power Platform can read the specific secrets you want to reference. This capability enables support for environment variables with Azure Key Vault secrets connecting via a private link, enhancing security and providing a more robust integration.

1. Set up Azure Virtual Network support for Power Platform to integrate environment variables with Azure Key Vault secrets without exposing them to the public internet. For detailed instructions, go to set up virtual network.

2. Ensure that the Azure subscription for Key Vault and Power Platform Virtual Network are in the same tenant, as cross-tenant integration isn't supported.

3. Ensure that the user who creates the environment variables has appropriate permissions to the Azure Key Vault resource. For more details, go to Configure the Azure key Vault

4. Create a key vault and establish a private link connection. The steps to create the key vault should include the following actions:

    - Disable public access.
    - Create a private endpoint.
    - Select the virtual network and subnet where you want this private endpoint to be created. Ensure to connect the Virtual Network (virtual network) delegated to Power Platform.
    - Validate the private link connectivity.

    For detailed steps, go to Set up Virtual Network support for Power Platform.

5. Create environment variables secrets by linking to the Azure Key Vault.

Environment variables frequently asked questions

Article • 10/25/2024

In this article find the frequently asked question (FAQs) for environment variables.

Why can't I see the value for my environment variable?

If the environment variable is in a managed solution, you won't be able to see the value unless you look inside of the **Default solution**. This behavior is by design, since the environment variable value is an unmanaged customization.

How can I view where environment variables are being used?

Either through selecting **Show dependencies** in the solution interface, while authoring components, or in source control and in the solution file by viewing the app or flow metadata.

Are data source environment variables the same as connections?

No. Although they're related. A connection represents a credential or authentication required to interact with the connector. Data source environment variables store parameters that are required by one or more actions in the connector and these parameters often vary depending on the action. For example, a SharePoint Online connection doesn't store any information about sites, lists, or document libraries. Therefore calling the connector requires both a valid connection and some additional parameters.

Can data source environment variables be used with shared connections such as SQL Server with SQL authentication?

Generally no. Shared connections with SQL Server store the parameters required to connect to data within the connection. For example, the Server and Database name are provided when creating the connection and therefore are always derived from the connection.

Data source environment variables are used for connectors that rely on user based authentication such as Microsoft Entra ID because the parameters can't be derived from the connection. For these reasons authentication with SQL Server, which is a shared connection, won't use data source environment variables.

Can my automated ALM pipeline use different values files for different environments?

Yes. Solution packager accepts file name as input parameters so your pipeline can pack a different values file into the solution depending on the environment type it’s executing against.

What if someone inadvertently deletes a value?

If not already prevented by dependency system, runtime uses the last known value as a fallback.

If a value is changed, when does the new value get used in canvas apps and cloud flows?

It may take up to an hour to fully publish updated environment variables because the value is pushed into the apps and flows asynchronously.

Are premium licenses required?

No. While ALM requires Dataverse (or Dynamics 365 for Customer Engagement), use of premium connectors isn't required. The one caveat is if you're using the Dataverse connector to interact with environment variables as you would with other data records like accounts or contacts. Previously this was the only way to use environment variables in canvas apps and flows.

Is there a limit to the number of environment variables I can have?

No, there is no hard limit to the number of environment variables allowed in an environment, but user experience will become difficult when there are too many environment variables to select from.

Can environment variable display names and descriptions be localized?

Yes.

Should I use environment variables instead of storing configuration data in custom tables?

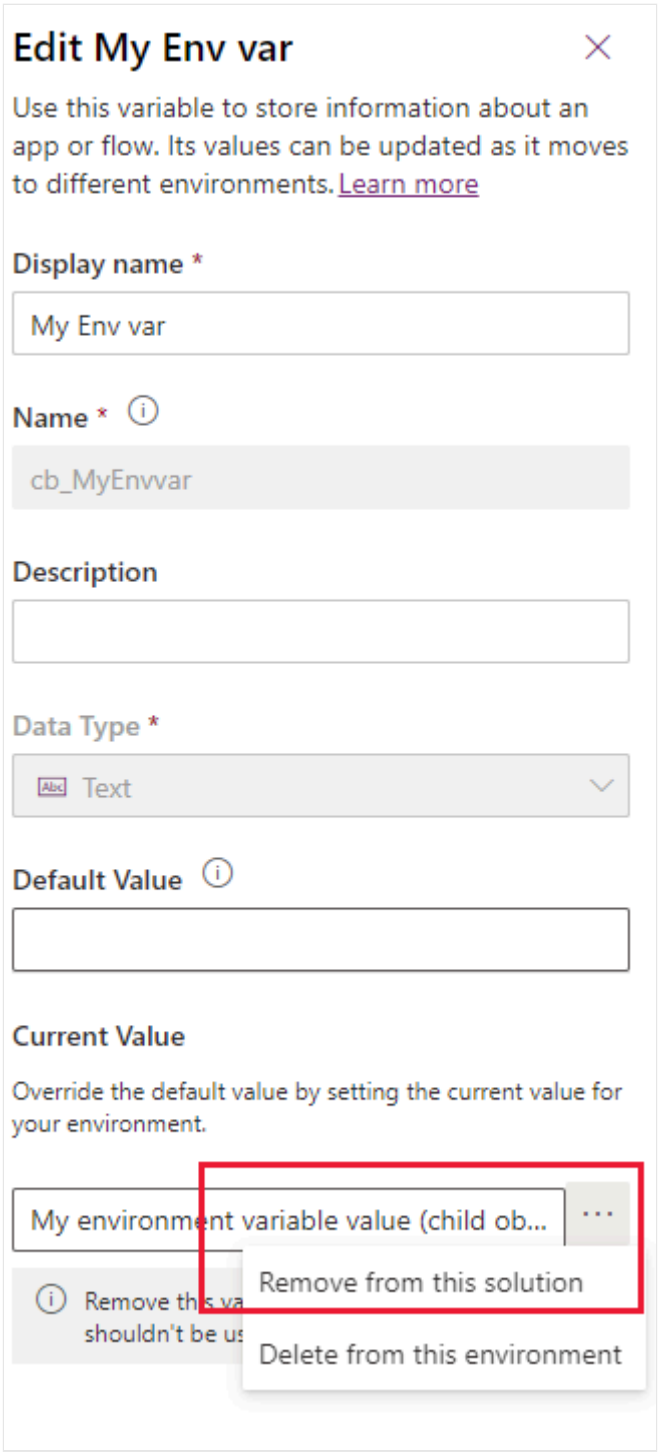
Yes if your configuration data isn't relational. Environment variables should be used for key: value pairs and when the value likely needs to different in other environments. Other tools such as the Configuration migration utility are better suited for migration of relational configuration data stored within custom tables. Unlike other configuration data, environment variables are migrated within solutions and therefore much simpler to manage and more performant to import.

How do I remove a value from an environment variable?

You might want to remove the value of an environment variable from your solution before exporting the solution. Then, the existing value remains in your development environment, but isn't exported in the solution. This approach allows a new value to be provided while importing the solution into another environment.

To remove the value, follow these steps:

1. In the solution where the environment variable is located select the environment variable to display the properties.
2. Under **Current Value**, select **...** > **Remove from this solution**.



Can I use environment variables in custom connectors?

Yes. Environment variable support in custom connectors

Use settings to provide customized app experiences

Article • 03/13/2023

Settings are solution components that enable makers and administrators to quickly configure apps to provide a customized experience. Settings can be used to enable or disable features or configure feature behavior for a single app or all apps within an environment.

Settings are made up of three subcomponents: Setting definition, setting environment value, and setting app value.

Subcomponent	Description

Setting definition	• Application authors, administrators, or partners can create a setting definition that includes properties such as name, description, data type, default value, and more.
	• They can then, via code, use the setting's value to enable or disable or configure the feature they are delivering.
	• They can include the setting definition in the solution that is used to deliver the feature to their customers.
	• Example:
	  ◦ The *Async save handler* for model-driven apps is a feature from Power Apps that uses settings.
	  ◦ The setting is of type *Yes/No* and the default value of this setting is *No*.
	  ◦ Therefore, by default, the *Async save handler* feature will be disabled for all model-driven apps.

Setting environment value	• A setting environment value can be used to override the default value, as specified in the setting definition.
	• Example:
	  ◦ Extending the example above, an environment administrator in a customer's organization can add a setting environment value for the *Async save handler* setting and set it to *Yes*.
	  ◦ This setting environment value will override the default value and will apply to all apps in that environment.
	  ◦ This will enable the *Async save handler* feature for all model-driven apps in that environment.

Subcomponent	Description

Setting app value	• A setting app value can be used to override the default value, as specified in the setting definition, and the setting environment value (if one exists).
	• Example:
	  ◦ Once again, extending the example above, an application author in the same environment above, can add a setting app value for the *Async save handler* setting for an app they are authoring and set it to *No*
	  ◦ This setting app value will override the setting environment value and apply only to that single app.
	  ◦ This will enable the *Async save handler* feature for that single app.

> ⓘ Note
>
> To follow the steps listed below you need to have **Solution preview on**. From the **Solutions** area in Power Apps, on the command bar, ensure you have **Solution preview on**. If **Solution preview off** is displayed, select the option to enable the preview. More information: **Solution view**

Setting definition

A setting definition specifies the base properties of a setting. The full list of properties that can be configured on a setting definition are listed below. Some of these properties can't be changed after the setting is created.

Property	Description
Display name	The name displayed to consumers of the setting in all user interfaces where settings are displayed.
Name	The unique name of the setting in an environment. Name is automatically generated based on the display name provided but can be changed before the setting is created. Once a setting is created, the **Name** can't be changed as it may be referenced in applications or code. **Name** has a prefix that corresponds to the solution publisher. This prefix is intended to give the setting a unique name if you want to import them into another solution or environment in the future (which would have a different prefix).
Description	The description helps others understand what the setting is used for in all user interfaces where settings are displayed.

Property	Description
Data type	The data type of a setting controls how the setting's value is stored. Data type can be set to **Number**, **String**, or **Yes/No**. Data type can't be changed after the setting is created.
Default value	The default value becomes available after you select a **Data type**. It specifies the setting's value that will be used unless it is overridden by a setting environment value or a setting app value.
Value can be changed for	A setting can be overridden at one of the following levels : • **Environment and app**, allows both the setting environment value and setting app values to override the default value. • **Environment only**, allows only the setting environment value to override the default value. • **App only**, allows only setting app values to override the default value. • **None**, the setting can't be overridden.
Release level	Release level is used to inform the framework and other consumers of the setting about the state of the feature that the setting is used with. Release level can be set to **Generally available** or **Preview**.
Information Url	A link to documentation to help consumers of the setting understand the purpose of the setting. Will be used as a *Learn more* link in all user interfaces where settings are displayed.

Adding a new setting definition

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you want to add the setting to.
4. In the command bar, select **New** > **More** > **Setting** > **Setting definition**.
5. In the **New setting** dialog, provide values for each of the properties based on your requirements. For information about setting definition properties, go to: Setting definition
6. When you are done providing values for the properties, select **Save**.

Adding an existing setting definition

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you want to add the setting to.

4. In the command bar, select **Add existing** > **More** > **Setting**.
5. In the **Add existing setting definition** dialog, select one or more settings that you want to add.
6. When you are done selecting settings, select **Next**
7. In the **Selected setting definition** dialog, for each setting you have selected, you will have the option to **Include setting definition**. You can also **Include setting environment value** for each setting, if one exists.
8. Select **Add** to add the setting definition and/or setting environment values.

Updating a setting definition

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you created the setting in.
4. In the tree view, select **Settings** > **Setting definitions**.
5. Select the setting definition that you want to update.
6. In the **Edit setting** dialog, update values for any of the properties you want to change.
   Note that some properties can't be updated after a setting has been created. Additionally, in most cases you will not be able to update settings definitions that you don't own.
7. When you are done updating the values for the properties, select **Save**.

Removing a setting definition

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you created or added the setting to.
4. In the tree view, select **Settings** > **Setting definitions**.
5. Select the setting definition you want to remove.
6. In the command bar, select **Remove** > **Remove from this solution**.
   Remove from this solution removes the setting definition from the current solution, but it will continue to be a part of the default solution or any other solution it was added to.

Deleting a setting definition

1. Sign in to Power Apps.

2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you created or added the setting to.
4. In the tree view, select **Settings** > **Setting definitions**.
5. Select the setting definition you want to delete.
6. In the command bar, select **Remove** > **Delete from this environment**.
   Delete from this environment deletes the setting definition from the current environment and it will no longer be a part of any solutions in that environment. You can only delete setting definitions that you own.

Setting environment value

A setting environment value is used to override the setting's default value for all apps in an environment. Use a setting environment value when the setting's default value is not what you want to be used for apps in your environment.

Adding a new setting environment value

1. Sign in to Power Apps.

2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

3. From the list of solutions, open the solution you want to add the setting environment value to.

4. If the setting definition *is* available in the solution:
   a. Select the setting definition.
   b. In the **Edit setting value** dialog, in the **Setting environment value** section, select **New value**.
   c. Provide the value, and then select **Save**.

   If the setting definition *is not* available in the solution:
   a. On the command bar, select **New** > **More** > **Setting** > **Setting environment value**.
   b. Select the setting you want to add the setting environment value for, and then select **Add**.
   c. In the **New setting environment value** dialog, in the **Setting environment value** section, select **New value**.
   d. Provide the value, and then select **Save**.

Adding an existing setting environment value

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you want to add the setting environment value to.
4. If the setting definition *is* available in the solution:
   a. Select the setting definition.
   b. In the **Edit setting value** dialog, in the **Setting environment value** section, select **Add existing value**.
   c. Update the value if needed, and then select **Save**.

   If the setting definition *is not* available in the solution:
   a. On the command bar, select **Add existing** > **More** > **Setting**.
   b. In the **Add existing setting definition** dialog, select one or more settings that you want to add setting environment values for.
   c. When you are done selecting settings, select **Next**
   d. In the **Selected setting definition** dialog, for each setting you have selected, you will have the option to **Include setting environment value**, if one exists. You can also **Include setting definition** for each setting if you want.
   e. Select **Add** to add the setting environment values and/or setting definitions.

Updating a setting environment value

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you added the settings environment value to.
4. In the tree view, select **Settings** > **Setting environment values**.
5. Select the setting environment value that you want to update.
6. In the **Edit setting** dialog, in the **Setting environment value** section, update the value, and then select **Save**.

Removing a setting environment value

1. Sign in to Power Apps.

2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you created or added the setting to.
4. In the tree view, select **Settings** > **Setting environment values**.
5. Select the setting environment value you want to remove.
6. On the command bar, select **Remove** > **Remove from this solution**.
   Remove from this solution removes the setting environment value from the current solution but it will continue to be a part of the default solution or any other solution it was added to.

Deleting a setting environment value

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you created or added the setting to.
4. In the tree view, select **Settings** > **Setting environment values**.
5. Select the setting environment value you want to delete.
6. On the command bar, select **Remove** > **Delete from this environment**.
   Delete from this environment deletes the setting environment value from the current environment and it will no longer be a part of any solutions in that environment.

Setting app value

Setting app value is used to override the setting's default value and any setting environment value for a single app. Use a setting app value when the setting environment value is not what you want to be used for your app. If a setting environment value does not exist, use a setting app value when the setting's default value is not what you want to be used for your app.

> **Note**
>
> To follow the steps listed below you need to use the new **app designer**. Currently the app designer only displays Power Apps platform settings. For non-platform settings please use the solution explorer as outlined below.

Adding or updating a setting app value using the app designer

1. Open the app you want to add the setting app value for in the app designer.
2. On the command bar, select **Settings**.
3. In the **Settings** dialog, select the **Features** or **Upcoming** tab.
   The **Features** tab displays all settings that have release level set to **Generally available**. The **Upcoming** tab displays all settings that have release level set to **Preview**.
4. Add or update an app value for the setting you want.
5. Save and publish the app.

Deleting a setting app value using the app designer

1. Open the app you want to remove the setting app value for in the app designer.
2. On the command bar, select **Settings**.
3. In the **Settings** dialog, select the **Features** or **Upcoming** tab.
4. Select **Reset to environment value** next to the setting app value you want to delete. This makes the setting value fall back to the setting environment value if one exists. If no setting environment value exists, it will fall back to the setting's default value.
   Note that the option to **Reset to environment value** is only displayed if a setting app value was previously added for that setting.
5. Save and publish the app.

Adding or updating a setting app value using the solution explorer

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you want to add the setting app value to.
4. If the setting definition or setting environment value is not available in the solution, add one of them. Go to **Adding an existing setting definition** or **Adding an existing setting environment value**.
5. Select the setting definition or setting environment value.
6. In the **Edit setting value** dialog, in the **Setting app values** section, find the app that you want to add the setting app value for. Note that using the solution explorer you can only add setting app values for apps that are in the current solution.
7. Provide the value and select **Save**.
8. For the setting app value to take effect you will have to republish the app using the app designer or solution explorer.

Deleting a setting app value using the solution explorer

1. Sign in to Power Apps.
2. In the navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. From the list of solutions, open the solution you want to delete the setting app value from.
4. If the setting definition or setting environment value is not available in the solution, add one of them. More information: Adding an existing setting definition or Adding an existing setting environment value.
5. Select the setting definition or setting environment value.
6. In the **Edit setting value** dialog, in the **Setting app values** section, find the app that you want to delete the setting app value for. Note that using the solution explorer you can only remove setting app values for apps that are in the current solution.
7. Select **...** next to the setting app value, and then select **Reset to environment**.
8. Select **Save**.
9. For the deletion of the setting app value to take effect you will have to republish the app using the app designer or solution explorer.

Getting or updating a setting value via code

For the methods available, go to Get or update a setting value using client API.

Use a connection reference in a solution with Microsoft Dataverse

A *connector* is a proxy or a wrapper around an API that allows the underlying service to talk to Microsoft Power Automate, Microsoft Power Apps, and Azure Logic Apps. It provides a way for users to connect their accounts and use a set of prebuilt actions and triggers to build their apps and workflows.

A connection is a stored authentication credential for a connector, for example OAuth credentials for the SharePoint connector.

A *connection reference* is a solution component that contains a reference to a connection about a specific connector. Both solution-aware canvas apps and operations within a solution-aware flow bind to a connection reference instead of directly to a connection. During solution import into a target environment, a connection is provided for all the connection references so any referencing flows can be turned on automatically after the import completes. To change a specific connection associated with a canvas app or flow, you edit the connection reference component within the solution.

Add connection references to a solution

Connection references can be added to a solution in different ways:

- When you're using the solution explorer to create a new connection reference in a solution.
- When you import a solution. To learn more, go to Import solutions.
- Implicitly when you build your canvas apps and flows that are defined in a Microsoft Dataverse solution.

> **Note**
>
> - Canvas apps and flows handle connections differently. Flows use connection references for all connectors, whereas canvas apps only use them for implicitly shared (non-OAuth) connections, such as SQL Server Authentication. More information: Security and types of authentication
> - A connection reference is automatically created when you create new connections from the flow designer or Power Apps Studio.

- Canvas apps and flows added from outside solutions will not automatically be upgraded to use connection references.
- Connection references get associated with canvas apps only at the time a data source is added to the app. To upgrade apps you must remove the connection from the app and then add a connection containing an associated connection reference.

Manually add a connection reference using solution explorer

1. Sign in to Power Apps or Power Automate.
2. On the left pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Create a new or open an existing solution.
4. On the command bar, select **New** > **More** > **Connection Reference**.
5. On the **New Connection Reference** pane, enter the following information. Required columns are denoted with an asterisk (*).
    - **Display name**: Enter a unique and useful name to help differentiate this connection reference from others.
    - **Add a description**: Enter text that describes the connection.
    - **Connector**: Select an existing connector from the list such as in the screenshot here. You can also select **New** to create a new connection for this connection reference. Once your finished creating a new connection, select **Refresh** to select your connection from the list.
    - **Connection**: Based on the **Connector** you selected, select an existing connection or select **New connection** to create one.
6. Select **Create**.

Connection reference naming

The display name of a connection reference should be unique so different connection references can be differentiated by name alone. By default, a connection reference name includes the target connector, the current solution name for context, and a random suffix to ensure uniqueness. Consider adjusting the connection reference name to something unique and something that explains what it will be used for.

Reuse connections in a solution flow

Flows created outside a solution use connections directly. Flows created in a solution use connection references and the connection reference points at the connection. To reuse a connection within a solution flow, you first need to create a connection reference pointing at that connection.

Update a flow to use connection references instead of connections

When a flow isn't in a solution, it uses connections. If that flow is then added into solution, it will continue to use connections initially. Flows can be updated to use connections references instead of connections in one of two ways:

1. If the flow is exported in an unmanaged solution and imported, the connections will be removed and replaced with connection references.

2. When a solution flow is opened, the flow checker on the flow details page will show a warning to **Use connection references**. The warning message contains an action to **Remove connections so connection references can be added**. Selecting that action will remove connections from the trigger and actions in the flow and allow connection references to be selected and created.

Automatic use of connection references in a solution flow

When an action is added to a solution flow, Power Automate will try to reuse existing connection references from the current solution or other solutions before creating a new connection reference. To ensure that the connection reference is inside the same solution as the flow, create or add a connection reference in the same solution and reference that connection reference from the flow.

Share connections with another user so flows can be enabled

When a flow is turned on (enabled), the user turning on the flow needs to own or have permission to use all the connections in the flow. This is usually accomplished by having the flow owner create the connections inside all the connection references that the flow uses. If a user other than the flow owner provides the connections on a flow, then the flow needs to be turned on by the owner of those connections or the connections need to be shared with the user who is turning on the flow.

> ⓘ **Note**
>
> OAuth connections can only be explicitly shared with a user representing a service principal.

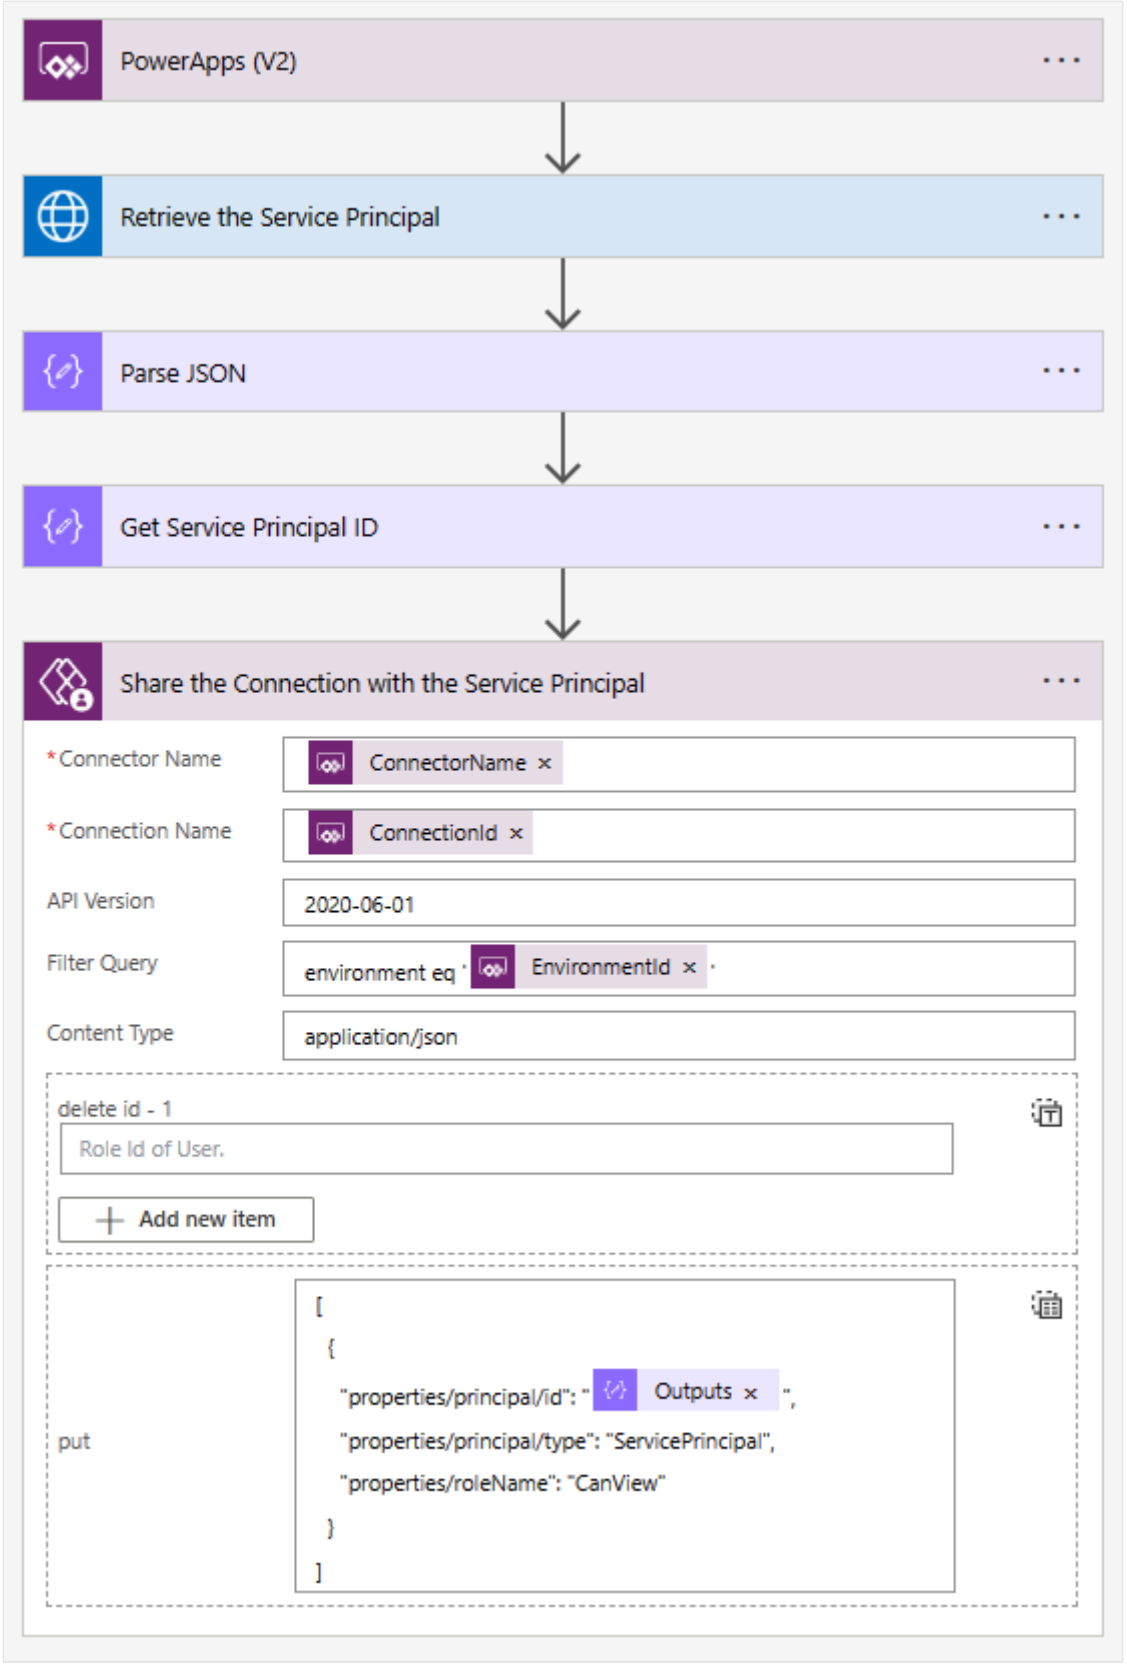
Manual sharing of connections for flow enablement

Sharing connections can be accomplished with the following steps.

1. Go to Power Apps and select the environment containing the connection.
2. Select **Connections** on the left navigation pane, and then select the connection you want to share. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. From the menu, select **Share**.
4. From the sharing screen, enter the name of the user (service principal) who will enable the flow.
5. For the permissions, select **Can use**.
6. To complete the sharing, select **Save**.

Automated sharing of connections for flow enablement

To automate sharing of connections, use the Edit Connection Role Assignment action on the Power Apps for Makers connector.



Limits

- Connection references are now saved asynchronously. Unlike during the preview period, there's no longer a limit to how many flows can reference the same connection reference. When connection references are updated, an info banner that links to a panel containing asynchronous update details appears.

- There's also no limit to the number of actions in each flow that can be associated with the connection reference.
- Canvas apps don't recognize connection references on custom connectors. To work around this limitation, after a solution is imported to an environment the app must be edited to remove and then readd the custom connector connection. Note, if this app is in a managed solution, proceeding to edit the app will create an unmanaged layer. More information: Solution layers

Known issues

This section describes known issues with connection references.

Copy environment breaks connection references for custom connectors

Custom connectors use an environment-specific identifier to reference a custom connector. After a copy environment operation, a new connection reference must be created to the new custom connector. Then, any apps or flows using the old connection references will need to be fixed.

Custom connectors need to be imported in a separate solution from their connection references

Custom connectors need to be imported in a separate solution, before connection references or flows. Export a solution containing only the custom connector first.

FAQ

How do I fix an "Invalid Connection" error?

If the connection reference is showing as "invalid" where a red exclamation point appears on the flow details page, this means the underlying connection is in a bad state. When this occurs, check and fix the underlying connection by updating the connection, or replace the connection.

What is the ConnectionAuthorizationFailed error? Why can't I turn on (activate) a flow?

The "ConnectionAuthorizationFailed" error indicates that the user trying to activate the flow doesn't have permissions to at least one of the connections the flow is using. To resolve the situation, select from one of the following resolutions:

- The users owning the connections needs to share *all* the connections with the user turning on (activating) the flow.
- If one user owns all the connections in the flow, then that user can turn on (activate) the flow.

Once the flow has been turned on by the owner of the connections, then the flow has permissions to use those connections. From that point on, any co-owner of the flow can turn on the flow.

Can a flow be enabled by the owner of its connections and then ownership transferred to another user?

Yes. When a flow is turned on (enabled) by the owner of the connections used by the flow, then the flow gets explicit permission to use those connections. Co-owners of the flow can then turn the flow off and on as needed.

Permissions granted to apps and flows using a connection can be seen in the details page for that connection in the **Apps using this connection** and **Flows using this connection** tabs.

If the flow is edited to add new actions that use additional connection references with new connections, then the owner of those new connections either needs to initially turn on the flow themselves or share the connections with the owner who turns on the flow. More information: Share app resources

Can ownership of a connection reference be transferred to another user?

Ownership of a connection reference can't be transferred to another user from the Solutions area in Power Apps (make.powerapps.com).

However, the classic solution explorer can be used to change privileges of a connection reference including sharing.

Translate label text

Article • 02/15/2022

The standard tables include default text for labels that are available in many different languages. However, when you customize a form, such as adding or changing columns, or create custom tables, you may need the labels for those components to appear in different languages. You can import translated label text for customized tables for your apps so that the label text displays in languages other than the base language.

When you translate label text for a form, you are modifying the base language of the form as part of a form customization. When you do this, you create active unmanaged changes to the labels. Subsequently, if you don't modify the base language translation for a component, such as a column, and then export the translation file, the column's object id won't be exported. This is because the export doesn't see any modifications done to the base language label of that column.

High-level process

1. Export the translations from the solution that contains the tables that you want to translate label text. Then, open the translations XML file and add the translated text. More information: Translate customized table and column text into other languages
2. Import the translations. More information: Import translated table and column text back into an app

Common issues with translating form label text

Form label translations don't appear in the layers

Imported translations may not appear when you view the solution layers for a component. Make sure the translations are on the <Label> level when you view the solution layer. Note that "displayname" tags are at the attribute level, so they will not translate labels. The "DisplayName" tags are actually for form labels and will translate form's labels. For more information about viewing solution layers, see Solution layers.

Form label translations don't appear specifically for the base language

The translation export and import feature is a tool for used so your apps can display translated label text for customized components. It isn't designed to be used in managing all labels including the base language.

On translation export, if no changes were made to the base language label, no translations will be exported in CrmTranslations.xml.

On translation import, if translations for any label in the base language column were changed in CrmTranslations.xml, the changes won't take effect.

If the issue is base language specific, do the following:

1. Change the translations for the base language using the form designer for each label that was changed.
2. Use translation export and import to add translations for other provisioned languages.
3. Export the active unmanaged solution as managed.
4. Import this solution into the target environment.

Form Label translation descriptions appear when exporting as unmanaged, but are "" when exporting as managed

This can happen because the label has no translations. The following behavior occurs:

- The unmanaged solution is filled with the display name: <label description="example" languagecode="1033">
- The managed solution is empty, which is seen as non-existent and falls back to the display name: <label description="" languagecode="1033">

Translate customized table, form, and column text into other languages

Article • 03/13/2023

After you create customized table and column text in your unmanaged solution, you may want to translate it into other languages.

> **Important**
>
> When you export translations, the export translations feature exports translations for the table. So, that means even if the solution contains only a single form, labels for all the forms for the table will be exported. Make sure you only modify the form's labels when importing the translations back otherwise another component translation you modify will be added as a dependency to the solution.

1. Sign into Power Apps and select **Solutions** from the left navigation. If the item isn't in the left navigation pane, select ...More and then select the item you want.
2. Select the unmanaged solution you want, on the command bar select **...**, select **Translations**, and then select **Export translations**.
3. After the export completes the exported translations compressed (zip) file is downloaded to your browser's default download folder and contains the exported labels.
4. Extract the XML file from the compressed (.zip) file.
5. Open the CrmTranslations.xml file in Excel.
6. Select the sheet named **Localized Labels**.
7. Notice there is already a column with the base language code id, such as 1033 (English U.S.) Add a column with the language code id for every language you want to translate labels. For example, add a column for 1034 (Spanish traditional).
8. Add the translated text in the new column for the object names and object ids that you want.

	A	B	C	D	E
1	**Entity name**	**Object ID**	**Object Column Name**	**1033**	**1034**

Next steps

Import translated table and column text

Import translated table, form, and column text back into an app

Article • 03/13/2023

If you have customized table or column text, such as column labels or drop-down list values, you can provide the users in your organization who are not working with the base language version of your environment with this customized text in their own languages. To do so, you export the text strings for all your customizations so that they can be translated into the languages you use in your organization.

After the translation, you need to import the translated text strings into your environment before users can take advantage of the changes.

> **Important**
>
> - The file that you import must be a compressed file that contains the CrmTranslations.xml and the [Content_Types].xml file at the root.
> - You can't import translated text that is over 500 characters long. If any of the items in your translation file are longer than 500 characters, the import process will fail. If the import process fails, review the line in the file that caused the failure, reduce the number of characters, and try to import again. Also note that after you import translated text, you must republish customizations.

1. Sign in to Power Apps at https://make.powerapps.com.
2. Select **Solutions**, and select the unmanaged solution from which to import the translated text. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. In the solution explorer, on the Actions toolbar, select **Translations**, and then select **Import translations**.
4. In the **Import Translated Text** dialog box, specify the file that contains the translated text, and then select **Import**.
5. When the import is complete, select **Close**.

> **Note**

Publishing customizations can interfere with normal system operation. We recommend you schedule publishing when it's least disruptive to users.

Community tools

Easy Translator is a tool that XrmToolBox community developed for Power Apps. Use Easy Translator to export and import translations with contextual information.

Next steps

Export customized table and column text for translation

Update localized labels for forms

Article • 12/07/2024

This article describes how to update existing localized labels that were created following the steps in the article Translate localizable text for model-driven apps.

Updating localized labels overview

When you create a new model-driven app form and add columns to the form, the form creates a copy of the localized labels for those columns in the base language. Once a form is created, changing the localized label text for a column in the base language doesn't update the localized label on the form. However, you can change the column, tab, and section labels that can be localized for a form using the form designer. For more information about customized text, go to Configure column properties on a form.

To update localized labels for forms through the export translations Excel file, you need to correctly identify the object ID corresponding to each tab, section, or column. The following sections explain how to do this.

Identify the object ID for form labels

1. Create a solution and add the form as part of this new solution.
2. Export the solution as managed.
3. Unzip the solution file and open the customizations.xml file with an XML or text editor.
4. Find the tab, section, or column of the form that has the localized label you want to update.
5. Once you find the tab, section, or column, check if there's `labelid` property defined. If yes, then the value of `labelid` attribute is the object ID for the localized label. If not, then the value of the ID attribute is the object ID for localized label.

For example, say you want to find the object ID for attribute `websiteurl`. Search for that attribute in the customizations.xml file in the `formxml` section.

XML

```
<row>
<cell id="{e6441984-4343-813a-aa7e-e2747ad35390}" showlabel="true" labelid="
{aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb}">
<labels>
<label description="Website" languagecode="1033" />
```

```
</labels>
<control id="websiteurl" classid="{71716B6C-711E-476c-8AB8-5D11542BFB47}"
datafieldname="websiteurl" disabled="false" />
</cell>
</row>
```

In the example, since the `labelid` property is defined, the object ID is *aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb*.

Now that you have the object ID, you can follow the steps to export the translations file. Open the file, to locate the object ID to make your localized text updates for the tab, section, or column. For more information about how to translate the customized text into another language, go to Translate customized table, form, and column text into other languages.

What if you can't find the asset in customizations XML?

When you export a model-driven form, only the diff between the active layer and last managed layer is exported. If you don't make any changes to the tab, section, or column, the asset doesn't appear in the customizations.xml.

You can modify the label or any other property of the asset using the form designer, and then export the changes to find the object ID.

Alternate way to find the object ID of a localized label

There are two alternative ways to find the object ID for a localized label:

- Find the full form XML of the form by viewing the **Properties** page for the solution layers of the model-driven app form. For more information about solution layers, go to View the solution layers for a component.
- You can also make an OData call to retrieve the form xml if you know the form ID.
  - `[environmentURL]/api/data/v9.0/systemforms(b0742891-2411-494b-bfe7-93bc20356399)?$select=formxml`

Tools available to diagnose solutions

Article • 02/15/2022

There are two tools available for diagnosing solutions in Power Apps.

- Object checker
- Solution checker

Object checker

Object checker and solution checker are similar and share much of the same infrastructure. However, object checker runs *live diagnostics on the database* and can analyze issues based on the metadata and layering of a given solution object - regardless of which solution(s) the object is in. Therefore, object checker is better suited for troubleshooting application lifecycle (ALM) related issues in test and production environments. More information: Use object checker to diagnose a solution component

Solution checker

Solution checker runs offline analysis on a single solution file. Solution checker requires the solution be exported before you can run a solution diagnostic. Solution checker is best suited for development environments or analyzing a solution prior to committing it to a source control repository. More information: Use solution checker to validate your model-driven apps in Power Apps

Debug a model-driven app with Monitor

Use object checker to diagnose a solution component (preview)

Article • 11/13/2024

[This topic is pre-release documentation and is subject to change.]

Object checker runs real-time diagnostics on component objects within your solution. If issues are detected, a recommendation is returned that describes how to fix the issue. This might include documentation, instructions, or a click-able action that can fix the issue for you.

Example issues object checker detects

- Active layer hiding customizations.
- Malformed or corrupted metadata.

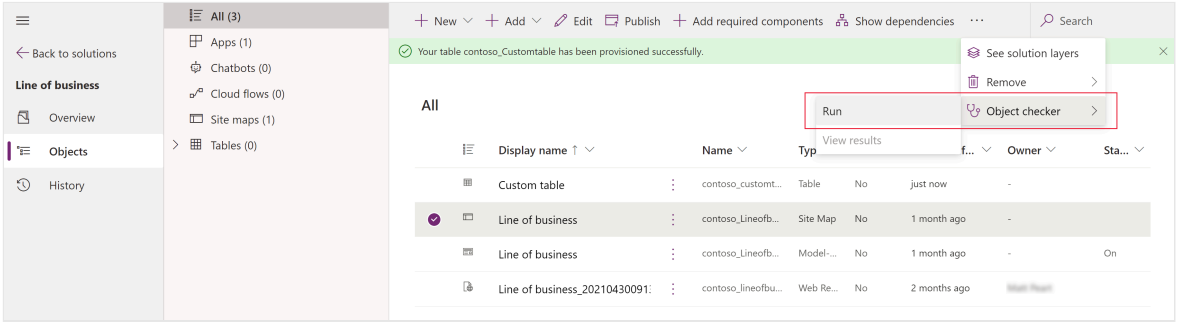
Run object checker and view the results

1. Sign into Power Apps, and then select **Solutions** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.

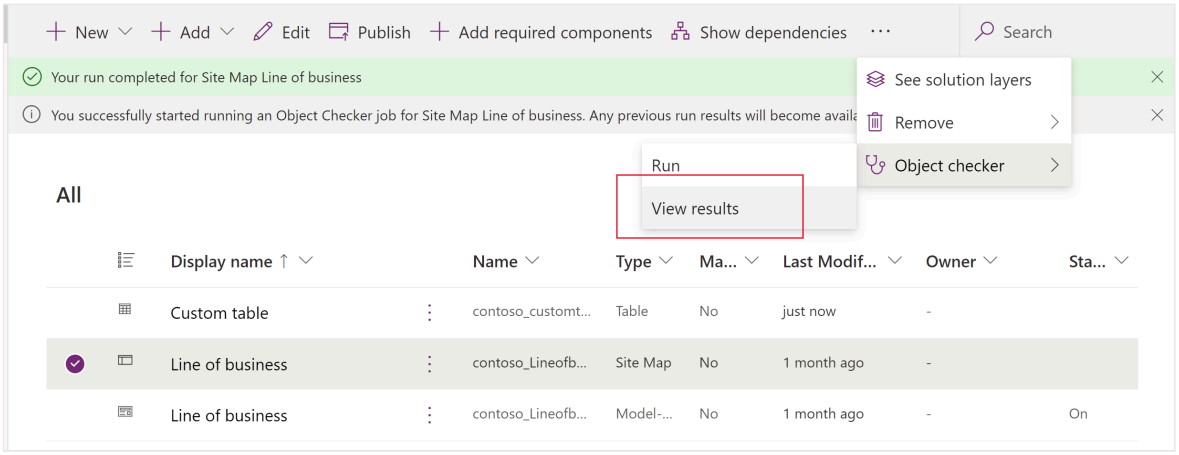
2. Open a solution that contains the problematic object. You can run object checker within either managed and unmanaged solutions.

3. Select a single object, such as a model-driven app or a site map.

4. On the command bar, select **...** > **Object checker** > **Run**.



5. When object checker finishes, on the command bar, select **...** > **Object checker** > **View results**



6. The results are displayed in the right pane. If issues are detected, follow the prompt to resolve the issue.

7. Select **Close** to close the object checker results pane.

Current limitations

- Object checker currently only works with model-driven app and site map components.
- Object Checker rules might fail if customizations haven't been published. When this condition occurs, the following exception can be observed in the '**Multiple sitemaps detection rule**':

```text
Exception encountered while executing rule:
System.ServiceModel.FaultException`1[Microsoft.Xrm.Sdk.OrganizationServ
iceFault]: The value passed for ConditionOperator.In is empty.
```

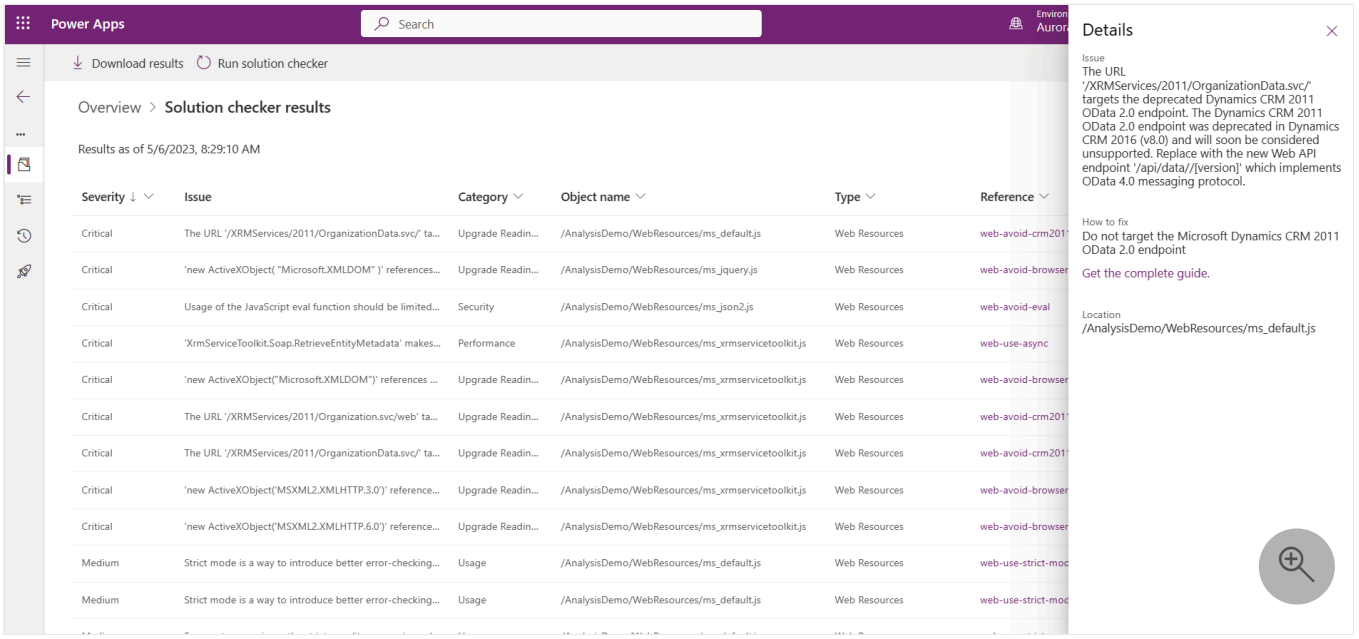
Improve solution performance, stability and reliability

06/19/2025

Solutions are used to distribute Power Platform objects, such as apps, tables, flows, web resources, and plugins. This article introduces the solution checker feature, a powerful tool that performs a comprehensive static analysis of your solution objects against a set of best practice rules. By using solution checker, you can quickly identify problematic patterns in your components and receive detailed reports that highlight issues, affected components, and provide links to documentation on how to resolve each issue. This ensures your solutions are optimized for performance, stability, and reliability.



Solution checker works with unmanaged solutions that can be exported from an environment.

You can run solution checker either from Power Apps (make.powerapps.com) or by using PowerShell.

How solution checker helps you

To deliver on complex business requirements, makers often can end up with highly advanced solutions that customize and extend the Power Platform. With advanced implementations come an increased risk where performance, stability, and reliability issues become introduced, which can negatively impact the user experience. Identifying and understanding how to resolve these issues can be complicated and time consuming. With the solution checker feature, you can perform a check within seconds on your solution, which uses a set of best practice rules to quickly identify problematic patterns. After the check completes, you receive a detailed report in Power Apps as well as in an email message that lists the issues identified, the components and code affected, and links to documentation that describes how to resolve each issue.

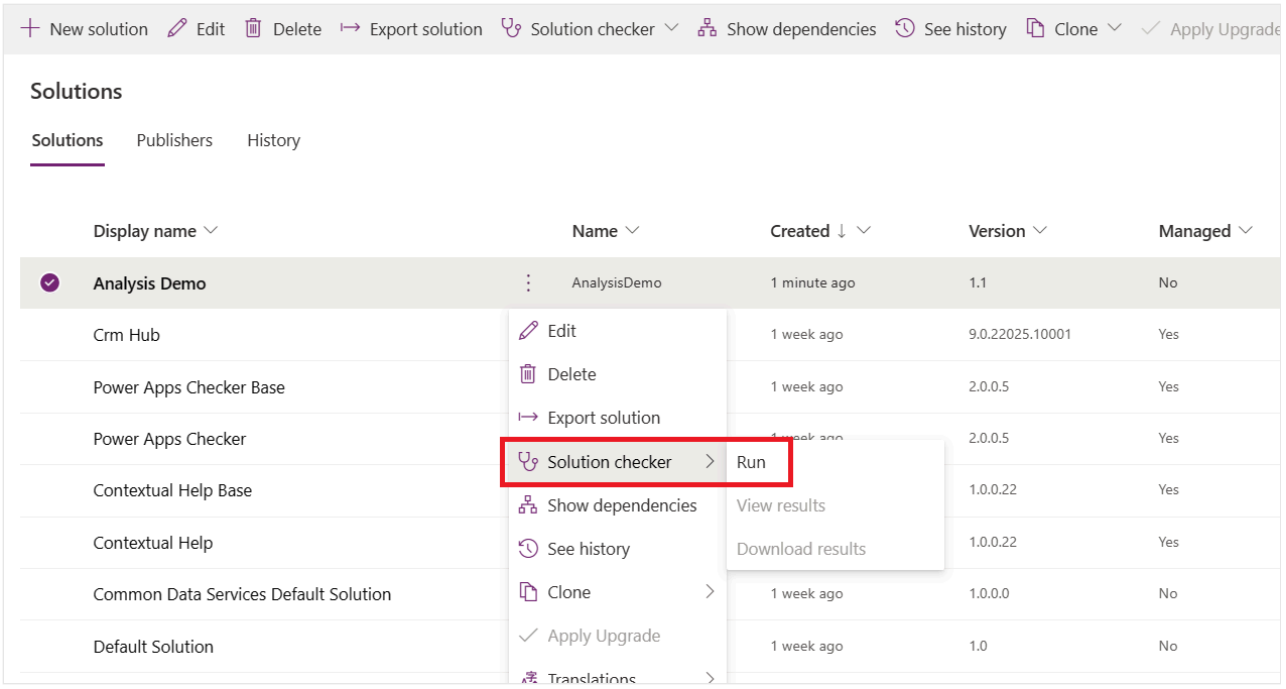
The solution checker analyzes these solution components:

- Dataverse custom workflow activities
- Dataverse web resources (HTML and JavaScript)
- Dataverse configurations, such as SDK message steps
- Power Automate flows (via flow checker)
- Power Fx expressions (via app checker)

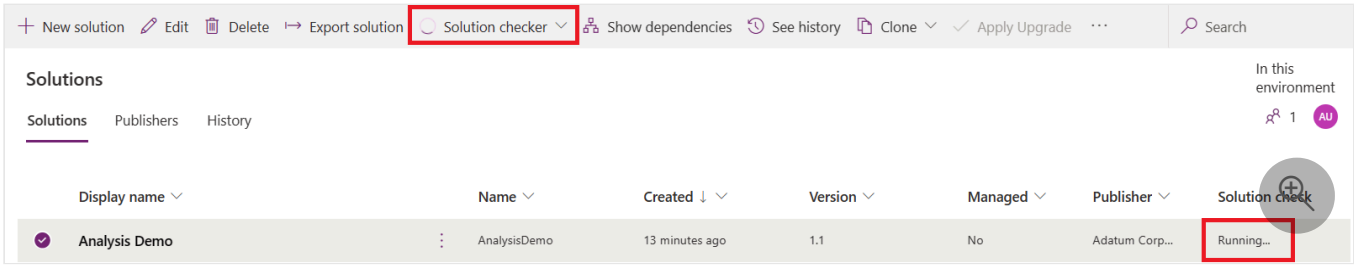
> **Note**
>
> - Solution checker supports global variables for ECMAScript 2015 (ES6) and up to ECMAScript 2018 (ES9) syntax. When JavaScript is detected using global variables later than ES6 or syntax later than ES9, a web-unsupported-syntax issue for the web resource is reported.
> - Use of solution checker doesn't guarantee that a solution import will be successful. The static analysis checks performed against the solution don't know the configured state of the destination environment and import success might be dependent on other solutions or configurations in the environment.

Run the solution checker

1. Sign in to Power Apps.
2. In the left pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Next to the unmanaged solution that you want to analyze, select **...**, point to **Solution checker**, and then select **Run**.



4. The **Solution checker** command button has a loading indicator, and you'll notice a **Running...** state in the **Solution check** column of the **Solution** list.



> **Note**
>
> - The solution checker can take a few minutes to complete the analysis.
> - You'll receive an email notification and a notification in the **Notifications** area of the Power Apps site when the check is completed.

5. View the report when the check is completed.

Cancel a check

After you submit a solutions check in your environment, the check can be canceled through the status pane on the upper right area of the **Solutions** page.

When you cancel a check, the solution check stops running and the solution check status returns to the previous state.

Solution checker states

When you install the solution checker in your environment, the **Solution check** column becomes available in the **Solutions** list. This column displays the solution analysis states for a solution.

Expand table

State	Description
Hasn't been run	The solution has never been analyzed.
Running	The solution is being analyzed.
Couldn't be completed	Solution analysis was requested but the analysis didn't complete successfully.
Results as of *date and time*	Solution analysis completed and results are available for download.
Couldn't be completed. Result as of *date and time*	The latest analysis request didn't complete successfully. The last successful results can be downloaded.
Checked by Microsoft	This is a Microsoft-managed solution. Solution analysis isn't permitted on these solutions.
Checked by Publisher	This is a non-Microsoft managed solution. Currently, solution analysis isn't available for these solutions.

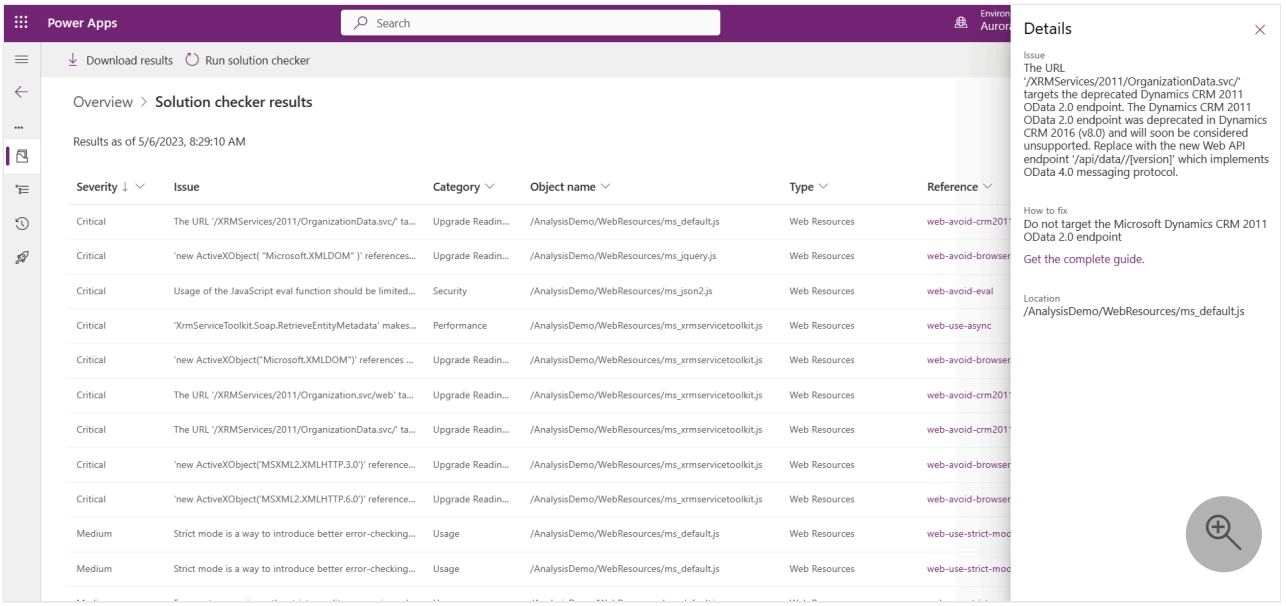
Review the solution checker report

When a solution check is completed, you can view the analysis report in the portal, or you can download the report from your web browser. In the portal, you have options to sort results by **Issue**, **Location** or by **Severity** and view detailed information for issues detected in your solution.

1. In the left pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.

2. Next to the unmanaged solution where you want to view the solution checker report, select **...**, point to **Solution checker**, and then select **View results**.

3. Select an issue to view the details and guidance on how to resolve.



The solution check results are also available for download. The solution checker zip file is downloaded to the folder specified by your web browser. The download report is in Excel format and contains several visualizations and columns that assist you in identifying the impact, type, and location of each issue detected in your solution. A link to detailed guidance about how to resolve the issue is also provided.

1. In the left pane, select **Solutions**. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Next to the unmanaged solution where you want to download the solution checker report, select **...**, point to **Solution checker**, and then select **Download results**.
3. The solution checker zip file is downloaded to the folder specified by your web browser.

Here's a summary of each column in the report.

Expand table

Report column	Description	Applies-to component
Issue	The title of the issue identified in the solution.	All
Category	The categorization of the issue identified, such as **Performance**, **Maintainability**, **Usage**, **Supportability**, **Design**, **Security**, **Accessibility**, or **Upgrade readiness**.	All
Severity	Represents the potential impact of the issue identified. Available impact types are **Critical**, **High**, **Medium**, **Low**, and **Informational**.	All
Guidance	Link to article detailing the issue, impact, and recommended action.	All
Component	The solution component where the issue was identified.	All
Location	The location and/or source file of the component where the issue that was identified occurred, such as the assembly or JavaScript file name.	All

Report column	Description	Applies-to component
Line #	The line number reference of the issue in the impacted web resource component.	Web resources
Module	Module name where the issue identified in the assembly was detected.	Custom workflow activity
Type	Type of the issue identified in the assembly.	Custom workflow activity
Member	Member of the issue identified in the assembly.	Custom workflow activity
Statement	The code statement or configuration that resulted in the issue.	All
Comments	Details about the issue that include high-level resolution steps.	All

Run solution checker rules locally

You can run solution checker rules in your development environment to detect issues much sooner as you create your solution resources. This is currently supported for web resources (JavaScript and TypeScript). For more details, go to the NPM package @microsoft/eslint-plugin-power-apps .

Run solution checker using PowerShell

A PowerShell module is available that you can use to interact directly with the service. The Microsoft.PowerApps.Checker.PowerShell module can be used for analysis of unmanaged solutions for Power Apps environments, or to automate and integrate the service into your build and release pipelines. More information: Microsoft.PowerApps.Checker.PowerShell Overview

Best practice rules used by solution checker

The following table lists the component type, rule description, severity, and category. Critical violations are blocked or warned when configured for solution checker enforcement with managed environments. More information: Use solution checker in Managed Environments

Expand table

Solution component	Rule name	Rule description	Severity	Category
Plug-in or workflow activity	meta-remove-dup-reg	Avoid duplicate Dataverse plug-in registrations.	Critical	Performance

Solution component	Rule name	Rule description	Severity	Category
Plug-in or workflow activity	meta-avoid-reg-no-attribute	Include filtering attributes with Dataverse plug-in registrations.	Medium	Performance
Plug-in or workflow activity	meta-avoid-reg-retrieve	Use caution with Dataverse plug-ins registered for Retrieve and RetrieveMultiple messages.	Medium	Performance
Plug-in or workflow activity	meta-remove-inactive	Remove inactive configurations in Dataverse.	Low	Maintainability
Plug-in or workflow activity	meta-avoid-crm4-event	Don't use Microsoft Dynamics CRM 4.0 plug-in registration stage.	Medium	Upgrade readiness
Plug-in or workflow activity	meta-avoid-retrievemultiple-annotation	Avoid registering a plugin on RetrieveMultiple of annotation.	High	Usage
Model-driven app	meta-license-sales-entity-operations	Solution contains entities with restricted SDK messages and operations that require a valid Dynamics 365 license.	Low	Licensing
Model-driven app	meta-license-fieldservice-customcontrols	Solution contains custom controls that require a valid Dynamics 365 Field Service license.	Low	Licensing
Model-driven app	meta-license-fieldservice-entity-operations	Solution contains entities with restricted SDK messages and operations that require a valid Dynamics 365 Field Service license.	Low	Licensing
Web Resources	use-async	Interact with HTTP and HTTPS resources asynchronously.	Critical	Performance
Web Resources	avoid-modals	Avoid using modal dialogs.	High	Supportability
Web Resources	avoid-dom-form		High	Supportability
Web Resources	avoid-dom-form-event		High	Supportability
Web Resources	avoid-crm2011-service-odata	Don't target the Microsoft Dynamics CRM 2011 OData 2.0 endpoint.	Critical	Upgrade readiness
Web Resources	avoid-crm2011-service-soap	Don't target the Microsoft Dynamics CRM 2011 SOAP services.	Critical	Upgrade readiness

Solution component	Rule name	Rule description	Severity	Category
Web Resources	avoid-loadtheme	Don't use `loadTheme` Fluent v8 API.	Low	Supportability
Web Resources	avoid-browser-specific-api	Don't use Internet Explorer legacy APIs or browser plug-ins.	Critical	Upgrade readiness
Web Resources	avoid-unpub-api		High	Supportability
Web Resources	avoid-window-top		High	Supportability
Web Resources	avoid-2011-api	Don't use the deprecated Microsoft Dynamics CRM 2011 object model. Instead follow Dataverse Web API documentation.	High	Upgrade readiness
Web Resources	use-relative-uri	Don't use absolute Dataverse endpoint URLs.	Medium	Maintainability
Web Resources	use-cached-webresource		Medium	Performance
Web Resources	use-client-context	Use client contexts.	Medium	Upgrade readiness
Web Resources	use-navigation-api	Use navigation API parameters.	Medium	Upgrade readiness
Web Resources	use-offline		Medium	Upgrade readiness
Web Resources	do-not-make-parent-assumption		High	Design
Web Resources	use-org-setting	Use organization settings.	Medium	Upgrade readiness
Web Resources	use-global-context		Medium	Upgrade readiness
Web Resources	use-grid-api	Use the grid APIs.	Medium	Upgrade readiness
Web Resources	use-utility-dialogs		Medium	Usage
Web Resources	avoid-isActivityType	Replace Xrm.Utility.isActivityType method with new Xrm.Utility.gettableMetadata and don't use in ribbon rules.	Medium	Upgrade readiness

Solution component	Rule name	Rule description	Severity	Category
Web Resources	meta-avoid-silverlight	Silverlight web resource usage is deprecated.	Medium	Upgrade readiness
Web Resources	remove-debug-script	Avoid including debug script in nondevelopment environments.	Medium	Usage
Web Resources	use-strict-mode	Use strict mode when possible.	Medium	Usage
Web Resources	use-strict-equality-operators	Use strict equality operators.	Medium	Usage
Web Resources	avoid-eval	Don't use the `eval` function or its functional equivalents.	Critical	Security
Web Resources	avoid-with	Don't use the 'with' operator.	High	Performance
Web Resources	remove-alert	Don't use the 'alert' function or its functional equivalents.	Medium	Usage
Web Resources	remove-console	Avoid using methods on console.	Medium	Usage
Web Resources	avoid-ui-refreshribbon	Avoid using refreshRibbon in form onload and EnableRule.	Critical	Performance
Web Resources	use-getsecurityroleprivilegesinfo	Avoid userSettings.securityRolePrivileges. Use userSettings.getSecurityRolePrivilegesInfo instead.	High	Performance
Web Resources	use-appsidepane-api	Use Xrm.App.sidePanes.createPane instead of Xrm.Panels.loadPanel.	Medium	Upgrade readiness
Web Resources	web-sdl-no-cookies	HTTP cookies are an old client-side storage mechanism with inherent risks and limitations. Use Web Storage, IndexedDB, or other modern methods instead.	Medium	Security
Web Resources	web-sdl-no-document-domain	Writes to document.domain property must be reviewed to avoid bypass of same-origin checks. Usage of top level domains such as azurewebsites.net is strictly prohibited.	Medium	Security
Web Resources	web-sdl-no-document-write	Calls to document.write or document.writeln manipulate DOM directly without any sanitization and should be avoided. Use	Medium	Security

Solution component	Rule name	Rule description	Severity	Category
		document.createElement() or similar methods instead.		
Web Resources	web-sdl-no-html-method	Direct calls to method html() often (for example, in jQuery framework) manipulate DOM without any sanitization and should be avoided. Use document.createElement() or similar methods instead.	Medium	Security
Web Resources	web-sdl-no-inner-html	Assignments to innerHTML or outerHTML properties manipulate DOM directly without any sanitization and should be avoided. Use document.createElement() or similar methods instead.	Medium	Security
Web Resources	web-sdl-no-insecure-url	Insecure protocols such as HTTP or FTP should be replaced by their encrypted counterparts (HTTPS, FTPS) to avoid sending potentially sensitive data over untrusted networks in plaintext.	Medium	Security
Web Resources	web-sdl-no-msapp-exec-unsafe	Calls to MSApp.execUnsafeLocalFunction() bypass script injection validation and should be avoided.	Medium	Security
Web Resources	web-sdl-no-postmessage-star-origin	Always provide specific target origin, not * when sending data to other windows using postMessage to avoid data leakage outside of trust boundary.	Medium	Security
Web Resources	web-sdl-no-winjs-html-unsafe	Calls to WinJS.Utilities.setInnerHTMLUnsafe() and similar methods don't perform any input validation and should be avoided. Use WinJS.Utilities.setInnerHTML() instead.	Medium	Security
Canvas App	app-formula-issues-high	Go to Power Apps formula reference for additional details.	Critical	Design
Canvas App	app-formula-issues-medium	Refer to Power Apps formula references for additional details.	Medium	Design
Canvas App	app-formula-issues-low	Refer to Power Apps formula references for additional details.	Low	Design
Canvas App	app-use-delayoutput-text-input	Use delayed load in some scenarios to improve performance.	Medium	Performance

Solution component	Rule name	Rule description	Severity	Category
Canvas App	app-reduce-screen-controls	Limit the number of app controls for improved performance.	Medium	Performance
Canvas App	app-include-accessible-label	Use explicit labels to improve app accessibility.	Medium	Accessibility
Canvas App	app-include-alternative-input	Ensure all interactive elements are accessible to alternative inputs.	Medium	Accessibility
Canvas App	app-avoid-autostart	Avoid using autostart on players within an app.	Medium	Accessibility
Desktop flow	desktopflow-avoid-unsafe-password	Passwords are managed insecurely in the flow.	High	Security
Desktop flow	desktopflow-avoid-subflow-recursion	Recursive calls detected between subflows, potentially causing an infinite loop.	Medium	Design
Desktop flow	desktopflow-avoid-infinite-loop	Infinite loop detected in the flow, potentially causing it to run indefinitely.	Medium	Design
Desktop flow	desktopflow-avoid-incomplete-if-branch	Incomplete If action detected, lacking content or only containing actions in the Else branch.	Low	Design
Desktop flow	desktopflow-avoid-excessive-nested-ifs	Nested If clauses exceed five levels.	Low	Maintainability
Desktop flow	desktopflow-avoid-empty-on-error-block	"On block error" action is empty and not handling errors.	Low	Design
Desktop flow	desktopflow-limit-argument-count	Total input/output variables exceed the 25-variable limit.	Low	Maintainability
Desktop flow	desktopflow-input-argument-default-value	Input/output variables aren't using default values.	Low	Maintainability
Desktop flow	desktopflow-limit-variable-name-length	Variable name exceeds the 25-character limit.	Low	Maintainability
Desktop flow	desktopflow-avoid-excessive-wait-actions	Misuse of wait actions detected, with more than 10 wait actions causing potential bottlenecks.	Low	Performance
Desktop flow	desktopflow-avoid-immense-wait-duration	Immense wait time detected, exceeding the 600-second limit for hardcoded wait actions.	Low	Performance

Common issues and resolutions for Solution Checker

ⓘ **Note:** The author created this article with assistance from AI. Learn more

Common issues and resolutions for solution checker

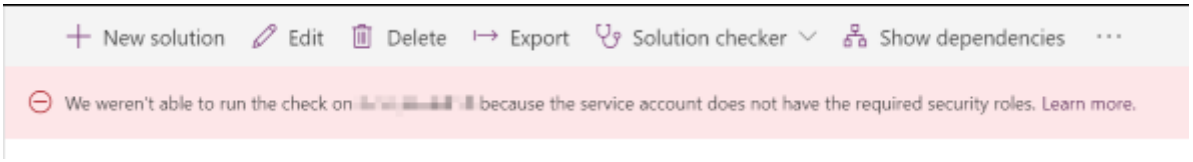
This article lists some common issues that you might encounter while using solution checker. Where applicable, workarounds are provided.

You're unable to use solution checker to run analysis or download results

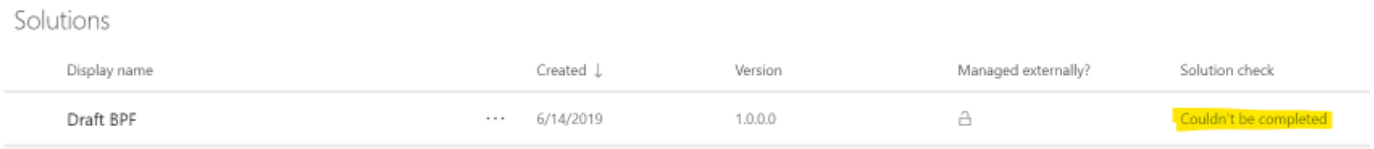
Shortly after submitting a solution checker request to run an analysis or download results the operation doesn't complete and an error message is displayed, such as:

> "*We weren't able to run the check on **[Solution Name]** solution. Try running it again.*"

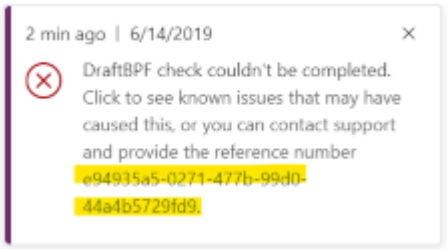
Whenever possible, solution checker attempts to return a specific error message with a link to details about the potential cause and resolution steps. Select **'Learn more'** for details.



Failures that occur during background processing of the analysis will fail with **'Couldn't be completed'** status and return an error message in the Power Apps portal as well as send email notification to the requestor.



Selecting the portal notification will link to this page of common issues for further troubleshooting. If one of the provided common issues doesn't resolve the problem, a reference number is also returned. Provide this reference number to Microsoft Support for further investigation.



Solution checker fails to check Default solution

Solution checker exports the solution from the Microsoft Power Platform environment for analysis. Exporting the Default solution isn't supported and the check may not complete successfully. More information: Solution Checker fails to export large solutions.

Solution checker fails due to unsupported version of Power Apps Checker

Solution checker is a feature enabled by the Power Apps Checker app. If you have installed a Power Apps Checker app version earlier than version **1.0.0.47**, solution checker runs may fail to complete successfully. You should upgrade your Power Apps Checker version from the Power Platform admin center.

However, if you have a Power Apps Checker version earlier than version **1.0.0.45** installed, we recommend that you delete the solution and install it again. Due to recent schema changes, upgrade of Power Apps Checker from versions earlier than version **1.0.0.45** may fail.

If you want to keep the past results from solution checker, export the results from a previous run or export all solution checker data using Export data to Excel to export the data from the following tables:

- Analysis Component
- Analysis Job
- Analysis Result
- Analysis Result Detail

How to uninstall Power Apps Checker

To uninstall the Power Apps Checker solution:

1. As a System Administrator or as a System Customizer, open the Power Apps portal by going to https://make.powerapps.com/environments.
2. Select **Solutions**.

3. Select **Power Apps Checker**, and then on the solutions toolbar select **Delete**.

How to install Power Apps Checker

To install Power Apps Checker back into your environment:

1. As a System Administrator or as a System Customizer, open up your Power Apps portal by going to https://make.powerapps.com/environments.
2. Select **Solutions**.
3. On the solution toolbar select **Solution checker**, and then select **Install**.

Solution checker can't access environments in Administration Mode

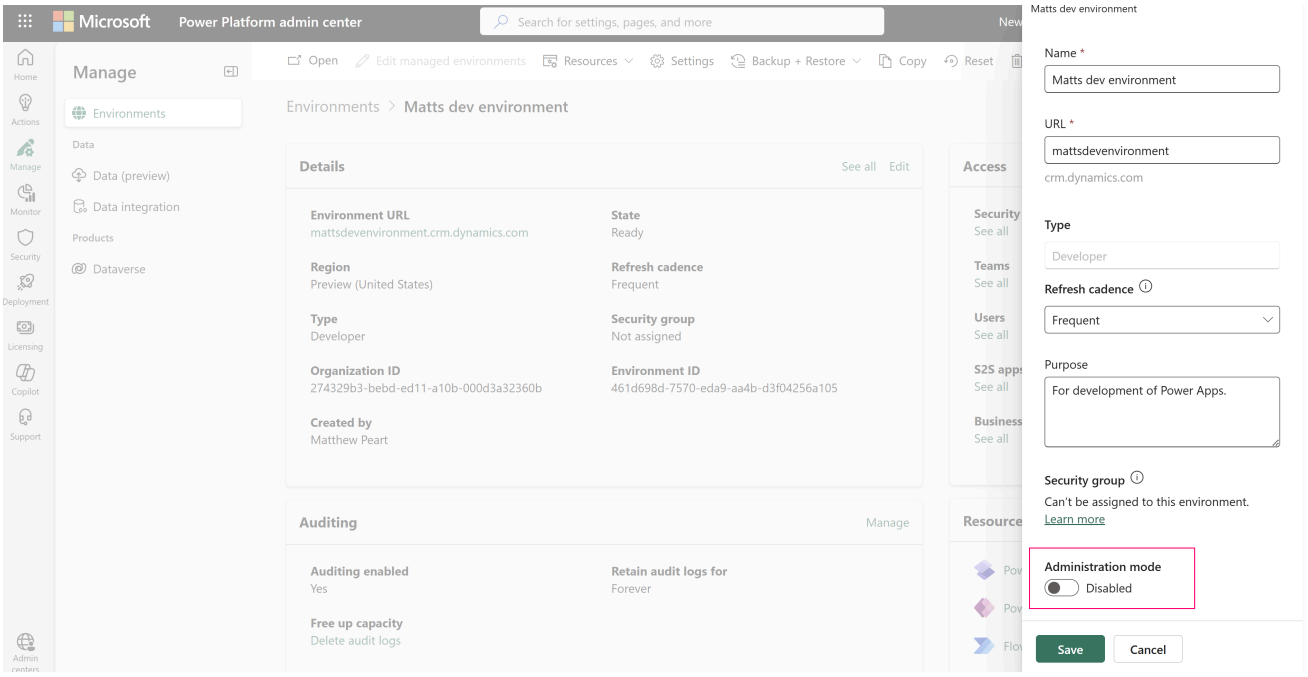
Environments that have been placed into Administration Mode purposely restrict access to only users with System Administrator and System Customizer roles. Because the Power Apps Checker application identity has neither of these roles assigned by default, it can't access organizations operating in this mode.

In order to use solution checker in this organization, Administration Mode must be disabled.

How to disable administration mode

To disable administration mode for an organization instance:

1. Sign in to the Power Platform admin center.
2. Open the environment that has issues running solution checker, and then select **Edit**.
3. Set **Administration mode** to **Disabled**, and then select **Save**.



4. Run solution checker again.

Solution checker fails due to missing security roles

The application user for solution checker requires the following security roles assigned in order to provide the necessary privileges to communicate with the Dataverse organization. If any of these roles aren't assigned to the user '**Power Apps Checker Application**', attempts to run analysis, download results, and run cancellation will fail. This occurs most often when customers have automation in place that removes security roles from unexpected users. The following security roles contain minimum required permissions:

- Export Customizations (Solution Checker)
- Service Writer
- Solution Checker

How to assign missing security roles

To assign missing security roles to the Power Apps Checker Application user:

1. In the Power Platform admin center, open your environment, then select **Users** > **app users list**.
2. Select the **Power Apps Checker Application** user from the list of users.
3. Select **Edit security roles** on the command bar.
4. Select checkboxes for the roles listed above, and then select **Save**.
5. Run solution checker again.

Solution checker fails due to restricted access mode

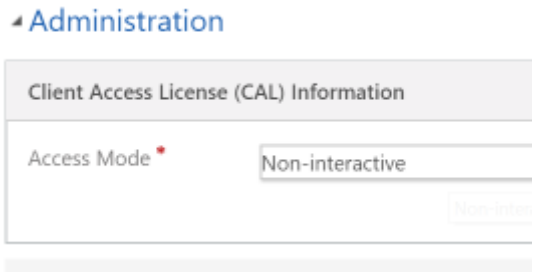
The application user for solution checker requires an access mode of **'Non-Interactive'** or **'Read-Write'** in order to communicate with the Dataverse organization. If the access mode has been changed to another value such as **'Administrative'**, then attempts to run analysis, download results, and run cancellation will fail.

To resolve this issue, you must update the **Power Apps Checker Application** user with 'Non-interactive' access mode.

How to update user access mode

To update the access mode for the Power Apps Checker user:

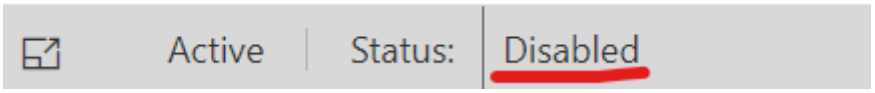
1. In Power Apps (make.powerapps.com) select you environment and then select **Settings** > **Advanced settings** > **Administration** > **Users** to open the legacy user settings.
2. Open the **Power Apps Checker Application** user from the list of users.
3. Scroll to the **Administration** > **Client Access License (CAL) Information** section of the form and select **'Non-interactive'** in the **Access Mode** drop-down control.



4. Save and close the user form.
5. Run solution checker again.

Solution Checker fails due to disabled application user

The Power Apps Checker application user in the Dataverse organization containing solutions to be analyzed must be enabled. If the application user becomes disabled, requests to analyze solutions in the same organization will fail. If receiving this error message, first verify that the Power Apps Checker application user is indeed disabled. Then follow the mitigation steps provided below.



How to activate the Power Apps Checker application user

1. In the Power Platform Admin center, open the environment and go to **Settings** > **User's + Permissions** > **Users**.
2. In the **Application Users** view, select the **Power Apps Checker Application** user.
3. On the command bar, select **Activate**
4. In the **Confirm User Activation** message, select **Activate**.

Solution checker remains in a Running state for more than 30 minutes

Solution checker may remain in a running state indefinitely if the analyzed solution contains plugin components developed using .NET Standard 2.0. Plugins using .NET Standard 2.0 aren't currently supported in solution checker and should be excluded from analysis. Exclude the plugin component by either removing it from the target solution, or by using the 'ExcludedFileNamePattern' parameter in the Power Apps Checker PowerShell module.

Common plugin conditions that cause solution checker to fail

When solution checker receives and processes analysis requests, it must call the Dataverse endpoint to retrieve/update relevant job data and export the selected solution(s). Each interaction made by the solution checker service with the Dataverse could potentially trigger one or more plugin steps that have been registered on message submitted in the request. These plugins may in turn introduce conditions that prevent the message from being handled as expected by the Dataverse and interrupt the ability of solution checker to process the requested analysis job. Similar situations can occur when downloading solution checker job results or canceling an in-progress analysis job.

Typical Dataverse operations requested by solution checker:

- Retrieve solution, `systemuser`, and organization table data
- Create, update, and retrieve analysis job, analysis component, and analysis result table data
- Export solutions

Plugin step registered to execute in context of an unlicensed user

When solution checker fails due to an "unlicensed user" exception, it's often caused by a triggered plugin step configured to execute in the context of a specific system user that is currently unlicensed. Ensure that any plugin steps that could be triggered by solution checker execute in context of a licensed user.

> **Important**
>
> It is highly recommended that plugin steps be configured to execute in context of the calling user rather than specific users which are subject to assigned license being revoked.

Plugin step performs operations that require privileges not granted to Power Apps Checker application user

When solution checker fails due to Dataverse denying access based on a missing privilege, it's often caused by a triggered plugin step that performs operations that require privileges not currently granted to the Power Apps Checker application user. Either reconfigure the plugin step to not execute on the operation invoked by solution checker or grant the Power Apps Checker application user the necessary privileges to execute the custom plugin step.

Plugin step unexpectedly interrupts execution by throwing InvalidPluginExecutionException

Solution checker may fail due to the errors "ISV code aborted the operation" or "An unexpected error occurred from ISV code". When this occurs, it indicates a plugin step was triggered that explicitly interrupted execution by throwing an InvalidPluginExcecutionException or that an error wasn't caught properly in plugin code. Either reconfigure the plugin step to not execute on the operation invoked by solution checker or adjust the plugin implementation not to interrupt execution based on the conditions presented by solution checker.

Common operations invoked by solution checker include Create and Update. These operations can occur on the following tables: Analysis Job, Analysis Component, or Analysis Result.

Solution checker fails due to disabled first-party application in Microsoft Entra ID

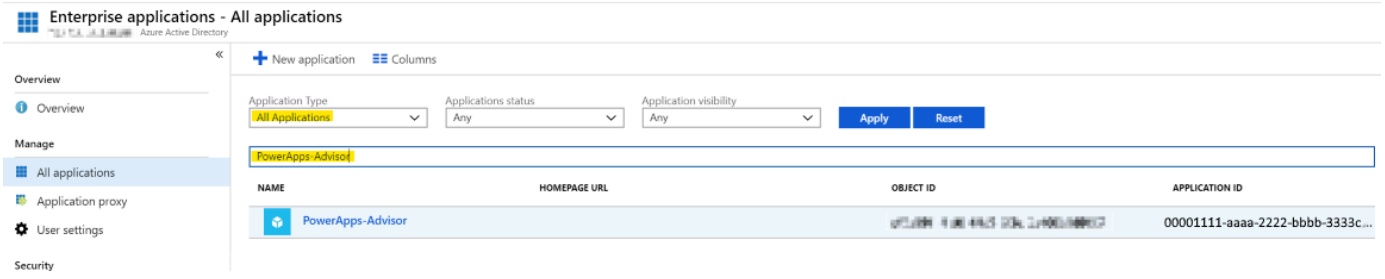
The first-party enterprise application identity used by solution checker (PowerApps-Advisor) shouldn't be disabled in Microsoft Entra ID. If disabled, the identity can't authenticate when requesting bearer tokens for Dataverse and other required resource providers on-behalf of the requesting user.

Follow the below steps to verify that the application identity hasn't been disabled in Microsoft Entra and if necessary enable the application.

How to verify and/or modify application enabled status

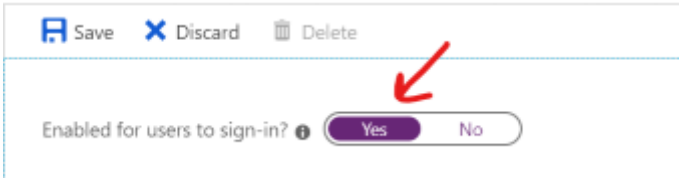
To verify and/or modify the enabled status of the PowerApps-Advisor enterprise application identity

1. Access your tenant in the Microsoft Entra Portal.
2. Navigate to **Enterprise Applications**.
3. Select **All Application** and search for **'PowerApps-Advisor'**.



4. Select **'PowerApps-Advisor'** to view the app details.
5. Select **Properties**.
6. Check the state of **Enabled for users to sign in**. If **'No'**, then the application has been disabled.

7. Select the radio control to switch the value to **'Yes'**. This enables the application.



8. Select **Save**. The application is now enabled. You may need to wait a few minutes for change to propagate.
9. Run solution checker again.

> **Important**
>
> You must have administrator privileges in Microsoft Entra ID (Microsoft Entra ID) in order to edit enterprise applications.

Solution checker fails to export solutions with draft business process flow components

If a solution contains a business process flow component in draft state that has never been previously activated, then solution checker will fail to export the solution for analysis. This error isn't unique to solution checker and is caused by the business process flow having a dependency on a backing (custom) table component that doesn't get created until the business process flow is activated for the first time. This issue can also occur if a business process flow is activated from within solution explorer.

Reference KB Article #4337537: Invalid Export - Business Process table Missing for details about the issue and steps to resolve.

Solution checker fails to export solutions with model-driven app components

If a solution contains a model-driven app, solution checker might fail to export the solution for analysis. This error is caused by role-based security for sharing of apps. If the Power Apps Checker application user doesn't have appropriate access to model-driven apps, any solutions containing them will fail to export with solution checker.

To resolve this issue, grant the **Environment Maker** security role to the Power Apps Checker application user.

Solution checker fails to export patched solutions

If a solution has had a patch applied, solution checker will fail to export the solution for analysis. When a solution has had a patch applied, the original solution becomes locked and it can't be

changed or exported as long as there are dependent patches that exist in the organization that identify the solution as the parent solution.

To resolve this issue, clone the solution so that all patches related to the solution are rolled into the newly created solution. This unlocks the solution and allows the solution to be exported from the system. For more information, see Clone a Solution.

Solution checker won't analyze empty solutions

If solution checker exports a solution that contains no components to analyze, it terminates further processing and consider the run a failure. Ensure that the selected solution submitted for a solution checker analysis contains at least one component.

Solution checker fails to export large solutions

The primary scenario for failure to export a large solution from the environment involves a timeout exception on the export request. This occurs if the request exceeds 20 minutes. Large solutions, such as the Default Solution, may fail to get exported within this time frame, and the check won't complete successfully. If solution checker encounters a timeout during export, it retries three times before it fails to process the job, so it may take over an hour before you receive a failure notification.

The workaround is to create smaller solutions with fewer components to be analyzed. If the large file size of the solution is due to many plug-in assembly components, see guidance to Optimize custom assembly development.

> **Important**
>
> To minimize false positives, ensure you add dependent customizations. When you create a solution and add these components, include the following:
>
> - When you add plug-ins, include the SDK Message Processing Steps for the plug-in.
> - When you add table forms, include the JavaScript web resources attached to the form events.
> - When you add JavaScript web resources, include any dependent JavaScript web resources.
> - When you add HTML web resources, include any dependent scripts that are defined within the HTML web resource.

- When you add custom workflows, include the assembly used within the workflow.

Line number references for issues in HTML resources with embedded JavaScript aren't correct

When HTML web resources are processed within solution checker, the HTML web resource is processed separately than the JavaScript within the HTML web resource. Due to this, the line number of the violation found within `<script>` of the HTML web resource won't be correct.

Web-unsupported-syntax issue for web resources

Solution checker supports global variables for ECMAScript 2015 (ES6) and up to ECMAScript 2018 (ES9) syntax. When solution checker analyzes JavaScript using global variables later than ES6, or syntax later than ES9, a web-unsupported-syntax issue for the web resource is reported.

Multiple violations reported for plug-ins and workflow activities based on call scope

For plug-in and workflow activity rules where the issue is only relevant in the calling context, the solution checker tool starts its analysis at the `IPlugin` interface implementation and traverses a call graph to detect issues within the scope of that implementation. In some cases, many call paths may arrive at the same location where the issue is detected. Since the issue is relevant to the call scope, the tool may report based on that scope to provide a better picture of impact rather than on distinct locations. As a result, multiple issues may reference a single location that should be fixed.

app-formula-issues-high may show different number of errors than those shown in design mode

The solution checker lists the number of the errors found in the app, *including those from tests*. The app checker in design mode only shows errors from screen controls and components. If the error count shown in the app checker in design mode is smaller, open the Test Studio and search for the errors in the expressions used in tests.

Solution checker violations reported for code components

Solution checker reports multiple violations when run on the solution that has code components built in debug mode. One common error that occurs in debug mode is `web-avoid-eval`. Solution checker is targeted to validate code for production use, thus code components must be built using proper buildMode: `npm run build -- --buildMode production` or `msbuild /p:configuration=Release` depending on your building system. More information: Create and build a code component

If there are errors occurring in `bundle.js` introduced by code components, you can exclude this file from analysis. More information: Microsoft.PowerApps.Checker.PowerShell module and PAC CLI

Best practices and guidance for the Dataverse

Best practices and guidance for model-driven apps

Last updated on 06/12/2023

`avoid-2011-api`

Article • 07/18/2022

Don't use the deprecated Microsoft Dynamics CRM 2011 object model. Instead, follow Dataverse Web API documentation.

`avoid-browser-specific-api`

Article • 07/18/2022

Don't use Internet Explorer legacy APIs or browser plug-ins.

Recommendation

Examples of APIs you shouldn't use include `XMLHTTP`, `XMLDOM`, and `DOMDocument`.

`avoid-crm2011-service-odata`

Article • 07/18/2022

Don't target the Microsoft Dynamics CRM 2011 OData 2.0 endpoint.

Recommendation

More information: Odata V2 Deprecation notice.

`avoid-crm2011-service-soap`

Article • 09/09/2023

Don't target the Microsoft Dynamics CRM 2011 SOAP services.

Recommendation

For details on the correct Dataverse services to use, go to Microsoft Dataverse SDK for .NET.

`avoid-dom-form`

Article • 02/14/2023

Don't use the Document Object Model (DOM) of model-driven apps directly. This isn't a supported approach in Dynamics 365 or Power Apps. Use the supported Client API object model instead.

Options

- By default, violations are only reported when certain `Xrm` or `Mscrm` calls are made in the same file, so that violations outside of Dataverse are not reported. The `requireXrm` option, which is `true` by default, can be set to `false` to report all violations regardless of `Xrm` or `Mscrm` usage
  - Example: `"@microsoft/power-apps/avoid-dom-form": ["error", { requireXrm: false }]`

`avoid-dom-form-event`

Article • 02/14/2023

Don't register or unregister handles to the Document Object Model (DOM) events of model-driven apps. This isn't a supported approach in Dynamics 365 or Power Apps. Use the supported Client-side event handlers instead.

Options

- By default, violations are only reported when certain `Xrm` or `Mscrm` calls are made in the same file, so that violations outside of Dataverse are not reported. The `requireXrm` option, which is `true` by default, can be set to `false` to report all violations regardless of `Xrm` or `Mscrm` usage
  - Example: `"@microsoft/power-apps/avoid-dom-form-event": ["error", { requireXrm: false }]`

`avoid-isactivitytype`

Article • 07/21/2022

Replace `Xrm.Utility.isActivityType` with `Xrm.Utility.getEntityMetadata` and don't use in ribbon rules.

Recommendation

For details on the correct Xrm.Utility functions go to the Xrm.Utility.getEntityMetadata documentation.

`avoid-loadtheme`

Article • 02/27/2023

`loadTheme` is a way to provide a theme in global (and only global) scope, which will affect your entire application. We recommend that you replace `loadTheme` with `ThemeProvider`. That way, your application consistently has one way of providing a theme.

Recommendation

For details on the correct `ThemeProvider` usage go to the ThemeProvider documentation.

`avoid-modals`

Article • 10/20/2022

Avoid using `showModalDialog()`.

Recommendation

Instead, go to the documentation for the XRM Navigation API.

`avoid-ui-refreshribbon`

Article • 07/18/2022

Don't use `ui.refreshRibbon` during evaluation of ribbon rules. This API triggers duplicated network calls from ribbon and degrades performance. Use promises and asynchronous patterns.

`avoid-unpub-api`

Article • 07/18/2022

Avoid using unpublished (private) functionality as it is not guaranteed to continue working and utilizing it may break your code in the future.

Recommendation

Avoid using unsupported namespaces, global objects, global functions, and CSS styles.

`avoid-window-top`

Article • 07/21/2022

Don't use `window.top` or `window.parent.parent`. Using either of these fields will likely result in cross-origin security errors when hosted outside of the primary web client. Develop an alternate approach. For more information, go to best practices: avoid-window-top.

`do-not-make-parent-assumption`

Article • 07/21/2022

Don't assume that the usage of `global.parent`, `window.parent`, `window.opener`, or `this.parent` from JavaScript web resources will result in the same context across versions or client types, for example mobile, tablet, and browser. Consider a different approach when attempting to interact with one of these contexts. For more information, go to best practices: avoid-window-top.

`use-appsidepane-api`

Article • 10/24/2023

Use Xrm.App.sidePanes.createPane instead of Xrm.Panels.loadPanel.

Recommendation

The Xrm.Panels.loadPanel API is being replaced with Xrm.App.sidePanes.createPane because the former only supports a single pane while the latter supports multiple panes. For more information, go to Use with Xrm.App.panels.loadPanel.

`use-async`

Article • 07/18/2022

Interact with HTTP and HTTPS resources asynchronously.

Recommendation

For more information, go to asynchronous HTTP best practices.

`use-cached-webresource`

Article • 07/21/2022

Don't use a relative or absolute URL that retrieves a web resource from the server rather than from the cache. Web resource URLs should always be relative to ensure caching support. Additionally, don't include `/WebResources/` within the URL path as it will refer to the caller's default organization.

`use-client-context`

Article • 07/18/2022

Don't use `Xrm.Page`. Although `Xrm.Page` is deprecated, `parent.Xrm.Page` will continue to work with HTML web resources embedded in forms as this is the only way to access the form context from the HTML web resource. For a more comprehensive list of appropriate replacements for `Xrm.Page` functionality, go to Client API Deprecations.

`use-getsecurityroleprivilegesinfo`

Article • 07/18/2022

Avoid `userSettings.securityRolePrivileges`. This returns only privilege GUIDs, which are difficult to work with. You might be making extra network requests to get further details about the privilege GUID and that degrades performance. Use userSettings.getSecurityRolePrivilegesInfo() instead, which gives you more details about each security role privilege.

`use-global-context`

Article • 07/18/2022

Don't use `Xrm.Page.context`. For access to the global context use `Xrm.Utility.getGlobalContext`.

Recommendation

For more detail on appropriate replacement APIs, go to Client API deprecations.

`use-grid-api`

Article • 07/21/2022

Don't use deprecated APIs in the grid object model. Replace these calls with the `data` property of the grid row object.

Recommendation

For more detail on the specific replacement calls, go to Client API deprecations.

`use-navigation-api`

Article • 07/18/2022

Use navigation API parameters instead of utility parameters.

Recommendation

For more information on deprecations and the associated replacements, go to Client API deprecations.

`use-offline`

Article • 07/18/2022

Don't use `Xrm.Mobile.offline`. Instead, use `Xrm.WebApi.offline.`

Recommendation

For a more comprehensive list of deprecations and replacements, go to Client API deprecations.

`use-org-setting`

Article • 07/18/2022

Use organization settings. Specifically:

- Calls to `Xrm.Page.context.getIsAutoSaveEnabled()` should be replaced with `Xrm.Utility.getGlobalContext().organizationSettings.isAutoSaveEnabled`
- Calls to `Xrm.Page.context.getOrgLcid()` should be replaced with `Xrm.Utility.getGlobalContext().organizationSettings.languageId`
- Calls to `Xrm.Page.context.getOrgUniqueName()` should be replaced with `Xrm.Utility.getGlobalContext().organizationSettings.uniqueName`

Recommendation

For more information, go to Client API deprecations.

`use-relative-uri`

Article • 07/18/2022

Don't use absolute Microsoft Dataverse endpoint URLs.

Recommendation

Don't use an absolute reference to a Microsoft Dataverse endpoint. Microsoft Dataverse endpoint URLs should be constructed using the appropriate client API function along with a relative path to the desired endpoint.

`use-utility-dialogs`

Article • 02/14/2023

Use Web API dialogs in form and ribbon commands.

Recommendation

Alerts should be replaced with `Xrm.Navigation.openAlertDialog`, while confirms should be replaced with `Xrm.Navigation.openConfirmDialog`. For more information, go to Xrm.Navigation.

Options

- By default, violations are only reported when certain `Xrm` or `Mscrm` calls are made in the same file, so that violations outside of Dataverse are not reported. The `requireXrm` option, which is `true` by default, can be set to `false` to report all violations regardless of `Xrm` or `Mscrm` usage
  - Example: `"@microsoft/power-apps/use-utility-dialogs": ["error", { requireXrm: false }]`

Catalog in Power Platform

Building from scratch every time by recreating branding, layouts, links, complex connectors and flows, and more is painful and error-prone. Organizations where developers and makers build and share customized and reusable components and templates get more value from Power Platform. Successful organizations adopt a *fusion teams* model where pro-developers, makers, and admins all work together to deliver the best solutions for their users, and derive the highest value possible from Power Platform.

> **ⓘ Important**
>
> - The catalog needs to be set up by an admin before you can use it, including permissions. More information Administer the catalog.
> - The catalog only works with Microsoft Dataverse environments. Environments without Dataverse aren't supported at this time.
> - You need a Managed Environment in order to submit solutions to the catalog. However, you can install catalog items from any environment. More information: Managed Environments overview

In any organization, there might be many components and templates distributed among many environments. The catalog in Power Platform enables developers and makers to:

- Crowd-source and find templates and components within their organization easily
- Find and install the latest and authoritative version of a component
- Get started with templates and components that provide immediate value

Components include things like:

- AI prompts
- Copilot app templates
- AI plugins
- Power Platform dataflows
- Custom connectors
- Power Apps component framework controls
- Power Automate flows
- Canvas apps
- Model-driven apps

Templates are items that represent an advanced starting point for components. Templates connect to their enterprise systems and resources and utilize an organization's themes.

Terminology

These terms are important to understand when using the catalog:

Expand table

Term	Description
Catalog Item	The unit of interaction with the catalog is called an item. - An item is what is being submitted to or installed from the catalog. - Typically, an item is a Dataverse solution or package deployer package. An item can contain a fully built application, a template for a Power App or flow, or a Power Platform code-first component such as a custom connector or Power Apps component framework (PCF) control.
Catalog Publisher	The owning entity of the application. For example, the publisher can be the human resources IT team or another line of business team. - A group of people in an organization that are responsible for managing its lifecycle. - Support and engineering contacts can be provided. - Note that the catalog publisher is different from the solution publisher.
Submission	The act of sharing an item involves submitting it to the catalog. This act creates a *submission request* in the system.
Submission Request	The result of a submission. This request can be approved or declined. When auto approval is configured for the catalog, no approval is required.
Discovery	Act of finding items within a catalog by authorized users.
Acquisition	Act of installing the item to a target environment by a developer.

Catalog basics

The catalog needs to be set up by an admin before you can use it, including privileges. More information: Administer the catalog.

You might choose to have multiple catalogs across environments for different regions, departments, or any group. Most organizations only need one catalog. A catalog admin can set up new catalogs in the Power Platform admin center.

You can submit unmanaged solutions to the catalog for other makers to install and use for themselves, as one of these two catalog item types:

- A **template**: A copy of your unmanaged solution that other makers can edit however they choose. Updates to the original unmanaged solution won't update templates, as templates are no longer "connected" to the solution it came from. If you want other

makers to have the ability to change the catalog components as they see fit, use a template.

> **Note**
>
> Currently, certain components aren't supported for use as templates. The supported components for templates are:
> - Table and its sub components like forms, saved queries, relationships, table maps.
> - Environment variables.
> - Canvas apps.
> - Modern workflows.
> - `AiModel` and its subcomponents like `AiConfig`.
> - Web resources.
> - Power Apps component framework components. This includes modern solution aware components created using the Power Apps component framework. For example custom API, `AiPlugin`, and `AIPlugin` operation.

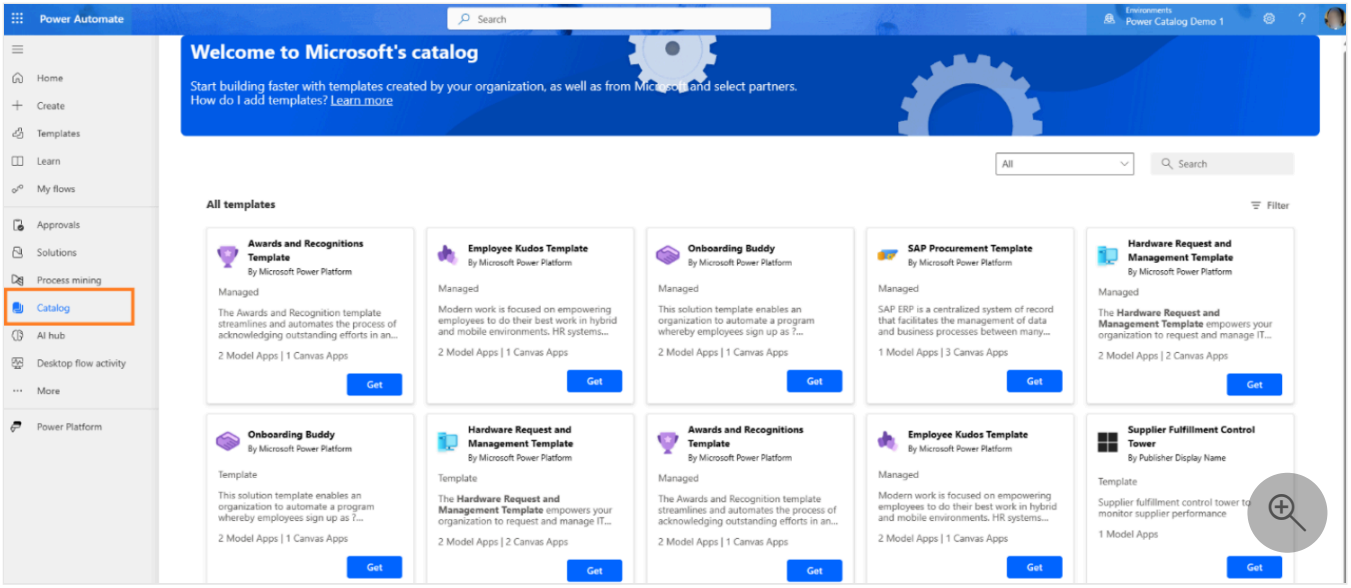
- A **managed item**: Managed items can be updated with more versions as the original solution is updated, but are generally restricted from editing. If you want makers to use your solution *as is* and you also want to keep copies updated with your changes in the future, use a managed item. Managed items are useful for a variety of scenarios for makers:
  - Use the assets of the managed item as is and make no changes.
  - Build custom functionality on top of the assets in the managed item without changing the original components.
  - Use the assets to assist with building your own solutions. For example, PCF components, custom connectors, and so on.

Admins can administer catalogs, manage access and security, approve catalog items, and more in the Catalog Manager, which is the dedicated workspace for admins of the catalog. The catalog itself is designed for makers of any level of experience to publish, discover, and acquire useful catalog items for themselves.

Discovery

The catalog area is available in Power Apps and Power Automate. On the catalog page are tiles representing all catalog items available to your organization. This includes items published by your organization, approved partners who have access to your environments, as well as many

published by Microsoft, such as AI prompts, Copilot app templates, dataflow templates, enterprise templates, PCF controls, plug-ins, and more.



On the page itself are the following controls:

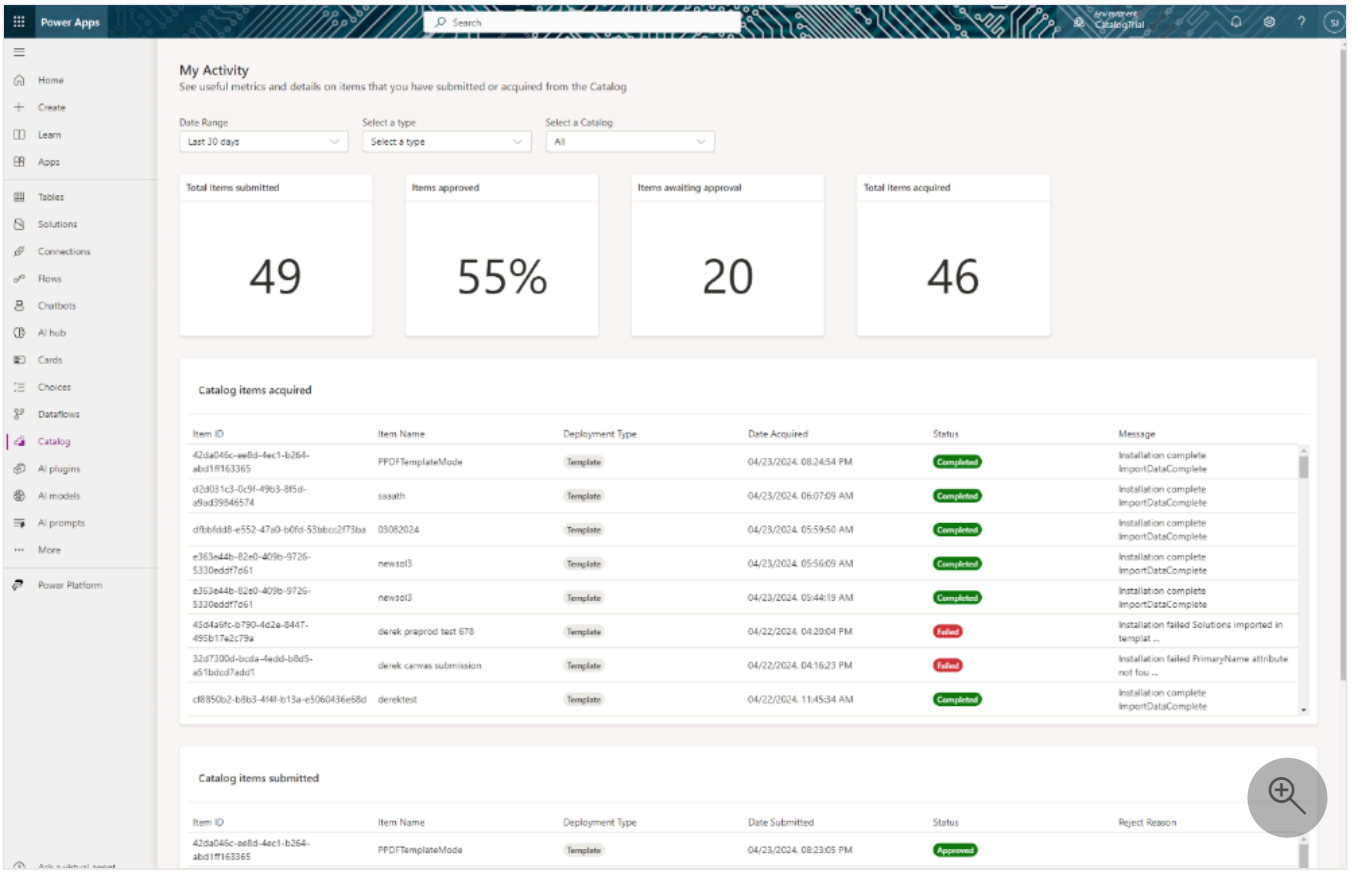
- Search box (searches the titles of available catalog items)
- Filters (filters for publisher, type, category, and more)
- Catalog selector (some organizations might choose to create multiple catalogs for regions or departments). Users can have access to one or more catalogs.

The list of Microsoft published catalog items that will be available in your catalog out of the box are:

- AI Prompts
- Copilot app templates
- Enterprise templates
- Power Platform dataflows
- PCF controls
- Plug-ins
- Retail cloud templates
- Copilot agents

My Activity

Linked in the banner of the catalog page is the **My Activity** page. This shows useful info on items you have submitted and acquired, including approval status.



Filters on top of the page allow you to look at different date ranges, types of catalog items, and across different catalogs (if you have multiple catalogs set up in your tenant).

- Metrics on this page:
  - **Total items submitted**: Sum of all items you submitted.
  - **Items approved**: Sum of all items you submitted that were approved by your admin.
  - **Items awaiting approval**: Sum of all items you submitted that your admin has not responded to yet.
  - **Items acquired**: Sum of all items you acquired from the catalog.

- Catalog items acquired table:
  - **Item ID**: Unique identifier for the acquired item.
  - **Item name**: Display name for the acquired item.
  - **Deployment type**: Whether item is a template or managed.
  - **Date acquired**: Date item was last acquired.
  - **Status**: Current status of the acquired item, such as completed or failed.
  - **Message**: Status message, can explain why an item failed.

- Catalog items submitted table:
  - **Item ID**: Unique identifier for the submitted item.
  - **Item name**: Display name for the submitted item.
  - **Deployment type**: Whether item is a template or managed.
  - **Date submitted**: Date item was last submitted.

- **Status**: Current status of the submitted item, such as approved, rejected, or pending approval.
- **Reject reason**: Why a submitted item was rejected by an admin.

Frequently asked questions (FAQ)

The following are frequently asked questions related to catalog in Power Platform.

Where do I provide feedback on catalog?

Ask questions and submit feedback at: github.com/microsoft/PowerPlatform-Catalog/discussions

What are the items in the catalog?

The catalog items are actually packages. A package contains one or more solutions and some metadata. The Power Apps experiences can submit individual solutions. The Power Platform CLI experience can be used to create a package containing multiple solutions.

What are solution templates? What does it mean to install an unmanaged solution?

The use of a solution as a *solution template* is a new scenario we're making available with the catalog. When a maker acquires a solution template, they'll get a new unmanaged copy of that solution. Multiple copies of that unmanaged solution can exist in the same environment and each has a unique identifier.

Catalog item install looks a lot like solution import. Are they the same thing?

A catalog item is a package that contains one or more solutions. Installation of a package containing a single solution with no other package configuration looks similar to a solution import.

Will the catalog support PCF components within solutions? What about other solution component types?

Yes, distribution of PCF controls is made easier by using a catalog. Any solution component can be contained in a solution in the catalog.

Can the templates have multiple owners so people know who to reach out to for more information?

Yes, ownership information is part of the metadata for a catalog item. The ownership can be a group with multiple people in it.

Is there a way to add documentation such as a user guide when submitting a template?

Yes, documentation links are part of the metadata for a catalog item.

Can catalogs be shared to security groups?

Yes, catalog permissions can be targeted at specific security groups.

View, submit, and install catalog items

Article • 11/14/2024

In any organization, there might be many components and templates distributed among many environments. The catalog in Power Platform enables developers and makers to:

- Crowd-source and find templates and components within their organization easily
- Find and install the latest and authoritative version of a component
- Get started with templates and components that provide immediate value

> **Important**
>
> You need a Managed Environment in order to submit items to the catalog. You can however install catalog items from any environment. More information: Managed Environments overview

Before reading this article, you should:

- Learn about the catalog
- Learn how administrators setup and configure the catalog

> **Note**
>
> Developers can also use the Power Platform CLI, Dataverse SDK for .NET, and Dataverse Web API to perform the operations described here. Catalog in Power Platform for developers

Access controls

The catalog has a separate set of access controls from Power Platform. This means makers in a given environment don't automatically get permissions to publish and acquire items from the catalog. There are four access roles:

Expand table

Role	Enables user to:
Catalog Submitter	Submit items to the catalog

Role	Enables user to:
Catalog Consumer	Discover and install items from the catalog
Catalog Approver	Approve submissions to the catalog. Catalog approvers can be users from your central IT department or line of business that your organization wants to empower to participate in the approvals process.
Catalog Admin	Administer the catalog.

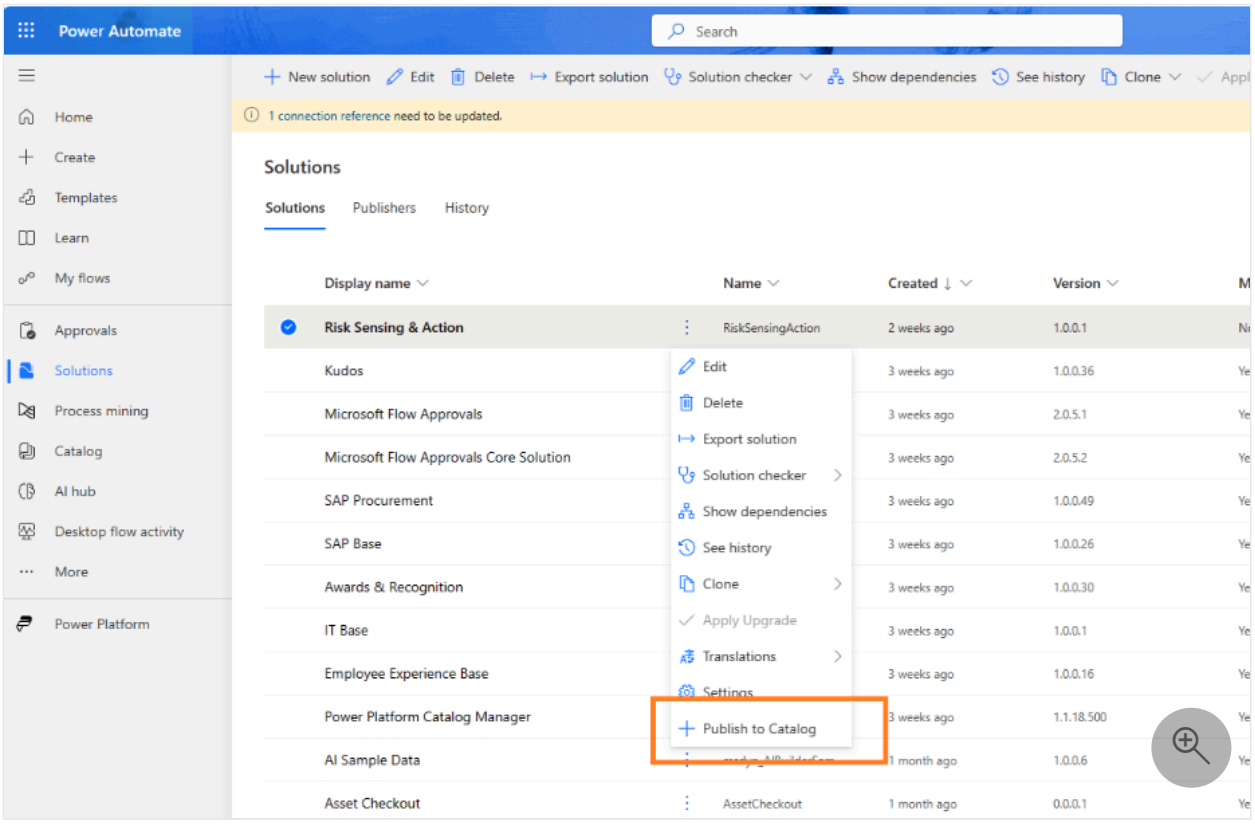
Any environment that has a catalog sees these roles inside of Power Platform admin center, and can be assigned to groups or individuals just like any other security roles.

Power Platform admins and system customizers already have full access to the catalog. However, don't assign these roles for generally managing catalog access, and instead use one of the roles in the previous table.

Submission

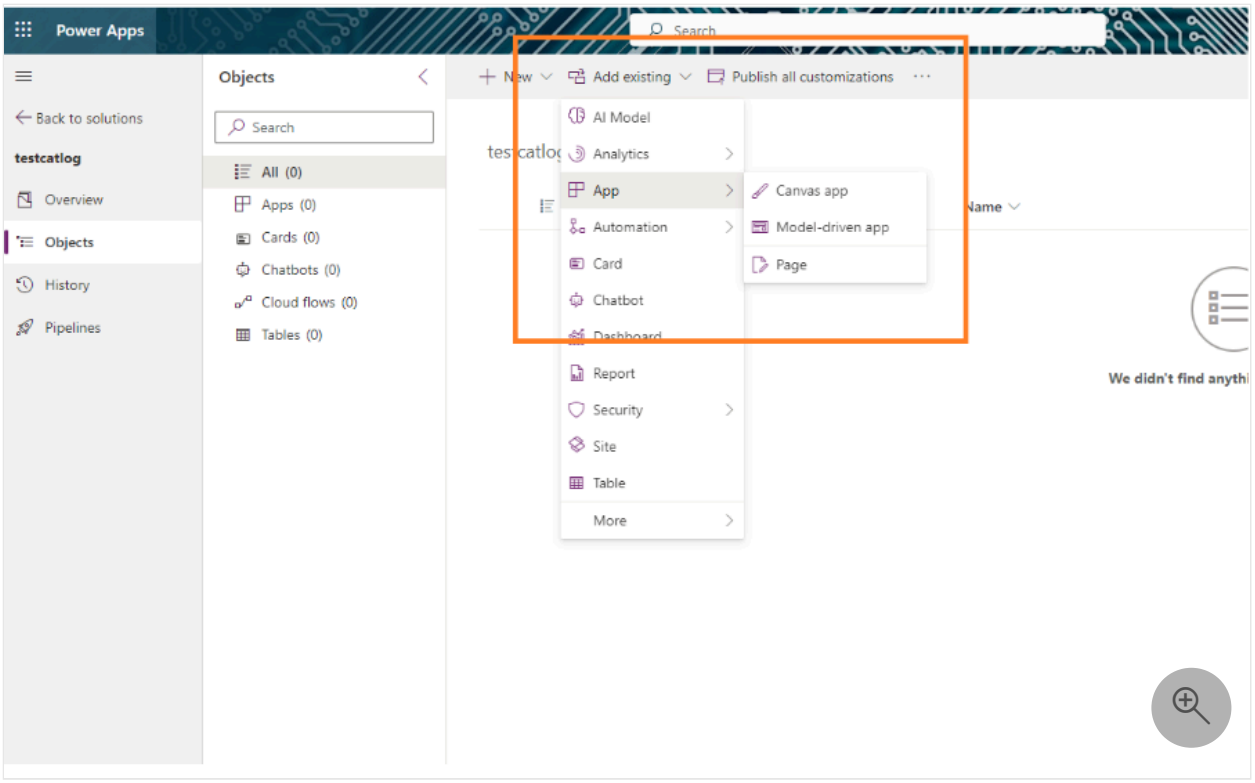
Unmanaged solutions in your environment can be published to the catalog. In your normal course of creating solutions, you might decide that what you're building would be useful as a reusable artifact for yourself or others in your organization.

Navigate to your solutions page, and any unmanaged solution has a new option for **Publish to Catalog** in the three vertical dots next to the solution display name. This option is disabled for anyone without the **Catalog Submitter** role.

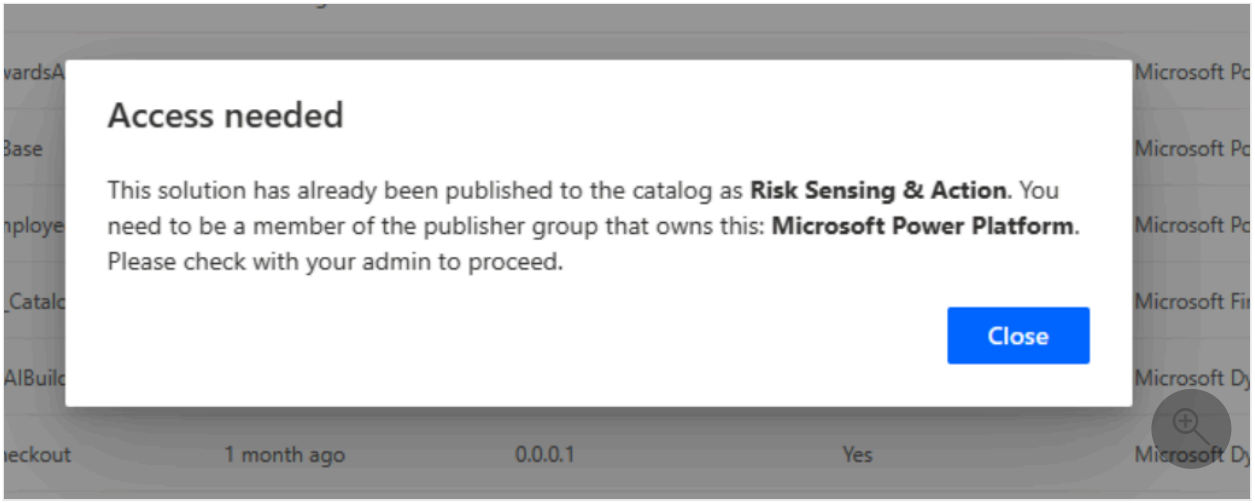


> **Note**
>
> This option is not enabled for managed solutions. You can't submit managed solutions into the catalog.

You can't submit an app, flow, or other component directly into the catalog. You must first ensure it exists in an unmanaged solution. You can add it to an unmanaged solution by selecting **New solution** on top of the **Solutions** area or by selecting an existing one from the list, and then selecting **Add existing** in the top menu in the solution itself, and adding your desired component (such as an app or a flow).



> **Note**
>
> Any maker with the **Catalog Submitter** role in a given environment will be able to publish. However, after a solution is published, a maker needs to be a part of the publishing group to re-publish that same solution again. You see this error if you don't have access, which you can request from your admin.



When you select **Publish to Catalog**, there's a wizard with four steps:

Step 1: Add your solution

1. **Select a catalog**: If you have multiple catalogs set up, you can select which catalog you would like to publish this item to.

2. Select **managed item** or **template** for your submission.

    - **Managed items** can't be edited by other makers, your environment shares a single copy, and that copy can be versioned with updates over time. Makers can then update their solutions with your updates.
    - A **template** is a standalone copy that can be edited, makers can have as many copies as they want, and won't automatically update solutions in environments when new updates are published.

3. **Select a primary component**: A solution might have many components in it. You might want makers to open a specific component for editing after they install it, such as opening Canvas Studio for your canvas app. Set the primary component to whichever you think is the "focus" of the solution, otherwise, set **Unspecified**, and installers go the solution itself.

Resubmitting items

If you're resubmitting an item, you get an alert message notifying you about the resubmission. You're prompted with a version field. The last digit of the version number is automatically incremented for you. You can modify the version number if you like, but don't set the version number to a lower number from this interface. Updating the version number in the catalog submission updates the version number in the original solution as well.

Keep these points in mind when resubmitting items:

- Resubmitting a **template** replaces the previous item in the catalog, and doesn't affect any solutions already using the previous catalog item. Makers who now install your resubmission get your newest version.
- Resubmitting **managed items** will update the catalog item with your most recent version, and the next time makers see your catalog item in an environment where that catalog item was already installed, they'll see an **Update** button, which installs the most recent changes to the managed item into that environment, and then all solutions using that managed item will be updated as well.
- You can't resubmit a managed item as a template, and vice versa.

Step 2: Catalog info

Enter the following information:

Expand table

Field	Instructions
Title	Rename the item if needed before it gets submitted to catalog. The default is the solution name. You can't edit title when submitted a managed item.
Description	Provide details on this catalog item. Makers read your description in the catalog gallery to find out more about it.
Business justification	By default, your admin must approve all catalog submissions before they're added to the catalog. This field provides a justification for your submission to your admin.
Works with	A flow that you're building might be intended to **work with** canvas apps and model apps, for example. Indicate here what your catalog item is intended to work with.
Business categories	Select up to five business categories that describe your catalog item. Makers use these categories to search for catalog items that are of interest to them.
Publisher	Select an existing publisher in this environment, or create a new publisher, to connect to this catalog submission. A maker can't resubmit a catalog item unless they're part of the publishing group that submitted the item the first time.
Author	This defaults to the current user, but you can change it if needed

Step 3: Solution info

Enter the following information:

Expand table

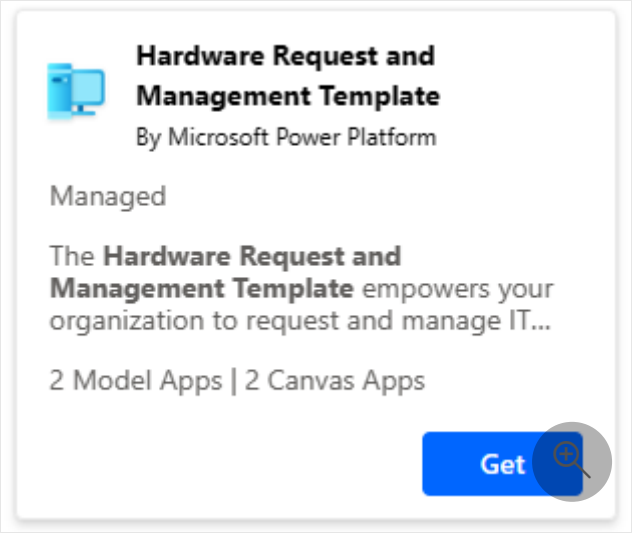
Field	Instructions
Solution icon	Attach an icon to your solution (216 x 216 pixel) to help identify it in the catalog gallery
template images	Attach some screenshots or other visuals that can help makers understand more details about this catalog item
Help link	Add the URL for any help documentation
Privacy policy link	Add the URL for any privacy policy documentation
Legal terms link	Add the URL for any legal terms documentation

Step 4: Review and finish

This last step provides a summary of all the info you provided. If everything looks good, select **Submit** to publish to the catalog. As previously mentioned, if your catalog requires an approver before submission can complete, you need to wait for approval. Contact your admin or approver if you need the process accelerated.

Acquisition

As makers browse the **Discover** page and find catalog items that are useful for them, they can acquire those artifacts and install a copy into their environment to start using or building with. Selecting **Get** on any template or managed item opens a details popup that contains information like description, links, included components, business categories, expandable screenshots, and more.



If the details meet what the maker is looking for, they can select **Get** on the details popup to start the acquisition wizard.

> ⓘ Note
>
> If the catalog item is a managed item, and has already been installed in the environment, you can't install the managed item again, as the environment shares that managed item. If the managed item has already been installed in an environment, and an update has been published to the managed item, you see an **Update** button instead of **Get**, which updates the shared managed solution in the environment. If the managed item was already updated, and no new updates have been published, the **Update** button is disabled until a new update is published.

The acquisition wizard has four steps:

Step 1: Check connections

This step checks the connections for the solution to make sure they're working for you in your environment. If there are any connection issues, you see a red status notification, and can resolve by selecting the ellipsis (...) next to the problematic connection to update it.

Step 2: Environment variables

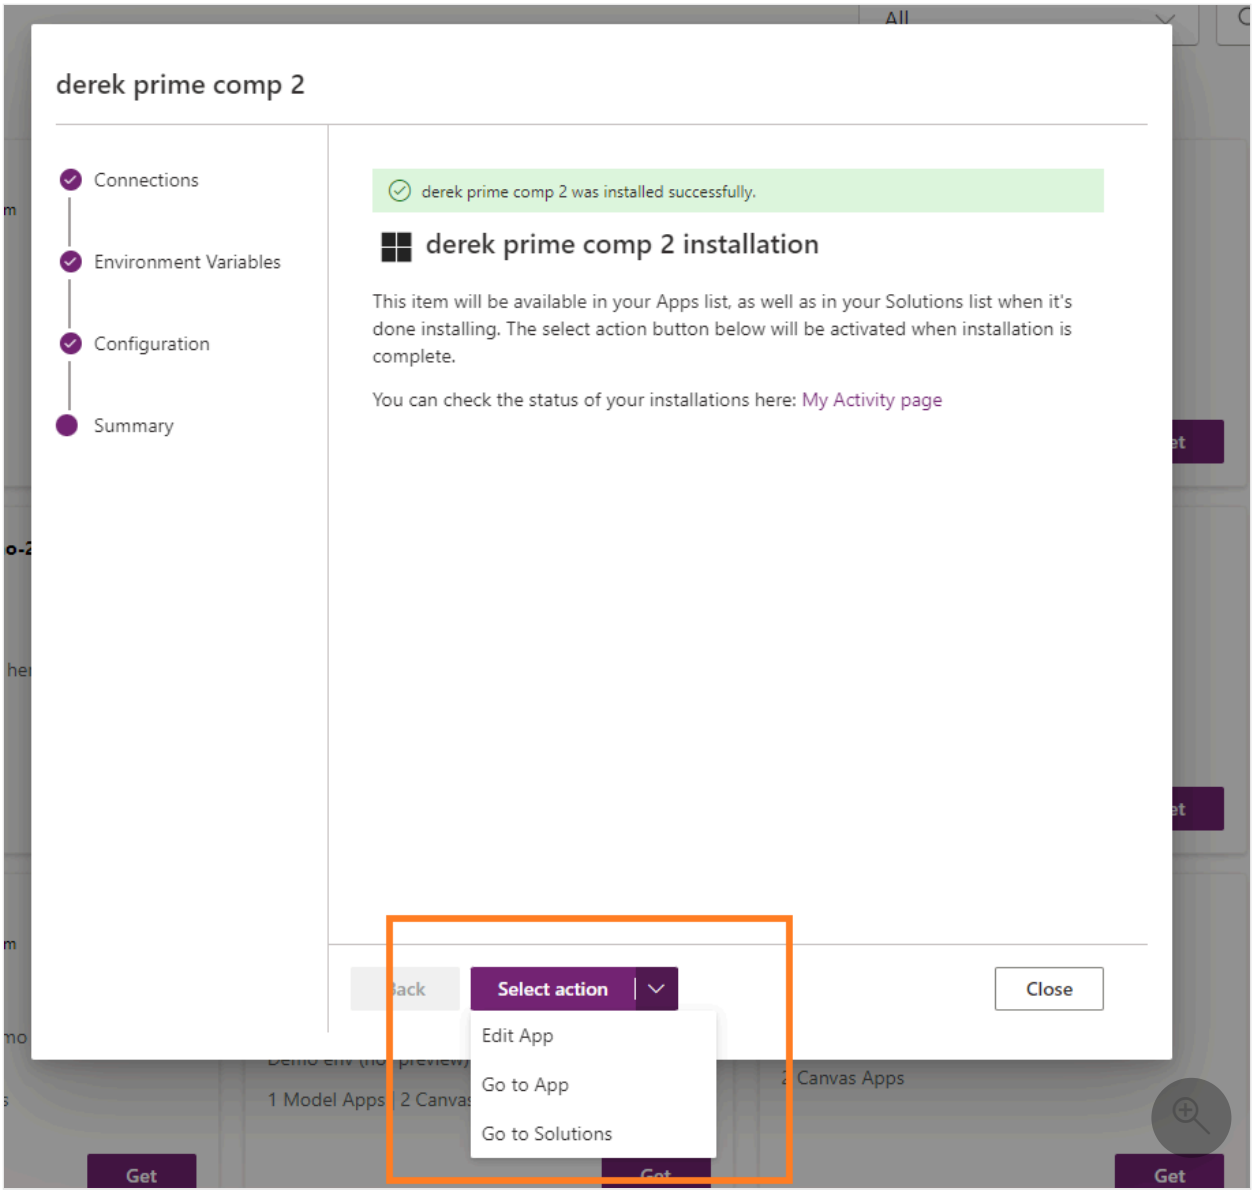
The publishing maker might decide some environment variables need to be specified before you can acquire the solution. Typically, these variables are set to some default value. If unsure of what to fill out, check with the author of the catalog item or in the details of the catalog listing, available on the catalog details. More information: Step 2: Catalog info

Step 3: Configuration

The publishing maker determines this step, if they want you to provide any additional information for using the solution. This might include things like, "*What days of the week do you run a report?*". If no additional information needed, this step is blank.

Step 4: Summary

When you reach the final step, the summary screen, you're now waiting for the catalog item to install into your environment. Depending on the complexity, this might take from less than a minute to several minutes. When complete, you're given several options in the dropdown, depending on what's included in the catalog item, and if the author set a primary component. The following is an example where a canvas app is the primary component of the catalog item:



In this example, you can:

- **Edit App**: Opens the app in Canvas Studio
- **Go to App**: Takes you to the app screen, if you aren't ready to edit yet
- **Go to Solutions**: Opens the solution file

Depending on what is contained in the catalog item package, different options appear.

After the catalog item is installed, you can find the catalog item:

- In the **Unmanaged solutions** list in the solutions page if the catalog item was a **template**
- In the **Managed solutions** list in the solutions page if the catalog item was a **managed item**

As previously mentioned, templates can be acquired as many times as you like, each as its own copy. The catalog appends a suffix to the unmanaged solution display name to differentiate the different copies. Managed items can be acquired only once into the

managed solutions list, and all makers in the environment share the same managed solution. This means you can't acquire a managed item back into the same environment it was published from and the **Update** button is disabled.

Self-service data prep with dataflows

Article • 02/15/2022

As the volume of data continues to grow, so does the challenge of shaping that data into well-structured, actionable information. You want data that's ready for apps, AI workloads, or analytics so that you can quickly turn volumes of data into actionable insights. With self-service data prep in the Power Apps portal, you can transform and load data to Microsoft Dataverse or your organization's Azure Data Lake Storage Gen2 account with just a few clicks.

Dataflows were introduced to help organizations unify data from disparate sources and prepare it for consumption. You can easily create dataflows using familiar, self-service tools to ingest, transform, integrate, and enrich big data. When creating a dataflow, you will define data source connections, ETL (extract, transform, load) logic, and destination to load the resulting data to. Once created, you can configure a dataflow's refresh schedule to indicate how frequently it should run. In addition, the new model-driven calculation engine makes the process of data preparation more manageable, more deterministic, and less cumbersome for dataflow customers. With dataflows, tasks that once required a data IT organization to create and oversee (and many hours or days to complete) can now be handled with a few clicks by individuals who aren't even data scientists, such as app creators, business analysts and report creators.

Dataflows store data in tables. An table is a set of rows used to store data, similar to how a table stores data within a database. Customers can define custom table schema or leverage the Common Data Model's standard tables. The Common Data Model is a shared data language for business and analytical applications to use. The Common Data Model metadata system enables consistency of data and its meaning across applications and business processes such as Power Apps, Power BI, some Dynamics 365 apps (model-driven apps), and Azure, which store data in conformance with the Common Data Model. A dataflow's resulting tables can then be stored in either of the following:

- **Dataverse.** Lets you securely store and manage data that's used by business applications built using Power Apps and Power Automate.
- **Azure Data Lake Storage Gen2.** Lets you collaborate with people in your organization using Power BI, Azure Data, and AI services or custom-built line-of-business applications that read data from the lake. Dataflows that load data to an Azure Data Lake Storage Gen2 account store data in Common Data Model folders. **Common Data Model folders** contain schematized data and metadata in a standardized format to facilitate data exchange and to enable full interoperability

across services that produce or consume data stored in an organization's Azure Data Lake Storage account as the shared storage layer.

You can use dataflows to ingest data from a large and growing set of supported on-premises and cloud-based data sources including Excel, Azure SQL Database, SharePoint, Azure Data Explorer, Salesforce, Oracle database, and more.

After selecting the data source, you can use the Power Query low-code/no-code experience to transform the data and map it to standard tables in the Common Data Model or create custom tables. Advanced users can directly edit a dataflow's M-language to fully customize dataflows, similar to the Power Query experience that millions of Power BI Desktop and Excel users already know.

Once you've created and saved a dataflow, you will need to run it in the cloud. You can choose to trigger a dataflow to run manually or schedule the frequency for the Power Platform Dataflow service to run it for you. When a dataflow completes a run, its data is available to use. To get dataflow data loaded into Dataverse, the Common Data Service connector can be used in Power Apps, Power Automate, Excel, and all other applications that support the Dataverse connector. To get from dataflows stored in your organization's Azure Data Lake Storage Gen2 account, you can used the Power Platform Dataflow connector in Power BI Desktop or access the files directly in the lake.

How to use dataflows

The previous section provided background on dataflows technology. In this section, you get a tour of how dataflows can be used in an organization.

> ⓘ **Note**
>
> You must have a paid Power Apps plan to use dataflows, but you are not charged separately for using dataflows.

Load data to Dataverse

Dataflows can be used to populate tables in the Common Data Service that are then used in Power Apps applications. With a few clicks, you can integrate data from online and on-premises data sources.

Extend the Common Data Model for your business needs

For organizations that want to extend and build upon the Common Data Model, dataflows enable business intelligence professionals to customize the standard tables or create new ones. This self-service approach to customizing the data model can then be used with dataflows to build Power BI dashboards that are tailored to an organization.

Extend your capabilities with Azure Data and AI services

Power Platform dataflows can be configured to store dataflow data in your organization's Azure Data Lake Storage Gen2 account. When an environment is connected to your organization's data lake, data scientists and developers can leverage powerful Azure products such as Azure Machine Learning, Azure Databricks, Azure Data Factory, and more.

For more information about Azure Data Lake Storage Gen2 and dataflows integration, including how to create dataflows that reside in your organization's Azure Data Lake, see Connect Azure Data Lake Storage Gen2 for dataflow storage.

Summary of self-service data prep for big data in Power Apps

There are multiple scenarios and examples where dataflows can enable you to get better control—and faster insights—from your business data. Other people in your organization can leverage dataflows either via Dataverse, the Power Platform Dataflow connector in Power BI, or via direct access to Dataflow's **Common Data Service** folder in your organization's Azure Data Lake Storage Gen2 account. Using a standard data model (schema) defined by the Common Data Model, business applications can depend on a table's schema, and be abstracted from how the data was created or from which data source. When a dataflow completes a scheduled run, the data is ready for modeling and creation of apps, flows, or BI insights in a very short period... in what used to take months, or longer, to create.

The standardized format of the Common Data Model allows people in your organization to create apps that generate quick, easy, and automatic visuals and reports. Those include, but aren't limited to:

- Mapping your data from various sources to standard tables in the Common Data Model to unify data and leverage the known schema to drive out-of-the-box applications.
- Creating your own custom tables to unify data across your organization.

- Creating Power BI reports and dashboards that leverage dataflow data.
- Creating integration with Azure Data and AI services via your organization's Azure Data Lake Storage Gen2 account.

Next steps

This article provided an overview of self-service data prep in the Power Apps portal, and the ways you can use it. The following topics go into more detail about common usage scenarios for dataflows:

- Creating and using dataflows in Power Apps
- Add data to a table in Dataverse
- Connect Azure Data Lake Storage Gen2 for dataflow storage
- Using an on-premises data gateway in Power Platform dataflows

For more information about Power Query and scheduled refresh, you can read these articles:

- Query overview in Power BI Desktop
- Configuring scheduled refresh

For more information about the Common Data Model, you can read its overview article:

- Common Data Model - overview

Create and use dataflows in Power Apps

With advanced data preparation available in Power Apps, you can create a collection of data called a dataflow, which you can then use to connect with business data from various sources, clean the data, transform it, and then load it to Microsoft Dataverse or your organization's Azure Data Lake Gen2 storage account.

A dataflow is a collection of tables that are created and managed in environments in the Power Apps service. You can add and edit tables in your dataflow, as well as manage data refresh schedules, directly from the environment in which your dataflow was created.

Once you create a dataflow in the Power Apps portal, you can get data from it using the Dataverse connector or Power BI Desktop Dataflow connector, depending on which destination you chose when creating the dataflow.

There are three primary steps to using a dataflow:

1. Author the dataflow in the Power Apps portal. You select the destination to load the output data to, the source to get the data from, and the Power Query steps to transform the data using Microsoft tools that are designed to make doing so straightforward.

2. Schedule dataflow runs. This is the frequency in which the Power Platform Dataflow should refresh the data that your dataflow will load and transform.

3. Use the data you loaded to the destination storage. You can build apps, flows, Power BI reports, and dashboards or connect directly to the dataflow's Common Data Model folder in your organization's lake using Azure data services like Azure Data Factory, Azure Databricks, or any other service that supports the Common Data Model folder standard.

The following sections look at each of these steps so you can become familiar with the tools provided to complete each step.

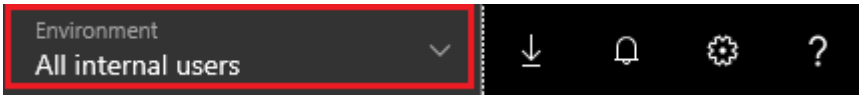
Create a dataflow

Dataflows are created in one environment. Therefore, you'll only be able to see and manage them from that environment. In addition, individuals who want to get data from your dataflow must have access to the environment in which you created it.

> **ⓘ Important**
>
> - Creating dataflows is currently not available with Power Apps Developer Plan licenses.

- The Firefox web browser currently isn't supported for the "Download refresh history file" action in Power Apps dataflows. More information: [You receive the error message "There was a problem refreshing the dataflow"]

1. Sign in to Power Apps, and verify which environment you're in, find the environment switcher near the right side of the command bar.

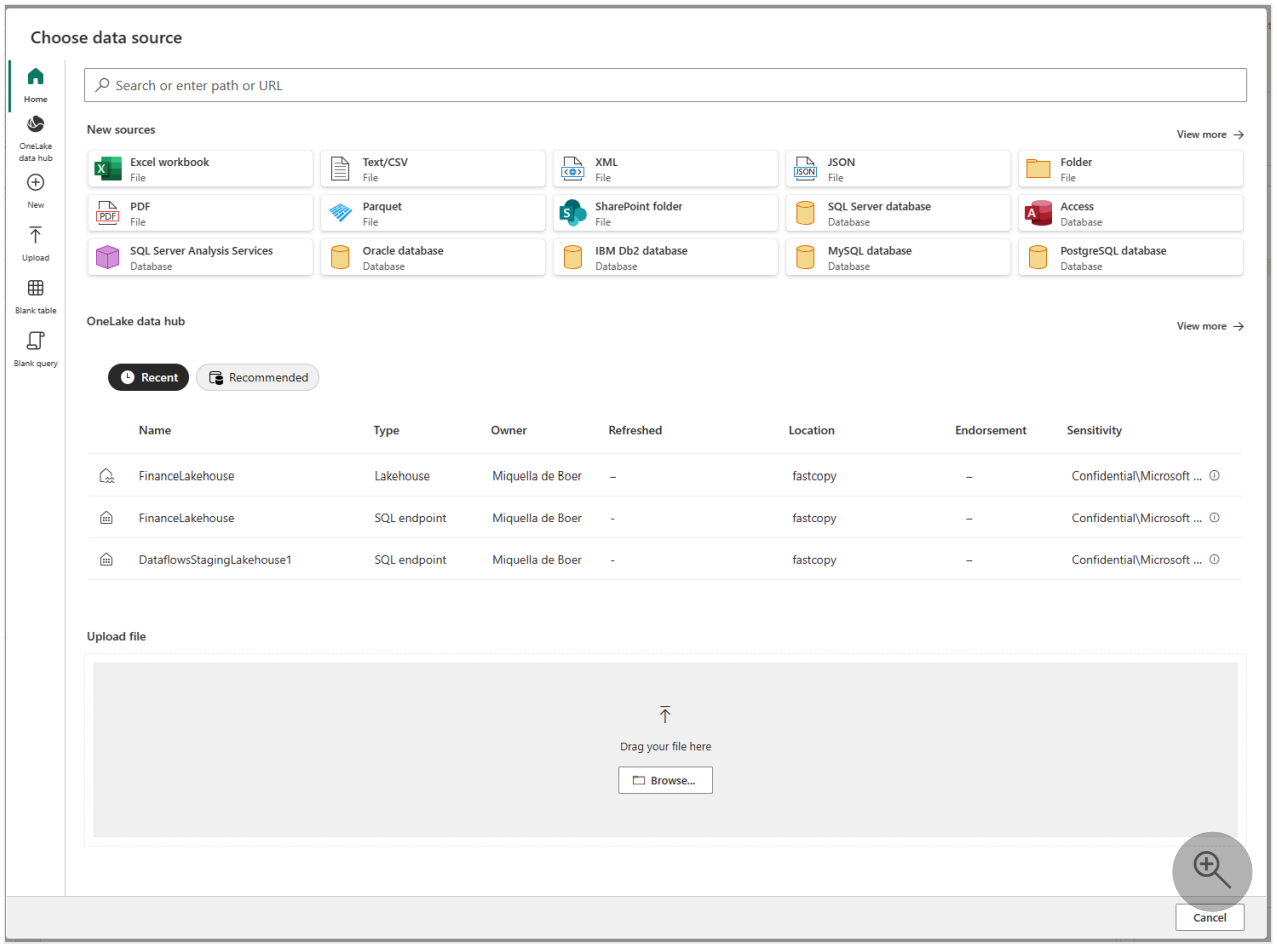


2. On the left navigation pane, select **Dataflows**. If the item isn't in the side panel pane, select ...More and then select the item you want.

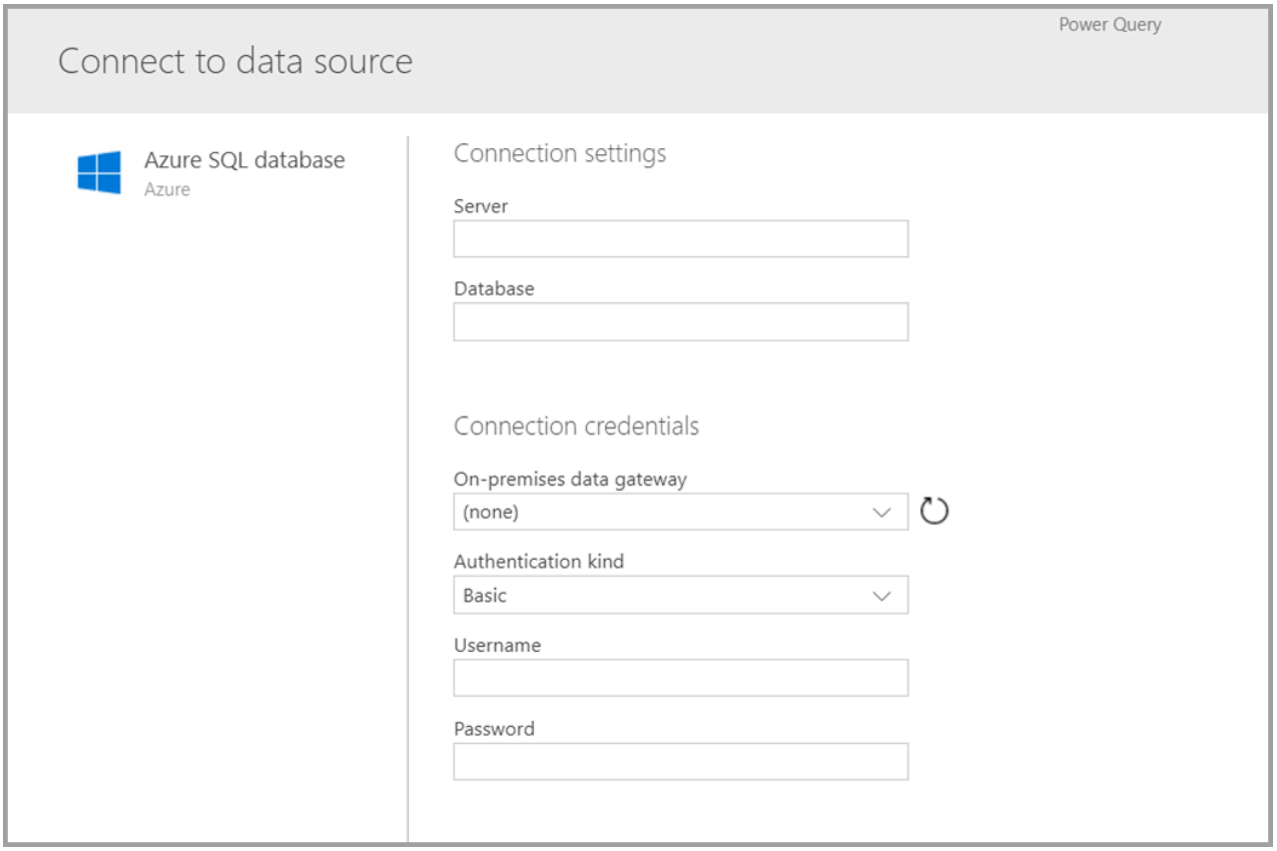
3. Select **New dataflow**. On the **New Dataflow** page, enter a **Name** for the dataflow. By default, dataflows store tables in Dataverse. Select **Analytical entities only** if you want tables to be stored in your organization's Azure Data Lake storage account. Select **Create**.

   > **Important**
   >
   > There's only one owner of any dataflow—the person who created it. Only the owner can edit the dataflow. Authorization and access to data created by the dataflow depend on the destination you loaded data to. Data loaded into Dataverse will be available via the Dataverse Connector and requires the person accessing the data to be authorized to Dataverse. Data loaded into your organization's Azure Data Lake Gen2 storage account is accessible via the Power Platform Dataflow connector and access to it requires membership within the environment it was created in.

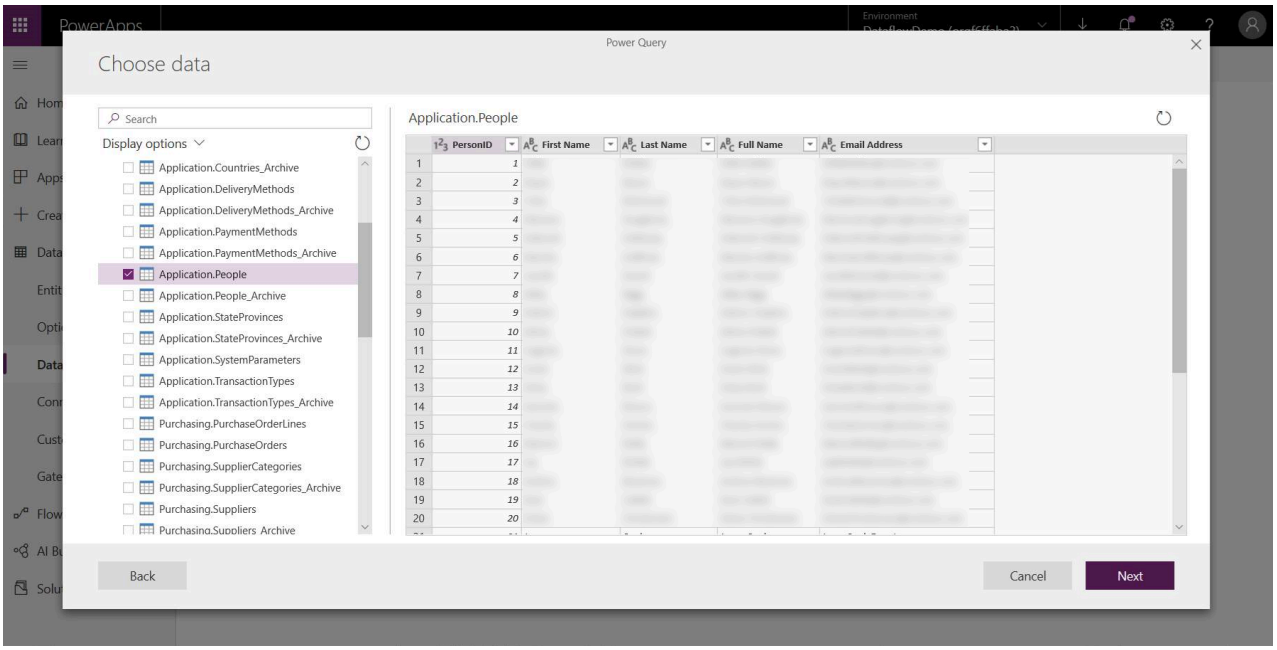
4. On the **Choose data source** page, select the data source where the tables are stored. The selection of data sources displayed allows you to create dataflow tables.



5. After you select a data source, you're prompted to provide the connection settings, including the account to use when connecting to the data source. Select **Next**.



6. Once connected, you select the data to use for your table. When you choose data and a source, the Power Platform Dataflow service will subsequently reconnect to the data source in order to keep the data in your dataflow refreshed, at the frequency you select later in the setup process.

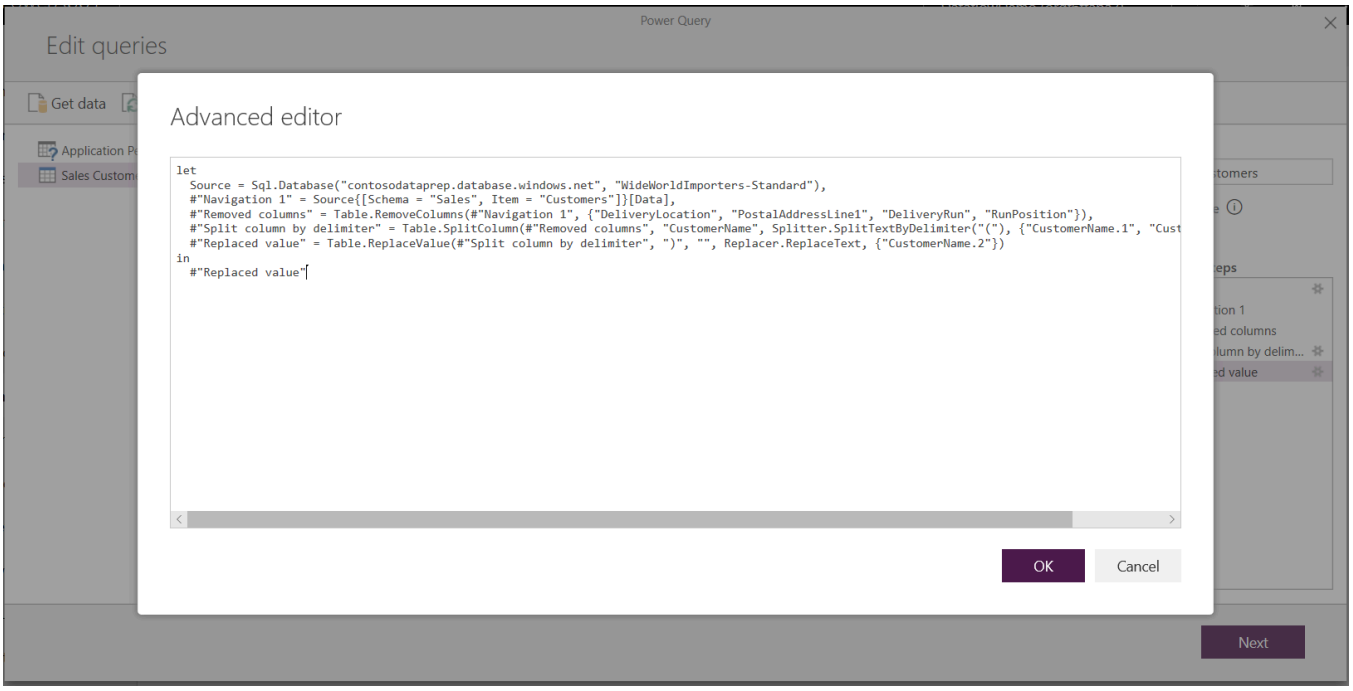


Now that you've selected the data to use in the table, you can use the dataflow editor to shape or transform that data into the format necessary for use in your dataflow.

Use the dataflow editor to shape or transform data

You can shape your data selection into a form that works best for your table using a Power Query editing experience, similar to the Power Query Editor in Power BI Desktop. To learn more about Power Query, see Query overview in Power BI Desktop.

If you want to see the code that Query Editor is creating with each step, or if you want to create your own shaping code, you can use the advanced editor.

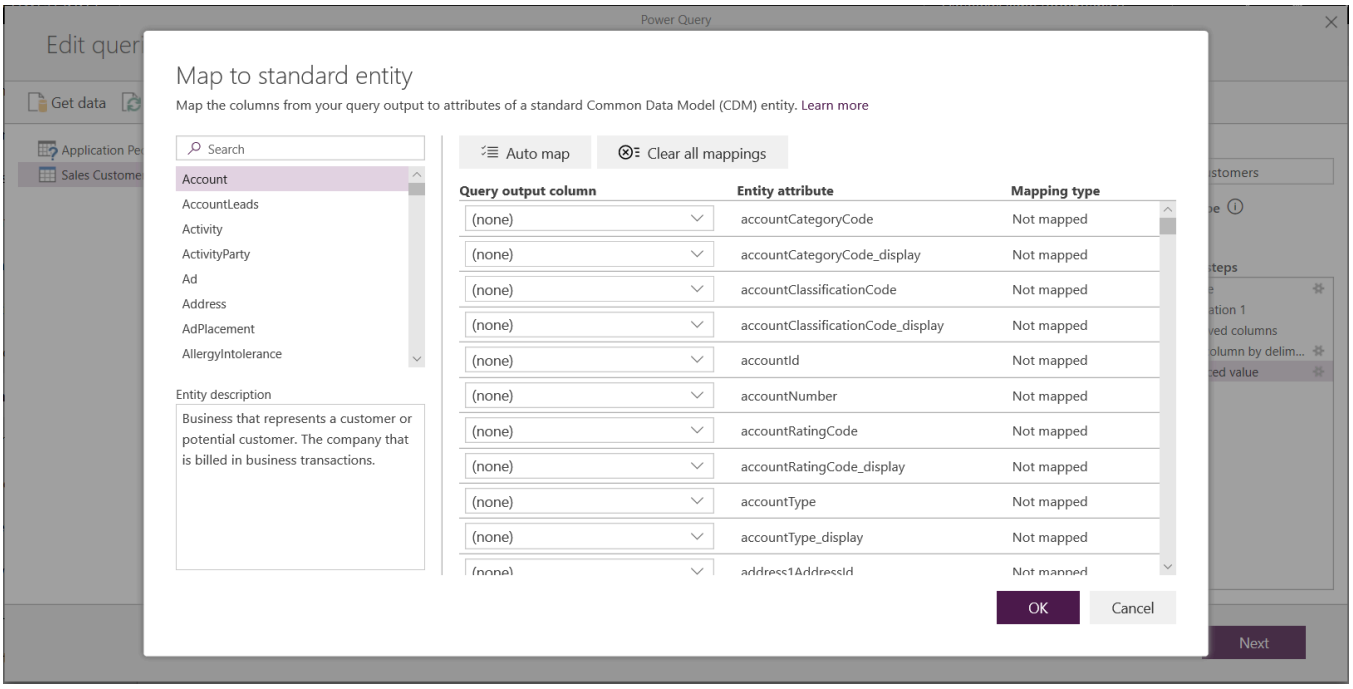


Dataflows and the Common Data Model

Dataflows tables include new tools to easily map your business data to the Common Data Model, enrich it with Microsoft and non-Microsoft data, and gain simplified access to machine learning. These new capabilities can be leveraged to provide intelligent and actionable insights into your business data. Once you've completed any transformations in the edit queries step described below, you can map columns from your data source tables to standard table columns as defined by the Common Data Model. Standard tables have a known schema defined by the Common Data Model.

For more information about this approach, and about the Common Data Model, see The Common Data Model.

To leverage the Common Data Model with your dataflow, select the **Map to Standard** transformation in the **Edit Queries** dialog. In the **Map tables** screen that appears, select the standard table that you want to map.



When you map a source column to a standard column, the following occurs:

1. The source column takes on the standard column name (the column is renamed if the names are different).

2. The source column gets the standard column data type.

To keep the Common Data Model standard table, all standard columns that aren't mapped get *Null* values.

All source columns that aren't mapped remain as is to ensure that the result of the mapping is a standard table with custom columns.

Once you've completed your selections and your table and its data settings are complete, you're ready for the next step, which is selecting the refresh frequency of your dataflow.

Set the refresh frequency

Once your tables have been defined, you should schedule the refresh frequency for each of your connected data sources.

Dataflows use a data refresh process to keep data up to date. In the **Power Platform Dataflow authoring tool**, you can choose to refresh your dataflow manually or automatically on a scheduled interval of your choice.

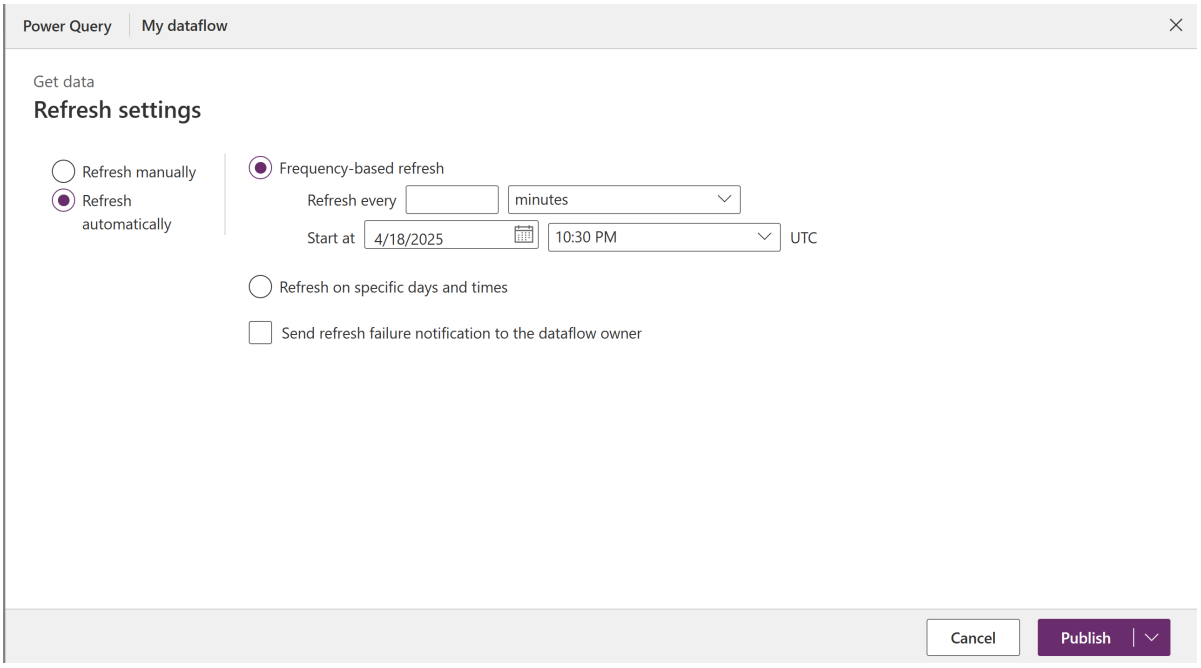
Schedule a refresh automatically

1. Select **Refresh automatically**.

2. Enter the dataflow frequency:

    - **Frequency-based refresh**. Set how often in 30-minute increments, start date, and time in UTC.

    - **Refresh on specific days and times**. Choose time zone, frequency (daily or weekly) and time of day in 30-minute increments.



3. Select **Publish.**

Some organizations might want to use their own storage for creation and management of dataflows. You can integrate dataflows with Azure Data Lake Storage Gen2 if you follow the requirements to set up the storage account properly. More information: Connect Azure Data Lake Storage Gen2 for dataflow storage

Troubleshooting data connections

There might be occasions when connecting to data sources for dataflows runs into issues. This section provides troubleshooting tips when issues occur.

- **Salesforce connector.** Using a trial account for Salesforce with dataflows results in a connection failure with no information provided. To resolve this, use a production Salesforce account or a developer account for testing.

- **SharePoint connector.** Make sure you supply the root address of the SharePoint site, without any subfolders or documents. For example, use a link similar to `https://microsoft.sharepoint.com/teams/ObjectModel`.

- **JSON File connector.** Currently you can connect to a JSON file using basic authentication only. For example, a URL similar to `https://XXXXX.blob.core.windows.net/path/file.json?sv=2019-01-01&si=something&sr=c&sig=123456abcdefg` is currently not supported.

- **Azure Synapse Analytics.** Dataflows don't currently support Microsoft Entra authentication for Azure Synapse Analytics. Use basic authentication for this scenario.

> ⓘ Note
>
> If you use data loss prevention (DLP) policies to block the **HTTP with Microsoft Entra (preauthorized)** connector then **SharePoint** and **OData** connectors will fail. The **HTTP with Microsoft Entra (preauthorized)** connector needs to be allowed in DLP policies for **SharePoint** and **OData** connectors to work.

Troubleshoot the error: Connection to Dataverse failed. Please check the link below on how to fix this issue

Users might receive an error message if the connection they're using for export requires a fix. In this case, the user receives an error message that states **Connection to Dataverse failed. Please check the link below on how to fix this issue**.

To resolve this issue:

1. In Power Apps (make.powerapps.com), select **Connections** from the left navigation pane. If the item isn't in the side panel pane, select ...More and then select the item you want.
2. Locate the **Microsoft Dataverse (legacy)** connection.
3. Select the **Fix connection** link in the **Status** column, and follow the instructions on your screen.

After the fix completes, retry the export.

You receive the error message "There was a problem refreshing the dataflow"

This error occurs when you try to refresh the dataflow while using the Firefox web browser. To work around this issue use a different web browser, such as Microsoft Edge or Google Chrome.

Next steps

The following articles are useful for further information and scenarios when using dataflows:

- Add data to a table in Dataverse
- Using an on-premises data gateway in Power Platform dataflows
- Connect Azure Data Lake Storage Gen2 for dataflow storage
- Use dataflows in solutions

Get insights from your data

Article • 05/31/2024

Microsoft Dataverse is the intelligent data platform that powers Dynamics 365 apps and the Power Platform. All Dynamics 365 data is hosted in Dataverse. The data included data from finance and operations apps and customer engagement apps like Dynamics 365 Sales and Dynamics 365 Customer Service. Dynamics 365 applications can be extended with Power Platform tools like Power Apps, Power Automate, and Power Pages for low-code and pro-code extensions. Data from Power Platform apps is also hosted in Dataverse.

When you understand the data and its intent, Dataverse provides turnkey capabilities in a consistent manner for all your data. Dataverse isn't just a database or storage, it encompasses everything needed to build integrated applications, processes, and in turn provides insights from the data it hosts. Dataverse also provides a comprehensive governance framework for your data including granular role based security and audit and compliance. Because it's a low-code data platform, developers can spend more time focusing on business needs through the configuration of the system and less time building infrastructure.

There are several approaches to getting insights from your data hosted by Dataverse:

- Quick view is a data exploration feature built into Power Apps. When you build a low-code app, either by extending Dynamics 365 or with your own data, quick view is enabled by default. There's no need to create reports to inquire and explore data. You can save these reports as required and later extend them in Power BI Desktop - the authoring tool for Power BI.

- Power BI with Dataverse data. As a low-code maker or a business analyst, you can use Power BI with Dataverse data to create rich reports and embed these reports within pages and forms in Power Apps.

- Link to Fabric feature provides a no-copy, no-ETL, fully managed software as a service (SaaS) integration. The link to Microsoft Fabric feature enables data engineers and business analysts to use all the tools of Microsoft Fabric to combine Dataverse data with their own data.

- Azure Synapse Link enables continuous export of data to your own Azure data lake and enables IT admins and data integration specialists to create data pipelines.

Data export service, bring your own device (BYOD), and Export to Data Lake were features introduced in Dynamics 365 apps to export data for analytics and data

integration scenarios. These services enabled IT admins and specialists to export data into external databases or data lakes and build data integration pipelines. While we have improved these services over the years with updates, as part of unification of Dynamics 365 with the Power Platform, we rearchitected the same capabilities of these disparate services into simpler, unified experiences built into Power Apps (make.powerapps.com). When you transition to Fabric link or upgrading to Azure Synapse Link, these features provide you with an easy ramp to benefit from AI and Copilot investments in Dataverse and Fabric. Go to the transition from legacy integration services article for more information about how you can transition to Dataverse insights.

Use Power BI with Microsoft Dataverse data

Article • 05/06/2022

Power BI is a comprehensive collection of services and tools that you use to visualize your business data. The following connector, templates, and features are available that make it easy to visualize and analyze Microsoft Dataverse data or the Dynamics 365 Sales and Dynamics 365 Customer Service apps data with Power BI.

- **Dataverse connector**: Dataverse allows you to connect directly to your data using Power BI Desktop to create reports and publish them to Power BI. From Power BI, reports can be used in dashboards, shared to other users and accessed cross platform on Power BI mobile apps. This connector is the most recent version and uses the tabular data stream (TDS) protocol. More information: Create a Power BI report
- **Common Data Service (legacy) connector**: This is the earlier version of the connector. Use this connector when the query results will be greater than 80 MB. This version also supports paging of the query results and building reports that use the image data type.
- **Dataflow templates**: Dataflows help organizations unify data from disparate sources and prepare it for consumption. You can easily create dataflows using familiar, self-service tools to ingest, transform, integrate, and enrich big data. Once you create a dataflow in Power Apps, you can get data from it using the Common Data Service connector or Power BI Desktop Dataflow connector. More information: Create and use dataflows in Power Apps
- **Power BI template apps**: Power BI template apps are integrated packages of pre-built Power BI dashboards and reports. Using Power BI template apps with Dynamics 365 Sales provides a convenient, powerful, and quick way to access and analyze your sales data. For more information, see these articles:
  - Sales analytics
  - Service analytics
- **Embed Power BI reports on a form**: You can use Power BI reports in Power Apps model-driven apps to bring rich reporting and analytics to your system forms and empower your users to accomplish more. More information: Embed a Power BI report in a model-driven system form
- **Embed Power BI reports on a system dashboard**: Use can add Power BI reports to the dashboards and include in the solution with Environment Variables for ALM. More information: Create or edit a Power BI embedded system dashboard

- **Tabular Data Stream (TDS) endpoint**: Use the TDS endpoint for Dataverse to view table data in Power BI Desktop. More information: View table data in Power BI Desktop

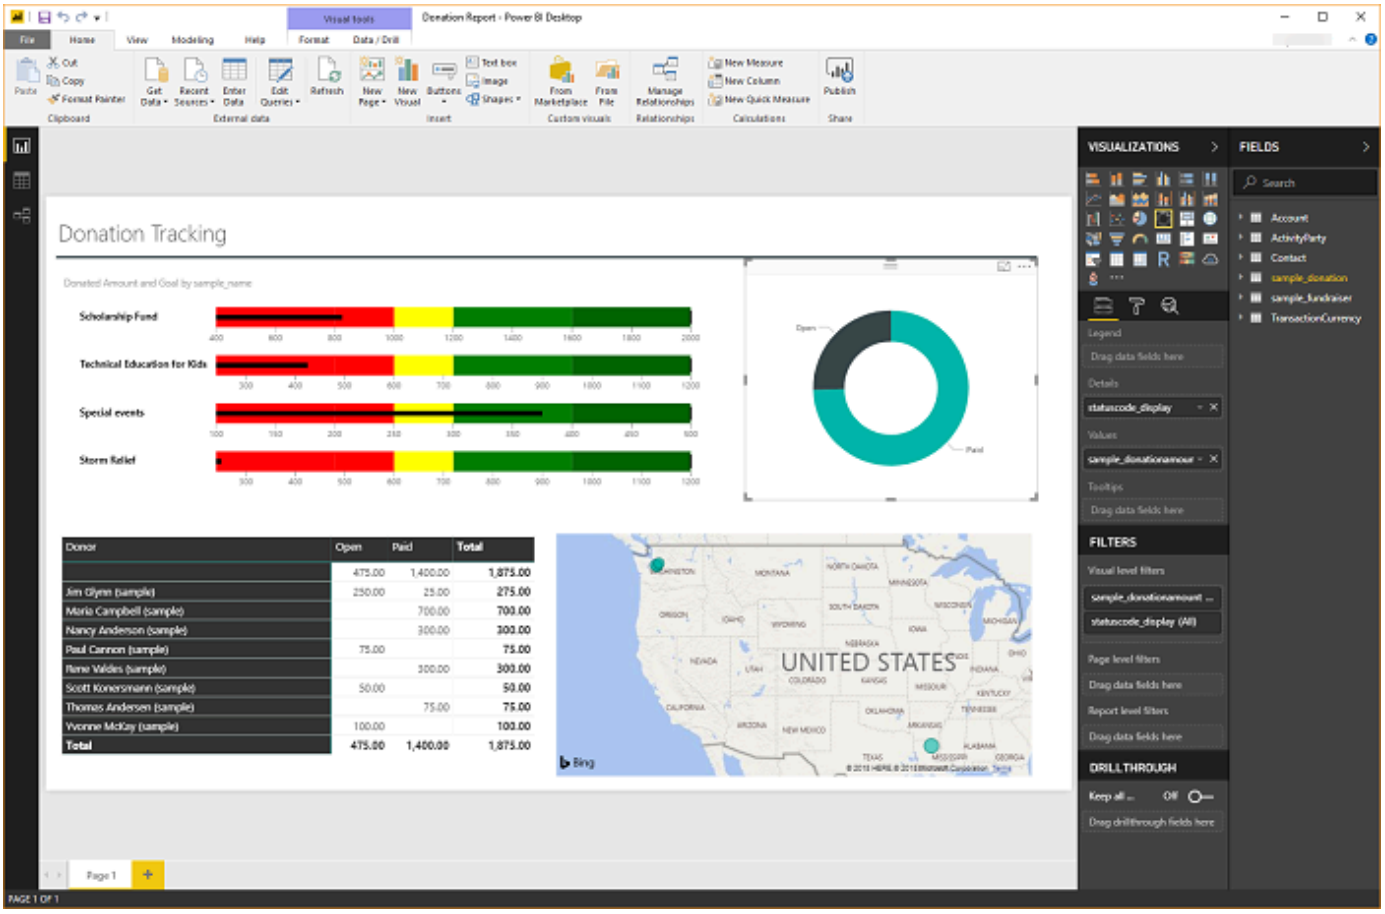
Use Power BI

Create a Power BI report using data from Dataverse

Microsoft Dataverse allows you to connect directly to your data using Power BI Desktop to create reports and publish them to Power BI. From Power BI, reports can be used in dashboards, shared to other users, and accessed cross platform on Power BI mobile apps.



Prerequisites

To use Power BI with Dataverse, you need the following items:

- Download and install Power BI Desktop, which is a free application that runs on your local computer. You can download Power BI desktop here.
- A Power Platform environment with the following privileges:
  - To access data in a table, you must have read privileges to the table.
  - To modify a table in Power Apps (make.powerapps.com), you must have a security role that includes maker privileges, such as system customizer or environment maker.
- You must have the appropriate Power BI license to build and share Power BI reports.

- To use the **Dataverse** connector, the **Enable TDS endpoint** setting must be enabled in your environment. More information: Manage feature settings

> **Note**
>
> Most proxy servers don't handle the Tabular Data Stream (TDS) protocol data used by the Dataverse connector for Power BI.

Connect to Dataverse using a connector

Dataverse connector

1. Open **Power BI Desktop**. Select **Get data from other sources**.
2. In the **Get Data** list, select **Dataverse**, and then select **Connect**.
3. If you're prompted, select or enter your user credentials, and then select **Connect**.
4. The list of Power Platform environments with Dataverse appears. In the list of environments, expand the environment you want, select the tables you want, and then select **Load**.
5. Select from the following **Data Connectivity** mode options:

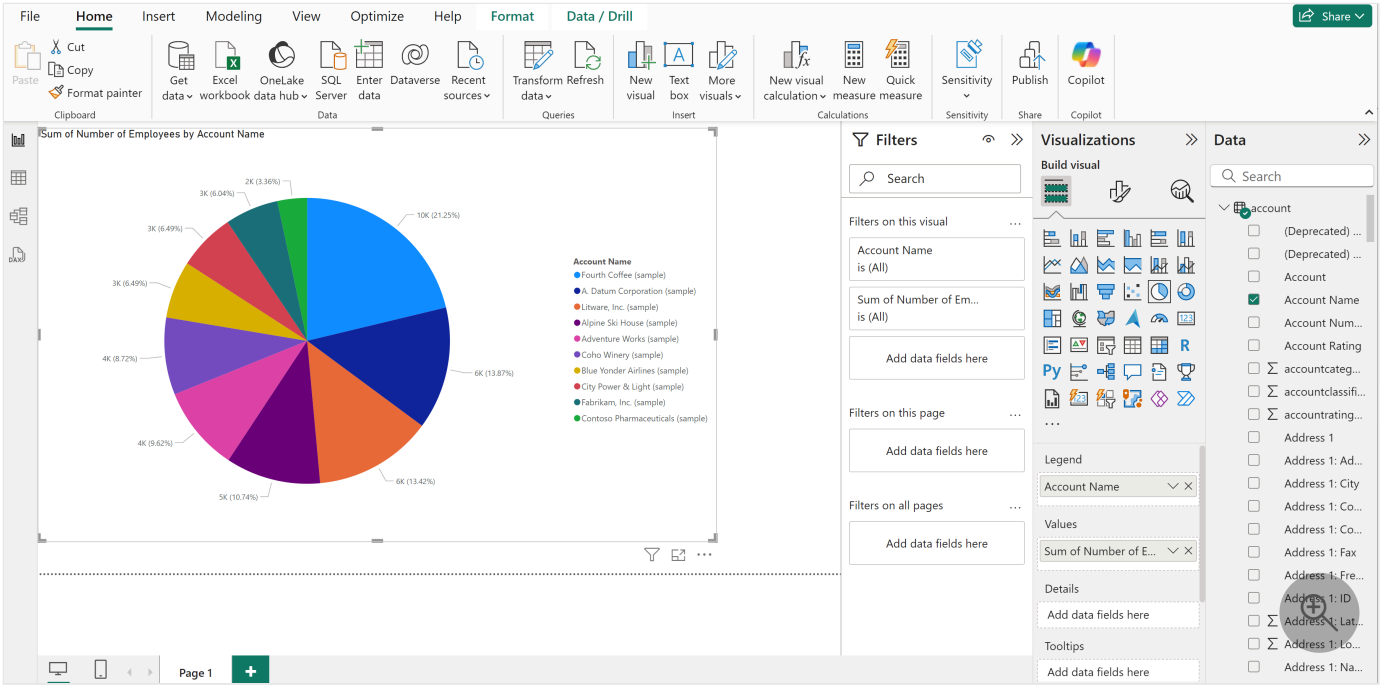
    - **Import**: We recommend that you import data to Power BI wherever possible. With this mode, data is cached in the Power BI service and imported on a scheduled interval.
    - **DirectQuery**: Connects directly to the data in Dataverse. Use this mode for real-time data retrieval. This mode can also more strictly enforce the Dataverse security model. More information: DirectQuery model guidance in Power BI Desktop.

6. Select **OK**. You might be prompted to sign in using the same credentials you use to connect to Power Apps and Dataverse. Select **Connect**.

> **Important**
>
> To use the Dataverse connector, TCP ports 1433 and/or 5558 need to be open to connect. If only port 5558 is enabled, you must append that port number to the environment URL, such as *yourenvironmentid.crm.dynamics.com,5558*.

Build reports using Dataverse tables

After loading the tables by using a connector, you can begin building reports, or repeat the previous steps to add additional tables. For example, in the **Columns** pane, select the **name** column and then select the **numberofemployees** column. In the **Visualizations** pane, select **Pie chart**. These selections add a new visualization to your report canvas.



Special column types

Choice columns

Choice columns are used in tables to provide a drop-down list of items to a user to make a single selection in apps and flows. When using the Dataverse connector, choice columns are presented as two columns to show both the unique value, and the display item value.

For example, if you had a choice column on your table called `approvalstatus`, you would see two columns in Power BI:

- `approvalstatus` - This column shows a unique integer value for each item in your choice. `approvalstatus` can help when you apply filters so the filters won't be impacted when you make future changes to the display name.
- `approvalstatusname` - This column shows the friendly display name of the item and is most commonly used when presenting the option in a table or chart.

Expand table

`approvalstatus`	`approvalstatusname`
1	Submitted
2	In Review
3	Approved
4	Rejected

Performance impact and choice name columns

When retrieving the label name for a choice column, Dataverse makes a join with the internal `stringmap` table (where localized labels are stored). This is executed for each label/name column. Note that, this join and doing filters against the label name column, rather than the value column, can significantly impact report query performance.

Choices columns

Choices are similar to choice columns with the difference being that users can select multiple items from the list. Choices aren't currently fully supported with the Dataverse connector. When you use the Dataverse connector with choices columns, you only receive the integer values, which are comma separated. The item label name columns aren't returned. For more information about the Dataverse data types not supported with the Dataverse connector, see Supported operations and data types.

Lookups

Lookup columns use a many-to-one (N:1) table relationship between the table you're working with and the target row type defined for the lookup. Lookups are presented in Power BI Desktop as two columns, `lookupid` and `lookupid-name`.

Navigating relationships

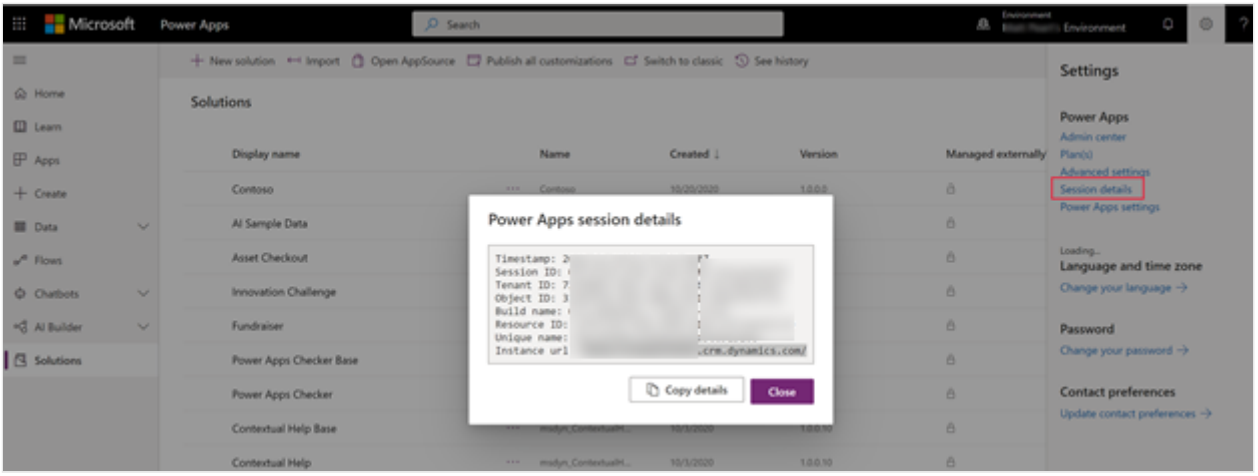
Relationships in Dataverse require you to create a relationship within Power BI desktop between the two tables using a GUID column, this is a system-generated unique identifier that ensures relationships are created for the create rows where ambiguity or duplication might exist with other columns. You can read more about managing relationships in Power BI desktop here.

While some relationships might be automatically created, you can still review and ensure the correct relationships are established when creating your report:

- The lookup column on the table contains the GUID of the row in the related table.
- The related table has a column in the format "[tableName]ID" that contains the GUID, for example `Accountid` or `MyCustomtableid`
- Using the Power BI desktop Manage Relationships feature, you would create a new relationship between your lookup column, and the ID column on the related table.

Find your environment URL

1. Open Power Apps, select the environment you're going to connect to, select **Settings** in the top-right corner, and then select **Session details**.



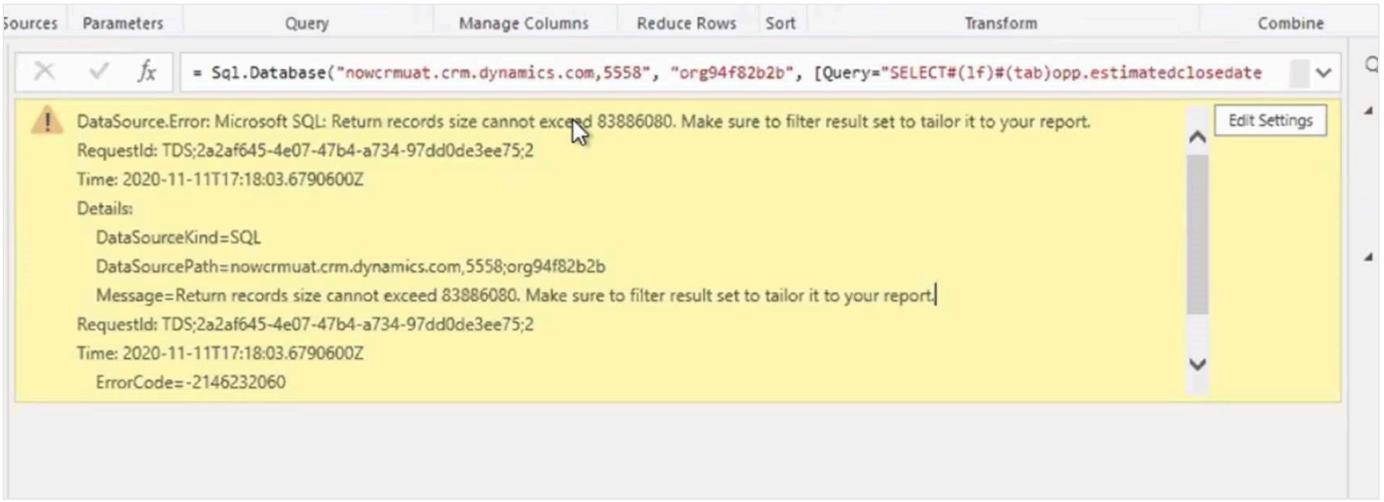
2. In the **Power Apps session details** dialog box, select **Copy Details**.

3. Paste the session details somewhere such as Notepad so that you can copy only the **Instance url**. The instance URL is the unique URL for your environment. The URL is in the format: `https://yourenvironmentid.crm.dynamics.com/`. Keep this somewhere handy so you can use it when creating your Power BI reports.

Troubleshooting

Error message: Return records size can't exceed 83886080

This error can occur with the Dataverse connector when you run or design a report with a result set greater than 80 MB. TDS has a result set size limit of 80 MB.



To work around this limit, optimize the query adding filters and dropping columns so that the query returns less data.

Workaround for very large number of lookups or choice columns

If the error message occurs in Power BI when you try to connect to a table with a very large number of lookups or choice columns, the following manual workaround might allow you to connect to the table. The account, contact, and opportunity table might encounter this issue when they're extensively customized with additional lookups or choice columns.

Manually connect to the table in a Power BI report:

1. In Power BI desktop with the report loaded, select **Transform Data** to load Power Query.
2. Select **New Source** > **Blank Query**.
3. **Name** your query.
4. Select **Advanced Editor** on the **Home** tab of Power BI Desktop.
5. Replace the query text with this query text.

```
let
    Source = CommonDataService.Database("<myenvironment.crmX>.dynamics.com"),
    dbo_contact = Source{[Schema="dbo",Item="contact"]}[Data],
    #"selectedcolumns" = Table.SelectColumns(dbo_contact,{"fullname",
"emailaddress1"})
in
    #"selectedcolumns"
```

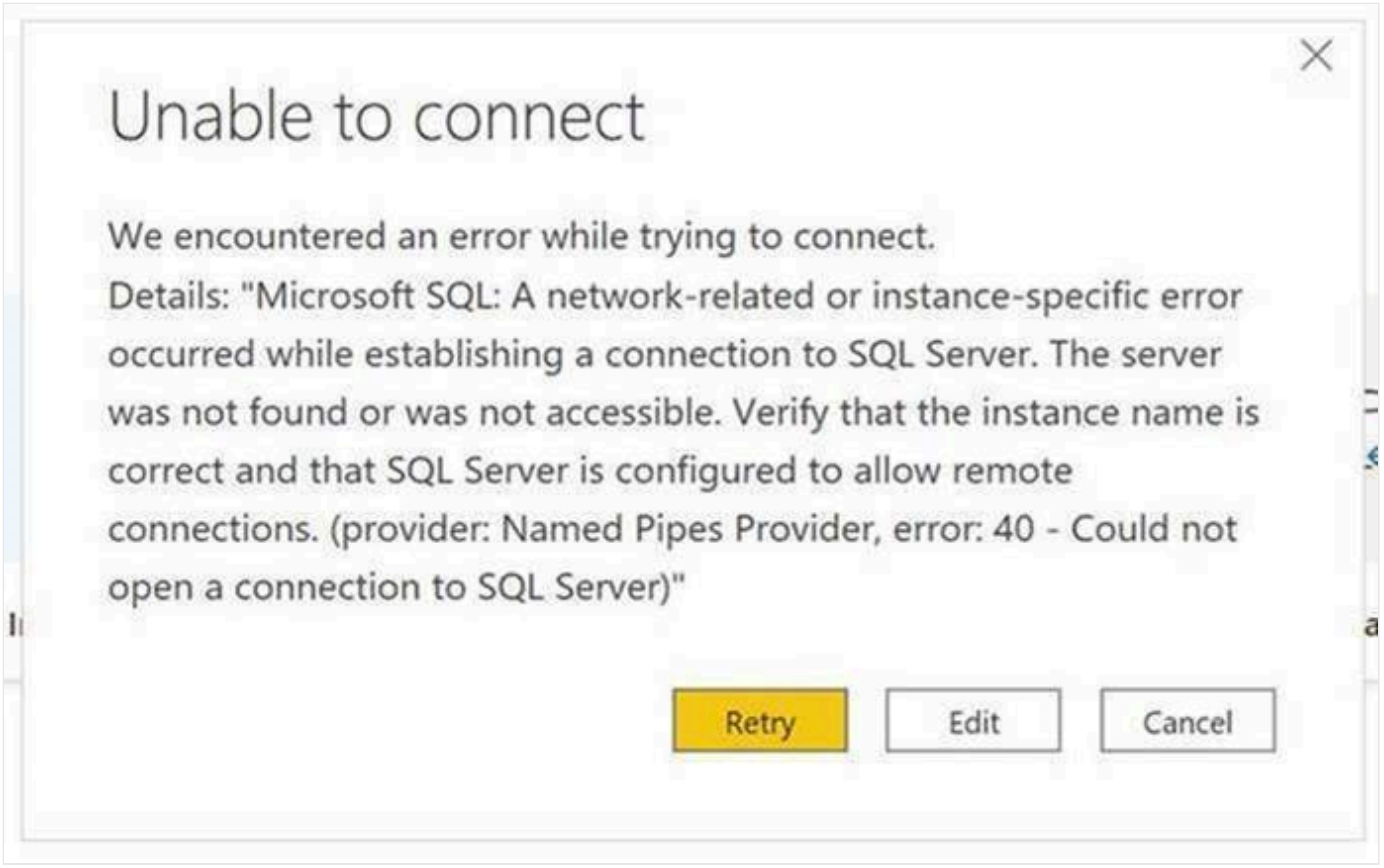
6. Replace *myenvironment.crmX* in the query text with your environment domain value, such as *contoso.crm4*.

7. Select **Done**.
8. Select **Choose columns** to add any additional needed columns.
9. Select **Close and Apply** to save model changes.
10. When prompted, select **Direct Query** for the new query.

The query can now be used in the report.

Error message: Unable to connect (provider Named Pipes Provider, error: 40 – Could not open a connection to SQL Server)

When this error message occurs, the connector fails to connect to the TDS endpoint. This can occur when the URL used with the connector includes *https://* and/or the ending */*.



Remove the https:// and ending forward slash so that the URL is in the form *orgname.crm.dynamics.com*.

Troubleshooting connection issues

For information about troubleshooting connection issues when using the TDS endpoint, see Troubleshooting connection problems.

View table data in Power BI Desktop

Article • 08/08/2024

Use Power BI Desktop to view tables in Microsoft Dataverse. The table row data that you can access from your environment is read-only. Data access uses the Dataverse security model that is the same used to access table row data using a Power Apps app.

Prerequisites

- Enable the Tabular Data Stream (TDS) endpoint (on by default). More information: Manage feature settings.
- Power BI Desktop. Get it now

View table data

1. Sign into Power Apps, and then select the appropriate environment from the top-right corner.

2. On the left navigation pane select **Tables**. If the item isn't in the side panel pane, select ...More and then select the item you want.

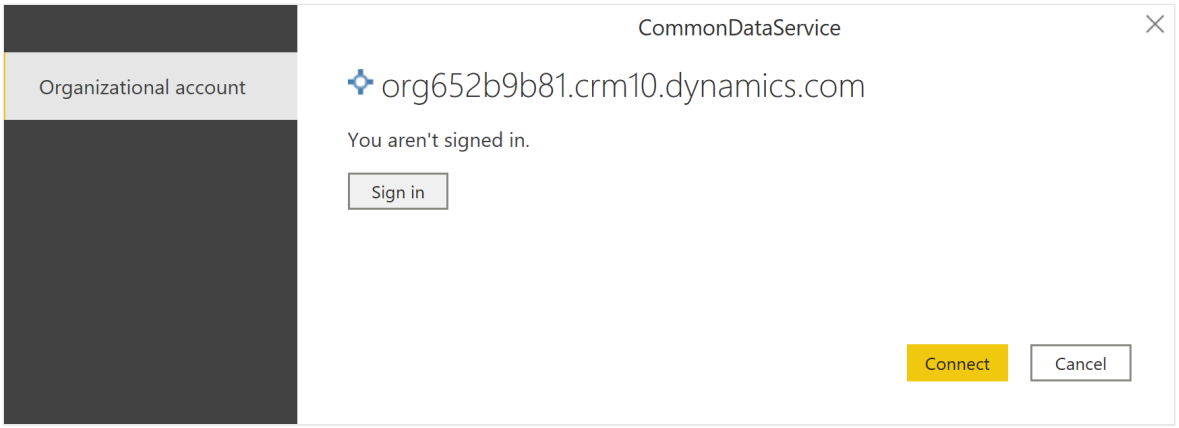
3. Select **Analyze** > **Analyze in Power BI** on the command bar.

   The pbids file for your environment is downloaded to your browser's default download folder.

   > **Note**
   >
   > To be able to download the file, you must have read access to the analysis component (msdyn_analysiscomponent) custom table privilege in Dataverse. Users with the environment maker security role have full access to this privilege.

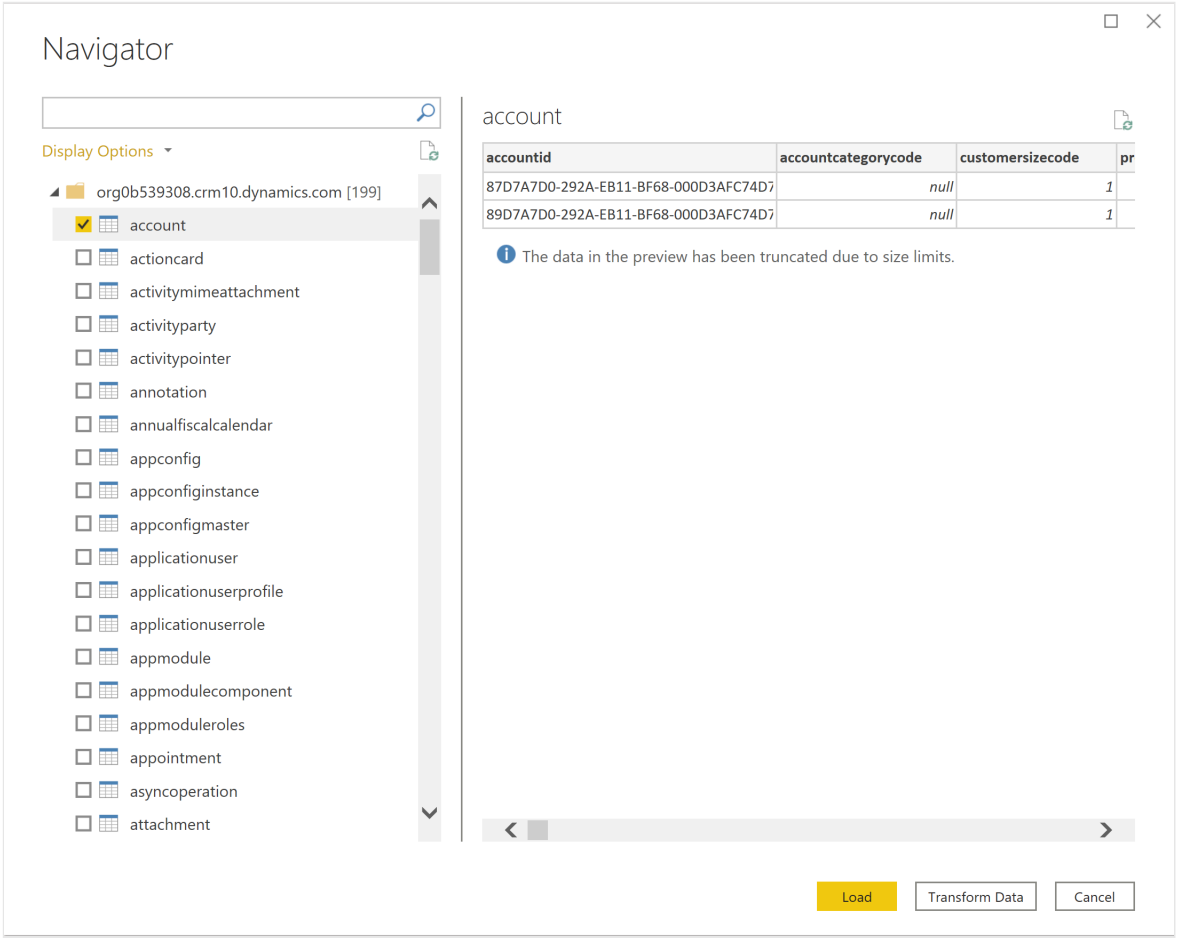
4. Open the .pbids file to access it in Power BI Desktop.

5. The pbids file is loaded in Power BI Desktop. In the dialog box, select **Organizational account**, select **Sign in**, and then in the browser window that appears select or enter your credentials.



6. In the dialog box in Power BI Desktop, select **Connect**.

   The environment appears in the Power BI Desktop **Navigator** window. Expand it to view the tables available to analyze. Select a table to preview its data.



7. After you're finished selecting the tables you want to analyze, select **Load** to build a report.

For more information about Power BI Desktop, see Get started with Power BI Desktop.

> **Note**
>
> SQL options, such as a T-SQL queries aren't supported.

> **Tip**
>
> The **Power BI modeling guidance for Power Platform** article provides implementation guidance and best practices on how to create a Power BI data model that connects to Dataverse:
>
> - Performance and security considerations when connecting Power BI to Dataverse.
> - Dataverse connector best practices.
> - Working with large datasets using Azure Synapse Link for Dataverse.
> - Considerations for DirectQuery.

Transition from legacy data integration services

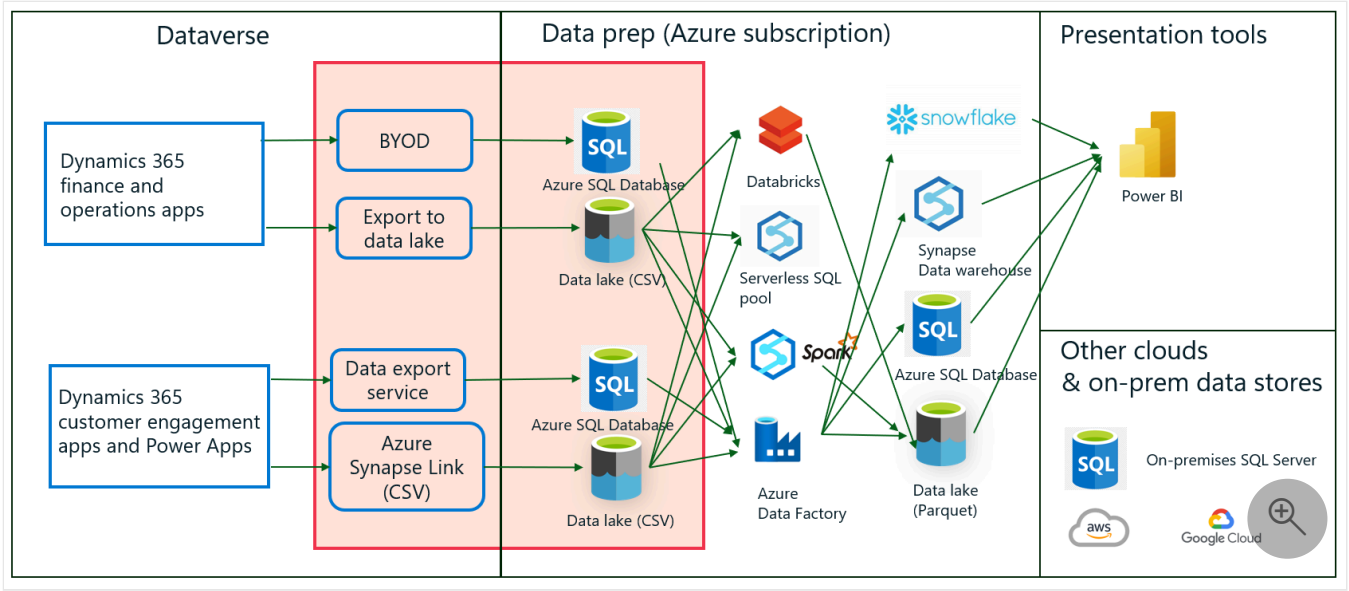
Data export service, bring your own database (BYOD), and Export to Data Lake were features introduced in Dynamics 365 apps to export data for analytics and data integration scenarios. These services enabled IT admins and specialists to export data into external databases or data lakes and build data integration pipelines. While we improved these services over the years with updates as part of unification of Dynamics 365 with the power platform, we rearchitected the same capabilities of these disparate services into simpler, unified experiences built into Power Apps (make.powerapps.com). With a transition to Microsoft Fabric link or upgrade to Azure Synapse Link, the rearchitected services provide you with an easy ramp to benefit from AI and Copilot investments in Microsoft Dataverse and Fabric.

If you're a customer using any of the previous generation services, this article provides guidance on upgrading to the new experiences, benefiting from innovations, as well as reducing end-to-end expenses and effort.

Based on preview customer surveys, we also compiled a high level cost and benefits estimate to help you with the transition. Links to more information and videos, links to join forums and weekly office hour sessions to engage with the product team, Microsoft specialists, and fellow users are also provided here. We strive to enhance these services with community participation.

Before transition

If you're a customer using legacy services BYOD, data export service, or Export to Data lake, you might have a data integration architecture similar to the one shown here. The highlighted box indicates the data pipelines your organization might have built to leverage the data exported from Dynamics 365 and Dataverse. You can use a selection of tools from Microsoft, as well as others, to copy and integrate Dynamics data with your own data. You can also transform and aggregate data by copying into multiple stores – shown in the data prep box of the diagram. You can use Power BI or another tool to visualize data and create actionable insights. You might have pipelines built to export data to an on-premises system and other clouds.



After transition

There are two data integration patterns enabled in Power Apps:

- Azure Synapse Link enables continuous export of data similar to BYOD, Export to Data Lake, or data export service. This option is enabled for IT admins and data integration specialists.
- Link to Fabric feature provides a no-copy, no-extract, transform, and load (ETL), fully managed software as a service (SaaS) integration.

These options are complementary. Here's a detailed comparison of the data integration services.

If you're a finance and operations apps customer currently using BYOD or Export to Data Lake features, by upgrading to Azure Synapse Link or Fabric link, you can benefit from a simplified data integration architecture resulting in reduced operational costs:

- Easy to configure and maintain via Power Apps (make.powerapps.com). Built-in integration with Azure Synapse and Fabric.
- Azure Synapse Link and Fabric link are fully managed services. Each requires minimal ongoing management overhead.
- New services offer the same data shapes as previous services. Your existing downstream integration pipelines can remain as-is.
- Minimal impact to operational workloads, you don’t need to manage workloads and schedule data exports.

Secure, end-to-end data integration pipelines:

- With Fabric link, your data doesn’t leave the Dataverse governance boundary while authorized Fabric users can securely access data that resides within Dataverse.

- Azure Synapse Link service enables you to restrict access to your storage accounts with firewalls while enabling Dataverse to export data with managed identities for Azure, a security feature built into Microsoft Entra.

If you're a Dynamics 365 customer engagement customer using data export service or classic Azure Synapse Link with data exports in CSV format, you can benefit from efficient reporting enabled with the industry standard Delta or Parquet data format:

- Built-in Delta Lake or Parquet conversion option reduces the need to build your own pipelines for analytics and operational reporting.
- Delta Lake or Parquet format enables faster, more responsive queries & reports and scales to larger datasets of any size.
- Data in lake is compressed to 1/3 to 1/8 the original size, resulting in smaller files that reduce data query and carrying costs.

Expand table

Link to Fabric	Azure Synapse Link
No copy, no ETL direct integration with Fabric.	Export data to your own storage account and integrate with Azure Synapse, Fabric, and other tools.
Data stays in Dataverse. Users get secure access in Microsoft Fabric.	Data stays in your own storage. You manage access to users.
All tables chosen by default.	System administrators can choose required tables.
Consumes additional Dataverse storage.	Consumes your own storage and other compute and integration tools.

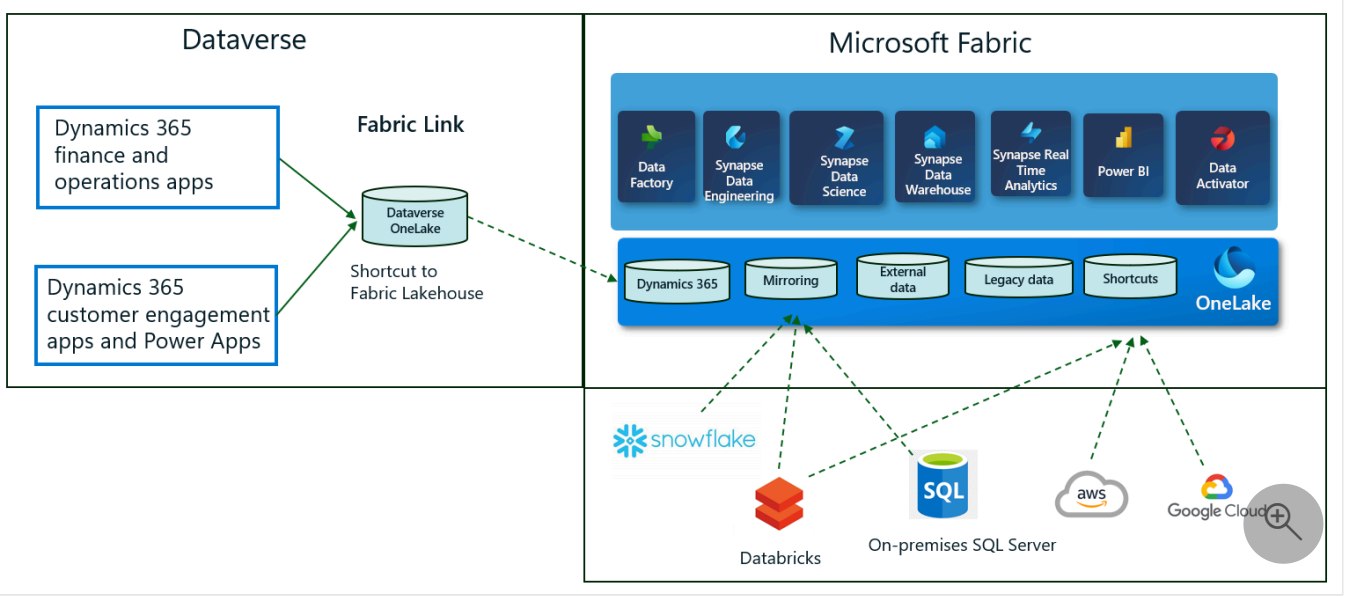
Which option should I use?

If your organization is already using Fabric or planning to transition in the coming months, we recommend using the Fabric link feature. You can continue to use the Azure Synapse Link service if your immediate focus is to upgrade from your current services.

Simplification with Fabric link

If you're already consuming data using Power BI, using a data warehouse, or using dataflows and notebooks to transform data, the link to Fabric feature provides immediate value. You can simplify your data integration architecture by removing the need to have your own storage account or Synapse services for Dataverse data. Instead of paying for Azure resources like storage and compute, you pay for the increase in Dataverse storage. Compute charges such as

near real-time data updates and management overhead is also factored into Dataverse storage. Fabric link option is like having a near real time read-only replica of your data optimized for insights.



Query this replica using T-SQL, Apache Spark, Python as well as other workloads in Fabric. You can also access this data using any tool that can consume T-SQL or can consume data from Azure Data Lake Storage.

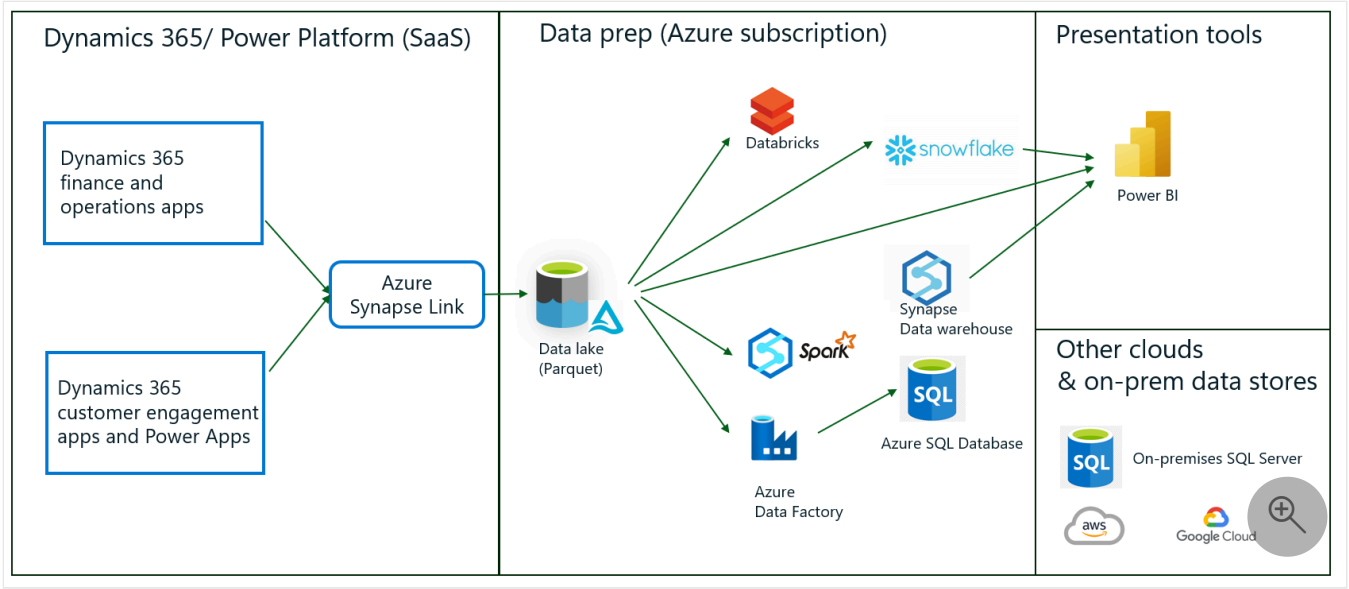
As a Dynamics or Power Apps customer, you get a Dataverse storage quota based on the number of licenses you purchased. The Fabric link feature uses this database quota. You can buy more storage add-ons if the data volume exceeds your quota.

You can continue to retain Azure platform as a service (PaaS) services, like Databricks and SQL Database, in your own subscription. Recently announced Fabric features like data mirroring and shortcuts can help you further simplify your data integration.

Examples of cost reductions achieved with the simplicity derived from Fabric integration feature are described here.

Upgrading to Azure Synapse Link

By upgrading to Azure Synapse Link and enabling Delta or Parquet conversion, you can eliminate Dataverse data prep pipelines in your solution. Azure Synapse Link service exports the same data shapes into your storage account in a more performant Delta or Parquet format. You can continue to use existing tools and Azure services like storage and Azure Synapse Analytics query with minimal disruptions to your production environments.

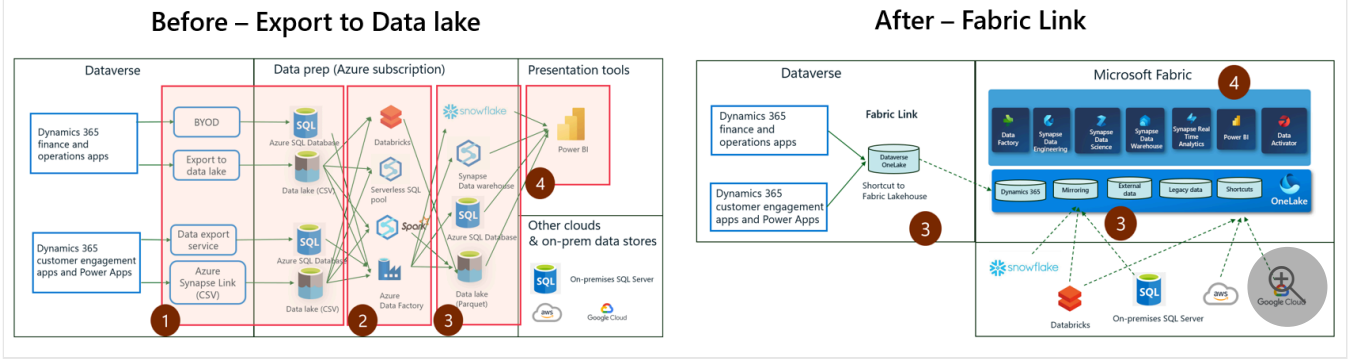


Understanding benefits and cost reductions

Simplicity achieved with Fabric link and Azure Synapse Link yields reductions in end-to-end costs. Consider the following examples that are based on preview customer experiences.

Example 1: Transition from BYOD or Export to Data Lake to Fabric link

Consider the case where you transition to Fabric link from Export to Data Lake.



As indicated in the before and after diagrams in this article, customer retired export to data lake service (1) as well as staging data stores (2) with Fabric link. For operational insights, (4), they consumed data in OneLake directly in Power BI. Some of the insights require data merge, transformation, and aggregation (3). Instead of using disparate Azure services, they standardized on the same tools built into Fabric.

Innovations in Dataverse and Fabric enable simplifications and cost reductions:

- Dataverse comes with a built-in OneLake store. Operational data from Dynamics 365 and Power Apps are replicated to built-in lake store near real-time (to avoid influence to

operational workloads) and linked securely to Fabric via shortcuts. There's no need to bring Azure storage and secure data that's exported out. Your data doesn't leave the Dataverse governance boundary and authorized users in Fabric can work with data using all Fabric workloads.

- Export to data lake and data export service exports data in CSV format. CSV files aren't suitable for direct consumption due to poor query performance as well as occasional read/write contention issues. The before transition solution uses Azure Data Factory to periodically ingest and convert raw data into an Azure SQL Database or an Azure data warehouse. This layer isn't needed in the after transition solution since Dataverse built-in OneLake data is maintained in Delta or Parquet format – the same open format that is native to Microsoft Fabric. Delta or Parquet format, along with optimizations in Fabric removes the need to maintain additional data stores for caching and improving query performance while eliminating read/ write contention. You can create Power BI reports using Direct Lake over data in OneLake without any additional data stages.
- While operational insights can be performed using the data already available in OneLake, you might have additional data from other systems. This data might need to be combined, reshaped, and aggregated with Dataverse data. Fabric provides an integrated environment, which provides best of breed tools like dataflows, Azure Data Factory, and Spark. Use these tools as opposed to configuring and provisioning tools standalone, where you adopt the tools of your choice. Integrated billing, source control, and security enable simpler management and governance.
- While you can continue to use Power BI service for reporting purposes, Fabric introduces Direct Lake mode reporting, which leverages the in-memory indexes built into Delta or Parquet format therefore removing the need to use Power BI import mode reports.

These innovations yield end-to-end cost savings in addition to the benefits discussed earlier. The tables here outline the line items of costs along with a comparison of before and after solutions. You can use this table as a guideline to estimate expected cost savings.

Expand table

Cost savings line item	Before cost - export to data lake	After cost - Fabric link
Set-up and configuration	Need to use multiple tools. - Pay for multiple software licenses and subscriptions. - System configuration efforts. - Effort to build and validate data pipelines. - Continued governance,	Simpler configuration experience in Power Platform. Purchase Fabric capacity and pay for use for all services. You only pay for what you use. In some cases, you're billed by the second. No ETL pipelines needed for Dataverse data.

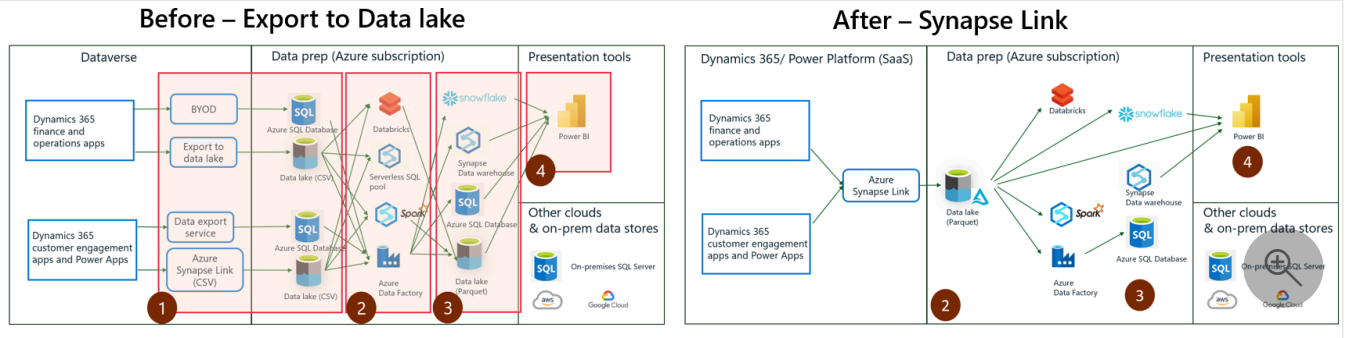
Cost savings line item	Before cost - export to data lake	After cost - Fabric link
	management, and monitoring. - Training of users.	
Data staging (1, 2)	Cost incurred for Azure services. - Azure storage cost including cost of IO. - Synapse Analytics (SQL serverless query). - Azure Data Factory jobs to copy data. - Staging data stores, such as Azure SQL Database.	Cost increase in Dataverse storage For example, if you sync 500 GB of data from Dynamics 365, Dataverse storage could increase by around 100 GB (assuming five to eight times data compression).
Operating Costs - data prep (3)	- Azure storage staging area. - Data pipelines. - Data ingestion into Azure SQL or data warehouse. - Development of maintenance data.	Spending shifts to Fabric where you pay for consumption with a shared capacity.
Operating costs – reporting (4) - Power BI datasets. - Reporting.	Synapse analytics (SQL query). Power BI capacity and storage for import mode reports.	As your data is compressed (for example 1/3 to 1/6 original size), your reporting and query costs reduce accordingly. New features, like Direct Lake reporting, reduce consumption of Power BI storage consumption.

> **Note**
>
> These estimates are provided to enable estimating the spend after transition. While these estimates are based on experience from preview customers, actual costs incurred in your environment as well as data compression can vary depending on volume and composition of data.

Example 2: Upgrade to Azure Synapse Link

Upgrading to Azure Synapse Link is an option to consider if you're not currently using Fabric – or not planning to transition in the coming months.

As indicated in the before and after diagrams here, customer retired Export to Data Lake service (1) as well as staging data stores (2) with Azure Synapse Link. Data stores used for data staging, such as intermediate Azure SQL Databases, are retired as Dataverse data is saved in Delta or Parquet format – a more performant and compressed data format. Downstream pipelines used for data merge, transformation, and aggregation, (3), as well as presentation tools (4), such as Power BI, remain unchanged.



Azure Synapse Link provides an easy upgrade path for customers looking to extend their existing investments with minimal changes. As we discuss here, innovations in Dataverse enable easy transition from finance and operations apps services like Export to Data Lake and BYOD.

1. Azure Synapse Link enables easy configuration of Azure storage and Synapse services within the Power Apps (make.powerapps.com). Several limitations of Export to Data Lake are removed:
   a. A uniform experience enables choosing data from all Dynamics 365 apps including both finance and operations and customer engagement apps. You can maintain a single service to export data from all Dynamics 365 and Power Apps.
   b. Table limitations present with Export to Data Lake go away. You can choose up to 1,000 tables for each Azure Synapse Link profile within a single storage account. You can create multiple profiles (export pipelines) each with up to 1,000 tables.
   c. Azure Synapse Link provides built-in support for using firewall restricted storage accounts to export data.
   d. No need to configure Azure resources. Azure Synapse Link provisions and configures Azure resources on your behalf.
   e. Azure Synapse Link exports data in the same format as Export to Data Lake or BYOD enabling you to retain existing pipelines.

2. Both Export to Data Lake and data export service export data in CSV format. CSV files aren't suited for direct consumption due to poor query performance as well as occasional read/write contention issues. Before transition uses Azure Data Factory to periodically ingest and convert raw data into a SQL Azure Database or an Azure data warehouse. This layer isn't needed in the 'after transition since Azure Synapse Link exports data in Delta or

Parquet, which removes the need to maintain additional data stores for caching and improving query performance while eliminating read/write contention.

3. Continue to use your existing data pipelines for combining, reshaping, and aggregating additional data from other systems.

4. Continue to use Power BI service for reporting purposes. Fabric introduces Direct Lake mode reporting that leverages the in-memory indexes built into Delta or Parquet format, which removes the need to use Power BI import mode reports.

These innovations yield end-to-end cost savings in addition to the benefits discussed earlier. The tables here outline the line items of costs along with a comparison of before and after solutions. Use the table as a guideline to estimate expected cost savings.

Expand table

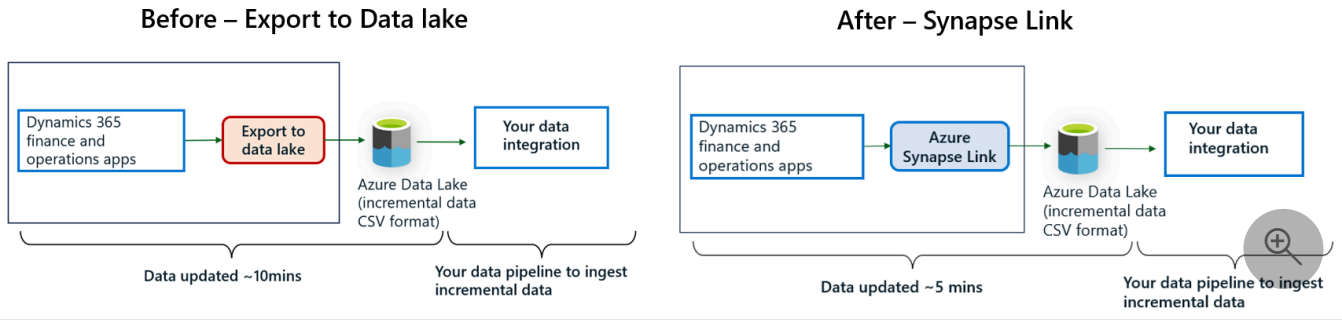
Cost savings line item	Before cost - Export to Data Lake	After cost - Azure Synapse Link
Set-up and configuration	Must use multiple tools. - Pay for multiple software licenses and subscriptions. - System configuration efforts. - Effort to build and validate data pipelines. - Continued governance, management, and monitoring. - Training of users.	Simpler configuration experience in Power Platform. No ETL pipelines needed for Dataverse data.
Data staging (1, 2)	Cost incurred for Azure services. - Azure storage cost including cost of IO. - Synapse Analytics (SQL serverless query). - Azure Data Factory jobs to copy data. - Staging data stores, such as Azure SQL Database.	Azure Synapse Link requires you to provide a Spark pool to convert data to Parquet format. Depending on the frequency of data sync, as well as the volume of data changes, Spark pool costs can vary. Small to medium data changes (per month): - $600 to $2,000 for hourly refresh. - $1,200 to $4,100 for 15-minute refresh. Medium to large data changes (per month): - $1,200 to $2,500 for hourly refresh. - $2,500 to $8,300 for 15-minute refresh.
Operating costs - data prep (3)	- Azure storage staging area. - Data pipelines. - Data ingestion into Azure SQL Database or data	Same costs as indicated above, however, you might not need to aggregate Dataverse data due to Parquet conversion.

Cost savings line item	Before cost - Export to Data Lake	After cost - Azure Synapse Link
	warehouse. - Development and maintenance data.	
Operating costs - reporting (4): - Power BI datasets. - Reporting.	Synapse Analytics (SQL query). Power BI capacity.	As your data is compressed, for example 1/3 to 1/6 original size, your reporting and query costs reduce accordingly.

> **Important**
>
> These estimates are provided to enable estimating the spend after transition. While these estimates are based on experience from preview customers, actual costs incurred in your environment as well as data compression can vary depending on volume and composition of data.

Example 3: Incrementally ingesting data to a data warehouse

If you're currently consuming incremental data from Export to Data Lake feature to populate a downstream data pipeline, you can continue to use the same pipeline. As shown here, Azure Synapse Link service can export incremental data changes in the same format as changes feed into Export to Data Lake.



Azure Synapse Link service provides several enhancements over Export to Data Lake for incremental data changes:

- Initial data load is included within change folders. This makes it easy for the same pipeline to consume both the initial load as well as incremental updates.
- Change data isn't deleted in case of a reinitialization of a table.
- System creates a time-stamped folder structure and metadata that helps you read the changes in chronological order. Change data once written, is never updated. This

approach is better suited to process changes using big data ingestion tools like Azure Data Factory.
- You can configure how often you want the change feeds updated in folders with Azure Synapse Link, as low as five minutes.

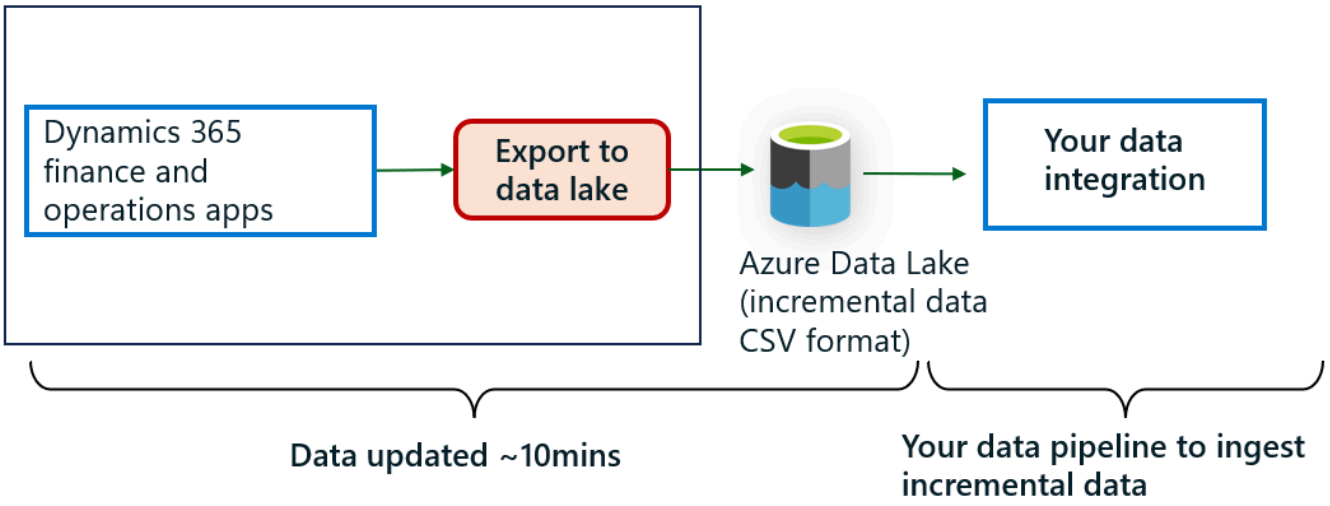
When you transition to Fabric or Azure Synapse Link, the change in cost is minimal for incremental data changes.

Understanding benefits – more real-time reporting

Fabric not only simplifies your data integration architecture, but also reduces the need to copy or replicate data. The underlying data format in Fabric, the industry standard Delta or Parquet format, can be directly consumed by Power BI, dataflows, notebooks, and other workloads eliminating the need for caching and staging areas.

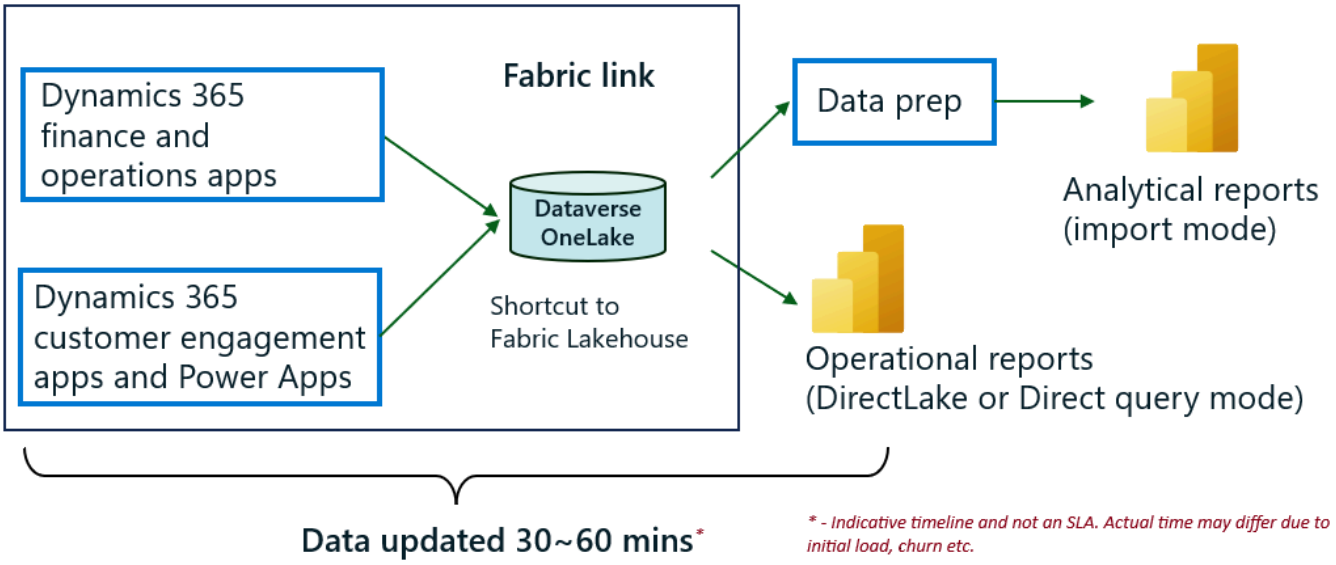
If you upgrade to Azure Synapse Link and continue to export data, your data is saved in Delta or Parquet format, which can reduce the steps in your own data pipelines for operational reporting.

Consider the time taken to refresh an operational report, such as inventory analysis or month-end financial analysis. These reports might require data aggregation of millions of rows of data from multiple tables in Dynamics 365 Finance. Using Export to Data Lake service, CSV data is exported within 10 minutes. This data might need to be imported into a Power BI report to provide better response times. Power BI refresh can be performed up to 24 times a day (every 30 minutes). Depending on how the report is designed, refresh can take several minutes to complete refresh. Using this approach, users can see data within 60 minutes of an update. These timelines are indicative. Actual sync time depends on factors such as the initial data load size, data churn rate, and the volume of change.



Operational reports that source data using Fabric link can leverage Direct Lake mode or DirectQuery mode in Fabric, which leverages the in-memory index built into Delta or Parquet

files. In these modes, you don't need to schedule refresh of Power BI reports as the report always shows latest Dataverse data updated in Fabric.



The Fabric link service updates data in Dataverse OneLake within the hour as of this point in time. Dataverse triggers data update jobs every 15 minutes and depending on the volume of data changes, you might see updated Parquet files within 15 to 45 minutes. These timelines are indicative. Actual sync time depends on several factors including the initial data load size, data churn rate, and the volume of changes. In situations with high transaction volumes, such as processes in Dynamics 365 finance and operations apps generating millions of records in a short time, or processes like the master planning feature included with Dynamics 365 Supply Chain Management that delete and re-create large volumes of records, Synapse Link must synchronize all changes including deletes. In these high-volume scenarios, data availability within the indicated timeframes can't be guaranteed.

If you're consuming incremental data feeds from Dynamics 365 with Export to Data Lake service for near-real time data integration scenarios (example 3). Upgrade to Azure Synapse Link enables you to run the same data pipelines.

Limitations and changes to behavior

You might find a few changes in table formats introduced that help avoid conflicts. More information: Known limitations.

Also verify that you have the latest updates, which address some of the known issues. To learn more about the upcoming roadmap and stay in touch with the product team, join the preview Viva Engage group.

Frequently asked questions when transitioning from legacy data integration services

Summarize this article for me

This article discusses the frequently asked questions with transition from legacy data integration services to Fabric link or Azure Synapse Link for Dataverse.

Data export service, bring your own database (BYOD), and export to data lake were features introduced in Dynamics 365 apps to export data for analytics and data integration scenarios. These services enabled IT admins and specialists to export data into external databases or data lakes and build data integration pipelines. While we improved these services over the years with updates, as part of unification of Dynamics 365 with the Power Platform, the same capabilities are rearchitected for these disparate services into simpler, unified experiences built into Power Apps (make.powerapps.com). The unified and improved service is called link to Azure Synapse.

Also available is a service named link to Microsoft Fabric where you can directly integrate Microsoft Dataverse, the data platform behind Dynamics 365 as well as Power Apps with Microsoft Fabric with no-copy, no-ETL required. Whether you link to Microsoft Fabric or upgrade to Azure Synapse Link, the rearchitected services provide you with an easy ramp to benefit from AI and Copilot investments in Dataverse and Fabric.

What is the difference between Link to Azure Synapse and link to Fabric?

Link to Azure Synapse and link to Fabric services are built into Dataverse, the platform powering Power Apps and all Dynamics 365 products.

Azure Synapse Link continuously exports data from Dynamics 365 and Power Apps to your own storage account, allowing IT professionals to build and manage data integration pipelines with Azure Synapse Analytics as well as other tools.

In contrast, link to Fabric offers a no-copy, no-ETL integration directly with Microsoft Fabric, keeping data within the Dataverse governance boundary for enhanced security. Fabric Link uses Dataverse managed storage, removing the need to configure and manage your own storage. When using link to Fabric, you might notice an increase in Dataverse storage consumption.

Both these services operate across PowerApps, Dynamics 365 customer engagement apps like Dynamics 365 Sales, Dynamics 365 Customer Service, as well as Dynamics 365 finance and operations apps.

Expand table

Link to Fabric	Azure Synapse Link
No copy, no extract, transform, load (ETL) direct integration with Fabric.	Export data to your own storage account and integrate with Azure Synapse, Fabric, and other tools.
Data stays in Dataverse. Users get secure access in Microsoft Fabric.	Data stays in your own storage. You manage access to users.
All tables chosen by default.	System administrators can choose required tables.
Consumes additional Dataverse storage.	Consumes your own storage and other compute and integration tools.

What option should I consider if I want to use Microsoft Fabric?

Fabric Link provides a seamless, no-copy integration with Dataverse and Microsoft Fabric, eliminating the need to manage complex data export processes. With link to Microsoft Fabric, your data stays securely within your Dataverse environment, while authorized users in Microsoft Fabric can access the data, making it easier for your team to leverage data for insights without the hassle of managing separate storage and integration solutions. This streamlined approach can lead to cost savings and more efficient data utilization, especially if you're already using Power BI. [Go to this article](/powerapps-docs/maker/data-platform/azure-synapse-link-transition-from-FnO.md#Simplification with Fabric link) for a comparison of total cost of ownership (TCO) between link to Microsoft Fabric and link to Azure Synapse.

Using the Fabric Link transition tool provided by Dynamics 365 FastTrack team, you can create a Fabric data warehouse with the same data shapes as export to data lake feature and minimize the effort to transition your existing reports and data pipelines.

What option should I consider if I want to keep the data export solution?

Upgrading from export to data lake to Azure Synapse Link enables you to preserve your investments with minimal changes. While Azure Synapse Link simplifies data integration by

continuously exporting data in a more efficient Delta Parquet format, it provides similar outputs as export to data lake service therefore reducing the effort to switch. You can use Power BI, Microsoft Fabric as well as many non-Microsoft tools that support Delta Parquet format to work with your Dynamics 365 data. You can also secure your storage account with firewalls and enable restricted access via managed identities, ensuring secure data access and compliance. Go to this article for a comparison of total cost of ownership (TCO) between link to Fabric and link to Azure Synapse.

Using the Synapse Link transition tool provided by Dynamics 365 FastTrack team you can create a Synapse workspace with similar data shapes as export to data lake feature and reduce the effort to transition your existing reports and data pipelines.

We don't use Power BI or Fabric with Dynamics 365 data, can I extract change data?

If you use Power BI or Microsoft Fabric to gain insights from your Dynamics 365 or Power Apps data, Fabric Link provides the most benefits while simplifying data integration efforts. However, if you're using non-Microsoft tools and/or use export to data lake change feeds to incrementally export data to your downstream data warehouse, you can use Synapse Link incremental data exports instead. More information

Using the The Data integration tool provided by Dynamics 365 FastTrack team you can create a pipeline to incrementally copy change data into an Azure SQL database, Synapse dedicated pool or an on-premises database.

Are there differences in columns/schema between Export to Data Lake and Fabric Link or Synapse Link?

Fabric Link and Synapse Link represent a unification of legacy services built into Dynamics 365. The same capabilities are rearchitected to transform these disparate services into simpler, unified experiences built into Power Apps (make.powerapps.com). In the process, to avoid conflicts, minor changes are made to the schema. The underlying data engine behind Fabric Link and Synapse Link is the same so the changes apply both to Fabric Link and Synapse Link options:

- Renaming SQL reserved words such as `Level_, Resource_`.
- ID field in export to data lake tables become `FnO_Id`.

- Deleted rows are included. For example, Synapse Link and Fabric Link perform what is referred to as a "soft delete." You can use the `isDelete` flag to identify deleted rows and remove them.
- TimeZoneID (TZID) fields are removed because these are legacy fields no longer used in finance and operations apps.
- Fields that contain binary data are removed.
- `nVarChar(max)` fields are included but data is truncated at 2,000 characters.

For more information, go to working with Finance and Operations data and metadata.

Using the Fabric Link transition tool provided by Dynamics 365 FastTrack team, you can create a Fabric data warehouse with the same data shapes as export to data lake feature and minimize the effort to transition your existing reports and data pipelines.

Using the Synapse Link transition tool provided by Dynamics 365 FastTrack team you can create a Synapse workspace with similar data shapes as export to data lake feature and reduce the effort to transition your existing reports and data pipelines.

Using the data integration tools provided by Dynamics 365 FastTrack team you can create a pipeline to incrementally copy change data into an Azure SQL database, Synapse dedicated pool or an on-premises database.

Why are all Dataverse tables auto selected with Fabric Link, why can’t I select only the Dataverse tables I need?

By selecting **Link to Microsoft Fabric**, the system adds all nonsystem Dataverse tables that have the **Track changes** property enabled. You can’t remove these tables as some of these tables might be used by Dynamics 365 as well as partner applications and removing them can cause the applications to fail.

Enabling link to Fabric feature (or a Dynamics 365 application that contains insights features) might result in an increase in Dataverse database storage consumption. You can view additional storage consumption as additional files in the environment storage capacity details view in the Power Platform admin center. For example, you might notice an additional file "Account-Analytics" if you selected the "Account" table for Fabric link. Also note that the chart only displays tables consuming highest storage. You can get a list of tables using the menu on top right of the chart.

Export to data lake service is working well for us. Why did you retire these services?

As part of the Dynamics 365 platform unification project, we consolidated several services that "exported data" in Dynamics 365 applications to a single service under the brand name Synapse Link for Dataverse. Using our learnings, many shortcomings of existing services were addressed in Synapse Link while maintaining same data formats – so that you can upgrade your investments with minimal disruptions. Fabric link service is a new, no-copy, no-ETL solution, which enables you to leverage innovations in Fabric without having to invest in data pipelines. It's a "read-replica" of your data for authorized users in Fabric.

Why can't I find some Tables and Entities from Finance and Operations in tables in Link to Fabric or Link to Azure Synapse

Azure Synapse Link or Fabric link enables tables where the "change tracking" property is enabled. Currently, change tracking can't be enabled for all finance and operations entities. The **Track changes** option is unavailable for entities created in finance and operations in the past for data migration. In some entities, enabling change tracking might fail with the error message **chosen entity doesn't pass the validation rules** or the **Track changes** checkbox is disabled for some entities.

For more information about entity validation rules and how you can fix them, go to Enable row version change tracking for data entities. You might need developer assistance to complete the steps. If the chosen entity is unavailable because of the change tracking limitation, choose the tables that comprise the data from that entity.

You can use the EntityUtil solution provided by the FastTrack team to create entity shapes using tables.

Is BYOD service retired? Is there a retirement date?

As part of the Dynamics 365 platform unification project, several services that exported data in Dynamics 365 applications are consolidated. BYOD is a service that exports entity data into a customers own Azure SQL database. While a retirement date for BYOD service hasn't been determined, we recommend that you transition to Synapse Link or Fabric link services. Fabric link service is a new, no-copy, no-ETL solution, which enables you to query your data with SQL similar to a "read-replica" of your data in Fabric.

Will you retire Synapse Link in the future?

As part of the platform unification project, we have consolidated several services that exported data in Dynamics 365 applications to a service under the brand name Synapse Link for Dataverse. Fabric link, a no-copy, no-ETL solution, which enables you to leverage innovations in Fabric without having to invest in data pipelines is also available. Link to Fabric is a "read-replica" of your data for authorized users in Fabric.

While many customers are excited to adopt Fabric, we also understand some customers want to continue to export data and build their own integration pipelines. As such, we want to enable you to export data well into the future.

Will export to data lake service stop since it's deprecated after November 1, 2024?

Export to data lake service is deprecated as of November 1, 2024 and support will be limited. You can reduce the risk by beginning the transition process now. We plan to decommission export to data lake service beginning March 25, 2025 as customers transition to Synapse Link and Fabric link services. We plan to start the decommissioning process with customers who have completed the transition as well as customers who aren't actively using the service. You'll be notified before the decommission process begins and have the option to ask for a past due extension via the link aka.ms/SynapseLinkPastDue.

My transition might run beyond deprecation date, is there a process to get an extension?

Export to data lake service is deprecated as of November 1, 2024, but will continue to operate under limited support until March 25, 2025. If you haven't done so already, you should begin the transition process now.

To help customers who might need more time to complete their transition, we introduced an in-product "past due extend" option. You can apply for a one-time "past due extension" by taking the survey the Azure Synapse Link area in Power Apps (make.powerapps.com) or the link aka.ms/SynapseLinkPastDue. This option is available only to customers who are currently validating either Synapse Link or Fabric Link services.

If a past due extension is approved, you receive a confirmation e-mail and the extended date is shown within the product. You can join the community and stay in touch via the forum or weekly office hours at aka.ms/SynapseLinkforDynamics.

I have completed the transition, how can I uninstall export to data lake feature?

If you aren't using this feature in your environment, ask your finance and operations apps administrator to uninstall this feature. To uninstall, visit the environment page in life cycle services (LCS), navigate to the **Environment Add-ins** section, and then select the **Uninstall** option in the **Export to Data lake** environment add-in.

I received an email about transitioning Azure Synapse Analytics workspaces to private links before 1 August 2026. What do I need to do?

As described in the email, the trusted services function that allows Azure Synapse Analytics to access Azure Storage accounts and Azure Key Vault using a managed identity and firewall exception will be retired on **1 August 2026**.

If you decide to transition your Synapse workspace to private links as described in the email, complete the following steps to ensure Azure Synapse Link for Dataverse continues to work as expected:

1. Create a Synapse workspace with a managed virtual network. A managed virtual network isolates your Synapse workspace and is required to use managed private endpoints. Follow the steps in Azure Synapse Analytics managed virtual network.

2. Create a managed private endpoint for your storage account (ADLS Gen 2). This replaces the trusted services firewall exception with a private, secure connection. Follow the steps in Create a managed private endpoint to your data source.

3. Enable these network settings:

    - On the **storage account**: enable **Allow Azure services and resources to access this storage account** (under **Networking** > **Firewalls and virtual networks**).
    - On the **Synapse workspace**: enable **Allow Azure services and resources to access this workspace** (under **Networking**).

    Both settings must be enabled for Azure Synapse Link to connect successfully.

After completing these steps, your Synapse workspace connects to the storage account through a private endpoint instead of the trusted services firewall exception.

[Link your Dataverse environment to Microsoft Fabric and unlock deep insights]

Last updated on 02/20/2026

Link your Dataverse environment to Microsoft Fabric and unlock deep insights

Microsoft Dataverse direct link to Microsoft Fabric enables organizations to extend their Power Apps and Dynamics 365 enterprise applications, and business processes into Fabric. The **Link to Microsoft Fabric** feature built into Power Apps makes all your Dynamics 365 and Power Apps data available in Microsoft OneLake, the built-in data lake for Microsoft Fabric.

- No need to export data, build extract, transform, load (ETL) pipelines, or use our partner integration tools.
- With shortcuts from Dataverse directly into OneLake, your data stays in Dataverse while authorized users get to work with data in Fabric.
- Link data from all Dynamics 365 apps, including Dynamics 365 Finance and Operations apps.
- Build Power Apps and automations to drive action from insights in OneLake.

Microsoft OneLake, a data lake built into Fabric, helps eliminate data silos. Combine data from your applications and devices web sites, mobile apps, sensors, and signals from your warehouse and factories with data from your business processes in Dynamics 365, such as sales, cases, inventory, and orders, to predict potential delays or shortages that affect keeping your promises to customers. Dataverse creates shortcuts to OneLake, which enables you to work with data without making multiple copies.

Dataverse also generates an enterprise-ready Microsoft Fabric Lakehouse and SQL endpoint and a Power BI dataset for your Power Apps and Dynamics 365 data. This makes it easier for data analysts, data engineers, and database admins to combine business data with data already present in OneLake using Spark, Python, or SQL. As data gets updated, changes are reflected in lakehouse automatically.

Low-code makers can build apps and automations to orchestrate business processes and react to insights found in Fabric. By adding those insights back to Dataverse as virtual tables connected to OneLake, makers build low-code apps with Power Apps, Power Pages, or Power Automate using the design tools already available. Using connectors to over 1,000 apps, makers create business processes that span Dynamics 365 as well as many other enterprise applications.

Watch this video to learn about accessing Dataverse data in Fabric:

https://learn-video.azurefd.net/vod/player?id=ddd288c6-e47a-4bc6-974b-4fe0f1a49362&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fazure-synapse-link-view-in-fabric

Link to Fabric from Power Apps

From the **Tables** area in Power Apps (make.powerapps.com), makers link to Fabric by selecting **Analyze** > **Link to Microsoft Fabric** on the command bar.

When you select the command for the first time, a wizard driven experience links your Dataverse environment to a Fabric workspace. A Fabric Lakehouse, SQL endpoint, a Power BI dataset are created and Dataverse tables are linked to the lakehouse via shortcuts.

Once the link is set up, you can grant other users access to the Fabric workspace so that they can work with Dataverse data using all Fabric workloads. The lakehouse, SQL endpoint, and Power BI dataset are updated with new data as changes occur in Dataverse. More information: Link to Microsoft Fabric

Direct access to your data in Microsoft OneLake

Link to Fabric creates a direct and secure Link between your data in Dataverse and a Fabric workspace. There's no need to provide a storage account or Synapse workspaces. When you link to Fabric from Power Apps, the system creates an optimized replica of your data in delta parquet format, the native format of Fabric and OneLake, using Dataverse storage such that your operational workloads aren't impacted. This replica is governed and secured by Dataverse and stays within the same region as your Dataverse environment while enabling Fabric workloads to operate on this data.

Admins can manage tables linked to OneLake from the **Azure Synapse Link for Dataverse** page. By opening the **Microsoft OneLake** link, admins view tables added by makers, add more tables, and migrate the link to other environments. Tables added to OneLake consume Dataverse storage and admins can see storage consumption in the Power Platform admin center.

> **Note**
>
> By selecting **Link to Microsoft Fabric**, the system adds all nonsystem Dataverse tables that have the **Track changes** property enabled. You can add more tables later.
>
> If you used this feature during public preview, you can continue to use the tables selected earlier. If you choose the **Link to Fabric** option in new environments (or unlink and relink existing environments), all tables are added.
>
> Enabling this feature results in an increase in **Dataverse database** storage consumption. You can view additional storage consumption in the environment storage capacity details view in Power Platform admin center. For an example, you notice an additional file

`Account-Analytics` if you selected the `Account` table for Fabric link. Also note that the chart only displays tables consuming the most storage. You can get a complete list of tables using the menu on the top right of the chart.

Comparing Link to Fabric with Azure Synapse Link for Dataverse

Azure Synapse Link for Dataverse enables IT admins to export data to their own storage and build data integration pipelines. Azure Synapse Link assists with provisioning and configuring Azure resources within an integrated experience.

Link to Fabric feature enables direct connectivity between your data in Dataverse with Microsoft Fabric without the need to bring your own storage and Synapse workspaces. Link to Fabric leverages storage built into Dataverse and removes the need to provision and manage your own storage.

This table provides a comparison between the options.

Expand table

Link to Fabric	Azure Synapse Link
No copy, no ETL direct integration with Microsoft Fabric.	Export data to your own storage account and integrate with Synapse, Microsoft Fabric, and other tools.
Data stays in Dataverse - users get secure access in Microsoft Fabric.	Data stays in your own storage. You manage access to users.
All tables chosen by default.	System administrators can choose required tables.
Consumes additional Dataverse storage.	Consumes your own storage as well as other compute and integration tools.

You can connect existing Azure Synapse Links with Microsoft Fabric and benefit from Fabric innovations like Power BI DirectLake mode reports and integrated Spark and data pipelines. You must create an Azure Synapse Link for Dataverse profile and enable the **Delta parquet conversion for Fabric link** option. This option isn't available for Azure Synapse Link for Dataverse profiles that use the CSV output format.

Next steps

Link to Microsoft Fabric

Last updated on 01/09/2026

Link to Microsoft Fabric

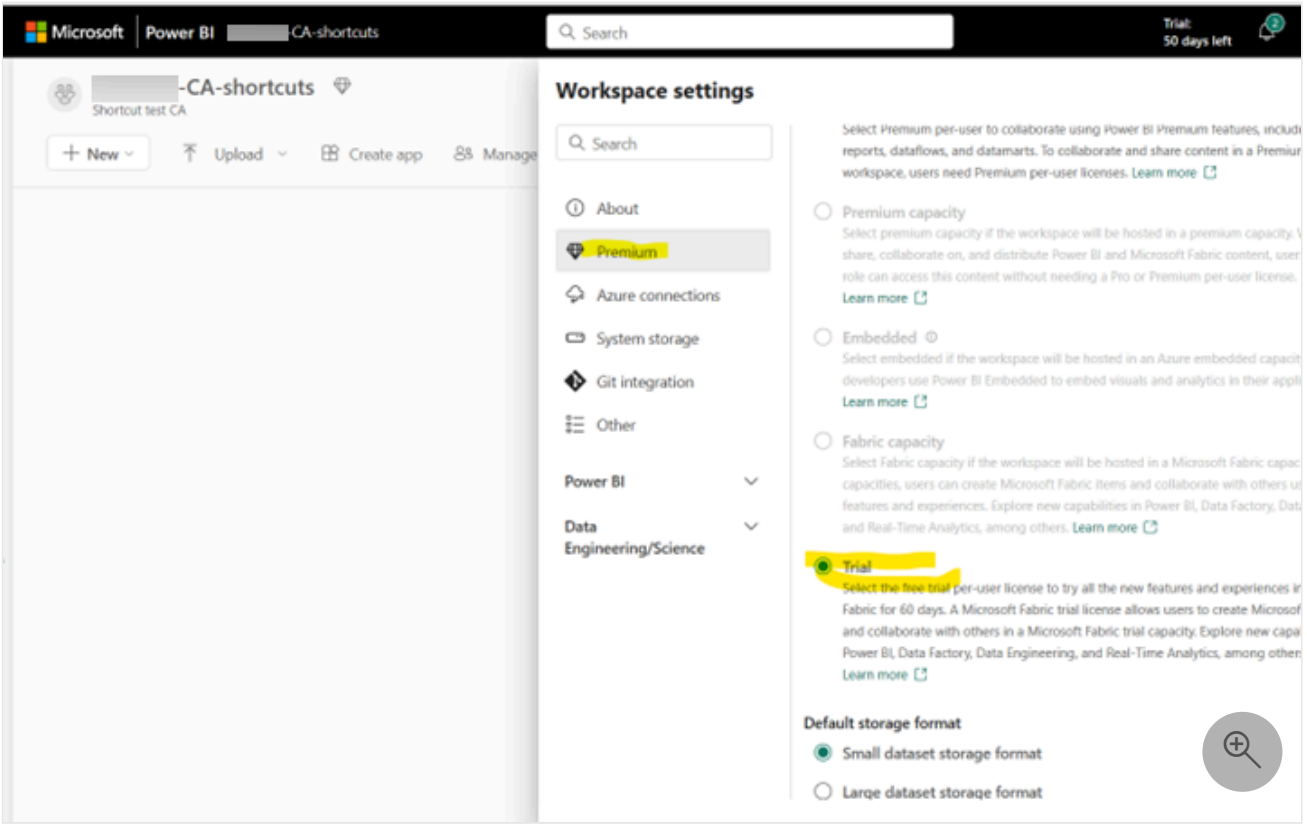
Microsoft Fabric integration with Microsoft Dataverse allows you to seamlessly link your Power Platform environment to Microsoft Fabric, enabling advanced data analysis and reporting capabilities. This guide provides step-by-step instructions on configuring your environment, linking it to Microsoft Fabric, and managing linked tables.

You can use an existing Dataverse environment or create a new developer environment if you want to try this feature. More information: Create a developer environment

Prerequisites

- You must have the System Administrator security role in the Power Platform environment to enable **Link to Fabric** or **Synapse Link**. This role is also required to add application users in your environment who need access to work with this feature by using the Power Platform admin center.
- You must be an administrator of the Power BI workspace.
- If you want the system to create a Power BI workspace, you need to have Power BI Capacity Administrator access to a capacity within the same region as the Dataverse environment.
- A Power BI premium license or Fabric capacity within the same Azure geographical region as your Dataverse environment is required. If you don't have Power BI premium license or Fabric capacity within the same geographical region, you can buy a capacity or sign up for a free Fabric trial capacity. More information: Fabric (preview) trial
- Your administrator needs to grant you access to create Fabric lakehouses and artifacts. You can find these settings in the Fabric admin portal. Go to **Tenant Settings** > **Microsoft Fabric** > **Users can create Fabric items**, **Tenant settings** > **Workspace settings** > **Create workspaces** as well as **Tenant settings** > **oneLake settings** > **Users can access data stored in OneLake with apps external to Fabric**.
- If you plan to use workspace identity authentication, you must be a workspace admin to create and manage a workspace identity. The workspace you're creating the identity for can't be a My Workspace. More information: Workspace identity in Fabric
- If you plan to use workspace identity authentication, the workspace identity must be onboarded as an application user in the Dataverse environment and granted the appropriate role (commonly System Administrator) so it can access Dataverse data on behalf of Fabric.

- You must have permissions in Fabric to manage connections via **Settings** > **Manage connections and gateways**.
- To confirm whether you have access to the required premium capacity, go to Power BI, open the workspace, and select **Workspace settings** > **Premium**. Make sure that **Trial** or **Premium capacity** is selected.



Create a link to Fabric

Link to Microsoft Fabric from the Power Apps **Tables** area: Select **Analyze** > **Link to Microsoft Fabric** on the command bar.

1. Sign into https://make.powerapps.com.
2. Select the environment you want, select **Tables** on the left navigation pane, and then select **Analyze** > **Link to Microsoft Fabric** on the command bar.
3. If you're linking to Fabric for the first time, a wizard appears. You can launch Fabric with the same option in subsequent runs.
4. The wizard starts with **Validate configuration**, which checks your prerequisites and Fabric subscription settings. If you don't have a Fabric capacity in the same geography or region as your Dataverse environment, the wizard notifies you to get a capacity in the required geography.

5. Next, choose the **Workspace** tab in the wizard. First, select a Fabric workspace. For that workspace, you also choose a connection for the first time. When creating a connection, you can select from three authentication options: **Organizational Account**, **Service Principal**, or **Workspace Identity**.

   - **Workspace Identity**:
     To use this option, you must first create a workspace identity in Fabric:

     a. In Fabric, open the target workspace.

     b. Go to **Workspace settings** > **Workspace Identity**.

     c. Select **+ Workspace Identity** to create it.
     - Note the name of the workspace identity (it matches the workspace name).

     d. For more information, go to Workspace identity in Fabric.

   - **Create an application user with worskpace identity**:
     After you create the identity, add it as an application user in Dataverse:
     - Go to **Power Platform admin center** > **Users (See all)** > **App users list**.

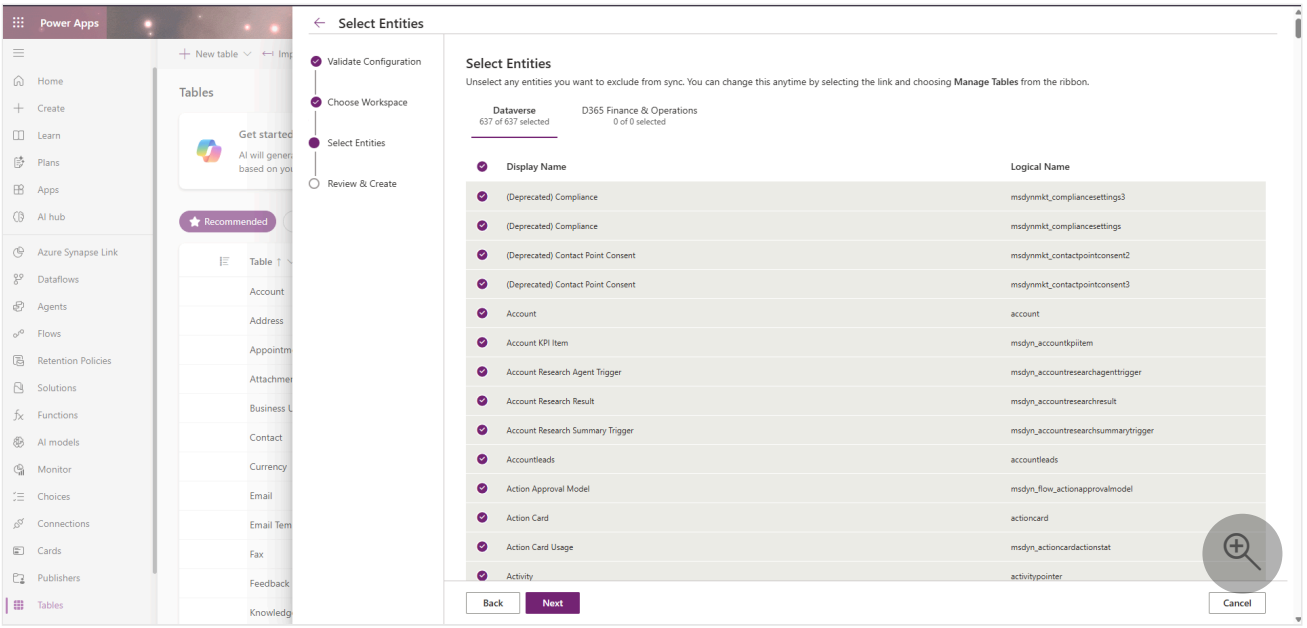
    - Select **+ New app user**, then **+ Add an app**, search for the workspace name you noted earlier(srr-athena-test in the above example), and add it.
    - Assign the correct **Business unit** and **System Administrator** role, then select **Create**. For detailed steps, go to the Create an application user in Dataverse step.

- **Service Principal**:
  To use this option, go to the create an application user with workspace identity previous step to create a service principal. Then, follow these steps:
  a. First, add the service principal as an application user in Dataverse following the same process described in the **Workspace Identity** section.
  b. After adding the application user, return to the **Link to Fabric** wizard.
  c. In the connection setup, provide the following details for your service principal:
    - **Tenant ID**: Your Azure tenant identifier.
    - **Client ID**: The application (client) ID of your service principal.
    - **Key**: The client secret or certificate for authentication.
  d. Save the connection to complete the setup.

- **Organizational Account**:
  Provide your credentials and save the connection. To change credentials later, select **Switch account** and provide new credentials.

6. You can expect to see shortcuts to all your tables within the selected workspace. If you don't see workspaces, ask the system to create a workspace. Go to Troubleshooting common issues if you don't see the desired workspace.

7. Next, in the **Select Entities** step, choose the tables you want to sync to Fabric. By default, all Dataverse tables where the **Track changes** property is enabled are selected. Clear any tables you don't want to sync. Only selected tables consume storage in Fabric, so you can optimize costs by excluding tables you don't need.



> **Note**
>
> You can change this selection anytime after setup by selecting the link and choosing **Manage Tables** from the ribbon. More information: Add or remove tables linked to Fabric

8. Review your selections in the **Review & Create** step. When you're done, select **Create** to create the workspace, create shortcuts, and to perform the initialization for the first time.

9. When complete, Fabric lakehouse opens in a separate browser tab.

> **Note**
>
> It might take up to 60 minutes to update data in OneLake including the conversion to delta parquet format. If you selected a table that contains a lot of data, the initial load time might take longer. When you open Fabric lakehouse, the links appear as **unidentified** until the initial sync is completed. More information: Troubleshooting common issues
>
> When the initial sync is complete, the system continuously refreshes updates in Dataverse in the lakehouse. It might take up to 60 minutes for the data to be refreshed especially during peak load periods.
>
> If you have more than 2,000 active Dataverse tables, Link to Fabric can fail with an error. Go to Troubleshooting common issues for help with resolving issues.
>
> The link was labeled as **Microsoft OneLake** and is now labeled **Link to Fabric**.

Manage link to Fabric

This section describes how to add or remove tables linked to Fabric, configure the link to use workspace identity, and share the data connection with other users.

Add or remove tables linked to Fabric

Admins can manage tables linked to Fabric from the **Azure Synapse Link for Dataverse** page. If this environment is linked to Fabric, you see a link called **Link to Fabric**.

Add tables to Fabric

1. Sign into Power Apps.

   > **Note**
   >
   > This feature is enabled by default on all environments. Power Platform admins can disable this feature in the Power Platform admin center. More information: Environment settings: Microsoft Fabric

2. Select **Azure Synapse Link** from the left navigation pane, and then select **Link to Fabric**.

3. Open Fabric by selecting **View in Microsoft Fabric**.

4. Add more table links to Fabric by selecting **Manage tables**.

5. When you add a table, the system performs an initial sync and indexes the data. When the initial sync is completed, a shortcut to OneLake is created. View the status of tables by selecting **Manage tables**. Use the **Refresh Fabric tables** option to add the newly enabled table in Fabric. You might need to review the report and downstream data flows to see that they aren't impacted by the change.

   > **Note**
   >
   > If your environment is linked to a Dynamics 365 finance and operations environment, the add tables option enables you to include tables from finance and operations apps. Learn more: Choose finance and operations data in Azure Synapse Link for Dataverse

6. When the sync status is **Active**, as data gets updated, your data changes are shown in reports created in Fabric.

7. If a new column is added to a table that's already part of the profile (also known as a metadata change), you can use the **Refresh Fabric tables** option, from the command bar, to update the change in Fabric. The update occurs after the next table data change is triggered. You might need to review the report and downstream data flows to confirm that they aren't impacted by the change.

8. You can also **Unlink**, which removes the Fabric link to your Dataverse environment. When unlinking, the Fabric lakehouse is also removed.

> **Note**
>
> If you've installed Dynamics 365 apps such as Customer Insights, the tables required for the app are also included in the **Link to Fabric** link.

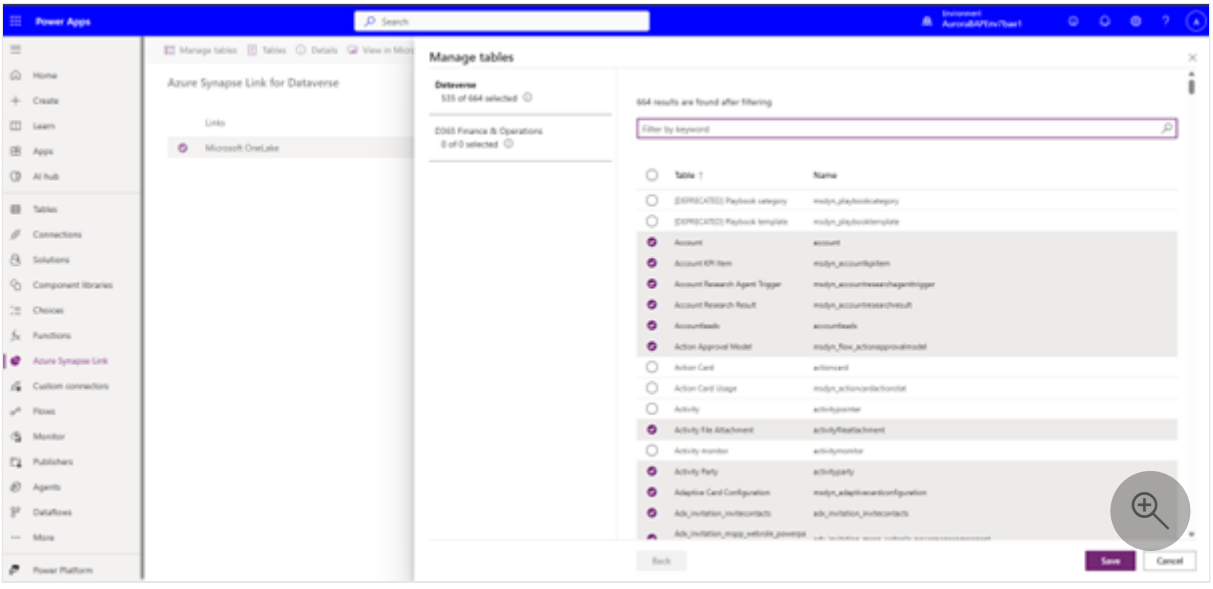
Remove tables from Fabric

You can stop syncing specific Dataverse and finance and operations apps tables to reduce storage costs and optimize your Fabric workspace. After accessing **Manage tables** (as described in step 4 in Manage link to Fabric), follow these steps to unlink tables:

1. The **Manage tables** pane shows all Dataverse and finance and operations apps tables currently linked to Fabric.

2. Tables that are already syncing are checked.

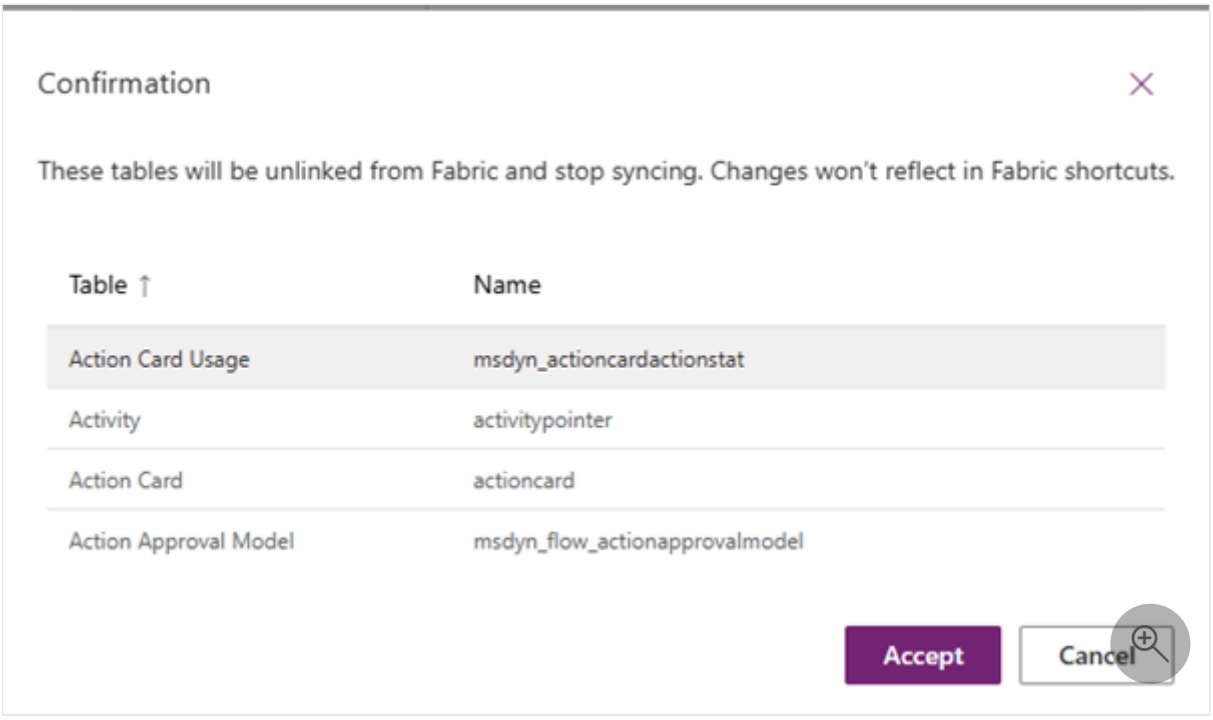
3. To stop syncing a table, clear the option to select it.



4. To keep syncing, leave it checked.

5. After making your selections, select **Save**.

6. A confirmation dialog appears listing the tables that stop syncing.



7. Review the list, and then select **Confirm**.

After confirmation:

- Shortcuts for the unselected tables are removed from the Fabric lakehouse.
- Selected tables are removed from the internal storage that are synchronized to Fabric via shortcuts. This ensures that you're paying only for the storage of tables that you selected.
- Synchronization stops immediately for those tables no longer selected.
- Remaining tables continue syncing without interruption.

> ⓘ **Important**
>
> - Some system tables and tables required by Microsoft add-ins can't be removed. More information: [Are there system tables that are automatically synchronized and can't be unlinked?]
> - Removing a table doesn't delete the table in Dataverse; it only removes the OneLake shortcut and stops data sync.
> - If you need to add tables later, repeat the same steps and check the tables you want to include. More information: [Manage link to Fabric].

Configure Fabric link to use workspace identity

If you linked your Dataverse environment to Fabric earlier using an organizational account, you can switch to workspace identity or service principal. Workspace identity is a Fabric managed service principal bound to a specific workspace; it removes the need to manage secrets and enables secure, keyless authentication for Fabric items that connect to Dataverse.

Things to verify before you begin

Before proceeding, ensure you meet the requirements described in the Prerequisites section, and specifically verify these three essential items:

- Workspace identity exists: The target Fabric workspace must have a workspace identity configured. Go to **Workspace settings** > **Workspace Identity**. If the identity doesn't exist, create it first. More information: Workspace identity in Fabric
- Dataverse application user: The same workspace identity must be onboarded as an application user in the Dataverse environment and granted the appropriate role (commonly System Administrator) so it can access Dataverse data on behalf of Fabric. This might already be in place if you followed the **Workspace Identity** steps in the Create a link to Fabric section previously.
- Rights to edit connections: You must have permissions in Fabric to manage connections via **Settings** > **Manage connections and gateways**.

What changes?

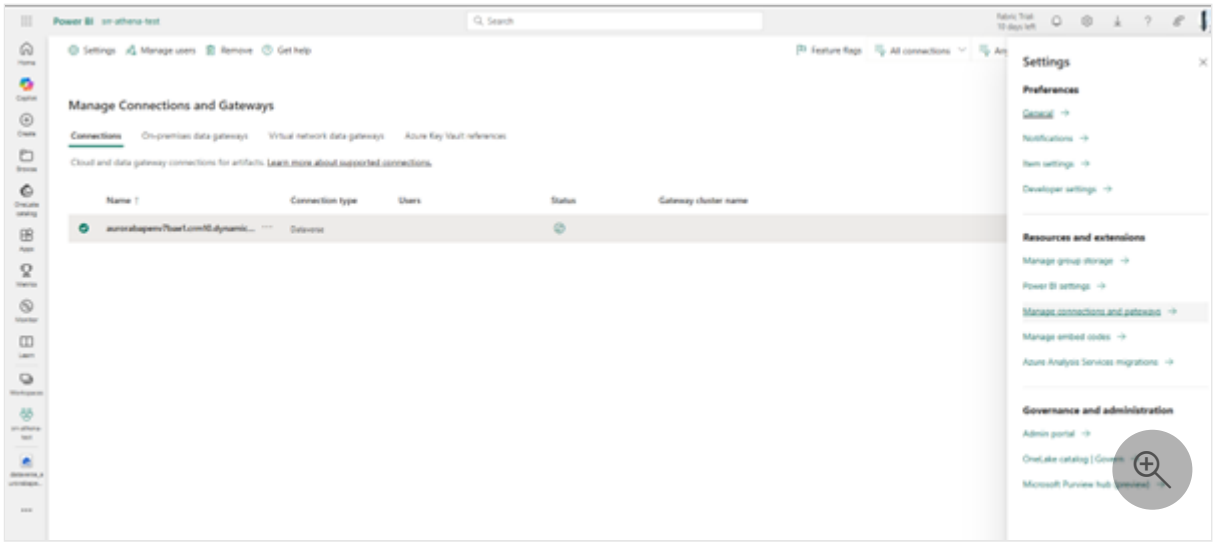
After you update the connection's authentication method to Workspace identity, all Fabric items that use that connection (for example, Lakehouses via OneLake shortcuts, Dataflows Gen2, pipelines, semantic models) authenticate with your workspace identity going forward.

Before you begin

Identify the connection name. When you used **Link to Microsoft Fabric**, the system created a Dataverse connection that typically includes (or matches) your environment name. You update this specific connection.

Switch to workspace identity authentication

1. **Open Fabric settings**
    - In Microsoft Fabric, select the gear icon (top right) and choose **Settings** > **Manage connections and gateways**.

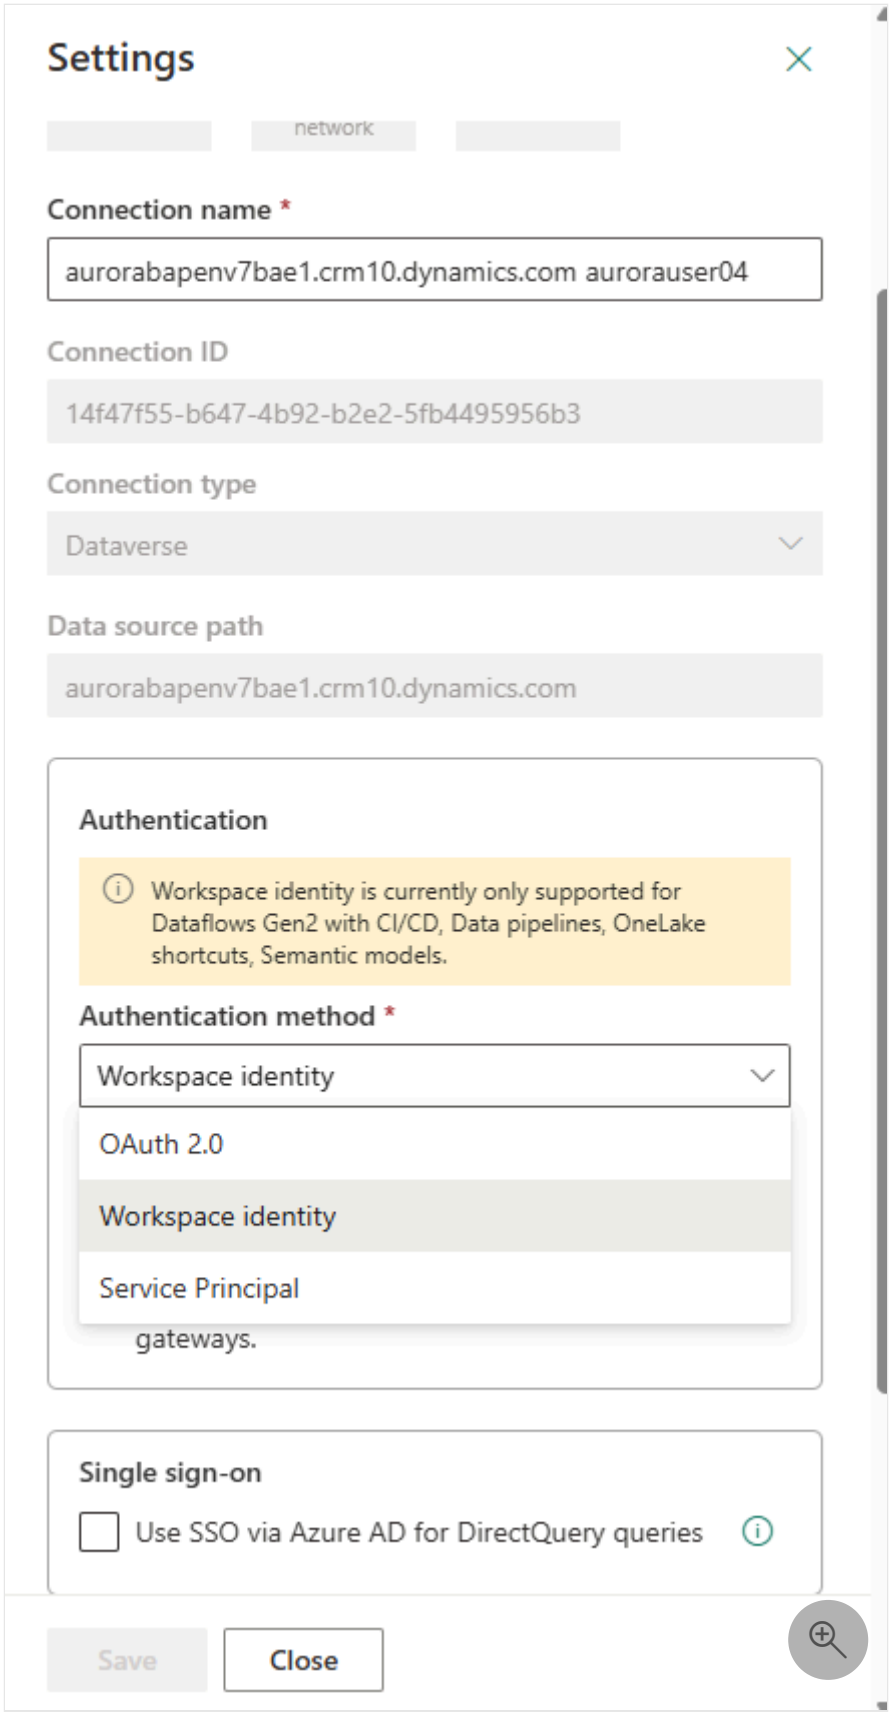


2. **Locate the Dataverse connection created by Link to Fabric**

    - In **Manage connections and gateways**, open the **Connections** tab (if not already selected).
    - Find the connection associated with your Dataverse environment. The **Link to Fabric** wizard typically creates this connection and names it using your environment's name so it's easy to recognize.

3. **Open the connection's management pane**

    - Select the ellipsis (⋮) next to the connection and choose **Settings** to open its settings.



4. **Switch the authentication method to Workspace identity**

- In the connection's **Settings** pane, go to **Authentication**.
- From the **Authentication method** dropdown, select **Workspace identity**.
- Select **Save** to apply the change.

> **Note**
>
> If your items run through a gateway, review your gateway and cloud connection policies as applicable. Fabric's manage connections and gateways experience governs connection usage, including gateway scenarios for shareable cloud connections.

Share the data connection with other users

The system creates a data connection between the Power Platform environment and Fabric workspace using the credentials of the user at the time of link creation. If you use the **Fabric link** option from the Power Apps **Tables** area, the system creates the connection and asks you to save it. If you use the **Synapse Link** option, you must create a data connection yourself before enabling the link.

The system uses this connection to enable Fabric users to connect to Dataverse - the data store behind the Power Platform environment. If you want to enable other users to add or remove tables to Fabric link, you need to share this data connection with other users.

1. Follow steps 1-2 from Switch to workspace identity authentication to access **Manage connections and gateways** and locate your Dataverse connection.
2. Once you select the correct data connection, select **...** > **Manage users**. Then you're shown users who have access to this connection.
3. Enter the name or email of other users who need access to data. When you select a user, specify either the **Owner** role or **Reader** role. You only need to provide reader role to enable them to consume data. The users you specify receive an e-mail confirming access to data.

You might need to grant access to other users to this workspace so that they can work with data. Depending on the need for data access, you might need to secure the data in this workspace before you share this data with others. You can secure the lakehouse as well as tables within the lakehouse using OneLake security. More information: OneLake security overview

You can only create user based connections at this time.

Link existing Azure Synapse Link for Dataverse links with Fabric

You can link your existing Azure Synapse Link for Dataverse profiles with Fabric from the **Azure Synapse Link for Dataverse** area. You need to select the **Enable Parquet/Delta lake** option to

enable the view in the Fabric feature for Azure Synapse Link for Dataverse profiles.

To enable an existing link, follow these steps:

1. Sign into Power Apps.
2. Select **Azure Synapse Link** from the left navigation.
3. Select an existing Azure Synapse Link for Dataverse profile, and then select **Link to Microsoft Fabric**.
4. You're prompted to choose a Power BI premium workspace to continue. A list of workspaces in the same region as your environment are displayed. If you don't see a workspace in the drop-down list, you might need to create one, and then return to this task. More information Link to Microsoft Fabric
5. Select **OK**. Validations are performed and the required artifacts are created in Fabric.
6. Select **View in Microsoft Fabric** open Fabric lakehouse.
7. You can add or remove tables using by selecting **Manage tables**. When you add a table, an initial sync is performed. When the initial sync is completed, select **Refresh Fabric tables** to refresh the Dataverse shortcut added to your Fabric lakehouse.

> **Note**
>
> - Select **Enable Parquet/Delta lake** to enable the view in Fabric.
> - Existing Azure Synapse Link for Dataverse profiles where the data is saved as CSV files can't be linked to Microsoft Fabric.
> - Currently, Azure Synapse Link profiles secured with managed identities, formerly Managed Service Identity (MSI), can't be linked to Microsoft Fabric.

Next steps

Work with Dataverse data and generate Power BI reports

Last updated on 04/27/2026

Work with Dataverse data and generate Power BI reports

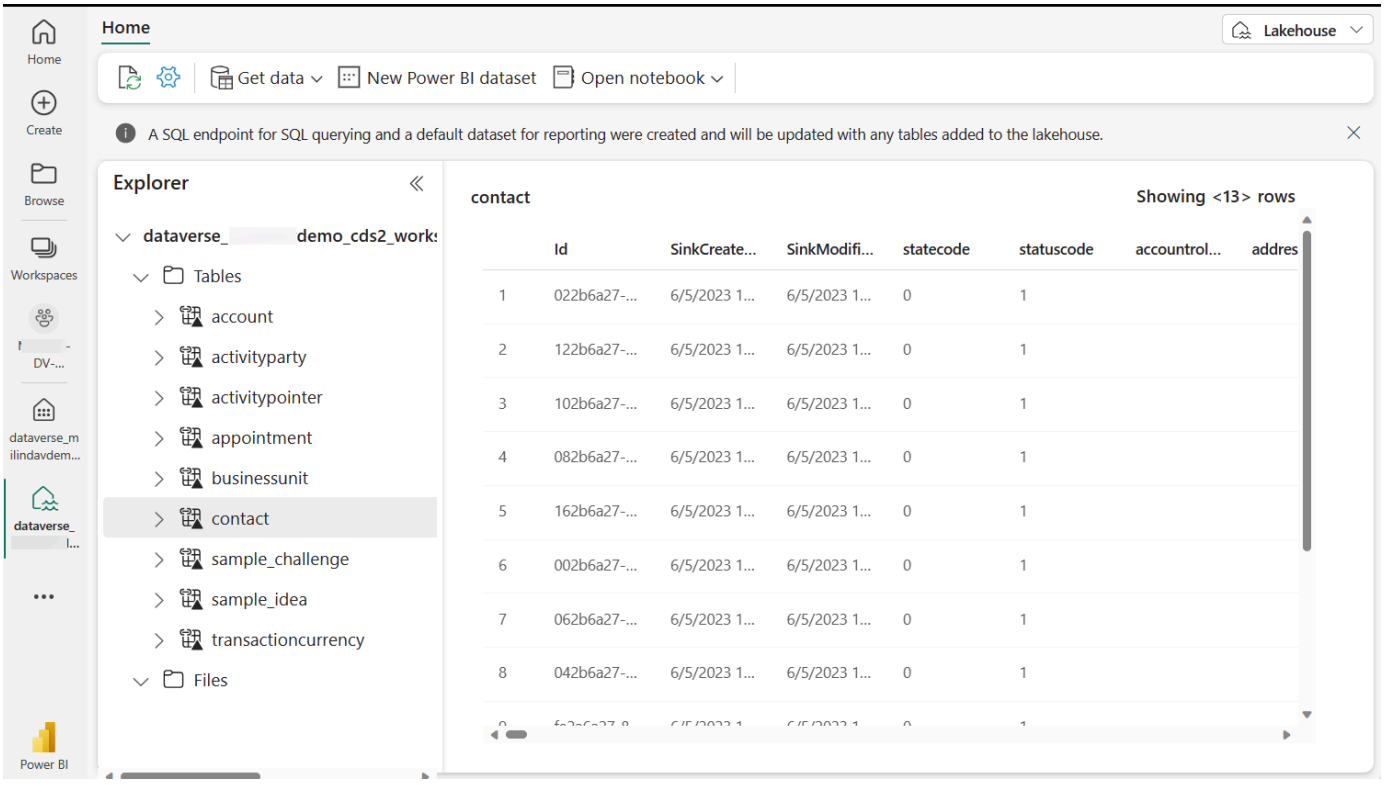
This section describes the different ways you can work with Microsoft Dataverse data in Microsoft Fabric and generate reports in Power BI.

You can view the Fabric lakehouse, SQL endpoint, and the default dataset generated by Dataverse in the Fabric workspace you chose earlier.

When you select **Link to Microsoft Fabric**, a Dataverse generated Fabric lakehouse opens. You can go to other Fabric features and work with Fabric and Power BI.

Explore the Dataverse generated Fabric lakehouse

The tables you selected are added to the Fabric lakehouse and displayed in Power BI as shown here. These tables are linked to your Power Platform environment using **Dataverse shortcuts**. As data changes in Dataverse, the Dataverse shortcuts in Fabric reflect the latest data.

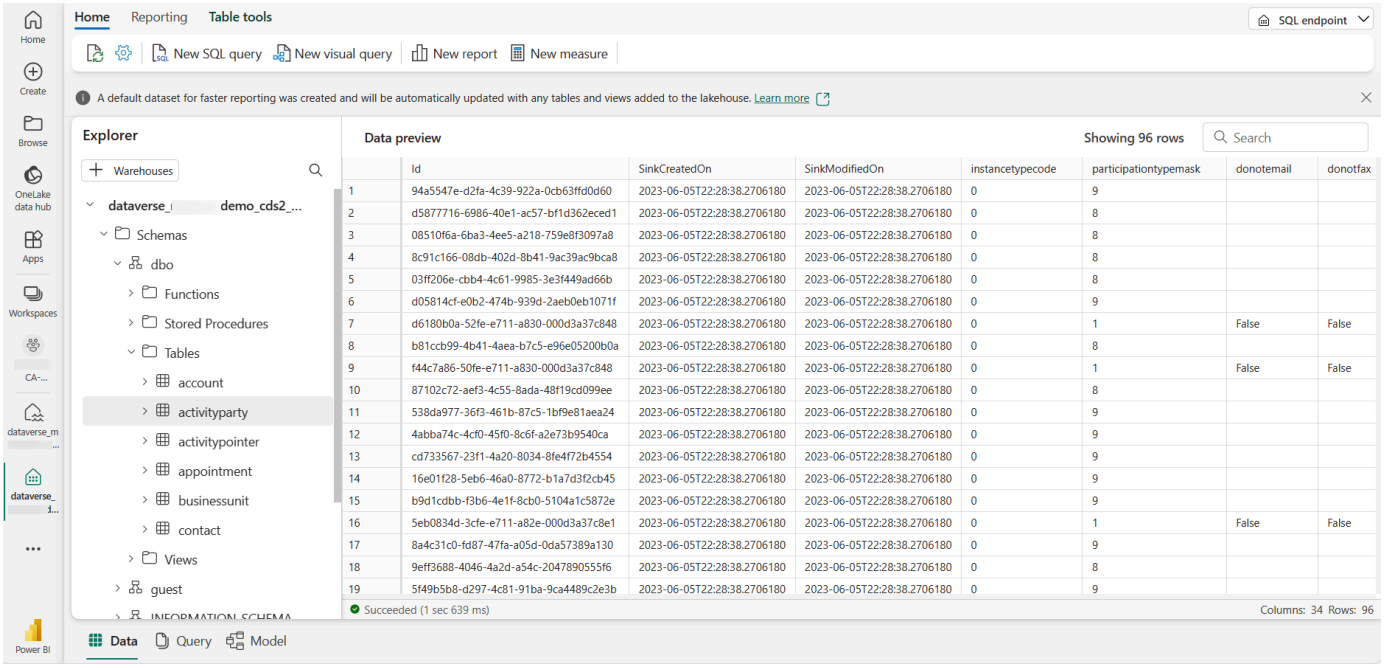


Note that Dataverse manages these shortcuts. You shouldn't delete or remove these shortcuts in Fabric. If you accidentally delete a link, you can go to the **Azure Synapse Link for Dataverse** area in Power Apps and select **Refresh Fabric links** to re-create the links.

Explore data with SQL endpoint

You can open SQL endpoint and query Dataverse data with SQL and generate views in Fabric.

In Power BI, select **SQL endpoint** from the top right context menu. The data is displayed in a SQL friendly experience where you can create SQL queries and views.



Autocreate a Power BI report

Choose the default dataset generated by Dataverse, and then select **Auto-create report**. A Power BI report with the data you have selected is created.

Link your Dataverse environment to Microsoft Fabric and unlock deep insights

Last updated on 04/30/2026

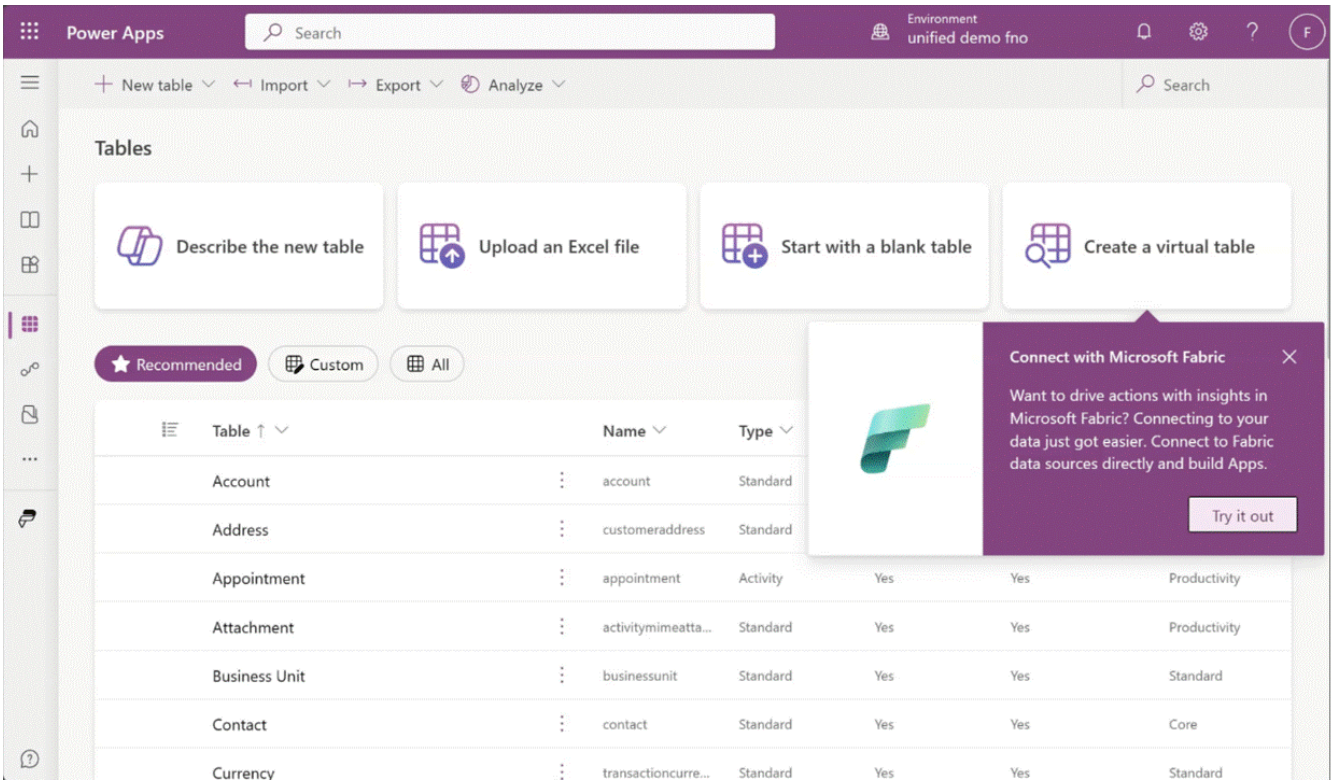
Build apps and automations, and drive action with insights from Microsoft Fabric

Link to Microsoft Fabric in Microsoft Dataverse enables extending your data and insights in Dynamics 365 and Power Apps in Fabric. Bring your own data into Fabric and combine, reshape, and aggregate data with data from Dataverse. Use Fabric tools such as SQL, Spark, and dataflows to work with your data within Fabric. For example:

- Combine financial data from Dynamics 365 with financial data from other systems to derive consolidated insights.
- Merge historical data ingested into Microsoft OneLake from legacy systems with current business data from Dynamics 365 and Dataverse.
- Combine weblogs and telemetry data from your website with product and order details from Dynamics 365.
- Apply machine learning to detect anomalies and exceptions within your data.

Insights aren't complete unless you can drive action and business processes. Bring insights you found in Fabric to build apps, drive business processes with Power Automate without data copy, no-ETL (extract, transform, load), or non-Microsoft integration tools.

With Dataverse virtual tables sourced with Fabric, your low-code app builders connect to data in OneLake and build Power Apps and drive business actions. Additionally, with Power Pages, low-code makers can build external facing websites and drive action from OneLake insights with partners, suppliers, and customers.



Prerequisites

- An existing Dataverse environment or you can create a new developer environment. More information: Create a developer environment
- Contributor or administrator access to a Fabric workspace with data.

If you don't have Power BI premium license or Fabric capacity, you can sign up for a free Fabric trial capacity.

If you don't have a workspace with data, create a workspace with sample data using the lakehouse tutorial.

Create a virtual table with Fabric data

Follow these steps to create a virtual table using Fabric data.

> **Note**
>
> This feature is enabled by default with all environments. Admins can disable this feature in the Power Platform admin center in the environment feature settings.

1. Sign into Power Apps, and then select **Tables** on the left navigation pane.

2. On the command bar, select **New table** > **Create a virtual table**.

3. Select **Microsoft Fabric** as the connection, and then select **Next**.
4. Select a **Microsoft Fabric workspace** from the available list of workspaces. All workspace where you have access are available in the list.
5. Choose a **Microsoft Fabric Lakehouse** from the drop-down list. All lakehouses and data warehouses within the workspace selected previously are available to choose.
6. On the **Data** page, select a table from the list of tables shown from the lakehouse. Select **Configure table and column names that will be used in Dataverse** if you want to rename any of the fields or tables in Dataverse or to specify additional properties available for you in Dataverse. Select **Next**.
7. If you selected the **Configure table and column names that will be used in Dataverse** checkbox, you're shown the table and column properties and you can modify them here. When you're done modifying them select **Next**.
8. Verify that the field chosen for **primary key field** is a unique field. You might need to verify the default field selected by the system as the primary key.

   > ⓘ **Note**
   >
   > While the table you selected from Fabric Lakehouse might not have a primary key defined, you need to select a field that is unique to continue. If you don't select a unique field, the table might not show all the records. While the wizard selects a field based on metadata available, the selection might not be accurate.

9. Review the information shown, and then select **Finish**.

A new Dataverse virtual table is created with data from Fabric.

Building apps and taking action with insights

You can build an app with the virtual table sourced with Fabric data in Power Apps (make.powerapps.com). From the **Home** page, select **Start with data** > **Select an existing table**, select the virtual table created earlier, and then select **Create app**. Provide a name for your app and build the app by following the wizard.

> ⓘ **Note**

Virtual tables created with data from Microsoft Fabric OneLake are read-only. Currently, you can't modify the data in Fabric OneLake with Power Apps.

Microsoft Fabric Link for Dataverse FAQ

This article provides information about frequently asked questions when you link Microsoft Dataverse to Microsoft Fabric.

General

What authentication methods are supported for Fabric link?

Fabric link supports three authentication methods when creating a connection:

- **Organizational Account**: Provide your credentials and save the connection.
- **Service Principal**: Provide Tenant ID, Client ID, and Key for authentication.
- **Workspace Identity**: Uses a Fabric-managed service principal bound to a specific workspace.

What happens when I unlink from Fabric?

When you unlink, the Fabric lakehouse is removed along with all shortcuts to your Dataverse tables.

Table support and limitations

Which Dataverse tables are selected by default when linking to Fabric?

During the initial **Link to Fabric** setup, the **Select Entities** step shows all Dataverse tables where the **Track changes** property is enabled. By default, all these tables are selected. You can clear any tables you don't want to sync before completing the wizard. Only selected tables are linked to Fabric and consume storage, so you can optimize costs by excluding tables you don't need. You can change your selection anytime after setup by using **Manage Tables**.

Which Dataverse tables aren't supported for Fabric link?

Any table that doesn't have change tracking enabled isn't supported. Additionally, certain Dataverse tables, such as postcomment, postregarding, postlike, post, and postrole, aren't available for customers to enable synchronization through Fabric link. In some cases, these tables might appear when Dataverse long term retention is enabled. If that happens, a subset or all records from these tables might be exported. This is expected behavior for long term retention scenarios.

> **Important**
>
> - These tables shouldn't be selected for synchronization.
> - Their presence doesn't indicate full support for incremental sync.

Can I add or remove specific tables from Fabric link?

Yes, you can manage which tables are linked:

- Add more table links to Fabric by selecting **Manage tables**.
- To stop syncing specific tables, clear them in the **Manage tables** pane and then select **Save**
- After confirmation, shortcuts for unselected tables are removed from the Fabric Lakehouse and sync stops immediately.

> **Important**
>
> Removing a table doesn't delete the table in Dataverse; it only removes the OneLake shortcut and stops data sync.

Are elastic tables supported for Fabric link?

Yes, elastic tables are supported with Fabric link. Ensure that change tracking is enabled for elastic tables in Dataverse for the sync to happen.

Are Finance and Operations apps tables supported?

If your environment is linked to a Dynamics 365 finance and operations environment, the add tables option enables you to include tables from finance and operations apps. Finance and operations apps tables aren't autoselected when creating the initial Fabric link.

Are there system tables that are automatically synchronized and can't be unlinked?

Yes, certain system tables are automatically synchronized in Link to Fabric and can't be unlinked by users. Examples of these system tables include:

- bot
- msdyn_copilotknowledgeinteraction
- desktopflowmodule
- flowmachine
- flowmachinegroup
- workflow

These tables are essential for system functionality and are always included in the synchronization process.

Microsoft provided add-ins and table selection

Fabric link table selection is also dependent on Microsoft provided add-ins such as Business Process Advisor (BPA) and Customer Insights - Journeys. These products use the same pipeline to export data from Dataverse to provide transformed insights.

The tables that you can't unselect depends on which add-on products you enabled. When you enable an add-in (for example, Customer Insights - Journeys), the specific tables required by that add-in are added to the entityanalyticsconfig table in Dataverse.

Any table that has **isenabledforadls** set to **true** in the entityanalyticsconfig table can't be selected from the Fabric link.

What happens when I add a new column to a linked table?

If a new column is added to a table that's already part of the profile (metadata change), you can use the **Refresh Fabric tables** option from the command bar to update the change in Fabric. The update occurs after the next table data change is triggered.

Data Synchronization

How long does initial data synchronization take?

Initial sync time depends on several factors including table size, number of updates and transactions happening in the environment, number of tables, and row count. The data is converted to delta parquet format during this process. When you open Fabric Lakehouse, the links appear as **unidentified** until the initial sync is completed.

How often is data refreshed in Fabric?

When the initial sync is complete, the system continuously refreshes updates in Dataverse in the lakehouse. Incremental updates typically take up to one hour to appear, though actual timing depends on table size, number of updates and transactions happening in the environment, number of tables, row count, and system load periods.

Why am I seeing differences in `SinkModifiedOn` and `ModifiedOn` columns?

This is expected behavior. `ModifiedOn` is the date and time a record was last changed in Dataverse, while `SinkModifiedOn` is the date and time the record was written to the Dataverse data lake from where Fabric shortcuts point to. `SinkModifiedOn` is typically later than `ModifiedOn`, and the difference depends on factors such as batch size, system load, and the number of records being processed.

> **Important**
>
> In the case of long-running transactions in finance and operations apps, a record might be synchronized multiple times to ensure no data loss. In this scenario, `SinkModifiedOn` reflects the last synchronization time, not the first. For example, if a record is synced 10 times within an hour, `SinkModifiedOn` shows the time of the 10th sync even though the data was available from the first sync itself. Use caution when building latency reports based on the difference between `SinkModifiedOn` and `ModifiedOn`, as it can give a misleading impression of actual data availability.

Limitations and Errors

What are the limits for Fabric Link?

If you have more than 2,000 active Dataverse tables, Link to Fabric can fail with an error.

Can I link existing Azure Synapse Link profiles to Fabric?

You can link your existing Azure Synapse Link for Dataverse profiles with Fabric if you select the **Enable Parquet/Delta lake** option. However:

- Existing profiles where the data is saved as CSV files can't be linked to Fabric.
- Azure Synapse Link profiles secured with managed identities currently can't be linked to Fabric.

Troubleshooting common issues with link to Fabric

If you experience an error message when using link to Fabric with Microsoft Dataverse, here are suggestions and more information about how to resolve the issue.

Expand table

Error message	How to resolve
You must have Power BI premium or Fabric capacity in the same region {Region}. You can also get a Fabric trial. You won't receive this error after April 30, 2024. Instead, you're shown an error if you don't have capacity in the same geography.	You need a Power BI premium of a Fabric capacity in the same region as your Dataverse environment. Power BI premium per user capacity isn't sufficient. You can get a free trial capacity by visiting Fabric (preview) trial. More information: Prerequisites
Creation of Fabric workspace failed. You can try again. If this issue persists contact Microsoft customer support with the corelation ID.	You must be a Power BI Capacity Administrator or have contributor access to a capacity within the same geography as your Dataverse environment. Currently, the system supports these premium capacity SKUs described in the Prerequisites. Verify with your Power BI Tenant admin that you have permissions to create workspaces. You can find this setting in Power BI Admin portal under **Tenant settings** > **workspace settings** > **Create workspaces**. If the issue isn't resolved, contact Microsoft customer support with the provided reference ID
Creation of Fabric lakehouse failed. You can try again. If this issue persists contact Microsoft customer support with the corelation ID.	Verify with your Power BI Tenant admin that you have permissions to create OneLake shortcuts. You can find this setting in Power BI Admin portal under **Admin Portal** > **Tenant Settings** > **Microsoft Fabric** > **Users can create Fabric items**. More information: Prerequisites If the issue isn't resolved after several retries, you can contact Microsoft customer support with the provided reference ID.
We ran into an issue, Creaton of Fabric Lakehouse failed.	Verify with your Power BI tenant admin that you have permissions to create artifacts in Fabric. You can find this setting in Power BI admin portal under **Tenant settings** > **oneLake settings** > **Users can access data stored in OneLake with apps external to Fabric**.

Error message	How to resolve
	More information: Prerequisites If the issue isn't resolved after several retries, you can contact Microsoft customer support with the provided reference ID.
Your organization doesn't appear to have Microsoft Fabric. You can get a trial.	Contact your administrator or get a trial version of Microsoft Fabric.
You need to get a trial version of Fabric to get started.	You need a Power BI premium of a Fabric capacity. Power BI premium per user capacity isn't sufficient. You can get a free trial capacity by visiting: Fabric (preview) trial
You need to be a system administrator to link to Fabric.	You need the system administrator security role in Dataverse to perform this operation. More information: Security roles and privileges
Newly added fields in tables aren't reflected in Fabric Lakehouse.	When a new field is added to a Dataverse table, the newly added column isn't added to Fabric Linked workspaces automatically. To include newly added columns, select **Synapse Link** in Power Apps (make.powerapps.com), select the Microsoft OneLake or the Azure Synapse Link profile and select **Refresh Fabric tables**. This action refreshes the table metadata in Fabric Lakehouse.
Error message "Unauthorized. Access to target location https://[...].crm3.dynamics.com/ denied" when accessing Dataverse tables in Fabric Lakehouse.	This error message indicates that the user accessing tables in Fabric doesn't have the required permissions to access Dataverse tables. This error might be shown even if the same user has access to the tables in Dataverse. The Link to Fabric wizard in Power Apps creates a data connection at the time of creating the Link to Fabric. This data connection uses credentials of the user, it's possible that: - The password of the user who created the connection has changed or has expired. - The user account of the user who created the Fabric link is inactive. - Other users who need to access Dataverse tables in Fabric Lakehouse don't have access to the data connection. More information: Share the data connection with other users
Error message "A back end error occurred. The Fabric to Dataverse connection ID ... is not valid for this user. Please check that you have access to this connection, and that the connection is connected	This error message indicates that the user selecting the **Refresh Fabric tables** option in the Azure Synapse Link page doesn't have the required permissions. This error might be shown even when the user has access to the tables in Dataverse and is a system

Error message	How to resolve
to this organization, with URL ... You can try again, if this issue persists please contact support.	administrator. The link to Fabric wizard in Power Apps creates a data connection at the time of creating the link to Fabric. This data connection uses credentials of the user, it's possible that: - The password of the user who created the connection has changed or has expired. - The user account of the user who created the Fabric link is inactive. - The user performing the **Refresh Fabric tables** option doesn't have access to the data connection. More information: Share the data connection with other users
All tables from Dataverse show as **Unidentified** in Fabric Lakehouse.	You might see this error message while your data is being initialized for the first time. If this issue persists for more than several hours, go to **Synapse Link** in Power Apps (make.powerapps.com), choose the Microsoft OneLake or the Azure Synapse Link profile and select **Refresh Fabric Links**. This refreshes the table metadata in Fabric Lakehouse.
Tables from Dynamics 365 finance and operations apps are missing.	System auto selects nonsystem tables with **Change tracking** property set to **Yes** when creating a Fabric Link. To select more tables, open **Microsoft OneLake** profile in **Synapse Link** and select **Manage Tables**. If you have a finance and operations environment linked to this Power Platform environment, you can also select tables from finance and operations apps. Finance and operations apps tables aren't autoselected with Fabric Link. More information: Add Finance and Operations tables
There are {.. #tables} tables enabled for change tracking in your environment. Addition of more than 2,000 tables isn't supported.	Fabric link feature currently can't be enabled on environments with more than 2,000 change tracking enabled tables.

Link to Microsoft Fabric

Last updated on 04/27/2026

What is Azure Synapse Link for Dataverse?

Azure Synapse Link for Dataverse enables you to get near real-time insights over your data in Microsoft Dataverse. With a tight seamless integration between Dataverse and Azure Synapse Analytics, Azure Synapse Link enables you to run analytics, business intelligence and machine learning scenarios on your data.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed May 2021 and continues to export data to Azure Data Lake as well as Azure Synapse Analytics.

Using Azure Synapse Link, continuously export data from Dataverse to:

- Azure Synapse Analytics
- Azure Data Lake Storage Gen2

The Azure Synapse Link for Dataverse is a service designed for enterprise big data analytics by delivering scalable high availability with disaster recovery capabilities. Data is stored in the Common Data Model format, which provides semantic consistency across apps and deployments.

The Azure Synapse Link for Dataverse provides these features:

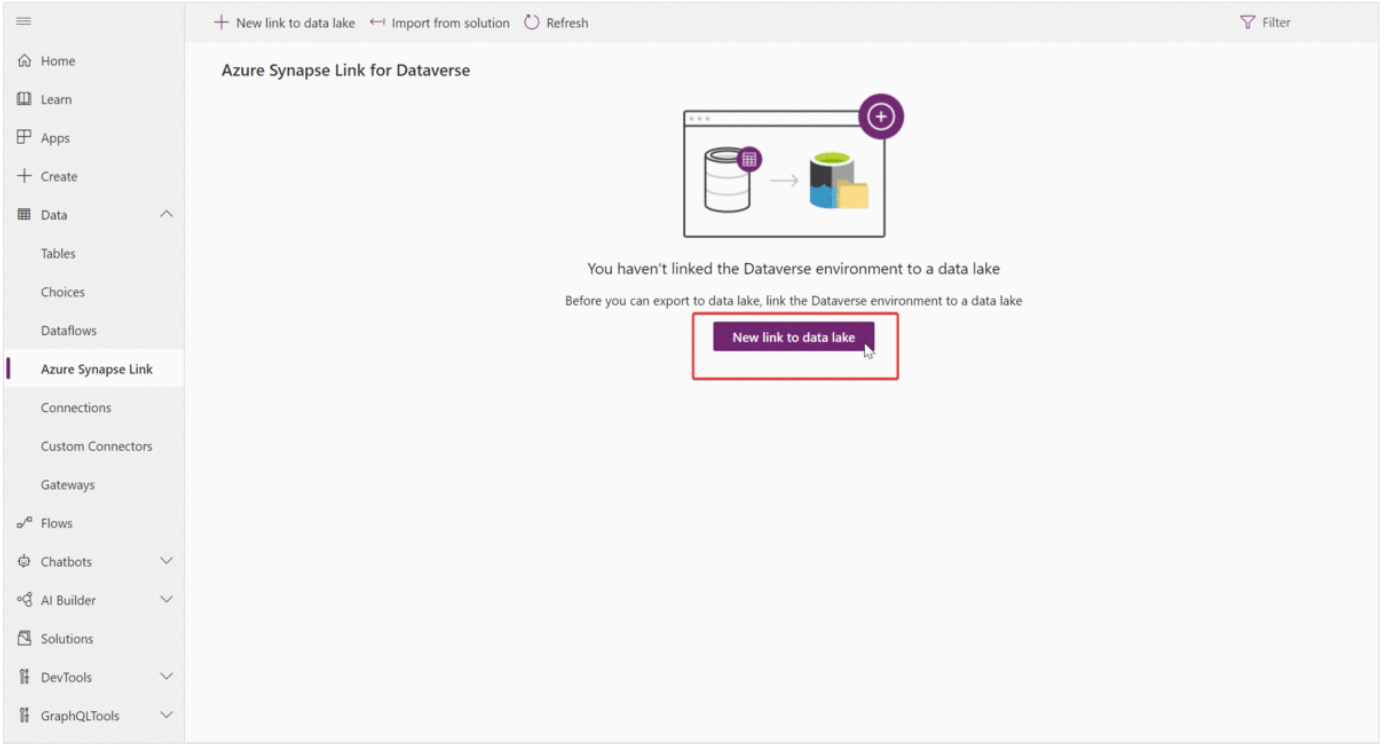
- Linking or unlinking the environment to Azure Synapse Analytics and/or Azure Data Lake Storage Gen2 in your Azure subscription.
- Continuous replication of tables to Azure Synapse Analytics and/or Azure Data Lake Storage Gen2 in your Azure subscription.
- Replication of both standard and custom tables as well as create, update, and delete (CUD) transactions.
- Fewer clicks to process, transform, and visualize your data in Azure Synapse Analytics.

- Serverless data lake exploration, data integration, and big data processing in Azure Synapse Analytics.
- Facilitated metadata discovery and interoperability between data producers and consumers such as Apache Spark, Power BI, Azure Data Factory, Azure Databricks, and Azure Machine Learning.

The Azure Synapse Link for Dataverse service supports initial and incremental writes for table data and metadata. Any data or metadata changes in Dataverse are automatically pushed to the Azure Synapse metastore and Azure Data Lake, depending on the configuration, without any additional action. This is a push, rather than pull, operation. Changes are pushed to the destination without you needing to set up refresh intervals.

Both standard and custom tables can be exported. Notice that the change tracking table attribute in Dataverse is used to keep the data synchronized in an efficient manner by detecting what data has changed since it was initially extracted or last synchronized.

All create, update, and delete operations are exported from Dataverse to the data lake. For example, when a user deletes an Account table row in Dataverse, the transaction is replicated in the destination location.



Rapidly analyze your Dataverse data in Azure Synapse Analytics

Azure Synapse Analytics is a limitless analytics service that brings together data integration, enterprise data warehousing, and big data analytics. It gives you the freedom to query data on your terms, using either serverless or dedicated resources—at scale. It also allows you to build analytics solutions on top of the Apache Spark engine. With Azure Synapse you can ingest, explore, prepare, manage, and serve data for immediate business intelligence and machine learning needs all from a single service.

Flexibly analyze your Dataverse data with Azure Data Lake Storage Gen2

Azure Data Lake is a storage solution that allows you to process data on demand, scale instantly, and only pay per job. It provides enterprise-grade security, auditing and support. Azure Data Lake is a great landing page for your Dataverse data before being utilized in another service or application. Each business is different and has different scenarios; Azure Data Lake gives you the flexibility to customize consumption and transition your data to other destinations.

Create an Azure Synapse Link for Dataverse with your Azure Synapse Workspace

Summarize this article for me

You can use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Synapse Analytics to explore your data and accelerate time to insight. This article shows you how to perform the following tasks:

1. Connect your Dataverse data to your Azure Synapse Analytics workspace with the Azure Synapse Link service.
2. Manage Dataverse tables included in the Azure Synapse Link.
3. Monitor your Azure Synapse Link.
4. Unlink your Azure Synapse Link.
5. Relink your Azure Synapse Link.
6. View your data in Azure Synapse Analytics.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

- Dataverse: You must have the Dataverse **system administrator** security role.
- The tables you want to export via Azure Synapse Link must have the **Track changes** property enabled. More information: Advanced options
- The Azure Synapse Workspace that you link with can't have data exfiltration protection enabled. More information: Create a workspace with data exfiltration protection enabled

Azure Data Lake Storage Gen2 requirements

You must have an Azure Data Lake Storage Gen2 account and the following roles:

- **Owner**
- **Storage Blob Data Contributor**
- **Storage Blob Data Owner**

Owner role requirement: The Owner role is required because adding the managed identity of the Azure Synapse Link service to the storage account is a privileged operation. This managed identity enables the service to perform synchronization from Dataverse to Synapse. Currently, the Owner role is required and custom roles with similar privileges aren't supported for this step.

Privileges for managed identity:

- **Owner and Storage Account Contributor:** Required only during first-time setup to create the filesystem in the storage account and are assigned on the storage account. After the setup, these privileges can be removed without impacting sync operations.
- **Storage Blob Data Contributor:** Required for normal blob operations during regular sync.
- **Storage Blob Data Owner:** Currently required for managing both data and access permissions in scenarios involving Azure Data Lake Storage Gen2.

Your storage account must enable **Hierarchical namespace** for both initial setup and delta sync.

Allow storage account key access is required only for the initial setup because the service uses Shared Key authorization to perform privileged operations such as creating the filesystem and establishing the link before switching to managed identity authentication. After setup, key-based access is no longer needed.

Your storage account must have permitted scope for copy operations set to **From any storage account**.

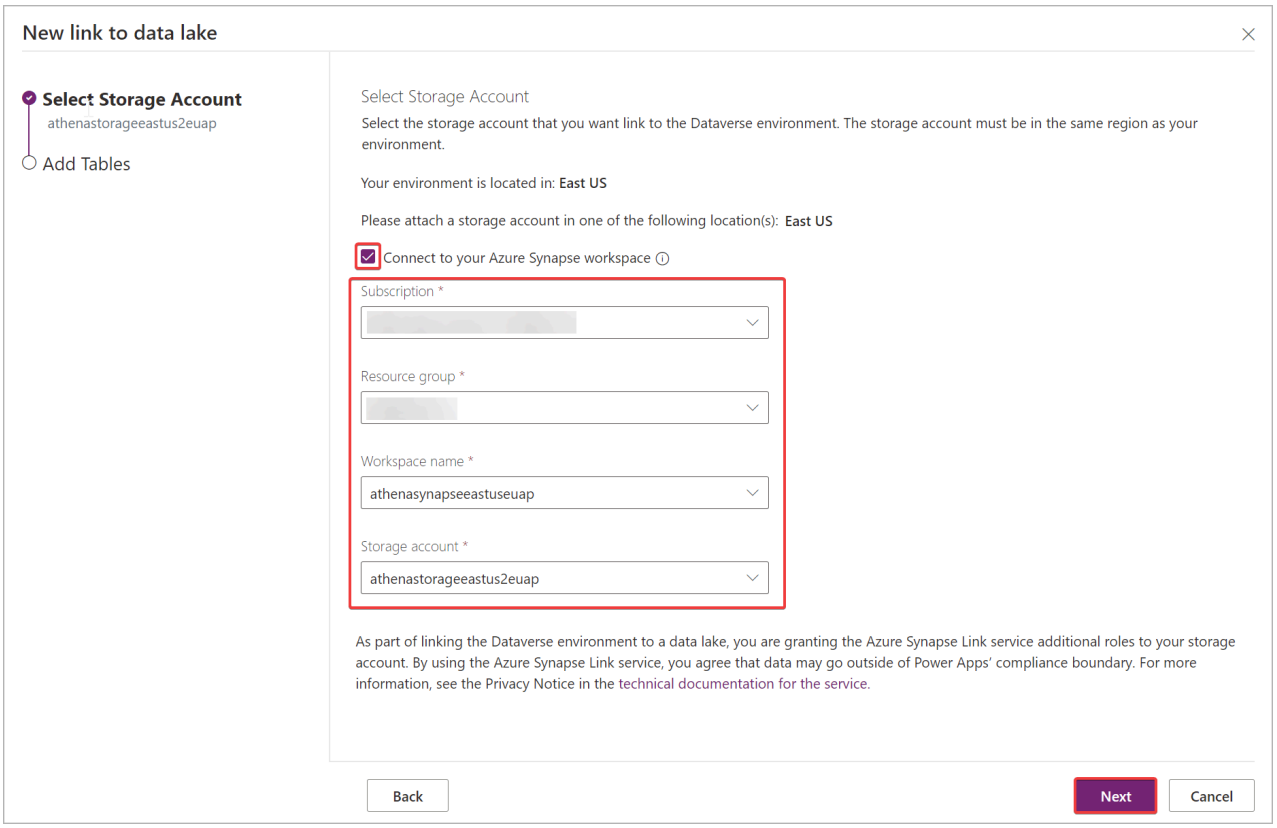
- Synapse workspace: You must have a Synapse workspace and the **Synapse Administrator** role access within the Synapse Studio. The Synapse workspace must be in the same region as your Azure Data Lake Storage Gen2 account. The storage account must be added as a linked service within the Synapse Studio. To create a Synapse workspace, go to Creating a Synapse workspace.

> ⓘ **Note**
>
> - The storage account and Synapse workspace must be created in the same Microsoft Entra tenant as your Power Apps tenant.
> - To set **Enabled from selected virtual networks and IP addresses** for linked storage account and workspace, you must create an Azure Synapse Link with managed identities. More information: Use managed identities for Azure with your Azure data lake storage (without managed identities set up, you must enable **public network access** for Azure resources for both initial setup and delta sync.)

- Synapse workspaces featuring managed private endpoints, data exfiltration protection, or managed virtual networks aren't supported.
- You must have **Reader** role access to the resource group with the storage account and Synapse workspace.
- When you add multiple users to the synapse workspace, they must have the **Synapse Administrator** role access within the Synapse Studio and the **Storage Blob Data Contributor** role on the Azure Data Lake Storage Gen2 account.
- The creation of Synapse Link profiles under a single DV environment is limited to a maximum of 10.

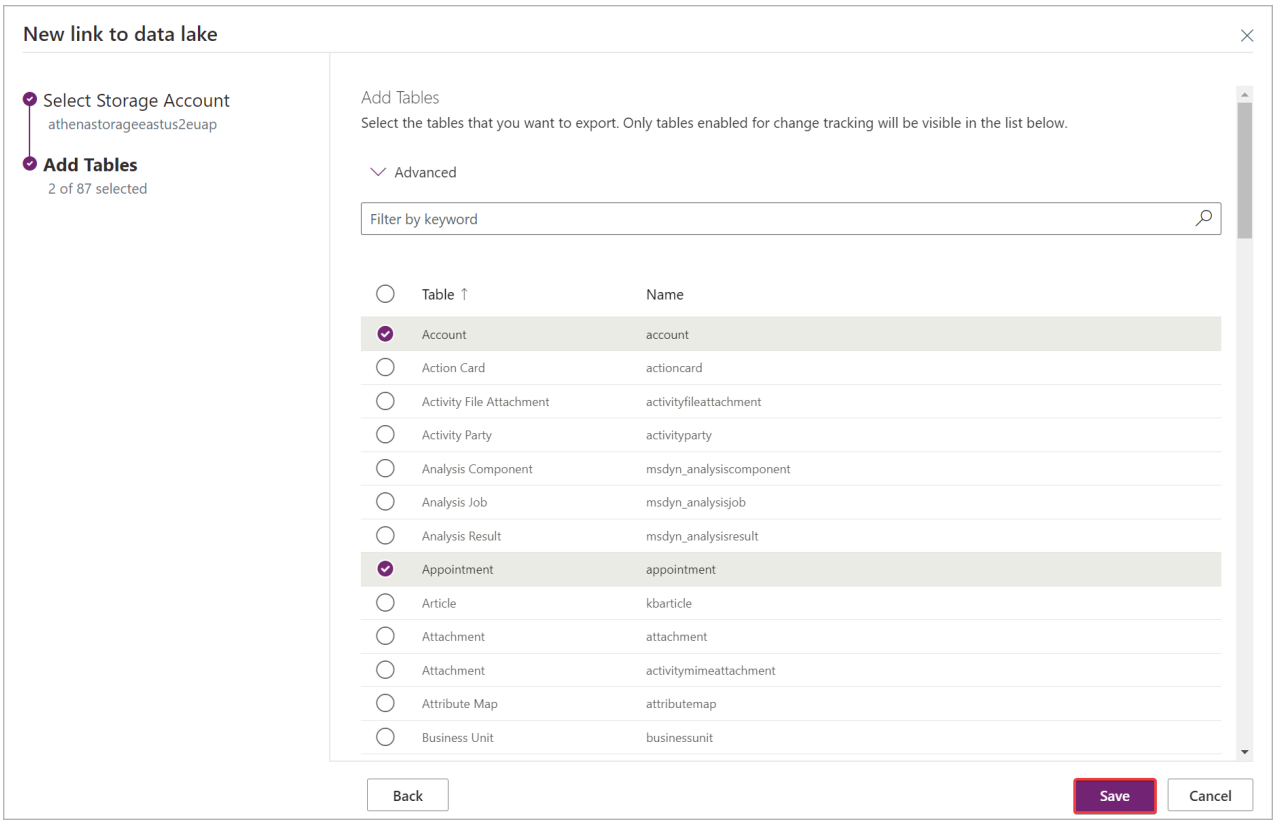
Connect Dataverse to Synapse workspace

1. Sign in to Power Apps and select your preferred environment.
2. On the left navigation pane, select **Azure Synapse Link**. If **Azure Synapse Link** isn't visible in the side pane, select **...More** and choose **Discover all**. Select **Azure Synapse Link** in the **Data Management** section.
3. On the command bar, select **+ New link**.
4. Select the **Connect to your Azure Synapse workspace** option.
5. Select the **Subscription**, **Resource group**, **Workspace name**, and **Storage account**. Ensure that the Synapse workspace and storage account meet the requirements specified in the Prerequisites section. Select **Next**.



> **Note**
>
> As part of linking the environment to a data lake, you grant the Azure Synapse Link service access to your storage account. Ensure that you followed the prerequisites of creating and configuring the Azure data lake storage account, and granting yourself an owner role on the storage account. Additionally, you grant the Power Platform Dataflows service access to your storage account. More information: Self-service data prep with dataflows.

6. Choose the tables you want to export either by selecting them one by one or by entering a comma separated list of tables in the search box, and then select **Save**. Only tables with the Track changes property enabled can be exported. More information: Advanced options.



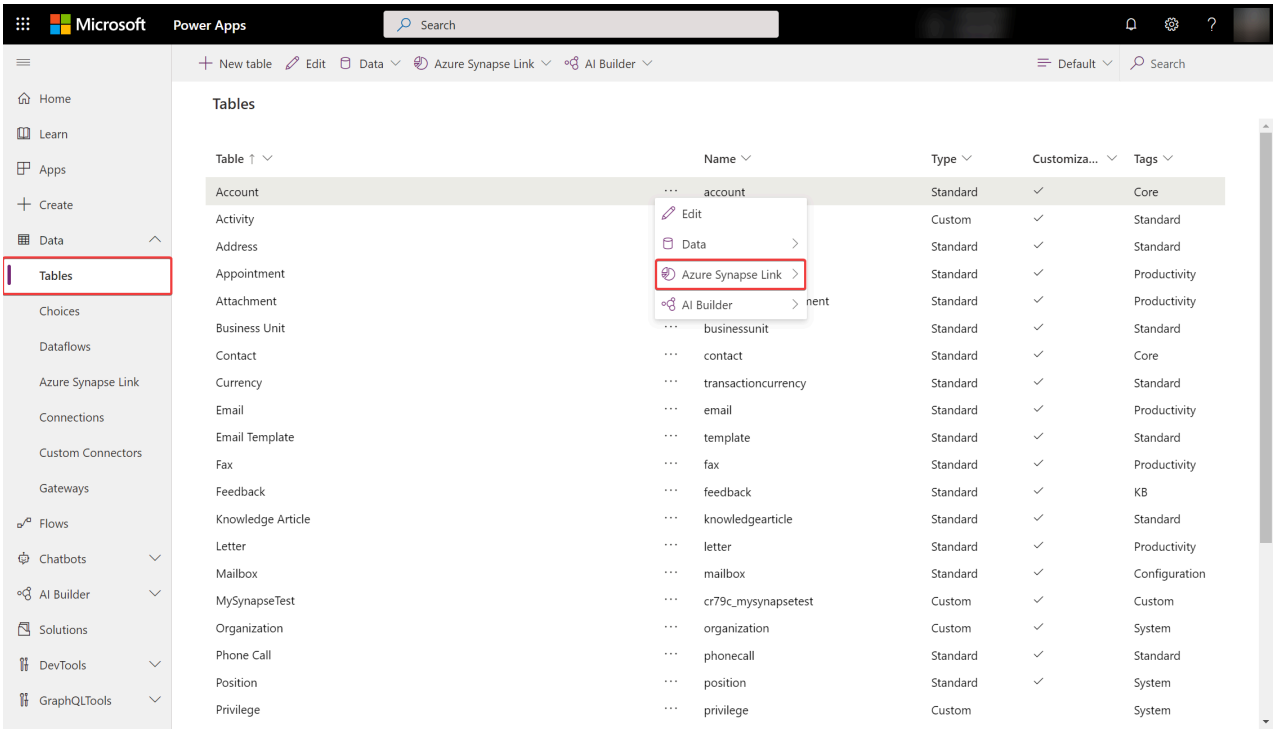
You can follow the steps above to create a link from one environment to multiple Azure Synapse Analytics workspaces and Azure data lakes in your Azure subscription by adding an Azure data lake as a linked service on a Synapse workspace. Similarly, you could create a link from multiple environments to the same Azure Synapse Analytics workspace and Azure data lake, all within the same tenant.

> **Note**
>
> The Azure Synapse Link for Dataverse service is seamlessly integrated into the Power Platform as an out-of-the-box feature. It meets the security and governance standards set for the Power Platform data storage and governance. More information: Data storage and governance
>
> The data exported by Azure Synapse Link service is encrypted at transit using Transport Layer Security(TLS) 1.2 or higher and encrypted at rest in Azure Data Lake Storage Gen2. Additionally, transient data in the blob storage is also encrypted at rest. Encryption in Azure Data Lake Storage Gen2 helps you protect your data, implement enterprise security policies, and meet regulatory compliance requirements. More information: Azure Data Encryption-at-Rest More information: Configure Azure Storage firewalls and virtual networks

Manage table data to the Synapse workspace

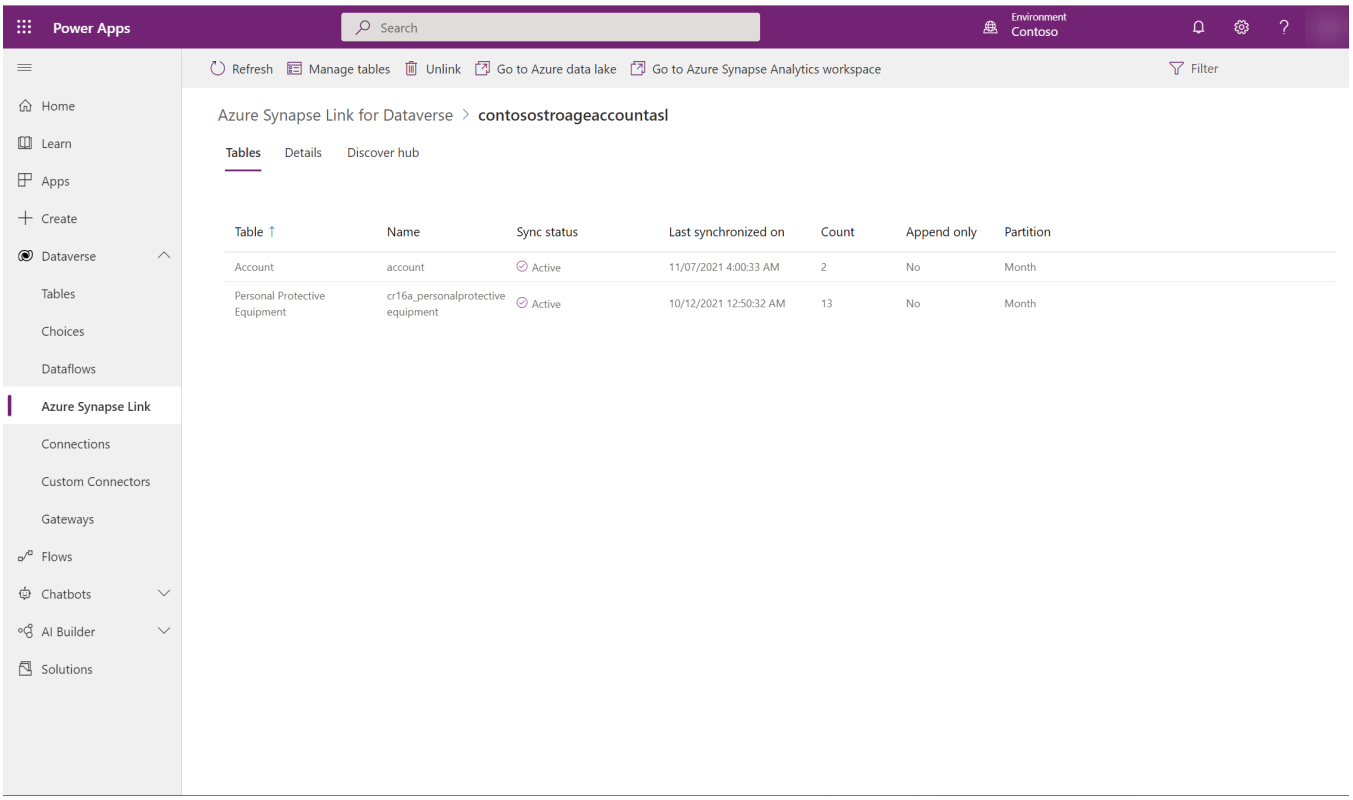
After you set up the Azure Synapse Link, you can manage the tables that are exported in one of two ways:

- In the Power Apps (make.powerapps.com) **Azure Synapse Link** area, select **Manage tables** on the command bar to add or remove one or more linked tables.
- On the Power Apps maker portal **Tables** area, select **...** next to a table, and then select the linked data lake where you want to export table data.



Monitor your Azure Synapse Link

After you set up the Azure Synapse Link, you can monitor the Azure Synapse Link on the **Tables** tab.



- There will be a list of tables that are a part of the selected Azure Synapse Link.
- There are different stages the sync status circulates through. **NotStarted** indicates that the table is waiting to be synced. Once the table initial sync is **Completed**, there's a post processing stage where incremental updates won't take place. This might take several hours depending on the size of your data. As the incremental updates start taking place, the date for the last sync will be regularly updated.
- The **Count** column shows the number rows written. When **Append only** is set to **No**, this is the total number of records. When **Append Only** is set to **Yes**, this is the total number of changes.
- The **Append only** and **Partition strategy** columns show the usage of different advanced configurations.

Unlinking an Azure Synapse Link

1. Select the desired Azure Synapse Link to unlink.
2. Select **Unlink** from the command bar.
3. To delete both the data lake file system as well as the Synapse Database, type the link name to confirm.
4. Select **Yes**, and allow a few minutes for everything to be unlinked and deleted.

> **Important**

The custom database objects you create within the Azure Synapse Link database are deleted once the unlink is completed.

You need to implement your own version control for your custom database objects scripts to ensure you have a backup.

Relinking an Azure Synapse Link

If you deleted the file system when unlinking, follow the steps above to relink the same Synapse workspace and data lake. If you didn't delete the file system when unlinking, you must clear the data to relink:

1. Navigate the Azure Synapse Analytics.
2. Select the **...** for the unlinked database and select **New notebook** > **Empty notebook**.
3. Attach the notebook to an Apache Spark pool by selecting a pool from the drop-down menu. If you don't have an Apache Spark pool, select **Manage pools** to create one.
4. Enter the following script, replace **<DATABASE_NAME>** with the name of the database to unlink, and run the notebook.

SQL

```
%%sql
DROP DATABASE <DATABASE_NAME> CASCADE
```

5. After running the notebook, refresh the database list from the left panel. If the database still exists, try right clicking on the database and selecting **Delete**.
6. Navigate to Power Apps, and relink the Synapse workspace and data lake.

Access near real-time data and read-only snapshot data

After creating an Azure Synapse Link, two versions of the table data will be synchronized in Azure Synapse Analytics and/or Azure Data Lake Storage Gen2 in your Azure subscription by default to ensure you can reliably consume updated data in the lake at any given time:

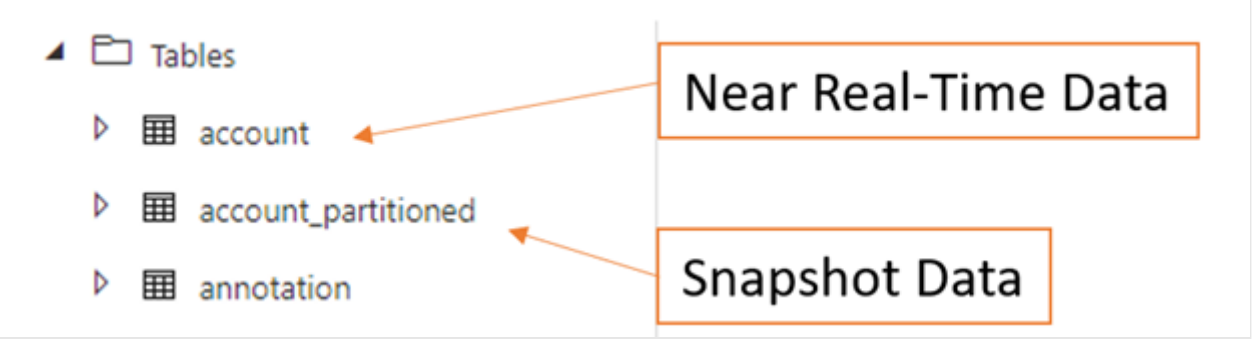
- Near real-time data: Provides a copy of data synchronized from Dataverse via Azure Synapse Link in an efficient manner by detecting what data has changed since it was initially extracted or last synchronized.

- Snapshot data: Provides a read-only copy of near real-time data that is updated at regular intervals (in this case every hour).

> **Note**
>
> - Near real-time sync performance depends on several factors including the initial data load size, data churn rate, and the volume of changes. In situations with high transaction volumes, such as processes in Finance and Operations apps generating millions of records in a short time, or processes like the master planning feature included with Dynamics 365 Supply Chain Management that delete and re-create large volumes of records. Synapse Link must synchronize all changes including deletes. In these high-volume scenarios, data availability in near real-time can't be guaranteed.
> - To create read-only snapshot data, ensure that the **Permitted scope for copy operations** setting is configured to **From any storage account**. More information: Configure the permitted scope for copy operations

1. Select the desired Azure Synapse Link, and then select the **Go to Azure Synapse Analytics workspace** from the top panel.
2. Expand **Lake Databases** from the left panel, select **dataverse**-*environmentName*-*organizationUniqueName*, and then expand **Tables**.

All **Near Real-Time Data Tables** are listed and available for analysis with the naming convention *DataverseTableName*. All **Snapshot Data Tables** are listed and available for analysis with the naming convention *DataverseTableName*_partitioned.



What's next?

After successfully using the Azure Synapse Link for Dataverse service, discover how you can analyze and consume your data with **Discover Hub**. To access **Discover Hub**, go to **Power Apps** > **Azure Synapse Link**. Select your linked service and then select the **Discover Hub** tab. Here you can find recommended tools and curated documentation to help you get the most value

out of your data.

Last updated on 02/18/2026

Create an Azure Synapse Link for Dataverse with Azure Data Lake

You can use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Data Lake Storage Gen2 to enable various analytics scenarios. This article shows you how to perform the following tasks:

1. Connect your Dataverse data to your Azure Data Lake Storage Gen2 account with the Azure Synapse Link service.
2. Manage Dataverse tables included in the Azure Synapse Link.
3. Monitor your Azure Synapse Link.
4. Unlink your Azure Synapse Link.
5. Relink your Azure Synapse Link.
6. View your data in Azure Data Lake and understand the file structure.

> ⓘ **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

- Azure Data Lake Storage Gen2: You must have an Azure Data Lake Storage Gen2 account and **Owner** and **Storage Blob Data Contributor** role access. Your storage account must enable **Hierarchical namespace** for both initial setup and delta sync. **Allow storage account key access** is required only for the initial setup. Your storage account must have Permitted scope for copy operations set to **From any storage account**.

> ⓘ **Note**
>
> - The storage account must be created in the same Microsoft Entra tenant as your Power Apps tenant.
> - To set **Enabled from selected virtual networks and IP addresses** for linked storage account to grant access from selected IP addresses, you must create an Azure Synapse

Link with managed identities.Use managed identities for Azure with your Azure data lake storage (without managed identities set up, you must enable public network access for Azure resources for both initial setup and delta sync.)

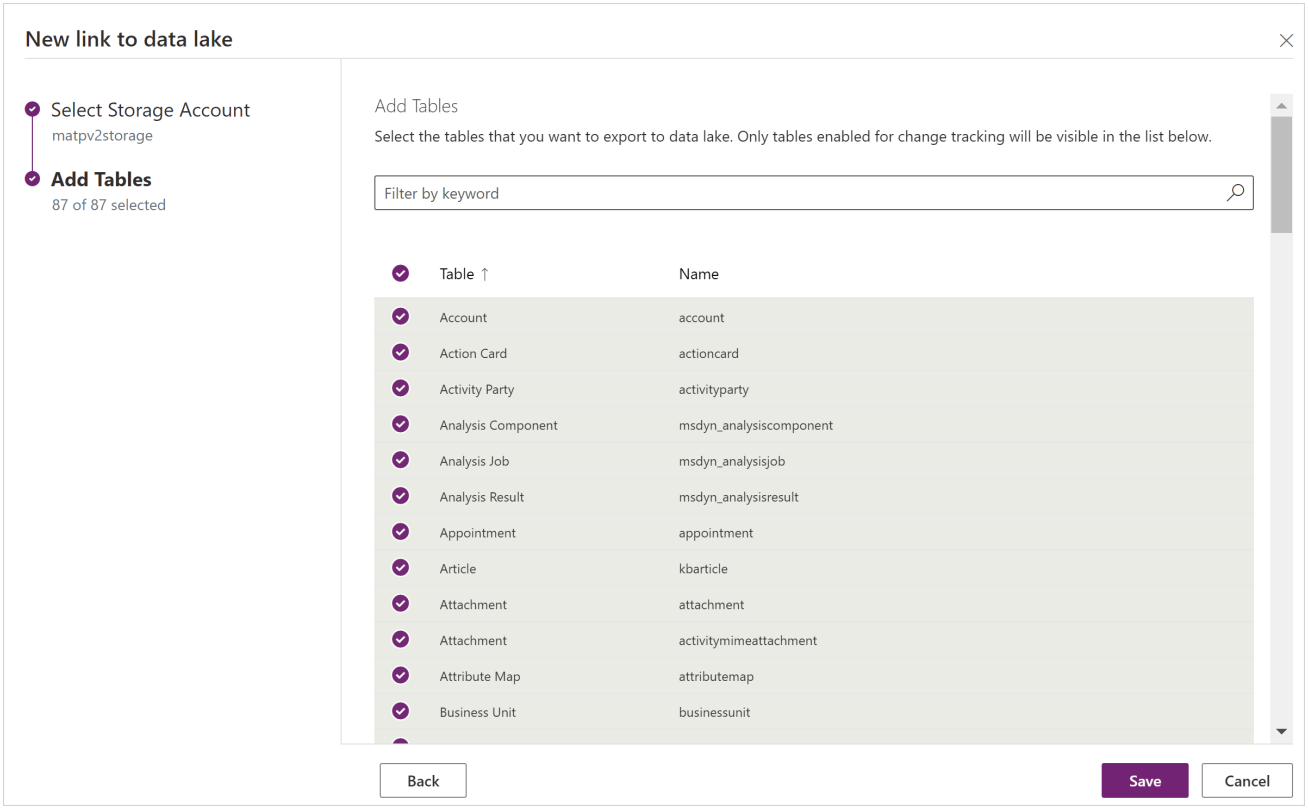
- We strongly recommend that you enable the soft delete feature on the storage account selected for this purpose. Enabling soft delete enables you to recover from accidental data deletes faster.
- You must have **Reader** role access to the resource group with the storage account.
- To link the environment to Azure Data Lake Storage Gen2, you must have the Dataverse system administrator security role.
- Only tables that have change tracking enabled can be exported.
- The creation of Azure Synapse Link profiles under a single Dataverse environment is limited to a maximum of 10.

Connect Dataverse to Azure Data Lake Storage Gen2

1. Sign in to Power Apps and select your preferred environment.
2. On the left navigation pane, select **Azure Synapse Link**. If **Azure Synapse Link** isn't visible in the side panel, select **...More** and select **Discover all**. **Azure Synapse Link** is in the **Data Management** section.
3. On the command bar, select **+ New link to data lake**.
4. Select the **Subscription**, **Resource group**, and **Storage account**. Ensure that storage account meets the requirements specified in the Prerequisites section. Select **Next**.

   > **Note**
   >
   > As part of linking the environment to a data lake, you grant the Azure Synapse Link service access to your storage account. Ensure that you followed the prerequisites of creating and configuring the Azure data lake storage account, and granting yourself an owner role on the storage account. Additionally, you grant the Power Platform Dataflows service access to your storage account. More information: Self-service data prep with dataflows.

5. Choose the tables you want to export either by selecting them one by one or by entering a comma separated list of tables in the search box, and then select **Save**. Only tables with the **Track changes** property can be exported. More information: Advanced options for tables.



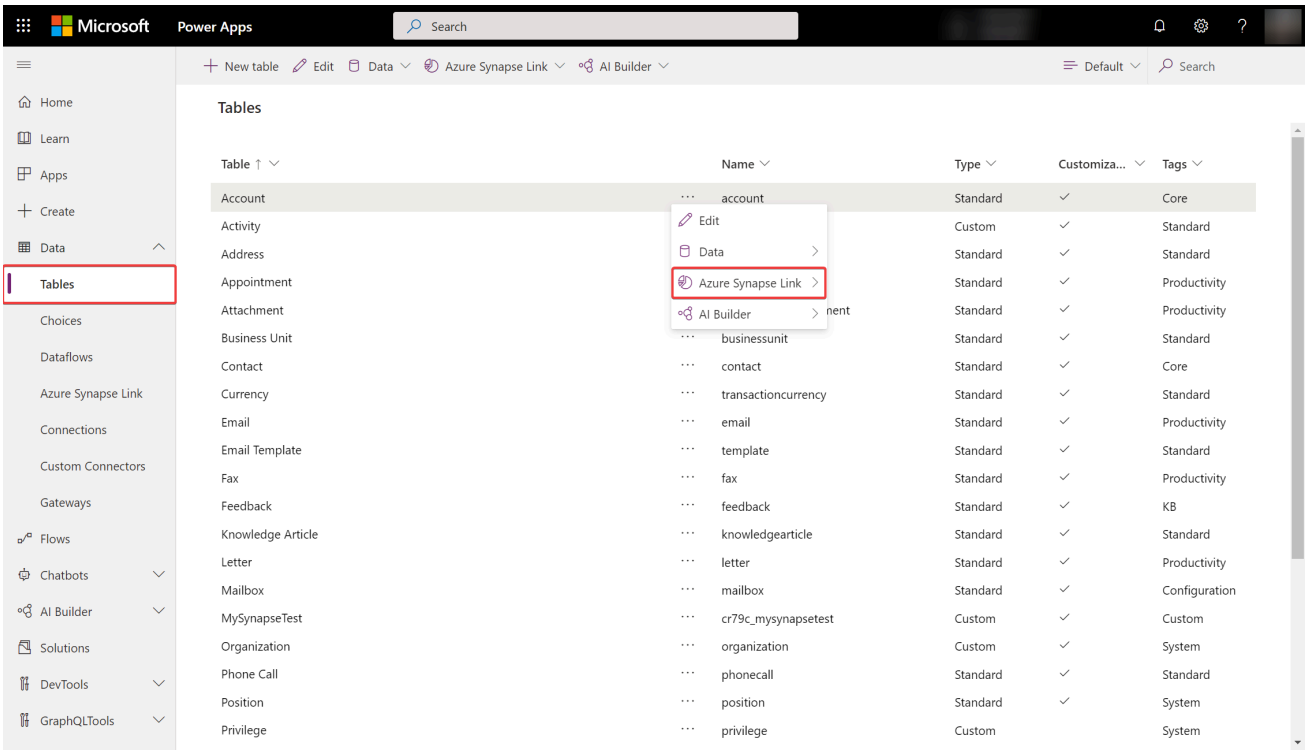
You can follow the steps in this article to create a link from one environment to multiple Azure data lakes in your Azure subscription. Similarly, you can create a link from multiple environments to the same Azure Data Lake, all within the same tenant.

> **Note**
>
> The Azure Synapse Link for Dataverse service is seamlessly integrated into the Power Platform as an out-of-the-box feature. It meets the security and governance standards set for the Power Platform data storage and governance. More information: Data storage and governance
>
> The data exported by Azure Synapse Link service is encrypted in transit by using Transport Layer Security (TLS) 1.2 or higher and encrypted at rest in Azure Data Lake Storage Gen2. Additionally, transient data in the blob storage is also encrypted at rest. Encryption in Azure Data Lake Storage Gen2 helps you protect your data, implement enterprise security policies, and meet regulatory compliance requirements. For more information, see Azure Data Encryption-at-Rest.

Manage table data to the data lake

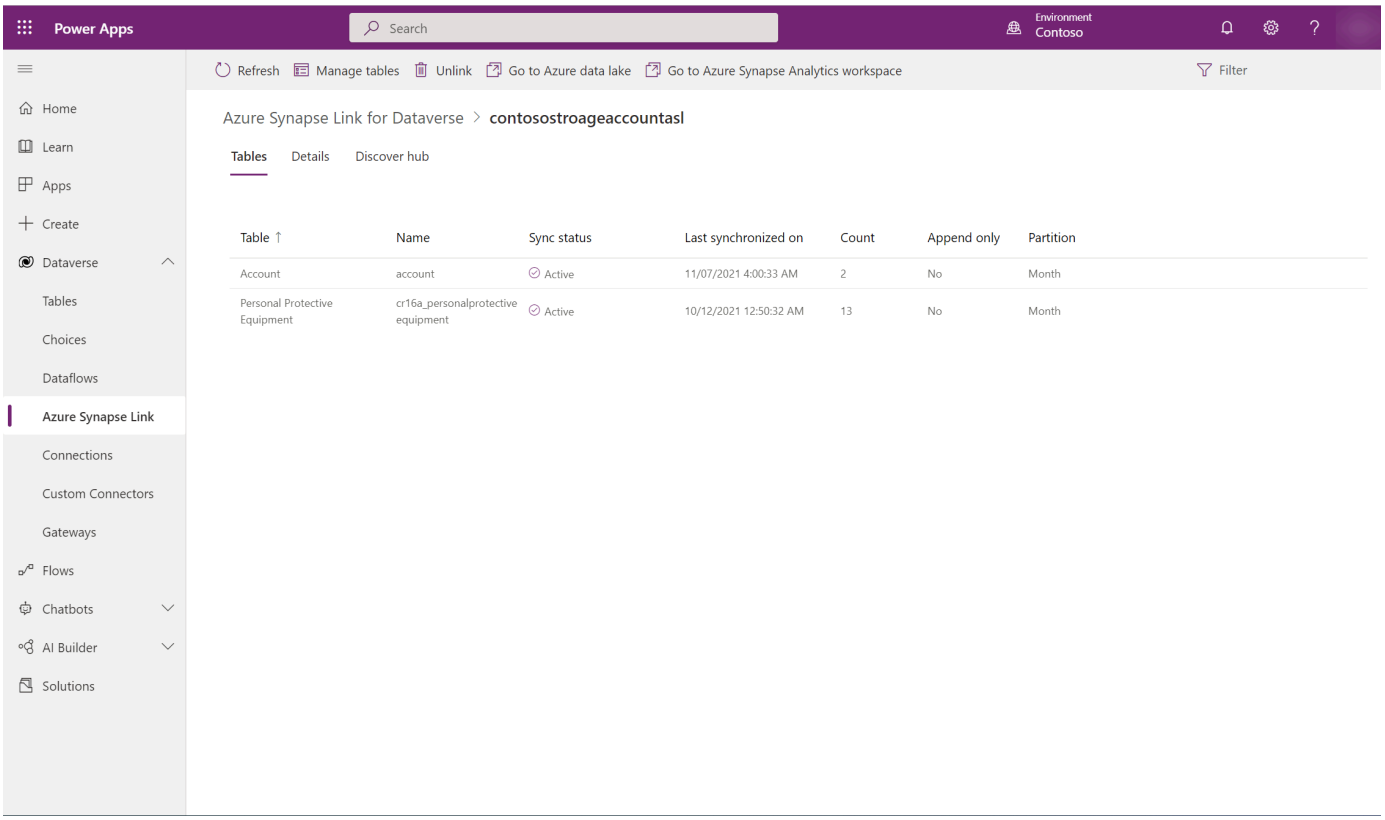
After you set up the Azure Synapse Link, you can manage the tables that are exported in one of two ways:

- On the Power Apps maker portal **Azure Synapse Link** area, select **Manage tables** on the command bar to add or remove one or more linked tables.
- On the Power Apps maker portal **Tables** area, select **...** next to a table, and then select the linked data lake where you want to export table data.



Monitor your Azure Synapse Link

After you set up the Azure Synapse Link, you can monitor the Azure Synapse Link under the **Tables** tab.



- There will be a list of tables that are a part of the selected Azure Synapse Link.
- There are different stages the sync status circulates through. **NotStarted** indicates that the table is waiting to be synced. Once the table initial sync is **Completed**, there's a post processing stage where incremental updates won't take place. This might take several hours depending on the size of your data. As the incremental updates start taking place, the date for the last sync will be regularly updated.
- The **Count** column shows the number rows written. When **Append only** is set to **No**, this is the total number of records. When **Append Only** is set to **Yes**, this is the total number of changes.
- The **Append only** and **Partition strategy** columns show the usage of different advanced configurations.

Unlinking an Azure Synapse Link

1. Select the Azure Synapse Link to unlink.

2. Select **Unlink data lake** from the command bar.

3. To delete both the data lake file system, select **Delete data lake file system**.

4. Select **Yes**, and allow a few minutes for everything to be unlinked and deleted.

Relinking an Azure Synapse Link

If you deleted the file system when unlinking, follow the preceding steps to relink the same data lake. If you didn't delete the file system when unlinking, you must clear the data to relink:

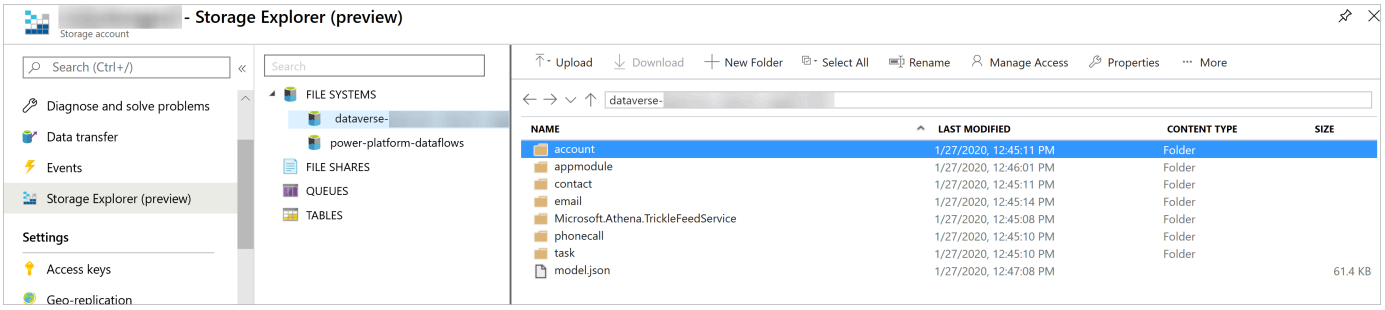
1. Go to the Azure Data Lake.
2. Delete the Dataverse container.
3. Go to Power Apps, and relink the data lake.

View your data in Azure Data Lake Storage Gen2

1. Select the desired Azure Synapse Link, and then select **Go to Azure data lake** from the top panel.
2. Expand **File Systems**, and then select dataverse-*environmentName*-*organizationUniqueName*.

The model.json file, along with its name and version, provides a list of tables that have been exported to the data lake. The model.json file also includes the initial sync status and sync completion time.

A folder that includes snapshot comma-delimited (CSV format) files is displayed for each table exported to the data lake.

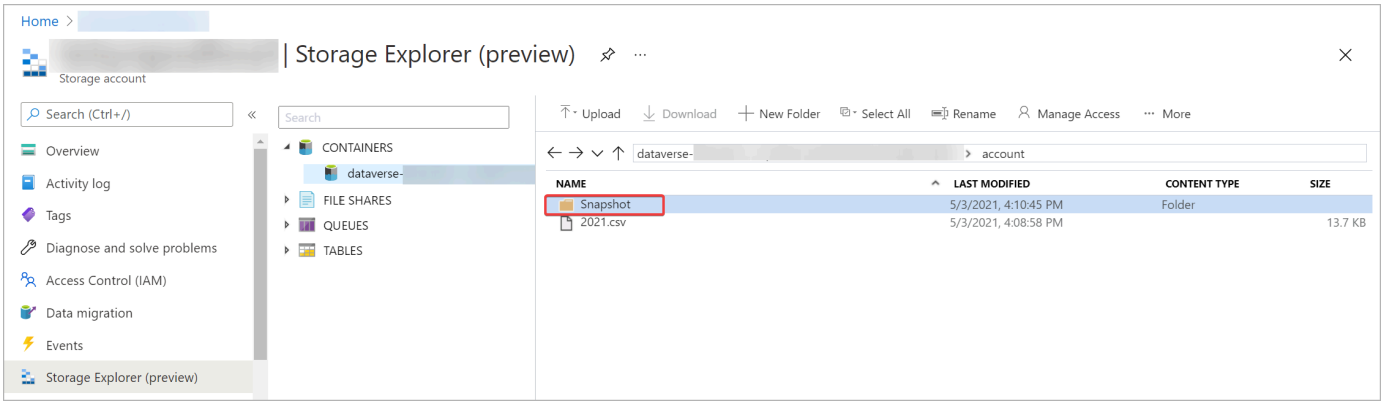


Link a Synapse workspace to an existing Azure Synapse Link profile with data lake only

1. In a web browser's address bar, append `?athena.updateLake=true` to the web address that ends with **exporttodatalake**.
2. Select an existing profile from the Azure Synapse Link area, and then select extended option.
3. Select **Link to Azure Synapse Analytics Workspace** and allow a few minutes for everything to be linked.

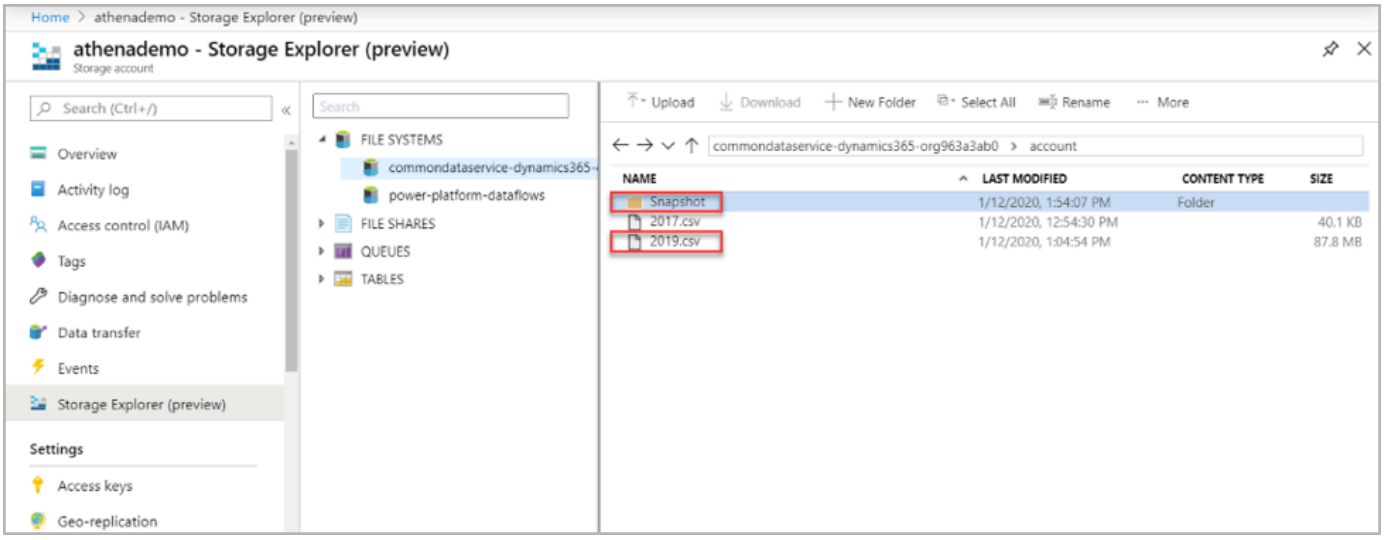
Continuous snapshot updates

Microsoft Dataverse data can continuously change through create, update, and delete transactions. Snapshots provide a read-only copy of data that's updated at regular intervals, in this case every hour. This ensures that at any given point, a data analytics consumer can reliably consume data in the lake.



When tables are added as part of the initial export, the table data is written to the table.csv files under the corresponding folders in the data lake. This is the T1 interval, where a snapshot read-only file named *table*-T1.csv—for example, Account-T1.csv or Contacts-T1.csv—is created. Additionally, the model.json file is updated to point to these snapshot files. Opening model.json, you can view the snapshot details.

Here's an example of an Account.csv partitioned file and snapshot folder in the data lake.

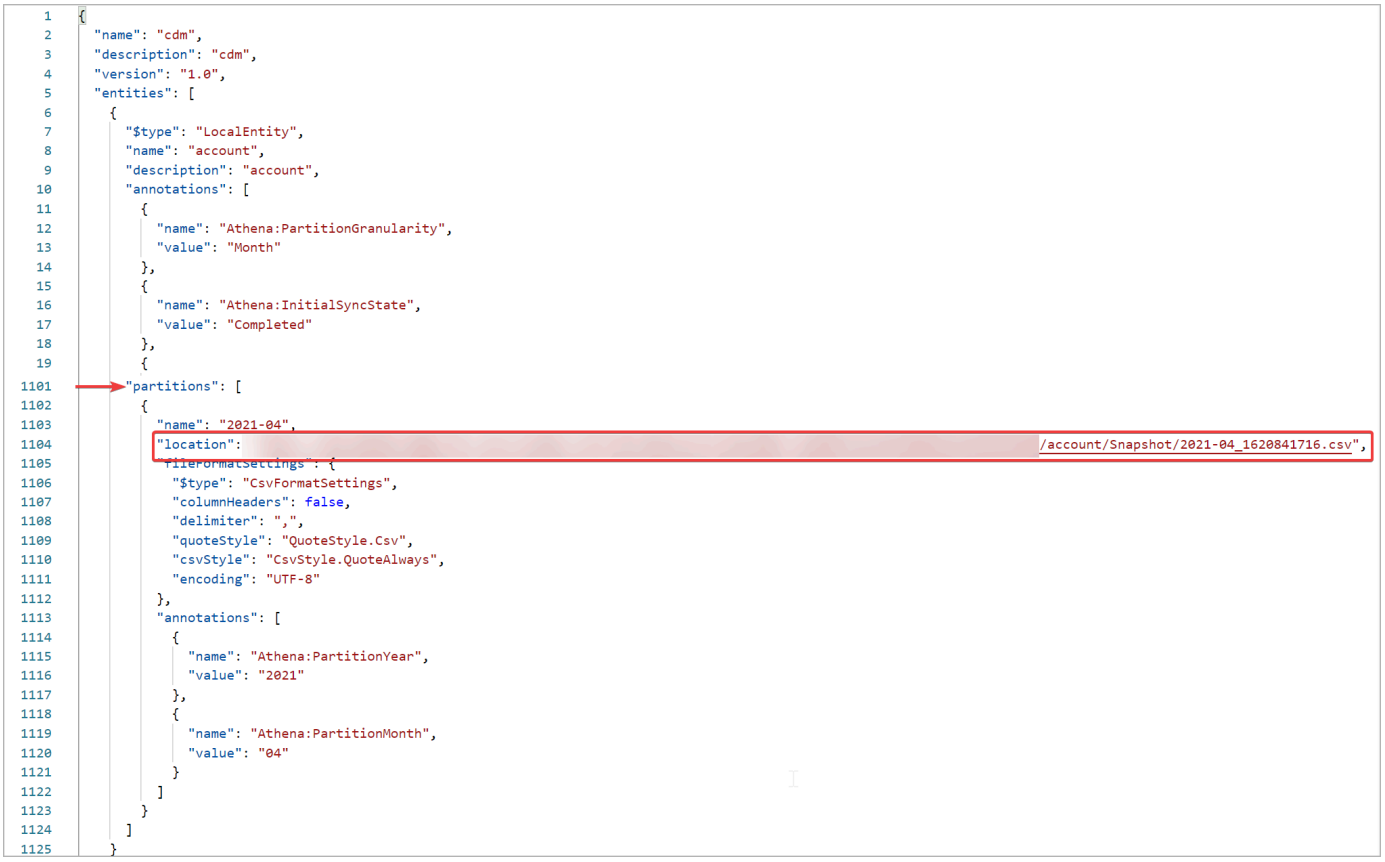


Changes in Dataverse are continuously pushed to the corresponding CSV files by using the trickle feed engine. This is the T2 interval, where another snapshot is taken. *table*-T2.csv—for example, Accounts-T2.csv or Contacts-T2.csv (assuming there are changes for the table) —and model.json are updated to the new snapshot files. Any new person who views snapshot data from T2 onward is directed to the newer snapshot files. This way, the original snapshot viewer can continue to

work on the older snapshot T1 files while newer viewers can read the latest updates. This is useful in scenarios that have longer-running downstream processes.

> **Note**
>
> - A new snapshot file is created only when there's a data update.
> - Only the latest five snapshot files are retained. Stagnant data is automatically removed from your Azure Data Lake Storage Gen 2 account.

Here's an example of the model.json file, which always points to the latest time-stamped account snapshot file.



What's next?

After successfully using the Azure Synapse Link for Dataverse service, discover how you can analyze and consume your data with **Discover Hub**. To access **Discover Hub**, go to **Power Apps** > **Azure Synapse Link**. Select your linked service and then select the **Discover Hub** tab. Here you can find recommended tools and curated documentation to help you get the most value out of

your data.

Azure Synapse Link for Dataverse Advanced Configuration

Azure Synapse Link FAQ

Last updated on 04/09/2026

Advanced configuration options in Azure Synapse Link

Azure Synapse Link offers multiple ways to write and read your data to fit various analytical scenarios. Depending on your analytical scenario, you can choose a specific configuration from the options below.

Expand table

Scenario	Applies to	Available configuration options
Operational reporting	Microsoft Dataverse tables, finance and operations tables, and entities.	Synapse Analytics with Delta lake option provides better query response times especially applicable for querying large amounts of data. More information: Synapse Link with Delta lake option
Operational reporting	Dataverse tables only.	Synapse Link with "In place update" configuration option provides CSV files in your data lake that are updated near-real time. This is a legacy option available for Dataverse tables. This option isn't supported for tables from finance and operations apps.
Data integration	Dataverse tables and finance and operations tables and entities.	"**Append only** option provides CSV files that contain incremental data. You can build pipelines that consume incremental data and populate downstream systems **User-specified data partition** feature enables choosing a custom data partitioning strategy specifically for Dataverse tables. Finance and operations table data are partitioned by the system based on appropriate partition strategy. This option isn't available for finance and operations apps.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as export to data lake. Microsoft renamed the service in May 2021. The service continues to export data to Azure Data Lake Storage as well as Azure Synapse Analytics. Starting Sept-2023, Azure Synapse Link also enables you to choose data from Dynamics 365 finance and operations applications. Not all integration patterns are supported with finance and operations apps. For guidance on

transitioning from export to data lake feature in finance and operations apps to Synapse Link, go to the Transition guide.

This article covers advanced configuration settings available for Dataverse tables. These options aren't available for finance and operations apps.

1. In-place updates vs. append-only writes.
2. User-specified data partitioning.

In-place updates vs. append-only writes

While writing Dataverse table data to the Azure data lake, based on the `createdOn` value, which is the date and time when the record was created, there are two different settings to choose from. They are, **In place update** and **Append only**.

The default setting (for tables where `createdOn` is available) is to do an in-place update or upsert (update or insert) of the incremental data in the destination. If the change is new and a corresponding row doesn't exist in the lake, in the case of a create, the destination files are scanned, and the changes are inserted into the corresponding file partition in the lake. If the change is an update and a row exists in the lake, the corresponding file in the lake is updated, rather than inserted, with the incremental data. In other words, the default setting for all CUD (create, update, delete) changes in Dataverse tables, where `createdOn` is available, is to do an in place update in the destination, in Azure data lake.

You can switch the default behavior of an in place update by using an optional setting called **Append only**. Rather than an **In place update**, in **Append only** mode, incremental data from Dataverse tables are appended to the corresponding file partition in the lake. This is a per table setting and available as a checkbox under **Advanced** > **Show advanced configuration settings**. For Dataverse tables with **Append only** turned on, all the CUD changes are incrementally appended to the corresponding destination files in the lake. When you choose this option, the partition strategy defaults to **Year** and when data is written to the data lake, it's partitioned by yearly basis. **Append only** is also the default setting for Dataverse tables that don't have `createdOn` value.

This table describes how rows are handled in the lake against CUD events for each of the data write options.

Expand table

Event	In place update	Append only
Create	The row is inserted in the partition file and is based on the `createdOn` value on the row.	The row is added to the end of the partition file and is based on the `createdOn` value of the record.
Update	If the row exists in the partition file, then it's replaced or updated with updated data. If it doesn't exist, it's inserted in the file.	The row, along with the updated version, is added to the end of the partition file.
Delete	If the row exists in the partition file, it's removed from the file.	The row is added to the end of the partition file with `IsDelete column = True`.

> ⓘ **Note**
>
> For Dataverse tables where **Append only** is enabled, deleting a row in the source doesn't delete or remove the row in the lake. Instead, the deleted row is appended as a new row in the lake and the `isDeleted` column is set to **True**.
>
> Dirty read (**ALLOW_INCONSISTENT_READS**) for serverless is enabled for append only mode. **ALLOW_INCONSISTENT_READS** means that user is able to read the files that can be constantly modified while the `SELECT` query is running. Results are consistent and equivalent to reading a snapshot of the file. (It isn't equivalent to database snapshot isolation because of the different snapshot generation time.)
>
> Not all CUD changes are captured in **append only**: The Synapse Link processes changes in data in groups or "batches" before publishing them to the data lake. As a result, if the user makes changes within a short time interval, not all CUD changes are captured in the data lake.

Here are some more details on when to use either of the options.

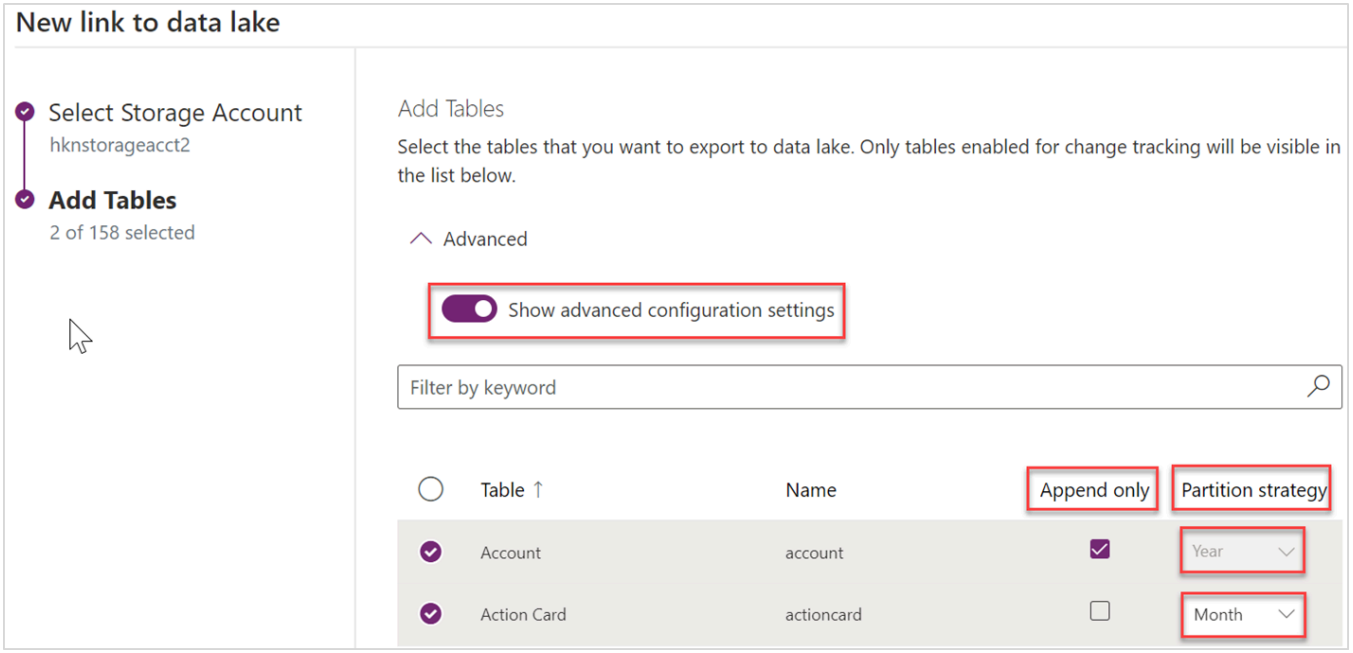
- **In place update** (legacy): This option is the default setting and recommended only if you want to connect directly to the data in lake and need the current state (not history or incremental changes). The file contains the full data set and can be utilized via Power BI or by copying the entire dataset for ETL (Extract, Transfer, Load) pipelines.

  > ⓘ **Important**
  >
  > **In place update** is a legacy mode and doesn't scale well with high data volumes or when changes are frequent. If your table has a large amount of data or experiences a

high rate of creates, updates, or deletes, use **Append only** instead to ensure reliable and performant data export.

- **Append only**: Select this option if you aren't directly connecting to data in the lake and want to incrementally copy data to another target using ETL pipelines. This option provides a history of changes to enable AI and ML scenarios. This is the recommended option for tables with large data volumes or frequent data changes.

You can toggle the **Show advanced configuration settings** under **Advanced** in Azure Synapse Link for Dataverse to customize your data partition strategy and select options to write to the Azure data lake.



Data partitioning

When you write Dataverse table data to Azure Data Lake Storage by using Azure Synapse Link, the tables are partitioned in the lake based on the `createdOn` value on each row in the source. The default partition strategy is by month, so data is partitioned in Azure Data Lake on a monthly basis.

Based on the Dataverse table volume and data distribution, you can choose to partition your data by year. With this option, when Dataverse table data is written to the Azure data lake, it's partitioned on a yearly basis based on the `createdOn` value on each row in the source. For tables without the `createdOn` column, the rows of data are partitioned into a new file every 5,000,000 records. This is a per table setting and is available as a checkbox under **Advanced** > **Show advanced configuration settings**.

Here are examples of how data can be handled in the lake with a yearly or monthly partition strategy.

Use managed identities for Azure with your Azure data lake storage

Summarize this article for me

Azure Data Lake Storage provides a layered security model. This model enables you to secure and control the level of access to your storage accounts that your applications and enterprise environments demand, based on the type and subset of networks or resources used. When network rules are configured, only applications requesting data over the specified set of networks or through the specified set of Azure resources can access a storage account. You can limit access to your storage account to requests originating from specified IP addresses, IP ranges, subnets in an Azure Virtual Network (VNet), or resource instances of some Azure services.

Managed identities for Azure, formerly known as Managed Service Identity (MSI), help with the management of secrets. Microsoft Dataverse customers using Azure capabilities create a managed identity (part of enterprise policy creation) that can be used for one or more Dataverse environments. This managed identity that will be provisioned in your tenant is then used by Dataverse to access your Azure data lake.

With managed identities, access to your storage account is restricted to requests originating from the Dataverse environment associated with your tenant. When Dataverse connects to storage on behalf of you, it includes additional context information to prove that the request originates from a secure, trusted environment. This allows storage to grant Dataverse access to your storage account. Managed identities are used to sign the context information in order to establish trust. This adds application-level security in addition to the network and infrastructure security provided by Azure for connections between Azure services.

Before you start

- Azure CLI is required on your local machine. Download and install
- You need the following PowerShell modules. If you don't have them, open PowerShell and run these commands:
  - Azure Az PowerShell module: `Install-Module -Name Az`
  - Azure Az.Resources PowerShell module: `Install-Module -Name Az.Resources`
  - Power Platform admin PowerShell module: `Install-Module -Name Microsoft.PowerApps.Administration.PowerShell`
- Clone the PowerApps-Samples repository on GitHub to a location where you can run PowerShell commands: `git clone https://github.com/microsoft/PowerApps-Samples.git`.

Scripts are organized in subfolders under `powershell/managed-identities/Source`. Run each script from its specific subfolder—for example, `Source\Identity`.

- We recommend that you create a new storage container under the same Azure resource group to onboard this feature.

> **Important**
>
> Don't move scripts out of their folders. Scripts rely on relative paths and shared files in the repository structure.

Enable enterprise policy for the selected Azure subscription

> **Important**
>
> You must have **Azure subscription Owner** role access to complete this task. Obtain your Azure **Subscription ID** from the overview page for the Azure resource group.

1. Open Azure CLI with run as administrator and sign into your Azure subscription using the command: `az login` More information: Sign in with Azure CLI
2. (Optional) if you have multiple Azure subscriptions, make sure to run `Update-AzConfig -DefaultSubscriptionForLogin { Azure subscription id }` to update your default subscription.
3. In PowerShell, change to the `Source` folder within the repository you cloned as part of Before you start.
4. To enable the enterprise policy for the selected Azure subscription, run the PowerShell script **./SetupSubscriptionForPowerPlatform.ps1**.

    - Provide the Azure subscription ID.

Create enterprise policy

> **Important**
>
> You must have **Azure resource group Owner** role access to complete this task. Obtain your Azure **Subscription ID**, **Location**, and **Resource group** name, from the overview page for the Azure resource group.

1. In PowerShell, change to the `Source\Identity` subfolder and run the script to create the enterprise policy:

   PowerShell

   ```
   cd <path-to-repo>\powershell\managed-identities\Source\Identity
   .\CreateIdentityEnterprisePolicy.ps1
   ```

   - Provide the Azure subscription ID.
   - Provide the Azure resource group name.
   - Provide preferred enterprise policy name.
   - Provide the Azure resource group location.

2. Save the copy of the **ResourceId** after policy creation.

> **Note**
>
> The following are the valid **location** inputs supported for policy creation. Select the location that's most appropriate for you.

Locations available for enterprise policy

United States EUAP

United States

Grant reader access to the enterprise policy via Azure

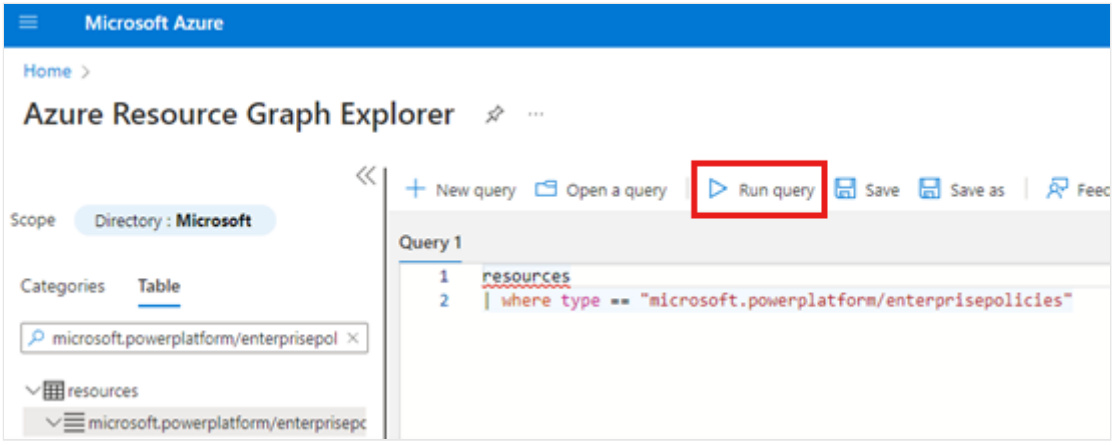
Dynamics 365 admins, and Power Platform admins can access the Power Platform admin center to assign environments to the enterprise policy. To access the enterprise policies, Azure Key vault admin membership is required to grant the **Reader role** to the Dynamics 365 or Power Platform admin. Once the reader role is granted, the Dynamics 365 or Power Platform admins will see the enterprise policies on the Power Platform admin center.

Only the Dynamics 365 and Power Platform admins who were granted the reader role to the enterprise policy can 'add environment' to the policy. Other Dynamics 365 and PowerPlatform admins might be able to view the enterprise policy, but they'll get an error when they try to add environment.

> **ⓘ Important**
>
> You must have - `Microsoft.Authorization/roleAssignments/write` permissions, such as User Access Administrator or Owner to complete this task.

1. Sign into the Azure portal.
2. Obtain the Dynamics 365 Power Platform admin user's **ObjectID**.
   a. Go to the **Users** area.
   b. Open the Dynamics 365 or Power Platform admin user.
   c. Under the overview page for the user, copy the **ObjectID**.
3. Obtain the enterprise policies ID:
   a. Go to the Azure **Resource Graph Explorer**.

b. Run this query: `resources | where type == 'microsoft.powerplatform/enterprisepolicies'`



c. Scroll to the right of the results page and select the **See details** link.

d. On the **Details** page, copy the ID.

4. Open Azure CLI and run the following command, replacing the `<objId>` with the user's **ObjectID** and the `<EP Resource Id>` with the enterprise policy ID.

   - `New-AzRoleAssignment -ObjectId <objId> -RoleDefinitionName Reader -Scope <EP Resource Id>`

Connect enterprise policy to Dataverse environment

> **Important**
>
> You must have the **Power Platform administrator** or **Dynamics 365 administrator** role to complete this task. You must have the **Reader** role for the enterprise policy to complete this task.

1. Obtain the Dataverse environment ID.
   a. Sign into the Power Platform admin center.
   b. Select **Manage** > **Environments**, and then open your environment.
   c. In the **Details** section, copy the **Environment ID**.
2. From the `Source\Identity` subfolder, run this PowerShell script: `./NewIdentity.ps1`

   - Provide the Dataverse environment ID.
   - Provide the **ResourceId**.

     StatusCode = **202** indicates the link was successfully created.

3. Sign into the Power Platform admin center.
4. Select **Manage** > **Environments**, and then open the environment you specified earlier.

5. In the **Recent operations** area, select **Full history** to validate the connection of the new identity.

Configure network access to the Azure Data Lake Storage Gen2

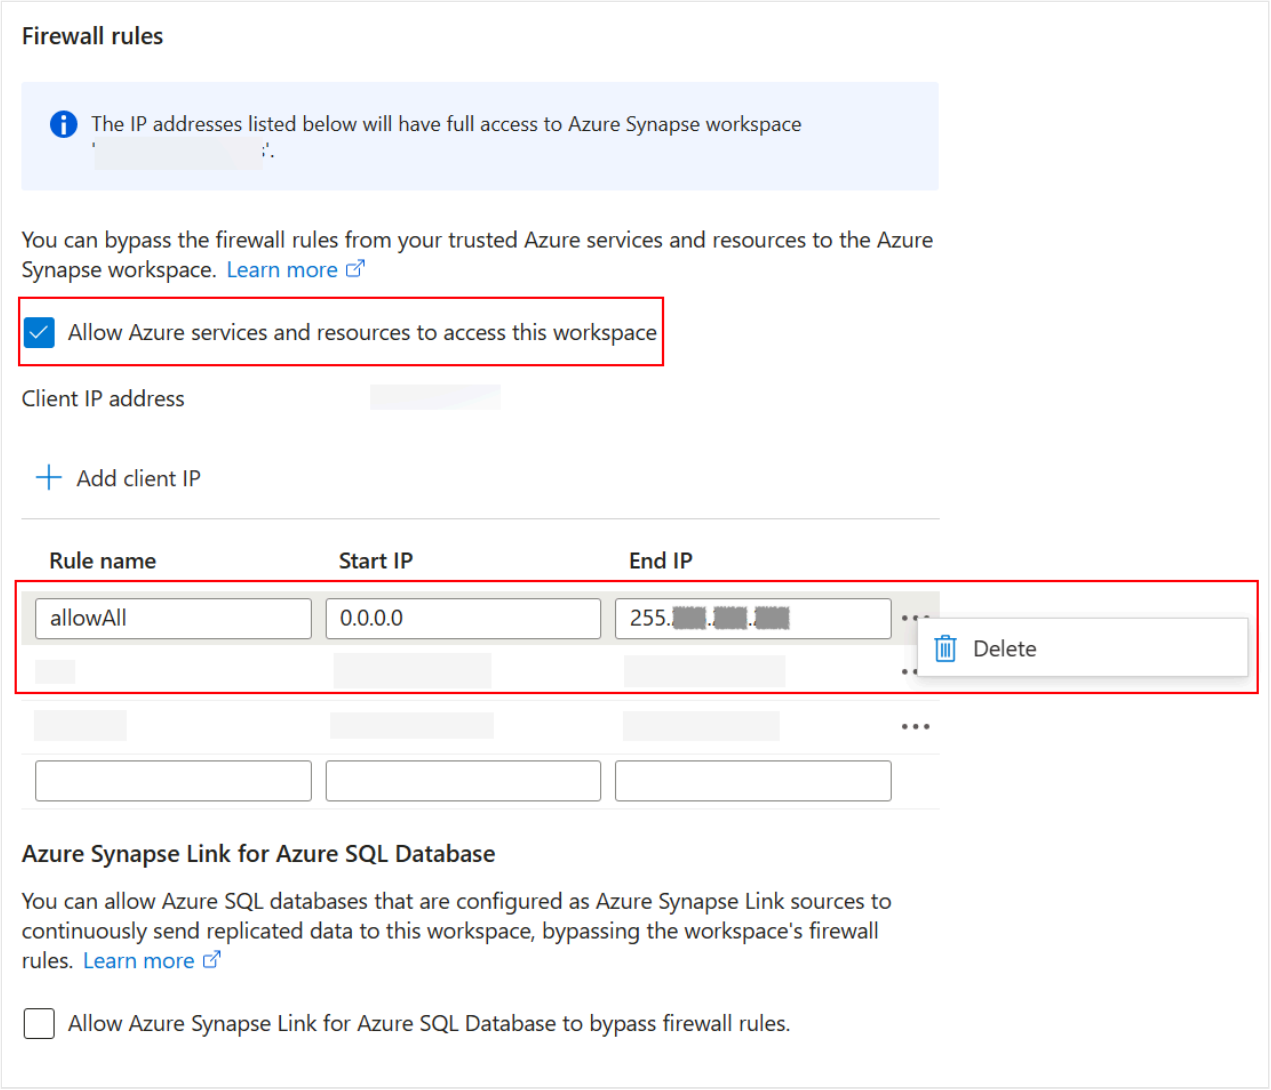
> **Important**
>
> You must have an Azure Data Lake Storage Gen2 **Owner** role to complete this task.

1. Go to the Azure portal.
2. Open the storage account connected to your Azure Synapse Link for Dataverse profile.
3. On the left navigation pane, select **Networking**. Then, on the **Firewalls and virtual networks** tab select the following settings:
   a. **Enabled from selected virtual networks and IP addresses**.
   b. Under **Resource instances**, select **Allow Azure services on the trusted services list to access this storage account**
4. Select **Save**.

Configure network access to the Azure Synapse Workspace

> **Important**
>
> You must have an Azure **Synapse administrator** role to complete this task.

1. Go to the Azure portal.
2. Open the Azure Synapse workspace connected to your Azure Synapse Link for Dataverse profile.
3. On the left navigation pane, select **Networking**.
4. Select **Allow Azure services and resources to access this workspace**.
5. If there are **IP firewall rules** created for all IP range, delete them to restrict public network access.



6. Add a new **IP firewall rule** based on the client IP address.
7. Select **Save** when done. More information: Azure Synapse Analytics IP firewall rules

Create a new Azure Synapse Link for Dataverse with managed identity

> **Important**
>
> Dataverse: You must have the Dataverse **system administrator** security role. Additionally, tables you want to export via Azure Synapse Link must have the **Track changes** property enabled. More information: Advanced options
>
> Azure Data Lake Storage Gen2: You must have an Azure Data Lake Storage Gen2 account and **Owner** and **Storage Blob Data Contributor** role access. Your storage account must enable **Hierarchical namespace** for both initial setup and delta sync. **Allow storage account key access** is required only for the initial setup.
>
> Synapse workspace: You must have a Synapse workspace and the **Synapse Administrator** role access within the Synapse Studio. The Synapse workspace must be in the same region

as your Azure Data Lake Storage Gen2 account. The storage account must be added as a linked service within the Synapse Studio. To create a Synapse workspace, go to Creating a Synapse workspace.

When you create the link, Azure Synapse Link for Dataverse gets details about the currently linked enterprise policy under the Dataverse environment then caches the identity client secret URL to connect to Azure.

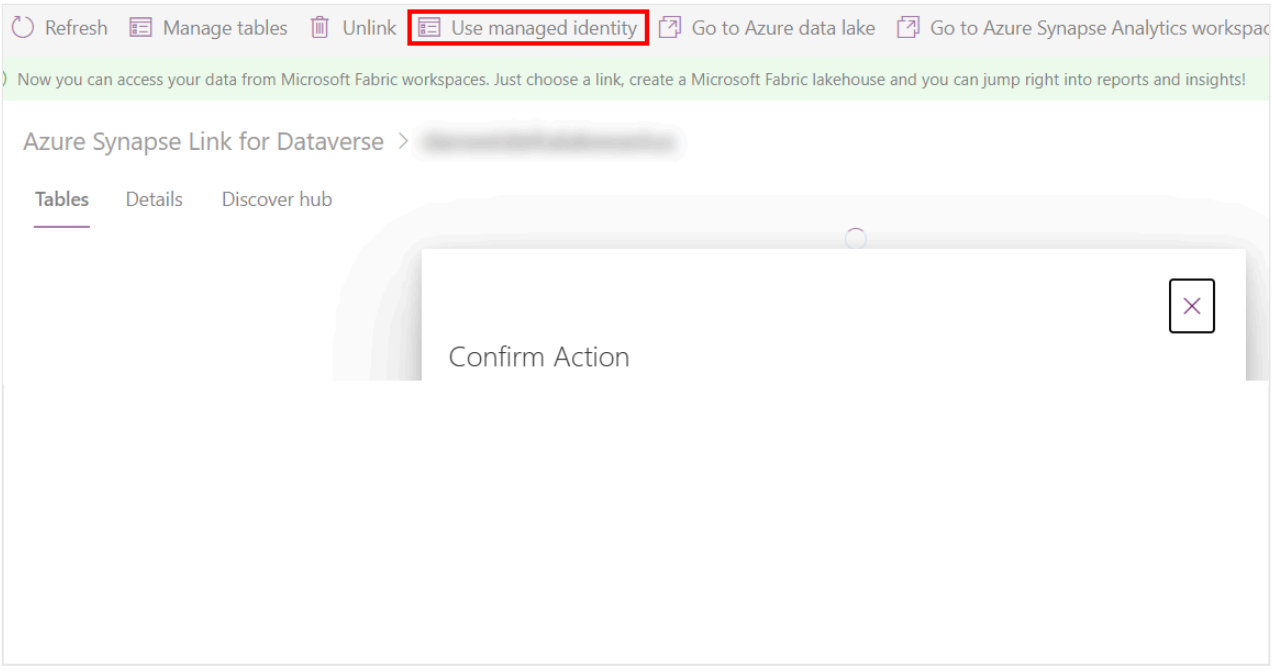
1. Sign into Power Apps and select your environment.
2. On the left navigation pane, select **Azure Synapse Link**, and then select **+ New link**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Fill in the appropriate fields, according to the intended setup. Select the **Subscription**, **Resource group**, and **Storage account**. To connect Dataverse to Synapse workspace, select the **Connect to your Azure Synapse workspace** option. For Delta Lake data conversion select a Spark pool.
4. Select **Select Enterprise Policy with Managed Service Identity**, and then select **Next**.
5. Add the tables you want to export, and then select **Save**.

Enable managed identity for an existing Azure Synapse Link profile

> **Note**
>
> To make the **Use managed identity** command available in Power Apps, you need to finish the above setup to connect the enterprise policy to your Dataverse environment. More information: Connect enterprise policy to Dataverse environment

1. Go to an existing Synapse Link profile from Power Apps (make.powerapps.com).

2. Select **Use managed identity**, and then confirm.



Troubleshooting

If you receive 403 errors during the link creation:

- Managed identities take extra time to grant transient permission during initial sync. Give it some time and try the operation again later.
- Make sure the linked storage doesn't have the existing Dataverse container(**dataverse-environmentName-organizationUniqueName**) from the same environment.
- You can identify the linked enterprise policy and `policyArmId` by running the PowerShell script `./GetIdentityEnterprisePolicyforEnvironment.ps1` from the `Source\Identity` subfolder, with the Azure **Subscription ID** and **Resource group** name.
- You can unlink the enterprise policy by running the PowerShell script `./RevertIdentity.ps1` from the `Source\Identity` subfolder, with the Dataverse environment ID and `policyArmId`.
- You can remove the enterprise policy by running the PowerShell script **.\RemoveIdentityEnterprisePolicy.ps1** from the `Source\Identity` subfolder, with `policyArmId`.

Known limitation

Only one enterprise policy can connect to the Dataverse environment simultaneously. If you need to create multiple Azure Synapse Link links with managed identity enabled, make sure all linked Azure resources are under the same resource group.

What is Azure Synapse Link for Dataverse?

Last updated on 02/25/2026

Choose finance and operations data in Azure Synapse Link for Dataverse

Microsoft Azure Synapse Link for Dataverse lets you choose data from Dynamics 365 finance and operations apps. Use Azure Synapse Link to continuously export data from finance and operations apps into Azure Synapse Analytics and Azure Data Lake Storage Gen2.

Azure Synapse Link for Dataverse is a service that's designed for enterprise big data analytics. It provides scalable high availability together with disaster recovery capabilities. Data is stored in the Common Data Model format, which provides semantic consistency across apps and deployments.

Azure Synapse Link for Dataverse offers the following features that you can use with finance and operations data:

- You can choose both standard and custom finance and operations entities and tables.
- Continuous replication of entity and table data is supported. Create, update, and delete (CUD) transactions are also supported.
- You can link or unlink the environment to Azure Synapse Analytics and/or Data Lake Storage Gen2 in your Azure subscription. You don't have to go to the Azure portal or Microsoft Dynamics Lifecycle Services for system configuration.
- You can choose data and explore by using Azure Synapse. You don't have to run external tools to configure Synapse Analytics workspaces.
- All features of Azure Synapse Link for Dataverse are supported. These features include availability in all regions, saving as Parquet Delta files, and restricted storage accounts.
- The table limits in the Export to Data Lake service aren't applicable in Azure Synapse Link for Dataverse.
- By default, saving in Parquet Delta Lake format is enabled for finance and operations data, so that query response times are faster.

> **Note**
>
> This feature is generally available with finance and operations application versions shown in the following list. If you haven't yet applied these application versions, install the latest cumulative update to use this feature.
>
> - 10.0.38 (PU62) cumulative update 7.0.7120.59 or later
> - 10.0.37 (PU61) cumulative update 7.0.7068.109 or later.
> - 10.0.36 (PU60) cumulative update 7.0.7036.133 or later.

You might need to apply additional updates for recent fixes. More information: [Known limitations with finance and operations tables]

If you're planning to adopt the export to data lake feature in finance and operations apps, consider adopting Azure Synapse Link with finance and operations data support instead. Go to the software lifecycle announcements related to **export to data lake feature** for more details. For guidance and tools to upgrade from export to data lake to Azure Synapse Link go to **transition from legacy data generation services** as well as **TechTalk Series: Synapse Link for Dataverse: Transitioning from Export to Azure Data Lake to Synapse Link**

Prerequisites

- You must have a finance and operations sandbox (Tier-2) or higher environment. You can also use an environment provisioned with an ERP-based template.

  > **Note**
  >
  > With the availability of **Power Platform environment provisioned with ERP-based templates**, also known as *unified environments*, Microsoft offers limited support for cloud hosted environments (CHE) as of June 1, 2024. If you're using cloud hosted environments, consider moving to **Power Platform environment provisioned with ERP based templates**.

- You can't add finance and operations data to an existing storage account that's configured with Azure Synapse Link. You must have access to an Azure subscription so that you can create a new Synapse Link profile.

- Depending on how you plan to consume finance and operations data, there are additional prerequisites as shown here.

Expand table

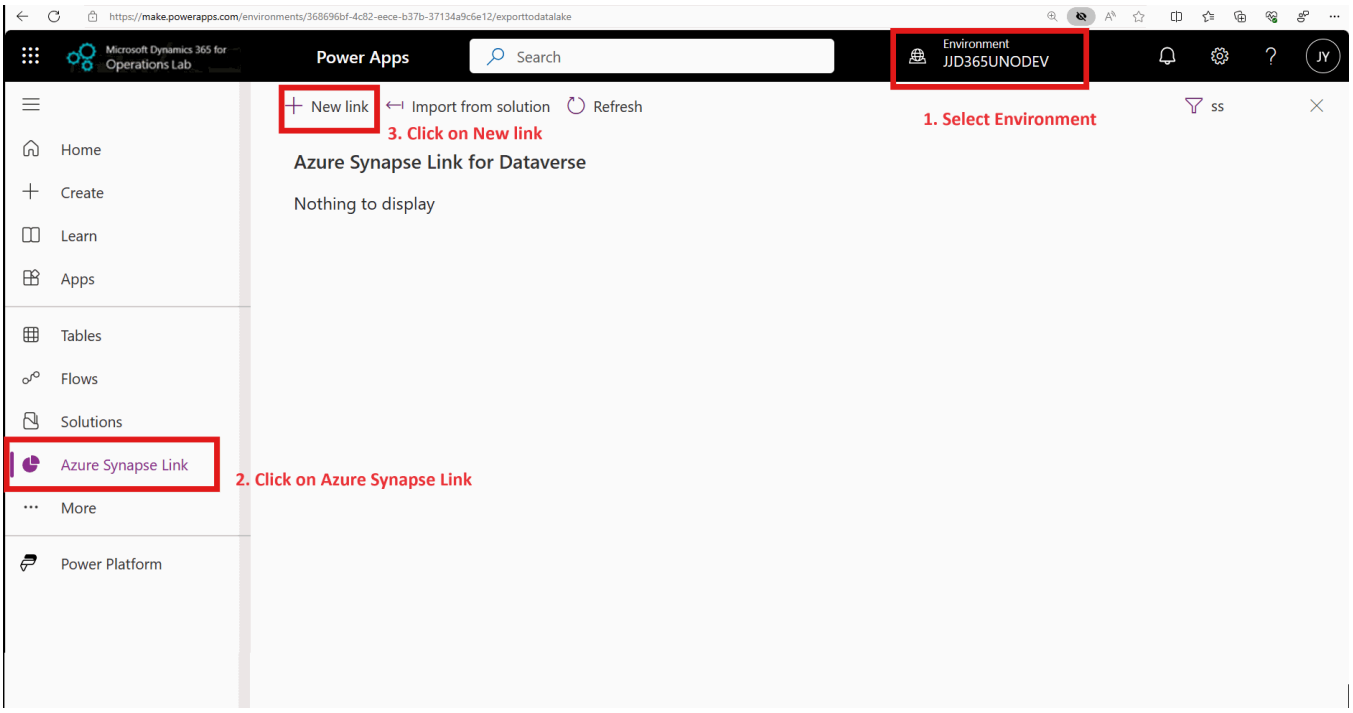
How you plan to consume data	Azure Synapse Link feature you use	Prerequisites and Azure resources needed
Access finance and operations tables via Microsoft Fabric No need to bring your own storage, Synapse	Link to Fabric	Microsoft Fabric workspace

How you plan to consume data	Azure Synapse Link feature you use	Prerequisites and Azure resources needed
workspace, or Spark pool because the system uses Dataverse storage and compute resources		
Access finance and operations tables via Synapse query Finance and operations tables are saved in delta parquet format enabling better read performance. You can't choose finance and operations tables to be saved in CSV format.	Go to Add finance and operations tables in Azure Synapse Link	Azure Data lake Azure Synapse workspace Azure Synapse Spark pool
Load incremental data changes into your own downstream data warehouse The system saves incremental changes into files in CSV format. No need to bring Synapse workspace or Spark pool because your data is saved in CSV format.	Go to Access incremental data changes from finance and operations Also go to Azure Synapse Link - incremental update)	Azure data lake

Add finance and operations tables in Azure Synapse Link

You can enable both finance and operations tables and finance and operations entities in Azure Synapse Link for Dataverse. This section is focused on finance and operations tables.

1. Sign in to Power Apps and select the environment you want.
2. On the left navigation pane, select **Azure Synapse Link**.
3. On the command bar of the **Synapse Link** page, select **+ New link to data lake**.
4. Select **Connect to your Azure Synapse Analytics workspace**, and then select the **Subscription**, **Resource group**, and **Workspace name**.
5. Select **Use Spark pool for processing**, and then select the precreated Spark pool and storage account.
6. Select **Next**.
7. Add the tables you want to export. You can choose finance and operations tables provided the prerequisites are met.
8. Select **Advanced**, select **Show advanced configuration settings** and enter the time interval, in minutes, for how often the incremental updates should be captured. The options **Append only** and **Partition** available at the table level are ignored for finance and operations tables because the system determines the partitioning strategy.
9. Select **Save**. Tables selected are initialized and ready for reporting.



Note

- Finance and operations apps tables are allowed only in Azure Synapse Link. Makers can't see them in the **Tables** area in Power Apps (make.powerapps.com).
- You don't have to define finance and operations apps tables as virtual tables, and you don't have to enable change tracking for each table.
- You can't add finance and operations tables into an existing Synapse Link profile that contained Dataverse tables. You need to create a new profile. Once you create a new profile, you can add tables from both finance and operations as well as Dataverse.
- To include finance and operations tables in Synapse Link, you must enable the Delta lake feature in your Synapse Link profile. Finance and operations table selection isn't visible if your Synapse Link profile isn't configured for Delta lake.
- Delta lake conversion time interval determines how often table data is updated in delta format. For near real time updates, enter 5, 15 or 60 minutes as the desired updated time interval. Choose 1440 for daily time interval if near real-time updates aren't required. Delta conversion consumes compute resources from the Spark pool you have provided in the configuration of the Synapse Link profile. The lower the time interval, the more compute resources are consumed and you can incur more cost. You can monitor the Spark pool cost in Azure portal to see the compute cost.

- The time interval chosen for Spark conversion might not reflect the actual data freshness you observe in the lake. By entering 15 minutes as the time interval, you request Delta conversion jobs to be triggered every 15 minutes in case there are data changes. Depending on the size of the Spark compute pool and the amount of incremental data available for processing, the actual data refresh observed in the lake could be more than 15 minutes. You can increase the size of the Spark pool to achieve better data refresh times. More information: Recommended spark pool configuration

- In the event that the system ran into an error during initial sync or updates, you receive an error and a link to trouble-shooting documents that can be used to diagnose and resolve the error.

Known limitations and changes to behavior

If you are transitioning from export to data lake feature in finance and operations, you might find a few changes to the behavior as described here. To learn more about the upcoming roadmap and stay in touch with the product team, join the preview Viva Engage group.

- **Don't see all tables?** Microsoft continues to enable all actively used finance and operations apps tables in Azure Synapse Link with application updates. If you have a previous version of finance and operations apps, not all required tables are enabled by default. You can enable more tables yourself by extending table properties and enabling the change tracking feature. For more information about how to enable change tracking, go to Enable row version change tracking for tables.
- **Don't see your custom tables?** You must enable change tracking for them. More information: Enable row version change tracking for tables. If you're using a cloud hosted environment (CHE), you must perform a database sync operation to reflect the changes.
- **Special fields** such as `TimeZoneID` (TZID), binary fields in finance and operations tables aren't enabled in Azure SynapseL Link.
- **Synapse Link retains deleted rows** from finance and operations tables. You can identify and filter out deleted rows using the `isDelete` field. Go to Working with data and metadata for more information.
- **Staging tables, temporary tables, and deprecated tables**, where names begin with `del_` in finance and operations apps, aren't allowed in Azure Synapse Link.
- The following tables, known as *kernel* tables in finance and operations apps, are supported by Fabric and Synapse Link. These tables are special, and you don't need to enable change tracking. Also, they're updated every 24 hours and not updated near-real time as the data doesn't change frequently: `DATAAREA`, `USERINFO`, `SECURITYROLE`,

`SECURITYUSERROLE`, `SQLDICTIONARY`, `PARTITIONS`, `SECURITYPRIVILEGE`, `TIMEZONESLIST`, `SECURITYDUTY`, `SECURITYSUBROLE`, `SECURITYUSERROLECONDITION`, `DATABASELOG`, `SECURITYROLERUNTIME`, `SECURITYROLEPRIVILEGEEXPLODEDGRAPH`, `SECURITYROLEDUTYEXPLODEDGRAPH`, `TIMEZONESRULESDATA`, `SECURITYROLEEXPLODEDGRAPH`, `USERDATAAREAFILTER`, `SYSINHERITANCERELATIONS`.

- Master company data sharing is a preview feature in finance and operations apps. Tables that participate in the master company data sharing feature are supported with Synapse Link or Fabric link features. Data exported from these tables are keyed by all company records, not only the master company. This is done to enable simpler reporting so you don't need to use master company data sharing logic to expand data. However, if you're transitioning from previous data export solutions, you might need to filter out data from non-master companies.
- Table inheritance and derived tables are concepts in finance and operations apps. When choosing a derived table from finance and operations apps, fields from the corresponding base table currently aren't included. For example, if you choose the `DirPerson` table, a table derived from `DirPartyTable` also known as the base table, exported data contains fields from the base table `DirPartyTable` You need to select the base table in addition to the derived table if you need access to these fields. You can use this FastTrack solution provided on GitHub. This solution creates views, which include columns from base tables.
- **Memo fields and long descriptions of type `nVarchar(Max)`** are included in Synapse Link. However, the field size is truncated to 2,000 characters.
- **ID fields from finance and operations tables are renamed to FnO_Id** to avoid field name conflicts with Dataverse tables.
- **Fields with SQL reserved words** are renamed by attaching a trailing character. Ex. `Level` becomes `Level_` and `Resource` becomes `Resource_`.

Recent fixes applicable to finance and operations tables

If you are on a previous version of finance and operations, you need to update to the latest version to apply fixes to several issues. These issues and fixes are mentioned here for reference purposes only. When you update to the latest version, all fixes are applied.

- **AOS Authorized fields**: If the table selected contains data columns that are secured via **AOS Authorization**, those columns are ignored and the exported data doesn't contain the column. For example in a custom table named *CustTable*, the column *TaxLicenseNum* has the metadata property **AOS Authorization** set to **Yes**. This column is ignored when *CustTable* data is exported with Azure Synapse Link.

  > ⓘ Note

Update your finance and operations environment to these versions or later to enable AOS authorized fields:

- PU 63:7.0.7198.105
- PU 62:7.0.7120.159

With this update, AOS authorization fields are added to tables:

- Incremental updates include this column.
- Modified records show these columns and value.
- Full refresh includes these fields and all values.

- **Extensible Data security**: When a finance and operations table added to Azure Synapse Link is secured via extensible data security policies, the system might not export data. This issue is fixed in the latest application update.

  > ⓘ Note
  >
  > Available updates to finance and operations tables with Azure Synapse Link for Dataverse:
  >
  > - Version 10.0.39 (PU63) cumulative update 10.0.1860.50
  > - Version 10.0.38 (PU62) cumulative update 10.0.1777.135
  > - Version 10.0.37 (PU61) cumulative update 10.0.1725.175
  >
  > You'll need to apply a quality build where the system applies a bypass for extensible data security policies for the Azure Synapse Link service.

- **Tables with valid time stamp behavior**: If there are finance and operations app tables that exhibit valid time stamp behavior, only the data rows that are currently valid are exported with Azure Synapse Link. For example, the **ExchangeRate** table contains both current and previous exchange rates. Only currently valid exchange rates are exported in Azure Synapse Link. This issue is fixed in the latest application update shown here.

  > ⓘ Note
  >
  > Available updates to finance and operations tables with Azure Synapse Link for Dataverse:
  >
  > - Version 10.0.40 (PU64) platform update 7.0.7120.179
  > - Version 10.0.39 (PU63) platform update 7.0.7198.143
  > - Version 10.0.38 (PU62) platform update 7.0.7279.58

With this update, expired data rows are added to tables. You need to perform a full refresh to include previous rows.

- **Fields of Array type**: If the table selected contains data columns that are of **Array** type, those columns are ignored and the exported data doesn't contain the column. For example, in a custom table named *WHSInventTable*, columns **FilterCode** and **FilterGroup** are of type array. These columns aren't exported with Azure Synapse Link. This issue is fixed in the latest application update shown here.

  > ⓘ Note
  >
  > Available updates to finance and operations tables with Azure Synapse Link for Dataverse:
  > - Version 10.0.41 (PU65) platform update 7.0.7367.153 or later
  > - Version 10.0.42 (PU66) platform update 7.0.7452.84 or later
  > - Version 10.0.43 (PU67) platform update 7.0.7521.153 or later
  >
  > With this update, Array type fields are added to tables. You need to perform a full refresh to include previous rows. Above updates also contain the fix for Array fields of Enumerated data types.

- Extended invoice length is a feature enabled with finance and operations version 10.0.40 and later.

  > ⓘ Note
  >
  > Extended vendor invoice number feature is enabled with updates to finance and operations tables with Azure Synapse Link for Dataverse:
  > - Version 10.0.41 (PU65) platform update 7.0.7367.134 or later
  > - Version 10.0.42 (PU66) platform update 7.0.7452.72 or later
  > - Version 10.0.43 (PU67) platform update 7.0.7521.0 or later

- **Deleted rows missing from derived tables** issue is addressed in updates mentioned below. When choosing a derived table from finance and operations apps. For example, if you choose the `DirPerson` table, a table derived from `DirPartyTable` also known as the base table, deleted markers from derived and base tables are missing in exported data.

  > ⓘ Note

Deleted rows missing from derived tables is enabled with updates to finance and operations tables with Azure Synapse Link for Dataverse:

- Version 10.0.40 (PU64) platform update 7.0.7279.199 or later
- Version 10.0.41 (PU65) platform update 7.0.7367.136 or later
- Version 10.0.42 (PU66) platform update 7.0.7452.75 or later

- **NULL values in finance and operations fields** aren't reflected as empty strings in exported data and might cause export failures. While NULL values are not expected to be present in finance and operations data, there might be NULL values inserted via data integration.

  > ⓘ **Note**
  >
  > Null value handling support for exported data for finance and operations tables is enabled with:
  >
  > - Version 10.0.41 (PU65) platform update 7.0.7367.149 or later
  > - Version 10.0.42 (PU66) platform update 7.0.7452.88 or later
  > - Version 10.0.43 (PU67) platform update 7.0.7497.0 or later

- Finance and operations apps tables added to an Azure Synapse Link profile might be removed when a back-up is restored in Dataverse. You can copy and paste a comma separated list of tables into the search box within the manage tables option to select a list of tables at once.

- When a finance and operations apps database is restored, tables added to an Azure Synapse Link profile need to be reinitialized. Before reinitializing finance and operations tables, you must also restore the Dataverse database. After restoring the database, you must add finance and operations tables into the profile. You can copy and paste a comma separated list of tables into the search box within the manage tables option to select a list of tables at once.

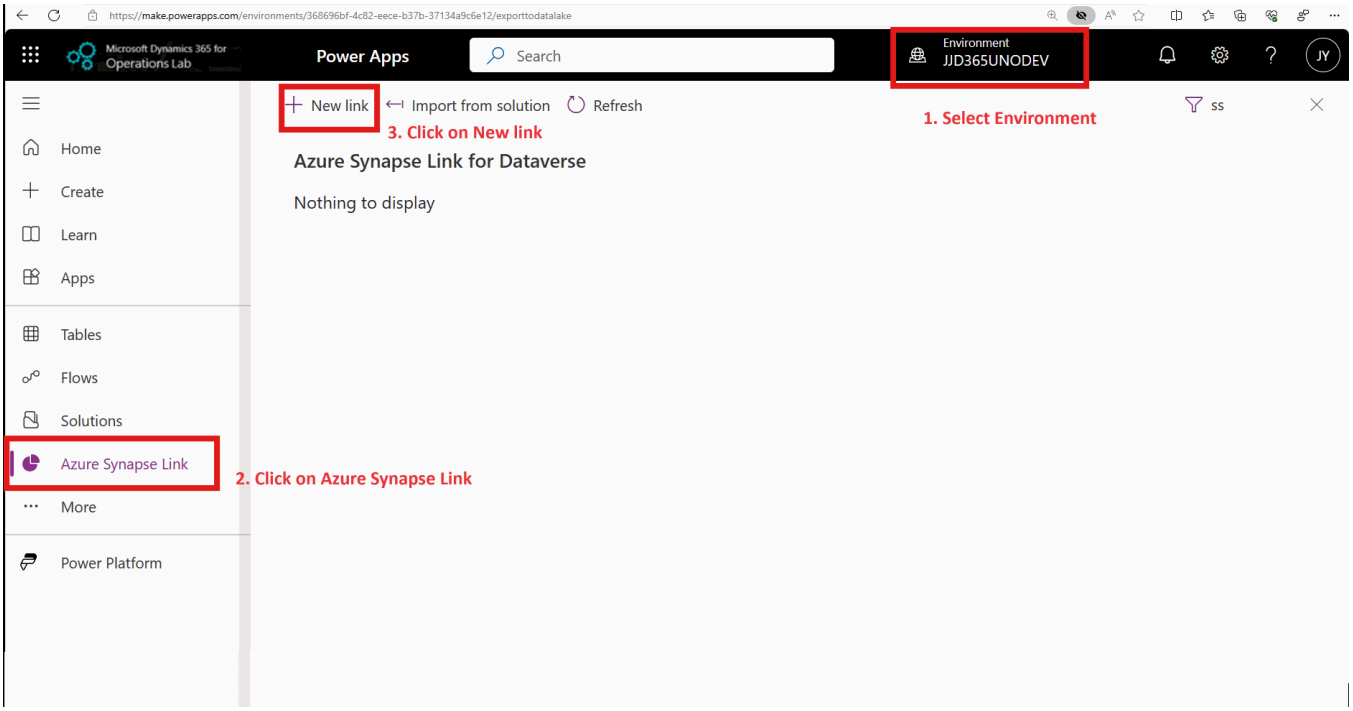
- Finance and operations apps tables included in an Azure Synapse Link profile can't be migrated to a different environment using the import and export profile feature in Azure Synapse Link.

Access incremental data changes from finance and operations

To load incremental data changes from finance and operations into your own downstream data warehouse, create an Azure Synapse Link profile that provides only incremental data. Azure Synapse Link provides an initial export of all data rows and then provides you with access to data that changed periodically. The data is provided in CSV files stored in time stamped folders and you can easily consume the data using Azure Data factory or other data tools. More information: Azure Synapse Link - incremental update

To create an Azure Synapse Link profile with incremental data:

1. Sign in to Power Apps and select the environment you want.
2. On the left navigation pane, select **Azure Synapse Link**.
3. On the **Azure Synapse Link for Dataverse** page, select **+ New link** on the command bar.
4. Select **Subscription**, **Resource group** and a **Storage account**. You don't need to provide a Synapse workspace or a Spark pool.
5. Select **Next**. The option to choose tables appears.
6. Select **Advanced**, select **Show advanced configuration settings**, and then enable the option **Enable incremental update folder structure**
7. In the **Time interval** field, choose the desired frequency for reading incremental data. Using this frequency, the system partitions data into time stamped folders such that you can read the data without being impacted by ongoing write operations.
8. Select the Dataverse tables you want. You can also select finance and operations tables. The options **Append only** and **Partition** available at a table level are ignored. Data files are always appended and data is partitioned yearly.
9. Select **Save**. Tables selected are initialized and you see incremental data in the storage account.



> **Note**
>
> If you're upgrading from the export to data lake feature, enabling the incremental data changes option provides similar change data as the Change feeds feature
>
> We recommend that you create separate Azure Synapse Link profiles for incremental data and tables for ease of management.
>
> When you choose tables and enable incremental data changes, the row count shown in the Azure Synapse Link details page for each table reflects the total number of changes, not the number of records in the table.
>
> Data rows that contain deleted records from Finance and Operations tables contain the `uniqueidentifier` (ID) field. They don't contain the body of the record. Your downstream data pipeline might need to look up the corresponding fields using the ID field.
>
> The finance and operations table limitations are also applicable to incremental data from tables. More information:Known limitations with finance and operations entities

Working with data and metadata

Enumerated fields are coded data fields in finance and operations apps. For example, the **AssetTrans** table contains a field called **TransType**, which is an **Enumerated** field. Table fields contain numeric codes like 110, 120, or 131, which represent detailed descriptions like "Depreciation," "Lease" or "Major repairs." You can access these detailed descriptions by using the **GlobalOptionsMetadata** table that's automatically exported when you choose a table that contains enumerated fields. Enumerated fields are also called choice labels or, formerly, option sets. More information: Choice labels

If there are metadata changes to finance and operations tables, for example, a new field is added to a table, and the data exported in Azure Synapse Link reflects the latest metadata inclusive of the change. More information: Azure Synapse Link FAQ. If you're using Azure Synapse Link to query the data, you see the updated metadata reflected in Azure Synapse Link. If you consume incremental data changes, you can locate updated metadata within the incremental data folder with the latest date stamp. More information: Incremental folder structure

You'll also notice additional metadata fields appended by the system for each data row. Explanation of these fields is shown here.

Expand table

Metadata field	What this field contains	Equivalent field or feature in export to data lake
`createdon`	Indicates the date and time the record was created	Derived from `Created Date` time field in each finance and operations records.
`Createdtransactionid`	Not used	Not used
`Id`	Record ID is used by the system to uniquely identify records	Contains the `RecID` field of the record from finance and operations. This value is converted from an integer to a GUID.
`IsDelete`	If True this record is deleted from Dataverse or finance and operations	In case of a delete at source, export to data lake deletes the row from the destination data lake immediately. Azure Synapse Link performs a "soft delete" for table data in Delta format such that you can identify deleted rows without consuming change feeds. If you want to read active records, you can filter records where `isDelete` is True. In case of table data in Delta files, soft deleted rows are purged after 28 days. `IsDelete` field is also available in incremental updates and can be used to identify rows that are deleted. The body of the records with `isDelete` true are empty. Use system fields such as **Id** field to determine values of other fields. For example, you can look up the latest row for incremental update where `isDelete` is False, with the latest version number and sync modified on date for a given ID.
`modifiedon`	Indicates the date and time the record was last modified	This field is populated from modified date time field in finance and operations tables.
`modifiedtransactionid`	Used internally	Because `modifiedtransactionid` is used internally, don't use this field.
`SinkCreatedOn`	Indicates the date the record was written to the data lake. If there's a CSV change data (incremental update), data, and time data was written to lake is shown. For table data in Delta format, indicates the date and time of Delta Lake conversion.	You can use this date similar to the data lake modified date time field in the export to data lake feature.

Metadata field	What this field contains	Equivalent field or feature in export to data lake
`SinkModifiedOn`	Indicates the date the record was modified. In case of tables in Delta format files as well as incremental CSV files, contains the same date time as `SinkCreatedOn`.	You can use this date similar to the data lake modified date time field in export to data lake feature.
`sysdatastatecode`	If 1, this record is archived using the long term data retention feature. If 0 this is a live record.	You can use this field to identify finance and operations records that have been archived (and deleted from live data). The same field is available for for CSV change data (incremental update).
`sysrowversion`	Version number maintained in each finance and operations apps record that determines whether changes have been made to data. This field is used by the system to determine incremental or delta changes to process.	`sysrowversion` is used internally. You can use this field as a *watermark* to determine the last version of record that was updated. This field might be empty for Dynamics 365 customer engagement apps tables.
`tableid`	Contains a unique ID of each table	Contains the table ID from finance and operations.
`versionnumber`	Used internally - contains the last version of the row that has been synced to the data lake.	Similar to the `sysrowversion` this field contains the last processed version for Dynamics customer engagement apps tables. In case of Dynamics finance and operations apps tables, this field contains the same value as `sysrowversion`.

Reacting to system events and generating audit reports

Azure Synapse Link generates events when data transfer activities are completed or an issue is encountered. These events are recorded in Dataverse tables. You can create automated actions and audit reports using these Dataverse tables. For example, if you have an automated data pipeline that continuously copies changed data rows from your data lake to another location, special actions might be required when a table is inactivated or reactivated, or when table metadata is updated. Creating events enables you to automate these tasks.

If you used business events generated by the export to data lake feature in finance and operations to react to system events, you can continue to get alerted via Azure Synapse Link service. Synapse Link service contains additional configuration data that you can use to generate audit reports and Power Apps to monitor specific data of interest. For more information about receiving and consuming events from Synapse Link go to this article.

This table summarizes events form export to data lake and discusses how you can improve with Synapse Link configuration data.

Expand table

Export to data lake event	Scenario	How you can use configuration data in Synapse Link
Initialize complete	When you select a table, the system makes an initial copy of the data. This event indicates that initialization for a selected table has been completed. If multiple tables are enabled in the environment, you receive multiple events as initialization is completed for each table.	You can monitor Dataverse tables **Synapse Link Profile Entity State** and **Synapse Link external table state**. **InitialSyncProcessCompletedTime** and **InitialSyncState** return the initial sync completion status, which includes both metadata and data. The initial sync state is updated as **Completed** once the initial sync completes. You can also get additional information such as record counts for each table. Synapse Link doesn't delete previous change data in CSV files (incremental update) when you reinitialize a table.
Metadata changed	This event indicates that table metadata has changed. For example, a new column has been added to the table, or, in rarer cases, a column has been deleted. You receive multiple events for each table, one for each metadata change. If you have downstream data pipelines that can't react to metadata changes (a situation that is known as schema drift), you can detect changes by using these events and modify downstream pipelines.	The **Initial Sync Metadata Created Time** field in the **Synapse Link Profile Entity State** table is updated when metadata changes are detected. Use this field to force metadata changes to downstream pipelines using metadata stored in the lake.
Deactivated	This event indicates that a previously active table has been	There's no "deactivate" option in Synapse Link. You can however, delete a table from a Synapse Link

Export to data lake event	Scenario	How you can use configuration data in Synapse Link
	deactivated. When a table is deactivated, data that is changed in finance and operations apps isn't updated in the data lake	profile. You can find deleted tables in the Dataverse table **Synapse Link Profile Entity State**.
Activated	This event indicates that a previously inactivated table has been reactivated. When a table is reactivated, the system reinitializes data in the data lake. You might later receive an **Initialize complete** event.	There's no deactivate or activate option in Synapse Link. You can delete a table and readd the table into a Synapse Link profile. A new record is added in the **Synapse Link Profile Entity State** table when a table is added. You can monitor the status of the table during initialize stage using the Dataverse tables **Synapse Link Profile Entity State** and **Synapse Link external table state**.
Error	This event indicates that the data sync process has paused due to an error.	**Synapse Link Profile Entity State** status field indicates the status of tables.
Lake switch	This event indicates that the system administrator has modified the destination of the data lake.	This event isn't applicable. Changing a data lake associated with a Synapse Link profile as well as changing configuration options isn't supported. However, Synapse Link supports multiple profiles. This means, an administrator can create multiple Synapse Link profiles with tables (the same table can be added to multiple profiles). Read the Dataverse table **Synapse Link profile** to find configuration data on all profiles including deleted profiles.

Enable finance and operations data entities in Azure Synapse Link

You can enable both finance and operations entities and finance and operations apps tables in Azure Synapse Link for Dataverse. This section is focused on finance and operations data entities.

The process of enabling finance and operations entities has the following steps. Each step is explained in the following subsections.

1. Enable finance and operations virtual entities in the Power Apps maker portal. This step lets you use finance and operations entities in Power Apps (make.powerapps.com) to build apps. You can also use them with Azure Synapse Link.

2. Enable row version change tracking for Entities. You must complete this step to enable Azure Synapse Link to use finance and operations entities.

After you complete both steps, you can select finance and operations entities in Azure Synapse Link under **Dataverse tables**. To create Azure Synapse Link for Dataverse in Delta Lake format, follow the steps in Export Dataverse data in Delta Lake format.

> **Note**
>
> Finance and operations entities start with the prefix **mserp_**.

Enable finance and operations virtual entities in Power Apps

You must enable finance and operations entities as virtual tables in Dataverse. Makers can then use the chosen finance and operations entities to build apps, and the entities can also be used with Azure Synapse Link.

To enable finance and operations entities, follow the steps in Enable Microsoft Dataverse virtual entities.

> **Tip**
>
> To validate Azure Synapse Link features, use a few of the sample entities from the following list. They appear under the **Dataverse tables** section in Azure Synapse Link.
>
> - **MainAccountBiEntity** – This entity contains a list of ledger accounts.
> - **ExchangeRateBiEntity** – This entity contains exchange rates in the system.
> - **InventTableBiEntity** – This entity contains a list of inventory items.

Enable change tracking for finance and operations entities

When you enable change tracking for finance and operations entities, they appear under Dataverse tables in Azure Synapse Link. Finance and operations entities start with the prefix **mserp_**.

To enable change tracking, follow these steps.

1. In Power Apps, select **Tables** on the left navigation pane, and then select the table you want.
2. Select **Properties** > **Advanced options**.

3. Select the **Track changes** option, and then select **Save**. If the option is unavailable, go to Known limitations with finance and operations entities).

Known limitations with finance and operations entities

Currently, there are several limitations with finance and operations entities and Azure Synapse Link. To learn more about the upcoming roadmap and stay in touch with product team, join the preview Viva Engage group aka.ms/SynapseLinkforDynamics.

- Enabling change tracking might fail with the error message "chosen entity doesn't pass the validation rules..." or the **Track changes** checkbox might be disabled for some tables that are virtual tables. Currently, change tracking can't be enabled for all finance and operations entities. The **Track changes** checkbox is unavailable for entities created in finance and operations in the past for data migration.

  > **Note**
  >
  > For a list of finance and operations entities that pass validation rules, run the **Data entity row version change tracking validation report** available in finance and operations apps at path **System administration/Setup/Row version change tracking/Data entity row version change tracking validation report.** This report shows entities that pass and fail validation rules. You can also use this report to enable row version change tracking for entities that pass data validation rules. To enable change tracking for an entity, choose **Row version Change Tracking** from the menu, and then choose **Enable change tracking**.
  >
  > For more information about entity validation rules and how you can fix them, go to Enable row version change tracking for data entities. You might need developer assistance to complete the steps.
  >
  > If the chosen entity is unavailable because of the change tracking limitation, you might be able to choose the tables that comprise the data from that entity. You can use EntityUtil solution provided by the FastTrack team to create entity shapes using tables.

- In case of a database restore operation in Dataverse, finance and operations entities enabled in Azure Synapse Link are removed. To re-enable entities, you need to re-enable corresponding virtual tables for all selected entities, re-enable change tracking, and reselect the tables in Azure Synapse Link.

Azure Synapse Link for Dataverse troubleshooting guide

Article • 10/15/2024

When you open an Azure Synapse Link profile, you might see an error with a message and link to this article. In addition, users might also see **Error** status next to tables that are already in an Azure Synapse Link profile. Use this troubleshooting guide to diagnose and fix error conditions with Azure Synapse Link for Dataverse.

Expand table

Error message	Cause	Resolution
MSI-801: Azure Synapse Link is unable to access storage account secured via MSI. Data updates are paused.	You have enabled managed services identify (MSI) to the storage account selected for this Azure Synapse Link profile. Azure Synapse Link service doesn't have access to the storage account due to MSI configuration issues and the service has paused. Revisit and verify MSI configuration	Verify that the MSI policy isn't deleted. Validate that MSI is granted with the required access privileges. More information: MSI configuration Once the required access is granted, the service resumes.
ADLS-802: Azure Synapse Link is unable to access storage account. Data updates are paused.	Azure Synapse Link service can't access storage account and the service has paused. Permissions associated with storage account assigned to Azure Synapse Link profile might have changed or the storage account doesn't exist.	Verify that the storage account exists and that the Azure Synapse Link service has owner access to storage account. More information: Prerequisites Once required access is granted, the service resumes.
CT-803: Row version change tracking configuration key disabled in linked environment. Data updates in some tables may be paused.	Azure Synapse Link service requires the configuration key **enable row version change tracking** enabled in the linked finance and operations apps environment. This configuration key is disabled in the linked environment and the service has paused finance and operations apps tables from the linked environment. It's possible that a database restore operation caused the configuration to be reverted. Enable the configuration key and remove and readd finance and operations apps tables to resume.	Your administrator must reenable the finance and operations apps configuration key. More information: Add configurations in a finance and operations apps environment The service resumes when the configuration key is reenabled.

Error message	Cause	Resolution
	Impacted tables are initialized to reflect new data.	
DV-804: This environment is in admin mode and service is paused.	When a Power Platform environment is in administration mode all services including Azure Synapse Link service are temporarily paused. When **Administration mode** is **Disabled**, the services are resumed.	Verify with your environment administrator and ensure that the environment is operational. Also verify that the **Background operations** environment setting is **Enabled** after **Administration mode** is **Disabled**. Azure Synapse Link service resumes when the environment is operational.
SYN-805: Synapse workspace isn't accessible.	Azure Synapse Link service can't access the Synapse workspace associated with this profile. Synapse tables might not be created immediately when you resolve this issue. The system creates tables in the Synapse workspace when data gets updated in Dataverse.	In the Synapse workspace networking configuration, enable the option **Allow Azure services and resources to access this workspace**.
SYN-806: Default storage container in Synapse workspace isn't accessible.	Synapse workspace associated with this Azure Synapse Link profile doesn't contain a primary Azure Data Lake Storage Gen2 file system. The default storage container might be deleted or the default storage container isn't accessible. A default storage container is used by Synapse workspace as temporary storage in creating the file system. A default storage container must be provided when creating a Synapse workspace. It's possible that this storage container was deleted or no longer accessible.	Ask your administrator to launch Synapse workspace and verify the name of the primary Azure Data Lake Storage Gen2 file system. Also verify that an Azure Data Lake Storage Gen2 storage container exists with that name within the same subscription. If the storage container is missing, create a storage container with the same name.
SYN-809: Synapse workspace {name} has data exfiltration policies enabled. You need to choose another workspace.	Synapse Link profiles with Delta conversion option requires Synapse workpaces without data exfiltration policies. You have likely chosen a Synapse workspace with data exfiltration policies, which inteferes with Synapse Link compute services.	Ask your administrator to provide a Synapse workspace where data exfilteration policies aren't enabled. You might also consider using Fabric link as an alternative to Synapse Link.
SYN-810: The default storage	Synapse Link profiles with Delta conversion option requires Synapse	Ask your administrator to remove network restrictions associated

Error message	Cause	Resolution
container associated with Synapse workspace is network restricted.	workpaces with a default storage container. If the default storage container associated with the select Synapse workspace has network restrictions applied, Synapse Link compute services are unable to perform the required updates.	with the default storage container associated with the Synapse workspace chosen or choose another Synapse workspace.
SPARK-807: Spark compute pool {name} in {Synapse workspace} is no longer available. Data updates are paused.	Azure Synapse Link service requires a Spark pool in order to process data into delta format. The Spark pool provided with this Azure Synapse Link profile is deleted or no longer available. It's also possible that access to the Synapse workspace have been restricted. Once you resolve the issue, Azure Synapse Link service resumes data updates when the data changes.	Verify that the Spark pool with the chosen name exists. If you or someone deleted this Spark pool, create the Spark pool with the same name.
SPARK-808: Spark compute pool {name} in {Synapse workspace} is insufficient. One or more tables could not be updated.	Azure Synapse Link service uses the Spark pool provided in the configuration to convert files to Delta parquet format as and when data is updated. When a large batch of data is available for update, the size of the Spark pool provided in the Azure Synapse Link profile might not provide sufficient compute power. This can happen especially when you add large tables as the initialization process creates a large batch of data. This might also result in case you have a "pay as you go" subscriptions with limited capacity. The Spark pools within these types of subscriptions are limited in capacity.	Increase the number of cores in the assigned Spark pool. The system consumes the increased capacity in case of larger workloads and scale down as needed. More information: Recommended Spark pool sizes for Delta conversion
CT-809: Row version change tracking property disabled in table. Data updates are paused.	Azure Synapse Link service requires enabling the **Row version change tracking** metadata property. This property is disabled for the table and the table is no longer updated. Updating this metadata property in finance and operations requires developer intervention. It's possible	Re-enable the row version change tracking metadata property to resume this table. You might need an administrator or developer to re-enable the property using developer tools. More information: Enable row

Error message	Cause	Resolution
	that the property was disabled after the Azure Synapse Link profile was created.	version change tracking for tables for details.
CT-810: The **Allow Row version change tracking** property of this table is set to No.	Azure Synapse Link service requires enabling the **Allow row version change tracking** metadata property to be set to **Yes**. Updating this metadata property in finance and operations requires developer intervention. It's possible that the property was disabled after the Synapse Link profile was created.	Re-enable the row version change tracking metadata property to resume this table. You might need an administrator or developer to re-enable the property using developer tools. More information: Enable row version change tracking for tables for details.
FnO-810: Linked finance and operations environment is unavailable or paused.	Finance and operations apps environment linked to this Azure Synapse Link profile is either unavailable or in maintenance mode. Azure Synapse Link service is unable to contact the environment and the service has paused tables sourced from finance and operations apps. In the case of cloud-hosted environments, it's possible that the environment is in a paused state.	Verify with your administrator that the linked environment isn't paused and isn't in maintenance mode. Azure Synapse Link service resumes when the environment is in operational mode.
FnO-811: Linked finance and operations environment needs to be updated.	Finance and operations apps environment linked to this Azure Synapse Link profile needs to be updated to the latest version. If you're currently on finance and operations versions PU60, PU61, or PU62, you must update to the latest cumulative updates 10.0.36 (PU 60) - 7.0.7036.133 or later 10.0.37 (PU 61) - 7.0.7068.109 or later 10.0.38 (PU 62) - 7.0.7120.59 or later The required updates are included in cumulative update 10.0.39 (PU63)	Contact your finance and operations apps administrator and apply the latest version updates to your environment.
FnO-812: Need to create additional indexes in your finance and operations environment.	When you select tables from a finance and operations apps environment, the system creates additional indexes in the database to enable performant data initialization and updates. This error indicates that indexes are missing for tables. This might be due to several reasons.	If this is a CHE environment, contact the owner of the environment. If this is a sandbox or production environment, no action is needed. The system enables indexes on

Error message	Cause	Resolution
	if you're receiving this error from a Cloud Hosted Environment (CHE), you need to enable specific flights and indexes as outlined in documentation. If you're receiving this error from a sandbox or a production environment, index creation might be delayed due to heavy database operations.	completion of peak workloads in finance and operations.
FnO-813: There is an unexpected NULL value in the field <...>. Verify data in the table and correct values as needed.	This error is the result of a data issue found by the service when transferring data from finance and operations apps. The finance and operations service doesn't allow NULL values in data fields. Therefore a NULL value is unexpected by the service. A space character represents the absence of a value in finance and operations apps. However, during data migration, especially using external tools, a NULL value might have been entered into a data field.	You can examine the table using the finance and operation app user interface or using a tool to resolve the issue. The system resumes once the data issue has been resolved. You don't need to reinitialize the table.
The following app(s) were not present in your tenant:...: Azure Synapse Link cannot get all required app permission to create profile.	Missing App ID surfaced in UI error message. Here's the complete list of required app permissions: • Export to data lake: `7f15f9d9-cad0-44f1-bbba-d36650e07765` • Common Data Service - Azure Data Lake Storage: `546068c3-99b1-4890-8e93-c8aeadcfe56a` • Insights Apps Platform Prod: `99ff962b-6252-4b98-8478-0c65a3ea1925`	Ask your administrator to add missing permissions in your Azure tenant by following these steps: • Open PowerShell and connect to Azure with an authenticated account using the command: `Connect-AzAccount` • Add the principal by running the following command for the app ID: `New-AzADServicePrincipal -ApplicationId '7f15f9d9-cad0-44f1-bbba-d36650e07765'`

Receive Azure Synapse Link for Dataverse notifications in Power Apps

Article • 03/22/2024

The state of your Azure Synapse Link for Dataverse is stored in a Microsoft Dataverse table with real-time updates. You can customize a notification using Power Automate flows or Power BI to stay on top of the state of your Azure Synapse Link for Dataverse activity instead of manually checking the Azure Synapse Link for Dataverse profile page in Power Apps (make.powerapps.com).

The Azure Synapse Link for Dataverse profile and its synchronization status are stored in six system-generated read-only tables within Dataverse. These tables are designed to refresh and update in real time, ensuring that the information contained within them remains accurate and up to date at all times.

How notification works with Azure Synapse Link for Dataverse

To customize a notification, monitor the data changes in a Dataverse table related to the synchronization status of Azure Synapse Link. By tracking these changes, you can export the updated data for visualization using Power BI or set up an automated cloud flow that activates whenever there's a change in the Azure Synapse Link for Dataverse state. This is achieved by reading the row change from any of the Azure Synapse Link state tables.

Connector to use for a Power Automate flow

We recommend users have the appropriate Power Platform licensing to use Power Automate to customize the trigger function. Use the Dataverse connector, which triggers a flow when a row is added, modified, or deleted in the selected Dataverse table. More information: Trigger flows when a row is added, modified, or deleted - Power Automate

Several options are available for using Power Automate to send notifications. Here are some examples.

Expand table

Action	Connector reference
Send a Teams instant message	Microsoft Teams
Send a text message to mobile device	Azure Communication Services SMS
Send an email to one or more recipients	Mail Office 365 Outlook
Send a notification to Power Apps or Power BI	Power Apps Notification Power BI

Dataverse tables and columns used to track state

There are tables that store all Azure Synapse Link profile information. The two main tables listed below provide all sync state information for your Azure Synapse Link profile.

Expand table

Table name	Description	Table reference
Azure Synapse Link external table state	This table has data only if you have Delta Lake profile. This table represents external nonpartitioned tables state in connected Synapse workspace. One record per synced entity including metadata table like option set.	synapselinkexternaltablestate
Azure Synapse Link profile table state	This table represents the sync state of the Azure Synapse Link entity in Azure Data Lake storage. One record per synced entity excluding metadata table such as option set.	synapselinkprofileentitystate

Here are some useful columns for monitoring the health of your Azure Synapse Link in each table:

- `EntityName` and `SynapseWorkspaceName` can be used as the primary identification of the selected table. Synapse workspace name is the same as Azure Synapse Link profile name shown in Power Apps.

- `LastSynchronizedOn` returns the date and time when the latest round of the Delta Lake conversion was successfully completed for each table.
- `RecordCount` returns the total number of records in the Delta Lake profile, minus soft-delete records for each table.
- `TableState` is marked as **created** if the link to the data lake and Delta Lake conversion is active and error-free.

A soft-delete in the Azure Synapse Link external table state table is performed: `LastSyncState` and `TableState` are marked as deleted for removed tables.

Azure Synapse Link profile entity state tables:

- `EntityName` and profile can be used as the primary identification of the selected table. The profile is the same as the Azure Synapse Link profile name shown in Power Apps.
- `InitialSyncProcessCompletedTime` and `InitialSyncState` return the initial sync completion status, which includes both metadata and raw data. The initial sync state marks as **Completed** once the initial sync completes.
- `LakeRecordCount` returns the total records exported to Data Lake in CSV format.
- `LastSyncedDataTime` returns the date and time when the latest round of the data lake file updated or created successfully for each table.
- `SyncState` shows as **InProgress** if the link to data lake is active and error-free.

> **Note**
>
> `LakeRecordCount` is different from Dataverse record count for the following reasons:
>
> - Sync latency.
> - Append-only mode captures transactions and appends one additional row for each CUD operation.

The remaining four tables provide additional details for Azure Synapse Link setup information:

Expand table

Table name	Description	Table reference
Azure Synapse database	This table captures linked Azure Data Lake storage and Synapse workspace and setup metadata information (one record per Azure Synapse Link profile).	synapsedatabase

Table name	Description	Table reference
Azure Synapse Link profile	This table captures Azure Synapse Link profile information (one record per Azure Synapse Link profile). A soft-delete in this table is performed: `ProfileState` is marked as **deleted** for deleted profile.	synapselinkprofile
Azure Synapse Link profile entity	This table captures entity metadata within the connected Azure Synapse Link profile (one record per synced table).	synapselinkprofileentity
Azure Synapse Link schedule	This table captures Azure Synapse Link profile information for incremental folder update or delta lake conversion time interval (one record per Azure Synapse Link profile).	RecurrenceInterval

Azure Synapse Link for Dataverse FAQ

This article provides information on frequently asked questions about exporting Microsoft Dataverse table data to Azure Synapse Analytics and Azure Data Lake.

Can I manually perform tasks such as creating, updating, deleting, or setting autodelete policies for data files in the connected Azure storage?

Data files shouldn't be modified by a customer and no customer files should be placed in the data folders.

> ⓘ **Note**
>
> To drop stale and stagnant data in the data lake without breaking the Azure Synapse Link, consider using the feature Query and analyze the incremental updates

How can I access my table relationships?

To access many-to-many relationships, the relationship is available as a table to select from the **Add tables** page for a new link and from the **Manage tables** for a preexisting link.

> ⓘ **Note**
>
> All relationships data is in Append-only mode by default when written in CSV format.

How can I get estimated costs before adding Azure Synapse Link?

Azure Synapse Link is a free feature with Dataverse. Utilizing Azure Synapse Link for Dataverse doesn't incur additional charges under Dataverse. However, consider potential costs for the Azure service:

- Data storage in Azure Data Lake Storage Gen2: Azure Storage Data Lake Gen2 Pricing | Microsoft Azure
- Data consumption cost (such as Synapse Workspace): Pricing - Azure Synapse Analytics | Microsoft Azure For comprehensive Microsoft Cost Management information, go to: Plan to manage Azure costs - Microsoft Cost Management | Microsoft Learn

What happens when I add a column?

When you add a new column to a table in the source, it's also added at the end of the file in the destination in the corresponding file partition. While the rows that existed before the addition of the column are't shown in the new column, new or updated rows show the newly added column.

What happens when I delete a column?

When you delete a column from a table in the source, the column isn't dropped from the destination. Instead, the rows are no longer updated and are marked as null while preserving the previous rows.

What happens if I change the data type of a column?

Changing the data type of a column is a breaking change and you need to unlink and relink.

What happens when I delete a row?

Deleting a row is handled differently based on which data write options you choose:

- In-place update with CSV format: This is the default mode. When you delete a table row in this mode, the row is also deleted from the corresponding data partition in the Azure Data Lake. In other words, data is hard deleted from the destination.
- Append-only with CSV format and incremental folder update: In this mode, when a Dataverse table row is deleted, it isn't hard deleted from the destination. Instead, a row is added and set as `isDeleted=True` to the file in the corresponding data partition in Azure Data Lake.
- Export to Delta lake format: Azure Synapse Link performs a soft delete on data during the next delta synchronization cycle, followed by a hard delete after 30 days.

Why am I not seeing a column header in the exported file?

Azure Synapse Link follows the Common Data Model to make it possible for data and its meaning to be shared across applications and business processes such as Microsoft Power Apps, Power BI, Dynamics 365, and Azure. In each CDM folder, metadata like a column header is stored in the model.json file. More information: Common Data Model and Azure Data Lake Storage Gen2 | Microsoft Learn

Why does the Model.json file increase or change in length for the data types and doesn't keep what is defined in Dataverse?

Model.json keeps the database length for the column's size. Dataverse has a concept of database length for each column. If you create a column with a size of 200 and later reduce it to 100, Dataverse still allows your existing data to be present in Dataverse. It does that by keeping `DBLength` to 200 and `MaxLength` to 100. What you see in Model.json is `DBLength` and if you use that for downstream processes you'll never provision lesser space for your Dataverse columns.

> **Note**
>
> Memo fields are defined as `varchar(max)` with a default maximum length of 9999.

What date and time formats can be expected in exported Dataverse tables?

There are three date and time formats that can be expected in the exported Dataverse tables.

Expand table

Column Name	Format	Data Type	Example
SinkCreatedOn and **SinkModifiedOn**	M/d/yyyy H:mm:ss tt	datetime	6/28/2021 4:34:35 PM

Column Name	Format	Data Type	Example
CreatedOn	yyyy-MM-dd'T'HH:mm:ss.sssssssXXX	datetimeOffset	2018-05-25T16:21:09.0000000+00:00
All Other Columns	yyyy-MM-dd'T'HH:mm:ss'Z'	datetime	2021-06-25T16:21:12Z

> **Note**
>
> **CreatedOn** data type changed from `datetime` to `datetimeOffset` on 07/29/2022. To edit the data type format for a table created before the change, drop and readd the table.
>
> You can choose different column behaviors for a Date and Time column in Dataverse, which updates the data type format. More information: Behavior and format of the Date and Time column

Why am I seeing 1.csv or 1_001.csv file names instead of regular date time partitioned file names for some Dataverse tables?

This behavior is expected when you choose append-only export mode and have tables without a valid **CreatedOn** column. Blobs are organized into files such as 1.csv, 2.csv (employing custom partitioning due to the absence of a valid creation date). When any partition approaches 95% of the MaxBlockPerBlobLimit, the system automatically generates a new file—illustrated here as 1_001.csv.

When should I use a yearly or monthly partition strategy?

For Dataverse tables where data volume is high within a year, we recommend you use monthly partitions. Doing so results in smaller files and better performance. Additionally, if the rows in Dataverse tables are updated frequently, splitting into multiple smaller files helps improve performance in the case of in-place update scenarios. Delta Lake is only available with yearly partition due to its superior performance compared to CSV format.

What is append only mode and what is the difference between append only and in-place update mode?

In append only mode, incremental data from Dataverse tables are appended to the corresponding file partition in the lake. For more information: Advanced Configuration Options in Azure Synapse Link

When do I use append only mode for a historical view of changes?

Append only mode is the recommended option for writing Dataverse table data to the lake, especially when the data volumes are high within a partition with frequently changing data. Again, this is a commonly used and highly recommended option for enterprise customers. Additionally, you can choose to use this mode for scenarios where the intent is to incrementally review changes from Dataverse and process the changes for ETL, AI, and ML scenarios. Append only mode provides a history of changes, instead of the latest change or in place update, and enables several time series from AI scenarios, such as prediction or forecasting analytics based on historical values.

How do I retrieve the most up-to-date row of each record and exclude deleted rows when I export data in append only mode?

In append only mode, you should identify the latest version of record with the same ID using `VersionNumber` and `SinkModifiedOn` then apply `isDeleted=0` on the latest version.

Why do I see duplicated version numbers when I export data using append only mode?

For append only mode, if Azure Synapse Link for Dataverse doesn't get an acknowledgment from the Azure data lake that the data has been committed due to any reason such as network delays, Azure Synapse Link retries in those scenarios and commit the data again. The downstream consumption should be made resilient to this scenario by filtering data using `SinkModifiedOn`.

Why am I seeing differences in `SinkModifiedOn` and `ModifiedOn` columns?

This is expected behavior. `ModifiedOn` is the date and time a record was last changed in Dataverse, while `SinkModifiedOn` is the date and time the record was written to the data lake. `SinkModifiedOn` is typically later than `ModifiedOn`, and the difference depends on factors such as batch size, system load, and the number of records being processed.

> **Important**
>
> In the case of long-running transactions in finance and operations apps, a record might be synchronized multiple times to ensure no data loss. In this scenario, `SinkModifiedOn` reflects the last synchronization time, not the first. For example, if a record is synced 10 times within an hour, `SinkModifiedOn` shows the time of the 10th sync even though the data was available in the lake from the first sync itself. Use caution when building latency reports based on the difference between `SinkModifiedOn` and `ModifiedOn`, as it can give a misleading impression of actual data availability.

Which Dataverse tables aren't supported for export?

Any table that doesn't have change tracking enabled isn't supported in addition to following system tables:

- Attachment
- Calendar
- Calendarrule

Certain Dataverse tables, such as postcomment, postregarding, postlike, post, and postrole, aren't available for customers to enable synchronization through Azure Synapse Link.

In some cases, these tables might appear when Dataverse long term retention is enabled. If that happens, a subset or all records from these tables might be exported. This is expected behavior for long term retention scenarios.

> **Important**

- These tables shouldn't be selected for synchronization.
- Their presence doesn't indicate full support for incremental sync.

> **Note**
>
> You can add the audit table for export using Azure Synapse Link for Dataverse. However, the export of the audit table is only supported with Delta Lake profiles.

I'm using export to delta lake feature, can I stop the Apache Spark job or change the execution time?

The Delta Lake conversion job is triggered when there was a data change in the configured time interval. There's no option to stop or pause the Apache Spark pool. However, you can modify the time interval after the link creation under Manage tables > Advanced Time interval.

Does Azure Synapse Link support lookup columns?

Lookup columns are made up of an ID and a value. Lookup values only change on the root table. To better reflect the value of a lookup column, we recommend joining with the original root table to get the latest value.

Does Azure Synapse Link support calculated columns?

In Dataverse, calculated columns keep only the formula information and the real value depends on the base table column. So calculated columns are only supported when all columns are located within the same exported table.

Which Dataverse tables use append only mode by default?

All tables that don't have a createdOn field is synced using append only mode by default. This includes relationship tables and the ActivityParty table.

Why do I see the error message - Content of directory on path can't be listed?

- Dataverse data is stored in the connected storage container. You need the "Storage Blob Data Contributor" role in the linked storage account to perform read and query operations through Synapse Workspace.
- If you choose to export data with Delta Lake format, your CSV file is cleaned up after the Delta Lake conversion. You need to query data with **non_partitioned** tables through Synapse Workspace.

Why do I see the error message - can't bulk load because the file is incomplete or couldn't be read (CSV file only)?

Dataverse data can continuously change through creating, updating, and deleting transactions. This error is caused by the underlying file being changed when you read data from it. So, for tables with continuous changes, change your consumption pipeline to use snapshot data (partitioned tables) to consume. More information: Troubleshoot serverless SQL pool

How can I use Azure Synapse Link to archive critical data?

Azure Synapse Link for Dataverse is designed for analytics purposes. We recommend customers use long-term-retention for archive purposes. More information: Dataverse long term data retention overview

Why don't I see any data changes in the data lake when records have been deleted in Dataverse?

For any direct SQL call to remove a record, the Azure Synapse Link for Dataverse service doesn't trigger because BPO.Delete isn't being called. For a sample feature, go to How to clean up inherited access.

Azure Synapse Link for Dataverse

Transport the Azure Synapse Link for Dataverse configuration across environments

Article • 02/22/2023

In Power Apps, solutions are used to transport apps and components from one environment to another, or to apply a set of customizations to existing apps. Making the Azure Synapse Link for Dataverse configurations solution-aware enables basic application lifecycle management (ALM) abilities such as distribution, copy, and backup and restore of the Azure Synapse Link for Dataverse configuration.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

This section describes the prerequisites necessary to transport the Azure Synapse Link for Dataverse configuration across environments.

- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Azure Synapse Link for Dataverse Advanced Configuration Options enabled.** This guide assumes that you have already toggled the Show advanced configuration settings under Advanced when creating Azure Synapse Link for Dataverse Azure Synapse Link Advanced Configuration Settings.

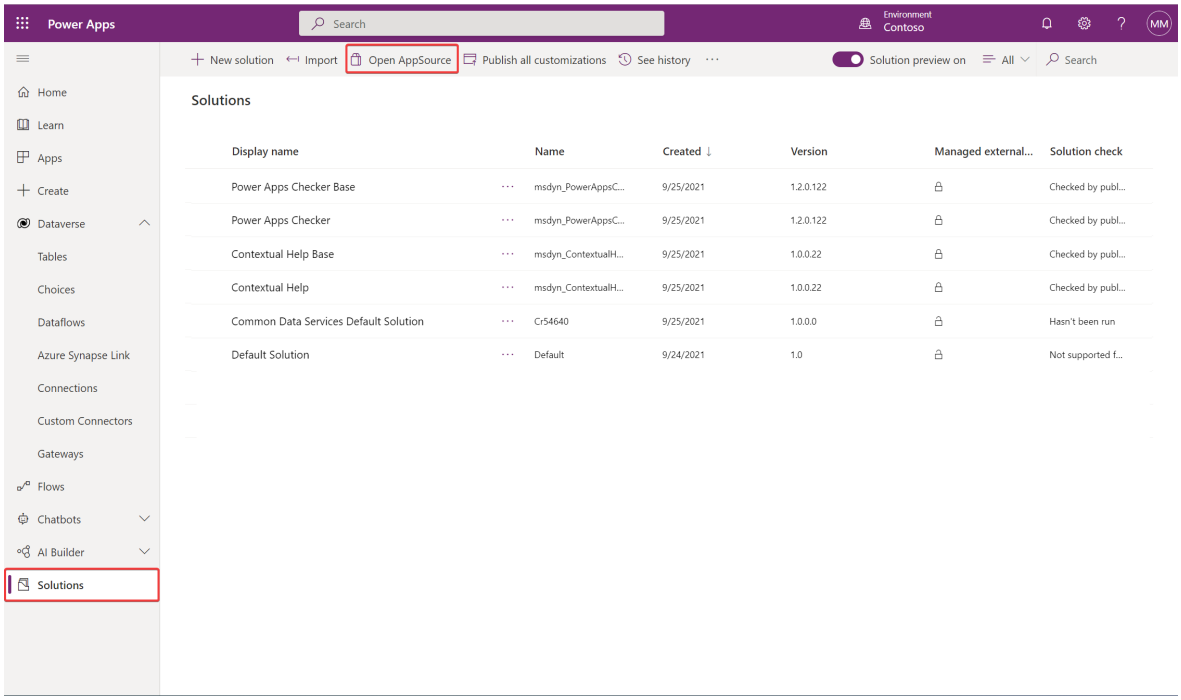
Install the Azure Synapse Link for Dataverse solution

> **Note**
>
> The Azure Synapse Link for Dataverse solution must be installed in both the source and the destination environments.

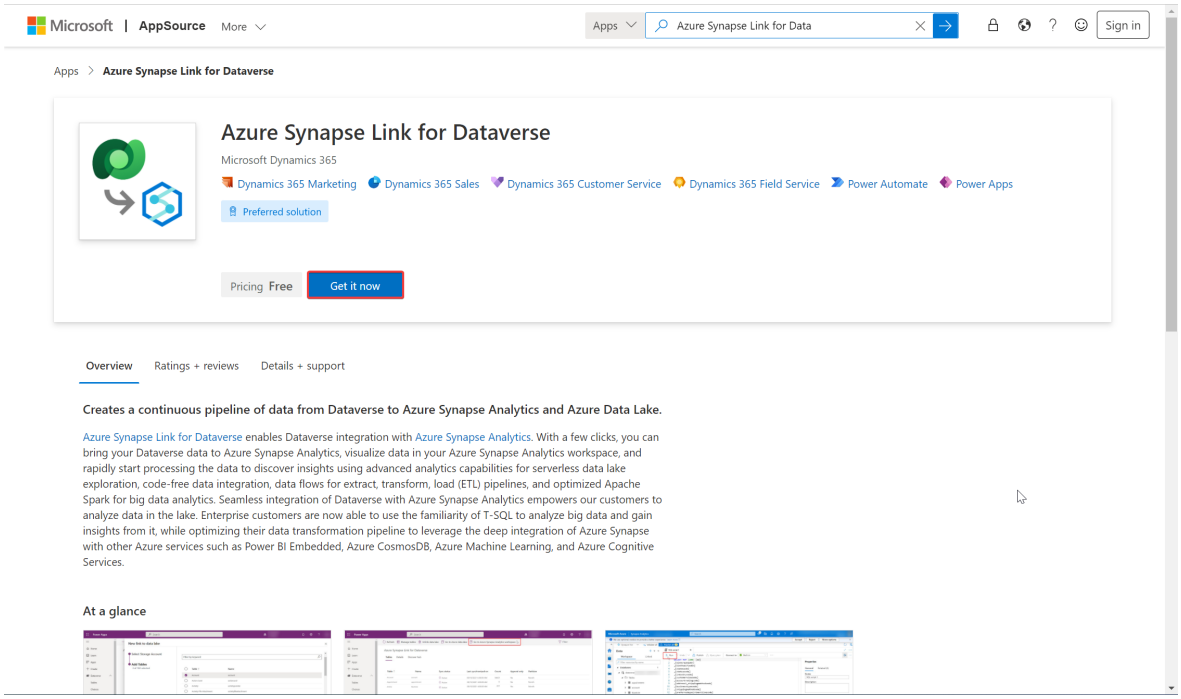
1. Sign into Power Apps, and then select the source environment for the Azure Synapse Link for Dataverse configuration.

2. On the left navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

3. Select **Open AppSource**.



4. Select for the solution named **Azure Synapse Link for Dataverse**, and then select **Get it now**.



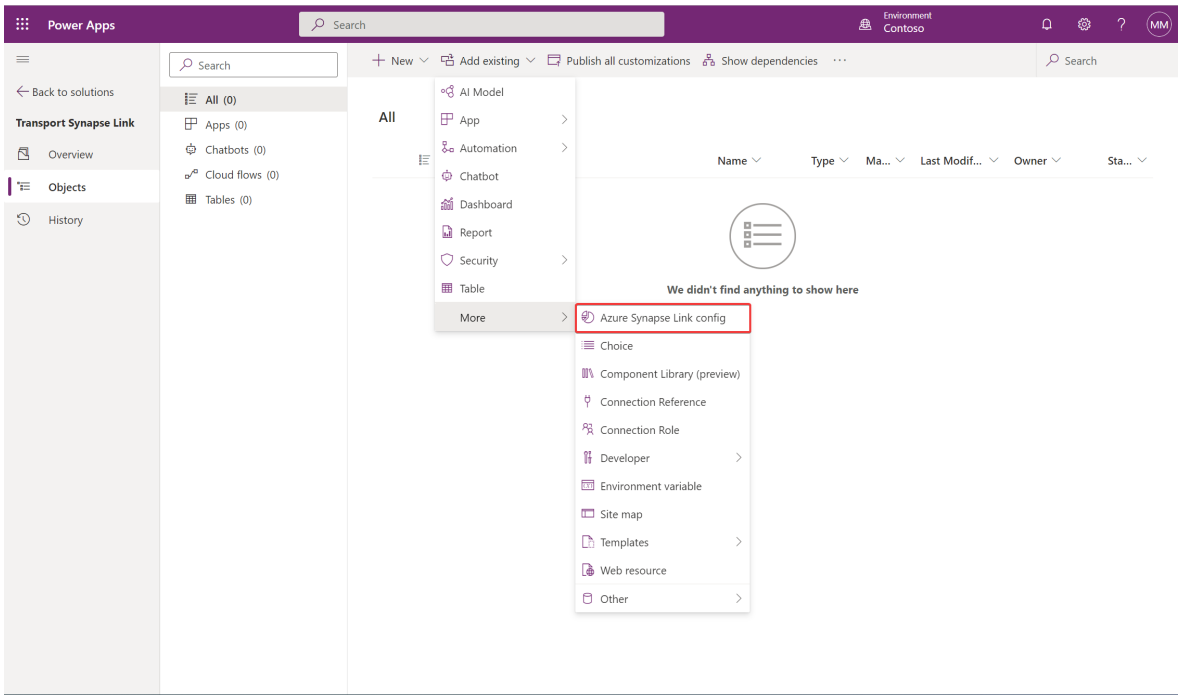
5. Repeat above steps in the destination environment. You need the **Azure Synapse Link for Dataverse** solution in both the source and destination environments.

Add an Azure Synapse Link configuration to a solution

1. Sign into Power Apps, select the source environment, and then on the left navigation pane, select **Solutions**. If the item isn't in the left navigation pane, select ...More and then select the item you want.

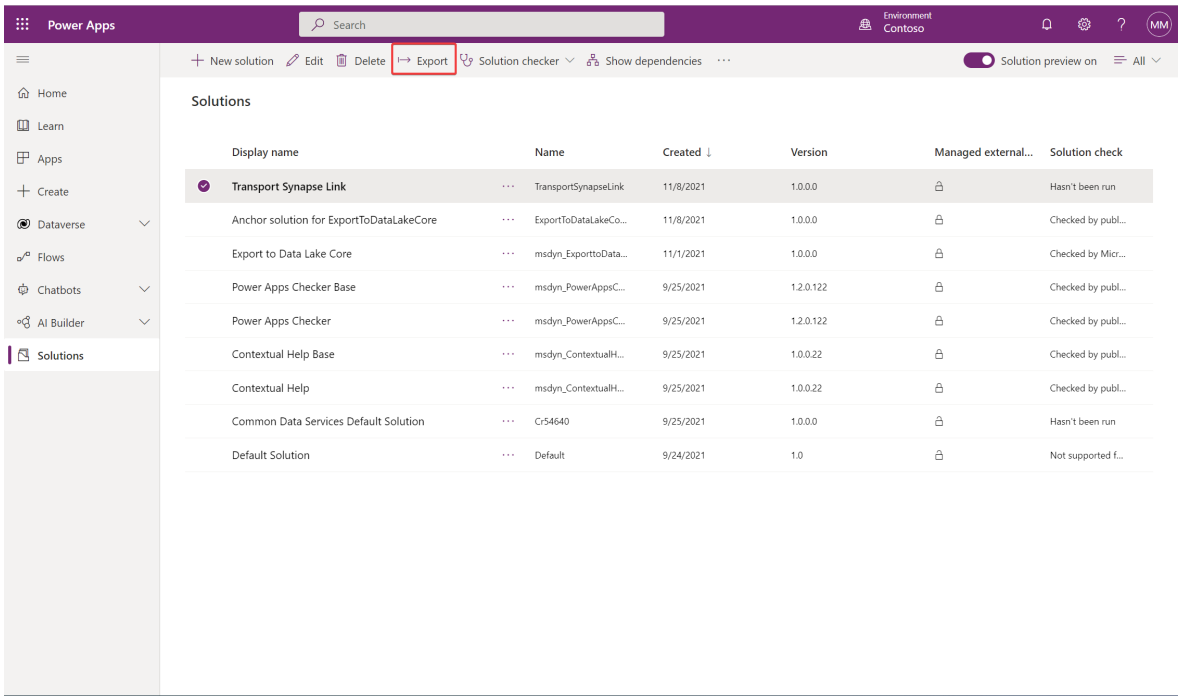
2. Select **New solution**. Provide a **Name**, **Publisher**, and **Version Number**.

3. Open the solution you created in the previous step, select **Add existing** > **More** > **Azure Synapse Link config**.



4. Select the link configurations that you want, and then select **Add**.

5. In the **Solutions** area, select the solution, and then on the command bar, select **Export**.

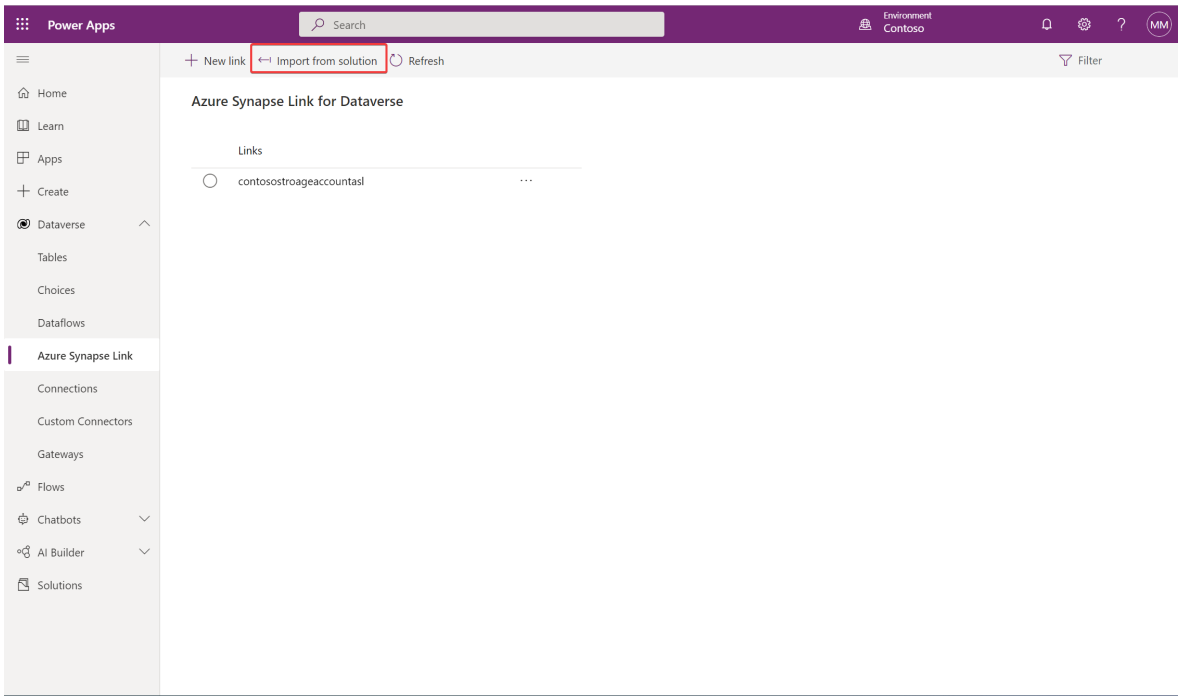


6. In the **Before you export** pane, select **Publish** to publish all changes before you export, and then select **Next**.

> **Note**
>
> Once the solution has been configured and exported, it is not updated automatically. Any updates you make to the configuration will require you to re-export and re-import the solution.

Import the solution that contains the Azure Synapse Link configuration

1. In the destination environment, import the solution under the **Solutions** tab.
2. In the destination environment, import the solution under the **Dataverse** > **Azure Synapse Link** tab.



Verify the Azure Synapse Link configuration

In the destination environment, verify that you can see the new Azure Synapse Link from the solution addition to the list of links.

Azure Synapse Link for Dataverse

Manage your Azure Synapse Link during environment lifecycle events

Article • 02/15/2022

Azure Synapse Link for Dataverse provides a continuous pipeline of data from Dataverse to Azure Synapse Analytics and/or Azure Data Lake. Once the link is created it continuously writes all the initial data as well as any incremental data. When you make changes to your Power Platform environment, this can affect the state of your Azure Synapse Link for Dataverse. This article explains the behavior of the Azure Synapse Link for Dataverse and possible user action during environment lifecycle events.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Environment lifecycle events overview

Environment operation	Synapse link	Data	User action
Backup and restore	Stops syncing	Maintained	Use solutions to transport the link across environments
Copy	Source continues syncing	Source is maintained	Use solutions to transport the link across environments
Delete	Stops syncing	Maintained	None
Edit the properties	Error	Maintained	Unlink and relink
Move	Source stops syncing	Source is maintained	Use solutions to transport the link across environments
Recover	Continue syncing	Maintained	None
Reset	Removed	Maintained	Delete data before recreating the link

Backup and restore an environment

Azure Synapse Link for Dataverse profiles are not part of an environment backup or the subsequent restore. Once an environment is restored, use solutions to export and import the configuration to preserve the configuration of the Azure Synapse Link across environments.

Copy an environment

Azure Synapse Link for Dataverse profiles are not copied as part of the copy an environment process. To preserve the configuration of the Azure Synapse Link across environments, use solutions to export and import the configuration.

Delete an environment

When an environment is deleted, all Azure Synapse Link profiles are deleted and the data sync is stopped. All data written at the time of deletion is still available in your Azure Synapse Analytics workspace and/or Azure Data Lake.

Edit the properties of an environment

Azure Synapse Link for Dataverse profiles will fail if the environment name or URL environment properties are changed. You will need to unlink the Azure Synapse Link, optionally deleting the file system, and create a new link.

Move an environment

If an environment is migrated from one tenant to another, all Azure Synapse Link profiles are deleted and the data sync is stopped. All data written at the time of deletion is still available in your Azure Synapse Analytics workspace and/or Azure Data Lake. To preserve the configuration of the Azure Synapse Link across environments, use solutions to export and import the configuration.

Recover an environment

When recovering a deleted environment within the grace period, all Azure Synapse Link for Dataverse will be available and will continue syncing data with no user action as long as the data in your Azure Synapse Analytics workspace and/or Azure Data Lake has not been modified.

Reset an environment

If an environment is reset, all Azure Synapse Link for Dataverse profiles will be removed from the environment. All the corresponding data in Azure Synapse Analytics workspace and/or Azure Data Lake will still be available but will not be synced. You may need to clean up the data in the Azure Synapse Analytics workspace and/or Azure Data Lake and you'll need to re-create the Azure Synapse Link for Dataverse.

Query Azure Synapse Link for Dataverse data with serverless SQL pool

Article • 02/15/2022

You can use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Synapse Analytics to explore your data and accelerate time to insight. This article shows you how to query your Dataverse data with built-in serverless SQL pool in your Azure Synapse Analytics workspace.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

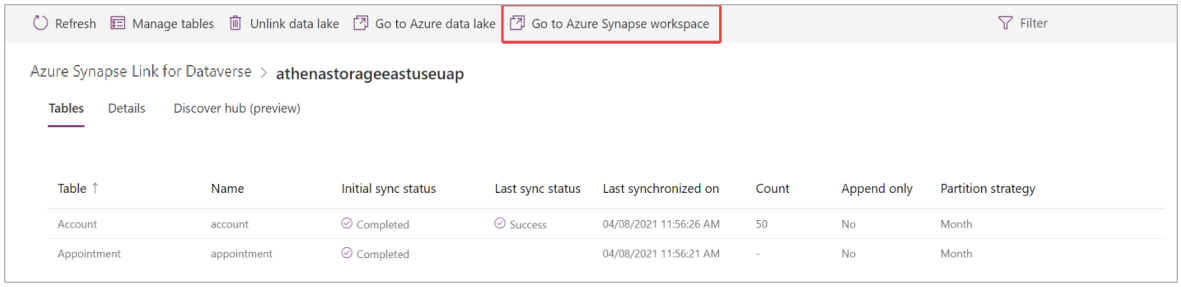
This section describes the prerequisites necessary to query your Dataverse data after using the Azure Synapse Link for Dataverse service.

- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.
- **Synapse administrator.** You must be granted the **Synapse Administrator** role access within Synapse studio.

Query your Dataverse data with serverless SQL pool

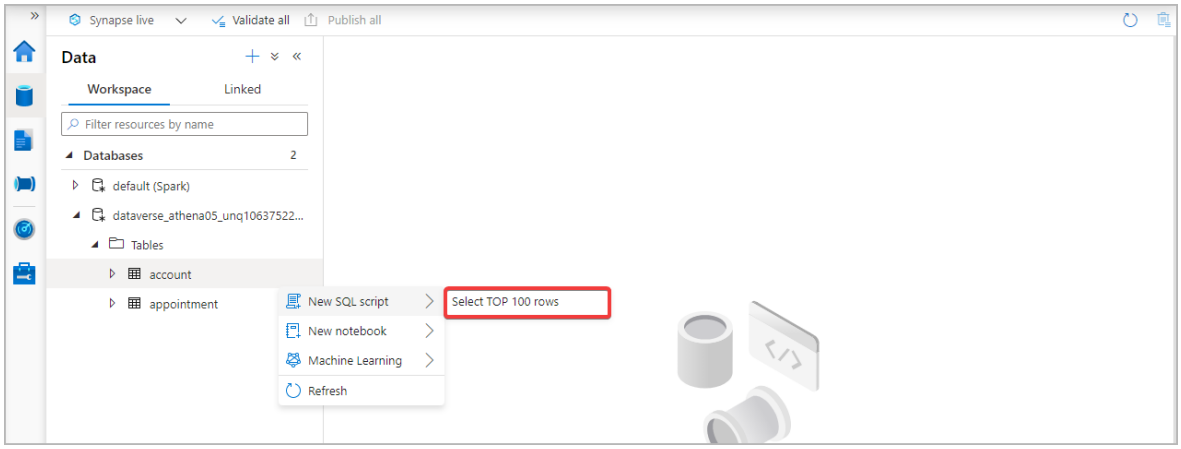
> **Note**
>
> Azure Synapse Link for Dataverse does not support the use of dedicated SQL pools at this time.

1. In Power Apps, select your desired Azure Synapse Link from the list, and then select **Go to Azure Synapse workspace**.

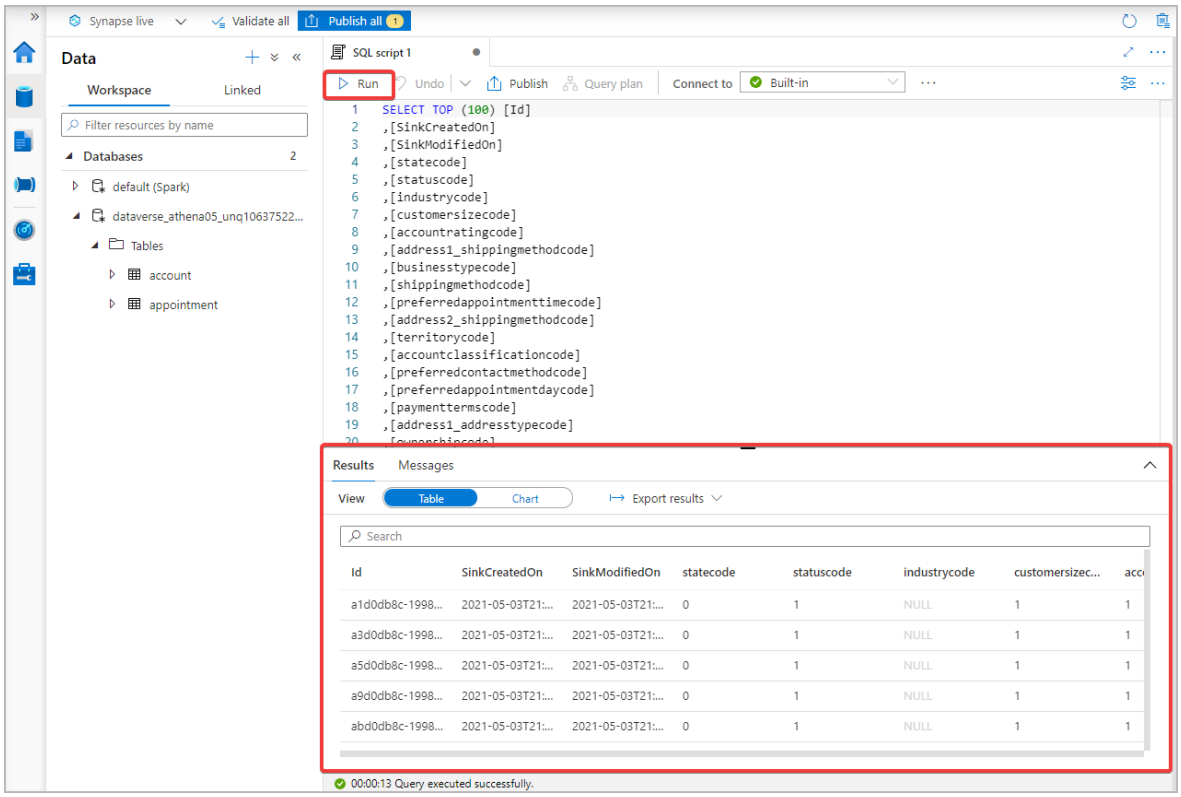


2. Expand **Lake database**, select your Dataverse container. Your exported tables are displayed under the **Tables** directory on the left sidebar.

3. Right-click the desired table and select **New SQL script** > **Select TOP 100 rows**.



4. Select **Run**. Your query results are displayed on the **Results** tab. Alternatively, you can edit the script to your needs.



Query multiple Dataverse databases with serverless SQL pool

> **Note**
>
> Querying multiple Dataverse databases requires that both Dataverse environments are in the same region.

1. Add another Azure Data Lake Storage Gen2 account as a Linked service to the same Azure Synapse Analytics workspace where the current link resides.
2. Follow the configuration steps to create a new Azure Synapse Link with the new Azure Synapse Analytics and Azure Data Lake combination.
3. Navigate to the shared Synapse workspace and expand **Databases**. Select one of the Dataverse containers. Your exported tables are displayed under the **Tables** directory on the left sidebar.
4. Right-click a table, and then select **New SQL script** > **Select TOP 100 rows**.
5. Edit the query to combine the two datasets. For instance, you can join the datasets based on a unique ID value.
6. Select **Run**. Your query results are displayed on the **Results** tab.

Query and analyze the incremental updates with Azure Synapse Link for Dataverse

Article • 04/29/2025

Microsoft Dataverse data (including data from Dynamics 365 apps and finance and operations) can continuously change through create, update, and delete transactions. With the incremental update option, you can build incremental data pipelines that apply these changes to downstream systems and databases. Azure Synapse Link for Dataverse exports incremental data in time stamped folders that contain data changes within user-specified time intervals.

You can leverage incremental update feature for several scenarios:

- **Update a downstream datastore or a data warehouse**. You might need to apply changes from your Power Apps and Dynamics 365 data into a downstream datastore. Incremental update is a standard capability in most data transformation tools, such as Azure Data Factory. However, for the incremental update feature to work, you must identify the records that changed in source tables. The incremental update feature provides changed data as a set of files such that you don't need to detect changes by comparing before and after images of tables.

- **Analyze changes in large datasets**. If you need to analyze changes in large datasets, the incremental update feature provides a continuous stream of data in small batches such that you don't need to store all data. With this option you can drop stale and stagnant data to save data storage costs as well as track data changes relevant for a user-specified time period.

Azure Synapse Link for Dataverse also provides the option to export and maintain a replica of tables in your Azure Data Lake (Gen 2) storage. You can configure Azure Synapse Link to export incremental data in addition to exporting a replica of tables. Each configuration (known as a "Synapse Link profile") can export either tables or incremental data. While you can create multiple profiles, you can't configure both tables and incremental updates within the same profile.

> **Important**
>
> An initial time stamped folder is created when you enable this feature with a copy of your data. Subsequent timestamp and table folders are created only when there's a data update during the user-specified time interval.
>
> Once you create a Synapse Link profile with the incremental update feature, the configuration applies to all selected tables within the Synapse Link profile.

This feature can't be enabled with the option: **Connect to your Azure Synapse workspace**. For customers who require Azure Synapse analytics access, follow this instruction to setup the link: [Create an Azure Synapse Link for Dataverse with your Azure Synapse Workspace]

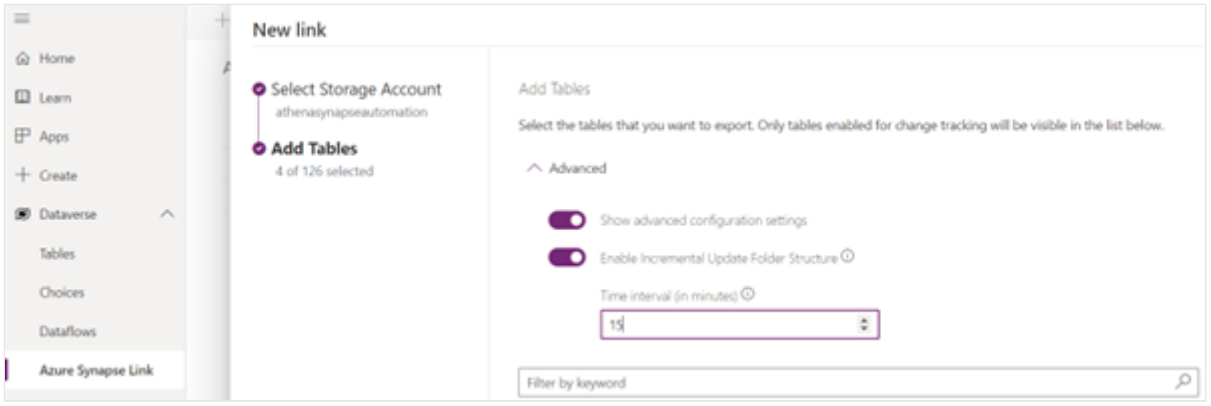
This feature is equivalent to the [Change feeds feature in export to data lake] built into Dynamics 365 finance and operations apps. Customers using the **Change feeds** feature have the option to enable a Synapse Link profile with change data without having to export table data.

Prerequisites

This guide assumes that you have already met the prerequisites to create an Azure Synapse Link. More information: Create an Azure Synapse Link for Dataverse with Azure Data Lake

Create a Synapse Link profile to export incremental data

1. Sign in to Power Apps and select your environment.
2. On the left navigation pane, select **Azure Synapse Link**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. On the command bar, select **+ New link**.
4. Select the **Subscription**, **Resource group**, and **Storage account**. Select **Next**.
5. Don't select the option **Connect to your Azure Synapse workspace**. If you choose this option, the incremental update feature is disabled.
6. Add the tables you want to export. If your Dataverse environment is linked to finance and operations apps, you can also select tables from finance and operations apps.
7. Select **Advanced**.
8. Turn on **Show advanced configuration settings** and **Enable Incremental Update Folder Structure**.
9. Enter the time interval (in minutes) for how often the incremental updates should be captured, and then select **Save**.



> **Note**
>
> The minimum time interval is 5 minutes. That means the incremental update folder is created every five minutes and contain the changes that occurred within the time interval. This setting is also configurable after the link creation via **Manage tables**. Maximum time interval is 1,140 minutes (or 24 hours).
>
> Ensure **Connect to your Azure Synapse workspace Azure Synapse workspace** isn't checked in the first page of setup.
>
> Incremental data in time stamped folders are stored as comma separated value text files (CSV files). You can't use the Delta conversion feature for incremental data and obtain incremental files in a Delta parquet format.

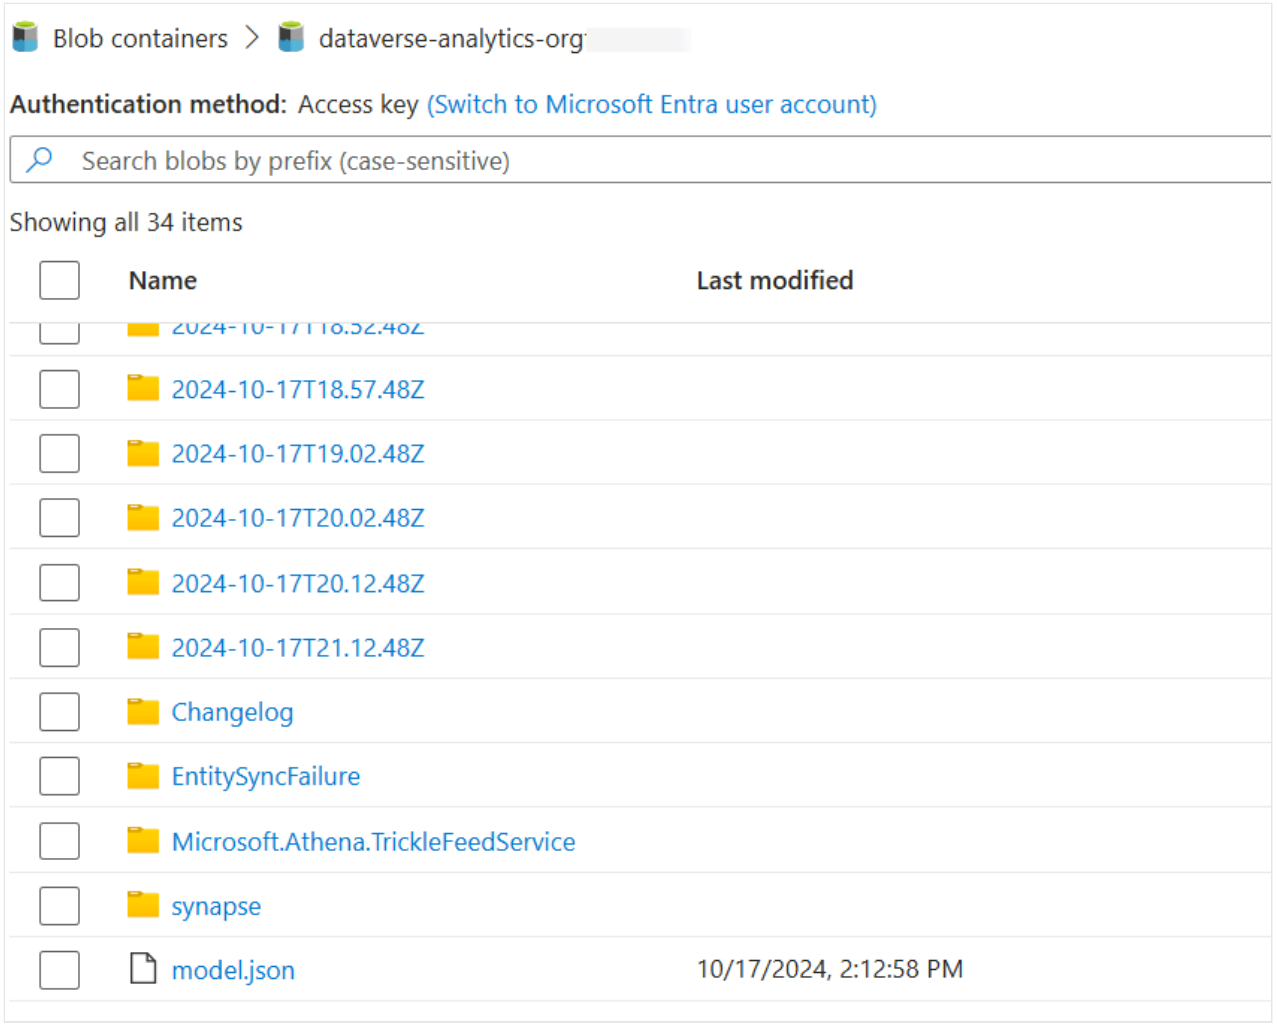
View incremental folder at Microsoft Azure Storage

When you create a Synapse Link profile with incremental data, the system makes an initial copy of all tables and stores it in the first incremental update folder. Once the initial copy is created, the system creates subsequent update folders with changed data. If there are no changes in any of the tables selected, you won't see incremental data folders.

To see incremental data folders in the storage account:

1. Select the desired Azure Synapse Link, and then select **Go to Azure data lake** on the command bar.
2. Select the **Containers** under **Data Storage**.
3. Select **dataverse**-*environmentName-organizationUniqueName*. Incremental updates folders are named by creation timestamp ("yyyy-MM-dd'T'HH:mm:ss.SSSz") in UTC. Notice that the time difference between time stamped folders is the time interval specified by you in advanced settings.

4. Within each time stamped folder, there are folders for each table. Not all tables chosen might have changed during the time interval and you only see folders corresponding to tables whose data changed.



> **Note**
>
> Due to the retry mechanism features, an extra empty timestamp folder might be created within the user-specified time interval.

Consume incremental data

You can copy incremental data into an Azure SQL Database or a data warehouse using data integration tools such as Azure Data Factory or Azure Synapse Analytics pipelines. We provide a sample data pipeline that can be used for this purpose. For more information:Copy Dataverse data into Azure SQL.

If you're a Dynamics 365 finance and operations apps customer transitioning from the change feeds feature you can use Data integration sample tools provided in GitHub to update existing data pipelines used with the change feeds feature.

You can also build your own data pipeline to consume incremental data. However, you need to consider the following best practices when designing your own pipeline:

- **Consume data from previous time stamped folders only**: This way, you can avoid read-write conflicts with the Synapse Link service, which might be continuously updating data in the current folder. You can find the current folder by viewing the **Changelog/changelog.info** file. This file is a read-only file which contains a single row with the folder name that is currently updated. You shouldn't update this file as it can cause system instability.
- You can view the **model.json** file located within each time stamped folder to read metadata such as column names for the data contained in table folders. Notice that each model.json file in the folder located within time stamped folders contain metadata for all the tables, not just the tables contained within the time stamped folder.
- Avoid using other log files such as the Synapse.log file. This file is used for internal purposes and might not reflect accurate data.
- Consider deleting obsolete incremental folders from your Azure Data lake after you have finished processing. At present, Synapse Link maintains a lease on these files in Azure Storage to recover from any failures. The system might release the lease after some time. You should only delete incremental folders that are *older than 24 hours* to avoid any conflicts with system operation.
- You shouldn't modify or delete the "current folder" that is the folder contained in the **Changelog/changelog.info** file. If you change this file, the system pauses processing data.

What is Azure Synapse Link for Dataverse?

Create a view of your Azure Synapse Link for Dataverse data

Summarize this article for me

Use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Synapse Analytics to explore your data and accelerate time to insight. This article shows you how to create a view of your Dataverse data in your Azure Synapse Analytics workspace.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

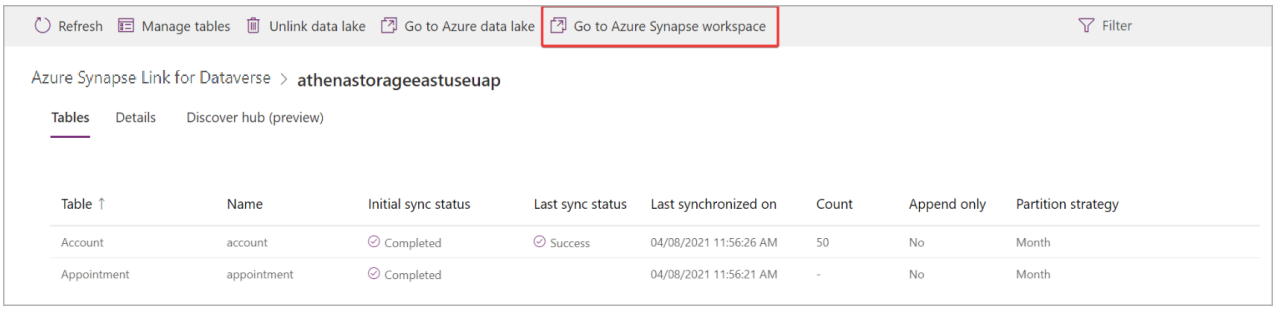
Prerequisites

This section describes the prerequisites necessary to create a view of your Dataverse data after using the Azure Synapse Link for Dataverse service.

- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.
- **Synapse administrator.** You must be granted **Synapse Administrator** role access within Synapse studio.

Create a view of your Dataverse data

1. In Power Apps, select your Azure Synapse Link from the list, and then select **Go to Azure Synapse workspace**.



2. Create User-defined schema within Synapse SQL

```SQL
CREATE SCHEMA [SCHEMA NAME]
GO
```

3. Run a create view script by specifying a **view name**, the **column names**, **Dataverse database name** under the new **schema**, and then exported **table name**.

```SQL
CREATE OR ALTER VIEW [SCHEMA NAME].[VIEW NAME]
AS
SELECT [COLUMN NAMES]
FROM [DATAVERSE DATABASE NAME].[dbo].[TABLE NAME]
```

Use a view of your Dataverse data

You can use views in your queries the same way you use views in SQL Server queries. The view is created and available under the **Views** folder in SQL Server Management Studio (SSMS).

> **Important**
>
> Custom database objects created by a customer within the Azure Synapse Link database are deleted once the unlink is completed.
>
> Customers will need to implement their own version control of their custom database objects scripts to ensure they have a backup.

Transform Azure Synapse Link for Dataverse data with Apache Spark

Article • 08/25/2022

You can use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Synapse Analytics to explore your data and accelerate time to insight. This article shows you how to transform your Dataverse data using the Apache Spark engine available in your Synapse workspace.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

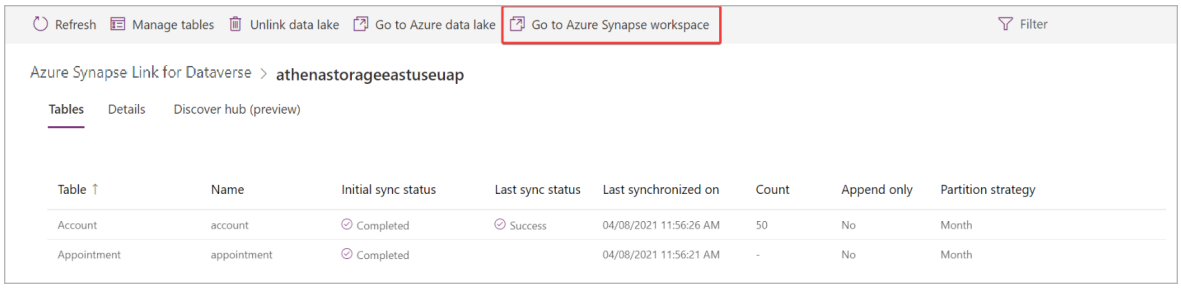
Prerequisites

This section describes the prerequisites necessary to transform Dataverse data with Apache Spark after using the Azure Synapse Link for Dataverse service.

- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.
- **Synapse administrator.** You must be granted the **Synapse Administrator** role access within Synapse studio.

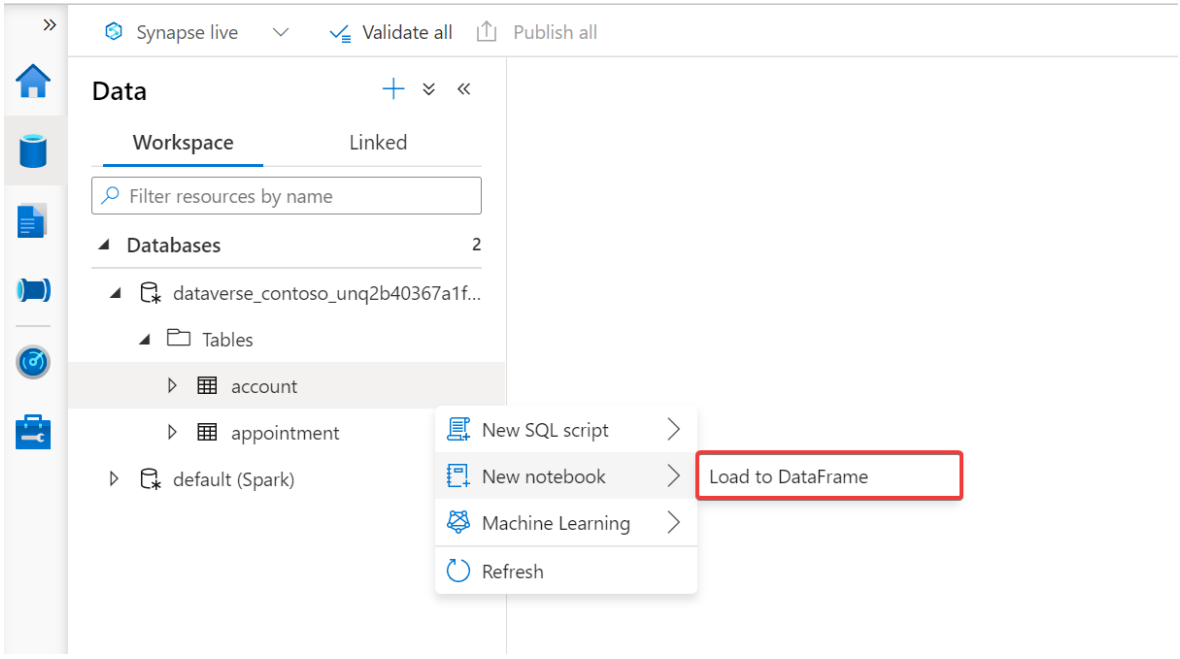
Transform your data with an Apache Spark notebook

1. In Power Apps, select your desired Azure Synapse Link from the list, and then select **Go to Azure Synapse workspace**.

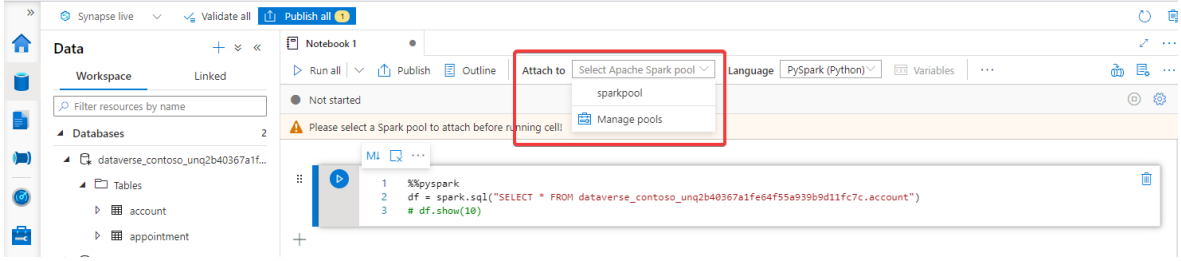


2. Expand **Databases**, select your Dataverse container. Your exported tables are displayed under the **Tables** directory on the left sidebar.

3. Right-click the desired table and select **New notebook** > **Load to DataFrame**.



4. Attach the notebook to an Apache Spark pool by selecting a pool from the drop-down menu. If you do not have an Apache Spark pool, select **Manage pools** to create one.



5. Add code cells to transform your data. Run individual cells by selecting the play button at the left of each cell or run all the cells in succession by selecting **Run all** from the top bar.

What is Apache Spark in Azure HDInsight

Copy Dataverse data into Azure SQL

Article • 02/08/2023

Use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Synapse Analytics to explore your data and accelerate time to insight. This article shows you how to run Azure Synapse pipelines or Azure Data Factory to copy data from Azure Data Lake Storage Gen2 to an Azure SQL Database with incremental updates feature enabled in Azure Synapse Link.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics. This template is a code sample. We encourage you to use this template as guidance to test out the functionality of retrieving data from Azure Data Lake Storage Gen2 to Azure SQL Database using the pipeline provided.

Prerequisites

1. Azure Synapse Link for Dataverse. This guide assumes that you've already met the prerequisites to create an Azure Synapse Link with Azure Data Lake. More information: Prerequisites for an Azure Synapse Link for Dataverse with your Azure Data Lake
2. Create an Azure Synapse Workspace or Azure Data Factory under the same Microsoft Entra tenant as your Power Apps tenant.
3. Create an Azure Synapse Link for Dataverse with the **incremental folder update enabled** to set the time interval. More information: Query and analyze the incremental updates
4. Microsoft.EventGrid provider needs to be registered for trigger. More information: Azure portal. Note: If you are using this feature in Azure Synapse Analytics, ensure that your subscription is also registered with Data Factory resource provider, otherwise you'll get an error stating that the creation of an "Event Subscription" failed.
5. Create an Azure SQL database with the **Allow Azure services and resources to access this server** property enabled. More information: What should I know when setting up my Azure SQL Database (PaaS)?
6. Create and configure an Azure integration runtime. More information: Create Azure integration runtime - Azure Data Factory & Azure Synapse

> **Important**
>
> Using this template might incur additional costs. These costs are related to the usage of Azure Data Factory or Synapse workspace pipeline and are billed on a monthly basis. The cost of using pipelines mainly depends on the time interval for incremental update and the data volumes. To plan and manage the cost of using this feature, go to: Monitor costs at pipeline level with cost analysis
>
> It's important to take these additional costs into consideration when deciding to use this template as they are not optional and must be paid in order to continue using this feature.

Use the solution template

Synapse Analytics

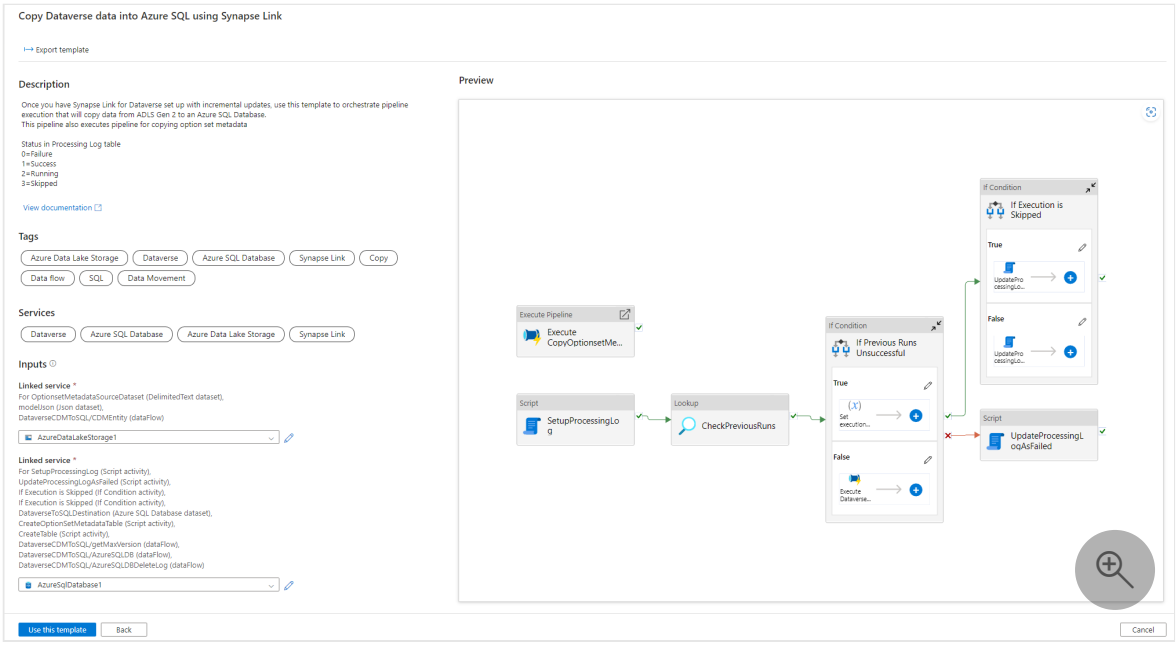
1. Go to the Azure portal and open Azure Synapse workspace.
2. Select **Integrate** > **Browse gallery**.
3. Select **Copy Dataverse data into Azure SQL using Synapse Link** from the integration gallery.

Configure the solution template

1. Create a linked service to Azure Data Lake Storage Gen2, which is connected to Dataverse using the appropriate authentication type. To do this, select **Test connection to validate the connectivity,** and then select **Create**.

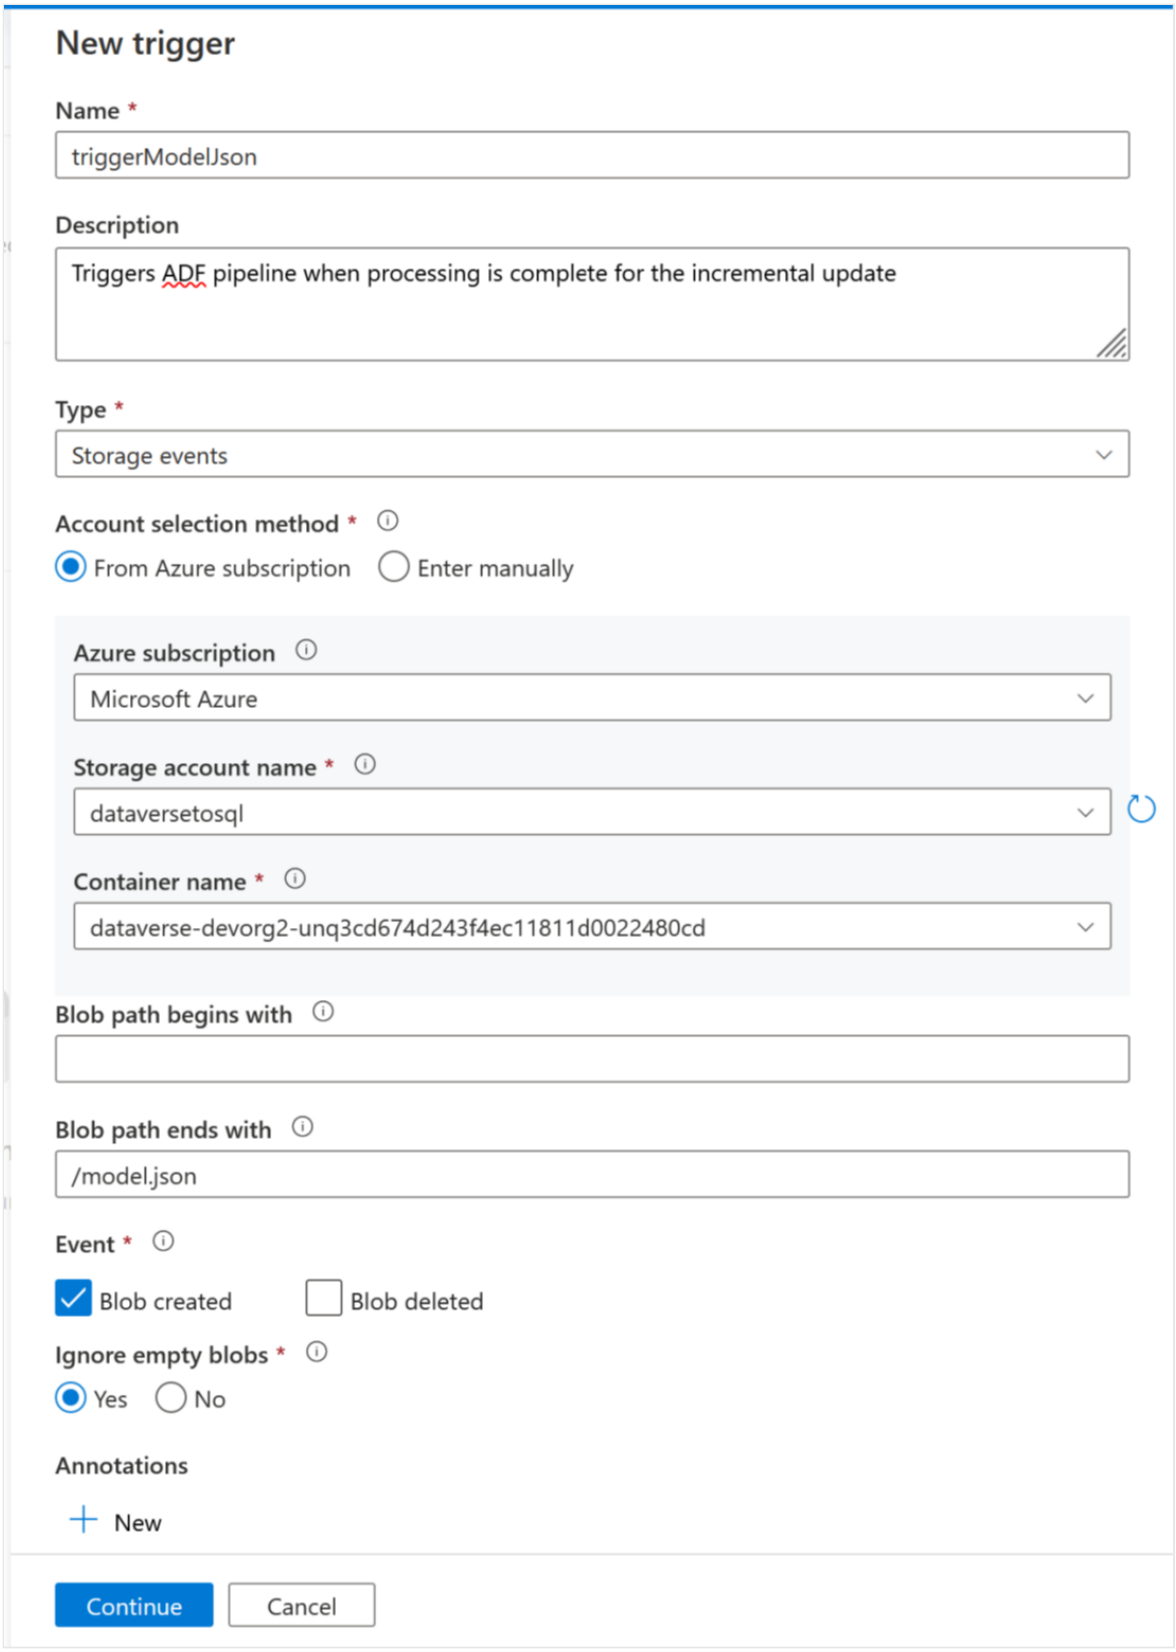
2. Similar to the previous steps, create a linked service to Azure SQL Database where Dataverse data will be synced.

3. Once **Inputs** are configured, select **Use this template**.



4. Now a trigger can be added to automate this pipeline, so that the pipeline can always process files when incremental updates are completed periodically. Go to **Manage** > **Trigger**, and create a trigger using the following properties:

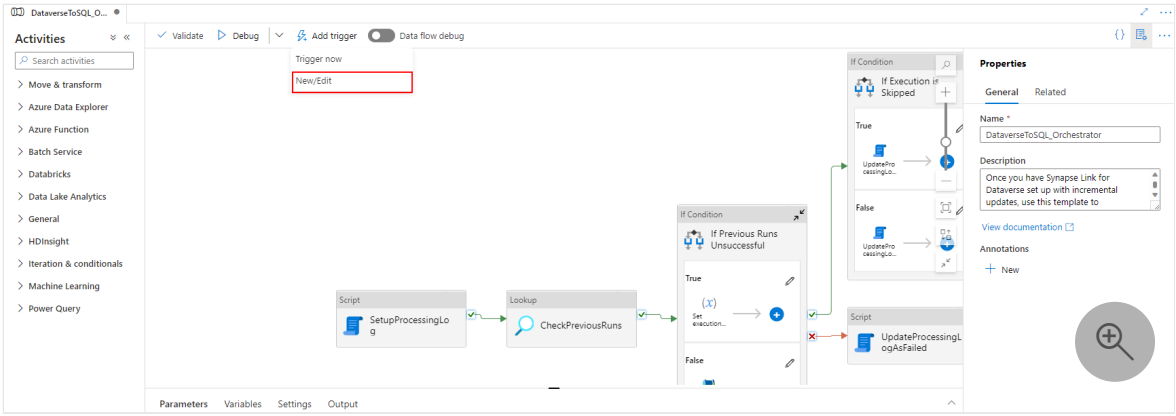
    - **Name**: Enter a name for the trigger, such as *triggerModelJson*.
    - **Type**: **Storage events**.
    - **Azure subscription**: Select the subscription that has Azure Data Lake Storage Gen2.
    - **Storage account name**: Select the storage that has Dataverse data.
    - **Container name**: Select the container created by Azure Synapse Link.
    - **Blob path ends with**: */model.json*
    - **Event**: **Blob created**.
    - **Ignore empty blobs**: **Yes**.
    - **Start trigger**: Enable **Start trigger on creation**.



5. Select **Continue** to proceed to the next screen.

6. On the next screen, the trigger validates the matching files. Select **OK** to create the trigger.

7. Associate the trigger with a pipeline. Go to the pipeline imported earlier, and then select **Add trigger** > **New/Edit**.



8. Select the trigger in the earlier step, and then select **Continue** to proceed to the next screen where the trigger validates the matching files.

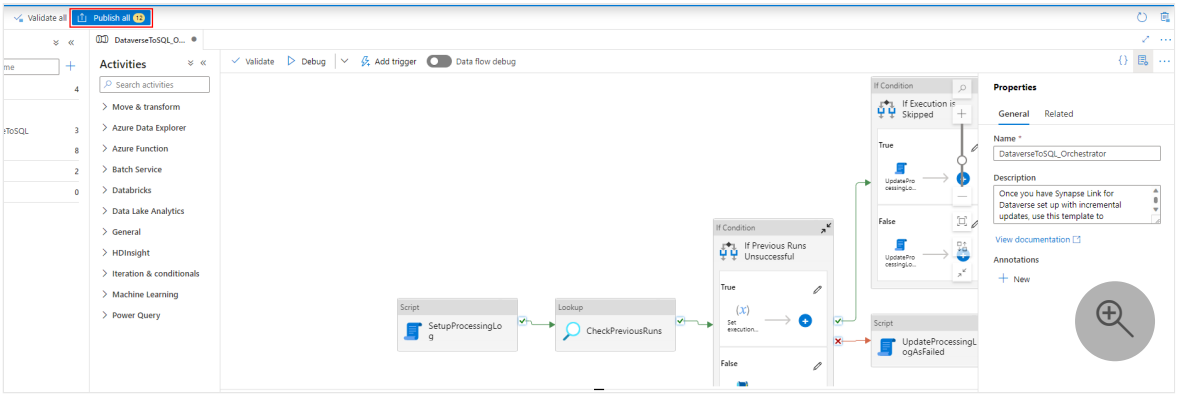
9. Select **Continue** to proceed to the next screen.

10. In the **Trigger Run Parameter** section, enter the below parameters, and then select **OK**.

    - **Container**: `@split(triggerBody().folderPath,'/')[0]`
    - **Folder**: `@split(triggerBody().folderPath,'/')[1]`

11. After associating the trigger with the pipeline, select **Validate all**.

12. Once validation succeeds, select **Publish All**.



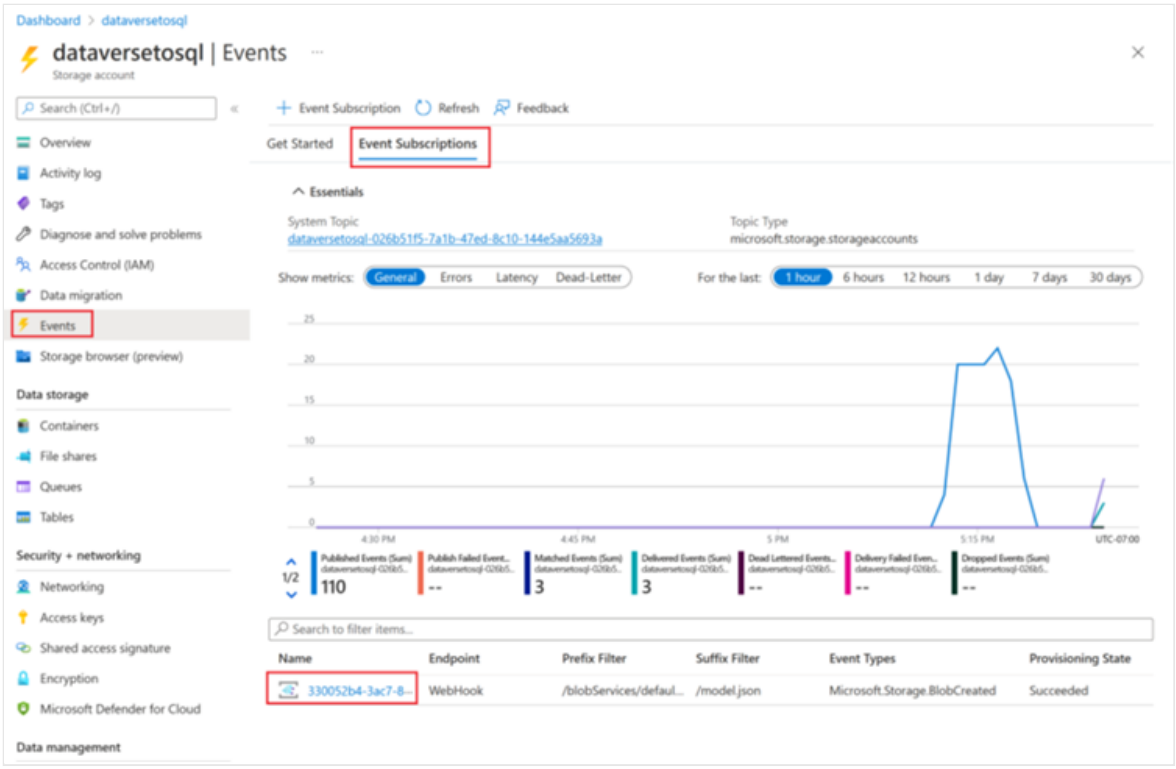
13. Select **Publish** to publish all the changes.

Add an event subscription filter

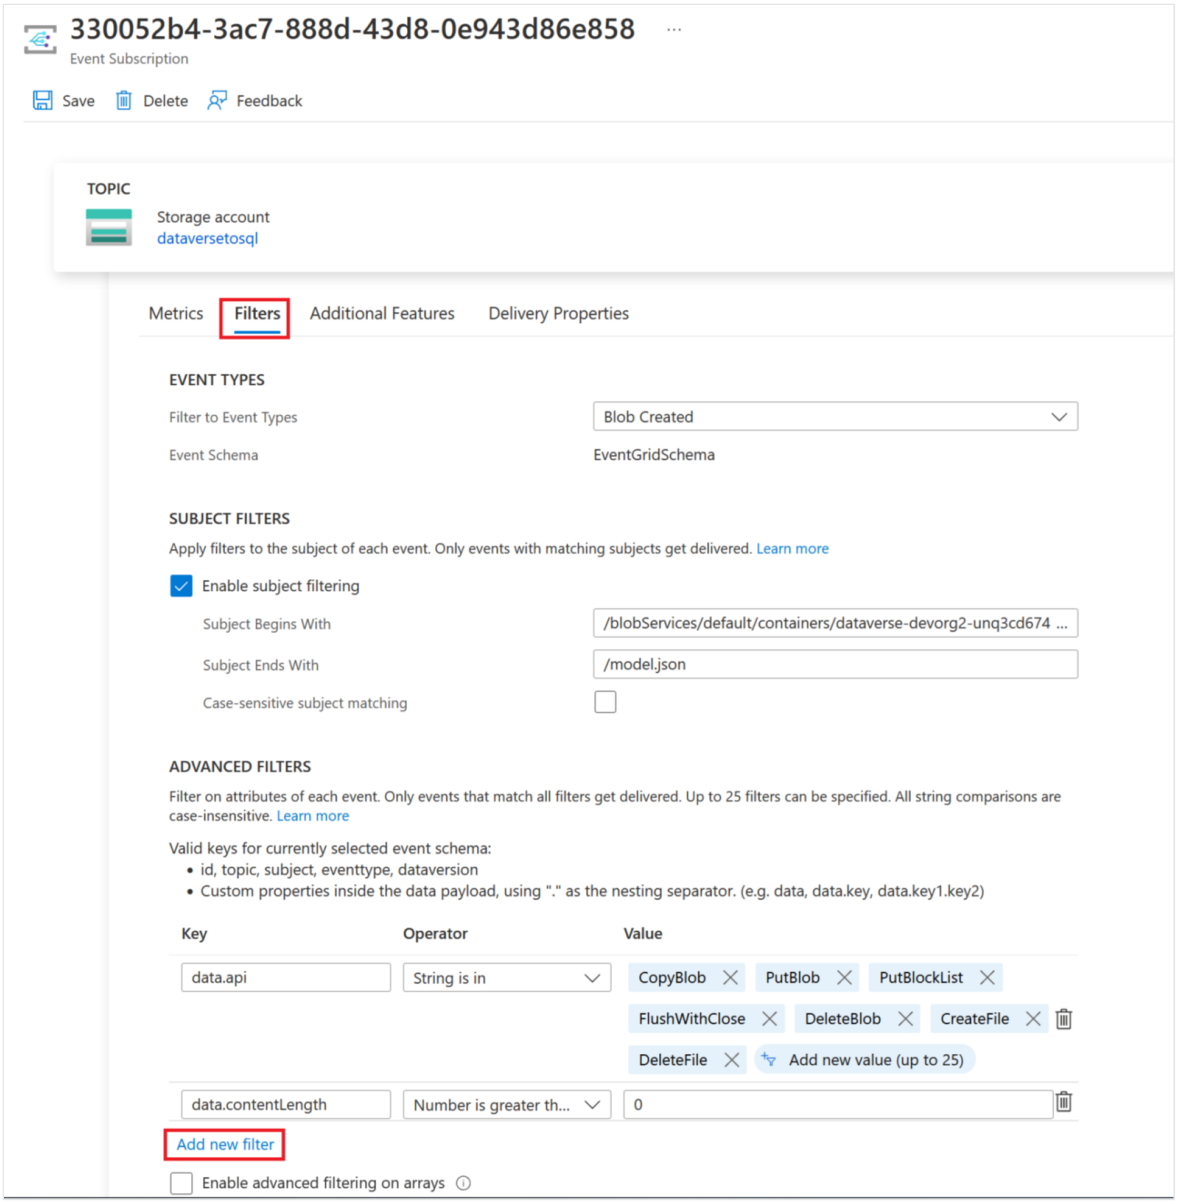
To ensure that the trigger fires only when model.json creation is complete, advanced filters need to be updated for the trigger's event subscription. An event is registered against the storage account the first time the trigger runs.

1. Once a trigger run completes, go to storage account > **Events** > **Event Subscriptions**.

2. Select the event that was registered for the model.json trigger.



3. Select the **Filters** tab, and then select **Add new filter**.



4. Create the filter:

   - **Key**: **subject**
   - **Operator**: **String does not end with**
   - **Value**: */blobs/model.json*

5. Remove the **CopyBlob** parameter from **data.api Value** array.

6. Select **Save** to deploy the additional filter.

Visualize Azure Synapse Link for Dataverse data with Power BI

Article • 02/15/2022

You can use the Azure Synapse Link to connect your Microsoft Dataverse data to Azure Synapse Analytics to explore your data and accelerate time to insight. This article shows you how to generate a Power BI report by connecting to the serverless SQL endpoint from your Azure Synapse Analytics workspace.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

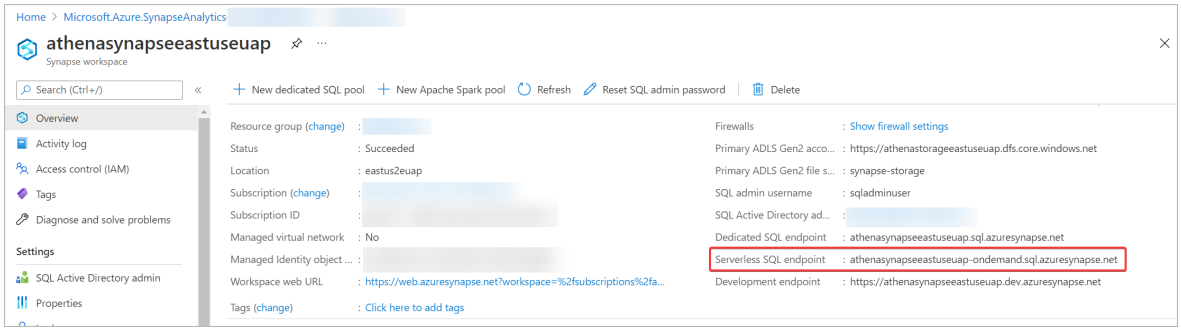
This section describes the prerequisites necessary to access Dataverse choices with Power BI after using the Azure Synapse Link for Dataverse service.

- **Power BI Desktop**. Get it now
- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.

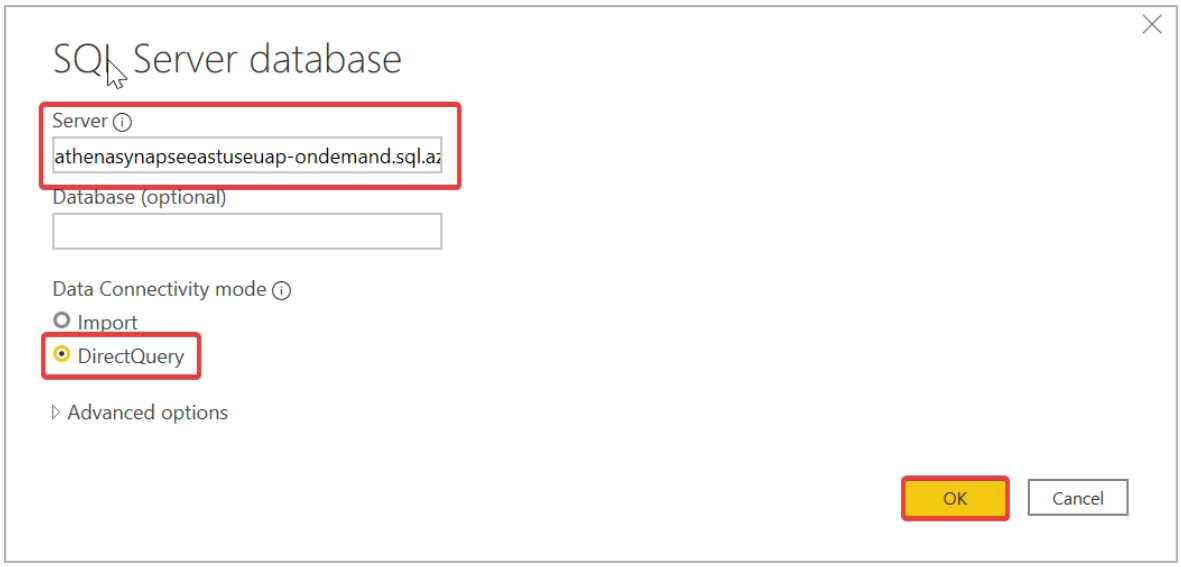
Connect to your Azure Synapse Analytics workspace to Power BI

1. Open Power BI Desktop.
2. Select **Get data** > **More...**.
3. Select **Azure** > **Azure Synapse Analytics (SQL DW)** > **Connect**.

4. Go to your Azure Synapse Analytics workspace and copy the **Serverless SQL endpoint**.

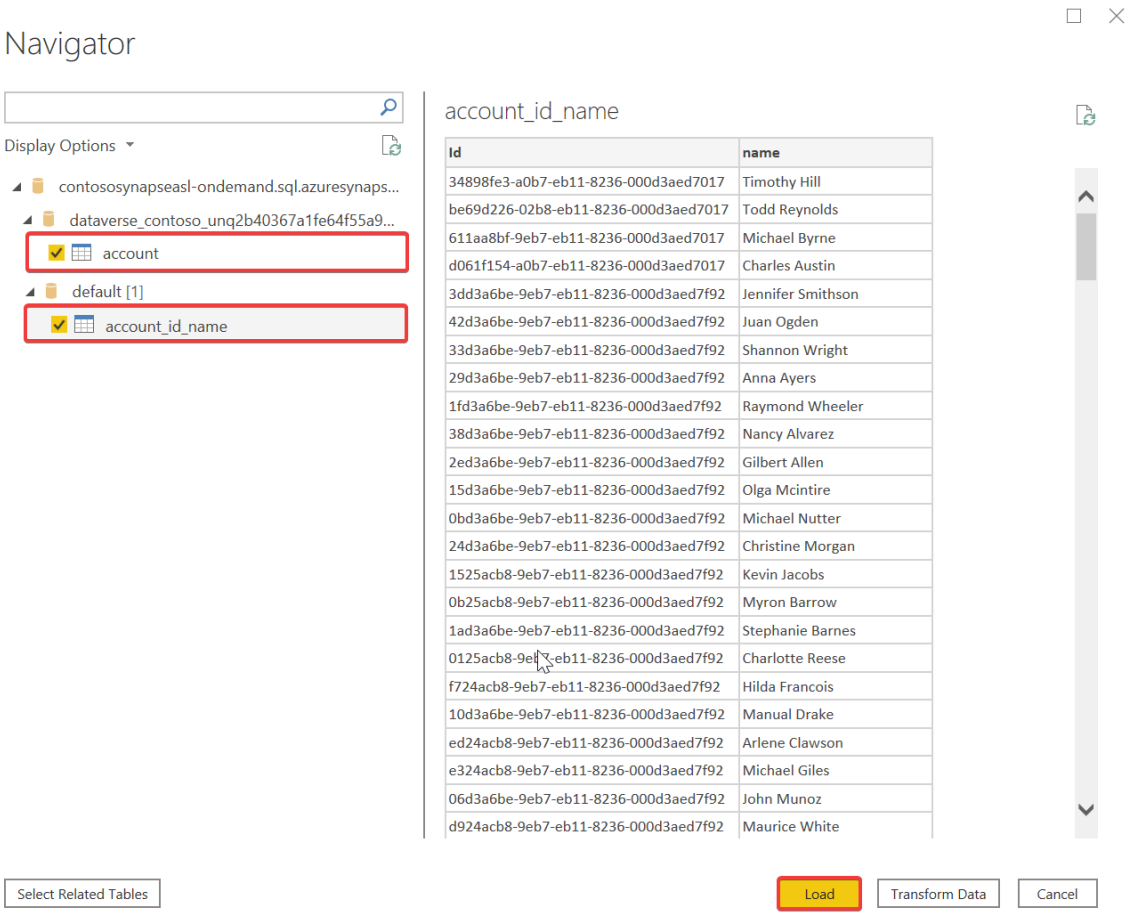


5. Paste the endpoint for the **Server**. Select **DirectQuery** for the **Data Connectivity mode**. Select **OK**.



6. If prompted, sign in with your Microsoft Account.

7. Select the container and the preferred table from the Navigator, and then select **Load**. Optionally, expand *default* to access tables created with an Apache Spark notebook.



> **Note**
>
> If you receive a credentials error, go to **File** > **Options and settings** > **Data source settings** and clear the permissions for the serverless SQL endpoint. Repeat the above steps.

8. Select fields from the **Fields** pane to create a simple table or create other visualizations.

Copy exported Dataverse data to dedicated SQL pool

Article • 02/15/2022

After creating a continuous pipeline of data from Dataverse to your Synapse workspace with Azure Synapse Link for Dataverse, you can copy the data to dedicated SQL pool with Synapse Pipelines.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

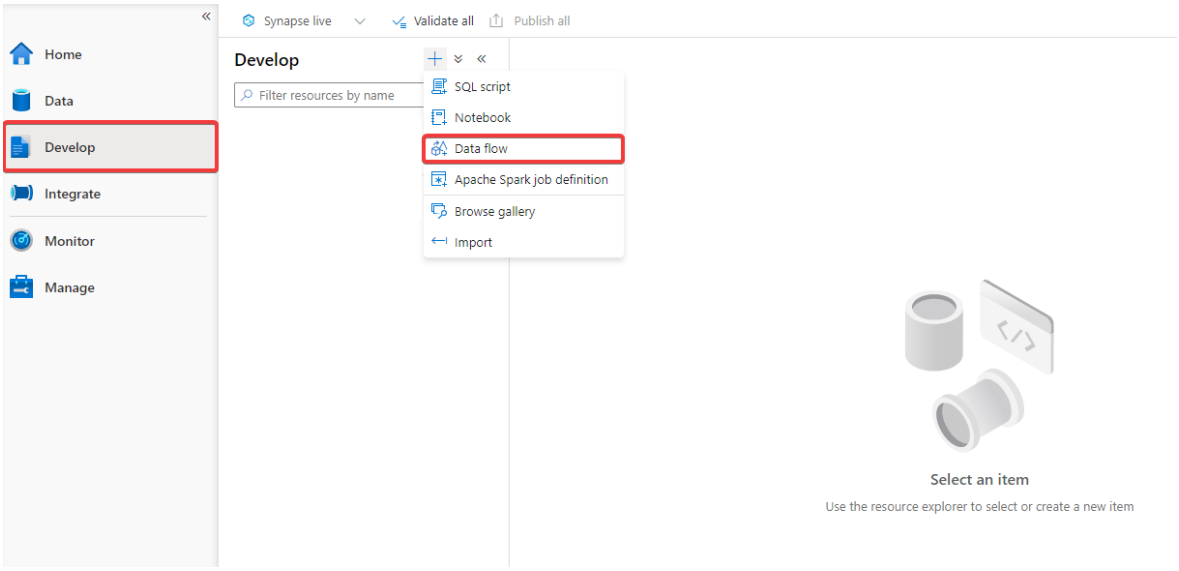
This section describes the prerequisites necessary to copy your Dataverse data to dedicated SQL pool after using the Azure Synapse Link for Dataverse service.

- **Azure Synapse Link for Dataverse.** This guide assumes that you've already exported Dataverse data by using Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.
- **Synapse administrator.** You must be granted the **Synapse Administrator** role access within Synapse studio.
- **Dedicated SQL Pool.** This guide assumes that you've already created a dedicated SQL pool. You can create a dedicated SQL pool under the **Manage** tab in your Synapse workspace.

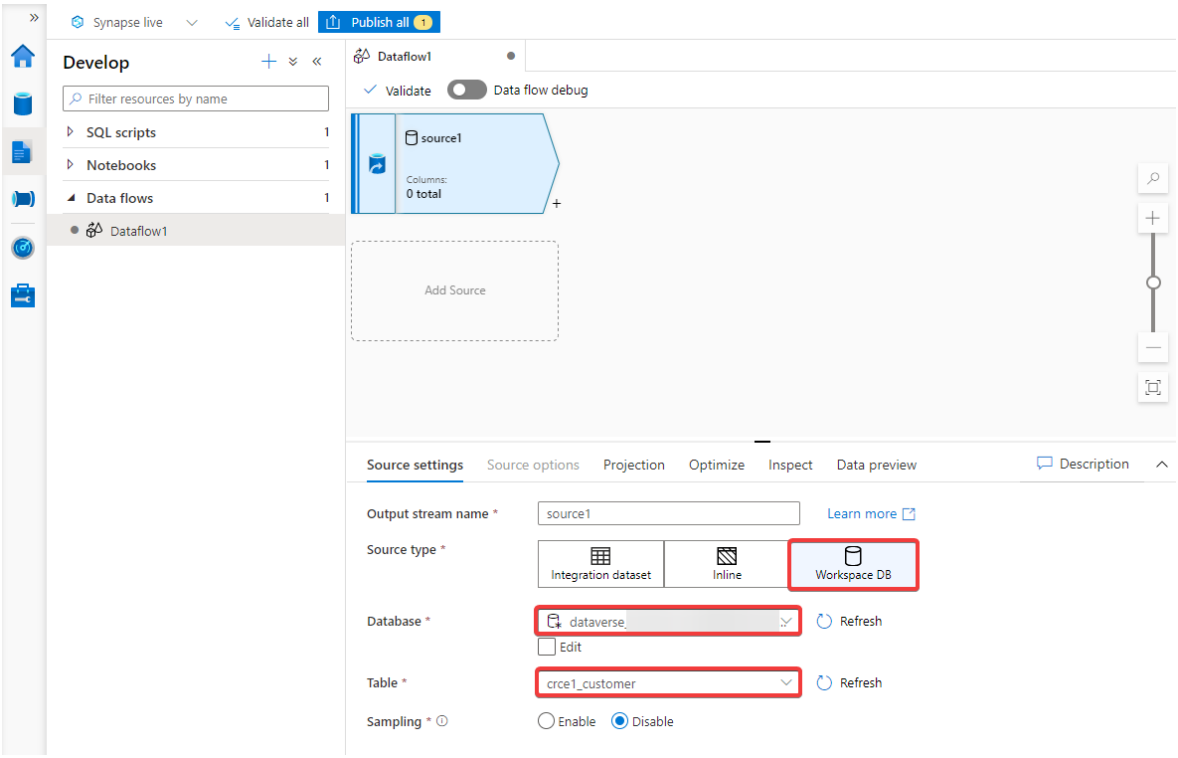
Copy the exported Dataverse data to dedicated SQL pool

1. Navigate to your Azure Synapse Analytics workspace.

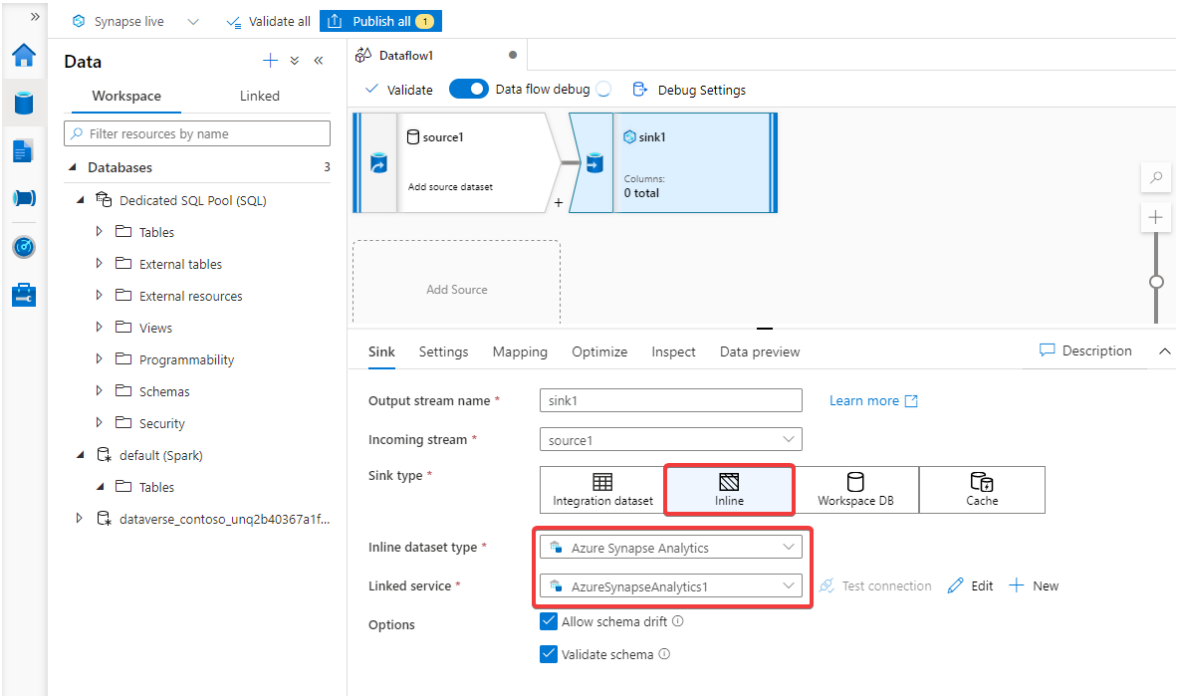
2. Open the **Develop** tab and create a new **Data flow**. Turn on **data flow debug**. This can take several minutes to complete.



3. Create a **Source** and specify the **Source type** as **Workspace DB** and select the **Database** that contains the Dataverse data and **Table** you want to copy.



4. Create a **Sink** and specify the **Sink type** as **Inline** and **Inline dataset type** as **Azure Synapse Analytics**. Select your dedicated SQL pool as the **Linked service**. If the dedicated SQL pool is not already a linked service, create a new connection.



5. Under the **Settings** tab, **Refresh** the **Schema Name**. Select *sys* and for the **Table name** select *all_columns*. Optionally, configure the other settings.

6. Navigate to the **Integrate** tab of the Synapse workspace and create a new **Pipeline**.

7. Expand the **Move & Transform** activity and drag and drop **Data flow** into the workspace.

8. Open the **Settings** and ensure that you have selected the data flow created in the previous steps.

9. Run your pipeline. Optionally, **Add trigger** to specify a time for the pipeline to run.

What is dedicated SQL pool

Read the incremental updates of Dataverse data

Article • 02/15/2022

After creating a continuous pipeline of data from Microsoft Dataverse to your Synapse workspace with Azure Synapse Link for Dataverse, you can read the incremental updates of a specified time interval. Every Dataverse table exported with Azure Synapse Link for Dataverse contains a *SinkModifiedOn* column which can be used to get the incremental updates.

> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

This section describes the prerequisites necessary to read the incremental updates of your exported Dataverse data.

- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse and that all tables are syncing with **Append-only** mode.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.
- **Synapse administrator.** You must be granted the **Synapse Administrator** role access within Synapse studio.

Read the Incremental Updates of your Dataverse data

1. Navigate to your Azure Synapse Analytics workspace.
2. Select **Develop** from the left side panel, then select + > **SQL script**.

3. Paste the following SQL query and replace **CONTAINER_NAME** with the name of the container, **TABLE_NAME** with the name of the Dataverse table, and **TIMESTAMP_START** and **TIMESTAMP_END** with the time interval in UTC format (YYYY-MM-DDTHH:MM:SS).

```SQL
    SELECT *
    FROM [CONTAINER_NAME].[dbo].[TABLE_NAME]
    WHERE [SinkModifiedOn] >= TIMESTAMP_START AND [SinkModifiedOn] <=
TIMESTAMP_END
```

4. **Run** the query and a table containing the incremental updates to the Dataverse table from the specified time interval will be displayed.

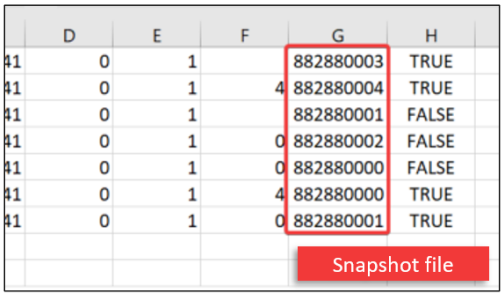
Azure Synapse Link for Dataverse

Access Dataverse choices (option sets) with serverless SQL pool

Article • 02/15/2022

For columns that use Microsoft Dataverse Choices, choice values are written as an integer label and not a text label to maintain consistency during edits. The integer-to-text label mapping is stored in the *Microsoft.Athena.TrickleFeedService/table-EntityMetadata.json* file. This article covers how to access the integer-to-text label mapping using serverless SQL pool.



> **Note**
>
> Azure Synapse Link for Microsoft Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

This section describes the prerequisites necessary to consume Dataverse data with serverless SQL pool after using the Azure Synapse Link for Dataverse service.

- **Azure Synapse Link for Dataverse:** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse with and Azure Synapse Analytics workspace.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.

Consuming Dataverse choices with serverless SQL pool

1. Navigate to your Azure Synapse Analytics workspace.
2. Select **Develop** from the left side panel, then select + > **SQL script**.
3. Paste the following SQL query and replace <**STORAGE_ACCOUNT**> with the storage account name and <**CONTAINER_NAME**> with the name of the container.

SQL

```
    SELECT [EntityName], [OptionSetName], [Option], [IsUserLocalizedLabel],
[LocalizedLabelLanguageCode], [LocalizedLabel]
    FROM OPENROWSET (
        BULK
'https://<STORAGE_ACCOUNT>.dfs.core.windows.net/<CONTAINER_NAME>/Microsoft.A
thena.TrickleFeedService/*-EntityMetadata.json',
        FORMAT = 'csv',
        FIELDTERMINATOR ='0x0b',
        FIELDQUOTE = '0x0b',
        ROWTERMINATOR = '0x0b'
    ) WITH (doc nvarchar(max)) AS rows
    CROSS APPLY OPENJSON(doc, '$.OptionSetMetadata')
    WITH (
            [EntityName] nvarchar(4000) '$.EntityName',
            [OptionSetName] nvarchar(4000) '$.OptionSetName',
            [Option] int '$.Option',
            [IsUserLocalizedLabel] nvarchar(4000) '$.IsUserLocalizedLabel',
            [LocalizedLabelLanguageCode] int '$.LocalizedLabelLanguageCode',
            [LocalizedLabel] nvarchar(4000) '$.LocalizedLabel'
    )
```

4. **Run** the query. A table containing the Dataverse choices is displayed.
5. Join the Dataverse choices with your Dataverse table and store the view in a new database using a three-part naming convention - *[database-name].[schema-name].[table-name]*.

Azure Synapse Link for Dataverse

Quickstart: Use serverless SQL pool

Export Dataverse data in Delta Lake format

Summarize this article for me

Use Azure Synapse Link for Dataverse to export your Microsoft Dataverse data in Delta Lake format. Delta Lake is the native format for Microsoft Fabric as well as many other tools like Azure Databricks. Exporting data in Delta lake format directly from Dataverse eliminates the need to have a separate Delta Lake conversion processes on your own and accelerates time to insight. This article provides information about this feature and shows you how to perform the following tasks:

- Explains Delta Lake and Parquet and why you should export data in this format.
- Export your Dataverse data to your Azure Synapse Analytics workspace in Delta Lake format with the Azure Synapse Link.
- Monitor your Azure Synapse Link and data conversion.
- View your data from Azure Data Lake Storage Gen2.
- View your data from Synapse Workspace.
- View your data in Microsoft Fabric.

What is Delta Lake?

Delta Lake is an open-source project that enables building a lakehouse architecture on top of data lakes. Delta Lake provides ACID (atomicity, consistency, isolation, and durability) transactions, scalable metadata handling, and unifies streaming and batch data processing on top of existing data lakes. Azure Synapse Analytics is compatible with Linux Foundation Delta Lake. The current version of Delta Lake included with Azure Synapse has language support for Scala, PySpark, and .NET. More information: What is Delta Lake?. You can also learn more from the Introduction to Delta Tables video.

Apache Parquet is the baseline format for Delta Lake, enabling you to leverage the efficient compression and encoding schemes that are native to the format. Parquet file format uses column-wise compression. It's efficient and saves storage space. Queries that fetch specific column values need not read the entire row data thus improving performance. Therefore, serverless SQL pool needs less time and fewer storage requests to read the data.

Why use Delta Lake?

- **Scalability**: Delta Lake is built on top of Open-source Apache license, which is designed to meet industry standards for handling large-scale data processing workloads.
- **Reliability**: Delta Lake provides ACID transactions, ensuring data consistency and reliability even in the face of failures or concurrent access.

- **Performance**: Delta Lake leverages the columnar storage format of Parquet, providing better compression and encoding techniques, which can lead to improved query performance compared to query CSV files.
- **Cost-effective**: The Delta Lake file format is a highly compressed data storage technology that offers significant potential storage savings for businesses. This format is specifically designed to optimize data processing and potentially reduce the total amount of data processed or running time required for on-demand computing.
- **Data protection compliance**: Delta Lake with Azure Synapse Link provides tools and features including soft-delete and hard-delete to comply various data privacy regulations, including General Data Protection Regulation (GDPR).

How Delta Lake works with Azure Synapse Link for Dataverse?

When setting up an Azure Synapse Link for Dataverse, you can enable the **export to Delta Lake** feature and connect with a Synapse workspace and Spark pool. Azure Synapse Link exports the selected Dataverse tables in CSV format at designated time intervals, processing them through a Delta Lake conversion Spark job. Upon the completion of this conversion process, CSV data is cleaned up for storage saving. Additionally, a series of maintenance jobs are scheduled to run on a daily basis, automatically performing compaction and vacuuming processes to merge and clean up data files to further optimize storage and improve query performance.

> ⓘ **Important**
>
> - If you're upgrading from CSV to Delta Lake with existing custom views, we recommend updating the script to replace all **partitioned** tables to **non_partitioned.** Do this by looking for instances of `_partitioned` and replace them with an empty string.
> - For the Dataverse configuration, append-only is enabled by default to export CSV data in `appendonly` mode. The Delta Lake table will have an in-place update structure because the Delta Lake conversion comes with a periodic merge process.
> - You need to provision a Spark pool (compute resources) in your own Azure subscription for Delta conversion. This Spark pool is used to perform periodic Delta conversions based on the time interval chosen by you.
> - There are no costs incurred with the creation of Spark pools. Charges are only incurred once a Spark job is executed on the target Spark pool and the Spark instance is instantiated on demand. These costs are related to the usage of Azure Synapse workspace Spark and are billed monthly. The cost of conducting Spark

computing mainly depends on the time interval for incremental update and the data volumes. More information: Azure Synapse Analytics pricing

- You need to create a Spark pool with the current version (go to the version table in In-place upgrade from previous versions). If you're using a previous Spark version, perform an in-place upgrade for your existing profiles. More information: In-place upgrade from previous versions

> **Note**
>
> The Azure Synapse Link status in Power Apps (make.powerapps.com) reflects the Delta Lake conversion state:
>
> - `Count` shows the number of records in the Delta Lake table.
> - `Last synchronized on` Datetime represents the last successful conversion timestamp.
> - `Sync status` is shown as **active** once the data sync and Delta Lake conversion completes, indicating that the data is ready for consumption.

Prerequisites

- Dataverse: You must have the Dataverse **system administrator** security role. Additionally, tables you want to export via Azure Synapse Link must have the **Track changes** property enabled. More information: Advanced options
- Azure Data Lake Storage Gen2: You must have an Azure Data Lake Storage Gen2 account and **Owner** and **Storage Blob Data Contributor** role access. Your storage account must enable **Hierarchical namespace** and **public network access** for both initial setup and delta sync. **Allow storage account key access** is required only for the initial setup.
- Synapse workspace: You must have a Synapse workspace and **Owner** role in access control(IAM) and the **Synapse Administrator** role access within the Synapse Studio. The Synapse workspace must be in the same region as your Azure Data Lake Storage Gen2 account. The storage account must be added as a linked service within the Synapse Studio. To create a Synapse workspace, go to Creating a Synapse workspace.
- An Apache Spark pool in the connected Azure Synapse workspace with the current Apache Spark version (go to version requirements) using this recommended Spark Pool configuration. For information about how to create a Spark Pool, go to Create new Apache Spark pool.
- The Microsoft Dynamics 365 minimum version requirement to use this feature is 9.2.22082. More information: Opt in to early access updates

Recommended Spark Pool configuration

This configuration can be considered a bootstrap step for average use cases.

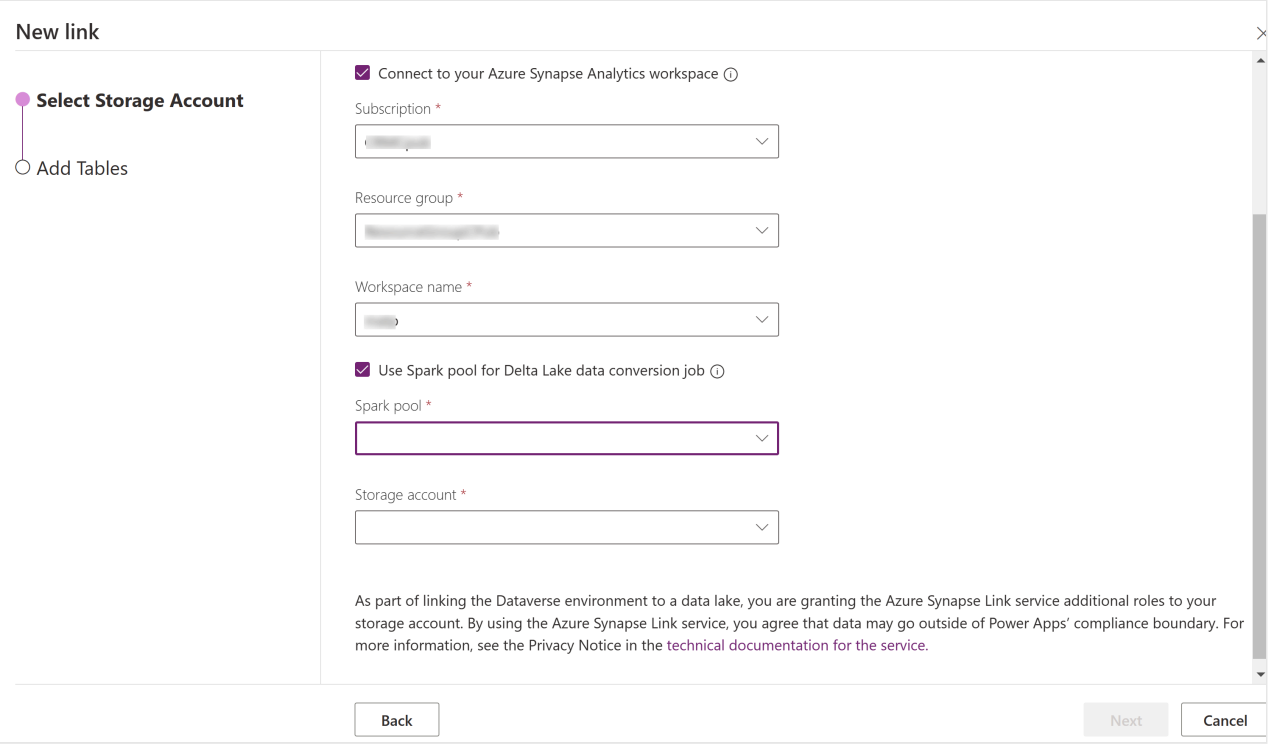
- Node size: small (4 vCores / 32 GB)
- Autoscale: Enabled
- Number of nodes: 3 to 10 (or 20 if needed. [1]More information below.)
- Automatic pausing: Enabled
- Number of minutes idle: 5
- Apache Spark: 3.5 (go to version requirements for latest)
- Dynamically allocate executors: Enabled
- Default number of executors: 1 to 9

> **Important**
>
> - Use the Spark pool exclusively for Delta Lake conversation operation with Synapse Link for Dataverse. For optimal reliability and performance, avoid running other Spark jobs using the same Spark pool.
> - You might need to increase the number of nodes of the Spark pool if you expect a large number of rows to be processed. If the size of the Spark pool is insufficient, Delta conversion jobs might fail
> - The same Spark pool is used by the system to run a nightly job that compacts Delta files in the lake between 11 PM and 6 AM local time. The system determines the night time to run this job based on the location of your Dataverse environment. You can't provide a specific time window. This option reduces the size of Delta files by merging files known as "compaction." In rare cases, this job might interfere with the incremental conversion job. You can increase the number of nodes to 20 in case you notice these failures.
> - You're only charged for the spark pool nodes actually utilized. Increasing the number of nodes might not result in higher charges.

Connect Dataverse to Synapse workspace and export data in Delta Lake format

1. Sign into Power Apps and select the environment you want.
2. On the left navigation pane, select **Azure Synapse Link**. If the item isn't in the side panel pane, select ...More and then select the item you want.

3. On the command bar, select **+ New link**
4. Select **Connect to your Azure Synapse Analytics workspace**, and then select the **Subscription**, **Resource group**, and **Workspace name**.
5. Select **Use Spark pool for processing**, and then select the precreated **Spark pool** and **Storage account**.



6. Select **Next**.
7. Add the tables you want to export, and then select **Advanced**.
8. Optionally, select **Show advanced configuration settings** and enter the time interval, in minutes, for how often the incremental updates should be captured.
9. Select **Save**.

Monitor your Azure Synapse Link and data conversion

1. Select the Azure Synapse Link you want, and then select **Go to Azure Synapse Analytics workspace** on the command bar.
2. Select **Monitor** > **Apache Spark applications**. More information: Use Synapse Studio to monitor your Apache Spark applications

View your data from Synapse workspace

1. Select the Azure Synapse Link you want, and then select **Go to Azure Synapse Analytics workspace** on the command bar.
2. Expand **Lake Databases** on the left pane, select **dataverse-***environmentNameorganizationUniqueName*, and then expand **Tables**. All Parquet tables are listed and available for analysis with the naming convention *DataverseTableName*. **(Non_partitioned Table)**.

> **Note**
>
> Don't use tables with the naming convention *_partitioned*. When you choose Delta parquet as the format, tables with the *_partition* naming convention are used as staging tables and removed after they're used by the system.

View your data from Azure Data Lake Storage Gen2

1. Select the Azure Synapse Link you want, and then select **Go to Azure data lake** on the command bar.
2. Select the **Containers** under **Data Storage**.
3. Select **dataverse- **environmentName-organizationUniqueName*. All parquet files are stored in the **deltalake** folder.

In-place upgrade from previous versions

Current versions and requirements

The following table shows the current and previous versions for Azure Synapse Link with Delta Lake. When you upgrade or create a new configuration, use the current versions listed below.

Expand table

Component	Current version	Previous version	Status	Reference link
Apache Spark	3.5	3.4	3.4 retired	Apache Spark 3.4 runtime
Delta Lake	3.0	2.4	-	Delta Lake compatibility

Upgrade from Apache Spark 3.4 to 3.5

In accordance with the Synapse runtime for Apache Spark lifecycle policy, Azure Synapse runtime for Apache Spark 3.4 is retired. After the end of the support date, the retired runtimes

are unavailable for new Spark pools and existing workflows with Spark 3.4 pools won't be executed and metadata temporarily remains in the Synapse workspace. More information: Azure Synapse Runtime for Apache Spark 3.4.

To ensure that your existing Synapse Link profiles continue to process data, upgrade your Synapse Link profiles using the in-place upgrade process here.

Prerequisites for upgrade

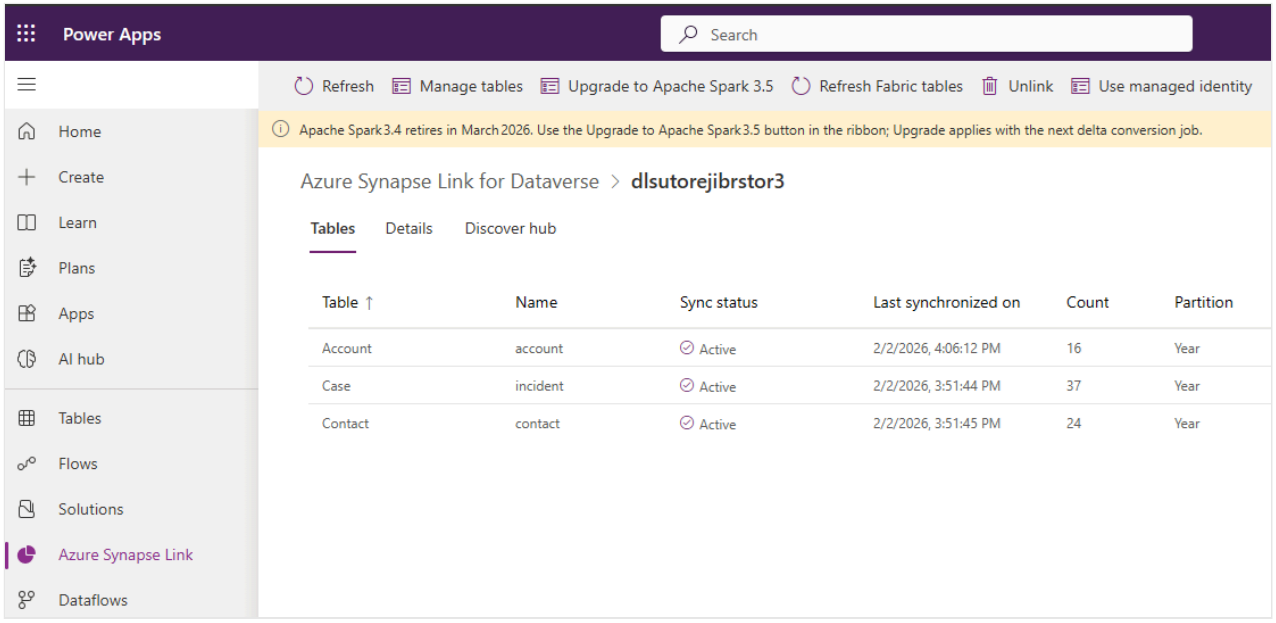
- You must have an existing Azure Synapse Link for Dataverse Delta lake profile running with a previous Apache Spark version.
- You must create a new Synapse Spark pool with the current Spark version (go to versions and requirements table), *using the same or higher nodes hardware configuration within the same Synapse workspace*. For information about how to create a Spark pool, go to Create new Apache Spark pool. This Spark pool should be created independent of your existing pool - *don't delete your current Spark pool or create the new pool with the same name*.

Upgrade steps

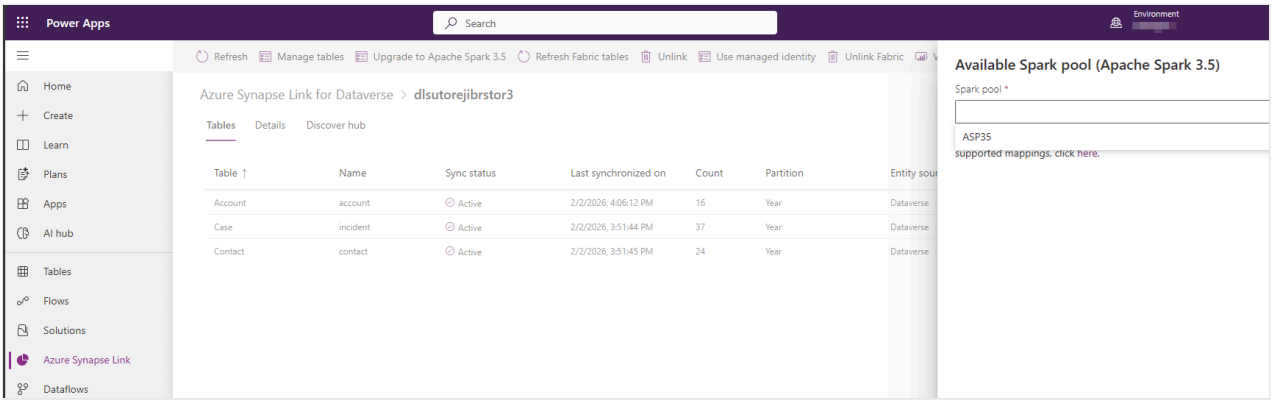
1. Sign in to Power Apps and select your preferred environment.

2. On the left navigation pane, select **Azure Synapse Link**. If the item isn't in the left navigation pane, select **...More** and then select the item you want.

3. If you're using a retired Spark version, an error message indicating that support has ended appears. Select the upgrade button in the ribbon to begin the upgrade process.



4. In the upgrade dialog, select the available Spark pool with the current version from the dropdown list.



5. Select **Update** to complete the upgrade.

> **Note**
>
> - The Spark pool upgrade occurs only when a new Delta Lake conversion Spark job is triggered. Ensure you have at least one data change after selecting **Update**.
> - After selecting **Update**, the upgrade process can take up to 48 hours to complete due to the cache. During this time, the old Spark pool continues to be used for Delta Lake conversion until the upgrade is fully applied in the backend. Don't delete the old Spark pool until you have confirmed that the new Spark pool is being used for Delta Lake conversion jobs. If the new Spark pool isn't used for Delta Lake conversion after two days, contact Microsoft to get support.

What is Azure Synapse Link for Dataverse?

Last updated on 03/11/2026

Ingest exported Dataverse data with Azure Data Factory

Article • 04/13/2022

After exporting data from Microsoft Dataverse to Azure Data Lake Storage Gen2 with Azure Synapse Link for Dataverse, you can use Azure Data Factory to create dataflows, transform your data, and run analysis.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

This article shows you how to perform the following tasks:

1. Set the Data Lake Storage Gen2 storage account with the Dataverse data as a *source* in a Data Factory dataflow.
2. Transform the Dataverse data in Data Factory with a dataflow.
3. Set the Data Lake Storage Gen2 storage account with the Dataverse data as a *sink* in a Data Factory dataflow.
4. Run your dataflow by creating a pipeline.

Prerequisites

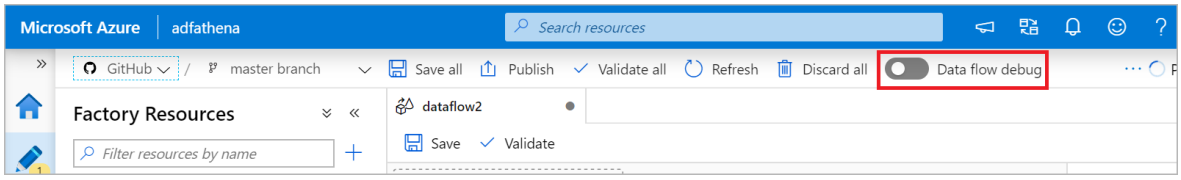
This section describes the prerequisites necessary to ingest exported Dataverse data with Data Factory.

- **Azure roles.** The user account that's used to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, go to the Azure portal, select your username in the upper-right corner, select ..., and then select **My permissions**. If you have access to multiple subscriptions, select the appropriate one. To create and manage child resources for Data Factory in the Azure portal—including datasets, linked services, pipelines, triggers, and integration runtimes—you must belong to the *Data Factory Contributor* role at the resource group level or above.

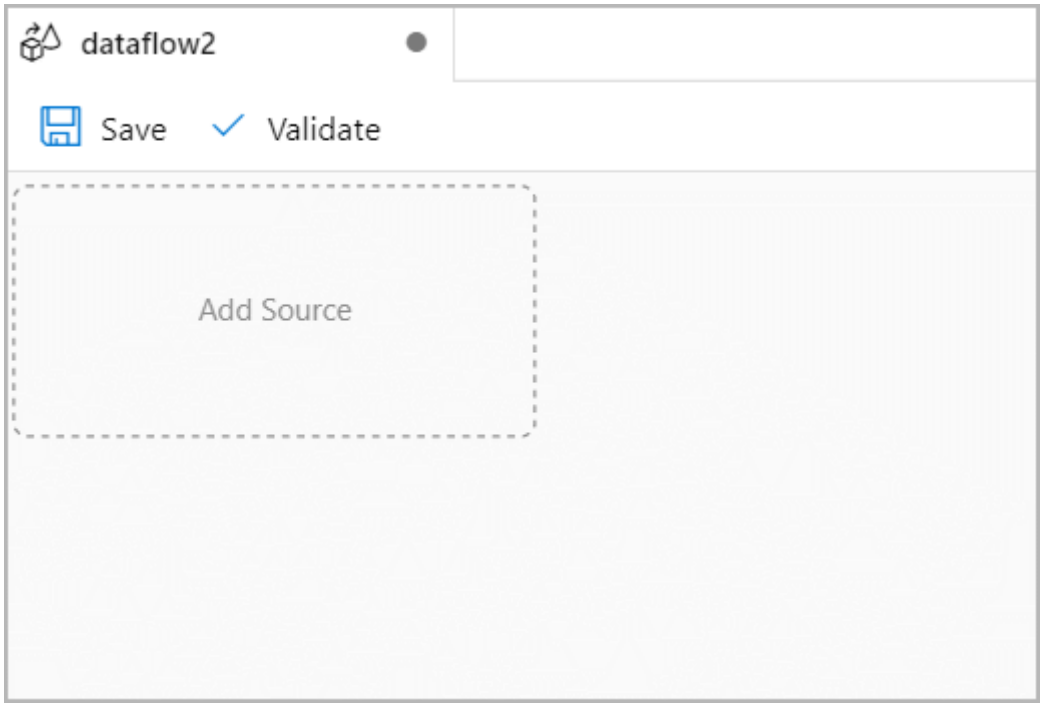
- **Azure Synapse Link for Dataverse.** This guide assumes that you've already exported Dataverse data by using Azure Synapse Link for Dataverse. In this example, the account table data is exported to the data lake.
- **Azure Data Factory.** This guide assumes that you've already created a data factory under the same subscription and resource group as the storage account containing the exported Dataverse data.

Set the Data Lake Storage Gen2 storage account as a source

1. Open Azure Data Factory and select the data factory that is on the same subscription and resource group as the storage account containing your exported Dataverse data. Then select **Create data flow** from the home page.
2. Turn on **Data flow debug** mode and select your preferred time to live. This might take up to 10 minutes, but you can proceed with the following steps.



3. Select **Add Source.**



4. Under **Source settings**, do the following:
    - **Output stream name**: Enter the name you want.

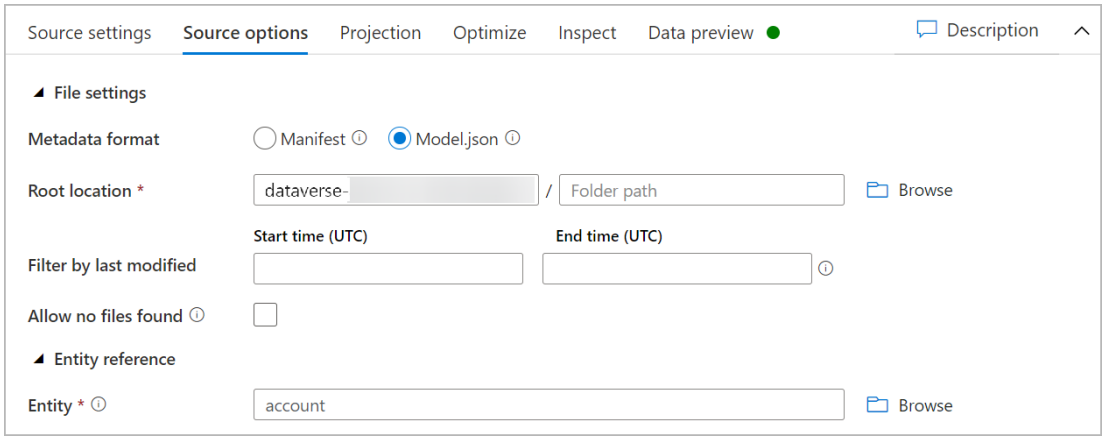
- **Source type**: Select **Inline**.
- **Inline dataset type**: Select **Common Data Model**.
- **Linked Service**: Select the storage account from the drop-down menu, and then link a new service by providing your subscription details and leaving all default configurations.
- **Sampling**: If you want to use all your data, select **Disable**.

5. Under **Source options**, do the following:

   - **Metadata format**: Select **Model.json**.

   - **Root location**: Enter the container name in the first box (**Container**) or **Browse** for the container name and select **OK**.

   - **Entity**: Enter the table name or **Browse** for the table.



6. Check the **Projection** tab to ensure that your schema has been imported successfully. If you do not see any columns, select **Schema options** and check the **Infer drifted column types** option. Configure the formatting options to match your data set then select **Apply**.

7. You can view your data in the **Data preview** tab to ensure the Source creation was complete and accurate.

Transform your Dataverse data

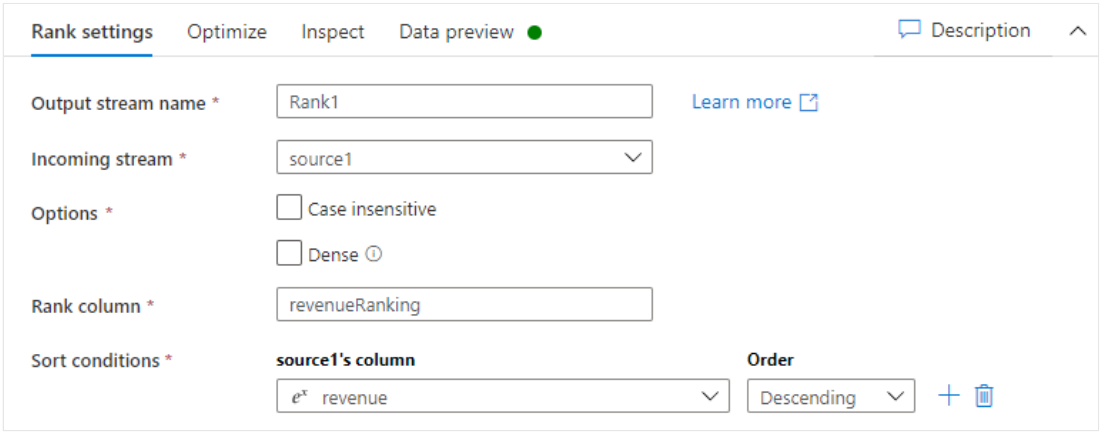
After setting the exported Dataverse data in the Azure Data Lake Storage Gen2 account as a source in the Data Factory dataflow, there are many possibilities for transforming your data. More information: Azure Data Factory

Follow these instructions to create a rank for the each row by the *revenue* field of the account table.

1. Select + in the lower-right corner of the previous transformation, and then search for and select **Rank**.

2. On the **Rank settings** tab, do the following:

    - **Output stream name**: Enter the name you want, such as *Rank1*.
    - **Incoming Stream**: Select the source name you want. In this case, the source name from the previous step.
    - **Options**: Leave the options unchecked.
    - **Rank column**: Enter the name of the rank column generated.
    - **Sort conditions**: Select the *revenue* column and sort by *Descending* order.



3. You can view your data in the **data preview** tab where you will find the new *revenueRank* column at the right-most position.

Set the Data Lake Storage Gen2 storage account as a sink

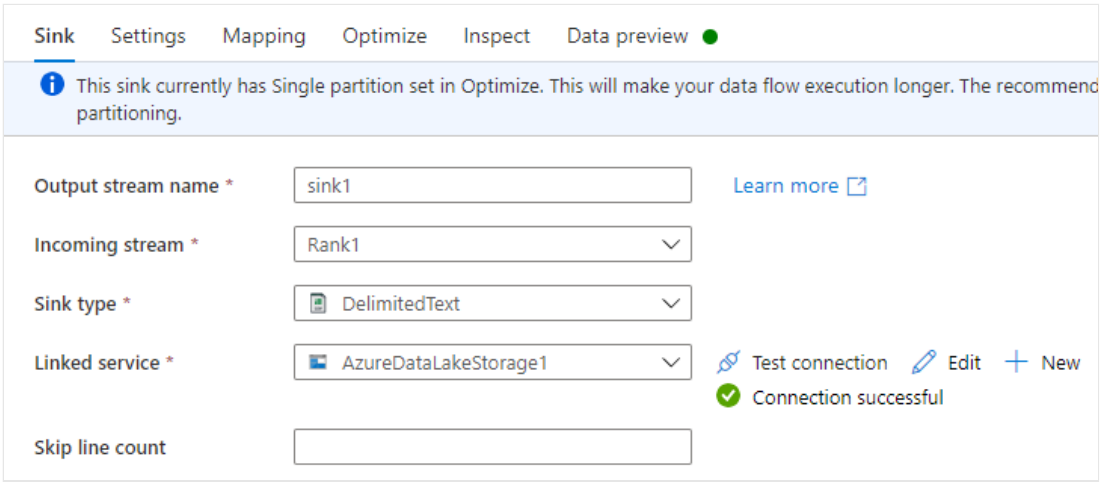
Ultimately, you must set a sink for your dataflow. Follow these instructions to place your transformed data as a delimited text file in the data lake.

1. Select + in the lower-right corner of the previous transformation, and then search for and select **Sink**.

2. On the **Sink** tab, do the following:

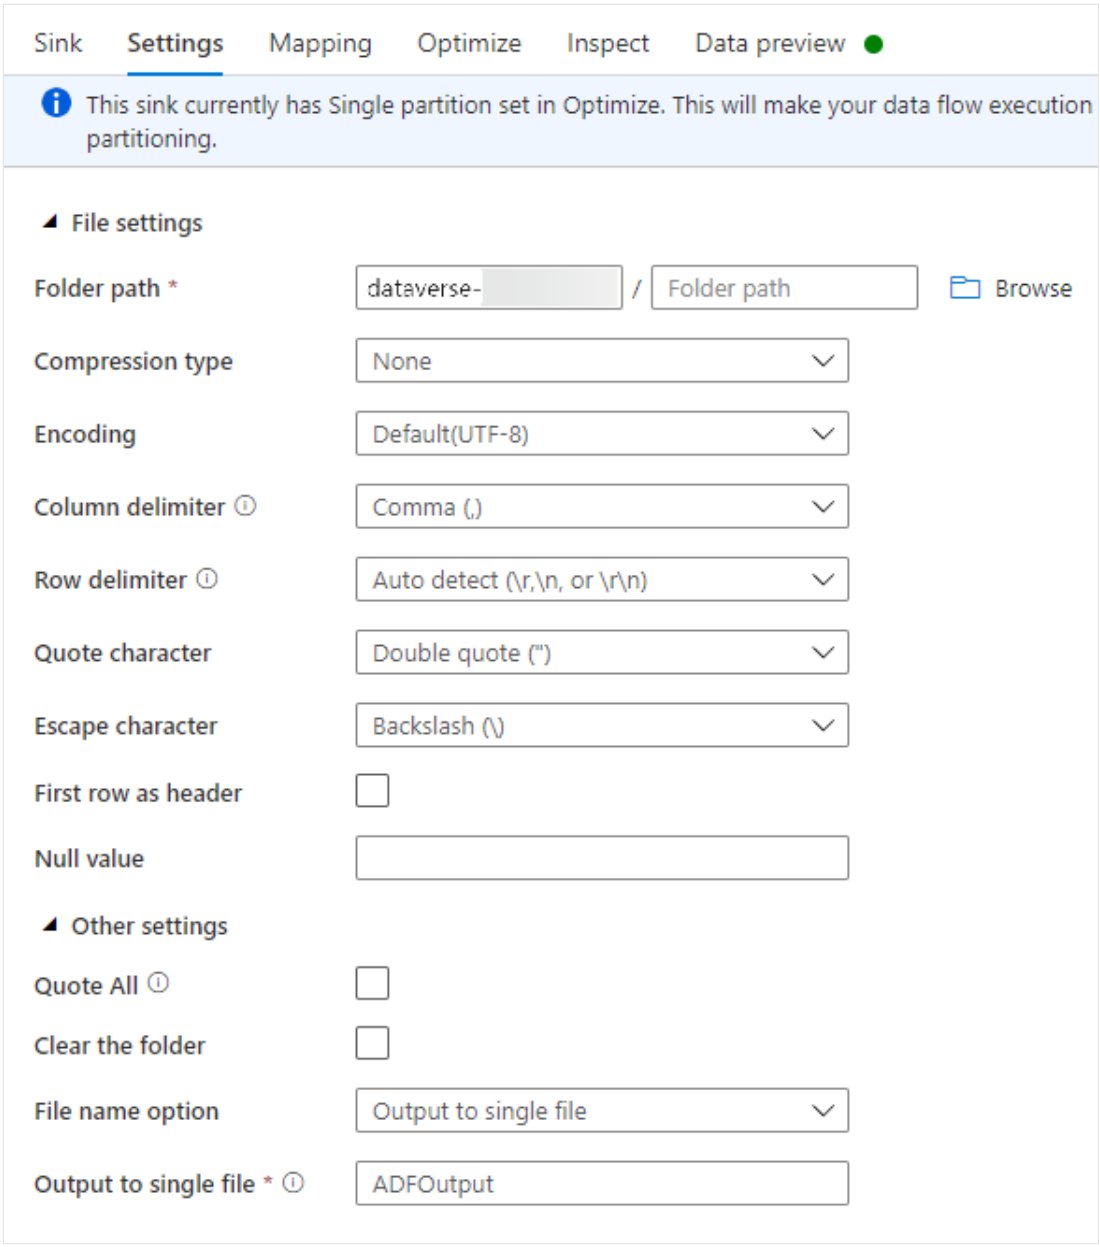
    - **Output stream name**: Enter the name you want, such as *Sink1*.
    - **Incoming stream**: Select the source name you want. In this case, the source name from the previous step.

- **Sink type**: Select **DelimitedText**.
- **Linked service**: Select your Data Lake Storage Gen2 storage container that has the data you exported by using the Azure Synapse Link for Dataverse service.



3. On the **Settings** tab, do the following:

- **Folder path**: Enter the container name in the first box (**File system**) or **Browse** for the container name and select **OK**.
- **File name option**: Select **output to single file**.
- **Output to single file**: Enter a file name, such as *ADFOutput*
- Leave all other default settings.

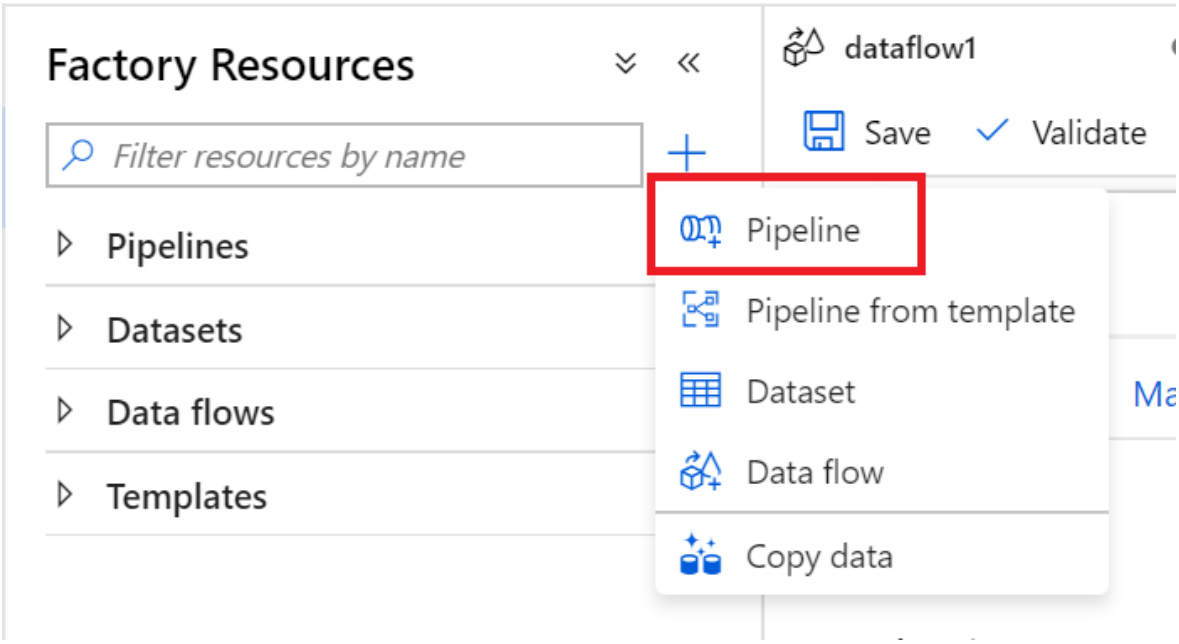


4. On the **Optimize** tab, set the **Partition option** to **Single partition**.

5. You can view your data in the **Data preview** tab.

Run your dataflow

1. In the left pane under **Factory Resources**, select +, and then select **Pipeline**.



2. Under **Activities**, select **Move & Transform**, and then drag **Data flow** to the workspace.

3. Select **Use existing data flow**, and then select the dataflow that you created in the previous steps.

4. Select **Debug** from the command bar.

5. Let the dataflow run until the bottom view shows that is has been completed. This might take a few minutes.

6. Go to the final destination storage container, and find the transformed table data file.

Analyze Dataverse data in Azure Data Lake Storage Gen2 with Power BI

Copy Dataverse data from multiple data Lakes to a single data lake

Article • 02/15/2022

After exporting data from Microsoft Dataverse to Azure Data Lake Storage Gen2 with Azure Synapse Link for Dataverse, you can use Azure Data Factory to create a pipeline that copies data from multiple data lakes to a single data lake.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

This article shows you how to perform the following tasks:

1. Create a pipeline from an official Microsoft template.
2. Configure the template.
3. Run the pipeline.

Prerequisites

This section describes the prerequisites necessary to copy exported Dataverse data from multiple data lakes to a single data lake.

- **Azure roles.** The user account that's used to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, go to the Azure portal, select your username in the upper-right corner, select **...**, and then select **My permissions**. If you have access to multiple subscriptions, select the appropriate one. To create and manage child resources for Data Factory in the Azure portal—including datasets, linked services, pipelines, triggers, and integration runtimes—you must belong to the *Data Factory Contributor* role at the resource group level or above.
- **Azure Synapse Link for Dataverse.** This guide assumes that you've already exported Dataverse data to multiple data lakes by using Azure Synapse Link for Dataverse.

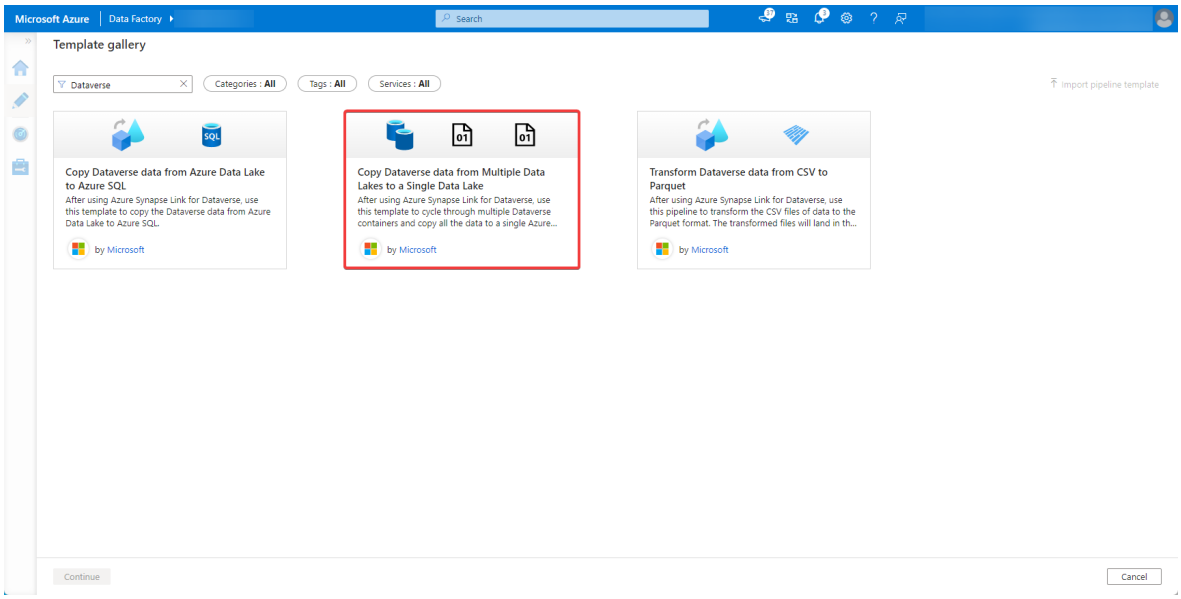
- **Azure Data Factory.** This guide assumes that you've already created a data factory under the same subscription and resource group as the storage account containing the exported Dataverse data.

Copy Dataverse data to a single data lake

1. Open Azure Data Factory and select the data factory that is on the same subscription and resource group as the storage accounts containing your exported Dataverse data. Then select **Author** from the left panel.

2. Select + > **Pipeline** > **Template gallery**.

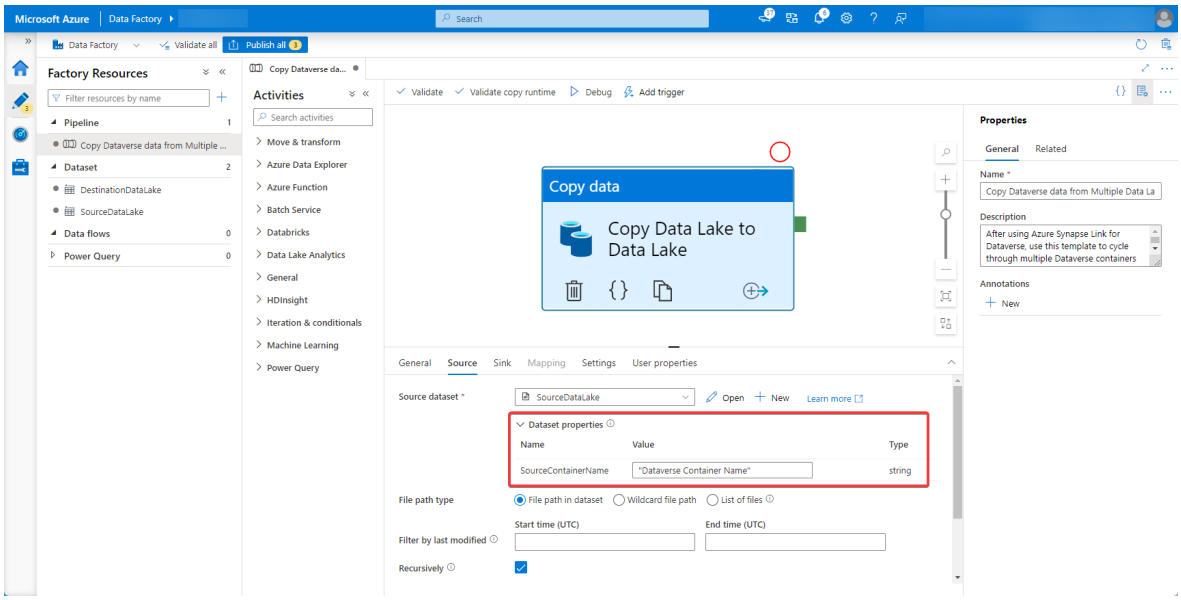
3. Search for and select the **Copy Dataverse data from Multiple Data Lakes to a Single Data Lake** template created by Microsoft.



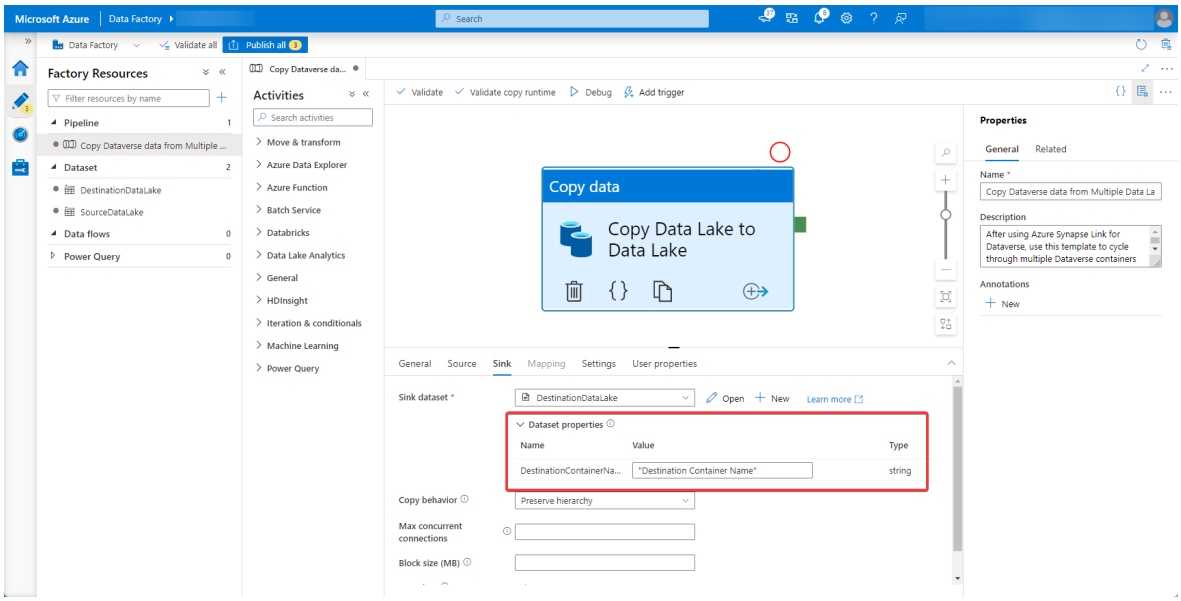
4. Select a **Linked service** for the *SourceDataLake* and the *DestinationDataLake*. Parameterize the *SourceDataLake* **Linked Service** to iterate through multiple data lakes. More information Parameterize linked services in Azure Data Factory and Azure Synapse Analytics.

5. Select **Use this template**.

6. Under the **Source** tab, replace the *SourceContainerName* with the source Dataverse data lake.



7. On the **Sink** tab, replace the *DestinationContainerName* with the destination container name for your copied Dataverse data.



8. To run the pipeline, select **Debug** from the top bar and optionally **Add trigger** to copy data on a schedule.

Azure Synapse Link for Dataverse

Transform Dataverse data from CSV to Parquet with a pipeline template

Article • 02/15/2022

After exporting data from Microsoft Dataverse to Azure Data Lake Storage Gen2 with Azure Synapse Link for Dataverse, you can use Azure Data Factory to create a pipeline that copies data from the data lake to Azure SQL.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

This article shows you how to perform the following tasks:

1. Create a pipeline from a Microsoft template.
2. Configure the template.
3. Run the pipeline.

Prerequisites

This section describes the prerequisites necessary to transform Dataverse data to from CSV to Parquet.

- **Azure roles.** The user account that's used to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, go to the Azure portal, select your username in the upper-right corner, select **...**, and then select **My permissions**. If you have access to multiple subscriptions, select the appropriate one. To create and manage child resources for Data Factory in the Azure portal—including datasets, linked services, pipelines, triggers, and integration runtimes—you must belong to the *Data Factory Contributor* role at the resource group level or above.
- **Azure Synapse Link for Dataverse.** This guide assumes that you've already exported Dataverse data by using Azure Synapse Link for Dataverse. In this example, the account table data is exported to the data lake.

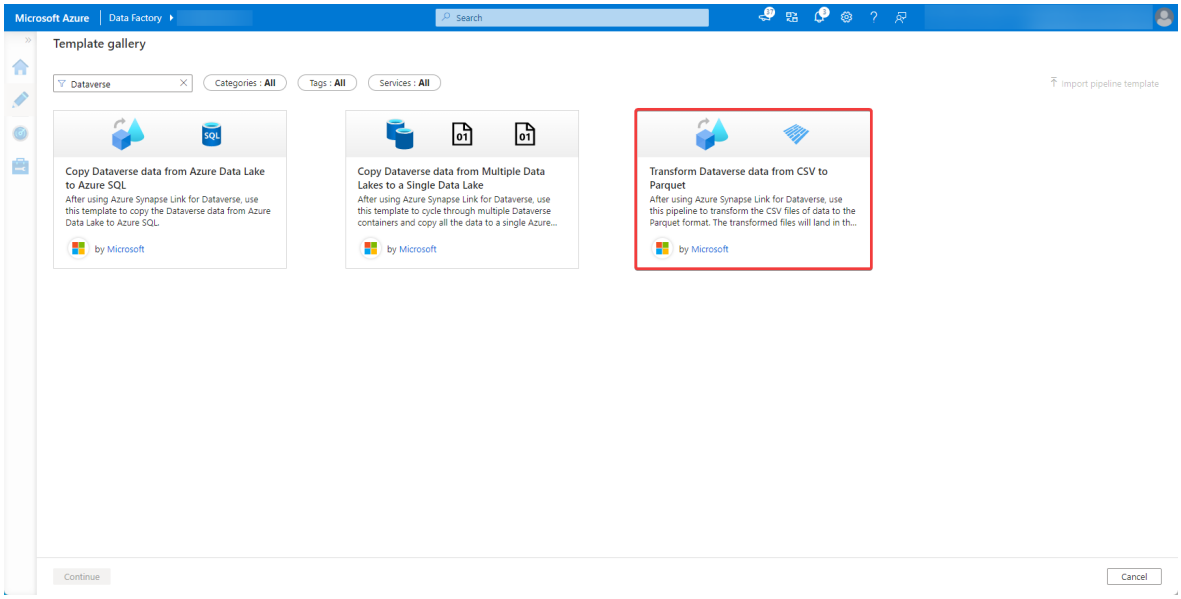
- **Azure Data Factory.** This guide assumes that you've already created a data factory under the same subscription and resource group as the storage account containing the exported Dataverse data.

Transform Dataverse data from CSV to Parquet with a Pipeline Template

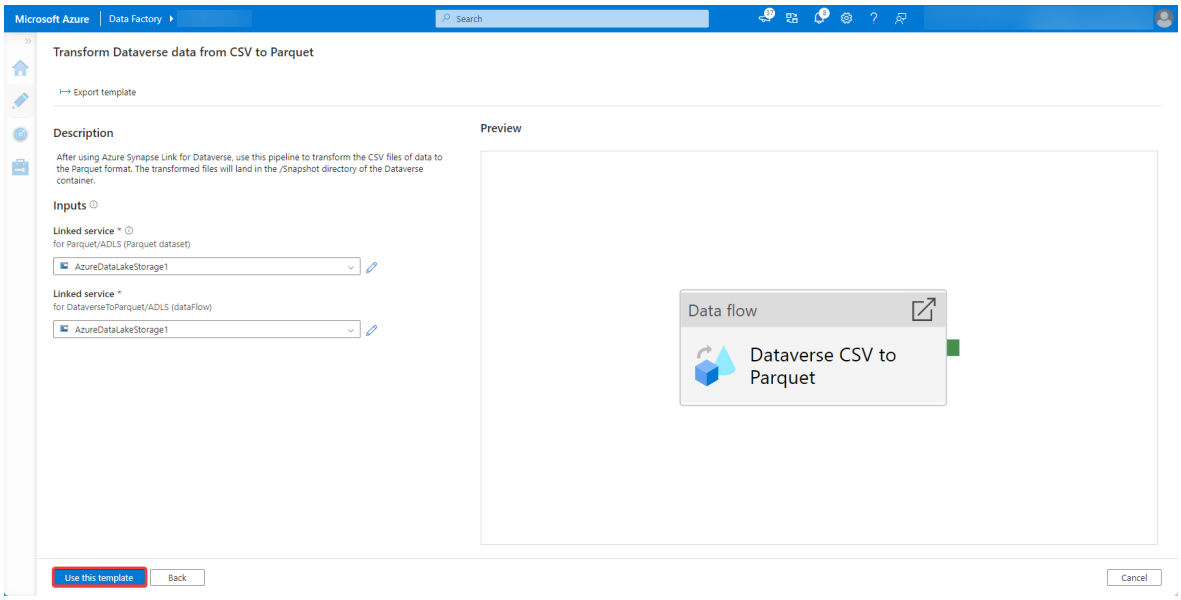
1. Open Azure Data Factory and select the data factory that is on the same subscription and resource group as the storage account containing your exported Dataverse data. Then select **Author** from the left panel.

2. Select + > **Pipeline** > **Template gallery**.

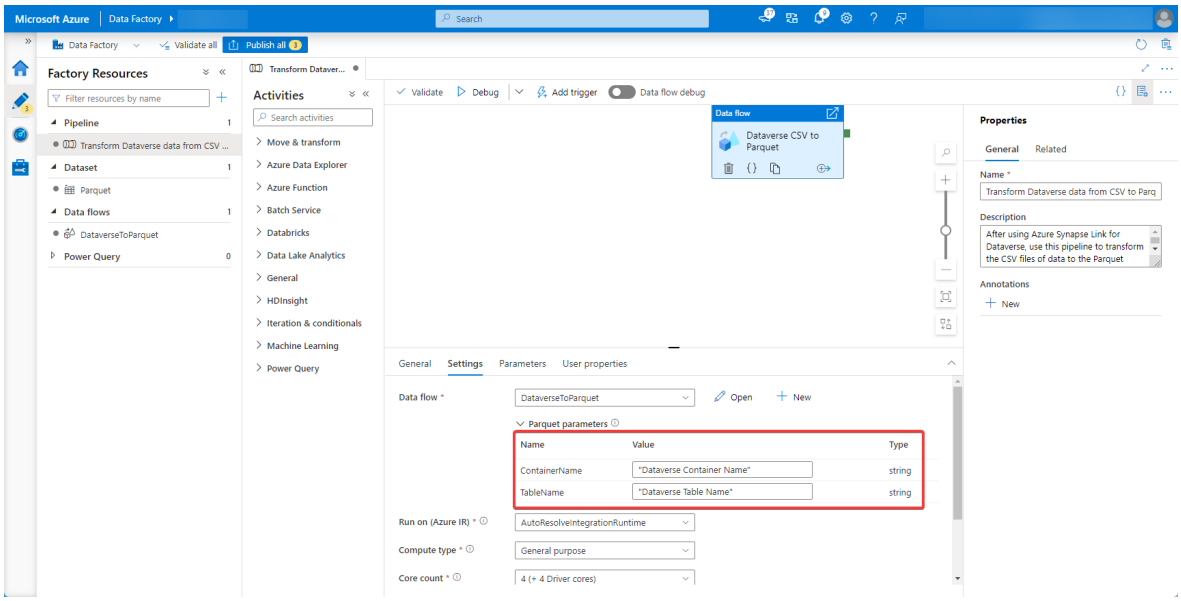
3. Search for and select the **Transform Dataverse data from CSV to Parquet** template created by Microsoft.



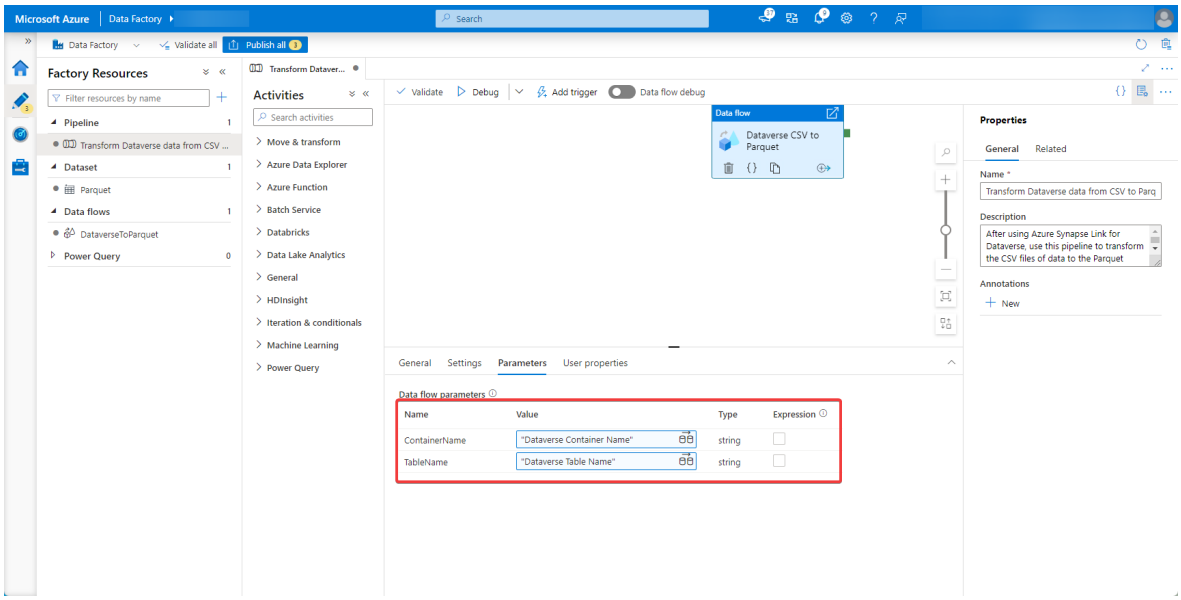
4. Input the Azure Data Lake Storage Gen2 account containing the exported Dataverse data for the first entry and the destination Azure Data Lake Storage Gen2 account where the parquet files will be created for the second entry. Select **Use this template**.



5. Select the data flow **Settings** tab and replace the values for *ContainerName* and *TableName*.



6. Select the data flow **Parameters** tab and replace the values for *ContainerName* and *TableName*.



7. Navigate to the pipeline and run it. Optionally, **Add trigger** to transform the data at specific time intervals.

Analyze Microsoft Dataverse data in Azure Data Lake Storage Gen2 with Power BI

Article • 02/15/2022

After exporting data from Microsoft Dataverse to Azure Data Lake Storage Gen2 with Azure Synapse Link for Dataverse, you can use Power BI to create business reports and analytics. This can be useful for sales managers and sales associates to refine and build additional reports and dashboards in Power BI.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

This article shows you how to perform the following tasks:

1. Connect the Data Lake Storage Gen2 storage container containing the exported Dataverse data to Power BI.
2. Create a report in Power BI that graphs account owners and their respective total account revenue.

Prerequisites

This section describes the prerequisites necessary to consume Dataverse data with Power BI by using the Azure Synapse Link for Dataverse service.

- **Power BI Desktop.** Get it now
- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse. In this example, the account table data is exported to the data lake and will generate a report by using the account table columns.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.

Connect the Data Lake Storage Gen2 storage to Power BI Desktop

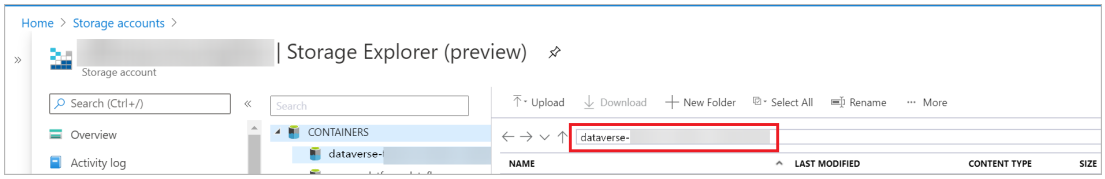
1. Open Power BI Desktop, and sign in.

2. Select **Get data** > **More**.

3. On the **Get Data** page, select **Azure** > **Azure Data Lake Storage Gen2** > **Connect.**

4. Enter the storage container name in the format `https://accountname.dfs.core.windows.net/containername/` and replace **accountname** and **containername** with your storage account's information.

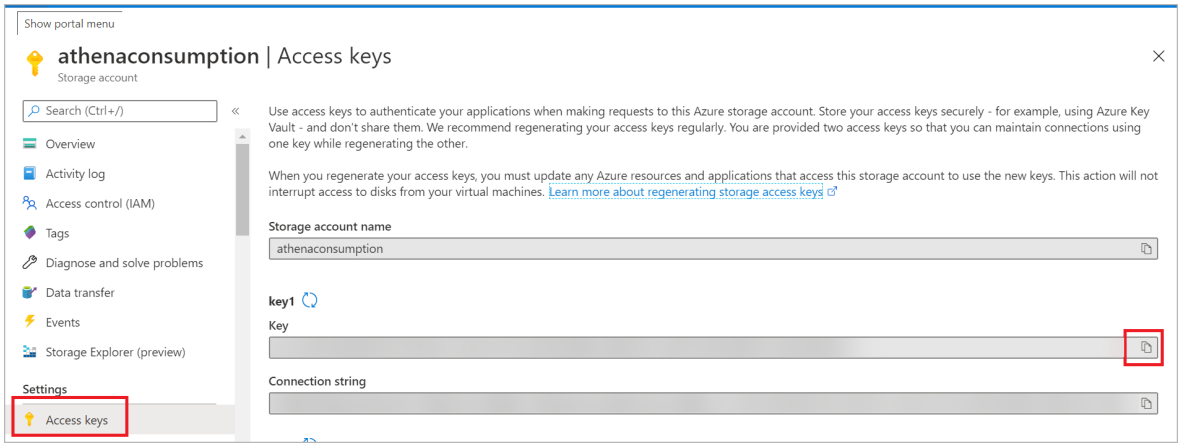
   - Find the storage account name by going to **Azure** > **Storage accounts**, and then select the Data Lake Storage Gen2 account that's populated with the exported Dataverse data.
   - Find the container name by going to **Storage Explorer (preview)** > **Containers** and select the name of the container with the exported Dataverse data.

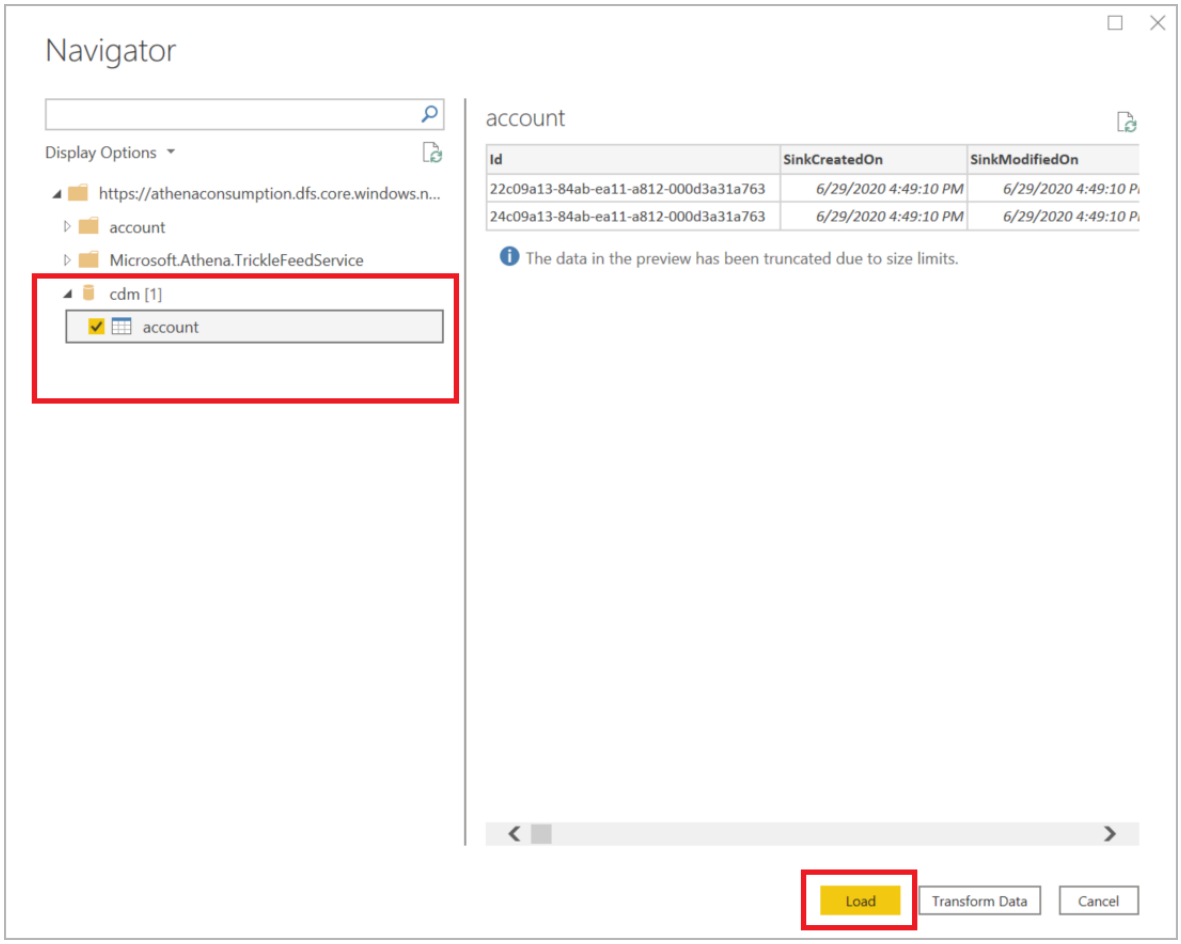
5. Select **CDM Folder View (Beta)**, and then select **OK**.

6. If prompted to sign in, you can sign in with your Microsoft Entra account or with the **Account key**. To sign in with an **Account key**, select the option from the left side bar.

7. Find the account key by going back to the storage account settings and selecting **Access keys** from the left pane. Copy the first key and paste it in Power BI. Select **OK**.

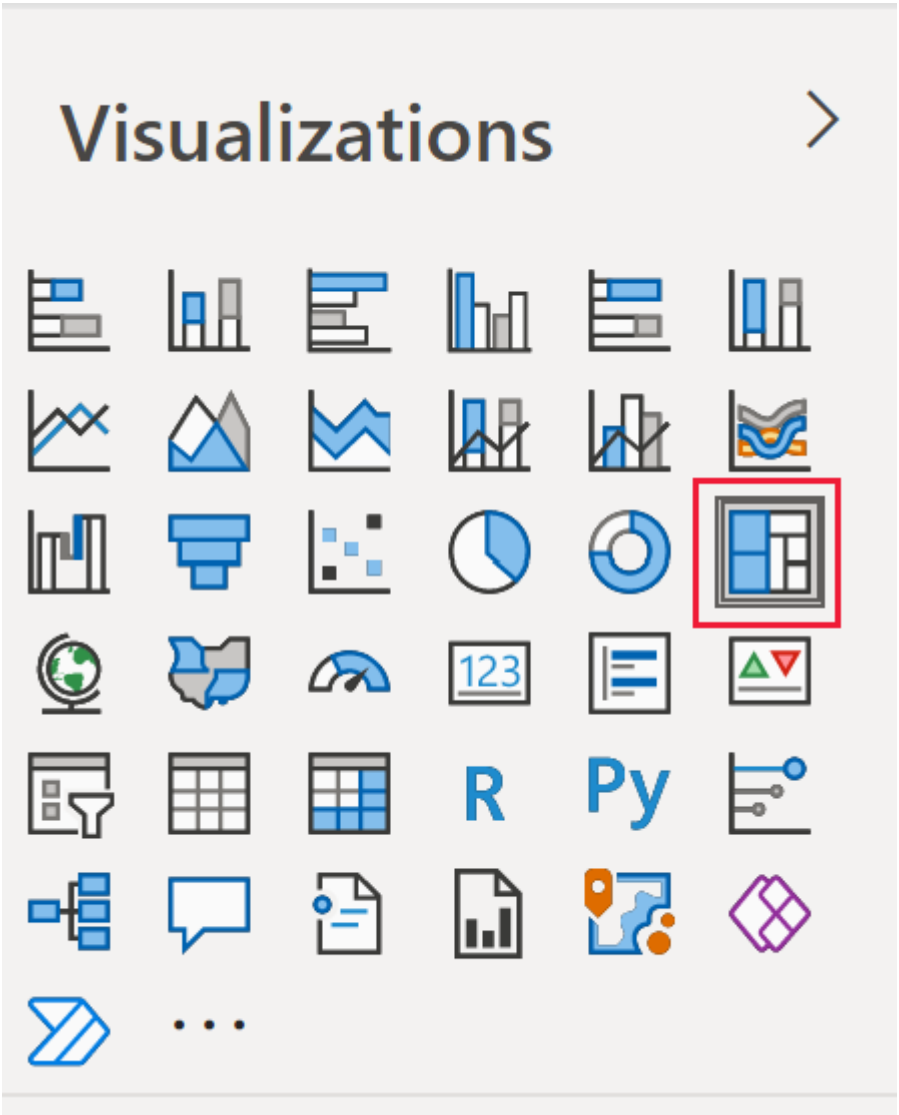
   


8. After successfully connecting to your storage account, expand the **cdm** directory and select the tables that you want to analyze. Then, select **Load**.

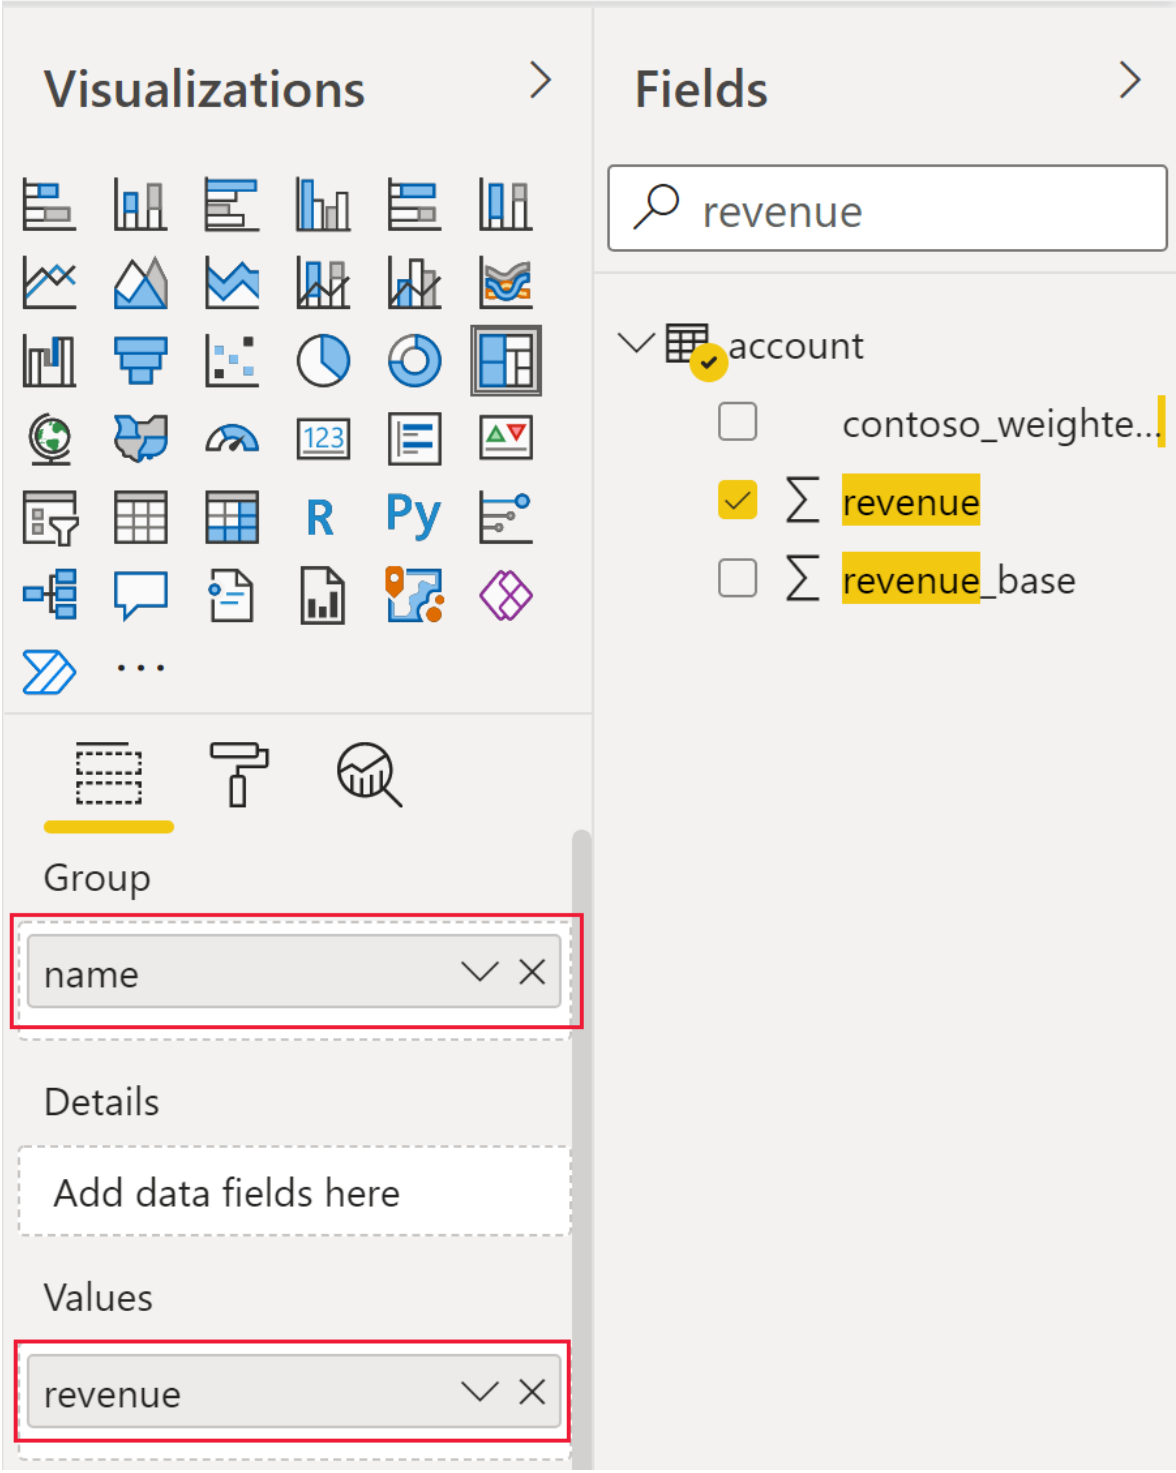


Create a Power BI report with account revenue by account name

1. Under the **Visualizations** menu, select **Treemap**.



2. On the **Columns** menu, search for and select the columns **name** and **revenue**. After you select them, the columns will appear on the **Visualizations** menu for the legend and values, respectively.



A tree map chart appears that separates each account name by color and indicates the total revenue for each account by size.

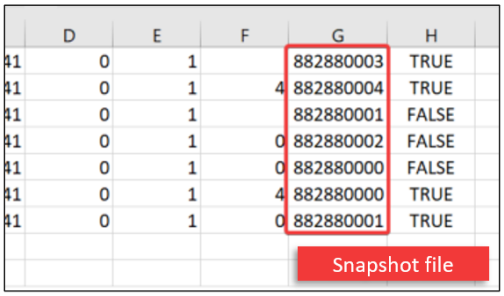
Ingest Dataverse data in Azure Data Lake Storage Gen2 with Azure Data Factory

Access Dataverse choices (option sets) with Azure Data Factory

Article • 02/15/2022

For columns that use Microsoft Dataverse choices, choice values are written as an integer label and not a text label to maintain consistency during edits. The integer-to-text label mapping is stored in the *Microsoft.Athena.TrickleFeedService/table-EntityMetadata.json* file. This article covers how to access the integer-to-text label mapping using Azure Data Factory.



> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

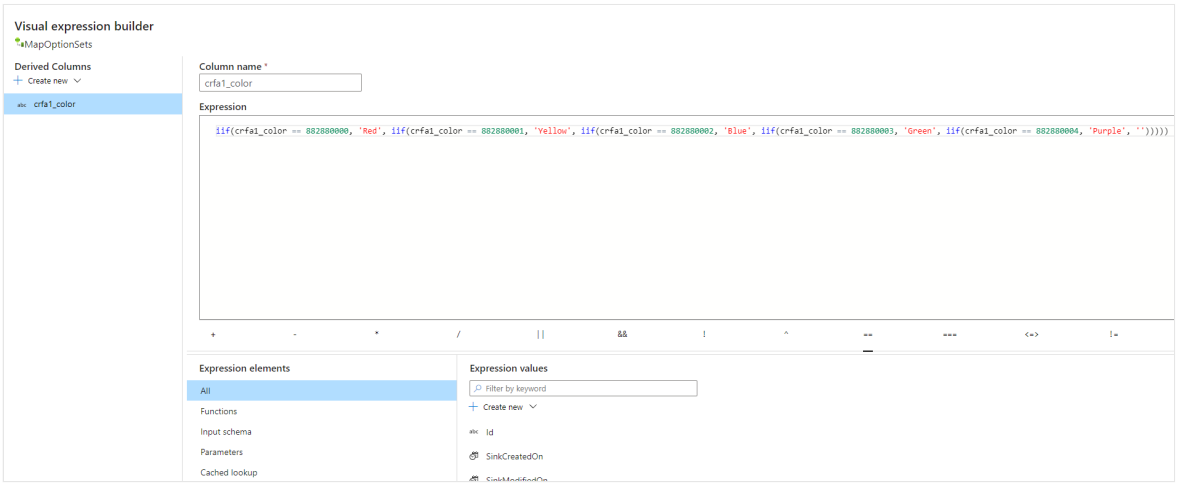
This section describes the prerequisites necessary to access Dataverse choices with Azure Data Factory after using the Azure Synapse Link for Dataverse service.

- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.

Consuming Dataverse choices with Azure Data Factory

To add a column containing the text label of the Dataverse choice using Azure Data Factory, complete the following steps:

1. Go to Azure Data Factory.
2. Create a new data flow and set the source as the Azure Data Lake Storage Gen2 with your Dataverse data.
3. Add a **Derived Column** transformation step and provide a new name for the column.
4. **Open expression builder** and build an expression with a series of `iff` functions to map the integer choice label to the text choice label that is found in the *Microsoft.Athena.TrickleFeedService/table-EntityMetadata.json* file.



5. Add a sink to the data flow and run the pipeline.

Azure Synapse Link for Dataverse

Access choice labels directly from Azure Synapse Link for Dataverse

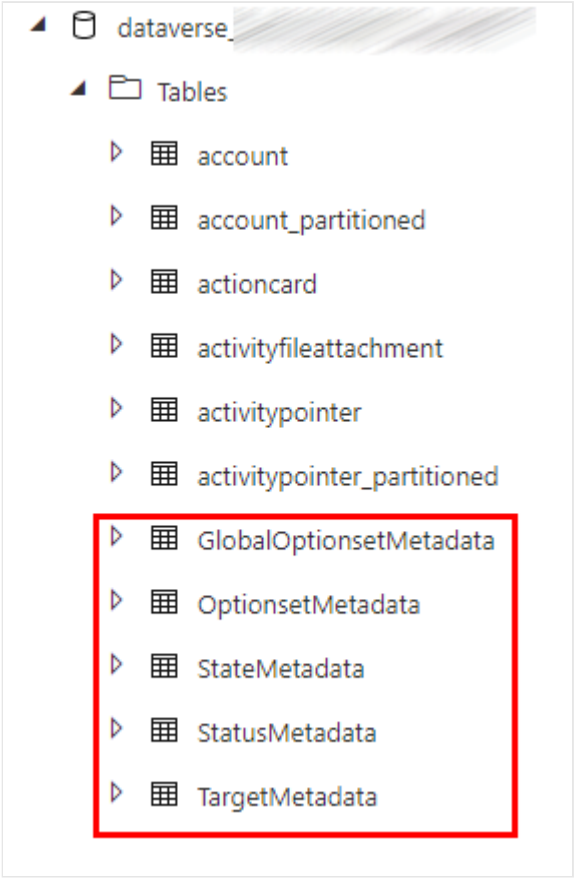
Article • 05/03/2022

Microsoft Dataverse provides rich metadata that can be used directly within Power Apps. A choice (picklist) is one of the most used types of columns that can be included in a table. It defines a set of options. When a choice is displayed in a form, it uses a drop-down list control. You can define a choice to use a set of options defined within itself (locally) or it can use a set of options defined elsewhere (globally), which can be used by other choice columns.

For more information about choice columns, go to Create and edit global choices overview.

After creating an Azure Synapse Link, the following five tables are created in a folder named **OptionsetMetadata** in Azure Data Lake Storage Gen2:

- OptionsetMetadata
- GlobalOptionsetMetadata
- StateMetadata
- StatusMetadata
- TargetMetadata



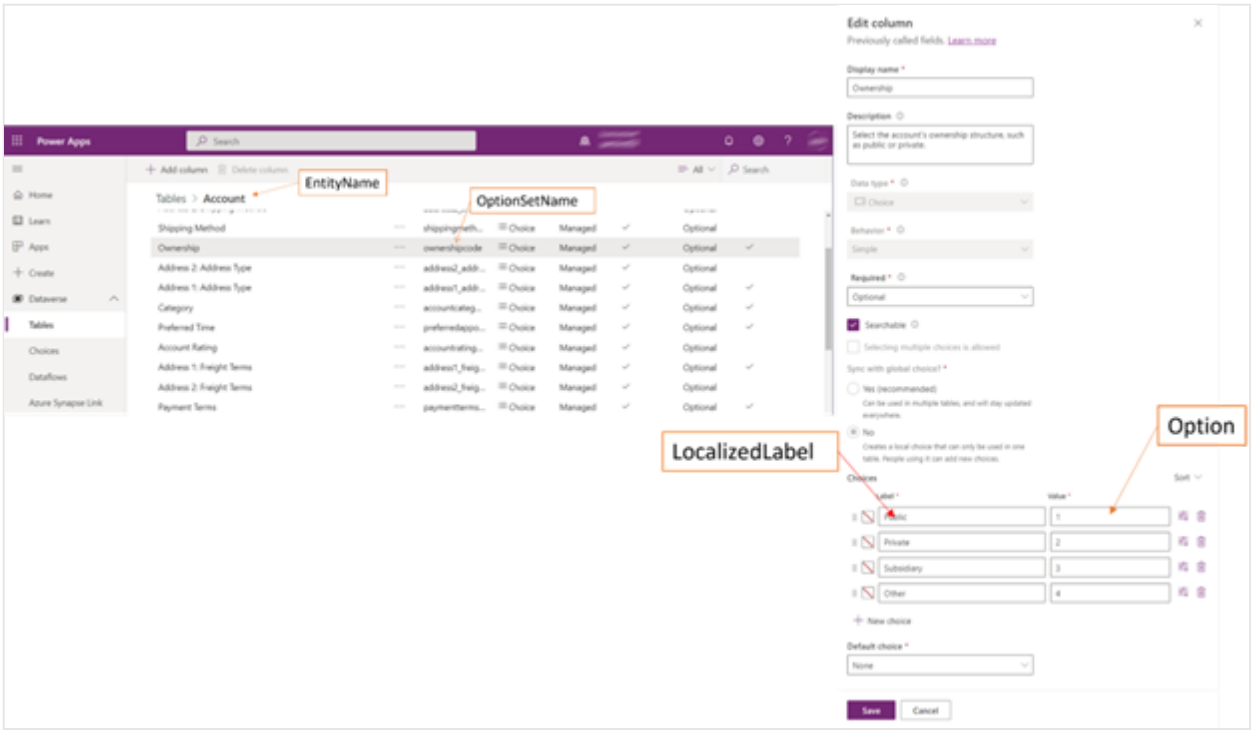
StateMetadata and **StatusMetadata** store the **State** and **Status** choice value to retrieve. **TargetMetadata** stores table relationships metadata to retrieve.

Column name	Data type	Sample value	Description
EntityName	String	account	Current Dataverse table name.
AttributeName	String	transactioncurrencyid	Current column name
ReferencedEntity	String	transactioncurrency	Related Dataverse table name
ReferencedAttribute	String	transactioncurrencyid	Related column name

More information: Table relationships overview.

OptionsetMetadata stores the local choices label metadata in the imported Dataverse tables. **GlobalOptionsetMetadata** stores the global choices label metadata and follows the same table schema plus one extra column, **GlobalOptionSetName**, a combination of table and choice name.

Column name	Data type	Sample value	Description
EntityName	String	account	Dataverse table name.
OptionSetName	String	ownershipcode	Column name.
Option	Bigint	1	User-specified numerical label when the choice item is created.
IsUserLocalizedLabel	Boolean	False	Return False by default.
LocalizedLabelLanguageCode	Bigint	1033	The language code of the choice label, such as 1033 for English (United States) or 1034 for Spanish (Spain).
LocalizedLabel	String	Public	User-specified text label when the choice item is created.
GlobalOptionSetName (GlobalOptionsetMetadata only)	String	socialprofile_community	a combination of table and choice name



In the Dataverse tables, the choice column contains a user-specified numerical value, which is the same as **Option** value in **OptionsetMetadata** table described above.

Prerequisite

Azure Synapse Link for Dataverse. This article assumes that you have already exported data from Dataverse by using Azure Synapse Link for Dataverse.

Access choice metadata

1. Select the desired Azure Synapse Link and select the **Go to Azure Synapse Analytics workspace** on the command bar.
2. Expand **Lake Databases** on the left pane, select **dataverse**-*environmentName*-*organizationUniqueName*, and then expand **Tables**. All the choice metadata listed is available for analysis.

To consume Dataverse choice columns with serverless SQL pool.

1. Right-click the database icon, then select **New SQL script** > **Empty script**.
2. Apply a join SQL script to join the choice metadata with your Dataverse table and store the view in a new database.

Example SQL script to join choice metadata

Replace **<DATABASE_NAME>**,**<COLUMN_NAME>** and **<TABLE_NAME>** with the name of the database, column and table to replace numerical choice value to meaningful text label

SQL

```
SELECT [LocalizedLabel] as [<COLUMN_NAME>]
FROM [<DATABASE_NAME>].[dbo].[<TABLE_NAME>_partitioned]
LEFT JOIN [<DATABASE_NAME>].[dbo].[OptionsetMetadata]
ON ([<DATABASE_NAME>].[dbo].[OptionsetMetadata].[Option] =
[<DATABASE_NAME>].[dbo].[<TABLE_NAME>_partitioned].[<COLUMN_NAME>] AND
[<DATABASE_NAME>].[dbo].[OptionsetMetadata].[OptionSetName] = <COLUMN_NAME>)
```

For more information about how to consume multiple option set values, you would have to use Using Common Table Expressions.

Access Dataverse choices with Power BI

Article • 02/15/2022

For columns that use Microsoft Dataverse choices, choice values are written as an integer label and not a text label to maintain consistency during edits. The integer-to-text label mapping is stored in the *Microsoft.Athena.TrickleFeedService/table-EntityMetadata.json* file. This article covers how to access the integer-to-text label mapping using Power BI.

> **Note**
>
> Azure Synapse Link for Dataverse was formerly known as Export to data lake. The service was renamed effective May 2021 and will continue to export data to Azure Data Lake as well as Azure Synapse Analytics.

Prerequisites

This section describes the prerequisites necessary to access Dataverse choices with Power BI after using the Azure Synapse Link for Dataverse service.

- **Power BI Desktop.** Get it now
- **Azure Synapse Link for Dataverse.** This guide assumes that you have already exported data from Dataverse by using the Azure Synapse Link for Dataverse.
- **Storage Account Access.** You must be granted one of the following roles for the storage account: Storage Blob Data Reader, Storage Blob Data Contributor, or Storage Blob Data Owner.

Consuming Dataverse choices with Power BI

1. Open Power BI Desktop.

2. Select **Get Data** > **Blank query** and then open the **Advanced Editor**.

3. Paste the following query and replace **<STORAGE>** with the storage account name, **<CONTAINER>** with the name of the container, and **<TABLE>** with the name of the Dataverse table.

PowerQueryM

```
  let
    Source =
AzureStorage.DataLake("https://<STORAGE>.dfs.core.windows.net/<CONTAINER>/Mi
crosoft.Athena.TrickleFeedService/<TABLE>-EntityMetadata.json"),
    #"https://<STORAGE> dfs core windows net/<CONTAINER>/Microsoft Athena
TrickleFeedService/_<TABLE>-EntityMetadata json" = Source{[#"Folder
Path"="https://<STORAGE>.dfs.core.windows.net/<CONTAINER>/Microsoft.Athena.T
rickleFeedService/",Name="<TABLE>-EntityMetadata.json"]}[Content],
    #"Imported JSON" = Json.Document(#"https://<STORAGE> dfs core windows
net/<CONTAINER>/Microsoft Athena TrickleFeedService/_<TABLE>-EntityMetadata
json",1252),
    OptionSetMetadata = #"Imported JSON"[OptionSetMetadata],
    #"Converted to Table" = Table.FromList(OptionSetMetadata,
Splitter.SplitByNothing(), null, null, ExtraValues.Error),
    #"Expanded Column1" = Table.ExpandRecordColumn(#"Converted to Table",
"Column1", {"EntityName", "OptionSetName", "Option", "IsUserLocalizedLabel",
"LocalizedLabelLanguageCode", "LocalizedLabel"}, {"Column1.EntityName",
"Column1.OptionSetName", "Column1.Option", "Column1.IsUserLocalizedLabel",
"Column1.LocalizedLabelLanguageCode", "Column1.LocalizedLabel"})
  in
    #"Expanded Column1"
```

This populates a dataset with the choices and various metadata for that choice that you can join with your Dataverse table data to display the text label for the choice.

Azure Synapse Link for Dataverse

Connect to Dataverse with Model Context Protocol

The Model Context Protocol (MCP) is an open protocol that enables seamless integration between large language model (LLM) applications and external data sources and tools. Microsoft Dataverse can act as an MCP server, providing intelligent access to tables and records to various MCP clients like Copilot Studio agents, Visual Studio (VS) Code GitHub Copilot, GitHub Copilot CLI, Claude desktop, Claude Code, and many others. This integration standardizes and streamlines the interaction between AI models and Dataverse data, making it more efficient and effective for developers to apply Dataverse's rich data capabilities within their AI-driven applications.

To use Dataverse as an MCP server, you need to enable and configure the MCP server and allowed clients for your Power Platform environment. Once configured, you can connect to the Dataverse MCP server using different MCP clients. More information: Configure the Dataverse MCP server for an environment

Dataverse MCP server URL

The Dataverse MCP remote server URL follows this format:

`https://{dataverseOrgName}.crm.dynamics.com/api/mcp`

For example, if your Dataverse organization name is `contoso`, the MCP server URL is:

`https://contoso.crm.dynamics.com/api/mcp`

Connect to a Dataverse MCP server

There are multiple ways to connect to a Dataverse MCP server:

- Microsoft Copilot Studio. To learn how to connect to MCP through Dataverse MCP go to Connect to Dataverse with model context protocol in Microsoft Copilot Studio.
- Visual Studio GitHub Copilot and Copilot CLI. To learn how to connect to GitHub Copilot in Visual Studio Code or Copilot CLI go to Connect Dataverse MCP with GitHub Copilot in Visual Studio Code and Copilot CLI.
- Non-Microsoft clients such as Claude desktop and Claude Code. To learn how to connect through Dataverse MCP go to Connect Dataverse MCP with non-Microsoft clients.

List of tools

Once connected to the Dataverse MCP Server, you can choose from various tools in the Power Platform environment.

Expand table

Tool	Description
create_record	Inserts a new row into a Dataverse table and returns the GUID.
describe_table	Retrieves the T-SQL schema of a specified table.
list_tables	Lists all tables in the Dataverse environment.
read_query	Executes SELECT queries to fetch data from Dataverse.
update_record	Updates an existing row in a Dataverse table.
Create Table	Creates a new table with a specified schema.
Update Table	Modifies schema or metadata of an existing table.
Delete Table	Deletes a table from Dataverse.
Delete Record	Deletes a row from a Dataverse table.
Search	Searches through keywords over Dataverse for specific record.
Fetch	Retrieves full content of record in Dataverse using entity name and ID.

> **Note**
>
> Starting December 15, 2025 Dataverse MCP tools are charged when accessed by AI agents created outside of Microsoft Copilot Studio. If you have Dynamics 365 Premium licenses (such as Dynamics 365 Sales Premium, Finance Premium, Supply Chain Premium, and Customer Service Premium) or a Microsoft 365 Copilot User Subscription License (USL), you aren't charged for accessing Dynamics 365 data, even when that data is accessed from outside Microsoft Copilot Studio.

The Search tool is billed at the same Copilot Credit rate as Tenant graph grounding, while all other tools follow the Text and generative AI tools (basic) per 10 response Copilot credit rate. For information about Copilot billing, go to Billing rates and management.

Next steps

Configure the Dataverse MCP server for an environment

Last updated on 03/30/2026

Configure the Dataverse MCP server for an environment

This article provides detailed instructions about how to enable, manage, configure, and disable the Dataverse Model Context Protocol (MCP) server for environments within the Power Platform admin center. It's intended for Power Platform administrators handling managed environments and also covers prerequisites for enabling the server.

Prerequisites

- Power Platform administrator role in order to access Dataverse MCP server environment settings, enable allowed MCP clients, create or edit an environment group, and change connector policies.
- The steps described in this article require that the environment is a Managed Environment.
- By default, the Microsoft Copilot Studio client for Dataverse MCP is enabled for all environments. You must enable the additional clients in the Power Platform admin center before you can connect to the client.

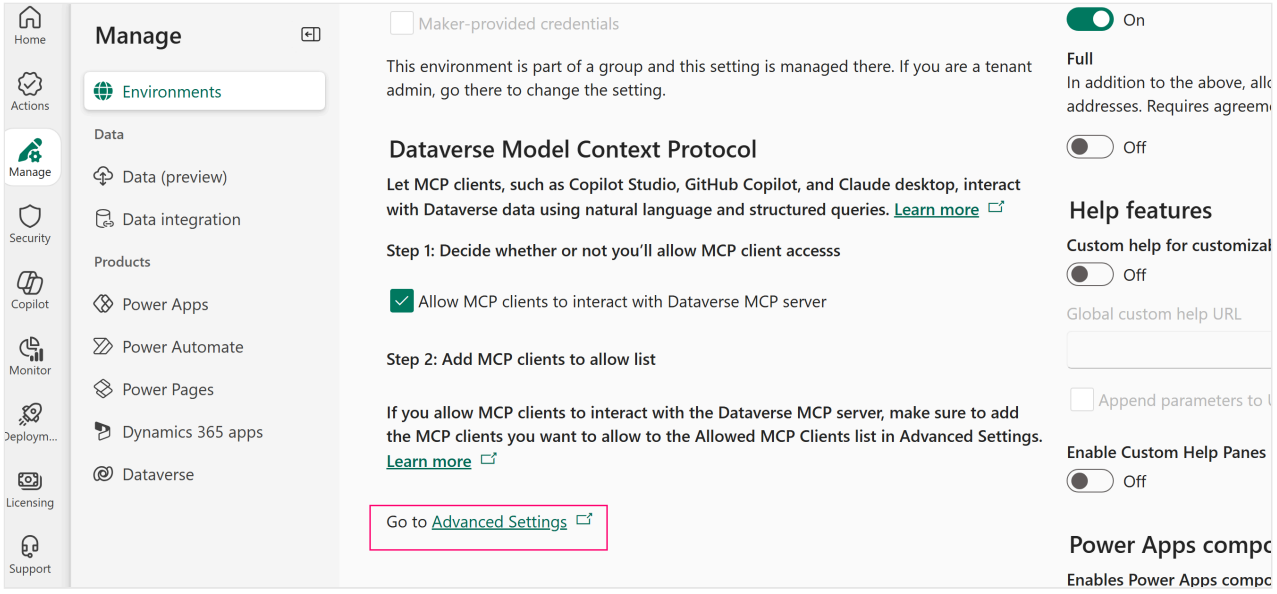
Configure and manage the Dataverse MCP server

By default, Dataverse MCP server is enabled for Copilot Studio. To enable non-Microsoft MCP clients, such as Visual Studio GitHub Copilot and Claude, follow these steps:

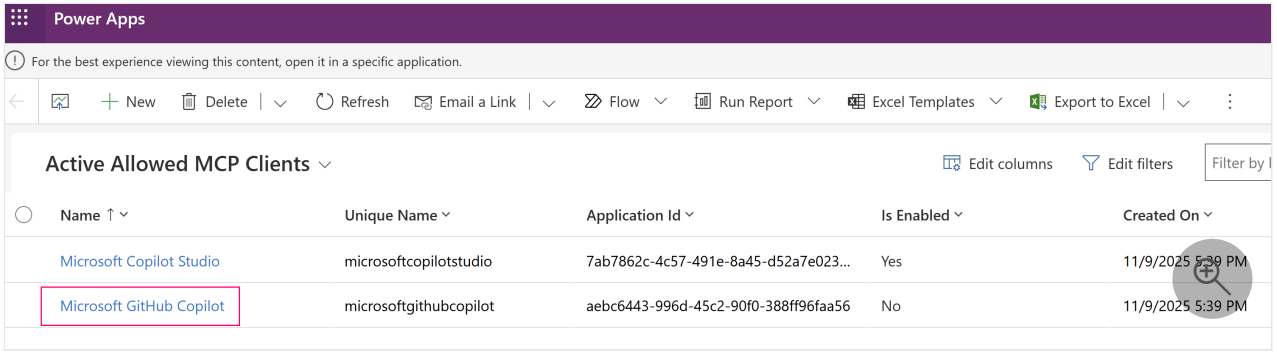
1. Go to Power Platform admin center. Select **Manage** > **Environments**.

2. Select the **Environment Name** where you want to turn on the Dataverse MCP server, and then select **Settings**. Under **Settings**, select **Product** > **Features**. Scroll down to locate **Dataverse Model Context Protocol** and make sure **Allow MCP clients to interact with Dataverse MCP server** is turned on.

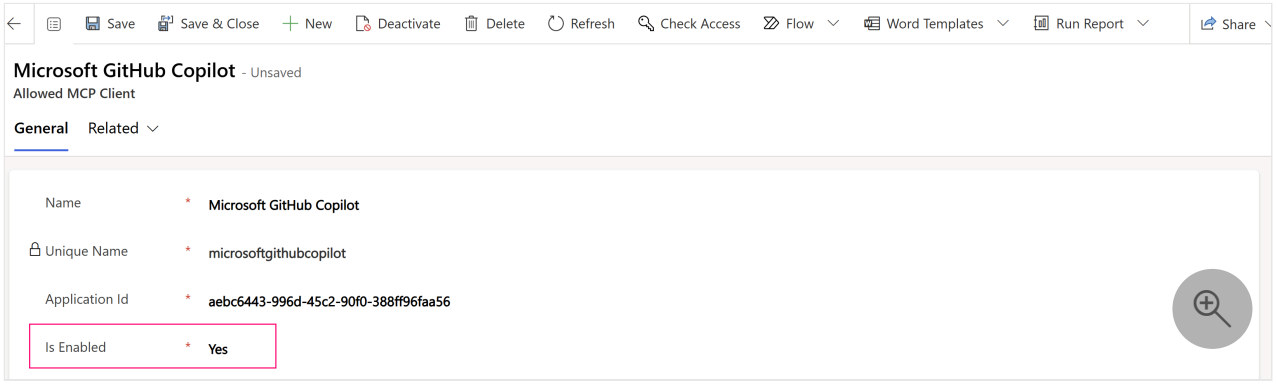
3. Select **Advanced Settings**.



4. The list of available clients is shown. Open the client record you want. In this example, the **Microsoft GitHub Copilot** client is enabled.



5. On the MCP client record, set **Is Enabled** to **Yes**.



6. Select **Save & Close**.

7. Repeat steps 4-7 to enable other clients as needed.

Disable the Dataverse MCP server for an environment

By default the **Allow MCP clients to interact with Dataverse MCP server** is turned on for Copilot Studio. Admins can disable MCP for Dataverse by clearing the setting.

> ⚠ **Warning**
>
> Disabling the Dataverse MCP Server stops all tools and agents that rely on it. Any ongoing development or AI integration testing using MCP is also interrupted.

Write effective instructions for a Dataverse MCP server agent

When you configure your agent in Copilot Studio or Visual Studio Code to use a Dataverse MCP server, clear and well-structured instructions are key to guiding how the agent operates. These instructions help the agent understand its role, what capabilities it has via the MCP server tools, and how to carry out workflows reliably and consistently.

Agent instructions are natural-language directives that tell your agent what it should do, how it should behave, and how to use the MCP tools available to it. They give important context so the agent can:

- Select and call the right MCP tools.
- Fill in tool inputs correctly.
- Decide when to use tools versus generating answers directly.
- Follow the desired tone or behavior patterns during conversations.

Principles for effective instructions

When writing instructions for a Dataverse MCP server agent, consider the following guidelines:

1. Define the agent's purpose clearly.

   State the agent's role in simple terms. For example: "Assist with customer data queries, updates, and record management using Dataverse MCP tools."

   Include tone or restrictions if applicable such as, "always respond in a professional tone" or "do not expose sensitive fields in responses."

2. Outline skills and tool actions.

   Tell the agent which high-level tasks it can perform with the MCP tools. For example:

- Retrieve or filter records using the read_query tool.
- Create or update records with `create_record` and `update_record`.
- Explore table schema with `describe_table`.

Phrase these as actionable instructions, such as "Use the read_query tool to fetch records when the user asks for data retrieval."

3. Add workflow guidance.

   For common processes (like looking up a record or updating a field), add step-by-step guidance. For example: "When updating a record, first identify it using a read_query call, then use update_record with the appropriate field values."

   Providing this context helps the agent orchestrate the right sequence of MCP tool calls.

Add instructions in Visual Studio Code or Copilot Studio

You can use a markdown structured block of instructions as a starting point for your own agent's instructions.

Add instructions in Visual Studio Code

1. Open Visual Studio Code.
2. Open the **Chat** pane.
3. Select **Settings** > **Chat Instructions**.
4. Select **New instruction file**.
5. Copy and paste the instruction content into the new file, such as the sample instructions.

Add instructions in Copilot Studio

1. Open Copilot Studio.
2. Select your agent.
3. Go to **System instructions** and paste your agent instructions, such as the sample instructions.

Sample agent instructions

Markdown

```
## Role
Act as an autonomous agent responsible for interacting with the Microsoft Dataverse
app.
```

```
## Objective
Your objective is to respond to tasks provided by the user. First execute each step
of the provided task workflow using your MCP tools. Check if you have achieved your
objective after each tool call. If you have not achieved your objective then
continue to execute the next step in the task workflow. Do not ask for user
intervention,if you have to run an operation externally in case dataverse doesnt
support that operation. you are allowed to run it without user confirmation. Also
do not ask confirmation for delete table or delete record operation, you can
delete.

## MCP tool selection instructions
 - Whenever you have to use logical table name, call the list_tables tools to get
that logical table name.
 - Whenever you have to use column/attribute name, call the describe_table tool to
get the column/attribute name.

## MCP tool usage instructions

- Before executing an MCP tool, always review the tool description and
restrictions.
- Always strictly follow the description of each MCP tool and perform actions
without any deviation from the tool description.
- Provide higher precedence to tool description over general knowledge.
- Always review the tool documentation and restrictions before running any query or
operation. Strictly validate each planned action against the tool's rules and
supported features before execution.
- For read_query tool, there are restrictions on SQL conditions. Always refer to
the tool description for supported and unsupported sql keywords before generating
the sql query and ensure only supported conditions/keywords are used.

## Reasoning instructions

- Think out loud and reason step by step.
- Before each tool call, plan and verify the action conforms to the tool
description.
- After each tool call, reflect on the result and determine the next step.
- If an exception, error, or warning is observed, communicate it clearly to the
user and retry based on the error message.
- When answering questions about data, DO NOT rely on general knowledge - always
use tools to retrieve accurate, current data.
- DO NOT stop reasoning until all tasks are complete or an unrecoverable error
occurs.
- Only ask clarifying questions if the task requirements are ambiguous.
```

Connect to Dataverse with model context protocol

Connect to Dataverse with model context protocol FAQ

Last updated on 04/01/2026

Connect to Dataverse with model context protocol in Microsoft Copilot Studio

This article explains how to set up and use the Microsoft Dataverse model context protocol (MCP) server with Microsoft Copilot Studio. By following the steps in this article, you can interact with Dataverse, asking natural language questions like *show me my contacts* and receive answers based on stored data.

Prerequisites

- The Microsoft Copilot Studio MCP client must be allowed in the environment. More information: Configure and manage the Dataverse MCP server for an environment

Connect to Dataverse using an MCP server in Microsoft Copilot Studio

1. Go to Power App and select your environment from the top right environment selector.
2. From the left navigation pane, select **Agents** > **Create new agent**. If the item isn't in the side panel pane, select ...More and then select the item you want.
3. Select **Create**.
4. Scroll down to the **Tools** section and select **+ Add tool**.
5. Select **Model Context Protocol**, and then select **Dataverse MCP Server**.
    - If there's no existing Dataverse connection, you're prompted to connect one.
6. Select **Add to agent**.

The individual tools available on this MCP server can be viewed and modified by selecting **...** > **Edit** next to the **Dataverse MCP Server** tool.

You can now interact with the Dataverse MCP Server tool in the **Test your agent** chat pane. Try commands like "list tables in Dataverse," "describe table account," or "how many accounts do I

have."

Connect to Dataverse with Model Context Protocol

Last updated on 11/14/2025

Connect Dataverse MCP with GitHub Copilot in Visual Studio Code and Copilot CLI

This article explains how to set up and use the Microsoft Dataverse model context protocol (MCP) server with GitHub Copilot in Visual Studio Code and GitHub Copilot CLI.

GitHub Copilot in Visual Studio Code

Prerequisites

- The **Microsoft GitHub Copilot** MCP client must be allowed in the environment. More information: Configure and manage the Dataverse MCP server for an environment
- Visual Studio Code installed with GitHub Copilot extension. More information: GitHub Copilot extension for Visual Studio Code

Steps to connect to Dataverse MCP server in Visual Studio Code

1. Open Visual Studio Code. Select **View** > **Command Palette** (Ctrl+Shift+P), type **MCP: Add Server**, and then select **HTTP or Server Sent Events**.

2. Paste your instance URL, such as `https://contoso.crm.dynamics.com/`, append */api/mcp* to it, and press Enter. You can get the instance URL at make.powerapps.com > **Settings** (gear icon) > **Session details** > **Instance url**.

   This step generates the MCP server configuration in Visual Studio Code.

3. Type a MCP server name or press Enter to accept the default name.

4. Choose **Global** or **workspace**.

5. Press **Ctrl+Alt+I** and ensure that agent mode is selected.

GitHub Copilot CLI

Prerequisites

- GitHub Copilot CLI installed. More information: GitHub Copilot CLI
- The **Microsoft GitHub Copilot** MCP client must be allowed in the environment. More information: Configure and manage the Dataverse MCP server for an environment

Option 1: Manually add the MCP server

You can configure the Dataverse MCP server in GitHub Copilot CLI by editing the MCP configuration file directly.

1. Open your MCP configuration file. For global configuration, edit `~/.copilot/mcp-config.json`. For project-scoped configuration, edit `.mcp/copilot/mcp.json` in your project directory.

2. Add the following JSON snippet. Replace `<your org URL>` with your Dataverse environment URL (for example, `https://contoso.crm.dynamics.com`).

   JSON

   ```
   {
     "mcpServers": {
       "DataverseMcp": {
         "type": "http",
         "url": "<your org URL>/api/mcp"
       }
     }
   }
   ```

3. Save the file and restart GitHub Copilot CLI for the changes to take effect.

Option 2: Use the Dataverse plugin from the Awesome Copilot marketplace

The Awesome Copilot marketplace provides a Dataverse plugin that includes an `mcp-configure` skill. This skill guides you through configuring the Dataverse MCP server interactively, including environment discovery and endpoint selection.

1. Add the Awesome Copilot marketplace to your Copilot CLI:

   Bash

   ```
   copilot plugin marketplace add github/awesome-copilot
   ```

2. Install the Dataverse plugin:

   Bash

   ```
   copilot plugin install dataverse@awesome-copilot
   ```

3. In a Copilot chat session, use the `/dataverse:mcp-configure` skill to configure the Dataverse MCP server. The skill walks you through selecting your environment and choosing between the generally available (`/api/mcp`) and preview (`/api/mcp_preview`) endpoints.

Connect to Dataverse with Model Context Protocol

Last updated on 04/30/2026

Connect to Dataverse with model context protocol in non-Microsoft clients

Summarize this article for me

You can connect to Microsoft Dataverse using a non-Microsoft model context protocol (MCP) client, such as Claude desktop or Claude Code. There are two approaches for connecting non-Microsoft clients to a Dataverse MCP server:

- **Local proxy**: Use the `@microsoft/dataverse` npm package to run a local proxy that connects to the Dataverse MCP server on your behalf.
- **Remote endpoint**: Connect directly to the Dataverse MCP server remote endpoint (`/api/mcp`) by registering a custom Microsoft Entra app.

Prerequisites

- The Dataverse MCP server must be enabled for the environment. More information: Configure and manage the Dataverse MCP server for an environment
- For the local proxy approach: Node.js (version 18 or later) installed on your machine.
- For the remote endpoint approach: Access to register an application in Microsoft Entra ID.

Connect using the local proxy

The `@microsoft/dataverse` npm package provides a local proxy that handles authentication and communication with the Dataverse MCP server. This approach is recommended for most non-Microsoft MCP clients that can run local MCP servers.

Grant tenant admin consent

A tenant administrator must grant admin consent for the Dataverse CLI app before users can authenticate. Navigate to the following URL in a browser, replacing `{your-tenant-id}` with your Microsoft Entra tenant ID:

```
https://login.microsoftonline.com/{your-tenant-id}/adminconsent?client_id=0c412cc3-0dd6-449b-987f-05b053db9457
```

Sign in with a tenant administrator account and accept the permissions prompt. This step only needs to be completed once per tenant.

Enable the Dataverse CLI client in the Power Platform admin center

Before you can connect using the local proxy, the **Dataverse CLI** client must be enabled as an allowed MCP client in your environment.

1. Go to Power Platform admin center. Select **Manage** > **Environments**.
2. Select the environment where you want to enable the client, and then select **Settings**.
3. Under **Settings**, select **Product** > **Features**. Scroll down to locate **Dataverse Model Context Protocol** and select **Advanced Settings**.
4. Locate the **Dataverse CLI** client (app ID `0c412cc3-0dd6-449b-987f-05b053db9457`) and set **Is Enabled** to **Yes**.
5. Select **Save & Close**.

> **Note**
>
> If the **Dataverse CLI** entry doesn't appear in the list of available clients, you can add it manually. Create a new client entry with any name and specify the app ID `0c412cc3-0dd6-449b-987f-05b053db9457`, and then enable it.

Install the local proxy

You can install the `@microsoft/dataverse` package globally or run it directly with `npx`.

To install globally, run the following command in a terminal:

Bash

```
npm install -g @microsoft/dataverse
```

Alternatively, you can use `npx` to run the proxy without installing it globally:

Bash

```
npx @microsoft/dataverse mcp https://yourorg.crm.dynamics.com
```

> **Tip**
>
> To connect to the preview endpoint (`/api/mcp_preview`) instead of the generally available endpoint (`/api/mcp`), add the `--preview` parameter to the command. For example: `npx @microsoft/dataverse mcp https://yourorg.crm.dynamics.com --preview`. The preview

endpoint must be enabled in your environment. More information: Use preview tools and upcoming features in Dataverse MCP server

Configure the local proxy in Claude desktop

This section describes how to configure the Dataverse MCP server local proxy in Claude desktop. If you haven't already done so, download and install Claude desktop.

1. Open Claude desktop and go to **File** > **Settings** > **Developer**.
2. Select **Edit Config** to open the `claude_desktop_config.json` file.
3. Add the following JSON snippet to the file. Replace `<friendly name>` with a name you can easily remember (for example, *MyDataverseMCPServer*) and replace `<your org URL>` with your Dataverse environment URL (for example, `https://contoso.crm.dynamics.com`).

   JSON

   ```
   {
     "mcpServers": {
       "<friendly name>": {
         "command": "npx",
         "args": [
           "-y",
           "@microsoft/dataverse",
           "mcp",
           "<your org URL>"
         ]
       }
     }
   }
   ```

4. Save the file.

Verify the connection in Claude desktop

1. Exit Claude desktop by selecting **File** > **Exit**, and then reopen it to apply the changes.
2. Sign in with your credentials when prompted to authenticate to your Dataverse environment.
3. Select **Search and tools** to verify that the Dataverse MCP server and its tools are available. You should see the friendly name you configured (for example, *MyDataverseMCPServer*).
4. Select the MCP server name to view the list of tools that are supported by the server.

Tip

You can enable and disable individual tools for each MCP server registered with Claude desktop. This gives you control over which tools are available for use.

Configure the local proxy in Claude Code

This section describes how to configure the Dataverse MCP server local proxy in Claude Code. If you haven't already done so, download and install Claude Code.

Run the following command to add the Dataverse MCP server. Replace `https://yourorg.crm.dynamics.com` with your Dataverse environment URL.

Bash

```
claude mcp add dataverse -t stdio -- npx -y @microsoft/dataverse mcp
https://yourorg.crm.dynamics.com
```

Verify and interact with the connection in Claude Code

1. Restart Claude Code to apply the changes.
2. Sign in with your credentials when prompted to authenticate to your Dataverse environment.
3. Verify that the Dataverse MCP server and its tools are available. You should see the friendly name you configured (for example, *MyDataverseMCPServer*).
4. Select the MCP server name to view the list of tools that are supported by the server.

If you have data in the Dataverse environment, you can test the setup by asking *list tables in Dataverse*, *describe table account*, or *how many accounts do I have*. More information: Add and remove sample data

Tip

If you have other MCP servers registered with Claude Code, include *Dataverse* in your prompt to specify which MCP server to use.

Connect using the remote endpoint

You can connect non-Microsoft MCP clients directly to the Dataverse MCP server remote endpoint without using a local proxy. This approach requires you to register a custom application in Microsoft Entra ID and add its client ID to the allowed clients list in the Power Platform admin center.

Register a custom Microsoft Entra app

Register an application in Microsoft Entra ID to use for authentication when connecting to the Dataverse MCP server. For general information about app registration, go to Register an application with the Microsoft identity platform.

Follow these steps to register an app for use with the Dataverse MCP server:

1. Sign in to the Microsoft Entra admin center.
2. Go to **Identity** > **Applications** > **App registrations**, and then select **New registration**.
3. Enter a name for your application (for example, *Dataverse MCP Client*), configure the supported account types for your scenario, and then select **Register**.
4. On the **Overview** page, note the **Application (client) ID**. You need this value to configure the allowed client in the Power Platform admin center and to configure your MCP client.

Configure API permissions for the Dataverse MCP server

After you register the app, you must grant it permissions to access the Dataverse MCP server.

1. In the app registration, select **API permissions** from the left navigation pane.
2. Select **Add a permission**.
3. Select **Microsoft APIs**, and then select **Dynamics CRM**.
4. Select the **mcp.tools** permission, and then select **Add permissions**.

> **Note**
>
> The authentication flow used by the Entra app depends on the MCP client you're using. Refer to your MCP client's documentation for the supported authentication methods.

Add the custom app to the allowed clients list

After you register the Entra app, add its client ID to the list of allowed MCP clients for your environment.

1. Go to Power Platform admin center. Select **Manage** > **Environments**.
2. Select the environment where you want to allow the client, and then select **Settings**.
3. Under **Settings**, select **Product** > **Features**. Scroll down to locate **Dataverse Model Context Protocol** and select **Advanced Settings**.
4. Add a new client entry. Enter a name for the client and specify the **Application (client) ID** from your Entra app registration.
5. Set **Is Enabled** to **Yes**.

6. Select **Save & Close**.

Connect to the remote endpoint

Configure your MCP client to connect to the Dataverse MCP server at the following URL:

`https://<your org URL>/api/mcp`

For example: `https://contoso.crm.dynamics.com/api/mcp`

Use the **Application (client) ID** from your Entra app registration for authentication. Refer to your MCP client's documentation for specific configuration steps.

Use preview tools and upcoming features in Dataverse MCP server

To help customers experiment with new capabilities and provide early feedback, the Microsoft Dataverse model context protocol (MCP) server includes preview tools that enable upcoming features before they're generally available (GA).

This article explains what preview tools are, what to expect when you use them, and how administrators can turn on the the preview features for Dataverse MCP server setting from the Power Platform admin center to access the latest Dataverse MCP server enhancements.

What are preview tools?

Preview tools are early versions of Dataverse MCP server capabilities released for customer evaluation. They allow makers, developers, and system integrators to:

- Try out new API endpoints and behaviors before GA.
- Validate integration scenarios.
- Provide feedback that shapes final product design.
- Prepare internal systems for upcoming releases.

Preview tools might not yet support full functionality, scale, or GA features.

Prerequisites

The environment must be enabled and configured for Dataverse MCP server. More information: Configure the Dataverse MCP server for an environment

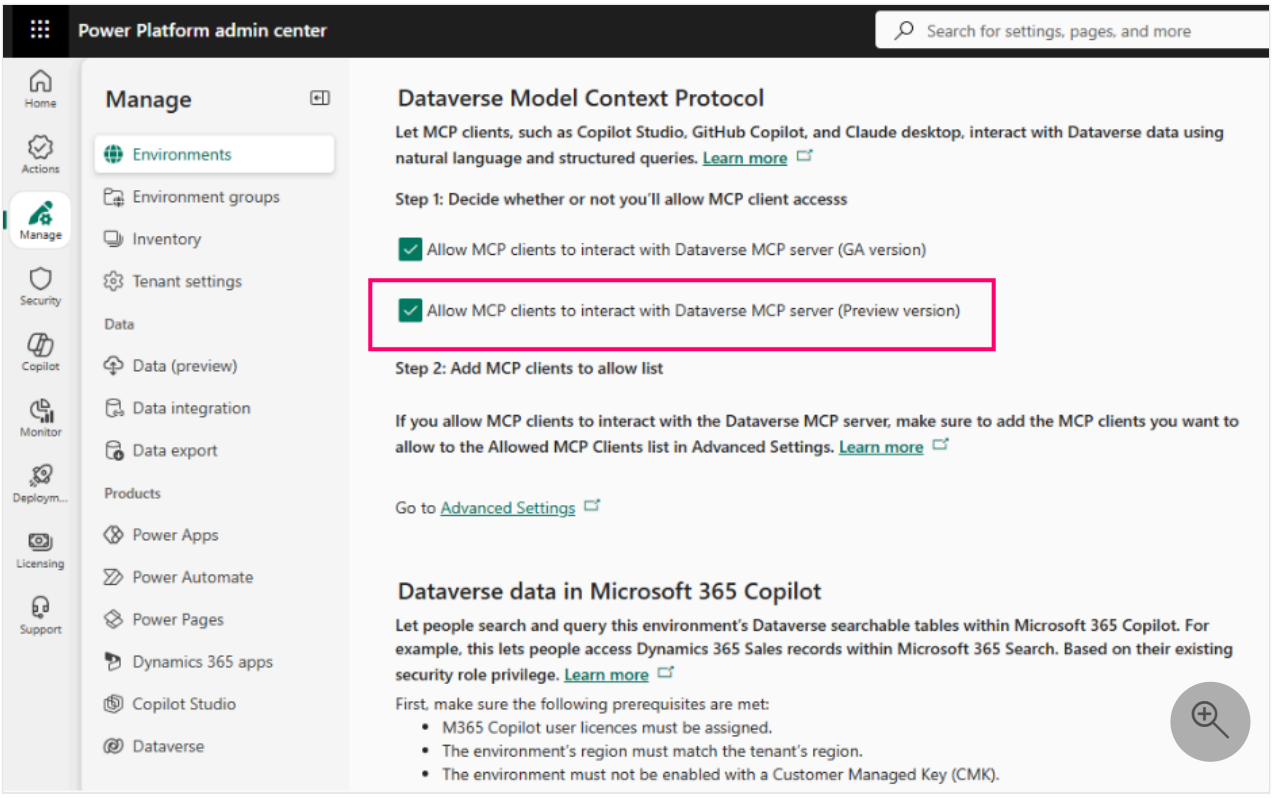
Enable preview features for Dataverse MCP server

Administrators can enable preview features using feature settings available in the Power Platform admin center. Once enabled, all users and copilots in the environment gain access to the new tools.

Follow these steps to enable preview capabilities:

1. Sign in to the Power Platform admin center
2. Select **Manage** > **Environments**.
3. Open the **Environment** where you want to turn on the Dataverse MCP server, and then select **Settings** on the command bar.
4. Expand **Product**, and then select **Features**.

5. Scroll down to locate **Dataverse Model Context Protocol** and enable **Allow MCP clients to interact with Dataverse MCP server (Preview version)**.



The environment might take a few minutes to apply the changes.

Connect to Dataverse MCP server (preview)

Once the environment setting for preview features are enabled, you can connect to the Dataverse MCP server preview endpoint.

Connect from Microsoft Copilot Studio

When adding a connector in Copilot Studio, select the connector named **Microsoft Dataverse MCP Server (Preview)**.

This connector is different from the standard **Microsoft Dataverse MCP Server** connector and is required specifically for preview features.

Connect using Claude, GitHub, or other non-Microsoft MCP clients

Use the preview endpoint `https://<orgUrl>/api/mcp_preview`.

Examples:

- `https://contoso.crm.dynamics.com/api/mcp_preview`
- `https://org123.crm4.dynamics.com/api/mcp_preview`

This endpoint makes available all preview tools and capabilities.

What happens after enabling preview for Dataverse MCP server

Once preview is enabled:

- MCP Server makes available the corresponding preview tools automatically.
- Agents and Copilots can begin calling these new endpoints immediately.
- You might notice additional system-generated logs or messages marked as **Preview**.
- Behavior might change as Microsoft iterates based on feedback.

If you encounter any issues, you can disable the **Allow MCP clients to interact with Dataverse MCP server (Preview version)** environment setting at any time.

About preview tools

Expand table

Topic	Details
Support	Preview tools aren't covered by Microsoft support agreements.
Breaking changes	Preview APIs might change without notice.
Performance	Features might not meet production-grade reliability.

Connect to Dataverse with model context protocol FAQ

Summarize this article for me

This article provides answers to frequently asked questions about using Microsoft Dataverse with a model context protocol (MCP) server.

I can't authenticate. What is the problem?

Verify that the Dataverse environment URL in your MCP client configuration is correct. Go to Power Apps, select the correct environment, and then select **Settings** (gear icon) > **Session details** to confirm your instance URL.

Also verify that the MCP client you're using is enabled in the Power Platform admin center. More information: Configure and manage the Dataverse MCP server for an environment

Which MCP tools are available and what do they do?

The Dataverse MCP server provides tools for common data operations such as querying records, creating and updating rows, describing table schemas, and listing tables. For the full list of tools and descriptions, go to Connect to Dataverse with Model Context Protocol.

Can I restrict which tables or records are accessible through the MCP server?

Yes. The Dataverse MCP server respects Dataverse security roles and row-level security. Users can only access tables and records that their security role permits. No additional MCP-specific access controls are needed beyond standard Dataverse security configuration.

Are there costs associated with using the Dataverse MCP server?

Starting December 15, 2025, Dataverse MCP tools are charged when accessed by AI agents created outside of Microsoft Copilot Studio. If you have qualifying Dynamics 365 Premium licenses or a Microsoft 365 Copilot User Subscription License (USL), you aren't charged for

accessing Dynamics 365 data. For information about billing rates, go to Connect to Dataverse with Model Context Protocol.

Can I use the Dataverse MCP server with multiple environments?

Yes. Each Dataverse environment can have its own MCP server configuration. You can connect to multiple environments by configuring separate MCP server entries in your client, each pointing to a different environment URL.

> **Tip**
>
> If you use Microsoft Copilot Studio, you can use the MCP onboarding wizard to connect your agent to Dataverse MCP servers across multiple environments. The wizard guides you through server configuration and authentication setup. More information: **Connect your agent to an existing MCP server**

What should I do if a Dataverse MCP tool returns an error?

If a tool returns an error, try rephrasing your prompt and submitting it again. Use more specific language to describe what you want to accomplish. If the error persists, verify that you have the appropriate Dataverse permissions for the operation you're attempting.

Why don't I see the Search tool in the Dataverse MCP server?

The Search tool is only available when Dataverse search is enabled for your environment. If Dataverse search isn't turned on, the Search tool doesn't appear in the list of available MCP tools. To enable Dataverse search, go to Configure Dataverse search for your environment.

Why do I see different tools on the /api/mcp and /api/mcp_preview endpoints?

The /api/mcp endpoint provides the generally available set of Dataverse MCP tools, while the /api/mcp_preview endpoint includes additional preview tools that are being evaluated before general availability. Preview tools might change or be removed without notice. To access the

preview tools, an administrator must enable the preview features setting in the Power Platform admin center. More information: Use preview tools and upcoming features in Dataverse MCP server

How do I enable debug logging for the local proxy?

If you experience issues with the local proxy (`@microsoft/dataverse`), you can enable debug logging to capture detailed output for troubleshooting. Add the `--log-level` and `--log-file` arguments to the proxy command:

Bash

```
npx @microsoft/dataverse mcp https://yourorg.crm.dynamics.com --log-level Debug --log-file
```

The log file is written to the system temporary directory. The default location depends on your operating system:

Expand table

Operating system	Log file location
Windows	`C:\Users\<username>\AppData\Local\Temp\`
Linux	`/tmp/`
macOS	The directory specified by the `$TMPDIR` environment variable, typically `/var/folders/.../T/`. Run `echo $TMPDIR` in a terminal to find the exact path.

You can share the output log file with Microsoft when opening a support incident to help diagnose the issue.

Last updated on 03/11/2026

What is Dataverse intelligence?

[This article is prerelease documentation and is subject to change.]

Microsoft Dataverse intelligence extends Work IQ to bring business data understanding to AI agents and Microsoft Copilot. Work IQ helps agents understand work artifacts like files, meetings, and messages. Dataverse intelligence builds on this foundation by enabling agents to understand and act on your business data.

With Dataverse intelligence, you can define reusable business context that agents use to understand what your data means, follow your organization's processes when taking actions, and read and update Dataverse records reliably. This business context is shared across agents, so you define it once and use it everywhere.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Prerequisites

- Microsoft 365 admin role (AI administrator, Global administrator) to access Microsoft 365 admin center Copilot settings. More information: Enable Microsoft 365 admin center Copilot Dataverse settings
- Power Platform administrator role to access Dataverse intelligence environment settings. More information: Enable Dataverse intelligence
- The environment where you use Dataverse intelligence must be a Managed Environment.
- The environment must be enabled and configured for Dataverse MCP server preview. Business skills are only available for use with the preview version of Dataverse MCP server. More information: Use preview tools and upcoming features in Dataverse MCP server

Enable Microsoft 365 admin center Copilot Dataverse settings (preview)

1. Go to Microsoft 365 admin center. Select **Copilot** > **Settings**.
2. Locate and select **Dataverse data available in Microsoft 365 Copilot**.

3. Select **All users**, or
4. Select **Specific groups** and enter the list of Entra security groups.
5. Select **Save** to save the setting changes.

Enable Dataverse intelligence (preview)

1. Go to Power Platform admin center. Select **Manage** > **Environments**.
2. Open the environment where you want to turn on the Dataverse MCP server, and then select **Settings** > **Product** > **Features**.
3. Scroll down to locate **Dataverse intelligence**.

    - Turn on **Allow data availability in M365 copilot**, and/or...
    - Turn on **Enable Dataverse intelligence (Work IQ) for agents and AI experiences**.

4. Make sure **Allow MCP clients to interact with Dataverse MCP server (Preview version)** is enabled. If it's not, enable it.
5. Select **Save** to save the setting changes.

Business skills overview

Create and use business skills

Last updated on 03/30/2026

Business skills overview

Summarize this article for me

[This article is prerelease documentation and is subject to change.]

Business skills are natural-language instructions that capture how your organization gets work done. They represent your business processes, policies, and domain knowledge in a format that agents can understand and follow. Each skill describes how to complete a specific type of work—the steps involved, the information required, and the business rules that apply.

Agents discover and use business skills as needed at runtime to complete tasks according to your organization's processes. When multiple agents use the same skill, they follow the same process, ensuring consistent behavior across your organization.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

> **Important**
>
> Business skills are not executable code. They contain natural-language instructions that guide agent behavior, similar to how you might document a process for a new employee.

Key capabilities include:

- Reusability—Define a process once and use it across multiple agents and surfaces
- Consistency—Agents follow the same process definition, reducing variation in outcomes
- Maintainability—Update a skill in one place to change behavior across all agents that use it
- Governance—Control who can create, modify, and share business skills using Dataverse security. Each skill has an owner; sharing follows Dataverse RBAC patterns
- Solution-aware—A solution aware object that appears in Solution explorer and can be moved across environments

Skill structure

Business skills use a layered structure for efficient discovery and retrieval.

Expand table

Layer	Content	Purpose
Metadata	Name and description	Enables agents to quickly discover relevant skills
Instructions	Full skill body	Contains the complete process definition

Agents query metadata to find applicable skills, then retrieve full instructions only when needed.

Security and governance

Business skills follow Dataverse security patterns. Each skill has an owner who controls access through standard sharing mechanisms. Users these security roles can work with business skills.

Expand table

Security role	Privileges
Basic User	Can create skills (owned by them) Can use skills shared with them. Can't publish environment-wide.
Environment Maker	Can create and share skills (owned by them) Can manage solution deployment
System Administrator or System Customizer	Can create and share skills Can manage solution deployment

Next steps

Create and use business skills

Configure the Dataverse MCP server for an environment

Last updated on 03/10/2026

Create and use business skills

[This article is prerelease documentation and is subject to change.]

This article explains how to create and manage business skills that ground agents in your organization's processes. You'll learn how to enable the required features, author skill content, test skills with agents, and manage skills across environments.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Prerequisites

- The environment must be enabled and configured for Dataverse MCP server preview. Business skills are only available for use with the preview version of Dataverse MCP server.
- The environment where you create and use business skills must be a Managed Environment. More information: Use preview tools and upcoming features in Dataverse MCP server
- The environment must be enabled for Dataverse intelligence.

Open the business skills page

1. Go to Power Apps.
2. In the left navigation pane, select **More**, and then select **Business skills (preview)**.

> **Tip**
>
> Pin the **Business skills** page to the left navigation pane for quick access.

The **Business skills** page is the central hub for managing all business process knowledge in your environment. From here, you can create, edit, share, and organize the skills that agents use to follow your organization's processes.

Manage business skills

Create a business skill

1. Select **New business skill** on the command bar, or select the **Create a business skill** card.
2. Enter a name for your skill. A unique name is generated automatically with the preferred solution's prefix.
3. In the **Description** field, describe the skill's purpose and when it should be followed. Agents use this description to understand when to perform the skill.
4. In the **Instructions** section, write the step-by-step process in markdown format. Use the **Edit markdown** and **Preview** options to switch between editing and previewing your instructions.
5. Select **Save**.
6. After saving, you can add resource files in the **Resources** section. Select **Add Files** to attach reference materials such as policy documents, SOPs, templates, forms, or calculations (20 MB limit).

> **Note**
>
> All skills are active by default. Deactivate a skill

Upload a business skill

You can quickly create a business skill by uploading existing skills.

1. Select **Upload business skill** on the command bar, or select the **Upload a business skill** card.
2. Drag and drop a file into the upload area, or select **Select from device** to browse for a file.
3. Upload a `Skill.md` (markdown) or `.zip` file of your skill (30 MB limit).
4. The business skill gets uploaded and saved. You can edit the skill once uploaded.

Edit a business skill

1. Open a skill in the **Business skills** page by selecting its name in the list, or select a skill and then select **Edit** from the command bar or the three-dot menu (⋮).
2. Update the **Name**, **Description**, **Instructions**, or **Resources** as needed.
3. Select **Save**.

Create or update skills using the Dataverse MCP server (preview)

You can also create and update skills through an agent connected to the Dataverse MCP server (preview):

1. Add Dataverse MCP server (preview) as a tool to any agent in Microsoft Copilot Studio or connect to it from coding agents in Visual Studio Code or non-Microsoft clients.
2. Ask your agent to create a new skill or update an existing one.
3. Provide your business process information.
4. The business skill is saved in the environment you used to connect to the MCP server.

Share a business skill

Skills are user-owned by default. You can share skills with specific users or teams and control their level of access.

1. Select a skill, and then select **Share** from the command bar or the three-dot menu (⋮).
2. Search for and add the users or teams you want to share with.
3. For each user or team, choose a permission level:

    - **Viewer** - Can view the skill only.
    - **Co-owner** - Can view and edit the skill.

4. Select **Share**.

Select **Manage access** to review who has access, change permission levels, or remove access. Pending invitations that haven't been shared yet are shown on the **Pending invites** tab.

Change skill visibility

You can make a business skill visible to everyone in the organization or restrict it to just the owner and shared users.

1. Select a skill, and then select **Viewable by** from the command bar or the three-dot menu (⋮).
2. In the **Viewable by** dialog, select one of the following:

    - **Individual** - Only the owner and users the skill is shared with can see the skill. This is the default.
    - **Organization** - All users in the environment with at least basic user privileges can see the skill.

3. Select **Save**.

Deactivate a skill

To prevent a skill from being used by agents until you have finalized it:

1. Select a skill, and then select **Deactivate** from the command bar or the three-dot menu (⋮).

Deactivating a skill doesn't delete it, but prevents agents from discovering or using it. To reactivate, select the skill and then select **Activate**.

Delete a skill

To permanently remove a business skill:

1. Select a skill, and then select **Delete** from the command bar or the three-dot menu (⋮).

> ⊗ **Caution**
>
> Deleting a skill is permanent and can't be undone. Any agents that reference the deleted skill can no longer use it.

Use business skills

After you create business skills in your environment, AI agents can use them to understand and run business processes. Access skills through the Dataverse MCP server (preview).

- To start using business skills, connect to the Dataverse MCP server (preview) in Microsoft Copilot Studio or from agent mode in Visual Studio Code or non-Microsoft clients.
- Try asking your agent, "Show me all business skills in this environment." The agent retrieves a list of all the skills in your connected environment by using the Dataverse MCP server.
- Start testing by asking your agent a relevant scenario that matches your skill's intended use case. For example, if you created a skill for logging call transcripts into Dataverse, provide a sample transcript to your agent and ask it to log the transcript information in Dataverse.

  > 💡 **Tip**

> If your agent doesn't automatically fetch skill details, try adding "Using business skills" before your actual prompt. For example, "Using business skills log this transcript in Dataverse."

- Remember to add any other relevant tools, including MCP servers and connectors, that the agent needs access to for successfully executing your business processes defined in skills.
- Confirm your intended actions were successful and continue to iterate on the skill instructions based on results.

Add business skills to a solution

Business skills are solution-aware, which means you can package them into solutions for application lifecycle management (ALM). This allows you to move skills between environments as part of your deployment process.

To add a skill to a solution:

1. Sign in to Power Apps and select your environment.
2. Go to **Solutions** and open an existing solution or create a new one.
3. Select **Add existing** > **Business skill** from the top navigation bar.
4. Choose the skills you want to add to your solution, and then select **Add**.

Best practices for creating business skills

- Write clear, specific instructions. Vague instructions lead to inconsistent agent behavior.
- Use descriptive names and descriptions. Help agents discover the right skill for the task.
- Keep skills focused. One skill, one process. Create separate skills for distinct workflows.
- Test with real scenarios. Validate behavior before sharing broadly.
- A well-structured business skill should include:
  - Description:
    - What the skill does and when to use it.
    - Specific trigger phrases. For example, "Use when user asks about order status or mentions shipment tracking".
  - Step-by-step instructions:
    - Numbered steps in the process sequence.
    - What happens at each stage and how to validate before moving to the next step.
  - Examples:
    - Concrete examples showing expected inputs and outputs for common scenarios.
  - Troubleshooting:

    - Common errors with causes and solutions.
    - Recovery steps for failures.
  - Input and output specifications:
    - Required vs optional parameters with expected formats.
    - Output fields and success criteria.
    - Required tools for successful execution of skill.

Sample business skills for getting started

To help you get started, sample business skills are available: Business skills repo on GitHub

This open source GitHub repository also has a downloadable solution. Install the solution in your environment to explore working examples and use them as templates for your own skills. Refer to the ReadMe file located in the repository for more instructions on how you start using these sample skills.

License requirements for tables

Article • 02/08/2023

App makers can use most of the tables available within Microsoft Dataverse (including custom tables and tables that are part of the Common Data Model) to create apps and flows for users who have a Power Apps or Power Automate license.

In some cases, tables contain complex business logic or are tied to customer engagement apps in Dynamics 365 (Dynamics 365 Sales, Customer Service, Field Service, Marketing, or Project Service Automation) that require app users to have a specific license. This topic provides licensing information for tables with complex business logic and tables that are tied to Dynamics 365 apps (termed as restricted tables).

Tables with complex business logic

Tables that include the following complex server-side logic require users of an app or flow that uses these tables to have a Power Apps or Power Automate license:

- Code plug-ins (for more information, see Plug-in development)
- Real-time workflows (for more information, see Workflow processes)

> **Note**
>
> Only workflows that are converted to a real-time workflow are considered real-time and synchronous. Workflows that are run in the background can still be used with the appropriate Power Apps plan and do not require additional licenses.

To know whether or not you added complex business logic to your tables, review the list of plug-in assemblies and workflows configured in your environment. For the list of tables which may contain server side logic after installing a Dynamics 365 app (such as Dynamics 365 Sales or Dynamics 365 Customer Service), see Complex tables requiring Power Apps or Power Automate licenses

Impacting license requirements when adding complex business logic

App makers can add code plug-ins and real-time workflows to tables within Dataverse, but doing so could change the license requirements for users of apps already deployed.

App makers should be cautious when adding complex business logic to a table and should first check which apps use the table and whether users of those apps have the appropriate licenses.

Restricted tables

Restricted tables are not standard tables within Dataverse, but are included in one of the customer engagement apps in Dynamics 365 (Dynamics 365 Sales, Customer Service, Field Service, Marketing, or Project Service Automation) or a third-party solution. For example, the knowledge article, goal, and entitlement tables.

> **Note**
>
> Apps and flows that use these tables require the app and flow user to be licensed appropriately-not the maker or developer of the app or flow.

tables that are tied to the functionality of Dynamics 365 apps (such as Dynamics 365 Sales or Dynamics 365 Customer Service) require app users to have the corresponding license for that application if they want to create, update, or delete rows within the tables. For a full list of restricted tables, see Restricted tables requiring Dynamics 365 licenses.

Licensing examples

Barb and Isaac are creating apps in Power Apps using Dataverse to store their data.

Table creation

- No user can create a new restricted table; Microsoft reserves the right to create and define them for Dynamics 365 apps (such as Dynamics 365 Sales or Dynamics 365 Customer Service)
- Users can create custom tables with Dynamics 365, Power Apps, or Power Automate license
- For existing restricted tables, a user can add rows with the appropriate Dynamics 365 app license

Create apps using Power Apps

- Barb and Isaac can create a canvas or model-driven app accessing restricted tables with a Dynamics 365 license
- Barb and Isaac can create a canvas or model driven app accessing custom tables with either Dynamics 365 or Power Apps license

Use apps

Barb wants to use two canvas apps:

- App 1 – uses the Appointment table along with a custom table that stores related information
- App 2 – uses the Appointment table along with the Work Order table, which is a restricted table

Isaac wants to use two model-driven apps:

- App 3 – uses the Appointment table along with a custom table that stores related information
- App 4 – uses the Appointment table along with the Work Order table, which is a restricted table

Barb and Isaac need the following licenses:

- Barb can use App 1 with a Dynamics 365 app license or a Power Apps license.
- Barb can use App 2 only with a Dynamics 365 app license because there is a restricted table accessed by the app.
- Isaac can use App 3 with a Dynamics 365 app license or a Power Apps license.
- Isaac can use App 4 only with a Dynamics 365 app license because there is a restricted table accessed by the app.

Create flows using Power Automate

Now, let's see what happens when Isaac adds a real-time workflow to the custom table that both Barb and Isaac are using in their apps.

- Isaac can create a workflow accessing restricted tables with a Dynamics 365 app license

- Barb and Isaac can create a workflow accessing custom tables with either Dynamics 365 app or Power Automate license

Use flows

- Barb or Isaac can run the workflow accessing restricted tables with a Dynamics 365 app license
- Barb or Isaac can run the workflow accessing custom tables with either Dynamics 365 app or Power Automate license

More about licensing

For more information about licensing, see Licensing overview.

For the latest information on licensing requirements for tables, see the Power Apps licensing guide.

Complex tables and licensing

Article • 02/15/2022

> **Important**
>
> *This topic is applicable only for older Power Apps Plan 1 and Plan 2 licenses.*
>
> Complex tables are applicable *only* for the older Power Apps Plan 1 and Plan 2 licenses, and not for the latest Power Apps per app and Power Apps per user plans.
>
> For the latest information on licensing requirements for tables, see the **Power Apps licensing guide** .

Tables that include the following complex server-side logic require users of an app or flow that uses these tables to have a Power Apps Plan 2 or Power Automate Plan 2 license:

- Code plug-ins. More information: Plug-in development
- Real-time workflows. More information: Workflow processes

> **Note**
>
> Only workflows that are converted to a real-time workflow are considered real-time and synchronous. Workflows that are run in the background can still be used with the appropriate Power Apps plan and do not require additional licenses.

To know whether or not you've added complex business logic to your tables, review the list of plug-in assemblies and workflows configured in your environment.

Complex tables installed with Dynamics 365 apps

The following table lists tables that contain complex server-side logic out-of-the-box as part of the installation of customer engagement apps in Dynamics 365 (Dynamics 365 Sales, Customer Service, Field Service, Marketing, and Project Service Automation). This list is intended as a guide. Depending on the Dynamics 365 apps and versions installed in your environment, the list of complex tables may vary.

> **Note**
>
> If you are using the Microsoft Dataverse and have not installed a Dynamics 365 app or third-party solution, your environment won't have tables containing complex server-side logic.

Restricted tables requiring Dynamics 365 licenses

App makers, who are building custom apps, can use all of the Microsoft Dataverse tables available within Common Data Model to create apps and flows for users who have any version of Power Apps and Power Automate license.

However, a smaller set of tables tied to Dynamics 365 apps (Dynamics 365 Sales, Customer Service, Field Service, Marketing, or Project Service Automation) require canvas and model-driven app users to have a license for the corresponding Dynamics 365 app if they need to create, update, or delete rows within the tables. These are referred to as restricted tables.

Tables might be restricted to a Dynamics 365 app license for the following reasons:

- The table is used to store and maintain product-specific configuration data that should typically be not used outside of the application.
- The table is accompanied by advanced logic that creates and maintains data in a specific way when used within a Dynamics 365 product.

If an app or flow only reads information from a table, a Dynamics 365 app license isn't required and an appropriate Power Apps or Power Automate license is all that's needed.

Restricted tables for create, update, and delete operations

The following table lists the restricted tables and the associated Dynamics 365 license requirements for users who create, update, or delete data stored within these tables.

> **Note**
>
> Dynamics 365 Customer Engagement Plan and Dynamics 365 Plan licenses are no longer available for purchase and is referenced here only for the benefit of existing customers who have bought these licenses in the past.

[1] *Case table actions permitted with only Power Apps, Power Automate, Power Pages or Microsoft Copilot Studio license:*
Power Apps, Power Automate, or Copilot Studio licensed users can ‘create’ cases; can ‘read’, ‘update’ and ‘delete’ self-created cases to enable scenarios including employee self-service and case creation on behalf of customers. Power Apps, Power Automate, or Copilot Studio licensed users can only perform ‘read’ operation on cases created by other users. They can't ‘update’, ‘resolve’, ‘route’, ‘close’,‘delete’,‘assign’,‘duplicate’, ‘merge’, ‘create child cases’ or perform any other custom operation on cases created by others. Users can't act as a customer service agent, can't manage cases.

[2] *Work Order table requires Dynamics 365 for Field Service license in most scenarios except for users self-reporting issues (for example, an employee reporting a facilities issue) in which case creating, reading, updating, and deleting work orders is permitted with the Power Apps or Power Pages license. Users can't complete/close work orders or act in a manner similar to that of performing or completing service.*

Licensing

For more information on Power Apps, Power Automate, Power Pages, Copilot Studio, and Dynamics 365 licenses, see Licensing overview page.

SharePoint, OneNote, and OneDrive integration with Microsoft Dataverse

Article • 02/15/2022

Dataverse provides support for SharePoint, OneDrive, and OneNote integration. Integration with these services requires that you first enable SharePoint integration.

Microsoft 365 service	Description	More information
SharePoint	Lets app users manage common document types, such as Word, Excel, PowerPoint, OneNote, and create folders to save and manage those documents that are seamlessly stored in SharePoint from within Dataverse apps.	Manage your documents using SharePoint Set up SharePoint integration
OneDrive for Business	App users can create and manage private documents that can be accessed from within Dataverse apps.	Enable OneDrive for Business
OneNote	App users can use OneNote to take or review notes from within Dataverse rows.	Set up OneNote integration

Translate customized table, form, and column text into other languages

Article • 03/13/2023

After you create customized table and column text in your unmanaged solution, you may want to translate it into other languages.

> **Important**
>
> When you export translations, the export translations feature exports translations for the table. So, that means even if the solution contains only a single form, labels for all the forms for the table will be exported. Make sure you only modify the form's labels when importing the translations back otherwise another component translation you modify will be added as a dependency to the solution.

1. Sign into Power Apps and select **Solutions** from the left navigation. If the item isn't in the left navigation pane, select ...More and then select the item you want.
2. Select the unmanaged solution you want, on the command bar select **...**, select **Translations**, and then select **Export translations**.
3. After the export completes the exported translations compressed (zip) file is downloaded to your browser's default download folder and contains the exported labels.
4. Extract the XML file from the compressed (.zip) file.
5. Open the CrmTranslations.xml file in Excel.
6. Select the sheet named **Localized Labels**.
7. Notice there is already a column with the base language code id, such as 1033 (English U.S.) Add a column with the language code id for every language you want to translate labels. For example, add a column for 1034 (Spanish traditional).
8. Add the translated text in the new column for the object names and object ids that you want.

	A	B	C	D	E
1	**Entity name**	**Object ID**	**Object Column Name**	**1033**	**1034**
2	Solution	14f57dce-98ca-ea11-a812-000d3a59f6ff	friendlyname	Contoso Sales app	
3	Publisher	016839c8-98ca-ea11-a812-000d3a59f6ff	friendlyname	Contoso Inc

10	account	98b09426-95ab-4f21-87a0-f6775f2b4210	DisplayName	Email Address 2	Dirección de correo electrónico 2
11	account	b254ab69-de5a-4edb-8059-bdeb6863c544	Description	Type the primary email address for t	Escriba la dirección de correo
12	account	b254ab69-de5a-4edb-8059-bdeb6863c544	DisplayName	Email	
13	account	ca8d0a94-8569-4154-b511-718e11635449	Description	Type the city for the primary addres	Escriba la ciudad para la dirección principa
14	account	ca8d0a94-8569-4154-b511-718e11635449	DisplayName	Address 1: City	

9. When you're finished adding your translations, save, and zip up the package so you can Import translated table and column text.

> **Note**
>
> Not all content can be translated using this tool. This includes labels for sitemap areas, groups, and subareas. To translate these labels, **use the More Titles property in the sitemap designer**.

Community tools

Easy Translator is a tool that XrmToolBox community developed for Power Apps. Use Easy Translator to export and import translations with contextual information.

> **Note**
>
> The community tools are not supported by Microsoft. If you have questions about the tool, please contact the publisher. More Information: **XrmToolBox**.

Next steps

Import translated table and column text

Import translated table, form, and column text back into an app

Article • 03/13/2023

If you have customized table or column text, such as column labels or drop-down list values, you can provide the users in your organization who are not working with the base language version of your environment with this customized text in their own languages. To do so, you export the text strings for all your customizations so that they can be translated into the languages you use in your organization.

After the translation, you need to import the translated text strings into your environment before users can take advantage of the changes.

> **Important**
>
> - The file that you import must be a compressed file that contains the CrmTranslations.xml and the [Content_Types].xml file at the root.
> - You can't import translated text that is over 500 characters long. If any of the items in your translation file are longer than 500 characters, the import process will fail. If the import process fails, review the line in the file that caused the failure, reduce the number of characters, and try to import again. Also note that after you import translated text, you must republish customizations.

1. Sign in to Power Apps at https://make.powerapps.com.
2. Select **Solutions**, and select the unmanaged solution from which to import the translated text. If the item isn't in the left navigation pane, select ...More and then select the item you want.
3. In the solution explorer, on the Actions toolbar, select **Translations**, and then select **Import translations**.
4. In the **Import Translated Text** dialog box, specify the file that contains the translated text, and then select **Import**.
5. When the import is complete, select **Close**.

> **Note**

Publishing customizations can interfere with normal system operation. We recommend you schedule publishing when it's least disruptive to users.

Community tools

Easy Translator is a tool that XrmToolBox community developed for Power Apps. Use Easy Translator to export and import translations with contextual information.

> **Note**
>
> The community tools are not supported by Microsoft. If you have questions about the tool, please contact the publisher. More Information: **XrmToolBox**.

Next steps

Export customized table and column text for translation

Privileges required for Dataverse customization

App users can personalize the system and even share some of their customizations with others. Only users with the correct privileges can apply changes for everyone.

> **Note**
>
> - This section assumes you know how to work with security roles. For more information about working with security roles, see Security roles and privileges.
> - For some feature and data access, a system customizer security role might be required. More information: A copied system customizer security role might not provide the same access.

System administrator and system customizer security roles

Anyone who customizes the system needs at least the system customizer security role associated with their account. This security role gives you the permission you need to customize in Microsoft Dataverse.

Expand table

System administrator	System customizer
Has full permission to customize the system and manage the environment.	Has permission to customize the system.
Can view all data in the system.	Can view all custom tables in the system but only view rows (records) in the account, contact, and activity tables that they create.

The difference between the system administrator and system customizer security roles is that a system administrator has read privileges on most records in the system and can see everything. Assign the system customizer role to someone who needs to perform customization tasks and has access to all the custom tables but only has access to the account, contact, and activity rows (records) they create. However, testing is an important part of customizing the system. If

system customizers can't see any data, they need to create rows (records) to test their customizations. By default, system customizers have full access to custom tables. If you want to have the same limitations that exist for system tables, you need to adjust the system customizer security role so that the access level is **User** rather than **Organization** for custom tables.

Add a security role to a user

For information about how a Power Platform admin can add a security role to a user, go to Add users to a security role

Delegate customization tasks

You might want to delegate some tasks to trusted people so that they can apply changes they need. Keep in mind that anyone can have multiple security roles associated with their user account and that privileges and access rights granted by security roles are based on the *least restrictive* level of permissions.

This means that you can give the system customizer security role to someone who already has another security role, perhaps a sales manager. This access lets them customize the system in addition to other privileges they already have. You don't need to edit the security role they already have, and you can remove the system customizer security role from the person's user account when you want.

Test customizations without customization privileges

Always test customizations by using a user account that doesn't have customization privileges. This approach ensures that people without the system administrator or system customizer security roles can use your customizations. To test effectively, you need access to two user accounts: one account with the system administrator security role and another account that has the security roles representing the people who use the customizations.

> ⓘ **Important**
>
> Don't attempt to remove your system administrator security role if you have only one user account. The system warns you if you try, but if you proceed, you might not be able to get it back. Most security roles don't allow editing of a user's security roles.

Microsoft Dataverse API limits overview

Article • 01/31/2023

Dataverse API limits help ensure service levels, availability, and quality. Dataverse API limits are part of the Power Platform Request limits and allocations. This article will introduce limits specifically for Dataverse applicable for Power Apps, Power Automate, and customer engagement apps (Dynamics 365 Sales, Dynamics 365 Customer Service, Dynamics 365 Field Service, Dynamics 365 Marketing, and Dynamics 365 Project Service Automation) connecting to Dataverse.

For information about limits for all areas within Power Platform, see Power Platform Request limits and allocations.

There are two categories of limits that apply for Dataverse: *Entitlement* and *Service protection* limits as summarized below.

Expand table

Service Protection limits	**Power Platform Request (API Entitlement) limits**
Immediately return 429 Too Many Requests when limits are exceeded.	Enforced for Power Automate flows but will have provisions for occasional overages on Dataverse, when enforced
Evaluated in a 5-minute sliding window.	Evaluated in a 24-hour period.
Applies to all external requests to Dataverse web services.	Applies to all compute operations and analytics originating from internal or external requests.
Developer is responsible for avoiding conditions that can cause errors and managing retry when they occur.	Administrator is responsible to manage assigned capacity. They can purchase capacity add-ons to increase limits.
Enforced today within the product.	- Will be enforced after preview report, available today for administrators to track and estimate usage, is made generally available. -Preview reports are available now.
More information: https://aka.ms/serviceprotectionlimits	More information: https://aka.ms/PlatformLimits

Entitlement limits

These limits represent the number of requests users are entitled to make each day. The allocated limit depends on the type of license assigned to each user.

If any user exceeds their request entitlement, the administrator would be notified and would be able to assign Power Apps and Power Automate request capacity to that user. Users won't be blocked from using apps for occasional and reasonable overages at this point of time.

For Dataverse, API requests include all data operations that interact with table rows where rows are created, retrieved, updated, or deleted (CRUD). Special operations such as *share* and *assign* are included because they're considered updates. These requests can be from any client or application and using any endpoint. These include, but aren't limited to, operations performed by plug-ins, async workflows, custom controls, and $batch (ExecuteMultiple) operations. There's a small set of system internal operations that are excluded, like sign in, sign out, and system metadata operations.

> **Important**
>
> Power Platform API request allocations include use of Power Automate, AI Builder, and Connector APIs. All requests through a connector that result in a Dataverse request will represent 1 Power Platform request.

For details on these entitlement limits, see Microsoft Power Platform requests allocations based on licenses.

For information about viewing and allocating capacity add-ons, see Capacity add-ons.

For information about purchasing individual capacity add-ons see the Power Apps and Power Automate Licensing Guide.

Service protection limits

To ensure consistent availability and performance for everyone we apply some limits to how APIs are used with Dataverse. Service protection API limits help ensure that users running applications can't interfere with each other based on resource constraints. The limits won't affect normal users of the platform. Only applications that perform a large number of API requests may be affected. The limits provide a level of protection from random and unexpected surges in request volumes that threaten the availability and performance characteristics of the Dataverse platform.

We limit the number of concurrent connections per user account, the number of API requests per connection, and the amount of execution time that can be used for each

connection. These metrics are evaluated within a five-minute sliding window. When one of these limits is exceeded, an exception will be thrown by the platform.

> **Note**
>
> Service protection limits apply to all external web service requests, not only the CRUD operations on tables counted against entitlement limits.
>
> Service protection API limits aren't applied against API calls made within workflows, custom workflow activities, or plug-in code. These operations are invoked internally.

Service protection limits are only encountered by applications that perform a high volume of data operations. We recommend that developers building applications that perform a high volume of data operations apply patterns to retry operations after a period of time when these exceptions are returned. Applying these patters will allow the application to respond to exceptions the service sends and reduce the total number of requests and achieve the highest possible throughput.

For information about the specific errors that can be returned and how developers can apply patterns to respond to these errors, see Service Protection API Limits.

Migrate Microsoft Access data to Microsoft Dataverse

Article • 04/26/2023

Microsoft Access users can now choose to migrate their data into Dataverse or Dataverse for Teams to make use of Azure cloud security and Microsoft Power Platform functionality. Migrating Access data to Dataverse provides many new opportunities for interaction and management of data.

Watch this short video about migrating Access data to Dataverse.
https://learn-video.azurefd.net/vod/player?id=c151d1a0-3a30-4715-95cb-aab380611592&locale=en-us&embedUrl=%2Fpower-apps%2Fmaker%2Fdata-platform%2Fmigrate-access-to-dataverse

Migration is handled in Access using the export feature, and the migration tool that streamlines the process.

> **Note**
>
> Learn how to prepare MS Access for Migration

Once migrated, Access users can continue using their existing desktop client to manage their data. They're also able to use Power Platform to manage their data. Plus, they can:

- Create applications for desktop, laptop, phone, and tablet.
- Create automated processes based on the data and services in Dataverse or Dataverse for Teams.
- Create AI-driven virtual assistants based on the data.
- Perform deep analysis on the stored data using business intelligence.

Before you migrate, there are a few key factors to consider. Currently, Dataverse and Dataverse for Teams don't support every data type that is in Access. Additionally, some data types in Dataverse and Dataverse for Teams may have different data limits. More information: Data types and sizes for Access data migration to Dataverse

Dataverse and Dataverse for Teams offer differing features that you can use to best meet your needs. Dataverse for Teams is targeted at users who want to have Power Platform functionality within the Microsoft Teams application. Dataverse is included with licenses of Dynamics 365 or Power Apps. Organizations that have a Dataverse for Teams environment can choose later to upgrade to Dataverse.

Expand table

Dataverse	Dataverse for Teams
All available data types supported.	Relational data, image, and file data support, built on the core of Dataverse.
Dataverse enterprise-grade capabilities, including advanced Role-Based Access Control, highly extensible business logic, sophisticated reporting, and robust offline.	Use apps, chatbots, and automations backed by Dataverse embedded in Teams on any platform.
Existing premium connectors to enterprise systems such as SAP, Oracle, and so on.	Some data types are not supported or have minimal functionality (Currency, Date Only, Customer).
Standalone premium apps, bots, and automations outside of Teams.	Not all controls are available, such as bar code scanner, interface tools, and formulas.

Total storage capacity is also different. Dataverse and Dataverse for Teams have a heterogenous data storage platform, which allows for storing different types of data in ways that help improve performance and lower cost of maintenance.

Access

Dataverse[1]

Dataverse for Teams

2-GB storage on local machine

- 10-GB relational database
- 20-GB file and image blob storage
- 2-GB log storage in non-relational storage
- You can purchase additional capacity as needed in any of the store types
- 2-GB storage (up to 1 million records) per Team
- Images, files, and logs stored separately in blob storage (counts towards 2-GB limit)

[1] Single base license

For more information, go to How are Dataverse for Teams and Dataverse different?

Comparison of Access and Dataverse Terminology

Users integrating Access with Dataverse or Dataverse for Teams may find some differences in names for general features and functions. This section provides a guide to understand naming differences.

Unlike Access, Dataverse and Dataverse for Teams are data sources. The user interface layer will depend on what Power Platform feature you are using: Power Apps, Power Automate, Power BI, or Microsoft Copilot Studio. The lists below encompass naming differences and similarities at the database layer only.

Expand table

Access	Dataverse and Dataverse for Teams	Comments
Primary Key	Primary Key	The usage is the same but the key contents are different
Calculated Field	Calculated Column (property)	Dataverse does not have a calculated column data type but rather allows calculations to be created on individual data types like whole number, decimal, or text
Row	Row or record	Sometimes referred to as a record in Dataverse and Dataverse for Teams
Short Text	Text	Supported for migration
Long Text	Multiline Text	Supported for migration
Rich Text	Rich Text	Supported for migration
Number: Single	Float	Supported for migration
Number: Double	Float	Supported for migration
Large Number	Big Integer (BigInt)	Supported for migration, usable through Dataverse API, Power Apps UI does not currently support this
Number: Decimal	Decimal	Supported for migration
Yes/No	Yes/No	Supported for migration
Int	Whole Number	Supported for migration

Access	Dataverse and Dataverse for Teams	Comments
Multi-Select Options	Choices	Supported for migration
GUID	Unique Identifier	In Dataverse and Dataverse for Teams, this is currently only used as a key
Hyperlink	URL	Supported for migration
Unique Index	Alternate Key	Not supported for migration
Multi-Value Lookup	Choice	Supported for migration

Migrating Access databases into Dataverse solutions

To enable application lifecycle management (ALM), Dataverse uses solutions to allow for the management, and distribution of content including apps, tables, and more. A solution is a package of components such as tables, relationships, or other items that can be distributed across multiple Dataverse environments through solution export and import.

The Access migration tool allows users to choose if they wish to export their Access databases directly into a solution. Access databases in solutions are exported as an unmanaged solution. A solution must exist or be created in Dataverse prior to the migration to be used for the migration process. To learn more about solutions, go to: Solution Concepts

Data types and sizes for Access data migration to Dataverse

Article • 01/26/2023

When you migrate from Microsoft Access to Microsoft Dataverse or Microsoft Dataverse for Teams, you should be aware of a few differences in the data types. These differences include supported types, data type names, and column capacity.

When you migrate, a validation will be executed to ensure:

- The table only includes supported data types.
- The column values in the rows being migrated don't exceed the size limits of Dataverse.

This validation is done to prevent data loss. If a table has columns that exceed the maximum column value in Dataverse, or the table contains data types not supported by Dataverse, the user will be alerted by the Access migration tool validator and will be provided additional information.

Users can choose to either cancel the migration completely, or to continue to migrate all supported content and keep the unsupported content in an Access table.

> **Note**
>
> Learn how to prepare MS Access for Migration

Access data types supported by Dataverse

In the following table, the data type mappings supported can assist you in planning your data migration.

Access data type	Dataverse data type	Can migrate?
Short Text	Text	Yes
Long Text	Multiline text	Yes
Autonumber	Autonumber	Yes
Date/Time	Date and Time	Yes
Currency	Currency	Yes
Number: Decimal	Decimal Number	Yes
Float	Number:Single, Number:Double	Yes[1]

Access data type	Dataverse data type	Can migrate?
Yes/No	Yes/No	Yes
Int	Whole Number	Yes
Lookup Wizard	Lookup	Yes
Multi-Value Lookups	Choice	Yes[2]
Hyperlink	URL	Yes
Attachment	File	Yes[3]

[1]Dataverse includes a float data type. However, it has lower limits than Access a min/max of +/- 100,000,000,000 or +/- 99,999,999,999.99999. A maximum of five decimal places is supported. Users will be informed of this limitation during migration and can opt out if they require greater than five decimal places.

[2]One column multi-value lookups only. Because of the difference in how Dataverse and Access identify these lookups, a manual process is needed in Access before migration. More information: Export multi-value lookup Access Fields to Dataverse choice columns

[3] Attachments can be migrated for single attachments per column at this time.

Access data types not supported for migration to Dataverse

- OLE Object
- Calculated[4]
- Rich Text

[4]When you migrate, the calculated field will migrate the last calculated value into a column. Users will need to configure new calculation columns in Dataverse. More information: Define calculated columns to automate calculations

Access and Dataverse data size comparison

You'll notice some Dataverse columns don't have the same size capacity as Access. As noted above, if a column contains data too large to be migrated, the migration tool alerts the user that the contents can't be migrated. This is to prevent data loss. This decision isn't based on the maximum possible size for the column, but rather the size of the actual data in each row.

Access/Dataverse data type	Access limit	Dataverse limit
Short Text/Text	255 characters	4,000 characters

Access/Dataverse data type	Access limit	Dataverse limit
Long Text/Multiline Text	1 GB	1,048,576 characters
Autonumber	2,147,483,647	4,000 characters
Date and Time	Standard date and time	Standard data and time
Currency[5]	Min/max -922,337,203,685,477/+922,337,203,685,477	Min/max -922,337,203,685,477/+922,337,203,685,477
Decimal Number	Min/max -10^28-1/+10^28-1 up to 28 decimals	Min/max -100,000,000,000/+100,000,000,000 up to 10 decimal places
Float (Number:Single)	-3.402823E38 to -1.401298E-45 for negative values and 1.401298E-45 to 3.402823E38 for positive values.	Min/max -100,000,000,000/+100,000,000,000 up to five decimal places
Float (Number:Double)	-1.79769313486231E308 to -4.94065645841247E-324 for negative values and 4.94065645841247E-324 to 1.79769313486231E308 for positive values.	Min/max -100,000,000,000/+100,000,000,000 up to five decimal places
Yes/No	Boolean	Boolean
Int/Whole Number	Min/max -2^31/+2^31	Min/max -2,147,483,647/+2,147,483,647
Lookup Wizard/ Lookup	Multiple column return	Single column return

[5]The migration tool assumes the currency coming from Access is the Dataverse base currency.

Calculated fields in Access will currently create a column for the content type in Dataverse that stores the calculated value. This could be text, whole number, decimal, and so on. Dataverse can be used to create calculated fields to enable calculations.

Export multi-value lookup Access Fields to Dataverse choice columns

Both Access and Dataverse offer users the ability to provide a list of multiple values a user can select from in a row. The ways these are implemented are different.

Access uses a multi-value lookup, which is a lookup that allows the user to enter any number of values, which will then be presented as a dropdown list for selection. Access has the ability to have more than one column of values for this function.

Dataverse uses choice columns, which are an enumerated list of values that each have a string label associated to them. Users locate and choose the values in a dropdown list using the label values that are stored in the background as an enum selection with a relationship to the table where the labels are stored.

Because of these differences, migrating multi-value lookup columns from Access into Dataverse presents some challenges. The following process must be followed to migrate:

1. Access can only start with a single column multi-value lookup.
2. Access users must add a new column to the multi-value lookup to act as the enum value expected by Dataverse.
3. At export, Dataverse will store this as two columns, which allows both Dataverse and Access to use the lookup appropriately in forms.

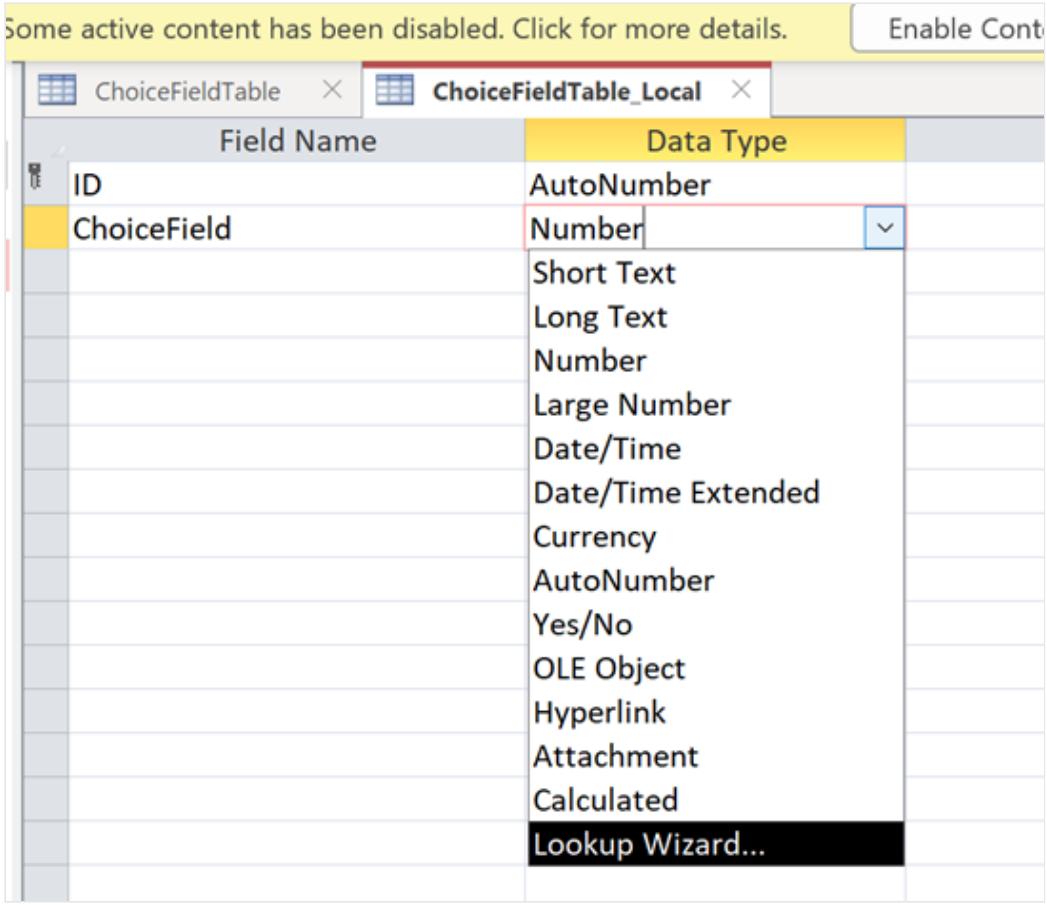
Creating a valid choice field for export to Dataverse

To successfully migrate a choice field from Access, the field must be created in a manner that is similar to the steps described here.

1. Create a new table in Access.

2. Add a **Number** field to the table. It must be a **Number** field to support export to Dataverse.

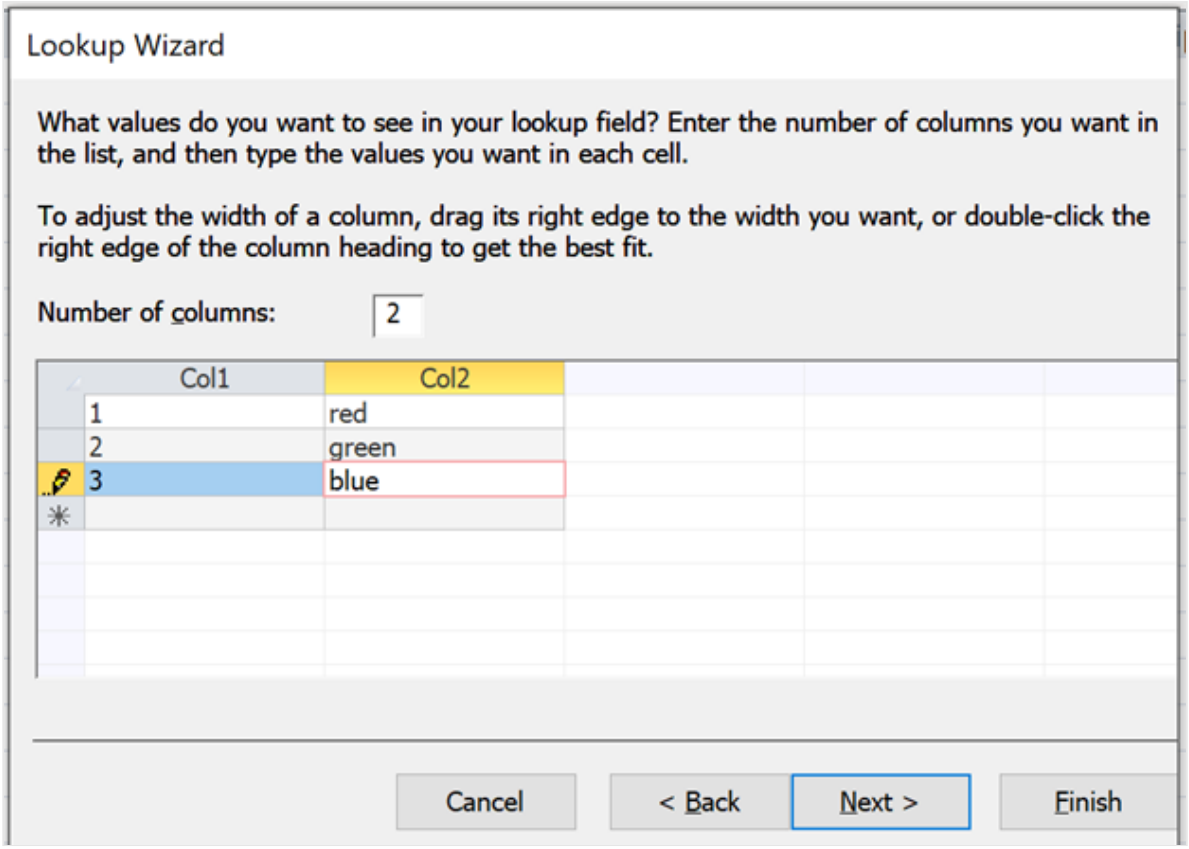
3. Go to **Design View** in Access. Select the new field, and then select **Lookup Wizard**.



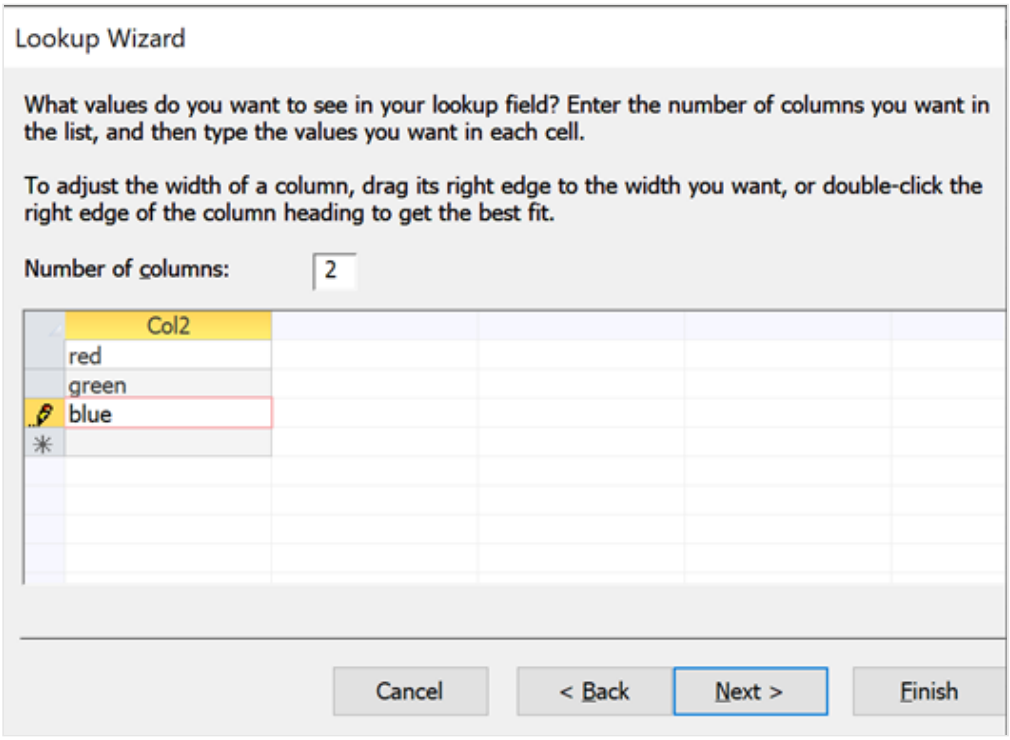
4. In the Lookup Wizard, select the **I will type in the values that I want** option, and then select **Next**.

5. In the next dialog, enter *2* for the number of columns and then select the field below **Col1**.

6. In **Col1** enter values for three rows by entering *1*, *2*, and *3*. In **Col2** enter values for three rows by entering *red*, *green*, and *blue*.



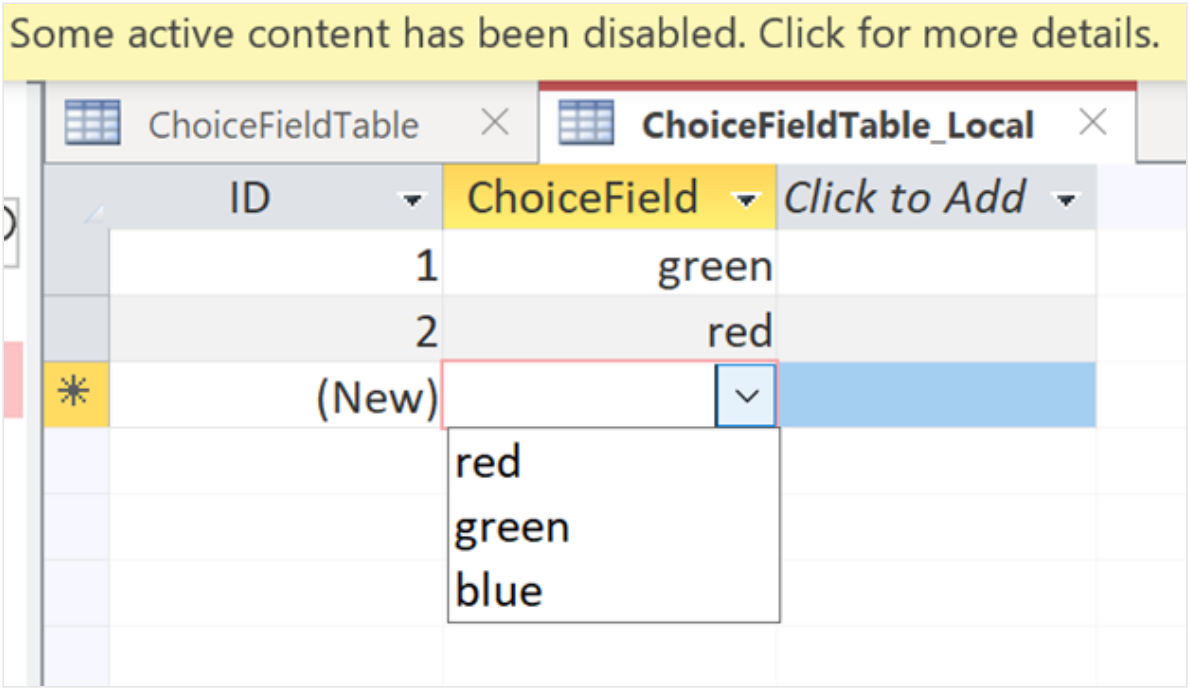
7. Select the separator between **Col1** and **Col2** and slide it to the left so that only **Col2** appears.



8. Select **Next** > **Next** > **Finish** to complete the Lookup Wizard.

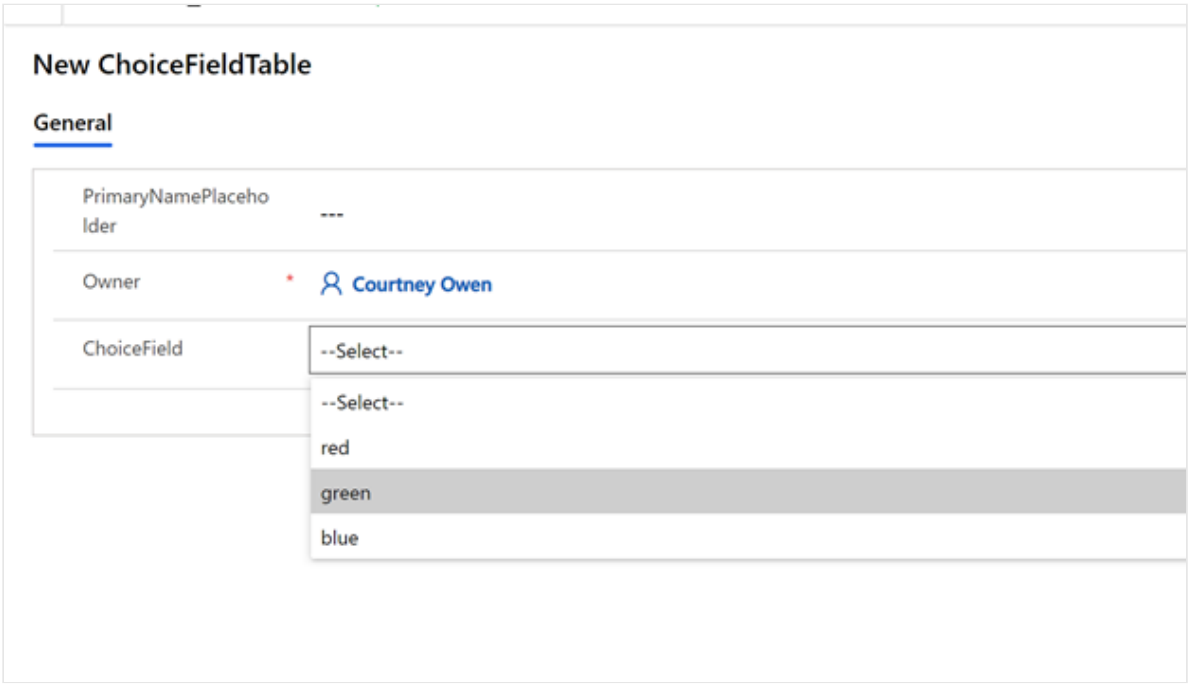
9. Save your changes and return to the **Datasheet View**.

10. Create a new record to validate the choice field works as expected. It should appear like this if it was configured properly.



11. Close the table and migrate it to Dataverse.

12. If everything worked properly, the choice column in Dataverse will appear like this when adding a new record.



Migrate Number:Single and Number:Double columns to Dataverse

Both Access and Dataverse include the ability to store floating point numbers. Access uses `Number:Single` and `Number:Double` for this. These data types are often used for any number column. Dataverse has a **Floating Point Number** data type, but it has some limitations with how it's implemented. Dataverse only allows a maximum of five decimal places with a minimum/maximum value of -/+ 100,000,000,000. When migrating, the validator informs you that by migrating this data as a float you'll lose some decimal precision. If that's acceptable, you can migrate the tables automatically. During the migration process any rows that exceed the min/max size limits won't be migrated and will be stored locally in a file in Access just as with any other out of range data type.

However, if you need to migrate but don't want to lose decimal precision, you can migrate Access `Number:Single` and `Number:Double` by changing the data type in Access. You can use the Access table designer and change the type of `Number:Single` and `Number:Double` columns to **Decimal**, which support up to 10 decimal places in Dataverse. Then any row that doesn't exceed the minimum/maximum decimal limits can be migrated.

Migrate Microsoft Access data to Microsoft Dataverse

System tables and columns in Dataverse and Dataverse for Teams

Article • 05/11/2022

Both Dataverse and Dataverse for Teams have several tables and columns that need to be present for data types and features to work properly. These are part of the default organizations and cannot be removed. When migrating from Access to Dataverse, you'll see columns added to tables after the migration and additional linked tables added in Access to support the columns. This document provides an overview of the tables and columns that will be added.

> ⓘ Note
>
> Learn how to prepare MS Access for migration.

Tables

The following tables are included in environments of Dataverse and Dataverse for Teams and may appear as a linked table in Access after migration. These tables can't be deleted.

- **Currency**: Used for currency transactions.
- **Users**: Stores users of the environment that use the apps or data. Used in lookup columns that are created by default.
- **Teams**: Stores teams of users in the environment that use the apps or data. Used in lookup columns that are created by default.
- **Business Unit**: Stores business units users belong to in the environment that use the apps or data. Used in lookup columns that are created by default.

> ⓘ Note
>
> - The tables are present and usable but not displayed by default in Dataverse for Teams.
> - The Currency table is linked in Access only when a currency column is added to the table.

Columns

The following columns are included in all tables of Dataverse and Dataverse for Teams and may be visible in Access linked tables. These columns can't be deleted.

- **Primary Name**: A user-friendly text string used to identify rows. The name is chosen by the user. In Access you can choose which field you want to use during migration, or it will be picked for you. If an Access table has no text fields, a text field will be created named Primary Name Placeholder which will be used to fill this need. It will be set to "optional" and will accept null values.
- **Primary ID**: A unique identifier string used to identify rows. This is system generated and is the primary key. This column is present and usable but not displayed by default in Dataverse and Dataverse for Teams environments.
- **CreatedBy**: A lookup column to the Users table selecting the user who created the row.
- **CreatedBy (Delegate)**: A lookup column to the Users table selecting the user who created the row as a delegate for another user.
- **CreatedOn**: A date-time column that records the date and time a row was created, stored in UTC format.
- **Currency**: A lookup to the Currency column (logical name `Transactioncurrency`) to retrieve the details of a transaction currency for the purposes of calculating against the base currency. This column is visible in Access linked tables only when a currency column is added to the table.
- **Exchange Rate**: The exchange rate value retrieved from the transaction currency on the Currency table at the time the row was created. The column is visible in Access linked tables only when an exchange rate column is added to the table. This column is present and usable but not displayed by default in Dataverse, Dataverse for Teams environments, or Access linked tables.
- **Import Sequence Number**: The row's place in the sequence of imported records that added it to the table.
- **ModifiedBy**: A lookup column to the Users table selecting the user who modified the row.
- **ModifiedBy (Delegate)**: A lookup column to the Users table selecting the user who modified the row as a delegate for another user.
- **ModifiedOn**: A date-time column that records the date and time a row was modified, stored in UTC format.
- **Owner**: The unique OwnerID assigned to the user selected as the Owning User from the Users table. This column is present and usable but not displayed by default in Access linked tables.
- **Owning Business Unit**: A lookup to the Business Unit table to select the appropriate business unit that owns the row.

- **Owning Team**: A lookup to the Teams table to select the appropriate team that owns the row.
- **Owning User**: A lookup to the Users table to select the appropriate user that owns the row.
- **Record Created On**: Date and time that a row was migrated.
- **Status**: An option set that allows a user to pick the state of a row.
- **Status Reason**: An option set related to Status that allows a user to pick the status reason of a row based on the status selected.
- **Time Zone Rule Version**: Internal-only used to determine which set of time zone rules apply.
- **UTC Conversion Time Zone Code**: The time zone offset code that was in use at the time the row was created.
- **Version Number**: The version number of a row used to track previous changes if auditing is enabled.

Migrate Microsoft Access data to Microsoft Dataverse

Data types and sizes for Access data migration to Dataverse

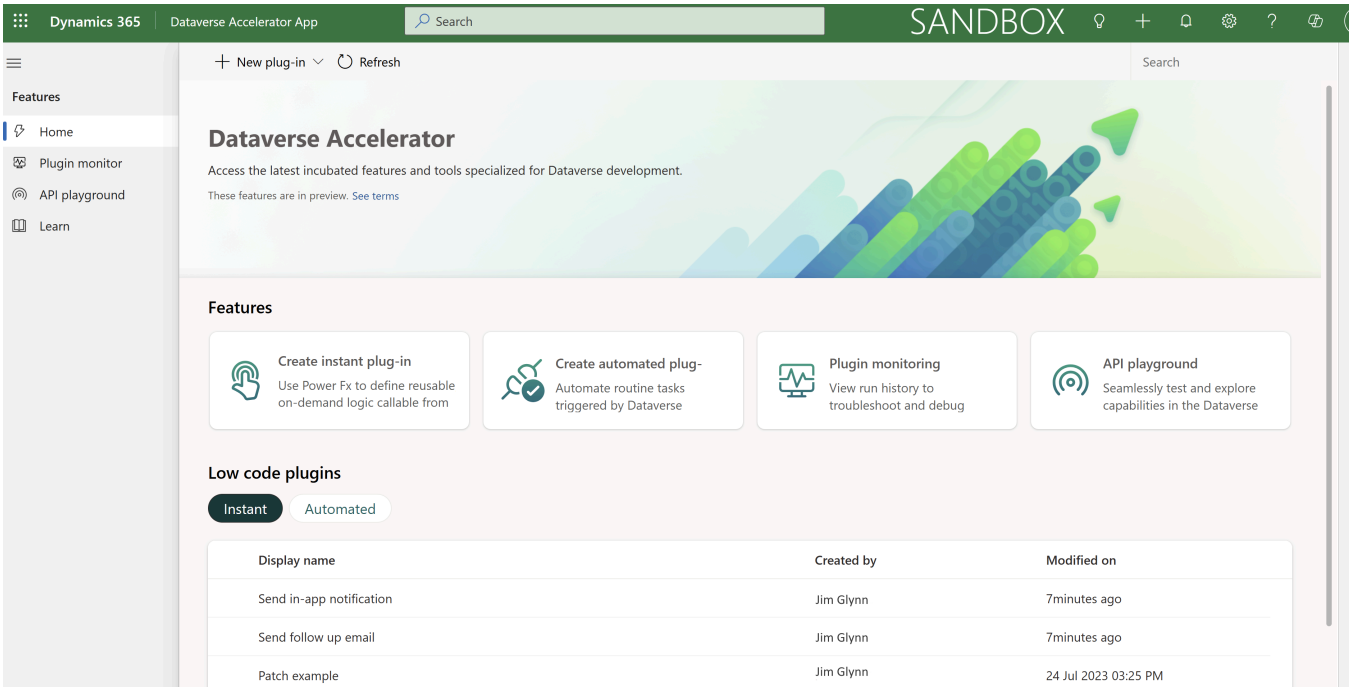
Get preview features early with the Dataverse accelerator (preview)

Summarize this article for me

[This topic is pre-release documentation and is subject to change.]

> **Important**
>
> The Dataverse accelerator, monitor plug-ins, and API playground features are deprioritized and aren't be delivered as features. For information about preview feature availability, go to Power Apps preview program.

The Microsoft Dataverse accelerator is a model-driven application that provides access to select preview features and tooling related to Dataverse development. The featured set of capabilities include early prototype experiences that represent backlog features scheduled to be in the native platform and tools for enriching Dataverse development for makers, delivered in a convenient and accessible web application built with low-code.



While preview features shouldn't be used in production instances, the accelerator offers the opportunity to proactively evaluate, share feedback, and prepare for integration. Using features available with the Dataverse accelerator helps you leverage cutting-edge capabilities to enhance productivity, optimize Dataverse processes, and maintain a competitive edge in Power Platform.

> **Important**

- This is a preview feature.
- Preview features aren't meant for production use and might have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

The Dataverse accelerator interface adheres to the same UX and accessibility standards as any Microsoft Power Platform experience. Furthermore, it serves as a demonstration of our platform's powerful low-code capability to ship enterprise-grade applications.

Features available with the Dataverse accelerator

Expand table

Feature	Description
Low-code plug-ins	Reusable, real-time workflows that execute a specific set of commands within Dataverse. Low-code plug-ins run server-side and are triggered by personalized event handlers, defined in Power Fx. For more information about how to use this feature, go to Low-code plug-ins.
Plug-in monitor	A modern interface to surface the existing plug-in trace log table in Dataverse environments, designed for developing and debugging Dataverse plug-ins and custom APIs. For more information about how to use this feature, go to Plug-in monitor.
API playground	A preauthenticated software testing tool that helps makers quickly and conveniently interact with the Dataverse Web API. For more information about how to use this feature, go to API playground.

Note

If all features aren't available in the Dataverse accelerator app, update the app. More information: update the Dataverse accelerator app.

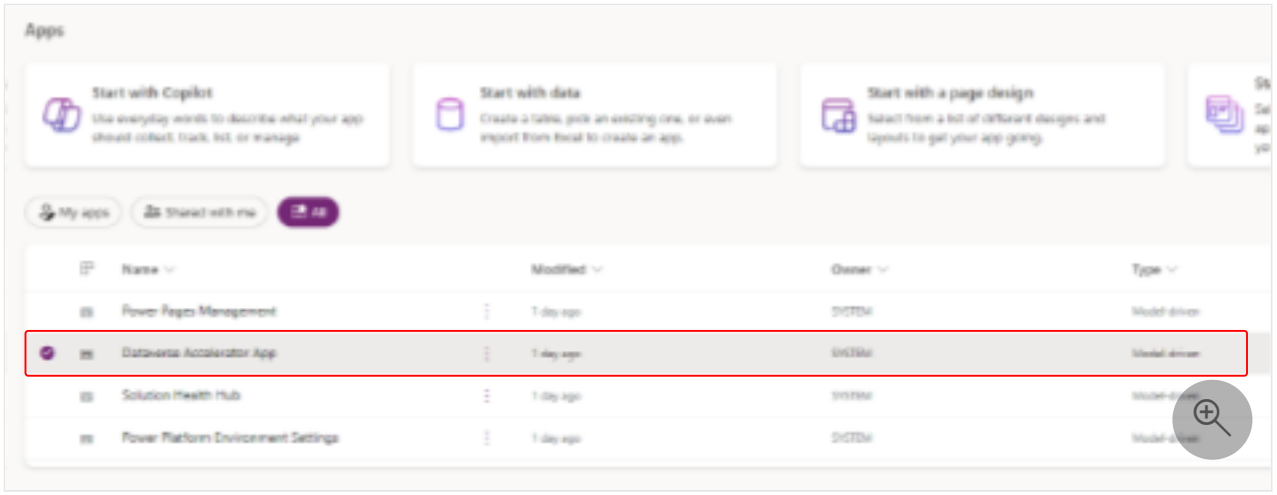
Play the Dataverse accelerator

Play the Dataverse accelerator app in any environment where it's installed.

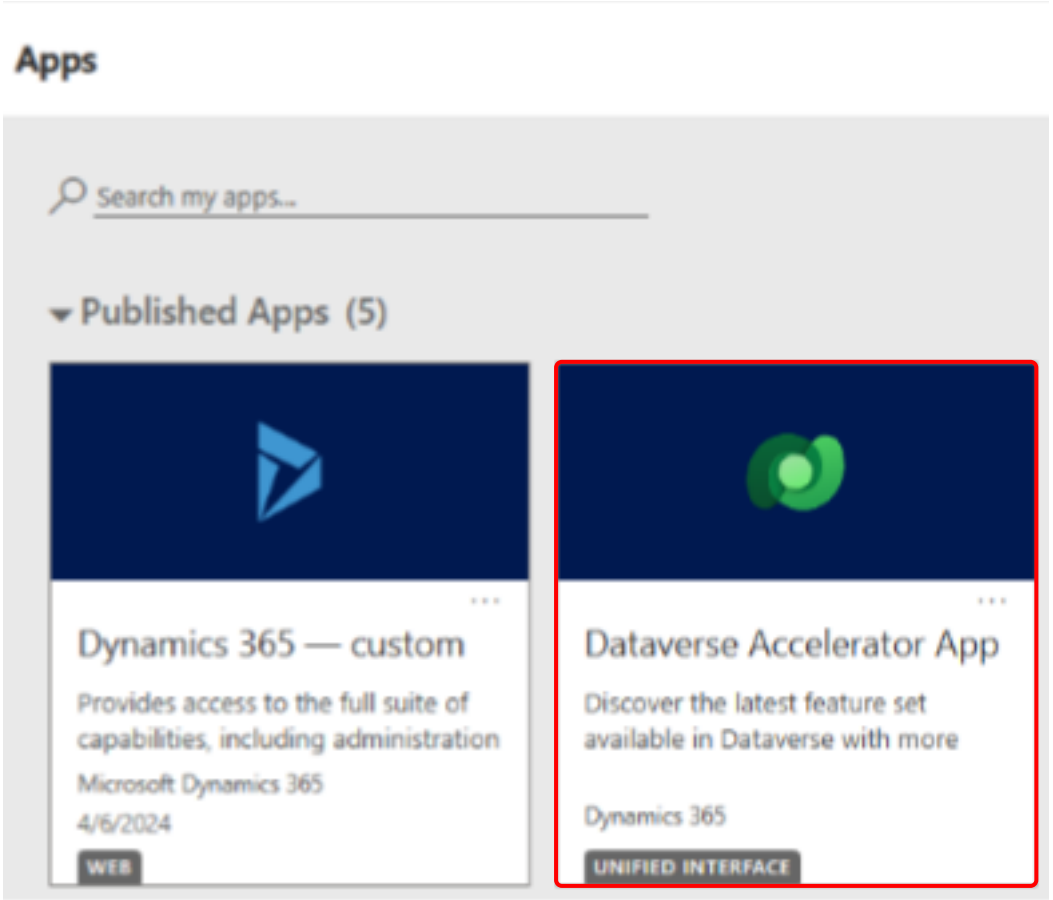
The app is automatically available in all new Microsoft Dataverse environments. If your environment doesn't already have it, you can install the Dataverse accelerator.

The app appears in two places:

1. In Power Apps, select **Apps**



2. On the Power Apps or Dynamics 365 home page.



When you play the Dataverse accelerator, features are displayed in the accelerator that you can try out.

Prerequisites to run the Dataverse accelerator

You must have the following privileges in your Dataverse environment:

- Security role: System customizer.

- App-level access to the Dataverse accelerator model driven app, such as system customizer or direct access from a security role.

Prerequisites for managing the app

You must have the following security role assignment and your Dataverse environment must be the same or later than the minimum version:

- Security role: You must have the system administrator security role in the environment.
- A Dataverse environment with minimum database (DB) version of `9.2.22122.00148`. Check the database version:
  - In the Power Platform admin center select **Manage** > **Environments**, and then select the environment you want. Select **Detailed view**, and under **Version** the version is displayed.
  - By using the RetrieveVersion function with your browser. Type `https://<your org>.<your region code>.dynamics.com/api/data/v9.2/RetrieveVersion` in your browser address bar and view the JSON returned.

Install or update the Dataverse accelerator

If the Dataverse accelerator isn't already installed or if you want to install the latest version, Power Platform admins should follow these steps:

1. In the Power Platform admin center, select **Manage** > **Environments**, select the environment you want, and then select **Resources** > **Dynamics 365 apps** on the command bar. If you're using the earlier version of the admin center, expand **Resources**, and then select **Dynamics 365 apps**.
2. Find **Dataverse Accelerator** in the list.
   - If **Update available** appears next to the **Dataverse Accelerator**, select the app and then select **Update**.
   - Otherwise, select **Install app**, select **Dataverse Accelerator** in the list, and then select **Next**.
3. Follow the instructions on your screen to install the app or apply the update.

Uninstall the Dataverse accelerator

You can delete the Dataverse accelerator app from an environment using Power Platform CLI.

> **Note**
>
> Deleting the Dataverse accelerator app doesn't delete all underlying capabilities presented in the app. The app provides a modern shell to the underlying platform API.

Using Power Platform CLI, connect to the target environment and execute the three solution delete commands here:

PowerShell

```
pac solution delete --solution-name msdyn_DataverseAcceleratorApp
pac solution delete --solution-name DataverseAccelerator
pac solution delete --solution-name DataverseAccelerator_Anchor
```

Frequently asked questions (FAQs)

What is Dataverse accelerator?

Dataverse accelerator is a toolkit designed to expedite the development process within the Dataverse environment. It provides capabilities designed to help makers get more out of Dataverse by providing modern experiences for new and existing Dataverse features.

Who can use Dataverse accelerator?

Members of the system customizer security role have access to the app and underlying features. A custom security role can also be assigned to a user by the environment's system admin with similar privileges if desired.

What are the key benefits of using Dataverse accelerator?

Dataverse accelerator offers experimental and preview features that are designed to enhance or accelerate development in certain areas of Dataverse capabilities. Although in preview, accessing these features earlier in development can help you stay competitive and know about features coming in the native platform.

Is Dataverse accelerator compatible with my existing Dataverse environment?

Yes, Dataverse accelerator is compatible with existing Power Platform environments that have a Dataverse database enabled. It can be installed into your environment to enhance development capabilities without disrupting ongoing operations.

How do I install Dataverse Accelerator?

Follow the install instructions of this article to install the Dataverse accelerator, which points to the documentation for installing any Dynamics 365 app in a Dataverse environment.

If I don't want the Dataverse accelerator installed in my environment, can I delete it?

Yes, you can remove any instance of the Dataverse accelerator from an environment. To remove the Dataverse accelerator from your environment, follow the delete instructions of this article.

Can I customize Dataverse accelerator components to fit my specific requirements?

The Dataverse Accelerator app provides an experience on top of existing capabilities available in Dataverse by default. Several settings related to the experiences provided in the app are surfaced, and are based on and limited to the context of the respective features. However, don't customize any of the managed solution components.

Is there a cost associated with using Dataverse accelerator?

The features available in the Dataverse accelerator are available at no additional cost for users with appropriate licenses for Power Platform and Dataverse. However, additional costs might apply for storage capacity utilized by some of the features.

Where can I find support and resources for Dataverse accelerator?

See the section on contacting help and support for instructions on getting support either with the features in the Dataverse accelerator, or if you encounter problems using the Dataverse accelerator application.

How often is Dataverse accelerator updated?

Dataverse accelerator is regularly updated to incorporate new features, improvements, and bug fixes. Major updates are announced based on the individual features, and are indicated in the feature details, which are available in the app itself, release notes, and blog posts.

Contacting help and support

For issues with the Dataverse accelerator solution installation or with features, such as low-code plug-ins errors, use the help + support experience and include the following information:

- Problem type: **Dataverse Web API and SDK**
- Problem subtype: **Accelerator kit for Dataverse**

Limitations and known issues

The Dataverse accelerator isn't available in GCC or GCC High environments.

Monitor and troubleshoot Dataverse plug-in runs (preview)

Summarize this article for me

[This topic is pre-release documentation and is subject to change.]

> **Important**
>
> The Dataverse accelerator, monitor plug-ins, and API playground features are deprioritized and aren't be delivered as features. For information about preview feature availability, go to Power Apps preview program.

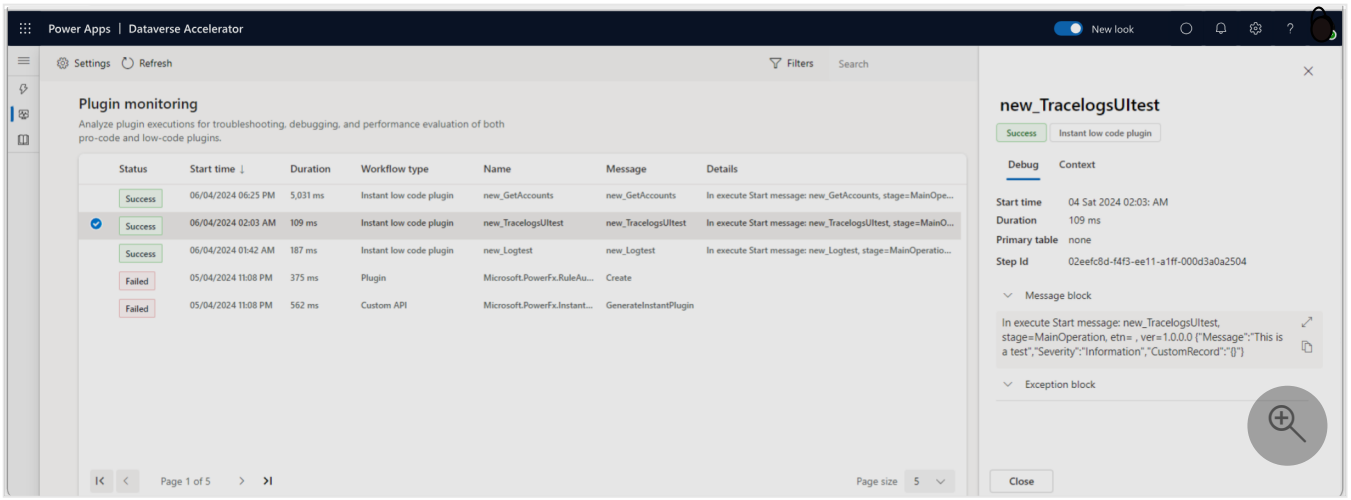
Use tracing to troubleshoot low-code and pro code plug-ins. Tracing helps makers by recording run-time information as an aid in diagnosing the cause of failures, or for general validation of certain states during development.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

The plug-in monitoring module of the Dataverse accelerator is an enhanced view of the existing tracing and logging capabilities available in Microsoft Dataverse for plug-ins. The interface helps improve the troubleshooting and debugging processes during development phase by collocating relevant details in a modern treatment.

All events surfaced in the app are read from the Trace table for 24 hours by the following workflow types:

- Plug-ins
- Custom APIs
- Instant and automated low-code plug-ins



Prerequisites

You must have the following security role assignment and access to the Dataverse accelerator app:

- Security role: Both system customizer and system administrator security roles have the necessary privileges to enable logs and use the app by default.
- Alternatively, you can create custom roles with specific access to each capability by configuring the following privileges:
  - To *read* logs, organization-level read privilege to the Trace table is required.
  - To *enable* logging in the environment, organization-level write privilege in the Organization table's `PluginTraceLogSetting` is required.

Key features

- Centralized log viewer: Access and view trace logs from Dataverse custom APIs, low-code plug-ins, and pro code plug-in executions in an environment from one central location.
- Filtering capabilities: Conveniently filter log history to quickly find logs relevant to your debugging needs.

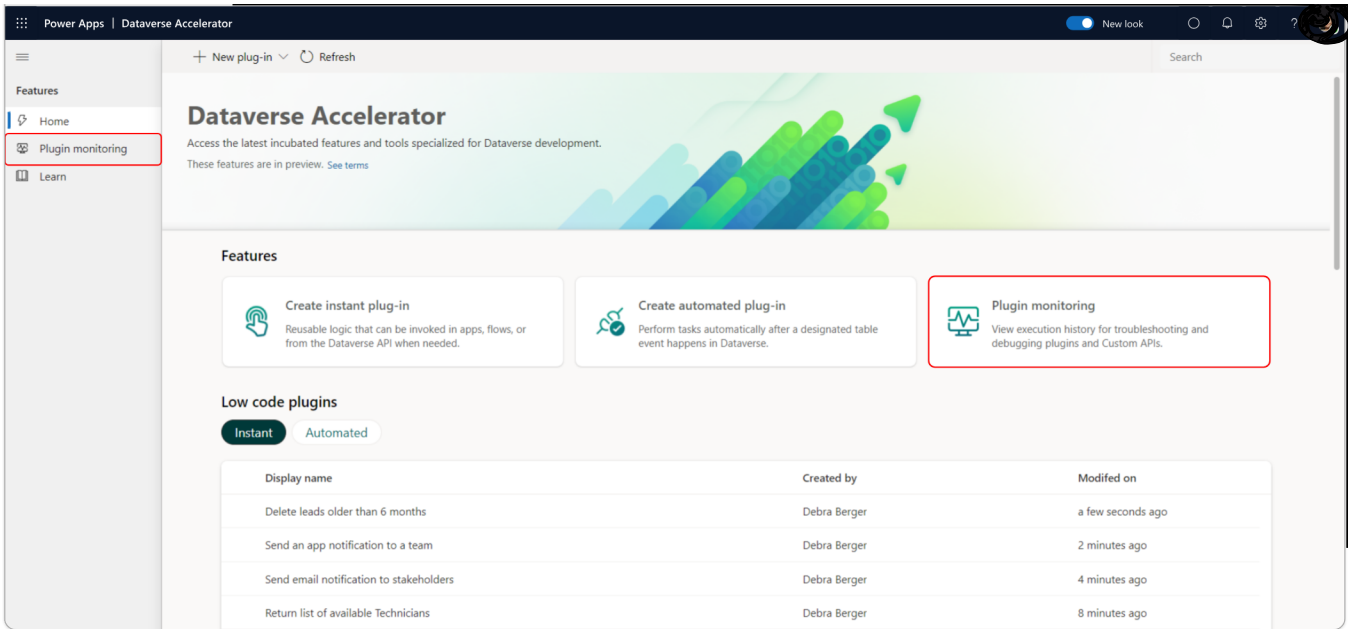
Installation

This feature is available in the Dataverse accelerator app. Go to the Dataverse accelerator article for installation instructions.

Try the plug-in monitoring feature

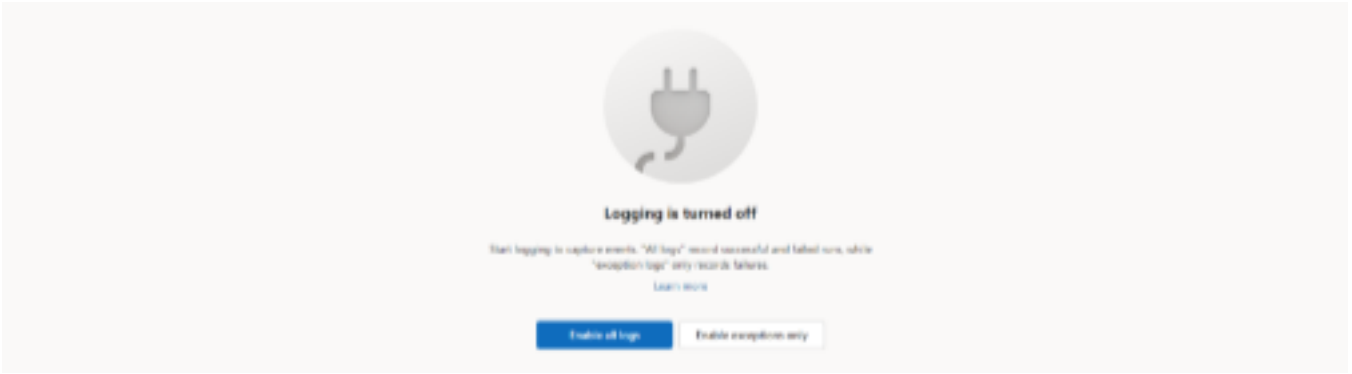
1. Play the Dataverse accelerator.

2. Go to the **Plugin monitoring** feature (on the left navigation pane or the feature card on the landing screen).

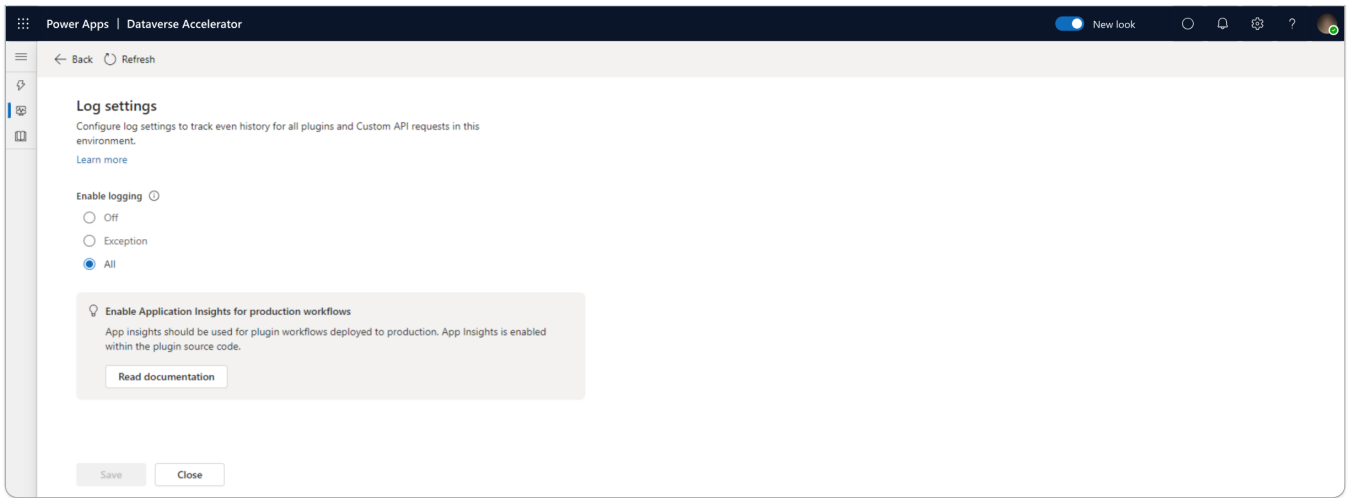


Enable log capturing

If log capturing isn't enabled in your environment, the landing page displays an off state with two options to enable logging: **All** or **Exceptions**. Choose the appropriate option based on your needs, go to the Logging and tracing article for more information.



You can change these settings later on the **Settings** screen if needed, which can be accessed on the command bar of the main screens.



> **Tip**
>
> Tracing and logging are ideal for debugging during plug-in development. For plug-in workflows in production, use Azure App Insights for monitoring.

View logs

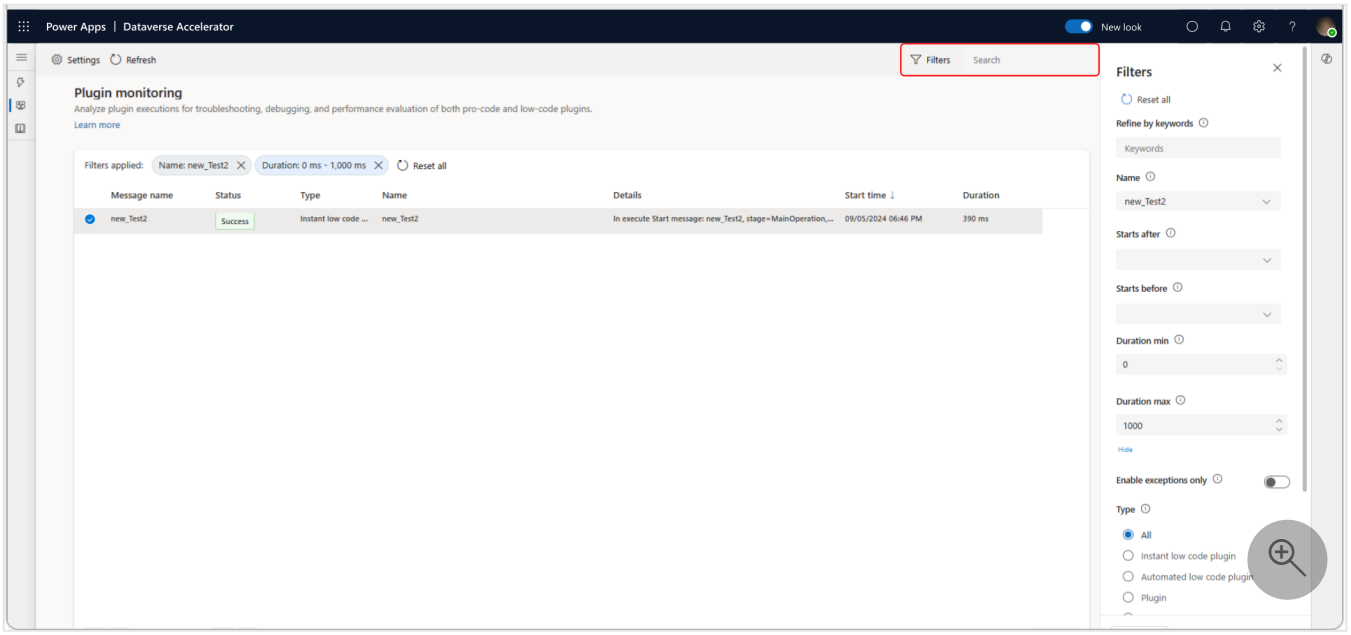
When logs are enabled, plug-in events start to show in the main list displayed on the screen.

> **Tip**
>
> If there are no logs showing, you can create and run a new low-code plug-in to start showing logs.

Filter logs

Utilize the filtering capabilities to quickly find logs relevant to the plug-ins you're working on.

Select **Filter** on the top right side of the command bar to open the filter pane. You can also quickly filter by keywords using the search bar.



Expand table

Filter	Description
Name	Select the logical name of the plug-in.
Starts after / before	The date time for when the plug-in was invoked.
Enable exception only	Shows runs with failure status.
Duration min / max	Minimum and maximum range of the plug-in duration.
Type	The classification of the plug-in workflow. Available types include: • Instant low-code plug-in • Automated low-code plug-in • Plug-ins • Custom API
Mode	Whether the plug-in is synchronous or asynchronous.

Read log details

Select a specific log entry to view detailed information about the plug-in execution. Log details include timestamp, plug-in name, execution status, output parameters, error messages, and more. Message block and exception block fields are displayed below the basic details in the pane, and are expanded if data exists in the respective columns.

Best practices

Examine log details

- Select a specific log entry to view detailed information about the plug-in execution.
- Log details might include timestamp, plug-in name, execution status, input/output parameters, error messages, and more.

Troubleshoot issues

- Use the information provided in the trace logs to troubleshoot any issues that arise during plug-in execution.
- Analyze error messages, input/output parameters, and execution details to identify the root cause of the problem.
- Use trace messages to provide helpful pointers. Writing to the trace service is available in the Dataverse SDK and in low-code plug-ins as the Trace function in Power Fx.

Take action

- Based on the insights gathered from trace logs, take appropriate action to address any performance issues or bugs identified.
- This might involve adjusting plug-in configurations, updating code logic, or seeking assistance from support resources.

Plan to test

- Make it a habit to plan test cases you can execute in trace logs to validate plug-in performance during development.
- Address any issues or anomalies promptly to maintain the overall stability and reliability of your Dataverse plug-ins.

Monitor plug-in performance

- Regularly monitor plug-in performance in production by reviewing trace logs registered with Application Insights.
- Keep an eye on execution status, error messages, and any anomalies that might indicate performance issues or bugs.

FAQs

What privileges are required to access the Trace Log Viewer?

You must have at least read privileges to the Trace table to view logs.

Who can enable log capturing within the environment?

System administrators with the appropriate security role can enable log capturing within their environment. Specifically, write access to the Organization table is needed to update the PluginTraceLogSetting column value.

Can I filter log history to find specific logs?

Yes, the trace log viewer provides filtering capabilities, allowing users to conveniently find logs relevant to their debugging needs.

Is the plug-in monitoring feature available in all environments?

The feature is delivered through the Dataverse accelerator and is available in all environments that have the app installed. The app is automatically installed in all new environments, but can also be installed in older environments by following the install instructions.

After I enabled logging, it still shows the "Logging is turned off" screen

If you have the correct privileges and are certain you have enabled logging, refresh the browser tab. You can validate whether logging is enabled using the legacy experience.

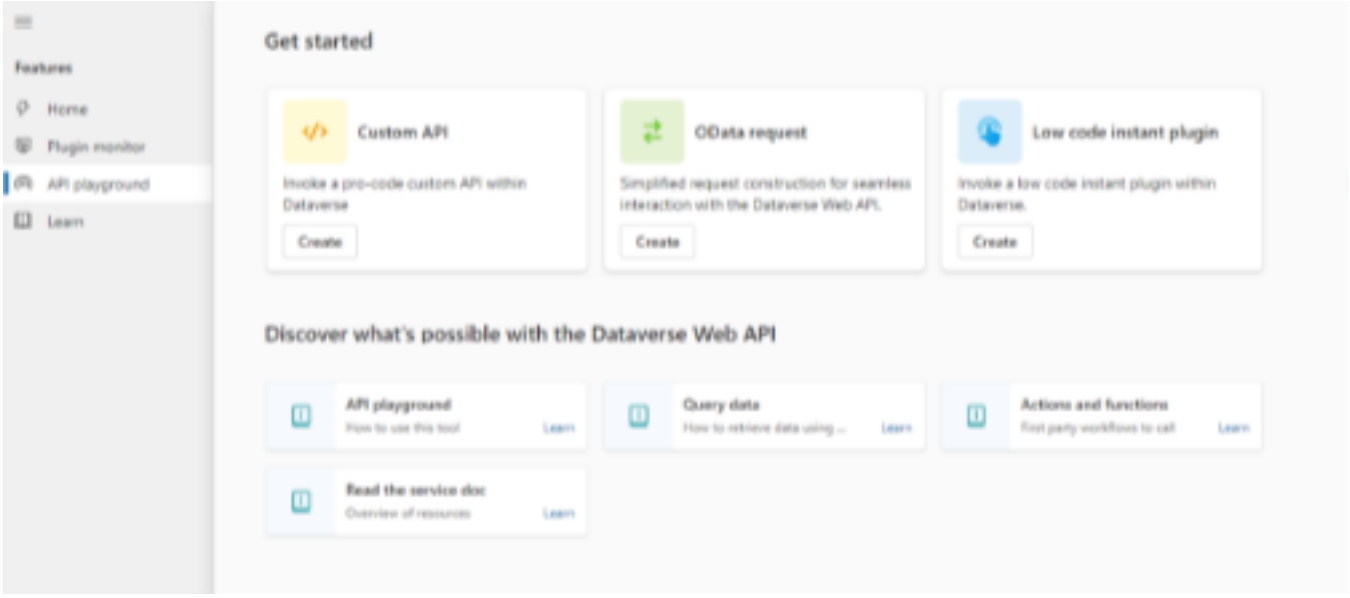
Explore and test Dataverse in the Web API playground (preview)

Summarize this article for me

[This topic is pre-release documentation and is subject to change.]

> **Important**
>
> The Dataverse accelerator, monitor plug-ins, and API playground features are deprioritized and aren't be delivered as features. For information about preview feature availability, go to Power Apps preview program.

The API playground is a preauthenticated software testing tool that helps makers quickly and conveniently interact with the Microsoft Dataverse Web API.



This web application allows developers to test and experiment with different API endpoints without the need for extensive setup or authentication processes. It also conveniently presents certain available actions and links to documentation for faster learning.

Use this tool to explore what's possible in the RESTful API, test user-defined workflows, and more.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers

can get early access and provide feedback.

Key features

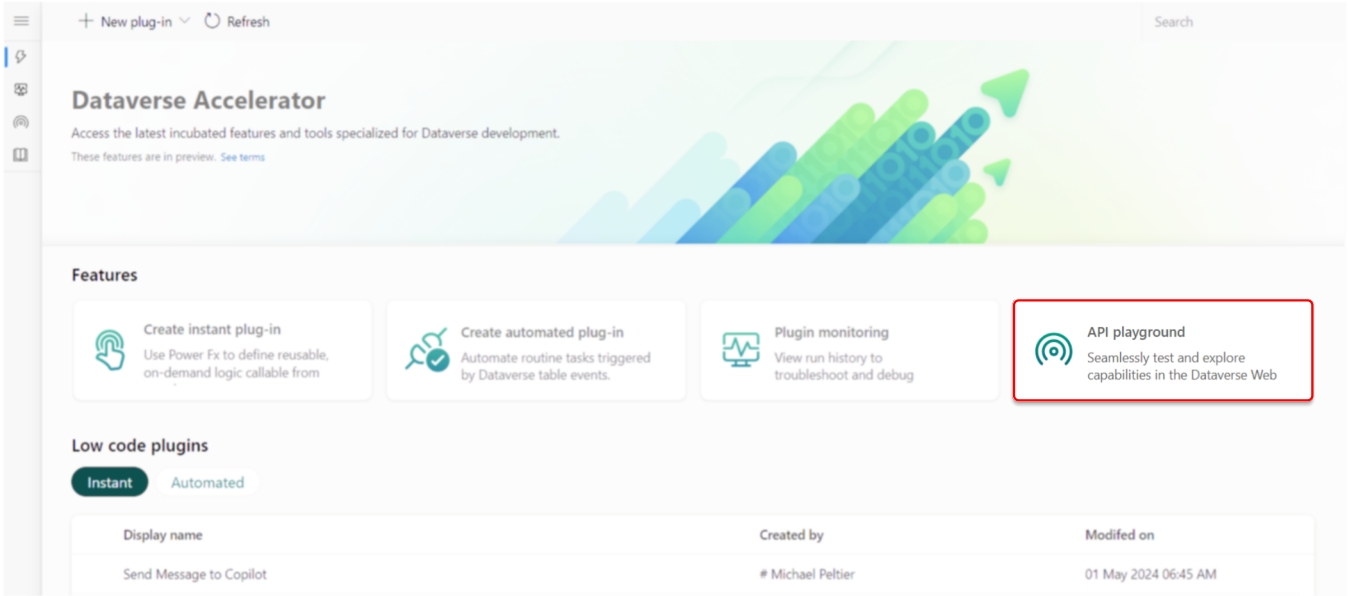
- Preauthenticated: The API playground comes preauthenticated, so developers can start testing and experimenting with API endpoints right away.
- Web-based: With the API playground, developers can quickly interact with the Dataverse Web API without the need for extensive setup like software downloads or non-Microsoft account setup. You can access the tool from the Dataverse accelerator, a Microsoft app available in all new Dataverse environments and can be installed in any environment.
- Convenient: Presents the various actions and capabilities available in the Dataverse Web API, making it easy to quickly learn what's possible and how to implement it.

Prerequisites

You must have access to Dataverse, and access to play the Dataverse accelerator app. Members of the system customizer security role have access to play the app.

Get started

To get started with the API playground, play the Dataverse accelerator, and then select the **API playground** page.



Make requests to the Dataverse Web API

On the landing screen, choose the request type to open the request editor by selecting **Create** on any of the top cards.

Three request types are presented:

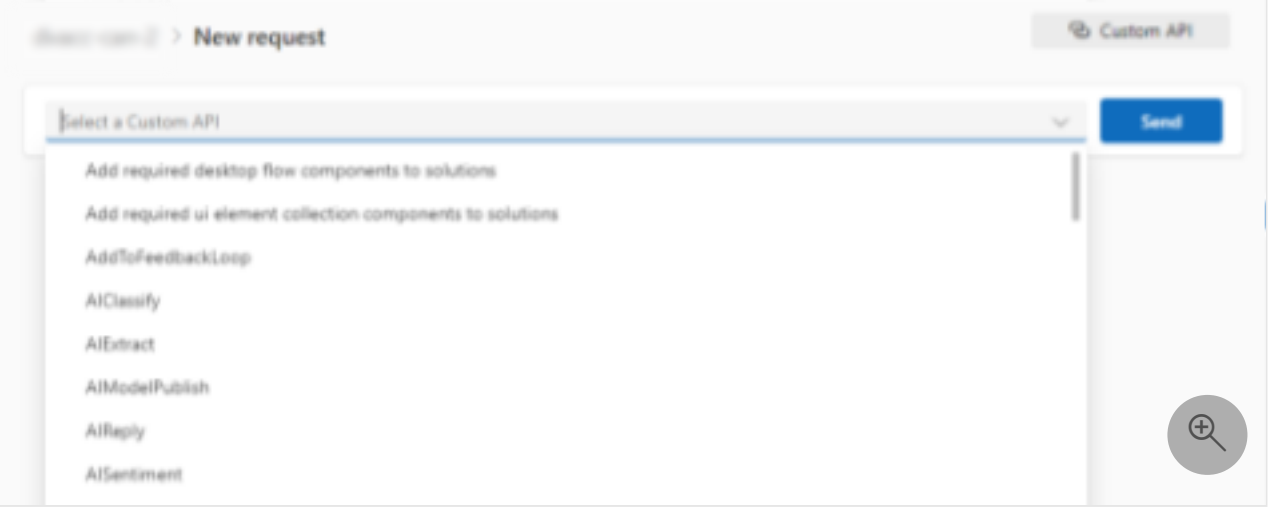
Expand table

Type	Description
Custom API	This includes any Dataverse Web API actions, functions from Microsoft, or any public user-defined custom APIs registered in the working environment.
Instant plug-in	Instant plug-ins are classified as any user-defined workflows registered as a custom API in the environment with a related FxExpression.
OData request	Allows more granular control over the request inputs to send OData requests.

Request a custom API or instant plug-in

These request types are designed to simplify calling plug-ins available in the working environment.

1. Select an option from the main dropdown list, which presents the available plug-ins in the current environment.



2. If parameters are available, they're displayed in the **Query params** table that appears. Provide values for required parameters.

> **Note**
>
> Checkboxes to the left of each parameter indicate whether they are included in the request. Required parameters have disabled checkboxes while optional parameters have editable ones.

3. Select **Send**.

4. Observe the response in the lower section of the screen.

> **Note**
>
> The interface provides a convenient listing of all available plug-ins in the environment. When selected, the associated parameters with data types are presented. Behind the scenes an OData call is still being made, but the interface simplifies the construction of the call.

Make an OData request

OData requests allow more options for request parameters.

1. Select the **HTTP request method** in the first dropdown list.

2. Type in the *endpoint Url*. Only include the request URL after `[OrgUrl]/api/data/v9.2/`

3. Add *query parameters* using one of the two methods:

   a. In the URL.

      i. After the question mark (`?`) character in the URL, type in the query parameter key.

      ii. Type an equals (`=`) character after the key.

      iii. Type in the value.

      The keys and values will automatically populate the parameter table in the interface.

   b. Manually add query parameters by selecting **+ Add param**. This adds an empty parameter row to the table that you can type values into. The URL is updated dynamically as values are entered.

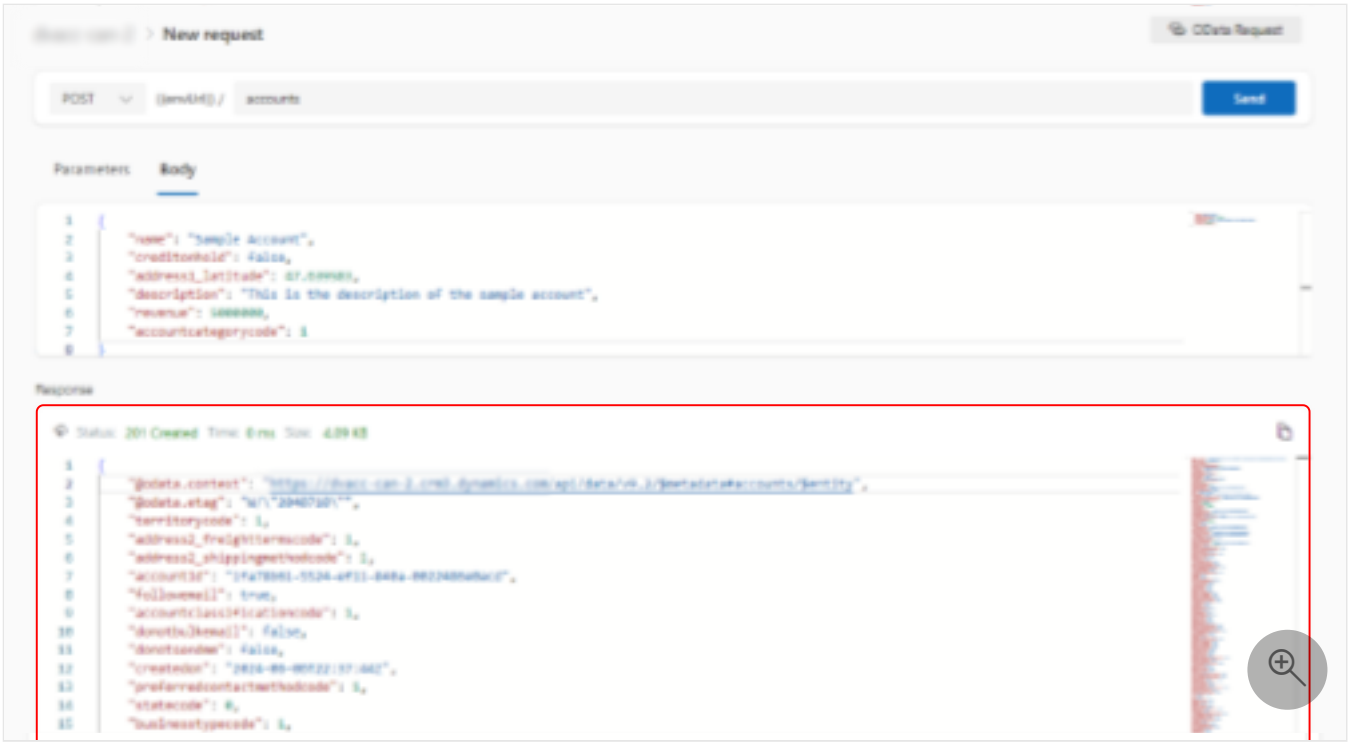
4. Optionally provide a body (if using all request methods except GET) by selecting the **Body** tab, and then enter the body value in the editor control.

5. Select **Send**.

6. Observe the response in the lower section.

View the response

After a request is sent, the response is displayed in the lower half of the screen.



The response status provides quick metrics on the request:

- Status message
- Duration (in milliseconds)
- Size (in kilobytes)

The response body is displayed below the response status. Select the copy icon to copy the response body to your clipboard.

FAQs

What privileges are required to access the API playground tool?

You must have access to the Dataverse accelerator app to use the tool.

Does the API playground tool only connect to the Dataverse Web API?

Yes, the API playground tool only connects to the Dataverse Web API. No other services are available to connect to in this interface.

How does the API playground tool authenticate to the Dataverse Web API?

The tool uses the authentication token of the logged in user that is required to play the Dataverse accelerator application.

Is the API playground feature available in all environments?

The feature is delivered through the Dataverse accelerator and is available in all environments that have the app installed. The app is automatically installed in all new environments, but can also be installed in older environments by following the install instructions.

Security concepts in Microsoft Dataverse

06/03/2025

One of the key features of Dataverse is its rich security model that can adapt to many business usage scenarios. This security model is only in play when there's a Dataverse database in the environment. As an administrator, you likely won't be building the entire security model yourself, but will often be involved in the process of managing users and making sure they have the proper configuration and troubleshooting security access related issues.

> **Tip**
>
> Check out the following video: Microsoft Dataverse – Security Concepts Shown In Demos.

Role-based security

Dataverse uses role-based security to group together a collection of privileges. These security roles can be associated directly to users, or they can be associated with Dataverse teams and business units. Users can then be associated with the team, and therefore all users associated with the team benefit from the role. A key concept of Dataverse security to understand is all privilege grants are accumulative with the greatest amount of access prevailing. If you gave broad organization level read access to all contact records, you can't go back and hide a single record.

Business units

> **Tip**
>
> Check out the following video: Modernize business units.

Business units work with security roles to determine the effective security that a user has. Business units are a security modeling building block that helps in managing users and the data they can access. Business units define a security boundary. Every Dataverse database has a single root business unit.

You can create child business units to help further segment your users and data. Every user assigned to an environment belongs to a business unit. While business units could be used to

model 1:1 a true organization hierarchy, more often they lean more towards just defined security boundaries to help achieve the security model needs.

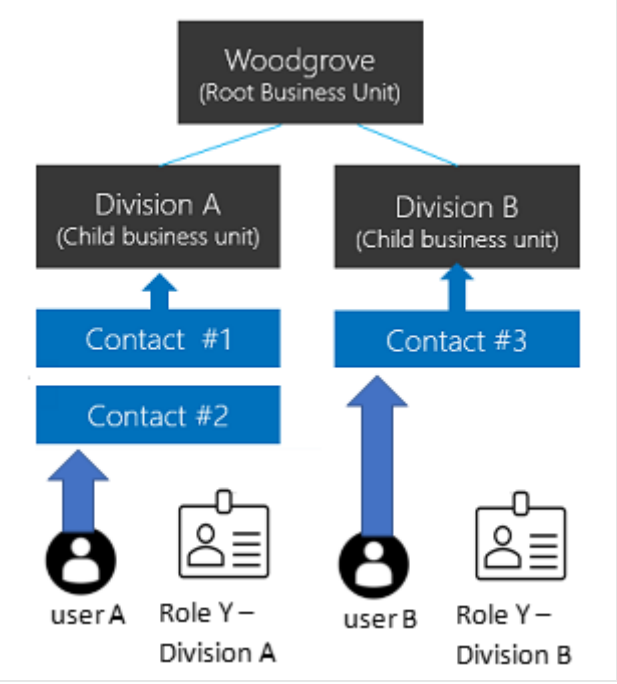
To better understand, let's look at the following example. We have three business units. Woodgrove is the root business unit and will always be at the top, that is unchangeable. We've created two other child business units A and B. Users in these business units have different access needs. When we associate a user with this environment, we can set the user to be in one of these three business units. Where the user is associated determines which business unit owns the records that user is the owner of. Having that association allows us to tailor a security role to allow the user to see all records in that business unit.

Hierarchical data access structure

Customers can use an organization structure where data and user are compartmentalized in a tree-like hierarchy.

When we associate a user with this environment, we can set the user to be in one of these three business units and assign a security role from the business unit to the user. The business unit the user is associated with determines which business unit owns the records when the user creates a record. By having that association it allows us to tailor a security role, which allows the user to see records in that business unit.

User A is associated with Division A and assigned a security role Y from Division A. This allows user A to access the Contact #1 and Contact #2 records. While user B in Division B can't access Division A's Contact records but can access Contact #3 record.

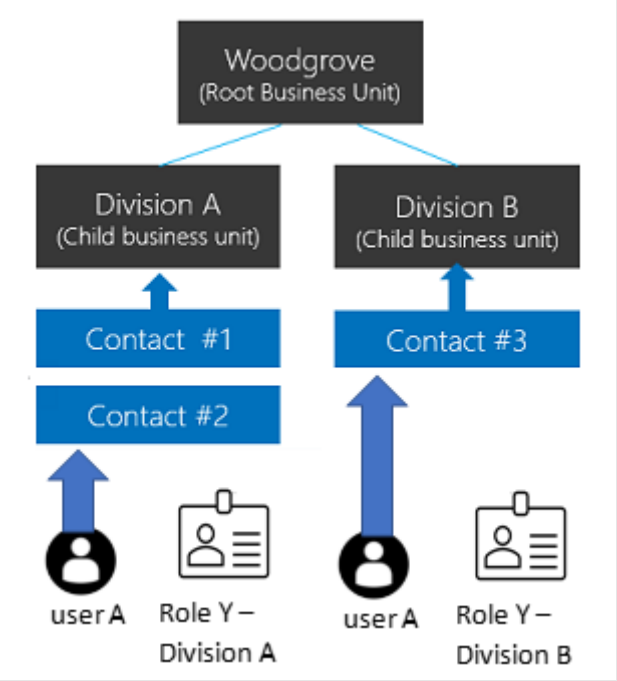


Matrix data access structure (Modernized Business Units)

Customers can use an organization structure where data is compartmentalized in a tree-like hierarchy, and users can work and access any business unit's data regardless of what the business unit the user is assigned to.

When we associate a user with this environment, we can set the user to be in one of these three business units. For each business unit that a user needs to access data, a security role from that business unit is assigned to the user. When the user creates a record, the user can set the business unit to own the record.

User A can be associated with any of the business units, including the root business unit. A security role Y from Division A is assigned to user A which gives the user access to Contact #1 and Contact #2 records. A security role Y from Division B is assigned to user A which gives the user access to Contact #3 record.



Enable the Matrix data access structure

> **Note**
>
> Before you enable this feature, you must publish all your customizations to enable all your new unpublished tables for the feature. If you find that you have unpublished tables that aren't working with this feature after you have turned it on, you can set the **RecomputeOwnershipAcrossBusinessUnits** setting using the OrgDBOrgSettings tool for Microsoft Dynamics CRM. Setting **RecomputeOwnershipAcrossBusinessUnits** to true allows the Owning Business Unit field to be set and updated.

New admin center

1. Sign in to the Power Platform admin center as an admin (Dynamics 365 admin or Microsoft Power Platform admin).
2. In the navigation pane, select **Manage**.
3. In the **Manage** pane, select **Environments**, and then choose the environment that you want to enable this feature for.
4. Select **Settings** > **Product** > **Features**.
5. Turn **On** the **Record ownership across business units** switch.
6. Select **Save**.

After this feature switch is turned on, you can select Business unit when you assign a security role to a user. This allows you to assign security role from different business units to a user. The user also requires a security role from the business unit that the user is assigned to with user settings privileges to run model-driven apps. You can refer to the Basic User security role to find how these user settings privileges are enabled.

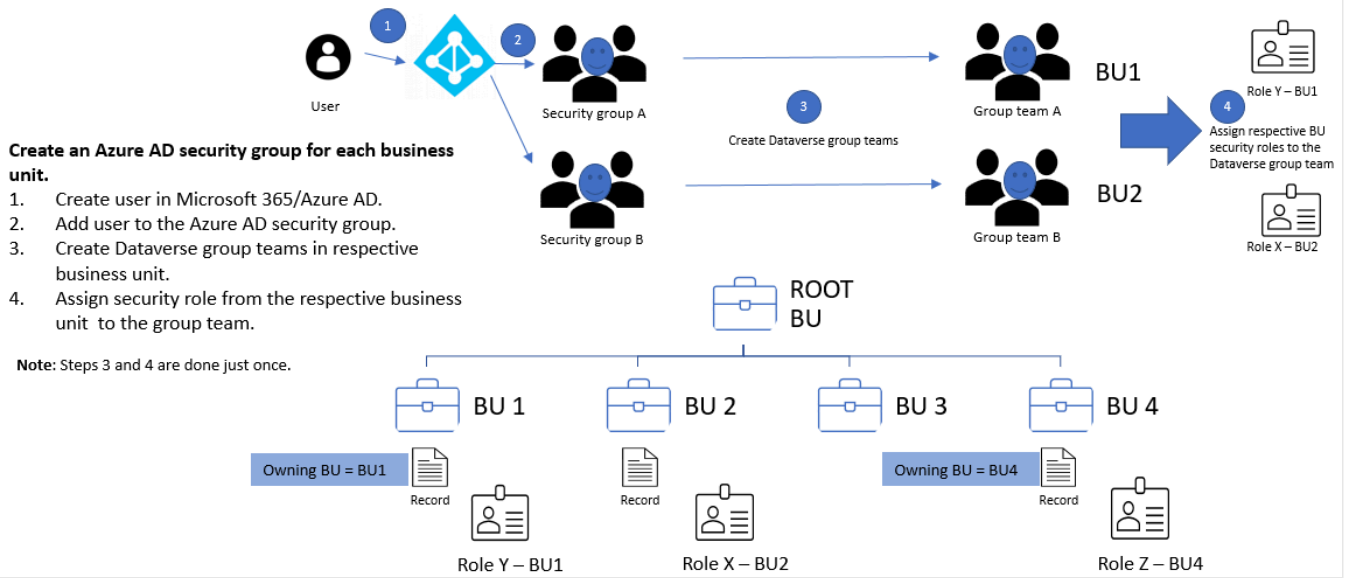
You can assign a user as record owner in any business unit without the need to assign a security role in the record's owning business unit as long as the user has a security role that has Read privilege to the record table. See Record Ownership in Modernized Business Units.

> **Note**
>
> This feature switch is stored in the **EnableOwnershipAcrossBusinessUnits** setting and can be set using the OrgDBOrgSettings tool for Microsoft Dynamics CRM.

Associate a business unit with a Microsoft Entra security group

You can use a Microsoft Entra security group to map your business unit for streamlining your user administration and role assignment.

Create a Microsoft Entra security group for each business unit and assign the respective business unit security role to each group team.



For each business unit, create a Microsoft Entra security group. Create a Dataverse group team for each Microsoft Entra security group. Assign the respective security role from the business unit to each Dataverse group team. The user in the above diagram will be created in the root business unit when the user accesses the environment. It's fine to have the user and the Dataverse group teams to be in the root business unit. They only have access to data in the business unit where the security role is assigned.

Add users into the respective Microsoft Entra security group to grant them access to the business unit. The users can immediately run the app and access its resources/data.

In the matrix data access, where users can work and access data from multiple business units, add the users to the Microsoft Entra security groups that mapped to those business units.

Owning Business Unit

Each record has an **Owning Business Unit** column, which determines which business unit owns the record. This column defaults to the user's business unit when the record is created and can't be changed except when the feature switch is turned ON.

> **Note**
>
> When you change which business unit owns a record, be sure to check out the following for cascade effects: Using SDK for .NET to configure cascading behavior.

You can manage whether you want to allow your user to set the Owning Business Unit column when the feature switch is ON. To set the Owning Business Unit column, you need to grant the user's security role the Business Unit table's **Append To** privilege with local level permission.

To allow your user to set this column, you can enable this column in the following:

1. Form - both the body and header.
2. View.
3. Column mappings. If you're using the AutoMapEntity, you can specify the column in your column mapping.

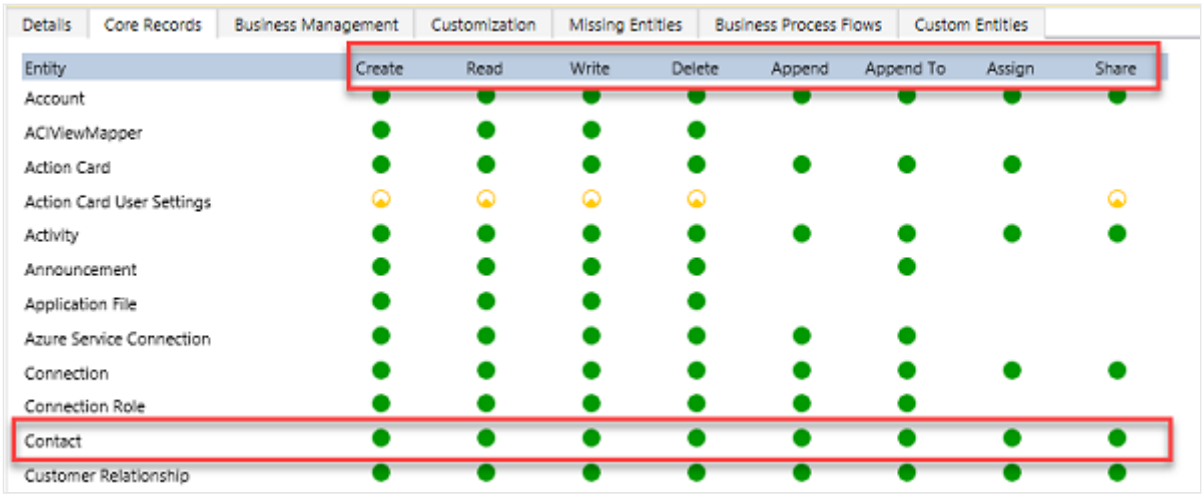
> **Note**
>
> If you have a job/process to sync data between environments and the **Owning Business Unit** is included as part of the schema, your job fails with a **Foreign KEY** constraint violation if the target environment doesn't have the same **Owning Business Unit** value.
>
> You can either remove the **Owning Business Unit** column from the source schema, or update the **Owning Business Unit** column value of the Source to any of the business units of the target.
>
> If you have a job/process to copy data from an environment to an external resource, for example Power BI, you'll need to select or deselect the **Owning Business Unit** column from your source. Select it if your resource can receive it otherwise deselect it.

Table/record ownership

Dataverse supports two types of record ownership. Organization owned, and User or Team owned. This is a choice that happens at the time the table is created and can't be changed. For security purposes, records that are organization owned, the only access level choices is either the user can do the operation or can't. For user and team owned records, the access level choices for most privileges are tiered Organization, Business Unit, Business Unit and Child Business Unit or only the user's own records. That means for read privilege on contact, I could set user owned, and the user would only see their own records.

To give another example, let's say User A is associated with Division A, and we give them Business Unit level Read access on Contact. They'd be able to see Contact #1 and #2 but not Contact #3.

When you configure or edit security role privileges, you're setting the access level for each option. The following is an example of the Security Role privilege editor.



In the above you can see the standard privilege types for each table Create, Read, Write, Delete, Append, Append To, Assign and Share. You can edit each of these individually. The visual display of each will match the key below as to what level of access you've granted.

In the above example, we have given organization level access to Contact which means that the user in Division A could see and update contacts owned by anyone. In fact, one of the most common administrative mistakes is getting frustrated with permissions and just over granting access. Very quickly a well-crafted security model starts looking like Swiss cheese (full of holes!).

Record Ownership in Modernized Business Units

In **Modernized Business units**, you can have users being owners of records across any business units. All the users need is a security role (any business unit) which has Read privilege to the record table. The users don't need to have a security role assigned in each business unit where the record resides.

If **Record ownership across business units** was enabled in your production environment during the Preview period, you need to perform the following to enable this record ownership across business unit:

1. Install the Organization Settings editor
2. Set the **RecomputeOwnershipAcrossBusinessUnits** organization settings to true. When this setting is set to true, the system is locked and can take up to 5 minutes to do the recomputation to enable the capability where users can now own records across business units without the need to have separate security role assigned from each business unit. This allows an owner of a record to assign their record to someone outside of the record's owning business unit.

3. Set **AlwaysMoveRecordToOwnerBusinessUnit** to false. This makes the record remain in the original owning business unit when the record ownership is changed.

For all non-production environments, you just need to set **AlwaysMoveRecordToOwnerBusinessUnit** to false to use this capability.

> ⓘ **Note**
>
> If you turn off either the **Record ownership across business units** feature or set the **RecomputeOwnershipAcrossBusinessUnits** setting to false using the OrgDBOrgSettings tool for Microsoft Dynamics CRM, you won't be able to set or update the Owning Business unit field, and all records where the Owning Business Unit field is different from the owner's business unit will be updated to the owner's business unit.

Teams (including group teams)

Teams are another important security building block. Teams are owned by a Business Unit. Every Business Unit has one default team that is automatically created when the Business Unit is created. The default team members are managed by Dataverse and always contain all users associated with that Business Unit. You can't manually add or remove members from the default team, they're dynamically adjusted by the system as new users are associated/disassociated with business units. There are two types of teams, owning teams and access teams.

- Owning Teams can own records, which give any team member direct access to that record. Users can be members of multiple teams. This allows it to be a powerful way of granting permissions to users in a broad way without micromanaging access at the individual user level.
- Access teams are discussed in the next section as part of record sharing.

Record sharing

Individual records can be shared on a one-by-one basis with another user. This is a powerful way of handling exceptions that don't fall into the record ownership or is a member of a business unit access model. It should be an exception, though, because it's a less performant way of controlling access. Sharing is tougher to troubleshoot because it's not a consistently implemented access control. Sharing can be done at both the user and team level. Sharing with a team is a more efficient way of sharing. A more advanced concept of sharing is with Access Teams, which provides auto-creation of a team and sharing of record access with the team is based on an Access Team Template (template of permissions) which is applied. Access teams

can also be used without the templates, with manually adding or removing its members. Access teams are more performant because they don't allow owning records by the team or having security roles assigned to the team. Users get access because the record is shared with the team and the user is a member.

Record-level security in Dataverse

You might be wondering – what determines access to a record? That sounds like a simple question but for any given user it's the combination of all their security roles, the business unit they're associated with, the teams they're members of and the records that are shared with them. The key thing to remember is all access is accumulative across all those concepts in the scope of a Dataverse database environment. These entitlements are only granted within a single database and are individually tracked in each Dataverse database. This all requires they have an appropriate license to access Dataverse.

Column-level security in Dataverse

Sometimes record-level control of access isn't adequate for some business scenarios. Dataverse has a column-level security feature to allow more granular control of security at the column level. Column-level security can be enabled on all custom columns and most system columns. Most system columns that include personal identifiable information (PII) are capable of being individually secured. Each column's metadata defines if that is an available option for the system column.

Column-level security is enabled on a column by column basis. Access is then managed by creating a Column Security Profile. The profile contains all column that have column-level security enabled and the access granted by that specific profile. Each column can be controlled within the profile for Create, Update and Read access. Column Security Profiles are then associated with a user or Teams to grant those privileges to the users to the records they already have access to. It's important to note that column-level security has nothing to do with record-level security. A user must already have access to the record for the Column Security Profile to grant them any access to the columns. Column-level security should be used as needed and not excessively as it can add overhead that is detrimental if over used.

Managing security across multiple environments

Security roles and Column Security Profiles can be packaged up and moved from one environment to the next using Dataverse solutions. Business Units and Teams must be created and managed in each environment along with the assignment of users to the necessary security components.

Configuring users environment security

Once roles, teams, and business units are created in an environment, it's time to assign the users their security configurations. First, when you create a user, you associate the user with a business unit. By default, this is the root business unit in the organization. They're also added to the default team of that business unit.

In addition, you would assign any security roles that user needs. You would also add them as members of any teams. Remember teams can also have security roles, so the effective rights of the user is the combination of directly assigned security roles combined with those of any teams they're members of. Security is always additive offering the least restrictive permission of any of their entitlements. The following is a good walkthrough of configuring environment security.

If you have used column-level security, you would need to associate the user or a team of the user to one of the Column Securities Profiles you created.

Security is a complex article and is best accomplished as a joint effort between the application makers and the team administering the users' permissions. Any major changes should be coordinated well in advance of deploying the changes into the environment.

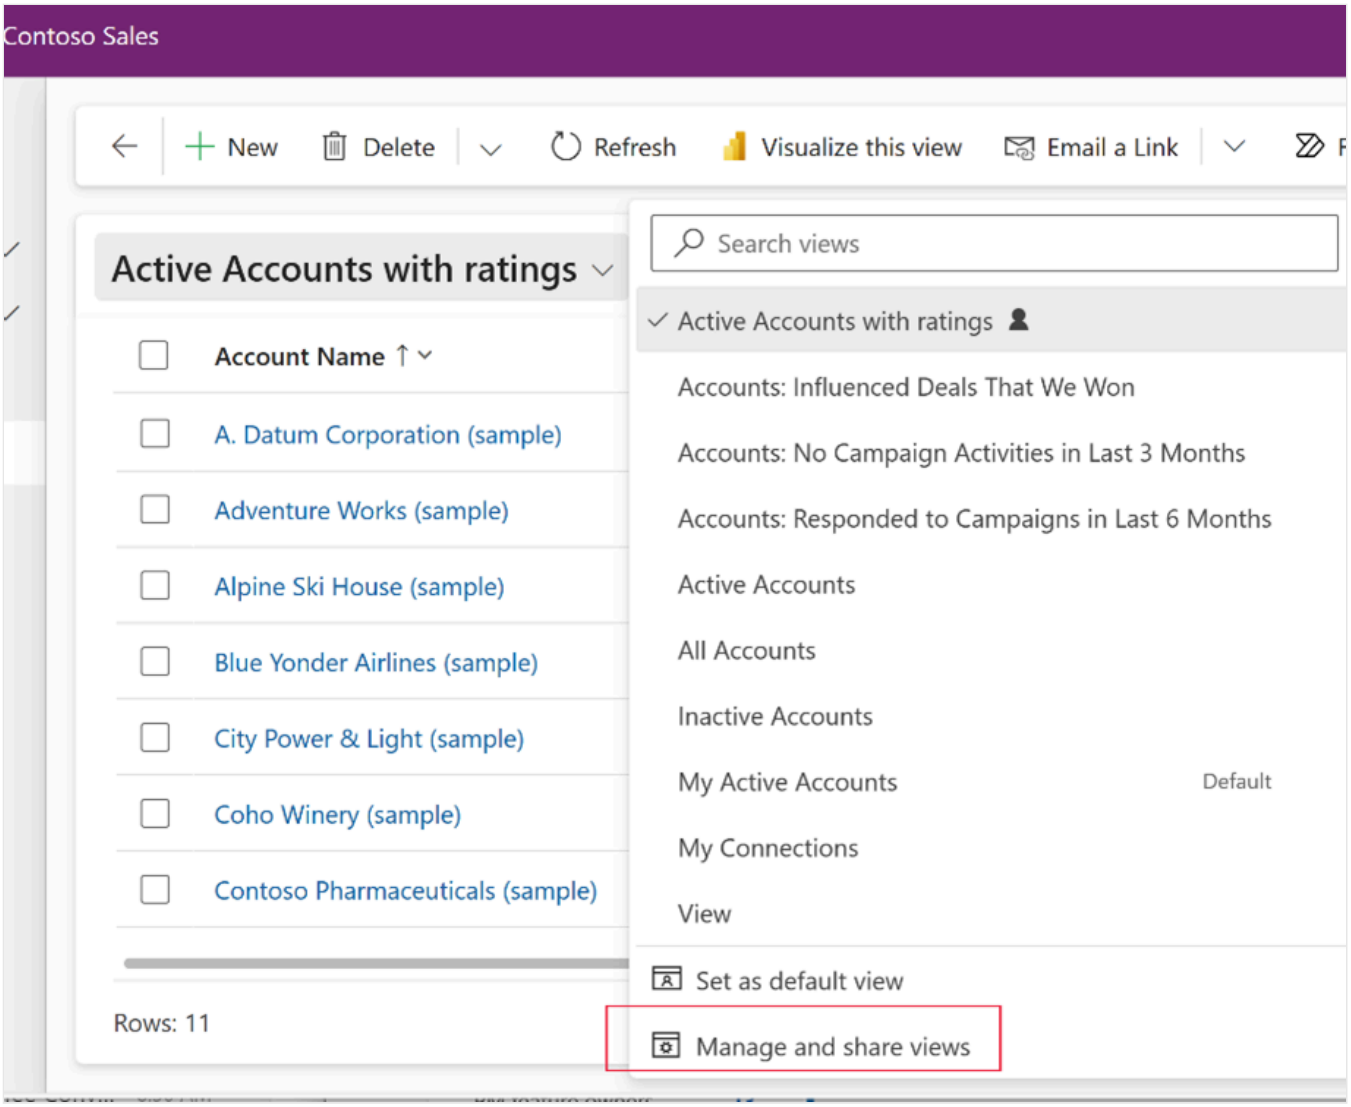
Configure environment security
Security roles and privileges

Manage access to public system views

Admins can manage the views that users can access in model-driven apps by using security roles. When a user plays a model-driven app, they only have access to the system views that apply to the security roles they're assigned.

System views are special views that model-driven apps depend on, which exist for system tables or are automatically created when you create custom tables. These views have specific purposes and some additional capabilities. By default, all system views are for **everyone**. When a Power Platform admin manages a view with a security role, only the users who are assigned with the selected security role are able to see the view in the view selector. The other system views aren't filtered from the view selector dropdown list. Users can still access all the views when they navigate to the **Manage and share views** option.

After a Power Platform admin turns on the manage table list views feature, users can set their own default view from the list of views that the admin manages and their own personal views from the **Manage and share views** option in a model-driven app.



Data access continues to be secured with security role privileges, which means only records that a user has access to are displayed by the views. Having access to a particular view doesn't mean you also have access to the data that's available in the view.

> **Note**
>
> This feature filters views that appear in the table list view selector. All system and associated views continue to display in subgrids and associated grids that have a view selector.

Prerequisites

- Confirm that the orgdbsettings `EnableRoleBasedSystemViews' property is set to **true** using the OrganizationSettingsEditor tool.
- System administrator security role membership in the Microsoft Dataverse environment.
- Turning on auditing is recommended, but not required.

System views in a Dataverse environment

System views are predefined views that exist for all system tables. These views can include Public, Quick Find, Advanced Find, Associated, or Lookup. When an admin or maker creates a view from Power Apps (make.powerapps.com), the view becomes a public view. You can manage public views with security roles.

Commonly used public view examples

You can manage the table list of views with your business users based on the users' security role assignment. Admins select the applicable system views and manage these views with security roles. When the user navigates to a table list form, they can access the system views that were managed with the security roles that are assigned to them. The selected system views with security role aren't visible to users who don't have the security role assigned.

Examples of public views:

Expand table

Table	Public view
Account	My Active Accounts
Account	Accounts: No Campaign Activities in Last 3 months
Lead	My Open Leads
Lead	All Leads
Case	All Cases
Case	Cases I follow
Case	My Cases
Case	My Resolved cases
Contact	All Contacts
Contact	Contact I follow
Contact	Inactive contacts

Turn on manage table list views

1. Make sure you enable the table list views feature in your environment. More information: Prerequisites
2. You manage public views with security roles. If you need to create new security roles, go to Security roles and privileges for more information about security roles.
3. Create a solution and add the tables and their corresponding views that you manage.
4. Export the solution.
5. Import the solution into your production environment.

> **Tip**
>
> Inform your users that their system views are now filtered based on their security role assignment.

Manage public views with security roles

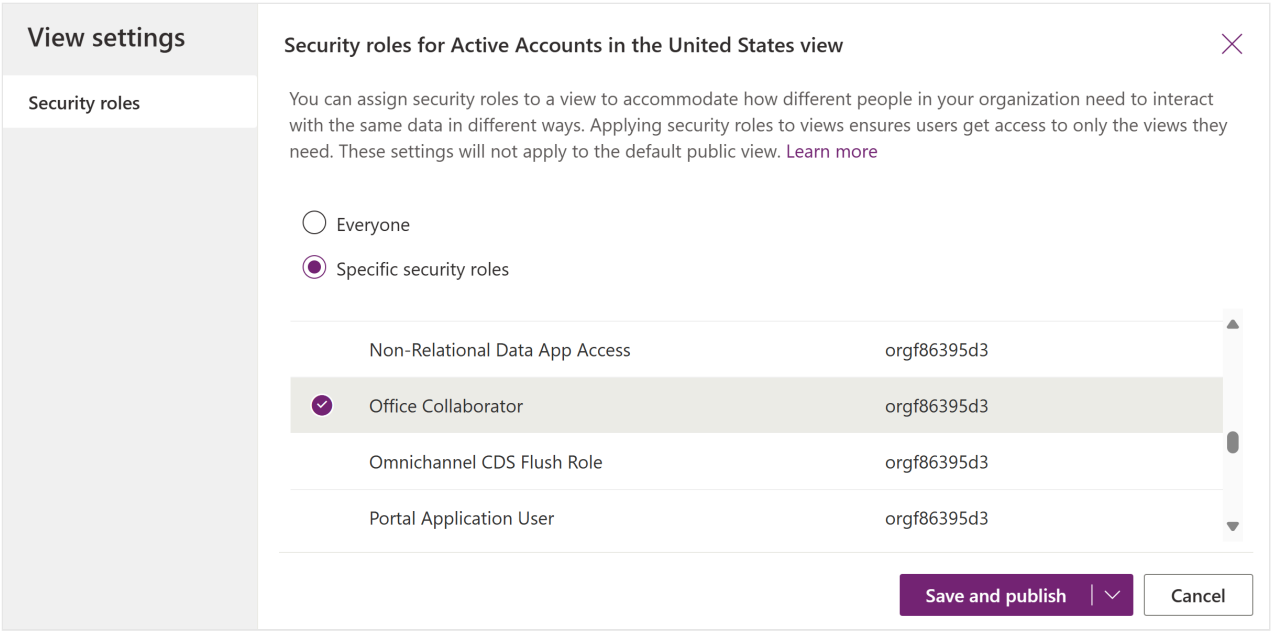
All system views can be managed with security roles. Once they're managed, users with the assigned security roles only view these views in the view selector.

> **Note**
>
> System views are denoted as **Public** view type in Power Apps (make.powerapps.com). Only public views can be managed. Default public views can't be assigned security roles for access.

Manage system views with security roles

1. Sign in to Power Apps.
2. On the left navigation pane, select **Solutions**, and then open the solution that has the table with the view you want to manage. If the item isn't in the side panel, select **...More** and then select the item you want.
3. Open a table, such as the account table, and then select the **Views** area.
4. Select the nondefault public view that you want, and then on the command bar, select **View settings**.
5. Select the **Specific security roles** option.
6. Select the security roles that you want to assign to the public view.

7. When you're done selecting the security roles, select **Save and Publish**.



> **Note**
>
> When you make changes to the 'EnableRoleBasedSystemViews' and **View settings**:
>
> 1. Setting the OrganizationSettingsEditor tool `EnableRoleBasedSystemViews` property to **true** is effective immediately.
> 2. Setting a view with security roles is effective immediately after you select **Save and publish**.
> 3. Changing a view setting from 'Specify security role' to 'Everyone' can take up to 24 hours to be effective or until the user signs out and back in.
>
> If you select multiple views and go to the view settings, only the first selected Views can be updated. You're required to select individual view to update the view settings.

> **Important**
>
> The security roles as listed under **View settings** are from the *root business unit*. Business unit level security roles are inherited from the root business unit. When you select the security roles from **View settings**, the system automatically applies filtering to users who are assigned the corresponding business unit level security roles.

Microsoft Dataverse Developer Guide

Summarize this article for me

Microsoft Dataverse is the underlying data platform for Power Apps, providing core functionality such as server-side logic (plug-ins and workflows), business process flows, a sophisticated security model, and an extensible platform for developers. This guide helps developers understand how to extend Dataverse with code to build custom line-of-business apps for users, businesses, independent software vendors (ISVs), and systems integrators (SIs).

There are many ways developers can contribute to creating apps that use Dataverse. While you can build an application with code using Dataverse as your data source, most projects use either model-driven apps or canvas apps to generate the experience that people use.

Working with model-driven apps

Model-driven apps are built on Dataverse, and can only connect to a Dataverse environment. Dataverse stores all the data that defines a model-driven app.

Model-driven apps use Solutions to share customizations and extensions.

Model-driven apps also have many points where developers can write code to extend them. For information about what developers can do with model-driven apps, see Model-driven apps Developer Guide.

Some examples of model-driven apps available from Microsoft are Dynamics 365 Customer Service, Dynamics 365 Field Service, and Dynamics 365 Marketing.

Understand when to write code

Because Dataverse includes many capabilities for people to configure custom business logic without writing code, the most common scenarios for developers involve filling gaps where existing features don't provide the functionality you need. Fortunately, Dataverse provides many points for developers to extend the common functionality by using code.

As a developer, it's important to understand what you can do without writing code. Familiarize yourself with these capabilities. For more information, see What is Dataverse?

Content for on-premises deployments

Dataverse isn't available for on-premises deployments. Content in this guide doesn't include information about options that are only available for on-premises or internet facing

deployments (IFD). For information related to these options, see the Developer Guide for Dynamics 365 Customer Engagement (on-premises).

Dataverse community tools

Article • 02/15/2022

View Layout Replicator and View Designer are a couple of the many tools available in a Power Platform community developed app named XrmToolBox. XrmToolBox is a Windows application that connects to Microsoft Dataverse.

> **Note**
>
> These tools are provided by XrmToolBox and are not supported by Microsoft. If you have questions pertaining to the tool, please contact the publisher. More information: **XrmToolBox**.

For more information about XrmToolBox and other Dataverse community tools, go to Developer tools.

Live monitor overview

Article • 11/19/2024

Live monitor is a tool that offers makers the ability to view a stream of events from a user's session to diagnose and troubleshoot problems. Makers of canvas apps can use Live monitor either to view events while building a new app in Power Apps Studio or to monitor published apps during runtime. Makers of model-driven apps can monitor page navigation, command executions, form-related issues, and other major actions to understand app behavior and make improvements.

Benefits

Live monitor can help you diagnose and troubleshoot problems faster, and build more reliable apps. It provides a deep view of your app by logging all the key activities that occur in the app as it runs. Live monitor also provides a better understanding of how the events and formulas contained in your app work, so you can improve performance and identify any errors or problems.

Debugging an app

The key to debugging a problem is to have a better understanding of what your app does, and how it does it. Sometimes it's difficult to isolate a problem by just looking at the app formulas, or even by reviewing runtime errors. Watching the events as they occur in your app can help you understand the order of events and how your app is performing, to spot errors and diagnose problems faster.

Some examples of problems and queries that you can uncover when using Live monitor are:

- **A high number of network calls**
  - Is the app fetching data too frequently?
  - Can you optimize the app to only fetch data when required?
  - Are timer controls firing too often?
  - Are too many events occurring when the app starts? Can fetching some of the data be delayed?

- **Retrieve data from the same data source**
  - Can you use different patterns such as caching data in collections or variables instead of fetching the same data multiple times?

- **The response data size**
  - Can you use query filters to reduce the amount of requested data?
- **The duration of the request**
  - Are connectors and plug-ins optimized?
  - Can you reduce the size of the response by using query filters?
- **Errors**
  - Have you configured the required permissions to run the app correctly?
  - Are your requests throttled by the platform?

Prerequisites

You'll need the following security role membership in the environment to use Live monitor.

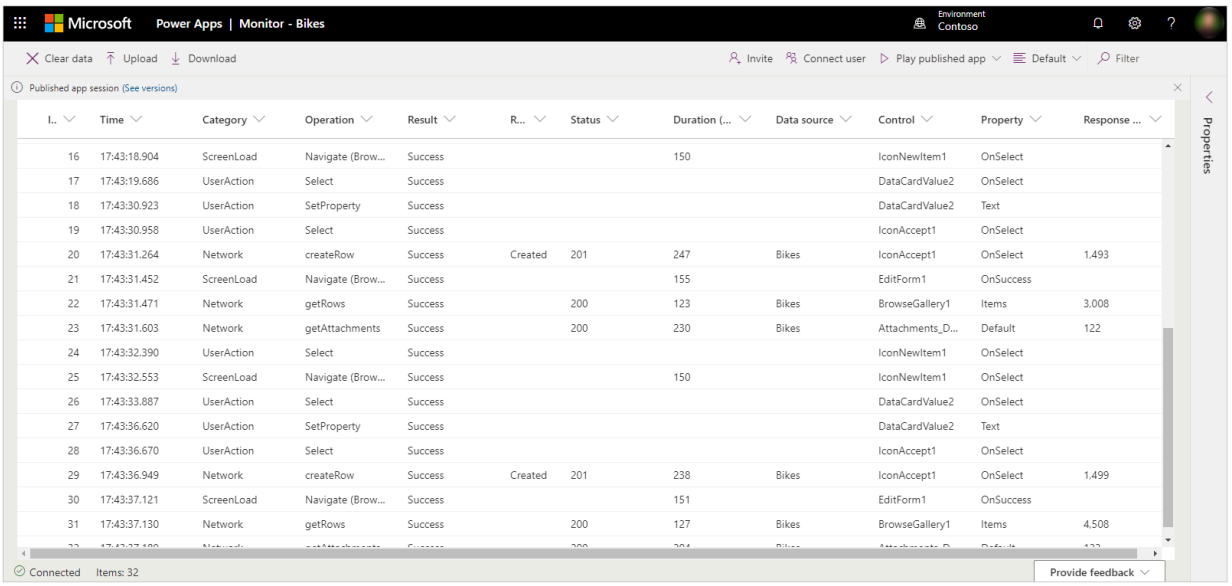
Expand table

App type	Required security role
Canvas app	Environment Admin or Environment Maker
Model-driven app	System Administrator or System Customizer for the Dataverse organization

More information: Configure user security to resources in an environment

Live monitor dashboard

You can review various properties for each event inside Live monitor. Depending on the event category, some of these properties might not contain data. The following image shows an example of the Live monitor dashboard for canvas apps.



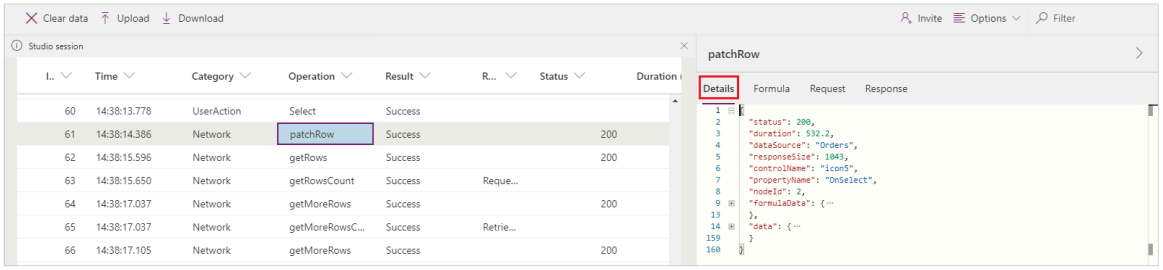
Expand table

Column name	Description
Id	The sequence number for the events.
Time	The time the event occurred.
Category	The type of event, such as *Network*.
Operation	The resulting internal operation name of the request inside the app. For example, *createRow* is the operation name from the **Patch** function.
Result	The text description of the status code. For example, a 429 status will appear as an "*Error*" in the result column. Row colors also help to identify any errors and warnings quickly.
Result Info	The detailed translation of error codes and results. For example, a 429 status code will appear as "Too many requests" in this column.
Status	The HTTP status code of a network request. For example, a 2XX code represents a successful request, whereas a 4XX code represents an error.
Duration	Duration can mostly be used to understand the performance of network calls in the app, but it also depends on the type of event. For example, for a network request, duration is the time taken for the request to be sent and a response to be received.
Data Source	The name of the data source accessed by the raised event operation (for example, the name of a Microsoft Dataverse table).
Control	The control name associated with this event
Property	The active control property of the raised event.

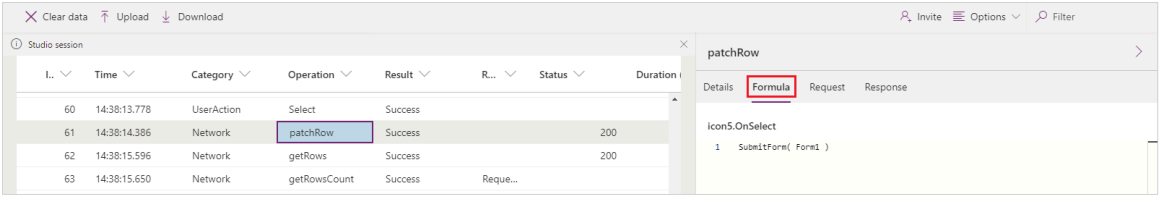
Column name	Description
Response size	For a network request event, represents the size of the response received from the sender to your app, in bytes.

When you select an event in the grid, a panel displays additional details about the event. The panel has four tabs:

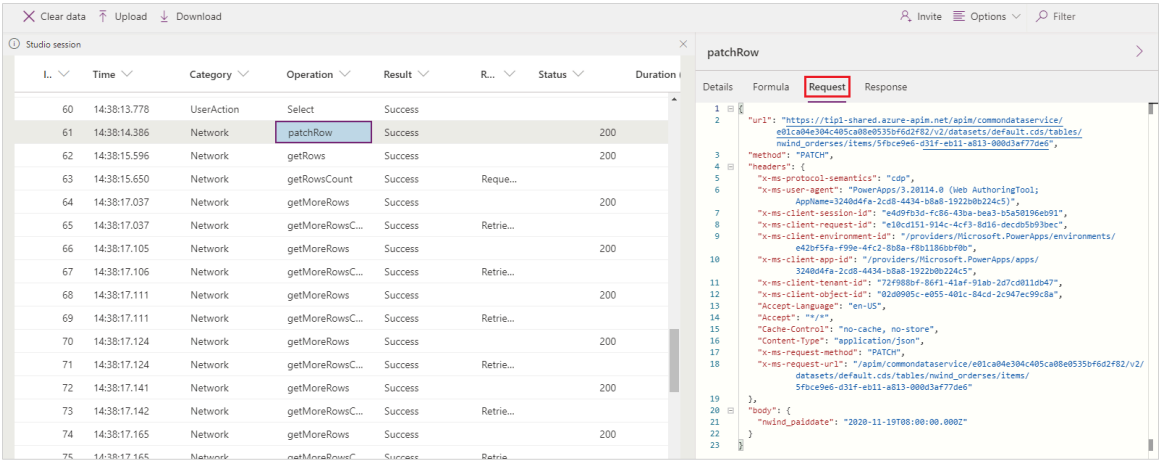
- **Details**: Shows a high-level overview of the event that you select. Some of the data might be collapsed in the tree view. You can expand and drill down to view content.



- **Formula**: Shows the related formula from your app for the selected event. The name of the control property triggering the event is displayed on top of the tab and inside the event table.



- **Request**: Shows the HTTP request that was sent.



- **Response**: Shows the HTTP response that was received. You can view the response in JSON format.

Debugging canvas apps with Live monitor

Article • 11/19/2024

Live monitor is available by default for all canvas apps. Using Live monitor, you can trace events as they occur in a canvas app during the authoring experience in Power Apps Studio, or you can use Monitor to debug the published version of a canvas app. More information: Live monitor overview

Get started with Live monitor in canvas apps

To open Monitor when authoring an app

1. Sign in to Power Apps.
2. Create a new app, or edit an existing app.
3. On the left pane, select **Advanced tools**.
4. Select **Open live monitor**.

This action opens Live monitor in a new browser tab and connects it to your existing Power Apps Studio session.

A notification appears at the top to show the current monitoring session as a *Studio session*.

> **Tip**
>
> Live monitor has no impact on your app. You can use Live monitor with any app in a test environment or in production.

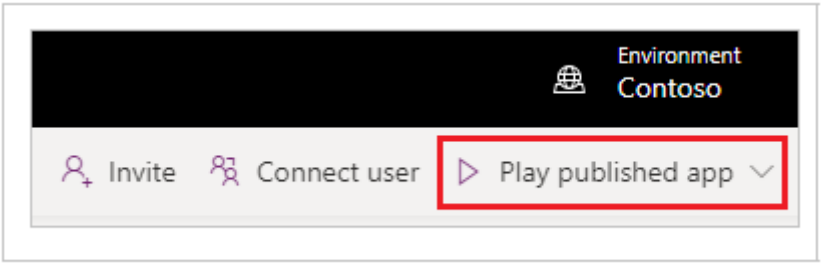
Open Live monitor for a published app

You can also use Live monitor to debug the published app in the web player.

To open Live monitor for a published app

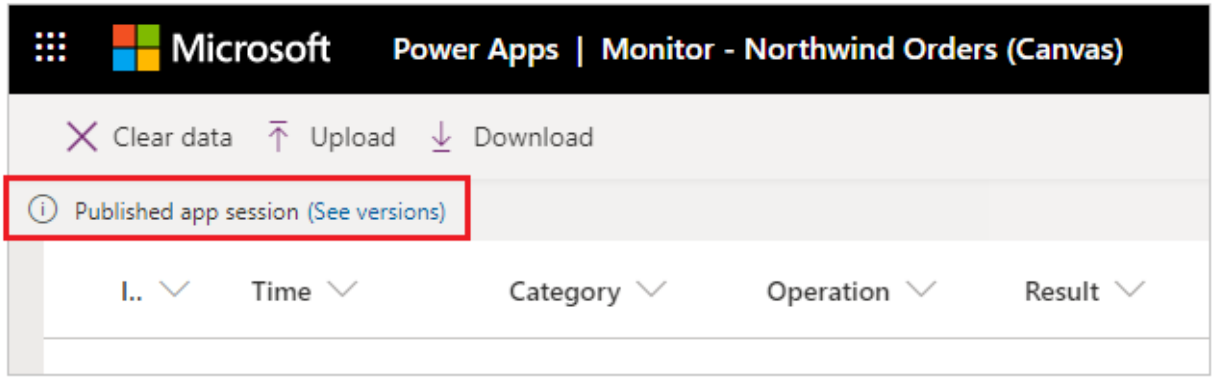
1. Sign in to Power Apps.
2. On the left pane, select **Apps**.

3. Select an app from the list.
4. Select the drop-down menu next to **Details** and then select, **Live monitor**.
5. Select **Play published app**.



This action opens the published app in a new browser tab and connects it to your current Live monitor session. You'll immediately see events in Live monitor when the app is loaded in the web player, and as you interact with the published app.

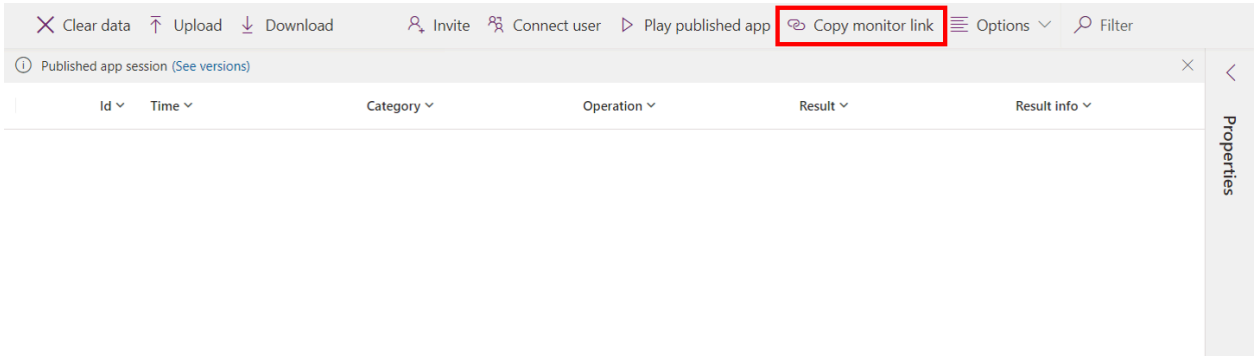
Live monitor also displays a notification that the monitoring session that's currently open is for the published version of the app.



For apps running on Power Apps mobile (preview)

Follow the above steps, but select **Copy monitor link** instead of **Play published app**. Use the copied link on your device to open a monitored session for the published app. Make sure the link is opened using Power Apps mobile, not a browser.

> **Note**
>
> **Copy monitor link** is available in https://make.preview.powerapps.com

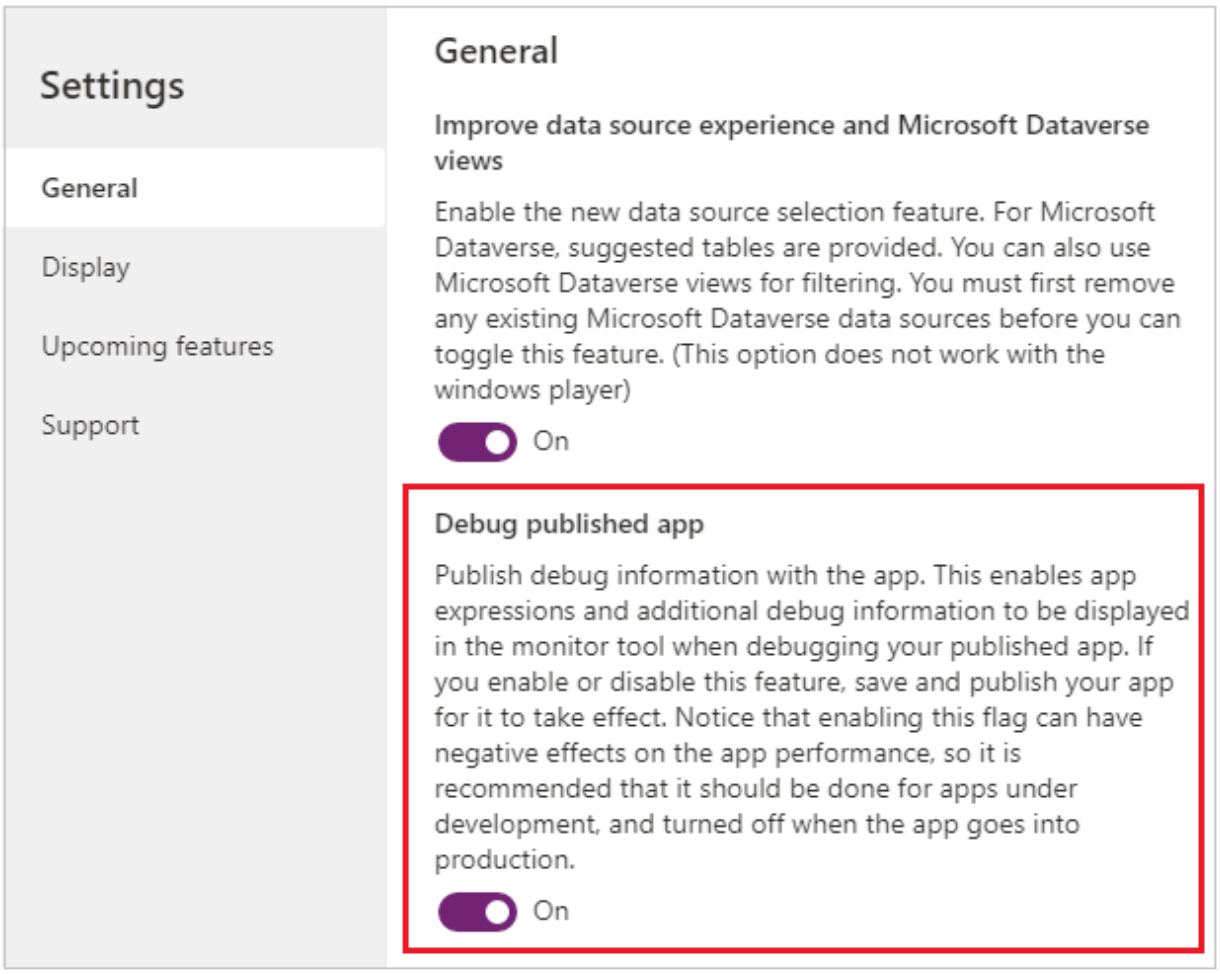


Setting: Debug published app

If you want to view the source expressions in Live Monitor for the published app, you need to turn on the setting to publish the expressions with the app. This setting is similar to generating a debug file in traditional development. Publishing source expressions with your app is optional. Even when this setting is off, you'll be able to see the events happening in your app, but you won't be able to map these events to specific expressions or formulas.

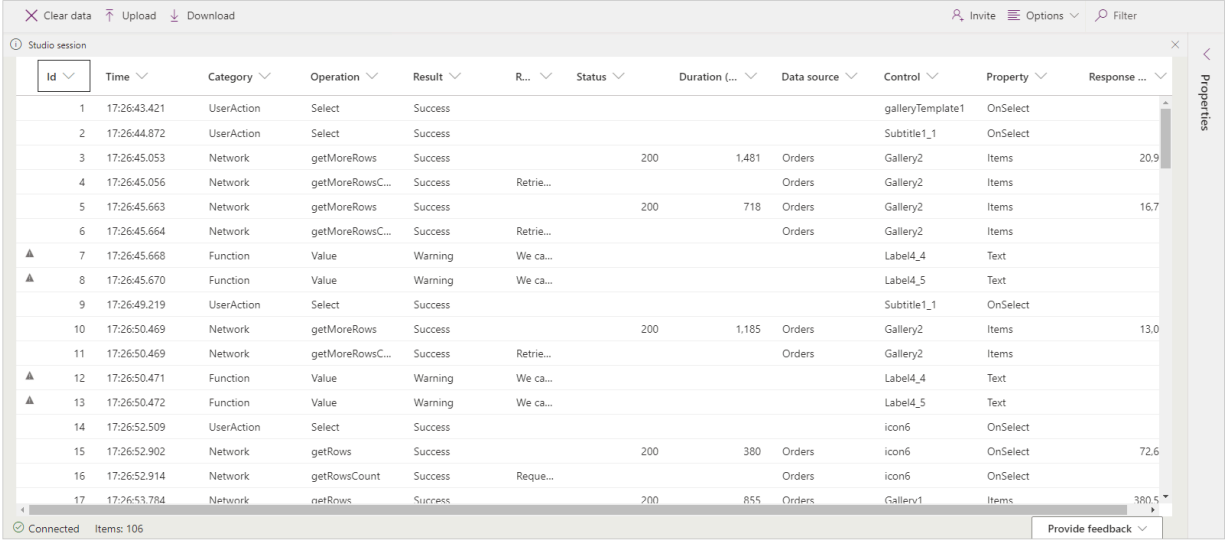
To enable this setting, go to **File** > **Settings**, and then turn on **Debug published app**.

> **Note**
>
> Enabling this setting has a detrimental impact on the performance of your app for all your users. To minimize the impact, disable this setting as soon as you no longer need to view source expressions when debugging your published app.



View events in Live monitor

To view events from your app, play the app in Power Apps Studio. Live monitor will then display the table of events as they're occurring, along with specific details.



Example: Using Live monitor with canvas apps

In this example, you'll use the Northwind Sample Data app included with the Northwind sample solution.

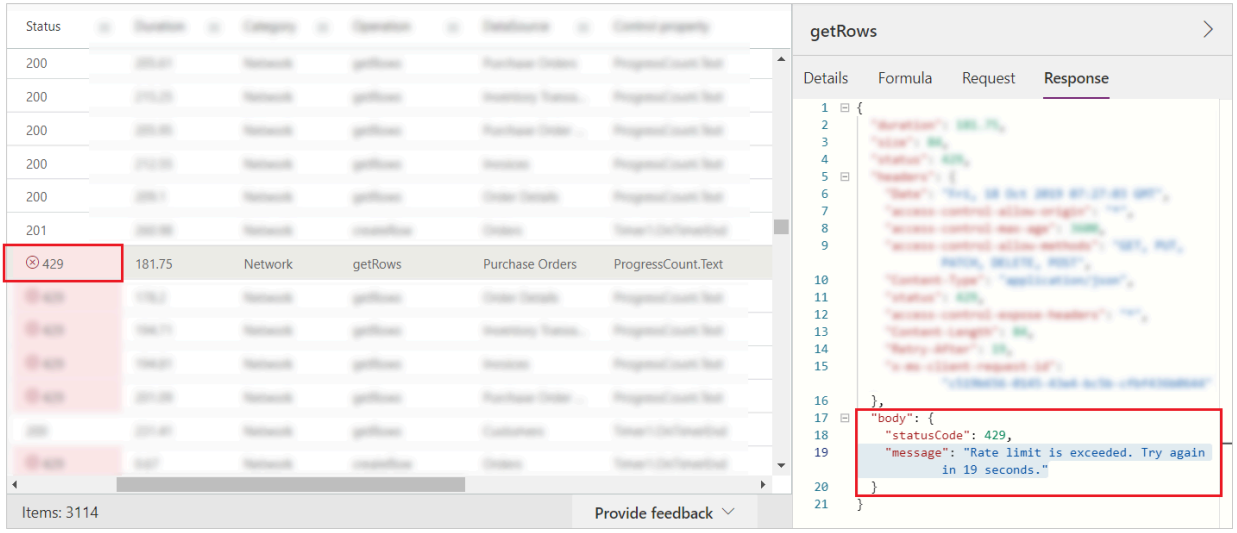
The *Northwind sample solution* is a canvas app that loads sample data into Microsoft Dataverse. You can also create a new app or use an existing app instead.

Background

Consider the scenario where an app has been deployed, and the initial version of the app experiences performance degradation. The app also intermittently generates errors with no clear pattern. Loading data in the app succeeds most of the time, but fails sometimes.

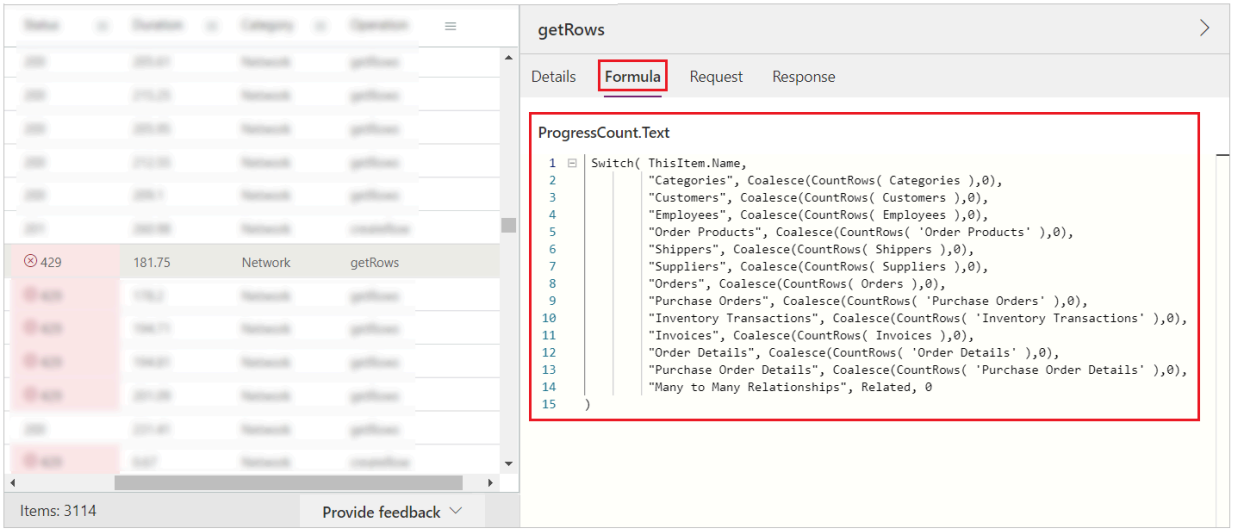
When you check Live monitor, you see data operations as expected. However, you also see several responses that have HTTP status code 429, indicating that there have been too many requests in a specific timeframe.

When you select such an event, you see the error as "Rate limit exceeded. Try again in XX seconds."



Analysis

The problem needs further analysis to understand why requests are getting throttled. In Live monitor, you see that for each **createRow** call, there are several **getRows** requests from the **ProgressCount.Text** property, each to a different entity. These entities aren't the entities the app is creating rows for. The **ProgressCount.Text** formula is seen in Live monitor, as shown in the following image.



For each record added, the formula is evaluated again and **CountRows** is called on several entities. This behavior results in **getRows** in the log, because **CountRows** isn't delegated for Dataverse. For each single request to add a record, you're potentially making 12 additional requests to count the rows in each entity.

These extra requests intermittently cause errors because the Dataverse platform is throttling the requests to the service. This also explains the overall performance problem.

Debug a model-driven app with Live monitor

Article • 11/19/2024

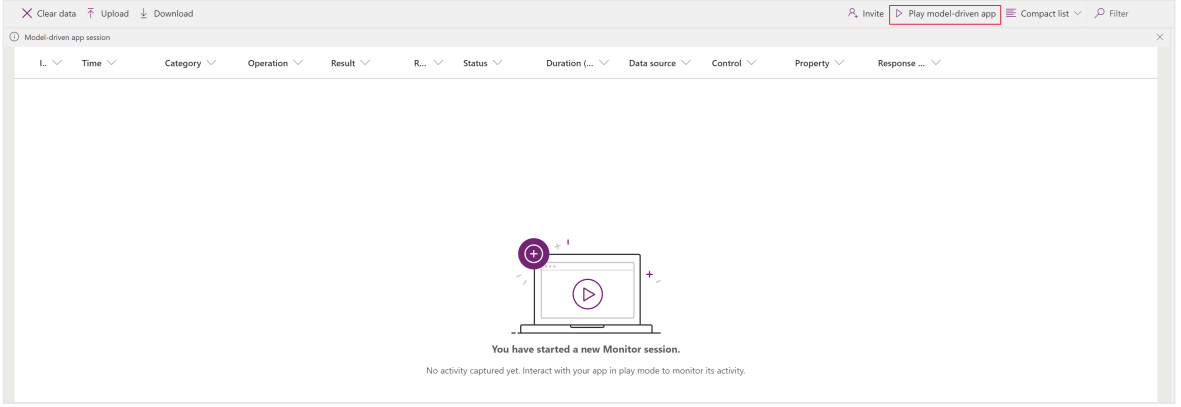
Live monitor can help you debug and diagnose problems and help you build faster, more reliable apps. Live monitor provides a deep view into how an app runs by providing a log of all key activities in your app as the app runs. You can also collaboratively debug a published model-driven app with a support engineer or debug issues of another user's session. For more information on how to collaboratively debug a published model-driven app, go to Collaborative troubleshooting using Live monitor.

> **Important**
>
> Live monitor for model-driven app requires the client version of your model-driven app to be 1.4.5973-2307.2 or later.

For more information about when you should monitor an app, see Monitor overview. To run Live monitor with a canvas app, see Debugging canvas apps with Live monitor.

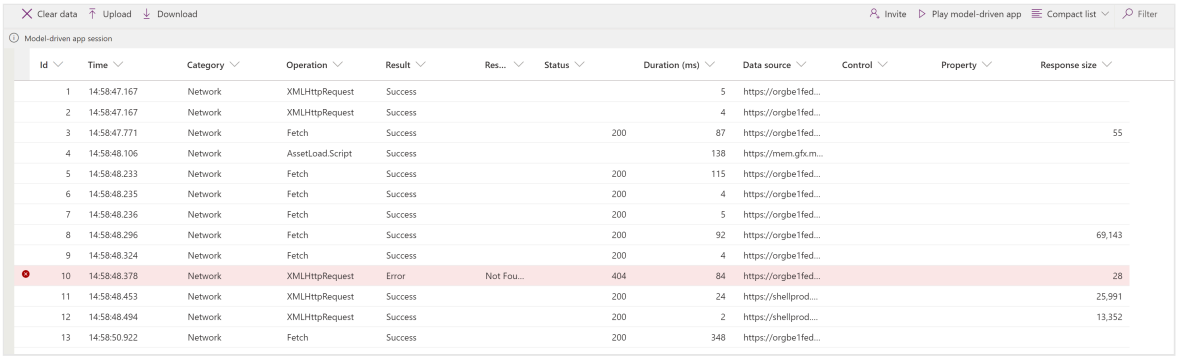
Use Live monitor to diagnose a model-driven app

1. Sign into Power Apps, and then select **Apps** from the left navigation pane.
2. Select the model-driven app that you want to monitor, and then select **Live monitor** on the command bar.
3. In the web page that opens, select **Play model-driven app** to open your app.



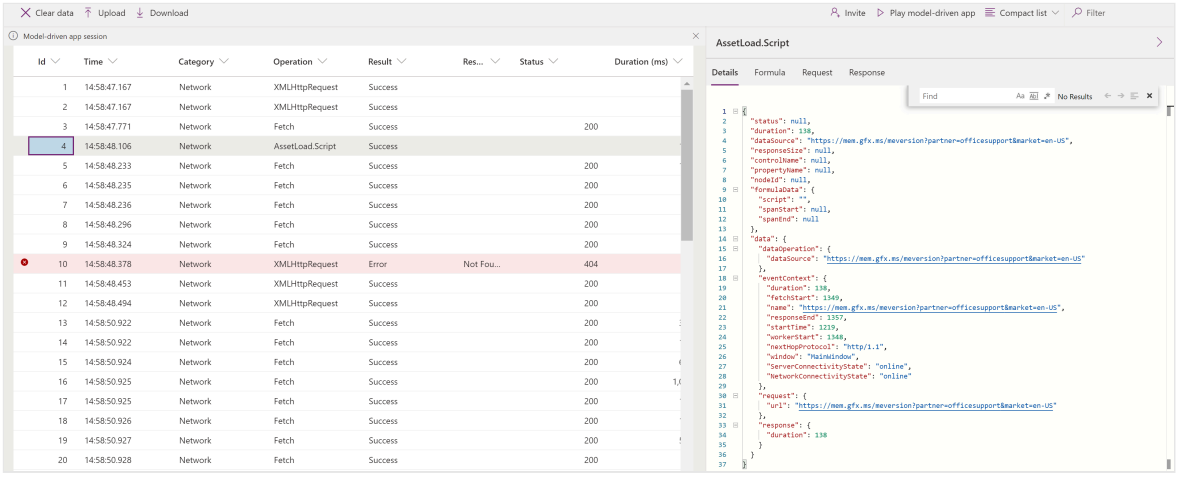
> **Note**
>
> Alternatively, you can run a model-driven app and add "&monitor=true" to the end of the URL in the browser. Then, select **Live monitor** on the command bar to start a monitoring session in a new tab.

4. After the app is opened from Live monitor, you'll see a **Join monitor debug session?** dialog box. This lets you know that any data from the app will be sent to the Live monitor owner. Select **Join**. Events begin to flow to the Live monitor session screen as they occur in the app.



Id	Time	Category	Operation	Result	Res...	Status	Duration (ms)	Data source	Control	Property	Response size
1	14:58:47.167	Network	XMLHttpRequest	Success			5	https://orgbe1fed...			
2	14:58:47.167	Network	XMLHttpRequest	Success			4	https://orgbe1fed...			
3	14:58:47.771	Network	Fetch	Success		200	87	https://orgbe1fed...			55
4	14:58:48.106	Network	AssetLoad.Script	Success			138	https://mem.gfx.m...			
5	14:58:48.233	Network	Fetch	Success		200	115	https://orgbe1fed...			
6	14:58:48.235	Network	Fetch	Success		200	4	https://orgbe1fed...			
7	14:58:48.236	Network	Fetch	Success		200	5	https://orgbe1fed...			
8	14:58:48.296	Network	Fetch	Success		200	92	https://orgbe1fed...			69,143
9	14:58:48.324	Network	Fetch	Success		200	4	https://orgbe1fed...			
10	14:58:48.378	Network	XMLHttpRequest	Error	Not Fou...	404	84	https://orgbe1fed...			28
11	14:58:48.453	Network	XMLHttpRequest	Success		200	24	https://shellprod...			25,991
12	14:58:48.494	Network	XMLHttpRequest	Success		200	2	https://shellprod...			13,352
13	14:58:50.922	Network	Fetch	Success		200	348	https://orgbe1fed...			

5. Select an event to display additional information in the right pane.



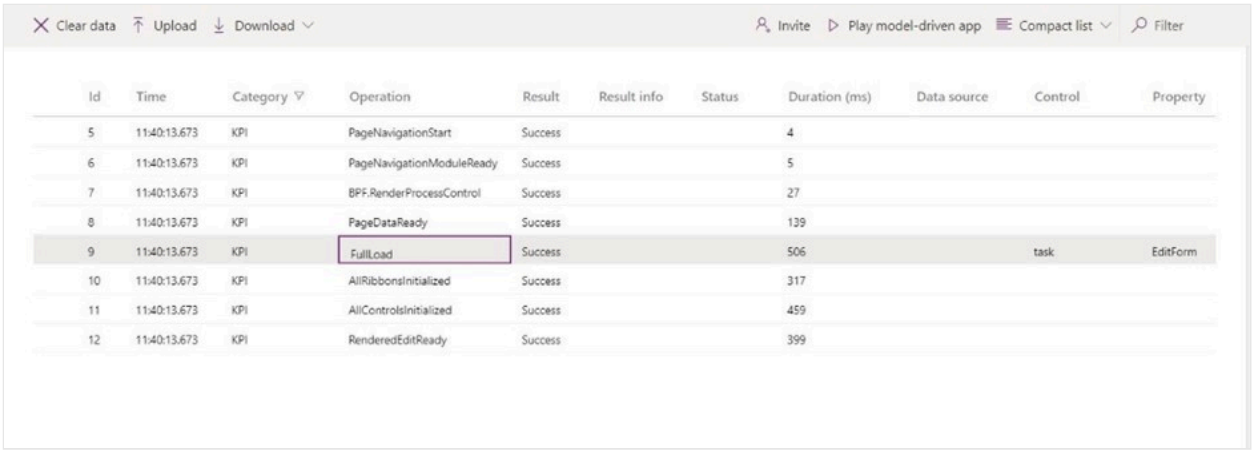
Events monitored

Page navigation, command executions, form saves, and other major actions will send key performance indicators and network events to Live monitor.

FullLoad

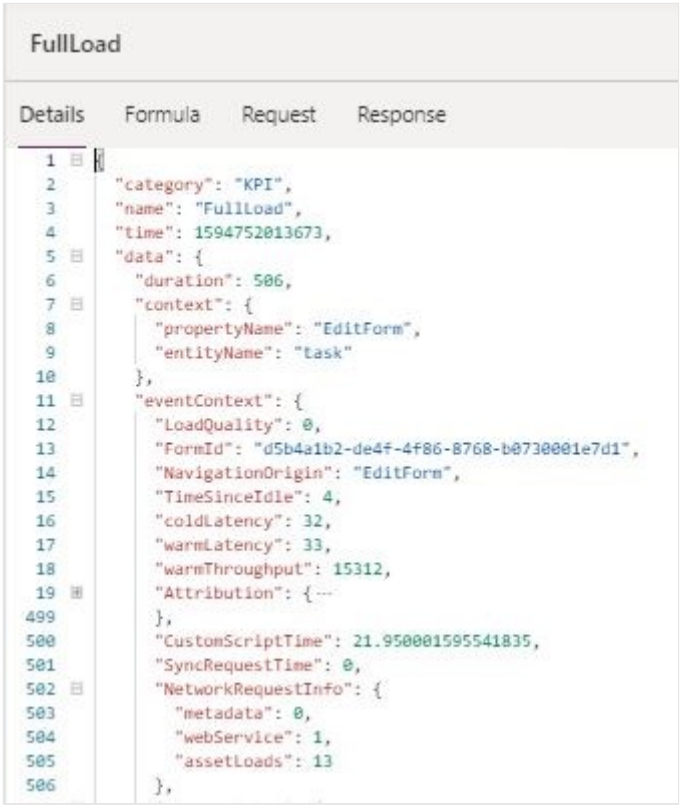
FullLoad signifies the complete load of a page navigation, such as an edit form load. This event waits for certain network requests to complete and all rendering to finish, so the

form can be ready before FullLoad completes.



Id	Time	Category	Operation	Result	Result info	Status	Duration (ms)	Data source	Control	Property
5	11:40:13.673	KPI	PageNavigationStart	Success			4			
6	11:40:13.673	KPI	PageNavigationModuleReady	Success			5			
7	11:40:13.673	KPI	BPF.RenderProcessControl	Success			27			
8	11:40:13.673	KPI	PageDataReady	Success			139			
9	11:40:13.673	KPI	FullLoad	Success			506		task	EditForm
10	11:40:13.673	KPI	AllRibbonsInitialized	Success			317			
11	11:40:13.673	KPI	AllControlsInitialized	Success			459			
12	11:40:13.673	KPI	RenderedEditReady	Success			399			

Select a FullLoad event to display the **Details** tab.

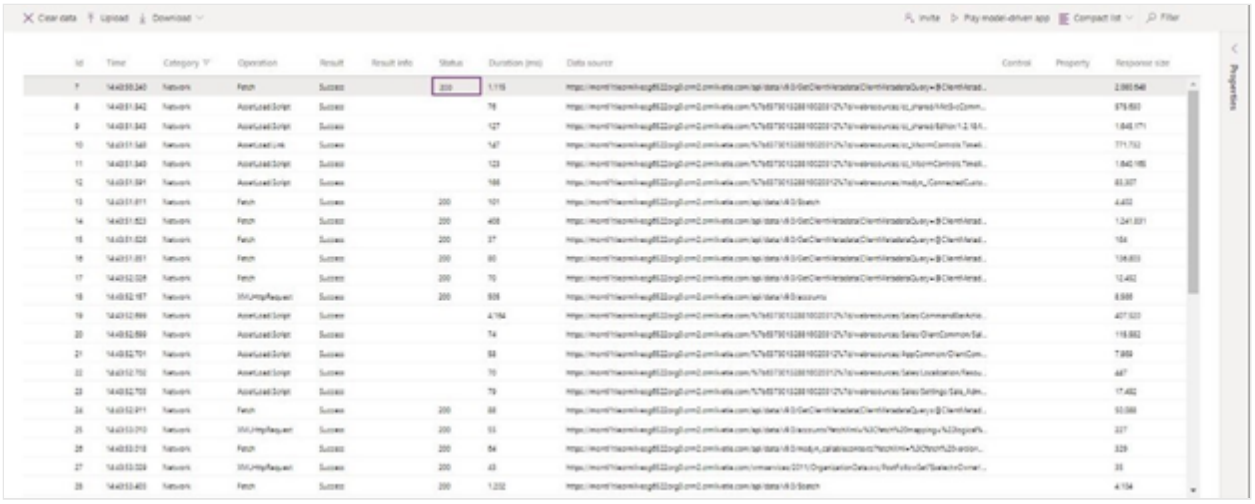


```
{
  "category": "KPI",
  "name": "FullLoad",
  "time": 1594752013673,
  "data": {
    "duration": 506,
    "context": {
      "propertyName": "EditForm",
      "entityName": "task"
    },
    "eventContext": {
      "LoadQuality": 0,
      "FormId": "d5b4a1b2-de4f-4f86-8768-b0730001e7d1",
      "NavigationOrigin": "EditForm",
      "TimeSinceIdle": 4,
      "coldLatency": 32,
      "warmLatency": 33,
      "warmThroughput": 15312,
      "Attribution": {···
      },
      "CustomScriptTime": 21.950001595541835,
      "SyncRequestTime": 0,
      "NetworkRequestInfo": {
        "metadata": 0,
        "webService": 1,
        "assetLoads": 13
      },
```

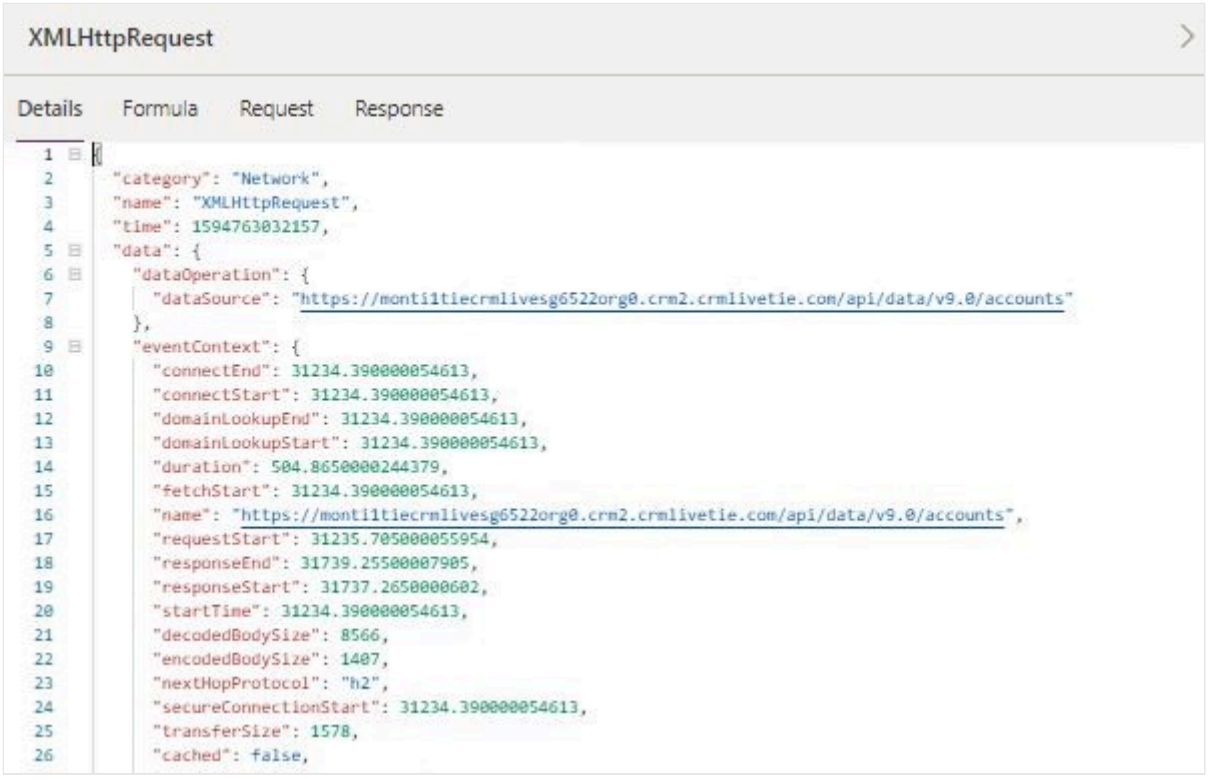
The FullLoad event captures many statistics about the page load. You can see the task edit form loaded in 506 ms, and selecting the row reveals information in the property pane. You can see details on `customScriptTime` (time spent execute custom JavaScript), `loadType` (0 = first-time loading page type, 1 = first time loading entity, 2 = first-time loading record, 3 = exact record has been visited), and `FormId` (form identifier for further diagnosis). Expanding **Attribution** gives a breakdown of custom JS execution time by type, publisher, solution, version, web resource, and method. This can help identify bottlenecks in form load time.

Network

The **Network** events reveal details about each request made from the app.



Select a Network event to display the **Details** tab.

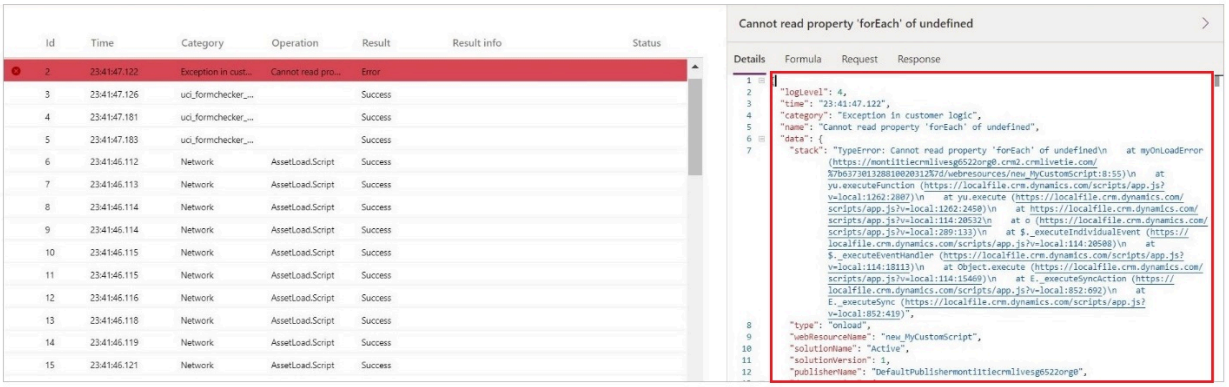


Earlier you learned about Live monitor and how to use it to model-driven apps. Let's look at a few scenarios where Live monitor can assist you in solving script errors, unexpected behavior, and slowdowns.

Custom script errors

Sometimes, a bug in the custom JS causes a script error or functionality problem when loading a page. While this usually produces a call stack in the dialog, it's hard to always know where it's coming from or decode the error. Live monitor receives events from the app with more details about the errors, so you can debug more quickly, and easily.

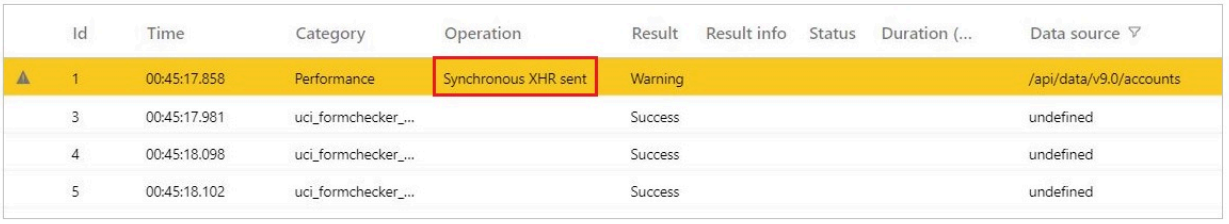
For example, imagine a user is experiencing a script error dialog on account form load. You can use Live monitor to get more details on the event. Once the scenario is reproduced, you can see the script error produces an error event highlighted in red. Selecting this row gives you not only the **call stack** but the **publisher name**, **solution name/version**, **web resource name**, and **type** (such as *onload*, *onchange*, *RuleEvaluation*, and *CustomControl*). In this example, it looks like a typo in the script.



Slow performance

Browser developer tools can help profile slow page loads, but there's much data to filter though and it's not clear what is important to look at. Live monitor solves this problem by showing relevant events that contribute to page load performance.

For example, imagine a user is experiencing slow account form loads, and the browser is constantly freezing up. In this case, after you reproduce the issue, you can see a performance warning telling you that a synchronous **XMLHttpRequest** was sent during the load which degraded performance.



See previous blog post for how to alleviate synchronous XMLHttpRequest (XHR) performance problems.

For every page load, the data platform sends all KPI for the loading sequence as well as network request details as mentioned earlier.

Use Live monitor to troubleshoot model-driven app behavior

Article • 11/19/2024

Live monitor is a tool that can help app makers debug and diagnose problems, which help them build faster, more reliable apps. Live monitor provides a deep view into how an app runs by providing a log of all activities in the app as it runs.

To help you isolate certain model-driven app features, you can filter on specific categories, such as forms or the Copilot control.

Create a Live monitor session

Sign in to Power Apps, select **Solutions** on the left navigation pane, open the solution that contains the app you want to monitor, select the app, and then select **Live monitor** on the command bar.

On the Live monitor page, select **Play model-driven** app on the command bar. For more information about creating a Live monitor session, go to Use Live monitor to troubleshoot page behavior in model-driven apps.

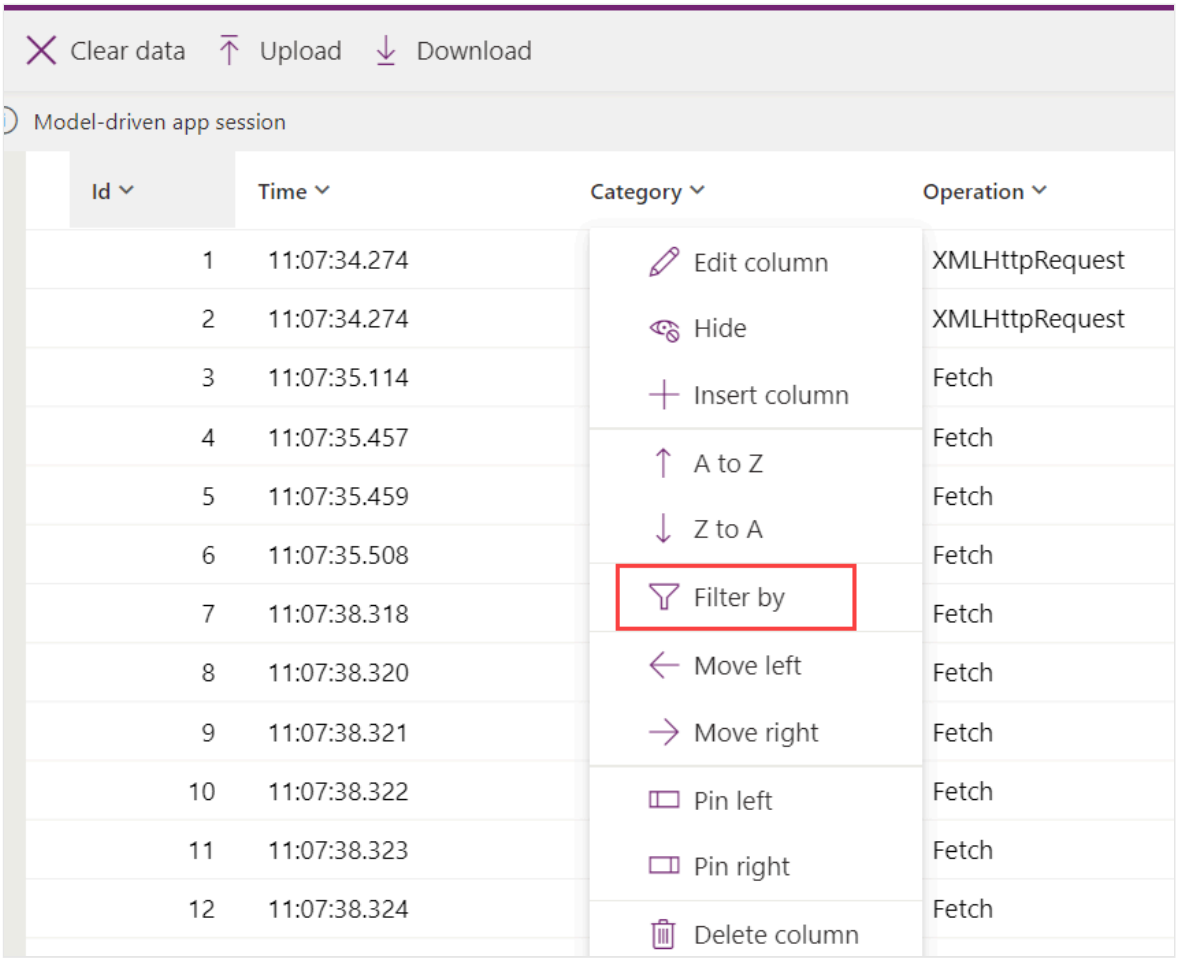
Filter Live monitor for form-related issues

Filtering on model-driven app form-related events in Live monitor can provide information about related tables, tables, controls, and components on a form in Live monitor as your app runs.

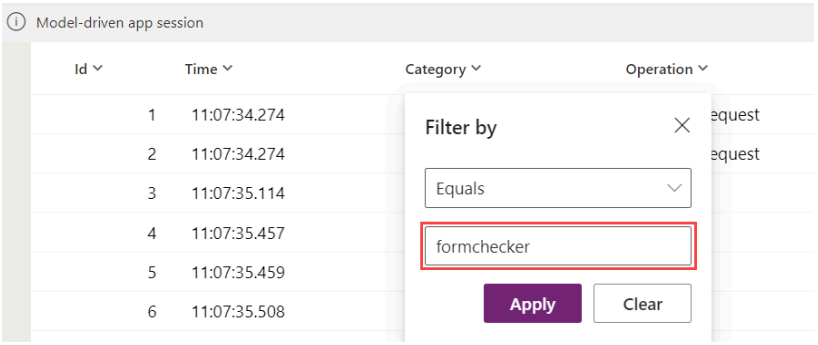
There are many situations where Live monitor can help makers understand why a form behaves a certain way. Many form issues are based on business rules, JavaScript, form events, or client API that admins and makers set. Live monitor can also help identify whether the issue experienced is designed out-of-the-box or is due to a customization. It provides details that can help answer the following questions:

- Why aren't rows showing in the related menu of a table?
- Why a control is disabled/enabled or visible/hidden
- Why is a row in a read-only state?

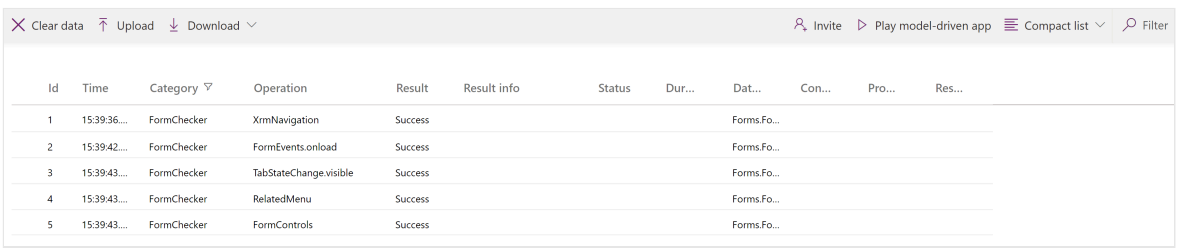
1. On the browser window running Live monitor, select the **Category** column, and then select **Filter by**.



2. Select **Equals** or **Contains** from the dropdown list, and then enter `formchecker` in the box. Select **Apply**.



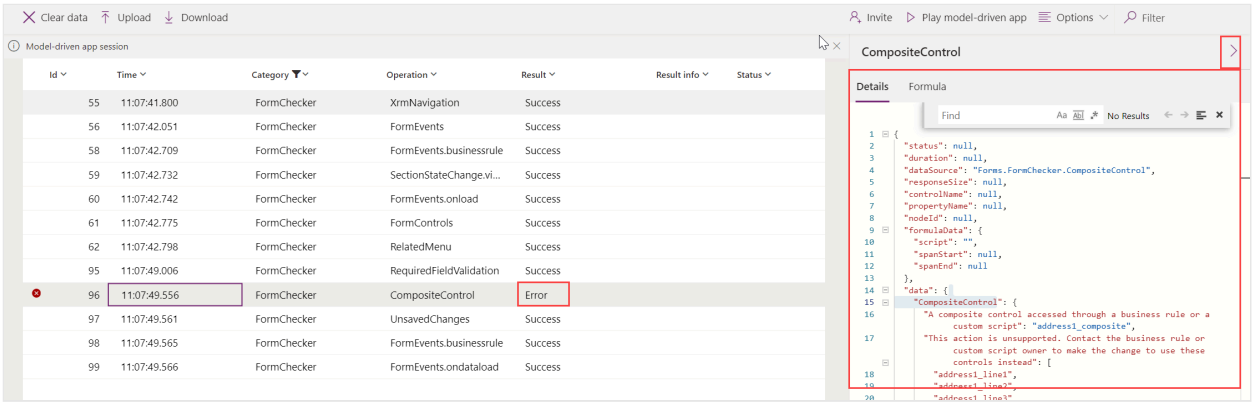
3. The categories are now filtered. The **Operation** column can be expanded to see the full name of the events that are tracked by selecting and holding the right side of the column and dragging to the right. As you use the app and open and use a form, Live monitor updates the list of events.



4. While the app is running in the monitored session, perform actions within the model-driven app consistent with normal use of the app. For example, open and change data using a table form.

Use Live monitor to understand form behavior

For each row with Live monitor, detailed information about the form event can be reviewed. For example, imagine you have a question about an error taking place within the form. You go to that form in the app and select the appropriate form component. Then return to the browser with Live monitor enabled and review the results either with or without filtering. In this case, there's an error on the composite control. By expanding areas of the **Details**, you can learn more about the event itself.



There are many types of events that are monitored, including the standard form events like `onload`, `onsave`, and `onclose`.

As you continue to use the app that's being monitored, Live monitor updates the information in the list of events. For forms, there are many different scenarios that you can troubleshoot and find additional information on the form, control, or table currently being worked on.

Form-checking areas and events

Areas for form monitoring include the following.

Expand table

App area	Description
Control state	Details about the state of the visible, enabled, and label source of a control when the form is loaded.
Related menu	Details about the state of related menu items. Examples: Why is a menu item not being displayed?

App area	Description
	Where does the menu item come from?
Tab / section / control state change	Details on who (via the callstack) has caused a form component—such as a tab, section, or control—to change the component's visibility and enabled state.
Navigation	Details about what's causing navigation or unexpected dialogs by tracing the callstack of these `Xrm.Navigation` client API methods: `openAlertDialog(), openConfirmDialog(), openDialog(), openErrorDialog(), navigateTo(), openForm(), openTaskFlow(), openUrl(), openWebResource()`
Unsupported customizations	Details about unsupported client API access before the form is ready. Examples: Accessing `parent.Xrm.Page` in iFrame before the form is fully loaded. Accessing `Xrm.Page` in a form web resource outside of form handler contexts using `window.setTimeout()` to periodically call the form client API. Accessing `Xrm.Page` in `updateView()` method of the Power Apps control framework control code.

Examples of the supported form-related events in Live monitor include:

- FormEvents.onsave
- XrmNavigation
- FormEvents.onload
- FormControls
- TabStateChange.visible
- RelatedMenu
- ControlStateChange.disabled
- ControlStateChange.visible
- SectionStateChange.visible
- UnsupportedClientApi

Filter Live monitor for Copilot control-related issues

1. On the browser window running Live monitor, select the **Category** column, and then select **Filter by**.
2. Select **Equals** or **Contains** from the dropdown list, and then enter `CopilotEvent` in the box. Select **Apply**.

Copilot control events

Events for Copilot control monitoring include the following.

Expand table

Event name	Description
AdaptiveCardActionData	Data sent to submit action for adaptive card
adaptiveCardContent	Content of adaptiveCard
AISummarize	This message is logged in case the summarize feature is off and logs the fcb status
AutoTriggerSummarizeHandler.isAutoTriggeredSummaryEnabled	Tells if auto trigger is enabled
ClientActionCalled	Logs the name of the client action and payload passed ot it
CopilotResponse	Response from the copilot
DVCopilotAction	isDVChatEnabled: if dv chat is enabled for the org or not
DynamicContextSentToBot	Dynamics context sent to bot
EnvironmentHostedBotSchemaName	Logs the environment bot schema name
ExecutingAction	Adaptive card action is getting executed
isSummaryEnabledForEntity	Tells if summarize is enabled for the entity
queryStructuredDataRequest	Request sent to query structure data
queryStructuredDataResponse	Response from query structure data
SessionContextSentToBot	Session context sent to bot
SummarizeResponse	Logs the response for the summarize
UserPrompt	Prompt entered by the User

Close a monitoring session

To close the monitoring session, close the browser tab where the monitored model-driven app is playing.

Troubleshoot form issues in model-driven apps

10/10/2025

This article has information to help fix some of the common issues you might encounter while working with model-driven app forms.

> **Important**
>
> - The tools described in this article are designed for troubleshooting purposes; they aren't meant to be used in day-to-day production scenarios, even though you can use them for troubleshooting issues in production environments.
> - These troubleshooting tools only affect the current user session unless otherwise noted (for example, when a browser tab accesses the model-driven app). They don't change system customizations or affect any other users or sessions. After the current session is closed, the effect is no longer applied.
> - Most of the tools are available in all the production environments. Some of them mentioned in the article might not be deployed to your organization yet; new tools are added periodically.
> - Tools listed in this article are written in a scenario-driven way. You can use them independently to troubleshoot different types of issues.
> - Use URL parameters to disable various form components and View registered form event handlers and libraries in Monitor are critical and fundamental tools you'll frequently use to troubleshoot many scenarios.
> - For more information on how to use Monitor, see Use Monitor to troubleshoot model-driven app form behavior

Use URL parameters to disable various form components

When you're troubleshooting issues with forms, you need to use the URL parameters to disable components as you work to isolate the specific component that caused the issue. We recommend that you use the flags one at a time to narrow down the cause of the issue. You can use the following URL parameters:

- **DisableFormCommandbar**

Disables the command bar on the form. It only disables the command bar on form pages and not supports list (grid), dashboard, etc.

```
HTTP

https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableFormCommandbar=true
```

- **DisableFormHandlers**

  Disables all the form handlers. If you use the **DisableFormHandlers=true** flag, it disables the following event handlers: OnLoad, OnSave, business rule, OnChange, and TabStateChange.

  To learn more about obtaining event or library indices for granular controls, see View registered form event handlers and libraries in monitor.

  ```
  HTTP

  https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableFormHandlers=true
  ```

  - **&flags=DisableFormHandlers=*eventName***

    Disables the form handler by specifying the event name, for example, ****DisableFormHandlers=onload**.

    ```
    HTTP

    https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableFormHandlers=true
    ```

  - **&flags=DisableFormHandlers=*eventName_index***

    Disables the event handler at the specified index for any supported event name. For example, `DisableFormHandlers=true_0` disables all the event handlers at index 0. `DisableFormHandlers=onload_2` disables the OnLoad event handler at index 2.

  - **&flags=DisableFormHandlers=*eventName_startIndex_endIndex***

    Disables all the event handlers within the given range by specifying `startIndex` and `endIndex` values (both are included). For example, `DisableFormHandlers=true_0_2`

disables all the event handlers of index 0, 1, and 2. `DisableFormHandlers=onload_2_5` disables the OnLoad event handler of index 2, 3, 4, and 5. If you have more event handlers, you can use this approach to narrow down problematic handlers quickly.

> **Note**
>
> Business rules are authored in the business rule designer, compiled into the client-side script, and registered in multiple form events, such as `OnLoad`, `OnSave`, and `OnChange`. The way to disable business rules are similar to other form events. However, there are a few key differences:
>
> - When you use `DisableFormHandlers=true`, `businessrule`, `businessrule_*index*`, or `businessrule_*startIndex_endIndex*`, you're disabling all business rules in all the form events they're registered to.
> - For example, the following image shows instructions on refreshing business rules in the backend. You only need to do it once in your organization, and you can revert your changes after troubleshooting.
>
> 
>
>
> - After you perform the above action and refresh the form, you'll see different message with additional information, as shown in the following image:
>
> >

- **DisableFormLibraries**

  Disables form libraries and prevents the libraries from being loaded. To learn more about obtaining event or library indices for granular controls, see View registered form event handlers and libraries in monitor . The usage is similar to `DisableFormHandlers`, except it doesn't take an event name as the value.

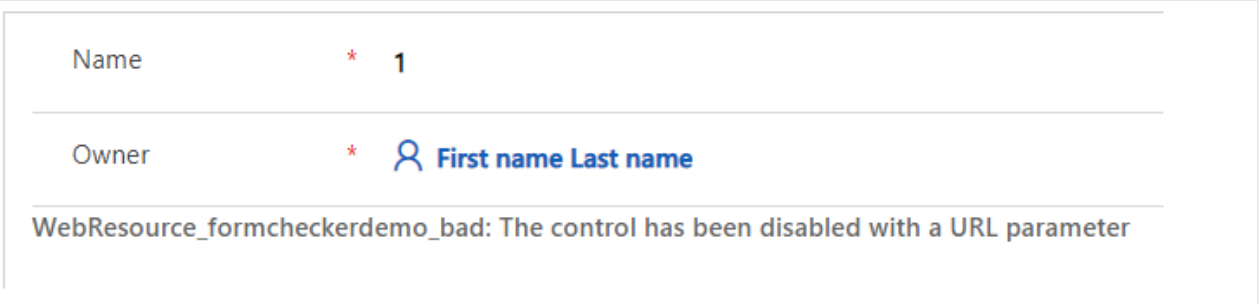
- **&flags=DisableFormLibraries=true**: Disable all the form libraries.
- **&flags=DisableFormLibraries=*index***: Disable form libraries at the specified index.
- **&flags=DisableFormLibraries=*startIndex_endIndex***: Disable form libraries in the range of startIndex and endIndex (both included).

- **DisableWebResourceControls**

  Disables all the web resource controls on the form.

  ```
  HTTP

  https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableWebResourceControls=true
  ```

- **DisableFormControl**

  Disables a form control. Specify the control name to disable the control. If you see that the issue goes away with **&flags=DisableWebResourceControls=true**, and there's more than one web resource control on the form, you can use this flag to further identify the control that's causing the issue.

  ```
  HTTP

  https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableFormControl=controlname
  ```

- **DisableBusinessProcessFlow**

  Disables all the business process flows on the form.

  ```
  HTTP

  https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableBusinessProcessFlow=true
  ```

- **navbar** This isn't a **flag** parameter; instead, use **navbar=off** in the URL.

You can also add multiple URL parameters separated with a comma (,).

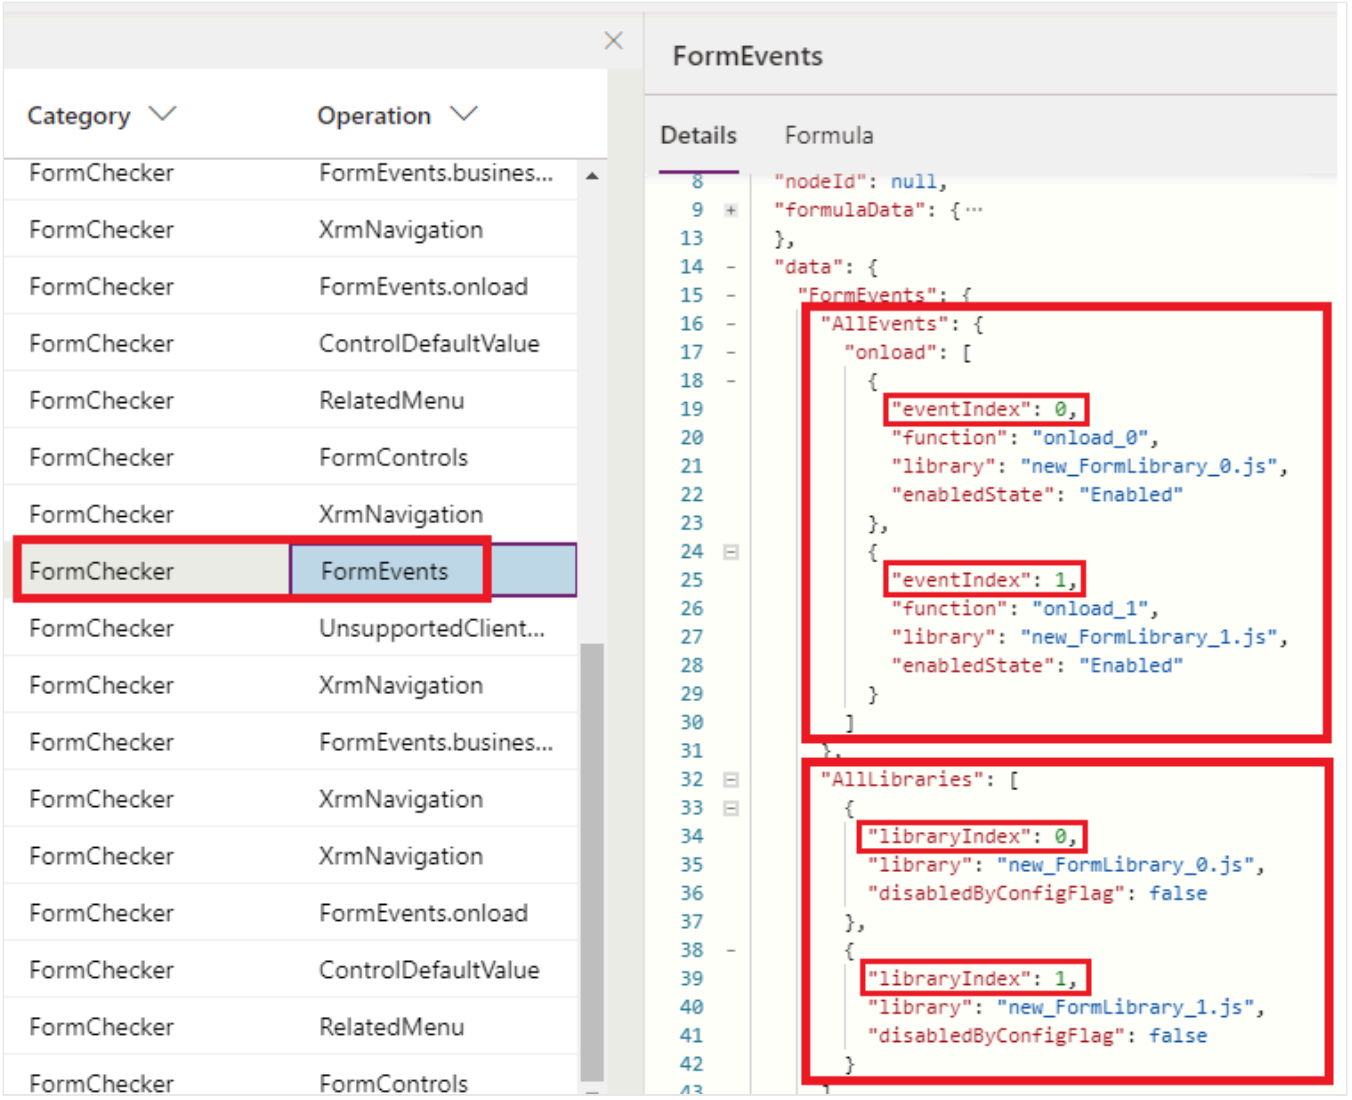
Http

```
https://myorg.crm.dynamics.crm/main.aspx?appid=00000000-0000-0000-0000-000000000000&pagetype=entityrecord&id=00000000-0000-0000-0000-000000000000**&flags=DisableFormHandlers=true,DisableWebResourceControls=true,DisableFormCommandbar=true,DisableBusinessProcessFlow=true&navbar=off
```

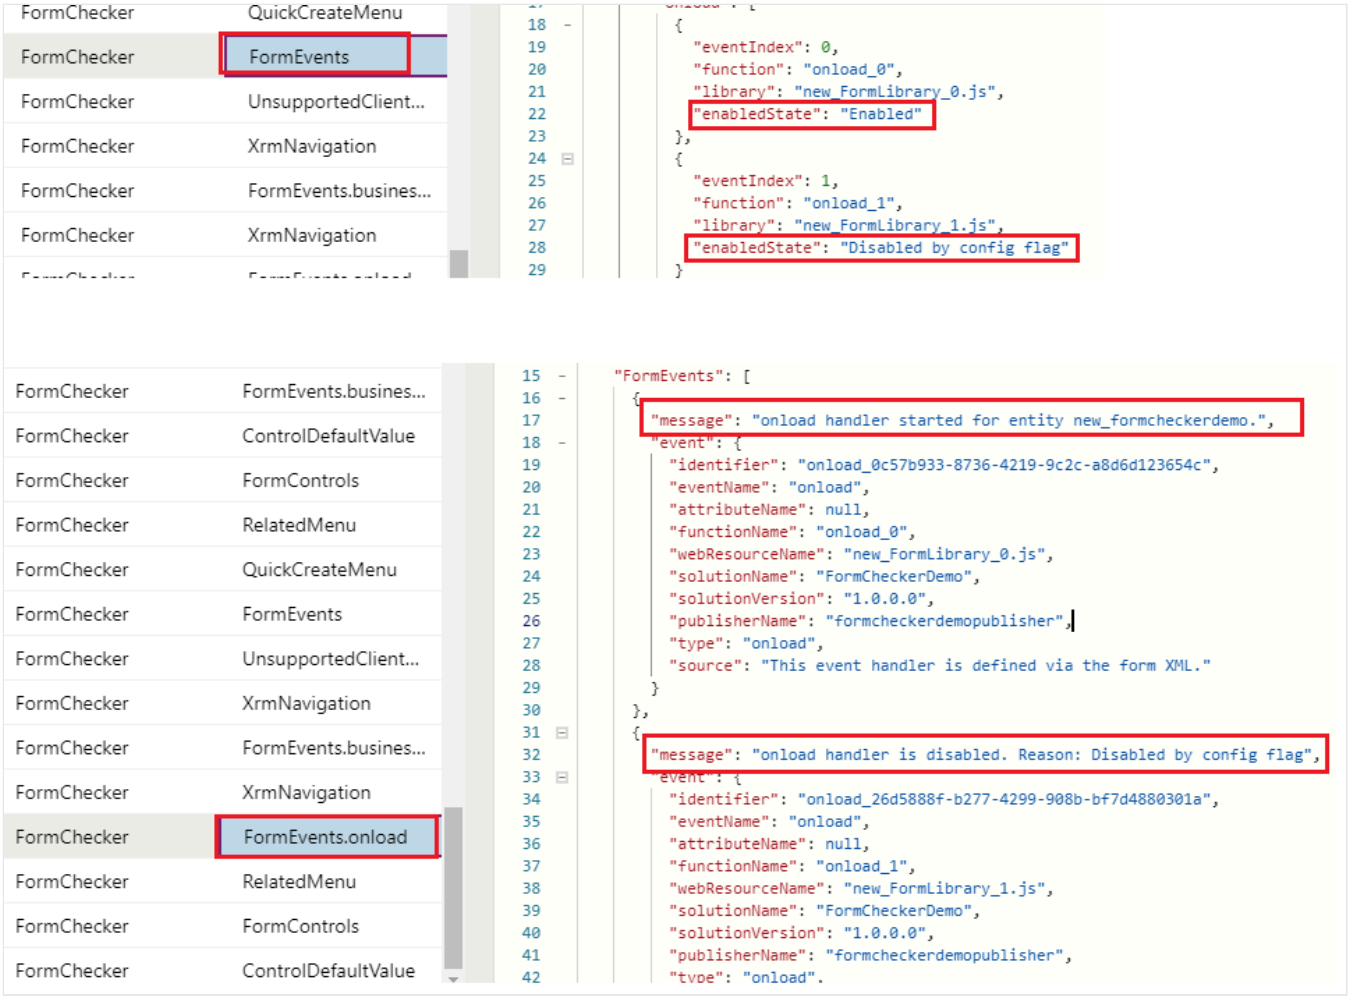
> ⓘ **Note**
>
> The difference between **DisableFormHandlers** and **DisableFormLibraries** are:
>
> - The **DisableFormHandlers** flag disables form handlers regardless of the containing form libraries. In contrast, the **DisableFormLibraries** flag disables the form libraries (web resources) regardless of the functions (event handlers) included in the libraries. Simply put, **DisableFormLibraries** makes sure the specified JavaScript web resource files aren't loaded.
> - The **DisableFormHandlers** flag doesn't prevent the containing form library from being loaded. Thus it doesn't stop the JavaScript code present in the library but not registered as an event handler from being executed. For example, if a form library `new_myscript.js` is written in the following way (not recommended practice):
> - You should start with **DisableFormHandlers** to see if the issue goes away, and if not, you can try **DisableFormLibraries**. Disabling any script always involves some risks of potentially breaking your form scenarios. However, the latter tend to have more side effects because of the disablement of the entire JavaScript files.
>
> ```
> // new_myscript.js
> alert("First alert that's not registered in any form events but will still be triggered when the form loads!");
>
> function myOnloadHandler () {
>     alert("Second alert that's registered in the form onload event!");
> }
> ```
>
> - Assuming the `myOnloadHandler` is registered as an `OnLoad` event handler, the `DisableFormHandlers=true` flag only prevents the second alert, whereas the `DisableFormLibraries=true` flag prevents both alerts.

View registered form event handlers and libraries in monitor

To view registered form event handles and libraries, you can view the `FormEvents` operation in Monitor.



You need the `eventIndex` and `libraryIndex` parameter values when using the **DisableFormHandlers** or **DisableFormLibraries** URL flags. After an event or library is disabled, you'll see the event enabled state in both **FormEvents** operation (an overall view of all registered event handlers of all events), and **FormEvents.*eventName*** operation (details logged when a specific event happens).



Unexpected behaviors when loading a form

Some common issues that can cause unexpected behavior when a model-driven app form is loaded are:

- Columns or controls don't have the values you expect.
- Controls aren't disabled or aren't enabled.
- Controls aren't shown or aren't hidden.

How to troubleshoot

There are multiple reasons why unexpected behaviors occur when a form opens. One of the most common is the OnLoad scripts that run synchronously or asynchronously to change the column or control behavior. To determine whether your script is causing the issue, you can disable the form handlers by appending **&flags=DisableFormHandlers=true** at the end of your app URL.

If the unexpected behavior stops occurring after you disabled the form handler, it's a strong indication that the specific form handler is causing this behavior. When you identify the script that's causing this behavior, follow up with the script owner to further troubleshoot this issue.

Saving in progress error message

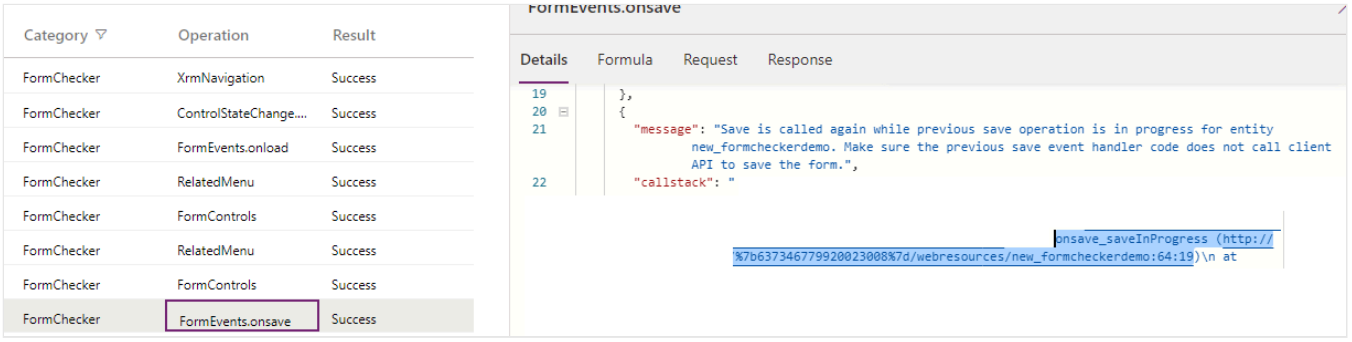
Sometimes when you save a form, you see a **Saving in Progress** error message.

This error occurs when the form OnSave event is triggered before the previous OnSave event completes. This behavior isn't supported, and the error appears by design because calling the `OnSave` event before the previous `OnSave` event is complete causes recursive save loops with unintended consequences.

A typical cause for this error is the script that calls the `save()` method in the OnSave event handler. Another possible cause might be concurrent `save()` calls in the `setTimeout()` method, which might cause the error to intermittently show up, depending on whether the prior `save()` call was completed before another `save()` call was made.

How to troubleshoot

In Monitor, the `FormEvents.onsave` operation provides all the details that are causing the error (this call stack is modified for demonstration purposes). The call stack tells what exact web resource, function, line, and row number causing this error. The form checker can't detect the error if the issue can't be reproduced.



Follow up with the script owner to further troubleshoot the issue.

Intermittent form errors

The most common cause of intermittent or random form errors is using unsupported client API methods. These errors have the following characteristics:

- They occur only for specific records, users, regions, or browsers, or only during periods when the network or service load is high.
- They rarely occur in support instances.
- They might occur once on a computer, and the same error might occur again after you clear the browser cache.

- formContext.getControl or formContext.getControl(arg).getAttribute() randomly returns null for a valid control or column.

There are many ways to write unsupported client API methods, and they all share a common pattern: they cause a race condition in the form load pipeline. Because they introduce a race condition, the issue only occurs when the custom script executes before the form is fully ready to be accessed via the client API. Many factors can cause a race condition:

- In the JavaScript web resource, code is put into a global scope executes immediately when the web resource file is loaded, without waiting for the form to be accessible. Make sure the code is executed inside a valid form handler, such as an OnLoad handler.

```
// Bad custom script example

// this is a bad place to invoke client API, this API will fail intermittently
// Move it into a form handler, such as onload
Xrm.Page.getAttribute("myAttribute").setDisabled(true);

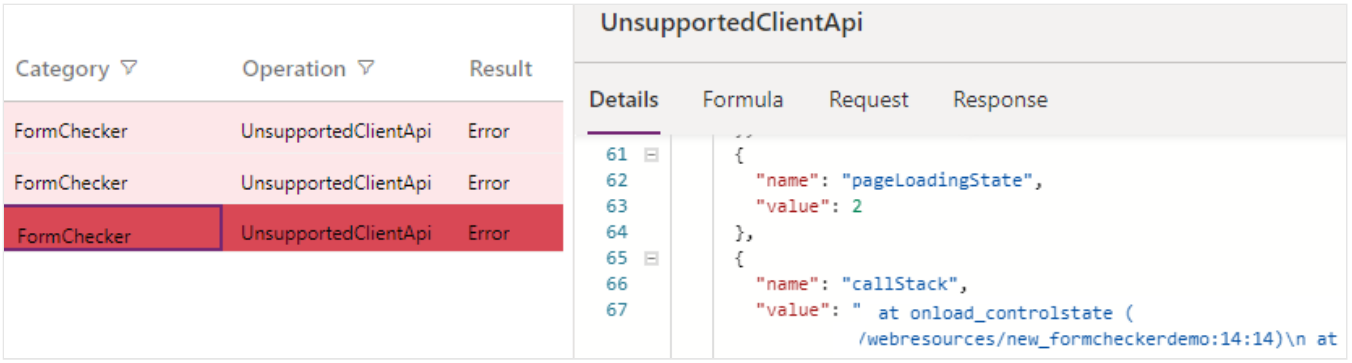
function myOnloadHandler(executionContext) {
    // this is a recommended place to put your client API code in
}
```

- In the Power Apps component framework component script file, client API methods are accessed inside the init or updateView function. The `init()` and `updateView()` functions are executed immediately when the component is loaded, without waiting for the form to be readily accessible. You can't use unsupported Client API methods in Power Apps component framework components.

Client API is accessed inside a `window.setTimeout()` function in the web resource file. The page state is unpredictable when the `setTimeout()` method executes the wrapped function. Due to the nature of the timer function, when the execution occurs, the page might be in a transitional state (during page load or save) that's not readily accessible by the Client API.

How to troubleshoot

Using Monitor, you can access information that helps you determine when the unsupported client access occurred and when the access occurred at the wrong time due to a race condition. However, Form Checker doesn't report such unsupported client access when the unsupported code happens to execute at the right time that doesn't cause an issue.



> **Note**
>
> The call stack is modified for illustration purposes. The call stack shows details like web resource, function, and the line causing the error.

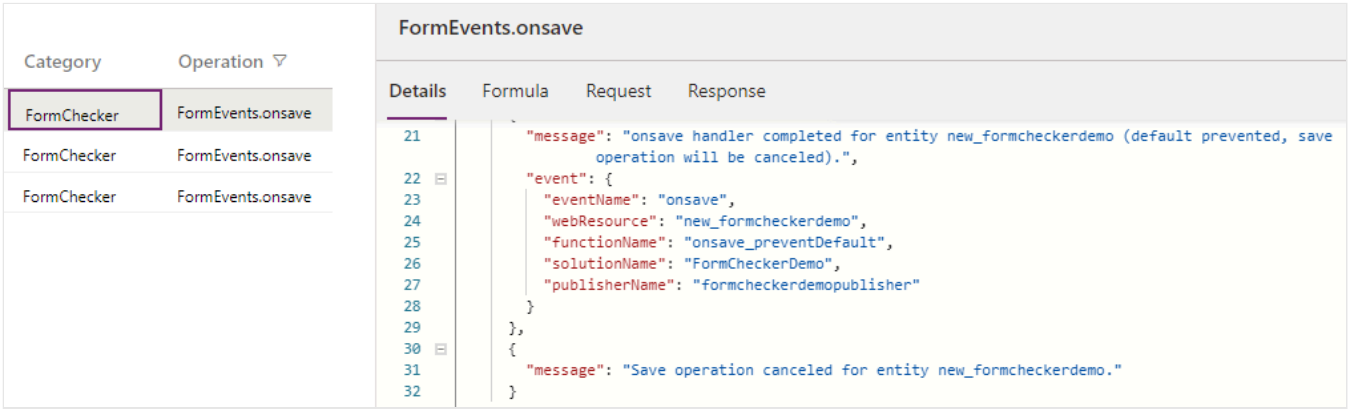
Follow up with the script owner to further troubleshoot the issue.

The form or record isn't saved when you try to save the form

A common cause is an OnSave event handler that calls the executionContext.getEventArgs().preventDefault() method to cancel the save operation.

How to troubleshoot

In Monitor, the `FormEvents.onsave` operation provides all the details of why the save event is canceled details than that are available from the form UI itself.



Follow up with the script owner to further troubleshoot the issue.

Form freezes, loads slowly, or throws unexplained errors

There are many possible reasons for a form to freeze, load slowly, or throw a "Web resource method doesn't exist" script error or an error that isn't a common script error. Some of the possible reasons include:

- Bad `OnLoad` scripts.
- Web resource controls.
- Ribbon button scripts and rules.
- Synchronous network requests.
- Custom plug-ins.
- Business process flow errors.

How to troubleshoot

Determine if the issue reproduces without involving forms. If it does, then there's a broader issue that should be investigated out of the form's context. Actual ownership of the problem depends on the particular details case by case.

- If you believe this issue only occurs on forms, see Use URL parameters to disable various form components to narrow down the component that's causing the issue.
- If you identify that certain form libraries/script files caused the issue, follow up with the owner who made these customizations to find out the root cause of the issue.
- If you identify that web resource controls cause the issue with the **DisableWebResourceControls** flag, then you can use the `DisableFormControl` flag to disable each one-by-one until the problem is longer reproduced. The last disabled control that doesn't reproduce the issue is the one that's causing the issue. Follow up with the owner of the control to further troubleshoot the issue.
- If you identify that the issue is caused by the command bar/ribbon with the **DisableFormCommandbar** flag, it means this isn't an issue with the form but an issue with the command bar. Use Command Checker to troubleshoot individual commands and identify which one is causing the issue.

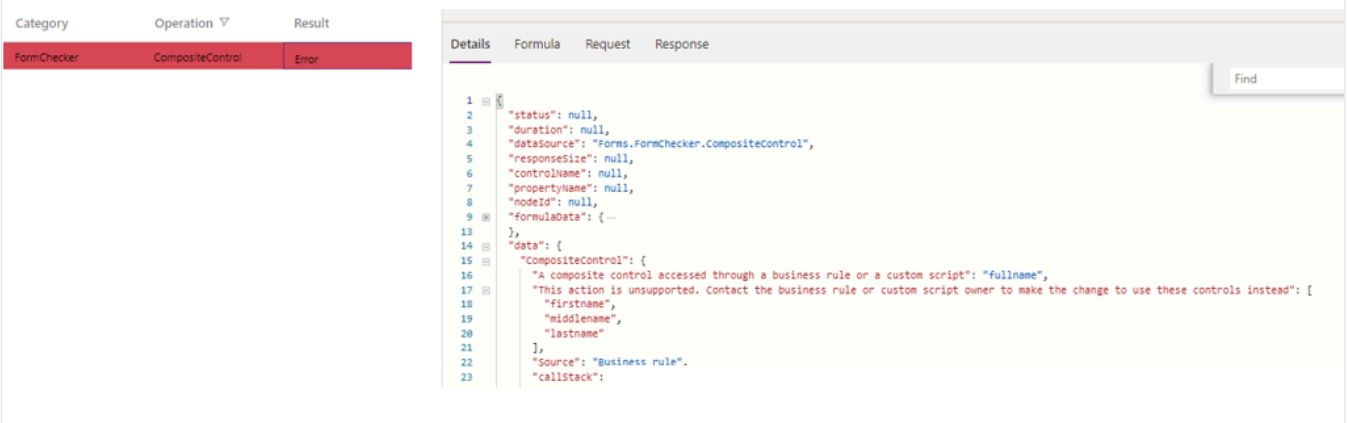
A business rule or custom script isn't working

This issue occurs if a business rule or custom script that used to work in the legacy web client stopped working in Unified Interface. One of the main reasons for this error to occur is when a business rule or script in Unified Interface references a control that isn't available in Unified Interface.

How to troubleshoot

One of the reasons that the business rule or script isn't working in Unified Interface is that the controls that are part of them don't exist in Unified Interface. Composite controls exist in the web client, but in Unified Interface composite control is broken down into parts and is stored differently. For example, if the column `fullname` is part of the business rule or custom script, columns `firstname`, `middlename`, or `lastname` should be used instead.

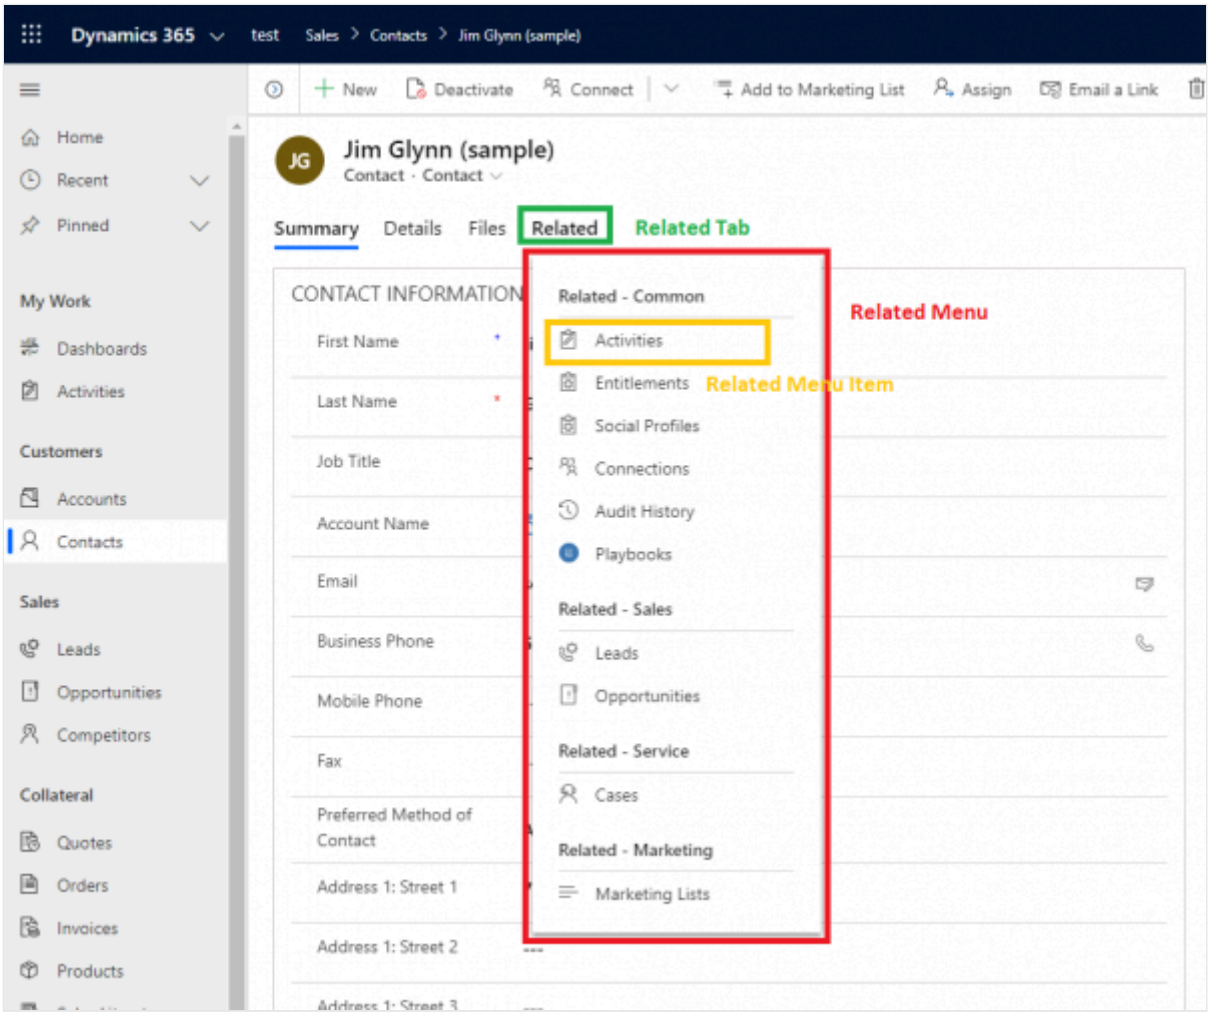
Once you launch form checker, you're able to see more details in the `CompositeControl` operation including the composite control that's causing the problem, the columns that can be used in the business rule or custom script instead and a full call stack (the call stack is modified for demonstration purposes).



Follow up with the corresponding owner of the business rule or custom script to change the control suggested by the form checker.

Related menu item doesn't appear in Related tab

Most forms have a **Related** tab. It opens the **Related menu** with **Related menu items**.



A **Related menu item** might not appear as expected.

How to troubleshoot

A related menu item might not appear because:

Relationship between the main and related table isn't configured correctly

There should be a one-to-many or many-to-many relationship between the main table and the related table. A form shows a row from the main table. The related table is the one that should appear in the **Related** menu of the form. If these relationships don't exist, the related menu item doesn't appear.

To verify, go to the Power Apps portal, select **Tables**, and select the table that has the relationships you want to view.

Dataverse created the relationship between the main and related table and isn't customizable

The **Related** menu doesn't show related tables from certain relationships created by Dataverse. These relationships are marked as noncustomizable.

The AssociatedMenuConfiguration.IsCustomizable property indicates whether the relationship can be customized. The easiest way to check is by querying the relationship using Web API to view the AssociatedMenuConfiguration complex type data.

Suppose you want to check whether the relationship between the Business Unit and Goal tables is customizable. The `SchemaName` of this relationship is business_unit_goal. Enter this URL in your browser:

HTTP

```
GET [Organization
URI]/api/data/v9.2/RelationshipDefinitions(SchemaName='business_unit_goal')/Micros
oft.Dynamics.CRM.OneToManyRelationshipMetadata?$select=AssociatedMenuConfiguration
```

You can also get the same data by querying the table definition:

HTTP

```
GET [Organization
URI]/api/data/v9.2/EntityDefinitions(LogicalName='businessunit')/OneToManyRelation
ships(SchemaName='business_unit_goal')/AssociatedMenuConfiguration
```

The response for either request might look like this:

JSON

```
{
    "@odata.context": "[Organization
URI]/api/data/v9.2/$metadata#RelationshipDefinitions/Microsoft.Dynamics.CRM.OneToM
anyRelationshipMetadata(AssociatedMenuConfiguration)/$entity",
    "MetadataId": "2124b4bd-f013-df11-a16e-00155d7aa40d",
    "AssociatedMenuConfiguration": {
        "Behavior": "UseCollectionName",
        "Group": "Details",
        "Order": null,
        "IsCustomizable": false,
        "Icon": null,
        "ViewId": "00000000-0000-0000-0000-000000000000",
        "AvailableOffline": true,
        "MenuId": null,
        "QueryApi": null,
        "Label": {
            "LocalizedLabels": [],
            "UserLocalizedLabel": null
        }
```

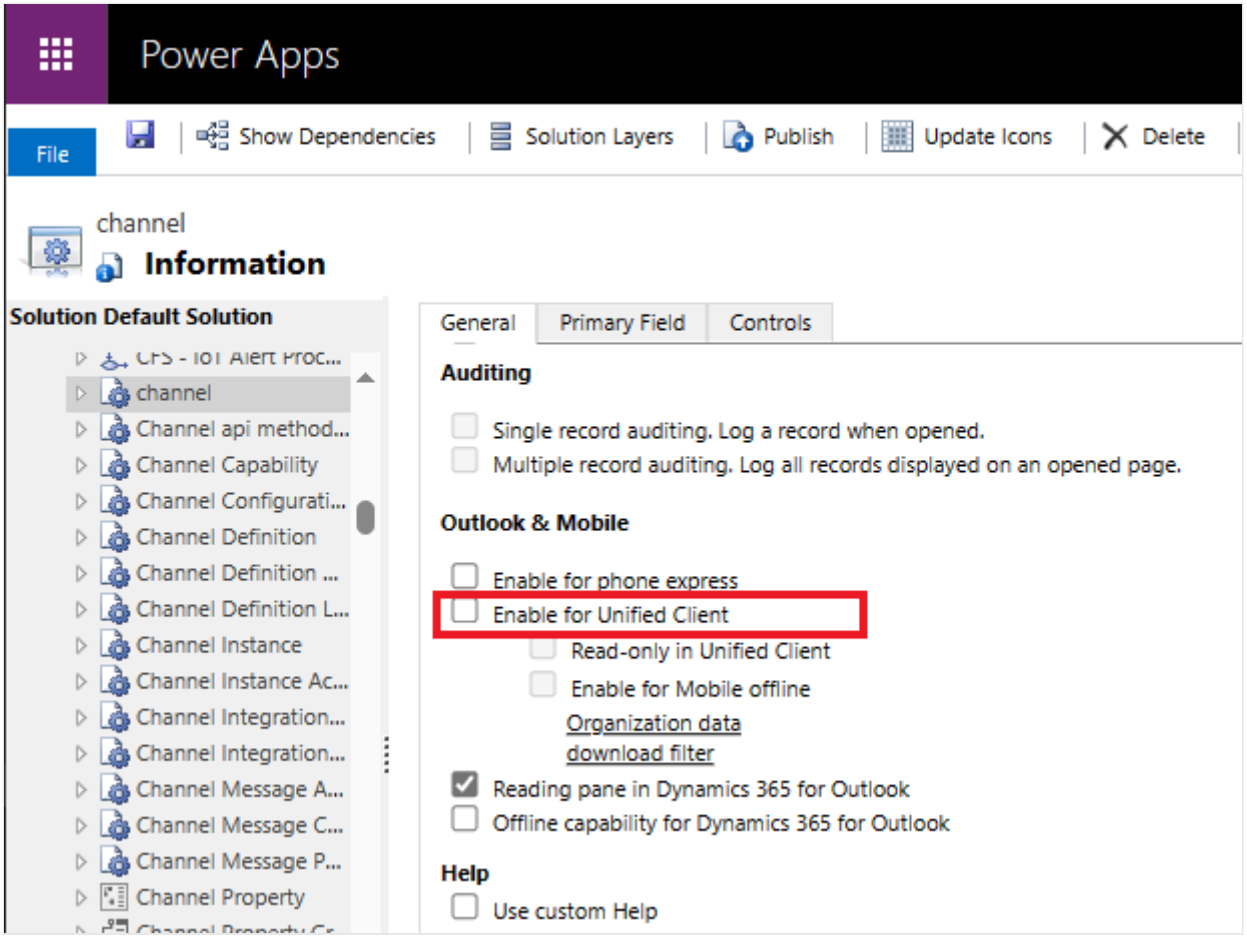
```
    }
}
```

Observe that `IsCustomizable` is `false`. Therefore, the relationship isn't customizable and **Goal** doesn't appear in the **Related** menu.

Related table isn't enabled for Unified Client

If the table was created in Web Client (deprecated since 2019), it might not appear because it's disabled for Unified Client.

To verify, go to Solution explorer and select the table (entity). Ensure that **Enable for Unified Client** is checked.



Tables created with the modern designer don't have this issue. They're always enabled for Unified Client.

> ⓘ **Note**
>
> Certain system tables can't be enabled for Unified Client. For example, **Process Session** can't be used in model-driven apps.

Audit History doesn't appear in Related tab

Audit History isn't in the Related menu.

How to troubleshoot

Audit history isn't supported in these cases:

- Tables that aren't enabled for auditing. Check the table's IsAuditEnabled property to confirm.
- System tables that don't support Audit History
- Mobile apps
- Offline mode
- Dynamics for Outlook

Unexpected related menu item appears in related tab

A **Related menu item** might appear when it shouldn't.

How to troubleshoot

A related menu item might appear because:

Related table has self-referencing many-to-many relationship with the main table

The system ignores form XML customizations for self-referencing many-to-many relationships. The system ignores these customizations because it isn't possible to indicate whether the customizations are for the primary table or the related table, which are both the same table in this case. Therefore, the system ignores these customizations.

If you modify the form XML to hide the related menu item, it still appears. Any form XML customizations for self-referencing relationships are ignored, like changing the order or the label of the related item.

Some system tables can't be hidden

For example, custom tables always show **Activities** related menu item. It isn't possible to hide it with the form designer or by modifying the form XML.

Related menu items aren't translated as expected

The text for related menu items aren't in the expected language.

How to troubleshoot

If some related menu items are displaying in a different language from the user's language, check whether the form XML is missing translated labels.

Check the form XML to see if there are labels defined for each language. For example, this form XML shows that the `navContacts` item only has a US English (1033) label: `Contacts`.

XML

```
<NavBarByRelationshipItem Id="navContacts" Area="Sales" Sequence="10064"
RelationshipName="contact_customer_accounts" Show="true">
  <Titles>
    <Title LCID="1033" Title="Contacts" />
  </Titles>
</NavBarByRelationshipItem>
```

To fix this issue, add the translated labels to the form XML. For example, this form XML shows that the `navContacts` item with both US English (1033) and German (1031) labels.

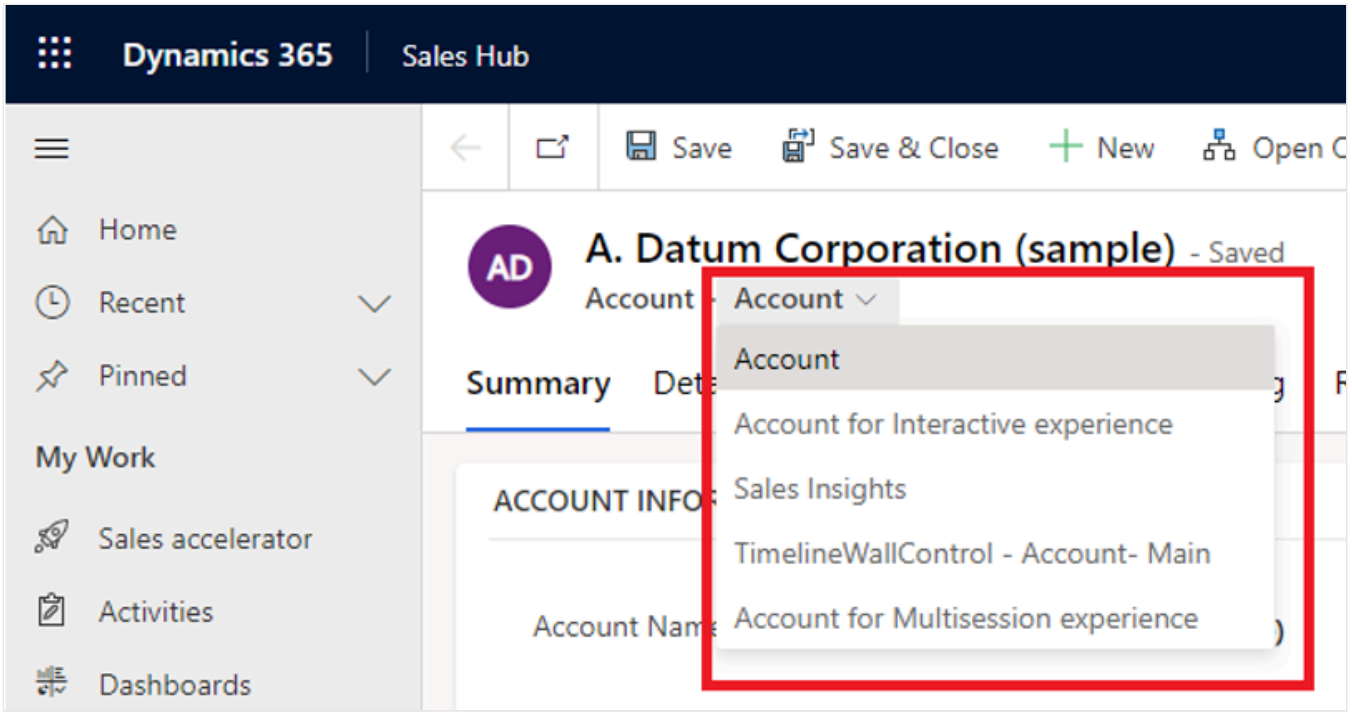
XML

```
<NavBarByRelationshipItem Id="navContacts" Area="Sales" Sequence="10064"
RelationshipName="contact_customer_accounts" Show="true">
  <Titles>
    <Title LCID="1033" Title="Contacts" />
    <Title LCID="1031" Title="Kontakte" />
  </Titles>
</NavBarByRelationshipItem>
```

If the text for the user's language isn't defined, the system uses the organization's base language. If that doesn't exist either, the system uses the US English text.

Why is a form showing or not showing in the form selector?

The form selector is a dropdown that allows users to switch between different forms for a particular table.



You need to understand the conditions that control whether the form is displayed.

How to troubleshoot

A form is available in the selector when all of these conditions are met:

1. User has permission to access the form.
2. Form is added to the app module.
3. Form isn't hidden with Client API.
4. For Dynamics Customer Service workspace forms, **ShowInFormSelector** is set to **True**.

If a form isn't showing in the form selector,

1. Check the affected user's security roles.
2. Check if the form is added to the app module.
3. Disable custom scripts.

Why an expected default form isn't shown by default?

When there are multiple forms for a table, the desired one isn't used as the default.

How to troubleshoot

The following criteria determine the first form shown to the user:

1. If a formId is provided when opening a form, then that form is shown. A formId can be provided through Client API functions like openForm or in a URL.
2. Otherwise, the most recent form that the user picked is shown. The system remembers the latest selection from the form selector.
3. If the user hasn't used the form selector before, the system uses the form order.

If the form isn't available to the user, the system continues to find an appropriate form to show.

A form is available to the user when:

1. User has permission to access the form.
2. Form is added to the app module.

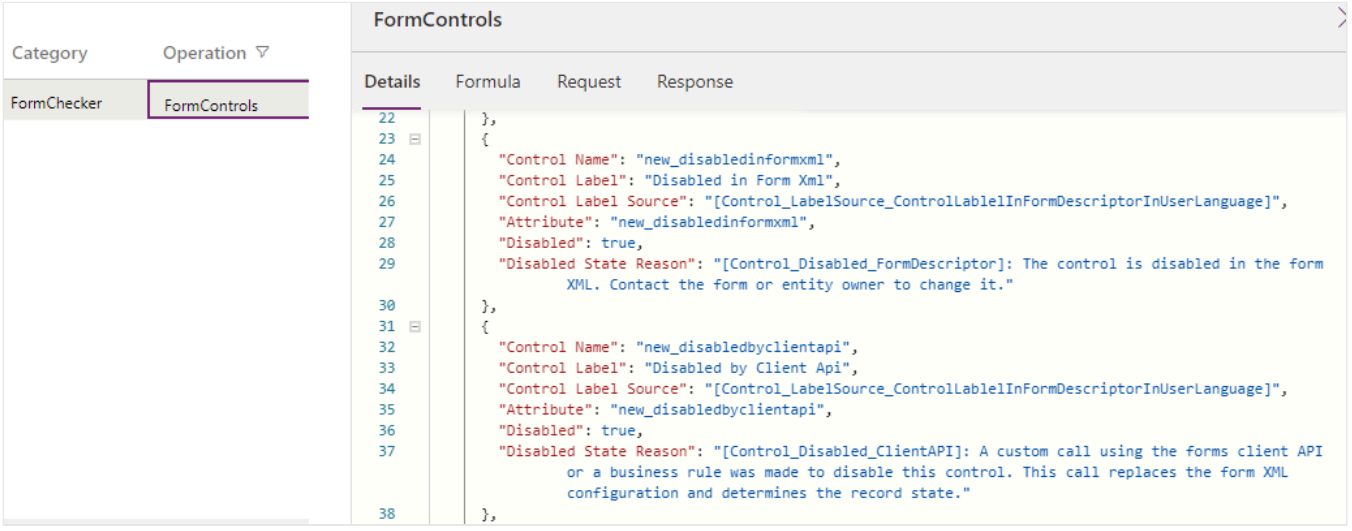
If no forms are available to the user, then the the fallback form is used.

Why a control is disabled/enabled or visible/hidden

There are many possible reasons why a control might be disabled or hidden when the form is loaded.

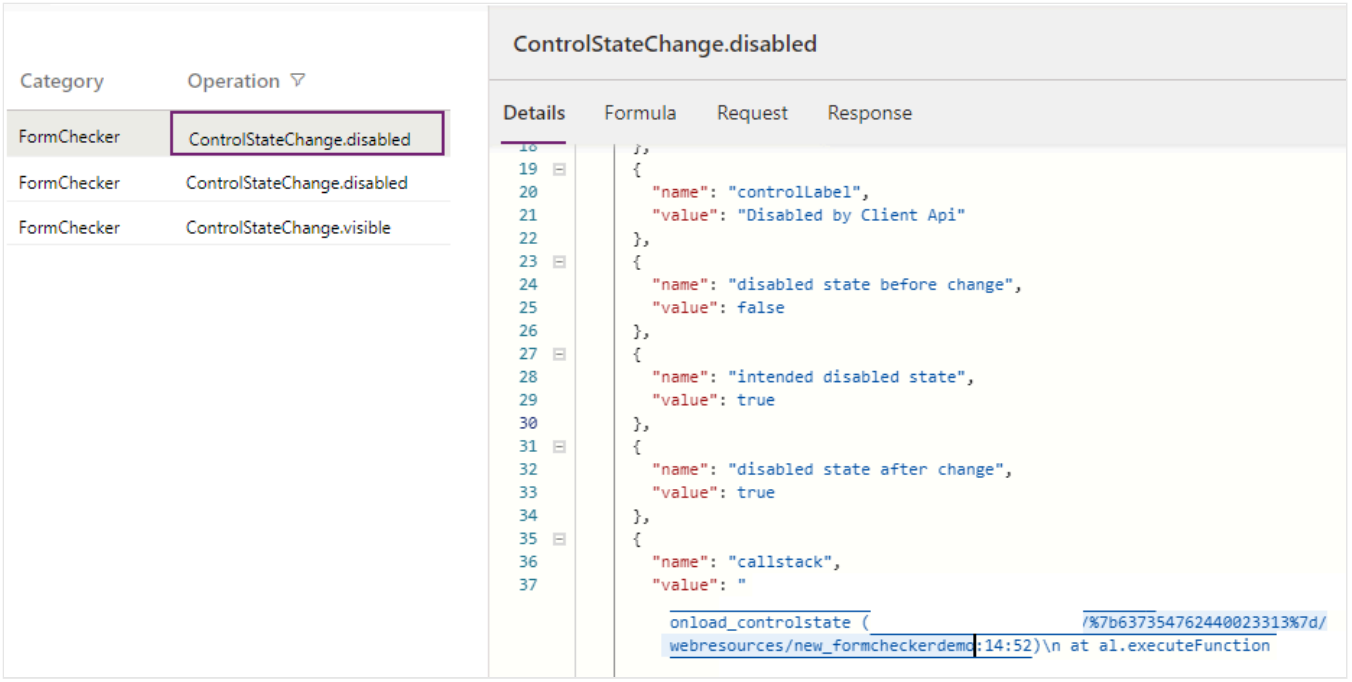
How to troubleshoot

You can use Monitor to view the `FormControls` operation that includes all the details about the initial control state when the form loads.



Another place to check is the `ControlStateChange.visible` or `ControlStateChange.disabled` operation that explains why the control disable or visible state is changed at any time on the form. This operation explains the control state before the change, intended state change that

might succeed, and the state after the change. Not all control state change attempts are successful. For a control disabled by form XML, you can enable it through client API in an `OnLoad` event handler. However, if control is disabled for security reasons, it's highly unlikely an attempt to enable it through client API would successfully change the state.



A control can be disabled by using the following list of rules in order. If a rule is met, then the following rules are ignored. If you want to change whether a control is disabled, you must change the input to the rule used for the result or to a rule earlier in the list.

- If the flags `DisableWebResourceControls=true` or `DisableFormControl=<control name>` are passed and the control is affected by these flags, the control is disabled.
- If the owning table is read-only in Unified Interface in table definitions, the control is disabled.
- If the table isn't available in offline mode, the control is disabled.
- If the current user doesn't have write permissions on the record, the control is disabled.
- If the column definition has `IsValidforCreate` set to false, the control is disabled.
- If the column definition has `IsValidforUpdate` set to false, the control is disabled.
- If the current user doesn't have `Assign to` privilege, the owner column is disabled.
- If the user doesn't have write permissions on the column defined by field-level security, the control is disabled.
- If a client API script enables or disables the control, the control disabled state honors that setting.
- If the control is disabled in the form designer, the control is disabled.
- If the user doesn't have `Append To` privilege for the lookup control's table, or `Append` privilege on the current record's table, the lookup control is disabled

Finally, if the control passes all the above checks, the record state determines whether the control is disabled. The control is enabled by default on active records and disabled on inactive records.

> **Note**
>
> The difference between `FormControls` and `ControlStateChange` is that the `FormControls` operation reflects the initial control state when the form is loaded, while the `ControlStateChange` operation reflects the state change at any time on the form, whether it's during form load, in OnChange or OnSave events after the form is loaded.

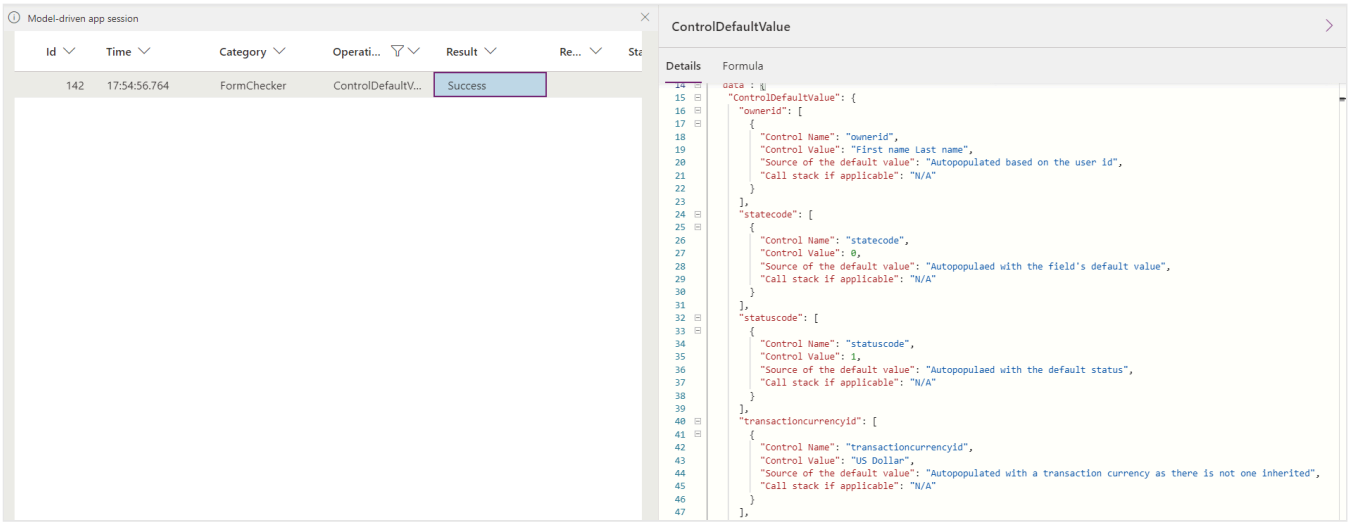
> **Important**
>
> A control's disabled and hidden state can change multiple times when a form is first loaded. To know the reason why a control is hidden or disabled, make sure to check the **last** operation logged in the monitor. For example, if there are no `ControlStateChange.visible/ControlStateChange.hidden` operations for the control being investigated, the value and reasoning will be in the `FormControls` operation. Otherwise, it's the value and reason in the **last** `ControlStateChange.visible/ControlStateChange.hidden` operation. You can order logs by timestamp to search for the last operation.

Why a control has a certain value on form load

A control might not have a specific value on form load as the user expected.

How to troubleshoot

There are many possible reasons why control can have a value when a form loads. The `ControlDefaultValue` operation in Monitor explains the source of the default values.



If multiple updates are happening to a control's value, an `Update Sequence` indicates the final value. For example, here's a control with a default value and then overridden with a value passed with a client API script. There's a call stack provided.

There are scenarios where columns are populated based on a relationship column mapping, in which case the event shows that.

```
"ControlDefaultValue": {
  "transactioncurrencyid": [
    {
      "Control Name": "transactioncurrencyid",
      "Control Value": "US Dollar",
      "Source of the default value": "Relationship field mapping",
      "Call stack if applicable": "N/A"
    }
  ],
  "address1_city": [
    {
      "Control Name": "address1_city",
      "Control Value": "Renton",
      "Source of the default value": "Relationship field mapping",
      "Call stack if applicable": "N/A"
    }
  ],
```

Verify where the value is coming from and take action based on the following table:

Expand table

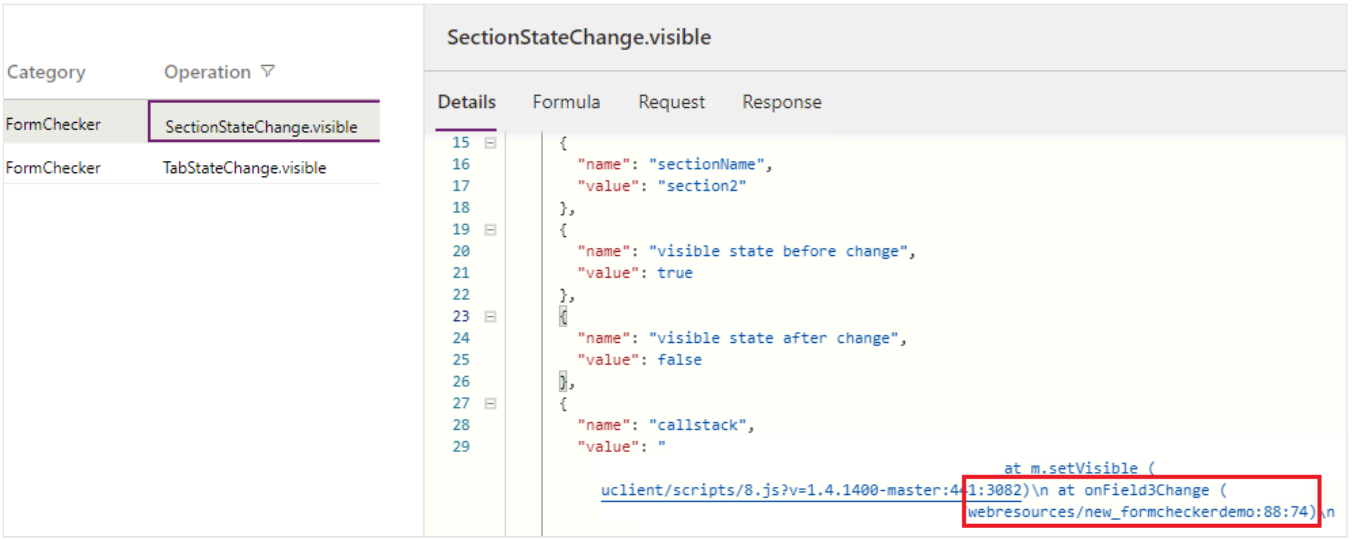
Source	How to fix
Client API script	Contact the script owner.
Default value	Check the control's configuration.
Relationship column mapping	Check the relationship configuration and update the column mapping.
Value passed by page input data passed via URL	Check the API that opens the specific form with the issue, it's passing the value.

Why a tab or section is visible or hidden

There are many possible reasons why a tab or section might be hidden or visible.

How to troubleshoot

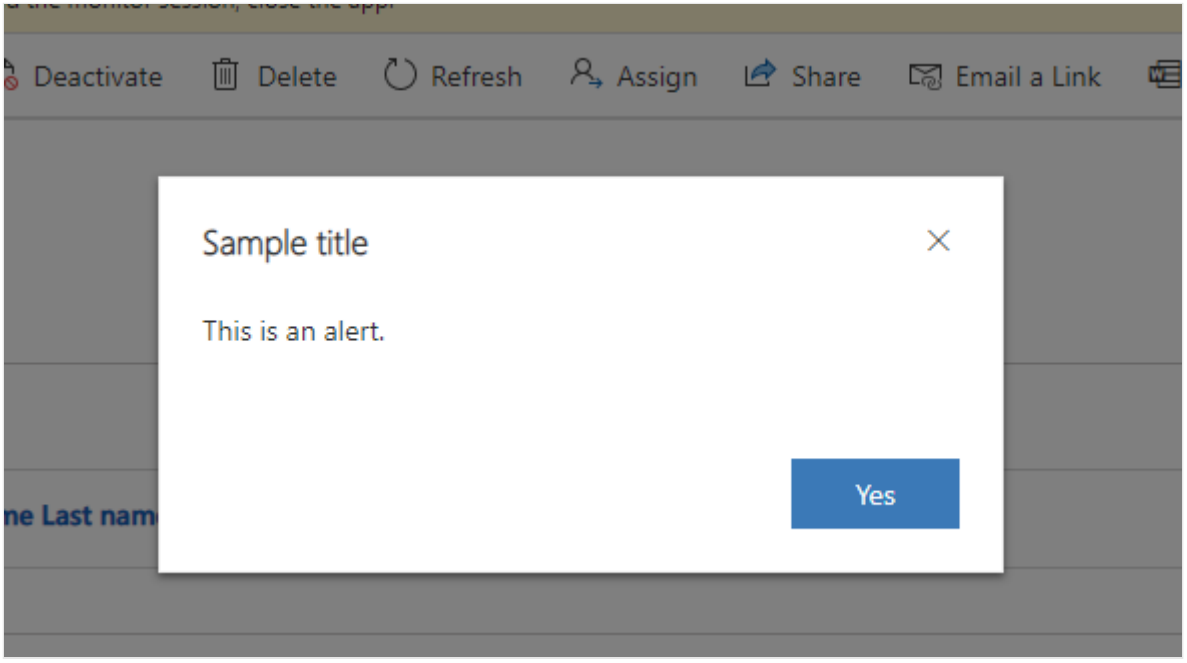
The `TabStateChange` or `SectionStateChange` operations in Monitor explain the visible state change, as shown in the following image. If a script causes it, then the call stack would reveal the web resource file, line number, and function name that caused this behavior.



Follow up according to the suggestion in the state reason or the owner of the web resource/business rules to change or fix the behavior.

Unexpected dialogs or navigation

There are many possible reasons why a dialog appears, or navigation happens unexpectedly. One of the common causes is the Xrm.Navigation API methods are called to open a record or a form by a custom script. For example, when you open a form, an alert appears, as shown in the following image.



How to troubleshoot

The `XrmNavigation` operation in Monitor contains call stack that helps you identify the script that's causing unexpected behavior.

Follow up with the owner of the web resource to change or fix the behavior.

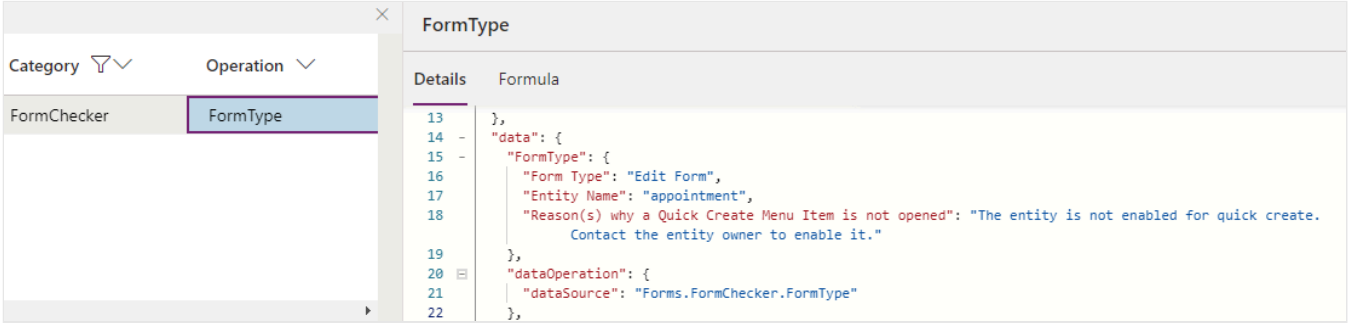
Opening another form instead of a quick create form

When opening a quick create form from a lookup or a grid, another form might open (edit or main form) instead of a quick create form. There are few reasons why this issue can happen:

- The main form dialog force flag is being set.
- Quick create form isn't available.

How to troubleshoot

You can use Monitor to view the `FormType` operation that includes all the reasons why a quick create form isn't opened.



You need to follow up with the table owner who has disabled quick create through table definitions (metadata).

Table doesn't appear in the quick create menu flyout

When opening the global quick create menu, not all tables are available. Some possible reasons:

- Table isn't enabled for quick create. Check if the table supports quick create and that it's enabled.
- Table isn't added to the app. Ensure all required components are added to an app.
- No quick create form is available for the table. Create a quick create form.
- Table is read-only.
- User doesn't have permission to access the quick create form. Check if the user has appropriate security roles.
- User doesn't have create privilege for the table.
- Table doesn't support create privilege.

How to troubleshoot

You can use Monitor to view the `QuickCreateMenu` operation, which includes all the tables and reasons why they're filtered from the quick create menu flyout.

See the following examples to understand the reasons for filtering. Based on the explanations, contact the responsible party or make changes accordingly.

```
"post": [
  "The entity is not enabled for quick create. Contact the entity owner to enable it.",
  "The entity is not enabled for Unified Client. Contact the entity owner to enable it.",
  "The entity's mobile client visibility cannot be modified. Contact the entity owner to fix it."
],
```

```
"new_a1": [
  "There is no quick create form available for the entity. Contact the entity owner to make sure there is a quick create form added."
]
```

```
"new_a6": [
  "The entity is not part of the app module. Contact the app owner to add the entity."
],
```

Unexpected unsaved changes message

When working on forms, you get the *unsaved changes* message on the form footer when you navigate from the current form or save the form without any changes.

How to troubleshoot

The *unsaved changes* error appears when you change the form and when the changes aren't saved. If you didn't make any changes manually, they could come from a JavaScript, plug-in, or

business rule. You can use Monitor to view the `UnsavedChanges` operation that helps find the source of the changes. You can filter by OperationType `UnsavedChanges`.

The `all attributes modified` section includes a quick summary of the columns causing the unsaved changes error and their values. The `unsaved changes` section shows what happened to the columns in detail. For every column, you can see a list of controls that could be causing a change. The value change is also displayed (previousValue, newValue), and a call stack.

The following screenshot shows the root cause of the issue. You can see that the change came from the `OnLoad` script.

```
"data": {
  "UnsavedChanges": [
    {
      "Reported from": "Form footer"
    },
    {
      "All attributes modified": {
        "Account": {
          "fax": 123,
          "name": "New account name"
        }
      }
    },
    {
      "Unsaved changes": {
        "Account": {
          "fax": [
            {
              "message": "Attribute with name 'fax' has been modified. The change could be coming from any of the below controls:",
              "controlNames": [
                "fax"
              ],
              "previousValue": null,
              "newValue": 123,
              "callStack":  at onload  /webresources/new_onload:3:33)  at Object.runFormOnLoadScripts
            }
          ],
          "name": [
            {
              "message": "Attribute with name 'name' has been modified. The change could be coming from any of the below controls:",
              "controlNames": [
                "name"
              ],
              "previousValue": null,
              "newValue": "Account name",
              "callStack": "The change was manually done by the user."
            },
            {
              "message": "Attribute with name 'name' has been modified. The change could be coming from any of the below controls:",
              "controlNames": [
                "name"
              ],
              "previousValue": "Account name",
              "newValue": "New account name",
              "callStack": "The change was manually done by the user."
            }
          ]
        }
      }
    }
  }
```

> **Note**
>
> If the user has manually made the changes on the form, a call stack won't be provided.

Verify where the change is coming from and if the behavior is expected or not. If a script causes the change, the original web resource can be traced back in the call stack. In most cases,

it's a script. Make a decision based on the web resource itself.

Business required column doesn't block saving

Business required columns is a usability feature that helps prevent users from saving a record with an empty value in that column. In model-driven apps and Power Pages, the following scenarios don't block saving a record when a required column has an empty value:

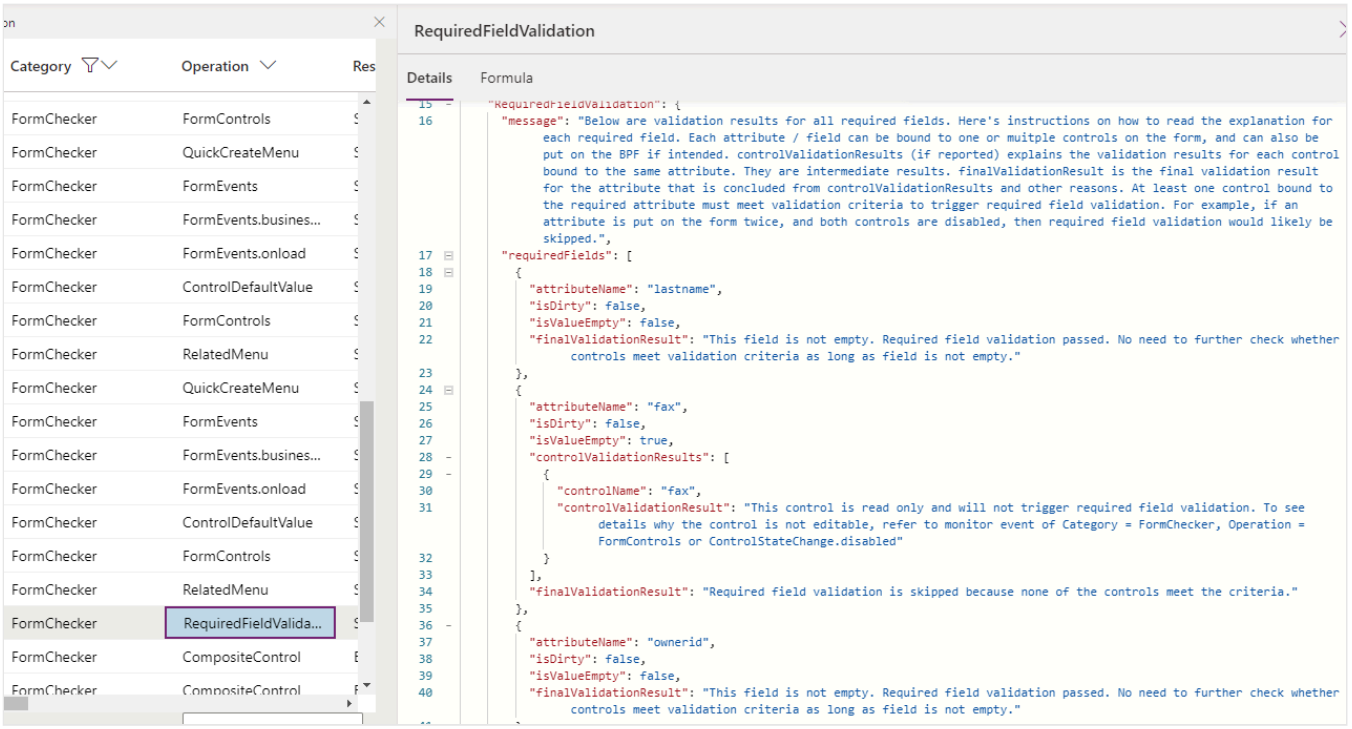
- The column is hidden from the form, either because of column properties or a client-side script using the control.setVisible Client API .
- The column is on a hidden form tab or section.
- A client-side script changes the column's required level using the setRequiredLevel Client API.
- The user isn't using model-driven apps or Power Pages to create the record. Client applications using Dataverse APIs aren't blocked from saving records when column AttributeMetadata.RequirementLevel is set to AttributeRequiredLevel.ApplicationRequired. Learn more about column requirement level

When you need to enforce data integrity, you should use entity business rules and other server-side validation instead, such as synchronous plug-ins.

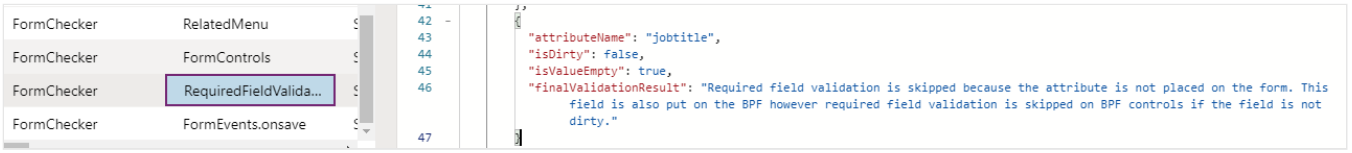
How to troubleshoot

The `RequiredFieldValidation` operation is logged when a save is attempted, regardless of whether save is successful or not. This operation explains why each business required column blocks or doesn't block the save operation.

The following image is an example of this operation. The message explains how to read the detailed reports of each required column. In this example, `fax` column is bound to one control, and the control of the same name is read-only. Therefore it won't trigger required column validation.



The following image is another example that `jobtitle` is a business required column on the business process flow but not on the form, and the column isn't modified. Thus it doesn't block the save operation even when it's empty.



Follow up

Most times, the behavior is by design, and the `RequiredFieldValidation` operation explains why this column behaves in a certain way in form save operation. If the required column validation is skipped on a column because the control is disabled or hidden, as the first example illustrated, see the form checker suggestions for further analysis.

This might lead to another troubleshooting scenario such as Why a control is disabled/enabled or visible/hidden.

Can't create a record because of insufficient permissions to a secured field, even though that field isn't in the form

This might happen when users create a record (row) from a different form. They get the error message **The user does not have create permissions to a secured field** even though they haven't entered a value for that field (column), or that field isn't on the form.

When table **A** has a lookup field to table **B**, creating a record **A** from record **B** automatically sets lookup fields on it to **B**, even if those fields aren't on the form.

For example:

1. Account table has a lookup field, `primarycontactid`, to the contact table.
2. User opens a contact form for **Robin Danielsen**.
3. User opens the lookup field, `parentaccountid`, on the form and selects the button to create a new account.
4. New account form opens, with the `primarycontactid` field automatically set to **Robin Danielsen**.

If the `primarycontactid` field is secured and the user doesn't have permissions to edit it, they get an error when they try to save the new account. They can clear the field before saving it. However, if that field isn't on the form, they can't clear it. A workaround is to create the account from the account page instead of from a contact form.

Some columns aren't displayed on the merge dialog

The merge dialog uses the default main form definition for the table and selectively renders most, but not all the columns in the dialog. This Form Checker operation explains why some of the columns aren't displayed on the merge dialog, even that they might be displayed on the main form.

How to troubleshoot

The following `MergeDialog.load` operation explains the reason why some columns aren't displayed.

In this example, `parentcustomerid` column on the contact form isn't supported in the merge dialog. The business card column isn't displayed because the containing section is hidden in the main form XML definition. Even though showing the owning section in the main form via client API is possible, the merge dialog honors the form XML configuration as event handlers aren't supported on the merge dialog.

"displayedState": false,
"displayStateReason": "This control is not displayed because the containing section (name = BusinessCard, label = null) is hidden in the main form."

Collaborative troubleshooting using Live Monitor

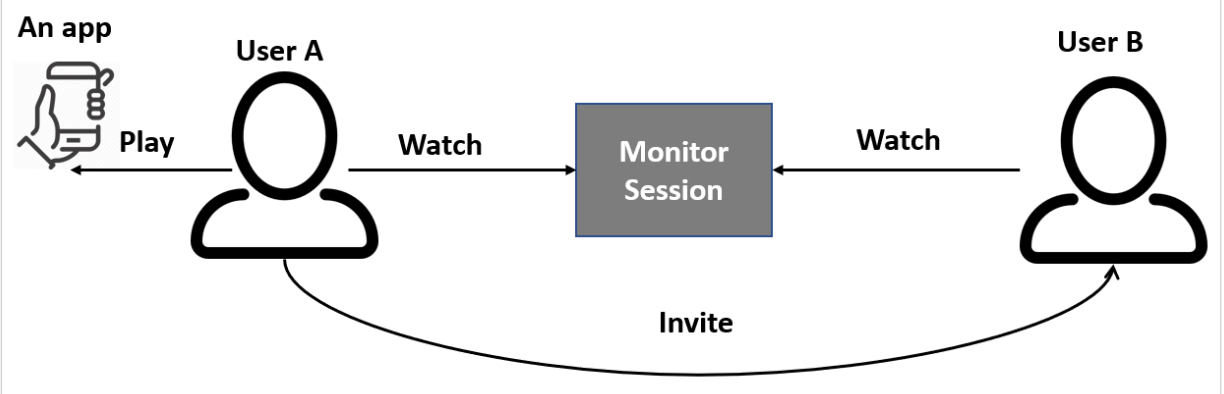
Article • 11/19/2024

Live monitor offers two features to enable collaborative troubleshooting and debugging of canvas and model-driven app problems in Power Apps:

- **Invite** enables makers to share a monitoring session by inviting other members within the same organization to the same Live monitor session. For example, a maker troubleshooting a performance problem with Power Apps can invite a member from the technical support team to concurrently view all the events flowing through the same troubleshooting Live monitor session.
- **Connect user** enables makers and support teams to share a link with users to open a published app and connect it to a Live monitor session so that support teams can watch the sequence of events generated by the user's interaction.

Invite user

With canvas apps and published model-driven apps, makers can share a real-time Live monitor session with others, such as support technicians, to help investigate problems. When you invite other users to your Live monitor session, you can quickly collaborate and debug an app together, without the need to share your screen. When you invite others to participate in a session, they see the exact same app events in their own browser without having to open the app or reproduce the specific scenario that you're debugging. You and other participants can browse, view, and inspect the app events independently, without stepping on each other or handing control back and forth to identify the problem.



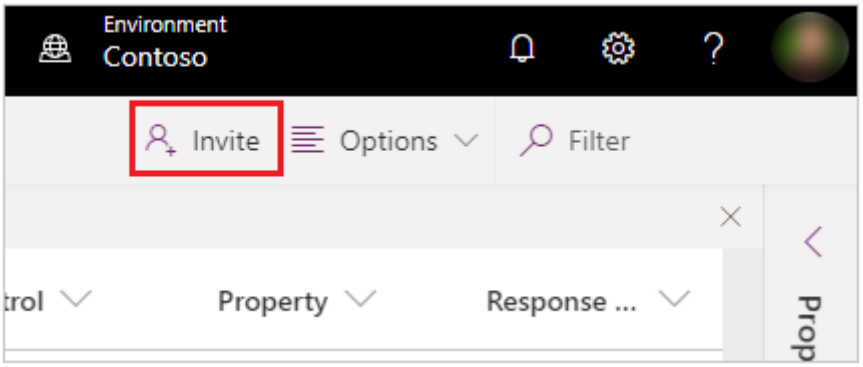
When using the **Invite** feature for a published app:

1. User A plays the published app from Power Apps.
2. User A invites User B to a Live monitor session.
3. User B joins the Live monitor session with the link that User A sent.
4. User A interacts with the app.
5. User B watches the events generated from User A's interaction with the app in their own Live monitor window.

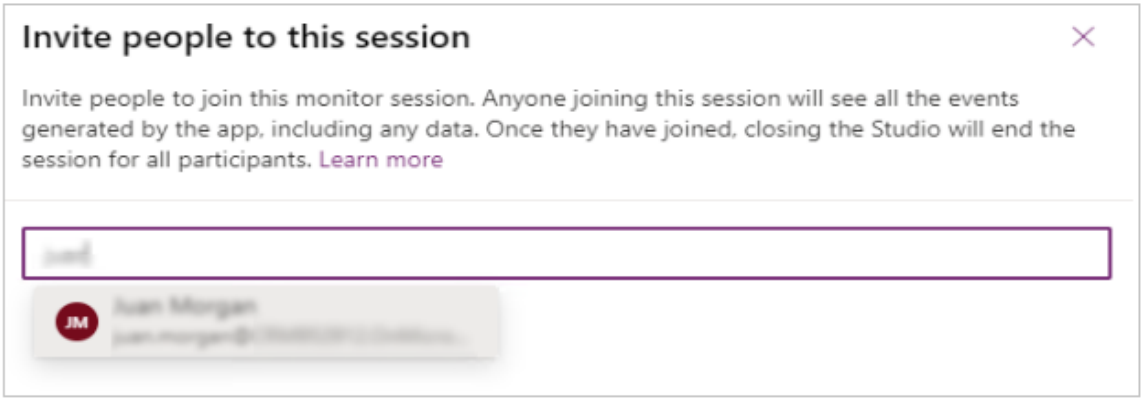
> **Note**
>
> You can invite any user in your organization to a Live monitor session. Users joining the session will see all the events generated by the app, including any data.

To invite a user to watch a monitoring session

1. Select **Invite** from the command bar.



2. Enter the Microsoft Entra user name or alias of the user whom you want to invite to the Live monitor session.

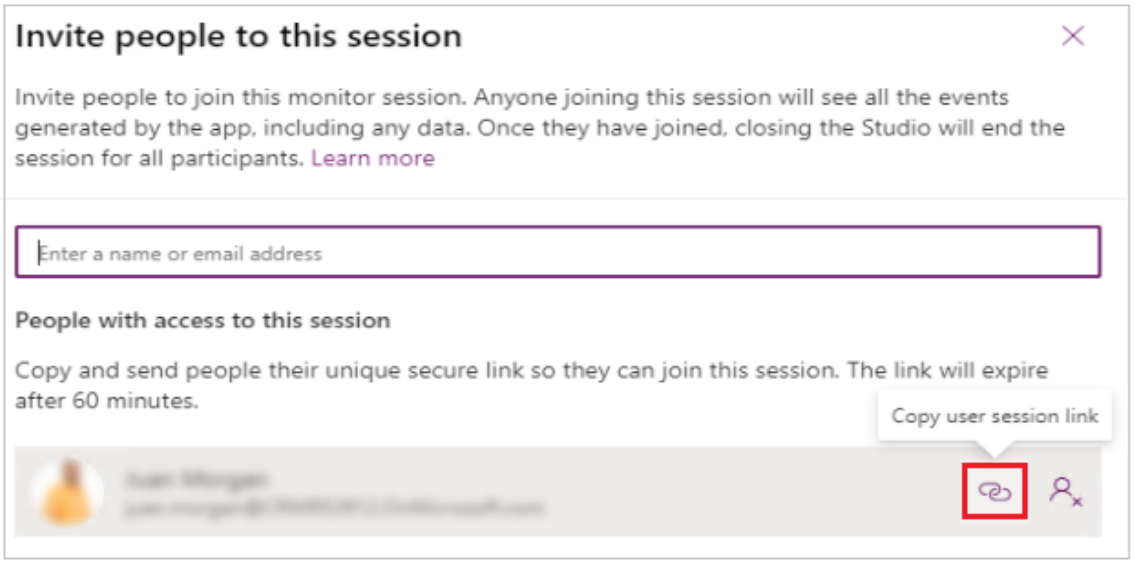


3. Select the user for whom you want to generate a link to the current Live monitor session.

> **Note**

The link is unique for each user. It can't be shared between users. The link expires after 60 minutes.

4. Select the link icon to copy the session link, and then send it to the user you've invited to the session.

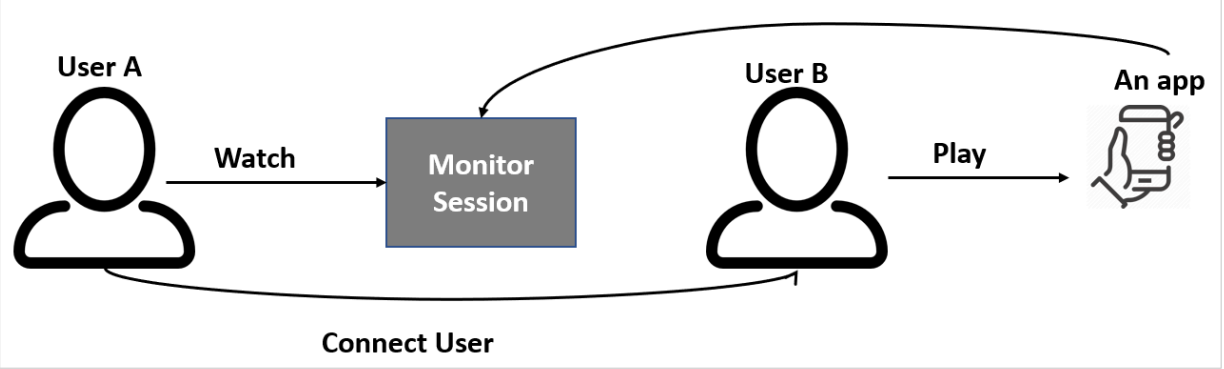


Repeat steps 2 through 4 for each user you want to invite.

The users who have received the link can use it to open the Live monitor and connect to your Live monitor session.

Connect user

With **Connect user**, a maker can enable a user to open a published canvas or model-driven app and connect by using a monitoring session. You can watch the sequence of events the user generates while interacting with the app, and help with problem investigation.



ⓘ Note

- With **Connect user**, makers and support teams share a link with users to open a published app and connect it to a Live monitor session, so support teams can watch the sequence of events generated by the user's interaction with the app.
- **Connect user** requires that the app be published with Power Apps version 3.20042 or later for canvas apps and client version 1.4.5973-2307.2 or later for model-driven apps. To make this feature available in earlier versions of a canvas app, publish the app again.

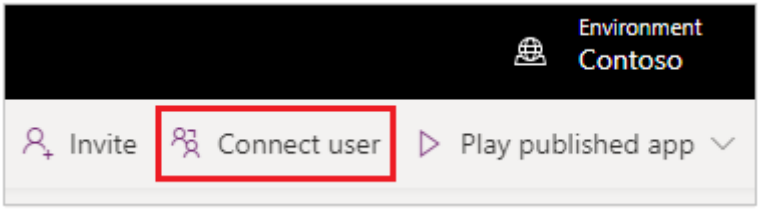
When using the **Connect user** feature for a published app:

1. User A chooses the app to monitor and opens Live monitor.
2. User A selects **Connect user**, and share the generated session link with User B.
3. User B plays the published app by selecting the link that was shared by User A.
4. User A watches the monitored session as User B interacts with the app.

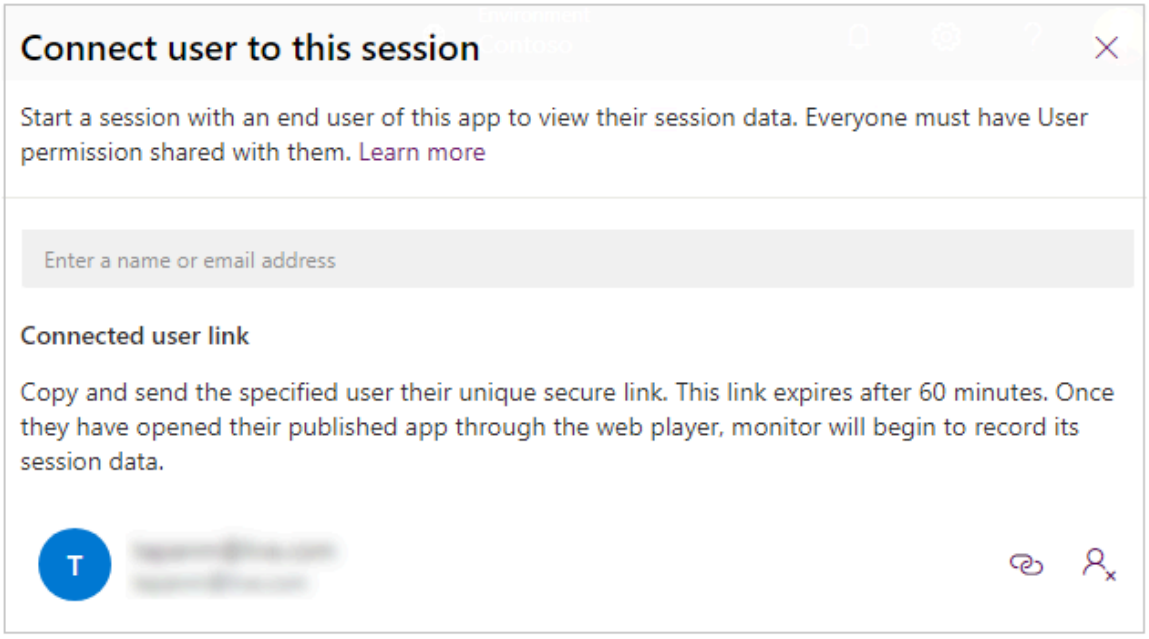
To connect a user to a monitoring session

1. Open Live monitor for the published app.

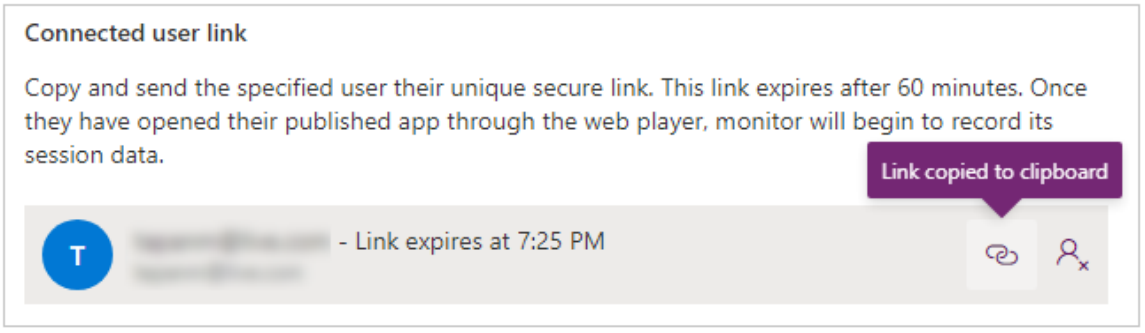
2. Select **Connect user**.



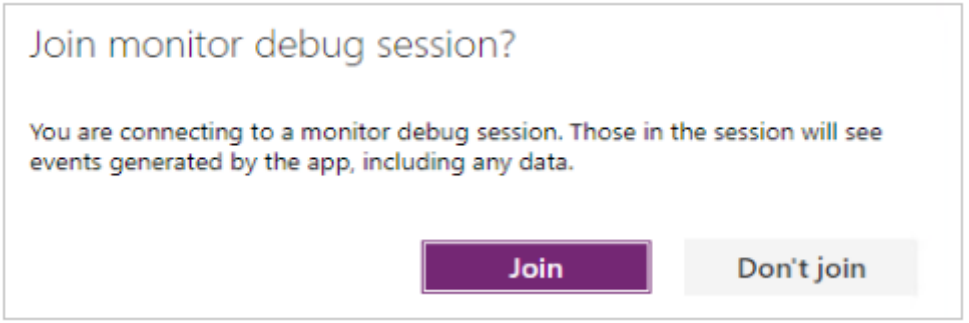
3. Search for and select the user who you want to connect to.



4. Copy the link, and share it with the user so they can play the app.



5. After you share the link, the user selects it to open the app and is notified that they're joining a monitoring session. The same link can be used to open the app in a monitored session on Power Apps mobile.



The user can now interact with the app, and Live monitor will show events for this interaction.

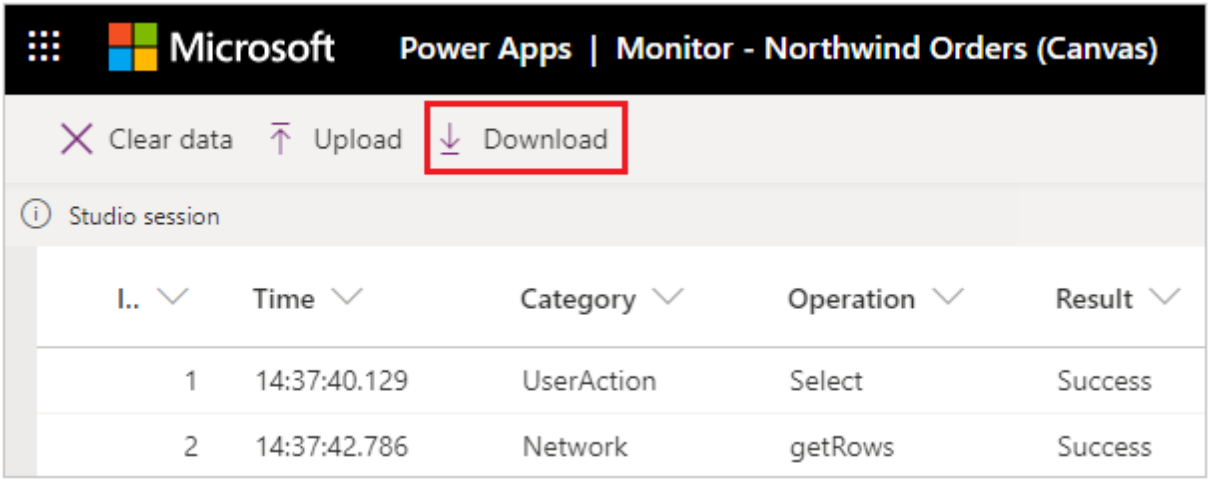
Advanced monitoring concepts

Article • 11/19/2024

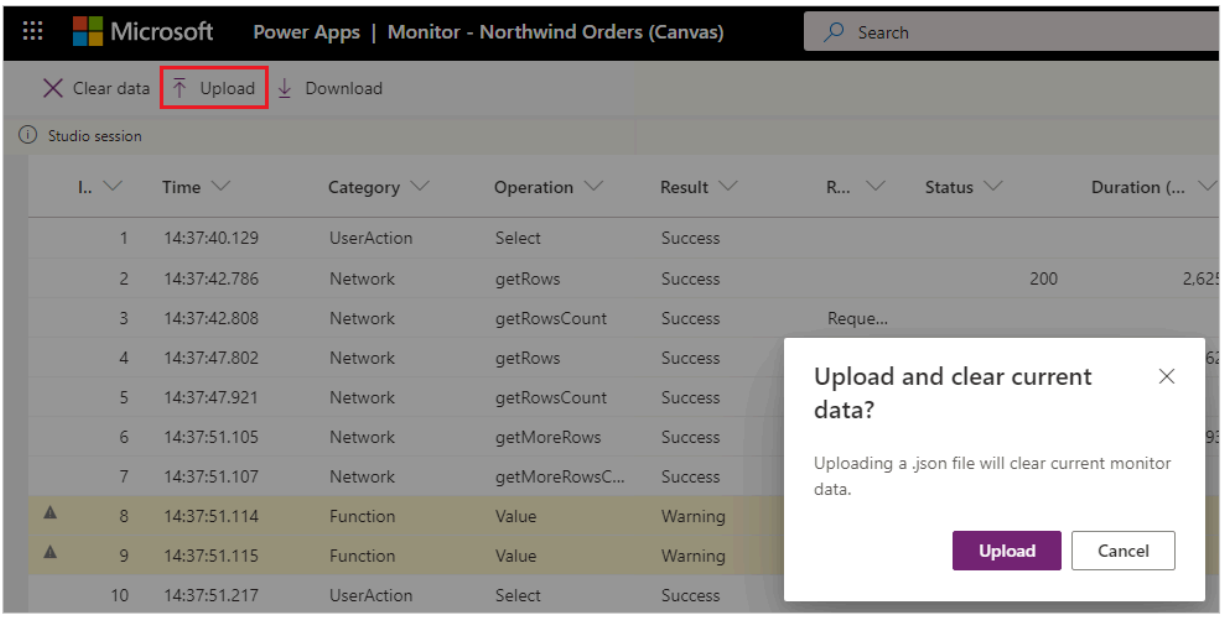
In this article, you'll learn about downloading and uploading trace files in Live monitor, events supported by Live monitor, and scenarios that Live monitor doesn't support.

Download and upload trace files

You can download the events listed in Supported events for offline analysis. Events can be downloaded in .json or .csv format, and you can share them with others. The .csv files can only be downloaded, not uploaded, but if you download the events in .json format, you can upload them later into Live monitor for analysis. You can also attach a trace file to support service requests, which can help speed up getting the solution to your problem.



Select **Upload** to load a .json trace file to Live monitor. This option removes any events currently displayed in the Live monitor table and replaces the details with events contained in the trace file.



Supported events

Live monitor supports several events for canvas apps and model-driven apps. The following table includes examples of the supported event categories and types.

Expand table

Canvas apps	Model-driven apps
• Data connectors • Network events (error status codes highlighted) • Screen load metrics • Cross-screen dependency warning • User actions such as *Navigate*, *Select*, and *SetProperty* • Custom Trace() • Delegated versus non-delegated queries • Verbose switch (internal telemetry) • Delegation • Function • Network • Parsing • Performance • Scenario • ScreenLoad • Telemetry • UserAction • Verbose	• Form events, such as load and save • Network • Page navigation • Command executions

Unsupported scenarios for Live monitor

Live monitor doesn't support the scenarios in the following table.

Expand table

Description	App type
Live monitor connected to a canvas app embedded in a model-driven app or custom page.	Canvas
Live monitor connected to a SharePoint custom form app.	Canvas
Live monitor connected to a Microsoft Teams embedded app. As an alternative, you can play the app in a web player for diagnostics purposes.	Canvas

Common issues and resolutions for Power Apps

Summarize this article for me

Summary

This article provides solutions to common problems that you might encounter when you create or use Power Apps. The article organizes problems by functional area, such as connectors, Power Automate integrations, Power Fx, and Power Apps Studio. Each section includes troubleshooting steps and links to related documentation.

Before you troubleshoot specific problems, review Power Apps troubleshooting strategies for guidance on how to identify the source of a problem. That article outlines key principles for debugging both functional and performance problems.

Common Power Apps issue areas

- Connectors and delegation
- Power Automate Integration
- Power Fx
- Regional performance issues
- Power Apps Studio and Forms
- Browser performance
- Power Apps for Windows

Connectors and delegation

For an overview of how tabular and action connectors work, see Connections.

For details about delegation, see Understanding delegation in a canvas app.

For a description of how to monitor the data being sent and returned, see Debugging canvas apps with Monitor.

- **You don't have the correct permissions to use a connection.**

  Users might encounter this message in two situations:

  - The application shares an implicit connection that isn't a secure implicit connection. To resolve the problem, share the connection with the end user, but consider that this

approach isn't recommended. The author should convert all connections to secure implicit connections.

  - The application uses a secure implicit connection. In this case, republishing the app might resolve the problem.

- **Automatic Next links for galleries and grids don't work for action-based connectors.**

  Action-based connectors don't support next links. Next links are properties on query results that allow a gallery or grid to automatically load the next set of results. For more information, see Overview of connectors for canvas apps.

- **Sharing a Canvas app using SharePoint connector**

  For more information about how to share an app for SharePoint, see Connect to SharePoint from a canvas app.

- **SQL data sources no longer add a `[dbo]` prefix to the data source name.**

  For more information about this change, see Connect to SQL Server from Power Apps.

- **Custom connectors and Microsoft Dataverse**

  You need to make adjustments if you built your app with Power Apps that:
  - Is version 2.0.540 or earlier.
  - Relies on a Dataverse database.
  - Uses at least one custom connector from a separate environment.

  First, deploy the custom connector to the same environment as the database. Then, update the app to use the newly deployed connector. Otherwise, a dialog notifies users that the API wasn't found. For more information, see Environments overview.

- **Column names with spaces**

  If you're using a list created using Microsoft Lists, a SharePoint library, or an Excel table in which a column name contains a space, use single quotes with the column name, for example `someList.'Color Tag'`.

- **Apps that connect to on-premises SharePoint**

  If you share an app that relies on connections that aren't automatically shared (for example, an on-premises SharePoint site), users who open the app in a browser see a dialog box with no text when they select or tap **Sign in**. To close the dialog box, select or tap the close (X) icon in the upper-right corner.

The dialog box doesn't appear if you open the app in Power Apps Studio or Power Apps mobile. For more information about shared connections, see Share app resources.

- **For apps that are created from data, only the first 500 records of a data source can be accessed.**

  Power Apps works with large data sources by delegating operations to the data source. For operations that can't be delegated, Power Apps shows a warning at authoring time and operates on only the first 500 records of the data source. For more information, see the Delegation overview.

- **Excel data must be formatted as a table.**

  For information about limitations when you use Excel as a data source, see Cloud-storage connections.

- **Microsoft Lists is supported but not SharePoint libraries, some types of list columns, or columns that support multiple values or selections.**

  For more information, see SharePoint Online.

- **Sign-in issues on certain Android mobile devices when using authenticator**

  On certain devices and in certain scenarios, you might experience sign-in failures when you use an authenticator. This problem happens because of a limitation that the OEM imposes. For more information, see ADALError: BROKER_AUTHENTICATOR_NOT_RESPONDING.

- **Apps cannot save null/blank values to data sources**

  If your app can't save null or blank values to data sources, the **Formula-level error management** feature might be disabled. To fix this problem, go to **Settings** > **Updates** > **Retired** and make sure the **Formula-level error management** feature is enabled.

Power Automate integration

- **Power Automate flows are orphaned in Power Apps.**

  Power Automate flows that you add by using an older version of the Power Apps panel might become orphaned and removed. To fix this problem, re-add the flows manually.

- **Power Apps custom pages (in a model-driven app) are out of synchronization with embedded Power Automate flow metadata.**

The metadata for a Power Automate flow might get out of synchronization with a model-driven app's custom page if you update the flow after embedding it. To update the metadata, follow these steps for each embedded flow:

1. Edit the custom pages that use the flow.
2. Open the Power Automate pane and refresh the flow.
3. Save and republish the custom page.

When you're done, follow these steps:

1. Edit the model-driven app.
2. Make a minor change to trigger the save option.
3. Save and publish the model-driven app.

Power Fx

For more information about Power Fx, see Microsoft Power Fx.

- **`Connection.Connected` returns the wrong value during OnStart in Power Apps for Windows.**

  While offline, the **Connection.Connected** formula might wrongly return **true** immediately after starting an app in Power Apps for Windows. As a workaround, use a Timer control to delay the execution of the logic depending on it.

- **Issues with Date-time**

  For more information about date and time problems, see:
  - Troubleshoot Canvas app date time issues
  - Troubleshoot Model driven app date time issues

Regional performance

- **Performance degradation when opening Power Apps Studio in China**

  Power Apps Studio might take more than 30 seconds to load in China. This problem doesn't affect tenants that 21Vianet hosts locally.

Power Apps Studio and forms

The Power Apps Studio hosts the app editing and publishing experience.

- **Problems with startup**

If you have trouble accessing or starting Power Apps, see Troubleshooting startup or sign-in issues for Power Apps.

- **Problems changing dimensions or orientation of SharePoint forms**

  If you have problems with the **Screen size + orientation** settings for custom SharePoint forms, use the **Custom** size to work around the problem:

  1. Reset the setting by selecting the **Small** size.
  2. Toggle **Orientation** to **Portrait** and then back to **Landscape**.
  3. Select **Custom** and enter a desired screen size. For reference, the preset values are:
     - "Width: 270, Height: 480" for the Small Portrait size.
     - "Width: 720, Height: 480" for the Small Landscape size.

- **Copying and pasting screens across apps**

  Copying and pasting screens across apps isn't currently supported. To work around this problem:

  1. Add a new screen to your target app.
  2. Copy the controls from the screen in your source app.
  3. Paste the controls into the screen of your target app.

- **Changing the layout of SharePoint forms**

  When you customize SharePoint forms in certain languages, if you try to change the layout from **Portrait** (default) to **Landscape**, the app might show multiple errors (yellow triangles in controls). To resolve these errors and retain the landscape layout, select **Undo**.

- **Changing a flow in a shared app**

  If you add a flow to an app and share the app, and then make changes to the flow, such as adding a service or modifying a connection, more steps are required. You must also first remove the flow from the shared app. Next, re-add the flow to the app. Finally, re-share the app.

- **Changing a "Title" field in a table**

  If you change the **Title** field for a table that other tables reference through one or more lookups, an error occurs when you try to save the change. To work around this problem:

  1. Remove any lookups to the table you want to change.
  2. Change the table's **Title** field.
  3. Re-create the lookups.

  For more information about lookups, see Create a relationship between tables.

- **When Power Apps generates an app from data, the field used for sorting and searching isn't automatically configured.**

  To configure the field, edit the Items formula for the gallery, as described in Filter and sort a gallery.

- **It can sometimes take a moment before a newly shared app can be used.**

  In some cases, a newly shared app isn't immediately available. Wait a few moments, and it should become available.

- **In the Form control, you can't change data by using a custom card.**

  The stock custom card is missing the Update property, which is required to write back changes. To work around this problem:

  1. Select the **Form** control, and insert a card by using the right-hand pane based on the field that you want the card to show.
  2. Unlock the card, as described in Understanding data cards.
  3. Remove or rearrange controls within the card as you see fit, just as you would with the custom card.

- **Card gallery is deprecated.**

  Existing apps that use this feature continue to run for now, but you can't add a card gallery. Replace card galleries with the new Edit form and Display form controls.

Browser performance

- **Browser running out of memory**

  If you're using the 32-bit version of Google Chrome or Microsoft Edge and the browser runs out of memory while you're using Power Apps, consider using the 64-bit version.

Power Apps for Windows

- **Power Apps mobile app for the Windows platform doesn't support the Dropbox connector.**

  A pop-up dialog shows the following message in this situation:

  > We can't connect to the service you need right now. Check your network connection or try again later.

When this issue occurs, consider using a web player on the Windows platform.

- **Microsoft Entra Conditional Access with the policy *Require device to be marked as compliant* doesn't work in Power Apps for Windows.**

  When the Conditional Access policy is set to *Require device to be marked as compliant* in Microsoft Entra ID, users receive the following sign-in error and can't access their Power Apps.

  > The application contains sensitive information and can only be accessed from devices or client applications that meet your enterprise management compliance policy.

  To work around the issue, they can use a browser.

Next steps

If your issue isn't listed in this article, you can search for more support resources, or contact Microsoft support. For more information, see Get Help + Support.

Get session and app ID details

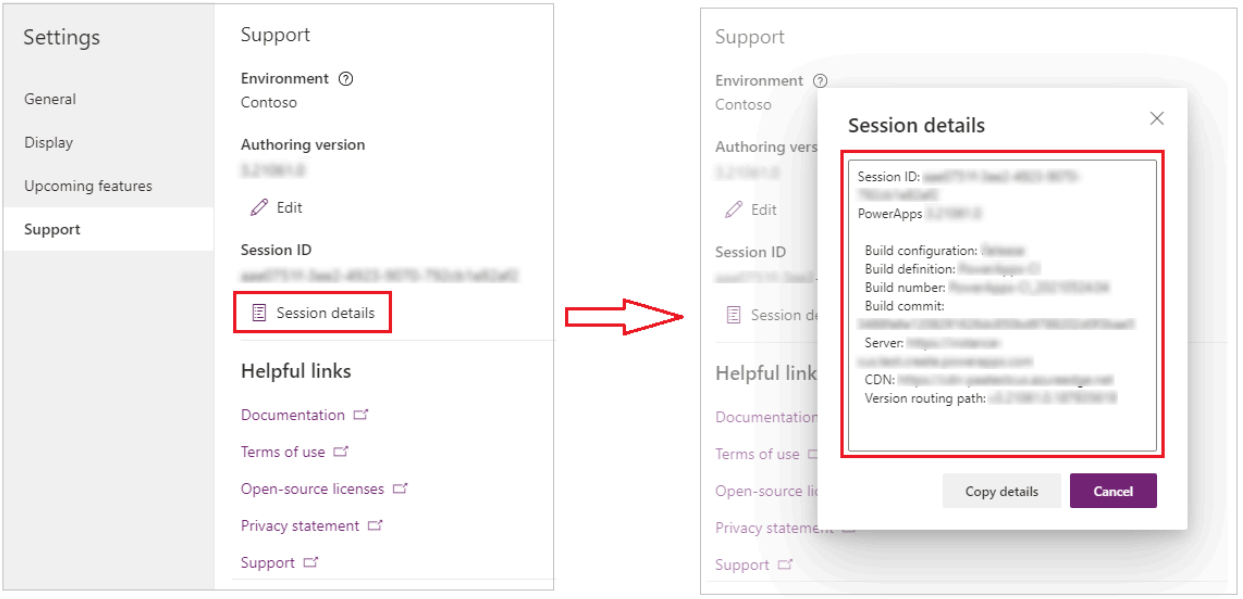
07/30/2025

If you find a problem with an app in Power Apps, you can help Microsoft troubleshoot the problem much more effectively with a session ID, an app ID, or both.

Get the session ID for a canvas app

When editing a canvas app

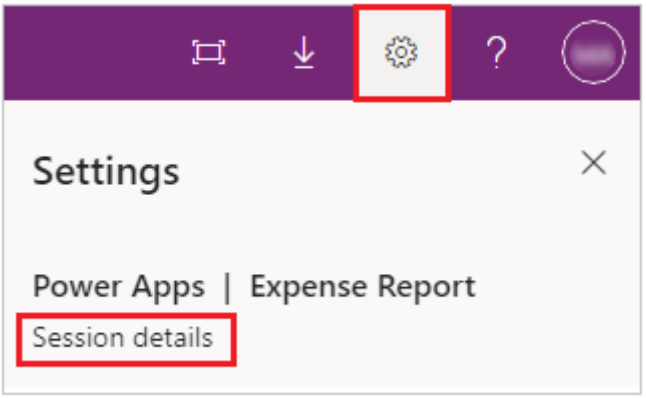
1. Select **Settings**.
2. Select **Support** > **Session details**.



3. Select **Copy details** to copy all session to clipboard.

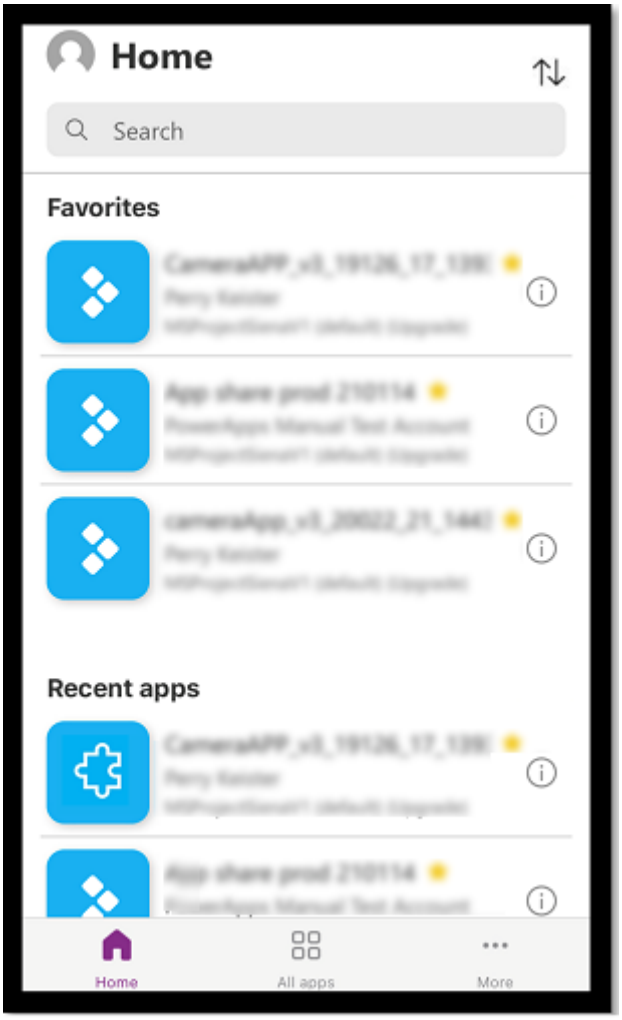
When running a canvas app in a browser

1. In the upper-right corner, select the **Settings** icon .
2. Select **Session details**.

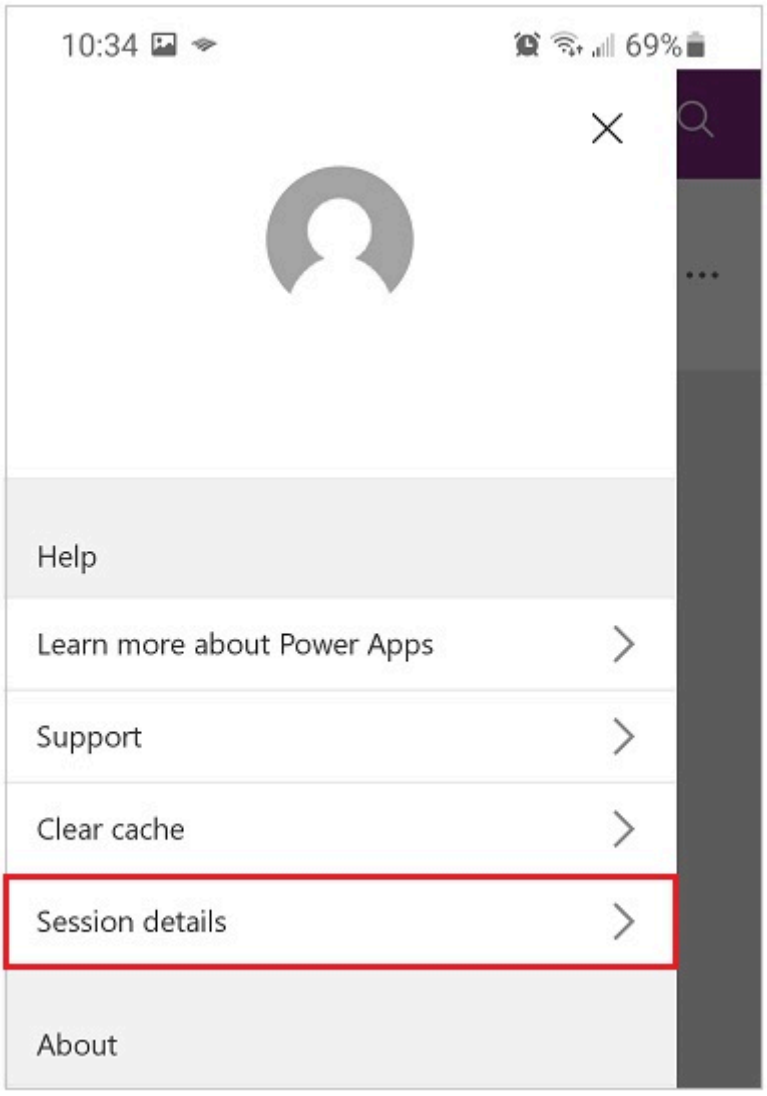


When running a canvas app on a phone or a tablet

1. In the upper-left corner, select your profile picture.



2. Select **Session details**.

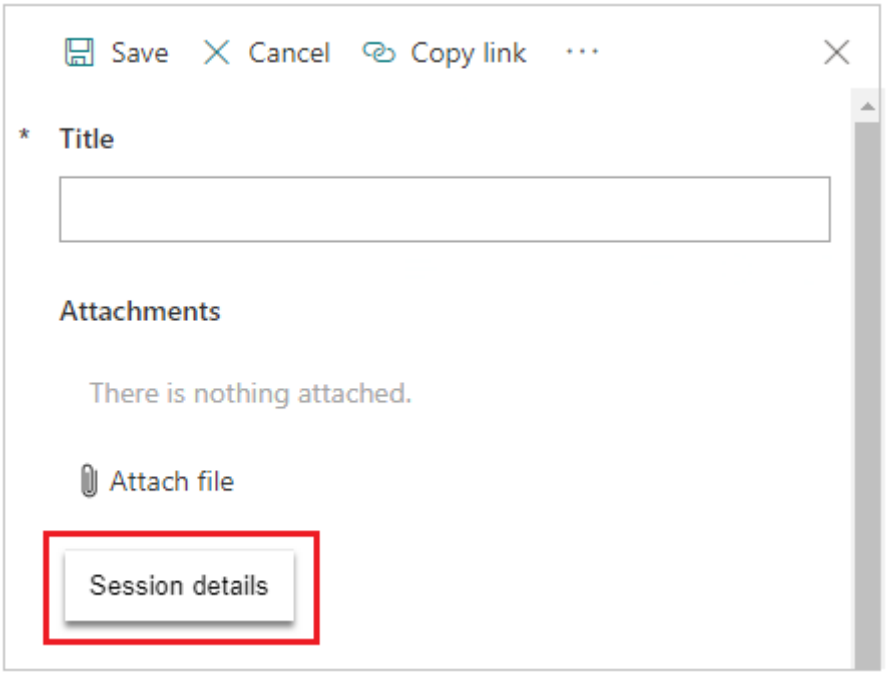


When running an embedded canvas app or form

1. Do one of these steps:

    - While holding down the Alt key, right-click the app or form.
    - Tap the app or form with two fingers for 1-2 seconds, and then release.

2. Select **Session details**.



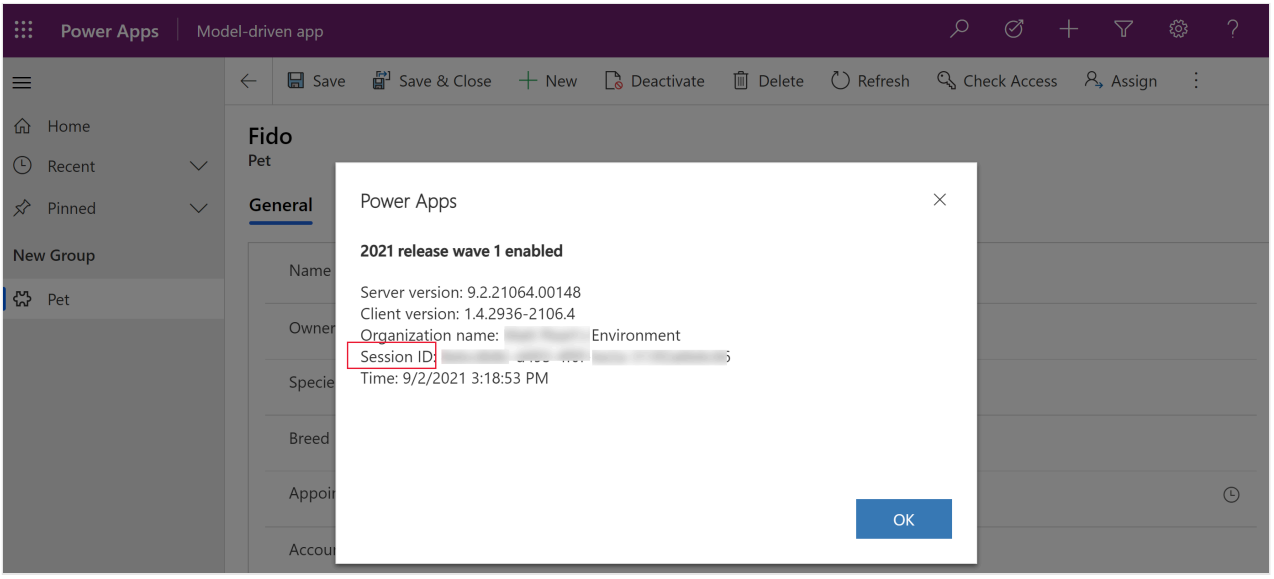
Get the session ID for a model-driven app

When editing a model-driven app

1. From the preview pane in app designer, on the command bar in the model-driven app displayed, select **Settings** (gear).
2. Select **About**.

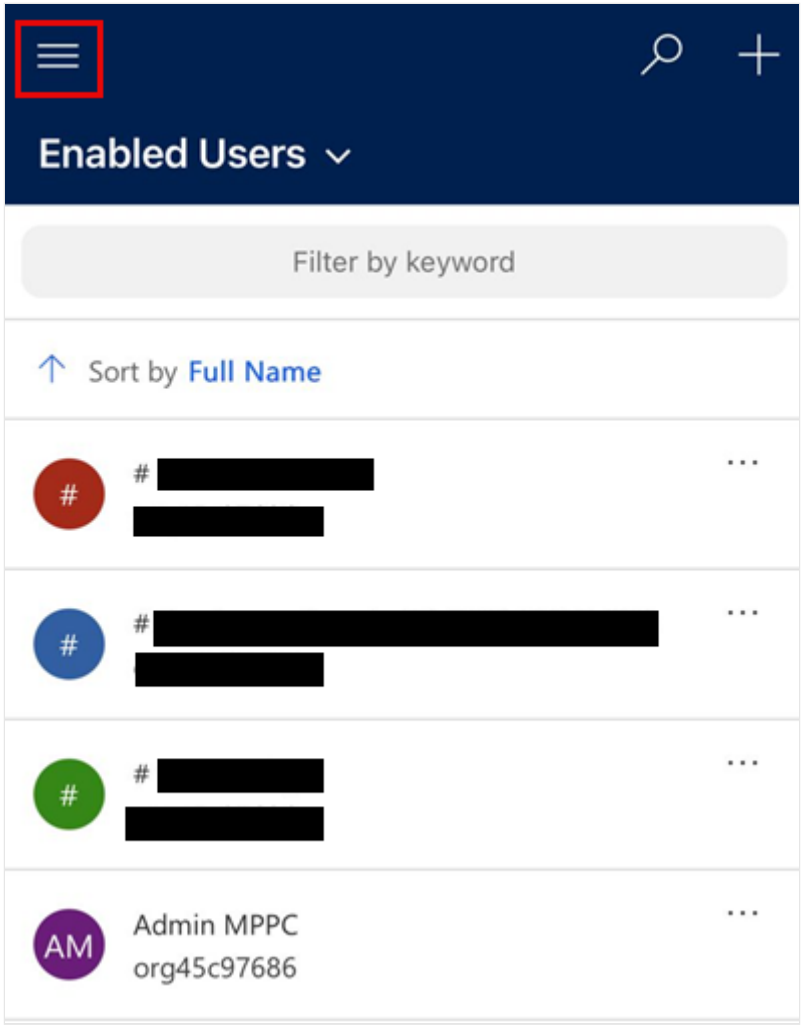
When running a model-driven app in a browser

1. On the command bar in a model-driven app, select **Settings** (gear).
2. Select **About**.

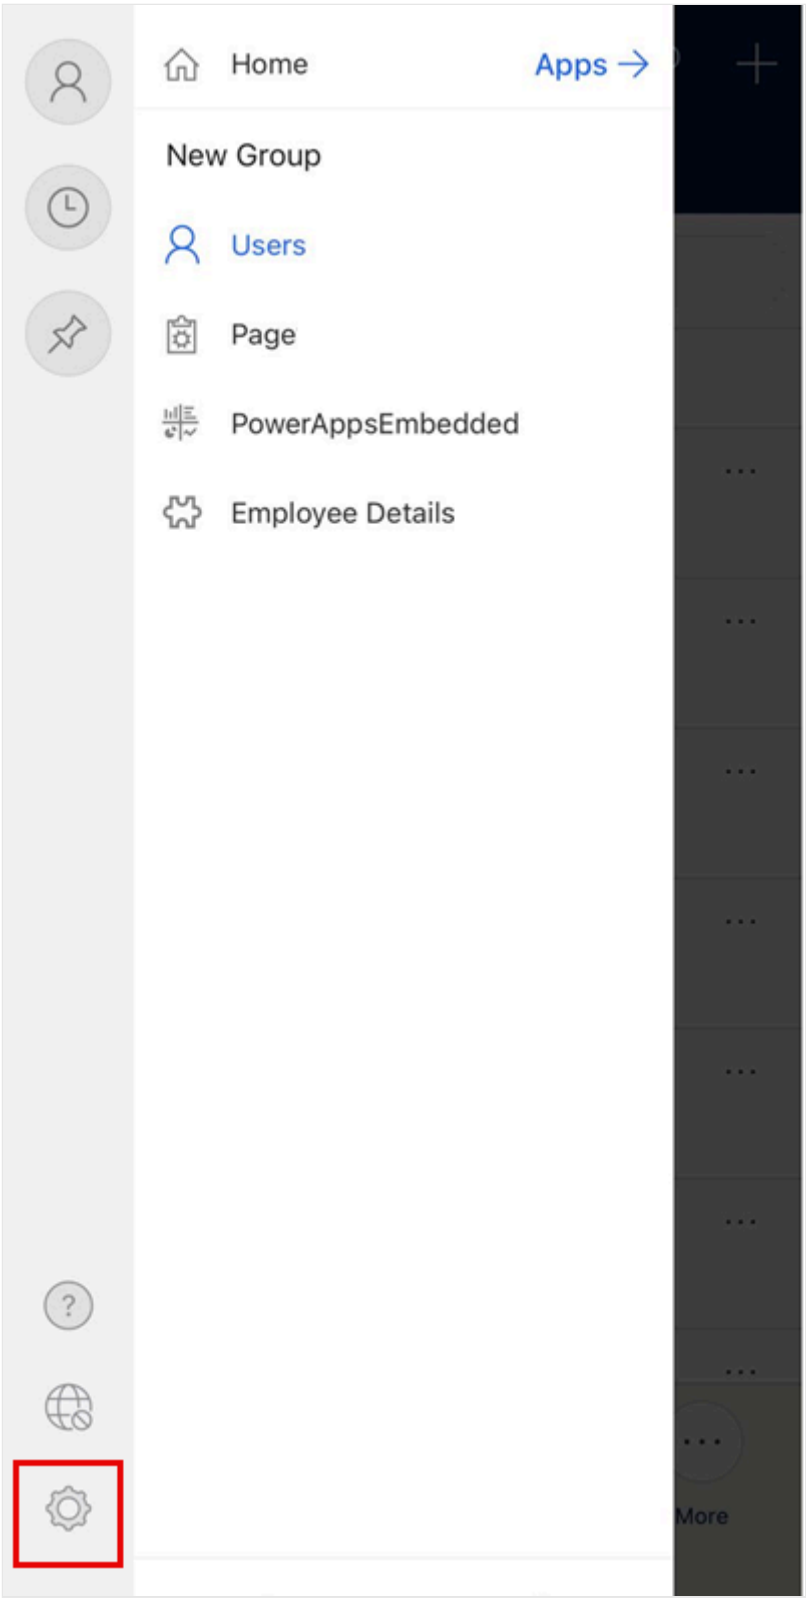


When running a model-driven app on a phone or a tablet

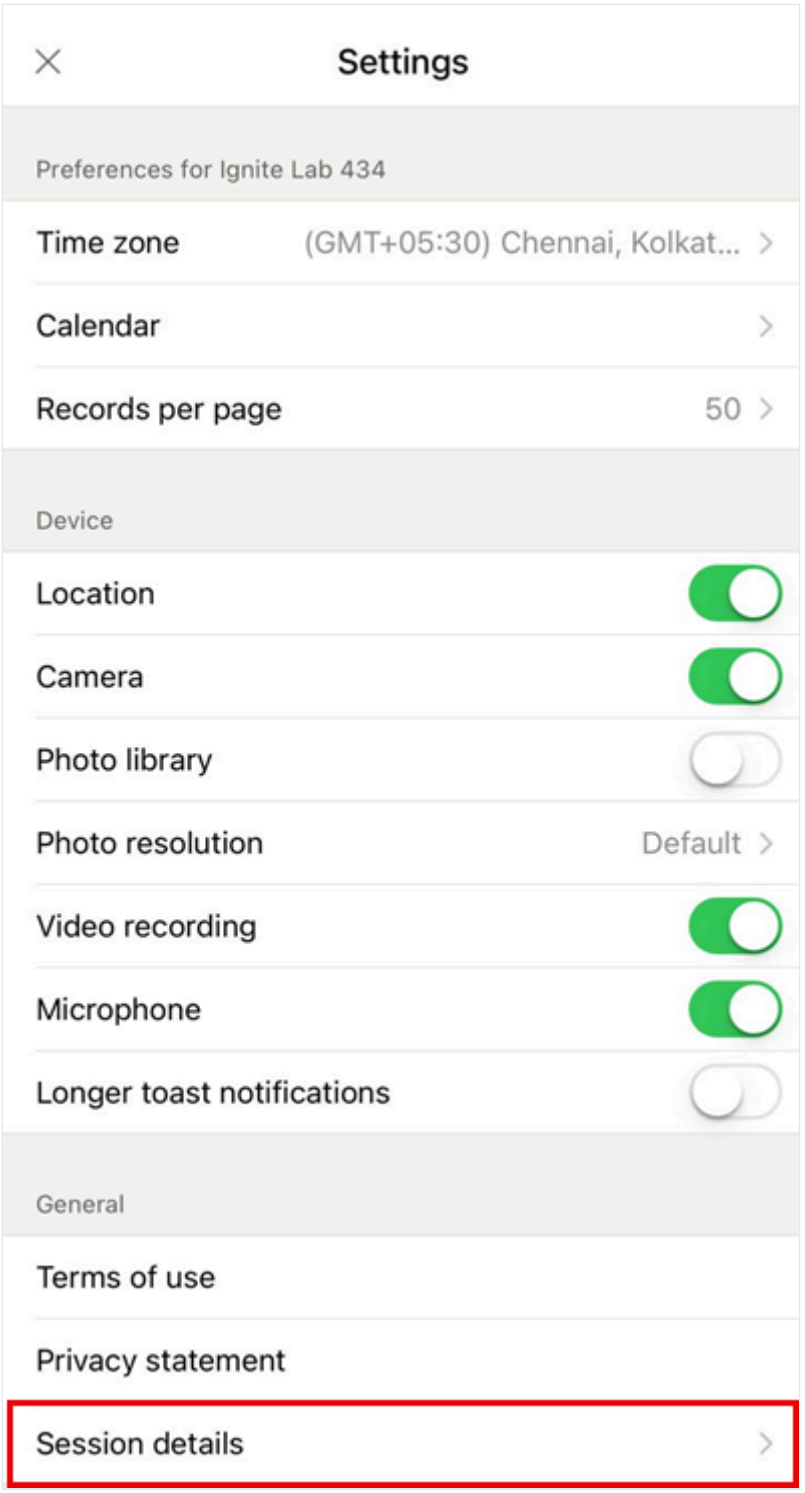
1. In the upper left corner, select the hamburger icon (the three lines).



2. Select the settings icon (gear) in the lower left corner of the screen.



3. Select **Session Details** at the bottom of the screen.

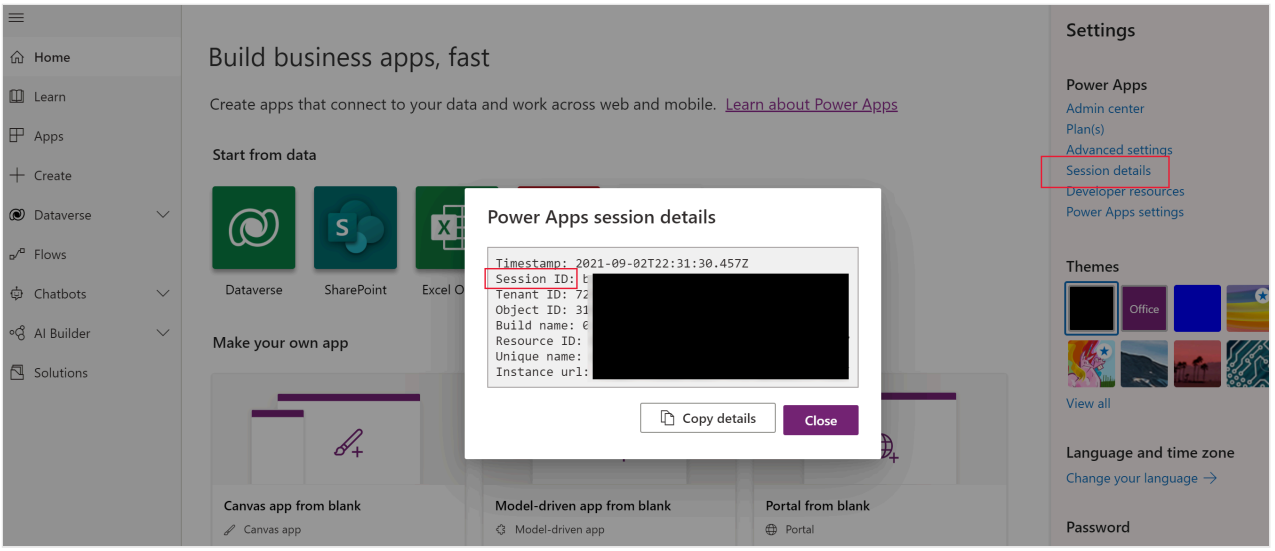


4. Review the session details.

Get the session ID for Power Apps (make.powerapps.com)

1. Sign into Power Apps (make.powerapps.com), and then, on the command bar, select **Settings** (gear).

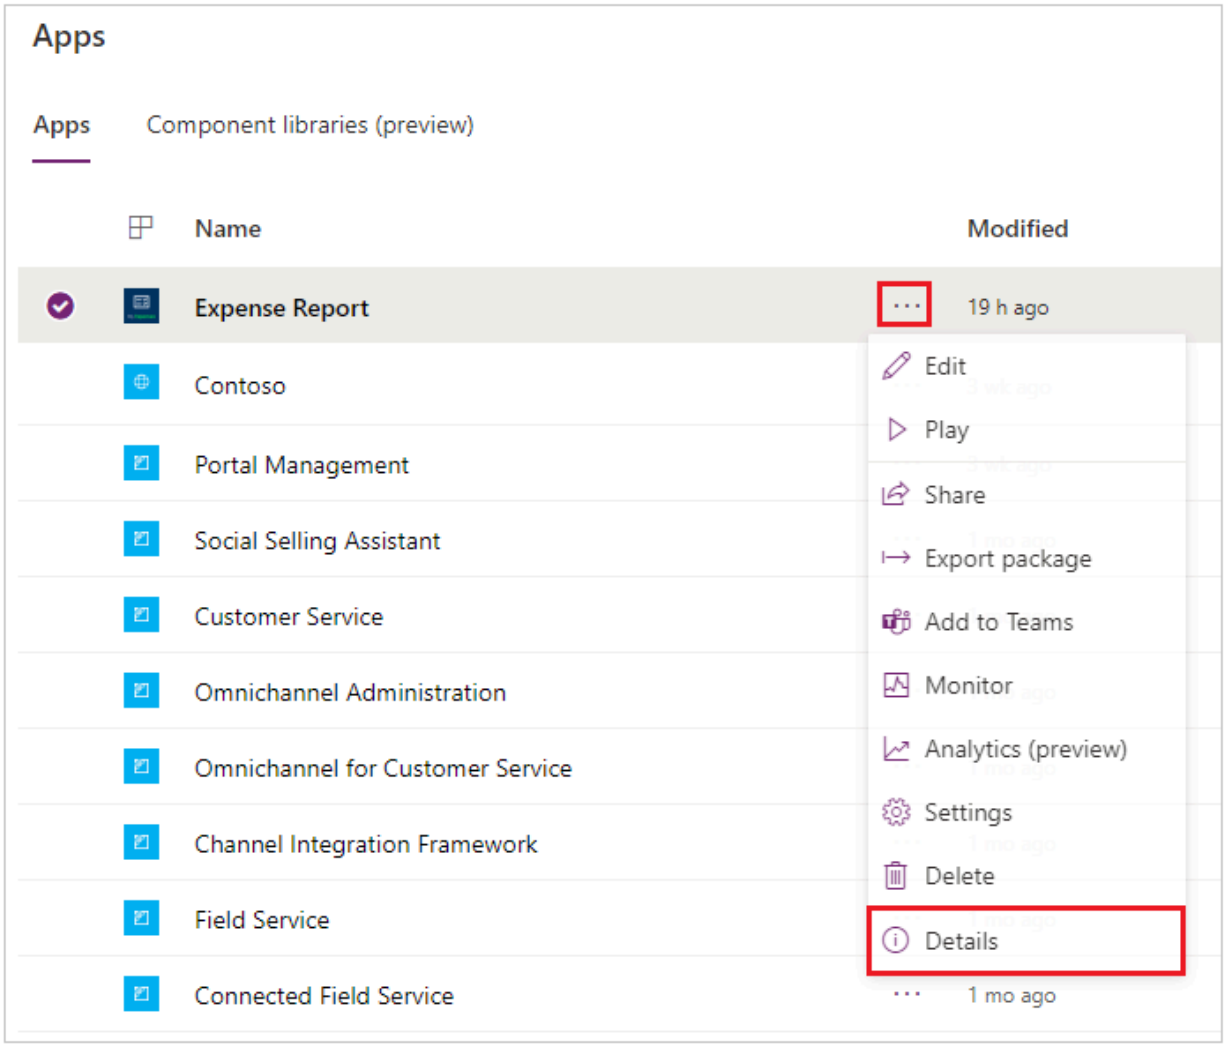
2. Select the **Session details**.



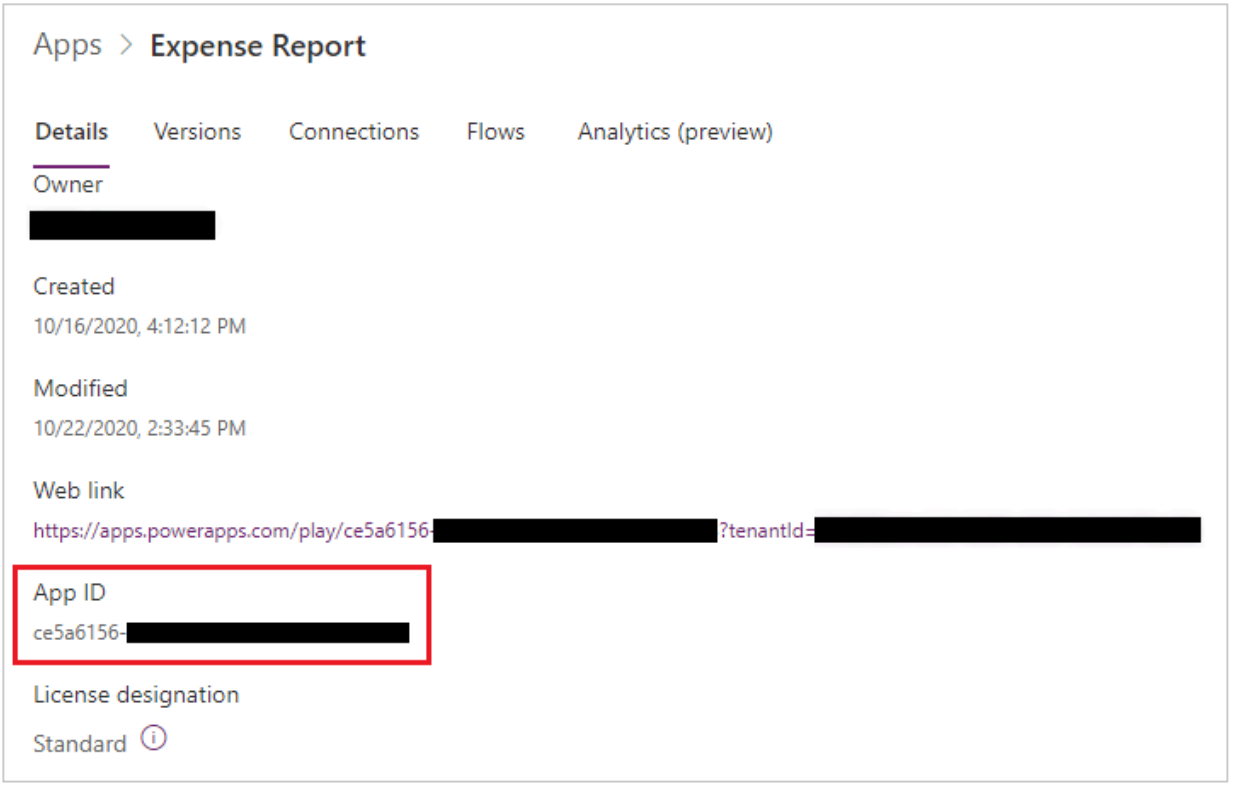
Get an app ID

Get the app ID for either a canvas or model-driven app:

1. Sign in to Power Apps.
2. Near the left edge, select **Apps**.
3. Select ··· (More Commands).
4. Select **Details**.



The app ID appears at the bottom of the **Details** pane for that app.



Create an effective support request

Article • 07/09/2024

If an app isn't behaving as expected, it could be an issue with your Power Apps configuration or a system outside of Power Apps.

Depending on the issue, you can get help from the following individuals or organizations:

Expand table

Type of issue	Who can help best
App	Creators of the app, administrators
Power Apps	Microsoft
External data sources and integrations	Users responsible for the external system

Differences between app bugs and Power Apps bugs

An *app* bug is unexpected behavior in a particular app. In comparison, a *Power Apps* bug is unexpected behavior in the system that creates, runs, or manages the app. An underlying Power Apps bug might cause an app bug, making it difficult to determine if the bug is an app or Power Apps bug.

Here are some distinguishing signs.

Expand table

App bug	Power Apps bug
Able to reproduce an issue in a specific app	Able to create an app that reproduces an issue
Requires access to *specific* data connections	*Any* data connection reproduces the issue, which might require a specific configuration of the data source
Affects only a single app in a single organization	Affects apps in multiple organizations or has the potential to affect them
Complicated app with components not relevant to the issue	Minimal repro app that shows an issue with a few components

App bug	Power Apps bug
Mentions custom features and code	Mentions specific Power Apps features
Microsoft documentation doesn't exist for the affected feature	Microsoft documentation exists for the affected feature and explains its expected behavior

Example app bugs

The following examples show app bugs and how users can describe them as steps to app owners, so owners can reproduce and resolve the bugs.

1. Canvas app doesn't show invoices.
   a. Sign in to your canvas app, such as Contoso.
   b. On your Home screen, select **My Invoices**.

      - Expected behavior: Invoices created by the user are displayed.
      - Actual behavior: No invoices are shown.

2. Model-driven app doesn't show invoices.
   a. Sign in to the Contoso app in your environment.
   b. On the **Dashboard** page, select **Invoices** on the site map.
   c. On the **Invoices** page, set the view to **My active invoices**. The list of invoices are displayed.

      - Expected behavior: Invoices created by the user are displayed.
      - Actual behavior: No invoices are shown.

Bugs can have great variance because features, user interfaces, and tables are specific to an app and organization, making the cause of bugs different for everyone. For example, **invoice** isn't a built-in table in Power Apps. There isn't a specialized feature in canvas apps for filtering records by a certain user, therefore the app maker must write Power Fx expressions or configure data connectors. Similarly, the maker must configure **Views** in model-driven apps to display desired records.

There isn't sufficient information in either of the examples to determine if there's a Power Apps issue. The creators of the app are best suited to investigate app issues.

Example Power Apps bugs

If app creators investigate and find what they classify as a Power Apps bug, they might report them similarly to the following examples.

1. **Canvas app Filter function returns no results when filter text contains asterisk character**
   a. A minimal repro app is attached to demonstrate the issue.
   b. This app contains a simple collection: `TestTable` with data `[{Name: "a"}, {Name: "*b"}]`.
   c. There are two **Table** controls in the app. Both controls are configured to show the **Name** column.
   d. **Table1** has **Items** set to `Filter(TestTable, Name="a")`.
   e. **Table2** has **Items** set to `Filter(TestTable, Name="*b")`.

      - Expected behavior: **Table1** shows the record `{Name: "a"}`, matching the **Filter** function's condition `Name="a"`. **Table2** shows the record `{Name: "*b"}`, matching the **Filter** function's condition `Name="*b"`.
      - Actual behavior: **Table1** shows expected record but **Table2** doesn't show any records.
      - Notes: Same behavior is observed with other dataset controls like **Gallery**, when **Items** are set to the same expressions.

2. **Model-driven app View returns no results when filter condition contains asterisk character**
   a. Create a **View** for any table.
   b. Remove all filters for the view.
   c. Add a filter for the primary column, matching text that starts with **b*.
   d. Add this view and the table to any model-driven app.
   e. Save and publish all changes.
   f. Run the app.
   g. Add a few records with different values for the primary column. Ensure one column starts with **b*.
   h. Go to the table's page.
   i. Change the view to the newly created view.

      - Expected behavior: Grid shows records with primary column values that start with **b*.
      - Actual behavior: No records shown.
      - Notes: When the filter condition doesn't use an asterisk, like *b*, the filter works as expected.

These Power Apps bugs describe issues with specific Power Apps features: the **Filter** function for the canvas app and View filters for the model-driven app.

A good support request provides enough information for anybody to reproduce the issue easily. The author might mention the result of their investigative actions or

troubleshooting they tried when attempting to isolate the issue. For example, the author might mention the issue only occurs in the Chrome browser but not in Firefox.

What makes a good Power Apps support request

A good support request frames an issue as a Power Apps bug, not an app bug. Follow these guidelines, where applicable, to help Microsoft understand and resolve the issue quickly.

Have a descriptive title

The title should mention:

1. A specific Power Apps feature
2. The unexpected behavior
3. The conditions that cause the bug to happen

Example of a bad title: "Gallery control is blank"

Example of a good title: "Filter function returns no results when filter text contains asterisk character"

Attach a simplified app, not the original app

For issues with running an app, provide a minimal repro app for canvas apps, or a vanilla repro solution for model-driven apps.

> **ⓘ Important**
>
> The goal of a good support request is to include enough information so that anyone can reproduce the issue on their own device.
>
> If you can show that the bug is a Power Apps bug instead of an app bug, with a minimal or vanilla repro app, Microsoft can resolve it swiftly. Without these repro apps, the resolution might be delayed or the support request might not be accepted.

Exceptions

A minimal or vanilla repro app isn't always feasible or needed for these issues:

- Data access and saves from a specific data source
- Specific user data, such as user permissions
- Licensing
- Offline operation
- General server issues

Regardless, simplify your app as much as possible and isolate the issue for canvas or model-driven apps.

Attach a network trace

For data and server issues, examining network communications between the client and server helps isolate the problematic layer. A record of network calls is known as a network trace.

You can either use Monitor or browser development tools to record a network trace.

Be sure to start recording just before reproducing the issue and end the recording right after you successfully reproduced it. This brief interval minimizes irrelevant information in the trace that might cause delays in Microsoft's handling of the support request.

Provide detailed steps to reproduce the issue

If you created a minimal or vanilla repro app, describe *how to reproduce the issue* in that app. Don't describe issues with the app where you originally found the problem.

Mention the observed behavior and the expected behavior.

Provide screenshots or videos

For user interface issues, screenshots or videos can more quickly clarify the steps to reproduce the bug, rather than a written description.

Link to official documentation

Include links to Microsoft documentation to clarify the affected feature and its expected behavior.

For issues with professional development features, provide a link to the documentation for the API function that doesn't work.

Simplify code samples

If the issue involves coding and other professional development features, simplify the code first. Usually, just a few lines of code are needed to demonstrate a Power Apps bug. Deploy the app in a fresh environment with no other customizations. Verify the issue occurs and attach a snippet of the problematic code.

Examples of professional development features in Power Apps:

- Power Apps components
- Custom form scripts in model-driven apps
- Power Fx or JavaScript commands in model-driven apps
- Web resources for model-driven apps

Mention specific configuration steps so that others can reproduce the issue in their own environment.

Provide system info

An issue might happen only on a specific version of Power Apps, a browser, or an environment. Provide the session ID so that Microsoft can use these details.

Add notes from your investigation

You might try different configurations to eliminate possible causes. Mention these configurations in the support request. This inclusion helps others understand the issue better and avoid repeating the same steps.

Submitting a Power Apps support request

Before submitting a support request, check if the bug is a known issue. If the bug isn't already known, you can create a support request to report the bug.

Change authoring version for Power Apps Studio

07/08/2025

The default version of a Power Apps Studio session is determined by your environment's location and refresh cadence. This default version of Power Apps Studio changes when an update is released for your environment based on configured refresh cadence.

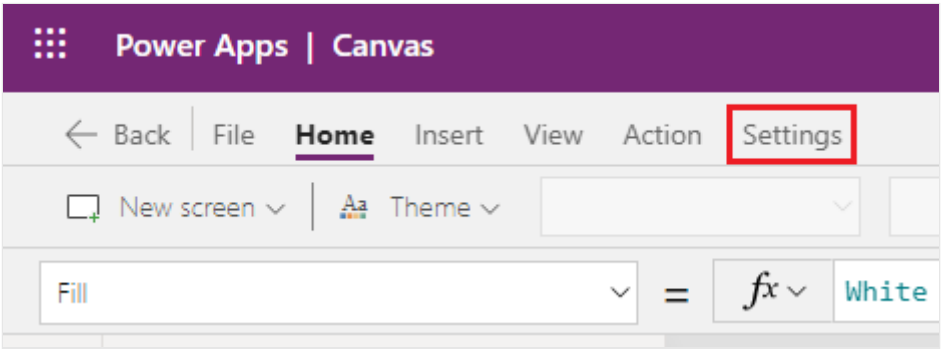
You can now change the authoring version of your current Power Apps Studio session from the version loaded by default, to an earlier or later version as available for your environment.

> **Important**
>
> Change the authoring version of a current Power Apps Studio session only when needed, such as to work around an issue as instructed by Microsoft support.

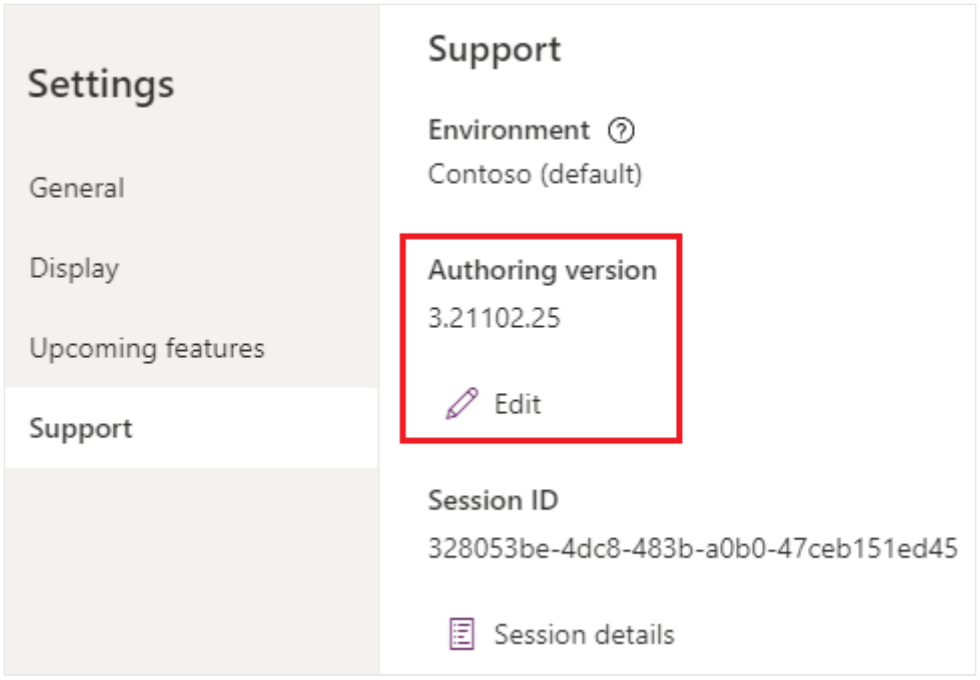
How you check and change the authoring version of your current Power Apps Studio depends on whether you have an app already open, or not.

Check Power Apps Studio version when an app is open

1. Open an existing or a new app in Power Apps Studio.
2. Select **Settings**.



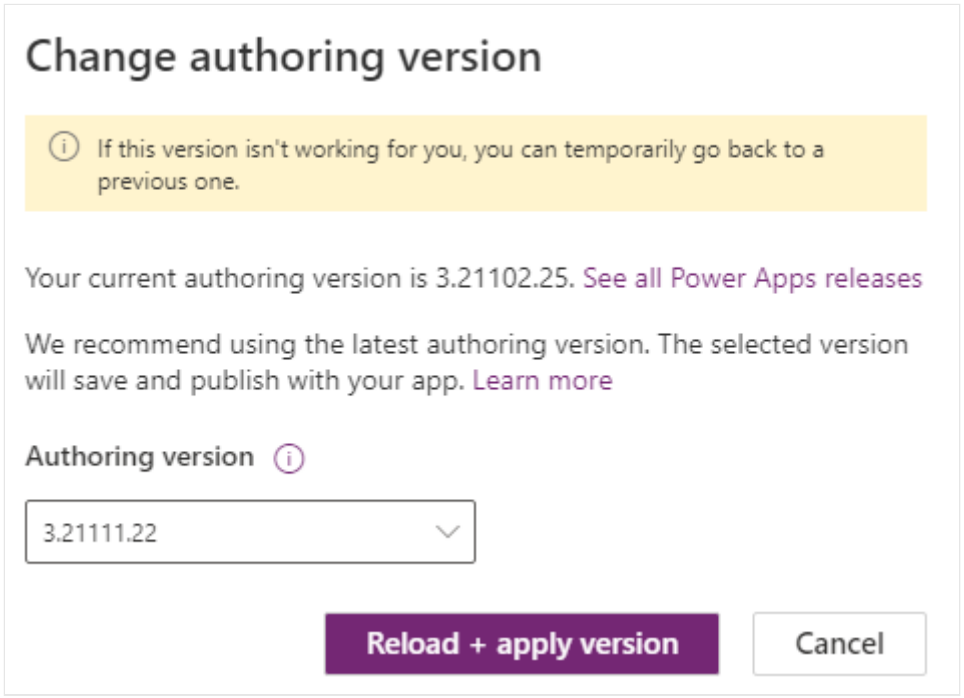
3. Select **Support** and review your existing Power Apps Studio version for the current session.



Change Power Apps Studio version

1. If you're instructed to change the version of your current Power Apps Studio session, follow the steps to see the current version.

2. From the list of available authoring versions, choose the version you want, and then select **Reload + apply version**.



Tip

The default version for your environment will have **(recommended)** next to the authoring version number.

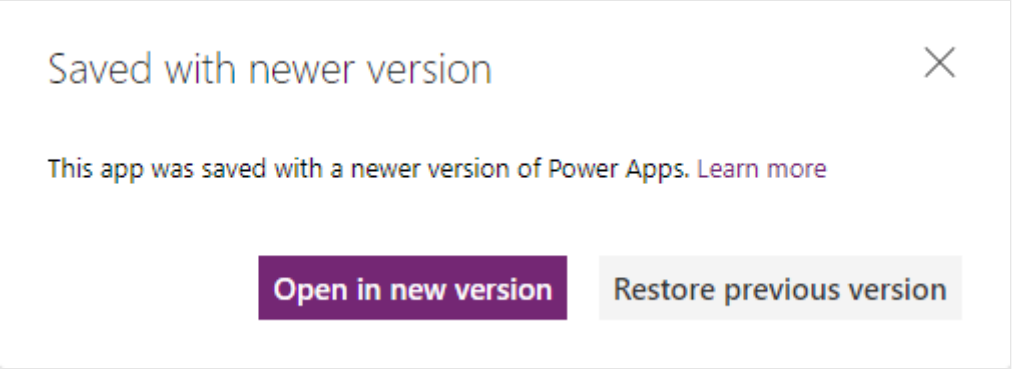
3. (Optional) Save the app when you're prompted to save the changes if you had an app already open that wasn't saved.
4. Select **Open** or **New** to work with the app inside Power Apps Studio using the version you selected.

You're now editing the app in the Power Apps Studio version you've selected. Since the authoring version change only persists for the current Power Apps Studio session, repeat the above steps when you want to work with the same app again.

> ⓘ **Note**
>
> You can't change the authoring version of Power Apps Studio when a you author custom page content or edit an existing custom page.

Known limitations and workarounds

- Selecting **Reload + apply version** only changes the current authoring session to the version you choose. This change doesn't persist for future sessions. New Power Apps Studio sessions always start with the default Power Apps Studio version for your environment.
- To update the app with the Power Apps Studio version you selected, you must save the app with the chosen Power Apps Studio version.
- If you save an app using a version newer than the default for your environment, you might not be able to open that app using the default version of Power Apps Studio. In that case, you'll see the following dialog:



- Select **Open in new version** to open your app for editing until your environment's default version gets updated to the app's current version.
- Select **Restore previous version** to see all versions for the app, and revert to an older version saved with the default Power Apps Studio version associated with your environment.

  > **Note**
  >
  > If you choose to restore the app to a previous version, you'll lose any changes made between your latest and previous app versions.

- You cannot change authoring versions if coauthoring is enabled.

Troubleshooting startup or sign-in issues for Power Apps

Summarize this article for me

This article helps you resolve some common issues or errors that might occur when starting up or signing in to Power Apps.

Common issues or errors

The following are some common issues or errors that might appear when you start up or sign in to Power Apps.

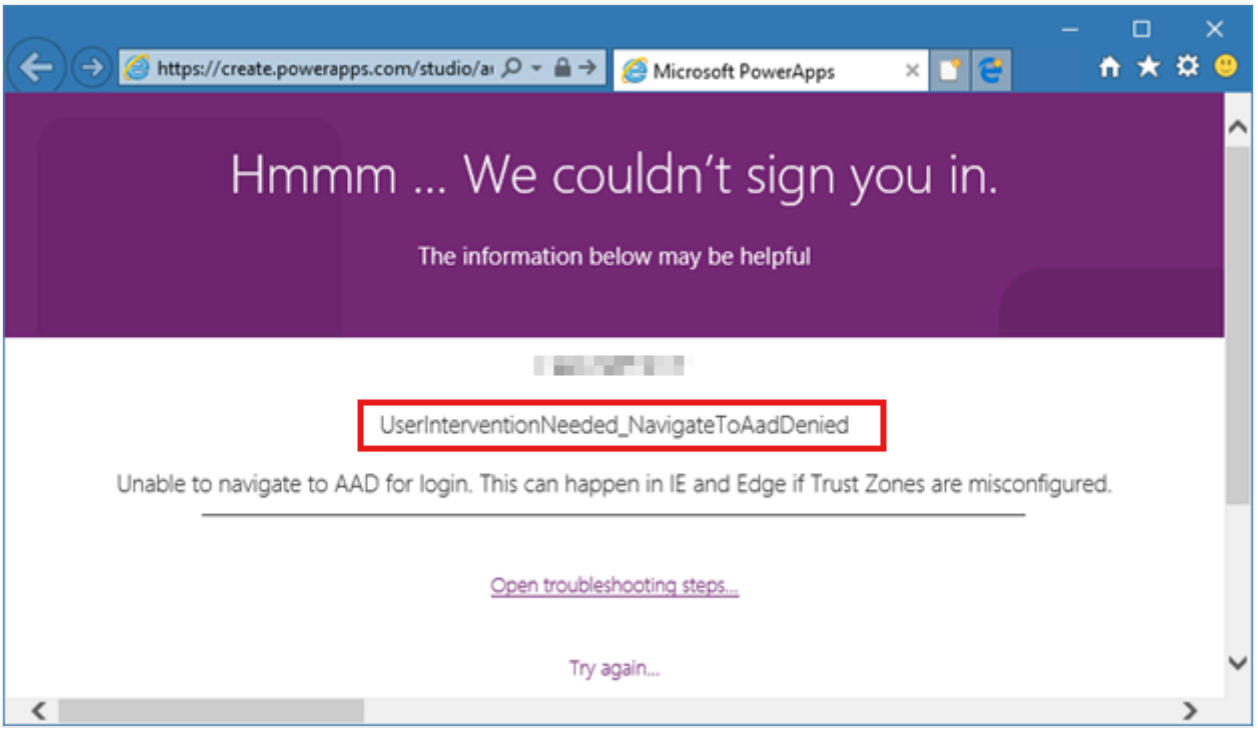
- You're prompted to sign in every time an app is embedded in another client such as SharePoint and Microsoft Teams. The Power Apps opening experience starts and halts until you sign in.
- Error message related to cookie settings.

  > Hmmm... Something went wrong.
  > thirdPartyCookiesBlocked
  > Please enable third party-cookies and site data in your browser settings. If you are using Chrome's Incognito mode, you can uncheck the 'Block third-party cookies' option on the Incognito landing page.
  > Try again

- "Sign in required" message when signing in to Power Apps, especially in InPrivate or incognito mode.

  > Sign in required
  > Please select sign in to continue.
  > Session ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
  >
  > AADSTS50058: A silent sign-in request was sent but no user is signed in. The cookies used to represent the user's session were not sent in the request to Microsoft Entra ID. This can happen if the user is using Internet Explorer or Edge, and the web app sending the silent sign-in request is in different IE security zone than the Microsoft Entra endpoint (login.microsoftonline.com).
  > Trace ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
  > Correlation ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
  > Timestamp: xxxx-xx-xx xx:xx:xxZ

- "Hmmm ... We couldn't sign you in" message.



- "WebAuthoring abnormal termination" message.

> WebAuthoring abnormal termination.
>
> Client date/time: <Client Time>Thh:mm:ss.sssZ
> Version: 2.0.602
> Session ID: xxxx-xxxxx-xxxxxxx--xxxxxxxx
> description: {"error":{"detail":{"exception":{}},"colno":0,"filename":"
> <`https://paaeuscdn.azureedge.net/v2.0.602.0/studio/openSource/modified/winjs/js/base.js?v=39de0f2edf1`>...",
> "lineno":0,"message":"Script error","initErrorEvent":"
> [function]","bubbles":false,"cancelBubble":false,"cancelable":false,"currentTarget":"
> [window]", "defaultPrevented":true,
> "eventPhase":2,"isTrusted":true,"srcElement":"[window]","target":"
> [window]","timeStamp":1490711965955,"type":"error","initEvent":"
> [function]","preventDefault":" [function]",
> "stopImmediatePropagation":"[function]","stopPropagation":"
> [function]","AT_TARGET":2,"BUBBLING_PHASE":3,"CAPTURING_PHASE":1},"errorLine":0,
> "errorCharacter":0,
> "errorUrl":"
> <`https://paaeuscdn.azureedge.net/v2.0.602.0/studio/openSource/modified/winjs/js/base.js?v=39de0f2edf1`>... error","setPromise":"[function]","exception":{}}
> stack: null

> errorNumber: 0
> errorMessage: Script error

- UserInterventionNeeded_CookiesBlocked
- UserInterventionNeeded_StorageBlocked
- UserInterventionNeeded_NavigateToAadTimeout
- UserInterventionNeeded_NavigateToAadDenied
- UserInterventionNeeded_StorageLost
- AadError

Resolution

Try the following steps to resolve the issue:

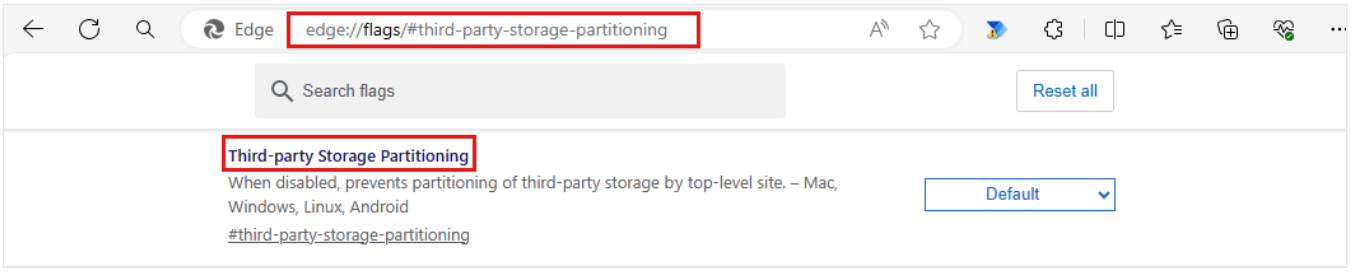
1. Enable third-party cookies and local data in your browser or app.
2. Clear your browser's cache and cookies and try again. Cached data can sometimes prevent you from signing in.
3. Try signing in with a different browser. For a list of supported browsers, see system requirements.
4. Check your network connection to make sure it's stable.
5. If you're getting Microsoft Entra errors, they're usually related to user authentication and authorization. The error page might contain additional information that can help diagnose and fix the problem. To resolve Microsoft Entra errors, you might need assistance from your IT department.
6. Check the "Third-party Storage Partitioning" setting in your browser to make sure it's disabled.

   > ⓘ **Note**
   >
   > Consider this resolution step only when you experience sign-in or sign-out issues under one of the following conditions:
   >
   > - You use a device that has multiple Microsoft Entra identity sign-ins to access different applications.

- You access multiple applications using Microsoft Entra across more than one tab. When you sign out of one tab, you observe that you aren't signed out of the second tab.
- You access Power Apps that are embedded via an iframe in a third-party website.
- You access a canvas app that's embedded in a model-driven app form.

Check the "Third-party Storage Partitioning" setting in Microsoft Edge or Google Chrome

- In Microsoft Edge, you can check the setting by navigating to `edge://flags/#third-party-storage-partitioning` using the address bar.
- In Google Chrome, you can check the setting by navigating to `chrome://flags/#third-party-storage-partitioning` using the address bar.



Enable storage of third-party cookies and local data in your browser or app

Power Apps stores some data locally, such as user identity and preferences, using your browser's capabilities. Problems occur if the browser blocks the storage of such local data, or third-party cookies set by Power Apps.

Most browsers allow settings to reflect the changes immediately. You might also need to close all the browser windows and reopen them instead.

To enable this setting for the Power Apps and Dynamics 365 mobile apps for iOS, you need to work through the iOS settings linked to the app rather than through the browser settings for iOS.

These instructions are shown on the following tabs.

Microsoft Edge

- Option 1: Enable storage of third-party cookies and local data for all sites

    1. Select **Settings** > **Cookies and site permissions**.
    2. Expand **Cookies and data stored**.
    3. Ensure the **Block third-party cookies** setting is disabled.
    4. If present, remove the following sites from the site-specific cookie configuration under **Block** and **Clear on exit**:
        - `https://create.powerapps.com`
        - `https://*.create.powerapps.com`
        - `https://make.*.powerapps.com`
        - `https://make.powerapps.com`
        - `https://login.microsoftonline.com`
        - `https://apps.*.powerapps.com`
        - `https://apps.powerapps.com`
        - (Only for sovereign clouds) US Government version URLs.

- Option 2: Create exceptions to allow the storage of third-party cookies and local data for Power Apps and associated services

    > **Note**
    >
    > The following steps require your Edge browser version to be 87 or above.

    1. Select **Settings** > **Cookies and site permissions**.
    2. Expand **Cookies and data stored**.
    3. Select **Add** under **Allow** and add:
        - `[*.]powerapps.com`
    4. Select **Clear browsing data on close**.
    5. Ensure **Cookies and other site data** is disabled. If you want to keep it enabled, select **Add** instead, and then add:
        - `[*.]powerapps.com`

Clear your browser cache

The browser cache is stored on your device's hard drive. When you visit a website, your browser downloads certain information that allows it to load faster when you revisit the same website in the future. Some Power Apps features use the browser cache to provide a faster user

experience. In some cases, you might want to clear your browser cache. Here are the instructions for different browsers:

- Microsoft Edge
- Google Chrome
- Safari on Mac

Next steps

If your issue isn't listed in this article, you can search for more support resources or contact Microsoft support. For more information, see Get Help + Support.

App access checker for model-driven apps

07/22/2025

Use the app access checker tool to identify common issues found for a specific user that can occur when running a model-driven app.

Issues found by the app access checker include:

- If an app is visible to the user or not.
- The reason why an app is visible or not visible to the user.
- If the user has the required license.

How to use the app access checker

Power Platform admins and makers can use the app access checker to search apps based on user principal name (UPN) or email address.

Open the diagnostics page in your browser by typing https://*environmentURL*/WebResources/msdyn_AppAccessChecker.html, such as `https://contoso.crm.dynamics.com/WebResources/msdyn_AppAccessChecker.html`. Then enter the UPN or email address in the box and then select **Search**.

How to interpret the results

- **Visible**.
  - If the user doesn't have read privilege on the app module table, none of the apps are visible to the user, and **No** is displayed.
  - If the user has read and/or write privilege on the app module table, then all the apps are visible and **Yes** is displayed.
- **License**.
  - If the user has appropriate licensing to play the app, **Yes** is displayed.
  - Select the **details** link on either **Yes** or **No** result for each app to get information on how the user is or isn't able to access.
- **Security**.
  - If the user has create or write privilege on the app module table, **Yes** is displayed. If the user isn't associated to one or more security roles assigned to the app, check if the user is member of a team and whether the team is associated with that security role.

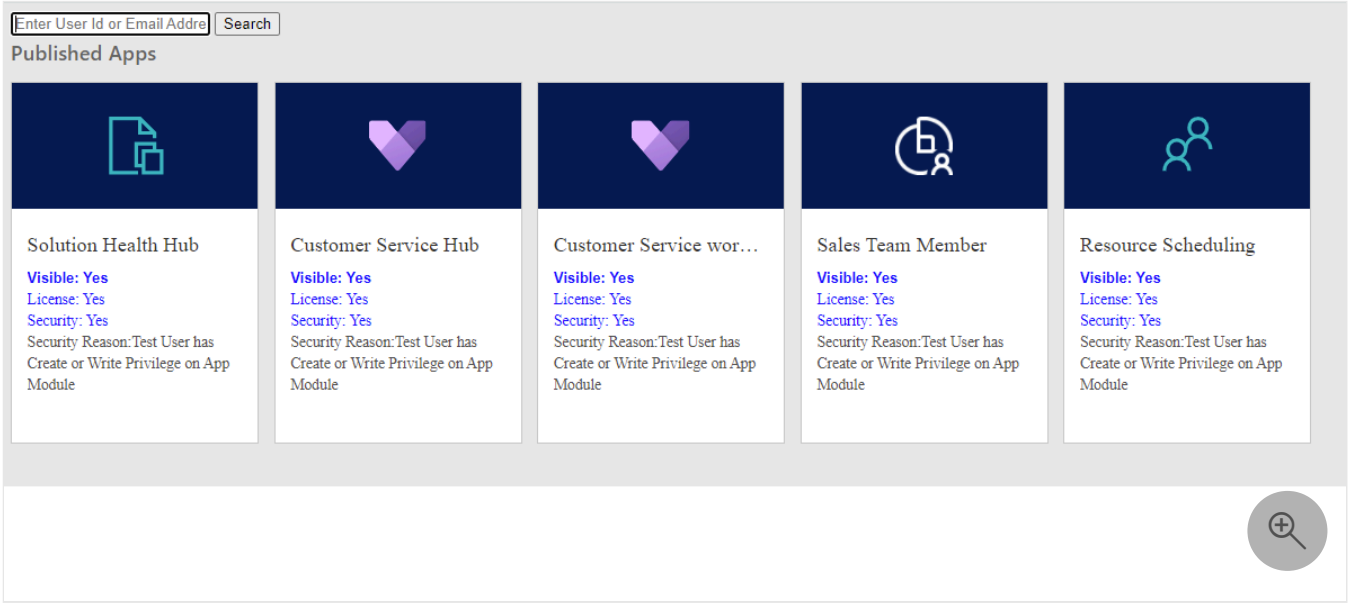
Licensing terminology and how model-driven apps are accessed

In order for an app to be visible to a user, both the results for **License** and **Security** must be **Yes**. If a user doesn't have an appropriate license, the error message might give information about what **service plans** could be used to give access to the app. Note that **Licenses** aren't the same as service plans. A **License** is what is assigned to users in Microsoft Entra and usually has multiple service plans. For a list of all licenses and what service plans are included, go to the licensing service plan reference. Referencing the Microsoft Dataverse licensing error message and the service plan reference list can help diagnose user licensing issues.

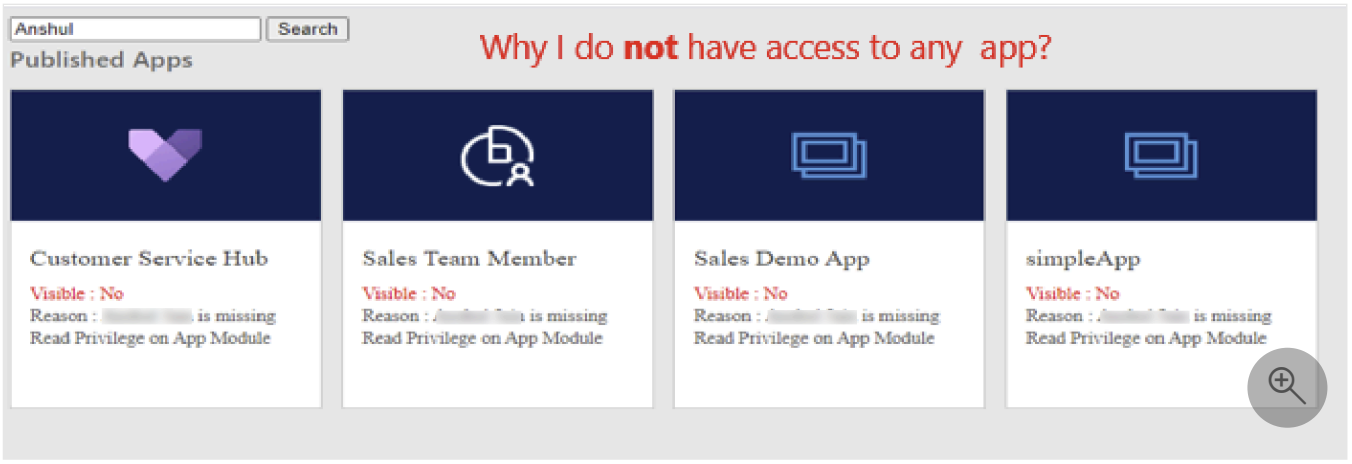
Also be aware that Dataverse caches the service plans that are assigned to users, so Microsoft Entra License assignments might not immediately reflect in Dataverse. To update the cached service plan assignments in Dataverse, have users sign out and sign back in. If the issue persists, it could be a result of Microsoft Entra caching, and the user should wait about 30 minutes, then sign out and sign back in again.

Example results

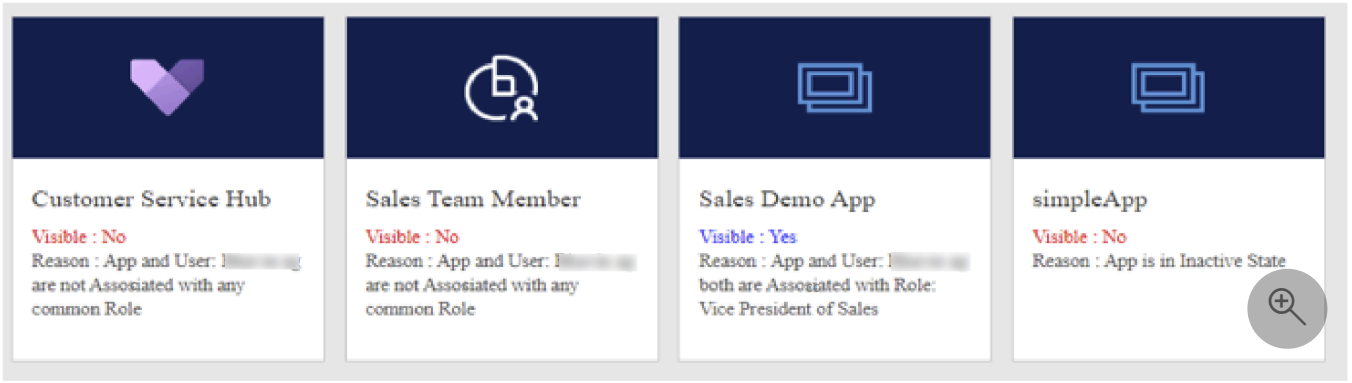
User has access to all visible apps in the environment.

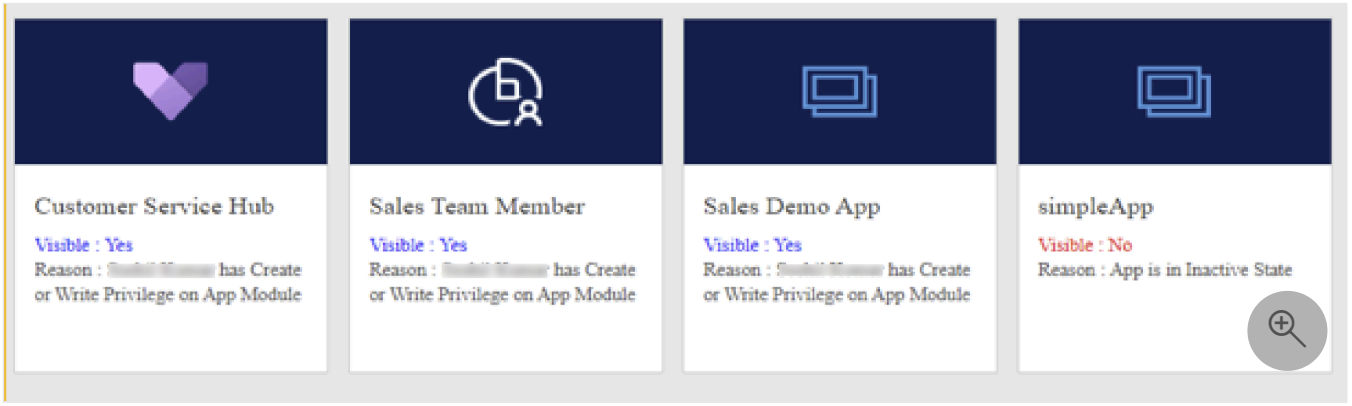


User doesn't have visibility or access to any apps in the environment because of missing security role membership associated with each app.

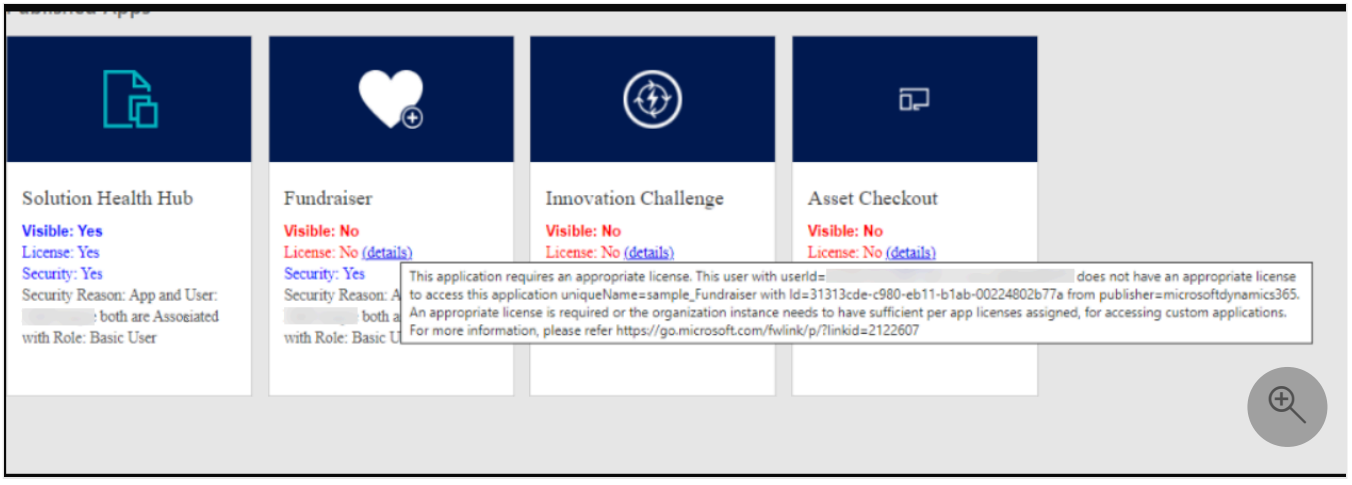


Two examples where the user has visibility to some apps but not others because of missing security role membership associated with the app.

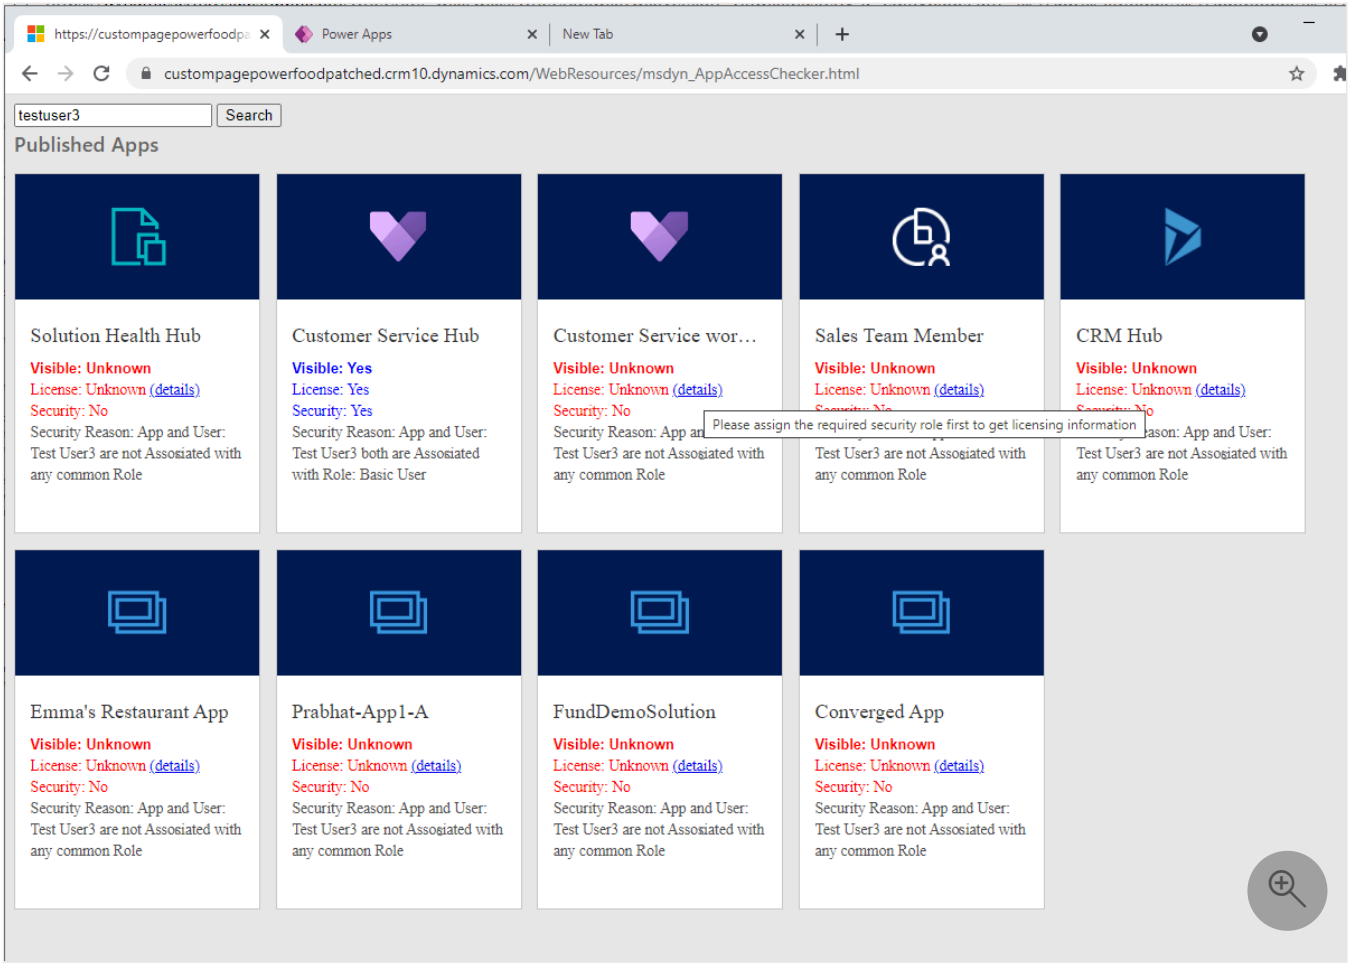




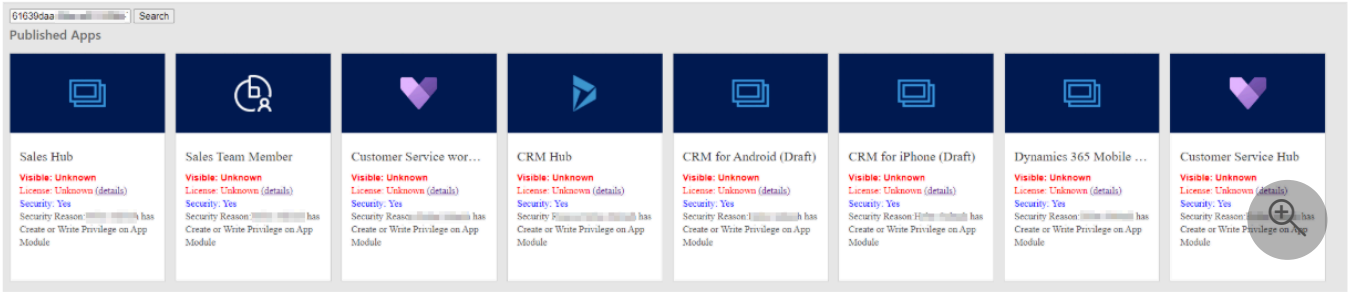
In this example, the user has the required security privilege for the app but doesn't have the required license to access some of the apps.



In this example, the user doesn't have the required security privilege, so the app access checker isn't able to show licensing details.



If **Security** is **Yes** and **License** is **No** or **Unknown** contact Help + support. More information: Get Help + support



Limitation

- App access checker doesn't show details for the Outlook App. This is because that information is only visible to Power Platform administrators.

Share a model-driven app

Troubleshoot Power Query issues

When you use Power Query for Excel to create a custom table that contains data from external sources, you may receive the following error:

> "Your Microsoft Entra administrator has set a policy that prevents you from using this feature. Please contact your administrator, who can grant permissions for this feature on your behalf."

The error appears if Power Query can't access the organization's data in Power Apps or Microsoft Dataverse. This situation arises under two sets of circumstances:

- A Microsoft Entra tenant administrator has disallowed users' ability to consent to apps that access company data on their behalf.
- Using an unmanaged Active Directory tenant. An unmanaged tenant is a directory without a global administrator that was created to complete a self-service signup offer. To fix this scenario, users must first convert to a managed tenant and then follow one of the two solutions to this issue. The solutions are described in the next section.

To resolve this issue, the Microsoft Entra administrator must follow either of the procedures that are presented later in this article.

Allow users to consent to apps that access company data

This approach is perhaps easier than the next, but it allows for broader permissions.

1. In the Azure portal, open the **Microsoft Entra ID** pane, and then select **User settings**.
2. Next to **Users can consent to apps accessing company data on their behalf**, select **Yes**, and then select **Save**.

Allow Power Query to access company data

As an alternative, the tenant administrator can give consent to Power Query without modifying tenant-wide permissions.

1. Install Azure PowerShell.
2. Run the following PowerShell commands:

    - `Login-AzureRmAccount` (and sign in as the tenant admin)

- `New-AzureRmADServicePrincipal -ApplicationId 00001111-aaaa-2222-bbbb-3333cccc4444`

The advantage of this approach (versus the tenant-wide solution) is that this solution is very targeted. It provisions only the **Power Query** service principal, but no other permission changes are made to the tenant.

Update personal data

Users can update mashups and other information (such as query names and mashup metadata) through the Query Editor and through the **Options** dialog box that's accessible from the Query Editor.

In Power Apps, you access the Query Editor by doing the following:

1. Go to the **Data** pane, expand it, and then select **Tables**.
2. Select the ellipsis (...), and then select **Edit Queries**.
3. In the ribbon, select **Options**, and then select **Export Diagnostics**.

Delete personal data

Most data is deleted automatically within 30 days. For data and metadata around mashups, users must remove all their mashups through Power Apps. All of the associated data and metadata will be deleted within 30 days.

To remove mashups from Power Apps:

1. Remove the Data Integrator projects, which can be removed from the namesake tab.
2. Select the ellipsis (...), and then select **Delete**.

If you created a mashup through the "New tables from data (Technical Preview)" feature, you can remove it by doing the following:

1. Select the ellipsis (...), and then select **Edit queries**.
2. In the ribbon, select **Options**.
3. Select **Remove all queries**.
   After you confirm that you want to delete your queries, they are deleted.

Export personal data

To export personal data, users can do the following:

1. Open the Query Editor.
2. In the ribbon, select **Options**.
3. Select **Export Diagnostics**.

In Power Apps, you can access the Query Editor by doing the following:

1. Go to the **Data** pane, expand it, and then select **Tables**.
2. Select the ellipsis (...), and then select **Edit Queries**.
3. In the ribbon, select **Options**, and then select **Export Diagnostics**.

System-generated logs about user actions on the user interface (UI) can be accessed in the Azure portal.

FAQ about using AI responsibly in Power Apps

Summarize this article for me

An AI system includes not only the technology, but also the people who use it, the people affected by it, and the environment in which it's deployed. Microsoft Responsible AI FAQs are intended to help you understand how AI technology works, the choices system owners and users can make that influence system performance and behavior, and the importance of thinking about the whole system, including the technology, the people, and the environment. You can use Responsible AI FAQs to better understand specific AI systems and features that Microsoft develops.

Responsible AI FAQs are part of a broader effort to put our AI principles into practice. To find out more, see Microsoft AI principles.

FAQ for Power Apps vibe experience (preview)

Summarize this article for me

What is Power Apps vibe?

Power Apps vibe is an AI-powered app creation experience that helps makers quickly build functional business applications using natural language. Makers describe what they want to build, and vibe translates those descriptions into working app experiences, including data, screens, and logic. At a high level, Power Apps vibe takes maker prompts and optional context as input and produces a draft app that makers can review, refine, and publish.

What can Power Apps vibe do?

Power Apps vibe helps makers create apps faster by generating a fully functional app (including app structures, screens, and interactions) based on natural language descriptions. Makers can iteratively refine their apps by adjusting prompts, editing generated outputs, and previewing changes in real time. Power Apps vibe is designed to accelerate early app creation and reduce the effort required to get from an idea to a usable application.

What is the intended use of Power Apps vibe?

Power Apps vibe is intended to support makers who want to quickly prototype, explore, and build business applications without starting from scratch. It helps makers translate ideas into working apps, learn app-building concepts through iteration, and accelerate time to value.

How was Power Apps vibe evaluated? What metrics are used to measure performance?

Power Apps vibe is evaluated using a combination of qualitative and quantitative methods. Evaluation includes user studies with makers to assess the quality of generated outputs, usability of the experience, and how effectively Power Apps vibe supports app creation workflows. Feedback from these studies helps identify strengths, gaps, and opportunities for improvement.

In addition to qualitative feedback, telemetry data is monitored to understand how makers use Power Apps vibe in practice. This data includes metrics such as feature usage, completion and

success rates, and the ratio of positive to negative feedback signals. Before release, Power Apps vibe undergoes extensive functional testing to validate reliability and behavior across supported scenarios. For more information, see the Privacy Statement.

What are the limitations of Power Apps vibe? How can users minimize the impact of Power Apps vibe's limitations when using the system?

Like other AI-powered experiences, Power Apps vibe has known limitations. Generated apps might not always fully reflect a maker's intent. They might require extra refinement or might not be suitable for complex or highly customized production scenarios without further modification. Outputs are based on the information provided by the maker and the capabilities available in the platform.

Known limitations include:

- Non-English languages aren't supported.
- Supports image attachment up to 2 MB.
- You can't access or edit apps created outside of Power Apps vibe.
- If you export an app and edit it outside Power Apps vibe (for example, in VS Code), redeploying via PAC CLI creates a new app, and it disconnects from the original plan.
- Currently, you can only have one app per plan; multiple apps within a single plan aren't supported.
- You can't open preexisting plans in Power Apps vibe.
- Canvas and model-driven apps aren't supported; you can't recommend, open, or edit these app types in Power Apps vibe.
- Existing tables aren't automatically recommended during data model proposal; you can manually add existing tables to your plan.
- Editing existing Dataverse tables via chat isn't currently supported; you can make changes to these tables through the data editor manually.
- Direct code edits in Code view or Split view aren't supported; you can't modify code directly in these views.
- You can't directly create proposed technologies (apart from code apps) from the plan; you must add additional technologies manually.

Makers can minimize the impact of these limitations by:

- Providing clear, specific descriptions of their app requirements.
- Iterating on prompts and reviewing generated outputs carefully.
- Testing app behavior and data interactions before publishing.
- Treating generated apps as a starting point rather than a finished solution.

Makers are ultimately responsible for validating that their apps meet their functional, security, and compliance requirements.

What operational factors and settings allow for effective and responsible use of Power Apps vibe?

Effective and responsible use of Power Apps vibe depends on how makers configure and interact with the system. Makers should:

- Clearly describe business scenarios, users, and tasks when prompting
- Review generated content before saving or sharing it
- Test apps in appropriate environments prior to broader use
- Follow organizational governance, data, and compliance policies

How do I provide feedback for Power Apps vibe?

- Select the thumbs up or thumbs down in the chat pane to provide feedback on a specific action.
- Select the **Give feedback** icon in the command bar to provide general feedback, report an issue, or share suggestions.

FAQ for Power Apps in agents

These frequently asked questions (FAQs) describe the AI impact of Power Apps in agents for model-driven apps.

What is Power Apps in agents?

Power Apps in agents enables users to interact with data from Power Apps model-driven apps directly in Microsoft 365 Copilot through natural language. When makers deploy a declarative agent for a model-driven app, users can query records, view data in grids, create and edit records, and receive AI-generated summaries, all through a Copilot conversation, without switching to the app.

The agent connects to the model-driven app's underlying Dataverse tables and uses the same data exploration capabilities that power the Grid view experience in model-driven apps.

What are the system's capabilities?

The system can:

- Query and filter records across tables configured in the model-driven app using natural language
- Display results as an interactive grid, consistent with the Grid view in the app
- Show individual record details using a Form, consistent with the Form experience in model-driven apps
- Create and update records using the Form widget in Copilot
- Hand off to the full model-driven app for actions that require the complete app experience

What is the system's intended use?

Power Apps in agents serves two audiences:

- **For makers**: Extend the reach of an existing Power Apps model-driven app by making its data accessible to users directly in Microsoft 365 Copilot. Deploy a declarative agent for your app. No additional app development is required beyond the initial setup.

- **For end users**: Help business users access and act on their organization's data without leaving Microsoft 365 Copilot, reducing context-switching and enabling faster decisions in the flow of work. It's not intended to replace the full model-driven app experience, but to make common data tasks – querying, reviewing, and updating records – accessible

through Microsoft 365 Copilot. When more complex actions are needed, it also serves as a handoff point directly to the model-driven app.

How was Power Apps in agents evaluated? What metrics are used to measure performance?

The system was evaluated across a range of query types, table configurations, record volumes, and user scenarios. Evaluation focused on query accuracy, widget render fidelity, and the correctness of information presented in them.

If you encounter problems, submit feedback through Microsoft 365 Copilot. Microsoft uses your feedback to improve products and services. For more information, see Data, privacy, and security for Azure OpenAI Service.

What are the limitations of Power Apps in agents? How can users minimize the impact of these limitations?

- **Query accuracy**: Data retrieval results might not always match the user's intent on the first attempt. Iterate by using natural language to refine results, such as by guiding Copilot on which column or field you meant in your original ask.
- **Unsupported field types in forms**: The form fill experience doesn't support certain field types. For those fields, open the full model-driven app to complete or edit the record.
- **Non-English languages are unsupported**: Power Apps in agents currently supports English-language queries and responses only. If you interact in other languages, you might receive inaccurate or unexpected results.

What operational factors and settings allow for effective and responsible use of the system?

Data retrieval is powered by the data exploration agent. Power Apps in agents leverages the Data Exploration Agent, the same underlying AI capability that powers the Grid view experience in Power Apps model-driven apps. As a result, the quality and accuracy of data retrieval is benchmarked against and consistent with the data exploration experience users already have in model-driven apps.

Form filling is powered by form fill assistance. Power Apps in agents leverages Form Fill Assistance, the same underlying AI capability that powers field suggestions in Power Apps model-driven app forms. As a result, the quality and accuracy of prefilled values is benchmarked against and consistent with the form-filling experience users already have in model-driven apps. Users should review prefilled values before saving.

How do I provide feedback?

Use the thumbs up or thumbs down controls in Microsoft 365 Copilot to provide feedback on individual responses. Microsoft uses this feedback to improve products and services.

FAQ for building apps and tables through conversation

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of build apps and tables through conversation feature.

What is build apps and tables through conversation?

Build apps and tables through conversation is a feature in the Power Apps that allows you to describe the app or table that you want to build, and AI will design it for you. To start, you use natural language to tell the AI assistant what kind of information you want to collect, track, or show. The assistant will generate a Dataverse table and use it to build your canvas app. The AI assistant is available from the Power Apps home page.

What are the system's capabilities?

This capability is powered by Azure OpenAI Service, which uses powerful language models. These language models generate new text in English that looks and sounds like text written by humans.

Using Azure OpenAI service as a foundation, build apps through conversation considers your app description to propose relevant data tables on which to build your app. As part of data generation, the system recommends relevant columns, sample row data, and data types that you can customize. The sample data is for illustration only and is fictitious. No real association is intended or inferred.

What is the system's intended use?

Build apps and tables through conversation is intended to simplify your app creation process by automatically generating a data table on which your app will be built. AI-generated content may have mistakes. Make sure it's accurate and appropriate before using it. For more information, read the full terms.

How was build apps and tables through conversation evaluated? What metrics are used to

measure performance?

Build apps and tables through conversation underwent substantial testing before the feature was released. If you encounter issues with the content being generated, please submit feedback. Your feedback will be used to improve Microsoft products and services. IT admins for your organization will be able to view and manage your feedback data.

For more information, see: Data, privacy, and security for Azure OpenAI Service

What are the limitations of build apps and tables through conversation? How can users minimize the impact of the build apps through conversation limitations when using the system?

This capability is in the process of rolling out, and may not be available in your region yet.

This capability may be subject to usage limits or capacity throttling.

The following are requirements to access this feature:

- Your account must have English (United States), French, German, Spanish, Dutch, Danish, Italian, Japanese, or Portuguese (Brazil) as the browser language.
- Have a Microsoft Dataverse database in your environment.
- AI Builder must be enabled for your environment to use the AI models or controls leveraging AI models:

    1. Sign in to the Power Platform admin center.
    2. Go to **Environments** > [select an environment] > **Settings** > **Features**.
    3. On the **Features** settings page, under **AI Builder**, enable or disable **AI Builder preview models**.

For more information, see Copilot in Power Apps overview

What operational factors and settings allow for effective and responsible use of the system?

Follow these procedures to make the most of the feature:

- Use everyday words to describe what your app should collect, track, list, or manage such as the following:
  - “Collect RSVPs for the team birthday party”
  - “Track sales leads”
- Customize the data table with prompts such as:
  - “Add a column for …”
  - “Remove the … row”
  - “Change the data type for the … column to… ”
- When in doubt, you can ask the AI assistant for help by typing, “Give me suggestions”

FAQ for generate app descriptions with Copilot

Article • 05/28/2025

These frequently asked questions (FAQ) describe the AI impact of Power Apps generate app descriptions with Copilot feature.

What is generate app descriptions with Copilot?

With the AI-generated app descriptions feature, Makers can use AI to generate descriptions for their canvas and model-driven apps. Makers can generate a description from app **Settings** or when you publish the app. By using AI to generate descriptions, Makers can focus on building their apps and allow AI to assist in summarizing the purpose of the apps for end-users.

What are the system's capabilities?

It can take the contents of your app and provide a brief description of the app for makers to share with their end-users.

What is the system's intended use?

As an AI assistant to makers, it provides a brief description of your app that end-users can see.

How was generate app descriptions with Copilot evaluated? What metrics are used to measure performance?

We evaluate the feature both qualitatively and quantitatively. To assess the quality of the feature, we're conducting user studies with makers to gather their feedback on their experiences, thoughts about the feature's quality, and suggestions for improvement. Additionally, we're monitoring telemetry data to track the number of makers who tried the feature, the success rate of the feature, and the ratio of positive to negative feedback. Before releasing the Copilot feature in preview, we conducted extensive testing to ensure its functionality. If you encounter any issues with the content generated, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of generate app descriptions with Copilot? How can users minimize the impact of the generate app descriptions with Copilot limitations when using the system?

- To use this capability, you must be in a Managed Environment.
- This capability is powered by Azure OpenAI Service.
- This capability is in process of rolling out, and might not be available in your region yet.
- This capability can be subject to usage limits or capacity throttling.

For canvas apps (preview)

- Preview features aren't meant for production use and might have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.
- For more information, go to preview terms.
- Your environment must be in the United States region.
- This feature doesn't support non-English language browsers.

What operational factors and settings allow for effective and responsible use of the system?

If you get this error, **Something happened and we weren't able to generate a description for you**, this might be due to capacity limits. We recommend you give the system some time before trying again.

FAQ for edit your app with Copilot

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of Power Apps' for edit your app with Copilot feature.

What is edit your app with Copilot?

With edit your app with Copilot feature, makers can delegate some tasks of app development to an AI assistant by telling Copilot their requirements. Makers can expect actions such as add, edit, or style controls, work with containers, and bulk edits. This allows makers to concentrate on designing the app while maintaining oversight of all actions taken by Copilot.

What are the system's capabilities?

The following system capabilities supported:

- Add a screen using pre-existing templates.
- Add and modify properties of a single control, limited to classic controls only.
- Update multiple controls at once.
- Work with containers.
- Provide default suggestions for users to help in typing.
- Use templatized formulas such as Navigate() to create buttons that perform specific actions, like navigating to the Home screen, and SubmitForm() for creating a Submit button for Form2.

The following controls are supported:

- Screen
- Container
- Gallery
- Form
- Button
- Label
- TextInput

What is the system's intended use?

As an AI assistant that helps people find information, Copilot provides the following list of UI actions for makers that are included in the preview release scope:

- Add a screen using existing screen templates
- Add and update properties of a single classic control
- Bulk updates controls on a single screen
- Work with containers
- Provide default suggestions to guide users on what to type in
- Offer the following templatized formulas to build your app:
  - Navigate(): For example, "Create a button for Home that navigates to the Home Screen"

How was edit your app with Copilot evaluated? What metrics are used to measure performance?

We evaluate the feature both qualitatively and quantitatively. To assess the quality of the feature, we're conducting user studies with makers to gather their feedback on their experiences, thoughts about the feature's quality, and suggestions for improvement. Additionally, we're monitoring telemetry data to track the number of makers who tried the feature, the success rate of the feature, and the ratio of positive to negative feedback. Before releasing the Copilot feature in preview, we conducted extensive testing to ensure its functionality. If you encounter any issues with the content generated, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of edit your app with Copilot? How can users minimize the impact of edit your app with Copilot limitations when using the system?

- To use this capability, you must have a Microsoft Dataverse database in your environment.
- Preview features aren't meant for production use and might have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.
- For more information, see preview terms.
- This capability is powered by Azure OpenAI Service.
- This capability is in process of rolling out, and might not be available in your region yet.
- This capability can be subject to usage limits or capacity throttling.
- Your environment must be in the United States region.
- This feature doesn't support non-English language input.

- This feature only supports limited controls and actions as listed in the intended use section. Microsoft is actively working on expanding the scope of this feature and support more actions incrementally.

What operational factors and settings allow for effective and responsible use of the system?

Here are some tips to help you get the most out of this feature:

- Use simple language to explain the changes you want to make to your app, such as "add a new screen" or "insert 2 buttons."
- If the results you get aren't what you expected, try being more precise. For example, you could say "add a new button to the selected container," "change the color of the selected button to red", or "display Screen 2 when Button1 is selected."
- You can also try using the default suggestions provided in the Copilot panel and then customize them to suit your needs. And if you still can't get the desired results, send us your feedback.

FAQ for Copilot chat in model-driven apps

05/28/2025

This FAQ describes the AI impact of Power Apps model-driven apps Copilot chat feature.

What is Copilot chat in model-driven apps?

Copilot chat for model-driven apps in Power Apps is a feature for app users to get insights about the data in their apps through conversation in natural language. Copilot chat helps app users boost their productivity through AI-powered insights and intuitive app navigation. This feature is available throughout the model-driven app.

What are the system's capabilities?

It can answer questions about the configured tables in an app, and aids in navigation through queries such as "Take me to *page name*."

What is the system's intended use?

As an AI assistant to end users, it provides answers to questions about the configured data in the app, and helps with app navigation.

How was Copilot chat in model-driven apps evaluated? What metrics are used to measure performance?

Copilot chat in model-driven apps underwent substantial testing before the feature was released in preview. If you encounter issues while using Copilot chat in model-driven apps, submit your feedback. Your feedback is used to improve Microsoft products and services. For more information, go to: Data, privacy, and security for Azure OpenAI Service

What are the limitations of Copilot chat in model-driven apps? How can users minimize the impact of the Copilot chat in model-driven apps limitations when using the system?

To use this capability your environment must be in the US region.

Copilot chat in model-driven apps is a preview feature. Preview features aren't meant for production use and may have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.

Copilot chat is not supported with the Power Apps mobile app.

This capability may be subject to usage limits or capacity throttling.

What operational factors and settings allow for effective and responsible use of the system?

Follow these procedures to make the most of the feature:

- Use everyday words to describe your question about the data:
  - "How many high priority tickets were created last month?"
  - "How many tickets were closed in July?"
- Clearly identify which page you want to navigate to:
  - "Take me to *page name*, " such as "Take me to Accounts."

Responsible AI FAQs for Power Apps

FAQ for Copilot control in canvas apps

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of Copilot control in canvas apps.

What is Copilot control in canvas apps?

Copilot control in canvas apps is a feature for app users to get insights about their data through conversation in natural language. Copilot control helps app users boost their productivity through AI-powered insights.

What are the system's capabilities?

It can answer questions about the data configured for the Copilot control in a canvas app.

What is the system's intended use?

As an AI assistant to end users, it provides answers to questions about the data configured for the Copilot control in a canvas app.

How was Copilot control in canvas apps evaluated? What metrics are used to measure performance?

Copilot control in canvas apps underwent substantial testing before the feature was released in preview. If you encounter issues while using Copilot control in canvas apps, please submit feedback. Your feedback will be used to improve Microsoft products and services. For more information, read the Privacy Statement.

What are the limitations of Copilot control in canvas apps? How can users minimize the impact of the Copilot control in canvas apps limitations when using the system?

To use this capability your environment must be in the US region. Preview features aren't meant for production use and may have restricted functionality. These features are available

before an official release so that customers can get early access and provide feedback. This capability may be subject to usage limits or capacity throttling. Currently, the Copilot control can only answer questions for smaller datasets. The only exception to this is when the Copilot control is configured with Dataverse.

What operational factors and settings allow for effective and responsible use of the system?

Follow these steps to make the most of the feature:

As a maker, you can:

- Configure the Copilot control to the appropriate data source, keeping in mind its limitation about smaller datasets except when configured with Dataverse.
- Edit the Copilot control properties to clarify what the control has been connected to and what it can answer questions about

As an app user, use everyday words to describe your question about the data such as:

- How many high priority tickets were created last month?
- How many tickets were closed in July?

FAQ about using Copilot in the rich text editor

Article • 05/28/2025

Here are some common questions and answers about using Copilot in the rich text editor.

What is Copilot in the rich text editor?

Copilot is a feature that uses AI to suggest content ideas based on your input. It helps you draft better content faster.

How does Copilot work?

Copilot uses advanced language models to generate content suggestions that match your tone, style, and purpose. You can choose from different types of content, such as emails, replies, or follow-ups. You can also adjust the tone and length of the content to suit your customers' preferences.

What can I use Copilot for?

You can use Copilot for various scenarios where you need to communicate with your customers effectively. For example, you can use Copilot to:

- Quickly create emails to follow up, reply to inquiries, and move a deal forward.
- Write engaging and personalized messages that resonate with your customers.
- Save time and energy by using ready-made content suggestions.

How do I use Copilot?

Using Copilot is easy and intuitive. Here are the steps to use Copilot in the rich text editor:

- Start typing your content in the rich text editor. You can use a word, a phrase, or a sentence as your input.
- Wait for Copilot to generate content suggestions based on your input. You can see the suggestions in a pop-up window next to your cursor.
- Choose the suggestion that best fits your needs. You can select on it to insert it into your content, or you can copy and paste it.
- Review and edit the content as needed. You can change the wording, add details, or delete parts of the content. Make sure the content is accurate, relevant, and appropriate

for your customers.
- Send the content to your customers when you're satisfied.

How did you evaluate Copilot?

We tested and evaluated Copilot on various datasets and scenarios to ensure its quality and performance. We used the following metrics to measure Copilot's performance:

- Accuracy: How well the content suggestions match the input and the context
- Relevance: How well the content suggestions address the customer's needs and expectations
- Diversity: How well the content suggestions offer different options and perspectives
- Readability: How easy the content suggestions are to read and understand

What are the limitations of Copilot in the rich text editor?

Copilot is a powerful and helpful feature, but it isn't perfect. It has some limitations that you should be aware of and respect. These limitations include:

- Language: Copilot only supports the English language for now. If you need to write in another language, you can't use Copilot.
- Suggestions: Copilot only provides suggestions, not final content. You're responsible for reviewing and editing the content before you send it to your customers. You shouldn't rely on Copilot to write your content for you.
- Ethics: Copilot is designed to help you create ethical and responsible content. However, Copilot may not be able to detect or prevent offensive, harmful, or misleading content. You should always use your own judgment and follow your company's policies and values when using Copilot.

Are there any settings I should change for effective and responsible use of Copilot in the rich text editor?

- Copilot in the rich text editor doesn't provide a way to change its behavior.
- Follow these suggestions to make the most of Copilot in the rich text editor:
    - Choose the right prompt to generate content and choose the right tone and length for the content. You can enter a group of keywords or a full sentence, but keep all the keywords on the same topic.

- Always review and edit Copilot's suggestions before sending them to your customer.

FAQ for Excel to table and app

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of the Excel to table and app feature.

What is Excel to table and app?

Excel to table and app allows makers to bring their own Excel file or SharePoint list and convert that to a Dataverse table and an app along with it. The feature accepts an Excel file or SharePoint list and produces a Dataverse table as the output. When a maker uses the feature from the home page or the **Apps** area, it can also generate an app based on the Dataverse table. When Copilot is enabled in the current environment, it leverages Azure OpenAI Service to generate the best-fitting table and column metadata based on the uploaded Excel file or SharePoint list.

What can Excel to table and app do?

Excel to table and app converts the first range of tabular data from the first tab of the uploaded Excel file or SharePoint list to a Dataverse table by generating column metadata and ingesting data to the created table. When Copilot capability is enabled in this environment, Copilot assists with the table creation by generating table names, descriptions, along with column names and data types based on the uploaded Excel data or SharePoint list.

What is/are Excel to table and app's intended use(s)?

Excel to table and app is intended to assist makers to migrate their existing data from Excel into Power Platform. It ensures new or less experienced makers can move away from their existing Excel file based system or SharePoint lists to Dataverse tables and be put in the position of having a working app connected to that data so they can understand how apps in Power Apps are built.

How was Excel to table and app evaluated? What metrics are used to measure performance?

We have set up reports and dashboards to track the usage, net promoter score (NPS), and engagement of the feature. We have also set up monitors to track the success rate of table

creation, data ingestion, and AI inference. Top errors that occur to the users are logged as part of our monitors to help us understand what's causing the issues.

What are the limitations of Excel to table and app? How can users minimize the impact of Excel to table and app's limitations when using the system?

- When Copilot is enabled for the environment, Excel to table and app currently produces metadata output in U.S. English, Czech, Danish, German, Spanish, Finnish, French, Italian, Dutch, Norwegian, Polish, Portuguese, Swedish, or Turkish. Users can manually update their metadata before creating their tables and apps to minimize the impact.
- The Copilot capability of Excel to table and app is currently supported in limited regions. Users located in regions that don't currently support this Copilot feature are still able to use the upload and table and app creation feature without Copilot assistance.
- The autogenerated metadata of Excel to table and app might not be 100% accurate. Users can minimize the impact by reviewing the metadata before table and app creation.

What operational factors and settings allow for effective and responsible use of Excel to table and app?

- Users can configure the metadata settings of the table including display name, plural name, description, primary column, and schema name. This affects the metadata settings of the table when the table is created.
- Users can configure the metadata settings of the columns of the table including display name, data type, format, whether the column is required, schema name, and some other settings specific to each selected data type, such as choices and default choice when the datatype is choices.
- Users can configure whether the table should use first row of data as column headers. When this is turned on, the first row of the uploaded Excel file or SharePoint list is used as the header of the table.
- Users can configure the ownership of the table. Ownership depends on whether the data of the table is owned by specific users, teams, or the entire organization.

- The Excel file uploaded by users is stored in Dataverse and isn't deleted automatically after table creation. If an Excel file contains personal data and a user wants to delete it, they must manually delete it from the File Upload table. Open the **File Upload** table in Power Apps (make.powerapps.com), select **Edit** in the **File Upload columns and data** area, and then delete the Excel file from the table.

How can I use this feature in a Power Platform environment that is created outside of the United States or Switzerland?

To do this, turn on data movement across regions. More information: Enable copilots and generative AI features outside United States and Switzerland

FAQ for SharePoint List to table and app

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of the SharePoint List to table and app feature.

What is SharePoint List to table and app?

SharePoint List to table and app allows makers to bring their own SharePoint List and convert that to a Dataverse table and an app along with it. The feature accepts a SharePoint List and produces a Dataverse table as the output. When a maker uses the feature from the home page or the Apps area, it can also generate an app based on the Dataverse table. When Copilot is enabled in the current environment, it leverages Azure OpenAI Service to generate the best-fitting table and column metadata based on the selected SharePoint List.

What can SharePoint List to table and app do?

SharePoint List to table and app converts the selected SharePoint List to a Dataverse table by generating column metadata and ingesting data from the SharePoint List to the created Dataverse table. When Copilot capability is enabled in this environment, Copilot assists with the table creation by generating column descriptions and data types based on the selected SharePoint List. Copilot will not read all of the customer data to generate the metadata. Copilot will not change any of the customer data from the original source.

What is/are SharePoint List to table and app's intended use(s)?

SharePoint List to table and app is intended to assist makers to migrate their existing data from SharePoint List into Power Platform. It ensures new or less experienced makers can move away from their existing SharePoint based system to Dataverse tables and be put in the position of having a working app connected to that data so they can understand how apps in Power Apps are built.

How was SharePoint List to table and app evaluated? What metrics are used to measure performance?

We have set up reports and dashboards to track the usage, net promoter score (NPS), and engagement of the feature. We have also set up monitors to track the success rate of table creation, data ingestion, and AI inference. Top errors that occur to the users are logged as part of our monitors to help us understand what's causing the issues.

What are the limitations of SharePoint List to table and app? How can users minimize the impact of SharePoint List to table and app's limitations when using the system?

When Copilot is enabled for the environment, SharePoint List to table and app will produce metadata output according to user's language setting if it's configured to be U.S. English, Czech, Danish, German, Spanish, Finnish, French, Italian, Dutch, Norwegian, Polish, Portuguese, Swedish, or Turkish. If user is not using one of the supported languages, Copilot will produce metadata in U.S. English by default. User can manually update their metadata before creating their tables and apps to minimize the impact.

The Copilot capability of SharePoint List to table and app is currently supported in limited regions. Users located in regions that don't currently support this Copilot feature are still able to use the SharePoint List to table and app feature without Copilot assistance.

The autogenerated metadata of SharePoint List to table and app might not be 100% accurate. Users can minimize the impact by reviewing the metadata before table and app creation.

What operational factors and settings allow for effective and responsible use of SharePoint List to table and app?

Users can configure the metadata settings of the table including display name, plural name, description, primary column, and schema name. This affects the metadata settings of the table when the table is created.

Users can configure the metadata settings of the columns of the table including display name, data type, format, whether the column is required, schema name, and some other settings specific to each selected data type, such as choices and default choice when the datatype is choices.

Users can configure the ownership of the table. Ownership depends on whether the data of the table is owned by specific users, teams, or the entire organization.

How can I use this feature in a Power Platform environment that is created outside of the United States or Switzerland?

To do this, turn on data movement across regions. More information: Enable copilots and generative AI features outside United States and Switzerland

FAQ about form fill assistance

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of form fill assistance in model-driven apps.

What is form fill assistance?

Form fill assistance provides users AI-generated optional suggestions for fields in a form based on the data they frequently use, or based on text or image they have copied and used smart paste (via button or keyboard shortcut) to paste into the form, or based on the file contents the user provides through the files capability. These suggestions are entirely optional, and don't get saved until the user explicitly accepts them.

What can form fill assistance do?

Based on user's recent usage of the app, or based on text or image they have copied and used smart paste (via button or keyboard shortcut) to paste into the form, or based on the file contents the user provides through the files capability, optional suggestions for empty form fields are shown. The user can choose to accept, reject, or ignore these suggestions. Ignoring these optional suggestions is equivalent to rejecting the suggestions. Suggestions also include citations for reference by users.

What is the intended use of form fill assistance?

Help users fill forms more efficiently by providing optional suggestions based on the user's recent app usage or based on text or image they have copied and used smart paste (via button or keyboard shortcut) to paste into the form, or based on the file contents the user provides through the files capability. Users always need to choose to accept these suggestions in order to save them, otherwise these suggestions automatically get discarded.

How was form fill assistance evaluated? What metrics are used to measure performance?

In our evaluations, we look at how good the suggestions are based on how often they're accepted in the form. We also look at how often suggestions are generated. Moreover, the suggestions are evaluated for satisfying Microsoft's responsible AI principles.

What are the limitations of form fill assistance? How can users minimize the impact of form fill assistance's limitations when using the system?

The suggestions are optional and AI-generated. Users should ensure these suggestions are accurate and appropriate before accepting them.

What operational factors and settings allow for effective and responsible use of form fill assistance?

Users are always required to review suggestions and explicitly accept the suggestions that are accurate and appropriate.

How do I provide feedback?

To provide feedback about this feature, users can provide feedback by providing a compliment, reporting a problem, or making a suggestion.

Related information

Use form filling assistance in model-driven apps

Responsible AI FAQ for Copilot in the timeline

05/28/2025

These frequently asked questions (FAQ) describe the AI impact in the timeline highlights feature.

What is Copilot in the timeline?

Copilot is a feature that uses AI to generate highlights based on timeline activities.

How does Copilot work?

Copilot uses advanced language models to generate content suggestions that refer to the activities in the timeline and generate highlights. Timeline highlights show details from activities such as notes, emails, tasks, appointments, phone calls, and conversations.

What can I use Copilot for?

You can use Copilot for various scenarios where you need to communicate with your customers effectively. For example, you can use Copilot to:

- Summarize activities in the timeline.
- Shorthand catchup on activities in the timeline for entities, such as Case, Account, Contact, Lead, Opportunity, and other custom entities where the timeline is available.
- Save time and energy by using ready-made activity highlights.

How do I use Copilot?

Using Copilot is easy and intuitive.

To use Copilot in the timeline:

1. Select the chevron in the **Timeline highlights** section, and then wait for Copilot to generate highlights based on activities in the timeline.
2. Do either of the following actions:
   a. Edit the highlights before reusing them: Select **Copy**, and then paste the highlights into a note and edit them as needed. You can change the wording, add details, or

delete parts of the content. Make sure the content is accurate, relevant, and appropriate for your customers.

b. Reuse the highlights as-is: Select **Copy**, and then paste the highlights in notes or wherever you want to share them.

3. Send the content to your collaborators.

How did you evaluate Copilot?

We tested and evaluated Copilot on various datasets and scenarios to ensure its quality and performance.

We used the following metrics to measure Copilot's performance:

- **Accuracy**: How well the generated highlights match the input and the context
- **Relevance**: How well the generated highlights address the customer's needs and expectations
- **Diversity**: How well the generated highlights offer different options and perspectives
- **Readability**: How easy the generated highlights are to read and understand

What are the limitations of Copilot in the timeline?

Copilot is a powerful and helpful feature, but it isn't perfect. It has some limitations that you should be aware of and respect. These limitations include:

- **Language**: Many languages are supported in Copilot scenarios. While the quality is expected to be highest in English, the quality in the other languages is expected to improve over time.

  The following languages are available for Copilot in the timeline:
  - Danish
  - Dutch
  - English
  - French
  - German
  - Italian
  - Japanese
  - Portuguese (Brazil)
  - Spanish
  - Thai

    - Simplified Chinese
    - Czech
    - Finnish
    - Greek
    - Korean
    - Norwegian (Bokmål)
    - Polish
    - Russian
    - Swedish
    - Turkish
    - Vietnamese

- **Suggestions**: Copilot only provides suggestions, not final content. You're responsible for reviewing and editing the content before you send it to your customers. You shouldn't rely on Copilot to write your content for you.

- **Ethics**: Copilot is designed to help you create ethical and responsible content. However, Copilot may not be able to detect or prevent offensive, harmful, or misleading content. You should always use your own judgment and follow your company's policies and values when using Copilot.

Are there any settings I should change for effective and responsible use of Copilot in the timeline?

Copilot in the timeline doesn't provide a way to change its behavior. Timeline highlights are generated based on the activities in timeline such as notes, emails, tasks, phone calls, appointments, and conversations.

Always review and edit Copilot's suggestions before sending them to your collaborators.

FAQ about using Copilot with Power Fx

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of using Copilot to write or explain Power Fx formulas.

What is Copilot for Power Fx?

Power Apps Studio has several features to help makers understand and write Power Fx. Makers can use the formula bar to explain code, or use Power Fx comments in the formula bar to describe a formula and receive a suggested Power Fx expression. Additionally, the inline action bar on supported controls provides the ability to describe a formula and receive a suggested formula and a suggested property to apply the formula to.

What are the system's capabilities?

- Write a comment in the formula bar that describes a formula to receive a suggested Power Fx expression.
- Receive an explanation for the current formula displayed in the formula bar.
- Open Copilot from a supported control's inline action bar to describe a formula and receive a suggested formula and suggested property to apply it to.

What is the system's intended use?

- Generate a single Power Fx expression from an English description.
- Generate an English description of the formula shown in the formula bar.

What languages are supported?

Because Power Fx can be used across many different features, each generally available (GA) feature may have a different set of supported languages the meet Microsoft's responsible AI standards. For details on language support for specific features see, Create Power Fx formulas with Copilot

How was Power Fx with Copilot evaluated? What metrics are used to measure performance?

We qualitatively test the model's Power Fx formula generation and descriptions against an internally built set of Power Fx formulas and descriptions. Additionally, we're monitoring telemetry data to track the number of makers who tried the feature, the success rate of the feature, and the ratio of positive to negative feedback. Before releasing the Copilot feature in preview, we conducted extensive testing to ensure its functionality. If you encounter any issues with the content generated, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of Power Fx with Copilot? How can users minimize the impact of Power Fx Copilot limitations when using the system?

- Named Formulas and User Defined Functions can't be generated with Copilot at this time.
- Variables have to be in use (declared) already for Copilot to use them, it doesn't introduce new variables.
- Preview features aren't meant for production use and might restrict functionality. These features are available before an official release so that customers can get early access and provide feedback.
- More information available in preview terms.
- This capability is powered by Azure OpenAI Service.
- This capability is in process of rolling out, and might not be available in your region yet.
- This capability can be subject to usage limits or capacity throttling.
- Your environment must be in the United States region.
- This feature doesn't support non-English language input.

What operational factors and settings allow for effective and responsible use of the system?

Here are some tips to help you get the most out of this feature:

- Use simple language to explain the formula you're looking for, such as "if myvariable is true, return green" or "filter mylist on IDs that are larger than 5".
- If the results you get aren't what you expected, try being more precise with exact names of variables, controls and field names, or try rephrasing the question.
- If you still can't get the desired results, send us your feedback.

FAQs for field suggestions by Copilot

05/28/2025

These frequently asked questions (FAQs) describe the AI impact of field suggestions by Copilot in Power Apps.

What is field suggestions by Copilot?

In Power Apps Studio, when a maker connects a gallery or form to a data table, Power Apps automatically selects certain system-generated key columns, such as ID, created on, or modified on. These columns might not be relevant to the app users. Moreover, makers have to manually select each field, which can be a tedious process for large data tables. With field suggestions, Copilot can recommend relevant columns to the gallery or form when the developer binds it to data using the table's metadata. This feature can save makers time in field configuration, thereby accelerating the app building process.

What are the system's capabilities?

At the time, a maker first binds to or changes data source of a gallery or form to a data table, Copilot will automatically suggest up to 10 of the most relevant fields. A maker must approve the suggestions for it to take effect. Makers can adjust the results easily as they change fields today.

Supported controls:

- Gallery
- Form (classic)
- Form (modern)
- Table (modern)
- Supported views and forms (model-driven apps)
- Quick view form
- Quick create form
- New view

Supported data sources:

- Dataverse
- SQL
- SharePoint list

What is the system's intended use?

The system is intended to help makers save time in app editing by preloading and selecting the most relevant fields when data source change happens.

How was field suggestions by Copilot evaluated? What metrics are used to measure performance?

We evaluate the feature both qualitatively and quantitatively. To assess the quality of the feature, we're conducting user studies with makers to gather their feedback on their experiences, thoughts about the feature's quality, and suggestions for improvement. Additionally, we're monitoring telemetry data to track the number of makers who tried the feature, the success rate of the feature, and the ratio of positive to negative feedback. Before releasing the Copilot feature, we conducted extensive testing to ensure its functionality. If you encounter any issues with the content generated, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of field suggestions by Copilot? How can users minimize the impact of field suggestions by Copilot limitations when using the system?

- Copilot will only use the table's metadata to make recommendations, it doesn't allow maker to provide natural language input to specify what columns they want. If you think this is critical, send us feedback.
- This capability is powered by Azure OpenAI Service.
- This capability is in the process of rolling out and might not be available in your region yet.
- This capability may be subject to usage limits or capacity throttling.
- Your environment must be in the United States region.
- This feature doesn't support non-English language input.
- This feature only supports limited controls and actions as listed in the intended use section. - Microsoft is actively working on expanding the scope of this feature and support more actions incrementally.

What operational factors and settings allow for effective and responsible use of the system?

Copilot will only read your table's metadata (so table name, description, column name, description, column's data type) to make recommendations and select fields. To yield the best quality, it's strongly recommended that when you create your data source, use meaningful names and descriptions for both the table and the columns.

Column suggestions by Copilot

FAQ on filtering, sorting, and searching Power Apps galleries with Copilot

05/25/2025

These frequently asked questions (FAQ) describe the AI effect of filtering, sorting, and searching Power Apps canvas galleries with Copilot.

What is filtering, sorting, and searching with Copilot?

Filtering, sorting, and searching with Copilot is a feature for users of Power Apps who want to filter their galleries using natural language. It surfaces in galleries of canvas apps that use SharePoint as their backend. There are plans to expand to other data sources in the future.

What are the system’s capabilities?

It takes the user's input and uses advanced language models to filter, sort, and search the gallery. The user can then add more filters, view and remove current filters, or accept to persist the filtered view.

What is the system’s intended use?

As an AI assistant to users, it filters the gallery based on the user's input.

How was filtering, sorting, and searching with Copilot evaluated? What metrics are used to measure performance?

We evaluate the feature both qualitatively and quantitatively. To assess the quality of the feature, we're conducting studies with users to gather feedback on their experiences, thoughts about the feature's quality, and suggestions for improvement. We're also monitoring customer data to track the number of users who tried the feature, the success rate of the feature, and the ratio of positive feedback to negative feedback.

Before releasing the feature in preview, we conducted extensive testing to ensure its functionality. If you encounter any issues with your experience, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins

have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of filtering, sorting, and searching with Copilot? How can users minimize the effect of the filtering, sorting, and searching with Copilot limitations when using the system?

- To use this capability, you must be a premium user.
- Preview features aren't meant for production use and might have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.
- For more information, go to preview terms.
- This capability is powered by Azure OpenAI Service.
- This capability might be subject to usage limits or capacity throttling.
- Your environment must be in the United States region or the **Move data across regions** checkbox must be selected in Power Platform admin center.
- This feature doesn't support non-English language input.

What operational factors and settings allow for effective and responsible use of the system?

If you get this error, **Sorry, Copilot can't help right now. Try again later.**, this might be due to capacity limits. We recommend that you give the system some time before trying again.

FAQ for agent builder in canvas apps

08/14/2025

These frequently asked questions (FAQ) describe the AI impact of agent builder in canvas apps.

What is agent builder?

Agent builder lets users create copilot agents to automate their processes. The goal of agent builder is to help users create copilot agents using their existing applications. Agent builder takes your app metadata and the desired agent goal to create a step-by-step process the user currently takes to complete the process they're looking to automate. This process is then combined with deterministically extracted skills from the app to create a Copilot Studio copilot on the user's behalf with instructions, actions, triggers, and knowledge. Once created, the user can edit, test, and publish the agent through Microsoft Copilot Studio.

What can agent builder do?

Agent builder can help a user create an agent. Agent builder can generate suggestions for which processes within an app we can automate. Using the suggestion and/or the sentence the user provided for what the desired goal for the agent is agent builder provides a process for how the user currently completes the task. Agent builder also extracts actions, triggers, and knowledge from the app metadata. Using the process instructions generated from agent builder and the triggers, knowledge, and actions extracted from agent builder the user can edit, test, and publish the agent in Microsoft Copilot Studio.

What is the intended use of agent builder?

The intended use of agent builder is to create agents to automate processes with a focus on data entry. The system allows the user to automate the process of data through generating an agent that takes on the steps the user would take to accomplish the task. The system wasn't designed, and we don't recommend customers to create agents for medical, legal, or hiring purposes. Agent builder was also not designed to be used to create an agent that has nothing to do with the app or generate an agent from an app that has no content.

How was agent builder evaluated? What metrics are used to measure performance?

We qualitatively tested the model's agent generation capabilities by testing against an internal set of benchmark applications and expected high quality agent outputs. Additionally, we have set up reports and dashboards to track the usage, net promoter score (NPS), and engagement of the feature. We have also set up monitors to track the success rate of agent generation, app understanding, and AI inference. Top errors that occur to the users are logged as part of our monitors to help us understand what's causing the issues. If you encounter any issues with the content generated, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of agent builder? How can users minimize the impact of agent builder's limitations when using the system?

- This feature is only currently available for Power Apps canvas applications.
- This capability is powered by Azure OpenAI Service.
- This capability is in the process of rolling out and might not be available in your region yet.
- This capability can be subject to usage limits or capacity throttling.

What operational factors and settings allow for effective and responsible use of agent builder?

Follow these procedures to make the most out of the feature:

- Use everyday words to describe the desired goal for agent:
  - "Submit completed claim forms to the database for processing"
  - "Generate reports for claims filed within a specific date range"
- Review all suggestions for accuracy and appropriateness before proceeding to the next step.

Authenticating actions after publishing

If your agent is missing authentication to perform an action or is configured to request user authentication, it sends a message to the user asking for credentials. If an agent's flow is

interrupted because it can't receive information or an action failed, it can't continue the session. If you want your agent to run autonomously, each action must be configured with working maker authentication that doesn't require user input. You can also instruct your agent to not request credentials from users.

Because triggers use maker authentication, be aware of what data potential users can access through a published agent that has triggers. See the Data protection with triggers section for more information.

Build an agent to automate your business process

FAQ for plans in Power Apps

Summarize this article for me

What is plans?

Plans in Power Apps is an AI-powered experience that builds an end-to-end business solution in minutes. Describe your business problem in natural language and include images, like a screenshot of a legacy app or a process diagram. Plans outlines user roles and requirements, and generates a complete Power Platform solution with objects like Dataverse tables, Power Apps (canvas and model-driven apps), Power Automate cloud flows, Power Pages sites, Power BI, and Microsoft Copilot Studio agents. You can iterate and refine your business requirements in your plan to get a more precise solution that fits your needs. In the latest preview features, makers will be able to see a fully functioning code app generated by AI that will directly address the business problem and saving makers more time.

What can plans do?

Plans builds an end-to-end business solution based on a description of a business problem and can include images, like a legacy app or process diagram. A complete plan outlines user roles and requirements, and includes an end-to-end Power Platform solution with objects like Dataverse tables, Power Apps (canvas and model-driven apps), Power Automate cloud flows, Power Pages, Power BI, and Microsoft Copilot Studio agents. It can also generate a code app based on the business requirements and data objects using the latest preview features.

What is plans intended use?

Plans lets makers describe their business problem and quickly get a comprehensive plan and a working code app. The plan includes user stories, data schema, and apps, flows, and agents to build. This approach saves time and helps users learn and integrate different Power Platform products.

The plan also serves as documentation that users can refer to later.

How was plans evaluated? What metrics are used to measure performance?

We evaluate the feature both qualitatively and quantitatively. To check quality, we conduct user studies with makers to get feedback on their experiences, thoughts about the feature's quality,

and suggestions for improvement. Also, monitor telemetry data to track the number of makers who try the feature, the feature's success rate, and the ratio of positive to negative feedback. Before releasing the feature, run extensive testing to check its functionality. If you find any issues with the generated content, provide feedback. Microsoft uses your feedback to improve products and services. Your organization's IT admins can access your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of plans? How can users minimize the impact of system or product name's limitations when using the system?

- To use this capability, you need a Microsoft Dataverse database in your environment.
- This capability is powered by Azure OpenAI Service.
- This capability can be subject to usage limits or capacity throttling.
- This feature lets you use a maximum input size of 4,000 tokens, including both text and images (about 3,000 words if your input only has text).
- ThePower Apps vibe experience is onlyavailable in English.

What operational factors and settings allow for effective and responsible use of plans?

- Use these tips to get the most out of this feature:
- Clearly describe the business problems end to end, including the types of user involved and the tasks they need to finish.
- If you upload an image, explain what the image shows in the text and explicitly ask plan designer to use it. For example, say "Use the ERD attached."
- If the results aren't what you expect, keep iterating the plan by selecting the specific part you want to edit and typing your requirement.
- Try the default suggestions in the banner, then customize them to suit your needs. If you still can't get the results you want, send us your feedback.

How do I provide feedback for plans?

- Select the thumbs up or thumbs down in the plan document to provide feedback on a specific section.
- Select the **Give feedback** icon in the command bar to provide general feedback for your experience usings plans.

FAQ for rename controls in canvas apps with Copilot

05/25/2025

These frequently asked questions (FAQ) describe the AI impact of Power Apps rename controls in canvas apps with Copilot feature.

What is rename Canvas controls with Copilot?

With rename canvas controls with Copilot feature, makers can delegate renaming Canvas controls during app development to an AI assistant. When makers rename a control manually, they can expect Copilot to show up with renaming suggestions for other controls with valid property value. Makers can preview the suggestions before applying, ensuring full control over Copilot's suggestions. This feature's goal is to save makers time and effort otherwise spent manually renaming controls one by one, ensuring app maintainability and easy reference of controls in logic.

What are the system’s capabilities?

The following system capabilities are supported:

- Provide control rename suggestions based on primary property of the controls and naming convention/pattern used by maker during manual rename.
- Enable makers to apply all or selected rename suggestions.
- Apply rename to multiple controls at once, per the suggestions shown in preview.
- Copilot nudges the maker when they manually rename a control, and there are other controls of the same type under the same screen with valid, nondefault value such as **Button** or **Text** in **Text** property.
- Text property can be a Text literal or a formula returning Text type.
- Any formulas referencing the control name is automatically updated to use the rename.

The following controls are supported:

- Button
- Label

Support for more controls is coming soon.

What is the system’s intended use?

As an AI assistant that helps people rename Canvas controls, Copilot provides the following list of UI actions for makers that are included in the preview release scope:

- Click on Copilot icon when it appears near Tree View after a manual rename action.
- Copilo only appears if there are other controls of the same type under the same screen with valid, nondefault value such as **Button** or **Text** in **Text** property.
- Preview control renaming suggestions provided by Copilot.
- Apply one or more rename suggestions at once.

How was rename Canvas controls with Copilot evaluated? What metrics are used to measure performance?

We evaluate the feature both qualitatively and quantitatively. To assess the quality of the feature, we're conducting user studies with makers to gather their feedback on their experiences, thoughts about the feature's quality, and suggestions for improvement. Additionally, we're monitoring telemetry data to track the number of makers who tried the feature and the success rate and acceptance rate of the feature. Before releasing the Copilot feature in preview, we conducted extensive testing to ensure its functionality. If you encounter any issues with the content generated, provide feedback. Your feedback is used to enhance Microsoft's products and services. Your organization's IT admins have access to your feedback data for management purposes. For more information, read the Privacy Statement.

What are the limitations of rename Canvas controls with Copilot? How can users minimize the impact of rename Canvas controls with Copilot limitations when using the system?

- Preview features aren't meant for production use and might have restricted functionality. These features are available before an official release so that customers can get early access and provide feedback.
- For more information, see preview terms.
- This capability is powered by Azure OpenAI Service.
- This capability is in process of rolling out, and might not be available in your region yet.
- This capability can be subject to usage limits or capacity throttling.
- Your environment must be in the United States region.
- This feature doesn't support non-English language input.

- This feature only supports limited controls and actions as listed in the intended use section. Microsoft is actively working on expanding the scope of this feature and support more controls incrementally.

What operational factors and settings allow for effective and responsible use of the system?

Here are some tips to help you get the most out of this feature:

- Use this feature after Text property of controls has been set to ensure quality results from Copilot. For example, a button with default Text property value "Button" or invalid Text property value If() won't be considered for rename. And if you still can't get the desired results, send us your feedback.
- Use standard and relevant name and naming pattern when manually renaming a control so Copilot can reference it while suggesting renames. Avoid use of special characters and space. For example, renaming a button to "collectResponse" will provide better renaming suggestions for other buttons than "collect_1"
- Ensure New Analysis Engine app setting is enabled in your app. Go to Settings, click Updates, New, and then turn on New analysis engine toggle to true.

Rename controls in canvas apps with Copilot (preview)

FAQ about Copilot visualizations on a view (preview)

05/28/2025

These frequently asked questions (FAQ) describe the AI impact of in visualizing data in a view.

What are Copilot visualizations on a view?

Copilot-generated visualization provides users with an option to view AI-generated chart for the rows in a view in a model-driven app. Users can select the Visualize button on the view page to see an AI-generated chart that aggregates the records in the view to show trends and distributions.

What can Copilot visualizations do?

Copilot-generated visualizations are generated based on the columns in the view. Users can change the chart or select areas of the chart to drill into the visualization generated by Copilot to do data analysis.

What is the intended use of Copilot visualizations?

Copilot-generated visualizations are intended for users to visualize the rows of data in a view as a chart. Users can apply filters or change chart type to personalize the chart, and interact with the chart and the tabular data side by side to explore the data in the app.

How were Copilot visualizations evaluated? What metrics are used to measure performance?

We continuously evaluated and tested Copilot visualization with different datasets and scenarios to measure quality and performance. We evaluated the accuracy and relevance of the chart generated for a view based on the type of data visualized. The type of charts generated were also evaluated for satisfying Microsoft's responsible AI principles.

What are the limitations of Copilot visualizations? How can users minimize the impact of the limitations when using the system?

Copilot visualizations are not shown to users by default. Users need to select the Visualize option on the page to see AI-generated chart. Copilot visualizations present users with a suggested chart for the data that users can review and edit. In addition, this capability is only available for environments with English as the base language.

What operational factors and settings allow for effective and responsible use of Copilot charts?

Users need to select the Visualize option on the page to see AI-generated chart. Copilot visualizations present users with a suggested chart for the data that users can review and edit.

How do I provide feedback on Copilot charts?

To provide feedback about this feature, users can select the thumbs up or thumbs down button and optionally, type in comments to describe their feedback and submit their response.

Visualize data in a view with Copilot

FAQ for Agent APIs and Agent Response component

06/18/2025

These frequently asked questions (FAQ) describe the AI impact of Agent APIs feature in model-driven apps.

What is Agent APIs and Agent Response component?

Microsoft Power Apps has introduced APIs and code components designed to interface with the topics created within Microsoft Copilot Studio (MCS) from model-driven apps. These APIs are available as XRM and PCF. The code component is available in the Form Designer to be added to forms.

What are capabilities of the Agent APIs and Agent Response component?

The new APIs can either call a specific topic in MCS or send a prompt that MCS orchestrates. The response from both APIs is a JSON structure the caller can use within their model driven app. The APIs are available for use in the Xrm events of model driven apps and also use within custom PCF control.

The Agent Response component provides a simplified component to call the Agent API with a topic for MCS. The component renders the results of the MCS response in the form.

What is the intended use of the Agent APIs and Agent Response component?

The APIs are intended to allow customization of model driven apps to include application calls to MCS and allow the results to be integrated into the app. It provides a simplified process to call MCS.

How was Agent APIs and Agent Response component evaluated? What metrics are used to

measure performance?

In our evaluations, we look at how accurately the response is from MCS. MCS responses are evaluated for satisfying Microsoft's responsible AI principles.

What are the limitations of Agent APIs and Agent Response component? How can users minimize the impact of the Agent APIs limitations when using the system?

The APIs and component are optional for makers to use and makers need to consider how best to use the APIs and component within their customizations.

What operational factors and settings allow for effective and responsible use of the feature?

Makers are required to ensure that the MCS topics are returning accurate and appropriate responses. Makers using the API are responsible to handle the response as part of their customization.

In addition, makers are strongly encouraged to indicate to users where AI has been used in the user experience. This is like how Microsoft shows "AI-generated content may be incorrect".

FAQ about generative pages in model-driven apps

These frequently asked questions (FAQ) describe the AI impact of generative pages in model-driven apps.

What are generative pages?

Generative pages simplify the app design process for model-driven app makers through AI code generation. By describing their needs in natural language, makers can create fully structured pages in their apps. The system processes these requirements and intelligently generates React code that covers both the frontend user experience and business logic, ensuring modern, consumer-grade UI experiences for enterprise applications. Makers must publish these pages before they're available to users in apps.

What can you do with generative pages?

With generative pages, makers can create and refine app pages in real time through an interactive, conversational experience. They can adjust elements, layout, and functionality to perfectly match their vision. This capability helps ensure designs adhere to best practices and deliver high-quality user experiences, making the app development process more efficient and intuitive. When makers are satisfied with the generated page, they can publish them so they're available when playing the app.

What is the intended use of generative pages?

The intended use of generative pages is to streamline the app design process for model-driven app makers. By leveraging AI to generate React code based on natural language descriptions, makers can quickly create pages that meet their specific requirements. This tool is designed to enhance productivity and ensure that app designs are both functional and visually appealing.

How were generative pages evaluated? What metrics are used to measure performance?

In our evaluations, we measure how often the agent can generate syntactically correct code, and we also test how good the code generation is in terms of UX design and meeting functional requirements. Moreover, the agent is evaluated for satisfying Microsoft’s responsible AI principles.

Are the images from the include images option AI-generated?

No. When the **Include images** option is enabled, the resulting images aren't AI-generated. They're sourced from a library of curated stock images. The option only decides whether images are needed based on the prompt and then selects the most relevant images from this library.

What are the limitations of generative pages? How can users minimize the impact of generative page limitations when using the system?

The current limitations of generative pages include:

- Pages can only connect to Dataverse tables and perform CRUD operations.
- Generative pages are only available in US environments.
- The code generated by generative pages isn't guaranteed to be production-ready or compliant with your organization's standards.
  - While the agent makes a best-effort attempt to produce high-quality code with accessibility and security best practices in mind, you're responsible for validating the code output to ensure it aligns with your organizational policies and compliance requirements.

Makers can minimize the impact of these limitations by testing any generated code before publishing it to users.

What operational factors and settings allow for effective and responsible use of generative pages?

Effective and responsible use of generative pages involves setting clear guidelines for app design requirements and ensuring that makers provide comprehensive descriptions. Regular training on best practices for using the tool and monitoring its performance can help maintain high standards. Additionally, incorporating user feedback and continuously improving the system based on real-world usage can enhance its effectiveness.

Makers are always required to publish generative pages before they're made available to users. Extensive testing of any code before making it available to users in an app is always encouraged.

FAQ about Power Apps MCP server invoke_data_entry tool

These frequently asked questions (FAQ) describe the AI impact of Power Apps MCP Server invoke_data_entry tool in Power Apps.

What is the invoke_data_entry tool in Power Apps MCP?

Create your own AI agent that utilizes the Power Apps MCP Server's invoke_data_entry tool to create records in Dataverse. This tool accepts various formats of unstructured input, such as PDF or Excel files, and creates draft records in Microsoft Dataverse based on the inputs. You can review and edit these draft records using the agent feed, and save to Dataverse once ready.

What can the invoke_data_entry tool do?

The invoke_data_entry tool can accept unstructured inputs, such as PDF or Excel files, parse them, and identify how to fill in Dataverse forms from these unstructured inputs in order to create a record. These are presented as suggestions for users to review in agent feed, where users can choose to save them to Dataverse. At this time, no records get automatically created in Dataverse.

What is the invoke_data_entry tool's intended use(s)?

The data entry agent (form fill) tool can take an unstructured input, such as PDF or Excel files, and create a Dataverse record based on its contents. This is a manual process today, but with the tool, customers can create an agent to automatically create a draft record. This draft can be reviewed in the agent feed, and once the user chooses to save, the record gets written to Dataverse.

How was the invoke_data_entry tool evaluated? What metrics are used to measure performance?

In our evaluations, we look at how good the suggestions are based on the provided input files, and how often they're accepted in the form to be saved in the record in Dataverse. Moreover, the suggestions are evaluated for satisfying Microsoft's responsible AI principles.

What are the limitations of the invoke_data_entry tool? How can users minimize the impact of invoke_data_entry tool's limitations when using the system?

At this time, the invoke_data_entry tool only supports a limited number of unstructured input formats, and only creates records in Dataverse. The tool isn't supported for use with an unsupported input format or for creating records in a non-Dataverse data source.

What operational factors and settings allow for effective and responsible use of the invoke_data_entry tool?

The invoke_data_entry tool is effective when used with the supported file formats provided as inputs, and is used to create records in Dataverse. Agent feed must be used by users to review invoke_data_entry tool's draft records and saving these to Dataverse once ready.

How do I provide feedback on the invoke_data_entry tool?

Users can provide feedback on the invoke_data_entry tool while reviewing the draft records in the agent feed.
