Virtual machines in Azure

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

Azure virtual machines (VMs) are one of several types of on-demand, scalable computing resources that Azure offers. Typically, you choose a virtual machine when you need more control over the computing environment than the other choices offer. This article gives you information about what you should consider before you create a virtual machine, how you create it, and how you manage it.

An Azure virtual machine gives you the flexibility of virtualization without having to buy and maintain the physical hardware that runs it. However, you still need to maintain the virtual machine by performing tasks, such as configuring, patching, and installing the software that runs on it.

Azure virtual machines can be used in various ways. Some examples are:

- **Development and test** – Azure virtual machines offer a quick and easy way to create a computer with specific configurations required to code and test an application.
- **Applications in the cloud** – Because demand for your application can fluctuate, it might make economic sense to run it on a virtual machine in Azure. You pay for extra virtual machines when you need them and shut them down when you don't.
- **Extended datacenter** – virtual machines in an Azure virtual network can easily be connected to your organization's network.

What do I need to think about before creating a virtual machine?

There's always a multitude of design considerations when you build out an application infrastructure in Azure. These aspects of a virtual machine are important to think about before you start:

- The names of your resources
- The location where the resources are stored
- The size of the virtual machine
- The maximum number of virtual machines that can be created
- The operating system that the virtual machine runs

- The configuration of the virtual machine after it starts
- The related resources that the virtual machine needs

> **Note**
>
> Trusted Launch as default (TLaD) is available in preview for new Generation 2 Virtual machines (VMs). With TLaD, any new Generation 2 VMs created through any client tools defaults to Trusted Launch with secure boot and vTPM enabled. Register for the TLaD preview to validate the default changes in your respective environment and prepare for the upcoming change.

Parts of a VM and how they're billed

When you create a virtual machine, you're also creating resources that support the virtual machine. These resources come with their own costs that should be considered.

The default resources supporting a virtual machine and how they're billed are detailed in the following table:

Expand table

Resource	Description	Cost
Virtual network	For giving your virtual machine the ability to communicate with other resources	Virtual Network pricing
A virtual Network Interface Card (NIC)	For connecting to the virtual network	There's no separate cost for NICs. However, there's a limit to how many NICs you can use based on your VM's size. Size your VM accordingly and reference Virtual Machine pricing.
A private IP address and sometimes a public IP address.	For communication and data exchange on your network and with external networks	IP Addresses pricing
Network security group (NSG)	For managing the network traffic to and from your VM. For example, you might need to open port 22 for SSH access, but you might want to block traffic to port 80. Blocking and allowing port access is done through the NSG.	There are no additional charges for network security groups in Azure.

Resource	Description	Cost
OS Disk and possibly separate disks for data.	It's a best practice to keep your data on a separate disk from your operating system, in case you ever have a VM fail, you can detach the data disk, and attach it to a new VM.	All new virtual machines have an operating system disk and a local disk. Azure doesn't charge for local disk storage. The operating system disk, which is usually 127GiB but is smaller for some images, is charged at the regular rate for disks. You can see the cost for attach Premium (SSD based) and Standard (HDD) based disks to your virtual machines on the managed disks pricing page.
In some cases, a license for the OS	For providing your virtual machine runs to run the OS	The cost varies based on the number of cores on your VM, so size your VM accordingly. The cost can be reduced through the Azure Hybrid Benefit.

You can also choose to have Azure can create and store public and private SSH keys - Azure uses the public key in your VM and you use the private key when you access the VM over SSH. Otherwise, you need a username and password.

By default, these resources are created in the same resource group as the VM.

Locations

There are multiple geographical regions around the world where you can create Azure resources. Usually, the region is called **location** when you create a virtual machine. For a virtual machine, the location specifies where the virtual hard disks are stored.

This table shows some of the ways you can get a list of available locations.

Expand table

Method	Description
Azure portal	Select a location from the list when you create a virtual machine.
Azure PowerShell	Use the Get-AzLocation command.
REST API	Use the List locations operation.

Method	Description
Azure CLI	Use the az account list-locations operation.

Availability

There are multiple options to manage the availability of your virtual machines in Azure.

- **Availability Zones** are physically separated zones within an Azure region. Availability zones guarantee virtual machine connectivity to at least one instance at least 99.99% of the time when you have two or more instances deployed across two or more Availability Zones in the same Azure region.
- **Virtual Machine Scale Sets** let you create and manage a group of load balanced virtual machines. The number of virtual machine instances can automatically increase or decrease in response to demand or a defined schedule. Scale sets provide high availability to your applications, and allow you to centrally manage, configure, and update many virtual machines. Virtual machines in a scale set can also be deployed into multiple availability zones, a single availability zone, or regionally.

Fore more information see Availability options for Azure virtual machines and SLA for Azure virtual machines.

Sizes and pricing

The size of the virtual machine that you use is determined by the workload that you want to run. The size that you choose then determines factors such as processing power, memory, storage capacity, and network bandwidth. Azure offers a wide variety of sizes to support many types of uses.

Azure charges an hourly price based on the virtual machine's size and operating system. For partial hours, Azure charges only for the minutes used. Storage is priced and charged separately.

Scaling to multiple VMs

The number of virtual machines that your application uses can scale up and out to whatever is required to meet your needs. Azure offers several automatic scaling systems and instance types based on the size of your workload. For more information on scaling, compare VM-based compute products.

Virtual machine total core limits

Your subscription has default quota limits in place that could impact the deployment of many virtual machines for your project. The current limit on a per subscription basis is 20 virtual machine total cores per region. Limits can be raised by filing a support ticket requesting an increase Quota and capacity are checked separately during deployment. Even with approved quota, deployment can still fail if there isn't enough capacity in the target region or availability zone.

Managed disks

Managed disks handles Azure Storage account creation and management in the background for you, and ensures that you don't have to worry about the scalability limits of the storage account. You specify the disk size and the performance tier (Standard or Premium), and Azure creates and manages the disk. As you add disks or scale the virtual machine up and down, you don't have to worry about the storage being used. If you're creating new virtual machines, use the Azure CLI or the Azure portal to create virtual machines with Managed OS and data disks. If you have virtual machines with unmanaged disks, you can convert your virtual machines to be backed with managed disks.

You can also manage your custom images in one storage account per Azure region, and use them to create hundreds of virtual machines in the same subscription. For more information about managed disks, see the managed disks Overview.

Distributions

Microsoft Azure supports various Linux and Windows distributions. You can find available distributions in the marketplace, Azure portal or by querying results using CLI, PowerShell, and REST APIs.

This table shows some ways that you can find the information for an image.

Expand table

Method	Description
Azure portal	The values are automatically specified for you when you select an image to use.
Azure PowerShell	Get-AzVMImagePublisher -Location *location* Get-AzVMImageOffer -Location *location* -Publisher *publisherName*

Method	Description
	Get-AzVMImageSku -Location *location* -Publisher *publisherName* -Offer *offerName*
REST APIs	List image publishers List image offers List image skus
Azure CLI	az vm image list-publishers --location *location* az vm image list-offers --location *location* --publisher *publisherName* az vm image list-skus --location *location* --publisher *publisherName* --offer *offerName*

Microsoft works closely with partners to ensure the images available are updated and optimized for an Azure runtime. For more information on Azure partner offers, see the Azure Marketplace

Cloud-init

Azure supports for cloud-init across most Linux distributions that support it. We're actively working with our Linux partners to make cloud-init enabled images available in the Azure Marketplace. These images make your cloud-init deployments and configurations work seamlessly with virtual machines and virtual machine scale sets.

For more information, see Using cloud-init on Azure Linux virtual machines.

Storage

- Introduction to Microsoft Azure Storage
- Add a disk to a Linux virtual machine using the azure-cli
- How to attach a data disk to a Linux virtual machine in the Azure portal

Local temporary storage

Some Azure VM sizes include local temporary ephemeral storage, with some of the newer sizes using Temporary local NVMe disks. Local temporary storage uses additional disks provisioned directly as local storage to an Azure virtual machine host, rather than on remote Azure Storage. This type of storage is best suited for data that does not need to be retained permanently, such as caches, buffers, and temporary files. Since data stored on these disks isn't backed up, it's lost when the VM is deallocated or deleted. The ephemeral storage is recreated on startup. Local ephemeral disks are different from Ephemeral OS disks.

Local temporary disks present just like other remote storage such as Premium SSD v2 disks, but have added performance benefits and don't count against the IOPS and throughput limits of the VM.

The following lists key characteristics of local ephemeral storage:

- **Ultra-low latency**: Read/write operations occur on hardware physically co-located with the VM's compute resources, minimizing network hops and enabling sub-millisecond response times.
- **Superior IOPS and throughput**: Performance scales with the underlying local storage, often delivering 8-10 times higher IOPS than Standard HDDs when using Premium SSD as the base, with limits tied to the VM size (up to the NVMe disk capacity, capped at 2,040 GiB).

Azure VM sizes featuring a 'd' in their naming convention - such as the Da***d***sv6, Ea***d***sv6, and FXm***d***sv2 series - include dedicated local NVMe storage. These sizes enable placing temporary files, swap space, or high-I/O components like SQL Server's `tempdb` database files on the ephemeral disk for enhanced performance.

Service disruptions

At Microsoft, we work hard to make sure that our services are always available to you when you need them. Forces beyond our control sometimes impact us in ways that cause unplanned service disruptions.

Microsoft provides a Service Level Agreement (SLA) for its services as a commitment for uptime and connectivity. The SLA for individual Azure services can be found at Azure Service Level Agreements.

Azure already has many built-in platform features that support highly available applications. For more about these services, read Disaster recovery and high availability for Azure applications.

This article covers a true disaster recovery scenario, when a whole region experiences an outage due to major natural disaster or widespread service interruption. These are rare occurrences, but you must prepare for the possibility that there's an outage of an entire region. If an entire region experiences a service disruption, the locally redundant copies of your data would temporarily be unavailable. If you enabled geo-replication, three additional copies of your Azure Storage blobs and tables are stored in a different region. In the event of a complete regional outage or a disaster in which the primary region isn't recoverable, Azure remaps all of the DNS entries to the geo-replicated region.

In the case of a service disruption of the entire region where your Azure virtual machine application is deployed, we provide the following guidance for Azure virtual machines.

Option 1: Initiate a failover by using Azure Site Recovery

You can configure Azure Site Recovery for your VMs so that you can recover your application with a single click in matter of minutes. You can replicate to Azure region of your choice and not restricted to paired regions. You can get started by replicating your virtual machines. You can create a recovery plan so that you can automate the entire failover process for your application. You can test your failovers beforehand without impacting production application or the ongoing replication. In the event of a primary region disruption, you just initiate a failover and bring your application in target region.

Option 2: Wait for recovery

In this case, no action on your part is required. Know that we're working diligently to restore service availability. You can see the current service status on our Azure Service Health Dashboard.

This option is the best if you don't set up Azure Site Recovery, read-access geo-redundant storage, or geo-redundant storage prior to the disruption. If you set up geo-redundant storage or read-access geo-redundant storage for the storage account where your VM virtual hard drives (VHDs) are stored, you can look to recover the base image VHD and try to provision a new VM from it. This option isn't preferred because there are no guarantees of synchronization of data, which means this option isn't guaranteed to work.

> **Note**
>
> Be aware that you don't have any control over this process, and it will only occur for region-wide service disruptions. Because of this, you must also rely on other application-

specific backup strategies to achieve the highest level of availability. For more information, see the section on Data strategies for disaster recovery.

Resources for service disruptions

- Start protecting your applications running on Azure virtual machines using Azure Site Recovery
- To learn more about how to implement a disaster recovery and high availability strategy, see Disaster recovery and high availability for Azure applications.
- To develop a detailed technical understanding of a cloud platform's capabilities, see Azure resiliency technical guidance.
- If the instructions aren't clear, or if you would like Microsoft to do the operations on your behalf, contact Customer Support.

Data residency

In Azure, the feature to enable storing customer data in a single region is currently only available in the Southeast Asia Region (Singapore) of the Asia Pacific Geo and Brazil South (Sao Paulo State) Region of Brazil Geo. For all other regions, customer data is stored in Geo. For more information, see Trust Center.

Compare virtual machine-based compute products

Article • 05/07/2025

Microsoft Azure offers various virtual machine based compute products designed to meet different workload requirements. Standard Virtual Machines (VMs), Virtual Machine Scale Sets (VMSS), and Compute Fleet are some of the compute products that provide flexibility and scalability for various applications.

Virtual Machines (VMs) are the fundamental building blocks of Azure compute. They offer full control over the operating system and applications, making them suitable for a wide range of workloads. VMs provide the flexibility to choose the operating system, size, and configuration that best fits your needs.

Virtual Machine Scale Sets (VMSS) extend the capabilities of VMs by enabling the deployment and management of a group of VMs. This service is ideal for applications that require high availability or scalability. VMSS can ensure that your applications can handle varying loads efficiently by automatically increasing or decreasing the number of VMs in response to changes in demand.

Compute Fleet is designed for large-scale, distributed computing environments. It allows you to manage and orchestrate a fleet of VMs across multiple regions and availability zones. This service is particularly beneficial for high-performance computing (HPC) applications, big data processing, and other workloads that require significant computational power and distributed resources.

The product you select depends on the workload you intend to run. Check out the product comparison table in this article or in the Azure portal to choose between these solutions.

Product comparison table

Expand table

	Virtual Machines	**Virtual Machine Scale Sets**	**Compute Fleet**
Product Description	Create and manually configure individual VMs.	Load-balanced, automatically scaling VM groups with workload optimization across multiple availability zones.	Provision thousands of mixed-size VMs for performance and high availability.

	Virtual Machines	Virtual Machine Scale Sets	Compute Fleet
Instances	Single instances deployed individually	2 to 1,000 instances	Up to 10,000 instances
Product Differences See top product capabilities and limitations side by side	- Deploy and manage each VM individually - Fine-tune custom applications - Assigned to one availability zone at a time	- Up to 1,000 mixed-size VMs in a group - Scale automatically - Fault domains for high availability - Integrate Azure Spot VMs to cut costs - Optimized for stateless or stateful workloads	- Up to 10,000 mixed-size VMs in a group - Fault domains for high availability - Hyper-scale with demand - Maintain capacity with Spot VMs to cut costs - Optimize allocation by price, capacity, or both
Use Case Find the right product for your project	- Small, simple jobs - Specialized single-instance apps - Test configurations and experiment with Azure	- Scaling beyond a single VM - Platform engineering or infrastructure as code - Moving on-premises apps to the cloud - Parallelized high-performance computing workloads - Databases - Batch processing - Maintain performance while controlling costs - Mix VM sizes for more flexibility	- Large scale, highly parallelized workloads or batch jobs - Flexibility with VM sizes - Large scale cost optimization with Azure Spot

Product specifications

Cost

The cost of any Azure VM environment depends upon the number of VM instances, their configuration, and selected add-on services. There's no added charge for using Virtual Machine Scale Sets or Compute Fleet.

Expand table

Virtual Machines	Virtual Machine Scale Sets	Compute Fleet
- Billed as an individual VM instance - Cost-effective for consistent load and traffic	**Optimize costs with VMSS** - VMSS can automatically use less capacity when load/traffic is low, and optimizes cost while accommodating the dips and spikes of cyclical, intermittent, and growing workloads - Use 100% Spot VMs, or mix with standard ones, to cut cost	**Optimize costs with Compute Fleet** - Combine discounts (like reserved instances and savings plans) with Spot VM savings, plus rank the top VM sizes you want Fleet to prioritize - Your fleet will maintain capacity with discounted Spot VMs to optimize cost

Next steps

Take advantage of the latest performance and features available for your workloads by changing the size of a virtual machine.

Utilize Microsoft's in-house designed ARM processors with Azure Cobalt VMs.

Learn how to Monitor Azure virtual machines.

Quickstart: Create a Linux virtual machine with the Azure CLI on Azure

Applies to: ✔ Linux VMs

Deploy to Azure

This quickstart shows you how to use the Azure CLI to deploy a Linux virtual machine (VM) in Azure. Use the Azure CLI to create and manage Azure resources from the command line or in scripts.

If you don't have an Azure subscription, create a free account before you begin.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, select **Try it** from the upper right corner of a code block. You can also open Cloud Shell in a separate browser tab by going to https://shell.azure.com/bash. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and select **Enter** to run it.

If you prefer to install and use the CLI locally, this quickstart requires Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Log in to Azure using the CLI

To run commands in Azure by using the CLI, you need to sign in first. Sign in by using the `az login` command.

Create a resource group

A resource group is a container for related resources. You must place all resources in a resource group. Use the az group create command to create a resource group with the previously defined `$MY_RESOURCE_GROUP_NAME` and `$REGION` parameters.

Bash

```
export RANDOM_ID="$(openssl rand -hex 3)"
export MY_RESOURCE_GROUP_NAME="myVMResourceGroup$RANDOM_ID"
```

```
export REGION=EastUS
az group create --name $MY_RESOURCE_GROUP_NAME --location $REGION
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMResourceGroup",
  "location": "eastus",
  "managedBy": null,
  "name": "myVMResourceGroup",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null,
  "type": "Microsoft.Resources/resourceGroups"
}
```

Create the virtual machine

To create a VM in this resource group, use the `vm create` command.

The following example creates a VM and adds a user account. The `--generate-ssh-keys` parameter causes the CLI to look for an available SSH key in `~/.ssh`. If it finds one, it uses that key. If not, it generates and stores a key in `~/.ssh`. The `--public-ip-sku Standard` parameter ensures that the machine is accessible through a public IP address. Finally, it deploys the latest `Ubuntu 22.04` image.

Configure all other values by using environment variables.

Bash

```
export MY_VM_NAME="myVM$RANDOM_ID"
export MY_USERNAME=azureuser
export MY_VM_IMAGE="Canonical:0001-com-ubuntu-minimal-jammy:minimal-22_04-lts-
gen2:latest"
az vm create \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --name $MY_VM_NAME \
    --image $MY_VM_IMAGE \
    --admin-username $MY_USERNAME \
    --assign-identity \
    --generate-ssh-keys \
    --public-ip-sku Standard
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

Results:

JSON

```
{
  "fqdns": "",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMResourceGroup/providers/Microsoft.Compute/virtualMa
chines/myVM",
  "location": "eastus",
  "macAddress": "00-0D-3A-10-4F-70",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.147.208.85",
  "resourceGroup": "myVMResourceGroup",
  "zones": ""
}
```

Enable Azure AD Authentication for a Linux virtual machine in Azure

The following code example deploys a Linux VM and then installs the extension to enable Azure AD Authentication for a Linux VM. VM extensions are small applications that provide post-deployment configuration and automation tasks on Azure virtual machines.

Bash

```
az vm extension set \
    --publisher Microsoft.Azure.ActiveDirectory \
    --name AADSSHLoginForLinux \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --vm-name $MY_VM_NAME
```

Store IP address of VM to use with SSH

Run the following command to store the IP address of the VM as an environment variable:

Bash

```
export IP_ADDRESS=$(az vm show --show-details --resource-group
$MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME --query publicIps --output tsv)
```

SSH into the VM

You can now SSH into the VM by running the output of the following command in your ssh client of choice:

Bash

```
ssh -o StrictHostKeyChecking=no $MY_USERNAME@$IP_ADDRESS
```

Quickstart: Create a Linux virtual machine in the Azure portal

Summarize this article for me

Applies to: ✔ Linux VMs

Azure virtual machines (VMs) can be created through the Azure portal. The Azure portal is a browser-based user interface to create Azure resources. This quickstart shows you how to use the Azure portal to deploy a Linux virtual machine (VM) running Ubuntu Server 22.04 LTS. To see your VM in action, you also SSH to the VM and install the NGINX web server.

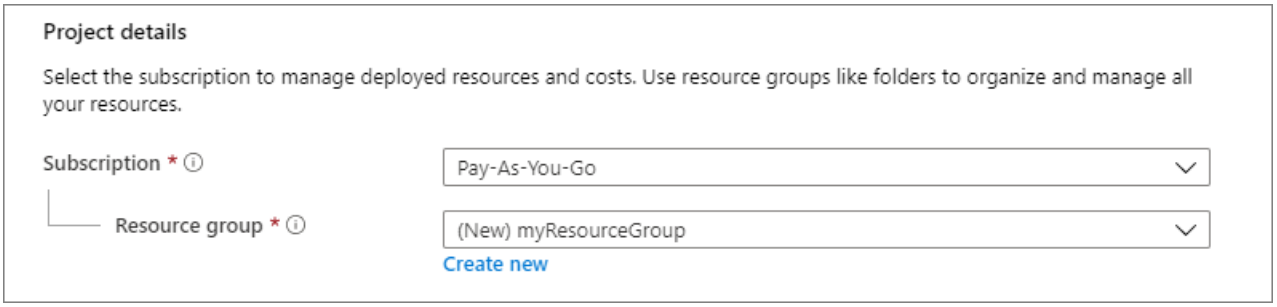
If you don't have an Azure subscription, create a free account before you begin.

Sign in to Azure

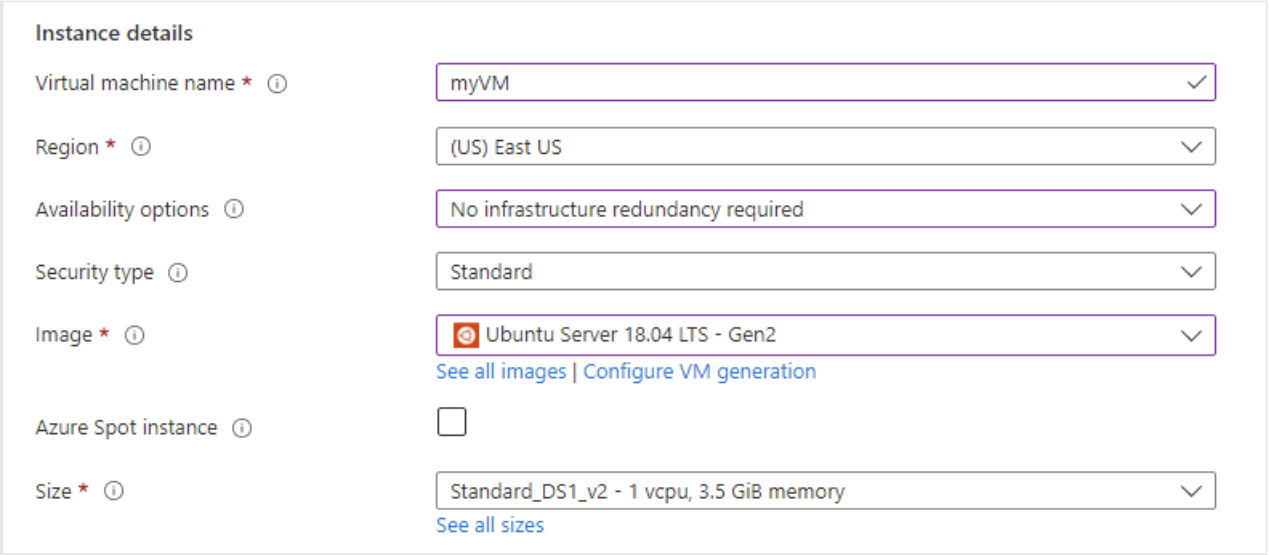
Sign in to the Azure portal.

Create virtual machine

1. Enter *virtual machines* in the search.
2. Under **Services**, select **Virtual machines**.
3. In the **Virtual machines** page, select **Create** and then **Virtual machine**. The **Create a virtual machine** page opens.
4. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected and then choose to **Create new** resource group. Enter *myResourceGroup* for the name.*.



5. Under **Instance details**, enter *myVM* for the **Virtual machine name**. Under **Availability options**, select *No infrastructure redundancy required*. Under **Security type**, select *Standard*. Choose *Ubuntu Server 22.04 LTS - Gen2* for your **Image**. Leave the other defaults. The default size and pricing is only shown as an example. Size availability and pricing are dependent on your region and subscription.



> **Note**
>
> Some users will now see the option to create VMs in multiple zones. To learn more about this new capability, see Create virtual machines in an availability zone.
>
> >

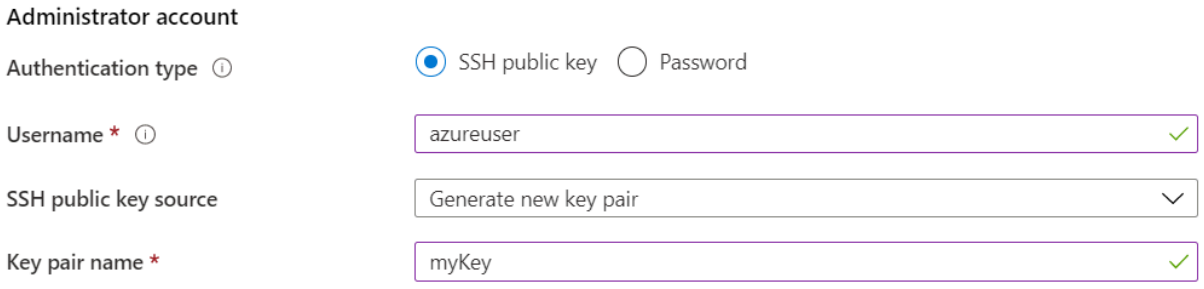
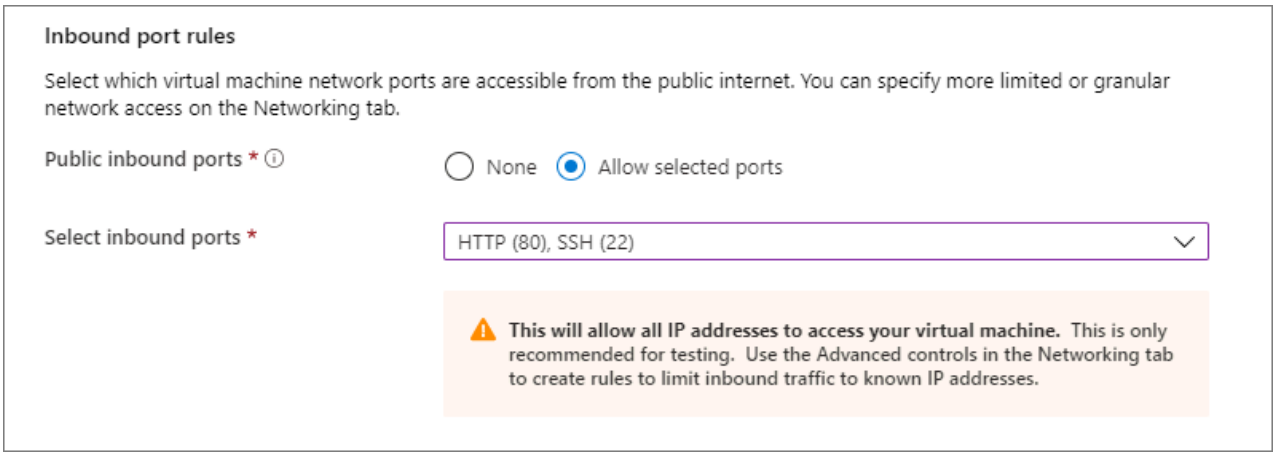
6. Under **Administrator account**, for **Authentication type**, select **SSH public key**.

7. In **Username** enter *azureuser*.

8. For **SSH public key source**, leave the default of **Generate new key pair**, and then enter *myKey* for the **Key pair name**.



9. Under **Inbound port rules** > **Public inbound ports**, choose **Allow selected ports** and then select **SSH (22)** and **HTTP (80)** from the drop-down.



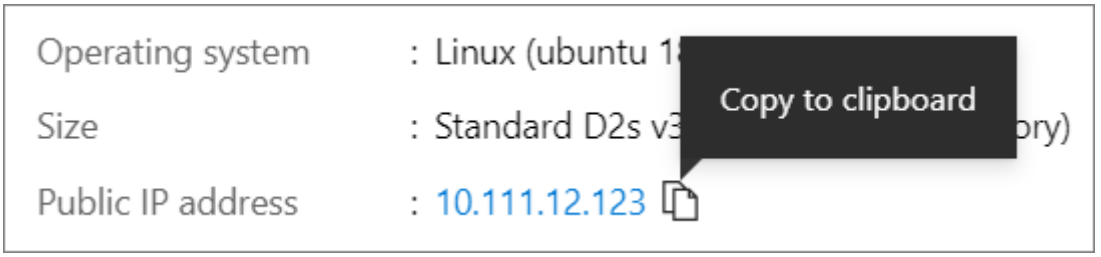
10. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page. A final validation runs.

11. On the **Create a virtual machine** page, review the details about the VM you're about to create. When you're ready, select **Create**.

12. When the **Generate new key pair** window opens, select **Download private key and create resource**. Your key file will be download as **myKey.pem**. Make sure you know where the `.pem` file was downloaded; you'll need the path to it in the next step.

13. When the deployment is finished, select **Go to resource**.

14. On the page for your new VM, select the public IP address and copy it to your clipboard.



Connect to virtual machine

Create an SSH connection with the VM.

1. If you're on a Windows machine, open a PowerShell prompt. If you're on a Mac or Linux machine, open a Bash prompt and set read-only permission on the .pem file using `chmod 400 ~/Downloads/myKey.pem`.

2. At your prompt, open an SSH connection to your virtual machine. Replace the IP address with the one from your VM, and replace the path to the `.pem` with the path to where the key file was downloaded.

Console

```
ssh -i ~/Downloads/myKey.pem azureuser@10.111.12.123
```

> **Tip**
>
> The SSH key you created can be used the next time your create a VM in Azure. Just select the **Use a key stored in Azure** for **SSH public key source** the next time you create a VM. You already have the private key on your computer, so you won't need to download anything.

Install web server

To see your VM in action, install the NGINX web server. From your SSH session, update your package sources and then install the latest NGINX package.

Ubuntu

Bash

```
sudo apt-get -y update
sudo apt-get -y install nginx
```

When done, type `exit` to leave the SSH session.

View the web server in action

Use a web browser of your choice to view the default NGINX welcome page. Type the public IP address of the VM as the web address. The public IP address can be found on the VM overview page or as part of the SSH connection string you used earlier.

Clean up resources

Delete resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources.

1. On the Overview page for the VM, under **Essentials**, select the link to the resource group you created for this Quickstart.
2. At the top of the page for the resource group, select **Delete resource group**.
3. A page will open warning you that you are about to delete resources. Type the name of the resource group, select **Delete**, and confirm deletion to finish deleting the resources and the resource group.

Auto-shutdown

If the VM is still needed, Azure provides an Auto-shutdown feature for virtual machines to help manage costs and ensure you aren't billed for unused resources.

1. On the **Operations** section for the VM, select the **Auto-shutdown** option.
2. A page will open where you can configure the auto-shutdown time. Select the **On** option to enable and then set a time that works for you.
3. Once you have set the time, select **Save** at the top to enable your Auto-shutdown configuration.

> ⓘ **Note**

Remember to configure the time zone correctly to match your requirements, as (UTC) Coordinated Universal Time is the default setting in the Time zone dropdown.

For more information see Auto-shutdown.

Next step

In this quickstart, you deployed a Linux virtual machine and installed a basic web server.

To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Azure Linux virtual machine tutorial

Last updated on 02/06/2026

Quickstart: Create a Linux virtual machine in Azure with PowerShell

Applies to: ✔ Linux VMs

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to deploy a Linux virtual machine (VM) in Azure. This quickstart uses the latest Debian marketplace image. To see your VM in action, you'll also SSH to the VM and install the NGINX web server.

If you don't have an Azure subscription, create a free account before you begin.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Create a resource group

Create an Azure resource group with New-AzResourceGroup. A resource group is a logical container into which Azure resources are deployed and managed:

Azure PowerShell

```
New-AzResourceGroup -Name 'myResourceGroup' -Location 'EastUS'
```

Create a virtual machine

We will be automatically generating an SSH key pair to use for connecting to the VM. The public key that is created using `-GenerateSshKey` will be stored in Azure as a resource, using the name you provide as `SshKeyName`. The SSH key resource can be reused for creating additional VMs. Both the public and private keys will also be downloaded for you. When you create your SSH key pair using the Cloud Shell, the keys are stored in a storage account that is automatically created by Cloud Shell. Don't delete the storage account, or the file share in it, until after you have retrieved your keys or you will lose access to the VM.

You will be prompted for a user name that will be used when you connect to the VM. You will also be asked for a password, which you can leave blank. Password log in for the VM is disabled when using an SSH key.

In this example, you create a VM named *myVM*, in *East US*, using the *Standard_B2s* VM size.

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName 'myResourceGroup' `
    -Name 'myVM' `
    -Location 'East US' `
    -image Debian11 `
    -size Standard_B2s `
    -PublicIpAddressName myPubIP `
    -OpenPorts 80 `
    -GenerateSshKey `
    -SshKeyName mySSHKey
```

The output will give you the location of the local copy of the SSH key. For example:

Output

```
Private key is saved to /home/user/.ssh/1234567891
Public key is saved to /home/user/.ssh/1234567891.pub
```

Cost information isn't presented during the virtual machine creation process for PowerShell like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

It will take a few minutes for your VM to be deployed. When the deployment is finished, move on to the next section.

Install NGINX

To see your VM in action, install the NGINX web server.

Azure PowerShell

```
Invoke-AzVMRunCommand `
   -ResourceGroupName 'myResourceGroup' `
   -Name 'myVM' `
   -CommandId 'RunShellScript' `
   -ScriptString 'sudo apt-get update && sudo apt-get install -y nginx'
```

The `-ScriptString` parameter requires version `4.27.0` or later of the `Az.Compute` module.

View the web server in action

Get the public IP address of your VM:

Azure PowerShell

```
Get-AzPublicIpAddress -Name myPubIP -ResourceGroupName myResourceGroup | select
"IpAddress"
```

Use a web browser of your choice to view the default NGINX welcome page. Enter the public IP address of the VM as the web address.

Clean up resources

When no longer needed, you can use the Remove-AzResourceGroup cmdlet to remove the resource group, VM, and all related resources:

Azure PowerShell

```
Remove-AzResourceGroup -Name 'myResourceGroup'
```

Next steps

In this quickstart, you deployed a simple virtual machine, created a Network Security Group and rule, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Azure Linux virtual machine tutorials

Last updated on 02/06/2026

Quickstart: Use Terraform to create a Linux VM

Article • 08/22/2024

Applies to: ✔ Linux VMs

Article tested with the following Terraform and Terraform provider versions:

This article shows you how to create a complete Linux environment and supporting resources with Terraform. Those resources include a virtual network, subnet, public IP address, and more.

Terraform enables the definition, preview, and deployment of cloud infrastructure. Using Terraform, you create configuration files using HCL syntax. The HCL syntax allows you to specify the cloud provider - such as Azure - and the elements that make up your cloud infrastructure. After you create your configuration files, you create an *execution plan* that allows you to preview your infrastructure changes before they're deployed. Once you verify the changes, you apply the execution plan to deploy the infrastructure.

In this article, you learn how to:

- ✔ Create a random value for the Azure resource group name using random_pet.
- ✔ Create an Azure resource group using azurerm_resource_group.
- ✔ Create a virtual network (VNET) using azurerm_virtual_network.
- ✔ Create a subnet using azurerm_subnet.
- ✔ Create a public IP using azurerm_public_ip.
- ✔ Create a network security group using azurerm_network_security_group.
- ✔ Create a network interface using azurerm_network_interface.
- ✔ Create an association between the network security group and the network interface using azurerm_network_interface_security_group_association.
- ✔ Generate a random value for a unique storage account name using random_id.
- ✔ Create a storage account for boot diagnostics using azurerm_storage_account.
- ✔ Create a Linux VM using azurerm_linux_virtual_machine
- ✔ Create an AzAPI resource azapi_resource.
- ✔ Create an AzAPI resource to generate an SSH key pair using azapi_resource_action.

Prerequisites

- Install and configure Terraform

Implement the Terraform code

> **Note**
>
> The sample code for this article is located in the Azure Terraform GitHub repo. You can view the log file containing the test results from current and previous versions of Terraform.
>
> See more articles and sample code showing how to use Terraform to manage Azure resources

1. Create a directory in which to test the sample Terraform code and make it the current directory.

2. Create a file named `providers.tf` and insert the following code:

```Terraform
terraform {
  required_version = ">=0.12"

  required_providers {
    azapi = {
      source  = "azure/azapi"
      version = "~>1.5"
    }
    azurerm = {
      source  = "hashicorp/azurerm"
      version = "~>2.0"
    }
    random = {
      source  = "hashicorp/random"
      version = "~>3.0"
    }
  }
}

provider "azurerm" {
  features {}
}
```

3. Create a file named `ssh.tf` and insert the following code:

```Terraform
```

```
resource "random_pet" "ssh_key_name" {
  prefix    = "ssh"
  separator = ""
}

resource "azapi_resource_action" "ssh_public_key_gen" {
  type        = "Microsoft.Compute/sshPublicKeys@2022-11-01"
  resource_id = azapi_resource.ssh_public_key.id
  action      = "generateKeyPair"
  method      = "POST"

  response_export_values = ["publicKey", "privateKey"]
}

resource "azapi_resource" "ssh_public_key" {
  type      = "Microsoft.Compute/sshPublicKeys@2022-11-01"
  name      = random_pet.ssh_key_name.id
  location  = azurerm_resource_group.rg.location
  parent_id = azurerm_resource_group.rg.id
}

output "key_data" {
  value = azapi_resource_action.ssh_public_key_gen.output.publicKey
}
```

4. Create a file named `main.tf` and insert the following code:

Terraform

```
resource "random_pet" "rg_name" {
  prefix = var.resource_group_name_prefix
}

resource "azurerm_resource_group" "rg" {
  location = var.resource_group_location
  name     = random_pet.rg_name.id
}

# Create virtual network
resource "azurerm_virtual_network" "my_terraform_network" {
  name                = "myVnet"
  address_space       = ["10.0.0.0/16"]
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
}

# Create subnet
resource "azurerm_subnet" "my_terraform_subnet" {
  name                 = "mySubnet"
  resource_group_name  = azurerm_resource_group.rg.name
  virtual_network_name =
azurerm_virtual_network.my_terraform_network.name
```

```
  address_prefixes     = ["10.0.1.0/24"]
}

# Create public IPs
resource "azurerm_public_ip" "my_terraform_public_ip" {
  name                = "myPublicIP"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
  allocation_method   = "Dynamic"
}

# Create Network Security Group and rule
resource "azurerm_network_security_group" "my_terraform_nsg" {
  name                = "myNetworkSecurityGroup"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  security_rule {
    name                       = "SSH"
    priority                   = 1001
    direction                  = "Inbound"
    access                     = "Allow"
    protocol                   = "Tcp"
    source_port_range          = "*"
    destination_port_range     = "22"
    source_address_prefix      = "*"
    destination_address_prefix = "*"
  }
}

# Create network interface
resource "azurerm_network_interface" "my_terraform_nic" {
  name                = "myNIC"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  ip_configuration {
    name                          = "my_nic_configuration"
    subnet_id                     =
azurerm_subnet.my_terraform_subnet.id
    private_ip_address_allocation = "Dynamic"
    public_ip_address_id          =
azurerm_public_ip.my_terraform_public_ip.id
  }
}

# Connect the security group to the network interface
resource "azurerm_network_interface_security_group_association"
"example" {
  network_interface_id      =
azurerm_network_interface.my_terraform_nic.id
  network_security_group_id =
azurerm_network_security_group.my_terraform_nsg.id
}
```

```
# Generate random text for a unique storage account name
resource "random_id" "random_id" {
  keepers = {
    # Generate a new ID only when a new resource group is defined
    resource_group = azurerm_resource_group.rg.name
  }

  byte_length = 8
}

# Create storage account for boot diagnostics
resource "azurerm_storage_account" "my_storage_account" {
  name                     = "diag${random_id.random_id.hex}"
  location                 = azurerm_resource_group.rg.location
  resource_group_name      = azurerm_resource_group.rg.name
  account_tier             = "Standard"
  account_replication_type = "LRS"
}

# Create virtual machine
resource "azurerm_linux_virtual_machine" "my_terraform_vm" {
  name                  = "myVM"
  location              = azurerm_resource_group.rg.location
  resource_group_name   = azurerm_resource_group.rg.name
  network_interface_ids =
[azurerm_network_interface.my_terraform_nic.id]
  size                  = "Standard_DS1_v2"

  os_disk {
    name                 = "myOsDisk"
    caching              = "ReadWrite"
    storage_account_type = "Premium_LRS"
  }

  source_image_reference {
    publisher = "Canonical"
    offer     = "0001-com-ubuntu-server-jammy"
    sku       = "22_04-lts-gen2"
    version   = "latest"
  }

  computer_name  = "hostname"
  admin_username = var.username

  admin_ssh_key {
    username   = var.username
    public_key =
azapi_resource_action.ssh_public_key_gen.output.publicKey
  }

  boot_diagnostics {
    storage_account_uri =
azurerm_storage_account.my_storage_account.primary_blob_endpoint
  }
}
```

5. Create a file named `variables.tf` and insert the following code:

Terraform

```
variable "resource_group_location" {
  type        = string
  default     = "eastus"
  description = "Location of the resource group."
}

variable "resource_group_name_prefix" {
  type        = string
  default     = "rg"
  description = "Prefix of the resource group name that's combined with
a random ID so name is unique in your Azure subscription."
}

variable "username" {
  type        = string
  description = "The username for the local account that will be
created on the new VM."
  default     = "azureadmin"
}
```

6. Create a file named `outputs.tf` and insert the following code:

Terraform

```
output "resource_group_name" {
  value = azurerm_resource_group.rg.name
}

output "public_ip_address" {
  value =
azurerm_linux_virtual_machine.my_terraform_vm.public_ip_address
}
```

Initialize Terraform

Run terraform init to initialize the Terraform deployment. This command downloads the Azure provider required to manage your Azure resources.

Console

```
terraform init -upgrade
```

Key points:

- The `-upgrade` parameter upgrades the necessary provider plugins to the newest version that complies with the configuration's version constraints.

Create a Terraform execution plan

Run terraform plan to create an execution plan.

Console

```
terraform plan -out main.tfplan
```

Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

Apply a Terraform execution plan

Run terraform apply to apply the execution plan to your cloud infrastructure.

Console

```
terraform apply main.tfplan
```

Key points:

- The example `terraform apply` command assumes you previously ran `terraform plan -out main.tfplan`.
- If you specified a different filename for the `-out` parameter, use that same filename in the call to `terraform apply`.
- If you didn't use the `-out` parameter, call `terraform apply` without any parameters.

Cost information isn't presented during the virtual machine creation process for Terraform like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

Verify the results

Azure CLI

1. Get the Azure resource group name.

   Console

   ```
   resource_group_name=$(terraform output -raw resource_group_name)
   ```

2. Run az vm list with a JMESPath query to display the names of the virtual machines created in the resource group.

   Azure CLI

   ```
   az vm list \
     --resource-group $resource_group_name \
     --query "[].{\"VM Name\":name}" -o table
   ```

Clean up resources

When you no longer need the resources created via Terraform, do the following steps:

1. Run terraform plan and specify the `destroy` flag.

   Console

   ```
   terraform plan -destroy -out main.destroy.tfplan
   ```

   Key points:

   - The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.

- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

2. Run terraform apply to apply the execution plan.

```
Console

terraform apply main.destroy.tfplan
```

Troubleshoot Terraform on Azure

Troubleshoot common problems when using Terraform on Azure

Next steps

In this quickstart, you deployed a simple virtual machine using Terraform. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Quickstart: Create a Linux VM cluster in Azure using Terraform

Article • 08/22/2024

Applies to: ✔ Linux VMs

This article shows you how to create a Linux VM cluster (containing two Linux VM instances) in Azure using Terraform.

In this article, you learn how to:

- ✔ Create a random value for the Azure resource group name using random_pet.
- ✔ Create an Azure resource group using azurerm_resource_group.
- ✔ Create a virtual network using azurerm_virtual_network
- ✔ Create a subnet using azurerm_subnet
- ✔ Create a public IP using azurerm_public_ip
- ✔ Create a load balancer using azurerm_lb
- ✔ Create a load balancer address pool using azurerm_lb_backend_address_pool
- ✔ Create a network interface using azurerm_network_interface
- ✔ Create a managed disk using azurerm_managed_disk
- ✔ Create a availability set using azurerm_availability_set
- ✔ Create a Linux virtual machine using azurerm_linux_virtual_machine
- ✔ Create an AzAPI resource azapi_resource.
- ✔ Create an AzAPI resource to generate an SSH key pair using azapi_resource_action.

Prerequisites

- Install and configure Terraform

Implement the Terraform code

> ⓘ **Note**
>
> The sample code for this article is located in the Azure Terraform GitHub repo. You can view the log file containing the test results from current and previous versions of Terraform.

See more [articles and sample code showing how to use Terraform to manage Azure resources]

1. Create a directory in which to test the sample Terraform code and make it the current directory.

2. Create a file named `providers.tf` and insert the following code:

```Terraform
terraform {
  required_version = ">=1.0"
  required_providers {
    azapi = {
      source  = "azure/azapi"
      version = "~>1.5"
    }
    azurerm = {
      source  = "hashicorp/azurerm"
      version = "~>3.0"
    }
    random = {
      source  = "hashicorp/random"
      version = "~>3.0"
    }
  }
}
provider "azurerm" {
  features {}
}
```

3. Create a file named `ssh.tf` and insert the following code:

```Terraform
resource "random_pet" "ssh_key_name" {
  prefix    = "ssh"
  separator = ""
}

resource "azapi_resource_action" "ssh_public_key_gen" {
  type        = "Microsoft.Compute/sshPublicKeys@2022-11-01"
  resource_id = azapi_resource.ssh_public_key.id
  action      = "generateKeyPair"
  method      = "POST"

  response_export_values = ["publicKey", "privateKey"]
}

resource "azapi_resource" "ssh_public_key" {
```

```
  type      = "Microsoft.Compute/sshPublicKeys@2022-11-01"
  name      = random_pet.ssh_key_name.id
  location  = azurerm_resource_group.rg.location
  parent_id = azurerm_resource_group.rg.id
}

output "key_data" {
  value = azapi_resource_action.ssh_public_key_gen.output.publicKey
}
```

4. Create a file named `main.tf` and insert the following code:

Terraform

```
resource "random_pet" "rg_name" {
  prefix = var.resource_group_name_prefix
}

resource "azurerm_resource_group" "rg" {
  name     = random_pet.rg_name.id
  location = var.resource_group_location
}

resource "random_pet" "azurerm_virtual_network_name" {
  prefix = "vnet"
}

resource "azurerm_virtual_network" "test" {
  name                = random_pet.azurerm_virtual_network_name.id
  address_space       = ["10.0.0.0/16"]
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
}

resource "random_pet" "azurerm_subnet_name" {
  prefix = "sub"
}

resource "azurerm_subnet" "test" {
  name                 = random_pet.azurerm_subnet_name.id
  resource_group_name  = azurerm_resource_group.rg.name
  virtual_network_name = azurerm_virtual_network.test.name
  address_prefixes     = ["10.0.2.0/24"]
}

resource "azurerm_public_ip" "test" {
  name                = "publicIPForLB"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
  allocation_method   = "Static"
}

resource "azurerm_lb" "test" {
```

```
  name                = "loadBalancer"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  frontend_ip_configuration {
    name                 = "publicIPAddress"
    public_ip_address_id = azurerm_public_ip.test.id
  }
}

resource "azurerm_lb_backend_address_pool" "test" {
  loadbalancer_id = azurerm_lb.test.id
  name            = "BackEndAddressPool"
}

resource "azurerm_network_interface" "test" {
  count               = 2
  name                = "acctni${count.index}"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  ip_configuration {
    name                          = "testConfiguration"
    subnet_id                     = azurerm_subnet.test.id
    private_ip_address_allocation = "Dynamic"
  }
}

resource "azurerm_availability_set" "avset" {
  name                         = "avset"
  location                     = azurerm_resource_group.rg.location
  resource_group_name          = azurerm_resource_group.rg.name
  platform_fault_domain_count  = 2
  platform_update_domain_count = 2
  managed                      = true
}

resource "random_pet" "azurerm_linux_virtual_machine_name" {
  prefix = "vm"
}

resource "azurerm_linux_virtual_machine" "test" {
  count                 = 2
  name                  =
"${random_pet.azurerm_linux_virtual_machine_name.id}${count.index}"
  location              = azurerm_resource_group.rg.location
  availability_set_id   = azurerm_availability_set.avset.id
  resource_group_name   = azurerm_resource_group.rg.name
  network_interface_ids =
[azurerm_network_interface.test[count.index].id]
  size                  = "Standard_DS1_v2"

  # Uncomment this line to delete the OS disk automatically when
deleting the VM
  # delete_os_disk_on_termination = true
```

```
  # Uncomment this line to delete the data disks automatically when
deleting the VM
  # delete_data_disks_on_termination = true

  source_image_reference {
    publisher = "Canonical"
    offer     = "UbuntuServer"
    sku       = "16.04-LTS"
    version   = "latest"
  }

  admin_ssh_key {
    username   = var.username
    public_key =
azapi_resource_action.ssh_public_key_gen.output.publicKey
  }

  os_disk {
    caching              = "ReadWrite"
    storage_account_type = "Standard_LRS"
    name                 = "myosdisk${count.index}"
  }

  computer_name  = "hostname"
  admin_username = var.username
}

resource "azurerm_managed_disk" "test" {
  count                = 2
  name                 = "datadisk_existing_${count.index}"
  location             = azurerm_resource_group.rg.location
  resource_group_name  = azurerm_resource_group.rg.name
  storage_account_type = "Standard_LRS"
  create_option        = "Empty"
  disk_size_gb         = "1024"
}

resource "azurerm_virtual_machine_data_disk_attachment" "test" {
  count              = 2
  managed_disk_id    = azurerm_managed_disk.test[count.index].id
  virtual_machine_id =
azurerm_linux_virtual_machine.test[count.index].id
  lun                = "10"
  caching            = "ReadWrite"
}
```

5. Create a file named `variables.tf` and insert the following code:

Terraform

```
variable "resource_group_location" {
  type        = string
```

```
  description = "Location for all resources."
  default     = "eastus"
}

variable "resource_group_name_prefix" {
  type        = string
  description = "Prefix of the resource group name that's combined with
a random ID so name is unique in your Azure subscription."
  default     = "rg"
}

variable "username" {
  type        = string
  description = "The username for the local account that will be
created on the new VM."
  default     = "azureadmin"
}
```

6. Create a file named `outputs.tf` and insert the following code:

Terraform

```
output "resource_group_name" {
  value = azurerm_resource_group.rg.name
}

output "virtual_network_name" {
  value = azurerm_virtual_network.test.name
}

output "subnet_name" {
  value = azurerm_subnet.test.name
}

output "linux_virtual_machine_names" {
  value = [for s in azurerm_linux_virtual_machine.test : s.name[*]]
}
```

Initialize Terraform

Run terraform init to initialize the Terraform deployment. This command downloads the Azure provider required to manage your Azure resources.

Console

```
terraform init -upgrade
```

Key points:

- The `-upgrade` parameter upgrades the necessary provider plugins to the newest version that complies with the configuration's version constraints.

Create a Terraform execution plan

Run terraform plan to create an execution plan.

Console

```
terraform plan -out main.tfplan
```

Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

Apply a Terraform execution plan

Run terraform apply to apply the execution plan to your cloud infrastructure.

Console

```
terraform apply main.tfplan
```

Key points:

- The example `terraform apply` command assumes you previously ran `terraform plan -out main.tfplan`.
- If you specified a different filename for the `-out` parameter, use that same filename in the call to `terraform apply`.
- If you didn't use the `-out` parameter, call `terraform apply` without any parameters.

Cost information isn't presented during the virtual machine creation process for Terraform like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

Verify the results

Azure CLI

1. Get the Azure resource group name.

   Console

   ```
   resource_group_name=$(terraform output -raw resource_group_name)
   ```

2. Run az vm list with a JMESPath query to display the names of the virtual machines created in the resource group.

   Azure CLI

   ```
   az vm list \
     --resource-group $resource_group_name \
     --query "[].{\"VM Name\":name}" -o table
   ```

Clean up resources

When you no longer need the resources created via Terraform, do the following steps:

1. Run terraform plan and specify the `destroy` flag.

   Console

   ```
   terraform plan -destroy -out main.destroy.tfplan
   ```

   Key points:

   - The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
   - The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

2. Run terraform apply to apply the execution plan.

```
Console

terraform apply main.destroy.tfplan
```

Quickstart: Create an Ubuntu Linux virtual machine using a Bicep file

Article • 08/22/2024

Applies to: ✔ Linux VMs

This quickstart shows you how to use a Bicep file to deploy an Ubuntu Linux virtual machine (VM) in Azure.

Bicep is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. It provides concise syntax, reliable type safety, and support for code reuse. Bicep offers the best authoring experience for your infrastructure-as-code solutions in Azure.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

Review the Bicep file

The Bicep file used in this quickstart is from Azure Quickstart Templates.

Bicep

```
@description('The name of your Virtual Machine.')
param vmName string = 'simpleLinuxVM'

@description('Username for the Virtual Machine.')
param adminUsername string

@description('Type of authentication to use on the Virtual Machine. SSH key
is recommended.')
@allowed([
  'sshPublicKey'
  'password'
])
param authenticationType string = 'password'

@description('SSH Key or password for the Virtual Machine. SSH key is
recommended.')
@secure()
param adminPasswordOrKey string

@description('Unique DNS Name for the Public IP used to access the Virtual
Machine.')
```

```
param dnsLabelPrefix string =
toLower('${vmName}-${uniqueString(resourceGroup().id)}')

@description('The Ubuntu version for the VM. This will pick a fully patched
image of this given Ubuntu version.')
@allowed([
  'Ubuntu-2004'
  'Ubuntu-2204'
])
param ubuntuOSVersion string = 'Ubuntu-2004'

@description('Location for all resources.')
param location string = resourceGroup().location

@description('The size of the VM')
param vmSize string = 'Standard_D2s_v3'

@description('Name of the VNET')
param virtualNetworkName string = 'vNet'

@description('Name of the subnet in the virtual network')
param subnetName string = 'Subnet'

@description('Name of the Network Security Group')
param networkSecurityGroupName string = 'SecGroupNet'

@description('Security Type of the Virtual Machine.')
@allowed([
  'Standard'
  'TrustedLaunch'
])
param securityType string = 'TrustedLaunch'

var imageReference = {
  'Ubuntu-2004': {
    publisher: 'Canonical'
    offer: '0001-com-ubuntu-server-focal'
    sku: '20_04-lts-gen2'
    version: 'latest'
  }
  'Ubuntu-2204': {
    publisher: 'Canonical'
    offer: '0001-com-ubuntu-server-jammy'
    sku: '22_04-lts-gen2'
    version: 'latest'
  }
}
var publicIPAddressName = '${vmName}PublicIP'
var networkInterfaceName = '${vmName}NetInt'
var osDiskType = 'Standard_LRS'

      adminPassword: adminPasswordOrKey
      linuxConfiguration: ((authenticationType == 'password') ? null :
linuxConfiguration)
    }
    securityProfile: (securityType == 'TrustedLaunch') ? securityProfileJson
: null
  }
}

resource vmExtension 'Microsoft.Compute/virtualMachines/extensions@2023-09-
01' = if (securityType == 'TrustedLaunch' &&
securityProfileJson.uefiSettings.secureBootEnabled &&
securityProfileJson.uefiSettings.vTpmEnabled) {
  parent: vm
  name: extensionName
  location: location
  properties: {
    publisher: extensionPublisher
    type: extensionName
    typeHandlerVersion: extensionVersion
    autoUpgradeMinorVersion: true
    enableAutomaticUpgrade: true
    settings: {
      AttestationConfig: {
        MaaSettings: {
          maaEndpoint: maaEndpoint
          maaTenantName: maaTenantName
        }
      }
    }
  }
```

```
}

output adminUsername string = adminUsername
output hostname string = publicIPAddress.properties.dnsSettings.fqdn
output sshCommand string = 'ssh
${adminUsername}@${publicIPAddress.properties.dnsSettings.fqdn}'
```

Several resources are defined in the Bicep file:

- Microsoft.Network/virtualNetworks/subnets: create a subnet.
- Microsoft.Storage/storageAccounts: create a storage account.
- Microsoft.Network/networkInterfaces: create a NIC.
- Microsoft.Network/networkSecurityGroups: create a network security group.
- Microsoft.Network/virtualNetworks: create a virtual network.
- Microsoft.Network/publicIPAddresses: create a public IP address.
- Microsoft.Compute/virtualMachines: create a virtual machine.

Deploy the Bicep file

1. Save the Bicep file as **main.bicep** to your local computer.
2. Deploy the Bicep file using either Azure CLI or Azure PowerShell.

   CLI

   Azure CLI

   ```
   az group create --name exampleRG --location eastus

   az deployment group create --resource-group exampleRG --template-
   file main.bicep --parameters adminUsername=<admin-username>
   ```

   > **Note**
   >
   > Replace **<admin-username>** with a unique username. You'll also be prompted to enter adminPasswordOrKey.

   When the deployment finishes, you should see a message indicating the deployment succeeded.

Cost information isn't presented during the virtual machine creation process for Bicep like it is for the Azure portal. If you want to learn more about how cost works for virtual

machines, see the Cost optimization Overview page.

Review deployed resources

Use the Azure portal, Azure CLI, or Azure PowerShell to list the deployed resources in the resource group.

CLI

Azure CLI

```azurecli
az resource list --resource-group exampleRG
```

Clean up resources

When no longer needed, use the Azure portal, Azure CLI, or Azure PowerShell to delete the VM and all of the resources in the resource group.

CLI

Azure CLI

```azurecli
az group delete --name exampleRG
```

Next steps

In this quickstart, you deployed a simple virtual machine using a Bicep file. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Quickstart: Create an Ubuntu Linux virtual machine by using an ARM template

Article • 08/22/2024

Applies to: ✔ Linux VMs

This quickstart shows you how to use an Azure Resource Manager template (ARM template) to deploy an Ubuntu Linux virtual machine (VM) in Azure.

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with ARM templates, select the **Deploy to Azure** button. The template opens in the Azure portal.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

Review the template

For more information on this template, see Deploy a simple Ubuntu Linux VM 18.04-LTS.

JSON

              "maaTenantName": "[variables('maaTenantName')]"
            }
          }
        }
      },
      "dependsOn": [
        "[resourceId('Microsoft.Compute/virtualMachines',
parameters('vmName'))]"
      ]
    }
  ],
  "outputs": {
    "adminUsername": {
      "type": "string",
      "value": "[parameters('adminUsername')]"
    },
    "hostname": {
      "type": "string",
      "value": "[reference(resourceId('Microsoft.Network/publicIPAddresses',
variables('publicIPAddressName')), '2023-09-01').dnsSettings.fqdn]"
```

```
    },
    "sshCommand": {
      "type": "string",
      "value": "[format('ssh {0}@{1}', parameters('adminUsername'),
reference(resourceId('Microsoft.Network/publicIPAddresses',
variables('publicIPAddressName')), '2023-09-01').dnsSettings.fqdn)]"
    }
  }
}
```

Several resources are defined in the template:

- Microsoft.Network/virtualNetworks/subnets: create a subnet.
- Microsoft.Storage/storageAccounts: create a storage account.
- Microsoft.Network/networkInterfaces: create a NIC.
- Microsoft.Network/networkSecurityGroups: create a network security group.
- Microsoft.Network/virtualNetworks: create a virtual network.
- Microsoft.Network/publicIPAddresses: create a public IP address.
- Microsoft.Compute/virtualMachines: create a virtual machine.

Deploy the template

1. Select the following image to sign in to Azure and open a template. The template creates a key vault and a secret.

   Deploy to Azure

2. Select or enter the following values. Use the default values, when available.

   - **Subscription**: select an Azure subscription.
   - **Resource group**: select an existing resource group from the drop-down, or select **Create new**, enter a unique name for the resource group, and select **OK**.
   - **Region**: select a region. For example, **Central US**.
   - **Admin username**: provide a username, such as *azureuser*.
   - **Authentication type**: You can choose between an SSH key or a password.
   - **Admin Password Or Key** depending on what you choose for authentication type:
     - If you choose **password**, the password must be at least 12 characters long and meet the defined complexity requirements.
     - If you choose **sshPublicKey**, paste in the contents of your public key.
   - **DNS label prefix**: enter a unique identifier to use as part of the DNS label.

- **Ubuntu OS version**: select which version of Ubuntu you want to run on the VM.
- **Location**: the default is the same location as the resource group, if it already exists.
- **VM size**: select the size to use for the VM.
- **Virtual Network Name**: name to be used for the vNet.
- **Subnet Name**: name for the subnet the VM should use.
- **Network Security Group Name**: name for the NSG.

3. Select **Review + create**. After validation completes, select **Create** to create and deploy the VM.

Cost information isn't presented during the virtual machine creation process for ARM templates like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

The Azure portal is used to deploy the template. In addition to the Azure portal, you can also use the Azure CLI, Azure PowerShell, and REST API. To learn other deployment methods, see Deploy templates.

Review deployed resources

You can use the Azure portal to check on the VM and other resource that were created. After the deployment is finished, select **Resource groups** to see the VM and other resources.

Clean up resources

When no longer needed, delete the resource group, which deletes the VM and all of the resources in the resource group.

1. Select the **Resource group**.
2. On the page for the resource group, select **Delete resource group**.
3. When prompted, type the name of the resource group and then select **Delete**.

Next steps

In this quickstart, you deployed a virtual machine by using an ARM template. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Create and Manage Linux VMs with the Azure CLI

Feedback

Was this page helpful? Yes No

Provide product feedback | Get help at Microsoft Q&A

Quickstart: Create a Windows virtual machine with the Azure CLI

Applies to: ✔ Windows VMs

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. This quickstart shows you how to use the Azure CLI to deploy a virtual machine (VM) in Azure that runs Windows Server 2022. To see your VM in action, you then RDP to the VM and install the IIS web server.

If you don't have an Azure subscription, create a free account before you begin.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/bash. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press **Enter** to run it.

Create a resource group

Create a resource group with the az group create command. An Azure resource group is a logical container into which Azure resources are deployed and managed. The following example creates a resource group named *myResourceGroup* in the *Central US* location. Replace the value of the variables as needed.

Azure CLI

```
subscription="SubscriptionIDName"
resourcegroup="myResourceGroupCLI"
location="centralus"
az account set --subscription $subscription
az group create --name $resourcegroup --location $location
```

Create virtual machine

Create a VM with az vm create. The following example creates a VM named *myVM*. This example uses *azureuser* for an administrative user name. Replace the values of the variables as needed.

You'll be prompted to supply a password that meets the password requirements for Azure VMs.

Using the example below, you'll be prompted to enter a password at the command line. You could also add the `--admin-password` parameter with a value for your password. The user name and password will be used when you connect to the VM.

Azure CLI

```
vmname="myVM"
username="azureuser"
az vm create \
    --resource-group $resourcegroup \
    --name $vmname \
    --image Win2022AzureEditionCore \
    --public-ip-sku Standard \
    --admin-username $username
```

It takes a few minutes to create the VM and supporting resources. The following example output shows the VM create operation was successful.

Output

```
{
  "fqdns": "",
  "id":
"/subscriptions/<guid>/resourceGroups/myResourceGroup/providers/Microsoft.Compute/v
irtualMachines/myVM",
  "location": "centralus",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroupCLI"
  "zones": ""
}
```

Take a note your own `publicIpAddress` in the output when you create your VM. This IP address is used to access the VM later in this article.

Cost information isn't presented during the virtual machine creation process for CLI like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

Install web server

To see your VM in action, install the IIS web server.

Azure CLI

```
az vm run-command invoke -g $resourcegroup \
   -n $vmname \
   --command-id RunPowerShellScript \
   --scripts "Install-WindowsFeature -name Web-Server -IncludeManagementTools"
```

Open port 80 for web traffic

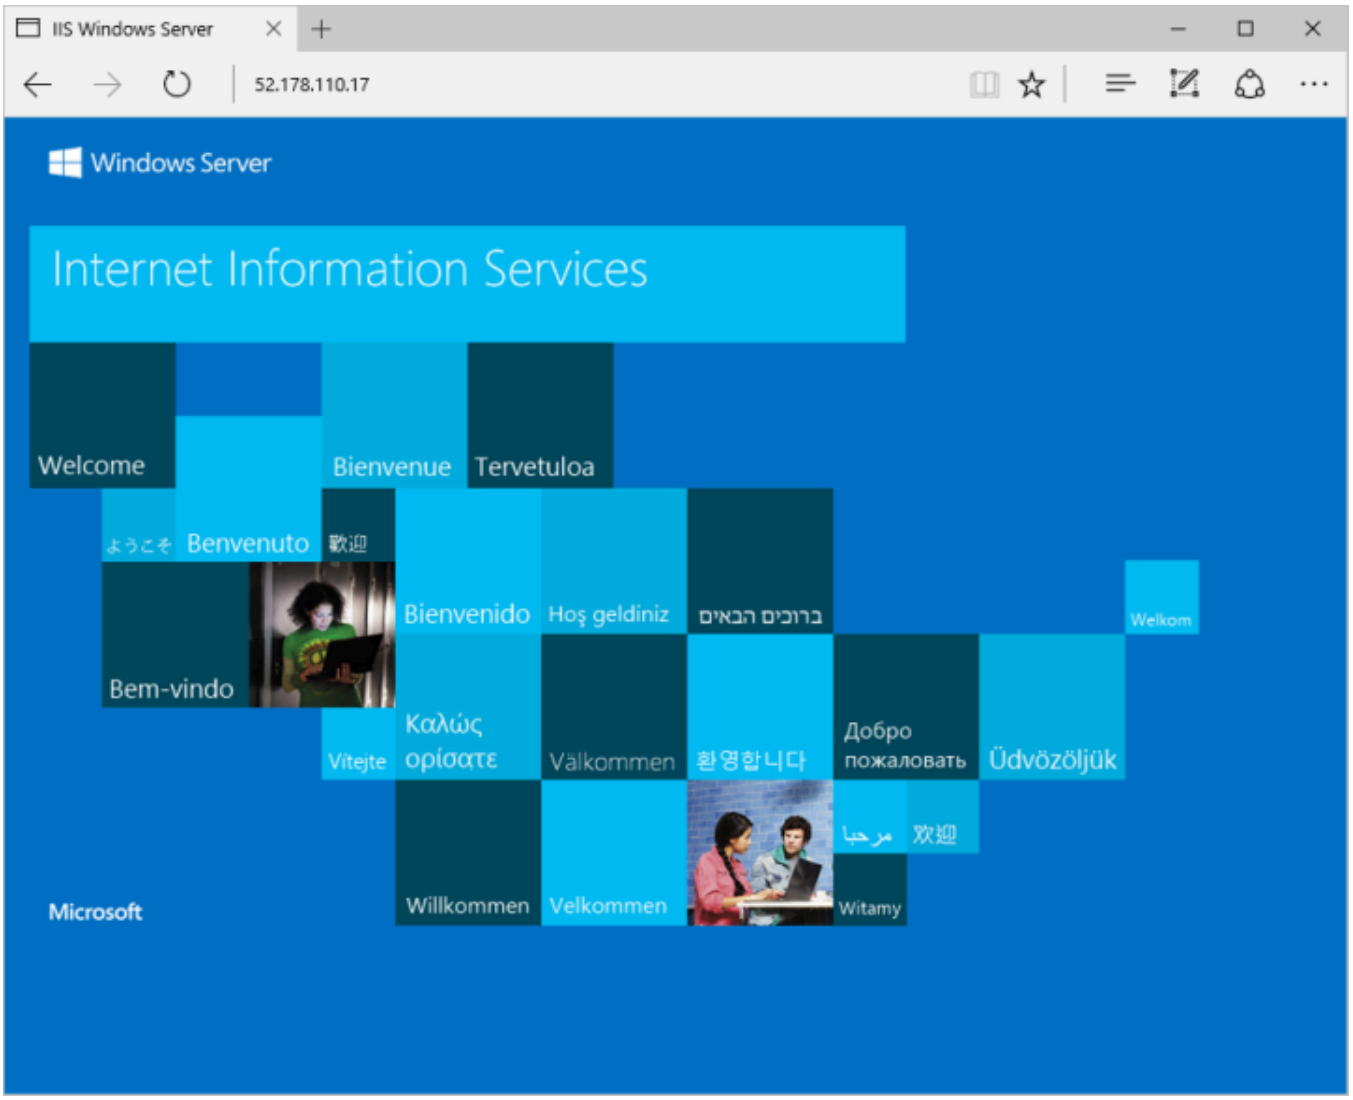
By default, only RDP connections are opened when you create a Windows VM in Azure. Use az vm open-port to open TCP port 80 for use with the IIS web server:

Azure CLI

```
az vm open-port --port 80 --resource-group $resourcegroup --name $vmname
```

View the web server in action

With IIS installed and port 80 now open on your VM from the Internet, use a web browser of your choice to view the default IIS welcome page. Use the public IP address of your VM obtained in a previous step. The following example shows the default IIS web site:



Clean up resources

When no longer needed, you can use the az group delete command to remove the resource group, VM, and all related resources:

Azure CLI

```
az group delete --name $resourcegroup
```

Next steps

In this quickstart, you deployed a simple virtual machine, open a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Windows VMs.

Azure Windows virtual machine tutorials

Last updated on 02/06/2026

Quickstart: Create a Windows virtual machine in the Azure portal

Applies to: ✔ Windows VMs

Azure virtual machines (VMs) can be created through the Azure portal. This method provides a browser-based user interface to create VMs and their associated resources. This quickstart shows you how to use the Azure portal to deploy a virtual machine (VM) in Azure that runs Windows Server 2022 Datacenter. To see your VM in action, you then RDP to the VM and install the IIS web server.

If you don't have an Azure subscription, create a free account before you begin.

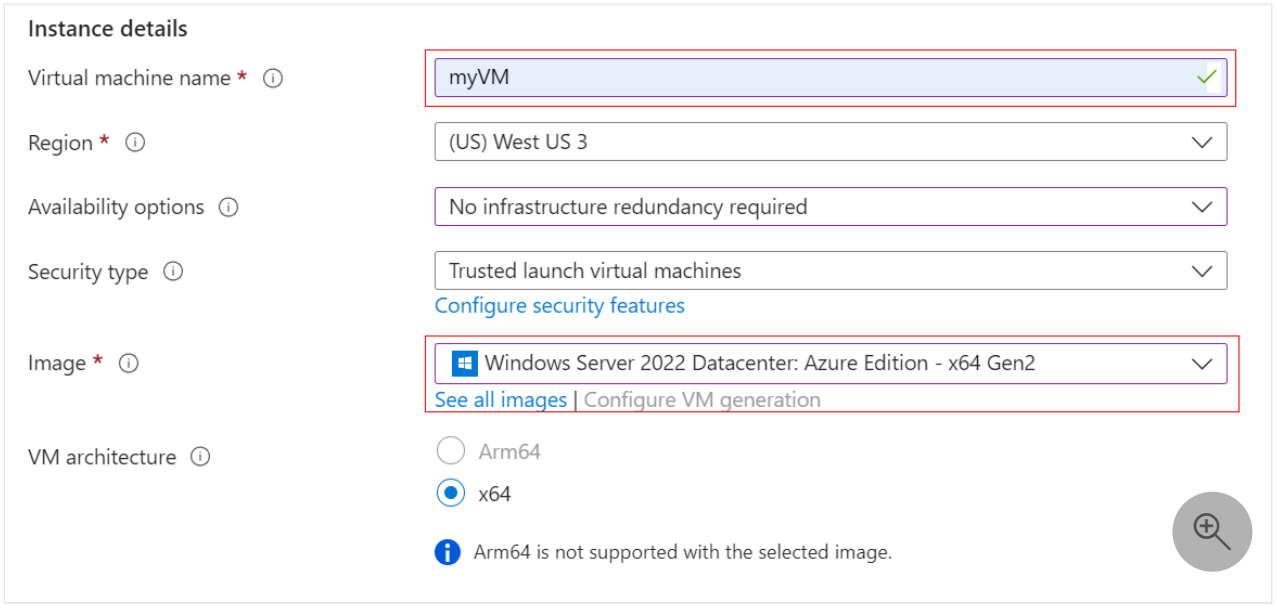
> **Important**
>
> The steps outlined in this quickstart are solely for education purposes and aren't intended for deployments to a production environment.

Sign in to Azure

Sign in to the Azure portal.

Create virtual machine

1. Enter *virtual machines* in the search.
2. Under **Services**, select **Virtual machines**.
3. In the **Virtual machines** page, select **Create** from the menu at the top of the page and then select **Virtual machine** from the drop-down. The **Create a virtual machine** page opens.
4. Under **Instance details**, enter *myVM* for the **Virtual machine name** and choose *Windows Server 2022 Datacenter: Azure Edition - x64 Gen 2* for the **Image**. The page will fill in the other fields with defaults and use the VM name to create similar names for the other resources that are needed.



> **Note**
>
> Some users will now see the option to create VMs in multiple zones. To learn more about this new capability, see Create virtual machines in an availability zone.
>
> >

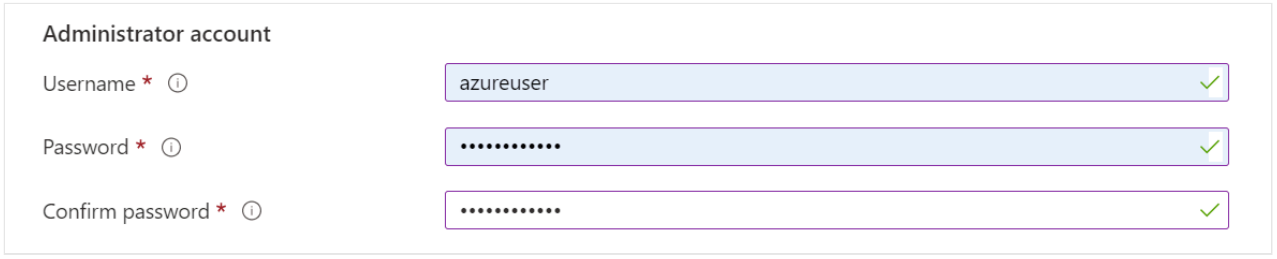
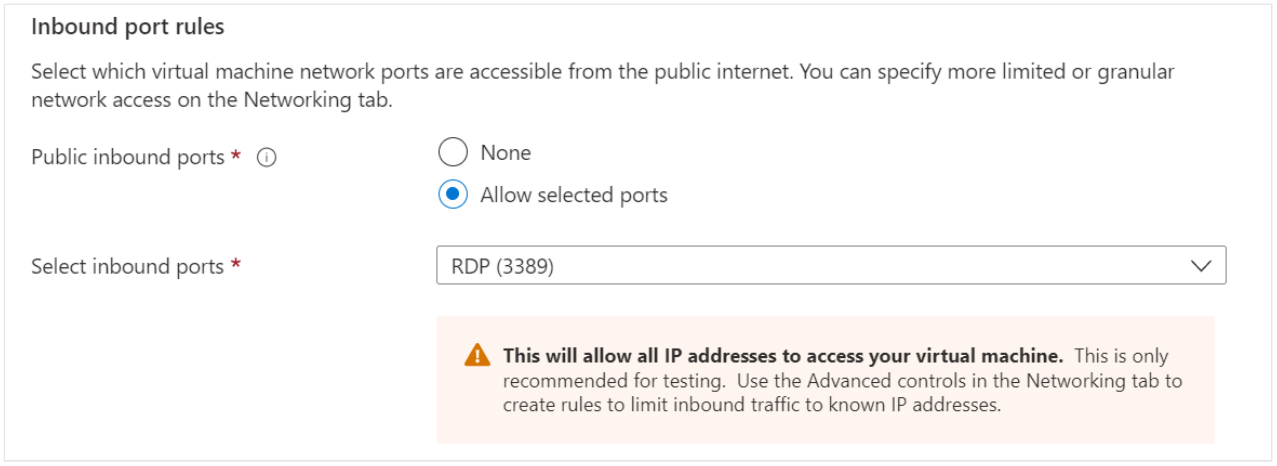
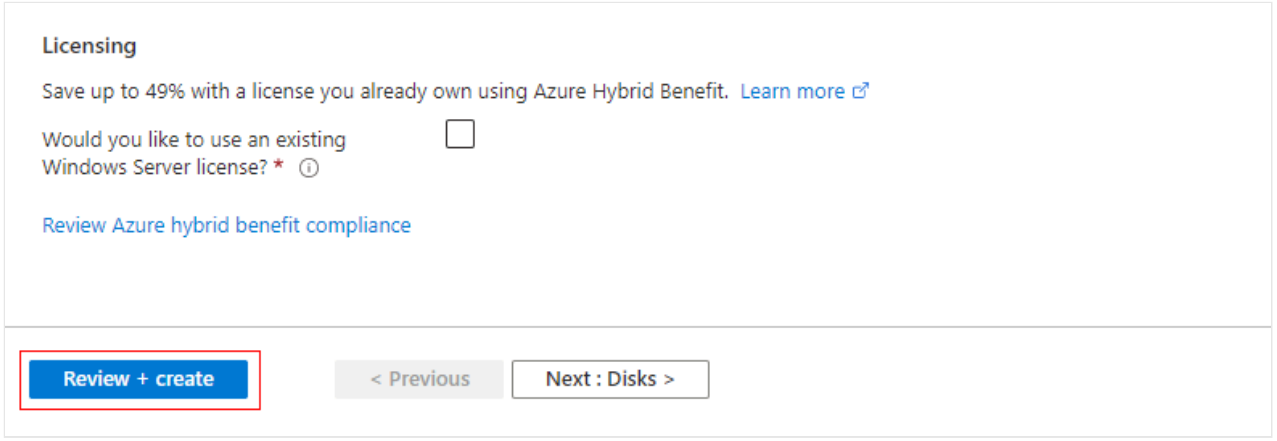
5. Under **Administrator account**, provide a username, such as *azureuser* and a password. The password must be at least 12 characters long and meet the defined complexity requirements.



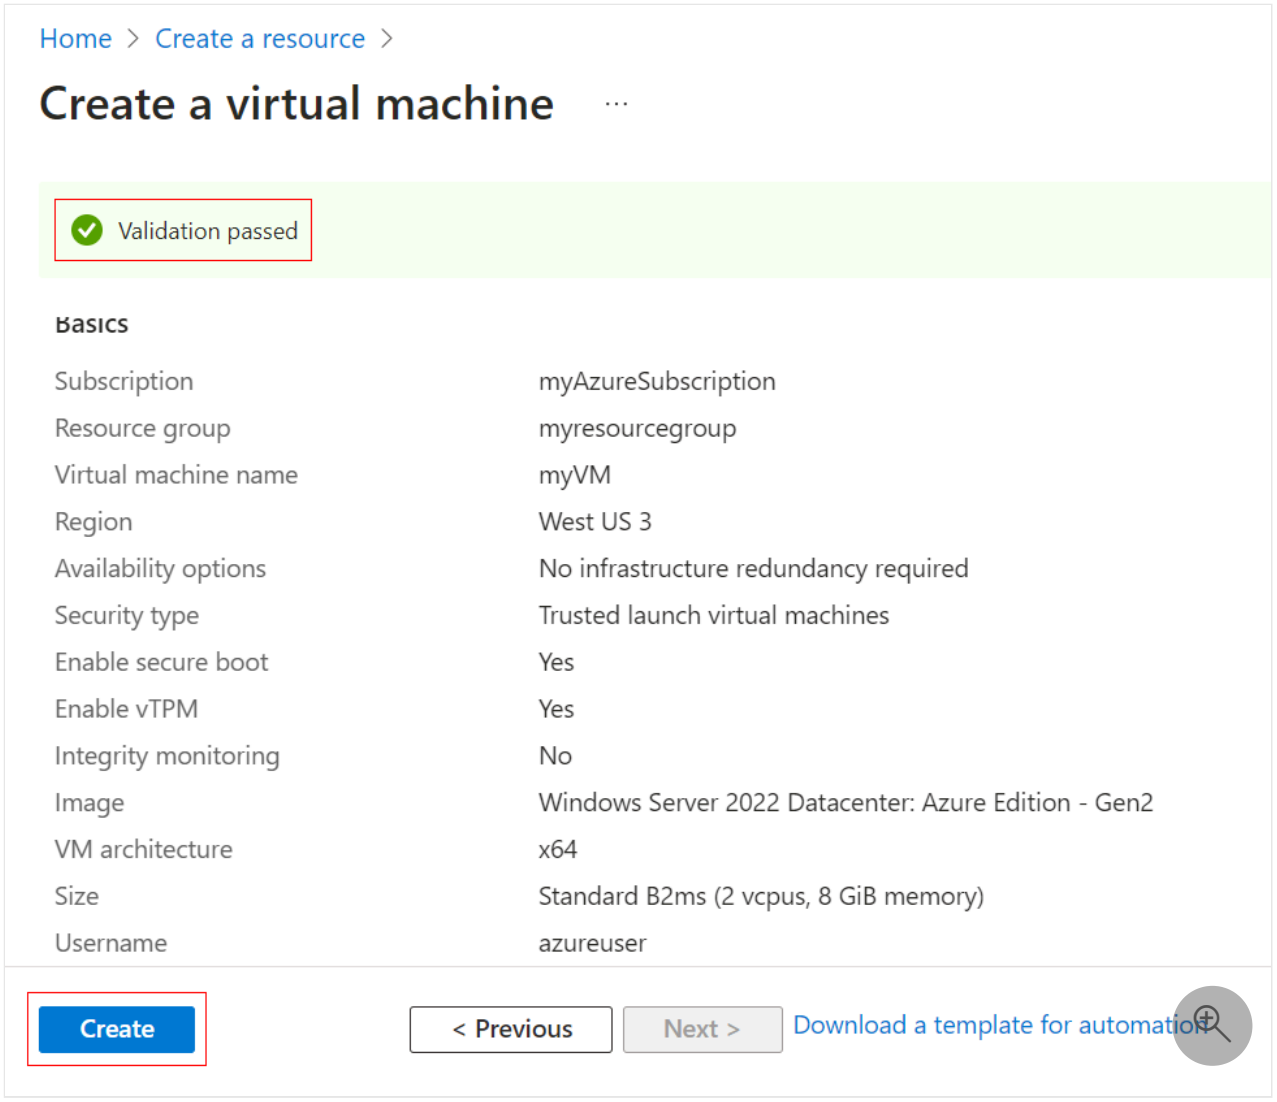
6. Under **Inbound port rules**, choose **Allow selected ports** and then select **RDP (3389)** and **HTTP (80)** from the drop-down.



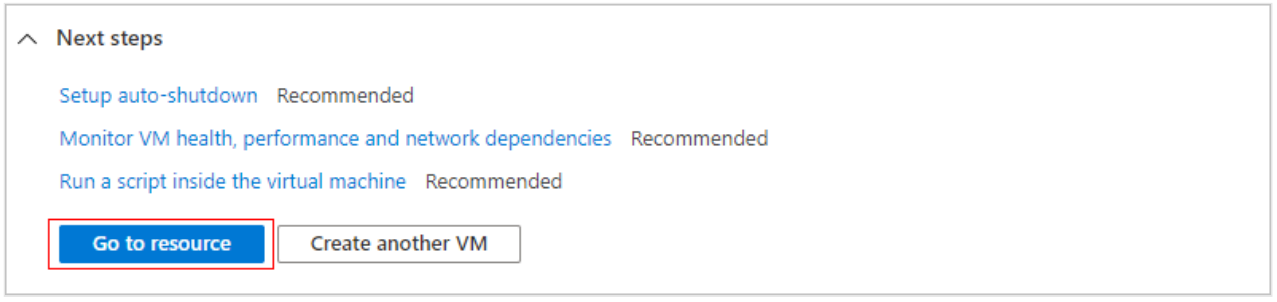
7. At the top of the page, select the **Management** tab.
8. In the **Auto-shutdown** section, select the **Enable auto-shutdown** option.
9. Select a **Shutdown time** and the **Time zone** to use (UTC is the default). Optionally you can choose to be notified by e-mail before the shutdown. For more information see Auto-shutdown.
10. Leave the remaining defaults and then select the **Review + create** button at the bottom of the page.



11. After validation runs, select the **Create** button at the bottom of the page.



12. After deployment is complete, select **Go to resource**.



Connect to virtual machine

Create a remote desktop connection to the virtual machine. These directions tell you how to connect to your VM from a Windows computer. On a Mac, you need an RDP client such as this Remote Desktop Client from the Mac App Store.

1. On the overview page for your virtual machine, select **Connect** and then select **Connect** again from the drop-down.

2. In the **Native RDP** page, select the **Check access** button to make sure port 3389 is available.
3. Select **Download RDP file** to download the connection file to your computer.
4. Open the downloaded RDP file and click **Connect** when prompted.
5. You may receive a certificate warning during the sign-in process. Click **Yes** or **Continue** to create the connection.

Install web server

To see your VM in action, install the IIS web server. Open a PowerShell prompt on the VM and run the following command:

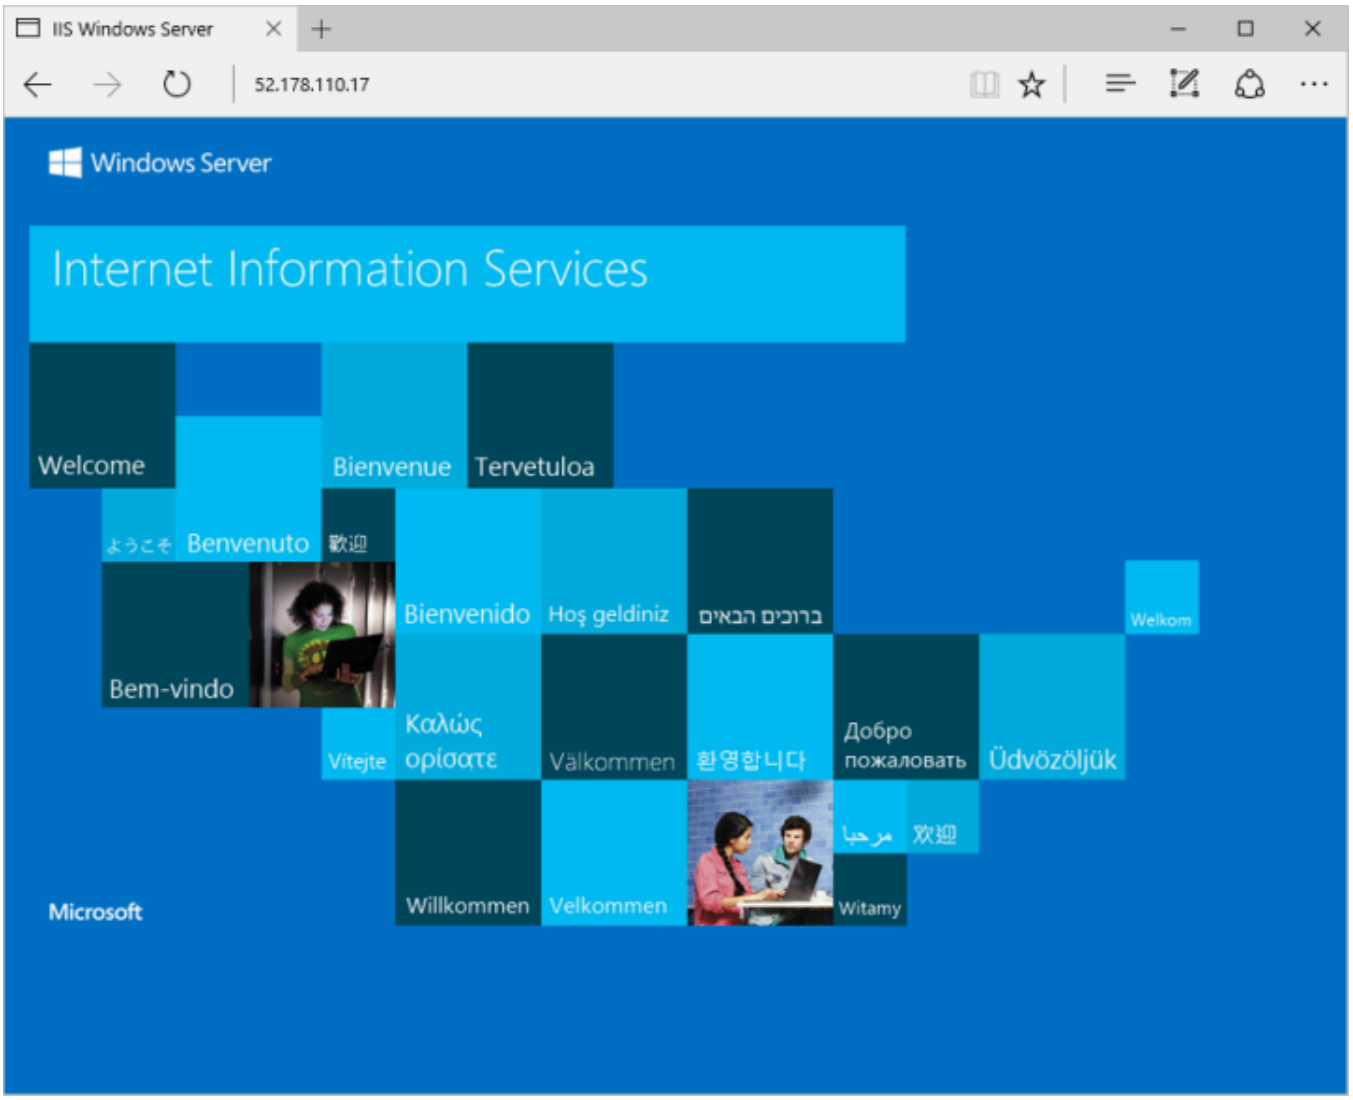
PowerShell

```
Install-WindowsFeature -name Web-Server -IncludeManagementTools
```

When done, close the RDP connection to the VM.

View the IIS welcome page

In the portal, select the VM and in the overview of the VM, hover over the IP address to show **Copy to clipboard**. Copy the IP address and paste it into a browser tab. The default IIS welcome page will open, and should look like this:



Clean up resources

Delete resources

When no longer needed, you can delete the resource group, virtual machine, and all related resources.

1. On the Overview page for the VM, select the **Resource group** link.
2. At the top of the page for the resource group, select **Delete resource group**.
3. A page will open warning you that you are about to delete resources. Type the name of the resource group and select **Delete** to finish deleting the resources and the resource group.

Next steps

In this quickstart, you deployed a simple virtual machine, opened a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue

to the tutorial for Windows VMs.

Azure Windows virtual machine tutorials

Last updated on 03/27/2026

Quickstart: Create a Windows virtual machine in Azure with PowerShell

Applies to: ✔ Windows VMs

The Azure PowerShell module is used to create and manage Azure resources from the PowerShell command line or in scripts. This quickstart shows you how to use the Azure PowerShell module to deploy a virtual machine (VM) in Azure that runs Windows Server 2016. You also bring Remote Desktop Portal (RDP) to the VM and install the IIS web server, to show the VM in action.

If you don't have an Azure subscription, create a free account before you begin.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Open Cloudshell** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the code blocks, paste them into the Cloud Shell, and press enter to run the them.

Create resource group

Create an Azure resource group with New-AzResourceGroup. A resource group is a logical container into which Azure resources are deployed and managed.

Azure PowerShell

```
New-AzResourceGroup -Name 'myResourceGroup' -Location 'centralus'
```

Create virtual machine

Create a VM with New-AzVM. Provide names for each of the resources and the `New-AzVM` cmdlet creates if they don't already exist.

When prompted, provide a username and password to be used as the sign-in credentials for the VM:

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName 'myResourceGroup' `
    -Name 'myVM' `
    -Location 'centralus' `
    -Image 'MicrosoftWindowsServer:WindowsServer:2022-datacenter-azure-
edition:latest' `
    -VirtualNetworkName 'myVnet' `
    -SubnetName 'mySubnet' `
    -SecurityGroupName 'myNetworkSecurityGroup' `
    -PublicIpAddressName 'myPublicIpAddress' `
    -OpenPorts 80,3389
```

Cost information isn't presented during the virtual machine creation process for PowerShell like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

Install web server

To see your VM in action, install the IIS web server. Open a PowerShell prompt on the VM and run the following command:

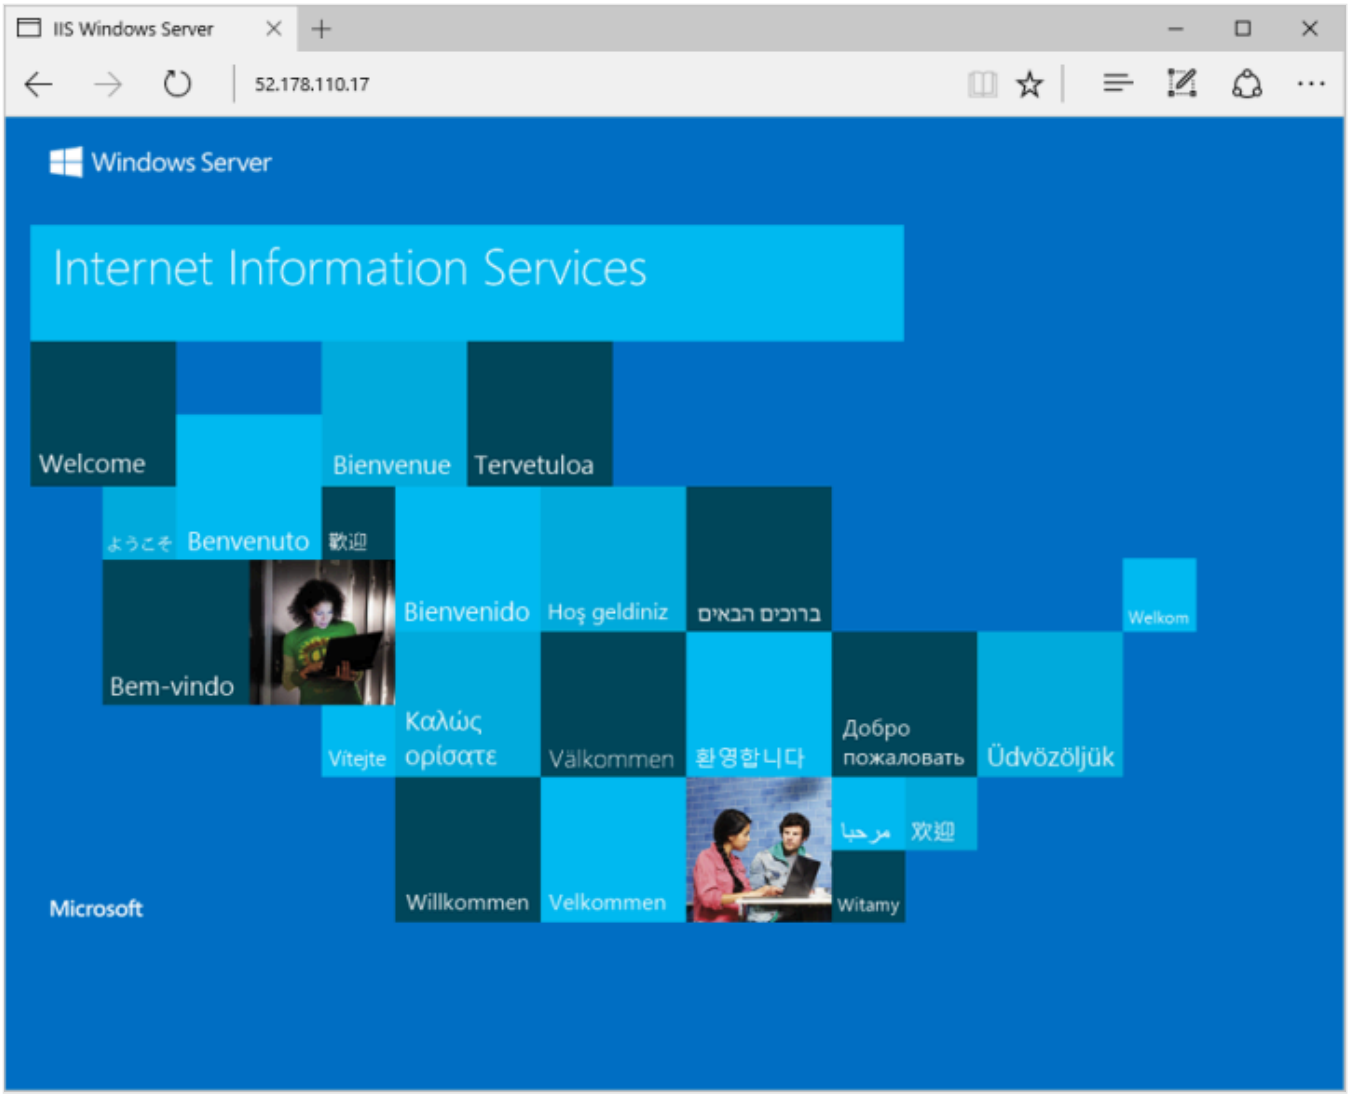
Azure PowerShell

```
Invoke-AzVMRunCommand -ResourceGroupName 'myResourceGroup' -VMName 'myVM' -
CommandId 'RunPowerShellScript' -ScriptString 'Install-WindowsFeature -Name Web-
Server -IncludeManagementTools'
```

The `-ScriptString` parameter requires version `4.27.0` or later of the `Az.Compute` module.

View the web server in action

With IIS installed and port 80 now open on your VM from the Internet, use a web browser of your choice to view the default IIS welcome page. Use the public IP address of the VM that you created. The following example shows the default IIS web site:



Clean up resources

When no longer needed, you can use the Remove-AzResourceGroup cmdlet to remove the resource group, VM, and all related resources:

Azure PowerShell

```
Remove-AzResourceGroup -Name 'myResourceGroup'
```

Next steps

In this quickstart, you deployed a simple virtual machine, opened a network port for web traffic, and installed a basic web server. To learn more about Azure virtual machines, continue to the tutorial for Windows VMs.

Azure Windows virtual machine tutorials

Quickstart: Use Terraform to create a Windows VM

Article • 08/28/2024

Applies to: ✔ Windows VMs

This article shows you how to create a complete Windows environment and supporting resources with Terraform. Those resources include a virtual network, subnet, public IP address, and more.

Terraform enables the definition, preview, and deployment of cloud infrastructure. Using Terraform, you create configuration files using HCL syntax. The HCL syntax allows you to specify the cloud provider - such as Azure - and the elements that make up your cloud infrastructure. After you create your configuration files, you create an *execution plan* that allows you to preview your infrastructure changes before they're deployed. Once you verify the changes, you apply the execution plan to deploy the infrastructure.

In this article, you learn how to:

- ✔ Create a random value for the Azure resource group name using random_pet.
- ✔ Create an Azure resource group using azurerm_resource_group.
- ✔ Create a virtual network (VNET) using azurerm_virtual_network.
- ✔ Create a subnet using azurerm_subnet.
- ✔ Create a public IP using azurerm_public_ip.
- ✔ Create a network security group using azurerm_network_security_group.
- ✔ Create a network interface using azurerm_network_interface.
- ✔ Create an association between the network security group and the network interface using azurerm_network_interface_security_group_association.
- ✔ Generate a random value for a unique storage account name using random_id.
- ✔ Create a storage account for boot diagnostics using azurerm_storage_account.
- ✔ Create a Windows VM with an IIS web server using azurerm_windows_virtual_machine.
- ✔ Create a Windows VM extension using azurerm_virtual_machine_extension.

Prerequisites

- **Azure subscription**: If you don't have an Azure subscription, create a free account before you begin.

- Install and configure Terraform

Implement the Terraform code

> **Note**
>
> The sample code for this article is located in the Azure Terraform GitHub repo. You can view the log file containing the test results from current and previous versions of Terraform.
>
> See more articles and sample code showing how to use Terraform to manage Azure resources

1. Create a directory in which to test the sample Terraform code and make it the current directory.

2. Create a file named `providers.tf` and insert the following code:

   Terraform

   ```
   terraform {
     required_version = ">=1.0"

     required_providers {
       azurerm = {
         source  = "hashicorp/azurerm"
         version = "~>3.0"
       }
       random = {
         source  = "hashicorp/random"
         version = "~>3.0"
       }
     }
   }

   provider "azurerm" {
     features {}
   }
   ```

3. Create a file named `main.tf` and insert the following code:

   Terraform

   ```
   resource "azurerm_resource_group" "rg" {
     location = var.resource_group_location
     name     = "${random_pet.prefix.id}-rg"
   ```

```
}

# Create virtual network
resource "azurerm_virtual_network" "my_terraform_network" {
  name                = "${random_pet.prefix.id}-vnet"
  address_space       = ["10.0.0.0/16"]
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
}

# Create subnet
resource "azurerm_subnet" "my_terraform_subnet" {
  name                 = "${random_pet.prefix.id}-subnet"
  resource_group_name  = azurerm_resource_group.rg.name
  virtual_network_name =
azurerm_virtual_network.my_terraform_network.name
  address_prefixes     = ["10.0.1.0/24"]
}

# Create public IPs
resource "azurerm_public_ip" "my_terraform_public_ip" {
  name                = "${random_pet.prefix.id}-public-ip"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name
  allocation_method   = "Dynamic"
}

# Create Network Security Group and rules
resource "azurerm_network_security_group" "my_terraform_nsg" {
  name                = "${random_pet.prefix.id}-nsg"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  security_rule {
    name                       = "RDP"
    priority                   = 1000
    direction                  = "Inbound"
    access                     = "Allow"
    protocol                   = "*"
    source_port_range          = "*"
    destination_port_range     = "3389"
    source_address_prefix      = "*"
    destination_address_prefix = "*"
  }
  security_rule {
    name                       = "web"
    priority                   = 1001
    direction                  = "Inbound"
    access                     = "Allow"
    protocol                   = "Tcp"
    source_port_range          = "*"
    destination_port_range     = "80"
    source_address_prefix      = "*"
    destination_address_prefix = "*"
  }
```

```
}

# Create network interface
resource "azurerm_network_interface" "my_terraform_nic" {
  name                = "${random_pet.prefix.id}-nic"
  location            = azurerm_resource_group.rg.location
  resource_group_name = azurerm_resource_group.rg.name

  ip_configuration {
    name                          = "my_nic_configuration"
    subnet_id                     =
azurerm_subnet.my_terraform_subnet.id
    private_ip_address_allocation = "Dynamic"
    public_ip_address_id          =
azurerm_public_ip.my_terraform_public_ip.id
  }
}

# Connect the security group to the network interface
resource "azurerm_network_interface_security_group_association"
"example" {
  network_interface_id      =
azurerm_network_interface.my_terraform_nic.id
  network_security_group_id =
azurerm_network_security_group.my_terraform_nsg.id
}

# Create storage account for boot diagnostics
resource "azurerm_storage_account" "my_storage_account" {
  name                     = "diag${random_id.random_id.hex}"
  location                 = azurerm_resource_group.rg.location

  min_upper   = 1
  min_numeric = 1
  min_special = 1
  special     = true
}

resource "random_pet" "prefix" {
  prefix = var.prefix
  length = 1
}
```

4. Create a file named `variables.tf` and insert the following code:

```terraform
variable "resource_group_location" {
  default     = "eastus"
  description = "Location of the resource group."
}

variable "prefix" {
  type        = string
  default     = "win-vm-iis"
  description = "Prefix of the resource name"
}
```

5. Create a file named `outputs.tf` and insert the following code:

```terraform
output "resource_group_name" {
  value = azurerm_resource_group.rg.name
}

output "public_ip_address" {
  value = azurerm_windows_virtual_machine.main.public_ip_address
}

output "admin_password" {
  sensitive = true
  value     = azurerm_windows_virtual_machine.main.admin_password
}
```

Initialize Terraform

Run terraform init to initialize the Terraform deployment. This command downloads the Azure provider required to manage your Azure resources.

```console
terraform init -upgrade
```

Key points:

- The `-upgrade` parameter upgrades the necessary provider plugins to the newest version that complies with the configuration's version constraints.

Create a Terraform execution plan

Run terraform plan to create an execution plan.

```
Console

terraform plan -out main.tfplan
```

Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

Apply a Terraform execution plan

Run terraform apply to apply the execution plan to your cloud infrastructure.

```
Console

terraform apply main.tfplan
```

Key points:

- The example `terraform apply` command assumes you previously ran `terraform plan -out main.tfplan`.
- If you specified a different filename for the `-out` parameter, use that same filename in the call to `terraform apply`.
- If you didn't use the `-out` parameter, call `terraform apply` without any parameters.

Cost information isn't presented during the virtual machine creation process for Terraform like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

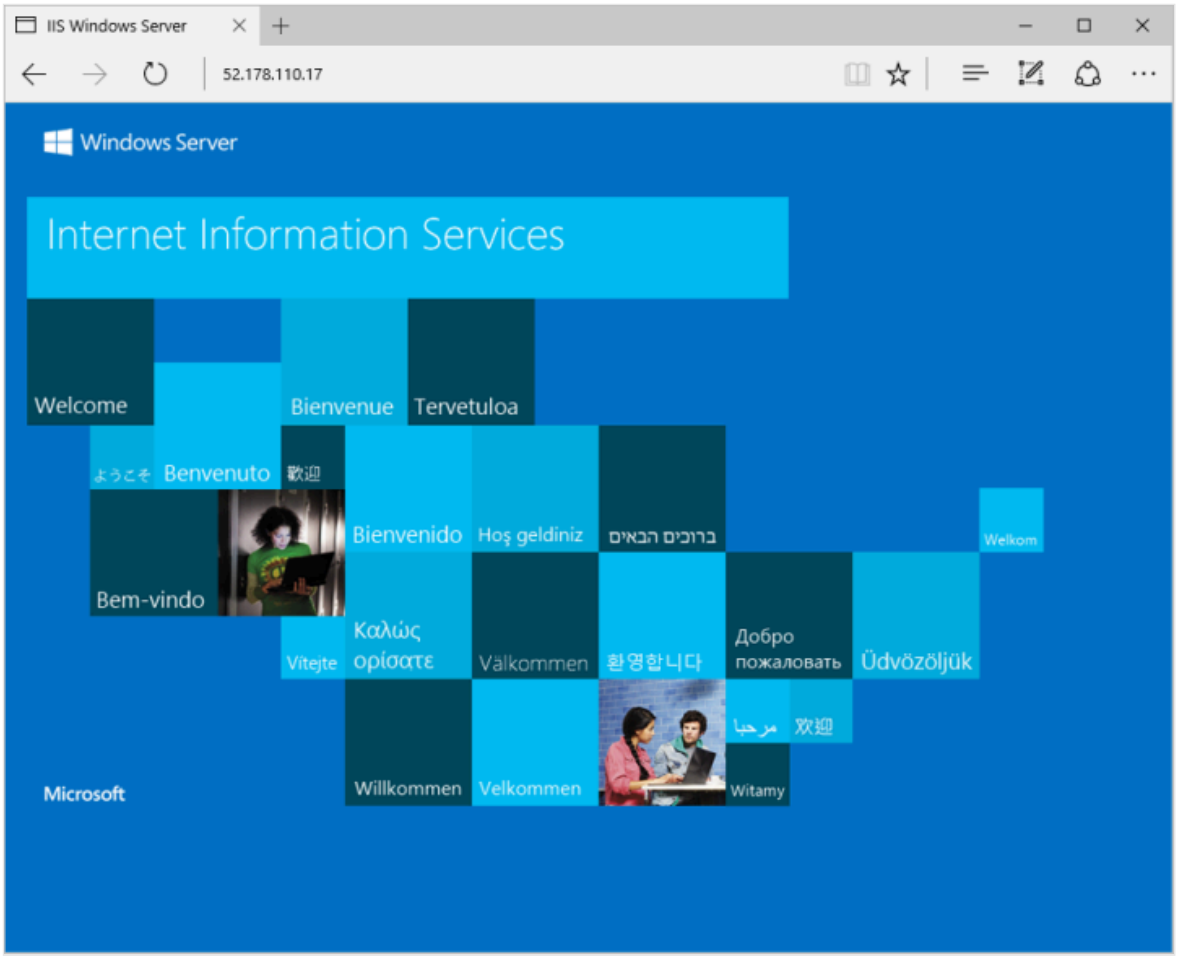
Verify the results

1. Run the following command to get the VM's public IP address and make note of it:

```
Azure CLI

echo $(terraform output -raw public_ip_address)
```

2. With IIS installed and port 80 now open on your VM from the Internet, use a web browser of your choice to view the default IIS welcome page. Use the public IP address of your VM obtained from the previous command. The following example shows the default IIS web site:



Clean up resources

When you no longer need the resources created via Terraform, do the following steps:

1. Run terraform plan and specify the `destroy` flag.

```
Console

terraform plan -destroy -out main.destroy.tfplan
```

Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

2. Run terraform apply to apply the execution plan.

```
Console

terraform apply main.destroy.tfplan
```

Troubleshoot Terraform on Azure

Troubleshoot common problems when using Terraform on Azure

Next steps

In this quickstart, you deployed a simple virtual machine using Terraform. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Quickstart: Create a Windows VM cluster in Azure using Terraform

Article • 08/27/2024

Applies to: ✔ Windows VMs

This article shows you how to create a Windows VM cluster (containing three Windows VM instances) in Azure using Terraform.

- ✔ Create a random value for the Azure resource group name using random_pet.
- ✔ Create an Azure resource group using azurerm_resource_group.
- ✔ Create a random value for the Windows VM host name random_string.
- ✔ Create a random password for the Windows VMs using random_password.
- ✔ Create a Windows VM using the compute module.
- ✔ Create a virtual network along with subnet using the network module.

Prerequisites

- Install and configure Terraform

Implement the Terraform code

> **Note**
>
> The sample code for this article is located in the Azure Terraform GitHub repo. You can view the log file containing the test results from current and previous versions of Terraform.
>
> See more articles and sample code showing how to use Terraform to manage Azure resources

1. Create a directory in which to test the sample Terraform code and make it the current directory.

2. Create a file named `providers.tf` and insert the following code:

```
Terraform
```

```
terraform {
  required_version = ">=1.0"
```

```
  required_providers {
    azurerm = {
      source  = "hashicorp/azurerm"
      version = "~>3.0"
    }
    random = {
      source  = "hashicorp/random"
      version = "~>3.0"
    }
  }
}
provider "azurerm" {
  features {}
}
```

3. Create a file named `main.tf` and insert the following code:

Terraform

```
resource "random_pet" "rg_name" {
  prefix = var.resource_group_name_prefix
}

resource "azurerm_resource_group" "rg" {
  name     = random_pet.rg_name.id
  location = var.resource_group_location
}

resource "random_string" "windows_server_vm_hostname" {
  length  = 8
  lower   = true
  upper   = false
  special = false
}

resource "random_pet" "windows_server_public_ip_dns" {
  prefix = "dns"
}

resource "random_password" "password" {
  length  = 16
  special = true
  lower   = true
  upper   = true
  numeric = true
}

# The following module is a Terraform Verified Module.
# For more information about Verified Modules, see
# https://github.com/azure/terraform-azure-modules/
module "windows_server" {
  count                        = 3 # Define 3 Windows Server VMs
  source                       = "Azure/compute/azurerm"
```

```
  resource_group_name           = azurerm_resource_group.rg.name
  vnet_subnet_id                = module.network.vnet_subnets[0]
  is_windows_image              = true
  vm_hostname                   =
"vm-${random_string.windows_server_vm_hostname.result}-${count.index}"
  delete_os_disk_on_termination = true
  admin_password                = random_password.password.result
  vm_os_simple                  = "WindowsServer"
  public_ip_dns                 =
["${random_pet.windows_server_public_ip_dns.id}-${count.index}"]
}

# The following module is a Terraform Verified Module.
# For more information about Verified Modules, see
# https://github.com/azure/terraform-azure-modules/
module "network" {
  source              = "Azure/network/azurerm"
  resource_group_name = azurerm_resource_group.rg.name
  version             = "5.2.0"
  subnet_prefixes     = ["10.0.1.0/24"]
  subnet_names        = ["subnet1"]
  use_for_each        = true
}
```

4. Create a file named `variables.tf` and insert the following code:

Terraform

```
variable "resource_group_location" {
  type        = string
  default     = "eastus"
  description = "Location for all resources."
}

variable "resource_group_name_prefix" {
  type        = string
  default     = "rg"
  description = "Prefix of the resource group name that's combined with
a random value so name is unique in your Azure subscription."
}
```

5. Create a file named `outputs.tf` and insert the following code:

Terraform

```
output "resource_group_name" {
  value = azurerm_resource_group.rg.name
}

output "windows_vm_public_names" {
  value = module.windows_server[*].public_ip_dns_name
```

```
}

output "vm_public_ip_addresses" {
  value = module.windows_server[*].public_ip_address
}

output "vm_private_ip_addresses" {
  value = module.windows_server[*].network_interface_private_ip
}

output "vm_hostnames" {
  value = module.windows_server[*].vm_names
}
```

Initialize Terraform

Run terraform init to initialize the Terraform deployment. This command downloads the Azure provider required to manage your Azure resources.

Console

```
terraform init -upgrade
```

Key points:

- The `-upgrade` parameter upgrades the necessary provider plugins to the newest version that complies with the configuration's version constraints.

Create a Terraform execution plan

Run terraform plan to create an execution plan.

Console

```
terraform plan -out main.tfplan
```

Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.

- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

Apply a Terraform execution plan

Run terraform apply to apply the execution plan to your cloud infrastructure.

Console

```
terraform apply main.tfplan
```

Key points:

- The example `terraform apply` command assumes you previously ran `terraform plan -out main.tfplan`.
- If you specified a different filename for the `-out` parameter, use that same filename in the call to `terraform apply`.
- If you didn't use the `-out` parameter, call `terraform apply` without any parameters.

Cost information isn't presented during the virtual machine creation process for Terraform like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

Verify the results

Azure CLI

1. Get the Azure resource group name.

   Console

   ```
   resource_group_name=$(terraform output -raw resource_group_name)
   ```

2. Run az vm list with a JMESPath query to display the names of the virtual machines created in the resource group.

   Azure CLI

   ```
   az vm list \
     --resource-group $resource_group_name \
   ```

```
    --query "[].{\"VM Name\":name}" -o table
```

Clean up resources

When you no longer need the resources created via Terraform, do the following steps:

1. Run terraform plan and specify the `destroy` flag.

   Console

   ```
   terraform plan -destroy -out main.destroy.tfplan
   ```

   Key points:

   - The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
   - The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

2. Run terraform apply to apply the execution plan.

   Console

   ```
   terraform apply main.destroy.tfplan
   ```

Quickstart: Create a Windows virtual machine using a Bicep file

Applies to: ✔ Windows VMs

This quickstart shows you how to use a Bicep file to deploy a Windows virtual machine (VM) in Azure. Availability of VM sizes, images, and features can vary by Azure region and subscription SKU.

Bicep is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. It provides concise syntax, reliable type safety, and support for code reuse. Bicep offers the best authoring experience for your infrastructure-as-code solutions in Azure.

Prerequisites

- If you don't have an Azure subscription, create a free account before you begin.
- Install Bicep tools
- Install Azure CLI (version 2.20.0 or later) or Azure PowerShell (Az module 5.6.0 or later).
- Signed in to Azure with the correct subscription selected. Use Azure CLI's az login command, or Azure PowerShell's Connect-AzAccount.

Review the Bicep file

The Bicep file used in this quickstart is from Azure Quickstart Templates. The template relies on the following parameters:

Expand table

Parameter	Default value	Allowed values	Constraints
`adminUsername`	*No default (required)*	Any valid Windows admin username	Required. Cannot use reserved usernames such as `admin` or `administrator`.
`vmSize`	`Standard_DS1_v2`	Region-dependent Azure VM sizes	Size availability depends on the selected region and subscription quota.
`location`	Resource group location	Any Azure region	Some VM sizes and images are not available in all regions.
`windowsOSVersion`	`2019-Datacenter`	Supported Windows Server images in Azure	Image availability varies by region.

Parameter	Default value	Allowed values	Constraints
		Marketplace	

Bicep

```
@description('Username for the Virtual Machine.')
param adminUsername string

@description('Password for the Virtual Machine.')
@minLength(12)
@secure()
param adminPassword string

@description('Unique DNS Name for the Public IP used to access the Virtual
Machine.')
param dnsLabelPrefix string = toLower('${vmName}-${uniqueString(resourceGroup().id,
vmName)}')

@description('Name for the Public IP used to access the Virtual Machine.')
param publicIpName string = 'myPublicIP'

@description('Allocation method for the Public IP used to access the Virtual
Machine.')
param publicIPAllocationMethod string = 'Static'

@description('SKU for the Public IP used to access the Virtual Machine.')
param publicIpSku string = 'Standard'

@description('The Windows version for the VM. This will pick a fully patched image
of this given Windows version.')
@allowed([

        }
      ]
    }
    diagnosticsProfile: {
      bootDiagnostics: {
        enabled: true
        storageUri: storageAccount.properties.primaryEndpoints.blob
      }
    }
    securityProfile: ((securityType == 'TrustedLaunch') ? securityProfileJson :
null)
  }
}

resource vmExtension 'Microsoft.Compute/virtualMachines/extensions@2022-03-01' = if
((securityType == 'TrustedLaunch') &&
((securityProfileJson.uefiSettings.secureBootEnabled == true) &&
(securityProfileJson.uefiSettings.vTpmEnabled == true))) {
  parent: vm
  name: extensionName
  location: location
  properties: {
    publisher: extensionPublisher
    type: extensionName
    typeHandlerVersion: extensionVersion
    autoUpgradeMinorVersion: true
    enableAutomaticUpgrade: true
    settings: {
      AttestationConfig: {
        MaaSettings: {
          maaEndpoint: maaEndpoint
          maaTenantName: maaTenantName
        }
      }
    }
  }
}

output hostname string = publicIp.properties.dnsSettings.fqdn
```

Several resources are defined in the Bicep file:

- Microsoft.Network/virtualNetworks/subnets: create a subnet.
- Microsoft.Storage/storageAccounts: create a storage account.
- Microsoft.Network/publicIPAddresses: create a public IP address.
- Microsoft.Network/networkSecurityGroups: create a network security group.

- Microsoft.Network/virtualNetworks: create a virtual network.
- Microsoft.Network/networkInterfaces: create a NIC.
- Microsoft.Compute/virtualMachines: create a virtual machine.

Deploy the Bicep file

1. Save the Bicep file as **main.bicep** to your local computer.
2. Deploy the Bicep file using either Azure CLI or Azure PowerShell.

CLI

Azure CLI

```
exampleRG=myResourceGroupName
adminUserName=myAdminUserName

az group create --name exampleRG --location eastus
az deployment group create --resource-group exampleRG --template-file
main.bicep --parameters adminUserName=<admin-username>
```

> **Note**
>
> Replace <**adminUserName**> with a unique username. You'll also be prompted to enter adminPassword. The minimum password length is 12 characters.

When the deployment finishes, you should see a messaged indicating the deployment succeeded. Use Azure CLI to verify that the virtual machine was created successfully by checking that the deployment provisioning state is `Succeeded`.

Azure CLI

```
 az deployment group show --resource-group exampleRG --name main --query
properties.provisioningState
```

Cost information isn't presented during the virtual machine creation process for Bicep like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

Review deployed resources

Use the Azure portal, Azure CLI, or Azure PowerShell to list the deployed resources in the resource group.

CLI

Azure CLI

```
az resource list --resource-group exampleRG
```

Clean up resources

When no longer needed, use the Azure portal, Azure CLI, or Azure PowerShell to delete the VM and all of the resources in the resource group.

CLI

Azure CLI

```
az group delete --name exampleRG
```

Next steps

In this quickstart, you deployed a simple virtual machine using a Bicep file. To learn more about Azure virtual machines, continue to the tutorial for Linux VMs.

Quickstart: Create a Windows virtual machine using a template

Article • 08/22/2024

Applies to: ✔ Windows VMs

This quickstart shows you how to use an Azure Resource Manager template to deploy a Windows virtual machine (VM) in Azure.

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using templates, select the **Deploy to Azure** button. The template opens in the Azure portal.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

Review the template

The template used in this quickstart is from Azure Quickstart Templates.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "metadata": {
    "_generator": {
      "name": "bicep",
      "version": "0.16.2.56959",
      "templateHash": "14427937023370378081"
    }
  },
  "parameters": {
    "adminUsername": {
      "type": "string",
```

```
      "metadata": {
        "description": "Username for the Virtual Machine."
      }
    },
    "adminPassword": {
      "type": "securestring",
      "minLength": 12,
      "metadata": {
        "description": "Password for the Virtual Machine."
      }
    },
    "dnsLabelPrefix": {
      "type": "string",
      "defaultValue": "[toLower(format('{0}-{1}', parameters('vmName'),
uniqueString(resourceGroup().id, parameters('vmName'))))]",
      "metadata": {
        "description": "Unique DNS Name for the Public IP used to access the
Virtual Machine."
      }
    },
    "publicIpName": {
      "type": "string",
      "defaultValue": "myPublicIP",
      "metadata": {
        "description": "Name for the Public IP used to access the Virtual
Machine."
      }
    },
    "publicIPAllocationMethod": {
      "type": "string",

    }
  }
}
```

Several resources are defined in the template:

- Microsoft.Network/virtualNetworks/subnets: create a subnet.
- Microsoft.Storage/storageAccounts: create a storage account.
- Microsoft.Network/publicIPAddresses: create a public IP address.
- Microsoft.Network/networkSecurityGroups: create a network security group.
- Microsoft.Network/virtualNetworks: create a virtual network.
- Microsoft.Network/networkInterfaces: create a NIC.
- Microsoft.Compute/virtualMachines: create a virtual machine.

Deploy the template

1. Select the following image to sign in to Azure and open a template. The template creates a key vault and a secret.

2. Select or enter the following values. Use the default values, when available.

   - **Subscription**: select an Azure subscription.
   - **Resource group**: select an existing resource group from the drop-down, or select **Create new**, enter a unique name for the resource group, and then select **OK**.

- **Region**: select a region. For example, **Central US**.
- **Admin username**: provide a username, such as *azureuser*.
- **Admin password**: provide a password to use for the admin account. The password must be at least 12 characters long and meet the defined complexity requirements.
- **DNS label prefix**: enter a unique identifier to use as part of the DNS label.
- **OS version**: select which OS version you want to run on the VM.
- **VM size**: select the size to use for the VM.
- **Location**: the default is the same location as the resource group, if it already exists.

3. Select **Review + create**. After validation completes, select **Create** to create and deploy the VM.

Cost information isn't presented during the virtual machine creation process for ARM templates like it is for the Azure portal. If you want to learn more about how cost works for virtual machines, see the Cost optimization Overview page.

The Azure portal is used to deploy the template. In addition to the Azure portal, you can also use the Azure PowerShell, Azure CLI, and REST API. To learn other deployment methods, see Deploy templates.

Review deployed resources

You can use the Azure portal to check on the VM and other resource that were created. After the deployment is finished, select **Resource groups** to see the VM and other resources.

Clean up resources

When no longer needed, delete the resource group, which deletes the VM and all of the resources in the resource group.

1. Select the **Resource group**.
2. On the page for the resource group, select **Delete resource group**.
3. When prompted, type the name of the resource group and then select **Delete**.

Next steps

In this quickstart, you deployed a simple virtual machine using a Resource Manager template. To learn more about Azure virtual machines, continue to the tutorial for

managing VMs.

Create virtual machines in a scale set using Azure portal

Article • 04/28/2025

This article steps through using Azure portal to create a Virtual Machine Scale Set.

Sign in to Azure

Sign in to the Azure portal.

Create a Virtual Machine Scale Set

You can deploy a scale set with a Windows Server image or Linux image such as RHEL, Ubuntu, or SLES.

1. In the Azure portal search bar, search for and select **Virtual Machine Scale Sets**.
2. Select **Create** on the **Virtual Machine Scale Sets** page.
3. In the **Basics** tab, under **Project details**, make sure the correct subscription is selected and create a new resource group called *myVMSSResourceGroup*.
4. Under **Scale set details**, set *myScaleSet* for your scale set name and select a **Region** that is close to your area.
5. Under **Orchestration**, select *Flexible* Orchestration Mode.
6. Under **Security type**, select *Trusted launch virtual machines*.
7. Under **Scaling**, keep it the Scaling mode as *Manual*.
8. Under **Instance count**, set the **initial instance count** field to *5*. You can set this number up to 1000
9. Under **Instance details**, select a marketplace image for **Image**. Select any of the Supported Distros.
10. Under **Administrator account** configure the admin username and set up an associated password or SSH public key.
    - A **Password** must be at least 12 characters long and meet three out of the four following complexity requirements: one lower case character, one upper case

character, one number, and one special character. For more information, see username and password requirements.

- If you select a Linux OS disk image, you can instead choose **SSH public key**. You can use an existing key or create a new one. In this example, we will have Azure generate a new key pair for us. For more information on generating key pairs, see create and use SSH keys.

Create a Virtual Machine Scale Set (VMSS) ...

Basics | Spot | Disks | Networking | Management | Health | Advanced | Tags | Review + create

At no added cost, a VMSS offers automatic scaling and performance optimization, infrastructure flexibility, and options to mix VM sizes, zones, and fault domains—all with simple, centralized group VM management. Already have VMs? Just create a new flexible VMSS, and attach existing VMs to your new scale set to get enhanced availability, resiliency, and capacity and cost optimization. Learn more about VMSS

Project details

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription * : Visual Studio Enterprise Subscription

Resource group * : (New) myVMSSResourceGroup

Create new

Scale set details

Virtual machine scale set name * : myScaleSet

Region * : (US) East US

Availability zone : None

Orchestration

A scale set has a "scale set model" that defines the attributes of virtual machine instances (size, number of data disks, etc). As the number of instances in the scale set changes, new instances are added based on the scale set model.
Learn more about the scale set model

Orchestration mode * :
- (●) **Flexible:** achieve high availability at scale with identical or multiple virtual machine types
- ( ) **Uniform:** optimized for large scale stateless workloads

Security type : Trusted launch virtual machines

Configure security features

Scaling

Scaling mode :
- (●) **Manually update the capacity:** Maintain a fixed amount of instances.
- ( ) Autoscaling: Scaling based on a CPU metric, on any schedule.
- ( ) **No scaling profile:** manual attach virtual machines after deployment

Subscription needs Microsoft.Insights registration to use autoscaling. Learn more

Instance count * : 5

Configure scaling options

Instance details

Image * : Ubuntu Server 20.04 LTS - x64 Gen2

See all images | Configure VM generation

VM architecture :
- ( ) Arm64
- (●) x64

Size * :

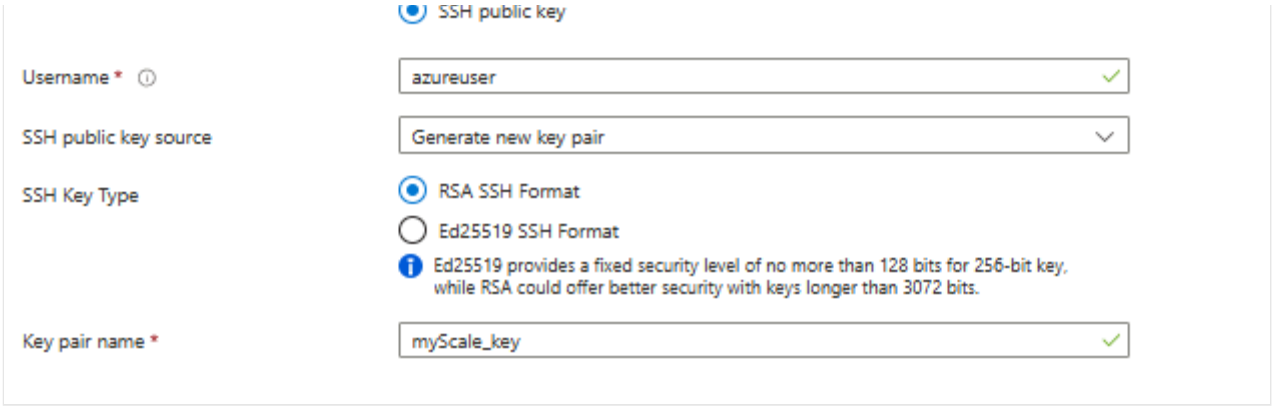
Selected sizes
Standard D2s v3
Select up to 5 sizes

Enable Hibernation : [ ]

Hibernate does not currently support Trusted launch and Confidential virtual machines for Linux images. Learn more

Administrator account

Authentication type :
- ( ) Password



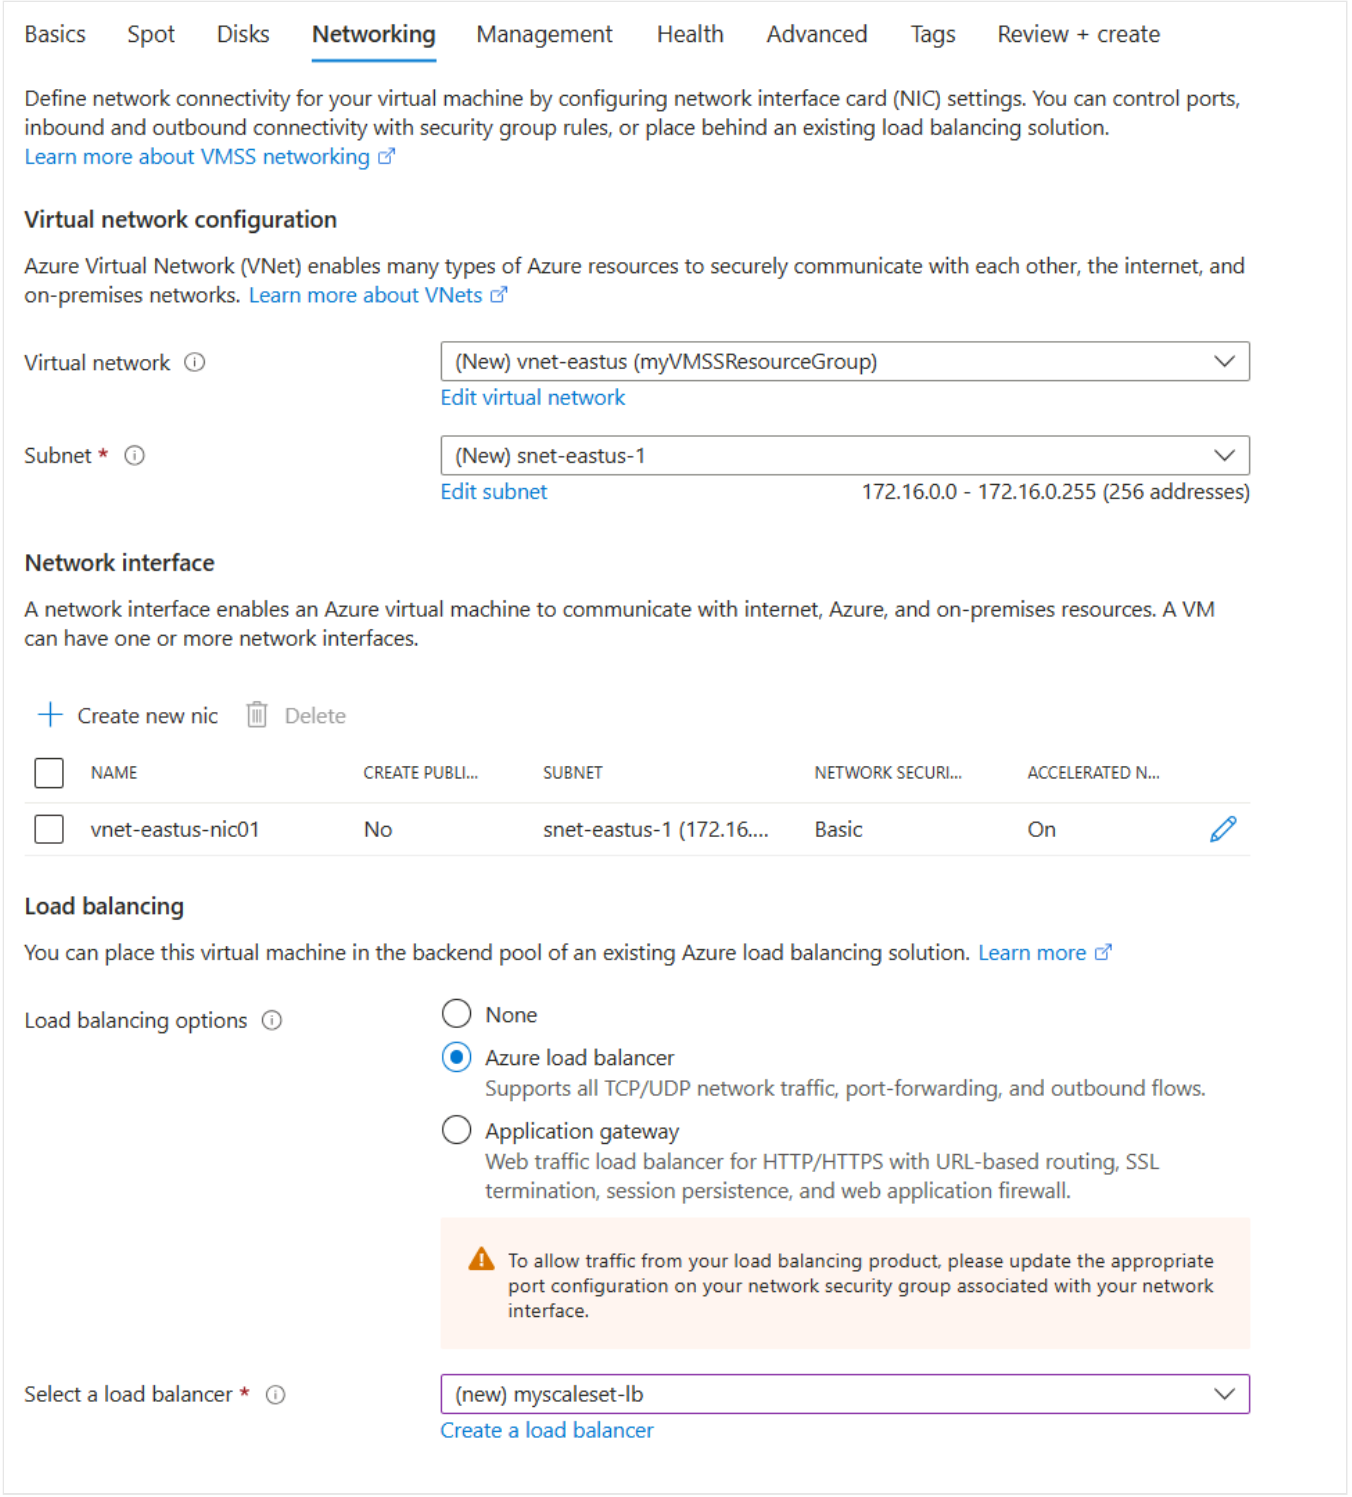
11. Select **Next: Spot** to move to the Spot virtual machine configuration options. For this quickstart, leave the default Spot configurations.

12. Select **Next: Disks** to move the disk configuration options. For this quickstart, leave the default disk configurations.

13. Select **Next: Networking** to move the networking configuration options.

14. On the **Networking** page, under **Load balancing**, select **Azure load balancer**.

15. In **Select a load balancer**, select a load balancer or create a new one.



16. When you're done, select **Review + create**.

17. After it passes validation, select **Create** to deploy the scale set.

Clean up resources

When no longer needed, delete the resource group, scale set, and all related resources. To do so, select the resource group for the scale set and then select **Delete**.

Next steps

Learn how to create a Flexible scale with Azure CLI.

Create virtual machines in a scale set using Azure CLI

Article • 09/19/2024

Deploy to Azure

This article steps through using the Azure CLI to create a Virtual Machine Scale Set.

Make sure that you've installed the latest Azure CLI and are logged in to an Azure account with az login.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, select **Open Cloud Shell** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/cli. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Define environment variables

Define environment variables as follows.

Bash

```
export RANDOM_ID="$(openssl rand -hex 3)"
export MY_RESOURCE_GROUP_NAME="myVMSSResourceGroup$RANDOM_ID"
export REGION=EastUS
export MY_VMSS_NAME="myVMSS$RANDOM_ID"
export MY_USERNAME=azureuser
export MY_VM_IMAGE="Ubuntu2204"
export MY_VNET_NAME="myVNet$RANDOM_ID"
export NETWORK_PREFIX="$(($RANDOM % 254 + 1))"
export MY_VNET_PREFIX="10.$NETWORK_PREFIX.0.0/16"
export MY_VM_SN_NAME="myVMSN$RANDOM_ID"
export MY_VM_SN_PREFIX="10.$NETWORK_PREFIX.0.0/24"
export MY_APPGW_SN_NAME="myAPPGWSN$RANDOM_ID"
export MY_APPGW_SN_PREFIX="10.$NETWORK_PREFIX.1.0/24"
export MY_APPGW_NAME="myAPPGW$RANDOM_ID"
export MY_APPGW_PUBLIC_IP_NAME="myAPPGWPublicIP$RANDOM_ID"
```

Create a resource group

A resource group is a logical container into which Azure resources are deployed and managed. All resources must be placed in a resource group. The following command creates a resource group with the previously defined $MY_RESOURCE_GROUP_NAME and $REGION parameters.

Bash

```
az group create --name $MY_RESOURCE_GROUP_NAME --location $REGION -o JSON
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxxx",
  "location": "eastus",
  "managedBy": null,
  "name": "myVMSSResourceGroupxxxxxx",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null,
  "type": "Microsoft.Resources/resourceGroups"
}
```

Create network resources

Now you'll create network resources. In this step you're going to create a virtual network, one subnet 1 for Application Gateway, and one subnet for VMs. You also need to have a public IP to attach your Application Gateway to reach your web application from the internet.

Create virtual network and subnet

Bash

```
az network vnet create  --name $MY_VNET_NAME  --resource-group
$MY_RESOURCE_GROUP_NAME --location $REGION  --address-prefix $MY_VNET_PREFIX
--subnet-name $MY_VM_SN_NAME --subnet-prefix $MY_VM_SN_PREFIX -o JSON
```

Results:

JSON

```

        "provisioningState": "Succeeded",
        "resourceGroup": "myVMSSResourceGroupxxxxxx",
        "type": "Microsoft.Network/virtualNetworks/subnets"
      }
    ],
    "type": "Microsoft.Network/virtualNetworks",
    "virtualNetworkPeerings": []
  }
}
```

Create Application Gateway resources

Azure Application Gateway requires a dedicated subnet within your virtual network. The following command creates a subnet named $MY_APPGW_SN_NAME with a specified address prefix named $MY_APPGW_SN_PREFIX in your virtual network $MY_VNET_NAME.

Bash

```
az network vnet subnet create  --name $MY_APPGW_SN_NAME  --resource-group
$MY_RESOURCE_GROUP_NAME --vnet-name  $MY_VNET_NAME --address-prefix
$MY_APPGW_SN_PREFIX -o JSON
```

Results:

JSON

```
{
  "addressPrefix": "10.66.1.0/24",
  "delegations": [],
  "etag": "W/\"xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx\"",
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxxx/providers/Microsoft.Ne
twork/virtualNetworks/myVNetxxxxxx/subnets/myAPPGWSNxxxxxx",
  "name": "myAPPGWSNxxxxxx",
  "privateEndpointNetworkPolicies": "Disabled",
  "privateLinkServiceNetworkPolicies": "Enabled",
  "provisioningState": "Succeeded",
  "resourceGroup": "myVMSSResourceGroupxxxxxx",
  "type": "Microsoft.Network/virtualNetworks/subnets"
}
```

The following command creates a standard, zone redundant, static, public IPv4 in your resource group.

Bash

```
az network public-ip create  --resource-group $MY_RESOURCE_GROUP_NAME --name
$MY_APPGW_PUBLIC_IP_NAME --sku Standard   --location $REGION  --allocation-
method static --version IPv4 --zone 1 2 3 -o JSON
```

Results:

JSON

```
{
  "publicIp": {
    "ddosSettings": {
      "protectionMode": "VirtualNetworkInherited"
    },
    "etag": "W/\"xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx\"",
    "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxxx/providers/Microsoft.Ne
twork/publicIPAddresses//myAPPGWPublicIPxxxxxx",
    "idleTimeoutInMinutes": 4,
    "ipAddress": "X.X.X.X",
    "ipTags": [],
    "location": "eastus",
```

```
    "name": "/myAPPGWPublicIPxxxxxx",
    "provisioningState": "Succeeded",
    "publicIPAddressVersion": "IPv4",
    "publicIPAllocationMethod": "Static",
    "resourceGroup": "myVMSSResourceGroupxxxxxx",
    "resourceGuid": "xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
    "sku": {
      "name": "Standard",
      "tier": "Regional"
    },
    "type": "Microsoft.Network/publicIPAddresses",
    "zones": [
      "1",
      "2",
      "3"
    ]
  }
}
```

In this step, you create an Application Gateway that you're going to integrate with your Virtual Machine Scale Set. This example creates a zone redundant Application Gateway with Standard_v2 SKU and enables Http communication for the Application Gateway. The public IP $MY_APPGW_PUBLIC_IP_NAME created in previous step is attached to the Application Gateway.

Bash

```
az network application-gateway create   --name $MY_APPGW_NAME --location
$REGION --resource-group $MY_RESOURCE_GROUP_NAME --vnet-name $MY_VNET_NAME -
-subnet $MY_APPGW_SN_NAME --capacity 2  --zones 1 2 3 --sku Standard_v2   --
http-settings-cookie-based-affinity Disabled   --frontend-port 80 --http-
settings-port 80   --http-settings-protocol Http --public-ip-address
$MY_APPGW_PUBLIC_IP_NAME --priority 1001 -o JSON
```

JSON

```

Create a Virtual Machine Scale Set

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Now create a Virtual Machine Scale Set with az vmss create. The following example creates a zone redundant scale set with an instance count of *2* with public IP in subnet $MY_VM_SN_NAME within your resource group $MY_RESOURCE_GROUP_NAME, integrates the Application Gateway, and generates SSH keys. Make sure to save the SSH keys if you need to log into your VMs via ssh.

Bash

```
az vmss create --name $MY_VMSS_NAME --resource-group $MY_RESOURCE_GROUP_NAME
--image $MY_VM_IMAGE --admin-username $MY_USERNAME --generate-ssh-keys --
public-ip-per-vm --orchestration-mode Uniform --instance-count 2 --zones 1 2
3 --vnet-name $MY_VNET_NAME --subnet $MY_VM_SN_NAME --vm-sku Standard_DS2_v2
--upgrade-policy-mode Automatic --app-gateway $MY_APPGW_NAME --backend-pool-
name appGatewayBackendPool -o JSON
```

Results:

JSON

```
{
  "vmss": {
    "doNotRunExtensionsOnOverprovisionedVMs": false,
    "orchestrationMode": "Uniform",

Install ngnix with Virtual Machine Scale Sets extensions

The following command uses the Virtual Machine Scale Sets extension to run a custom script that installs ngnix and publishes a page that shows the hostname of the Virtual Machine that your HTTP requests hits.

Bash

```
az vmss extension set --publisher Microsoft.Azure.Extensions --version 2.0
--name CustomScript --resource-group $MY_RESOURCE_GROUP_NAME --vmss-name
$MY_VMSS_NAME --settings '{ "fileUris":
["https://raw.githubusercontent.com/Azure-Samples/compute-automation-
configurations/master/automate_nginx.sh"], "commandToExecute":
"./automate_nginx.sh" }' -o JSON
```

Results:

JSON

```

    ]
}
```

Define an autoscale profile

To enable autoscale on a scale set, first define an autoscale profile. This profile defines the default, minimum, and maximum scale set capacity. These limits let you control cost by not continually creating VM instances and balance acceptable performance with a minimum number of instances that remain in a scale-in event. The following example sets the default, minimum capacity of two VM instances, and a maximum capacity of 10:

Bash

```
az monitor autoscale create --resource-group $MY_RESOURCE_GROUP_NAME --
resource  $MY_VMSS_NAME --resource-type
Microsoft.Compute/virtualMachineScaleSets --name autoscale --min-count 2 --
max-count 10 --count 2
```

Results:

JSON

```
{
  "enabled": true,
  "id": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxx/providers/microsoft.ins
ights/autoscalesettings/autoscale",
  "location": "eastus",
  "name": "autoscale",
  "namePropertiesName": "autoscale",
  "notifications": [
    {
      "email": {
        "customEmails": [],
        "sendToSubscriptionAdministrator": false,
        "sendToSubscriptionCoAdministrators": false
      },
      "webhooks": []
    }
  ],
  "predictiveAutoscalePolicy": {
    "scaleLookAheadTime": null,
    "scaleMode": "Disabled"
  },
  "profiles": [
    {
      "capacity": {
        "default": "2",
        "maximum": "10",
        "minimum": "2"
      },
      "fixedDate": null,
      "name": "default",
```

```
      "recurrence": null,
      "rules": []
    }
  ],
  "resourceGroup": "myVMSSResourceGroupxxxxx",
  "systemData": null,
  "tags": {},
  "targetResourceLocation": null,
  "targetResourceUri": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxxx/providers/Microsoft.Co
mpute/virtualMachineScaleSets/myVMSSxxxxxx",
  "type": "Microsoft.Insights/autoscaleSettings"
}
```

Create a rule to autoscale out

The following command creates a rule that increases the number of VM instances in a scale set when the average CPU load is greater than 70% over a 5-minute period. When the rule triggers, the number of VM instances increases by three.

Bash

```
az monitor autoscale rule create --resource-group $MY_RESOURCE_GROUP_NAME --
autoscale-name autoscale --condition "Percentage CPU > 70 avg 5m" --scale
out 3
```

Results:

JSON

```
{
  "metricTrigger": {
    "dimensions": [],
    "dividePerInstance": null,
    "metricName": "Percentage CPU",
    "metricNamespace": null,
    "metricResourceLocation": null,
    "metricResourceUri": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxxx/providers/Microsoft.Co
mpute/virtualMachineScaleSets/myVMSSxxxxxx",
    "operator": "GreaterThan",
    "statistic": "Average",
    "threshold": "70",
    "timeAggregation": "Average",
    "timeGrain": "PT1M",
    "timeWindow": "PT5M"
  },
  "scaleAction": {
    "cooldown": "PT5M",
```

```
    "direction": "Increase",
    "type": "ChangeCount",
    "value": "3"
  }
}
```

Create a rule to autoscale in

Create another rule with `az monitor autoscale rule create` that decreases the number of VM instances in a scale set when the average CPU load then drops below 30% over a 5-minute period. The following example defines the rule to scale in the number of VM instances by one.

Bash

```
az monitor autoscale rule create --resource-group  $MY_RESOURCE_GROUP_NAME --autoscale-name autoscale --condition "Percentage CPU < 30 avg 5m" --scale in 1
```

Results:

JSON

```
{
  "metricTrigger": {
    "dimensions": [],
    "dividePerInstance": null,
    "metricName": "Percentage CPU",
    "metricNamespace": null,
    "metricResourceLocation": null,
    "metricResourceUri": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/myVMSSResourceGroupxxxxxx/providers/Microsoft.Compute/virtualMachineScaleSets/myVMSSxxxxxx",
    "operator": "LessThan",
    "statistic": "Average",
    "threshold": "30",
    "timeAggregation": "Average",
    "timeGrain": "PT1M",
    "timeWindow": "PT5M"
  },
  "scaleAction": {
    "cooldown": "PT5M",
    "direction": "Decrease",
    "type": "ChangeCount",
    "value": "1"
  }
}
```

Test the page

The following command shows you the public IP of your Application Gateway. Paste the IP address into a browser page for testing.

Bash

```
az network public-ip show --resource-group $MY_RESOURCE_GROUP_NAME --name
$MY_APPGW_PUBLIC_IP_NAME --query [ipAddress]  --output tsv
```

Clean up resources (optional)

To avoid Azure charges, you should clean up unneeded resources. When you no longer need your scale set and other resources, delete the resource group and all its resources with az group delete. The `--no-wait` parameter returns control to the prompt without waiting for the operation to complete. The `--yes` parameter confirms that you wish to delete the resources without another prompt to do so. This tutorial cleans up resources for you.

Create virtual machines in a scale set using PowerShell

Article • 08/22/2024

This article steps through using PowerShell to create a Virtual Machine Scale Set.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Create resource group

Create an Azure resource group with New-AzResourceGroup. A resource group is a logical container into which Azure resources are deployed and managed.

Azure PowerShell

```
New-AzResourceGroup -Name 'myVMSSResourceGroup' -Location 'EastUS'
```

Create a Virtual Machine Scale Set

Now create a Virtual Machine Scale Set with New-AzVmss. The following example creates a scale set with an instance count of *two* running Windows Server 2019 Datacenter edition.

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

Azure PowerShell

```
New-AzVmss `
    -ResourceGroup "myVMSSResourceGroup" `
    -Name "myScaleSet" `
    -OrchestrationMode "Flexible" `
    -Location "East US" `
    -InstanceCount "2" `
    -ImageName "Win2019Datacenter"
```

Clean up resources

When you delete a resource group, all resources contained within, such as the VM instances, virtual network, and disks, are also deleted. The `-Force` parameter confirms that you wish to delete the resources without another prompt to do so. The `-AsJob` parameter returns control to the prompt without waiting for the operation to complete.

Azure PowerShell

```
Remove-AzResourceGroup -Name "myResourceGroup" -Force -AsJob
```

Next steps

Learn how to create a scale set in the Azure portal.

Quickstart: Create a Windows Virtual Machine Scale Set with Bicep

Article • 08/22/2024

A Virtual Machine Scale Set allows you to deploy and manage a set of auto-scaling virtual machines. You can scale the number of VMs in the Virtual Machine Scale Set manually, or define rules to autoscale based on resource usage like CPU, memory demand, or network traffic. An Azure load balancer then distributes traffic to the VM instances in the Virtual Machine Scale Set. In this quickstart, you create a Virtual Machine Scale Set and deploy a sample application with Bicep.

Bicep is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. It provides concise syntax, reliable type safety, and support for code reuse. Bicep offers the best authoring experience for your infrastructure-as-code solutions in Azure.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

Review the Bicep file

The Bicep file used in this quickstart is from Azure Quickstart Templates.

Bicep

```
@description('String used as a base for naming resources. Must be 3-61
characters in length and globally unique across Azure. A hash is prepended
to this string for some resources, and resource-specific information is
appended.')
@minLength(3)
@maxLength(61)
param vmssName string

@description('Size of VMs in the VM Scale Set.')
param vmSku string = 'Standard_D2s_v3'

@description('The Windows version for the VM. This will pick a fully patched
image of this given Windows version. Allowed values: 2008-R2-SP1, 2012-
Datacenter, 2012-R2-Datacenter & 2016-Datacenter, 2019-Datacenter.')
@allowed([
  '2019-DataCenter-GenSecond'
  '2016-DataCenter-GenSecond'
  '2022-datacenter-azure-edition'
```

```
])
param windowsOSVersion string = '2022-datacenter-azure-edition'

@description('Security Type of the Virtual Machine.')

            }
          }
        ]
      }
    ]
  }
}

output applicationUrl string =
uri('http://${publicIPAddress.properties.dnsSettings.fqdn}', '/MyApp')
```

The following resources are defined in the Bicep file:

- Microsoft.Network/virtualNetworks
- Microsoft.Network/publicIPAddresses
- Microsoft.Network/loadBalancers
- Microsoft.Compute/virtualMachineScaleSets
- Microsoft.Insights/autoscaleSettings

Define a scale set

To create a Virtual Machine Scale Set with a Bicep file, you define the appropriate resources. The core parts of the Virtual Machine Scale Set resource type are:

Expand table

Property	Description of property	Example template value
type	Azure resource type to create	Microsoft.Compute/virtualMachineScaleSets
name	The scale set name	myScaleSet
location	The location to create the scale set	East US
sku.name	The VM size for each scale set	Standard_A1

Property	Description of property	Example template value
	instance	
sku.capacity	The number of VM instances to initially create	2
upgradePolicy.mode	VM instance upgrade mode when changes occur	Automatic
imageReference	The platform or custom image to use for the VM instances	Microsoft Windows Server 2016 Datacenter
osProfile.computerNamePrefix	The name prefix for each VM instance	myvmss
osProfile.adminUsername	The username for each VM instance	azureuser
osProfile.adminPassword	The password for each VM instance	P@ssw0rd!

To customize a Virtual Machine Scale Set Bicep file, you can change the VM size or initial capacity. Another option is to use a different platform or a custom image.

Add a sample application

To test your Virtual Machine Scale Set, install a basic web application. When you deploy a Virtual Machine Scale Set, VM extensions can provide post-deployment configuration and automation tasks, such as installing an app. Scripts can be downloaded from GitHub or provided to the Azure portal at extension run-time. To apply an extension to your Virtual Machine Scale Set, add the `extensionProfile` section to the resource example above. The extension profile typically defines the following properties:

- Extension type
- Extension publisher
- Extension version
- Location of configuration or install scripts
- Commands to execute on the VM instances

The Bicep file uses the PowerShell DSC extension to install an ASP.NET MVC app that runs in IIS.

An install script is downloaded from GitHub, as defined in `url`. The extension then runs `InstallIIS` from the `IISInstall.ps1` script, as defined in `function` and `Script`. The ASP.NET app itself is provided as a Web Deploy package, which is also downloaded from GitHub, as defined in `WebDeployPackagePath`:

Deploy the Bicep file

1. Save the Bicep file as `main.bicep` to your local computer.
2. Deploy the Bicep file using either Azure CLI or Azure PowerShell.

CLI

Azure CLI

```
az group create --name exampleRG --location eastus
az deployment group create --resource-group exampleRG --template-
file main.bicep --parameters vmssName=<vmss-name>
```

Replace <*vmss-name*> with the name of the Virtual Machine Scale Set. It must be 3-61 characters in length and globally unique across Azure. You'll be prompted to enter `adminPassword`.

> **Note**
>
> When the deployment finishes, you should see a message indicating the deployment succeeded. It can take 10-15 minutes for the Virtual Machine Scale Set to be created and apply the extension to configure the app.

Validate the deployment

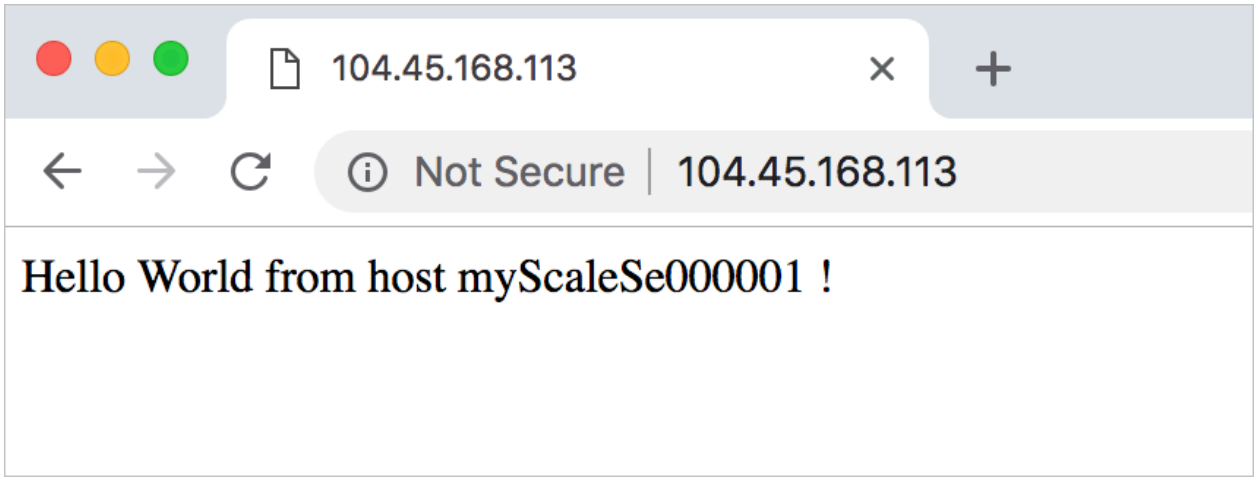
To see your Virtual Machine Scale Set in action, access the sample web application in a web browser. Obtain the public IP address of your load balancer using Azure CLI or Azure PowerShell.

CLI

Azure CLI

```
az network public-ip show --resource-group exampleRG
```

Enter the public IP address of the load balancer in to a web browser in the format *http://publicIpAddress/MyApp*. The load balancer distributes traffic to one of your VM instances, as shown in the following example:



Clean up resources

When no longer needed, use the Azure portal, Azure CLI, or Azure PowerShell to remove the resource group and its resources.

CLI

Azure CLI

```
az group delete --name exampleRG
```

Next steps

In this quickstart, you created a Windows Virtual Machine Scale Set with a Bicep file and used the PowerShell DSC extension to install a basic ASP.NET app on the VM instances. To learn more, continue to the tutorial for how to create and manage Azure Virtual Machine Scale Sets.

Create and manage Azure Virtual Machine Scale Sets

Create virtual machines in a scale set using an ARM template

Article • 08/22/2024

This article steps through using an ARM template to create a Virtual Machine Scale Set.

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

ARM template

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

ARM templates let you deploy groups of related resources. In a single template, you can create the Virtual Machine Scale Set, install applications, and configure autoscale rules. With the use of variables and parameters, this template can be reused to update existing, or create additional, scale sets. You can deploy templates through the Azure portal, Azure CLI, or Azure PowerShell, or from continuous integration / continuous delivery (CI/CD) pipelines.

Review the template

```
armasm
```

```

                }
              ]
            }
          ]
        }
      }
    ]
  }
```

These resources are defined in the template:

- Microsoft.Network/virtualNetworks
- Microsoft.Network/publicIPAddresses
- Microsoft.Network/loadBalancers
- Microsoft.Compute/virtualMachineScaleSets
- Microsoft.Insights/autoscaleSettings
- Microsoft.Network/networkSecurityGroups

Define a scale set

To create a scale with a template, you define the appropriate resources. The core parts of the Virtual Machine Scale Set resource type are:

Expand table

Property	Description of property	Example template value
type	Azure resource type to create	Microsoft.Compute/virtualMachineScaleSets
name	The scale set name	myScaleSet
location	The location to create the scale set	East US
sku.name	The VM size for each scale set instance	Standard_A1
sku.capacity	The number of VM instances to initially create	2
imageReference	The platform or custom image to use for the VM instances	Canonical Ubuntu Server 16.04-LTS
osProfile.computerNamePrefix	The name prefix for each VM instance	myvmss

Property	Description of property	Example template value
osProfile.adminUsername	The username for each VM instance	azureuser
osProfile.adminPassword	The password for each VM instance	P@ssw0rd!

To customize a scale set template, you can change the VM size or initial capacity. Another option is to use a different platform or a custom image.

Add a sample application

To test your scale set, install a basic web application. When you deploy a scale set, VM extensions can provide post-deployment configuration and automation tasks, such as installing an app. Scripts can be downloaded from Azure storage or GitHub, or provided to the Azure portal at extension run-time. To apply an extension to your scale set, you add the *extensionProfile* section to the preceding resource example. The extension profile typically defines the following properties:

- Extension type
- Extension publisher
- Extension version
- Location of configuration or install scripts
- Commands to execute on the VM instances

The template uses the Custom Script Extension to install Bottle, a Python web framework, and a simple HTTP server.

Two scripts are defined in **fileUris** - *installserver.sh*, and *workserver.py*. These files are downloaded from GitHub, then *commandToExecute* runs `bash installserver.sh` to install and configure the app.

Deploy the template

You can also deploy a Resource Manager template by using Azure CLI:

Azure CLI

```
# Create a resource group
az group create --name myResourceGroup --location EastUS

# Deploy template into resource group
```

```
az deployment group create -g myResourceGroup -f azuredeploy.json --
parameters _artifactsLocation=https://raw.githubusercontent.com/Azure/azure-
quickstart-templates/master/application-workloads/python/vmss-bottle-
autoscale/azuredeploy.json
```

Answer the prompts to provide a scale set name, instance count, and admin credentials for the VM instances. It takes a few minutes for the scale set and supporting resources to be created.

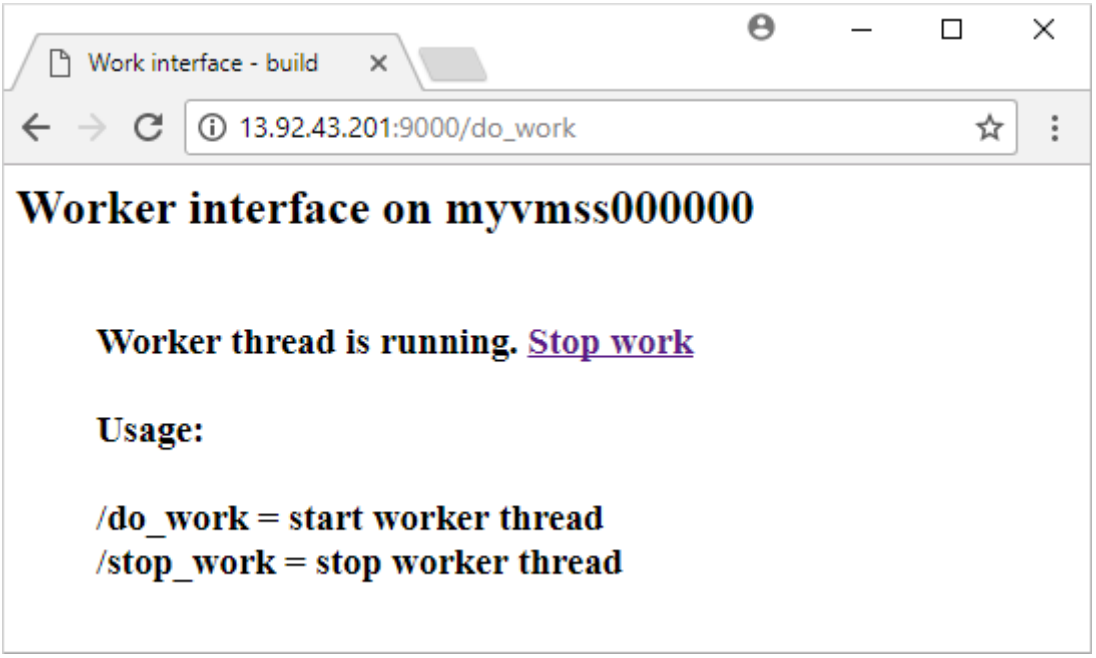
Validate the deployment

To see your scale set in action, access the sample web application in a web browser. Obtain the public IP address of the load balancer with az network public-ip list as follows:

Azure CLI

```
az network public-ip list \
    --resource-group myResourceGroup \
    --query [*].ipAddress -o tsv
```

Enter the public IP address of the load balancer in to a web browser in the format *http://publicIpAddress:9000/do_work*. The load balancer distributes traffic to one of your VM instances, as shown in the following example:



Clean up resources

When no longer needed, you can use az group delete to remove the resource group, scale set, and all related resources as follows. The `--no-wait` parameter returns control to the prompt without waiting for the operation to complete. The `--yes` parameter confirms that you wish to delete the resources without an additional prompt to do so.

Azure CLI

```
az group delete --name myResourceGroup --yes --no-wait
```

Tutorial: Create and Manage Linux VMs with the Azure CLI

Article • 04/06/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure virtual machines provide a fully configurable and flexible computing environment. This tutorial covers basic Azure virtual machine deployment items such as selecting a VM size, selecting a VM image, and deploying a VM. You learn how to:

- ✔ Create and connect to a VM
- ✔ Select and use VM images
- ✔ View and use specific VM sizes
- ✔ Resize a VM
- ✔ View and understand VM state

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Create resource group

Below, we declare environment variables. A random suffix is appended to resource names that need to be unique for each deployment.

Bash

```
export RANDOM_SUFFIX=$(openssl rand -hex 3)
export REGION="eastus2"
export MY_RESOURCE_GROUP_NAME="myResourceGroupVM$RANDOM_SUFFIX"
az group create --name $MY_RESOURCE_GROUP_NAME --location $REGION
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxx-xxxxx-xxxxx-
xxxxx/resourceGroups/myResourceGroupVMxxx",
  "location": "eastus2",
  "name": "myResourceGroupVMxxx",
```

```
  "properties": {
    "provisioningState": "Succeeded"
  }
}
```

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine. In this example, a resource group named *myResourceGroupVM* is created in the *eastus2* region.

The resource group is specified when creating or modifying a VM, which can be seen throughout this tutorial.

Create virtual machine

When you create a virtual machine, several options are available such as operating system image, disk sizing, and administrative credentials. The following example creates a VM named *myVM* that runs SUSE Linux Enterprise Server (SLES). A user account named *azureuser* is created on the VM, and SSH keys are generated if they do not exist in the default key location (*~/.ssh*).

Bash

```
export MY_VM_NAME="myVM$RANDOM_SUFFIX"
az vm create \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --name $MY_VM_NAME \
    --image SuseSles15SP5 \
    --public-ip-sku Standard \
    --admin-username azureuser \
    --generate-ssh-keys
```

It may take a few minutes to create the VM. Once the VM has been created, the Azure CLI outputs information about the VM. Take note of the `publicIpAddress`; this address can be used to access the virtual machine.

JSON

```
{
  "fqdns": "",
  "id": "/subscriptions/xxxxx-xxxxx-xxxxx-
xxxxx/resourceGroups/myResourceGroupVMxxx/providers/Microsoft.Compute/virtualMachi
nes/myVMxxx",
  "location": "eastus2",
  "macAddress": "00-0D-3A-23-9A-49",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
```

```
  "publicIpAddress": "52.174.34.95",
  "resourceGroup": "myResourceGroupVMxxx"
}
```

Connect to VM

You can now connect to the VM with SSH in the Azure Cloud Shell or from your local computer. Replace the example IP address with the `publicIpAddress` noted in the previous step.

To connect to the VM, first retrieve the public IP address using the Azure CLI. Execute the following command to store the IP address in a variable: `export IP_ADDRESS=$(az vm show --show-details --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME --query publicIps --output tsv)`

Once you have the IP address, use SSH to connect to the VM. The following command connects to the VM using the `azureuser` account and the retrieved IP address: `ssh -o StrictHostKeyChecking=no azureuser@$IP_ADDRESS`

Understand VM images

The Azure Marketplace includes many images that can be used to create VMs. In the previous steps, a virtual machine was created using a SUSE image. In this step, the Azure CLI is used to search the marketplace for an Ubuntu image, which is then used to deploy a second virtual machine.

To see a list of the most commonly used images, use the az vm image list command.

Bash

```
az vm image list --output table
```

The command output returns the most popular VM images on Azure.

Output

```

```

A full list can be seen by adding the `--all` parameter. The image list can also be filtered by `--publisher` or `--offer`. In this example, the list is filtered for all images, published by OpenLogic, with an offer that matches *0001-com-ubuntu-server-jammy*.

Bash

```
az vm image list --offer 0001-com-ubuntu-server-jammy --publisher Canonical --all
--output table
```

Example partial output:

Output

```

> **Note**
>
> Canonical has changed the **Offer** names they use for the most recent versions. Before Ubuntu 20.04, the **Offer** name is UbuntuServer. For Ubuntu 20.04 the **Offer** name is `0001-com-ubuntu-server-focal` and for Ubuntu 22.04 it's `0001-com-ubuntu-server-jammy`.

To deploy a VM using a specific image, take note of the value in the *Urn* column, which consists of the publisher, offer, SKU, and optionally a version number to identify the image. When specifying the image, the image version number can be replaced with `latest`, which selects the latest version of the distribution. In this example, the `--image` parameter is used to specify the latest version of a Ubuntu 22.04.

Bash

```
export MY_VM2_NAME="myVM2$RANDOM_SUFFIX"
az vm create --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM2_NAME --image
Canonical:0001-com-ubuntu-server-jammy:22_04-lts:latest --generate-ssh-keys
```

Understand VM sizes

A virtual machine size determines the amount of compute resources such as CPU, GPU, and memory that are made available to the virtual machine. Virtual machines need to be sized appropriately for the expected work load. If workload increases, an existing virtual machine can be resized.

VM Sizes

The following table categorizes sizes into use cases.

Expand table

Type	Description
General purpose	Balanced CPU-to-memory. Ideal for dev / test and small to medium applications and data solutions.
Compute optimized	High CPU-to-memory. Good for medium traffic applications, network appliances, and batch processes.
Memory optimized	High memory-to-core. Great for relational databases, medium to large caches, and in-memory analytics.
Storage optimized	High disk throughput and IO. Ideal for Big Data, SQL, and NoSQL databases.
GPU	Specialized VMs targeted for heavy graphic rendering and video editing.
High performance	Our most powerful CPU VMs with optional high-throughput network interfaces (RDMA).

Find available VM sizes

To see a list of VM sizes available in a particular region, use the az vm list-sizes command.

Bash

```
az vm list-sizes --location $REGION --output table
```

Example partial output:

Output

```
  MaxDataDiskCount    MemoryInMb  Name                        NumberOfCores
OsDiskSizeInMb    ResourceDiskSizeInMb
------------------  ------------  --------------------  --------------  -------
```

```
---------  ----------------------
4                   8192          Standard_D2ds_v4           2
1047552           76800
8                   16384         Standard_D4ds_v4           4
1047552           153600
16                  32768         Standard_D8ds_v4           8
1047552           307200
32                  65536         Standard_D16ds_v4          16
1047552           614400
32                  131072        Standard_D32ds_v4          32
1047552           1228800
32                  196608        Standard_D48ds_v4          48
1047552           1843200
32                  262144        Standard_D64ds_v4          64
1047552           2457600
4                   8192          Standard_D2ds_v5           2
1047552           76800
8                   16384         Standard_D4ds_v5           4
1047552           153600
16                  32768         Standard_D8ds_v5           8
1047552           307200
32                  65536         Standard_D16ds_v5          16
1047552           614400
32                  131072        Standard_D32ds_v5          32
1047552           1228800
32                  196608        Standard_D48ds_v5          48
1047552           1843200
32                  262144        Standard_D64ds_v5          64
1047552           2457600
32                  393216        Standard_D96ds_v5          96
1047552           3686400
```

Create VM with specific size

In the previous VM creation example, a size was not provided, which results in a default size. A VM size can be selected at creation time using az vm create and the `--size` parameter.

Bash

```
export MY_VM3_NAME="myVM3$RANDOM_SUFFIX"
az vm create \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --name $MY_VM3_NAME \
    --image SuseSles15SP5 \
    --size Standard_D2ds_v4  \
    --generate-ssh-keys
```

Resize a VM

After a VM has been deployed, it can be resized to increase or decrease resource allocation. You can view the current size of a VM with az vm show:

```
Bash

az vm show --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME --query
hardwareProfile.vmSize
```

Before resizing a VM, check if the desired size is available on the current Azure cluster. The az vm list-vm-resize-options command returns the list of sizes.

```
Bash

az vm list-vm-resize-options --resource-group $MY_RESOURCE_GROUP_NAME --name
$MY_VM_NAME --query [].name
```

If the desired size is available, the VM can be resized from a powered-on state, although it will be rebooted during the operation. Use the az vm resize command to perform the resize.

```
Bash

az vm resize --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME --size
Standard_D4s_v3
```

If the desired size is not available on the current cluster, the VM needs to be deallocated before the resize operation can occur. Use the az vm deallocate command to stop and deallocate the VM. Note that when the VM is powered back on, any data on the temporary disk may be removed. The public IP address also changes unless a static IP address is being used. Once deallocated, the resize can occur.

After the resize, the VM can be started.

```
Bash

az vm start --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME
```

VM power states

An Azure VM can have one of many power states. This state represents the current state of the VM from the standpoint of the hypervisor.

Power states

Expand table

Power State	Description
Starting	Indicates the virtual machine is being started.
Running	Indicates that the virtual machine is running.
Stopping	Indicates that the virtual machine is being stopped.
Stopped	Indicates that the virtual machine is stopped. Virtual machines in the stopped state still incur compute charges.
Deallocating	Indicates that the virtual machine is being deallocated.
Deallocated	Indicates that the virtual machine is removed from the hypervisor but still available in the control plane. Virtual machines in the Deallocated state do not incur compute charges.
-	Indicates that the power state of the virtual machine is unknown.

Find the power state

To retrieve the state of a particular VM, use the az vm get-instance-view command. Be sure to specify a valid name for a virtual machine and resource group.

Bash

```
az vm get-instance-view \
    --name $MY_VM_NAME \
    --resource-group $MY_RESOURCE_GROUP_NAME \
    --query instanceView.statuses[1] --output table
```

Output:

Output

```
Code                Level    DisplayStatus
------------------  -------  ---------------
PowerState/running  Info     VM running
```

To retrieve the power state of all the VMs in your subscription, use the Virtual Machines - List All API with parameter **statusOnly** set to *true*.

Management tasks

During the life-cycle of a virtual machine, you may want to run management tasks such as starting, stopping, or deleting a virtual machine. Additionally, you may want to create scripts to automate repetitive or complex tasks. Using the Azure CLI, many common management tasks can be run from the command line or in scripts.

Get IP address

This command returns the private and public IP addresses of a virtual machine.

```Bash
az vm list-ip-addresses --resource-group $MY_RESOURCE_GROUP_NAME --name
$MY_VM_NAME --output table
```

Stop virtual machine

```Bash
az vm stop --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME
```

Start virtual machine

```Bash
az vm start --resource-group $MY_RESOURCE_GROUP_NAME --name $MY_VM_NAME
```

Deleting VM resources

Depending on how you delete a VM, it may only delete the VM resource, not the networking and disk resources. You can change the default behavior to delete other resources when you delete the VM. For more information, see Delete a VM and attached resources.

Deleting a resource group also deletes all resources in the resource group, like the VM, virtual network, and disk. The `--no-wait` parameter returns control to the prompt without waiting for the operation to complete. The `--yes` parameter confirms that you wish to delete the resources without an additional prompt to do so.

Next steps

In this tutorial, you learned about basic VM creation and management such as how to:

- ✓ Create and connect to a VM
- ✓ Select and use VM images
- ✓ View and use specific VM sizes
- ✓ Resize a VM
- ✓ View and understand VM state

Advance to the next tutorial to learn about VM disks.

Create and Manage VM disks

Tutorial - Manage Azure disks with the Azure CLI

Article • 12/06/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure virtual machines (VMs) use disks to store the operating system, applications, and data. When you create a VM, it is important to choose a disk size and configuration appropriate to the expected workload. This tutorial shows you how to deploy and manage VM disks. You learn about:

- ✓ OS disks and temporary disks
- ✓ Data disks
- ✓ Standard and Premium disks
- ✓ Disk performance
- ✓ Attaching and preparing data disks
- ✓ Disk snapshots

Default Azure disks

When an Azure virtual machine is created, two disks are automatically attached to the virtual machine.

Operating system disk - Operating system disks can be sized up to 2 TB, and hosts the VMs operating system. The OS disk is labeled */dev/sda* by default. The disk caching configuration of the OS disk is optimized for OS performance. Because of this configuration, the OS disk **should not** be used for applications or data. For applications and data, use data disks, which are detailed later in this tutorial.

Temporary disk - Temporary disks use a solid-state drive that is located on the same Azure host as the VM. Temp disks are highly performant and may be used for operations such as temporary data processing. However, if the VM is moved to a new host, any data stored on a temporary disk is removed. The size of the temporary disk is determined by the VM size. Temporary disks are labeled */dev/sdb* and have a mountpoint of */mnt*.

Azure data disks

To install applications and store data, additional data disks can be added. Data disks should be used in any situation where durable and responsive data storage is desired. The size of the virtual machine determines how many data disks can be attached to a VM.

VM disk types

Azure provides two types of disks.

Standard disks - backed by HDDs, and delivers cost-effective storage while still being performant. Standard disks are ideal for a cost effective dev and test workload.

Premium disks - backed by SSD-based, high-performance, low-latency disk. Perfect for VMs running production workload. VM sizes with an **S** in the size name, typically support Premium Storage. For example, DS-series, DSv2-series, GS-series, and FS-series VMs support premium storage. When you select a disk size, the value is rounded up to the next type. For example, if the disk size is more than 64 GB, but less than 128 GB, the disk type is P10.

Expand table

Premium SSD sizes	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80
Disk size in GiB	4	8	16	32	64	128	256	512	1,024	2,048	4,096	8,192	16,384	32,767
Base provisioned	120	120	120	120	240	500	1,100	2,300	5,000	7,500	7,500	16,000	18,000	20,000

Premium SSD sizes	P1	P2	P3	P4	P6	P10	P15	P20	P30	P40	P50	P60	P70	P80
IOPS per disk														
**Expanded provisioned IOPS per disk	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	8,000	16,000	20,000	20,000	20,000	20,000
Base provisioned Throughput per disk	25 MB/s	25 MB/s	25 MB/s	25 MB/s	50 MB/s	100 MB/s	125 MB/s	150 MB/s	200 MB/s	250 MB/s	250 MB/s	500 MB/s	750 MB/s	900 MB/s
**Expanded provisioned throughput per disk	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	300 MB/s	600 MB/s	900 MB/s	900 MB/s	900 MB/s	900 MB/s
Max burst IOPS per disk	3,500	3,500	3,500	3,500	3,500	3,500	3,500	3,500	30,000*	30,000*	30,000*	30,000*	30,000*	30,000*
Max burst throughput per disk	170 MB/s	170 MB/s	170 MB/s	170 MB/s	170 MB/s	170 MB/s	170 MB/s	170 MB/s	1,000 MB/s*	1,000 MB/s*	1,000 MB/s*	1,000 MB/s*	1,000 MB/s*	1,000 MB/s*
Max burst duration	30 min	30 min	30 min	30 min	30 min	30 min	30 min	30 min	Unlimited*	Unlimited*	Unlimited*	Unlimited*	Unlimited*	Unlimited*
Eligible for reservation	No	No	No	No	No	No	No	No	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year	Yes, up to one year

*Applies only to disks with on-demand bursting enabled.
** Only applies to disks with performance plus (preview) enabled.

When you provision a premium storage disk, unlike standard storage, you are guaranteed the capacity, IOPS, and throughput of that disk. For example, if you create a P50 disk, Azure provisions 4,095-GB storage capacity, 7,500 IOPS, and 250-MB/s throughput for that disk. Your application can use all or part of the capacity and performance. Premium SSD disks are designed to provide low single-digit millisecond latencies and target IOPS and throughput described in the preceding table 99.9% of the time.

While the above table identifies max IOPS per disk, a higher level of performance can be achieved by striping multiple data disks. For instance, 64 data disks can be attached to Standard_GS5 VM. If each of these disks is sized as a P30, a maximum of 80,000 IOPS can be achieved. For detailed information on max IOPS per VM, see VM types and sizes.

Launch Azure Cloud Shell

Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open Cloud Shell, select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Create and attach disks

Data disks can be created and attached at VM creation time or to an existing VM.

Attach disk at VM creation

Create a resource group with the az group create command.

Azure CLI

```
az group create --name myResourceGroupDisk --location eastus
```

Create a VM using the az vm create command. The following example creates a VM named *myVM*, adds a user account named *azureuser*, and generates SSH keys if they do not exist. The `--datadisk-sizes-gb` argument is used to specify that an additional disk should be created and attached to the virtual machine. To create and attach more than one disk, use a space-delimited list of disk size values. In the following example, a VM is created with two data disks, both 128 GB. Because the disk sizes are 128 GB, these disks are both configured as P10s, which provide maximum 500 IOPS per disk.

Azure CLI

```
az vm create \
  --resource-group myResourceGroupDisk \
  --name myVM \
  --image Ubuntu2204 \
  --size Standard_DS2_v2 \
  --admin-username azureuser \
  --generate-ssh-keys \
  --data-disk-sizes-gb 128 128
```

Attach disk to existing VM

To create and attach a new disk to an existing virtual machine, use the az vm disk attach command. The following example creates a premium disk, 128 gigabytes in size, and attaches it to the VM created in the last step.

Azure CLI

```
az vm disk attach \
    --resource-group myResourceGroupDisk \
    --vm-name myVM \
    --name myDataDisk \
    --size-gb 128 \
    --sku Premium_LRS \
    --new
```

Prepare data disks

Once a disk has been attached to the virtual machine, the operating system needs to be configured to use the disk. The following example shows how to manually configure a disk. This process can also be automated using cloud-init, which is covered in a later tutorial.

Create an SSH connection with the virtual machine. Replace the example IP address with the public IP of the virtual machine.

Console

```
ssh azureuser@10.101.10.10
```

Partition the disk with `parted`.

Bash

```
sudo parted /dev/sdc --script mklabel gpt mkpart xfspart xfs 0% 100%
```

Write a file system to the partition by using the `mkfs` command. Use `partprobe` to make the OS aware of the change.

Bash

```
sudo mkfs.xfs /dev/sdc1
sudo partprobe /dev/sdc1
```

Mount the new disk so that it is accessible in the operating system.

```
```

```Bash
sudo mkdir /datadrive && sudo mount /dev/sdc1 /datadrive
```

The disk can now be accessed through the `/datadrive` mountpoint, which can be verified by running the `df -h` command.

```Bash
df -h | grep -i "sd"
```

The output shows the new drive mounted on `/datadrive`.

```Bash
Filesystem      Size  Used Avail Use% Mounted on
/dev/sda1        29G  2.0G   27G   7% /
/dev/sda15      105M  3.6M  101M   4% /boot/efi
/dev/sdb1        14G   41M   13G   1% /mnt
/dev/sdc1        50G   52M   47G   1% /datadrive
```

To ensure that the drive is remounted after a reboot, it must be added to the */etc/fstab* file. To do so, get the UUID of the disk with the `blkid` utility.

```Bash
sudo -i blkid
```

The output displays the UUID of the drive, `/dev/sdc1` in this case.

```Bash
/dev/sdc1: UUID="33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e" TYPE="xfs"
```

> ⓘ **Note**
>
> Improperly editing the **/etc/fstab** file could result in an unbootable system. If unsure, refer to the distribution's documentation for information on how to properly edit this file. It is also recommended that a backup of the /etc/fstab file is created before editing.

Open the `/etc/fstab` file in a text editor as follows:

```Bash
sudo nano /etc/fstab
```

Add a line similar to the following to the */etc/fstab* file, replacing the UUID value with your own.

```Bash
UUID=33333333-3b3b-3c3c-3d3d-3e3e3e3e3e3e   /datadrive  xfs    defaults,nofail   1  2
```

When you are done editing the file, use `Ctrl+O` to write the file and `Ctrl+X` to exit the editor.

Now that the disk has been configured, close the SSH session.

```Bash
exit
```

Take a disk snapshot

When you take a disk snapshot, Azure creates a read only, point-in-time copy of the disk. Azure VM snapshots are useful to quickly save the state of a VM before you make configuration changes. In the event of an issue or error, VM can be restored using a snapshot. When a VM has more than one disk, a snapshot is taken of each disk independently of the others. To take application consistent backups, consider stopping the VM before you take disk snapshots. Alternatively, use the Azure Backup service, which enables you to perform automated backups while the VM is running.

Create snapshot

Before you create a snapshot, you need the ID or name of the disk. Use az vm show to show the disk ID. In this example, the disk ID is stored in a variable so that it can be used in a later step.

Azure CLI

```
osdiskid=$(az vm show \
   -g myResourceGroupDisk \
   -n myVM \
   --query "storageProfile.osDisk.managedDisk.id" \
   -o tsv)
```

Now that you have the ID, use az snapshot create to create a snapshot of the disk.

Azure CLI

```
az snapshot create \
    --resource-group myResourceGroupDisk \
    --source "$osdiskid" \
    --name osDisk-backup
```

Create disk from snapshot

This snapshot can then be converted into a disk using az disk create, which can be used to recreate the virtual machine.

Azure CLI

```
az disk create \
   --resource-group myResourceGroupDisk \
   --name mySnapshotDisk \
   --source osDisk-backup
```

Restore virtual machine from snapshot

To demonstrate virtual machine recovery, delete the existing virtual machine using az vm delete.

Azure CLI

```
az vm delete \
--resource-group myResourceGroupDisk \
--name myVM
```

Create a new virtual machine from the snapshot disk.

Azure CLI

```
az vm create \
    --resource-group myResourceGroupDisk \
    --name myVM \
    --attach-os-disk mySnapshotDisk \
    --os-type linux
```

Reattach data disk

All data disks need to be reattached to the virtual machine.

Find the data disk name using the az disk list command. This example places the name of the disk in a variable named `datadisk`, which is used in the next step.

Azure CLI

```
datadisk=$(az disk list \
   -g myResourceGroupDisk \
   --query "[?contains(name,'myVM')].[id]" \
   -o tsv)
```

Use the az vm disk attach command to attach the disk.

Azure CLI

```
az vm disk attach \
   –g myResourceGroupDisk \
   --vm-name myVM \
   --name $datadisk
```

Next steps

In this tutorial, you learned about VM disks topics such as:

- ✓ OS disks and temporary disks
- ✓ Data disks
- ✓ Standard and Premium disks
- ✓ Disk performance
- ✓ Attaching and preparing data disks
- ✓ Disk snapshots

Tutorial: Create a custom image of an Azure VM with the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Custom images are like marketplace images, but you create them yourself. Custom images can be used to bootstrap configurations such as preloading applications, application configurations, and other OS configurations. In this tutorial, you create your own custom image of an Azure virtual machine. You learn how to:

- ✔ Create an Azure Compute Gallery (formerly known as Shared Image Gallery)
- ✔ Create an image definition
- ✔ Create an image version
- ✔ Create a VM from an image
- ✔ Share a gallery

This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you're running the Azure CLI version 2.35.0 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Overview

An Azure Compute Gallery simplifies custom image sharing across your organization. Custom images are like marketplace images, but you create them yourself. Custom images can be used to bootstrap configurations such as preloading applications, application configurations, and other OS configurations.

The Azure Compute Gallery lets you share your custom VM images with others. Choose which images you want to share, which regions you want them to be available in, and who you want to share them with.

The Azure Compute Gallery feature has multiple resource types:

Expand table

Resource	Description
Image source	This is a resource that can be used to create an **image version** in a gallery. An image source can be an existing Azure VM that is either generalized or specialized, a managed image, a snapshot, or an image version in another gallery.
Gallery	Like the Azure Marketplace, a **gallery** is a repository for managing and sharing images and VM applications, but you control who has access.
Image definition	Image definitions are created within a gallery and carry information about the image and requirements for using it internally. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.
Image version	An **image version** is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an **image version** to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

Before you begin

The following steps show how to take an existing VM and turn it into a reusable custom image that you can use to create new VM instances.

To complete the example in this tutorial, you must have an existing virtual machine. If needed, you can see the CLI quickstart to create a VM to use for this tutorial. When working through the tutorial, replace the resource names where needed.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Create a gallery

A gallery is the primary resource used for enabling image sharing.

Allowed characters for gallery name are uppercase or lowercase letters, digits, dots, and periods. The gallery name can't contain dashes. Gallery names must be unique within

your subscription.

Create a gallery using az sig create. The following example creates a resource group named gallery named *myGalleryRG* in *East US*, and a gallery named *myGallery*.

Azure CLI

```
az group create --name myGalleryRG --location eastus
az sig create --resource-group myGalleryRG --gallery-name myGallery
```

Get information about the VM

You can see a list of VMs that are available using az vm list.

Azure CLI

```
az vm list --output table
```

Once you know the VM name and what resource group it is in, get the ID of the VM using az vm get-instance-view.

Azure CLI

```
az vm get-instance-view -g MyResourceGroup -n MyVm --query id
```

Copy the ID of your VM to use later.

Create an image definition

Image definitions create a logical grouping for images. They're used to manage information about the image versions that are created within them.

Image definition names can be made up of uppercase or lowercase letters, digits, dots, dashes, and periods.

For more information about the values you can specify for an image definition, see Image definitions.

Create an image definition in the gallery using az sig image-definition create.

In this example, the image definition is named *myImageDefinition*, and is for a specialized Linux OS image.

Azure CLI

```
az sig image-definition create \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   --publisher myPublisher \
   --offer myOffer \
   --sku mySKU \
   --os-type Linux \
   --os-state specialized
```

Copy the ID of the image definition from the output to use later.

Create the image version

Create an image version from the VM using az sig image-version create.

Allowed characters for image version are numbers and periods. Numbers must be within the range of a 32-bit integer. Format: *MajorVersion.MinorVersion.Patch*.

In this example, the version of our image is *1.0.0* and we're going to create two replicas in the *West Central US* region, one replica in the *South Central US* region and one replica in the *East US 2* region using zone-redundant storage. The replication regions must include the region the source VM is located.

Replace the value of `--managed-image` in this example with the ID of your VM from the previous step.

Azure CLI

```
az sig image-version create \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   --gallery-image-version 1.0.0 \
   --target-regions "westcentralus" "southcentralus=1"
"eastus=1=standard_zrs" \
   --replica-count 2 \
   --managed-image "/subscriptions/<Subscription
ID>/resourceGroups/MyResourceGroup/providers/Microsoft.Compute/virtualMachin
es/myVM"
```

ⓘ Note

You need to wait for the image version to completely finish being built and replicated before you can use the same managed image to create another image version.

You can also store your image in Premium storage by a adding `--storage-account-type premium_lrs`, or Zone Redundant Storage by adding `--storage-account-type standard_zrs` when you create the image version.

Create the VM

Create the VM using az vm create using the `--specialized` parameter to indicate the image is a specialized image.

Use the image definition ID for `--image` to create the VM from the latest version of the image that is available. You can also create the VM from a specific version by supplying the image version ID for `--image`.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

Azure CLI

```
az group create --name myResourceGroup --location eastus
az vm create --resource-group myResourceGroup \
    --name myVM2 \
    --image "/subscriptions/<Subscription
ID>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myGalle
ry/images/myImageDefinition" \
    --specialized
```

Share the gallery

You can share images across subscriptions using Azure role-based access control (Azure RBAC). You can share images at the gallery, image definition or image version level. Any user that has read permissions to an image version, even across subscriptions, will be able to deploy a VM using the image version.

We recommend that you share with other users at the gallery level. To get the object ID of your gallery, use az sig show.

Azure CLI

```
az sig show \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --query id
```

Use the object ID as a scope, along with an email address and az role assignment create to give a user access to the Azure Compute Gallery. Replace `<email-address>` and `<gallery iD>` with your own information.

Azure CLI

```
az role assignment create \
   --role "Reader" \
   --assignee <email address> \
   --scope <gallery ID>
```

For more information about how to share resources using Azure RBAC, see Add or remove Azure role assignments using Azure CLI.

Azure Image Builder

Azure also offers a service, built on Packer, Azure VM Image Builder. Describe your customizations in a template, and it will handle the image creation.

Next steps

In this tutorial, you created a custom VM image. You learned how to:

- ✓ Create an Azure Compute Gallery
- ✓ Create an image definition
- ✓ Create an image version
- ✓ Create a VM from an image
- ✓ Share a gallery

Advance to the next tutorial to learn about Virtual Machine Scale Sets.

Create a virtual machine scale set

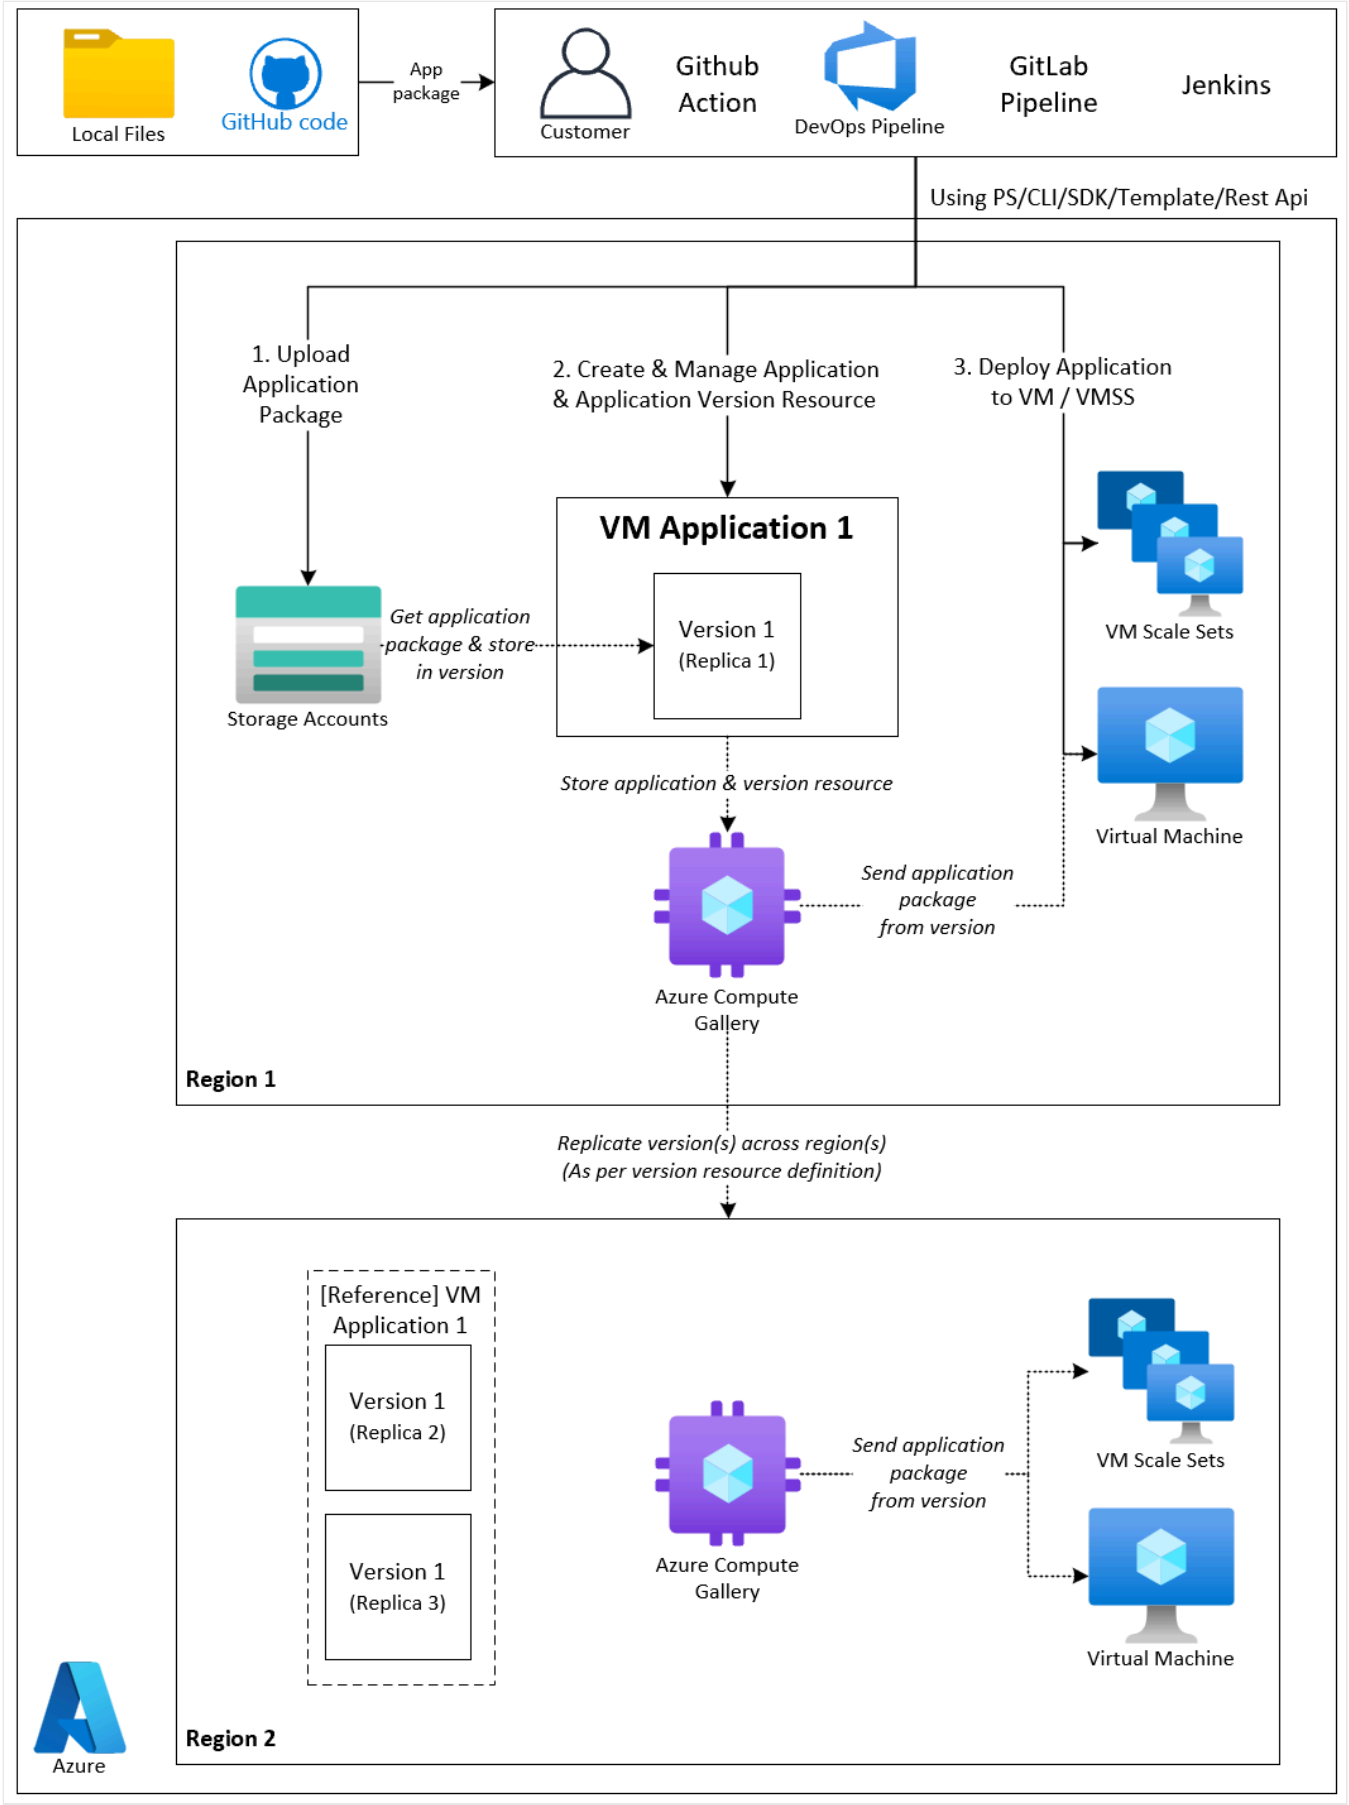
Create and deploy VM Application

Summarize this article for me

VM Application is a resource type in Azure Compute Gallery that simplifies publishing, deployment, management, sharing, and global distribution of applications and scripts for your virtual machines. VM Applications support a wide range of scenarios, including high-scale deployments, low-latency requirements, failure resiliency, secure trusted rollouts, fleet-wide consistency, microservice architectures, and post-deployment management. Learn more about VM Applications.

To create and deploy applications on Azure VM, first package and upload your application to Azure Storage Account as a storage blob. Then create `Azure VM application` resource and `VM application version` resource referencing these storage blobs. Azure stores and replicates these blobs in regional managed storage accounts. Finally, deploy the application on any VM or Virtual Machine Scale Sets by passing application reference in `applicationProfile`.



Prerequisites

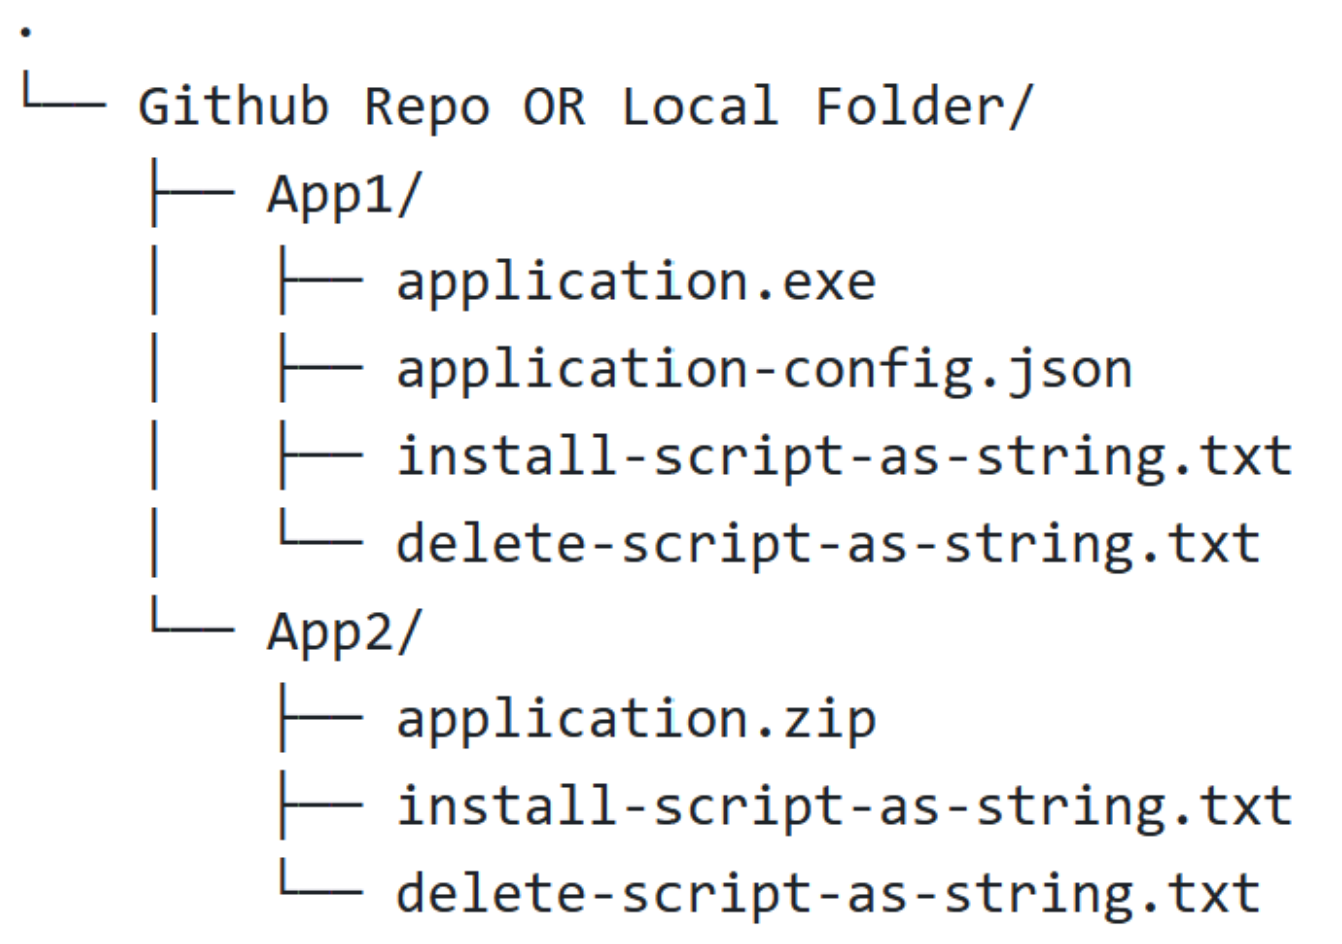
1. Create Azure storage account and storage container. This container is used to upload your application files.

2. Create Azure Compute Gallery for storing and sharing application resources.
3. Create user-assigned managed identity and assign to Azure Compute Gallery

> ⓘ Note
>
> Create your storage account with anonymous access disabled for improved security. Use a managed identity assigned to Azure Compute Gallery to publish your VM Applications securely without requiring SAS tokens.

Package the application

Before publishing the VM Application resource in Azure Compute Gallery, package your application files for upload to Azure Storage Account. The following diagram shows possible folder structures for organizing your application files:



1. Package the application files

VM Application requires a single file as the application package.

- If your application installation requires a single executable file (.exe, .msi, .sh, .ps, etc.) then you can use it as the application package.
- If your application requires multiple files (executables, dependencies, scripts, metadata, etc.), archive them into a single file (`.zip`, `.tar`, `.tar.gz`) and use this file as the application package.
- For microservice application, you can package and publish each microservice as a separate Azure VM Application. This modularization facilitates application reusability, cross-team development, and sequential installation of microservices using `order` property in the applicationProfile.

Learn more about creating application packages for Azure VM Applications.

2. (Optional) Package the application configuration file

- You can provide the configuration file separately using `defaultConfigurationLink` in the `publishingProfile` of the VM Application. This reduces the overhead of archiving and unarchiving application packages.
- Configuration files can also be passed during app deployment using `configurationReference` property in the `applicationProfile` of the VM enabling customized installation per VM.
- If both properties are set, `configurationReference` overrides the configuration passed using `defaultConfigurationLink`.

3. Create the install script

After the application and configuration blob is downloaded on the VM, Azure executes the provided install script to install the application. **The install script is provided as a string** and has a maximum character limit of 4,096 chars. The install commands should be written assuming the application package and the configuration file are in the current directory.

There may be few operations required to be performed in the install script

- **(Optional) Use the right command interpreter** The default command interpreter used by Azure are `/bin/bash` on Linux OS and `cmd.exe` on Windows OS. It's possible to use a different interpreter like Chocolatey or PowerShell, if its installed on the machine. Call the executable and pass the commands to it. For example, `powershell.exe -command '<powershell command>'`. If you're using PowerShell, you need to be using version 3.11.0 of the Az.Storage module.

- **(Optional) Rename application blob and configuration blob** Azure can't retain the original blob name and the file extensions. Azure downloads the application file with the

name of the VM application resource published on Azure Compute Gallery. So if name of VM App is "VMApp1", the file downloaded on VM has the name "VMApp1" without an extension. The configuration file has a default name as "VMApp1-config" without a file extension.

You can rename the file with the file extension using the install script or you can also pass the names in `packageFileName` and `configFileName` properties of the publishingProfile of VM Application version resource. Azure uses these names instead of default names while downloading the files.

- **Unarchive application blob** For archived application packages, it needs to be unarchived before installing the application. Use .zip or .tar since most OS has built-in support for unarchiving these formats. For other formats, make sure the Guest OS provides support.

- **Convert the script to string** The install script is passed as a string for the `install` property in the `publishingProfile` of Azure VM Application version resource.

- **Install quietly and synchronously** Install applications quietly or silently without any user interface prompts. Since the installation runs on a VM where customer input isn't available, you must use silent or unattended installation flags. Additionally, if the application installer spawns background or child processes or runs asynchronously, the parent script might return before the installation completes. To ensure the full installation finishes before Azure marks the operation as successful, use wait flags or blocking commands. This approach helps when installation involves multiple steps that run asynchronously or you need to verify installation completes before the subsequent application in the `order` sequence begins.

  Common examples include:
  - **Windows .msi**: `start /wait msiexec /i app.msi /quiet /qn`
  - **Windows .exe**: `start /wait app.exe /silent` or `start /wait app.exe /quiet` or `start /wait app.exe /S`
  - **PowerShell**: `Start-Process -FilePath '.\app.exe' -ArgumentList '/quiet' -Wait`
  - **Linux .sh**: `./install.sh --silent` (shell scripts run synchronously by default)
  - **Linux .deb**: `sudo DEBIAN_FRONTEND=noninteractive dpkg -i app.deb` (runs synchronously by default)
  - **Linux .rpm**: `sudo rpm -ivh app.rpm` (runs synchronously by default)

- **(Optional) Set right execution policy and permissions** After unarchiving, file permissions could be reset. It's a good practice to set the right permissions before executing the files.

- **(Optional) Set verbose execution and logging** VM Applications automatically captures any output from the install script and stores it in a stdout file on the VM. Use this

capability to log installation progress, debug failures, and verify successful deployments.
    - **Enable verbose mode** to capture application installer logs. Bash: `set -x`, PowerShell: `$VerbosePreference='Continue'`, Cmd: `@echo on`.
    - **Add custom messages** to track script progress. Bash: `echo "Install started"`, PowerShell: `Write-Output "Install started"`, Cmd: `echo Install started`

    You can retrieve these logs using Run Command or by connecting to the VM. The `stdout` and `stderr` files are located at the following path
    - Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>/`
    - Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.9\Downloads\<application name>\<application version>/`

- **(Optional) Move application and configuration blob to appropriate location** Azure downloads the application blob and configuration blob to following locations. The install script must move the files to appropriate locations when necessary.

    Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>`

    Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.16\Downloads\<application name>\<application version>`

Here are few sample install scripts based on the file extension of the application blob. If `packageFileName` & `configFileName` properties are provided in the `publishingProfile` with file name and extension, remove the code for renaming files in following scripts.

.TAR

Replace `VMApp1` with your VM App name in application package (VMApp1) and configuration file (VMApp1-config). Replace `app.tar` with desired app name. Replace `config.yaml` with your desired config name.

Install using bash without config file:

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && bash ./install.sh
```

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && sudo
DEBIAN_FRONTEND=noninteractive dpkg -i ./app.deb
```

Install using bash with config file:

Bash

```
mv VMApp1 app.tar && mv VMApp1-config config.yaml && tar -xf app.tar && chmod -
R +xr . && bash ./install.sh --config config.yaml
```

If config file is packaged within the tar file

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && sudo debconf-set-
selections < config.cfg && sudo DEBIAN_FRONTEND=noninteractive dpkg -i
./app.deb
```

4. Create the remove script

The `remove` script enables you to define the operations for removing the application. The `remove` script is provided as a string and has a maximum character limit of 4,096 characters. Write the commands assuming the application package and the configuration file are in the current directory. During uninstall operation, Azure runs the uninstall script and then deletes all files from the repository.

There are few operations that the `remove` script must perform.

- **Uninstall application:** Properly uninstall the application from the VM. For example:

CMD

CMD on Windows:

cli

```
start /wait uninstall.exe /quiet
```

cli

```
start /wait python.exe /uninstall /quiet
```

cli

```
start /wait msiexec /x app.msi /quiet /qn
```

- **Remove residual files:** If the application installation creates files in other parts of the file system, remove those files.

Upload the application files to Azure storage account

> ⓘ **Important**
>
> Before uploading files or generating SAS URLs, assign roles to the user, service principal, or managed identity that performs these operations on the target Storage account or container:
>
> - Storage Blob Data Contributor or Storage Blob Data Owner: required to upload, modify, or delete blobs.
> - For generating SAS with Azure AD (for example, using `--auth-mode` login in CLI/PowerShell), also assign Storage Blob Delegator at the storage account scope.

1. Upload your application and configuration files to a container in your Azure storage account.

Upload your packaged application and optional configuration file as blobs. Block blobs work for most scenarios.

Optionally, if you need to use page blobs, byte-align your files before uploading using one of the following scripts:

CLI

Azure CLI

```
inputFile="<the file you want to pad>"

# Get the file size
fileSize=$(stat -c %s "$inputFile")

# Calculate the remainder when divided by 512
```

```
remainder=$((fileSize % 512))

if [ "$remainder" -ne 0 ]; then
  # Calculate how many bytes to pad
  difference=$((512 - remainder))

  # Create padding (empty bytes)
  dd if=/dev/zero bs=1 count=$difference >> "$inputFile"
fi
```

2. Generate SAS or Blob URL for the application package and the configuration file

Once the application and configuration files are uploaded to the storage account, you need to generate a Blob URL or SAS URL with read privilege for these blobs. These URLs are then provided as reference while creating the VM Application version resource.

> ⓘ **Note**
>
> Use of blob URL with managed identity is strongly recommended for improved security and privacy.

Use blob URL:

- If managed identity is assigned to Azure Compute Gallery.
- If storage account is enabled for anonymous access. Use this method only for testing since its insecure.

Use SAS URL:

- If storage account is disabled for anonymous access and managed identity isn't assigned to Azure Compute Gallery.

Blob URL = https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${BLOB_NAME}
SAS URL = https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${BLOB_NAME}?${SAS_TOKEN}

CLI using Blob URL

Use the following script if managed identity is assigned to Azure Compute Gallery. This approach uses blob URLs without SAS tokens.

Azure CLI

```
#!/bin/bash
set -euo pipefail

# === CONFIGURATION ===
STORAGE_ACCOUNT="your-storage-account-name"
CONTAINER_NAME="your-container-name"
APP_FILE="./path/to/your-app-file"           # Path to your application payload
file
CONFIG_FILE="./path/to/your-config-file"     # Path to your configuration file
(optional)

# === LOGIN (if not already logged in) ===
az login --only-show-errors

# === CREATE CONTAINER IF NOT EXISTS ===
az storage container create \
  --name "$CONTAINER_NAME" \
  --account-name "$STORAGE_ACCOUNT" \
  --auth-mode login \
  --only-show-errors

# === UPLOAD APPLICATION FILE ===
APP_BLOB_NAME=$(basename "$APP_FILE")
az storage blob upload \
  --account-name "$STORAGE_ACCOUNT" \
  --container-name "$CONTAINER_NAME" \
  --name "$APP_BLOB_NAME" \
  --file "$APP_FILE" \
  --auth-mode login \
  --overwrite \
  --only-show-errors

# === UPLOAD CONFIG FILE (optional) ===
if [ -n "$CONFIG_FILE" ] && [ -f "$CONFIG_FILE" ]; then
  CONFIG_BLOB_NAME=$(basename "$CONFIG_FILE")
  az storage blob upload \
    --account-name "$STORAGE_ACCOUNT" \
    --container-name "$CONTAINER_NAME" \
    --name "$CONFIG_BLOB_NAME" \
    --file "$CONFIG_FILE" \
    --auth-mode login \
    --overwrite \
    --only-show-errors
fi

# === GENERATE BLOB URLs ===
echo "Generating Blob URLs..."

APP_BLOB_URL="https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME
}/${APP_BLOB_NAME}"
echo "Application file: $APP_BLOB_URL"
```

```
if [ -n "$CONFIG_FILE" ] && [ -f "$CONFIG_FILE" ]; then

CONFIG_BLOB_URL="https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${CONFIG_BLOB_NAME}"
  echo "Configuration file: $CONFIG_BLOB_URL"
fi
```

Create the VM Application

To create the VM Application, first create the **VM Application** resource, which describes the application. Then create **VM Application Version** resource within it, which contains the VM application payload and scripts to install, update, and delete the application. Payload is supplied using Blob URL or SAS URL to the blob container in Azure Storage Account.

Refer schema for VM Application and VM Application version resource to learn more about each property.

Template

Use the following ARM template to create an Azure Compute Gallery, VM Application, and VM Application version. This template demonstrates the key properties and configuration options for publishing your application package.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2020-06-01/deploymentTemplate.json#",

            },
          ],
          "excludeFromLatest": false,
          "replicaCount": 2,
          "storageAccountType": "[parameters('storageAccountType')]"
        },
        "safetyProfile": {
          "allowDeletionOfReplicatedLocations": true
        },
        "endOfLifeDate": "[parameters('endOfLifeDate')]"
      }
    }
  ]
}
```

Deploy the VM Apps

One or more VM Applications can now be referenced in the `applicationProfile` of Azure VM or Azure Virtual Machine Scale Sets. Azure then pulls the payload of the VM Application and installs it on each VM using the provided install script. The `order` property defines the sequential order in which the VM Applications are installed on the VM.

Refer schema of applicationProfile of the VM / Virtual Machine Scale Sets to learn more about each property.

Template

Use the following ARM template to deploy VM Application on Azure VM or Azure Virtual Machine Scale Sets. This template demonstrates the key properties and configuration options for deploying your VM application.

Deploy VM Application on Virtual Machine Scale Sets

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",

Tutorial - How to use cloud-init to customize a Linux virtual machine in Azure on first boot

Article • 05/02/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

In a previous tutorial, you learned how to SSH to a virtual machine (VM) and manually install NGINX. To create VMs in a quick and consistent manner, some form of automation is typically desired. A common approach to customize a VM on first boot is to use cloud-init. In this tutorial you learn how to:

- ✔ Create a cloud-init config file
- ✔ Create a VM that uses a cloud-init file
- ✔ View a running Node.js app after the VM is created
- ✔ Use Key Vault to securely store certificates
- ✔ Automate secure deployments of NGINX with cloud-init

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

Cloud-init overview

Cloud-init is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. As cloud-init runs during the initial boot process, there are no additional steps or required agents to apply your configuration.

Cloud-init also works across distributions. For example, you don't use **apt-get install** or **yum install** to install a package. Instead you can define a list of packages to install. Cloud-init automatically uses the native package management tool for the distro you select.

We are working with our partners to get cloud-init included and working in the images that they provide to Azure. For detailed information cloud-init support for each distribution, see Cloud-init support for VMs in Azure.

Create cloud-init config file

To see cloud-init in action, create a VM that installs NGINX and runs a simple 'Hello World' Node.js app. The following cloud-init configuration installs the required packages, creates a Node.js app, then initializes and starts the app.

At your bash prompt or in the Cloud Shell, create a file named *cloud-init.txt* and paste the following configuration. For example, type `sensible-editor cloud-init.txt` to create the file and see a list of available editors. Make sure that the whole cloud-init file is copied correctly, especially the first line:

YAML

```
#cloud-config
package_upgrade: true
packages:
  - nginx
  - nodejs
  - npm
write_files:
  - owner: www-data:www-data
    path: /etc/nginx/sites-available/default
    defer: true
    content: |
      server {
        listen 80;
        location / {
          proxy_pass http://localhost:3000;
          proxy_http_version 1.1;
          proxy_set_header Upgrade $http_upgrade;
          proxy_set_header Connection keep-alive;
          proxy_set_header Host $host;
          proxy_cache_bypass $http_upgrade;
        }
      }
  - owner: azureuser:azureuser
    path: /home/azureuser/myapp/index.js
    defer: true
    content: |
      var express = require('express')
      var app = express()
      var os = require('os');
      app.get('/', function (req, res) {
        res.send('Hello World from host ' + os.hostname() + '!')
      })
      app.listen(3000, function () {
        console.log('Hello world app listening on port 3000!')
      })
runcmd:
  - service nginx restart
  - cd "/home/azureuser/myapp"
  - npm init
```

```
  - npm install express -y
  - nodejs index.js
```

For more information about cloud-init configuration options, see cloud-init config examples.

Create virtual machine

Before you can create a VM, create a resource group with az group create. The following example creates a resource group. In these commands, a random suffix is appended to the resource group and VM names to prevent name collisions during repeated deployments.

Bash

```
export RANDOM_SUFFIX=$(openssl rand -hex 3)
export RESOURCE_GROUP="myResourceGroupAutomate$RANDOM_SUFFIX"
export REGION="eastus2"
az group create --name $RESOURCE_GROUP --location $REGION
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxx-xxxxx-xxxxx-
xxxxx/resourceGroups/myResourceGroupAutomatexxx",
  "location": "eastus",
  "managedBy": null,
  "name": "myResourceGroupAutomatexxx",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null,
  "type": "Microsoft.Resources/resourceGroups"
}
```

Now create a VM with az vm create. Use the `--custom-data` parameter to pass in your cloud-init config file. Provide the full path to the *cloud-init.txt* config if you saved the file outside of your present working directory. The following example creates a VM; note that the VM name is also appended with the random suffix.

Bash

```
export VM_NAME="myAutomatedVM$RANDOM_SUFFIX"
az vm create \
    --resource-group $RESOURCE_GROUP \
    --name $VM_NAME \
```

```
    --image Ubuntu2204 \
    --admin-username azureuser \
    --generate-ssh-keys \
    --custom-data cloud-init.txt
```

Results:

JSON

```
{
  "fqdns": "",
  "id":
"/subscriptions/xxxxx/resourceGroups/myResourceGroupAutomatexxx/providers/Microsof
t.Compute/virtualMachines/myAutomatedVMxxx",
  "location": "eastus",
  "name": "myAutomatedVMxxx",
  "powerState": "VM running",
  "publicIpAddress": "x.x.x.x",
  "resourceGroup": "myResourceGroupAutomatexxx",
  "zones": ""
}
```

It takes a few minutes for the VM to be created, the packages to install, and the app to start. There are background tasks that continue to run after the Azure CLI returns you to the prompt. It may be another couple of minutes before you can access the app. When the VM has been created, take note of the `publicIpAddress` displayed by the Azure CLI. This address is used to access the Node.js app via a web browser.

To allow web traffic to reach your VM, open port 80 from the Internet with az vm open-port:

Bash

```
az vm open-port --port 80 --resource-group $RESOURCE_GROUP --name $VM_NAME
```

Results:

JSON

```
{
  "endpoints": [
    {
      "name": "80",
      "protocol": "tcp",
      "publicPort": 80,
      "privatePort": 80
    }
  ],
  "id":
```

```
"/subscriptions/xxxxx/resourceGroups/myResourceGroupAutomatexxx/providers/Microsoft.Compute/virtualMachines/myAutomatedVMxxx",
  "location": "eastus",
  "name": "myAutomatedVMxxx"
}
```

Test web app

Now you can open a web browser and enter the public IP address in the address bar. Provide your own public IP address from the VM create process. Your Node.js app is displayed as shown in the following example:

Next steps

In this tutorial, you configured VMs on first boot with cloud-init. You learned how to:

- ✓ Create a cloud-init config file
- ✓ Create a VM that uses a cloud-init file
- ✓ View a running Node.js app after the VM is created
- ✓ Use Key Vault to securely store certificates
- ✓ Automate secure deployments of NGINX with cloud-init

Advance to the next tutorial to learn how to create custom VM images.

Create custom VM images

Tutorial: Create and manage Azure virtual networks for Linux virtual machines with the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure virtual machines use Azure networking for internal and external network communication. This tutorial walks through deploying two virtual machines and configuring Azure networking for these VMs. The examples in this tutorial assume that the VMs are hosting a web application with a database back-end, however an application is not deployed in the tutorial. In this tutorial, you learn how to:

- ✔ Create a virtual network and subnet
- ✔ Create a public IP address
- ✔ Create a front-end VM
- ✔ Secure network traffic
- ✔ Create a back-end VM

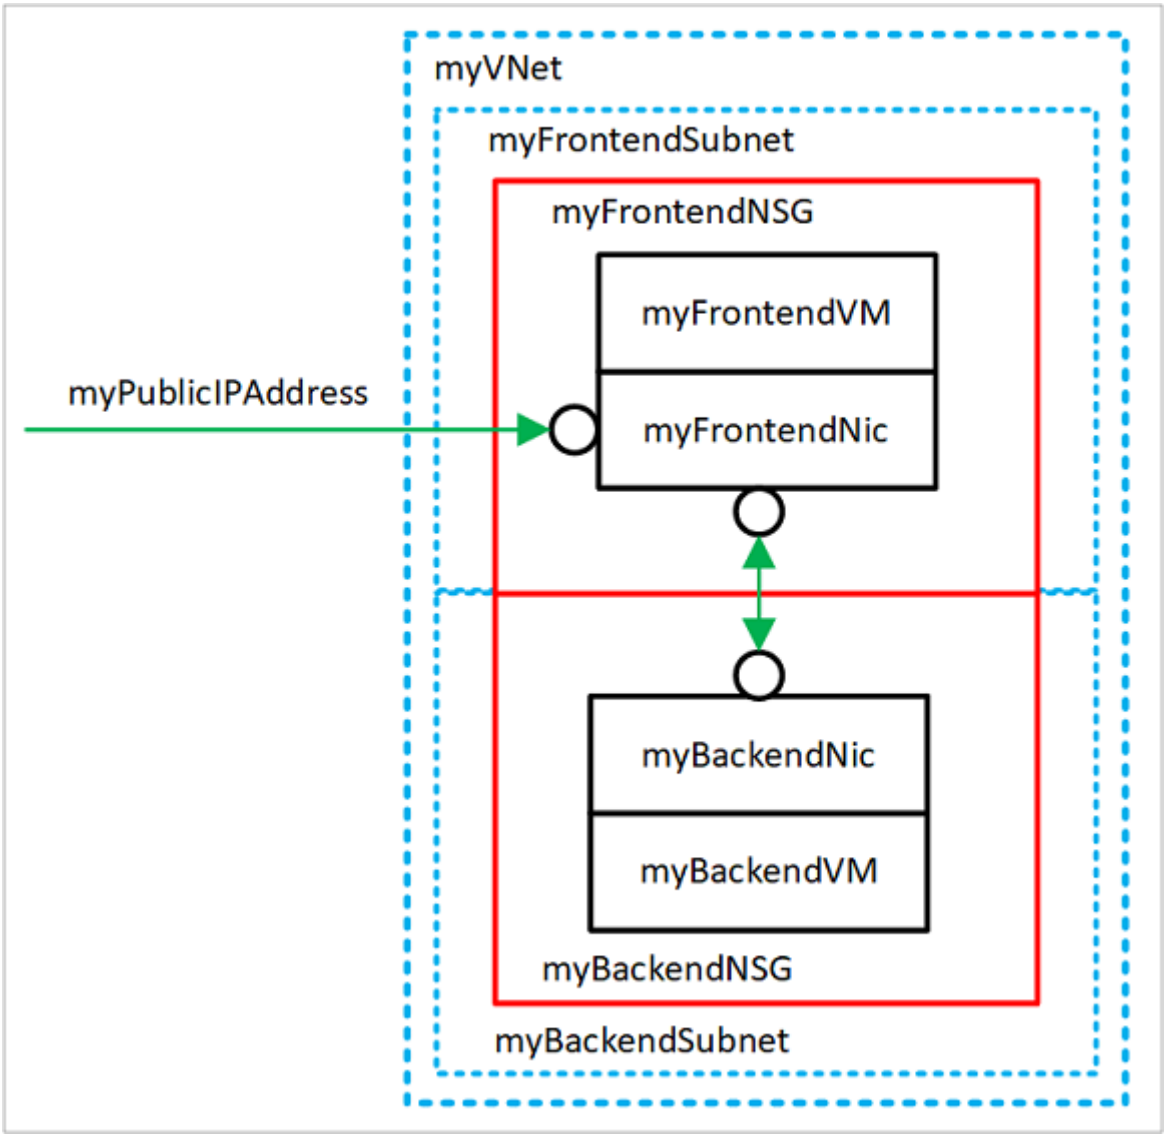
This tutorial uses the CLI within the Azure Cloud Shell, which is constantly updated to the latest version. To open the Cloud Shell, select **Try it** from the top of any code block.

If you choose to install and use the CLI locally, this tutorial requires that you are running the Azure CLI version 2.0.30 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install Azure CLI.

VM networking overview

Azure virtual networks enable secure network connections between virtual machines, the internet, and other Azure services such as Azure SQL Database. Virtual networks are broken down into logical segments called subnets. Subnets are used to control network flow, and as a security boundary. When deploying a VM, it generally includes a virtual network interface, which is attached to a subnet.

As you complete the tutorial, the following virtual network resources are created:



- *myVNet* - The virtual network that the VMs use to communicate with each other and the internet.
- *myFrontendSubnet* - The subnet in *myVNet* used by the front-end resources.
- *myPublicIPAddress* - The public IP address used to access *myFrontendVM* from the internet.
- *myFrontentNic* - The network interface used by *myFrontendVM* to communicate with *myBackendVM*.
- *myFrontendVM* - The VM used to communicate between the internet and *myBackendVM*.
- *myBackendNSG* - The network security group that controls communication between the *myFrontendVM* and *myBackendVM*.
- *myBackendSubnet* - The subnet associated with *myBackendNSG* and used by the back-end resources.
- *myBackendNic* - The network interface used by *myBackendVM* to communicate with *myFrontendVM*.
- *myBackendVM* - The VM that uses port 22 and 3306 to communicate with *myFrontendVM*.

Create a virtual network and subnet

For this tutorial, a single virtual network is created with two subnets. A front-end subnet for hosting a web application, and a back-end subnet for hosting a database server.

Before you can create a virtual network, create a resource group with az group create. The following example creates a resource group named *myRGNetwork* in the eastus location.

Azure CLI

```
az group create --name myRGNetwork --location eastus
```

Create virtual network

Use the az network vnet create command to create a virtual network. In this example, the network is named *mvVNet* and is given an address prefix of *10.0.0.0/16*. A subnet is also created with a name of *myFrontendSubnet* and a prefix of *10.0.1.0/24*. Later in this tutorial a front-end VM is connected to this subnet.

Azure CLI

```
az network vnet create \
  --resource-group myRGNetwork \
  --name myVNet \
  --address-prefix 10.0.0.0/16 \
  --subnet-name myFrontendSubnet \
  --subnet-prefix 10.0.1.0/24
```

Create subnet

A new subnet is added to the virtual network using the az network vnet subnet create command. In this example, the subnet is named *myBackendSubnet* and is given an address prefix of *10.0.2.0/24*. This subnet is used with all back-end services.

Azure CLI

```
az network vnet subnet create \
  --resource-group myRGNetwork \
  --vnet-name myVNet \
  --name myBackendSubnet \
  --address-prefix 10.0.2.0/24
```

At this point, a network has been created and segmented into two subnets, one for front-end services, and another for back-end services. In the next section, virtual machines are created and connected to these subnets.

Create a public IP address

A public IP address allows Azure resources to be accessible on the internet. The allocation method of the public IP address can be configured as dynamic or static. By default, a public IP address is dynamically allocated. Dynamic IP addresses are released when a VM is deallocated. This behavior causes the IP address to change during any operation that includes a VM deallocation.

The allocation method can be set to static, which ensures that the IP address remains assigned to a VM, even during a deallocated state. When using a statically allocated IP address, the IP address itself cannot be specified. Instead, it is allocated from a pool of available addresses.

Azure CLI

```
az network public-ip create --resource-group myRGNetwork --name
myPublicIPAddress
```

When creating a VM with the az vm create command, the default public IP address allocation method is dynamic. When creating a virtual machine using the az vm create command, include the `--public-ip-address-allocation static` argument to assign a static public IP address. This operation is not demonstrated in this tutorial, however in the next section a dynamically allocated IP address is changed to a statically allocated address.

Change allocation method

The IP address allocation method can be changed using the az network public-ip update command. In this example, the IP address allocation method of the front-end VM is changed to static.

First, deallocate the VM.

Azure CLI

```
az vm deallocate --resource-group myRGNetwork --name myFrontendVM
```

Use the az network public-ip update command to update the allocation method. In this case, the `--allocation-method` is being set to *static*.

Azure CLI

```
az network public-ip update --resource-group myRGNetwork --name
myPublicIPAddress --allocation-method static
```

Start the VM.

Azure CLI

```
az vm start --resource-group myRGNetwork --name myFrontendVM --no-wait
```

No public IP address

Often, a VM does not need to be accessible over the internet. To create a VM without a public IP address, use the `--public-ip-address ""` argument with an empty set of double quotes. This configuration is demonstrated later in this tutorial.

Create a front-end VM

Use the az vm create command to create the VM named *myFrontendVM* using *myPublicIPAddress*.

Azure CLI

```
az vm create \
  --resource-group myRGNetwork \
  --name myFrontendVM \
  --vnet-name myVNet \
  --subnet myFrontendSubnet \
  --nsg myFrontendNSG \
  --public-ip-address myPublicIPAddress \
  --image Ubuntu2204 \
  --generate-ssh-keys
```

Secure network traffic

A network security group (NSG) contains a list of security rules that allow or deny network traffic to resources connected to Azure Virtual Networks (VNet). NSGs can be associated to subnets or individual network interfaces. When an NSG is associated with

a network interface, it applies only the associated VM. When an NSG is associated to a subnet, the rules apply to all resources connected to the subnet.

Network security group rules

NSG rules define networking ports over which traffic is allowed or denied. The rules can include source and destination IP address ranges so that traffic is controlled between specific systems or subnets. NSG rules also include a priority (between 1—and 4096). Rules are evaluated in the order of priority. A rule with a priority of 100 is evaluated before a rule with priority 200.

All NSGs contain a set of default rules. The default rules cannot be deleted, but because they are assigned the lowest priority, they can be overridden by the rules that you create.

The default rules for NSGs are:

- **Virtual network** - Traffic originating and ending in a virtual network is allowed both in inbound and outbound directions.
- **Internet** - Outbound traffic is allowed, but inbound traffic is blocked.
- **Load balancer** - Allow Azure's load balancer to probe the health of your VMs and role instances. If you are not using a load balanced set, you can override this rule.

Create network security groups

A network security group can be created at the same time as a VM using the az vm create command. When doing so, the NSG is associated with the VMs network interface and an NSG rule is auto created to allow traffic on port *22* from any source. Earlier in this tutorial, the front-end NSG was auto-created with the front-end VM. An NSG rule was also auto created for port 22.

In some cases, it may be helpful to pre-create an NSG, such as when default SSH rules should not be created, or when the NSG should be attached to a subnet.

Use the az network nsg create command to create a network security group.

Azure CLI

```
az network nsg create --resource-group myRGNetwork --name myBackendNSG
```

Instead of associating the NSG to a network interface, it is associated with a subnet. In this configuration, any VM that is attached to the subnet inherits the NSG rules.

Update the existing subnet named *myBackendSubnet* with the new NSG.

Azure CLI

```
az network vnet subnet update \
  --resource-group myRGNetwork \
  --vnet-name myVNet \
  --name myBackendSubnet \
  --network-security-group myBackendNSG
```

Secure incoming traffic

When the front-end VM was created, an NSG rule was created to allow incoming traffic on port 22. This rule allows SSH connections to the VM. For this example, traffic should also be allowed on port *80*. This configuration allows a web application to be accessed on the VM.

Use the az network nsg rule create command to create a rule for port *80*.

Azure CLI

```
az network nsg rule create \
  --resource-group myRGNetwork \
  --nsg-name myFrontendNSG \
  --name http \
  --access allow \
  --protocol Tcp \
  --direction Inbound \
  --priority 200 \
  --source-address-prefix "*" \
  --source-port-range "*" \
  --destination-address-prefix "*" \
  --destination-port-range 80
```

The front-end VM is only accessible on port *22* and port *80*. All other incoming traffic is blocked at the network security group. It may be helpful to visualize the NSG rule configurations. Return the NSG rule configuration with the az network rule list command.

Azure CLI

```
az network nsg rule list --resource-group myRGNetwork --nsg-name
myFrontendNSG --output table
```

Secure VM to VM traffic

Network security group rules can also apply between VMs. For this example, the front-end VM needs to communicate with the back-end VM on port *22* and *3306*. This configuration allows SSH connections from the front-end VM, and also allow an application on the front-end VM to communicate with a back-end MySQL database. All other traffic should be blocked between the front-end and back-end virtual machines.

Use the az network nsg rule create command to create a rule for port 22. Notice that the `--source-address-prefix` argument specifies a value of *10.0.1.0/24*. This configuration ensures that only traffic from the front-end subnet is allowed through the NSG.

Azure CLI

```
az network nsg rule create \
  --resource-group myRGNetwork \
  --nsg-name myBackendNSG \
  --name SSH \
  --access Allow \
  --protocol Tcp \
  --direction Inbound \
  --priority 100 \
  --source-address-prefix 10.0.1.0/24 \
  --source-port-range "*" \
  --destination-address-prefix "*" \
  --destination-port-range "22"
```

Now add a rule for MySQL traffic on port 3306.

Azure CLI

```
az network nsg rule create \
  --resource-group myRGNetwork \
  --nsg-name myBackendNSG \
  --name MySQL \
  --access Allow \
  --protocol Tcp \
  --direction Inbound \
  --priority 200 \
  --source-address-prefix 10.0.1.0/24 \
  --source-port-range "*" \
  --destination-address-prefix "*" \
  --destination-port-range "3306"
```

Finally, because NSGs have a default rule allowing all traffic between VMs in the same VNet, a rule can be created for the back-end NSGs to block all traffic. Notice here that the `--priority` is given a value of *300*, which is lower that both the NSG and MySQL rules. This configuration ensures that SSH and MySQL traffic is still allowed through the NSG.

Azure CLI

```
az network nsg rule create \
  --resource-group myRGNetwork \
  --nsg-name myBackendNSG \
  --name denyAll \
  --access Deny \
  --protocol Tcp \
  --direction Inbound \
  --priority 300 \
  --source-address-prefix "*" \
  --source-port-range "*" \
  --destination-address-prefix "*" \
  --destination-port-range "*"
```

Create back-end VM

Now create a virtual machine, which is attached to the *myBackendSubnet*. Notice that the `--nsg` argument has a value of empty double quotes. An NSG does not need to be created with the VM. The VM is attached to the back-end subnet, which is protected with the pre-created back-end NSG. This NSG applies to the VM. Also, notice here that the `--public-ip-address` argument has a value of empty double quotes. This configuration creates a VM without a public IP address.

Azure CLI

```
az vm create \
  --resource-group myRGNetwork \
  --name myBackendVM \
  --vnet-name myVNet \
  --subnet myBackendSubnet \
  --public-ip-address "" \
  --nsg "" \
  --image Ubuntu2204 \
  --generate-ssh-keys
```

The back-end VM is only accessible on port *22* and port *3306* from the front-end subnet. All other incoming traffic is blocked at the network security group. It may be helpful to visualize the NSG rule configurations. Return the NSG rule configuration with the az network rule list command.

Azure CLI

```
az network nsg rule list --resource-group myRGNetwork --nsg-name
myBackendNSG --output table
```

Next steps

In this tutorial, you created and secured Azure networks as related to virtual machines. You learned how to:

- ✓ Create a virtual network and subnet
- ✓ Create a public IP address
- ✓ Create a front-end VM
- ✓ Secure network traffic
- ✓ Create back-end VM

To learn about protecting your VM disks, see Backup and disaster recovery for disks.

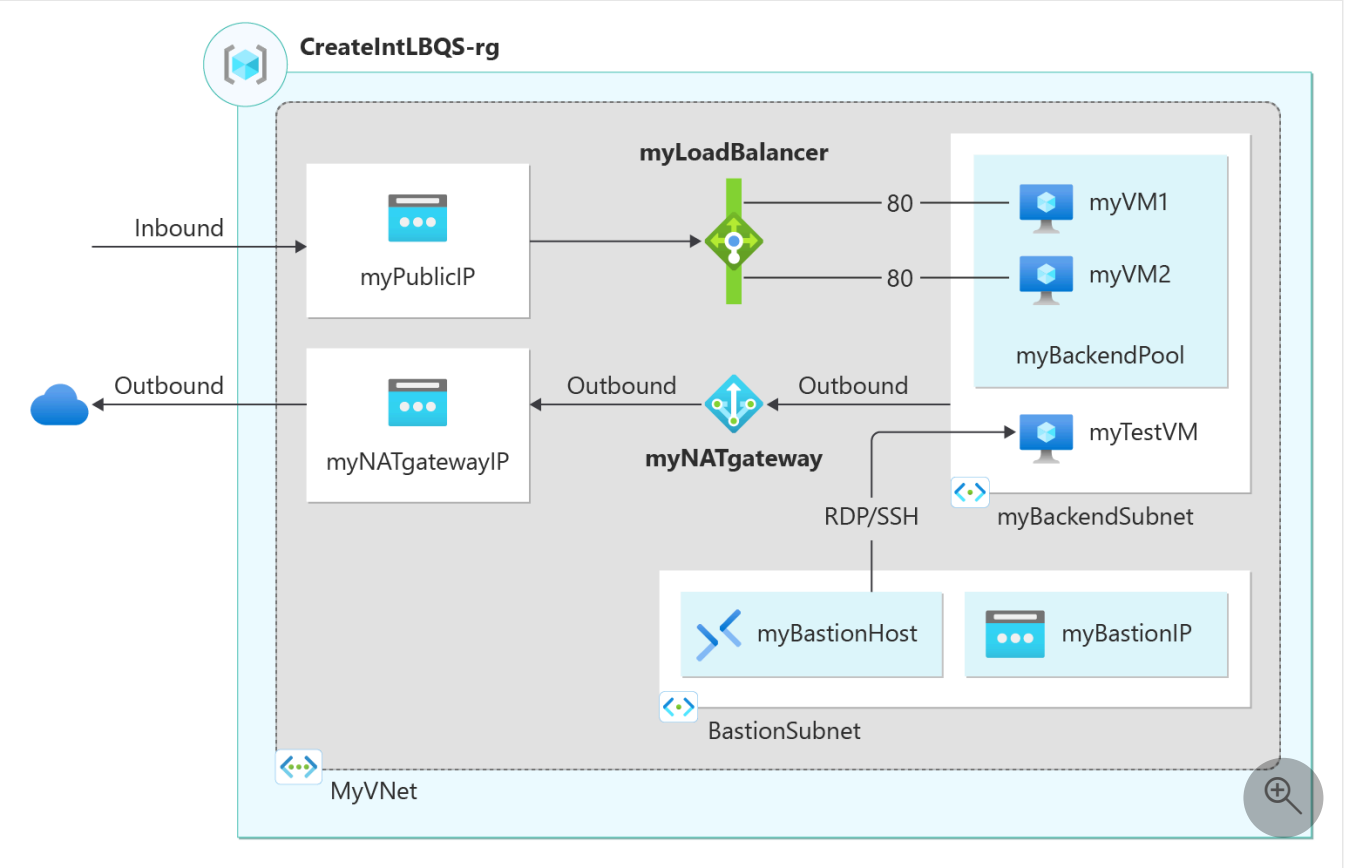
Quickstart: Create a public load balancer to load balance VMs using the Azure CLI

Get started with Azure Load Balancer by using the Azure CLI to create a public load balancer and two virtual machines. Along with these resources, you deploy Azure Bastion, NAT Gateway, a virtual network, and the required subnets.



If you don't have an Azure account, create a free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Get started with Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Authenticate to Azure using Azure CLI.

    - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use and manage extensions with the Azure CLI.
    - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.
- This quickstart requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with az group create:

Azure CLI

```
az group create \
  --name CreatePubLBQS-rg \
  --location eastus
```

Create a virtual network

Before you deploy VMs and test your load balancer, create the supporting virtual network and subnet.

Create a virtual network using az network vnet create. The virtual network and subnet contain the resources deployed later in this article.

Azure CLI

```
az network vnet create \
  --resource-group CreatePubLBQS-rg \
  --location eastus \
  --name myVNet \
  --address-prefixes 10.1.0.0/16 \
  --subnet-name myBackendSubnet \
  --subnet-prefixes 10.1.0.0/24
```

Create a public IP address

To access your web app on the Internet, you need a public IP address for the load balancer.

Use az network public-ip create to create the public IP for the load balancer frontend.

Azure CLI

```
az network public-ip create \
  --resource-group CreatePubLBQS-rg \
  --name myPublicIP \
  --sku Standard \
  --zone 1 2 3
```

To create a zonal public IP address in Zone 1 instead, use the following command:

Azure CLI

```
az network public-ip create \
  --resource-group CreatePubLBQS-rg \
  --name myPublicIP \
  --sku Standard \
  --zone 1
```

Create a load balancer

This section details how you can create and configure the following components of the load balancer:

- A frontend IP pool that receives the incoming network traffic on the load balancer
- A backend IP pool where the frontend pool sends the load balanced network traffic
- A health probe that determines health of the backend VM instances
- A load balancer rule that defines how traffic is distributed to the VMs

Create the load balancer resource

Create a public load balancer with az network lb create:

Azure CLI

```
az network lb create \
  --resource-group CreatePubLBQS-rg \
  --name myLoadBalancer \
  --sku Standard \
  --public-ip-address myPublicIP \
  --frontend-ip-name myFrontEnd \
  --backend-pool-name myBackEndPool
```

If the public IP created is zonal, the specified zone needs to be defined when creating the public load balancer.

Azure CLI

```
az network lb create \
  --resource-group CreatePubLBQS-rg \
  --name myLoadBalancer \
  --sku Standard \
  --public-ip-address myPublicIP \
  --frontend-ip-name myFrontEnd \
  --public-ip-zone 1 \
  --backend-pool-name myBackEndPool
```

Create the health probe

A health probe checks all virtual machine instances to ensure they can send network traffic.

A virtual machine with a failed probe check is removed from the load balancer. The virtual machine is added back into the load balancer when the failure is resolved.

Create a health probe with az network lb probe create:

Azure CLI

```
az network lb probe create \
  --resource-group CreatePubLBQS-rg \
  --lb-name myLoadBalancer \
  --name myHealthProbe \
  --protocol tcp \
  --port 80
```

Create the load balancer rule

A load balancer rule defines:

- Frontend IP configuration for the incoming traffic
- The backend IP pool to receive the traffic
- The required source and destination port

Create a load balancer rule with az network lb rule create:

Azure CLI

```
az network lb rule create \
  --resource-group CreatePubLBQS-rg \
  --lb-name myLoadBalancer \
  --name myHTTPRule \
  --protocol tcp \
  --frontend-port 80 \
  --backend-port 80 \
  --frontend-ip-name myFrontEnd \
  --backend-pool-name myBackEndPool \
  --probe-name myHealthProbe \
  --disable-outbound-snat true \
  --idle-timeout 15 \
  --enable-tcp-reset true
```

Create a network security group

For a standard load balancer, the VMs in the backend pool are required to have network interfaces that belong to a network security group.

Use az network nsg create to create the network security group:

Azure CLI

```
az network nsg create \
  --resource-group CreatePubLBQS-rg \
  --name myNSG
```

Create a network security group rule

Create a network security group rule using az network nsg rule create:

Azure CLI

```
az network nsg rule create \
  --resource-group CreatePubLBQS-rg \
  --nsg-name myNSG \
  --name myNSGRuleHTTP \
  --protocol '*' \
  --direction inbound \
  --source-address-prefix '*' \
  --source-port-range '*' \
  --destination-address-prefix '*' \
  --destination-port-range 80 \
  --access allow \
  --priority 200
```

Create a bastion host

In this section, you create the resources for Azure Bastion. Azure Bastion is used to securely manage the virtual machines in the backend pool of the load balancer.

> **Important**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

Create a public IP address

Use az network public-ip create to create a public ip address for the bastion host. The public IP is used by the bastion host for secure access to the virtual machine resources.

Azure CLI

```
az network public-ip create \
  --resource-group CreatePubLBQS-rg \
  --name myBastionIP \
  --sku Standard \
  --zone 1 2 3
```

Create a bastion subnet

Use az network vnet subnet create to create a bastion subnet. The bastion subnet is used by the bastion host to access the virtual network.

Azure CLI

```
az network vnet subnet create \
  --resource-group CreatePubLBQS-rg \
  --name AzureBastionSubnet \
  --vnet-name myVNet \
  --address-prefixes 10.1.1.0/27
```

Create bastion host

Use az network bastion create to create a bastion host. The bastion host is used to connect securely to the virtual machine resources created later in this article.

Azure CLI

```
az network bastion create \
  --resource-group CreatePubLBQS-rg \
  --name myBastionHost \
  --public-ip-address myBastionIP \
  --vnet-name myVNet \
  --location eastus
```

It can take a few minutes for the Azure Bastion host to deploy.

Create backend servers

In this section, you create:

- Two network interfaces for the virtual machines
- Two virtual machines to be used as backend servers for the load balancer

Create network interfaces for the virtual machines

Create two network interfaces with az network nic create:

Azure CLI

```
array=(myNicVM1 myNicVM2)
for vmnic in "${array[@]}"
do
  az network nic create \
      --resource-group CreatePubLBQS-rg \
      --name $vmnic \
      --vnet-name myVNet \
      --subnet myBackEndSubnet \
      --network-security-group myNSG
done
```

Create virtual machines

Create the virtual machines with az vm create:

Azure CLI

```
az vm create \
  --resource-group CreatePubLBQS-rg \
  --name myVM1 \
  --nics myNicVM1 \
  --image win2019datacenter \
```

```
    --admin-username azureuser \
    --zone 1 \
    --no-wait
```

Azure CLI

```
az vm create \
  --resource-group CreatePubLBQS-rg \
  --name myVM2 \
  --nics myNicVM2 \
  --image win2019datacenter \
  --admin-username azureuser \
  --zone 2 \
  --no-wait
```

It can take a few minutes for the VMs to deploy. You can continue to the next steps while the VMs are creating.

> **Note**
>
> Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.
>
> The default outbound access IP is disabled when one of the following events happens:
>
> - A public IP address is assigned to the VM.
> - The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
> - An Azure NAT Gateway resource is assigned to the subnet of the VM.
>
> VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.
>
> For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Add virtual machines to load balancer backend pool

Add the virtual machines to the backend pool with az network nic ip-config address-pool add:

Azure CLI

```
array=(myNicVM1 myNicVM2)
for vmnic in "${array[@]}"
do
  az network nic ip-config address-pool add \
   --address-pool myBackendPool \
   --ip-config-name ipconfig1 \
   --nic-name $vmnic \
   --resource-group CreatePubLBQS-rg \
   --lb-name myLoadBalancer
done
```

Create NAT gateway

To provide outbound internet access for resources in the backend pool, create a NAT gateway.

Create public IP

Use az network public-ip create to create a single IP for the outbound connectivity.

Azure CLI

```
az network public-ip create \
  --resource-group CreatePubLBQS-rg \
  --name myNATgatewayIP \
  --sku Standard \
  --zone 1 2 3
```

To create a zonal redundant public IP address in Zone 1 instead, use the following command:

Azure CLI

```
az network public-ip create \
  --resource-group CreatePubLBQS-rg \
  --name myNATgatewayIP \
  --sku Standard \
  --zone 1
```

Create NAT gateway resource

Use az network nat gateway create to create the NAT gateway resource. The public IP created in the previous step is associated with the NAT gateway.

Azure CLI

```
az network nat gateway create \
  --resource-group CreatePubLBQS-rg \
```

```
    --name myNATgateway \
    --public-ip-addresses myNATgatewayIP \
    --idle-timeout 10
```

Associate NAT gateway with subnet

Configure the source subnet in virtual network to use a specific NAT gateway resource with az network vnet subnet update.

Azure CLI

```
  az network vnet subnet update \
    --resource-group CreatePubLBQS-rg \
    --vnet-name myVNet \
    --name myBackendSubnet \
    --nat-gateway myNATgateway
```

Install IIS

Use az vm extension set to install IIS on the virtual machines and set the default website to the computer name.

Azure CLI

```
  array=(myVM1 myVM2)
    for vm in "${array[@]}"
    do
     az vm extension set \
       --publisher Microsoft.Compute \
       --version 1.8 \
       --name CustomScriptExtension \
       --vm-name $vm \
       --resource-group CreatePubLBQS-rg \
       --settings '{"commandToExecute":"powershell Add-WindowsFeature Web-Server;
powershell Add-Content -Path \"C:\\inetpub\\wwwroot\\Default.htm\" -Value
$($env:computername)"}'
  done
```

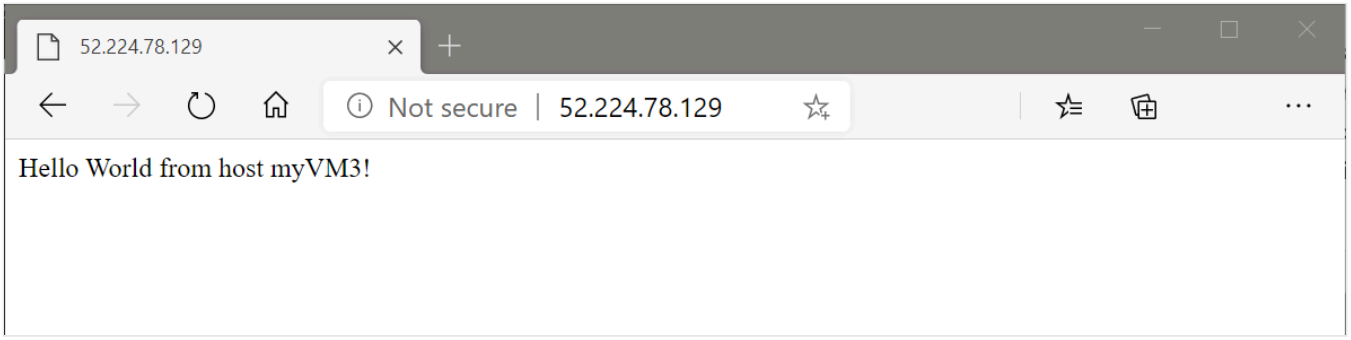
Test the load balancer

To get the public IP address of the load balancer, use az network public-ip show.

Copy the public IP address, and then paste it into the address bar of your browser.

Azure CLI

```
az network public-ip show \
  --resource-group CreatePubLBQS-rg \
  --name myPublicIP \
  --query ipAddress \
  --output tsv
```



Clean up resources

When no longer needed, use the az group delete command to remove the resource group, load balancer, and all related resources.

Azure CLI

```
az group delete \
  --name CreatePubLBQS-rg
```

Next steps

In this quickstart:

- You created a standard public load balancer
- Attached two virtual machines
- Configured the load balancer traffic rule and health probe
- Tested the load balancer

To learn more about Azure Load Balancer, continue to:

What is Azure Load Balancer?

Tutorial: Create and manage a Virtual Machine Scale Set with the Azure CLI

Article • 08/22/2024

A Virtual Machine Scale Set allows you to deploy and manage a set of virtual machines. Throughout the lifecycle of a Virtual Machine Scale Set, you may need to run one or more management tasks. In this tutorial you learn how to:

- ✓ Create a resource group
- ✓ Create a Virtual Machine Scale Set
- ✓ Scale out and in
- ✓ Stop, Start and restart VM instances

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

This article requires version 2.0.29 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a Virtual Machine Scale Set. Create a resource group with the az group create command. In this example, a resource group named *myResourceGroup* is created in the *eastus* region.

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

The resource group name is specified when you create or modify a scale set throughout this tutorial.

Create a scale set

> **Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub

You create a Virtual Machine Scale Set with the az vmss create command. The following example creates a scale set named *myScaleSet*, and generates SSH keys if they don't exist:

Azure CLI

```
az vmss create \
  --resource-group myResourceGroup \
  --name myScaleSet \
  --orchestration-mode flexible \
  --image <SKU image> \
  --admin-username azureuser \
  --generate-ssh-keys
```

It takes a few minutes to create and configure all the scale set resources and VM instances. To distribute traffic to the individual VM instances, a load balancer is also created.

View information about the VM instances in your scale set

To view a list of VM instances in a scale set, use az vm list as follows:

Azure CLI

```
az vm list --resource-group myResourceGroup --output table
```

The following example output shows two VM instances in the scale set:

Output

```
Name                 ResourceGroup    Location    Zones
-------------------  ---------------  ----------  -------
myScaleSet_instance1  myResourceGroup  eastus
myScaleSet_instance2  myResourceGroup  eastus
```

To see additional information about a specific VM instance, use az vm show and specify the VM name.

Azure CLI

```
az vm show --resource-group myResourceGroup --name myScaleSet_instance1
```

Output

```
{
  "hardwareProfile": {
    "vmSize": "Standard_DS1_v2",
  },
  "id":
"/subscriptions/resourceGroups/myResourceGroup/providers/Microsoft.Compute/v

isks/myScaleSet_instance1_disk1",
        "resourceGroup": "myResourceGroup",
        "storageAccountType": "Premium_LRS"
      },
      "name": "myScaleSet_instance1_disk1",
      "osType": "Linux",
    }
  },
  "tags": {},
  "timeCreated": "2022-11-16T20:32:15.024581+00:00",
  "type": "Microsoft.Compute/virtualMachines",
```

```
  "virtualMachineScaleSet": {
    "id":
"/subscriptions/resourceGroups/myResourceGroup/providers/Microsoft.Compute/v
irtualMachineScaleSets/myScaleSet",
    "resourceGroup": "myResourceGroup"
  },
}
```

Create a scale set with a specific VM instance size

When you created a scale set at the start of the tutorial, a default VM SKU of *Standard_D1_v2* was provided for the VM instances. You can specify a different VM instance size based on the output from az vm list-sizes. The following example would create a scale set with the `--vm-sku` parameter to specify a VM instance size of *Standard_F1*. As it takes a few minutes to create and configure all the scale set resources and VM instances, you don't have to deploy the following scale set:

Azure CLI

```azurecli
az vmss create \
  --resource-group myResourceGroup \
  --name myScaleSet \
  --orchestration-mode flexible \
  --image <SKU image> \
  --vm-sku Standard_F1 \
  --admin-user azureuser \
  --generate-ssh-keys
```

Change the capacity of a scale set

When you created a scale set at the start of the tutorial, two VM instances were deployed by default. You can specify the `--instance-count` parameter with az vmss create to change the number of instances created with a scale set. To increase or decrease the number of VM instances in your existing scale set, you can manually change the capacity. The scale set creates or removes the required number of VM instances, then configures the load balancer to distribute traffic.

To manually increase or decrease the number of VM instances in the scale set, use az vmss scale. The following example sets the number of VM instances in your scale set to *3*:

Azure CLI

```
az vmss scale \
  --resource-group myResourceGroup \
  --name myScaleSet \
  --new-capacity 3
```

It takes a few minutes to update the capacity of your scale set. To see the number of instances you now have in the scale set, use az vm list and query on the associated resource group.

Azure CLI

```
az vm list --resource-group myResourceGroup --output table
```

Output

```
Name                 ResourceGroup    Location    Zones
-------------------  ---------------  ----------  -------
myScaleSet_instance1  myResourceGroup  eastus
myScaleSet_instance2  myResourceGroup  eastus
myScaleSet_instance3  myResourceGroup  eastus
```

Stop and deallocate VM instances in a scale set

To stop all the VM instances in a scale set, use az vmss stop.

Azure CLI

```
az vmss stop \
  --resource-group myResourceGroup \
  --name myScaleSet
```

To stop individual VM instances in a scale set, use az vm stop and specify the instance name.

Azure CLI

```
az vm stop \
  --resource-group myResourceGroup \
  --name myScaleSet_instance1
```

Stopped VM instances remain allocated and continue to incur compute charges. If you instead wish the VM instances to be deallocated and only incur storage charges, use az vm deallocate and specify the instance names you want deallocated.

Azure CLI

```
az vm deallocate \
  --resource-group myResourceGroup \
  --name myScaleSet_instance1
```

Start VM instances in a scale set

To start all the VM instances in a scale set, use az vmss start.

Azure CLI

```
az vmss start \
  --resource-group myResourceGroup \
  --name myScaleSet
```

To start individual VM instances in a scale set, use az vm start and specify the instance name.

Azure CLI

```
az vm start \
  --resource-group myResourceGroup \
  --name myScaleSet_instance1
```

Restart VM instances in a scale set

To restart all the VM instances in a scale set, use az vmss restart.

Azure CLI

```
az vmss restart \
  --resource-group myResourceGroup \
  --name myScaleSet
```

To restart individual VM instances in a scale set, use az vm restart and specify the instance name.

Azure CLI

```
az vm restart \
  --resource-group myResourceGroup \
  --name myScaleSet_instance1
```

Clean up resources

When you delete a resource group, all resources contained within, such as the VM instances, virtual network, and disks, are also deleted. The `--no-wait` parameter returns control to the prompt without waiting for the operation to complete. The `--yes` parameter confirms that you wish to delete the resources without an extra prompt to do so.

Azure CLI

```
az group delete --name myResourceGroup --no-wait --yes
```

Next steps

In this tutorial, you learned how to perform some basic scale set creation and management tasks with the Azure CLI:

- ✓ Create a resource group
- ✓ Create a scale set
- ✓ View and use specific VM sizes
- ✓ Manually scale a scale set
- ✓ Perform common scale set management tasks such as stopping, starting and restarting your scale set

Advance to the next tutorial to learn how to connect to your scale set instances.

Use data disks with scale sets

Tutorial: Create and Manage Windows VMs with Azure PowerShell

Article • 10/28/2024

Applies to: ✔ Windows VMs

Azure virtual machines provide a fully configurable and flexible computing environment. This tutorial covers basic Azure virtual machine (VM) deployment tasks like selecting a VM size, selecting a VM image, and deploying a VM. You learn how to:

- ✔ Create and connect to a VM
- ✔ Select and use VM images
- ✔ View and use specific VM sizes
- ✔ Resize a VM
- ✔ View and understand VM state

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Create resource group

Create a resource group with the New-AzResourceGroup command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a virtual machine. In the following example, a resource group named *myResourceGroupVM* is created in the *EastUS* region:

Azure PowerShell

```
New-AzResourceGroup `
   -ResourceGroupName "myResourceGroupVM" `
   -Location "EastUS"
```

The resource group is specified when creating or modifying a VM, which can be seen throughout this tutorial.

Create a VM

When creating a VM, several options are available like operating system image, network configuration, and administrative credentials. This example creates a VM named *myVM*, running the default version of Windows Server 2016 Datacenter.

Set the username and password needed for the administrator account on the VM with Get-Credential:

Azure PowerShell

```
$cred = Get-Credential
```

Create the VM with New-AzVM.

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName "myResourceGroupVM" `
    -Name "myVM" `
    -Location "EastUS" `
    -VirtualNetworkName "myVnet" `
    -SubnetName "mySubnet" `
    -SecurityGroupName "myNetworkSecurityGroup" `
    -PublicIpAddressName "myPublicIpAddress" `
    -Credential $cred
```

Connect to VM

After the deployment has completed, create a remote desktop connection with the VM.

Run the following commands to return the public IP address of the VM. Take note of this IP Address so you can connect to it with your browser to test web connectivity in a future step.

Azure PowerShell

```
Get-AzPublicIpAddress `
   -ResourceGroupName "myResourceGroupVM"  | Select IpAddress
```

Use the following command, on your local machine, to create a remote desktop session with the VM. Replace the IP address with the *publicIPAddress* of your VM. When prompted, enter the credentials used when creating the VM.

PowerShell

```
mstsc /v:<publicIpAddress>
```

In the **Windows Security** window, select **More choices** and then **Use a different account**. Type the username and password you created for the VM and then click **OK**.

Understand marketplace images

The Azure marketplace includes many images that can be used to create a new VM. In the previous steps, a VM was created using the Windows Server 2016 Datacenter image. In this step, the PowerShell module is used to search the marketplace for other Windows images, which can also be used as a base for new VMs. This process consists of finding the publisher, offer, SKU, and optionally a version number to identify the image.

Use the Get-AzVMImagePublisher command to return a list of image publishers:

Azure PowerShell

```
Get-AzVMImagePublisher -Location "EastUS"
```

Use the Get-AzVMImageOffer to return a list of image offers. With this command, the returned list is filtered on the specified publisher named `MicrosoftWindowsServer`:

Azure PowerShell

```
Get-AzVMImageOffer `
   -Location "EastUS" `
   -PublisherName "MicrosoftWindowsServer"
```

The results will look something like this example:

PowerShell

```
Offer             PublisherName          Location
-----             -------------          --------
Windows-HUB       MicrosoftWindowsServer EastUS
WindowsServer     MicrosoftWindowsServer EastUS
WindowsServer-HUB MicrosoftWindowsServer EastUS
```

The Get-AzVMImageSku command will then filter on the publisher and offer name to return a list of image names.

Azure PowerShell

```
Get-AzVMImageSku `
   -Location "EastUS" `
   -PublisherName "MicrosoftWindowsServer" `
   -Offer "WindowsServer"
```

The results will look something like this example:

PowerShell

```
Skus                                      Offer         PublisherName
Location
----                                      -----         -------------
--------
2008-R2-SP1                               WindowsServer
MicrosoftWindowsServer EastUS
2008-R2-SP1-smalldisk                     WindowsServer
MicrosoftWindowsServer EastUS
2012-Datacenter                           WindowsServer
MicrosoftWindowsServer EastUS

```

This information can be used to deploy a VM with a specific image. This example deploys a VM using the latest version of a Windows Server 2016 with Containers image.

```
```

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName "myResourceGroupVM" `
    -Name "myVM2" `
    -Location "EastUS" `
    -VirtualNetworkName "myVnet" `
    -SubnetName "mySubnet" `
    -SecurityGroupName "myNetworkSecurityGroup" `
    -PublicIpAddressName "myPublicIpAddress2" `
    -ImageName "MicrosoftWindowsServer:WindowsServer:2016-Datacenter-with-
Containers:latest" `
    -Credential $cred
```

Understand VM sizes

The VM size determines the amount of compute resources like CPU, GPU, and memory that are made available to the VM. Virtual machines should be created using a VM size appropriate for the workload. If a workload increases, an existing virtual machine can also be resized.

VM Sizes

The following table categorizes sizes into use cases.

Expand table

Type	Common sizes	Description
General purpose	B, Dsv3, Dv3, DSv2, Dv2, Av2, DC	Balanced CPU-to-memory. Ideal for dev / test and small to medium applications and data solutions.
Compute optimized	Fsv2	High CPU-to-memory. Good for medium traffic applications, network appliances, and batch processes.
Memory optimized	Esv3, Ev3, M, DSv2, Dv2	High memory-to-core. Great for relational databases, medium to large caches, and in-memory analytics.
Storage optimized	Lsv2, Ls	High disk throughput and IO. Ideal for Big Data, SQL, and NoSQL databases.
GPU	NV, NVv2, NC, NCv2, NCv3, ND	Specialized VMs targeted for heavy graphic rendering and video editing.
High performance	H	Our most powerful CPU VMs with optional high-throughput network interfaces (RDMA).

Find available VM sizes

To see a list of VM sizes available in a particular region, use the Get-AzVMSize command.

Azure PowerShell

```
Get-AzVMSize -Location "EastUS"
```

Resize a VM

After a VM has been deployed, it can be resized to increase or decrease resource allocation.

Before resizing a VM, check if the size you want is available on the current VM cluster. The Get-AzVMSize command returns a list of sizes.

Azure PowerShell

```
Get-AzVMSize -ResourceGroupName "myResourceGroupVM" -VMName "myVM"
```

If the size is available, the VM can be resized from a powered-on state, however it is rebooted during the operation.

Azure PowerShell

```
$vm = Get-AzVM `
   -ResourceGroupName "myResourceGroupVM"  `
   -VMName "myVM"
$vm.HardwareProfile.VmSize = "Standard_DS3_v2"
Update-AzVM `
   -VM $vm `
   -ResourceGroupName "myResourceGroupVM"
```

If the size you want isn't available on the current cluster, the VM needs to be deallocated before the resize operation can occur. Deallocating a VM will remove any data on the temp disk, and the public IP address will change unless a static IP address is being used.

Azure PowerShell

```
Stop-AzVM `
   -ResourceGroupName "myResourceGroupVM" `
   -Name "myVM" -Force
```

```
$vm = Get-AzVM `
   -ResourceGroupName "myResourceGroupVM"  `
   -VMName "myVM"
$vm.HardwareProfile.VmSize = "Standard_E2s_v3"
Update-AzVM -VM $vm `
   -ResourceGroupName "myResourceGroupVM"
Start-AzVM `
   -ResourceGroupName "myResourceGroupVM"  `
   -Name $vm.name
```

VM power states

An Azure VM can have one of many power states.

Expand table

Power State	Description
Starting	The virtual machine is being started.
Running	The virtual machine is running.
Stopping	The virtual machine is being stopped.
Stopped	The VM is stopped. Virtual machines in the stopped state still incur compute charges.
Deallocating	The VM is being deallocated.
Deallocated	Indicates that the VM is removed from the hypervisor but is still available in the control plane. Virtual machines in the `Deallocated` state do not incur compute charges.
-	The power state of the VM is unknown.

To get the state of a particular VM, use the Get-AzVM command. Be sure to specify a valid name for a VM and resource group.

Azure PowerShell

```
Get-AzVM `
    -ResourceGroupName "myResourceGroupVM" `
    -Name "myVM" `
    -Status | Select @{n="Status"; e={$_.Statuses[1].Code}}
```

The output will look something like this example:

PowerShell

```
Status
------
PowerState/running
```

To retrieve the power state of all the VMs in your subscription, use the Virtual Machines - List All API with parameter **statusOnly** set to *true*.

Management tasks

During the lifecycle of a VM, you may want to run management tasks like starting, stopping, or deleting a VM. Additionally, you may want to create scripts to automate repetitive or complex tasks. Using Azure PowerShell, many common management tasks can be run from the command line or in scripts.

Stop a VM

Stop and deallocate a VM with Stop-AzVM:

Azure PowerShell

```
Stop-AzVM `
   -ResourceGroupName "myResourceGroupVM" `
   -Name "myVM" -Force
```

If you want to keep the VM in a provisioned state, use the -StayProvisioned parameter.

Start a VM

Azure PowerShell

```
Start-AzVM `
   -ResourceGroupName "myResourceGroupVM" `
   -Name "myVM"
```

Deleting VM resources

You can delete a VM, but by default this only deletes the VM resource, not the disks and networking resources the VM uses. You can change the default behavior to delete other resources when you delete the VM. For more information, see Delete a VM and attached resources.

Next steps

In this tutorial, you learned about basic VM creation and management such as how to:

- ✓ Create and connect to a VM
- ✓ Select and use VM images
- ✓ View and use specific VM sizes
- ✓ Resize a VM
- ✓ View and understand VM state

Advance to the next tutorial to learn about VM disks.

Create and Manage VM disks

Tutorial: Manage disks with Azure PowerShell

Article • 12/06/2024

Azure virtual machines (VMs) use disks to store operating systems (OS), applications, and data. When you create a VM, it's important to choose an appropriate disk size and configuration for the expected workload.

This tutorial covers deployment and management of VM disks. In this tutorial, you learn how to:

- ✓ Create, attach, and initialize a data disk
- ✓ Verify a disk's status
- ✓ Initialize a disk
- ✓ Expand and upgrade a disk
- ✓ Detach and delete a disk

Prerequisites

You must have an Azure account with an active subscription. If you don't have an Azure subscription, create a free account before you begin.

Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

Expand table

Option	Example/Link
Select **Try It** in the upper-right corner of a code or command block. Selecting **Try It** doesn't automatically copy the code or command to Cloud Shell.	
Go to https://shell.azure.com, or select the **Launch Cloud Shell** button to open Cloud Shell in your browser.	Launch Cloud Shell

Option	Example/Link
Select the **Cloud Shell** button on the menu bar at the upper right in the Azure portal.	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl**+**Shift**+**V** on Windows and Linux, or by selecting **Cmd**+**Shift**+**V** on macOS.
4. Select **Enter** to run the code or command.

Create a VM

The exercises in this tutorial require a VM. Follow the steps in this section to create one.

Before you begin, find the `$azRegion` variable located in the first line of sample code and update the value to reflect your desired region. For example, to specify the **Central US** region, use `$azRegion = "Central US"`. Next, use the code to deploy a VM within a new resource group. You're prompted for username and password values for the VM's local administrator account.

Azure PowerShell

```
$azRegion = "[Your Region]"
$azResourceGroup = "myDemoResourceGroup"
$azVMName = "myDemoVM"
$azDataDiskName = "myDemoDataDisk"

New-AzVm `
    -Location $azRegion `
    -ResourceGroupName $azResourceGroup `
    -Name $azVMName `
    -Size "Standard_D2s_v3" `
    -VirtualNetworkName "myDemoVnet" `
    -SubnetName "myDemoSubnet" `
    -SecurityGroupName "myDemoNetworkSecurityGroup" `
    -PublicIpAddressName "myDemoPublicIpAddress"
```

The output confirms the VM's successful creation.

Output

```
ResourceGroupName        : myDemoResourceGroup
Id                       :
/subscriptions/{GUID}/resourceGroups/myDemoResourceGroup/providers/Microsoft
.Compute/virtualMachines/myDemoTestVM
VmId                     : [{GUID}]
Name                     : myDemoVM
Type                     : Microsoft.Compute/virtualMachines
Location                 : centralus
Tags                     : {}
HardwareProfile          : {VmSize}
NetworkProfile           : {NetworkInterfaces}
OSProfile                : {ComputerName, AdminUsername,
WindowsConfiguration, AllowExtensionOperations, RequireGuestProvisionSignal}
ProvisioningState        : Succeeded
StorageProfile           : {ImageReference, OsDisk, DataDisks}
FullyQualifiedDomainName : mydemovm-abc123.Central US.cloudapp.azure.com
```

The VM is provisioned, and two disks are automatically created and attached.

- An **operating system disk**, which hosts the virtual machine's operating system.
- A **temporary disk**, which is primarily used for operations such as temporary data processing.

Add a data disk

We recommend that you separate application and user data from OS-related data when possible. If you need to store user or application data on your VM, you'll typically create and attach additional data disks.

Follow the steps in this section to create, attach, and initialize a data disk on the VM.

Create the data disk

This section guides you through the creation of a data disk.

1. Before a data disk can be created, you must first create a disk object. The following code sample uses the New-AzDiskConfig cmdlet to configure a disk object.

   Azure PowerShell

   ```
   $diskConfig = New-AzDiskConfig `
       -Location $azRegion `
       -CreateOption Empty `
   ```

```
    -DiskSizeGB 128 `
    -SkuName "Standard_LRS"
```

2. After the disk object is created, use the New-AzDisk cmdlet to provision a data disk.

Azure PowerShell

```
$dataDisk = New-AzDisk `
    -ResourceGroupName $azResourceGroup `
    -DiskName $azDataDiskName `
    -Disk $diskConfig
```

You can use the Get-AzDisk cmdlet to verify that the disk was created.

Azure PowerShell

```
Get-AzDisk `
    -ResourceGroupName $azResourceGroup `
    -DiskName $azDataDiskName
```

In this example, the output confirms that the disk was created. The `DiskState` and `ManagedBy` property values confirm that the disk is not yet attached.

Output

```
ResourceGroupName             : myDemoResourceGroup
ManagedBy                     :
ManagedByExtended             : {}
OsType                        :
DiskSizeGB                    : 128
DiskSizeBytes                 : 137438953472
ProvisioningState             : Succeeded
DiskIOPSReadWrite             : 500
DiskMBpsReadWrite             : 60
DiskState                     : Unattached
Name                          : myDemoDataDisk
```

Attach the data disk

A data disk must be attached to a VM before the VM can access it. Complete the steps in this section to create a reference for the VM, connect the disk, and update the VM's configuration.

1. Get the VM to which you'll attach the data disk. The following sample code uses the Get-AzVM cmdlet to create a reference to the VM.

Azure PowerShell

```
$vm = Get-AzVM `
    -ResourceGroupName $azResourceGroup `
    -Name $azVMName
```

2. Next, attach the data disk to the VM's configuration with the Add-AzVMDataDisk cmdlet.

Azure PowerShell

```
$vm = Add-AzVMDataDisk `
    -VM $vm `
    -Name $azDataDiskName `
    -CreateOption Attach `
    -ManagedDiskId $dataDisk.Id `
    -Lun 1
```

3. Finally, update the VM's configuration with the Update-AzVM cmdlet.

Azure PowerShell

```
Update-AzVM `
    -ResourceGroupName $azResourceGroup `
    -VM $vm
```

After a brief pause, the output confirms a successful attachment.

Output

```
RequestId IsSuccessStatusCode StatusCode ReasonPhrase
--------- ------------------- ---------- ------------
                         True         OK OK
```

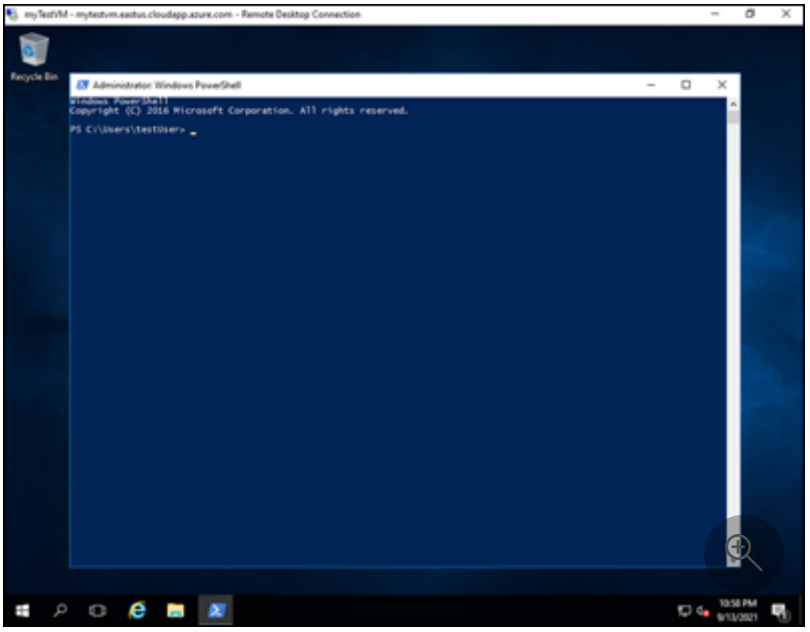
Initialize the data disk

After a data disk is attached to the VM, the OS needs to be configured to use the disk. The following section provides guidance on how to connect to the remote VM and configure the first disk added.

1. Sign in to the Azure portal.

2. Locate the VM to which you've attached the data disk. Create a Remote Desktop Protocol (RDP) connection and sign in as the local administrator.

3. After you establish an RDP connection to the remote VM, select the Windows **Start** menu. Enter **PowerShell** in the search box and select **Windows PowerShell** to open a PowerShell window.



4. In the open PowerShell window, run the following script.

PowerShell

```
Get-Disk | Where PartitionStyle -eq 'raw' |
    Initialize-Disk -PartitionStyle MBR -PassThru |
    New-Partition -AssignDriveLetter -UseMaximumSize |
    Format-Volume -FileSystem NTFS -NewFileSystemLabel "myDemoDataDisk"
-Confirm:$false
```

The output confirms a successful initialization.

Output

```
DriveLetter FileSystemLabel FileSystem DriveType HealthStatus
OperationalStatus SizeRemaining   Size
----------- --------------- ---------- --------- ------------ ---------
-------- -------------   ----
F           myDemoDataDisk  NTFS       Fixed     Healthy      OK
127.89 GB 128 GB
```

Expand a disk

You can expand Azure disks to provide extra storage capacity when your VM is low on available disk space.

Some scenarios require data to be stored on the OS disk. For example, you may be required to support legacy applications that install components on the OS drive. You may also have the need to migrate an on-premises physical PC or VM with a larger OS drive. In such cases, it may become necessary to expand a VM's OS disk.

Shrinking an existing disk isn't supported, and can potentially result in data loss.

Update the disk's size

Follow the steps below to resize either the OS disk or a data disk.

> **ⓘ Important**
>
> If your disk meets the requirements in **Expand without downtime**, you can skip steps 2 and 6.
>
> Shrinking an existing disk isn't supported and may result in data loss.
>
> After expanding the disks, you need to expand the volume in the operating system to take advantage of the larger disk.

1. Select the VM that contains the disk that you'll resize with the `Get-AzVM` cmdlet.

   Azure PowerShell

   ```
   $vm = Get-AzVM `
     -ResourceGroupName $azResourceGroup `
     -Name $azVMName
   ```

2. Before you can resize a VM's disk, you must stop the VM. Use the `Stop-AzVM` cmdlet to stop the VM. You'll be prompted for confirmation.

   > **ⓘ Important**
   >
   > Before you initiate a VM shutdown, always confirm that there are no important resources or data that could be lost.

   Azure PowerShell

   ```
   Stop-AzVM `
       -ResourceGroupName $azResourceGroup `
       -Name $azVMName
   ```

After a short pause, the output confirms that the machine is successfully stopped.

Output

```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status      : Succeeded
StartTime   : 9/13/2021 7:10:23 PM
EndTime     : 9/13/2021 7:11:12 PM
Error       :
```

3. After the VM is stopped, get a reference to either the OS or data disk attached to the VM with the `Get-AzDisk` cmdlet.

   The following example selects the VM's OS disk.

   Azure PowerShell

   ```
   $disk= Get-AzDisk `
       -ResourceGroupName $azResourceGroup `
       -DiskName $vm.StorageProfile.OsDisk.Name
   ```

   The following example selects the VM's first data disk.

   Azure PowerShell

   ```
       $disk= Get-AzDisk `
           -ResourceGroupName $azResourceGroup `
           -DiskName $vm.StorageProfile.DataDisks[0].Name
   ```

4. Now that you have a reference to the disk, set the size of the disk to 250 GiB.

   > **ⓘ Important**
   >
   > The new size should be greater than the existing disk size. The maximum allowed is 4,095 GiB for OS disks.

   Azure PowerShell

   ```
   $disk.DiskSizeGB = 250
   ```

5. Next, update the disk image with the `Update-AzDisk` cmdlet.

   Azure PowerShell

```
Update-AzDisk `
    -ResourceGroupName $azResourceGroup `
    -Disk $disk -DiskName $disk.Name
```

The disk image is updated, and the output confirms the disk's new size.

Output

```
ResourceGroupName             : myDemoResourceGroup
ManagedBy                     :
/subscriptions/{GUID}/resourceGroups/myDemoResourceGroup/providers/Micr
osoft.Compute/virtualMachines/myDemoVM
Sku                           :
Microsoft.Azure.Management.Compute.Models.DiskSku
TimeCreated                   : 9/135/2021 6:41:10 PM
CreationData                  :
Microsoft.Azure.Management.Compute.Models.CreationData
DiskSizeGB                    : 250
DiskSizeBytes                 : 268435456000
UniqueId                      : {GUID}
ProvisioningState             : Succeeded
DiskIOPSReadWrite             : 500
DiskMBpsReadWrite             : 60
DiskState                     : Reserved
Encryption                    :
Microsoft.Azure.Management.Compute.Models.Encryption
Id                            :
/subscriptions/{GUID}/resourceGroups/myDemoResourceGroup/providers/Micr
osoft.Compute/disks/myDemoDataDisk
Name                          : myDemoDataDisk
Type                          : Microsoft.Compute/disks
Location                      : centralus
```

6. Finally, restart the VM with the `Start-AzVM` cmdlet.

Azure PowerShell

```
Start-AzVM `
    -ResourceGroupName $azResourceGroup `
    -Name $azVMName
```

After a short pause, the output confirms that the machine is successfully started.

Output

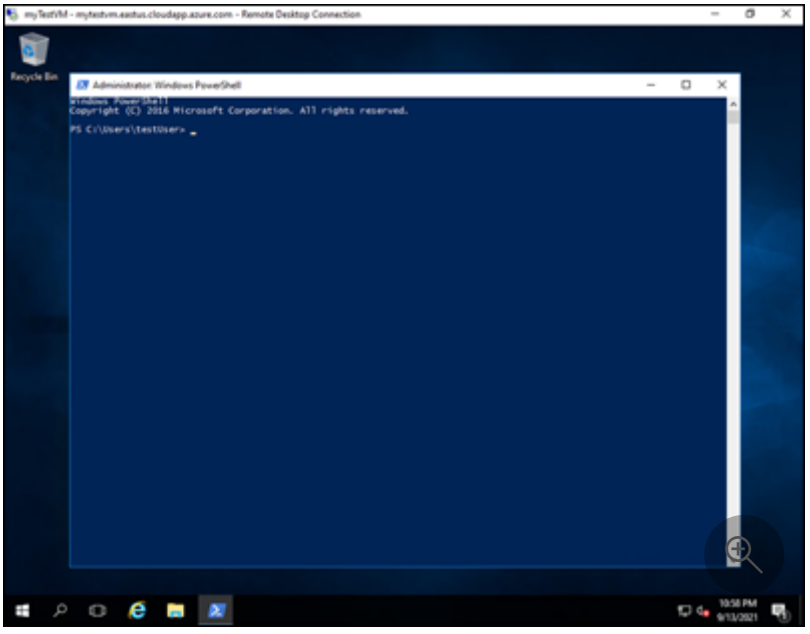
```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status      : Succeeded
StartTime   : 9/13/2021 7:44:54 PM
```

```
EndTime      : 9/13/2021 7:45:15 PM
Error        :
```

Expand the disk volume in the OS

Before you can take advantage of the new disk size, you need to expand the volume within the OS. Follow the steps below to expand the disk volume and take advantage of the new disk size.

1. Sign in to the Azure portal.
2. Locate the VM to which you've attached the data disk. Create a Remote Desktop Protocol (RDP) connection and sign in. If you no longer have access to an administrative account, create a credential object for a specified user name and password with the Get-Credential cmdlet.
3. After you've established an RDP connection to the remote VM, select the Windows **Start** menu. Enter **PowerShell** in the search box and select **Windows PowerShell** to open a PowerShell window.



4. Open PowerShell and run the following script. Change the value of the `-DriveLetter` variable as appropriate. For example, to resize the partition on the **F:** drive, use `$driveLetter = "F"`.

PowerShell

```powershell
$driveLetter = "[Drive Letter]"
$size = (Get-PartitionSupportedSize -DriveLetter $driveLetter)
Resize-Partition `
```

```
    -DriveLetter $driveLetter `
    -Size $size.SizeMax
```

5. Minimize the RDP window and switch back to Azure Cloud Shell. Use the `Get-AzDisk` cmdlet to verify that the disk was resized successfully.

Azure PowerShell

```
Get-AzDisk `
    -ResourceGroupName $azResourceGroup | Out-Host -Paging
```

Upgrade a disk

There are several ways to respond to changes in your organization's workloads. For example, you may choose to upgrade a standard HDD to a premium SSD to handle increased demand.

Follow the steps in this section to upgrade a managed disk from standard to premium.

1. Select the VM that contains the disk that you'll upgrade with the `Get-AzVM` cmdlet.

Azure PowerShell

```
$vm = Get-AzVM `
  -ResourceGroupName $azResourceGroup `
  -Name $azVMName
```

2. Before you can upgrade a VM's disk, you must stop the VM. Use the `Stop-AzVM` cmdlet to stop the VM. You'll be prompted for confirmation.

> **ⓘ Important**
>
> Before you initiate a VM shutdown, always confirm that there are no important resources or data that could be lost.

Azure PowerShell

```
Stop-AzVM `
    -ResourceGroupName $azResourceGroup `
    -Name $azVMName
```

After a short pause, the output confirms that the machine is successfully stopped.

Output

```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status      : Succeeded
StartTime   : 9/13/2021 7:10:23 PM
EndTime     : 9/13/2021 7:11:12 PM
Error       :
```

3. After the VM is stopped, get a reference to either the OS or data disk attached to the VM with the `Get-AzDisk` cmdlet.

   The following example selects the VM's OS disk.

Azure PowerShell

```
$disk= Get-AzDisk `
    -ResourceGroupName $azResourceGroup `
    -DiskName $vm.StorageProfile.OsDisk.Name
```

   The following example selects the VM's first data disk.

Azure PowerShell

```
    $disk= Get-AzDisk `
        -ResourceGroupName $azResourceGroup `
        -DiskName $vm.StorageProfile.DataDisks[0].Name
```

4. Now that you have a reference to the disk, set the disk's SKU to **Premium_LRS**.

Azure PowerShell

```
$disk.Sku =
[Microsoft.Azure.Management.Compute.Models.DiskSku]::new('Premium_LRS')
```

5. Next, update the disk image with the `Update-AzDisk` cmdlet.

Azure PowerShell

```
Update-AzDisk `
    -ResourceGroupName $azResourceGroup `
    -Disk $disk -DiskName $disk.Name
```

   The disk image is updated. Use the following example code to validate that the disk's SKU has been upgraded.

Azure PowerShell

```
$disk.Sku.Name
```

The output confirms the disk's new SKU.

Output

```
Premium_LRS
```

6. Finally, restart the VM with the `Start-AzVM` cmdlet.

Azure PowerShell

```
Start-AzVM `
    -ResourceGroupName $azResourceGroup `
    -Name $azVMName
```

After a short pause, the output confirms that the machine is successfully started.

Output

```
OperationId : abcd1234-ab12-cd34-123456abcdef
Status      : Succeeded
StartTime   : 9/13/2021 7:44:54 PM
EndTime     : 9/13/2021 7:45:15 PM
Error       :
```

Detach a data disk

You can detach a data disk from a VM when you want to attach it to a different VM, or when it's no longer needed. By default, detached disks are not deleted to prevent unintentional data loss. A detached disk will continue to incur storage charges until it's deleted.

1. First, select the VM to which the disk is attached with the `Get-AzVM` cmdlet.

Azure PowerShell

```
$vm = Get-AzVM `
   -ResourceGroupName $azResourceGroup `
   -Name $azVMName
```

2. Next, detach the disk from the VM with the `Remove-AzVMDataDisk` cmdlet.

Azure PowerShell

```
Remove-AzVMDataDisk `
    -VM $vm `
    -Name $azDataDiskName
```

3. Update the state of the VM with the `Update-AzVM` cmdlet to remove the data disk.

Azure PowerShell

```
Update-AzVM `
    -ResourceGroupName $azResourceGroup `
    -VM $vm
```

After a short pause, the output confirms that the VM is successfully updated.

Output

```
RequestId IsSuccessStatusCode StatusCode ReasonPhrase
--------- ------------------- ---------- ------------
                         True         OK OK
```

Delete a data disk

When you delete a VM, data disks attached to the VM remain provisioned and continue to incur charges until they're deleted. This default behavior helps prevent data loss caused by unintentional deletion.

You can use the following sample PowerShell script to delete unattached disks. The retrieval of disks is limited to the **myDemoResourceGroup** because the `-ResourceGroupName` switch is used with the `Get-AzDisk` cmdlet.

Azure PowerShell

```
# Get all disks in resource group $azResourceGroup
$allDisks = Get-AzDisk -ResourceGroupName $azResourceGroup

# Determine the number of disks in the collection
if($allDisks.Count -ne 0) {

    Write-Host "Found $($allDisks.Count) disks."

    # Iterate through the collection
    foreach ($disk in $allDisks) {

        # Use the disk's "ManagedBy" property to determine if it is
```

```
unattached
        if($disk.ManagedBy -eq $null) {

            # Confirm that the disk can be deleted
            Write-Host "Deleting unattached disk $($disk.Name)."
            $confirm = Read-Host "Continue? (Y/N)"
            if ($confirm.ToUpper() -ne 'Y') { break }
            else {

                # Delete the disk
                $disk | Remove-AzDisk -Force
                Write-Host "Unattached disk $($disk.Name) deleted."
            }
        }
    }
}
```

The unattached data disk is deleted as shown by the output.

Output

```
Name      : abcd1234-ab12-cd34-ef56-abcdef123456
StartTime : 9/13/2021 10:14:05 AM
EndTime   : 9/13/2021 10:14:35 AM
Status    : Succeeded
Error     :
```

Clean up resources

When no longer needed, delete the resource group, VM, and all related resources. You can use the following sample PowerShell script to delete the resource group created earlier in this tutorial.

> **⊗ Caution**
>
> Use caution when deleting a resource group. To avoid the loss of important data, always confirm that there are no important resources or data contained within the resource group before it is deleted.

Azure PowerShell

```
    Remove-AzResourceGroup -Name $azResourceGroup
```

You're prompted for confirmation. After a short pause, the `True` response confirms that the **myDemoResourceGroup** is successfully deleted.

Output

```
Confirm
Are you sure you want to remove resource group 'myDemoResourceGroup'
[Y] Yes  [N] No  [S] Suspend  [?] Help (default is "Y"): Y
True
```

Next steps

In this tutorial, you learned how to:

- ✓ Create, attach, and initialize a data disk
- ✓ Verify a disk's status
- ✓ Initialize a disk
- ✓ Expand and upgrade a disk
- ✓ Detach and delete a disk

Advance to the next tutorial to learn how to automate VM configuration.

Automate VM configuration

Tutorial: Create Windows VM images with Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

Images can be used to bootstrap deployments and ensure consistency across multiple VMs. In this tutorial, you create your own specialized image of an Azure virtual machine using PowerShell and store it in an Azure Compute Gallery (formerly known as Shared Image Gallery). You learn how to:

- ✔ Create an Azure Compute Gallery
- ✔ Create an image definition
- ✔ Create an image version
- ✔ Create a VM from an image
- ✔ Share a gallery

Before you begin

The steps below detail how to take an existing VM and turn it into a re-usable custom image that you can use to create new VMs.

To complete the example in this tutorial, you must have an existing virtual machine. If needed, you can see the PowerShell quickstart to create a VM to use for this tutorial. When working through the tutorial, replace the resource names where needed.

Overview

an Azure Compute Gallery simplifies custom image sharing across your organization. Custom images are like marketplace images, but you create them yourself. Custom images can be used to bootstrap configurations such as preloading applications, application configurations, and other OS configurations.

The Azure Compute Gallery lets you share your custom VM images with others. Choose which images you want to share, which regions you want to make them available in, and who you want to share them with.

The Azure Compute Gallery feature has multiple resource types:

Expand table

Resource	Description
Image source	This is a resource that can be used to create an **image version** in a gallery. An image source can be an existing Azure VM that is either generalized or specialized, a managed image, a snapshot, or an image version in another gallery.
Gallery	Like the Azure Marketplace, a **gallery** is a repository for managing and sharing images and VM applications, but you control who has access.
Image definition	Image definitions are created within a gallery and carry information about the image and requirements for using it internally. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.
Image version	An **image version** is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an **image version** to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Get the VM

You can see a list of VMs that are available in a resource group using Get-AzVM. Once you know the VM name and what resource group, you can use `Get-AzVM` again to get the VM object and store it in a variable to use later. This example gets a VM named *sourceVM* from the *myResourceGroup* resource group and assigns it to the variable *$sourceVM*.

Azure PowerShell

```
$sourceVM = Get-AzVM `
   -Name sourceVM `
   -ResourceGroupName myResourceGroup
```

Create a resource group

Create a resource group with the New-AzResourceGroup command.

An Azure resource group is a logical container into which Azure resources are deployed and managed. In the following example, a resource group named *myGalleryRG* is created in the *EastUS* region:

Azure PowerShell

```
$resourceGroup = New-AzResourceGroup `
   -Name 'myGalleryRG' `
   -Location 'EastUS'
```

Create a gallery

A gallery is the primary resource used for enabling image sharing. Allowed characters for gallery name are uppercase or lowercase letters, digits, dots, and periods. The gallery name cannot contain dashes. Gallery names must be unique within your subscription.

Create a gallery using New-AzGallery. The following example creates a gallery named *myGallery* in the *myGalleryRG* resource group.

Azure PowerShell

```
$gallery = New-AzGallery `
   -GalleryName 'myGallery' `
   -ResourceGroupName $resourceGroup.ResourceGroupName `
   -Location $resourceGroup.Location `
   -Description 'Azure Compute Gallery for my organization'
```

Create an image definition

Image definitions create a logical grouping for images. They are used to manage information about the image versions that are created within them. Image definition names can be made up of uppercase or lowercase letters, digits, dots, dashes and periods. For more information about the values you can specify for an image definition, see Image definitions.

Create the image definition using New-AzGalleryImageDefinition. In this example, the gallery image is named *myGalleryImage* and is created for a specialized image.

Azure PowerShell

```
$galleryImage = New-AzGalleryImageDefinition `
   -GalleryName $gallery.Name `
   -ResourceGroupName $resourceGroup.ResourceGroupName `
   -Location $gallery.Location `
   -Name 'myImageDefinition' `
   -OsState specialized `
   -OsType Windows `
   -Publisher 'myPublisher' `
   -Offer 'myOffer' `
   -Sku 'mySKU'
```

Create an image version

Create an image version from a VM using New-AzGalleryImageVersion.

Allowed characters for image version are numbers and periods. Numbers must be within the range of a 32-bit integer. Format: *MajorVersion.MinorVersion.Patch*.

In this example, the image version is *1.0.0* and it's replicated to both *East US* and *South Central US* datacenters. When choosing target regions for replication, you need to include the *source* region as a target for replication.

To create an image version from the VM, use `$vm.Id.ToString()` for the `-Source`.

Azure PowerShell

```
   $region1 = @{Name='South Central US';ReplicaCount=1}
   $region2 = @{Name='East US';ReplicaCount=2}
   $targetRegions = @($region1,$region2)

New-AzGalleryImageVersion `
   -GalleryImageDefinitionName $galleryImage.Name`
   -GalleryImageVersionName '1.0.0' `
   -GalleryName $gallery.Name `
   -ResourceGroupName $resourceGroup.ResourceGroupName `
   -Location $resourceGroup.Location `
   -TargetRegion $targetRegions  `
   -Source $sourceVM.Id.ToString() `
   -PublishingProfileEndOfLifeDate '2030-12-01'
```

It can take a while to replicate the image to all of the target regions.

Create a VM

Once you have a specialized image, you can create one or more new VMs. Using the New-AzVM cmdlet. To use the image, use `Set-AzVMSourceImage` and set the `-Id` to the image definition ID ($galleryImage.Id in this case) to always use the latest image version.

Replace resource names as needed in this example.

Azure PowerShell

```
# Create some variables for the new VM.
$resourceGroup = "myResourceGroup"
$location = "South Central US"
$vmName = "mySpecializedVM"

# Create a resource group
New-AzResourceGroup -Name $resourceGroup -Location $location

# Create the network resources.
$subnetConfig = New-AzVirtualNetworkSubnetConfig -Name mySubnet -
AddressPrefix 192.168.1.0/24
$vnet = New-AzVirtualNetwork -ResourceGroupName $resourceGroup -Location
$location `
  -Name MYvNET -AddressPrefix 192.168.0.0/16 -Subnet $subnetConfig
$pip = New-AzPublicIpAddress -ResourceGroupName $resourceGroup -Location
$location `
  -Name "mypublicdns$(Get-Random)" -AllocationMethod Static -
IdleTimeoutInMinutes 4
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig -Name
myNetworkSecurityGroupRuleRDP  -Protocol Tcp `
  -Direction Inbound -Priority 1000 -SourceAddressPrefix * -SourcePortRange
* -DestinationAddressPrefix * `
  -DestinationPortRange 3389 -Access Deny
$nsg = New-AzNetworkSecurityGroup -ResourceGroupName $resourceGroup -
Location $location `
  -Name myNetworkSecurityGroup -SecurityRules $nsgRuleRDP
$nic = New-AzNetworkInterface -Name $vmName -ResourceGroupName
$resourceGroup -Location $location `
  -SubnetId $vnet.Subnets[0].Id -PublicIpAddressId $pip.Id -
NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration using $imageVersion.Id to specify
the image version.
$vmConfig = New-AzVMConfig -VMName $vmName -VMSize Standard_D1_v2 | `
Set-AzVMSourceImage -Id $galleryImage.Id | `
Add-AzVMNetworkInterface -Id $nic.Id

# Create a virtual machine
New-AzVM -ResourceGroupName $resourceGroup -Location $location -VM $vmConfig
```

Share the gallery

We recommend that you share access at the gallery level. Use an email address and the Get-AzADUser cmdlet to get the object ID for the user, then use New-AzRoleAssignment to give them access to the gallery. Replace the example email, alinne_montes@contoso.com in this example, with your own information.

Azure PowerShell

```
# Get the object ID for the user
$user = Get-AzADUser -StartsWith alinne_montes@contoso.com
# Grant access to the user for our gallery
New-AzRoleAssignment `
   -ObjectId $user.Id `
   -RoleDefinitionName Reader `
   -ResourceName $gallery.Name `
   -ResourceType Microsoft.Compute/galleries `
   -ResourceGroupName $resourceGroup.ResourceGroupName
```

Clean up resources

When no longer needed, you can use the Remove-AzResourceGroup cmdlet to remove the resource group, and all related resources:

Azure PowerShell

```
# Delete the gallery
Remove-AzResourceGroup -Name myGalleryRG

# Delete the VM
Remove-AzResourceGroup -Name myResoureceGroup
```

Azure Image Builder

Azure also offers a service, built on Packer, Azure VM Image Builder. Simply describe your customizations in a template, and it will handle the image creation.

Next steps

In this tutorial, you created a specialized VM image. You learned how to:

- ✓ Create an Azure Compute Gallery
- ✓ Create an image definition
- ✓ Create an image version
- ✓ Create a VM from an image

✓ Share a gallery

Advance to the next tutorial to learn about Virtual Machine Scale Sets.

Create a virtual machine scale set

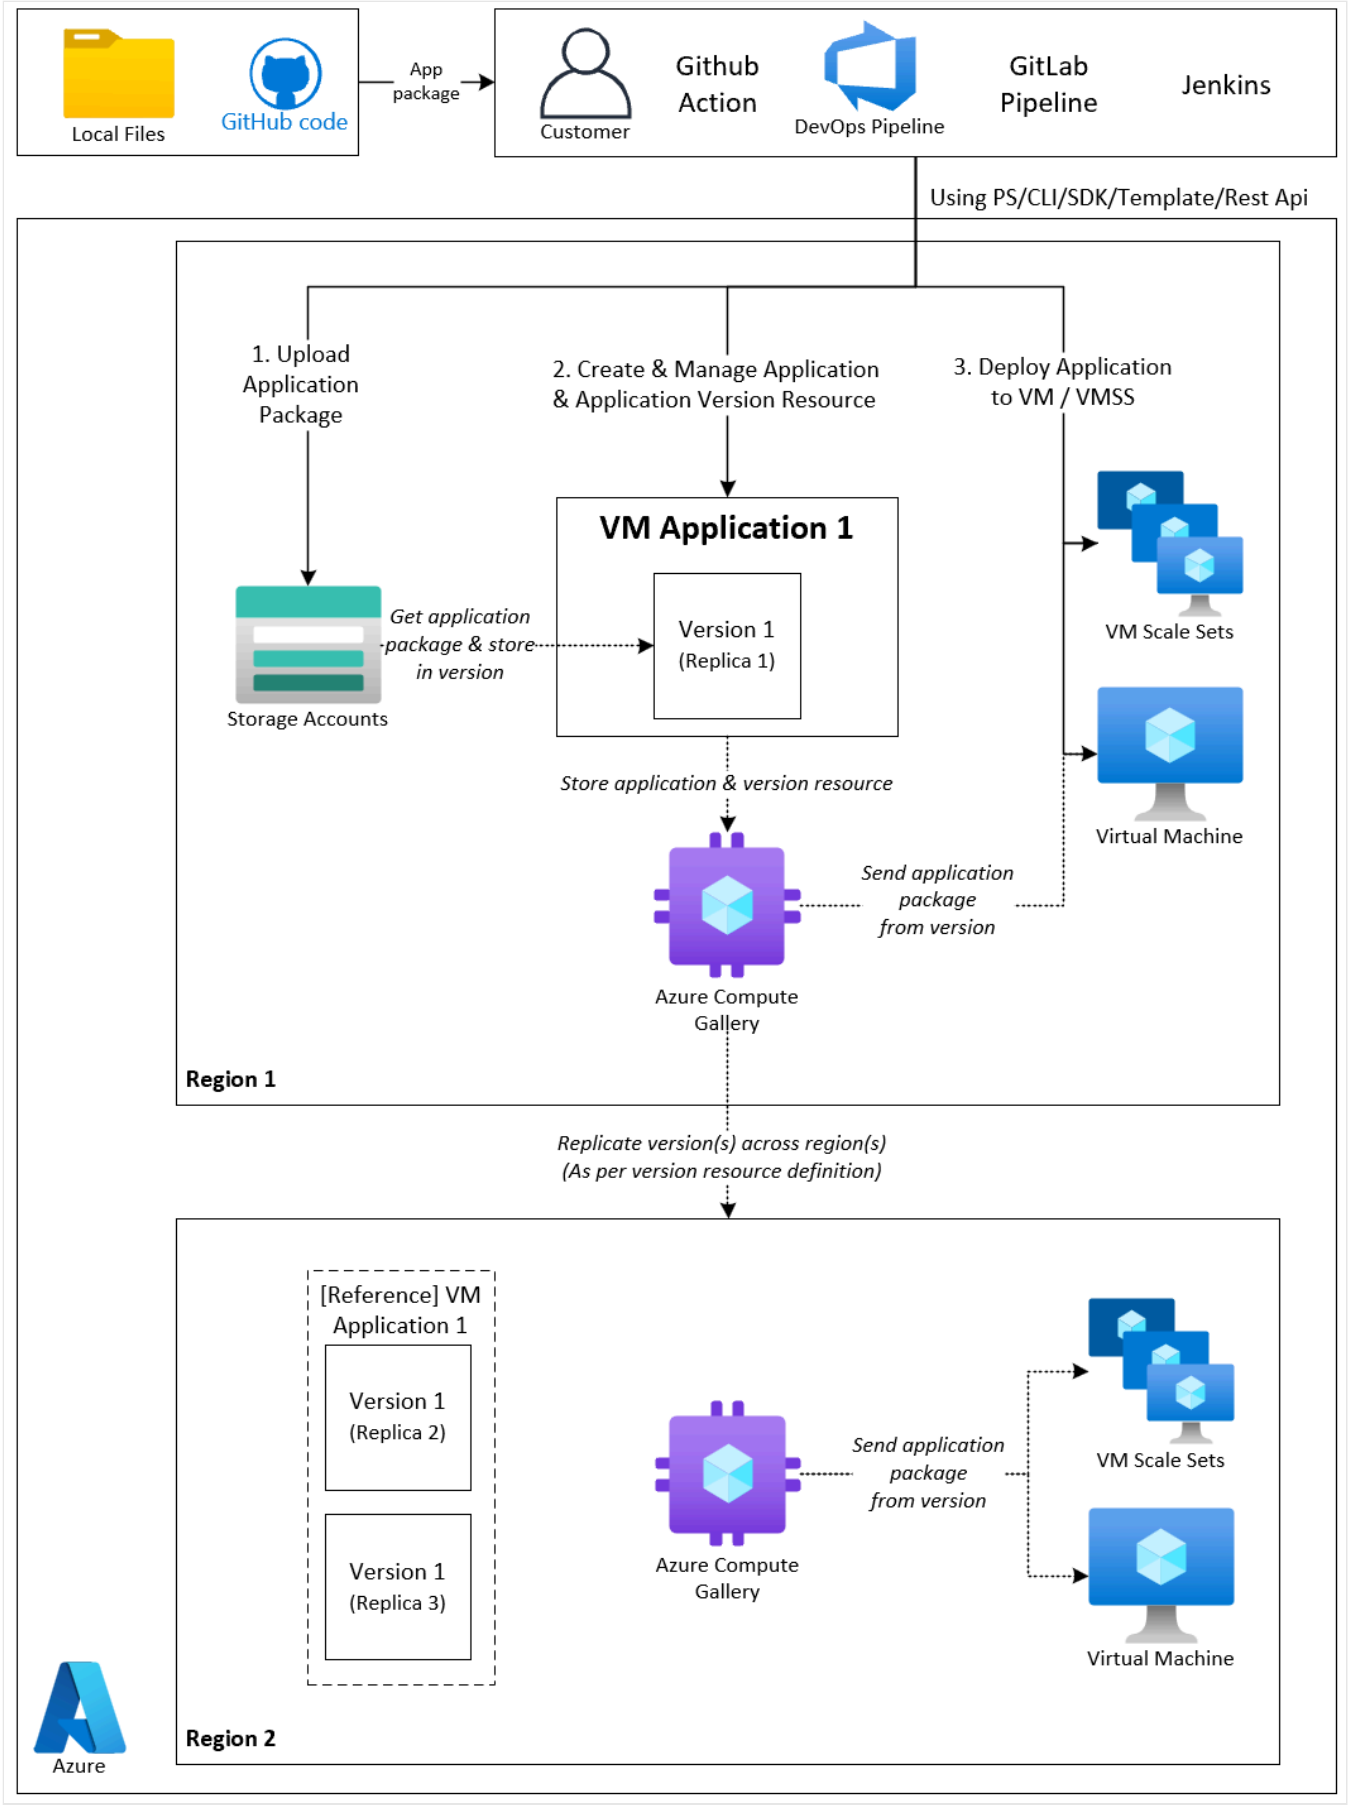
Create and deploy VM Application

Summarize this article for me

VM Application is a resource type in Azure Compute Gallery that simplifies publishing, deployment, management, sharing, and global distribution of applications and scripts for your virtual machines. VM Applications support a wide range of scenarios, including high-scale deployments, low-latency requirements, failure resiliency, secure trusted rollouts, fleet-wide consistency, microservice architectures, and post-deployment management. Learn more about VM Applications.

To create and deploy applications on Azure VM, first package and upload your application to Azure Storage Account as a storage blob. Then create `Azure VM application` resource and `VM application version` resource referencing these storage blobs. Azure stores and replicates these blobs in regional managed storage accounts. Finally, deploy the application on any VM or Virtual Machine Scale Sets by passing application reference in `applicationProfile`.



Prerequisites

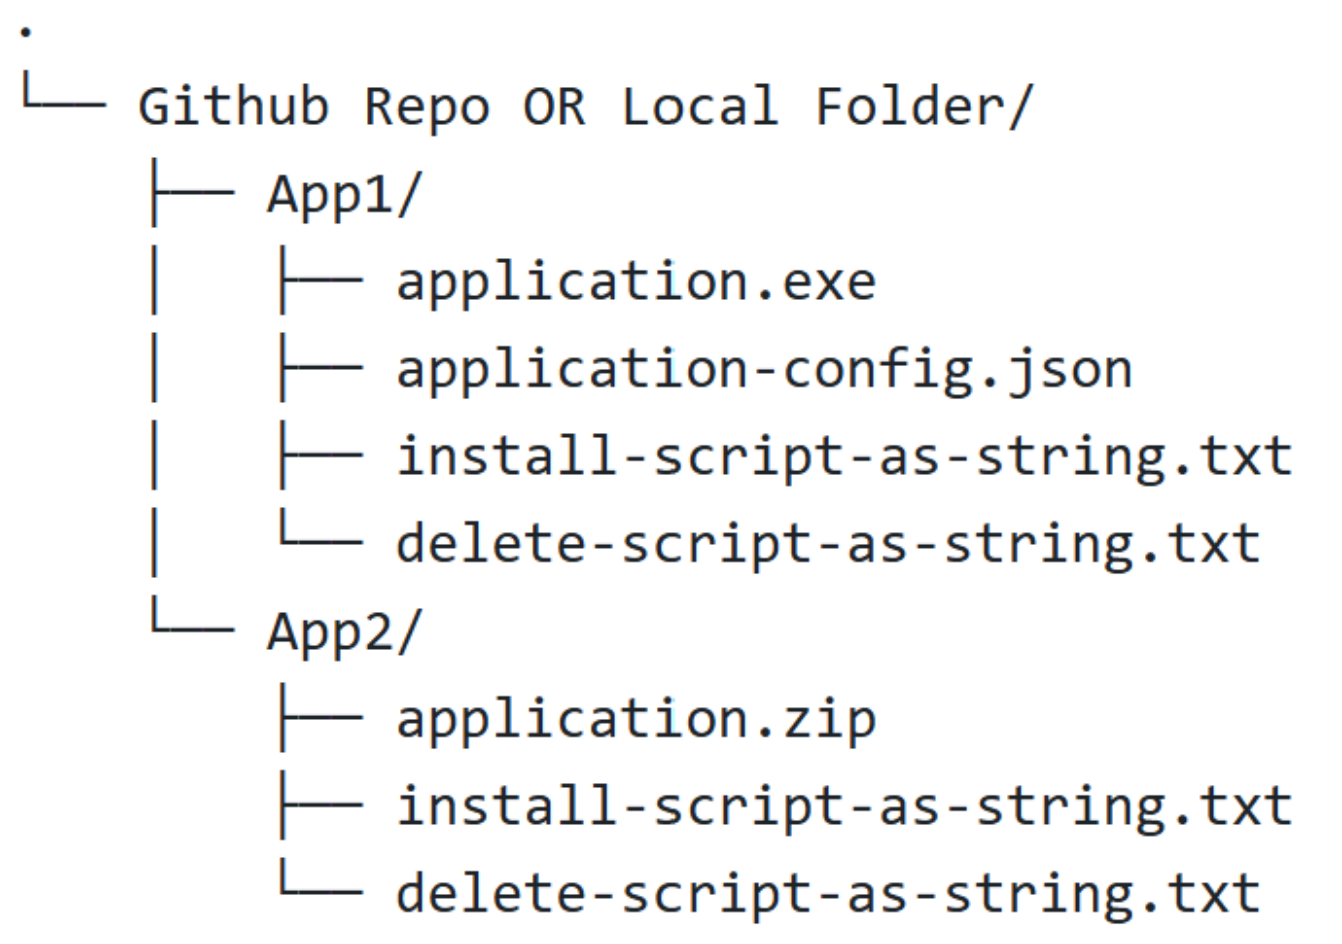
1. Create Azure storage account and storage container. This container is used to upload your application files.

2. Create Azure Compute Gallery for storing and sharing application resources.
3. Create user-assigned managed identity and assign to Azure Compute Gallery

> ⓘ Note
>
> Create your storage account with anonymous access disabled for improved security. Use a managed identity assigned to Azure Compute Gallery to publish your VM Applications securely without requiring SAS tokens.

Package the application

Before publishing the VM Application resource in Azure Compute Gallery, package your application files for upload to Azure Storage Account. The following diagram shows possible folder structures for organizing your application files:



1. Package the application files

VM Application requires a single file as the application package.

- If your application installation requires a single executable file (.exe, .msi, .sh, .ps, etc.) then you can use it as the application package.
- If your application requires multiple files (executables, dependencies, scripts, metadata, etc.), archive them into a single file (`.zip`, `.tar`, `.tar.gz`) and use this file as the application package.
- For microservice application, you can package and publish each microservice as a separate Azure VM Application. This modularization facilitates application reusability, cross-team development, and sequential installation of microservices using `order` property in the applicationProfile.

Learn more about creating application packages for Azure VM Applications.

2. (Optional) Package the application configuration file

- You can provide the configuration file separately using `defaultConfigurationLink` in the `publishingProfile` of the VM Application. This reduces the overhead of archiving and unarchiving application packages.
- Configuration files can also be passed during app deployment using `configurationReference` property in the `applicationProfile` of the VM enabling customized installation per VM.
- If both properties are set, `configurationReference` overrides the configuration passed using `defaultConfigurationLink`.

3. Create the install script

After the application and configuration blob is downloaded on the VM, Azure executes the provided install script to install the application. **The install script is provided as a string** and has a maximum character limit of 4,096 chars. The install commands should be written assuming the application package and the configuration file are in the current directory.

There may be few operations required to be performed in the install script

- **(Optional) Use the right command interpreter** The default command interpreter used by Azure are `/bin/bash` on Linux OS and `cmd.exe` on Windows OS. It's possible to use a different interpreter like Chocolatey or PowerShell, if its installed on the machine. Call the executable and pass the commands to it. For example, `powershell.exe -command '<powershell command>'`. If you're using PowerShell, you need to be using version 3.11.0 of the Az.Storage module.

- **(Optional) Rename application blob and configuration blob** Azure can't retain the original blob name and the file extensions. Azure downloads the application file with the

name of the VM application resource published on Azure Compute Gallery. So if name of VM App is "VMApp1", the file downloaded on VM has the name "VMApp1" without an extension. The configuration file has a default name as "VMApp1-config" without a file extension.

You can rename the file with the file extension using the install script or you can also pass the names in `packageFileName` and `configFileName` properties of the publishingProfile of VM Application version resource. Azure uses these names instead of default names while downloading the files.

- **Unarchive application blob** For archived application packages, it needs to be unarchived before installing the application. Use .zip or .tar since most OS has built-in support for unarchiving these formats. For other formats, make sure the Guest OS provides support.

- **Convert the script to string** The install script is passed as a string for the `install` property in the `publishingProfile` of Azure VM Application version resource.

- **Install quietly and synchronously** Install applications quietly or silently without any user interface prompts. Since the installation runs on a VM where customer input isn't available, you must use silent or unattended installation flags. Additionally, if the application installer spawns background or child processes or runs asynchronously, the parent script might return before the installation completes. To ensure the full installation finishes before Azure marks the operation as successful, use wait flags or blocking commands. This approach helps when installation involves multiple steps that run asynchronously or you need to verify installation completes before the subsequent application in the `order` sequence begins.

  Common examples include:
  - **Windows .msi**: `start /wait msiexec /i app.msi /quiet /qn`
  - **Windows .exe**: `start /wait app.exe /silent` or `start /wait app.exe /quiet` or `start /wait app.exe /S`
  - **PowerShell**: `Start-Process -FilePath '.\app.exe' -ArgumentList '/quiet' -Wait`
  - **Linux .sh**: `./install.sh --silent` (shell scripts run synchronously by default)
  - **Linux .deb**: `sudo DEBIAN_FRONTEND=noninteractive dpkg -i app.deb` (runs synchronously by default)
  - **Linux .rpm**: `sudo rpm -ivh app.rpm` (runs synchronously by default)

- **(Optional) Set right execution policy and permissions** After unarchiving, file permissions could be reset. It's a good practice to set the right permissions before executing the files.

- **(Optional) Set verbose execution and logging** VM Applications automatically captures any output from the install script and stores it in a stdout file on the VM. Use this

capability to log installation progress, debug failures, and verify successful deployments.
    - **Enable verbose mode** to capture application installer logs. Bash: `set -x`, PowerShell: `$VerbosePreference='Continue'`, Cmd: `@echo on`.
    - **Add custom messages** to track script progress. Bash: `echo "Install started"`, PowerShell: `Write-Output "Install started"`, Cmd: `echo Install started`

    You can retrieve these logs using Run Command or by connecting to the VM. The `stdout` and `stderr` files are located at the following path
    - Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>/`
    - Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.9\Downloads\<application name>\<application version>/`

- **(Optional) Move application and configuration blob to appropriate location** Azure downloads the application blob and configuration blob to following locations. The install script must move the files to appropriate locations when necessary.

    Linux: `/var/lib/waagent/Microsoft.CPlat.Core.VMApplicationManagerLinux/<application name>/<application version>`

    Windows: `C:\Packages\Plugins\Microsoft.CPlat.Core.VMApplicationManagerWindows\1.0.16\Downloads\<application name>\<application version>`

Here are few sample install scripts based on the file extension of the application blob. If `packageFileName` & `configFileName` properties are provided in the `publishingProfile` with file name and extension, remove the code for renaming files in following scripts.

.TAR

Replace `VMApp1` with your VM App name in application package (VMApp1) and configuration file (VMApp1-config). Replace `app.tar` with desired app name. Replace `config.yaml` with your desired config name.

Install using bash without config file:

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && bash ./install.sh
```

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && sudo
DEBIAN_FRONTEND=noninteractive dpkg -i ./app.deb
```

Install using bash with config file:

Bash

```
mv VMApp1 app.tar && mv VMApp1-config config.yaml && tar -xf app.tar && chmod -
R +xr . && bash ./install.sh --config config.yaml
```

If config file is packaged within the tar file

Bash

```
mv VMApp1 app.tar && tar -xf app.tar && chmod -R +xr . && sudo debconf-set-
selections < config.cfg && sudo DEBIAN_FRONTEND=noninteractive dpkg -i
./app.deb
```

4. Create the remove script

The `remove` script enables you to define the operations for removing the application. The `remove` script is provided as a string and has a maximum character limit of 4,096 characters. Write the commands assuming the application package and the configuration file are in the current directory. During uninstall operation, Azure runs the uninstall script and then deletes all files from the repository.

There are few operations that the `remove` script must perform.

- **Uninstall application:** Properly uninstall the application from the VM. For example:

CMD

CMD on Windows:

cli

```
start /wait uninstall.exe /quiet
```

cli

```
start /wait python.exe /uninstall /quiet
```

cli

```
start /wait msiexec /x app.msi /quiet /qn
```

- **Remove residual files:** If the application installation creates files in other parts of the file system, remove those files.

Upload the application files to Azure storage account

> ⓘ **Important**
>
> Before uploading files or generating SAS URLs, assign roles to the user, service principal, or managed identity that performs these operations on the target Storage account or container:
>
> - Storage Blob Data Contributor or Storage Blob Data Owner: required to upload, modify, or delete blobs.
> - For generating SAS with Azure AD (for example, using `--auth-mode` login in CLI/PowerShell), also assign Storage Blob Delegator at the storage account scope.

1. Upload your application and configuration files to a container in your Azure storage account.

Upload your packaged application and optional configuration file as blobs. Block blobs work for most scenarios.

Optionally, if you need to use page blobs, byte-align your files before uploading using one of the following scripts:

CLI

Azure CLI

```
inputFile="<the file you want to pad>"

# Get the file size
fileSize=$(stat -c %s "$inputFile")

# Calculate the remainder when divided by 512
```

```
remainder=$((fileSize % 512))

if [ "$remainder" -ne 0 ]; then
  # Calculate how many bytes to pad
  difference=$((512 - remainder))

  # Create padding (empty bytes)
  dd if=/dev/zero bs=1 count=$difference >> "$inputFile"
fi
```

2. Generate SAS or Blob URL for the application package and the configuration file

Once the application and configuration files are uploaded to the storage account, you need to generate a Blob URL or SAS URL with read privilege for these blobs. These URLs are then provided as reference while creating the VM Application version resource.

> ⓘ **Note**
>
> Use of blob URL with managed identity is strongly recommended for improved security and privacy.

Use blob URL:

- If managed identity is assigned to Azure Compute Gallery.
- If storage account is enabled for anonymous access. Use this method only for testing since its insecure.

Use SAS URL:

- If storage account is disabled for anonymous access and managed identity isn't assigned to Azure Compute Gallery.

Blob URL = https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${BLOB_NAME}
SAS URL = https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${BLOB_NAME}?${SAS_TOKEN}

CLI using Blob URL

Use the following script if managed identity is assigned to Azure Compute Gallery. This approach uses blob URLs without SAS tokens.

Azure CLI

```
#!/bin/bash
set -euo pipefail

# === CONFIGURATION ===
STORAGE_ACCOUNT="your-storage-account-name"
CONTAINER_NAME="your-container-name"
APP_FILE="./path/to/your-app-file"           # Path to your application payload
file
CONFIG_FILE="./path/to/your-config-file"     # Path to your configuration file
(optional)

# === LOGIN (if not already logged in) ===
az login --only-show-errors

# === CREATE CONTAINER IF NOT EXISTS ===
az storage container create \
  --name "$CONTAINER_NAME" \
  --account-name "$STORAGE_ACCOUNT" \
  --auth-mode login \
  --only-show-errors

# === UPLOAD APPLICATION FILE ===
APP_BLOB_NAME=$(basename "$APP_FILE")
az storage blob upload \
  --account-name "$STORAGE_ACCOUNT" \
  --container-name "$CONTAINER_NAME" \
  --name "$APP_BLOB_NAME" \
  --file "$APP_FILE" \
  --auth-mode login \
  --overwrite \
  --only-show-errors

# === UPLOAD CONFIG FILE (optional) ===
if [ -n "$CONFIG_FILE" ] && [ -f "$CONFIG_FILE" ]; then
  CONFIG_BLOB_NAME=$(basename "$CONFIG_FILE")
  az storage blob upload \
    --account-name "$STORAGE_ACCOUNT" \
    --container-name "$CONTAINER_NAME" \
    --name "$CONFIG_BLOB_NAME" \
    --file "$CONFIG_FILE" \
    --auth-mode login \
    --overwrite \
    --only-show-errors
fi

# === GENERATE BLOB URLs ===
echo "Generating Blob URLs..."

APP_BLOB_URL="https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME
}/${APP_BLOB_NAME}"
echo "Application file: $APP_BLOB_URL"
```

```
if [ -n "$CONFIG_FILE" ] && [ -f "$CONFIG_FILE" ]; then

CONFIG_BLOB_URL="https://${STORAGE_ACCOUNT}.blob.core.windows.net/${CONTAINER_NAME}/${CONFIG_BLOB_NAME}"
  echo "Configuration file: $CONFIG_BLOB_URL"
fi
```

Create the VM Application

To create the VM Application, first create the **VM Application** resource, which describes the application. Then create **VM Application Version** resource within it, which contains the VM application payload and scripts to install, update, and delete the application. Payload is supplied using Blob URL or SAS URL to the blob container in Azure Storage Account.

Refer schema for VM Application and VM Application version resource to learn more about each property.

Template

Use the following ARM template to create an Azure Compute Gallery, VM Application, and VM Application version. This template demonstrates the key properties and configuration options for publishing your application package.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2020-06-01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {
    "galleryName": {
      "type": "string"
    },

          "storageAccountType": "[parameters('storageAccountType')]"
        },
        "safetyProfile": {
          "allowDeletionOfReplicatedLocations": true
        },
        "endOfLifeDate": "[parameters('endOfLifeDate')]"
      }
    }
  ]
}
```

Deploy the VM Apps

One or more VM Applications can now be referenced in the `applicationProfile` of Azure VM or Azure Virtual Machine Scale Sets. Azure then pulls the payload of the VM Application and installs it on each VM using the provided install script. The `order` property defines the sequential order in which the VM Applications are installed on the VM.

Refer schema of applicationProfile of the VM / Virtual Machine Scale Sets to learn more about each property.

Template

Use the following ARM template to deploy VM Application on Azure VM or Azure Virtual Machine Scale Sets. This template demonstrates the key properties and configuration options for deploying your VM application.

Deploy VM Application on Virtual Machine Scale Sets

JSON

```

Tutorial - Deploy applications to a Windows virtual machine in Azure with the Custom Script Extension

Article • 08/22/2024

Applies to: ✔ Windows ✔ Flexible scale sets ✔ Uniform scale sets

To configure virtual machines (VMs) in a quick and consistent manner, you can use the Custom Script Extension for Windows. In this tutorial you learn how to:

- ✔ Use the Custom Script Extension to install IIS.
- ✔ Create a VM that uses the Custom Script Extension.
- ✔ View a running IIS site after the extension is applied.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, select **Open Cloudshell** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Custom script extension overview

The Custom Script Extension downloads and executes scripts on Azure VMs. This extension is useful for post-deployment configuration, software installation, or any other configuration or management task. You can download scripts from Azure storage or GitHub, or you can provide scripts to the Azure portal at extension run time.

The Custom Script extension integrates with Azure Resource Manager templates and can be run by using the Azure CLI, PowerShell, Azure portal, or the Azure Virtual Machine REST API.

You can use the Custom Script Extension with both Linux and Windows VMs.

Create virtual machine

Set the administrator username and password for the VM with Get-Credential:

Azure PowerShell

```
$cred = Get-Credential
```

Now you can create the VM with New-AzVM. The following example creates a VM named *myVM* in the *EastUS* location. If they don't already exist, the resource group *myResourceGroupAutomate* and supporting network resources are created. To allow web traffic, the cmdlet also opens port *80*.

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName "myResourceGroupAutomate" `
    -Name "myVM" `
    -Location "East US" `
    -VirtualNetworkName "myVnet" `
    -SubnetName "mySubnet" `
    -SecurityGroupName "myNetworkSecurityGroup" `
    -PublicIpAddressName "myPublicIpAddress" `
    -OpenPorts 80 `
    -Credential $cred
```

The resources and VM take a few minutes to be created.

Automate IIS install

Use Set-AzVMExtension to install the Custom Script Extension. The extension runs `powershell Add-WindowsFeature Web-Server` to install the IIS webserver and then updates the *Default.htm* page to show the hostname of the VM:

Azure PowerShell

```
Set-AzVMExtension -ResourceGroupName "myResourceGroupAutomate" `
    -ExtensionName "IIS" `
    -VMName "myVM" `
    -Location "EastUS" `
    -Publisher Microsoft.Compute `
    -ExtensionType CustomScriptExtension `
    -TypeHandlerVersion 1.8 `
    -SettingString '{"commandToExecute":"powershell Add-WindowsFeature Web-
Server; powershell Add-Content -Path \"C:\\inetpub\\wwwroot\\Default.htm\" -
Value $($env:computername)"}'
```

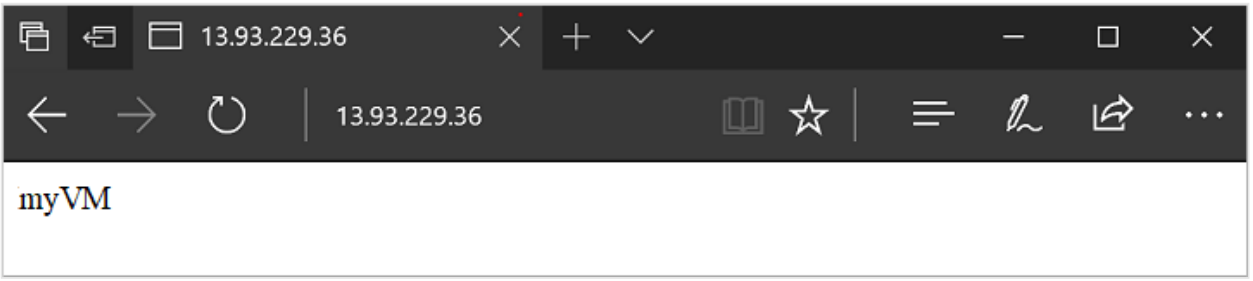
Test web site

Obtain the public IP address of your load balancer with Get-AzPublicIPAddress. The following example obtains the IP address for `myPublicIPAddress` created earlier:

Azure PowerShell

```
Get-AzPublicIPAddress `
    -ResourceGroupName "myResourceGroupAutomate" `
    -Name "myPublicIPAddress" | select IpAddress
```

You can then enter the public IP address in to a web browser. The website is displayed, including the hostname of the VM that the load balancer distributed traffic to as in the following example:



Next steps

In this tutorial, you automated the IIS install on a VM. You learned how to:

- ✓ Use the Custom Script Extension to install IIS.
- ✓ Create a VM that uses the Custom Script Extension.
- ✓ View a running IIS site after the extension is applied.

Advance to the next tutorial to learn how to create custom VM images.

Create custom VM images

Tutorial: Create and manage Azure virtual networks for Windows virtual machines with Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Windows VMs

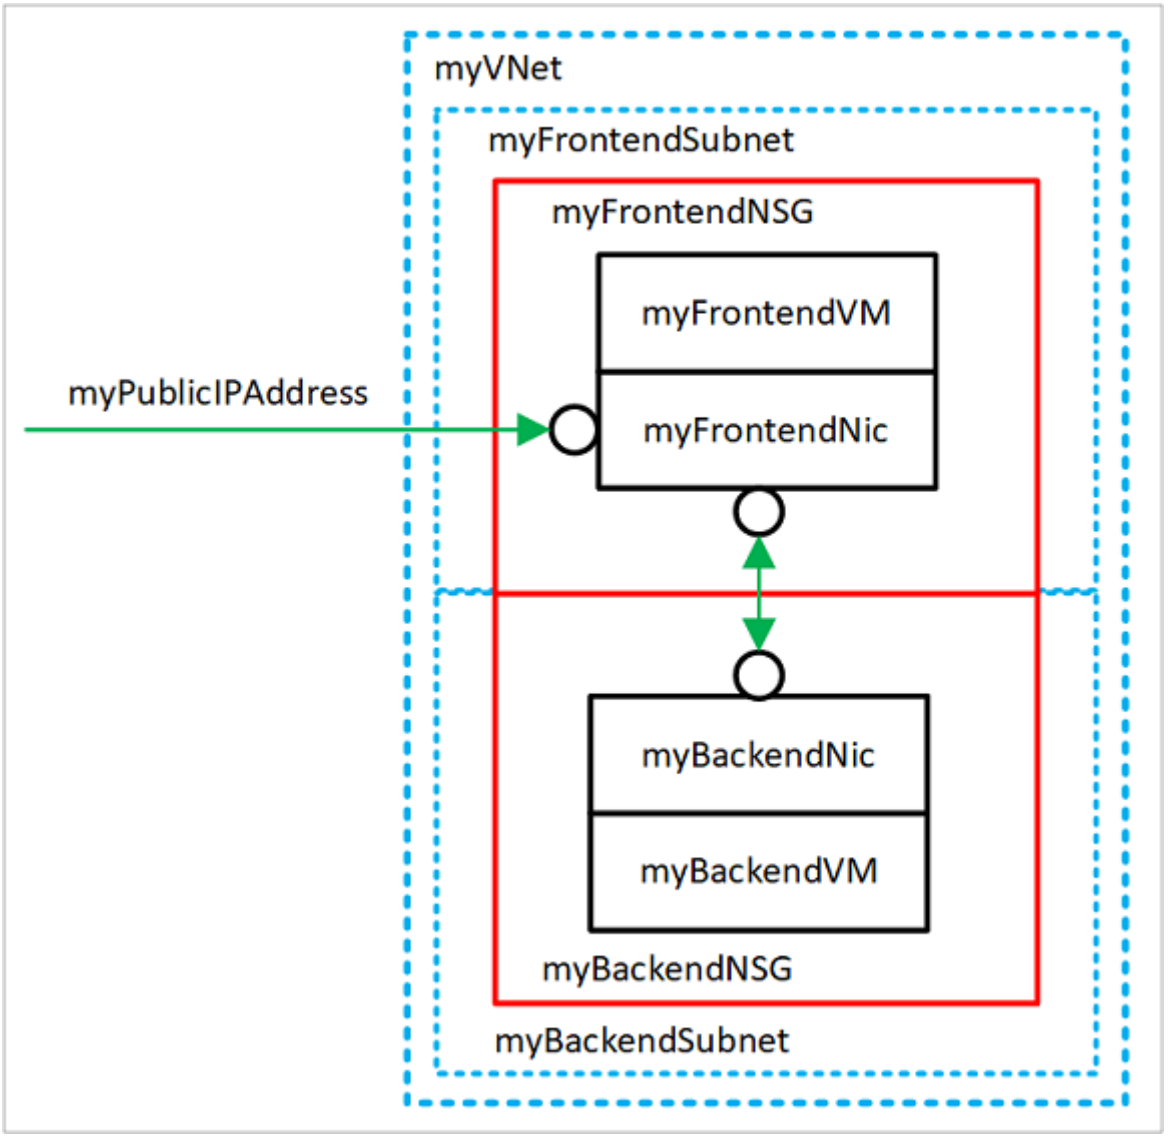
Azure virtual machines use Azure networking for internal and external network communication. This tutorial walks through deploying two virtual machines and configuring Azure networking for these VMs. The examples in this tutorial assume that the VMs are hosting a web application with a database back-end, however an application isn't deployed in the tutorial. In this tutorial, you learn how to:

- ✓ Create a virtual network and subnet
- ✓ Create a public IP address
- ✓ Create a front-end VM
- ✓ Secure network traffic
- ✓ Create back-end VM

VM networking overview

Azure virtual networks enable secure network connections between virtual machines, the internet, and other Azure services such as Azure SQL Database. Virtual networks are broken down into logical segments called subnets. Subnets are used to control network flow, and as a security boundary. When deploying a VM, it generally includes a virtual network interface, which is attached to a subnet.

While completing this tutorial, you can see these resources created:



- *myVNet* - The virtual network that the VMs use to communicate with each other and the internet.
- *myFrontendSubnet* - The subnet in *myVNet* used by the front-end resources.
- *myPublicIPAddress* - The public IP address used to access *myFrontendVM* from the internet.
- *myFrontendNic* - The network interface used by *myFrontendVM* to communicate with *myBackendVM*.
- *myFrontendVM* - The VM used to communicate between the internet and *myBackendVM*.
- *myBackendNSG* - The network security group that controls communication between the *myFrontendVM* and *myBackendVM*.
- *myBackendSubnet* - The subnet associated with *myBackendNSG* and used by the back-end resources.
- *myBackendNic* - The network interface used by *myBackendVM* to communicate with *myFrontendVM*.
- *myBackendVM* - The VM that uses port 1433 to communicate with *myFrontendVM*.

Launch Azure Cloud Shell

The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Create subnet

For this tutorial, a single virtual network is created with two subnets. A front-end subnet for hosting a web application, and a back-end subnet for hosting a database server.

Before you can create a virtual network, create a resource group using New-AzResourceGroup. The following example creates a resource group named *myRGNetwork* in the *EastUS* location:

Azure PowerShell

```
New-AzResourceGroup -ResourceGroupName myRGNetwork -Location EastUS
```

Create a subnet configuration named *myFrontendSubnet* using New-AzVirtualNetworkSubnetConfig:

Azure PowerShell

```
$frontendSubnet = New-AzVirtualNetworkSubnetConfig `
  -Name myFrontendSubnet `
  -AddressPrefix 10.0.0.0/24
```

And, create a subnet configuration named *myBackendSubnet*:

Azure PowerShell

```
$backendSubnet = New-AzVirtualNetworkSubnetConfig `
  -Name myBackendSubnet `
  -AddressPrefix 10.0.1.0/24
```

Create virtual network

Create a VNET named *myVNet* using *myFrontendSubnet* and *myBackendSubnet* using New-AzVirtualNetwork:

Azure PowerShell

```
$vnet = New-AzVirtualNetwork `
  -ResourceGroupName myRGNetwork `
  -Location EastUS `
  -Name myVNet `
  -AddressPrefix 10.0.0.0/16 `
  -Subnet $frontendSubnet, $backendSubnet
```

At this point, a network has been created and segmented into two subnets, one for front-end services, and another for back-end services. In the next section, virtual machines are created and connected to these subnets.

Create a public IP address

A public IP address allows Azure resources to be accessible on the internet. The allocation method of the public IP address can be configured as dynamic or static. By default, a public IP address is dynamically allocated. Dynamic IP addresses are released when a VM is deallocated. This behavior causes the IP address to change during any operation that includes a VM deallocation.

The allocation method can be set to static, which makes sure that the IP address stays assigned to a VM, even during a deallocated state. If you are using a static IP address, the IP address itself can't be specified. Instead, it's allocated from a pool of available addresses.

Create a public IP address named *myPublicIPAddress* using New-AzPublicIpAddress:

Azure PowerShell

```
$pip = New-AzPublicIpAddress `
  -ResourceGroupName myRGNetwork `
  -Location EastUS `
  -AllocationMethod Dynamic `
  -Name myPublicIPAddress
```

You could change the -AllocationMethod parameter to `Static` to assign a static public IP address.

Create a front-end VM

For a VM to communicate in a virtual network, it needs a virtual network interface (NIC). Create a NIC using New-AzNetworkInterface:

Azure PowerShell

```
$frontendNic = New-AzNetworkInterface `
  -ResourceGroupName myRGNetwork `
  -Location EastUS `
  -Name myFrontend `
  -SubnetId $vnet.Subnets[0].Id `
  -PublicIpAddressId $pip.Id
```

Set the username and password needed for the administrator account on the VM using Get-Credential. You use these credentials to connect to the VM in additional steps:

Azure PowerShell

```
$cred = Get-Credential
```

Create the VMs using New-AzVM.

Azure PowerShell

```
New-AzVM `
   -Credential $cred `
   -Name myFrontend `
   -PublicIpAddressName myPublicIPAddress `
   -ResourceGroupName myRGNetwork `
   -Location "EastUS" `
   -Size Standard_D1 `
   -SubnetName myFrontendSubnet `
   -VirtualNetworkName myVNet
```

Secure network traffic

A network security group (NSG) contains a list of security rules that allow or deny network traffic to resources connected to Azure Virtual Networks (VNet). NSGs can be associated to subnets or individual network interfaces. An NSG that is associated with a network interface only applies to the associated VM. When an NSG is associated to a subnet, the rules apply to all resources connected to the subnet.

Network security group rules

NSG rules define networking ports over which traffic is allowed or denied. The rules can include source and destination IP address ranges so that traffic is controlled between specific systems or subnets. NSG rules also include a priority (between 1—and 4096). Rules are evaluated in the order of priority. A rule with a priority of 100 is evaluated before a rule with priority 200.

All NSGs contain a set of default rules. The default rules can't be deleted, but because they are assigned the lowest priority, they can be overridden by the rules that you create.

- **Virtual network** - Traffic originating and ending in a virtual network is allowed both in inbound and outbound directions.
- **Internet** - Outbound traffic is allowed, but inbound traffic is blocked.
- **Load balancer** - Allow Azure's load balancer to probe the health of your VMs and role instances. If you are not using a load balanced set, you can override this rule.

Create network security groups

Create an inbound rule named *myFrontendNSGRule* to allow incoming web traffic on *myFrontendVM* using New-AzNetworkSecurityRuleConfig:

Azure PowerShell

```
$nsgFrontendRule = New-AzNetworkSecurityRuleConfig `
  -Name myFrontendNSGRule `
  -Protocol Tcp `
  -Direction Inbound `
  -Priority 200 `
  -SourceAddressPrefix * `
  -SourcePortRange * `
  -DestinationAddressPrefix * `
  -DestinationPortRange 80 `
  -Access Allow
```

You can limit internal traffic to *myBackendVM* from only *myFrontendVM* by creating an NSG for the back-end subnet. The following example creates an NSG rule named *myBackendNSGRule*:

Azure PowerShell

```
$nsgBackendRule = New-AzNetworkSecurityRuleConfig `
  -Name myBackendNSGRule `
  -Protocol Tcp `
  -Direction Inbound `
  -Priority 100 `
  -SourceAddressPrefix 10.0.0.0/24 `
```

```
  -SourcePortRange * `
  -DestinationAddressPrefix * `
  -DestinationPortRange 1433 `
  -Access Allow
```

Add a network security group named *myFrontendNSG* using New-AzNetworkSecurityGroup:

Azure PowerShell

```
$nsgFrontend = New-AzNetworkSecurityGroup `
  -ResourceGroupName myRGNetwork `
  -Location EastUS `
  -Name myFrontendNSG `
  -SecurityRules $nsgFrontendRule
```

Now, add a network security group named *myBackendNSG* using New-AzNetworkSecurityGroup:

Azure PowerShell

```
$nsgBackend = New-AzNetworkSecurityGroup `
  -ResourceGroupName myRGNetwork `
  -Location EastUS `
  -Name myBackendNSG `
  -SecurityRules $nsgBackendRule
```

Add the network security groups to the subnets:

Azure PowerShell

```
$vnet = Get-AzVirtualNetwork `
  -ResourceGroupName myRGNetwork `
  -Name myVNet
$frontendSubnet = $vnet.Subnets[0]
$backendSubnet = $vnet.Subnets[1]
$frontendSubnetConfig = Set-AzVirtualNetworkSubnetConfig `
  -VirtualNetwork $vnet `
  -Name myFrontendSubnet `
  -AddressPrefix $frontendSubnet.AddressPrefix `
  -NetworkSecurityGroup $nsgFrontend
$backendSubnetConfig = Set-AzVirtualNetworkSubnetConfig `
  -VirtualNetwork $vnet `
  -Name myBackendSubnet `
  -AddressPrefix $backendSubnet.AddressPrefix `
  -NetworkSecurityGroup $nsgBackend
Set-AzVirtualNetwork -VirtualNetwork $vnet
```

Create a back-end VM

The easiest way to create the back-end VM for this tutorial is by using a SQL Server image. This tutorial only creates the VM with the database server, but doesn't provide information about accessing the database.

Create *myBackendNic*:

Azure PowerShell

```
$backendNic = New-AzNetworkInterface `
  -ResourceGroupName myRGNetwork `
  -Location EastUS `
  -Name myBackend `
  -SubnetId $vnet.Subnets[1].Id
```

Set the username and password needed for the administrator account on the VM with Get-Credential:

Azure PowerShell

```
$cred = Get-Credential
```

Create *myBackendVM*.

Azure PowerShell

```
New-AzVM `
   -Credential $cred `
   -Name myBackend `
   -ImageName "MicrosoftSQLServer:SQL2016SP1-WS2016:Enterprise:latest" `
   -ResourceGroupName myRGNetwork `
   -Location "EastUS" `
   -SubnetName MyBackendSubnet `
   -VirtualNetworkName myVNet
```

The image in this example has SQL Server installed, but it isn't used in this tutorial. It's included to show you how you can configure a VM to handle web traffic and a VM to handle database management.

Next steps

In this tutorial, you created and secured Azure networks as related to virtual machines.

- ✓ Create a virtual network and subnet

- ✓ Create a public IP address
- ✓ Create a front-end VM
- ✓ Secure network traffic
- ✓ Create a back-end VM

To learn about protecting your VM disks, see Backup and disaster recovery for disks.

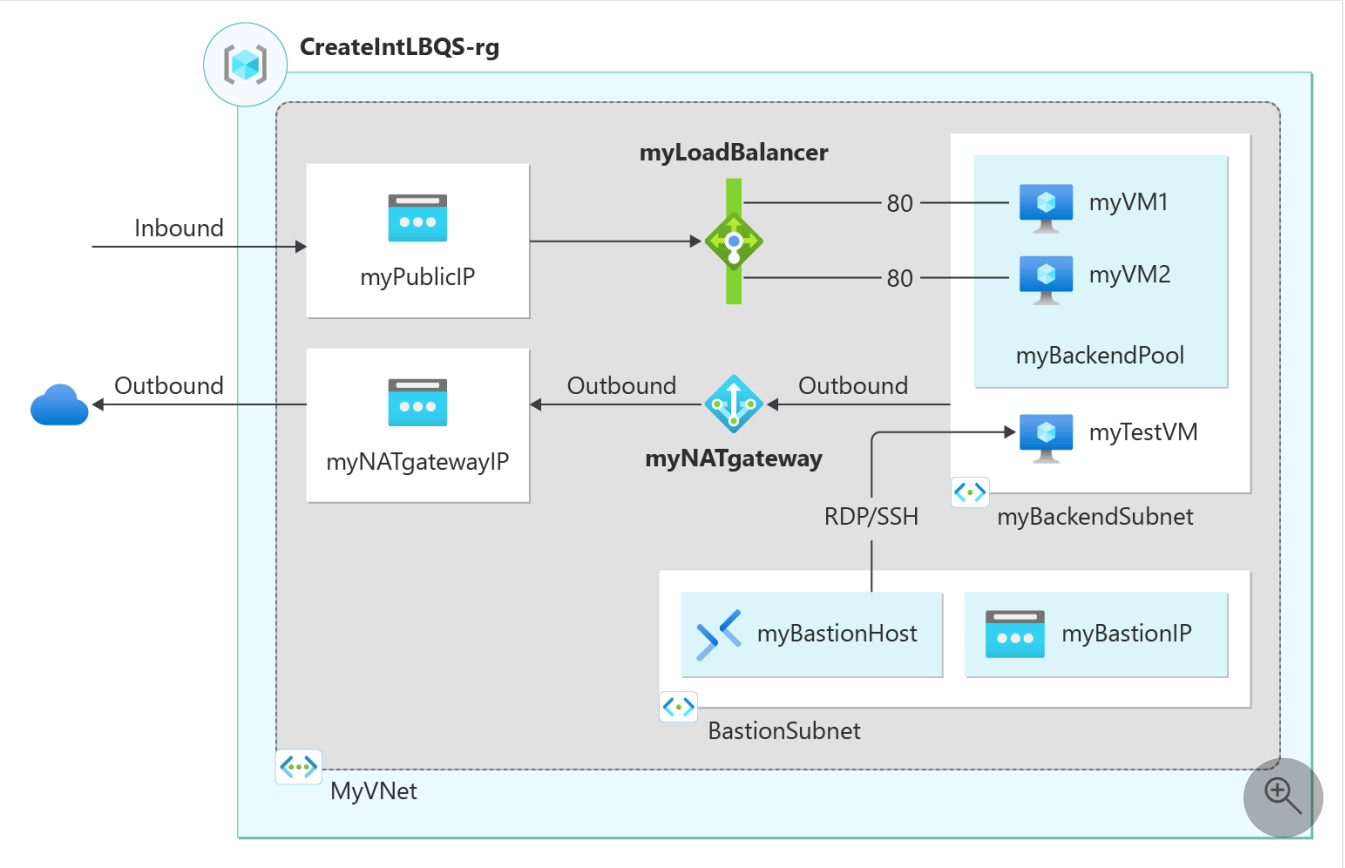
Quickstart: Create a public load balancer to load balance VMs using Azure PowerShell

Get started with Azure Load Balancer by using Azure PowerShell to create a public load balancer and two virtual machines. Also, you deploy other resources including Azure Bastion, NAT Gateway, a virtual network, and the required subnets.



Prerequisites

- An Azure account with an active subscription. Create an account for free
- Azure PowerShell installed locally or Azure Cloud Shell

If you choose to install and use PowerShell locally, this article requires the Azure PowerShell module version 5.4.1 or later. Run `Get-Module -ListAvailable Az` to find the installed version. If you need to upgrade, see Install Azure PowerShell module. If you're running PowerShell locally, you also need to run `Connect-AzAccount` to create a connection with Azure.

Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with New-AzResourceGroup:

Azure PowerShell

```
$rg = @{
    Name = 'CreatePubLBQS-rg'
    Location = 'westus2'
}
New-AzResourceGroup @rg
```

Create a public IP address

Use New-AzPublicIpAddress to create a public IP address.

Azure PowerShell

```
$publicip = @{
    Name = 'myPublicIP'
    ResourceGroupName = $rg.name
    Location = 'westus2'
    Sku = 'Standard'
    AllocationMethod = 'static'
    Zone = 1,2,3
}
New-AzPublicIpAddress @publicip
```

To create a zonal public IP address in zone 1, use the following command:

Azure PowerShell

```
$publicip = @{
    Name = 'myPublicIP'
    ResourceGroupName = $rg.name
    Location = 'westus2'
    Sku = 'Standard'
    AllocationMethod = 'static'
    Zone = 1
}
New-AzPublicIpAddress @publicip
```

Create a load balancer

This section details how you can create and configure the following components of the load balancer:

- Create a frontend IP with New-AzLoadBalancerFrontendIpConfig for the frontend IP pool. This IP receives the incoming traffic on the load balancer

- Create a backend address pool with New-AzLoadBalancerBackendAddressPoolConfig for traffic sent from the frontend of the load balancer. This pool is where your backend virtual machines are deployed
- Create a health probe with Add-AzLoadBalancerProbeConfig that determines the health of the backend VM instances
- Create a load balancer rule with Add-AzLoadBalancerRuleConfig that defines how traffic is distributed to the VMs
- Create a public load balancer with New-AzLoadBalancer

Azure PowerShell

```
## Place public IP created in previous steps into variable. ##
$pip = @{
    Name = 'myPublicIP'
    ResourceGroupName = $rg.name
}
$publicIp = Get-AzPublicIpAddress @pip

## Create load balancer frontend configuration and place in variable. ##
$fip = @{
    Name = 'myFrontEnd'
    PublicIpAddress = $publicIp
}
$feip = New-AzLoadBalancerFrontendIpConfig @fip

## Create backend address pool configuration and place in variable. ##
$bepool = New-AzLoadBalancerBackendAddressPoolConfig -Name 'myBackEndPool'

## Create the health probe and place in variable. ##
$probe = @{
    Name = 'myHealthProbe'
    Protocol = 'tcp'
    Port = '80'
    IntervalInSeconds = '360'
    ProbeCount = '5'
}
$healthprobe = New-AzLoadBalancerProbeConfig @probe

## Create the load balancer rule and place in variable. ##
$lbrule = @{
    Name = 'myHTTPRule'
    Protocol = 'tcp'
    FrontendPort = '80'
    BackendPort = '80'
    IdleTimeoutInMinutes = '15'
    FrontendIpConfiguration = $feip
    BackendAddressPool = $bePool
}
$rule = New-AzLoadBalancerRuleConfig @lbrule -EnableTcpReset -DisableOutboundSNAT
```

```
## Create the load balancer resource. ##
$loadbalancer = @{
    ResourceGroupName = $rg.name
    Name = 'myLoadBalancer'
    Location = 'westus2'
    Sku = 'Standard'
    FrontendIpConfiguration = $feip
    BackendAddressPool = $bePool
    LoadBalancingRule = $rule
    Probe = $healthprobe
}
New-AzLoadBalancer @loadbalancer
```

Configure virtual network

Before you deploy VMs and test your load balancer, create the supporting virtual network resources.

Create a virtual network for the backend virtual machines.

Create a network security group to define inbound connections to your virtual network.

Create an Azure Bastion host to securely manage the virtual machines in the backend pool.

Use a NAT gateway to provide outbound internet access to resources in the backend pool of your load balancer.

Create virtual network, network security group, bastion host, and NAT gateway

- Create a virtual network with New-AzVirtualNetwork
- Create a network security group rule with New-AzNetworkSecurityRuleConfig
- Create an Azure Bastion host with New-AzBastion
- Create a network security group with New-AzNetworkSecurityGroup
- Create the NAT gateway resource with New-AzNatGateway
- Use New-AzVirtualNetworkSubnetConfig to associate the NAT gateway to the subnet of the virtual network

> **Important**

Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

Azure PowerShell

```
## Create public IP address for NAT gateway ##
$ip = @{
    Name = 'myNATgatewayIP'
    ResourceGroupName = $rg.name
    Location = 'westus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
}
$publicIP = New-AzPublicIpAddress @ip

## Create NAT gateway resource ##
$nat = @{
    ResourceGroupName = $rg.name
    Name = 'myNATgateway'
    IdleTimeoutInMinutes = '10'
    Sku = 'Standard'
    Location = 'westus2'
    PublicIpAddress = $publicIP
}
$natGateway = New-AzNatGateway @nat

## Create backend subnet config ##
$subnet = @{
    Name = 'myBackendSubnet'
    AddressPrefix = '10.1.0.0/24'
    NatGateway = $natGateway
}
$subnetConfig = New-AzVirtualNetworkSubnetConfig @subnet

## Create Azure Bastion subnet. ##
$bastsubnet = @{
    Name = 'AzureBastionSubnet'
    AddressPrefix = '10.1.1.0/24'
}
$bastsubnetConfig = New-AzVirtualNetworkSubnetConfig @bastsubnet

## Create the virtual network ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = $rg.name
    Location = 'westus2'
    AddressPrefix = '10.1.0.0/16'
    Subnet = $subnetConfig,$bastsubnetConfig
}
$vnet = New-AzVirtualNetwork @net
```

```
## Create public IP address for bastion host. ##
$ip = @{
    Name = 'myBastionIP'
    ResourceGroupName = $rg.name
    Location = 'westus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
}
$publicip = New-AzPublicIpAddress @ip

## Create bastion host ##
$bastion = @{
    ResourceGroupName = $rg.name
    Name = 'myBastion'
    PublicIpAddress = $publicip
    VirtualNetwork = $vnet
}
New-AzBastion @bastion -AsJob

## Create rule for network security group and place in variable. ##
$nsgrule = @{
    Name = 'myNSGRuleHTTP'
    Description = 'Allow HTTP'
    Protocol = '*'
    SourcePortRange = '*'
    DestinationPortRange = '80'
    SourceAddressPrefix = 'Internet'
    DestinationAddressPrefix = '*'
    Access = 'Allow'
    Priority = '2000'
    Direction = 'Inbound'
}
$rule1 = New-AzNetworkSecurityRuleConfig @nsgrule

## Create network security group ##
$nsg = @{
    Name = 'myNSG'
    ResourceGroupName = $rg.name
    Location = 'westus2'
    SecurityRules = $rule1
}
New-AzNetworkSecurityGroup @nsg
```

Create virtual machines

In this section, you create the two virtual machines for the backend pool of the load balancer.

- Create two network interfaces with New-AzNetworkInterface
- Set an administrator username and password for the VMs with Get-Credential

- Create the virtual machines with:
  - New-AzVM
  - New-AzVMConfig
  - Set-AzVMOperatingSystem
  - Set-AzVMSourceImage
  - Add-AzVMNetworkInterface

Azure PowerShell

```
# Set the administrator and password for the VMs. ##
$cred = Get-Credential

## Place the virtual network into a variable. ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = $rg.name
}
$vnet = Get-AzVirtualNetwork @net

## Place the load balancer into a variable. ##
$lb = @{
    Name = 'myLoadBalancer'
    ResourceGroupName = $rg.name
}
$bepool = Get-AzLoadBalancer @lb  | Get-AzLoadBalancerBackendAddressPoolConfig

## Place the network security group into a variable. ##
$ns = @{
    Name = 'myNSG'
    ResourceGroupName = $rg.name
}
$nsg = Get-AzNetworkSecurityGroup @ns

## For loop with variable to create virtual machines for load balancer backend pool.
##
for ($i=1; $i -le 2; $i++){

    ## Command to create network interface for VMs ##
    $nic = @{
        Name = "myNicVM$i"
        ResourceGroupName = $rg.name
        Location = 'westus2'
        Subnet = $vnet.Subnets[0]
        NetworkSecurityGroup = $nsg
        LoadBalancerBackendAddressPool = $bepool
    }
    $nicVM = New-AzNetworkInterface @nic
```

```
    ## Create a virtual machine configuration for VMs ##
    $vmsz = @{
        VMName = "myVM$i"
        VMSize = 'Standard_DS1_v2'
    }
    $vmos = @{
        ComputerName = "myVM$i"
        Credential = $cred
    }
    $vmimage = @{
        PublisherName = 'MicrosoftWindowsServer'
        Offer = 'WindowsServer'
        Skus = '2019-Datacenter'
        Version = 'latest'
    }
    $vmConfig = New-AzVMConfig @vmsz `
        | Set-AzVMOperatingSystem @vmos -Windows `
        | Set-AzVMSourceImage @vmimage `
        | Add-AzVMNetworkInterface -Id $nicVM.Id

    ## Create the virtual machine for VMs ##
    $vm = @{
        ResourceGroupName = $rg.name
        Location = 'westus2'
        VM = $vmConfig
        Zone = "$i"
    }
    New-AzVM @vm -AsJob
}
```

The deployments of the virtual machines and bastion host are submitted as PowerShell jobs. To view the status of the jobs, use Get-Job:

Azure PowerShell

```
Get-Job

Id     Name            PSJobTypeName   State         HasMoreData     Location
Command
--     ----            -------------   -----         -----------     --------
-------
1      Long Running O… AzureLongRunni… Completed     True            localhost
New-AzBastion
2      Long Running O… AzureLongRunni… Completed     True            localhost
New-AzVM
3      Long Running O… AzureLongRunni… Completed     True            localhost
New-AzVM
```

Ensure the **State** of the VM creation is **Completed** before moving on to the next steps.

> ⓘ Note

Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.

The default outbound access IP is disabled when one of the following events happens:

- A public IP address is assigned to the VM.
- The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
- An Azure NAT Gateway resource is assigned to the subnet of the VM.

VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.

For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Install IIS

Use Set-AzVMExtension to install the Custom Script Extension.

The extension runs `PowerShell Add-WindowsFeature Web-Server` to install the IIS webserver and then updates the Default.htm page to show the hostname of the VM:

ⓘ Important

Ensure the virtual machine deployments have completed from the previous steps before proceeding. Use `Get-Job` to check the status of the virtual machine deployment jobs.

Azure PowerShell

```
## For loop with variable to install custom script extension on virtual machines. ##
for ($i=1; $i -le 2; $i++)
{
$ext = @{
    Publisher = 'Microsoft.Compute'
    ExtensionType = 'CustomScriptExtension'
    ExtensionName = 'IIS'
    ResourceGroupName = $rg.name
    VMName = "myVM$i"
    Location = 'westus2'
    TypeHandlerVersion = '1.8'
    SettingString = '{"commandToExecute":"powershell Add-WindowsFeature Web-Server;
```

```
powershell Add-Content -Path \"C:\\inetpub\\wwwroot\\Default.htm\" -Value
$($env:computername)"}'
}
Set-AzVMExtension @ext -AsJob
}
```

The extensions are deployed as PowerShell jobs. To view the status of the installation jobs, use Get-Job:

Azure PowerShell

```
Get-Job

Id     Name            PSJobTypeName   State         HasMoreData     Location
Command
--     ----            -------------   -----         -----------     --------
-------
8      Long Running O… AzureLongRunni… Running       True            localhost
Set-AzVMExtension
9      Long Running O… AzureLongRunni… Running       True            localhost
Set-AzVMExtension
```

Ensure the **State** of the jobs is **Completed** before moving on to the next steps.

Test the load balancer

Use Get-AzPublicIpAddress to get the public IP address of the load balancer:

Azure PowerShell

```
$ip = @{
    ResourceGroupName = $rg.name
    Name = 'myPublicIP'
}
Get-AzPublicIPAddress @ip | select IpAddress
```

Copy the public IP address, and then paste it into the address bar of your browser. The default page of IIS Web server is displayed on the browser.

Clean up resources

When no longer needed, you can use the Remove-AzResourceGroup command to remove the resource group, load balancer, and the remaining resources.

Azure PowerShell

```
Remove-AzResourceGroup -Name $rg.name
```

Next steps

In this quickstart, you:

- Created an Azure Load Balancer
- Attached two VMs to the load balancer
- Tested the load balancer

To learn more about Azure Load Balancer, continue to:

What is Azure Load Balancer?

Tutorial: Create and manage a Virtual Machine Scale Set with Azure PowerShell

Article • 08/22/2024

A Virtual Machine Scale Set allows you to deploy and manage a set of virtual machines. Throughout the lifecycle of a Virtual Machine Scale Set, you may need to run one or more management tasks. In this tutorial you learn how to:

- ✓ Create a resource group
- ✓ Create a Virtual Machine Scale Set
- ✓ Scale out and in
- ✓ Stop, Start and restart VM instances

If you don't have an Azure subscription, create a free account before you begin.

Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

Expand table

Option	Example/Link
Select **Try It** in the upper-right corner of a code or command block. Selecting **Try It** doesn't automatically copy the code or command to Cloud Shell.	
Go to https://shell.azure.com, or select the **Launch Cloud Shell** button to open Cloud Shell in your browser.	
Select the **Cloud Shell** button on the menu bar at the upper right in the Azure portal.	

To use Azure Cloud Shell:

1. Start Cloud Shell.

2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl**+**Shift**+**V** on Windows and Linux, or by selecting **Cmd**+**Shift**+**V** on macOS.
4. Select **Enter** to run the code or command.

Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed. A resource group must be created before a Virtual Machine Scale Set. Create a resource group with the New-AzResourceGroup command. In this example, a resource group named *myResourceGroup* is created in the *EastUS* region.

Azure PowerShell

```
New-AzResourceGroup -ResourceGroupName "myResourceGroup" -Location "EastUS"
```

The resource group name is specified when you create or modify a scale set throughout this tutorial.

Create a Virtual Machine Scale Set

First, set an administrator username and password for the VM instances with Get-Credential:

Azure PowerShell

```
$cred = Get-Credential
```

Now create a Virtual Machine Scale Set with New-AzVmss. To distribute traffic to the individual VM instances, a load balancer is also created. The load balancer includes rules to distribute traffic on TCP port 80, and allow remote desktop traffic on TCP port 3389 and PowerShell remoting on TCP port 5985:

> **ⓘ Important**
>
> Starting November 2023, VM scale sets created using PowerShell and Azure CLI will default to Flexible Orchestration Mode if no orchestration mode is specified. For more information about this change and what actions you should take, go to

[Breaking Change for VMSS PowerShell/CLI Customers - Microsoft Community Hub](#)

Azure PowerShell

```
New-AzVmss `
  -ResourceGroupName "myResourceGroup" `
  -VMScaleSetName "myScaleSet" `
  -OrchestrationMode "Flexible" `
  -Location "EastUS" `
  -Credential $cred
```

It takes a few minutes to create and configure all the scale set resources and VM instances. To distribute traffic to the individual VM instances, a load balancer is also created.

View the VM instances in a scale set

To view a list of VM instances in a scale set, use Get-AzVM as follows:

Azure PowerShell

```
Get-AzVM -ResourceGroupName "myResourceGroup"
```

The following example output shows two VM instances in the scale set:

Output

```
ResourceGroupName                Name Location          VmSize  OsType
ProvisioningState
-----------------                ---- --------          ------  ------
-----------------
myResourceGroup   myScaleSet_instance1   eastus Standard_DS1_v2 Windows
Succeeded
myResourceGroup   myScaleSet_instance2   eastus Standard_DS1_v2 Windows
Succeeded
```

To view additional information about a specific VM instance, use Get-AzVM and specify the VM name.

Azure PowerShell

```
Get-AzVM -ResourceGroupName "myResourceGroup" -name "myScaleSet_instance1"
```

Output

```
ResourceGroupName      : myresourcegroup
Id                     :
/subscriptions/resourceGroups/myresourcegroup/providers/Microsoft.Compute/vi
rtualMachines/myScaleSet_instance1
VmId                   : d27b5fde-d469-4087-b08f-87d0bd8df786
Name                   : myScaleSet_instance1
Type                   : Microsoft.Compute/virtualMachines
Location               : eastus
Tags                   : {}
HardwareProfile        : {VmSize}
NetworkProfile         : {NetworkInterfaces}
OSProfile              : {ComputerName, AdminUsername, WindowsConfiguration,
Secrets, AllowExtensionOperations, RequireGuestProvisionSignal}
ProvisioningState      : Succeeded
StorageProfile         : {ImageReference, OsDisk, DataDisks}
VirtualMachineScaleSet : {Id}
TimeCreated            : 11/16/2022 11:02:02 PM
```

Create a scale set with a specific VM instance size

When you created a scale set at the start of the tutorial, a default VM SKU of *Standard_D1_v2* was provided for the VM instances. You can specify a different VM instance size with the `-VMSize` parameter to specify a VM instance size of *Standard_F1*.

Azure PowerShell

```
New-AzVmss `
  -ResourceGroupName "myResourceGroup" `
  -VMScaleSetName "myScaleSet" `
  -OrchestrationMode "Flexible" `
  -VMSize "Standard_F1" `
  -Location "EastUS" `
  -Credential $cred
```

Change the capacity of a scale set

When you created a scale set, two VM instances were deployed by default. To increase or decrease the number of VM instances in the scale set, you can manually change the capacity. The scale set creates or removes the required number of VM instances, then configures the load balancer to distribute traffic.

First, create a scale set object with Get-AzVmss, then specify a new value for `sku.capacity`. To apply the capacity change, use Update-AzVmss. The following example sets the number of VM instances in your scale set to *3*:

Azure PowerShell

```
# Get current scale set
$vmss = Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName
"myScaleSet"

# Set and update the capacity of your scale set
$vmss.sku.capacity = 3
Update-AzVmss -ResourceGroupName "myResourceGroup" -Name "myScaleSet" -
VirtualMachineScaleSet $vmss
```

It takes a few minutes to update the capacity of your scale set. To see the number of instances you now have in the scale set, use Get-Az:

Azure PowerShell

```
Get-AzVm -ResourceGroupName "myResourceGroup"
```

The following example output shows that the capacity of the scale set is now *3*:

Output

```
ResourceGroupName                Name Location          VmSize  OsType
ProvisioningState
-----------------                ---- --------          ------  ------    --
---------------
myResourceGroup   myScaleSet_instance1   eastus Standard_DS1_v2 Windows
Succeeded
myResourceGroup   myScaleSet_instance2   eastus Standard_DS1_v2 Windows
Succeeded
myResourceGroup   myScaleSet_instance3   eastus Standard_DS1_v2 Windows
Succeeded
```

Stop and deallocate VM instances in a scale set

To stop individual VM instances, use Stop-AzVm and specify the instance names.

Azure PowerShell

```
Stop-AzVM -ResourceGroupName "myResourceGroup" -name "myScaleSet_instance1"
```

By default, stopped VMs are deallocated and don't incur compute charges. If you wish the VM to remain in a provisioned state when stopped, add the `-StayProvisioned` parameter to the preceding command. Stopped VMs that remain provisioned incur regular compute charges.

Start VM instances in a scale set

To start all the VM instances in a scale set, use Start-AzVmss.

Azure PowerShell

```
Start-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName
"myScaleSet"
```

To start an individual VM instance in a scale set, use Start-AzVM and specify the instance name.

Azure PowerShell

```
Start-AzVM -ResourceGroupName "myResourceGroup" -name "myScaleSet_instance1"
```

Restart VM instances in a scale set

To restart all the VMs in a scale set, use Restart-AzVmss.

Azure PowerShell

```
Restart-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName
"myScaleSet"
```

To restart an individual instance, use [Restart-AzVM] and specify the instance name.

Azure PowerShell

```
Restart-AzVM -ResourceGroupName "myResourceGroup" -name
"myScaleSet_instance1"
```

Clean up resources

When you delete a resource group, all resources contained within, such as the VM instances, virtual network, and disks, are also deleted. The `-Force` parameter confirms

that you wish to delete the resources without an extra prompt to do so. The `-AsJob` parameter returns control to the prompt without waiting for the operation to complete.

Azure PowerShell

```
Remove-AzResourceGroup -Name "myResourceGroup" -Force -AsJob
```

Next steps

In this tutorial, you learned how to perform some basic scale set creation and management tasks with Azure PowerShell:

- ✓ Create a resource group
- ✓ Create a scale set
- ✓ View and use specific VM sizes
- ✓ Manually scale a scale set
- ✓ Perform common scale set management tasks such as stopping, starting and restarting your scale set

Advance to the next tutorial to learn how to connect to your scale set instances.

Use data disks with scale sets

Virtual Machines

Service: Compute

API Version: 2025-11-01

Operations

Expand table

Assess Patches	Assess patches on the VM.
Attach Detach Data Disks	Attach and detach data disks to/from the virtual machine.
Capture	Captures the VM by copying virtual hard disks of the VM and outputs a template that can be used to create similar VMs.
Convert To Managed Disks	Converts virtual machine disks from blob-based to managed disks. Virtual machine must be stop-deallocated before invoking this operation.
Create Or Update	The operation to create or update a virtual machine. Please note some properties can be set only during virtual machine creation.
Deallocate	Shuts down the virtual machine and releases the compute resources. You are not billed for the compute resources that this virtual machine uses.
Delete	The operation to delete a virtual machine.
Generalize	Sets the OS state of the virtual machine to generalized. It is recommended to sysprep the virtual machine before performing this operation. For Windows, please ...
Get	Retrieves information about the model view or the instance view of a virtual machine.
Install Patches	Installs patches on the VM.
Instance View	Retrieves information about the run-time state of a virtual machine.
List	Lists all of the virtual machines in the specified resource group. Use the nextLink property in the response to get the next page of virtual machines.
List All	Lists all of the virtual machines in the specified subscription. Use the nextLink property in the response to get the next page of virtual machines.
List Available Sizes	Lists all available virtual machine sizes to which the specified virtual machine can be resized.
List By Location	Gets all the virtual machines under the specified subscription for the specified

	location.
migrate To VM Scale Set	Migrate a virtual machine from availability set to Flexible Virtual Machine Scale Set.
Perform Maintenance	The operation to perform maintenance on a virtual machine.
Power Off	The operation to power off (stop) a virtual machine. The virtual machine can be restarted with the same provisioned resources. You are still charged for this vi...
Reapply	The operation to reapply a virtual machine's state.
Redeploy	Shuts down the virtual machine, moves it to a new node, and powers it back on.
Reimage	Reimages (upgrade the operating system) a virtual machine which don't have a ephemeral OS disk, for virtual machines who have a ephemeral OS disk the virtual ma...
Restart	The operation to restart a virtual machine.
Retrieve Boot Diagnostics Data	The operation to retrieve SAS URIs for a virtual machine's boot diagnostic logs.
Run Command	Run command on the VM.
Simulate Eviction	The operation to simulate the eviction of spot virtual machine.
Start	The operation to start a virtual machine.
Update	The operation to update a virtual machine.

Create and manage Windows VMs in Azure using Java

Article • 08/22/2024

Applies to: ✔ Windows VMs

An Azure Virtual Machine (VM) needs several supporting Azure resources. This article covers creating, managing, and deleting VM resources using Java. You learn how to:

- ✔ Create a Maven project
- ✔ Add dependencies
- ✔ Create credentials
- ✔ Create resources
- ✔ Perform management tasks
- ✔ Delete resources
- ✔ Run the application

It takes about 20 minutes to do these steps.

Create a Maven project

1. If you haven't already done so, install Java.
2. Install Maven.
3. Create a new folder and the project:

```
mkdir java-azure-test
cd java-azure-test

mvn archetype:generate -DgroupId=com.fabrikam -DartifactId=testAzureApp
-DarchetypeArtifactId=maven-archetype-quickstart -
DinteractiveMode=false
```

Add dependencies

1. Under the `testAzureApp` folder, open the `pom.xml` file and add the build configuration to <project> to enable the building of your application:

XML

```xml
<build>
  <plugins>
    <plugin>
        <groupId>org.codehaus.mojo</groupId>
        <artifactId>exec-maven-plugin</artifactId>
        <configuration>
            <mainClass>com.fabrikam.testAzureApp.App</mainClass>
        </configuration>
    </plugin>
  </plugins>
</build>
```

2. Add the dependencies that are needed to access the Azure Java SDK.

XML

```xml
<dependency>
  <groupId>com.azure</groupId>
  <artifactId>azure-identity</artifactId>
  <version>1.3.6</version>
</dependency>
<dependency>
  <groupId>com.azure.resourcemanager</groupId>
  <artifactId>azure-resourcemanager</artifactId>
  <version>2.8.0</version>
</dependency>
```

3. Save the file.

Set up authentication

Learn how to set up authentication.

Create the management client

1. Open the `App.java` file under `src\main\java\com\fabrikam` and make sure this package statement is at the top:

Java

```java
package com.fabrikam.testAzureApp;
```

2. Create AzureResourceManager:

Java

```
TokenCredential credential = new EnvironmentCredentialBuilder()
            .authorityHost(AzureAuthorityHosts.AZURE_PUBLIC_CLOUD)
            .build();

// Please finish 'Set up authentication' step first to set the four
environment variables: AZURE_SUBSCRIPTION_ID, AZURE_CLIENT_ID,
AZURE_CLIENT_SECRET, AZURE_TENANT_ID
AzureProfile profile = new AzureProfile(AzureEnvironment.AZURE);

AzureResourceManager azureResourceManager =
AzureResourceManager.configure()
        .withLogLevel(HttpLogDetailLevel.BASIC)
        .authenticate(credential, profile)
        .withDefaultSubscription();
```

Create resources

Create the resource group

All resources must be contained in a Resource group.

To specify values for the application and create the resource group, add this code to the try block in the main method:

Java

```
System.out.println("Creating resource group...");
ResourceGroup resourceGroup = azure.resourceGroups()
    .define("myResourceGroup")
    .withRegion(Region.US_EAST)
    .create();
```

Create the availability set

Availability sets make it easier for you to maintain the virtual machines used by your application.

To create the availability set, add this code to the try block in the main method:

Java

```
System.out.println("Creating availability set...");
AvailabilitySet availabilitySet = azure.availabilitySets()
    .define("myAvailabilitySet")
```

```
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")
    .create();
```

Create the public IP address

A Public IP address is needed to communicate with the virtual machine.

To create the public IP address for the virtual machine, add this code to the try block in the main method:

Java

```
System.out.println("Creating public IP address...");
PublicIpAddress publicIPAddress = azure.publicIpAddresses()
    .define("myPublicIP")
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")
    .withDynamicIP()
    .create();
```

Create the virtual network

A virtual machine must be in a subnet of a Virtual network.

To create a subnet and a virtual network, add this code to the try block in the main method:

Java

```
System.out.println("Creating virtual network...");
Network network = azure.networks()
    .define("myVN")
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")
    .withAddressSpace("10.0.0.0/16")
    .withSubnet("mySubnet", "10.0.0.0/24")
    .create();
```

Create the network interface

A virtual machine needs a network interface to communicate on the virtual network.

To create a network interface, add this code to the try block in the main method:

```
```

Java

```
System.out.println("Creating network interface...");
NetworkInterface networkInterface = azure.networkInterfaces()
    .define("myNIC")
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")
    .withExistingPrimaryNetwork(network)
    .withSubnet("mySubnet")
    .withPrimaryPrivateIPAddressDynamic()
    .withExistingPrimaryPublicIPAddress(publicIPAddress)
    .create();
```

Create the virtual machine

Now that you created all the supporting resources, you can create a virtual machine.

To create the virtual machine, add this code to the try block in the main method:

Java

```
System.out.println("Creating virtual machine...");
VirtualMachine virtualMachine = azure.virtualMachines()
    .define("myVM")
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")
    .withExistingPrimaryNetworkInterface(networkInterface)
    .withLatestWindowsImage("MicrosoftWindowsServer", "WindowsServer",
"2012-R2-Datacenter")
    .withAdminUsername("azureuser")
    .withAdminPassword("Azure12345678")
    .withComputerName("myVM")
    .withExistingAvailabilitySet(availabilitySet)
    .withSize("Standard_DS1")
    .create();
Scanner input = new Scanner(System.in);
System.out.println("Press enter to get information about the VM...");
input.nextLine();
```

> ⓘ **Note**
>
> This tutorial creates a virtual machine running a version of the Windows Server operating system. To learn more about selecting other images, see Navigate and select Azure virtual machine images with Windows PowerShell and the Azure CLI.

If you want to use an existing disk instead of a marketplace image, use this code:

Java

```
Disk managedDisk = azure.disks().define("myosdisk")
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")

.withWindowsFromVhd("https://mystorage.blob.core.windows.net/vhds/myosdisk.v
hd")
    .withStorageAccountName("mystorage")
    .withSizeInGB(128)
    .withSku(DiskSkuTypes.PREMIUM_LRS)
    .create();

azure.virtualMachines().define("myVM")
    .withRegion(Region.US_EAST)
    .withExistingResourceGroup("myResourceGroup")
    .withExistingPrimaryNetworkInterface(networkInterface)
    .withSpecializedOSDisk(managedDisk, OperatingSystemTypes.WINDOWS)
    .withExistingAvailabilitySet(availabilitySet)
    .withSize(VirtualMachineSizeTypes.STANDARD_DS1)
    .create();
```

Perform management tasks

During the lifecycle of a virtual machine, you may want to run management tasks such as starting, stopping, or deleting a virtual machine. Additionally, you may want to create code to automate repetitive or complex tasks.

When you need to do anything with the VM, you need to get an instance of it. Add this code to the try block of the main method:

Java

```
VirtualMachine vm =
azure.virtualMachines().getByResourceGroup("myResourceGroup", "myVM");
```

Get information about the VM

To get information about the virtual machine, add this code to the try block in the main method:

Java

```
System.out.println("hardwareProfile");
System.out.println("    vmSize: " + vm.size());
System.out.println("storageProfile");
System.out.println("  imageReference");
```

```
System.out.println("    publisher: " +
vm.storageProfile().imageReference().publisher());
System.out.println("    offer: " +
vm.storageProfile().imageReference().offer());
System.out.println("    sku: " +
vm.storageProfile().imageReference().sku());
System.out.println("    version: " +
vm.storageProfile().imageReference().version());
System.out.println("  osDisk");
System.out.println("    osType: " + vm.storageProfile().osDisk().osType());
System.out.println("    name: " + vm.storageProfile().osDisk().name());
System.out.println("    createOption: " +
vm.storageProfile().osDisk().createOption());
System.out.println("    caching: " +
vm.storageProfile().osDisk().caching());
System.out.println("osProfile");
System.out.println("    computerName: " + vm.osProfile().computerName());
System.out.println("    adminUserName: " + vm.osProfile().adminUsername());
System.out.println("    provisionVMAgent: " +
vm.osProfile().windowsConfiguration().provisionVMAgent());
System.out.println(
        "    enableAutomaticUpdates: " +
vm.osProfile().windowsConfiguration().enableAutomaticUpdates());
System.out.println("networkProfile");
System.out.println("    networkInterface: " +
vm.primaryNetworkInterfaceId());
System.out.println("vmAgent");
System.out.println("  vmAgentVersion: " +
vm.instanceView().vmAgent().vmAgentVersion());
System.out.println("    statuses");
for (InstanceViewStatus status : vm.instanceView().vmAgent().statuses()) {
    System.out.println("    code: " + status.code());
    System.out.println("    displayStatus: " + status.displayStatus());
    System.out.println("    message: " + status.message());
    System.out.println("    time: " + status.time());
}
System.out.println("disks");
for (DiskInstanceView disk : vm.instanceView().disks()) {
    System.out.println("  name: " + disk.name());
    System.out.println("  statuses");
    for (InstanceViewStatus status : disk.statuses()) {
        System.out.println("    code: " + status.code());
        System.out.println("    displayStatus: " + status.displayStatus());
        System.out.println("    time: " + status.time());
    }
}
System.out.println("VM general status");
System.out.println("  provisioningStatus: " + vm.provisioningState());
System.out.println("  id: " + vm.id());
System.out.println("  name: " + vm.name());
System.out.println("  type: " + vm.type());
System.out.println("VM instance status");
for (InstanceViewStatus status : vm.instanceView().statuses()) {
    System.out.println("  code: " + status.code());
    System.out.println("  displayStatus: " + status.displayStatus());
```

```
}
System.out.println("Press enter to continue...");
input.nextLine();
```

Stop the VM

You can stop a virtual machine and keep all its settings, but continue to be charged for it, or you can stop a virtual machine and deallocate it. When a virtual machine is deallocated, all resources associated with it are also deallocated and billing ends for it.

To stop the virtual machine without deallocating it, add this code to the try block in the main method:

Java

```
System.out.println("Stopping vm...");
vm.powerOff();
System.out.println("Press enter to continue...");
input.nextLine();
```

If you want to deallocate the virtual machine, change the PowerOff call to this code:

Java

```
vm.deallocate();
```

Start the VM

To start the virtual machine, add this code to the try block in the main method:

Java

```
System.out.println("Starting vm...");
vm.start();
System.out.println("Press enter to continue...");
input.nextLine();
```

Resize the VM

Many aspects of deployment should be considered when deciding on a size for your virtual machine. For more information, see VM sizes.

To change size of the virtual machine, add this code to the try block in the main method:

Java

```
System.out.println("Resizing vm...");
vm.update()
    .withSize(VirtualMachineSizeTypes.STANDARD_DS2)
    .apply();
System.out.println("Press enter to continue...");
input.nextLine();
```

Add a data disk to the VM

To add a data disk to the virtual machine that is 2 GB in size, has a LUN of 0, and a caching type of ReadWrite, add this code to the try block in the main method:

Java

```
System.out.println("Adding data disk...");
vm.update()
    .withNewDataDisk(2, 0, CachingTypes.READ_WRITE)
    .apply();
System.out.println("Press enter to delete resources...");
input.nextLine();
```

Delete resources

Because you are charged for resources used in Azure, it is always good practice to delete resources that are no longer needed. If you want to delete the virtual machines and all the supporting resources, all you have to do is delete the resource group.

1. To delete the resource group, add this code to the try block in the main method:

   Java

   ```
   System.out.println("Deleting resources...");
   azure.resourceGroups().deleteByName("myResourceGroup");
   ```

2. Save the App.java file.

Run the application

It should take about five minutes for this console application to run completely from start to finish.

1. To run the application, use this Maven command:

```
mvn compile exec:java
```

2. Before you press **Enter** to start deleting resources, you could take a few minutes to verify the creation of the resources in the Azure portal. Click the deployment status to see information about the deployment.

ComputeManager.Configurable	The interface allowing configurations to be set.

Use the Azure SDK for Go for control plane operations

Learn how to provision, configure, and manage Azure resources programmatically by using the Azure SDK for Go management libraries. Common control-plane workflows include creating resource groups, managing storage and networking infrastructure, and handling virtual machine (VM) lifecycle operations such as create, start, stop, resize, update, and delete. If you want the higher-level introduction to how management libraries fit into the Azure SDK for Go, start with Overview of the Azure SDK for Go management libraries. This article focuses on the Go control-plane patterns you reuse across services, and links to data plane guidance when the runtime path moves from resource management to working with service data.

What is the Azure control plane?

The Azure control plane is the set of APIs that control the lifecycle of Azure resources - creating, updating, configuring, and deleting them. Every operation you perform in the Azure portal, Azure CLI, or infrastructure-as-code tool ultimately calls these control plane APIs.

The Azure SDK for Go exposes the control plane through a family of `arm*` packages under `github.com/Azure/azure-sdk-for-go/sdk/resourcemanager/`. Each package maps to an Azure resource provider and follows a consistent pattern:

1. Authenticate by using the `azidentity` package.
2. Create a typed client for the resource you want to manage.
3. Call methods on the client to create, read, update, or delete resources.
4. Handle long-running operations by using pollers.

Common scenarios for Go control plane automation include:

- Provisioning infrastructure for deployment pipelines
- Managing VM lifecycle operations such as create, update, delete, start, stop, and resize
- Building custom CLIs and operators for platform teams
- Implementing GitOps-style infrastructure reconciliation
- Automating compliance auditing and drift detection

Authentication

All management operations require an authenticated credential from the azidentity package. The package provides credential types for every environment including local development, CI/CD pipelines, and production workloads running in Azure. All credential types implement the same `azcore.TokenCredential` interface, so you can swap them without changing client code.

After you get a credential, create a client factory for the package and then ask it for the typed client you need:

Go

```go
// Create credential that auto-discovers authentication (Azure CLI, env vars,
managed identity)
cred, err := azidentity.NewDefaultAzureCredential(nil)

// Construct a client factory, then the typed client for management operations
clientFactory, err := armresources.NewClientFactory(subscriptionID, cred, nil)
rgClient := clientFactory.NewResourceGroupsClient()
```

Current `arm*` package docs usually show the client factory pattern because it centralizes shared configuration for related clients. Many packages also expose direct `New<ResourceType>Client(subscriptionID, credential, options)` constructors, but `NewClientFactory(...).New<ResourceType>Client()` is the pattern you'll most often see on pkg.go.dev. For local development, `DefaultAzureCredential` usually picks up your Azure CLI sign-in. In CI/CD and deployed workloads, you can switch to environment-based credentials or managed identity without changing the rest of your client code.

For a full guide on credential types and best practices, see Authentication with the Azure SDK for Go and the azidentity package documentation.

Client packages and typed clients

Management packages are under `github.com/Azure/azure-sdk-for-go/sdk/resourcemanager/<service>/arm<service>`. Install the identity package and only the `arm*` packages you plan to use. For example, if you're only managing VMs and resource groups, you only need `armcompute` and `armresources`. Each package contains clients for the resources in that service. For example, `armcompute` has clients for virtual machines, disks, images, and related compute resources.

A single management package often contains several clients, with each client focused on one resource type or operation group. For example, `armcompute` includes clients for virtual

machines, disks, images, and related resources. After you choose the package for a service, create one client factory and reuse it to create the typed clients that match the resources you want to manage.

Go

```go
clientFactory, err := armcompute.NewClientFactory(subscriptionID, cred, nil)
if err != nil {
    return err
}
vmClient := clientFactory.NewVirtualMachinesClient()
```

This package and client factory pattern is consistent across the `resourcemanager` modules. It's a useful shortcut when you're scanning pkg.go.dev or asking an agent to find the right client for a task.

Long-running operations

Many management operations, such as creating clusters, deleting resource groups, and upgrading infrastructure, run asynchronously. Methods prefixed with `Begin` start the server-side work and return a poller immediately. Your code can decide whether to wait or keep doing other work:

Go

```go
// Start an asynchronous operation (returns immediately)
poller, err := client.BeginCreateOrUpdate(ctx, resourceGroupName, parameters, nil)
if err != nil {
    return err
}

// Block until the operation completes or fails
result, err := poller.PollUntilDone(ctx, nil)
if err != nil {
    return err
}
```

A successful `Begin*` call only means Azure accepted the request. The operation can still fail later while the poller runs. That's why both the initial call and `PollUntilDone` need error handling. Use `PollUntilDone` when you want the simplest flow. Use `poller.Poll` and `poller.Done` when you need custom wait logic or progress reporting.

For more details on patterns, see the Common usage patterns in Azure SDK for Go.

Error handling

Management operations return structured errors you can inspect for specific error codes:

Go

```go
import "github.com/Azure/azure-sdk-for-go/sdk/azcore"

// Check if the error is an Azure service error with structured details
var respErr *azcore.ResponseError
if errors.As(err, &respErr) {
    fmt.Printf("Error code: %s\n", respErr.ErrorCode)
    fmt.Printf("Status code: %d\n", respErr.StatusCode)
}
```

Most `CreateOrUpdate` operations are idempotent. Calling them on an existing resource updates the resource instead of failing.

Provision a resource example

This example shows the common control plane pattern: authenticate, create a resource with tags and timeout, and check the result. Use this pattern as a template for all management operations because the credential, context, and subscription ID pattern applies to all `arm*` clients.

Go

```go
package main

import (
    "context"
    "fmt"
    "log"
    "os"
    "time"

    "github.com/Azure/azure-sdk-for-go/sdk/azcore/to"
    "github.com/Azure/azure-sdk-for-go/sdk/azidentity"
    "github.com/Azure/azure-sdk-for-go/sdk/resourcemanager/resources/armresources"
)

func main() {
    // Read subscription ID from environment (avoid hardcoding)
    subscriptionID := os.Getenv("AZURE_SUBSCRIPTION_ID")
    if subscriptionID == "" {
        log.Fatal("AZURE_SUBSCRIPTION_ID not set")
    }
```

```
    // Create credential that auto-discovers authentication
    cred, err := azidentity.NewDefaultAzureCredential(nil)
    if err != nil {
        log.Fatalf("failed to create credential: %v", err)
    }

    // Set a timeout for the entire operation (prevents hanging indefinitely)
    ctx, cancel := context.WithTimeout(context.Background(), 2*time.Minute)
    defer cancel()

    // Create a client factory for this management package
    clientFactory, err := armresources.NewClientFactory(subscriptionID, cred, nil)
    if err != nil {
        log.Fatalf("failed to create client factory: %v", err)
    }

    // Create the typed client for resource groups
    rgClient := clientFactory.NewResourceGroupsClient()

    // Many ARM models use pointer fields for optional values.
    resp, err := rgClient.CreateOrUpdate(ctx, "example-rg",
armresources.ResourceGroup{
        Location: to.Ptr("eastus"),
        Tags: map[string]*string{
            "env":  to.Ptr("dev"),
            "team": to.Ptr("platform"),
        },
    }, nil)
    if err != nil {
        log.Fatalf("failed to create or update resource group: %v", err)
    }

    fmt.Printf("resource group %s ready in %s\n", *resp.Name, *resp.Location)
}
```

Resource groups

The armresources package manages resource groups - the fundamental organizational containers in Azure. Every Azure resource exists within a resource group, making this the starting point for any provisioning workflow.

Use it to create and update resource groups with location and tags, list groups across a subscription, and delete groups along with all contained resources. Resource group creation is synchronous and idempotent. Deletion is asynchronous and permanent.

Listing resource groups also introduces an important control-plane pattern: many read operations use pagers. When you enumerate resource groups or other large ARM collections, create a pager and iterate until `pager.More()` returns `false`.

Go

```
pager := rgClient.NewListPager(nil)
for pager.More() {
    page, err := pager.NextPage(ctx)
    if err != nil {
        return err
    }

    for _, group := range page.ResourceGroupListResult.Value {
        fmt.Println(*group.Name)
    }
}
```

Resource group management code sample.

For a getting started guide, see the armresources package documentation.

Virtual machines

The armcompute package is a canonical control-plane example because VM management is mostly lifecycle work: create or update a VM, start or stop it, resize it, and delete it. In Go, these workflows use the same `DefaultAzureCredential`, `context.Context`, and client factory pattern shown in the resource group example, so once that pattern is in place you can apply it across compute operations without changing your authentication approach.

If you need a quick starting point, create the compute client factory and then ask it for the typed VM client:

Go

```
clientFactory, err := armcompute.NewClientFactory(subscriptionID, cred, nil)
if err != nil {
    return err
}
vmClient := clientFactory.NewVirtualMachinesClient()
```

For full VM samples and operation-specific guidance, see the existing virtual machine management samples and the armcompute package documentation. Use those references for complete request models and long-running operation details instead of duplicating large VM templates in this article.

Key Vault

The armkeyvault package manages the lifecycle of Azure Key Vault instances. This package handles the control plane for vault infrastructure. Use the separate `azsecrets`, `azkeys`, and `azcertificates` data plane packages to read and write secrets, keys, and certificates.

Use this package to provision vaults with the appropriate SKU and security settings, such as soft delete and purge protection. You can also manage access policies for principals, configure network access and private endpoints, and enable diagnostic logging. You can integrate vault provisioning into application onboarding workflows.

Key Vault management code sample.

For runtime-side Key Vault clients, see Use the Azure SDK for Go for data plane operations.

For a getting started guide, see the armkeyvault package documentation.

AKS clusters

The armcontainerservice package manages Azure Kubernetes Service clusters across their full lifecycle.

Use this package to create clusters with configurable networking, Kubernetes version, and managed identity. You can add and scale node pools, upgrade control plane and node versions, enable add-ons like Azure Policy and monitoring, and query cluster health for operational dashboards. All cluster operations are long-running and follow the poller pattern.

AKS management code sample.

For a getting started guide, see the armcontainerservice package documentation.

RBAC and authorization

The armauthorization package manages Azure Role-Based Access Control. Use it to automate least-privilege access policies across subscriptions and resource groups.

Use it to list and search built-in roles, assign roles to principals (users, service principals, managed identities, or groups) at any scope, create custom role definitions with fine-grained permissions, and audit assignments for compliance reporting and drift detection. Assign roles to groups rather than individuals, and use built-in roles where possible.

For a getting started guide, see the armauthorization package documentation.

Virtual networks and network security

The armnetwork package manages Azure virtual networking infrastructure.

Use it to create virtual networks and subnets, configure network security groups with inbound and outbound rules, set up private endpoints for PaaS services, automate network peering across regions, and implement hub-and-spoke topologies programmatically.

Network management code sample.

For a getting started guide, see the armnetwork package documentation.

Container registry

The armcontainerregistry package manages Azure Container Registry instances.

Use it to provision registries with the appropriate SKU and geo-replication, configure authentication (admin, service principal, or managed identity), manage webhooks for CI/CD, enable vulnerability scanning, and apply retention policies to images. You often use Container Registry alongside Azure Kubernetes Service. First, provision the registry, and then reference it during cluster creation.

Container Registry management code sample.

For a getting started guide, see the armcontainerregistry package documentation.

Storage accounts

The armstorage package manages Azure Storage accounts.

Use it to create storage accounts with the right performance tier and redundancy, manage access keys and shared access signatures, configure blob lifecycle policies, and set up diagnostic logging. Storage accounts are a common dependency for many applications, so automating their provisioning and configuration is a common control-plane scenario.

Storage account management code sample.

For a getting started guide, see the armstorage package documentation.

Azure Resource Graph sample queries for Azure Virtual Machines

Article • 08/22/2024

This page is a collection of Azure Resource Graph sample queries for Azure Virtual Machines.

Sample queries

Count of OS update installation done

Returns a list of status of OS update installation runs done for your machines in last seven days.

Kusto

```
PatchAssessmentResources
| where type !has 'softwarepatches'
| extend machineName = tostring(split(id, '/', 8)), resourceType =
tostring(split(type, '/', 0)), tostring(rgName = split(id, '/', 4))
| extend prop = parse_json(properties)
| extend lTime = todatetime(prop.lastModifiedDateTime), OS =
tostring(prop.osType), installedPatchCount =
tostring(prop.installedPatchCount), failedPatchCount =
tostring(prop.failedPatchCount), pendingPatchCount =
tostring(prop.pendingPatchCount), excludedPatchCount =
tostring(prop.excludedPatchCount), notSelectedPatchCount =
tostring(prop.notSelectedPatchCount)
| where lTime > ago(7d)
| project lTime, RunID=name,machineName, rgName, resourceType, OS,
installedPatchCount, failedPatchCount, pendingPatchCount,
excludedPatchCount, notSelectedPatchCount
```

Azure CLI

Azure CLI

```
az graph query -q "PatchAssessmentResources | where type !has
'softwarepatches' | extend machineName = tostring(split(id, '/', 8)),
resourceType = tostring(split(type, '/', 0)), tostring(rgName =
split(id, '/', 4)) | extend prop = parse_json(properties) | extend lTime
= todatetime(prop.lastModifiedDateTime), OS = tostring(prop.osType),
installedPatchCount = tostring(prop.installedPatchCount),
failedPatchCount = tostring(prop.failedPatchCount), pendingPatchCount =
```

```
tostring(prop.pendingPatchCount), excludedPatchCount =
tostring(prop.excludedPatchCount), notSelectedPatchCount =
tostring(prop.notSelectedPatchCount) | where lTime > ago(7d) | project
lTime, RunID=name,machineName, rgName, resourceType, OS,
installedPatchCount, failedPatchCount, pendingPatchCount,
excludedPatchCount, notSelectedPatchCount"
```

Count of virtual machines by availability state and Subscription ID

Returns the count of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated by their availability state across each of your subscriptions.

Kusto

```
HealthResources
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'
| summarize count() by subscriptionId, AvailabilityState =
tostring(properties.availabilityState)
```

Azure CLI

Azure CLI

```
az graph query -q "HealthResources | where type =~
'microsoft.resourcehealth/availabilitystatuses' | summarize count() by
subscriptionId, AvailabilityState =
tostring(properties.availabilityState)"
```

Count of virtual machines by power state

Returns count of virtual machines (type `Microsoft.Compute/virtualMachines`) categorized according to their power state. For more information on power states, see Power states overview.

Kusto

```
Resources
| where type == 'microsoft.compute/virtualmachines'
| summarize count() by PowerState =
tostring(properties.extended.instanceView.powerState.code)
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type ==
'microsoft.compute/virtualmachines' | summarize count() by PowerState =
tostring(properties.extended.instanceView.powerState.code)"
```

Count virtual machines by OS type

Building on the previous query, we're still limiting by Azure resources of type `Microsoft.Compute/virtualMachines`, but are no longer limiting the number of records returned. Instead, we used `summarize` and `count()` to define how to group and aggregate the values by property, which in this example is `properties.storageProfile.osDisk.osType`. For an example of how this string looks in the full object, see explore resources - virtual machine discovery.

Kusto

```
Resources
| where type =~ 'Microsoft.Compute/virtualMachines'
| summarize count() by tostring(properties.storageProfile.osDisk.osType)
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type =~
'Microsoft.Compute/virtualMachines' | summarize count() by
tostring(properties.storageProfile.osDisk.osType)"
```

Count virtual machines by OS type with extend

A different way to write the 'Count virtual machines by OS type' query is to `extend` a property and give it a temporary name for use within the query, in this case **os**. **os** is then used by `summarize` and `count()` as in the referenced example.

Kusto

```
Resources
| where type =~ 'Microsoft.Compute/virtualMachines'
| extend os = properties.storageProfile.osDisk.osType
| summarize count() by tostring(os)
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type =~
'Microsoft.Compute/virtualMachines' | extend os =
properties.storageProfile.osDisk.osType | summarize count() by
tostring(os)"
```

Get all New alerts from the past 30 days

This query provides a list of all the user's New alerts, from the past 30 days.

Kusto

```
iotsecurityresources
| where type == 'microsoft.iotsecurity/locations/devicegroups/alerts'
| where todatetime(properties.startTimeUtc) > ago(30d) and properties.status
== 'New'
```

Azure CLI

Azure CLI

```
az graph query -q "iotsecurityresources | where type ==
'microsoft.iotsecurity/locations/devicegroups/alerts' | where
todatetime(properties.startTimeUtc) > ago(30d) and properties.status ==
'New'"
```

Get virtual machine scale set capacity and size

This query looks for virtual machine scale set resources and gets various details including the virtual machine size and the capacity of the scale set. The query uses the `toint()` function to cast the capacity to a number so that it can be sorted. Finally, the columns are renamed into custom named properties.

Kusto

```
Resources
| where type=~ 'microsoft.compute/virtualmachinescalesets'
| where name contains 'contoso'
| project subscriptionId, name, location, resourceGroup, Capacity =
toint(sku.capacity), Tier = sku.name
| order by Capacity desc
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type=~
'microsoft.compute/virtualmachinescalesets' | where name contains
'contoso' | project subscriptionId, name, location, resourceGroup,
Capacity = toint(sku.capacity), Tier = sku.name | order by Capacity
desc"
```

List all extensions installed on a virtual machine

First, this query uses `extend` on the virtual machines resource type to get the ID in uppercase (`toupper()`) the ID, get the operating system name and type, and get the virtual machine size. Getting the resource ID in uppercase is a good way to prepare to join to another property. Then, the query uses `join` with `kind` as `leftouter` to get virtual machine extensions by matching an uppercase `substring` of the extension ID. The portion of the ID before `/extensions/\<ExtensionName\>` is the same format as the virtual machines ID, so we use this property for the `join`. `summarize` is then used with `make_list` on the name of the virtual machine extension to combine the name of each extension where *ID*, *OSName*, *OSType*, and *VMSize* are the same into a single array property. Lastly, we `order by` lowercase *OSName* with `asc`. By default, `order by` is descending.

Kusto

```
Resources
| where type == 'microsoft.compute/virtualmachines'
| extend
  JoinID = toupper(id),
  OSName = tostring(properties.osProfile.computerName),
  OSType = tostring(properties.storageProfile.osDisk.osType),
  VMSize = tostring(properties.hardwareProfile.vmSize)
| join kind=leftouter(
  Resources
```

```
  | where type == 'microsoft.compute/virtualmachines/extensions'
  | extend
    VMId = toupper(substring(id, 0, indexof(id, '/extensions'))),
    ExtensionName = name
) on $left.JoinID == $right.VMId
| summarize Extensions = make_list(ExtensionName) by id, OSName, OSType,
VMSize
| order by tolower(OSName) asc
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type ==
'microsoft.compute/virtualmachines' | extend JoinID = toupper(id),
OSName = tostring(properties.osProfile.computerName), OSType =
tostring(properties.storageProfile.osDisk.osType), VMSize =
tostring(properties.hardwareProfile.vmSize) | join kind=leftouter(
Resources | where type == 'microsoft.compute/virtualmachines/extensions'
| extend  VMId = toupper(substring(id, 0, indexof(id, '/extensions'))),
ExtensionName = name ) on \$left.JoinID == \$right.VMId | summarize
Extensions = make_list(ExtensionName) by id, OSName, OSType, VMSize |
order by tolower(OSName) asc"
```

List available OS updates for all your machines grouped by update category

Returns a list of pending OS for your machines.

Kusto

```
PatchAssessmentResources
| where type !has 'softwarepatches'
| extend prop = parse_json(properties)
| extend lastTime = properties.lastModifiedDateTime
| extend updateRollupCount =
prop.availablePatchCountByClassification.updateRollup, featurePackCount =
prop.availablePatchCountByClassification.featurePack, servicePackCount =
prop.availablePatchCountByClassification.servicePack, definitionCount =
prop.availablePatchCountByClassification.definition, securityCount =
prop.availablePatchCountByClassification.security, criticalCount =
prop.availablePatchCountByClassification.critical, updatesCount =
prop.availablePatchCountByClassification.updates, toolsCount =
prop.availablePatchCountByClassification.tools, otherCount =
prop.availablePatchCountByClassification.other, OS = prop.osType
| project lastTime, id, OS, updateRollupCount, featurePackCount,
```

```
servicePackCount, definitionCount, securityCount, criticalCount,
updatesCount, toolsCount, otherCount
```

Azure CLI

Azure CLI

```
az graph query -q "PatchAssessmentResources | where type !has
'softwarepatches' | extend prop = parse_json(properties) | extend
lastTime = properties.lastModifiedDateTime | extend updateRollupCount =
prop.availablePatchCountByClassification.updateRollup, featurePackCount
= prop.availablePatchCountByClassification.featurePack, servicePackCount
= prop.availablePatchCountByClassification.servicePack, definitionCount
= prop.availablePatchCountByClassification.definition, securityCount =
prop.availablePatchCountByClassification.security, criticalCount =
prop.availablePatchCountByClassification.critical, updatesCount =
prop.availablePatchCountByClassification.updates, toolsCount =
prop.availablePatchCountByClassification.tools, otherCount =
prop.availablePatchCountByClassification.other, OS = prop.osType |
project lastTime, id, OS, updateRollupCount, featurePackCount,
servicePackCount, definitionCount, securityCount, criticalCount,
updatesCount, toolsCount, otherCount"
```

List of Linux OS update installation done

Returns a list of status of Linux Server - OS update installation runs done for your machines in last seven days.

Kusto

```
PatchAssessmentResources
| where type has 'softwarepatches' and properties has 'version'
| extend machineName = tostring(split(id, '/', 8)), resourceType =
tostring(split(type, '/', 0)), tostring(rgName = split(id, '/', 4)),
tostring(RunID = split(id, '/', 10))
| extend prop = parse_json(properties)
| extend lTime = todatetime(prop.lastModifiedDateTime), patchName =
tostring(prop.patchName), version = tostring(prop.version),
installationState = tostring(prop.installationState), classifications =
tostring(prop.classifications)
| where lTime > ago(7d)
| project lTime, RunID, machineName, rgName, resourceType, patchName,
version, classifications, installationState
| sort by RunID
```

Azure CLI

Azure CLI

```
az graph query -q "PatchAssessmentResources | where type has
'softwarepatches' and properties has 'version' | extend machineName =
tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/',
0)), tostring(rgName = split(id, '/', 4)), tostring(RunID = split(id,
'/', 10)) | extend prop = parse_json(properties) | extend lTime =
todatetime(prop.lastModifiedDateTime), patchName =
tostring(prop.patchName), version = tostring(prop.version),
installationState = tostring(prop.installationState), classifications =
tostring(prop.classifications) | where lTime > ago(7d) | project lTime,
RunID, machineName, rgName, resourceType, patchName, version,
classifications, installationState | sort by RunID"
```

List of virtual machines and associated availability states by resource IDs

Returns the latest list of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated by availability state. The query also provides the associated resource ID based on `properties.targetResourceId`, for easy debugging and mitigation. Availability states can be one of four values: Available, Unavailable, Degraded, and Unknown. For more information on what each of the availability states mean, see Azure Resource Health overview.

Kusto

```
HealthResources
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'
| summarize by ResourceId = tolower(tostring(properties.targetResourceId)),
AvailabilityState = tostring(properties.availabilityState)
```

Azure CLI

Azure CLI

```
az graph query -q "HealthResources | where type =~
'microsoft.resourcehealth/availabilitystatuses' | summarize by
ResourceId = tolower(tostring(properties.targetResourceId)),
AvailabilityState = tostring(properties.availabilityState)"
```

List of virtual machines by availability state and power state with Resource IDs and resource Groups

Returns list of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated on their power state and availability state to provide a cohesive state of health for your virtual machines. The query also provides details on the resource group and resource ID associated with each entry for detailed visibility into your resources.

Kusto

```
Resources
| where type =~ 'microsoft.compute/virtualmachines'
| project resourceGroup, Id = tolower(id), PowerState = tostring(
properties.extended.instanceView.powerState.code)
| join kind=leftouter (
  HealthResources
  | where type =~ 'microsoft.resourcehealth/availabilitystatuses'
  | where tostring(properties.targetResourceType) =~
'microsoft.compute/virtualmachines'
  | project targetResourceId =
tolower(tostring(properties.targetResourceId)), AvailabilityState =
tostring(properties.availabilityState))
  on $left.Id == $right.targetResourceId
| project-away targetResourceId
| where PowerState != 'PowerState/deallocated'
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type =~
'microsoft.compute/virtualmachines' | project resourceGroup, Id =
tolower(id), PowerState = tostring(
properties.extended.instanceView.powerState.code) | join kind=leftouter
( HealthResources | where type =~
'microsoft.resourcehealth/availabilitystatuses' | where
tostring(properties.targetResourceType) =~
'microsoft.compute/virtualmachines' | project targetResourceId =
tolower(tostring(properties.targetResourceId)), AvailabilityState =
tostring(properties.availabilityState)) on \$left.Id ==
\$right.targetResourceId | project-away targetResourceId | where
PowerState != 'PowerState/deallocated'"
```

List of virtual machines that aren't Available by Resource Ids

Returns the latest list of virtual machines (type `Microsoft.Compute/virtualMachines`) aggregated by their availability state. The populated list only highlights virtual machines whose availability state isn't *Available* to ensure you're aware of all the concerning states your virtual machines are in. When all your virtual machines are Available, you can expect to receive no results.

Kusto

```
HealthResources
| where type =~ 'microsoft.resourcehealth/availabilitystatuses'
| where tostring(properties.availabilityState) != 'Available'
| summarize by ResourceId = tolower(tostring(properties.targetResourceId)),
AvailabilityState = tostring(properties.availabilityState)
```

Azure CLI

Azure CLI

```
az graph query -q "HealthResources | where type =~
'microsoft.resourcehealth/availabilitystatuses' | where
tostring(properties.availabilityState) != 'Available' | summarize by
ResourceId = tolower(tostring(properties.targetResourceId)),
AvailabilityState = tostring(properties.availabilityState)"
```

List of Windows Server OS update installation done

Returns a list of status of Windows Server - OS update installation runs done for your machines in last seven days.

Kusto

```
PatchAssessmentResources
| where type has 'softwarepatches' and properties !has 'version'
| extend machineName = tostring(split(id, '/', 8)), resourceType =
tostring(split(type, '/', 0)), tostring(rgName = split(id, '/', 4)),
tostring(RunID = split(id, '/', 10))
| extend prop = parse_json(properties)
| extend lTime = todatetime(prop.lastModifiedDateTime), patchName =
tostring(prop.patchName), kbId = tostring(prop.kbId), installationState =
tostring(prop.installationState), classifications =
tostring(prop.classifications)
| where lTime > ago(7d)
| project lTime, RunID, machineName, rgName, resourceType, patchName, kbId,
classifications, installationState
| sort by RunID
```

Azure CLI

Azure CLI

```
az graph query -q "PatchAssessmentResources | where type has
'softwarepatches' and properties !has 'version' | extend machineName =
tostring(split(id, '/', 8)), resourceType = tostring(split(type, '/',
0)), tostring(rgName = split(id, '/', 4)), tostring(RunID = split(id,
'/', 10)) | extend prop = parse_json(properties) | extend lTime =
todatetime(prop.lastModifiedDateTime), patchName =
tostring(prop.patchName), kbId = tostring(prop.kbId), installationState
= tostring(prop.installationState), classifications =
tostring(prop.classifications) | where lTime > ago(7d) | project lTime,
RunID, machineName, rgName, resourceType, patchName, kbId,
classifications, installationState | sort by RunID"
```

List virtual machines with their network interface and public IP

This query uses two `leftouter` `join` commands to bring together virtual machines created with the Resource Manager deployment model, their related network interfaces, and any public IP address related to those network interfaces.

Kusto

```
Resources
| where type =~ 'microsoft.compute/virtualmachines'
| extend nics=array_length(properties.networkProfile.networkInterfaces)
| mv-expand nic=properties.networkProfile.networkInterfaces
| where nics == 1 or nic.properties.primary =~ 'true' or isempty(nic)
| project vmId = id, vmName = name,
vmSize=tostring(properties.hardwareProfile.vmSize), nicId = tostring(nic.id)
| join kind=leftouter (
  Resources
  | where type =~ 'microsoft.network/networkinterfaces'
  | extend ipConfigsCount=array_length(properties.ipConfigurations)
  | mv-expand ipconfig=properties.ipConfigurations
  | where ipConfigsCount == 1 or ipconfig.properties.primary =~ 'true'
  | project nicId = id, publicIpId =
tostring(ipconfig.properties.publicIPAddress.id))
  on nicId
| project-away nicId1
| summarize by vmId, vmName, vmSize, nicId, publicIpId
| join kind=leftouter (
  Resources
  | where type =~ 'microsoft.network/publicipaddresses'
  | project publicIpId = id, publicIpAddress = properties.ipAddress)
```

```
on publicIpId
| project-away publicIpId1
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type =~
'microsoft.compute/virtualmachines' | extend
nics=array_length(properties.networkProfile.networkInterfaces) | mv-
expand nic=properties.networkProfile.networkInterfaces | where nics == 1
or nic.properties.primary =~ 'true' or isempty(nic) | project vmId = id,
vmName = name, vmSize=tostring(properties.hardwareProfile.vmSize), nicId
= tostring(nic.id) | join kind=leftouter ( Resources | where type =~
'microsoft.network/networkinterfaces' | extend
ipConfigsCount=array_length(properties.ipConfigurations) | mv-expand
ipconfig=properties.ipConfigurations | where ipConfigsCount == 1 or
ipconfig.properties.primary =~ 'true' | project nicId = id, publicIpId =
tostring(ipconfig.properties.publicIPAddress.id)) on nicId | project-
away nicId1 | summarize by vmId, vmName, vmSize, nicId, publicIpId |
join kind=leftouter ( Resources | where type =~
'microsoft.network/publicipaddresses' | project publicIpId = id,
publicIpAddress = properties.ipAddress) on publicIpId | project-away
publicIpId1"
```

Show all virtual machines ordered by name in descending order

To list only virtual machines (which are type `Microsoft.Compute/virtualMachines`), we can match the property **type** in the results. Similar to the previous query, `desc` changes the `order by` to be descending. The `=~` in the type match tells Resource Graph to be case insensitive.

Kusto

```
Resources
| project name, location, type
| where type =~ 'Microsoft.Compute/virtualMachines'
| order by name desc
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | project name, location, type | where type
=~ 'Microsoft.Compute/virtualMachines' | order by name desc"
```

Show first five virtual machines by name and their OS type

This query uses `top` to only retrieve five matching records that are ordered by name. The type of the Azure resource is `Microsoft.Compute/virtualMachines`. `project` tells Azure Resource Graph which properties to include.

Kusto

```
Resources
| where type =~ 'Microsoft.Compute/virtualMachines'
| project name, properties.storageProfile.osDisk.osType
| top 5 by name desc
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type =~
'Microsoft.Compute/virtualMachines' | project name,
properties.storageProfile.osDisk.osType | top 5 by name desc"
```

Summarize virtual machine by the power states extended property

This query uses the extended properties on virtual machines to summarize by power states.

Kusto

```
Resources
| where type == 'microsoft.compute/virtualmachines'
| summarize count() by
tostring(properties.extended.instanceView.powerState.code)
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type ==
'microsoft.compute/virtualmachines' | summarize count() by
tostring(properties.extended.instanceView.powerState.code)"
```

Virtual machines matched by regex

This query looks for virtual machines that match a regular expression (known as *regex*). The **matches regex @** allows us to define the regex to match, which is `^Contoso(.*)[0-9]+$`. That regex definition is explained as:

- `^` - Match must start at the beginning of the string.
- `Contoso` - The case-sensitive string.
- `(.*)` - A subexpression match:
  - `.` - Matches any single character (except a new line).
  - `*` - Matches previous element zero or more times.
- `[0-9]` - Character group match for numbers 0 through 9.
- `+` - Matches previous element one or more times.
- `$` - Match of the previous element must occur at the end of the string.

After matching by name, the query projects the name and orders by name ascending.

Kusto

```
Resources
| where type =~ 'microsoft.compute/virtualmachines' and name matches regex
@'^Contoso(.*)[0-9]+$'
| project name
| order by name asc
```

Azure CLI

Azure CLI

```
az graph query -q "Resources | where type =~
'microsoft.compute/virtualmachines' and name matches regex
@'^Contoso(.*)[0-9]+\$' | project name | order by name asc"
```

Red Hat workloads on Azure

Article • 10/28/2024

Applies to: ✔ Linux VMs

Red Hat workloads are supported through a variety of offerings on Azure. Red Hat Enterprise Linux (RHEL) images are at the core of RHEL workloads, as is the Red Hat Update Infrastructure (RHUI). Red Hat JBoss EAP is also supported on Azure, see Red Hat JBoss EAP.

For more information about running RHEL workloads on Azure, see the following video: https://www.youtube-nocookie.com/embed/11arYjecfxU?si=m0X-28xd1-zYUoqG

Red Hat Enterprise Linux images

Azure offers a wide offering of RHEL images on Azure. These images are made available through two different licensing models: pay-as-you-go and bring-your-own-subscription (BYOS). New RHEL images on Azure are published when new RHEL versions are released and updated throughout their lifecycles, as necessary.

Pay-as-you-go images

Azure offers a variety of RHEL pay-as-you-go images. These images come properly entitled for RHEL and are attached to a source of updates (Red Hat Update Infrastructure). These images charge a premium fee for the RHEL entitlement and updates. RHEL pay-as-you-go image variants include:

- RHEL
- RHEL for SAP
- RHEL for SAP with High Availability (HA) and Update Services
- RHEL with High Availability (HA) and Update Services

You might want to use the pay-as-you-go images if you don't want to worry about paying separately for the appropriate number of subscriptions.

Red Hat Gold Images

Azure also offers Red Hat Gold Images (`rhel-byos`). These images might be useful to customers who have existing Red Hat subscriptions and want to use them in Azure. You're required to enable your existing Red Hat subscriptions for Red Hat Cloud Access

before you can use them in Azure. Access to these images is granted automatically when your Red Hat subscriptions are enabled for Cloud Access and meet the eligibility requirements. Using these images allows a customer to avoid double billing that might be incurred from using the pay-as-you-go images.

- Learn how to enable your Red Hat subscriptions for Cloud Access with Azure.
- Learn how to locate Red Hat Gold Images in the Azure portal, the Azure CLI, or PowerShell cmdlet.

> **Note**
>
> Double billing is incurred when a user pays twice for RHEL subscriptions. This scenario usually happens when a customer uses Red Hat Subscription-Manager to attach an entitlement on a RHEL pay-as-you-go VM. For example, a customer who uses Subscription-Manager to attach an entitlement for SAP packages on a RHEL pay-as-you-go image is indirectly double billed because they pay twice for RHEL. They pay once through the pay-as-you-go premium fee and once through their SAP subscription. This scenario doesn't happen to BYOS image users.

Generation 2 images

Generation 2 virtual machines (VMs) provide some newer features compared to Generation 1 VMs. For more information, see the Generation 2 documentation. The key difference from a RHEL image perspective is that Generation 2 VMs use a UEFI instead of BIOS firmware interface. They also use a GUID Partition Table (GPT) instead of a master boot record (MBR) on boot time. Use of a GPT allows for, among other things, OS disk sizes larger than 2 TB. In addition, the Mv2 series VMs run only on Generation 2 images.

RHEL Generation 2 images are available in the Azure Marketplace. Look for "gen2" in the image SKU in the list of all images that appears when you use the Azure CLI. Go to the **Advanced** tab in the VM deploy process to deploy a Generation 2 VM.

Red Hat Update Infrastructure

Azure provides Red Hat Update Infrastructure only for pay-as-you-go RHEL VMs. RHUI is effectively a mirror of the Red Hat CDNs but is only accessible to the Azure pay-as-you-go RHEL VMs. You have access to the appropriate packages depending on which RHEL image you've deployed. For example, a RHEL for SAP image has access to the SAP packages in addition to base RHEL packages.

RHUI update behavior

RHEL images connected to RHUI update by default to the latest minor version of RHEL when a `yum update` is run. This behavior means that a RHEL 7.4 VM might get upgraded to RHEL 7.7 if a `yum update` operation is run on it. This behavior is by design for RHUI. To mitigate this upgrade behavior, switch from regular RHEL repositories to Extended Update Support repositories.

Red Hat JBoss EAP

Microsoft and Azure have partnered to develop a variety of solutions for running Red Hat Middleware on Azure. Learn more about JBoss EAP on Azure Virtual Machines, Azure App service and Azure Red Hat OpenShift at Red Hat JBoss EAP on Azure.

Ubuntu Server to Ubuntu Pro in-place upgrade on Azure

Article • 03/17/2025

Customers can now upgrade their Ubuntu Server (version 16.04 or higher) virtual machines to Ubuntu Pro without redeployment or downtime. This method is recommended for customers wishing to convert their servers from versions that are End of Life (EOL) status.

> **ⓘ Important**
>
> EOL versions are not officially supported unless they have the PRO entitlement. For an updated list of versions that are EOL, check the official Canonical Release Cycle page.

> **⚠ Warning**
>
> - Only Ubuntu images on the Azure Marketplace **published by Canonical** can be converted to "UBUNTU_PRO"
> - Images published by any other vendors or custom images are not supported

What's Ubuntu Pro?

Ubuntu Pro is a cross-cloud OS, optimized for Azure, and security maintained for 10 years. The secure use of open-source software allows the operating system to use the latest technologies while meeting internal governance and compliance requirements. Ubuntu Pro provides Extended Security Maintenance (ESM) for infrastructure and applications support, providing security patching for all Ubuntu packages.

Why developers and devops choose Ubuntu Pro for Azure

- Access to security updates for 23,000+ packages including Apache Kafka, NGINX, MongoDB, Redis, and PostgreSQL integrated into system tools (for example Azure Update Manager, apt)

- Security hardening and audit tools (CIS) to establish a security baseline across your systems (helps meeting the Azure Linux Security Baseline policy)
- Federal Information Processing Standard (FIPS) 140-2 certified modules
- Common Criteria (CC) EAL2 provisioning packages
- Kernel Live patch: kernel patches delivered immediately, without the need to reboot
- Optimized performance: optimized kernel, with improved boot speed, outstanding runtime performance, and advanced device support
- 10-year security maintenance: Ubuntu Pro 18.04 Long-Term Support (LTS) provides security maintenance until April 2028
- Developer friendly: Ubuntu offers developers the latest libraries and tools to innovate with the latest technologies
- Nonstop security: Canonical publishes images ensuring security is present from the moment an instance launches
- Portability: Ubuntu is available in all regions with content mirrors to reduce the need to go across regions or out to the Internet for updates
- Consistent experience across platforms: from edge to multicloud, Ubuntu provides the same experience regardless of the platform. It ensures consistency of your CI/CD pipelines and management mechanisms.

> **ⓘ Important**
>
> Converting to Ubuntu Pro is an **irreversible** process.

Convert to Ubuntu Pro using the Azure CLI

The following command enables Ubuntu Pro on a virtual machine in Azure:

Azure

```
az vm update -g myResourceGroup -n myVmName --license-type UBUNTU_PRO
```

Execute these commands inside the VM:

Bash

```
sudo apt install ubuntu-pro-client
sudo pro auto-attach
```

> **ⓘ Important**
>
> The change of the "licenseType" property may take some time to propagate thru the system. If the auto-attach process fails, wait for a few minutes, and try again. If the auto-attach process continues to fail, open a support ticket with Microsoft. If the `pro --version` is lower than 28, execute this command:

Bash

```
sudo apt install ubuntu-pro-client
```

Validate the license

use the `pro status --all` command to validate the license:

Expected output:

Output

```
SERVICE      ENTITLED    STATUS    DESCRIPTION
cc-eal       yes         disabled  Common Criteria EAL2 Provisioning
Packages
cis          yes         disables  Security compliance and audit tools
esm-apps     yes         enabled   Expanded Security Maintenance and audit
tools
esm-infra    yes         enabled   Expanded Security Maintenance for
infrastructure
fips         yes         disabled  NIST-certified core packages
fips-updates yes         disabled  NIST-certified core packages with
priority security updates
livepatch    yes         enabled   Canonical Livepatch service
```

Create an Ubuntu Pro VM using the Azure CLI

You can create a new VM using the Ubuntu Server images and apply Ubuntu Pro at the time of creation.

Both of the following commands enable Ubuntu Pro on a virtual machine in Azure. Choose which to run based on whether you want to use SSH keys or an administrator user and password.

To create the VM and use **SSH keys**:

Azure

```
az vm create -g myResourceGroup -n myVmName --generate-ssh-keys --license-type UBUNTU_PRO --image ubuntu2204
```

To create the VM and use an **administrator user and password**:

Azure

```
az vm create -g myResourceGroup -n myVmName --admin-username Username --license-type UBUNTU_PRO --image ubuntu2204
```

> **Note**
>
> For more information on ways to connect to Linux machines, see Connect to a Linux VM.

Execute these commands inside the VM:

Bash

```
sudo apt install ubuntu-pro-client
sudo pro auto-attach
```

> **Note**
>
> For systems with advantage tools using version 28 or higher, installed the system will perform a `pro attach` during a reboot.

Check licensing model using the Azure CLI

> **Tip**
>
> You can query the metadata in *Azure Instance Metadata Service* to determine the virtual machine's *licenseType* value. You can use the `az vm get-instance-view` command to check the status. Look for the *licenseType* field in the response. If the field exists and the value is UBUNTU_PRO, your virtual machine has Ubuntu Pro enabled. Learn more about attested metadata.

Azure

```
az vm get-instance-view -g MyResourceGroup -n MyVm
```

Billing

Visit the pricing calculator for more details on Ubuntu Pro pricing. To cancel the Pro subscription during the preview period, open a support ticket through the Azure portal.

Next steps after launching an Ubuntu Pro VM

With the availability of outbound internet access, Ubuntu Pro automatically enables premium features including Live Patch and Extended Security Maintenance for Main and Universe repositories. Should any specific hardening be required, check `usg` to harden your servers for CIP and FIPS tutorials. Learn more about networking requirements (such as egress traffic, endpoints and ports) by reading Ubuntu Pro Client network requirements.

Frequently Asked Questions

Does shutting down the machine stop billing?

Launching Ubuntu Pro from Azure Marketplace is you pay as you go and only charges for running machines.

Are there volume discounts?

Yes. Contact your Microsoft sales representative.

Are Reserved Instances available?

Yes.

If the customer doesn't perform the `auto attach` function, will they still get attached to pro on reboot?

If the customer doesn't perform the *auto attach*, they still get the Pro attached upon reboot. However, this action only applies if they're using version 28 of the Pro client.

- For Ubuntu 20.04+, this process works as expected.
- For Ubuntu 16.04 and 18.04, this process doesn't work due to older versions of the Pro client installed.

Do images converted to UbuntuPro or UbuntuPro images include support from Canonical?

No, at present, neither UbuntuPro images nor virtual machines converted to UbuntuPro come with support from Canonical.

- For issues that are reproducible in Azure and affect all customers, Microsoft Azure support will collaborate with Canonical to resolve the problem together.
- For dedicated support, please use the following link to contact Canonical.

Deploy OpenShift Container Platform 4.x in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Deployment of OpenShift Container Platform (OCP) 4.2 is now supported in Azure via the Installer-Provisioned Infrastructure (IPI) model. The landing page for trying OpenShift 4 is try.openshift.com. To install OCP 4.2 in Azure, visit the Red Hat OpenShift Cluster Manager page. Red Hat credentials are required to access this site.

Notes

- A Microsoft Entra service principal (SP) is required to install and run OCP 4.x in Azure
  - The SP must be granted the API permission of **Application.ReadWrite.OwnedBy** for Azure Active Directory Graph
  - A Microsoft Entra tenant administrator must grant Admin Consent for this API permission to take effect
  - The SP must be granted **Contributor** and **User Access Administrator** roles to the subscription
- The installation model for OCP 4.x is different than 3.x and there are no Azure Resource Manager templates available for deploying OCP 4.x in Azure
- If issues are encountered during the installation process, contact the appropriate company (Microsoft or Red Hat)

Expand table

Issue Description	Contact Point
Azure specific issues (Microsoft Entra ID, SP, Azure Subscription, etc.)	Microsoft
OpenShift-specific issues (Installation failures / errors, Red Hat subscription, etc.)	Red Hat

Next steps

- Getting started with OpenShift Container Platform

OpenShift Container Platform or OKD deployment to Azure Stack Hub

Applies to: ✔ Linux VMs ✔ Flexible scale sets

You can deploy OpenShift in Azure Stack Hub. Some key differences exist between Azure and Azure Stack Hub, so deployment and capabilities differ slightly.

Currently, the Azure Cloud Provider doesn't work in Azure Stack Hub. You can't use disk attach for persistent storage in Azure Stack Hub. Instead, you can configure other storage options such as Network File System (NFS), Internet Small Computer Systems Interface (iSCSI), and GlusterFS. Or, you can enable Container Native Storage (CNS) and use GlusterFS for persistent storage. If you enable CNS, the deployment adds three more nodes with storage for GlusterFS usage.

Deploy OpenShift 4.x On Azure Stack Hub

Red Hat manages the Red Hat Enterprise Linux CoreOS (RHCOS) image for OpenShift 4.x. The deployment process gets the image from a Red Hat endpoint. As a result, you don't need to get an image from the Azure Stack hub Marketplace.

Follow the steps in the OpenShift documentation at Installing a cluster on Azure Stack Hub using ARM templates.

> ⚠ **Warning**
>
> If you have an issue with OpenShift, contact Red Hat for support.

Next steps

Installing a cluster on Azure Stack Hub using ARM templates.

Install the Elastic Stack (ELK) on an Azure VM

Article • 05/02/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article walks you through how to deploy Elasticsearch, Logstash, and Kibana, on an Ubuntu VM in Azure. To see the Elastic Stack in action, you can optionally connect to Kibana and work with some sample logging data.

Additionally, you can follow the Deploy Elastic on Azure Virtual Machines module for a more guided tutorial on deploying Elastic on Azure Virtual Machines.

In this tutorial you learn how to:

- ✔ Create an Ubuntu VM in an Azure resource group
- ✔ Install Elasticsearch, Logstash, and Kibana on the VM
- ✔ Send sample data to Elasticsearch with Logstash
- ✔ Open ports and work with data in the Kibana console

This deployment is suitable for basic development with the Elastic Stack. For more on the Elastic Stack, including recommendations for a production environment, see the Elastic documentation and the Azure Architecture Center.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Get started with Azure Cloud Shell.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Authenticate to Azure using Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use and manage extensions with the Azure CLI.

    - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

- This article requires version 2.0.4 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

Create a resource group

In this section, environment variables are declared for use in subsequent commands. A random suffix is appended to resource names for uniqueness.

Bash

```
export RANDOM_SUFFIX=$(openssl rand -hex 3)
export RESOURCE_GROUP="myResourceGroup$RANDOM_SUFFIX"
export REGION="eastus2"
az group create --name $RESOURCE_GROUP --location $REGION
```

Results:

JSON

```
{
  "id": "/subscriptions/xxxxx/resourceGroups/myResourceGroupxxxxxx",
  "location": "eastus",
  "managedBy": null,
  "name": "myResourceGroupxxxxxx",
  "properties": {
    "provisioningState": "Succeeded"
  },
  "tags": null,
  "type": "Microsoft.Resources/resourceGroups"
}
```

Create a virtual machine

This section creates a VM with a unique name, while also generating SSH keys if they do not already exist. A random suffix is appended to ensure uniqueness.

Bash

```
export VM_NAME="myVM$RANDOM_SUFFIX"
az vm create \
    --resource-group $RESOURCE_GROUP \
    --name $VM_NAME \
    --image Ubuntu2204 \
```

```
    --admin-username azureuser \
    --generate-ssh-keys
```

When the VM has been created, the Azure CLI shows information similar to the following example. Take note of the publicIpAddress. This address is used to access the VM.

Results:

JSON

```
{
  "fqdns": "",
  "id":
"/subscriptions/xxxxx/resourceGroups/myResourceGroupxxxxxx/providers/Microsoft.Com
pute/virtualMachines/myVMxxxxxx",
  "location": "eastus",
  "macAddress": "xx:xx:xx:xx:xx:xx",
  "powerState": "VM running",
  "privateIpAddress": "10.0.0.4",
  "publicIpAddress": "x.x.x.x",
  "resourceGroup": "$RESOURCE_GROUP"
}
```

SSH into your VM

If you don't already know the public IP address of your VM, run the following command to list it:

Azure CLI

```
az network public-ip list --resource-group $RESOURCE_GROUP --query [].ipAddress
```

Use the following command to create an SSH session with the virtual machine. Substitute the correct public IP address of your virtual machine. In this example, the IP address is *40.68.254.142*.

Bash

```
export PUBLIC_IP_ADDRESS=$(az network public-ip list --resource-group
$RESOURCE_GROUP --query [].ipAddress -o tsv)
```

Install the Elastic Stack

In this section, you import the Elasticsearch signing key and update your APT sources list to include the Elastic package repository. This is followed by installing the Java runtime environment which is required for the Elastic Stack components.

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
wget -qO - https://artifacts.elastic.co/GPG-KEY-elasticsearch | sudo apt-key add -
echo "deb https://artifacts.elastic.co/packages/5.x/apt stable main" | sudo tee -a
/etc/apt/sources.list.d/elastic-5.x.list
"
```

Install the Java Virtual Machine on the VM and configure the JAVA_HOME variable:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
sudo apt install -y openjdk-8-jre-headless
export JAVA_HOME=/usr/lib/jvm/java-8-openjdk-amd64
"
```

Run the following command to update Ubuntu package sources and install Elasticsearch, Kibana, and Logstash.

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
  wget -qO elasticsearch.gpg https://artifacts.elastic.co/GPG-KEY-elasticsearch
  sudo mv elasticsearch.gpg /etc/apt/trusted.gpg.d/

  echo "deb https://artifacts.elastic.co/packages/7.x/apt stable main" | sudo tee
/etc/apt/sources.list.d/elastic-7.x.list

  sudo apt update

  # Now install the ELK stack
  sudo apt install -y elasticsearch kibana logstash
"
```

> ⓘ **Note**
>
> Detailed installation instructions, including directory layouts and initial configuration, are maintained in Elastic's documentation

Start Elasticsearch

Start Elasticsearch on your VM with the following command:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
sudo systemctl start elasticsearch.service
"
```

This command produces no output, so verify that Elasticsearch is running on the VM with this curl command:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
sleep 11
sudo curl -XGET 'localhost:9200/'
"
```

If Elasticsearch is running, you see output like the following:

Results:

JSON

```
{
  "name" : "w6Z4NwR",
  "cluster_name" : "elasticsearch",
  "cluster_uuid" : "SDzCajBoSK2EkXmHvJVaDQ",
  "version" : {
    "number" : "5.6.3",
    "build_hash" : "1a2f265",
    "build_date" : "2017-10-06T20:33:39.012Z",
    "build_snapshot" : false,
    "lucene_version" : "6.6.1"
  },
  "tagline" : "You Know, for Search"
}
```

Start Logstash and add data to Elasticsearch

Start Logstash with the following command:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
sudo systemctl start logstash.service
```

```
"
```

Test Logstash to make sure it's working correctly:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
# Time-limited test with file input instead of stdin
sudo timeout 11s /usr/share/logstash/bin/logstash -e 'input { file { path =>
"/var/log/syslog" start_position => "end" sincedb_path => "/dev/null"
stat_interval => "1 second" } } output { stdout { codec => json } }' || echo
"Logstash test completed"
"
```

This is a basic Logstash pipeline that echoes standard input to standard output.

Set up Logstash to forward the kernel messages from this VM to Elasticsearch. To create the Logstash configuration file, run the following command which writes the configuration to a new file called vm-syslog-logstash.conf:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
cat << 'EOF' > vm-syslog-logstash.conf
input {
    stdin {
        type => "stdin-type"
    }

    file {
        type => "syslog"
        path => [ "/var/log/*.log", "/var/log/*/*.log", "/var/log/messages",
"/var/log/syslog" ]
        start_position => "beginning"
    }
}

output {

    stdout {
        codec => rubydebug
    }
    elasticsearch {
        hosts  => "localhost:9200"
    }
}
EOF
"
```

Test this configuration and send the syslog data to Elasticsearch:

Bash

```
# Run Logstash with the configuration for 60 seconds
sudo timeout 60s /usr/share/logstash/bin/logstash -f vm-syslog-logstash.conf &
LOGSTASH_PID=$!

# Wait for data to be processed
echo "Processing logs for 60 seconds..."
sleep 65

# Verify data was sent to Elasticsearch with proper error handling
echo "Verifying data in Elasticsearch..."
ES_COUNT=$(sudo curl -s -XGET 'localhost:9200/_cat/count?v' | tail -n 1 | awk
'{print $3}' 2>/dev/null || echo "0")

# Make sure ES_COUNT is a number or default to 0
if ! [[ "$ES_COUNT" =~ ^[0-9]+$ ]]; then
    ES_COUNT=0
    echo "Warning: Could not get valid document count from Elasticsearch"
fi

echo "Found $ES_COUNT documents in Elasticsearch"

if [ "$ES_COUNT" -gt 0 ]; then
    echo "✅ Logstash successfully sent data to Elasticsearch"
else
    echo "❌ No data found in Elasticsearch, there might be an issue with Logstash
configuration"
fi
```

You see the syslog entries in your terminal echoed as they are sent to Elasticsearch. Use CTRL+C to exit out of Logstash once you've sent some data.

Start Kibana and visualize the data in Elasticsearch

Edit the Kibana configuration file (/etc/kibana/kibana.yml) and change the IP address Kibana listens on so you can access it from your web browser:

text

```
server.host: "0.0.0.0"
```

Start Kibana with the following command:

Bash

```
ssh azureuser@$PUBLIC_IP_ADDRESS -o StrictHostKeyChecking=no "
sudo systemctl start kibana.service
```

```
"
```

Open port 5601 from the Azure CLI to allow remote access to the Kibana console:

Azure CLI

```
az vm open-port --port 5601 --resource-group $RESOURCE_GROUP --name $VM_NAME
```

Next steps

In this tutorial, you deployed the Elastic Stack into a development VM in Azure. You learned how to:

- ✓ Create an Ubuntu VM in an Azure resource group
- ✓ Install Elasticsearch, Logstash, and Kibana on the VM
- ✓ Send sample data to Elasticsearch from Logstash
- ✓ Open ports and work with data in the Kibana console

What is confidential computing?

Article • 05/07/2025

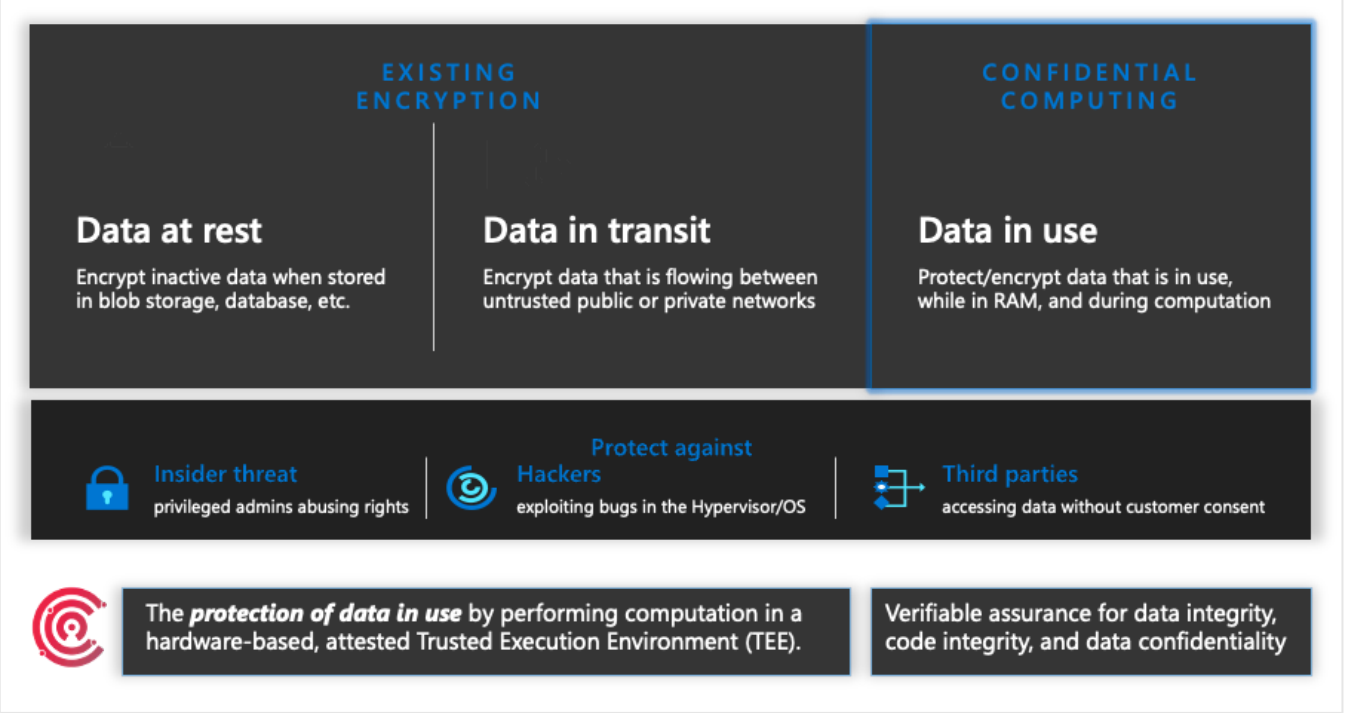
Confidential computing is an industry term established by the Confidential Computing Consortium (CCC), which is part of the Linux Foundation. The CCC defines confidential computing in this way:

"Confidential Computing protects data in use by performing computation in a hardware-based, attested Trusted Execution Environment.

"These secure and isolated environments prevent unauthorized access or modification of applications and data while they are in use, thereby increasing the security level of organizations that manage sensitive and regulated data."

Microsoft is one of the founding members of the CCC and provides Trusted Execution Environments (TEEs) in Azure based on this CCC definition.

Reducing the attack surface



Azure already encrypts data at rest and in transit. Confidential computing helps to protect data in use, including protection for cryptographic keys. Azure confidential computing helps customers prevent unauthorized access to data in use, including from the cloud operator, by processing data in a hardware-based and attested TEE. When Azure confidential computing is enabled and properly configured, Microsoft can't access unencrypted customer data.

The threat model aims to reduce trust or remove the ability for a cloud provider operator or other actors in the tenant's domain from accessing code and data while it's being executed.

Azure uses a hardware root of trust that isn't controlled by the cloud provider, which is designed to prevent unauthorized access or modification of the environment.

When confidential computing is used with data encryption at rest and in transit, it extends data protections further to protect data while confidential computing is in use. This capability is beneficial for organizations that seek further protection for sensitive data and applications hosted in cloud environments.

Industry partnership

The CCC brings together hardware vendors, cloud providers, and software developers to accelerate the adoption of TEE technologies and standards. Microsoft helped to cofound the CCC in 2019 and has chaired both the governing body and the Technical Advisory Council.

High-performance computing (HPC) on Azure

Introduction to HPC

https://www.youtube-nocookie.com/embed/rKURT32faJk

High-performance computing (HPC), also called *big compute*, uses a large number of CPU or GPU-based computers to solve complex mathematical tasks.

Many industries use HPC to solve some of their most difficult problems. These include workloads such as:

- Genomics
- Oil and gas simulations
- Finance
- Semiconductor design
- Engineering
- Weather modeling

How is HPC different on the cloud?

One of the primary differences between an on-premises HPC system and one in the cloud is the ability for resources to dynamically be added and removed as they're needed. Dynamic scaling removes compute capacity as a bottleneck and instead allow customers to right size their infrastructure for the requirements of their jobs.

The following articles provide more detail about this dynamic scaling capability.

- Big Compute Architecture Style
- Autoscaling best practices

Implementation checklist

As you're looking to implement your own HPC solution on Azure, ensure you've reviewed the following topics:

- ✓ Choose the appropriate architecture based on your requirements

- ✓ Know which compute options is right for your workload
- ✓ Identify the right storage solution that meets your needs
- ✓ Decide how you're going to manage all your resources
- ✓ Optimize your application for the cloud
- ✓ Secure your Infrastructure

Infrastructure

There are many infrastructure components that are necessary to build an HPC system. Compute, storage, and networking provide the underlying components, no matter how you choose to manage your HPC workloads.

Compute

Azure offers a range of sizes that are optimized for both CPU & GPU intensive workloads.

CPU-based virtual machines

- Linux VMs
- Windows VMs

GPU-enabled virtual machines

N-series VMs feature NVIDIA GPUs designed for compute-intensive or graphics-intensive applications including artificial intelligence (AI) learning and visualization.

- Linux VMs
- Windows VMs

Storage

Large-scale Batch and HPC workloads have demands for data storage and access that exceed the capabilities of traditional cloud file systems. There are many solutions that manage both the speed and capacity needs of HPC applications on Azure:

- Azure NetApp Files
- Storage Optimized Virtual Machines
- Blob, table, and queue storage
- Azure SMB File storage
- Azure Managed Lustre

For more information comparing Lustre, GlusterFS, and BeeGFS on Azure, review the Parallel Files Systems on Azure e-book and the Lustre on Azure blog.

Networking

H16r, H16mr, A8, and A9 VMs can connect to a high throughput back-end RDMA network. This network can improve the performance of tightly coupled parallel applications running under Microsoft Message Passing Interface better known as MPI or Intel MPI.

- RDMA Capable Instances
- Virtual Network
- ExpressRoute

Management

Do-it-yourself

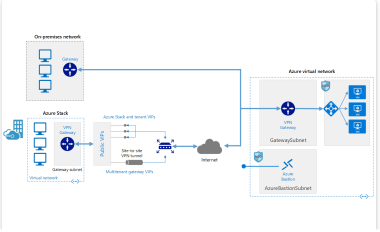
Building an HPC system from scratch on Azure offers a significant amount of flexibility, but it is often very maintenance intensive.

1. Set up your own cluster environment in Azure virtual machines or Virtual Machine Scale Sets.
2. Use Azure Resource Manager templates to deploy leading workload managers, infrastructure, and applications.
3. Choose HPC and GPU VM sizes that include specialized hardware and network connections for MPI or GPU workloads.
4. Add high-performance storage for I/O-intensive workloads.

Hybrid and cloud Bursting

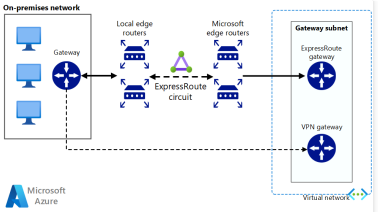
If you have an existing on-premises HPC system that you'd like to connect to Azure, there are several resources to help get you started.

First, review the Options for connecting an on-premises network to Azure article in the documentation. From there, you can find additional information on these connectivity options:



Connect an on-premises network to Azure using a VPN gateway

This reference architecture shows how to extend an on-premises network to Azure, using a site-to-site virtual private network (VPN).



Connect an on-premises network to Azure using ExpressRoute with VPN failover

Implement a highly available and secure site-to-site network architecture that spans an Azure virtual network and an on-premises network connected using ExpressRoute with VPN gateway failover.

Once network connectivity is securely established, you can start using cloud compute resources on-demand with the bursting capabilities of your existing workload manager.

Marketplace solutions

There are many workload managers offered in the Microsoft Marketplace.

- SUSE Linux Enterprise Server for HPC
- Azure Data Science VM for Windows and Linux
- UberCloud

Azure Batch

Azure Batch is a platform service for running large-scale parallel and HPC applications efficiently in the cloud. Azure Batch schedules compute-intensive work to run on a managed

pool of virtual machines, and can automatically scale compute resources to meet the needs of your jobs.

SaaS providers or developers can use the Batch SDKs and tools to integrate HPC applications or container workloads with Azure, stage data to Azure, and build job execution pipelines.

In Azure Batch all the services are running on the Cloud. The following image shows how the architecture looks with Azure Batch, having the scalability and job schedule configurations running in the Cloud while the results and reports can be sent to your on-premises environment.

Azure CycleCloud

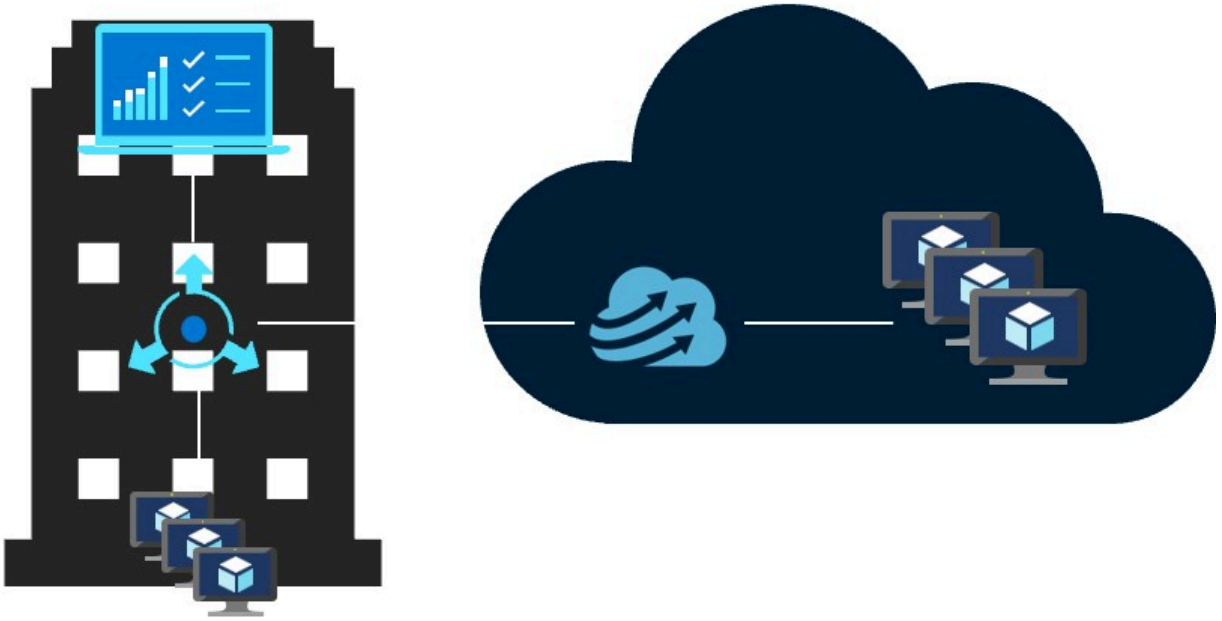
Azure CycleCloud Provides the simplest way to manage HPC workloads using any scheduler (like Slurm, Grid Engine, HPC Pack, HTCondor, LSF, PBS Pro, or Symphony), on Azure

CycleCloud allows you to:

- Deploy full clusters and other resources, including scheduler, compute VMs, storage, networking, and cache
- Orchestrate job, data, and cloud workflows
- Give admins full control over which users can run jobs, as well as where and at what cost
- Customize and optimize clusters through advanced policy and governance features, including cost controls, Active Directory integration, monitoring, and reporting
- Use your current job scheduler and applications without modification
- Take advantage of built-in autoscaling and battle-tested reference architectures for a wide range of HPC workloads and industries

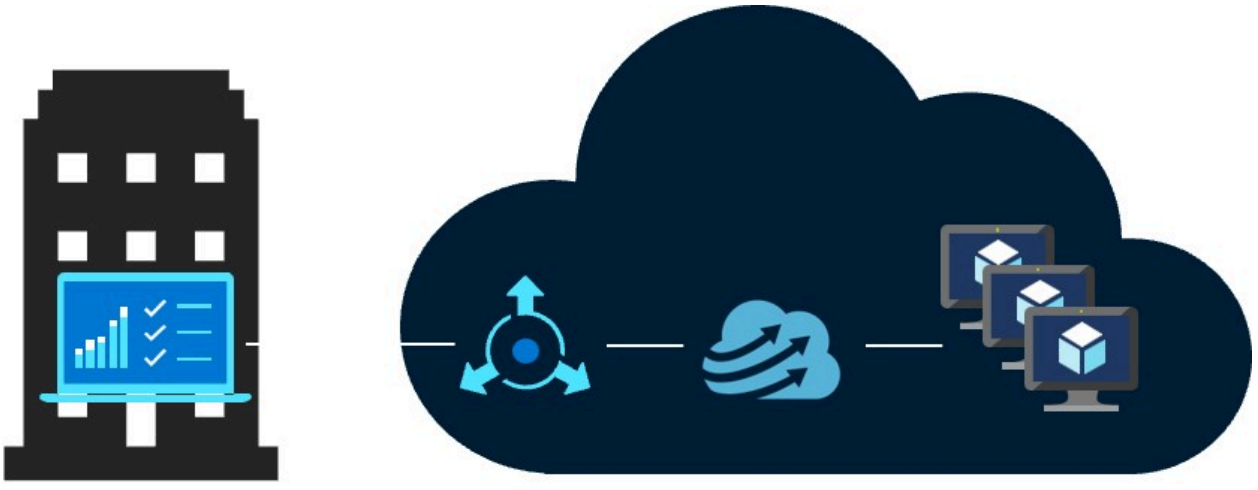
Hybrid / cloud bursting model

In this Hybrid example diagram, we can see clearly how these services are distributed between the cloud and the on-premises environment. Having the opportunity to run jobs in both workloads.



Cloud native model

The following cloud native model example diagram shows how the workload in the cloud will handle everything while still conserving the connection to the on-premises environment.



Comparison chart

Expand table

Feature	Azure Batch	Azure CycleCloud
Scheduler	Batch APIs and tools and command-line scripts in the Azure portal (Cloud Native).	Use standard HPC schedulers such as Slurm, PBS Pro, LSF, Grid Engine, and HTCondor, or extend CycleCloud autoscaling plugins to work with your own scheduler.

Feature	Azure Batch	Azure CycleCloud
Compute Resources	Software as a Service Nodes – Platform as a Service	Platform as a Service Software – Platform as a Service
Monitor Tools	Azure Monitor	Azure Monitor, Grafana
Customization	Custom image pools, Third Party images, Batch API access.	Use the comprehensive RESTful API to customize and extend functionality, deploy your own scheduler, and support into existing workload managers
Integration	Data Factory in Microsoft Fabric, Azure Data Factory, Azure CLI	Built-In CLI for Windows and Linux
User type	Developers	Classic HPC administrators and users
Work Type	Batch, Workflows	Tightly coupled (Message Passing Interface/MPI).
Windows Support	Yes	Varies, depending on scheduler choice

Workload managers

The following are examples of cluster and workload managers that can run in Azure infrastructure. Create stand-alone clusters in Azure VMs or burst to Azure VMs from an on-premises cluster.

- Alces Flight Compute
- Altair PBS Works
- Rescale
- Altair Grid Engine
- Microsoft HPC Pack
  - HPC Pack for Windows
  - HPC Pack for Linux

Containers

Containers can also be used to manage some HPC workloads. Services like the Azure Kubernetes Service (AKS) make it simple to deploy a managed Kubernetes cluster in Azure.

- Azure Kubernetes Service (AKS)
- Container Registry

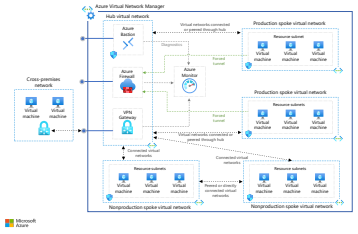
Cost management

Managing your HPC cost on Azure can be done through a few different ways. Ensure you've reviewed the Azure purchasing options to find the method that works best for your organization.

Security

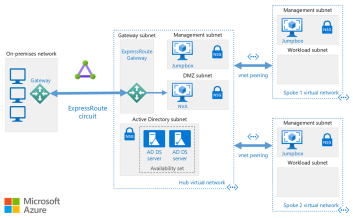
For an overview of security best practices on Azure, review the Azure Security Documentation.

In addition to the network configurations available in the Cloud Bursting section, you can implement a hub/spoke configuration to isolate your compute resources:



Implement a hub-spoke network topology in Azure

The hub is a virtual network (VNet) in Azure that acts as a central point of connectivity to your on-premises network. The spokes are VNets that peer with the hub, and can be used to isolate workloads.



Implement a hub-spoke network topology with shared services in Azure

This reference architecture builds on the hub-spoke reference architecture to include shared services in the hub that can be consumed by all spokes.

HPC applications

Run custom or commercial HPC applications in Azure. Several examples in this section are benchmarked to scale efficiently with additional VMs or compute cores. Visit the Microsoft Marketplace for ready-to-deploy solutions.

> **Note**
>
> Check with the vendor of any commercial application for licensing or other restrictions for running in the cloud. Not all vendors offer pay-as-you-go licensing. You might need a licensing server in the cloud for your solution, or connect to an on-premises license server.

Engineering applications

- MATLAB Distributed Computing Server
- StarCCM+

Graphics and rendering

- Autodesk Maya, 3ds Max, and Arnold on Azure Batch

AI and deep learning

- Microsoft Cognitive Toolkit

MPI providers

- Microsoft MPI

Remote visualization

Run GPU-powered virtual machines in Azure in the same region as the HPC output for the lowest latency, access, and to visualize remotely through Azure Virtual Desktop.

- GPU-optimized virtual machine sizes
- Configure GPU acceleration for Azure Virtual Desktop

Performance benchmarks

- Compute benchmarks

Other important information

- Ensure your vCPU quota has been increased before attempting to run large-scale workloads.

High-performance computing on InfiniBand enabled HB-series and N-series VMs

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure's InfiniBand enabled H-series and N-series VMs are designed to deliver leadership-class performance, Message Passing Interface (MPI) scalability, and cost efficiency for a variety of real-world HPC and AI workloads. These high-performance computing (HPC) optimized VMs are used to solve some of the most computationally intensive problems in science and engineering such as: fluid dynamics, earth modeling, weather simulations, etc.

These articles describe how to get started on the InfiniBand-enabled H-series and N-series VMs on Azure as well as optimal configuration of the HPC and AI workloads on the VMs for scalability.

Features and capabilities

The InfiniBand enabled HB-series and N-series VMs are designed to provide the best HPC performance, MPI scalability, and cost efficiency for HPC workloads. See HB-series and N-series VMs to learn more about the features and capabilities of the VMs.

RDMA and InfiniBand

RDMA capable HB-series and N-series VMs communicate over the low latency and high bandwidth InfiniBand network. The RDMA capability over such an interconnect is critical to boost the scalability and performance of distributed-node HPC and AI workloads. The InfiniBand enabled H-series and N-series VMs are connected in a non-blocking fat tree with a low-diameter design for optimized and consistent RDMA performance. See Enable InfiniBand to learn more about setting up InfiniBand on the InfiniBand enabled VMs.

Message passing interface

The SR-IOV enabled HB-series and N-series support almost all MPI libraries and versions. Some of the most commonly used MPI libraries are: Intel MPI, OpenMPI, HPC-X, MVAPICH2, MPICH, Platform MPI. All remote direct memory access (RDMA) verbs are supported. See Set up MPI to learn more about installing various supported MPI libraries and their optimal configuration.

Get started

The first step is to select the HB-series and N-series VM type optimal for the workload based on the VM specifications and RDMA capability. Second, configure the VM by enabling InfiniBand. There are various methods to doing this including using optimized VM images with drivers baked-in; see Optimization for Linux and Enable InfiniBand for details. Third, for distributed node workloads, choosing and configuring MPI appropriately is critical. See Set up MPI for details. Fourth, for performance and scalability, optimally configure the workloads by following guidance specific to the VM family, such as for HBv3-series overview and HC-series overview.

Next steps

- Learn about configuring and optimizing the InfiniBand enabled HB-series and N-series VMs.
- Review the HBv3-series overview and HC-series overview to learn about optimally configuring workloads for performance and scalability.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- Test your knowledge with a learning module on optimizing HPC applications on Azure.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Set up Azure HPC or AI VMs

08/22/2024

This how-to guide explains how to create a basic Azure virtual machine (VM) for HPC and AI with NVIDIA or AMD GPUs. These VM sizes are intended for workloads that require high-performance computing (HPC sizes), or GPU-accelerated computing (AI sizes).

Choose your VM size

Azure VMs have many different options, called VM sizes. There are different series of VM sizes for HPC and VM sizes GPU-optimized computing. Select the appropriate VM size for the workload you want to use. For help with selecting sizes, see the VM selector tool.

Not all Azure products are available in all Azure regions. For more information, see the current list of products available by region.

Create your VM

Before you can deploy a workload, you need to create your VM through the Azure portal.

Depending on your VM's operating system, review either the Linux VM quickstart or Windows VM quickstart. Then, create your VM with the following settings:

1. For **Subscription**, select the Azure subscription that you want to use for this VM.
2. For **Region**, select a region with capacity available for your VM size.
3. For **Image**, select the image of the VM you chose in the previous section.

   > **Note**
   >
   > For the purpose of example, this guide uses the image **NVIDIA GPU-Optimized Image for AI & HPC – v21.04.1 – Gen 1**. If you're using another image, you might need to install other software, like the NVIDIA driver and Docker, before proceeding.

4. For **Size**, select the HPC or GPU instance type. For more information, see how to choose your VM size.
5. For **SSH public key source**, select **Generate a new key pair**.
6. Wait for key validation to complete.

7. When prompted, select **Download private key and create resource**.

   > ⓘ Note
   >
   > Downloading the key pair is necessary to SSH into your VM for later configuration.

8. For **Key pair name**, enter a name for your key pair.

9. Under the **Networking** tab, make sure **Accelerated Networking** is disabled.

10. Optionally, add a data disk to your VM. For more information, see how to add a data disk to a Linux VM or to a Windows VM.

    > ⓘ Note
    >
    > Adding a data disk helps you store models, data sets, and other necessary components for benchmarking.

11. Select **Review + create** to create your VM.

Connect to your VM

Connect to your new VM using SSH, which allows you to perform further configuration. Some connection methods include:

- Connect over SSH on Linux or macOS
- Connect over SSH on Windows
- Connect over SSH using Azure Bastion

Set up VM

Set up your new VM for HPC or AI workloads. Install the newest NVIDIA or AMD GPU driver, which maps to your VM size.

- Install NVIDIA GPU drivers on N-series VMs running Linux
- Install NVIDIA GPU drivers on N-series VMs running Windows
- Install AMD GPU drivers on N-series VMs running Windows

Next steps

- High performance computing VM sizes

- GPU optimized virtual machine sizes

Configure and optimize the InfiniBand enabled H-series and N-series VMs

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article shares some guidance on configuring and optimizing the InfiniBand-enabled HB-series and N-series VMs for HPC.

VM images

On InfiniBand (IB) enabled VMs, the appropriate IB drivers are required to enable RDMA.

- The Ubuntu-HPC VM images in the Marketplace come preconfigured with the appropriate NVIDIA IB drivers and GPU drivers.
- The AlmaLinux-HPC VM images in the Marketplace come preconfigured with the appropriate NVIDIA IB drivers and GPU drivers.

These VM images are based on the base Ubuntu and AlmaLinux marketplace VM images. Scripts used in the creation of these VM images from their base marketplace images are on the azhpc-images repo.

On GPU enabled N-series VMs, the appropriate GPU drivers are additionally required. This can be available by the following methods:

- Use the Ubuntu-HPC VM images or AlmaLinux-HPC VM images that come preconfigured with the NVIDIA GPU drivers and GPU compute software stack (CUDA, NCCL).
- Add the GPU drivers through the VM extensions.
- Install the GPU drivers manually.
- Some other VM images on the Marketplace also come preinstalled with the NVIDIA GPU drivers, including some VM images from NVIDIA.

Depending on the workloads' Linux distro and version needs, Ubuntu-HPC VM images and AlmaLinux-HPC VM images on the Marketplace are the easiest way to get started with HPC and AI workloads on Azure. It's also recommended to create custom VM images with workload specific customization and configuration for reuse.

VM sizes supported by the HPC VM images

InfiniBand OFED support

The latest Azure HPC marketplace images come with Mellanox OFED 5.1 and above, which do not support ConnectX3-Pro InfiniBand cards. ConnectX-3 Pro InfiniBand cards require MOFED 4.9 LTS version. These VM images only support ConnextX-5 and newer InfiniBand cards. The following VM size support matrix for the InfiniBand OFED in these HPC VM images:

- HB-series: HB, HC, HBv2, HBv3, HBv4
- N-series: NDv2, NDv4

GPU driver support

Currently only the Ubuntu-HPC VM images and AlmaLinux-HPC VM images come preconfigured with the NVIDIA GPU drivers and GPU compute software stack (CUDA, NCCL).

The VM size support matrix for the GPU drivers in supported HPC VM images is as follows:

- N-series: NDv2, NDv4 VM sizes are supported with the NVIDIA GPU drivers and GPU compute software stack (CUDA, NCCL).
- The other 'NC' and 'ND' VM sizes in the N-series are supported with the NVIDIA GPU drivers.

All of the VM sizes in the N-series support Gen 2 VMs, though some older ones also support Gen 1 VMs. Gen 2 support is also indicated with a "01" at the end of the image URN or version.

SR-IOV enabled VMs

Ubuntu-HPC VM images

For SR-IOV enabled RDMA capable VMs, Ubuntu-HPC VM images versions 18.04, 20.04, and 22.04 are suitable. These VM images come preconfigured with the Mellanox OFED drivers for RDMA, NVIDIA GPU drivers, GPU compute software stack (CUDA, NCCL), and commonly used MPI libraries and scientific computing packages. Refer to the VM size support matrix.

- The available or latest versions of the VM images can be listed with the following information using CLI or Marketplace.

  Output

  ```
  "publisher": "Microsoft-DSVM",
  "offer": "Ubuntu-HPC",
  ```

- Scripts used in the creation of the Ubuntu-HPC VM images from a base Ubuntu Marketplace image are on the azhpc-images repo.

AlmaLinux-HPC VM images

For SR-IOV enabled RDMA capable VMs, AlmaLinux-HPC VM images versions 8.5, 8.6, and 8.7 are suitable. These VM images come preconfigured with the Mellanox OFED drivers for RDMA, NVIDIA GPU drivers, GPU compute software stack (CUDA, NCCL), and commonly used MPI libraries and scientific computing packages. Refer to the VM size support matrix.

- The available or latest versions of the VM images can be listed with the following information using CLI or Marketplace.

  Output

  ```
  "publisher": "AlmaLinux",
  "offer": "AlmaLinux-HPC",
  ```

- Scripts used in the creation of the AlmaLinux-HPC VM images from a base AlmaLinux Marketplace image are on the azhpc-images repo.

Additionally, more details on what's included in the Ubuntu-HPC VM images and AlmaLinux-HPC VM images, and how to deploy them are in Azure HPC VM images.

RHEL VM images

The base RHEL-based non-HPC VM images on the Marketplace can be configured for use on the SR-IOV enabled RDMA capable VMs. Learn more about enabling InfiniBand and setting up MPI on the VMs.

Ubuntu VM images

The base Ubuntu Server 20.04 LTS and 22.04 LTS VM images in the Marketplace are supported for both SR-IOV and non-SR-IOV RDMA capable VMs. Learn more about enabling InfiniBand and setting up MPI on the VMs.

- Instructions for enabling InfiniBand on the Ubuntu VM images are in a TechCommunity article.

> **Note**
>
> Mellanox OFED 5.1 and above don't support ConnectX3-Pro InfiniBand cards on SR-IOV enabled N-series VM sizes with FDR InfiniBand (e.g. NCv3). Please use LTS Mellanox OFED version 4.9-0.1.7.0 or older on the N-series VM's with ConnectX3-Pro cards. For more information, see **Linux InfiniBand Drivers**.

SUSE Linux Enterprise Server VM images

SLES 12 SP3 for HPC, SLES 12 SP3 for HPC (Premium), SLES 12 SP1 for HPC, SLES 12 SP1 for HPC (Premium), SLES 12 SP4 and SLES 15 VM images in the Marketplace are supported. These VM images come preloaded with the Network Direct drivers for RDMA (on the non-SR-IOV VM sizes) and Intel MPI version 5.1. Learn more about setting up MPI on the VMs.

Optimize VMs

The following are some optional optimization settings for improved performance on the VM.

Update LIS

If necessary for functionality or performance, Linux Integration Services (LIS) drivers can be installed or updated on supported OS distros, especially is deploying using a custom image or an older OS version such as RHEL 6.x or earlier version of 7.x.

Bash

```
wget https://aka.ms/lis
tar xzf lis
pushd LISISO
sudo ./upgrade.sh
```

Reclaim memory

Improve performance by automatically reclaiming memory to avoid remote memory access.

Bash

```
sudo echo 1 >/proc/sys/vm/zone_reclaim_mode
```

Keep reclaim memory mode persistent after VM reboots:

Bash

```
sudo echo "vm.zone_reclaim_mode = 1" >> /etc/sysctl.conf sysctl -p
```

Disable firewall and SELinux

Bash

```
sudo systemctl stop iptables.service
sudo systemctl disable iptables.service
sudo systemctl mask firewalld
sudo systemctl stop firewalld.service
sudo systemctl disable firewalld.service
sudo iptables -nL
sudo sed -i -e's/SELINUX=enforcing/SELINUX=disabled/g' /etc/selinux/config
```

Disable cpupower

Bash

```
sudo service cpupower status
```

If enabled, disable it:

Bash

```
sudo service cpupower stop
sudo systemctl disable cpupower
```

Configure WALinuxAgent

Bash

```
sudo sed -i -e 's/# OS.EnableRDMA=y/OS.EnableRDMA=y/g' /etc/waagent.conf
```

Optionally, the WALinuxAgent may be disabled before running a job then enabled post-job for maximum VM resource availability to the HPC workload.

Next steps

- Learn more about enabling InfiniBand on the InfiniBand-enabled HB-series and N-series VMs.
- Learn more about installing and running various supported MPI libraries on the VMs.
- Review the HBv3-series overview and HC-series overview.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Last updated on 08/22/2024

Enable InfiniBand

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

RDMA capable HB-series and N-series VMs communicate over the low latency and high bandwidth InfiniBand network. The RDMA capability over such an interconnect is critical to boost the scalability and performance of distributed-node HPC and AI workloads. The InfiniBand enabled HB-series and N-series VMs are connected in a non-blocking fat tree with a low-diameter design for optimized and consistent RDMA performance.

There are various ways to enable InfiniBand on the capable VM sizes.

> **Note**
>
> Try VM assist for faster diagnostics. We recommend that you run VM assist for Windows or VM assist for Linux. These script-based diagnostic tools help you to identify common issues that affect the Azure VM Guest Agent and overall VM health.
>
> If you're experiencing performance problems with virtual machines, before contacting support, run these tools.

VM Images with InfiniBand drivers

See VM Images for a list of supported VM Images on the Marketplace, which come pre-loaded with InfiniBand drivers (for SR-IOV or non-SR-IOV VMs) or can be configured with the appropriate drivers for RDMA capable VMs. The Ubuntu-HPC and AlmaLinux-HPC VM images in the marketplace are the easiest way to get started.

InfiniBand Driver VM Extensions

On Linux, the InfiniBandDriverLinux VM extension can be used to install the Mellanox OFED drivers and enable InfiniBand on the SR-IOV enabled HB-series and N-series VMs.

On Windows, the InfiniBandDriverWindows VM extension installs Windows Network Direct drivers (on non-SR-IOV VMs) or Mellanox OFED drivers (on SR-IOV VMs) for RDMA connectivity. In certain deployments of A8 and A9 instances, the HpcVmDrivers extension is added automatically. Note that the HpcVmDrivers VM extension is being deprecated; it will not be updated.

To add the VM extension to a VM, you can use Azure PowerShell cmdlets. For more information, see Virtual machine extensions and features. You can also work with extensions for

VMs deployed in the classic deployment model.

Manual installation

Mellanox OpenFabrics drivers (OFED) can be manually installed on the SR-IOV enabled HB-series and N-series VMs.

Linux

The OFED drivers for Linux can be installed with the example below. Though the example here is for RHEL, but the steps are general and can be used for any compatible Linux operating system such as Ubuntu (22.04, 24.04) and SLES (12 SP4+ and 15). More examples for other distros are on the azhpc-images repo. The inbox drivers also work as well, but the Mellanox OFED drivers provide more features.

Bash

```
MLNX_OFED_DOWNLOAD_URL=http://content.mellanox.com/ofed/MLNX_OFED-5.0-
2.1.8.0/MLNX_OFED_LINUX-5.0-2.1.8.0-rhel7.7-x86_64.tgz
# Optionally verify checksum
wget --retry-connrefused --tries=3 --waitretry=5 $MLNX_OFED_DOWNLOAD_URL
tar zxvf MLNX_OFED_LINUX-5.0-2.1.8.0-rhel7.7-x86_64.tgz

KERNEL=( $(rpm -q kernel | sed 's/kernel\-//g') )
KERNEL=${KERNEL[-1]}
# Uncomment the lines below if you are running this on a VM
#RELEASE=( $(cat /etc/redhat-release | awk '{print $4}') )
#yum -y install
http://olcentgbl.trafficmanager.net/redhat/${RELEASE}/updates/x86_64/kernel-
devel-${KERNEL}.rpm
sudo yum install -y kernel-devel-${KERNEL}
sudo ./MLNX_OFED_LINUX-5.0-2.1.8.0-rhel7.7-x86_64/mlnxofedinstall --kernel $KERNEL -
-kernel-sources /usr/src/kernels/${KERNEL} --add-kernel-support --skip-repo
```

Windows

For Windows, download and install the Mellanox OFED for Windows drivers.

Enable IP over InfiniBand (IB)

If you plan to run MPI jobs, you typically don't need IPoIB. The MPI library will use the verbs interface for IB communication (unless you explicitly use the TCP/IP channel of MPI library). But if you have an app that uses TCP/IP for communication and you want to run over IB, you can

use IPoIB over the IB interface. Use the following commands (for RHEL) to enable IP over InfiniBand.

> **Important**
>
> To avoid issues, ensure you aren't running older versions of Microsoft Azure Linux Agent (waagent). We recommend using at least version 2.4.0.2 before enabling IP over IB.

Bash

```
sudo sed -i -e 's/# OS.EnableRDMA=n/OS.EnableRDMA=y/g' /etc/waagent.conf
sudo systemctl restart waagent
```

Next steps

- Learn more about installing and running various supported MPI libraries on the VMs.
- Review the HBv3-series overview and HC-series overview.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Last updated on 12/03/2025

Set up Message Passing Interface for HPC

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The Message Passing Interface (MPI) is an open library and defacto standard for distributed memory parallelization. It's commonly used across many HPC workloads. HPC workloads on the RDMA capable HB-series and N-series VMs can use MPI to communicate over the low latency and high bandwidth InfiniBand network.

- The SR-IOV enabled VM sizes on Azure allow almost any flavor of MPI to be used with Mellanox OFED.
- On non-SR-IOV enabled VMs, supported MPI implementations use the Microsoft Network Direct (ND) interface to communicate between VMs. Hence, only Microsoft MPI (MS-MPI) 2012 R2 or later and Intel MPI 5.x versions are supported. Later versions (2017, 2018) of the Intel MPI runtime library may or may not be compatible with the Azure RDMA drivers.

For SR-IOV enabled RDMA capable VMs, Ubuntu-HPC VM images and AlmaLinux-HPC VM images are suitable. These VM images come optimized and preloaded with the OFED drivers for RDMA and various commonly used MPI libraries and scientific computing packages and are the easiest way to get started.

Though the examples here are for RHEL, but the steps are general and can be used for any compatible Linux operating system such as Ubuntu (18.04, 20.04, 22.04) and SLES (12 SP4 and 15 SP4). More examples for setting up other MPI implementations on others distros is on the azhpc-images repo.

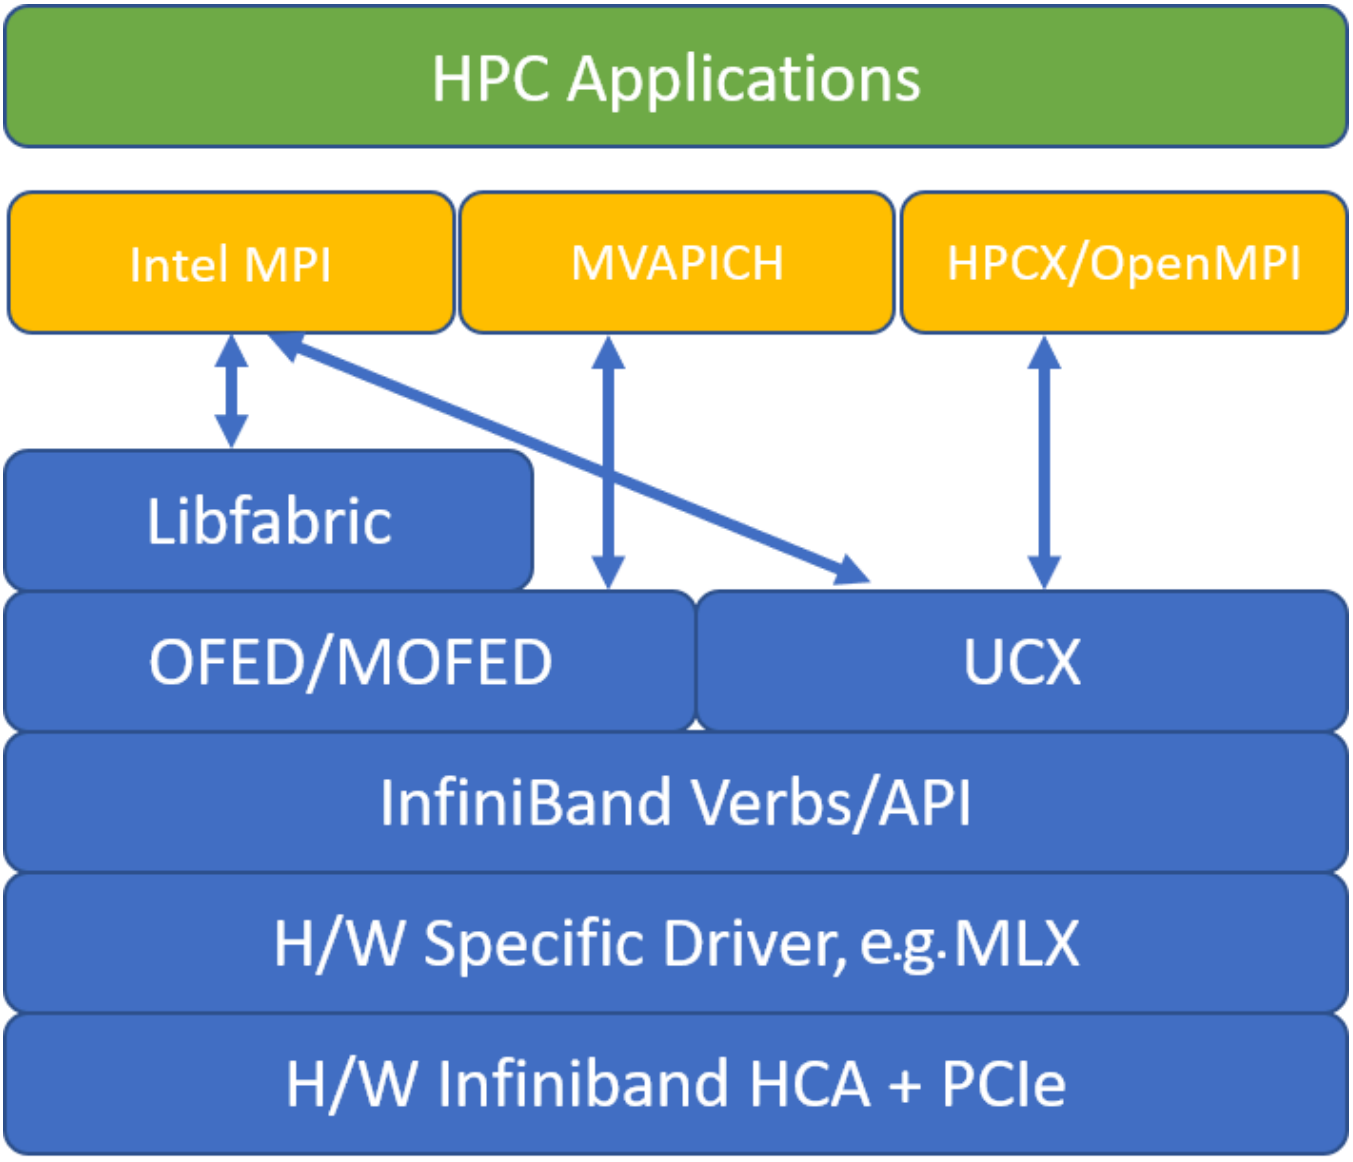
> **Note**
>
> Running MPI jobs on SR-IOV enabled VMs with certain MPI libraries (such as Platform MPI) may require setting up of partition keys (p-keys) across a tenant for isolation and security. Follow the steps in the **Discover partition keys** section for details on determining the p-key values and setting them correctly for an MPI job with that MPI library.

> **Note**
>
> The code snippets below are examples. We recommend using the latest stable versions of the packages, or referring to the **azhpc-images repo**.

Choosing MPI library

If an HPC application recommends a particular MPI library, try that version first. If you have flexibility regarding which MPI you can choose, and you want the best performance, try HPC-X. Overall, the HPC-X MPI performs the best by using the UCX framework for the InfiniBand interface, and takes advantage of all the Mellanox InfiniBand hardware and software capabilities. Additionally, HPC-X and OpenMPI are ABI compatible, so you can dynamically run an HPC application with HPC-X that was built with OpenMPI. Similarly, Intel MPI, MVAPICH, and MPICH are ABI compatible.

The following figure illustrates the architecture for the popular MPI libraries.



HPC-X

The HPC-X software toolkit contains UCX and HCOLL and can be built against UCX.

Bash

```
HPCX_VERSION="v2.6.0"
HPCX_DOWNLOAD_URL=https://azhpcstor.blob.core.windows.net/azhpc-images-store/hpcx-
```

```
v2.6.0-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-redhat7.7-x86_64.tbz
wget --retry-connrefused --tries=3 --waitretry=5 $HPCX_DOWNLOAD_URL
tar -xvf hpcx-${HPCX_VERSION}-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-redhat7.7-x86_64.tbz
mv hpcx-${HPCX_VERSION}-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-redhat7.7-x86_64
${INSTALL_PREFIX}
HPCX_PATH=${INSTALL_PREFIX}/hpcx-${HPCX_VERSION}-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-
redhat7.7-x86_64
```

The following command illustrates some recommended mpirun arguments for HPC-X and OpenMPI.

Bash

```
mpirun -n $NPROCS --hostfile $HOSTFILE --map-by
ppr:$NUMBER_PROCESSES_PER_NUMA:numa:pe=$NUMBER_THREADS_PER_PROCESS -report-bindings
$MPI_EXECUTABLE
```

where:

Expand table

Parameter	Description
`NPROCS`	Specifies the number of MPI processes. For example: `-n 16`.
`$HOSTFILE`	Specifies a file containing the hostname or IP address, to indicate the location of where the MPI processes run. For example: `--hostfile hosts`.
`$NUMBER_PROCESSES_PER_NUMA`	Specifies the number of MPI processes that run in each NUMA domain. For example, to specify four MPI processes per NUMA, you use `--map-by ppr:4:numa:pe=1`.
`$NUMBER_THREADS_PER_PROCESS`	Specifies the number of threads per MPI process. For example, to specify one MPI process and four threads per NUMA, you use `--map-by ppr:1:numa:pe=4`.
`-report-bindings`	Prints MPI processes mapping to cores, which is useful to verify that your MPI process pinning is correct.
`$MPI_EXECUTABLE`	Specifies the MPI executable built linking in MPI libraries. MPI compiler wrappers do this automatically. For example: `mpicc` or `mpif90`.

An example of running the OSU latency microbenchmark is as follows:

Bash

```
${HPCX_PATH}mpirun -np 2 --map-by ppr:2:node -x UCX_TLS=rc
${HPCX_PATH}/ompi/tests/osu-micro-benchmarks-5.3.2/osu_latency
```

Optimizing MPI collectives

MPI Collective communication primitives offer a flexible, portable way to implement group communication operations. They're widely used across various scientific parallel applications and have a significant impact on the overall application performance. Refer to the TechCommunity article for details on configuration parameters to optimize collective communication performance using HPC-X and HCOLL library for collective communication.

As an example, if you suspect your tightly coupled MPI application is doing an excessive amount of collective communication, you can try enabling hierarchical collectives (HCOLL). To enable those features, use the following parameters.

Bash

```
-mca coll_hcoll_enable 1 -x HCOLL_MAIN_IB=<MLX device>:<Port>
```

> **Note**
>
> With HPC-X 2.7.4+, it may be necessary to explicitly pass LD_LIBRARY_PATH if the UCX version on MOFED vs. that in HPC-X is different.

OpenMPI

Install UCX as described above. HCOLL is part of the HPC-X software toolkit and doesn't requires special installation.

OpenMPI can be installed from the packages available in the repo.

Bash

```
sudo yum install -y openmpi
```

We recommend building a latest, stable release of OpenMPI with UCX.

Bash

```
OMPI_VERSION="4.0.3"
OMPI_DOWNLOAD_URL=https://download.open-mpi.org/release/open-
mpi/v4.0/openmpi-${OMPI_VERSION}.tar.gz
wget --retry-connrefused --tries=3 --waitretry=5 $OMPI_DOWNLOAD_URL
tar -xvf openmpi-${OMPI_VERSION}.tar.gz
cd openmpi-${OMPI_VERSION}
./configure --prefix=${INSTALL_PREFIX}/openmpi-${OMPI_VERSION} --with-
```

```
ucx=${UCX_PATH} --with-hcoll=${HCOLL_PATH} --enable-mpirun-prefix-by-default --with-platform=contrib/platform/mellanox/optimized && make -j$(nproc) && make install
```

For optimal performance, run OpenMPI with `ucx` and `hcoll`. Also see the example with HPC-X.

Bash

```
${INSTALL_PREFIX}/bin/mpirun -np 2 --map-by node --hostfile ~/hostfile -mca pml ucx --mca btl ^vader,tcp,openib -x UCX_NET_DEVICES=mlx5_0:1  -x UCX_IB_PKEY=0x0003 ./osu_latency
```

Check your partition key as mentioned above.

Intel MPI

Download your choice of version of Intel MPI. The Intel MPI 2019 release switched from the Open Fabrics Alliance (OFA) framework to the Open Fabrics Interfaces (OFI) framework, and currently supports libfabric. There are two providers for InfiniBand support: mlx and verbs. Change the I_MPI_FABRICS environment variable depending on the version.

- Intel MPI 2019 and 2021: use `I_MPI_FABRICS=shm:ofi`, `I_MPI_OFI_PROVIDER=mlx`. The `mlx` provider uses UCX. Usage of verbs has been found to be unstable and less performant. See the TechCommunity article for more details.
- Intel MPI 2018: use `I_MPI_FABRICS=shm:ofa`
- Intel MPI 2016: use `I_MPI_DAPL_PROVIDER=ofa-v2-ib0`

Here are some suggested mpirun arguments for Intel MPI 2019 update 5+.

Bash

```
export FI_PROVIDER=mlx
export I_MPI_DEBUG=5
export I_MPI_PIN_DOMAIN=numa

mpirun -n $NPROCS -f $HOSTFILE $MPI_EXECUTABLE
```

where:

Expand table

Parameter	Description
`FI_PROVIDER`	Specifies which libfabric provider to use, which will affect the API, protocol, and network used. verbs is another option, but generally mlx gives you better performance.

Parameter	Description
`I_MPI_DEBUG`	Specifies the level of extra debug output, which can provide details about where processes are pinned, and which protocol and network are used.
`I_MPI_PIN_DOMAIN`	Specifies how you want to pin your processes. For example, you can pin to cores, sockets, or NUMA domains. In this example, you set this environmental variable to numa, which means processes will be pinned to NUMA node domains.

Optimizing MPI collectives

There are some other options that you can try, especially if collective operations are consuming a significant amount of time. Intel MPI 2019 update 5+ supports the provide mlx and uses the UCX framework to communicate with InfiniBand. It also supports HCOLL.

Bash

```
export FI_PROVIDER=mlx
export I_MPI_COLL_EXTERNAL=1
```

Non SR-IOV VMs

For non SR-IOV VMs, an example of downloading the 5.x runtime free evaluation version is as follows:

Bash

```
wget http://registrationcenter-
download.intel.com/akdlm/irc_nas/tec/9278/l_mpi_p_5.1.3.223.tgz
```

For installation steps, see the Intel MPI Library Installation Guide. Optionally, you may want to enable ptrace for non-root non-debugger processes (needed for the most recent versions of Intel MPI).

Bash

```
echo 0 | sudo tee /proc/sys/kernel/yama/ptrace_scope
```

SUSE Linux

For SUSE Linux Enterprise Server VM image versions - SLES 12 SP3 for HPC, SLES 12 SP3 for HPC (Premium), SLES 12 SP1 for HPC, SLES 12 SP1 for HPC (Premium), SLES 12 SP4 and SLES

15, the RDMA drivers are installed and Intel MPI packages are distributed on the VM. Install Intel MPI by running the following command:

```bash
sudo rpm -v -i --nodeps /opt/intelMPI/intel_mpi_packages/*.rpm
```

MVAPICH

The following is an example of building MVAPICH2. Note newer versions may be available than what is used below.

```bash
wget http://mvapich.cse.ohio-state.edu/download/mvapich/mv2/mvapich2-2.3.tar.gz
tar -xv mvapich2-2.3.tar.gz
cd mvapich2-2.3
./configure --prefix=${INSTALL_PREFIX}
make -j 8 && make install
```

An example of running the OSU latency microbenchmark is as follows:

```bash
${INSTALL_PREFIX}/bin/mpirun_rsh -np 2 -hostfile ~/hostfile MV2_CPU_MAPPING=48
./osu_latency
```

The following list contains several recommended `mpirun` arguments.

```bash
export MV2_CPU_BINDING_POLICY=scatter
export MV2_CPU_BINDING_LEVEL=numanode
export MV2_SHOW_CPU_BINDING=1
export MV2_SHOW_HCA_BINDING=1

mpirun -n $NPROCS -f $HOSTFILE $MPI_EXECUTABLE
```

where:

Expand table

Parameter	Description
`MV2_CPU_BINDING_POLICY`	Specifies which binding policy to use, which will affect how processes are pinned to core IDs. In this case, you specify `scatter`, so processes are evenly

Parameter	Description
	scattered among the NUMA domains.
`MV2_CPU_BINDING_LEVEL`	Specifies where to pin processes. In this case, you set it to numanode, which means processes are pinned to units of NUMA domains.
`MV2_SHOW_CPU_BINDING`	Specifies if you want to get debug information about where the processes are pinned.
`MV2_SHOW_HCA_BINDING`	Specifies if you want to get debug information about which host channel adapter each process is using.

Platform MPI

Install required packages for Platform MPI Community Edition.

Bash

```
sudo yum install libstdc++.i686
sudo yum install glibc.i686
Download platform MPI at
https://www.ibm.com/developerworks/downloads/im/mpi/index.html
sudo ./platform_mpi-09.01.04.03r-ce.bin
```

Follow the installation process.

MPICH

Install UCX as described above. Build MPICH.

Bash

```
wget https://www.mpich.org/static/downloads/3.3/mpich-3.3.tar.gz
tar -xvf mpich-3.3.tar.gz
cd mpich-3.3
./configure --with-ucx=${UCX_PATH} --prefix=${INSTALL_PREFIX} --with-device=ch4:ucx
make -j 8 && make install
```

Running MPICH.

Bash

```
${INSTALL_PREFIX}/bin/mpiexec -n 2 -hostfile ~/hostfile -env UCX_IB_PKEY=0x0003 -
bind-to hwthread ./osu_latency
```

Check your partition key as mentioned above.

OSU MPI Benchmarks

Download OSU MPI Benchmarks and untar.

```Bash
wget http://mvapich.cse.ohio-state.edu/download/mvapich/osu-micro-benchmarks-5.5.tar.gz
tar -xvf osu-micro-benchmarks-5.5.tar.gz
cd osu-micro-benchmarks-5.5
```

Build Benchmarks using a particular MPI library:

```Bash
CC=<mpi-install-path/bin/mpicc>CXX=<mpi-install-path/bin/mpicxx> ./configure
make
```

MPI Benchmarks are under `mpi/` folder.

Discover partition keys

Discover partition keys (p-keys) for communicating with other VMs within the same tenant (Availability Set or Virtual Machine Scale Set).

```Bash
/sys/class/infiniband/mlx5_0/ports/1/pkeys/0
/sys/class/infiniband/mlx5_0/ports/1/pkeys/1
```

The larger of the two is the tenant key that should be used with MPI. Example: If the following are the p-keys, 0x800b should be used with MPI.

```Bash
cat /sys/class/infiniband/mlx5_0/ports/1/pkeys/0
0x800b
cat /sys/class/infiniband/mlx5_0/ports/1/pkeys/1
0x7fff
```

Note interfaces are named as `mlx5_ib*` inside HPC VM images.

Also note that as long as the tenant (Availability Set or Virtual Machine Scale Set) exists, the PKEYs remain the same. This is true even when nodes are added/deleted. New tenants get different PKEYs.

Set up user limits for MPI

Set up user limits for MPI.

Bash

```
cat << EOF | sudo tee -a /etc/security/limits.conf
*               hard    memlock         unlimited
*               soft    memlock         unlimited
*               hard    nofile          65535
*               soft    nofile          65535
EOF
```

Set up SSH keys for MPI

Set up SSH keys for MPI types that require it.

Bash

```
ssh-keygen -f /home/$USER/.ssh/id_rsa -t rsa -N ''
cat << EOF > /home/$USER/.ssh/config
Host *
    StrictHostKeyChecking no
EOF
cat /home/$USER/.ssh/id_rsa.pub >> /home/$USER/.ssh/authorized_keys
chmod 600 /home/$USER/.ssh/authorized_keys
chmod 644 /home/$USER/.ssh/config
```

The above syntax assumes a shared home directory, else `.ssh` directory must be copied to each node.

Scaling HPC applications

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Optimal scale-up and scale-out performance of HPC applications on Azure requires performance tuning and optimization experiments for the specific workload. This section and the VM series-specific pages offer general guidance for scaling your applications.

Application setup

The azurehpc repo contains many examples of:

- Setting up and running applications optimally.
- Configuration of file systems, and clusters.
- Tutorials on how to get started easily with some common application workflows.

Optimally scaling MPI

The following suggestions apply for optimal application scaling efficiency, performance, and consistency:

- For smaller scale jobs (< 256K connections) use: `UCX_TLS=rc,sm`
- For larger scale jobs (> 256K connections) use: `UCX_TLS=dc,sm`
- To calculate the number of connections for your MPI job, use: `Max Connections = (processes per node) x (number of nodes per job) x (number of nodes per job)`

Adaptive Routing

Adaptive Routing (AR) allows Azure Virtual Machines (VMs) running EDR and HDR InfiniBand to automatically detect and avoid network congestion by dynamically selecting optimal network paths. As a result, AR offers improved latency and bandwidth on the InfiniBand network, which in turn drives higher performance and scaling efficiency. For more information, see TechCommunity article.

Process pinning

- Pin processes to cores using a sequential pinning approach (as opposed to an autobalance approach).
- Binding by Numa/Core/HwThread is better than default binding.

- For hybrid parallel applications (OpenMP+MPI), use four threads and one MPI rank per [CCX](HB-series virtual machines overview including info on CCXs) on HB and HBv2 VM sizes.
- For pure MPI applications, experiment with between one to four MPI ranks per CCX for optimal performance on HB and HBv2 VM sizes.
- Some applications with extreme sensitivity to memory bandwidth may benefit from using a reduced number of cores per CCX. For these applications, using three or two cores per CCX may reduce memory bandwidth contention and yield higher real-world performance or more consistent scalability. In particular, MPI 'Allreduce' may benefit from this approach.
- For larger scale runs, it's recommended to use UD or hybrid RC+UD transports. Many MPI libraries/runtime libraries use these transports internally (such as UCX or MVAPICH2). Check your transport configurations for large-scale runs.

Compiling applications

▼ Click to expand

Though not necessary, compiling applications with appropriate optimization flags provides the best scale-up performance on HB and HC-series VMs.

AMD Optimizing C/C++ Compiler

The AMD Optimizing C/C++ Compiler (AOCC) compiler system offers a high level of advanced optimizations, multi-threading, and processor support that includes global optimization, vectorization, inter-procedural analyses, loop transformations, and code generation. AOCC compiler binaries are suitable for Linux systems having GNU C Library (glibc) version 2.17 and above. The compiler suite consists of a C/C++ compiler (clang), a Fortran compiler (FLANG), and a Fortran front end to Clang (Dragon Egg).

Clang

Clang is a C, C++, and Objective-C compiler handling preprocessing, parsing, optimization, code generation, assembly, and linking. Clang supports the `-march=znver1` flag to enable best code generation and tuning for AMD's Zen based x86 architecture.

FLANG

The FLANG compiler is a recent addition to the AOCC suite (added April 2018) and is currently in prerelease for developers to download and test. Based on Fortran 2008, AMD extends the GitHub version of FLANG. The FLANG compiler supports all Clang compiler options and other number of FLANG-specific compiler options.

DragonEgg

DragonEgg is a gcc plugin that replaces GCC's optimizers and code generators from the LLVM project. DragonEgg that comes with AOCC works with gcc-4.8.x, has been tested for x86-32/x86-64 targets, and has been successfully used on various Linux platforms.

GFortran is the actual frontend for Fortran programs responsible for preprocessing, parsing, and semantic analysis generating the GCC GIMPLE intermediate representation (IR). DragonEgg is a GNU plugin, plugging into GFortran compilation flow. It implements the GNU plugin API. With the plugin architecture, DragonEgg becomes the compiler driver, driving the different phases of compilation. After following the download and installation instructions, Dragon Egg can be invoked using:

Bash

```
gfortran [gFortran flags]
   -fplugin=/path/AOCC-1.2-Compiler/AOCC-1.2-
   FortranPlugin/dragonegg.so [plugin optimization flags]
   -c xyz.f90 $ clang -O3 -lgfortran -o xyz xyz.o $./xyz
```

PGI Compiler

PGI Community Edition 17 is confirmed to work with AMD EPYC. A PGI-compiled version of STREAM does deliver full memory bandwidth of the platform. The newer Community Edition 18.10 (Nov 2018) should likewise work well. Use this CLI command to compile with the Intel Compiler:

Bash

```
pgcc $(OPTIMIZATIONS_PGI) $(STACK) -DSTREAM_ARRAY_SIZE=800000000 stream.c -o
stream.pgi
```

Intel Compiler

Intel Compiler 18 is confirmed to work with AMD EPYC. Use this CLI command to compile with the Intel Compiler.

Bash

```
icc -o stream.intel stream.c -DSTATIC -DSTREAM_ARRAY_SIZE=800000000 -mcmodel=large -
shared-intel -Ofast –qopenmp
```

GCC Compiler

For HPC workloads, AMD recommends GCC compiler 7.3 or newer. Older versions, such as 4.8.5 included with RHEL 7.4, aren't recommended. GCC 7.3, and newer, delivers higher performance on HPL, HPCG, and DGEMM tests.

Bash

```
gcc $(OPTIMIZATIONS) $(OMP) $(STACK) $(STREAM_PARAMETERS) stream.c -o stream.gcc
```

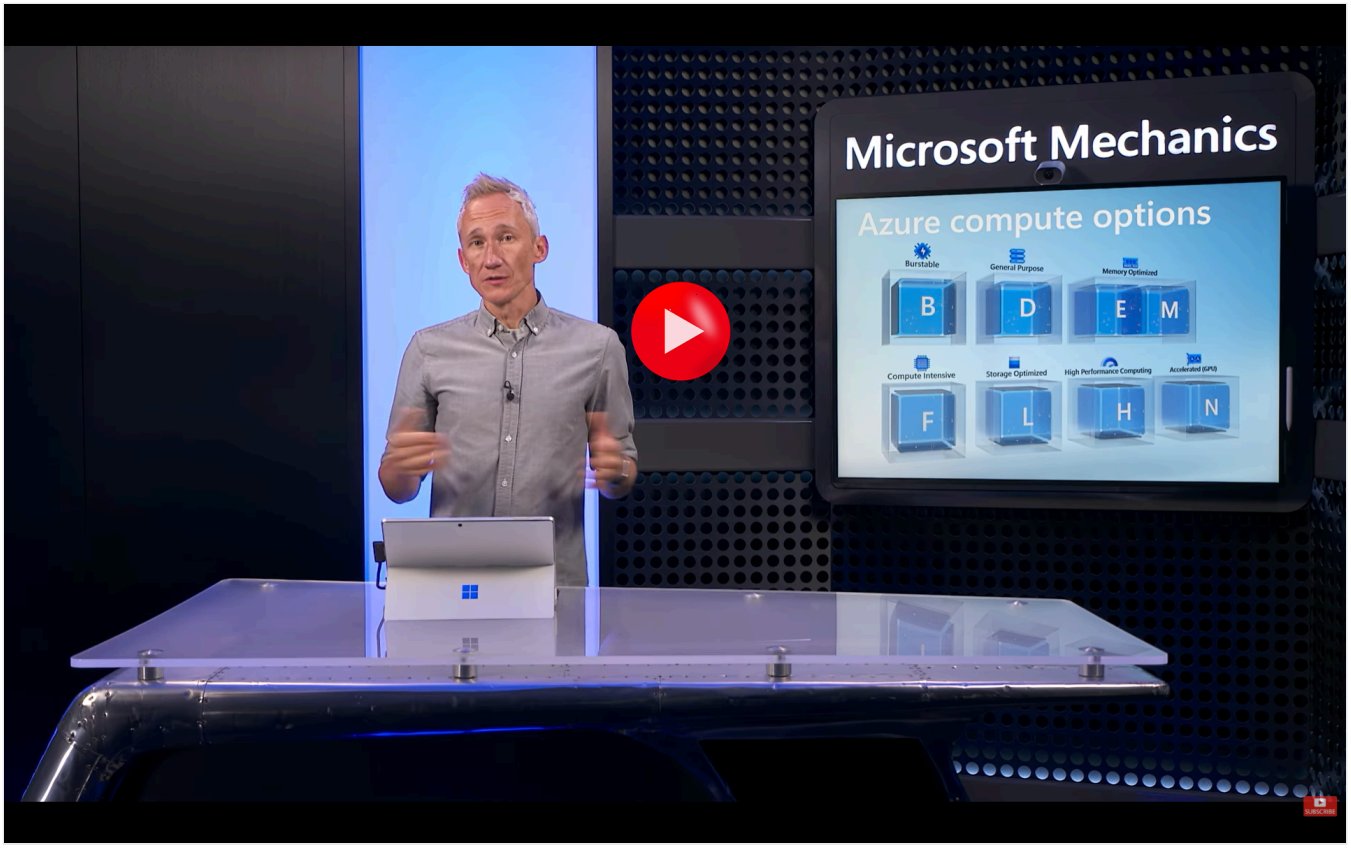
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

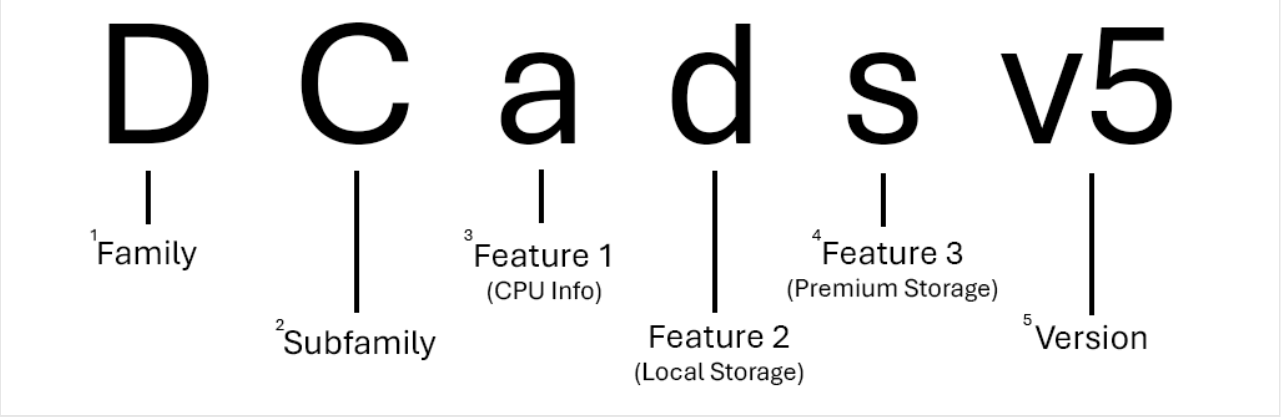
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

Family list

Expand table

Family	Workloads	Series List
A-family	Entry-level economical	Av2-series Previous-gen A-family series
B-family	Burstable	Bsv2-series Basv2-series Bpsv2-series Previous-gen B-family series
D-family	Enterprise-grade applications Relational databases	Dsv7 and Ddsv7 series Dlsv7 and Dldsv7 series

Family	Workloads	Series List
	In-memory caching Data analytics	Dasv7 and Dadsv7 series Dalsv7 and Daldsv7 series Dpsv6 and Dplsv6-series Dpdsv6 and Dpldsv6-series Dasv6 and Dadsv6-series Dalsv6 and Daldsv6-series Dsv6 and Ddsv6-series Dlsv6 and Dldsv6-series Dpsv5 and Dpdsv5-series Dplsv5 and Dpldsv5-series Dlsv5 and Dldsv5-series Dv5 and Dsv5-series Ddv5 and Ddsv5-series Dasv5 and Dadsv5-series Previous-gen D-family series
DC-family	D-family with confidential computing	DCasv5 and DCadsv5-series DCas_cc_v5 and DCads_cc_v5-series DCesv6-series DCedsv6-series DCasv6 and DCadsv6-series DCsv3 and DCdsv3-series Previous-gen DC-family

Compute optimized

Compute optimized VM sizes have a high CPU-to-memory ratio. These sizes are good for medium traffic web servers, network appliances, batch processes, and application servers.

Family list

List of compute optimized VM size families:

Expand table

Family	Workloads	Series List
F-family	Medium traffic web servers Network appliances Batch processes Application servers	Fasv7 and Fadsv7 series Famsv7 and Famdsv7 series Falsv7 and Faldsv7 series Fasv6, Falsv6, and Famsv6-series Fsv2-series Previous-gen F-family

Family	Workloads	Series List
FX-family	Electronic Design Automation (EDA) Large memory relational databases Medium to large caches In-memory analytics	FX-series FXmsv2-series FXmdsv2-series

To learn more about a specific size family or series, select the tab for that family and scroll to find your desired size series.

Memory optimized

Memory optimized VM sizes offer a high memory-to-CPU ratio that is great for relational database servers, medium to large caches, and in-memory analytics.

Family list

List of memory optimized VM sizes with links to each series' family page section:

Expand table

Family	Workloads	Series List

Azure virtual machine sizes naming conventions

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This page outlines the naming conventions used for Azure VMs. VMs use these naming conventions to denote varying features and specifications.

Naming convention explanation

[Family] + *[Sub-family]** + **[# of vCPUs]** + *[Constrained vCPUs]** + **[Additive Features]** + *[Accelerator Type]** + *[Memory Capacity]** + **[Version]**

Expand table

Value	Explanation
Family	Indicates the VM Family Series. For more information, see the list of VM size families by type.
*Subfamily	Used for specialized VM differentiations such as: B = memory bandwidth optimized C = confidential (for DC, EC, NCC series) C = compute intensive (for HC, NC, NCC series) D = AI training and inference optimized G = cloud gaming and remote desktop optimized V = visualization and graphics optimized X = extra memory
# of vCPUs	Denotes the number of vCPUs of the VM
*Constrained vCPUs	Used for certain VM sizes only. Denotes the number of vCPUs for the constrained vCPU capable size
Additive Features	Lower case letters denote additive features, such as: a = AMD-based processor b = remote storage bandwidth optimized d = includes local temporary disks e = encrypted; contains confidential TDX capabilities f = flat ratio (1:1) of vCPU to memory size i = isolated size l = low memory; decreased vCPU to memory ratio m = memory intensive; highest vCPU to memory ratio in a particular series n = network optimized; increased vCPU to network bandwidth ratio o = increased vCPU to local SSD storage capacity ratio p = ARM-based processor r = includes RDMA (InfiniBand) secondary network

Value	Explanation
	s = compatible with any premium SSD type t = tiny memory; smallest vCPU to memory ratio in a particular size
*Accelerator Type	Denotes the type of hardware accelerator in the specialized/GPU SKUs. Only new specialized/GPU SKUs launched from Q3 2020 have the hardware accelerator in the name.
*Memory Capacity	Denotes M-series memory capacity, rounded to the nearest TiB.
Version	Denotes the version number of the VM Family Series

Example breakdown

[Family] + *[Sub-family]** + **[# of vCPUs]** + *[Constrained vCPUs]** + **[Additive Features]** + *[Accelerator Type]** + *[Memory Capacity]** + **[Version]**

Example 1: M48ds_1_v3

Expand table

Value	Explanation
Family	M
# of vCPUs	48
Additive Features	d = local temp disk s = Premium Storage capable
Memory Capacity	974 GiB ≈ 1 TiB
Version	v3

Example 2: NV16as_v4

Expand table

Value	Explanation
Family	N
Subfamily	V

Value	Explanation
# of vCPUs	16
Additive Features	a = AMD-based processor s = Premium Storage capable
Version	v4

Example 3: NC4as_T4_v3

Expand table

Value	Explanation
Family	N
Subfamily	C
# of vCPUs	4
Additive Features	a = AMD-based processor s = Premium Storage capable
Accelerator Type	T4
Version	v3

Example 4: M8-2ms_v2 (Constrained vCPU)

Expand table

Value	Explanation
Family	M
# of vCPUs	8
Constrained vCPUs	2
Additive Features	m = memory intensive s = Premium Storage capable
Version	v2

Example 5: E96bds_v5 (a SQL Server preferred option)

Expand table

Value	Explanation
Family	Eb
# of vCPUs	96
Additive Features	b = memory d = includes local temporary disks s = Premium Storage capable
Version	v5

Change the size of a virtual machine

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This article shows you how to change an existing virtual machine's VM size.

After you create a VM, you can scale it up or down by changing the VM size. This process works whether the VM is currently running or has already been deallocated.

In some cases, you must deallocate the VM before resizing. Deallocation may be required if the new size isn't available on the hardware cluster currently hosting the VM. Even when deallocation isn't required, changing the size of a running VM will cause it to restart. For this reason, resizing a VM should be considered a disruptive operation, especially for stateful workloads.

> ⚠ **Warning**
>
> If the virtual machine is currently running, changing its size will cause it to restart.
>
> Deallocating the VM also releases any dynamic IP addresses assigned to the VM. The OS and data disks are not affected.
>
> If a resize operation fails, the VM model will still display the requested size, but the VM will continue running on its previous size until the resize is successfully allocated. This behavior applies to both the Azure portal, and all GET operations, as the displayed size always reflects the latest applied configuration, not the actual running size.

Choose the right SKU

When resizing a VM, it's important to choose the right SKU based on the signals from the VM to determine whether you need more CPU, memory, or storage capacity:

- If the VM is running a CPU-intensive workload, such as a database server or a web server with high traffic, you may need to choose a SKU with more CPU cores. For more information, see Compute optimized sizes.
- If the VM is running a memory-intensive workload, such as a machine learning model or a big data application, you may need to choose a SKU with more memory. For more information, see Memory optimized sizes.
- If the VM is running out of storage capacity, you may need to choose a SKU with more storage. For more information, see Storage optimized sizes.

- If your VM uses Premium Storage, make sure that you choose an **s** version of the size to get Premium Storage support. For example, choose Standard_E4**s**_v3 instead of Standard_E4_v3.

For more information on choosing the right SKU, you can use the following resources:

- Sizes for VMs in Azure: This article lists all the VM sizes available in Azure.
- Azure VM Selector : This tool helps you find the right VM SKU based on your workload type, OS and software, and deployment region.

Limitations

1. You can't resize a VM size that has a local temp disk to a VM size with no local temp disk and vice versa.

   The only combinations allowed for resizing are:

- VM (with local temp disk) -> VM (with local temp disk); and
- VM (with no local temp disk) -> VM (with no local temp disk).

  For a work-around, see How do I migrate from a VM size with local temp disk to a VM size with no local temp disk? . The work-around can be used to resize a VM with no local temp disk to VM with a local temp disk. You create a snapshot of the VM with no local temp disk > create a disk from the snapshot > create VM from the disk with appropriate VM size that supports VMs with a local temp disk.

2. You can't resize a VM size that has a SCSI-based VM to a VM size that has a remote NVMe-enabled VM.

   For a workaround, see How can I resize a SCSI-based VM to a remote NVMe-enabled VM of a different size?

Change the VM size

Select an option for changing the VM size:

Portal

To change the VM size using the Azure portal:

1. Open the Azure portal .

2. Type *virtual machines* in the search. Under **Services**, select **Virtual machines**.
3. In the **Virtual machines** page, select the virtual machine you want to resize.
4. In the left menu, in the **Availability + scale** section, select **size**.
5. Pick a new compatible size from the list of available sizes and then select **Resize**.

If your VM is still running and you don't see the size you want in the list, stopping the virtual machine may reveal more sizes.

Next steps

- For more scalability, run multiple VM instances and scale out.
- For more SKU selection information, see Sizes for virtual machines in Azure.
- To determine VM sizes by workload type, OS and software, or deployment region, see Azure VM Selector.
- For more information on Virtual Machine Scale Sets sizes, see Automatically scale machines in a VMSS.
- For more cost management planning information, see the Plan and manage your Azure costs module.

Azure Cobalt processor-based Virtual Machines

Article • 03/25/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Cobalt 100-based Virtual Machines (VMs) are powered by Azure's first-generation Cobalt 100 processor. These VMs offer an attractive option for a wide range of scale-out and cloud-native Linux-based workloads, including data analytics, web and application servers, open-source databases, caches, and more. These VMs utilize Microsoft's first 64-bit Arm-based CPU, which was fully designed by Microsoft. The Cobalt 100 processor, based on the Arm's Neoverse N2 design, aims to enhance performance and power efficiency for broad range of workloads. Operating at 3.4 GHz, the Azure Cobalt 100 processor provides an entire physical core for each virtual machine vCPU.

List of VM series by family

The following section lists the VM series supported by Cobalt 100 processors. To find detailed information on a series, including specifications and recommended workloads, check out the links in the *Series* column.

Cobalt 100-based VMs

Expand table

Family	Memory Ratio	Series
General Purpose	2 GiB: 1 vCPU	Dplsv6-series, Dpldsv6-series
General Purpose	4 GiB: 1 vCPU	Dpsv6-series, Dpdsv6-series
Memory Optimized	8 GiB: 1 vCPU	Epsv6-series, Epdsv6-series

To learn how to deploy these VMs for cloud-native applications on AKS, check out Azure Kubernetes Service (AKS) demo on Cobalt 100 VMs.

To find the most up-to-date regional availability, visit the Virtual Machines section at the bottom of the Product Availability by Region page.

Guest OS Support for Cobalt 100 VMs

The following section lists the Guest OS support for Cobalt 100 VMs.

Guest OS Support

Expand table

Guest OS	Version
AlmaLinux	8+
Azure Linux	2
Debian	11+
Flatcar	N/A
Kali Linux	N/A
QNX Neutrino RTOS	7.1
Red Hat Enterprise Linux (RHEL)	8.6+
SUSE Linux Enterprise Server (SLES)	15 SP4+
Ubuntu	20.04+
Windows 11 Client	N/A

To find the most up-to-date Guest OS support, visit Azure portal. Under "Instance Details," select "See all images," then click the "Image Type" filter to select "Arm64."

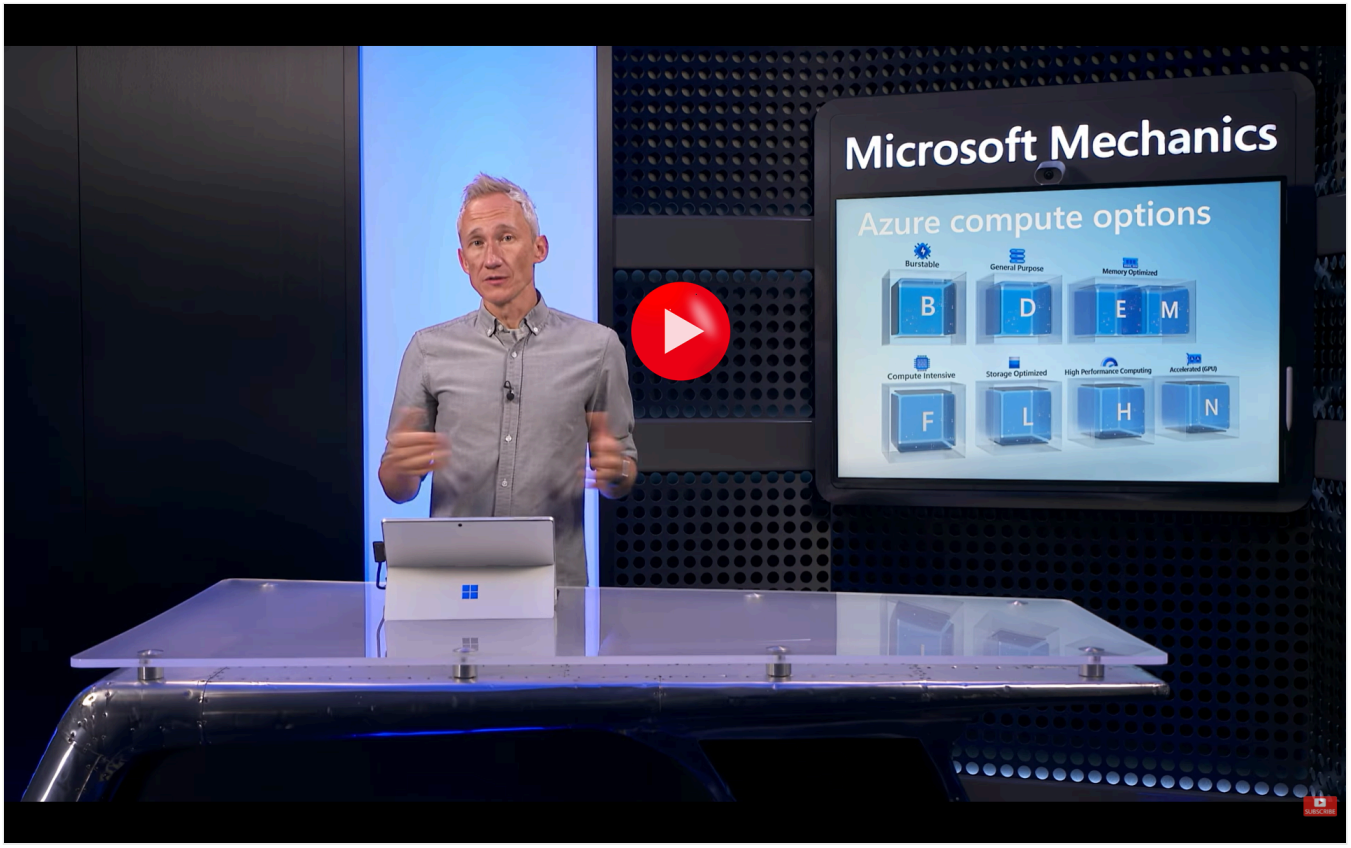
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

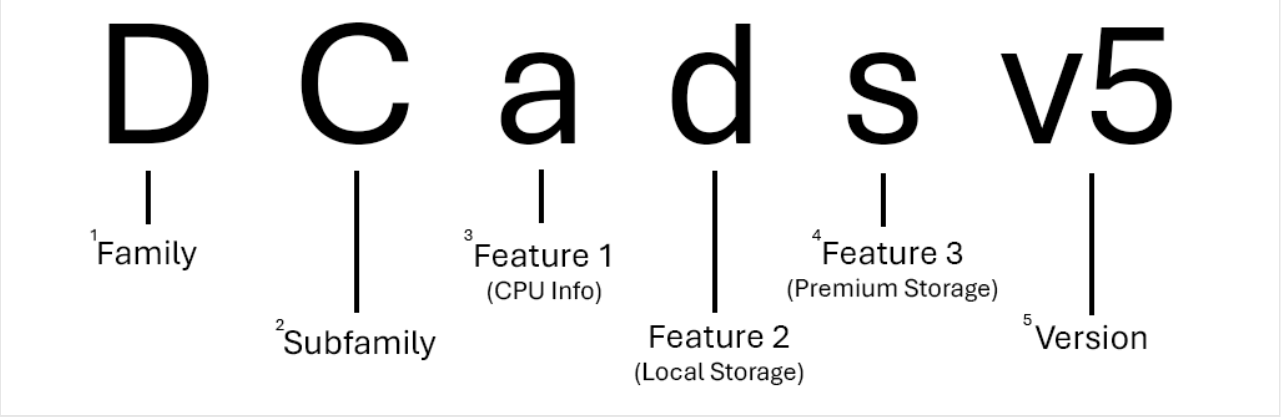
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

Family list

Expand table

Family	Workloads	Series List
A-family	Entry-level economical	Av2-series Previous-gen A-family series

'A' family general purpose VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'A' family of VM size series are one of Azure's general purpose VM instances. They're designed for entry-level workloads, such as development and test environments, small to medium databases, and low-traffic web servers.

Workloads and use cases

Cost Efficiency: A-series VMs are some of the most budget-friendly options available on Azure, making them a good choice for projects with limited financial resources or those that do not require high-performance compute capabilities.

General Workloads: A-series VMs are well-suited for handling basic applications, light web servers, and small databases that do not demand extensive CPU, memory, or I/O performance.

Entry-Level Applications: A-series VMs can serve as a good starting point for deploying applications that are not expected to scale significantly. They provide a platform for applications and services that require less processing power.

Series in family

Av2-series

The Av2-series VMs can be deployed on a variety of hardware types and processors. Av2-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), the Intel® Xeon® Platinum 8272CL (Cascade Lake), the Intel® Xeon® 8171M 2.1 GHz (Skylake), the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors. Av2-series VMs have CPU performance and memory configurations best suited for entry level workloads like development and test. The size is throttled to offer consistent processor performance for the running instance, regardless of the hardware it is deployed on. To determine the physical hardware on which this size is deployed, query the virtual hardware from within the Virtual Machine. Some example use cases include development and test servers, low traffic web servers, small to medium databases, proof-of-concepts, and code repositories.

View the full Av2-series page.

'B' family general purpose VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'B' family of VM size series are one of Azure's general purpose VM instances. While traditional Azure virtual machines provide fixed CPU performance, B-series virtual machines are the only VM type that use credits for CPU performance provisioning. B-series VMs utilize a CPU credit model to track how much CPU is consumed - the virtual machine accumulates CPU credits when a workload is operating below the base CPU performance threshold and uses credits when running above the base CPU performance threshold until all of its credits are consumed. Upon consuming all the CPU credits, a B-series virtual machine is throttled back to its base CPU performance until it accumulates the credits to CPU burst again.

Read more about the B-series CPU credit model.

Workloads and use cases

Usage Flexibility: B-family VMs are best suited for workloads that do not require constant full CPU performance.

Ideal Applications: B-family VMs are ideal applications include web servers, proof of concepts, small databases, and development build environments.

Performance Needs: Some workloads often have burstable performance requirements, meaning they only need high performance sporadically. B-family VMs are perfect for this use case.

Series in family

Basv2-series

Basv2-series virtual machines run on the AMD's third Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache configuration. This series provides low cost CPU burstable general purpose virtual machines. Basv2-series virtual machines utilize a CPU credit model to track how much CPU is consumed. The virtual machine accumulates CPU credits when a workload is operating below the base CPU performance threshold and uses credits when running above the base CPU performance threshold, until all of its credits are consumed. Upon consuming all the CPU credits, a Basv2-series virtual machine is throttled back to its base CPU performance until it accumulates the credits to CPU burst again.

Basv2-series virtual machines offer a balance of compute, memory, and network resources, and are a cost effective way to run a broad spectrum of general purpose workloads. These include large scale micro-services, small and medium databases, virtual desktops, and business-critical applications. This series also offers an affordable option to run your code repositories and dev/test environments. Basv2-Series offers virtual machines of up-to 32 vCPU and 128 Gib of RAM, with max network bandwidth of upto 6,250 Mbps and max uncached disk throughput of 600 Mbps. Basv2-series virtual machines also support attachments of Standard SSD, Standard HDD, Premium SSD disk types with a default Remote-SSD support. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

View the full Basv2-series page.

Expand table

Network	2 - 4 NICs	6250 Mbps
Accelerators	None	

Bpsv2-series

The Bpsv2-series virtual machines are based on the Arm architecture, featuring the Ampere® Altra® Arm-based processor operating at 3.0 GHz, delivering outstanding price-performance for general-purpose workloads. These virtual machines offer a range of VM sizes, from 0.5 GiB to up to 4 GiB of memory per vCPU, to meet the needs of applications that don't need the full performance of the CPU continuously, such as development and test servers, low traffic web servers, small databases, micro services, servers for proof-of-concepts, build servers, and code repositories. These workloads typically have burstable performance requirements. The Bpsv2-series VMs provides you with the ability to purchase a VM size with baseline performance that can build up credits when it's using less than its baseline performance. When the VM has accumulated credits, the VM can burst above the baseline using up to 100% of the vCPU when your application requires higher CPU performance.

View the full Bpsv2-series page.

B Series CPU Credit Model

Article • 10/31/2024

While traditional Azure virtual machines provide fixed CPU performance, B-series virtual machines are the only VM type that use credits for CPU performance provisioning. B-series VMs utilize a CPU credit model to track how much CPU is consumed - the virtual machine accumulates CPU credits when a workload is operating below the base CPU performance threshold and uses credits when running above the base CPU performance threshold until all of its credits are consumed. Upon consuming all the CPU credits, a B-series virtual machine is throttled back to its base CPU performance until it accumulates the credits to CPU burst again.

Credit concepts and definitions

- Base CPU performance = The minimum CPU performance threshold a VM will have available always. This level sets the bar for net credit accumulation when the CPU utilization is below the base CPU performance level and net credit consumption when the CPU utilization is above the base CPU performance.
- Initial Credits = The number of credits allocated to a B-series virtual machine when a VM is deployed.
- Credits banked/hour = The number of credits a B-series virtual machine accumulates per hour if the VM is idle (no CPU performance consumption).
- Max Banked Credits = The maximum number/upper limit of credits a B-series virtual machine can accumulate. Upon reaching this upper limit, a B-series VM can no longer accumulate more credits.
- CPU Credits Consumed = The number of CPU credits spent during the measurement time-period.
- CPU Credits Remaining = The number of CPU credits available to consume for a given B-series VM.
- Percentage CPU = CPU performance of a given VM during a measurement period.

Credits accumulation and consumption

The credit accumulation and consumption rates are set such that a VM running at exactly its base performance level will have neither a net accumulation or consumption

of bursting credits. A VM has a net credit increase whenever it's running below its base CPU performance level and will have a net decrease in credits whenever the VM is utilizing the CPU more than its base CPU performance level.

To conduct calculations on credit accumulations and consumptions, customers can utilize the holistic 'credits banked per minute' formula => `((Base CPU performance * number of vCPU) - (Percentage CPU * number of vCPU))/100`.

Putting this calculation into action, let's say that a customer deploys the Standard_B2ts_v2 VM size and their workload demands 10% of the 'Percentage CPU' or CPU performance, then the 'credits banked per minute' calculation will be as follows: `((20*2) - (10*2))/100 = 0.2 credits/minute`. In such a scenario, a B-series VM is accumulating credits given the 'Percentage CPU' per CPU performance requirement is below the 'Base CPU performance' of the Standard_B2ts_v2.

Similarly, utilizing the example of a Standard_B32as_v2 VM size, if the workload demands 60% of the CPU performance for a measurement of time - then the 'credits banked per minute' calculation will be as follows: `((40*32) - (60*32))/100 = -6.4 credits/minute`. Here the negative result implies the B-series VM is consuming credits given the 'Percentage CPU'/CPU performance requirement is above the 'Base CPU performance' of the Standard_B32as_v2.

Credit monitoring

To monitor B-series specific credit metrics, customers can utilize the Azure monitor data platform, see Overview of metrics in Microsoft Azure. Azure monitor data platform can be accessed via the Azure portal and other orchestration paths, and via programmatic API calls to Azure monitor. Via Azure monitor data platform, customers can access B-series credit model-specific metrics such as 'CPU Credits Consumed', 'CPU Credits Remaining', and 'Percentage CPU' for their given B-series size in real time.

Bsv2-series sizes

Summarize this article for me

Bsv2-series virtual machines run on Intel® Xeon® Platinum 8573C (Emerald Rapids), Intel® Xeon® Platinum 8473C (Sapphire Rapids), or Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper threaded configuration, providing low-cost CPU burstable general purpose virtual machines. Bsv2-series virtual machines utilize a CPU credit model to track how much CPU is consumed. The virtual machine accumulates CPU credits when a workload is operating below the base CPU performance threshold and, uses credits when running above the base CPU performance threshold until all of its credits are consumed. Upon consuming all the CPU credits, a Bsv2-series virtual machine is throttled back to its base CPU performance until it accumulates the credits to CPU burst again.

Bsv2-series virtual machines offer a balance of compute, memory, and network resources and are a cost-effective way to run a broad spectrum of general-purpose workloads. These include large-scale micro-services, small and medium databases, virtual desktops, and business-critical applications; and are also an affordable option to run your code repositories and dev/test environments. Bsv2-series offers virtual machines of up to 32 vCPU and 128 GiB of RAM, with max network bandwidth of up to 6,250 Mbps and max uncached disk throughput of 600 Mbps. Bsv2-series virtual machines also support attachments of Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Basv2 sizes series

Summarize this article for me

Basv2-series virtual machines run on the AMD's third Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache configuration. This series provides low cost CPU burstable general purpose virtual machines. Basv2-series virtual machines utilize a CPU credit model to track how much CPU is consumed. The virtual machine accumulates CPU credits when a workload is operating below the base CPU performance threshold and uses credits when running above the base CPU performance threshold, until all of its credits are consumed. Upon consuming all the CPU credits, a Basv2-series virtual machine is throttled back to its base CPU performance until it accumulates the credits to CPU burst again.

Basv2-series virtual machines offer a balance of compute, memory, and network resources, and are a cost effective way to run a broad spectrum of general purpose workloads. These include large scale micro-services, small and medium databases, virtual desktops, and business-critical applications. This series also offers an affordable option to run your code repositories and dev/test environments. Basv2-Series offers virtual machines of up-to 32 vCPU and 128 Gib of RAM, with max network bandwidth of upto 6,250 Mbps and max uncached disk throughput of 600 Mbps. Basv2-series virtual machines also support attachments of Standard SSD, Standard HDD, Premium SSD types with a default Remote-SSD support. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Bpsv2 sizes series

Summarize this article for me

The Bpsv2-series virtual machines are based on the Arm architecture, featuring the Ampere® Altra® Arm-based processor operating at 3.0 GHz, delivering outstanding price-performance for general-purpose workloads. These virtual machines offer a range of VM sizes, from 0.5 GiB to up to 4 GiB of memory per vCPU, to meet the needs of applications that don't need the full performance of the CPU continuously, such as development and test servers, low traffic web servers, small databases, micro services, servers for proof-of-concepts, build servers, and code repositories. These workloads typically have burstable performance requirements. The Bpsv2-series VMs provides you with the ability to purchase a VM size with baseline performance that can build up credits when it's using less than its baseline performance. When the VM has accumulated credits, the VM can burst above the baseline using up to 100% of the vCPU when your application requires higher CPU performance.

'D' family general purpose VM size series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'D' family of VM sizes are one of Azure's general purpose VM sizes. They're designed for a variety of demanding workloads, such as enterprise applications, web and application servers, development and test environments, and batch processing tasks. Equipped with faster processors and more memory per core than the A-series, D-series VMs offer a strong performance balance, making them suitable for applications that require both high computational power and substantial memory resources. They are particularly favored for running enterprise-grade applications, supporting moderate to high-traffic web servers, and performing data-intensive batch processing.

Workloads and use cases

Balanced Performance: D-series VMs provide a solid balance between CPU capabilities and memory size, which makes them suitable for most production workloads. They are equipped with faster processors compared to the A-series and provide more memory per core.

Enterprise Applications: They are well-suited for running enterprise applications like SAP, Microsoft Dynamics, or large relational databases that require both high computational power and substantial memory.

Development and Test Environments: With their balanced resources, D-series VMs are ideal for development and testing environments where developers need to simulate production conditions closely.

Web and Application Servers: They provide the necessary resources to host web servers and application servers that experience moderate to heavy traffic, ensuring smooth and responsive user experiences.

Batch Processing: D-series VMs are efficient for handling batch processing tasks that require processing large amounts of data quickly, thanks to their fast processors and ample memory.

Gaming Servers: The high-performance capabilities of D-series VMs make them suitable for gaming servers where latency and speed are critical for a good user experience.

Series in family

Dsv7 series and Ddsv7 series

Dsv7 series

Dsv7-series virtual machines run on the Intel® Xeon® 6 6973PC (Granite Rapids) processor, reaching an all-core turbo clock speed of 3.6 GHz with a maximum turbo frequency is 4.2 GHz. This new processor features Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512), and Intel® Advanced Matrix Extensions. Dsv7-series virtual machines provide better performance for most general-purpose workloads compared to the prior generation for example increased networking, increased remote storage performance, upgraded CPU, and elevated memory bandwidth. Dsv7-series virtual machines are ideal for many general computing workloads such as e-commerce systems, web applications, desktop virtualization solutions, application servers, and more.

Dsv7-series virtual machines don't have any temporary storage thus lowering the price of entry. You can attach Standard SSDs, Standard HDDs, Premium SSDs, and Premium SSD V2 disk storage to these virtual machines. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dlsv7 series and Dldsv7 series

Dlsv7 series

Dlsv7-series virtual machines run on Intel® Xeon® 6 6973PC (Granite Rapids) processor reaching an all-core turbo clock speed of 3.6 GHz with a maximum turbo frequency is 4.2

GHz. This new processor features Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512), and Intel® Advanced Matrix Extensions. These virtual machines offer up to 248 vCPUs and 496 GiB of RAM. Dlsv7-series virtual machines provide better performance for most general-purpose workloads compared to the prior generation, for example increased networking, increased remote storage performance, upgraded CPU, and elevated memory bandwidth. These virtual machine sizes can reduce costs when running non-memory intensive applications. Dlsv7-series virtual machines are ideal for many general computing workloads such as e-commerce systems, web applications, desktop virtualization solutions, application servers, and more.

Dlsv7-series virtual machines don't have any temporary storage, thus lowering the price of entry. You can attach Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines

Dpsv6 and Dplsv6-series

Dpsv6-series

The Dpsv6-series virtual machines are powered by Azure's first-generation Cobalt 100 processor, delivering outstanding performance for general-purpose workloads. The Azure Cobalt 100 processor operates at 3.4 GHz and provides an entire physical core for each virtual machine vCPU. These virtual machines offer 4 GiB of memory per vCPU and a wide range of vCPU sizes. These VMs meet the requirements of most scale-out enterprise workloads such as web and application servers, small to medium databases, caches, and more. Dpsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. For more information, see pricing for disks. Dpsv6-series virtual machines offer up to 96 vCPU and 384 GiB of RAM. These VMs come without local disk, providing a better value proposition for workloads that don't require local temporary storage.

The Dpsv5-series and Dpdsv5-series virtual machines are based on the Arm architecture, delivering outstanding price-performance for general-purpose workloads. These virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer a range of vCPU sizes, up to 4 GiB of memory per vCPU, and temporary storage options able to meet the requirements of scale-out and most enterprise workloads such as web and application servers, small to medium databases, caches, and more.

View the full Dpsv5-series page.

Accelerators	None	

Dlsv5 and Dldsv5-series

Dlsv5-series

Dlsv5-series virtual machines run on Intel® Xeon® Platinum 8473C (Sapphire Rapids), or Intel® Xeon® Platinum 8370C (Ice Lake) processor reaching an all core turbo clock speed of up to 3.5 GHz. These virtual machines offer up to 96 vCPU and 192 GiB of RAM. These VM sizes can reduce cost when not running memory intensive applications.

Dlsv5-series virtual machines don't have any temporary storage thus lowering the price of entry. You can attach Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. See pricing for disks.

Dav4 and Dasv4-series

Dav4-series

The Dav4-series run on 2nd Generation AMD EPYC™ 7452 (up to 3.35GHz) or 3rd Generation EPYC™ 7763v processors (up to 3.5GHz). The Dav4-series sizes offer a combination of vCPU, memory and temporary storage for most production workloads. Data disk storage is billed separately from virtual machines. To use premium SSD, use the Dasv4 sizes. The pricing and billing meters for Dasv4 sizes are the same as the Dav4-series.

Accelerators	None	

Ddv4 and Ddsv4-series

Ddv4-series

The Ddv4 and Ddsv4-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors in a hyper-threaded configuration, providing a better value proposition for most general-purpose workloads. It features an all core Turbo clock speed of 3.4 GHz, Intel® Turbo Boost Technology 2.0, Intel® Hyper-Threading Technology and Intel® Advanced Vector Extensions 512 (Intel® AVX-512). They also support Intel® Deep Learning Boost. These new VM sizes will have 50% larger local storage, as well as better local disk IOPS for both read and write compared to the Dv3/Dsv3 sizes with Gen2 VMs. D-series use cases include enterprise-grade applications, relational databases, in-memory caching, and analytics.

View the full Ddv4-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	2 - 64 vCPUs	Intel Xeon Platinum 8370C (Ice Lake) [x86-64] Intel Xeon Platinum 8272CL (Cascade Lake) [x86-64] Intel Xeon Platinum 8573C (Emerald Rapids) [x86-64]

Remote Storage	4 - 32 Disks	3200 - 80000 IOPS 48 - 1200 MBps
Network	2 - 8 NICs	5000 - 30000 Mbps Interfaces: NetVSC, ConnectX, MANA
Accelerators	None	

Dv3 and Dsv3-series

Dv3-series

The Dv3-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors in a hyper-threaded configuration, providing a better value proposition for most general purpose workloads. Memory has been expanded (from ~3.5 GiB/vCPU to 4 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyperthreading. The Dv3-series no longer has the high memory VM sizes of the D/Dv2-series, those have been moved to the memory optimized Ev3 and Esv3-series. Example D-series use cases include enterprise-grade applications, relational databases, in-memory caching, and analytics.

Dv2 and Dsv2-series

Dv2-series

The Dv2 and DSv2-series, a follow-on to the original D-series, feature a more powerful CPU and optimal CPU-to-memory configuration making them suitable for most

production workloads. The Dv2-series is about 35% faster than the D-series. Dv2-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors with the Intel Turbo Boost Technology 2.0. The Dv2-series has the same memory and disk configurations as the D-series.

Dsv7 sizes series

Summarize this article for me

> **Note**
>
> - This VM series is currently in **Preview**.
> - See the Preview Terms Of Use | Microsoft Azure for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Dsv7-series virtual machines run on the Intel® Xeon® 6 6973PC (Granite Rapids) processor, reaching an all-core turbo clock speed of 3.6 GHz with a maximum turbo frequency is 4.2 GHz. This new processor features Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512), and Intel® Advanced Matrix Extensions. Dsv7-series virtual machines provide better performance for most general-purpose workloads compared to the prior generation for example increased networking, increased remote storage performance, upgraded CPU, and elevated memory bandwidth. Dsv7-series virtual machines are ideal for many general computing workloads such as e-commerce systems, web applications, desktop virtualization solutions, application servers, and more.

Dsv7-series virtual machines don't have any temporary storage thus lowering the price of entry. You can attach Standard SSDs, Standard HDDs, Premium SSDs, and Premium SSD v2 storage to these virtual machines. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dasv7 sizes series

Summarize this article for me

Dasv7-series VMs utilize AMD's 5th Generation EPYC™ 9005 processors that can achieve a boosted maximum frequency of up to 4.5 GHz. These virtual machines offer up to 160 vCPU and 640 GiB of RAM. The Dasv7-series sizes offer a combination of vCPU and memory for most production workloads. The new VMs with no local disk provide a better value proposition for workloads that don't require local temporary storage.

Dadsv7 sizes series

Summarize this article for me

Dadsv7-series VMs utilize AMD's 5th Generation EPYC™ 9005 processors that can achieve a boosted maximum frequency of up to 4.5 GHz. These virtual machines offer up to 160 vCPU and 640 GiB of RAM. The Dadsv7-series sizes offer a combination of vCPU, memory and fast local NVMe temporary storage for most production workloads. Dadsv7-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Host specifications

Dsv6 sizes series

Summarize this article for me

Dsv6-series virtual machines run on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor reaching an all-core turbo clock speed of 3.0 GHz. This new processor features Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512), and Intel® Advanced Matrix Extensions. These virtual machines offer up to 192 vCPU and 768 GiB of RAM. Dsv6-series virtual machines provide a better performance for most general-purpose workloads compared to the prior generation (for example, increased scalability, upgraded CPU, elevated memory bandwidth, faster remote storage access).

Dsv6-series virtual machines don't have any temporary storage thus lowering the price of entry. You can attach Standard SSDs, Standard HDDs, Premium SSDs, and Premium SSD v2 storage to these virtual machines. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Daldsv6 sizes series

Summarize this article for me

Daldsv6-series VMs utilize AMD's 4th Generation EPYC™ 9004 processors that can achieve a boosted maximum frequency of 3.7GHz. These virtual machines offer up to 96 vCPUs, 192 GiB of RAM, and up to 5,280 GiB of fast local NVMe temporary storage. These VM sizes can reduce cost when running non-memory intensive applications. Daldsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dpsv6 sizes series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows Client VMs ✔ Flexible scale sets ✔ Uniform scale sets

The Dpsv6-series virtual machines are powered by Azure's first-generation Cobalt 100 processor, delivering outstanding performance for general-purpose workloads. The Azure Cobalt 100 processor operates at 3.4 GHz and provides an entire physical core for each virtual machine vCPU. These virtual machines offer 4 GiB of memory per vCPU and a wide range of vCPU sizes. These VMs meet the requirements of most scale-out enterprise workloads such as web and application servers, small to medium databases, caches, and more. Dpsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. For more information, see pricing for disks. Dpsv6-series virtual machines offer up to 96 vCPU and 384 GiB of RAM. These VMs come without local disk, providing a better value proposition for workloads that don't require local temporary storage.

Dv5 sizes series

The Dv5 and Dsv5-series virtual machines run on Intel® Xeon® Platinum 8473C (Sapphire Rapids), Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper threaded configuration, providing a better value proposition for most general-purpose workloads. This new processor features an all core turbo clock speed of 3.5 GHz with Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512) and Intel® Deep Learning Boost. These virtual machines offer a combination of vCPUs and memory to meet the requirements associated with most enterprise workloads, such as small-to-medium databases, low-to-medium traffic web servers, application servers and more. The Dv5 and Dsv5-series provide a better value proposition for workloads that don't require local temp disk. For information about similar virtual machines with local disk, see Ddv5 and Ddsv5-series VMs.

Dasv5 sizes series

Dasv5-series VMs utilize AMD's 3rd Generation EPYC™ 7763v and AMD's 4th Generation EPYC™ 9004 processors. The Dasv5-series sizes offer a combination of vCPU and memory for most production workloads. The new VMs with no local disk provide a better value proposition for workloads that do not require local temp disk.

Host specifications

Dadsv5 sizes series

Summarize this article for me

Dadsv5-series utilize AMD's third Generation EPYC™ 7763v processors and AMD's 4th Generation EPYC™ 9004 processors. The Dadsv5-series sizes offer a combination of vCPU, memory, and temporary storage for most production workloads. The new VMs have 50% larger local storage and better local disk IOPS for both read and write compared to the Dav4/Dasv4 sizes with Gen2 VMs.

Dadsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dpsv5 sizes series

Summarize this article for me

The Dpsv5-series and Dpdsv5-series virtual machines are based on the Arm architecture, delivering outstanding price-performance for general-purpose workloads. These virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer a range of vCPU sizes, up to 4 GiB of memory per vCPU, and temporary storage options able to meet the requirements of scale-out and most enterprise workloads such as web and application servers, small to medium databases, caches, and more.

Dnsv6 sizes series (Preview)

Summarize this article for me

Dnsv6-series virtual machines run on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor reaching an all-core turbo clock speed of 3.0 GHz. These virtual machines offer up to 128 vCPU and 512 GiB of RAM. Dnsv6-series virtual machines, an extension of our standard Dsv6-series provides better networking performance for most general-purpose workloads. It also provides increased scalability, upgraded CPU, elevated memory bandwidth, and faster remote storage access compared to the prior generation.

Network Optimized VMs enhance accelerated networking by providing hardware acceleration of initial connection setup for certain traffic types, a task previously performed in software. These enhancements reduce the end-to-end latency for initially establishing a connection or initial packet flow, and allow a VM to scale up the number of connections it manages more quickly, subject to application constraints.

The new Network Optimized sizes make use of enhancements provided by Azure Boost to deliver increased network bandwidth per vCPU, a greater number of vNICs, and improved connection setup performance. The Dnsv6 offers up to 200 Gbps network bandwidth, 15 vNICs and up to 400k Connection per Second (CPS).

These VM sizes are relevant for workloads such as network virtual appliances, large-scale e-commerce applications that require the ability to handle a high number of user connections, and data transfers and media processing tasks that involve transferring large amounts of data quickly. Other applications will also benefit from increased network connection setup performance.

Dnsv6-series virtual machines don't have any temporary storage thus lowering the price of entry. You can attach Standard SSDs, Standard HDDs, Premium SSDs, and Premium SSD v2 storage to these virtual machines. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dndsv6 sizes series (Preview)

Summarize this article for me

Dndsv6-series virtual machines run on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor reaching an all- core turbo clock speed of 3.0 GHz. These virtual machines offer up to 128 vCPU and 512 GiB of RAM. Dndsv6-series virtual machines, an extension of our standard Ddsv6-series, provide better networking performance for most general-purpose workloads. It also provides increased scalability, upgraded CPU, elevated memory bandwidth, and faster remote storage access compared to the prior generation.

Network Optimized VMs enhance accelerated networking by providing hardware acceleration of initial connection setup for certain traffic types, a task previously performed in software. These enhancements reduce the end-to-end latency for initially establishing a connection or initial packet flow and allow a VM to scale up the number of connections it manages more quickly, subject to application constraints.

The new Network Optimized sizes make use of enhancements provided by Azure Boost to deliver increased network bandwidth per vCPU, a greater number of vNICs, and improved connection setup performance. The Dndsv6 offers up to 200 Gbps network bandwidth, 15 vNICs and up to 400k Connection per Second (CPS).

These VM sizes are relevant for workloads such as network virtual appliances, large-scale e-commerce applications that require the ability to handle a high number of user connections, and data transfers and media processing tasks that involve transferring large amounts of data quickly. Other applications will also benefit from increased network connection setup performance.

Dndsv6-series virtual machines offer local storage disks. You can attach Standard SSDs, Standard HDDs, Premium SSDs, and Premium SSD v2 storage to these virtual machines. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dnlsv6 sizes series (Preview)

Summarize this article for me

Dnlsv6-series virtual machines run on 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) CPU processor reaching an all- core turbo clock speed of up to 3.0 GHz. These virtual machines offer up to 128 vCPU and 256 GiB of RAM. These VM sizes can reduce costs when running non-memory intensive applications. Dnlsv6-series virtual machines, an extension of our standard Dlsv6-series, provide better networking performance for most general-purpose workloads.

Network Optimized VMs enhance accelerated networking by providing hardware acceleration of initial connection setup for certain traffic types, a task previously performed in software. These enhancements reduce the end-to-end latency for initially establishing a connection or initial packet flow, and allow a VM to scale up the number of connections it manages more quickly, subject to application constraints.

The new Network Optimized sizes make use of enhancements provided by Azure Boost to deliver increased network bandwidth per vCPU, a greater number of vNICs, and improved connection setup performance. The Dnlsv6 offers up to 200 Gbps network bandwidth, 15 vNICs and up to 400k Connection per Second (CPS).

These VM sizes are relevant for workloads such as network virtual appliances, large-scale e-commerce applications that require the ability to handle a high number of user connections, and data transfers and media processing tasks that involve transferring large amounts of data quickly. Other applications will also benefit from increased network connection setup performance.

Dnlsv6-series virtual machines don't have any temporary storage, thus lowering the price of entry. You can attach Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dnldsv6 sizes series (Preview)

Summarize this article for me

Dnldsv6-series virtual machines run on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor reaching an all- core turbo clock speed of up to 3.0 GHz. These virtual machines offer up to 128 vCPU and 256 GiB of RAM and fast, local SSD storage up to 4x1760 GiB. These VM sizes can reduce cost when running non-memory intensive applications. Dnldsv6-series virtual machines, an extension of our standard Dldsv6-series, provide better networking performance for most general-purpose workloads.

Network Optimized VMs enhance accelerated networking by providing hardware acceleration of initial connection setup for certain traffic types, a task previously performed in software. These enhancements reduce the end-to-end latency for initially establishing a connection or initial packet flow, and allow a VM to scale up the number of connections it manages more quickly, subject to application constraints.

The new Network Optimized sizes make use of enhancements provided by Azure Boost to deliver increased network bandwidth per vCPU, a greater number of vNICs, and improved connection setup performance. The Dnldsv6 offers up to 200 Gbps network bandwidth, 15 vNICs and up to 400k Connection per Second (CPS).

These VM sizes are relevant for workloads such as network virtual appliances, large-scale e-commerce applications that require the ability to handle a high number of user connections, and data transfers and media processing tasks that involve transferring large amounts of data quickly. Other applications will also benefit from increased network connection setup performance.

Dnldsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Dav4 sizes series

Summarize this article for me

The Dav4-series run on 2nd Generation AMD EPYC™ 7452 (up to 3.35GHz) or 3rd Generation EPYC™ 7763v processors (up to 3.5GHz). The Dav4-series sizes offer a combination of vCPU, memory and temporary storage for most production workloads. Data disk storage is billed separately from virtual machines. To use Premium SSD, use the Dasv4 sizes. The pricing and billing meters for Dasv4 sizes are the same as the Dav4-series.

'DC' family general purpose VM size series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'DC' series family are one of Azure's security focused general purpose VM instances. They're designed for confidential computing offering enhanced data protection and integrity with various hardware-based Trusted Execution Environments (TEEs). These VMs work well for many general computing workloads, e-commerce systems, web front ends, desktop virtualization solutions, sensitive databases, other enterprise applications and more.

Workloads and use cases

Data Protection: DC-series VMs are ideal for applications that manage, store, and process sensitive data, such as personal identifiable information (PII), financial data, health records, and other types of confidential information. The hardware-based encryption ensures that data is protected at rest and during processing.

Regulatory Compliance: For businesses that need to comply with stringent regulatory requirements for data privacy and security (like GDPR, HIPAA, or financial industry regulations), DC-series VMs provide a hardware-assured environment that can help meet these compliance demands.

Series in family

DCasv6 and DCadsv6-series

DCasv6-series

Azure's DCasv6-series virtual machines provide robust confidential computing capabilities, ensuring code and data remain secure during processing. Companies can migrate sensitive workloads to cloud infrastructure without modifying existing applications. The series runs on AMD's fourth-generation EPYC™ processors configured for multi-threaded operations with enhanced L3 cache architecture.

AMD's SEV-SNP technology creates hardware-isolated environments that prevent unauthorized access from hypervisors, host management systems, and administrative users. This isolation protects virtual machines from neighboring VMs, hypervisor vulnerabilities, and both hardware and software-based security threats.

The platform includes hardware-based VM memory encryption alongside native support for confidential disk encryption feature. Organizations can implement OS disk encryption at boot through customer-managed keys (CMK) or platform-managed keys (PMK). This feature is fully integrated with Azure KeyVault and Azure Managed HSM ensuring FIPS 140-2 Level 3 compliance.

DCasv6 instances provide balanced memory-to-vCPU ratios suitable for production environments. Configurations scale up to 96 vCPUs paired with 384 GiB RAM and remote storage connectivity. These specifications support diverse workloads including e-commerce platforms, web services, desktop virtualization, secure databases, enterprise applications and more.

View the full DCasv6-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	2 - 96 vCPUs	AMD EPYC 9004 (Genoa) [x86-64]
Memory	8 - 384 GiB	
Local Storage	None	
Remote Storage	8 - 64 Disks	4,000 - 175,000 IOPS 90 - 4,320 MBps Disk Types: Standard SDD/HDD, Premium SSD, Premium SSD v2
Network	2 - 8 NICs	12,500 - 34,000 Mbps Interfaces: NetVSC, ConnectX
Accelerators	None	

DCasv5 and DCadsv5-series

DCasv5-series

DCasv5-series VMs offer a combination of vCPU and memory for most production workloads. These confidential VMs use AMD's third-Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache. These processors can achieve a boosted maximum frequency of 3.5 GHz. Both series offer Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP). SEV-SNP provides hardware-isolated VMs that protect data from other VMs, the hypervisor, and host management code.

Confidential VMs offer hardware-based VM memory encryption. These series also offer OS disk pre-encryption before VM provisioning with different key management solutions. These VMs with no local disk provide a better value proposition for workloads where you don't need a local temporary disk. For more information, see the FAQ for Azure VM sizes with no local temporary disk.

View the full DCasv5-series page.

Network	2 - 8 NICs	3,000 - 20,000 Mbps Interfaces: NetVSC, ConnectX
Accelerators	None	

DCesv6-series

The DCesv6-series are Azure confidential VMs that protect the confidentiality and integrity of code and data while it's being processed. Organizations can use these VMs to seamlessly bring confidential workloads to the cloud without any code changes to the application. These machines are powered by Intel® 5th Generation Xeon® Scalable processors reaching an all-core turbo clock speed of 3.0 GHz and Intel® AMX for AI acceleration.

With the support of Intel® Trust Domain Extensions (TDX), these VMs are hardened from the cloud virtualized environment by denying the hypervisor, other host management code, and administrators access to the VM memory and state. It helps to protect VMs against a broad range of sophisticated hardware and software attacks.

These VMs have native support for confidential disk encryption meaning organizations can encrypt their VM disks at boot with either a customer-managed key (CMK), or platform-managed key (PMK). This feature is fully integrated with Azure Key Vault or Azure Managed HSM with validation for FIPS 140-2 Level 3.

The DCesv6-series offers a balance of memory to vCPU performance. With up to 128 vCPUs, 512 GB of RAM, and support for remote disk storage, this size series works well for many general computing workloads, e-commerce systems, web front ends, desktop virtualization solutions, sensitive databases, other enterprise applications.

View the full DCesv6-series page.

DCas_cc_v5 and DCads_cc_v5-series

DCas_cc_v5-series

Confidential child capable VMs allow you to borrow resources from the parent VM you deploy, to create AMD SEV-SNP protected child VMs. The parent VM has almost complete feature parity with any other general purpose Azure VM (for example, D-series VMs). This parent-child deployment model can help you achieve higher levels of isolation from the Azure host and parent VM. These confidential child capable VMs are built on the same hardware that powers our Azure confidential VMs. Azure confidential VMs are now generally available. The DCas_cc_v5-series sizes offer a combination of vCPU and memory for most production workloads. These new VMs with no local disk provide a better value proposition for workloads that do not require local temp disk.

DCsv3 and DCdsv3-series

DCsv3-series

The DCsv3-series Azure Virtual Machines help protect the confidentiality and integrity of your code and data while they're being processed in the public cloud. By using Intel® Software Guard Extensions and Intel® Total Memory Encryption - Multi Key, customers can ensure their data is always encrypted and protected in use. These machines are powered by the latest 3rd Generation Intel® Xeon Scalable processors, and use Intel® Turbo Boost Max Technology 3.0 to reach 3.5 GHz. With this generation, CPU Cores have increased 6x (up to a maximum of 48 physical cores). Encrypted Memory (EPC) has increased 1500x to 256 GB. Regular Memory has increased 12x to 384 GB. All these changes substantially improve the performance and unlock entirely new scenarios.

Network	2 - 8 NICs	
Accelerators	None	

DCsv2-series

The DCsv2-series virtual machines help protect the confidentiality and integrity of your data and code while it's processed in the public cloud. DCsv2-series leverage Intel® Software Guard Extensions (SGX), which enable customers to use secure enclaves for protection. These machines are backed by 3.7 GHz Intel® Xeon E-2288G (Coffee Lake) with SGX technology. With Intel® Turbo Boost Max Technology 3.0 these machines can go up to 5.0 GHz. Example confidential use cases include: databases, blockchain, multiparty data analytics, fraud detection, anti-money laundering, usage analytics, intelligence analysis and machine learning.

> **Note**
>
> DCsv2-series virtual machines (VMs) are scheduled for retirement on June 30, 2026.

DCasv5 sizes series

DCasv5-series VMs offer a combination of vCPU and memory for most production workloads. These confidential VMs use AMD's third-Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache. These processors can achieve a boosted maximum frequency of 3.5 GHz. Both series offer Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP). SEV-SNP provides hardware-isolated VMs that protect data from other VMs, the hypervisor, and host management code. Confidential VMs offer hardware-based VM memory encryption. These series also offer OS disk pre-encryption before VM provisioning with different key management solutions. These VMs with no local disk provide a better value proposition for workloads where you don't need a local temporary disk. For more information, see the FAQ for Azure VM sizes with no local temporary disk.

DCasv6 sizes series

Summarize this article for me

Azure's DCasv6-series virtual machines provide robust confidential computing capabilities, ensuring code and data remain secure during processing. Companies can migrate sensitive workloads to cloud infrastructure without modifying existing applications. The series runs on AMD's fourth-generation EPYC™ processors configured for multi-threaded operations with enhanced L3 cache architecture.

AMD's SEV-SNP technology creates hardware-isolated environments that prevent unauthorized access from hypervisors, host management systems, and administrative users. This isolation protects virtual machines from neighboring VMs, hypervisor vulnerabilities, and both hardware and software-based security threats.

The platform includes hardware-based VM memory encryption alongside native support for confidential disk encryption feature. Organizations can implement OS disk encryption at boot through customer-managed keys (CMK) or platform-managed keys (PMK). This feature is fully integrated with Azure KeyVault and Azure Managed HSM ensuring FIPS 140-2 Level 3 compliance.

DCasv6 instances provide balanced memory-to-vCPU ratios suitable for production environments. Configurations scale up to 96 vCPUs paired with 384 GiB RAM and remote storage connectivity. These specifications support diverse workloads including e-commerce platforms, web services, desktop virtualization, secure databases, enterprise applications and more.

DCsv3 sizes series

The DCsv3-series Azure Virtual Machines help protect the confidentiality and integrity of your code and data while they're being processed in the public cloud. By using Intel® Software Guard Extensions and Intel® Total Memory Encryption - Multi Key, customers can ensure their data is always encrypted and protected in use. These machines are powered by the latest 3rd Generation Intel® Xeon Scalable processors, and use Intel® Turbo Boost Max Technology 3.0 to reach 3.5 GHz. With this generation, CPU Cores have increased 6x (up to a maximum of 48 physical cores). Encrypted Memory (EPC) has increased 1500x to 256 GB. Regular Memory has increased 12x to 384 GB. All these changes substantially improve the performance and unlock entirely new scenarios.

DCsv2 sizes series

The DCsv2-series virtual machines help protect the confidentiality and integrity of your data and code while it's processed in the public cloud. DCsv2-series leverage Intel® Software Guard Extensions (SGX), which enable customers to use secure enclaves for protection. These machines are backed by 3.7 GHz Intel® Xeon E-2288G (Coffee Lake) with SGX technology. With Intel® Turbo Boost Max Technology 3.0 these machines can go up to 5.0 GHz. Example confidential use cases include: databases, blockchain, multiparty data analytics, fraud detection, anti-money laundering, usage analytics, intelligence analysis and machine learning.

> **Note**
>
> DCsv2-series virtual machines (VMs) are scheduled for retirement on June 30, 2026.

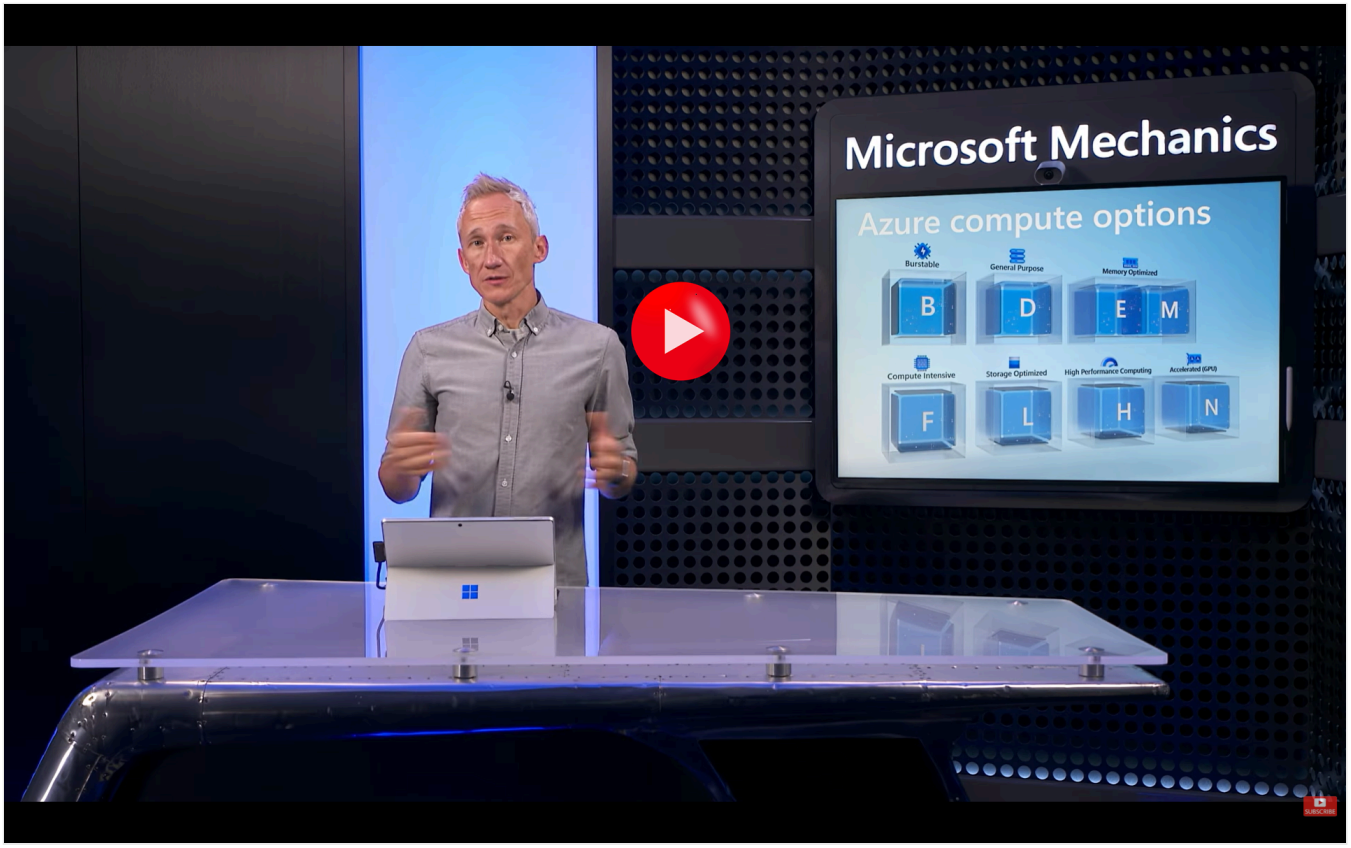
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

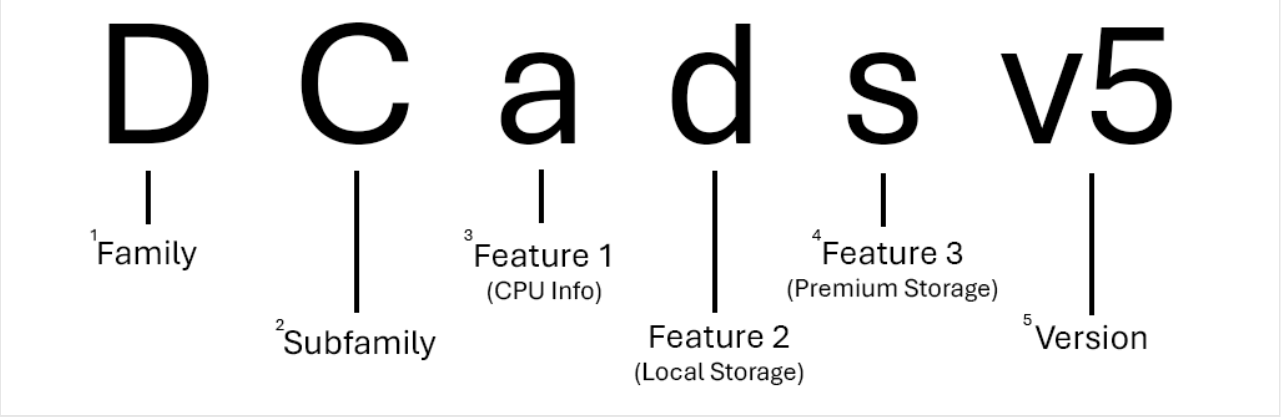
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

Family list

Expand table

Family	Workloads	Series List
A-family	Entry-level economical	Av2-series Previous-gen A-family series

'F' family compute optimized VM size series

09/09/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'F' family of VM size series are one of Azure's compute-optimized VM instances. They're designed for workloads that require high CPU performance, such as batch processing, web servers, analytics, and gaming. Featuring a high CPU-to-memory ratio, F-series VMs are equipped with powerful processors to handle applications that demand more CPU capacity relative to memory. This makes them particularly effective for scenarios where fast and efficient processing is critical, allowing businesses to run their compute-bound applications efficiently and cost-effectively.

Workloads and use cases

Web Servers: F-series VMs are excellent for hosting web servers and applications that require significant compute capability to handle web traffic efficiently without necessarily needing large amounts of memory.

Batch Processing: F-series VMs are ideal for batch jobs and other processing tasks that involve handling large volumes of data or tasks in a queue but are more CPU-intensive than memory-intensive.

Application Servers: Applications that require quick processing and do not have high memory demands can benefit from F-series VMs. These can include medium traffic application servers, back-end servers for enterprise applications, and other similar tasks. Gaming Servers: Due to their high CPU performance, F-series VMs are also suitable for gaming servers where fast processing is critical for a good gaming experience.

Analytics: F-series VMs can be used for data analytics applications that require processing speed to crunch numbers and perform calculations more than they require a large amount of memory.

Series in family

Fasv7 series and Fadsv7 series

Fasv7 series

The Fasv7-series utilizes AMD's 5th Generation EPYC™ 9005 processor that can achieve a boosted maximum frequency of up to 4.5 GHz. The Fasv7 VM series comes without Simultaneous Multithreading (SMT), meaning a vCPU is now mapped to a full physical core, allowing software processes to run on dedicated and uncontested resources. These new full core VMs suit workloads demanding the highest CPU performance. Fasv7-series offers up to 80 full core and 320 GiB of RAM. The new VMs with no local disk provide a better value proposition for workloads that do not require local temporary storage. This series is optimized for scientific simulations, financial and risk analysis, gaming, rendering and other workloads able to take advantage of the exceptional performance.

View the full Fasv7-series page.

Network	2 - 15 NICs	16000 - 80000 Mbps
Accelerators	None	

Famsv7 series and Famdsv7 series

Famsv7 series

The Famsv7-series utilizes AMD's 5th Generation EPYC™ 9005 processor that can achieve a boosted maximum frequency of up to 4.5 GHz. The Famsv7-series VM comes without Simultaneous Multithreading (SMT), meaning a vCPU is now mapped to a full physical core, allowing software processes to run on dedicated and uncontested resources. These new full core VMs suit workloads demanding the highest CPU performance. Famsv7-series offers up to 80 full core vCPUs and 640 GiB of RAM. These VMs offer a combination of core and memory that is ideal for memory-intensive enterprise applications. The new VMs with no local disk provide a better value proposition for workloads that do not require local temporary storage. This series is optimized for scientific simulations, financial and risk

analysis, gaming, rendering and other workloads able to take advantage of the exceptional performance.

Accelerators	None	

Falsv7 series and Faldsv7 series

Falsv7 series

The Falsv7-series utilizes AMD's 5th Generation EPYC™ 9005 processor that can achieve a boosted maximum frequency of up to 4.5 GHz. The Falsv7 VM series comes without Simultaneous Multithreading (SMT), meaning a vCPU is now mapped to a full physical core, allowing software processes to run on dedicated and uncontested resources. These new full core VMs suit workloads demanding the highest CPU performance. Falsv7-series offers up to 80 full core and 160 GiB of RAM. These VM sizes can reduce cost when running non-memory intensive applications. The new VMs with no local disk provide a better value proposition for workloads that do not require local temporary storage. This series is optimized for scientific simulations, financial and risk analysis, gaming, rendering and other workloads able to take advantage of the exceptional performance.

Fadsv7 sizes series

The Fadsv7-series utilizes AMD's 5th Generation EPYC™ 9005 processor that can achieve a boosted maximum frequency of up to 4.5 GHz. The Fadsv7 VM series comes without Simultaneous Multithreading (SMT), meaning a vCPU is now mapped to a full physical core, allowing software processes to run on dedicated and uncontested resources. These new full core VMs suit workloads demanding the highest CPU performance. Fadsv7-series offers up to 80 full core and 320 GiB of RAM. The new VMs with local disk are ideal for workloads that require local temporary storage. This series is optimized for scientific simulations, financial and risk analysis, gaming, rendering and other workloads able to take advantage of the exceptional performance.

Fsv2-series

The Fsv2-series sizes run on the Intel® Xeon® Platinum 8573C (Emerald Rapids), Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake) processors, or the Intel® Xeon® Platinum 8168 (Skylake) processors. Processor availability varies by region; sizes may run on any of the listed processors.

The Fsv2-series features a sustained all core Turbo clock speed of 3.4 GHz and a maximum single-core turbo frequency of 3.7 GHz. Intel® AVX-512 instructions are new on Intel Scalable Processors. These instructions provide up to a 2X performance boost to vector processing workloads on both single and double precision floating point operations. In other words, they're really fast for any computational workload. Fsv2-series VMs feature Intel® Hyper-Threading Technology.

'FX' family general purpose VM size series

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'FX' family of VM size series are one of Azure's specialized compute-optimized VM instances, designed primarily workloads that require significant CPU capabilities. These VMs use the latest Intel Ice Lake processors and are optimized for compute-intensive tasks such as financial modeling, scientific simulations, and heavy calculations. With a high frequency and a large cache per core, FX-series VMs provide exceptional computational power, making them ideal for scenarios demanding extensive processing resources and rapid execution of complex operations.

Workloads and use cases

Electronic Design Automation (EDA): FX-series VMs are well-suited for EDA workloads, which require high CPU clock speeds and high memory-to-CPU ratios. These workloads benefit from the high single-core performance and large memory capacity of FX-series VMs.

Batch Processing: FX-series VMs are excellent for high-throughput batch processing jobs, such as those involving large-scale data analysis and transformation, where rapid processing is critical.

Data Analytics: FX-series VMs are suitable for intensive data analytics applications, especially those that require quick iteration and processing of large data sets.

Series in family

FX-series

The FX-series runs on the Intel® Xeon® Gold 6246R (Cascade Lake) processors. It features an all-core-turbo frequency of 4.0 GHz, 21 GB RAM per vCPU, up to 1 TB total RAM, and local temporary storage. The FX-series will benefit workloads that require a high CPU clock speed and high memory to CPU ratio, workloads with high per-core licensing costs, and applications requiring a high single-core performance. A typical use case for FX-series is the Electronic Design Automation (EDA) workload. FX-series VMs

feature Intel® Turbo Boost Technology 2.0, Intel® Hyper-Threading Technology, and Intel® Advanced Vector Extensions 512 (Intel® AVX-512).

FXmsv2 sizes series

Summarize this article for me

The FXmsv2-series Virtual Machine (VM) runs on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor in a hyper threaded configuration. FXv2-series VMs features an all-core-turbo frequency up to 4.0 GHz. These virtual machines offer up to 96 vCPU and up to 1832 GiB of RAM. The FXmsv2-series benefits workloads that are ideal for memory-intensive enterprise applications requiring a high memory to CPU ratio, high performance, high CPU clock speed, higher remote storage IOPs and throughput. Typical use-cases for FX-series are the Electronic Design Automation (EDA) and SQL workloads

FXmsv2-series virtual machines don't support local storage, thus offering a lower price point for entry. You can attach Standard SSDs, Standard HDDs, Premium SSDs, and Premium SSD v2 storage to these virtual machines. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

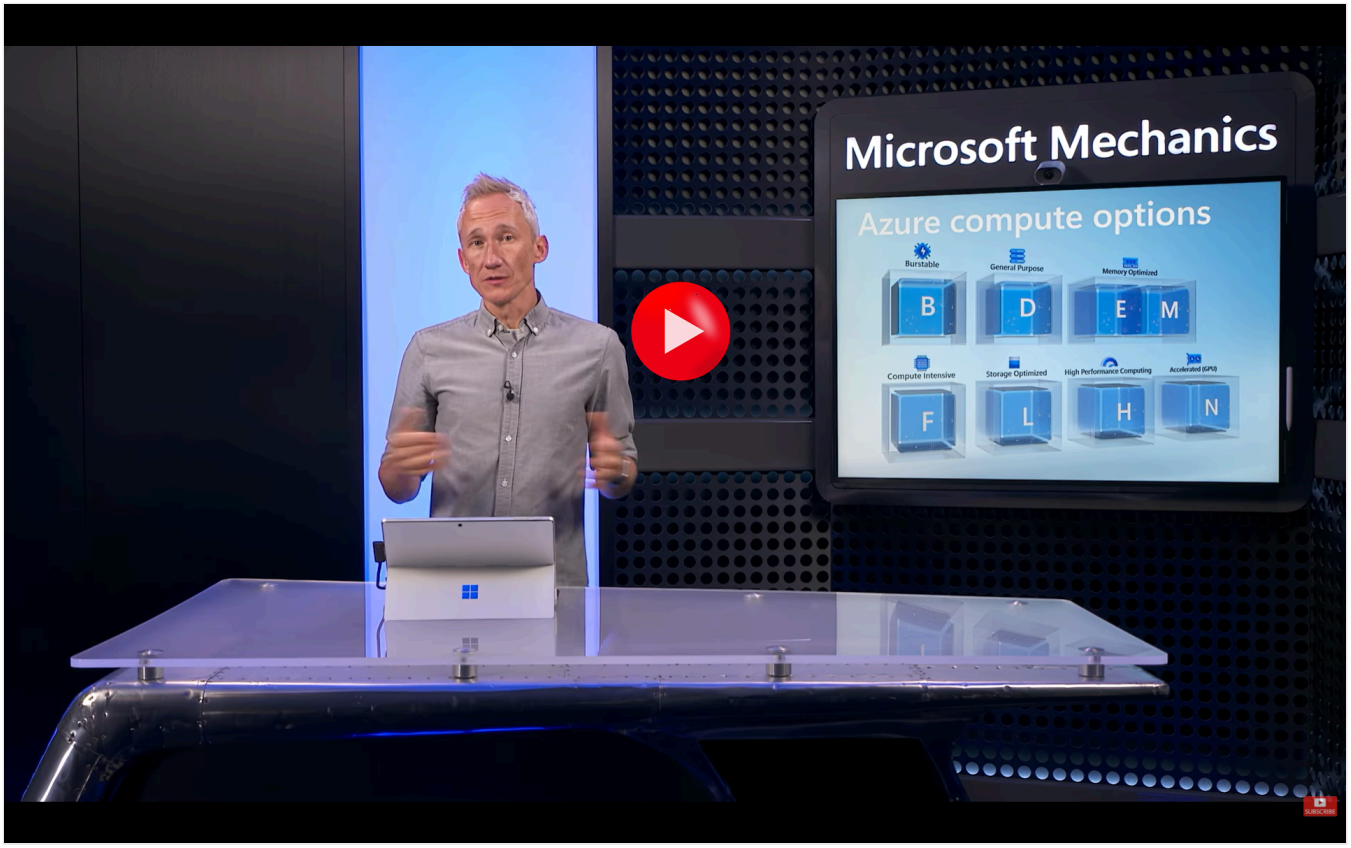
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

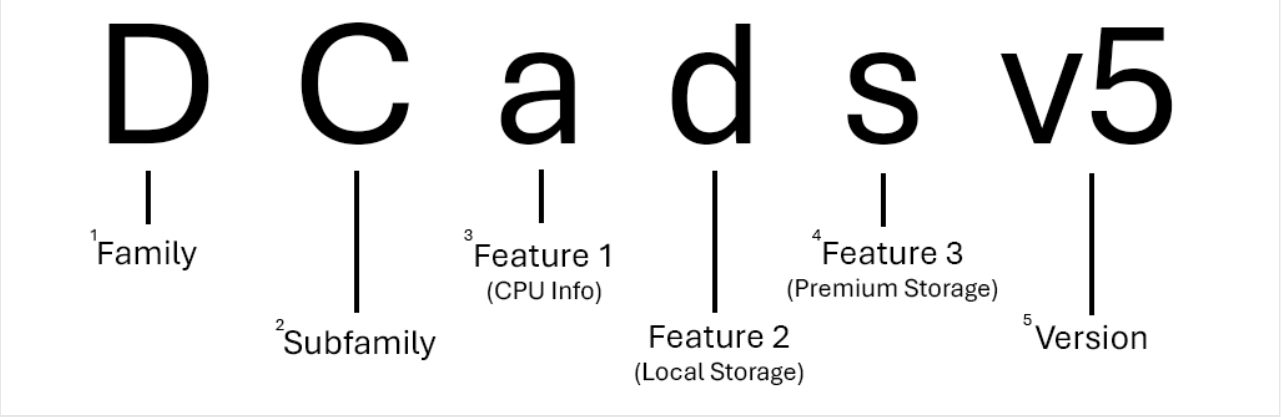
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

'E' family memory optimized VM size series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'E' family of VM size series are one of Azure's memory-optimized VM instances. They're designed for memory-intensive workloads, such as large databases, big data analytics, and enterprise applications that require significant amounts of RAM to maintain high performance. Equipped with high memory-to-core ratios, E-series VMs support applications and services that benefit from faster data access and more efficient data processing capabilities. This makes them particularly well-suited for scenarios involving in-memory databases and extensive data processing tasks where ample memory is crucial for optimal performance.

Workloads and use cases

Memory-Intensive Workloads: E-family VMs are for workloads that demands a large memory footprint to efficiently handle tasks, such as simulations, large-scale computations in scientific research, or financial risk modeling.

Large Databases and SQL Servers: E-family VMs are ideal for hosting large relational databases like SQL Server and NoSQL databases that benefit from high memory capacities for improved performance in data processing and transaction handling.

Enterprise Applications: E-family VMs are suitable for resource-intensive enterprise applications, including large-scale ERP and CRM systems, where the availability of ample memory is crucial for managing complex transactions and user loads.

Big Data Applications: E-family VMs are effective for big data analytics applications that need to process vast amounts of data in memory to speed up analysis and insights generation.

In-Memory Computing: E-family VMs are great for in-memory databases (e.g., SAP HANA) that require large amounts of RAM to keep the entire dataset in memory, allowing for ultra-fast data processing and query responses.

Data Warehousing: E-family VMs provide the necessary resources for data warehousing solutions that handle and analyze large datasets, improving query performance and reducing response times.

Series in family

Esv7 and Edsv7-series

Esv7 series

Esv7-series virtual machines run on the Intel® Xeon® 6973PC (Granite Rapids) processor, reaching an all-core turbo clock speed of 3.6 GHz with a maximum turbo frequency is 4.2 GHz. This new processor features Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512), and Intel® Advanced Matrix Extensions. These virtual machines offer up to 372 vCPUs and 2,832 GiB of RAM. Esv7-series virtual machines are ideal for memory-intensive workloads, such as relational database servers, large databases, data analytics engines, in-memory caches, and more.Esv7-series virtual machines provide better performance for most general-purpose workloads compared to the prior generation, for example increased networking, increased remote storage performance, upgraded CPU, and elevated memory bandwidth.

Esv7-series virtual machines are ideal for memory-intensive workloads, such as SQL and NoSQL database servers, data analytics engines, data warehousing workloads, business intelligence applications, in-memory databases such as SAP and Redis, and in-memory analytics and more.

View the full Esv7-series page.

Easv7 series and Eadsv7 series

Easv7 series

Easv7-series VMs utilize AMD's 5th Generation EPYC™ 9005 processors that can achieve a boosted maximum frequency of up to 4.5 GHz. These virtual machines offer up to 160 vCPU and 1280 GiB of RAM. The Easv7-series sizes offer a combination of vCPU and memory that is ideal for memory-intensive enterprise applications. The new VMs with no local disk provide a better value proposition for workloads that don't require local temporary storage.

View the full Easv7-series page.

Ebsv6 and Ebdsv6-series

Ebsv6-series

The Ebsv6-series virtual machines run on the fifth Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor and deliver higher remote storage performance compared to the previous generation. The Ebsv6-series is ideal for storage throughput intensive workloads. These virtual machines offer up to 800,000 IOPS and 14,000 MBps of remote disk storage performance. Additionally, the Ebsv6 VM series offer up to 192vCPU and 1,832 GiB of RAM providing larger processing power to consolidate workloads. Refer to the Premium SSD, Premium SSD v2, and Ultra disks to attain published disk performance.

Epsv6 and Epdsv6-series

Epsv6-series

The Epsv6-series virtual machines are powered by Azure's first-generation Cobalt 100 processor, delivering outstanding performance for memory optimized workloads. The Azure Cobalt 100 processor operates at 3.4 GHz and provides an entire physical core for each virtual machine vCPU. These virtual machines offer 8 GiB of memory per vCPU and a wide range of vCPU sizes. These VMs are best suited for memory-intensive scale-out and enterprise workloads, such as relational database servers, large databases, data analytics engines, in-memory caches, and more. Epsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. For more information, see pricing for disks. Epsv6-series virtual machines offer up to 96 vCPU and 672 GiB of RAM. These VMs come without local disk, providing a better value proposition for workloads that don't require local temporary storage.

Easv6 and Eadsv6-series

Easv6-series

Easv6-series VMs utilize AMD's fourth Generation EPYC™ 9004 processors that can achieve a boosted maximum frequency of 3.7 GHz. These virtual machines offer up to 96 vCPU and 672 GiB of RAM. The Easv6-series sizes offer a combination of vCPU and memory that is ideal for memory-intensive enterprise applications. The new VMs with no local disk provide a better value proposition for workloads that don't require local temporary storage.

Ev5 and Esv5-series

Ev5-series

Esv5-series virtual machines run on Intel® Xeon® Platinum 8473C (Sapphire Rapids), or Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper threaded configuration. This new processor features an all core turbo clock speed of 3.5 GHz with Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512) and Intel® Deep Learning Boost. These virtual machines offer up to 104 vCPU and 672 GiB of RAM. Esv5-series virtual machines don't have temporary storage thus lowering the price of entry.

Esv5-series supports Standard SSD, Standard HDD, and Premium SSD disk types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Edv5 and Edsv5-series

Edv5-series

Edv5-series virtual machines run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper threaded configuration. This new processor features an all core turbo clock speed of 3.5 GHz with Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512) and Intel® Deep Learning Boost. These virtual machines offer up to 104 vCPU and 672 GiB of RAM and fast, local SSD storage up to 3800 GiB. Edv5-series virtual machines are ideal for memory-intensive enterprise applications and applications that benefit from low latency, high-speed local storage.

Edv5-series virtual machines support Standard SSD and Standard HDD disk types. To use Premium SSD or Ultra Disk storage, select Edsv5-series virtual machines. Disk storage is billed separately from virtual machines.

Epsv6 sizes series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows Client VMs ✔ Flexible scale sets ✔ Uniform scale sets

The Epsv6-series virtual machines are powered by Azure's first-generation Cobalt 100 processor, delivering outstanding performance for memory optimized workloads. The Azure Cobalt 100 processor operates at 3.4 GHz and provides an entire physical core for each virtual machine vCPU. These virtual machines offer 8 GiB of memory per vCPU and a wide range of vCPU sizes. These VMs are best suited for memory-intensive scale-out and enterprise workloads, such as relational database servers, large databases, data analytics engines, in-memory caches, and more. Epsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. For more information, see pricing for disks. Epsv6-series virtual machines offer up to 96 vCPU and 672 GiB of RAM. These VMs come without local disk, providing a better value proposition for workloads that don't require local temporary storage.

Epdsv6 sizes series

Applies to: ✔ Linux VMs ✔ Windows Client VMs ✔ Flexible scale sets ✔ Uniform scale sets

The Epdsv6-series virtual machines are powered by Azure's first-generation Cobalt 100 processor, delivering outstanding performance for memory optimized workloads. The Azure Cobalt 100 processor operates at 3.4 GHz and provides an entire physical core for each virtual machine vCPU. These virtual machines offer 8 GiB of memory per vCPU and a wide range of vCPU sizes. These VMs are best suited for memory-intensive scale-out and enterprise workloads, such as relational database servers, large databases, data analytics engines, in-memory caches, and more. Epdsv6-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines. For more information, see pricing for disks. Epdsv6-series virtual machines offer up to 96 vCPU, up to 672 GiB of RAM, and up to 5,280 GiB of fast local NVMe temporary storage.

Easv6 sizes series

Summarize this article for me

Easv6-series VMs utilize AMD's fourth Generation EPYC™ 9004 processors that can achieve a boosted maximum frequency of 3.7 GHz. These virtual machines offer up to 96 vCPU and 672 GiB of RAM. The Easv6-series sizes offer a combination of vCPU and memory that is ideal for memory-intensive enterprise applications. The new VMs with no local disk provide a better value proposition for workloads that don't require local temporary storage.

Host specifications

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.

Ev5 sizes series

Summarize this article for me

Ev5-series virtual machines run on Intel® Xeon® Platinum 8573C (Emerald Rapids), Intel® Xeon® Platinum 8473C (Sapphire Rapids) or Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper threaded configuration. This new processor features an all core turbo clock speed of 3.5 GHz with Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512) and Intel® Deep Learning Boost. These virtual machines offer up to 104 vCPU and 672 GiB of RAM. Esv5-series virtual machines don't have temporary storage thus lowering the price of entry.

Ev5-series supports Standard SSD, Standard HDD, and Premium SSD types. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Ensv6 sizes series (Preview)

Summarize this article for me

Ensv6-series virtual machines run on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor reaching an all- core turbo clock speed of up to 3.0 GHz. These virtual machines offer up to 128 vCPU and 1024 GiB of RAM. Ensv6-series virtual machines are ideal for memory-intensive enterprise applications and applications that benefit from low latency, high-speed local storage.

Network Optimized VMs enhance accelerated networking by providing hardware acceleration of initial connection setup for certain traffic types, a task previously performed in software. These enhancements reduce the end-to-end latency for initially establishing a connection or initial packet flow, and allow a VM to scale up the number of connections it manages more quickly, subject to application constraints.

The Ensv6 VMs offer up to 200 Gbps network bandwidth, 15 vNICs and up to 400k Connection per Second (CPS). The series also includes up to 128 vCPU and 1024 GiB of RAM.

Both series provide up to 3x improvement in NW BW/vCPU than the current generation Intel Ev6 VMs. This series will be relevant for workloads such as network virtual appliances, large-scale e-commerce applications, express route, application gateway, and more that require the ability to handle a high number of user connections and data transfers. They're also suited for media processing tasks that involve transferring large amounts of data quickly, and other applications that benefit from high NW BW/vCPU and CPS & flow limit configurations.

Endsv6 sizes series (Preview)

Summarize this article for me

Endsv6-series virtual machines run on the 5th Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor reaching an all- core turbo clock speed of up to 3.0 GHz. These virtual machines offer up to 128 vCPU and 1024 GiB of RAM. Endsv6-series virtual machines are ideal for memory-intensive enterprise applications and applications that benefit from low latency, high-speed local storage.

Network Optimized VMs enhance accelerated networking by providing hardware acceleration of initial connection setup for certain traffic types, a task previously performed in software. These enhancements reduce the end-to-end latency for initially establishing a connection or initial packet flow, and allow a VM to scale up the number of connections it manages more quickly, subject to application constraints.

Endsv6 VMs offer up to 200 Gbps network bandwidth, 15 vNICs and up to 400k Connection per Second (CPS). Both series also include up to 128 vCPU and 1024 GiB of RAM.

Both series provide up to 3x improvement in NW BW/vCPU than the current generation Intel Ev6 VMs. This series will be relevant for workloads such as network virtual appliances, large-scale e-commerce applications, express route, application gateway, and more that requires the ability to handle a high number of user connections and data transfers. They're also suited for media processing tasks that involve transferring large amounts of data quickly, and other applications that benefit from high NW BW/vCPU and CPS & flow limit configurations.

The Endsv6 series comes with a local disk. We recommend choosing Premium SSD, Premium SSD v2, or Ultra Disks to attain the published disk performance.

Epsv5 sizes series

Summarize this article for me

Epsv5-series virtual machines feature the Ampere® Altra® Arm-based processor operating at 3.0 GHz, which provides an entire physical core for each virtual machine vCPU. These virtual machines offer up to 32 vCPU and 208 GiB of RAM and are ideal for memory-intensive scale-out and most Enterprise workloads. Epsv5-series virtual machines support Standard SSD, Standard HDD, and Premium SSD types with no local-SSD support. You can also attach Ultra Disk storage based on its regional availability. Disk storage is billed separately from virtual machines.

Host specifications

Edv4 sizes series

Summarize this article for me

Edv4-series sizes run on the Intel® Xeon® Platinum 8573C (Emerald Rapids), Intel® Xeon® Platinum 8370C (Ice Lake) or the Intel® Xeon® Platinum 8272CL (Cascade Lake) processors. The Edv4 virtual machine sizes feature up to 504 GiB of RAM, in addition to fast and large local SSD storage (up to 2,400 GiB). These virtual machines are ideal for memory-intensive enterprise applications and applications that benefit from low latency, high-speed local storage. You can attach Standard SSDs and Standard HDDs disk storage to the Edv4 VMs.

'Eb' family memory optimized VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'Eb' family of VM size series are one of Azure's memory-optimized VM instances. They're designed for memory-intensive workloads with high remote storage performance, such as large databases, big data analytics, and enterprise applications that require significant amounts of RAM to maintain high performance. Equipped with high memory-to-core ratios, Eb-series VMs support applications and services that benefit from faster data access and more efficient data processing capabilities. This makes them particularly well-suited for scenarios involving in-memory databases and extensive data processing tasks where ample memory is crucial for optimal performance.

Workloads and use cases

Memory-Intensive Workloads: Eb-family VMs are for workloads that demand a large memory footprint to efficiently handle tasks, such as simulations, large-scale computations in scientific research, or financial risk modeling.

Large Databases and SQL Servers: Eb-family VMs are ideal for hosting large relational databases like SQL Server and NoSQL databases that benefit from high memory capacities for improved performance in data processing and transaction handling.

Enterprise Applications: Eb-family VMs are suitable for resource-intensive enterprise applications, including large-scale ERP and CRM systems, where the availability of ample memory is crucial for managing complex transactions and user loads.

Big Data Applications: Eb-family VMs are effective for big data analytics applications that need to process vast amounts of data in memory to speed up analysis and insights generation.

In-Memory Computing: Eb-family VMs are great for in-memory databases (e.g., SAP HANA) that require large amounts of RAM to keep the entire dataset in memory, allowing for ultra-fast data processing and query responses.

Data Warehousing: Eb-family VMs provide the necessary resources for data warehousing solutions that handle and analyze large datasets, improving query performance and reducing response times.

Series in family

Ebsv6 and Ebdsv6-series

Ebsv6-series

The Ebsv6-series virtual machines run on the fifth Generation Intel® Xeon® Platinum 8573C (Emerald Rapids) processor and deliver higher remote storage performance compared to the previous generation. The Ebsv6-series is ideal for storage throughput intensive workloads. These virtual machines offer up to 800,000 IOPS and 14,000 MBps of remote disk storage performance. Additionally, the Ebsv6 VM series offer up to 192vCPU and 1,832 GiB of RAM providing larger processing power to consolidate workloads. Refer to the Premium SSD, Premium SSD v2, and Ultra disks to attain published disk performance.

View the full Ebsv6-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	2 - 192 vCPUs	Intel Xeon Platinum 8573C (Emerald Rapids) [x86-64]
Memory	16 - 1832 GiB	
Local Storage	None	
Remote Storage	8 - 64 Disks	8800 - 800000 IOPS 253 - 14000 MBps
Network	2 - 8 NICs	12500 - 200000 Mbps
Accelerators	None	

Ebdsv5 and Ebsv5-series

The Ebdsv5 and Ebsv5 series run on the Intel® Xeon® Platinum 8370C (Ice Lake) processors in a hyper-threaded configuration. The series are ideal for various memory-intensive enterprise applications. The Ebsv5 and Ebdsv5 VMs offer up to 260000 IOPS and 8000 MBps of remote disk storage throughput. Both series also include up to 672 GiB of RAM. The Ebdsv5 series has local SSD storage up to 3800 GiB. Both series provide a 3X increase in remote storage performance of data-intensive workloads compared to prior VM generations. You can use these series to consolidate existing workloads on fewer VMs or smaller VM sizes while achieving potential cost savings. The Ebdsv5 series comes with a local disk and Ebsv5 is without

a local disk. We recommend choosing Premium SSD, Premium SSD v2 or Ultra disks to attain the published disk performance.

Ebdsv5 and Ebsv5 series

Summarize this article for me

The memory-optimized Ebsv5 and Ebdsv5 Azure virtual machine (VM) series deliver higher remote storage performance in each VM size than the Ev4 series. The increased remote storage performance of the Ebsv5 and Ebdsv5 VMs is ideal for storage throughput-intensive workloads. For example, relational databases and data analytics applications.

The Ebsv5 and Ebdsv5 VMs offer up to 260000 IOPS and 8000 MBps of remote disk storage throughput. Both series also include up to 672 GiB of RAM. The Ebdsv5 series has local SSD storage up to 3800 GiB. Both series provide a 3X increase in remote storage performance of data-intensive workloads compared to prior VM generations. You can use these series to consolidate existing workloads on fewer VMs or smaller VM sizes while achieving potential cost savings. The Ebdsv5 series comes with a local disk and Ebsv5 is without a local disk. We recommend choosing Premium SSD, Premium SSD v2 or Ultra Disks to attain the published disk performance.

The Ebdsv5 and Ebsv5 series run on the Intel® Xeon® Platinum 8370C (Ice Lake) processors in a hyper-threaded configuration. The series are ideal for various memory-intensive enterprise applications. They feature:

- Up to 512 GiB of RAM
- Intel® Turbo Boost Technology 2.0
- Intel® Hyper-Threading Technology
- Intel® Advanced Vector Extensions 512 (Intel® AVX-512)
- Support for Intel® Deep Learning Boost
- NVMe interface for higher remote disk storage IOPS and throughput performance

Important

- Accelerated networking is required and turned on by default on all Ebsv5 and Ebdsv5 VMs.
- Ebsv5 and Ebdsv5-series VMs can **burst their disk performance** and get up to their bursting max for up to 30 minutes at a time.
- The E112i size is offered as NVMe only to provide the highest IOPS and throughput performance. See the NVMe VM spec table to see the improved performance details.

Ebdsv5 series

Ebdsv5-series sizes run on the Intel® Xeon® Platinum 8370C (Ice Lake) processors. The Ebdsv5 VM sizes feature up to 672 GiB of RAM, in addition to fast and large local SSD storage (up to 3800 GiB). These VMs are ideal for memory-intensive enterprise applications and applications that benefit from high remote storage performance, low latency, high-speed local storage. Remote Data disk storage is billed separately from VMs.

- Premium Storage: Supported
- Premium Storage caching: Supported
- Live Migration: Supported
- Memory Preserving Updates: Supported
- VM Generation Support: Generation 1 and Generation 2
- Accelerated Networking: Supported (required)
- Ephemeral OS Disks: Supported
- Nested virtualization: Supported
- NVMe Interface: Supported only on Generation 2 VMs
- SCSI Interface: Supported on Generation 1 and 2 VMs

Size table definitions

- Storage capacity is shown in units of GiB or 1024^3 bytes. When you compare disks measured in GB (1000^3 bytes) to disks measured in GiB (1024^3) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps = 10^6 bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.

- To learn how to get the best storage performance for your VMs, see Virtual machine and disk performance.
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see Virtual machine network bandwidth.

  Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see Optimize network throughput for Azure virtual machines. To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see Bandwidth/Throughput testing (NTTTCP).

Ebsv5 NVMe FAQ

How is the NVMe enabled Ebsv5 different from the L series VM that Azure offers?

The NVMe enabled Ebsv5 series is designed to offer the highest Azure Managed Disk storage performance. The L series VMs are designed to offer higher IOPS and throughout on the local NVMe disks, which are ephemeral. Refer to the VM sizes documentation for details on the performance offered by the Ebsv5 and L series.

What I/O size is recommended to achieve the published performance?

To achieve the maximum IOPS, we recommend using a 4 KiB or 8 KiB block size. For maximum performance throughput, you can choose to use one of the following block sizes: 64 KiB, 128 KiB, 256 KiB, 512 KiB or 1024 KiB. However, it's important to optimize the I/O size based on the specific requirements of your application and to use the recommended block sizes only as a guideline.

What workloads benefit with NVMe on Ebsv5 family?

The Ebsv5 VM families are suitable for various workloads that require high I/O and improved remote storage performance. Some examples of such workloads include:

- Online transaction processing (OLTP) workloads: These workloads involve frequent, small, and fast database transactions, such as online banking, e-commerce, and point-of-sale systems.
- Online analytical processing (OLAP) workloads: These workloads involve complex queries and large-scale data processing, such as data mining, business intelligence, and decision support systems.
- Data warehousing workloads: These workloads involve collecting, storing, and analyzing large volumes of data from multiple sources, such as customer data, sales data, and financial data.
- Replication and disaster recovery workloads: These workloads involve replicating data between multiple databases or sites for backup and disaster recovery purposes.
- Database development and testing workloads: These workloads involve creating, modifying, and testing database schemas, queries, and applications.

What platforms and generations support NVMe VMs?

NVMe VMs are only accessible on the platform with the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor. However, support for more platforms and generations is coming soon. Stay informed by following our product launch announcements in Azure updates.

The Azure region I need doesn't support NVMe, when will NVMe be available?

Watch out for our product launch announcements in the Azure updates.

What sizes in the Ebsv5 and Ebdsv5 family support NVMe?

The sizes E2-E112i support NVMe on Ebsv5 and Ebdsv5 families.

What sizes in the Ebsv5 and Ebdsv5 family support SCSI?

All sizes (E2-E96) on the Ebsv5 and Ebsdv5 families support SCSI except E112i.

I have a SCSI Ebsv5 VM. How do I switch to NVMe of the same VM size?

The steps to switch from SCSI to NVMe are the same as explained here.

How can I switch back to SCSI interface from NVMe VM?

To switch back to SCSI from NVMe, follow the same steps as explained here.

What is the price for NVMe Ebsv5 prices?

The NVMe enabled Ebsv5 and Ebdsv5 VMs are the same price as SCSI VMs. Refer to the pricing pages for Windows and Linux. With NVMe, you get higher performance at no extra cost.

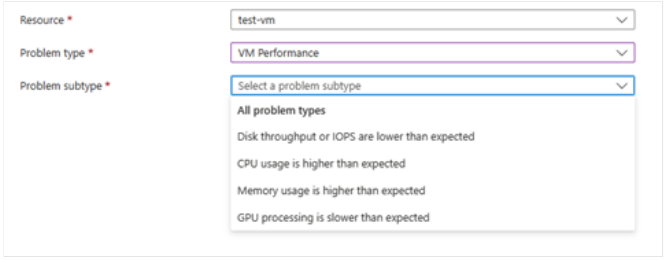
How can I try before purchasing this VM series? Is preview still available?

The preview period for this offer is over, and it is now generally available for purchase. You can request a quota for one of the available Azure regions to try out the new NVMe Ebsv5 or Ebdsv5 sizes.

Reporting Issues

My VMs don't reach the published performance limits. Where do I report this issue?

If you see performance issues, you can submit a support ticket. Provide all relevant information on the ticket, such as the subscription, VM size used, region, logs, and screenshot.



How can I get more help if I run into issues while setting up the VMs with the NVMe interface?

If you run into issues while creating or resizing Ebsv5 or Ebdsv5 to NVMe, and need assistance, you can submit a support ticket.

'EC' sub-family memory optimized VM size series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'EC' sub-family of VM size series are one of Azure's security focused memory-optimized VM instances. They're designed for confidential computing with enhanced data protection and integrity, featuring various hardware-based Trusted Execution Environments (TEEs). These instances are ideal for memory-intensive workloads, such as large databases, big data analytics, and enterprise applications that require significant amounts of RAM to maintain high performance.

Workloads and use cases

Memory-Intensive Workloads: Any workload that demands a large memory footprint to efficiently handle tasks, such as simulations, large-scale computations in scientific research, or financial risk modeling.

Large Databases and SQL Servers: They are ideal for hosting large relational databases like SQL Server and NoSQL databases that benefit from high memory capacities for improved performance in data processing and transaction handling.

Enterprise Applications: Suitable for resource-intensive enterprise applications, including large-scale ERP and CRM systems, where the availability of ample memory is crucial for managing complex transactions and user loads.

Big Data Applications: Effective for big data analytics applications that need to process vast amounts of data in memory to speed up analysis and insights generation.

In-Memory Computing: Such as in-memory databases (e.g., SAP HANA) that require large amounts of RAM to keep the entire dataset in memory, allowing for ultra-fast data processing and query responses.

Data Warehousing: Provides the necessary resources for data warehousing solutions that handle and analyze large datasets, improving query performance and reducing response times.

Series in family

ECasv6 and ECadsv6-series

ECasv6-series

Azure's ECasv6-series virtual machines provide robust confidential computing capabilities, ensuring code and data remain secure during processing. Companies can migrate sensitive workloads to cloud infrastructure without modifying existing applications. The series runs on AMD's fourth-generation EPYC™ processors configured for multi-threaded operations with enhanced L3 cache architecture. AMD's SEV-SNP technology creates hardware-isolated environments that prevent unauthorized access from hypervisors, host management systems, and administrative users. This isolation protects virtual machines from neighboring VMs, hypervisor vulnerabilities, and both hardware and software-based security threats.

The platform includes hardware-based VM memory encryption alongside native support for confidential disk encryption feature. Organizations can implement OS disk encryption at boot through customer-managed keys (CMK) or platform-managed keys (PMK). This feature is fully integrated with Azure KeyVault and Azure Managed HSM ensuring FIPS 140-2 Level 3 compliance.

ECasv6 instances provide balanced memory-to-vCPU ratios suitable for production environments. Configurations scale up to 96 vCPUs paired with 672 GiB RAM and remote storage connectivity. These specifications support diverse workloads including e-commerce platforms, web services, desktop virtualization, secure databases, enterprise applications and more.

View the full ECasv6-series page.

Part	**Quantity** **Count Units**	**Specs** **SKU ID, Performance Units, etc.**
Processor	2 - 96 vCPUs	AMD EPYC™ 9004 (Genoa) [x86-64]
Memory	16 - 672 GiB	
Local Storage	None	
Remote Storage	8 - 64 Disks	4000 - 175000 IOPS 90 - 4320 MBps
Network	2 - 8 NICs	12500 - 34000 Mbps
Accelerators	None	

ECas_ccv5 and ECads_ccv5-series

Confidential child capable VMs allow you to borrow resources from the parent VM you deploy, to create AMD SEV-SNP protected child VMs. The parent VM has almost complete feature parity with any other general purpose Azure VM (for example, E-series VMs). This parent-child deployment model can help you achieve higher levels of isolation from the Azure host and parent VM. These confidential child capable VMs are built on the same hardware that powers our Azure confidential VMs. Azure confidential VMs are now generally available.

ECasv5 and ECadsv5-series

Article • 12/03/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

The ECasv5-series and ECadsv5-series are confidential VMs for use in Confidential Computing.

These confidential VMs use AMD's third-Generation EPYC™ 7763v processor in a multi-threaded configuration with up to 256 MB L3 cache. This processor can achieve a boosted maximum frequency of 3.5 GHz. Both series offer Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP). SEV-SNP provides hardware-isolated VMs that protect data from other VMs, the hypervisor, and host management code. Confidential VMs offer hardware-based VM memory encryption. These series also offer OS disk pre-encryption before VM provisioning with different key management solutions.

These VM series also offer a combination of vCPUs and memory to meet the requirements of most memory-intensive enterprise applications.

ECasv5-series

ECasv5-series VMs offer a combination of vCPU and memory for memory-intensive enterprise applications. These VMs with no local disk provide a better value proposition for workloads where you don't need a local temp disk. For more information, see the FAQ for Azure VM sizes with no local temporary disk.

This series supports Standard SSD, Standard HDD, and Premium SSD disk types. Billing for disk storage and VMs is separate. To estimate your costs, use the Pricing Calculator.

> **Note**
>
> There are some pricing differences based on your encryption settings for confidential VMs.

ECasv5-series feature support

Supported features in ECasv5-series VMs:

- Premium Storage
- Premium Storage caching
- VM Generation 2

Unsupported features in ECasv5-series VMs:

- Live Migration

- Memory Preserving Updates
- Accelerated Networking
- Ephemeral OS Disks
- Nested Virtualization

ECesv6 series

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs

The ECesv6-series are Azure confidential VMs that can be used to protect the confidentiality and integrity of your code and data while it's being processed in the public cloud. Organizations can use these VMs to seamlessly bring confidential workloads to the cloud without any code changes to the application.

These machines are powered by Intel® 5th Generation Xeon® Scalable processors reaching an all-core turbo clock speed of 3.0 GHz and Intel® Advanced Matrix Extensions (AMX) for AI acceleration.

Featuring Intel® Trust Domain Extensions (TDX), these VMs are hardened from the cloud virtualized environment by denying the hypervisor, other host management code and administrators access to the VM memory and state. It helps to protect VMs against a broad range of sophisticated hardware and software attacks.

These VMs have native support for confidential disk encryption meaning organizations can encrypt their VM disks at boot with either a customer-managed key (CMK), or platform-managed key (PMK). This feature is fully integrated with Azure KeyVault or Azure Managed HSM with validation for FIPS 140-2 Level 3.

> **Note**
>
> There are some pricing differences based on your encryption settings for confidential VMs.

ECesv6-series feature support

Supported features in ECesv6-series VMs:

- Premium Storage
- Premium Storage caching
- VM Generation 2

Unsupported features in ECesv6-series VMs:

- Live Migration
- Memory Preserving Updates
- Accelerated Networking

- Nested Virtualization

ECesv6-series

The ECesv6 VMs offer even higher memory to vCPU ratio and an all new VM size with up to 64 vCPUs and 512 GiB of RAM. These VMs are ideal for memory intensive applications, large relational database servers, business intelligence applications, and critical applications that process sensitive and regulated data.

This series supports Standard SSD, Standard HDD, and Premium SSD types. Billing for disk storage and VMs is separate. To estimate your costs, use the Pricing Calculator.

Size table definitions

- Storage capacity is shown in units of GiB or 1024^3 bytes. When you compare disks measured in GB (1000^3 bytes) to disks measured in GiB (1024^3) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps = 10^6 bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache mode is set to **None**.
- To learn how to get the best storage performance for your VMs, see Virtual machine and disk performance.
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see Virtual machine network bandwidth.

  Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see Optimize network throughput for Azure virtual machines. To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see Bandwidth/Throughput testing (NTTTCP).

'M' family memory optimized VM size series

06/06/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'M' family of VM size series are one of Azure's ultra memory-optimized VM instances designed for extremely memory-intensive workloads, such as large in-memory databases, data warehousing, and high-performance computing (HPC). Equipped with substantial RAM capacities and high vCPU capabilities, the M-family VMs support applications and services that require massive amounts of memory and significant computational power. High resource allocation makes the M-family particularly well-suited for handling tasks such as heavy SQL Server and other RDBMS workloads, complex scientific simulations, real-time data processing, and large-scale enterprise resource planning (ERP) systems, ensuring peak performance for the most demanding data-centric applications.

Workloads and use cases

SQL Server workloads with high memory needs: The M-family is particularly effective for running SQL Server machines with high memory requirements, such as for online transaction processing (OLTP) or data analytics.

In-memory databases: The M-family is particularly effective for running in-memory databases that require large amounts of RAM like SQL Server, or SAP HANA.

Big data applications: The M-family is ideal for handling big data applications that need to process and analyze huge datasets in memory, improving performance and reducing the time to insights.

Data warehousing: M-family VMs provide the performance and memory needed for data warehousing applications, facilitating faster queries and better handling of large volumes of data.

Enterprise applications: The M-family supports large-scale enterprise applications, including ERP and CRM systems, which benefit from having more memory to manage larger datasets and more complex transactions efficiently.

Heavy workloads in virtualized environments: The M-family is well-equipped to handle heavy virtualized environments, offering substantial memory for hosting multiple virtual machines and applications on a single physical server.

Series in family

Mbsv3 and Mbdsv3-series

Mbsv3-series

The Memory-and-storage optimized Mbv3 VM series are based on the 4th generation Intel® Xeon® Scalable processors and deliver higher remote disk storage performance. These new VM sizes offer up to 650,000 IOPS and 10 GBps of remote disk storage throughput Premium SSD v2 and Ultra Disk, up to 4 TiB of RAM and up to 650,000 IOPS and 10 GBps throughput to remote disk storage with NVMe interface by using Ultra Disk and Premium SSD v2.

The increased remote storage performance of these VMs is ideal for storage throughput-intensive workloads such as relational databases and data analytics applications.

The resource allocation and high-performance capabilities of the Mbv3 VM series make them particularly well suited for SQL Server workloads with high memory needs, such as critical online transaction processing (OLTP), data analytics, in-memory databases, data warehousing, and the consolidation of SQL Server workloads for efficient management of multiple SQL Server instances.

Network	8 NICs	8,000 - 50,000 Mbps
Accelerators	None	

Msv3 and Mdsv3 Medium Memory series

Msv3-MM-series

The Msv3 Medium Memory(MM) Virtual Machine (VM) series, powered by 4th generation Intel® Xeon® Scalable processors, are the next generation of memory-optimized VM sizes delivering faster performance, lower total cost of ownership (TCO) and improved resilience to failures compared to previous generation Mv2 VMs. The Msv3 MM offers VM sizes of up to 4TB of memory and 4,000 MBps throughput to remote storage and provides up to 25% networking performance improvements over previous generations.

Mdsv3 Very High Memory series

The Mdsv3 Very High Memory (VHM) series, powered by 4th generation Intel® Xeon® Platinum 8490H (Sapphire Rapids) processor with an all core base frequency of 1.9 GHz and 3.5 GHz single core turbo frequency, are the next generation of memory-optimized VM sizes delivering faster performance, lower total cost of ownership and improved resilience to failures compared to the previous generation. The Mv3 VHM sizes offer 32TB of memory, up to 8 GBps of throughput for remote storage, and provide up to 185 Gbps of networking performance with the current VHM generation.

Msv2 and Mdsv2 Medium Memory series

Msv2-series

The Msv2 Medium Memory VM Series features Intel® Xeon® Platinum 8280 (Cascade Lake) processor with an all core base frequency of 2.7 GHz and 4.0 GHz single core turbo frequency. With these VMs, customers achieve increased flexibility with local disk and diskless options. Customers also have access to a set of new isolated VM sizes with more CPU and memory that go up to 192 vCPU with 4 TiB of memory.

Accelerators	None	

Mv2-series

The Mv2-series features high throughput, low latency platform running on a hyper-threaded Intel® Xeon® Platinum 8180M 2.5GHz (Skylake) processor with an all core base frequency of 2.5 GHz and a max turbo frequency of 3.8 GHz. All Mv2-series virtual machine sizes can use both standard and premium persistent disks. Mv2-series instances are memory optimized VM sizes providing unparalleled computational performance to support large in-memory databases and workloads, with a high memory-to-CPU ratio that is ideal for relational database servers, large caches, and in-memory analytics.

Msv3 High Memory sizes series

The Msv3 High Memory (HM) Virtual Machine (VM) series are the next generation of memory-optimized VM sizes delivering faster performance, lower total cost of ownership and improved resilience to failures compared to the previous generation, Mv2-series VMs. Msv3 HM offers VM sizes with memory ranging from 6TB to 16TB, up to 8,000 MBps throughout to remote storage, and up to 25% networking performance improvements over previous generations.

Host specifications

Msv2 High Memory sizes series

The Msv2 High Memory series features high throughput, low latency platform running on a hyper-threaded Intel® Xeon® Platinum 8180M 2.5GHz (Skylake) processor with an all core base frequency of 2.5 GHz and a max turbo frequency of 3.8 GHz. All Msv2 High Memory series virtual machine sizes can use both standard and premium persistent disks. Msv2 High Memory series instances are memory optimized VM sizes providing unparalleled computational performance to support large in-memory databases and workloads, with a high memory-to-CPU ratio that is ideal for relational database servers, large caches, and in-memory analytics.

Mdsv3 Very High Memory sizes series

Summarize this article for me

The Mdsv3 Very High Memory (VHM) series, powered by 4th generation Intel® Xeon® Platinum 8490H (Sapphire Rapids) processor with an all core base frequency of 1.9 GHz and 3.5 GHz single core turbo frequency, are the next generation of memory-optimized VM sizes delivering faster performance, lower total cost of ownership and improved resilience to failures compared to the previous generation. The Mv3 VHM sizes offer 32TB of memory, up to 8 GBps of throughput for remote storage, and provide up to 185 Gbps of networking performance with the current VHM generation.

Host specifications

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	896 - 1,792 vCPUs	Intel Xeon Platinum 8490H (Sapphire Rapids) [x86-64]
Memory	30,400 GiB	
Local Storage	1 Disk	4,096 GiB
Remote Storage	64 Disks	110,000 IOPS 8,000 MBps
Network	8 NICs	185,000 Mbps
Accelerators	None	

For features supported by this series, see the Feature support section.

Sizes in series

Basics

vCPUs (Qty.) and Memory for each size

Expand table

Size Name	vCPUs (Qty.)	Memory (GiB)
Standard_M896ixds_32_v3	896	30,400
Standard_M896ixds_24_v3	896	23088
Standard_M1792ixds_32_v3	1,792	30,400

VM Basics resources

- Disable SMT to run SQL Server on a VM with more than 64 vCores per NUMA node.
- VHM VM Sizes are virtual machine sizes that are Isolated to a specific hardware type and dedicated to a single customer.
- The Standard_M896ixds_32_v3 VM is the Microsoft recommended VM type with 32TB to host S/4HANA workload. This VM type has Simultaneous Multithreading (SMT) disabled. With that complies with the SAP recommendations stated in SAP note #2711650 for the specific underlying hardware used in Azure to host this Virtual Machine (VM) type. With typical S/4HANA workload, tests this VM realized the best performance.
- The Standard_M1792ixds_32_v3 VM has Simultaneous Multithreading (SMT) enabled and is ideal for analytical workloads as documented in SAP note #2711650 for the specific underlying hardware used in Azure to host this VM type. Typical S/4HANA workloads may show performance regressions compared to the Standard_M896ixds_32_v3 VM type. It is acknowledged that S/4HANA customer workloads are varying and can be different in nature. As a result, there might be cases where S/4HANA customer workloads could eventually benefit. And the Standard_M1792ixds_32_v3 VM type could provide performance improvements compared to the Standard_M896ixds_32_v3 VM type for a customer specific S/4HANA workload. Evaluating and hosting S/4HANA workload on Standard_M1792ixds_32_v3 is in the customer's own responsibilities.
- It's also important to note that these VMs are compatible with only certain generation 2 Images. For a list of images that are compatible with the Mdsv3-series, please see below
  - Windows Server 2022 Datacenter Edition latest builds
  - SUSE Linux enterprise Server 15 SP4 and later
  - Red Hat Enterprise Linux 8.8 or later
  - Ubuntu 23.10 or later
- Check vCPU quotas

Mbsv3 sizes series

Summarize this article for me

The Memory-and-storage optimized Mbv3 VM series are based on the 4th generation Intel® Xeon® Scalable processors and deliver higher remote disk storage performance. These new VM sizes offer up to 650,000 IOPS and 10 GBps of remote disk storage throughput Premium SSD v2 and Ultra Disk, up to 4 TiB of RAM and up to 650,000 IOPS and 10 GBps throughput to remote disk storage with NVMe interface by using Ultra Disk and Premium SSD v2.

The increased remote storage performance of these VMs is ideal for storage throughput-intensive workloads such as relational databases and data analytics applications.

The resource allocation and high-performance capabilities of the Mbv3 VM series make them particularly well suited for SQL Server workloads with high memory needs, such as critical online transaction processing (OLTP), data analytics, in-memory databases, data warehousing, and the consolidation of SQL Server workloads for efficient management of multiple SQL Server instances.

Msv2 and Mdsv2 isolated sizes retirement

06/06/2025

On March 31, 2027, Azure will retire the Msv2 and Mdsv2-series Medium Memory virtual machines (VM) listed:

- Msv2 Medium Memory Diskless
  - Standard_M192is_v2
  - Standard_M192ims_v2
- Mdsv2 Medium Memory with Disk
  - Standard_M192ids_v2
  - Standard_M192idms_v2

From now to March 31, 2027, you can continue to use the VMs listed without disruption. On March 31, 2027, the remaining VMs with these specific sizes on your subscription will be set to a deallocated state. These VMs are stopped and removed from the host. These VMs won't be billed in the deallocated state. To avoid service disruptions, refer to the instructions listed to migrate to your selected Mv3 replacement size by March 31, 2027.

Migrate workloads to Mv3 Medium Memory Series VMs

The Msv3 and Mdsv3 Medium Memory Series, powered by 4th generation Intel® Xeon® Scalable processors, are the next generation of memory-optimized VM sizes delivers faster performance, lower total cost of ownership and improvement to failures, compared to previous generation Mv2 VMs. The Mv3 MM series offers VM sizes of up to 4TB of memory and 4,000 MBps throughout to remote storage and provides up to 25% networking performance improvements over previous generations.

Follow the instructions listed to migrate your M192i(d)(m)s VM to your chosen Msv3 and Mdsv3 Medium Memory Series replacement.

Migration steps

1. Choose a series and size for migration. Use the pricing calculator for further insights.
2. Get quota for the target VM series.
3. Check whether the existing M192i(d)(m)s_v2 VM is part of an Availability Set or Proximity Placement Group, which can be verified in Azure portal in the VM properties.

4. If the VM isn't part of an Availability Set nor a Proximity Placement Group, it can be resized.

5. If the VM isn't part of an Availability Set, but is part of a Proximity Placement Group, you need to shut down all VMs in the PPG, resize then restart the M192i(d)(m)s_v2 VMs, then restart the other VMs in the PPG.

6. If the VM is part of an Availability Set, check your records to determine if the Availability Set is pinned to a specific M-series compute cluster for proximity purposes (for example, to collocate with services like NFS that shares hosted on Azure NetApp Files). If you aren't sure about pinning having taken place, open an Azure Support Request to confirm.

7. If your VM is part of a non-pinned Availability Set, you need to shut down all VMs in that particular Availability Set and go through the resize procedure for every VM of the Availability Set.

8. If the VM is part of a non-pinned Availability set and a Proximity Placement Group, you have two options:

    - Shut down all VMs in the PPG, resize then restart the M192i(d)(m)s_v2 VMs, then restart the other VMs in the PPG.

    - Switch availability options to Availability Zone as described using the open source supported script and procedure linked or setting up Database Replication (for example, HANA System Replication, SQL Server AlwaysOn).
        - How to Migrate a Highly Available SAP System in Azure from Availability Set to Availability Zone

9. If your VM is part of a pinned Availability set or if you can't switch your availability option to Availability Zone (as recommended above), open an Azure Support request to assist with resizing.

Help and support

If you have questions, ask community experts in Microsoft Q&A. If you have a support plan and need technical help, create a support request:

In the Help + support page, select Create a support request. Follow the New support request page instructions. Use the following values:

1. For Issue type, select Technical.

2. For Service, select My services.

3. For Service type, select Virtual Machine running Windows/Linux or Virtual Machine running SAP in case you run SAP application workloads.
4. For Resource, select your VM.
5. For Problem type, select Assistance with resizing my VM.
6. For Problem subtype, select the option that applies to you.
7. Follow instructions in the Solutions and Details tabs, as applicable, and then Review + create.

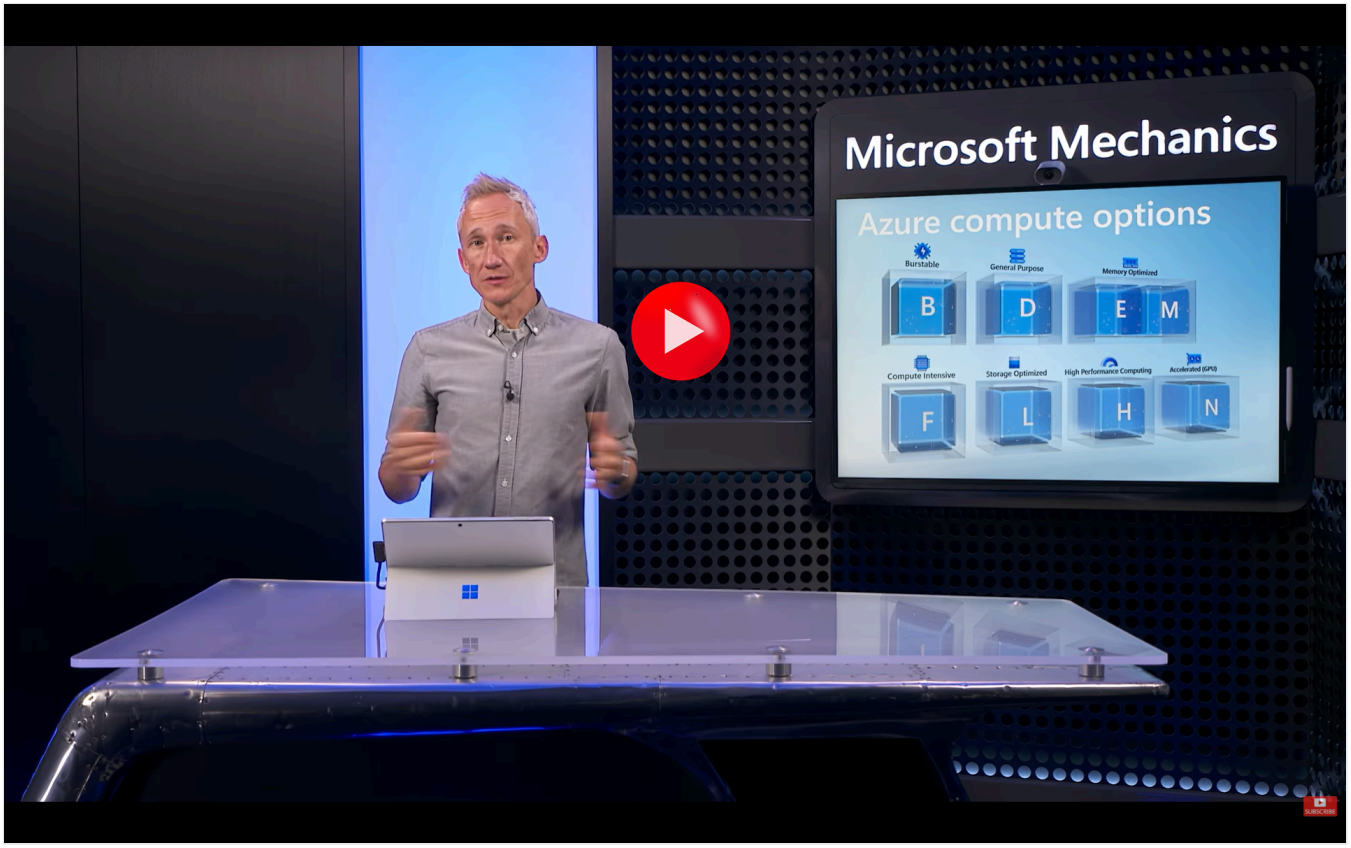
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

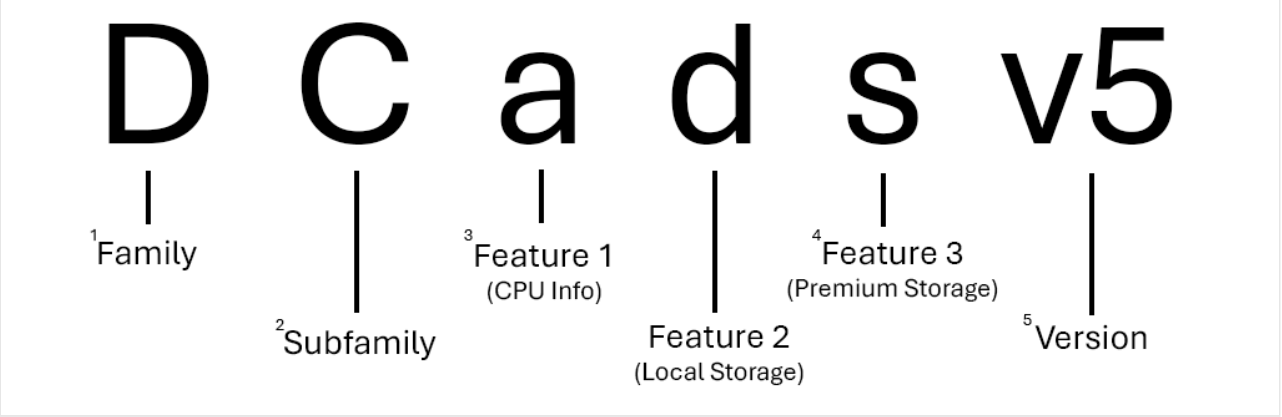
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

'L' family storage optimized VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'L' family of VM size series are one of Azure's storage-optimized VM instances. They're designed for workloads that require high disk throughput and I/O, such as databases, big data applications, and data warehousing. Equipped with high disk throughput and large local disk storage capacities, L-series VMs support applications and services that benefit from low latency and high sequential read and write speeds. This makes them particularly well-suited for handling tasks like large-scale log processing, real-time big data analytics, and scenarios involving large databases that perform frequent disk operations, ensuring efficient performance for storage-heavy applications.

Workloads and use cases

Big Data Applications: L-family VMs are perfect for big data applications that need to process, analyze, and manipulate large datasets stored directly on local disks, benefiting from the high I/O performance.

Database Servers: L-family VMs provide the necessary local disk performance for SQL Server, MySQL, PostgreSQL, and other database servers that benefit from fast access to disk storage.

File Servers: L-family VMs can be used effectively as file servers within a network, handling large files and serving them with high throughput, especially useful in environments with large media files.

Video Editing and Rendering: The high disk throughput and capacity of L-family VMs are beneficial for video editing and rendering tasks, where large video files are frequently read and written to disk.

Series in family

Lsv2-series

The Lsv2-series features high throughput, low latency, directly mapped local NVMe storage running on the AMD EPYC™ 7551 processor with an all core boost of 2.55GHz and a max boost of 3.0GHz. The Lsv2-series VMs come in sizes from 8 to 80 vCPU in a simultaneous multi-threading

configuration. There is 8 GiB of memory per vCPU, and one 1.92TB NVMe SSD M.2 device per 8 vCPUs, with up to 19.2TB (10x1.92TB) available on the L80s v2.

View the full Lsv2-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	8 - 80 vCPUs	AMD EPYC 7551 (Naples) [x86-64]
Memory	64 - 640 GiB	
Local Storage	1 Temp Disk 1 - 10 NVMe Disks	80 - 800 GiB Temp Disks 1.92 TiB NVMe Disks
Remote Storage	16 - 32 Disks	8000 - 80000 IOPS 160 - 1400 MBps
Network	2 - 8 NICs	3200 - 16000+ Mbps Interfaces: NetVSC, ConnectX
Accelerators	None	

Lsv3-series

The Lsv3-series of Azure Virtual Machines (Azure VMs) features high-throughput, low latency, directly mapped local NVMe storage. These VMs run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake) processor in a hyper-threaded configuration. This new processor features an all-core turbo clock speed of 3.5 GHz with Intel® Turbo Boost Technology, Intel® Advanced-Vector Extensions 512 (Intel® AVX-512) and Intel® Deep Learning Boost. The Lsv3-series VMs are available in sizes from 8 to 80 vCPUs. There are 8 GiB of memory allocated per vCPU, and one 1.92TB NVMe SSD device allocated per 8 vCPUs, with up to 19.2TB (10x1.92TB) available on the L80s_v3 size.

> **Note**
>
> The Lsv3-series VMs are optimized to use the local disk on the node attached directly to the VM rather than using durable data disks. This method allows for greater IOPS and throughput for your workloads. The Lsv3, Lasv3, Lsv2, and Ls-series VMs don't support the creation of a host cache to increase the IOPS achievable by durable data disks.

The high throughput and IOPS of the local disk makes the Lsv3-series VMs ideal for NoSQL stores such as Apache Cassandra and MongoDB. These stores replicate data across multiple VMs to achieve persistence in the event of the failure of a single VM.

View the full Lsv3-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	8 - 80 vCPUs	Intel Xeon Platinum 8370C (Ice Lake) [x86-64]
Memory	64 - 640 GiB	
Local Storage	1 Temp Disk 1 - 10 NVMe Disks	80 - 800 GiB Temp Disks 1.92 TiB NVMe Disks
Remote Storage	16 - 32 Disks	12800 - 80000 IOPS 290 - 2160 MBps
Network	4 - 8 NICs	12500 - 32000 Mbps Interfaces: NetVSC, ConnectX
Accelerators	None	

Lasv3-series

The Lasv3-series of Azure Virtual Machines (Azure VMs) features high-throughput, low latency, directly mapped local NVMe storage. These VMs run on an AMD 3rd Generation EPYC™ 7763v processor in a multi-threaded configuration with an L3 cache of up to 256 MB that can achieve a boosted maximum frequency of 3.5 GHz. The Lasv3-series VMs are available in sizes from 8 to 80 vCPUs in a simultaneous multi-threading configuration. There are 8 GiB of memory per vCPU, and one 1.92 TB NVMe SSD device per 8 vCPUs, with up to 19.2 TB (10x1.92TB) available on the L80as_v3 size.

Note

The Lasv3-series VMs are optimized to use the local disk on the node attached directly to the VM rather than using durable data disks. This method allows for greater IOPS and throughput for your workloads. The Lsv3, Lasv3, Lsv2, and Ls-series don't support the creation of a local cache to increase the IOPS achievable by durable data disks.

The high throughput and IOPS of the local disk makes the Lasv3-series VMs ideal for NoSQL stores such as Apache Cassandra and MongoDB. These stores replicate data across multiple VMs to achieve persistence in the event of the failure of a single VM.

Laosv4 sizes series

Summarize this article for me

The Laosv4-series of Azure Virtual Machines (VMs) features high-throughput, low latency, directly mapped local NVMe storage. These VMs utilize AMD's fourth Generation EPYC™ 9004 processors that can achieve a boosted maximum frequency of 3.7GHz. The Laosv4-series VMs are available in sizes from 2 to 32 vCPUs, with 8 GiB of memory allocated per vCPU and 720GB of local NVMe temp disk capacity allocated per vCPU, with up to 23TB (12x1.92TB) of local temp disk capacity available on the L32aos_v4 size.

These VMs are perfect for distributed, scale-out workloads that require high amounts of local storage capacity per vCPU and the ability to move that data quickly over the network or to an Azure remote storage backend. Workloads like storage caching layers, Elasticsearch, distributed file systems, big data analytics, relational and NoSQL databases, and data warehouses all benefit from the dense storage capabilities of Laosv4 VMs.

Laosv4-series VMs support Standard SSD, Standard HDD, and Premium SSD remote disk types. You can also attach Ultra Disk storage based on its regional availability. Remote Disk storage is billed separately from virtual machines. For more information, see pricing for disks.

Optimize performance on Lsv3, Lasv3, and Lsv2-series Linux VMs

Article • 08/22/2024

> ⊗ **Caution**
>
> This article references CentOS, a Linux distribution that is End Of Life (EOL) status. Please consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Applies to: ✔ Linux VMs ✔ Uniform scale sets

Lsv3, Lasv3, and Lsv2-series Azure Virtual Machines (Azure VMs) support various workloads that need high I/O and throughput on local storage across a wide range of applications and industries. The L-series is ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases, including Cassandra, MongoDB, Cloudera, and Redis.

Several builds are available Azure Marketplace due to work with partners in Linux. These builds are optimized for Lsv3, Lasv3, and Lsv2-series performance. Available builds include the following and later versions of:

- Ubuntu 16.04
- RHEL 8.0 and clones, including CentOS, Rocky Linux, and Alma Linux
- Debian 9
- SUSE Linux 15
- Oracle Linux 8.0

This article provides tips and suggestions to ensure your workloads and applications achieve the maximum performance designed into the VMs.

AMD EPYC™ chipset architecture

Lasv3 and Lsv2-series VMs use AMD EPYC™ server processors based on the Zen micro-architecture. AMD developed Infinity Fabric (IF) for EPYC™ as scalable interconnect for its NUMA model that can be used for on-die, on-package, and multi-package communications. Compared with QPI (Quick-Path Interconnect) and UPI (Ultra-Path Interconnect) used on Intel modern monolithic-die processors, AMD's many-NUMA small-die architecture can bring both performance benefits and challenges. The actual

effects of memory bandwidth and latency constraints might vary depending on the type of workloads running.

Tips to maximize performance

- If you're uploading a custom Linux GuestOS for your workload, Accelerated Networking is turned off by default. If you intend to enable Accelerated Networking, enable it at the time of VM creation for best performance.
- To gain max performance, run multiple jobs with deep queue depth per device.
- Avoid mixing NVMe admin commands (for example, NVMe SMART info query, etc.) with NVMe I/O commands during active workloads. Lsv3, Lasv3, and Lsv2 NVMe devices are backed by Hyper-V NVMe Direct technology, which switches into “slow mode” whenever any NVMe admin commands are pending. Lsv3, Lasv3, and Lsv2 users might see a dramatic performance drop in NVMe I/O performance if that happens.
- Lsv2 users aren't recommended to rely on device NUMA information (all 0) reported from within the VM for data drives to decide the NUMA affinity for their apps. The recommended way for better performance is to spread workloads across CPUs if possible.
- The maximum supported queue depth per I/O queue pair for Lsv3, Lasv3, and Lsv2 VM NVMe device is 1024. Lsv3, Lasv3, and Lsv2 users are recommended to limit their (synthetic) benchmarking workloads to queue depth 1024 or lower to avoid triggering queue full conditions, which can reduce performance.
- The best performance is obtained when I/O is done directly to each of the raw NVMe devices with no partitioning, no file systems, no RAID config, etc. Before starting a testing session, ensure the configuration is in a known fresh/clean state by running `blkdiscard` on each of the NVMe devices. To obtain the most consistent performance during benchmarking, it's recommended to precondition the NVMe devices before testing by issuing random writes to all of the devices' LBAs twice as defined in the SNIA Solid State Storage Enterprise Performance Test Specification.

Utilizing local NVMe storage

Local storage on the 1.92 TB NVMe disk on all Lsv3, Lasv3, and Lsv2 VMs is ephemeral. During a successful standard reboot of the VM, the data on the local NVMe disk persists. The data doesn't persist on the NVMe if the VM is redeployed, deallocated, or deleted. Data doesn't persist if another issue causes the VM, or the hardware it's running on, to become unhealthy. When scenario happens, any data on the old host is securely erased.

There are also cases when the VM needs to be moved to a different host machine, for example, during a planned maintenance operation. Planned maintenance operations and some hardware failures can be anticipated with Scheduled Events. Use Scheduled Events to stay updated on any predicted maintenance and recovery operations.

In the case that a planned maintenance event requires the VM to be recreated on a new host with empty local disks, the data needs to be resynchronized (again, with any data on the old host being securely erased). This scenario occurs because Lsv3, Lasv3, and Lsv2-series VMs don't currently support live migration on the local NVMe disk.

There are two modes for planned maintenance.

Standard VM customer-controlled maintenance

- The VM is moved to an updated host during a 30-day window.
- Lsv3, Lasv3, and Lsv2 local storage data could be lost, so backing-up data prior to the event is recommended.

Automatic maintenance

- Occurs if the customer doesn't execute customer-controlled maintenance, or because of emergency procedures, such as a security zero-day event.
- Intended to preserve customer data, but there's a small risk of a VM freeze or reboot.
- Lsv3, Lasv3, and Lsv2 local storage data could be lost, so backing-up data prior to the event is recommended.

For any upcoming service events, use the controlled maintenance process to select a time most convenient to you for the update. Prior to the event, back up your data in premium storage. After the maintenance event completes, you can return your data to the refreshed Lsv3, Lasv3, and Lsv2 VMs local NVMe storage.

Scenarios that maintain data on local NVMe disks include:

- The VM is running and healthy.
- The VM is rebooted in place (by you or Azure).
- The VM is paused (stopped without deallocation).
- Most the planned maintenance servicing operations.

Scenarios that securely erase data to protect the customer include:

- The VM is redeployed, stopped (deallocated), or deleted (by you).

- The VM becomes unhealthy and has to service heal to another node due to a hardware issue.
- A few of the planned maintenance servicing operations that require the VM to be reallocated to another host for servicing.

Frequently asked questions

The following are frequently asked questions about these series.

How do I start deploying L-series VMs?

Much like any other VM, use the Portal, Azure CLI, or PowerShell to create a VM.

Does a single NVMe disk failure cause all VMs on the host to fail?

If a disk failure is detected on the hardware node, the hardware is in a failed state. When this problem occurs, all VMs on the node are automatically deallocated and moved to a healthy node. For Lsv3, Lasv3, and Lsv2-series VMs, this problem means that the customer's data on the failing node is also securely erased. The customer needs to recreate the data on the new node.

Do I need to change the blk_mq settings?

RHEL/CentOS 7.x automatically uses blk-mq for the NVMe devices. No configuration changes or settings are necessary.

Optimize performance on Lsv3, Lasv3, and Lsv2-series Windows VMs

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Uniform scale sets

Lsv3, Lasv3, and Lsv2-series Azure Virtual Machines (Azure VMs) support various workloads that need high I/O and throughput on local storage across a wide range of applications and industries. The L-series is ideal for Big Data, SQL, NoSQL databases, data warehousing and large transactional databases, including Cassandra, MongoDB, Cloudera, and Redis.

Lsv3, Lasv3, and Lsv2-series VMs are designed to work with the needs of Windows and Linux operating systems for better performance with hardware and the software.

Software and hardware tuning resulted in the optimized version of Windows Server 2019 Datacenter, released to the Azure Marketplace (and later versions), which support maximum performance on the NVMe devices in L-series VMs.

This article provides tips and suggestions to ensure your workloads and applications achieve the maximum performance designed into the VMs.

AMD EPYC™ chipset architecture

Lasv3 and Lsv2-series VMs use AMD EPYC™ server processors based on the Zen micro-architecture. AMD developed Infinity Fabric (IF) for EPYC™ as a scalable interconnect for its NUMA model that can be used for on-die, on-package, and multi-package communications. Compared with QPI (Quick-Path Interconnect) and UPI (Ultra-Path Interconnect), used on Intel modern monolithic-die processors, AMD's many-NUMA small-die architecture can bring both performance benefits and challenges. The actual effects of memory bandwidth and latency constraints can vary depending on the type of workloads.

Tips for maximizing performance

- To gain max performance, run multiple jobs with deep queue depth per device.
- Avoid mixing NVMe admin commands (for example, NVMe SMART info query) with NVMe I/O commands during active workloads. Lsv3, Lasv3, and Lsv2 NVMe devices are backed by Hyper-V NVMe Direct technology, which switches into "slow

mode" whenever any NVMe admin commands are pending. Lsv3, Lasv3, and Lsv2 users might see a dramatic performance drop in NVMe I/O performance if that scenario happens.

- It's not recommended for Lsv2 users to rely on device NUMA information (all 0) reported from within the VM for data drives to decide the NUMA affinity for their apps. For better performance, it's recommended to spread workloads across CPUs if possible.
- The maximum supported queue depth per I/O queue pair for Lsv3, Lasv3, and Lsv2 VM NVMe device is 1024. Lsv3, Lasv3, and Lsv2 users are recommended to limit their (synthetic) benchmarking workloads to queue depth 1024 or lower to avoid triggering queue full conditions, which can reduce performance.
- The best performance is obtained when I/O is done directly to each of the raw NVMe devices with no partitioning, no file systems, no RAID config, etc.

Utilizing local NVMe storage

Local storage on the 1.92 TB NVMe disk on all Lsv3, Lasv3, and Lsv2 VMs is ephemeral. During a successful standard reboot of the VM, the data on the local NVMe disk persists. The data doesn't persist on the NVMe if the VM is redeployed, deallocated, or deleted. Data doesn't persist if another issue causes the VM, or the hardware on which the VM is running, to become unhealthy. When this scenario happens, any data on the old host is securely erased.

There are also cases when the VM needs to be moved to a different host machine; for example, during a planned maintenance operation. Planned maintenance operations and some hardware failures can be anticipated with Scheduled Events. Use Scheduled Events to stay updated on any predicted maintenance and recovery operations.

In the case that a planned maintenance event requires the VM to be recreated on a new host with empty local disks, the data needs to be resynchronized (again, with any data on the old host being securely erased). This scenario occurs because Lsv3, Lasv3, and Lsv2-series VMs don't currently support live migration on the local NVMe disk.

There are two modes for planned maintenance: standard VM customer-controlled maintenance and automatic maintenance.

For any upcoming service events, use the controlled maintenance process to select a time most convenient to you for the update. Prior to the event, back up your data in premium storage. After the maintenance event completes, return your data to the refreshed Lsv2 VMs local NVMe storage.

Scenarios that maintain data on local NVMe disks include when:

- The VM is running and healthy.
- The VM is rebooted in place by you or by Azure.
- The VM is paused (stopped without deallocation).
- Most planned maintenance servicing operations.

Scenarios that securely erase data to protect the customer include when:

- The VM is redeployed, stopped (deallocated), or deleted by you.
- The VM becomes unhealthy and has to service heal to another node due to a hardware issue.
- A few the planned maintenance servicing operations that require the VM to be reallocated to another host for servicing.

Standard VM customer-controlled maintenance

In standard VM customer-controlled maintenance, the VM is moved to an updated host during a 30-day window.

Lsv3, Lasv3, and Lsv2 local storage data might be lost, so backing-up data prior to the event is recommended.

Automatic maintenance

Automatic maintenance occurs if the customer doesn't execute customer-controlled maintenance. Automatic maintenance can also occur because of emergency procedures, such as a security zero-day event.

This type of maintenance is intended to preserve customer data, but there's a small risk of a VM freeze or reboot.

Lsv3, Lasv3, and Lsv2 local storage data might be lost, so backing-up data prior to the event is recommended.

Frequently asked questions

The following are frequently asked questions about these series.

How do I start deploying L-series VMs?

Much like any other VM, create a VM using the Azure portal, through the Azure Command-Line Interface (Azure CLI), or through PowerShell.

Does a single NVMe disk failure cause all VMs on the host to fail?

If a disk failure is detected on the hardware node, the hardware is in a failed state. When this problem occurs, all VMs on the node are automatically deallocated and moved to a healthy node. For Lsv3, Lasv3, and Lsv2-series VMs, this scenario means that the customer's data on the failing node is also securely erased. The customer needs to recreate the data on the new node.

Do I need to make polling adjustments in Windows Server 2012 or Windows Server 2016?

NVMe polling is only available on Windows Server 2019 and later versions on Azure.

Can I switch back to a traditional interrupt service routine (ISR) model?

Lasv3, and Lsv2-series VMs are optimized for NVMe polling. Updates are continuously provided to improve polling performance.

Can I adjust the polling settings in Windows Server 2019 or later versions?

The polling settings aren't user adjustable.

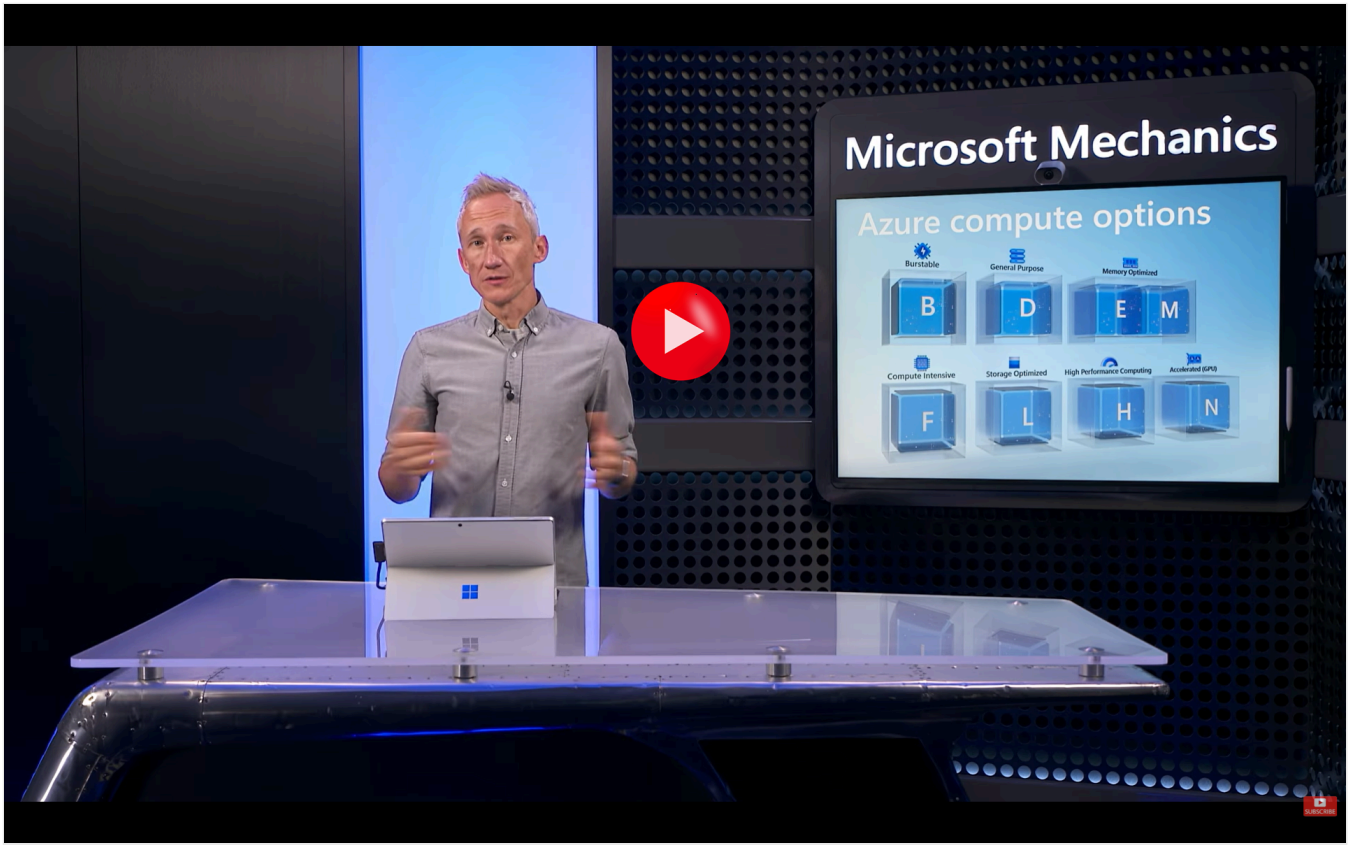
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

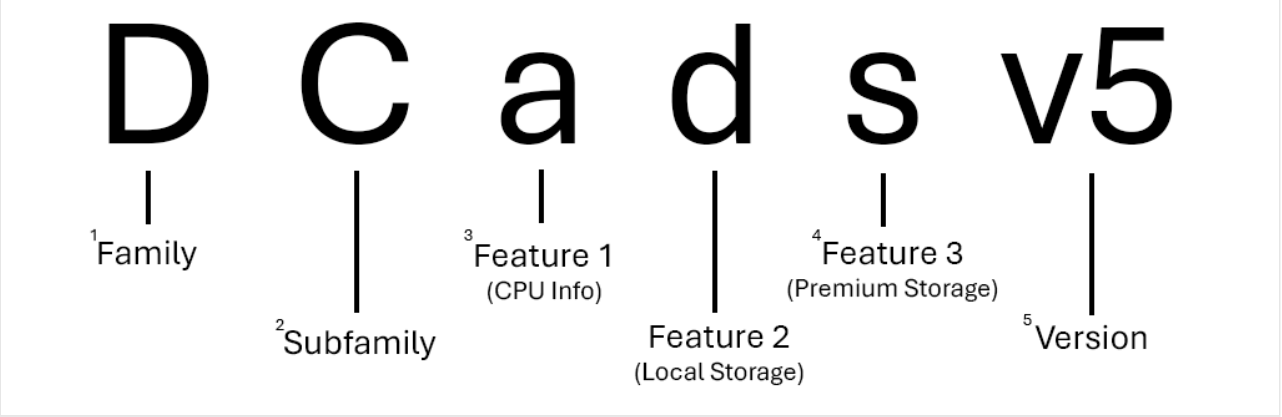
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

'NC' sub-family GPU accelerated VM size series

06/06/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'NC' sub-family of VM size series are one of Azure's GPU-optimized VM instances. They're designed for compute-intensive workloads, such as AI and machine learning model training, high-performance computing (HPC), and graphics-intensive applications. Equipped with powerful NVIDIA GPUs, NC-series VMs offer substantial acceleration for processes that require heavy computational power, including deep learning, scientific simulations, and 3D rendering. This makes them particularly well-suited for industries such as technology research, entertainment, and engineering, where rendering and processing speed are critical to productivity and innovation.

Workloads and use cases

AI and Machine Learning: NC-series VMs are ideal for training complex machine learning models and running AI applications. The NVIDIA GPUs provide significant acceleration for computations typically involved in deep learning and other intensive training tasks.

High-Performance Computing (HPC): These VMs are suitable for scientific simulations, rendering, and other HPC workloads that can be accelerated by GPUs. Fields like engineering, medical research, and financial modeling often use NC-series VMs to handle their computational needs efficiently.

Graphics Rendering: NC-series VMs are also used for graphics-intensive applications, including video editing, 3D rendering, and real-time graphics processing. They are particularly useful in industries such as game development and movie production.

Remote Visualization: For applications requiring high-end visualization capabilities, such as CAD and visual effects, NC-series VMs can provide the necessary GPU power remotely, allowing users to work on complex graphical tasks without needing powerful local hardware.

Simulation and Analysis: These VMs are also suitable for detailed simulations and analyses in areas like automotive crash testing, computational fluid dynamics, and weather modeling, where GPU capabilities can significantly speed up processing times.

Series in family

NCads_H100_v5-series

The NCads H100 v5 series virtual machines (VMs) are a new addition to the Azure GPU family. You can use this series for real-world Azure Applied AI training and batch inference workloads. The NCads H100 v5 series virtual machines are powered by NVIDIA H100 NVL GPU and 4th-generation AMD EPYC™ Genoa processors. The VMs feature up to 2 NVIDIA H100 NVL GPUs with 94GB memory each, up to 96 non-multithreaded AMD EPYC Genoa processor cores and 640 GiB of system memory. These VMs are ideal for real-world Applied AI workloads, such as:

- GPU-accelerated analytics and databases
- Batch inferencing with heavy pre- and post-processing
- Autonomy model training
- Oil and gas reservoir simulation
- Machine learning (ML) development
- Video processing
- AI/ML web services

View the full NCads_H100_v5-series page.

Expand table

Part	**Quantity** **Count Units**	**Specs** **SKU ID, Performance Units, etc.**
Processor	40 - 80 vCPUs	AMD EPYC (Genoa) [x86-64]
Memory	320 - 640 GiB	
Local Storage	1 Disk	3576 - 7152 GiB IOPS (RR) MBps (RR)
Remote Storage	8 - 16 Disks	100000 - 240000 IOPS 3000 - 7000 MBps
Network	2 - 4 NICs	40,000 - 80,000 Mbps
Accelerators	1 - 2 GPUs	Nvidia PCIe H100 GPU (94GB)

NCCads_H100_v5-series

The NCCads H100 v5 series of virtual machines are a new addition to the Azure GPU family. In this VM SKU, Trusted Execution Environment (TEE) spans confidential VM on the CPU and attached GPU, enabling secure offload of data, models, and computation to the GPU. The NCCads H100 v5 series is powered by 4th-generation AMD EPYC™ Genoa processors and

NVIDIA H100 Tensor Core GPU. These VMs feature 1 NVIDIA H100 NVL GPUs with 94 GB memory, 40 non-multithreaded AMD EPYC Genoa processor cores, and 320 GiB of system memory. These VMs are ideal for real-world Applied AI workloads, such as:

- GPU-accelerated analytics and databases
- Batch inferencing with heavy pre- and post-processing
- Machine Learning (ML) development
- Video processing
- AI/ML web services

NCv3-series

NCv3-series VMs are powered by NVIDIA Tesla V100 GPUs. These GPUs can provide 1.5x the computational performance of the NCv2-series. Customers can take advantage of these updated GPUs for traditional HPC workloads such as reservoir modeling, DNA sequencing, protein analysis, Monte Carlo simulations, and others. The NC24rs v3 configuration provides a low latency, high-throughput network interface optimized for tightly coupled parallel computing workloads. In addition to the GPUs, the NCv3-series VMs are also powered by Intel Xeon E5-2690 v4 (Broadwell) CPUs.

> **Important**
>
> For this VM series, the vCPU (core) quota in your subscription is initially set to 0 in each region. Request a vCPU quota increase for this series in an available region. These

SKUs aren't available to trial or Visual Studio Subscriber Azure subscriptions. Your subscription level might not support selecting or deploying these SKUs.

Accelerators	1 - 4	Nvidia Tesla V100 GPU (16GB)

NCasT4_v3-series

The NCasT4_v3-series virtual machines are powered by Nvidia Tesla T4 GPUs and AMD EPYC 7V12(Rome) CPUs. The VMs feature up to 4 NVIDIA T4 GPUs with 16 GB of memory each, up to 64 non-multithreaded AMD EPYC 7V12 (Rome) processor cores(base frequency of 2.45 GHz, all-cores peak frequency of 3.1 GHz and single-core peak frequency of 3.3 GHz) and 440 GiB of system memory. These virtual machines are ideal for deploying AI services- such as real-time inferencing of user-generated requests, or for interactive graphics and visualization workloads using NVIDIA's GRID driver and virtual GPU technology. Standard GPU compute workloads based around CUDA, TensorRT, Caffe, ONNX and other frameworks, or GPU-accelerated graphical applications based on OpenGL and DirectX can be deployed economically, with close proximity to users, on the NCasT4_v3 series.

Migrate your Standard_NC24rs_v3 virtual machine size by September 30, 2025

06/26/2025

> **Note**
>
> All the NCv3-series VM sizes, including Standard_NC24rs_v3, will be retired on September 30, 2025. For retirement details and SKU migration guidance, please refer to the NCv3-series retirement page rather than this page.

On September 30, 2025, Microsoft Azure will retire the Standard_NC24rs_v3 virtual machine (VM) size in NCv3-series virtual machines (VMs). To avoid any disruption to your service, we recommend that you change the VM sizing from the Standard_NC24rs_v3 to the newer VM series in the same NC product line.

Microsoft recommends the Azure NCadsH100_v5-series VMs, which offer greater GPU memory bandwidth per GPU, improved accelerated networking capabilities, and larger and faster local solid state drives. These VMs are targeted for GPU accelerated midrange AI training, batch inferencing, and high-performance computing simulation workloads.

However, depending on the workload being run, regional affinity, and cost preferences, other VMs that may be migrated to from Standard_NC24rs_v3 include NVadsA10_v5, NCasT4_v3, and NVadsV710_v5:

Expand table

Workload	Recommended SKU to Migrate to
High GPU compute workloads such as real-time inferencing and LLM inferencing.	NCadsH100_v5 which has the best inference per dollar value.
Offline inferencing workloads where latency is not the primary concern, and there is an interest in purchasing smaller VM SKUs or reducing costs.	NCasT4_v3
Graphics, visualization, or small AI workloads where optimal performance is not a priority.	NVadsA10_v5, NVadsV710_v5

How does the retirement of the Standard_NC24rs_v3 affect me?

After September 30, 2025, any remaining Standard_NC24rs_v3 VM subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. The Standard_NC24rs_v3 VM size will no longer be under SLA or have support included.

> **Note**
>
> This retirement announcement doesn't apply to NCasT4_v3, NC_A100_v4, and NCadsH100_v5 series virtual machines.

What action do I need to take before the retirement date?

You need to resize or deallocate your Standard_NC24rs_v3 VM size. We recommend that you change VM sizes for these workloads from the original Standard_NC24rs_v3 VM size to the NCadsH100_v5-series VMs (or an alternative).

The NCadsH100_v5-series is powered by NVIDIA H100 NVL GPU and 4th-generation AMD EPYC™ Genoa processors. The VMs feature up to 2 NVIDIA H100 NVL GPUs with 94GB memory each, up to 96 non-multithreaded AMD EPYC Genoa processor cores and 640 GiB of system memory. Check Azure Regions by Product page for region availability. Visit the Azure Virtual Machine pricing page for pricing information.

Steps to change VM size

1. Choose a series and size. Refer to the above tables for Microsoft's recommendation. You can also file a support request if more assistance is needed.
2. Request quota for the new target VM).
3. Resize the virtual machine.

Help and support

If you have a support plan and you need technical help, create a support request.

1. Under *Issue type*, select **Technical**.
2. Under *Subscription*, select your subscription.
3. Under *Service*, click **My services**.
4. Under *Service type*, select **Virtual Machine running Windows/Linux**.
5. Under *Summary*, enter the summary of your request.
6. Under *Problem type*, select **Assistance with resizing my VM.**

7. Under *Problem subtype*, select the option that applies to you.

Migrate your NCv3-series virtual machines by September 30, 2025

08/29/2025

> **Note**
>
> If you're currently using the NCv3-series Azure VMs in either of these regions, you can disregard the general NCv3-series retirement date of September 30, 2025, and continue to use the NCv3-series Azure VMs in that region until the respective extension date:
>
> The US Central region has an extension and a retirement date of **February 28, 2026**.
>
> The West Europe region has an extension and a retirement date of **February 28, 2026**.
>
> The East US 2 region has an extension and a retirement date of **February 28, 2026**.
>
> The Canada Central region has an extension and a retirement date of **March 31, 2026**.
>
> The US Gov Virginia, US Gov Arizona, Jio India West, and China North 3 regions have an extension and a retirement date of **June 30, 2026**.

On September 30, 2025, Microsoft Azure will retire the Standard_NC6s_v3, Standard_NC12s_v3, Standard_NC24s_v3, and Standard_NC24rs_v3 virtual machines (VMs) in NCv3-series virtual machines (VMs). To avoid any disruption to your service, we recommend that you change the VM sizing for your workloads from the current NCv3-series VMs to the newer VM series in the same NC product line.

Microsoft is recommending the Azure NCadsH100_v5-series VMs, which offer greater GPU memory bandwidth per GPU, improved accelerated networking capabilities, and larger and faster local solid state drives. These VMs are targeted for GPU accelerated midrange AI training, batch inferencing, and high-performance computing simulation workloads. For regions where NCadsH100_v5 is not available, please migrate to the other recommended SKUs below.

Depending on the workload being run, regional affinity, and cost preferences, other VMs that may be migrated to from the NCv3-series VMs include NVadsA10_v5, NCasT4_v3, and NVadsV710_v5:

Expand table

Workload	Recommended SKU to Migrate to
High GPU compute workloads such as real-time inferencing and LLM inferencing.	NCadsH100_v5 which has the best inference per dollar value.
Offline inferencing workloads where latency is not the primary concern, and there is an interest in purchasing smaller VM SKUs or reducing costs.	NCasT4_v3
Graphics, visualization, or small AI workloads where optimal performance is not a priority.	NVadsA10_v5, NVadsV710_v5

How does the retirement of the NCv3-series virtual machines affect me?

After September 30th, any remaining NCv3-series virtual machines (VMs) subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. NCv3 will no longer be under SLA or have support included.

> **Note**
>
> This retirement only impacts the virtual machine sizes in the original NCv3-series powered by NVIDIA V100 GPUs. This retirement announcement doesn't apply to NCasT4_v3, NC_A100_v4, and NCadsH100_v5 series virtual machines.

What action do I need to take before the retirement date?

You need to resize or deallocate your NCv3-series VMs. We recommend that you change VM sizes for these workloads from the original NCv3-series VMs to the NCadsH100_v5-series VMs (or an alternative).

The NCadsH100_v5-series is powered by NVIDIA H100 NVL GPU and 4th-generation AMD EPYC™ Genoa processors. The VMs feature up to 2 NVIDIA H100 NVL GPUs with 94GB memory each, up to 96 non-multithreaded AMD EPYC Genoa processor cores and 640 GiB of system memory. Check Azure Regions by Product page for region availability. Visit the Azure Virtual Machine pricing page for pricing information.

Steps to change VM size

1. Choose a series and size. Refer to the above tables for Microsoft's recommendation. You can also file a support request if more assistance is needed.
2. Request quota for the new target VM.
3. You can resize the virtual machine.

Help and support

If you have a support plan and you need technical help, create a support request.

1. Under *Issue type*, select **Technical**.
2. Under *Subscription*, select your subscription.
3. Under *Service*, click **My services**.
4. Under *Service type*, select **Virtual Machine running Windows/Linux**.
5. Under *Summary*, enter the summary of your request.
6. Under *Problem type*, select **Assistance with resizing my VM.**
7. Under *Problem subtype*, select the option that applies to you.

NCasT4_v3 sizes series

Summarize this article for me

The NCasT4_v3-series virtual machines(VM) are powered by NVIDIA Tesla T4 GPUs and AMD EPYC 7V12(Rome) CPUs. The VMs feature up to 4 NVIDIA T4 GPUs with 16 GB of memory each, up to 64 non-multithreaded AMD EPYC 7V12 (Rome) processor cores(base frequency of 2.45 GHz, all-cores peak frequency of 3.1 GHz and single-core peak frequency of 3.3 GHz) and 440 GiB of system memory. These VMs are ideal for deploying AI services- such as real-time inferencing of user-generated requests, or for interactive graphics and visualization workloads using NVIDIA's GRID driver and virtual GPU technology. Standard GPU compute workloads based around CUDA, TensorRT, Caffe, ONNX and other frameworks, or GPU-accelerated graphical applications based on OpenGL and DirectX can be deployed economically, with close proximity to users, on the NCasT4_v3 series.

On NCasT4_v3-series VMs, the Azure NVIDIA GPU driver extension installs CUDA drivers. For graphics and visualization workloads, manually install the Azure-supported GRID drivers.

NC RTX PRO 6000 Blackwell Server Edition v6 sizes series

These NC RTX PRO 6000 BSE v6 VMs are powered by NVIDIA RTX PRO 6000 Blackwell Server Edition GPUs, each featuring 96 GB of ultra-fast GDDR7 memory and the latest Blackwell architecture to enable breakthrough performance in multimodal AI, physical AI, and high-fidelity graphics. The VM host is equipped with Intel Granite Rapids CPUs, providing all-core turbo frequency of up to 4.2 GHz to handle demanding pre- and post-processing steps efficiently. These VMs are ideal for converged AI and visual computing workloads, such as:

- Real-time digital twin and NVIDIA Omniverse simulation.
- LLM Inference and RAG (Retrieval-Augmented Generation) for models under 70B parameters.
- High-fidelity 3D rendering, product design, and video streaming.
- GPU-accelerated desktop virtualization (VDI) with NVIDIA RTX Virtual Workstation.
- Scientific visualization and High-Performance Computing (HPC) using FP32.
- Agentic AI application development and deployment.

'ND' sub-family GPU accelerated virtual machine size series

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'ND' family of VM size series are one of Azure's GPU-accelerated VM instances. They're designed for deep learning, AI research, and high-performance computing tasks that benefit from powerful GPU acceleration. Equipped with NVIDIA GPUs, ND-series VMs offer specialized capabilities for training and inference of complex machine learning models, facilitating faster computations and efficient handling of large datasets. This makes them particularly well-suited for academic and commercial applications in AI development and simulation, where cutting-edge GPU technology is crucial for achieving rapid and accurate results in neural network processing and other computationally intensive tasks.

Workloads and use cases

AI and Deep Learning: ND-family VMs are ideal for training and deploying complex deep learning models. Equipped with powerful NVIDIA GPUs, they provide the computational power necessary for handling extensive neural network training with large datasets, significantly reducing training times.

High-Performance Computing (HPC): ND-family VMs are suitable for HPC applications that require GPU acceleration. Fields such as scientific research, engineering simulations (e.g., computational fluid dynamics), and genomic processing can benefit from the high-throughput computing capabilities of ND-series VMs.

Graphics Rendering: ND-family's GPUs make them a great choice for graphics-intensive tasks, including real-time rendering for animation and video production, as well as high-fidelity simulations for virtual reality environments.

Remote Visualization: ND-family VMs can be used for remote visualization of data-intensive tasks, where high-end GPU capabilities are necessary to process and render complex visualizations over the cloud, facilitating access from less powerful client machines.

Series in family

ND-series V1

The ND-series virtual machines are a new addition to the GPU family designed for AI, and Deep Learning workloads. They offer excellent performance for training and inference. ND instances are powered by NVIDIA Tesla P40 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. These instances provide excellent performance for single-precision floating point operations, for AI workloads utilizing Microsoft Cognitive Toolkit, TensorFlow, Caffe, and other frameworks. The ND-series also offers a much larger GPU memory size (24 GB), enabling to fit much larger neural net models. Like the NC-series, the ND-series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

View the full ND-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	6 - 24 vCPUs	Intel Xeon E5-2690 v4 (Broadwell) [x86-64]
Memory	112 - 448 GiB	
Local Storage	1 Disk	736 - 2948 GiB
Remote Storage	12 - 32 Disks	20000 - 80000 IOPS 200 - 800 MBps
Network	4 - 8 NICs	
Accelerators	1 - 4 GPUs	Nvidia Tesla P40 GPU (24GB)

NDv2-series

The NDv2-series virtual machine is a new addition to the GPU family designed for the needs of the most demanding GPU-accelerated AI, machine learning, simulation, and HPC workloads.

NDv2 is powered by 8 NVIDIA Tesla V100 NVLINK-connected GPUs, each with 32 GB of GPU memory. Each NDv2 VM also has 40 non-HyperThreaded Intel Xeon Platinum 8168 (Skylake) cores and 672 GiB of system memory.

NDv2 instances provide excellent performance for HPC and AI workloads utilizing CUDA GPU-optimized computation kernels, and the many AI, ML, and analytics tools that

support GPU acceleration 'out-of-box,' such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks.

Critically, the NDv2 is built for both computationally intense scale-up (harnessing 8 GPUs per VM) and scale-out (harnessing multiple VMs working together) workloads. The NDv2 series now supports 100-Gigabit InfiniBand EDR backend networking, similar to that available on the HB series of HPC VM, to allow high-performance clustering for parallel scenarios including distributed training for AI and ML. This backend network supports all major InfiniBand protocols, including those employed by NVIDIA's NCCL2 libraries, allowing for seamless clustering of GPUs.

ND_A100_v4-series

The ND A100 v4 series virtual machine(VM) is a new flagship addition to the Azure GPU family. These sizes are designed for high-end Deep Learning training and tightly coupled scale-up and scale-out HPC workloads.

The ND A100 v4 series starts with a single VM and eight NVIDIA Ampere A100 40GB Tensor Core GPUs. ND A100 v4-based deployments can scale up to thousands of GPUs with an 1.6 TB/s of interconnect bandwidth per VM. Each GPU within the VM is provided with its own dedicated, topology-agnostic 200 GB/s NVIDIA Mellanox HDR InfiniBand connection. These connections are automatically configured between VMs occupying the same Azure Virtual Machine Scale Set, and support GPU Direct RDMA.

Each GPU features NVLINK 3.0 connectivity for communication within the VM with 96 physical 2nd-generation AMD Epyc™ 7V12 (Rome) CPU cores behind them.

These instances provide excellent performance for many AI, ML, and analytics tools that support GPU acceleration 'out-of-the-box,' such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks. Additionally, the scale-out InfiniBand interconnect supports a large set of existing AI and HPC tools that are built on NVIDIA's NCCL2 communication libraries for seamless clustering of GPUs.

ND sizes series

Summarize this article for me

> **Important**
>
> The ND-series has retired as of September 6th, 2023, and is no longer available. Please refer to the ND-series retirement page for more information.

The ND-series virtual machines are a new addition to the GPU family designed for AI, and Deep Learning workloads. They offer excellent performance for training and inference. ND instances are powered by NVIDIA Tesla P40 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. These instances provide excellent performance for single-precision floating point operations, for AI workloads utilizing Microsoft Cognitive Toolkit, TensorFlow, Caffe, and other frameworks. The ND-series also offers a much larger GPU memory size (24 GB), enabling to fit much larger neural net models. Like the NC-series, the ND-series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

Migrate your ND series virtual machines by September 6, 2023

03/17/2025

Based on feedback we've received from customers we're happy to announce that we're extending the retirement date by one year to 6 September 2023, for the Azure ND-Series virtual machine to give you more time to plan your migration.

As we continue to bring modern and optimized virtual machine instances to Azure leveraging the latest innovations in datacenter technologies, we thoughtfully plan how we retire aging hardware. With this in mind, we're retiring our ND GPU VM sizes, powered by NVIDIA Tesla P40 GPUs on 6 September 2023.

How does the ND-series migration affect me?

After 6 September 2023, any remaining ND size virtual machines remaining in your subscription will be set to a deallocated state. These virtual machines will be stopped and removed from the host. These virtual machines will no longer be billed in the deallocated state.

This VM size retirement only impacts the VM sizes in the ND-series. This retirement doesn't impact the newer NCv3, NC T4 v3, and ND v2 series virtual machines.

What actions should I take?

You'll need to resize or deallocate your ND virtual machines. We recommend moving your GPU workloads to another GPU Virtual Machine size. Learn more about migrating your workloads to another GPU Accelerated Virtual Machine size.

Next steps

Learn more about migrating your workloads to other GPU Azure Virtual Machine sizes.

If you have questions, contact us through customer support.

NDv2 sizes series

The NDv2-series virtual machine is a new addition to the GPU family designed for the needs of the most demanding GPU-accelerated AI, machine learning, simulation, and HPC workloads.

NDv2 is powered by 8 NVIDIA Tesla V100 NVLINK-connected GPUs, each with 32 GB of GPU memory. Each NDv2 VM also has 40 non-HyperThreaded Intel Xeon Platinum 8168 (Skylake) cores and 672 GiB of system memory.

NDv2 instances provide excellent performance for HPC and AI workloads utilizing CUDA GPU-optimized computation kernels, and the many AI, ML, and analytics tools that support GPU acceleration 'out-of-box,' such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks.

Critically, the NDv2 is built for both computationally intense scale-up (harnessing 8 GPUs per VM) and scale-out (harnessing multiple VMs working together) workloads. The NDv2 series now supports 100-Gigabit InfiniBand EDR backend networking, similar to that available on the HB series of HPC VM, to allow high-performance clustering for parallel scenarios including distributed training for AI and ML. This backend network supports all major InfiniBand protocols, including those employed by NVIDIA's NCCL2 libraries, allowing for seamless clustering of GPUs.

ND GB200-v6 sizes series

The ND-GB200-v6 series virtual machine (VM) is a flagship addition to the Azure GPU family, delivering unmatched performance for Deep Learning training, Generative AI, and HPC workloads. These VMs leverage the NVIDIA GB200 Tensor Core GPUs, built on the Blackwell architecture, which offer significant advancements in computational power, memory bandwidth, and scalability over previous generations. Each ND-GB200-v6 VM is powered by two NVIDIA Grace CPUs and four NVIDIA Blackwell GPUs. The GPUs are interconnected via fifth-generation NVLink, providing a total of 4× 1.8 TB/s NVLink bandwidth per VM. This robust scale-up interconnect enables seamless, high-speed communication between GPUs within the VM. In addition, the VM offers a scale-out backend network with 4× 400 GB/s NVIDIA Quantum-2 CX7 InfiniBand connections per VM, ensuring high-throughput and low-latency communication when interconnecting multiple VMs. NVIDIA GB200 NVL72 connects up to 72 GPUs per rack, enabling system to operate as a single computer. This 72 GPU rack scale system comprised of groups of 18 ND GB200 v6 VMs delivering up to 1.4 Exa-FLOPS of FP4 Tensor Core throughput, 13.5 TB of shared high bandwidth memory, 130TB/s of cross sectional NVLINK bandwidth, and 28.8Tb/s scale-out networking.

With 128 vCPUs per VM supporting the overall system, the architecture is optimized to efficiently distribute workloads and memory demands for AI and scientific applications. This design enables seamless multi-GPU scaling and robust handling of large-scale models. These instances deliver best-in-class performance for AI, ML, and analytics workloads with out-of-the-box support for frameworks like TensorFlow, PyTorch, JAX, RAPIDS, and more. The scale-out InfiniBand interconnect is optimized for existing AI and HPC tools built on NVIDIA's NCCL communication libraries, ensuring efficient distributed computing across large clusters.

ND GB300-v6 sizes series

Summarize this article for me

The NDGB300v6 series is Azure's next-generation GPU VM line purpose-built for large-scale AI, especially high-throughput inference for reasoning and agentic systems. These VMs are powered by NVIDIA GB300 NVL72 rackscale systems (Blackwell Ultra GPUs + Grace CPUs). Each ND-GB300-v6 VM has two NVIDIA Grace CPUs and four NVIDIA Blackwell B300 GPUs. The GPUs are interconnected via fifth-generation NVLINK, providing a total of 4× 1.8 TB/s NVLINK bandwidth per VM. Each GPU also has 800 Gb/s InfiniBand connectivity, enabling cluster-scale performance with low latency. There are 18 VMs per rack, so effectively 72 NVIDIA Blackwell Ultra GPUs with 36 NVIDIA Grace CPUs, exposing ~37 TB of fast memory (~20TB High Bandwidth Memory, ~17TB of CPU Memory), 130 TB/s of intrarack NVLink bandwidth.

At rack scale, ND GB300 v6 delivers up to 1.44 exaFLOPS FP4 Tensor Core performance per NVL72 domain and has demonstrated ~1.1 million tokens/second LLM inference throughput per rack, which is ~27% higher than ND GB200 v6. See here for more details. Compared to GB200, GB300 provides ~1.5× FP4 compute, 50% higher HBM capacity (288 GB HBM3E per GPU vs. 192 GB), and 2x the back-end network bandwidth per GPU (800Gbps vs 400 Gbps).

The ND GB300 v6 architecture builds on the ND v6 GB200 to efficiently distribute workloads and memory demands across multiple GPUs, driving markedly higher inference throughput for long context and multimodal workloads AI and scientific applications. These instances deliver best-in-class performance for AI, ML, and analytics workloads with out-of-the-box support for frameworks like PyTorch, Tensorflow, JAX, RAPIDS, and more.

ND-H100-v5 sizes series

The ND H100 v5 series virtual machine (VM) is a new flagship addition to the Azure GPU family. This series is designed for high-end Deep Learning training and tightly coupled scale-up and scale-out Generative AI and HPC workloads.

The ND H100 v5 series starts with a single VM and eight NVIDIA H100 Tensor Core GPUs. ND H100 v5-based deployments can scale up to thousands of GPUs with 3.2 Tbps of interconnect bandwidth per VM. Each GPU within the VM is provided with its own dedicated, topology-agnostic 400 Gb/s NVIDIA Quantum-2 CX7 InfiniBand connection. These connections are automatically configured between VMs occupying the same virtual machine scale set, and support GPU Direct RDMA.

Each GPU features NVLINK 4.0 connectivity for communication within the VM, and the instance has 96 physical fourth Gen Intel Xeon Scalable processor cores.

These instances provide excellent performance for many AI, ML, and analytics tools that support GPU acceleration 'out-of-the-box,' such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks. Additionally, the scale-out InfiniBand interconnect supports a large set of existing AI and HPC tools that are built on NVIDIA's NCCL communication libraries for seamless clustering of GPUs.

ND-H200-v5 size series

The ND v5 H200 series virtual machine (VM) is designed to deliver exceptional performance for AI and high-performance computing (HPC) workloads. These VMs leverage the power of the NVIDIA H200 Tensor Core GPU, which offer a 76% increase in High Bandwidth Memory over the H100 GPUs to deliver higher performance on state-of-the-art Generative AI models. With 141 GB of high-speed memory, and 4.8 TB/s of memory bandwidth, the H200 GPU can handle larger datasets and more complex models, making it ideal for generative AI and scientific computing.

The ND H200 v5 series starts with a single VM and eight NVIDIA H200 Tensor Core GPUs, interconnected with 900 GB/s NVLink. ND H200 v5-based deployments can scale up to thousands of GPUs with 3.2Tb/s of interconnect bandwidth per VM. Each GPU within the VM is provided with its own dedicated, topology-agnostic 400 Gb/s NVIDIA Quantum-2 CX7 InfiniBand connection. These connections are automatically configured between VMs occupying the same virtual machine scale set, and support GPUDirect RDMA.

These instances provide excellent performance for many AI, ML, and analytics tools that support GPU acceleration "out-of-the-box" such as TensorFlow, Pytorch, Caffe, RAPIDS, and other frameworks. Additionally, the scale-out InfiniBand interconnect is supported by a large set of existing AI and HPC tools that are built on NVIDIA's NCCL communication libraries for seamless clustering of GPUs.

ND-MI300X-v5 sizes series

The ND MI300X v5 series virtual machine (VM) is a new flagship addition to the Azure GPU family. It was designed for high-end Deep Learning training and tightly coupled scale-up and scale-out Generative AI and HPC workloads.

The ND MI300X v5 series VM starts with eight AMD Instinct MI300 GPUs and two fourth Gen Intel Xeon Scalable processors for a total 96 physical cores. Each GPU within the VM is then connected to one another via 4th-Gen AMD Infinity Fabric links with 128 GB/s bandwidth per GPU and 896 GB/s aggregate bandwidth.

ND MI300X v5-based deployments can scale up to thousands of GPUs with 3.2 Tb/s of interconnect bandwidth per VM. Each GPU within the VM is provided with its own dedicated, topology-agnostic 400 Gb/s NVIDIA Quantum-2 CX7 InfiniBand connection. These connections are automatically configured between VMs occupying the same virtual machine scale set, and support GPUDirect RDMA.

These instances provide excellent performance for many AI, ML, and analytics tools that support GPU acceleration "out-of-the-box," such as TensorFlow, Pytorch, and other frameworks. Additionally, the scale-out InfiniBand interconnect supports a large set of existing AI and HPC tools that are built on AMD's ROCm Communication Collectives Library (RCCL) for seamless clustering of GPUs.

'NG' sub-family GPU accelerated VM size series

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'NG' family of VM size series are one of Azure's GPU-optimized VM instances, specifically designed for cloud gaming and remote desktop applications. They harness powerful AMD Radeon™ PRO GPUs to deliver high-quality, interactive gaming experiences in the cloud, optimized for rendering complex graphics and streaming high-definition video. This ensures gamers enjoy a seamless, responsive gaming environment accessible from any device. Additionally, NG-series VMs provide a high-quality, responsive remote desktop experience, making them ideal for users needing reliable, high-performance access to desktop applications from anywhere in the world.

Workloads and use cases

Cloud Gaming: NG-family VMs harness powerful AMD Radeon™ PRO GPUs to deliver high-quality, interactive gaming experiences in the cloud.

Remote Destkop: NG-family VMs can be used for remote desktop applications, providing users with a high-quality, responsive user experience.

Series in family

NGads V620-series

The NGads V620 series are GPU-enabled virtual machines with CPU, memory resources and storage resources balanced to generate and stream high quality graphics for a high performance, interactive gaming experience hosted in Azure. They're powered by AMD Radeon(tm) PRO V620 GPU and AMD EPYC 7763 (Milan) CPUs. The AMD Radeon PRO V620 GPUs have a maximum frame buffer of 32 GB, which can be divided up to four ways through hardware partitioning. The AMD EPYC CPUs have a base clock speed of 2.45 GHz and a boost1 speed of 3.5Ghz. VMs are assigned full cores instead of threads, enabling full access to AMD’s powerful “Zen 3” cores.

NGads instances come in four sizes, allowing customers to right-size their gaming environments for the performance and cost that best fits their business needs. The NG-

series virtual machines feature partial GPUs to enable you to pick the right-sized virtual machine for GPU accelerated graphics applications and virtual desktops. The vm sizes start with 1/4 of a GPU with 8-GiB frame buffer up to a full GPU with 32-GiB frame buffer. The NGads VMs also feature Direct Disk NVMe ranging from 1 to 4x 960 GB disks per VM.

> **Note**
>
> Max boost for AMD EPYC processors is the maximum frequency achievable by any single core on the processor under normal operating conditions for server systems.)

'NV' sub-family GPU accelerated VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'NV' family of VM size series are one of Azure's GPU-accelerated VM instances, specifically designed for graphics-intensive applications such as graphics rendering, simulation, and virtual desktops. Equipped with NVIDIA or AMD GPUs, NV-series VMs provide a robust platform for rendering and processing graphics-heavy tasks, making them ideal for organizations that require virtual workstations with powerful graphical capabilities. These VMs support scenarios where remote visualization, real-time collaboration, and 3D visualization are necessary, allowing users to efficiently run graphic-intensive applications directly from Azure's cloud environment.

Workloads and use cases

Virtual Desktop Infrastructure (VDI): NV-family VMs are well-suited for virtual desktops that require GPU capabilities for tasks such as graphic design, video editing, and CAD applications. They provide the graphical performance necessary for smooth operation in remote desktop scenarios.

3D Visualization: NV-family VMs are ideal for running 3D applications that demand high-performance rendering, such as architectural visualizations, medical imaging, and other professional-grade graphics tasks.

Remote Graphics Work: NV-series VMs are beneficial for industries that rely on graphics-intensive software, allowing professionals to access and use applications like Adobe Photoshop, Autodesk AutoCAD, or Dassault SOLIDWORKS remotely with near-native performance.

High-Resolution Image Processing: NV-series VMs are ideal for handling extremely large vRAM applications such as high-resolution image processing and analysis. This includes tasks in fields like geospatial analysis, satellite image processing, and professional photo editing, where handling massive image files and performing complex manipulations in real-time are crucial for productivity and performance.

Video Streaming: NV-family VMs are suitable for streaming high-resolution video content, including training videos and virtual events, ensuring high-quality delivery without local hardware constraints.

Local Storage	1 Disk	340 - 1440 GiB
Remote Storage	24 - 64	
Network	1 - 4 NICs	
Accelerators	1/2 - 2 GPUs	Nvidia Tesla M60 GPU (16GB)

NVv3-series

> **Important**
>
> NVv3-series VMs are planned to retire on September 30, 2026. Migrate to NVads-A10 v5-series or NVads-v710 v5-series before this date to avoid service disruption. For full migration details, see the NVv3-series retirement guide. For resizing steps, see Change the size of a virtual machine.

The NVv3-series virtual machines are powered by NVIDIA Tesla M60 GPUs and NVIDIA GRID technology with Intel E5-2690 v4 (Broadwell) CPUs and Intel Hyper-Threading Technology. These virtual machines are targeted for GPU accelerated graphics applications and virtual desktops where customers want to visualize their data, simulate results to view, work on CAD, or render and stream content. Additionally, these virtual machines can run single precision workloads such as encoding and rendering. NVv3 virtual machines support Premium Storage and come with twice the system memory (RAM) when compared with its predecessor NV-series.

Each GPU in NVv3 instances comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

View the full NVv3-series page.

Network	1 - 8 NICs	5000 - 80000 Mbps Interfaces: NetVSC, ConnectX
Accelerators	1/6 - 2 GPUs	Nvidia A10 GPU (24GB)

NVads-v710 v5-series

The NVads V710 v5-series virtual machines are powered by AMD Radeon™ Pro V710 GPUs and AMD EPYC™ 9V64 F (Genoa) CPUs with a base frequency of 3.95 GHz and all-cores peak frequency of 4.3 GHz. VMs take advantage of the AMD Simultaneous Multithreading technology to assign dedicated vCPU threads to each VM. Both Windows and Linux VMs are supported.

The series provides five options ranging from 1/6 of a GPU with 4-GiB frame buffer to a full V710 GPU with 24-GiB frame buffer. No other GPU licensing is required for use of AMD GPU-based VMs. The NVads V710 v5 VMs also support NVMe for ephemeral local storage capability. The NVads V710 v5-series enables right-sizing for demanding GPU-accelerated graphics applications and cloud-based virtual desktops to provide a seamless end user experience while providing a cost-effective choice for a full range of graphics-enabled virtual desktop experiences. The VMs are also sized to deliver high-quality, interactive gaming experiences in the cloud, optimized for rendering and streaming complex graphics.

The NVads V710 v5-series virtual machines also support small to medium AI/ML inference workloads such as Small Language Model (SLMs), recommendation systems and semantic indexing, by taking advantage of the computational IP blocks in the Radeon Pro V710 GPUs.

Migrate your NV and NV_Promo series virtual machines by September 6, 2023

03/17/2025

We're happy to announce that we're extending the retirement date by one year to September 6, 2023, for the Azure NV-Series and NV_Promo Series virtual machine to give you more time to plan your migration.

We continue to bring modern and optimized virtual machine (VM) instances to Azure by using the latest innovations in datacenter technologies. As we innovate, we also thoughtfully plan how we retire aging hardware. With this context in mind, we're retiring our NV-series Azure VM sizes on September 6, 2023.

How does the NV series migration affect me?

After September 6, 2023, any remaining NV and NV_Promo-size VMs remaining in your subscription will be set to a deallocated state. These VMs will be stopped and removed from the host. These VMs will no longer be billed in the deallocated state.

The current VM size retirement only affects the VM sizes in the NV series. This retirement doesn't affect the NVv3 and NVv4 series VMs.

What actions should I take?

You'll need to resize or deallocate your NV VMs. We recommend moving your GPU visualizations or graphics workloads to another GPU accelerated VM size.

Learn more about migrating your workloads to other GPU Azure VM sizes.

If you have questions, contact us through customer support.

NV series migration guide

> **Important**
>
> The NV-series is retired as of September 6th, 2023, and is no longer available. Please refer to the NV-series retirement page for more information.

As more powerful GPU VM sizes become available in Azure datacenters, assess your workloads and migrate virtual machines (VMs) in the NV and NV_Promo series. These legacy VMs can be migrated into new VM series, such as NVsv3 and NVasv4, for better performance with reduced cost. The NVsv3 VM series is powered by Nvidia M60 GPUs. The NVasv4 series is powered by AMD Radeon Instinct MI25 GPUs.

The main differences between the NV and NV_Promo series and the newer NVsv3 and NVasv4 series are:

- Improved performance.
- Support for Premium storage.
- The option to choose from a fractional GPU size to multi-GPU configurations.

Both the NVsv3 and NVasv4 series have more modern cores and greater capacity.

The following section summarizes the differences between the legacy NV series and the NVsv3 and NVv4 series.

NVsv3 series

The NVv3-series VMs are powered by NVIDIA Tesla M60 GPUs and NVIDIA GRID technology with Intel E5-2690 v4 (Broadwell) CPUs and Intel Hyper-Threading Technology. These VMs are targeted for GPU accelerated graphics applications and virtual desktops where customers want to:

- Visualize their data.
- Simulate results to view.
- Work on CAD.
- Render and stream content.

These VMs can also run single precision workloads, such as encoding and rendering.

NVv3 VMs support Premium storage and come with twice the system memory (RAM) when compared with the NV series. For the most up-to-date specifications, see GPU accelerated compute VM sizes: NVsv3 series.

Expand table

Current VM size	Target VM size	Difference in specification
Standard_NV6 Standard_NV6_Promo	Standard_NV12s_v3	vCPU: 12 (+6) Memory: GiB 112 (+56) Temp storage (SSD) GiB: 320 (-20) Max data disks: 12 (-12) Accelerated networking: Yes Premium storage: Yes
Standard_NV12 Standard_NV12_Promo	Standard_NV24s_v3	vCPU: 24 (+12) Memory: GiB 224 (+112) Temp storage (SSD) GiB: 640 (-40) Max data disks: 24 (-24) Accelerated networking: Yes Premium storage: Yes
Standard_NV24 Standard_NV24_Promo	Standard_NV48s_v3	vCPU: 48 (+24) Memory: GiB 448 (+224) Temp storage (SSD) GiB: 1280 (-160) Max data disks: 32 (-32) Accelerated networking: Yes Premium storage: Yes

NVv4 series

NVv4-series VMs are powered by AMD Radeon Instinct MI25 GPUs and AMD EPYC 7V12 (Rome) CPUs. With the NVv4 series, Azure introduces VMs with partial GPUs. Choose the right size VM for GPU accelerated graphics applications and virtual desktops that start at one-eighth of a GPU with a 2-GiB frame buffer to a full GPU with a 16-GiB frame buffer.

NVv4 VMs currently support only the Windows guest operating system. For the most up-to-date specifications, see GPU accelerated compute VM sizes: NVv4 series.

Current VM size	Target VM size	Difference in specification
		Temp storage (SSD) GiB: 352 (+12) Max data disks: 16 (-8) Accelerated networking: Yes Premium storage: Yes
Standard_NV12 Standard_NV12_Promo	Standard_NV32as_v4	vCPU: 32 (+20) Memory: GiB 112 Temp storage (SSD) GiB: 704 (+24) Max data disks: 32 (+16) Accelerated networking: Yes Premium storage: Yes
Standard_NV24 Standard_NV24_Promo	N/A	N/A

Migration steps for general changes

To deal with general changes:

1. Choose a series and size for migration.
2. Get a quota for the target VM series.
3. Resize the current NV-series VM size to the target size.

If the target size is NVv4, make sure to remove the Nvidia GPU driver and install the AMD GPU driver.

Migration steps for breaking changes

To deal with breaking changes, follow the steps in the next sections.

Select a target size for migration

After you assess your current usage, decide what type of GPU VM you need. Depending on the workload requirements, you have a few different choices. Here's how to choose:

- If the workload is graphics or visualizations and has a hard dependency on using the Nvidia GPU, migrate to the NVsv3 series.
- If the workload is graphics or visualizations and has no hard dependency on a specific type of GPU, migrate to the NVsv3 or NVVasv4 series.

> **Note**
>
> A best practice is to select a VM size based on both cost and performance. The recommendations in this article are based on a one-to-one comparison of performance metrics for the NV and NV_Promo sizes and the nearest match in another VM series. Before you decide on the right size, get a cost comparison by using the Azure Pricing Calculator.

Get a quota for the target VM family

Follow the guide to request an increase in vCPU quota by VM family. Select the NVSv3 series or NVv4 series as the VM family name depending on the target VM size you selected for migration.

Resize the current VM

You can resize the VM.

FAQ

Q: Which GPU driver should I use for the target VM size?

A: For the NVsv3 series, use the Nvidia GRID driver. For NVv4, use the AMD GPU drivers.

Q: I use the Nvidia GPU driver extension today. Will it work for the target VM size?

A: The current Nvidia driver extension will work for NVsv3. Use the AMD GPU driver extensions if the target VM size is NVv4.

Q: Which target VM series should I use if I have dependency on CUDA?

A: NVv3 supports CUDA. The NVv4 VM series with the AMD GPUs doesn't support CUDA.

Last updated on 07/11/2025

NVv3 sizes series

> **Note**
>
> The NVv3-series will be retired on September 30, 2026. Refer to the NVv3-series retirement page for more information and migration recommendations.

The NVv3-series virtual machines are powered by NVIDIA Tesla M60 GPUs and NVIDIA GRID technology with Intel E5-2690 v4 (Broadwell) CPUs and Intel Hyper-Threading Technology. These virtual machines are targeted for GPU accelerated graphics applications and virtual desktops where customers want to visualize their data, simulate results to view, work on CAD, or render and stream content. Additionally, these virtual machines can run single precision workloads such as encoding and rendering. NVv3 virtual machines support Premium Storage and come with twice the system memory (RAM) when compared with its predecessor NV-series.

Each GPU in NVv3 instances comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

Migrate your NVv3-series virtual machines by September 30, 2026

09/20/2025

> **Note**
>
> 1-year and 3-year RI purchases for the NVv3-series will end September 30, 2025.

On September 30, 2026, Microsoft Azure will retire the Standard_NV12s_v3, Standard_NV24s_v3, Standard_NV24ms_v3, Standard_NV32ms_v3, and Standard_NV48s_v3 virtual machines (VMs) in the NVv3-series virtual machines (VMs). To avoid any disruptions to your service, we recommend that you change the VM sizing for your workloads from the current NVv3-series VMs to the newer VM series in the same NV product line.

Microsoft is recommending the Azure NVadsA10_v5-series VMs, which offer greater GPU memory bandwidth per GPU. With the NVadsA10_v5-series VMs, Azure introduces VMs with partial NVIDIA GPUs and each VM instance comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user or 25 concurrent users can connect to the VM for a virtual application scenario. These VMs are targeted for GPU accelerated graphics applications, virtual desktops, visualizations, or small AI workloads.

Depending on the workload being run, regional affinity, and cost preferences, other VMs that may be migrated to from the NVv3-series VMs include NCasT4_v3 and NVadsV710_v5:

Expand table

Workload	Recommended SKU to Migrate to
GPU accelerated graphics applications, virtual desktops, visualizations, or small AI workloads.	NVadsA10_v5
Offline inferencing workloads where latency is not a primary concern, and there is an interest in purchasing smaller VM SKUs or reducing costs.	NCasT4_v3
Graphics, visualization, or small AI workloads such as SLM inferencing and semantic search where optimal performance is not a priority or there is an interest in reducing costs.	NVadsV710_v5

How does the retirement of the NVv3-series virtual machines affect me?

After September 30th, 2026, any remaining NVv3-series virtual machines (VMs) subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. NVv3 will no longer be under SLA or have support included.

> **Note**
>
> This retirement only impacts the virtual machine sizes in the NVv3-series powered by NVIDIA Tesla M60 GPUs. For NVv4-series virtual machines, please refer to the NVv4-series virtual machines retirement guide. This retirement announcement does not apply to NVadsA10_v5 or NVadsV710_v5 series virtual machines.

What action do I need to take before the retirement date?

You need to resize or deallocate your NVv3-series VMs. We recommend that you change VM sizes for these workloads from the original NVv3-series VMs to the NVadsA10_v5-series VMs (or an alternative).

The NVadsA10_v5-series is powered by NVIDIA A10 GPUs and AMD EPYC™ 74F3V(Milan) processors. The VMs feature up to 2 NVIDIA A10 GPUs with 24GB memory each, up to 72 non-multithreaded AMD EPYC 74F3V processor cores and 880 GiB of system memory. Check Azure Regions by Product page for region availability. Visit the Azure Virtual Machine pricing page for pricing information.

Steps to change VM size

1. Choose a series and size. Refer to the above tables for Microsoft's recommendation. You can also file a support request if more assistance is needed.
2. Request quota for the new target VM.
3. You can resize the virtual machine.

Help and support

If you have a support plan and you need technical help, create a support request.

1. Under *Issue type*, select **Technical**.
2. Under *Subscription*, select your subscription.

3. Under *Service*, click **My services**.

4. Under *Service type*, select **Virtual Machine running Windows/Linux**.

5. Under *Summary*, enter the summary of your request.

6. Under *Problem type*, select **Assistance with resizing my VM.**

7. Under *Problem subtype*, select the option that applies to you.

NVv4 sizes series

Summarize this article for me

> **Note**
>
> The NVv4-series will be retired on September 30, 2026. Refer to the NVv4-series retirement page for more information and migration recommendations.

The NVv4-series virtual machines are powered by AMD Radeon Instinct MI25 GPUs and AMD EPYC 7V12(Rome) CPUs with a base frequency of 2.45GHz, all-cores peak frequency of 3.1GHz and single-core peak frequency of 3.3GHz. With NVv4-series Azure is introducing virtual machines with partial GPUs. Pick the right sized virtual machine for GPU accelerated graphics applications and virtual desktops starting at 1/8th of a GPU with 2 GiB frame buffer to a full GPU with 16 GiB frame buffer. NVv4 virtual machines currently support only Windows guest operating system.

Migrate your NVv4-series virtual machines by September 30, 2026

09/20/2025

> **Note**
>
> There is a known resize operation error that occurs when migrating from the NVv4-series to the NVads_V710_v5-series. Microsoft is working on a fix that will be implemented in April 2026. In the meantime, we suggest that you follow this workaround.

> **Note**
>
> 1-year and 3-year RI purchases for the NVv4-series will end September 30, 2025.

On September 30, 2026, Microsoft Azure will retire the Standard_NV4as_v4, Standard_NV8as_v4, Standard_NV16as_v4, and Standard_NV32as_v4 virtual machines (VMs) in NVv4-series virtual machines (VMs). To avoid any disruption to your service, we recommend that you change the VM sizing for your workloads from the current NVv4-series VMs to the newer VM series in the same NV product line.

Microsoft is recommending the Azure NVads_V710_v5-series VMs, which offer greater GPU memory bandwidth per GPU. The NVads_V710_v5-series VMs take advantage of the AMD Simultaneous Multithreading technology to assign dedicated vCPU threads to each VM and support NVMe for ephemeral local storage capability.

The NVads_V710_v5-series enables right-sizing for demanding GPU-accelerated graphics applications and cloud-based virtual desktops to provide a seamless end user experience while providing a cost-effective choice for a full range of graphics-enabled virtual desktop experiences. The VMs are also sized to deliver high-quality, interactive gaming experiences in the cloud, optimized for rendering and streaming complex graphics. In addition, the NVads_V710_v5-series supports small AI inference workloads such as Small Language Model (SLMs), recommendation systems, and semantic indexing, by taking advantage of the computational IP blocks in the Radeon Pro V710 GPUs.

Expand table

Workload	Recommended SKU to Migrate to

GPU accelerated graphics applications, virtual desktops, and visualizations.	NVads_V710_v5

How does the retirement of the NVv4-series virtual machines affect me?

After September 30th, 2026, any remaining NVv4-series virtual machines (VMs) subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. NVv4 will no longer be under SLA or have support included.

> **Note**
>
> This retirement only impacts the virtual machine sizes in the NVv4-series powered by AMD Radeon Instinct MI25 GPUs. For NVv3-series virtual machines, please refer to the NVv3-series virtual machines retirement guide. This retirement announcement does not apply to NVadsA10_v5 or NVads_V710_v5 series virtual machines.

What action do I need to take before the retirement date?

You need to resize or deallocate your NVv4-series VMs. We recommend that you change VM sizes for these workloads from the original NVv4-series VMs to the NVads_V710_v5-series VMs (or an alternative).

The NVads_V710_v5-series is powered by AMD Radeon™ Pro V710 GPUs and AMD EPYC™ 9V64 F (Genoa) processors. The VMs feature up to 1 AMD Radeon™ Pro V710 GPU with 24GB memory each, up to 28 multithreaded AMD EPYC 9V64 F processor cores and 160 GiB of system memory. Check Azure Regions by Product page for region availability. Visit the Azure Virtual Machine pricing page for pricing information.

Steps to change VM size

1. Choose a series and size. Refer to the above tables for Microsoft's recommendation. You can also file a support request if more assistance is needed.

2. Request quota for the new target VM.

3. You can resize the virtual machine.

Help and support

If you have a support plan and you need technical help, create a support request.

1. Under *Issue type*, select **Technical**.

2. Under *Subscription*, select your subscription.

3. Under *Service*, click **My services**.

4. Under *Service type*, select **Virtual Machine running Windows/Linux**.

5. Under *Summary*, enter the summary of your request.

6. Under *Problem type*, select **Assistance with resizing my VM.**

7. Under *Problem subtype*, select the option that applies to you.

NVadsA10_v5 sizes series

The NVadsA10v5-series virtual machines are powered by NVIDIA A10 GPUs and AMD EPYC 74F3V(Milan) CPUs with a base frequency of 3.2 GHz, all-cores peak frequency of 4.0 GHz. With NVadsA10v5-series Azure is introducing virtual machines with partial NVIDIA GPUs. Pick the right sized virtual machine for GPU accelerated graphics applications and virtual desktops starting at 1/6th of a GPU with 4-GiB frame buffer to a full A10 GPU with 24-GiB frame buffer. Each virtual machine instance in NVadsA10v5-series comes with a GRID license. This license gives you the flexibility to use an NV instance as a virtual workstation for a single user, or 25 concurrent users can connect to the VM for a virtual application scenario.

NVads V710 v5-series

The NVads V710 v5-series virtual machines are powered by AMD Radeon™ Pro V710 GPUs and AMD EPYC™ 9V64 F (Genoa) CPUs with a base frequency of 3.95 GHz and all-cores peak frequency of 4.3 GHz. VMs take advantage of the AMD Simultaneous Multithreading technology to assign dedicated vCPU threads to each VM. Both Windows and Linux VMs are supported.

The series provides five options ranging from 1/6 of a GPU with 4-GiB frame buffer to a full V710 GPU with 24-GiB frame buffer. No other GPU licensing is required for use of AMD GPU-based VMs. The NVads V710 v5 VMs also support NVMe for ephemeral local storage capability. The NVads V710 v5-series enables right-sizing for demanding GPU-accelerated graphics applications and cloud-based virtual desktops to provide a seamless end user experience while providing a cost-effective choice for a full range of graphics-enabled virtual desktop experiences. The VMs are also sized to deliver high-quality, interactive gaming experiences in the cloud, optimized for rendering and streaming complex graphics.

The NVads V710 v5-series virtual machines also support small to medium AI/ML inference workloads such as Small Language Model (SLMs), recommendation systems and semantic indexing, by taking advantage of the computational IP blocks in the Radeon Pro V710 GPUs.

Install NVIDIA GPU drivers on N-series VMs running Linux

> **⊗ Caution**
>
> This article references CentOS, a Linux distribution that is End Of Life (EOL) status. Please consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Applies to: ✔ Linux VMs

> **ⓘ Important**
>
> To align with inclusive language practices, we've replaced the term "blacklist" with "blocklist" throughout this documentation. This change reflects our commitment to avoiding terminology that might carry unintended negative connotations or perceived racial bias. However, in code snippets and technical references where "blacklist" is part of established syntax or tooling (for example, configuration files, command-line parameters), the original term is retained to preserve functional accuracy. This usage is strictly technical and doesn't imply any discriminatory intent.

To take advantage of the GPU capabilities of Azure N-series VMs backed by NVIDIA GPUs, you must install NVIDIA GPU drivers. The NVIDIA GPU Driver Extension installs appropriate NVIDIA CUDA or GRID drivers on an N-series VM. Install or manage the extension using the Azure portal or tools such as the Azure CLI or Azure Resource Manager templates. See the NVIDIA GPU Driver Extension documentation for supported distributions and deployment steps.

If you choose to install NVIDIA GPU drivers manually, this article provides supported distributions, drivers, and installation and verification steps. Manual driver setup information is also available for Windows VMs.

For N-series VM specs, storage capacities, and disk details, see GPU Linux VM sizes.

> **⚠ Warning**
>
> Installing NVIDIA drivers using methods other than those outlined in this guide may result in failure of the intended driver installation. To ensure proper functionality and support, follow only the installation steps and use the driver versions specified in this documentation.

Supported distributions and drivers

NVIDIA CUDA drivers

For the latest CUDA drivers and supported operating systems, visit the NVIDIA website. Ensure that you install or upgrade to the latest supported CUDA drivers for your distribution.

> **Note**
>
> The latest supported CUDA driver for original NC-series SKU VMs is currently 470.82.01. Later driver versions aren't supported on the K80 cards in NC.

> **Note**
>
> The Azure NVads A10 v5 VMs only support GRID 17.x or higher driver versions. The vGPU driver for the A10 SKU is a unified driver that supports both graphics and compute workloads.

> **Caution**
>
> Secure Boot and vTPM should be disabled because the process hangs when they're enabled.

> **Tip**
>
> As an alternative to manual CUDA driver installation on a Linux VM, you can deploy an Azure Data Science Virtual Machine image. The DSVM edition for Ubuntu 16.04 LTS preinstalls NVIDIA CUDA drivers, the CUDA Deep Neural Network Library, and other tools.

NVIDIA GRID drivers

> **Note**
>
> vGPU18 is available for the NCasT4_v3-series.
>
> vGPU18 is now available for the NVadsA10_v5-series in **public regions only**. vGPU18 for the NVadsA10_v5-series is **not** supported in the Mooncake and Fairfax regions yet. We'll

provide an update once vGPU18 becomes supported for the NVadsA10_v5-series in the Mooncake and Fairfax regions.

Microsoft redistributes NVIDIA GRID driver installers for NV and NVv3-series VMs used as virtual workstations or for virtual applications. Install only these GRID drivers on Azure NV VMs, only on the operating systems listed in the following table. These drivers include licensing for GRID Virtual GPU Software in Azure. You don't need to set up an NVIDIA vGPU software license server.

The GRID drivers redistributed by Azure don't work on most non-NV series VMs, like NC, NCv2, NCv3, ND, and NDv2-series VMs, but they work on NCasT4v3 series.

For more information on the specific vGPU and driver branch versions, visit the NVIDIA website.

Expand table

Distribution	Driver
Ubuntu 20.04 LTS, 22.04 LTS, 24.04 LTS	NVIDIA vGPU 18.5, driver branch R570
Red Hat Enterprise Linux 8.6, 8.8, 8.9, 8.10, 9.0, 9.2, 9.3, 9.4, 9.5	NVIDIA vGPU 18.5, driver branch R570
SUSE Linux Enterprise Server 15 SP2, 12 SP2,12 SP5	
Rocky Linux 8.4	

Note

For Azure NVads A10 v5 VMs, we recommend that you use the latest driver version. The latest NVIDIA major driver branch (n) is only backward compatibile with the previous major branch (n-1). For example, vGPU 17.x is backward compatible with vGPU 16.x only. Driver failures might occur on any VMs still running n-2 or lower when the latest drive branch is rolled out to Azure hosts.

NVs_v3 VMs only support **vGPU 16 or lower** driver versions.

GRID Driver 17.3 currently supports only the NCasT4_v3 series of VMs. To use this driver, download and install GRID Driver 17.3 manually.

GRID drivers are having issues with installation on Azure kernel 6.11. To unblock, downgrade the kernel to version 6.8. For more information, see Known Issues.

Visit GitHub for the complete list of all previous Nvidia GRID driver links.

> ⚠ **Warning**
>
> Installation of third-party software on Red Hat products can affect the Red Hat support terms. See the Red Hat Knowledgebase article.

Install CUDA drivers on N-series VMs

Here are steps to install CUDA drivers from the NVIDIA CUDA Toolkit on N-series VMs.

C and C++ developers can optionally install the full Toolkit to build GPU-accelerated applications. For more information, see the CUDA Installation Guide.

To install CUDA drivers, make an SSH connection to each VM. To verify that the system has a CUDA-capable GPU, run the following command:

Bash

```
lspci | grep -i NVIDIA
```

Output is similar to the following example (showing an NVIDIA Tesla K80 card):

```
af8a:00:00.0 3D controller: NVIDIA Corporation GK210GL [Tesla K80] (rev a1)
```

lspci lists the PCIe devices on the VM, including the InfiniBand NIC and GPUs, if any. If lspci doesn't return successfully, you may need to install LIS on CentOS/RHEL.

Then run installation commands specific for your distribution.

Ubuntu

Ubuntu packages NVIDIA proprietary drivers. Those drivers come directly from NVIDIA and are simply packaged by Ubuntu so that they can be automatically managed by the system. Downloading and installing drivers from another source can lead to a broken system. Moreover, installing third-party drivers requires extra steps on VMs with TrustedLaunch and Secure Boot enabled. They require the user to add a new Machine Owner Key for the system to boot. Drivers from Ubuntu are signed by Canonical and will work with Secure Boot.

1. Install `ubuntu-drivers` utility:

```bash
sudo apt update && sudo apt install -y ubuntu-drivers-common
```

2. Install the latest NVIDIA drivers:

```bash
sudo ubuntu-drivers install
```

3. Reboot the VM after the GPU driver is installed:

```bash
sudo reboot
```

4. Download and install the CUDA toolkit from NVIDIA:

> **Note**
>
> The example shows the CUDA package path for Ubuntu 24.04 LTS. Use the path that's specific to the version you plan to use.
>
> Visit the NVIDIA Download Center or the NVIDIA CUDA Resources page for the full path that's specific to each version.

```bash
wget
https://developer.download.nvidia.com/compute/cuda/repos/ubuntu2404/x86_64/cuda
-keyring_1.1-1_all.deb
sudo apt install -y ./cuda-keyring_1.1-1_all.deb
sudo apt update
sudo apt -y install cuda-toolkit-12-5
```

The installation can take several minutes.

5. Reboot the VM after installation completes:

```bash
sudo reboot
```

6. Verify that the GPU is correctly recognized (after reboot):

```
Bash
nvidia-smi
```

NVIDIA driver updates

We recommend that you periodically update NVIDIA drivers after deployment.

```
Bash
sudo apt update
sudo apt full-upgrade
```

CentOS or Red Hat Enterprise Linux

1. Update the kernel (recommended). If you choose not to update the kernel, ensure that the versions of `kernel-devel`, and `dkms` are appropriate for your kernel.

```
sudo yum install kernel kernel-tools kernel-headers kernel-devel
sudo reboot
```

2. Install the latest Linux Integration Services for Hyper-V and Azure. Check if LIS is required by verifying the results of lspci. If all GPU devices are listed as expected, installing LIS isn't required.

   LIS is applicable to Red Hat Enterprise Linux, CentOS, and the Oracle Linux Red Hat Compatible Kernel 5.2-5.11, 6.0-6.10, and 7.0-7.7. Refer to the Linux Integration Services documentation for more details. Skip this step if you plan to use CentOS/RHEL 7.8 (or higher versions) as LIS is no longer required for these versions.

```
Bash
wget https://aka.ms/lis
tar xvzf lis
cd LISISO

sudo ./install.sh
sudo reboot
```

3. Reconnect to the VM and continue installation with the following commands:

```
Bash
sudo rpm -Uvh https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm
sudo yum-config-manager --add-repo https://developer.download.nvidia.com/compute/cuda/repos/rhel7/x86_64/cuda-rhel7.repo
sudo yum clean all
sudo yum -y install nvidia-driver-latest-dkms cuda-drivers
```

The installation can take several minutes.

> **Note**
>
> Visit Fedora and Nvidia CUDA repo to pick the correct package for the CentOS or RHEL version you want to use.

For example, CentOS 8 and RHEL 8 need the following steps.

```
Bash
sudo rpm -Uvh https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
sudo yum install dkms

sudo wget https://developer.download.nvidia.com/compute/cuda/repos/rhel8/x86_64/cuda-rhel8.repo -O /etc/yum.repos.d/cuda-rhel8.repo

sudo yum install cuda-drivers
```

4. To optionally install the complete CUDA toolkit, type:

```
Bash
sudo yum install cuda
```

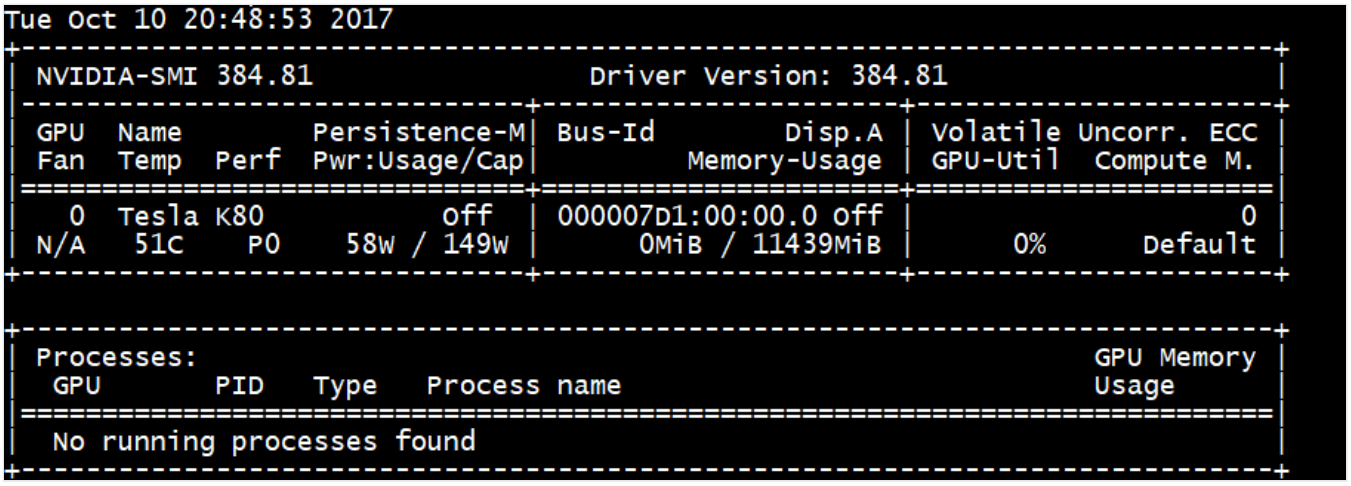
> **Note**
>
> If you see an error message related to missing packages like vulkan-filesystem, you may need to edit /etc/yum.repos.d/rh-cloud, look for optional-rpms, and set enabled to 1.

5. Reboot the VM and proceed to verify the installation.

Verify driver installation

To query the GPU device state, SSH to the VM and run the nvidia-smi command-line utility installed with the driver.

If the driver is installed, Nvidia SMI lists the **GPU-Util** as 0% until you run a GPU workload on the VM. Your driver version and GPU details may be different from the ones shown.



RDMA network connectivity

RDMA network connectivity can be enabled on RDMA-capable N-series VMs such as NC24r deployed in the same availability set or in a single placement group in a virtual machine (VM) scale set. The RDMA network supports Message Passing Interface (MPI) traffic for applications running with Intel MPI 5.x or a later version:

Distributions

Deploy RDMA-capable N-series VMs from one of the images in the Azure Marketplace that supports RDMA connectivity on N-series VMs:

- **Ubuntu 16.04 LTS** - Configure RDMA drivers on the VM and register with Intel to download Intel MPI:

    1. Install dapl, rdmacm, ibverbs, and mlx4

        Bash

        ```
        sudo apt-get update

        sudo apt-get install libdapl2 libmlx4-1
        ```

    2. In /etc/waagent.conf, enable RDMA by uncommenting the following configuration lines. You need root access to edit this file.

```
OS.EnableRDMA=y

OS.UpdateRdmaDriver=y
```

3. Add or change the following memory settings in KB in the /etc/security/limits.conf file. You need root access to edit this file. For testing purposes you can set memlock to unlimited. For example: `<User or group name> hard memlock unlimited`.

```
<User or group name> hard    memlock <memory required for your application in KB>

<User or group name> soft    memlock <memory required for your application in KB>
```

4. Install Intel MPI Library. Either purchase and download the library from Intel or download the free evaluation version.

```Bash
wget http://registrationcenter-download.intel.com/akdlm/irc_nas/tec/9278/l_mpi_p_5.1.3.223.tgz
```

   Only Intel MPI 5.x runtimes are supported.

   For installation steps, see the Intel MPI Library Installation Guide.

5. Enable ptrace for non-root non-debugger processes (needed for the most recent versions of Intel MPI).

```Bash
echo 0 | sudo tee /proc/sys/kernel/yama/ptrace_scope
```

- **CentOS-based 7.4 HPC** - RDMA drivers and Intel MPI 5.1 are installed on the VM.
- **CentOS-based HPC** - CentOS-HPC 7.6 and later (for SKUs where InfiniBand is supported over SR-IOV). These images have Mellanox OFED and MPI libraries pre-installed.

> **Note**
>
> CX3-Pro cards are supported only through LTS versions of Mellanox OFED. Use LTS Mellanox OFED version (4.9-0.1.7.0) on the N-series VMs with ConnectX3-Pro cards. For

more information, see Linux Drivers.

Also, some of the latest Azure Marketplace HPC images have Mellanox OFED 5.1 and later, which don't support ConnectX3-Pro cards. Check the Mellanox OFED version in the HPC image before using it on VMs with ConnectX3-Pro cards.

The following images are the latest CentOS-HPC images that support ConnectX3-Pro cards:

- OpenLogic:CentOS-HPC:7.6:7.6.2020062900
- OpenLogic:CentOS-HPC:7_6gen2:7.6.2020062901
- OpenLogic:CentOS-HPC:7.7:7.7.2020062600
- OpenLogic:CentOS-HPC:7_7-gen2:7.7.2020062601
- OpenLogic:CentOS-HPC:8_1:8.1.2020062400
- OpenLogic:CentOS-HPC:8_1-gen2:8.1.2020062401

Install GRID drivers on NV or NVv3-series VMs

To install NVIDIA GRID drivers on NV or NVv3-series VMs, make an SSH connection to each VM and follow the steps for your Linux distribution.

Ubuntu

1. Run the `lspci` command. Verify that the NVIDIA M60 card or cards are visible as PCI devices.

2. Install updates.

   Bash

   ```
   sudo apt-get update
   sudo apt-get upgrade -y
   sudo apt-get dist-upgrade -y
   sudo apt-get install build-essential ubuntu-desktop -y
   sudo apt-get install linux-azure -y
   ```

3. Disable the Nouveau kernel driver, which is incompatible with the NVIDIA driver. (Only use the NVIDIA driver on NV or NVv2 VMs.) To disable the driver, create a file in `/etc/modprobe.d` named `nouveau.conf` with the following content:

```
blacklist nouveau
blacklist lbm-nouveau
```

4. Reboot the VM and reconnect. Exit X server:

```Bash
sudo systemctl stop lightdm.service
```

5. Download and install the GRID driver:

```Bash
wget -O NVIDIA-Linux-x86_64-grid.run https://go.microsoft.com/fwlink/?
linkid=874272
chmod +x NVIDIA-Linux-x86_64-grid.run
sudo ./NVIDIA-Linux-x86_64-grid.run
```

6. When you're asked whether you want to run the nvidia-xconfig utility to update your X configuration file, select **Yes**.

7. After installation completes, copy /etc/nvidia/gridd.conf.template to a new file gridd.conf at location /etc/nvidia/.

```Bash
sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

8. Add the following to `/etc/nvidia/gridd.conf`:

```
IgnoreSP=FALSE
EnableUI=FALSE
```

9. Remove the following from `/etc/nvidia/gridd.conf` if it's present:

```
FeatureType=0
```

10. Reboot the VM and proceed to verify the installation.

Install GRID driver on Ubuntu with Secure Boot enabled

The GRID driver installation process does not offer any options to skip kernel module build and installation and select a different source of signed kernel modules, so secure boot has to be disabled in Linux VMs in order to use them with GRID, after installing signed kernel modules.

CentOS or Red Hat Enterprise Linux

1. Update the kernel and DKMS (recommended). If you choose not to update the kernel, ensure that the versions of `kernel-devel` and `dkms` are appropriate for your kernel.

   Bash

   ```
   sudo yum update
   sudo yum install kernel-devel
   sudo rpm -Uvh https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm
   sudo yum install dkms
   sudo yum install hyperv-daemons
   ```

2. Disable the Nouveau kernel driver, which is incompatible with the NVIDIA driver. (Only use the NVIDIA driver on NV or NV3 VMs.) To do this, create a file in `/etc/modprobe.d` named `nouveau.conf` with the following content:

   ```
   blacklist nouveau
   blacklist lbm-nouveau
   ```

3. Reboot the VM, reconnect, and install the latest Linux Integration Services for Hyper-V and Azure. Check if LIS is required by verifying the results of lspci. If all GPU devices are listed as expected, installing LIS isn't required.

   Skip this step if you plan to use CentOS/RHEL 7.8 (or higher versions) as LIS is no longer required for these versions.

   Bash

   ```
   wget https://aka.ms/lis
   tar xvzf lis
   cd LISISO

   sudo ./install.sh
   sudo reboot
   ```

4. Reconnect to the VM and run the `lspci` command. Verify that the NVIDIA M60 card or cards are visible as PCI devices.

5. Download and install the GRID driver:

```Bash
wget -O NVIDIA-Linux-x86_64-grid.run https://go.microsoft.com/fwlink/?linkid=874272
chmod +x NVIDIA-Linux-x86_64-grid.run

sudo ./NVIDIA-Linux-x86_64-grid.run
```

6. When you're asked whether you want to run the nvidia-xconfig utility to update your X configuration file, select **Yes**.

7. After installation completes, copy /etc/nvidia/gridd.conf.template to a new file gridd.conf at location /etc/nvidia/.

```Bash
sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

8. Add two lines to `/etc/nvidia/gridd.conf`:

```
IgnoreSP=FALSE
EnableUI=FALSE
```

9. Remove one line from `/etc/nvidia/gridd.conf` if it's present:

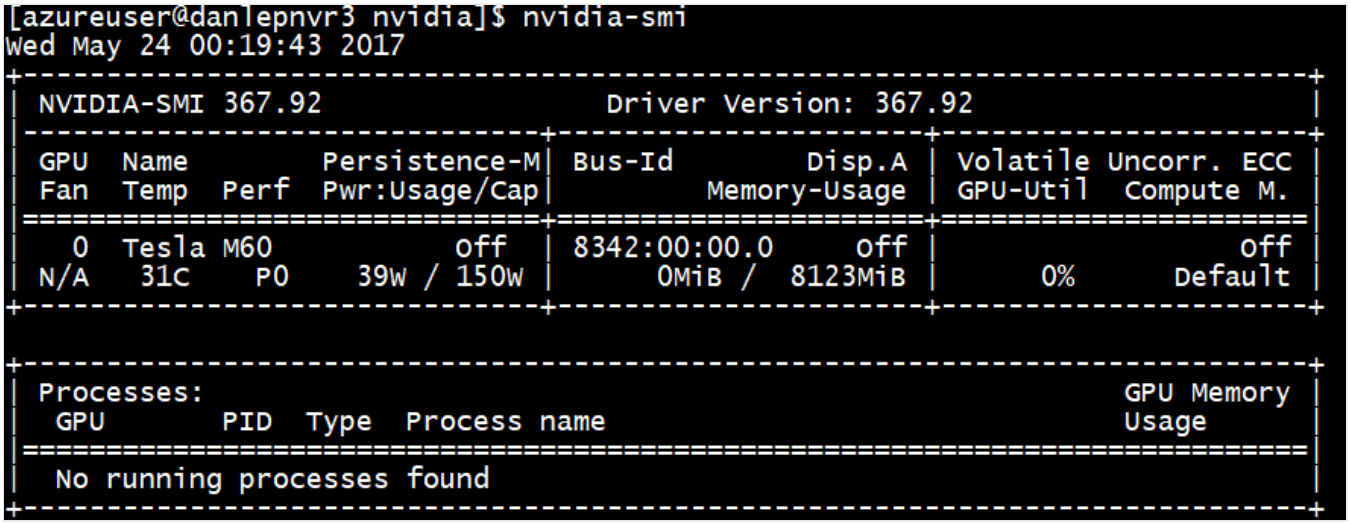
```
FeatureType=0
```

10. Reboot the VM and proceed to verify the installation.

Verify driver installation

To query the GPU device state, SSH to the VM and run the nvidia-smi command-line utility installed with the driver.

If the driver is installed, Nvidia SMI will list the **GPU-Util** as 0% until you run a GPU workload on the VM. Your driver version and GPU details may be different from the ones shown.



X11 server

If you need an X11 server for remote connections to an NV or NVv2 VM, x11vnc is recommended because it allows hardware acceleration of graphics. The BusID of the M60 device must be manually added to the X11 configuration file (usually `etc/X11/xorg.conf`). Add a `"Device"` section similar to the following:

```
Section "Device"
    Identifier     "Device0"
    Driver         "nvidia"
    VendorName     "NVIDIA Corporation"
    BoardName      "Tesla M60"
    BusID          "PCI:0@your-BusID:0:0"
EndSection
```

Additionally, update your `"Screen"` section to use this device.

You can find the decimal BusID by running

Bash

```
nvidia-xconfig --query-gpu-info | awk '/PCI BusID/{print $4}'
```

The BusID can change when a VM gets reallocated or rebooted. Therefore, you may want to create a script to update the BusID in the X11 configuration when a VM is rebooted. For example, create a script named `busidupdate.sh` (or another name you choose) with contents similar to the following:

Bash

```
#!/bin/bash
XCONFIG="/etc/X11/xorg.conf"
OLDBUSID=`awk '/BusID/{gsub(/"/, "", $2); print $2}' ${XCONFIG}`
NEWBUSID=`nvidia-xconfig --query-gpu-info | awk '/PCI BusID/{print $4}'`

if [[ "${OLDBUSID}" == "${NEWBUSID}" ]] ; then
        echo "NVIDIA BUSID not changed - nothing to do"
else
        echo "NVIDIA BUSID changed from \"${OLDBUSID}\" to \"${NEWBUSID}\": Updating
${XCONFIG}"
        sed -e 's|BusID.*|BusID          '\"${NEWBUSID}\"'|' -i ${XCONFIG}
fi
```

Then create an entry for your update script in `/etc/rc.d/rc3.d` so the script is invoked as root on boot.

Troubleshooting

- You can set persistence mode using `nvidia-smi` so the output of the command is faster when you need to query cards. To set persistence mode, run `nvidia-smi -pm 1`. If the VM is restarted, the mode setting goes away. You can always script the mode setting to run upon startup.
- If you updated the NVIDIA CUDA drivers to the latest version and find RDMA connectivity is no longer working, reinstall the RDMA drivers to reestablish that connectivity.
- During installation of LIS, if a certain CentOS/RHEL OS version (or kernel) is not supported for LIS, an error “Unsupported kernel version” is thrown. Report this error along with the OS and kernel versions.
- If jobs are interrupted by ECC errors on the GPU (either correctable or uncorrectable), first check to see if the GPU meets any of Nvidia's RMA criteria for ECC errors. If the GPU is eligible for RMA, contact support about getting it serviced; otherwise, reboot your VM to reattach the GPU as described here. Less invasive methods, such as `nvidia-smi -r`, don't work with the virtualization solution deployed in Azure.

Next steps

- To capture a Linux VM image with your installed NVIDIA drivers, see How to generalize and capture a Linux virtual machine.

Install NVIDIA GPU drivers on N-series VMs running Windows

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

To take advantage of the GPU capabilities of Azure N-series VMs backed by NVIDIA GPUs, you must install NVIDIA GPU drivers. The NVIDIA GPU Driver Extension installs appropriate NVIDIA CUDA or GRID drivers on an N-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the NVIDIA GPU Driver Extension documentation for supported operating systems and deployment steps.

If you choose to install NVIDIA GPU drivers manually, this article provides supported operating systems, drivers, and installation and verification steps. Manual driver setup information is also available for Linux VMs.

For basic specs, storage capacities, and disk details, see GPU Windows VM sizes.

> ⚠ **Warning**
>
> Installing NVIDIA drivers using methods other than those outlined in this guide may result in failure of the intended driver installation. To ensure proper functionality and support, please follow only the installation steps and use the driver versions specified in this documentation.

Supported operating systems and drivers

NVIDIA Tesla (CUDA) drivers

> ⓘ **Note**
>
> The Azure NVads A10 v5 VMs only support vGPU 17.x or higher driver version. The vGPU driver for the A10 SKU is a unified driver that supports both graphics and compute workloads.

NVIDIA Tesla (CUDA) drivers for all NC* and ND-*series VMs (optional for NV*-series) are generic and not Azure specific. For the latest drivers, visit the NVIDIA website.

> 💡 **Tip**

As an alternative to manual CUDA driver installation on a Windows Server VM, you can deploy an Azure Data Science Virtual Machine image. The DSVM editions for Windows Server 2016 preinstall NVIDIA CUDA drivers, the CUDA Deep Neural Network Library, and other tools.

NVIDIA GRID/vGPU drivers

> **Note**
>
> vGPU18 is available for the NCasT4_v3-series.
>
> vGPU18 is now available for the NVadsA10_v5-series in **Public, China, and Azure Government regions only**.

> **Note**
>
> For Azure NVads A10 v5 VMs we recommend customers to always be on the latest driver version. The latest NVIDIA major driver branch(n) is only backward compatbile with the previous major branch(n-1). For eg, vGPU 17.x is backward compatible with vGPU 16.x only. Any VMs still runnig n-2 or lower may see driver failures when the latest drive branch is rolled out to Azure hosts.
>
> NVs_v3 VMs only support **vGPU 16 or lower** driver version.
>
> Windows server 2019 support is only available till vGPU 16.x.

Microsoft redistributes NVIDIA GRID driver installers for NV, NVv3, and NVads A10 v5-series VMs used as virtual workstations or for virtual applications. Install only these GRID drivers on Azure NV-series VMs, only on the operating systems listed in the following table. These drivers include licensing for GRID Virtual GPU Software in Azure. You don't need to set up a NVIDIA vGPU software license server.

The GRID drivers redistributed by Azure don't work on non-NV series VMs like NCv2, NCv3, ND, and NDv2-series VMs. The one exception is the NCas_T4_V3 VM series where the GRID drivers enable the graphics functionalities similar to NV-series.

The Nvidia extension always installs the latest driver.

For Windows 11 up to and including 25H2, Windows 10 up to and including 22H2, Server 2019, Server 2022, Server 2025:

- GRID 18.6 (573.76) (.exe)

The following links to previous versions are provided to support dependencies on older driver versions.

For Windows Server 2016 1607, 1709:

- GRID 14.1 (512.78) (.exe) is the last supported driver from NVIDIA. The newer 15.x and above don't support Windows Server 2016.

For Windows Server 2012 R2:

- GRID 13.1 (472.39) (.exe)
- GRID 13 (471.68) (.exe)

For links to all previous Nvidia GRID driver versions, visit GitHub.

Driver installation

1. Connect by Remote Desktop to each N-series VM.
2. Download, extract, and install the supported driver for your Windows operating system.

After GRID driver installation on a VM, a restart is required. After CUDA driver installation, a restart is not required.

Verify driver installation

Please note that the NVIDIA Control panel is only accessible with the GRID driver installation. If you have installed CUDA drivers then the NVIDIA control panel will not be visible.

You can verify driver installation in Device Manager.

> **Note**
>
> If you're running Windows 10 build 1903 or higher, dxdiag shows no information in the 'Display' tab. Use the 'Save All Information' option at the bottom and the output file shows the information related to NVIDIA GPU.

To query the GPU device state, run the nvidia-smi command-line utility installed with the driver.

1. Open a command prompt and change to the **C:\Program Files\NVIDIA Corporation\NVSMI** directory.
2. Run `nvidia-smi`. If the driver is installed, Nvidia SMI will list the **GPU-Util** as N/A until you run a GPU workload on the VM.

RDMA network connectivity

RDMA network connectivity can be enabled on RDMA-capable N-series VMs such as NC24r deployed in the same availability set or in a single placement group in a virtual machine scale set. The HpcVmDrivers extension must be added to install Windows network device drivers that enable RDMA connectivity. To add the VM extension to an RDMA-enabled N-series VM, use Azure PowerShell cmdlets for Azure Resource Manager.

To install the latest version 1.1 HpcVMDrivers extension on an existing RDMA-capable VM named myVM in the West US region:

PowerShell

```
Set-AzVMExtension -ResourceGroupName "myResourceGroup" -Location "westus" -VMName
"myVM" -ExtensionName "HpcVmDrivers" -Publisher "Microsoft.HpcCompute" -Type
"HpcVmDrivers" -TypeHandlerVersion "1.1"
```

For more information, see Virtual machine extensions and features for Windows.

The RDMA network supports Message Passing Interface (MPI) traffic for applications running with Microsoft MPI or Intel MPI 5.x.

Next steps

- Developers building GPU-accelerated applications for the NVIDIA Tesla GPUs can also download and install the latest CUDA Toolkit. For more information, see the CUDA Installation Guide.

Install AMD GPU drivers on NVads V710-series Linux VMs

Applies to: ✔ Linux VMs

> **Important**
>
> To align with inclusive language practices, we've replaced the term "blacklist" with "blocklist" throughout this documentation. This change reflects our commitment to avoiding terminology that might carry unintended negative connotations or perceived racial bias. However, in code snippets and technical references where "blacklist" is part of established syntax or tooling (for example, configuration files, command-line parameters), the original term is retained to preserve functional accuracy. This usage is strictly technical and doesn't imply any discriminatory intent.

NVads V710-series

To leverage the GPU capabilities of Azure's new NVads V710-series virtual machines running Linux, you'll need to install AMD GPU drivers. The AMD GPU driver extension streamlines this process by automating driver installation for NVv710-series VMs. You can manage the extension via the Azure portal, Azure PowerShell, or Azure Resource Manager (ARM) templates. For details on supported operating systems and deployment steps, see AMD GPU Driver Extension documentation.

The marketplace image comes preloaded with the AMD GPU driver, helping accelerate VM setup. This guide explains how to install AMD GPU drivers on Azure NVads V710-series Linux virtual machines (VMs). It covers both automated and manual installation methods specifically for **Ubuntu**.

ROCm

> **Note**
>
> Currently, Azure provides installation instructions for:
>
> - Ubuntu 22.04
> - Ubuntu 24.04
>
> For other Linux distributions, see:

- Quick start installation guide - ROCm installation (Linux)
- ROCm release history - ROCm Documentation

Install the AMD Linux Driver to leverage the full capabilities of the AMD Radeon PRO V710 GPU on an NVv5-V710 GPU Linux instance in Microsoft Azure. The sections that follow provide detailed instructions for installing the Linux driver and running inference workloads using ROCm on this instance type.

Quick start options

Option 1: Use the AMD GPU driver extension

The simplest method is using the AMD GPU Driver Extension, which automates driver installation for NVv710-series VMs. You can deploy this extension through:

- Azure portal
- Azure PowerShell
- Azure Resource Manager templates

Option 2: Use pre-configured marketplace image

A marketplace image is available with pre-installed AMD GPU drivers, allowing for faster VM deployment.

Option 3: Manual installation

Follow these instructions for manual driver installation and configuration.

ROCm driver installation

Prerequisites

System requirements:

- Disk size must exceed 64GB for optimal performance
- Supported distributions: Ubuntu 22.04 or Ubuntu 24.04
- Virtual Function Device ID: 7461 (AMD Radeon PRO V710 GPU)

Step 1: Verify your system

Follow these steps to verify that your GPU card is detected on your system.

1. Check your Linux distribution:

   ```Bash
   cat /etc/*release
   ```

2. Check your kernel version:

   ```Bash
   uname -srmv
   ```

3. Verify your GPU card is detected:

   ```Bash
   sudo lspci -d 1002:7461
   ```

   You should see output similar to:

   ```
   c3:00.0 Display controller: Advanced Micro Devices, Inc. [AMD/ATI] Device 7461
   ```

Step 2: Install the driver

The driver installation commands are slightly different depending on whether you're running Ubuntu 22.04 or 24.04.

For Ubuntu 22.04

```Bash
sudo apt update
sudo apt install "linux-headers-$(uname -r)" "linux-modules-extra-$(uname -r)"
sudo apt install python3-setuptools python3-wheel
sudo usermod -a -G render,video $LOGNAME
wget https://repo.radeon.com/amdgpu-install/7.0.1/ubuntu/jammy/amdgpu-
install_7.0.1.70001-1_all.deb
sudo apt install ./amdgpu-install_7.0.1.70001-1_all.deb
```

```
sudo apt update
sudo apt install amdgpu-dkms rocm
```

For Ubuntu 24.04

Bash

```
sudo apt update
sudo apt install "linux-headers-$(uname -r)" "linux-modules-extra-$(uname -r)"
sudo apt install python3-setuptools python3-wheel
sudo usermod -a -G render,video $LOGNAME # Add the current user to the render and
video groups
wget https://repo.radeon.com/amdgpu-install/7.0.1/ubuntu/noble/amdgpu-
install_7.0.1.70001-1_all.deb
sudo apt install ./amdgpu-install_7.0.1.70001-1_all.deb
sudo apt update
sudo apt install amdgpu-dkms rocm
```

Step 3: Load and verify the driver

Follow these steps to load and verify the driver.

1. Load the driver:

   Bash

   ```
   sudo modprobe amdgpu
   ```

2. Check that the driver loaded successfully:

   Bash

   ```
   sudo dmesg | grep amdgpu
   ```

3. Verify driver status with AMD-SMI:

   Bash

   ```
   amd-smi monitor
   ```

Step 4: Enable automatic loading on reboot

Follow these steps to enable automatic loading on reboot.

1. Search for blocklist entries:

```bash
grep amdgpu /etc/modprobe.d/* -rn
```

2. If the driver is blocklisted, remove the blocklist:

```bash
sudo nano /etc/modprobe.d/blacklist.conf
```

3. Delete the line containing `blacklist amdgpu`, then update initramfs:

```bash
sudo update-initramfs -uk all
```

4. Reboot to apply changes:

```bash
sudo reboot
```

Graphics and ROCm installation

This section covers installing the AMD driver for graphics workloads with ROCm libraries and development tools.

Prerequisites

System requirements:

- Ubuntu 22.04 with kernel 6.5
- Disk size greater than 64GB
- Desktop environment (for graphics workloads, use Ubuntu Desktop ISO)

Pre-installation steps

Complete the following pre-installation steps.

1. Update package list:

```bash
```

```
sudo apt update
```

2. Install Python packages:

```Bash
sudo apt install python3-setuptools python3-wheel
```

3. Add user to required groups:

```Bash
sudo usermod -a -G render,video $LOGNAME
```

4. Install kernel headers:

```Bash
sudo apt install "linux-headers-$(uname -r)" "linux-modules-extra-$(uname -r)"
```

Blocklist default driver

Follow these steps to blocklist the default driver.

1. Check if the driver is already blocklisted:

```Bash
grep amdgpu /etc/modprobe.d/* -rn
```

2. If not blocklisted, add it:

```Bash
sudo vim /etc/modprobe.d/blacklist.conf
```

3. Add this line:

```
blacklist amdgpu
```

4. Apply changes:

Bash

```
sudo update-initramfs -uk all
```

5. Reboot the system:

Bash

```
sudo reboot
```

Install AMD driver with graphics support

Follow these steps to install the AMD driver with graphics support.

1. Upgrade the system:

Bash

```
sudo apt upgrade
```

2. Download the installer:

Bash

```
wget -N -P /tmp/ https://repo.radeon.com/amdgpu-
install/6.1.4/ubuntu/jammy/amdgpu-install_6.1.60104-1_all.deb
```

3. If a previous driver exists, remove it:

Bash

```
sudo amdgpu-uninstall
sudo apt remove amdgpu-install --purge
```

4. Install the new driver:

Bash

```
sudo apt-get install /tmp/amdgpu-install_6.1.60104-1_all.deb
sudo amdgpu-install --usecase=workstation,rocm,amf --opencl=rocr --vulkan=pro --
-no-32 --accept-eula
```

5. Load the driver:

Bash

```
sudo modprobe amdgpu
```

6. Verify installation:

```Bash
sudo dmesg | grep amdgpu
```

To remove a blocklist, see Enable automatic loading on reboot.

X11 remote server configuration

After installing the graphics driver, follow these steps to configure a virtual display with hardware acceleration for remote access.

Step 1: Install required packages

```Bash
sudo apt install net-tools
sudo apt install x11vnc
```

Step 2: Configure GDM3

Follow these steps to configure GDM3.

1. Edit the GDM3 configuration:

```Bash
sudo vim /etc/gdm3/custom.conf
```

2. Modify to include:

```ini
[daemon]
AutomaticLoginEnable=true
AutomaticLogin=your_username
WaylandEnable=false
```

3. Restart GDM3:

Bash

```
sudo systemctl restart gdm3
```

Step 3: Configure X11

Follow these steps to configure X11.

1. Get your GPU's Bus ID:

Bash

```
lspci -d 1002: | awk '{print $1}'
```

2. Convert the hex Bus ID to decimal format. For example, `3a9e:00:00.0` becomes `3841536`.

3. Edit the X configuration file `/usr/share/X11/xorg.conf.d/00-amdgpu.conf`:

```
Section "Device"
    Identifier "Card0"
    Driver "amdgpu"
    BusID "PCI:3841536:0:0"
EndSection

Section "Screen"
    Identifier "Screen0"
    Device "Card0"
    Monitor "Monitor0"
EndSection
```

4. Edit `/usr/share/X11/xorg.conf.d/10-amdgpu.conf`:

```
Section "OutputClass"
    Identifier "Card0"
    MatchDriver "amdgpu"
    Driver "amdgpu"
    Option "PrimaryGPU" "yes"
EndSection
```

5. Reboot and load the driver:

Bash

```
sudo reboot
```

6. After reboot, run the following commands:

```Bash
sudo systemctl stop gdm
sudo modprobe amdgpu
sudo systemctl start gdm
```

Step 4: Start VNC server

To start the server, run the following command.

```Bash
x11vnc --forever -find
```

> ⓘ **Note**
>
> X11 configuration only works with Ubuntu Desktop images, not Server images.

Troubleshooting

Downgrade to kernel 6.5

If you're running kernel 6.8, you can downgrade to 6.5 for compatibility by following these steps.

1. Check loaded kernels:

```Bash
dpkg --list | egrep -i --color 'linux-image|linux-headers|linux-modules' | awk '{ print $2 }'
```

2. Install kernel 6.5:

```Bash
sudo apt install linux-image-6.5.0-1025-azure
```

3. Remove kernel 6.8:

```
Bash
sudo apt purge linux-headers-6.8.0-1025-azure linux-image-6.8.0-1025-azure
linux-modules-6.8.0-1025-azure
```

4. Edit GRUB:

```
Bash
sudo vim /etc/default/grub
```

5. Set kernel 6.5 as default:

```

GRUB_DEFAULT="Advanced options for Ubuntu>Ubuntu, with Linux 6.5.0-1025-azure"
```

6. Update GRUB and reboot:

```
Bash
sudo update-grub
sudo reboot
```

7. Verify kernel version:

```
Bash
uname -a
```

Uninstalling the AMD GPU driver

To completely remove the AMD GPU driver, run the following commands:

```
Bash
dkms status
sudo amdgpu-install --uninstall
sudo amdgpu-uninstall
sudo apt autoremove --purge amdgpu-install
sudo reboot
```

Verify removal:

Bash

```
dkms status
```

Install AMD GPU drivers on N-series VMs running Windows

Applies to: Windows VMs ✔ Flexible scale sets

> **Note**
>
> The AMD GPU Driver Extension installs AMD GPU drivers on a NVads V710 v5 Series, NGads V620 Series and NVv4-series. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the AMD GPU Driver Extension documentation for supported operating systems and deployment steps.

NVads V710 v5 Series

To take advantage of the GPU capabilities of the new Azure NVads V710 v5 series VMs running Windows, AMD GPU drivers must be installed. The AMD GPU Driver Extension installs AMD GPU drivers on a NVads V710 v5-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the AMD GPU Driver Extension documentation for supported operating systems and deployment steps.

If you choose to install AMD GPU drivers manually, this article provides supported operating systems, drivers, and installation and verification steps.

Only GPU drivers published by Microsoft are supported on NVads V710 v5 series VMs. Don't install GPU drivers from any other source.

For basic specs, storage capacities, and disk details, see GPU Windows VM sizes.

Expand table

OS	Driver
Windows 10 22h2 Windows 11 23H2, 24H2, 25h2	25.Q4 (.exe)
Windows Server 2025, Windows 11 EMS	25.Q4 (.exe)

OS	Driver
Windows Server 2022	25.Q4 (.exe)

VM Creation

Create the VMs using CLI. (Azure AMD GPU driver extensions don't support NVads V710 v5 Series during preview)

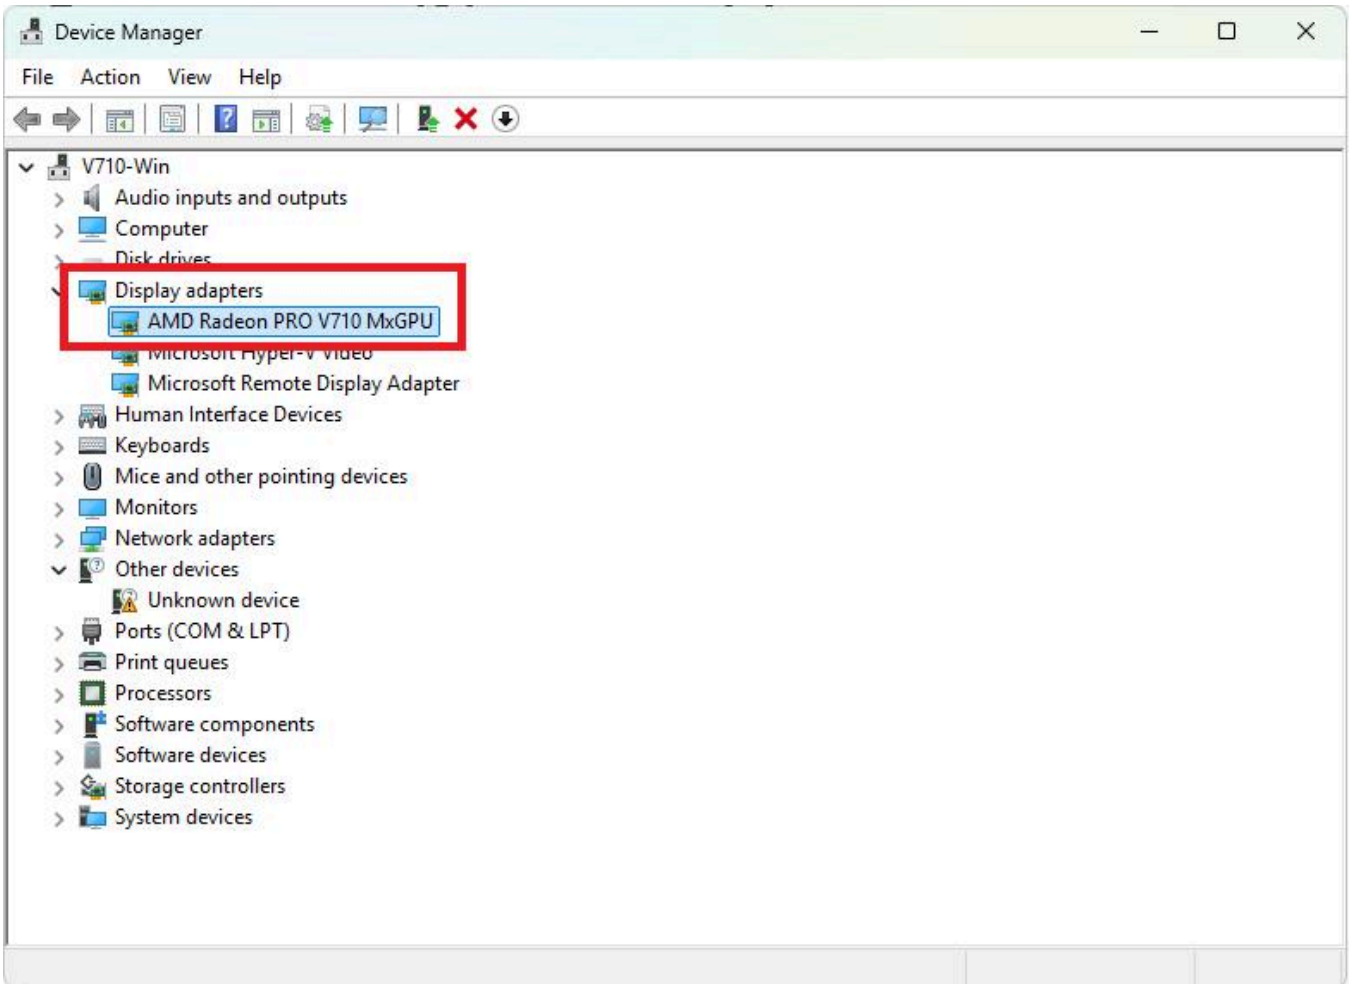
- Review the CLI VM creation documentation.

Driver installation

1. Connect by Remote Desktop to each NVads V710 v5-series VM.
2. Download the EXE file to a local drive.
3. If you need to uninstall the previous driver version, run "setup.exe -factoryresetinstall" from a command line.
4. For a first-time driver installation, double-click or run “setup.exe” from a command line.
5. Reboot the VM.

Verify driver installation

You can verify driver installation in Device Manager. The following example shows successful configuration of the Radeon Pro V710 card on an NVads V710 v5 VM. The exact driver date and version will depend on the driver package released.



NGads V620 Series

The AMD Software: Cloud Edition drivers must be installed to take advantage of the GPU capabilities of Azure NGads V620 Series VMs.

Requirements

Expand table

OS	Driver
Windows 11 64-bit version 21H2, 22H2, 23H2, 24H2 Windows 10 64-bit version 20H2, 21H2, 22H2, 23H2, 24H2	25.1.1
Windows 11 EMS 64-bit 21H2, 22H2, 23H2, 24H2 Windows Server 2022 64-bit	25.1.1
Windows 10 EMS 64-bit 21H2, 22H2, 23H2, 24H2 Windows Server 2019 LTSC (version 1809)	25.1.1

VM Creation

Create the VMs using CLI. (Azure AMD GPU driver extensions don't support NGads V620 Series during preview)

1. Review the CLI VM creation documentation.

Driver installation

1. Connect by Remote Desktop to each NGads V620-series VM
2. Download the EXE file to a local drive
3. If you need to uninstall the previous driver version, run "setup.exe -factoryresetinstall" from a command line
4. For a first-time driver installation, double-click or run “setup.exe” from a command line
5. Reboot the VM

Verify driver installation

1. You can verify driver installation in Device Manager. The following example shows successful configuration of the Radeon Pro V620 card on an Azure NGads V620 VM. The exact driver date and version will depend on the driver package released.

NVv4 Series

To take advantage of the GPU capabilities of the new Azure NVv4 series VMs running Windows, AMD GPU drivers must be installed. The AMD GPU Driver Extension installs AMD GPU drivers on a NVv4-series VM. Install or manage the extension using the Azure portal or tools such as Azure PowerShell or Azure Resource Manager templates. See the AMD GPU Driver Extension documentation for supported operating systems and deployment steps.

If you choose to install AMD GPU drivers manually, this article provides supported operating systems, drivers, and installation and verification steps.

Only GPU drivers published by Microsoft are supported on NVv4 VMs. Don't install GPU drivers from any other source.

For basic specs, storage capacities, and disk details, see GPU Windows VM sizes.

Supported operating systems and drivers

Expand table

OS	Driver
Windows 11 64-bit 21H2, 22H2, 23H2, 24H2 Windows 10 64-bit 21H2, 22H2, 20H2	23Q3 MR 4.1 Hotfix (.exe)
Windows Server 2022, Windows 11 EMS	23.Q3 MR 4.1 Hotfix (.exe)
Windows Server 2019, Windows 10 EMS	23.Q3 MR 4.1 Hotfix (.exe)

Previous supported driver versions for Windows builds up to 1909 are 20.Q4-1 (.exe) and 21.Q2-1 (.exe)

> **Note**
>
> If you use build 1903/1909 then you may need to update the following group policy for optimal performance. These changes are not needed for any other Windows builds.

> [Computer Configuration->Policies->Windows Settings->Administrative Templates->Windows Components->Remote Desktop Services->Remote Desktop Session Host->Remote Session Environment], set the Policy [Use WDDM graphics display driver for Remote Desktop Connections] to Disabled.

Driver installation

> **Note**
>
> Follow these steps if you see "Error 184 - AMD Installer cannot continue due to an unsupported Operating System" error on Windows 10 EMS / Windows 11 EMS.

> Go to C:\AMD\AMD Software Azure NVv4 Guest Driver 23Q3\Packages\Drivers\Display\WT6A_INF Right click and install on the *.inf file.

> For Windows10 EMS: u9397288.inf

> For Windows11 EMS: u2397344.inf

1. Connect by Remote Desktop to each NVv4-series VM.

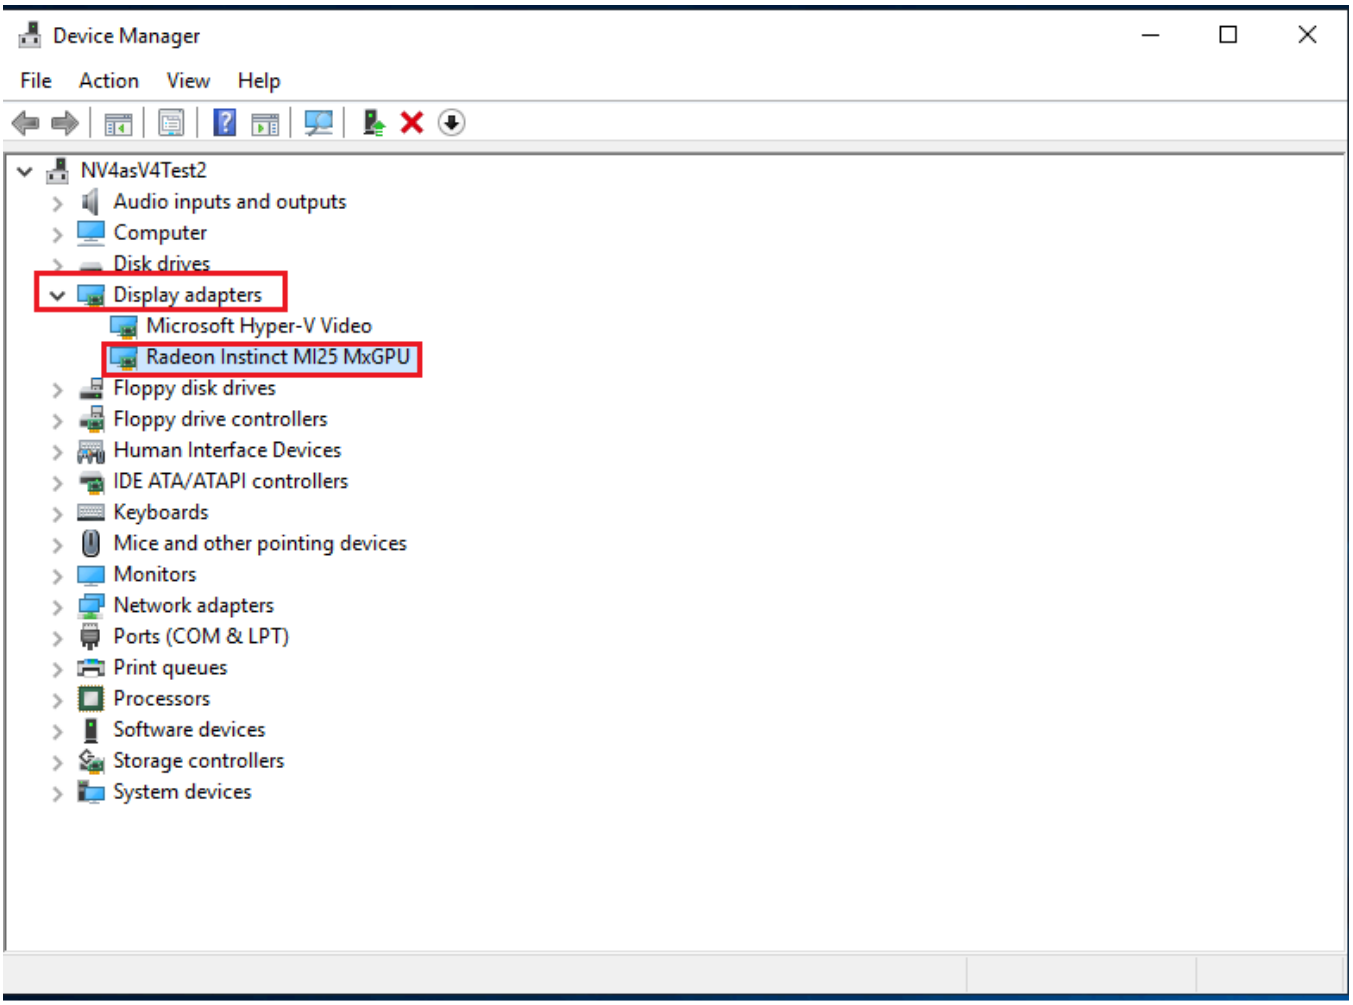
2. If you need to uninstall the previous driver version, download the AMD cleanup utility. Don't use the utility that comes with the previous version of the driver.

3. Download and install the latest driver.

4. Reboot the VM.

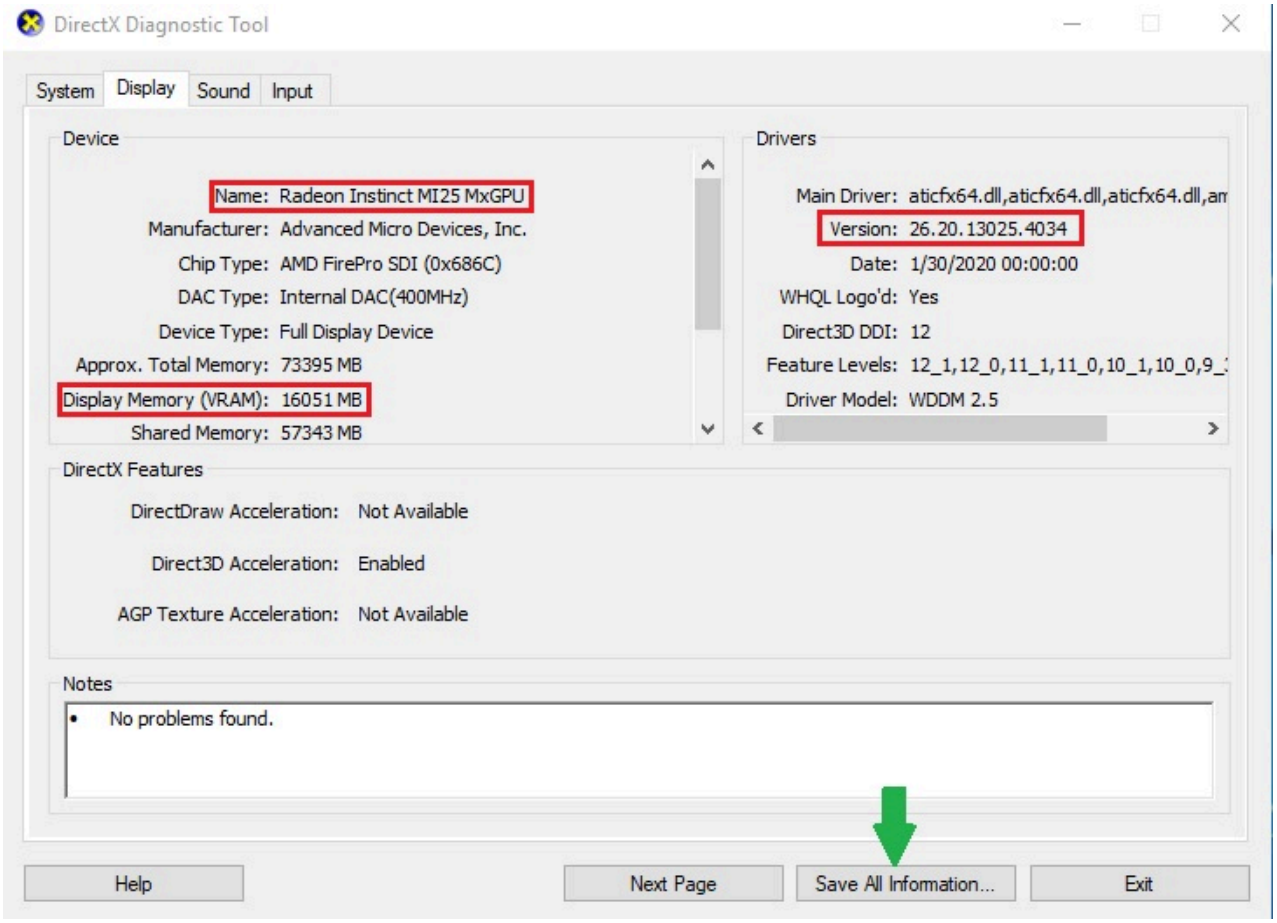
Verify driver installation

1. You can verify driver installation in Device Manager. The following example shows successful configuration of the Radeon Instinct MI25 card on an Azure NVv4 VM.



1. You can use dxdiag to verify the GPU display properties including the video RAM. The following example shows a 1/2 partition of the Radeon Instinct MI25 card on an Azure

NVv4 VM.



2. If you're running Windows 10 build 1903 or higher, dxdiag shows no information in the 'Display' tab. Use the 'Save All Information' option at the bottom and the output file shows the information related to AMD MI25 GPU.

```

Migration Guide for GPU Compute Workloads in Azure

As more powerful GPUs become available in the marketplace and in Microsoft Azure datacenters, we recommend re-assessing the performance of your workloads and considering migrating to newer GPUs.

For the same reason, as well as to maintain a high-quality and reliable service offering, Azure periodically retires the hardware that powers older VM sizes. The first group of GPU products to be retired in Azure are the original NC, NC v2 and ND-series VMs, powered by NVIDIA Tesla K80, P100, and P40 datacenter GPU accelerators respectively. These products will be retired on August 31st 2023, and the oldest VMs in this series launched in 2016.

Since then, GPUs have made incredible strides alongside the entire deep learning and HPC industry, typically exceeding a doubling in performance between generations. Since the launch of NVIDIA K80, P40, and P100 GPUs, Azure has shipped multiple newer generations and categories of VM products geared at GPU-accelerated compute and AI, based around NVIDIA's T4, V100, and A100 GPUs, and differentiated by optional features such as InfiniBand-based interconnect fabrics. These are all options we encourage customers to explore as migration paths.

In most cases, the dramatic increase in performance offered by newer generations of GPUs lowers overall TCO by decreasing the duration of job, for burstable jobs- or reducing the quantity of overall GPU-enabled VMs required to cover a fixed-size demand for compute resources, even though costs per GPU-hour may vary. In addition to these benefits, customers may improve Time-to-Solution via higher-performing VMs, and improve the health and supportability of their solution by adopting newer software, CUDA runtime, and driver versions.

Migration vs. Optimization

Azure recognizes that customers have a multitude of requirements that may dictate the selection of a specific GPU VM product, including GPU architectural considerations, interconnects, TCO, Time to Solution, and regional availability based on compliance locality or latency requirements- and some of these even change over time.

At the same time, GPU acceleration is a new and rapidly evolving area.

Thus, there is no true one-size fits-all guidance for this product area, and a migration is a perfect time to re-evaluate potentially dramatic changes to a workload- like moving from a clustered deployment model to a single large 8-GPU VM or vice versa, leveraging reduced precision datatypes, adopting features like Multi-Instance GPU, and much more.

These sorts of considerations- when made the context of already dramatic per-generation GPU performance increases, where a feature such as the addition of TensorCores can increase performance by an order of magnitude, are extremely workload-specific.

Combining migration with application re-architecture can yield immense value and improvement in cost and time-to-solution.

However, these sorts of improvements are beyond the scope of this document, which aims to focus on direct equivalency classes for generalized workloads that may be run by customers today, to identify the most similar VM options in both price *and* performance per GPU to existing VM families undergoing retirement.

Thus, this document assumes that the user may not have any insight or control over workload-specific properties like the number of required VM instances, GPUs, interconnects, and more.

Recommended Upgrade Paths

NC-Series VMs featuring NVIDIA K80 GPUs

The NC (v1)-Series VMs are Azure's oldest GPU-accelerated compute VM type, powered by 1 to 4 NVIDIA Tesla K80 datacenter GPU accelerators paired with Intel Xeon E5-2690 v3 (Haswell) processors. Once a flagship VM type for demanding AI, ML, and HPC applications, they remained a popular choice late into the product lifecycle (particularly via NC-series promotional pricing) for users who valued having a very low absolute cost per GPU-hour over GPUs with higher throughput-per-dollar.

Today, given the relatively low compute performance of the aging NVIDIA K80 GPU platform, in comparison to VM series featuring newer GPUs, a popular use case for the NC-series is real-time inference and analytics workloads, where an accelerated VM must be available in a steady state to serve request from applications as they arrive. In these cases the volume or batch size of requests may be insufficient to benefit from more performant GPUs. NC VMs are also popular for developers and students learning about, developing for, or experimenting with GPU acceleration, who need an inexpensive cloud-based CUDA deployment target upon which to iterate that doesn't need to perform to production levels.

In general, NC-Series customers should consider moving directly across from NC sizes to NC T4 v3 sizes, Azure's new GPU-accelerated platform for light workloads powered by NVIDIA Tesla T4 GPUs.

NC v2-Series VMs featuring NVIDIA Tesla P100 GPUs

The NC v2-series virtual machines are a flagship platform originally designed for AI and Deep Learning workloads. They offered excellent performance for Deep Learning training, with per-GPU performance roughly 2x that of the original NC-Series and are powered by NVIDIA Tesla P100 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. Like the NC and ND -Series, the NC v2-Series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

In general, NCv2-Series customers should consider moving directly across to NC A100 v4 sizes, Azure's new GPU-accelerated platform powered by NVIDIA Ampere A100 PCIe GPUs.

ND-Series VMs featuring NVIDIA Tesla P40 GPUs

The ND-series virtual machines are a midrange platform originally designed for AI and Deep Learning workloads. They offered excellent performance for batch inferencing via improved single-precision floating point operations over their predecessors and are powered by NVIDIA Tesla P40 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. Like the NC and NC v2-Series, the ND-Series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

NP-Series VMs

> **Important**
>
> NP-series sizes (Standard_NP10s, Standard_NP20s, Standard_NP40s) are scheduled for **retirement on May 31, 2027**. After this date, remaining NP-series VMs are automatically deallocated, stop working, stop incurring charges, and no longer have SLA or support. Managed disk data is preserved.
>
> **Reserved Instance purchase cutoff**: Purchases of 1-year and 3-year Azure Reserved VM Instances for NP-series ended on **April 2, 2026**. Customers with capacity planning tied to Reserved Instances should migrate or adjust reservations accordingly.

The NP-series VMs are powered by AMD Xilinx Alveo U250 FPGAs and are used for custom FPGA-accelerated workloads such as ML inference, video transcoding, and database search & analytics. Unlike GPU-based VM series, NP-series use FPGA acceleration via Xilinx XRT/Vitis toolchains. Migrating to GPU-based alternatives requires porting workloads from FPGA-based frameworks to GPU-based frameworks such as CUDA.

Recommended migration targets based on workload characteristics:

- NCasT4_v3 (NVIDIA T4) – Best for inference, interactive graphics, and cost-sensitive workloads.
- NDv2 (NVIDIA V100 with NVLink) – Best for GPU-accelerated AI training and HPC workloads requiring high GPU memory and interconnect.
- NCads_H100_v5 (NVIDIA H100) – Best for modern AI training and batch inference on the latest GPU generation.

Expand table

Current VM Size	Target VM Size	GPU	GPU Count	GPU Generation	vCPUs	Memory (GiB)
Standard_NP10s	Standard_NC4as_T4_v3	NVIDIA T4	1	Turing	4	28
Standard_NP20s	Standard_NC16as_T4_v3 or Standard_ND40rs_v2 (training)	NVIDIA T4 or V100	1 or 8	Turing or Volta	16 or 40	110 or 672
Standard_NP40s	Standard_NC64as_T4_v3 or	NVIDIA T4 or	4 or 1	Turing or Hopper	64 or 24	440 or 220

Current VM Size	Target VM Size	GPU	GPU Count	GPU Generation	vCPUs	Memory (GiB)
	Standard_NC24ads_A100_v4 (high-end)	H100				

Migration Steps

General Changes

1. Choose a series and size for migration. Leverage the pricing calculator for further insights.
2. Get quota for the target VM series
3. Resize the current N* series VM size to the target size. This may also be a good time to update the operating system used by your Virtual Machine image, or adopt one of the HPC images with drivers pre-installed as your starting point.

   > **Important**
   >
   > Your VM image may have been produced with an older version of the CUDA runtime, NVIDIA driver, and (if applicable, for RDMA-enabled sizes only) Mellanox OFED drivers than your new GPU VM series requires, which can be updated by following the instructions in the Azure Documentation.

Breaking Changes

Select target size for migration

After assessing your current usage, decide what type of GPU VM you need. Depending on the workload requirements you have few different choices.

> **Note**
>
> A best practice is to select a VM size based on both cost and performance. The recommendations in this guide are based on a general-purpose, one-to-one comparison of performance metrics and the nearest match in another VM series. Before deciding on the right size, get a cost comparison using the Azure Pricing Calculator.
>
> **NP-series customers**: When selecting alternatives to NP-series VMs, consider both cost and performance. Newer GPU generations (T4, V100, H100) can significantly reduce time-to-

solution for AI and analytics workloads. For detailed NP-series migration guidance, see the NP-Series VMs section above.

> **Important**
>
> All legacy NC, NC v2 and ND-Series sizes are available in multi-GPU sizes, including 4-GPU sizes with and without InfiniBand interconnect for scale-out, tightly-coupled workloads that demand more compute power than a single 4-GPU VM, or a single K80, P40, or P100 GPU can supply respectively. Although the recommendations above offer a straightforward path forward, users of these sizes should consider achieving their performance goals with more powerful NVIDIA V100 GPU-based VM series like the NC v3-Series and ND v2-series, which typically enable the same level of workload performance at lower costs and with improved manageability by providing considerably greater performance per GPU and per VM before multi-GPU and multi-node configurations are required, respectively.

Get quota for the target VM family

Follow the guide to request an increase in vCPU quota by VM family. Select the target VM size you have selected for migration.

Resize the current virtual machine

You can resize the virtual machine.

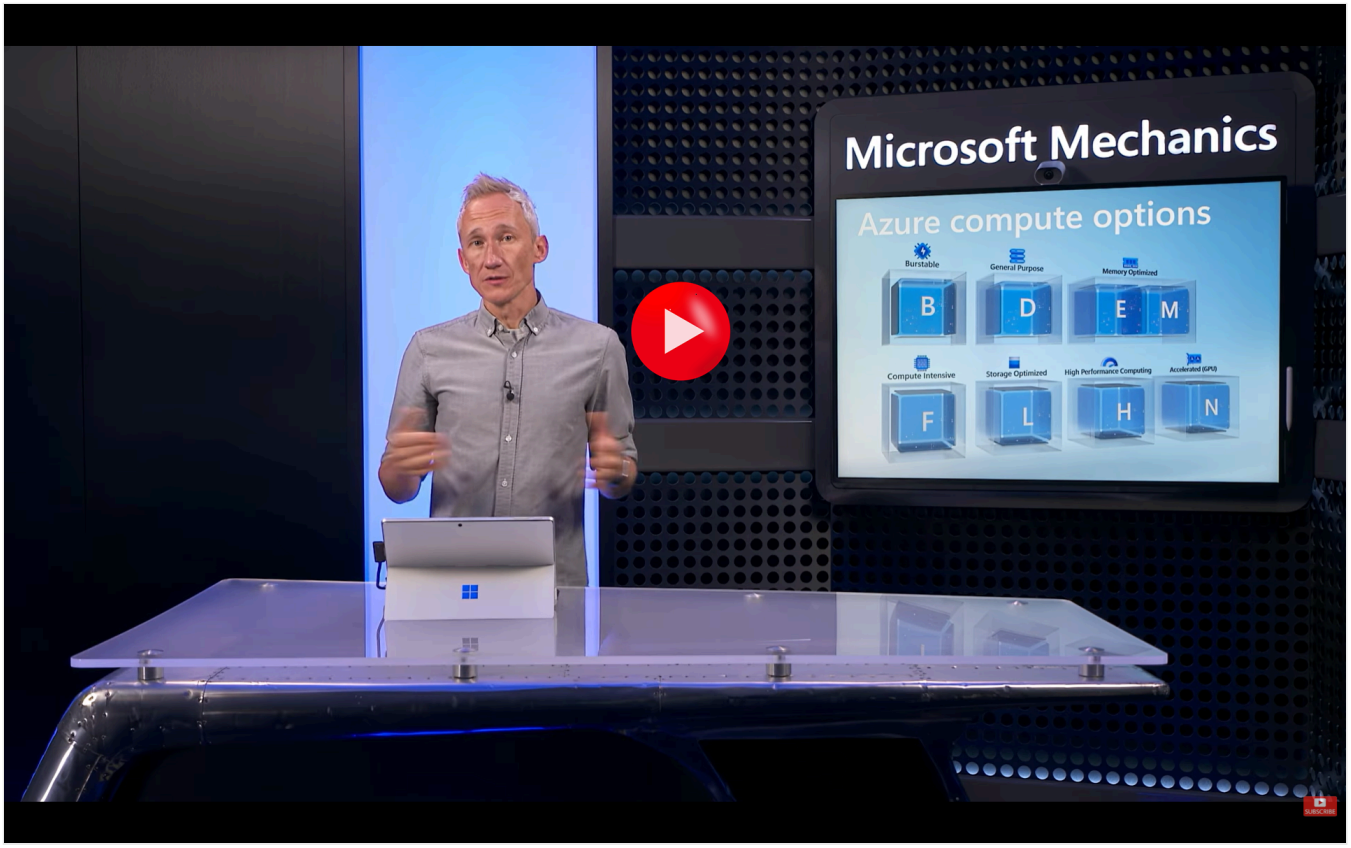
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

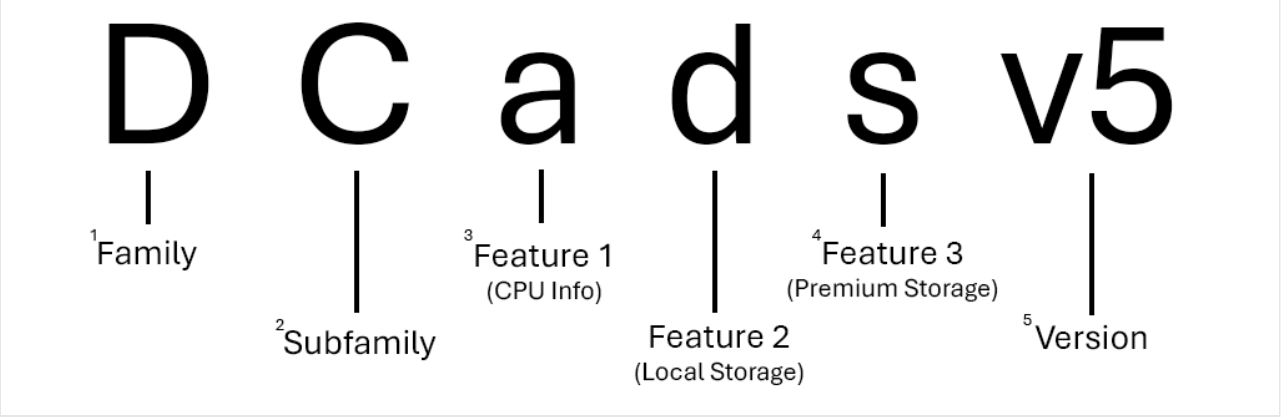
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

Family list

Expand table

Family	Workloads	Series List
A-family	Entry-level economical	Av2-series Previous-gen A-family series
B-family	Burstable	Bsv2-series Basv2-series Bpsv2-series Previous-gen B-family series
D-family	Enterprise-grade applications Relational databases	Dsv7 and Ddsv7 series Dlsv7 and Dldsv7 series

Family	Workloads	Series List
	In-memory caching Data analytics	Dasv7 and Dadsv7 series Dalsv7 and Daldsv7 series Dpsv6 and Dplsv6-series Dpdsv6 and Dpldsv6-series Dasv6 and Dadsv6-series Dalsv6 and Daldsv6-series Dsv6 and Ddsv6-series Dlsv6 and Dldsv6-series Dpsv5 and Dpdsv5-series Dplsv5 and Dpldsv5-series Dlsv5 and Dldsv5-series Dv5 and Dsv5-series Ddv5 and Ddsv5-series Dasv5 and Dadsv5-series Previous-gen D-family series

NMads MA35D series

Summarize this article for me

The NMads MA35D-Series virtual machines are Azure's first SKU to offer specialized hardware (Xilinx MA35D "Supernova") accelerated VM optimized for batch and real-time video transcoding workloads. The VM series are powered by 4th generation AMD EPYC™ Genoa processors. It offers 1 ASIC video processing unit (VPU) with 8GB of memory in addition to 16 vCPUs, 32GB of RAM, 76GB of temporary storage, and 4Gbps of network bandwidth.

Compared with existing general-purpose CPU or GPU based solutions, the NMads MA35D-Series VM SKU provides higher throughout and lower latency while maintaining a lower TCO for customers. The VM series presents a huge opportunity to save on infrastructure costs and improve performance and efficiency on video transcoding. Additionally, the VM provides access to modern codecs such as AV1 to further improve efficiency for video processing. It is the ideal choice for running your video transcoding workloads on the cloud.

Host specifications

Table definitions

Expected network bandwidth is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see Virtual machine network bandwidth

Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance depends on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see Optimize network throughput for Azure virtual machines.

To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see Bandwidth/Throughput testing (NTTTCP).

'NP' family storage optimized VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

> **Note**
>
> Azure NP-series VMs are scheduled for retirement on May 31, 2027. For more information, see NP-series virtual machine migration guidance

The 'NP' subfamily of VM size series are one of Azure's storage-optimized VM instances. They're designed for workloads that require high disk throughput and I/O, such as databases, big data applications, and data warehousing. High disk throughput and large local disk storage capacities on L-series VMs support applications and services that benefit from low latency and high sequential read and write speeds. This makes them well suited for handling tasks like large-scale log processing, real-time big data analytics, and scenarios involving large databases that perform frequent disk operations, ensuring efficient performance for storage-heavy applications.

Workloads and use cases

Real-Time Data Processing: NP-family VMs excel in environments where data needs to be processed in real time with minimal latency, such as in financial trading, real-time analytics, and network data processing.

Custom AI and Machine Learning: NP-family VMs are suitable for accelerating AI and machine learning inference tasks, where the FPGA can be programmed to execute specific algorithms sometimes faster than typical CPU or GPU-based solutions.

Genomics and Life Sciences: NP-family VMs can significantly speed up genomic sequencing tasks and other life sciences applications that benefit from custom hardware acceleration.

Video Transcoding and Streaming: FPGAs can be used to accelerate video processing tasks such as transcoding and real-time video streaming, optimizing performance and reducing processing times.

Signal Processing: NP-family VMs are ideal for applications in telecommunications and signal processing where rapid manipulation and analysis of signals are necessary.

Database Acceleration: NP-family VMs can enhance database operations, especially for custom search operations and large-scale database queries, by offloading these tasks to the FPGA.

Series in family

NP-series

The NP-series virtual machines are powered by Xilinx U250 FPGAs for accelerating workloads including machine learning inference, video transcoding, and database search & analytics. NP-series VMs are also powered by Intel Xeon 8171M (Skylake) CPUs with all core turbo clock speed of 3.2 GHz.

View the full np-series page.

Frequently asked questions

Q: What's the difference between Xilinx U250 and the AMD Alveo U250?

A: AMD Acquired Xilinx and renamed their FPGA line to Alveo. They are identical and use the same drivers, but the original Xilinx page redirects to AMD's new site.

Q: How to request quota for NP VMs?

A: Follow this page Increase VM-family vCPU quotas. NP VMs are available in East US, West US2, SouthCentral US, West Europe, SouthEast Asia, Japan East, and Canada Central.

Q: What version of Vitis should I use?

A: Xilinx recommends Vitis 2022.1, you can also use the Development VM marketplace options (Vitis 2022.1 Development VM for Ubuntu 18.04, Ubuntu 20.04, and CentOS 7.8)

Q: Do I need to use NP VMs to develop my solution?

A: No, you can develop on-premises and deploy to the cloud. Make sure to follow the attestation documentation to deploy on NP VMs.

Q: What shell version is supported and how can I get the development files?

A: The FPGAs in Azure NP VMs support Xilinx Shell 2.1 (gen3x16-xdma-shell_2.1). See Xilinx Page Xilinx/Azure with Alveo U250 to get the development shell files.

Q: Which file returned from attestation should I use when programming my FPGA in an NP VM?

A: Attestation returns two xclbins, **design.bit.xclbin** and **design.azure.xclbin**. Use **design.azure.xclbin**.

Q: Where should I get all the XRT / Platform files?

A: Visit Xilinx's Microsoft-Azure site for all files.

Q: What Version of XRT should I use?

A: xrt_202210.2.13.479

Q: What is the target deployment platform?

A: Use the following platforms.

- xilinx-u250-gen3x16-xdma-platform-2.1-3_all
- xilinx-u250-gen3x16-xdma-validate_2.1-3005608.1

Q: Which platform should I target for development?

A: xilinx-u250-gen3x16-xdma-2.1-202010-1-dev_1-2954688_all

Q: What are the supported Operating Systems?

A: Xilinx and Microsoft validated Ubuntu 18.04 LTS, Ubuntu 20.04 LTS, and CentOS 7.8.

> Xilinx has created the following marketplace images to simplify the deployment of these VMs:
>
> - Xilinx Alveo U250 2022.1 Deployment VM Ubuntu18.04
> - Xilinx Alveo U250 2022.1 Deployment VM Ubuntu20.04
> - Xilinx Alveo U250 2022.1 Deployment VM CentOS7.8

Q: Can I deploy my Own Ubuntu / CentOS VMs and install XRT / Deployment Target Platform?

A: Yes.

Q: If I deploy my own Ubuntu18.04 VM then what are the required packages and steps?

A: Follow the guidance in Xilinx XRT documentation Xilinx XRT documentation

> Install the following packages.
>
> - xrt_202210.2.13.479_18.04-amd64-xrt.deb
> - xrt_202210.2.13.479_18.04-amd64-azure.deb
> - xilinx-u250-gen3x16-xdma-platform-2.1-3_all_18.04.deb.tar.gz
> - xilinx-u250-gen3x16-xdma-validate_2.1-3005608.1_all.deb

Q: If I deploy my own Ubuntu20.04 VM then what are the required packages and steps?

A: Follow the guidance in Xilinx XRT documentation Xilinx XRT documentation

> Install the following packages.
>
> - xrt_202210.2.13.479_20.04-amd64-xrt.deb
> - xrt_202210.2.13.479_20.04-amd64-azure.deb
> - xilinx-u250-gen3x16-xdma-platform-2.1-3_all_18.04.deb.tar.gz
> - xilinx-u250-gen3x16-xdma-validate_2.1-3005608.1_all.deb

Q: If I deploy my own CentOS7.8 VM then what are the required packages and steps?

A: Follow the guidance in Xilinx XRT documentation Xilinx XRT documentation

> Install the following packages.
>
> - xrt_202210.2.13.479_7.8.2003-x86_64-xrt.rpm
> - xrt_202210.2.13.479_7.8.2003-x86_64-azure.rpm
> - xilinx-u250-gen3x16-xdma-platform-2.1-3.noarch.rpm.tar.gz
> - xilinx-u250-gen3x16-xdma-validate-2.1-3005608.1.noarch.rpm

Q: What are the differences between on-premises FPGAs and NP VMs?

A:
- Regarding XOCL/XCLMGMT:
On Azure NP VMs, only the role endpoint (Device ID 5005), which uses the XOCL driver, is present.

In on-premises FPGAs, both the management endpoint (Device ID 5004) and role endpoint (Device ID 5005), which use the XCLMGMT and XOCL drivers respectively, are present.

- Regarding XRT:
On Azure NP VMs, the XDMA 2.1 platform only supports Host_Mem(SB).
To enable Host_Mem(SB) (up to 1-Gb RAM): sudo xbutil host_mem --enable --size 1g
To disable Host_Mem(SB): sudo xbutil host_mem --disable

Starting on XRT2021.1:

On-premises FPGA in Linux exposes M2M data transfer.
This feature isn't supported in Azure NP VMs.

Q: Can I run xbmgmt commands?

A: No, on Azure VMs there's no management support directly from the Azure VM.

Q: Do I need to load a PLP?

A: No, the PLP is loaded automatically for you, so there's no need to load via xbmgmt commands.

Q: Does Azure support different PLPs?

A: Not at this time. We only support the PLP provided in the deployment platform packages.

Q: How can I query the PLP information?

A: Need to run xbutil query and look at the lower portion.

Q: Do Azure NP VMs support FPGA bitstreams with Networking GT Kernel connections?

A: No. The FPGA Attestation service performs a series of validations on a design checkpoint file and generates an error if the user's application contains connections to the FPGA card's QSFP networking ports.

FPGA attestation for Azure NP-Series VMs (Preview)

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The FPGA Attestation service performs a series of validations on a design checkpoint file (called a "netlist") generated by the Xilinx toolset and produces a file that contains the validated image (called a "bitstream") that can be loaded onto the Xilinx U250 FPGA card in an NP series VM.

> **Note**
>
> - The Azure NP-series FPGA Attestation Service will close to new preview sign-ups on May 1, 2026.
> - The attestation service will remain available to previously approved users until June 1, 2026. Bitstreams that have already been attested will continue to function on NP-series virtual machines until the platform retirement date.
> - This change is related to the upcoming retirement of NP-series virtual machines. For more information, see NP-series virtual machine migration guidance.
> - See the Preview Terms Of Use | Microsoft Azure for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.
> - Sign up for the public preview.

News

The current attestation service is using Vitis 2021.1 from Xilinx, on Sept 26th 2022, we'll be moving to Vitis 2022.1. The change should be transparent to most users. Once your designs are "attested" using Vitis 2022.1, you should be moving to XRT2022.1. Xilinx published new marketplace images based on XRT 2022.1. Please note that current designs already attested on Vitis 2020.2 or 2021.1, works on the current deployment marketplace images and new images based on XRT2022.1

As part of the move to 2021.1, Xilinx introduced a new DRC that might affect some designs previously working on Vitis 2020.2 regarding BUFCE_LEAF failing attestation, for more details

here: Xilinx AR 75980 UltraScale/UltraScale+ BRAM: CLOCK_DOMAIN = Common Mode skew checks.

Prerequisites

You need an Azure subscription and an Azure Storage account. The subscription gives you access to Azure and the storage account is used to hold your netlist and output files of the attestation service.

We provide PowerShell and Bash scripts to submit attestation requests. The scripts use Azure CLI, which can run on Windows and Linux. PowerShell can run on Windows, Linux, and macOS.

Azure CLI download (required)

PowerShell for Windows, Linux, and macOS download (only for PowerShell scripts)

You need to have your tenant and subscription ID authorized to submit to the attestation service. Visit https://aka.ms/AzureFPGAAttestationPreview to request access.

Building your design for attestation

The preferred Xilinx toolset for building designs is Vitis 2022.1. Netlist files that were created with an earlier version of the toolset and are still compatible with 2022.1 can be used. Ensure you've loaded the correct shell to build against. The currently supported version is `xilinx_u250_gen3x16_xdma_2_1_202010_1`. The support files can be downloaded from the Xilinx Alveo lounge.

You must include the following argument to Vitis (v++ cmd line) to build an `xclbin` file that contains a netlist instead of a bitstream.

```
--advanced.param compiler.acceleratorBinaryContent=dcp
```

Logging into Azure

Before performing any operations with Azure, you must log into Azure and set the subscription that is authorized to call the service. Use the `az login` and `az account set -s <Sub ID or Name>` commands for this purpose. Further information about this process is documented here: Sign in with Azure CLI. Use either the **sign in interactively** or **sign in with credentials** option on the command line.

Creating a storage account and blob container

Your netlist file must be uploaded to an Azure storage blob container for access by the attestation service.

For more information on creating the account, a container, and uploading your netlist as a blob to that container, see Quickstart: Create, download, and list blobs with Azure CLI.

You can also use the Azure portal for this as well.

Upload your netlist file to Azure blob storage

There are several ways to copy the file; an example using the az storage upload cmdlet is shown below. The az commands run on both Linux and Windows. You can choose any name for the "blob" name but make sure to retain the `xclbin` extension.

```
az storage blob upload --account-name <storage account to receive netlist> --container-name <blob container name> --name <blob filename> --file <local file with netlist>
```

Running the attestation scripts

To run the scripts, you will need to provide the name of your storage account, the name of the blob container where the netlist file is stored and the name of the netlist file. Also, you need to create a Service shared access signature (SAS) that grants read/write access to your container (not the netlist). This SAS is used by the attestation service to make a local copy of your netlist file and to write back the resulting output files of the validation process to your container.

An overview of shared access signatures is available here with specific information about the Service SAS available here. The Service SAS page includes an important caution about protecting the generated SAS. Read the caution to understand the need to keep the SAS protected from malicious or unintended use.

You can generate a SAS for your container using the az storage container generate-sas cmdlet. Specify an expiry time in UTC format that is at least a few hours past the time of submission; around 6 hours should be more than adequate.

If you wish to use virtual directories, you must include the directory hierarchy as part of the container argument. For example, if you have a container named “netlists” and have a virtual directory named “image1” that contains the netlist blob, you would specify “netlists/image1” as the container name. Add any extra directory names to specify a more detailed hierarchy.

PowerShell

PowerShell

```
$sas=$(az storage container generate-sas --account-name <storage acct name> --name
<blob container name> --https-only --permissions rwc --expiry <e.g., 2021-01-
07T17:00Z> --output tsv)

.\Validate-FPGAImage.ps1 -StorageAccountName <storage acct name> -Container <blob
container name> -BlobContainerSAS $sas -NetlistName <netlist blob filename>
```

Bash

Bash

```
sas=az storage container generate-sas --account-name <storage acct name> --name
<blob container name> --https-only --permissions rwc --expiry <2021-01-07T17:00Z> -
-output tsv

validate-fpgaimage.sh --storage-account <storage acct name> --container <blob
container name> --netlist-name <netlist blob filename> --blob-container-sas $sas
```

Checking on the status of your submission

The Attestation service will return the orchestration ID of your submission. The submission scripts automatically start monitoring the submission by polling for completion. The orchestration ID is the primary way for us to review what happened to your submission so please keep that in case you have an issue. As reference points, attestation takes about 30 minutes to complete for a small netlist file (300MB in size); a 1.6GB file took an hour.

You can call the Monitor-Validation.ps1 script at any time to get status and results of attestation, providing the orchestration ID as an argument:

`.\Monitor-Validation.ps1 -OrchestrationId <orchestration ID>`

Alternatively, you can submit HTTP post request to the attestation service endpoint:

`https://fpga-attestation.azurewebsites.net/api/ComputeFPGA_HttpGetStatus`

The request body should contain your Subscription ID, Tenant ID, and orchestration ID of your attestation request:

JSON

```
{
  "OrchestrationId": "<orchestration ID>",
  "ClientSubscriptionId": "<your subscription ID>",
```

```
  "ClientTenantId": "<your tenant ID>"
}
```

Post validation steps

The service will write its output back to your container. If the validation pass succeeds, your container will have the original netlist file (abc.xclbin), a file with the bitstream (abc.bit.xclbin), a file that identifies the private location of your stored bitstream (abc.azure.xclbin) and four log files: one for the startup process (abc-log.txt) and one each for the three parallel phases that perform the validation. These are named *logPhaseX.txt where X is a number for the phase. The azure.xclbin is used on your VM to signal the uploading of your validated image to the U250.

If validation failed, an error-*.txt file is written indicating which step failed. Also check the log files if the error log indicates that attestation failed. When contacting us for support, please be sure to include all these files as part of the support request along with the orchestration ID.

You can use the Azure portal to create your container as well as uploading your netlist and downloading the bitstream and log files. Submitting an attestation request and monitoring its progress through the portal is not supported at this time and must be done through scripts as described above.

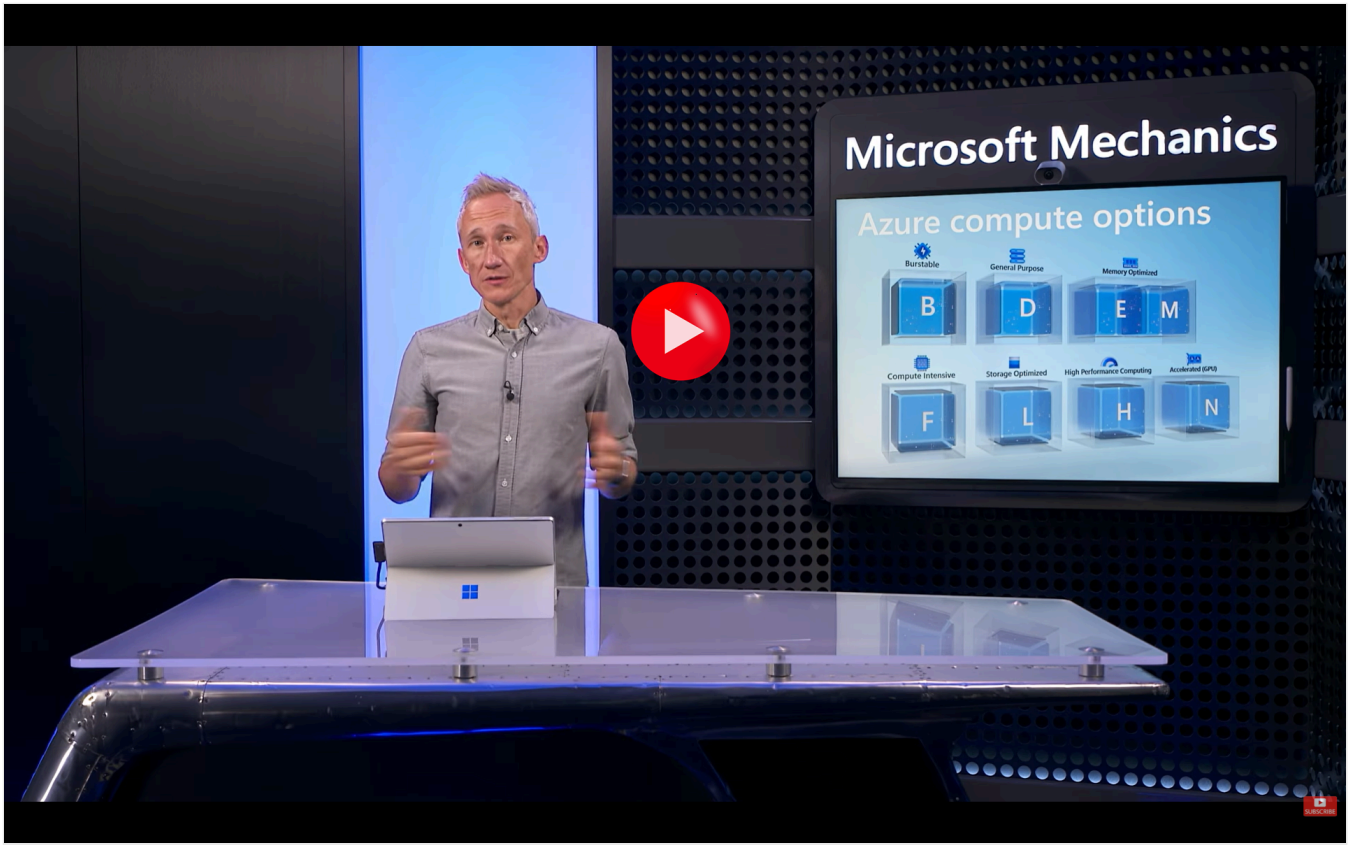
Sizes for virtual machines in Azure

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machine (VM) sizes are designed to provide a wide range of options for hosting your servers and their workloads in the cloud. Sizes are categorized into different families and types, each optimized for specific purposes. Users can choose the most suitable VM size based on their requirements, such as CPU, memory, storage, and network bandwidth.

This article describes what sizes are, gives an overview of the available sizes and shows different options for Azure virtual machine instances you can use to run your apps and workloads.



VM size and series naming

Azure VM sizes follow specific naming conventions to denote varying features and specifications. Each character in the name represents different aspects of the VM. These include the VM family, number of vCPUs, and extra features like premium storage or included accelerators.

VM naming is further broken down into the 'Series' name and the 'Size' name. Size names include extra characters representing the number of vCPUs, type of storage, etc.

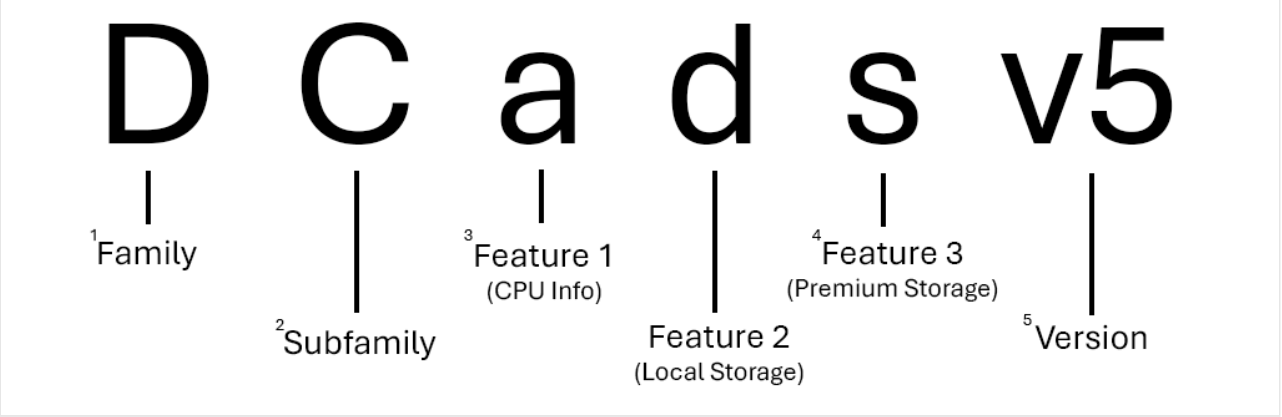
Expand table

Category	Description	Links
Type	Basic categorization by intended workload.	General purpose Compute optimized Memory optimized Storage optimized GPU accelerated FPGA accelerated
Series	Group of sizes with similar hardware and features.	Enter the 'Series' tab here.
Size	Specific VM configuration, including vCPUs, memory, and accelerators.	Enter the 'Size' tab here.

Name structure breakdown

Series

Here's a breakdown of a 'General purpose, **DCads_v5**-series' size series.



[1] Most families are represented using one letter, but others such as GPU sizes (`ND-series`, `NV-series`, etc.) use two.

[2] Most subfamilies are represented with a single upper case letter, but others (such as `Ebsv5-series`) are still considered subfamilies of their parent family due to feature differences.

[3] If no feature letter for a CPU is listed, the series uses Intel x86-64 CPUs. If the CPU is AMD, it's listed as `a`. If the CPU is ARM based (Microsoft Cobalt or Ampere Altra), it's listed as `p`.

[4] There can be any number of extra features in a size name. There could be none (`Dv5-series`) or there could be three (`Dplds_v6-series`).

[5] Version numbers only appear in the size name if there are multiple versions of the same

series. If you're using the first version of a series (`HB-series`, `B-series`, etc.) it's often not included in the size name.

> **Note**
>
> Not all sizes will have subfamilies, support accelerators, or specify the CPU vendor. For more information on VM size naming conventions, see Azure VM sizes naming conventions.

List of VM size families by type

This section contains a list of all current generation size series with tabs dedicated to each size family. Each group has a 'Series List' column with a linked list of all available size series, These links will bring you to the family page for that series, where you can find detailed information on each size in that series or go to the series' page for a list of sizes in that series.

To learn more about a size family, select the 'family' tab under each type section. There you can read a summary on the family, see the workloads it's recommended for, and view the full family page with specifications for all series in that family.

General purpose

General purpose VM sizes provide balanced CPU-to-memory ratio. Ideal for testing and development, small to medium databases, and low to medium traffic web servers.

Family list

Expand table

Family	Workloads	Series List
A-family	Entry-level economical	Av2-series Previous-gen A-family series
B-family	Burstable	Bsv2-series Basv2-series Bpsv2-series Previous-gen B-family series
D-family	Enterprise-grade applications Relational databases	Dsv7 and Ddsv7 series Dlsv7 and Dldsv7 series

Family	Workloads	Series List
	In-memory caching Data analytics	Dasv7 and Dadsv7 series Dalsv7 and Daldsv7 series Dpsv6 and Dplsv6-series Dpdsv6 and Dpldsv6-series Dasv6 and Dadsv6-series Dalsv6 and Daldsv6-series Dsv6 and Ddsv6-series Dlsv6 and Dldsv6-series Dpsv5 and Dpdsv5-series Dplsv5 and Dpldsv5-series Dlsv5 and Dldsv5-series Dv5 and Dsv5-series Ddv5 and Ddsv5-series Dasv5 and Dadsv5-series Previous-gen D-family series
DC-family	D-family with confidential computing	DCasv5 and DCadsv5-series DCas_cc_v5 and DCads_cc_v5-series DCesv6-series DCedsv6-series DCasv6 and DCadsv6-series DCsv3 and DCdsv3-series Previous-gen DC-family

Compute optimized

Compute optimized VM sizes have a high CPU-to-memory ratio. These sizes are good for medium traffic web servers, network appliances, batch processes, and application servers.

Family list

List of compute optimized VM size families:

Expand table

Family	Workloads	Series List
F-family	Medium traffic web servers Network appliances Batch processes Application servers	Fasv7 and Fadsv7 series Famsv7 and Famdsv7 series Falsv7 and Faldsv7 series Fasv6, Falsv6, and Famsv6-series Fsv2-series Previous-gen F-family

'HB' sub-family storage optimized VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'HB' sub-family of VM size series are one of Azure's high-performance computing (HPC) optimized H-family VM instances. They're designed for compute-intensive workloads, such as computational fluid dynamics, finite element analysis, and large-scale scientific simulations. HB-series VMs, equipped with high-performance AMD EPYC processors and fast memory, deliver exceptional CPU and memory bandwidth. They're ideal for applications that need extensive computational resources to handle large-scale calculations and data processing. They're well-suited for industries such as engineering, scientific research, and data analysis. In these fields, processing speed and accuracy are essential for maintaining productivity and driving innovation.

Workloads and use cases

Computational Fluid Dynamics (CFD): HB family VMs are ideal for simulations in fields like aerospace, automotive design, and manufacturing, where fluid dynamics calculations are intensive.

Finite Element Analysis (FEA): HB family VMs are suitable for engineering analyses that simulate physical phenomena, requiring intensive computational power to model complex systems and materials.

Weather Forecasting: HB family VMs can handle the massive datasets and complex simulations required for high-resolution weather modeling and forecasting.

Seismic Processing: HB family VMs are in the oil and gas industry, HB family VMs can process seismic data to help map and understand subsurface structures.

Scientific Research: HB family VMs support a wide range of scientific research that requires large-scale mathematical modeling, including physics and computational chemistry simulations.

Genomics and Bioinformatics: HB family VMs are also used in life sciences for genomic analysis, where large amounts of data need to be processed quickly to decode genetic information.

Series in family

HBv2-series

HBv2-series VMs are optimized for applications that are driven by memory bandwidth, such as fluid dynamics, finite element analysis, and reservoir simulation. HBv2 VMs feature 120 AMD EPYC 7V12 processor cores, 4 GB of RAM per CPU core, and no simultaneous multithreading. Each HBv2 VM provides up to 350 GB/s of memory bandwidth, and up to 4 teraFLOPS of FP64 compute. HBv2-series VMs feature 200 Gb/sec Mellanox HDR InfiniBand. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. These VMs support Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is recommended.

View the full hbv2-series page.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	16 - 120 vCPUs	AMD EPYC 7V12 (Rome) [x86-64]
L3 Cache	1536 MB	
Memory	456 GB	350 GB/s
Local Storage	1 Temp Disk 1 NVMe Disk	480 GiB 960 GiB
Remote Storage	8 Disks	
Network	8 vNICs 1 InfiniBand HDR NIC	40 Gb/s 200 Gb/s
Accelerators	None	

HBv3-series

HBv3-series Virtual Machines (VMs) are designed for very demanding computing tasks. They help with things like studying how liquids move, analyzing structures, predicting weather, and processing earthquake data. They also support oil reservoir modeling and testing computer chip designs. HBv3 VMs feature up to 120 AMD EPYC™ 7V73X (Milan-X) CPU cores, 448 GB of RAM, and no simultaneous multithreading. HBv3-series VMs also provide 350 GB/sec of memory bandwidth (amplified up to 630 GB/s), up to 96 MB of L3 cache per core (1536 MB total per VM), up to 7 GB/s of block device SSD performance, and clock frequencies up to 3.5 GHz. All HBv3-series VMs feature 200 Gb/sec High Data Rate (HDR) InfiniBand from NVIDIA

Networking to enable supercomputer-scale Message Pass Interface (MPI) workloads. These VMs are connected in a nonblocking fat tree for optimized and consistent RDMA performance. The HDR InfiniBand fabric also supports Adaptive Routing and Dynamic Connected Transport (DCT), along with standard Reliable Connection (RC) and Unreliable Datagram (UD) transports. These features improve performance, make scaling easier, and keep results consistent.

Expand table

Part	Quantity Count Units	Specs SKU ID, Performance Units, etc.
Processor	16 - 120 vCPUs	AMD EPYC 7V73X (Milan-X) [x86-64]
L3 Cache	1536 MB	
Memory	448 GB	350 GB/s
Local Storage	1 Temp Disk 2 NVMe Disks	480 GiB 960 GiB
Remote Storage	32 Disks	
Network	8 vNICs 1 InfiniBand HDR NIC	40 Gb/s 200 Gb/s
Accelerators	None	

HBv4-series

HBv4-series VMs are optimized for many high-performance computing (HPC) workloads. These include:

- Computational fluid dynamics
- Finite element analysis
- Frontend and backend Electronic Design Automation (EDA)
- Rendering and graphics work
- Molecular dynamics
- Computational geoscience
- Weather simulation
- Financial risk analysis

HBv4 VMs feature up to 176 AMD EPYC™ 9V33X ("Genoa-X") CPU cores with AMD's 3D V-Cache, clock frequencies up to 3.7 GHz, and no simultaneous multithreading. HBv4-series VMs also provide 768 GB of RAM, 2304 MB L3 cache. Each VM has 2304 MB of L3 cache that

delivers up to 5.7 TB/s of bandwidth. This boosts DRAM bandwidth of 780 GB/s, giving an average of 1.2 TB/s of effective memory speed for many workloads. The VMs also provide up to 12 GB/s (reads) and 7 GB/s (writes) of block device SSD performance.

All HBv4-series VMs feature 400 Gb/s NDR InfiniBand from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. NDR continues to support features like Adaptive Routing and the Dynamically Connected Transport (DCT). This newest generation of InfiniBand also brings greater support for offload of MPI collectives, optimized real-world latencies due to congestion control intelligence, and enhanced adaptive routing capabilities. These features enhance application performance, scalability, and consistency, and their usage is recommended.

Remote Storage	32 Disks	
Network	8 vNICs 1 InfiniBand NDR NIC	80 Gb/s 400 Gb/s
Accelerators	None	

HBv5-series

HBv5-series VMs are optimized for the most memory bandwidth-intensive HPC applications, including:

- Computational fluid dynamics
- Automotive and aerospace simulations
- Weather modeling
- Energy research
- Molecular dynamics simulations

- Computer-aided engineering and other HPC workloads

HBv5 VMs feature 6.7 TB/s of memory bandwidth across 432 GB of high-bandwidth memory (HBM) and up to 368 4th Generation AMD EPYC™ processor cores with 4 GHz boost frequencies, 3.5 GHz base frequencies, and no simultaneous multithreading.

Each HBv5-series VM also includes 14.3 TiB of local NVMe SSD storage with up to 50 GB/s (reads) and 30 GB/s (writes) of block device performance.

All HBv5-series VMs feature 800 Gb/s per node (4 x 200 Gb/s CX-7 NIC) of InfiniBand connectivity from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a nonblocking fat tree for optimized and consistent RDMA performance.

The InfiniBand NICs support features like Adaptive Routing, Dynamically Connected Transport (DCT), hardware acceleration of MPI collectives, and congestion control. These features enhance application performance, scalability, and consistency, and their usage is recommended for optimal performance and cost efficiency.

HBv2 series virtual machine overview

> **ⓘ Important**
>
> **HBv2-series VMs are scheduled for retirement on May 31, 2027.** This applies to all HBv2 sizes: Standard_HB120rs_v2, Standard_HB120-96rs_v2, Standard_HB120-64rs_v2, Standard_HB120-32rs_v2, and Standard_HB120-16rs_v2. After this date, HBv2 VMs will be set to a deallocated state, stop working, stop incurring billing charges, and lose SLA and support. Plan your migration to current-generation HPC alternatives before the retirement date.

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets.

Maximizing high performance compute (HPC) application performance on AMD EPYC requires a thoughtful approach memory locality and process placement. Below we outline the AMD EPYC architecture and our implementation of it on Azure for HPC applications. We use the term **pNUMA** to refer to a physical NUMA domain, and **vNUMA** to refer to a virtualized NUMA domain.

Physically, an HBv2-series server is 2 * 64-core EPYC 7V12 CPUs for a total of 128 physical cores. Simultaneous Multithreading (SMT) is disabled on HBv2. These 128 cores are divided into 16 sections (8 per socket), each section containing 8 processor cores. Azure HBv2 servers also run the following AMD BIOS settings:

Output

```
Nodes per Socket (NPS) = 2
L3 as NUMA = Disabled
NUMA domains within VM OS = 4
C-states = Enabled
```

As a result, the server boots with 4 NUMA domains (2 per socket). Each domain is 32 cores in size. Each NUMA has direct access to 4 channels of physical DRAM operating at 3,200 MT/s.

To provide room for the Azure hypervisor to operate without interfering with the VM, we reserve 8 physical cores per server.

VM topology

We reserve these 8 hypervisor host cores symmetrically across both CPU sockets, taking the first 2 cores from specific Core Complex Dies (CCDs) on each NUMA domain, with the remaining cores for the HBv2-series VM. The CCD boundary isn't equivalent to a NUMA boundary. On HBv2, a group of four consecutive (4) CCDs is configured as a NUMA domain, both at the host server level and within a guest VM. Thus, all HBv2 VM sizes expose 4 NUMA domains that appear to an OS and application. 4 uniform NUMA domains, each with different number of cores depending on the specific HBv2 VM size.

Process pinning works on HBv2-series VMs because we expose the underlying silicon as-is to the guest VM. We strongly recommend process pinning for optimal performance and consistency.

Hardware specifications

Expand table

Hardware Specifications	HBv2-series VM
Cores	120 (SMT disabled)
CPU	AMD EPYC 7V12
CPU Frequency (non-AVX)	~3.1 GHz (single + all cores)
Memory	4 GB/core (480 GB total)
Local Disk	960 GiB NVMe (block), 480 GB SSD (page file)
Infiniband	200 Gb/s HDR Mellanox ConnectX-6
Network	50 Gb/s Ethernet (40 Gb/s usable) Azure second Gen SmartNIC

Software specifications

Expand table

Software Specifications	HBv2-series VM
Max MPI Job Size	36000 cores (300 VMs in a single virtual machine scale set with singlePlacementGroup=true)
MPI Support	HPC-X, Intel MPI, OpenMPI, MVAPICH2, MPICH, Platform MPI
Additional Frameworks	UCX, libfabric, PGAS

Software Specifications	HBv2-series VM
Azure Storage Support	Standard and Premium Disks (maximum 8 disks)
OS Support for SRIOV RDMA	RHEL 7.9+, Ubuntu 18.04+, SLES 12 SP5+, WinServer 2016+
Orchestrator Support	CycleCloud, Batch, AKS; cluster configuration options

> **Note**
>
> Windows Server 2012 R2 isn't supported on HBv2 and other VMs with more than 64 (virtual or physical) cores. For more information, see Supported Windows guest operating systems for Hyper-V on Windows Server.

Availability and purchasing

> **Important**
>
> **Reserved Instance purchase end date**: 1-year and 3-year Reserved Instance purchases for HBv2-series VMs ended on April 2, 2026. Avoid new long-term RI commitments on HBv2-series. Existing RIs remain valid until their expiration date.

- **Pay-as-you-go**: HBv2-series VMs remain available on a pay-as-you-go basis until retirement on **May 31, 2027**.
- **Plan migration**: Begin planning and testing migrations to current-generation HPC alternatives ahead of the retirement date. If you have active RIs for HBv2, consider exchanging them for supported HPC series RIs or trading them in for an Azure Savings Plan for compute. For more information, see Exchange and refund Azure reservations.

Migrate to current-generation HPC VMs

HBv2-series VMs will be retired on May 31, 2027. Microsoft recommends migrating to the following current-generation HPC VM series:

Expand table

Recommended series	Key characteristics
HBv5-series	4th Gen AMD EPYC (Zen4), up to 368 cores, HBM3 memory, NDR InfiniBand – best for memory bandwidth-intensive workloads
HX-series	AMD EPYC 9004, up to 176 cores, large L3 cache – suited for memory-capacity-intensive HPC workloads
HBv4-series	4th Gen AMD EPYC (Genoa), up to 176 cores, NDR InfiniBand – strong all-round HPC replacement
HBv3-series	3rd Gen AMD EPYC (Milan), up to 120 cores, HDR InfiniBand – comparable generation step-up from HBv2

Before migrating, validate your workloads on the target series:

- **MPI and RDMA**: Confirm compatibility with the target InfiniBand fabric (HDR vs. NDR) and your MPI library version.
- **Memory bandwidth**: Run representative benchmarks to confirm performance parity or improvement on the target series.
- **Application testing**: Complete end-to-end testing of your HPC applications on the target series before production migration.

Next steps

- For migration to current-generation HPC VMs, see the Migrate to current-generation HPC VMs section in this article.
- For more information about AMD EPYC architecture and multi-chip architectures, see the HPC Tuning Guide for AMD EPYC Processors.
- For latest announcements on HPC workload examples, and performance results see Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.
- For more information on the current-generation HBv5 series, see HBv5-series overview.

HBv2 sizes series

> **Important**
>
> **HBv2-series VMs are scheduled for retirement on May 31, 2027.** This applies to all HBv2 sizes: Standard_HB120rs_v2, Standard_HB120-96rs_v2, Standard_HB120-64rs_v2, Standard_HB120-32rs_v2, and Standard_HB120-16rs_v2. After this date, HBv2 VMs will be set to a deallocated state, stop working, stop incurring billing charges, and lose SLA and support. Plan your migration to current-generation HPC alternatives before the retirement date. For migration guidance, see the Migration guidance section below.

HBv2-series VMs are optimized for applications that are driven by memory bandwidth, such as fluid dynamics, finite element analysis, and reservoir simulation. HBv2 VMs feature 120 AMD EPYC 7V12 processor cores, 4 GB of RAM per CPU core, and no simultaneous multithreading. Each HBv2 VM provides up to 350 GB/s of memory bandwidth, and up to 4 teraFLOPS of FP64 compute. HBv2-series VMs feature 200 Gb/sec Mellanox HDR InfiniBand. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. These VMs support Adaptive Routing and the Dynamic Connected Transport (DCT, in addition to standard RC and UD transports). These features enhance application performance, scalability, and consistency, and their usage is recommended.

> **Note**
>
> HBv2-series is scheduled for retirement on May 31, 2027. For new HPC architecture planning, consider current-generation alternatives such as HBv5-series, HX-series, HBv4-series, or HBv3-series VMs.

Backend Network	InfiniBand HDR

Migration guidance

HBv2-series VMs will be retired on May 31, 2027. Microsoft recommends migrating to the following current-generation HPC VM series before the retirement date:

Expand table

Recommended series	Key characteristics
HBv5-series	4th Gen AMD EPYC (Zen4), up to 368 cores, HBM3 memory, NDR InfiniBand – best for memory bandwidth-intensive workloads
HX-series	AMD EPYC 9004, up to 176 cores, large L3 cache – suited for memory-capacity-intensive HPC workloads
HBv4-series	4th Gen AMD EPYC (Genoa), up to 176 cores, NDR InfiniBand – strong all-round HPC replacement
HBv3-series	3rd Gen AMD EPYC (Milan), up to 120 cores, HDR InfiniBand – comparable generation step-up from HBv2

When selecting a replacement size, consider the following:

- **MPI and RDMA requirements**: Verify that your MPI library and InfiniBand fabric (HDR vs. NDR) are supported on the target series.
- **Memory bandwidth**: Benchmark your workload on the target series to confirm performance parity or improvement.
- **Workload compatibility**: Test application correctness and performance on the target series before production migration.

HBv2-series virtual machine sizes

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Performance testing was conducted across multiple HBv2-series size VMs. The following table summarizes key findings from these tests.

Expand table

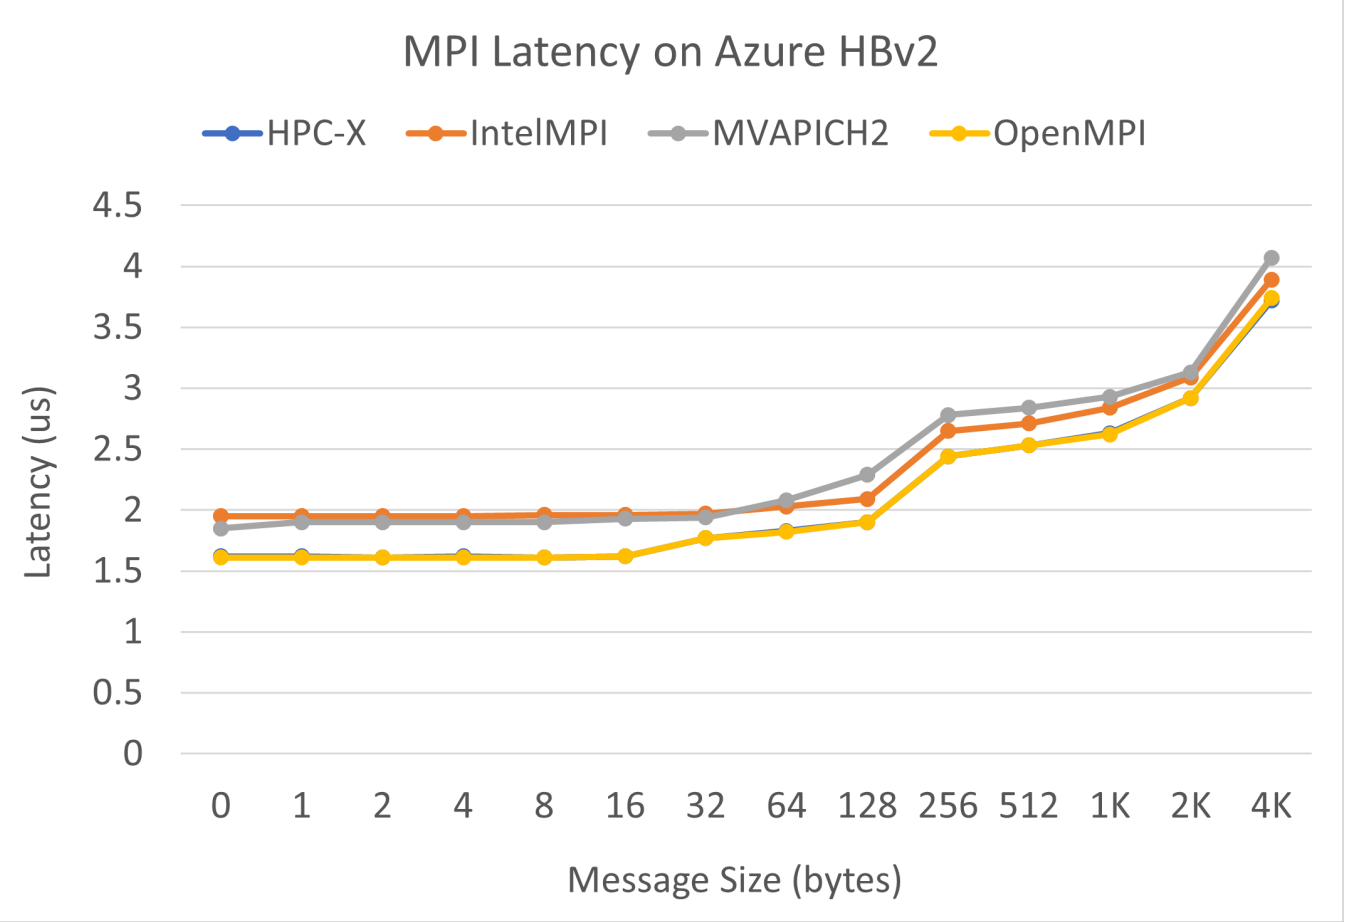
Workload	HBv2
STREAM Triad	350 GB/s (21-23 GB/s per CCX)
High-Performance Linpack (HPL)	4 TeraFLOPS (Rpeak, FP64), 8 TeraFLOPS (Rmax, FP32)
RDMA latency & bandwidth	1.2 microseconds, 190 Gb/s
FIO on local NVMe SSD	2.7 GB/s reads, 1.1 GB/s writes; 102k IOPS reads, 115 IOPS writes
IOR on 8 * Azure Premium SSD (P40 Managed Disks, RAID0)**	1.3 GB/s reads, 2.5 GB/writes; 101k IOPS reads, 105k IOPS writes

MPI latency

MPI latency test from the OSU Micro-Benchmark (OMB) suite is run. Sample scripts are on GitHub.

Bash

```
./bin/mpirun_rsh -np 2 -hostfile ~/hostfile MV2_CPU_MAPPING=[INSERT CORE #]
./osu_latency
```

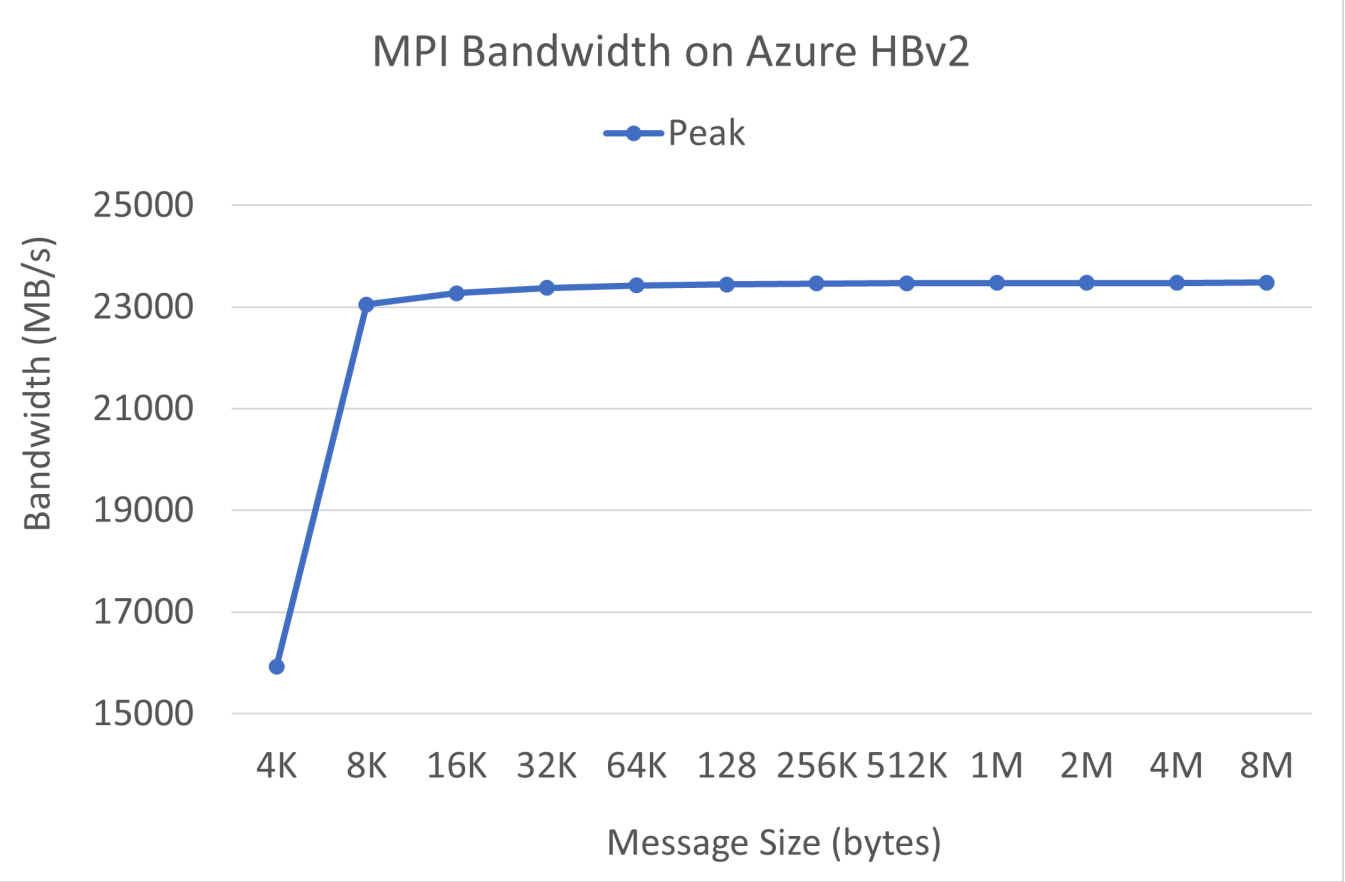


MPI bandwidth

MPI bandwidth test from the OSU microbenchmark suite is run. Sample scripts are on GitHub.

Bash

```
./mvapich2-2.3.install/bin/mpirun_rsh -np 2 -hostfile ~/hostfile MV2_CPU_MAPPING=
[INSERT CORE #] ./mvapich2-2.3/osu_benchmarks/mpi/pt2pt/osu_bw
```



Mellanox Perftest

The Mellanox Perftest package has many InfiniBand tests such as latency (ib_send_lat) and bandwidth (ib_send_bw). The following command serves as an example.

Bash

```
numactl --physcpubind=[INSERT CORE #]  ib_send_lat -a
```

HBv3-series virtual machine overview

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

An HBv3-series server features 2 * 64-core EPYC 7V73X CPUs for a total of 128 physical "Zen3" cores with AMD 3D V-Cache. Simultaneous Multithreading (SMT) is disabled on HBv3. These 128 cores are divided into 16 sections (8 per socket), each section containing 8 processor cores with uniform access to a 96 MB L3 cache. Azure HBv3 servers also run the following AMD BIOS settings:

Output

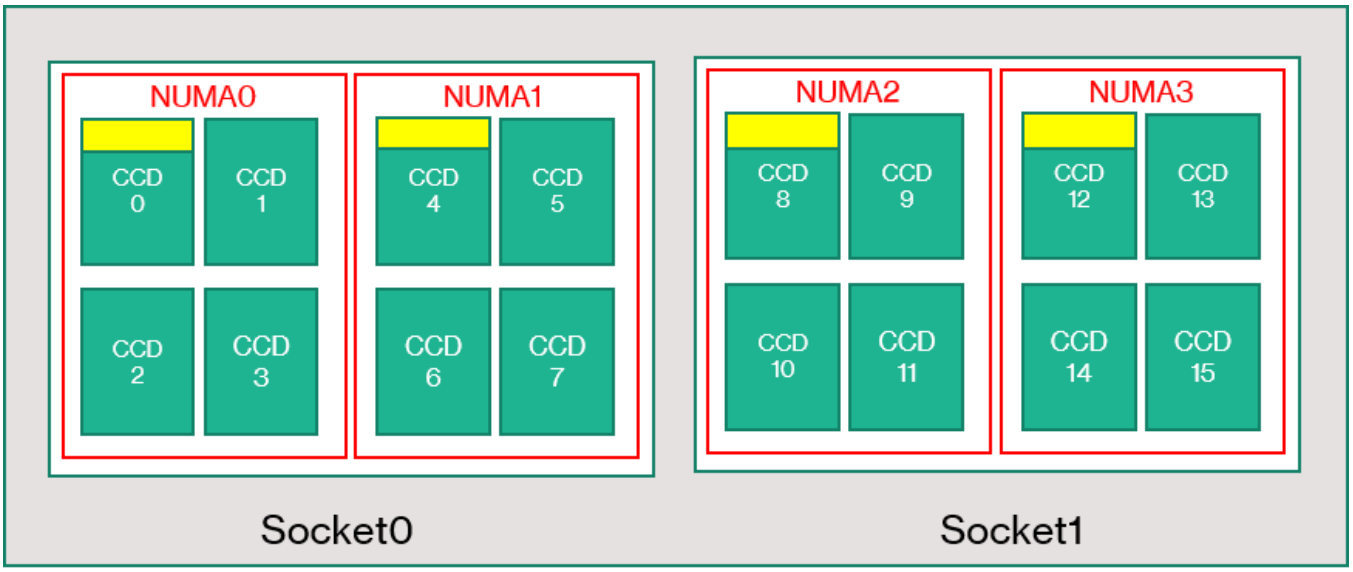
```
Nodes per Socket (NPS) = 2
L3 as NUMA = Disabled
NUMA domains within VM OS = 4
C-states = Enabled
```

As a result, the server boots with 4 NUMA domains (2 per socket). Each domain is 32 cores in size. Each NUMA has direct access to 4 channels of physical DRAM operating at 3,200 MT/s.

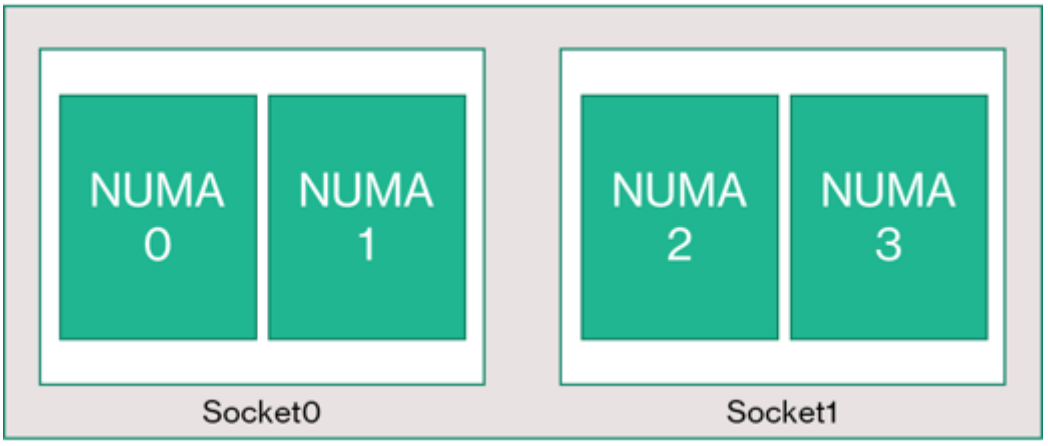
To provide room for the Azure hypervisor to operate without interfering with the VM, we reserve 8 physical cores per server.

VM topology

The following diagram shows the topology of the server. We reserve these 8 hypervisor host cores (yellow) symmetrically across both CPU sockets, taking the first 2 cores from specific Core Complex Dies (CCDs) on each NUMA domain, with the remaining cores for the HBv3-series VM (green).



The CCD boundary isn't equivalent to a NUMA boundary. On HBv3, a group of four consecutive (4) CCDs is configured as a NUMA domain, both at the host server level and within a guest VM. Thus, all HBv3 VM sizes expose 4 NUMA domains that appear to an OS and application as shown. 4 uniform NUMA domains, each with different number of cores depending on the specific HBv3 VM size.



Each HBv3 VM size is similar in physical layout, features, and performance of a different CPU from the AMD EPYC 7003-series, as follows:

Expand table

HBv3-series VM size	NUMA domains	Cores per NUMA domain	Similarity with AMD EPYC
Standard_HB120rs_v3	4	30	Dual-socket EPYC 7773X
Standard_HB120-96rs_v3	4	24	Dual-socket EPYC 7643
Standard_HB120-64rs_v3	4	16	Dual-socket EPYC 7573X
Standard_HB120-32rs_v3	4	8	Dual-socket EPYC 7373X
Standard_HB120-16rs_v3	4	4	Dual-socket EPYC 72F3

> **Note**
>
> The constrained cores VM sizes only reduce the number of physical cores exposed to the VM. All global shared assets (RAM, memory bandwidth, L3 cache, GMI and xGMI connectivity, InfiniBand, Azure Ethernet network, local SSD) stay constant. This capability allows a customer to pick a VM size best tailored to a given set of workload or software licensing needs.

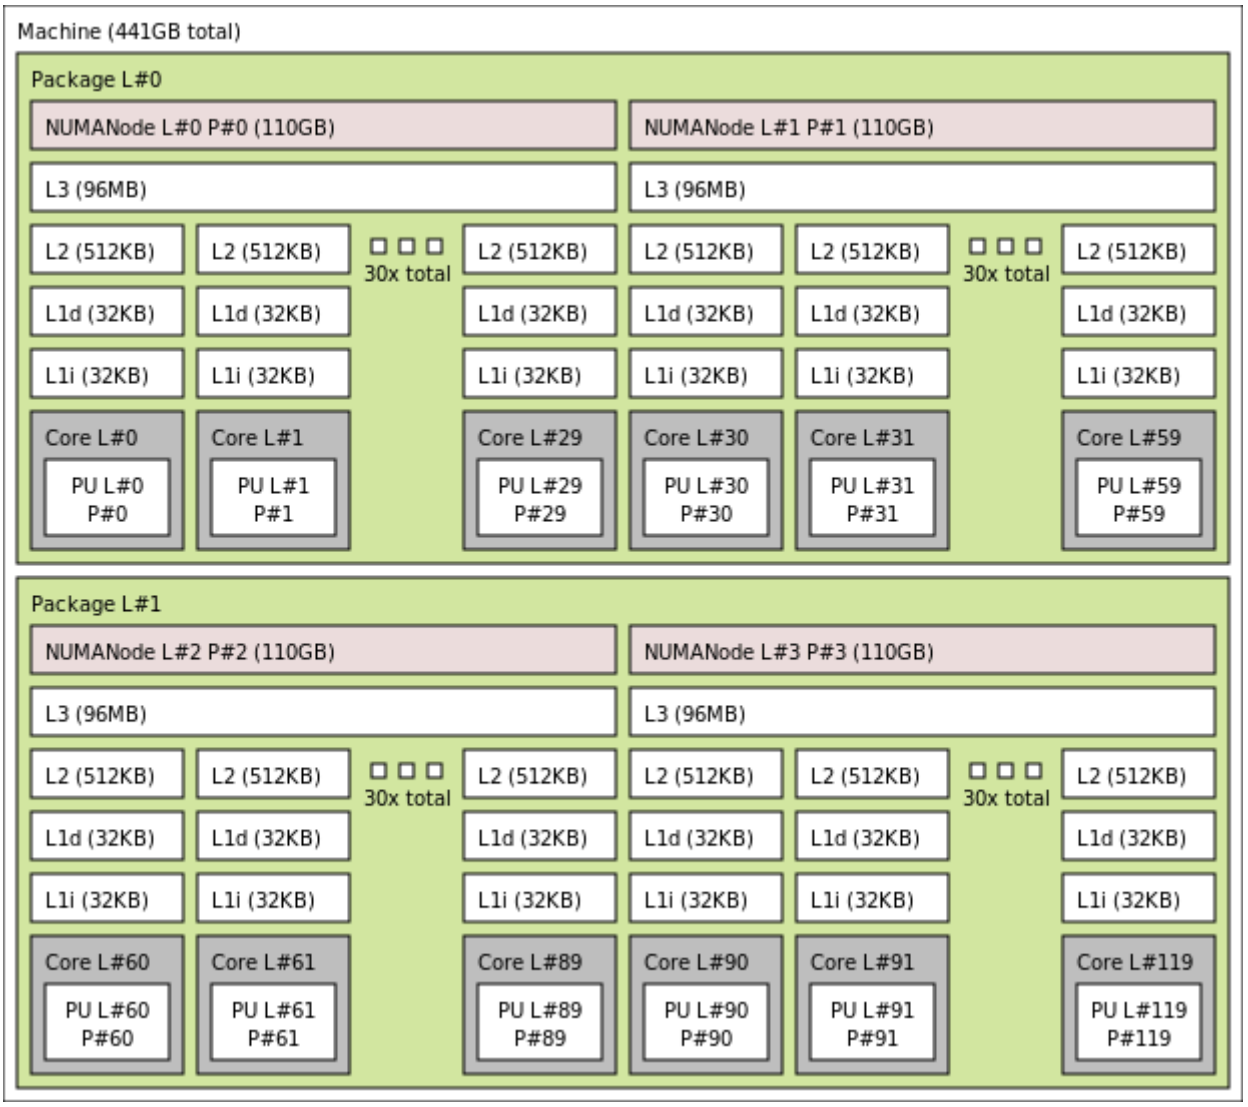
The virtual NUMA mapping of each HBv3 VM size is mapped to the underlying physical NUMA topology. The hardware topology is shown directly, without potentially misleading abstraction.

The exact topology for the various HBv3 VM size appears as follows using the output of lstopo :

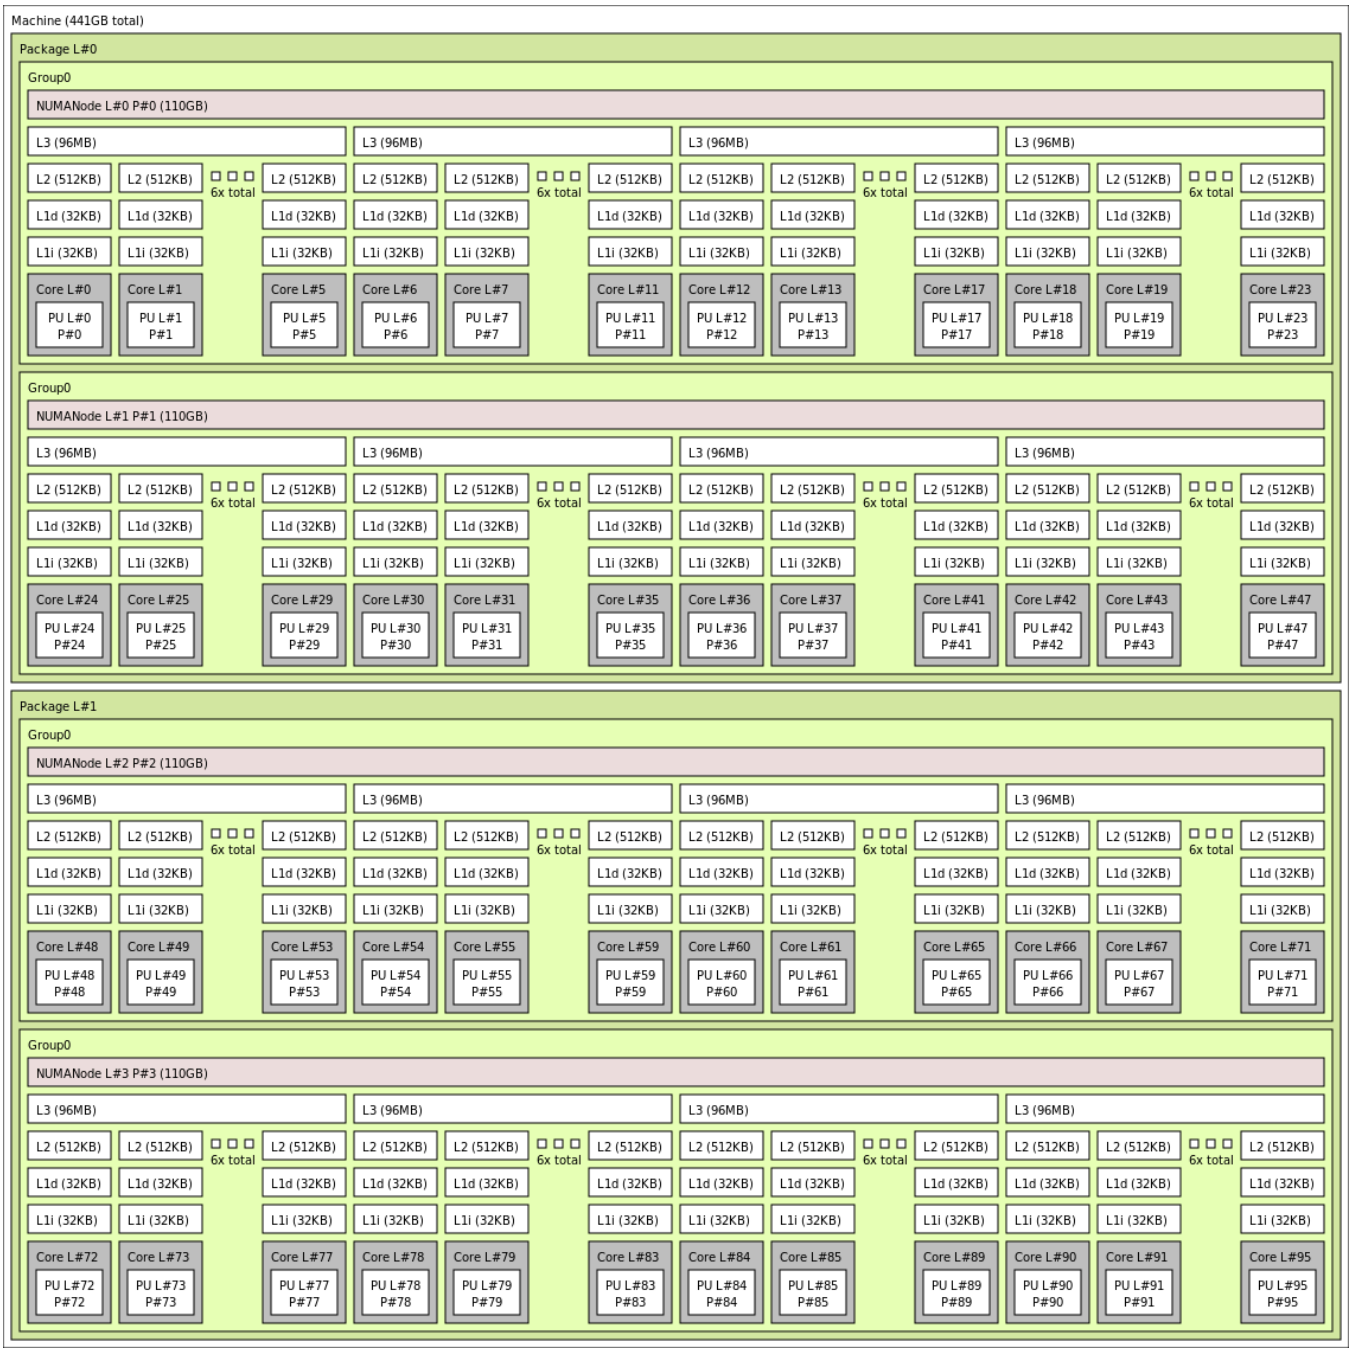
Bash

```
lstopo-no-graphics --no-io --no-legend --of txt
```

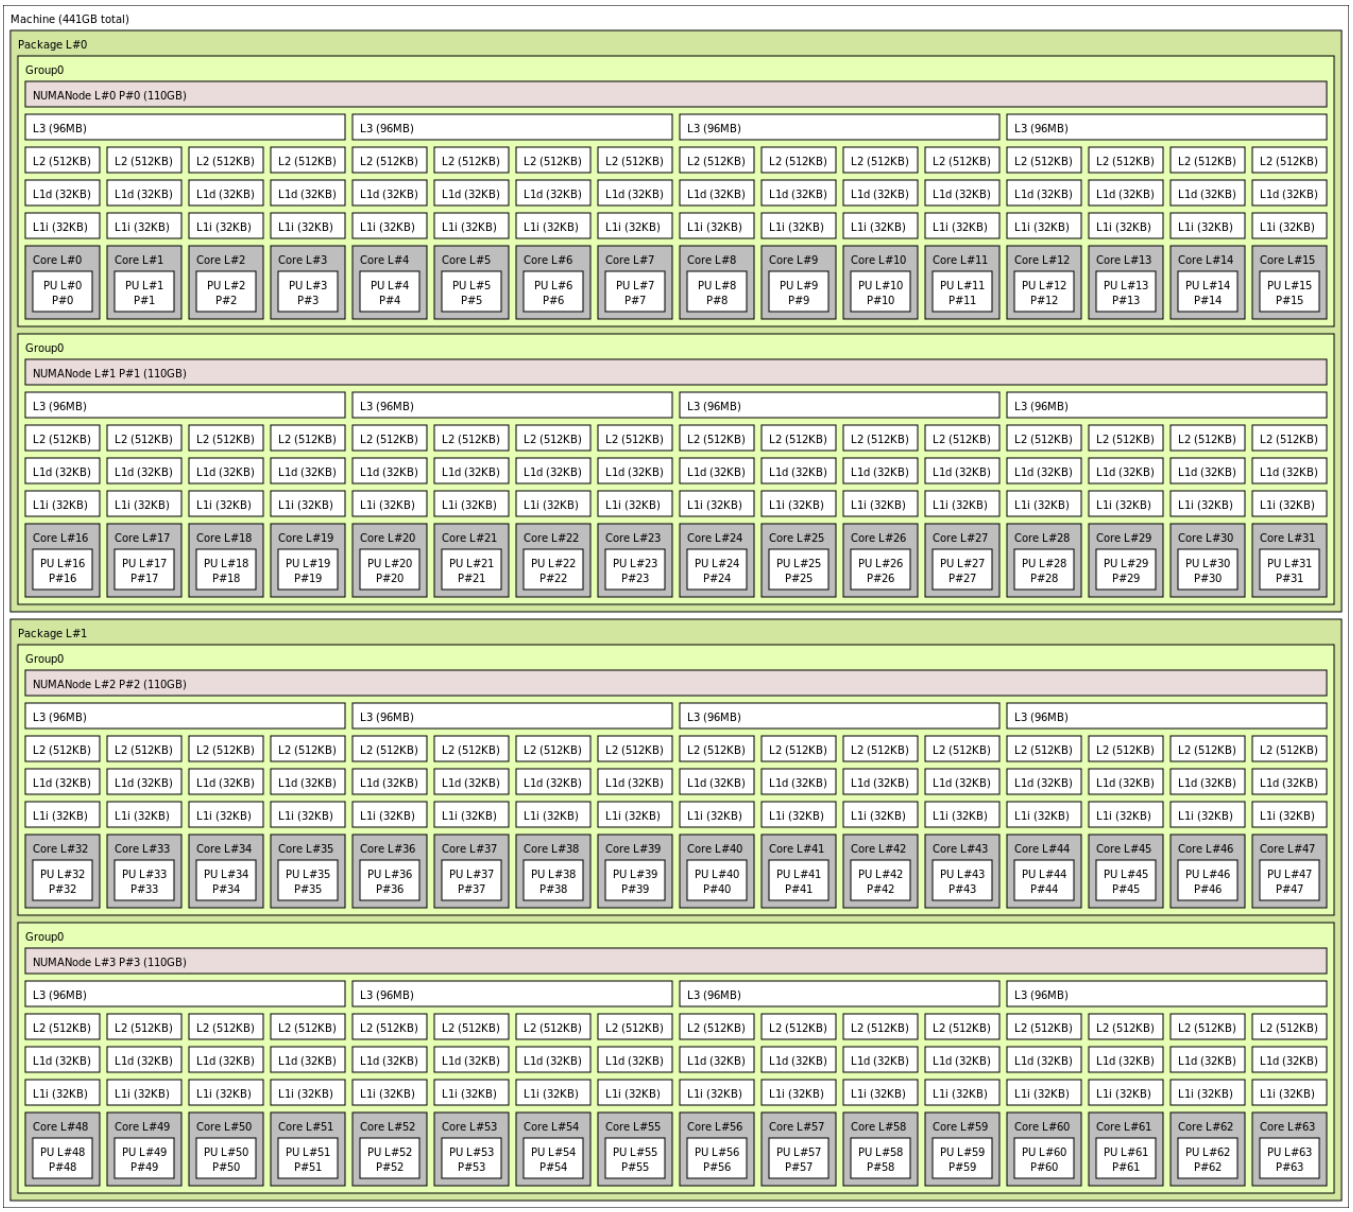
▼ Click to view lstopo output for Standard_HB120rs_v3



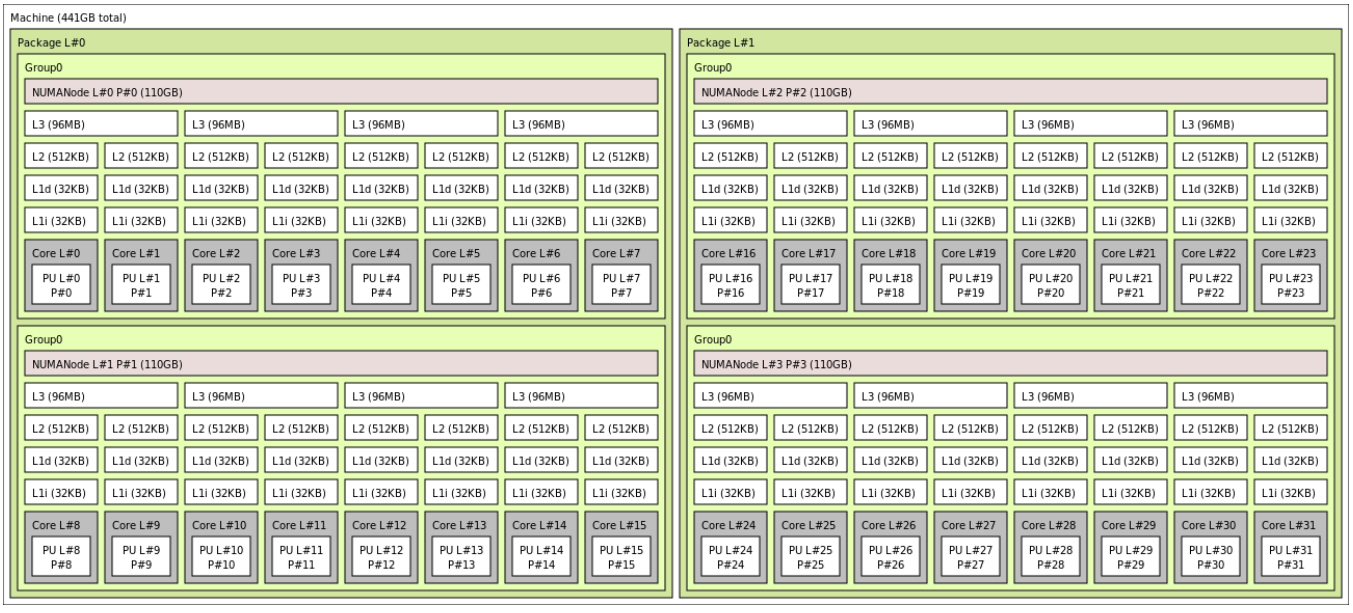
▼ Click to view lstopo output for Standard_HB120rs-96_v3



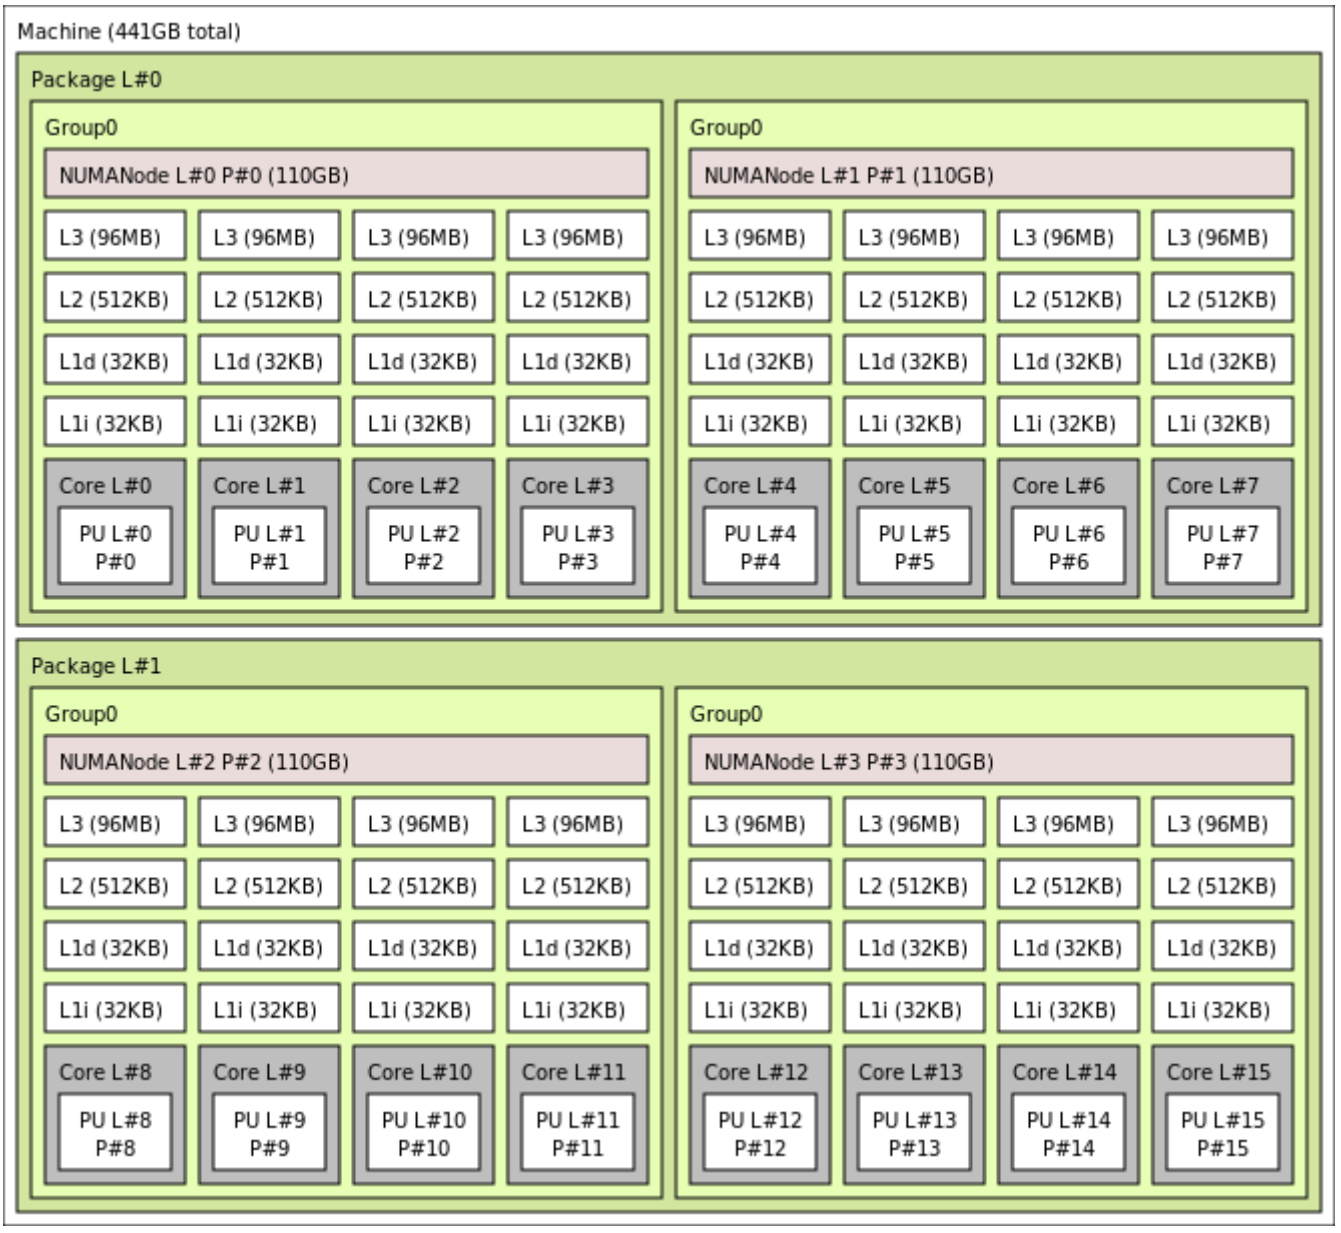
▼ Click to view lstopo output for Standard_HB120rs-64_v3



▼ Click to view lstopo output for Standard_HB120rs-32_v3



▼ Click to view lstopo output for Standard_HB120rs-16_v3



InfiniBand networking

HBv3 VMs also feature NVIDIA Mellanox HDR InfiniBand network adapters (ConnectX-6) operating at up to 200 Gigabits/sec. The NIC is passed through to the VM via SRIOV, enabling network traffic to bypass the hypervisor. As a result, customers load standard Mellanox OFED drivers on HBv3 VMs as they would a bare metal environment.

HBv3 VMs support Adaptive Routing, the Dynamic Connected Transport (DCT, along with standard RC and UD transports), and hardware-based offload of MPI collectives to the onboard processor of the ConnectX-6 adapter. These features enhance application performance, scalability, and consistency, and usage of them is recommended.

Temporary storage

HBv3 VMs feature 3 physically local SSD devices. One device is preformatted to serve as a page file and it appeared within your VM as a generic "SSD" device.

Two other, larger SSDs are provided as unformatted block NVMe devices via NVMeDirect. As the block NVMe device bypasses the hypervisor, it has higher bandwidth, higher IOPS, and lower latency per IOP.

When paired in a striped array, the NVMe SSD provides up to 7 GB/s reads and 3 GB/s writes, and up to 186,000 IOPS (reads) and 201,000 IOPS (writes) for deep queue depths.

Hardware specifications

Expand table

Hardware specifications	HBv3-series VMs
Cores	120, 96, 64, 32, or 16 (SMT disabled)
CPU	AMD EPYC 7V73X
CPU Frequency (non-AVX)	3.0 GHz (all cores), 3.5 GHz (up to 10 cores)
Memory	448 GB (RAM per core depends on VM size)
Local Disk	2 * 960 GB NVMe (block), 480 GB SSD (page file)
Infiniband	200 Gb/s Mellanox ConnectX-6 HDR InfiniBand
Network	50 Gb/s Ethernet (40 Gb/s usable) Azure second Gen SmartNIC

Software specifications

Expand table

Software specifications	HBv3-series VMs
Max MPI Job Size	36,000 cores (300 VMs in a single Virtual Machine Scale Set with singlePlacementGroup=true)

HBv3 sizes series

Summarize this article for me

HBv3-series Virtual Machines (VMs) are designed for very demanding computing tasks. They help with things like studying how liquids move, analyzing structures, predicting weather, and processing earthquake data. They also support oil reservoir modeling and testing computer chip designs. HBv3 VMs feature up to 120 AMD EPYC™ 7V73X (Milan-X) CPU cores, 448 GB of RAM, and no simultaneous multithreading. HBv3-series VMs also provide 350 GB/sec of memory bandwidth (amplified up to 630 GB/s), up to 96 MB of L3 cache per core (1536 MB total per VM), up to 7 GB/s of block device SSD performance, and clock frequencies up to 3.5 GHz. All HBv3-series VMs feature 200 Gb/sec High Data Rate (HDR) InfiniBand from NVIDIA Networking to enable supercomputer-scale Message Pass Interface (MPI) workloads. These VMs are connected in a nonblocking fat tree for optimized and consistent RDMA performance. The HDR InfiniBand fabric also supports Adaptive Routing and Dynamic Connected Transport (DCT), along with standard Reliable Connection (RC) and Unreliable Datagram (UD) transports. These features improve performance, make scaling easier, and keep results consistent.

HBv3-series virtual machine performance

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Performance expectations using common HPC microbenchmarks are as follows:

Expand table

Workload	HBv3
STREAM Triad	330-350 GB/s (amplified up to 630 GB/s)
High-Performance Linpack (HPL)	4 TF (Rpeak, FP64), 8 TF (Rpeak, FP32) for 120-core VM size
RDMA latency & bandwidth	1.2 microseconds (1 byte), 192 GB/s (one-way)
FIO on local NVMe SSDs (RAID0)	7 GB/s reads, 3 GB/s writes; 186k IOPS reads, 201k IOPS writes

Process pinning

Process pinning works well on HBv3-series VMs because we expose the underlying silicon as-is to the guest VM. We strongly recommend process pinning for optimal performance and consistency.

MPI latency

The MPI latency test from the OSU microbenchmark suite can be executed as shown. Sample scripts are on GitHub.

Bash

```
./bin/mpirun_rsh -np 2 -hostfile ~/hostfile MV2_CPU_MAPPING=[INSERT CORE #]
./osu_latency
```

MPI bandwidth

The MPI bandwidth test from the OSU Micro-Benchmark (OMB) suite can be executed as shown. Sample scripts are on GitHub.

Bash

```
./mvapich2-2.3.install/bin/mpirun_rsh -np 2 -hostfile ~/hostfile MV2_CPU_MAPPING=
[INSERT CORE #] ./mvapich2-2.3/osu_benchmarks/mpi/pt2pt/osu_bw
```

Mellanox Perftest

The Mellanox Perftest package has many InfiniBand tests such as latency (ib_send_lat) and bandwidth (ib_send_bw). The following command serves as an example.

Bash

```
numactl --physcpubind=[INSERT CORE #]  ib_send_lat -a
```

HBv4-series virtual machine overview

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

An HBv4-series server features 2 * 96-core EPYC 9V33X CPUs for a total of 192 physical "Zen4" cores with AMD 3D-V Cache. Simultaneous Multithreading (SMT) is disabled on HBv4. These 192 cores are divided into 24 sections (12 per socket), each section containing eight processor cores with uniform access to a 96 MB L3 cache. Azure HBv4 servers also run the following AMD BIOS settings:

Bash

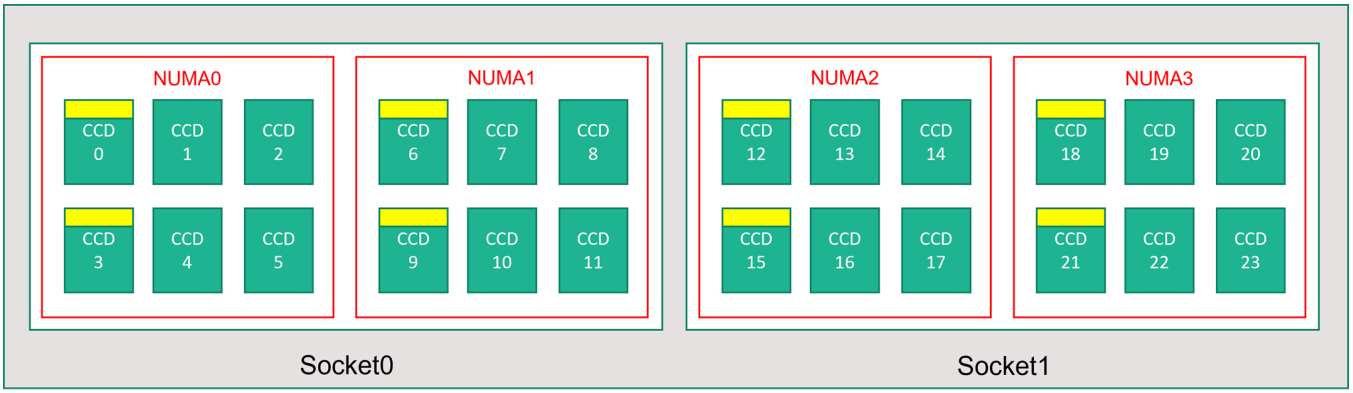
```
Nodes per Socket (NPS) = 2
L3 as NUMA = Disabled
NUMA domains within VM OS = 4
C-states = Enabled
```

As a result, the server boots with four NUMA domains (2 per socket) each 48-cores in size. Each NUMA has direct access to six channels of physical DRAM.

To provide room for the Azure hypervisor to operate without interfering with the VM, we reserve 16 physical cores per server.

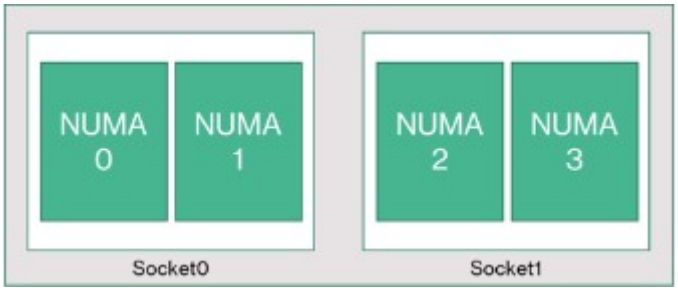
VM topology

The following diagram shows the topology of the server. We reserve these 16 hypervisor host cores (yellow) symmetrically across both CPU sockets, taking the first two cores from specific Core Complex Dies (CCDs) in each NUMA domain, with the remaining cores for the HBv4-series VM (green).



The CCD boundary is different from a NUMA boundary. On HBv4, a group of six (6) consecutive CCDs is configured as a NUMA domain, both at the host server level and within a guest VM.

Thus, all HBv4 VM sizes expose four uniform NUMA domains that appear to an OS and application as shown below, each with different number of cores depending on the specific HBv4 VM size.



Each HBv4 VM size is similar in physical layout, features, and performance of a different CPU from the AMD EPYC 9V33X, as follows:

Expand table

HBv4-series VM size	NUMA domains	Cores per NUMA domain	Similarity with AMD EPYC
Standard_HB176rs_v4	4	44	Dual-socket EPYC 9V33X
Standard_HB176-144rs_v4	4	36	Dual-socket EPYC 9V33X
Standard_HB176-96rs_v4	4	24	Dual-socket EPYC 9V33X
Standard_HB176-48rs_v4	4	12	Dual-socket EPYC 9V33X
Standard_HB176-24rs_v4	4	6	Dual-socket EPYC 9V33X

> **Note**
>
> - The constrained cores VM sizes only reduce the number of physical cores exposed to the VM. All global shared assets (RAM, memory bandwidth, L3 cache, GMI and xGMI connectivity, InfiniBand, Azure Ethernet network, local SSD) stay constant. This allows a customer to pick a VM size best tailored to a given set of workload or software licensing needs.
> - We are currently experiencing a core mapping issue on the HBv4-series parent size Standard_HB176rs_v4.

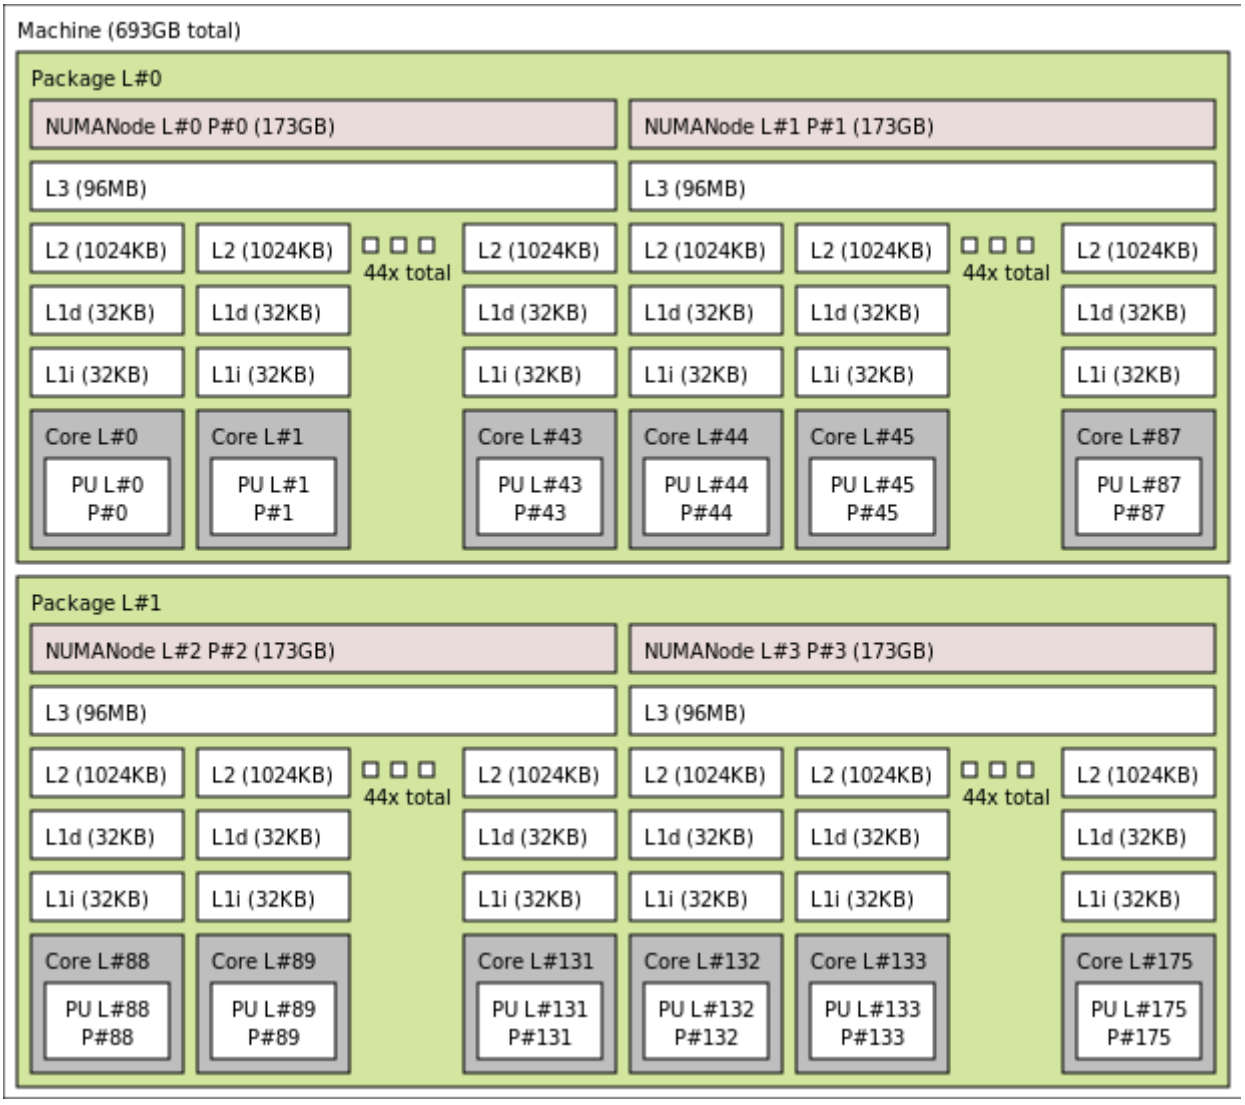
The virtual NUMA mapping of each HBv4 VM size is mapped to the underlying physical NUMA topology. There's no potential misleading abstraction of the hardware topology.

The exact topology for the various HBv4 VM size appears as follows using the output of lstopo:

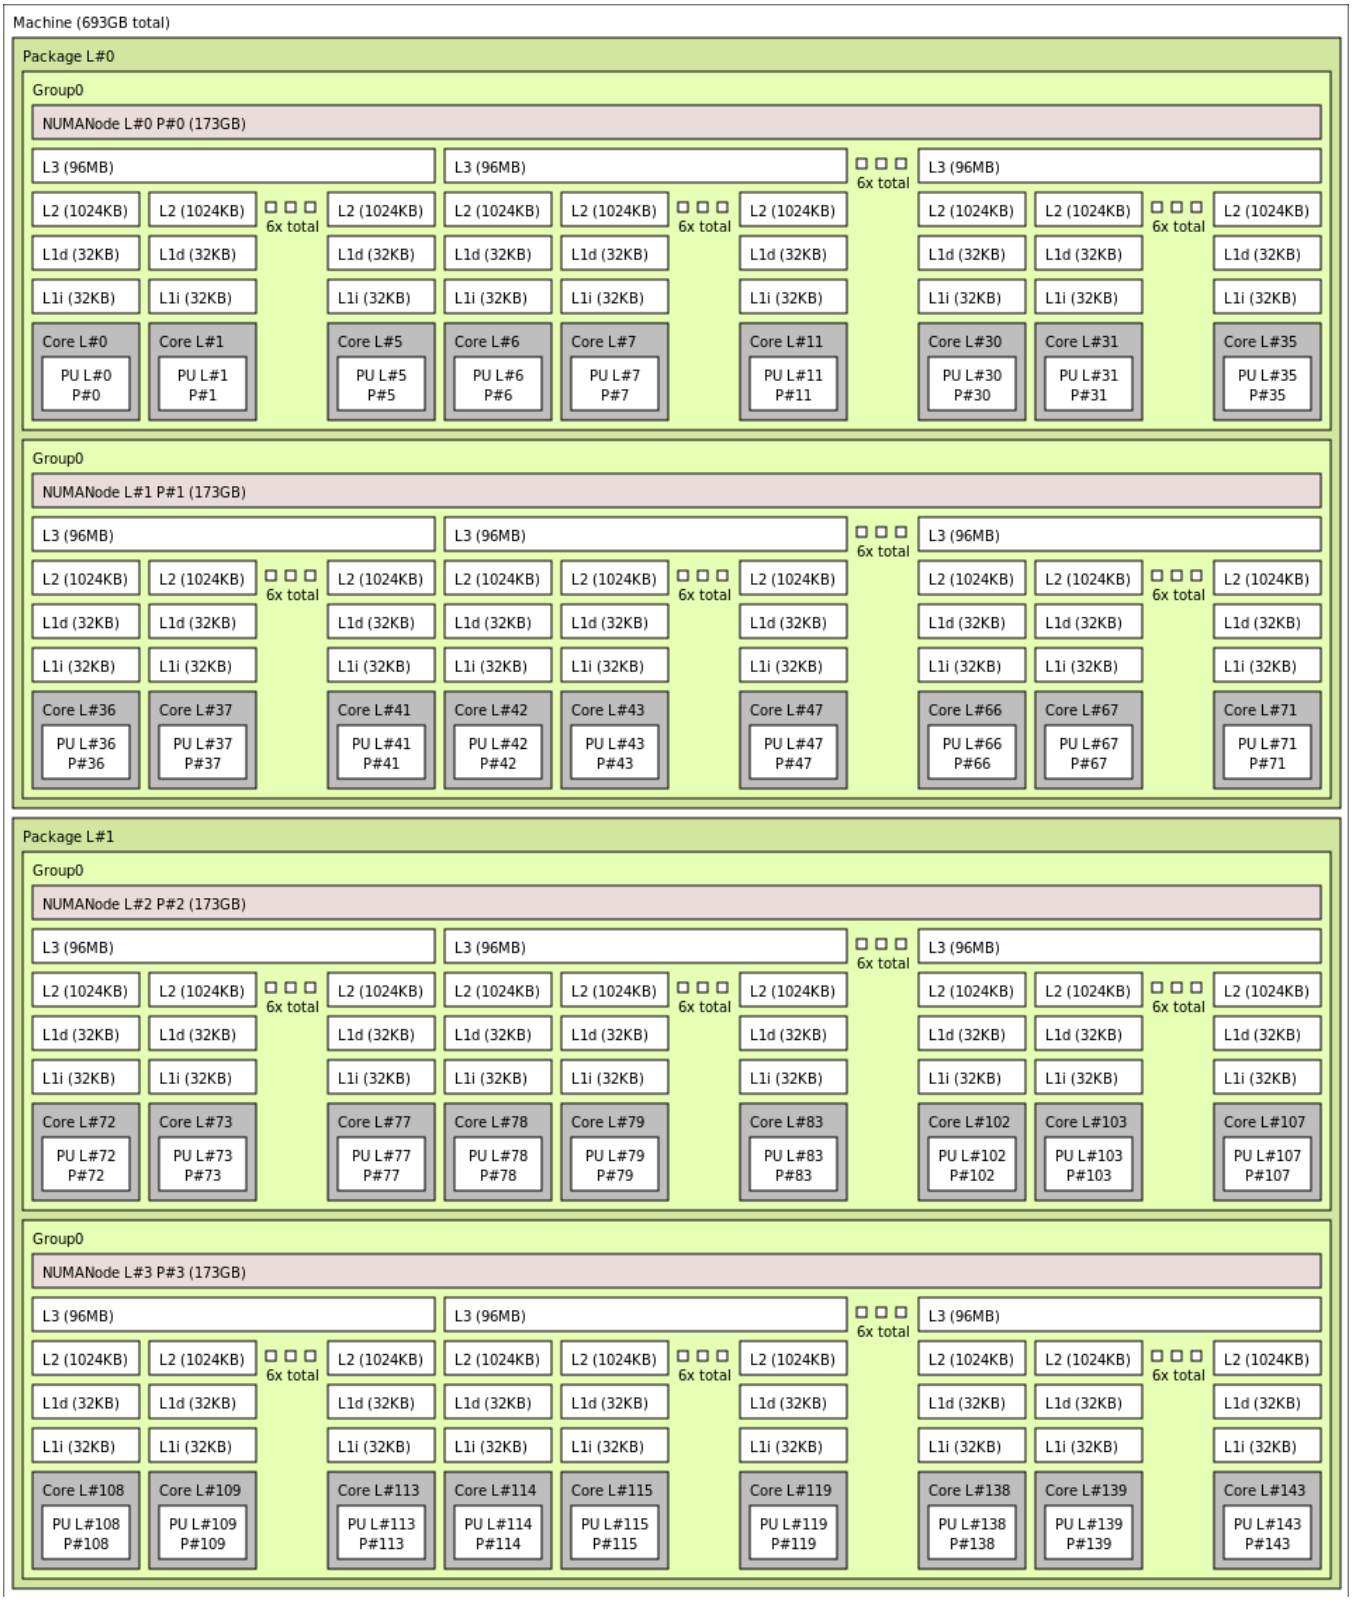
Bash

```
lstopo-no-graphics --no-io --no-legend --of txt
```

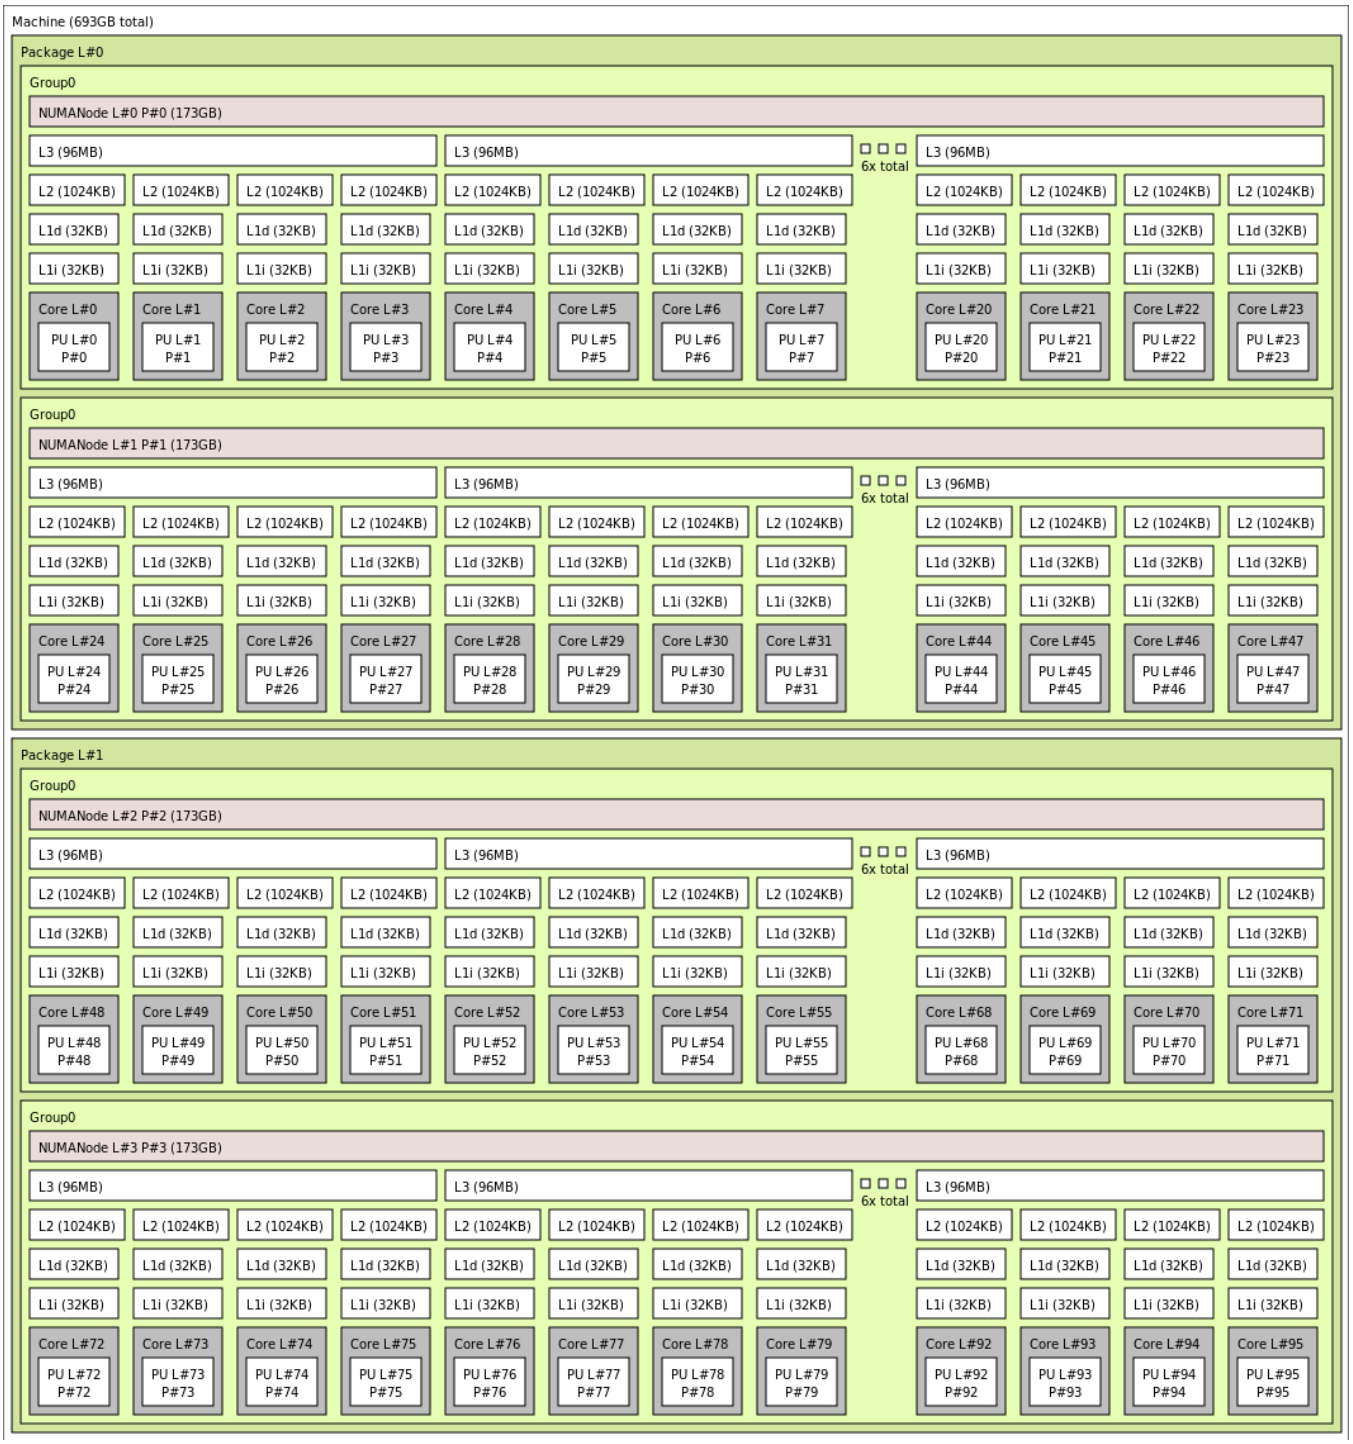
▼ Select to view lstopo output for Standard_HB176rs_v4



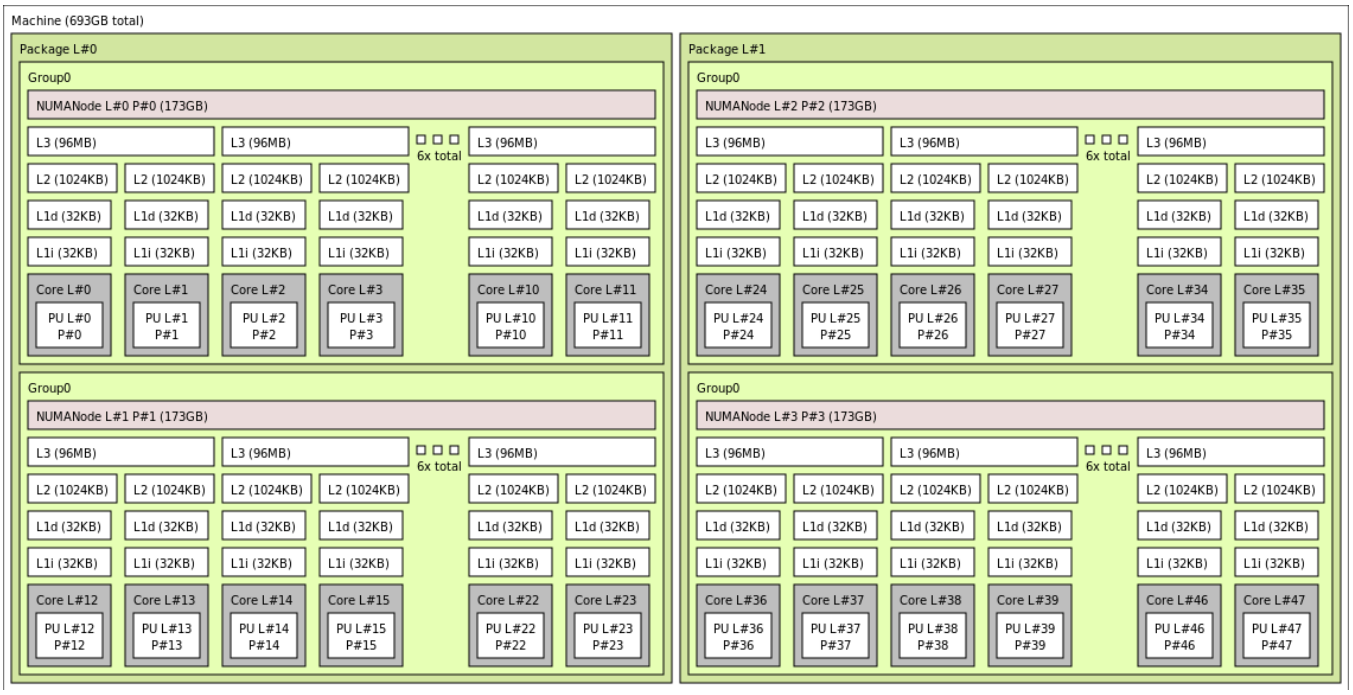
▼ Select to view lstopo output for Standard_HB176-144rs_v4



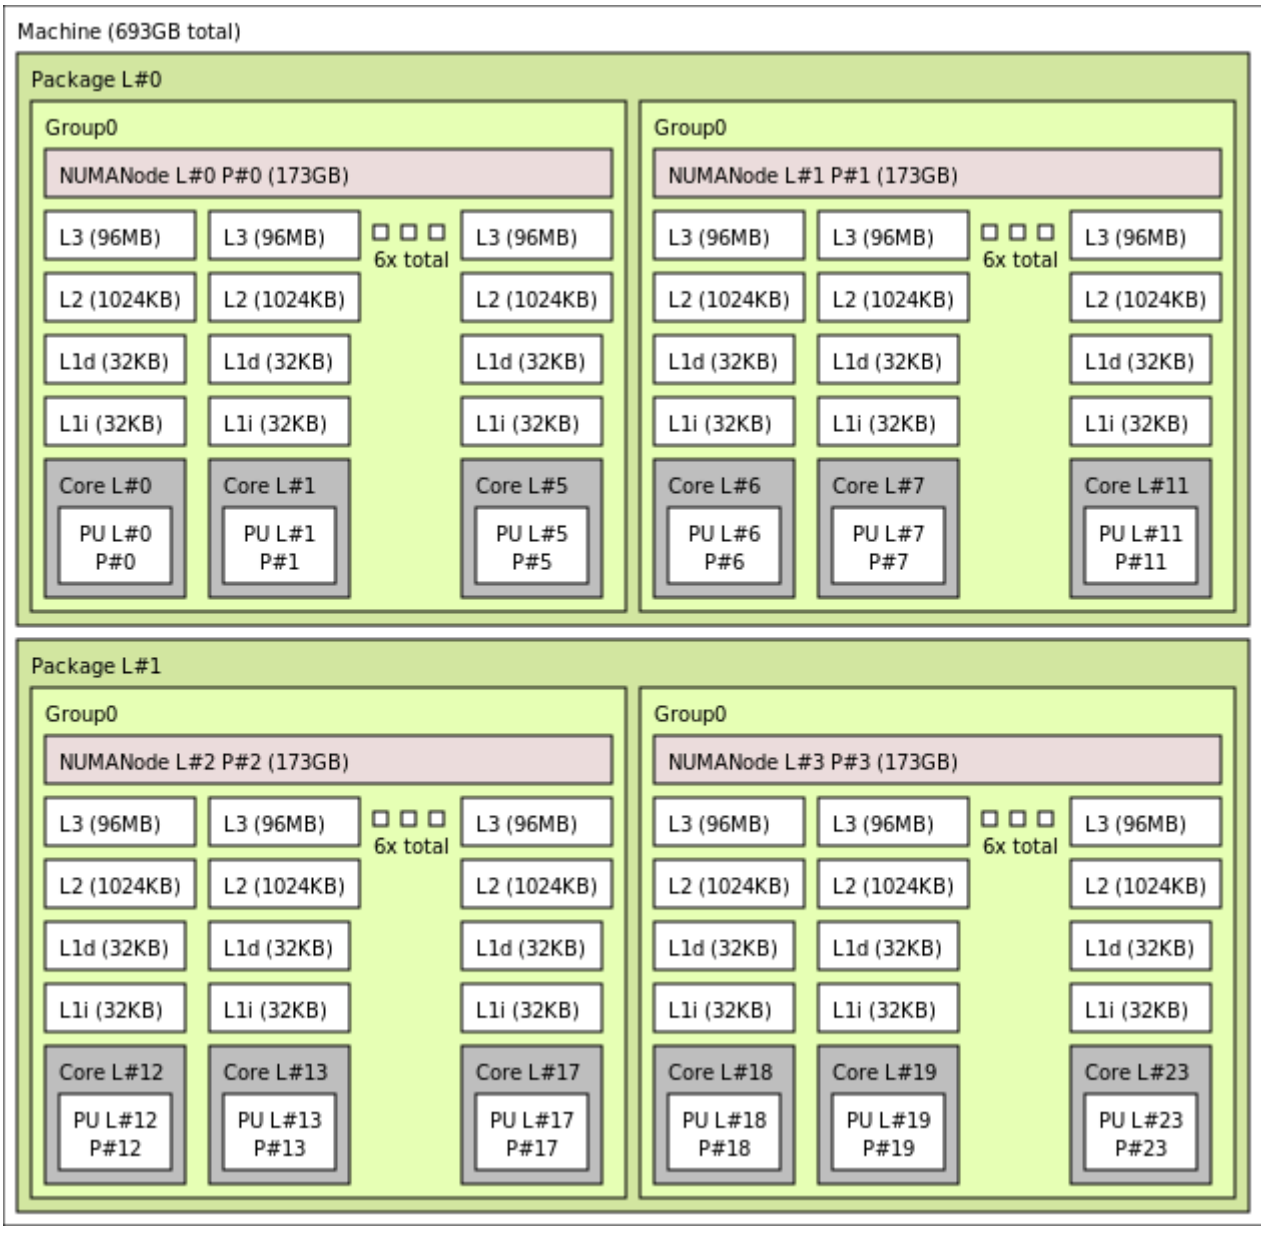
▼ Select to view lstopo output for Standard_HB176-96rs_v4



▼ Select to view lstopo output for Standard_HB176-48rs_v4



▼ Select to view lstopo output for Standard_HB176-24rs_v4



InfiniBand networking

HBv4 VMs also feature NVIDIA Mellanox NDR InfiniBand network adapters (ConnectX-7) operating at up to 400 Gigabits/sec. The NIC is passed through to the VM via SRIOV, enabling network traffic to bypass the hypervisor. As a result, customers load standard Mellanox OFED drivers on HBv4 VMs as they would a bare metal environment.

HBv4 VMs support Adaptive Routing, Dynamic Connected Transport (DCT, in addition to the standard RC and UD transports), and hardware-based offload of MPI collectives to the onboard processor of the ConnectX-7 adapter. These features enhance application performance, scalability, and consistency, and usage of them is recommended.

Temporary storage

HBv4 VMs feature three physically local SSD devices. One device is preformatted to serve as a page file and it appeared within your VM as a generic "SSD" device.

Two other, larger SSDs are provided as unformatted block NVMe devices via NVMeDirect. As the block NVMe device bypasses the hypervisor, it has higher bandwidth, higher IOPS, and lower latency per IOP.

When paired in a striped array, the NVMe SSD provides up to 12 GB/s reads and 7 GB/s writes, and up to 186,000 IOPS (reads) and 201,000 IOPS (writes) for deep queue depths.

Hardware specifications

Expand table

Hardware specifications	HBv4-series VMs
Cores	176, 144, 96, 48, or 24 (SMT disabled)
CPU	AMD EPYC 9V33X
CPU Frequency (non-AVX)	2.55 GHz base, 3.7 GHz peak boost
Memory	768 GB (RAM per core depends on VM size)
Local Disk	2 * 1.8-TB NVMe (block), 480 GB SSD (page file)
InfiniBand	400 Gb/s Mellanox ConnectX-7 NDR InfiniBand
Network	100 Gb/s Ethernet (80 Gb/s usable) Azure second Gen SmartNIC

Software specifications

Expand table

Software specifications	HBv4-series VMs
Max MPI Job Size	52,800 cores (300 VMs in a single virtual machine scale set with singlePlacementGroup=true)
MPI Support	HPC-X (2.13 or higher), Intel MPI (2021.7.0 or higher), OpenMPI (4.1.3 or higher), MVAPICH2 (2.3.7 or higher), MPICH (4.1 or higher)
Additional Frameworks	UCX, libfabric, PGAS, or other InfiniBand based runtimes
Azure Storage Support	Standard and Premium Disks (maximum 32 disks), Azure NetApp Files, Azure Files, Azure HPC Cache, Azure Managed Lustre File System
Supported and Validated OS	AlmaLinux 8.6, 8.7, Ubuntu 20.04+
Recommended OS for Performance	AlmaLinux HPC 8.7, Ubuntu-HPC 20.04+
Orchestrator Support	Azure CycleCloud, Azure Batch, AKS; cluster configuration options

Note

- These VMs support only Generation 2.
- Official kernel-level support from AMD starts with RHEL 8.6 and AlmaLinux 8.6, which is a derivative of RHEL.
- Windows Server 2012 R2 isn't supported on HBv4 and other VMs with more than 64 (virtual or physical) cores. For more information, see Supported Windows guest operating systems for Hyper-V on Windows Server. Windows Server 2022 is required for 144 and 176 core sizes, Windows Server 2016 also works for 24, 48, and 96 core sizes, Windows Server works for only 24 and 48 core sizes.

Important

Recommended image URN: almalinux:almalinux-hpc:8_7-hpc-gen2:8.7.2023060101, To deploy this image over Azure CLI, ensure the following parameters are included **--plan 8_7-hpc-gen2 --product almalinux-hpc --publisher almalinux**. For scaling tests please use the recommended URN along with the new HPC-X tarball.

> **Note**
>
> - NDR support is added in UCX 1.13 or later. Older UCX versions will report the above runtime error. UCX Error: Invalid active speed `[1677010492.951559] [updsb-vm-0:2754 :0] ib_iface.c:1549 UCX ERROR Invalid active_speed on mlx5_ib0:1: 128`.
> - Ibstat shows low speed (SDR): Older Mellanox OFED (MOFED) versions don't support NDR and it may report slower IB speeds. Use MOFED versions MOFED 5.6-1.0.3.3 or above.

HBv4 sizes series

Summarize this article for me

HBv4-series VMs are optimized for many high-performance computing (HPC) workloads. These include:

- Computational fluid dynamics
- Finite element analysis
- Frontend and backend Electronic Design Automation (EDA)
- Rendering and graphics work
- Molecular dynamics
- Computational geoscience
- Weather simulation
- Financial risk analysis

HBv4 VMs feature up to 176 AMD EPYC™ 9V33X ("Genoa-X") CPU cores with AMD's 3D V-Cache, clock frequencies up to 3.7 GHz, and no simultaneous multithreading. HBv4-series VMs also provide 768 GB of RAM, 2304 MB L3 cache. Each VM has 2304 MB of L3 cache that delivers up to 5.7 TB/s of bandwidth. This boosts DRAM bandwidth of 780 GB/s, giving an average of 1.2 TB/s of effective memory speed for many workloads. The VMs also provide up to 12 GB/s (reads) and 7 GB/s (writes) of block device SSD performance.

All HBv4-series VMs feature 400 Gb/s NDR InfiniBand from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. NDR continues to support features like Adaptive Routing and the Dynamically Connected Transport (DCT). This newest generation of InfiniBand also brings greater support for offload of MPI collectives, optimized real-world latencies due to congestion control intelligence, and enhanced adaptive routing capabilities. These features enhance application performance, scalability, and consistency, and their usage is recommended.

HBv4-series virtual machine performance

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Performance expectations using common HPC microbenchmarks are as follows:

Expand table

Workload	HBv4
STREAM Triad	750-780 GB/s of DDR5, up to 5.7 TB/s of 3D V-Cache bandwidth
High-Performance Linpack (HPL)	Up to 7.6 TF (Rpeak, FP64) for 144-core VM size
RDMA latency & bandwidth	< 2 microseconds (1 byte), 400 Gb/s (one-way)
FIO on local NVMe SSDs (RAID0)	12 GB/s reads, 7 GB/s writes; 186k IOPS reads, 201k IOPS writes

Process pinning

Process pinning works well on HBv4-series VMs because we expose the underlying silicon as-is to the guest VM. We strongly recommend process pinning for optimal performance and consistency.

Memory bandwidth test

The STREAM memory test can be run using the scripts in this GitHub repository.

Bash

```
git clone https://github.com/Azure/woc-benchmarking
cd woc-benchmarking/apps/hpc/stream/
sh build_stream.sh
sh stream_run_script.sh $PWD “hbrs_v4”
```

Compute performance test

The HPL benchmark can be run using the script in this GitHub repository.

Bash

```
git clone https://github.com/Azure/woc-benchmarking
cd woc-benchmarking/apps/hpc/hpl
sh hpl_build_script.sh
sh hpl_run_scr_hbv4.sh $PWD
```

MPI latency

The MPI latency test from the OSU microbenchmark suite can be executed as shown. Sample scripts are on GitHub.

Bash

```
module load mpi/hpcx
mpirun -np 2 --host $src,$dst --map-by node -x LD_LIBRARY_PATH
$HPCX_OSU_DIR/osu_latency
```

MPI bandwidth

The MPI bandwidth test from the OSU microbenchmark suite can be executed per below. Sample scripts are on GitHub.

Bash

```
module load mpi/hpcx
mpirun -np 2 --host $src,$dst --map-by node -x LD_LIBRARY_PATH $HPCX_OSU_DIR/osu_bw
```

[!NOTE] Define source(src) and destination(dst).

Mellanox Perftest

The Mellanox Perftest package has many InfiniBand tests such as latency (ib_send_lat) and bandwidth (ib_send_bw). An example command is below.

Console

```
numactl --physcpubind=[INSERT CORE #]  ib_send_lat -a
```

> **Note**
>
> The NUMA node affinity for InfiniBand NIC is NUMA0.

Next steps

Last updated on 02/10/2026

HBv5-series virtual machine overview

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

An HBv5-series server features 4 * 96-core 4th Generation AMD EPYC™ CPUs for a total of 384 physical "Zen4" cores with Simultaneous Multithreading (SMT) disabled. These 384 cores are divided into 48 Core Chiplet Dies (CCDs) sections (12 per socket), and each CCD containing eight processor cores with uniform access to a 32 MB L3 cache. Azure HBv5 servers also run the following AMD BIOS settings:

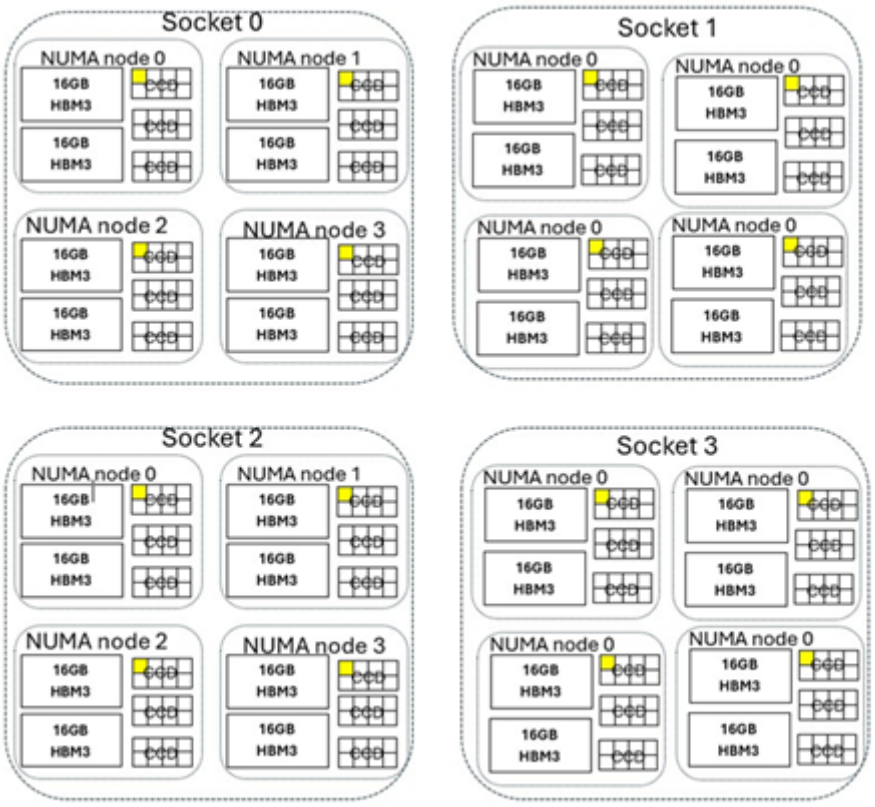
```bash
Nodes per Socket (NPS) = 4
L3 as NUMA = Disabled
Total NUMA domains within VM OS = 16 (4 per socket)
NUMA domains within VM OS = 4
C-states = Enabled
Determinism Mode = Power
```

As a result, the server boots with 16 NUMA domains (4 per socket) each 24-cores in size. Each NUMA has direct access two 16GB HBM3 modules.

To provide room for the Azure hypervisor to operate without interfering with the VM, we reserve 4 physical cores per NUMA and 16 per server.

VM topology

The following diagram shows the topology of the server. We reserve these 16 hypervisor host cores (yellow), taking the first core from specific Core Complex Dies (CCDs) in each NUMA domain, with the remaining cores for the HBv5-series VM (green).



The CCD boundary is different from a NUMA boundary. On HBv5, a group of six (6) consecutive CCDs is configured as a NUMA domain, both at the host server level and within a guest VM. Thus, all HBv5 VM sizes expose four uniform NUMA domains that appear to an OS and application as shown beneath, each with different number of cores depending on the specific HBv5 VM size.

Each HBv5 VM size is similar in physical layout, features, and performance of a different CPU from the AMD EPYC 9V33X, as follows:

Expand table

HBv5-series VM size	NUMA domains	Cores per NUMA domain
Standard_HB368rs_v5	16	23
Standard_HB368-336rs_v5	16	21
Standard_HB368-288rs_v5	16	18
Standard_HB368-240rs_v5	16	15
Standard_HB368-192rs_v5	16	12
Standard_HB368-144rs_v5	16	9
Standard_HB368-96rs_v5	16	6
Standard_HB368-48rs_v5	16	3

> **Note**
>
> - The constrained cores VM sizes only reduce the number of physical cores exposed to the VM. All global shared assets (RAM, memory bandwidth, L3 cache, GMI and xGMI connectivity, InfiniBand, Azure Ethernet network, local SSD) stay constant with the parent VM size. It allows the customer to pick a VM size best tailored to a given set of workload or software licensing needs.
> - Four CPU cores/CCD are needed to saturate memory bandwidth. This requirement means those Standard_HB368-144rs_v5, Standard_HB368-96rs_v5, and Standard_HB368-48rs_v5 VM sizes can't achieve full memory bandwidth of the server.

The virtual NUMA mapping of each HBv5 VM size is mapped to the underlying physical NUMA topology. There's no potential misleading abstraction of the hardware topology.

The exact topology for the various HBv5 VM size appears as follows using the output of lstopo :

Bash

```
lstopo-no-graphics --no-io --no-legend --of txt
```

▼ Select to view lstopo output for Standard_HB368rs_v5

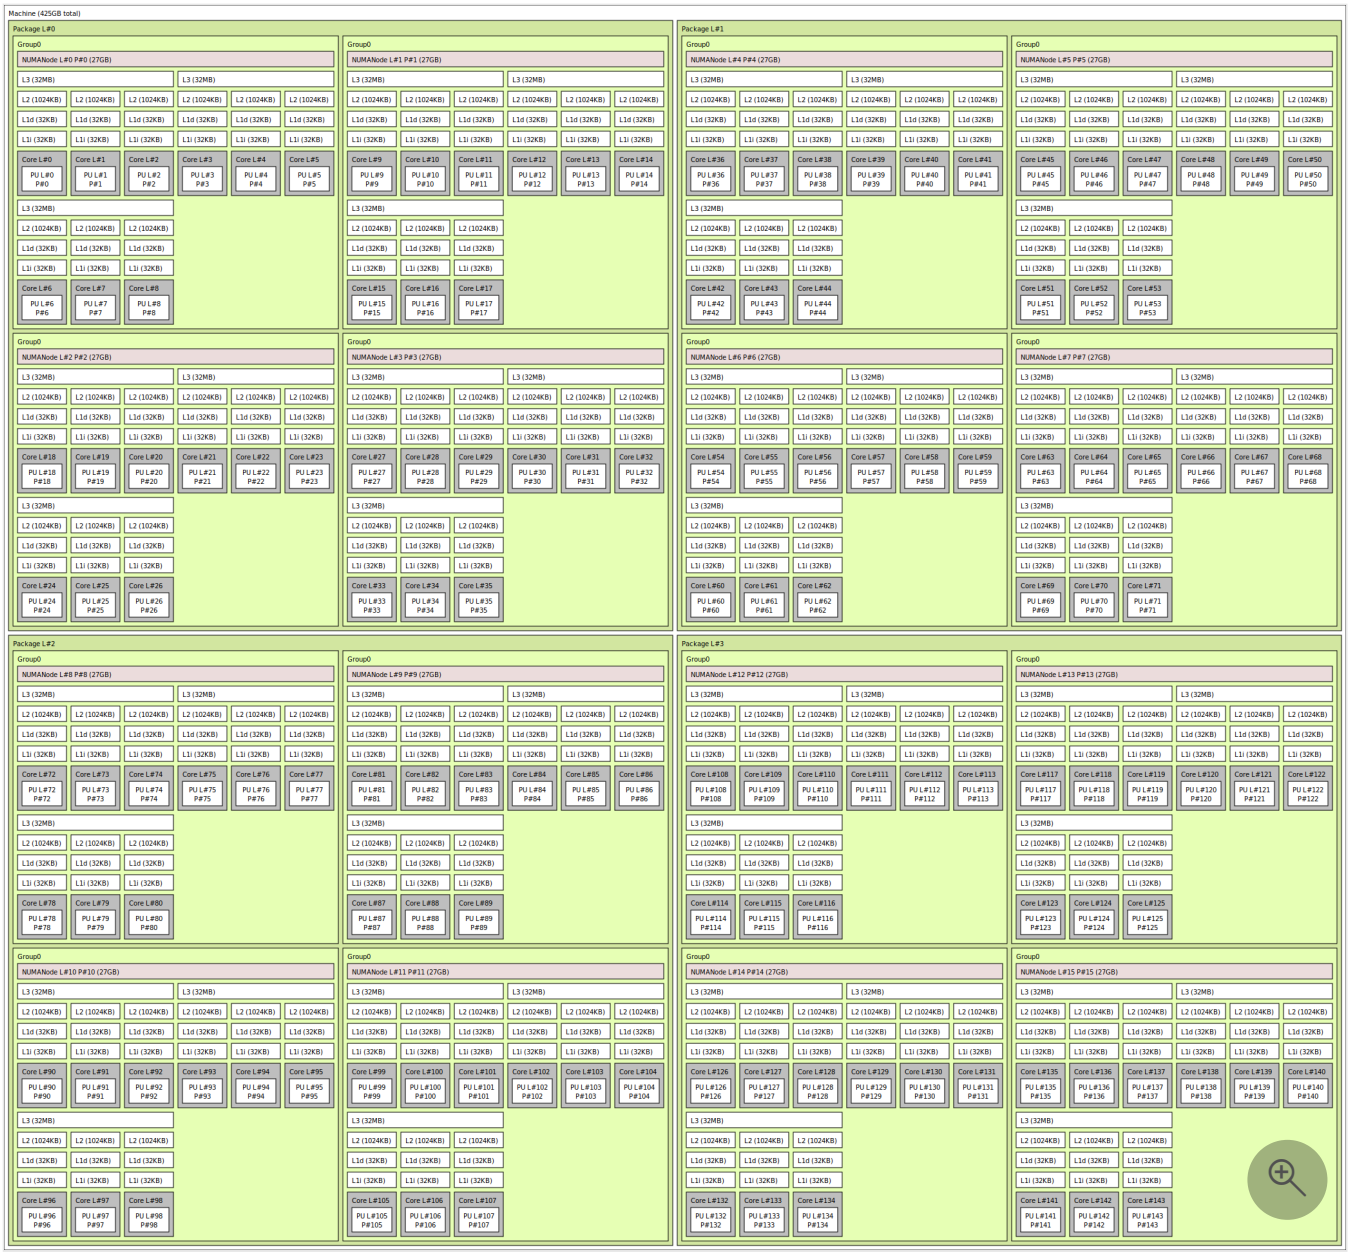
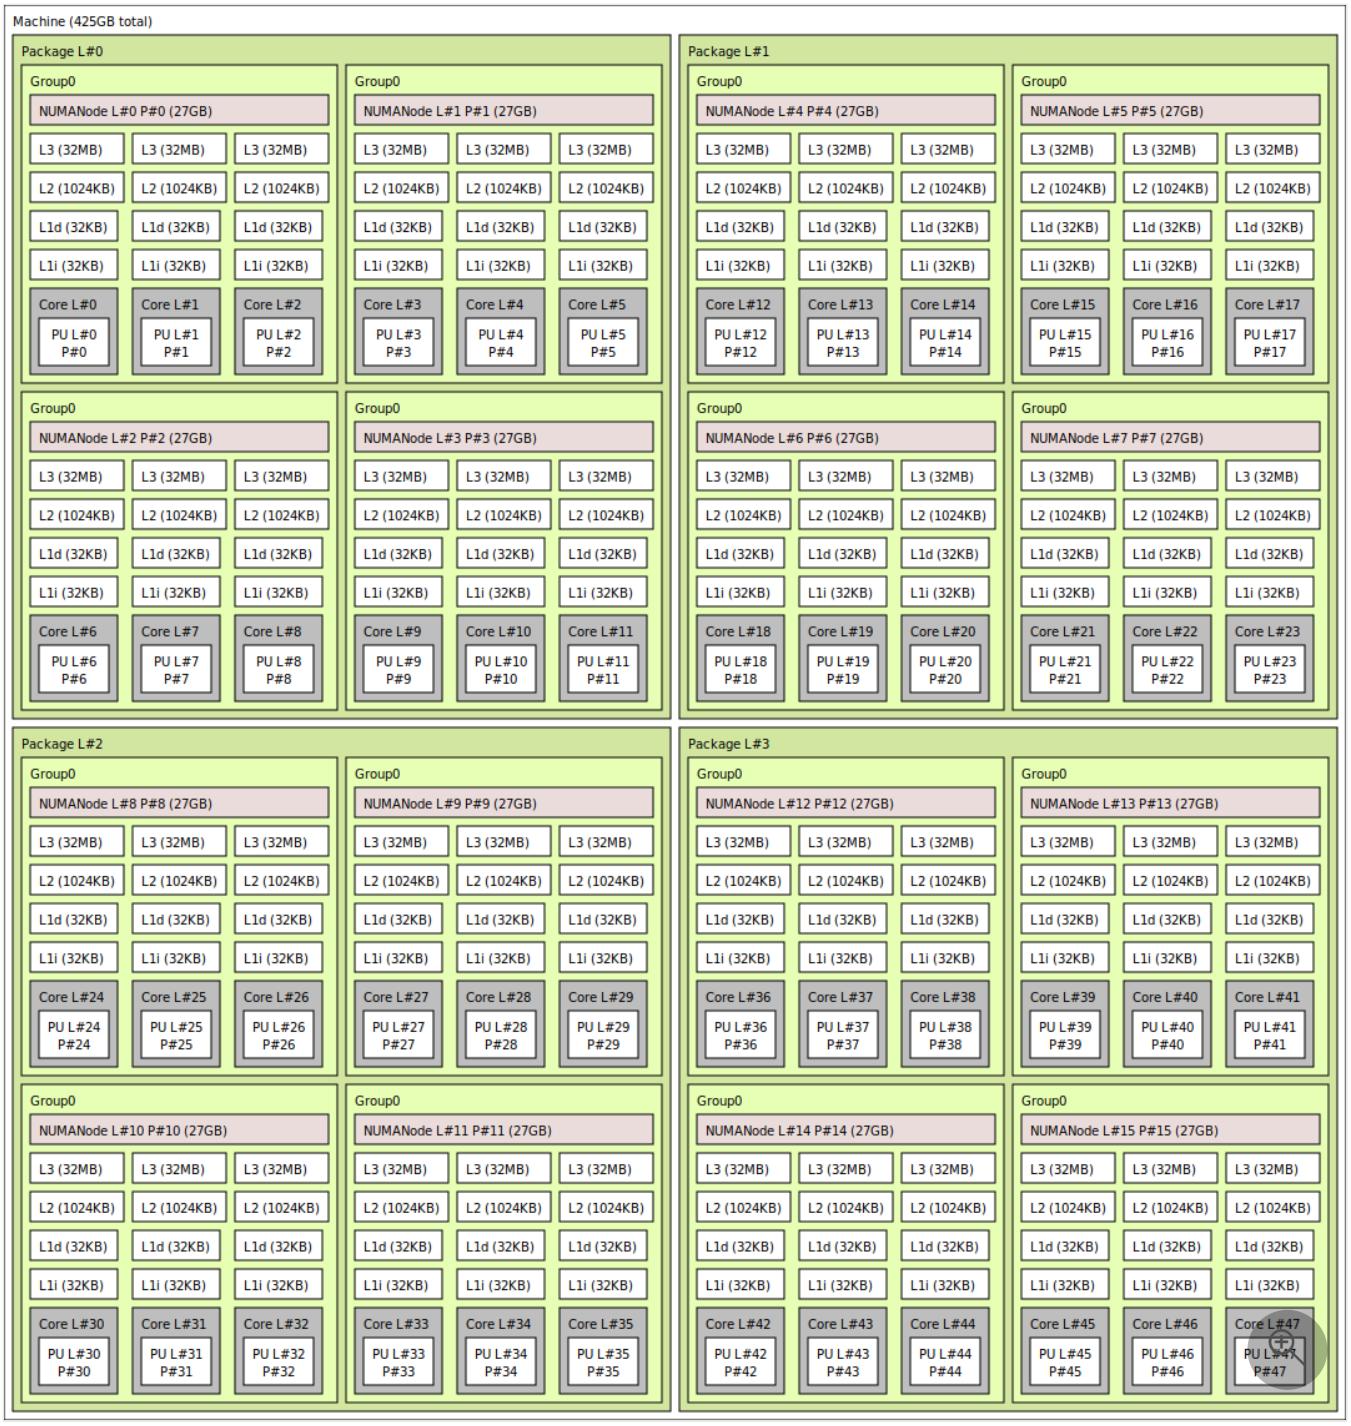
▼ Select to view lstopo output for Standard_HB368-144rs_v5



▼ Select to view lstopo output for Standard_HB368-96rs_v5

▼ Select to view lstopo output for Standard_HB368-48rs_v5



InfiniBand networking

HBv5 VMs also feature 4 NVIDIA Quantum-2 CX7 InfiniBand (NDR) adapters each operating at up to 200 Gigabits/sec for a total of 800 Gigabits/sec per VM. One NIC connects to each of the 4 CPUs on each VM. The NIC is passed through to the VM via SRIOV, enabling network traffic to bypass the hypervisor. As a result, customers load standard Mellanox OFED drivers on HBv5 VMs as they would a bare metal environment.

HBv5 VMs support Adaptive Routing, Dynamic Connected Transport (DCT, in addition to the standard RC and UD transports), and hardware-based offload of MPI collectives to the onboard processor of the ConnectX-7 adapter. These features enhance application performance, scalability, and consistency, and usage of them is recommended.

Best practices for InfiniBand configuration

- Use a validated VM image. Choose an image with tested drivers and NDR InfiniBand-ready software:
  - **Recommended**: AlmaLinux 8.10 from the AlmaLinux HPC shared image gallery
    The Azure HPC team provides access to AlmaLinux 8.10 from the AlmaLinux HPC shared image gallery, and this image is built using Azure HPC VM Image scripts.
  - **Also supported**: Azure HPC marketplace images (Ubuntu-HPC 18.04, Ubuntu-HPC 20.04)

- Select the optimal InfiniBand transport protocol
  - For *smaller-scale jobs*:

    Bash

    ```
    UCX_TLS=rc,sm
    ```

  - For *larger-scale jobs*:

    Bash

    ```
    UCX_TLS=dc,sm UCX_MAX_RNDV_RAILS=1
    ```

- Disable multi-rail for multi-node jobs

  Bash

  ```
  export UCX_MAX_RNDV_RAILS=1
  ```

- Use the latest stable versions
  - UCX: **1.14.0 rc4** (as of September 2025)
  - HPC-X MPI: **hpcx-v2.18-gcc-mlnx_ofed-redhat8-cuda12-x86_64** (as of September 2025)

Best Practices for running MPI Jobs on HBv5

- Apply the *hpc-compute* tuned profile, which is optimized for HPC workloads:

  Bash

  ```
  sudo dnf install -y tuned
  sudo systemctl enable --now tuned
  ```

```
sudo tuned-adm profile hpc-compute
```

- Enable Transparent Huge Pages (THP) to improve memory efficiency for large allocations:

```Bash
echo madvise | sudo tee /sys/kernel/mm/transparent_hugepage/enabled
echo madvise | sudo tee /sys/kernel/mm/transparent_hugepage/defrag
```

- Enable NUMA balancing for better memory locality:

```Bash
echo 1 | sudo tee /proc/sys/kernel/numa_balancing
```

- Drop caches before running jobs as this reduces variability and improves consistency:

```Bash
echo 3 | sudo tee /proc/sys/vm/drop_caches
```

- Use HPCX MPI library on Azure HPC-optimized images:

```Bash
module load mpi/hpcx
```

- MPI process placement and core affinity
  - Pin MPI processes to physical cores
  - Avoid oversubscription
  - Use symmetric rank distribution per CCD (1–7 ranks per CCD)
    - Each HBv5 VM has **48 CCDs**, so supported configurations include:
      `48, 96, 144, 192, 288, 336 ranks per VM`
  - Example command:

```Bash
mpirun -np <number_of_ranks> \
  --map-by ppr:<ranks_per_CCD>:l3cache \
  --rank-by slot \
  --bind-to core \
  <other_options> <executable> <arguments>
```

Optimal configuration depends on workload. Symmetric rank distribution usually performs best, but some workloads can benefit from using all 368 cores per VM. Benchmark multiple

configurations to determine the best setting.

(Topology reference: 16 NUMA regions, 48 CCDs per VM.)

- For multi VM jobs at scale, disable multi rail in UCX, using:

```bash
export UCX_MAX_RNDV_RAILS=1
```

Temporary storage

HBv5 VMs feature 9 physically local NVMe SSD devices. One device is preformatted to serve as a page file and appears in your VM as a generic *SSD* device. 8 other, larger SSDs are provided as unformatted block NVMe devices.

As the block NVMe device bypasses the hypervisor, it has higher bandwidth, higher IOPS, and lower latency per IOP. When paired in a striped array, the NVMe SSD is expected to provide up to 50 GB/s of read bandwidth and 30 GB/s of write bandwidth for large block sizes.

Combined, the 8 NVMe devices provide 15 TiB of total local storage per VM.

Support	

> ⓘ Note
>
> - These VMs support only Generation 2 VMs.
> - All Red Hat Enterprise Linux (RHEL) versions earlier than 8.10, including derivatives such as CentOS and AlmaLinux, are deprecated.
> - Windows Server isn't supported on HBv5.

Known Issues with IB RDMA and NUMA Node Affinity

Issue Overview

On certain virtual machines (VMs), the InfiniBand RDMA device names (such as mlx5_[0-3]) may not align correctly with their respective NUMA node affinities. Ideally, each RDMA device should be mapped as follows:

- mlx5_0 is on NUMA node: 0
- mlx5_1 is on NUMA node: 4
- mlx5_2 is on NUMA node: 8
- mlx5_3 is on NUMA node: 12

However, an incorrect mapping example could be:

- mlx5_0 is on NUMA node: 4
- mlx5_1 is on NUMA node: 8
- mlx5_2 is on NUMA node: 12
- mlx5_3 is on NUMA node: 0

This misalignment can lead to performance degradation, particularly when running multimode MPI workloads.

Verifying RDMA device to NUMA node mapping

To confirm whether your RDMA devices are correctly mapped to NUMA nodes, execute the following script:

Bash

```
for d in /sys/class/infiniband/*;
do
dev=$(basename "$d")
node=$(cat "$d/device/numa_node")
echo "$dev is on NUMA node: $node"
done
```

Compare the output with the ideal mapping listed above.

Solution: Persistent device naming with Udev rules

To remediate the misalignment issue, follow these steps:

1. Create a new file in /etc/udev/rules.d/, for example: 99-rdma-persistent-naming.rules
2. Add the following lines to the file:

   Bash

   ```
   ACTION=="add", SUBSYSTEMS=="pci", KERNELS=="0101:00:00.0",
   PROGRAM="rdma_rename %k NAME_FIXED mlx5_ib0"
   ACTION=="add", SUBSYSTEMS=="pci", KERNELS=="0102:00:00.0",
   PROGRAM="rdma_rename %k NAME_FIXED mlx5_ib1"
   ACTION=="add", SUBSYSTEMS=="pci", KERNELS=="0103:00:00.0",
   PROGRAM="rdma_rename %k NAME_FIXED mlx5_ib2"
   ACTION=="add", SUBSYSTEMS=="pci", KERNELS=="0104:00:00.0",
   PROGRAM="rdma_rename %k NAME_FIXED mlx5_ib3"
   ```

3. Reload udev rules and trigger device events:

   Bash

   ```
   # udevadm control --reload
   # udevadm trigger --type=devices --action=add
   ```

This solution ensures that RDMA device naming persists across VM reboots.

HBv5 sizes series

HBv5-series VMs are optimized for the most memory bandwidth-intensive HPC applications, including:

- Computational fluid dynamics
- Automotive and aerospace simulations
- Weather modeling
- Energy research
- Molecular dynamics simulations
- Computer-aided engineering and other HPC workloads

HBv5 VMs feature 6.7 TB/s of memory bandwidth across 432 GB of high-bandwidth memory (HBM) and up to 368 4th Generation AMD EPYC™ processor cores with 4 GHz boost frequencies, 3.5 GHz base frequencies, and no simultaneous multithreading.

Each HBv5-series VM also includes 14.3 TiB of local NVMe SSD storage with up to 50 GB/s (reads) and 30 GB/s (writes) of block device performance.

All HBv5-series VMs feature 800 Gb/s per node (4 x 200 Gb/s CX-7 NIC) of InfiniBand connectivity from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a nonblocking fat tree for optimized and consistent RDMA performance.

The InfiniBand NICs support features like Adaptive Routing, Dynamically Connected Transport (DCT), hardware acceleration of MPI collectives, and congestion control. These features enhance application performance, scalability, and consistency, and their usage is recommended for optimal performance and cost efficiency.

FIO on local NVMe SSDs (RAID0)	50 GB/s reads, 30 GB/s writes

Process pinning

Process pinning works well on HBv5-series VMs because we expose the underlying silicon as-is to the guest VM. We strongly recommend process pinning for optimal performance and consistency.

STREAM Memory bandwidth test

The STREAM memory test can be run using the scripts in this GitHub repository.

Bash

```
git clone https://github.com/Azure/woc-benchmarking
cd woc-benchmarking/apps/hpc/stream/
sh build_stream.sh
sh stream_run_script.sh $PWD “hbrs_v5”
```

Compute performance test

The HPL benchmark can be run using the script in this GitHub repository.

Bash

```
git clone https://github.com/Azure/woc-benchmarking
cd woc-benchmarking/apps/hpc/hpl
sh hpl_build_script.sh
sh hpl_run_scr_HBv5.sh $PWD
```

MPI latency

The MPI latency test from the OSU microbenchmark suite can be executed as shown. Sample scripts are on GitHub.

Bash

```
module load mpi/hpcx
mpirun -np 2 --host $src,$dst --map-by node -x LD_LIBRARY_PATH
$HPCX_OSU_DIR/osu_latency
```

> **Note**
>
> Define source(src) and destination(dst).

MPI bandwidth

The MPI bandwidth test from the OSU microbenchmark suite can be executed per below. Sample scripts are on GitHub.

Bash

```
module load mpi/hpcx
mpirun -np 2 --host $src,$dst --map-by node -x LD_LIBRARY_PATH $HPCX_OSU_DIR/osu_bw
```

'HC' sub-family storage optimized VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'HC' family of VM size series are one of Azure's high-performance computing (HPC) optimized VM instances. These VMs are designed for compute-intensive workloads that need substantial CPU power. Examples include genomic sequencing, engineering simulations, and financial modeling. HB-series VMs use high-performance Intel Xeon Scalable processors and fast memory. HC-series VMs deliver exceptional computational performance and memory bandwidth, for applications that demand intense processing power to handle complex calculations and massive data sets efficiently. They're well-suited for industries such as healthcare, finance, and engineering, where rapid data processing and simulation accuracy are critical for advanced research and development.

Workloads and use cases

Genomic Sequencing: HC-series VMs provide the computational power needed for genomic sequencing, enabling researchers to process and analyze large genetic datasets quickly.

Engineering Simulations: Ideal for running complex simulations in fields such as automotive, aerospace, and mechanical engineering. These simulations often include finite element analysis (FEA) and computational fluid dynamics (CFD).

Financial Modeling: These VMs can handle the high demands of financial applications, including risk analysis and quantitative simulations, which require massive computational resources to execute many calculations quickly.

Scientific Research: HC-series VMs support a wide range of scientific computing needs, particularly in physics and chemistry, where large-scale computations and data analysis are crucial.

Weather Forecasting and Climate Simulation: They are used in meteorology for high-resolution weather modeling and climate simulations, which require processing large datasets and performing complex simulations.

Series in family

HC-series

HC-series Virtual Machine (VM)s are built for heavy computing tasks. They handle jobs like analyzing complex structures, studying how molecules behave, and running advanced chemistry simulations. HC VMs feature 44 Intel Xeon Platinum 8168 processor cores, 8 GB of RAM per CPU core, and no hyperthreading. Intel Xeon Platinum processors work with Intel's software tools, including the Intel Math Kernel Library. They also support advanced vector processing features like AVX-512 for faster calculations.

HC-series VMs feature 100 Gb/sec Mellanox EDR InfiniBand. These VMs are connected in a nonblocking fat tree for optimized and consistent RDMA performance. These VMs also supports Adaptive Routing and Dynamic Connected Transport (DCT), along with standard Reliable Connection (RC) and Unreliable Datagram (UD) transports. These features enhance application performance, scalability, and consistency, and their usage is recommended.

HC-series virtual machine overview

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Maximizing HPC application performance on Intel Xeon Scalable Processors requires a thoughtful approach to process placement on this new architecture. Here, we outline our implementation of it on Azure HC-series VMs for HPC applications. We'll use the term “pNUMA” to refer to a physical NUMA domain, and “vNUMA” to refer to a virtualized NUMA domain. Similarly, we'll use the term “pCore” to refer to physical CPU cores, and “vCore” to refer to virtualized CPU cores.

Physically, an HC-series server is 2 * 24-core Intel Xeon Platinum 8168 CPUs for a total of 48 physical cores. Each CPU is a single pNUMA domain, and has unified access to six channels of DRAM. Intel Xeon Platinum CPUs feature a 4x larger L2 cache than in prior generations (256 KB/core -> 1 MB/core), while also reducing the L3 cache compared to prior Intel CPUs (2.5 MB/core -> 1.375 MB/core).

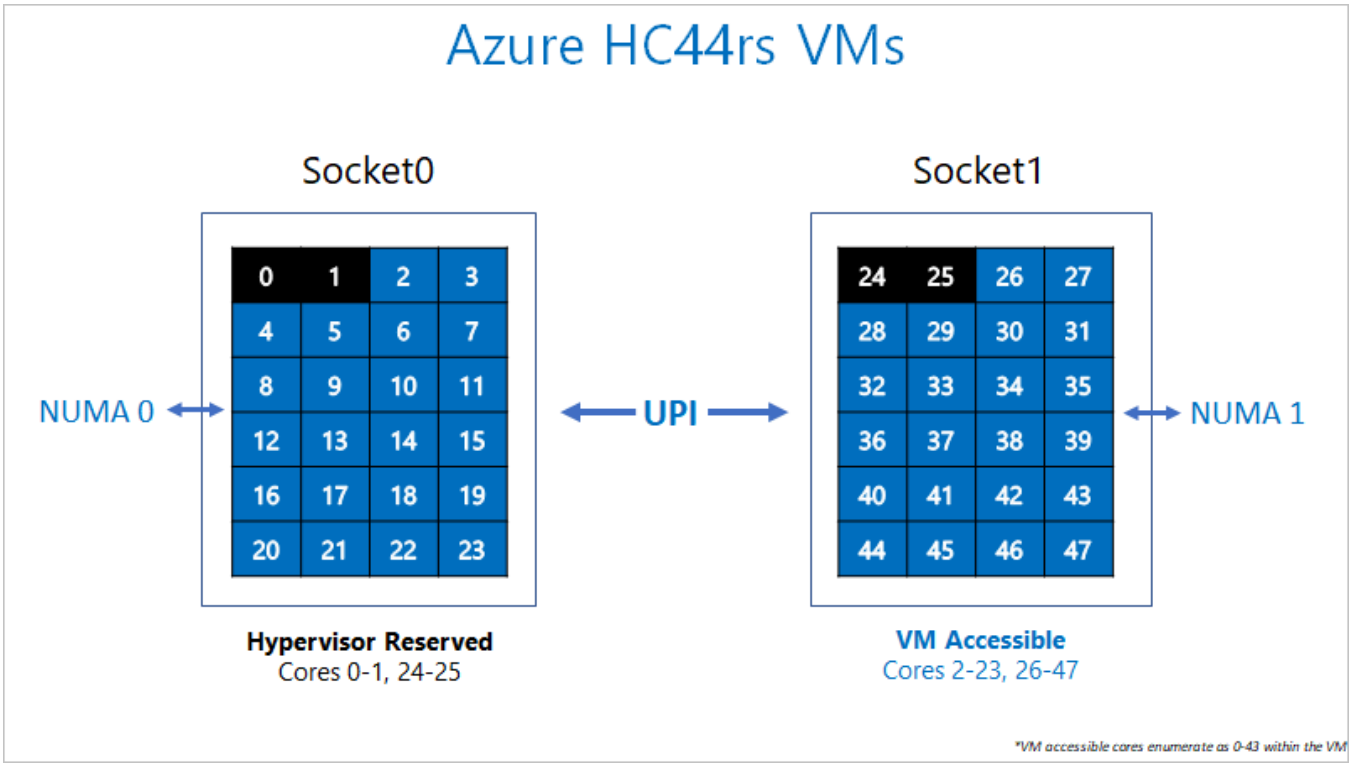
The above topology carries over to the HC-series hypervisor configuration as well. To provide room for the Azure hypervisor to operate without interfering with the VM, we reserve pCores 0-1 and 24-25 (that is, the first 2 pCores on each socket). We then assign pNUMA domains all remaining cores to the VM. Thus, the VM will see:

`(2 vNUMA domains) * (22 cores/vNUMA) = 44` cores per VM

The VM has no knowledge that pCores 0-1 and 24-25 weren't given to it. Thus, it exposes each vNUMA as if it natively had 22 cores.

Intel Xeon Platinum, Gold, and Silver CPUs also introduce an on-die 2D mesh network for communication within and external to the CPU socket. We strongly recommend process pinning for optimal performance and consistency. Process pinning will work on HC-series VMs because the underlying silicon is exposed as-is to the guest VM.

The following diagram shows the segregation of cores reserved for Azure Hypervisor and the HC-series VM.



Hardware specifications

HC sizes series

> **Important**
>
> Azure Virtual Machines HC-series sizes (Standard_HC44rs, Standard_HC44-16rs, Standard_HC44-32rs) will be retired on May 31, 2027. After this date, any remaining HC-series VMs will be deallocated, stop running, and will no longer incur charges. HC-series will no longer have SLA or support following retirement. Sales of 1-year and 3-year Reserved Instances for HC-series ended on April 2, 2026. For more information, see Migrate your HC-series virtual machines by May 31, 2027.

HC-series Virtual Machine (VM)s are built for heavy computing tasks. They handle jobs like analyzing complex structures, studying how molecules behave, and running advanced chemistry simulations. HC VMs feature 44 Intel Xeon Platinum 8168 processor cores, 8 GB of RAM per CPU core, and no hyperthreading. Intel Xeon Platinum processors work with Intel's software tools, including the Intel Math Kernel Library. They also support advanced vector processing features like AVX-512 for faster calculations.

HC-series VMs feature 100 Gb/sec Mellanox EDR InfiniBand. These VMs are connected in a nonblocking fat tree for optimized and consistent RDMA performance. These VMs also supports Adaptive Routing and Dynamic Connected Transport (DCT), along with standard Reliable Connection (RC) and Unreliable Datagram (UD) transports. These features enhance application performance, scalability, and consistency, and their usage is recommended.

Migration and alternatives

To avoid service disruption, plan to migrate your HC-series workloads before May 31, 2027. For current-generation HPC alternatives, consider:

- **HBv5-series** – Offers higher compute performance and better price-performance than HBv4, suitable for most memory-bandwidth intensive HPC workloads.
- **HX-series** – Optimized for high-memory HPC workloads with approximately twice the memory capacity of HBv4, ideal for large-scale EDA and molecular dynamics.

For migration steps, see Change the size of a virtual machine.

'HX' sub-family storage optimized VM size series

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The 'HX' family of VM size series are one of Azure's high-memory, high-performance computing (HPC) optimized VM instances. They're built for tasks that need a lot of memory and strong CPU power. Examples include in-memory databases, big data analysis, and advanced scientific simulations. HX-series VMs, equipped with expansive memory and powerful CPUs, delivers the resources to efficiently handle large datasets and perform rapid data processing. They work well for financial services, scientific research, and business planning. These areas need real-time handling of large amounts of data to stay efficient and drive new ideas.

Workloads and use cases

In-Memory Databases: HX-series VMs are excellent for hosting in-memory databases like SAP HANA, which require extensive memory to maintain large datasets in RAM for ultra-fast processing and access.

Big Data Analytics: They can handle big data analytics applications that need to process vast amounts of data in memory to speed up analysis, which is critical for real-time decision-making.

Genomic Research: Genomics research often involves large-scale data analysis, where high memory capacity can significantly enhance performance by allowing more of the dataset to be held in memory, speeding up the analysis.

Financial Simulations: Banks use HX-series VMs for fast trading and risk checks. These systems process huge amounts of data quickly to predict stock trends and figure out credit risks right away.

ERP Systems: HX-series VMs offer plenty of memory and strong processing power. Large business systems rely on these features to manage large amounts of data and keep many users working at once.

Series in family

HB-series

HX-series VMs are optimized for workloads that require significant memory capacity with twice the memory capacity as HBv4. For example, workloads such as silicon design can use HX-series VMs to enable EDA customers targeting the most advanced manufacturing processes to run their most memory-intensive workloads.

HX VMs feature up to 176 AMD EPYC™ 9V33X ("Genoa-X") CPU cores with AMD's 3D V-Cache, clock frequencies up to 3.7 GHz, and no simultaneous multithreading. HX-series VMs also provide 1408 GB of RAM, 2.3 GB L3 cache. The 2.3 GB L3 cache per VM can deliver up to 5.7 TB/s of bandwidth to amplify up to 780 GB/s of bandwidth from DRAM, for a blended average of 1.2 TB/s of effective memory bandwidth across a broad range of customer workloads. The VMs also provide up to 12 GB/s (reads) and 7 GB/s (writes) of block device SSD performance.

All HX-series VMs feature 400 Gb/s NDR InfiniBand from NVIDIA Networking to enable supercomputer-scale MPI workloads. These VMs are connected in a non-blocking fat tree for optimized and consistent RDMA performance. NDR continues to support features like Adaptive Routing and the Dynamically Connected Transport (DCT). This newest generation of InfiniBand also brings greater support for offload of MPI collectives, optimized real-world latencies due to congestion control intelligence, and enhanced adaptive routing capabilities. These features enhance application performance, scalability, and consistency, and their usage is recommended.

View the full HX-series page.

HX-series virtual machine overview

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

An HX-series server features 2 * 96-core EPYC 9V33X CPUs for a total of 192 physical "Zen4" cores with AMD 3D-V Cache. Simultaneous Multithreading (SMT) is disabled on HX. These 192 cores are divided into 24 sections (12 per socket), each section containing 8 processor cores with uniform access to a 96 MB L3 cache. Azure HX servers also run the following AMD BIOS settings:

Bash

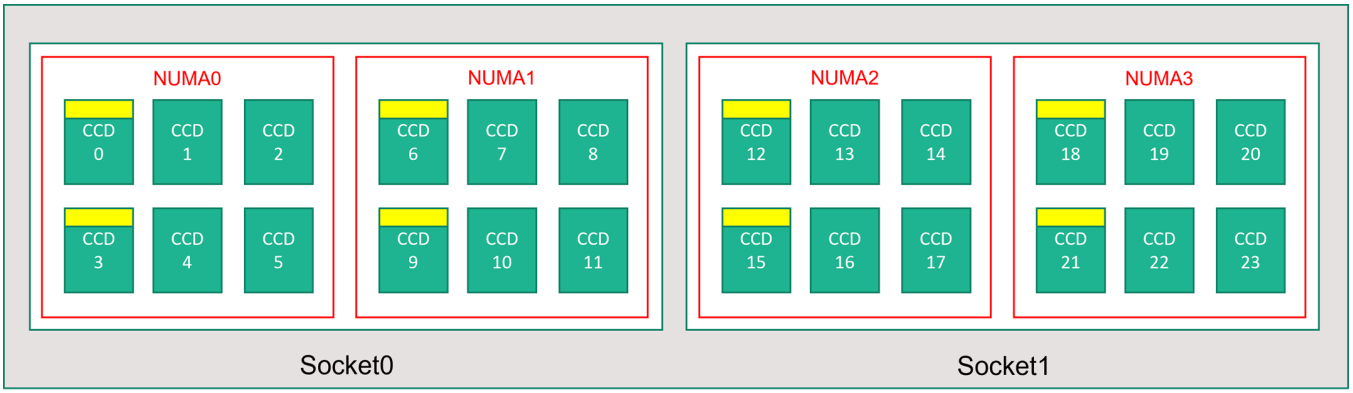
```
Nodes per Socket (NPS) = 2
L3 as NUMA = Disabled
NUMA domains within VM OS = 4
C-states = Enabled
```

As a result, the server boots with 4 NUMA domains (2 per socket) each 48-cores in size. Each NUMA has direct access to 6 channels of physical DRAM.

To provide room for the Azure hypervisor to operate without interfering with the VM, we reserve 16 physical cores per server.

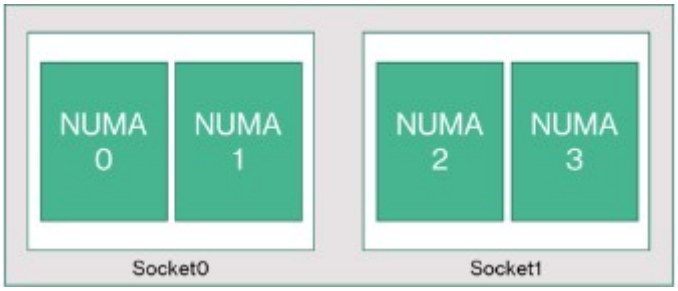
VM topology

The following diagram shows the topology of the server. We reserve these 16 hypervisor host cores (yellow) symmetrically across both CPU sockets, taking the first 2 cores from specific Core Complex Dies (CCDs) in each NUMA domain, with the remaining cores for the HX-series VM (green).



The CCD boundary is different from a NUMA boundary. On HX, a group of six (6) consecutive CCDs is configured as a NUMA domain, both at the host server level and within a guest VM.

Thus, all HX VM sizes expose 4 uniform NUMA domains that appear to an OS and application as shown each with different number of cores depending on the specific HX VM size.



Each HX VM size is similar in physical layout, features, and performance of a different CPU from the AMD EPYC 9004-series, as follows:

Expand table

HX-series VM size	NUMA domains	Cores per NUMA domain	Similarity with AMD EPYC
Standard_HX176rs	4	44	Dual-socket EPYC 9V33X
Standard_HX176-144rs	4	36	Dual-socket EPYC 9V33X
Standard_HX176-96rs	4	24	Dual-socket EPYC 9V33X
Standard_HX176-48rs	4	12	Dual-socket EPYC 9V33X
Standard_HX176-24rs	4	6	Dual-socket EPYC 9V33X

> **Note**
>
> - The constrained cores VM sizes only reduce the number of physical cores exposed to the VM. All global shared assets (RAM, memory bandwidth, L3 cache, GMI and xGMI connectivity, InfiniBand, Azure Ethernet network, local SSD) stay constant. It allows a customer to pick a VM size best tailored to a given set of workload or software licensing needs.
> - We are currently experiencing a core mapping issue on the HX-series parent size Standard_HX176rs.

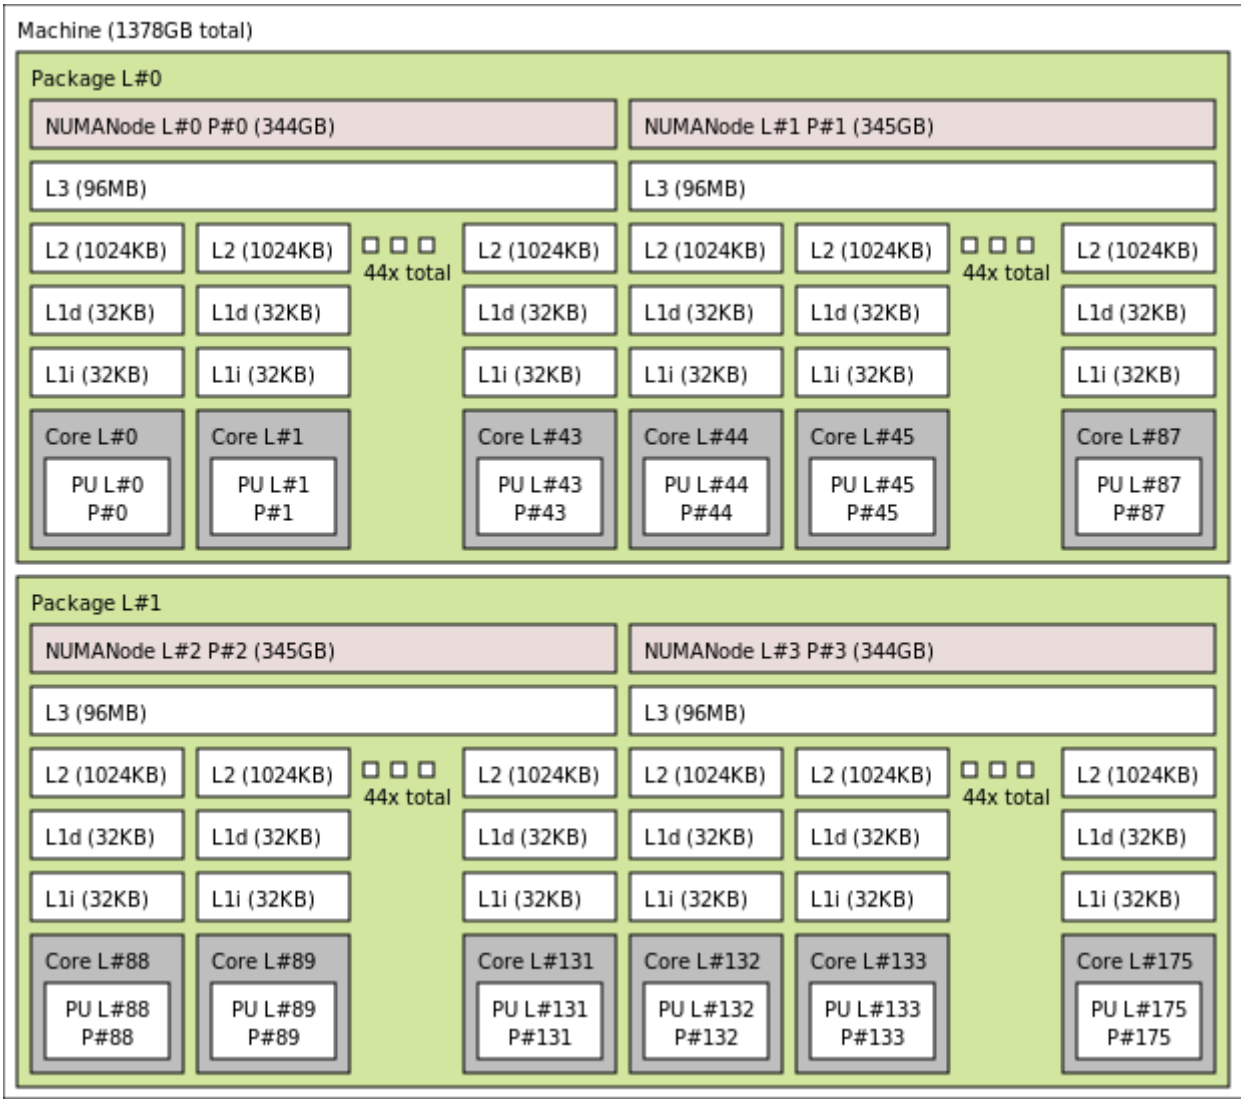
The virtual NUMA mapping of each HX VM size is mapped to the underlying physical NUMA topology. There is no potential misleading abstraction of the hardware topology.

The exact topology for the various HX VM size appears as follows using the output of lstopo:

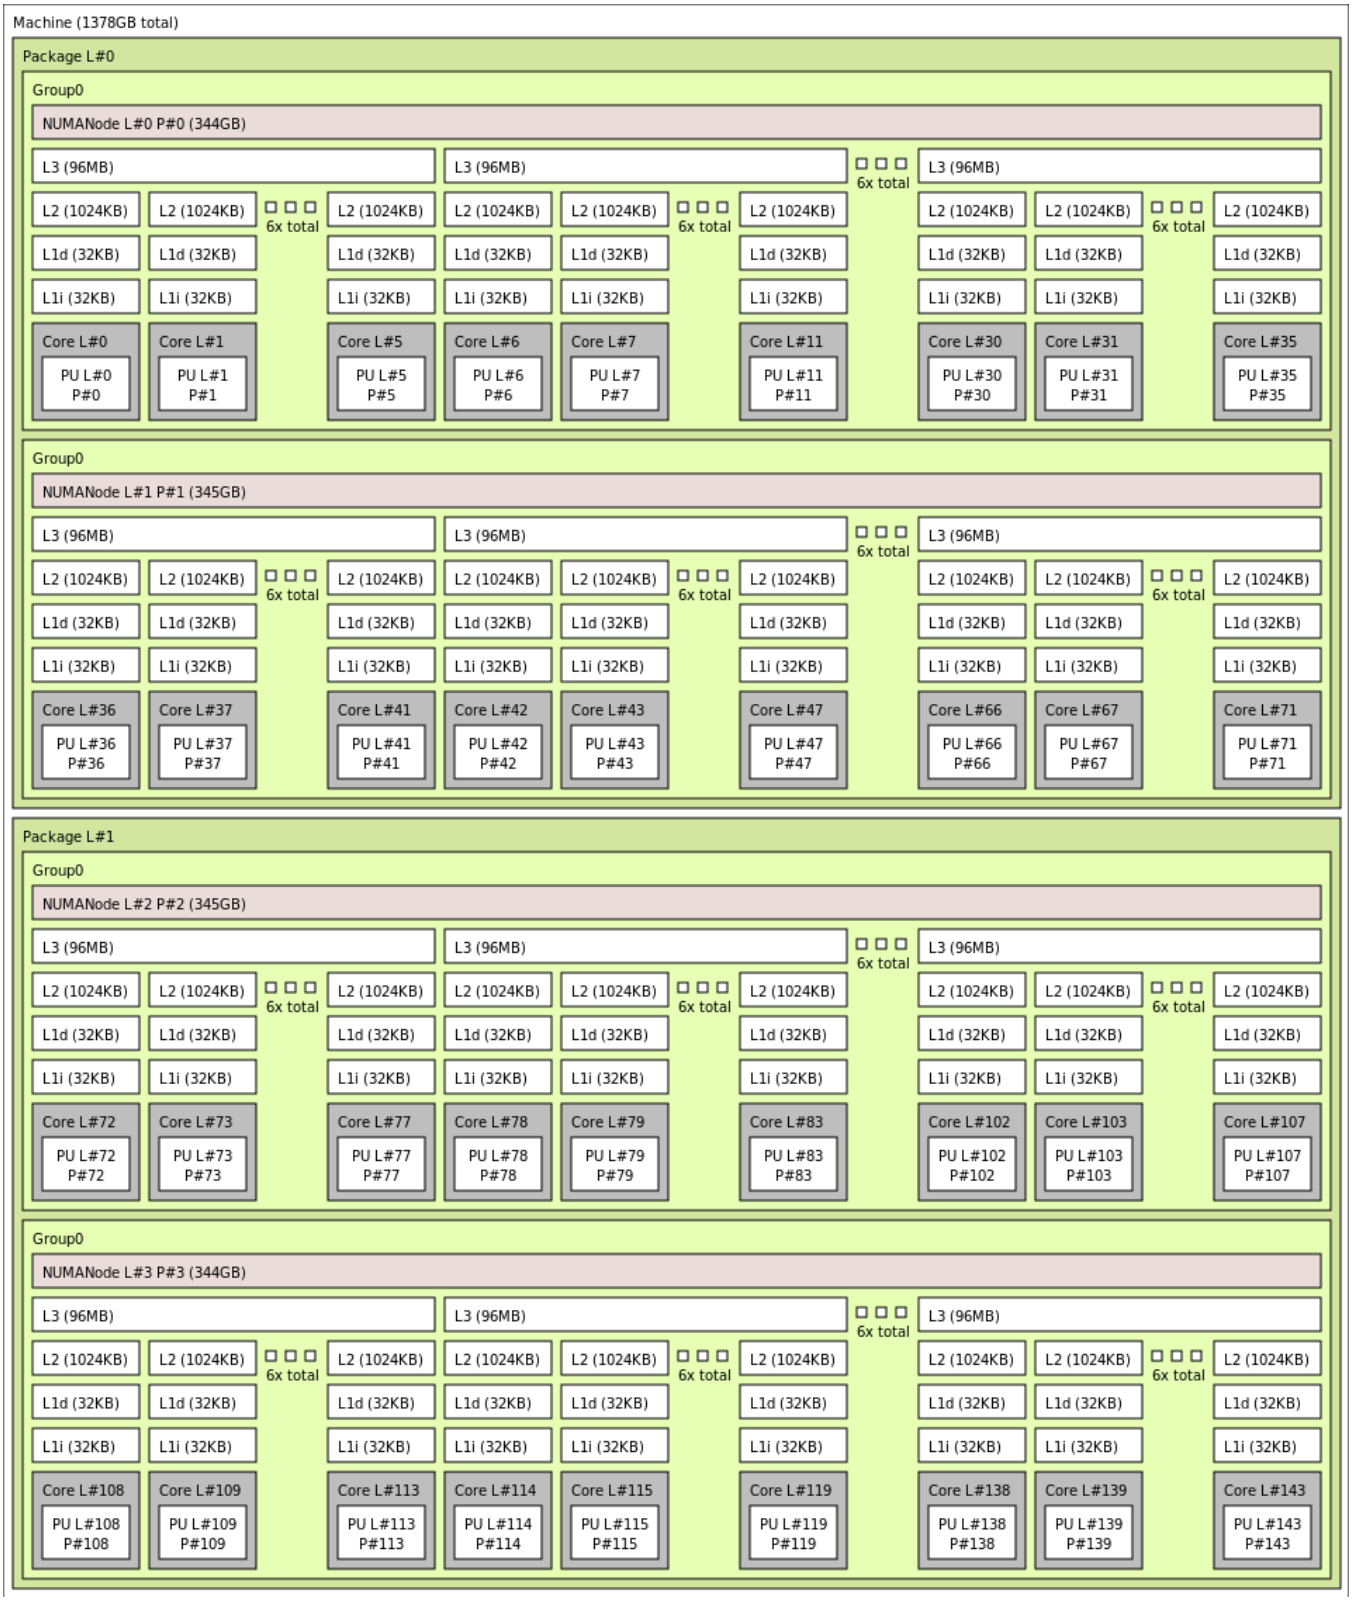
Bash

```
lstopo-no-graphics --no-io --no-legend --of txt
```

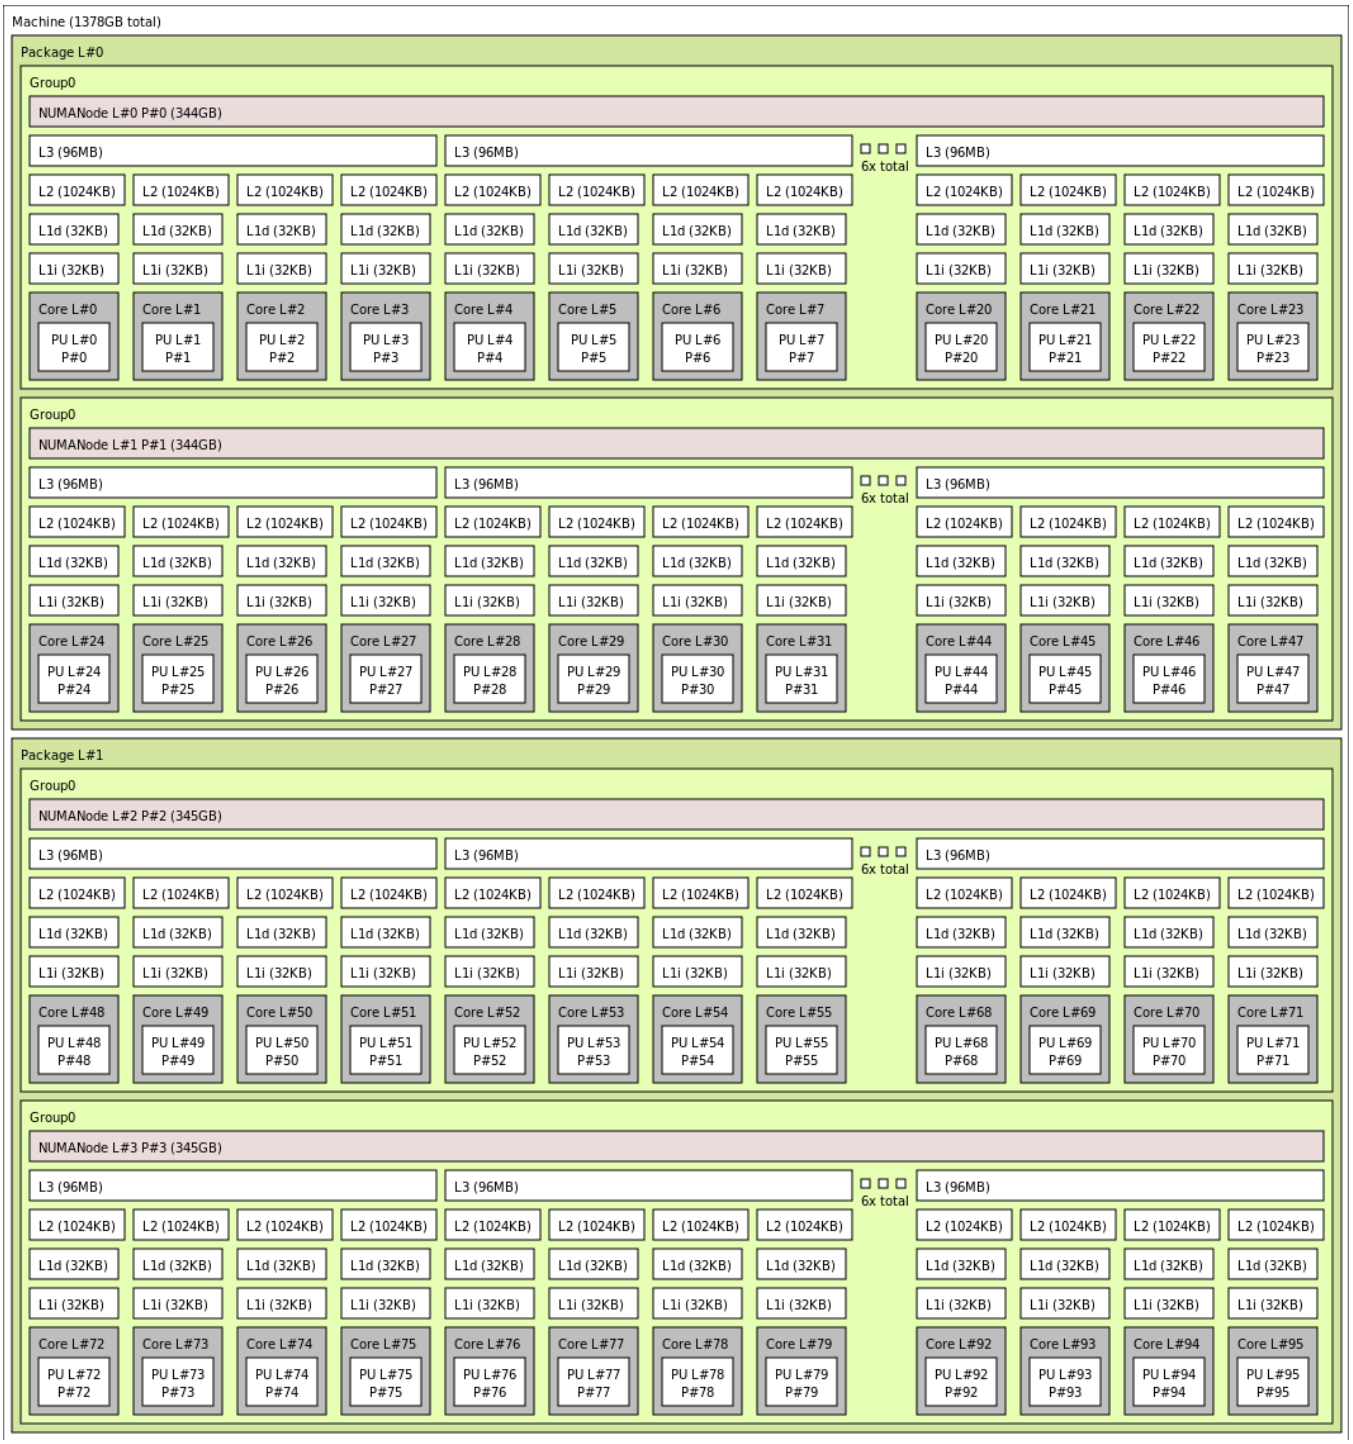
▼ Click to view lstopo output for Standard_HX176rs



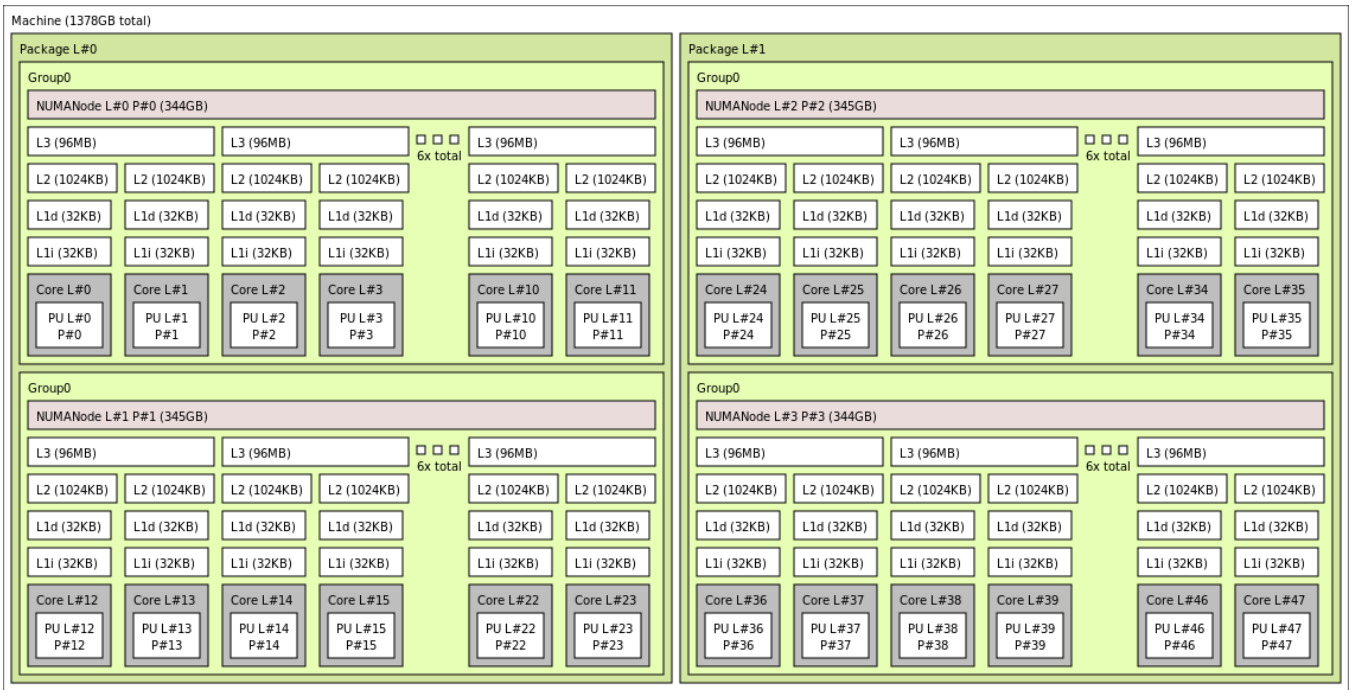
▼ Click to view lstopo output for Standard_HX176-144rs



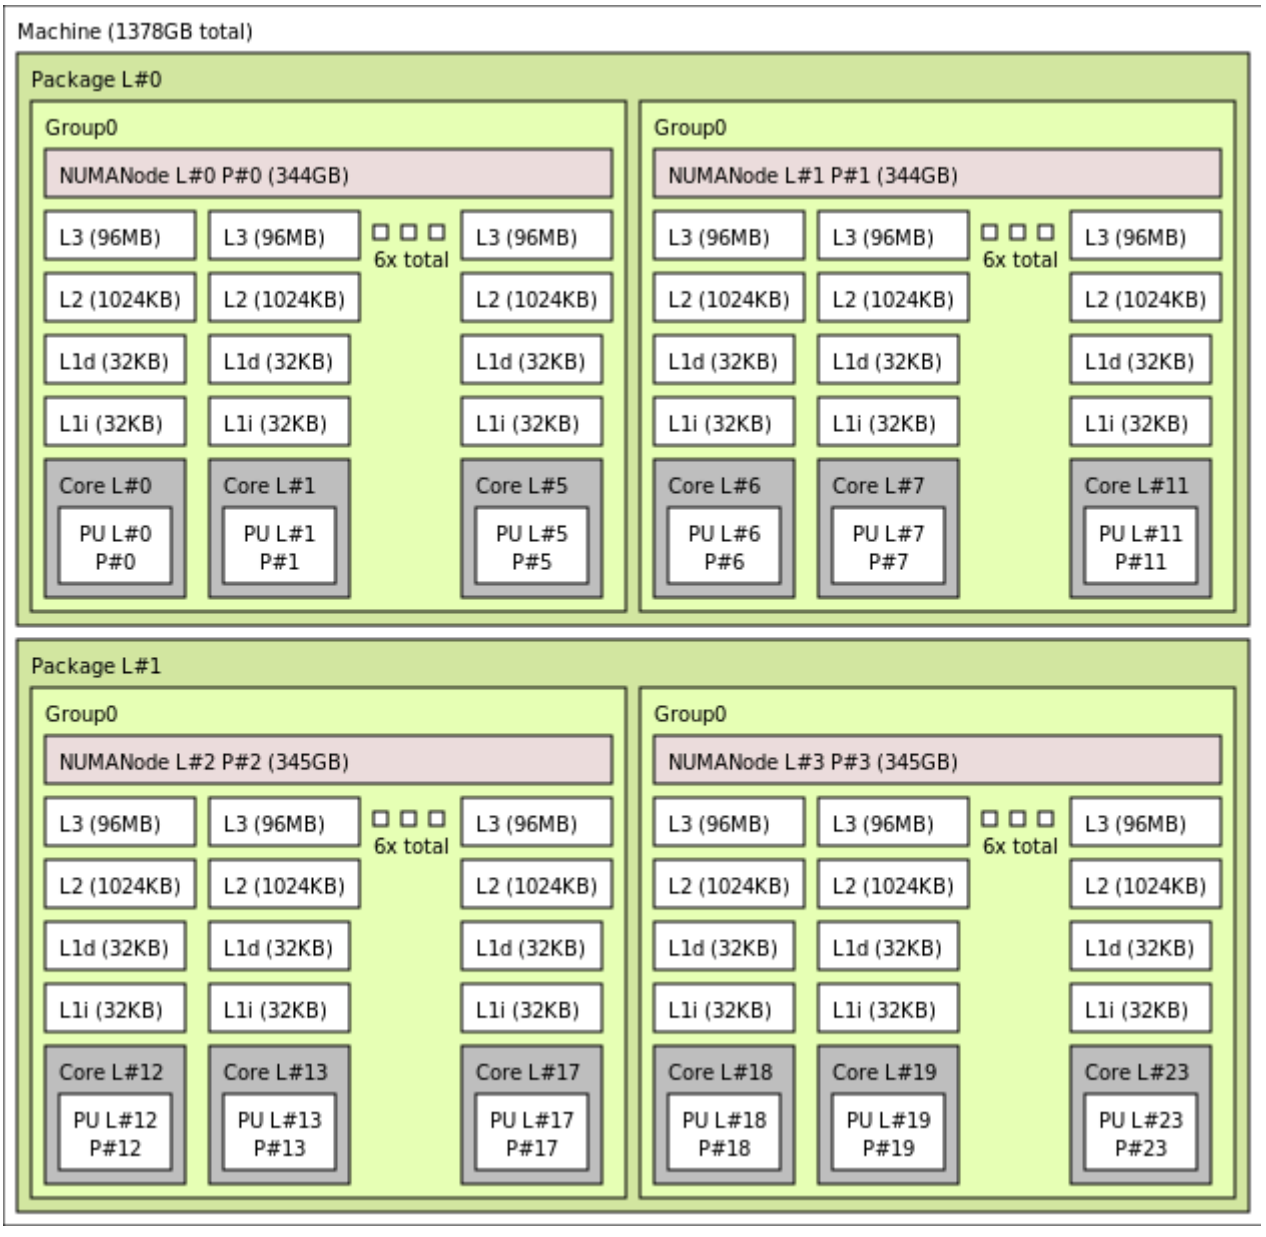
▼ Click to view lstopo output for Standard_HX176-96rs



▼ Click to view lstopo output for Standard_HX176-48rs



▼ Click to view lstopo output for Standard_HX176-24rs



InfiniBand networking

HX VMs also feature NVIDIA Mellanox NDR InfiniBand network adapters (ConnectX-7) operating at up to 400 Gigabits/sec. The NIC is passed through to the VM via SRIOV, enabling network traffic to bypass the hypervisor. As a result, customers load standard Mellanox OFED drivers on HX VMs as they would a bare metal environment.

HX VMs support Adaptive Routing, Dynamic Connected Transport (DCT, in addition to standard RC and UD transports), and hardware-based offload of MPI collectives to the onboard processor of the ConnectX-7 adapter. These features enhance application performance, scalability, and consistency, and usage of them is recommended.

Temporary storage

HX VMs feature 3 physically local SSD devices. One device is preformatted to serve as a page file and it appeared within your VM as a generic "SSD" device.

Two other, larger SSDs are provided as unformatted block NVMe devices via NVMeDirect. As the block NVMe device bypasses the hypervisor, it has higher bandwidth, higher IOPS, and lower latency per IOP.

When paired in a striped array, the NVMe SSD provides up to 12 GB/s reads and 7 GB/s writes, and up to 186,000 IOPS (reads) and 201,000 IOPS (writes) for deep queue depths.

Hardware specifications

Expand table

Hardware specifications	HX-series VMs

HX-series virtual machine performance

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Performance expectations using common HPC microbenchmarks are as follows:

Expand table

Workload	HX
STREAM Triad	750-780GB/s of DDR5, up to 5.7 TB/s of 3D-V Cache bandwidth
High-Performance Linpack (HPL)	Up to 7.6 TF (Rpeak, FP64) for 144-core VM size
RDMA latency & bandwidth	< 2 microseconds (1 byte), 400 Gb/s (one-way)
FIO on local NVMe SSDs (RAID0)	12 GB/s reads, 7 GB/s writes; 186k IOPS reads, 201k IOPS writes

Memory bandwidth test

The STREAM memory test can be run using the scripts in this GitHub repository.

Bash

```
git clone https://github.com/Azure/woc-benchmarking
cd woc-benchmarking/apps/hpc/stream/
sh build_stream.sh
sh stream_run_script.sh $PWD “hbrs_v4”
```

Compute performance test

The HPL benchmark can be run using the script in this GitHub repository.

Bash

```
git clone https://github.com/Azure/woc-benchmarking
cd woc-benchmarking/apps/hpc/hpl
sh hpl_build_script.sh
sh hpl_run_scr_hbv4.sh $PWD
```

MPI latency

The MPI latency test from the OSU microbenchmark suite can be executed as shown. Sample scripts are on GitHub.

```Bash
module load mpi/hpcx
mpirun -np 2 --host $src,$dst --map-by node -x LD_LIBRARY_PATH
$HPCX_OSU_DIR/osu_latency
```

MPI bandwidth

The MPI bandwidth test from the OSU microbenchmark suite can be executed as shown. Sample scripts are on GitHub.

```Bash
module load mpi/hpcx
mpirun -np 2 --host $src,$dst --map-by node -x LD_LIBRARY_PATH
$HPCX_OSU_DIR/osu_bw
```

[!NOTE] Define source(src) and destination(dst).

Mellanox Perftest

The Mellanox Perftest package has many InfiniBand tests such as latency (ib_send_lat) and bandwidth (ib_send_bw). An example command is shown.

```Console
numactl --physcpubind=[INSERT CORE #]  ib_send_lat -a
```

[!NOTE] NUMA node affinity for InfiniBand NIC is NUMA0.

Next steps

- Learn about scaling MPI applications.
- Review the performance and scalability results of HPC applications on the HX VMs at the TechCommunity article.

- Read about the latest announcements, HPC workload examples, and performance results at the Azure HPC Microsoft Community Hub.

Set up Azure HPC or AI VMs

08/22/2024

This how-to guide explains how to create a basic Azure virtual machine (VM) for HPC and AI with NVIDIA or AMD GPUs. These VM sizes are intended for workloads that require high-performance computing (HPC sizes), or GPU-accelerated computing (AI sizes).

Choose your VM size

Azure VMs have many different options, called VM sizes. There are different series of VM sizes for HPC and VM sizes GPU-optimized computing. Select the appropriate VM size for the workload you want to use. For help with selecting sizes, see the VM selector tool.

Not all Azure products are available in all Azure regions. For more information, see the current list of products available by region.

Create your VM

Before you can deploy a workload, you need to create your VM through the Azure portal.

Depending on your VM's operating system, review either the Linux VM quickstart or Windows VM quickstart. Then, create your VM with the following settings:

1. For **Subscription**, select the Azure subscription that you want to use for this VM.
2. For **Region**, select a region with capacity available for your VM size.
3. For **Image**, select the image of the VM you chose in the previous section.

   > **Note**
   >
   > For the purpose of example, this guide uses the image **NVIDIA GPU-Optimized Image for AI & HPC – v21.04.1 – Gen 1**. If you're using another image, you might need to install other software, like the NVIDIA driver and Docker, before proceeding.

4. For **Size**, select the HPC or GPU instance type. For more information, see how to choose your VM size.
5. For **SSH public key source**, select **Generate a new key pair**.
6. Wait for key validation to complete.

7. When prompted, select **Download private key and create resource**.

   > ⓘ Note
   >
   > Downloading the key pair is necessary to SSH into your VM for later configuration.

8. For **Key pair name**, enter a name for your key pair.

9. Under the **Networking** tab, make sure **Accelerated Networking** is disabled.

10. Optionally, add a data disk to your VM. For more information, see how to add a data disk to a Linux VM or to a Windows VM.

    > ⓘ Note
    >
    > Adding a data disk helps you store models, data sets, and other necessary components for benchmarking.

11. Select **Review + create** to create your VM.

Connect to your VM

Connect to your new VM using SSH, which allows you to perform further configuration. Some connection methods include:

- Connect over SSH on Linux or macOS
- Connect over SSH on Windows
- Connect over SSH using Azure Bastion

Set up VM

Set up your new VM for HPC or AI workloads. Install the newest NVIDIA or AMD GPU driver, which maps to your VM size.

- Install NVIDIA GPU drivers on N-series VMs running Linux
- Install NVIDIA GPU drivers on N-series VMs running Windows
- Install AMD GPU drivers on N-series VMs running Windows

Next steps

- High performance computing VM sizes

- GPU optimized virtual machine sizes

Set up InfiniBand

Article • 11/21/2024

> This article references CentOS, a Linux distribution that is nearing End Of Life (EOL) status. Please consider your use and plan accordingly. For more information, see the CentOS End Of Life guidance.

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

> **Tip**
>
> Try the **Virtual machines selector tool** to find other sizes that best fit your workload.

This article shares some information on RDMA-capable instances to be used over an InfiniBand (IB) network. The InfiniBand network architecture features a full fat-tree design(that is a network topology that provides high bandwidth and low latency), ensuring non-blocking, bisectional symmetry. This configuration provides equal bandwidth between any two virtual machines (VMs) within the same virtual machine scale set (VMSS).

RDMA-capable instances

Most of the HPC VM sizes feature a network interface for remote direct memory access (RDMA) connectivity. Selected N-series sizes designated with 'r' are also RDMA-capable. This interface is in addition to the standard Azure Ethernet network interface available in the other VM sizes.

This secondary interface allows the RDMA-capable instances to communicate over an InfiniBand network, operating at HDR rates for HBv4, HBv3, HBv2, EDR rates for HB, HC, HX, NDv2, and FDR rates for H16r, H16mr, and other RDMA-capable N-series virtual machines. These RDMA capabilities can boost the scalability and performance of Message Passing Interface (MPI) based applications.

> **Note**
>
> **SR-IOV support**: In Azure HPC, currently there are two classes of VMs depending on whether they are SR-IOV enabled for InfiniBand. Currently, almost all the newer

generation, RDMA-capable or InfiniBand enabled VMs on Azure are SR-IOV enabled except for H16r, H16mr, and NC24r. RDMA is only enabled over the InfiniBand network and is supported for all RDMA-capable VMs. IP over IB is only supported on the SR-IOV enabled VMs. RDMA is not enabled over the Ethernet network.

- **Operating System** - Linux distributions such as CentOS, RHEL, AlmaLinux, Ubuntu, SUSE are commonly used. Windows Server 2016 and newer versions are supported on all the HPC series VMs. Note that Windows Server 2012 R2 is not supported on HBv2 onwards as VM sizes with more than 64 (virtual or physical) cores. See VM Images for a list of supported Linux VM images on the Azure Marketplace and how they can be configured appropriately. The respective VM size pages also list out the software stack support.
- **InfiniBand and Drivers** - On InfiniBand enabled VMs, the appropriate drivers are required to enable RDMA. See enabling InfiniBand to learn about VM extensions or manual installation of InfiniBand drivers.
- **MPI** - The SR-IOV enabled VM sizes on Azure allow almost any flavor of MPI to be used with Mellanox OFED. See Setup MPI for HPC for more details on setting up MPI on HPC VMs on Azure.

  > ⓘ Note
  >
  > **RDMA network address space**: The RDMA network in Azure reserves the address space 172.16.0.0/16. To run MPI applications on instances deployed in an Azure virtual network, make sure that the virtual network address space does not overlap the RDMA network.

Cluster configuration options

Azure provides several options to create clusters of HPC VMs that can communicate using the RDMA network, including:

- **Virtual machines** - Deploy the RDMA-capable HPC VMs in the same scale set or availability set (when you use the Azure Resource Manager deployment model). If you use the classic deployment model, deploy the VMs in the same cloud service.
- **Virtual machine scale sets** - In a virtual machine scale set, ensure that you limit the deployment to a single placement group for InfiniBand communication within the

scale set. For example, in a Resource Manager template, set the `singlePlacementGroup` property to `true`.

Note that the maximum scale set size that can be spun up with `singlePlacementGroup=true` is capped at 100 VMs by default. If your HPC job scale needs are higher than 100 VMs in a single tenant, you may request an increase, open an online customer support request at no charge. The limit on the number of VMs in a single scale set can be increased to 300. Note that when deploying VMs using Availability Sets the maximum limit is at 200 VMs per Availability Set.

Also, VMSS serves as the isolation boundary between workloads within the same cluster, ensuring that instances in different VMSSs remain isolated from each other to guarantee security.

> ⓘ **Note**
>
> **MPI among virtual machines**: If RDMA (e.g. using MPI communication) is required between virtual machines, ensure that the VMs are in the same virtual machine scale set or availability set.

- **Azure CycleCloud** - Create an HPC cluster using Azure CycleCloud to run MPI jobs.
- **Azure Batch** - Create an Azure Batch pool to run MPI workloads. To use compute-intensive instances when running MPI applications with Azure Batch, see Use multi-instance tasks to run Message Passing Interface (MPI) applications in Azure Batch.
- **Microsoft HPC Pack** - HPC Pack includes a runtime environment for MS-MPI that uses the Azure RDMA network when deployed on RDMA-capable Linux VMs. For example deployments, see Set up a Linux RDMA cluster with HPC Pack to run MPI applications.

Deployment considerations

- **Azure subscription** – To deploy more than a few compute-intensive instances, consider a pay-as-you-go subscription or other purchase options. If you're using an Azure free account, you can use only a limited number of Azure compute cores.
- **Pricing and availability** - Check VM pricing and availability by Azure regions.

- **Cores quota** – You might need to increase the cores quota in your Azure subscription from the default value. Your subscription might also limit the number of cores you can deploy in certain VM size families, including the H-series. To request a quota increase, open an online customer support request at no charge. (Default limits may vary depending on your subscription category.)

  > **Note**
  >
  > Contact Azure Support if you have large-scale capacity needs. Azure quotas are credit limits, not capacity guarantees. Regardless of your quota, you are only charged for cores that you use.

- **Virtual network** – An Azure virtual network is not required to use the compute-intensive instances. However, for many deployments you need at least a cloud-based Azure virtual network, or a site-to-site connection if you need to access on-premises resources. When needed, create a new virtual network to deploy the instances. Adding compute-intensive VMs to a virtual network in an affinity group is not supported.

- **Resizing** – Because of their specialized hardware, you can only resize compute-intensive instances within the same size family (H-series or N-series). For example, you can only resize an H-series VM from one H-series size to another. Additional considerations around InfiniBand driver support and NVMe disks may need to be considered for certain VMs.

Next steps

- Learn more about configuring your VMs, enabling InfiniBand, setting up MPI and optimizing HPC applications for Azure at HPC Workloads.
- Review the HBv3-series overview and HC-series overview.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Configure and optimize the InfiniBand enabled H-series and N-series VMs

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article shares some guidance on configuring and optimizing the InfiniBand-enabled HB-series and N-series VMs for HPC.

VM images

On InfiniBand (IB) enabled VMs, the appropriate IB drivers are required to enable RDMA.

- The Ubuntu-HPC VM images in the Marketplace come preconfigured with the appropriate NVIDIA IB drivers and GPU drivers.
- The AlmaLinux-HPC VM images in the Marketplace come preconfigured with the appropriate NVIDIA IB drivers and GPU drivers.

These VM images are based on the base Ubuntu and AlmaLinux marketplace VM images. Scripts used in the creation of these VM images from their base marketplace images are on the azhpc-images repo.

On GPU enabled N-series VMs, the appropriate GPU drivers are additionally required. This can be available by the following methods:

- Use the Ubuntu-HPC VM images or AlmaLinux-HPC VM images that come preconfigured with the NVIDIA GPU drivers and GPU compute software stack (CUDA, NCCL).
- Add the GPU drivers through the VM extensions.
- Install the GPU drivers manually.
- Some other VM images on the Marketplace also come preinstalled with the NVIDIA GPU drivers, including some VM images from NVIDIA.

Depending on the workloads' Linux distro and version needs, Ubuntu-HPC VM images and AlmaLinux-HPC VM images on the Marketplace are the easiest way to get started with HPC and AI workloads on Azure. It's also recommended to create custom VM images with workload specific customization and configuration for reuse.

VM sizes supported by the HPC VM images

InfiniBand OFED support

The latest Azure HPC marketplace images come with Mellanox OFED 5.1 and above, which do not support ConnectX3-Pro InfiniBand cards. ConnectX-3 Pro InfiniBand cards require MOFED 4.9 LTS version. These VM images only support ConnextX-5 and newer InfiniBand cards. The following VM size support matrix for the InfiniBand OFED in these HPC VM images:

- HB-series: HB, HC, HBv2, HBv3, HBv4
- N-series: NDv2, NDv4

GPU driver support

Currently only the Ubuntu-HPC VM images and AlmaLinux-HPC VM images come preconfigured with the NVIDIA GPU drivers and GPU compute software stack (CUDA, NCCL).

The VM size support matrix for the GPU drivers in supported HPC VM images is as follows:

- N-series: NDv2, NDv4 VM sizes are supported with the NVIDIA GPU drivers and GPU compute software stack (CUDA, NCCL).
- The other 'NC' and 'ND' VM sizes in the N-series are supported with the NVIDIA GPU drivers.

All of the VM sizes in the N-series support Gen 2 VMs, though some older ones also support Gen 1 VMs. Gen 2 support is also indicated with a "01" at the end of the image URN or version.

SR-IOV enabled VMs

Ubuntu-HPC VM images

For SR-IOV enabled RDMA capable VMs, Ubuntu-HPC VM images versions 18.04, 20.04, and 22.04 are suitable. These VM images come preconfigured with the Mellanox OFED drivers for RDMA, NVIDIA GPU drivers, GPU compute software stack (CUDA, NCCL), and commonly used MPI libraries and scientific computing packages. Refer to the VM size support matrix.

- The available or latest versions of the VM images can be listed with the following information using CLI or Marketplace.

  Output

  ```
  "publisher": "Microsoft-DSVM",
  "offer": "Ubuntu-HPC",
  ```

- Scripts used in the creation of the Ubuntu-HPC VM images from a base Ubuntu Marketplace image are on the azhpc-images repo.

AlmaLinux-HPC VM images

For SR-IOV enabled RDMA capable VMs, AlmaLinux-HPC VM images versions 8.5, 8.6, and 8.7 are suitable. These VM images come preconfigured with the Mellanox OFED drivers for RDMA, NVIDIA GPU drivers, GPU compute software stack (CUDA, NCCL), and commonly used MPI libraries and scientific computing packages. Refer to the VM size support matrix.

- The available or latest versions of the VM images can be listed with the following information using CLI or Marketplace.

  Output

  ```
  "publisher": "AlmaLinux",
  "offer": "AlmaLinux-HPC",
  ```

- Scripts used in the creation of the AlmaLinux-HPC VM images from a base AlmaLinux Marketplace image are on the azhpc-images repo.

Additionally, more details on what's included in the Ubuntu-HPC VM images and AlmaLinux-HPC VM images, and how to deploy them are in Azure HPC VM images.

RHEL VM images

The base RHEL-based non-HPC VM images on the Marketplace can be configured for use on the SR-IOV enabled RDMA capable VMs. Learn more about enabling InfiniBand and setting up MPI on the VMs.

Ubuntu VM images

The base Ubuntu Server 20.04 LTS and 22.04 LTS VM images in the Marketplace are supported for both SR-IOV and non-SR-IOV RDMA capable VMs. Learn more about enabling InfiniBand and setting up MPI on the VMs.

- Instructions for enabling InfiniBand on the Ubuntu VM images are in a TechCommunity article.

> **Note**
>
> Mellanox OFED 5.1 and above don't support ConnectX3-Pro InfiniBand cards on SR-IOV enabled N-series VM sizes with FDR InfiniBand (e.g. NCv3). Please use LTS Mellanox OFED version 4.9-0.1.7.0 or older on the N-series VM's with ConnectX3-Pro cards. For more information, see **Linux InfiniBand Drivers**.

SUSE Linux Enterprise Server VM images

SLES 12 SP3 for HPC, SLES 12 SP3 for HPC (Premium), SLES 12 SP1 for HPC, SLES 12 SP1 for HPC (Premium), SLES 12 SP4 and SLES 15 VM images in the Marketplace are supported. These VM images come preloaded with the Network Direct drivers for RDMA (on the non-SR-IOV VM sizes) and Intel MPI version 5.1. Learn more about setting up MPI on the VMs.

Optimize VMs

The following are some optional optimization settings for improved performance on the VM.

Update LIS

If necessary for functionality or performance, Linux Integration Services (LIS) drivers can be installed or updated on supported OS distros, especially is deploying using a custom image or an older OS version such as RHEL 6.x or earlier version of 7.x.

Bash

```
wget https://aka.ms/lis
tar xzf lis
pushd LISISO
sudo ./upgrade.sh
```

Reclaim memory

Improve performance by automatically reclaiming memory to avoid remote memory access.

Bash

```
sudo echo 1 >/proc/sys/vm/zone_reclaim_mode
```

Keep reclaim memory mode persistent after VM reboots:

Bash

```
sudo echo "vm.zone_reclaim_mode = 1" >> /etc/sysctl.conf sysctl -p
```

Disable firewall and SELinux

Bash

```
sudo systemctl stop iptables.service
sudo systemctl disable iptables.service
sudo systemctl mask firewalld
sudo systemctl stop firewalld.service
sudo systemctl disable firewalld.service
sudo iptables -nL
sudo sed -i -e's/SELINUX=enforcing/SELINUX=disabled/g' /etc/selinux/config
```

Disable cpupower

Bash

```
sudo service cpupower status
```

If enabled, disable it:

Bash

```
sudo service cpupower stop
sudo systemctl disable cpupower
```

Configure WALinuxAgent

Bash

```
sudo sed -i -e 's/# OS.EnableRDMA=y/OS.EnableRDMA=y/g' /etc/waagent.conf
```

Optionally, the WALinuxAgent may be disabled before running a job then enabled post-job for maximum VM resource availability to the HPC workload.

Next steps

- Learn more about enabling InfiniBand on the InfiniBand-enabled HB-series and N-series VMs.
- Learn more about installing and running various supported MPI libraries on the VMs.
- Review the HBv3-series overview and HC-series overview.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Last updated on 08/22/2024

Azure HPC/AI VM images

09/04/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article shares some information on HPC/AI VM images to be used to launch InfiniBand enabled H-series and GPU enabled N-series VMs.

The Azure HPC team is offering optimized and pre-configured Linux VM images for HPC and AI workloads. These VM images are:

- Based on upstream Ubuntu and AlmaLinux marketplace VM images.
- Pre-configured with NVIDIA Mellanox OFED driver for InfiniBand, NVIDIA GPU drivers, popular MPI libraries, vendor tuned HPC libraries, and recommended performance optimizations.
- Including optimizations and recommended configurations to deliver optimal performance, consistency, and reliability.

Availability on Azure

You may use the HPC/AI images when creating a VM from either Azure Marketplace or Azure CLI. For other deployment methods, refer to the section of Deploying HPC VM Images.

Azure Marketplace

Search for `Ubuntu HPC` by the publisher `Microsoft-DSVM`, or `AlmaLinux HPC` by the publisher `AlmaLinux`.

Azure CLI

Run the following commands to find image URNs of the HPC images:

Ubuntu-HPC

```
az vm image list --publisher microsoft-dsvm --offer ubuntu-hpc --output table --
all
```

All images support Gen 2 VMs.

AlmaLinux-HPC

```
az vm image list --publisher almalinux --offer almalinux-hpc --output table --all
```

All images support both Gen 1 and Gen 2 VMs.

Supported VM sizes

The HPC VM images support the following VM sizes:

- Standard_HB60rs
- Standard_HB120rs_v2
- Standard_HB120rs_v3
- Standard_HB120rs_v4
- Standard_HC44rs
- Standard_ND40rs_v2
- Standard_ND96asr_v4
- Standard_ND96amsr_A100_v4
- Standard_ND96isr_H100_v5
- Standard_ND96isr_H200_v5
- Standard_ND96isr_MI300X_v5

Refer to Azure VM sizes for the latest H- and N-series VM size support matrix.

Installed software packages

- Mellanox OFED 24.01-0.3.3.1
- Pre-configured IPoIB (IP-over-InfiniBand)
- Popular InfiniBand based MPI Libraries
  - HPC-X v2.18 with/without PMIx-4
  - Intel MPI 2021.12.0
  - MVAPICH2 2.3.7-1
  - OpenMPI 5.0.2 with PMIx-4
- Communication Runtimes
  - Libfabric
  - OpenUCX
  - NCCL 2.21.5-1
  - NCCL RDMA Sharp Plugin
- Optimized libraries

    - AMD Optimizing C/C++ and Fortran Compilers 4.0.0-1
    - Intel MKL 2024.0.0.49673
- GPU Drivers
    - NVIDIA GPU Driver 535.161.08
    - NVIDIA Peer Memory (GPU Direct RDMA)
    - NVIDIA Fabric Manager
    - CUDA 12.4
- GDRCopy 2.3
- Data Center GPU Manager 3.3.3
- Azure HPC Diagnostics Tool
- SKU based customizations
    - Topology files
    - NCCL configuration
- Moby 24.0.7-ubuntu22.04u1
- NVIDIA Docker container 24.0.7-1
- Azure Managed Lustre 2.15.4-42-gd6d405d
- Moneo v0.3.5
- Azure HPC Health Checks v0.4.2

An installed version index within the VM image is located at this location: `/opt/azurehpc/component_versions.txt`.

MPI libraries and software packages are available as environment modules. To load an MPI library/package, run:

```
module load mpi/<mpi-library-name>
module load <package-name>
```

Configuration and optimization

Refer to the azhpc-images repo at GitHub for the latest details on what packages and configuration is included in each VM image. The included configurations are based on optimization recommendations from vendors and partners, as well as learnings from common HPC workloads and usage practices in traditional HPC systems.

- Azure Linux Agent (WAAgent)
    - Limit waagent's (VM agent running on every Azure Linux VM) usage of CPU/memory resources.
    - Optionally, consider disabling waagent at the beginning of your job script, and enabling it back at the end, for CPU sensitive workloads as follows:

```
sudo systemctl stop waagent
<HPC job>
sudo systemctl restart waagent
```

- Higher Memory Limits
  - Set max-locked-memory limit to unlimited
  - Set number of open files limit to 65535
- Zone Reclaim mode
  - Set zone_reclaim_mode to 1
- Disable firewall daemon to help MPI job launchers

Deploying HPC VM images

As shown, the HPC VM images are available from Azure Marketplace and Azure CLI. They can be deployed through a variety of deployment vehicles on Azure (Azure CycleCloud, Azure Batch, ARM templates, etc.). AzureHPC scripts provide an easy way to quickly deploy an HPC cluster using these images.

High-performance computing on InfiniBand enabled HB-series and N-series VMs

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure's InfiniBand enabled H-series and N-series VMs are designed to deliver leadership-class performance, Message Passing Interface (MPI) scalability, and cost efficiency for a variety of real-world HPC and AI workloads. These high-performance computing (HPC) optimized VMs are used to solve some of the most computationally intensive problems in science and engineering such as: fluid dynamics, earth modeling, weather simulations, etc.

These articles describe how to get started on the InfiniBand-enabled H-series and N-series VMs on Azure as well as optimal configuration of the HPC and AI workloads on the VMs for scalability.

Features and capabilities

The InfiniBand enabled HB-series and N-series VMs are designed to provide the best HPC performance, MPI scalability, and cost efficiency for HPC workloads. See HB-series and N-series VMs to learn more about the features and capabilities of the VMs.

RDMA and InfiniBand

RDMA capable HB-series and N-series VMs communicate over the low latency and high bandwidth InfiniBand network. The RDMA capability over such an interconnect is critical to boost the scalability and performance of distributed-node HPC and AI workloads. The InfiniBand enabled H-series and N-series VMs are connected in a non-blocking fat tree with a low-diameter design for optimized and consistent RDMA performance. See Enable InfiniBand to learn more about setting up InfiniBand on the InfiniBand enabled VMs.

Message passing interface

The SR-IOV enabled HB-series and N-series support almost all MPI libraries and versions. Some of the most commonly used MPI libraries are: Intel MPI, OpenMPI, HPC-X, MVAPICH2, MPICH, Platform MPI. All remote direct memory access (RDMA) verbs are supported. See Set up MPI to learn more about installing various supported MPI libraries and their optimal configuration.

Get started

The first step is to select the HB-series and N-series VM type optimal for the workload based on the VM specifications and RDMA capability. Second, configure the VM by enabling InfiniBand. There are various methods to doing this including using optimized VM images with drivers baked-in; see Optimization for Linux and Enable InfiniBand for details. Third, for distributed node workloads, choosing and configuring MPI appropriately is critical. See Set up MPI for details. Fourth, for performance and scalability, optimally configure the workloads by following guidance specific to the VM family, such as for HBv3-series overview and HC-series overview.

Next steps

- Learn about configuring and optimizing the InfiniBand enabled HB-series and N-series VMs.
- Review the HBv3-series overview and HC-series overview to learn about optimally configuring workloads for performance and scalability.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- Test your knowledge with a learning module on optimizing HPC applications on Azure.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Last updated on 08/22/2024

Known issues with HB-series and N-series VMs

09/22/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article attempts to list recent common issues and their solutions when using the HB-series and N-series HPC and GPU VMs.

Cache topology on Standard_HB120rs_v3

`lstopo` displays incorrect cache topology on the Standard_HB120rs_v3 VM size. It may display that there's only 32 MB L3 per nonuniform memory access (NUMA) node. However, in practice, there's indeed 120 MB L3 per NUMA as expected since the same 480 MB of L3 to the entire VM is available as with the other constrained-core HBv3 VM sizes. This incorrect display is a cosmetic error and shouldn't affect workloads.

qp0 Access Restriction

To prevent low-level hardware access that can result in security vulnerabilities, Queue Pair 0 isn't accessible to guest VMs. This restriction should only affect actions typically associated with administration of the ConnectX InfiniBand network interface card (NIC) and running some InfiniBand diagnostics like ibdiagnet, but not end-user applications.

MOFED installation on Ubuntu

On Ubuntu-18.04 based marketplace VM images with kernels version `5.4.0-1039-azure #42` and newer, some older Mellanox OFED are incompatible causing an increase in VM boot time up to 30 minutes in some cases. This issue is reported in both Mellanox OFED versions 5.2-1.0.4.0 and 5.2-2.2.0.0. The issue is resolved with Mellanox OFED 5.3-1.0.0.1. If it's necessary to use the incompatible OFED, a solution is to use the **Canonical:UbuntuServer:18_04-lts-gen2:18.04.202101290** marketplace VM image, or older and not to update the kernel.

Accelerated Networking on HB, HC, HBv2, HBv3, HBv4, HX, NDv2 and NDv4

Azure Accelerated Networking is now available on the RDMA and InfiniBand capable. It's also available on SR-IOV enabled VM sizes HB, HC, HBv2, HBv3, HBv4, HX, NDv2, and NDv4. This

capability now allows enhanced throughout (up to 30 Gbps) and latencies over the Azure Ethernet network. Though this enhanced throughput is separate from the RDMA capabilities over the InfiniBand network, some platform changes for this capability could affect behavior of certain MPI implementations when running jobs over InfiniBand. Specifically the InfiniBand interface on some VMs may have a slightly different name (mlx5_1 as opposed to earlier mlx5_0). This issue may require tweaking of the MPI command lines, especially when using the UCX interface (commonly with OpenMPI and HPC-X).

For more information on this issue, see the TechCommunity article with instructions on how to address any observed issues.

InfiniBand driver installation on non-SR-IOV VMs

Currently H16r, H16mr, and NC24r aren't SR-IOV enabled. For more information on the InfiniBand stack bifurcation, see Azure VM sizes - HPC. InfiniBand can be configured on the SR-IOV enabled VM sizes with the OFED drivers while the non-SR-IOV VM sizes require ND drivers. This IB support is available appropriately for RHEL and Ubuntu.

Duplicate MAC with cloud-init with Ubuntu on H-series and N-series VMs

There's a known issue with cloud-init on Ubuntu VM images as it tries to bring up the IB interface. This issue can happen either on VM reboot or when trying to create a VM image after generalization. The VM boot logs may show an error like so:

Output

```
“Starting Network Service...RuntimeError: duplicate mac found! both 'eth1' and
'ib0' have mac”.
```

This 'duplicate MAC with cloud-init on Ubuntu" is a known issue. Newer kernels plan to resolve the issue. If this issue is encountered, the workaround is:

1. Deploy the (Ubuntu 18.04) marketplace VM image
2. Install the necessary software packages to enable IB (instruction here)
3. Edit waagent.conf and set EnableRDMA=y
4. Disable networking in cloud-init:

   Bash

   ```
   echo network: {config: disabled} | sudo tee /etc/cloud/cloud.cfg.d/99-
   ```

```
disable-network-config.cfg
```

5. To remove the MAC, edit netplan's networking configuration file generated by cloud-init:

```
Bash

sudo bash -c "cat > /etc/netplan/50-cloud-init.yaml" <<'EOF'
network:
  ethernets:
    eth0:
      dhcp4: true
  version: 2
EOF
```

DRAM on HB-series VMs

HB-series VMs can only expose 228 GB of RAM to guest VMs at this time. Similarly, 458 GB on HBv2 and 448 GB on HBv3 VMs. This limitation is due to a known limitation of Azure hypervisor to prevent pages from being assigned to the local DRAM of AMD CCXs (NUMA domains) reserved for the guest VM.

GSS Proxy

GSS Proxy has a known bug in RHEL 7.5 that can manifest as a significant performance and responsiveness penalty when used with NFS. This bug can be mitigated with:

```
Bash

sudo sed -i 's/GSS_USE_PROXY="yes"/GSS_USE_PROXY="no"/g' /etc/sysconfig/nfs
```

Cache Cleaning

On HPC systems, it's often useful to clean up the memory after a job finishes before the next user is assigned the same node. After running applications in Linux, you may find that your available memory reduces while your buffer memory increases, despite not running any applications.

```
[root@mun-smc05 ~]# free -g
              total        used        free      shared  buff/cache   available
Mem:            251           0         233           0          17         248
Swap:             3           0           3
```

Using `numactl -H` shows which NUMAnodes the memory is buffered with (possibly all). In Linux, users can clean the caches in three ways to return buffered or cached memory to ‘free’.

You need to be root or have sudo permissions.

Bash

```
sudo echo 1 > /proc/sys/vm/drop_caches [frees page-cache]
sudo echo 2 > /proc/sys/vm/drop_caches [frees slab objects e.g. dentries, inodes]
sudo echo 3 > /proc/sys/vm/drop_caches [cleans page-cache and slab objects]
```

Thermal alerts and reduced performance due to thermal degradation of NVIDIA GPUs in ND H100/H200 v5 VMs

Microsoft has identified an issue that may cause some GPUs that have been in service for extended periods to show thermal alerts or reduced performance. In some cases, this can be due to software reporting errors in older NVIDIA drivers, while in others it may indicate a true hardware issue, with thermal degradation over time resulting in throttling and reduced performance.

To ensure accurate monitoring, we recommend upgrading to NVIDIA driver version 570.124.06 or higher. If thermal alerts or throttling continue after the upgrade, this may point to a hardware problem. Microsoft is proactively replacing hardware that is currently exhibiting persistent thermal throttling, as well as units identified as being at elevated risk. We remain committed to maintaining optimal system performance and reliability for our customers.

Kernel warnings

You may ignore the following kernel warning messages when booting an HB-series VM under Linux. This is due to a known limitation of the Azure hypervisor that will be addressed over time.

Output

```
[  0.004000] WARNING: CPU: 4 PID: 0 at arch/x86/kernel/smpboot.c:376
topology_sane.isra.3+0x80/0x90

```

Next steps

- Review the HB-series overview and HC-series overview to learn about optimally configuring workloads for performance and scalability.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher-level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Set up Message Passing Interface for HPC

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The Message Passing Interface (MPI) is an open library and defacto standard for distributed memory parallelization. It's commonly used across many HPC workloads. HPC workloads on the RDMA capable HB-series and N-series VMs can use MPI to communicate over the low latency and high bandwidth InfiniBand network.

- The SR-IOV enabled VM sizes on Azure allow almost any flavor of MPI to be used with Mellanox OFED.
- On non-SR-IOV enabled VMs, supported MPI implementations use the Microsoft Network Direct (ND) interface to communicate between VMs. Hence, only Microsoft MPI (MS-MPI) 2012 R2 or later and Intel MPI 5.x versions are supported. Later versions (2017, 2018) of the Intel MPI runtime library may or may not be compatible with the Azure RDMA drivers.

For SR-IOV enabled RDMA capable VMs, Ubuntu-HPC VM images and AlmaLinux-HPC VM images are suitable. These VM images come optimized and preloaded with the OFED drivers for RDMA and various commonly used MPI libraries and scientific computing packages and are the easiest way to get started.

Though the examples here are for RHEL, but the steps are general and can be used for any compatible Linux operating system such as Ubuntu (18.04, 20.04, 22.04) and SLES (12 SP4 and 15 SP4). More examples for setting up other MPI implementations on others distros is on the azhpc-images repo.

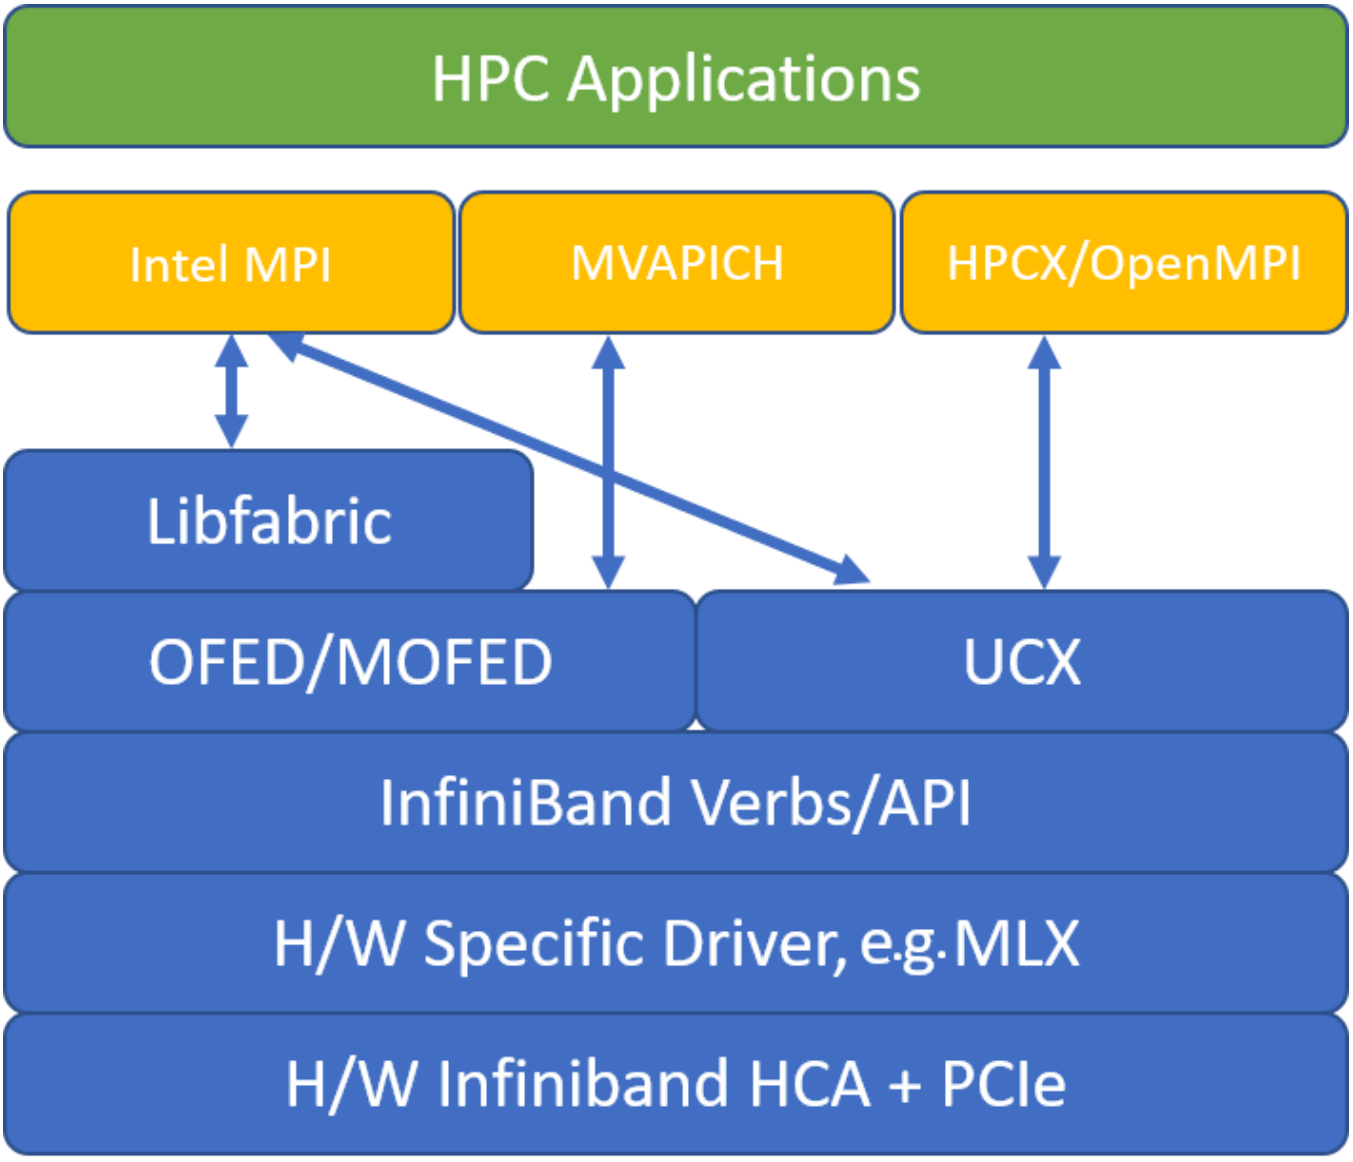
> **Note**
>
> Running MPI jobs on SR-IOV enabled VMs with certain MPI libraries (such as Platform MPI) may require setting up of partition keys (p-keys) across a tenant for isolation and security. Follow the steps in the **Discover partition keys** section for details on determining the p-key values and setting them correctly for an MPI job with that MPI library.

> **Note**
>
> The code snippets below are examples. We recommend using the latest stable versions of the packages, or referring to the **azhpc-images repo**.

Choosing MPI library

If an HPC application recommends a particular MPI library, try that version first. If you have flexibility regarding which MPI you can choose, and you want the best performance, try HPC-X. Overall, the HPC-X MPI performs the best by using the UCX framework for the InfiniBand interface, and takes advantage of all the Mellanox InfiniBand hardware and software capabilities. Additionally, HPC-X and OpenMPI are ABI compatible, so you can dynamically run an HPC application with HPC-X that was built with OpenMPI. Similarly, Intel MPI, MVAPICH, and MPICH are ABI compatible.

The following figure illustrates the architecture for the popular MPI libraries.



HPC-X

The HPC-X software toolkit contains UCX and HCOLL and can be built against UCX.

Bash

```
HPCX_VERSION="v2.6.0"
HPCX_DOWNLOAD_URL=https://azhpcstor.blob.core.windows.net/azhpc-images-store/hpcx-
```

```
v2.6.0-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-redhat7.7-x86_64.tbz
wget --retry-connrefused --tries=3 --waitretry=5 $HPCX_DOWNLOAD_URL
tar -xvf hpcx-${HPCX_VERSION}-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-redhat7.7-x86_64.tbz
mv hpcx-${HPCX_VERSION}-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-redhat7.7-x86_64
${INSTALL_PREFIX}
HPCX_PATH=${INSTALL_PREFIX}/hpcx-${HPCX_VERSION}-gcc-MLNX_OFED_LINUX-5.0-1.0.0.0-
redhat7.7-x86_64
```

The following command illustrates some recommended mpirun arguments for HPC-X and OpenMPI.

Bash

```
mpirun -n $NPROCS --hostfile $HOSTFILE --map-by
ppr:$NUMBER_PROCESSES_PER_NUMA:numa:pe=$NUMBER_THREADS_PER_PROCESS -report-bindings
$MPI_EXECUTABLE
```

where:

Expand table

Parameter	Description
`NPROCS`	Specifies the number of MPI processes. For example: `-n 16`.
`$HOSTFILE`	Specifies a file containing the hostname or IP address, to indicate the location of where the MPI processes run. For example: `--hostfile hosts`.
`$NUMBER_PROCESSES_PER_NUMA`	Specifies the number of MPI processes that run in each NUMA domain. For example, to specify four MPI processes per NUMA, you use `--map-by ppr:4:numa:pe=1`.
`$NUMBER_THREADS_PER_PROCESS`	Specifies the number of threads per MPI process. For example, to specify one MPI process and four threads per NUMA, you use `--map-by ppr:1:numa:pe=4`.
`-report-bindings`	Prints MPI processes mapping to cores, which is useful to verify that your MPI process pinning is correct.
`$MPI_EXECUTABLE`	Specifies the MPI executable built linking in MPI libraries. MPI compiler wrappers do this automatically. For example: `mpicc` or `mpif90`.

An example of running the OSU latency microbenchmark is as follows:

Bash

```
${HPCX_PATH}mpirun -np 2 --map-by ppr:2:node -x UCX_TLS=rc
${HPCX_PATH}/ompi/tests/osu-micro-benchmarks-5.3.2/osu_latency
```

Optimizing MPI collectives

MPI Collective communication primitives offer a flexible, portable way to implement group communication operations. They're widely used across various scientific parallel applications and have a significant impact on the overall application performance. Refer to the TechCommunity article for details on configuration parameters to optimize collective communication performance using HPC-X and HCOLL library for collective communication.

As an example, if you suspect your tightly coupled MPI application is doing an excessive amount of collective communication, you can try enabling hierarchical collectives (HCOLL). To enable those features, use the following parameters.

Bash

```
-mca coll_hcoll_enable 1 -x HCOLL_MAIN_IB=<MLX device>:<Port>
```

> **Note**
>
> With HPC-X 2.7.4+, it may be necessary to explicitly pass LD_LIBRARY_PATH if the UCX version on MOFED vs. that in HPC-X is different.

OpenMPI

Install UCX as described above. HCOLL is part of the HPC-X software toolkit and doesn't requires special installation.

OpenMPI can be installed from the packages available in the repo.

Bash

```
sudo yum install -y openmpi
```

We recommend building a latest, stable release of OpenMPI with UCX.

Bash

```
OMPI_VERSION="4.0.3"
OMPI_DOWNLOAD_URL=https://download.open-mpi.org/release/open-
mpi/v4.0/openmpi-${OMPI_VERSION}.tar.gz
wget --retry-connrefused --tries=3 --waitretry=5 $OMPI_DOWNLOAD_URL
tar -xvf openmpi-${OMPI_VERSION}.tar.gz
cd openmpi-${OMPI_VERSION}
./configure --prefix=${INSTALL_PREFIX}/openmpi-${OMPI_VERSION} --with-
```

```
ucx=${UCX_PATH} --with-hcoll=${HCOLL_PATH} --enable-mpirun-prefix-by-default --with-platform=contrib/platform/mellanox/optimized && make -j$(nproc) && make install
```

For optimal performance, run OpenMPI with `ucx` and `hcoll`. Also see the example with HPC-X.

Bash

```
${INSTALL_PREFIX}/bin/mpirun -np 2 --map-by node --hostfile ~/hostfile -mca pml ucx --mca btl ^vader,tcp,openib -x UCX_NET_DEVICES=mlx5_0:1  -x UCX_IB_PKEY=0x0003 ./osu_latency
```

Check your partition key as mentioned above.

Intel MPI

Download your choice of version of Intel MPI. The Intel MPI 2019 release switched from the Open Fabrics Alliance (OFA) framework to the Open Fabrics Interfaces (OFI) framework, and currently supports libfabric. There are two providers for InfiniBand support: mlx and verbs. Change the I_MPI_FABRICS environment variable depending on the version.

- Intel MPI 2019 and 2021: use `I_MPI_FABRICS=shm:ofi`, `I_MPI_OFI_PROVIDER=mlx`. The `mlx` provider uses UCX. Usage of verbs has been found to be unstable and less performant. See the TechCommunity article for more details.
- Intel MPI 2018: use `I_MPI_FABRICS=shm:ofa`
- Intel MPI 2016: use `I_MPI_DAPL_PROVIDER=ofa-v2-ib0`

Here are some suggested mpirun arguments for Intel MPI 2019 update 5+.

Bash

```
export FI_PROVIDER=mlx
export I_MPI_DEBUG=5
export I_MPI_PIN_DOMAIN=numa

mpirun -n $NPROCS -f $HOSTFILE $MPI_EXECUTABLE
```

where:

Expand table

Parameter	Description
`FI_PROVIDER`	Specifies which libfabric provider to use, which will affect the API, protocol, and network used. verbs is another option, but generally mlx gives you better performance.

Parameter	Description
`I_MPI_DEBUG`	Specifies the level of extra debug output, which can provide details about where processes are pinned, and which protocol and network are used.
`I_MPI_PIN_DOMAIN`	Specifies how you want to pin your processes. For example, you can pin to cores, sockets, or NUMA domains. In this example, you set this environmental variable to numa, which means processes will be pinned to NUMA node domains.

Optimizing MPI collectives

There are some other options that you can try, especially if collective operations are consuming a significant amount of time. Intel MPI 2019 update 5+ supports the provide mlx and uses the UCX framework to communicate with InfiniBand. It also supports HCOLL.

Bash

```
export FI_PROVIDER=mlx
export I_MPI_COLL_EXTERNAL=1
```

Non SR-IOV VMs

For non SR-IOV VMs, an example of downloading the 5.x runtime free evaluation version is as follows:

Bash

```
wget http://registrationcenter-
download.intel.com/akdlm/irc_nas/tec/9278/l_mpi_p_5.1.3.223.tgz
```

For installation steps, see the Intel MPI Library Installation Guide. Optionally, you may want to enable ptrace for non-root non-debugger processes (needed for the most recent versions of Intel MPI).

Bash

```
echo 0 | sudo tee /proc/sys/kernel/yama/ptrace_scope
```

SUSE Linux

For SUSE Linux Enterprise Server VM image versions - SLES 12 SP3 for HPC, SLES 12 SP3 for HPC (Premium), SLES 12 SP1 for HPC, SLES 12 SP1 for HPC (Premium), SLES 12 SP4 and SLES

15, the RDMA drivers are installed and Intel MPI packages are distributed on the VM. Install Intel MPI by running the following command:

```bash
sudo rpm -v -i --nodeps /opt/intelMPI/intel_mpi_packages/*.rpm
```

MVAPICH

The following is an example of building MVAPICH2. Note newer versions may be available than what is used below.

```bash
wget http://mvapich.cse.ohio-state.edu/download/mvapich/mv2/mvapich2-2.3.tar.gz
tar -xv mvapich2-2.3.tar.gz
cd mvapich2-2.3
./configure --prefix=${INSTALL_PREFIX}
make -j 8 && make install
```

An example of running the OSU latency microbenchmark is as follows:

```bash
${INSTALL_PREFIX}/bin/mpirun_rsh -np 2 -hostfile ~/hostfile MV2_CPU_MAPPING=48
./osu_latency
```

The following list contains several recommended `mpirun` arguments.

```bash
export MV2_CPU_BINDING_POLICY=scatter
export MV2_CPU_BINDING_LEVEL=numanode
export MV2_SHOW_CPU_BINDING=1
export MV2_SHOW_HCA_BINDING=1

mpirun -n $NPROCS -f $HOSTFILE $MPI_EXECUTABLE
```

where:

Expand table

Parameter	Description
`MV2_CPU_BINDING_POLICY`	Specifies which binding policy to use, which will affect how processes are pinned to core IDs. In this case, you specify `scatter`, so processes are evenly

Parameter	Description
	scattered among the NUMA domains.
`MV2_CPU_BINDING_LEVEL`	Specifies where to pin processes. In this case, you set it to numanode, which means processes are pinned to units of NUMA domains.
`MV2_SHOW_CPU_BINDING`	Specifies if you want to get debug information about where the processes are pinned.
`MV2_SHOW_HCA_BINDING`	Specifies if you want to get debug information about which host channel adapter each process is using.

Platform MPI

Install required packages for Platform MPI Community Edition.

Bash

```
sudo yum install libstdc++.i686
sudo yum install glibc.i686
Download platform MPI at
https://www.ibm.com/developerworks/downloads/im/mpi/index.html
sudo ./platform_mpi-09.01.04.03r-ce.bin
```

Follow the installation process.

MPICH

Install UCX as described above. Build MPICH.

Bash

```
wget https://www.mpich.org/static/downloads/3.3/mpich-3.3.tar.gz
tar -xvf mpich-3.3.tar.gz
cd mpich-3.3
./configure --with-ucx=${UCX_PATH} --prefix=${INSTALL_PREFIX} --with-device=ch4:ucx
make -j 8 && make install
```

Running MPICH.

Bash

```
${INSTALL_PREFIX}/bin/mpiexec -n 2 -hostfile ~/hostfile -env UCX_IB_PKEY=0x0003 -
bind-to hwthread ./osu_latency
```

Check your partition key as mentioned above.

OSU MPI Benchmarks

Download OSU MPI Benchmarks and untar.

```Bash
wget http://mvapich.cse.ohio-state.edu/download/mvapich/osu-micro-benchmarks-5.5.tar.gz
tar -xvf osu-micro-benchmarks-5.5.tar.gz
cd osu-micro-benchmarks-5.5
```

Build Benchmarks using a particular MPI library:

```Bash
CC=<mpi-install-path/bin/mpicc>CXX=<mpi-install-path/bin/mpicxx> ./configure
make
```

MPI Benchmarks are under `mpi/` folder.

Discover partition keys

Discover partition keys (p-keys) for communicating with other VMs within the same tenant (Availability Set or Virtual Machine Scale Set).

```Bash
/sys/class/infiniband/mlx5_0/ports/1/pkeys/0
/sys/class/infiniband/mlx5_0/ports/1/pkeys/1
```

The larger of the two is the tenant key that should be used with MPI. Example: If the following are the p-keys, 0x800b should be used with MPI.

```Bash
cat /sys/class/infiniband/mlx5_0/ports/1/pkeys/0
0x800b
cat /sys/class/infiniband/mlx5_0/ports/1/pkeys/1
0x7fff
```

Note interfaces are named as `mlx5_ib*` inside HPC VM images.

Also note that as long as the tenant (Availability Set or Virtual Machine Scale Set) exists, the PKEYs remain the same. This is true even when nodes are added/deleted. New tenants get different PKEYs.

Set up user limits for MPI

Set up user limits for MPI.

Bash

```
cat << EOF | sudo tee -a /etc/security/limits.conf
*               hard    memlock         unlimited
*               soft    memlock         unlimited
*               hard    nofile          65535
*               soft    nofile          65535
EOF
```

Set up SSH keys for MPI

Set up SSH keys for MPI types that require it.

Bash

```
ssh-keygen -f /home/$USER/.ssh/id_rsa -t rsa -N ''
cat << EOF > /home/$USER/.ssh/config
Host *
    StrictHostKeyChecking no
EOF
cat /home/$USER/.ssh/id_rsa.pub >> /home/$USER/.ssh/authorized_keys
chmod 600 /home/$USER/.ssh/authorized_keys
chmod 644 /home/$USER/.ssh/config
```

The above syntax assumes a shared home directory, else `.ssh` directory must be copied to each node.

Next steps

- Learn about the InfiniBand enabled HB-series and N-series VMs.
- Review the HBv3-series overview and HC-series overview.
- Read Optimal MPI process placement for HB-series VMs.
- Read about the latest announcements, HPC workload examples, and performance results at the Azure Compute Tech Community Blogs.
- For a higher level architectural view of running HPC workloads, see High Performance Computing (HPC) on Azure.

Last updated on 09/17/2024

Scaling HPC applications

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Optimal scale-up and scale-out performance of HPC applications on Azure requires performance tuning and optimization experiments for the specific workload. This section and the VM series-specific pages offer general guidance for scaling your applications.

Application setup

The azurehpc repo contains many examples of:

- Setting up and running applications optimally.
- Configuration of file systems, and clusters.
- Tutorials on how to get started easily with some common application workflows.

Optimally scaling MPI

The following suggestions apply for optimal application scaling efficiency, performance, and consistency:

- For smaller scale jobs (< 256K connections) use: `UCX_TLS=rc,sm`
- For larger scale jobs (> 256K connections) use: `UCX_TLS=dc,sm`
- To calculate the number of connections for your MPI job, use: `Max Connections = (processes per node) x (number of nodes per job) x (number of nodes per job)`

Adaptive Routing

Adaptive Routing (AR) allows Azure Virtual Machines (VMs) running EDR and HDR InfiniBand to automatically detect and avoid network congestion by dynamically selecting optimal network paths. As a result, AR offers improved latency and bandwidth on the InfiniBand network, which in turn drives higher performance and scaling efficiency. For more information, see TechCommunity article.

Process pinning

- Pin processes to cores using a sequential pinning approach (as opposed to an autobalance approach).
- Binding by Numa/Core/HwThread is better than default binding.

- For hybrid parallel applications (OpenMP+MPI), use four threads and one MPI rank per [CCX](HB-series virtual machines overview including info on CCXs) on HB and HBv2 VM sizes.
- For pure MPI applications, experiment with between one to four MPI ranks per CCX for optimal performance on HB and HBv2 VM sizes.
- Some applications with extreme sensitivity to memory bandwidth may benefit from using a reduced number of cores per CCX. For these applications, using three or two cores per CCX may reduce memory bandwidth contention and yield higher real-world performance or more consistent scalability. In particular, MPI 'Allreduce' may benefit from this approach.
- For larger scale runs, it's recommended to use UD or hybrid RC+UD transports. Many MPI libraries/runtime libraries use these transports internally (such as UCX or MVAPICH2). Check your transport configurations for large-scale runs.

Compiling applications

▼ Click to expand

Though not necessary, compiling applications with appropriate optimization flags provides the best scale-up performance on HB and HC-series VMs.

AMD Optimizing C/C++ Compiler

The AMD Optimizing C/C++ Compiler (AOCC) compiler system offers a high level of advanced optimizations, multi-threading, and processor support that includes global optimization, vectorization, inter-procedural analyses, loop transformations, and code generation. AOCC compiler binaries are suitable for Linux systems having GNU C Library (glibc) version 2.17 and above. The compiler suite consists of a C/C++ compiler (clang), a Fortran compiler (FLANG), and a Fortran front end to Clang (Dragon Egg).

Clang

Clang is a C, C++, and Objective-C compiler handling preprocessing, parsing, optimization, code generation, assembly, and linking. Clang supports the `-march=znver1` flag to enable best code generation and tuning for AMD's Zen based x86 architecture.

FLANG

The FLANG compiler is a recent addition to the AOCC suite (added April 2018) and is currently in prerelease for developers to download and test. Based on Fortran 2008, AMD extends the GitHub version of FLANG. The FLANG compiler supports all Clang compiler options and other number of FLANG-specific compiler options.

DragonEgg

DragonEgg is a gcc plugin that replaces GCC's optimizers and code generators from the LLVM project. DragonEgg that comes with AOCC works with gcc-4.8.x, has been tested for x86-32/x86-64 targets, and has been successfully used on various Linux platforms.

GFortran is the actual frontend for Fortran programs responsible for preprocessing, parsing, and semantic analysis generating the GCC GIMPLE intermediate representation (IR). DragonEgg is a GNU plugin, plugging into GFortran compilation flow. It implements the GNU plugin API. With the plugin architecture, DragonEgg becomes the compiler driver, driving the different phases of compilation. After following the download and installation instructions, Dragon Egg can be invoked using:

Bash

```
gfortran [gFortran flags]
   -fplugin=/path/AOCC-1.2-Compiler/AOCC-1.2-
   FortranPlugin/dragonegg.so [plugin optimization flags]
   -c xyz.f90 $ clang -O3 -lgfortran -o xyz xyz.o $./xyz
```

PGI Compiler

PGI Community Edition 17 is confirmed to work with AMD EPYC. A PGI-compiled version of STREAM does deliver full memory bandwidth of the platform. The newer Community Edition 18.10 (Nov 2018) should likewise work well. Use this CLI command to compile with the Intel Compiler:

Bash

```
pgcc $(OPTIMIZATIONS_PGI) $(STACK) -DSTREAM_ARRAY_SIZE=800000000 stream.c -o
stream.pgi
```

Intel Compiler

Intel Compiler 18 is confirmed to work with AMD EPYC. Use this CLI command to compile with the Intel Compiler.

Bash

```
icc -o stream.intel stream.c -DSTATIC -DSTREAM_ARRAY_SIZE=800000000 -mcmodel=large -
shared-intel -Ofast –qopenmp
```

GCC Compiler

For HPC workloads, AMD recommends GCC compiler 7.3 or newer. Older versions, such as 4.8.5 included with RHEL 7.4, aren't recommended. GCC 7.3, and newer, delivers higher performance on HPL, HPCG, and DGEMM tests.

Bash

```
gcc $(OPTIMIZATIONS) $(OMP) $(STACK) $(STREAM_PARAMETERS) stream.c -o stream.gcc
```

NVMe Overview

Article • 08/22/2024

NVM Express (NVMe) is a communication protocol that facilitates faster and more efficient data transfer between servers and storage systems by using nonvolatile memory (NVM). With NVMe, data can be transferred at the highest throughput and with the fastest response times. In this overview, learn about NVMe support on virtual machines (VM) created in Azure.

NVMe offers higher input/output operations per second (IOPS) and higher throughput in megabytes per second (MBps). This capability can significantly improve the performance of both temporary (local) and remote NVMe disk storage with Azure managed disks. Higher performance is especially beneficial for I/O-intensive workloads that require fast data transfer to the Azure managed disks.

Benefits

Azure storage performance with NVMe disks

The performance gains that your applications can achieve depend on several factors, including VM type, VM size, and I/O block size. To identify the ideal block size and to achieve peak transfer rates, test on the individual VM sizes. It's important to optimize the I/O size based on the specific requirements of your application. For more information on the performance capabilities of individual VM types, see the documentation about VM sizes in Azure.

Workloads

The VM families that use NVMe disks demonstrate performance benefits compared to Small Computer System Interface (SCSI) across various workloads that require higher I/O and improved storage performance. These workloads include application servers, web servers, databases, data warehousing, and analytics. You can achieve these benefits across VMs that use temporary and/or remote NVMe disks.

Azure Boost & NVMe VM benefits

Azure Boost is a Microsoft-designed system that offloads server virtualization processes traditionally performed by the hypervisor and host OS onto purpose-built software and

hardware. Offloading these processes enables faster storage and networking performance for Azure VM customers.

One of the primary advantages of Azure Boost is its ability to enhance the throughput of Azure managed disks and local storage. This enhancement is enabled by offloading the storage processing tasks to hardware dedicated for Azure Boost.

Azure Boost also optimizes performance by using the industry-standard NVMe interface, which capitalizes on the low latency and internal parallelism of solid-state storage drives. For details on the performance that Azure Boost offers, refer to the Microsoft blog post about general availability of Azure Boost.

SCSI to NVMe

For v6, Ebsv5, and greater VMs; you need to transition from SCSI to NVMe. For more information, read about SCSI to NVMe using Linux.

Supportability

VM sizes

Typically, the older generations of general purpose, memory optimized, and compute optimized VMs (D/Ev5 or Fv2 and older) support SCSI. The newer generations (Ebsv5, Da/Ea/Fav6 and newer) typically support only the NVMe storage interface (or some offering supports SCSI and NVMe, both interfaces, Ebsv5 is an example of such offering). Also, starting from Da/Ea/Fav6 and some of the future offering, we have introduced the NVMe interface for the local SSD disks.

For specifics about which VM generations support which storage types, check the documentation about VM sizes in Azure.

VM image generation

If you think your workload benefits from NVMe performance, you must switch to the Generation 2 VMs. To create a Generation 2 VM, follow the documented steps.

> **Note**
>
> We currently do not support NVMe disks on Generation 1 VMs.

If you attempt to use a Generation 1 VM image, you won't be able to select an NVMe-capable VM or you receive an error message stating `that the selected image is not supported for NVMe.`

Availability of Support

NVMe support is available in more than 50 of the most popular OS images. We're not adding NVMe support to older OS images. However, we continuously improve the OS image coverage. For updates on the latest OS image support for both Linux and Windows, we recommend this documentation on OS image that supports NVMe.

If the OS you want to use doesn't support NVMe, use a VM series that still has SCSI support. Many of the latest Azure VM generations are NVMe-only and require an OS image that supports NVMe.

How to create a VM with the NVMe interface

You can enable NVMe during VM creation by using methods such as:

- Azure portal
- Azure CLI
- Azure PowerShell
- Azure Resource Manager templates

To create an NVMe-enabled VM, you must first enable the NVMe option on a VM and select the NVMe disk controller type for the VM. You can also update a VM to NVMe when stopped and deallocated, if the VM size supports NVMe.

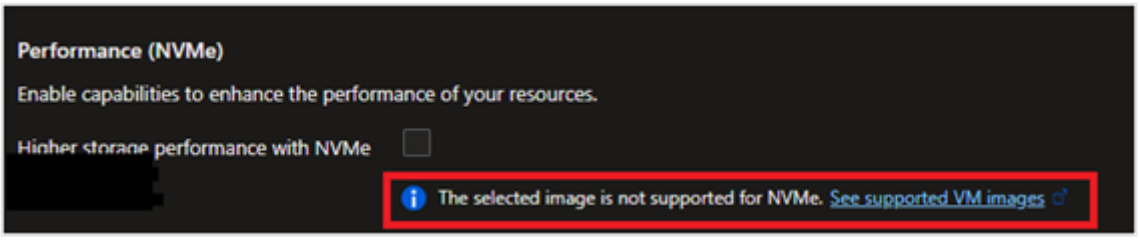
Mark as NVMe capable

You can create NVMe interface enabled VM only by using an image (available in Marketplace, or shared in Azure Compute Gallery within your company) marked as NVMe.

> ⚠ **Warning**
>
> If you use an unmarked image, a SCSI-based VM is created, and the VM might not perform as you intended.

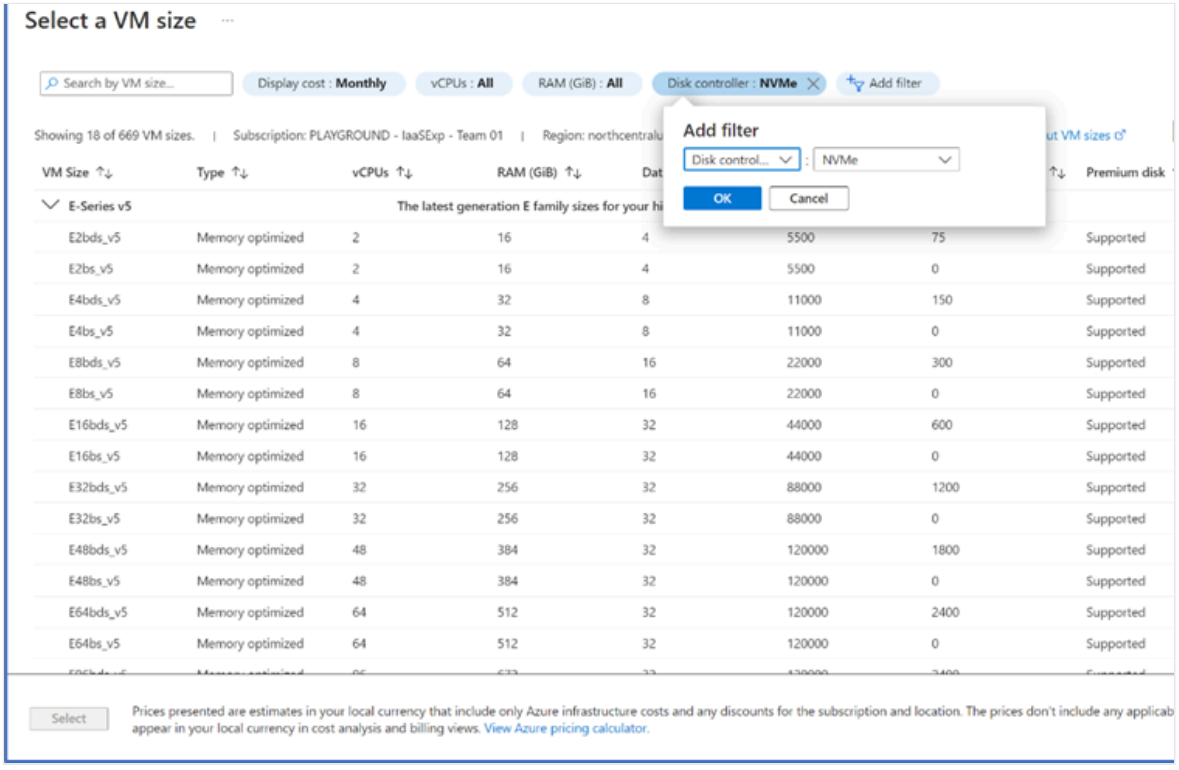
To create VMs with an NVMe interface, it's essential to choose one of the supported OS images marked as NVMe. If your current OS image isn't supported for NVMe, you get

this error message: `"The selected image is not supported for NVMe. See supported VM images."`

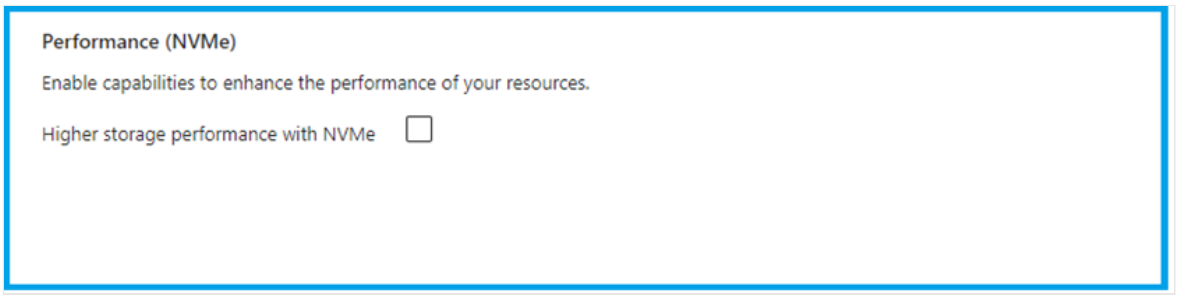


Using Azure portal to enable the NVMe interface during VM creation

1. Add a disk controller filter. To find the NVMe-eligible sizes, select **See All Sizes**, select the **Disk controller** filter, and then select **NVMe**.



2. Enable the NVMe feature by going to the **Advanced** tab and selecting the checkbox under **Performance (NVMe)**.



3. Verify that the feature is enabled by going to the **Review and Create** tab and confirming that the **Disk controller type** value is **NVMe**.

FAQ for Temp NVMe disks

This article addresses some common questions about support for temporary Non-Volatile Memory Express (NVMe) disks on virtual machines (VMs) created in Azure. In this article, the term "temp disk" is referring to the temporary disk that is created on local SSD.

What are the prerequisites to create temp disk that uses NVMe interface for my VM?

NVMe support for local temp disks varies at a virtual machine (VM) family level. All of the new v6 VMs with local disk support NVMe temp disks, but v5 VMs and earlier versions may not support NVMe local temp disks, as most of those sizes local disks are on the SCSI interface. Some VM families like L-series, include attached NVMe SSDs from Lsv2 generation VMs onward. Refer to the VM family overviews to determine if NVMe temp disks are supported. Also, note your Guest OS needs to have NVMe driver support in order to use local NVMe, which most of the recent OS releases have by default.

How are temp NVMe disks in my Dl/D/E_v6 VMs different from remote NVMe disks?

A key difference is that temp NVMe disks are transient and data on the VMs can disappear, but data on remote NVMe disks stays. Factor in this difference when you're choosing your VM's storage options.

Unlike the previous D/E series VMs, the new v6 VMs come with raw, unformatted NVMe disks. Customers should initialize and format the disks into a file system of their preference after the VM starts up.

The Dl/D/E v6 series VMs are optimized to use the local temp NVMe disk on the node attached directly to the VM rather than previously used local Small Computer System Interface (SCSI) disks. This method allows for higher input/output operations per second and higher throughput for your workloads.

What changes should I prepare for when configuring my VMs with temp NVMe disks?

- Disks should be initialized and formatted after the VM starts up. After user-initiated stops, deallocations, or planned maintenance and Azure-initiated automatic recovery events, the VMs start up with only raw temp NVMe disks. No temp NVMe disks are visible to applications until after they're initialized and formatted.
- You can span separate NVMe drives into one as needed after the VM starts up.
- A Windows pagefile is placed on persistent OS disks (unless you're using the ephemeral OS feature), but you can move it to temp NVMe disks as needed after the VM starts up.
- The ephemeral OS feature, if you use it, converts one or several NVMe disks (depending on the VM and image size) into a slower SCSI/VHD-based disk, similar to how it was on v5 and older VMs. For the larger VM sizes, the remaining drives stay as raw unformatted NVMe.
- The list of resource Stock Keeping Units (SKUs) in the REST API exposes several capabilities of virtual machines. The next iteration of VM sizes uses the faster and more efficient NVMe protocol for local storage, instead of the SCSI protocol that earlier VM sizes use.

  For Azure virtual machines, SCSI-based local storage is a temporary resource disk, and the `MaxResourceVolumeMB` value specifies the size of this disk. In contrast, the `NVMeDiskSizeInMiB` value specifies the size of NVMe-based local storage.

What is the minimum encryption offered by Azure for the temp NVMe disks?

All local NVMe disks on Azure virtual machines (VMs) have built-in encryption enabled by default for data protection. Temp NVMe disks support the feature of data encryption at rest. A unique data encryption key (DEK) encrypts the data for each temp NVMe disk assigned to the VM. A key encryption key (KEK) helps protect the DEK. When you delete a VM, the data on its temp NVMe disk is cryptographically erased. All the v6 VMs that are introduced from 2024 and onward, have their local NVMe drives encrypted by default using hardware based encryption with a Platform Managed Key.

- Data is encrypted using XTS-AES-256, AES-256-GCM, or a stronger cipher.
- Device generates a unique Media Encryption Key (MEK) for each disk in the VM.
- The MEK is:
  - Generated and stored entirely within the device hardware.
  - Never exposed to the host, VM, or any external component including the operator, or Azure system.
- All encryption and decryption operations occur within the device using the MEK.

- The MEK is destroyed when you delete your VM, ensuring that no component can access the data afterward.

What is Enhanced Encryption at Rest?

Enhanced Encryption at rest is another layer of protection that's available on the Azure V6-series and Lsv4-series VMs through support for TCG-OPAL standards. You don't need to take any action for this feature, it's the default for these VM types.

- Azure infrastructure generates and securely stores a PIN value for each MEK.
- The PIN is passed through a Key Derivation Function (KDF) within the storage device to generate a Key Encrypting Key (KEK). The PIN acts as a Platform management key (PMK).
- The MEK is encrypted using the KEK and stored internally within the storage device.
- The KEK isn't stored anywhere and the storage device dynamically generates the KEK when the PIN is used to successfully authenticate it. Without this PIN, the device can't decrypt its own stored data—even if physically accessed.
- The storage device is authenticated when the VM starts. It’s locked when the VM stops, which ensures data is accessible only while the VM is running.

How can I resize a v5 or older VM with a temp disk to v6?

See the FAQ for Azure VM sizes with no local temporary disk.

How can I identify my temp NVMe disk?

You can run the following command for Windows:

PowerShell

```
Get-PhysicalDisk | where { $_.FriendlyName.contains("NVMe Direct Disk")}
```

You can run the following command for Linux:

```
sudo nvme id-ns /dev/nvme0n1 -b | dd bs=1 skip=384 status=none | sed 's/\x00*$//'
```

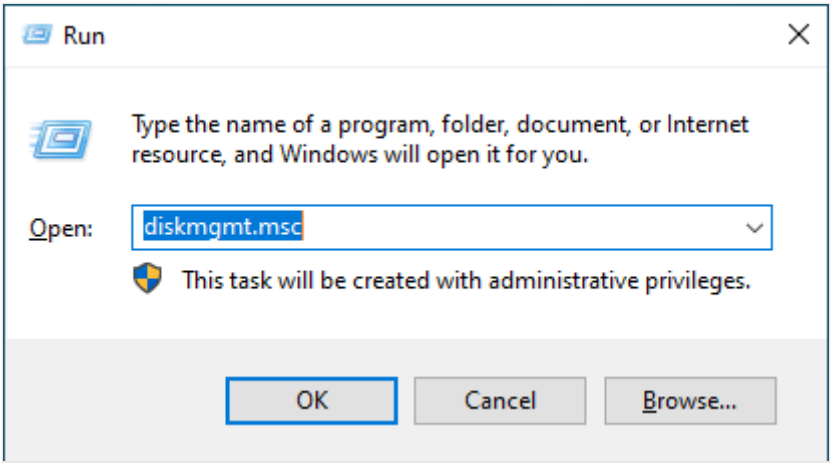
How can I format and initialize temp NVMe disks in Windows when I create a VM?

You can use the GUI or Azure PowerShell.

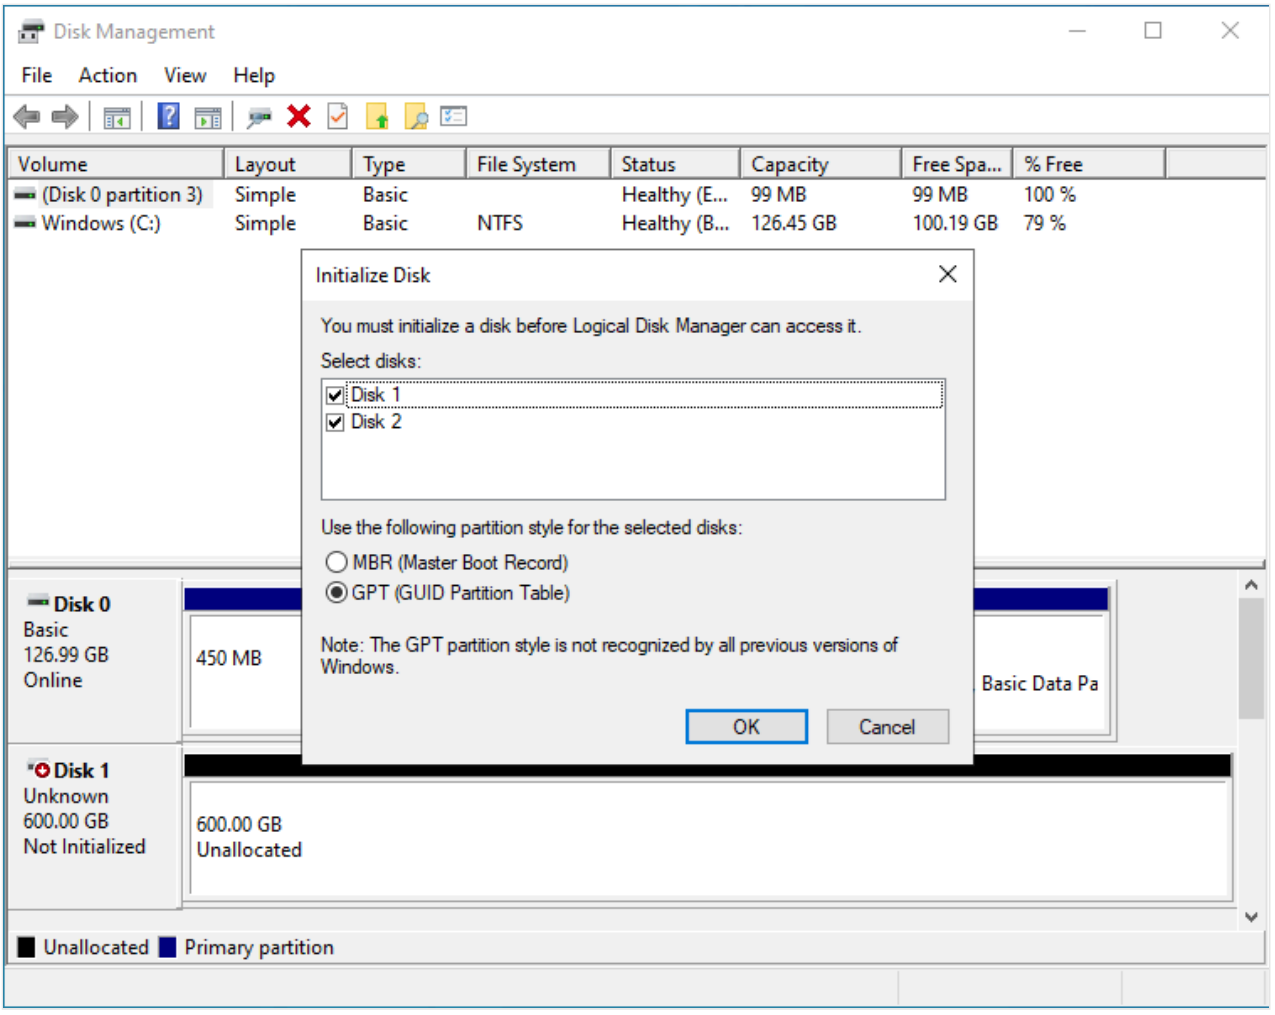
GUI

> **Tip**
>
> The following GUI example is meant for illustrative purposes. We recommend that you create scripts to automate this workflow for production deployments.

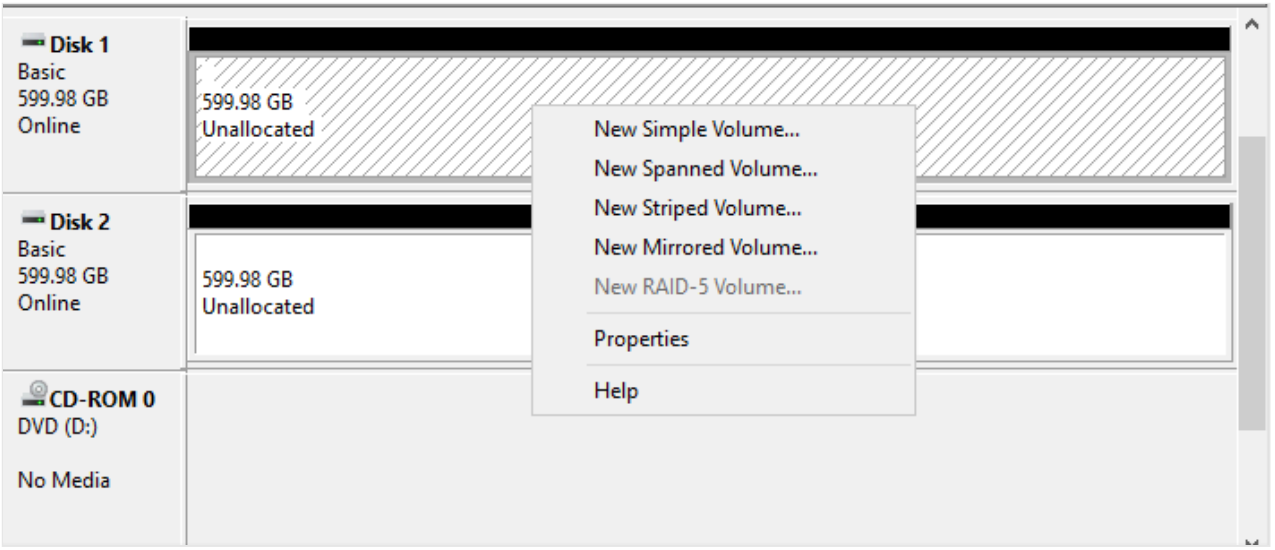
1. Select Windows logo key + R to open the **Run** dialog. Type **diskmgmt.msc** and select the Enter key.



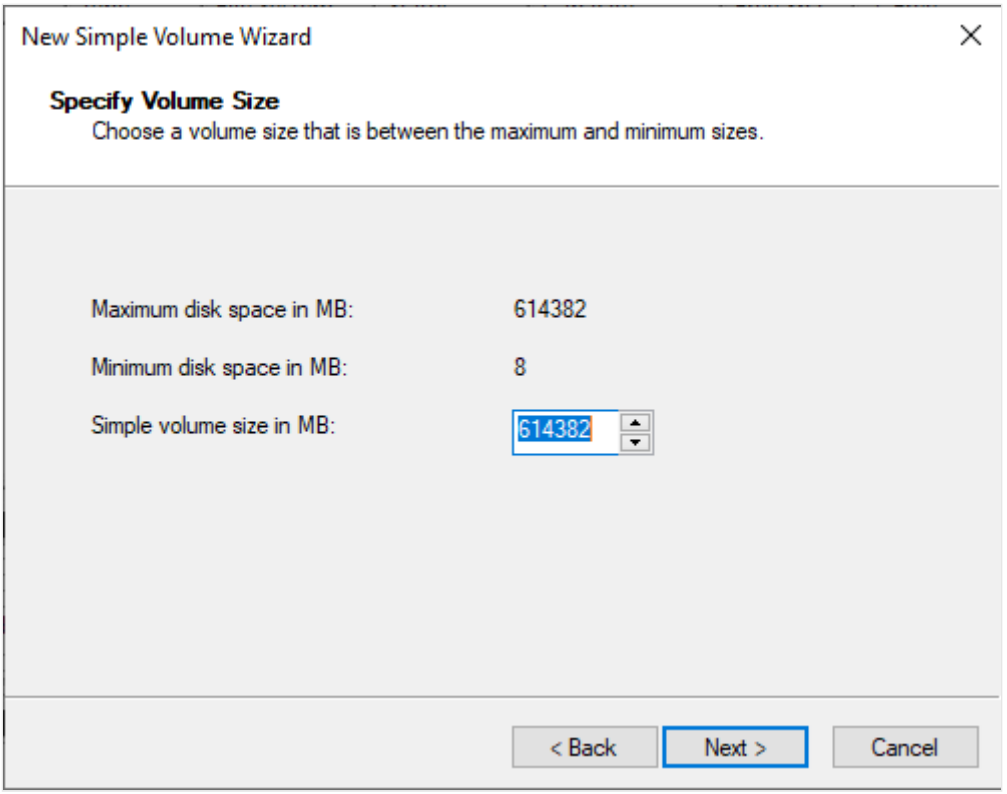
2. Select a partition style (**MBR** or **GPT**) and the disks to be initialized, and then select **OK**.



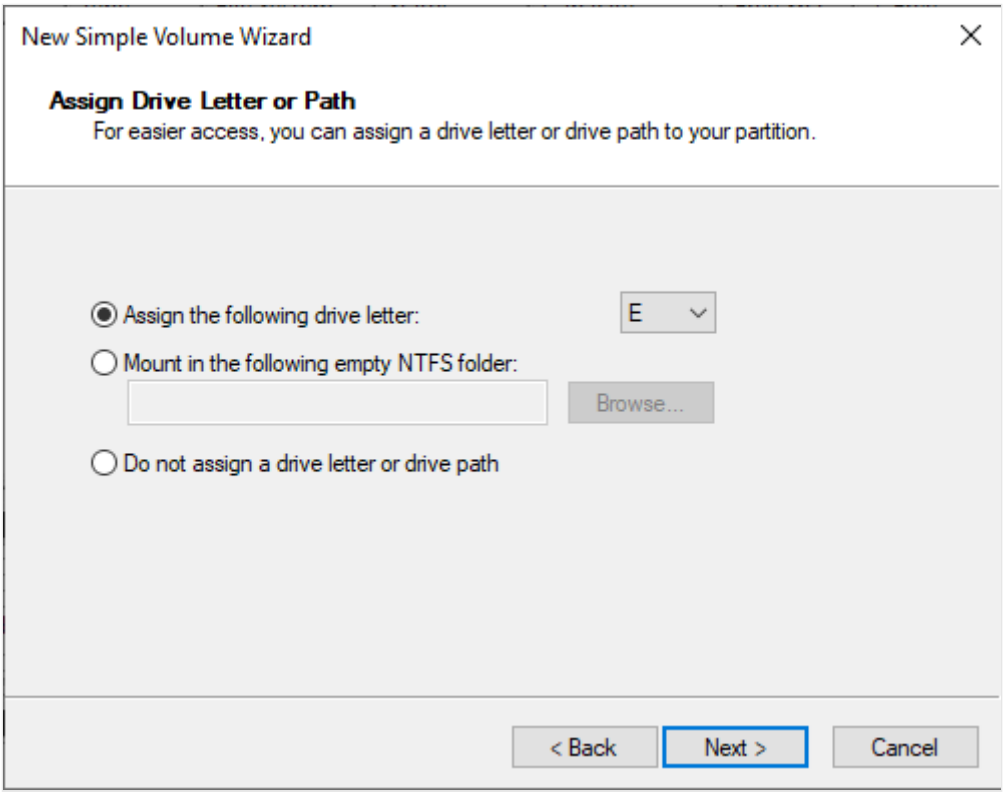
3. Right-click the disk to be partitioned, and then select **New Simple Volume**.



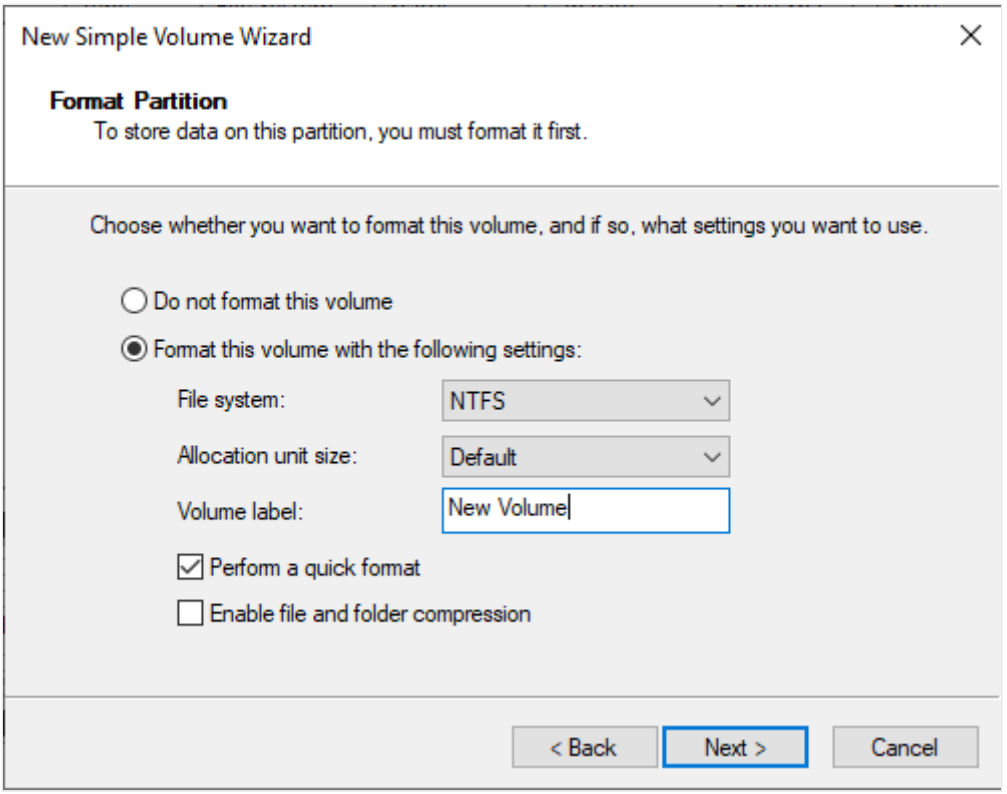
4. To specify items such as volume size, drive letter, file system, and volume label, follow the New Simple Volume Wizard. Select the **Next** button to advance through the wizard.



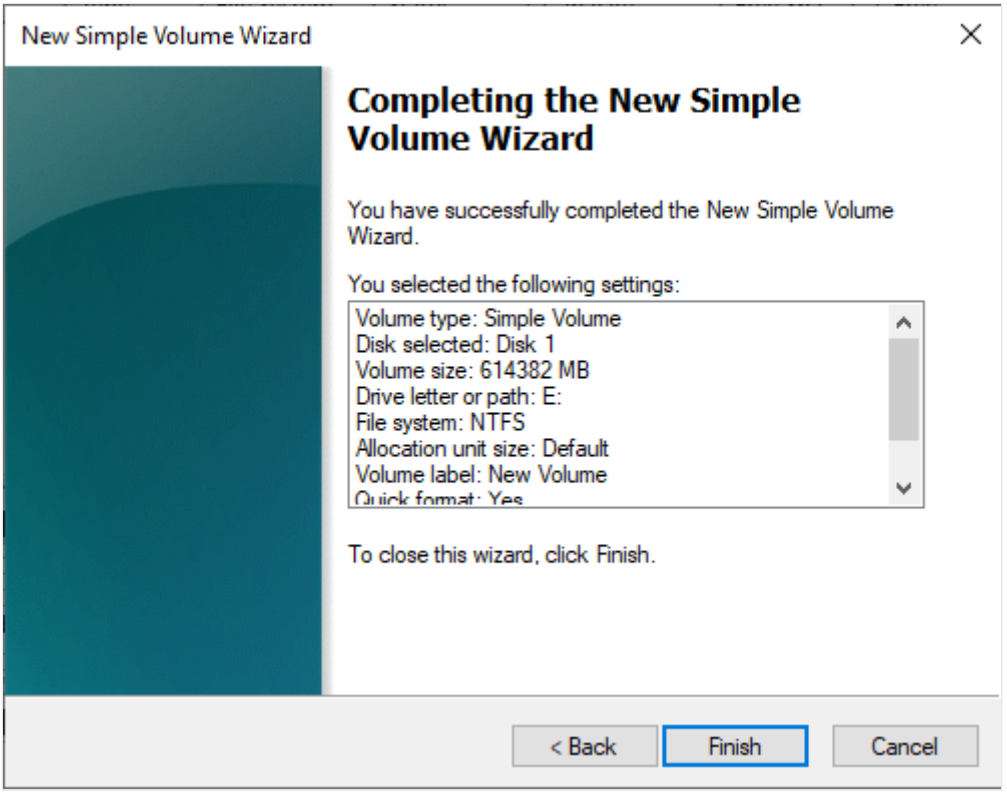
New Simple Volume Wizard
Specify Volume Size
Choose a volume size that is between the maximum and minimum sizes.
Maximum disk space in MB:
614382
Minimum disk space in MB:
8
Simple volume size in MB:
614382
< Back
Next >
Cancel



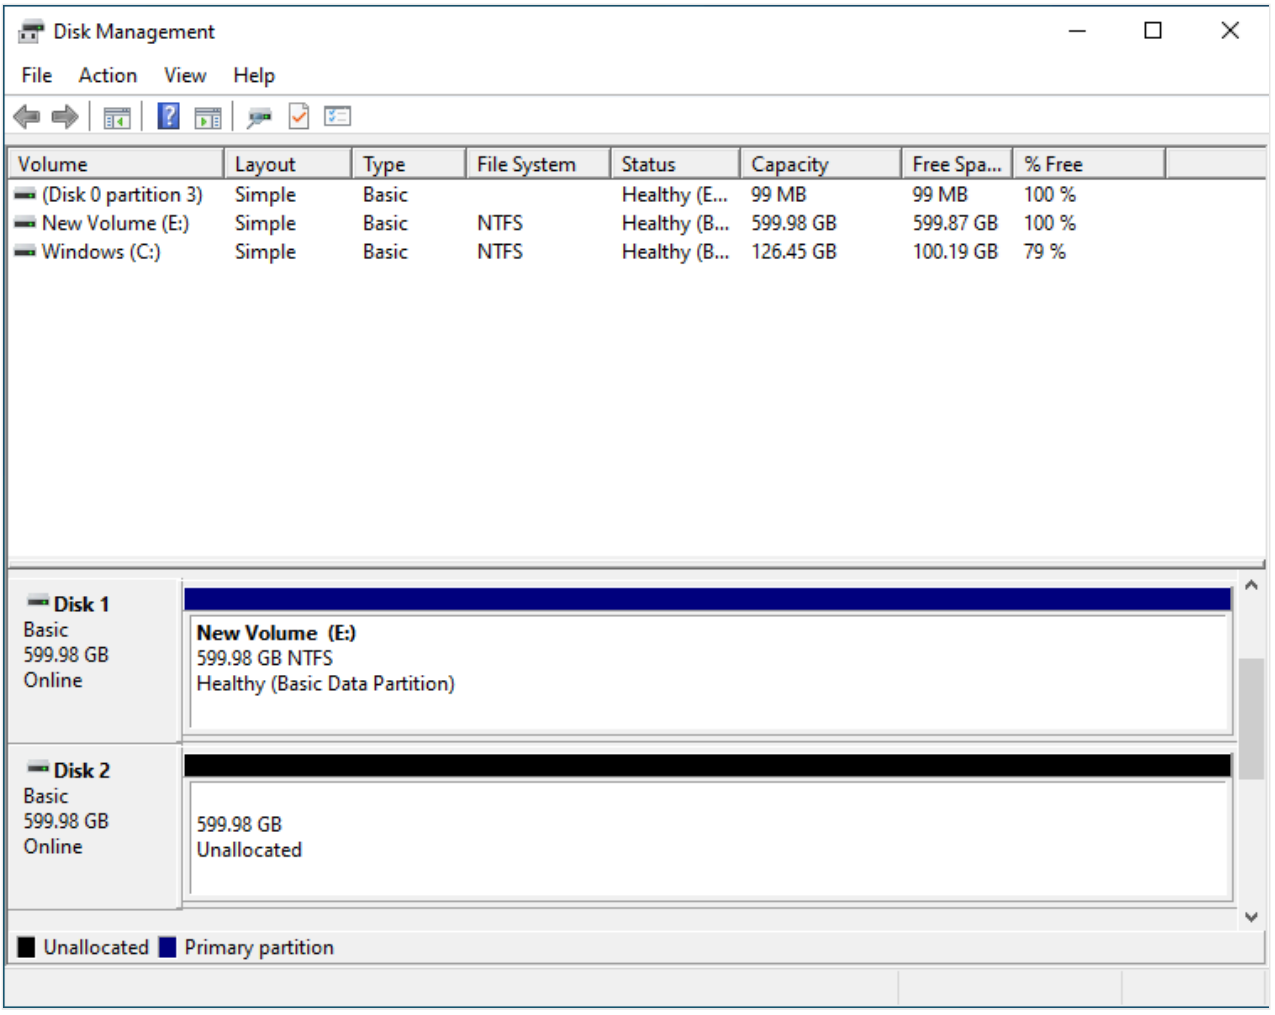
New Simple Volume Wizard
Assign Drive Letter or Path
For easier access, you can assign a drive letter or drive path to your partition.
Assign the following drive letter:
E
Mount in the following empty NTFS folder:
Browse...
Do not assign a drive letter or drive path
< Back
Next >
Cancel



5. To complete the partition and format, review your settings and then select **Finish**.



6. Confirm that the formatted and initialized NVMe disks appear in the Windows Disk Management tool, similar to how **New Volume (E:)** appears in this example.



Azure PowerShell script

> **Tip**
>
> The following script initializes, formats, and assigns drive letters. However, it erases all data on the disk. You should thoroughly test it on your VMs before deploying it in production.

PowerShell

```
# Select the raw NVMe disks to partition and format

$RawNvmeDisks = Get-PhysicalDisk -CanPool $True | where {
$_.FriendlyName.contains("NVMe Direct Disk")}

# Create a pool of the existing disks

New-StoragePool -FriendlyName NVMePool -StorageSubsystemFriendlyName "Windows
Storage*" -PhysicalDisks $RawNvmeDisks -ResiliencySettingNameDefault Simple

#Create a new disk, initialize, partition, and format

$Disk = New-VirtualDisk -FriendlyName NVMeTemporary -StoragePoolFriendlyName
NVMePool -NumberOfColumns @($RawNvmeDisks).count  -PhysicalDiskRedundancy 0 -
```

```
ResiliencySettingName "Simple" -UseMaximumSize

$Disk | Initialize-Disk

#Create a partition and format. Ignore the pop-up.

New-Partition -DiskId $Disk.UniqueId  -AssignDriveLetter -UseMaximumSize | Format-
Volume
```

How can I format and initialize temp NVMe disks in Linux?

The following script provides an example of initializing temp NVMe disks in Linux. The script enumerates all temp NVMe disks on the VM, combines the disks into a single RAID 0 array, and creates a formatted partition of the specified file system.

Temp NVMe disks are distinguished by the model number, which appears as `Microsoft NVMe Direct Disk` to the guest OS. This script uses the `nvme-cli id-ctrl` command to query the model number of each NVMe device.

The script first checks for any already-created temp NVMe disk volumes (identified by the `filesystem` label). If an array appears to be present, the script verifies the array's integrity and repeats the initialization process if necessary. The array reinitializes in the following cases:

- One or more array temp disks are missing.
- There are temp disks not already incorporated into the array.
- The disk array is in an otherwise invalid or unknown state.
- Associated configuration files are missing or invalid.

```
#!/bin/bash

# Script requirements:
#   nvme-cli
#   mdadm
#   gdisk

readonly USAGE="Usage: $(basename "$0") <filesystem> <filesystem mount point
(optional)>"

# Label used to identify the NVMe array file system and associated disks
# Can't exceed 16 characters
readonly RAID0_FILESYSTEM_LABEL="azure_nvme_temp"
# Device path used for the RAID 0 NVMe array
# Choose any unoccupied device path of format /dev/mdX (X = 0 to 99)
readonly RAID0_DEVICE_PATH="/dev/md0"
```

```
# Formatted RAID 0 partition is mounted here
readonly DEFAULT_MOUNT_POINT="/mnt/${RAID0_FILESYSTEM_LABEL}"

filesystem="$1"
if [ ! "$filesystem" ]; then
    printf "No filesystem specified. Usage: $USAGE\n"
    exit 1
fi
if ! [ -x "$(command -v mkfs.$filesystem)" ]; then
    printf "Filesystem \"$filesystem\" not supported by mkfs\n$USAGE\n"
    exit 1
fi

mount_point="$2"
if [ ! "$mount_point" ]; then
    printf "No mount point specified. Using default: $DEFAULT_MOUNT_POINT\n"
    mount_point=$DEFAULT_MOUNT_POINT
fi

# Make sure mdadm.conf is present
mdadm_conf_path=""
if [ -e "/etc/mdadm/mdadm.conf" ]; then
    mdadm_conf_path="/etc/mdadm/mdadm.conf"
elif [ -e "/etc/mdadm.conf" ]; then
    mdadm_conf_path="/etc/mdadm.conf"
else
    printf "Couldn't find mdadm.conf file"
    exit 1

        else
            for device in "${nvme_direct_disks[@]}"
            do
                if ! mdadm --examine $device &> /dev/null; then
                    reinit_raid0=true
                    break
                fi
            done
        fi
    else
        reinit_raid0=true
    fi

    if [ "$reinit_raid0" = true ]; then
        echo "Errors found in NVMe RAID 0 temp array device or configuration.
Reinitializing."

        # Remove the file system and partition table, and stop the RAID 0 array
        if [ "$nvme_raid0_present" = true ]; then
            if [ -e ${RAID0_DEVICE_PATH}p1 ]; then
                umount ${RAID0_DEVICE_PATH}p1
                wipefs -a -f ${RAID0_DEVICE_PATH}p1
            fi
            sgdisk -o $RAID0_DEVICE_PATH &> /dev/null
            mdadm --stop $RAID0_DEVICE_PATH
        fi

        # Remove any mdadm metadata from all NVMe Direct Disks
        for device in "${nvme_direct_disks[@]}"
        do
            printf "Clearing mdadm superblock from $device\n"
            mdadm --zero-superblock $device &> /dev/null
        done

        # Remove any associated entries in fstab and mdadm.conf
        sed -i.bak "/$RAID0_FILESYSTEM_LABEL/d" /etc/fstab
        sed -i.bak "/$RAID0_FILESYSTEM_LABEL/d" $mdadm_conf_path
    else
        printf "Valid NVMe RAID 0 array present and no additional Direct Disks
found. Skipping\n"
        exit 0
    fi
```

```
fi

if [ "$nvme_direct_disk_count" -eq 0 ]; then
    printf "No NVMe Direct Disks found\n"
    exit 1
elif [ "$nvme_direct_disk_count" -eq 1 ]; then
    additional_mdadm_params="--force"
fi

# Initialize enumerated disks as RAID 0
printf "Creating RAID 0 array from:\n"
printf "${nvme_direct_disks[*]}\n\n"
if ! mdadm --create $RAID0_DEVICE_PATH --verbose $additional_mdadm_params --
name=$RAID0_FILESYSTEM_LABEL --level=0 --raid-devices=$nvme_direct_disk_count
${nvme_direct_disks[*]}; then
    printf "Failed to create RAID 0 array\n"
    exit 1
fi

# Create a GPT partition entry
readonly GPT_PARTITION_TYPE_GUID="0FC63DAF-8483-4772-8E79-3D69D8477DE4"
printf "\nCreating GPT on $RAID0_DEVICE_PATH..\n"
sgdisk -o $RAID0_DEVICE_PATH &> /dev/null
if ! sgdisk --new 1::0 --typecode 1:$GPT_PARTITION_TYPE_GUID $RAID0_DEVICE_PATH  &>
/dev/null; then
    printf "Failed to create partition on $RAID0_DEVICE_PATH\n"
    exit 1
fi

# Format the partition
partition_path="${RAID0_DEVICE_PATH}p1"
printf "\nCreating $filesystem filesystem..\n"
if ! mkfs.$filesystem -q -L $RAID0_FILESYSTEM_LABEL $partition_path; then
    printf "Failed to create $filesystem filesystem\n"
    exit 1
fi
printf "The operation has completed successfully.\n"

# Add the partition to /etc/fstab
echo "LABEL=$RAID0_FILESYSTEM_LABEL $mount_point $filesystem defaults,nofail 0 0" >>
/etc/fstab

# Add RAID 0 array to mdadm.conf
mdadm --detail --scan >> $mdadm_conf_path
update-initramfs -u

# Mount the partition
printf "\nMounting filesystem to $mount_point..\n"
mkdir $mount_point &> /dev/null
if ! mount -a; then
    printf "Failed to automount partition\n"
    exit 1
fi
printf "The operation has completed successfully.\n"
```

```
exit 0
```

For RHEL/CentOS based distributions, replace `update-initramfs -u` to `dracut --force` to regenerate initramfs file. If script stops execution with "Couldn't find mdadm.conf file", then you can create mdadm.conf file using the following command:

```
sudo touch /etc/mdadm/mdadm.conf
```

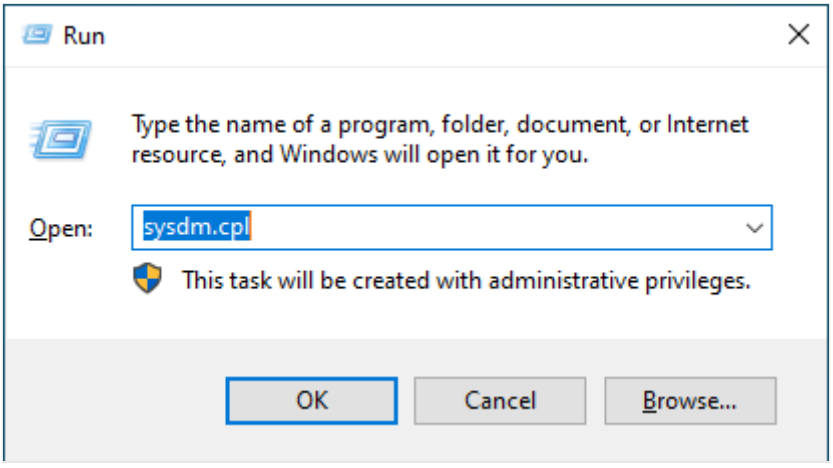
How can I move the Windows pagefile from an OS disk to a temp NVMe disk?

You can use the GUI or Azure PowerShell.

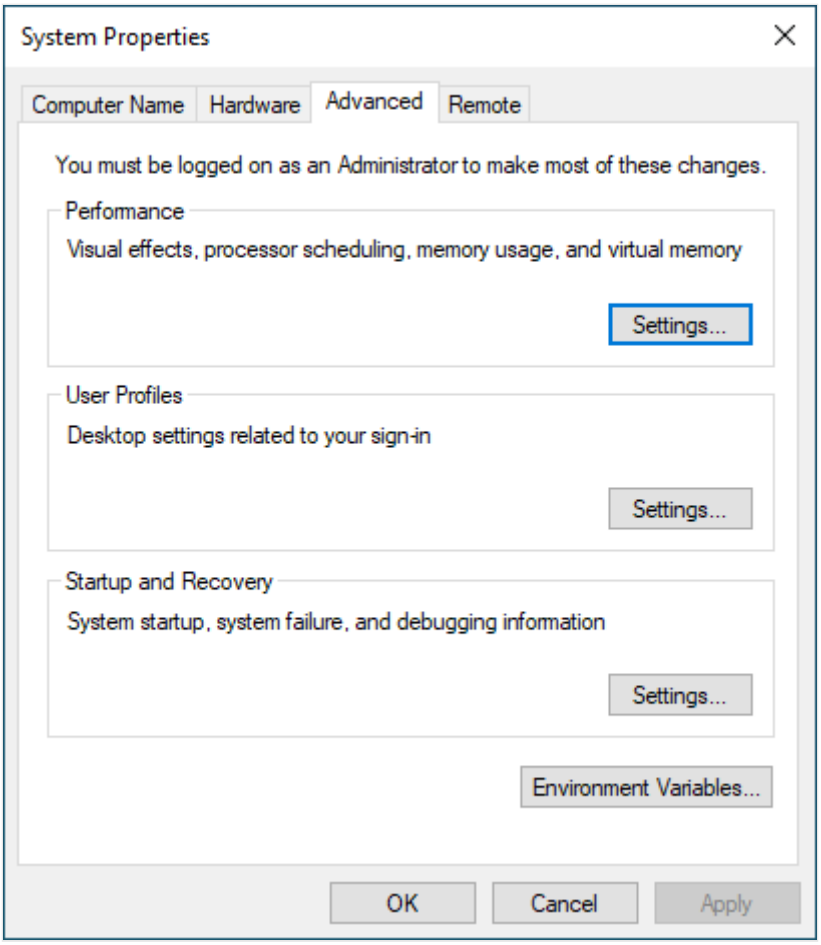
GUI

> **Tip**
>
> The following GUI example is meant for illustrative purposes. We recommend that you create scripts to automate this workflow for production deployments.

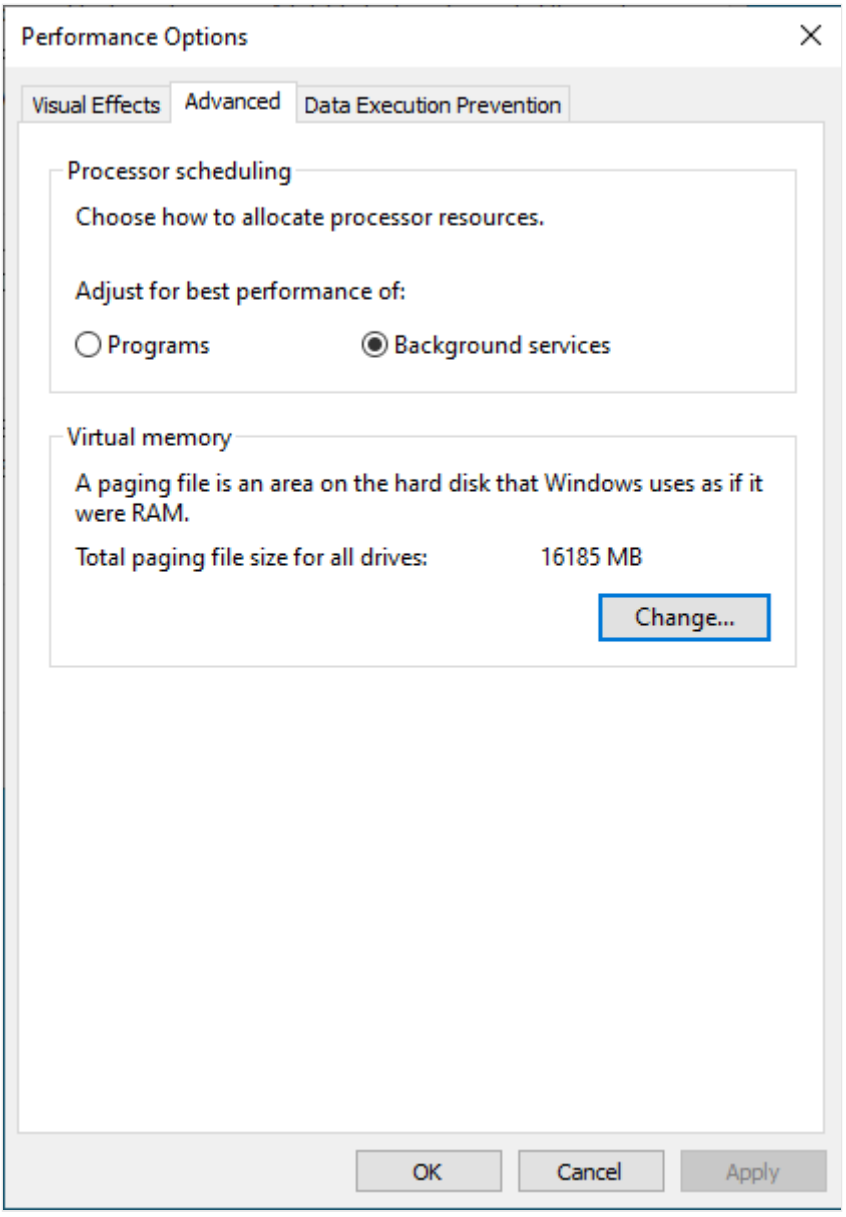
1. Select Windows logo key + R to open the **Run** dialog. Type **sysdm.cpl** and select the Enter key.



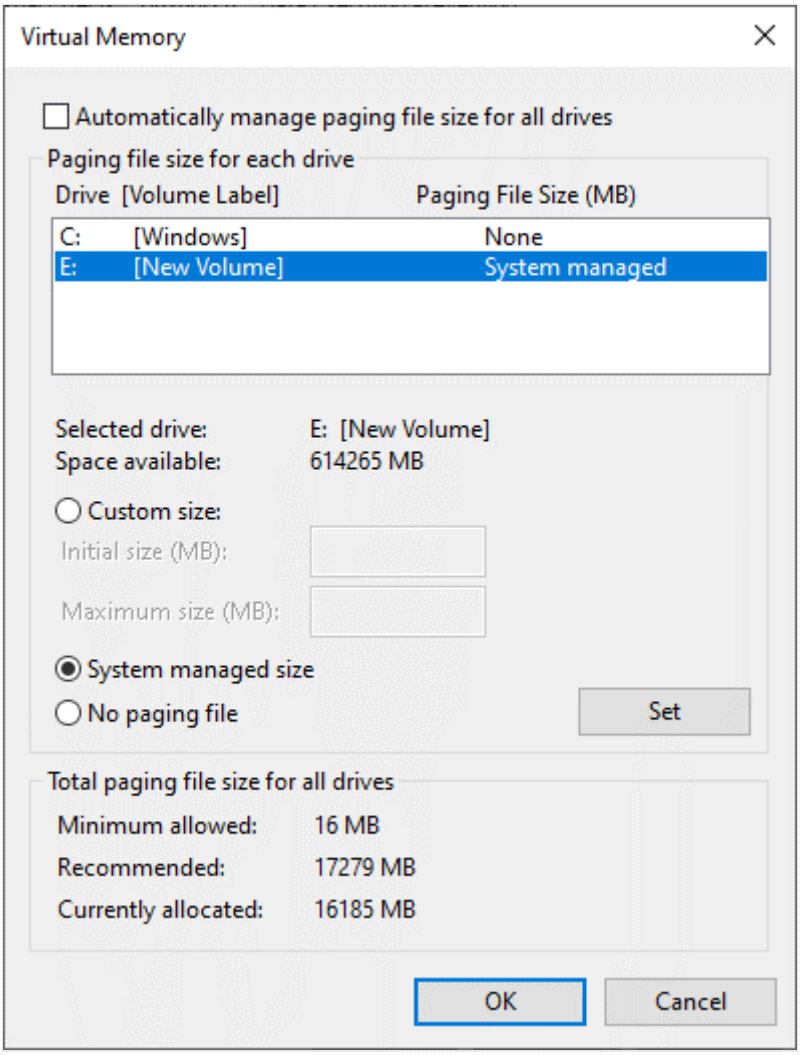
2. Select the **Advanced** tab, and then select the **Settings** button in the **Performance** section.



3. In the **Performance Options** dialog, select the **Advanced** tab, and then select the **Change** button in the **Virtual memory** section.



4. Clear the **Automatically manage paging file size for all drives** checkbox. If a pagefile is set to your OS disk, select your OS disk, select the **No paging file** option, and then select the **Set** button. Select your local temp NVMe drive, select the **System managed size** option, and then select the **Set** button. Select **OK** to close all dialogs.



You might need to restart your VM for these changes to take effect.

Azure PowerShell script

PowerShell

```
$OsDisk = "C:"
# This value can vary, depending on which drive letter is assigned to the disk
$NVMeDisk = "E:"

# Disable automatic pagefile management
$Computer = Get-WmiObject Win32_computersystem -EnableAllPrivileges
$Computer.AutomaticManagedPagefile = $false
$Computer.Put()

# Delete the pagefile on the OS disk
$PageFile = Get-WmiObject -Query "select * from Win32_PageFileSetting where
name='$OsDisk\\pagefile.sys'"
$PageFile.Delete()

# Create a new pagefile on the NVMe drive with system-managed size
Set-WMIInstance -Class Win32_PageFileSetting -Arguments
@{name="$NVMeDisk\\pagefile.sys"; InitialSize=0; MaximumSize=0} -EnableAllPrivileges
```

You might need to restart your VM for these changes to take effect.

How can I move the Linux swap file from an OS disk to a temp NVMe disk?

1. Select the NVMe disk used for swap space:

```
root@D2adsv6:/ # lsblk -p
    NAME              MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
    /dev/nvme1n1      259:0    0   30G  0 disk
    ├─/dev/nvme1n1p1  259:1    0 29.9G  0 part /
    └─/dev/nvme1n1p15 259:3    0  106M  0 part /boot/efi
    /dev/nvme0n1      259:4    0   75G  0 disk
```

2. Create swap space on the disk:

```
root@D2adsv6:/ # mkswap /dev/nvme0n1
Setting up swapspace version 1, size = 75 GiB (80530632704 bytes)
no label, UUID=064bdcfb-86ae-49f3-bf9d-b956493e2a1d
```

3. Enable the swap space:

```
root@D2adsv6:/ # swapon /dev/nvme0n1
```

4. Check that the swap space is set up properly:

```
root@D2adsv6:/ # swapon -s
Filename                                Type            Size    Used
Priority
/dev/nvme0n1                            partition       78643196        0
-2
```

5. Append the swap space to `/etc/fstab` to make it persistent across restarts:

```
root@D2adsv6:/ # echo '/dev/nvme0n1 swap swap defaults 0 0' >> /etc/fstab
```

What considerations do I need to be aware of for maintenance events, VM redeployments, and VM restarts?

Temp NVMe disks attached to V6 VMs are ephemeral, similar to temp drives on other VM series. This means that you lose all data on the VM after redeployment or during a maintenance event. For more information on maintenance events and downtime, see Understand VM reboots: Maintenance vs. downtime.

If the VM moved to new hardware, these drives unmount, and new unmounted disks are presented to the operating system when it comes back up. If the VM didn't change hardware, the temp NVMe disks might still be present. The preceding script for mounting the drives checks for unmounted drives before it tries to mount.

It's a best practice to run the mounting script automatically every time the VM starts and delay any other startup scripts that need the drives until after the mounting script finishes running.

Why are my temporary disk write speeds different than published specifications?

Temporary disk performance is influenced by several factors, such as block size, workload read/write patterns, queue depth (QD). Published performance specifications represent best-case scenarios, based on 4k random block sizes with multiple workers (≥8) at QD≥64 per worker for peak IOPS, and large sequential block sizes (≥128k) for maximum throughput. Write performance may also be affected by data patterns, SSD state (overprovisioned capacity, percent of LBA written), and background activities such as garbage collection. Performance figures assume the device is in a fresh-out-of-box (FOB) state, which provides the highest speeds. Once the disk reaches steady state after SNIA-standard preconditioning specifications, write performance may be lower than FOB levels.

FAQ for remote NVMe disks

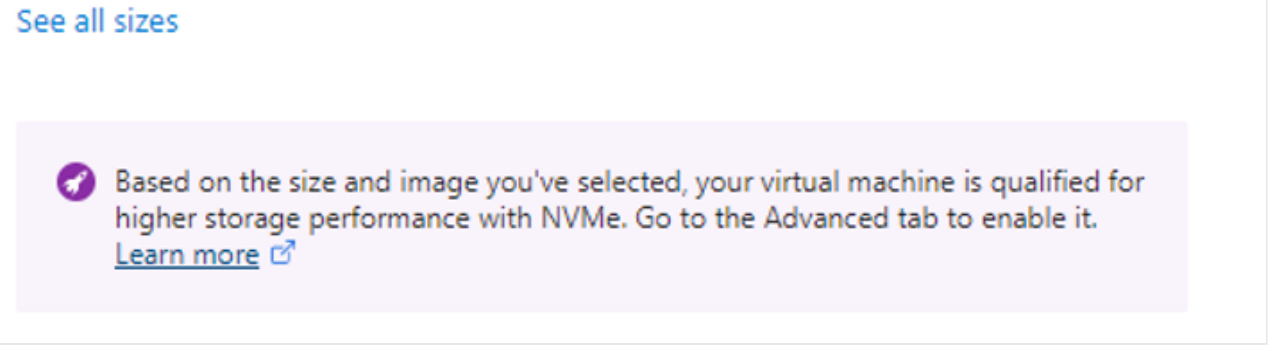
This article addresses some common questions about support for remote NVM Express (NVMe) disks on virtual machines (VMs) created in Azure.

What are the prerequisites to enable the remote NVMe interface on my VM?

The `DiskControllerTypes` is defined during VM configuration and is determined by the selected VM size as either NVMe or Small Computer System Interface (SCSI). If you don't specify a `DiskControllerTypes` value, the platform automatically chooses the default controller based on the VM size configuration.

To enable the remote NVMe interface on your VM, you must meet the following prerequisites:

- Most modern Azure VM sizes support the NVMe disk controller type for remote storage. Support begins with Ebsv5 VM sizes and later generations (v6, v7).
- Select the operating system image that's tagged with NVMe support. For VM sizes that support the NVMe interface, Azure automatically configures the NVMe disk controller type during VM creation. The NVMe setting in the Advanced tab is selected by default and cannot be changed.



- Opt in to NVMe by selecting the NVMe disk controller type in the Azure portal or in the Azure Resource Manager, Azure CLI, or Azure PowerShell template. For step-by-step instructions, refer to the general NVMe FAQ.

How can I resize a SCSI-based VM to a remote NVMe-enabled VM of a different size?

You can use the following process to either:

- Resize a SCSI-based VM created using an untagged image to an NVMe-enabled VM of a different size without re-creating the VM configurations and without tagging the image.
- Resize a SCSI-based VM to an NVMe-enabled VM of a different size without re-creating the VM configurations.

The source VM can be either:

- An untagged OS image that supports remote NVMe.
- An NVMe-tagged OS image.

To resize the VM, use the following command to run an Azure PowerShell script that sets the destination `discontrollertype` value of the VM as NVMe:

PowerShell

```
azure-nvme-VM-update.ps1 [-subscription_id] <String> [-resource_group_name]
<String> [-vm_name] <String> [[-disk_controller_change_to] <String>] [-
vm_size_change_to] <String> [[-start_vm_after_update] <Boolean>] [[-write_logfile]
<Boolean>]
```

For more details, refer to SCSI to NVMe for Linux VMs

How can I check if an image is tagged as NVMe?

To check if an image is tagged as NVMe, use the following command:

```
az vm image show --urn URN_OF_IMAGE
```

How do I create an image definition that supports NVMe for remote disks?

To create an image definition that supports NVMe for remote disks, complete the following steps:

1. Upload an NVMe-supported virtual hard disk (VHD) to your storage account. AzCopy is a fast way, but you can also use the portal to upload.

```
azcopy copy <local path to your VHD> <container in your storage account>
```

2. Create an image gallery by using Azure PowerShell, the portal, or the Azure CLI.

3. Create an image definition. Be sure to include `--feature DiskControllerTypes=SCSI,NVMe`.

   Here's an Azure CLI example:

```
az sig image-definition create --resource-group <resourceGroupName> --gallery-name <galleryName> --gallery-image-definition <imageName> --publisher <publisher> --offer <offerName> --sku <skuName> --os-type <osType> --os-state <osState> --feature DiskControllerTypes=SCSI,NVMe
```

4. Create the image version with the NVMe-supported VHD.

   Here's an Azure CLI example:

```
az sig image-version create --resource-group <resourceGroupName> --gallery-name <galleryName> --gallery-image-definition <imageName> --gallery-image-version <version> --target-regions <region1> <region2> --replica-count <replicaCount> --os-vhd-uri <NVMe-supported vhd uri> --os-vhd-storage-account <storageAccount>
```

Which Azure disk storage options are compatible with remote NVMe disks?

NVMe sizes can be combined with Azure Standard HDD, Standard SSD, Premium SSD v1, Premium SSD v2, and Ultra Disk Storage. For more information on Azure disk offerings, see Azure managed disk types.

Does Azure support live resizing on disks with NVMe VM sizes?

Live resizing of NVMe is supported on Azure Premium SSD v1 disks, Premium SSD v2 disks, Standard SSDs, and Standard HDDs. You can also add remote NVMe disks without restarting the VM.

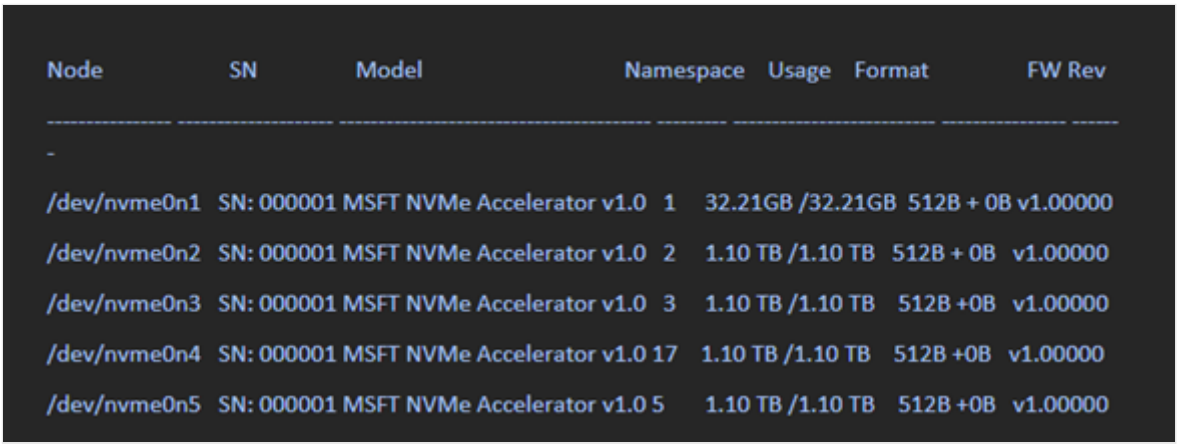
How can I identify remote NVMe disks on a Linux VM?

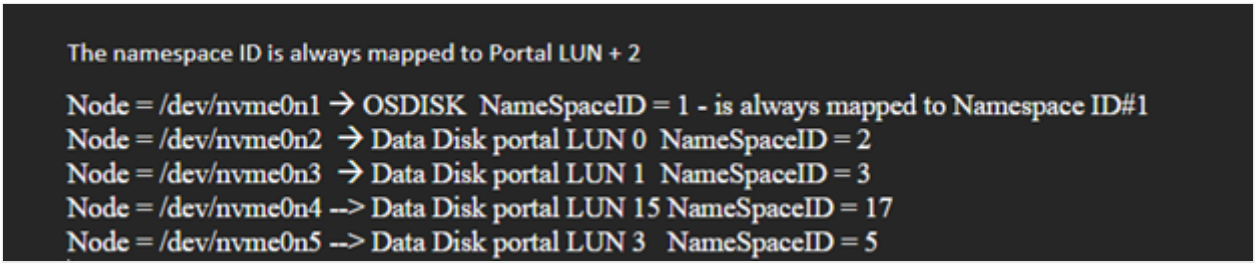
1. Get the `nvme-cli` package:

```
sudo apt install nvme-cli
```

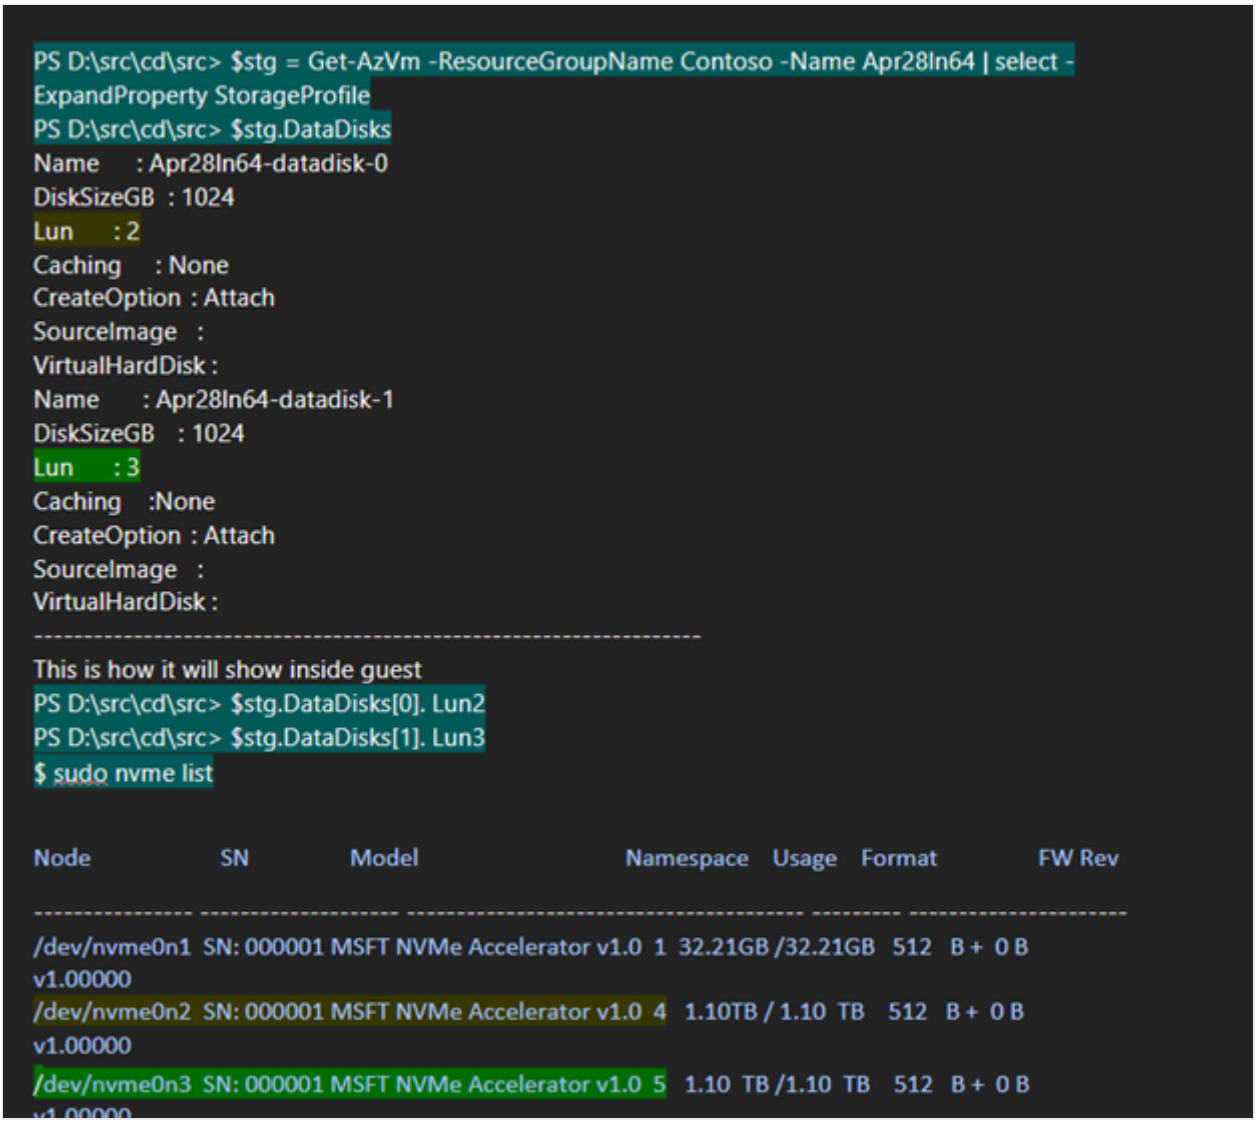
2. Run the NVMe `list` command to fetch NVMe disk details:

```
sudo nvme list
```





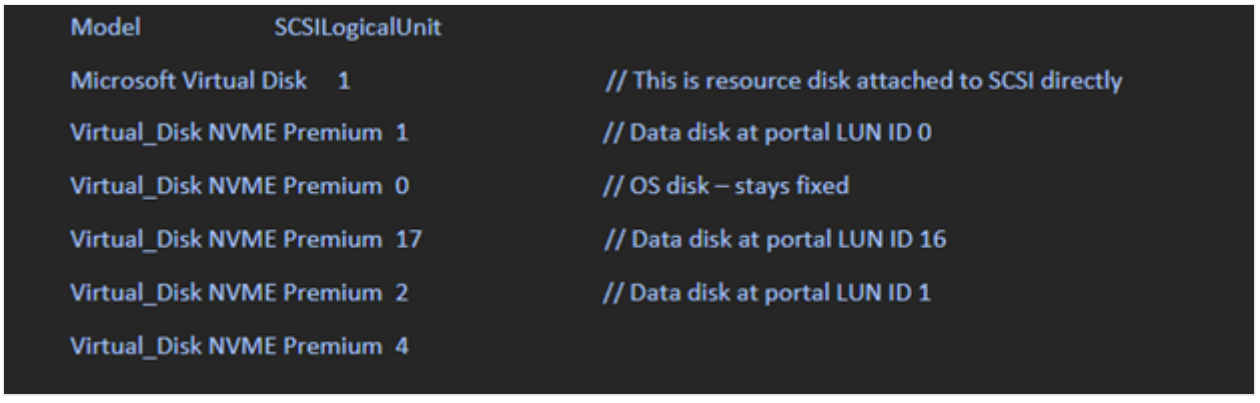
Here's how the data appears in response to Azure PowerShell commands:



How can I identify NVMe disks on a Windows VM?

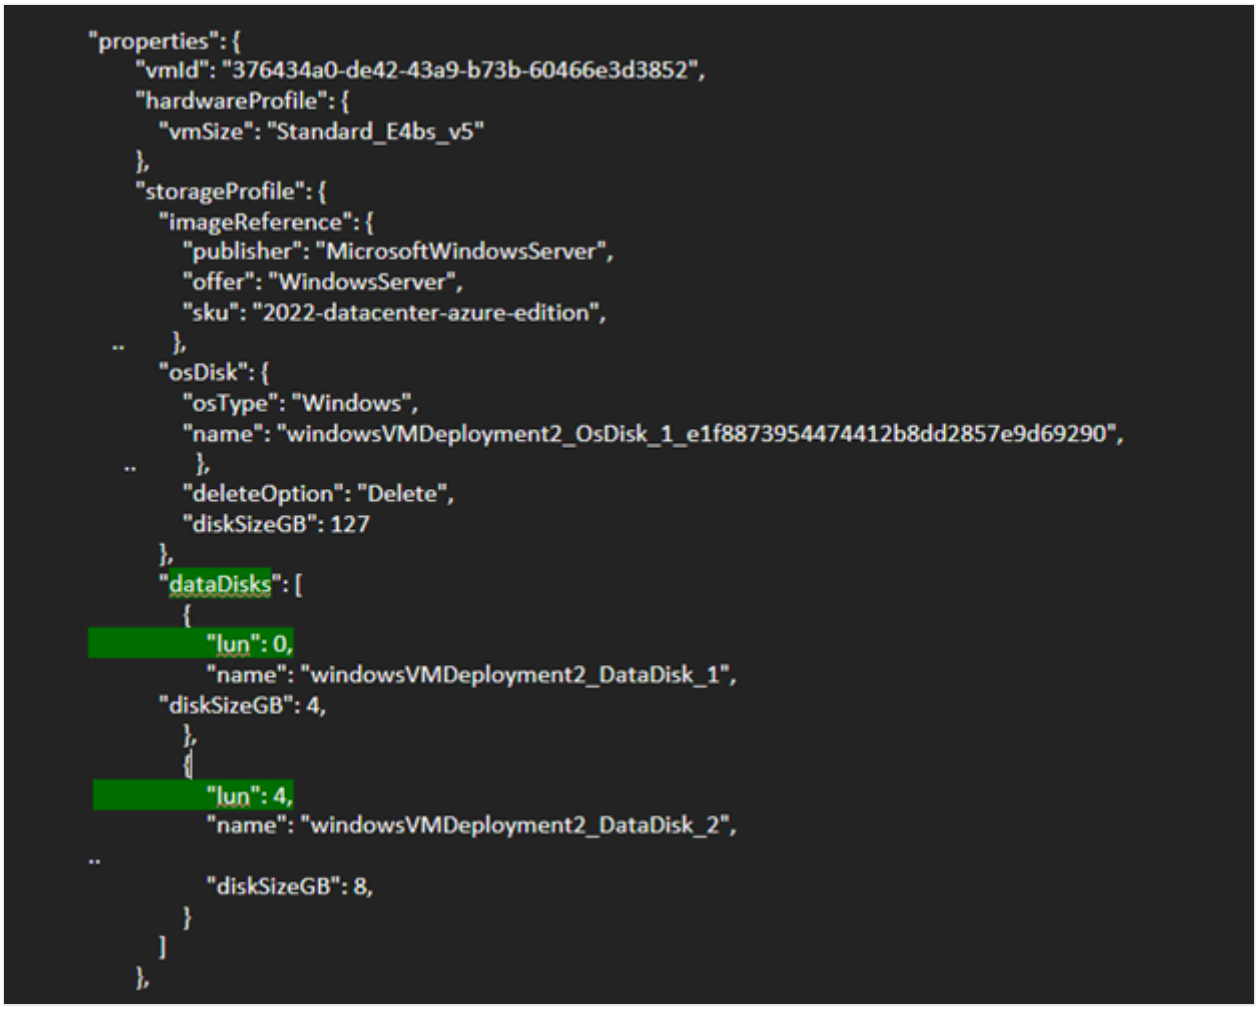
Open Azure PowerShell and use the following command:

```
wmic diskdrive get model,scsilogicalunit
```

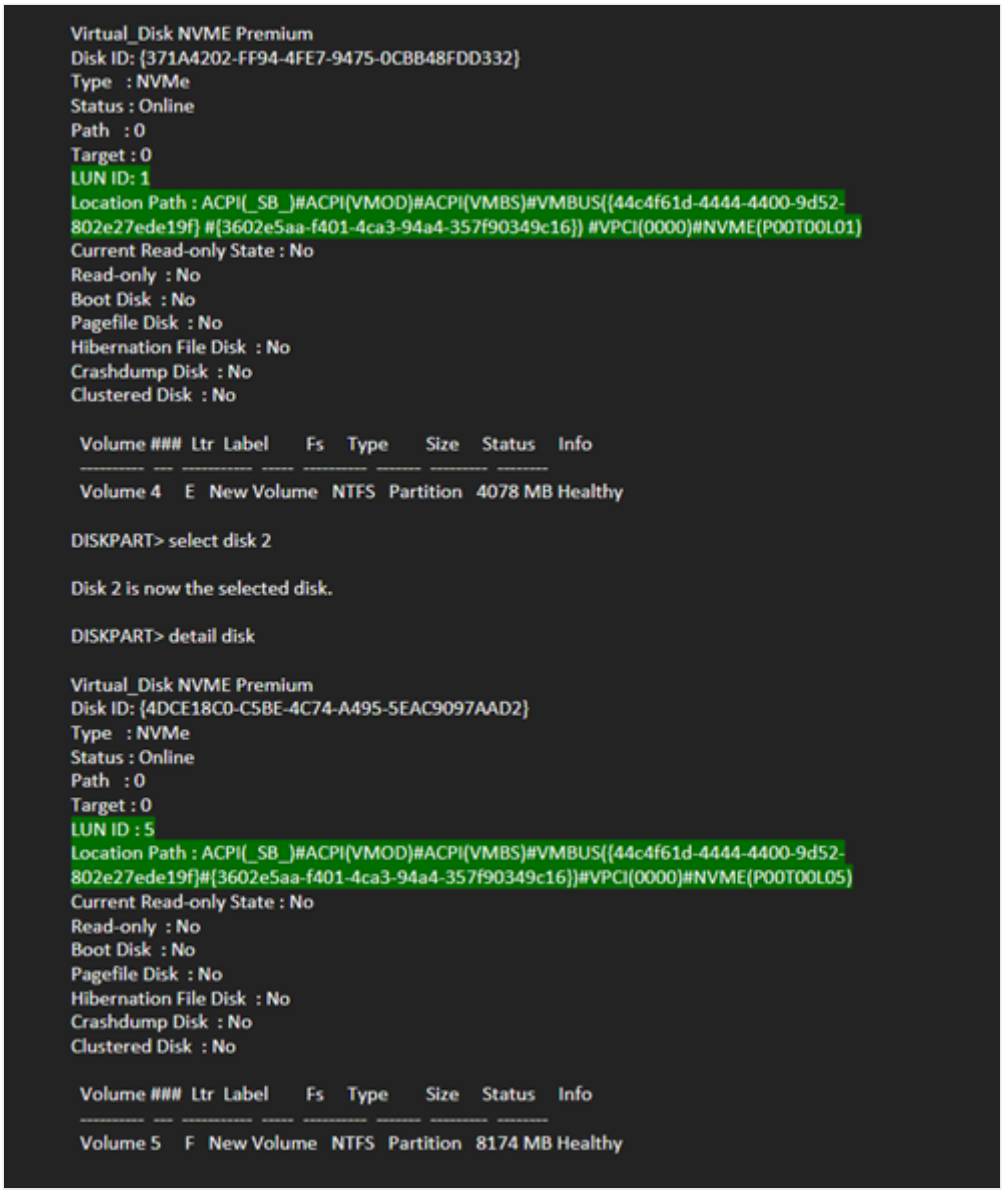


The ASAP attached disks are presented in the guest with the model string `Virtual_Disk NVMe Premium`. The SCSI logical unit has the value for the portal-visible LUN ID incremented by 1.

Here's a snapshot of how NVMe disks appear in an NVMe-enabled Windows VM:



The following snapshot shows guest output for data disks attached at LUN 0 and LUN 4 (CRP). The LUN ID is equivalent to the namespace ID.



Are shared disks in remote disks supported with NVMe-enabled VMs?

The shared disk feature is supported for Premium SSD, Premium SSD v2, and Ultra Disk Storage disks. Shared Disks using NVMe isn't supported with the OS Windows Server 2019.

Can a data disk be detached from a SCSI-based VM and then attached to an NVMe-based VM?

Yes. A data disk can be detached from a SCSI-based VM and attached to an NVMe-based VM. Once attached, the disk type will automatically convert to NVMe.

Will all my VM's disks be attached to one NVMe controller, or are they distributed across multiple controllers?

Older Azure VM types (such as Ebsv6) attach all disks to a single NVMe controller. Select newer VM sizes (V7 and above, running on Intel and ARM hardware) automatically distribute disks across multiple controllers and separate cached disks (including the OS disk) and uncached data disks for improved performance and reliability.

How are disks assigned to controllers, and what should I know about disk management?

Boot and cached data disks are assigned to the cached controller and uncached data disks go to the uncached controller. Controller assignment is automatic based on disk caching policy selected in the VM settings.

If you need to change the caching policy of a disk, it is recommended to stop the VM, change the caching policy, and then start the VM again for stable operation. This helps avoid inconsistent states or remapping issues. OS disk caching changes are non-functional and will be disabled in future updates.

How can I identify and manage disks across controllers in Linux and Windows?

> **Note**
>
> Using UUIDs (Linux) or GUIDs (Windows) ensures disks are correctly identified and remounted after VM events, upgrades, or controller changes. If device names change after reboots or disk operations, rely on UUIDs/GUIDs or persistent naming for automation and scripting.

Windows

- Open Disk Management (`diskmgmt.msc`) to see all disks and their controller assignments.

- Or use PowerShell for more details:

PowerShell

```
Get-PhysicalDisk | Select-Object DeviceID, FriendlyName, SerialNumber, BusType
```

This lists all physical disks, including NVMe devices and their properties.

Supported OS images for remote NVMe

The following lists provide up-to-date information on which OS images are tagged as supported for remote NVM Express (NVMe).

> **Important**
>
> Only Gen2 VM images with security type "Standard" or "Trusted Launch" support NVMe. For more information, see **FAQ for NVMe**. Older operating systems cannot support NVMe due to OS driver limitations. If an older version of the OS is not included in the list below, it means that NVMe support is not present for that OS.

For specifics about which virtual machine (VM) generations support which storage types, check the documentation about VM sizes in Azure.

For more information about enabling the NVMe interface on virtual machines created in Azure, review the FAQ for remote NVMe disks.

Supported Linux OS images

> **Note**
>
> For Linux virtual machines using NVMe-attached storage, Microsoft recommends setting the kernel parameter `nvme_core.io_timeout` to `240` seconds. This setting effectively disables OS-level NVMe IO timeouts, ensuring that Azure's host-level timeout mechanism takes precedence to handle disk failures or interruptions. Some older Linux images may have the default `io_timeout` set to 30 seconds, which can cause the OS to timeout IOs before Azure can intervene.

- Azure Linux 3.0
- Almalinux 8.x
- Almalinux 9.x
- Debian 11
- Debian 12
- Oracle Linux 7.9
- Oracle Linux 8.5 and newer
- Oracle Linux 9.0 and newer
- RHEL 7.9
- RHEL 8.6 and newer
- RHEL 9.0 and newer

Converting Virtual Machines Running Linux from SCSI to NVMe

07/16/2025

In this article, we discuss the process of converting virtual machines (VM) running Linux from SCSI to NVMe storage. By migrating to NVMe, you can take advantage of its improved performance and scalability.

SCSI vs NVMe

Azure VMs support two types of storage interfaces: Small Computer System Interface (SCSI) and NVMe. The SCSI interface is a legacy standard that provides physical connectivity and data transfer between computers and peripheral devices. NVMe is similar to SCSI in that it provides connectivity and data transfer, but NVMe is a faster and more efficient interface for data transfer between servers and storage systems.

Support for SCSI interface VMs

Azure continues to support the SCSI interface on the versions of VM offerings that provide SCSI storage. However, not all new VM series have SCSI storage as an option going forward.

What is changing for your VM?

Changing the host interface from SCSI to NVMe doesn't change the remote storage (OS disk or data disks), but change the way the operating systems sees the disks.

Expand table

Disk	SCSI enabled VM	NVMe VM with SCSI tempdisk (e.g. Ebds_v5)	NVMe VM with NVMe tempdisk
OS disk	/dev/sda	/dev/nvme0n1	/dev/nvme0n1
Temp Disk	/dev/sdb	/dev/sda	/dev/nvme1n1
First Data Disk	/dev/sdc	/dev/nvme0n2	/dev/nvme0n2

Tip

Some VM types have more than one temporary disk (e.g. E64ds_v6)

In the following sections, we provide a guide to convert your Azure VM from SCSI to NVMe using Azure Boost ensuring you can take full advantage of these performance improvements and maintain a competitive edge in the cloud computing landscape.

Migrate your virtual machine (VM) from SCSI to NVMe

In order to migrate from SCSI to NVMe, some steps need to be followed:

1. Check if your virtual machine series supports NVMe
2. Check your operating system for NVMe readiness
3. Convert your virtual machine to NVMe
4. Check your operating system

1. Check if your virtual machine series supports NVMe

The supported virtual machines to support NVMe attached disks is described on the Azure Boost overview site in the availability table.

2. Check your operating system for NVMe readiness

The operating system needs to support NVMe devices, includes for example, device drivers and initrdm, the temporary file system used during boot, need to be prepared. In addition to that you need to validate the mount points of the file systems as they check if you use the SCSI device name (/dev/sdX).

The migration script automatically can take care of these readiness checks for you when using the `-FixOperatingSystemSettings`.

2.1 Check Controller Type of VM

2.1.1 Check Controller Type using PowerShell

PowerShell

```
PS C:\Users\user1> $vm = Get-AzVM -name [your-vm-name]
PS C:\Users\user1> $vm.StorageProfile.DiskControllerType
```

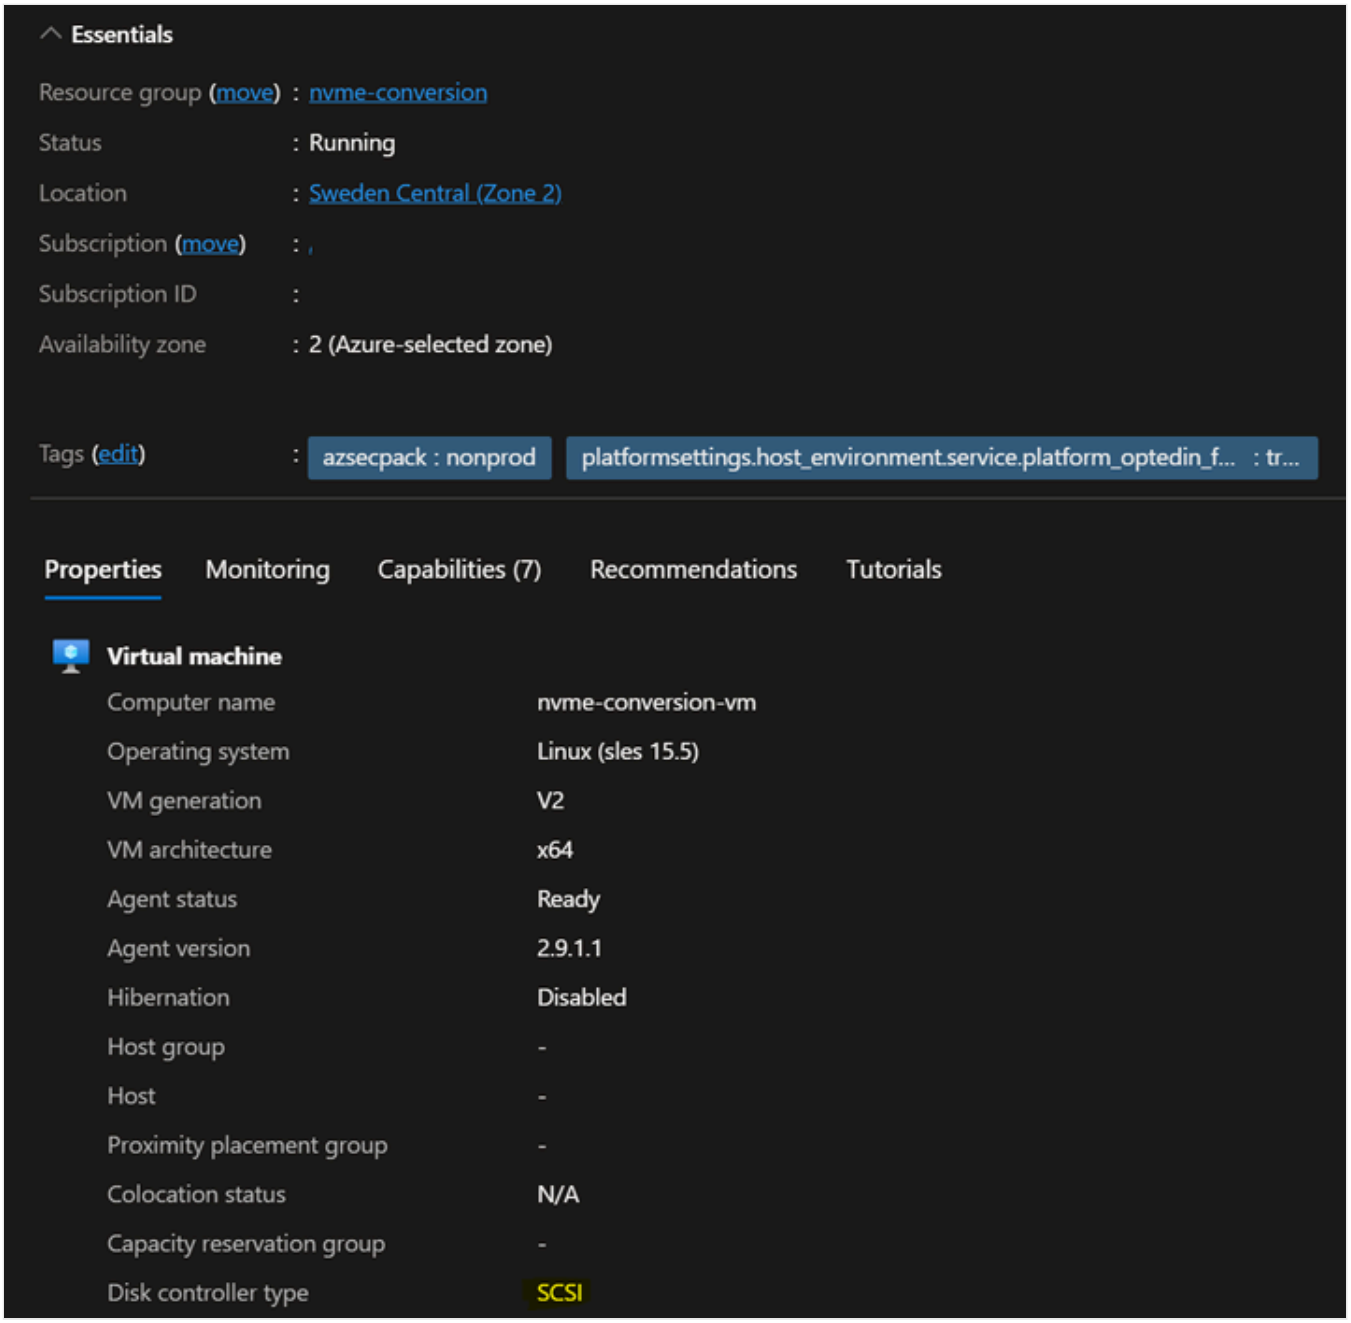
```
SCSI
PS C:\Users\user1>
```

2.1.2 Check Controller Type using Azure CLI

PowerShell

```
$ az vm show --name [your-vm-name] --resource-group [your-resource-group-name]
{
"additionalCapabilities": {
...
 "storageProfile": {
 ...
   "diskControllerType": "SCSI",
 ...
```

2.1.3 Check Controller Type using Azure portal



2.2 Prepare for migration

The Migration script can automatically take care about the prerequisites when using the `-FixOperatingSystemSettings` parameter.

If you want to manually take care of the required changes validate

- NVMe modules installed and part of initrd/initramfs
- GRUB configuration includes the parameter nvme_core.io_timeout=240
- /etc/fstab checks for devices

Please check back with your OS vendor to cover all required commands to update initrd/initramfs.

2.2.1 Prepare PowerShell

> **Tip**
>
> This step is not required when running the script in Azure CloudShell

1. Install PowerShell using https://aka.ms/powershell
2. Connect to Azure using `Connect-AzAccount` and select the correct subscription using `Select-AzSubscription -Subscription [your-subscription-id]`
3. Set the Execution Policy using `Set-ExecutionPolicy -ExecutionPolicy Unrestricted`

2.2.2 Download the script

You can download the script using a PowerShell command

PowerShell

```
Invoke-WebRequest -Uri "https://raw.githubusercontent.com/Azure/SAP-on-Azure-Scripts-and-Utilities/refs/heads/main/Azure-NVMe-Utils/Azure-NVMe-Conversion.ps1" -OutFile ".\NVMe-Conversion.ps1"
```

2.3 Run the migration

The script has multiple parameters available:

Expand table

Parameter	Description	Required
`-ResourceGroupName`	The Resource Group Name of your VM	Yes
`-VMName`	The name of your Virtual Machine on Azure	Yes
`-NewControllerType`	The storage controller type the VM should get converted to (NVMe or SCSI)	Yes
`-VMSize`	Azure VM SKU you want to convert the VM to	Yes
`-StartVM`	Start the VM after conversion	No
`-IgnoreSKUCheck`	Ignore the check of the VM SKU	No
`-IgnoreWindowsVersionCheck`	Ignore the Windows Version check	No

Parameter	Description	Required
`-FixOperatingSystemSettings`	Automatically fix the OS settings using Azure RunCommands	No
`-WriteLogfile`	Create a Log File	No
`-IgnoreAzureModuleCheck`	Do not run the check for installed Azure modules	No
`-IgnoreOSCheck`	Do not check for OS readiness, expectation is that the OS is ready	No
`-SleepSeconds`	Time for Azure to settle changes before starting the VM	No

Sample Command:

PowerShell

```
# Example usage
.\Azure-NVMe-Conversion.ps1 -ResourceGroupName <your-RG> -VMName <your-VMname> -
NewControllerType <NVMe/SCSI> -VMSize <new-VM-SKU> -StartVM -
FixOperatingSystemSettings
```

> **Tip**
>
> You can always revert back to SCSI, the script will share a command with you to directly revert to your original configuration.

2.3.1 Sample output

PowerShell

```
PS /home/philipp> ./NVMe-Conversion.ps1 -ResourceGroupName testrg -VMName testvm -
NewControllerType NVMe -VMSize Standard_E4bds_v5 -StartVM -
FixOperatingSystemSettings
00:00 - INFO      - Starting script Azure-NVMe-Conversion.ps1

```
01:54 - INFO      - Start after update enabled for VM testvm
01:54 - INFO      - Waiting for 15 seconds before starting the VM
02:09 - INFO      - Starting VM testvm
03:31 - INFO      - VM testvm started
03:31 - INFO      - As the virtual machine got started using the script you can
check the operating system now
03:31 - INFO      - If you have any issues after the conversion you can revert the
changes by running the script with the old settings
03:31 - IMPORTANT - Here is the command to revert the changes:
03:31 - INFO      -    .\Azure-NVMe-Conversion.ps1 -ResourceGroupName testrg -
VMName testvm -NewControllerType SCSI -VMSize Standard_E4s_v3 -StartVM
03:31 - INFO      - Script ended at 06/27/2025 15:45:11
03:31 - INFO      - Exiting
PS /home/philipp>
```

If you have challenges accessing the operating system afterwards try to check

- Serial Console for Linux operating systems
- Screenshot from the operating system in Azure portal

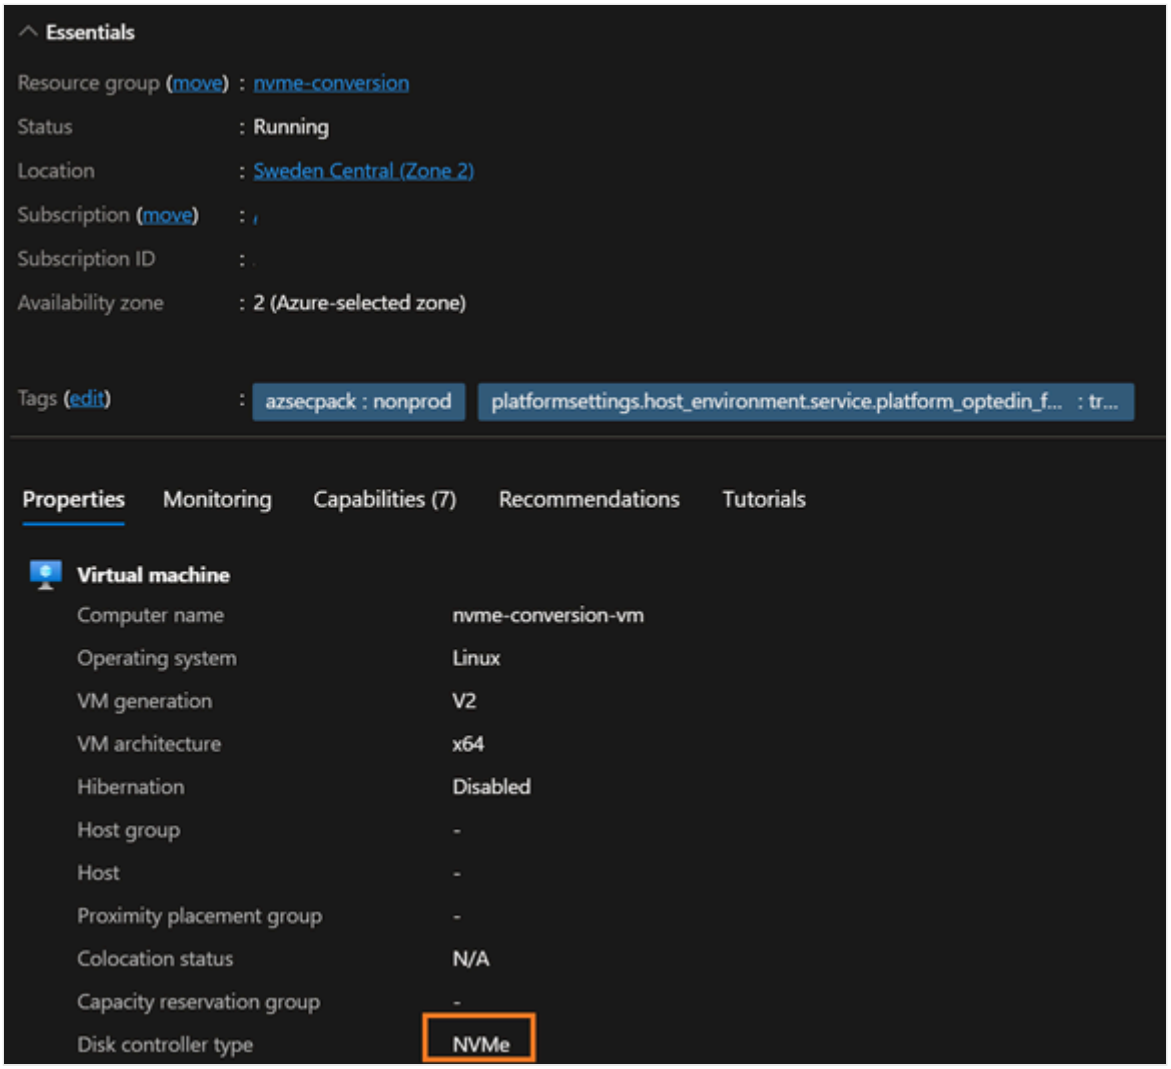
When something happens you can always revert back to SCSI using the command shown at the end of the script:

PowerShell

```
.\Azure-NVMe-Conversion.ps1 -ResourceGroupName testrg -VMName testvm -
NewControllerType SCSI -VMSize Standard_E4s_v3 -StartVM
```

2.4 Check the result

2.4.1 Check result in Azure portal



2.4.2 Check result in PowerShell

Powershell

```
PS C:\Users> $vm = Get-AzVM -name [your-vm-name]
PS C:\Users> $vm.StorageProfile.DiskControllerType
NVMe
PS C:\Users>
```

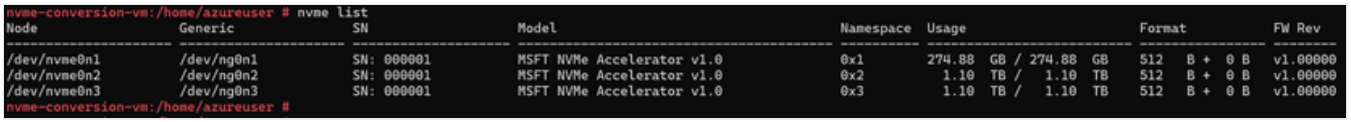
3. Check your operating system

3.1 Check devices

You can check the devices using nvme command, if the nvme command is missing, install the "nvme-cli" package.

`nvme list`

The output should show the OS disk and the data disks.



3.2 Get udev file for NVMe (Optional)

On SCSI virtual machines, the udev rules integrated in waagent (Azure agent) created links in `/dev/disk/azure/scsi1/lunX` to identify the data disks. As SCSI isn't used anymore, the rules don't apply.

With one of the two available options to deploy NVMe enabled udev rules you see new symbolic links in the directory `/dev/disk/azure/data/by-lun`. This directory is the replacement for `/dev/disk/azure/scsi1`.

Bash

```
nvme-conversion-vm:/usr/lib/udev/rules.d # ls -l /dev/disk/azure/data/by-lun/
total 0
lrwxrwxrwx 1 root root 19 Jun 7 13:52 0 -> ../../../../nvme0n2
lrwxrwxrwx 1 root root 19 Jun 7 13:52 1 -> ../../../../nvme0n3
nvme-conversion-vm:/usr/lib/udev/rules.d #
```

3.2.1 Manual download of udev file

To download the new udev rules file, use this command: `curl https://raw.githubusercontent.com/Azure/SAP-on-Azure-Scripts-and-Utilities/refs/heads/main/NVMe-Preflight-Check/88-azure-nvme-data-disk.rules` and then run `udevadm control --reload-rules && udevadm trigger` to reload the udev rules.

3.2.2 Ready to install packages using Azure VM utils

There are precompiled packages available on Index of /results/cjp256/azure-vm-utils/ for multiple distributions.

Multiple distributions started already to integrate the package. You can directly install it from their repository.

Expand table

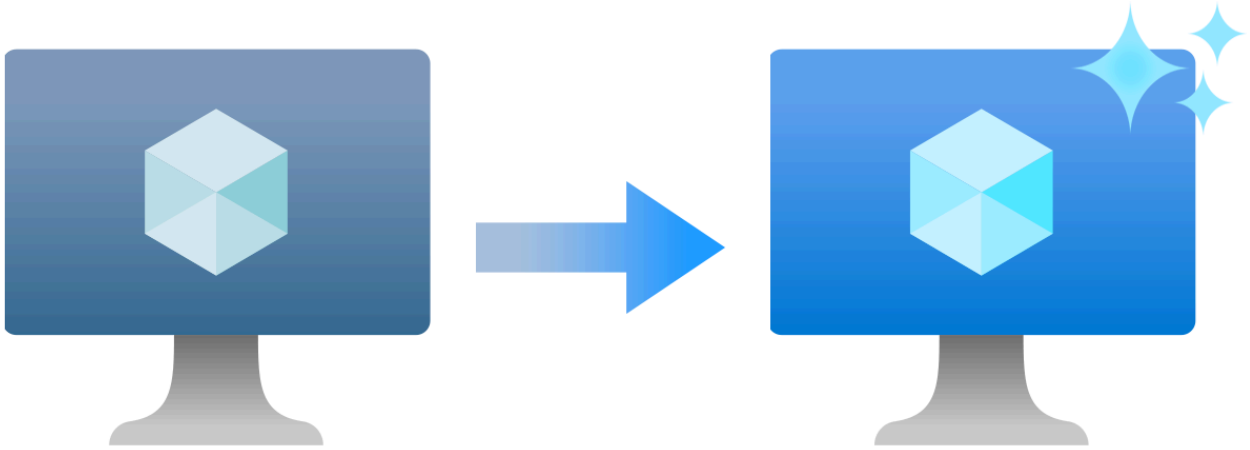
Distribution	Minimum version
SUSE	SLES 15 SP5 or newer

Distribution	Minimum version
RedHat	RHEL 9.6 or newer
Ubuntu	Ubuntu 25.04 or newer

Previous-gen and retired VM size series

03/17/2025

Azure virtual machine sizes are the amount of resources allocated to a virtual machine in the cloud. These resources are a portion of the physical server's hardware capabilities. A *size series* is a collection of all sizes that are available within a single physical server's hardware. As a size series' physical hardware ages and newer components are released, Microsoft stops deploying more of previously established series' hardware. Once users migrate off of said hardware or the hardware becomes sufficiently outdated, it's retired to make room for new infrastructure.



When hardware becomes *previous-gen* or begins the retirement process, we recommend migrating workloads to newer generation hardware. Newer hardware provides better performance and future scalability. Migrating also helps you to avoid any potential issues that may arise from using outdated hardware. By keeping your hardware up-to-date, you can ensure that your workloads are running smoothly and efficiently.

This article describes the various states of older hardware and explains the processes behind these states.

Previous-gen sizes

Previous generation size series **are not currently retired** and can still be used. These sizes are still fully supported, but they aren't guaranteed to receive more capacity. We recommend migrating to the latest generation replacements as soon as possible, especially when trying to scale up your installations.

There are two types of previous-gen sizes; *next-gen available* and *capacity limited*.

Next-gen available

Size series listed as *next-gen available* means that while no capacity limitation plans have been made, there are sufficient deployments of newer alternative sizes to justify considering these series "previous-gen". *Next-gen available* series have no formal announcement of retirement timelines, but they'll eventually be retired.

For a list of previous-gen size series that are considered *next-gen available*, see the list of previous-gen sizes.

Capacity limited

Size series listed as *capacity limited* means no extra capacity for this series will be deployed. Similar to *next-gen available* previous-gen series, there are sufficient deployments of newer alternative sizes available to replace *capacity limited* size deployments.

If you had one VM running on a *capacity limited* size and require another VM of a similar size in the same series, there is no guarantee that capacity will be able to fulfill this request. Any new VMs should be created using sizes in series that aren't considered previous-gen. Migrating to sizes considered *next-gen available* is not recommended since these sizes are also similarly outdated.

For a list of previous-gen size series that are considered *capacity limited*, see the list of previous-gen sizes.

Retired sizes

Retired size series are **no longer available** and can't be used. If you have VMs running on sizes with **retirement announced** status, migrate to a newer next-gen size as soon as possible.

Retiring hardware is necessary over time to ensure that the latest and greatest technology is available on Azure. Retirement ensures that the hardware is reliable, secure, and efficient. It also allows for the latest features and capabilities that may not be present on previous generations of hardware.

Hardware which is currently listed as *previous-gen* are often preparing for retirement which will be announced formally prior to the retirement date.

For information on size series that have been retired or are scheduled for retirement, see the list of retired sizes.

Migrate to newer sizes

Migrating to newer sizes allows you to keep up with the latest hardware and features available on Azure.

Some size series have specific migration instructions due to the unique hardware or software features. To see a list of migration guide, see retired size migration guides and previous-gen size migration guides.

For sizes without specific instructions, you can resize your VM to a newer size using the Azure portal, Azure PowerShell, Azure CLI, or Terraform. Make sure that the new size has support for all features that your workload requires.

Next steps

- For more information on VM sizes, see Sizes for virtual machines in Azure.
- For a list of retired sizes, see Retired Azure VM sizes.
- For a list of previous-gen sizes, see Previous generation Azure VM sizes.

Previous generation Azure VM size series

This article provides a list of all size series that are considered *previous-gen*. Status is listed as *next-gen available* or *capacity limited* based on capacity. For sizes that require it there are *migration guides* to help move to replacement sizes.

> **Note**
>
> Series listed as *previous-gen* are **not currently retired** and can still be used. However, series announced for retirement will have restrictions when deploying through new subscriptions. To view retired size series, see Retired Azure VM size series.

What are previous-gen size series?

Previous generation virtual machine size series are running on older hardware. While they can still be used and are fully supported, there are newer generations available. It's recommended to migrate to the latest generation replacements.

To learn more about previous-gen sizes, retirement, and the status states of previous-gen size series, see the size series retirement overview.

General purpose previous-gen sizes

Av1-series retirement

03/17/2025

On August 31, 2024, we retire Basic and Standard A-series virtual machines (VMs). Before that date, migrate your workloads to Av2-series VMs, which provide more memory per vCPU and faster storage on solid-state drives (SSDs). The remaining VMs with these specific sizes on your subscription will be set to a deallocated state. These VMs will be stopped and removed from the host. These VMs will no longer be billed in the deallocated state.

> **Note**
>
> In some cases, you must deallocate the VM prior to resizing. This can happen if the new size is not available on the hardware cluster that is currently hosting the VM.

Migrate workloads to Av2-series VMs

You can resize your virtual machines to the Av2-series using the Azure portal, PowerShell, or the CLI. Below are examples on how to resize your VM using the Azure portal and PowerShell.

> **Important**
>
> Resizing a virtual machine results in a restart. We recommend that you perform actions that result in a restart during off-peak business hours.

Azure portal

1. Open the Azure portal.
2. Type *virtual machines* in the search.
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select the virtual machine you want to resize.
5. In the left menu, select **size**.
6. Pick a new Av2 size from the list of available sizes and select **Resize**.

Azure PowerShell

1. Set the resource group and VM name variables. Replace the values with information of the VM you want to resize.

```
```

```powershell
$resourceGroup = "myResourceGroup"
$vmName = "myVM"
```

2. List the VM sizes that are available on the hardware cluster where the VM is hosted.

```powershell
Get-AzVMSize -ResourceGroupName $resourceGroup -VMName $vmName
```

3. Resize the VM to the new size.

```powershell
$vm = Get-AzVM -ResourceGroupName $resourceGroup -VMName $vmName
$vm.HardwareProfile.VmSize = "<newAv2VMsize>"
Update-AzVM -VM $vm -ResourceGroupName $resourceGroup
```

Help and support

If you have questions, ask community experts in Microsoft Q&A. If you have a support plan and need technical help, create a support request:

1. In the Help + support page, select **Create a support request**. Follow the **New support request** page instructions. Use the following values:

   - For **Issue type**, select **Technical**.
   - For **Service**, select **My services**.
   - For **Service type**, select **Virtual Machine running Windows/Linux**.
   - For **Resource**, select your VM.
   - For **Problem type**, select **Assistance with resizing my VM**.
   - For **Problem subtype**, select the option that applies to you.

Follow instructions in the **Solutions** and **Details** tabs, as applicable, and then **Review + create**.

Bv1 sizes series

Summarize this article for me

> **Note**
>
> These virtual machine sizes are a previous generation series. While older VM sizes are supported until further notice, we recommended using newer generations for improved performance and security. Check out the sizes overview's list of VM size families by type for a selection of newer sizes.

The B-series VMs can be deployed on various hardware types and processors, so competitive bandwidth allocation is provided. B-series run on the third Generation Intel® Xeon® Platinum 8370C (Ice Lake), the Intel® Xeon® Platinum 8272CL (Cascade Lake), the Intel® Xeon® 8171M 2.1 GHz (Skylake), the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors. B-series VMs are ideal for workloads that don't need the full performance of the CPU continuously, like web servers, proof of concepts, small databases, and development build environments. These workloads typically have burstable performance requirements. To determine the physical hardware on which this size is deployed, query the virtual hardware from within the virtual machine. The B-series provides you with the ability to purchase a VM size with baseline performance that can build up credits when its using less than its baseline. When the VM has accumulated credits, the VM can burst above the baseline using up to 100% of the vCPU when your application requires higher CPU performance.

Read more about the B-series CPU credit model.

Dv3 sizes series

Summarize this article for me

> **Note**
>
> These virtual machine sizes are a previous generation series. While older VM sizes are supported until further notice, we recommended using newer generations for improved performance and security. Check out the sizes overview's list of VM size families by type for a selection of newer sizes.

The Dv3-series run on the Intel® Xeon® Platinum 8573C (Emerald Rapids), Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1GHz (Skylake), Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell), or the Intel® Xeon® E5-2673 v3 2.4 GHz (Haswell) processors in a hyper-threaded configuration, providing a better value proposition for most general purpose workloads. Memory has been expanded (from ~3.5 GiB/vCPU to 4 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyperthreading. The Dv3-series no longer has the high memory VM sizes of the D/Dv2-series, those have been moved to the memory optimized Ev3 and Esv3-series. Example D-series use cases include enterprise-grade applications, relational databases, in-memory caching, and analytics.

DCsv2-series retirement

This migration guide is designed for users of DCsv2-series virtual machines (VMs), which are scheduled for retirement on **June 30, 2026**. To ensure minimal disruption and to continue optimizing cost and performance, this guide helps you transition to the latest series VMs.

This document covers:

- Recommended options for migration
- Detailed migration steps
- Frequently Asked Questions

By migrating to newer VM series, you gain access to improved price-performance ratios, broader regional availability, and the latest hardware capabilities.

Recommended options for migration

Before June 30, 2026, migrate your workloads to one of the following options that best aligns with your business needs:

- If you want to continue using the enclave-based offering with Intel SGX technology, migrate your workloads to DCdsv3 virtual machines. The DCdsv3 VMs offer significant improvements, including enhanced performance and increased memory capacity, making the DCdsv3-series a more robust and efficient choice.
- To lift and shift into a VM based programming model, consider DCasv5/DCadsv5/ECasv5/ECadsv5 VMs, DCasv6/ECasv6 series (currently in preview), or DC/ECesv6 (currently in preview) confidential VMs (CVMs).
- If you already have or plan to transition to containerized workloads and want to lift and shift your containerized applications consider using Azure Confidential Container Instances (C-ACI) serverless infrastructure. If you need to orchestrate containerized workloads, consider using Virtual nodes on Azure Container Instances (C-VN2) for Azure Kubernetes Service (AKS).

Additionally, there may be changes to your Azure Virtual Machines billing because of this retirement. Refer to our Azure Virtual Machines pricing page for more information.

Migration Steps

Start planning your migration from DCsv2-series today.

Identify the Target Migration Option

- Learn more about the different migration options and their benefits in the section *Recommended options for migration*.
- Evaluate your current VM's workload and performance requirements and identify the target migration option.

Check and Request Quota Increases

- Before resizing and migration, verify that your subscription has sufficient quota for the target VM series.
- Request more quota through the Azure portal if needed.

Complete Migration

- Complete migration as soon as possible to prevent business impact and to take advantage of the improved performance, and extensive regional coverage of our new confidential computing offerings.
- Dependent on chosen migration option follows the documentation below.
- For technical questions, issues, and help get answers from community experts in Microsoft Q&A.

Migrate workloads to DCdsv3-series VMs

To continue using the enclave-based offering with Intel SGX technology, migrate your workloads to DCdsv3 virtual machines. First, check if your desired DCdsv3-series SKU is available in your current region. If it is, you can resize your virtual machines to the DCdsv3-series using the Azure portal, PowerShell, or the CLI. Below are examples of how to resize your VM using the Azure portal, PowerShell, and Azure CLI.

> **ⓘ Important**
>
> Resizing a virtual machine results in a restart. We recommend that you perform actions that result in a restart during off-peak business hours.
>
> Deallocating the VM also releases any dynamic IP addresses assigned to the VM. The OS and data disks are not affected.
>
> Additionally, if your DCsv2 VMs are running in North Central US, Canada East, Australia Southeast, or UK West, please follow the instructions in the next section.

Azure portal

1. Open the Azure portal.
2. Type *virtual machines* in the search.
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select the virtual machine you want to resize.
5. Stop (deallocate) the VM.
6. In the left menu under Availability + scale, select **Size** option.
7. Pick a new DCdsv3 size from the list of available sizes and select **Resize**.
8. **Start the VM** after resizing.

Refer to the full Azure VM resizing guide for more detailed instructions.

Azure PowerShell

1. Open a PowerShell session

2. Authenticate your device and set your subscription.

```PowerShell
Connect-AzAccount –UseDeviceAuthentication
Set-AzContext -SubscriptionName "Your-Subscription-Name"
```

3. Set the resource group and VM name variables. Replace the values with information of the VM you want to resize.

```PowerShell
$resourceGroup = "myResourceGroup"
$vmName = "myVM"
```

4. Stop the VM.

```PowerShell
Stop-AzVM -Name $vmName -ResourceGroupName $resourceGroup
```

5. List the VM sizes that are available on the hardware cluster where the VM is hosted.

```PowerShell
Get-AzVMSize -ResourceGroupName $resourceGroup -VMName $vmName
```

6. Resize the VM to the new size.

PowerShell

```
$vm = Get-AzVM -ResourceGroupName $resourceGroup -VMName $vmName
$vm.HardwareProfile.VmSize = "<newDCdsv3VMsize>"
Update-AzVM -VM $vm -ResourceGroupName $resourceGroup
Start-AzVM -ResourceGroupName $resourceGroup -Name $vmName
```

Azure CLI

1. Open a terminal session and ensure you have Azure CLI installed (or use the portal cli)

2. Authenticate your device and set your subscription.

   PowerShell

   ```
   az login
   az account set --subscription "<subscriptionIdHere>”
   ```

3. Set the resource group, VM name and new size variables. Replace the values with information of the VM you want to resize.

   PowerShell

   ```
   resourceGroup="myResourceGroup"
   vmName="myVM"
   newSize=<newDCdsv3VMsize> # ex: Standard_DC24ds_v3
   ```

4. Resize the VM to the new size.

   PowerShell

   ```
   az vm deallocate --resource-group $resourceGroup --name $vmName
   az vm resize --resource-group $resourceGroup --name $vmName --size $newSize
   az vm start --resource-group $resourceGroup --name $vmName
   ```

Important Notice for DCsv2 VMs running in North Central US, Canada East, Australia Southeast, or UK West

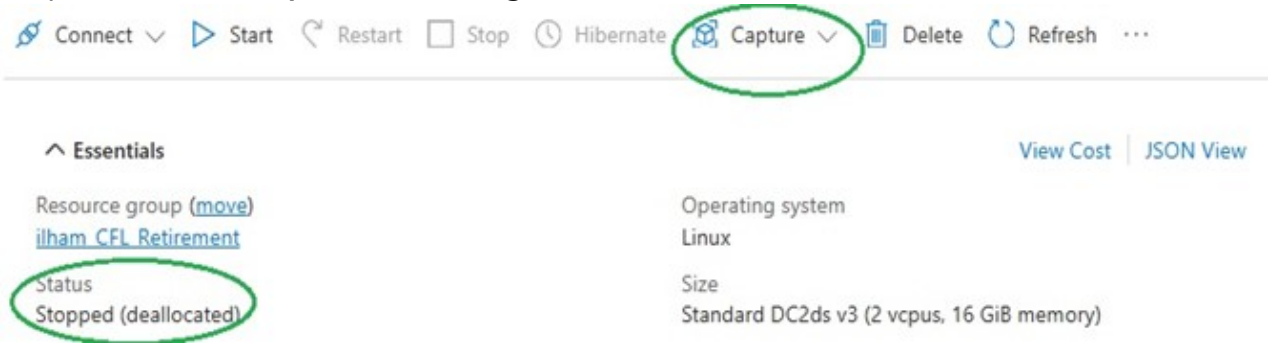
If your DCsv2 VMs are running in North Central US, Canada East, Australia Southeast, or UK West, please consider migrating them to the available regions listed below where the DCdsv3 SKU is available or explore our new generation of confidential computing offerings.

> ⓘ **Note**

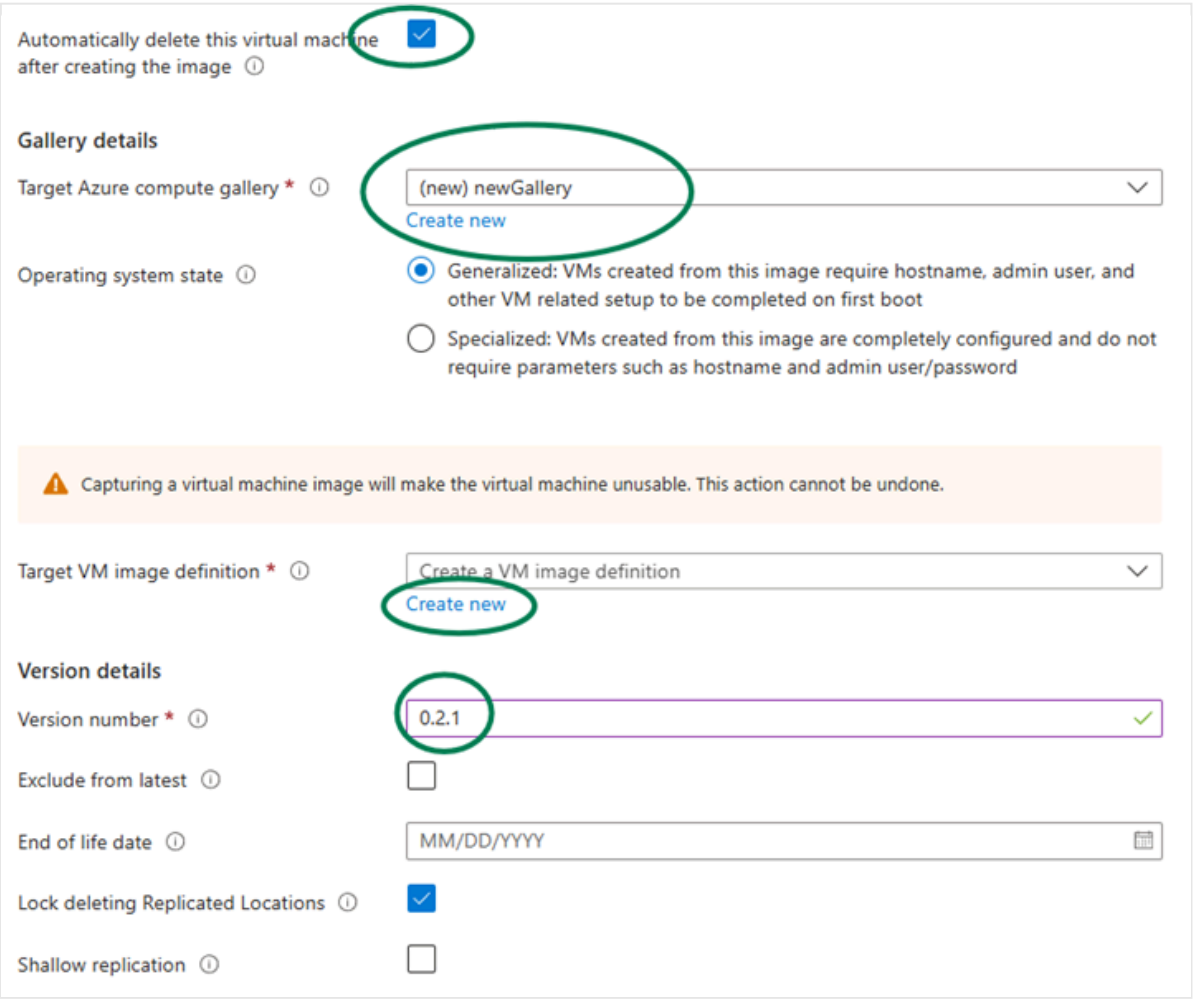
Available Regions:
Australia East, Canada Central, Central India, Central US, East US, East US 2, West US, West US 2, South Central US, Germany North, Germany West Central, Italy North, Japan East, Japan West, North Europe, South India, Southeast Asia, UK South, West Europe, UAE Central, UAE North, Switzerland North

To migrate your VMs to one of these available regions, follow these steps:

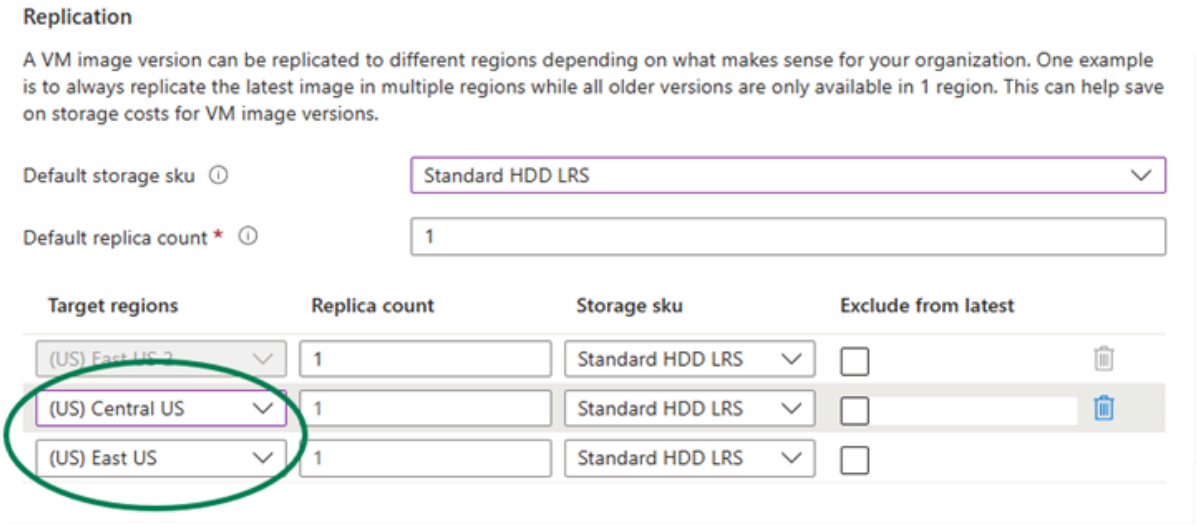
1. Identify the **target region** from the list above.
2. Prepare your VMs for migration by ensuring all data is backed up.
3. Verify that your subscription has sufficient quota for the DCdsv3-series VMs in the target region. Request a quota through the Azure portal if needed.
4. Navigate to VM you want to resize in the portal.
5. **Stop the VM** and wait for status of the VM to be Stopped (deallocated).
6. Find the **Capture** drop down in the overview tab of the VM (circled bellow). From the drop-down select **capture**, then image.



7. When you reach **the image creation page**:
    - Ensure you select **Automatically delete this virtual machine** after creating the image.
    - If you don't have a gallery, select **Create new** in the gallery option and name your gallery.
    - Fill in the name and other required options.
    - Create an image definition if none is available.
    - Read the descriptions for specialized vs generalized images and choose your option. (If not sure, generalized should work for most cases.)



- Continue to fill in the other options. In the replication section of the image capture option, add the region where you wish to relocate your VM. You'll need to select the target region from the dropdown menu.



8. Go to your gallery and select the image you captured. In the top left, select **Create a VM**.

- Fill in all options and ensure you select the new region and new size.
- If you don't see the size you want, ensure **No infrastructure redundancy required** is selected and that your requested region supports the desired size.

Migrate to new generation offerings

- To lift and shift into a VM based programming model, consider DCasv5/DCadsv5/ECasv5/ECadsv5 VMs, DCasv6/ECasv6 series (currently in preview) or DC/ECesv6 (currently in preview) confidential VMs (CVMs).
- If you already have or plan to transition to containerized workloads and want to lift and shift your containerized applications consider using Azure Confidential Container Instances (C-ACI) serverless infrastructure.
- If you need to orchestrate containerized workloads, consider using Virtual nodes on Azure Container Instances (C-VN2) for Azure Kubernetes Service (AKS).

Frequently Asked Questions

How does the DCsv2-series retirement affect me?

If you're running your workload on DCsv2-series, either by using virtual machines, Virtual Machine Scale Sets or by having app-enclave aware containers running on Azure Kubernetes Service, this retirement affects you.

What is the migration timeline?

On June 30, 2026, DCsv2-series virtual machines (VMs) will be retired. Before that date, please migrate your workloads to DCdsv3-series virtual machines. In case you prefer global availability and want to lift and shift your workloads consider using DCasv5/DCadsv5/ECasv5/ECadsv5 VMs, DCasv6/ECasv6 series (currently in preview) or DC/ECesv6 (currently in preview) confidential VMs (CVMs), or Azure Confidential Container Instances (C-ACI) serverless infrastructure.

Will DCsv2-series VMs still allow new customer sign-ups?

Starting from July 1, 2025, capacity restrictions will be applied to DCsv2-series virtual machines and no new subscription will be allowed.

Will Microsoft continue to support my current workload?

Yes, support continues for your workloads on DCsv2 virtual machines until the retirement date. You continue to receive SLA assurance, infrastructure updates, and maintenance.

Will other services built on top of the DCsv2 SKU still be available after the SKU retires?

No, all uses of the DCsv2 SKU retires simultaneously in June 2026, including those on Azure Kubernetes Service and Azure Virtual Machine Scale Sets.

Will DCsv2-series VMs provide any new features during the retirement period?

No, we aren't taking any feature requests or building new features for the DCsv2-series VMs. Instead, we focus on next-generation lift-and-shift offerings with more memory per vCPU, faster SSD storage, global availability, and a cloud-native approach with containerized workloads and serverless infrastructure.

Will DCsv2-series and DCsv3-series VMs be available in new regions?

No, we won't deploy DCsv2-series, DCsv3-series, and DCdsv3-series VMs in new Azure regions. Check availability in the existing DCsv3/DCdsv3 regions.

I'm using EPID Attestation (IAS). Can I continue using it on DCdsv3 VM?

No, you can't continue using Intel SGX Attestation Service Utilizing Intel EPID (IAS for short) on DCdsv3 VM. This feature isn't supported and won't be supported, as Intel announced IAS end of support on April 2, 2025. If you didn't transition away from IAS, please transition now.

How can I get a quota for the target VM size?

Follow the guide to request an increase in vCPU quota by VM family.

Can I resize to a VM size with no local temp disk?

You can't resize a VM size that has a local temp disk to a VM size with no local temp disk and vice versa. This means that you can resize from DCsv2-series VMs size to DCdsv3-series VMs, but you can't resize from DCsv2-series VMs size to DCsv3-series VMs.

I don't need a local temp disk, and I would like to resize to DCsv3-series virtual machines while keeping the same price as I was charged for DCsv2. How do I migrate from a VM size with a local temp disk to a VM size with no local temp disk?

If you're sure that you don't need a local temp disk, for a work-around, see How do I migrate from a VM size with local temp disk to a VM size with no local temp disk? The work-around can be used to resize a VM with no local temp disk to VM with a local temp disk. You create a snapshot of the VM with no local temp disk, then create a disk from the snapshot and lastly create VM from the disk with appropriate VM size that supports VMs with a local temp disk.

Does changing to a VM without a local temp disk break my custom scripts, custom images, or OS images that have scratch files or page files on a local temp disk?

If the custom OS image points to the local temp disk, the image might not work correctly with this diskless size.

Are my OS and data disks affected when resizing from DCsv2 to DCdsv3?

Deallocating the VM also releases any dynamic IP addresses assigned to the VM. The OS and data disks aren't affected.

What impact will migration from DCsv2 to DCdsv3 have on my dynamic IP addresses?

Deallocating the VM also releases any dynamic IP addresses assigned to the VM. If you need to retain the same IP addresses, consider using static IP addresses and set them in the network settings ahead of to migration (resize to DCdsv3).

What should I do if there are no DCdsv3-series VMs available in my current region?

If there are no DCdsv3-series VMs available in your current region, you can consider the following options:

- Check Availability in Nearby Regions: Look for DCdsv3-series VMs in nearby regions that might have the required capacity.
- Contact Azure Support: Reach out to Azure Support for assistance and to explore alternative solutions that meet your requirements.

How does migration affect my current billing?

During the migration and resize from DCsv2-series to DCdsv3-series VMs with a local temp disk, there is a price change. However, you'll receive a newer generation CPU, more RAM for the same number of cores, be able to attach more data disks, and have a larger local temp disk. For more information see Azure Virtual Machines pricing page for more information.

Are there any cost-saving options available during migration?

If you decide that you don't need a local temp disk, the price remains the same, and you'll still benefit from more RAM and the ability to attach more data disks. This option will require more effort after the resize to avoid using the local temp disk. For a workaround, please refer to how do I migrate from a VM size with local temp disk to a VM size with no local temp disk?

I'm on Reserved Instances (RIs) with DCsv2. How Do I Handle Migration?

If you have active Reserved Instances for DCsv2-series VMs, follow these steps:

1. Review Current Reservations

    - Check your active RIs in the Azure portal.
    - Identify which RIs expires or are affected by the VM retirement.

2. Migrate and Manage Your RIs
   Depending on your business needs, consider these options:

- Exchange Existing Reservations:
  - Swap current RIs for a new VM series without any penalties.
  - Refer to the RI Exchange Guide
- Trade-In for Savings Plan:
  - Convert your existing RIs into an Azure Savings Plan for compute.
  - This offers flexibility across VM families and regions.
  - Follow the Azure RI Trade-In Tutorial.
- Purchase New RIs:
  - Buy new reservations that align with your new VM series.
  - Consider shorter terms (1-year) for flexibility

How can I get transition help and support during migration?

If you have any questions, you can create a support request through the Azure portal for technical help.

What will happen after retirement date?

After June 30, 2026, any remaining DCsv2-series virtual machine subscriptions will stop working and will no longer incur billing charges. To avoid disruption, please migrate ahead of the retirement schedule.

Help and support

If you have questions, ask community experts in Microsoft Q&A. If you have a support plan and need technical help, create a support request:

1. In the Help + support page, select **Create a support request**. Follow the **New support request** page instructions. Use the following values:

    - For **Issue type**, select **Technical**.
    - For **Service**, select **My services**.
    - For **Service type**, select **Virtual Machine running Windows/Linux**.
    - For **Resource**, select your VM.
    - For **Problem type**, select **Assistance with resizing my VM**.
    - For **Problem subtype**, select the option that applies to you.

Follow instructions in the **Solutions** and **Details** tabs, as applicable, and then **Review + create**.

Ev3 and Esv3-series

07/23/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

The Ev3 and Esv3-series run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1 GHz (Skylake), or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell) processor in a hyper-threaded configuration, providing a better value proposition for most general purpose workloads, and bringing the Ev3 into alignment with the general purpose VMs of most other clouds. Memory has been expanded (from 7 GiB/vCPU to 8 GiB/vCPU) while disk and network limits have been adjusted on a per core basis to align with the move to hyperthreading. The Ev3 is the follow up to the high memory VM sizes of the D/Dv2 families.

Ev3-series

Ev3-series instances run on the 3rd Generation Intel® Xeon® Platinum 8370C (Ice Lake), Intel® Xeon® Platinum 8272CL (Cascade Lake), Intel® Xeon® 8171M 2.1 GHz (Skylake), or the Intel® Xeon® E5-2673 v4 2.3 GHz (Broadwell) processors, and feature Intel Turbo Boost Technology 2.0. Ev3-series instances are ideal for memory-intensive enterprise applications.

Data disk storage is billed separately from virtual machines. To use premium storage disks, use the ESv3 sizes. The pricing and billing meters for ESv3 sizes are the same as Ev3-series.

Ev3-series VM's feature Intel® Hyper-Threading Technology.

[1] Constrained core sizes available.

[2] Instance is isolated to hardware dedicated to a single customer.

[3] Esv3-series VMs can burst their disk performance and get up to their bursting max for up to 30 minutes at a time.

[4] Accelerated networking can only be applied to a single NIC.

Size table definitions

- Storage capacity is shown in units of GiB or 1024^3 bytes. When you compare disks measured in GB (1000^3 bytes) to disks measured in GiB (1024^3) remember that capacity numbers given in GiB may appear smaller. For example, 1023 GiB = 1098.4 GB.
- Disk throughput is measured in input/output operations per second (IOPS) and MBps where MBps = 10^6 bytes/sec.
- Data disks can operate in cached or uncached modes. For cached data disk operation, the host cache mode is set to **ReadOnly** or **ReadWrite**. For uncached data disk operation, the host cache

mode is set to **None**.

- To learn how to get the best storage performance for your VMs, see Virtual machine and disk performance.
- **Expected network bandwidth** is the maximum aggregated bandwidth allocated per VM type across all NICs, for all destinations. For more information, see Virtual machine network bandwidth.

  Upper limits aren't guaranteed. Limits offer guidance for selecting the right VM type for the intended application. Actual network performance will depend on several factors including network congestion, application loads, and network settings. For information on optimizing network throughput, see Optimize network throughput for Azure virtual machines. To achieve the expected network performance on Linux or Windows, you may need to select a specific version or optimize your VM. For more information, see Bandwidth/Throughput testing (NTTTCP).

Lsv2 sizes series

The Lsv2-series features high throughput, low latency, directly mapped local NVMe storage running on the AMD EPYC™ 7551 processor with an all core boost of 2.55GHz and a max boost of 3.0GHz. The Lsv2-series VMs come in sizes from 8 to 80 vCPU in a simultaneous multi-threading configuration. There is 8 GiB of memory per vCPU, and one 1.92TB NVMe SSD M.2 device per 8 vCPUs, with up to 19.2TB (10x1.92TB) available on the L80s v2.

Migrate your NP-series virtual machines by May 31, 2027

> **Note**
>
> 1-year and 3-year purchases for the NP-series end April 2, 2026.

Microsoft Azure has announced the retirement of its NP-series virtual machines. The NP-series, introduced for FPGA-accelerated workloads, is powered by Intel Xeon 8171M (Skylake) CPUs and AMD Xilinx Alveo U250 FPGAs. These VMs are designed for accelerating workloads including machine learning inference, video transcoding, and database search & analytics.

How does the retirement of the NP-series virtual machines affect me?

After May 31, 2027, any remaining NP-series virtual machines (VMs) subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. NP-series will be no longer under SLA or have support included.

What action do I need to take before the retirement date?

To avoid service disruption, please resize or deallocate your NP-series VMs and change your VM sizes to a product that meets your workload requirements.

Suggested alternative Azure VM sizes

To ensure continuity and optimal performance, we recommend transitioning to one of the following Azure GPU VM families based on your workload needs:

- NDv2 VMs – designed for the needs of the most demanding GPU-accelerated AI, machine learning, simulation, and HPC workloads.
- NCads_H100_v5 VMs – real-world Azure Applied AI training and batch inference workloads.
- NCasT4_v3 – ideal for deploying AI services, such as real-time inferencing of user-generated requests, or for interactive graphics and visualization workloads.

Check Azure Regions by Product page for region availability. Visit the Azure Virtual Machine pricing page for pricing information.

Steps to change VM size

1. Choose a series and size. Review the documentation for the series to understand the capabilities and limitations of the VMs in that series.
2. Request quota for the new target VM.
3. You can resize the virtual machine.

Help and support

If you have a support plan and you need technical help, create a support request.

1. Under *Issue type*, select **Technical**.
2. Under *Subscription*, select your subscription.
3. Under *Service*, click **My services.**
4. Under *Service type*, select **Virtual Machine running Windows/Linux.**
5. Under *Summary*, enter the summary of your request.
6. Under *Problem type*, select **Assistance with resizing my VM.**
7. Under *Problem subtype*, select the option that applies to you.

Migrate your HC-series virtual machines by May 31, 2027

> **Note**
>
> 1-year and 3-year purchases for the HC-series end April 2, 2026.

Microsoft Azure has announced the retirement of its HC-series virtual machines effective May 31, 2027. Introduced in 2019, HC-series VMs are equipped with Intel Xeon Platinum 8168 processors, 8 GB of RAM per CPU core, and a 100 Gb/sec Mellanox EDR InfiniBand. Since launching this series, Microsoft introduced HBv5, HBv4, HX, and HBv3 series virtual machines. These newer offerings pack the latest technological improvements in compute, memory, and backend networking. This enables superior performance, scaling efficiency, and cost-effectiveness for a wide range of high-performance computing workloads.

Impacted sizes

The following HC-series VM sizes are being retired on May 31, 2027:

- Standard_HC44rs
- Standard_HC44-16rs
- Standard_HC44-32rs

How does the retirement of the HC-series virtual machines affect me?

After May 31, 2027, any remaining HC-series virtual machines (VMs) subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. HC-series will no longer be under SLA or have support included.

What action do I need to take before the retirement date?

To avoid service disruption, deallocate your HC-series VMs and migrate these workloads to newer HPC-optimized SKUs such as HBv5, HBv4, HX, or HBv3 series (or an alternative that

meets your workload requirements).

Suggested alternative Azure VM sizes

To ensure continuity and optimal performance, we recommend transitioning from the current HC-series VMs to newer VM series within Azure's HPC portfolio. HBv5-series offers higher performance and better price-performance than HBv4, making it well-suited for most HPC workloads. HX-series is optimized for high-memory HPC workloads with approximately twice the memory capacity of HBv4.

Expand table

Workload	Recommended VM to migrate to
Memory-bandwidth intensive HPC applications (for example, CFD, structural mechanics, energy research, weather, and climate, chemistry & materials)	HBv5, HBv4, HBv3
Memory capacity/latency bound (for example, silicon design/EDA)	HX, HBv5, HBv3
Compute bound (for example, financial calculations, rendering)	HX, HBv4, HBv3
Intel-specific requirements (for example, Intel MKL, ISV certification on Xeon)	Ddsv6/Edsv6, Ddsv5/Edsv5, Ddsv4/Edsv4

> **Note**
>
> These virtual machine recommendations are listed in order of cost performance benefit to customers from most to least.

Check Azure Regions by Product page for region availability. Visit the Azure Virtual Machine pricing page for pricing information.

Steps to change VM size

1. Choose a series and size. Review the table above for Microsoft's recommendation. You can also file a support request if more assistance is needed.
2. Request quota for the new target VM.
3. Resize the virtual machine.

Help and support

If you have a support plan and you need technical help, create a support request.

1. Under *Issue type*, select **Technical**.
2. Under *Subscription*, select your subscription.
3. Under *Service*, select **My services.**
4. Under *Service type*, select **Virtual Machine running Windows/Linux.**
5. Under *Summary*, enter the summary of your request.
6. Under *Problem type*, select **Assistance with resizing my VM.**
7. Under *Problem subtype*, select the option that applies to you.

Migrate your HBv2-series virtual machines by May 31, 2027

> **Note**
>
> 1-year and 3-year purchases for the HBv2-series end April 2, 2026.

Microsoft Azure has announced the retirement of its HBv2-series virtual machines effective May 31, 2027. Introduced in 2020, the HBv2-series is equipped with 120 AMD EPYC 7V12 processor cores, 4 GB of RAM per CPU core, up to 350 GB/s of memory bandwidth, and up to 4 teraFLOPS of FP64 compute. Since launching this series, Microsoft introduced HBv5, HBv4, HX-series, and HBv3 series virtual machines. These newer offerings pack the latest technological improvements in compute, memory, and backend networking, enabling superior performance, scaling efficiency, and cost-effectiveness for a wide range of high-performance computing workloads.

How does the retirement of the HBv2-series virtual machines affect me?

After May 31, 2027, any remaining HBv2-series virtual machines (VMs) subscriptions will be set to a deallocated state. They'll stop working and no longer incur billing charges. HBv2-series will be no longer under SLA or have support included.

What action do I need to take before the retirement date?

To avoid service disruption, resize or deallocate your HBv2-series VMs and migrate these workloads to newer HPC-optimized SKUs such as HBv5, HBv4, HX, and HBv3-series virtual machines (or an alternative that meets your workload requirements).

Suggested alternative Azure VM sizes

To ensure continuity and optimal performance, we recommend transitioning from the current HBv2-series VMs to newer VM series within Azure's HPC portfolio.

Retired Azure VM size series

This article provides a list of all sizes that are retired or have been announced for retirement. For sizes that require it there are migration guides to help move to replacement sizes.

> ⚠ **Warning**
>
> Series with *Retirement Status* listed as *Retired* are **no longer available** and can't be provisioned.
>
> Virtual Machines (VMs) announced for retirement will have restrictions when deploying through new subscriptions. We recommend using the latest generation VMs to ensure best price-performance and to benefit from extended capacity availability over time for new deployments.

What are retired size series?

Retired virtual machine size series are running on older hardware which is no longer supported. The hardware is with newer generations of hardware.

Series with *Retirement Status* listed as *Announced* are still available, but will be retired on the *Planned Retirement Date*. At the listed retirement date, any remaining VMs in a retired series are deallocated, stop working, stop incurring charges, and no longer have SLA or support. It's recommended that you plan your migration to a replacement series well before the listed retirement date.

To learn more about size series retirement, previous-gen sizes, and the retirement process, see the size series retirement overview.

> ⓘ **Important**
>
> If you're currently using one of the size series listed as *Retired*, view the migration guide to switch to a replacement series as soon as possible.

Previous-gen size series aren't retired and still fully supported, but they have limitations similar to series that are announced for retirement. For a list of previous-gen sizes, see previous generation Azure VM sizes.

Support for Generation 2 VMs on Azure

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Support for Generation 2 virtual machines (VMs) is now available on Azure. You can also upgrade existing Generation 1 virtual machines to Generation 2 with Trusted launch. Review the considerations on this page and the upgrade guidance before choosing or upgrading a generation.

Generation 2 VMs support key features that aren't supported in Generation 1 VMs. These features include increased memory, Intel Software Guard Extensions (Intel SGX), and virtualized persistent memory (vPMEM). Generation 2 VMs running on-premises, have some features that aren't supported in Azure yet. For more information, see the Features and capabilities section.

Generation 2 VMs use the new UEFI-based boot architecture rather than the BIOS-based architecture used by Generation 1 VMs. Compared to Generation 1 VMs, Generation 2 VMs might have improved boot and installation times. For an overview of Generation 2 VMs and some of the differences between Generation 1 and Generation 2, see Should I create a Generation 1 or 2 virtual machine in Hyper-V?.

Generation 2 VM sizes

Azure now offers Generation 2 support for the following selected VM series:

Expand table

Type	Generation 2 supported size families	Not supported size families
General purpose	B-family, D-family	A-family
Compute optimized	F-family, Fx-family	
Memory optimized	E-family, Eb-family, M-family	
Storage optimized	L-family	
GPU	NC-family, ND-family, NV-family	NC-series, NV-series
High Performance Compute	HBv2-series, HBv3-series, HBv4-series, HC-series, HX-series	

[1] Mv2-series, DC-series, NDv2-series, Msv2 and Mdsv2-series Medium Memory do not support Generation 1 VM images and only support a subset of Generation 2 images. Please see Mv2-

series documentation, ND A100 v4-series, NDv2-series, and Msv2 and Mdsv2 Medium Memory Series for details.

Generation 2 VM images in Azure Marketplace

Generation 2 VMs support the following Marketplace images:

- Windows Server 2025, 2022, 2019, 2016, 2012 R2, 2012
- Windows 11 Pro, Windows 11 Enterprise
- Windows 10 Pro, Windows 10 Enterprise
- SUSE Linux Enterprise Server 15 SP3, SP2
- SUSE Linux Enterprise Server 12 SP4
- Ubuntu Server 22.04 LTS, 20.04 LTS, 18.04 LTS, 16.04 LTS
- RHEL 9,5, 9.4, 9.3, 9.2, 9.1, 9.0, 8.10, 8.9, 8.8, 8.7, 8.6, 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, 7.6, 7.5, 7.4, 7.0
- Cent OS 8.4, 8.3, 8.2, 8.1, 8.0, 7.7, 7.6, 7.5, 7.4
- Oracle Linux 9.3, 9.2, 9.1, 9.0, 8.9, 8.8, 8.7, 8.6, 8.5, 8.4, 8.3, 8.2, 8.1, 7.9, 7.9, 7.8, 7.7

> **Note**
>
> Specific Virtual machine sizes like Mv2-Series, DC-series, ND A100 v4-series, NDv2-series, Msv2 and Mdsv2-series may only support a subset of these images - please look at the relevant virtual machine size documentation for complete details.

On-premises vs. Azure Generation 2 VMs

Azure doesn't currently support some of the features that on-premises Hyper-V supports for Generation 2 VMs.

Expand table

Generation 2 feature	On-premises Hyper-V	Azure
Secure boot	✔	With trusted launch
Shielded VM	✔	✘
vTPM	✔	With trusted launch
Virtualization-based security (VBS)	✔	✔

Creating a Generation 2 VM

Azure Resource Manager Template

To create a simple Windows Generation 2 VM, see Create a Windows virtual machine from a Resource Manager template To create a simple Linux Generation 2 VM, see How to create a

Linux virtual machine with Azure Resource Manager templates

Marketplace image

In the Azure portal or Azure CLI, you can create Generation 2 VMs from a Marketplace image that supports UEFI boot.

Azure portal

Below are the steps to create a Generation 2 (Gen2) VM in Azure portal.

1. Sign in to the Azure portal.
2. Search for **Virtual Machines**
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select **Add**, and then select **Virtual machine**.
5. Under **Project details**, make sure the correct subscription is selected.
6. Under **Resource group**, select **Create new** and type a name for your resource group or select an existing resource group from the dropdown.
7. Under **Instance details**, type a name for the virtual machine name and choose a region
8. Under **Image**, select a Generation 2 image from the **Marketplace images to get started**

   > **Tip**
   >
   > If you don't see the Generation 2 version of the image you want in the drop-down, select **See all images** and then change the **Image Type** filter to **Gen 2**.

9. Select a VM size that supports Generation 2. See a list of supported sizes.
10. Fill in the **Administrator account** information and then **Inbound port rules**
11. At the bottom of the page, select **Review + Create**
12. On the **Create a virtual machine** page, you can see the details about the VM you are about to deploy. Once validation shows as passed, select **Create**.

PowerShell

You can also use PowerShell to create a VM by directly referencing the Generation 1 or Generation 2 SKU.

For example, use the following PowerShell cmdlet to get a list of the SKUs in the `WindowsServer` offer.

```
PowerShell
```

```
Get-AzVMImageSku -Location westus2 -PublisherName MicrosoftWindowsServer -Offer
WindowsServer
```

If you're creating a VM with Windows Server 2019 as the OS, then you can select a Generation 2 (UEFI) image which looks like this:

PowerShell

```
2019-datacenter-gensecond
```

If you're creating a VM with Windows 10 as the OS, then you can select a Generation 2 (UEFI) image which looks like this:

PowerShell

```
20H2-PRO-G2
```

See the Features and capabilities section for a current list of supported Marketplace images.

Azure CLI

Alternatively, you can use the Azure CLI to see any available Generation 2 images, listed by **Publisher**.

Azure CLI

```
az vm image list --publisher Canonical --sku gen2 --output table --all
```

Managed image or managed disk

You can create a Generation 2 VM from a managed image or managed disk in the same way you would create a Generation 1 VM.

Virtual machine scale sets

You can also create Generation 2 VMs by using virtual machine scale sets. In the Azure CLI, use Azure scale sets to create Generation 2 VMs.

> **Note**

Alternatively, you can upgrade an existing Generation 1 VM to Generation 2 with Trusted launch. For more information, see Upgrade existing Gen1 VMs to Gen2-Trusted launch.

Frequently asked questions

- **Are Generation 2 VMs available in all Azure regions?**
  Yes. But not all generation 2 VM sizes are available in every region. The availability of the Generation 2 VM depends on the availability of the VM size.

- **Is there a price difference between Generation 1 and Generation 2 VMs?**
  No.

- **I have a .vhd file from my on-premises Generation 2 VM. Can I use that .vhd file to create a Generation 2 VM in Azure?** Yes, you can bring your Generation 2 .vhd file to Azure and use that to create a Generation 2 VM. Use the following steps to do so:

  1. Upload the .vhd to a storage account in the same region where you'd like to create your VM.

  2. Create a managed disk from the .vhd file. Set the Hyper-V Generation property to V2. The following PowerShell commands set Hyper-V Generation property when creating managed disk.

     PowerShell

     ```
     $sourceUri = 'https://xyzstorage.blob.core.windows.net/vhd/abcd.vhd'. #
     <Provide location to your uploaded .vhd file>
     $osDiskName = 'gen2Diskfrmgenvhd'  #<Provide a name for your disk>
     $diskconfig = New-AzDiskConfig -Location '<location>' -DiskSizeGB 127 -
     AccountType Standard_LRS -OsType Windows -HyperVGeneration "V2" -SourceUri
     $sourceUri -CreateOption 'Import'
     New-AzDisk -DiskName $osDiskName -ResourceGroupName '<Your Resource
     Group>' -Disk $diskconfig
     ```

  3. Once the disk is available, create a VM by attaching this disk. The VM created will be a Generation 2 VM. When the Generation 2 VM is created, you can optionally generalize the image of this VM. By generalizing the image, you can use it to create multiple VMs.

- **How do I increase the OS disk size?**

  OS disks larger than 2 TiB are new to Generation 2 VMs. By default, OS disks are smaller than 2 TiB for Generation 2 VMs. You can increase the disk size up to a recommended maximum of 4 TiB. Use the Azure CLI or the Azure portal to increase the OS disk size. For

information about how to expand disks programmatically, see **Resize a disk** for Windows or Linux.

To increase the OS disk size from the Azure portal:

1. In the Azure portal, go to the VM properties page.
2. To shut down and deallocate the VM, select the **Stop** button.
3. In the **Disks** section, select the OS disk you want to increase.
4. In the **Disks** section, select **Configuration**, and update the **Size** to the value you want.
5. Go back to the VM properties page and **Start** the VM.

You might see a warning for OS disks larger than 2 TiB. The warning doesn't apply to Generation 2 VMs. However, OS disk sizes larger than 4 TiB are not supported.

- **Do Generation 2 VMs support accelerated networking?**
  Yes. For more information, see Create a VM with accelerated networking.
- **Do Generation 2 VMs support Secure Boot or vTPM in Azure?** Both vTPM and Secure Boot are features of trusted launch for Generation 2 VMs. For more information, see Trusted launch.
- **Is VHDX supported on Generation 2?**
  No, Generation 2 VMs on Azure support only VHD.
- **Do Generation 2 VMs support Azure Ultra Disk Storage?**
  Yes.
- **Can I migrate a VM from Generation 1 to Generation 2?**
  Azure Virtual Machines supports upgrading existing Generation 1 VMs to Generation 2 by upgrading to the Trusted launch security type. See Upgrade existing Gen1 VMs to Gen2-Trusted launch for steps and prerequisites.
- **Why is my VM size not enabled in the size selector when I try to create a Generation 2 VM?**

  This may be solved by doing the following:

  1. Verify that the **VM Generation** property is set to **Gen 2**.
  2. Verify you are searching for a VM size which supports Generation 2 VMs.

Virtual machine sizes that provide isolation in Azure

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Compute offers virtual machine sizes that are isolated to a specific hardware type and dedicated to a single customer. Isolated sizes run on specific hardware generations. They're deprecated when the hardware generation is retired or a new generation becomes available.

Isolated virtual machine sizes are best suited for workloads that require a high degree of isolation from other customers' workloads. This requirement sometimes applies to compliance and regulatory standards. Utilizing an isolated size guarantees that your virtual machine is the only one running on that specific server instance.

Additionally, as the isolated size virtual machines are large, customers may choose to subdivide the resources of these virtual machines by using Azure support for nested virtual machines.

Isolated VM sizes

FAQ

Q: What specific scenarios benefit most from isolated VM sizes?

A: Isolated VM sizes run on dedicated physical servers for maximum security and consistency. These sizes are best for regulated workloads, highly sensitive data, and performance-critical systems.

Q: How are isolated VMs different from Azure Dedicated Hosts and Confidential VMs?

A: Isolated VMs run on a single physical server dedicated exclusively for one VM for strict compliance and isolation. Dedicated Hosts reserve an entire physical host for multiple VMs belonging to a single customer, giving full control on VM placement and maintenance scheduling. Confidential VMs use hardware-based encryption to protect data without requiring physical isolation.

Q: Is the size going to be retired or only its "isolation" feature?

A: If a VM sizes is published as isolated but doesn't have an "i" in its name, only the isolation feature is being retired (unless stated otherwise). VM sizes with an "i" in the name are deprecated entirely. We provide reminders 12 months in advance of the official deprecation of the isolated size.

Q: Is there downtime if my VM moves to nonisolated hardware?

A: For sizes where only isolation is retired (not the size), no action is needed and there's no downtime. If isolated is required, the announcement will include a recommended replacement size. Moving to that sizes requires resizing your VM.

Q: Is there any cost difference when moving from an isolated VM to a non-isolated VM?

A: Yes, isolated VM sizes carry a premium compared to non-isolated sizes. The premium is roughly 10% higher for isolated VMs

Q: What should I do if the isolated VM size I need is not available in my region?

A: Choose an alternative isolated SKU with similar specs or deploy to one of the supported regions.

Next steps

Customers can also choose to further subdivide the resources of these isolated virtual machines by using Azure support for nested virtual machines.

Compute benchmark scores for Linux VMs

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

> **Note**
>
> This page is no longer being maintained and is planned for archival on 12/16/2024.
>
> Azure is no longer publishing CoreMark since the metric has limited ability to inform users of the expected performance of a virtual machine across various attributes. For the most accurate results on a specific virtual machine, Azure recommends users run their workload(s) on that virtual machine to verify performance.

The following CoreMark benchmark scores show compute performance for Azure's high-performance VM lineup running Ubuntu 18.04. Compute benchmark scores are also available for Windows VMs.

Azure (Coremark) TOC

Expand table

Type	Families
Compute optimized	Fsv2, FXMDVS

About CoreMark

CoreMark is a benchmark that tests the functionality of a microcontroller (MCU) or central processing unit (CPU). CoreMark is not system dependent, so it functions the same regardless of the platform (e.g. big or little endian, high-end or low-end processor).

Linux numbers were computed by running CoreMark on Ubuntu 18.04. CoreMark was configured with the number of threads set to the number of virtual CPUs, and concurrency set to `PThreads`. The target number of iterations was adjusted based on expected performance to provide a runtime of at least 20 seconds (typically much longer). The final score represents the number of iterations completed divided by the number of seconds it took to run the test. Each test was run at least seven times on each VM. Test run dates shown above. Tests run on multiple VMs across Azure public regions the VM was supported in on the date run.

Running Coremark on Azure VMs

Download:

CoreMark is an open source tool that can be downloaded from GitHub.

Building and Running:

To build and run the benchmark, type:

```
> make
```

Full results are available in the files `run1.log` and `run2.log`. `run1.log` contains CoreMark results. These are the benchmark results with performance parameters. `run2.log` contains benchmark results with validation parameters.

Run Time:

By default, the benchmark will run between 10-100 seconds. To override, use `ITERATIONS=N`

```
% make ITERATIONS=10
```

above flag will run the benchmark for 10 iterations. **Results are only valid for reporting if the benchmark ran for at least 10 seconds!**

Parallel Execution:

Use `XCFLAGS=-DMULTITHREAD=N` where N is number of threads to run in parallel. Several implementations are available to execute in multiple contexts.

```
% make XCFLAGS="-DMULTITHREAD=4 -DUSE_PTHREAD"
```

The above will compile the benchmark for execution on 4 cores.

Recommendations for best results

- The benchmark needs to run for at least 10 seconds, probably longer on larger systems.
- All source files must be compiled with same flags.
- Do not change source files other than `core_portme*` (use `make check` to validate)
- Multiple runs are suggested for best results.

Coverage

Older end-of-life series may not be shown. N series not shown as they are GPU centric and Coremark doesn't measure GPU performance. Newer series may not have been benchmarked yet. Previous versions of this document cited benchmark runs from Ubuntu 16.04 which resulted in slightly lower performance than the current benchmarks running on Ubuntu 18.04.

GPU Series

Performance of GPU based VM series is best understood by using GPU appropriate benchmarks and running at the scale required for your workloads. Azure ranks among the best there:

- Top 10 Supercomputer: November 2021 | TOP500 (Azure powered #10: Voyager-EUS2)
- Machine Learning: MLCommons Training: v1.1 Results | MLCommons (2 highest at scale and largest in the cloud)

Next steps

- For storage capacities, disk details, and additional considerations for choosing among VM sizes, see Sizes for virtual machines.

Compute benchmark scores for Windows VMs

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

> **Note**
>
> This page is no longer being maintained and is planned for archival on 12/16/2024.
>
> Azure is no longer publishing CoreMark since the metric has limited ability to inform users of the expected performance of a virtual machine across various attributes. For the most accurate results on a specific virtual machine, Azure recommends users run their workload(s) on that virtual machine to verify performance.

The following CoreMark benchmark scores show compute performance for select Azure VMs running Windows Server 2019. Compute benchmark scores are also available for Linux VMs.

About CoreMark

CoreMark is a benchmark that tests the functionality of a microcontroller (MCU) or central processing unit (CPU). CoreMark isn't system dependent, so it functions the same regardless of the platform (for example, big or little endian, high-end or low-end processor).

Windows numbers were computed by running CoreMark on Windows Server 2019. CoreMark was configured with the number of threads set to the number of virtual CPUs, and concurrency set to `PThreads`. The target number of iterations was adjusted based on expected performance to provide a runtime of at least 20 seconds (typically much longer). The final score represents the number of iterations completed divided by the number of seconds it took to run the test. Each test was run at least seven times on each VM. Test run

dates shown above. Tests run on multiple VMs across Azure public regions the VM was supported in on the date run.

Windows numbers were computed by running CoreMark on Windows Server 2019. CoreMark was configured with the number of threads set to the number of virtual CPUs, and concurrency set to `PThreads`. The target number of iterations was adjusted based on expected performance to provide a runtime of at least 20 seconds (typically much longer). The final score represents the number of iterations completed divided by the number of seconds it took to run the test. Each test was run at least seven times on each VM. Test run dates shown above. Tests run on multiple VMs across Azure public regions the VM was supported in on the date run. (Coremark doesn't properly support more than 64 vCPUs on Windows, therefore SKUs with > 64 vCPUs have been marked as N/A.)

Running Coremark on Azure VMs

Download:

CoreMark is an open source tool that can be downloaded from GitHub.

Building and Running:

To build and run the benchmark, type:

```
> make
```

Full results are available in the files `run1.log` and `run2.log`. `run1.log` contains CoreMark results with performance parameters. `run2.log` contains benchmark results with validation parameters.

Run Time:

By default, the benchmark will run between 10-100 seconds. To override, use `ITERATIONS=N`

```
% make ITERATIONS=10
```

above flag will run the benchmark for 10 iterations. **Results are only valid for reporting if the benchmark ran for at least 10 seconds!**

Parallel Execution:

Use `XCFLAGS=-DMULTITHREAD=N` where N is number of threads to run in parallel. Several implementations are available to execute in multiple contexts.

```
% make XCFLAGS="-DMULTITHREAD=4 -DUSE_PTHREAD"
```

The above will compile the benchmark for execution on 4 cores.

Recommendations for best results

- The benchmark needs to run for at least 10 seconds, probably longer on larger systems.
- All source files must be compiled with same flags.
- Don't change source files other than `core_portme*` (use `make check` to validate)
- Multiple runs are suggested for best results.

GPU Series

Performance of GPU based VM series is best understood by using GPU appropriate benchmarks and running at the scale required for your workloads. Azure ranks among the best there:

- Top 10 Supercomputer: November 2021 | TOP500 (Azure powered #10: Voyager-EUS2)
- Machine Learning: MLCommons Training: v1.1 Results | MLCommons (2 highest at scale and largest in the cloud)

Next steps

- For storage capacities, disk details, and other considerations for choosing among VM sizes, see Sizes for virtual machines.

States and billing status of Azure Virtual Machines

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Virtual Machines (VM) instances go through different states. There are *provisioning* and *power* states. This article describes these states and highlights when customers are billed for instance usage.

Get states using Instance View

The instance view API provides VM running-state information. For more information, see Virtual Machines - Instance View.

Azure Resources Explorer provides a simple UI for viewing the VM running state: Resource Explorer.

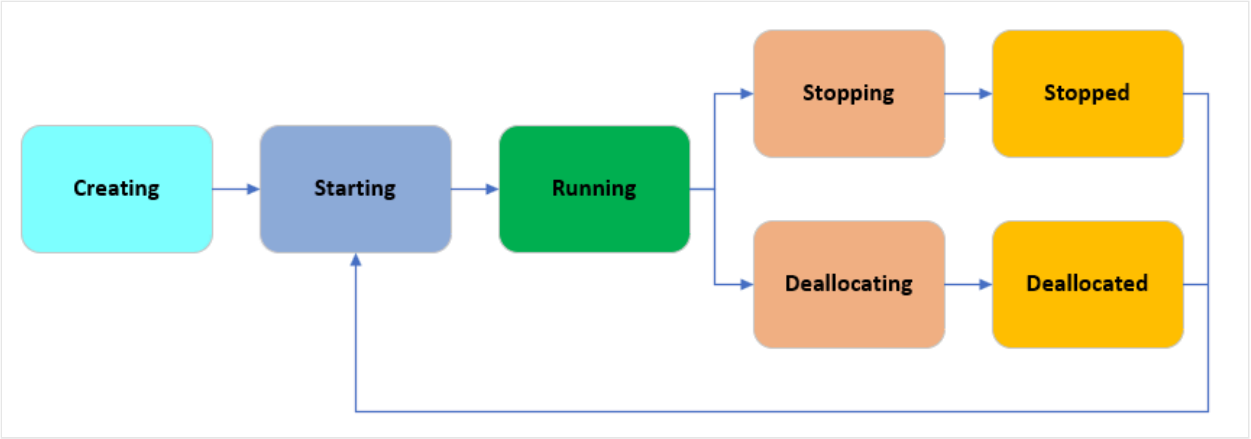
The VM provisioning state is available, in slightly different forms, from within the VM properties `provisioningState` and the InstanceView. In the VM InstanceView, there's an element within the `status` array in the form of `ProvisioningState/<state>[/<errorCode>]`.

To retrieve the power state of all the VMs in your subscription, use the Virtual Machines - List All API with parameter `statusOnly` set to `true`.

> **Note**
>
> Virtual Machines - List All API with parameter `statusOnly` set to `true` retrieves the power states of all VMs in a subscription. However, in some rare situations, the power state may not available due to intermittent issues in the retrieval process. In such situations, we recommend retrying using the same API or using Azure Resource Health to check the power state of your VMs.

Power states and billing

The power state represents the last known state of the VM.



The following table provides a description of each instance state and indicates whether that state is billed for instance usage.

Expand table

Power state	Description	Billing
Creating	Virtual machine is allocating resources.	Not Billed*
Starting	Virtual machine is powering up.	Billed
Running	Virtual machine is fully up. This state is the standard working state.	Billed
Stopping	This state is transitional between running and stopped.	Billed
Stopped	The virtual machine is allocated on a host but not running. Also called *PoweredOff* state or *Stopped (Allocated)*. This state can be result of invoking the `PowerOff` API operation or invoking shutdown from within the guest OS. The *Stopped* state might also be observed briefly during VM creation or while starting a VM from *Stopped (Deallocated)* state.	Billed
Deallocating	This state is transitional between *Running* and *Deallocated*.	Not billed*
Deallocated	The virtual machine has released the lease on the underlying hardware. If the machine is powered off it is shown as *Stopped (Deallocated)*. If it has entered hibernation it is shown as *Hibernated (Deallocated)*	Not billed*

* Some Azure resources, such as Disks and Networking continue to incur charges.

Example of PowerState in JSON:

JSON

```
{
  "code": "PowerState/running",
  "level": "Info",
```

```
    "displayStatus": "VM running"
  }
```

Provisioning states

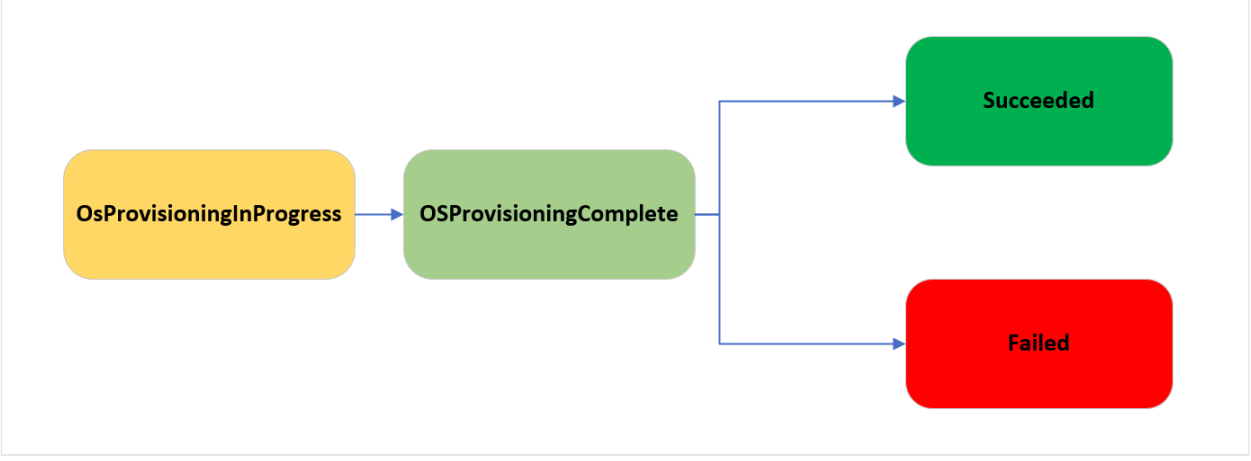
The provisioning state is the status of a user-initiated, control-plane operation on the VM. These states are separate from the power state of a VM.

Expand table

Provisioning state	Description
Creating	Virtual machine is being created.
Updating	Virtual machine is updating to the latest model. Some non-model changes to a virtual machine such as start and restart fall under the updating state.
Failed	Last operation on the virtual machine resource was unsuccessful.
Succeeded	Last operation on the virtual machine resource was successful.
Deleting	Virtual machine is being deleted.
Migrating	Seen when migrating from Azure Service Manager to Azure Resource Manager.

OS Provisioning states

OS Provisioning states only apply to virtual machines created with a generalized OS image. Specialized images and disks attached as OS disk don't display these states. The OS provisioning state isn't shown separately. It's a substate of the Provisioning State in the VM InstanceView. For example, `ProvisioningState/creating/osProvisioningComplete`.



Expand table

OS Provisioning state	Description
OSProvisioningInProgress	The VM is running and the initialization (setup) of the Guest OS is in progress.
OSProvisioningComplete	This state is a short-lived state. The virtual machine quickly transitions from this state to *Success*. If extensions are still being installed, you continue to see this state until installation is complete.
Succeeded	The user-initiated actions have completed.
Failed	Represents a failed operation. For more information and possible solutions, see the error code.

Troubleshooting VM states

To troubleshoot specific VM state issues, see Troubleshoot Windows VM deployments and Troubleshoot Linux VM deployments.

To troubleshoot hibernation, see Troubleshoot VM hibernation.

For other troubleshooting help visit Azure Virtual Machines troubleshooting documentation.

Next steps

- Review the Azure Cost Management and Billing documentation
- Use the Azure Pricing calculator to plan your deployments.
- Learn more about monitoring your VM, see Monitor virtual machines in Azure.

Check vCPU quotas

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

The vCPU quotas for virtual machines and scale sets are arranged in two tiers for each subscription, in each region. The first tier is the Total Regional vCPUs, and the second tier is the various VM size family cores such as the D-series vCPUs. Anytime a new VM is deployed the vCPUs for the VM must not exceed the vCPU quota for the VM size family or the total regional vCPU quota. If you exceed either of those quotas, the VM deployment won't be allowed. There is also a quota for the overall number of virtual machines in the region. The details on each of these quotas can be seen in the **Usage + quotas** section of the **Subscription** page in the Azure portal, or you can query for the values using the Azure CLI.

> **Note**
>
> Quota is calculated based on the total number of cores in use both allocated and deallocated. If you need additional cores, request a quota increase or delete VMs that are no longer needed.

Quota and capacity

Azure checks quota and capacity separately. Quota is your subscription's permission to deploy a certain number of vCPUs or VMs. Capacity is the actual compute resources available in the selected region or availability zone.

Even with sufficient quota, deployments can still fail if Azure doesn't have enough capacity for your requested VM size in the target region or zone. To improve deployment success, try a different VM size, zone, or region. For guaranteed capacity, see On-demand capacity reservation.

Check usage

CLI

You can check your quota usage using az vm list-usage.

Azure CLI

```
az vm list-usage --location "Central US" -o table
```

The output should look something like this:

```
Name                                 CurrentValue    Limit
-------------------------------  --------------  -------
Availability Sets                               0     2000
Total Regional vCPUs                           29      100
Virtual Machines                                7    10000
Virtual Machine Scale Sets                      0     2000
Standard DSv3 Family vCPUs                      8      100
Standard DSv2 Family vCPUs                      3      100
Standard Dv3 Family vCPUs                       2      100
Standard D Family vCPUs                         8      100
Standard Dv2 Family vCPUs                       8      100
Basic A Family vCPUs                            0      100
Standard A0-A7 Family vCPUs                     0      100
Standard A8-A11 Family vCPUs                    0      100
Standard DS Family vCPUs                        0      100
Standard G Family vCPUs                         0      100
Standard GS Family vCPUs                        0      100
Standard F Family vCPUs                         0      100
Standard FS Family vCPUs                        0      100
Standard Storage managed disks                  5    10000
Premium Storage managed disks                   5    10000
...
```

Reserved VM Instances

Reserved VM Instances, scoped to a single subscription without VM size flexibility, will add a new aspect to the vCPU quotas. These values describe the number of instances of the stated size that must be deployable in the subscription. They work as a placeholder in the quota system to ensure that quota is reserved to ensure Azure reservations are deployable in the subscription. For example, if a specific subscription has 10 Standard_D1 reservations the usages limit for Standard_D1 reservations will be 10. Azure will ensure that there are always at least 10 vCPUs available in the Total Regional vCPUs quota to be used for Standard_D1 instances and there are at least 10 vCPUs available in the Standard D Family vCPU quota to be used for Standard_D1 instances.

If a quota increase is required to either purchase a Single Subscription RI, you can request a quota increase on your subscription.

Constrained vCPU sizes for database workloads

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

> **Tip**
>
> Try the **Virtual Machine selector tool** to find other sizes that best fit your workload.

Some database workloads require high memory, storage, and I/O bandwidth, but don't benefit from a high number of cores. Products designed for these workloads are often licensed on a per-CPU-core basis. This licensing system means that a VM size with otherwise ideal specifications but an excessive vCPU count can cause a substantial increase in licensing costs. To help manage your costs, Azure offers predefined VM sizes with a lowered vCPU count to help to reduce the cost of software licensing, while maintaining the same memory, storage, and I/O bandwidth.

The original size's available vCPU count can be reduced to either one half or one quarter of the original size specification. These new VM sizes have a suffix that specifies the number of available vCPUs to make them easier for you to identify. Learn more about VM size naming conventions.

Example workload

The licensing fees charged for SQL Server are based on the available vCPU count. Third party products should count the available vCPUs and report it as the amount to be used and licensed. This constraint results in a 50% to 75% increase in the ratio of the VM specs to available (billable) vCPUs while maintaining the benefits of the original VM size's specifications.

Specification comparison

The Standard_E32s_v5 VM size comes with 32 vCPUs, 256 GiB of RAM, 32 disks, and 80,000 IOPs of I/O bandwidth. The pre-defined Standard_E32-16s_v5 and Standard_E32-8s_v5 VM sizes comes with 16 and 8 active vCPUs respectively, while maintaining the memory, storage, and I/O bandwidth specifications of the Standard_E32s_v5.

Expand table

Size type	Size name	Disabled vCPUs	Active vCPUs	Memory, Storage, I/O
Base (Original)	Standard_E32s_v5	0	**32**	256 GiB, 32 Disks, 80,000 IOPs
Constrained	Standard_E32-**16**s_v5	16	**16**	256 GiB, 32 Disks, 80,000 IOPs
Constrained	Standard_E32-**8**s_v5	24	**8**	256 GiB, 32 Disks, 80,000 IOPs

> **Note**
>
> Disabled vCPUs are not available for use by the VM. If your VM has multiple workloads assigned to it then it may require more vCPUs. If possible, relocate secondary tasks to another virtual machine to avoid increased licensing costs.

Pricing

At this time, the VM pricing, remains the same as the original size. For more information, see Azure VM sizes for more cost-effective database workloads.

List of available sizes with constrained vCPUs

M-family sizes

Expand table

Size name	Active vCPUs	Base size
Standard_M8-2ms	2	M8ms
Standard_M8-4ms	4	M8ms

VM vCore Customization Feature: Disable Simultaneous Multi-Threading (SMT/HT) and Configurable Constrained Cores (Preview)

VM vCore Customization is a new Azure VM feature that gives you greater control over the CPU resources of a virtual machine. It consists of two related capabilities:

Disable Simultaneous Multi-Threading (Threads Per Core = 1): Allows you to run a VM with only one thread per physical CPU core, effectively turning off Simultaneous Multithreading (SMT). Disabling gives your VM full use of each physical core, which can improve performance for certain workloads (like some HPC or latency-sensitive applications) that benefit from exclusive core access.

Configurable Constrained Cores (Customize vCPUs): Allows you to **choose a custom number of vCPUs** for a new VM, lower than the default count for that VM size. It lets you allocate only the CPU cores you need, for example, to reduce licensing costs for software that is licensed per core (such as databases or analytics servers) while still getting the full memory and I/O of a larger VM.

Benefits: With these features, you can optimize VMs for both performance and cost:

Performance: Disabling hyperthreading can provide more consistent and sometimes higher single-thread performance by eliminating contention between threads on the same core.

Cost Optimization: Reducing the vCPU count of a VM can lower costs for software that charges per CPU. You could run a memory-intensive SQL Server on a VM with fewer vCPUs active, cutting SQL licensing fees, without paying for unused CPU capacity.

There's *no extra charge* to use these CPU configuration options. The base VM price remains the same as if you deployed the full-size VM with default settings. However, customers get reduced licensing costs for software billed per vCPU.

VM Customization Settings Configuration

You can configure the "Threads per core" and "vCPUs available" settings using the Azure portal, Azure Resource Manager templates (ARM), or command-line tools.

Azure portal

In the Azure portal, the VM creation workflow has a UI for these options.

Start creating a VM as usual (for example, click **Create a resource** > **Virtual Machine** and fill out the Basics tab).

1. In the Size section of the Basics tab, select a VM size that you want to use. Under the size selection, click the "Customize cores" button. This opens more fields for VM Customization.

2. To disable SMT, set Threads per core to 1. (Leave it at 2 if you want to keep hyperthreading enabled.)

3. To the vCPU count, set vCPUs available to your desired number of vCPUs. The portal provides valid values for the chosen VM size.

4. Continue with the rest of the VM creation (set up disks, networking, etc.) and create the VM.

Once the VM is deployed, it has the specified number of vCPUs. If you set Threads per core to 1, the VM's OS sees half the usual number of processors (since hyperthreading is off). If you reduced vCPUs, it would see that lower count.

Azure CLI

To disable SMT and configure cores during instance launch:

To disable SMT/HT, use the Azure CLI command and specify a value of 1 for vCPUsPerCore for the--cpu-options parameter. To configure cores, specify the number of CPU cores for vCPUsAvailable. In this example, to specify the default CPU core count for a Standard_D8s_v6 instance, specify a value of 8.

azure

```
Az vm create --resource-group ccctest-rg-01 --name ccctestvm01 --image Ubuntu2204 --size Standard_D8s_v6 --location eastus2euap --admin-username azureuser --generate-ssh-keys --public-ip-address """ --v-cpus-available 4 --v-cpus-per-core 1
```

PowerShell

To disable SMT and configure cores during instance launch

Use PowerShell and specify the properties on the underlying configuration object. To disable SMT/HT, specify a value of 1 for vCPUsPerCore for the --cpu-options parameter. To configure cores, specify the number of CPU cores for vCPUsAvailable.

PowerShell

```
$vmConfig = New-AzVMConfig -VMName "MyVM" -VMSize "Standard_D8s_v6"

$vmConfig.HardwareProfile.VmSizeProperties = New-Object
Microsoft.Azure.Management.Compute.Models.VMSizeProperties

$vmConfig.HardwareProfile.VmSizeProperties.VCPUsAvailable = 4

$vmConfig.HardwareProfile.VmSizeProperties.VCPUsPerCore = 1
```

Then proceed to set OS, network, etc., and use New-AzVM to create the VM. This approach uses the Azure PowerShell SDK objects directly to inject the values.

ARM Template (Azure Resource Manager)

For automation or scenarios where you need to deploy via infrastructure-as-code, you can use Azure Resource Manager templates to specify these CPU options. This can be used to disable SMT and deploy customized VMs via CLI or PowerShell as well (by deploying a template).

In your ARM template's resource definition for the virtual machine, the CPU options are specified under the hardwareProfile property of the VM. Specifically, you use vmSizeProperties inside hardwareProfile to set the values:

vCPUsPerCore - Set this to 1 to disable hyperthreading (for example, 1 thread per core). Omit this property or set to null/2 to use the default hyperthreading (2 threads per core).

vCPUsAvailable - Set this to the number of vCPUs you want active. If this property isn't set, the VM uses the default number of vCPUs for that size.

Here are brief examples of ARM template snippets for different scenarios:

Disable SMT (SMT/HT Off)

This snippet shows the setting to turn off SMT on a VM (the VM uses 1 thread per core)

JSON

```
"properties": {

"hardwareProfile": {

"vmSize": " Standard_D8s_v6",

"vmSizeProperties": {
```

```
"vCPUsPerCore": 1

}

},

...

}
```

In this case, if Standard_D8s_v6 normally has 8 vCPUs (4 cores * 2 threads), setting vCPUsPerCore: 1 means the VM has 4 vCPUs (one per core).

Constrain vCPU Count (Customize Cores)

This snippet shows a VM configured to use a specific number of vCPUs (fewer than the default)

JSON

```
"properties": {

"hardwareProfile": {

"vmSize": " Standard_D8s_v6",

"vmSizeProperties": {

"vCPUsAvailable": 2

}

},

...

}
```

Here, we requested two cores. On Standard_D8s_v6 (which is hyperthreaded by default), 2 *physical* cores are allocated, and since SMT is still on by default (2 threads per core), the VM has 4 logical vCPUs.

Disable SMT and Customize vCPUs

You can combine both settings as shown:

JSON

```
"properties": {

"hardwareProfile": {

"vmSize": " Standard_D8s_v6",

"vmSizeProperties": {

"vCPUsPerCore": 1,

"vCPUsAvailable": 2

}

},

...

}
```

In this example, vCPUsPerCore: 1 disables SMT, and vCPUsAvailable: 2 then requests 2 vCPUs. With SMT off, those 2 correspond one-to-one with two physical cores (no threading). The VM has two logical processors in the OS.

Make sure to use an API version **2021-07-01 or later** for the Microsoft.Compute/virtualMachines resource in your template, as that's when these properties were introduced.

Identify Supported vCores for Configuration

To determine which vCPUs can be constrained in a specific region, you can use the Azure CLI or the Azure portal.

Using Azure CLI

Run the following command to retrieve the list of compute SKUs for your subscription and region:

Azure

```
az vm list-skus --location {location} --resource-type virtualMachines --query "
[name=='VM_NAME_HERE']
```

- This command exports shows the supported vCPU configurations. The "vCPUsConstraintsAllowed" field outlines supported vCores.

Using Azure Portal

If you request a vCPU configuration that isn't supported, the portal will display an error message and provide a list of supported vCPU options for that VM size.

Considerations

Most Azure VM families support these features, but there are some important rules and considerations to understand when using the feature:

- You can only disable hyperthreading on VM sizes that use hyperthreading by default (for example, VMs with 2 threads per core).
- You can only *reduce* the number of vCPUs, not increase it beyond the VM's default. The vCPUsAvailable value specified must be less than or equal to the default vCPU count of the chosen VM size.
- On VM sizes that are hyperthreaded (default 2 threads/core), any custom vCPU count must be an even number.
- You can disable hyperthreading and constrain vCPUs at the same time on the same VM. In this case, both above rules apply.
- CPU options can only be specified at VM creation time or during a resize operation. You cannot dynamically adjust the core count or SMT setting on an allocated VM, this update requires the VM to be deallocated.
- If you move to a new VM size in the same family that also supports the feature, your settings are carried over by default.
- If you resize to a VM size that doesn't support the setting, the operation is blocked or error.
- Anytime you resize a VM (either within the same series or to a different series), a VM reboot occurs. Plan for downtime during the resize operation.
- In preview, only first-party Azure Marketplace images (Windows Server, Ubuntu, Red Hat, SUSE, etc.) and custom images are supported. The specialized Marketplace offerings such as SQL Server on Virtual Machines are not supported.

Azure VM sizes with no local temporary disk

> **Tip**
>
> Try the Virtual Machine selector tool to find other sizes that best fit your workload.

This article provides answers to frequently asked questions (FAQ) about Azure VM sizes that don't have a local temporary disk (that is, no local temp disk).

What does no local temp disk mean?

Traditionally, we have had VM sizes (for example, Standard_D2s_v3, Standard_E48_v3) that include a small local disk (that is, a D: Drive). With the VM series such as Dasv5 and Easv5 that small local disk no longer exists. However, you can still attach Standard HDD, Premium SSD or Ultra Disk to use as remote storage.

What if I still want a local temp disk?

If your workload requires a local temporary disk, we still offer sizes such as the Dadsv5.

> **Note**
>
> Local temporary disk isn't persistent; to ensure your data is persistent, please use Standard HDD, Premium SSD or Ultra Disk options.

Can I resize a VM size that has a local temp disk to a VM size with no local temp disk?

Resize between disk and diskless sizes is supported for Linux VMs. For Windows, the only combinations allowed for resizing are:

1. VM (with local temp disk) -> VM (with local temp disk); and
2. VM (with no local temp disk) -> VM (with no local temp disk).

If interested in a work around for Windows, please see next question.

> **Note**

If an image depends on the resource disk, or a pagefile or swapfile exists on the local temp disk, the diskless images won't work—instead, use the 'with disk' alternative.

How do I migrate my Windows VM from a size with local temp disk to a VM size with no local temp disk?

You can migrate by following these steps:

1. Connect to your Virtual Machine that has a local temporary disk (for example, a D: Drive) as a local admin.

2. Follow the guidelines on the "Temporarily move pagefile.sys to C drive" section of Use the D: drive as a data drive on a Windows VM to move the page file from the local temporary disk (D: drive) to the C: drive.

   > ⓘ **Note**
   >
   > Follow the guidelines on the "Temporarily move pagefile.sys to C drive" section of Use the D: drive as a data drive on a Windows VM to move page file from the local temporary disk (D: drive) to C: drive. **Deviation from the steps outlined will lead to the error message - "Unable to resize the VM since changing from resource disk to non-resource disk VM size and vice-versa is not allowed.**

3. Take a snapshot of the VM by following the steps outlined in Create a snapshot using the portal or Azure CLI.

4. Use snapshot to create a new diskless VM (such as, Dv5, Dsv5, Dasv5, Ev5, Esv5, Easv5 series) by following the steps outlined in Create a virtual machine from a snapshot with CLI.

Are VM sizes with no local temp disk supported by both Linux and Windows Operating Systems (OS)?

Yes.

Will this break my custom scripts, custom images or OS images that have scratch files or page files on a local temp disk?

If the custom OS image points to the local temp disk, the image might not work correctly with this diskless size.

Next steps

In this document, you learned more about the most frequent questions related to Azure VMs with no local temp disk. For more information about these VM sizes, see the following articles:

- Specifications for Dv5 and Dsv5-series
- Specifications for Dasv5 and Dadsv5-series
- Specifications for Ev5 and Esv5-series
- Specifications for Easv5 and Eadsv5-series

Store and share resources in Azure Compute Gallery

08/06/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure Compute Gallery helps you build structure and organization around your Azure resources, like images and applications. Compute Gallery provides:

- Global replication.[1]
- Versioning and grouping of resources for easier management.
- Highly available resources with zone-redundant storage (ZRS) accounts, in regions that support availability zones. ZRS offers resilience against zonal failures.
- Premium storage support with locally redundant storage (LRS).
- Sharing to the community, across subscriptions, and between Active Directory tenants.
- Scaling your deployments with resource replicas in each region.

With a gallery, you can share your resources with everyone. Or you can limit sharing to particular users, service principals, or Active Directory groups within your organization. You can replicate resources to multiple regions, for quicker scaling of your deployments.

[1] The Azure Compute Gallery service isn't a global resource. For disaster recovery scenarios, the best practice is to have at least two galleries in separate regions.

Images

For more information about storing images in Azure Compute Gallery, see Store and share images in Azure Compute Gallery.

VM apps

Although you can create an image of a virtual machine (VM) with apps preinstalled, you would need to update your image each time an application changes. Separating your application installation from your VM images means there's no need to publish a new image for every line of code change.

For more information about storing applications in Azure Compute Gallery, see VM applications.

Regional support

All public regions can be target regions, but certain regions require that customers go through a request process to gain access. To request the addition of a subscription to the allowlist for a region such as Australia Central or Australia Central 2, submit an access request.

Limits

The following limits apply when you deploy resources by using Azure Compute Gallery:

- You can have a maximum of 100 galleries per subscription, per region.
- You can have a maximum of 1,000 image definitions per subscription, per region.
- You can have a maximum of 10,000 image versions per subscription, per region.
- You can have a maximum 100 replicas per image version. However, 50 replicas should be sufficient for most use cases.
- The image size should be less than 2 TB, but you can use shallow replication to support larger image sizes (up to 32 TB).
- Resource movement isn't supported for Azure Compute Gallery resources.

For more information and for examples of how to check your current usage, see Check resource usage against limits.

Scaling

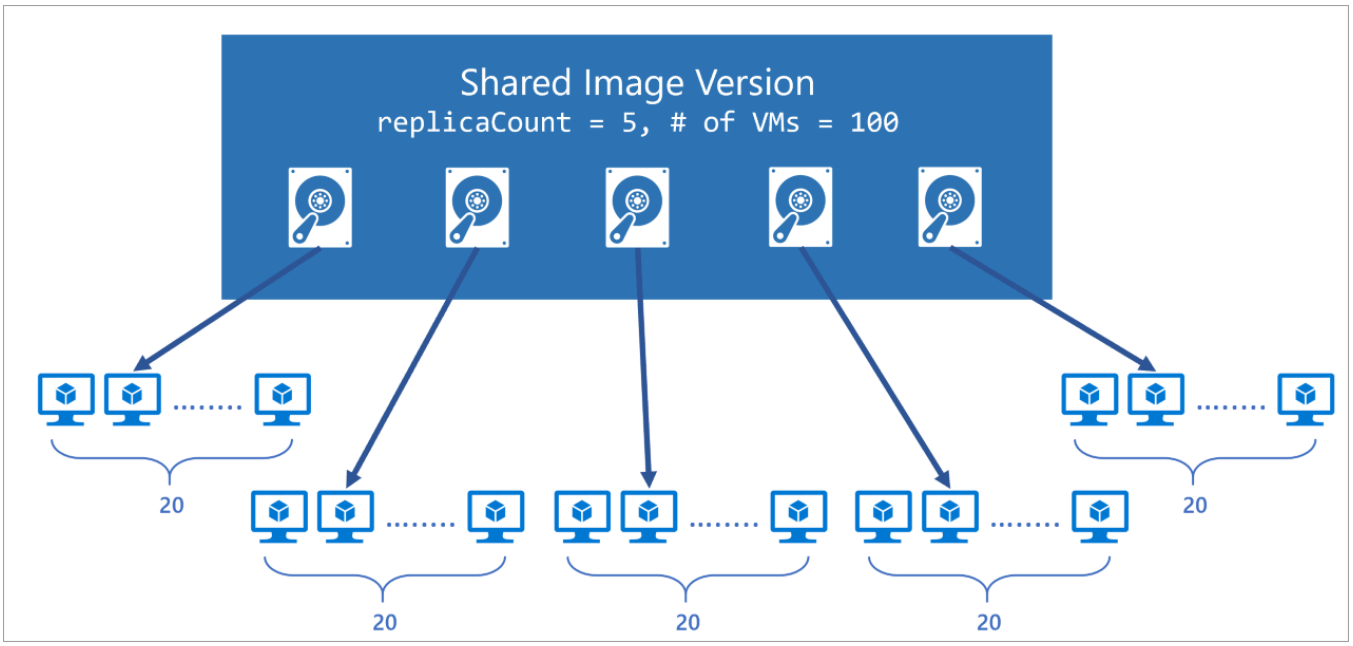
Azure Compute Gallery allows you to specify the number of replicas that you want to keep. In multiple-VM deployment scenarios, you can spread the VM deployments to other replicas. This action reduces the chance that overloading of a single replica throttles the process of instance creation.

With Compute Gallery, you can deploy up to 1,000 VM instances in a scale set. You can set a different replica count in each target region, based on the scale needs for the region. Because each replica is a copy of your resource, this approach helps scale your deployments linearly with each extra replica.

Although we understand that no two resources or regions are the same, here are general guidelines on how to use replicas in a region:

- For every 50 VMs that you create concurrently, we recommend that you keep one replica. For example, if you're creating 500 VMs concurrently by using the same image in a region, we suggest you keep at least 10 replicas of your image.
- For each scale set that you create concurrently, we recommend that you keep one replica.

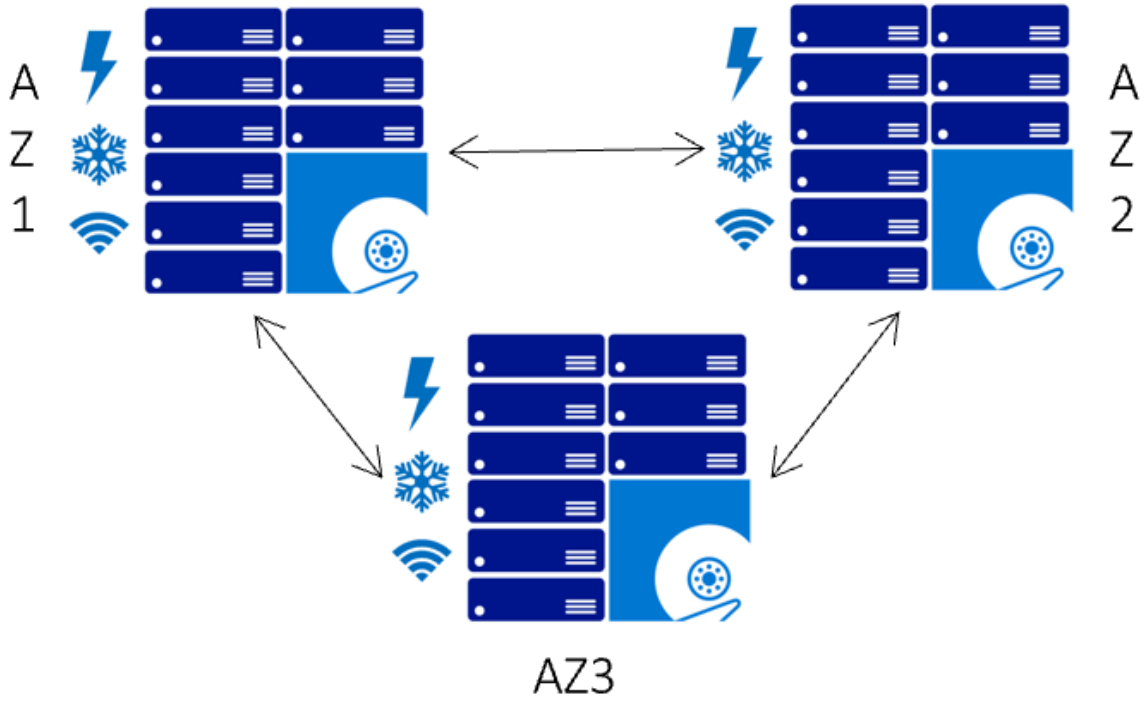
We always recommend that you overprovision the number of replicas due to factors like resource size, content, and OS type.



High availability

Azure ZRS provides resilience against the failure of an availability zone in a region. With the general availability of Azure Compute Gallery, you can choose to store your images in ZRS accounts in regions that have availability zones.

You can also choose the account type for each target region. The default storage account type is Standard LRS, but you can choose Standard ZRS for regions that have availability zones. For more information on the regional availability of ZRS, see Azure Storage redundancy.

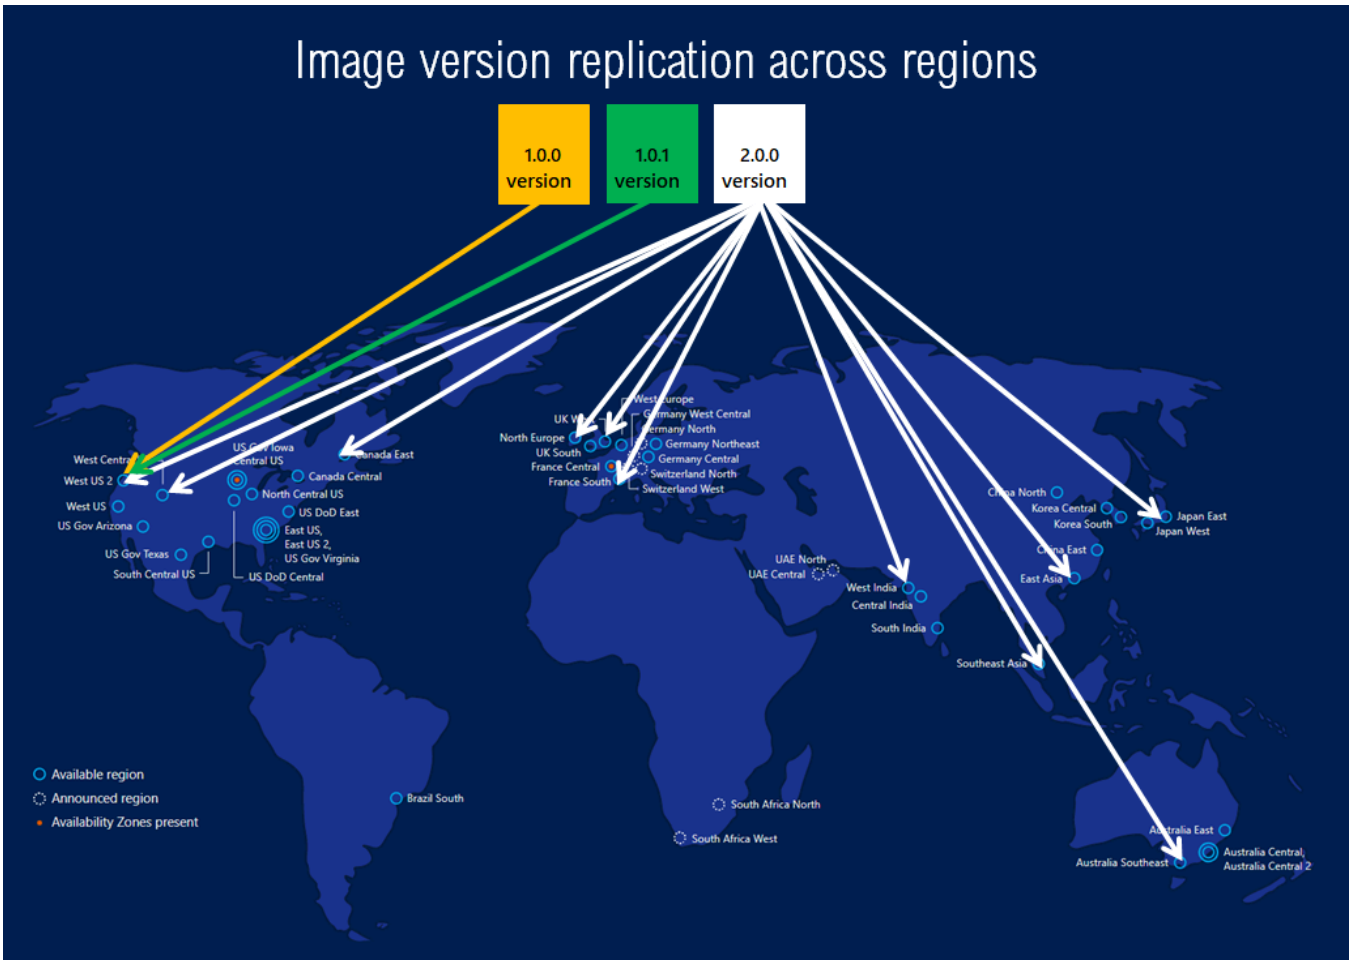


Replication

Azure Compute Gallery also allows you to replicate your resources to other Azure regions automatically. You can replicate each image version to different regions, depending on what makes sense for your organization. One example is to always replicate the latest image in multiple regions while all older image versions are available in only one region. This approach can help you save storage costs.

After creation time, you can update the regions that a resource is replicated to. The time that replication to other regions takes depends on the amount of data that you're copying and the number of regions that the version is replicated to. This process can take a few hours in some cases.

While the replication is happening, you can view its status per region. After the image replication is complete in a region, you can deploy a VM or scale set by using that resource in the region.



Trusted Launch validation for Azure Compute Gallery images (preview)

Trusted Launch validation for Azure Compute Gallery images is currently in preview. This preview is intended for testing, evaluation, and feedback purposes only. We don't recommend it for production workloads.

When you register for the preview, you agree to the supplemental terms of use. Some aspects of this feature might change with general availability.

What's changing

Starting with API 2025-03-03, all new Compute Gallery image definitions default to:

- `hyperVGeneration`: `V2`
- `SecurityType`: `TrustedLaunchSupported`

How Trusted Launch validation works

When you specify `TrustedLaunchSupported` or `TrustedLaunchandConfidentialVMSupported` in the Compute Gallery image definition, the platform automatically validates that the image is Trusted Launch capable. The platform adds the validation result to the image version property. This action ensures that the VM and scale set deployments that use these images can default to Trusted Launch if the validation is successful.

How to enable the preview

To try out Trusted Launch validation for Compute Gallery images, complete the following steps:

1. Register for Trusted Launch as a default feature.
2. Register for the Trusted Launch Validation preview.

After you enable the two features, all new VM and scale set deployments that use Compute Gallery image versions and that are validated successfully for Trusted Launch default to the Trusted Launch security type.

VM deployments from Azure Compute Gallery images

The following sections compare the current and new behaviors of VM deployments from Compute Gallery images, depending on Trusted Launch validation.

Current behavior without Trusted Launch validation

To create a Trusted Launch-supported, Gen2 OS image definition for Compute Gallery, you need to add the following `features` element in your deployment:

JSON

```
"features": [
    {
      "name": "SecurityType",
      "value": "TrustedLaunchSupported"
    }
],
"hyperVGeneration": "V2"
```

New behavior with Trusted Launch validation

`TrustedLaunchSupported` is enabled by default on new Compute Gallery image definitions if the deployment meets any of the following criteria:

- The use of API version 2025-03-03 or later for the `Microsoft.Compute/galleries` resource
- The absence of the `SecurityType` feature
- A `null` value for the `SecurityType` feature

Additionally, the Azure platform triggers validation for the OS image to ensure that it supports Trusted launch capabilities. The validation takes a minimum of one hour. Results are available as the image version property:

JSON

```
"validationsProfile": {
  "executedValidations": [
      {
        "type": "TrustedLaunch",
        "status": "Succeeded",
        "version": "0.0.2",
        "executionTime": "2025-07-10T21:27:33.0113984+00:00"
      }
    ],
}
```

You can choose to explicitly bypass the default for new Compute Gallery image definitions by setting `Standard` as the value for `SecurityType` under `features`:

JSON

```
"features": [
    {
```

```
        "name": "SecurityType",
        "value": "Standard"
      }
  ],
  "hyperVGeneration": "V2"
```

Sharing

There are three main ways to share images in Azure Compute Gallery, depending on which users you want to share with:

Expand table

Sharing with:	People	Groups	Service principal	All users in a specific subscription or tenant	Publicly with all users in Azure
Role-based access control (RBAC) sharing	Yes	Yes	Yes	No	No
RBAC + direct shared gallery	Yes	Yes	Yes	Yes	No
RBAC + community gallery	Yes	Yes	Yes	No	Yes

> **Note**
>
> You can use images with read permissions on them to deploy virtual machines and disks.
>
> When you use a direct shared gallery, images are distributed widely to all users in a subscription or tenant. A community gallery distributes images publicly. When you share images that contain intellectual property, use caution to prevent widespread distribution.

RBAC

Because the gallery, definition, and version are all resources, you can share them by using the built-in Azure RBAC roles. By using Azure RBAC roles, you can share these resources with other users, service principals, and groups. You can even share access with individuals outside the tenant where you created the resources.

After users have access to the resource version, they can use it to deploy a VM or a virtual machine scale set. Here's a sharing matrix that can help you understand what the users get access to:

Expand table

Shared with users	Compute gallery	Image definition	Image version
Compute gallery	Yes	Yes	Yes
Image definition	No	Yes	Yes

We recommend sharing at the gallery level for the best experience. We don't recommend sharing individual image versions. For more information about Azure RBAC, see Assign Azure roles and Share by using RBAC.

Directly sharing with a tenant or subscription

You can give specific subscriptions or tenants access to a direct shared gallery. Sharing a gallery with tenants and subscriptions gives them read-only access to your gallery. For more information, see Share a gallery with all users in a subscription or tenant.

Important considerations

- The feature of direct shared galleries is currently in preview and is subject to the preview terms for Azure Compute Gallery.
- To publish images to a direct shared gallery during the preview, you need to register for the preview. Creating VMs from a direct shared gallery is open to all Azure users.
- During the preview, you need to create a new gallery with the `sharingProfile.permissions` property set to `Groups`. When you use the Azure CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, and the property can't currently be updated.
- You can't currently create a flexible virtual machine scale set from an image that another tenant shares with you.

Limitations

During the preview:

- You can share only with subscriptions that are also in the preview.
- You can share up to 30 subscriptions and 5 tenants.
- A direct shared gallery can't contain encrypted image versions.

- Only the owner of a subscription, or a user or service principal assigned to the Compute Gallery Sharing Admin role at the subscription or gallery level, can enable group-based sharing.

Community gallery

To share a gallery with all Azure users, you can create a community gallery. Anyone who has an Azure subscription can use community galleries. Someone who creates a VM can browse through images shared with the community by using the Azure portal, the REST API, or the Azure CLI. Sharing images to the community is a new capability in Compute Gallery.

You can make your image galleries public and share them with Azure customers. When a gallery is marked as a community gallery, all images in it become available to all Azure customers as a new resource type under `Microsoft.Compute/communityGalleries`. Azure customers can see the galleries and use them to create VMs. Your original resources of the type `Microsoft.Compute/galleries` are still under your subscription and private.

For more information, see Share images by using a community gallery.

Activity log

The activity log displays recent activity on the gallery, image, or version. This information includes any configuration changes and when the item was created and deleted.

You can view the activity log in the Azure portal or create a diagnostic setting to send the log to a Log Analytics workspace. In the workspace, you can view events over time or analyze them with other collected data.

The following table lists a few example operations that relate to gallery operations in the activity log. For a complete list of possible log entries, see the Microsoft.Compute Resource Provider options.

Expand table

Operation	Description
`Microsoft.Compute/galleries/write`	Creates a new gallery or updates an existing one
`Microsoft.Compute/galleries/delete`	Deletes the gallery
`Microsoft.Compute/galleries/share/action`	Shares a gallery with different scopes
`Microsoft.Compute/galleries/images/read`	Gets the properties of a gallery image

Operation	Description
`Microsoft.Compute/galleries/images/write`	Creates a new gallery image or updates an existing one
`Microsoft.Compute/galleries/images/versions/read`	Gets the properties of a gallery image version

Billing

There's no extra charge for using the Azure Compute Gallery service. However, you're charged for the following resources:

- Storage costs for each replica. For images, the storage cost is charged as a snapshot. It's based on the occupied size of the image version, the number of replicas of the image version, and the number of regions that the version is replicated to.
- Network egress charges for replication of the first resource version from the source region to the replicated regions. Subsequent replicas are handled within the region, so there are no additional charges.

For example, let's say:

- You have an image of a 127-GB OS disk that occupies only 10 GB of storage, and you have one empty 32-GB data disk. The occupied size of each image would be only 10 GB.
- The image is replicated to three regions, and each region has two replicas. There are six total snapshots, each using 10 GB.

In this example, you're charged for the storage cost of each snapshot, based on the occupied size of 10 GB. You pay network egress charges for the first replica to be copied to the additional two regions.

For more information on the pricing of snapshots in each region, see Managed disks pricing. For more information on network egress, see Bandwidth pricing.

Best practices

- To prevent accidental deletion of images, use resource locks at the gallery level. For more information, see Lock your Azure resources to protect your infrastructure.
- Use ZRS wherever it's available, for high availability. You can configure ZRS on the replication tab when you create a version of the image or VM application. For information about which regions support ZRS, see Azure regions list.

- Keep a minimum of three replicas for production images. For every 20 VMs that you create concurrently, we recommend that you keep one replica.

  For example, if you create 1,000 VMs concurrently, you should keep 50 replicas. (You can have a maximum of 50 replicas per region.) To update the replica count, go to the gallery and select **Image Definition** > **Image Version** > **Update replication**.

- Maintain separate galleries for production and test images. Don't put both image types in a single gallery.

- For disaster recovery scenarios, have at least two galleries in separate regions. You can still use image versions in other regions, but if the region for one gallery goes down, you can't create new gallery resources or update existing ones.

- When you create an image definition, keep the **Publisher**, **Offer**, and **SKU** values consistent with Azure Marketplace images to easily identify OS versions.

  For example, if you're customizing a Windows Server 2019 image from Azure Marketplace and you store it as a Compute Gallery image, use the same **Publisher**, **Offer**, and **SKU** values that you used in the Azure Marketplace image.

- If you want to exclude a specific image version during creation of a VM or scale set, use `excludeFromLatest` when you publish images. See Gallery image versions - create or update.

- If you want to exclude a version in a specific region, use `regionalExcludeFromLatest` instead of the global `excludeFromLatest`. You can set both the global and regional `excludeFromLatest` flag, but the regional flag takes precedence.

```
"publishingProfile": {
  "targetRegions": [
    {
      "name": "brazilsouth",
      "regionalReplicaCount": 1,
      "regionalExcludeFromLatest": false,
      "storageAccountType": "Standard_LRS"
    },
    {
      "name": "canadacentral",
      "regionalReplicaCount": 1,
      "regionalExcludeFromLatest": true,
      "storageAccountType": "Standard_LRS"
    }
  ],
  "replicaCount": 1,
  "excludeFromLatest": true,
```

```
    "storageAccountType": "Standard_LRS"
  }
```

- To prevent accidental deletion of replicated regions and prevent outages, set `safetyProfile.allowDeletionOfReplicatedLocations` to `false` on image versions. You can also set this property by using allow-replicated-location-deletion in the Azure CLI.

```
{
"properties": {
  "publishingProfile": {
    "targetRegions": [
      {
        "name": "West US",
        "regionalReplicaCount": 1,
        "storageAccountType": "Standard_LRS",
        // encryption info
      }
    ],
     "replicaCount": 1,
     "publishedDate": "2018-01-01T00:00:00Z",
     "storageAccountType": "Standard_LRS"
  },
  "storageProfile": {
     "source": {
       "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroup}/providers/Mic
rosoft.Compute/images/{imageName}"
    },
  },
  "safetyProfile": {
     "allowDeletionOfReplicatedLocations" : false
   },
},
"location": "West US",
"name": "1.0.0"
}
```

- To block deletion of the image before its end-of-support date, set `BlockDeletionBeforeEndOfLife`. This feature helps protect against accidental deletion. You set it by using blockdeletionbeforeendoflife in the REST API.

SDK support

The following SDKs support creating galleries:

- .NET

- Java
- Node.js
- Python
- Go

Templates

You can create Azure Compute Gallery resources by using quickstart templates:

- Create a gallery
- Create an image definition in a gallery
- Create an image version in a gallery

What's new for Azure Compute Gallery

08/06/2025

This article lists updates to Azure Compute Gallery features.

July 2025 updates

- Starting with API version 2025-03-03, new Compute Gallery image definitions default to `hyperVGeneration` set to `V2` and `SecurityType` set to `TrustedLaunchSupported`.
- Trusted Launch validation for Azure Compute Gallery images is in preview.
- The ExcludefromLatest property excludes the use of an image version for creating resources to test images and safely rolling out the image to production. You can also set this property at the region level to exclude specific regions.
- The allowDeletionOfReplicatedLocations property indicates whether or not removing the gallery image version from replicated regions is allowed and prevents accidental deletion of regions.
- The BlockDeletionBeforeEndOfLife property enables customers to prevent deletion of images before the end-of-support date. You can opt out by explicitly setting `BlockDeletionBeforeEndOfLife` to `False`.
- Platform metadata, such as publisher, offer, or product information from a virtual machine (VM) created from an Azure Marketplace image, is carried over to the Compute Gallery image.

January 2023 updates

- Direct shared gallery is in preview.
- Best practices information is available.
- Replica count for image versions increased from 50 to 100.

Supported features

- ARM64 images
- Trusted Launch
- Confidential VMs
- Accelerated networking
- Replication mode: full and shallow
  - Image size for shallow replication support is up to 32 TB.
  - Shallow replication is only for test images.

Create a gallery for storing and sharing resources

08/06/2025

Azure Compute Gallery (formerly known as Shared Image Gallery) simplifies sharing resources, like images and application packages, across your organization.

Compute Gallery lets you share custom virtual machine (VM) images and application packages with others in your organization, within or across regions, or within a tenant. Choose what resources you want to share, the regions where you want to make them available, and the users you want to share them with. You can create multiple galleries so that you can logically group resources.

The gallery is a top-level resource that can be shared in multiple ways:

Expand table

Sharing with:	People	Groups	Service principal	All users in a specific subscription or tenant	Publicly with all users in Azure
Role-based access control (RBAC) sharing	Yes	Yes	Yes	No	No
RBAC + direct shared gallery	Yes	Yes	Yes	Yes	No
RBAC + community gallery	Yes	Yes	Yes	No	Yes

Requirements for gallery names

Allowed characters for a gallery name are uppercase letters (A-Z), lowercase letters (a-z), digits (0-9), dots (.), and underscores (_). The gallery name can't contain dashes (-). Gallery names must be unique within your subscription.

Create a private gallery

Portal

1. Sign in to the Azure portal.

2. Enter **Azure Compute Gallery** in the search box, and select **Azure Compute Gallery** in the results.
3. On the **Azure Compute Gallery** page, select **Add**.
4. On the **Create Azure compute gallery** pane, select the correct subscription.
5. For **Resource group**, select a resource group from the dropdown list. Or, select **Create new** and enter a name for the new resource group.
6. For **Name**, enter a name for the gallery.
7. For **Region**, select a region from the dropdown list.
8. You can enter a short description of the gallery, like **My gallery for testing**. Then select **Review + create**.
9. After validation passes, select **Create**.
10. When the deployment finishes, select **Go to resource**.

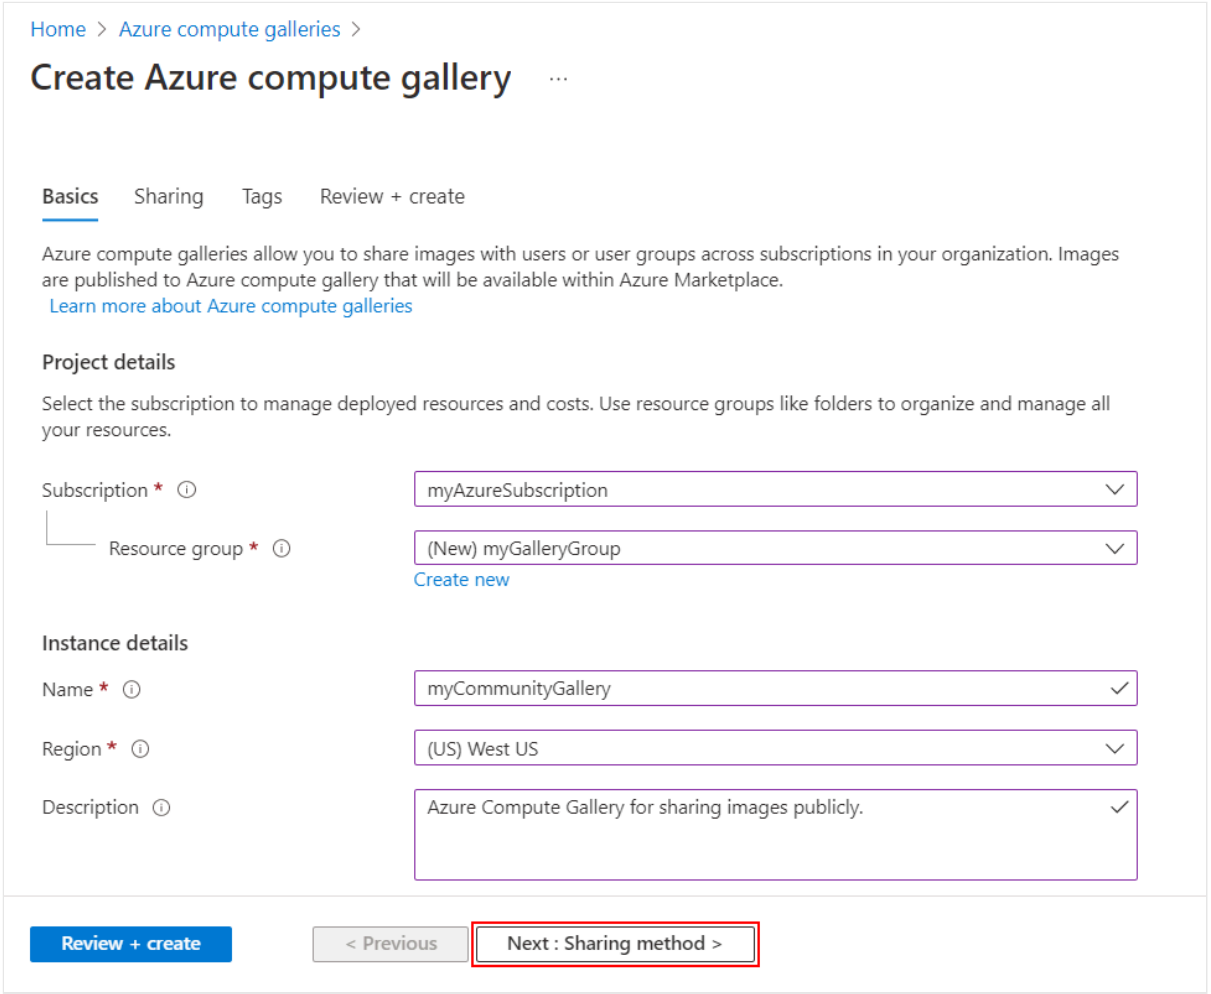
Create a direct shared gallery

> **Important**
>
> The *direct shared gallery* feature is currently in preview and is subject to the preview terms for Azure Compute Gallery.
>
> During the preview, you need to create a new gallery with the `sharingProfile.permissions` property set to `Groups`. When you use the Azure CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, and the property can't currently be updated.
>
> You can't currently create a flexible virtual machine scale set from an image that another tenant shared with you.

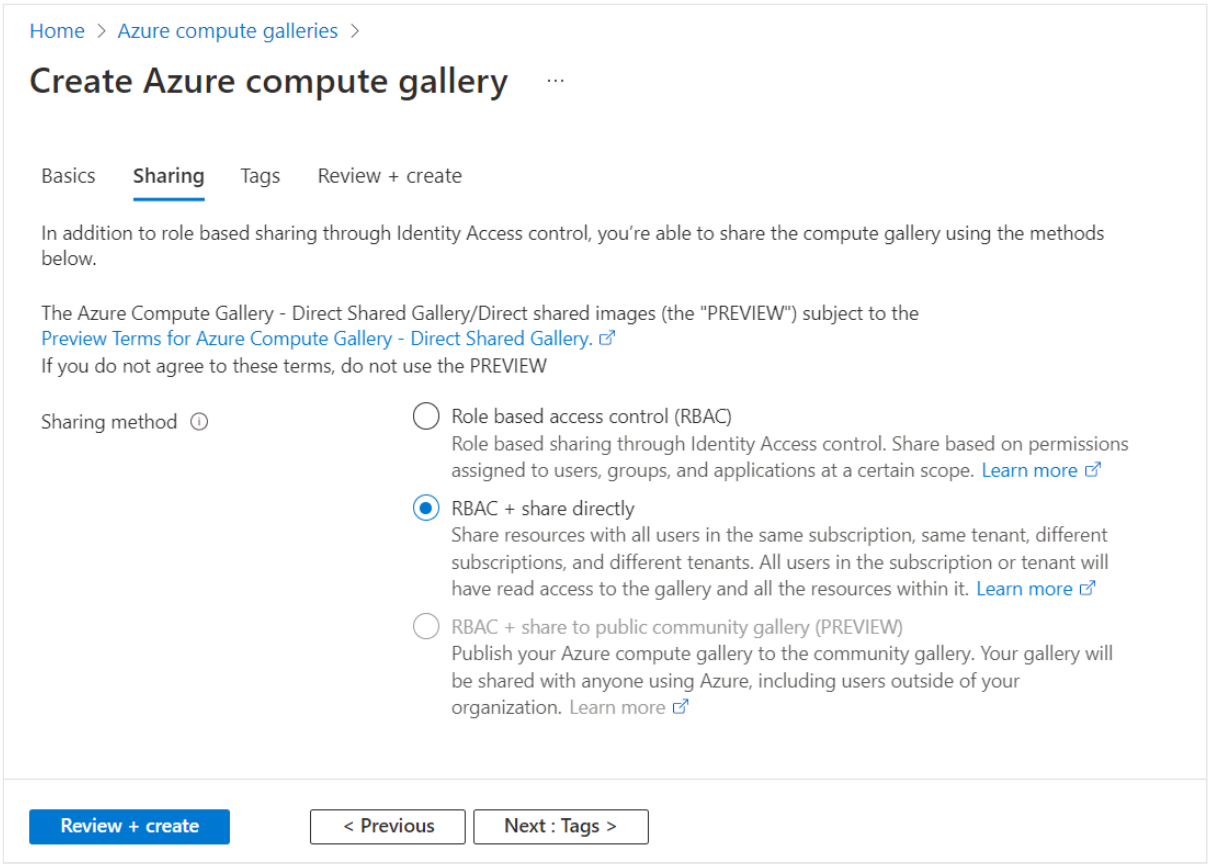
To start sharing a direct shared gallery with a subscription or tenant, see Share a gallery with a subscription or tenant.

Portal

1. Sign in to the Azure portal.
2. Enter **Azure Compute Gallery** in the search box, and select **Azure Compute Gallery** in the results.
3. On the **Azure Compute Gallery** page, select **Add**.
4. On the **Create Azure compute gallery** pane, on the **Basics** tab, select the correct subscription.
5. Complete all of the details on the **Basics** tab.
6. At the bottom of the pane, select **Next: Sharing method**.



7. On the **Sharing** tab, select **RBAC + share directly**.



8. When you finish, select **Review + create**.
9. After validation passes, select **Create**.
10. When the deployment finishes, select **Go to resource**.

To start sharing the gallery with a subscription or tenant, see Share a gallery with a subscription or tenant.

Create a community gallery

A community gallery is shared publicly with everyone. To create a community gallery, you create the gallery first and then enable it for sharing. The name of public instance of your gallery is the prefix that you provide, plus a GUID. To share your gallery publicly, be sure to create your gallery, image definitions, and image versions in the same region.

When you create an image to share with the community, you need to provide contact information. This information is *publicly available*, so be careful when you provide:

- Community gallery prefix
- Publisher support email
- Publisher URL
- Legal agreement URL

Information from your image definitions is also publicly available, like what you provide for **Publisher**, **Offer**, and **SKU**.

Only the following people can enable a gallery to go public to the community:

- The owner of a subscription
- A user or a service principal assigned to the Compute Gallery Sharing Admin role at the subscription or gallery level

To assign a role to a user, group, service principal, or managed identity, see Steps to assign an Azure role.

CLI

Use the `--public-name-prefix` value to create a name for the public version of your gallery. The `--public-name-prefix` value is the first part of the public name. The last part is a GUID, created by the platform, that's unique to your gallery.

Azure CLI

```
location=westus
galleryName=contosoGallery
resourceGroup=myCGRG
publisherUri=https://www.contoso.com
publisherEmail=support@contoso.com
eulaLink=https://www.contoso.com/eula
prefix=ContosoImages

az group create --name $resourceGroup --location $location

az sig create \
   --gallery-name $galleryName \
   --permissions community \
   --resource-group $resourceGroup \
   --publisher-uri $publisherUri \
   --publisher-email $publisherEmail \
   --eula $eulaLink \
   --public-name-prefix $prefix
```

The output of this command gives you the public name for your community gallery in the `sharingProfile` section, under `publicNames`.

To start sharing the gallery to all Azure users, see Share images by using a community gallery.

- Create an image definition and an image version.
- Create a VM from a generalized or specialized image in a gallery.
- Create a VM application in your gallery.

Soft Delete in Azure Compute Gallery (Preview)

09/30/2025

> **Important**
>
> The Soft Delete feature is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

The Soft Delete feature in Azure Compute Gallery (ACG) lets you recover accidentally deleted resources within a 7 day retention period. After this timeframe, the platform permanently deletes the resources. Currently, this feature is only available for ACG images.

Soft Delete is available for the following gallery types:

- Private
- Direct Shared Gallery
- Community Gallery

When a resource, such as an image, is deleted using Soft Delete, it isn't immediately removed from the system. Instead, it enters a *soft-deleted* state, during which it remains recoverable for up to seven days. This grace period gives you time to review and restore any resources that were mistakenly deleted, preventing permanent loss.

After the retention window expires, the deleted items are automatically purged and can't be recovered. Soft Delete is useful in environments where accidental deletions can disrupt workflows or cause data loss.

Prerequisites

- Register the Azure Compute Gallery Soft Delete feature in the Azure portal.
- Alternatively, register Azure Compute Gallery Soft Delete feature by running the following `az feature register` command from CLI:

```
az feature register --name SIGSoftDelete --namespace Microsoft.Compute
```

- The minimum API version required to use Soft Delete is `2024-03-03`.

Limitations

- Soft Delete is only supported in the Azure portal or Rest API with some limitations.
- You can't currently update the retention policy.
- Virtual Machine Apps Recovery isn't supported.
- Deleting a gallery or image definition with Soft Deleted resources isn't supported.
- Only the following users are allowed to enable Soft Delete: the owner of a subscription, user or service principal assigned to the Compute Gallery Sharing Admin role at the subscription or gallery level
- Not supported in National Clouds.
- You can't enable Soft Delete if the gallery or image definition and image version are in different locations.
- Virtual Machine Scale Sets in Flexible orchestration aren't compatible with the Soft Delete feature.
- When an image in a gallery with Soft Delete enabled has a failed provisioning state, it can't be deleted. The recommended workaround is to temporarily disable Soft Delete on the gallery, delete the image, and then re-enable Soft Delete.

Billing

Soft Delete is provided at no cost. After an image is soft deleted, only one replica per region is retained. You are charged for that single replica until the image is permanently deleted.

Enable Soft Delete on a gallery

You can enable Soft Delete on a new or existing gallery.

REST

To enable Soft Delete on an existing gallery, send the following `PUT` request. As part of the request, include and set the `Softdeletepolicy` and `isSoftDeleteEnabled` values to `true`.

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{rg
Name}/providers/Microsoft.Compute/galleries/{gallery-name}?api-version=2024-
03-03
{
"properties": {
"softDeletePolicy": {
"isSoftDeleteEnabled": true
}
```

```
},
"location": "{location}
}
```

Soft delete an image

Once Soft Delete is enabled on a gallery, all images in the gallery are soft deleted.

REST

To soft delete an image, send the following `DELETE` request on the resource you intend to delete.

rest

```
DELETE
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{rg
Name}/providers/Microsoft.Compute/galleries/{gallery-name}/images/{image-
defination-name}/versions/{version-name}?api-version=2024-03-03
```

List all soft deleted images

View a list of soft deleted images in a gallery or image definition.

REST

Send the following `GET` request on the resource of the image definition to list all the soft deleted images.

rest

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{rg
Name}/providers/Microsoft.Compute/galleries/{gallery-
name}/softDeletedArtifactTypes/Images/artifacts/{image-defination-
name}/versions?api-version=2024-03-03
```

Recover a soft deleted image

In this example, we demonstrate how to recover a soft deleted image.

REST

To recover soft deleted images in a gallery, send the following `PUT` request on the image version to be recovered along with the home region of the image.

rest

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{rg
Name}/providers/Microsoft.Compute/galleries/{gallery-name}/images/{image-
defination-name}/versions/{version-name}?api-version=2024-03-03
{
    "location": "eastus2euap"
}
```

Hard Delete an image

Hard Delete permanently deletes the image without the possibility of a recovery.

REST

To hard delete an image in a gallery, send the following `DELETE` request on the image version.

rest

```
DELETE
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{rg
Name}/providers/Microsoft.Compute/galleries/{gallery-
name}/softDeletedArtifactTypes/Images/artifacts/{image-defination-
name}/versions/{version-name}?api-version=2024-03-03
```

Frequently Asked Questions

Does Soft Delete become effective immediately upon being enabled in the gallery?

Yes, as long as the soft delete operation completes successfully.

Can I enable Soft Delete on an existing gallery and instantly delete and recover images, or is there a delay?

Yes, as long as the soft delete operation completes successfully.

Can I update the retention period beyond seven days?

No, currently you can't update the retention period.

Can I delete a gallery or image definition that has soft deleted images?

No, you can either delete all the soft deleted images or disable soft delete on the gallery to delete the image definition.

Share gallery resources across subscriptions and tenants by using RBAC

08/06/2025

Because a gallery, definition, and version are all resources in Azure Compute Gallery, you can share them by using the built-in Azure role-based access control (RBAC) roles. By using Azure RBAC roles, you can share these resources with other users, service principals, and groups. You can even share access with individuals outside the tenant where they were created.

After users have access, they can use the gallery resources to deploy a virtual machine (VM) or a virtual machine scale set. Here's a sharing matrix that can help you understand what the users get access to:

Expand table

Shared with users	Gallery	Image definition	Image version
Gallery	Yes	Yes	Yes
Image definition	No	Yes	Yes

We recommend sharing at the gallery level for the best experience. We don't recommend sharing individual image versions. For more information about Azure RBAC, see Assign Azure roles.

There are three main ways to share images in Compute Gallery, depending on which users you want to share with:

Expand table

Sharing with:	People	Groups	Service principal	All users in a specific subscription or tenant	Publicly with all users in Azure
RBAC sharing	Yes	Yes	Yes	No	No
RBAC + direct shared gallery	Yes	Yes	Yes	Yes	No
RBAC + community gallery	Yes	Yes	Yes	No	Yes

You can also create an app registration to share images between tenants.

> **Note**
>
> You can use images with read permissions on them to deploy virtual machines and disks.
>
> When you use a direct shared gallery, images are distributed widely to all users in a subscription or tenant. A community gallery distributes images publicly. When you share images that contain intellectual property, use caution to prevent widespread distribution.

Share by using RBAC

When you share a gallery by using RBAC, you need to provide the `imageID` value to anyone who creates a VM or scale set from the image. The person who's deploying the VM or scale set can't list the images that were shared with them via RBAC.

If you share gallery resources with someone outside your Azure tenant, they need your `tenantID` value to sign in and have Azure verify that they have access to the resource before they can use it within their own tenant. You need to provide the `tenantID` value. There is no way for someone outside your organization to query for this value.

For instructions on consuming an image shared via RBAC and creating a VM or a scale set, see:

- RBAC - Shared within your organization
- RBAC - Shared from another tenant

Portal

1. Sign in to the Azure portal.
2. On the page for your gallery, on the left menu, select **Access control (IAM)**.
3. Under **Add**, select **Add role assignment**. The **Add role assignment** pane opens.
4. Under **Role**, select **Reader**.
5. On the **Members** tab, ensure that the user is selected. For **Assign access to**, keep the default of **User, group, or service principal**.
6. Choose **Select members**. On the pane that opens, choose a user account.

7. If the user is outside your organization, the following message appears: **This user will be sent an email that enables them to collaborate with Microsoft**. Select the user with the email address, and then select **Save**.

Related content

- Create an image definition and an image version.
- Create a VM from a generalized or specialized image in a gallery.

Share gallery VM images across Azure tenants by using an app registration

08/06/2025

With Azure Compute Gallery, you can share a virtual machine (VM) image with another organization by using an app registration. For information about other sharing options, see Share gallery resources across subscriptions and tenants by using RBAC.

But, if you want to share images outside of your Azure tenant, at scale, you should create an app registration. Using an app registration can enable more complex sharing scenarios, like:

- Managing shared images when one company acquires another, and the Azure infrastructure is spread across separate tenants.
- Azure Partners manage Azure infrastructure on behalf of their customers. Customization of images is done within the partners tenant, but the infrastructure deployments will happen in the customer's tenant.

Create the app registration

Create an application registration that will be used by both tenants to share the image gallery resources.

1. Open the App registrations in the Azure portal.
2. Select **New registration** from the menu at the top of the page.
3. In **Name**, type *myGalleryApp*.
4. In **Supported account types**, select **Accounts in any organizational directory (Any Microsoft Entra directory - Multitenant) and personal Microsoft accounts (e.g. Skype, Xbox)**.
5. In **Redirect URI**, select *Web* from the **Select a platform** dropdown and type *https://www.microsoft.com*, then select **Register**. After the app registration has been created, the overview page will open.
6. On the overview page, copy the **Application (client) ID** and save for use later.
7. Select **Certificates & secrets**, and then select **New client secret**.
8. In **Description**, type *Gallery cross-tenant app secret*.
9. In **Expires**, change from the default of **6 months (recommended)** to **12 months** and then select **Add**.
10. Copy the value of the secret and save it to a safe place. You cannot retrieve it after you leave the page.

Give the app registration permission to use the gallery.

1. In the Azure portal, select the Azure Compute Gallery that you want to share with another tenant.
2. Select **select Access control (IAM)**, and under **Add role assignment** select *Add*.
3. Under **Role**, select **Reader**.
4. Under **Assign access to:**, leave this as **Microsoft Entra user, group, or service principal**.
5. Under **Select members**, type *myGalleryApp* and select it when it shows up in the list. When you are done, select **Review + assign**.

Give Tenant 2 access

Give Tenant 2 access to the application by requesting a sign-in using a browser. Replace *<Tenant2 ID>* with the tenant ID for the tenant that you would like to share your image gallery with. Users can see their tenant ID using the Azure CLI command `az account show`.

Replace *<Application (client) ID>* with the application ID of the app registration you created. When done making the replacements, paste the URL into a browser and follow the sign-in prompts to sign into Tenant 2.

```
https://login.microsoftonline.com/<Tenant 2 ID>/oauth2/authorize?client_id=
<Application (client)
ID>&response_type=code&redirect_uri=https%3A%2F%2Fwww.microsoft.com%2F
```

In the Azure portal sign in as Tenant 2 and give the app registration access to the resource group where you want to create the VM.

1. Select the resource group and then select **Access control (IAM)**. Under **Add role assignment** select **Add**.
2. Under **Role**, type **Contributor**.
3. Under **Assign access to:**, leave this as **Microsoft Entra user, group, or service principal**.
4. Under **Select members** type *myGalleryApp* then select it when it shows up in the list. When you are done, select **Review + assign**.

> **Note**
>
> You need to wait for the image version to completely finish being built and replicated before you can use the same managed image to create another image version.

> **Important**

You can't use the portal to deploy a VM from an image in another Azure tenant. To create a VM from an image shared between tenants, you must use the Azure CLI or Azure PowerShell.

Create the VM

You need the following information before you create a VM from an image shared with you by using an app registration:

- The tenant IDs from both the source subscription and the subscription where you want to create the VM
- The client ID of the app registration and the secret
- The image ID of the image that you want to use

CLI

Sign in the service principal for Tenant 1 by using the app ID, the app key, and the ID of Tenant 1. You can use `az account show --query "tenantId"` to get the tenant ID, if necessary.

The following example shows how to create a VM from a generalized image. If you're using a specialized image, see Create a VM using a specialized image version.

Azure CLI

```
tenant1='<ID for tenant 1>'
tenant2='<ID for tenant 2>'
appid='<client ID of the app registration>'
secret='<secret from the app registration>'

az account clear
az login --service-principal -u $appid -p $secret --tenant $tenant1
az account get-access-token
```

Sign in the service principal for Tenant 2 by using the app ID, the app key, and the ID of Tenant 2:

Azure CLI

```
az login --service-principal -u $appid -p $secret --tenant $tenant2
az account get-access-token
```

Create the VM. Replace the information in the following example with your own.

Azure CLI

```
imageid="<ID of the image that you want to use>"
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --image $imageid \
  --admin-username azureuser \
  --generate-ssh-keys
```

Share a gallery with all users in a subscription or tenant (preview)

08/06/2025

This article covers how to share a gallery with specific subscriptions or tenants by using a direct shared gallery in Azure Compute Gallery. Sharing a gallery with tenants and subscriptions gives them read-only access to it.

There are three main ways to share images in Compute Gallery, depending on which users you want to share with:

Expand table

Sharing with:	People	Groups	Service principal	All users in a specific subscription or tenant	Publicly with all users in Azure
Role-based access control (RBAC) sharing	Yes	Yes	Yes	No	No
RBAC + direct shared gallery	Yes	Yes	Yes	Yes	No
RBAC + community gallery	Yes	Yes	Yes	No	Yes

Important considerations

- The feature of direct shared galleries is currently in preview and is subject to the preview terms for Azure Compute Gallery.
- To publish images to a direct shared gallery during the preview, you need to register for the preview. No additional access is required to consume images.
- Creating virtual machines (VMs) from a direct shared gallery is open to all Azure users in the target subscription or tenant that the gallery is shared with.
- Access to the feature of direct shared galleries is gated because in most scenarios, RBAC or app sharing is sufficient for same-subscription and cross-tenant scenarios. Request access to the feature only if you want to share images widely with all users in the subscription or tenant, and if your business case requires access to direct shared galleries.
- You can use images with read permissions on them to deploy VMs and disks.

- When you use a direct shared gallery, images are distributed widely to all users in a subscription or tenant. A community gallery distributes images publicly. When you share images that contain intellectual property, use caution to prevent widespread distribution.

Limitations

During the preview:

- You can share up to 30 subscriptions and 5 tenants.
- Only images can be shared. You can't directly share a VM application during the preview.
- A direct shared gallery can't contain encrypted image versions.
- Only the owner of a subscription, or a user or service principal assigned to the Compute Gallery Sharing Admin role at the subscription or gallery level, can enable group-based sharing.
- Only REST API, Azure CLI, and Azure portal support is available in the feature preview. PowerShell and Terraform support is currently not available.
- Although portal support is available for this feature, consumption of images in the portal is available only from the pane for creating a VM or virtual machine scale set. There's no way to browse through direct shared images in the portal.
- The image version's region in the gallery should be the same as the home region. The creation of cross-region versions where the home region is different from the gallery is not supported. However, after the image is in the home region, it can be replicated to other regions.
- The feature is not available in government clouds.
- *Known issue*: When you create a VM from a direct shared image by using the Azure portal, if you select a region and an image and then change the region, you get an error message: "You can only create VM in the replication regions of this image." The message appears even when the image is replicated to that region.

  To eliminate the error, select a different region, and then switch back to the region that you want. If the image is available, it should clear the error message.

Prerequisites

You need to create a new direct shared gallery.

During the preview, a direct shared gallery has the `sharingProfile.permissions` property set to `Groups`. When you use the Azure CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, and the property can't currently be updated.

Share a gallery

Here's an overview of the sharing process:

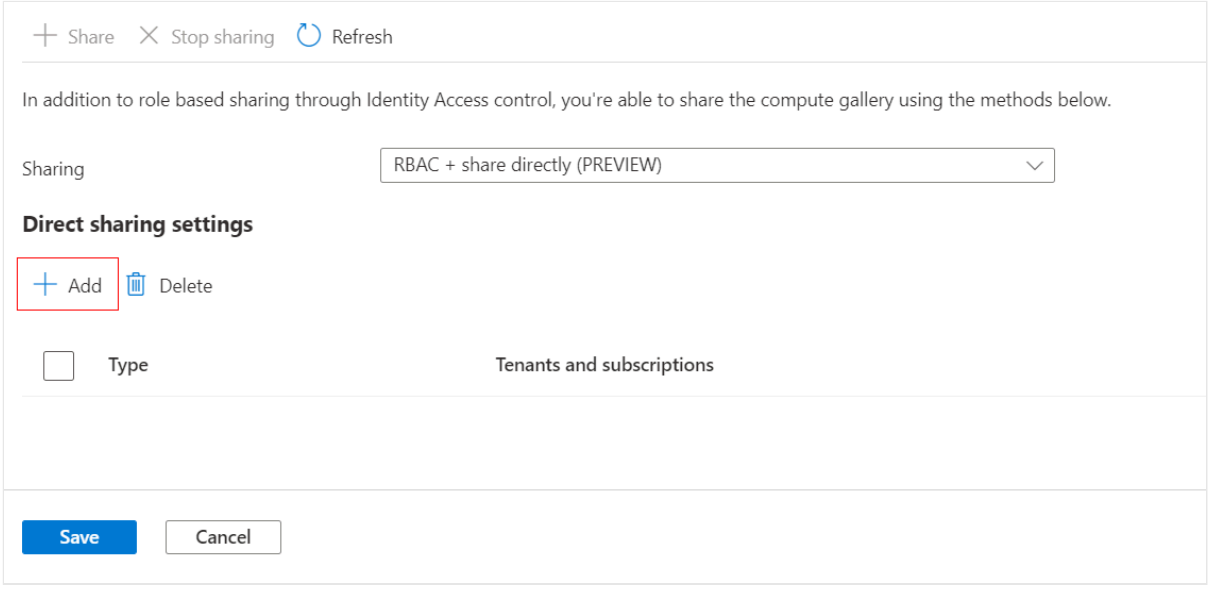
1. You create a gallery under `Microsoft.Compute/Galleries` and choose `groups` as a sharing option.
2. When you're ready, you share your gallery with subscriptions and tenants.
3. The Azure infrastructure creates proxy read-only regional resources under `Microsoft.Compute/SharedGalleries`.

Only subscriptions and tenants that you've shared your gallery with can interact with the proxy resources. They never interact with your private resources.

As the publisher of the private resource, you should consider the private resource as your handle to the public proxy resources. The subscriptions and tenants that you've shared your gallery with see the gallery name as the subscription ID where the gallery was created, followed by the gallery name.

Portal

1. On the page for the gallery, on the left menu, select **Sharing**.
2. Under **Direct sharing settings**, select **Add**.



3. If you want to share with someone within your organization, for **Type**, select **Subscription** or **Tenant**. Then choose the appropriate item in the **Tenants and subscriptions** dropdown list.

   If you want to share with someone outside your organization, select either **Subscription outside of my organization** or **Tenant outside of my organization**. Then paste or enter the ID in the text box.

   When a gallery is shared with the tenant, all subscriptions within the tenant get access to the image. They don't have to share it with individual subscriptions in the tenant.

4. When you finish adding items, select **Save**.

> ⓘ **Note**
>
> If you get the error "Failed to update Azure compute gallery," make sure that you have owner or Compute Gallery Sharing Admin permission on the gallery.

Share images by using a community gallery

08/06/2025

To share a gallery with all Azure users, you can create a community gallery. Anyone who has an Azure subscription can use community galleries. Someone who creates a virtual machine (VM) can browse through images shared with the community by using the Azure portal, the REST API, or the Azure CLI. Sharing images with the community is a new capability in Azure Compute Gallery.

You can make your image galleries public and share them with Azure customers. When a gallery is marked as a community gallery, all images in it become available to all Azure customers as a new resource type under `Microsoft.Compute/communityGalleries`. Azure customers can see the galleries and use them to create VMs. Your original resources of the type `Microsoft.Compute/galleries` are still under your subscription and private.

> **Important**
>
> Microsoft does not provide support for community images. For any image-related issues, contact the image publishers. However, Microsoft does provide commercially reasonable support to isolate any platform issue that involves a community image. You can find the publisher contact by querying the image.

There are three main ways to share images in Compute Gallery, depending on which users you want to share with:

Expand table

Sharing with:	People	Groups	Service principal	All users in a specific subscription or tenant	Publicly with all users in Azure
Role-based access control (RBAC) sharing	Yes	Yes	Yes	No	No
RBAC + direct shared gallery	Yes	Yes	Yes	Yes	No
RBAC + community gallery	Yes	Yes	Yes	No	Yes

> **Note**
>
> You can use images with read permissions on them to deploy virtual machines and disks.

When you use a direct shared gallery, images are distributed widely to all users in a subscription or tenant. A community gallery distributes images publicly. When you share images that contain intellectual property, use caution to prevent widespread distribution.

Disclaimer

Microsoft doesn't verify or test community images and associated publisher information. You're solely responsible for any community image that you deploy or use. You're responsible for your dealings with the publishers of images. For approved operating system base images, see the list in GitHub. For other images created by verified publishers, see Azure Marketplace.

Limitations for sharing images with the community

- You can't convert an existing private gallery (RBAC-enabled gallery) to a community gallery.
- You can't use a partner image from Azure Marketplace and publish it to the community.
- Encrypted images are not supported.
- The feature isn't available in government clouds.
- Image resources need to be created in the same region as the gallery. For example, if you create a gallery in West US, the image definitions and image versions should be created in West US if you want to make them available.
- You currently can't share VM applications with the community.

How sharing with the community works

You create a gallery resource under `Microsoft.Compute/Galleries` and choose `community` as a sharing option.

When you're ready, you flag your gallery as ready to be shared publicly. Only the owner of a subscription, or a user or service principal with the Compute Gallery Sharing Admin role at the subscription or gallery level, can enable a gallery to go public to the community. At this point, the Azure infrastructure creates proxy read-only regional resources under `Microsoft.Compute/CommunityGalleries`. These proxy resources are public.

Users can interact only with the proxy resources. They never interact with your private resources. As the publisher of a private resource, you should consider the private resource as your handle to the public proxy resources. The `prefix` value that you provide when you create the gallery is used, along with a GUID, to create the public-facing name for your gallery.

Azure users can see the latest image versions shared with the community in the portal, or query for them by using the Azure CLI. Only the latest version of an image is listed in the community gallery.

When you create a community gallery, you need to provide contact information for your images. This information helps facilitate communication between the consumer of the image and the publisher if the consumer needs assistance. Microsoft doesn't offer support for these images. This information is *publicly available*, so be careful when you provide it:

- Community gallery prefix.
- Publisher support email.
- Publisher URL.
- Legal agreement URL. Do not put secrets, passwords, share access signature (SAS) URIs, or any other sensitive information in this URL.

Information from your image definitions is also publicly available, including what you provide for **Publisher**, **Offer**, and **SKU**.

> ⚠ **Warning**
>
> If you want to stop sharing a gallery publicly, you can update the gallery to stop sharing. However, making the gallery private will prevent existing users of virtual machine scale sets from scaling their resources.

How an image publisher chooses between publishing to Azure Marketplace and a community gallery

When to publish to Azure Marketplace:

- You signed Azure Marketplace terms.
- You want to publish commercial images.
- You want to publish a stable version or major release.

When to publish to a community gallery:

- You can't sign Azure Marketplace terms and still want to share images publicly on Azure.
- You want to publish non-commercial images.
- You want to publish daily or nightly builds.

How an image consumer chooses between Azure Marketplace and community images

A consumer might choose Azure Marketplace images when that consumer needs:

- Microsoft-certified images.
- Images for production workloads.
- Microsoft and partner images.
- Paid images with additional software offerings.
- Images that Microsoft supports.

A consumer might choose community images when that consumer needs:

- A community version of an image published by an open-source community.
- Images from a trusted publisher with known contact information.
- Images for testing.
- Free images.
- Images supported by the image owners, not Microsoft.

Reporting issues with a community image

Using community-submitted VM images has several risks. Images could contain malware, security vulnerabilities, or intellectual property. To help create a secure and reliable experience for the community, you can report images when you see these issues.

The easiest way to report issues with a community gallery is to use the portal, which pre-fills information for the report:

- For issues with links or other information in the fields of an image definition, select **Report community image**.
- For malicious code or other issues in a specific image version, select **Report** under the **Report version** column in the table of image versions.

You can also use the following links to report issues, but the forms aren't pre-filled:

- For malicious images, report abuse.
- For violations of intellectual property, submit an infringement report.

Best practices

- Images published to the community gallery should be generalized and have no sensitive or machine-specific details. To learn more about preparing an image, see the OS-specific

information for Linux or Windows.

- If you want to block sharing images with the community at the organization level, create an Azure policy with the following policy rule:

```
  "policyRule": {
      "if": {
        "allOf": [
          {
            "field": "type",
            "equals": "Microsoft.Compute/galleries"
          },
          {
            "field":
"Microsoft.Compute/galleries/sharingProfile.permissions",
            "equals": "Community"
          }
        ]
      },
      "then": {
        "effect": "[parameters('effect')]"
      }
    }
```

FAQ

What are the charges for using a gallery that's shared with the community?

There are no charges for using the service itself. However, content publishers do receive:

- Storage charges for application versions and replicas in each of the regions (source and target). These charges are based on the chosen type of storage account.
- Network egress charges for replication across regions.

Consumers of the image might have to pay additional software costs if the base image is using an Azure Marketplace image with software charges.

Is it safe to use images shared with the community?

Users should exercise caution while using images from unverified sources. These images aren't subject to certification, and they're not scanned for malware or vulnerabilities.

If an image that's shared with the community doesn't work, who provides support?

Azure isn't responsible for any issues that users might encounter with community-shared images. The image publisher provides the support. If you need support, use the image publisher's contact information.

Is community gallery sharing part of Azure Marketplace?

No, community gallery sharing isn't part of Azure Marketplace. It's a feature of Azure Compute Gallery. Anyone who has an Azure subscription can use a community gallery to make their images public.

How do I request that an image shared with the community is replicated to a specific region?

Only the content publishers have control over the regions where their images are available. If you don't find an image in a specific region, contact the publisher directly.

Start sharing publicly

For a gallery to be shared publicly, it needs to be created as a community gallery. For more information, see Create a community gallery.

CLI

When you're ready to make the gallery available to the community, use the az sig share enable-community command. Only a user in the Owner role definition can enable a gallery for community sharing.

Azure CLI

```
az sig share enable-community \
   --gallery-name $galleryName \
   --resource-group $resourceGroup
```

To go back to only RBAC-based sharing, use the az sig share reset command.

To delete a gallery that's shared with the community, you must first run `az sig share reset` to stop sharing. Then you can delete the gallery.

> **Important**
>
> If you're listed as the owner of your subscription, but you're having trouble sharing the gallery publicly, you might need to explicitly add yourself as owner again.

To go back to only RBAC-based sharing, use the az sig share reset command.

To delete a gallery that's shared with the community, you must first run `az sig share reset` to stop sharing. Then you can delete the gallery.

Store and share images in an Azure Compute Gallery

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

An image is a copy of either a full VM (including any attached data disks) or just the OS disk, depending on how it's created. When you create a VM from the image, a copy of the VHDs in the image are used to create the disks for the new VM. The image remains in storage and can be used over and over again to create new VMs.

If you have a large number of images that you need to maintain, and would like to make them available throughout your company, you can use an Azure Compute Gallery as a repository.

When you use a gallery to store images, multiple resource types are created:

Expand table

Resource	Description
Image source	This is a resource that can be used to create an **image version** in a gallery. An image source can be an existing Azure VM that is either generalized or specialized, a managed image, a snapshot, a VHD or an image version in another gallery.
Gallery	Like the Azure Marketplace, a **gallery** is a repository for managing and sharing images and other resources, but you control who has access.
Image definition	Image definitions are created within a gallery and they carry information about the image and any requirements for using it to create VMs. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It's a definition of a type of image.
Image version	An **image version** is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an **image version** to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

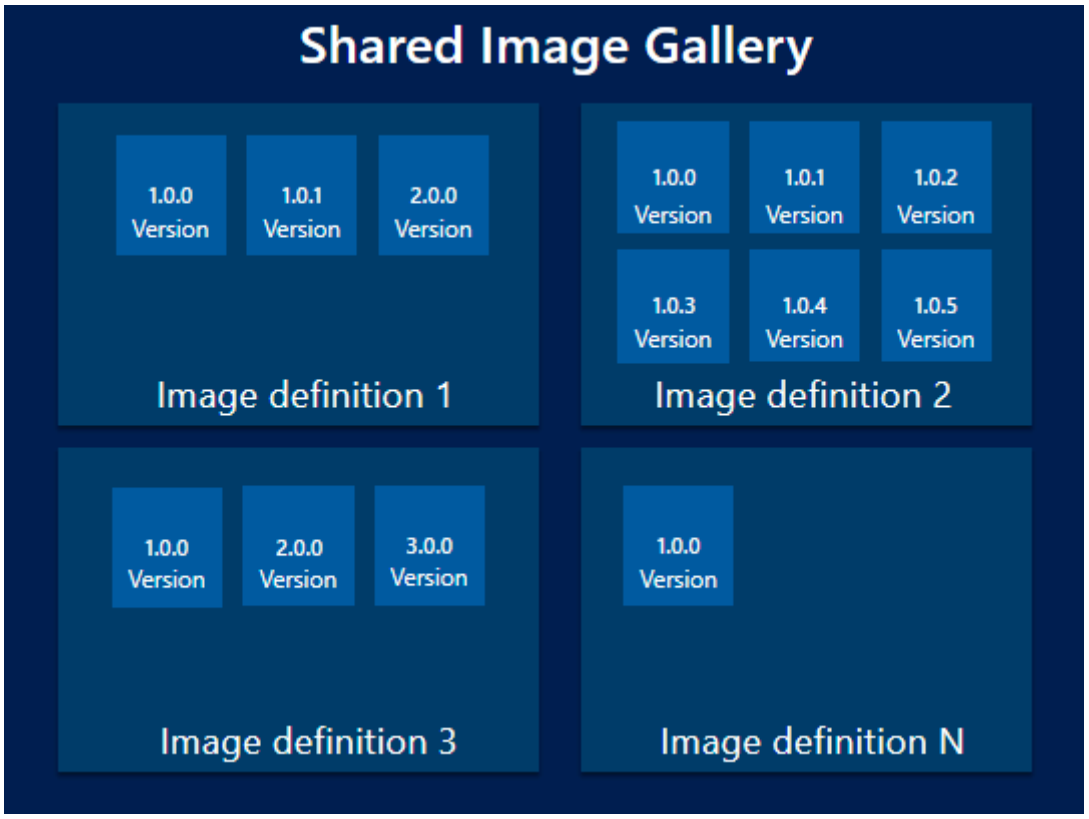

Image definitions

Image definitions are a logical grouping for versions of an image. The image definition holds information about why the image was created and also contains Image metadata such as, what OS it is for, features it supports and other information about using the image. An image definition is like a plan for all of the details around creating a specific image. You don't deploy a VM from an image definition, but from the image versions created from the definition.

There are three parameters for each image definition that are used in combination - **Publisher**, **Offer** and **SKU**. These are used to find a specific image definition. You can have image definitions that share one or two, but not all three values. For example, here are three image definitions and their values:

Expand table

Image Definition	Publisher	Offer	Sku
myImage1	Contoso	Finance	Backend
myImage2	Contoso	Finance	Frontend
myImage3	Testing	Finance	Frontend

All three of these have unique sets of values. The format is similar to how you can currently specify publisher, offer, and SKU for Azure Marketplace images in Azure PowerShell to get the latest version of a Marketplace image. Each image definition needs to have a unique set of these values.

The following parameters determine which types of image versions they can contain:

- Operating system state - You can set the OS state to generalized or specialized. This field is required.
- Operating system - can be either Windows or Linux. This field is required.
- Hyper-V generation - specify whether the image was created from a generation 1 or generation 2 Hyper-V VHD. Default is generation 1.

Image definitions contain metadata for the image to allow grouping of images that support the same features, plan, OS State, OS type and others. The following are other parameters that can be set on your image definition so that you can more easily track your resources:

- Description - use description to give more detailed information on why the image definition exists. For example, you might have an image definition for your front-end server that has the application preinstalled.
- EULA - can be used to point to an end-user license agreement specific to the image definition.
- Privacy Statement and Release notes - store release notes and privacy statements in Azure storage and provide a URI for accessing them as part of the image definition.
- End-of-life date - establish a default date after which the image shouldn't be used, for all image versions in the image definition. End-of-life dates are informational; users will still be able to create VMs from images and versions past the end-of-life date.
- Tag - you can add tags when you create your image definition. For more information about tags, see Using tags to organize your resources
- Minimum and maximum vCPU and memory recommendations - if your image has vCPU and memory recommendations, you can attach that information to your image definition.
- Disallowed disk types - you can provide information about the storage needs for your VM. For example, if the image isn't suited for standard HDD disks, you add them to the disallow list.

- Purchase plan information for Marketplace images - `-PurchasePlanPublisher`, `-PurchasePlanName`, and `-PurchasePlanProduct`. For more information about purchase plan information, see Find images in the Azure Marketplace and Supply Azure Marketplace purchase plan information when creating images.
- Architecture
  - x64 or ARM64 Architecture
- Features allow you to specify additional features and SecurityType(s) that are supported on the image, based on the type of gallery:

Expand table

Features	Accepted Values	Definition	Supported in
IsHibernateSupported	True, False	Create VMs with support for hibernation.	Private, direct shared, community
IsAcceleratedNetworkSupported	True, False	Create VMs with accelerated networking enabled. When set to `True` on Image definition, capturing VMs that don't support accelerated networking is not supported.	Private, direct shared, community
DiskControllerType	["SCSI", "NVMe"], ["SCSI"]	Set this to use either SCSI or NVMe disk type. NVMe VMs and disks can only be captured in image definitions that are tagged to be supporting NVMe.	Private, direct shared, community

When you specify a SecurityType using the `features` parameter, it limits the security features that are enabled on the VM. Some types limited, based on the type of gallery that they are stored in:

Expand table

SecurityType	Definition	Supported in
ConfidentialVMSupported	It's a generic Gen2 image that does not contain VMGS blob. Gen2 VM or Confidential VM can be created from this image type	Private, Direct shared, Community
Confidential VM	Only Confidential VMs can be created from this image type	Private
TrustedLaunchSupported	It's a generic Gen2 image that does not contain the VMGS blob. Gen2 VM or TrustedLaunch VM can be created from this image type.	Private, direct shared, community
TrustedLaunch	Only TrustedLaunch VM can be created from this image type	Private
TrustedLaunchAndConfidentialVmSupported	It's a generic Gen2 image that does not contain the VMGS blob. Gen2 VM, TrustedLaunch VM, or a ConfidentialVM can be created from this image type.	Private, direct shared, community

For more information, see the CLI examples for adding image definition features and SecurityType or the PowerShell examples.

**ConfidentialVM is only supported in the regions where it's available, You can find the supported regions here.

Image versions

An **image version** is what you use to create a VM. You can have multiple versions of an image as needed for your environment. When you use an **image version** to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

The properties of an image version are:

- Version number. This is used as the name of the image version. It is always in the format: MajorVersion.MinorVersion.Patch. When you specify to use **latest** when creating a VM, the latest image is chosen based on the highest MajorVersion, then MinorVersion, then Patch.
- Source. The source can be a VM, managed disk, snapshot, managed image, or another image version.
- End of life date. Indicate the end-of-life date for the image version. End-of-life dates are informational; users will still be able to create VMs from versions past the end-of-life date.

Generalized and specialized images

There are two operating system states supported by Azure Compute Gallery. Typically images require that the VM used to create the image has been generalized before taking the image. Generalizing is a process that removes machine and user specific information from the VM. For Linux, you can use waagent `-deprovision` or `-deprovision+user` parameters. For Windows, the Sysprep tool is used.

Specialized VMs haven't been through a process to remove machine specific information and accounts. Also, VMs created from specialized images don't have an `osProfile` associated with them. This means that specialized images will have some limitations in addition to some benefits.

- VMs and scale sets created from specialized images can be up and running quicker. Because they're created from a source that has already been through first boot, VMs created from these images boot faster.
- Accounts that could be used to log into the VM can also be used on any VM created using the specialized image that is created from that VM.
- VMs will have the **Computer name** of the VM the image was taken from. You should change the computer name to avoid collisions.
- The `osProfile` is how some sensitive information is passed to the VM, using `secrets`. This may cause issues using KeyVault, WinRM and other functionality that uses `secrets` in the `osProfile`. In some cases, you can use managed service identities (MSI) to work around these limitations.

> **Note**
>
> Generalized and specialized VM images contain an operating system disk and all the attached disks, if there any.

Updating resources

Once created, you can make some changes to the gallery resources. These are limited to:

Azure Compute Gallery:

- Description

Image definition:

- Recommended vCPUs
- Recommended memory
- Description
- End of life date
- ReleaseNotes

Image version:

- Regional replica count
- Target regions
- Exclude from latest
- End of life date

Sharing

There are three main ways to share images an Azure Compute Gallery, depending on who you want to share with:

Expand table

Sharing with:	People	Groups	Service Principal	All users in a specific subscription (or) tenant	Publicly with all users in Azure
RBAC Sharing	Yes	Yes	Yes	No	No
RBAC + Direct shared gallery	Yes	Yes	Yes	Yes	No
RBAC + Community gallery	Yes	Yes	Yes	No	Yes

RBAC Permissions required to create an ACG Image:

ACG images can be created by users from various sources, including virtual machines, disks/snapshots, and VHDs. The section outlines the various user permissions necessary for creating an Azure Compute Gallery image. Identifies without the necessary permissions will not be able to create ACG images.

VM as source

- Users will require write permission on the Virtual Machine to create an ACG Image version.
- For Azure SDK, use the property properties.storageProfile.source.virtualMachineId, This property requires API version 2023-07-03 or Version 1.4.0 (or higher) of .NET SDK

Expand table

Source type	Permissions Required
Virtual machine	Write
Disk/snapshot	Write
VHD	Write (listKeys)
Managed Image	Read
Gallery Image	Read

Refer to our documentation for additional information regarding Azure built-in roles, for granting RBAC permissions

Shallow replication

When you create an image version, you can set the replication mode to shallow for development and test. Shallow replication skips copying the image, so the image version is ready faster. But, it also means you can't deploy a large number of VMs from that image version. This is similar to the way that the older managed images worked.

Shallow replication can also be useful if you have large images (up to 32 TB) that aren't frequently deployed. Because the source image isn't copied, larger disks can be used.

But, they also can't be used for deploying large numbers of VMs concurrently.

To set an image for shallow replication, use `--replication-mode Shallow` with the Azure CLI.

SDK support

The following SDKs support creating Azure Compute Galleries:

- .NET
- Java
- Node.js
- Python
- Go

Templates

You can create Azure Compute Gallery resource using templates. There are several quickstart templates available:

- Create a gallery
- Create an image definition in a gallery
- Create an image version in a gallery

Frequently asked questions

- How can I list all the Azure Compute Gallery resources across subscriptions?
- Can I move my existing image to an Azure Compute Gallery?
- Can I create an image version from a specialized disk?
- Can I move the Azure Compute Gallery resource to a different subscription after it has been created?
- Can I replicate my image versions across clouds such as Microsoft Azure operated by 21Vianet, Azure Germany, or Azure Government Cloud?
- Can I replicate my image versions across subscriptions?
- Can I share image versions across Microsoft Entra tenants?
- How long does it take to replicate image versions across the target regions?
- What is the difference between source region and target region?
- How do I specify the source region while creating the image version?
- How do I specify the number of image version replicas to be created in each region?

- Can I create the gallery in a different location than the one for the image definition and image version?
- What are the charges for using an Azure Compute Gallery?
- What API version should I use when creating images?
- What API version should I use to create a VM or Virtual Machine Scale Set out of the image version?
- Can I update my Virtual Machine Scale Set created using managed image to use Azure Compute Gallery images?
- How can I update my code to use the new property and ensure permissions are granted accurately during VM image creation?
- Does deleting the Azure Compute Gallery images affect existing VMs created from it?

How can I list all the Azure Compute Gallery resources across subscriptions?

To list all the Azure Compute Gallery resources across subscriptions that you have access to on the Azure portal, follow the steps below:

1. Open the Azure portal.
2. Scroll down the page and select **All resources**.
3. Select all the subscriptions under which you'd like to list all the resources.
4. Look for resources of the **Azure Compute Gallery** type.

Azure CLI

To list all the Azure Compute Gallery resources, across subscriptions that you have permissions to, use the following command in the Azure CLI:

Azure CLI

```
   az account list -otsv --query "[].id" | xargs -n 1 az sig list --
subscription
```

Can I move my existing image to an Azure Compute Gallery?

Yes. There are 3 scenarios based on the types of images you may have.

Scenario 1: If you have a managed image, then you can create an image definition and image version from it. For more information, see Create and image definition and an image version.

Scenario 2: If you have an unmanaged image, you can create a managed image from it, and then create an image definition and image version from it.

Scenario 3: If you have a VHD in your local file system, then you need to upload the VHD to a managed image, then you can create an image definition and image version from it.

- If the VHD is of a Windows VM, see Upload a VHD.
- If the VHD is for a Linux VM, see Upload a VHD

Can I create an image version from a specialized disk?

Yes, can create a VM from a specialized image.

Can I move the Azure Compute Gallery resource to a different subscription after it has been created?

No, you can't move the gallery image resource to a different subscription. You can replicate the image versions in the gallery to other regions or copy an image from another gallery.

Can I replicate my image versions across clouds such as Azure operated by 21Vianet or Azure Germany or Azure Government Cloud?

No, you can't replicate image versions across clouds.

Can I replicate my image versions across subscriptions?

No, you may replicate the image versions across regions in a subscription and use it in other subscriptions through RBAC.

Can I share image versions across Microsoft Entra tenants?

Yes, you can use RBAC to share to individuals across tenants. But, to share at scale, see "Share gallery images across Azure tenants" using PowerShell or CLI.

How long does it take to replicate image versions across the target regions?

The image version replication time is entirely dependent on the size of the image and the number of regions it's being replicated to. However, as a best practice, it's recommended that you keep the image small, and the source and target regions close for best results. You can check the status of the replication using the -ReplicationStatus flag.

What is the difference between source region and target region?

Source region is the region in which your image version will be created, and target regions are the regions in which a copy of your image version will be stored. For each image version, you can only have one source region. Also, make sure that you pass the source region location as one of the target regions when you create an image version.

How do I specify the source region while creating the image version?

While creating an image version, you can use the **--location** argument in CLI and the **-Location** parameter in PowerShell to specify the source region. Ensure the managed image that you're using as the base image to create the image version is in the same location as the location in which you intend to create the image version. Also, make sure that you pass the source region location as one of the target regions when you create an image version.

How do I specify the number of image version replicas to be created in each region?

There are two ways you can specify the number of image version replicas to be created in each region:

1. The regional replica count which specifies the number of replicas you want to create per region.
2. The common replica count which is the default per region count in case regional replica count isn't specified.

Azure CLI

To specify the regional replica count, pass the location along with the number of replicas you want to create in that region: "South Central US=2".

If regional replica count isn't specified with each location, then the default number of replicas will be the common replica count that you specified.

To specify the common replica count in Azure CLI, use the **--replica-count** argument in the `az sig image-version create` command.

Can I create the gallery in a different location than the one for the image definition and image version?

Yes, it's possible. But, as a best practice, we encourage you to keep the resource group, gallery, image definition, and image version in the same location.

What are the charges for using an Azure Compute Gallery?

There are no charges for using an Azure Compute Gallery, except the storage charges for storing the image versions and network egress charges for replicating the image versions from source region to target regions.

What API version should I use when creating images?

To work with galleries, image definitions, and image versions, we recommend you use API version 2018-06-01. Zone Redundant Storage (ZRS) requires version 2019-03-01 or later.

What API version should I use to create a VM or Virtual Machine Scale Set out of the image version?

For VM and Virtual Machine Scale Set deployments using an image version, we recommend you use API version 2018-04-01 or higher.

Can I update my Virtual Machine Scale Set created using managed image to use Azure Compute Gallery images?

Yes, you can update the scale set image reference from a managed image to an Azure Compute Gallery image, as long as the OS type, Hyper-V generation, and the data disk layout matches between the images.

How can I update my code to use the new property and ensure permissions are granted accurately during VM image creation?

For Virtual Machine ID field, use VirtualMachineId field under GallerySource(GalleryImageVersionStorageProfile.GallerySource.VirtualMachineID). The new property requires api-version 2023-07-03 or version 1.4.0 (or higher) of .NET SDK

```
StorageProfile = new GalleryImageVersionStorageProfile()
            {
                GallerySource = new GalleryArtifactVersionFullSource()
                {
                    VirtualMachineId = new
ResourceIdentifier(virtualMachineId),
                }
            },
```

For VHD as a source, use StorageAccountID field under GallerySource under OSDiskImage or Data disk Image(GalleryImageVersionStorageProfile.OSDiskImage.GallerySource.StorageAccountId). The new property requires api-version 2022-03-03

```
StorageProfile = new GalleryImageVersionStorageProfile()
            {
                OSDiskImage = new GalleryOSDiskImage()
                {
                    GallerySource = new GalleryDiskImageSource()
                    {
                        StorageAccountId = new
ResourceIdentifier(storageAccountId),
                        Uri = new Uri(blobUri),
                    }
                }
            },
```

Does deleting the Azure Compute Gallery affect VMs created from it?

VMs created from the Azure Compute Gallery image remains unaffected due to their persistent disks. However, VMSS scale out operation will fail as they rely on the source image ID reference which would be lost once the Azure Compute Gallery image is deleted.

Troubleshoot

If you have issues with performing any operations on the gallery resources, consult the list of common errors in the troubleshooting guide.

In addition, you can post and tag your question with `azure-virtual-machines-images` at Q&A.

Create an image of a VM in the portal

An image can be created from a VM and then used to create multiple VMs.

For images stored in an Azure Compute Gallery (formerly known as Shared Image Gallery), you can use VMs that already have accounts created on them (specialized) or you can generalize the VM before creating the image to remove machine accounts and other machines specific information. To generalize a VM, see Generalized a VM. For more information, see Generalized and specialized images.

> **Important**
>
> Once you mark a VM as `generalized` in Azure, you cannot restart the VM. Legacy **managed images** are automatically marked as generalized.
>
> > When capturing an image of a virtual machine in Azure, the virtual machine will be temporarily stopped to ensure data consistency and prevent any potential issues during the image creation. This is because capturing an image requires a point-in-time snapshot of the virtual machine's disk. To avoid disruptions in a production environment, it's recommended you schedule the image capture process during a maintenance window or a time when the temporary downtime won't impacting critical services.

Capture a VM in the portal

1. Go to the Azure portal, then search for and select **Virtual machines**.
2. Select your VM from the list.
    - If you want a generalized image, see Generalize OS disk for Linux/Windows.
    - If you want a specialized image, no additional action is required.
3. On the page for the VM, on the upper menu, select **Capture**.

   The **Create an image** page appears.
4. For **Resource group**, either select **Create new** and enter a name, or select a resource group to use from the drop-down list. If you want to use an existing gallery, select the resource group for the gallery you want to use.
5. To create the image in a gallery, select **Yes, share it to a gallery as an image version**.

To only create a managed image, select **No, capture only a managed image**. The VM must have been generalized to create a managed image. The only other required information is a name for the image.

6. If you want to delete the source VM after the image has been created, select **Automatically delete this virtual machine after creating the image**. This is not recommended.
7. For **Gallery details**, select the gallery or create a new gallery by selecting **Create new**.
8. In **Operating system state** select generalized or specialized. For more information, see Generalized and specialized images.
9. Select an image definition or select **create new** and provide a name and information for a new Image definition.
10. Enter an image version number. If this is the first version of this image, type *1.0.0*.
11. If you want this version to be included when you specify *latest* for the image version, then leave **Exclude from latest** unchecked.
12. Select an **End of life** date. This date can be used to track when older images need to be retired.
13. Under Replication, select a default replica count and then select any additional regions where you would like your image replicated.
14. When you are done, select **Review + create**.
15. After validation passes, select **Create** to create the image.

Next steps

- Azure Compute Galleries overview

Last updated on 02/06/2026

Create an image definition and an image version

An Azure Compute Gallery simplifies custom image sharing across your organization. Custom images are like marketplace images, but you create them yourself. Images can be created from a VM, VHD, snapshot, managed image, or another image version.

The Azure Compute Gallery lets you share your custom VM images with others in your organization, within or across regions, within a Microsoft Entra tenant, or publicly using a community gallery. Choose which images you want to share, which regions you want to make them available in, and who you want to share them with. You can create multiple galleries so that you can logically group images. Many new features like ARM64, Accelerated Networking and TrustedVM are only supported through Azure Compute Gallery and not available for managed images.

The Azure Compute Gallery feature has multiple resource types:

Expand table

Resource	Description
Image source	This is a resource that can be used to create an **image version** in a gallery. An image source can be an existing Azure VM that is either generalized or specialized, a managed image, a snapshot, or an image version in another gallery.
Gallery	Like the Azure Marketplace, a **gallery** is a repository for managing and sharing images and VM applications, but you control who has access.
Image definition	Image definitions are created within a gallery and carry information about the image and requirements for using it internally. This includes whether the image is Windows or Linux, release notes, and minimum and maximum memory requirements. It is a definition of a type of image.
Image version	An **image version** is what you use to create a VM when using a gallery. You can have multiple versions of an image as needed for your environment. Like a managed image, when you use an **image version** to create a VM, the image version is used to create new disks for the VM. Image versions can be used multiple times.

Prerequisites

To complete this article, you must have an existing Azure Compute Gallery, and a source for your image available in Azure. Image sources can be:

- A VM in your subscription. You can capture an image from both specialized and generalized VMs.
- A Managed image,
- Managed OS and data disks.
- OS and data disks as VHDs in a storage account.
- Other image versions either in the same gallery or another gallery in the same subscription.

If the image will contain data disks, the data disk size cannot be more than 1 TB.

Image definition names can be made up of uppercase or lowercase letters, digits, dots, dashes and periods. For more information about the values you can specify for an image definition, see Image definitions.

Allowed characters for the image version are numbers and periods. Numbers must be within the range of a 32-bit integer. Format: *MajorVersion*.*MinorVersion*.*Patch*.

When working through this article, replace the resource names where needed.

For generalized images, see the OS specific guidance before capturing the image:

- **Linux**
  - Generic steps
  - CentOS
  - Debian
  - Flatcar
  - FreeBSD
  - Oracle Linux
  - OpenBSD
  - Red Hat
  - SUSE
  - Ubuntu
- **Windows**

  If you plan to run Sysprep before uploading your virtual hard disk (VHD) to Azure for the first time, make sure you have prepared your VM.

Community gallery

If you will be sharing your images using a community gallery, make sure that you create your gallery, image definitions, and image versions in the same region.

When users search for community gallery images, only the latest version of an image is shown.

> **Important**
>
> Information from your image definitions will be publicly available, like what you provide for **Publish**, **Offer**, and **SKU**.

Create an image

Choose an option below for creating your image definition and image version:

Portal

To create an image from a VM in the portal, see Capture an image of a VM.

To create an image using a source other than a VM, follow these steps.

1. Go to the Azure portal, then search for and select **Azure Compute Gallery**.
2. Select the gallery you want to use from the list.
3. On the page for your gallery, select **Add** from the top of the page and then select **VM image definition** from the drop-down.
4. on the **Add new image definition to Azure Compute Gallery** page, in the **Basics** tab, select a **Region**.
5. For **Image definition name**, type a name like *myImageDefinition*.
6. For **Operating system**, select the correct option based on your source.
7. For **VM generation**, select the option based on your source. In most cases, this will be *Gen 1*. For more information, see Support for generation 2 VMs.
8. For **Operating system state**, select the option based on your source. For more information, see Generalized and specialized.

9. For **Publisher**, type a unique name like *myPublisher*.
10. For **Offer**, type a unique name like *myOffer*.
11. For **SKU**, type a unique name like *mySKU*.
12. At the bottom of the page, select **Review + create**.
13. After the image definition passes validation, select **Create**.
14. When the deployment is finished, select **Go to resource**.
15. In the page for your image definition, on the **Get started** tab, select **Create a version**.
16. In **Region**, select the region where you want the image created. In some cases, the source must be in the same region where the image is created. If you aren't seeing your source listed in later drop-downs, try changing the region for the image. You can always replicate the image to other regions later.
17. For **Version number**, type a number like *1.0.0*. The image version name should follow *major.minor.patch* format using integers.
18. In **Source**, select the type of file you are using for your source from the drop-down. See the table below for specific details for each source type.

Expand table

Source	Other fields
Disks or snapshots	- For **OS disk** select the disk or snapshot from the drop-down. - To add a data disk, type the LUN number and then select the data disk from the drop-down.
Image version	- Select the **Source gallery** from the drop-down. - Select the correct image definition from the drop-down. - Select the existing image version that you want to use from the drop-down.
Managed image	Select the **Source image** from the drop-down. The managed image must be in the same region that you chose in **Instance details**.
VHD in a storage account	Select **Browse** to choose the storage account for the VHD.

19. In **Exclude from latest**, leave the default value of *No* unless you don't want this version used when creating a VM using `latest` instead of a version number.
20. For **End of life date**, select a date from the calendar for when you think this version should stop being used.
21. In the **Replication** tab, select the storage type from the drop-down.
22. Set the **Default replica count**, you can override this for each region you add.
23. You need to replicate to the source region, so the first replica in the list will be in the region where you created the image. You can add more replicas by selecting the region from the drop-down and adjusting the replica count as necessary.
24. When you are done, select **Review + create**. Azure will validate the configuration.
25. When image version passes validation, select **Create**.
26. When the deployment is finished, select **Go to resource**.

It can take a while to replicate the image to all of the target regions.

You can also capture an existing VM as an image, from the portal. For more information, see Create an image of a VM in the portal.

Create an image version in one tenant using the source image version in another tenant

In the subscription where the source image version exists, grant reader permissions to the user. Once the user has reader permission to the source image version, sign in to both accounts (source and target).

You will need the `tenantID` of the source image version, the `subscriptionID` for the subscription where the new image version will be stored (target), and the `resourceID` of the source image version. The target gallery image definition must already exist before you create the image version with `az sig image-version create` or `New-AzGalleryImageVersion`. Additionally, ensure that the source image version's region or replica and target region are the same.

CLI

Use the Azure CLI to create an image version in one tenant using the source image version in another tenant.

Azure CLI

```
# Set some variables
tenantID="<tenant ID for the source image version>"
subID="<subscription ID where the image version will be created>"
sourceImageVersionID="<resource ID of the source image version>"

# Sign in to the subscription where the new image version will be created
az login

# Sign in to the tenant where the source image version is available
az login --tenant $tenantID

# Sign back in to the subscription where the image version will be created and
ensure subscription context is set
az login
az account set --subscription $subID

# Create the image version from the source image version
az sig image-version create \
   --gallery-image-definition myImageDef \
   --gallery-image-version 1.0.0 \
   --gallery-name myGallery \
   --resource-group myResourceGroup \
   --image-version $sourceImageVersionID \
   --location myLocation
```

Create a VM from a generalized image version

Article • 08/22/2024

Create a VM from a generalized image version stored in an Azure Compute Gallery (formerly known as Shared Image Gallery). If you want to create a VM using a specialized image, see Create a VM from a specialized image.

This article shows how to create a VM from a generalized image:

- In your own gallery
- Shared within your organization using RBAC
- Shared across tenants using RBAC
- Shared to everyone in a community gallery
- Directly shared to your subscription or tenant

Your own gallery

CLI

List the image definitions in a gallery using az sig image-definition list to see the name and ID of the definitions.

Azure CLI

```
resourceGroup=myGalleryRG
gallery=myGallery
az sig image-definition list --resource-group $resourceGroup --gallery-
name $gallery --query "[].[name, id]" --output tsv
```

Create a VM using az vm create. To use the latest version of the image, set `--image` to the ID of the image definition.

This example is for creating a Linux VM secured with SSH. For Windows or to secure a Linux VM with a password, remove `--generate-ssh-keys` to be prompted for a password. If you want to supply a password directly, replace `--generate-ssh-keys` with `--admin-password`. Replace resource names as needed in this example.

Azure CLI

```
imgDef="/subscriptions/<subscription ID where the gallery is
located>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/gallerie
s/myGallery/images/myImageDefinition"
vmResourceGroup=myResourceGroup
location=eastus
vmName=myVM
adminUsername=azureuser

az group create --name $vmResourceGroup --location $location

az vm create\
   --resource-group $vmResourceGroup \
   --name $vmName \
   --image $imgDef \
   --admin-username $adminUsername \
   --generate-ssh-keys
```

You can also use a specific version by using the image version ID for the `--image` parameter. For example, to use image version *1.0.0* type: `--image "/subscriptions/<subscription ID where the gallery is located>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myGallery/images/myImageDefinition/versions/1.0.0"`.

RBAC - Shared within your organization

If the subscription where the gallery resides is within the same tenant, images shared through RBAC can be used to create VMs using the CLI and PowerShell.

You'll need to the `imageID` of the image you want to use and you need to make sure it's replicated to the region where you want to create the VM.

CLI

Make sure the state of the image is `Generalized`. If you want to use an image with the `Specialized` state, see Create a VM from a specialized image version.

Azure CLI

```
imgDef="/SharedGalleries/1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-
MYDIRECTSHARED/Images/myDirectDefinition/Versions/latest"
vmResourceGroup=myResourceGroup
location=westus
vmName=myVM
adminUsername=azureuser
```

```
az group create --name $vmResourceGroup --location $location

az vm create\
   --resource-group $vmResourceGroup \
   --name $vmName \
   --image $imgDef \
   --admin-username $adminUsername \
   --generate-ssh-keys
```

RBAC - Shared from another tenant

If the image you want to use is stored in a gallery that isn't in the same tenant (directory) then you need to sign in to each tenant to verify you have access.

You also need the `imageID` of the image you want to use and you need to make sure it's replicated to the region where you want to create the VM. You'll also need the `tenantID` for the source gallery and the `tenantID` for where you want to create the VM.

CLI

In this example, we're showing how to create a VM from a generalized image. If you're using a specialized image, see Create a VM using a specialized image version.

You need to sign in to the tenant where the image is stored, get an access token, then sign into the tenant where you want to create the VM. In this case, tenant1 is where the image is stored, and tenant2 is where you want to create the VM. This is how Azure authenticates that you have access to the image.

Azure CLI

```
tenant1='<ID for tenant 1>'
tenant2='<ID for tenant 2>'

az account clear
az login --tenant $tenant1
az account get-access-token
az login --tenant $tenant2
az account get-access-token
```

Create the VM. Replace the information in the example with your own. Before you create the VM, make sure that the image is replicated into the region where you want to create the VM.

Azure CLI

```
imageid="<ID of the image that you want to use>"
resourcegroup="<name for the resource group>"
location="<location where the image is replicated>"
user='<username for the VM>'
name='<name for the VM>'

az group create --location $location --resource-group $resourcegroup
az vm create \
  --resource-group $resourcegroup \
  --name $name \
  --image $imageid \
  --admin-username $user \
  --generate-ssh-keys
```

Community gallery

> **Important**
>
> Microsoft does not provide support for images in the community gallery.

Reporting issues with a community image

Using community-submitted virtual machine images has several risks. Images could contain malware, security vulnerabilities, or violate someone's intellectual property. To help create a secure and reliable experience for the community, you can report images when you see these issues.

The easiest way to report issues with a community gallery is to use the portal, which will pre-fill information for the report:

- For issues with links or other information in the fields of an image definition, select **Report community image**.
- If an image version contains malicious code or there are other issues with a specific version of an image, select **Report** under the **Report version** column in the table of image versions.

You can also use the following links to report issues, but the forms won't be pre-filled:

- Malicious images: Contact Abuse Report.
- Intellectual Property violations: Contact Infringement Report.

CLI

To create a VM using an image shared to a community gallery, use the unique ID of the image for the `--image` which will be in the following format:

```
/CommunityGalleries/<community gallery name, like: ContosoImages-
1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f>/Images/<image
name>/Versions/latest
```

Follow these instructions to get the list of Community images using CLI:

```
Step 1:  Show all 'Community images' in a specific location
az sig list-community --location westus2

Step 2: Once you have the public gallery name from Step 1, Get the Image
definition (Name) of the image by running the following command
az sig image-definition list-community --public-gallery-name <<public
gallery name>> --location westus2

Step 3: Finally, run the following command to list different image
versions available for the specific image
az sig image-version list-community --public-gallery-name
<<galleryname>> --gallery-image-definition <<image name>> --location
westus2
```

To get the public name of a community gallery from portal. Go to **Virtual machines** > **Create** > **Azure virtual machine** > **Image** > **See all images** > **Community Images** > **Public gallery name**.

In this example, we're creating a VM from a Linux image and creating SSH keys for authentication.

Azure CLI

```
imgDef="/CommunityGalleries/ContosoImages-1a2b3c4d-1234-abcd-1234-
1a2b3c4d5e6f>/Images/myLinuxImage/Versions/latest"
vmResourceGroup=myResourceGroup
location=eastus
vmName=myVM
adminUsername=azureuser

az group create --name $vmResourceGroup --location $location

az vm create\
```

```
    --resource-group $vmResourceGroup \
    --name $vmName \
    --image $imgDef \
    --admin-username $adminUsername \
    --generate-ssh-keys
```

When using a community image, you'll be prompted to accept the legal terms. The message looks like this:

Output

```
To create the VM from community gallery image, you must accept the
license agreement and privacy statement: http://contoso.com. (If you
want to accept the legal terms by default, please use the option '--
accept-term' when creating VM/VMSS) (Y/n):
```

Direct shared gallery

Important

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the Preview Terms for Azure Compute Gallery.

To publish images to a direct shared gallery during the preview, you need to register at https://aka.ms/directsharedgallery-preview. Creating VMs from a direct shared gallery is open to all Azure users.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

CLI

To create a VM using an image shared to your subscription or tenant, you need the unique ID of the image in the following format:

```
/SharedGalleries/<uniqueID>/Images/<image name>/Versions/latest
```

To find the `uniqueID` of a gallery that is shared with you, use az sig list-shared. In this example, we are looking for galleries in the West US region.

Azure CLI

```
region=westus
az sig list-shared --location $region --query "[].name" -o tsv
```

Use the gallery name to find the images that are available. In this example, we list all of the images in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

Azure CLI

```
galleryName="1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-myDirectShared"
 az sig image-definition list-shared \
   --gallery-unique-name $galleryName \
   --location $region \
   --query [*]."{Name:name,ID:uniqueId,OS:osType,State:osState}" -o
table
```

Make sure the state of the image is `Generalized`. If you want to use an image with the `Specialized` state, see Create a VM from a specialized image version.

Use the `Id` from the output, appended with `/Versions/latest` to use the latest version, as the value for `--image` to create a VM. In this example, we're creating a VM from a Linux image that is directly shared to us, and creating SSH keys for authentication.

Azure CLI

```
imgDef="/SharedGalleries/1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-
MYDIRECTSHARED/Images/myDirectDefinition/Versions/latest"
vmResourceGroup=myResourceGroup
location=westus
vmName=myVM
adminUsername=azureuser

az group create --name $vmResourceGroup --location $location

az vm create\
   --resource-group $vmResourceGroup \
   --name $vmName \
   --image $imgDef \
   --admin-username $adminUsername \
   --generate-ssh-keys
```

Create a VM using a specialized image version

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

Create a VM from a specialized image version stored in an Azure Compute Gallery (formerly known as Shared Image Gallery). If you want to create a VM using a generalized image version, see Create a VM from a generalized image version.

This article shows how to create a VM from a specialized image:

- In your own gallery
- Shared within your organization using RBAC
- Shared across tenants using RBAC
- Shared to everyone in a community gallery
- Directly shared to your subscription or tenant

> **ⓘ Important**
>
> When you create a new VM from a specialized image, the new VM retains the computer name of the original VM. Other computer-specific information, like the CMID, is also kept. This duplicate information can cause issues. When copying a VM, be aware of what types of computer-specific information your applications rely on.

Create a VM from your gallery

Create a VM from an internal gallery.

CLI

List the image definitions in a gallery using az sig image-definition list to see the name and ID of the definitions.

Azure CLI

```
resourceGroup=myGalleryRG
gallery=myGallery
az sig image-definition list \
   --resource-group $resourceGroup \
```

```
    --gallery-name $gallery \
    --query "[].[name, id]" \
    --output tsv
```

Create the VM using az vm create using the `--specialized` parameter to indicate that the image is a specialized image.

Use the image definition ID for `--image` to create the VM from the latest version of the image that is available. You can also create the VM from a specific version by supplying the image version ID for `--image`.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

Azure CLI

```
az group create --name myResourceGroup --location eastus
az vm create --resource-group myResourceGroup \
    --name myVM \
    --image "/subscriptions/<Subscription
ID>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myG
allery/images/myImageDefinition" \
    --specialized
```

RBAC - within your organization

If the subscription where the gallery resides is within the same tenant, images shared through RBAC can be used to create VMs using the CLI and PowerShell.

You'll need the `imageID` of the image you want to use and make sure the image is replicated to the region where you want to create the VM.

CLI

Azure CLI

```
image="/subscriptions/<Subscription
ID>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myG
allery/images/myImageDefinition"
vmResourceGroup='myResourceGroup'
location='westus'
vmName='myVM'

az group create --name $vmResourceGroup --location $location
```

```
az vm create\
   --resource-group $vmResourceGroup \
   --name $vmName \
   --image $image \
   --specialized
```

RBAC - from another tenant or organization

If the image you want to use is stored in a gallery that isn't in the same tenant (directory) then you will need to sign in to each tenant to verify you have access.

You'll need the `imageID` of the image you want to use and make sure the image is replicated to the region where you want to create the VM. You'll also need the `tenantID` for the source gallery and the `tenantID` for where you want to create the VM.

CLI

You need to sign in to the tenant where the image is stored, get an access token, then sign into the tenant where you want to create the VM. This is how Azure authenticates that you have access to the image.

Azure CLI

```
tenant1='<ID for tenant 1>'
tenant2='<ID for tenant 2>'

az account clear
az login --tenant $tenant1
az account get-access-token
az login --tenant $tenant2
az account get-access-token
```

Create the VM using az vm create using the `--specialized` parameter to indicate that the image is a specialized image.

Azure CLI

```
imageid=""/subscriptions/<Subscription
ID>/resourceGroups/myGalleryRG/providers/Microsoft.Compute/galleries/myG
allery/images/myImageDefinition""
resourcegroup="myResourceGroup"
location="West US 3"
```

```
name='myVM'

az group create --name $resourcegroup --location $location
az vm create --resource-group $resourcegroup \
    --name $name \
    --image $image \
    --specialized
```

Community gallery

> **Important**
>
> Microsoft does not provide support for images in the community gallery.

Reporting issues with a community image

Using community-submitted virtual machine images has several risks. Images could contain malware, security vulnerabilities, or violate someone's intellectual property. To help create a secure and reliable experience for the community, you can report images when you see these issues.

The easiest way to report issues with a community gallery is to use the portal, which will pre-fill information for the report:

- For issues with links or other information in the fields of an image definition, select **Report community image**.
- If an image version contains malicious code or there are other issues with a specific version of an image, select **Report** under the **Report version** column in the table of image versions.

You can also use the following links to report issues, but the forms won't be pre-filled:

- Malicious images: Contact Abuse Report.
- Intellectual Property violations: Contact Infringement Report.

CLI

To create a VM using an image shared to a community gallery, use the unique ID of the image for the `--image`, which will be in the following format:

```
```

```
/CommunityGalleries/<community gallery name, like: ContosoImages-
1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f>/Images/<image
name>/Versions/latest
```

As an end user, to get the public name of a community gallery, you need to use the portal. Go to **Virtual machines** > **Create** > **Azure virtual machine** > **Image** > **See all images** > **Community Images** > **Public gallery name**.

List all of the image definitions that are available in a community gallery using az sig image-definition list-community. In this example, we list all of the images in the *ContosoImage* gallery in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

Azure CLI

```
 az sig image-definition list-community \
   --public-gallery-name "ContosoImages-1a2b3c4d-1234-abcd-1234-
1a2b3c4d5e6f" \
   --location westus \
   --query [*]."{Name:name,ID:uniqueId,OS:osType,State:osState}" -o
table
```

To create a VM from a generalized image in a community gallery, see Create a VM from a generalized image version.

Create the VM using az vm create using the `--specialized` parameter to indicate that the image is a specialized image.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

Azure CLI

```
az group create --name myResourceGroup --location eastus
az vm create --resource-group myResourceGroup \
    --name myVM \
    --image "/CommunityGalleries/ContosoImages-f61bb1d9-3c5a-4ad2-99b5-
744030225de6/Images/LinuxSpecializedVersions/latest" \
    --specialized
```

When using a community image, you'll be prompted to accept the legal terms. The message will look like this:

Output

```
To create the VM from community gallery image, you must accept the
license agreement and privacy statement: http://contoso.com. (If you
want to accept the legal terms by default, please use the option '--
accept-term' when creating VM/VMSS) (Y/n):
```

Direct shared gallery

> **ⓘ Important**
>
> Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the Preview Terms for Azure Compute Gallery.
>
> To publish images to a direct shared gallery during the preview, you need to register at https://aka.ms/directsharedgallery-preview. Creating VMs from a direct shared gallery is open to all Azure users.
>
> During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

CLI

To create a VM using the latest version of an image shared to your subscription or tenant, you need the ID of the image in the following format:

```
/SharedGalleries/<uniqueID>/Images/<image name>/Versions/latest
```

To find the `uniqueID` of a gallery that is shared with you, use az sig list-shared. In this example, we're looking for galleries in the West US region.

Azure CLI

```azurecli
region=westus
az sig list-shared --location $region --query "[].name" -o tsv
```

Use the gallery name to find all of the images that are available. In this example, we list all of the images in *West US* and by name, the unique ID that is needed to create

a VM, OS and OS state.

Azure CLI

```
galleryName="1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-myDirectShared"
 az sig image-definition list-shared \
   --gallery-unique-name $galleryName \
   --location $region \
   --query [*]."{Name:name,ID:uniqueId,OS:osType,State:osState}" -o
table
```

Make sure the state of the image is `Specialized`. If you want to use an image with the `Generalized` state, see Create a VM from a generalized image version.

Create the VM using az vm create using the `--specialized` parameter to indicate that the image is a specialized image.

Use the `Id`, appended with `/Versions/latest` to use the latest version, as the value for `--image`` to create a VM.

In this example, we're creating a VM from the latest version of the *myImageDefinition* image.

Azure CLI

```
imgDef="/SharedGalleries/1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-
MYDIRECTSHARED/Images/myDirectDefinition/Versions/latest"
vmResourceGroup=myResourceGroup
location=westus
vmName=myVM

az group create --name $vmResourceGroup --location $location

az vm create\
   --resource-group $vmResourceGroup \
   --name $vmName \
   --image $imgDef \
   --specialized
```

List, update, and delete gallery resources

Article • 08/22/2024

You can manage your Azure Compute Gallery (formerly known as Shared Image Gallery) resources using the Azure CLI or Azure PowerShell.

List galleries shared with you

CLI

List Galleries shared with your subscription.

Azure CLI

```
region=westus
az sig list-shared --location $region
```

List Galleries shared with your tenant.

Azure CLI

```
region=westus
az sig list-shared --location $region --shared-to tenant
```

The output will contain the public `name` and `uniqueID` of the gallery that is shared with you. You can use the name of the gallery to query for images that are available through the gallery.

Here is example output:

Output

```
[
  {
    "location": "westus",
    "name": "1231b567-8a99-1a2b-1a23-123456789abc-MYDIRECTSHARED",
    "uniqueId": "/SharedGalleries/1231b567-8a99-1a2b-1a23-123456789abc-
MYDIRECTSHARED"
  }
]
```

Update resources

There are some limitations on what can be updated. The following items can be updated:

Azure Compute Gallery:

- Description

Image definition:

- Recommended vCPUs
- Recommended memory
- Description
- End of life date

Image version:

- Regional replica count
- Target regions
- Exclusion from latest
- End of life date

CLI

Update the description of a gallery using (az sig update.

Azure CLI

```
az sig update \
   --gallery-name myGallery \
   --resource-group myGalleryRG \
   --set description="My updated description."
```

Update the description of an image definition using az sig image-definition update.

Azure CLI

```
az sig image-definition update \
   --gallery-name myGallery\
   --resource-group myGalleryRG \
   --gallery-image-definition myImageDefinition \
   --set description="My updated description."
```

Update an image version to add a region to replicate to using az sig image-version update. This change will take a while as the image gets replicated to the new region.

Azure CLI

```
az sig image-version update \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   --gallery-image-version 1.0.0 \
   --add publishingProfile.targetRegions  name=eastus
```

This example shows how to use az sig image-version update to exclude this image version from being used as the *latest* image.

Azure CLI

```
az sig image-version update \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   --gallery-image-version 1.0.0 \
   --set publishingProfile.excludeFromLatest=true
```

This example shows how to use az sig image-version update to include this image version in being considered for *latest* image.

Azure CLI

```
az sig image-version update \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   --gallery-image-version 1.0.0 \
   --set publishingProfile.excludeFromLatest=false
```

Delete resources

You have to delete resources in reverse order, by deleting the image version first. After you delete all of the image versions, you can delete the image definition. After you delete all image definitions, you can delete the gallery.

CLI

Before you can delete a community shared gallery, you need to use az sig share reset to stop sharing the gallery publicly.

Delete an image version using az sig image-version delete.

Azure CLI

```
az sig image-version delete \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   --gallery-image-version 1.0.0
```

Delete an image definition using az sig image-definition delete.

Azure CLI

```
az sig image-definition delete \
   --resource-group myGalleryRG \
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition
```

Delete a gallery using az sig delete.

Azure CLI

```
az sig delete \
   --resource-group myGalleryRG \
   --gallery-name myGallery
```

Community galleries

ⓘ Important

Azure Compute Gallery – community galleries is currently in PREVIEW and subject to the **Preview Terms for Azure Compute Gallery - community gallery**.

To publish a community gallery, you'll need to **set up preview features in your Azure subscription**. Creating VMs from community gallery images is open to all Azure users.

To list your own galleries, and output the public names for your community galleries:

Azure CLI

```
az sig list --query [*]."
{Name:name,PublicName:sharingProfile.communityGalleryInfo.publicNames}"
```

> **Note**
>
> As an end user, to get the public name of a community gallery, you currently need to use the portal. Go to **Virtual machines** > **Create** > **Azure virtual machine** > **Image** > **See all images** > **Community Images** > **Public gallery name**.

List all of the image definitions that are available in a community gallery using az sig image-definition list-community.

In this example, we list all of the images in the *ContosoImage* gallery in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

Azure CLI

```
 az sig image-definition list-community \
   --public-gallery-name "ContosoImages-1a2b3c4d-1234-abcd-1234-
1a2b3c4d5e6f" \
   --location westus \
   --query [*]."{Name:name,ID:uniqueId,OS:osType,State:osState}" -o table
```

List image versions shared in a community gallery using az sig image-version list-community:

Azure CLI

```
az sig image-version list-community \
   --location westus \
   --public-gallery-name "ContosoImages-1a2b3c4d-1234-abcd-1234-
1a2b3c4d5e6f" \
   --gallery-image-definition myImageDefinition \
   --query [*]."{Name:name,UniqueId:uniqueId}" \
   -o table
```

Direct shared galleries

> **Important**

Azure Compute Gallery – direct shared gallery is currently in PREVIEW and subject to the Preview Terms for Azure Compute Gallery.

To publish images to a direct shared gallery during the preview, you need to register at https://aka.ms/directsharedgallery-preview. Creating VMs from a direct shared gallery is open to all Azure users.

During the preview, you need to create a new gallery, with the property `sharingProfile.permissions` set to `Groups`. When using the CLI to create a gallery, use the `--permissions groups` parameter. You can't use an existing gallery, the property can't currently be updated.

To find the `uniqueID` of a gallery that is shared with you, use az sig list-shared. In this example, we are looking for galleries in the West US region.

Azure CLI

```
region=westus
az sig list-shared --location $region --query "[].uniqueId" -o tsv
```

List all of the image definitions that are shared directly with you, use az sig image-definition list-shared.

In this example, we list all of the images in the gallery in *West US* and by name, the unique ID that is needed to create a VM, OS and OS state.

Azure CLI

```
name="1a2b3c4d-1234-abcd-1234-1a2b3c4d5e6f-myDirectShared"
 az sig image-definition list-shared \
   --gallery-unique-name $name
   --location $region \
   --query [*]."{Name:name,ID:uniqueId,OS:osType,State:osState}" -o table
```

List image versions directly shared to you using az sig image-version list-shared:

Azure CLI

```
imgDef="myImageDefinition"
az sig image-version list-shared \
   --location $region \
   --public-gallery-name $name \
   --gallery-image-definition $imgDef \
   --query [*]."{Name:name,UniqueId:uniqueId}" \
   -o table
```

Next steps

- Create an image definition and an image version.
- Create a VM from a generalized or specialized image in an Azure Compute Gallery.

Troubleshoot images in an Azure Compute Gallery

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

If you have problems performing any operations on Azure Compute Gallery (formerly known as Shared Image Gallery) resources, like galleries, image definitions, and image versions, run the failing command again in debug mode. You activate debug mode by passing the `--debug` switch with the Azure CLI and the `-Debug` switch with PowerShell. After you've located the error, follow this article to troubleshoot it.

Creating or modifying a gallery

The source id: <resourceID> must either be a managed image, virtual machine or another gallery image version	The <resourceID> value is incorrectly formatted	If you're using a VM, managed image, or gallery image version as the source image, check that the resource ID of the VM, managed image, or gallery image version is correct

Error Message	Cause	Mitigation
The source id: <resourceID> must be a managed disk or snapshot	The <resourceID> value is incorrectly formatted	If you're using disks and/or disk snapshots as sources for the image version, check that the resource IDs of the disks and/or disk snapshots are correct
Cannot create Gallery Image Version from: <resourceID> since the OS State in the parent gallery image (<OsState_1>) is not <OsState_2>	The operating system state (Generalized or Specialized) does not match the operating system state specified in the image definition	Either choose a source based on a VM with the operating system state of <OsState_1> or create a new image definition for VMs based on <OsState_2>
The resource with id '<resourceID>' has a different Hypervisor generation ['<V#_1>'] than the parent gallery image Hypervisor generation ['<V#_2>']	The hypervisor generation of the image version does not match the hypervisor generation specified in the image definition. The image definition operating system is <V#_1>, and the image version operating system is <V#_2>	Either choose a source with the same hypervisor generation as the image definition or create/choose a new image definition that has the same hypervisor generation as the image version
The resource with id '<resourceID>' has a different OS type ['<OsType_1>'] than the parent gallery image OS type generation ['<OsType _2>']	The hypervisor generation of the image version does not match the hypervisor generation specified in the image definition. The image definition operating system is <OsType_1>, and the image version operating system is <OsType_2>	Either choose a source with the same operating system (Linux/Windows) as the image definition or create/choose a new image definition that has the same operating system generation as the image version
Source virtual machine <resourceID> cannot contain an ephemeral OS disk	The source at <resourceID> contains an ephemeral OS disk. The Azure Compute Gallery does not currently support ephemeral OS disks	Choose a different source based on a VM that does not use an ephemeral OS disk
Source virtual machine <resourceID> cannot contain disk ['<diskID>'] stored in an UltraSSD account type	The disk <diskID> is an Ultra SSD disk. The Azure Compute Gallery does not currently support Ultra SSD disks	Use a source that contains only Premium SSD, Standard SSD, and/or Standard HDD managed disks

Error Message	Cause	Mitigation
Source virtual machine <resourceID > must be created from Managed Disks	The virtual machine in <resourceID> uses unmanaged disks	Use a source based on a VM that contains only Premium SSD, Standard SSD, and/or Standard HDD managed disks
Too many requests on source '<resourceID>'. Please reduce the number of requests on the source or wait some time before retrying	The source for this image version is currently being throttled because of too many requests	Try to create the image version later
The disk encryption set '<diskEncryptionSetID>' must be in the same subscription '<subscriptionID>' as the gallery resource	Disk encryption sets can be used only in the same subscription and region in which they were created	Create or use an encryption set in the same subscription and region as the image version
Encrypted source: '<resourceID>' is in a different subscription ID than the current gallery image version subscription '<subscriptionID_1>'. Please retry with an unencrypted source(s) or use the source's subscription '<subcriptionID_2>' to create the gallery image version	The Azure Compute Gallery does not currently support creating image versions in another subscription from another source image if the source image is encrypted	Use an unencrypted source or create the image version in the same subscription as the source
The disk encryption set <diskEncryptionSetID> was not found	The disk encryption might be incorrect	Check that the resource ID of the disk encryption set is correct
The image version name is invalid. The image version name should follow Major(int).Minor(int).Patch(int) format, for e.g: 1.0.0, 2018.12.1 etc	The valid format for an image version is three integers separated by a period. The image version name did not meet the valid format	Use an image version name that follows the format Major(int).Minor(int).Patch(int). For example: 1.0.0. or 2018.12.1
The value of parameter galleryArtifactVersion.properties.publishingProfile.targetRegions.encryption.dataDiskImages.diskEncryptionSetId is invalid	The resource ID of the disk encryption set used on a data disk image uses an invalid format	Ensure that the resource ID of the disk encryption set follows the format /subscriptions/<subscriptionID>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/<diskEncryptionSetName>
The value of parameter galleryArtifactVersion.properties.publishingProfile.targetRegions.encryption.osDiskImage.diskEncryptionSetId is invalid	The resource ID of the disk encryption set used on the OS disk image uses an invalid format	Ensure that the resource ID of the disk encryption set follows the format /subscriptions/<subscriptionID>/resourceGroups/<resourceGroupName>/pro

Error Message	Cause	Mitigation
		viders/Microsoft.Compute/<diskEncryptionSetName>
Cannot specify new data disk image encryption lun [<number>] with a disk encryption set in region [<region>] for update gallery image version request. To update this version, remove the new lun. If you need to change the data disk image encryption settings, you must create a new gallery image version with the correct settings.	You added encryption to the data disk of an existing image version. You can't add encryption to an existing image version	Create a new gallery image version or remove the added encryption settings
The gallery artifact version source can only be specified either directly under storageProfile or within individual OS or data disks. One and only one source type (user image, snapshot, disk, virtual machine) can be provided	The source ID is missing	Ensure that the source ID of the source is present
Source was not found: <resourceID>. Please make sure the source exists	The resource ID of the source might be incorrect	Ensure that the resource ID of the source is correct
A disk encryption set is required for disk 'galleryArtifactVersion.properties.publishingProfile.targetRegions.encryption.osDiskImage.diskEncryptionSetId' in target region '<region_1>' since disk encryption set '<diskEncryptionSetID>' is used for the corresponding disk in region '<region_2>'	Encryption has been used on the OS disk in <region_2>, but not in <region_1>	If you're using encryption on the OS disk, use encryption in all regions
A disk encryption set is required for disk 'LUN <number>' in target region '<region_1>' since disk encryption set '<diskEncryptionSetID>' is used for the corresponding disk in region '<region_2>'	Encryption has been used on the data disk at LUN <number> in <region_2>, but not in <region_1>	If you're using encryption on a data disk, use encryption in all regions
An invalid lun [<number>] was specified in encryption.dataDiskImages. The lun must be one of the following values ['0,9']	The LUN specified for the encryption does not match any of the LUNs for disks attached to the VM	Change the LUN in the encryption to the LUN of a data disk present in the VM
Duplicate luns '<number>' were specified in target region '<region>' en	The encryption settings used in <region> specified	Change the LUN in <region> to make sure that all the LUNs

Error Message	Cause	Mitigation
cryption.dataDiskImages	a LUN at least twice	are unique in <region>
OSDiskImage and DataDiskImage cannot point to same blob <sourceID>	The sources for the OS disk and at least one data disk are not unique	Change the source for the OS disk and/or data disks to ensure that the OS disk as well as each data disk is unique
Duplicate regions are not allowed in target publishing regions	A region is listed among the publishing regions more than once	Remove the duplicate region
Adding new Data Disks or changing the LUN of a Data Disk in an existing Image is not allowed	An update call to the image version either contains a new data disk or has a new LUN for a disk	Use the LUNs and data disks of the existing image version
The disk encryption set <diskEncryptionSetID> must be in the same subscription <subscriptionID> as the gallery resource	The Azure Compute Gallery does not currently support using a disk encryption set in a different subscription	Create the image version and disk encryption set in the same subscription
Replication failed in this region due to 'The GalleryImageVersion source resource size 2520 exceeds the max size 2048 supported	A data disk in the source is greater than 2TB	Resize the data disk to under 2 TB
Operation 'Update Gallery Image Version' is not on allowed on <version Number>; since it is marked for deletion. You can only retry the Delete operation (or wait for an ongoing one to complete)	You attempted to update a gallery image version that is in the process of being deleted	Wait for the deletion event to complete and recreate the image version again
Encryption is not supported for source resource '<sourceID>'. Please use a different source resource type which supports encryption or remove encryption properties	Currently the Azure Compute Gallery only supports encryption for VMs, disks, snapshots and managed images. One of the sources provided for the image version is not in the previous list of sources that support encryption	Remove the disk encryption set from the image version and contact the support team.

Creating or updating a VM or scale sets from an image version

Error Message	Cause	Mitigation
There is no latest image version exists for "<imageDefinitionResourceID>"	The image definition you used to deploy the virtual machine does not contain any image versions that are included in latest	Ensure that there is at least one image version that has 'Exclude from latest' set to False
The gallery image /subscriptions/<subscriptionID>/resourceGroups/<resourceGroup>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageName>/versions/<versionNumber> is not available in <region> region. Please contact image owner to replicate to this region, or change your requested region.	The version selected for deployment does not exist or does not have a replica in the indicated region	Ensure that the name of the image resource is correct and that there is at least one replica in the indicated region
The gallery image /subscriptions/<subscriptionID>/resourceGroups/<resourceGroup>/providers/Microsoft.Compute/galleries/<galleryName>/images/<imageName> is not available in <region> region. Please contact image owner to replicate to this region, or change your requested region	The image definition selected for deployment does not have any image versions that are included in latest and also in the indicated region	Ensure that there is at least one image version in the region that has 'Exclude from latest' set to False
The client has permission to perform action 'Microsoft.Compute/galleries/images/versions/read' on scope <resourceID>, however the current tenant <tenantID> is not authorized to access linked subscription <subscriptionID>	The virtual machine or scale set was created through a gallery image in another tenant. You've tried to make a change to the virtual machine or scale set, but you don't have access to the subscription that owns the image	Contact the owner of the subscription of the image version to grant read access to the image version
The gallery image <resourceID> is not available in <region> region. Please contact image owner to replicate to this region, or change your requested region.	The VM is being created in a region that's not among the list of published regions for the gallery image.	Either replicate the image to the region or create a VM in one of the regions in the gallery image's publishing regions
Parameter 'osProfile' is not allowed	Admin username, password, or SSH keys were provided for a VM that was created from a specialized image version	Don't include the admin username, password, or SSH keys if you intend to create a VM from that image. Otherwise, use a generalized ima

Error Message	Cause	Mitigation
		ge version and supply the admin username, password, or SSH keys
Required parameter 'osProfile' is missing (null)	The VM is created from a generalized image, and it's missing the admin username, password, or SSH keys. Because generalized images don't retain the admin username, password, or SSH keys, these fields must be specified during creation of a VM or scale set	Specify the admin username, password, or SSH keys, or use a specialized image version
Cannot update Virtual Machine Scale Set <vmssName> as the current OS state of the VM Scale Set is Generalized which is different from the updated gallery image OS state which is Specialized	The current source image for the scale set is a generalized source image, but it's being updated with a source image that is specialized. The current source image and the new source image for a scale set must be of the same state	To update the scale set, use a generalized image version
Disk encryption set <diskEncryptionSetID> in Azure Compute Gallery <versionID> belongs to subscription <subscriptionID_1> and cannot be used with resource '' in subscription <subscriptionID_2>	The disk encryption set used to encrypt the image version resides in a different subscription than the subscription to host the image version	Use the same subscription for the image version and disk encryption set
The resource with id <vmID> has a different plan ['{"name":"<name>","publisher":"<publisher>","product":"<product>","promotionCode":"<promotionCode>"}'] than the parent gallery image plan ['null']	The parent image definition for the image version being deployed does not have a purchase plan information	Create an image definition with the same purchase plan details from the error message and create the image version within the image definition
The VM or virtual machine scale set creation takes a long time	NA	Verify that the **OSType** of the image version that you're trying to create the VM or virtual machine scale set from has the same **OSType** of the source that you used to create the image version

Creating a disk from an image version

Expand table

Error Message	Cause	Mitigation
The value of parameter imageReference is invalid.	You've tried to export from a gallery Image version to a disk but used a LUN position that does not exist on the image.	Check the image version to see what LUN positions are in use

Sharing resources

The sharing of gallery, image definition, and image version resources across subscriptions is enabled using Azure role-based access control (Azure RBAC).

Replication speed

Use the **--expand ReplicationStatus** flag to check if the replication to all the specified target regions has finished. If not, wait for up to six hours for the job to finish. If it fails, trigger the command again to create and replicate the image version. If there are many target regions that the image version is being replicated to, consider doing the replication in phases.

Azure limits and quotas

Azure limits and quotas apply to all Azure Compute Gallery, image definition, and image version resources. Make sure you're within the limits for your subscriptions.

Create an encrypted image version with customer-managed keys

Article • 02/20/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Images in an Azure Compute Gallery (formerly known as Shared Image Gallery) are stored as snapshots. These images are automatically encrypted through server-side 256-bit encryption AES encryption. Server-side encryption is also FIPS 140-2 compliant. For more information about the cryptographic modules underlying Azure managed disks, see Cryptography API: Next Generation.

You can rely on platform-managed keys for the encryption of your images, or use your own keys. You can also use both of these features together for doubled encryption. If you choose to manage encryption with your own keys, you can specify a *customer-managed key* to use for encrypting and decrypting all disks in your images.

Server-side encryption through customer-managed keys uses Azure Key Vault. You can either import your RSA keys to your key vault or generate new RSA keys in Azure Key Vault.

Prerequisites

This article requires that you already have a disk encryption set in each region where you want to replicate your image:

- To use only a customer-managed key, see the articles about enabling customer-managed keys with server-side encryption by using the Azure portal or PowerShell.
- To use both platform-managed and customer-managed keys (for double encryption), see the articles about enabling double encryption at rest by using the Azure portal or PowerShell.

> **Important**
>
> You must use the link https://aka.ms/diskencryptionupdates to access the Azure portal. Double encryption at rest is not currently visible in the public Azure portal unless you use that link.

Limitations

When you're using customer-managed keys for encrypting images in an Azure Compute Gallery, these limitations apply:

- Encryption key sets must be in the same subscription as your image.
- Encryption key sets are regional resources, so each region requires a different encryption key set.
- After you've used your own keys to encrypt an image, you can't go back to using platform-managed keys for encrypting those images.
- ACG Image version source encrypted with CMK cannot be used as source to create another ACG Image version.
- Some of the features like replicating an SSE+CMK image, creating an image from SSE+CMK encrypted disk etc. are not supported through portal.

Creating the Image

PowerShell

To specify a disk encryption set for an image version, use New-AzGalleryImageVersion with the `-TargetRegion` parameter:

Azure PowerShell

```
$sourceId = <ID of the image version source>
$osDiskImageEncryption = @{DiskEncryptionSetId='subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/myRG/providers/Microsoft.Compute/diskEncryptionSets/myDESet'}
$dataDiskImageEncryption1 = @{DiskEncryptionSetId='subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/myRG/providers/Microsoft.Compute/diskEncryptionSets/myDESet1';Lun=1}
$dataDiskImageEncryption2 = @{DiskEncryptionSetId='subscriptions/00000000-0000-0000-0000-000000000000/resourceGroups/myRG/providers/Microsoft.Compute/diskEncryptionSets/myDESet2';Lun=2}
$dataDiskImageEncryptions = @($dataDiskImageEncryption1,$dataDiskImageEncryption2)
$encryption1 = @{OSDiskImage=$osDiskImageEncryption;DataDiskImages=$dataDiskImageEncryptions}
$region1 = @{Name='West
```

```
US';ReplicaCount=1;StorageAccountType=Standard_LRS;Encryption=$encryptio
n1}
$eastUS2osDiskImageEncryption =
@{DiskEncryptionSetId='subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myRG/providers/Microsoft.Compute/diskEncrypt
ionSets/myEastUS2DESet'}
$eastUS2dataDiskImageEncryption1 =
@{DiskEncryptionSetId='subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myRG/providers/Microsoft.Compute/diskEncrypt
ionSets/myEastUS2DESet1';Lun=1}
$eastUS2dataDiskImageEncryption2 =
@{DiskEncryptionSetId='subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/myRG/providers/Microsoft.Compute/diskEncrypt
ionSets/myEastUS2DESet2';Lun=2}
$eastUS2DataDiskImageEncryptions =
@($eastUS2dataDiskImageEncryption1,$eastUS2dataDiskImageEncryption2)
$encryption2 =
@{OSDiskImage=$eastUS2osDiskImageEncryption;DataDiskImages=$eastUS2DataD
iskImageEncryptions}
$region2 = @{Name='East US
2';ReplicaCount=1;StorageAccountType=Standard_LRS;Encryption=$encryption
2}
$targetRegion = @($region1, $region2)
```

Create the image

```
New-AzGalleryImageVersion `
   -ResourceGroupName $rgname `
   -GalleryName $galleryName `
   -GalleryImageDefinitionName $imageDefinitionName `
   -Name $versionName -Location $location `
   -SourceImageId $sourceId `
   -ReplicaCount 2 `
   -StorageAccountType Standard_LRS `
   -PublishingProfileEndOfLifeDate '2020-12-01' `
   -TargetRegion $targetRegion
```

Create the VM

You can create a virtual machine (VM) from an Azure Compute Gallery and use customer-managed keys to encrypt the disks. The syntax is the same as creating a generalized or specialized VM from an image. Use the extended parameter set and add `Set-AzVMOSDisk -Name $($vmName +"_OSDisk") -DiskEncryptionSetId $diskEncryptionSet.Id -CreateOption FromImage` to the VM configuration.

For data disks, add the `-DiskEncryptionSetId $setID` parameter when you use Add-AzVMDataDisk.

Next steps

Export an image version to a managed disk

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can export an image version's OS or data disk as a managed disk from an image version, which is stored in an Azure Compute Gallery (formerly known as Shared Image Gallery).

CLI

List the image versions in a gallery using az sig image-version list. In this example, we're looking for all of the image versions that are part of the *myImageDefinition* image definition in the *myGallery* gallery.

Azure CLI

```
az sig image-version list \
   --resource-group myResourceGroup\
   --gallery-name myGallery \
   --gallery-image-definition myImageDefinition \
   -o table
```

Set the `source` variable to the ID of the image version, then use az disk create to create the managed disk.

In this example, we export the OS disk of the image version to create a managed disk named *myManagedOSDisk*, in the *EastUS* region, in a resource group named *myResourceGroup*.

Azure CLI

```
source="/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<galleryImageDefinition>/versions/<imageVersion>"

az disk create --resource-group myResourceGroup --location EastUS --name myManagedOSDisk --gallery-image-reference $source
```

If you want to export a data disk from the image version, add `--gallery-image-reference-lun` to specify the LUN location of the data disk to be exported.

In this example, we export the data disk located at LUN 0 of the image version to create a managed disk named *myManagedDataDisk*, in the *EastUS* region, in a resource group named *myResourceGroup*.

Azure CLI

```
source="/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Compute/galleries/<galleryName>/images/<galleryImageDefinition>/versions/<imageVersion>"

az disk create --resource-group myResourceGroup --location EastUS --name myManagedDataDisk --gallery-image-reference $source --gallery-image-reference-lun 0
```

PowerShell

List the image versions in a gallery using Get-AzResource.

Azure PowerShell

```
Get-AzResource `
   -ResourceType Microsoft.Compute/galleries/images/versions | `
   Format-Table -Property Name,ResourceId,ResourceGroupName
```

Once you have all of the information you need, you can use Get-AzGalleryImageVersion to get the source image version you want to use and assign it to a variable. In this example, we're getting the `1.0.0` image version, of the `myImageDefinition` definition, in the `myGallery` source gallery, in the `myResourceGroup` resource group.

Azure PowerShell

```
$sourceImgVer = Get-AzGalleryImageVersion `
   -GalleryImageDefinitionName myImageDefinition `
   -GalleryName myGallery `
   -ResourceGroupName myResourceGroup `
   -Name 1.0.0
```

After setting the `source` variable to the ID of the image version, use New-AzDiskConfig to create a disk configuration, then New-AzDisk to create the disk.

In this example, we export the OS disk of the image version to create a managed disk named *myManagedOSDisk*, in the *EastUS* region, in a resource group named *myResourceGroup*.

Create a disk configuration.

Azure PowerShell

```
$diskConfig = New-AzDiskConfig `
   -Location EastUS `
   -CreateOption FromImage `
   -GalleryImageReference @{Id = $sourceImgVer.Id}
```

Create the disk.

Azure PowerShell

```
New-AzDisk -Disk $diskConfig `
   -ResourceGroupName myResourceGroup `
   -DiskName myManagedOSDisk
```

If you want to export a data disk on the image version, add a LUN ID to the disk configuration to specify the LUN location of the data disk to export.

In this example, we export the data disk located at LUN 0 of the image version to create a managed disk named *myManagedDataDisk*, in the *EastUS* region, in a resource group named *myResourceGroup*.

Create a disk configuration.

Azure PowerShell

```
$diskConfig = New-AzDiskConfig `
   -Location EastUS `
   -CreateOption FromImage `
   -GalleryImageReference @{Id = $sourceImgVer.Id; Lun=0}
```

Create the disk.

Azure PowerShell

```
New-AzDisk -Disk $diskConfig `
   -ResourceGroupName myResourceGroup `
   -DiskName myManagedDataDisk
```

Next steps

You can also create an image version from a managed disk.

Migrate Managed image to Azure compute gallery image version

Applies to: ✔ Linux Virtual Machine ✔ Windows Virtual Machine ✔ Virtual Machine Flex Scale Sets

Managed images is legacy method to generalize and capture Virtual Machine image. For the most current technology, customers are encouraged to use Azure compute gallery. All new features, like Arm64, Trusted launch, and Confidential Virtual Machine are only supported through Azure compute gallery. If you have an existing managed image, you can use it as a source and create an Azure compute gallery image.

Before you begin

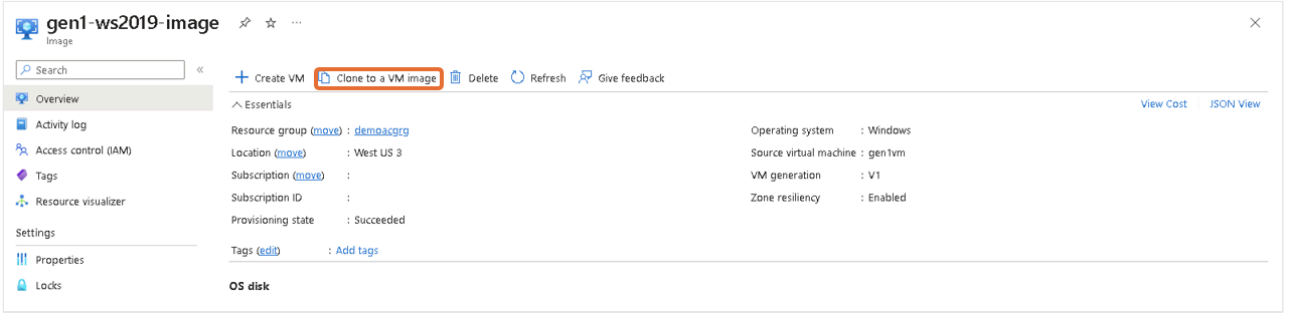
- Screenshot that shows the creation of an Azure Compute Gallery..
- Assign `Reader` permission on source managed image.
- Assign `Contributor` permission on target Azure compute gallery image definition.

Migrate Managed image to Azure Compute Gallery image

Portal

This section steps through using the Azure portal to migrate Managed image to existing Azure Compute Gallery.

1. Sign-in to Azure portal.
2. Navigate to `Managed image` to be migrated and select **Clone to a VM image**.



3. Provide following details on the `Create VM image version` page and select **Next : Replication >**:

   - Version number

- Target Azure compute gallery
- Target Virtual Machine image definition

4. Select following `Replication` configuration or select default values and select **Next : Encryption >**:

   - Default storage sku
   - Default replication count
   - Target replication regions

5. Select `SSE encryption type` or select default `Encryption at-rest with a platform managed key` and select **Next : Tags >**.

6. *Optional* Assign resource tags.

7. Validate the configuration on `Review + Create` page and select **Create** to complete the migration.

Next steps

Replace managed image reference with Azure compute gallery image version in the Virtual machine and flex scale sets deployment templates.

Supply Azure Marketplace purchase plan information when creating images

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

If you're creating an image in a shared gallery using an Azure Marketplace image source, you'll likely need to track purchase plan information. This article shows you how to find purchase plan information for a VM when creating an image definition. We also cover using this information to simplify supplying the purchase plan information when creating a VM for an image.

For more information about finding and using Marketplace images, see Find and use Azure Marketplace images.

Get the source VM information

If you still have the original VM, you can get the plan name, publisher, and product information from it using Get-AzVM. This example gets a VM named *myVM* in the *myResourceGroup* resource group and then displays the purchase plan information for the VM.

Azure PowerShell

```
$vm = Get-azvm `
   -ResourceGroupName myResourceGroup `
   -Name myVM
$vm.Plan
```

Create the image definition

Get the gallery you want to use to store the image. You can list all of the galleries first.

Azure PowerShell

```
Get-AzResource -ResourceType Microsoft.Compute/galleries | Format-Table
```

Then create variables for the gallery you want to use. In this example, we're creating a variable named `$gallery` for *myGallery* in the *myGalleryRG* resource group.

Azure PowerShell

```
$gallery = Get-AzGallery `
   -Name myGallery `
   -ResourceGroupName myGalleryRG
```

Create the image definition, using the `-PurchasePlanPublisher`, `-PurchasePlanProduct`, and `-PurchasePlanName` parameters.

Azure PowerShell

```
 $imageDefinition = New-AzGalleryImageDefinition `
   -GalleryName $gallery.Name `
   -ResourceGroupName $gallery.ResourceGroupName `
   -Location $gallery.Location `
   -Name 'myImageDefinition' `
   -OsState specialized `
   -OsType Linux `
   -Publisher 'myPublisher' `
   -Offer 'myOffer' `
   -Sku 'mySKU' `
   -PurchasePlanPublisher $vm.Plan.Publisher `
   -PurchasePlanProduct $vm.Plan.Product `
   -PurchasePlanName  $vm.Plan.Name
```

Then create your image version using New-AzGalleryImageVersion.

Create the VM

When you go to create a VM from the image, you can use the information from the image definition to pass in the publisher information using Set-AzVMPlan.

Azure PowerShell

```
# Create some variables for the new VM.
$resourceGroup = "mySIGPubVM"
$location = "West Central US"
$vmName = "mySIGPubVM"

# Create a resource group
New-AzResourceGroup -Name $resourceGroup -Location $location

# Create the network resources.
$subnetConfig = New-AzVirtualNetworkSubnetConfig `
   -Name mySubnet `
   -AddressPrefix 192.168.1.0/24
$vnet = New-AzVirtualNetwork `
   -ResourceGroupName $resourceGroup `
```

```
    -Location $location `
    -Name MYvNET `
    -AddressPrefix 192.168.0.0/16 `
    -Subnet $subnetConfig
$pip = New-AzPublicIpAddress `
    -ResourceGroupName $resourceGroup `
    -Location $location `
   -Name "mypublicdns$(Get-Random)" `
   -AllocationMethod Static `
   -IdleTimeoutInMinutes 4
$nsgRuleRDP = New-AzNetworkSecurityRuleConfig `
    -Name myNetworkSecurityGroupRuleRDP  `
    -Protocol Tcp `
    -Direction Inbound `
    -Priority 1000 `
    -SourceAddressPrefix * `
    -SourcePortRange * `
    -DestinationAddressPrefix * `
    -DestinationPortRange 3389 -Access Deny
$nsg = New-AzNetworkSecurityGroup `
    -ResourceGroupName $resourceGroup `
    -Location $location `
    -Name myNetworkSecurityGroup `
    -SecurityRules $nsgRuleRDP
$nic = New-AzNetworkInterface `
    -Name $vmName `
    -ResourceGroupName $resourceGroup `
    -Location $location `
   -SubnetId $vnet.Subnets[0].Id `
   -PublicIpAddressId $pip.Id `
   -NetworkSecurityGroupId $nsg.Id

# Create a virtual machine configuration using Set-AzVMSourceImage -Id
$imageDefinition.Id to use the latest available image version. Set-AZVMPlan
is used to pass the plan information in for the VM.

$vmConfig = New-AzVMConfig `
    -VMName $vmName `
    -VMSize Standard_D1_v2   | `
    Set-AzVMSourceImage -Id $imageDefinition.Id | `
    Set-AzVMPlan `
      -Publisher $imageDefinition.PurchasePlan.Publisher `
      -Product $imageDefinition.PurchasePlan.Product `
      -Name $imageDefinition.PurchasePlan.Name | `
    Add-AzVMNetworkInterface -Id $nic.Id

# Create the virtual machine
New-AzVM `
    -ResourceGroupName $resourceGroup `
    -Location $location `
    -VM $vmConfig
```

ARM

```

Deprecated images FAQ

This article answers common questions about what happens when Azure Marketplace images are deprecated.

> **ⓘ Important**
>
> Image deprecation doesn't affect all images the same way. The impact depends on whether the image requires a Marketplace purchase plan.
>
> - **Microsoft first-party images** (for example, Windows Server, Canonical Ubuntu, Red Hat, SUSE) don't require a purchase plan and continue to support backup, restore, and disaster recovery scenarios after deprecation.
> - **Third-party Marketplace images** that require a purchase plan (for example, CIS, F5, Cisco) are affected by additional Marketplace enforcement checks after deprecation.
>
> **Purchase plan information** refers to Marketplace billing terms that you must accept for certain third-party images. Only images that require a purchase plan are subject to enforcement checks after deprecation. To check whether your image has a purchase plan, see How do I check if my image has a purchase plan?. For more information, see Marketplace purchase plan.

Overview

When an Azure Marketplace image is deprecated, its availability for new deployments changes—but existing virtual machines (VMs) and virtual machine scale set (VMSS) instances continue running normally. This article explains platform behavior during image deprecation, which operations are impacted, and what actions (if any) you must take.

What image deprecation means

Deprecation removes the image from the Azure Marketplace catalog but doesn't remove OS disks of existing VMs.

Each deprecated image has an **enforcement date**, which is the specific date when restrictions take effect. The enforcement date is listed in your deprecation notification email, Azure Advisor

recommendations, and the Azure CLI or PowerShell output when you query the image. You typically receive at least 90 days' notice before the enforcement date.

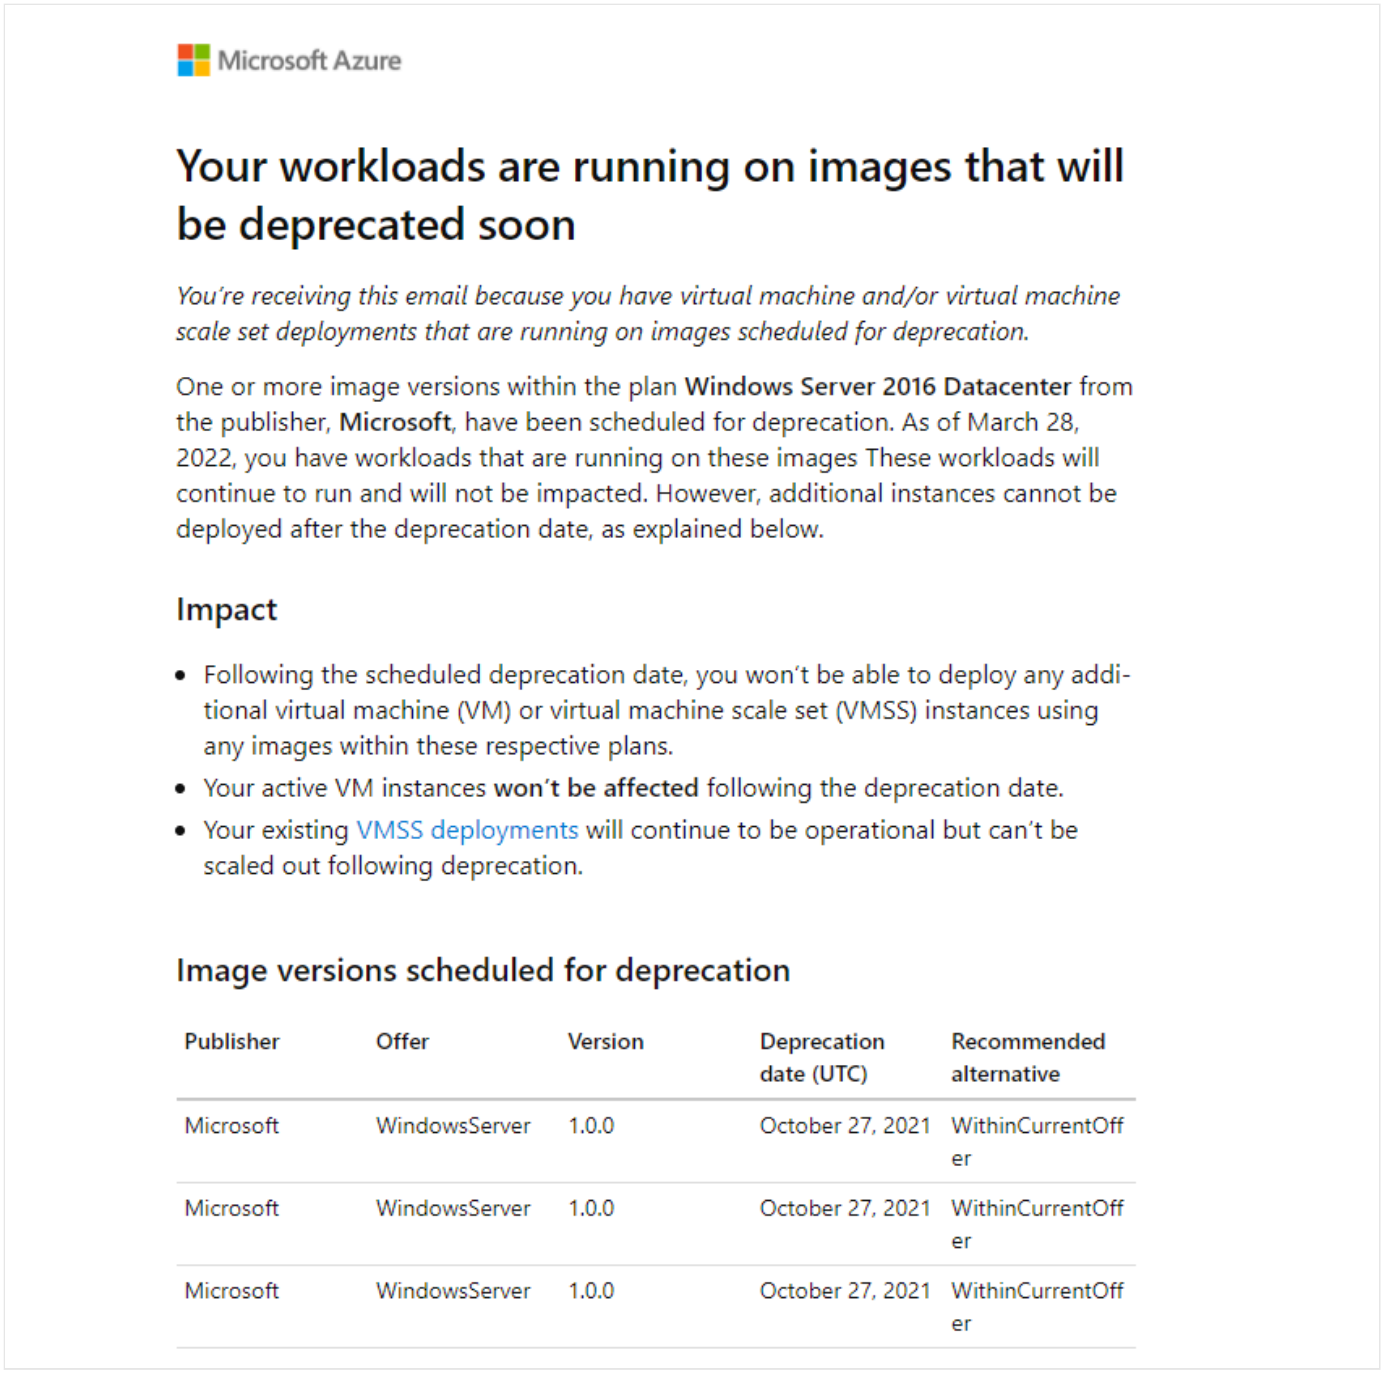
- You can't use a deprecated image for new VM or VMSS instance creation after the enforcement date.
- Existing VMs and VMSS instances that were created before the enforcement date continue operating normally.
- VMSS scale-out operations are blocked after the enforcement date because scaling out requires creating new instances from the deprecated image.

Key points

- **No action required for existing VMs:** Once created, VMs boot from their OS disk—not from the original image. Deprecation doesn't affect running VMs.
- **Most operations continue working:** Start, stop, restart, deallocate, and redeploy all work normally.
- **Backup and restore continue working for images without a purchase plan:** VM backup and restore operations, including restoring a backup to create a new VM, continue to work for Microsoft first-party and endorsed Linux images after deprecation.
- **Reimage is blocked:** This is the only VM operation affected because it requires recreating the OS disk from the source image.
- **VMSS instances continue running:** Existing instances aren't affected, but scale-out is blocked after enforcement.

What does it mean when I receive an image deprecation notice?

You receive an email notification when your virtual machine (VM) or virtual machine scale set runs on an image that's scheduled for deprecation. Publishers deprecate images for various reasons, including security concerns or when images reach end of life.



Microsoft Azure

Your workloads are running on images that will be deprecated soon

You're receiving this email because you have virtual machine and/or virtual machine scale set deployments that are running on images scheduled for deprecation.
