> You should never manually assign the public IP address assigned to an Azure virtual machine within the virtual machine's operating system. When you manually set the IP address within the operating system, ensure that it's the same address as the private IP

address assigned to the Azure network interface. Failure to assign the address correctly can cause loss of connectivity to the virtual machine. For more information, see Change IP address settings.

For more information about private IP addresses, see Private IP address.

12. Select **OK** to close the secondary IP address settings.
13. Select **OK** to close the adapter settings. Your RDP connection re-establishes.
14. Open a command prompt or PowerShell.
15. Enter `ipconfig /all` at the command line.
16. Verify the primary and secondary private IP addresses are present in the configuration.

PowerShell

```
PS C:\Users\azureuser> ipconfig /all

Windows IP Configuration

   Host Name . . . . . . . . . . . . : myVM
   Primary Dns Suffix  . . . . . . . :
   Node Type . . . . . . . . . . . . : Hybrid
   IP Routing Enabled. . . . . . . . : No
   WINS Proxy Enabled. . . . . . . . : No

Ethernet adapter Ethernet:

   Connection-specific DNS Suffix  . :
   Description . . . . . . . . . . . : Microsoft Hyper-V Network Adapter
   Physical Address. . . . . . . . . : 00-0D-3A-E6-CE-A3
   DHCP Enabled. . . . . . . . . . . : No
   Autoconfiguration Enabled . . . . : Yes

```

17. Ensure the primary private IP address used in windows is the same as the primary IP address of the Azure VM network interface. For more information, see No Internet access from Azure Windows VM that has multiple IP addresses.

Validation (Windows Server)

To validate connectivity to the internet from the secondary IP configuration via the public IP, use the following command. Replace 10.1.0.5 with the secondary private IP address you added to the Azure VM network interface.

PowerShell

```
ping -S 10.1.0.5 outlook.com
```

> **Note**
>
> For secondary IP configurations, you can ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

SUSE Linux Enterprise and openSUSE

▼ Expand

SUSE-based distributions use the `cloud-netconfig` plugin from the `cloud-netconfig-azure` package to manage the IP configuration. No manual steps are required on the part of the administrator. The first IP address of an interface set on the platform is assigned via DHCP. The cloud-netconfig plugin then probes the Azure Instance Metadata Service API continuously (once per minute) for more IP addresses assigned to the interface and adds/removes them as secondary IP addresses automatically.

This plugin should be installed and enabled on new images by default. Configuration steps for old workloads can be found here: https://www.suse.com/c/multi-nic-cloud-netconfig-ec2-azure/.

Ubuntu 14/16

▼ Expand

We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.

2. Ensure you're the root user. If you aren't, enter the following command:

```
Bash

sudo -i
```

3. Update the configuration file of the network interface (assuming **'eth0'**).

   - Keep the existing line item for dhcp. The primary IP address remains configured as it was previously.
   - Add a configuration for another static IP address with the following commands:

     ```
     Bash

     cd /etc/network/interfaces.d/
     ls
     ```

     You should see a .cfg file.

4. Open the file. You should see the following lines at the end of the file:

```
Bash

auto eth0
iface eth0 inet dhcp
```

5. Add the following lines after the lines that exist in the file. Replace `10.1.0.5` with your private IP address and subnet mask.

```
Bash

iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
```

   To add other private IP addresses, edit the file and add the new private IP addresses on subsequent lines:

```
Bash

iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
iface eth0 inet static
```

```
address 10.1.0.6
netmask 255.255.255.0
```

6. Save the file by using the following command:

```Bash
:wq
```

7. Reset the network interface with the following command:

```Bash
ifdown eth0 && ifup eth0
```

> **Important**
>
> Execute both ifdown and ifup in the same line if using a remote connection.

8. Verify the IP address is added to the network interface with the following command:

```Bash
ip addr list eth0
```

You should see the IP address you added as part of the list. Example:

```Bash
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Ubuntu 14/16)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

Bash

```
ping -I 10.1.0.5 outlook.com
```

> ⓘ **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Ubuntu 18.04+

▼ Expand

Starting on 18.04, `netplan` is used in Ubuntu for network management. We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.
2. Ensure you're the root user. If you are not, enter the following command:

   Bash

```
sudo -i
```

3. Create a file for the second interface and open it in a text editor:

```Bash
vi /etc/netplan/60-static.yaml
```

4. Add the following lines to the file, replacing `10.1.0.5/24` with your IP and subnet mask:

```Bash
network:
    version: 2
    ethernets:
        eth0:
            addresses:
                - 10.1.0.5/24
```

   To add private IP addresses, edit the file and add the new private IP addresses on subsequent lines:

```Bash
network:
    version: 2
    ethernets:
        eth0:
            addresses:
                - 10.1.0.5/24
                - 10.1.0.6/24
```

5. Save the file by using the following command:

```Bash
:wq
```

6. Test the changes with netplan try to confirm syntax:

```Bash
netplan try
```

> ⓘ Note

`netplan try` will apply the changes temporarily and roll back the changes after 120 seconds. If there's a loss of connectivity, wait 2 minutes, and then reconnect. At that time, the changes will have been rolled back.

7. Assuming no issues with **`netplan try`**, apply the configuration changes:

```
Bash

netplan apply
```

8. Verify the IP address is added to the network interface with the following command:

```
Bash

ip addr list eth0
```

You should see the IP address you added as part of the list. Example:

```
Bash

2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Ubuntu 18.04+)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

```
Bash

ping -I 10.1.0.5 outlook.com
```

ⓘ Note

For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when trying to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. Follow the appropriate documentation for your Linux distribution. The following method is one way to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure you replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Red Hat Enterprise Linux and others

▼ Expand

ⓘ Note

To configure the extra IP addresses in RHEL10.x, it's enough to restart NetworkManger with: `systemctl restart NetworkManger.service` or reboot the system. No other steps are required.

1. Open a terminal window.
2. Ensure you're the root user. If you aren't, enter the following command:

   Bash

   ```
   sudo -i
   ```

3. Enter your password and follow instructions as prompted. Once you're the root user, go to the network scripts folder with the following command:

```bash
cd /etc/sysconfig/network-scripts
```

4. List the related ifcfg files using the following command:

```bash
ls ifcfg-*
```

   You should see **ifcfg-eth0** as one of the files.

5. Create a new configuration file for each IP added to the system.

```bash
touch ifcfg-eth0:0
```

6. Open the *ifcfg-eth0:0* file with the following command:

```bash
vi ifcfg-eth0:0
```

7. Add content to the file, **eth0:0** in this case, with the following command. Replace `10.1.0.5` with your new private IP address and subnet mask.

```bash
DEVICE=eth0:0
BOOTPROTO=static
ONBOOT=yes
IPADDR=10.1.0.5
NETMASK=255.255.255.0
```

8. Save the file with the following command:

```bash
:wq
```

9. Create a config file per IP address to add with their corresponding values:

```bash
```

```
touch ifcfg-eth0:1
```

Bash

```
vi ifcfg-eth0:1
```

Bash

```
DEVICE=eth0:1
BOOTPROTO=static
ONBOOT=yes
IPADDR=10.1.0.6
NETMASK=255.255.255.0
```

Bash

```
:wq
```

10. Restart the network services and make sure the changes are successful by running the following commands:

Bash

```
systemctl restart NetworkManager.service
ifconfig
```

You should see the IP address or addresses you added in the list returned.

Bash

```
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.4  netmask 255.255.255.0  broadcast 10.1.0.255
    inet6 fe80::6245:bdff:fe7d:704a  prefixlen 64  scopeid 0x20<link>
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
    RX packets 858  bytes 244215 (238.4 KiB)
    RX errors 0  dropped 0  overruns 0  frame 0
    TX packets 1021  bytes 262077 (255.9 KiB)
    TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

eth0:0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.5  netmask 255.255.255.0  broadcast 10.1.0.255
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)

eth0:1: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.6  netmask 255.255.255.0  broadcast 10.1.0.255
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
```

Validation (Red Hat and others)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

Bash

```
ping -I 10.0.0.5 outlook.com
```

> ⓘ **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See the appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.0.0.5** with the private IP address that has a public IP address associated to it
  - **10.0.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Debian GNU/Linux

▼ Expand

We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.
2. Ensure you're the root user. If you aren't, enter the following command:

```bash
sudo -i
```

3. Update the configuration file of the network interface (assuming '**eth0**').

   - Keep the existing line item for dhcp. The primary IP address remains configured as it was previously.
   - Add a configuration for each static IP address using the following commands:

     ```bash
     cd /etc/network/interfaces.d/
     ls
     ```

     You should see a .cfg file.

4. Open the file. You should see the following lines at the end of the file:

```bash
auto eth0
iface eth0 inet dhcp
```

5. Add the following lines after the lines that exist in the file. Replace `10.1.0.5` with your private IP address and subnet mask.

```bash
iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
```

   Add the new IP addresses information in the configuration file:

```bash
iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
iface eth0 inet static
address 10.1.0.6
netmask 255.255.255.0
```

6. Save the file by using the following command:

```
Bash
:wq
```

7. Restart networking services for the changes to take effect. For Debian 8 and above, use:

```
Bash
systemctl restart networking
```

   For prior versions of Debian, you can use below commands:

```
Bash
service networking restart
```

8. Verify the IP address is added to the network interface with the following command:

```
Bash
ip addr list eth0
```

   You should see the IP address you added as part of the list. Example:

```
Bash
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Debian GNU/Linux)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

```
Bash
```

```
ping -I 10.1.0.5 outlook.com
```

> **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

- Learn more about public IP addresses in Azure.
- Learn more about private IP addresses in Azure.
- Learn how to Configure IP addresses for an Azure network interface.

Last updated on 02/19/2026

Assign multiple IP addresses to virtual machines using Azure PowerShell

An Azure Virtual Machine (VM) has one or more network interfaces (NIC) attached to it. Any NIC can have one or more static or dynamic public and private IP addresses assigned to it.

Assigning multiple IP addresses to a VM enables the following capabilities:

- Hosting multiple websites or services with different IP addresses and TLS/SSL certificates on a single server.
- Serve as a network virtual appliance, such as a firewall or load balancer.
- The ability to add any of the private IP addresses for any of the NICs to an Azure Load Balancer back-end pool. In the past, only the primary IP address for the primary NIC could be added to a back-end pool. For more information about load balancing multiple IP configurations, see Load balancing multiple IP configurations.

Every NIC attached to a VM has one or more IP configurations associated to it. Each configuration is assigned one static or dynamic private IP address. Each configuration may also have one public IP address resource associated to it. To learn more about IP addresses in Azure, see IP addresses in Azure.

> **Note**
>
> All IP configurations on a single NIC must be associated to the same subnet. If multiple IPs on different subnets are desired, multiple NICs on a VM can be used. To learn more about multiple NICs on a VM in Azure, see Create VM with Multiple NICs.

There's a limit to how many private IP addresses can be assigned to a NIC. There's also a limit to how many public IP addresses that can be used in an Azure subscription. See the Azure limits article for details.

This article explains how to add multiple IP addresses to a virtual machine using PowerShell.

Prerequisites

- An Azure account with an active subscription. Create an account for free.

- PowerShell environment in Azure Cloud Shell or Azure PowerShell installed locally. To learn more about using PowerShell in Azure Cloud Shell, see Azure Cloud Shell Quickstart.
  - If you choose to install and use PowerShell locally, this article requires the Azure PowerShell module version 5.4.1 or later. Run `Get-InstalledModule -Name Az` to find the installed version. If you need to upgrade, see Install Azure PowerShell module. Ensure your Az.Network module is 4.3.0 or later. To verify the installed module, use the command `Get-InstalledModule -Name "Az.Network"`. If the module requires an update, use the command `Update-Module -Name "Az.Network"` if necessary.
- Sign in to Azure PowerShell and ensure you've selected the subscription with which you want to use this feature. For more information, see Sign in with Azure PowerShell.

> **Note**
>
> Though the steps in this article assigns all IP configurations to a single NIC, you can also assign multiple IP configurations to any NIC in a multi-NIC VM. To learn how to create a VM with multiple NICs, see Create a VM with multiple NICs.

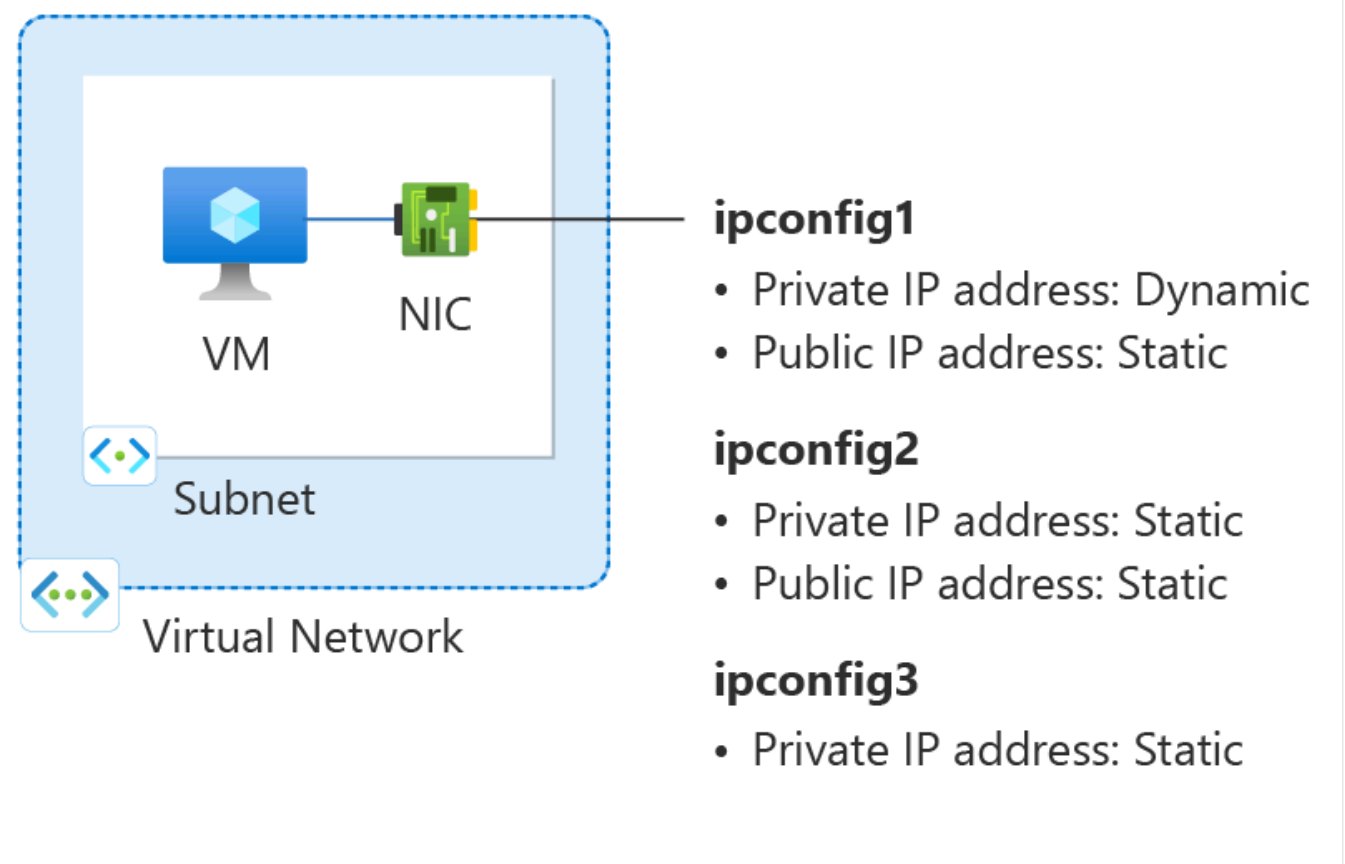

Figure: Diagram of network configuration resources created in this How-to article.

Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with New-AzResourceGroup named **myResourceGroup** in the **eastus2** location.

Azure PowerShell

```
$rg =@{
    Name = 'myResourceGroup'
    Location = 'eastus2'
}
New-AzResourceGroup @rg
```

Create a virtual network

In this section, you create a virtual network for the virtual machine.

Use New-AzVirtualNetwork and New-AzVirtualNetworkSubnetConfig to create a virtual network with one subnet.

Azure PowerShell

```
## Create backend subnet config ##
$subnet = @{
    Name = 'myBackendSubnet'
    AddressPrefix = '10.1.0.0/24'
}
$subnetConfig = New-AzVirtualNetworkSubnetConfig @subnet

## Create the virtual network ##
$vnet = @{
    Name = 'myVNet'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    AddressPrefix = '10.1.0.0/16'
    Subnet = $subnetConfig
}
New-AzVirtualNetwork @vnet
```

Create a primary public IP address

Use New-AzPublicIpAddress to create a primary public IP address.

Azure PowerShell

```
$ip1 = @{
    Name = 'myPublicIP-1'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
    IpAddressVersion = 'IPv4'
    Zone = 1,2,3
}
New-AzPublicIpAddress @ip1
```

Create a network security group

In this section, you create a network security group for the virtual machine and virtual network. You create a rule to allow connections to the virtual machine on port 22 for SSH.

Use New-AzNetworkSecurityGroup and New-AzNetworkSecurityRuleConfig to create the network security group and rules.

Azure PowerShell

```
## Create rule for network security group and place in variable. ##
$nsgrule1 = @{
    Name = 'myNSGRuleSSH'
    Description = 'Allow SSH'
    Protocol = '*'
    SourcePortRange = '*'
    DestinationPortRange = '22'
    SourceAddressPrefix = 'Internet'
    DestinationAddressPrefix = '*'
    Access = 'Allow'
    Priority = '200'
    Direction = 'Inbound'
}
$rule1 = New-AzNetworkSecurityRuleConfig @nsgrule1

## Create network security group ##
$nsg = @{
    Name = 'myNSG'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    SecurityRules = $rule1
}
New-AzNetworkSecurityGroup @nsg
```

Create a network interface

Use New-AzNetworkInterface and New-AzNetworkInterfaceIpConfig to create a network interface (NIC) for the virtual machine. The public IP address and network security group created previously are associated with the network interface. The network interface is attached to the virtual network you created previously.

Azure PowerShell

```
## Place the virtual network into a variable. ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = 'myResourceGroup'
}
$vnet = Get-AzVirtualNetwork @net

## Place the network security group into a variable. ##
$ns = @{
    Name = 'myNSG'
    ResourceGroupName = 'myResourceGroup'
}
$nsg = Get-AzNetworkSecurityGroup @ns

## Place the primary public IP address into a variable. ##
$pub1 = @{
    Name = 'myPublicIP-1'
    ResourceGroupName = 'myResourceGroup'
}
$pubIP1 = Get-AzPublicIPAddress @pub1

## Create a primary IP configuration for the network interface. ##
$IP1 = @{
    Name = 'ipconfig1'
    Subnet = $vnet.Subnets[0]
    PrivateIpAddressVersion = 'IPv4'
    PublicIPAddress = $pubIP1
}
$IP1Config = New-AzNetworkInterfaceIpConfig @IP1 -Primary

## Create a secondary IP configuration for the network interface. ##
$IP3 = @{
    Name = 'ipconfig3'
    Subnet = $vnet.Subnets[0]
    PrivateIpAddressVersion = 'IPv4'
    PrivateIpAddress = '10.1.0.6'
}
$IP3Config = New-AzNetworkInterfaceIpConfig @IP3

## Command to create a network interface. ##
$nic = @{
    Name = 'myNIC1'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    NetworkSecurityGroup = $nsg
```

```
    IpConfiguration = $IP1Config,$IP3Config
}
New-AzNetworkInterface @nic
```

> **Note**
>
> When adding a static IP address, you must specify an unused, valid address on the subnet the NIC is connected to.

Create a virtual machine

Use the following commands to create the virtual machine:

- New-AzVM
- New-AzVMConfig
- Set-AzVMOperatingSystem
- Set-AzVMSourceImage
- Add-AzVMNetworkInterface

Azure PowerShell

```
$cred = Get-Credential

## Place network interface into a variable. ##
$nic = @{
    Name = 'myNIC1'
    ResourceGroupName = 'myResourceGroup'
}
$nicVM = Get-AzNetworkInterface @nic

## Create a virtual machine configuration for VMs ##
$vmsz = @{
    VMName = 'myVM'
    VMSize = 'Standard_DS1_v2'
}
$vmos = @{
    ComputerName = 'myVM'
    Credential = $cred
}
$vmimage = @{
    PublisherName = 'Debian'
    Offer = 'debian-11'
    Skus = '11'
    Version = 'latest'
```

```
}
$vmConfig = New-AzVMConfig @vmsz `
      | Set-AzVMOperatingSystem @vmos -Linux `
      | Set-AzVMSourceImage @vmimage `
      | Add-AzVMNetworkInterface -Id $nicVM.Id

## Create the virtual machine for VMs ##
$vm = @{
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    VM = $vmConfig
    SshKeyName = 'mySSHKey'
    }
New-AzVM @vm -GenerateSshKey
```

Add secondary private and public IP address

Use New-AzPublicIpAddress to create a secondary public IP address.

Azure PowerShell

```
$ip2 = @{
    Name = 'myPublicIP-2'
    ResourceGroupName = 'myResourceGroup'
    Location = 'eastus2'
    Sku = 'Standard'
    AllocationMethod = 'Static'
    IpAddressVersion = 'IPv4'
    Zone = 1,2,3
}
New-AzPublicIpAddress @ip2
```

Use New-AzNetworkInterfaceIpConfig to create the secondary IP configuration for the virtual machine.

Azure PowerShell

```
## Place the virtual network into a variable. ##
$net = @{
    Name = 'myVNet'
    ResourceGroupName = 'myResourceGroup'
}
$vnet = Get-AzVirtualNetwork @net

## Place your virtual network subnet into a variable. ##
$sub = @{
    Name = 'myBackendSubnet'
    VirtualNetwork = $vnet
}
$subnet = Get-AzVirtualNetworkSubnetConfig @sub
```

```
## Place the secondary public IP address you created previously into a variable. ##
$pip = @{
    Name = 'myPublicIP-2'
    ResourceGroupName = 'myResourceGroup'
}
$pubIP2 = Get-AzPublicIPAddress @pip

## Place the network interface into a variable. ##
$net = @{
    Name = 'myNIC1'
    ResourceGroupName = 'myResourceGroup'
}
$nic = Get-AzNetworkInterface @net

## Create a secondary IP configuration for the network interface. ##
$IPc2 = @{
    Name = 'ipconfig2'
    Subnet = $vnet.Subnets[0]
    PrivateIpAddressVersion = 'IPv4'
    PrivateIpAddress = '10.1.0.5'
    PublicIPAddress = $pubIP2
}
$IP2Config = New-AzNetworkInterfaceIpConfig @IPc2

## Add the IP configuration to the network interface. ##
$nic.IpConfigurations.Add($IP2Config)

## Save the configuration to the network interface. ##
$nic | Set-AzNetworkInterface
```

Add IP addresses to a VM operating system

Connect and sign in to a VM you created with multiple private IP addresses. You must manually add all the private IP addresses, including the primary, that you added to the VM. Complete the following steps for your VM operating system.

Windows Server

▼ Expand

1. Open a command prompt or PowerShell.
2. Enter `ipconfig /all` at the command line. You see the **Primary** private IP address that was assigned through DHCP.
3. Enter `ncpa.cpl` at the command line to open the **Network Connections** configuration.
4. Open the **Properties** for the network adapter assigned the new IP addresses.

5. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.

6. Select **Use the following IP address:**. Enter the following values.

Expand table

Setting	Value
IP address:	Enter the **Primary** private IP address.
Subnet mask:	Enter a subnet mask based on your IP address. For example, if the subnet is a **/24** subnet then the subnet mask is **255.255.255.0**.
Default gateway:	The first IP address in the subnet. If your subnet is **10.0.0.0/24**, then the gateway IP address is **10.0.0.1**.

7. Select **Use the following DNS server addresses:**. Enter the following values.

Expand table

Setting	Value
Preferred DNS server:	Enter your primary DNS server. Enter the IP address of **168.63.129.16** to use the default Azure provided DNS.

8. Select the **Advanced** button.

9. Select **Add**.

10. Enter the private **IP address** you added to the Azure network interface. Enter the corresponding **Subnet mask**. Select **Add**.

11. Repeat the previous steps to add any more private IP addresses that you added to the Azure network interface.

> **Important**
>
> You should never manually assign the public IP address assigned to an Azure virtual machine within the virtual machine's operating system. When you manually set the IP address within the operating system, ensure that it's the same address as the private IP address assigned to the Azure network interface. Failure to assign the address correctly

can cause loss of connectivity to the virtual machine. For more information, see Change IP address settings.

For more information about private IP addresses, see Private IP address.

12. Select **OK** to close the secondary IP address settings.
13. Select **OK** to close the adapter settings. Your RDP connection re-establishes.
14. Open a command prompt or PowerShell.
15. Enter `ipconfig /all` at the command line.
16. Verify the primary and secondary private IP addresses are present in the configuration.

PowerShell

```
PS C:\Users\azureuser> ipconfig /all

Windows IP Configuration

   Host Name . . . . . . . . . . . . : myVM
   Primary Dns Suffix  . . . . . . . :

   NetBIOS over Tcpip. . . . . . . . : Enabled
```

17. Ensure the primary private IP address used in windows is the same as the primary IP address of the Azure VM network interface. For more information, see No Internet access from Azure Windows VM that has multiple IP addresses.

Validation (Windows Server)

To validate connectivity to the internet from the secondary IP configuration via the public IP, use the following command. Replace 10.1.0.5 with the secondary private IP address you added to the Azure VM network interface.

PowerShell

```
ping -S 10.1.0.5 outlook.com
```

> **Note**
>
> For secondary IP configurations, you can ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

SUSE Linux Enterprise and openSUSE

▼ Expand

SUSE-based distributions use the `cloud-netconfig` plugin from the `cloud-netconfig-azure` package to manage the IP configuration. No manual steps are required on the part of the administrator. The first IP address of an interface set on the platform is assigned via DHCP. The cloud-netconfig plugin then probes the Azure Instance Metadata Service API continuously (once per minute) for more IP addresses assigned to the interface and adds/removes them as secondary IP addresses automatically.

This plugin should be installed and enabled on new images by default. Configuration steps for old workloads can be found here: https://www.suse.com/c/multi-nic-cloud-netconfig-ec2-azure/.

Ubuntu 14/16

▼ Expand

We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.

2. Ensure you're the root user. If you aren't, enter the following command:

```
Bash
sudo -i
```

3. Update the configuration file of the network interface (assuming '**eth0**').

   - Keep the existing line item for dhcp. The primary IP address remains configured as it was previously.

   - Add a configuration for another static IP address with the following commands:

     ```
     Bash
     cd /etc/network/interfaces.d/
     ls
     ```

     You should see a .cfg file.

4. Open the file. You should see the following lines at the end of the file:

```
Bash
auto eth0
iface eth0 inet dhcp
```

5. Add the following lines after the lines that exist in the file. Replace `10.1.0.5` with your private IP address and subnet mask.

```
Bash
iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
```

   To add other private IP addresses, edit the file and add the new private IP addresses on subsequent lines:

```
Bash
iface eth0 inet static
address 10.1.0.5
```

```
netmask 255.255.255.0
iface eth0 inet static
address 10.1.0.6
netmask 255.255.255.0
```

6. Save the file by using the following command:

Bash

```
:wq
```

7. Reset the network interface with the following command:

Bash

```
ifdown eth0 && ifup eth0
```

> **ⓘ Important**
>
> Execute both ifdown and ifup in the same line if using a remote connection.

8. Verify the IP address is added to the network interface with the following command:

Bash

```
ip addr list eth0
```

You should see the IP address you added as part of the list. Example:

Bash

```
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Ubuntu 14/16)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

Bash

```
ping -I 10.1.0.5 outlook.com
```

> ⓘ Note
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Ubuntu 18.04+

▼ Expand

Starting on 18.04, `netplan` is used in Ubuntu for network management. We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.
2. Ensure you're the root user. If you are not, enter the following command:

```bash
sudo -i
```

3. Create a file for the second interface and open it in a text editor:

```bash
vi /etc/netplan/60-static.yaml
```

4. Add the following lines to the file, replacing `10.1.0.5/24` with your IP and subnet mask:

```bash
network:
    version: 2
    ethernets:
        eth0:
            addresses:
                - 10.1.0.5/24
```

   To add private IP addresses, edit the file and add the new private IP addresses on subsequent lines:

```bash
network:
    version: 2
    ethernets:
        eth0:
            addresses:
                - 10.1.0.5/24
                - 10.1.0.6/24
```

5. Save the file by using the following command:

```bash
:wq
```

6. Test the changes with netplan try to confirm syntax:

```bash
netplan try
```

> ⓘ Note
>
> `netplan try` will apply the changes temporarily and roll back the changes after 120 seconds. If there's a loss of connectivity, wait 2 minutes, and then reconnect. At that time, the changes will have been rolled back.

7. Assuming no issues with **`netplan try`**, apply the configuration changes:

```
Bash

netplan apply
```

8. Verify the IP address is added to the network interface with the following command:

```
Bash

ip addr list eth0
```

   You should see the IP address you added as part of the list. Example:

```
Bash

2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Ubuntu 18.04+)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

```
Bash

ping -I 10.1.0.5 outlook.com
```

> ⓘ Note
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when trying to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. Follow the appropriate documentation for your Linux distribution. The following method is one way to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure you replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Red Hat Enterprise Linux and others

▼ Expand

> ⓘ Note
>
> To configure the extra IP addresses in RHEL10.x, it's enough to restart NetworkManger with: `systemctl restart NetworkManger.service` or reboot the system. No other steps are required.

RHEL 8.6 & above, RHEL 9

Starting RHEL 8.6 & above and RHEL 9, "networkmanager-cloud-setup" package can handle multiple IP configurations and its associated route configuration.

1. Disabled cloud-init to handle secondary IP configuration in the respective files /etc/cloud/cloud.cfg.d/99-apply-network-config.cfg or /etc/cloud/cloud.cfg.d/91-azure_datasource.cfg. This will let NetworkManager and nm-cloud-setup manage the entire network configuration

Bash

```
[root@rhel8 ~]# cat /etc/cloud/cloud.cfg.d/99-apply-network-config.cfg
datasource:
  Azure:
     apply_network_config: False
```

2. Install "NetworkManager-cloud-setup" package if not already installed

Bash

```
]# yum install NetworkManager-cloud-setup
Red Hat Enterprise Linux 8 for x86_64 - BaseOS from RHUI (RPMs)
39 MB/s |  66 MB     00:01
Red Hat Enterprise Linux 8 for x86_64 - Supplementary (RPMs) from RHUI

Complete!
```

3. To enable “nm-cloud-setup” to handle secondary IP configuration, create nm-cloud-setup.service and nm-cloud-setup.timer (adjust OnBootSec & OnUnitActiveSec parameters to suit your requirement) files

Bash

```
[root@rhel8 ~]# cat /etc/systemd/system/nm-cloud-setup.service
[Unit]
```

```
Description=Automatically configure NetworkManager in cloud
Documentation=man:nm-cloud-setup(8)
Before=network-online.target
After=NetworkManager.service

[Service]
Environment=NM_CLOUD_SETUP_AZURE=yes
Type=oneshot
ExecStart=/usr/libexec/nm-cloud-setup

[Install]
WantedBy=NetworkManager.service
```

Bash

```
[root@rhel8 ~]# cat /etc/systemd/system/nm-cloud-setup.timer
[Unit]
Description=Periodically run nm-cloud-setup

[Timer]
OnBootSec=1min
OnUnitActiveSec=1min

[Install]
WantedBy=timers.target
```

4. Enable services are reload daemon

Bash

```
systemctl enable --now nm-cloud-setup.service
systemctl start nm-cloud-setup.service
systemctl enable --now nm-cloud-setup.timer
systemctl daemon-reload
```

5. Reboot VM & verify. VM should now successfully identify respective primary and secondary IPs.

RHEL 8.5 & below

1. Open a terminal window.

2. Ensure you're the root user. If you aren't, enter the following command:

   Bash

   ```
   sudo -i
   ```

3. Enter your password and follow instructions as prompted. Once you're the root user, go to the network scripts folder with the following command:

```Bash
cd /etc/sysconfig/network-scripts
```

4. List the related ifcfg files using the following command:

```Bash
ls ifcfg-*
```

   You should see **ifcfg-eth0** as one of the files.

5. Create a new configuration file for each IP added to the system.

```Bash
touch ifcfg-eth0:0
```

6. Open the *ifcfg-eth0:0* file with the following command:

```Bash
vi ifcfg-eth0:0
```

7. Add content to the file, **eth0:0** in this case, with the following command. Replace `10.1.0.5` with your new private IP address and subnet mask.

```Bash
DEVICE=eth0:0
BOOTPROTO=static
ONBOOT=yes
IPADDR=10.1.0.5
NETMASK=255.255.255.0
```

8. Save the file with the following command:

```Bash
:wq
```

9. Create a config file per IP address to add with their corresponding values:

Bash

```
touch ifcfg-eth0:1
```

Bash

```
vi ifcfg-eth0:1
```

Bash

```
DEVICE=eth0:1
BOOTPROTO=static
ONBOOT=yes
IPADDR=10.1.0.6
NETMASK=255.255.255.0
```

Bash

```
:wq
```

10. Restart the network services and make sure the changes are successful by running the following commands:

Bash

```
systemctl restart NetworkManager.service
ifconfig
```

You should see the IP address or addresses you added in the list returned.

Bash

```
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.4  netmask 255.255.255.0  broadcast 10.1.0.255
    inet6 fe80::6245:bdff:fe7d:704a  prefixlen 64  scopeid 0x20<link>
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
    RX packets 858  bytes 244215 (238.4 KiB)
    RX errors 0  dropped 0  overruns 0  frame 0
    TX packets 1021  bytes 262077 (255.9 KiB)
    TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

eth0:0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.5  netmask 255.255.255.0  broadcast 10.1.0.255
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
```

```
eth0:1: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.6  netmask 255.255.255.0  broadcast 10.1.0.255
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
```

Validation (Red Hat and others)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

Bash

```
ping -I 10.0.0.5 outlook.com
```

> ⓘ **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See the appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.0.0.5** with the private IP address that has a public IP address associated to it
  - **10.0.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Debian GNU/Linux

▼ Expand

We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.
2. Ensure you're the root user. If you aren't, enter the following command:

   Bash

   ```
   sudo -i
   ```

3. Update the configuration file of the network interface (assuming **'eth0'**).

   - Keep the existing line item for dhcp. The primary IP address remains configured as it was previously.
   - Add a configuration for each static IP address using the following commands:

     Bash

     ```
     cd /etc/network/interfaces.d/
     ls
     ```

     You should see a .cfg file.

4. Open the file. You should see the following lines at the end of the file:

   Bash

   ```
   auto eth0
   iface eth0 inet dhcp
   ```

5. Add the following lines after the lines that exist in the file. Replace `10.1.0.5` with your private IP address and subnet mask.

   Bash

   ```
   iface eth0 inet static
   address 10.1.0.5
   netmask 255.255.255.0
   ```

   Add the new IP addresses information in the configuration file:

   Bash

```
iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
iface eth0 inet static
address 10.1.0.6
netmask 255.255.255.0
```

6. Save the file by using the following command:

Bash

```
:wq
```

7. Restart networking services for the changes to take effect. For Debian 8 and above, use:

Bash

```
systemctl restart networking
```

For prior versions of Debian, you can use below commands:

Bash

```
service networking restart
```

8. Verify the IP address is added to the network interface with the following command:

Bash

```
ip addr list eth0
```

You should see the IP address you added as part of the list. Example:

Bash

```
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Debian GNU/Linux)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

```Bash
ping -I 10.1.0.5 outlook.com
```

> **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See appropriate documentation for your Linux distribution. The following method to accomplish this goal:

```Bash
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Assign multiple IP addresses to virtual machines using the Azure CLI

Summarize this article for me

An Azure Virtual Machine (VM) has one or more network interfaces (NIC) attached to it. Any NIC can have one or more static or dynamic public and private IP addresses assigned to it.

Assigning multiple IP addresses to a VM enables the following capabilities:

- Hosting multiple websites or services with different IP addresses and TLS/SSL certificates on a single server.
- Serve as a network virtual appliance, such as a firewall or load balancer.
- The ability to add any of the private IP addresses for any of the NICs to an Azure Load Balancer back-end pool. In the past, only the primary IP address for the primary NIC could be added to a back-end pool. For more information about load balancing multiple IP configurations, see Load balancing multiple IP configurations.

Every NIC attached to a VM has one or more IP configurations associated to it. Each configuration is assigned one static or dynamic private IP address. Each configuration may also have one public IP address resource associated to it. To learn more about IP addresses in Azure, see IP addresses in Azure.

> **Note**
>
> All IP configurations on a single NIC must be associated to the same subnet. If multiple IPs on different subnets are desired, multiple NICs on a VM can be used. To learn more about multiple NICs on a VM in Azure, see Create VM with Multiple NICs.

There's a limit to how many private IP addresses can be assigned to a NIC. There's also a limit to how many public IP addresses that can be used in an Azure subscription. See Azure limits for details.

This article explains how to add multiple IP addresses to a virtual machine using the Azure CLI.

Prerequisites

- An Azure account with an active subscription. Create an account for free.

- Use the Bash environment in Azure Cloud Shell. For more information, see Get started with Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Authenticate to Azure using Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use and manage extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.
- This tutorial requires version 2.0.28 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

> **Note**
>
> Though the steps in this article assigns all IP configurations to a single NIC, you can also assign multiple IP configurations to any NIC in a multi-NIC VM. To learn how to create a VM with multiple NICs, see Create a VM with multiple NICs.

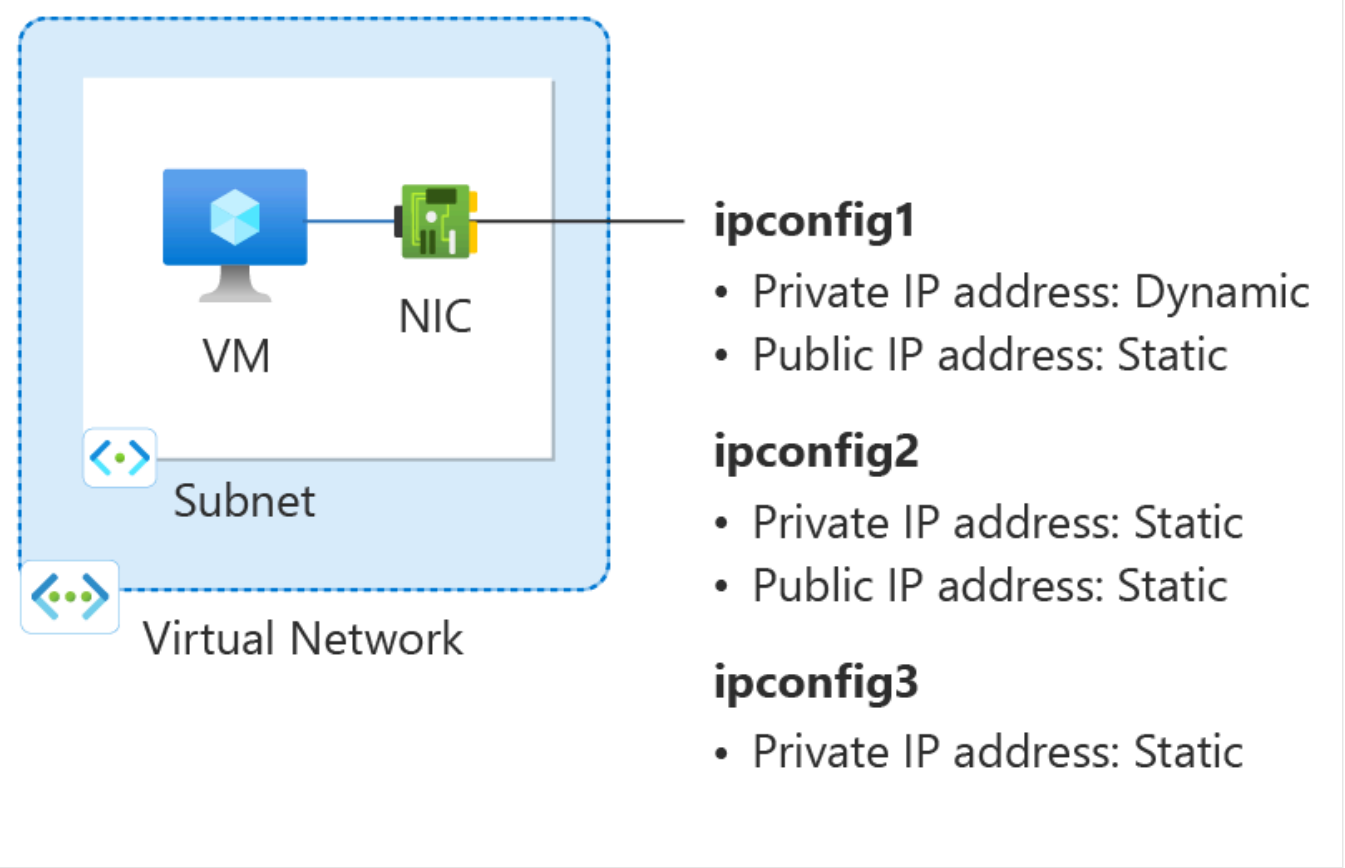

Figure: Diagram of network configuration resources created in this How-to article.

Create a resource group

An Azure resource group is a logical container into which Azure resources are deployed and managed.

Create a resource group with az group create named **myResourceGroup** in the **eastus2** location.

Azure CLI

```
az group create \
  --name myResourceGroup \
  --location eastus2
```

Create a virtual network

In this section, you create a virtual network for the virtual machine.

Use az network vnet create to create a virtual network.

Azure CLI

```
az network vnet create \
  --resource-group myResourceGroup \
  --location eastus2 \
  --name myVNet \
  --address-prefixes 10.1.0.0/16 \
  --subnet-name myBackendSubnet \
  --subnet-prefixes 10.1.0.0/24
```

Create public IP addresses

Use az network public-ip create to create two public IP addresses.

Azure CLI

```
az network public-ip create \
  --resource-group myResourceGroup \
  --name myPublicIP-1 \
  --sku Standard \
  --version IPv4 \
  --zone 1 2 3

az network public-ip create \
  --resource-group myResourceGroup \
  --name myPublicIP-2 \
  --sku Standard \
  --version IPv4 \
  --zone 1 2 3
```

Create a network security group

In this section, you create a network security group for the virtual machine and virtual network.

Use az network nsg create to create the network security group.

Azure CLI

```
az network nsg create \
  --resource-group myResourceGroup \
  --name myNSG
```

> **Note**
>
> The default rules of the network security group block all inbound access from the internet, including SSH. To connect to the virtual machine, use Azure Bastion. For more information,

see Quickstart: Deploy Azure Bastion with default settings.

Create a network interface

You use az network nic create to create the network interface for the virtual machine. The public IP addresses and the NSG created previously are associated with the NIC. The network interface is attached to the virtual network you created previously.

Azure CLI

```
az network nic create \
  --resource-group myResourceGroup \
  --name myNIC1 \
  --private-ip-address-version IPv4 \
  --vnet-name myVNet \
  --subnet myBackEndSubnet \
  --network-security-group myNSG \
  --public-ip-address myPublicIP-1
```

Create secondary private and public IP configuration

Use az network nic ip-config create to create the secondary private and public IP configuration for the NIC. Replace **10.1.0.5** with your secondary private IP address.

Azure CLI

```
az network nic ip-config create \
  --resource-group myResourceGroup \
  --name ipconfig2 \
  --nic-name myNIC1 \
  --private-ip-address 10.1.0.5 \
  --private-ip-address-version IPv4 \
  --vnet-name myVNet \
  --subnet myBackendSubnet \
  --public-ip-address myPublicIP-2
```

Create tertiary private IP configuration

Use az network nic ip-config create to create the tertiary private IP configuration for the NIC. Replace **10.1.0.6** with your secondary private IP address.

Azure CLI

```
az network nic ip-config create \
  --resource-group myResourceGroup \
  --name ipconfig3 \
  --nic-name myNIC1 \
  --private-ip-address 10.1.0.6 \
  --private-ip-address-version IPv4 \
  --vnet-name myVNet \
  --subnet myBackendSubnet
```

> **Note**
>
> When adding a static IP address, you must specify an unused, valid address on the subnet the NIC is connected to.

Create a virtual machine

Use az vm create to create the virtual machine.

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --nics myNIC1 \
  --image Ubuntu2204 \
  --admin-username azureuser \
  --authentication-type ssh \
  --generate-ssh-keys
```

Add IP addresses to a VM operating system

Connect and sign in to a VM you created with multiple private IP addresses. You must manually add all the private IP addresses, including the primary, that you added to the VM. Complete the following steps for your VM operating system.

Windows Server

▼ Expand

1. Open a command prompt or PowerShell.
2. Enter `ipconfig /all` at the command line. You see the **Primary** private IP address that was assigned through DHCP.

3. Enter `ncpa.cpl` at the command line to open the **Network Connections** configuration.
4. Open the **Properties** for the network adapter assigned the new IP addresses.
5. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.
6. Select **Use the following IP address:**. Enter the following values.

Expand table

Setting	Value
IP address:	Enter the **Primary** private IP address.
Subnet mask:	Enter a subnet mask based on your IP address. For example, if the subnet is a **/24** subnet then the subnet mask is **255.255.255.0**.
Default gateway:	The first IP address in the subnet. If your subnet is **10.0.0.0/24**, then the gateway IP address is **10.0.0.1**.

7. Select **Use the following DNS server addresses:**. Enter the following values.

Expand table

Setting	Value
Preferred DNS server:	Enter your primary DNS server. Enter the IP address of **168.63.129.16** to use the default Azure provided DNS.

8. Select the **Advanced** button.
9. Select **Add**.
10. Enter the private **IP address** you added to the Azure network interface. Enter the corresponding **Subnet mask**. Select **Add**.
11. Repeat the previous steps to add any more private IP addresses that you added to the Azure network interface.

> **Important**
>
> You should never manually assign the public IP address assigned to an Azure virtual machine within the virtual machine's operating system. When you manually set the IP address within the operating system, ensure that it's the same address as the private IP

address assigned to the Azure network interface. Failure to assign the address correctly can cause loss of connectivity to the virtual machine. For more information, see Change IP address settings.

For more information about private IP addresses, see Private IP address.

12. Select **OK** to close the secondary IP address settings.
13. Select **OK** to close the adapter settings. Your RDP connection re-establishes.
14. Open a command prompt or PowerShell.
15. Enter `ipconfig /all` at the command line.
16. Verify the primary and secondary private IP addresses are present in the configuration.

PowerShell

```
PS C:\Users\azureuser> ipconfig /all

Windows IP Configuration

   Host Name . . . . . . . . . . . . : myVM
   Primary Dns Suffix  . . . . . . . :

   DNS Servers . . . . . . . . . . . : 168.63.129.16
   NetBIOS over Tcpip. . . . . . . . : Enabled
```

17. Ensure the primary private IP address used in windows is the same as the primary IP address of the Azure VM network interface. For more information, see No Internet access from Azure Windows VM that has multiple IP addresses.

Validation (Windows Server)

To validate connectivity to the internet from the secondary IP configuration via the public IP, use the following command. Replace 10.1.0.5 with the secondary private IP address you added to the Azure VM network interface.

PowerShell

```
ping -S 10.1.0.5 outlook.com
```

> **Note**
>
> For secondary IP configurations, you can ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

SUSE Linux Enterprise and openSUSE

▼ Expand

SUSE-based distributions use the `cloud-netconfig` plugin from the `cloud-netconfig-azure` package to manage the IP configuration. No manual steps are required on the part of the administrator. The first IP address of an interface set on the platform is assigned via DHCP. The cloud-netconfig plugin then probes the Azure Instance Metadata Service API continuously (once per minute) for more IP addresses assigned to the interface and adds/removes them as secondary IP addresses automatically.

This plugin should be installed and enabled on new images by default. Configuration steps for old workloads can be found here: https://www.suse.com/c/multi-nic-cloud-netconfig-ec2-azure/.

Ubuntu 14/16

▼ Expand

We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.

2. Ensure you're the root user. If you aren't, enter the following command:

```
Bash

sudo -i
```

3. Update the configuration file of the network interface (assuming **'eth0'**).

   - Keep the existing line item for dhcp. The primary IP address remains configured as it was previously.
   - Add a configuration for another static IP address with the following commands:

     ```
     Bash

     cd /etc/network/interfaces.d/
     ls
     ```

     You should see a .cfg file.

4. Open the file. You should see the following lines at the end of the file:

```
Bash

auto eth0
iface eth0 inet dhcp
```

5. Add the following lines after the lines that exist in the file. Replace `10.1.0.5` with your private IP address and subnet mask.

```
Bash

iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
```

   To add other private IP addresses, edit the file and add the new private IP addresses on subsequent lines:

```
Bash

iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
iface eth0 inet static
```

```
address 10.1.0.6
netmask 255.255.255.0
```

6. Save the file by using the following command:

```Bash
:wq
```

7. Reset the network interface with the following command:

```Bash
ifdown eth0 && ifup eth0
```

> **Important**
>
> Execute both ifdown and ifup in the same line if using a remote connection.

8. Verify the IP address is added to the network interface with the following command:

```Bash
ip addr list eth0
```

You should see the IP address you added as part of the list. Example:

```Bash
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Ubuntu 14/16)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

Bash

```
ping -I 10.1.0.5 outlook.com
```

> ⓘ **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Ubuntu 18.04+

▼ Expand

Starting on 18.04, `netplan` is used in Ubuntu for network management. We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.
2. Ensure you're the root user. If you are not, enter the following command:

   Bash

```
sudo -i
```

3. Create a file for the second interface and open it in a text editor:

```Bash
vi /etc/netplan/60-static.yaml
```

4. Add the following lines to the file, replacing `10.1.0.5/24` with your IP and subnet mask:

```Bash
network:
    version: 2
    ethernets:
        eth0:
            addresses:
                - 10.1.0.5/24
```

   To add private IP addresses, edit the file and add the new private IP addresses on subsequent lines:

```Bash
network:
    version: 2
    ethernets:
        eth0:
            addresses:
                - 10.1.0.5/24
                - 10.1.0.6/24
```

5. Save the file by using the following command:

```Bash
:wq
```

6. Test the changes with netplan try to confirm syntax:

```Bash
netplan try
```

> ⓘ Note

`netplan try` will apply the changes temporarily and roll back the changes after 120 seconds. If there's a loss of connectivity, wait 2 minutes, and then reconnect. At that time, the changes will have been rolled back.

7. Assuming no issues with **`netplan try`**, apply the configuration changes:

```
Bash

netplan apply
```

8. Verify the IP address is added to the network interface with the following command:

```
Bash

ip addr list eth0
```

You should see the IP address you added as part of the list. Example:

```
Bash

2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Ubuntu 18.04+)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

```
Bash

ping -I 10.1.0.5 outlook.com
```

ⓘ Note

For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when trying to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. Follow the appropriate documentation for your Linux distribution. The following method is one way to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure you replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Red Hat Enterprise Linux and others

▼ Expand

ⓘ Note

To configure the extra IP addresses in RHEL10.x, it's enough to restart NetworkManger with: `systemctl restart NetworkManger.service` or reboot the system. No other steps are required.

1. Open a terminal window.
2. Ensure you're the root user. If you aren't, enter the following command:

   Bash

   ```
   sudo -i
   ```

3. Enter your password and follow instructions as prompted. Once you're the root user, go to the network scripts folder with the following command:

```bash
cd /etc/sysconfig/network-scripts
```

4. List the related ifcfg files using the following command:

```bash
ls ifcfg-*
```

   You should see **ifcfg-eth0** as one of the files.

5. Create a new configuration file for each IP added to the system.

```bash
touch ifcfg-eth0:0
```

6. Open the *ifcfg-eth0:0* file with the following command:

```bash
vi ifcfg-eth0:0
```

7. Add content to the file, **eth0:0** in this case, with the following command. Replace `10.1.0.5` with your new private IP address and subnet mask.

```bash
DEVICE=eth0:0
BOOTPROTO=static
ONBOOT=yes
IPADDR=10.1.0.5
NETMASK=255.255.255.0
```

8. Save the file with the following command:

```bash
:wq
```

9. Create a config file per IP address to add with their corresponding values:

```bash
```

```
touch ifcfg-eth0:1
```

Bash

```
vi ifcfg-eth0:1
```

Bash

```
DEVICE=eth0:1
BOOTPROTO=static
ONBOOT=yes
IPADDR=10.1.0.6
NETMASK=255.255.255.0
```

Bash

```
:wq
```

10. Restart the network services and make sure the changes are successful by running the following commands:

Bash

```
systemctl restart NetworkManager.service
ifconfig
```

You should see the IP address or addresses you added in the list returned.

Bash

```
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.4  netmask 255.255.255.0  broadcast 10.1.0.255
    inet6 fe80::6245:bdff:fe7d:704a  prefixlen 64  scopeid 0x20<link>
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
    RX packets 858  bytes 244215 (238.4 KiB)
    RX errors 0  dropped 0  overruns 0  frame 0
    TX packets 1021  bytes 262077 (255.9 KiB)
    TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

eth0:0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.5  netmask 255.255.255.0  broadcast 10.1.0.255
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)

eth0:1: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
    inet 10.1.0.6  netmask 255.255.255.0  broadcast 10.1.0.255
    ether 60:45:bd:7d:70:4a  txqueuelen 1000  (Ethernet)
```

Validation (Red Hat and others)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

Bash

```
ping -I 10.0.0.5 outlook.com
```

> ⓘ **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See the appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.0.0.5** with the private IP address that has a public IP address associated to it
  - **10.0.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Debian GNU/Linux

▼ Expand

We recommend looking at the latest documentation for your Linux distribution.

1. Open a terminal window.
2. Ensure you're the root user. If you aren't, enter the following command:

```bash
sudo -i
```

3. Update the configuration file of the network interface (assuming '**eth0**').

   - Keep the existing line item for dhcp. The primary IP address remains configured as it was previously.
   - Add a configuration for each static IP address using the following commands:

     ```bash
     cd /etc/network/interfaces.d/
     ls
     ```

     You should see a .cfg file.

4. Open the file. You should see the following lines at the end of the file:

```bash
auto eth0
iface eth0 inet dhcp
```

5. Add the following lines after the lines that exist in the file. Replace `10.1.0.5` with your private IP address and subnet mask.

```bash
iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
```

   Add the new IP addresses information in the configuration file:

```bash
iface eth0 inet static
address 10.1.0.5
netmask 255.255.255.0
iface eth0 inet static
address 10.1.0.6
netmask 255.255.255.0
```

6. Save the file by using the following command:

```
Bash
:wq
```

7. Restart networking services for the changes to take effect. For Debian 8 and above, use:

```
Bash
systemctl restart networking
```

   For prior versions of Debian, you can use below commands:

```
Bash
service networking restart
```

8. Verify the IP address is added to the network interface with the following command:

```
Bash
ip addr list eth0
```

   You should see the IP address you added as part of the list. Example:

```
Bash
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0d:3a:04:45:16 brd ff:ff:ff:ff:ff:ff
inet 10.1.0.5/24 brd 10.1.0.255 scope global eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.6/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet 10.1.0.4/24 brd 10.1.0.255 scope global secondary eth0
   valid_lft forever preferred_lft forever
inet6 fe80::20d:3aff:fe04:4516/64 scope link
   valid_lft forever preferred_lft forever
```

Validation (Debian GNU/Linux)

To ensure you're able to connect to the internet from your secondary IP configuration via the public IP associated with it, use the following command:

```
Bash
```

```
ping -I 10.1.0.5 outlook.com
```

> **Note**
>
> For secondary IP configurations, you can only ping to the Internet if the configuration has a public IP address associated with it. For primary IP configurations, a public IP address isn't required to ping to the Internet.

For Linux VMs, when attempting to validate outbound connectivity from a secondary NIC, you may need to add appropriate routes. See appropriate documentation for your Linux distribution. The following method to accomplish this goal:

Bash

```
echo 150 custom >> /etc/iproute2/rt_tables

ip rule add from 10.1.0.5 lookup custom
ip route add default via 10.1.0.1 dev eth2 table custom
```

- Ensure to replace:
  - **10.1.0.5** with the private IP address that has a public IP address associated to it
  - **10.1.0.1** to your default gateway
  - **eth2** to the name of your secondary NIC

Next steps

Create and manage a Windows virtual machine that has multiple NICs

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

Virtual machines (VMs) in Azure can have multiple virtual network interface cards (NICs) attached to them. A common scenario is to have different subnets for front-end and back-end connectivity. You can associate multiple NICs on a VM to multiple subnets, but those subnets must all reside in the same virtual network (vNet). This article details how to create a VM that has multiple NICs attached to it. You also learn how to add or remove NICs from an existing VM. Different VM sizes support a varying number of NICs, so size your VM accordingly.

> **Note**
>
> If multiple subnets are not required for a scenario, it may be more straightforward to utilize multiple IP configurations on a single NIC. Instructions for this setup can be found here.

Prerequisites

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myVnet*, and *myVM*.

Create a VM with multiple NICs

First, create a resource group. The following example creates a resource group named *myResourceGroup* in the *EastUs* location:

PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

Create virtual network and subnets

A common scenario is for a virtual network to have two or more subnets. One subnet may be for front-end traffic, the other for back-end traffic. To connect to both subnets,

you then use multiple NICs on your VM.

1. Define two virtual network subnets with New-AzVirtualNetworkSubnetConfig. The following example defines the subnets for *mySubnetFrontEnd* and *mySubnetBackEnd*:

   PowerShell

   ```
   $mySubnetFrontEnd = New-AzVirtualNetworkSubnetConfig -Name
   "mySubnetFrontEnd" `
       -AddressPrefix "192.168.1.0/24"
   $mySubnetBackEnd = New-AzVirtualNetworkSubnetConfig -Name
   "mySubnetBackEnd" `
       -AddressPrefix "192.168.2.0/24"
   ```

2. Create your virtual network and subnets with New-AzVirtualNetwork. The following example creates a virtual network named *myVnet*:

   PowerShell

   ```
   $myVnet = New-AzVirtualNetwork -ResourceGroupName "myResourceGroup" `
       -Location "EastUs" `
       -Name "myVnet" `
       -AddressPrefix "192.168.0.0/16" `
       -Subnet $mySubnetFrontEnd,$mySubnetBackEnd
   ```

Create multiple NICs

Create two NICs with New-AzNetworkInterface. Attach one NIC to the front-end subnet and one NIC to the back-end subnet. The following example creates NICs named *myNic1* and *myNic2*:

PowerShell

```
$frontEnd = $myVnet.Subnets|?{$_.Name -eq 'mySubnetFrontEnd'}
$myNic1 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `
    -Name "myNic1" `
    -Location "EastUs" `
    -SubnetId $frontEnd.Id

$backEnd = $myVnet.Subnets|?{$_.Name -eq 'mySubnetBackEnd'}
$myNic2 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `
    -Name "myNic2" `
    -Location "EastUs" `
    -SubnetId $backEnd.Id
```

Typically you also create a network security group to filter network traffic to the VM and a load balancer to distribute traffic across multiple VMs.

Create the virtual machine

Now start to build your VM configuration. Each VM size has a limit for the total number of NICs that you can add to a VM. For more information, see Windows VM sizes.

1. Set your VM credentials to the `$cred` variable as follows:

   PowerShell

   ```
   $cred = Get-Credential
   ```

2. Define your VM with New-AzVMConfig. The following example defines a VM named *myVM* and uses a VM size that supports more than two NICs (*Standard_DS3_v2*):

   PowerShell

   ```
   $vmConfig = New-AzVMConfig -VMName "myVM" -VMSize "Standard_DS3_v2"
   ```

3. Create the rest of your VM configuration with Set-AzVMOperatingSystem and Set-AzVMSourceImage. The following example creates a Windows Server 2016 VM:

   PowerShell

   ```
   $vmConfig = Set-AzVMOperatingSystem -VM $vmConfig `
       -Windows `
       -ComputerName "myVM" `
       -Credential $cred `
       -ProvisionVMAgent `
       -EnableAutoUpdate
   $vmConfig = Set-AzVMSourceImage -VM $vmConfig `
       -PublisherName "MicrosoftWindowsServer" `
       -Offer "WindowsServer" `
       -Skus "2016-Datacenter" `
       -Version "latest"
   ```

4. Attach the two NICs that you previously created with Add-AzVMNetworkInterface:

   PowerShell

   ```
   $vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic1.Id -
   Primary
   ```

```
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic2.Id
```

5. Create your VM with New-AzVM:

```
PowerShell

New-AzVM -VM $vmConfig -ResourceGroupName "myResourceGroup" -Location
"EastUs"
```

6. Add routes for secondary NICs to the OS by completing the steps in Configure the operating system for multiple NICs.

Add a NIC to an existing VM

To add a virtual NIC to an existing VM, you deallocate the VM, add the virtual NIC, then start the VM. Different VM sizes support a varying number of NICs, so size your VM accordingly. If needed, you can resize a VM.

1. Deallocate the VM with Stop-AzVM. The following example deallocates the VM named *myVM* in *myResourceGroup*:

```
PowerShell

Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

2. Get the existing configuration of the VM with Get-AzVm. The following example gets information for the VM named *myVM* in *myResourceGroup*:

```
PowerShell

$vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
```

3. The following example creates a virtual NIC with New-AzNetworkInterface named *myNic3* that is attached to *mySubnetBackEnd*. The virtual NIC is then attached to the VM named *myVM* in *myResourceGroup* with Add-AzVMNetworkInterface:

```
PowerShell

# Get info for the back end subnet
$myVnet = Get-AzVirtualNetwork -Name "myVnet" -ResourceGroupName
"myResourceGroup"
$backEnd = $myVnet.Subnets|?{$_.Name -eq 'mySubnetBackEnd'}

# Create a virtual NIC
```

```
$myNic3 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `
    -Name "myNic3" `
    -Location "EastUs" `
    -SubnetId $backEnd.Id

# Get the ID of the new virtual NIC and add to VM
$nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -
Name "MyNic3").Id
Add-AzVMNetworkInterface -VM $vm -Id $nicId | Update-AzVm -
ResourceGroupName "myResourceGroup"
```

Primary virtual NICs

One of the NICs on a multi-NIC VM needs to be primary. If one of the existing virtual NICs on the VM is already set as primary, you can skip this step. The following example assumes that two virtual NICs are now present on a VM and you wish to add the first NIC (`[0]`) as the primary:

PowerShell

```
# List existing NICs on the VM and find which one is primary
$vm.NetworkProfile.NetworkInterfaces

# Set NIC 0 to be primary
$vm.NetworkProfile.NetworkInterfaces[0].Primary = $true
$vm.NetworkProfile.NetworkInterfaces[1].Primary = $false

# Update the VM state in Azure
Update-AzVM -VM $vm -ResourceGroupName "myResourceGroup"
```

4. Start the VM with Start-AzVm:

PowerShell

```
Start-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM"
```

5. Add routes for secondary NICs to the OS by completing the steps in Configure the operating system for multiple NICs.

Remove a NIC from an existing VM

To remove a virtual NIC from an existing VM, you deallocate the VM, remove the virtual NIC, then start the VM.

1. Deallocate the VM with Stop-AzVM. The following example deallocates the VM named *myVM* in *myResourceGroup*:

   PowerShell

   ```
   Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
   ```

2. Get the existing configuration of the VM with Get-AzVm. The following example gets information for the VM named *myVM* in *myResourceGroup*:

   PowerShell

   ```
   $vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
   ```

3. Get information about the NIC remove with Get-AzNetworkInterface. The following example gets information about *myNic3*:

   PowerShell

   ```
   # List existing NICs on the VM if you need to determine NIC name
   $vm.NetworkProfile.NetworkInterfaces

   $nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -
   Name "myNic3").Id
   ```

4. Remove the NIC with Remove-AzVMNetworkInterface and then update the VM with Update-AzVm. The following example removes *myNic3* as obtained by `$nicId` in the preceding step:

   PowerShell

   ```
   Remove-AzVMNetworkInterface -VM $vm -NetworkInterfaceIDs $nicId | `
       Update-AzVm -ResourceGroupName "myResourceGroup"
   ```

5. Start the VM with Start-AzVm:

   PowerShell

   ```
   Start-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
   ```

Create multiple NICs with templates

Azure Resource Manager templates provide a way to create multiple instances of a resource during deployment, such as creating multiple NICs. Resource Manager templates use declarative JSON files to define your environment. For more information, see overview of Azure Resource Manager. You can use *copy* to specify the number of instances to create:

```JSON
"copy": {
    "name": "multiplenics",
    "count": "[parameters('count')]"
}
```

For more information, see creating multiple instances by using *copy*.

You can also use `copyIndex()` to append a number to a resource name. You can then create *myNic1*, *MyNic2* and so on. The following code shows an example of appending the index value:

```JSON
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of creating multiple NICs by using Resource Manager templates.

Add routes for secondary NICs to the OS by completing the steps in Configure the operating system for multiple NICs.

Configure guest OS for multiple NICs

Azure assigns a default gateway to the first (primary) network interface attached to the virtual machine. Azure does not assign a default gateway to additional (secondary) network interfaces attached to a virtual machine. Therefore, you are unable to communicate with resources outside the subnet that a secondary network interface is in, by default. Secondary network interfaces can, however, communicate with resources outside their subnet, though the steps to enable communication are different for different operating systems.

1. From a Windows command prompt, run the `route print` command, which returns output similar to the following output for a virtual machine with two attached network interfaces:

```
===========================================================================
====
Interface List
3...00 0d 3a 10 92 ce ......Microsoft Hyper-V Network Adapter #3
7...00 0d 3a 10 9b 2a ......Microsoft Hyper-V Network Adapter #4
===========================================================================
====
```

In this example, **Microsoft Hyper-V Network Adapter #4** (interface 7) is the secondary network interface that doesn't have a default gateway assigned to it.

2. From a command prompt, run the `ipconfig` command to see which IP address is assigned to the secondary network interface. In this example, 192.168.2.4 is assigned to interface 7. No default gateway address is returned for the secondary network interface.

3. To route all traffic destined for addresses outside the subnet of the secondary network interface to the gateway for the subnet, run the following command:

```
route add -p 0.0.0.0 MASK 0.0.0.0 192.168.2.1 METRIC 5015 IF 7
```

The gateway address for the subnet is the first IP address (ending in .1) in the address range defined for the subnet. If you don't want to route all traffic outside the subnet, you could add individual routes to specific destinations, instead. For example, if you only wanted to route traffic from the secondary network interface to the 192.168.3.0 network, you enter the command:

```
route add -p 192.168.3.0 MASK 255.255.255.0 192.168.2.1 METRIC 5015 IF
7
```

4. To confirm successful communication with a resource on the 192.168.3.0 network, for example, enter the following command to ping 192.168.3.4 using interface 7 (192.168.2.4):

```
ping 192.168.3.4 -S 192.168.2.4
```

You may need to open ICMP through the Windows firewall of the device you're pinging with the following command:

```
netsh advfirewall firewall add rule name=Allow-ping protocol=icmpv4
dir=in action=allow
```

5. To confirm the added route is in the route table, enter the `route print` command, which returns output similar to the following text:

```
===========================================================================
====
Active Routes:
Network Destination        Netmask          Gateway       Interface
Metric
          0.0.0.0          0.0.0.0      192.168.1.1      192.168.1.4
15
          0.0.0.0          0.0.0.0      192.168.2.1      192.168.2.4
5015
```

The route listed with *192.168.1.1* under **Gateway**, is the route that is there by default for the primary network interface. The route with *192.168.2.1* under **Gateway**, is the route you added.

Next steps

Review Windows VM sizes when you're trying to create a VM that has multiple NICs. Pay attention to the maximum number of NICs that each VM size supports.

How to create a Linux virtual machine in Azure with multiple network interface cards

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article details how to create a VM with multiple NICs with the Azure CLI.

Create supporting resources

Install the latest Azure CLI and log in to an Azure account using az login.

In the following examples, replace example parameter names with your own values. Example parameter names included *myResourceGroup*, *mystorageaccount*, and *myVM*.

First, create a resource group with az group create. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Create the virtual network with az network vnet create. The following example creates a virtual network named *myVnet* and subnet named *mySubnetFrontEnd*:

Azure CLI

```
az network vnet create \
    --resource-group myResourceGroup \
    --name myVnet \
    --address-prefix 10.0.0.0/16 \
    --subnet-name mySubnetFrontEnd \
    --subnet-prefix 10.0.1.0/24
```

Create a subnet for the back-end traffic with az network vnet subnet create. The following example creates a subnet named *mySubnetBackEnd*:

Azure CLI

```
az network vnet subnet create \
    --resource-group myResourceGroup \
```

```
    --vnet-name myVnet \
    --name mySubnetBackEnd \
    --address-prefix 10.0.2.0/24
```

Create a network security group with az network nsg create. The following example creates a network security group named *myNetworkSecurityGroup*:

Azure CLI

```
az network nsg create \
    --resource-group myResourceGroup \
    --name myNetworkSecurityGroup
```

Create and configure multiple NICs

Create two NICs with az network nic create. The following example creates two NICs, named *myNic1* and *myNic2*, connected the network security group, with one NIC connecting to each subnet:

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic1 \
    --vnet-name myVnet \
    --subnet mySubnetFrontEnd \
    --network-security-group myNetworkSecurityGroup
az network nic create \
    --resource-group myResourceGroup \
    --name myNic2 \
    --vnet-name myVnet \
    --subnet mySubnetBackEnd \
    --network-security-group myNetworkSecurityGroup
```

Create a VM and attach the NICs

When you create the VM, specify the NICs you created with `--nics`. You also need to take care when you select the VM size. There are limits for the total number of NICs that you can add to a VM. Read more about Linux VM sizes.

Create a VM with az vm create. The following example creates a VM named *myVM*:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image Ubuntu2204 \
    --size Standard_DS3_v2 \
    --admin-username azureuser \
    --generate-ssh-keys \
    --nics myNic1 myNic2
```

Add routing tables to the guest OS by completing the steps in Configure the guest OS for multiple NICs.

Add a NIC to a VM

The previous steps created a VM with multiple NICs. You can also add NICs to an existing VM with the Azure CLI. Different VM sizes support a varying number of NICs, so size your VM accordingly. If needed, you can resize a VM.

Create another NIC with az network nic create. The following example creates a NIC named *myNic3* connected to the back-end subnet and network security group created in the previous steps:

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic3 \
    --vnet-name myVnet \
    --subnet mySubnetBackEnd \
    --network-security-group myNetworkSecurityGroup
```

To add a NIC to an existing VM, first deallocate the VM with az vm deallocate. The following example deallocates the VM named *myVM*:

Azure CLI

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Add the NIC with az vm nic add. The following example adds *myNic3* to *myVM*:

Azure CLI

```
az vm nic add \
    --resource-group myResourceGroup \
```

```
    --vm-name myVM \
    --nics myNic3
```

Start the VM with az vm start:

Azure CLI

```
az vm start --resource-group myResourceGroup --name myVM
```

Add routing tables to the guest OS by completing the steps in Configure the guest OS for multiple NICs.

Remove a NIC from a VM

To remove a NIC from an existing VM, first deallocate the VM with az vm deallocate. The following example deallocates the VM named *myVM*:

Azure CLI

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Remove the NIC with az vm nic remove. The following example removes *myNic3* from *myVM*:

Azure CLI

```
az vm nic remove \
    --resource-group myResourceGroup \
    --vm-name myVM \
    --nics myNic3
```

Start the VM with az vm start:

Azure CLI

```
az vm start --resource-group myResourceGroup --name myVM
```

Create multiple NICs using Resource Manager templates

Azure Resource Manager templates use declarative JSON files to define your environment. You can read an overview of Azure Resource Manager. Resource Manager

templates provide a way to create multiple instances of a resource during deployment, such as creating multiple NICs. You use *copy* to specify the number of instances to create:

JSON

```
"copy": {
    "name": "multiplenics"
    "count": "[parameters('count')]"
}
```

Read more about creating multiple instances using *copy*.

You can also use a `copyIndex()` to then append a number to a resource name, which allows you to create `myNic1`, `myNic2`, etc. The following shows an example of appending the index value:

JSON

```
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of creating multiple NICs using Resource Manager templates.

Add routing tables to the guest OS by completing the steps in Configure the guest OS for multiple NICs.

Configure guest OS for multiple NICs

The previous steps created a virtual network and subnet, attached NICs, then created a VM. A public IP address and network security group rules that allow SSH traffic were not created. To configure the guest OS for multiple NICs, you need to allow remote connections and run commands locally on the VM.

To allow SSH traffic, create a network security group rule with az network nsg rule create as follows:

Azure CLI

```
az network nsg rule create \
    --resource-group myResourceGroup \
    --nsg-name myNetworkSecurityGroup \
    --name allow_ssh \
```

```
    --priority 101 \
    --destination-port-ranges 22
```

Create a public IP address with az network public-ip create and assign it to the first NIC with az network nic ip-config update:

Azure CLI

```
az network public-ip create --resource-group myResourceGroup --name
myPublicIP

az network nic ip-config update \
    --resource-group myResourceGroup \
    --nic-name myNic1 \
    --name ipconfig1 \
    --public-ip myPublicIP
```

To view the public IP address of the VM, use az vm show as follows::

Azure CLI

```
az vm show --resource-group myResourceGroup --name myVM -d --query publicIps
-o tsv
```

Now SSH to the public IP address of your VM. The default username provided in a previous step was *azureuser*. Provide your own username and public IP address:

Bash

```
ssh azureuser@137.117.58.232
```

To send to or from a secondary network interface, you have to manually add persistent routes to the operating system for each secondary network interface. In this article, *eth1* is the secondary interface. Instructions for adding persistent routes to the operating system vary by distro. See documentation for your distro for instructions.

When adding the route to the operating system, the gateway address is the first address of the subnet the network interface is in. For example, if the subnet has been assigned the range *10.0.2.0/24*, the gateway you specify for the route is *10.0.2.1* or if the subnet has been assigned the range *10.0.2.128/25*, the gateway you specify for the route is *10.0.2.129*. You can define a specific network for the route's destination, or specify a destination of *0.0.0.0*, if you want all traffic for the interface to go through the specified gateway. The gateway for each subnet is managed by the virtual network.

Once you've added the route for a secondary interface, verify that the route is in your route table with `route -n`. The following example output is for the route table that has the two network interfaces added to the VM in this article:

```
Bash

Kernel IP routing table
Destination     Gateway         Genmask         Flags Metric Ref    Use
Iface
0.0.0.0         10.0.1.1        0.0.0.0         UG    0      0        0 eth0
0.0.0.0         10.0.2.1        0.0.0.0         UG    0      0        0 eth1
10.0.1.0        0.0.0.0         255.255.255.0   U     0      0        0 eth0
10.0.2.0        0.0.0.0         255.255.255.0   U     0      0        0 eth1
168.63.129.16   10.0.1.1        255.255.255.255 UGH   0      0        0 eth0
169.254.169.254 10.0.1.1        255.255.255.255 UGH   0      0        0 eth0
```

Confirm that the route you added persists across reboots by checking your route table again after a reboot. To test connectivity, you can enter the following command, for example, where *eth1* is the name of a secondary network interface:

```
Bash

ping bing.com -c 4 -I eth1
```

Next steps

Review Linux VM sizes when trying to creating a VM with multiple NICs. Pay attention to the maximum number of NICs each VM size supports.

To further secure your VMs, use just in time VM access. This feature opens network security group rules for SSH traffic when needed, and for a defined period of time. For more information, see Manage virtual machine access using just in time.

Create an Azure Virtual Machine with Accelerated Networking

Deploy to Azure

This article describes how to create a Linux or Windows virtual machine (VM) with Accelerated Networking (AccelNet) enabled by using the Azure CLI command-line interface.

Prerequisites

Portal

- An Azure account with an active subscription. You can create an account for free.

Create a resource group and virtual network

Portal

Create a resource group

1. Sign in to the Azure portal.
2. In the search box at the top of the portal, enter **Resource group**. Select **Resource groups** in the search results.
3. Select **+ Create**.
4. In the **Basics** tab of **Create a resource group**, enter or select the following information:

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Enter **test-rg**.
Region	Select **East US 2**.

5. Select **Review + create**.

6. Select **Create**.

Create a virtual network

1. In the search box at the top of the portal, enter **Virtual network**. Select **Virtual networks** in the search results.

2. Select **+ Create**.

3. On the **Basics** tab of **Create virtual network**, enter or select the following information:

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Name	Enter **vnet-1**.
Region	Select **East US 2**.

4. Select **Next** to proceed to the **Security** tab.

5. Select **Next** to proceed to the **IP Addresses** tab.

6. In the address space box in **Subnets**, select the **default** subnet.

7. In **Edit subnet**, enter or select the following information:

Expand table

Setting	Value
Name	Enter **subnet-1**.
Starting address	Enter **10.0.0.0**.
Subnet size	Leave the default of **/24 (256 addresses)**.

8. Select **Save**.

9. Select **Review + create** at the bottom of the screen, and when validation passes, select **Create**.

Create Azure Bastion

Azure Bastion uses your browser to connect to VMs in your virtual network over secure shell (SSH) or remote desktop protocol (RDP) by using their private IP addresses. The VMs don't need public IP addresses, client software, or special configuration. For more information about Azure Bastion, see Azure Bastion.

> **Note**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

1. In the search box at the top of the portal, enter **Bastion**. Select **Bastions** in the search results.
2. Select **+ Create**.
3. In the **Basics** tab of **Create a Bastion**, enter or select the following information:

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Name	Enter **bastion**.
Region	Select **East US 2**.
Tier	Select **Developer**.
Virtual network	Select **vnet-1**.

4. Select **Review + create**.
5. Select **Create**.

Create a network interface with Accelerated Networking

Portal

Accelerated networking is enabled in the portal during virtual machine creation. Create a virtual machine in the following section.

> **Note**
>
> - The Accelerated Networking setting in the portal shows the user-selected state. Accelerated Networking allows choosing Disabled in the portal even if the VM size requires Accelerated Networking. VM sizes that require Accelerated Networking enable Accelerated Networking at runtime regardless of the user setting in the portal. Accelerated Networking is a required feature for general purpose VM sizes of v5 or higher.

Create a VM and attach the NIC

Portal

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
2. Select **+ Create** then **Azure virtual machine**.
3. In **Create a virtual machine** enter or select the following information in the **Basics** tab:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.

Setting	Value
Instance details	
Virtual machine name	Enter **vm-1**.
Region	Select **(US) East US 2**.
Availability options	Select **No infrastructure redundancy required**.
Security type	Select **Standard**.
Image	Select **Ubuntu Server 24.04 LTS - x64 Gen2**.
VM architecture	Leave the default of **x64**.
Size	Select a size.
Administrator account	
Authentication type	Select **SSH public key**.
Username	Enter a username.
SSH public key source	Select **Generate new key pair**.
Key pair name	Enter **vm-1-key**.
Inbound port rules	
Public inbound ports	Select **None**.

4. Select **Next: Disks** then **Next: Networking**.

5. In the Networking tab, enter or select the following information:

Expand table

Setting	Value
Network interface	
Virtual network	Select **vnet-1**.
Subnet	Select **subnet-1 (10.0.0.0/24)**.
Public IP	Select **None**.
Network interface (NIC) network security group	Select **Advanced**.
Configure network security group	Select **Create new**. In **Name** enter **nsg-1**.

Setting	Value
	Select **OK**.

6. Leave the rest of the options at the defaults and select **Review + create**.
7. Select **Create**.
8. When the **Generate new key pair** pop-up appears, select **Download private key and create resource**. The key file downloads as **vm-1-key.pem**. Make note of the download location for the `.pem` file. The private key is needed in later steps for connecting to the virtual machine with Azure Bastion.

Confirm that accelerated networking is enabled

Linux

1. In the Azure portal, search for and select *virtual machines*.
2. On the **Virtual machines** page, select your new VM.
3. On the VM's **Overview** page, select **Connect** then **Connect via Bastion**.
4. In the Bastion connection screen, change **Authentication Type** to **SSH Private Key from Local File**.
5. Enter the **Username** that you used when creating the virtual machine. In this example, the user is named **azureuser**, replace with the username you created.
6. In **Local File**, select the folder icon and browse to the private key file that was generated when you created the VM. The private key file is typically named `id_rsa` or `id_rsa.pem`.
7. Select **Connect**.
8. A new browser window opens with the Bastion connection to your VM.
9. From a shell on the remote VM, enter `uname -r` and confirm that the kernel version is one of the following versions, or greater:

   - **Ubuntu 16.04**: 4.11.0-1013.
   - **SLES SP3**: 4.4.92-6.18.
   - **RHEL**: 3.10.0-693, 2.6.32-573. RHEL 6.7-6.10 are supported if the Mellanox VF version 4.5+ is installed before Linux Integration Services 4.3+.

> **Note**
>
> Other kernel versions might be supported. For an updated list, see the compatibility tables for each distribution at Supported Linux and FreeBSD virtual machines for Hyper-V, and confirm that SR-IOV is supported. You can find more details in the release notes for Linux Integration Services for Hyper-V and Azure. *

10. Use the `lspci` command to confirm that the Mellanox VF device is exposed to the VM. The returned output should be similar to the following example:

    Output

    ```
    0000:00:00.0 Host bridge: Intel Corporation 440BX/ZX/DX - 82443BX/ZX/DX Host
    bridge (AGP disabled) (rev 03)
    0000:00:07.0 ISA bridge: Intel Corporation 82371AB/EB/MB PIIX4 ISA (rev 01)
    0000:00:07.1 IDE interface: Intel Corporation 82371AB/EB/MB PIIX4 IDE (rev 01)
    0000:00:07.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 02)
    0000:00:08.0 VGA compatible controller: Microsoft Corporation Hyper-V virtual
    VGA
    0001:00:02.0 Ethernet controller: Mellanox Technologies MT27500/MT27520 Family
    [ConnectX-3/ConnectX-3 Pro Virtual Function]
    ```

11. Use the `ethtool -S eth0 | grep vf_` command to check for activity on the virtual function (VF). If accelerated networking is enabled and active, you receive output similar to the following example:

    Output

    ```
    vf_rx_packets: 992956
    vf_rx_bytes: 2749784180
    vf_tx_packets: 2656684
    vf_tx_bytes: 1099443970
    vf_tx_dropped: 0
    ```

12. Close the Bastion connection to the VM.

Windows

Once you create the VM in Azure, connect to the VM and confirm that the Ethernet controller is installed in Windows.

1. In the Azure portal, search for and select *virtual machines*.

2. On the **Virtual machines** page, select your new VM.

3. On the VM's **Overview** page, select **Connect** then **Connect via Bastion**.

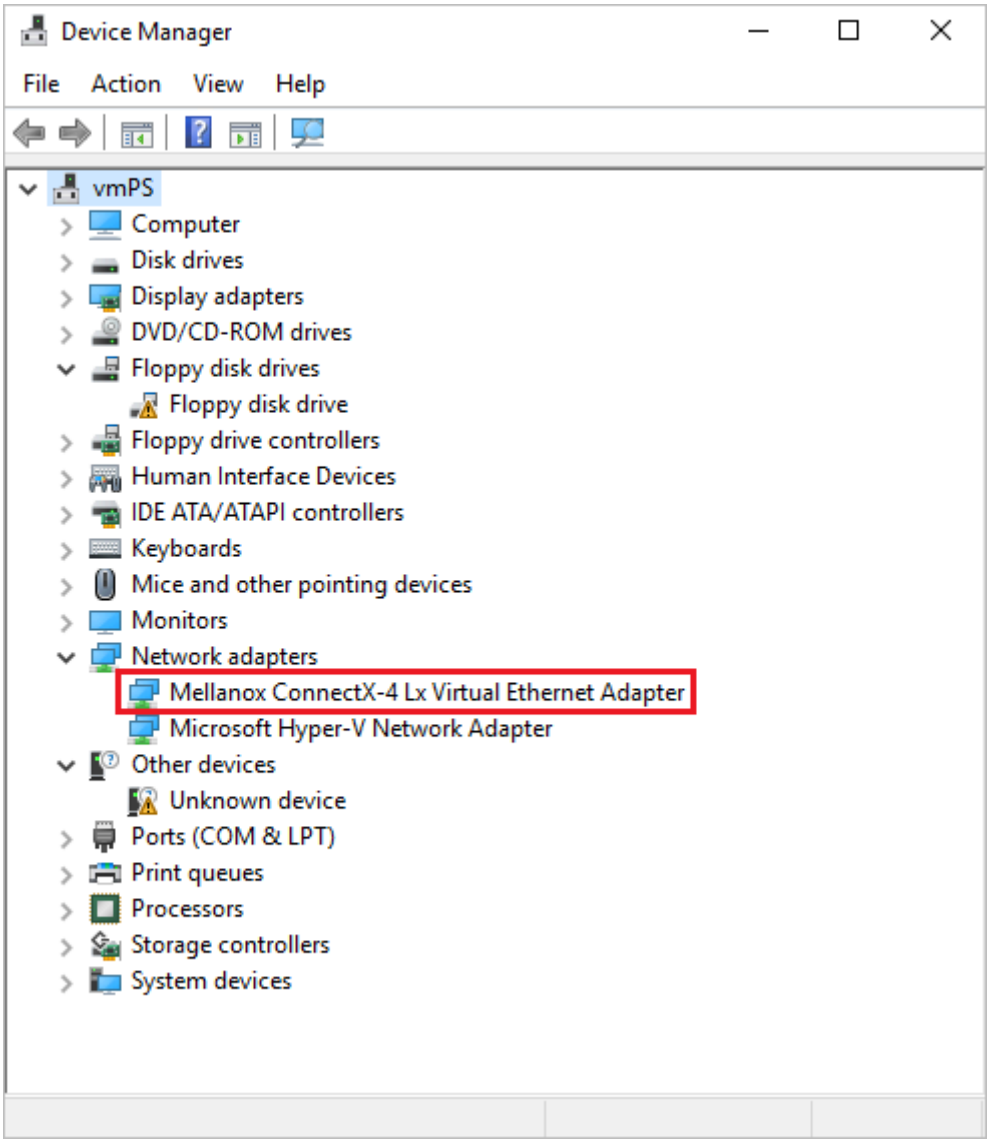
4. Enter the credentials you used when you created the VM, and then select **Connect**.

5. A new browser window opens with the Bastion connection to your VM.

6. On the remote VM, right-click **Start** and select **Device Manager**.

7. In the **Device Manager** window, expand the **Network adapters** node.

8. Confirm that the **Mellanox ConnectX-4 Lx Virtual Ethernet Adapter** appears, as shown in the following image:



The presence of the adapter confirms that Accelerated Networking is enabled for your VM.

9. Verify the packets are flowing over the VF interface from the output of the following command:

```
PowerShell
```

```
PS C:\ > Get-NetAdapter | Where-Object InterfaceDescription -like
"*Mellanox*Virtual*" | Get-NetAdapterStatistics

Name                            ReceivedBytes ReceivedUnicastPackets
SentBytes SentUnicastPackets
----                            ------------- ----------------------       --
------- ------------------
Ethernet 2                           492447549                 347643
7468446               34991
```

> **Note**
>
> If the Mellanox adapter fails to start, open an administrator command prompt on the remote VM and enter the following command:
>
> `netsh int tcp set global rss = enabled`

10. Close the Bastion connection to the VM.

Create an Azure Virtual Machine with Accelerated Networking

Deploy to Azure

This article describes how to create a Linux or Windows virtual machine (VM) with Accelerated Networking (AccelNet) enabled by using the Azure CLI command-line interface.

Prerequisites

Portal

- An Azure account with an active subscription. You can create an account for free.

Create a resource group and virtual network

Portal

Create a resource group

1. Sign in to the Azure portal.
2. In the search box at the top of the portal, enter **Resource group**. Select **Resource groups** in the search results.
3. Select **+ Create**.
4. In the **Basics** tab of **Create a resource group**, enter or select the following information:

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Enter **test-rg**.
Region	Select **East US 2**.

5. Select **Review + create**.

6. Select **Create**.

Create a virtual network

1. In the search box at the top of the portal, enter **Virtual network**. Select **Virtual networks** in the search results.

2. Select **+ Create**.

3. On the **Basics** tab of **Create virtual network**, enter or select the following information:

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Name	Enter **vnet-1**.
Region	Select **East US 2**.

4. Select **Next** to proceed to the **Security** tab.

5. Select **Next** to proceed to the **IP Addresses** tab.

6. In the address space box in **Subnets**, select the **default** subnet.

7. In **Edit subnet**, enter or select the following information:

Expand table

Setting	Value
Name	Enter **subnet-1**.
Starting address	Enter **10.0.0.0**.
Subnet size	Leave the default of **/24 (256 addresses)**.

8. Select **Save**.

9. Select **Review + create** at the bottom of the screen, and when validation passes, select **Create**.

Create Azure Bastion

Azure Bastion uses your browser to connect to VMs in your virtual network over secure shell (SSH) or remote desktop protocol (RDP) by using their private IP addresses. The VMs don't need public IP addresses, client software, or special configuration. For more information about Azure Bastion, see Azure Bastion.

> **Note**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

1. In the search box at the top of the portal, enter **Bastion**. Select **Bastions** in the search results.
2. Select **+ Create**.
3. In the **Basics** tab of **Create a Bastion**, enter or select the following information:

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Select **test-rg**.
Name	Enter **bastion**.
Region	Select **East US 2**.
Tier	Select **Developer**.
Virtual network	Select **vnet-1**.

4. Select **Review + create**.
5. Select **Create**.

Create a network interface with Accelerated Networking

Portal

Accelerated networking is enabled in the portal during virtual machine creation. Create a virtual machine in the following section.

> **Note**
>
> - The Accelerated Networking setting in the portal shows the user-selected state. Accelerated Networking allows choosing Disabled in the portal even if the VM size requires Accelerated Networking. VM sizes that require Accelerated Networking enable Accelerated Networking at runtime regardless of the user setting in the portal. Accelerated Networking is a required feature for general purpose VM sizes of v5 or higher.

Create a VM and attach the NIC

Portal

1. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines** in the search results.
2. Select **+ Create** then **Azure virtual machine**.
3. In **Create a virtual machine** enter or select the following information in the **Basics** tab:

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg**.

Setting	Value
Instance details	
Virtual machine name	Enter **vm-1**.
Region	Select **(US) East US 2**.
Availability options	Select **No infrastructure redundancy required**.
Security type	Select **Standard**.
Image	Select **Ubuntu Server 24.04 LTS - x64 Gen2**.
VM architecture	Leave the default of **x64**.
Size	Select a size.
Administrator account	
Authentication type	Select **SSH public key**.
Username	Enter a username.
SSH public key source	Select **Generate new key pair**.
Key pair name	Enter **vm-1-key**.
Inbound port rules	
Public inbound ports	Select **None**.

4. Select **Next: Disks** then **Next: Networking**.

5. In the Networking tab, enter or select the following information:

Expand table

Setting	Value
Network interface	
Virtual network	Select **vnet-1**.
Subnet	Select **subnet-1 (10.0.0.0/24)**.
Public IP	Select **None**.
Network interface (NIC) network security group	Select **Advanced**.
Configure network security group	Select **Create new**. In **Name** enter **nsg-1**.

Setting	Value
	Select **OK**.

6. Leave the rest of the options at the defaults and select **Review + create**.
7. Select **Create**.
8. When the **Generate new key pair** pop-up appears, select **Download private key and create resource**. The key file downloads as **vm-1-key.pem**. Make note of the download location for the `.pem` file. The private key is needed in later steps for connecting to the virtual machine with Azure Bastion.

Confirm that accelerated networking is enabled

Linux

1. In the Azure portal, search for and select *virtual machines*.
2. On the **Virtual machines** page, select your new VM.
3. On the VM's **Overview** page, select **Connect** then **Connect via Bastion**.
4. In the Bastion connection screen, change **Authentication Type** to **SSH Private Key from Local File**.
5. Enter the **Username** that you used when creating the virtual machine. In this example, the user is named **azureuser**, replace with the username you created.
6. In **Local File**, select the folder icon and browse to the private key file that was generated when you created the VM. The private key file is typically named `id_rsa` or `id_rsa.pem`.
7. Select **Connect**.
8. A new browser window opens with the Bastion connection to your VM.
9. From a shell on the remote VM, enter `uname -r` and confirm that the kernel version is one of the following versions, or greater:

   - **Ubuntu 16.04**: 4.11.0-1013.
   - **SLES SP3**: 4.4.92-6.18.
   - **RHEL**: 3.10.0-693, 2.6.32-573. RHEL 6.7-6.10 are supported if the Mellanox VF version 4.5+ is installed before Linux Integration Services 4.3+.

> **Note**
>
> Other kernel versions might be supported. For an updated list, see the compatibility tables for each distribution at Supported Linux and FreeBSD virtual machines for Hyper-V, and confirm that SR-IOV is supported. You can find more details in the release notes for Linux Integration Services for Hyper-V and Azure. *

10. Use the `lspci` command to confirm that the Mellanox VF device is exposed to the VM. The returned output should be similar to the following example:

    Output

    ```
    0000:00:00.0 Host bridge: Intel Corporation 440BX/ZX/DX - 82443BX/ZX/DX Host
    bridge (AGP disabled) (rev 03)
    0000:00:07.0 ISA bridge: Intel Corporation 82371AB/EB/MB PIIX4 ISA (rev 01)
    0000:00:07.1 IDE interface: Intel Corporation 82371AB/EB/MB PIIX4 IDE (rev 01)
    0000:00:07.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 02)
    0000:00:08.0 VGA compatible controller: Microsoft Corporation Hyper-V virtual
    VGA
    0001:00:02.0 Ethernet controller: Mellanox Technologies MT27500/MT27520 Family
    [ConnectX-3/ConnectX-3 Pro Virtual Function]
    ```

11. Use the `ethtool -S eth0 | grep vf_` command to check for activity on the virtual function (VF). If accelerated networking is enabled and active, you receive output similar to the following example:

    Output

    ```
    vf_rx_packets: 992956
    vf_rx_bytes: 2749784180
    vf_tx_packets: 2656684
    vf_tx_bytes: 1099443970
    vf_tx_dropped: 0
    ```

12. Close the Bastion connection to the VM.

Windows

Once you create the VM in Azure, connect to the VM and confirm that the Ethernet controller is installed in Windows.

1. In the Azure portal, search for and select *virtual machines*.

2. On the **Virtual machines** page, select your new VM.

3. On the VM's **Overview** page, select **Connect** then **Connect via Bastion**.

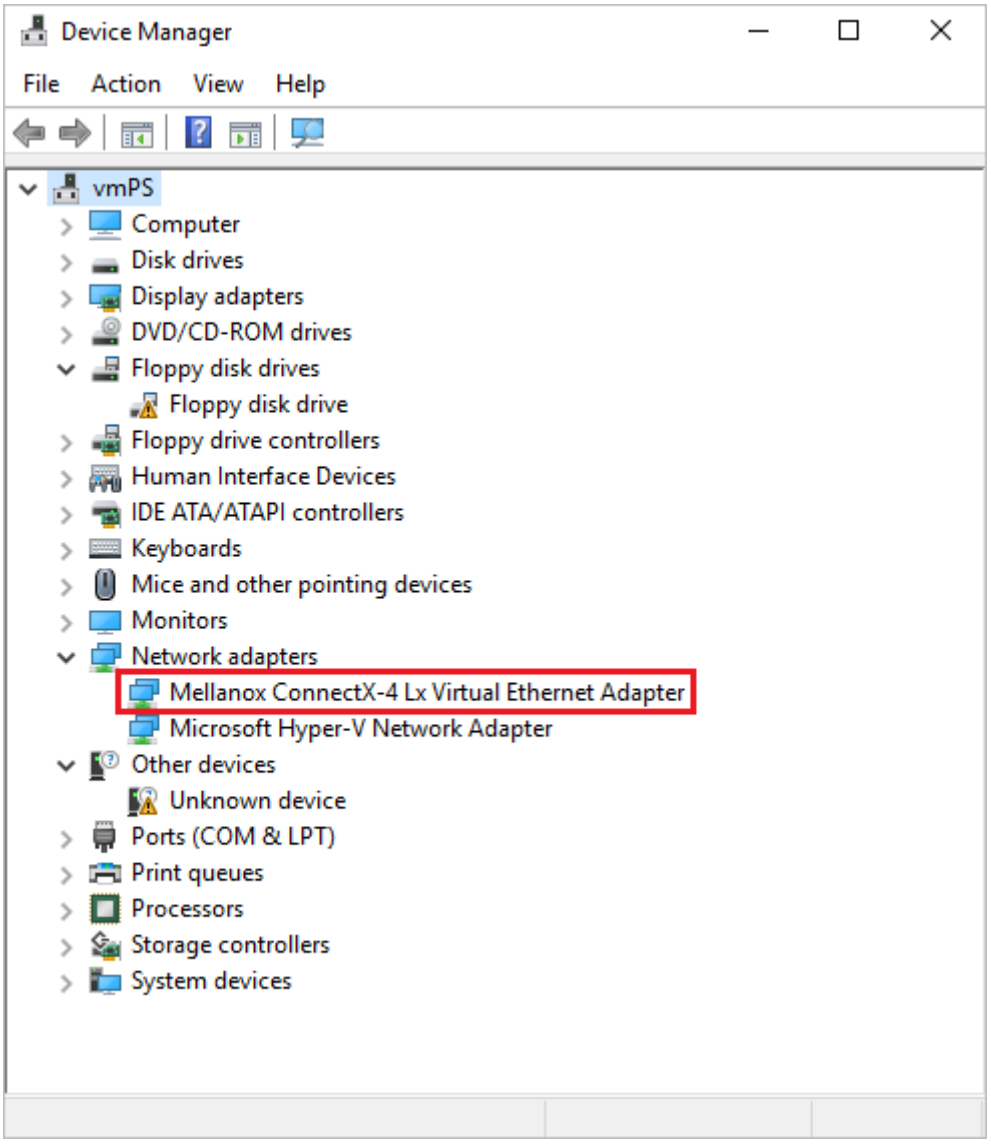
4. Enter the credentials you used when you created the VM, and then select **Connect**.

5. A new browser window opens with the Bastion connection to your VM.

6. On the remote VM, right-click **Start** and select **Device Manager**.

7. In the **Device Manager** window, expand the **Network adapters** node.

8. Confirm that the **Mellanox ConnectX-4 Lx Virtual Ethernet Adapter** appears, as shown in the following image:



The presence of the adapter confirms that Accelerated Networking is enabled for your VM.

9. Verify the packets are flowing over the VF interface from the output of the following command:

```
PowerShell
```

```
PS C:\ > Get-NetAdapter | Where-Object InterfaceDescription -like
"*Mellanox*Virtual*" | Get-NetAdapterStatistics

Name                            ReceivedBytes ReceivedUnicastPackets
SentBytes SentUnicastPackets
----                            ------------- ----------------------       --
------- ------------------
Ethernet 2                           492447549                 347643
7468446               34991
```

> **Note**
>
> If the Mellanox adapter fails to start, open an administrator command prompt on the remote VM and enter the following command:
>
> `netsh int tcp set global rss = enabled`

10. Close the Bastion connection to the VM.

Set up DPDK in a Linux virtual machine

Article • 10/02/2024

Data Plane Development Kit (DPDK) on Azure offers a faster user-space packet processing framework for performance-intensive applications. This framework bypasses the virtual machine's kernel network stack.

In typical packet processing that uses the kernel network stack, the process is interrupt-driven. When the network interface receives incoming packets, there's a kernel interrupt to process the packet and a context switch from the kernel space to the user space. DPDK eliminates context switching and the interrupt-driven method in favor of a user-space implementation that uses poll mode drivers for fast packet processing.

DPDK consists of sets of user-space libraries that provide access to lower-level resources. These resources can include hardware, logical cores, memory management, and poll mode drivers for network interface cards.

DPDK can run on Azure virtual machines that are supporting multiple operating system distributions. DPDK provides key performance differentiation in driving network function virtualization implementations. These implementations can take the form of network virtual appliances (NVAs), such as virtual routers, firewalls, VPNs, load balancers, evolved packet cores, and denial-of-service (DDoS) applications.

A list of setup instructions for DPDK on MANA VMs is available here: Microsoft Azure Network Adapter (MANA) and DPDK on Linux

Benefit

Higher packets per second (PPS): Bypassing the kernel and taking control of packets in the user space reduces the cycle count by eliminating context switches. It also improves the rate of packets that are processed per second in Azure Linux virtual machines.

Supported operating systems minimum versions

The following distributions from the Azure Marketplace are supported:

Expand table

Linux OS	Kernel version
Ubuntu 18.04	4.15.0-1014-azure+
SLES 15 SP1	4.12.14-8.19-azure+
RHEL 7.5	3.10.0-862.11.6.el7.x86_64+
Debian 10	4.19.0-1-cloud+

The noted versions are the minimum requirements. Newer versions are supported too.

A list of requirements for DPDK on MANA VMs is available here: Microsoft Azure Network Adapter (MANA) and DPDK on Linux

Custom kernel support

For any Linux kernel version that's not listed, see Patches for building an Azure-tuned Linux kernel. For more information, you can also contact aznetdpdk@microsoft.com.

Region support

All Azure regions support DPDK.

Prerequisites

Accelerated networking must be enabled on a Linux virtual machine. The virtual machine should have at least two network interfaces, with one interface for management. Enabling Accelerated networking on management interface isn't recommended. Learn how to create a Linux virtual machine with accelerated networking enabled.

In addition, DPDK uses RDMA verbs to create data queues on the Network Adapter. In the VM, ensure the correct RDMA kernel drivers are loaded. They can be mlx4_ib, mlx5_ib or mana_ib depending on VM sizes.

Install DPDK manually (recommended)

DPDK installation instructions for MANA VMs are available here: Microsoft Azure Network Adapter (MANA) and DPDK on Linux

Install build dependencies

RHEL

RHEL7.5

Bash

```
yum -y groupinstall "Infiniband Support"
sudo dracut --add-drivers "mlx4_en mlx4_ib mlx5_ib" -f
yum install -y gcc kernel-devel-`uname -r` numactl-devel.x86_64
librdmacm-devel libmnl-devel meson
```

Compile and install DPDK manually

1. Download the latest DPDK. Version 22.11 LTS or newer is recommended for Azure.
2. Build the default config with `meson builddir`.
3. Compile with `ninja -C builddir`.
4. Install with `DESTDIR=<output folder> ninja -C builddir install`.

Configure the runtime environment

After restarting, run the following commands once:

1. Hugepages

    - Configure hugepage by running the following command, once for each numa node:

    Bash

    ```
     echo 1024 | sudo tee
    /sys/devices/system/node/node*/hugepages/hugepages-2048kB/nr_hugepages
    ```

    - Create a directory for mounting with `mkdir /mnt/huge`.
    - Mount hugepages with `mount -t hugetlbfs nodev /mnt/huge`.
    - Check that hugepages are reserved with `grep Huge /proc/meminfo`.

- The example above is for 2M huge pages. 1G huge pages can also be used.

> ⓘ **Note**
>
> There is a way to modify the grub file so that hugepages are reserved on boot by following the instructions for the DPDK. The instructions are at the bottom of the page. When you're using an Azure Linux virtual machine, modify files under **/etc/config/grub.d** instead, to reserve hugepages across reboots.

2. MAC & IP addresses: Use `ifconfig -a` to view the MAC and IP address of the network interfaces. The *VF* network interface and *NETVSC* network interface have the same MAC address, but only the *NETVSC* network interface has an IP address. *VF* interfaces are running as subordinate interfaces of *NETVSC* interfaces.

3. PCI addresses

   - Use `ethtool -i <vf interface name>` to find out which PCI address to use for *VF*.

   - If *eth0* has accelerated networking enabled, make sure that testpmd doesn't accidentally take over the *VF* pci device for *eth0*. If the DPDK application accidentally takes over the management network interface and causes you to lose your SSH connection, use the serial console to stop the DPDK application. You can also use the serial console to stop or start the virtual machine.

4. Load *ibuverbs* on each reboot with `modprobe -a ib_uverbs`. For SLES 15 only, also load *mlx4_ib* with `modprobe -a mlx4_ib`.

Master PMD

DPDK applications must run over the master PMD that is exposed in Azure. If the application runs directly over the VF PMD, it doesn't receive all packets that are destined to the VM, since some packets show up over the synthetic interface. DPDK supports two types of master PMDs: NetVSC PMD and Failsafe PMD. A master PMD guarantees that the application receives all packets that are destined to it. It also makes sure that the application keeps running in DPDK mode over master PMD, even if the VF is revoked when the host is being serviced.

NetVSC PMD

NetVSC is the recommended PMD to run as a master PMD in Azure. It guarantees that the application receives all packets that are destined to it. It also makes sure that the application keeps running in DPDK mode, even if the VF is revoked when the host is being serviced. For more information about how to use and configure NetVSC PMD, see (https://doc.dpdk.org/guides/nics/netvsc.html).

Failsafe PMD

Note: running with failsafe PMD is not recommended in Azure. If your DPDK version is 22.11 LTS or newer, use NetVSC PMD is recommended.

As an alternative, you can run a DPDK application over the failsafe PMD. For more information about failsafe PMD see Fail-safe poll mode driver library .

Run testpmd

To run testpmd in root mode, use `sudo` before the *testpmd* command.

Basic: Sanity check, failsafe adapter initialization

1. Run the following commands to start a single port testpmd application:

```
Bash

testpmd -w <pci address from previous step> \
  -- -i \
  --port-topology=chained
```

2. Run the following commands to start a dual port testpmd application:

```
Bash

testpmd -w <pci address nic1> \
-w <pci address nic2> \
-- -i
```

After it's started, run `show port info all` to check port information. You should see one or two DPDK ports that are net_netvsc.

3. Use `start <port> /stop <port>` to start traffic.

The previous commands start *testpmd* in interactive mode, which is recommended for trying out testpmd commands.

Basic: Single sender/single receiver

The following commands periodically print the packets per second statistics:

1. On the TX side, run the following command:

```
Bash

testpmd \
  -l <core-list> \
  -n <num of mem channels> \
  -w <pci address of the device you plan to use> \
  -- --port-topology=chained \
  --nb-cores <number of cores to use for test pmd> \
  --forward-mode=txonly \
  --eth-peer=<port id>,<receiver peer MAC address> \
  --stats-period <display interval in seconds>
```

2. On the RX side, run the following command:

```
Bash

testpmd \
  -l <core-list> \
  -n <num of mem channels> \
  -w <pci address of the device you plan to use> \
  -- --port-topology=chained \
  --nb-cores <number of cores to use for test pmd> \
  --forward-mode=rxonly \
  --eth-peer=<port id>,<sender peer MAC address> \
  --stats-period <display interval in seconds>
```

When you're running the previous commands on a virtual machine, change *IP_SRC_ADDR* and *IP_DST_ADDR* in `app/test-pmd/txonly.c` to match the actual IP address of the virtual machines before you compile. Otherwise, the packets are dropped before reaching the receiver.

Advanced: Single sender/single forwarder

The following commands periodically print the packets per second statistics:

1. On the TX side, run the following command:

```bash
testpmd \
  -l <core-list> \
  -n <num of mem channels> \
  -w <pci address of the device you plan to use> \
  -- --port-topology=chained \
  --nb-cores <number of cores to use for test pmd> \
  --forward-mode=txonly \
  --eth-peer=<port id>,<receiver peer MAC address> \
  --stats-period <display interval in seconds>
```

2. On the FWD side, run the following command:

```bash
testpmd \
  -l <core-list> \
  -n <num of mem channels> \
  -w <pci address NIC1> \
  -w <pci address NIC2> \
  -- --nb-cores <number of cores to use for test pmd> \
  --forward-mode=io \
  --eth-peer=<recv port id>,<sender peer MAC address> \
  --stats-period <display interval in seconds>
```

When you're running the previous commands on a virtual machine, change *IP_SRC_ADDR* and *IP_DST_ADDR* in `app/test-pmd/txonly.c` to match the actual IP address of the virtual machines before you compile. Otherwise, the packets are dropped before reaching the forwarder. You can't have a third machine receive forwarded traffic, because the *testpmd* forwarder doesn't modify the layer-3 addresses, unless you make some code changes.

Install DPDK via system package (not recommended)

RHEL

```bash
sudo yum install -y dpdk
```

TCP/IP performance tuning for Azure VMs

Article • 04/21/2025

This article discusses common TCP/IP performance tuning techniques and some things to consider when you use them for virtual machines running on Azure. It provides a basic overview of the techniques and explored how virtual machines can be tuned.

Common TCP/IP tuning techniques

MTU, fragmentation, and large send offload

MTU

The maximum transmission unit (MTU) is the largest size frame (packet plus network access headers) specified in bytes that can be sent over a network interface. The MTU is a configurable setting. The default MTU used on Azure VMs, and the default setting on most network devices globally, is 1,500 bytes.

Fragmentation

Fragmentation occurs when a packet is sent that exceeds the MTU of a network interface. The TCP/IP stack breaks the packet into smaller pieces (fragments) that conform to the interface's MTU. Fragmentation occurs at the IP layer and is independent of the underlying protocol (such as TCP). When a 2,000-byte packet is sent over a network interface with an MTU of 1,500, the packet is broken down into one 1,500-byte packet and one 500-byte packet.

Network devices in the path between a source and destination can either drop packets that exceed the MTU or fragment the packet into smaller pieces.

The Don’t Fragment bit in an IP packet

The Don’t Fragment (DF) bit is a flag in the IP protocol header. The DF bit indicates that network devices on the path between the sender and receiver must not fragment the packet. This bit could be set for many reasons. (See the "Path MTU Discovery" section of this article for one example.) When a network device receives a packet with the Don’t Fragment bit set, and that packet exceeds the device's interface MTU, the standard behavior is for the device to drop the packet. The device sends an ICMP Fragmentation Needed message back to the original source of the packet.

Performance implications of fragmentation

Fragmentation can have negative performance implications. One of the main reasons for the effect on performance is the CPU/memory effect of the fragmentation and reassembly of packets. When a network device needs to fragment a packet, it has to allocate CPU/memory resources to perform fragmentation.

The same thing happens when the packet is reassembled. The network device must store all the fragments until they're received so it can reassemble them into the original packet.

Azure and fragmentation

Azure doesn't process fragmented packets with Accelerated Networking. When a VM receives a fragmented packet, the nonaccelerated path processes it. As a result, fragmented packets miss the benefits of Accelerated Networking, such as lower latency, reduced jitter, and higher packets per second. For this reason, we recommend avoiding fragmentation if possible.

Azure, by default, drops fragmented packets that arrive at the VM out of order, meaning the packets don't match the transmission sequence from the source endpoint. This issue can occur when packets travel over the internet or other large WANs.

Tune the MTU

You can improve internal Virtual Network throughput by increasing the MTU for your VM's traffic. However, if the VM communicates with destinations outside the Virtual Network that have a different MTU, fragmentation might occur and reduce performance.

For more information about setting the MTU on Azure VMs, see Configure Maximum Transmission Unit (MTU) for virtual machines in Azure.

Large send offload

Large send offload (LSO) can improve network performance by offloading the segmentation of packets to the ethernet adapter. When LSO is enabled, the TCP/IP stack creates a large TCP packet and sends it to the ethernet adapter for segmentation before forwarding it. The benefit of LSO frees the CPU from segmenting packets into sizes that conform to the MTU and offload that processing to the ethernet interface hardware. To learn more about the benefits of LSO, see Supporting large send offload.

When LSO is enabled, Azure customers might notice large frame sizes during packet captures. These large frame sizes might cause some customers to assume fragmentation is occurring or that a large MTU is being used when it’s not. With LSO, the ethernet adapter can advertise a

larger maximum segment size (MSS) to the TCP/IP stack to create a larger TCP packet. The ethernet adapter then breaks this entire nonsegmented frame into many smaller frames according to its MTU, which are visible in a packet capture performed on the VM.

TCP MSS window scaling and PMTUD

TCP maximum segment size

TCP maximum segment size (MSS) is a setting that limits the size of TCP segments, which avoids fragmentation of TCP packets. Operating systems typically use this formula to set MSS:

```
MSS = MTU - (IP header size + TCP header size)
```

The IP header and the TCP header are 20 bytes each, or 40 bytes total. An interface with an MTU of 1,500 has an MSS of 1,460. The MSS is configurable.

This setting is agreed to in the TCP three-way handshake when a TCP session is set up between a source and a destination. Both sides send an MSS value, and the lower of the two is used for the TCP connection.

Keep in mind that the MTUs of the source and destination aren't the only factors that determine the MSS value. Intermediary network devices, like VPN gateways, including Azure VPN Gateway, can adjust the MTU independently of the source and destination to ensure optimal network performance.

Path MTU Discovery

MSS is negotiated, but it might not indicate the actual MSS that can be used. Other network devices in the path between the source and the destination might have a lower MTU value than the source and destination. In this case, the device whose MTU is smaller than the packet drops the packet. The device sends back an ICMP Fragmentation Needed (Type 3, Code 4) message that contains its MTU. This ICMP message allows the source host to reduce its Path MTU appropriately. The process is called Path MTU Discovery (PMTUD).

The PMTUD process reduces network performance due to its inefficiency. When a network path's MTU is exceeded, packets must be retransmitted with a lower MSS. If a network firewall blocks the ICMP Fragmentation Needed message, the sender remains unaware of the need to lower the MSS and repeatedly retransmits the packet. For this reason, we advise against increasing the Azure VM MTU.

VPN and MTU

If you use VMs that perform encapsulation (like IPsec VPNs), there are some other considerations regarding packet size and MTU. VPNs add more headers to packets. The added headers increase the packet size and require a smaller MSS.

For Azure, we recommend that you set TCP MSS clamping to 1,350 bytes and tunnel interface MTU to 1,400. For more information, see the VPN devices and IPsec/IKE parameters page.

Latency, round-trip time, and TCP window scaling

Latency and round-trip time

The speed of light determines network latency over a fiber optic network. The round-trip time (RTT) between two network devices governs TCP network throughput.

Expand table

Route	Distance	One-way time	RTT
New York to San Francisco	4,148 km	21 ms	42 ms
New York to London	5,585 km	28 ms	56 ms
New York to Sydney	15,993 km	80 ms	160 ms

This table shows the straight-line distance between two locations. In networks, the distance is typically longer than the straight-line distance. Here's a simple formula to calculate minimum RTT as governed by the speed of light:

```
minimum RTT = 2 * (Distance in kilometers / Speed of propagation)
```

You can use 200 for the speed of propagation. The speed of propagation is the distance, in kilometers, that light travels in 1 millisecond.

Let's take New York to San Francisco as an example. The straight-line distance is 4,148 km. Entering that value into the equation results in the following equation:

```
Minimum RTT = 2 * (4,148 / 200)
```

The output of the equation is in milliseconds.

If you want to get the best network performance, the logical option is to select destinations with the shortest distance between them. You should also design your virtual network to optimize the path of traffic and reduce latency. For more information, see the "Network design considerations" section of this article.

Latency and round-trip time effects on TCP

Round-trip time has a direct effect on maximum TCP throughput. In TCP protocol, *window size* is the maximum amount of traffic that can be sent over a TCP connection before the sender needs to receive acknowledgment from the receiver. If the TCP MSS is set to 1,460 and the TCP window size is set to 65,535, the sender can send 45 packets before acknowledgment from the receiver. If the sender doesn't get acknowledgment, it retransmits the data. Here's the formula:

```
TCP window size / TCP MSS = packets sent
```

In this example, 65,535 / 1,460 is rounded up to 45.

This "waiting for acknowledgment" state, a mechanism to ensure reliable delivery of data, is what causes RTT to affect TCP throughput. The longer the sender waits for acknowledgment, the longer it needs to wait before sending more data.

Here's the formula for calculating the maximum throughput of a single TCP connection:

```
Window size / (RTT latency in milliseconds / 1,000) = maximum bytes/second
```

This table shows the maximum megabytes/per second throughput of a single TCP connection. (For readability, megabytes is used for the unit of measure.)

Expand table

TCP window size (bytes)	RTT latency (ms)	Maximum megabyte/second throughput	Maximum megabit/second throughput
65,535	1	65.54	524.29
65,535	30	2.18	17.48
65,535	60	1.09	8.74
65,535	90	0.73	5.83
65,535	120	0.55	4.37

If packets are lost, the maximum throughput of a TCP connection is reduced while the sender retransmits data it sent.

TCP window scaling

TCP window scaling is a technique that dynamically increases the TCP window size to allow more data to be sent before an acknowledgment is required. In the previous example, 45 packets would be sent before an acknowledgment was required. If you increase the number of

packets that can be sent before an acknowledgment is needed, you're reducing the number of times a sender is waiting for acknowledgment.

This table illustrates those relationships:

Expand table

TCP window size (bytes)	RTT latency (ms)	Maximum megabyte/second throughput	Maximum megabit/second throughput
65,535	30	2.18	17.48
131,070	30	4.37	34.95
262,140	30	8.74	69.91
524,280	30	17.48	139.81

But the TCP header value for TCP window size is only 2 bytes long, which means the maximum value for a receive window is 65,535. To increase the maximum window size, a TCP window scale factor was introduced.

The scale factor is also a setting that you can configure in an operating system. Here's the formula for calculating the TCP window size by using scale factors:

```
TCP window size = TCP window size in bytes * (2^scale factor)
```

Here's the calculation for a window scale factor of 3 and a window size of 65,535:

```
65,535 * (2^3) = 524,280 bytes
```

A scale factor of 14 results in a TCP window size of 14 (the maximum offset allowed). The TCP window size is 1,073,725,440 bytes (8.5 gigabits).

Support for TCP window scaling

Windows can set different scaling factors for different connection types. (Classes of connections include datacenter, internet, and so on.) You use the `Get-NetTCPConnection` PowerShell command to view the window scaling connection type:

PowerShell

```
Get-NetTCPConnection
```

You can use the `Get-NetTCPSetting` PowerShell command to view the values of each class:

PowerShell

```
Get-NetTCPSetting
```

You can set the initial TCP window size and TCP scaling factor in Windows by using the `Set-NetTCPSetting` PowerShell command. For more information, see Set-NetTCPSetting.

PowerShell

```
Set-NetTCPSetting
```

The following values are the effective TCP settings for `AutoTuningLevel`:

Expand table

AutoTuningLevel	Scaling factor	Scaling multiplier	Formula to calculate maximum window size
Disabled	None	None	Window size
Restricted	4	2^4	Window size * (2^4)
Highly restricted	2	2^2	Window size * (2^2)
Normal	8	2^8	Window size * (2^8)
Experimental	14	2^14	Window size * (2^14)

These settings are the most likely to affect TCP performance, but keep in mind that many other factors across the internet, outside the control of Azure, can also affect TCP performance.

Accelerated networking and receive side scaling

Accelerated networking

Virtual machine network functions historically are CPU intensive on both the guest VM and the hypervisor/host. The host CPU processes in software all packets that transit through the host, including all virtual network encapsulation and decapsulation. The more traffic that goes through the host, the higher the CPU load. If the host CPU is busy with other operations that affects network throughput and latency. Azure addresses this issue with accelerated networking.

Accelerated networking provides consistent ultralow network latency via the in-house programmable hardware of Azure and technologies like SR-IOV. Accelerated networking

moves much of the Azure software-defined networking stack off the CPUs and into FPGA-based SmartNICs. This change enables end-user applications to reclaim compute cycles that put less load on the VM decreasing jitter and inconsistency in latency. In other words, performance can be more deterministic.

Accelerated networking improves performance by allowing the guest VM to bypass the host and establish a datapath directly with a host's SmartNIC. Here are some benefits of accelerated networking:

- **Lower latency / higher packets per second (pps)**: Removing the virtual switch from the datapath eliminates the time packets spend in the host for policy processing and increases the number of packets that can be processed in the VM.
- **Reduced jitter**: Virtual switch processing depends on the amount of policy that needs to be applied and the workload of the CPU that's doing the processing. Offloading the policy enforcement to the hardware removes that variability by delivering packets directly to the VM, eliminating the host-to-VM communication and all software interrupts and context switches.
- **Decreased CPU utilization**: Bypassing the virtual switch in the host leads to less CPU utilization for processing network traffic.

To use accelerated networking, you need to explicitly enable it on each applicable VM. See Create a Linux virtual machine with Accelerated Networking for instructions.

Receive side scaling

Receive side scaling (RSS) is a network driver technology that distributes the receiving of network traffic more efficiently by distributing receive processing across multiple CPUs in a multiprocessor system. In simple terms, RSS allows a system to process more received traffic because it uses all available CPUs instead of just one. For a more technical discussion of RSS, see Introduction to receive side scaling.

To get the best performance when accelerated networking is enabled on a VM, you need to enable RSS. RSS can also provide benefits on VMs that don't use accelerated networking. For an overview of how to determine if RSS is enabled and how to enable it, see Optimize network throughput for Azure virtual machines.

TCP TIME_WAIT and TIME_WAIT assassination

TCP TIME_WAIT is another common setting that impacts network and application performance. Busy VMs frequently open and close many sockets, either as clients or servers. During normal TCP operations, a socket often enters the TIME_WAIT state and remains there for an extended

period. This state ensures the delivery of any remaining data on the socket before it closes. As a result, TCP/IP stacks typically prevent socket reuse by dropping the client's TCP SYN packet silently.

You can configure how long a socket remains in the TIME_WAIT state. The duration can range from 30 seconds to 240 seconds. Sockets are a finite resource, and their availability is configurable. Typically, about 30,000 sockets are available for use at any given time. If the system consumes all available sockets or if clients and servers use mismatched TIME_WAIT settings, the VM might attempt to reuse a socket still in the TIME_WAIT state. In such cases, new connections fail because the TCP SYN packets are silently dropped.

The value for port range for outbound sockets is configurable within the TCP/IP stack of an operating system. The same thing is true for TCP TIME_WAIT settings and socket reuse. Changing these numbers can potentially improve scalability. But, depending on the situation, these changes could cause interoperability issues. You should be careful if you change these values.

You can use TIME_WAIT assassination to address this scaling limitation. TIME_WAIT assassination allows a socket to be reused in certain situations, like when the sequence number in the IP packet of the new connection exceeds the sequence number of the last packet from the previous connection. In this case, the operating system allows the new connection to be established (it accepts the new SYN/ACK) and force close the previous connection that was in a TIME_WAIT state. This capability is supported on Windows VMs in Azure. To learn about support in other VMs, check with the OS vendor.

To learn about configuring TCP TIME_WAIT settings and source port range, see Settings that can be modified to improve network performance.

Virtual network factors that can affect performance

VM maximum outbound throughput

Azure provides various VM sizes and types, each with a different mix of performance capabilities. One of these capabilities is network throughput (or bandwidth), which is measured in megabits per second (Mbps). Because virtual machines are hosted on shared hardware, the network capacity needs to be shared fairly among the virtual machines using the same hardware. Larger virtual machines are allocated more bandwidth than smaller virtual machines.

The network bandwidth allocated to each virtual machine is measured on egress (outbound) traffic from the virtual machine. All network traffic leaving the virtual machine is counted

toward the allocated limit, regardless of destination. If a virtual machine has a 1,000-Mbps limit, that limit applies whether the outbound traffic is destined for another virtual machine in the same virtual network or one outside of Azure.

Ingress isn't measured or limited directly. But there are other factors, like CPU and storage limits, that can affect a virtual machine's ability to process incoming data.

Accelerated networking is designed to improve network performance, including latency, throughput, and CPU utilization. Accelerated networking can improve a virtual machine's throughput, but it can do that only up to the virtual machine's allocated bandwidth.

Azure virtual machines have at least one network interface attached to them. They might have several. The bandwidth allocated to a virtual machine is the sum of all outbound traffic across all network interfaces attached to the machine. In other words, the bandwidth is allocated on a per-virtual machine basis, regardless of how many network interfaces are attached to the machine.

Expected outbound throughput and the number of network interfaces supported by each VM size are detailed in Sizes for Windows virtual machines in Azure. To see maximum throughput, select a type, like **General purpose**, and then find the section about the size series on the resulting page (for example, "Dv2-series"). For each series, there's a table that provides networking specifications in the last column, which is titled "Max NICs / Expected network bandwidth (Mbps)."

The throughput limit applies to the virtual machine. Throughput isn't affected by these factors:

- **Number of network interfaces**: The bandwidth limit applies to the sum of all outbound traffic from the virtual machine.
- **Accelerated networking**: Though this feature can be helpful in achieving the published limit, it doesn't change the limit.
- **Traffic destination**: All destinations count toward the outbound limit.
- **Protocol**: All outbound traffic over all protocols counts towards the limit.

For more information, see Virtual machine network bandwidth.

Internet performance considerations

As discussed throughout this article, factors on the internet and outside the control of Azure can affect network performance. Here are some of those factors:

- **Latency**: The round-trip time between two endpoints is affected by issues on intermediate networks, by traffic that doesn't take the "shortest" distance path, and by

suboptimal peering paths.

- **Packet loss**: Packet loss is caused by network congestion, physical path issues, and underperforming network devices.
- **MTU size/Fragmentation**: Fragmentation along the path can lead to delays in data arrival or in packets arriving out of order, which can affect the delivery of packets.

Traceroute is a good tool for measuring network performance characteristics (like packet loss and latency) along every network path between a source device and a destination device.

Network design considerations

Along with the considerations discussed earlier in this article, the topology of a virtual network can affect the network's performance. For example, a hub-and-spoke design that backhauls traffic globally to a single-hub virtual network introduces network latency, which affects overall network performance.

The number of network devices that network traffic passes through can also affect overall latency. In a hub-and-spoke design, if traffic passes through a spoke network virtual appliance and a hub virtual appliance before transiting to the internet, the network virtual appliances introduce some latency.

Azure regions, virtual networks, and latency

Azure regions are made up of multiple datacenters that exist within a general geographic area. These datacenters might not be physically next to each other. In some cases, they're separated by as much as 10 kilometers. The virtual network is a logical overlay on top of the Azure physical datacenter network. A virtual network doesn't imply any specific network topology within the datacenter.

For example, two VMs that are in the same virtual network and subnet might be in different racks, rows, or even datacenters. They can be separated by feet of fiber optic cable or by kilometers of fiber optic cable. This variation could introduce variable latency (a few milliseconds difference) between different VMs.

The geographic placement of VMs, and the potential resulting latency between two VMs, is influenced by the configuration of availability sets, proximity placement groups, and availability zones. But the distance between datacenters in a region is region-specific and primarily influenced by datacenter topology in the region.

Source NAT port exhaustion

A deployment in Azure can communicate with endpoints outside of Azure on the public internet and/or in the public IP space. When an instance initiates an outbound connection, Azure dynamically maps the private IP address to a public IP address. After Azure creates this mapping, return traffic for the outbound originated flow can also reach the private IP address where the flow originated.

For every outbound connection, the Azure Load Balancer needs to maintain this mapping for some period of time. With the multitenant nature of Azure, maintaining this mapping for every outbound flow for every VM can be resource intensive. So there are limits that are set and based on the configuration of the Azure Virtual Network. Or, to say that more precisely, an Azure VM can only make some outbound connections at a given time. When these limits are reached, the VM won't make more outbound connections.

But this behavior is configurable. For more information about SNAT and SNAT port exhaustion, see this article.

Measure network performance on Azure

Many of the performance maximums in this article are related to the network latency / round-trip time (RTT) between two VMs. This section provides some suggestions for how to test latency/RTT and how to test TCP performance and VM network performance. You can tune and performance test the TCP/IP and network values discussed earlier by using the techniques described in this section. Enter latency, MTU, MSS, and window size values into the calculations provided earlier and compare theoretical maximums to actual values observed during testing.

Measure round-trip time and packet loss

TCP performance relies heavily on RTT and packet Loss. The PING utility available in Windows and Linux provides the easiest way to measure RTT and packet loss. The output of PING shows the minimum/maximum/average latency between a source and destination. It shows packet loss. PING uses the ICMP protocol by default. You can use PsPing to test TCP RTT. For more information, see PsPing.

ICMP and TCP pings don't measure the accelerated networking datapath. To measure the datapath, read about Latte and SockPerf in this article.

Measure actual bandwidth of a virtual machine

To accurately measure the bandwidth of Azure VMs, follow this guidance.

For more information on testing other scenarios, see these articles:

- Troubleshooting Expressroute network performance
- How to validate VPN throughput to a virtual network

Detect inefficient TCP behaviors

In packet captures, Azure customers might see TCP packets with TCP flags (SACK, DUP ACK, RETRANSMIT, and FAST RETRANSMIT) that could indicate network performance problems. These packets specifically indicate network inefficiencies that result from packet loss. But packet loss isn't necessarily caused by Azure performance problems. Performance issues could be the result of application, operating system, or other problems that might not be directly related to the Azure platform.

Also, keep in mind that some retransmission and duplicate ACKs are normal on a network. TCP protocols were built to be reliable. Evidence of these TCP packets in a packet capture doesn't necessarily indicate a systemic network problem, unless they're excessive.

Still, these packet types are indications that TCP throughput isn't achieving its maximum performance, for reasons discussed in other sections of this article.

Next steps

Now that you've learned about TCP/IP performance tuning for Azure VMs, consider exploring other factors for planning virtual networks. You can also learn more about connecting and configuring virtual networks.

Virtual machine network bandwidth

Azure virtual machine network throughput determines how much bandwidth your applications can use for network communication. Azure offers various virtual machine sizes and types, each with different network performance capabilities measured in megabits per second (Mbps). Understanding how bandwidth allocation works helps you optimize application performance and choose the right VM size for your workload requirements.

Each virtual machine size has a different mix of performance capabilities. One capability is network throughput (or bandwidth), measured in megabits per second (Mbps). Because virtual machines are hosted on shared hardware, the network capacity must be shared fairly among the virtual machines sharing the same hardware. Larger virtual machines are allocated relatively more bandwidth than smaller virtual machines.

The network bandwidth allocated to each virtual machine is measured on egress (outbound) traffic from the virtual machine. All network traffic leaving the virtual machine is counted toward the allocated limit, regardless of destination. For example, if a virtual machine has a 1,000-Mbps limit, that limit applies whether the outbound traffic is destined for another virtual machine in the same virtual network, or outside of Azure.

Ingress isn't measured or limited directly. However, there are other factors, such as CPU and storage limits, which can affect a virtual machine's ability to process incoming data.

Accelerated networking is a feature designed to improve network performance, including latency, throughput, and CPU utilization. While accelerated networking can improve a virtual machine's throughput, it can do so only up to the virtual machine's allocated bandwidth. To learn more about Accelerated networking, see Accelerated networking for Windows or Linux virtual machines.

Azure virtual machines must have one, but might have several, network interfaces attached to them. Bandwidth allocated to a virtual machine is the sum of all outbound traffic across all network interfaces attached to a virtual machine. In other words, the allocated bandwidth is per virtual machine, regardless of how many network interfaces are attached to the virtual machine. To learn how many network interfaces different Azure VM sizes support, see Azure Windows and Linux VM sizes.

Expected network throughput

Expected outbound throughput and the number of network interfaces supported by each VM size is detailed in Azure Windows and Linux VM sizes. Select a type, such as General purpose, then select a size and series on the resulting page, such as the Dv2-series. Each series has a table with networking specifications in the last column titled,

Max NICs / Expected network performance (Mbps).

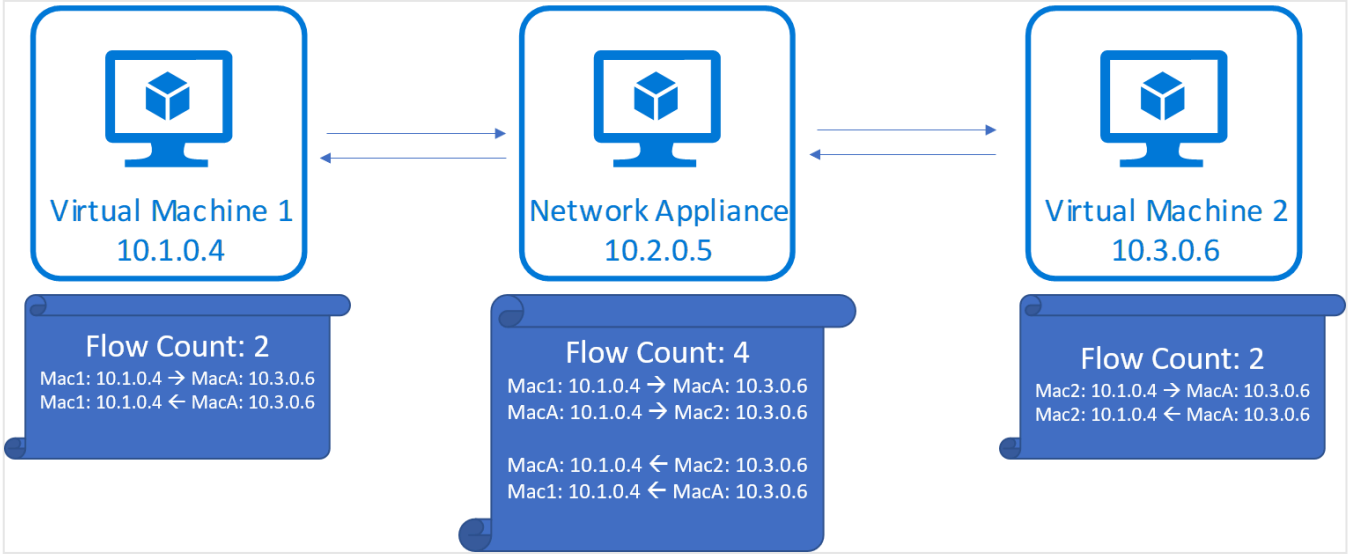
The throughput limit applies to the virtual machine. Throughput is unaffected by the following factors:

- **Number of network interfaces**: The bandwidth limit is cumulative of all outbound traffic from the virtual machine.
- **Accelerated networking**: Though the feature can be helpful in achieving the published limit, it doesn't change the limit.
- **Traffic destination**: All destinations count toward the outbound limit.
- **Protocol**: All outbound traffic over all protocols counts towards the limit.

Network flow limits

The number of network connections on a virtual machine at any moment can affect its network performance. The Azure networking stack uses data structures called **flows** to track each direction of a TCP/UDP connection. For a typical TCP/UDP connection, it creates two flows: one for inbound traffic and another for outbound traffic. A Five-tuple, consisting of protocol, local IP address, remote IP address, local port, and remote port, identifies each flow.

Data transfer between endpoints requires creation of several flows in addition to flows that perform the data transfer. Some examples are flows created for DNS resolution and flows created for load balancer health probes. Network virtual appliances (NVAs) such as gateways, proxies, firewalls, see flows created for connections terminated at the appliance and originated by the appliance.



Flow limits and active connections recommendations

Today, the Azure networking stack supports at least 500K total connections (500k inbound + 500k outbound flows) for all VM sizes. For the smallest sizes (2-7 vCPU), we recommend that your workload utilizes 100K or fewer total connections. Recommended connection limits vary based on the VM vCPU count and are shared below.

Azure Boost VM Sizes with MANA

Expand table

VM Size(#vCPUs)	Recommended Connection Limit
2-7	100,000
8-15	500,000
16-31	700,000
32-63	800,000
64+	2,000,000

Other VM Sizes

Expand table

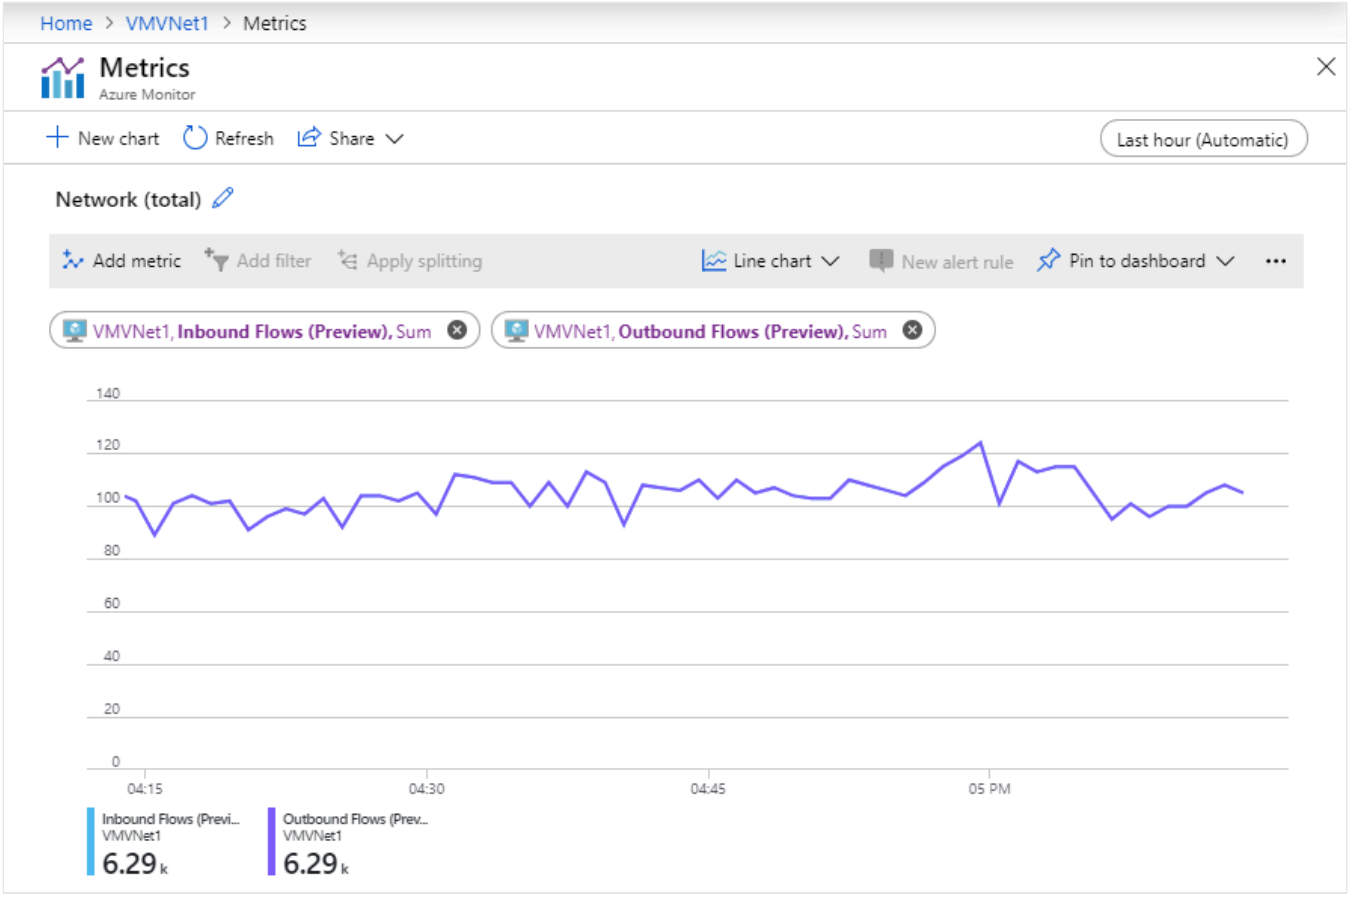
VM Size(#vCPUs)	Recommended Connection Limit
2-7	100,000
8-15	500,000
16-31	700,000
32-63	800,000
64+	1,000,000

Network Optimized VM sizes have improved network connection performance that differs from the limits above. For information on Network Optimized VM connection limits see the following article

Above the recommended limit, connections may be dropped or encounter reduced performance. Connection establishment and termination rates can also affect network performance as connection establishment and termination shares CPU with packet processing routines. We recommend that you benchmark workloads against expected traffic patterns and scale out workloads appropriately to match your performance needs. Microsoft has released a tool to make this easier, see NCPS Tool for more details.

Note, NVAs such as gateways, proxies, firewalls, and other applications that forward traffic should use half the recommended connection limits, as forwarding traffic consumes twice the number of flows when compared to typical client-server communication.

Metrics are available in Azure Monitor to track the number of network flows and the flow creation rate on your VM or Virtual Machine Scale Sets instances. It's possible that the number of flows tracked by your VM guest OS is different than the number of flows tracked by the Azure network stack for various reasons. To ensure your network connections aren't dropped, use the Inbound and Outbound Flows metric.



Next steps

- Optimize network throughput for a virtual machine operating system
- Test network throughput for a virtual machine.

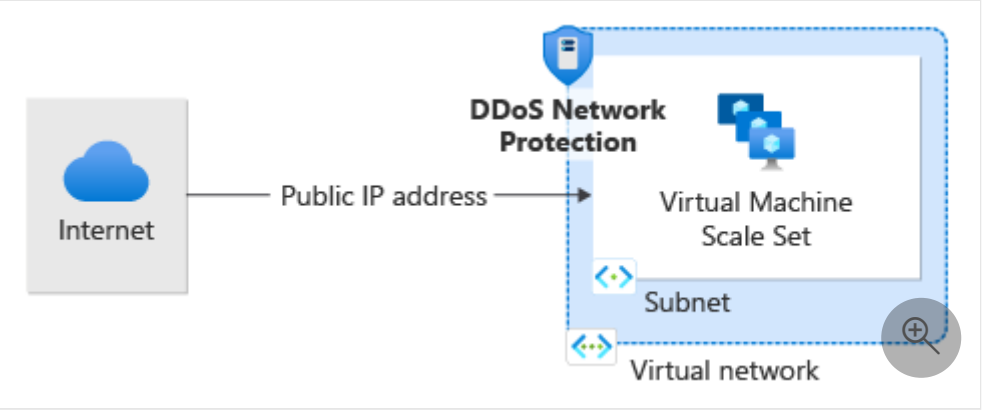
Quickstart: Create and configure Azure DDoS Network Protection using the Azure portal

Summarize this article for me

In this Quickstart, you create a DDoS protection plan and link it to a virtual network.

A DDoS protection plan defines a set of virtual networks that have DDoS Network Protection enabled, across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions under a single Microsoft Entra tenant to the same plan.



Prerequisites

- If you don't have an Azure subscription, create a free account before you begin.
- Sign in to the Azure portal. Ensure that your account is assigned to the network contributor role or to a custom role that is assigned the appropriate actions listed in the how-to guide on Permissions.

Create a DDoS protection plan

1. Select **Create a resource** in the upper left corner of the Azure portal.
2. Search the term *DDoS*. When **DDoS protection plan** appears in the search results, select it.
3. Select **Create**.
4. Enter or select the following values.

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Select **Create new** and enter **MyResourceGroup**.
Name	Enter **MyDdosProtectionPlan**.
Region	Enter **East US**.

5. Select **Review + create** then **Create**

> **Note**
>
> Although DDoS Protection Plan resources needs to be associated with a region, users can enable DDoS protection on Virtual Networks in different regions and across multiple subscriptions under a single Microsoft Entra tenant.

Enable DDoS protection for a virtual network

New virtual network

1. Select **Create a resource** in the upper left corner of the Azure portal.
2. Select **Networking**, and then select **Virtual network**.
3. Enter or select the following values then select **Next**.

Expand table

Setting	Value
Subscription	Select your subscription.
Resource group	Select **Use existing**, and then select **MyResourceGroup**
Name	Enter **MyVnet**.
Region	Enter **East US**.

4. In the *Security* pane, select **Enable** on the **Azure DDoS Network Protection** radio.

5. Select **MyDdosProtectionPlan** from the **DDoS protection plan** pane or create a new plan. The plan you select can be in the same, or different subscription than the virtual network, but both subscriptions must be associated to the same Microsoft Entra tenant.

6. Select **Next**. In the **IP addresses** pane, update the IP address space with the following values.

Expand table

Setting	Value
IPv4 address space	Enter **10.1.0.0/16**.
Subnet name	Under **Subnets**, select the **default** link and update the name to **mySubnet**.
Starting address	Enter **10.1.0.0**.
Size	Select **/24**.

7. Select **Save** > **Review + create** > **Create**.

> **Note**
>
> You cannot move a virtual network to another resource group or subscription when DDoS Protection is enabled for the virtual network. If you need to move a virtual network with DDoS Protection enabled, disable DDoS Protection first, move the virtual network, and then enable DDoS Protection. After the move, the auto-tuned policy thresholds for all the protected public IP addresses in the virtual network are reset.

Configure an Azure DDoS Protection Plan using Azure Firewall Manager

Azure Firewall Manager is a platform to manage and protect your network resources at scale. You can associate your virtual networks with a DDoS protection plan within Azure Firewall Manager. See Configure an Azure DDoS Protection Plan using Azure Firewall Manager.

Enable DDoS protection for all virtual networks

This built-in policy detects virtual networks within a defined scope that don't have DDoS Network Protection enabled. It can then optionally create a remediation task to enable protection for the virtual network. See Azure Policy built-in definitions for Azure DDoS Network Protection for full list of built-in policies.

View protected resources

First, check the details of your DDoS protection plan:

1. Search for **DDoS protection plans** in the **Search resources, services, and docs box** at the top of the Azure portal. When it appears, select it.
2. Select your DDoS protection plan from the list.
3. Under **Settings**, select **Protected resources**.
4. In the **Protected resources** page, you can view the resources that are protected by this DDoS protection plan.

Disable for a virtual network:

You can disable DDoS protection for a virtual network while keeping it enabled on other virtual networks. To disable DDoS protection for a virtual network, follow these steps.

1. Search for **Virtual Network** in the **Search resources, services, and docs box** at the top of the Azure portal. When it appears, select it.
2. Under **Settings**, select **DDoS Protection**.
3. Select **Disable** for **DDoS Network Protection**.

> **Note**
>
> Disabling DDoS protection for a virtual network won't delete the protection plan. You'll still incur costs if you only disable DDoS protection without deleting the plan. To avoid unnecessary charges, you need to delete the DDoS protection plan resource. See Clean up resources.

Clean up resources

You can keep your resources for the next tutorial. If no longer needed, delete the *MyResourceGroup* used in this example. When you delete the resource group, you also delete the DDoS protection plan and all its related resources. If you don't intend to use this DDoS protection plan, you should remove resources to avoid unnecessary charges.

> ⚠ **Warning**
>
> This action is irreversible.

1. In the Azure portal, search for and select **Resource groups**, or select **Resource groups** from the Azure portal menu.
2. Filter or scroll down to find the *MyResourceGroup* resource group.
3. Select the resource group, then select **Delete resource group**.
4. Type the resource group name to verify, and then select **Delete**.

> ⓘ **Note**
>
> To delete a DDoS protection plan, first dissociate all virtual networks from it.

Next steps

To learn how to configure metrics alerts through Azure Monitor, continue to the tutorials.

Configure Azure DDoS Protection metric alerts through portal

Last updated on 01/26/2026

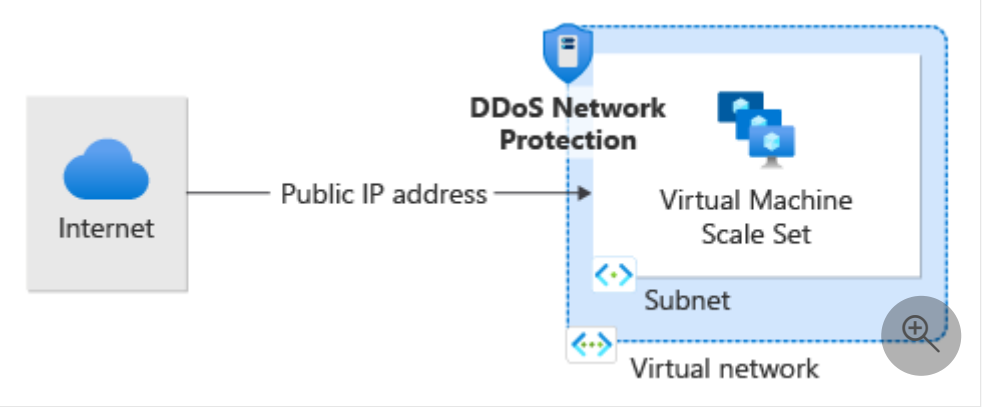
QuickStart: Create and configure Azure DDoS Network Protection using Azure PowerShell

Summarize this article for me

Get started with Azure DDoS Network Protection by using Azure PowerShell.

A DDoS protection plan defines a set of virtual networks that have DDoS Network Protection enabled, across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions to the same plan.

In this QuickStart, you'll create a DDoS protection plan and link it to a virtual network.



Prerequisites

- An Azure account with an active subscription. Create an account for free.
- Azure PowerShell installed locally or Azure Cloud Shell.

> **Note**
>
> We recommend that you use the Azure Az PowerShell module to interact with Azure. To get started, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services.

You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

Expand table

Option	Example/Link
Select **Try It** in the upper-right corner of a code or command block. Selecting **Try It** doesn't automatically copy the code or command to Cloud Shell.	
Go to https://shell.azure.com, or select the **Launch Cloud Shell** button to open Cloud Shell in your browser.	
Select the **Cloud Shell** button on the menu bar at the upper right in the Azure portal.	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl**+**Shift**+**V** on Windows and Linux, or by selecting **Cmd**+**Shift**+**V** on macOS.
4. Select **Enter** to run the code or command.

Create a DDoS Protection plan

In Azure, you allocate related resources to a resource group. You can either use an existing resource group or create a new one.

To create a resource group, use New-AzResourceGroup. In this example, we'll name our resource group *MyResourceGroup* and use the *East US* location:

Azure PowerShell

```
New-AzResourceGroup -Name MyResourceGroup -Location "East US"
```

Now create a DDoS protection plan named *MyDdosProtectionPlan*:

Azure PowerShell

```
New-AzDdosProtectionPlan -ResourceGroupName MyResourceGroup -Name
MyDdosProtectionPlan -Location "East US"
```

Enable DDoS for a virtual network

You can enable DDoS protection when creating a new virtual network or for an existing virtual network. Select the tab for your scenario.

New virtual network

In this example, we'll name our virtual network *MyVnet*:

Azure PowerShell

```
#Gets the DDoS protection plan ID
$ddosProtectionPlanID = Get-AzDdosProtectionPlan -ResourceGroupName
MyResourceGroup -Name MyDdosProtectionPlan

#Creates the virtual network
New-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup -Location
"East US" -AddressPrefix 10.0.0.0/16 -DdosProtectionPlan
$ddosProtectionPlanID.Id -EnableDdosProtection
```

Disable DDoS for a virtual network

To disable DDoS protection for a virtual network:

Azure PowerShell

```
# Gets the most updated version of the virtual network
$vnet = Get-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup
$vnet.DdosProtectionPlan = $null
$vnet.EnableDdosProtection = $false
$vnet | Set-AzVirtualNetwork
```

Validate and test

Check the details of your DDoS protection plan and verify that the command returns the correct details of your DDoS protection plan.

Azure PowerShell

```
Get-AzDdosProtectionPlan -ResourceGroupName MyResourceGroup -Name
MyDdosProtectionPlan
```

Check the details of your virtual network and verify the DDoS protection plan is enabled.

Azure PowerShell

```
Get-AzVirtualNetwork -Name MyVnet -ResourceGroupName MyResourceGroup
```

Clean up resources

You can keep your resources for the next tutorial. If no longer needed, delete the *MyResourceGroup* resource group. When you delete the resource group, you also delete the DDoS protection plan and all its related resources.

Azure PowerShell

```
Remove-AzResourceGroup -Name MyResourceGroup
```

> **Note**
>
> To delete a DDoS protection plan, first dissociate all virtual networks from it.

Next steps

To learn how to view and configure telemetry for your DDoS protection plan, continue to the tutorials.

View and configure DDoS protection telemetry

Last updated on 03/05/2026

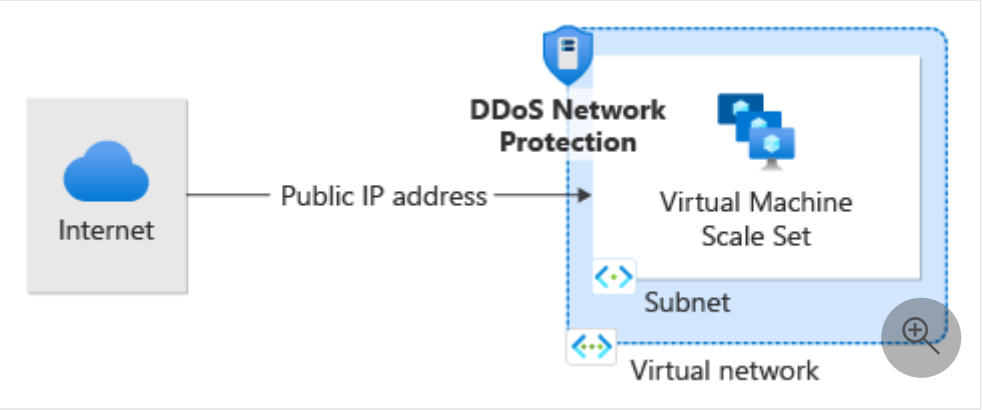
QuickStart: Create and configure Azure DDoS Network Protection using Azure CLI

Summarize this article for me

Get started with Azure DDoS Network Protection by using Azure CLI.

A DDoS protection plan defines a set of virtual networks that have DDoS Network Protection enabled, across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions to the same plan.

In this QuickStart, you'll create a DDoS protection plan and link it to a virtual network.



Prerequisites

- An Azure account with an active subscription. Create an account for free.
- Azure CLI installed locally or Azure Cloud Shell

Azure Cloud Shell

Azure hosts Azure Cloud Shell, an interactive shell environment that you can use through your browser. You can use either Bash or PowerShell with Cloud Shell to work with Azure services. You can use the Cloud Shell preinstalled commands to run the code in this article, without having to install anything on your local environment.

To start Azure Cloud Shell:

Expand table

Option	Example/Link
Select **Try It** in the upper-right corner of a code or command block. Selecting **Try It** doesn't automatically copy the code or command to	

Option	Example/Link
Cloud Shell.	
Go to https://shell.azure.com, or select the **Launch Cloud Shell** button to open Cloud Shell in your browser.	
Select the **Cloud Shell** button on the menu bar at the upper right in the Azure portal.	

To use Azure Cloud Shell:

1. Start Cloud Shell.
2. Select the **Copy** button on a code block (or command block) to copy the code or command.
3. Paste the code or command into the Cloud Shell session by selecting **Ctrl**+**Shift**+**V** on Windows and Linux, or by selecting **Cmd**+**Shift**+**V** on macOS.
4. Select **Enter** to run the code or command.

If you choose to install and use the CLI locally, this quickstart requires Azure CLI version 2.0.56 or later. To find the version, run `az --version`. If you need to install or upgrade, see Install the Azure CLI.

Create a DDoS Protection plan

In Azure, you allocate related resources to a resource group. You can either use an existing resource group or create a new one.

To create a resource group, use az group create. In this example, we'll name our resource group *MyResourceGroup* and use the *East US* location:

Azure CLI

```
az group create \
    --name MyResourceGroup \
    --location eastus
```

Now create a DDoS protection plan named *MyDdosProtectionPlan*:

Azure CLI

```
az network ddos-protection create \
    --resource-group MyResourceGroup \
```

```
    --name MyDdosProtectionPlan
```

Enable DDoS protection for a virtual network

You can enable DDoS protection when creating a new virtual network or for an existing virtual network. Select the tab for your scenario.

New virtual network

In this example, we'll name our virtual network *MyVnet*:

Azure CLI

```
az network vnet create \
    --resource-group MyResourceGroup \
    --name MyVnet \
    --location eastus \
    --ddos-protection-plan MyDdosProtectionPlan \
    --ddos-protection true
```

> **Note**
>
> You cannot move a virtual network to another resource group or subscription when DDoS Protection is enabled for the virtual network. If you need to move a virtual network with DDoS Protection enabled, disable DDoS Protection first, move the virtual network, and then enable DDoS Protection. After the move, the auto-tuned policy thresholds for all the protected public IP addresses in the virtual network are reset.

Disable DDoS protection for a virtual network

Update a given virtual network to disable DDoS protection:

Azure CLI

```
az network vnet update \
    --resource-group MyResourceGroup \
    --name MyVnet \
    --ddos-protection-plan MyDdosProtectionPlan \
    --ddos-protection false
```

Validate and test

First, check the details of your DDoS protection plan:

Azure CLI

```
az network ddos-protection show \
    --resource-group MyResourceGroup \
    --name MyDdosProtectionPlan
```

Verify that the command returns the correct details of your DDoS protection plan.

Clean up resources

You can keep your resources for the next tutorial. If no longer needed, delete the *MyResourceGroup* resource group. When you delete the resource group, you also delete the DDoS protection plan and all its related resources.

To delete the resource group, use az group delete:

Azure CLI

```
az group delete \
--name MyResourceGroup
```

> **Note**
>
> To delete a DDoS protection plan, first dissociate all virtual networks from it.

Next steps

To learn how to view and configure telemetry for your DDoS protection plan, continue to the tutorials.

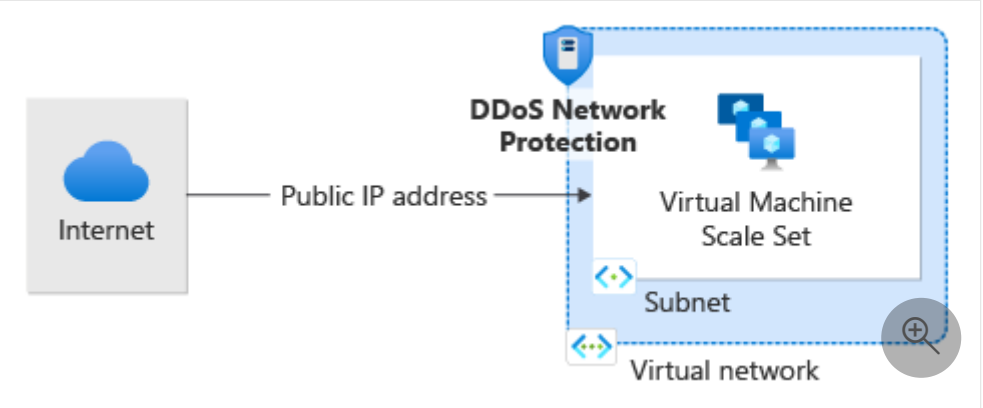
View and configure DDoS protection telemetry

Last updated on 01/26/2026

QuickStart: Create and configure Azure DDoS Network Protection using ARM template

Summarize this article for me

This QuickStart describes how to use an Azure Resource Manager template (ARM template) to create a distributed denial of service (DDoS) protection plan and virtual network, then enables the protection plan for the virtual network. An Azure DDoS Network Protection plan defines a set of virtual networks that have DDoS protection enabled across subscriptions. You can configure one DDoS protection plan for your organization and link virtual networks from multiple subscriptions to the same plan.



An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template opens in the Azure portal.

Deploy to Azure

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

Review the template

The template used in this quickstart is from Azure Quickstart Templates.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "metadata": {
    "_generator": {
      "name": "bicep",
      "version": "0.5.6.12127",
      "templateHash": "14909118711877377105"
    }
  },
  "parameters": {
    "ddosProtectionPlanName": {
      "type": "string",
      "metadata": {
        "description": "Specify a DDoS protection plan name."
      }
    },
    "virtualNetworkName": {
      "type": "string",
      "metadata": {
        "description": "Specify a DDoS virtual network name."
      }
    },
    "location": {
      "type": "string",
      "defaultValue": "[resourceGroup().location]",
      "metadata": {
        "description": "Specify a location for the resources."
      }
    },
    "vnetAddressPrefix": {
      "type": "string",
      "defaultValue": "172.17.0.0/16",
      "metadata": {
        "description": "Specify the virtual network address prefix"
      }
    },
    "subnetPrefix": {
      "type": "string",
      "defaultValue": "172.17.0.0/24",
      "metadata": {
        "description": "Specify the virtual network subnet prefix"
      }
    },
    "ddosProtectionPlanEnabled": {
      "type": "bool",
      "defaultValue": true,
      "metadata": {
        "description": "Enable DDoS protection plan."
      }
    }
```

```
  },
  "resources": [
    {
      "type": "Microsoft.Network/ddosProtectionPlans",
      "apiVersion": "2021-05-01",
      "name": "[parameters('ddosProtectionPlanName')]",
      "location": "[parameters('location')]"
    },
    {
      "type": "Microsoft.Network/virtualNetworks",
      "apiVersion": "2021-05-01",
      "name": "[parameters('virtualNetworkName')]",
      "location": "[parameters('location')]",
      "properties": {
        "addressSpace": {
          "addressPrefixes": [
            "[parameters('vnetAddressPrefix')]"
          ]
        },
        "subnets": [
          {
            "name": "default",
            "properties": {
              "addressPrefix": "[parameters('subnetPrefix')]"
            }
          }
        ],
        "enableDdosProtection": "[parameters('ddosProtectionPlanEnabled')]",
        "ddosProtectionPlan": {
          "id": "[resourceId('Microsoft.Network/ddosProtectionPlans',
parameters('ddosProtectionPlanName'))]"
        }
      },
      "dependsOn": [
        "[resourceId('Microsoft.Network/ddosProtectionPlans',
parameters('ddosProtectionPlanName'))]"
      ]
    }
  ]
}
```

The template defines two resources:

- Microsoft.Network/ddosProtectionPlans
- Microsoft.Network/virtualNetworks

Deploy the template

In this example, the template creates a new resource group, a DDoS protection plan, and a virtual network.

1. To sign in to Azure and open the template, select the **Deploy to Azure** button.

   Deploy to Azure

2. Enter the values to create a new resource group, DDoS protection plan, and virtual network name.

   - **Subscription**: Name of the Azure subscription where the resources will be deployed.
   - **Resource group**: Select an existing resource group or create a new resource group.
   - **Region**: The region where the resource group is deployed, such as East US.
   - **Ddos Protection Plan Name**: The name of for the new DDoS protection plan.
   - **Virtual Network Name**: Creates a name for the new virtual network.
   - **Location**: Function that uses the same region as the resource group for resource deployment.
   - **Vnet Address Prefix**: Use the default value or enter your virtual network address.
   - **Subnet Prefix**: Use the default value or enter your virtual network subnet.
   - **Ddos Protection Plan Enabled**: Default is `true` to enable the DDoS protection plan.

3. Select **Review + create**.

4. Verify that template validation passed and select **Create** to begin the deployment.

Review deployed resources

To copy the Azure CLI or Azure PowerShell command, select the **Copy** button. The **Try it** button opens Azure Cloud Shell to run the command.

CLI

Azure CLI

```azurecli
az network ddos-protection show \
  --resource-group MyResourceGroup \
  --name MyDdosProtectionPlan
```

The output shows the new resources.

CLI

Output

```

  "location": "eastus",
  "name": "MyDdosProtectionPlan",
  "provisioningState": "Succeeded",
  "resourceGroup": "MyResourceGroup",
  "resourceGuid": null,
  "tags": null,
  "type": "Microsoft.Network/ddosProtectionPlans",
  "virtualNetworks": [
    {
      "id": "/subscriptions/aaaa0a0a-bb1b-cc2c-dd3d-
eeeeee4e4e4e/resourceGroups/MyResourceGroup/providers/Microsoft.Network/virtual
Networks/MyVNet",
      "resourceGroup": "MyResourceGroup"
    }
  ]
}
```

Clean up resources

When you're finished, you can delete the resources. The command deletes the resource group and all the resources it contains.

CLI

Azure CLI

```
az group delete --name MyResourceGroup
```

> **Note**
>
> To delete a DDoS protection plan, first dissociate all virtual networks from it.

Tutorial: Migrate a virtual machine public IP address to Azure NAT Gateway

In this tutorial, you learn how to migrate your virtual machine's public IP address to a NAT gateway. You learn how to remove the IP address from the virtual machine. You reuse the IP address from the virtual machine for the NAT gateway.

Azure NAT Gateway is the recommended method for outbound connectivity. Azure NAT Gateway is a fully managed and highly resilient Network Address Translation (NAT) service. A NAT gateway doesn't have the same limitations of Source Network Address Translation (SNAT) port exhaustion as default outbound access. A NAT gateway replaces the need for a virtual machine to have a public IP address to have outbound connectivity.

For more information about Azure NAT Gateway, see What is Azure NAT Gateway?

In this tutorial, you learn how to:

- ✓ Remove the public IP address from the virtual machine.
- ✓ Associate the public IP address from the virtual machine with a NAT gateway.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- An Azure Virtual Machine with a public IP address assigned to its network interface. For more information on creating a virtual machine with a public IP, see Quickstart: Create a Windows virtual machine in the Azure portal.
  - For the purposes of this article, the example virtual machine is named **vm-1**. The example public IP address is named **public-ip**.

> **Note**
>
> Removal of the public IP address prevents direct connections to the virtual machine from the internet. RDP or SSH access won't function to the virtual machine after you complete this migration. To securely manage virtual machines in your subscription, use Azure Bastion. For more information on Azure Bastion, see What is Azure Bastion?

Remove public IP from virtual machine

In this section, you learn how to remove the public IP address from the virtual machine.

1. Sign in to the Azure portal.
2. In the search box at the top of the portal, enter **Virtual machine**. Select **Virtual machines**.
3. In **Virtual machines**, select **vm-1** or your virtual machine.
4. In the **Overview** of **vm-1**, select **Public IP address**.
5. In **public-ip**, select the **Overview** page in the left-hand column.
6. In **Overview**, select **Dissociate**.
7. Select **Yes** in **Dissociate public IP address**.

(Optional) Upgrade IP address

The NAT gateway resource requires a standard public IP address. In this section, you upgrade the IP you removed from the virtual machine in the previous section. If the IP address you removed is already a standard public IP, you can proceed to the next section.

1. In the search box at the top of the portal, enter **Public IP**. Select **Public IP addresses**.
2. In **Public IP addresses**, select **public-ip** or your basic IP address.
3. In the **Overview** of **public-ip**, select the IP address upgrade banner.
4. In **Upgrade to Standard SKU**, select the box next to **I acknowledge**. Select the **Upgrade** button.
5. When the upgrade is complete, proceed to the next section.

Create NAT gateway

In this section, you create a NAT gateway with the IP address you previously removed from the virtual machine. You assign the NAT gateway to your precreated subnet within your virtual network. The subnet name for this example is **default**.

1. In the search box at the top of the Azure portal, enter **NAT gateway**. Select **NAT gateways** in the search results.
2. Select **Create**.
3. Enter or select the following information in the **Basics** tab of **Create network address translation (NAT) gateway**.

Expand table

Setting	Value
Project details	
Subscription	Select your subscription.
Resource group	Select **test-rg** or your resource group.
Instance details	
NAT gateway name	Enter **nat-gateway**.
Region	Select your region. This example uses **East US 2**.
SKU	Select **Standard**.
TCP idle timeout (minutes)	Leave the default of **4**.

4. Select **Next**.
5. In the **Outbound IP** tab, select **+ Add public IP addresses or prefixes**.
6. In **Add public IP addresses or prefixes**, select **Public IP addresses**. Select the public IP address you removed from the virtual machine in the previous steps. In this example, it's **public-ip**.
7. Select **Next**.
8. In the **Networking** tab, in **Virtual network**, select your virtual network. In this example, it's **vnet-1**.
9. Leave the checkbox for **Default to all subnets** unchecked.
10. In **Select specific subnets**, select your subnet. In this example, it's **subnet-1**.
11. Select **Review + create**, then select **Create**.

Next step

In this article, you learned how to:

- Remove a public IP address from a virtual machine.
- Create a NAT gateway and use the public IP address from the virtual machine for the NAT gateway resource.

NAT gateway provides connectivity benefits and allows any virtual machine created within this subnet to have outbound connectivity without requiring a public IP address. For more information about NAT gateway and its connectivity benefits, see the Design virtual networks with NAT gateway documentation.

Advance to the next article to learn how to migrate default outbound access to Azure NAT Gateway:

Migrate outbound access to NAT gateway

Create a virtual machine with a static public IP address using the Azure portal, Azure PowerShell, or Azure CLI

Summarize this article for me

In this article, you create a virtual machine (VM) with a static public IP address. A public IP address enables you to communicate to a VM from the internet. Assign a static public IP address, rather than a dynamic address, to ensure the address never changes.

Public IP addresses have a nominal charge. There's a limit to the number of public IP addresses that you can use per subscription.

You can download the list of ranges (prefixes) for the Azure Public, US government, China, and Germany clouds.

Prerequisites

Azure portal

- An Azure account with an active subscription. You can create an account for free.

Create a virtual machine with a static public IP address

In this section, you create a virtual machine with a static public IP address using the Azure portal, Azure PowerShell, or Azure CLI. Along with the virtual machine, you create a public IP address and the other required resources.

Azure portal

Sign in to Azure

Sign in to the Azure portal.

Create a resource group

1. In the search box at the top of the portal, enter *Resource group*.
2. In the search results, select **Resource groups**.
3. Select **+ Create**.
4. In the **Basics** tab of **Create a resource group**, enter or select the following:

Expand table

Setting	Value
Subscription	Select your Azure subscription
Resource Group	Enter *myResourceGroup*.
Region	Select **East US**.

5. Select **Review + create**, then select **Create**.

Create a virtual machine

1. In the search box at the top of the portal, enter *Virtual machine*.
2. In the search results, select **Virtual machines**.
3. Select **+ Create**, then select **Azure virtual machine**.
4. In **Basics** tab of **Create a virtual machine**, enter or select the following:

Expand table

Setting	Value
Project Details	
Subscription	Select your Azure subscription
Resource Group	Select **myResourceGroup**.
Instance details	
Virtual machine name	Enter *myVM*.
Region	Select **East US**.
Availability Options	Select **No infrastructure redundancy required**.
Security type	Select **Standard**.

Setting	Value
Image	Select **Windows Server 2019 Datacenter - x64 Gen2**.
Size	Choose VM size or take default setting.
Administrator account	
Username	Enter a username.
Password	Enter a password.
Confirm password	Reenter password.
Public inbound ports	Select **None**.

> **Note**
>
> All public inbound ports are closed for this virtual machine. To manage your virtual machines, deploy Azure Bastion. For more information, see Quickstart: Deploy Azure Bastion from the Azure portal.

5. Select the **Networking** tab, or select **Next: Disks**, then **Next: Networking**.

6. In the **Networking** tab, enter or select the following:

Expand table

Setting	Value
Network interface	
Virtual network	Accept the default network name.
Subnet	Accept the default subnet configuration.
Public IP	Select **Create new**. In **Create public IP address**, enter *myPublicIP* in **Name**. **SKU**: select **Standard**. **Assignment**: select **Static**. Select **OK**.

> **Note**

The SKU of the virtual machine's public IP address must match the public IP SKU of Azure public load balancer when added to the backend pool of the load balancer. For details, see Azure Load Balancer.

7. Select **Review + create**.

8. Review the settings, and then select **Create**.

> ⚠ **Warning**
>
> Do not modify the IP address settings within the virtual machine's operating system. The operating system is unaware of Azure public IP addresses. Though you can add private IP address settings to the operating system, we recommend not doing so unless necessary. For more information, see Add a private IP address to an operating system.

> ⓘ **Note**
>
> Azure provides a default outbound access IP for VMs that either aren't assigned a public IP address or are in the backend pool of an internal basic Azure load balancer. The default outbound access IP mechanism provides an outbound IP address that isn't configurable.
>
> The default outbound access IP is disabled when one of the following events happens:
>
> - A public IP address is assigned to the VM.
> - The VM is placed in the backend pool of a standard load balancer, with or without outbound rules.
> - An Azure NAT Gateway resource is assigned to the subnet of the VM.
>
> VMs that you create by using virtual machine scale sets in flexible orchestration mode don't have default outbound access.
>
> For more information about outbound connections in Azure, see Default outbound access in Azure and Use Source Network Address Translation (SNAT) for outbound connections.

Clean up resources

When resources are no longer needed, delete all resources created in this article to avoid incurring charges.

Azure portal

Use the Azure portal to delete the resource group and all of the resources it contains:

1. Enter *myResourceGroup* in the search box at the top of the portal. When you see **myResourceGroup** in the search results, select it.
2. Select **Delete resource group**.
3. Enter *myResourceGroup* for **TYPE THE RESOURCE GROUP NAME:** and select **Delete**.

Next steps

In this article, you learned how to create a VM with a static public IP.

- Learn how to Configure IP addresses for an Azure network interface.
- Learn how to Assign multiple IP addresses to virtual machines using the Azure portal.
- Learn more about public IP addresses in Azure.

Add Custom Domain to Azure VM or resource

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

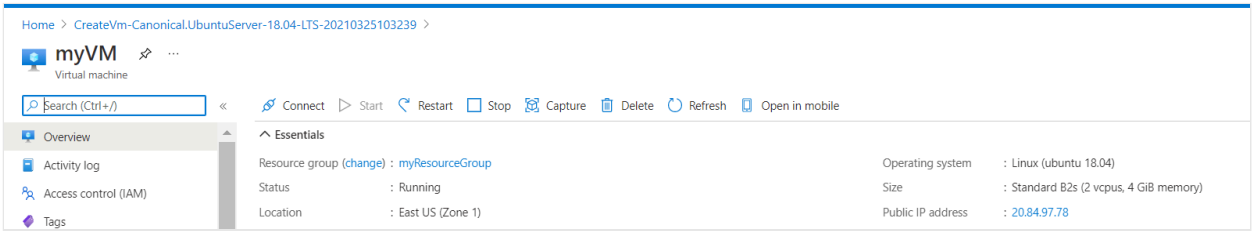
In Azure there are multiple ways to connect a custom domain to your VM or resource. For any resource with a public IP (Virtual Machine, Load Balancer, Application Gateway) the most straight-forward way is to create an A record set in your corresponding domain registrar.

Prerequisites

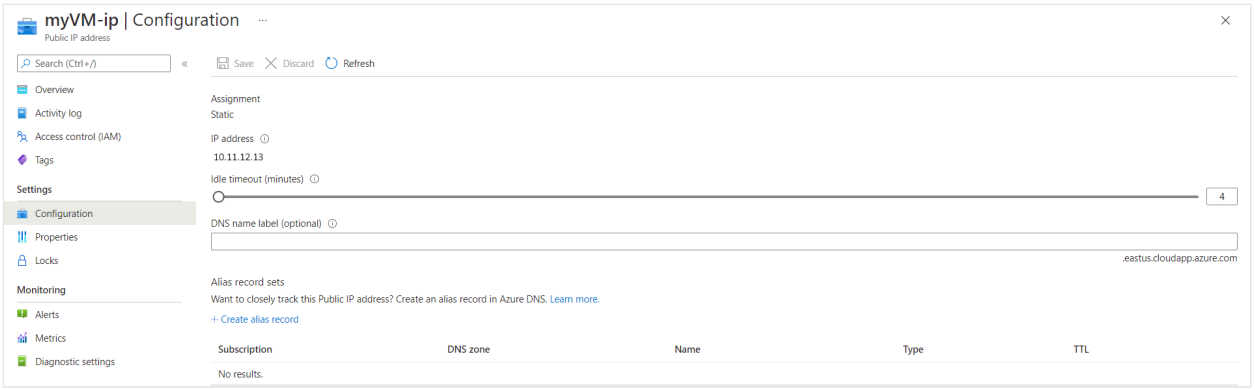
- You need a VM with a web server running. You can use the Quickstart to create a VM and add NGINX.
- The VM must be accessible to the web (open port 80, or 443). For a more secure deployment place your VM behind a load balancer or Application Gateway first. For more information, see Quickstart: Load Balancer.
- Have an existing domain and access to DNS settings. For more information, see Buy a custom domain for Azure App Service.

Add custom domain to VM public IP address

When you create a virtual machine in the Azure portal, a public IP resource for the virtual machine is automatically created. Your public IP address is shown in VM overview page.



If you select the IP address you can see more information on it. Check to make sure your **IP Assignment** is set to **Static**. A static IP address will not change if the VM or resource reboots or shuts down.



If your IP Address is not static, you will need to create an FQDN.

1. Select your VM in the portal.
2. In the left menu, select **Properties**
3. Under **Public IP address\DNS name label**, select your IP address. The **Configuration** page will open.
4. Under **DNS name label**, enter the prefix you want to use.
5. Select **Save** at the top of the page.
6. Select **Overview** in the left menu to return to the VM overview blade.
7. Verify that the *DNS name* appears correctly.

Open a browser and enter your IP address or FQDN and verify that it shows the web content running on your VM.

After verifying your static IP or FQDN, go to your domain provider and navigate to DNS settings. Add an *A record* pointing to your Public IP Address or FQDN. For example, the procedure for the GoDaddy domain registrar is as follows:

1. Sign in and select the custom domain you want to use.
2. In the **Domains** section, select **Manage All**, then select **DNS | Manage Zones**.
3. For **Domain Name**, enter your custom domain, then select **Search**.
4. From the DNS Management page, select Add, then select A in the Type list.
5. Complete the fields of the A entry:

    - Type: Leave **A** selected.
    - Host: Enter @
    - Points to: Enter the Public IP Address or FQDN of your VM.
    - TTL: Leave one hour selected.

6. Select **Save**.

The A record entry is added to the DNS records table.

After the record is created it usually takes about an hour for DNS propagate, but it can sometimes take up to 48 hours.

How to create a Linux virtual machine in Azure with multiple network interface cards

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article details how to create a VM with multiple NICs with the Azure CLI.

Create supporting resources

Install the latest Azure CLI and log in to an Azure account using az login.

In the following examples, replace example parameter names with your own values. Example parameter names included *myResourceGroup*, *mystorageaccount*, and *myVM*.

First, create a resource group with az group create. The following example creates a resource group named *myResourceGroup* in the *eastus* location:

Azure CLI

```
az group create --name myResourceGroup --location eastus
```

Create the virtual network with az network vnet create. The following example creates a virtual network named *myVnet* and subnet named *mySubnetFrontEnd*:

Azure CLI

```
az network vnet create \
    --resource-group myResourceGroup \
    --name myVnet \
    --address-prefix 10.0.0.0/16 \
    --subnet-name mySubnetFrontEnd \
    --subnet-prefix 10.0.1.0/24
```

Create a subnet for the back-end traffic with az network vnet subnet create. The following example creates a subnet named *mySubnetBackEnd*:

Azure CLI

```
az network vnet subnet create \
    --resource-group myResourceGroup \
```

```
    --vnet-name myVnet \
    --name mySubnetBackEnd \
    --address-prefix 10.0.2.0/24
```

Create a network security group with az network nsg create. The following example creates a network security group named *myNetworkSecurityGroup*:

Azure CLI

```
az network nsg create \
    --resource-group myResourceGroup \
    --name myNetworkSecurityGroup
```

Create and configure multiple NICs

Create two NICs with az network nic create. The following example creates two NICs, named *myNic1* and *myNic2*, connected the network security group, with one NIC connecting to each subnet:

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic1 \
    --vnet-name myVnet \
    --subnet mySubnetFrontEnd \
    --network-security-group myNetworkSecurityGroup
az network nic create \
    --resource-group myResourceGroup \
    --name myNic2 \
    --vnet-name myVnet \
    --subnet mySubnetBackEnd \
    --network-security-group myNetworkSecurityGroup
```

Create a VM and attach the NICs

When you create the VM, specify the NICs you created with `--nics`. You also need to take care when you select the VM size. There are limits for the total number of NICs that you can add to a VM. Read more about Linux VM sizes.

Create a VM with az vm create. The following example creates a VM named *myVM*:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --image Ubuntu2204 \
    --size Standard_DS3_v2 \
    --admin-username azureuser \
    --generate-ssh-keys \
    --nics myNic1 myNic2
```

Add routing tables to the guest OS by completing the steps in Configure the guest OS for multiple NICs.

Add a NIC to a VM

The previous steps created a VM with multiple NICs. You can also add NICs to an existing VM with the Azure CLI. Different VM sizes support a varying number of NICs, so size your VM accordingly. If needed, you can resize a VM.

Create another NIC with az network nic create. The following example creates a NIC named *myNic3* connected to the back-end subnet and network security group created in the previous steps:

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic3 \
    --vnet-name myVnet \
    --subnet mySubnetBackEnd \
    --network-security-group myNetworkSecurityGroup
```

To add a NIC to an existing VM, first deallocate the VM with az vm deallocate. The following example deallocates the VM named *myVM*:

Azure CLI

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Add the NIC with az vm nic add. The following example adds *myNic3* to *myVM*:

Azure CLI

```
az vm nic add \
    --resource-group myResourceGroup \
```

```
    --vm-name myVM \
    --nics myNic3
```

Start the VM with az vm start:

Azure CLI

```
az vm start --resource-group myResourceGroup --name myVM
```

Add routing tables to the guest OS by completing the steps in Configure the guest OS for multiple NICs.

Remove a NIC from a VM

To remove a NIC from an existing VM, first deallocate the VM with az vm deallocate. The following example deallocates the VM named *myVM*:

Azure CLI

```
az vm deallocate --resource-group myResourceGroup --name myVM
```

Remove the NIC with az vm nic remove. The following example removes *myNic3* from *myVM*:

Azure CLI

```
az vm nic remove \
    --resource-group myResourceGroup \
    --vm-name myVM \
    --nics myNic3
```

Start the VM with az vm start:

Azure CLI

```
az vm start --resource-group myResourceGroup --name myVM
```

Create multiple NICs using Resource Manager templates

Azure Resource Manager templates use declarative JSON files to define your environment. You can read an overview of Azure Resource Manager. Resource Manager

templates provide a way to create multiple instances of a resource during deployment, such as creating multiple NICs. You use *copy* to specify the number of instances to create:

JSON

```
"copy": {
    "name": "multiplenics"
    "count": "[parameters('count')]"
}
```

Read more about creating multiple instances using *copy*.

You can also use a `copyIndex()` to then append a number to a resource name, which allows you to create `myNic1`, `myNic2`, etc. The following shows an example of appending the index value:

JSON

```
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of creating multiple NICs using Resource Manager templates.

Add routing tables to the guest OS by completing the steps in Configure the guest OS for multiple NICs.

Configure guest OS for multiple NICs

The previous steps created a virtual network and subnet, attached NICs, then created a VM. A public IP address and network security group rules that allow SSH traffic were not created. To configure the guest OS for multiple NICs, you need to allow remote connections and run commands locally on the VM.

To allow SSH traffic, create a network security group rule with az network nsg rule create as follows:

Azure CLI

```
az network nsg rule create \
    --resource-group myResourceGroup \
    --nsg-name myNetworkSecurityGroup \
    --name allow_ssh \
```

```
    --priority 101 \
    --destination-port-ranges 22
```

Create a public IP address with az network public-ip create and assign it to the first NIC with az network nic ip-config update:

Azure CLI

```
az network public-ip create --resource-group myResourceGroup --name
myPublicIP

az network nic ip-config update \
    --resource-group myResourceGroup \
    --nic-name myNic1 \
    --name ipconfig1 \
    --public-ip myPublicIP
```

To view the public IP address of the VM, use az vm show as follows::

Azure CLI

```
az vm show --resource-group myResourceGroup --name myVM -d --query publicIps
-o tsv
```

Now SSH to the public IP address of your VM. The default username provided in a previous step was *azureuser*. Provide your own username and public IP address:

Bash

```
ssh azureuser@137.117.58.232
```

To send to or from a secondary network interface, you have to manually add persistent routes to the operating system for each secondary network interface. In this article, *eth1* is the secondary interface. Instructions for adding persistent routes to the operating system vary by distro. See documentation for your distro for instructions.

When adding the route to the operating system, the gateway address is the first address of the subnet the network interface is in. For example, if the subnet has been assigned the range *10.0.2.0/24*, the gateway you specify for the route is *10.0.2.1* or if the subnet has been assigned the range *10.0.2.128/25*, the gateway you specify for the route is *10.0.2.129*. You can define a specific network for the route's destination, or specify a destination of *0.0.0.0*, if you want all traffic for the interface to go through the specified gateway. The gateway for each subnet is managed by the virtual network.

Once you've added the route for a secondary interface, verify that the route is in your route table with `route -n`. The following example output is for the route table that has the two network interfaces added to the VM in this article:

```
Bash

Kernel IP routing table
Destination     Gateway         Genmask         Flags Metric Ref    Use
Iface
0.0.0.0         10.0.1.1        0.0.0.0         UG    0      0        0 eth0
0.0.0.0         10.0.2.1        0.0.0.0         UG    0      0        0 eth1
10.0.1.0        0.0.0.0         255.255.255.0   U     0      0        0 eth0
10.0.2.0        0.0.0.0         255.255.255.0   U     0      0        0 eth1
168.63.129.16   10.0.1.1        255.255.255.255 UGH   0      0        0 eth0
169.254.169.254 10.0.1.1        255.255.255.255 UGH   0      0        0 eth0
```

Confirm that the route you added persists across reboots by checking your route table again after a reboot. To test connectivity, you can enter the following command, for example, where *eth1* is the name of a secondary network interface:

```
Bash

ping bing.com -c 4 -I eth1
```

Next steps

Review Linux VM sizes when trying to creating a VM with multiple NICs. Pay attention to the maximum number of NICs each VM size supports.

To further secure your VMs, use just in time VM access. This feature opens network security group rules for SSH traffic when needed, and for a defined period of time. For more information, see Manage virtual machine access using just in time.

Create and manage a Windows virtual machine that has multiple NICs

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

Virtual machines (VMs) in Azure can have multiple virtual network interface cards (NICs) attached to them. A common scenario is to have different subnets for front-end and back-end connectivity. You can associate multiple NICs on a VM to multiple subnets, but those subnets must all reside in the same virtual network (vNet). This article details how to create a VM that has multiple NICs attached to it. You also learn how to add or remove NICs from an existing VM. Different VM sizes support a varying number of NICs, so size your VM accordingly.

> **Note**
>
> If multiple subnets are not required for a scenario, it may be more straightforward to utilize multiple IP configurations on a single NIC. Instructions for this setup can be found here.

Prerequisites

In the following examples, replace example parameter names with your own values. Example parameter names include *myResourceGroup*, *myVnet*, and *myVM*.

Create a VM with multiple NICs

First, create a resource group. The following example creates a resource group named *myResourceGroup* in the *EastUs* location:

PowerShell

```
New-AzResourceGroup -Name "myResourceGroup" -Location "EastUS"
```

Create virtual network and subnets

A common scenario is for a virtual network to have two or more subnets. One subnet may be for front-end traffic, the other for back-end traffic. To connect to both subnets,

you then use multiple NICs on your VM.

1. Define two virtual network subnets with New-AzVirtualNetworkSubnetConfig. The following example defines the subnets for *mySubnetFrontEnd* and *mySubnetBackEnd*:

   PowerShell

   ```
   $mySubnetFrontEnd = New-AzVirtualNetworkSubnetConfig -Name
   "mySubnetFrontEnd" `
       -AddressPrefix "192.168.1.0/24"
   $mySubnetBackEnd = New-AzVirtualNetworkSubnetConfig -Name
   "mySubnetBackEnd" `
       -AddressPrefix "192.168.2.0/24"
   ```

2. Create your virtual network and subnets with New-AzVirtualNetwork. The following example creates a virtual network named *myVnet*:

   PowerShell

   ```
   $myVnet = New-AzVirtualNetwork -ResourceGroupName "myResourceGroup" `
       -Location "EastUs" `
       -Name "myVnet" `
       -AddressPrefix "192.168.0.0/16" `
       -Subnet $mySubnetFrontEnd,$mySubnetBackEnd
   ```

Create multiple NICs

Create two NICs with New-AzNetworkInterface. Attach one NIC to the front-end subnet and one NIC to the back-end subnet. The following example creates NICs named *myNic1* and *myNic2*:

PowerShell

```
$frontEnd = $myVnet.Subnets|?{$_.Name -eq 'mySubnetFrontEnd'}
$myNic1 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `
    -Name "myNic1" `
    -Location "EastUs" `
    -SubnetId $frontEnd.Id

$backEnd = $myVnet.Subnets|?{$_.Name -eq 'mySubnetBackEnd'}
$myNic2 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `
    -Name "myNic2" `
    -Location "EastUs" `
    -SubnetId $backEnd.Id
```

Typically you also create a network security group to filter network traffic to the VM and a load balancer to distribute traffic across multiple VMs.

Create the virtual machine

Now start to build your VM configuration. Each VM size has a limit for the total number of NICs that you can add to a VM. For more information, see Windows VM sizes.

1. Set your VM credentials to the `$cred` variable as follows:

   PowerShell

   ```
   $cred = Get-Credential
   ```

2. Define your VM with New-AzVMConfig. The following example defines a VM named *myVM* and uses a VM size that supports more than two NICs (*Standard_DS3_v2*):

   PowerShell

   ```
   $vmConfig = New-AzVMConfig -VMName "myVM" -VMSize "Standard_DS3_v2"
   ```

3. Create the rest of your VM configuration with Set-AzVMOperatingSystem and Set-AzVMSourceImage. The following example creates a Windows Server 2016 VM:

   PowerShell

   ```
   $vmConfig = Set-AzVMOperatingSystem -VM $vmConfig `
       -Windows `
       -ComputerName "myVM" `
       -Credential $cred `
       -ProvisionVMAgent `
       -EnableAutoUpdate
   $vmConfig = Set-AzVMSourceImage -VM $vmConfig `
       -PublisherName "MicrosoftWindowsServer" `
       -Offer "WindowsServer" `
       -Skus "2016-Datacenter" `
       -Version "latest"
   ```

4. Attach the two NICs that you previously created with Add-AzVMNetworkInterface:

   PowerShell

   ```
   $vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic1.Id -
   Primary
   ```

```
$vmConfig = Add-AzVMNetworkInterface -VM $vmConfig -Id $myNic2.Id
```

5. Create your VM with New-AzVM:

```
PowerShell

New-AzVM -VM $vmConfig -ResourceGroupName "myResourceGroup" -Location
"EastUs"
```

6. Add routes for secondary NICs to the OS by completing the steps in Configure the operating system for multiple NICs.

Add a NIC to an existing VM

To add a virtual NIC to an existing VM, you deallocate the VM, add the virtual NIC, then start the VM. Different VM sizes support a varying number of NICs, so size your VM accordingly. If needed, you can resize a VM.

1. Deallocate the VM with Stop-AzVM. The following example deallocates the VM named *myVM* in *myResourceGroup*:

```
PowerShell

Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
```

2. Get the existing configuration of the VM with Get-AzVm. The following example gets information for the VM named *myVM* in *myResourceGroup*:

```
PowerShell

$vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
```

3. The following example creates a virtual NIC with New-AzNetworkInterface named *myNic3* that is attached to *mySubnetBackEnd*. The virtual NIC is then attached to the VM named *myVM* in *myResourceGroup* with Add-AzVMNetworkInterface:

```
PowerShell

# Get info for the back end subnet
$myVnet = Get-AzVirtualNetwork -Name "myVnet" -ResourceGroupName
"myResourceGroup"
$backEnd = $myVnet.Subnets|?{$_.Name -eq 'mySubnetBackEnd'}

# Create a virtual NIC
```

```
$myNic3 = New-AzNetworkInterface -ResourceGroupName "myResourceGroup" `
    -Name "myNic3" `
    -Location "EastUs" `
    -SubnetId $backEnd.Id

# Get the ID of the new virtual NIC and add to VM
$nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -
Name "MyNic3").Id
Add-AzVMNetworkInterface -VM $vm -Id $nicId | Update-AzVm -
ResourceGroupName "myResourceGroup"
```

Primary virtual NICs

One of the NICs on a multi-NIC VM needs to be primary. If one of the existing virtual NICs on the VM is already set as primary, you can skip this step. The following example assumes that two virtual NICs are now present on a VM and you wish to add the first NIC (`[0]`) as the primary:

PowerShell

```
# List existing NICs on the VM and find which one is primary
$vm.NetworkProfile.NetworkInterfaces

# Set NIC 0 to be primary
$vm.NetworkProfile.NetworkInterfaces[0].Primary = $true
$vm.NetworkProfile.NetworkInterfaces[1].Primary = $false

# Update the VM state in Azure
Update-AzVM -VM $vm -ResourceGroupName "myResourceGroup"
```

4. Start the VM with Start-AzVm:

PowerShell

```
Start-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM"
```

5. Add routes for secondary NICs to the OS by completing the steps in Configure the operating system for multiple NICs.

Remove a NIC from an existing VM

To remove a virtual NIC from an existing VM, you deallocate the VM, remove the virtual NIC, then start the VM.

1. Deallocate the VM with Stop-AzVM. The following example deallocates the VM named *myVM* in *myResourceGroup*:

   PowerShell

   ```
   Stop-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
   ```

2. Get the existing configuration of the VM with Get-AzVm. The following example gets information for the VM named *myVM* in *myResourceGroup*:

   PowerShell

   ```
   $vm = Get-AzVm -Name "myVM" -ResourceGroupName "myResourceGroup"
   ```

3. Get information about the NIC remove with Get-AzNetworkInterface. The following example gets information about *myNic3*:

   PowerShell

   ```
   # List existing NICs on the VM if you need to determine NIC name
   $vm.NetworkProfile.NetworkInterfaces

   $nicId = (Get-AzNetworkInterface -ResourceGroupName "myResourceGroup" -
   Name "myNic3").Id
   ```

4. Remove the NIC with Remove-AzVMNetworkInterface and then update the VM with Update-AzVm. The following example removes *myNic3* as obtained by `$nicId` in the preceding step:

   PowerShell

   ```
   Remove-AzVMNetworkInterface -VM $vm -NetworkInterfaceIDs $nicId | `
       Update-AzVm -ResourceGroupName "myResourceGroup"
   ```

5. Start the VM with Start-AzVm:

   PowerShell

   ```
   Start-AzVM -Name "myVM" -ResourceGroupName "myResourceGroup"
   ```

Create multiple NICs with templates

Azure Resource Manager templates provide a way to create multiple instances of a resource during deployment, such as creating multiple NICs. Resource Manager templates use declarative JSON files to define your environment. For more information, see overview of Azure Resource Manager. You can use *copy* to specify the number of instances to create:

```JSON
"copy": {
    "name": "multiplenics",
    "count": "[parameters('count')]"
}
```

For more information, see creating multiple instances by using *copy*.

You can also use `copyIndex()` to append a number to a resource name. You can then create *myNic1*, *MyNic2* and so on. The following code shows an example of appending the index value:

```JSON
"name": "[concat('myNic', copyIndex())]",
```

You can read a complete example of creating multiple NICs by using Resource Manager templates.

Add routes for secondary NICs to the OS by completing the steps in Configure the operating system for multiple NICs.

Configure guest OS for multiple NICs

Azure assigns a default gateway to the first (primary) network interface attached to the virtual machine. Azure does not assign a default gateway to additional (secondary) network interfaces attached to a virtual machine. Therefore, you are unable to communicate with resources outside the subnet that a secondary network interface is in, by default. Secondary network interfaces can, however, communicate with resources outside their subnet, though the steps to enable communication are different for different operating systems.

1. From a Windows command prompt, run the `route print` command, which returns output similar to the following output for a virtual machine with two attached network interfaces:

```
===========================================================================
====
Interface List
3...00 0d 3a 10 92 ce ......Microsoft Hyper-V Network Adapter #3
7...00 0d 3a 10 9b 2a ......Microsoft Hyper-V Network Adapter #4
===========================================================================
====
```

In this example, **Microsoft Hyper-V Network Adapter #4** (interface 7) is the secondary network interface that doesn't have a default gateway assigned to it.

2. From a command prompt, run the `ipconfig` command to see which IP address is assigned to the secondary network interface. In this example, 192.168.2.4 is assigned to interface 7. No default gateway address is returned for the secondary network interface.

3. To route all traffic destined for addresses outside the subnet of the secondary network interface to the gateway for the subnet, run the following command:

```
route add -p 0.0.0.0 MASK 0.0.0.0 192.168.2.1 METRIC 5015 IF 7
```

The gateway address for the subnet is the first IP address (ending in .1) in the address range defined for the subnet. If you don't want to route all traffic outside the subnet, you could add individual routes to specific destinations, instead. For example, if you only wanted to route traffic from the secondary network interface to the 192.168.3.0 network, you enter the command:

```
route add -p 192.168.3.0 MASK 255.255.255.0 192.168.2.1 METRIC 5015 IF
7
```

4. To confirm successful communication with a resource on the 192.168.3.0 network, for example, enter the following command to ping 192.168.3.4 using interface 7 (192.168.2.4):

```
ping 192.168.3.4 -S 192.168.2.4
```

You may need to open ICMP through the Windows firewall of the device you're pinging with the following command:

```
netsh advfirewall firewall add rule name=Allow-ping protocol=icmpv4
dir=in action=allow
```

5. To confirm the added route is in the route table, enter the `route print` command, which returns output similar to the following text:

```
===========================================================================
====
Active Routes:
Network Destination        Netmask          Gateway       Interface
Metric
          0.0.0.0          0.0.0.0      192.168.1.1      192.168.1.4
15
          0.0.0.0          0.0.0.0      192.168.2.1      192.168.2.4
5015
```

The route listed with *192.168.1.1* under **Gateway**, is the route that is there by default for the primary network interface. The route with *192.168.2.1* under **Gateway**, is the route you added.

Next steps

Review Windows VM sizes when you're trying to create a VM that has multiple NICs. Pay attention to the maximum number of NICs that each VM size supports.

Create a fully qualified domain name for a VM in the Azure portal

Article • 08/22/2024

Applies to: Applies to: ✔ Linux VMs ✔ Windows VMs

When you create a virtual machine (VM) in the Azure portal, a public IP resource for the virtual machine is automatically created. You use this public IP address to remotely access the VM. Although the portal doesn't create a fully qualified domain name, or FQDN, you can add one once the VM is created. This article demonstrates the steps to create a DNS name or FQDN. If you create a VM without a public IP address, you can't create an FQDN.

Create an FQDN

This article assumes that you've already created a VM. If needed, you can create a Linux or Windows VM in the portal. Follow these steps once your VM is up and running:

1. Select your VM in the portal.
2. In the left menu, select **Properties**
3. Under **Public IP address\DNS name label**, select your IP address.
4. Under **DNS name label**, enter the prefix you want to use.
5. Select **Save** at the top of the page.
6. Select **Overview** in the left menu to return to the VM overview blade.
7. Verify that the **DNS name** appears correctly.

Next steps

You can also manage DNS using Azure DNS zones.

DNS Name Resolution options for Linux virtual machines in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

Azure provides DNS name resolution by default for all virtual machines that are in a single virtual network. You can implement your own DNS name resolution solution by configuring your own DNS services on your virtual machines that Azure hosts. The following scenarios should help you choose the one that works for your situation.

- Name resolution that Azure provides
- Name resolution using your own DNS server

The type of name resolution that you use depends on how your virtual machines and role instances need to communicate with each other.

The following table illustrates scenarios and corresponding name resolution solutions:

Expand table

Scenario	Solution	Suffix
Name resolution between role instances or virtual machines in the same virtual network	Name resolution that Azure provides	hostname or fully-qualified domain name (FQDN)
Name resolution between role instances or virtual machines in different virtual networks	Customer-managed DNS servers that forward queries between virtual networks for resolution by Azure (DNS proxy). See Name resolution using your own DNS server.	FQDN only
Resolution of on-premises computers and service names from role instances or virtual machines in Azure	Customer-managed DNS servers (for example, on-premises domain controller, local read-only domain controller, or a DNS secondary synced by using zone transfers). See Name resolution using your own DNS server.	FQDN only
Resolution of Azure hostnames from on-premises computers	Forward queries to a customer-managed DNS proxy server in the corresponding virtual network. The proxy server forwards queries to Azure for resolution. See Name resolution using your own DNS server.	FQDN only

Scenario	Solution	Suffix
Reverse DNS for internal IPs	Name resolution using your own DNS server	n/a

Name resolution that Azure provides

Along with resolution of public DNS names, Azure provides internal name resolution for virtual machines and role instances that are in the same virtual network. In virtual networks that are based on Azure Resource Manager, the DNS suffix is consistent across the virtual network; the FQDN isn't needed. DNS names can be assigned to both network interface cards (NICs) and virtual machines. Although the name resolution that Azure provides does not require any configuration, it isn't the appropriate choice for all deployment scenarios, as seen on the preceding table.

Features and considerations

Features:

- No configuration is required to use name resolution that Azure provides.
- The name resolution service that Azure provides is highly available. You don't need to create and manage clusters of your own DNS servers.
- The name resolution service that Azure provides can be used along with your own DNS servers to resolve both on-premises and Azure hostnames.
- Name resolution is provided between virtual machines in virtual networks without need for the FQDN.
- You can use hostnames that best describe your deployments rather than working with auto-generated names.

Considerations:

- The DNS suffix that Azure creates can't be modified.
- You can't manually register your own records.
- WINS and NetBIOS aren't supported.
- Hostnames must be DNS-compatible. Names must use only 0-9, a-z, and '-', and they can't start or end with a '-'. See RFC 3696 Section 2.
- DNS query traffic is throttled for each virtual machine. Throttling shouldn't impact most applications. If request throttling is observed, ensure that client-side caching is enabled. For more information, see Getting the most from name resolution that Azure provides.

Getting the most from name resolution that Azure provides

Client-side caching:

Some DNS queries aren't sent across the network. Client-side caching helps reduce latency and improve resilience to network inconsistencies by resolving recurring DNS queries from a local cache. DNS records contain a Time-To-Live (TTL), which enables the cache to store the record for as long as possible without impacting record freshness. As a result, client-side caching is suitable for most situations.

Some Linux distributions don't include caching by default. We recommend that you add a cache to each Linux virtual machine after you check that there isn't a local cache already.

Several different DNS caching packages, such as dnsmasq, are available. Here are the steps to install dnsmasq on the most common distributions:

Ubuntu

1. Install the dnsmasq package:

```Bash
sudo apt-get install dnsmasq
```

2. Enable the dnsmasq service:

```Bash
sudo systemctl enable dnsmasq.service
```

3. Start the dnsmasq service:

```Bash
sudo systemctl start dnsmasq.service
```

Client-side retries

DNS is primarily a UDP protocol. Because the UDP protocol doesn't guarantee message delivery, the DNS protocol itself handles retry logic. Each DNS client (operating system) can exhibit different retry logic depending on the creator's preference:

- Windows operating systems retry after one second and then again after another two, four, and another four seconds.
- The default Linux setup retries after five seconds. You should change this to retry five times at one-second intervals.

To check the current settings on a Linux virtual machine, 'cat /etc/resolv.conf', and look at the 'options' line, for example:

```Bash
sudo cat /etc/resolv.conf
```

```config-conf
options timeout:1 attempts:5
```

The `/etc/resolv.conf` file is auto-generated and shouldn't be edited. The specific steps that add the 'options' line vary by distribution:

Ubuntu (uses resolvconf)

1. Add the options line to `/etc/resolvconf/resolv.conf.d/head` file.
2. Run `sudo resolvconf -u` to update.

SUSE (uses netconf)

1. Add `timeout:1 attempts:5` to the `NETCONFIG_DNS_RESOLVER_OPTIONS=""` parameter in `/etc/sysconfig/network/config`.
2. Run `sudo netconfig update` to update.

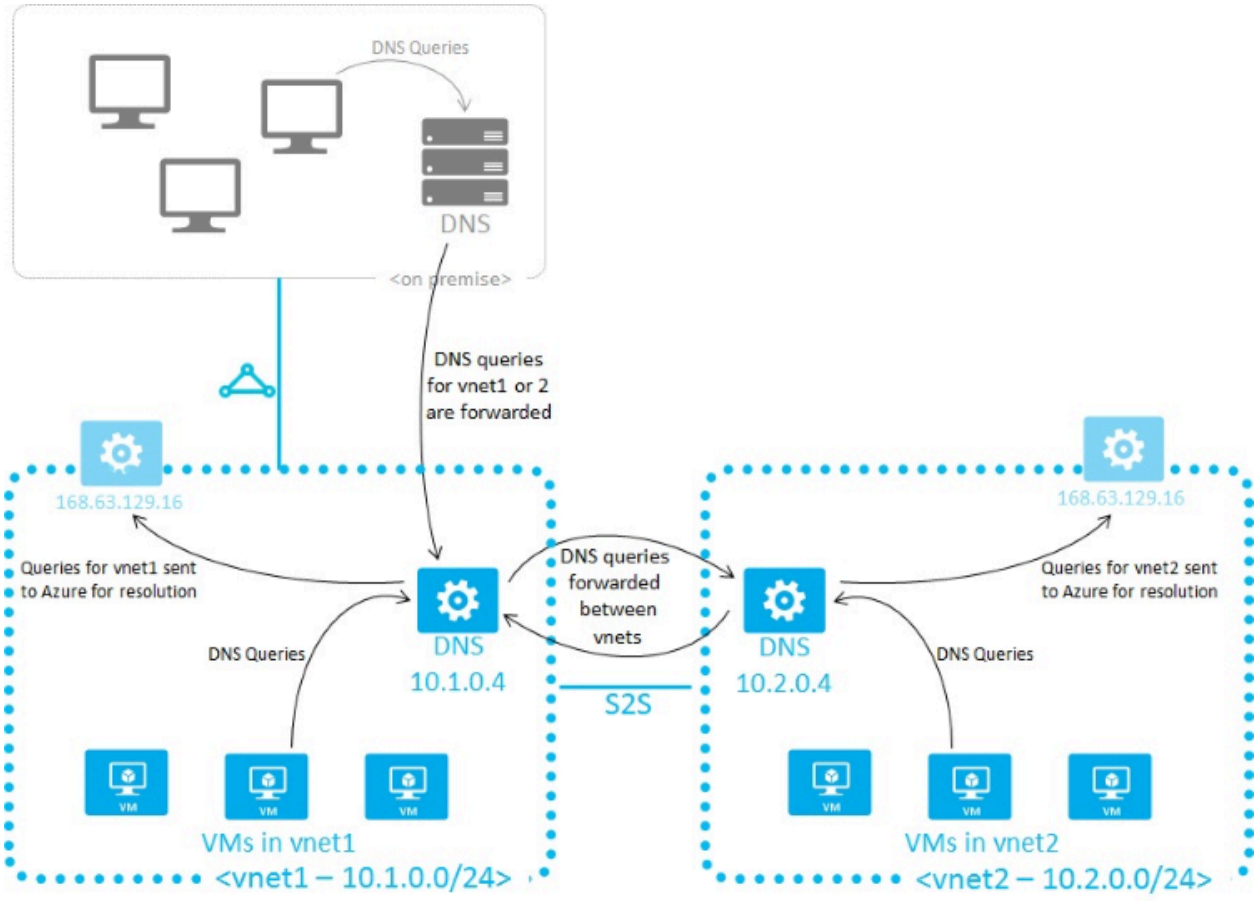
Name resolution using your own DNS server

Your name resolution needs may go beyond the features that Azure provides. For example, you might require DNS resolution between virtual networks. To cover this scenario, you can use your own DNS servers.

DNS servers within a virtual network can forward DNS queries to recursive resolvers of Azure to resolve hostnames that are in the same virtual network. For example, a DNS server that runs in Azure can respond to DNS queries for its own DNS zone files and forward all other queries to Azure. This functionality enables virtual machines to see both your entries in your zone files and hostnames that Azure provides (via the

forwarder). Access to the recursive resolvers of Azure is provided via the virtual IP 168.63.129.16.

DNS forwarding also enables DNS resolution between virtual networks and enables your on-premises machines to resolve hostnames that Azure provides. To resolve a virtual machine's hostname, the DNS server virtual machine must reside in the same virtual network and be configured to forward hostname queries to Azure. Because the DNS suffix is different in each virtual network, you can use conditional forwarding rules to send DNS queries to the correct virtual network for resolution. The following image shows two virtual networks and an on-premises network doing DNS resolution between virtual networks by using this method:



When you use name resolution that Azure provides, the internal DNS suffix is provided to each virtual machine by using DHCP. When you use your own name resolution solution, this suffix isn't supplied to virtual machines because the suffix interferes with other DNS architectures. To refer to machines by FQDN or to configure the suffix on your virtual machines, you can use PowerShell or the API to determine the suffix:

- For virtual networks that are managed by Azure Resource Manager, the suffix is available via the network interface card resource. You can also run the `azure network public-ip show <resource group> <pip name>` command to display the details of your public IP, which includes the FQDN of the NIC.

If forwarding queries to Azure doesn't suit your needs, you need to provide your own DNS solution. Your DNS solution needs to:

- Provide appropriate hostname resolution, for example via DDNS. If you use DDNS, you might need to disable DNS record scavenging. DHCP leases of Azure are long and scavenging may remove DNS records prematurely.
- Provide appropriate recursive resolution to allow resolution of external domain names.
- Be accessible (TCP and UDP on port 53) from the clients it serves and be able to access the Internet.
- Be secured against access from the Internet to mitigate threats posed by external agents.

> **Note**
>
> For best performance, when you use virtual machines in Azure DNS servers, disable IPv6 and assign an **Instance-Level Public IP** to each DNS server virtual machine.

Create virtual network interface cards and use internal DNS for VM name resolution on Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This article shows you how to set static internal DNS names for Linux VMs using virtual network interface cards (vNics) and DNS label names with the Azure CLI. Static DNS names are used for permanent infrastructure services like a Jenkins build server, which is used for this document, or a Git server.

The requirements are:

- an Azure account
- SSH public and private key files

Quick commands

If you need to quickly accomplish the task, the following section details the commands needed. More detailed information and context for each step can be found in the rest of the document, starting here. To perform these steps, you need the latest Azure CLI installed and logged in to an Azure account using az login.

Pre-Requirements: Resource Group, virtual network and subnet, Network Security Group with SSH inbound.

Create a virtual network interface card with a static internal DNS name

Create the vNic with az network nic create. The `--internal-dns-name` CLI flag is for setting the DNS label, which provides the static DNS name for the virtual network interface card (vNic). The following example creates a vNic named `myNic`, connects it to the `myVnet` virtual network, and creates an internal DNS name record called `jenkins`:

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic \
```

```
    --vnet-name myVnet \
    --subnet mySubnet \
    --internal-dns-name jenkins
```

Deploy a VM and connect the vNic

Create a VM with az vm create. The `--nics` flag connects the vNic to the VM during the deployment to Azure. The following example creates a VM named `myVM` with Azure Managed Disks and attaches the vNic named `myNic` from the preceding step:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --nics myNic \
    --image Ubuntu2204 \
    --admin-username azureuser \
    --ssh-key-value ~/.ssh/id_rsa.pub
```

Detailed walkthrough

A full continuous integration and continuous deployment (CiCd) infrastructure on Azure requires certain servers to be static or long-lived servers. It's recommended that Azure assets like the virtual networks and Network Security Groups are static and long lived resources that are rarely deployed. Once a virtual network has been deployed, it can be reused in new deployments without any adverse affects to the infrastructure. You can later add a Git repository server or a Jenkins automation server delivers CiCd to this virtual network for your development or test environments.

Internal DNS names are only resolvable inside an Azure virtual network. Because the DNS names are internal, they aren't resolvable to the outside internet, providing extra security to the infrastructure.

In the following examples, replace example parameter names with your own values. Example parameter names include `myResourceGroup`, `myNic`, and `myVM`.

Create the resource group

First, create the resource group with az group create. The following example creates a resource group named `myResourceGroup` in the `westus` location:

Azure CLI

```
az group create --name myResourceGroup --location westus
```

Create the virtual network

The next step is to build a virtual network to launch the VMs into. The virtual network contains one subnet for this walkthrough. For more information on Azure virtual networks, see Create a virtual network.

Create the virtual network with az network vnet create. The following example creates a virtual network named `myVnet` and subnet named `mySubnet`:

Azure CLI

```
az network vnet create \
    --resource-group myResourceGroup \
    --name myVnet \
    --address-prefix 192.168.0.0/16 \
    --subnet-name mySubnet \
    --subnet-prefix 192.168.1.0/24
```

Create the Network Security Group

Azure Network Security Groups are equivalent to a firewall at the network layer. For more information about Network Security Groups, see How to create NSGs in the Azure CLI.

Create the network security group with az network nsg create. The following example creates a network security group named `myNetworkSecurityGroup`:

Azure CLI

```
az network nsg create \
    --resource-group myResourceGroup \
    --name myNetworkSecurityGroup
```

Add an inbound rule to allow SSH

Add an inbound rule for the network security group with az network nsg rule create. The following example creates a rule named `myRuleAllowSSH`:

Azure CLI

```
az network nsg rule create \
    --resource-group myResourceGroup \
    --nsg-name myNetworkSecurityGroup \
    --name myRuleAllowSSH \
    --protocol tcp \
    --direction inbound \
    --priority 1000 \
    --source-address-prefix '*' \
    --source-port-range '*' \
    --destination-address-prefix '*' \
    --destination-port-range 22 \
    --access allow
```

Associate the subnet with the Network Security Group

To associate the subnet with the Network Security Group, use az network vnet subnet update. The following example associates the subnet name `mySubnet` with the Network Security Group named `myNetworkSecurityGroup`:

Azure CLI

```
az network vnet subnet update \
    --resource-group myResourceGroup \
    --vnet-name myVnet \
    --name mySubnet \
    --network-security-group myNetworkSecurityGroup
```

Create the virtual network interface card and static DNS names

To use DNS names for VM name resolution, you need to create virtual network interface cards (vNics) that include a DNS label. vNics are important as you can reuse them by connecting them to different VMs over the infrastructure lifecycle. This approach keeps the vNic as a static resource while the VMs can be temporary. By using DNS labeling on the vNic, we're able to enable simple name resolution from other VMs in the VNet. Using resolvable names enables other VMs to access the automation server by the DNS name `Jenkins` or the Git server as `gitrepo`.

Create the vNic with az network nic create. The following example creates a vNic named `myNic`, connects it to the `myVnet` virtual network named `myVnet`, and creates an internal

DNS name record called `jenkins`:

Azure CLI

```
az network nic create \
    --resource-group myResourceGroup \
    --name myNic \
    --vnet-name myVnet \
    --subnet mySubnet \
    --internal-dns-name jenkins
```

Deploy the VM into the virtual network infrastructure

We now have a virtual network and subnet, a Network Security Group acting as a firewall to protect our subnet by blocking all inbound traffic except port 22 for SSH, and a vNic. You can now deploy a VM inside this existing network infrastructure.

Create a VM with az vm create. The following example creates a VM named `myVM` with Azure Managed Disks and attaches the vNic named `myNic` from the preceding step:

Azure CLI

```
az vm create \
    --resource-group myResourceGroup \
    --name myVM \
    --nics myNic \
    --image Ubuntu2204 \
    --admin-username azureuser \
    --ssh-key-value ~/.ssh/id_rsa.pub
```

By using the CLI flags to call out existing resources, we instruct Azure to deploy the VM inside the existing network. To reiterate, once a VNet and subnet have been deployed, they can be left as static or permanent resources inside your Azure region.

Next steps

- Create your own custom environment for a Linux VM using Azure CLI commands directly
- Create a Linux VM on Azure using templates

Azure Virtual Machines security overview

This article provides an overview of core Azure security features for virtual machines.

Azure Virtual Machines lets you deploy a wide range of computing solutions in an agile way. The service supports Microsoft Windows, Linux, Microsoft SQL Server, Oracle, IBM, SAP, and Azure BizTalk Services. You can deploy any workload and any language on nearly any operating system.

Azure VMs provide the flexibility of virtualization without buying and maintaining physical hardware. You can build and deploy applications with the assurance that your data is protected in highly secure datacenters.

By using Azure, you can build security-enhanced, compliant solutions that:

- Protect virtual machines from viruses and malware
- Encrypt sensitive data
- Secure network traffic
- Identify and detect threats
- Meet compliance requirements

Trusted launch

Trusted launch is the default for newly created Generation 2 Azure VMs and Virtual Machine Scale Sets. Trusted launch protects against advanced and persistent attack techniques including boot kits, rootkits, and kernel-level malware.

Trusted launch provides:

- **Secure Boot**: Protects against installation of malware-based rootkits and boot kits by ensuring only signed operating systems and drivers can boot
- **vTPM (virtual Trusted Platform Module)**: A dedicated secure vault for keys and measurements that enables attestation and boot integrity verification
- **Boot Integrity Monitoring**: Uses attestation through Microsoft Defender for Cloud to verify boot chain integrity and alert on failures

You can enable trusted launch on existing VMs and Virtual Machine Scale Sets. For more information, see Trusted launch for Azure virtual machines.

Confidential computing

Azure confidential computing protects data while in use through hardware-based trusted execution environments. Confidential VMs use AMD SEV-SNP technology to create a

hardware-enforced boundary between your application and the virtualization stack.

Confidential VMs provide:

- **Hardware-based isolation**: Between virtual machines, hypervisor, and host management code.
- **Confidential OS disk encryption**: Binds disk encryption keys to the VM's TPM, making disk content accessible only to the VM.
- **Secure key release**: Cryptographic binding between platform attestation and VM encryption keys.
- **Attestation**: Customizable policies to ensure host compliance before deployment.

For more information, see Azure confidential VMs.

Virtual machine disk encryption

> **Important**
>
> Azure Disk Encryption is scheduled for retirement on **September 15, 2028**. Until that date, you can continue to use Azure Disk Encryption without disruption. On September 15, 2028, ADE-enabled workloads will continue to run, but encrypted disks will fail to unlock after VM reboots, resulting in service disruption.
>
> Use encryption at host for new VMs. All ADE-enabled VMs (including backups) must migrate to encryption at host before the retirement date to avoid service disruption. See Migrate from Azure Disk Encryption to encryption at host for details.

Azure provides several encryption options for managed disks:

- **Server-side encryption (SSE)**: Also called encryption at rest or Azure Storage encryption, SSE is always enabled and automatically encrypts data on Azure managed disks (OS and data disks) when persisting to storage clusters. Data is encrypted transparently using 256-bit AES encryption, which is FIPS 140-2 compliant. SSE doesn't affect disk performance and has no extra cost. However, SSE doesn't encrypt temp disks or disk caches.

- **Encryption at host**: Enhances SSE by encrypting temp disks and disk caches at rest, with data flowing encrypted to storage clusters. This encryption provides end-to-end encryption for your VM data. Encryption at host doesn't use your VM's CPU and doesn't affect performance. Temp disks and ephemeral OS disks are encrypted with platform-managed keys. OS and data disk caches are encrypted with either customer-managed or platform-managed keys, depending on the disk encryption type.

- **Confidential disk encryption**: For confidential VMs, this encryption binds disk encryption keys to the VM's TPM, making protected disk content accessible only to the VM.

By default, managed disks use platform-managed keys with no additional configuration required. For customer-managed keys, you can use Azure Key Vault, Azure Key Vault Managed HSM, or Azure Cloud HSM to control and manage your own encryption keys.

For more information, see Overview of managed disk encryption options and Server-side encryption of Azure Disk Storage.

Key management

Azure Key Vault provides secure storage for cryptographic keys, secrets, and certificates. Azure offers multiple key management solutions with different security levels:

- **Azure Key Vault Standard**: FIPS 140-2 Level 1 validated, multitenant service with software-protected keys.
- **Azure Key Vault Premium**: FIPS 140-3 Level 3 validated, multitenant service with HSM-protected keys.
- **Azure Key Vault Managed HSM**: FIPS 140-3 Level 3 validated, single-tenant service that provides full customer control over the HSM and key sovereignty.

For virtual machines, these services can store:

- **Disk encryption keys**: Customer-managed keys for encrypting managed disks through disk encryption sets.
- **SQL Server encryption keys**: Keys for transparent data encryption on SQL Server VMs.
- **Application secrets**: Keys and secrets used by applications running on your VMs.

You manage permissions and access to protected items through Microsoft Entra ID. You can audit key usage and retain full control over your encryption keys.

For more information, see What is Azure Key Vault?, What is Azure Key Vault Managed HSM?, and Key management in Azure.

Virtual machine backup

Azure Backup is a scalable solution that protects your VM data with zero capital investment and minimal operating costs. Application errors can corrupt your data, and human errors can introduce bugs. With Azure Backup, your virtual machines running Windows and Linux are protected.

Azure Backup provides:

- **Independent and isolated backups**: Backups are stored in a Recovery Services vault, which provides built-in management of recovery points and guards against accidental destruction of data
- **Application-consistent recovery points**: Captures the state of the application data at the time of backup for running VMs
- **No explicit outbound connectivity required**: All communication and data transfer happens on the Azure backbone network
- **Soft delete protection**: Deleted backup data is retained for 14 additional days, allowing recovery with no data loss
- **Cross Region Restore**: Restore Azure VMs in a secondary Azure paired region for disaster recovery scenarios

For more information, see What is Azure Backup? and Azure Backup service FAQ.

Azure Site Recovery

Azure Site Recovery helps orchestrate replication, failover, and recovery of workloads and apps so they're available from a secondary location if your primary location goes down.

Site Recovery:

- **Simplifies BCDR strategy**: Makes it easy to handle replication, failover, and recovery of multiple business workloads and apps from a single location
- **Provides flexible replication**: Replicate workloads running on Hyper-V VMs, VMware VMs, and Windows/Linux physical servers
- **Supports failover and recovery**: Provides test failovers for disaster recovery drills without affecting production environments
- **Eliminates secondary datacenters**: Replicate to Azure, eliminating the cost and complexity of maintaining a secondary site

For more information, see What is Azure Site Recovery?, How does Azure Site Recovery work?, and What workloads are protected by Azure Site Recovery?.

Virtual networking

Virtual machines require network connectivity. Azure requires virtual machines to be connected to an Azure virtual network.

An Azure virtual network is a logical construct built on top of the physical Azure network fabric. Each logical Azure virtual network is isolated from all other Azure virtual networks. This isolation helps ensure that network traffic in your deployments is not accessible to other Microsoft Azure customers.

For more information, see Azure network security overview and Virtual Network overview.

Security policy management

Microsoft Defender for Cloud helps you prevent, detect, and respond to threats. Defender for Cloud gives you increased visibility into, and control over, the security of your Azure resources. It provides integrated security monitoring and policy management across your Azure subscriptions.

Defender for Cloud helps you optimize and monitor VM security by:

- Providing security recommendations for virtual machines
- Monitoring the state of your virtual machines
- Providing Microsoft Defender for Servers with advanced threat protection

Microsoft Defender for Servers includes:

- Microsoft Defender for Endpoint integration for endpoint detection and response
- Vulnerability assessment for identifying security weaknesses
- Just-in-time VM access to reduce attack surface
- File integrity monitoring to detect changes to critical files
- Adaptive application controls for approved applications

For more information, see Introduction to Microsoft Defender for Cloud, Microsoft Defender for Servers, and Microsoft Defender for Cloud frequently asked questions.

Compliance

Azure Virtual Machines is certified for FISMA, FedRAMP, HIPAA, PCI DSS Level 1, and other key compliance programs. This certification makes it easier for your Azure applications to meet compliance requirements and for your business to address domestic and international regulatory requirements.

For more information, see Microsoft Trust Center: Compliance and Azure compliance documentation.

Apply Zero Trust principles to virtual machines in Azure

Article • 05/20/2025

Summary: To apply Zero Trust principles to Azure virtual machines, you must configure logical isolation with dedicated resource groups, leverage Role Based Access Control (RBAC), secure virtual machine boot components, enable customer-managed keys and double encryption, control installed applications, configure secure access and maintenance of virtual machines, and enable advanced threat detection and protection.

This article provides steps to apply the principles of Zero Trust to virtual machines in Azure:

Expand table

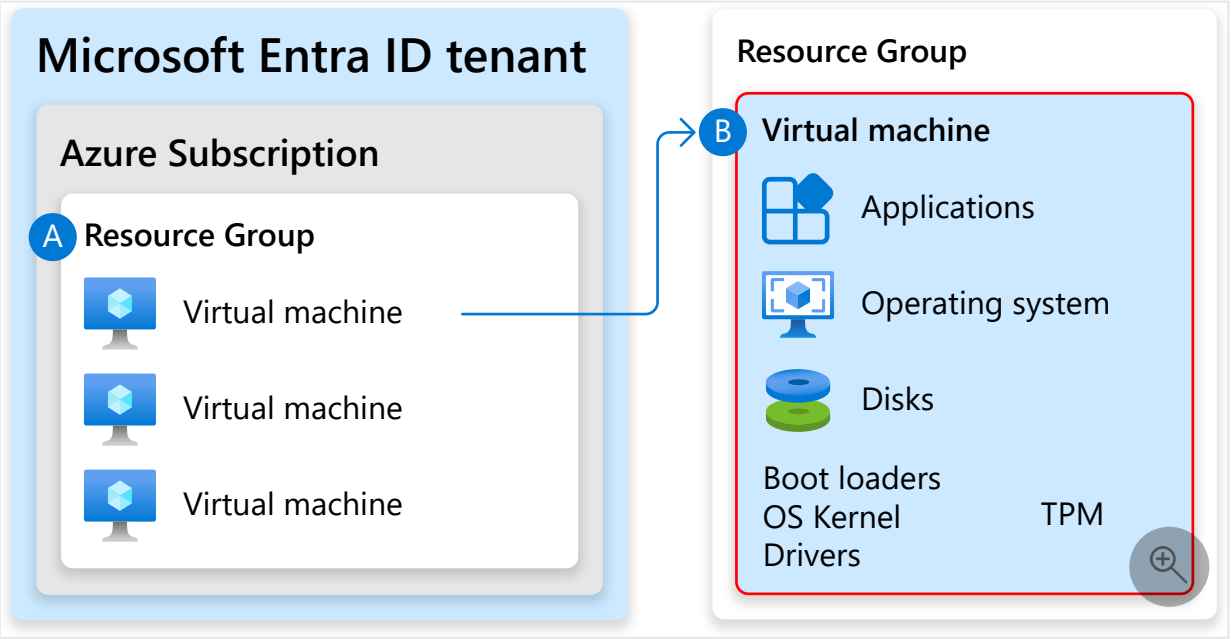
Zero Trust principle	Definition	Met by
Verify explicitly	Always authenticate and authorize based on all available data points.	Use secure access.
Use least privileged access	Limit user access with Just-In-Time and Just-Enough-Access (JIT/JEA), risk-based adaptive policies, and data protection.	Leverage Role Based Access Control (RBAC) and control the applications running on virtual machines.
Assume breach	Minimize blast radius and segment access. Verify end-to-end encryption and use analytics to get visibility, drive threat detection, and improve defenses.	Isolate virtual machines with resource groups, secure their components, use double encryption, and enable advanced threat detection and protection.

This article is part of a series of articles that demonstrate how to apply the principles of Zero Trust across an environment in Azure that includes a spoke virtual network (VNet) hosting a virtual machine-based workload. For an overview, see Apply Zero Trust principles to Azure infrastructure.

Logical architecture for virtual machines

Zero Trust principles for virtual machines are applied across the logical architecture, from the tenant and directory level down to the data and application layer within each virtual machine.

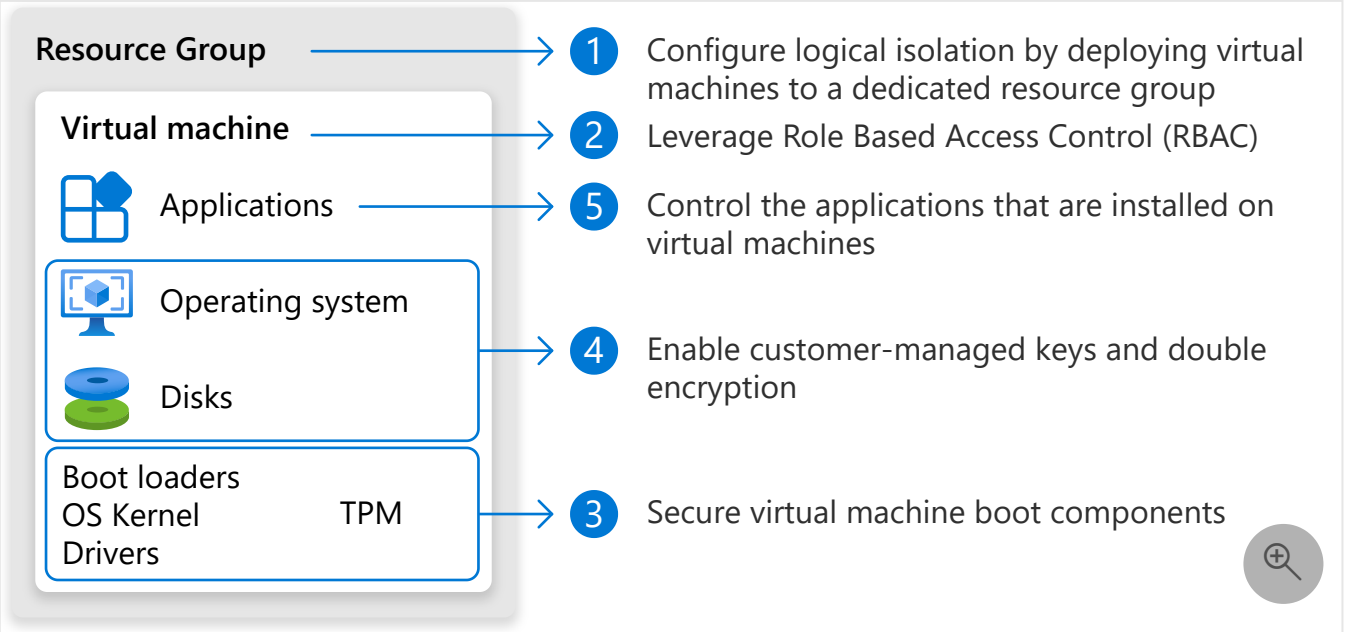
The following diagram shows the logical architecture components.



In this diagram:

- **A** is a set of virtual machines isolated within a dedicated resource group that resides within an Azure subscription.
- **B** is the logical architecture for a single virtual machine with the following components called out: applications, operating system, disks, boot loaders, OS Kernel, drivers, and the Trusted Platform Module (TPM) component.

This article walks through the steps to apply the principles of Zero Trust across this logical architecture, using these steps.



Expand table

Step	Task	Zero Trust principles applied
1	Configure logical isolation by deploying virtual machines to a dedicated resource group.	Assume breach
2	Leverage Role Based Access Control (RBAC).	Verify explicitly Use least privileged access
3	Secure virtual machine boot components including boot loaders, OS kernels, and drivers. Securely protect keys, certificates, and secrets in the Trusted Platform Module (TPM).	Assume breach
4	Enable customer-managed keys and double encryption.	Assume breach
5	Control the applications that are installed on virtual machines.	Use least privileged access
6	Configure secure access (not shown on the logical architecture figure).	Verify explicitly Use least privileged access Assume breach
7	Set up secure maintenance of virtual machines (not shown on the logical architecture figure).	Assume breach
8	Enable advanced threat detection and protection (not shown on the logical architecture figure).	Assume breach

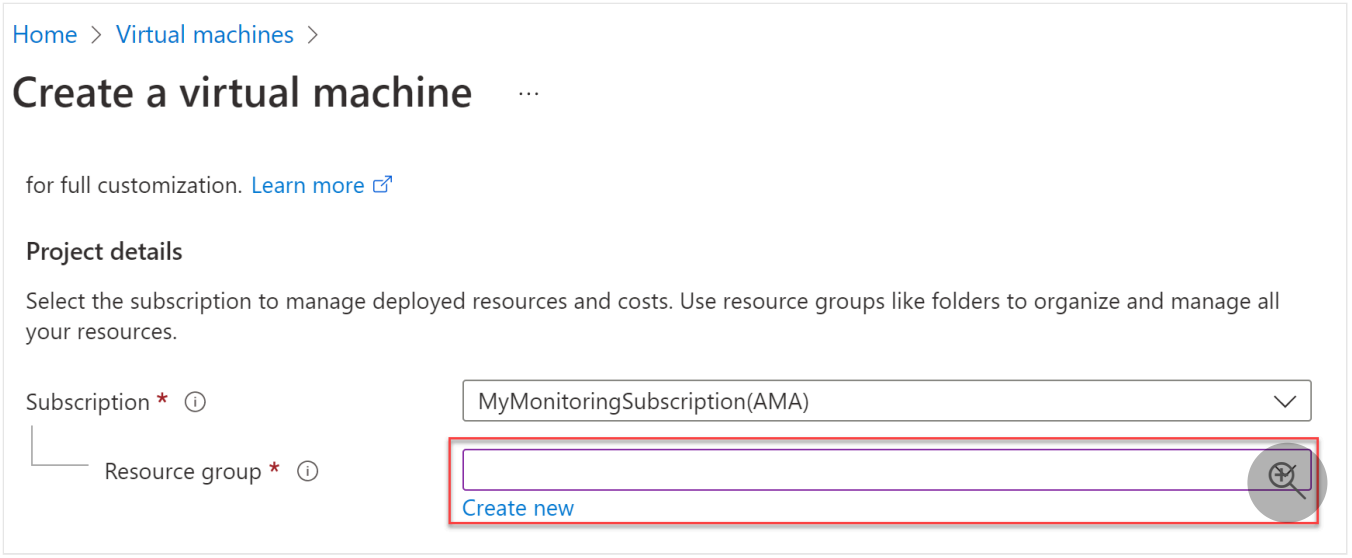
Step 1: Configure logical isolation for virtual machines

Begin by isolating virtual machines within a dedicated resource group. You can isolate virtual machines into different resource groups based on purpose, data classification, and governance requirements, such as the need to control permissions and monitoring.

Using dedicated resource groups allows you to set policies and permissions that apply to all the virtual machines within the resource group. You can then use role based access control (RBAC) to create least privileged access to the Azure resources contained in the resource group.

For more information on creating and managing resource groups, see Manage Azure resource groups by using the Azure portal.

You assign a virtual machine to a resource group when you first create the virtual machine, as shown here.



Step 2: Leverage Role Based Access Control (RBAC)

Zero Trust requires configuring least privileged access. To do so, you need to limit user access with just-in-time and just-enough access (JIT/JEA) based on their role, workload, and data classification.

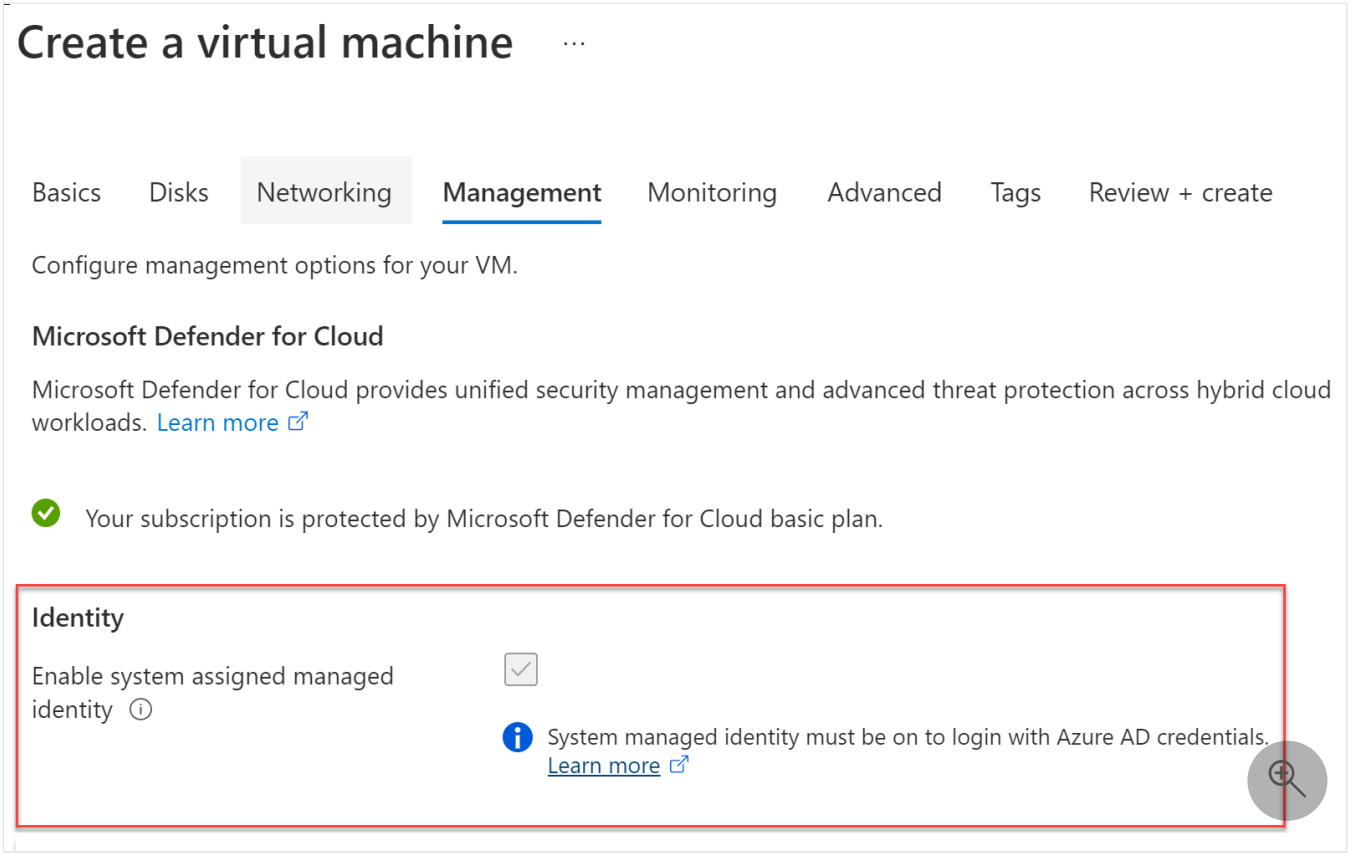
The following built-in roles are commonly used for virtual machine access:

- **Virtual Machine User Login:** View virtual machines in the portal and sign-in as a regular user.
- **Virtual Machine Administration Login:** View virtual machines in the portal and sign-in to virtual machines as an Administrator.
- **Virtual Machine Contributor:** Create and manage virtual machines, including reset root user's password and managed disks. Doesn't grant access to the management virtual network (VNet) or the ability to assign permissions to the resources.

To join a virtual machine to a VNet, you can use the custom permission **Microsoft.Network/virtualNetworks/subnets/join/action** to make a custom role.

When this custom role is used with Managed Identity and Conditional Access Policy, you can use device state, data classification, anomalies, location, and identity to force multifactor authentication and granularly allow access based on verified trust.

To extend your realm of control beyond the system and allow your Microsoft Entra ID tenant with Microsoft Intelligent Security Graph to support secure access, go to the **Management** blade of the virtual machine and turn on **System Assigned Managed Identity**, as shown here.



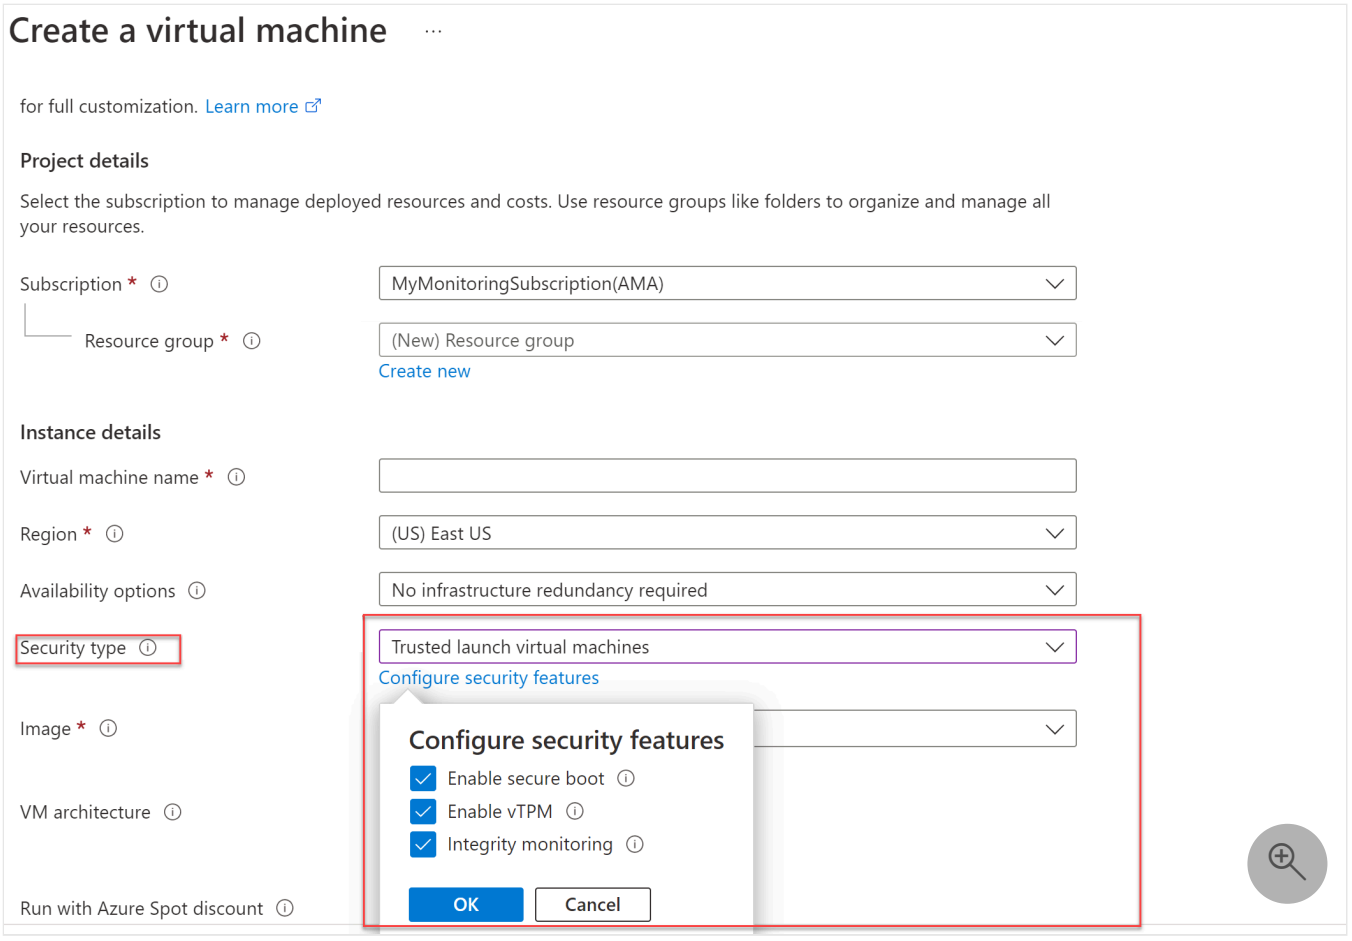
> **Note**
>
> This feature is only available for Azure Virtual Desktop, Windows Server 2019, Windows 10, and Linux Distros using certificate-based access.

Step 3: Secure virtual machine boot components

Follow these steps:

- When you create the virtual machine, be sure you configure security for the boot components. Enhanced deployment of virtual machines allows you to select security type and use Secure boot and vTPM.
- Securely deploy virtual machines with verified boot loaders, OS kernels, and drivers that are signed by trusted publishers to establish a "root ." If the image isn't signed by a trusted publisher, the virtual machine won't boot.
- Securely protect keys, certificates, and secrets in the virtual machines in a Trusted Platform Module.
- Gain insights and confidence of the entire boot chain's integrity.
- Ensure workloads are trusted and verifiable. The vTPM enables attestation by measuring the entire boot chain of your virtual machine (UEFI, OS, system, and drivers).

Enhanced deployment of virtual machines allows you to select security type and use secure boot and vTPM when you create them, as shown here.



Step 4: Enable customer-managed keys and double encryption

Using customer-managed keys and double encryption ensures that if a disk is exported, it isn't readable or able to function. By ensuring that the keys are privately held and disks are double encrypted, you protect against breaches that attempt to extract disk information.

For information on how to configure a customer-managed encryption key with Azure Key Vault, see Use the Azure portal to enable server-side encryption with customer-managed keys for managed disks. There's an additional cost for using Azure Key Vault.

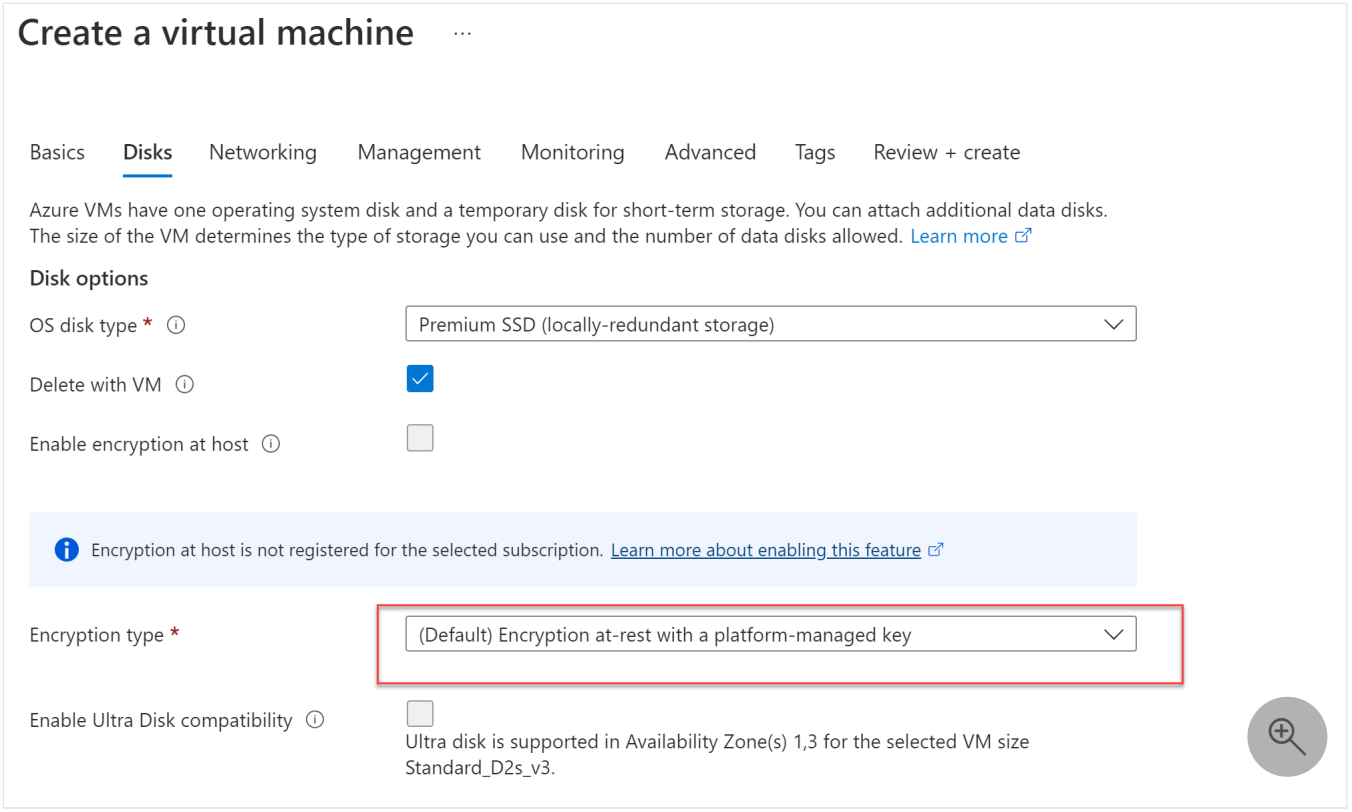
Enable server-side encryption of Azure Disk Storage for:

- FIPS 140-2 compliant transparent encryption with AES 256 encryption.
- Greater flexibility to manage controls.
- Hardware (HSM) or software-defined encryption.

Enable server-side encryption at the host for end-to-end encryption of your virtual machine data.

After completing these procedures, you use your customer-managed encryption key to encrypt the disks within your virtual machine.

You select the encryption type on the **Disks** blade for the virtual machine configuration. For **Encryption type**, select **Double encryption with platform-managed and customer-managed keys**, as shown here.



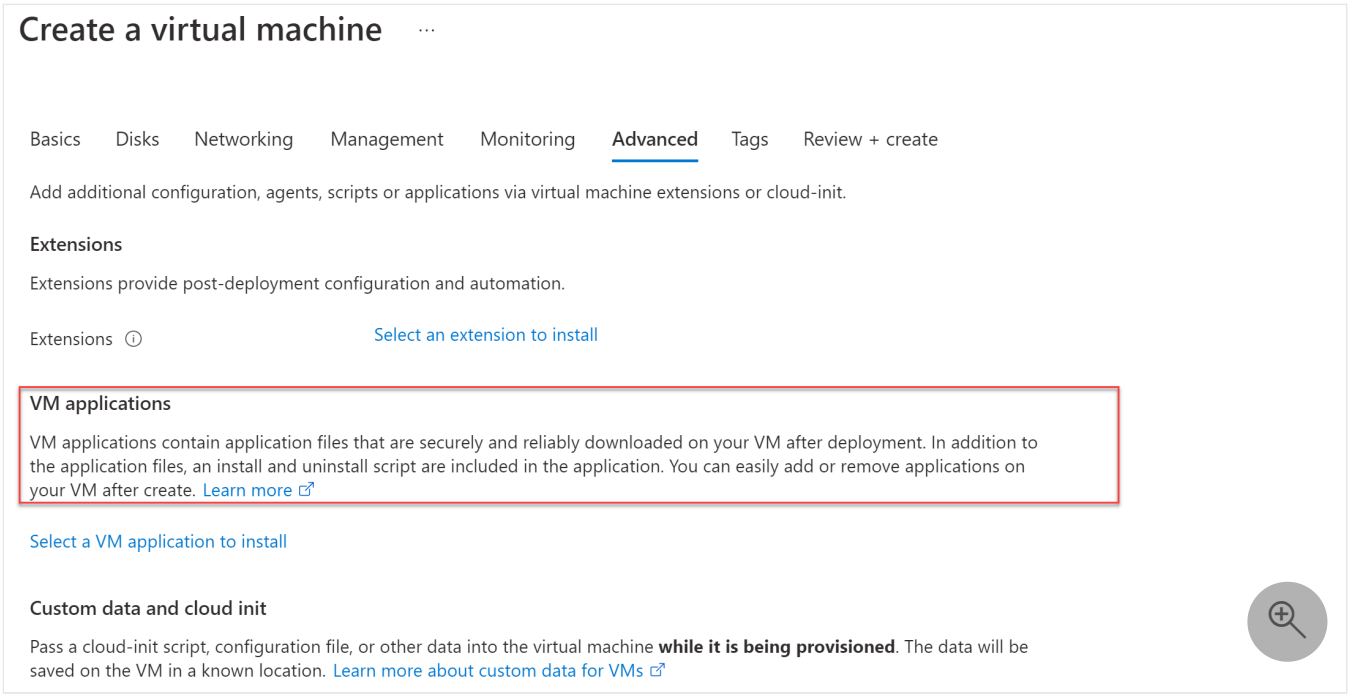
Step 5: Control the applications installed on virtual machines

It's important to control the applications that are installed on your virtual machines:

- Browser extensions (APIs) are difficult to secure which can lead to malicious URL delivery.
- Unsanctioned apps can go unpatched as they're shadow IT objects (the IT teams aren't prepared or have no knowledge that these are installed).

You can use the Virtual Machine Applications feature to control the applications that are installed on virtual machines. With this feature, you select which virtual machine applications to install. This feature uses the Azure Compute Gallery to simplify management of applications for virtual machines. When used together with RBAC, you can ensure that only trusted applications are available for users.

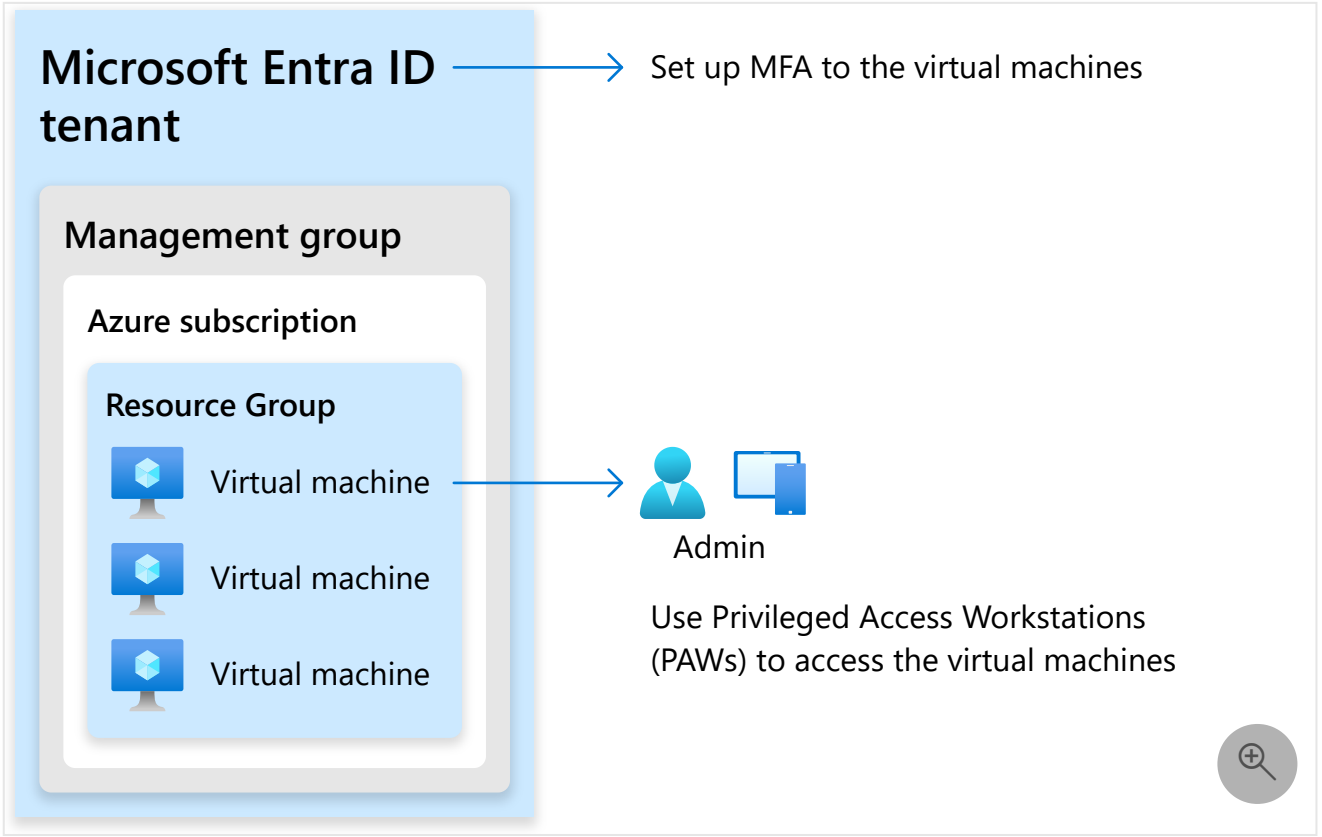
You select the virtual machine applications on the **Advanced** blade for the virtual machine configuration, as show here.



Step 6: Configure secure access

To configure secure access:

- Configure secure communication within the Azure environment between components that are accessing virtual machines directly
- Set up multifactor authentication with conditional access
- Use privileged access workstations (PAWs)



In the diagram:

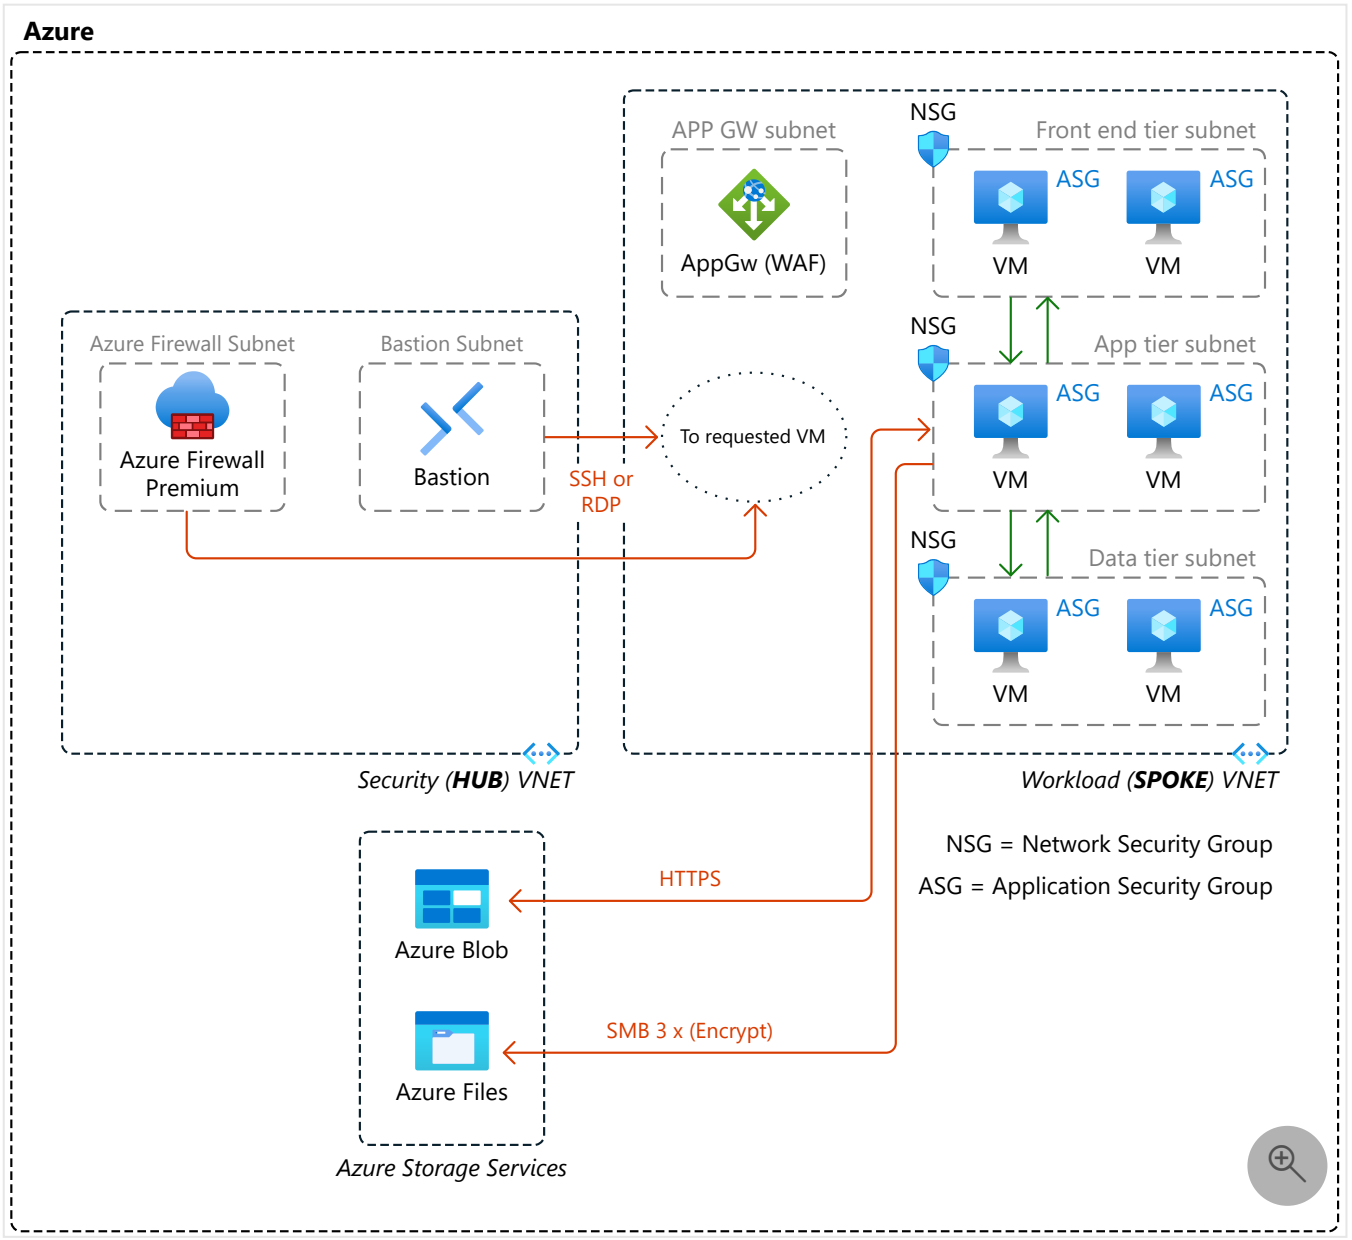
- multifactor authentication with conditional access is set up within Microsoft Entra ID and related portals.
- Admins use privileged access workstations (PAWs) to access virtual machines directly.

Configure secure communication within the Azure environment for virtual machines

First, be sure that communication between the components in the Azure environment is secure.

In the reference architecture, Azure Bastion provides secure connections to virtual machines. Azure Bastion acts as an RDP/SSH broker and doesn't interact with the RDP protocol of your physical system. This also enables you to reduce the number of public-facing IP addresses.

The following diagram shows the components of secure communications for virtual machines.

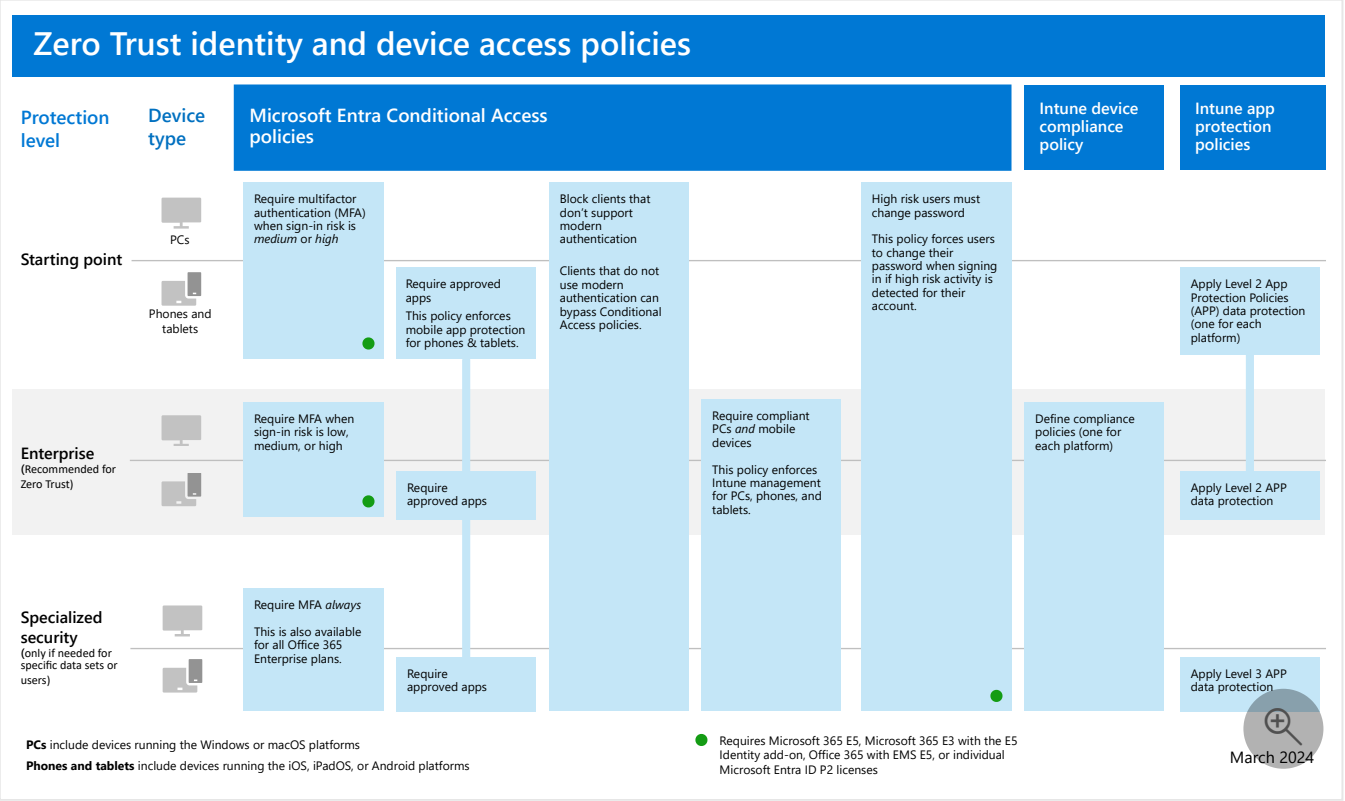


Set up multifactor authentication with conditional access

In Step 2. Leverage Role Based Access Control, you configured Microsoft Entra integration and managed identity. This allows you to set up Azure multifactor authentication for Azure Virtual Desktop or for servers running Windows Server 2019 or newer. You can also Log in to a Linux VM with Microsoft Entra credentials. The added benefit of this is the machine that connects to the virtual machine must also be registered to your Microsoft Entra ID tenant to be allowed to connect.

When configuring multifactor authentication with conditional access and related policies, use the recommended policy set for Zero Trust as a guide. This includes **Starting point** policies that don't require managing devices. Ideally, the devices accessing your virtual machines are managed and you can implement the **Enterprise** policies, which is recommended for Zero Trust. For more information, see Common Zero Trust identity and device access policies.

The following diagram shows the recommended policies for Zero Trust.



Remember that usernames and passwords can be 100% compromised. Using multifactor authentication, you reduce your risk of compromise by 99.9%. This requires Microsoft Entra ID P1 licenses.

> **Note**
>
> You can use VPNs used to connect to virtual machines in Azure as well. However, you should be sure to use methods to verify explicitly. Creating a tunnel that is "trusted" regardless of how they are used can be riskier than having specific connections that are highly verified.

No amount of security at the Network, Transport, or Application layers matters if you aren't coming from a trusted, verified, and secure source.

Use PAWs

Use Privileged Access Workstations (PAWs) to ensure devices that access virtual machines are healthy. PAWs are configured specifically for privileged access so that admins use a device that has:

- Security controls and policies that restrict local administrative access.
- Productivity tools to minimize the attack surface to only what's absolutely required for performing sensitive administrative tasks.

For more information on deployment options, see Privileged access deployment.

Step 7: Set up secure maintenance of virtual machines

Secure maintenance of virtual machines includes:

- Using anti-malware
- Automating virtual machine updates

Use anti-malware on virtual machines

Anti-malware helps protect your virtual machine from threats such as malicious files and adware, etc. You can use anti-malware software from an option of vendors such as Microsoft, Symantec, Trend Micro, and Kaspersky.

Microsoft Antimalware is a no-cost resource that provides real-time protection capability to assist in detection, quarantining and eradicating malicious software, spyware, and viruses:

- Runs in the background with the need of user interaction
- Provides alerts when unwanted or malicious software is downloaded, installed, or run
- Offers secure-by-default configuration and anti-malware monitoring
- Scheduled scanning
- Signature updates
- Antimalware Engine and Platform updates
- Active Protection
- Samples reporting
- Exclusions
- Antimalware event collection

Automate virtual machine updates

Automating updates to systems ensures they are protected from the latest malware and misconfiguration exploits. There's automatic updating with aid in the trusted platform verification process.

Concentrate on Azure Virtual Machine Maintenance and Updates to ensure your systems are hardened against configuration insecurities:

- Azure Automation Update Management can assist in the management of your update process. With this utility, you can check the update status of your systems, manage,

schedule, and reboot servers.
- The Azure Virtual Machine Agent is used to manage your virtual machines and gives you the ability to use extensions for management.

Operating systems supported by Update Management include the following:

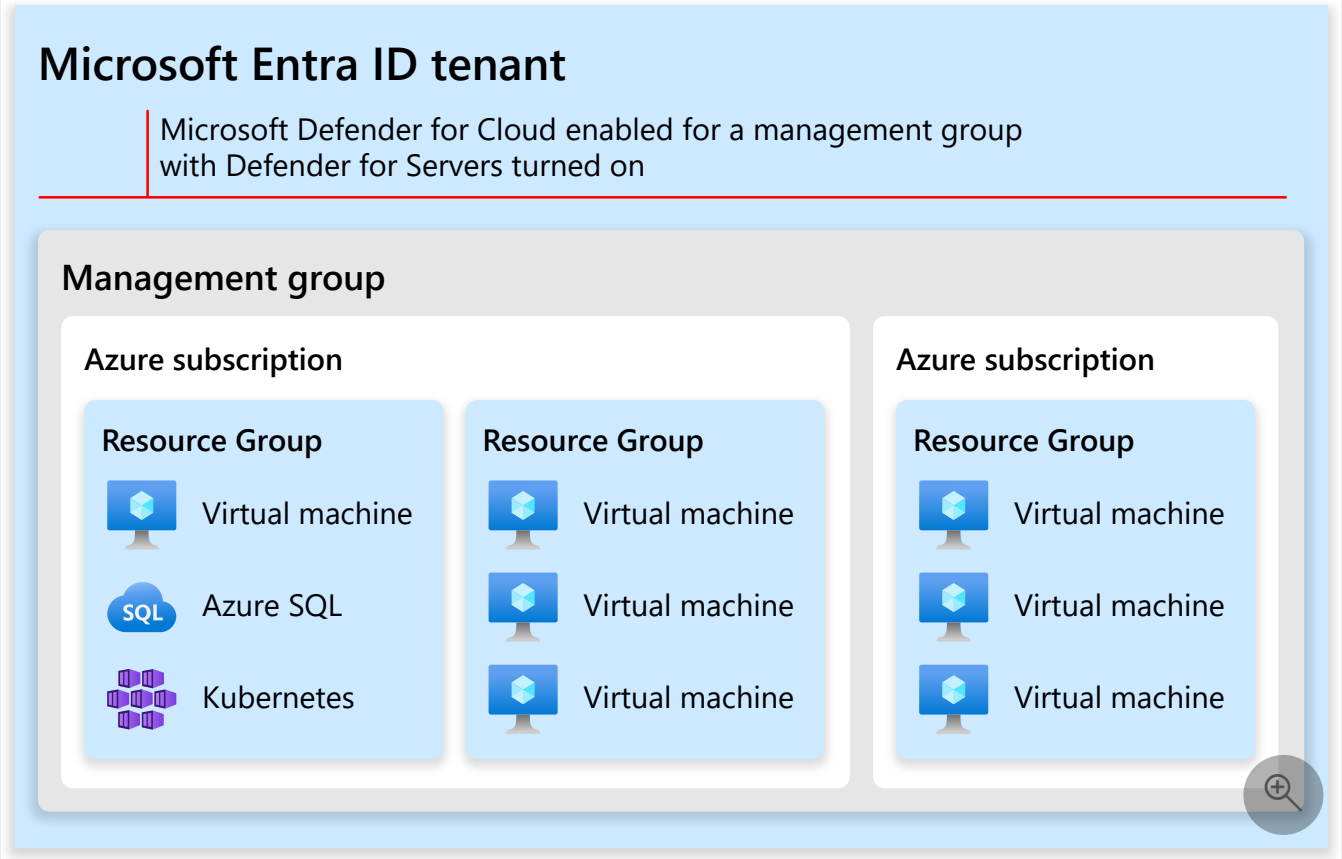
- Each Windows virtual machine - Update Management does a scan twice a day for each machine.
- Each Linux virtual machine - Update Management does a scan every hour.

See this additional guidance:

- Plan deployment for updating Windows VMs in Azure
- Use Azure Private Link to securely connect networks to Azure Automation Ensures virtual machines connect in an isolated controlled fashion and not over the internet for updates.

Step 8: Enable advanced threat detection and protection

Threat protection for Azure infrastructure is provided by Microsoft Defender for Cloud. This protection is extended to virtual machines when you provision Microsoft Defender for Servers, as shown in the following diagram.



In the diagram:

- As described in the Apply Zero Trust principles to Azure IaaS overview article, Defender for Cloud is enabled at the level of an Azure subscription or at the level of an Azure management group that includes multiple Azure subscriptions.
- In addition to enabling Defender for Cloud, Defender for Servers is provisioned.

Advanced threat protection verifies the activities occurring on virtual machines based on Microsoft's threat intelligence. It looks for specific configurations and activities that suggest that there could be a breach. It enables the **Verify explicitly** and **Assume breach** Zero Trust principles.

Microsoft Defender for Servers includes the following:

- Access to the Microsoft Defender for Endpoint data that is related to vulnerabilities, installed software, and alerts for your endpoints for endpoint detection and response (EDR).
- Defender for Cloud's integrated vulnerability assessment scanner for servers.
- Discover vulnerabilities and misconfigurations in real time with Microsoft Defender for Endpoint, and without the need of other agents or periodic scans.
- Defender for Cloud's integrated Qualys scanner for Azure and hybrid machines allows you to use a leading tool in real-time vulnerability identification without the need of a Qualys license.
- Implement Just-in-time virtual machine access in Defender for Cloud. This creates an explicit deny rule for RDP/SSH and gives you JIT access at the server level when you need it and allows you to limit the period of access.
- File integrity monitoring in Defender for Cloud provides you to change monitoring of files and registries of the operations system, application software, and other changes that allow you to validate the integrity of your file systems.
- Adaptive application controls in Defender for Cloud provides an automated solution for creating and defining allow list for known safe applications and generates security alerts if a new application runs other than those you define as safe for use.
- Adaptive network hardening in Defender for Cloud uses machine learning algorithms that calculate your current traffic, threat intelligence, indicators of compromise, and known trusted configurations to provide recommendations for hardening your Network Security Groups.

What is Microsoft Defender for Cloud?

> **Important**
>
> Microsoft Defender for Cloud is expanding to the Defender portal to provide a unified security experience across cloud and code environments. As part of this expansion, some features are now available in the Microsoft Defender Portal, and additional capabilities will be added to the Defender portal over time.
>
> This change is designed to:
>
> - Unlock new cloud and posture management experiences.
> - Provide deep integration with other Microsoft security services.
> - Empower security teams with streamlined workflows by bringing all tools together in one portal.
>
> To identify documentation specific for the Defender Portal, look for the portal entry point at the top of the article. This pivot indicates whether the content applies to the Defender portal or the Azure portal.
>
> Our documentation will be continuously updated to reflect these changes, so check back regularly for the latest guidance and feature availability.
>
> Review the **known limitations** article to understand current gaps during the preview phase.

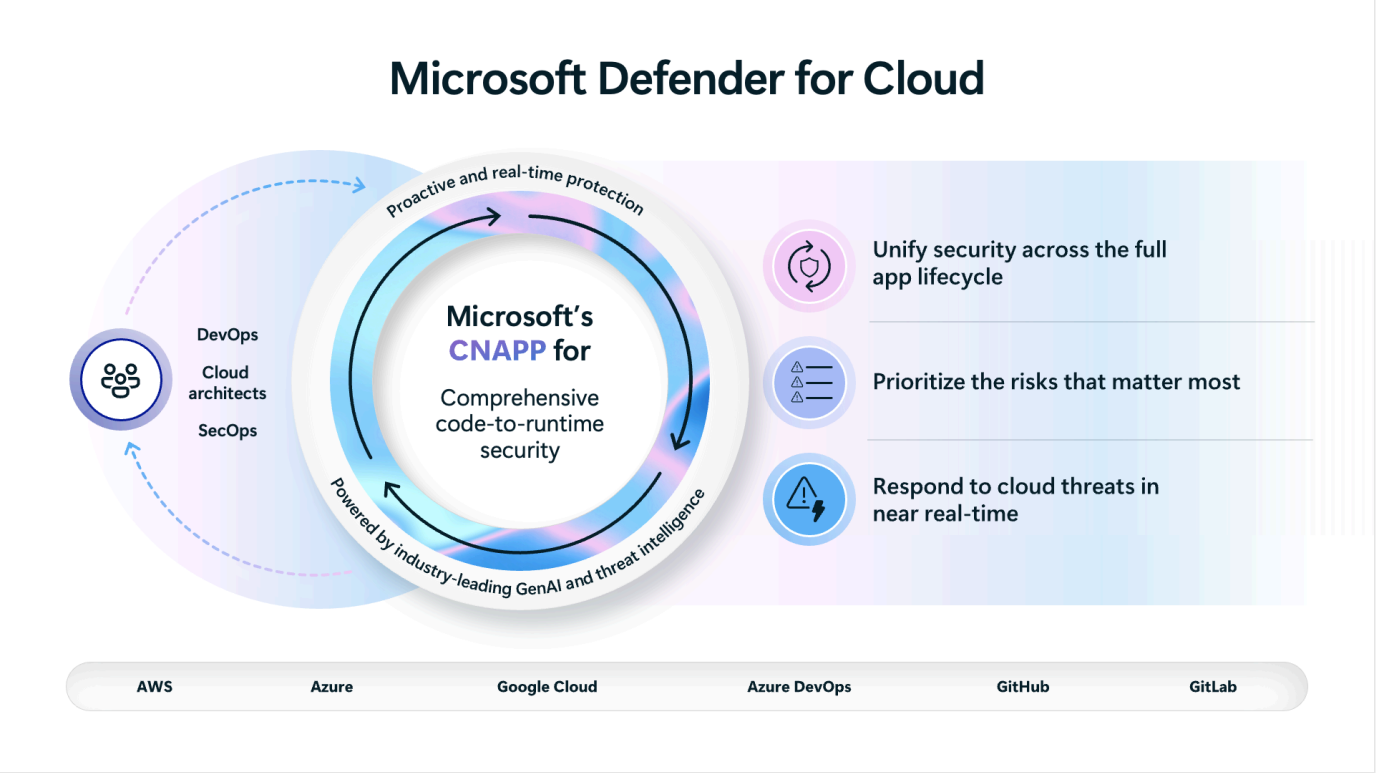
Microsoft Defender for Cloud is a Cloud Native Application Protection Platform (CNAPP), which is a unified solution that combines multiple cloud security tools to protect applications across their entire lifecycle. The solution provides a comprehensive view of your security posture across your cloud and on-premises resources. It also helps you secure multicloud and hybrid environments and integrates security into DevOps workflows. It has three core components:

- Cloud Security Posture Management (CSPM) checks and improves the security posture of cloud resources.
- Development Security Operations (DevSecOps) manages code-level security across multicloud and multi-pipeline environments.

- Cloud Workload Protection Platform (CWPP) defends workloads such as virtual machines (VMs), containers, storage, databases, and serverless functions from threats.

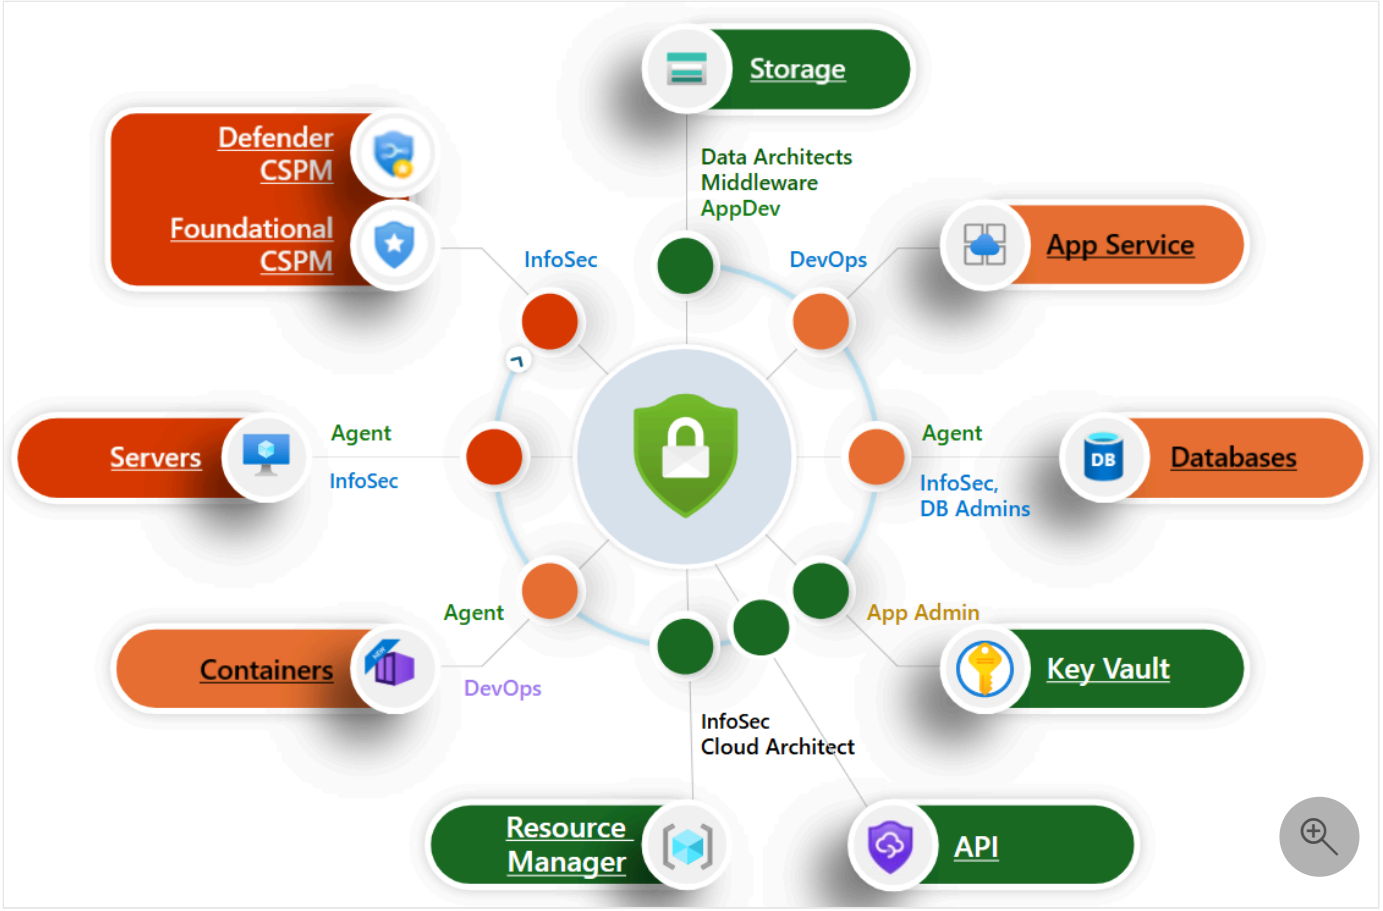
Defender for Cloud uses its broader Cloud Native Application Protection Platform (CNAPP) capabilities to unify protections into one experience. Defender for Cloud embeds security early in the development lifecycle. It helps DevOps teams find misconfigurations, apply policies, and fix risks early. Defender for Cloud integrates with the Defender XDR portal and the Microsoft Security ecosystem, offering unified posture management and SOC experiences.

In addition to its core CNAPP capabilities, Defender for Cloud delivers AI security and AI threat protection to safeguard generative AI workloads throughout their lifecycle. These features help you discover AI applications, identify vulnerabilities, reduce risks, and detect threats targeting your generative AI workloads.



> ⓘ Note
>
> For pricing information, check out the Defender for Cloud pricing page. You can also estimate costs with the Defender for Cloud cost calculator.

Cloud Native Application Protection Platform (CNAPP)



After you enable the Defender for Cloud solution on your Azure subscription, the system collects security data from your multicloud and DevOps environments. Defender for Cloud uses the data to provide insights, recommendations, and actions that help you protect your cloud workloads and resources. You can increase your cloud workloads protection and coverage by enabling additional plans that are listed in the following section.

Defender for Cloud's available plans and their CNAPP benefits include:

Expand table

Defender for Cloud plan	CNAPP benefits	Relevant links
Defender CSPM / Foundational CSPM	Provides advanced security posture capabilities including agentless vulnerability scanning, data-aware security posture, the cloud security graph, and advanced threat hunting.	Check out the differences between the CSPM plans. Enable the Defender CSPM plan.

Cloud security posture management (CSPM)

The security of your cloud and on-premises resources depends on proper configuration and deployment. Defender for Cloud recommendations help you secure your environment.

Defender for Cloud includes free Foundational CSPM capabilities. Enable advanced CSPM capabilities by using the Defender CSPM plan.

> **Note**
>
> Defender CSPM provides broad recommendation coverage in Defender for Cloud. Some recommendations are plan-specific and require you to enable specific CWPP plans to access them.

Expand table

Capability	What problem does it solve?	Get started	Defender plan
Centralized policy management	Define the security conditions that you want to maintain across your environment. The policy translates to recommendations that identify resource configurations that violate your security policy. The Microsoft cloud security benchmark is a built-in standard that applies security principles with detailed technical implementation guidance for Azure and other cloud providers (such as Amazon Web Services (AWS) and Google Cloud Platform (GCP).	Customize a security policy	Foundational CSPM (Free)
Secure score	Summarize your security posture based on the security recommendations. As you remediate recommendations, your secure score improves.	Track your secure score	Foundational CSPM (Free)
Multicloud coverage	Connect to your multicloud environments by using agentless methods for CSPM insight and CWPP protection.	Connect your Amazon AWS and Google GCP cloud resources to Defender for Cloud	Foundational CSPM (Free)
Cloud Security Posture Management (CSPM)	Use the dashboard to see weaknesses in your security posture.	Enable CSPM tools	Foundational CSPM (Free)
Advanced Cloud Security Posture Management	Get advanced tools to identify weaknesses in your security posture, including: - Governance to drive actions to improve your security posture - Regulatory compliance to verify compliance with security standards - Cloud security explorer to build a comprehensive view of your environment	Enable CSPM tools	Defender CSPM
Data Security Posture Management	Data security posture management automatically discovers datastores containing sensitive data, and helps reduce risk of data breaches.	Enable data security posture management	Defender CSPM or Defender for Storage
Attack path analysis	Model traffic on your network to identify potential risks before you implement changes to your environment.	Build queries to analyze paths	Defender CSPM
Cloud Security Explorer	A map of your cloud environment that lets you build queries to find security risks.	Build queries to find security risks	Defender CSPM

Capability	What problem does it solve?	Get started	Defender plan
Security governance	Drive security improvements through your organization by assigning tasks to resource owners and tracking progress in aligning your security state with your security policy.	Define governance rules	Defender CSPM
AI SPM	Provides a comprehensive view of your organization's AI Bill of Materials (AI BOM) which assesses the security posture of the scanned AI workloads.	Discover generative AI workloads	Defender CSPM

Development security operations (DevSecOps)

Defender for Cloud adds security to the start of development. It helps you secure code pipelines and environments, and monitor your security posture from one place. Defender for Cloud enables security teams to manage DevOps security across multi-pipeline environments.

Applications require security awareness at the code, infrastructure, and runtime levels to ensure that deployed applications are hardened against attacks.

Expand table

Capability	What problem does it solve?	Get started	Defender plan
Code pipeline insights	Empowers security teams with the ability to protect applications and resources from code to cloud across multi-pipeline environments, including GitHub, Azure DevOps, and GitLab. DevOps security findings, such as Infrastructure as Code (IaC) misconfigurations and exposed secrets, can then be correlated with other contextual cloud security insights to prioritize remediation in code.	Connect Azure DevOps, GitHub, and GitLab repositories to Defender for Cloud	Foundational CSPM (Free) and Defender CSPM

Cloud workload protection platform (CWPP)

Proactive security principles require implementing security practices to protect your workloads from threats. Cloud workload protection platforms (CWPP) provide workload-specific recommendations to guide you to the right security controls to protect your workloads.

When your environment is threatened, security alerts immediately indicate the nature and severity of the threat so you can plan your response. After identifying a threat in your environment, respond quickly to limit the risk to your resources.

Expand table

Capability	What problem does it solve?	Get started	Defender plan
Protect cloud servers	Provide server protections through Microsoft Defender for Endpoint or extended protection with just-in-time network access, file integrity monitoring, vulnerability assessment, and more.	Secure your multicloud and on-premises servers	Defender for Servers
Identify threats to your storage resources	Detect unusual and potentially harmful attempts to access or exploit your storage accounts by using advanced threat detection capabilities and Microsoft Threat Intelligence data to provide contextual security alerts.	Protect your cloud storage resources	Defender for Storage
Protect cloud databases	Protect your entire database estate with attack detection and threat response for the most popular database types in Azure to protect the database engines and data types, according to their attack surface and security risks.	Deploy specialized protections for cloud and on-premises databases	- Defender for Azure SQL Databases - Defender for SQL servers on machines - Defender for Open-source relational databases - Defender for Azure Cosmos DB
Protect containers	Secure your containers so you can improve, monitor, and maintain the security of your clusters, containers, and their applications with environment hardening, vulnerability assessments, and run-time protection.	Find security risks in your containers	Defender for Containers
Infrastructure service insights	Diagnose weaknesses in your application infrastructure that can leave your environment susceptible to attack.	- Identify attacks targeting applications running over App Service - Detect attempts to exploit Key Vault accounts - Get alerted on suspicious Resource Manager operations - Expose anomalous Domain	- Defender for App Service - Defender for Key Vault - Defender for Resource Manager - Defender for DNS

Capability	What problem does it solve?	Get started	Defender plan
		Name System (DNS) activities	
Security alerts	Get informed of real-time events that threaten the security of your environment. Alerts are categorized and assigned severity levels to indicate proper responses.	Manage security alerts	Any workload protection Defender plan
Security incidents	Identify attack patterns by correlating alerts. Integrate with Security Information and Event Management (SIEM), Security Orchestration, Automation, and Response (SOAR), and traditional IT deployment solutions that respond to threats and reduce risk.	Export alerts to SIEM, SOAR, or ITSM systems	Any workload protection Defender plan

Important

- As of August 1, 2023, customers with an existing subscription to Defender for DNS can continue to use the service as a standalone plan.
- For new subscriptions, alerts about suspicious DNS activity are included as part of Defender for Servers Plan 2 (P2).
- There's no change to the protection scope: Defender for DNS continues to protect all Azure resources connected to Azure's default DNS resolvers. The change affects how DNS protection is billed and bundled, not what resources are covered.

AI security and threat protection

Microsoft Defender for Cloud provides AI security posture management and AI threat protection to help you secure your generative AI workloads across their entire lifecycle.

Expand table

Type of AI security	Description	Relevant links
AI security posture management (SPM)	Helps you discover generative AI applications, identify vulnerabilities, and reduce risks by using built-in recommendations and attack path analysis.	Learn more about AI security posture management
AI threat protection	Uses advanced threat detection techniques to identify and respond to threats targeting your generative AI workloads.	AI threat protection

Defender for Cloud also includes a Data and AI security dashboard. This dashboard gives you a central place to monitor and manage your data and AI resources, track risks, and check protection status.

Azure security baseline for Virtual Machines - Linux Virtual Machines

> **Important**
>
> This security baseline is based on a previous version of Microsoft Cloud Security Benchmark (v1.0) and may contain outdated guidance. For the latest security guidance, see the Virtual Machines - Linux Virtual Machines documentation.

This security baseline applies guidance from the Microsoft cloud security benchmark version 1.0 to Virtual Machines - Linux Virtual Machines. The Microsoft cloud security benchmark provides recommendations on how you can secure your cloud solutions on Azure. The content is grouped by the security controls defined by the Microsoft cloud security benchmark and the related guidance applicable to Virtual Machines - Linux Virtual Machines.

You can monitor this security baseline and its recommendations using Microsoft Defender for Cloud. Azure Policy definitions will be listed in the Regulatory Compliance section of the Microsoft Defender for Cloud portal page.

When a feature has relevant Azure Policy Definitions, they are listed in this baseline to help you measure compliance with the Microsoft cloud security benchmark controls and recommendations. Some recommendations may require a paid Microsoft Defender plan to enable certain security scenarios.

> **Note**
>
> **Features** not applicable to Virtual Machines - Linux Virtual Machines have been excluded. To see how Virtual Machines - Linux Virtual Machines completely maps to the Microsoft cloud security benchmark, see the full Virtual Machines - Linux Virtual Machines security baseline mapping file.

Security profile

The security profile summarizes high-impact behaviors of Virtual Machines - Linux Virtual Machines, which may result in increased security considerations.

Expand table

Service Behavior Attribute	Value
Product Category	Compute
Customer can access HOST / OS	Full Access
Service can be deployed into customer's virtual network	True
Stores customer content at rest	True

Network security

For more information, see the Microsoft cloud security benchmark: Network security.

NS-1: Establish network segmentation boundaries

Features

Virtual Network Integration

Description: Service supports deployment into customer's private Virtual Network (VNet). Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

Reference: Virtual networks and virtual machines in Azure

Network Security Group Support

Description: Service network traffic respects Network Security Groups rule assignment on its subnets. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use network security groups (NSG) to restrict or monitor traffic by port, protocol, source IP address, or destination IP address. Create NSG rules to restrict your service's open ports (such as preventing management ports from being accessed from untrusted networks). Be aware that by default, NSGs deny all inbound traffic but allow traffic from virtual network and Azure Load Balancers.

When you create an Azure virtual machine (VM), you must create a virtual network or use an existing virtual network and configure the VM with a subnet. Ensure that all deployed subnets have a Network Security Group applied with network access controls specific to your applications trusted ports and sources.

Reference: Network security groups

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.ClassicCompute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
All network ports should be restricted on network security groups associated to your virtual machine	Azure Security Center has identified some of your network security groups' inbound rules to be too permissive. Inbound rules should not allow access from 'Any' or 'Internet' ranges. This can potentially enable attackers to target your resources.	AuditIfNotExists, Disabled	3.0.0

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Adaptive network hardening recommendations should be applied on internet facing virtual machines	Azure Security Center analyzes the traffic patterns of Internet facing virtual machines and provides Network Security Group rule recommendations that reduce the potential attack surface	AuditIfNotExists, Disabled	3.0.0

NS-2: Secure cloud services with network controls

Features

Disable Public Network Access

Description: Service supports disabling public network access either through using service-level IP ACL filtering rule (not NSG or Azure Firewall) or using a 'Disable Public Network Access' toggle switch. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Services such as iptables or firewalld may be installed in the Linux OS and provide network filtering to disable public access.

Identity management

For more information, see the Microsoft cloud security benchmark: Identity management.

IM-1: Use centralized identity and authentication system

Features

Azure AD Authentication Required for Data Plane Access

Description: Service supports using Azure AD authentication for data plane access. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use Azure Active Directory (Azure AD) as the default authentication method to control your data plane access.

Reference: Log in to a Linux virtual machine in Azure by using Azure AD and OpenSSH

Local Authentication Methods for Data Plane Access

Description: Local authentications methods supported for data plane access, such as a local username and password. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Feature notes: A local administrator account is created by default during the initial deployment of the virtual machine. Avoid the usage of local authentication methods or accounts, these should be disabled wherever possible. Instead use Azure AD to authenticate where possible.

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

IM-3: Manage application identities securely and automatically

Features

Managed Identities

Description: Data plane actions support authentication using managed identities. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Managed identity is traditionally leveraged by Linux VM to authenticate to other services. If the Linux VM supports Azure AD authentication then managed identity may be supported.

Configuration Guidance: Use Azure managed identities instead of service principals when possible, which can authenticate to Azure services and resources that support Azure Active Directory (Azure AD) authentication. Managed identity credentials are fully managed, rotated, and protected by the platform, avoiding hard-coded credentials in source code or configuration files.

Service Principals

Description: Data plane supports authentication using service principals. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Service principals may be used by applications running in the Linux VM.

Configuration Guidance: There is no current Microsoft guidance for this feature configuration. Please review and determine if your organization wants to configure this security feature.

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Virtual machines' Guest Configuration extension should be deployed with system-assigned managed identity	The Guest Configuration extension requires a system assigned managed identity. Azure virtual machines in the scope of this policy will be non-compliant when they have the Guest Configuration extension installed but do not have a system assigned managed identity. Learn more at https://aka.ms/gcpol	AuditIfNotExists, Disabled	1.0.1

IM-7: Restrict resource access based on conditions

Features

Conditional Access for Data Plane

Description: Data plane access can be controlled using Azure AD Conditional Access Policies. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Use Azure AD as a core authentication platform and a certificate authority to SSH into a Linux VM by using Azure AD and OpenSSH certificate-based authentication. This functionality allows organizations to manage access to VMs with Azure role-based access control (RBAC) and Conditional Access policies.

Configuration Guidance: Define the applicable conditions and criteria for Azure Active Directory (Azure AD) conditional access in the workload. Consider common use cases such as blocking or granting access from specific locations, blocking risky sign-in behavior, or requiring organization-managed devices for specific applications.

Reference: Log in to a Linux virtual machine in Azure by using Azure AD and OpenSSH

IM-8: Restrict the exposure of credential and secrets

Features

Service Credential and Secrets Support Integration and Storage in Azure Key Vault

Description: Data plane supports native use of Azure Key Vault for credential and secrets store. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Within the data plane or operating system, services may call Azure Key Vault for credentials or secrets.

Configuration Guidance: Ensure that secrets and credentials are stored in secure locations such as Azure Key Vault, instead of embedding them into code or configuration files.

Privileged access

For more information, see the Microsoft cloud security benchmark: Privileged access.

PA-1: Separate and limit highly privileged/administrative users

Features

Local Admin Accounts

Description: Service has the concept of a local administrative account. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Feature notes: Avoid the usage of local authentication methods or accounts, these should be disabled wherever possible. Instead use Azure AD to authenticate where possible.

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

Reference: Quickstart: Create a Linux virtual machine in the Azure portal

PA-7: Follow just enough administration (least privilege) principle

Features

Azure RBAC for Data Plane

Description: Azure Role-Based Access Control (Azure RBAC) can be used to managed access to service's data plane actions. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Use Azure AD as a core authentication platform and a certificate authority to SSH into a Linux VM by using Azure AD and OpenSSH certificate-based authentication. This

functionality allows organizations to manage access to VMs with Azure role-based access control (RBAC) and Conditional Access policies.

Configuration Guidance: With RBAC, specify who can log in to a VM as a regular user or with administrator privileges. When users join your team, you can update the Azure RBAC policy for the VM to grant access as appropriate. When employees leave your organization and their user accounts are disabled or removed from Azure AD, they no longer have access to your resources.

Reference: Log in to a Linux virtual machine in Azure by using Azure AD and OpenSSH

PA-8: Determine access process for cloud provider support

Features

Customer Lockbox

Description: Customer Lockbox can be used for Microsoft support access. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: In support scenarios where Microsoft needs to access your data, use Customer Lockbox to review, then approve or reject each of Microsoft's data access requests.

Data protection

For more information, see the Microsoft cloud security benchmark: Data protection.

DP-1: Discover, classify, and label sensitive data

Features

Sensitive Data Discovery and Classification

Description: Tools (such as Azure Purview or Azure Information Protection) can be used for data discovery and classification in the service. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
False	Not Applicable	Not Applicable

Configuration Guidance: This feature is not supported to secure this service.

DP-2: Monitor anomalies and threats targeting sensitive data

Features

Data Leakage/Loss Prevention

Description: Service supports DLP solution to monitor sensitive data movement (in customer's content). Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
False	Not Applicable	Not Applicable

Configuration Guidance: This feature is not supported to secure this service.

DP-3: Encrypt sensitive data in transit

Features

Data in Transit Encryption

Description: Service supports data in-transit encryption for data plane. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Certain communication protocols such as SSH are encrypted by default. However, other services such as HTTP must be configured to use TLS for encryption.

Configuration Guidance: Enable secure transfer in services where there is a native data in transit encryption feature built in. Enforce HTTPS on any web applications and services and ensure TLS v1.2 or later is used. Legacy versions such as SSL 3.0, TLS v1.0 should be disabled. For remote management of Virtual Machines, use SSH (for Linux) or RDP/TLS (for Windows) instead of an unencrypted protocol.

Reference: In-transit encryption in VMs

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Windows machines should be configured to use secure communication protocols	To protect the privacy of information communicated over the Internet, your machines should use the latest version of the industry-standard cryptographic protocol, Transport Layer Security (TLS). TLS secures communications over a network by encrypting a connection between machines.	AuditIfNotExists, Disabled	4.1.1

DP-4: Enable data at rest encryption by default

Features

Data at Rest Encryption Using Platform Keys

Description: Data at-rest encryption using platform keys is supported, any customer content at rest is encrypted with these Microsoft managed keys. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Feature notes: By default, managed disks use platform-managed encryption keys. All managed disks, snapshots, images, and data written to existing managed disks are automatically encrypted-at-rest with platform-managed keys.

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

Reference: Server-side encryption of Azure Disk Storage - Platform-managed keys

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.ClassicCompute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Virtual machines should encrypt temp disks, caches, and data flows between Compute and Storage resources	By default, a virtual machine's OS and data disks are encrypted-at-rest using platform-managed keys. Temp disks, data caches and data flowing between compute and storage aren't encrypted. Disregard this recommendation if: 1. using encryption-at-host, or 2. server-side encryption on Managed Disks meets your security requirements. Learn more in: Server-side encryption of Azure Disk Storage: https://aka.ms/disksse, Different disk encryption offerings: https://aka.ms/diskencryptioncomparison	AuditIfNotExists, Disabled	2.0.3

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: Linux virtual machines should enable Azure Disk Encryption or EncryptionAtHost.	By default, a virtual machine's OS and data disks are encrypted-at-rest using platform-managed keys; temp disks and data caches aren't encrypted, and data isn't encrypted when flowing between compute and storage resources. Use Azure Disk Encryption or EncryptionAtHost to encrypt all this data.Visit https://aka.ms/diskencryptioncomparison to compare encryption offerings. This policy requires two prerequisites to be deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	1.2.0-preview

DP-5: Use customer-managed key option in data at rest encryption when required

Features

Data at Rest Encryption Using CMK

Description: Data at-rest encryption using customer-managed keys is supported for customer content stored by the service. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: You can choose to manage encryption at the level of each managed disk, with your own keys. When you specify a customer-managed key, that key is used to protect and control access to the key that encrypts your data. Customer-managed keys offer greater flexibility to manage access controls.

Configuration Guidance: If required for regulatory compliance, define the use case and service scope where encryption using customer-managed keys are needed. Enable and implement data at rest encryption using customer-managed key for those services.

Virtual disks on Virtual Machines (VM) are encrypted at rest using either Server-side encryption or Azure disk encryption (ADE). Azure Disk Encryption leverages the DM-Crypt feature of Linux to encrypt managed disks with customer-managed keys within the guest VM. Server-side encryption with customer-managed keys improves on ADE by enabling you to use any OS types and images for your VMs by encrypting data in the Storage service.

Reference: Server-side encryption of Azure Disk Storage - Customer-managed keys

DP-6: Use a secure key management process

Features

Key Management in Azure Key Vault

Description: The service supports Azure Key Vault integration for any customer keys, secrets, or certificates. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use Azure Key Vault to create and control the life cycle of your encryption keys, including key generation, distribution, and storage. Rotate and revoke your keys in Azure Key Vault and your service based on a defined schedule or when there is a key retirement or compromise. When there is a need to use customer-managed key (CMK) in the workload, service, or application level, ensure you follow the best practices for key management: Use a key hierarchy to generate a separate data encryption key (DEK) with your key encryption key (KEK) in your key vault. Ensure keys are registered with Azure Key Vault and referenced via key IDs from the service or application. If you need to bring your own key (BYOK) to the service (such as importing HSM-protected keys from your on-premises HSMs into Azure Key Vault), follow recommended guidelines to perform initial key generation and key transfer.

Reference: Creating and configuring a key vault for Azure Disk Encryption

DP-7: Use a secure certificate management process

Features

Certificate Management in Azure Key Vault

Description: The service supports Azure Key Vault integration for any customer certificates. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
False	Not Applicable	Not Applicable

Configuration Guidance: This feature is not supported to secure this service.

Asset management

For more information, see the Microsoft cloud security benchmark: Asset management.

AM-2: Use only approved services

Features

Azure Policy Support

Description: Service configurations can be monitored and enforced via Azure Policy. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Azure Policy can be used to define the desired behavior for your organization's Windows VMs and Linux VMs. By using policies, an organization can enforce various conventions and rules throughout the enterprise and define and implement standard security configurations for Azure Virtual Machines. Enforcement of the desired behavior can help mitigate risk while contributing to the success of the organization.

Posture and vulnerability management

For more information, see the Microsoft cloud security benchmark: Posture and vulnerability management.

PV-3: Define and establish secure configurations for compute resources

Features

Azure Automation State Configuration

Description: Azure Automation State Configuration can be used to maintain the security configuration of the operating system. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use Azure Automation State Configuration to maintain the security configuration of the operating system.

Reference: Configure a VM with Desired State Configuration

Azure Policy Guest Configuration Agent

Description: Azure Policy guest configuration agent can be installed or deployed as an extension to compute resources. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Azure Policy Guest Configuration is now called Azure Automanage Machine Configuration.

Configuration Guidance: Use Microsoft Defender for Cloud and Azure Policy guest configuration agent to regularly assess and remediate configuration deviations on your Azure compute resources, including VMs, containers, and others.

Reference: Understand the machine configuration feature of Azure Automanage

Custom VM Images

Description: Service supports using user-supplied VM images or pre-built images from the marketplace with certain baseline configurations pre-applied. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use a pre-configured hardened image from a trusted supplier such as Microsoft or build a desired secure configuration baseline into the VM image template.

Reference: Tutorial: Create a custom image of an Azure VM with the Azure CLI

PV-4: Audit and enforce secure configurations for compute resources

Features

Trusted Launch Virtual Machine

Description: Trusted Launch protects against advanced and persistent attack techniques by combining infrastructure technologies like secure boot, vTPM, and integrity monitoring. Each technology provides another layer of defense against sophisticated threats. Trusted launch allows the secure deployment of virtual machines with verified boot loaders, OS kernels, and drivers, and securely protects keys, certificates, and secrets in the virtual machines. Trusted launch also provides insights and confidents of the entire boot chain's integrity and ensures workloads are trusted and verifiable. Trusted launch is integrated with Microsoft Defender for Cloud to ensure VMs are properly configured, by remotely attesting VM is booted in a healthy way. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature note: Trusted launch is available for generation 2 VMs. Trusted launch requires the creation of new virtual machines. You can't enable trusted launch on existing virtual machines that were initially created without it.

Configuration Guidance: Trusted launch may be enabled during the deployment of the VM. Enable all three - Secure Boot, vTPM, and integrity boot monitoring to ensure the best security posture for the virtual machine. Please note that there are a few prerequisites including onboarding your subscription to Microsoft Defender for Cloud, assigning certain Azure Policy initiatives, and configuring firewall policies.

Reference: Deploy a VM with trusted launch enabled

PV-5: Perform vulnerability assessments

Features

Vulnerability Assessment using Microsoft Defender

Description: Service can be scanned for vulnerability scan using Microsoft Defender for Cloud or other Microsoft Defender services embedded vulnerability assessment capability (including Microsoft Defender for server, container registry, App Service, SQL, and DNS). Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Follow recommendations from Microsoft Defender for Cloud for performing vulnerability assessments on your Azure virtual machines.

Backup and recovery

For more information, see the Microsoft cloud security benchmark: Backup and recovery.

BR-1: Ensure regular automated backups

Features

Azure Backup

Description: The service can be backed up by the Azure Backup service. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Enable Azure Backup and target Azure Virtual Machines (VM), as well as the desired frequency and retention periods. This includes complete system state backup. If you are using Azure disk encryption, Azure VM backup automatically handles the backup of customer-managed keys. For Azure Virtual Machines, you can use Azure Policy to enable automatic backups.

Reference: Backup and restore options for virtual machines in Azure

Azure security baseline for Virtual Machines - Windows Virtual Machines

> **Important**
>
> This security baseline is based on a previous version of Microsoft Cloud Security Benchmark (v1.0) and may contain outdated guidance. For the latest security guidance, see the Virtual Machines - Windows Virtual Machines documentation.

This security baseline applies guidance from the Microsoft cloud security benchmark version 1.0 to Virtual Machines - Windows Virtual Machines. The Microsoft cloud security benchmark provides recommendations on how you can secure your cloud solutions on Azure. The content is grouped by the security controls defined by the Microsoft cloud security benchmark and the related guidance applicable to Virtual Machines - Windows Virtual Machines.

You can monitor this security baseline and its recommendations using Microsoft Defender for Cloud. Azure Policy definitions will be listed in the Regulatory Compliance section of the Microsoft Defender for Cloud portal page.

When a feature has relevant Azure Policy Definitions, they are listed in this baseline to help you measure compliance with the Microsoft cloud security benchmark controls and recommendations. Some recommendations may require a paid Microsoft Defender plan to enable certain security scenarios.

> **Note**
>
> **Features** not applicable to Virtual Machines - Windows Virtual Machines have been excluded. To see how Virtual Machines - Windows Virtual Machines completely maps to the Microsoft cloud security benchmark, see the full Virtual Machines - Windows Virtual Machines security baseline mapping file.

Security profile

The security profile summarizes high-impact behaviors of Virtual Machines - Windows Virtual Machines, which may result in increased security considerations.

Expand table

Service Behavior Attribute	Value
Product Category	Compute
Customer can access HOST / OS	Full Access
Service can be deployed into customer's virtual network	True
Stores customer content at rest	True

Network security

For more information, see the Microsoft cloud security benchmark: Network security.

NS-1: Establish network segmentation boundaries

Features

Virtual Network Integration

Description: Service supports deployment into customer's private Virtual Network (VNet). Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

Reference: Virtual networks and virtual machines in Azure

Network Security Group Support

Description: Service network traffic respects Network Security Groups rule assignment on its subnets. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use network security groups (NSG) to restrict or monitor traffic by port, protocol, source IP address, or destination IP address. Create NSG rules to restrict your service's open ports (such as preventing management ports from being accessed from untrusted networks). Be aware that by default, NSGs deny all inbound traffic but allow traffic from virtual network and Azure Load Balancers.

When you create an Azure virtual machine (VM), you must create a virtual network or use an existing virtual network and configure the VM with a subnet. Ensure that all deployed subnets have a Network Security Group applied with network access controls specific to your applications trusted ports and sources.

Reference: Network security groups

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.ClassicCompute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
All network ports should be restricted on network security groups associated to your virtual machine	Azure Security Center has identified some of your network security groups' inbound rules to be too permissive. Inbound rules should not allow access from 'Any' or 'Internet' ranges. This can potentially enable attackers to target your resources.	AuditIfNotExists, Disabled	3.0.0

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Adaptive network hardening recommendations should be applied on internet facing virtual machines	Azure Security Center analyzes the traffic patterns of Internet facing virtual machines and provides Network Security Group rule recommendations that reduce the potential attack surface	AuditIfNotExists, Disabled	3.0.0

NS-2: Secure cloud services with network controls

Features

Disable Public Network Access

Description: Service supports disabling public network access either through using service-level IP ACL filtering rule (not NSG or Azure Firewall) or using a 'Disable Public Network Access' toggle switch. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use services at the OS-level such as Windows Defender Firewall to provide network filtering to disable public access.

Identity management

For more information, see the Microsoft cloud security benchmark: Identity management.

IM-1: Use centralized identity and authentication system

Features

Azure AD Authentication Required for Data Plane Access

Description: Service supports using Azure AD authentication for data plane access. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use Azure Active Directory (Azure AD) as the default authentication method to control your data plane access.

Reference: Log in to a Windows virtual machine in Azure by using Azure AD including passwordless

Local Authentication Methods for Data Plane Access

Description: Local authentications methods supported for data plane access, such as a local username and password. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Feature notes: A local administrator account is created by default during the initial deployment of the virtual machine. Avoid the usage of local authentication methods or accounts, these should be disabled wherever possible. Instead use Azure AD to authenticate where possible.

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

IM-3: Manage application identities securely and automatically

Features

Managed Identities

Description: Data plane actions support authentication using managed identities. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Managed identity is typically leveraged by Windows VM to authenticate to other services. If the Windows VM supports Azure AD authentication then managed identity may be supported.

Configuration Guidance: Use Azure managed identities instead of service principals when possible, which can authenticate to Azure services and resources that support Azure Active

Directory (Azure AD) authentication. Managed identity credentials are fully managed, rotated, and protected by the platform, avoiding hard-coded credentials in source code or configuration files.

Service Principals

Description: Data plane supports authentication using service principals. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Service principals may be used by applications running in the Windows VM.

Configuration Guidance: There is no current Microsoft guidance for this feature configuration. Please review and determine if your organization wants to configure this security feature.

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Virtual machines' Guest Configuration extension should be deployed with system-assigned managed identity	The Guest Configuration extension requires a system assigned managed identity. Azure virtual machines in the scope of this policy will be non-compliant when they have the Guest Configuration extension installed but do not have a system assigned managed identity. Learn more at https://aka.ms/gcpol	AuditIfNotExists, Disabled	1.0.1

IM-7: Restrict resource access based on conditions

Features

Conditional Access for Data Plane

Description: Data plane access can be controlled using Azure AD Conditional Access Policies. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Use Azure AD as a core authentication platform to RDP into Windows Server 2019 Datacenter edition and later, or Windows 10 1809 and later. You can then centrally control and enforce Azure role-based access control (RBAC) and Conditional Access policies that allow or deny access to the VMs.

Configuration Guidance: Define the applicable conditions and criteria for Azure Active Directory (Azure AD) conditional access in the workload. Consider common use cases such as blocking or granting access from specific locations, blocking risky sign-in behavior, or requiring organization-managed devices for specific applications.

Reference: Log in to a Windows virtual machine in Azure by using Azure AD including passwordless

IM-8: Restrict the exposure of credential and secrets

Features

Service Credential and Secrets Support Integration and Storage in Azure Key Vault

Description: Data plane supports native use of Azure Key Vault for credential and secrets store. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Within the data plane or operating system, services may call Azure Key Vault for credentials or secrets.

Configuration Guidance: Ensure that secrets and credentials are stored in secure locations such as Azure Key Vault, instead of embedding them into code or configuration files.

Privileged access

For more information, see the Microsoft cloud security benchmark: Privileged access.

PA-1: Separate and limit highly privileged/administrative users

Features

Local Admin Accounts

Description: Service has the concept of a local administrative account. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Feature notes: Avoid the usage of local authentication methods or accounts, these should be disabled wherever possible. Instead use Azure AD to authenticate where possible.

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

Reference: Quickstart: Create a Windows virtual machine in the Azure portal

PA-7: Follow just enough administration (least privilege) principle

Features

Azure RBAC for Data Plane

Description: Azure Role-Based Access Control (Azure RBAC) can be used to managed access to service's data plane actions. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Use Azure AD as a core authentication platform to RDP into Windows Server 2019 Datacenter edition and later, or Windows 10 1809 and later. You can then centrally control and enforce Azure role-based access control (RBAC) and Conditional Access policies that allow or deny access to the VMs.

Configuration Guidance: With RBAC, specify who can log in to a VM as a regular user or with administrator privileges. When users join your team, you can update the Azure RBAC policy for the VM to grant access as appropriate. When employees leave your organization and their user accounts are disabled or removed from Azure AD, they no longer have access to your resources.

Reference: Log in to a Windows virtual machine in Azure by using Azure AD including passwordless

PA-8: Determine access process for cloud provider support

Features

Customer Lockbox

Description: Customer Lockbox can be used for Microsoft support access. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: In support scenarios where Microsoft needs to access your data, use Customer Lockbox to review, then approve or reject each of Microsoft's data access requests.

Data protection

For more information, see the Microsoft cloud security benchmark: Data protection.

DP-1: Discover, classify, and label sensitive data

Features

Sensitive Data Discovery and Classification

Description: Tools (such as Azure Purview or Azure Information Protection) can be used for data discovery and classification in the service. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
False	Not Applicable	Not Applicable

Configuration Guidance: This feature is not supported to secure this service.

DP-2: Monitor anomalies and threats targeting sensitive data

Features

Data Leakage/Loss Prevention

Description: Service supports DLP solution to monitor sensitive data movement (in customer's content). Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
False	Not Applicable	Not Applicable

Configuration Guidance: This feature is not supported to secure this service.

DP-3: Encrypt sensitive data in transit

Features

Data in Transit Encryption

Description: Service supports data in-transit encryption for data plane. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Certain communication protocols such as SSH are encrypted by default. However, other services such as HTTP must be configured to use TLS for encryption.

Configuration Guidance: Enable secure transfer in services where there is a native data in transit encryption feature built in. Enforce HTTPS on any web applications and services and ensure TLS v1.2 or later is used. Legacy versions such as SSL 3.0, TLS v1.0 should be disabled. For remote management of Virtual Machines, use SSH (for Linux) or RDP/TLS (for Windows) instead of an unencrypted protocol.

Reference: In-transit encryption in VMs

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Windows machines should be configured to use secure communication protocols	To protect the privacy of information communicated over the Internet, your machines should use the latest version of the industry-standard cryptographic protocol, Transport Layer Security (TLS). TLS secures communications over a network by encrypting a connection between machines.	AuditIfNotExists, Disabled	4.1.1

DP-4: Enable data at rest encryption by default

Features

Data at Rest Encryption Using Platform Keys

Description: Data at-rest encryption using platform keys is supported, any customer content at rest is encrypted with these Microsoft managed keys. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	True	Microsoft

Feature notes: By default, managed disks use platform-managed encryption keys. All managed disks, snapshots, images, and data written to existing managed disks are automatically encrypted-at-rest with platform-managed keys.

Configuration Guidance: No additional configurations are required as this is enabled on a default deployment.

Reference: Server-side encryption of Azure Disk Storage - Platform-managed Keys

Microsoft Defender for Cloud monitoring

Azure Policy built-in definitions - Microsoft.ClassicCompute:

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Virtual machines should encrypt temp disks, caches, and data flows between Compute and Storage resources	By default, a virtual machine's OS and data disks are encrypted-at-rest using platform-managed keys. Temp disks, data caches and data flowing between compute and storage aren't encrypted. Disregard this recommendation if: 1. using encryption-at-host, or 2. server-side encryption on Managed Disks meets your security requirements. Learn more in: Server-side encryption of Azure Disk Storage: https://aka.ms/disksse, Different disk encryption offerings: https://aka.ms/diskencryptioncomparison	AuditIfNotExists, Disabled	2.0.3

Azure Policy built-in definitions - Microsoft.Compute:

Expand table

[Preview]: Linux virtual machines should enable Azure Disk Encryption or EncryptionAtHost.	By default, a virtual machine's OS and data disks are encrypted-at-rest using platform-managed keys; temp disks and data caches aren't encrypted, and data isn't encrypted when flowing between compute and storage resources. Use Azure Disk Encryption or EncryptionAtHost to encrypt all this data.Visit https://aka.ms/diskencryptioncomparison to compare encryption offerings. This policy requires two prerequisites to be deployed to the policy	AuditIfNotExists, Disabled	1.2.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
	assignment scope. For details, visit https://aka.ms/gcpol .		

DP-5: Use customer-managed key option in data at rest encryption when required

Features

Data at Rest Encryption Using CMK

Description: Data at-rest encryption using customer-managed keys is supported for customer content stored by the service. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: You can choose to manage encryption at the level of each managed disk, with your own keys. When you specify a customer-managed key, that key is used to protect and control access to the key that encrypts your data. Customer-managed keys offer greater flexibility to manage access controls.

Configuration Guidance: If required for regulatory compliance, define the use case and service scope where encryption using customer-managed keys are needed. Enable and implement data at rest encryption using customer-managed key for those services.

Virtual disks on Virtual Machines (VM) are encrypted at rest using either Server-side encryption or Azure disk encryption (ADE). Azure Disk Encryption leverages the BitLocker feature of Windows to encrypt managed disks with customer-managed keys within the guest VM. Server-side encryption with customer-managed keys improves on ADE by enabling you to use any OS types and images for your VMs by encrypting data in the Storage service.

Reference: Server-side encryption of Azure Disk Storage

DP-6: Use a secure key management process

Features

Key Management in Azure Key Vault

Description: The service supports Azure Key Vault integration for any customer keys, secrets, or certificates. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use Azure Key Vault to create and control the life cycle of your encryption keys, including key generation, distribution, and storage. Rotate and revoke your keys in Azure Key Vault and your service based on a defined schedule or when there is a key retirement or compromise. When there is a need to use customer-managed key (CMK) in the workload, service, or application level, ensure you follow the best practices for key management: Use a key hierarchy to generate a separate data encryption key (DEK) with your key encryption key (KEK) in your key vault. Ensure keys are registered with Azure Key Vault and referenced via key IDs from the service or application. If you need to bring your own key (BYOK) to the service (such as importing HSM-protected keys from your on-premises HSMs into Azure Key Vault), follow recommended guidelines to perform initial key generation and key transfer.

Reference: Create and configure a key vault for Azure Disk Encryption on a Windows VM

DP-7: Use a secure certificate management process

Features

Certificate Management in Azure Key Vault

Description: The service supports Azure Key Vault integration for any customer certificates. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
False	Not Applicable	Not Applicable

Configuration Guidance: This feature is not supported to secure this service.

Asset management

For more information, see the Microsoft cloud security benchmark: Asset management.

AM-2: Use only approved services

Features

Azure Policy Support

Description: Service configurations can be monitored and enforced via Azure Policy. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Azure Policy can be used to define the desired behavior for your organization's Windows VMs and Linux VMs. By using policies, an organization can enforce various conventions and rules throughout the enterprise and define and implement standard security configurations for Azure Virtual Machines. Enforcement of the desired behavior can help mitigate risk while contributing to the success of the organization.

Posture and vulnerability management

For more information, see the Microsoft cloud security benchmark: Posture and vulnerability management.

PV-3: Define and establish secure configurations for compute resources

Features

Azure Automation State Configuration

Description: Azure Automation State Configuration can be used to maintain the security configuration of the operating system. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use Azure Automation State Configuration to maintain the security configuration of the operating system.

Reference: Configure a VM with Desired State Configuration

Azure Policy Guest Configuration Agent

Description: Azure Policy guest configuration agent can be installed or deployed as an extension to compute resources. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature notes: Azure Policy Guest Configuration is now called Azure Automanage Machine Configuration.

Configuration Guidance: Use Microsoft Defender for Cloud and Azure Policy guest configuration agent to regularly assess and remediate configuration deviations on your Azure compute resources, including VMs, containers, and others.

Reference: Understand the machine configuration feature of Azure Automanage

Custom VM Images

Description: Service supports using user-supplied VM images or pre-built images from the marketplace with certain baseline configurations pre-applied. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Use a pre-configured hardened image from a trusted supplier such as Microsoft or build a desired secure configuration baseline into the VM image template

Reference: Tutorial: Create Windows VM images with Azure PowerShell

PV-4: Audit and enforce secure configurations for compute resources

Features

Trusted Launch Virtual Machine

Description: Trusted Launch protects against advanced and persistent attack techniques by combining infrastructure technologies like secure boot, vTPM, and integrity monitoring. Each technology provides another layer of defense against sophisticated threats. Trusted launch allows the secure deployment of virtual machines with verified boot loaders, OS kernels, and drivers, and securely protects keys, certificates, and secrets in the virtual machines. Trusted launch also provides insights and confidents of the entire boot chain's integrity and ensures workloads are trusted and verifiable. Trusted launch is integrated with Microsoft Defender for Cloud to ensure VMs are properly configured, by remotely attesting VM is booted in a healthy way. Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Feature note: Trusted launch is available for generation 2 VMs. Trusted launch requires the creation of new virtual machines. You can't enable trusted launch on existing virtual machines that were initially created without it.

Configuration Guidance: Trusted launch may be enabled during the deployment of the VM. Enable all three - Secure Boot, vTPM, and integrity boot monitoring to ensure the best security posture for the virtual machine. Please note that there are a few prerequisites including onboarding your subscription to Microsoft Defender for Cloud, assigning certain Azure Policy initiatives, and configuring firewall policies.

Reference: Deploy a VM with trusted launch enabled

PV-5: Perform vulnerability assessments

Features

Vulnerability Assessment using Microsoft Defender

Description: Service can be scanned for vulnerability scan using Microsoft Defender for Cloud or other Microsoft Defender services embedded vulnerability assessment capability (including Microsoft Defender for server, container registry, App Service, SQL, and DNS). Learn more.

Expand table

Supported	Enabled By Default	Configuration Responsibility
True	False	Customer

Configuration Guidance: Follow recommendations from Microsoft Defender for Cloud for performing vulnerability assessments on your Azure virtual machines.

Trusted Launch for Azure virtual machines

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure offers Trusted Launch as a seamless way to improve the security of Generation 2 virtual machines (VM). Trusted Launch protects against advanced and persistent attack techniques. Trusted Launch is composed of several coordinated infrastructure technologies that can be enabled independently. Each technology provides another layer of defense against sophisticated threats.

Trusted Launch is supported for both x64 and Arm64 architectures.

> **ⓘ Important**
>
> - Trusted Launch is the default state for newly created Azure Gen2 VM and scale sets. See the Trusted Launch FAQs if your new VM requires features that aren't supported with Trusted launch.
> - You can upgrade existing Azure Gen1 VMs to Gen2-Trusted launch to enable Secure Boot and vTPM. See Upgrade existing Gen1 VMs to Gen2-Trusted launch.
> - Existing VMs can have Trusted Launch enabled after being created. For more information, see Enable Trusted Launch on existing Gen2 VMs.
> - Existing virtual machine scale sets can have Trusted Launch enabled after being created. For more information, see Enable Trusted Launch on existing scale set.

Benefits

- Securely deploy VMs with verified boot loaders, operating system (OS) kernels, and drivers.
- Securely protect keys, certificates, and secrets in the VMs.
- Gain insights and confidence of the entire boot chain's integrity.
- Ensure that workloads are trusted and verifiable.

Virtual machines sizes

Expand table

Type	Supported size families	Currently not supported size families	Not supported size families
General purpose	B-family, D-family, Dpsv6-series[1], Dplsv6-series[1]	Dpsv5-series, Dpdsv5-series, Dplsv5-series, Dpldsv5-series	A-family, Dv2-series, Dv3-series, DC-Confidential-family
Compute optimized	F-family, Fx-family	All sizes supported.	
Memory optimized	E-family, Eb-family, Epsv6-series[1]	M-family	EC-Confidential-family
Storage optimized	L-family	All sizes supported.	
GPU	NC-family, ND-family, NV-family	NDasrA100_v4-series, NDm_A100_v4-series	NC-series, NV-series, NP-series
High Performance Compute	HBv2-series[2], HBv3-series, HBv4-series, HBv5-series, HC-series[3], HX-series	All sizes supported.	

[1]Arm64 Cobalt 100-based sizes that support Trusted Launch.

[2]HBv2-series is currently supported for Trusted Launch but is scheduled for retirement on May 31, 2027. For new HPC Trusted Launch deployments, prefer HBv5-series, HX-series, HBv4-series, or HBv3-series sizes.

[3]HC-series sizes (Standard_HC44rs, Standard_HC44-16rs, Standard_HC44-32rs) are scheduled for retirement on May 31, 2027. After this date, remaining HC-series VMs will be deallocated and stop incurring charges, and HC-series will no longer have SLA or support. Sales of 1-year and 3-year Reserved Instances ended April 2, 2026. For new HPC Trusted Launch deployments, consider HBv5-series for higher performance and better price-performance, or HX-series for high-memory HPC workloads. Plan to transition off HC-series well before the retirement date to avoid disruption.

> **Note**
>
> - Installation of the *CUDA & GRID drivers on Secure Boot-enabled Windows VMs* doesn't require any extra steps.
> - Installation of the *CUDA driver on Secure Boot-enabled Ubuntu VMs* requires extra steps. For more information, see Install NVIDIA GPU drivers on N-series VMs

running Linux. Secure Boot should be disabled for installing CUDA drivers on other Linux VMs.

- Installation of the *GRID driver* requires Secure Boot to be disabled for Linux VMs.
- *Not supported* size families don't support Generation 2 VMs. Change the VM size to equivalent *supported size families* for enabling Trusted Launch.

Operating systems supported

Expand table

OS	Version
Alma Linux	8.7, 8.8, 9.0
Azure Linux	1.0, 2.0

Red Hat Enterprise Linux	8.6, 8.8, 8.10, 9.4, 9.5, 9.6
Rocky Linux from CIQ	8.6, 8.10, 9.2, 9.4, 9.6
SUSE Enterprise Linux	15SP3, 15SP4, 15SP5
Ubuntu Server	18.04 LTS, 20.04 LTS, 22.04 LTS, 23.04, 23.10
Windows 10	Pro, Enterprise, Enterprise Multi-Session *
Windows 11	Pro, Enterprise, Enterprise Multi-Session *
Windows Server	2016, 2019, 2022, 2022-Azure-Edition, 2025, 2025-Azure-Edition *

* Variations of this OS are supported.

Note

Trusted Launch on Arm64 is supported when using applicable Arm64 Marketplace images for supported distributions and versions. For Cobalt 100 sizes, deploy Trusted Launch using Arm64 images available in Azure Marketplace.

More information

Regions:

- All public regions
- All Azure Government regions
- All Azure China regions

Pricing: Trusted Launch doesn't increase existing VM pricing costs.

Unsupported features

Currently, the following VM features aren't supported with Trusted Launch:

- Managed Image (customers are encouraged to use Azure Compute Gallery).
- Linux VM Hibernation

Secure Boot

At the root of Trusted Launch is Secure Boot for your VM. Secure Boot, which is implemented in platform firmware, protects against the installation of malware-based rootkits and boot kits. Secure Boot works to ensure that only signed operating systems and drivers can boot. It establishes a "root of trust" for the software stack on your VM.

With Secure Boot enabled, all OS boot components (boot loader, kernel, kernel drivers) require trusted publishers signing. Both Windows and select Linux distributions support Secure Boot. If Secure Boot fails to authenticate that the image is signed with a trusted publisher, the VM fails to boot. For more information, see Secure Boot.

vTPM

Trusted Launch also introduces virtual Trusted Platform Module (vTPM) for Azure VMs. This virtualized version of a hardware Trusted Platform Module is compliant with the TPM2.0 spec. It serves as a dedicated secure vault for keys and measurements.

Trusted Launch provides your VM with its own dedicated TPM instance that runs in a secure environment outside the reach of any VM. The vTPM enables attestation by measuring the entire boot chain of your VM (UEFI, OS, system, and drivers).

Trusted Launch uses the vTPM to perform remote attestation through the cloud. Attestations enable platform health checks and are used for making trust-based decisions. As a health check, Trusted Launch can cryptographically certify that your VM booted correctly.

If the process fails, possibly because your VM is running an unauthorized component, Microsoft Defender for Cloud issues integrity alerts. The alerts include details on which components failed to pass integrity checks.

Virtualization-based security

Virtualization-based security (VBS) uses the hypervisor to create a secure and isolated region of memory. Windows uses these regions to run various security solutions with increased protection against vulnerabilities and malicious exploits. Trusted Launch lets you enable hypervisor code integrity (HVCI) and Windows Defender Credential Guard.

HVCI is a powerful system mitigation that protects Windows kernel-mode processes against injection and execution of malicious or unverified code. It checks kernel mode drivers and binaries before they run, preventing unsigned files from loading into memory. Checks ensure that executable code can't be modified after it's allowed by HVCI to load. For more information about VBS and HVCI, see Virtualization-based security and hypervisor-enforced code integrity.

With Trusted Launch and VBS, you can enable Windows Defender Credential Guard. Credential Guard isolates and protects secrets so that only privileged system software can access them. It helps prevent unauthorized access to secrets and credential theft attacks, like Pass-the-Hash attacks. For more information, see Credential Guard.

Microsoft Defender for Cloud integration

Trusted Launch is integrated with Defender for Cloud to ensure that your VMs are properly configured. Defender for Cloud continually assesses compatible VMs and issues relevant recommendations:

- **Recommendation to enable Secure Boot**: The Secure Boot recommendation only applies for VMs that support Trusted Launch. Defender for Cloud identifies VMs that have Secure boot disabled. It issues a low-severity recommendation to enable it.
- **Recommendation to enable vTPM**: If vTPM is enabled for VM, Defender for Cloud can use it to perform guest attestation and identify advanced threat patterns. If Defender for Cloud identifies VMs that support Trusted Launch with vTPM disabled, it issues a low-severity recommendation to enable it.
- **Recommendation to install guest attestation extension**: If your VM has Secure Boot and vTPM enabled but it doesn't have the Guest Attestation extension installed, Defender for

Cloud issues low-severity recommendations to install the Guest Attestation extension on it. This extension allows Defender for Cloud to proactively attest and monitor the boot integrity of your VMs. Boot integrity is attested via remote attestation.

- **Attestation health assessment or boot integrity monitoring**: If your VM has Secure Boot and vTPM enabled and the Attestation extension installed, Defender for Cloud can remotely validate that your VM booted in a healthy way. This practice is known as boot integrity monitoring. Defender for Cloud issues an assessment that indicates the status of remote attestation.

  If your VMs are properly set up with Trusted Launch, Defender for Cloud can detect and alert you of VM health problems.

- **Alert for VM attestation failure**: Defender for Cloud periodically performs attestation on your VMs. The attestation also happens after your VM boots. If the attestation fails, it triggers a medium-severity alert.

  > ⓘ **Note**
  >
  > VM client boot attestation alerts surfaced in Microsoft Defender for Cloud are informational and are not currently presented in the Defender portal.

  VM attestation can fail for the following reasons:

  - The attested information, which includes a boot log, deviates from a trusted baseline. Any deviation can indicate that untrusted modules are loaded, and the OS could be compromised.
  - The attestation quote couldn't be verified to originate from the vTPM of the attested VM. An unverified origin can indicate that malware is present and could be intercepting traffic to the vTPM.

    > ⓘ **Note**
    >
    > Alerts are available for VMs with vTPM enabled and the Attestation extension installed. Secure Boot must be enabled for attestation to pass. Attestation fails if Secure Boot is disabled. If you must disable Secure Boot, you can suppress this alert to avoid false positives.

- **Alert for untrusted Linux kernel module**: For Trusted Launch with Secure Boot enabled, it's possible for a VM to boot even if a kernel driver fails validation and is prohibited from loading. If kernel driver validation failure happens, Defender for Cloud issues low-severity alerts. While there's no immediate threat, because the untrusted driver didn't load, these events should be investigated. Ask yourself:
  - Which kernel driver failed? Am I familiar with the failed kernel driver and do I expect it to load?
  - Is the exact version of the driver same as expected? Are the driver binaries intact? If failed driver is a partner driver, did the partner pass the OS compliance tests to get it signed?

(Preview) Trusted Launch as default

> **Important**
>
> Trusted Launch default is currently in preview. This Preview is intended for testing, evaluation, and feedback purposes only. Production workloads aren't recommended. When registering to preview, you agree to the supplemental terms of use. Some aspects of this feature might change with general availability (GA).

Trusted Launch as default (TLaD) is available in preview for new Gen2 Virtual machines (VM) and Virtual machine scale sets (scale sets).

TLaD is a fast and zero-touch means of improving the security posture of new Gen2 based Azure VM and Virtual Machine Scale Sets deployments. With Trusted Launch as default, any new Gen2 VMs or scale sets created through any client tools (like ARM template, Bicep) defaults to Trusted Launch VMs with secure boot and vTPM enabled.

The public preview release allows you to validate these changes in your respective environment for all new Azure Gen2 VM, scale set, and prepare for this upcoming change.

> **Note**
>
> All new Gen2 VM, scale set, deployments using any client tool (ARM template, Bicep, Terraform, etc.) defaults to Trusted launch post on-boarding to preview. This change does NOT override inputs provided as part of the deployment code.

Enable TLaD preview

Register preview feature `TrustedLaunchByDefaultPreview` under `Microsoft.Compute` namespace on virtual machine subscription. For more information, see Set up preview features in Azure subscription

To create a new Gen2 VM or scale set with Trusted launch default, execute your existing deployment script as is through Azure SDK, Terraform, or another method that isn't Azure portal, CLI, or PowerShell. The new VM or scale set created in the registered subscription results in a Trusted Launch VM or Virtual Machine Scale Set.

VM & scale sets deployments with TLaD preview

Existing behavior

To create Trusted launch VM & scale set, you need to add following securityProfile element in deployment:

JSON

```
"securityProfile": {
    "securityType": "TrustedLaunch",
    "uefiSettings": {
        "secureBootEnabled": true,
        "vTpmEnabled": true,
    }
}
```

Absence of securityProfile element in deployment code deploys VM & scale set without enabling Trusted launch.

Examples

- vm-windows-admincenter – The Azure Resource Manager (ARM) template deploys Gen2 VM without enabling Trusted launch.
- vm-simple-windows – The ARM template deploys Trusted launch VM (without default as `securityProfile` is explicitly added to ARM template)

New behavior

By using API version 2021-11-01 or higher AND on-boarding to preview, absence of `securityProfile` element from deployment will enable Trusted launch by default to new VM & scale set deployed if following conditions are met:

- Source Marketplace OS image supports Trusted launch.

- Source ACG OS image supports and is validated for Trusted launch.
- Source disk supports Trusted launch.
- VM size supports Trusted launch.

The deployment won't default to Trusted launch if one ore more of the listed condition(s) aren't met and complete successfully to create new Gen2 VM & scale set without Trusted launch.

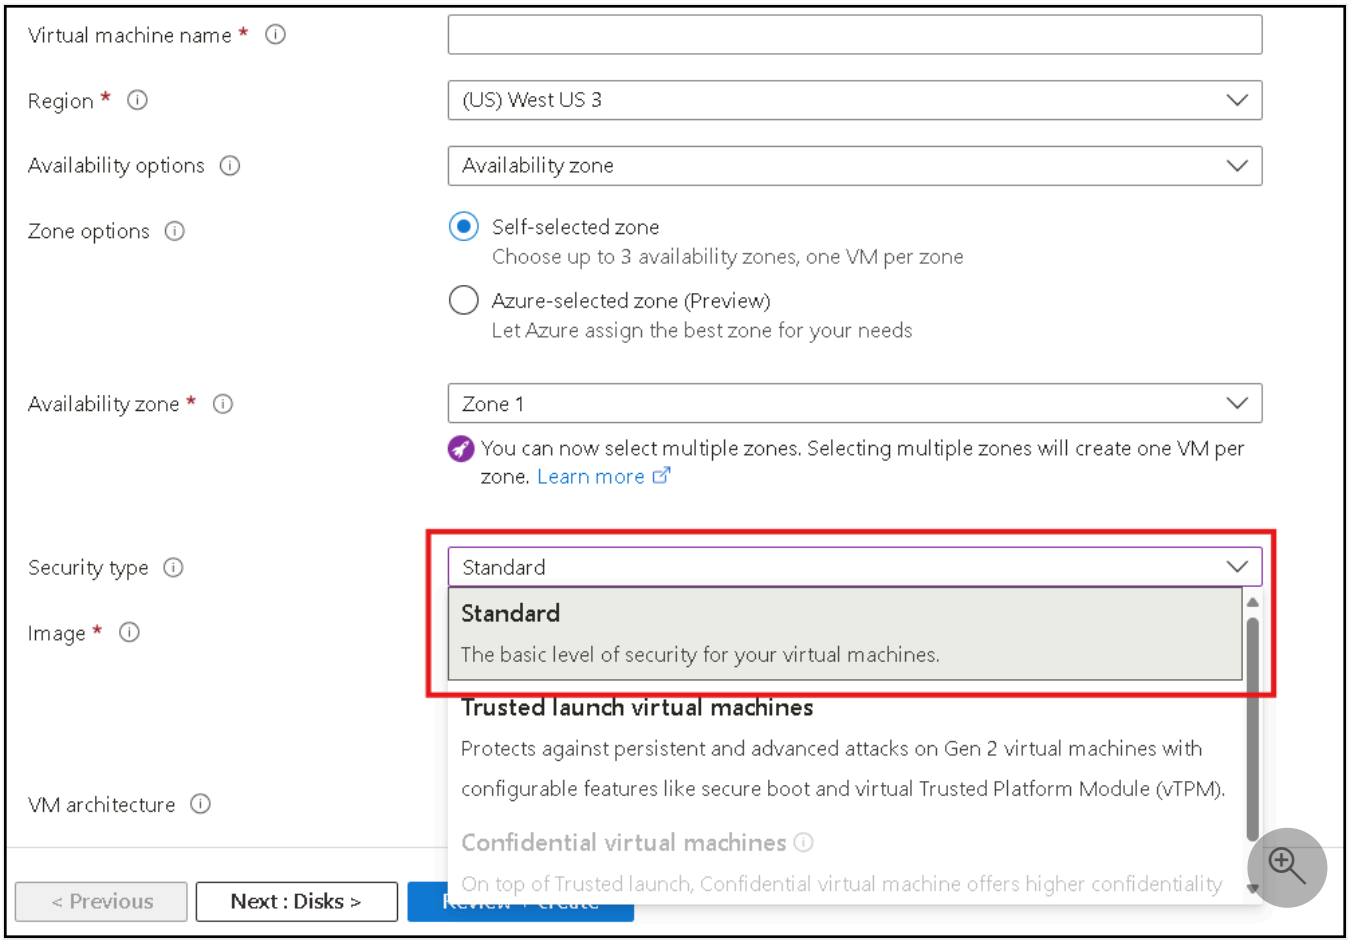
You can choose to explicitly bypass default for VM & scale set deployment by setting `Standard` as value of parameter `securityType`. For more information, see Can I disable Trusted Launch for a new VM deployment.

Known limitations

Unable to bypass Trusted launch default and create Gen2 (Non-Trusted launch) VM using Azure portal after registering to preview.

After registering subscription to preview, setting security type to `Standard` in Azure portal will deploy the VM or scale set `Trusted launch`. This limitation will be addressed prior to the Trusted launch default general availability.

To mitigate this limitation, you can un-register the preview feature by removing feature flag `TrustedLaunchByDefaultPreview` under `Microsoft.Compute` namespace on given subscription.



Unable to re-size VM or VMSS to un-supported Trusted launch VM size family (like M-Series) post default to Trusted launch.

Re-sizing Trusted launch VM to VM size family not supported with Trusted launch will not be supported.

As mitigation, please register feature flag `UseStandardSecurityType` under `Microsoft.Compute` namespace AND roll-back VM from Trusted launch to Gen2-only (Non-Trusted launch) by setting `securityType = Standard` using available client tools (except Azure portal).

TLaD preview feedback

Reach out to us with any feedback, queries, or concerns regarding this upcoming change at Trusted launch default preview feedback survey.

Disable TLaD preview

To disable the TLaD preview, unregister the preview feature `TrustedLaunchByDefaultPreview` under `Microsoft.Compute` namespace on virtual machine subscription. For more information, see Unregister preview feature

Last updated on 04/17/2026

Deploy a virtual machine with Trusted Launch enabled

Summarize this article for me

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets.

Trusted Launch is a way to improve the security of Generation 2 virtual machines (VMs). Trusted Launch protects against advanced and persistent attack techniques by combining infrastructure technologies like virtual Trusted Platform Module (vTPM) and secure boot.

Trusted Launch is supported on both x64 and Arm64 Generation 2 VMs where available, including Arm64 marketplace images.

Prerequisites

- We recommend that you onboard your subscription to Microsoft Defender for Cloud if it isn't already. Defender for Cloud has a free tier, which offers useful insights for various Azure and hybrid resources. With the absence of Defender for Cloud, Trusted Launch VM users can't monitor boot integrity of VM.
- If you have existing Generation 1 VMs, you can upgrade them to Generation 2 with Trusted launch. See Upgrade existing Gen1 VMs to Gen2-Trusted launch.
- Assign Azure policy initiatives to your subscription. These policy initiatives need to be assigned only once per subscription. Policies will help deploy and audit for Trusted Launch VMs while automatically installing all required extensions on all supported VMs.
  - Configure the Trusted Launch VMs' built-in policy initiative.
  - Configure prerequisites to enable Guest Attestation on Trusted Launch-enabled VMs.
  - Configure machines to automatically install the Azure Monitor and Azure Security agents on VMs.
- Allow the service tag `AzureAttestation` in network security group outbound rules to allow traffic for Azure Attestation. For more information, see Virtual network service tags.
- Make sure that the firewall policies allow access to `*.attest.azure.net`.

> **Note**
>
> If you're using a Linux image and anticipate that the VM might have kernel drivers either unsigned or not signed by the Linux distro vendor, you might want to consider turning off secure boot. In the Azure portal, on the **Create a virtual machine** page for the `Security`

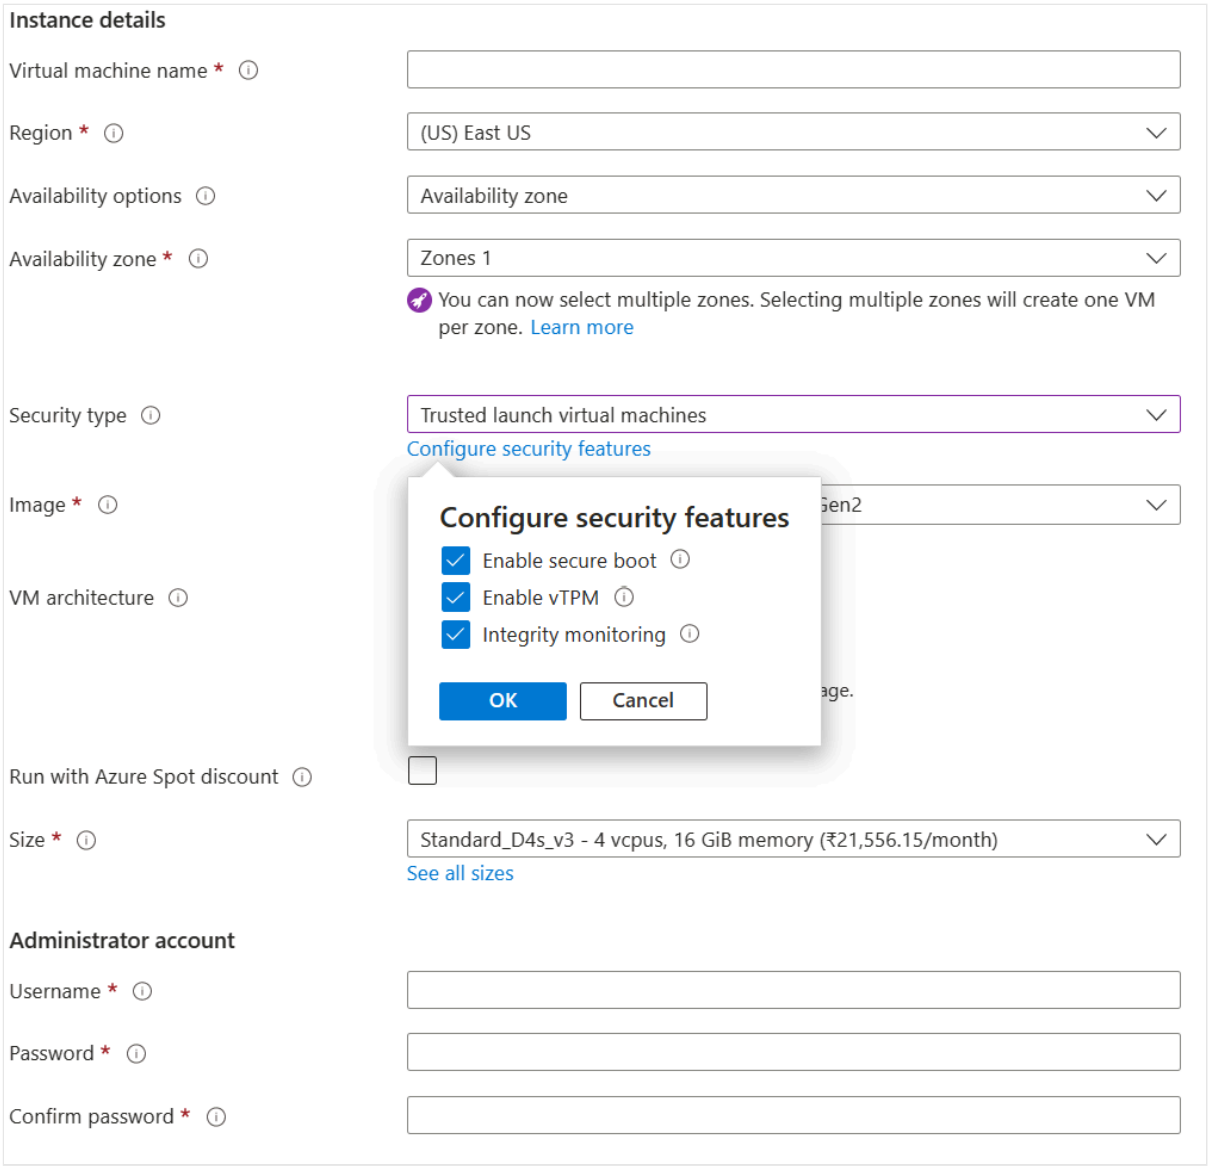
`type` parameter with **Trusted Launch Virtual Machines** selected, select **Configure security features** and clear the **Enable secure boot** checkbox. In the Azure CLI, PowerShell, or SDK, set the secure boot parameter to `false`.

Deploy a Trusted Launch VM

Choose one of the deployment methods to create a new Trusted launch VM

Portal

1. Sign in to the Azure portal.
2. Search for **Virtual Machines**.
3. Under **Services**, select **Virtual machines**.
4. On the **Virtual machines** page, select **Add**, and then select **Virtual machine**.
5. Under **Project details**, make sure the correct subscription is selected.
6. Under **Resource group**, select **Create new**. Enter a name for your resource group or select an existing resource group from the dropdown list.
7. Under **Instance details**, enter a name for the VM name and choose a region that supports Trusted Launch.
8. For **Security type**, select **Trusted launch virtual machines**. When the options **Secure boot**, **vTPM**, and **Integrity Monitoring** appear, select the appropriate options for your deployment. For more information, see Trusted Launch-enabled security features.



9. Under **Image**, select an image from **Recommended Gen 2 images compatible with Trusted launch**. Arm64 Gen2 images that support Trusted Launch are available in the Azure Marketplace. For a list, see Trusted Launch.

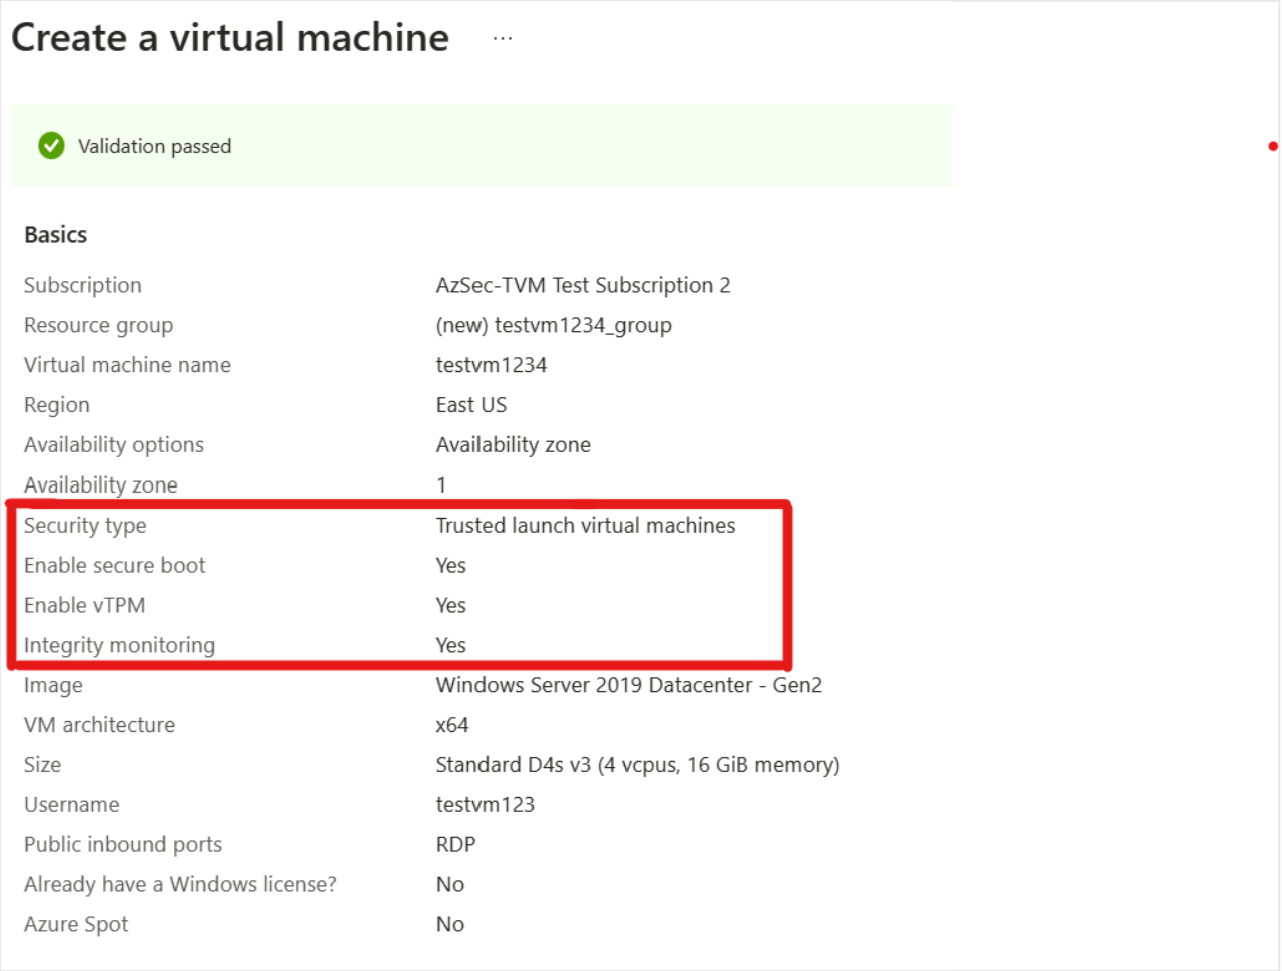
   > **Tip**
   >
   > If you don't see the Gen2 version of the image that you want in the dropdown list, select **See all images**. Then change the **Security type** filter to **Trusted Launch**.

10. Select a VM size that supports Trusted Launch. For more information, see the list of supported sizes.

11. Fill in the **Administrator account** information and then **Inbound port rules**.

12. At the bottom of the page, select **Review + Create**.

13. On the **Create a virtual machine** page, you can see the information about the VM you're about to deploy. After validation shows as passed, select **Create**.



It takes a few minutes for your VM to be deployed.

Deploy a Trusted Launch VM from an Azure Compute Gallery image

Azure Trusted Launch VMs support the creation and sharing of custom images by using Azure Compute Gallery. There are two types of images that you can create, based on the security types of the image:

- **Recommended**: Trusted Launch VM supported (TrustedLaunchSupported) images are images where the source doesn't have VM Guest state information and can be used to create either Generation 2 VMs or Trusted Launch VMs.
- Trusted Launch VM (TrustedLaunch) images are images where the source usually has VM Guest State information and can be used to create only Trusted Launch VMs.

Arm64 Gen2 images are supported. Ensure the image architecture matches the intended Arm64 VM size when creating Trusted Launch VMs.

Trusted Launch VM supported images

For the following image sources, the security type on the image definition should be set to `TrustedLaunchsupported`:

- Gen2 operating system (OS) disk VHD
- Gen2 Managed Image
- Gen2 Gallery Image version

No VM Guest State information can be included in the image source.

You can use the resulting image version to create either Azure Gen2 VMs or Trusted Launch VMs.

These images can be shared by using Azure Compute Gallery - Direct Shared Gallery and Azure Compute Gallery - Community Gallery.

> **Note**
>
> The OS disk VHD, Managed Image, or Gallery Image version should be created from a Gen2 image that's compatible with Trusted Launch VMs.

Portal

1. Sign in to the Azure portal.
2. Search for and select **VM image versions** in the search bar.
3. On the **VM image versions** page, select **Create**.
4. On the **Create VM image version** page, on the **Basics** tab:
   a. Select the Azure subscription.
   b. Select an existing resource group or create a new resource group.
   c. Select the Azure region.
   d. Enter an image version number.
   e. For **Source**, select either **Storage Blobs (VHD)** or **Managed Image** or another **VM Image Version**.
   f. If you selected **Storage Blobs (VHD)**, enter an OS disk VHD (without the VM Guest state). Make sure to use a Gen2 VHD.
   g. If you selected **Managed Image**, select an existing managed image of a Gen2 VM.
   h. If you selected **VM Image Version**, select an existing Gallery Image version of a Gen2 VM.
   i. For **Target Azure compute gallery**, select or create a gallery to share the image.
   j. For **Operating system state**, select either **Generalized** or **Specialized** depending on your use case. If you're using a managed image as the source, always select

Generalized. If you're using a storage blob (VHD) and want to select **Generalized**, follow the steps to generalize a Linux VHD or generalize a Windows VHD before you continue. If you're using an existing VM image version, select either **Generalized** or **Specialized** based on what's used in the source VM image definition.

k. For **Target VM Image Definition**, select **Create new**.

l. On the **Create a VM image definition** pane, enter a name for the definition. Make sure the security type is set to **Trustedlaunch Supported**. Enter the publisher, offer, and SKU information. Then select **OK**.

5. On the **Replication** tab, enter the replica count and target regions for image replication, if necessary.
6. On the **Encryption** tab, enter SSE encryption-related information, if necessary.
7. Select **Review + Create**.
8. After the configuration is successfully validated, select **Create** to finish creating the image.
9. After the image version is created, select **Create VM**.
10. On the **Create a virtual machine** page, under **Resource group**, select **Create new**. Enter a name for your resource group or select an existing resource group from the dropdown list.
11. Under **Instance details**, enter a name for the VM name and choose a region that supports Trusted Launch.
12. For **Security type**, select **Trusted launch virtual machines**. The **Secure Boot** and **vTPM** checkboxes are enabled by default.
13. Fill in the **Administrator account** information and then **Inbound port rules**.
14. On the validation page, review the details of the VM.
15. After the validation succeeds, select **Create** to finish creating the VM.

Trusted Launch VM images

The security type on the image definition should be set to `TrustedLaunch` for the following image sources:

- Trusted Launch VM capture
- Managed OS disk
- Managed OS disk snapshot

You can use the resulting image version to create Azure Trusted Launch VMs only.

Portal

1. Sign in to the Azure portal.
2. To create an Azure Compute Gallery Image from a VM, open an existing Trusted Launch VM and select **Capture**.
3. On the **Create an Image** page, allow the image to be shared to the gallery as a VM image version. Creation of managed images isn't supported for Trusted Launch VMs.
4. Create a new target Azure Compute Gallery or select an existing gallery.
5. Select the **Operating system state** as either **Generalized** or **Specialized**. If you want to create a generalized image, ensure that you generalize the VM to remove machine-specific information before you select this option. If Bitlocker-based encryption is enabled on your Trusted Launch Windows VM, you might not be able to generalize the same.
6. Create a new image definition by providing a name, publisher, offer, and SKU details. **Security type** for the image definition should already be set to **Trusted launch**.
7. Provide a version number for the image version.
8. Modify replication options, if necessary.
9. At the bottom of the **Create an Image** page, select **Review + Create**. After validation shows as passed, select **Create**.
10. After the image version is created, go to the image version directly. Alternatively, you can go to the required image version through the image definition.
11. On the **VM image version** page, select **+ Create VM** to go to the **Create a virtual machine** page.
12. On the **Create a virtual machine** page, under **Resource group**, select **Create new**. Enter a name for your resource group or select an existing resource group from the dropdown list.
13. Under **Instance details**, enter a name for the VM name and choose a region that supports Trusted Launch.
14. The image and the security type are already populated based on the selected image version. The **Secure Boot** and **vTPM** checkboxes are enabled by default.
15. Fill in the **Administrator account** information and then **Inbound port rules**.
16. At the bottom of the page, select **Review + Create**.
17. On the validation page, review the details of the VM.
18. After the validation succeeds, select **Create** to finish creating the VM.

If you want to use either a managed disk or a managed disk snapshot as a source of the image version (instead of a Trusted Launch VM), follow these steps.

1. Sign in to the Azure portal.
2. Search for **VM Image Versions** and select **Create**.
3. Provide the subscription, resource group, region, and image version number.
4. Select the source as **Disks and/or Snapshots**.

5. Select the OS disk as a managed disk or a managed disk snapshot from the dropdown list.
6. Select a **Target Azure Compute Gallery** to create and share the image. If no gallery exists, create a new gallery.
7. Select the **Operating system state** as either **Generalized** or **Specialized**. If you want to create a generalized image, ensure that you generalize the disk or snapshot to remove machine-specific information.
8. For the **Target VM Image Definition** select **Create new**. In the window that opens, select an image definition name and ensure that **Security type** is set to **Trusted launch**. Provide the publisher, offer, and SKU information and select **OK**.
9. The **Replication** tab can be used to set the replica count and target regions for image replication, if required.
10. The **Encryption** tab can also be used to provide SSE encryption-related information, if required.
11. Select **Create** on the **Review + create** tab to create the image.
12. After the image version is successfully created, select **+ Create VM** to go to the **Create a virtual machine** page.
13. Follow steps 12 to 18 as mentioned earlier to create a Trusted Launch VM by using this image version.

Trusted Launch built-in policies

To help users adopt Trusted Launch, Azure policies are available to help resource owners adopt Trusted Launch. The main objective is to help upgrade Generation 1 and 2 VMs that are Trusted launch capable.

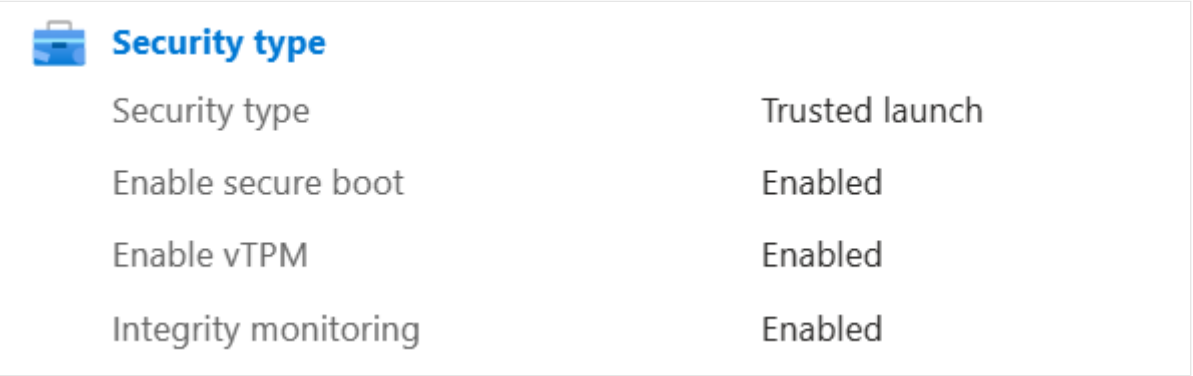
The **Virtual machine should have Trusted launch enabled** single policy checks if the VM is currently enabled with Trusted Launch security configurations. The **Disks and OS supported for Trusted launch** policy checks if previously created VMs have the capable Generation 2 OS and VM size to deploy a Trusted Launch VM.

These two policies come together to make the Trusted Launch policy initiative. This initiative enables you to group several related policy definitions to simplify assignments and management resources to include Trusted Launch configuration.

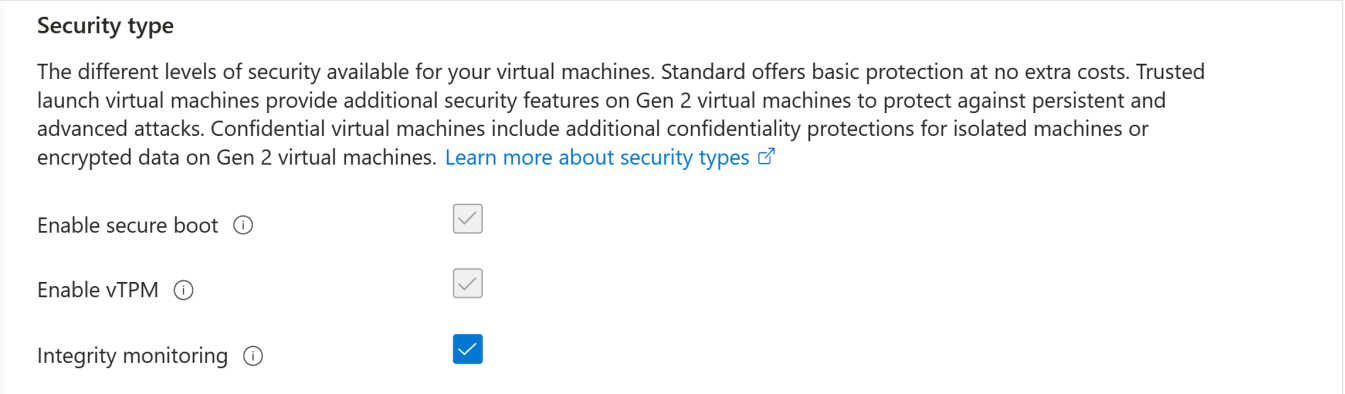
To learn more and start deploying, see Trusted Launch built-in policies.

Verify or update your settings

For VMs created with Trusted Launch enabled, you can view the Trusted Launch configuration by going to the **Overview** page for the VM in the Azure portal. The **Properties** tab shows the status of Trusted Launch features.



To change the Trusted Launch configuration, on the left menu, under **Settings**, select **Configuration**. In the **Security type** section, you can enable or disable **Secure Boot**, **vTPM**, and **Integrity monitoring**. Select **Save** at the top of the page when you're finished.



If the VM is running, you receive a message that the VM will restart. Select **Yes** and then wait for the VM to restart for changes to take effect.

Enable Trusted launch on existing Azure Gen2 VMs

Summarize this article for me

Applies to: ✔ Linux VM ✔ Windows VM

Azure Virtual Machines supports enabling Azure Trusted launch on existing Azure Generation 2 virtual machines (VM) by upgrading to the Trusted launch security type.

Trusted launch is a way to enable foundational compute security on Azure Generation 2 VMs and protects against advanced and persistent attack techniques like boot kits and rootkits. It does so by combining infrastructure technologies like Secure Boot, virtual Trusted Platform Module (vTPM), and boot integrity monitoring on your VM.

> ⓘ **Important**
>
> Support for enabling Trusted launch on existing Azure Generation 1 VMs is available. Refer to **Upgrade existing Azure Gen1 VMs to Gen2-Trusted launch**.

Prerequisites

Azure VM is configured with:

- Trusted launch supported size family.
- Trusted launch supported operating system (OS) version. For custom OS images or disks, the base image should be *Trusted launch capable*.
- For Arm64 VMs, use Trusted launch-capable Arm64 images from Azure Marketplace and a supported Arm64 size family. Cobalt 100-based Arm64 sizes support Trusted launch.
- Azure VM isn't using features currently not supported with Trusted launch.
- Azure Backup, if enabled, for VMs should be configured with the Enhanced Backup policy. The Trusted launch security type can't be enabled for VMs configured with *Standard policy* backup protection.
  - Existing Azure VM backup can be migrated from the *Standard* to the *Enhanced* policy. Follow the steps in Migrate Azure VM backups from Standard to Enhanced policy (preview).

Best practices

- Enable Trusted launch on a test Generation 2 VM and determine if any changes are required to meet the prerequisites before you enable Trusted launch on Generation 2 VMs associated with production workloads.
- Create restore points for Azure Generation 2 VMs associated with production workloads before you enable the Trusted launch security type. You can use the restore points to re-create the disks and Generation 2 VM with the previous well-known state.
- *For Linux VMs*, validate secure boot compatibility using `SBInfo` tool. Refer to Linux Trusted launch secure boot validation for distribution-based `SBInfo` installation commands.

Enable Trusted launch on an existing VM

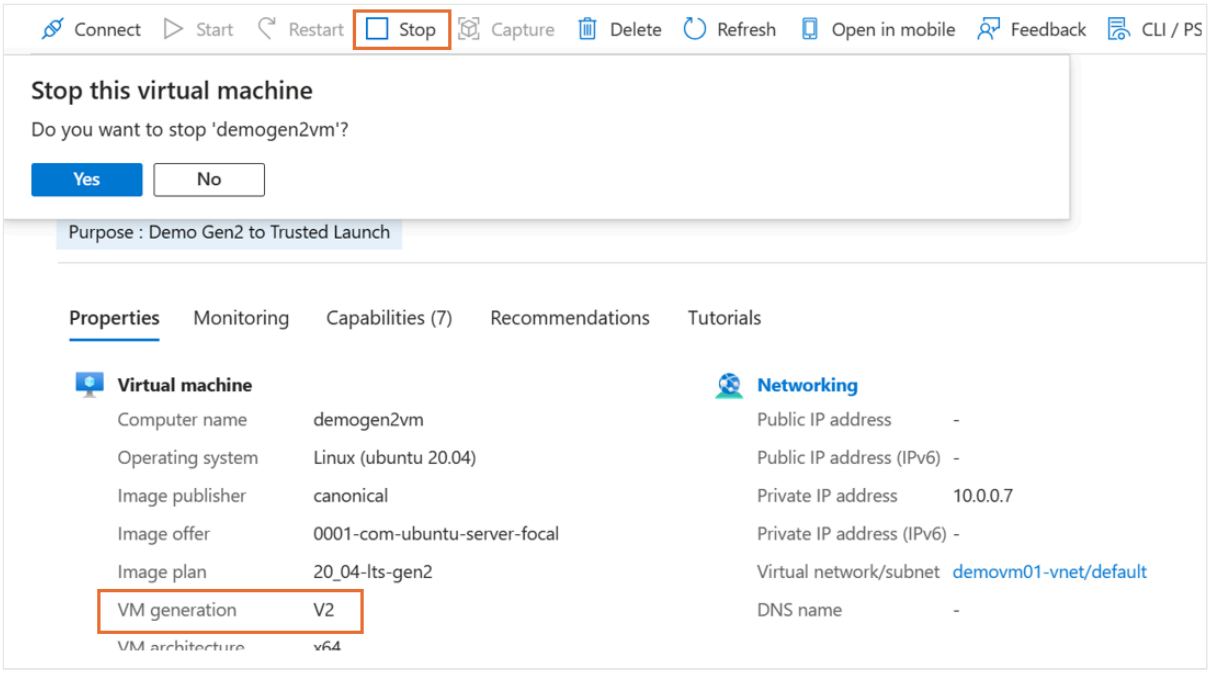
The following steps apply to both x64 and Arm64-based Generation 2 VMs when using Trusted launch-capable images.

> **Note**
>
> - These steps apply equally to x64 and Arm64 Gen2 VMs.
> - vTPM is enabled by default.
> - Secure boot isn't enabled by default. We strongly recommend that you enable Secure Boot, if you aren't using custom unsigned kernel or drivers. Secure Boot preserves boot integrity and enables foundational security for VMs.

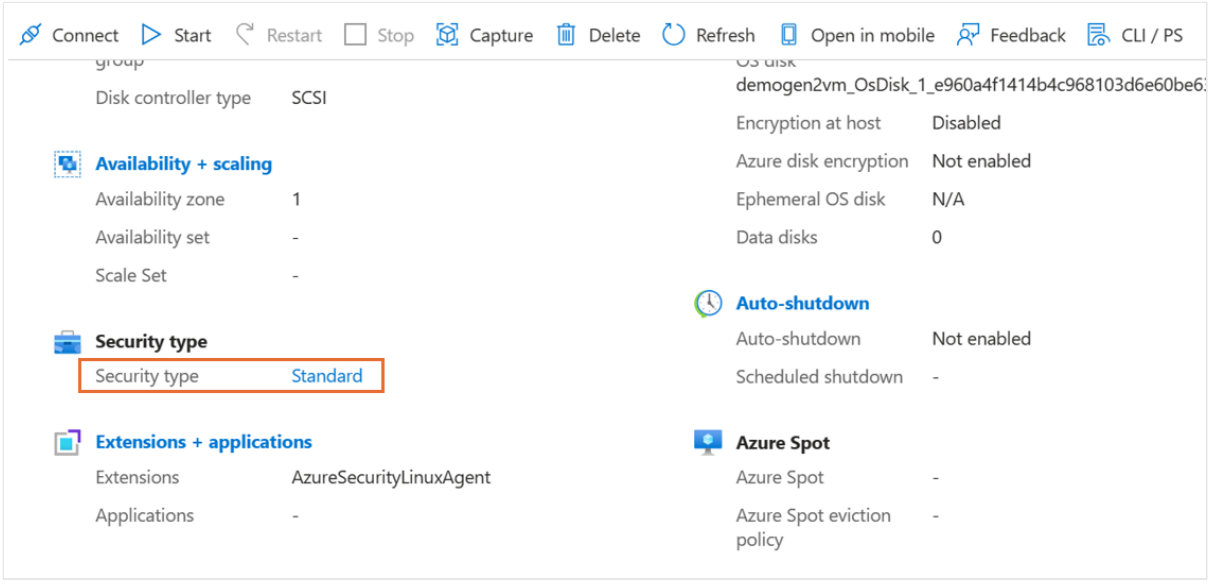
Portal

Enable Trusted launch on an existing Azure Generation 2 VM by using the Azure portal.

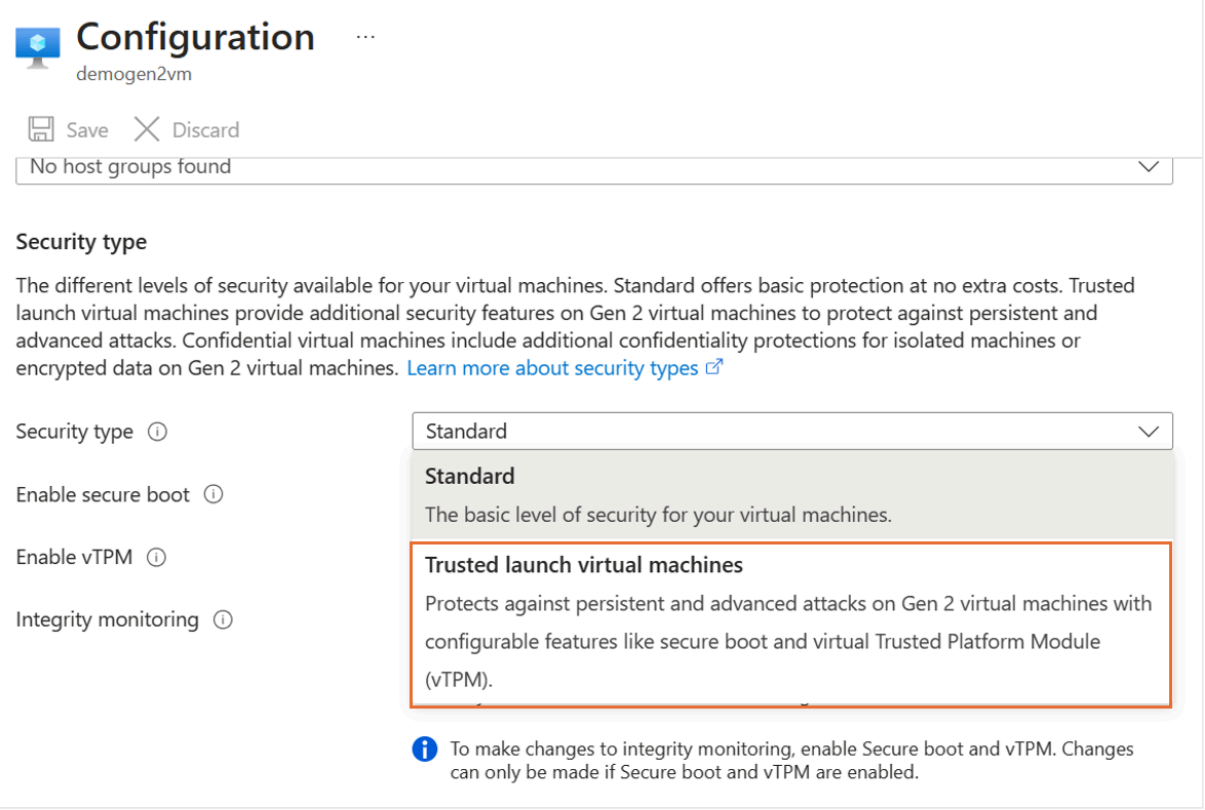
1. Sign in to the Azure portal.
2. Confirm that the VM generation is **V2** and select **Stop** for the VM.



3. On the **Overview** page in the VM properties, under **Security type**, select **Standard**. The **Configuration** page for the VM opens.

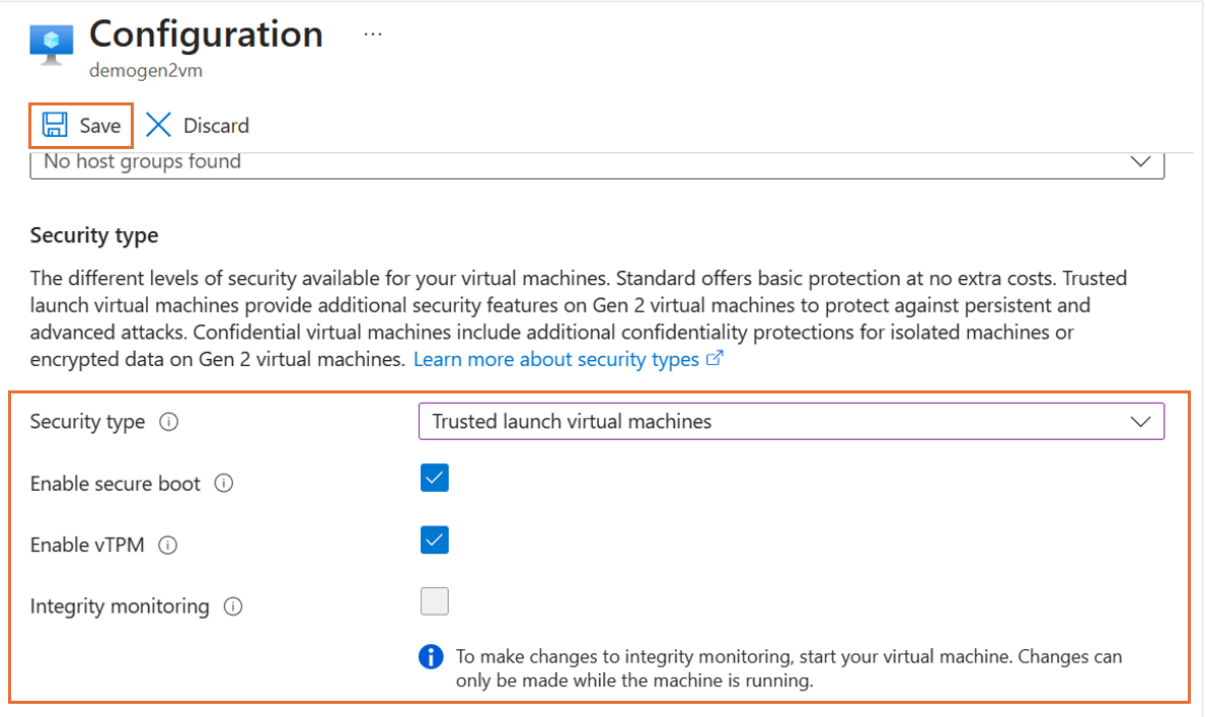


4. On the **Configuration** page, under the **Security type** section, select the **Security type** dropdown list.

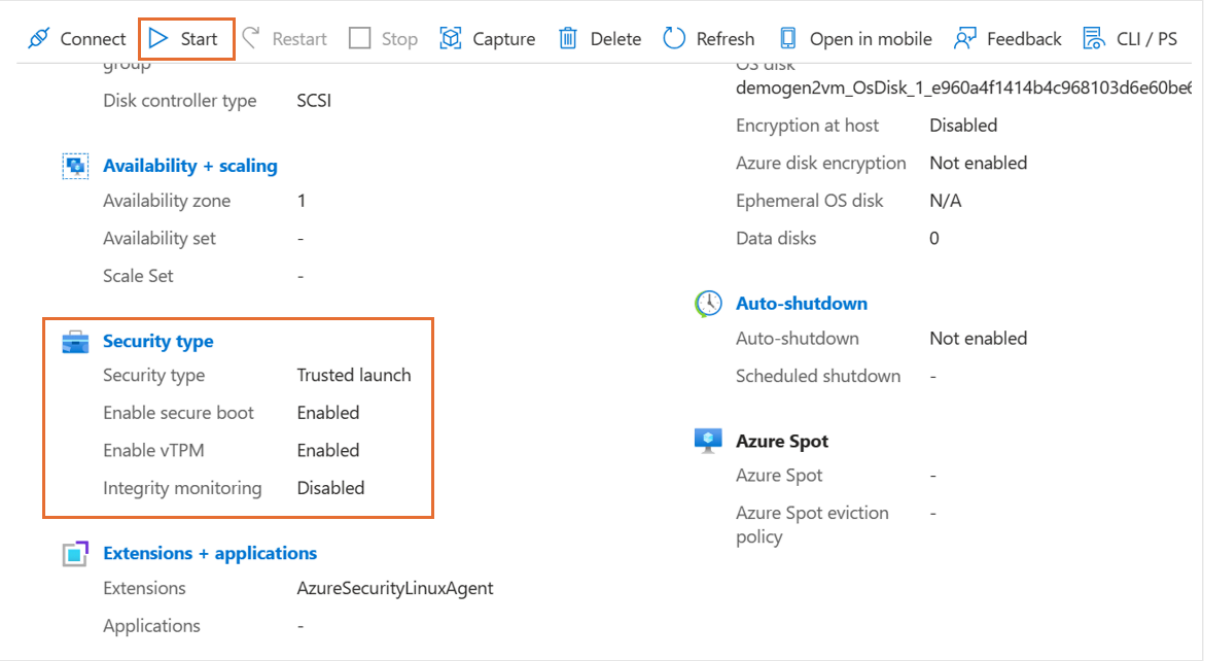


5. Under the dropdown list, select **Trusted launch**. Select checkboxes to enable **Secure Boot** and **vTPM**. After you make the changes, select **Save**.

> **Note**
>
> - Generation 2 VMs created by using Azure Compute Gallery (ACG), Managed image, or an OS disk can't be upgraded to Trusted launch by using the portal. Ensure that the OS version is supported for Trusted launch. Use PowerShell, the Azure CLI, or an Azure Resource Manager template (ARM template) to run the upgrade.



6. After the update successfully finishes, close the **Configuration** page. On the **Overview** page in the VM properties, confirm the **Security type** settings.



7. Start the upgraded Trusted launch VM. Verify that you can sign in to the VM by using either the Remote Desktop Protocol (RDP) for Windows VMs or the Secure Shell Protocol (SSH) for Linux VMs.

Roll back

> **Note**

Register feature `UseStandardSecurityType` under `Microsoft.Compute` namespace on virtual machine subscription for roll-back support. For more information, see Set up preview features in Azure subscription

To roll-back changes from Trusted launch to previous Gen2 known good configuration, you need to set `securityType` of VM to **Standard**.

Portal

Roll-back of Trusted launch to Gen2 (Non-Trusted launch) configuration is currently not supported in Azure portal.

Azure Advisor Recommendation

Azure Advisor populates an **Enable Trusted launch foundational excellence, and modern security for Existing Generation 2 VM(s)** operational excellence recommendation for existing Generation 2 VMs to adopt Trusted launch, a higher security posture for Azure VMs at no extra cost to you. Ensure Generation 2 VM has all prerequisites to migrate to Trusted launch, follow all the best practices including validation of OS image, VM Size, and creating restore points. For the Advisor recommendation to be considered complete, follow the steps outlined in the **Enable Trusted launch on an existing VM** to upgrade the virtual machines security type and enable Trusted launch.

What if there is Generation 2 VMs, that doesn't fit the prerequisites for Trusted launch?

For a Generation 2 VM that doesn't meet the prerequisites to upgrade to Trusted launch, look how to fulfill the prerequisites. For example, If using a virtual machine size not supported, look for an equivalent Trusted launch supported size that supports Trusted launch.

> **Note**
>
> Dismiss the recommendation if Gen2 virtual machine is configured with VM size families that are currently not supported with Trusted launch like MSv2-series.

Related content

- Refer to Deploy Trusted launch virtual machines for enabling Trusted launch on new virtual machine & scale set deployments.

- Refer to boot integrity monitoring for enabling boot integrity monitoring and monitor the health of the VM by using Microsoft Defender for Cloud.
- Learn more about Trusted launch and review frequently asked questions.
- Learn about Cobalt 100-based Arm64 VM sizes that support Trusted Launch.

Upgrade existing Azure Gen1 VMs to Trusted launch

Summarize this article for me

Applies to: ✔ Linux VM ✔ Windows VM ✔ Generation 1 VM

Azure Virtual Machines supports upgrading Generation 1 virtual machines (VM) to Generation 2 by upgrading to the Trusted launch security type.

Trusted launch is a way to enable foundational compute security on Azure Generation 2 VMs and protects against advanced and persistent attack techniques like boot kits and rootkits. It does so by combining infrastructure technologies like Secure Boot, virtual Trusted Platform Module (vTPM), and boot integrity monitoring on your VM.

> **ⓘ Important**
>
> - *Upgrade of Gen1 VMs to Gen2 without enabling Trusted launch* is **not supported**.
> - This upgrade path doesn't change the VM CPU architecture. To use Arm64 with Trusted launch, create a new VM from an Arm64 Trusted launch image in Azure Marketplace on supported **Cobalt 100 sizes** .

Prerequisites

- Azure VM is configured with:
  - Trusted launch supported size family.
  - Trusted launch supported operating system (OS) version (*excluding Windows Server 2016, Debian, Azure Linux*). For custom OS images or disks, the base image should be *Trusted launch capable*.
- Azure VM isn't using features currently not supported with Trusted launch.
- Azure Backup, if enabled, for VMs should be configured with the Enhanced Backup policy. The Trusted launch security type can't be enabled for VMs configured with *Standard policy* backup protection.
  - Existing Azure VM backup can be migrated from the *Standard* to the *Enhanced* policy. Follow the steps in Migrate Azure VM backups from Standard to Enhanced policy.
- Upgrade a test Gen1 VM to Trusted launch and determine if any changes are required to meet the prerequisites before you upgrade Gen1 VMs associated with production workloads to Trusted launch.
- Disable any *Windows OS volume encryption* including BitLocker before upgrade if enabled. All Windows OS volume encryptions should be re-enabled post successful

upgrade. This action isn't required for data disks or Linux OS volume.

Unsupported Gen1 VM configurations

Gen1 to Trusted launch VM upgrade is **NOT** supported if Gen1 VM is configured with:

- **Operating system**: Windows Server 2016, Azure Linux, Debian, and any other operating system not listed under Trusted launch supported operating system (OS) version. For *Windows Server 2016 only*, workaround is to update the Guest OS to Windows Server 2019 or 2022.
- **VM size**: Gen1 VM configured with VM size not listed under Trusted launch supported size families. As workaround, update the VM size to Trusted launch supported VM size family.
- **Azure Backup**: Gen1 VM configured with Azure Backup using *Standard policy*. As workaround, migrate Gen1 VM backups from Standard to Enhanced policy.
- **BitLocker or equivalent encryption**: Windows Gen1 VM *guest OS volume* is encrypted using BitLocker or equivalent encryption technology. As workaround, disable Windows OS volume encryption before upgrade and re-enable post successful completion of Trusted launch upgrade.

Best practices

> **Important**
>
> VM once upgraded to Trusted launch can't be rolled back to Gen1 configuration. It has to be fully recovered using Backup taken before upgrade.

- Take full backup OR Create restore points for Azure VMs associated with production workloads before you enable the Trusted launch security type. You can use the backup OR restore points to re-create the disks and VM with the previous Gen1 configuration well-known state.
- Review known issues and roll-back steps before executing Trusted launch upgrade.
- You won't be able to extend Windows OS disk system volume after `MBR to GPT conversion` as part of upgrade. Recommendation is to extend system volume for future before upgrading to Trusted launch.
- *Windows OS disk volume* should be defragmented using command `Defrag C: /U /V`. Defragmentation of OS volume reduces the risk of MBR (Master boot record) to GPT (GUID partition table) conversion failure by freeing up end of partitions. Refer to defrag.

- *For Linux VMs*, validate secure boot compatibility using `SBInfo` tool. Refer to Linux Trusted launch secure boot validation for distribution-based `SBInfo` installation commands.

Update Guest OS volume

Generation 2 VMs requires guest OS volume with following configurations:

- **GPT Disk layout**: Guest OS volume of Gen1 VMs is mostly set to `MBR` and requires to be updated to `GPT`
- **EFI system partition**: Guest OS volume of Gen1 VMs mostly doesn't include this partition.

Complete the update of OS volume with required configuration before upgrading Azure Gen1 VM to Trusted launch.

> **ⓘ Important**
>
> - Upgrade a test Gen1 VM to Trusted launch and determine if any changes are required to meet the prerequisites before you upgrade Gen1 VMs associated with production workloads to Trusted launch.

Windows

Using in-built MBR2GPT.exe utility, you can enable `GPT` disk layout AND add `EFI system partition` required for Gen2 upgrade.

> **⊗ Caution**
>
> You won't be able to extend Windows OS disk system volume after `MBR to GPT conversion`. Recommendation is to extend system volume for future before executing the upgrade.

> **ⓘ Note**
>
> Windows Server 2016 doesn't support `MBR2GPT.exe`. Workaround is to update the Guest OS to Windows Server 2019 or 2022 and followed by `MBR to GPT conversion`. Refer to In-place upgrade for VMs running Windows Server in Azure.

1. Remotely connect (using RDP or command-line) to Gen1 Windows VM for executing conversion.
2. Run command `MBR2GPT /validate /allowFullOS` and ensure `Disk layout validation` completes successfully. **Do not proceed** if the `Disk layout validation` fails. Refer to Known issues for list of common causes and associated resolution for failure. For more information and troubleshooting, see MBR2GPT troubleshooting.
3. Run command `MBR2GPT /convert /allowFullOS` to **execute** MBR to GPT conversion. Sample successful output:

   log

   ```
   If conversion is successful the disk can only be booted in GPT mode.
   These changes cannot be undone!

   MBR2GPT: Attempting to convert disk 0
   MBR2GPT: Retrieving layout of disk
   MBR2GPT: Validating layout, disk sector size is: 512 bytes
   MBR2GPT: Trying to shrink the OS partition
   MBR2GPT: Creating the EFI system partition
   MBR2GPT: Installing the new boot files
   MBR2GPT: Performing the layout conversion
   MBR2GPT: Migrating default boot entry
   MBR2GPT: Adding recovery boot entry
   MBR2GPT: Fixing drive letter mapping
   MBR2GPT: Conversion completed successfully
   MBR2GPT: Before the new system can boot properly you need to switch the
   firmware to boot to UEFI mode!
   ```

Upgrade Gen1 VM to Trusted launch

> ⓘ **Note**
>
> - vTPM is enabled by default.
> - Secure boot isn't enabled by default. We strongly recommend that you enable Secure Boot, if you aren't using custom unsigned kernel or drivers. Secure Boot preserves boot integrity and enables foundational security for VMs.

PowerShell

Make sure that you install the latest Azure PowerShell and are signed in to an Azure account with Connect-AzAccount.

Follow the steps to upgrade existing Gen1 VM to Gen2 and enable Trusted launch by using Azure PowerShell.

1. Sign in to the VM Azure subscription.

Azure PowerShell

```
Connect-AzAccount -SubscriptionId 00000000-0000-0000-0000-000000000000
```

2. Deallocate the VM.

Azure PowerShell

```
Stop-AzVM -ResourceGroupName myResourceGroup -Name myVm
```

3. Enable Trusted launch by setting `-SecurityType` to `TrustedLaunch`.

Azure PowerShell

```
Get-AzVM -ResourceGroupName myResourceGroup -VMName myVm `
    | Update-AzVM -SecurityType TrustedLaunch `
        -EnableSecureBoot $true -EnableVtpm $true
```

4. Validate `securityProfile` in the updated VM configuration.

Azure PowerShell

```
# Following command output should be `TrustedLaunch`

(Get-AzVM -ResourceGroupName myResourceGroup -VMName myVm `
    | Select-Object -Property SecurityProfile `
        -ExpandProperty SecurityProfile).SecurityProfile.SecurityType

# Following command output should return `SecureBoot` and `vTPM` settings
(Get-AzVM -ResourceGroupName myResourceGroup -VMName myVm `
    | Select-Object -Property SecurityProfile `
        -ExpandProperty SecurityProfile).SecurityProfile.Uefisettings
```

5. Start the VM.

Azure PowerShell

```
Start-AzVM -ResourceGroupName myResourceGroup -Name myVm
```

6. Start the upgraded Trusted launch VM. Verify that you can sign in to the VM by using either RDP (for Windows VMs) or SSH (for Linux VMs).

Roll back

Azure VM once upgraded to Trusted launch can't be rolled back to Gen1 configuration. You can disable Trusted launch to roll-back VM from Trusted launch to Gen2 (Non-Trusted launch) configuration.

Use the Backup or Restore point of Gen1 VM taken before upgrade and restore entire VM along with disks to roll back fully to Gen1 VM.

Known issues

VM image reference doesn't change post Trusted launch upgrade

Post upgrade of Azure Gen1 VM to Trusted launch, the image reference still reflects source as Gen1 OS image. Image reference not updated is a known limitation.

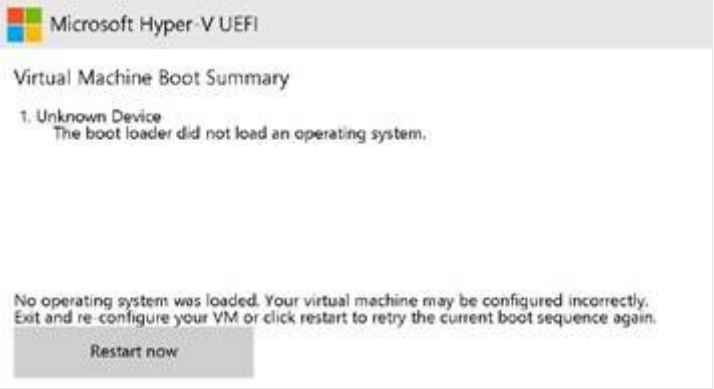
This limitation doesn't impacts the VM or hosted application functionality post Trusted launch upgrade. Following VM operations are impacted due to disconnect between image reference and running OS:

- **Guest patching**: For *Server* OS, Automatic guest patching installs updates based on the image reference of VM.
- **Reimage**: Reimaging VM using Gen1 image reference post Trusted launch upgrade causes VM boot failure.

Windows 11 boot fails after Trusted launch upgrade of Windows 10 VM

Windows 10 Gen1 VM is successfully upgraded to Trusted launch followed by successful Windows 11 in-place upgrade. However, the Windows 11 boot fails after Azure VM is stopped and started with error shown.

Resolution: This issue is fixed with 24H2 build version 26100.2314 and 23H2 build version 22631.5624.



> **Note**
>
> The upgrade can fail if you use outdated Windows 11 installation media. To avoid this issue, ensure you use the most recent Windows 11 image. You can download the latest ISO from the Microsoft Software Download page. If you have a volume licensing agreement, use the Microsoft 365 admin center to access updated Windows 11 images.

Windows Server 2022 boot fails after in-place upgrade of Trusted launch VM migrated from Gen1

Windows Server 2019 Gen1 VMs upgraded to Trusted launch followed by an in-place upgrade to Windows Server 2022 may fail to boot with **"The boot loader did not load an operating system"**. This issue is caused by a partition number mismatch in the UEFI boot entry after MBR-to-GPT conversion and is fixed in Windows Server 2025 and later. Take a snapshot of the OS disk before performing the in-place upgrade.

[Windows] MBR to GPT conversion fails with error Cannot find room for the EFI system partition

This error occurs for one of following reason:

- There's no free space available on the system volume
- System volume is corrupted. You can validate by trying to Shrink Volume by few MBs under Disk Management console. Use command `chkdsk C:/v/f` to repair system volume.
- `Virtual Disk` service isn't running or unable to communicate successfully. Service startup type should be set to `Manual`.

- `Optimize Drives` service isn't running or unable to communicate successfully. Service startup type should be set to `Manual`.
- System volume disk is already configured with four MBR partitions (maximum supported by MBR disk layout). You need to delete one of the partitions to make room for EFI system partition.

    1. Run `ReAgentc /info` to identify partition actively used by Recovery. Example: `Windows RE location: \\?\GLOBALROOT\device\harddisk0\partition4\Recovery\WindowsRE`
    2. Run PowerShell cmdlet `Get-Partition -DiskNumber 0` to identify current partitions that are configured.
    3. Run PowerShell cmdlet `Remove-Partition -DiskNumber 0 -PartitionNumber X` to remove any extra Recovery partition not actively used by Recovery service as identified in Step 1.

[Windows] MBR to GPT failed to update ReAgent.xml

For certain Windows OS versions like Windows 10, MBR2GPT generates pass-through error `MBR2GPT: Failed to update ReAgent.xml, please try to manually disable and enable WinRE.`

The warning indicates that `MBR2GPT.exe` was unable to update Recovery partition GUID in `C:\Windows\System32\Recovery\ReAgent.xml`. This issue shouldn't cause issue with Guest OS functionality or further upgrade operations like Windows 11 Upgrade to succeed or Windows 11 to work properly post Upgrade. `ReAgent.xml` is updated with correct GUID post Windows 11 upgrade, that is, if you don’t take any action between MBR2GPT conversion & Windows 11 upgrade, the GUID value in `ReAgent.xml` is synced with Windows recovery configuration.

To manually fix The warning, you can disable and re-enable WinRE post MBR2GPT conversion or post Gen1 to Trusted launch upgrade before Windows 11 upgrade using listed steps, these steps forces sync the WinRE GUID in `ReAgent.xml`

1. Complete Gen1 -> Trusted launch upgrade.
2. Run `reagentc /disable`
3. Run `reagentc /enable`
4. Run `reagentc /info`
5. Open `C:\Windows\System32\Recovery\ReAgent.xml` and validate BCD GUID in xml file is matching the output from Step 4.

[Windows] D Drive assigned to System Reserved Post upgrade

Temporary storage Drive letter assignment 'D' is changed to 'E' with previous letter assigned to System Reserved post-upgrade of Gen1 VM. Execute below steps manually post-upgrade to work around the issue:

After the upgrade check the disks on the server, if system reserved partition has the letter D, do the following actions:

1. Reconfigure pagefile from D: to C:
2. Reboot the VM
3. Remove letter D: from the partition
4. Reboot the VM to show the temporary storage disk with D: letter

Frequently asked questions

What if there is Generation 1 VMs, that doesn't fit the prerequisites for Trusted launch?

For a Generation 1 VM that doesn't meet the prerequisites to upgrade to Trusted launch, look how to fulfill the prerequisites. For example, If using a virtual machine size not supported, look for an equivalent Trusted launch supported size that supports Trusted launch.

Why is upgrade to Generation 2 only (without Trusted launch) not supported?

Trusted launch enables foundational compute security on Azure Generation 2 VMs with no extra cost associated. Also, Trusted launch VMs are majorly on parity with Generation 2 VMs. Hence, there's no added benefit for upgrading only to Generation 2 VM without enabling Trusted launch.

Related content

- Refer to Deploy Trusted launch virtual machines for enabling Trusted launch on new virtual machine & scale set deployments.
- Refer to boot integrity monitoring for enabling boot integrity monitoring and monitor the health of the VM by using Microsoft Defender for Cloud.

Last updated on 03/09/2026

Enable Trusted launch on existing Uniform scale set

06/18/2025

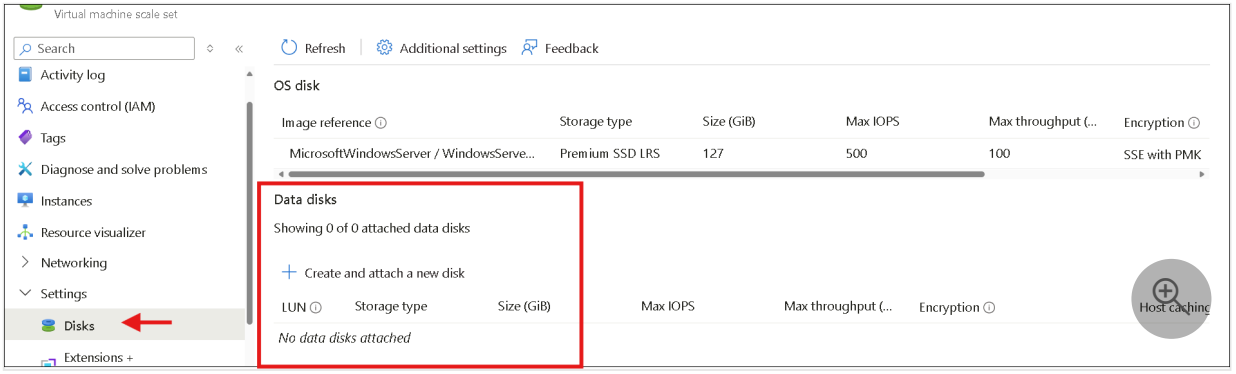
Applies to: ✔ Uniform scale set ✔ Flex scale set ✖ Service fabric

Azure Virtual machine Scale sets supports enabling Trusted launch on existing Uniform Scale sets virtual machine (VM) by upgrading to Trusted launch security type.

Trusted launch enables foundational compute security on Azure Generation 2 virtual machines & scale sets and protects them against advanced and persistent attack techniques like boot kits and rootkits. It does so by combining infrastructure technologies like Secure Boot, vTPM, and Boot Integrity Monitoring on your Scale set.

Limitations

- Enabling Trusted launch on existing virtual machine Scale sets with data disks attached requires upgrade mode set to Rolling upgrade with max surge
  - To validate if scale set is configured with data disk, navigate to scale set -> **Disks** under **Settings** menu -> check under heading **Data disks**



- Enabling Trusted launch on existing virtual machine Scale sets Flex is currently in preview. Register for preview of enabling Trusted launch on existing Flex scale set preview

- Enabling Trusted launch on existing Service fabric clusters and Service fabric managed clusters is currently not supported.

Prerequisites

- Scale set isn't dependent on features currently not supported with Trusted launch.
- Scale set should be configured with Trusted launch supported size family

> **Note**
>
> - Virtual machine size can be changed along with Trusted launch upgrade. Ensure quota for new VM Size is in-place to avoid upgrade failures. Refer to Check vCPU quotas.
> - Change to Virtual machine size re-creates the Virtual machine instance with new size and requires downtime of individual Virtual machine instance. It can be done in a Rolling Upgrade fashion to avoid Scale set downtime.

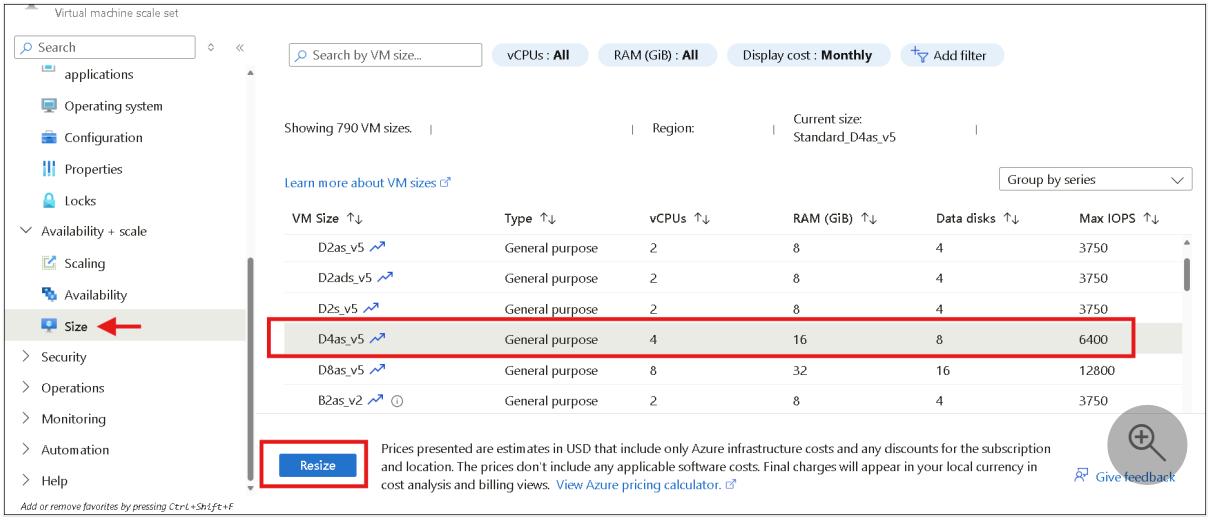
- Scale set should be configured with Trusted launch supported OS Image. For Azure compute gallery OS image, ensure image definition is marked as TrustedLaunchSupported

Enable Trusted launch on existing Scale set Uniform

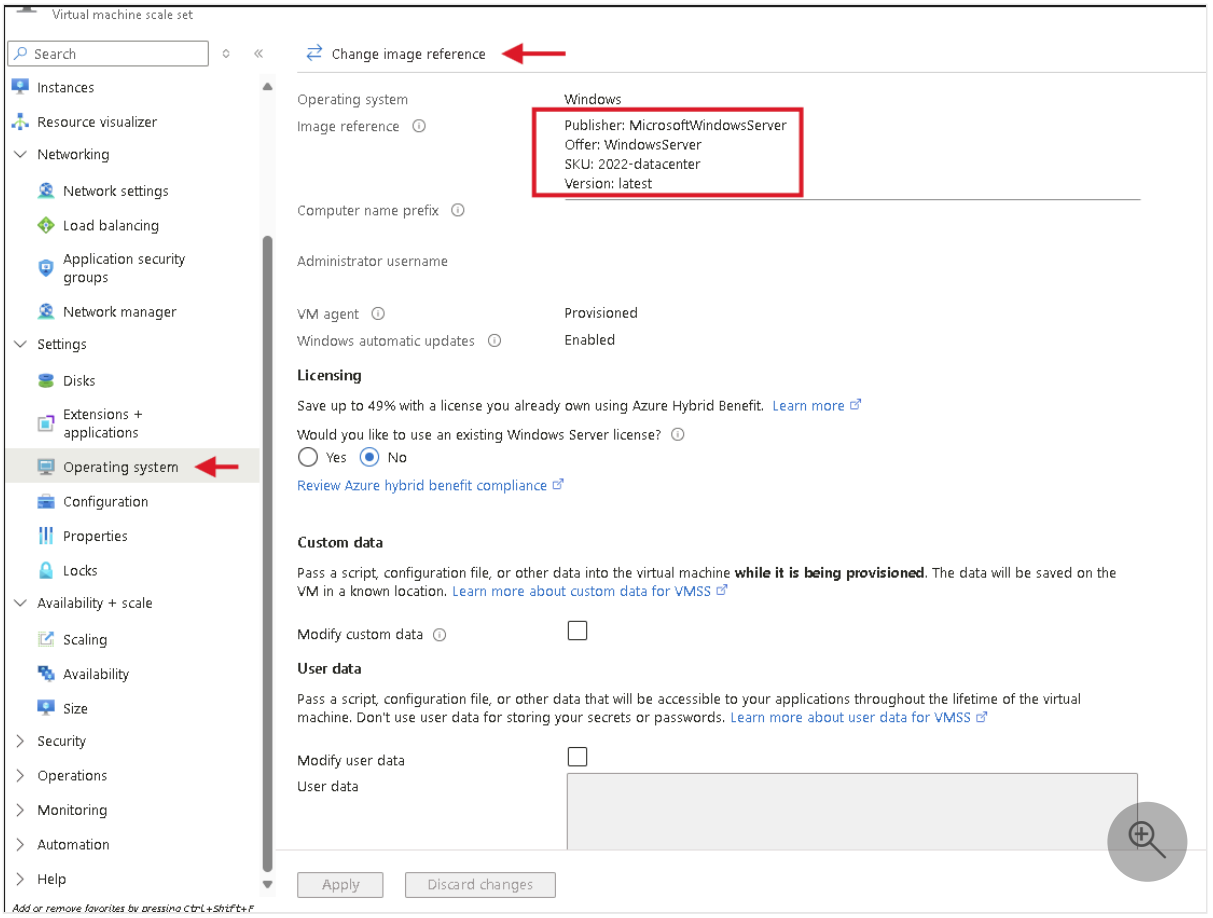
Portal

Following steps details how to enable Trusted launch on existing uniform scale set using Azure portal.

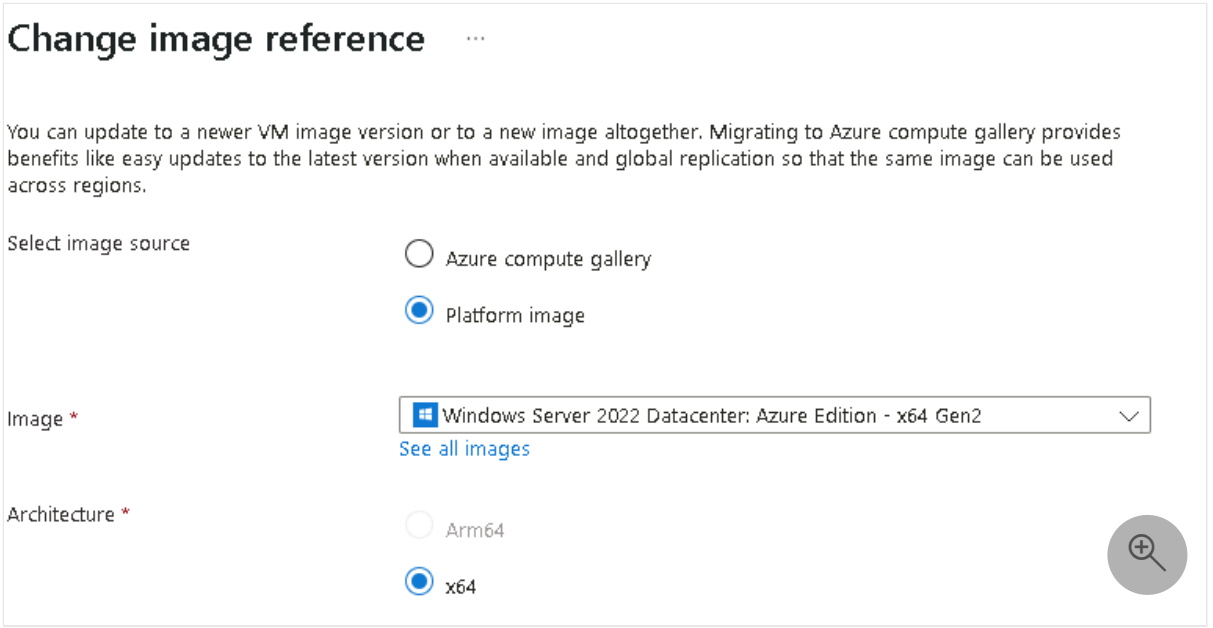
1. (Optional) **Scale set Size**: Navigate to `Size` under `Availability + scale` -> Modify the Scale set size if current size family isn't supported with Trusted launch security configuration -> Click **Apply**.



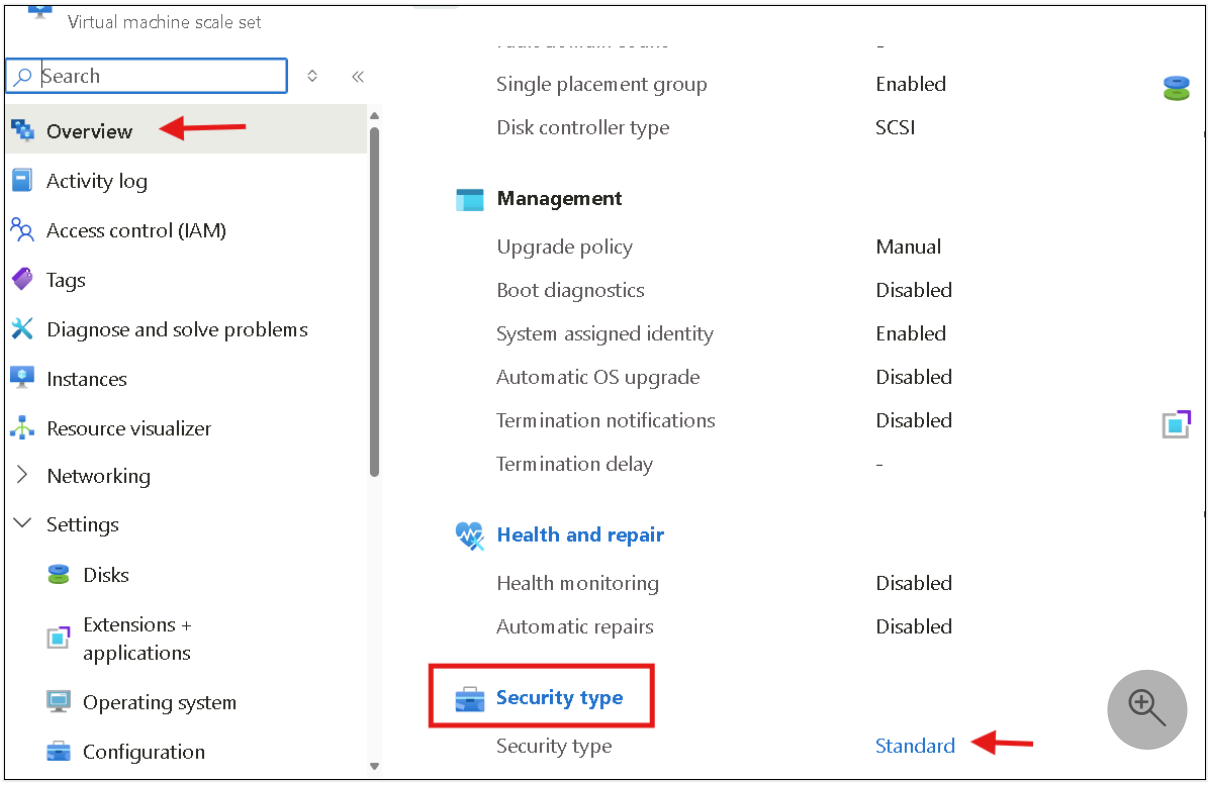
2. **OS Image**: Navigate to `Operating system` under `Settings` -> Click on `Change image reference`.



3. Update the OS Image reference to Gen2-Trusted launch supported OS image. Make sure the source Gen2 image has `TrustedLaunchSupported` security type if using Azure Compute Gallery OS image -> Click **Apply**.

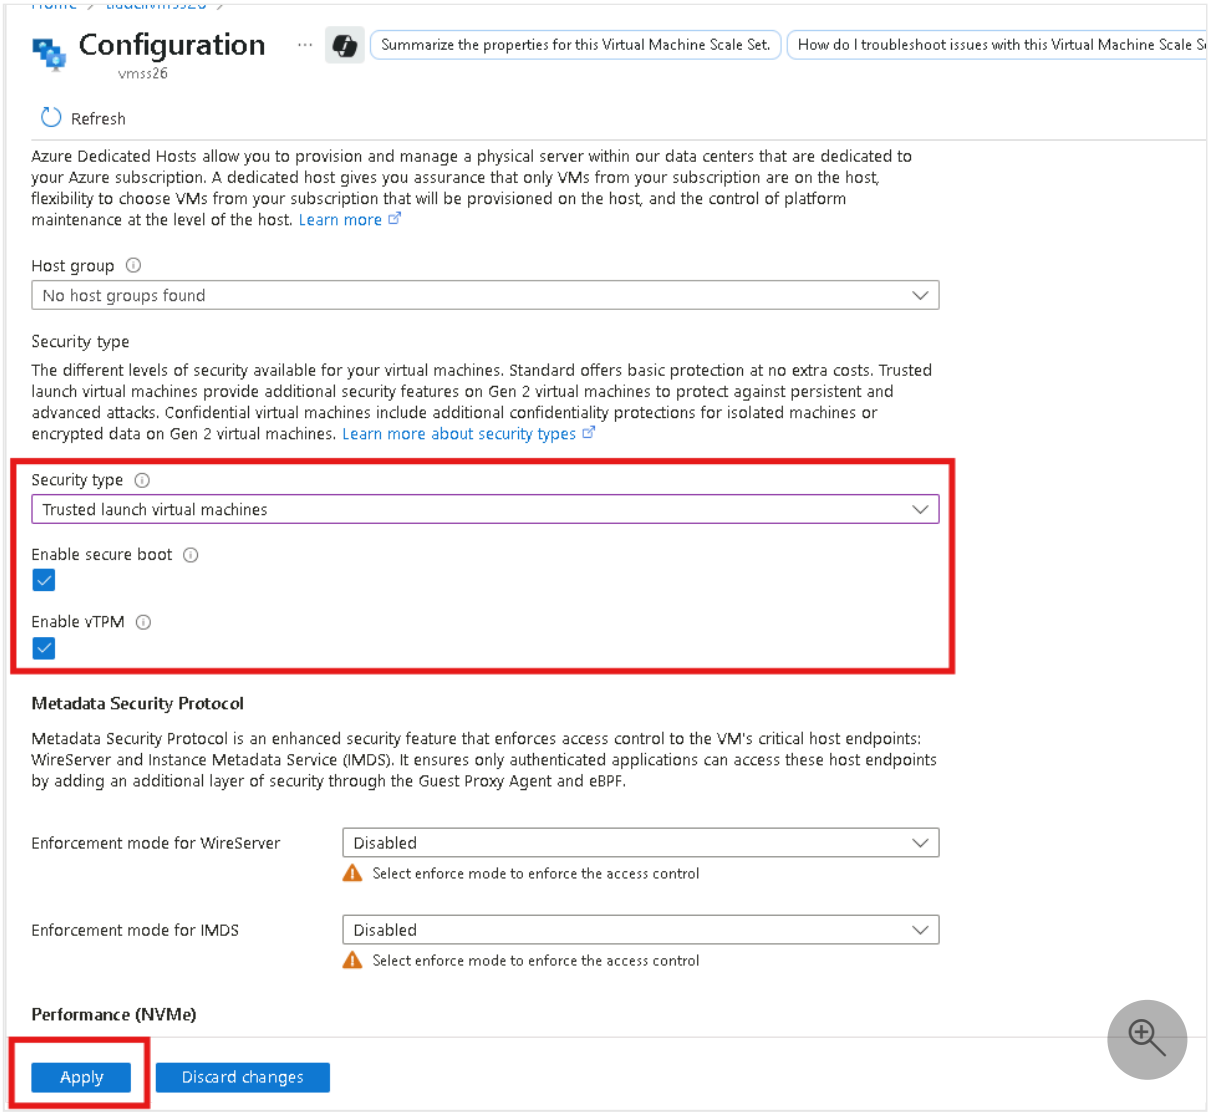


4. **Security type**: Click on **Standard** `Security type` on `Overview` page of scale set OR navigate to `Configuration` under `Settings`.

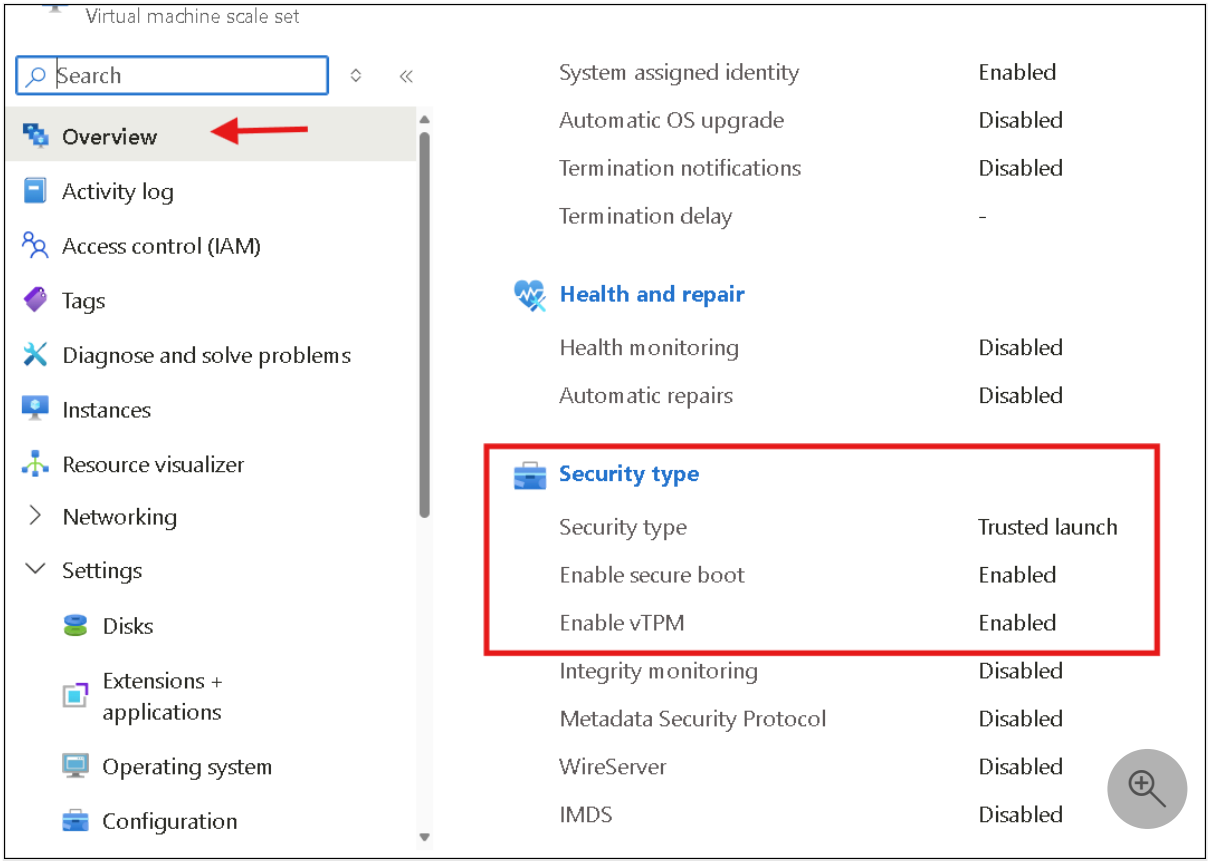


5. Update the security type drop-down on `Configuration` page from `Standard` to `Trusted launch` with `Enable secure boot` and `Enable vTPM` checked to enable Trusted Launch security configuration. Click `Yes` to confirm changes.

> ⓘ Note
>
> - **vTPM** is enabled by default.
> - **Secure Boot** should be enabled (not enabled by default) if you aren't using custom unsigned kernel or drivers. Secure Boot preserves boot integrity and enables foundational security for VM.

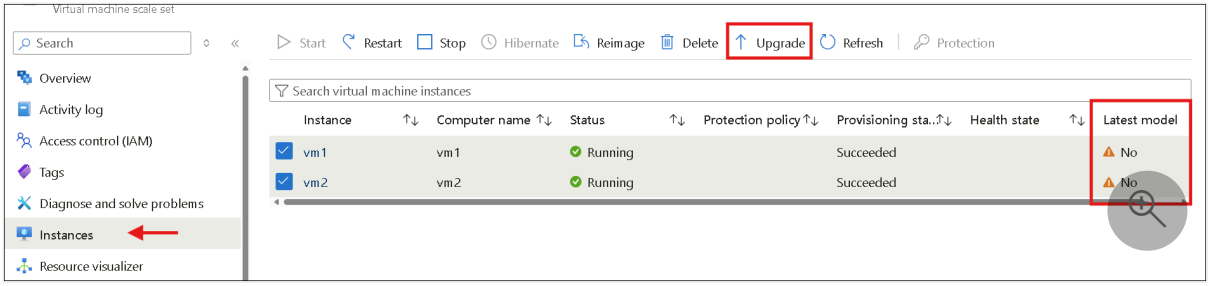


6. Validate the changes on the `Overview` page of scale set.



7. (Recommended) **Guest Attestation Extension**: Add Guest Attestation (GA) extension for Scale set resource, which enables Boot integrity monitoring for Scale set.

8. Update the VM instances manually if Scale set uniform upgrade mode is set to `Manual`.

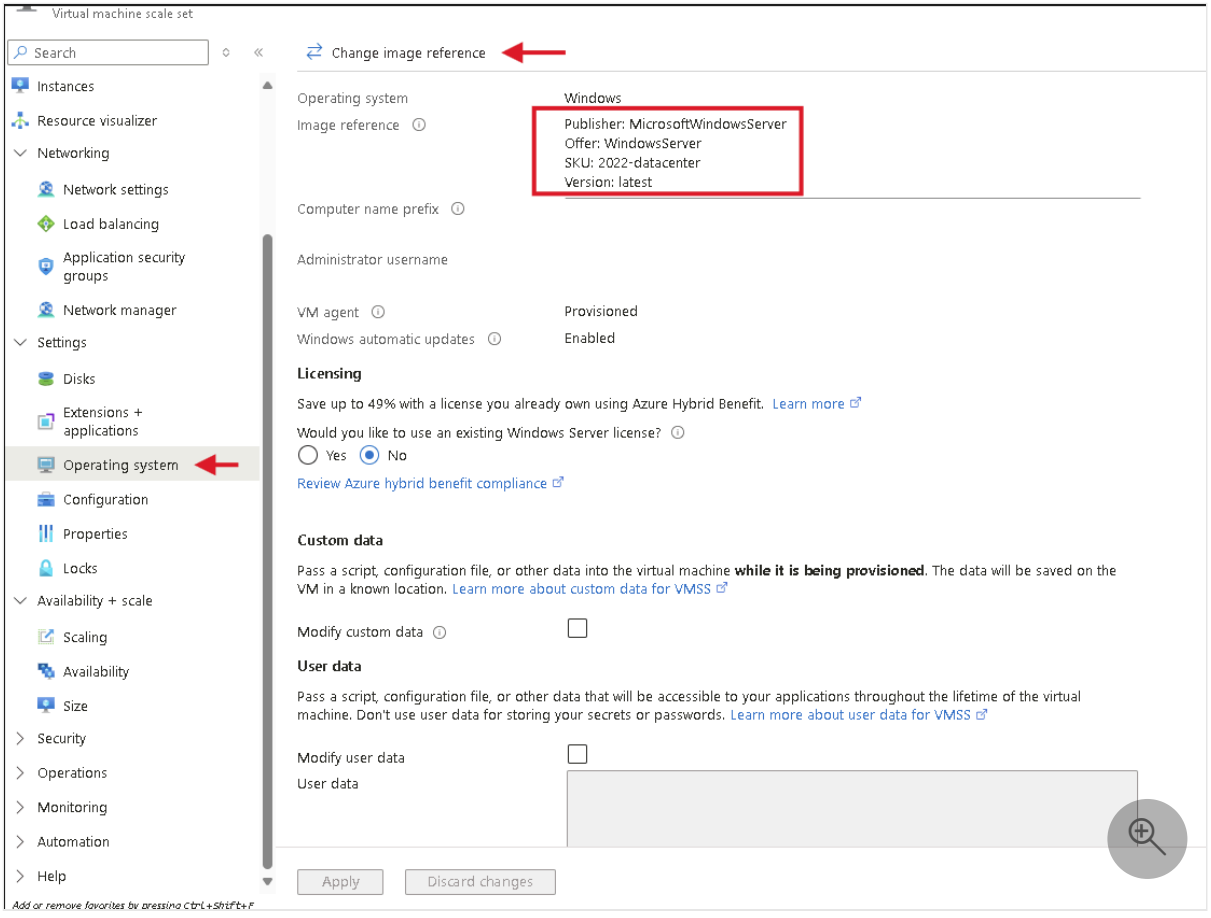


Roll-back

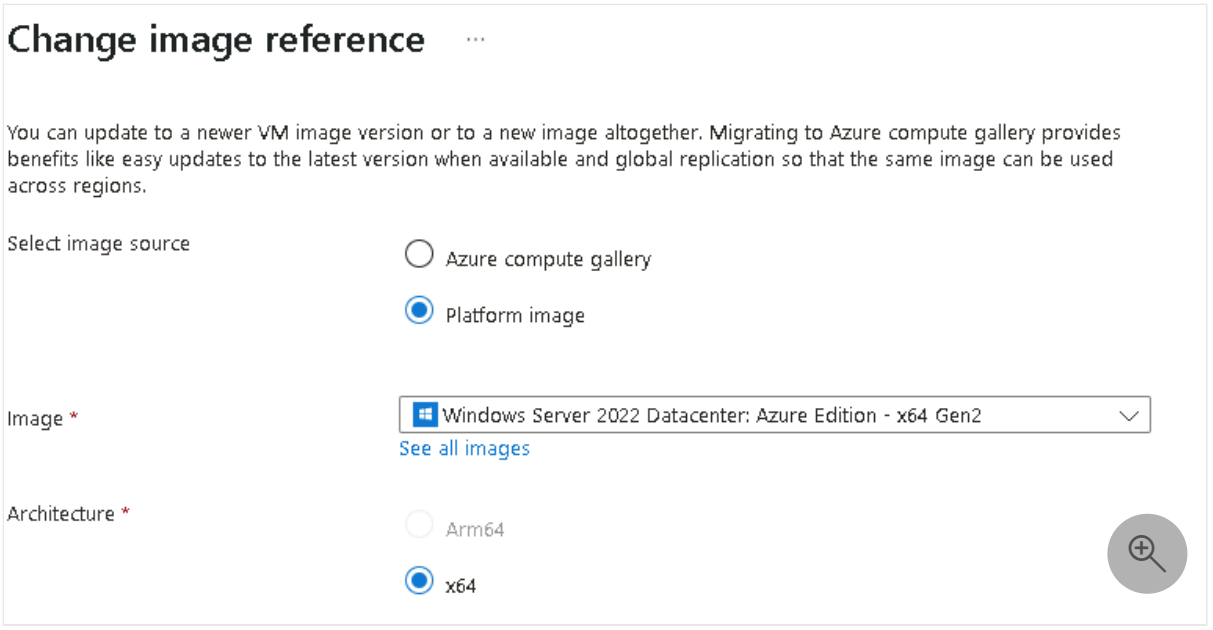
To roll-back changes from Trusted launch to previous known good configuration, you need to set `securityType` of Scale set to **Standard**.

Portal

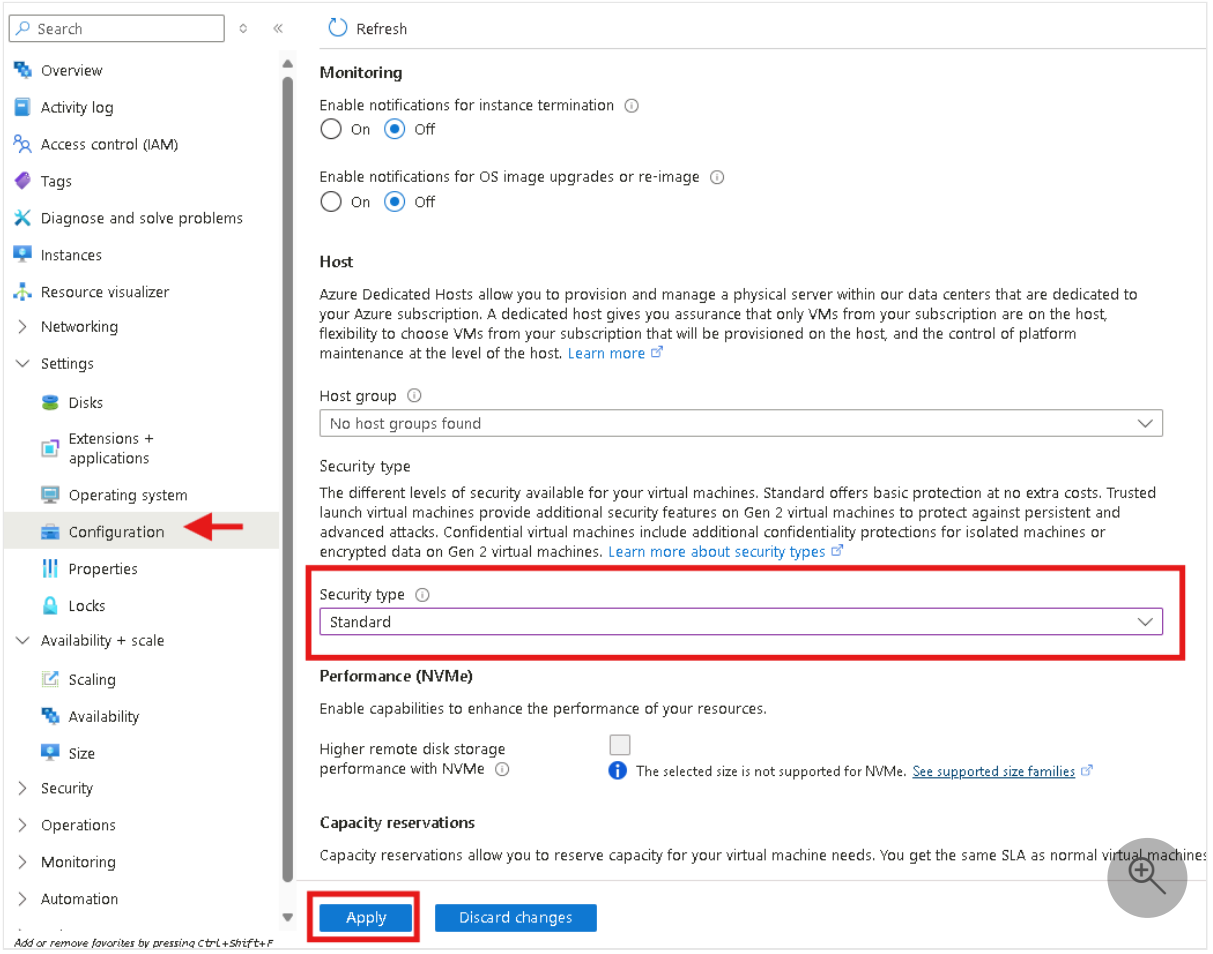
1. **OS Image**: Navigate to `Operating system` under `Settings`. Click on `Change image reference`.



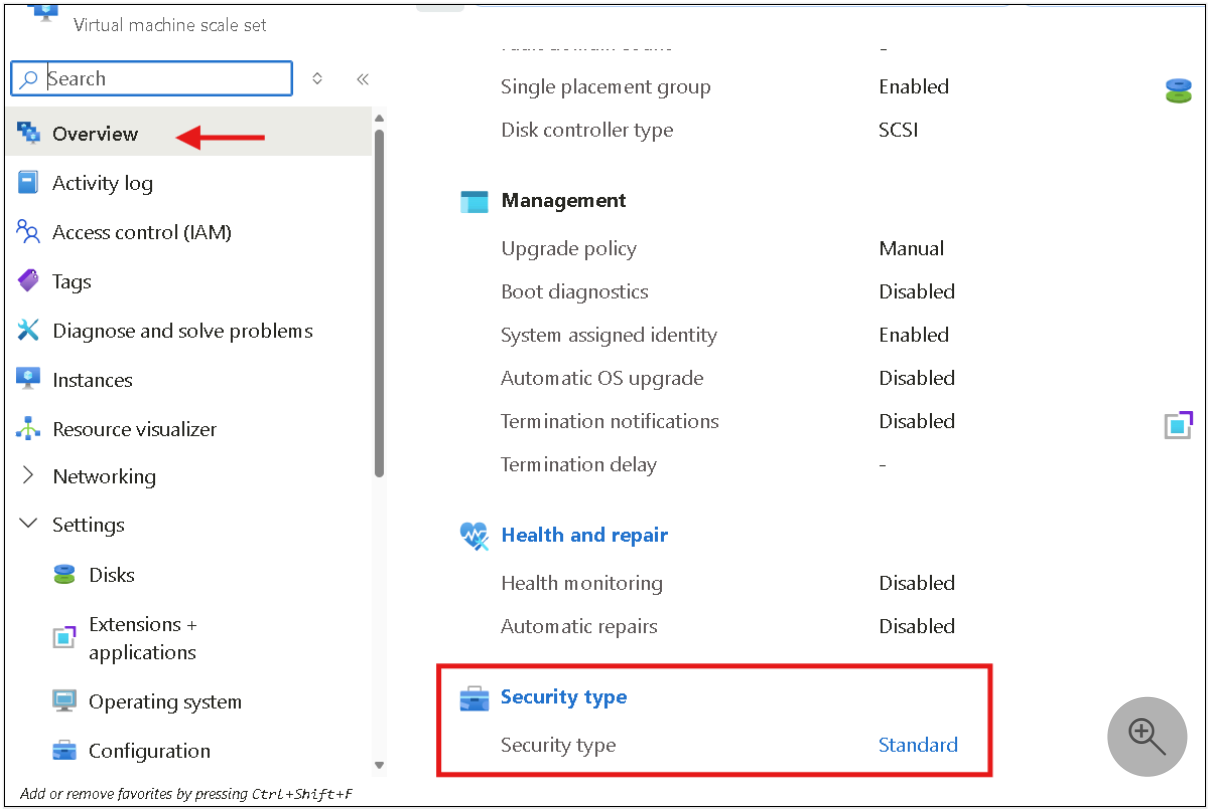
2. Update the OS Image reference to last known good configuration -> Click **Apply**.



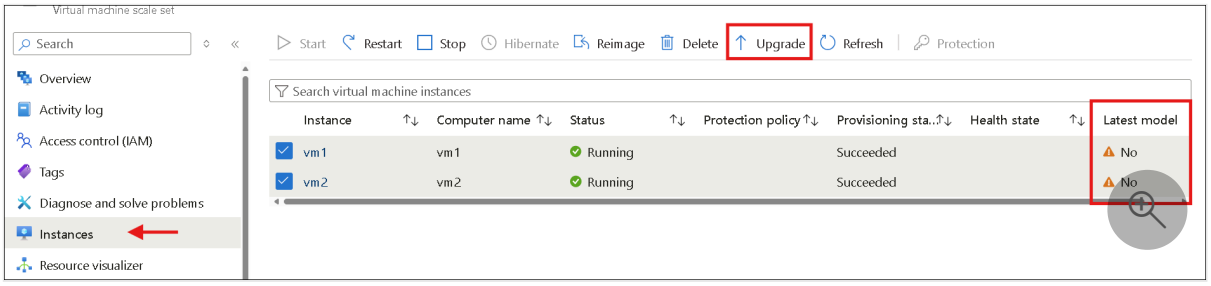
3. **Security type**: Navigate to `Configuration` page under `Settings` -> Update the security type drop-down on `Configuration` page from `Trusted launch` to `Standard` for disabling Trusted Launch security configuration. Click `Yes` to confirm changes.



4. Validate the changes on the `Overview` page of scale set.



5. Update the VM instances manually if Scale set uniform upgrade mode is set to `Manual`.



Next steps

(Recommended) Post-Upgrades enable Boot integrity monitoring to monitor the health of the VM using Microsoft Defender for Cloud.

Learn more about Trusted launch and review frequently asked questions.

Boot integrity monitoring overview

Article • 08/22/2024

To help Azure Trusted Launch better prevent malicious rootkit attacks on virtual machines (VMs), guest attestation through an Azure Attestation endpoint is used to monitor the boot sequence integrity. This attestation is critical to provide the validity of a platform's states.

Your Trusted Launch VM needs Secure Boot and virtual Trusted Platform Module (vTPM) to be enabled so that the attestation extensions can be installed. Microsoft Defender for Cloud offers reports based on Guest Attestation verifying status and that the boot integrity of your VM is set up correctly. To learn more about Microsoft Defender for Cloud integration, see Trusted Launch integration with Microsoft Defender for Cloud.

> **Important**
>
> Automatic Extension Upgrade is now available for the Boot Integrity Monitoring - Guest Attestation extension. For more information, see **Automatic Extension Upgrade**.

Prerequisites

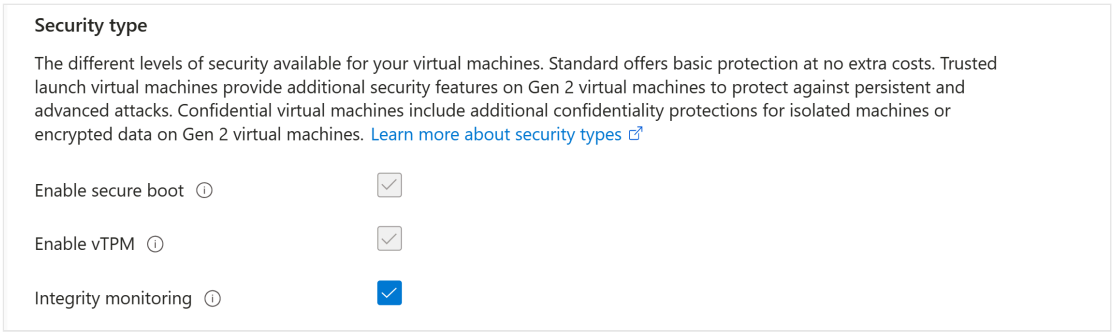
You need an active Azure subscription and a Trusted Launch VM.

Enable integrity monitoring

To enable integrity monitoring, follow the steps in this section.

Azure portal

1. Sign in to the Azure portal.
2. Select the resource (**Virtual Machines**).
3. Under **Settings**, select **Configuration**. On the **Security type** pane, select **Integrity monitoring**.



4. Save the changes.

On the VM **Overview** page, the security type for integrity monitoring should appear as **Enabled**.

This action installs the Guest Attestation extension, which you can refer to via the settings on the **Extensions + Applications** tab.

Troubleshooting guide for Guest Attestation extension installation

This section addresses attestation errors and solutions.

Symptoms

The Azure Attestation extension won't work properly when you set up a network security group (NSG) or a proxy. An error appears that looks similar to "`Microsoft.Azure.Security.WindowsAttestation.GuestAttestation` provisioning failed."

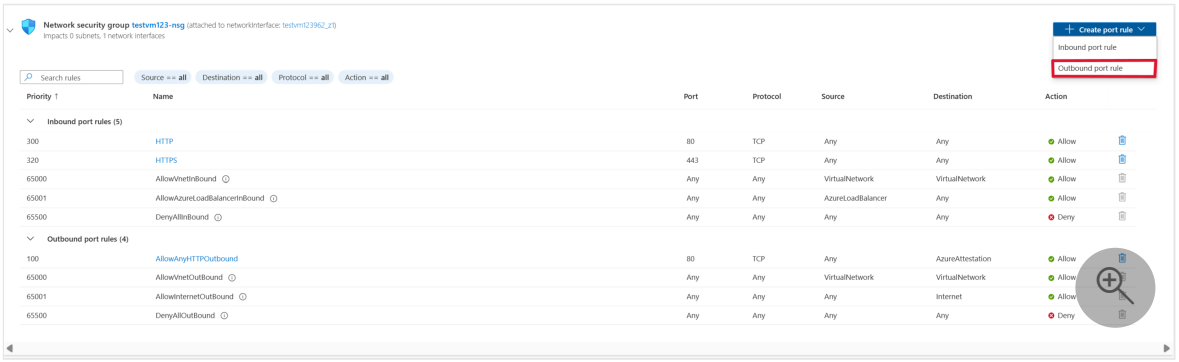
Solutions

In Azure, NSGs are used to help filter network traffic between Azure resources. NSGs contain security rules that either allow or deny inbound network traffic, or outbound network traffic from several types of Azure resources. The Azure Attestation endpoint should be able to communicate with the Guest Attestation extension. Without this

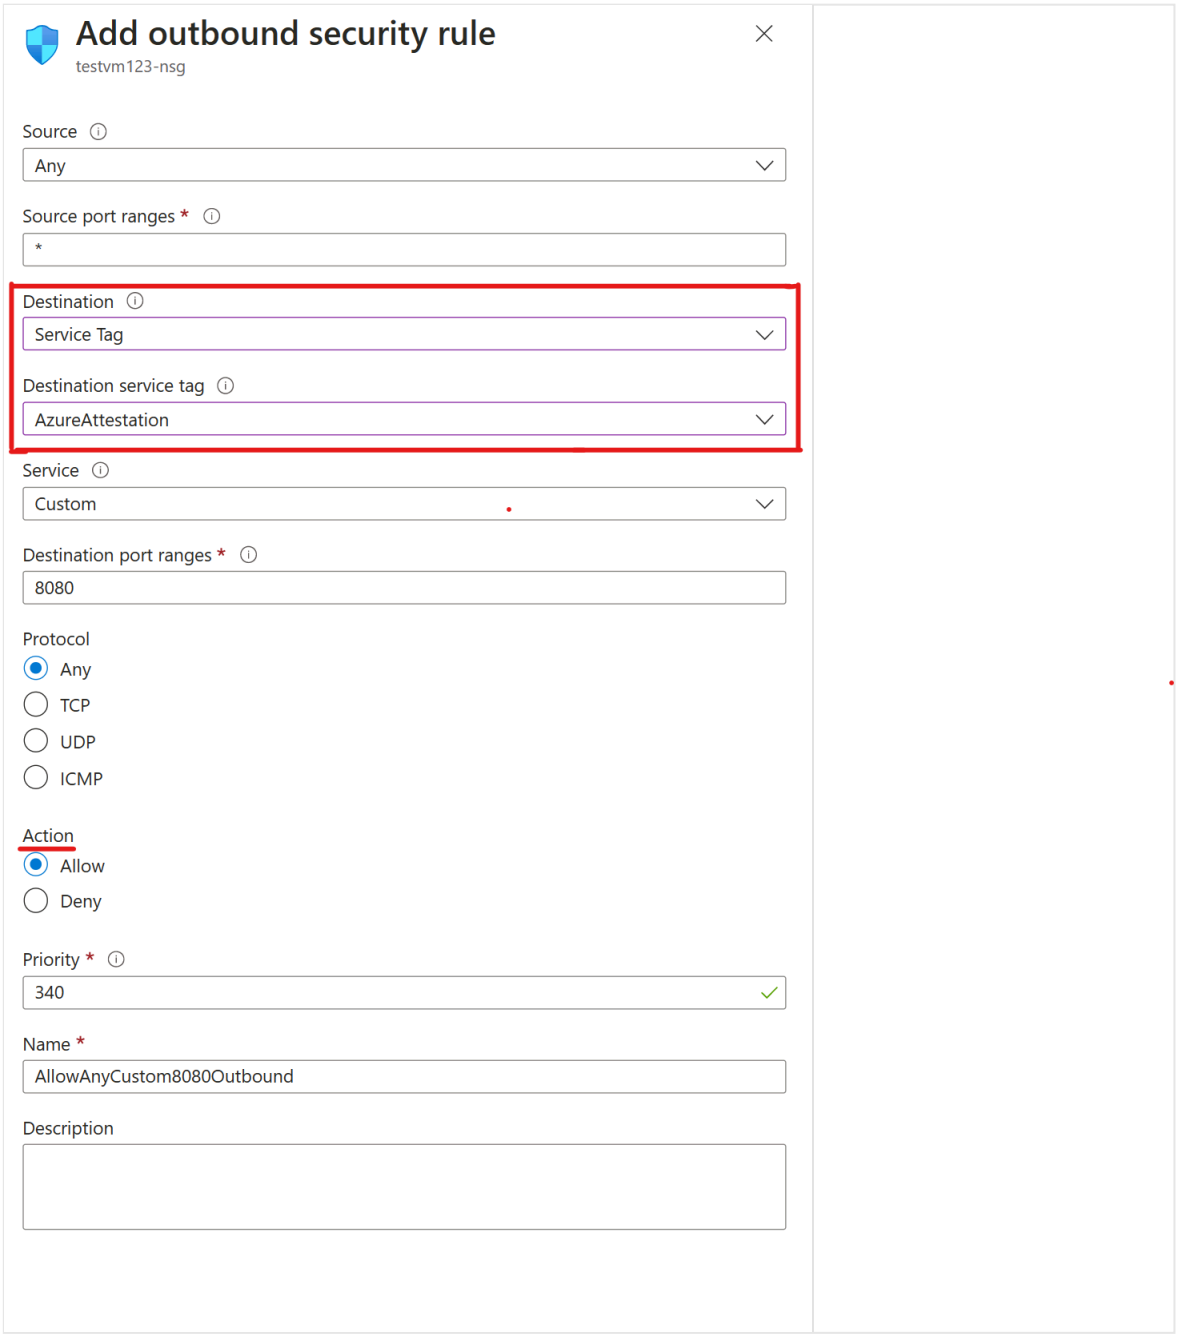
endpoint, Trusted Launch can't access guest attestation, which allows Microsoft Defender for Cloud to monitor the integrity of the boot sequence of your VMs.

To unblock Azure Attestation traffic in NSGs by using service tags:

1. Go to the VM that you want to allow outbound traffic.
2. On the leftmost pane, under **Networking**, select **Networking settings**.
3. Then select **Create port rule** > **Outbound port rule**.



4. To allow Azure Attestation, you make the destination a service tag. This setting allows for the range of IP addresses to update and automatically set rules that allow Azure Attestation. Set **Destination service tag** to **AzureAttestation** and set **Action** to **Allow**.

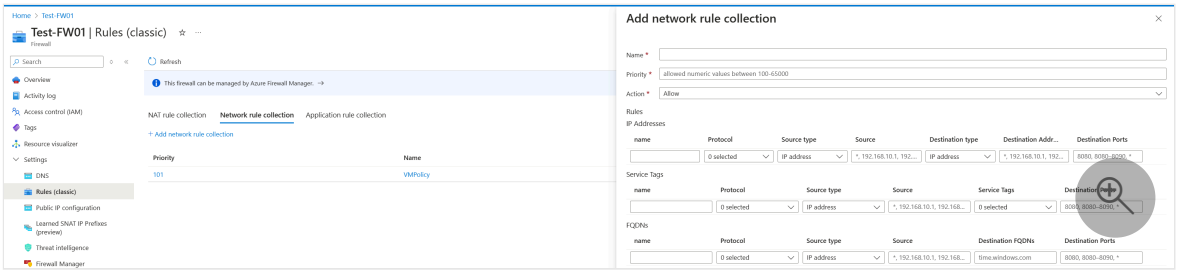


Firewalls protect a virtual network, which contains multiple Trusted Launch VMs. To unblock Azure Attestation traffic in a firewall by using an application rule collection:

1. Go to the Azure Firewall instance that has traffic blocked from the Trusted Launch VM resource.

2. Under **Settings**, select **Rules (classic)** to begin unblocking guest attestation behind the firewall.

3. Under **Network rule collection**, select **Add network rule collection**.



4. Configure the name, priority, source type, and destination ports based on your needs. Set **Service tag name** to **AzureAttestation** and set **Action** to **Allow**.

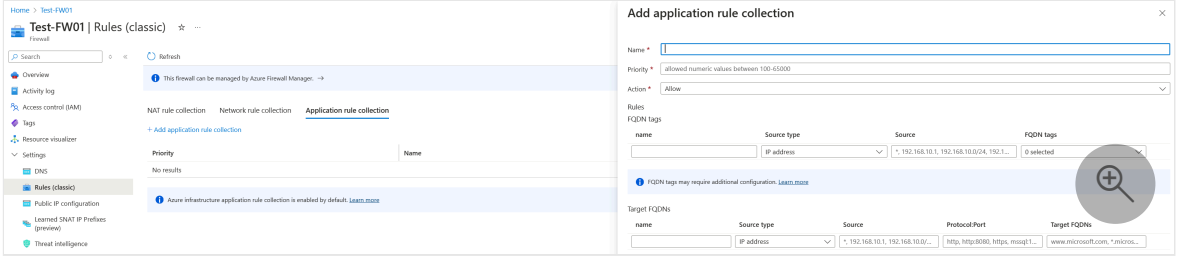
To unblock Azure Attestation traffic in a firewall by using an application rule collection:

1. Go to the Azure Firewall instance that has traffic blocked from the Trusted Launch VM resource.

   The rules collection must contain at least one rule that targets fully qualified domain names (FQDNs).

2. Select the application rule collection and add an application rule.

3. Select a name and a numeric priority for your application rules. Set **Action** for the rule collection to **Allow**.



4. Configure the name, source, and protocol. The source type is for a single IP address. Select the IP group to allow multiple IP addresses through the firewall.

Regional shared providers

Azure Attestation provides a regional shared provider in each available region. You can choose to use the regional shared provider for attestation or create your own

providers with custom policies. Any Microsoft Entra user can access shared providers. The policy associated with it can't be changed.

> **Note**
>
> You can configure the source type, service, destination port ranges, protocol, priority, and name.

Trusted launch FAQs

Summarize this article for me

Frequently asked questions (FAQs) about Azure Trusted Launch feature use cases, support for other Azure features, and fixes for common errors.

Use cases

This section answers questions about use cases for Trusted Launch.

Trusted Launch is supported on both x64 and Arm64 Generation 2 Azure VMs, including Cobalt 100-based Arm64 sizes when using supported images.

Why should I use Trusted Launch? What does Trusted Launch guard against?

Trusted Launch guards against boot kits, rootkits, and kernel-level malware. These sophisticated types of malware run in kernel mode and remain hidden from users. For example:

- **Firmware rootkits**: These kits overwrite the firmware of the virtual machine (VM) BIOS, so the rootkit can start before the operating system (OS).
- **Boot kits**: These kits replace the OS's bootloader so that the VM loads the boot kit before the OS.
- **Kernel rootkits**: These kits replace a portion of the OS kernel, so the rootkit can start automatically when the OS loads.
- **Driver rootkits**: These kits pretend to be one of the trusted drivers that the OS uses to communicate with the VM's components.

What are the differences between Secure Boot and measured boot?

In a Secure Boot chain, each step in the boot process checks a cryptographic signature of the subsequent steps. For example, the BIOS checks a signature on the loader, and the loader checks signatures on all the kernel objects that it loads, and so on. If any of the objects are compromised, the signature doesn't match and the VM doesn't boot. For more information, see Secure Boot.

How does Trusted Launch compare to Hyper-V Shielded VM?

Hyper-V Shielded VM is currently available on Hyper-V only. Hyper-V Shielded VM is typically deployed with Guarded Fabric. A Guarded Fabric consists of a Host Guardian Service (HGS), one or more guarded hosts, and a set of Shielded VMs. Hyper-V Shielded VMs are used in fabrics where the data and state of the VM must be protected from various actors. These actors are both fabric administrators and untrusted software that might be running on the Hyper-V hosts.

Trusted launch can be deployed as a standalone VM or as virtual machine scale sets on Azure without other deployment and management of HGS. All of the Trusted Launch features can be enabled with a simple change in deployment or a checkbox on the Azure portal.

What is VM Guest State (VMGS)?

VM Guest State (VMGS) is specific to Trusted Launch VMs. It's a blob managed by Azure and contains the unified extensible firmware interface (UEFI) Secure Boot signature databases and other security information. The lifecycle of the VMGS blob is tied to that of the OS disk.

Supported features and deployments

This section discusses Trusted Launch supported features and deployments.

Are Arm64 VM sizes and images supported with Trusted Launch?

Yes, Trusted Launch is supported for Arm64 VMs. Arm64 images with Trusted Launch are available in Azure Marketplace. The Cobalt 100-based Arm64 VM series support Trusted Launch. You can deploy Trusted Launch on these Arm64 sizes using validated marketplace images.

Is Azure Compute Gallery supported by Trusted Launch?

Trusted Launch now allows images to be created and shared through the Azure Compute Gallery (formerly Shared Image Gallery). The image source can be:

- An existing Azure VM that is either generalized or specialized.
- An existing managed disk or a snapshot.
- A virtual hard disk (VHD) or an image version from another gallery.

For more information about deploying a Trusted Launch VM by using the Azure Compute Gallery, see Deploy Trusted Launch VMs.

Is Azure Backup supported by Trusted Launch?

Trusted Launch now supports Azure Backup. For more information, see Support matrix for Azure VM backup.

Will Azure Backup continue working after I enable Trusted Launch?

Backups configured with the Enhanced policy continue to take backups of VMs after you enable Trusted Launch.

Are ephemeral OS disks supported by Trusted Launch?

Trusted Launch supports ephemeral OS disks. For more information, see Trusted Launch for ephemeral OS disks.

> **Note**
>
> For Trusted launch VMs created with ephemeral disks, Keys and secrets generated or sealed by the virtual Trusted Platform Module (vTPM) after the creation of the VM might not be persisted across operations like reimaging and platform events like service healing.

Are security features available with Trusted launch applicable to data disks as well?

Trusted launch provides foundational security for Operating system hosted in virtual machine by attesting its boot integrity. Trusted launch security features are applicable for running OS and OS disks only, they aren't applicable to data disks or OS binaries stored in data disks. For more information, see Trusted launch overview

Can a VM be restored by using backups taken before Trusted Launch was enabled?

Backups taken before you upgrade an existing Generation 2 VM to Trusted Launch can be used to restore the entire VM or individual data disks. They can't be used to restore or replace the OS disk only.

How can I find VM sizes that support Trusted Launch?

See the list of Generation 2 VM sizes that support Trusted Launch, which includes both x64 and Arm64 sizes.

Arm64 Cobalt 100-based VM sizes (Dpsv6, Dplsv6, Epsv6) support Trusted Launch. These Arm64 sizes are Gen2 and support Trusted Launch.

Use the following commands to check if a Generation 2 VM size doesn't support Trusted Launch.

CLI

Azure CLI

```
subscription="<yourSubID>"
region="westus"
vmSize="Standard_NC12s_v3"

az vm list-skus --resource-type virtualMachines  --location $region --query "[?
name=='$vmSize'].capabilities" --subscription $subscription
```

How can I validate that my OS image supports Trusted Launch?

See the list of OS versions supported with Trusted Launch.

Both x64 and Arm64 Gen2 images can support Trusted Launch. For Arm64 images, the CLI/PowerShell outputs show `architecture` as `Arm64` and the `features` include `SecurityType` with `TrustedLaunch` or `TrustedLaunchSupported`.

Marketplace OS images

Use the following commands to check if an Azure Marketplace OS image supports Trusted Launch.

CLI

Azure CLI

```
az vm image show --urn "MicrosoftWindowsServer:WindowsServer:2022-datacenter-
azure-edition:latest"
```

The response is similar to the following form. If `hyperVGeneration` is `V2` and `SecurityType` contains `TrustedLaunch` in the output, the Generation 2 OS image supports Trusted Launch.

JSON

```
{
  "architecture": "x64",
  "automaticOsUpgradeProperties": {
    "automaticOsUpgradeSupported": false
  },
  "dataDiskImages": [],
  "disallowed": {
    "vmDiskType": "Unmanaged"
  },
  "extendedLocation": null,
  "features": [
    {
      "name": "SecurityType",
      "value": "TrustedLaunchAndConfidentialVmSupported"
    },
    {
      "name": "IsAcceleratedNetworkSupported",
      "value": "True"
    },
    {
      "name": "DiskControllerTypes",
      "value": "SCSI, NVMe"
    },
    {
      "name": "IsHibernateSupported",
      "value": "True"
    }
  ],
  "hyperVGeneration": "V2",
  "id": "/Subscriptions/00000000-0000-0000-0000-
00000000000/Providers/Microsoft.Compute/Locations/westus/Publishers/MicrosoftWi
ndowsServer/ArtifactTypes/VMImage/Offers/WindowsServer/Skus/2022-datacenter-
azure-edition/Versions/20348.1906.230803",
  "imageDeprecationStatus": {
    "alternativeOption": null,
    "imageState": "Active",
    "scheduledDeprecationTime": null
  },
  "location": "westus",

  },
  "plan": null,
```

```
  "tags": null
}
```

For Arm64 Marketplace images (for example, `Canonical:0001-com-ubuntu-server-jammy:22_04-lts-arm64:latest`), the output shows `"architecture": "Arm64"` with `SecurityType` including `TrustedLaunchSupported`.

Azure Compute Gallery OS image

Use the following commands to check if an Azure Compute Gallery OS image supports Trusted Launch.

CLI

Azure CLI

```
az sig image-definition show `
    --gallery-image-definition myImageDefinition `
    --gallery-name myImageGallery `
    --resource-group myImageGalleryRg
```

The response is similar to the following form. If `hyperVGeneration` is `V2` and `SecurityType` contains `TrustedLaunch` in the output, the Generation 2 OS image supports Trusted Launch.

JSON

```
{
  "architecture": "x64",
  "features": [
    {
      "name": "SecurityType",
      "value": "TrustedLaunchSupported"
    }
  ],
  "hyperVGeneration": "V2",
  "id": "/subscriptions/00000000-0000-0000-0000-

      "max": 32,
      "min": 1
    },
    "vCPUs": {
      "max": 16,
      "min": 1
    }
  },
  "resourceGroup": "myImageGalleryRg",
  "tags": {},
  "type": "Microsoft.Compute/galleries/images"
}
```

How can I validate Secure boot compatibility for Gen1 or Gen2 VM before upgrade to Trusted launch?

To self-evaluate the presence of untrusted boot components or kernel modules in your existing Gen1/Gen2 Linux VMs before migrating to Trusted Launch, you can use the `SBInfo` tool from the Linux Security Package

1. Connect to your Azure Linux Gen1/Gen2 VM.
2. Install the SBInfo tool for the distribution your VM is running. It resides within the Linux Security Package.

Refer to Linux Trusted launch Secure boot validation for distribution-based `SBInfo` tool installation commands.

How do external communication drivers work with Trusted Launch VMs?

Adding component object model (COM) ports require that you disable Secure Boot. COM ports are disabled by default in Trusted Launch VMs.

Trusted launch as default (TLaD)

What is Trusted Launch as default?

Trusted launch as default (TLaD) is currently in preview for all clients AND generally available for Azure portal, PowerShell, and CLI. For more information, see Trusted launch default (Preview).

Does TLaD impacts existing VM & scale sets?

Trusted launch as default doesn't change existing Azure VMs, scale sets already running in your environment

Do I need to update my automation scripts or deployment templates?

You need to update the API versions for following resource providers to validate the Trusted launch default end to end experience as part of the preview:

- `Microsoft.Compute/virtualMachines` – API version `2021-11-01` or higher.
- `Microsoft.Compute/virtualMachineScaleSets` – API version `2021-11-01` or higher.

I'm currently using Gen2 VM or scale set without Trusted Launch and would like to continue using Non-Trusted Launch configuration after the TLaD general availability

Trusted Launch VMs provide you with foundational compute security at no extra cost. We strongly recommend that you don't disable them for new VM or scale set deployments. Reach out to us at Trusted launch default feedback.

See Can I disable Trusted launch for new deployment if you explicitly need to disable Trusted launch.

What could be possible situations where I must bypass Trusted launch defaults for VM or scale set?

You need to explicitly bypass Trusted launch default if one of the following scenarios applies to your Gen2 VM or scale set deployments:

- Gen2 VM is used to generate `TrustedLaunchSupported` or `TrustedLaunchAndConfidentialVMSupported` or `ConfidentialVMSupported` Azure compute gallery images via Azure image builder (AIB) or Packer. OR,
- Gen2 VM is used to create managed images*. OR,
- Gen2 Linux VM requires Hibernation enabled.

> **Note**
>
> For managed images, use Azure Compute Gallery for the latest capabilities. All new features, like ARM64, Trusted Launch, and Confidential VM are only supported through Azure Compute Gallery.

Can I disable Trusted Launch for a new VM deployment?

Trusted Launch VMs provide you with foundational compute security. We **strongly** recommend that you don't disable them for new VM or scale set deployments except if your deployments have dependency on:

- A VM size currently not supported
- Unsupported features with Trusted Launch
- An OS that doesn't support Trusted Launch
- VM used to generate TrustedLaunchSupported Azure compute gallery image

You can use the `securityType` parameter with the `Standard` value to disable Trusted Launch in new VM or scale set deployments by using Azure PowerShell (v10.3.0+) and the Azure CLI (v2.53.0+).

> **Note**
>
> - Parameter `securityType` with value `Standard` can be used if subscription has feature flag `UseStandardSecurityType` registered under `Microsoft.Compute` namespace. Refer to Setup feature in Azure subscription for steps to enable required feature.
> - We don't recommend disabling Secure Boot unless you're using custom unsigned kernel or drivers.

If you need to disable Secure Boot, under the VM's configuration, clear the **Enable Secure Boot** option.

Template

Sample `securityProfile` element of ARM template for using `securityType` parameter with value `Standard`

JSON

```
"securityProfile": {
    "securityType": "Standard",
    "uefiSettings": "[null()]"
}
```

Troubleshooting issues

This section answers questions about specific states, boot types, and common boot issues.

What should I do when my Trusted Launch VM has deployment failures?

This section provides more details on Trusted Launch deployment failures for you to take proper action to prevent them.

JSON

```
Virtual machine <vm name> failed to create from the selected snapshot because the
virtual Trusted Platform Module (vTPM) state is locked.
To proceed with the VM creation, please select a different snapshot without a
locked vTPM state.
For more assistance, please refer to “Troubleshooting locked vTPM state” in FAQ
page at https://aka.ms/TrustedLaunch-FAQ.
```

This deployment error happens when the snapshot or restore point provided is inaccessible or unusable for the following reasons:

1. Corrupt virtual machine guest state (VMGS).
2. vTPM in a locked state.
3. One or more critical vTPM indices are in an invalid state.

The listed reasons can happen if a user or workload running on the virtual machine sets the lock on vTPM or modifies critical vTPM indices that leave the vTPM in an invalid state.

Retrying with the same snapshot or restore point results in the same failure.

Resolution:

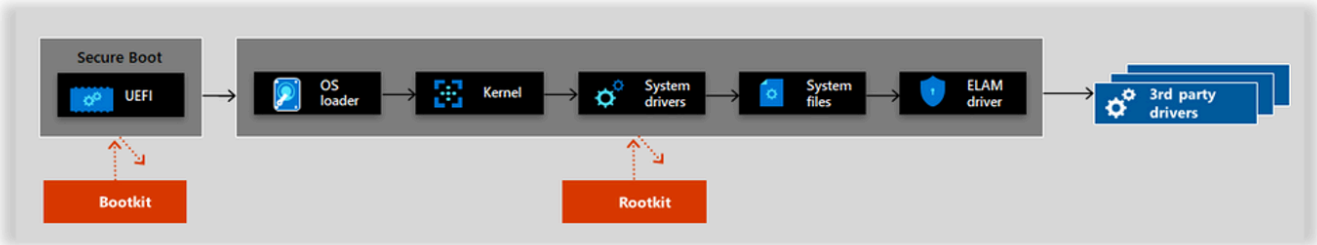
1. On the source Trusted Launch VM where the snapshot or restore point was generated, the vTPM errors must be rectified.
   a. For vTPM state modified by a workload on the virtual machine, you need to use the same to check the error states and bring the vTPM to a non-error state.

b. For vTPM state modified using trusted platform module (TPM) tools, then you should use the same tools to check the error states and bring the vTPM to a non-error state.

Once the snapshot or restore point is free from these errors, you can use same to create a new Trusted Launch VM.

Why is the Trusted Launch VM not booting correctly?

If unsigned components are detected from the UEFI (guest firmware), bootloader, OS, or boot drivers, a Trusted Launch VM doesn't boots. The Secure Boot setting in the Trusted Launch VM fails to boot if unsigned or untrusted boot components are encountered during the boot process and reports as a Secure Boot failure.

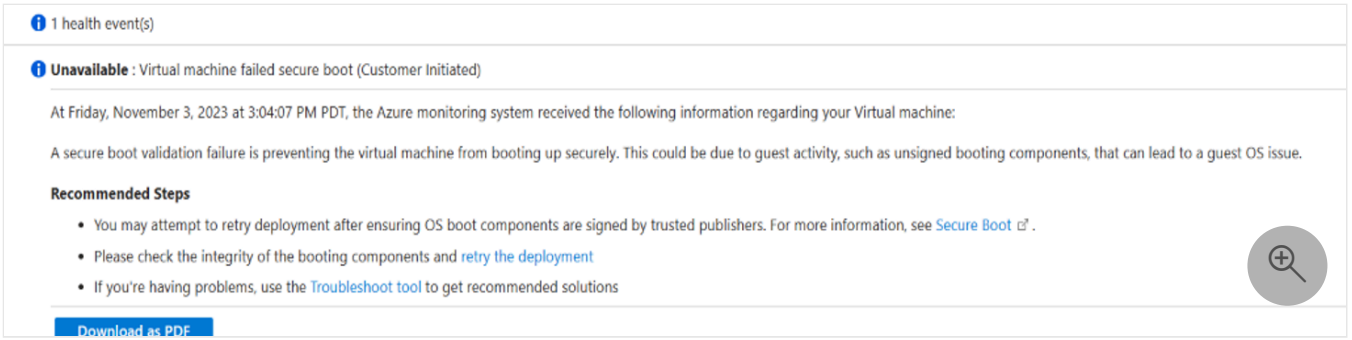


> **Note**
>
> Trusted Launch VMs that are created directly from an Azure Marketplace image shouldn't encounter Secure Boot failures. Azure Compute Gallery images with an original image source of Azure Marketplace and snapshots created from Trusted Launch VMs should also not encounter these errors.

How would I verify a no-boot scenario in the Azure portal?

When a VM becomes unavailable from a Secure Boot failure, `no-boot` means that VM has an OS component not signed by a trusted authority, which blocks booting a Trusted Launch VM. On VM deployment, you might see information from resource health within the Azure portal stating that there's a validation error in Secure Boot.

To access resource health from the VM configuration page, go to **Resource Health** under the **Help** pane.



If you verified that the no-boot is caused due to Secure Boot failure:

1. The image you're using is an older version that might have one or more untrusted boot components and is on a deprecation path. To remedy an outdated image, update to a supported newer image version.
2. The image you're using might be built outside of a marketplace source or the boot components modified and contain unsigned or untrusted boot components. To verify whether your image has unsigned or untrusted boot components, see the following section, "Verify Secure Boot failures."
3. If the preceding two scenarios don't apply, the VM is potentially infected with malware (bootkit/rootkit). Consider deleting the VM and re-creating a new VM from the same source image while you evaluate all the software being installed.

Why does my Trusted Launch VM show 50 MB less memory?

With Trusted Launch, an execution environment commonly known as "the paravisor" is created and runs inside the VM. Typically, about 50MB of memory is used by the paravisor and would show as "reserved" within the guest Operating System.

Verify Secure Boot failures

This section helps you verify Secure Boot failures.

Linux Trusted launch virtual machines

To verify which boot components are responsible for Secure Boot failures within an Azure Linux Trusted Launch VM, you can use the `SBInfo` tool from the Linux Security Package

1. Turn off Secure Boot.
2. Connect to your Azure Linux Trusted Launch VM.
3. Install the SBInfo tool for the distribution your VM is running. It resides within the Linux Security Package

Debian-based distributions

These commands apply to Ubuntu, Debian, and other Debian-based distributions.

Bash

```
echo "deb [arch=amd64] http://packages.microsoft.com/repos/azurecore/ trusty
main" | sudo tee -a /etc/apt/sources.list.d/azure.list

echo "deb [arch=amd64] http://packages.microsoft.com/repos/azurecore/ xenial
main" | sudo tee -a /etc/apt/sources.list.d/azure.list

echo "deb [arch=amd64] http://packages.microsoft.com/repos/azurecore/ bionic
main" | sudo tee -a /etc/apt/sources.list.d/azure.list

wget https://packages.microsoft.com/keys/microsoft.asc

wget https://packages.microsoft.com/keys/msopentech.asc

sudo apt-key add microsoft.asc && sudo apt-key add msopentech.asc

sudo apt update && sudo apt install azure-security
```

After you install the Linux Security Package for your distribution, run the `sbinfo` command to verify which boot components are responsible for Secure Boot failures by displaying all unsigned modules, kernels, and bootloaders.

Bash

```
sudo sbinfo -u -m -k -b
```

To learn more about the SBInfo diagnostic tool, you can run `sudo sbinfo -help`.

Why am I getting a boot integrity monitoring fault?

Trusted Launch for Azure VMs is monitored for advanced threats. If such threats are detected, an alert is triggered. Alerts are only available if enhanced security features in Microsoft Defender for Cloud are enabled.

Microsoft Defender for Cloud periodically performs attestation. If the attestation fails, a medium-severity alert is triggered. Trusted Launch attestation can fail for the following reasons:

- The attested information, which includes a log of the Trusted Computing Base (TCB), deviates from a trusted baseline (like when Secure Boot is enabled). Any deviation

indicates that untrusted modules were loaded and the OS might be compromised.
- The attestation quote couldn't be verified to originate from the vTPM of the attested VM. The verification failure indicates malware is present and might be intercepting traffic to the TPM.
- The attestation extension on the VM isn't responding. An unresponsive extension indicates a denial-of-service attack by malware or an OS admin.

Certificates

This section provides information on certificates.

How can I establish root of trust with Trusted Launch VMs?

The virtual TPM AK public certificate provides you with visibility for information on the full certificate chain (Root and Intermediate Certificates) to help you validate trust in the certificate and root chain. It provides information on instance properties so that you can trace back to the full chain. It ensures that you continually have the highest security posture for Trusted Launch

Download instructions

Package certificates, composed of .p7b (Full Certificate Authority) and .cer (Intermediate CA), reveal the signing and certificate authority. Copy the relevant content and use certificate tooling to inspect and assess details of certificates.

▼ Select to download the .crt that follows for the Azure Virtual TPM Root Certificate Authority 2023

Azure Virtual TPM Root Certificate Authority 2023

What Microsoft owned trusted certificates are built into Azure VMs?

For Windows VMs, Windows CA certificate is built in UEFI firmware. For Linux VMs, Microsoft UEFI CA certificate is built in UEFI firmware.

For Azure Linux VMs only, `Azure Services Linux Kmod PCA` certificate is also added in UEFI firmware for all Linux distributions. Linux Kmod PCA is used to sign Microsoft owned kernel modules.

Linux Kmod PCA certificate is added to make customer experience smoother when using Microsoft solutions like Azure Site Recovery (Site recovery) which installs a kernel module. The

Site recovery kernel module loads without any customer action to supply a key as Site recovery kernel module is signed using the trusted 'Azure Services Linux Kmod PCA' certificate.

Download instructions

Package certificates, composed of .p7b and .cer reveal the signing and certificate authority. Copy the relevant content and use certificate tooling to inspect and assess details of certificates.

▼ Select to download the .crt that follows for the Microsoft Windows CA

Microsoft Windows CA

▼ Select to download the .crt that follows for the Microsoft UEFI CA

Microsoft UEFI CA

▼ Select to view the .p7b content

Azure services Linux kmod PCA certificate:

Secure Boot UEFI keys

Article • 02/28/2025

For certain advanced scenarios, it's necessary for customizing secure boot keys. The secure boot UEFI keys customization allows you to modify unified extensible firmware interface (UEFI) keys – PK, KEK, DB, DBX – in your image for a secure boot capable Azure virtual machine (VM) (Trusted Launch and Confidential VM). With this feature, UEFI keys can be fully replaced or appended to default key databases.

When a secure boot Azure VM is deployed, signatures of all the boot components such as UEFI, shim/bootloader, kernel, and kernel modules/drivers are verified during the boot process. Verification fails if the boot component signatures don't match with a key in the trusted key databases, and the VM fails to boot. This failure can occur if: a component is signed by a key not found in the trusted key databases, the signing key is listed in the revoked key database, or a component is unsigned. Through custom secure boot UEFI keys, the necessary signatures can be supplied for a successful VM boot.

UEFI key customization is offered through Azure compute gallery resources. If you currently use a Marketplace image to create a Trusted Launch VM, you must first create Azure compute gallery resources using the Marketplace image to modify UEFI keys.

> **Note**
>
> Customizing UEFI keys is for advanced customers intimately familiar with inner workings of secure boot technology.

Prerequisites

The following Azure Compute Gallery resources are necessary for customizing UEFI keys:

- Gallery
- Image definition
- Image version

Currently, UEFI key customization is available only through the REST API.

You must attach a *VM image version* resource to a *VM image definition* resource with security-type set to *TrustedLaunchSupported* or *TrustedLaunchAndConfidentialVmSupported*. For detailed instructions on how to create an image definition resource, see Create an image definition and an image version. To create a VM image definition resource, you must also create a gallery resource. You can

choose the Azure portal, PowerShell, CLI, or REST API to create gallery and image definition resources.

ARM template

A generic ARM template is provided as a sample for creating an image version resource. For customizing UEFI keys, you also need to include *security-profile* block in the image version resource. Each scenario in the Scenarios section provides details on what goes inside the *securityProfile* block.

JSON

```
{
    "apiVersion": "2022-03-03",
    "type": "Microsoft.Compute/galleries/images/versions",
    "dependsOn": [
        "[concat('Microsoft.Compute/galleries/', parameters('galleryName'),
'/images/', parameters('imageDefinitionName'))]"
    ],
    "name": "[concat(parameters('galleryName'), '/',
parameters('imageDefinitionName'), '/', parameters('versionName'))]",
    "location": "[parameters('location')]",
    "properties": {
        "publishingProfile": {
            "replicaCount": "[parameters('defaultReplicaCount')]",
            "targetRegions": "[parameters('regionReplications')]",
            "excludeFromLatest": "[parameters('excludedFromLatest')]",
            "replicationMode": "[parameters('replicationMode')]"
        },
        "storageProfile": {
            "source": {
                "id": "[parameters('sourceVmId')]"
            }
        },
        "safetyProfile": {
            "allowDeletionOfReplicatedLocations": "
[parameters('allowDeletionOfReplicatedLocations')]"
        },
        "securityProfile": {}
    },
    "tags": {}
}
```

Scenarios

This section contains instructions on how to customize UEFI keys for common scenarios.

Scenario 1: Replace all UEFI keys

In this scenario, you fully replace all default keys (PK, KEK, DB, DBX) available in a Trusted Launch VM.

1. Create certificates and/or keys for each or PK, KEK, DB, and DBX. Refer to the Useful links section for detailed instructions for various operating systems.
2. Create a new image version. Use the following *securityProfile* ARM template block with the image version creation Generic ARM template. Replace `Base64 formatted certificate` and `Base64 formatted sha256 hash` JSON values with the real values.

JSON

```
"securityProfile": {
    "uefiSettings": {
        "signatureTemplateNames": [
            "NoSignatureTemplate"
        ],
        "additionalSignatures": {
            "pk": {
                "type": "x509",
                "value": [
                    "Base64 formatted certificate"
                ]
            },
            "kek": [
                {
                    "type": "x509",
                    "value": [
                        "Base64 formatted certificate"
                    ]
                }
            ],
            "db": [
                {
                    "type": "x509",
                    "value": [
                        "Base64 formatted certificate",
                        "Base64 formatted certificate"
                    ]
                }
            ],
            "dbx": [
                {
                    "type": "x509",
                    "value": [
                        "Base64 formatted certificate",
                        "Base64 formatted certificate"
                    ]
                },
                {
```

```
                    "type": "sha256",
                    "value": [
                        "Base64 formatted sha256 hash",
                        "Base64 formatted sha256 hash"
                    ]
                }
            ]
        }
    }
}
```

3. Create a Trusted Launch VM using Azure portal, PowerShell, CLI, or REST API with the same source image as the one you created using Azure compute gallery resources.
4. Once the Trusted Launch VM is in the *running* state, verify that your custom UEFI keys are in the UEFI key databases.

Scenario 2: Append keys to DB and DBX to a signature template

In this scenario, you append DB and DBX keys to the default values available in a Trusted Launch VM.

1. Create certificates and/or keys for each or DB and DBX. Refer to the Useful links section for detailed instructions for various operating systems.
2. Create a new image version. Use the following *securityProfile* ARM template block with the image version creation Generic ARM template. Replace `Base64 formatted certificate` and `Base64 formatted sha256 hash` JSON values with the real values.

JSON

```
"securityProfile": {
    "uefiSettings": {
        "signatureTemplateNames": [
            "MicrosoftUefiCertificateAuthorityTemplate"
        ],
        "additionalSignatures": {
            "db": [
                {
                    "type": "x509",
                    "value": [
                        "Base64 formatted certificate",
                        "Base64 formatted certificate"
                    ]
                }
            ],
            "dbx": [
                {
```

```
                    "type": "sha256",
                    "value": [
                        "Base64 formatted sha256 hash",
                        "Base64 formatted sha256 hash"
                    ]
                }
            ]
        }
    }
}
```

3. Create a Trusted Launch VM using Azure portal, PowerShell, CLI, or REST API with the same source image as the one you created using Azure compute gallery resources.
4. Once the Trusted Launch VM is in the *running* state, verify that your custom UEFI keys are in the UEFI key databases.

Scenario 3: Apply multiple signature templates

In this scenario, you replace default signature templates and inject multiple signature templates (UEFI, Windows) into a Trusted Launch VM.

1. Create a new image version. Use the following *securityProfile* ARM template block with the image version creation Generic ARM template.

JSON

```
"securityProfile": {
    "uefiSettings": {
        "signatureTemplateNames": [
            "MicrosoftUefiCertificateAuthorityTemplate",
            "MicrosoftWindowsTemplate"
        ]
    }
}
```

2. Create a Trusted Launch VM using Azure portal, PowerShell, CLI, or REST API with the same source image as the one you created using Azure compute gallery resources.
3. Once the Trusted Launch VM is in the *running* state, verify that your custom UEFI keys are in the UEFI key databases.

Verify keys in UEFI databases

To verify the keys stored in UEFI databases, use the following commands in the command line (SSH) on the desired VM.

```Bash
// For key(s) added to db
$ mokutil --db

// For keys(s) added to dbx
$ mokutil --dbx
```

Verify that the displayed keys are the ones supplied with the image version.

Considerations

- Clouds and regions are supported
- For public cloud, all regions are supported except the following regions: Austria East, Belgium Central, Chile Central, Indonesia Central, Israel Northwest, Jio India Central, Jio India West, Malaysia South, Malaysia West, Mexico Central, Qatar Central, South Central US 2, Southeast US, Southeast US 3, Switzerland West, Taiwan North, Taiwan Northwest, UK West, and West India
- USGov and China clouds are currently not supported

Useful links

- How to convert Base64 certificates: Base64 certificate encoding
- How to convert X.509 certificate to Base64: X.509 Certificate Public Key in Base64
- How to sign things for secure boot: Ubuntu, Redhat, Debian, Oracle

Enable just-in-time access

Defender for Servers in Microsoft Defender for Cloud provides a just-in-time machine access feature.

You can use Microsoft Defender for Cloud's just-in-time access to protect your Azure VMs from unauthorized network access. Many times firewalls contain allow rules that leave your VMs vulnerable to attack. JIT lets you allow access to your VMs only when the access is needed, on the ports needed, and for the period of time needed.

In this article, you learn how to set up and use just-in-time access, including how to:

- Enable just-in-time on VMs from the Azure portal or programmatically
- Request access to a VM that has just-in-time access enabled from the Azure portal or programmatically
- Audit just-in-time access activity to make sure your VMs are secured appropriately

Prerequisites

- Microsoft Defender for Servers Plan 2 must be enabled on the subscription.
- Supported VMs: VMs deployed through Azure Resource Manager, VMs protected by Azure Firewalls on the same VNET as the VM, AWS EC2 instances (Preview).
- Unsupported VMs: VMs deployed with classic deployment models, VMs protected by Azure Firewalls controlled by Azure Firewall Manager.
- To set up just-in-time access on your AWS VMs, you need to connect your AWS account to Microsoft Defender for Cloud.
- To create a JIT policy, the policy name, together with the targeted VM name, must not exceed a total of 56 characters.
- You need **Reader** and **SecurityReader** permissions, or a custom role can view the JIT status and parameters.
- For a custom role, assign the permissions summarized in the table. To create a least-privileged role for users that only need to request JIT access to a VM, use the Set-JitLeastPrivilegedRole script.

Expand table

User action	Permissions to set
Configure or edit a JIT policy for a VM	*Assign these actions to the role:* • On the scope of a subscription (or resource group when using API or PowerShell only) that is associated with the VM: `Microsoft.Security/locations/jitNetworkAccessPolicies/write` • On the scope of a subscription (or resource group when using API or PowerShell only) of VM: `Microsoft.Compute/virtualMachines/write`
Request JIT access to a VM	*Assign these actions to the user:* • `Microsoft.Security/locations/jitNetworkAccessPolicies/initiate/action` • `Microsoft.Security/locations/jitNetworkAccessPolicies/*/read` • `Microsoft.Compute/virtualMachines/read` • `Microsoft.Network/networkInterfaces/*/read` • `Microsoft.Network/publicIPAddresses/read`
Read JIT policies	*Assign these actions to the user:* • `Microsoft.Security/locations/jitNetworkAccessPolicies/read` • `Microsoft.Security/locations/jitNetworkAccessPolicies/initiate/action` • `Microsoft.Security/policies/read` • `Microsoft.Security/pricings/read` • `Microsoft.Compute/virtualMachines/read` • `Microsoft.Network/*/read`

> ⓘ **Note**
>
> Only the `Microsoft.Security` permissions are relevant for AWS. To create a least-privileged role for users that only need to request JIT access to a VM, use the Set-JitLeastPrivilegedRole script.

Work with JIT VM access using Microsoft Defender for Cloud

You can use Defender for Cloud or you can programmatically enable JIT VM access with your own custom options, or you can enable JIT with default, hard-coded parameters from Azure virtual machines.

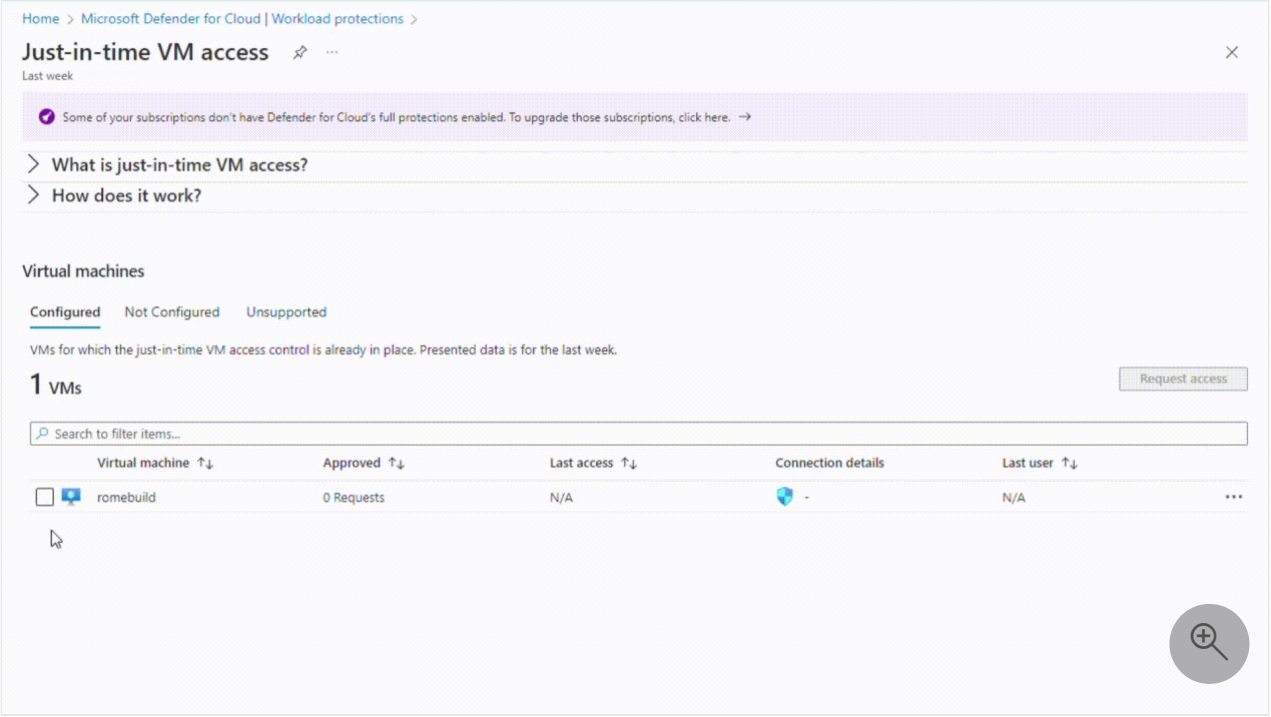
Just-in-time VM access shows your VMs grouped into:

- **Configured** - VMs configured to support just-in-time VM access, and shows:
  - the number of approved JIT requests in the last seven days
  - the last access date and time
  - the connection details configured
  - the last user
- **Not configured** - VMs without JIT enabled, but that can support JIT. We recommend that you enable JIT for these VMs.
- **Unsupported** - VMs that don't support JIT because:
  - Missing network security group (NSG) or Azure Firewall - JIT requires an NSG to be configured or a Firewall configuration (or both)
  - Classic VM - JIT supports VMs that are deployed through Azure Resource Manager.
  - Other - The JIT solution is disabled in the security policy of the subscription or the resource group.

Enable JIT on your VMs from Microsoft Defender for Cloud

From Defender for Cloud, you can enable and configure the JIT VM access.

1. Open **Workload protections** and, in the advanced protections, select **Just-in-time VM access**.



2. In the **Not configured** virtual machines tab, mark the VMs to protect with JIT and select **Enable JIT on VMs**.

   The JIT VM access page opens listing the ports that Defender for Cloud recommends protecting:

- 22 - SSH
- 3389 - RDP
- 5985 - WinRM
- 5986 - WinRM

To customize the JIT access:

a. Select **Add**.

b. Select one of the ports in the list to edit it or enter other ports. For each port, you can set the:

- **Protocol**
- **Allowed source IPs**
- **Maximum request time**

c. Select **OK**.

3. To save the port configuration, select **Save**.

Edit the JIT configuration on a JIT-enabled VM using Defender for Cloud

You can modify a VM's just-in-time configuration by adding and configuring a new port to protect for that VM, or by changing any other setting related to an already protected port.

To edit the existing JIT rules for a VM:

1. Open **Workload protections** and, in the advanced protections, select **Just-in-time VM access**.
2. In the **Configured** virtual machines tab, right-click on a VM and select **Edit**.
3. In the **JIT VM access configuration**, you can either edit the list of port or select Add a new custom port.
4. When you finish editing the ports, select **Save**.

Request access to a JIT-enabled VM from Microsoft Defender for Cloud

When a VM has JIT enabled, you have to request access to connect to it. You can request access in any of the supported ways, regardless of how you enabled JIT.

1. From the **Just-in-time VM access** page, select the **Configured** tab.
2. Select the VMs you want to access.
    - The icon in the **Connection Details** column indicates whether JIT is enabled on the network security group or firewall. If it's enabled on both, only the firewall icon appears.
    - The **Connection Details** column shows the user and ports that can access the VM.
3. Select **Request access**. The **Request access** window opens.
4. Under **Request access**, select the ports that you want to open for each VM, the source IP addresses that you want the port opened on, and the time window to open the ports.
5. Select **Open ports**.

> **Note**
>
> If a user who is requesting access is behind a proxy, you can enter the IP address range of the proxy.

Other ways to work with JIT VM access

Azure virtual machines

Enable JIT on your VMs from Azure virtual machines

You can enable JIT on a VM from the Azure virtual machines pages of the Azure portal.

> **Tip**
>
> If a VM already has JIT enabled, the VM configuration page shows that JIT is enabled. You can use the link to open the JIT VM access page in Defender for Cloud to view and change the settings.

1. From the Azure portal, search for and select **Virtual machines**.
2. Select the virtual machine you want to protect with JIT.
3. In the menu, select **Configuration**.

4. Under **Just-in-time access**, select **Enable just-in-time**.

   By default, just-in-time access for the VM uses these settings:

   - Windows machines:
     - RDP port: 3389
     - Maximum allowed access: 3 hours
     - Allowed source IP addresses: Any
   - Linux machines:
     - SSH port: 22
     - Maximum allowed access: 3 hours
     - Allowed source IP addresses: Any

5. To edit any of these values or add more ports to your JIT configuration, use Microsoft Defender for Cloud's just-in-time page:

   a. From Defender for Cloud's menu, select **Just-in-time VM access**.

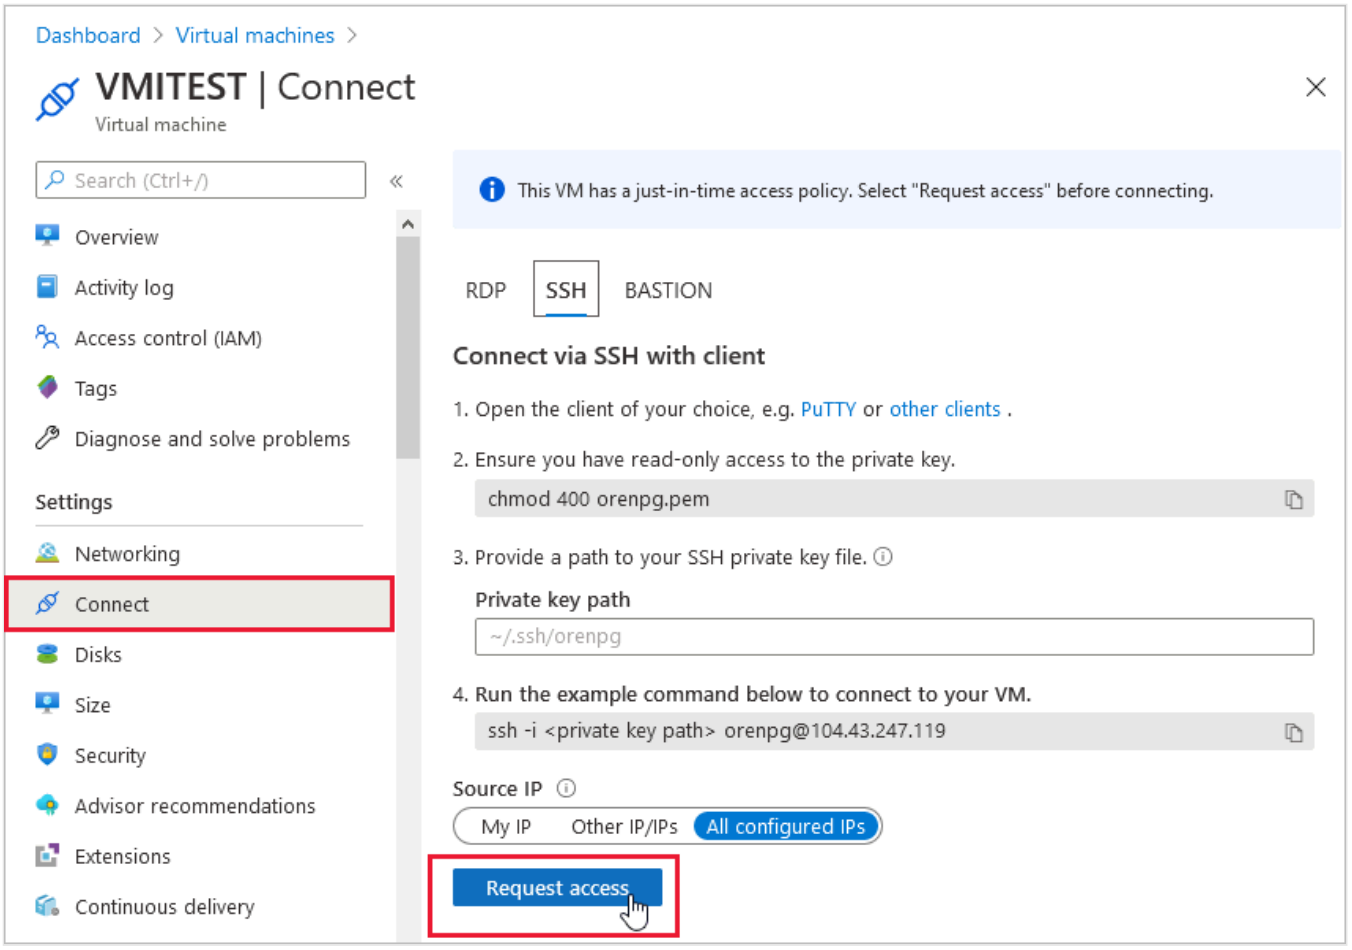
   b. From the **Configured** tab, right-click on the VM to which you want to add a port, and select **Edit**.

   c. Under **JIT VM access configuration**, you can either edit the existing settings of an already protected port or add a new custom port.

   d. When you've finished editing the ports, select **Save**.

Request access to a JIT-enabled VM from the Azure virtual machine's connect page

When a VM has a JIT enabled, you have to request access to connect to it. You can request access in any of the supported ways, regardless of how you enabled JIT.



To request access from Azure virtual machines:

1. In the Azure portal, open the virtual machines pages.
2. Select the VM to which you want to connect, and open the **Connect** page.

   Azure checks to see if JIT is enabled on that VM.

   - If JIT isn't enabled for the VM, you're prompted to enable it.
   - If JIT is enabled, select **Request access** to pass an access request with the requesting IP, time range, and ports that were configured for that VM.

> ⓘ **Note**
>
> After a request is approved for a VM protected by Azure Firewall, Defender for Cloud provides the user with the proper connection details (the port mapping from the DNAT table) to use to connect to the VM.

PowerShell

Enable JIT on your VMs using PowerShell

To enable just-in-time VM access from PowerShell, use the official Microsoft Defender for Cloud PowerShell cmdlet `Set-AzJitNetworkAccessPolicy`.

Example - Enable just-in-time VM access on a specific VM with the following rules:

- Close ports 22 and 3389
- Set a maximum time window of 3 hours for each so they can be opened per approved request
- Allow the user who is requesting access to control the source IP addresses
- Allow the user who is requesting access to establish a successful session upon an approved just-in-time access request

The following PowerShell commands create this JIT configuration:

1. Assign a variable that holds the just-in-time VM access rules for a VM:

   Azure PowerShell

   ```
   $JitPolicy = (@{

   id="/subscriptions/SUBSCRIPTIONID/resourceGroups/RESOURCEGROUP/providers/Microsoft.Compute/virtualMachines/VMNAME";
       ports=(@{
           number=22;
           protocol="*";
           allowedSourceAddressPrefix=@("*");
           maxRequestAccessDuration="PT3H"},
           @{
           number=3389;
           protocol="*";
           allowedSourceAddressPrefix=@("*");
           maxRequestAccessDuration="PT3H"})})
   ```

2. Insert the VM just-in-time VM access rules into an array:

   Azure PowerShell

   ```
   $JitPolicyArr=@($JitPolicy)
   ```

3. Configure the just-in-time VM access rules on the selected VM:

   Azure PowerShell

```
Set-AzJitNetworkAccessPolicy -Kind "Basic" -Location "LOCATION" -Name "default"
-ResourceGroupName "RESOURCEGROUP" -VirtualMachine $JitPolicyArr
```

Use the -Name parameter to specify a VM. For example, to establish the JIT configuration for two different VMs, VM1 and VM2, use: `Set-AzJitNetworkAccessPolicy -Name VM1` and `Set-AzJitNetworkAccessPolicy -Name VM2`.

Request access to a JIT-enabled VM using PowerShell

In the following example, you can see a just-in-time VM access request to a specific VM for port 22, for a specific IP address, and for a specific amount of time:

Run the following commands in PowerShell:

1. Configure the VM request access properties:

Azure PowerShell

```
$JitPolicyVm1 = (@{

id="/subscriptions/SUBSCRIPTIONID/resourceGroups/RESOURCEGROUP/providers/Micros
oft.Compute/virtualMachines/VMNAME";
    ports=(@{
        number=22;
        endTimeUtc="2020-07-15T17:00:00.3658798Z";
        allowedSourceAddressPrefix=@("IPV4ADDRESS")})})
```

2. Insert the VM access request parameters in an array:

Azure PowerShell

```
$JitPolicyArr=@($JitPolicyVm1)
```

3. Send the request access (use the resource ID from step 1)

Azure PowerShell

```
Start-AzJitNetworkAccessPolicy -ResourceId
"/subscriptions/SUBSCRIPTIONID/resourceGroups/RESOURCEGROUP/providers/Microsoft
.Security/locations/LOCATION/jitNetworkAccessPolicies/default" -VirtualMachine
$JitPolicyArr
```

Learn more in the PowerShell cmdlet documentation.

REST API

Enable JIT on your VMs using the REST API

The just-in-time VM access feature can be used via the Microsoft Defender for Cloud API. Use this API to get information about configured VMs, add new ones, request access to a VM, and more.

Learn more at JIT network access policies.

Request access to a JIT-enabled VM using the REST API

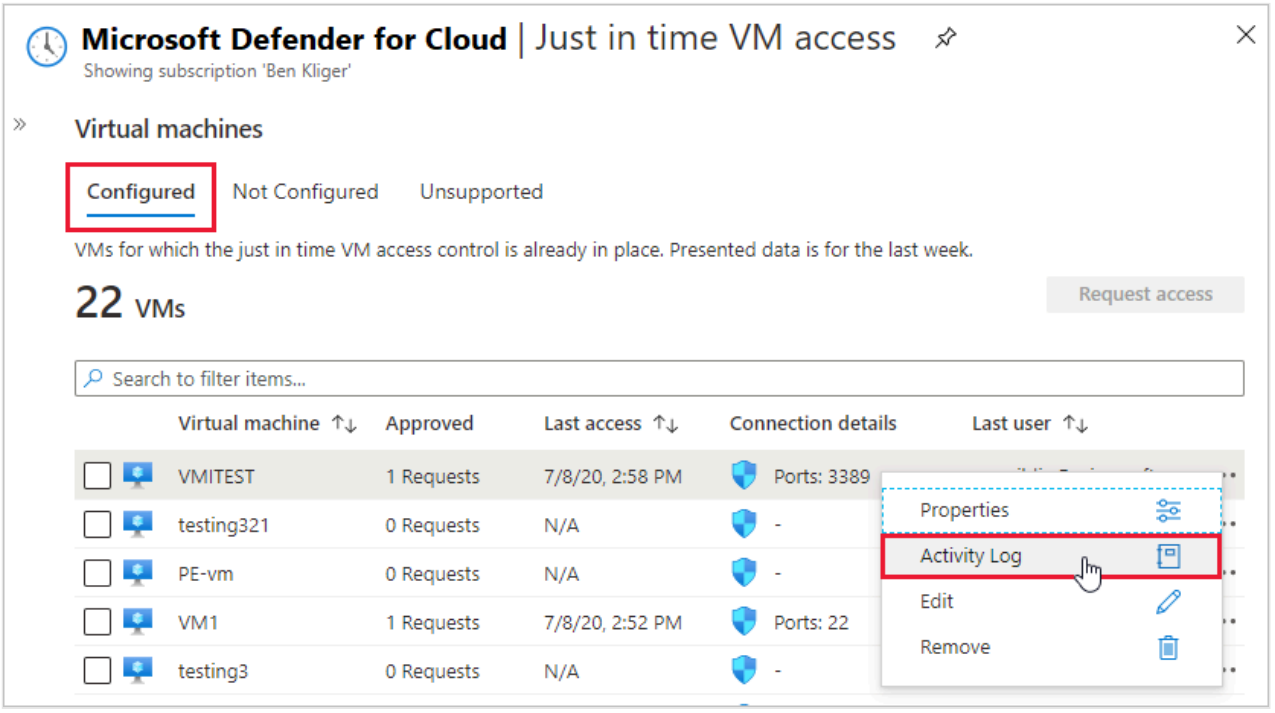
The just-in-time VM access feature can be used via the Microsoft Defender for Cloud API. Use this API to get information about configured VMs, add new ones, request access to a VM, and more.

Learn more at JIT network access policies.

Audit JIT access activity in Defender for Cloud

You can gain insights into VM activities using log search. To view the logs:

1. From **Just-in-time VM access**, select the **Configured** tab.
2. For the VM that you want to audit, open the ellipsis menu at the end of the row.
3. Select **Activity Log** from the menu.



The activity log provides a filtered view of previous operations for that VM along with time, date, and subscription.

4. To download the log information, select **Download as CSV**.

Next step

- Understand just-in-time VM access management

Secure and use policies on virtual machines in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

It's important to keep your virtual machine (VM) secure for the applications that you run. Securing your VMs can include one or more Azure services and features that cover secure access to your VMs and secure storage of your data. This article provides information that enables you to keep your VM and applications secure.

Antimalware

The modern threat landscape for cloud environments is dynamic, increasing the pressure to maintain effective protection in order to meet compliance and security requirements. Microsoft Antimalware for Azure is a free real-time protection capability that helps identify and remove viruses, spyware, and other malicious software. Alerts can be configured to notify you when known malicious or unwanted software attempts to install itself or run on your VM. It is not supported on VMs running Linux or Windows Server 2008.

Microsoft Defender for Cloud

Microsoft Defender for Cloud helps you prevent, detect, and respond to threats to your VMs. Defender for Cloud provides integrated security monitoring and policy management across your Azure subscriptions, helps detect threats that might otherwise go unnoticed, and works with a broad ecosystem of security solutions.

Defender for Cloud's just-in-time access can be applied across your VM deployment to lock down inbound traffic to your Azure VMs, reducing exposure to attacks while providing easy access to connect to VMs when needed. When just-in-time is enabled and a user requests access to a VM, Defender for Cloud checks what permissions the user has for the VM. If they have the correct permissions, the request is approved and Defender for Cloud automatically configures the Network Security Groups (NSGs) to allow inbound traffic to the selected ports for a limited amount of time. After the time has expired, Defender for Cloud restores the NSGs to their previous states.

Encryption

Two encryption methods are offered for managed disks. Encryption at the OS-level, which is Azure Disk Encryption, and encryption at the platform-level, which is server-side encryption.

Server-side encryption

Azure managed disks automatically encrypt your data by default when persisting it to the cloud. Server-side encryption protects your data and helps you meet your organizational security and compliance commitments. Data in Azure managed disks is encrypted transparently using 256-bit AES encryption, one of the strongest block ciphers available, and is FIPS 140-2 compliant.

Encryption does not impact the performance of managed disks. There is no additional cost for the encryption.

You can rely on platform-managed keys for the encryption of your managed disk, or you can manage encryption using your own keys. If you choose to manage encryption with your own keys, you can specify a *customer-managed key* to use for encrypting and decrypting all data in managed disks.

To learn more about server-side encryption, refer to either the articles for Windows or Linux.

Azure Disk Encryption

For enhanced Windows VM and Linux VM security and compliance, virtual disks in Azure can be encrypted. Virtual disks on Windows VMs are encrypted at rest using BitLocker. Virtual disks on Linux VMs are encrypted at rest using dm-crypt.

There is no charge for encrypting virtual disks in Azure. Cryptographic keys are stored in Azure Key Vault using software-protection, or you can import or generate your keys in Hardware Security Modules (HSMs) certified to FIPS 140 validated standards. These cryptographic keys are used to encrypt and decrypt virtual disks attached to your VM. You retain control of these cryptographic keys and can audit their use. A Microsoft Entra service principal provides a secure mechanism for issuing these cryptographic keys as VMs are powered on and off.

Key Vault and SSH Keys

Secrets and certificates can be modeled as resources and provided by Key Vault. You can use Azure PowerShell to create key vaults for Windows VMs and the Azure CLI for Linux VMs. You can also create keys for encryption.

Key vault access policies grant permissions to keys, secrets, and certificates separately. For example, you can give a user access to only keys, but no permissions for secrets. However, permissions to access keys or secrets or certificates are at the vault level. In other words, key vault access policy does not support object level permissions.

When you connect to VMs, you should use public-key cryptography to provide a more secure way to sign in to them. This process involves a public and private key exchange using the secure shell (SSH) command to authenticate yourself rather than a username and password. Passwords are vulnerable to brute-force attacks, especially on Internet-facing VMs such as web servers. With a secure shell (SSH) key pair, you can create a Linux VM that uses SSH keys for authentication, eliminating the need for passwords to sign-in. You can also use SSH keys to connect from a Windows VM to a Linux VM.

Managed identities for Azure resources

A common challenge when building cloud applications is how to manage the credentials in your code for authenticating to cloud services. Keeping the credentials secure is an important task. Ideally, the credentials never appear on developer workstations and aren't checked into source control. Azure Key Vault provides a way to securely store credentials, secrets, and other keys, but your code has to authenticate to Key Vault to retrieve them.

The managed identities for Azure resources feature in Microsoft Entra solves this problem. The feature provides Azure services with an automatically managed identity in Microsoft Entra ID. You can use the identity to authenticate to any service that supports Microsoft Entra authentication, including Key Vault, without any credentials in your code. Your code that's running on a VM can request a token from two endpoints that are accessible only from within the VM. For more detailed information about this service, review the managed identities for Azure resources overview page.

Policies

Azure policies can be used to define the desired behavior for your organization's VMs. By using policies, an organization can enforce various conventions and rules throughout the enterprise. Enforcement of the desired behavior can help mitigate risk while contributing to the success of the organization.

Azure role-based access control

Using Azure role-based access control (Azure RBAC), you can segregate duties within your team and grant only the amount of access to users on your VM that they need to perform their jobs. Instead of giving everybody unrestricted permissions on the VM, you can allow only certain actions. You can configure access control for the VM in the Azure portal, using the Azure CLI, orAzure PowerShell.

Next steps

- Walk through the steps to monitor virtual machine security by using Microsoft Defender for Cloud for Linux or Windows.

Azure Policy Regulatory Compliance controls for Azure Virtual Machines

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Regulatory Compliance in Azure Policy provides Microsoft created and managed initiative definitions, known as *built-ins*, for the **compliance domains** and **security controls** related to different compliance standards. This page lists the **compliance domains** and **security controls** for Azure Virtual Machines . You can assign the built-ins for a **security control** individually to help make your Azure resources compliant with the specific standard.

The title of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Policy Version** column to view the source on the Azure Policy GitHub repo.

> **Important**
>
> Each control is associated with one or more **Azure Policy** definitions. These policies might help you **assess compliance** with the control. However, there often isn't a one-to-one or complete match between a control and one or more policies. As such, **Compliant** in Azure Policy refers only to the policies themselves. This doesn't ensure that you're fully compliant with all requirements of a control. In addition, the compliance standard includes controls that aren't addressed by any Azure Policy definitions at this time. Therefore, compliance in Azure Policy is only a partial view of your overall compliance status. The associations between controls and Azure Policy Regulatory Compliance definitions for these compliance standards can change over time.

Australian Government ISM PROTECTED

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see Azure Policy Regulatory Compliance - Australian Government ISM PROTECTED. For more information about this compliance standard, see Australian Government ISM PROTECTED.

			Configuration assignments on virtual machines with no identities	
Identification and Authentication	IA.2.081	Store and transmit only cryptographically-protected passwords.	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0
Identification and Authentication	IA.2.081	Store and transmit only cryptographically-protected passwords.	Audit Windows machines that do not store passwords using reversible encryption	2.0.0
Identification and Authentication	IA.2.081	Store and transmit only cryptographically-protected passwords.	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Identification and Authentication	IA.2.081	Store and transmit only cryptographically-protected passwords.	Windows machines should meet requirements for 'Security Options - Network Security'	3.0.0
Identification and Authentication	IA.3.084	Employ replay-resistant authentication mechanisms for network access to privileged and nonprivileged accounts.	Windows machines should be configured to use secure communication protocols	4.1.1
Incident Response	IR.2.093	Detect and report events.	Monitor missing Endpoint Protection in Azure Security Center	3.0.0
Recovery	RE.2.137	Regularly perform and test data back-ups.	Audit virtual machines without disaster recovery configured	1.0.0
Recovery	RE.2.137	Regularly perform and test data back-ups.	Azure Backup should be enabled for Virtual Machines	3.0.0
Recovery	RE.3.139	Regularly perform complete, comprehensive and resilient data backups as organizationally-defined.	Audit virtual machines without disaster recovery configured	1.0.0
Recovery	RE.3.139	Regularly perform complete, comprehensive and resilient data	Azure Backup should be enabled for Virtual	3.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
		backups as organizationally-defined.	Machines	
Risk Assessment	RM.2.141	Periodically assess the risk to organizational operations (including mission, functions, image, or reputation), organizational assets, and individuals, resulting from the operation of organizational systems and the associated processing, storage, or transmission of CUI.	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Risk Assessment	RM.2.142	Scan for vulnerabilities in organizational systems and applications periodically and when new vulnerabilities affecting those systems and applications are identified.	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Risk Assessment	RM.2.143	Remediate vulnerabilities in accordance with risk assessments.	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Risk Assessment	RM.2.143	Remediate vulnerabilities in accordance with risk assessments.	Vulnerabilities in container security configurations should be remediated	3.0.0
Risk Assessment	RM.2.143	Remediate vulnerabilities in accordance with risk assessments.	Vulnerabilities in security configuration on your machines should be remediated	3.1.0
Risk Assessment	RM.2.143	Remediate vulnerabilities in accordance with risk assessments.	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	All network ports should be restricted on network security groups associated to your virtual machine	3.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Non-internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Windows machines should be configured to use secure communication protocols	4.1.1
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Windows machines should meet requirements for 'Security Options - Network Access'	3.0.0
System and Communications Protection	SC.1.175	Monitor, control, and protect communications (i.e., information transmitted or received by organizational systems) at the external boundaries and key internal boundaries of organizational systems.	Windows machines should meet requirements for 'Security Options - Network Security'	3.0.0
System and Communications Protection	SC.1.176	Implement subnetworks for publicly accessible system components that are physically or logically separated from internal networks.	Adaptive network hardening recommendations should	3.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
			be applied on internet facing virtual machines	
System and Communications Protection	SC.1.176	Implement subnetworks for publicly accessible system components that are physically or logically separated from internal networks.	All network ports should be restricted on network security groups associated to your virtual machine	3.0.0
System and Communications Protection	SC.1.176	Implement subnetworks for publicly accessible system components that are physically or logically separated from internal networks.	Internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC.2.179	Use encrypted sessions for the management of network devices.	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
System and Communications Protection	SC.3.177	Employ FIPS-validated cryptography when used to protect the confidentiality of CUI.	Audit Windows machines that do not store passwords using reversible encryption	2.0.0
System and Communications Protection	SC.3.181	Separate user functionality from system management functionality.	Audit Windows machines that have the specified members in the Administrators group	2.0.0
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	All network ports should be restricted on network security groups associated to your virtual machine	3.0.0
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	Internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	Non-internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	Windows machines should meet requirements for 'Security Options - Network Access'	3.0.0
System and Communications Protection	SC.3.183	Deny network communications traffic by default and allow network communications traffic by exception (i.e., deny all, permit by exception).	Windows machines should meet requirements for 'Security Options - Network Security'	3.0.0
System and Communications Protection	SC.3.185	Implement cryptographic mechanisms to prevent unauthorized disclosure of CUI during transmission unless otherwise protected by alternative physical safeguards.	Windows machines should be configured to use secure communication protocols	4.1.1
System and Communications Protection	SC.3.190	Protect the authenticity of communications sessions.	Windows machines should be configured to use secure communication protocols	4.1.1
System and Information Integrity	SI.1.210	Identify, report, and correct information and information system flaws in a timely manner.	Microsoft Antimalware for Azure should be configured to automatically update protection signatures	1.0.0
System and Information Integrity	SI.1.210	Identify, report, and correct information and information system flaws in a timely manner.	System updates on virtual machine scale sets should be installed	3.0.0
System and Information Integrity	SI.1.210	Identify, report, and correct information and information system flaws in a timely manner.	System updates should be installed on your machines	4.0.0
System and Information Integrity	SI.1.210	Identify, report, and correct information and information system flaws in a timely manner.	Vulnerabilities in security configuration on your machines should be remediated	3.1.0
System and Information Integrity	SI.1.210	Identify, report, and correct information and information system flaws in a timely manner.	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
System and Information Integrity	SI.1.211	Provide protection from malicious code at appropriate locations within organizational information systems.	Endpoint protection solution should be installed on virtual machine scale sets	3.0.0
System and Information Integrity	SI.1.211	Provide protection from malicious code at appropriate locations within organizational information systems.	Microsoft Antimalware for Azure should be configured to automatically update protection signatures	1.0.0
System and Information Integrity	SI.1.211	Provide protection from malicious code at appropriate locations within organizational information systems.	Microsoft IaaSAntimalware extension should be deployed on Windows servers	1.1.0
System and Information Integrity	SI.1.211	Provide protection from malicious code at appropriate locations within organizational information systems.	Monitor missing Endpoint Protection in Azure Security Center	3.0.0
System and Information Integrity	SI.1.212	Update malicious code protection mechanisms when new releases are available.	Microsoft Antimalware for Azure should be configured to automatically update protection signatures	1.0.0
System and Information Integrity	SI.1.213	Perform periodic scans of the information system and real-time scans of files from external sources as files are downloaded, opened, or executed.	Microsoft Antimalware for Azure should be configured to automatically update protection signatures	1.0.0
System and Information Integrity	SI.1.213	Perform periodic scans of the information system and real-time scans of files from external sources as files are downloaded, opened, or executed.	Microsoft IaaSAntimalware extension should be deployed on Windows servers	1.1.0
System and Information Integrity	SI.1.213	Perform periodic scans of the information system and real-time scans of files from external sources as files are downloaded, opened, or executed.	Monitor missing Endpoint Protection in Azure Security Center	3.0.0

FedRAMP High

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see Azure Policy Regulatory Compliance - FedRAMP High. For more information about this compliance standard, see FedRAMP High.

Posture and Vulnerability Management	PV-4	Audit and enforce secure configurations for compute resources	[Preview]: Secure Boot should be enabled on supported Windows virtual machines	4.0.0-preview
Posture and Vulnerability Management	PV-4	Audit and enforce secure configurations for compute resources	[Preview]: vTPM should be enabled on supported virtual machines	2.0.0-preview
Posture and Vulnerability Management	PV-4	Audit and enforce secure configurations for compute resources	Guest Configuration extension should be installed on your machines	1.0.3
Posture and Vulnerability Management	PV-4	Audit and enforce secure configurations for compute resources	Linux machines should meet requirements for the Azure compute security baseline	2.2.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
Posture and Vulnerability Management	PV-4	Audit and enforce secure configurations for compute resources	Virtual machines' Guest Configuration extension should be deployed with system-assigned managed identity	1.0.1
Posture and Vulnerability Management	PV-4	Audit and enforce secure configurations for compute resources	Windows machines should meet requirements of the Azure compute security baseline	2.0.0
Posture and Vulnerability Management	PV-5	Perform vulnerability assessments	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Posture and Vulnerability Management	PV-5	Perform vulnerability assessments	Machines should have secret findings resolved	1.0.2
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	[Preview]: System updates should be installed on your machines (powered by Update Center)	1.0.0-preview
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	Machines should be configured to periodically check for missing system updates	3.7.0
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	SQL servers on machines should have vulnerability findings resolved	1.0.0
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	System updates on virtual machine scale sets should be installed	3.0.0
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	System updates should be installed on your machines	4.0.0
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	Vulnerabilities in container security configurations should be remediated	3.0.0
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	Vulnerabilities in security configuration on your machines should be remediated	3.1.0
Posture and Vulnerability Management	PV-6	Rapidly and automatically remediate vulnerabilities	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0
Endpoint Security	ES-2	Use modern anti-malware software	Endpoint protection health issues should be resolved on your machines	1.0.0
Endpoint Security	ES-2	Use modern anti-malware software	Endpoint protection should be installed on your machines	1.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
Endpoint Security	ES-2	Use modern anti-malware software	Endpoint protection solution should be installed on virtual machine scale sets	3.0.0
Endpoint Security	ES-2	Use modern anti-malware software	Monitor missing Endpoint Protection in Azure Security Center	3.0.0
Endpoint Security	ES-2	Use modern anti-malware software	Windows Defender Exploit Guard should be enabled on your machines	2.0.0
Endpoint Security	ES-3	Ensure anti-malware software and signatures are updated	Endpoint protection health issues should be resolved on your machines	1.0.0
Backup and Recovery	BR-1	Ensure regular automated backups	Azure Backup should be enabled for Virtual Machines	3.0.0
Backup and Recovery	BR-2	Protect backup and recovery data	Azure Backup should be enabled for Virtual Machines	3.0.0
DevOps Security	DS-6	Enforce security of workload throughout DevOps lifecycle	Vulnerabilities in container security configurations should be remediated	3.0.0

NIST SP 800-171 R2

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see Azure Policy Regulatory Compliance - NIST SP 800-171 R2. For more information about this compliance standard, see NIST SP 800-171 R2.

Adaptive application controls for defining safe applications should be enabled on your machines	3.0.0
Configuration Management	3.4.8	Apply deny-by-exception (blacklisting) policy to prevent the use of unauthorized software or deny-all, permit-by-exception (whitelisting) policy to allow the execution of authorized software.	Allowlist rules in your adaptive application control policy should be updated	3.0.0
Configuration Management	3.4.9	Control and monitor user-installed software.	Adaptive application controls for defining safe applications should be enabled on your machines	3.0.0
Configuration Management	3.4.9	Control and monitor user-installed software.	Allowlist rules in your adaptive application control policy should be updated	3.0.0
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities	4.1.0
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Audit Linux machines that do not have the passwd file permissions set to 0644	3.1.0
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Audit Windows machines that do not store passwords using reversible encryption	2.0.0
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Deploy the Linux Guest Configuration extension to enable Guest Configuration assignments on Linux VMs	3.1.0
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Identification and Authentication	3.5.10	Store and transmit only cryptographically-protected passwords.	Windows machines should meet requirements for 'Security Options - Network Security'	3.0.0
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to allowing access to organizational systems.	Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities	4.1.0
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to allowing access to organizational systems.	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to allowing access to organizational systems.	Audit Linux machines that do not have the passwd file permissions set to 0644	3.1.0
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to allowing access to organizational systems.	Audit Windows machines that do not store passwords using reversible encryption	2.0.0
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to	Authentication to Linux machines should require SSH keys	3.2.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
		allowing access to organizational systems.		
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to allowing access to organizational systems.	Deploy the Linux Guest Configuration extension to enable Guest Configuration assignments on Linux VMs	3.1.0
Identification and Authentication	3.5.2	Authenticate (or verify) the identities of users, processes, or devices, as a prerequisite to allowing access to organizational systems.	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Identification and Authentication	3.5.4	Employ replay-resistant authentication mechanisms for network access to privileged and non-privileged accounts.	Windows machines should meet requirements for 'Security Options - Network Security'	3.0.0
Identification and Authentication	3.5.7	Enforce a minimum password complexity and change of characters when new passwords are created.	Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities	4.1.0
Identification and Authentication	3.5.7	Enforce a minimum password complexity and change of characters when new passwords are created.	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0
Identification and Authentication	3.5.7	Enforce a minimum password complexity and change of characters when new passwords are created.	Audit Windows machines that do not have the password complexity setting enabled	2.0.0
Identification and Authentication	3.5.7	Enforce a minimum password complexity and change of characters when new passwords are created.	Audit Windows machines that do not restrict the minimum password length to specified number of characters	2.1.0
Identification and Authentication	3.5.7	Enforce a minimum password complexity and change of characters when new passwords are created.	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Identification and Authentication	3.5.8	Prohibit password reuse for a specified number of generations.	Add system-assigned managed identity to enable Guest Configuration	4.1.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
			assignments on virtual machines with no identities	
Identification and Authentication	3.5.8	Prohibit password reuse for a specified number of generations.	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0
Identification and Authentication	3.5.8	Prohibit password reuse for a specified number of generations.	Audit Windows machines that allow re-use of the passwords after the specified number of unique passwords	2.1.0
Identification and Authentication	3.5.8	Prohibit password reuse for a specified number of generations.	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Media Protection	3.8.9	Protect the confidentiality of backup CUI at storage locations.	Azure Backup should be enabled for Virtual Machines	3.0.0

NIST SP 800-53 Rev. 4

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see Azure Policy Regulatory Compliance - NIST SP 800-53 Rev. 4. For more information about this compliance standard, see NIST SP 800-53 Rev. 4.

Identification and Authentication	IA-5	Authenticator Management	Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities	4.1.0
Identification and Authentication	IA-5	Authenticator Management	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0
Identification and Authentication	IA-5	Authenticator Management	Audit Linux machines that do not have the passwd file permissions set to 0644	3.1.0
Identification and Authentication	IA-5	Authenticator Management	Audit Windows machines that do not store passwords using reversible encryption	2.0.0
Identification and Authentication	IA-5	Authenticator Management	Authentication to Linux machines should require SSH keys	3.2.0
Identification and Authentication	IA-5	Authenticator Management	Deploy the Linux Guest Configuration extension to enable Guest Configuration assignments on Linux VMs	3.1.0
Identification and Authentication	IA-5	Authenticator Management	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities	4.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Add system-assigned managed identity to enable Guest Configuration assignments on VMs with a user-assigned identity	4.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Linux machines that do not have the passwd file permissions set to 0644	3.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Windows machines that allow re-use of the passwords after the specified number of unique passwords	2.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Windows machines that do not have the maximum password age set to specified number of days	2.1.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Windows machines that do not have the minimum password age set to specified number of days	2.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Windows machines that do not have the password complexity setting enabled	2.0.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Windows machines that do not restrict the minimum password length to specified number of characters	2.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Audit Windows machines that do not store passwords using reversible encryption	2.0.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Deploy the Linux Guest Configuration extension to enable Guest Configuration assignments on Linux VMs	3.1.0
Identification and Authentication	IA-5 (1)	Password-based Authentication	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0
Risk Assessment	RA-5	Vulnerability Monitoring and Scanning	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Risk Assessment	RA-5	Vulnerability Monitoring and Scanning	SQL servers on machines should have vulnerability findings resolved	1.0.0
Risk Assessment	RA-5	Vulnerability Monitoring and Scanning	Vulnerabilities in container security configurations should be remediated	3.0.0
Risk Assessment	RA-5	Vulnerability Monitoring and Scanning	Vulnerabilities in security configuration on your machines should be remediated	3.1.0
Risk Assessment	RA-5	Vulnerability Monitoring and Scanning	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0
System and Communications Protection	SC-3	Security Function Isolation	Endpoint protection solution should be installed on virtual machine scale sets	3.0.0
System and Communications Protection	SC-3	Security Function Isolation	Monitor missing Endpoint Protection in Azure Security Center	3.0.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
System and Communications Protection	SC-3	Security Function Isolation	Windows Defender Exploit Guard should be enabled on your machines	2.0.0
System and Communications Protection	SC-5	Denial-of-service Protection	IP Forwarding on your virtual machine should be disabled	3.0.0
System and Communications Protection	SC-7	Boundary Protection	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
System and Communications Protection	SC-7	Boundary Protection	All network ports should be restricted on network security groups associated to your virtual machine	3.0.0
System and Communications Protection	SC-7	Boundary Protection	Disk access resources should use private link	1.0.0
System and Communications Protection	SC-7	Boundary Protection	Internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC-7	Boundary Protection	IP Forwarding on your virtual machine should be disabled	3.0.0
System and Communications Protection	SC-7	Boundary Protection	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
System and Communications Protection	SC-7	Boundary Protection	Management ports should be closed on your virtual machines	3.0.0
System and Communications Protection	SC-7	Boundary Protection	Non-internet-facing virtual machines should be protected with network security groups	3.0.0
System and Communications Protection	SC-7 (3)	Access Points	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
System and Communications Protection	SC-7 (3)	Access Points	All network ports should be restricted on network security groups associated to your virtual machine	3.0.0
System and Communications Protection	SC-7 (3)	Access Points	Disk access resources should use private link	1.0.0
System and Communications	SC-7 (3)	Access Points	Internet-facing virtual machines should be protected with network	3.0.0

Identity and authentication	10	Identity and authentication	Audit Linux machines that do not have the passwd file permissions set to 0644	3.1.0
Identity and authentication	10	Identity and authentication	Audit Linux machines that have accounts without passwords	3.1.0
Identity and authentication	10	Identity and authentication	Audit VMs that do not use managed disks	1.0.0
Identity and authentication	10	Identity and authentication	Audit Windows machines that allow re-use of the passwords after the specified number of unique passwords	2.1.0
Identity and authentication	10	Identity and authentication	Audit Windows machines that do not have the maximum password age set to specified number of days	2.1.0
Identity and authentication	10	Identity and authentication	Audit Windows machines that do not have the minimum password age set to specified number of days	2.1.0
Identity and authentication	10	Identity and authentication	Audit Windows machines that do not have the password complexity setting enabled	2.0.0
Identity and authentication	10	Identity and authentication	Audit Windows machines that do not restrict the minimum password length to specified number of characters	2.1.0
Identity and authentication	10	Identity and authentication	Deploy the Linux Guest Configuration extension to enable Guest Configuration assignments on Linux VMs	3.1.0
Identity and authentication	10	Identity and authentication	Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	1.2.0

Domain	Control ID	Control title	Policy (Azure portal)	Policy version (GitHub)
Identity and authentication	10	Identity and authentication	Virtual machines should be migrated to new Azure Resource Manager resources	1.0.0
External interface protection	11	External interface protection	Adaptive application controls for defining safe applications should be enabled on your machines	3.0.0
External interface protection	11	External interface protection	Adaptive network hardening recommendations should be applied on internet facing virtual machines	3.0.0
External interface protection	11	External interface protection	All network ports should be restricted on network security groups associated to your virtual machine	3.0.0
External interface protection	11	External interface protection	Endpoint protection solution should be installed on virtual machine scale sets	3.0.0
External interface protection	11	External interface protection	Management ports of virtual machines should be protected with just-in-time network access control	3.0.0
Operational security	5.2	Vulnerability management	A vulnerability assessment solution should be enabled on your virtual machines	3.0.0
Operational security	5.2	Vulnerability management	Monitor missing Endpoint Protection in Azure Security Center	3.0.0
Operational security	5.2	Vulnerability management	System updates on virtual machine scale sets should be installed	3.0.0
Operational security	5.2	Vulnerability management	System updates should be installed on your machines	4.0.0
Operational security	5.2	Vulnerability management	Vulnerabilities in security configuration on your machines should be remediated	3.1.0
Operational security	5.2	Vulnerability management	Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	3.0.0
Operational security	5.3	Protective Monitoring	Adaptive application controls for defining safe applications should be enabled on your machines	3.0.0
Operational security	5.3	Protective Monitoring	Audit virtual machines without disaster recovery configured	1.0.0

Azure Policy built-in definitions for Azure Virtual Machines

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This page is an index of Azure Policy built-in policy definitions for Azure Virtual Machines. For additional Azure Policy built-ins for other services, see Azure Policy built-in definitions.

The name of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Version** column to view the source on the Azure Policy GitHub repo.

Expand table

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: A managed identity should be enabled on your machines	Resources managed by Automanage should have a managed identity.	Audit, Disabled	1.0.0-preview
[Preview]: Add user-assigned managed identity to enable Guest Configuration assignments on virtual machines	This policy adds a user-assigned managed identity to virtual machines hosted in Azure that are supported by Guest Configuration. A user-assigned managed identity is a prerequisite for all Guest Configuration assignments and must be added to machines before using any Guest Configuration policy definitions. For more information on Guest Configuration, visit https://aka.ms/gcpol.	AuditIfNotExists, DeployIfNotExists, Disabled	2.1.0-preview
[Preview]: Assign Built-In User-Assigned Managed Identity to Virtual Machine Scale Sets	Create and assign a built-in user-assigned managed identity or assign a pre-created user-assigned managed identity at scale to virtual machine scale sets. For more detailed documentation, visit aka.ms/managedidentitypolicy.	AuditIfNotExists, DeployIfNotExists, Disabled	1.1.0-preview
[Preview]: Assign Built-In User-Assigned Managed Identity to Virtual Machines	Create and assign a built-in user-assigned managed identity or assign a pre-created user-assigned managed identity at scale to virtual machines. For more detailed documentation, visit aka.ms/managedidentitypolicy.	AuditIfNotExists, DeployIfNotExists, Disabled	1.1.0-preview
[Preview]: Audit SSH Posture Control on Linux machines	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if SSH Server is not securely configured on the Linux machines.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Automanage Configuration Profile Assignment should be Conformant	Resources managed by Automanage should have a status of Conformant or ConformantCorrected.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Azure Backup should be enabled for Managed Disks	Ensure protection of your Managed Disks by enabling Azure Backup. Azure Backup is a secure and cost effective data protection solution for Azure.	AuditIfNotExists, Disabled	1.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: Azure Security agent should be installed on your Linux virtual machine scale sets	Install the Azure Security agent on your Linux virtual machine scale sets in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	2.0.0-preview
[Preview]: Azure Security agent should be installed on your Linux virtual machines	Install the Azure Security agent on your Linux virtual machines in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	2.0.0-preview
[Preview]: Azure Security agent should be installed on your Windows virtual machine scale sets	Install the Azure Security agent on your Windows virtual machine scale sets in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	2.1.0-preview
[Preview]: Azure Security agent should be installed on your Windows virtual machines	Install the Azure Security agent on your Windows virtual machines in order to monitor your machines for security configurations and vulnerabilities. Results of the assessments can seen and managed in Azure Security Center.	AuditIfNotExists, Disabled	2.1.0-preview
[Preview]: Boot Diagnostics should be enabled on virtual machines	Azure virtual machines should have boot diagniostics enabled.	Audit, Disabled	1.0.0-preview
[Preview]: ChangeTracking extension should be installed on your Linux virtual machine	Install ChangeTracking Extension on Linux virtual machines to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	2.0.0-preview
[Preview]: ChangeTracking extension should be installed on your Linux virtual machine scale sets	Install ChangeTracking Extension on Linux virtual machine scale sets to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	2.0.0-preview
[Preview]: ChangeTracking extension should be installed on your Windows virtual machine	Install ChangeTracking Extension on Windows virtual machines to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	2.0.0-preview
[Preview]: ChangeTracking extension should be installed on your Windows virtual machine scale sets	Install ChangeTracking Extension on Windows virtual machine scale sets to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitoring Agent.	AuditIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure Azure Defender for	Configure Windows machines to automatically install the Azure Defender for SQL agent where the Azure Monitor Agent is installed. Security Center collects	DeployIfNotExists, Disabled	1.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
SQL agent on virtual machine	events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Creates a resource group and Log Analytics workspace in the same region as the machine. Target virtual machines must be in a supported location.		
[Preview]: Configure backup for Azure Disks (Managed Disks) with a given tag to an existing backup vault in the same region	Enforce backup for all Azure Disks (Managed Disks) that contain a given tag to a central backup vault. Learn more at https://aka.ms/AB-DiskBackupAzPolicies	DeployIfNotExists, AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure backup for Azure Disks (Managed Disks) without a given tag to an existing backup vault in the same region	Enforce backup for all Azure Disks (Managed Disks) that do not contain a given tag to a central backup vault. Learn more at https://aka.ms/AB-DiskBackupAzPolicies	DeployIfNotExists, AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure ChangeTracking Extension for Linux virtual machine scale sets	Configure Linux virtual machine scale sets to automatically install the ChangeTracking Extension to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitor Agent.	DeployIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure ChangeTracking Extension for Linux virtual machines	Configure Linux virtual machines to automatically install the ChangeTracking Extension to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitor Agent.	DeployIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure ChangeTracking Extension for Windows virtual machine scale sets	Configure Windows virtual machine scale sets to automatically install the ChangeTracking Extension to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitor Agent.	DeployIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure ChangeTracking Extension for Windows virtual machines	Configure Windows virtual machines to automatically install the ChangeTracking Extension to enable File Integrity Monitoring(FIM) in Azure Security Center. FIM examines operating system files, Windows registries, application software, Linux system files, and more, for changes that might indicate an attack. The extension can be installed in virtual machines and locations supported by Azure Monitor Agent.	DeployIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure Linux Virtual Machines to be associated with a Data Collection Rule for ChangeTracking and Inventory	Deploy Association to link Linux virtual machines to the specified Data Collection Rule to enable ChangeTracking and Inventory. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure Linux VMs to install AMA for	Automate the deployment of Azure Monitor Agent extension on your Linux virtual machines for enabling ChangeTracking and Inventory. This policy will install the extension and configure it to use the specified user-assigned	DeployIfNotExists, Disabled	1.5.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
ChangeTracking and Inventory with user-assigned managed identity	managed identity if the OS and region are supported, and skip install otherwise. Learn more: https://aka.ms/AMAOverview.		
[Preview]: Configure Linux VMSS to be associated with a Data Collection Rule for ChangeTracking and Inventory	Deploy Association to link Linux virtual machine scale sets to the specified Data Collection Rule to enable ChangeTracking and Inventory. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure Linux VMSS to install AMA for ChangeTracking and Inventory with user-assigned managed identity	Automate the deployment of Azure Monitor Agent extension on your Linux virtual machine scale sets for enabling ChangeTracking and Inventory. This policy will install the extension and configure it to use the specified user-assigned managed identity if the OS and region are supported, and skip install otherwise. Learn more: https://aka.ms/AMAOverview.	DeployIfNotExists, Disabled	1.4.0-preview
[Preview]: Configure SSH Posture Control on Linux machines	This policy creates a Guest Configuration assignment to set SSH Posture Control on Linux machines.	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure supported Linux virtual machine scale sets to automatically install the Azure Security agent	Configure supported Linux virtual machine scale sets to automatically install the Azure Security agent. Security Center collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Target virtual machines must be in a supported location.	DeployIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure supported Linux virtual machine scale sets to automatically install the Guest Attestation extension	Configure supported Linux virtual machines scale sets to automatically install the Guest Attestation extension to allow Azure Security Center to proactively attest and monitor the boot integrity. Boot integrity is attested via Remote Attestation.	DeployIfNotExists, Disabled	6.1.0-preview
[Preview]: Configure supported Linux virtual machines to automatically enable Secure Boot	Configure supported Linux virtual machines to automatically enable Secure Boot to mitigate against malicious and unauthorized changes to the boot chain. Once enabled, only trusted bootloaders, kernel and kernel drivers will be allowed to run.	DeployIfNotExists, Disabled	5.0.0-preview
[Preview]: Configure supported Linux virtual machines to automatically install the Azure Security agent	Configure supported Linux virtual machines to automatically install the Azure Security agent. Security Center collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Target virtual machines must be in a supported location.	DeployIfNotExists, Disabled	7.0.0-preview
[Preview]: Configure supported Linux virtual machines to automatically install the Guest Attestation extension	Configure supported Linux virtual machines to automatically install the Guest Attestation extension to allow Azure Security Center to proactively attest and monitor the boot integrity. Boot integrity is attested via Remote Attestation.	DeployIfNotExists, Disabled	7.1.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: Configure supported virtual machines to automatically enable vTPM	Configure supported virtual machines to automatically enable vTPM to facilitate Measured Boot and other OS security features that require a TPM. Once enabled, vTPM can be used to attest boot integrity.	DeployIfNotExists, Disabled	2.0.0-preview
[Preview]: Configure supported Windows machines to automatically install the Azure Security agent	Configure supported Windows machines to automatically install the Azure Security agent. Security Center collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Target virtual machines must be in a supported location.	DeployIfNotExists, Disabled	5.1.0-preview
[Preview]: Configure supported Windows virtual machine scale sets to automatically install the Azure Security agent	Configure supported Windows virtual machine scale sets to automatically install the Azure Security agent. Security Center collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Target Windows virtual machine scale sets must be in a supported location.	DeployIfNotExists, Disabled	2.1.0-preview
[Preview]: Configure supported Windows virtual machine scale sets to automatically install the Guest Attestation extension	Configure supported Windows virtual machines scale sets to automatically install the Guest Attestation extension to allow Azure Security Center to proactively attest and monitor the boot integrity. Boot integrity is attested via Remote Attestation.	DeployIfNotExists, Disabled	4.1.0-preview
[Preview]: Configure supported Windows virtual machines to automatically enable Secure Boot	Configure supported Windows virtual machines to automatically enable Secure Boot to mitigate against malicious and unauthorized changes to the boot chain. Once enabled, only trusted bootloaders, kernel and kernel drivers will be allowed to run.	DeployIfNotExists, Disabled	3.0.0-preview
[Preview]: Configure supported Windows virtual machines to automatically install the Guest Attestation extension	Configure supported Windows virtual machines to automatically install the Guest Attestation extension to allow Azure Security Center to proactively attest and monitor the boot integrity. Boot integrity is attested via Remote Attestation.	DeployIfNotExists, Disabled	5.1.0-preview
[Preview]: Configure system-assigned managed identity to enable Azure Monitor assignments on VMs	Configure system-assigned managed identity to virtual machines hosted in Azure that are supported by Azure Monitor and do not have a system-assigned managed identity. A system-assigned managed identity is a prerequisite for all Azure Monitor assignments and must be added to machines before using any Azure Monitor extension. Target virtual machines must be in a supported location.	Modify, Disabled	6.0.0-preview
[Preview]: Configure VMs created with Shared Image Gallery images to install the Guest Attestation extension	Configure virtual machines created with Shared Image Gallery images to automatically install the Guest Attestation extension to allow Azure Security Center to proactively attest and monitor the boot integrity. Boot integrity is attested via Remote Attestation.	DeployIfNotExists, Disabled	2.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: Configure VMSS created with Shared Image Gallery images to install the Guest Attestation extension	Configure VMSS created with Shared Image Gallery images to automatically install the Guest Attestation extension to allow Azure Security Center to proactively attest and monitor the boot integrity. Boot integrity is attested via Remote Attestation.	DeployIfNotExists, Disabled	2.1.0-preview
[Preview]: Configure Windows Server to disable local users.	Creates a Guest Configuration assignment to configure disabling local users on Windows Server. This ensures that Windows Servers can only be accessed by AAD (Azure Active Directory) account or a list of explicitly allowed users by this policy, improving overall security posture.	DeployIfNotExists, Disabled	1.2.0-preview
[Preview]: Configure Windows Virtual Machines to be associated with a Data Collection Rule for ChangeTracking and Inventory	Deploy Association to link Windows virtual machines to specified Data Collection Rule to enable ChangeTracking and Inventory. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure Windows VMs to install AMA for ChangeTracking and Inventory with user-assigned managed identity	Automate the deployment of Azure Monitor Agent extension on your Windows virtual machines for enabling ChangeTracking and Inventory. This policy will install the extension and configure it to use the specified user-assigned managed identity if the OS and region are supported, and skip install otherwise. Learn more: https://aka.ms/AMAOverview.	DeployIfNotExists, Disabled	1.1.0-preview
[Preview]: Configure Windows VMSS to be associated with a Data Collection Rule for ChangeTracking and Inventory	Deploy Association to link Windows virtual machine scale sets to specified Data Collection Rule to enable ChangeTracking and Inventory. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	1.0.0-preview
[Preview]: Configure Windows VMSS to install AMA for ChangeTracking and Inventory with user-assigned managed identity	Automate the deployment of Azure Monitor Agent extension on your Windows virtual machine scale sets for enabling ChangeTracking and Inventory. This policy will install the extension and configure it to use the specified user-assigned managed identity if the OS and region are supported, and skip install otherwise. Learn more: https://aka.ms/AMAOverview.	DeployIfNotExists, Disabled	1.1.0-preview
[Preview]: Deploy Microsoft Defender for Endpoint agent on Linux virtual machines	Deploys Microsoft Defender for Endpoint agent on applicable Linux VM images.	DeployIfNotExists, AuditIfNotExists, Disabled	3.0.0-preview
[Preview]: Deploy Microsoft Defender for Endpoint agent on Windows virtual machines	Deploys Microsoft Defender for Endpoint on applicable Windows VM images.	DeployIfNotExists, AuditIfNotExists, Disabled	2.0.1-preview
[Preview]: Enable system-assigned identity to SQL VM	Enable system-assigned identity at scale to SQL virtual machines. You need to assign this policy at subscription level. Assign at resource group level will not work as expected.	DeployIfNotExists, Disabled	1.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: Guest Attestation extension should be installed on supported Linux virtual machines	Install Guest Attestation extension on supported Linux virtual machines to allow Azure Security Center to proactively attest and monitor the boot integrity. Once installed, boot integrity will be attested via Remote Attestation. This assessment applies to Trusted Launch and Confidential Linux virtual machines.	AuditIfNotExists, Disabled	6.0.0-preview
[Preview]: Guest Attestation extension should be installed on supported Linux virtual machines scale sets	Install Guest Attestation extension on supported Linux virtual machines scale sets to allow Azure Security Center to proactively attest and monitor the boot integrity. Once installed, boot integrity will be attested via Remote Attestation. This assessment applies to Trusted Launch and Confidential Linux virtual machine scale sets.	AuditIfNotExists, Disabled	5.1.0-preview
[Preview]: Guest Attestation extension should be installed on supported Windows virtual machines	Install Guest Attestation extension on supported virtual machines to allow Azure Security Center to proactively attest and monitor the boot integrity. Once installed, boot integrity will be attested via Remote Attestation. This assessment applies to Trusted Launch and Confidential Windows virtual machines.	AuditIfNotExists, Disabled	4.0.0-preview
[Preview]: Guest Attestation extension should be installed on supported Windows virtual machines scale sets	Install Guest Attestation extension on supported virtual machines scale sets to allow Azure Security Center to proactively attest and monitor the boot integrity. Once installed, boot integrity will be attested via Remote Attestation. This assessment applies to Trusted Launch and Confidential Windows virtual machine scale sets.	AuditIfNotExists, Disabled	3.1.0-preview
[Preview]: Linux machines should meet requirements for the Azure security baseline for Docker hosts	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. The machine is not configured correctly for one of the recommendations in the Azure security baseline for Docker hosts.	AuditIfNotExists, Disabled	1.2.0-preview
[Preview]: Linux machines should meet STIG compliance requirement for Azure compute	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the machine is not configured correctly for one of the recommendations in STIG compliance requirement for Azure compute. DISA (Defense Information Systems Agency) provides technical guides STIG (Security Technical Implementation Guide) to secure compute OS as required by Department of Defense (DoD). For more details, https://public.cyber.mil/stigs/.	AuditIfNotExists, Disabled	1.2.0-preview
[Preview]: Linux machines with OMI installed should have version 1.6.8-1 or later	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Due to a security fix included in version 1.6.8-1 of the OMI package for Linux, all machines should be updated to the latest release. Upgrade apps/packages that use OMI to resolve the issue. For more information, see https://aka.ms/omiguidance.	AuditIfNotExists, Disabled	1.2.0-preview
[Preview]: Linux virtual machines should use only signed and trusted boot components	All OS boot components (boot loader, kernel, kernel drivers) must be signed by trusted publishers. Defender for Cloud has identified untrusted OS boot components on one or more of your Linux machines. To protect your machines from potentially malicious components, add them to your allow list or remove the identified components.	AuditIfNotExists, Disabled	1.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
[Preview]: Linux virtual machines should use Secure Boot	To protect against the installation of malware-based rootkits and boot kits, enable Secure Boot on supported Linux virtual machines. Secure Boot ensures that only signed operating systems and drivers will be allowed to run. This assessment only applies to Linux virtual machines that have the Azure Monitor Agent installed.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Log Analytics Extension should be enabled for listed virtual machine images	Reports virtual machines as non-compliant if the virtual machine image is not in the list defined and the extension is not installed.	AuditIfNotExists, Disabled	2.0.1-preview
[Preview]: Machines should have ports closed that might expose attack vectors	Azure's Terms Of Use prohibit the use of Azure services in ways that could damage, disable, overburden, or impair any Microsoft server, or the network. The exposed ports identified by this recommendation need to be closed for your continued security. For each identified port, the recommendation also provides an explanation of the potential threat.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Managed Disks should be Zone Resilient	Managed Disks can be configured to be either Zone Aligned, Zone Redundant, or neither. Managed Disks with exactly one zone assignment are Zone Aligned. Managed Disks with a sku name that ends in ZRS are Zone Redundant. This policy assists in identifying and enforcing these resilience configurations for Managed Disks.	Audit, Deny, Disabled	1.0.0-preview
[Preview]: Network traffic data collection agent should be installed on Linux virtual machines	Security Center uses the Microsoft Dependency agent to collect network traffic data from your Azure virtual machines to enable advanced network protection features such as traffic visualization on the network map, network hardening recommendations and specific network threats.	AuditIfNotExists, Disabled	1.0.2-preview
[Preview]: Network traffic data collection agent should be installed on Windows virtual machines	Security Center uses the Microsoft Dependency agent to collect network traffic data from your Azure virtual machines to enable advanced network protection features such as traffic visualization on the network map, network hardening recommendations and specific network threats.	AuditIfNotExists, Disabled	1.0.2-preview
[Preview]: Secure Boot should be enabled on supported Windows virtual machines	Enable Secure Boot on supported Windows virtual machines to mitigate against malicious and unauthorized changes to the boot chain. Once enabled, only trusted bootloaders, kernel and kernel drivers will be allowed to run. This assessment applies to Trusted Launch and Confidential Windows virtual machines.	Audit, Disabled	4.0.0-preview
[Preview]: Set prerequisite for Scheduling recurring updates on Azure virtual machines.	This policy will set the prerequisite needed to schedule recurring updates on Azure Update Manager by configuring patch orchestration to 'Customer Managed Schedules'. This change will automatically set the patch mode to 'AutomaticByPlatform' and enables 'BypassPlatformSafetyChecksOnUserSchedule' to 'True' on Azure VMs. The prerequisite is not applicable for Arc-enabled servers. Learn more - https://learn.microsoft.com/en-us/azure/update-manager/dynamic-scope-overview?tabs=avms#prerequisites	DeployIfNotExists, Disabled	1.1.0-preview
[Preview]: System updates should be installed on your machines (powered by Update Center)	Your machines are missing system, security, and critical updates. Software updates often include critical patches to security holes. Such holes are frequently exploited in malware attacks so it's vital to keep your software updated. To install all outstanding patches and secure your machines, follow the remediation steps.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Virtual Machine Scale Sets	Virtual Machine Scale Sets can be configured to be either Zone Aligned, Zone Redundant, or neither. Virtual Machine Scale Sets that have exactly one entry in	Audit, Deny, Disabled	1.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
should be Zone Resilient	their zones array are considered Zone Aligned. In contrast, Virtual Machine Scale Sets with 3 or more entries in their zones array and a capacity of at least 3 are recognized as Zone Redundant. This policy helps identify and enforce these resilience configurations.		
[Preview]: Virtual machines guest attestation status should be healthy	Guest attestation is performed by sending a trusted log (TCGLog) to an attestation server. The server uses these logs to determine whether boot components are trustworthy. This assessment is intended to detect compromises of the boot chain which might be the result of a bootkit or rootkit infection. This assessment only applies to Trusted Launch enabled virtual machines that have Guest Attestation extension installed.	AuditIfNotExists, Disabled	1.0.0-preview
[Preview]: Virtual Machines should be Zone Aligned	Virtual Machines can be configured to be Zone Aligned or not. They are considered Zone Aligned if they have only one entry in their zones array. This policy ensures that they are configured to operate within a single availability zone.	Audit, Deny, Disabled	1.0.0-preview
[Preview]: vTPM should be enabled on supported virtual machines	Enable virtual TPM device on supported virtual machines to facilitate Measured Boot and other OS security features that require a TPM. Once enabled, vTPM can be used to attest boot integrity. This assessment only applies to trusted launch enabled virtual machines.	Audit, Disabled	2.0.0-preview
[Preview]: Windows machines should meet STIG compliance requirements for Azure compute	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the machine is not configured correctly for one of the recommendations in STIG compliance requirements for Azure compute. DISA (Defense Information Systems Agency) provides technical guides STIG (Security Technical Implementation Guide) to secure compute OS as required by Department of Defense (DoD). For more details, https://public.cyber.mil/stigs/.	AuditIfNotExists, Disabled	1.0.0-preview
A vulnerability assessment solution should be enabled on your virtual machines	Audits virtual machines to detect whether they are running a supported vulnerability assessment solution. A core component of every cyber risk and security program is the identification and analysis of vulnerabilities. Azure Security Center's standard pricing tier includes vulnerability scanning for your virtual machines at no extra cost. Additionally, Security Center can automatically deploy this tool for you.	AuditIfNotExists, Disabled	3.0.0
Adaptive application controls for defining safe applications should be enabled on your machines	Enable application controls to define the list of known-safe applications running on your machines, and alert you when other applications run. This helps harden your machines against malware. To simplify the process of configuring and maintaining your rules, Security Center uses machine learning to analyze the applications running on each machine and suggest the list of known-safe applications.	AuditIfNotExists, Disabled	3.0.0
Adaptive network hardening recommendations should be applied on internet facing virtual machines	Azure Security Center analyzes the traffic patterns of Internet facing virtual machines and provides Network Security Group rule recommendations that reduce the potential attack surface	AuditIfNotExists, Disabled	3.0.0
Add system-assigned managed identity to enable Guest Configuration assignments on virtual machines with no identities	This policy adds a system-assigned managed identity to virtual machines hosted in Azure that are supported by Guest Configuration but do not have any managed identities. A system-assigned managed identity is a prerequisite for all Guest Configuration assignments and must be added to machines before using any Guest Configuration policy definitions. For more information on Guest Configuration, visit https://aka.ms/gcpol.	modify	4.1.0
Add system-assigned managed	This policy adds a system-assigned managed identity to virtual machines hosted in Azure that are supported by Guest Configuration and have at least	modify	4.1.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
identity to enable Guest Configuration assignments on VMs with a user-assigned identity	one user-assigned identity but do not have a system-assigned managed identity. A system-assigned managed identity is a prerequisite for all Guest Configuration assignments and must be added to machines before using any Guest Configuration policy definitions. For more information on Guest Configuration, visit https://aka.ms/gcpol.		
All network ports should be restricted on network security groups associated to your virtual machine	Azure Security Center has identified some of your network security groups' inbound rules to be too permissive. Inbound rules should not allow access from 'Any' or 'Internet' ranges. This can potentially enable attackers to target your resources.	AuditIfNotExists, Disabled	3.0.0
Allowed virtual machine size SKUs	This policy enables you to specify a set of virtual machine size SKUs that your organization can deploy.	Deny	1.0.1
Allowlist rules in your adaptive application control policy should be updated	Monitor for changes in behavior on groups of machines configured for auditing by Azure Security Center's adaptive application controls. Security Center uses machine learning to analyze the running processes on your machines and suggest a list of known-safe applications. These are presented as recommended apps to allow in adaptive application control policies.	AuditIfNotExists, Disabled	3.0.0
Audit Linux machines that allow remote connections from accounts without passwords	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Linux machines that allow remote connections from accounts without passwords	AuditIfNotExists, Disabled	3.1.0
Audit Linux machines that do not have the passwd file permissions set to 0644	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Linux machines that do not have the passwd file permissions set to 0644	AuditIfNotExists, Disabled	3.1.0
Audit Linux machines that don't have the specified applications installed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the Chef InSpec resource indicates that one or more of the packages provided by the parameter are not installed.	AuditIfNotExists, Disabled	4.2.0
Audit Linux machines that have accounts without passwords	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Linux machines that have accounts without passwords	AuditIfNotExists, Disabled	3.1.0
Audit Linux machines that have the specified applications installed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the Chef InSpec resource indicates that one or more of the packages provided by the parameter are installed.	AuditIfNotExists, Disabled	4.2.0
Audit virtual machines without disaster recovery configured	Audit virtual machines which do not have disaster recovery configured. To learn more about disaster recovery, visit https://aka.ms/asr-doc.	auditIfNotExists	1.0.0
Audit VMs that do not use managed disks	This policy audits VMs that do not use managed disks	audit	1.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Audit Windows machines missing any of specified members in the Administrators group	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the local Administrators group does not contain one or more members that are listed in the policy parameter.	auditIfNotExists	2.0.0
Audit Windows machines network connectivity	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if a network connection status to an IP and TCP port does not match the policy parameter.	auditIfNotExists	2.0.0
Audit Windows machines on which the DSC configuration is not compliant	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the Windows PowerShell command Get-DSCConfigurationStatus returns that the DSC configuration for the machine is not compliant.	auditIfNotExists	3.0.0
Audit Windows machines on which the Log Analytics agent is not connected as expected	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the agent is not installed, or if it is installed but the COM object AgentConfigManager.MgmtSvcCfg returns that it is registered to a workspace other than the ID specified in the policy parameter.	auditIfNotExists	2.0.0
Audit Windows machines on which the specified services are not installed and 'Running'	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if result of the Windows PowerShell command Get-Service do not include the service name with matching status as specified by the policy parameter.	auditIfNotExists	3.0.0
Audit Windows machines on which Windows Serial Console is not enabled	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the machine does not have the Serial Console software installed or if the EMS port number or baud rate are not configured with the same values as the policy parameters.	auditIfNotExists	3.0.0
Audit Windows machines that allow re-use of the passwords after the specified number of unique passwords	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows machines that allow re-use of the passwords after the specified number of unique passwords. Default value for unique passwords is 24	AuditIfNotExists, Disabled	2.1.0
Audit Windows machines that are not joined to the specified domain	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the value of the Domain property in WMI class win32_computersystem does not match the value in the policy parameter.	auditIfNotExists	2.0.0
Audit Windows machines that are not set to the specified time zone	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the value of the property StandardName in WMI class Win32_TimeZone does not match the selected time zone for the policy parameter.	auditIfNotExists	3.0.0
Audit Windows machines that contain certificates expiring within the specified number of days	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if certificates in the specified store have an expiration date out of range for the number of days given as parameter. The policy also provides the option to only check for specific certificates or exclude specific certificates, and whether to report on expired certificates.	auditIfNotExists	2.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Audit Windows machines that do not contain the specified certificates in Trusted Root	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the machine Trusted Root certificate store (Cert:\LocalMachine\Root) does not contain one or more of the certificates listed by the policy parameter.	auditIfNotExists	3.0.0
Audit Windows machines that do not have the maximum password age set to specified number of days	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows machines that do not have the maximum password age set to specified number of days. Default value for maximum password age is 70 days	AuditIfNotExists, Disabled	2.1.0
Audit Windows machines that do not have the minimum password age set to specified number of days	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows machines that do not have the minimum password age set to specified number of days. Default value for minimum password age is 1 day	AuditIfNotExists, Disabled	2.1.0
Audit Windows machines that do not have the password complexity setting enabled	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows machines that do not have the password complexity setting enabled	AuditIfNotExists, Disabled	2.0.0
Audit Windows machines that do not have the specified Windows PowerShell execution policy	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the Windows PowerShell command Get-ExecutionPolicy returns a value other than what was selected in the policy parameter.	AuditIfNotExists, Disabled	3.0.0
Audit Windows machines that do not have the specified Windows PowerShell modules installed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if a module isn't available in a location specified by the environment variable PSModulePath.	AuditIfNotExists, Disabled	3.0.0
Audit Windows machines that do not restrict the minimum password length to specified number of characters	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows machines that do not restrict the minimum password length to specified number of characters. Default value for minimum password length is 14 characters	AuditIfNotExists, Disabled	2.1.0
Audit Windows machines that do not store passwords using reversible encryption	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows machines that do not store passwords using reversible encryption	AuditIfNotExists, Disabled	2.0.0
Audit Windows machines that don't have the specified applications installed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the application name is not found in any of the following registry paths: HKLM:SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall,	auditIfNotExists	2.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
	HKLM:SOFTWARE\Wow6432node\Microsoft\Windows\CurrentVersion\Uninstall, HKCU:Software\Microsoft\Windows\CurrentVersion\Uninstall.		
Audit Windows machines that have extra accounts in the Administrators group	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the local Administrators group contains members that are not listed in the policy parameter.	auditIfNotExists	2.0.0
Audit Windows machines that have not restarted within the specified number of days	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the WMI property LastBootUpTime in class Win32_Operatingsystem is outside the range of days provided by the policy parameter.	auditIfNotExists	2.0.0
Audit Windows machines that have the specified applications installed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the application name is found in any of the following registry paths: HKLM:SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall, HKLM:SOFTWARE\Wow6432node\Microsoft\Windows\CurrentVersion\Uninstall, HKCU:Software\Microsoft\Windows\CurrentVersion\Uninstall.	auditIfNotExists	2.0.0
Audit Windows machines that have the specified members in the Administrators group	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the local Administrators group contains one or more of the members listed in the policy parameter.	auditIfNotExists	2.0.0
Audit Windows VMs with a pending reboot	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the machine is pending reboot for any of the following reasons: component based servicing, Windows Update, pending file rename, pending computer rename, configuration manager pending reboot. Each detection has a unique registry path.	auditIfNotExists	2.0.0
Authentication to Linux machines should require SSH keys	Although SSH itself provides an encrypted connection, using passwords with SSH still leaves the VM vulnerable to brute-force attacks. The most secure option for authenticating to an Azure Linux virtual machine over SSH is with a public-private key pair, also known as SSH keys. Learn more: https://docs.microsoft.com/azure/virtual-machines/linux/create-ssh-keys-detailed.	AuditIfNotExists, Disabled	3.2.0
Azure Backup should be enabled for Virtual Machines	Ensure protection of your Azure Virtual Machines by enabling Azure Backup. Azure Backup is a secure and cost effective data protection solution for Azure.	AuditIfNotExists, Disabled	3.0.0
Cloud Services (extended support) role instances should be configured securely	Protect your Cloud Service (extended support) role instances from attacks by ensuring they are not expolosed to any OS vulnerabilities.	AuditIfNotExists, Disabled	1.0.0
Cloud Services (extended support) role instances should have an endpoint protection solution installed	Protect your Cloud Services (extended support) role instances from threats and vulnerabilities by ensuring an endpoint protection solution is installed on them.	AuditIfNotExists, Disabled	1.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Cloud Services (extended support) role instances should have system updates installed	Secure your Cloud Services (extended support) role instances by ensuring the latest security and critical updates are installed on them.	AuditIfNotExists, Disabled	1.0.0
Configure Azure Defender for Servers to be disabled for all resources (resource level)	Azure Defender for Servers provides real-time threat protection for server workloads and generates hardening recommendations as well as alerts about suspicious activities. This policy will disable the Defender for Servers plan for all resources (VMs, VMSSs and ARC Machines) in the selected scope (subscription or resource group).	DeployIfNotExists, Disabled	1.0.0
Configure Azure Defender for Servers to be disabled for resources (resource level) with the selected tag	Azure Defender for Servers provides real-time threat protection for server workloads and generates hardening recommendations as well as alerts about suspicious activities. This policy will disable the Defender for Servers plan for all resources (VMs, VMSSs and ARC Machines) that have the selected tag name and tag value(s).	DeployIfNotExists, Disabled	1.0.0
Configure Azure Defender for Servers to be enabled ('P1' subplan) for all resources (resource level) with the selected tag	Azure Defender for Servers provides real-time threat protection for server workloads and generates hardening recommendations as well as alerts about suspicious activities. This policy will enable the Defender for Servers plan (with 'P1' subplan) for all resources (VMs and ARC Machines) that have the selected tag name and tag value(s).	DeployIfNotExists, Disabled	1.0.0
Configure Azure Defender for Servers to be enabled (with 'P1' subplan) for all resources (resource level)	Azure Defender for Servers provides real-time threat protection for server workloads and generates hardening recommendations as well as alerts about suspicious activities. This policy will enable the Defender for Servers plan (with 'P1' subplan) for all resources (VMs and ARC Machines) in the selected scope (subscription or resource group).	DeployIfNotExists, Disabled	1.0.0
Configure backup on virtual machines with a given tag to a new recovery services vault with a default policy	Enforce backup for all virtual machines by deploying a recovery services vault in the same location and resource group as the virtual machine. Doing this is useful when different application teams in your organization are allocated separate resource groups and need to manage their own backups and restores. You can optionally include virtual machines containing a specified tag to control the scope of assignment. See https://aka.ms/AzureVMAppCentricBackupIncludeTag.	auditIfNotExists, AuditIfNotExists, deployIfNotExists, DeployIfNotExists, disabled, Disabled	9.3.0
Configure backup on virtual machines with a given tag to an existing recovery services vault in the same location	Enforce backup for all virtual machines by backing them up to an existing central recovery services vault in the same location and subscription as the virtual machine. Doing this is useful when there is a central team in your organization managing backups for all resources in a subscription. You can optionally include virtual machines containing a specified tag to control the scope of assignment. See https://aka.ms/AzureVMCentralBackupIncludeTag.	auditIfNotExists, AuditIfNotExists, deployIfNotExists, DeployIfNotExists, disabled, Disabled	9.3.0
Configure backup on virtual machines without a given tag to a new recovery services vault with a default policy	Enforce backup for all virtual machines by deploying a recovery services vault in the same location and resource group as the virtual machine. Doing this is useful when different application teams in your organization are allocated separate resource groups and need to manage their own backups and restores. You can optionally exclude virtual machines containing a specified tag to control the scope of assignment. See https://aka.ms/AzureVMAppCentricBackupExcludeTag.	auditIfNotExists, AuditIfNotExists, deployIfNotExists, DeployIfNotExists, disabled, Disabled	9.3.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Configure backup on virtual machines without a given tag to an existing recovery services vault in the same location	Enforce backup for all virtual machines by backing them up to an existing central recovery services vault in the same location and subscription as the virtual machine. Doing this is useful when there is a central team in your organization managing backups for all resources in a subscription. You can optionally exclude virtual machines containing a specified tag to control the scope of assignment. See https://aka.ms/AzureVMCentralBackupExcludeTag.	auditIfNotExists, AuditIfNotExists, deployIfNotExists, DeployIfNotExists, disabled, Disabled	9.3.0
Configure disaster recovery on virtual machines by enabling replication via Azure Site Recovery	Virtual machines without disaster recovery configurations are vulnerable to outages and other disruptions. If the virtual machine does not already have disaster recovery configured, this would initiate the same by enabling replication using preset configurations to facilitate business continuity. You can optionally include/exclude virtual machines containing a specified tag to control the scope of assignment. To learn more about disaster recovery, visit https://aka.ms/asr-doc.	DeployIfNotExists, Disabled	2.1.0
Configure disk access resources with private endpoints	Private endpoints connect your virtual networks to Azure services without a public IP address at the source or destination. By mapping private endpoints to disk access resources, you can reduce data leakage risks. Learn more about private links at: https://aka.ms/disksprivatelinksdoc.	DeployIfNotExists, Disabled	1.0.0
Configure Linux Machines to be associated with a Data Collection Rule or a Data Collection Endpoint	Deploy Association to link Linux virtual machines, virtual machine scale sets, and Arc machines to the specified Data Collection Rule or the specified Data Collection Endpoint. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	6.5.0
Configure Linux Server to disable local users.	Creates a Guest Configuration assignment to configure disabling local users on Linux Server. This ensures that Linux Servers can only be accessed by AAD (Azure Active Directory) account or a list of explicitly allowed users by this policy, improving overall security posture.	DeployIfNotExists, Disabled	1.3.0-preview
Configure Linux Virtual Machine Scale Sets to be associated with a Data Collection Rule or a Data Collection Endpoint	Deploy Association to link Linux virtual machine scale sets to the specified Data Collection Rule or the specified Data Collection Endpoint. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	4.4.0
Configure Linux virtual machine scale sets to run Azure Monitor Agent with system-assigned managed identity-based authentication	Automate the deployment of Azure Monitor Agent extension on your Linux virtual machine scale sets for collecting telemetry data from the guest OS. This policy will install the extension if the OS and region are supported and system-assigned managed identity is enabled, and skip install otherwise. Learn more: https://aka.ms/AMAOverview.	DeployIfNotExists, Disabled	3.6.0
Configure Linux virtual machine scale sets to run Azure Monitor Agent with user-assigned managed identity-based authentication	Automate the deployment of Azure Monitor Agent extension on your Linux virtual machine scale sets for collecting telemetry data from the guest OS. This policy will install the extension and configure it to use the specified user-assigned managed identity if the OS and region are supported, and skip install otherwise. Learn more: https://aka.ms/AMAOverview.	DeployIfNotExists, Disabled	3.8.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Configure Linux Virtual Machines to be associated with a Data Collection Rule or a Data Collection Endpoint	Deploy Association to link Linux virtual machines to the specified Data Collection Rule or the specified Data Collection Endpoint. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	4.4.0
Configure Linux virtual machines to run Azure Monitor Agent with system-assigned managed identity-based authentication	Automate the deployment of Azure Monitor Agent extension on your Linux virtual machines for collecting telemetry data from the guest OS. This policy will install the extension if the OS and region are supported and system-assigned managed identity is enabled, and skip install otherwise. Learn more: https://aka.ms/AMAOverview .	DeployIfNotExists, Disabled	3.6.0
Configure Linux virtual machines to run Azure Monitor Agent with user-assigned managed identity-based authentication	Automate the deployment of Azure Monitor Agent extension on your Linux virtual machines for collecting telemetry data from the guest OS. This policy will install the extension and configure it to use the specified user-assigned managed identity if the OS and region are supported, and skip install otherwise. Learn more: https://aka.ms/AMAOverview .	DeployIfNotExists, Disabled	3.8.0
Configure machines to receive a vulnerability assessment provider	Azure Defender includes vulnerability scanning for your machines at no extra cost. You don't need a Qualys license or even a Qualys account - everything's handled seamlessly inside Security Center. When you enable this policy, Azure Defender automatically deploys the Qualys vulnerability assessment provider to all supported machines that don't already have it installed.	DeployIfNotExists, Disabled	4.0.0
Configure managed disks to disable public network access	Disable public network access for your managed disk resource so that it's not accessible over the public internet. This can reduce data leakage risks. Learn more at: https://aka.ms/disksprivatelinksdoc .	Modify, Disabled	2.0.0
Configure periodic checking for missing system updates on azure virtual machines	Configure auto-assessment (every 24 hours) for OS updates on native Azure virtual machines. You can control the scope of assignment according to machine subscription, resource group, location or tag. Learn more about this for Windows: https://aka.ms/computevm-windowspatchassessmentmode, for Linux: https://aka.ms/computevm-linuxpatchassessmentmode .	modify	4.8.0
Configure secure communication protocols(TLS 1.1 or TLS 1.2) on Windows machines	Creates a Guest Configuration assignment to configure specified secure protocol version(TLS 1.1 or TLS 1.2) on Windows machine.	DeployIfNotExists, Disabled	1.0.1
Configure SQL Virtual Machines to automatically install Azure Monitor Agent	Automate the deployment of Azure Monitor Agent extension on your Windows SQL Virtual Machines. Learn more: https://aka.ms/AMAOverview .	DeployIfNotExists, Disabled	1.4.0
Configure SQL Virtual Machines to automatically install Microsoft Defender for SQL	Configure Windows SQL Virtual Machines to automatically install the Microsoft Defender for SQL extension. Microsoft Defender for SQL collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations).	DeployIfNotExists, Disabled	1.4.0
Configure SQL Virtual Machines to automatically install	Microsoft Defender for SQL collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Create	DeployIfNotExists, Disabled	1.6.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Microsoft Defender for SQL and DCR with a Log Analytics workspace	a resource group, a Data Collection Rule and Log Analytics workspace in the same region as the machine.		
Configure SQL Virtual Machines to automatically install Microsoft Defender for SQL and DCR with a user-defined LA workspace	Microsoft Defender for SQL collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Create a resource group and a Data Collection Rule in the same region as the user-defined Log Analytics workspace.	DeployIfNotExists, Disabled	1.7.0
Configure the Microsoft Defender for SQL Log Analytics workspace	Microsoft Defender for SQL collects events from the agent and uses them to provide security alerts and tailored hardening tasks (recommendations). Create a resource group and Log Analytics workspace in the same region as the machine.	DeployIfNotExists, Disabled	1.3.0
Configure time zone on Windows machines.	This policy creates a Guest Configuration assignment to set specified time zone on Windows virtual machines.	deployIfNotExists	2.1.0
Configure virtual machines to be onboarded to Azure Automanage	Azure Automanage enrolls, configures, and monitors virtual machines with best practice as defined in the Microsoft Cloud Adoption Framework for Azure. Use this policy to apply Automanage to your selected scope.	AuditIfNotExists, DeployIfNotExists, Disabled	2.4.0
Configure virtual machines to be onboarded to Azure Automanage with Custom Configuration Profile	Azure Automanage enrolls, configures, and monitors virtual machines with best practice as defined in the Microsoft Cloud Adoption Framework for Azure. Use this policy to apply Automanage with your own customized Configuration Profile to your selected scope.	AuditIfNotExists, DeployIfNotExists, Disabled	1.4.0
Configure Windows Machines to be associated with a Data Collection Rule or a Data Collection Endpoint	Deploy Association to link Windows virtual machines, virtual machine scale sets, and Arc machines to the specified Data Collection Rule or the specified Data Collection Endpoint. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	4.5.0
Configure Windows Virtual Machine Scale Sets to be associated with a Data Collection Rule or a Data Collection Endpoint	Deploy Association to link Windows virtual machine scale sets to the specified Data Collection Rule or the specified Data Collection Endpoint. The list of locations and OS images are updated over time as support is increased.	DeployIfNotExists, Disabled	3.3.0
Configure Windows virtual machine scale sets to run Azure Monitor Agent using system-assigned managed identity	Automate the deployment of Azure Monitor Agent extension on your Windows virtual machine scale sets for collecting telemetry data from the guest OS. This policy will install the extension if the OS and region are supported and system-assigned managed identity is enabled, and skip install otherwise. Learn more: https://aka.ms/AMAOverview .	DeployIfNotExists, Disabled	3.4.0

Deploy Log Analytics extension for Linux VMs. See deprecation notice below	Deploy Log Analytics extension for Linux VMs if the VM Image (OS) is in the list defined and the extension is not installed. Deprecation notice: The Log Analytics agent is on a deprecation path and won't be supported after August 31, 2024. You must migrate to the replacement 'Azure Monitor agent' prior to that date	deployIfNotExists	3.0.0
Deploy the Linux Guest Configuration extension to enable Guest Configuration assignments on Linux VMs	This policy deploys the Linux Guest Configuration extension to Linux virtual machines hosted in Azure that are supported by Guest Configuration. The Linux Guest Configuration extension is a prerequisite for all Linux Guest Configuration assignments and must be deployed to machines before using any Linux Guest Configuration policy definition. For more information on Guest Configuration, visit https://aka.ms/gcpol.	deployIfNotExists	3.1.0
Deploy the Windows Guest Configuration extension to enable Guest Configuration assignments on Windows VMs	This policy deploys the Windows Guest Configuration extension to Windows virtual machines hosted in Azure that are supported by Guest Configuration. The Windows Guest Configuration extension is a prerequisite for all Windows Guest Configuration assignments and must be deployed to machines before using any Windows Guest Configuration policy definition. For more information on Guest Configuration, visit https://aka.ms/gcpol.	deployIfNotExists	1.2.0
Disk access resources should use private link	Azure Private Link lets you connect your virtual network to Azure services without a public IP address at the source or destination. The Private Link platform handles the connectivity between the consumer and services over the Azure backbone network. By mapping private endpoints to diskAccesses, data leakage risks are reduced. Learn more about private links at: https://aka.ms/disksprivatelinksdoc.	AuditIfNotExists, Disabled	1.0.0
Disks and OS image should support TrustedLaunch	TrustedLaunch improves security of a Virtual Machine which requires OS Disk & OS Image to support it (Gen 2). To learn more about TrustedLaunch, visit https://aka.ms/trustedlaunch	Audit, Disabled	1.0.0
Endpoint protection health issues should be resolved on your machines	Resolve endpoint protection health issues on your virtual machines to protect them from latest threats and vulnerabilities. Azure Security Center supported endpoint protection solutions are documented here - https://docs.microsoft.com/azure/security-center/security-center-services?tabs=features-windows#supported-endpoint-protection-solutions. Endpoint protection assessment is documented here - https://docs.microsoft.com/azure/security-center/security-center-endpoint-protection.	AuditIfNotExists, Disabled	1.0.0
Endpoint protection should be installed on your machines	To protect your machines from threats and vulnerabilities, install a supported endpoint protection solution.	AuditIfNotExists, Disabled	1.0.0
Endpoint protection solution should be installed on virtual machine scale sets	Audit the existence and health of an endpoint protection solution on your virtual machines scale sets, to protect them from threats and vulnerabilities.	AuditIfNotExists, Disabled	3.0.0
Guest Configuration extension should be installed on your machines	To ensure secure configurations of in-guest settings of your machine, install the Guest Configuration extension. In-guest settings that the extension monitors include the configuration of the operating system, application configuration or presence, and environment settings. Once installed, in-guest policies will be available such as 'Windows Exploit guard should be enabled'. Learn more at https://aka.ms/gcpol.	AuditIfNotExists, Disabled	1.0.3

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Hotpatch should be enabled for Windows Server Azure Edition VMs	Minimize reboots and install updates quickly with hotpatch. Learn more at https://docs.microsoft.com/azure/automanage/automanage-hotpatch	Audit, Deny, Disabled	1.0.0
Internet-facing virtual machines should be protected with network security groups	Protect your virtual machines from potential threats by restricting access to them with network security groups (NSG). Learn more about controlling traffic with NSGs at https://aka.ms/nsg-doc	AuditIfNotExists, Disabled	3.0.0
IP Forwarding on your virtual machine should be disabled	Enabling IP forwarding on a virtual machine's NIC allows the machine to receive traffic addressed to other destinations. IP forwarding is rarely required (e.g., when using the VM as a network virtual appliance), and therefore, this should be reviewed by the network security team.	AuditIfNotExists, Disabled	3.0.0
Linux machines should meet requirements for the Azure compute security baseline	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if the machine is not configured correctly for one of the recommendations in the Azure compute security baseline.	AuditIfNotExists, Disabled	2.2.0
Linux machines should only have local accounts that are allowed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Managing user accounts using Azure Active Directory is a best practice for management of identities. Reducing local machine accounts helps prevent the proliferation of identities managed outside a central system. Machines are non-compliant if local user accounts exist that are enabled and not listed in the policy parameter.	AuditIfNotExists, Disabled	2.2.0
Linux virtual machine scale sets should have Azure Monitor Agent installed	Linux virtual machine scale sets should be monitored and secured through the deployed Azure Monitor Agent. The Azure Monitor Agent collects telemetry data from the guest OS. This policy will audit virtual machine scale sets with supported OS images in supported regions. Learn more: https://aka.ms/AMAOverview.	AuditIfNotExists, Disabled	3.3.0
Linux virtual machines should enable Azure Disk Encryption or EncryptionAtHost.	Although a virtual machine's OS and data disks are encrypted-at-rest by default using platform managed keys; resource disks (temp disks), data caches, and data flowing between Compute and Storage resources are not encrypted. Use Azure Disk Encryption or EncryptionAtHost to remediate. Visit https://aka.ms/diskencryptioncomparison to compare encryption offerings. This policy requires two prerequisites to be deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	1.2.1
Linux virtual machines should have Azure Monitor Agent installed	Linux virtual machines should be monitored and secured through the deployed Azure Monitor Agent. The Azure Monitor Agent collects telemetry data from the guest OS. This policy will audit virtual machines with supported OS images in supported regions. Learn more: https://aka.ms/AMAOverview.	AuditIfNotExists, Disabled	3.3.0
Local authentication methods should be disabled on Linux machines	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Linux servers don't have local authentication methods disabled. This is to validate that Linux Servers can only be accessed by AAD (Azure Active Directory) account or a list of explicitly allowed users by this policy, improving overall security posture.	AuditIfNotExists, Disabled	1.2.0-preview
Local authentication methods should be disabled on Windows Servers	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol. Machines are non-compliant if Windows servers don't have local authentication methods disabled. This is to validate that Windows Servers can only be accessed by AAD (Azure Active Directory) account or a list of explicitly allowed users by this policy, improving overall security posture.	AuditIfNotExists, Disabled	1.0.0-preview

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Log Analytics agent should be installed on your Cloud Services (extended support) role instances	Security Center collects data from your Cloud Services (extended support) role instances to monitor for security vulnerabilities and threats.	AuditIfNotExists, Disabled	2.0.0
Log Analytics extension should be enabled in virtual machine scale sets for listed virtual machine images	Reports virtual machine scale sets as non-compliant if the virtual machine image is not in the list defined and the extension is not installed.	AuditIfNotExists, Disabled	2.0.1
Machines should be configured to periodically check for missing system updates	To ensure periodic assessments for missing system updates are triggered automatically every 24 hours, the AssessmentMode property should be set to 'AutomaticByPlatform'. Learn more about AssessmentMode property for Windows: https://aka.ms/computevm-windowspatchassessmentmode, for Linux: https://aka.ms/computevm-linuxpatchassessmentmode.	Audit, Deny, Disabled	3.7.0
Machines should have secret findings resolved	Audits virtual machines to detect whether they contain secret findings from the secret scanning solutions on your virtual machines.	AuditIfNotExists, Disabled	1.0.2
Managed disks should be double encrypted with both platform-managed and customer-managed keys	High security sensitive customers who are concerned of the risk associated with any particular encryption algorithm, implementation, or key being compromised can opt for additional layer of encryption using a different encryption algorithm/mode at the infrastructure layer using platform managed encryption keys. The disk encryption sets are required to use double encryption. Learn more at https://aka.ms/disks-doubleEncryption.	Audit, Deny, Disabled	1.0.0
Managed disks should disable public network access	Disabling public network access improves security by ensuring that a managed disk isn't exposed on the public internet. Creating private endpoints can limit exposure of managed disks. Learn more at: https://aka.ms/disksprivatelinksdoc.	Audit, Disabled	2.0.0
Managed disks should use a specific set of disk encryption sets for the customer-managed key encryption	Requiring a specific set of disk encryption sets to be used with managed disks give you control over the keys used for encryption at rest. You are able to select the allowed encrypted sets and all others are rejected when attached to a disk. Learn more at https://aka.ms/disks-cmk.	Audit, Deny, Disabled	2.0.0
Management ports of virtual machines should be protected with just-in-time network access control	Possible network Just In Time (JIT) access will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	3.0.0
Management ports should be closed on your virtual machines	Open remote management ports are exposing your VM to a high level of risk from Internet-based attacks. These attacks attempt to brute force credentials to gain admin access to the machine.	AuditIfNotExists, Disabled	3.0.0
Microsoft Antimalware for Azure should be configured to automatically	This policy audits any Windows virtual machine not configured with automatic update of Microsoft Antimalware protection signatures.	AuditIfNotExists, Disabled	1.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
update protection signatures			
Microsoft IaaSAntimalware extension should be deployed on Windows servers	This policy audits any Windows server VM without Microsoft IaaSAntimalware extension deployed.	AuditIfNotExists, Disabled	1.1.0
Monitor missing Endpoint Protection in Azure Security Center	Servers without an installed Endpoint Protection agent will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	3.0.0
Non-internet-facing virtual machines should be protected with network security groups	Protect your non-internet-facing virtual machines from potential threats by restricting access with network security groups (NSG). Learn more about controlling traffic with NSGs at https://aka.ms/nsg-doc	AuditIfNotExists, Disabled	3.0.0
Only approved VM extensions should be installed	This policy governs the virtual machine extensions that are not approved.	Audit, Deny, Disabled	1.0.0
OS and data disks should be encrypted with a customer-managed key	Use customer-managed keys to manage the encryption at rest of the contents of your managed disks. By default, the data is encrypted at rest with platform-managed keys, but customer-managed keys are commonly required to meet regulatory compliance standards. Customer-managed keys enable the data to be encrypted with an Azure Key Vault key created and owned by you. You have full control and responsibility for the key lifecycle, including rotation and management. Learn more at https://aka.ms/disks-cmk .	Audit, Deny, Disabled	3.0.0
Private endpoints for Guest Configuration assignments should be enabled	Private endpoint connections enforce secure communication by enabling private connectivity to Guest Configuration for virtual machines. Virtual machines will be non-compliant unless they have the tag, 'EnablePrivateNetworkGC'. This tag enforces secure communication through private connectivity to Guest Configuration for Virtual Machines. Private connectivity limits access to traffic coming only from known networks and prevents access from all other IP addresses, including within Azure.	Audit, Deny, Disabled	1.1.0
Protect your data with authentication requirements when exporting or uploading to a disk or snapshot.	When export/upload URL is used, the system checks if the user has an identity in Azure Active Directory and has necessary permissions to export/upload the data. Please refer to aka.ms/DisksAzureADAuth.	Modify, Disabled	1.0.0
Require automatic OS image patching on Virtual Machine Scale Sets	This policy enforces enabling automatic OS image patching on Virtual Machine Scale Sets to always keep Virtual Machines secure by safely applying latest security patches every month.	deny	1.0.0
Schedule recurring updates using Azure Update Manager	You can use Azure Update Manager in Azure to save recurring deployment schedules to install operating system updates for your Windows Server and Linux machines in Azure, in on-premises environments, and in other cloud environments connected using Azure Arc-enabled servers. This policy will also change the patch mode for the Azure Virtual Machine to 'AutomaticByPlatform'. See more: https://aka.ms/umc-scheduled-patching	DeployIfNotExists, Disabled	3.12.0
SQL servers on machines should	SQL vulnerability assessment scans your database for security vulnerabilities, and exposes any deviations from best practices such as misconfigurations,	AuditIfNotExists, Disabled	1.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
have vulnerability findings resolved	excessive permissions, and unprotected sensitive data. Resolving the vulnerabilities found can greatly improve your database security posture.		
System updates on virtual machine scale sets should be installed	Audit whether there are any missing system security updates and critical updates that should be installed to ensure that your Windows and Linux virtual machine scale sets are secure.	AuditIfNotExists, Disabled	3.0.0
System updates should be installed on your machines	Missing security system updates on your servers will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	4.0.0
The legacy Log Analytics extension should not be installed on Linux virtual machine scale sets	Automatically prevent installation of the legacy Log Analytics Agent as the final step of migrating from legacy agents to Azure Monitor Agent. After you have uninstalled existing legacy extensions, this policy will deny all future installations of the legacy agent extension on Linux virtual machine scale sets. Learn more: https://aka.ms/migratetoAMA	Deny, Audit, Disabled	1.0.0
The legacy Log Analytics extension should not be installed on Linux virtual machines	Automatically prevent installation of the legacy Log Analytics Agent as the final step of migrating from legacy agents to Azure Monitor Agent. After you have uninstalled existing legacy extensions, this policy will deny all future installations of the legacy agent extension on Linux virtual machines. Learn more: https://aka.ms/migratetoAMA	Deny, Audit, Disabled	1.0.0
The legacy Log Analytics extension should not be installed on virtual machine scale sets	Automatically prevent installation of the legacy Log Analytics Agent as the final step of migrating from legacy agents to Azure Monitor Agent. After you have uninstalled existing legacy extensions, this policy will deny all future installations of the legacy agent extension on Windows virtual machine scale sets. Learn more: https://aka.ms/migratetoAMA	Deny, Audit, Disabled	1.0.0
The legacy Log Analytics extension should not be installed on virtual machines	Automatically prevent installation of the legacy Log Analytics Agent as the final step of migrating from legacy agents to Azure Monitor Agent. After you have uninstalled existing legacy extensions, this policy will deny all future installations of the legacy agent extension on Windows virtual machines. Learn more: https://aka.ms/migratetoAMA	Deny, Audit, Disabled	1.0.0
The Log Analytics extension should be installed on Virtual Machine Scale Sets	This policy audits any Windows/Linux Virtual Machine Scale Sets if the Log Analytics extension is not installed.	AuditIfNotExists, Disabled	1.0.1
Virtual Machine should have TrustedLaunch enabled	Enable TrustedLaunch on Virtual Machine for enhanced security, use VM SKU (Gen 2) that supports TrustedLaunch. To learn more about TrustedLaunch, visit https://learn.microsoft.com/en-us/azure/virtual-machines/trusted-launch	Audit, Disabled	1.0.0
Virtual machines and virtual machine scale sets should have encryption at host enabled	Use encryption at host to get end-to-end encryption for your virtual machine and virtual machine scale set data. Encryption at host enables encryption at rest for your temporary disk and OS/data disk caches. Temporary and ephemeral OS disks are encrypted with platform-managed keys when encryption at host is enabled. OS/data disk caches are encrypted at rest with either customer-managed or platform-managed key, depending on the encryption type selected on the disk. Learn more at https://aka.ms/vm-hbe.	Audit, Deny, Disabled	1.0.0
Virtual machines should be connected to a specified workspace	Reports virtual machines as non-compliant if they aren't logging to the Log Analytics workspace specified in the policy/initiative assignment.	AuditIfNotExists, Disabled	1.1.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Virtual machines should be migrated to new Azure Resource Manager resources	Use new Azure Resource Manager for your virtual machines to provide security enhancements such as: stronger access control (RBAC), better auditing, Azure Resource Manager based deployment and governance, access to managed identities, access to key vault for secrets, Azure AD-based authentication and support for tags and resource groups for easier security management	Audit, Deny, Disabled	1.0.0
Virtual machines should have the Log Analytics extension installed	This policy audits any Windows/Linux virtual machines if the Log Analytics extension is not installed.	AuditIfNotExists, Disabled	1.0.1
Virtual machines' Guest Configuration extension should be deployed with system-assigned managed identity	The Guest Configuration extension requires a system assigned managed identity. Azure virtual machines in the scope of this policy will be non-compliant when they have the Guest Configuration extension installed but do not have a system assigned managed identity. Learn more at https://aka.ms/gcpol	AuditIfNotExists, Disabled	1.0.1
Vulnerabilities in container security configurations should be remediated	Audit vulnerabilities in security configuration on machines with Docker installed and display as recommendations in Azure Security Center.	AuditIfNotExists, Disabled	3.0.0
Vulnerabilities in security configuration on your machines should be remediated	Servers which do not satisfy the configured baseline will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	3.1.0
Vulnerabilities in security configuration on your virtual machine scale sets should be remediated	Audit the OS vulnerabilities on your virtual machine scale sets to protect them from attacks.	AuditIfNotExists, Disabled	3.0.0
Windows Defender Exploit Guard should be enabled on your machines	Windows Defender Exploit Guard uses the Azure Policy Guest Configuration agent. Exploit Guard has four components that are designed to lock down devices against a wide variety of attack vectors and block behaviors commonly used in malware attacks while enabling enterprises to balance their security risk and productivity requirements (Windows only).	AuditIfNotExists, Disabled	2.0.0
Windows machines should be configured to use secure communication protocols	To protect the privacy of information communicated over the Internet, your machines should use the latest version of the industry-standard cryptographic protocol, Transport Layer Security (TLS). TLS secures communications over a network by encrypting a connection between machines.	AuditIfNotExists, Disabled	4.1.1
Windows machines should configure Windows Defender to update protection signatures within one day	To provide adequate protection against newly released malware, Windows Defender protection signatures need to be updated regularly to account for newly released malware. This policy is not applied to Arc connected servers and it requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For more information on Guest Configuration, visit https://aka.ms/gcpol .	AuditIfNotExists, Disabled	1.0.1

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Windows machines should enable Windows Defender Real-time protection	Windows machines should enable the Real-time protection in the Windows Defender to provide adequate protection against newly released malware. This policy is not applicable to arc connected servers and it requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For more information on Guest Configuration, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	1.0.1
Windows machines should meet requirements for 'Administrative Templates - Control Panel'	Windows machines should have the specified Group Policy settings in the category 'Administrative Templates - Control Panel' for input personalization and prevention of enabling lock screens. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Administrative Templates - MSS (Legacy)'	Windows machines should have the specified Group Policy settings in the category 'Administrative Templates - MSS (Legacy)' for automatic logon, screen saver, network behavior, safe DLL, and event log. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Administrative Templates - Network'	Windows machines should have the specified Group Policy settings in the category 'Administrative Templates - Network' for guest logons, simultaneous connections, network bridge, ICS, and multicast name resolution. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Administrative Templates - System'	Windows machines should have the specified Group Policy settings in the category 'Administrative Templates - System' for settings that control the administrative experience and Remote Assistance. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Accounts'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Accounts' for limiting local account use of blank passwords and guest account status. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Audit'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Audit' for forcing audit policy subcategory and shutting down if unable to log security audits. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Devices'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Devices' for undocking without logging on, installing print drivers, and formatting/ejecting media. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Interactive Logon'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Interactive Logon' for displaying last user name and requiring ctrl-alt-del. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for	Windows machines should have the specified Group Policy settings in the category 'Security Options - Microsoft Network Client' for Microsoft network client/server and SMB v1. This policy requires that the Guest Configuration	AuditIfNotExists, Disabled	3.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
'Security Options - Microsoft Network Client'	prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.		
Windows machines should meet requirements for 'Security Options - Microsoft Network Server'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Microsoft Network Server' for disabling SMB v1 server. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Network Access'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Network Access' for including access for anonymous users, local accounts, and remote access to the registry. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Network Security'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Network Security' for including Local System behavior, PKU2U, LAN Manager, LDAP client, and NTLM SSP. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Recovery console'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Recovery console' for allowing floppy copy and access to all drives and folders. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - Shutdown'	Windows machines should have the specified Group Policy settings in the category 'Security Options - Shutdown' for allowing shutdown without logon and clearing the virtual memory pagefile. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - System objects'	Windows machines should have the specified Group Policy settings in the category 'Security Options - System objects' for case insensitivity for non-Windows subsystems and permissions of internal system objects. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - System settings'	Windows machines should have the specified Group Policy settings in the category 'Security Options - System settings' for certificate rules on executables for SRP and optional subsystems. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Options - User Account Control'	Windows machines should have the specified Group Policy settings in the category 'Security Options - User Account Control' for mode for admins, behavior of elevation prompt, and virtualizing file and registry write failures. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Security Settings - Account Policies'	Windows machines should have the specified Group Policy settings in the category 'Security Settings - Account Policies' for password history, age, length, complexity, and storing passwords using reversible encryption. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Windows machines should meet requirements for 'System Audit Policies - Account Logon'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Account Logon' for auditing credential validation and other account logon events. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - Account Management'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Account Management' for auditing application, security, and user group management, and other management events. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - Detailed Tracking'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Detailed Tracking' for auditing DPAPI, process creation/termination, RPC events, and PNP activity. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - Logon-Logoff'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Logon-Logoff' for auditing IPSec, network policy, claims, account lockout, group membership, and logon/logoff events. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - Object Access'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Object Access' for auditing file, registry, SAM, storage, filtering, kernel, and other system types. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - Policy Change'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Policy Change' for auditing changes to system audit policies. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - Privilege Use'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - Privilege Use' for auditing nonsensitive and other privilege use. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'System Audit Policies - System'	Windows machines should have the specified Group Policy settings in the category 'System Audit Policies - System' for auditing IPsec driver, system integrity, system extension, state change, and other system events. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'User Rights Assignment'	Windows machines should have the specified Group Policy settings in the category 'User Rights Assignment' for allowing log on locally, RDP, access from the network, and many other user activities. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol.	AuditIfNotExists, Disabled	3.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Windows machines should meet requirements for 'Windows Components'	Windows machines should have the specified Group Policy settings in the category 'Windows Components' for basic authentication, unencrypted traffic, Microsoft accounts, telemetry, Cortana, and other Windows behaviors. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol .	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements for 'Windows Firewall Properties'	Windows machines should have the specified Group Policy settings in the category 'Windows Firewall Properties' for firewall state, connections, rule management, and notifications. This policy requires that the Guest Configuration prerequisites have been deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol .	AuditIfNotExists, Disabled	3.0.0
Windows machines should meet requirements of the Azure compute security baseline	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol . Machines are non-compliant if the machine is not configured correctly for one of the recommendations in the Azure compute security baseline.	AuditIfNotExists, Disabled	2.0.0
Windows machines should only have local accounts that are allowed	Requires that prerequisites are deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol . This definition is not supported on Windows Server 2012 or 2012 R2. Managing user accounts using Azure Active Directory is a best practice for management of identities. Reducing local machine accounts helps prevent the proliferation of identities managed outside a central system. Machines are non-compliant if local user accounts exist that are enabled and not listed in the policy parameter.	AuditIfNotExists, Disabled	2.0.0
Windows virtual machine scale sets should have Azure Monitor Agent installed	Windows virtual machine scale sets should be monitored and secured through the deployed Azure Monitor Agent. The Azure Monitor Agent collects telemetry data from the guest OS. Virtual machine scale sets with supported OS and in supported regions are monitored for Azure Monitor Agent deployment. Learn more: https://aka.ms/AMAOverview .	AuditIfNotExists, Disabled	3.2.0
Windows virtual machines should enable Azure Disk Encryption or EncryptionAtHost.	Although a virtual machine's OS and data disks are encrypted-at-rest by default using platform managed keys; resource disks (temp disks), data caches, and data flowing between Compute and Storage resources are not encrypted. Use Azure Disk Encryption or EncryptionAtHost to remediate. Visit https://aka.ms/diskencryptioncomparison to compare encryption offerings. This policy requires two prerequisites to be deployed to the policy assignment scope. For details, visit https://aka.ms/gcpol .	AuditIfNotExists, Disabled	1.1.1
Windows virtual machines should have Azure Monitor Agent installed	Windows virtual machines should be monitored and secured through the deployed Azure Monitor Agent. The Azure Monitor Agent collects telemetry data from the guest OS. Windows virtual machines with supported OS and in supported regions are monitored for Azure Monitor Agent deployment. Learn more: https://aka.ms/AMAOverview .	AuditIfNotExists, Disabled	3.2.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
VM Image Builder templates should use private link	Azure Private Link lets you connect your virtual network to Azure services without a public IP address at the source or destination. The Private Link platform handles the connectivity between the consumer and services over the Azure backbone network. By mapping private endpoints to your VM Image Builder building resources, data leakage risks are reduced. Learn more about private links at:	Audit, Disabled, Deny	1.1.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
A vulnerability assessment solution should be enabled on your virtual machines	Audits virtual machines to detect whether they are running a supported vulnerability assessment solution. A core component of every cyber risk and security program is the identification and analysis of vulnerabilities. Azure Security Center's standard pricing tier includes vulnerability scanning for your virtual machines at no extra cost. Additionally, Security Center can automatically deploy this tool for you.	AuditIfNotExists, Disabled	3.0.0
Adaptive application controls for defining safe applications should be enabled on your machines	Enable application controls to define the list of known-safe applications running on your machines, and alert you when other applications run. This helps harden your machines against malware. To simplify the process of configuring and maintaining your rules, Security Center uses machine learning to analyze the applications running on each machine and suggest the list of known-safe applications.	AuditIfNotExists, Disabled	3.0.0
All network ports should be restricted on network security groups associated to your virtual machine	Azure Security Center has identified some of your network security groups' inbound rules to be too permissive. Inbound rules should not allow access from 'Any' or 'Internet' ranges. This can potentially enable attackers to target your resources.	AuditIfNotExists, Disabled	3.0.0
Allowlist rules in your adaptive application control policy should be updated	Monitor for changes in behavior on groups of machines configured for auditing by Azure Security Center's adaptive application controls. Security Center uses machine learning to analyze the running processes on your machines and suggest a list of known-safe applications. These are presented as recommended apps to allow in adaptive application control policies.	AuditIfNotExists, Disabled	3.0.0
Audit virtual machines without disaster recovery configured	Audit virtual machines which do not have disaster recovery configured. To learn more about disaster recovery, visit https://aka.ms/asr-doc.	auditIfNotExists	1.0.0
Endpoint protection health issues should be resolved on your machines	Resolve endpoint protection health issues on your virtual machines to protect them from latest threats and vulnerabilities. Azure Security Center supported endpoint protection solutions are documented here - https://docs.microsoft.com/azure/security-center/security-center-services?tabs=features-windows#supported-endpoint-protection-solutions. Endpoint protection assessment is documented here - https://docs.microsoft.com/azure/security-center/security-center-endpoint-protection.	AuditIfNotExists, Disabled	1.0.0
Endpoint protection should be installed on your machines	To protect your machines from threats and vulnerabilities, install a supported endpoint protection solution.	AuditIfNotExists, Disabled	1.0.0

Name (Azure portal)	Description	Effect(s)	Version (GitHub)
Internet-facing virtual machines should be protected with network security groups	Protect your virtual machines from potential threats by restricting access to them with network security groups (NSG). Learn more about controlling traffic with NSGs at https://aka.ms/nsg-doc	AuditIfNotExists, Disabled	3.0.0
IP Forwarding on your virtual machine should be disabled	Enabling IP forwarding on a virtual machine's NIC allows the machine to receive traffic addressed to other destinations. IP forwarding is rarely required (e.g., when using the VM as a network virtual appliance), and therefore, this should be reviewed by the network security team.	AuditIfNotExists, Disabled	3.0.0
Machines should have secret findings resolved	Audits virtual machines to detect whether they contain secret findings from the secret scanning solutions on your virtual machines.	AuditIfNotExists, Disabled	1.0.2
Management ports should be closed on your virtual machines	Open remote management ports are exposing your VM to a high level of risk from Internet-based attacks. These attacks attempt to brute force credentials to gain admin access to the machine.	AuditIfNotExists, Disabled	3.0.0
Monitor missing Endpoint Protection in Azure Security Center	Servers without an installed Endpoint Protection agent will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	3.0.0
Non-internet-facing virtual machines should be protected with network security groups	Protect your non-internet-facing virtual machines from potential threats by restricting access with network security groups (NSG). Learn more about controlling traffic with NSGs at https://aka.ms/nsg-doc	AuditIfNotExists, Disabled	3.0.0
System updates should be installed on your machines	Missing security system updates on your servers will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	4.0.0
Virtual machines should be migrated to new Azure Resource Manager resources	Use new Azure Resource Manager for your virtual machines to provide security enhancements such as: stronger access control (RBAC), better auditing, Azure Resource Manager based deployment and governance, access to managed identities, access to key vault for secrets, Azure AD-based authentication and support for tags and resource groups for easier security management	Audit, Deny, Disabled	1.0.0
Vulnerabilities in container security configurations should be remediated	Audit vulnerabilities in security configuration on machines with Docker installed and display as recommendations in Azure Security Center.	AuditIfNotExists, Disabled	3.0.0
Vulnerabilities in security configuration on your machines should be remediated	Servers which do not satisfy the configured baseline will be monitored by Azure Security Center as recommendations	AuditIfNotExists, Disabled	3.1.0

Quickstart: Create a policy assignment to identify non-compliant resources using Azure portal

Article • 03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using Azure portal. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

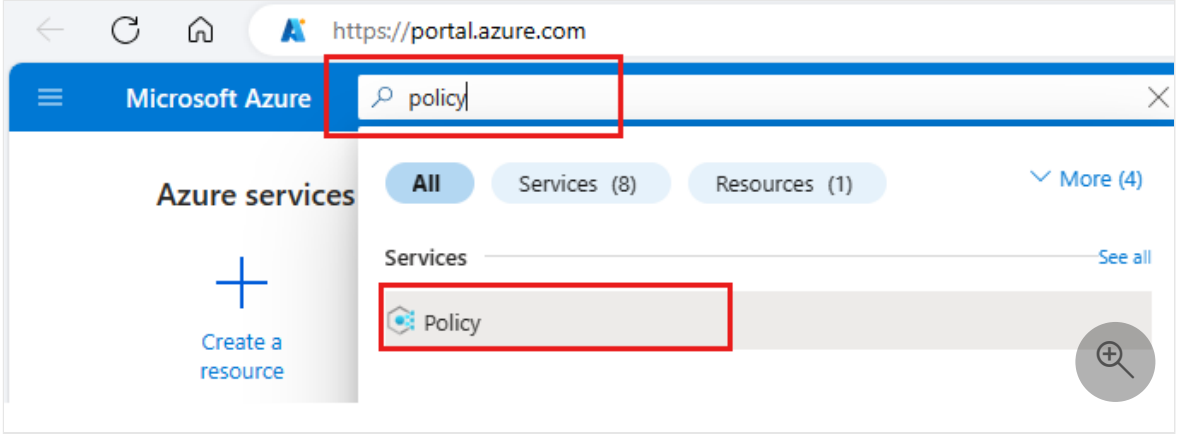
- If you don't have an Azure account, create a free account before you begin.
- A resource group with at least one virtual machine that doesn't use managed disks.

Create a policy assignment

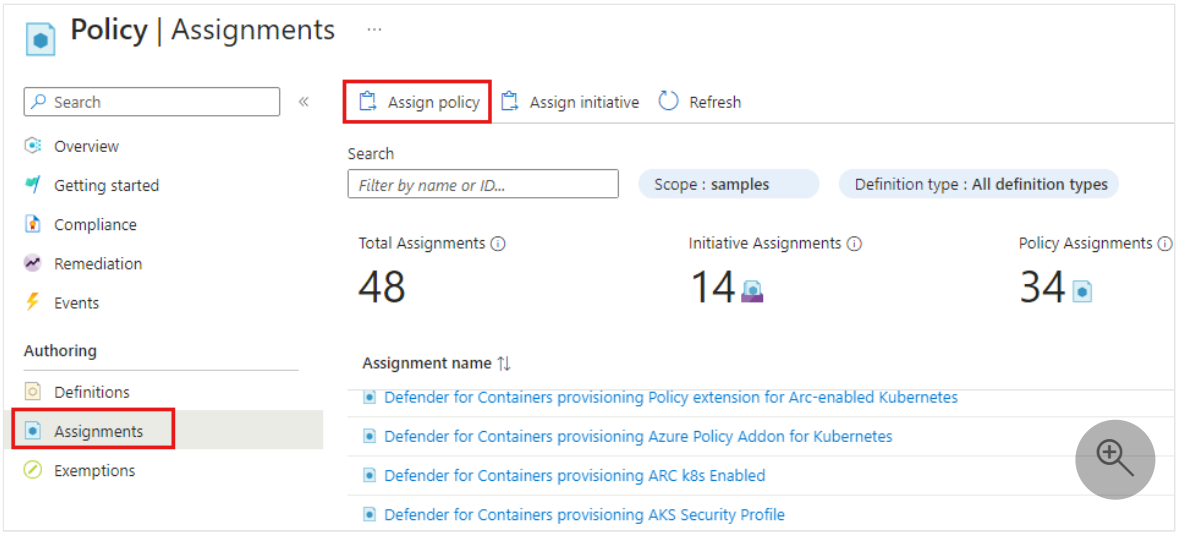
In this quickstart, you create a policy assignment with a built-in policy definition, Audit VMs that do not use managed disks.

1. Sign in to the Azure portal.

2. Search for *policy* and select it from the list.



3. Select **Assignments** on the **Policy** pane.



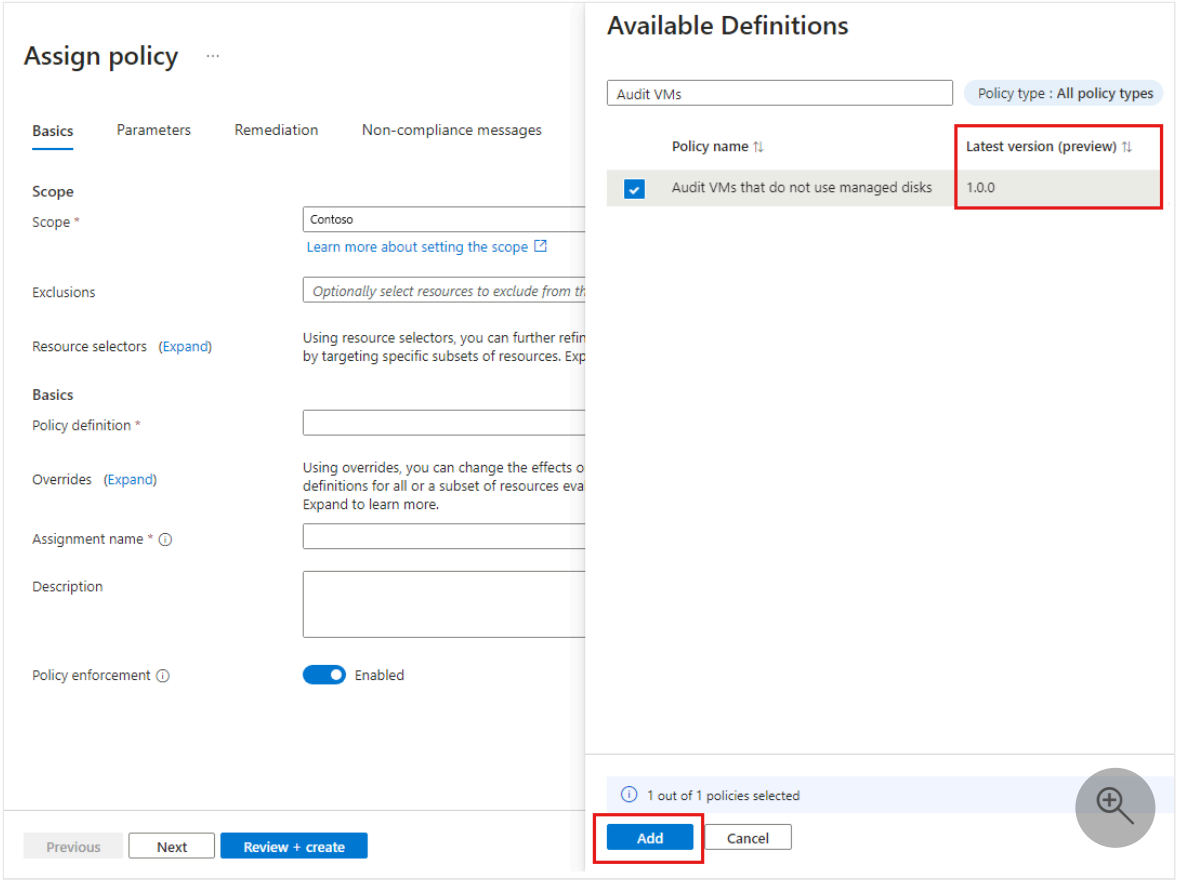
4. Select **Assign Policy** from the **Policy Assignments** pane.

5. On the **Assign Policy** pane **Basics** tab configure the following options:

Expand table

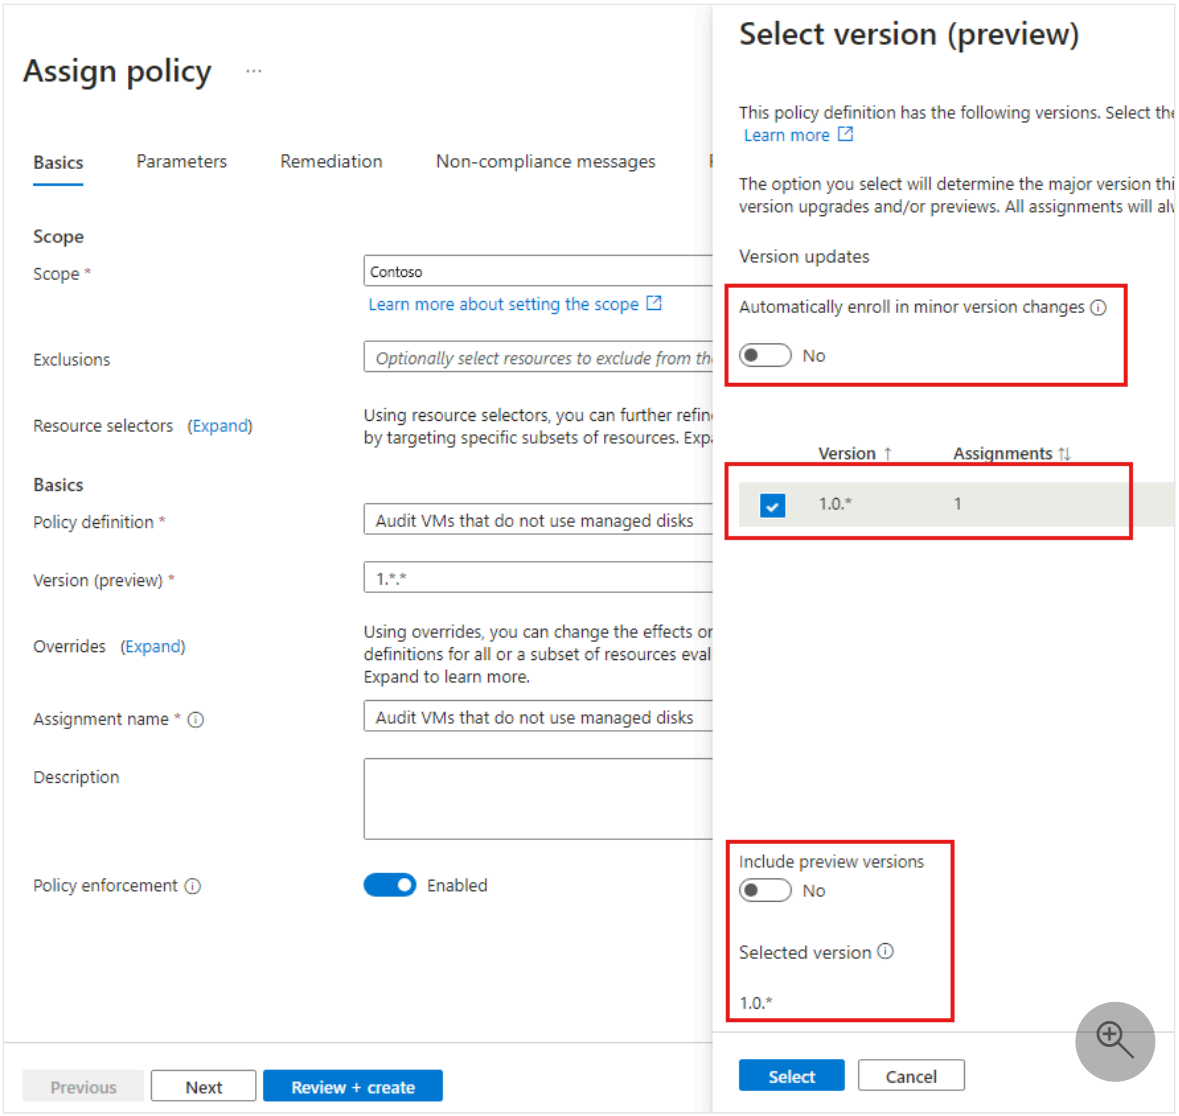
Field	Action
Scope	Use the ellipsis (`...`) and then select a subscription and a resource group. Then choose **Select** to apply the scope.
Exclusions	Optional and isn't used in this example.
Resource selectors	Skip resource selectors for this example. Resource selectors let you refine the resources affected by the policy assignment.
Policy definition	Select the ellipsis (`...`) to open the list of available definitions.
Available Definitions	Search the policy definitions list for *Audit VMs that do not use managed disks* definition, select the policy, and select **Add**. There's a column that shows the latest version of the definition.
Version (preview)	Accept the version in format `1.*.*` to ingest major, minor, and patch versions. Select the ellipsis (`...`) to view available versions and the options to enroll in minor version updates or preview versions. You must select a version to change the options. For more information, go to definition version within assignment.
Assignment name	By default uses the name of the selected policy. You can change it but for this example, use the default name.
Description	Optional to provide details about this policy assignment.

Field	Action
Policy enforcement	Defaults to *Enabled*. For more information, go to enforcement mode.



6. After a Policy definition is selected, you can change the **Version (preview)** options.

   For example, if you select the options shown in the image, the **Version (preview)** is changed to `1.0.*`.



7. Select **Next** to view each tab for **Parameters** and **Remediation**. No changes are needed for this example.

Expand table

Tab name	Options
Parameters	If the policy definition you selected on the **Basics** tab has parameters, you configure them on the **Parameters** tab. This example doesn't use parameters.
Remediation	You can create a managed identity. For this example, **Create a Managed Identity** is unchecked. This box *must* be checked when a policy or initiative includes a policy with either the deployIfNotExists or modify effect. For more information, go to managed identities and how remediation access control works.

8. Select **Next** and on the **Non-compliance messages** tab create a **Non-compliance message** like *Virtual machines should use managed disks*.

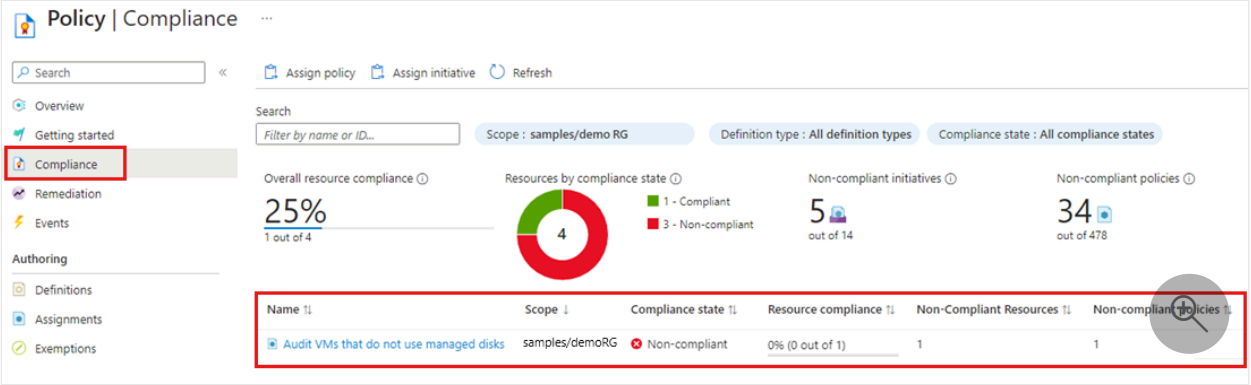
This custom message is displayed when a resource is denied or for non-compliant resources during regular evaluation.

9. Select **Next** and on the **Review + create** tab, review the policy assignment details.

10. Select **Create** to create the policy assignment.

Identify non-compliant resources

On the **Policy** pane, select **Compliance** and locate the *Audit VMs that do not use managed disks* policy assignment. The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.



The policy assignment shows resources that aren't compliant with a **Compliance state** of **Non-compliant**. To get more details, select the policy assignment name to view the **Resource Compliance**.

When a condition is evaluated against your existing resources and found true, then those resources are marked as non-compliant with the policy. The following table shows how different policy effects work with the condition evaluation for the resulting compliance state. Although you don't see the evaluation logic in the Azure portal, the compliance state results are shown. The compliance state result is either compliant or non-compliant.

Expand table

Resource State	Effect	Policy Evaluation	Compliance State
New or Updated	Audit, Modify, AuditIfNotExist	True	Non-Compliant
New or Updated	Audit, Modify, AuditIfNotExist	False	Compliant

Resource State	Effect	Policy Evaluation	Compliance State
Exists	Deny, Audit, Append, Modify, DeployIfNotExist, AuditIfNotExist	True	Non-Compliant
Exists	Deny, Audit, Append, Modify, DeployIfNotExist, AuditIfNotExist	False	Compliant

The `DeployIfNotExist` and `AuditIfNotExist` effects require the `IF` statement to be `TRUE` and the existence condition to be `FALSE` to be non-compliant. When `TRUE`, the `IF` condition triggers evaluation of the existence condition for the related resources.

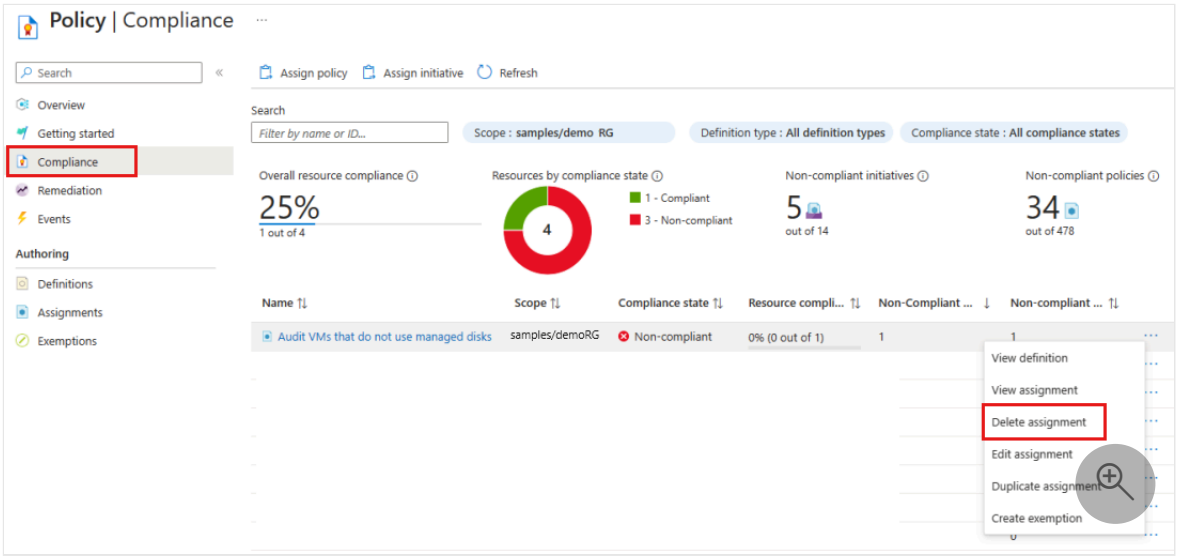
Clean up resources

You can delete a policy assignment from **Compliance** or from **Assignments**.

To remove the policy assignment created in this article, follow these steps:

1. On the **Policy** pane, select **Compliance** and locate the *Audit VMs that do not use managed disks* policy assignment.

2. Select the policy assignment's ellipsis and select **Delete assignment**.



Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

To learn more about how to assign policies that validate resource compliance, continue to the tutorial.

Quickstart: Create a policy assignment to identify non-compliant resources using Azure CLI

Article • 03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using Azure CLI. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

Azure CLI is used to create and manage Azure resources from the command line or in scripts. This guide uses Azure CLI to create a policy assignment and to identify non-compliant resources in your Azure environment.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Azure CLI.
- Visual Studio Code.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Connect to Azure

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

Azure CLI

```
az login
```

```
# Run these commands if you have multiple subscriptions
az account list --output table
az account set --subscription <subscriptionID>
```

Register resource provider

When a resource provider is registered, it's available to use in your Azure subscription.

To verify if `Microsoft.PolicyInsights` is registered, run `Get-AzResourceProvider`. The resource provider contains several resource types. If the result is `NotRegistered` run `Register-AzResourceProvider`:

Azure CLI

```
az provider show \
  --namespace Microsoft.PolicyInsights \
  --query "{Provider:namespace,State:registrationState}" \
  --output table

az provider register --namespace Microsoft.PolicyInsights
```

The Azure CLI commands use a backslash (`\`) for line continuation to improve readability. For more information, go to az provider.

Create policy assignment

Use the following commands to create a new policy assignment for your resource group. This example uses an existing resource group that contains a virtual machine *without* managed disks. The resource group is the scope for the policy assignment. This example uses the built-in policy definition Audit VMs that do not use managed disks.

Run the following commands and replace `<resourceGroupName>` with your resource group name:

Azure PowerShell

```
rgid=$(az group show --resource-group <resourceGroupName> --query id --
output tsv)

definition=$(az policy definition list \
  --query "[?displayName=='Audit VMs that do not use managed disks']".name \
  --output tsv)
```

The `rgid` variable stores the resource group ID. The `definition` variable stores the policy definition's name, which is a GUID.

Run the following command to create the policy assignment:

Azure CLI

```
az policy assignment create \
  --name 'audit-vm-managed-disks' \
  --display-name 'Audit VM managed disks' \
  --scope $rgid \
  --policy $definition \
  --description 'Azure CLI policy assignment to resource group'
```

- `name` creates the policy assignment name used in the assignment's `ResourceId`.
- `display-name` is the name for the policy assignment and is visible in Azure portal.
- `scope` uses the `$rgid` variable to assign the policy to the resource group.
- `policy` assigns the policy definition stored in the `$definition` variable.
- `description` can be used to add context about the policy assignment.

The results of the policy assignment resemble the following example:

Output

```
"description": "Azure CLI policy assignment to resource group",
"displayName": "Audit VM managed disks",
"enforcementMode": "Default",
"id":
"/subscriptions/{subscriptionID}/resourceGroups/{resourceGroupName}/provider
s/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks",
"identity": null,
"location": null,
"metadata": {
  "createdBy": "11111111-1111-1111-1111-111111111111",
  "createdOn": "2024-02-23T18:42:27.4780803Z",
  "updatedBy": null,
  "updatedOn": null
},
"name": "audit-vm-managed-disks",
```

If you want to redisplay the policy assignment information, run the following command:

Azure CLI

```
az policy assignment show --name "audit-vm-managed-disks" --scope $rgid
```

For more information, go to az policy assignment.

Identify non-compliant resources

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

Use the following command to identify resources that aren't compliant with the policy assignment you created:

Azure CLI

```
policyid=$(az policy assignment show \
  --name "audit-vm-managed-disks" \
  --scope $rgid \
  --query id \
  --output tsv)

az policy state list --resource $policyid --filter "(isCompliant eq false)"
```

The `policyid` variable uses an expression to get the policy assignment's ID. The `filter` parameter limits the output to non-compliant resources.

The `az policy state list` output is verbose, but for this article the `complianceState` shows `NonCompliant`:

Output

```
"complianceState": "NonCompliant",
"components": null,
"effectiveParameters": "",
"isCompliant": false,
```

For more information, go to az policy state.

Clean up resources

To remove the policy assignment, run the following command:

Azure CLI

```
az policy assignment delete --name "audit-vm-managed-disks" --scope $rgid
```

To sign out of your Azure CLI session:

Azure CLI

```
az logout
```

Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

To learn more about how to assign policies that validate resource compliance, continue to the tutorial.

Quickstart: Create a policy assignment to identify noncompliant resources using Terraform

Article • 04/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. This quickstart steps you through the process of creating a policy assignment to identify virtual machines that are not using managed disks.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Terraform enables the definition, preview, and deployment of cloud infrastructure. Using Terraform, you create configuration files using HCL syntax. The HCL syntax allows you to specify the cloud provider - such as Azure - and the elements that make up your cloud infrastructure. After you create your configuration files, you create an *execution plan* that allows you to preview your infrastructure changes before they're deployed. Once you verify the changes, you apply the execution plan to deploy the infrastructure.

In this article, you learn how to:

- ✓ Retrieve the current Azure client configuration.
- ✓ Create a Azure resource group with the generated random name.
- ✓ Create Subscription Policy Assignment to identify virtual machines that aren't using managed disks

Prerequisites

- Create an Azure account with an active subscription. You can create an account for free.
- Install and configure Terraform

Implement the Terraform code

The sample code for this article is located in the Azure Terraform GitHub repo. You can view the log file containing the test results from current and previous versions of

Terraform. See more articles and sample code showing how to use Terraform to manage Azure resources

1. Create a directory in which to test and run the sample Terraform code, and make it the current directory.

2. Create a file named `providers.tf` and insert the following code.

```Terraform
terraform {
  required_providers {
    azurerm = {
      source  = "hashicorp/azurerm"
      version = "~>4.0"
    }
    random = {
      source  = "hashicorp/random"
      version = "~>3.0"
    }
  }
}

provider "azurerm" {
  features {}
}
```

3. Create a file named `main.tf` and insert the following code.

```Terraform
# Create a random pet name to ensure unique resource group name
resource "random_pet" "rg_name" {
  prefix = var.resource_group_name_prefix
}

# Create a resource group
resource "azurerm_resource_group" "example" {
  location = var.resource_group_location
  name     = random_pet.rg_name.id
}

# Get the current subscription
data "azurerm_subscription" "current" {}

# Create a subscription policy assignment
resource "azurerm_subscription_policy_assignment" "auditvms" {
  name                 = "audit-vm-manageddisks"
  subscription_id      = coalesce(var.scope,
"/subscriptions/${data.azurerm_subscription.current.subscription_id}")
  policy_definition_id =
```

```
"/providers/Microsoft.Authorization/policyDefinitions/06a78e20-9358-41c9-923c-fb736d382a4d"
  description          = "Shows all virtual machines not using managed disks"
  display_name         = "Audit VMs without managed disks assignment"
}
```

4. Create a file named `variables.tf` and insert the following code.

Terraform

```
variable "resource_group_location" {
  type        = string
  default     = "eastus"
  description = "Location of the resource group."
}

variable "resource_group_name_prefix" {
  type        = string
  default     = "rg"
  description = "Prefix of the resource group name that's combined with a random ID so name is unique in your Azure subscription."
}

variable "scope" {
  type        = string
  default     = ""
  description = "Scope of the policy assignment."
}
```

5. Create a file named `outputs.tf` and insert the following code.

Terraform

```
output "resource_group_name" {
  value = azurerm_resource_group.example.name
}

output "assignment_id" {
  value = azurerm_subscription_policy_assignment.auditvms.id
}

output "subscription_id" {
  value = data.azurerm_subscription.current.subscription_id
}
```

Specify scope

A scope determines what resources or grouping of resources the policy assignment gets enforced on. It could range from a management group to an individual resource. To use any of the following scopes, update the `scope` variable in the `variables.tf` file. If you leave the `scope` variable value blank, the "subscription" scope is used.

- Subscription: `/subscriptions/<subscription_id>`
- Resource group: `/subscriptions/<subscription_id>/resourceGroups/<resource_group_name>`
- Resource: `/subscriptions/<subscription_id>/resourceGroups/<resource_group_name>/providers/<resource_provider_namespace>/[{parentResourcePath}/]`

Initialize Terraform

> **ⓘ Important**
>
> If you are using the 4.x azurerm provider, you must explicitly specify the Azure subscription ID to authenticate to Azure before running the Terraform commands.
>
> One way to specify the Azure subscription ID without putting it in the `providers` block is to specify the subscription ID in an environment variable named `ARM_SUBSCRIPTION_ID`.
>
> For more information, see the Azure provider reference documentation.

Run terraform init to initialize the Terraform deployment. This command downloads the Azure provider required to manage your Azure resources.

```
Console
terraform init -upgrade
```

Key points:

- The `-upgrade` parameter upgrades the necessary provider plugins to the newest version that complies with the configuration's version constraints.

Create a Terraform execution plan

Run terraform plan to create an execution plan.

```
Console

terraform plan -out main.tfplan
```

Key points:

- The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
- The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

Apply a Terraform execution plan

Run terraform apply to apply the execution plan to your cloud infrastructure.

```
Console

terraform apply main.tfplan
```

Key points:

- The example `terraform apply` command assumes you previously ran `terraform plan -out main.tfplan`.
- If you specified a different filename for the `-out` parameter, use that same filename in the call to `terraform apply`.
- If you didn't use the `-out` parameter, call `terraform apply` without any parameters.

Verify the results

1. Get the `_assignment\_id_` returned by `terraform apply`.

2. run the following command to view the resources that are not compliant under your new policy assignment.

   ```
   Console
   ```

```
armclient post
"/subscriptions/<subscription_id>/providers/Microsoft.PolicyInsights/po
licyStates/latest/queryResults?api-version=2019-10-
01&$filter=IsCompliant eq false and PolicyAssignmentId eq
'<policyAssignmentID>'&$apply=groupby((ResourceId))" > <json file to
direct the output with the resource IDs into>
```

3. The results are comparable to what you see listed under **Noncompliant resources** in the Azure portal view.

Clean up resources

When you no longer need the resources created via Terraform, do the following steps:

1. Run terraform plan and specify the `destroy` flag.

   Console

   ```
   terraform plan -destroy -out main.destroy.tfplan
   ```

   Key points:

   - The `terraform plan` command creates an execution plan, but doesn't execute it. Instead, it determines what actions are necessary to create the configuration specified in your configuration files. This pattern allows you to verify whether the execution plan matches your expectations before making any changes to actual resources.
   - The optional `-out` parameter allows you to specify an output file for the plan. Using the `-out` parameter ensures that the plan you reviewed is exactly what is applied.

2. Run terraform apply to apply the execution plan.

   Console

   ```
   terraform apply main.destroy.tfplan
   ```

Quickstart: Create a policy assignment to identify non-compliant resources using Azure PowerShell

Article • 03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using Azure PowerShell. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

The Azure PowerShell modules can be used to manage Azure resources from the command line or in scripts. This article explains how to use Azure PowerShell to create a policy assignment.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Azure PowerShell.
- Visual Studio Code.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Connect to Azure

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

Azure PowerShell

```
Connect-AzAccount
```

```
# Run these commands if you have multiple subscriptions
Get-AzSubScription
Set-AzContext -Subscription <subscriptionID>
```

Register resource provider

When a resource provider is registered, it's available to use in your Azure subscription.

To verify if `Microsoft.PolicyInsights` is registered, run `Get-AzResourceProvider`. The resource provider contains several resource types. If the result is `NotRegistered` run `Register-AzResourceProvider`:

Azure PowerShell

```
 Get-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights' |
   Select-Object -Property ResourceTypes, RegistrationState

Register-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights'
```

For more information, go to Get-AzResourceProvider and Register-AzResourceProvider.

Create policy assignment

Use the following commands to create a new policy assignment for your resource group. This example uses an existing resource group that contains a virtual machine *without* managed disks. The resource group is the scope for the policy assignment. This example uses the built-in policy definition Audit VMs that do not use managed disks.

Run the following commands and replace `<resourceGroupName>` with your resource group name:

Azure PowerShell

```
$rg = Get-AzResourceGroup -Name '<resourceGroupName>'

$definition = Get-AzPolicyDefinition |
  Where-Object { $_.DisplayName -eq 'Audit VMs that do not use managed
disks' }
```

The `$rg` variable stores properties for the resource group and the `$definition` variable stores the policy definition's properties. The properties are used in subsequent commands.

Run the following command to create the policy assignment:

Azure PowerShell

```
$policyparms = @{
Name = 'audit-vm-managed-disks'
DisplayName = 'Audit VM managed disks'
Scope = $rg.ResourceId
PolicyDefinition = $definition
Description = 'Az PowerShell policy assignment to resource group'
}

New-AzPolicyAssignment @policyparms
```

The `$policyparms` variable uses splatting to create parameter values and improve readability. The `New-AzPolicyAssignment` command uses the parameter values defined in the `$policyparms` variable.

- `Name` creates the policy assignment name used in the assignment's `ResourceId`.
- `DisplayName` is the name for the policy assignment and is visible in Azure portal.
- `Scope` uses the `$rg.ResourceId` property to assign the policy to the resource group.
- `PolicyDefinition` assigns the policy definition stored in the `$definition` variable.
- `Description` can be used to add context about the policy assignment.

The results of the policy assignment resemble the following example:

Output

```
Name               : audit-vm-managed-disks
ResourceId         :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers
/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks
ResourceName       : audit-vm-managed-disks
ResourceGroupName  : {resourceGroupName}
ResourceType       : Microsoft.Authorization/policyAssignments
SubscriptionId     : {subscriptionId}
PolicyAssignmentId :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers
/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks
Properties         :
Microsoft.Azure.Commands.ResourceManager.Cmdlets.Implementation.Policy.PsPol
icyAssignmentProperties
```

For more information, go to New-AzPolicyAssignment.

If you want to redisplay the policy assignment information, run the following command:

Azure PowerShell

```
Get-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

Identify non-compliant resources

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

Use the following command to identify resources that aren't compliant with the policy assignment you created:

Azure PowerShell

```
$complianceparms = @{
ResourceGroupName = $rg.ResourceGroupName
PolicyAssignmentName = 'audit-vm-managed-disks'
Filter = 'IsCompliant eq false'
}

Get-AzPolicyState @complianceparms
```

The `$complianceparms` variable uses splatting to create parameter values used in the `Get-AzPolicyState` command.

- `ResourceGroupName` gets the resource group name from the `$rg.ResourceGroupName` property.
- `PolicyAssignmentName` specifies the name used when the policy assignment was created.
- `Filter` uses an expression to find resources that aren't compliant with the policy assignment.

Your results resemble the following example and `ComplianceState` shows `NonCompliant`:

Output

```
Timestamp                : 2/14/2024 18:25:37
ResourceId               :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers
/microsoft.compute/virtualmachines/{vmId}
PolicyAssignmentId       :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers
/microsoft.authorization/policyassignments/audit-vm-managed-disks
PolicyDefinitionId       :
/providers/microsoft.authorization/policydefinitions/06a78e20-9358-41c9-
```

```
923c-fb736d382a4d
IsCompliant               : False
SubscriptionId            : {subscriptionId}
ResourceType              : Microsoft.Compute/virtualMachines
ResourceLocation          : {location}
ResourceGroup             : {resourceGroupName}
ResourceTags              : tbd
PolicyAssignmentName      : audit-vm-managed-disks
PolicyAssignmentOwner     : tbd
PolicyAssignmentScope     :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}
PolicyDefinitionName      : 06a78e20-9358-41c9-923c-fb736d382a4d
PolicyDefinitionAction    : audit
PolicyDefinitionCategory  : tbd
ManagementGroupIds        : {managementGroupId}
ComplianceState           : NonCompliant
AdditionalProperties      : {[complianceReasonCode, ]}
```

For more information, go to Get-AzPolicyState.

Clean up resources

To remove the policy assignment, run the following command:

Azure PowerShell

```
Remove-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope
$rg.ResourceId
```

To sign out of your Azure PowerShell session:

Azure PowerShell

```
Disconnect-AzAccount
```

Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

Quickstart: Create a policy assignment to identify non-compliant resources using Azure PowerShell

03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using Azure PowerShell. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

The Azure PowerShell modules can be used to manage Azure resources from the command line or in scripts. This article explains how to use Azure PowerShell to create a policy assignment.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Azure PowerShell.
- Visual Studio Code.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Connect to Azure

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

Azure PowerShell

```
Connect-AzAccount

# Run these commands if you have multiple subscriptions
```

```
Get-AzSubScription
Set-AzContext -Subscription <subscriptionID>
```

Register resource provider

When a resource provider is registered, it's available to use in your Azure subscription.

To verify if `Microsoft.PolicyInsights` is registered, run `Get-AzResourceProvider`. The resource provider contains several resource types. If the result is `NotRegistered` run `Register-AzResourceProvider`:

Azure PowerShell

```
Get-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights' |
  Select-Object -Property ResourceTypes, RegistrationState

Register-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights'
```

For more information, go to Get-AzResourceProvider and Register-AzResourceProvider.

Create policy assignment

Use the following commands to create a new policy assignment for your resource group. This example uses an existing resource group that contains a virtual machine *without* managed disks. The resource group is the scope for the policy assignment. This example uses the built-in policy definition Audit VMs that do not use managed disks.

Run the following commands and replace `<resourceGroupName>` with your resource group name:

Azure PowerShell

```
$rg = Get-AzResourceGroup -Name '<resourceGroupName>'

$definition = Get-AzPolicyDefinition |
  Where-Object { $_.DisplayName -eq 'Audit VMs that do not use managed disks' }
```

The `$rg` variable stores properties for the resource group and the `$definition` variable stores the policy definition's properties. The properties are used in subsequent commands.

Run the following command to create the policy assignment:

Azure PowerShell

```
$policyparms = @{
Name = 'audit-vm-managed-disks'
DisplayName = 'Audit VM managed disks'
Scope = $rg.ResourceId
PolicyDefinition = $definition
Description = 'Az PowerShell policy assignment to resource group'
}

New-AzPolicyAssignment @policyparms
```

The `$policyparms` variable uses splatting to create parameter values and improve readability. The `New-AzPolicyAssignment` command uses the parameter values defined in the `$policyparms` variable.

- `Name` creates the policy assignment name used in the assignment's `ResourceId`.
- `DisplayName` is the name for the policy assignment and is visible in Azure portal.
- `Scope` uses the `$rg.ResourceId` property to assign the policy to the resource group.
- `PolicyDefinition` assigns the policy definition stored in the `$definition` variable.
- `Description` can be used to add context about the policy assignment.

The results of the policy assignment resemble the following example:

Output

```
Name               : audit-vm-managed-disks
ResourceId         :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Micro
soft.Authorization/policyAssignments/audit-vm-managed-disks
ResourceName       : audit-vm-managed-disks
ResourceGroupName  : {resourceGroupName}
ResourceType       : Microsoft.Authorization/policyAssignments
SubscriptionId     : {subscriptionId}
PolicyAssignmentId :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Micro
soft.Authorization/policyAssignments/audit-vm-managed-disks
Properties         :
Microsoft.Azure.Commands.ResourceManager.Cmdlets.Implementation.Policy.PsPolicyAss
ignmentProperties
```

For more information, go to New-AzPolicyAssignment.

If you want to redisplay the policy assignment information, run the following command:

Azure PowerShell

```
Get-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

Identify non-compliant resources

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

Use the following command to identify resources that aren't compliant with the policy assignment you created:

Azure PowerShell

```
$complianceparms = @{
ResourceGroupName = $rg.ResourceGroupName
PolicyAssignmentName = 'audit-vm-managed-disks'
Filter = 'IsCompliant eq false'
}

Get-AzPolicyState @complianceparms
```

The `$complianceparms` variable uses splatting to create parameter values used in the `Get-AzPolicyState` command.

- `ResourceGroupName` gets the resource group name from the `$rg.ResourceGroupName` property.
- `PolicyAssignmentName` specifies the name used when the policy assignment was created.
- `Filter` uses an expression to find resources that aren't compliant with the policy assignment.

Your results resemble the following example and `ComplianceState` shows `NonCompliant`:

Output

```
Timestamp                : 2/14/2024 18:25:37
ResourceId               :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/micro
soft.compute/virtualmachines/{vmId}
PolicyAssignmentId       :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/micro
soft.authorization/policyassignments/audit-vm-managed-disks
PolicyDefinitionId       :
/providers/microsoft.authorization/policydefinitions/06a78e20-9358-41c9-923c-
fb736d382a4d
IsCompliant              : False
SubscriptionId           : {subscriptionId}
ResourceType             : Microsoft.Compute/virtualMachines
ResourceLocation         : {location}
ResourceGroup            : {resourceGroupName}
ResourceTags             : tbd
PolicyAssignmentName     : audit-vm-managed-disks
```

```
PolicyAssignmentOwner    : tbd
PolicyAssignmentScope    :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}
PolicyDefinitionName     : 06a78e20-9358-41c9-923c-fb736d382a4d
PolicyDefinitionAction   : audit
PolicyDefinitionCategory : tbd
ManagementGroupIds       : {managementGroupId}
ComplianceState          : NonCompliant
AdditionalProperties     : {[complianceReasonCode, ]}
```

For more information, go to Get-AzPolicyState.

Clean up resources

To remove the policy assignment, run the following command:

Azure PowerShell

```
Remove-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

To sign out of your Azure PowerShell session:

Azure PowerShell

```
Disconnect-AzAccount
```

Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

To learn more about how to assign policies that validate resource compliance, continue to the tutorial.

Tutorial: Create and manage policies to enforce compliance

Quickstart: Create a policy assignment to identify non-compliant resources using Azure PowerShell

03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using Azure PowerShell. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

The Azure PowerShell modules can be used to manage Azure resources from the command line or in scripts. This article explains how to use Azure PowerShell to create a policy assignment.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Azure PowerShell.
- Visual Studio Code.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Connect to Azure

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

Azure PowerShell

```
Connect-AzAccount

# Run these commands if you have multiple subscriptions
```

```
Get-AzSubScription
Set-AzContext -Subscription <subscriptionID>
```

Register resource provider

When a resource provider is registered, it's available to use in your Azure subscription.

To verify if `Microsoft.PolicyInsights` is registered, run `Get-AzResourceProvider`. The resource provider contains several resource types. If the result is `NotRegistered` run `Register-AzResourceProvider`:

Azure PowerShell

```
Get-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights' |
  Select-Object -Property ResourceTypes, RegistrationState

Register-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights'
```

For more information, go to Get-AzResourceProvider and Register-AzResourceProvider.

Create policy assignment

Use the following commands to create a new policy assignment for your resource group. This example uses an existing resource group that contains a virtual machine *without* managed disks. The resource group is the scope for the policy assignment. This example uses the built-in policy definition Audit VMs that do not use managed disks.

Run the following commands and replace `<resourceGroupName>` with your resource group name:

Azure PowerShell

```
$rg = Get-AzResourceGroup -Name '<resourceGroupName>'

$definition = Get-AzPolicyDefinition |
  Where-Object { $_.DisplayName -eq 'Audit VMs that do not use managed disks' }
```

The `$rg` variable stores properties for the resource group and the `$definition` variable stores the policy definition's properties. The properties are used in subsequent commands.

Run the following command to create the policy assignment:

Azure PowerShell

```
$policyparms = @{
Name = 'audit-vm-managed-disks'
DisplayName = 'Audit VM managed disks'
Scope = $rg.ResourceId
PolicyDefinition = $definition
Description = 'Az PowerShell policy assignment to resource group'
}

New-AzPolicyAssignment @policyparms
```

The `$policyparms` variable uses splatting to create parameter values and improve readability. The `New-AzPolicyAssignment` command uses the parameter values defined in the `$policyparms` variable.

- `Name` creates the policy assignment name used in the assignment's `ResourceId`.
- `DisplayName` is the name for the policy assignment and is visible in Azure portal.
- `Scope` uses the `$rg.ResourceId` property to assign the policy to the resource group.
- `PolicyDefinition` assigns the policy definition stored in the `$definition` variable.
- `Description` can be used to add context about the policy assignment.

The results of the policy assignment resemble the following example:

Output

```
Name               : audit-vm-managed-disks
ResourceId         :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Micro
soft.Authorization/policyAssignments/audit-vm-managed-disks
ResourceName       : audit-vm-managed-disks
ResourceGroupName  : {resourceGroupName}
ResourceType       : Microsoft.Authorization/policyAssignments
SubscriptionId     : {subscriptionId}
PolicyAssignmentId :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Micro
soft.Authorization/policyAssignments/audit-vm-managed-disks
Properties         :
Microsoft.Azure.Commands.ResourceManager.Cmdlets.Implementation.Policy.PsPolicyAss
ignmentProperties
```

For more information, go to New-AzPolicyAssignment.

If you want to redisplay the policy assignment information, run the following command:

Azure PowerShell

```
Get-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

Identify non-compliant resources

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

Use the following command to identify resources that aren't compliant with the policy assignment you created:

Azure PowerShell

```
$complianceparms = @{
ResourceGroupName = $rg.ResourceGroupName
PolicyAssignmentName = 'audit-vm-managed-disks'
Filter = 'IsCompliant eq false'
}

Get-AzPolicyState @complianceparms
```

The `$complianceparms` variable uses splatting to create parameter values used in the `Get-AzPolicyState` command.

- `ResourceGroupName` gets the resource group name from the `$rg.ResourceGroupName` property.
- `PolicyAssignmentName` specifies the name used when the policy assignment was created.
- `Filter` uses an expression to find resources that aren't compliant with the policy assignment.

Your results resemble the following example and `ComplianceState` shows `NonCompliant`:

Output

```
Timestamp                : 2/14/2024 18:25:37
ResourceId               :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/micro
soft.compute/virtualmachines/{vmId}
PolicyAssignmentId       :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/micro
soft.authorization/policyassignments/audit-vm-managed-disks
PolicyDefinitionId       :
/providers/microsoft.authorization/policydefinitions/06a78e20-9358-41c9-923c-
fb736d382a4d
IsCompliant              : False
SubscriptionId           : {subscriptionId}
ResourceType             : Microsoft.Compute/virtualMachines
ResourceLocation         : {location}
ResourceGroup            : {resourceGroupName}
ResourceTags             : tbd
PolicyAssignmentName     : audit-vm-managed-disks
```

```
PolicyAssignmentOwner    : tbd
PolicyAssignmentScope    :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}
PolicyDefinitionName     : 06a78e20-9358-41c9-923c-fb736d382a4d
PolicyDefinitionAction   : audit
PolicyDefinitionCategory : tbd
ManagementGroupIds       : {managementGroupId}
ComplianceState          : NonCompliant
AdditionalProperties     : {[complianceReasonCode, ]}
```

For more information, go to Get-AzPolicyState.

Clean up resources

To remove the policy assignment, run the following command:

Azure PowerShell

```
Remove-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

To sign out of your Azure PowerShell session:

Azure PowerShell

```
Disconnect-AzAccount
```

Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

To learn more about how to assign policies that validate resource compliance, continue to the tutorial.

Tutorial: Create and manage policies to enforce compliance

Quickstart: Create a policy assignment to identify non-compliant resources using Azure PowerShell

03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using Azure PowerShell. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

The Azure PowerShell modules can be used to manage Azure resources from the command line or in scripts. This article explains how to use Azure PowerShell to create a policy assignment.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Azure PowerShell.
- Visual Studio Code.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Connect to Azure

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

Azure PowerShell

```
Connect-AzAccount

# Run these commands if you have multiple subscriptions
```

```
Get-AzSubScription
Set-AzContext -Subscription <subscriptionID>
```

Register resource provider

When a resource provider is registered, it's available to use in your Azure subscription.

To verify if `Microsoft.PolicyInsights` is registered, run `Get-AzResourceProvider`. The resource provider contains several resource types. If the result is `NotRegistered` run `Register-AzResourceProvider`:

Azure PowerShell

```
Get-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights' |
  Select-Object -Property ResourceTypes, RegistrationState

Register-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights'
```

For more information, go to Get-AzResourceProvider and Register-AzResourceProvider.

Create policy assignment

Use the following commands to create a new policy assignment for your resource group. This example uses an existing resource group that contains a virtual machine *without* managed disks. The resource group is the scope for the policy assignment. This example uses the built-in policy definition Audit VMs that do not use managed disks.

Run the following commands and replace `<resourceGroupName>` with your resource group name:

Azure PowerShell

```
$rg = Get-AzResourceGroup -Name '<resourceGroupName>'

$definition = Get-AzPolicyDefinition |
  Where-Object { $_.DisplayName -eq 'Audit VMs that do not use managed disks' }
```

The `$rg` variable stores properties for the resource group and the `$definition` variable stores the policy definition's properties. The properties are used in subsequent commands.

Run the following command to create the policy assignment:

Azure PowerShell

```
$policyparms = @{
Name = 'audit-vm-managed-disks'
DisplayName = 'Audit VM managed disks'
Scope = $rg.ResourceId
PolicyDefinition = $definition
Description = 'Az PowerShell policy assignment to resource group'
}

New-AzPolicyAssignment @policyparms
```

The `$policyparms` variable uses splatting to create parameter values and improve readability. The `New-AzPolicyAssignment` command uses the parameter values defined in the `$policyparms` variable.

- `Name` creates the policy assignment name used in the assignment's `ResourceId`.
- `DisplayName` is the name for the policy assignment and is visible in Azure portal.
- `Scope` uses the `$rg.ResourceId` property to assign the policy to the resource group.
- `PolicyDefinition` assigns the policy definition stored in the `$definition` variable.
- `Description` can be used to add context about the policy assignment.

The results of the policy assignment resemble the following example:

Output

```
Name               : audit-vm-managed-disks
ResourceId         :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Micro
soft.Authorization/policyAssignments/audit-vm-managed-disks
ResourceName       : audit-vm-managed-disks
ResourceGroupName  : {resourceGroupName}
ResourceType       : Microsoft.Authorization/policyAssignments
SubscriptionId     : {subscriptionId}
PolicyAssignmentId :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Micro
soft.Authorization/policyAssignments/audit-vm-managed-disks
Properties         :
Microsoft.Azure.Commands.ResourceManager.Cmdlets.Implementation.Policy.PsPolicyAss
ignmentProperties
```

For more information, go to New-AzPolicyAssignment.

If you want to redisplay the policy assignment information, run the following command:

Azure PowerShell

```
Get-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

Identify non-compliant resources

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

Use the following command to identify resources that aren't compliant with the policy assignment you created:

Azure PowerShell

```
$complianceparms = @{
ResourceGroupName = $rg.ResourceGroupName
PolicyAssignmentName = 'audit-vm-managed-disks'
Filter = 'IsCompliant eq false'
}

Get-AzPolicyState @complianceparms
```

The `$complianceparms` variable uses splatting to create parameter values used in the `Get-AzPolicyState` command.

- `ResourceGroupName` gets the resource group name from the `$rg.ResourceGroupName` property.
- `PolicyAssignmentName` specifies the name used when the policy assignment was created.
- `Filter` uses an expression to find resources that aren't compliant with the policy assignment.

Your results resemble the following example and `ComplianceState` shows `NonCompliant`:

Output

```
Timestamp                : 2/14/2024 18:25:37
ResourceId               :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/micro
soft.compute/virtualmachines/{vmId}
PolicyAssignmentId       :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/providers/micro
soft.authorization/policyassignments/audit-vm-managed-disks
PolicyDefinitionId       :
/providers/microsoft.authorization/policydefinitions/06a78e20-9358-41c9-923c-
fb736d382a4d
IsCompliant              : False
SubscriptionId           : {subscriptionId}
ResourceType             : Microsoft.Compute/virtualMachines
ResourceLocation         : {location}
ResourceGroup            : {resourceGroupName}
ResourceTags             : tbd
PolicyAssignmentName     : audit-vm-managed-disks
```

```
PolicyAssignmentOwner    : tbd
PolicyAssignmentScope    :
/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}
PolicyDefinitionName     : 06a78e20-9358-41c9-923c-fb736d382a4d
PolicyDefinitionAction   : audit
PolicyDefinitionCategory : tbd
ManagementGroupIds       : {managementGroupId}
ComplianceState          : NonCompliant
AdditionalProperties     : {[complianceReasonCode, ]}
```

For more information, go to Get-AzPolicyState.

Clean up resources

To remove the policy assignment, run the following command:

Azure PowerShell

```
Remove-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope $rg.ResourceId
```

To sign out of your Azure PowerShell session:

Azure PowerShell

```
Disconnect-AzAccount
```

Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

To learn more about how to assign policies that validate resource compliance, continue to the tutorial.

Tutorial: Create and manage policies to enforce compliance

Quickstart: Create a policy assignment to identify non-compliant resources with REST API

Article • 03/04/2025

The first step in understanding compliance in Azure is to identify the status of your resources. In this quickstart, you create a policy assignment to identify non-compliant resources using REST API. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

This guide uses REST API to create a policy assignment and to identify non-compliant resources in your Azure environment. The examples in this article use PowerShell and the Azure CLI `az rest` commands. You can also run the `az rest` commands from a Bash shell like Git Bash.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Latest version of PowerShell or a Bash shell like Git Bash.
- Latest version of Azure CLI.
- Visual Studio Code.
- A resource group with at least one virtual machine that doesn't use managed disks.

Review the REST API syntax

There are two elements to run REST API commands: the REST API URI and the request body. For information, go to Policy Assignments - Create.

The following example shows the REST API URI syntax to create a policy definition.

HTTP

```
PUT
https://management.azure.com/{scope}/providers/Microsoft.Authorization/polic
```

```
yAssignments/{policyAssignmentName}?api-version=2023-04-01
```

- `scope`: A scope determines which resources or group of resources the policy assignment gets enforced on. It could range from a management group to an individual resource. Replace `{scope}` with one of the following patterns:
  - Management group: `/providers/Microsoft.Management/managementGroups/{managementGroup}`
  - Subscription: `/subscriptions/{subscriptionId}`
  - Resource group: `/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}`
  - Resource: `/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/{resourceProviderNamespace}/[{parentResourcePath}/]{resourceType}/{resourceName}`
- `policyAssignmentName`: Creates the policy assignment name for your assignment. The name is included in the policy assignment's `policyAssignmentId` property.

The following example is the JSON to create a request body file.

JSON

```
{
  "properties": {
    "displayName": "",
    "description": "",
    "policyDefinitionId":
"/providers/Microsoft.Authorization/policyDefinitions/11111111-1111-1111-
1111-111111111111",
    "nonComplianceMessages": [
      {
        "message": ""
      }
    ]
  }
}
```

- `displayName`: Display name for the policy assignment.
- `description`: Can be used to add context about the policy assignment.
- `policyDefinitionId`: The policy definition ID that to create the assignment.
- `nonComplianceMessages`: Set the message to use when a resource is evaluated as non-compliant. For more information, see assignment non-compliance messages.

Connect to Azure

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

Azure CLI

```azurecli
az login

# Run these commands if you have multiple subscriptions
az account list --output table
az account set --subscription <subscriptionID>
```

Use `az login` even if you're using PowerShell because the examples use Azure CLI az rest commands.

Create a policy assignment

In this example, you create a policy assignment and assign the Audit VMs that do not use managed disks definition.

A request body is needed to create the assignment. Save the following JSON in a file named *request-body.json*.

JSON

```json
{
  "properties": {
    "displayName": "Audit VM managed disks",
    "description": "Policy assignment to resource group scope created with
REST API",
    "policyDefinitionId":
"/providers/Microsoft.Authorization/policyDefinitions/06a78e20-9358-41c9-
923c-fb736d382a4d",
    "nonComplianceMessages": [
      {
        "message": "Virtual machines should use managed disks"
      }
    ]
  }
}
```

To create your policy assignment in an existing resource group scope, use the following REST API URI with a file for the request body. Replace `{subscriptionId}` and `{resourceGroupName}` with your values. The command displays JSON output in your shell.

Azure PowerShell

```
az rest --method put --uri
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Authorization/policyAssignments/audit
-vm-managed-disks?api-version=2023-04-01 --body `@request-body.json
```

In PowerShell, the backtick (`) is needed to escape the `at sign` (`@`) to specify a filename. In a Bash shell like Git Bash, omit the backtick.

For information, go to Policy Assignments - Create.

Identify non-compliant resources

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state. You use REST API to display the non-compliant resources for this policy assignment and the output is in JSON.

To identify non-compliant resources, run the following command. Replace `{subscriptionId}` and `{resourceGroupName}` with your values used when you created the policy assignment.

Azure PowerShell

```
az rest --method post --uri
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.PolicyInsights/policyStates/latest/qu
eryResults?api-version=2019-10-01 --uri-parameters `$filter="complianceState
eq 'NonCompliant' and PolicyAssignmentName eq 'audit-vm-managed-disks'"
```

The `filter` queries for resources that are evaluated as non-compliant with the policy definition named *audit-vm-managed-disks* that you created with the policy assignment. Again, notice the backtick is used to escape the dollar sign (`$`) in the filter. For a Bash client, a backslash (`\`) is a common escape character.

Your results resemble the following example:

JSON

```
{
  "@odata.context":
"https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/

    }
  ]
}
```

For more information, go to Policy States - List Query Results For Resource Group.

Clean up resources

To remove the policy assignment, use the following command. Replace `{subscriptionId}` and `{resourceGroupName}` with your values used when you created the policy assignment. The command displays JSON output in your shell.

Azure PowerShell

```
az rest --method delete --uri
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Authorization/policyAssignments/audit
-vm-managed-disks?api-version=2023-04-01
```

You can verify the policy assignment was deleted with the following command. A message is displayed in your shell.

Azure PowerShell

```
az rest --method get --uri
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Authorization/policyAssignments/audit
-vm-managed-disks?api-version=2023-04-01
```

Output

```
The policy assignment 'audit-vm-managed-disks' is not found.
```

For more information, go to Policy Assignments - Delete and Policy Assignments - Get.

Next steps

In this quickstart, you assigned a policy definition to identify non-compliant resources in your Azure environment.

To learn more about how to assign policies that validate resource compliance, continue to the tutorial.

Quickstart: Create a policy assignment to identify non-compliant resources by using ARM template

Article • 03/04/2025

In this quickstart, you use an Azure Resource Manager template (ARM template) to create a policy assignment that validates resource's compliance with an Azure policy. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template opens in the Azure portal.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Azure PowerShell or Azure CLI.
- Visual Studio Code and the Azure Resource Manager (ARM) Tools.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Review the template

The ARM template creates a policy assignment for a resource group scope and assigns the built-in policy definition Audit VMs that do not use managed disks.

Create the following ARM template as *policy-assignment.json*.

1. Open Visual Studio Code and select **File** > **New Text File**.
2. Copy and paste the ARM template into Visual Studio Code.
3. Select **File** > **Save** and use the filename *policy-assignment.json*.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {
    "policyAssignmentName": {
      "type": "string",
      "defaultValue": "audit-vm-managed-disks",
      "metadata": {
        "description": "Policy assignment name used in assignment's resource
ID"
      }
    },
    "policyDefinitionID": {
      "type": "string",
      "defaultValue":
"/providers/Microsoft.Authorization/policyDefinitions/06a78e20-9358-41c9-
923c-fb736d382a4d",
      "metadata": {
        "description": "Policy definition ID"
      }
    },
    "policyDisplayName": {
      "type": "string",
      "defaultValue": "Audit VM managed disks",
      "metadata": {
        "description": "Display name for Azure portal"
      }
    }
  },
  "resources": [
    {
      "type": "Microsoft.Authorization/policyAssignments",
      "apiVersion": "2023-04-01",
      "name": "[parameters('policyAssignmentName')]",
      "properties": {
        "policyDefinitionId": "[parameters('policyDefinitionID')]",
        "description": "Policy assignment to resource group scope created
with ARM template",
        "displayName": "[parameters('policyDisplayName')]",
        "nonComplianceMessages": [
          {
```

```
            "message": "Virtual machines should use managed disks"
          }
        ]
      }
    }
  ],
  "outputs": {
    "assignmentId": {
      "type": "string",
      "value": "[resourceId('Microsoft.Authorization/policyAssignments',
parameters('policyAssignmentName'))]"
    }
  }
}
```

The resource type defined in the ARM template is Microsoft.Authorization/policyAssignments.

The template uses three parameters to deploy the policy assignment:

- `policyAssignmentName` creates the policy assignment named *audit-vm-managed-disks*.
- `policyDefinitionID` uses the ID of the built-in policy definition. For reference, the commands to get the ID are in the section to deploy the template.
- `policyDisplayName` creates a display name that's visible in Azure portal.

For more information about ARM template files:

- To find more ARM template samples, go to Browse code samples.
- To learn more about template reference's for deployments, go to Azure template reference.
- To learn how to develop ARM templates, go to ARM template documentation.
- To learn about subscription-level deployments, go to Subscription deployments with ARM templates.

Deploy the ARM template

You can deploy the ARM template with Azure PowerShell or Azure CLI.

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

PowerShell

Azure PowerShell

```
Connect-AzAccount

# Run these commands if you have multiple subscriptions
Get-AzSubScription
Set-AzContext -Subscription <subscriptionID>
```

You can verify if `Microsoft.PolicyInsights` is registered. If it isn't, you can run a command to register the resource provider.

PowerShell

Azure PowerShell

```
Get-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights' |
   Select-Object -Property ResourceTypes, RegistrationState

Register-AzResourceProvider -ProviderNamespace
'Microsoft.PolicyInsights'
```

For more information, go to Get-AzResourceProvider and Register-AzResourceProvider.

The following commands display the `policyDefinitionID` parameter's value:

PowerShell

Azure PowerShell

```
(Get-AzPolicyDefinition |
  Where-Object { $_.Properties.DisplayName -eq 'Audit VMs that do not
use managed disks' }).ResourceId
```

The following commands deploy the policy definition to your resource group. Replace `<resourceGroupName>` with your resource group name:

PowerShell

Azure PowerShell

```
$rg = Get-AzResourceGroup -Name '<resourceGroupName>'
```

```
$deployparms = @{
Name = 'PolicyDeployment'
ResourceGroupName = $rg.ResourceGroupName
TemplateFile = 'policy-assignment.json'
}

New-AzResourceGroupDeployment @deployparms
```

The `$rg` variable stores properties for the resource group. The `$deployparms` variable uses splatting to create parameter values and improve readability. The `New-AzResourceGroupDeployment` command uses the parameter values defined in the `$deployparms` variable.

- `Name` is the deployment name displayed in the output and in Azure for the resource group's deployments.
- `ResourceGroupName` uses the `$rg.ResourceGroupName` property to get the name of your resource group where the policy is assigned.
- `TemplateFile` specifies the ARM template's name and location on your local computer.

You can verify the policy assignment's deployment with the following command:

PowerShell

The command uses the `$rg.ResourceId` property to get the resource group's ID.

Azure PowerShell

```
Get-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope
$rg.ResourceId
```

Output

```
Name               : audit-vm-managed-disks
ResourceId         :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks
ResourceName       : audit-vm-managed-disks
ResourceGroupName  : {resourceGroupName}
ResourceType       : Microsoft.Authorization/policyAssignments
SubscriptionId     : {subscriptionId}
PolicyAssignmentId :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks
Properties         :
```

```
Microsoft.Azure.Commands.ResourceManager.Cmdlets.Implementation.Policy.P
sPolicyAssignmentProperties
```

For more information, go to Get-AzPolicyAssignment.

Identify non-compliant resources

After the policy assignment is deployed, virtual machines that are deployed to the resource group are audited for compliance with the managed disk policy.

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

PowerShell

Azure PowerShell

```
$complianceparms = @{
ResourceGroupName = $rg.ResourceGroupName
PolicyAssignmentName = 'audit-vm-managed-disks'
Filter = 'IsCompliant eq false'
}

Get-AzPolicyState @complianceparms
```

The `$complianceparms` variable creates parameter values used in the `Get-AzPolicyState` command.

- `ResourceGroupName` gets the resource group name from the `$rg.ResourceGroupName` property.
- `PolicyAssignmentName` specifies the name used when the policy assignment was created.
- `Filter` uses an expression to find resources that aren't compliant with the policy assignment.

Your results resemble the following example and `ComplianceState` shows `NonCompliant`:

Output

```
Timestamp                : 2/26/2024 19:02:56
ResourceId               :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
```

```
ders/microsoft.compute/virtualmachines/{vmId}
PolicyAssignmentId       :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/microsoft.authorization/policyassignments/audit-vm-managed-disks
PolicyDefinitionId       :
/providers/microsoft.authorization/policydefinitions/06a78e20-9358-41c9-
923c-fb736d382a4d
IsCompliant              : False
SubscriptionId           : {subscriptionId}
ResourceType             : Microsoft.Compute/virtualMachines
ResourceLocation         : {location}
ResourceGroup            : {resourceGroupName}
ResourceTags             : tbd
PolicyAssignmentName     : audit-vm-managed-disks
PolicyAssignmentOwner    : tbd
PolicyAssignmentScope    :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}
PolicyDefinitionName     : 06a78e20-9358-41c9-923c-fb736d382a4d
PolicyDefinitionAction   : audit
PolicyDefinitionCategory : tbd
ManagementGroupIds       : {managementGroupId}
ComplianceState          : NonCompliant
AdditionalProperties     : {[complianceReasonCode, ]}
```

For more information, go to Get-AzPolicyState.

Clean up resources

PowerShell

Azure PowerShell

```powershell
Remove-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope
$rg.ResourceId
```

To sign out of your Azure PowerShell session:

Azure PowerShell

```powershell
Disconnect-AzAccount
```

Quickstart: Create a policy assignment to identify non-compliant resources by using a Bicep file

Article • 03/04/2025

In this quickstart, you use a Bicep file to create a policy assignment that validates resource's compliance with an Azure policy. The policy is assigned to a resource group and audits virtual machines that don't use managed disks. After you create the policy assignment, you identify non-compliant virtual machines.

Bicep is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. It provides concise syntax, reliable type safety, and support for code reuse. Bicep offers the best authoring experience for your infrastructure-as-code solutions in Azure.

When assigning a built-in policy or initiative definition, it's optional to reference a version. Policy assignments of built-in definitions default to the latest version and automatically inherit minor version changes unless otherwise specified.

Prerequisites

- If you don't have an Azure account, create a free account before you begin.
- Bicep.
- Azure PowerShell or Azure CLI.
- Visual Studio Code and the Bicep extension for Visual Studio Code.
- `Microsoft.PolicyInsights` must be registered in your Azure subscription. To register a resource provider, you must have permission to register resource providers. That permission is included in the Contributor and Owner roles.
- A resource group with at least one virtual machine that doesn't use managed disks.

Review the Bicep file

The Bicep file creates a policy assignment for a resource group scope and assigns the built-in policy definition Audit VMs that do not use managed disks.

Create the following Bicep file as *policy-assignment.bicep*.

1. Open Visual Studio Code and select **File** > **New Text File**.
2. Copy and paste the Bicep file into Visual Studio Code.

3. Select **File** > **Save** and use the filename *policy-assignment.bicep*.

Bicep

```
param policyAssignmentName string = 'audit-vm-managed-disks'
param policyDefinitionID string =
'/providers/Microsoft.Authorization/policyDefinitions/06a78e20-9358-41c9-
923c-fb736d382a4d'
param policyDisplayName string = 'Audit VM managed disks'

resource assignment 'Microsoft.Authorization/policyAssignments@2023-04-01' =
{
  name: policyAssignmentName
  scope: resourceGroup()
  properties: {
    policyDefinitionId: policyDefinitionID
    description: 'Policy assignment to resource group scope created with
Bicep file'
    displayName: policyDisplayName
    nonComplianceMessages: [
      {
        message: 'Virtual machines should use managed disks'
      }
    ]
  }
}

output assignmentId string = assignment.id
```

The resource type defined in the Bicep file is Microsoft.Authorization/policyAssignments.

The Bicep file uses three parameters to deploy the policy assignment:

- `policyAssignmentName` creates the policy assignment named *audit-vm-managed-disks*.
- `policyDefinitionID` uses the ID of the built-in policy definition. For reference, the commands to get the ID are in the section to deploy the template.
- `policyDisplayName` creates a display name that's visible in Azure portal.

For more information about Bicep files:

- To find more Bicep samples, go to Browse code samples.
- To learn more about template reference's for deployments, go to Azure template reference.
- To learn how to develop Bicep files, go to Bicep documentation.
- To learn about subscription-level deployments, go to Subscription deployments with Bicep files.

Deploy the Bicep file

You can deploy the Bicep file with Azure PowerShell or Azure CLI.

From a Visual Studio Code terminal session, connect to Azure. If you have more than one subscription, run the commands to set context to your subscription. Replace `<subscriptionID>` with your Azure subscription ID.

PowerShell

Azure PowerShell

```
Connect-AzAccount

# Run these commands if you have multiple subscriptions
Get-AzSubScription
Set-AzContext -Subscription <subscriptionID>
```

You can verify if `Microsoft.PolicyInsights` is registered. If it isn't, you can run a command to register the resource provider.

PowerShell

Azure PowerShell

```
Get-AzResourceProvider -ProviderNamespace 'Microsoft.PolicyInsights' |
   Select-Object -Property ResourceTypes, RegistrationState

Register-AzResourceProvider -ProviderNamespace
'Microsoft.PolicyInsights'
```

For more information, go to Get-AzResourceProvider and Register-AzResourceProvider.

The following commands display the `policyDefinitionID` parameter's value:

PowerShell

Azure PowerShell

```
(Get-AzPolicyDefinition |
  Where-Object { $_.Properties.DisplayName -eq 'Audit VMs that do not
```

```
use managed disks' }).ResourceId
```

The following commands deploy the policy definition to your resource group. Replace `<resourceGroupName>` with your resource group name:

PowerShell

Azure PowerShell

```
$rg = Get-AzResourceGroup -Name '<resourceGroupName>'

$deployparms = @{
Name = 'PolicyDeployment'
ResourceGroupName = $rg.ResourceGroupName
TemplateFile = 'policy-assignment.bicep'
}

New-AzResourceGroupDeployment @deployparms
```

The `$rg` variable stores properties for the resource group. The `$deployparms` variable uses splatting to create parameter values and improve readability. The `New-AzResourceGroupDeployment` command uses the parameter values defined in the `$deployparms` variable.

- `Name` is the deployment name displayed in the output and in Azure for the resource group's deployments.
- `ResourceGroupName` uses the `$rg.ResourceGroupName` property to get the name of your resource group where the policy is assigned.
- `TemplateFile` specifies the Bicep file's name and location on your local computer.

You can verify the policy assignment's deployment with the following command:

PowerShell

The command uses the `$rg.ResourceId` property to get the resource group's ID.

Azure PowerShell

```
Get-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope
$rg.ResourceId
```

Output

```
Name               : audit-vm-managed-disks
ResourceId         :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks
ResourceName       : audit-vm-managed-disks
ResourceGroupName  : {resourceGroupName}
ResourceType       : Microsoft.Authorization/policyAssignments
SubscriptionId     : {subscriptionId}
PolicyAssignmentId :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/Microsoft.Authorization/policyAssignments/audit-vm-managed-disks
Properties         :
Microsoft.Azure.Commands.ResourceManager.Cmdlets.Implementation.Policy.P
sPolicyAssignmentProperties
```

For more information, go to Get-AzPolicyAssignment.

Identify non-compliant resources

After the policy assignment is deployed, virtual machines that are deployed to the resource group are audited for compliance with the managed disk policy.

The compliance state for a new policy assignment takes a few minutes to become active and provide results about the policy's state.

PowerShell

Azure PowerShell

```
$complianceparms = @{
ResourceGroupName = $rg.ResourceGroupName
PolicyAssignmentName = 'audit-vm-managed-disks'
Filter = 'IsCompliant eq false'
}

Get-AzPolicyState @complianceparms
```

The `$complianceparms` variable creates parameter values used in the `Get-AzPolicyState` command.

- `ResourceGroupName` gets the resource group name from the `$rg.ResourceGroupName` property.

- `PolicyAssignmentName` specifies the name used when the policy assignment was created.
- `Filter` uses an expression to find resources that aren't compliant with the policy assignment.

Your results resemble the following example and `ComplianceState` shows `NonCompliant`:

Output

```
Timestamp                : 2/20/2024 18:55:45
ResourceId               :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/microsoft.compute/virtualmachines/{vmId}
PolicyAssignmentId       :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}/provi
ders/microsoft.authorization/policyassignments/audit-vm-managed-disks
PolicyDefinitionId       :
/providers/microsoft.authorization/policydefinitions/06a78e20-9358-41c9-
923c-fb736d382a4d
IsCompliant              : False
SubscriptionId           : {subscriptionId}
ResourceType             : Microsoft.Compute/virtualMachines
ResourceLocation         : {location}
ResourceGroup            : {resourceGroupName}
ResourceTags             : tbd
PolicyAssignmentName     : audit-vm-managed-disks
PolicyAssignmentOwner    : tbd
PolicyAssignmentScope    :
/subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}
PolicyDefinitionName     : 06a78e20-9358-41c9-923c-fb736d382a4d
PolicyDefinitionAction   : audit
PolicyDefinitionCategory : tbd
ManagementGroupIds       : {managementGroupId}
ComplianceState          : NonCompliant
AdditionalProperties     : {[complianceReasonCode, ]}
```

For more information, go to Get-AzPolicyState.

Clean up resources

PowerShell

Azure PowerShell

```
Remove-AzPolicyAssignment -Name 'audit-vm-managed-disks' -Scope
```

```
$rg.ResourceId
```

To sign out of your Azure PowerShell session:

Azure PowerShell

```
Disconnect-AzAccount
```

Next steps

What is Azure Bastion?

Summarize this article for me

Azure Bastion is a fully managed PaaS service that provides secure and seamless RDP/SSH connectivity to your virtual machines directly over TLS from the Azure portal, or via the native SSH or RDP client already installed on your local computer. Azure Bastion is deployed directly in your virtual network and supports all VMs in the virtual network using private IP addresses. When you connect via Azure Bastion, your virtual machines don't need a public IP address, agent, or special client software.

Azure Bastion is available in four SKUs: Developer, Basic, Standard, and Premium.

> **Note**
>
> Azure Bastion is one of the services that make up the Network Security category in Azure. Other services in this category include Azure DDoS Protection, Azure Firewall, and Azure Web Application Firewall. Each service has its own unique features and use cases. For more information on this service category, see Network Security.

Key benefits

Azure Bastion provides the following benefits:

- **Secure connectivity over TLS**: Connect to VMs using RDP/SSH over TLS on port 443. Learn more about connection methods and Kerberos authentication.
- **Protection from external threats**: Your VMs are protected from port scanning. Deploy with availability zones for additional resilience.
- **Scalability and flexibility**: Configure host scaling, use shareable links, and connect via IP address.
- **Reduced management overhead**: Deploy once and use virtual network peering to serve multiple networks.
- **Compliance and audit**: Use session recording for compliance requirements (Premium SKU).

SKUs

Azure Bastion offers four SKU tiers:

- **Premium**: Includes all Standard features plus session recording for compliance and private-only deployment.

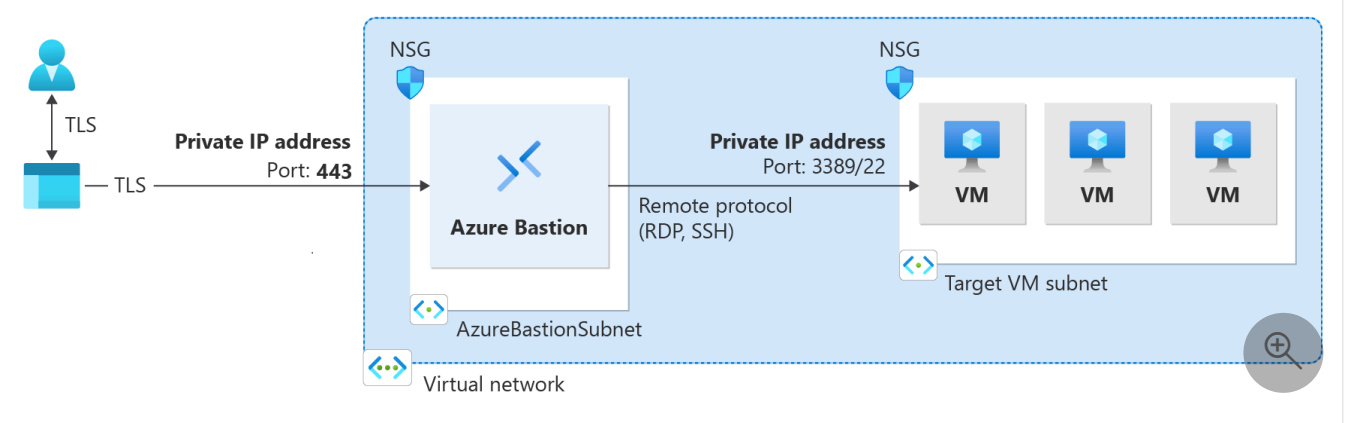
- **Standard**: Includes all Basic features plus scalability and advanced features (native client, shareable links, IP-based connections, custom ports, file transfer).
- **Basic**: Dedicated deployment with fixed capacity for production environments with moderate connection requirements.
- **Developer**: Free tier using shared infrastructure recommended for development and testing. Supports one VM at a time. Available in select regions.

For a complete feature comparison and capacity details, see Choose the right Azure Bastion SKU.

Architecture

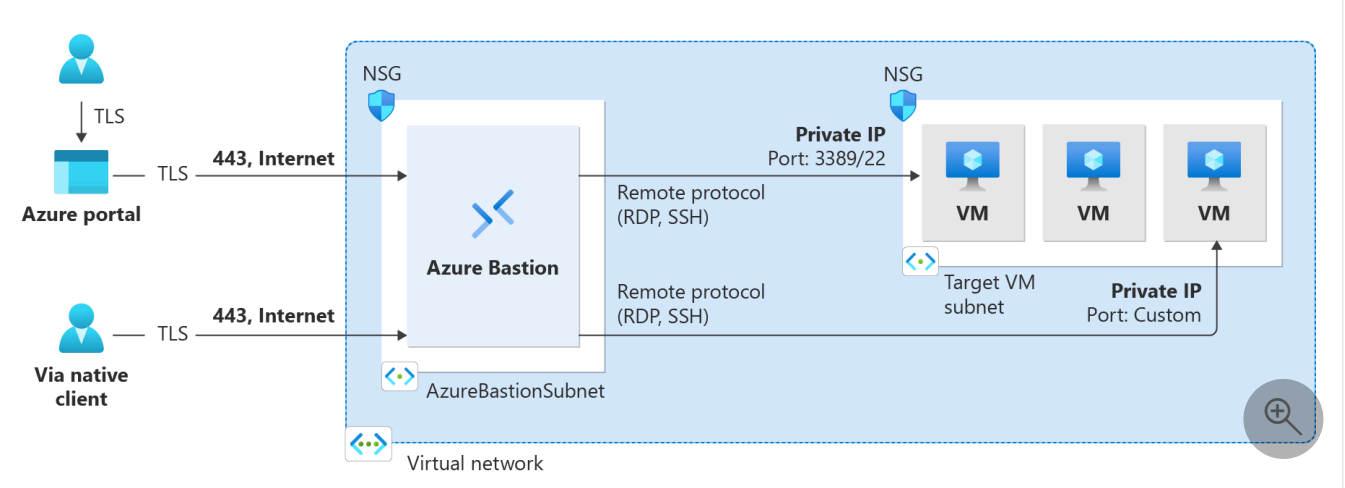
Azure Bastion offers three deployment architectures:

Private-only deployment: Premium SKU without public IP address for enhanced security.

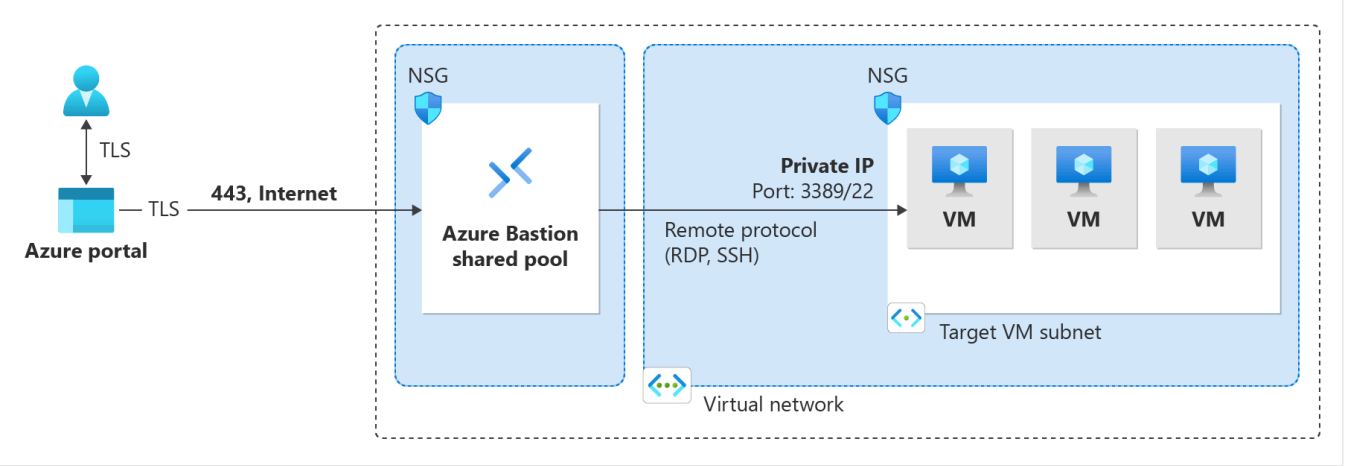


For detailed information about each architecture, deployment requirements, and network topology options, see Bastion design and architecture.

Dedicated deployment: Basic, Standard, and Premium SKUs deployed to your virtual network.



Developer: Shared infrastructure for development and testing environments.



Requirements

Deployment requirements vary by SKU. Developer uses shared infrastructure with no virtual network required. Basic, Standard, and Premium require a dedicated subnet (AzureBastionSubnet) and public IP address. Premium supports private-only deployment without a public IP.

For complete requirements including subnet sizing and NSG rules, see About Bastion configuration settings.

Connection methods

Azure Bastion supports multiple connection methods:

- **Browser-based connections**: Connect through the Azure portal using an HTML5 web client. Available for all SKU tiers. No additional client software required.
- **Native client connections**: Connect using the SSH or RDP client already installed on your local computer. Available for Standard and Premium SKUs. Supports Microsoft Entra ID authentication and file transfer.
- **Shareable links**: Create shareable links that allow users to connect to VMs without accessing the Azure portal. Available for Standard and Premium SKUs.

For more information about connection methods and authentication options, see About VM connections and features.

Pricing and SLA

Azure Bastion pricing combines hourly SKU charges with outbound data transfer costs. Billing starts from the moment Bastion is deployed, regardless of usage.

For pricing details, see Azure Bastion pricing. For SLA and reliability information, see Reliability in Azure Bastion.

What's new

Azure Bastion is continuously updated with new features and improvements. To learn about the latest updates and announcements, see What's new in Azure Bastion?

Troubleshooting and FAQ

For information about troubleshooting and frequently asked questions, see the troubleshooting guide and Azure Bastion FAQ.

Next steps

- Quickstart: Deploy Bastion automatically with default settings and Standard SKU
- Quickstart: Deploy Azure Bastion from the Azure portal
- Choose the right Azure Bastion SKU
- About Bastion configuration settings
- Azure Bastion FAQ
- Learn module: Introduction to Azure Bastion

Last updated on 02/04/2026

Quickstart: Deploy Azure Bastion from the Azure portal

In this quickstart, you learn how to deploy Azure Bastion to your virtual network from the Azure portal. You can deploy Bastion with default settings for a quick setup, configure custom settings to specify the SKU and scaling options, or use the free Developer SKU for basic connectivity. After you deploy Bastion, you can use SSH or RDP to connect to virtual machines (VMs) in the virtual network via Bastion by using the private IP addresses of the VMs. The VMs that you connect to don't need a public IP address, client software, an agent, or a special configuration. For more information about Bastion, see What is Azure Bastion?

The steps in this article help you:

- Deploy Bastion to your virtual network by using the Azure portal.
- Connect to your VM via the portal by using SSH or RDP connectivity and the VM's private IP address.
- Remove your VM's public IP address if you don't need it for anything else.

> **Important**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

Prerequisites

To complete this quickstart, you need these resources:

- An Azure subscription. If you don't already have one, you can activate your MSDN subscriber benefits or sign up for a free account.
- A virtual network to which you'll deploy Bastion.
- A virtual machine in the virtual network. This VM isn't part of the Bastion configuration and doesn't become a bastion host. You connect to this VM later in the exercise. If you don't have a VM, create one by using Quickstart: Create a Windows VM or Quickstart: Create a Linux VM.
- Required VM roles:
  - Reader role on the virtual machine

    - Reader role on the network adapter (NIC) with the private IP of the virtual machine

- Required VM inbound ports:
    - For Windows VMs: RDP (3389)
    - For Linux VMs: SSH (22)

- **For Developer SKU only**: The VM must be in a region that supports Bastion Developer.

> **Note**
>
> The use of Azure Bastion with Azure Private DNS zones is supported. However, there are restrictions. For more information, see the Azure Bastion FAQ.

Deploy Bastion

To deploy Bastion, sign in to the Azure portal and go to your VM or virtual network.

Select the tab for the deployment method you want to use:

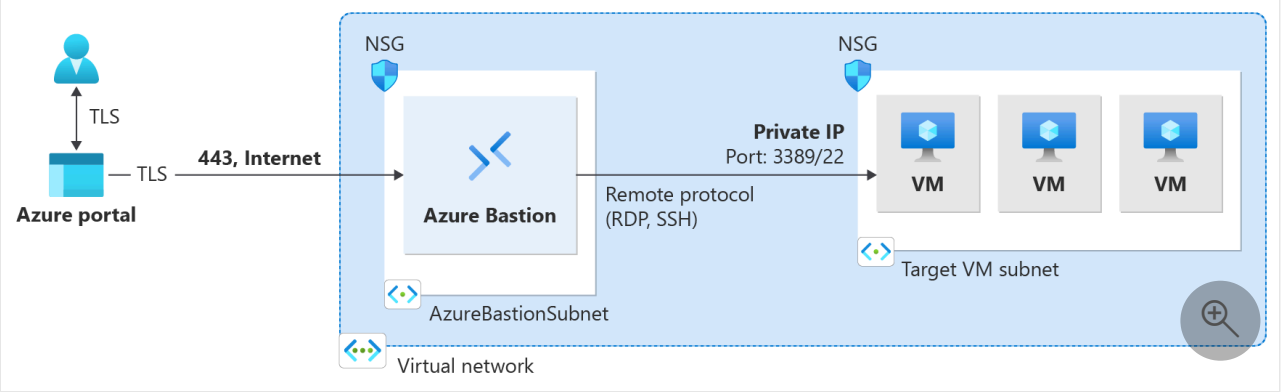
- **Default settings**: Quick one-click deployment with Standard SKU.
- **Custom settings**: Full control over SKU, scaling, availability zones, and other features.
- **Developer SKU (free)**: No-cost option with basic features for dev/test. Uses shared pool architecture. Limited to select regions.

> **Note**
>
> Dedicated deployments (Default and Custom settings) take approximately 10 minutes to complete. Developer SKU deploys in seconds.

Default settings

When you deploy Bastion using the **Deploy Bastion** option, Bastion deploys automatically with the Standard SKU and default settings based on your virtual network. You can configure additional settings or upgrade the SKU after deployment completes.

The following diagram shows the dedicated deployment architecture used by the Default settings options.



Default values:

To deploy Bastion with default settings:

1. Go to your virtual network (or VM). In the left pane, select **Connect** > **Bastion**.
2. In the **Bastion** pane, select **Deploy Bastion**.
3. Bastion deploys automatically with default settings. The deployment process takes about 10 minutes to complete.

Remove VM public IP address

When you connect to a VM by using Azure Bastion, you don't need a public IP address for your VM. If you aren't using the public IP address for anything else, you can dissociate it from your VM:

1. Go to your virtual machine. On the **Overview** page, click the **Public IP address** to open the Public IP address page.

2. On the **Public IP address** page, go to **Overview**. You can view the resource that this IP address is **Associated to**. Select **Dissociate** at the top of the pane.

3. Select **Yes** to dissociate the IP address from the VM network interface. After you dissociate the public IP address from the network interface, verify that it's no longer listed under **Associated to**.

4. After you dissociate the IP address, you can delete the public IP address resource. On the **Public IP address** pane for the VM, at the top of the **Overview** page, select **Delete**.

5. Select **Yes** to delete the public IP address.

Clean up resources

When you finish using the virtual network and the virtual machines, delete the resource group and all of the resources that it contains:

1. Enter the name of your resource group in the **Search** box at the top of the portal, and then select it from the search results.
2. Select **Delete resource group**.
3. Enter your resource group for **TYPE THE RESOURCE GROUP NAME**, and then select **Delete**.

Next steps

In this quickstart, you deployed Bastion to your virtual network. Next, you can connect to a virtual machine securely via Bastion, configure more features, and work with VM connections.

- Connect to a Windows VM: RDP | SSH
- Connect to a Linux VM: SSH | RDP
- Connect from a native client: Windows | Linux/SSH
- Connect to a scale set
- VM connections and features
- Azure Bastion configuration settings
- Bastion SKU comparison
- IP-based connections

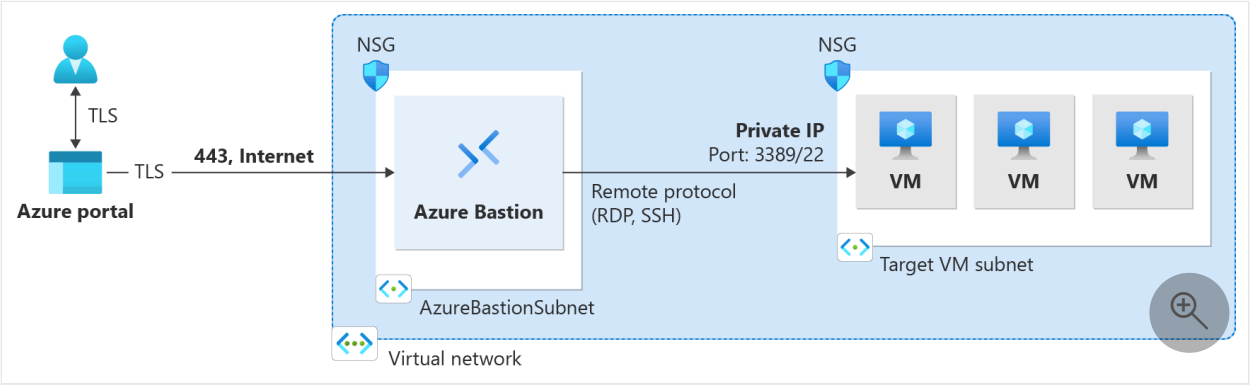
Last updated on 03/17/2026

Deploy Bastion using Azure PowerShell

Article • 03/03/2025

This article shows you how to deploy Azure Bastion using PowerShell. Azure Bastion is a PaaS service that's maintained for you, not a bastion host that you install on your VM and maintain yourself. An Azure Bastion deployment is per virtual network, not per subscription/account or virtual machine. For more information about Azure Bastion, see What is Azure Bastion?

Once you deploy Bastion to your virtual network, you can connect to your VMs via private IP address. This seamless RDP/SSH experience is available to all the VMs in the same virtual network. If your VM has a public IP address that you don't need for anything else, you can remove it.



In this article, you create a virtual network (if you don't already have one), deploy Azure Bastion using PowerShell, and connect to a VM. The examples show Bastion deployed using the Standard SKU tier, but you can use a different Bastion SKU, depending on the features you'd like to use. For more information, see Bastion SKUs.

You can also deploy Bastion by using the following other methods:

- Azure portal - Deploy Bastion with specified settings and SKUs
- Azure portal - Deploy Bastion with default settings and Standard SKU
- Deploy using Azure CLI

> **Note**
>
> The use of Azure Bastion with Azure Private DNS zones is supported. However, there are restrictions. For more information, see the Azure Bastion FAQ.

Before beginning

Verify that you have an Azure subscription. If you don't already have an Azure subscription, you can activate your MSDN subscriber benefits or sign up for a free account.

PowerShell

This article uses PowerShell cmdlets. To run the cmdlets, you can use Azure Cloud Shell. Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open Cloud Shell, just select **Open Cloudshell** from the upper-right corner of a code block. You can also open Cloud Shell on a separate browser tab by going to https://shell.azure.com/powershell. Select **Copy** to copy the blocks of code, paste them into Cloud Shell, and select the Enter key to run them.

You can also install and run the Azure PowerShell cmdlets locally on your computer. PowerShell cmdlets are updated frequently. If you haven't installed the latest version, the values specified in the instructions may fail. To find the versions of Azure PowerShell installed on your computer, use the `Get-Module -ListAvailable Az` cmdlet. To install or update, see Install the Azure PowerShell module.

Example values

You can use the following example values when creating this configuration, or you can substitute your own.

Example VNet and VM values:

Expand table

Name	Value
Virtual machine	TestVM
Resource group	TestRG1
Region	East US
Virtual network	VNet1
Address space	10.1.0.0/16
Subnets	FrontEnd: 10.1.0.0/24

Azure Bastion values:

Expand table

Name	Value
Name	VNet1-bastion
Subnet Name	FrontEnd
Subnet Name	AzureBastionSubnet
AzureBastionSubnet addresses	A subnet within your virtual network address space with a subnet mask /26 or larger. For example, 10.1.1.0/26.
Tier/SKU	Standard
Public IP address	Create new
Public IP address name	VNet1-ip
Public IP address SKU	Standard
Assignment	Static

Deploy Bastion

This section helps you create a virtual network, subnets, and deploy Azure Bastion using Azure PowerShell.

> **Important**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see Pricing and SKUs. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

1. Create a resource group, a virtual network, and a front end subnet to which you deploy the VMs that you'll connect to via Bastion. If you're running PowerShell locally, open your PowerShell console with elevated privileges and connect to Azure using the `Connect-AzAccount` command.

   Azure PowerShell

   ```
   New-AzResourceGroup -Name TestRG1 -Location EastUS `
   $frontendSubnet = New-AzVirtualNetworkSubnetConfig -Name FrontEnd `
   -AddressPrefix "10.1.0.0/24" `
   ```

```
$virtualNetwork = New-AzVirtualNetwork `
-Name TestVNet1 -ResourceGroupName TestRG1 `
-Location EastUS -AddressPrefix "10.1.0.0/16" `
-Subnet $frontendSubnet `
$virtualNetwork | Set-AzVirtualNetwork
```

2. Configure and set the Azure Bastion subnet for your virtual network. This subnet is reserved exclusively for Azure Bastion resources. You must create this subnet using the name value **AzureBastionSubnet**. This value lets Azure know which subnet to deploy the Bastion resources to. The example in the following section helps you add an Azure Bastion subnet to an existing VNet.

   - The smallest subnet AzureBastionSubnet size you can create is /26. We recommend that you create a /26 or larger size to accommodate host scaling.
     - For more information about scaling, see Configuration settings - Host scaling.
     - For more information about settings, see Configuration settings - AzureBastionSubnet.
   - Create the **AzureBastionSubnet** without any route tables or delegations.
   - If you use Network Security Groups on the **AzureBastionSubnet**, refer to the Work with NSGs article.

   Set the variable.

   Azure PowerShell

   ```
   $vnet = Get-AzVirtualNetwork -Name "TestVNet1" -ResourceGroupName
   "TestRG1"
   ```

   Add the subnet.

   Azure PowerShell

   ```
   Add-AzVirtualNetworkSubnetConfig `
   -Name "AzureBastionSubnet" -VirtualNetwork $vnet `
   -AddressPrefix "10.1.1.0/26" | Set-AzVirtualNetwork
   ```

3. Create a public IP address for Azure Bastion. The public IP is the public IP address of the Bastion resource on which RDP/SSH will be accessed (over port 443). The public IP address must be in the same region as the Bastion resource you're creating.

   Azure PowerShell

```
$publicip = New-AzPublicIpAddress -ResourceGroupName "TestRG1" `
-name "VNet1-ip" -location "EastUS" `
-AllocationMethod Static -Sku Standard
```

4. Create a new Azure Bastion resource in the AzureBastionSubnet using the New-AzBastion command. The following example uses the **Basic SKU**. However, you can also deploy Bastion using a different SKU by changing the -Sku value. The SKU you select determines the Bastion features and connect to VMs using more connection types. For more information, see Bastion SKUs.

   Azure PowerShell

   ```
   New-AzBastion -ResourceGroupName "TestRG1" -Name "VNet1-bastion" `
   -PublicIpAddressRgName "TestRG1" -PublicIpAddressName "VNet1-ip" `
   -VirtualNetworkRgName "TestRG1" -VirtualNetworkName "TestVNet1" `
   -Sku "Basic"
   ```

5. It takes about 10 minutes for the Bastion resources to deploy. You can create a VM in the next section while Bastion deploys to your virtual network.

Create a VM

You can create a VM using the Quickstart: Create a VM using PowerShell or Quickstart: Create a VM using the portal articles. Be sure you deploy the VM to the same virtual network to which you deployed Bastion. The VM you create in this section isn't a part of the Bastion configuration and doesn't become a bastion host. You connect to this VM later in this tutorial via Bastion.

The following required roles for your resources.

- Required VM roles:
  - Reader role on the virtual machine.
  - Reader role on the NIC with private IP of the virtual machine.

- Required inbound ports:
  - For Windows VMS - RDP (3389)
  - For Linux VMs - SSH (22)

Connect to a VM

You can use the Connection steps in the following section to connect to your VM. You can also use any of the following articles to connect to a VM. Some connection types

require the Bastion Standard SKU.

- Connect to a Windows VM
  - RDP
  - SSH
- Connect to a Linux VM
  - SSH
- Connect to a scale set
- Connect via IP address
- Connect from a native client
  - Windows client
  - Linux/SSH client

Connection steps

1. In the Azure portal, go to the virtual machine that you want to connect to.

2. At the top of the pane, select **Connect** > **Bastion** to go to the **Bastion** pane. You can also go to the **Bastion** pane by using the left menu.

3. The options available on the **Bastion** pane depend on the Bastion SKU.

   If you're using the **Basic SKU**, you connect to a Windows computer by using RDP and port 3389. Also for the Basic SKU, you connect to a Linux computer by using SSH and port 22. You don't have options to change the port number or the protocol. However, you can change the keyboard language for RDP by expanding **Connection Settings** on this pane.

   If you're using the **Standard SKU**, you have more connection protocol and port options available. Expand **Connection Settings** to see the options. Typically, unless you configure different settings for your VM, you connect to a Windows computer by using RDP and port 3389. You connect to a Linux computer by using SSH and port 22.

4. For **Authentication Type**, select the authentication type from the dropdown list. The protocol determines the available authentication types. Complete the required authentication values.

5. To open the VM session in a new browser tab, leave **Open in new browser tab** selected.

6. Select **Connect** to connect to the VM.

7. Confirm that the connection to the virtual machine opens directly in the Azure portal (over HTML5) by using port 443 and the Bastion service.

Using keyboard shortcut keys while you're connected to a VM might not result in the same behavior as shortcut keys on a local computer. For example, when you're connected to a Windows VM from a Windows client, Ctrl+Alt+End is the keyboard shortcut for Ctrl+Alt+Delete on a local computer. To do this from a Mac while you're connected to a Windows VM, the keyboard shortcut is fn+control+option+delete.

To enable audio output

You can enable remote audio output for your VM. Some VMs automatically enable this setting, whereas others require you to enable audio settings manually. The settings are changed on the VM itself. Your Bastion deployment doesn't need any special configuration settings to enable remote audio output. Audio input is not supported at the moment.

> ⓘ **Note**
>
> Audio output uses bandwidth on your internet connection.

To enable remote audio output on a Windows VM:

1. After you're connected to the VM, an audio button appears on the lower-right corner of the toolbar. Right-click the audio button, and then select **Sounds**.
2. A pop-up message asks if you want to enable the Windows Audio Service. Select **Yes**. You can configure more audio options in **Sound preferences**.
3. To verify sound output, hover over the audio button on the toolbar.

Remove VM public IP address

Azure Bastion doesn't use the public IP address to connect to the client VM. If you don't need the public IP address for your VM, you can disassociate the public IP address. See Dissociate a public IP address from an Azure VM.

Next steps

- To use Network Security Groups with the Azure Bastion subnet, see Work with NSGs.
- To understand VNet peering, see Virtual Network peering and Azure Bastion.

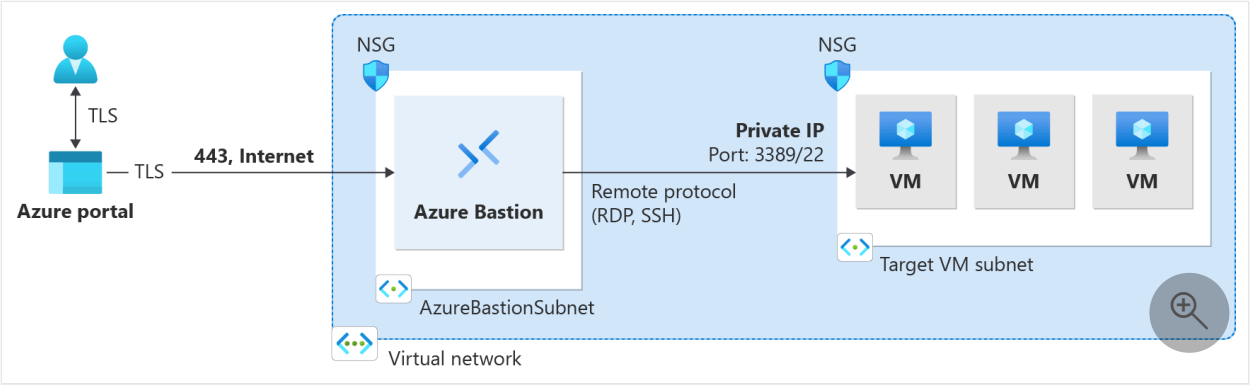
Deploy Bastion using Azure CLI

Article • 04/05/2024

This article shows you how to deploy Azure Bastion using CLI. Azure Bastion is a PaaS service that's maintained for you, not a bastion host that you install on your VM and maintain yourself. An Azure Bastion deployment is per virtual network, not per subscription/account or virtual machine. For more information about Azure Bastion, see What is Azure Bastion?

Once you deploy Bastion to your virtual network, you can connect to your VMs via private IP address. This seamless RDP/SSH experience is available to all the VMs in the same virtual network. If your VM has a public IP address that you don't need for anything else, you can remove it.



In this article, you create a virtual network (if you don't already have one), deploy Azure Bastion using CLI, and connect to a VM. You can also deploy Bastion by using the following other methods:

- Azure portal
- Azure PowerShell
- Quickstart - deploy with default settings

> **Note**
>
> The use of Azure Bastion with Azure Private DNS zones is supported. However, there are restrictions. For more information, see the Azure Bastion FAQ.

Before beginning

Azure subscription

Verify that you have an Azure subscription. If you don't already have an Azure subscription, you can activate your MSDN subscriber benefits or sign up for a free account.

Azure CLI

This article uses the Azure CLI. To run commands, you can use Azure Cloud Shell. The Azure Cloud Shell is a free interactive shell that you can use to run the steps in this article. It has common Azure tools preinstalled and configured to use with your account.

To open the Cloud Shell, just select **Try it** from the upper right corner of a code block. You can also launch Cloud Shell in a separate browser tab by going to https://shell.azure.com and toggle the dropdown in the left corner to reflect Bash or PowerShell. Select **Copy** to copy the blocks of code, paste it into the Cloud Shell, and press enter to run it.

Deploy Bastion

This section helps you deploy Azure Bastion using Azure CLI.

> **Important**
>
> Hourly pricing starts from the moment that Bastion is deployed, regardless of outbound data usage. For more information, see **Pricing** and **SKUs**. If you're deploying Bastion as part of a tutorial or test, we recommend that you delete this resource after you finish using it.

1. If you don't already have a virtual network, create a resource group and a virtual network using az group create and az network vnet create.

   Azure CLI

   ```
   az group create --name TestRG1 --location eastus
   ```

   Azure CLI

   ```
   az network vnet create --resource-group TestRG1 --name VNet1 --address-prefix 10.1.0.0/16 --subnet-name default --subnet-prefix 10.1.0.0/24
   ```

2. Use az network vnet subnet create to create the subnet to which Bastion will be deployed. The subnet you create must be named **AzureBastionSubnet**. This subnet

is reserve exclusively for Azure Bastion resources. If you don't have a subnet with the naming value **AzureBastionSubnet**, Bastion won't deploy.

- The smallest subnet AzureBastionSubnet size you can create is /26. We recommend that you create a /26 or larger size to accommodate host scaling.
  - For more information about scaling, see Configuration settings - Host scaling.
  - For more information about settings, see Configuration settings - AzureBastionSubnet.
- Create the **AzureBastionSubnet** without any route tables or delegations.
- If you use Network Security Groups on the **AzureBastionSubnet**, refer to the Work with NSGs article.

Azure CLI

```
az network vnet subnet create --name AzureBastionSubnet --resource-
group TestRG1 --vnet-name VNet1 --address-prefix 10.1.1.0/26
```

3. Create a public IP address for Azure Bastion. The public IP is the public IP address the Bastion resource on which RDP/SSH will be accessed (over port 443). The public IP address must be in the same region as the Bastion resource you're creating. For this reason, pay particular attention to the `--location` value that you specify.

Azure CLI

```
az network public-ip create --resource-group TestRG1 --name VNet1-ip --
sku Standard --location eastus
```

4. Use az network bastion create to create a new Azure Bastion resource for your virtual network. It takes about 10 minutes for the Bastion resource to create and deploy.

   The following example deploys Bastion using the **Basic** SKU tier. You can also deploy using other SKUs. The SKU determines the features that your Bastion deployment supports. If you don't specify a SKU in your command, the SKU defaults to Standard. For more information, see Bastion SKUs.

Azure CLI

```
az network bastion create --name VNet1-bastion --public-ip-address
VNet1-ip --resource-group TestRG1 --vnet-name VNet1 --location eastus -
-sku Basic
```

Connect to a VM

If you don't already have VMs in your virtual network, you can create a VM using Quickstart: Create a Windows VM, or Quickstart: Create a Linux VM

You can use any of the following articles, or the steps in the following section, to help you connect to a VM. Some connection types require the Bastion Standard SKU or higher.

- Connect to a Windows VM
  - RDP
  - SSH
- Connect to a Linux VM
  - SSH
- Connect to a scale set
- Connect via IP address
- Connect from a native client
  - Windows client
  - Linux/SSH client

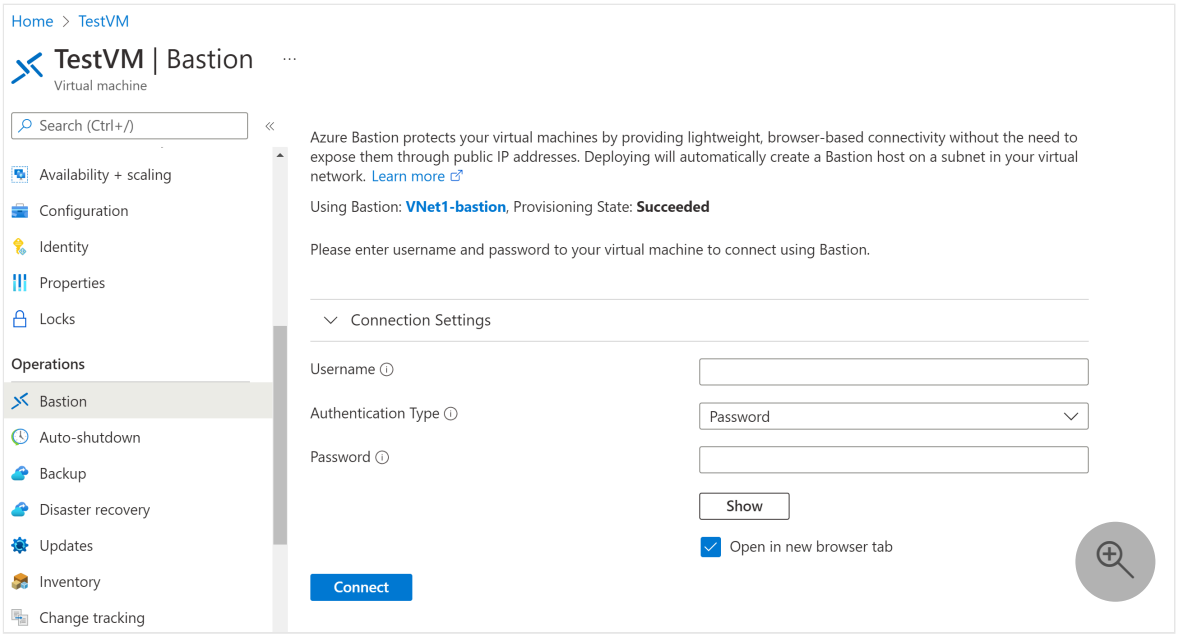
Connect using the portal

The following steps walk you through one type of connection using the Azure portal.

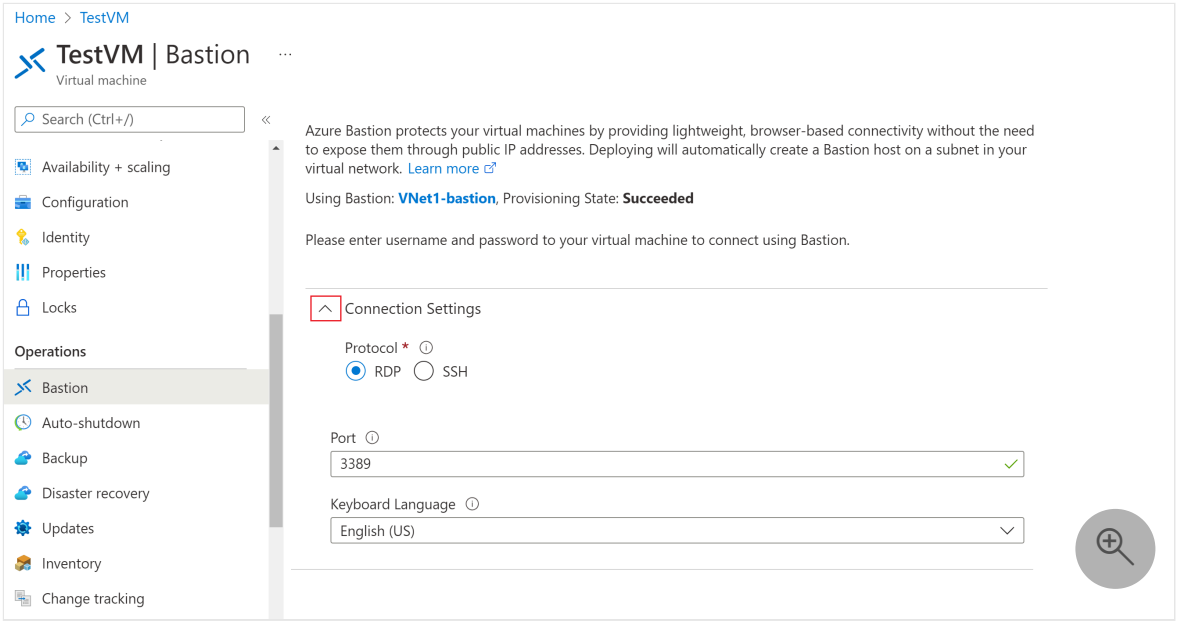
1. In the Azure portal, go to the virtual machine that you want to connect to.

2. At the top of the pane, select **Connect** > **Bastion** to go to the **Bastion** pane. You can also go to the **Bastion** pane by using the left menu.

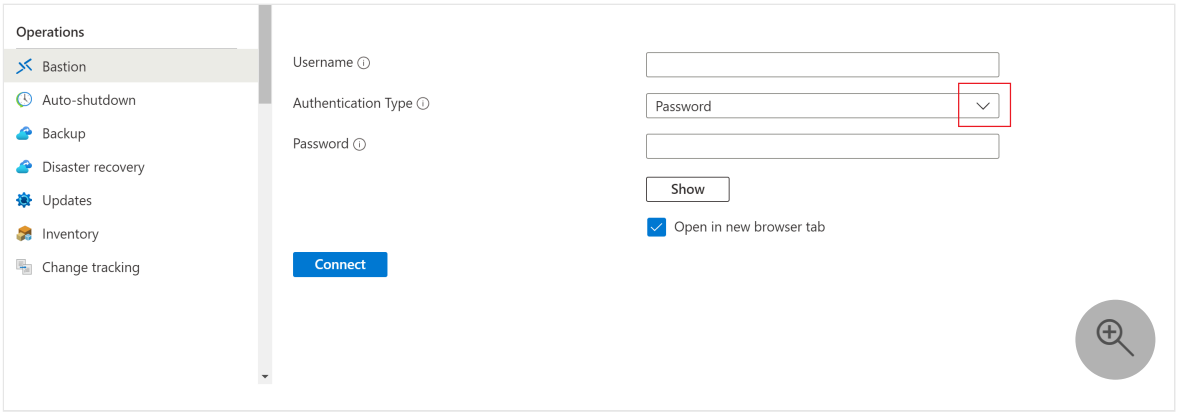
3. The options available on the **Bastion** pane depend on the Bastion SKU. If you're using the Basic SKU, you connect to a Windows computer by using RDP and port 3389. Also for the Basic SKU, you connect to a Linux computer by using SSH and port 22. You don't have options to change the port number or the protocol. However, you can change the keyboard language for RDP by expanding **Connection Settings**.



If you're using the Standard SKU, you have more connection protocol and port options available. Expand **Connection Settings** to see the options. Typically, unless you configure different settings for your VM, you connect to a Windows computer by using RDP and port 3389. You connect to a Linux computer by using SSH and port 22.



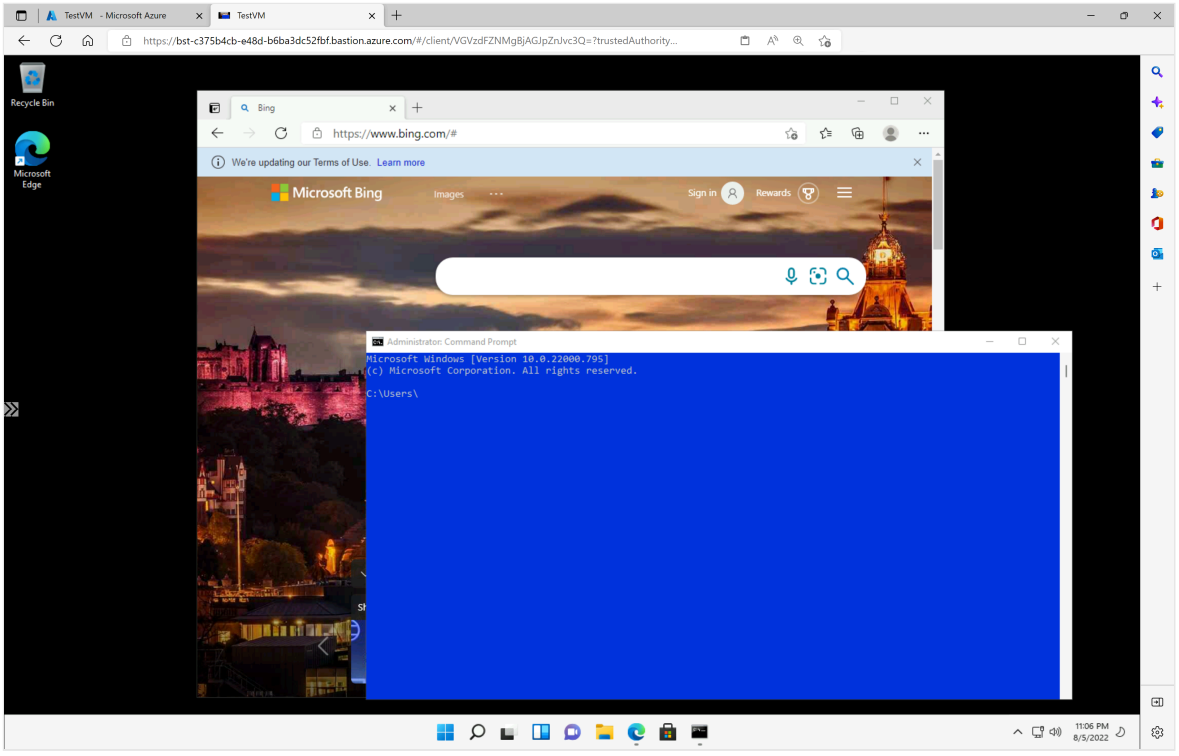
4. For **Authentication Type**, select from the dropdown list. The protocol determines the available authentication types. Complete the required authentication values.



5. To open the VM session in a new browser tab, leave **Open in new browser tab** selected.

6. Select **Connect** to connect to the VM.

7. Confirm that the connection to the virtual machine opens directly in the Azure portal (over HTML5) by using port 443 and the Bastion service.



> **Note**
>
> When you connect, the desktop of the VM will look different from the example screenshot.

Using keyboard shortcut keys while you're connected to a VM might not result in the same behavior as shortcut keys on a local computer. For example, when you're connected to a Windows VM from a Windows client, Ctrl+Alt+End is the keyboard

shortcut for Ctrl+Alt+Delete on a local computer. To do this from a Mac while you're connected to a Windows VM, the keyboard shortcut is Fn+Ctrl+Alt+Backspace.

To enable audio output

You can enable remote audio output for your VM. Some VMs automatically enable this setting, whereas others require you to enable audio settings manually. The settings are changed on the VM itself. Your Bastion deployment doesn't need any special configuration settings to enable remote audio output.

> **Note**
>
> Audio output uses bandwidth on your internet connection.

To enable remote audio output on a Windows VM:

1. After you're connected to the VM, an audio button appears on the lower-right corner of the toolbar. Right-click the audio button, and then select **Sounds**.
2. A pop-up message asks if you want to enable the Windows Audio Service. Select **Yes**. You can configure more audio options in **Sound preferences**.
3. To verify sound output, hover over the audio button on the toolbar.

Remove VM public IP address

Azure Bastion doesn't use the public IP address to connect to the client VM. If you don't need the public IP address for your VM, you can disassociate the public IP address. See Dissociate a public IP address from an Azure VM.

Next steps

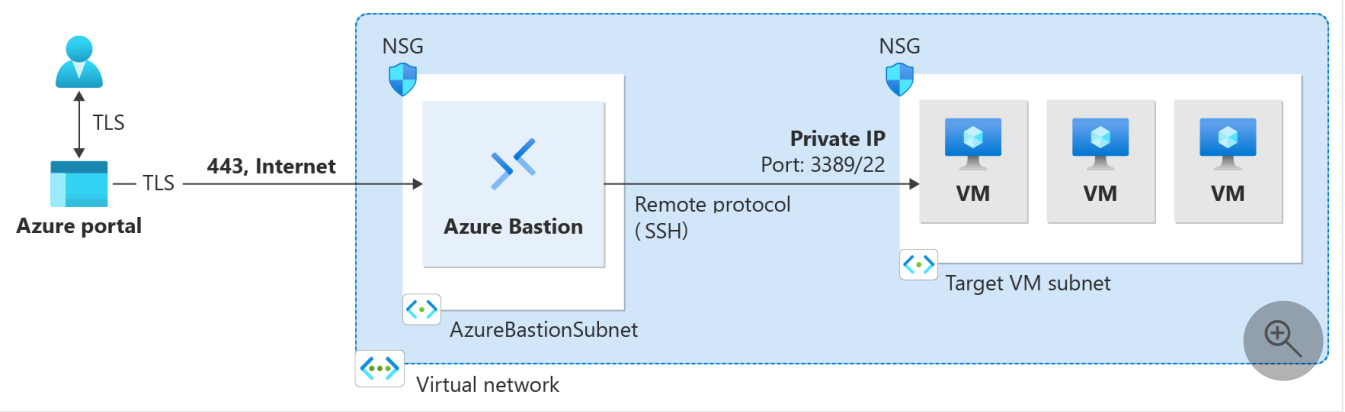
- To use Network Security Groups with the Azure Bastion subnet, see Work with NSGs.
- To understand VNet peering, see VNet peering and Azure Bastion.

Create an SSH connection to a Linux VM using Azure Bastion

This article describes how to create a secure SSH connection to your Linux virtual machines using Azure Bastion. You can connect through the Azure portal (browser-based), via a specified IP address, or using a native client on your local computer. When you use Azure Bastion, your virtual machines don't require a client, agent, or additional software. Azure Bastion securely connects to all virtual machines in the virtual network without exposing RDP/SSH ports to the public internet. For more information, see What is Azure Bastion?

For native client connections using Azure CLI, see Connect to a VM using a Linux native client or Connect to a VM using a Windows native client. To connect to a Linux VM using RDP, see Create an RDP connection to a Linux VM.

The following diagram shows the dedicated deployment architecture using an SSH connection.



Prerequisites

Before you begin, verify that you meet the following criteria:

- An Azure Bastion host deployed in the virtual network where the virtual machine is located, or in a peered virtual network. To set up a Bastion host, see Create a bastion host. The SKU you need depends on your connection method:

Expand table

Connection method	Minimum SKU	Additional configuration
Azure portal (browser)	Basic	None
Azure portal with custom ports	Standard	None
IP-based connection	Standard	IP-based connection enabled

Connection method	Minimum SKU	Additional configuration
Native client (SSH)	Standard	Native client support enabled

- A Linux virtual machine in the virtual network (or reachable from the virtual network for IP-based connections).
- **Required roles:**
  - Reader role on the virtual machine.
  - Reader role on the NIC with private IP of the virtual machine.
  - Reader role on the Azure Bastion resource.
  - Reader role on the virtual network of the target virtual machine (if the Bastion deployment is in a peered virtual network).
  - Virtual Machine Administrator Login or Virtual Machine User Login role (only required for Microsoft Entra ID authentication).
- **Ports:** In order to connect to the Linux VM via SSH, you must have the following ports open on your VM:
  - Inbound port: SSH (22) ***or***
  - Inbound port: Custom value (you'll then need to specify this custom port when you connect to the VM via Azure Bastion). This setting isn't available for the Basic or Developer SKU.

See the Azure Bastion FAQ for additional requirements.

Authentication methods

The following table shows which authentication methods are available for each connection method.

Expand table

Authentication method	Supported connection methods	Minimum SKU
Microsoft Entra ID	Azure portal, native client	Basic (portal), Standard (native client)
Username and password	Azure portal, IP address (portal), native client	Basic (portal), Standard (IP address, native client)
Password from Azure Key Vault	Azure portal	Basic
SSH private key from local file	Azure portal, IP address (portal),	Basic (portal), Standard (IP address,

Authentication method	Supported connection methods	Minimum SKU
	native client	native client)
SSH private key from Azure Key Vault	Azure portal	Basic

Authentication details

Configure the authentication settings for your connection. Not all authentication methods are available for every connection method. See the authentication methods table for availability.

Microsoft Entra ID

Available for: Azure portal, native client. Not supported for IP-based connections.

For prerequisites, setup steps, and connection instructions, see Configure Microsoft Entra ID authentication for Azure Bastion.

Key Vault configuration

If you're using Azure Key Vault to store a password or SSH private key, configure your Key Vault using the following requirements:

- If you didn't set up an Azure Key Vault resource, see Create a key vault and store your secret (password or SSH private key) as the value of a new Key Vault secret.
- Make sure you have **List** and **Get** access to the secrets stored in the Key Vault resource. To assign and modify access policies for your Key Vault resource, see Assign a Key Vault access policy.
- Store your secret in Azure Key Vault using the **PowerShell** or **Azure CLI** experience. Storing your secret via the Azure Key Vault portal experience interferes with the formatting and results in unsuccessful login. If you stored your private key as a secret using the portal experience and no longer have access to the original private key file, see Update SSH key to update access to your target VM with a new SSH key pair.

Connect to a virtual machine using SSH

Choose your connection method tab below to see the navigation steps for connecting to your VM. For available authentication methods per connection method, see the authentication methods table.

Azure portal

Use the Azure portal to create a browser-based SSH connection to your Linux virtual machine. This method connects directly through your browser. No native SSH client or additional software is required on your local computer. The Basic SKU or higher is required, or the Standard SKU if you need custom ports.

1. In the Azure portal, go to the virtual machine to which you want to connect. At the top of the virtual machine **Overview** page, select **Connect**, then select **Connect via Bastion** from the dropdown. This opens the **Bastion** page. You can also go to the Bastion page directly in the left pane.

2. On the **Bastion** page, the settings that you can configure depend on the Bastion SKU that your bastion host has been configured to use.

   - If you're using a SKU higher than the Basic SKU, **Connection Settings** values (ports and protocols) are visible and can be configured.
   - If you're using the Basic SKU or Developer SKU, you can't configure **Connection Settings** values. Instead, your connection uses the following default settings: SSH and port 22.
   - To view and select an available **Authentication Type**, use the dropdown.

3. Configure your authentication settings. For details, see Authentication details. Select **Connect**.

Limitations

- **IP-based connections:** IP-based connection doesn't work with force tunneling over VPN, or when a default route is advertised over an ExpressRoute circuit. Azure Bastion requires access to the internet. Force tunneling or default route advertisement results in traffic being dropped.
- **IP-based connections:** UDR isn't supported on the Bastion subnet, including with IP-based connections.
- **IP-based connections:** Microsoft Entra ID authentication isn't supported for IP-based SSH connections. For more information, see Microsoft Entra ID authentication.
- **Native client:** Signing in using an SSH private key stored in Azure Key Vault isn't supported with native client connections.
- **Native client:** This feature isn't supported in Cloud Shell.

Next steps

- Connect to a Linux VM using RDP
- What is Azure Bastion?
- Configure Microsoft Entra ID authentication for identity-based access.
- Transfer files to your virtual machine using a native client.
- Configure a shareable link for users without Azure portal access.
- Azure Bastion FAQ

Last updated on 03/17/2026

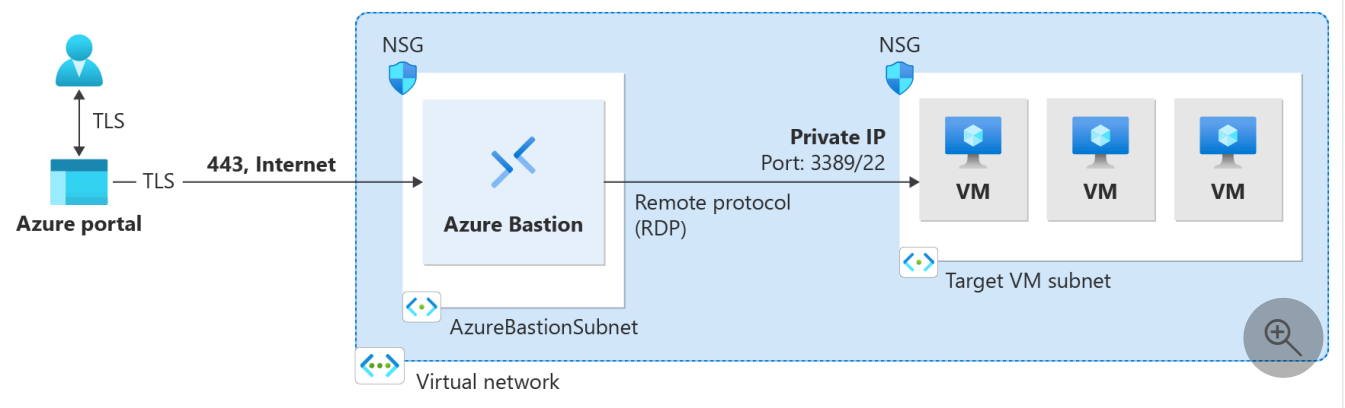
Create an RDP connection to a Windows VM using Azure Bastion

Summarize this article for me

This article describes how to create a secure RDP connection to your Windows virtual machines using Azure Bastion. You can connect through the Azure portal (browser-based), via a specified IP address, or using a native client on your local Windows computer. When you use Azure Bastion, your virtual machines don't require a client, agent, or additional software. Azure Bastion securely connects to all virtual machines in the virtual network without exposing RDP/SSH ports to the public internet. For more information, see What is Azure Bastion?

For native client connections using Azure CLI (including SSH and tunnel), see Connect to a VM using a native client. To connect to a Windows virtual machine using SSH, see Create an SSH connection to a Windows VM.

The following diagram shows the dedicated deployment architecture using an RDP connection.



Prerequisites

Before you begin, verify that you meet the following criteria:

- An Azure Bastion host deployed in the virtual network where the virtual machine is located, or in a peered virtual network. To set up a Bastion host, see Create a bastion host. The SKU you need depends on your connection method:

Expand table

Connection method	Minimum SKU	Additional configuration
Azure portal (browser)	Basic	None
Azure portal with custom ports	Standard	None

Connection method	Minimum SKU	Additional configuration
IP-based connection	Standard	IP-based connection enabled
Native client (RDP)	Standard	Native client support enabled

- Users connecting via RDP must have rights on the target virtual machine. If the user isn't a local administrator, add them to the **Remote Desktop Users** group.
- Azure Bastion uses RDP port 3389 by default. Custom ports require the Standard SKU or higher. To upgrade, see Upgrade a SKU.
- A Windows virtual machine in the virtual network (or reachable from the virtual network for IP-based connections).
- **Required roles:**
  - Reader role on the virtual machine.
  - Reader role on the NIC with the IP of the virtual machine.
  - Reader role on the Azure Bastion resource.
  - Reader role on the virtual network of the target virtual machine (if the Bastion deployment is in a peered virtual network).
  - Virtual Machine Administrator Login or Virtual Machine User Login role (only required for Microsoft Entra ID authentication).

See the Azure Bastion FAQ for additional requirements.

Authentication methods

The following authentication methods are available for RDP connections through Azure Bastion. Select an authentication method to see the corresponding steps.

Expand table

Authentication method	Supported connection methods	Minimum SKU
Microsoft Entra ID (Preview) (Preview for RDP)	Azure portal, native client	Basic (portal), Standard (native client)
Username and password	Azure portal, IP address (portal), native client	Basic (portal), Standard (IP address, native client)
Kerberos	Azure portal	Basic

Connect to a virtual machine using RDP

Select a connection method to see the corresponding steps. After you navigate to the Bastion connection page, choose your authentication method.

Azure portal

Use the Azure portal to create a browser-based RDP connection to your Windows virtual machine. This method connects directly through your browser. No native RDP client or additional software is required on your local computer. The Basic SKU or higher is required, or the Standard SKU if you need custom ports.

1. In the Azure portal, select your virtual machine. On the left pane select **Connect**, then select **Bastion**.
2. In the **Connection settings** tab, select **RDP** as the protocol, and enter the port number if you changed it from the default of 3389.
3. Select your authentication method. Microsoft Entra ID (Preview) is recommended. For other options, see Authentication methods.
4. Select **Connect** to open the RDP connection to your virtual machine in a new browser tab.

> **Note**
>
> For troubleshooting tips, see Troubleshooting RDP connections and Troubleshoot Microsoft Entra sign in for a Windows virtual machine in Azure or Arc-enabled Windows Server

Limitations

- **IP-based connections:** IP-based connection doesn't work with force tunneling over VPN, or when a default route is advertised over an ExpressRoute circuit. Azure Bastion requires access to the Internet and force tunneling, or the default route advertisement, results in traffic blackholing.
- **IP-based connections:** UDR isn't supported on the Bastion subnet, including with IP-based connections.
- **IP-based connections:** Custom ports and protocols aren't currently supported when connecting to a virtual machine via native client with IP-based connections.

- **Microsoft Entra ID:** Microsoft Entra authentication isn't supported for IP-based RDP connections. IP-based SSH connections via native client do support Entra ID authentication. For Entra ID auth details, see About Microsoft Entra ID authentication.
- **Session recording:** RDP + Entra ID authentication in the portal can't be used concurrently with graphical session recording.

Next steps

- Connect to a Windows VM using SSH
- What is Azure Bastion?
- Configure Microsoft Entra ID authentication for identity-based access.
- Configure Kerberos authentication for domain-joined virtual machines.
- Transfer files to your virtual machine using a native client.
- Configure a shareable link for users without Azure portal access.
- Azure Bastion FAQ

Last updated on 03/11/2026

What is Azure role-based access control (Azure RBAC)?

Article • 03/12/2024

Access management for cloud resources is a critical function for any organization that is using the cloud. Azure role-based access control (Azure RBAC) helps you manage who has access to Azure resources, what they can do with those resources, and what areas they have access to.

Azure RBAC is an authorization system built on Azure Resource Manager that provides fine-grained access management to Azure resources.

This video provides a quick overview of Azure RBAC.
https://www.youtube-nocookie.com/embed/Dzhm-garKBM

What can I do with Azure RBAC?

Here are some examples of what you can do with Azure RBAC:

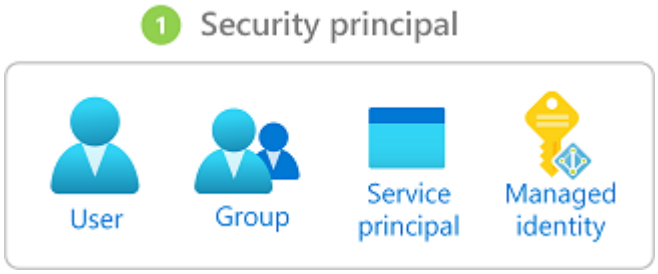
- Allow one user to manage virtual machines in a subscription and another user to manage virtual networks
- Allow a DBA group to manage SQL databases in a subscription
- Allow a user to manage all resources in a resource group, such as virtual machines, websites, and subnets
- Allow an application to access all resources in a resource group

How Azure RBAC works

The way you control access to resources using Azure RBAC is to assign Azure roles. This is a key concept to understand – it's how permissions are enforced. A role assignment consists of three elements: security principal, role definition, and scope.

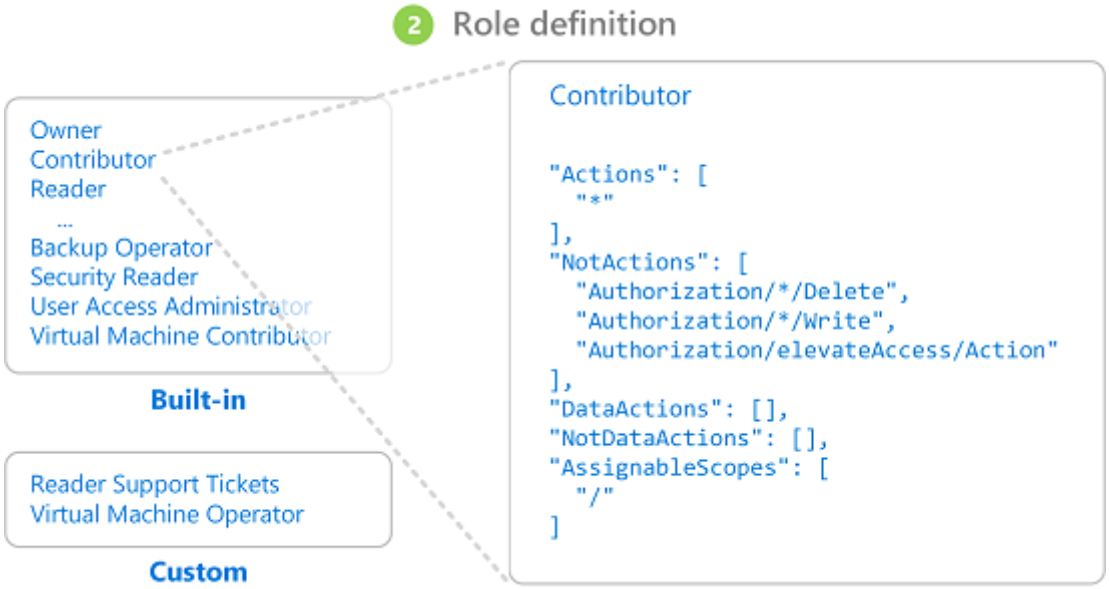
Security principal

A *security principal* is an object that represents a user, group, service principal, or managed identity that is requesting access to Azure resources. You can assign a role to any of these security principals.



Role definition

A *role definition* is a collection of permissions. It's typically just called a *role*. A role definition lists the actions that can be performed, such as read, write, and delete. Roles can be high-level, like owner, or specific, like virtual machine reader.



Azure includes several built-in roles that you can use. For example, the Virtual Machine Contributor role allows a user to create and manage virtual machines. If the built-in roles don't meet the specific needs of your organization, you can create your own Azure custom roles.

This video provides a quick overview of built-in roles and custom roles.
https://www.youtube-nocookie.com/embed/I1mefHptRgo

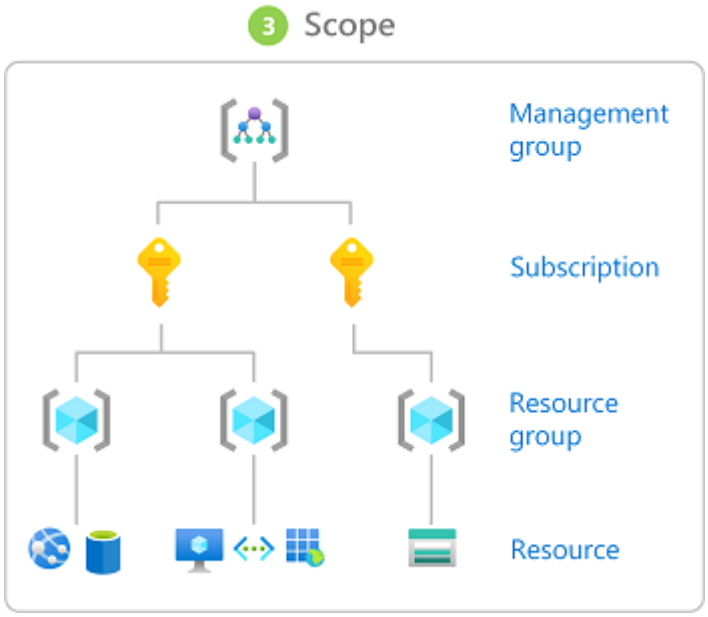
Azure has data actions that enable you to grant access to data within an object. For example, if a user has read data access to a storage account, then they can read the blobs or messages within that storage account.

For more information, see Understand Azure role definitions.

Scope

Scope is the set of resources that the access applies to. When you assign a role, you can further limit the actions allowed by defining a scope. This is helpful if you want to make someone a Website Contributor, but only for one resource group.

In Azure, you can specify a scope at four levels: management group, subscription, resource group, or resource. Scopes are structured in a parent-child relationship. You can assign roles at any of these levels of scope.

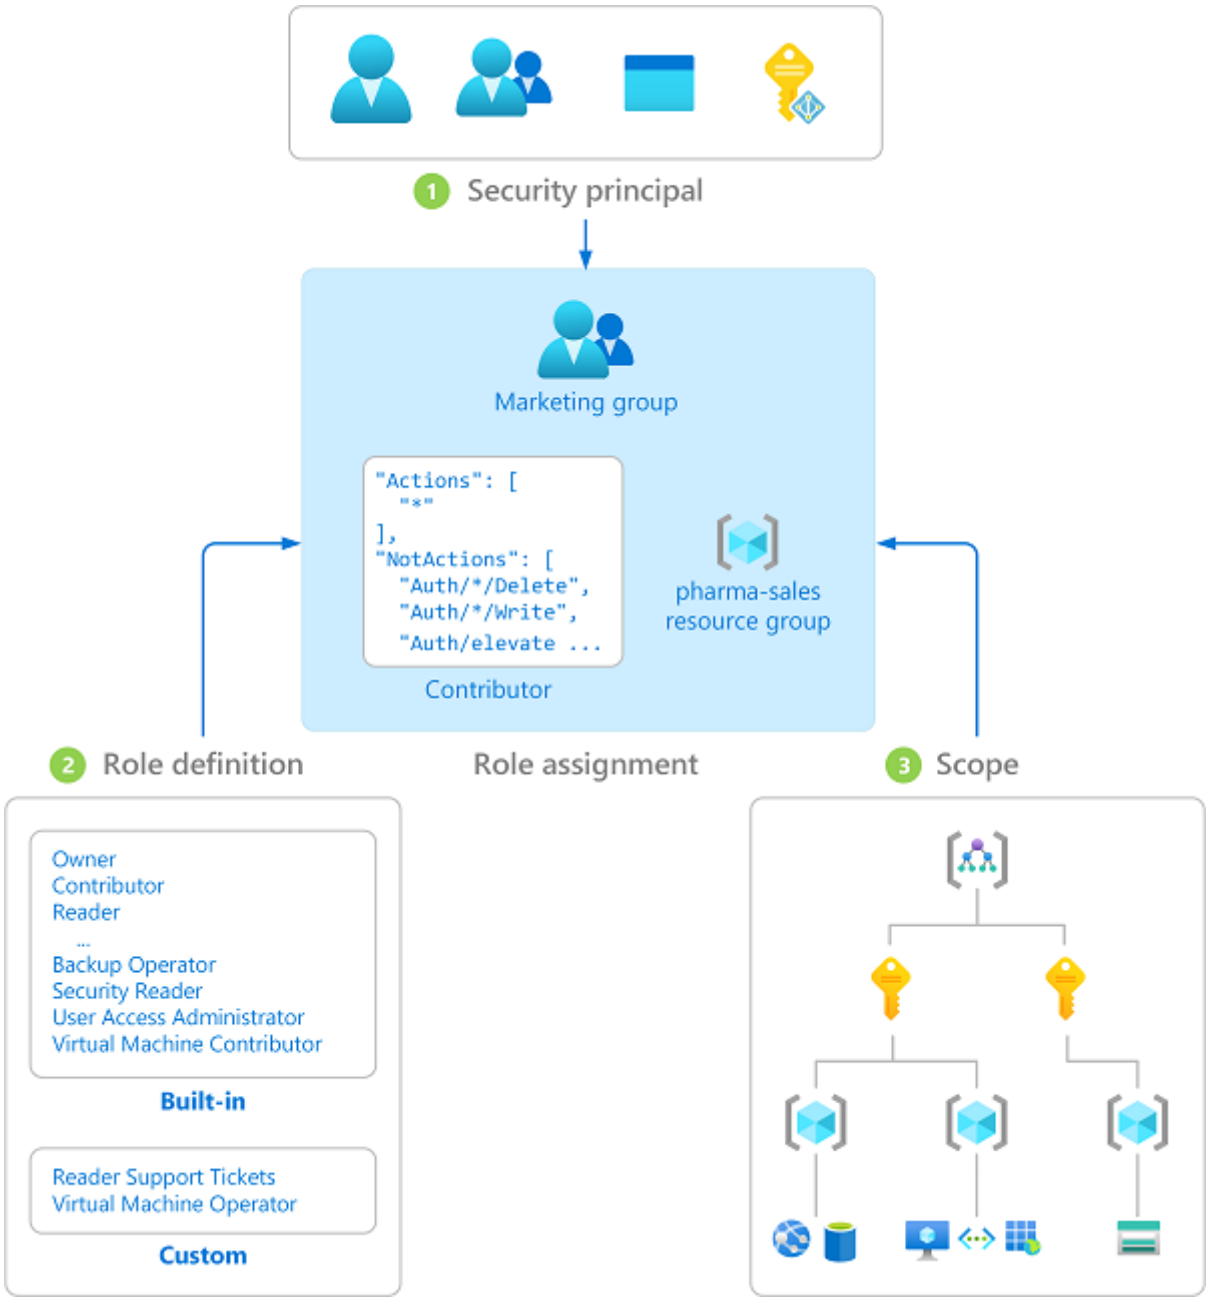


For more information about scope, see Understand scope.

Role assignments

A *role assignment* is the process of attaching a role definition to a user, group, service principal, or managed identity at a particular scope for the purpose of granting access. Access is granted by creating a role assignment, and access is revoked by removing a role assignment.

The following diagram shows an example of a role assignment. In this example, the Marketing group has been assigned the Contributor role for the pharma-sales resource group. This means that users in the Marketing group can create or manage any Azure resource in the pharma-sales resource group. Marketing users don't have access to resources outside the pharma-sales resource group, unless they're part of another role assignment.

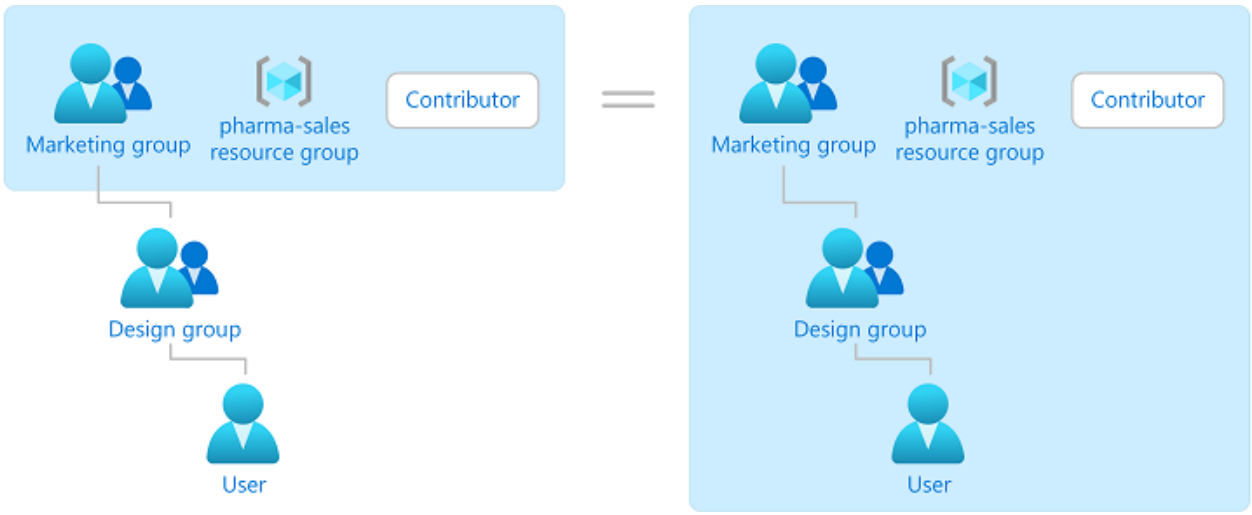


You can assign roles using the Azure portal, Azure CLI, Azure PowerShell, Azure SDKs, or REST APIs.

For more information, see Steps to assign an Azure role.

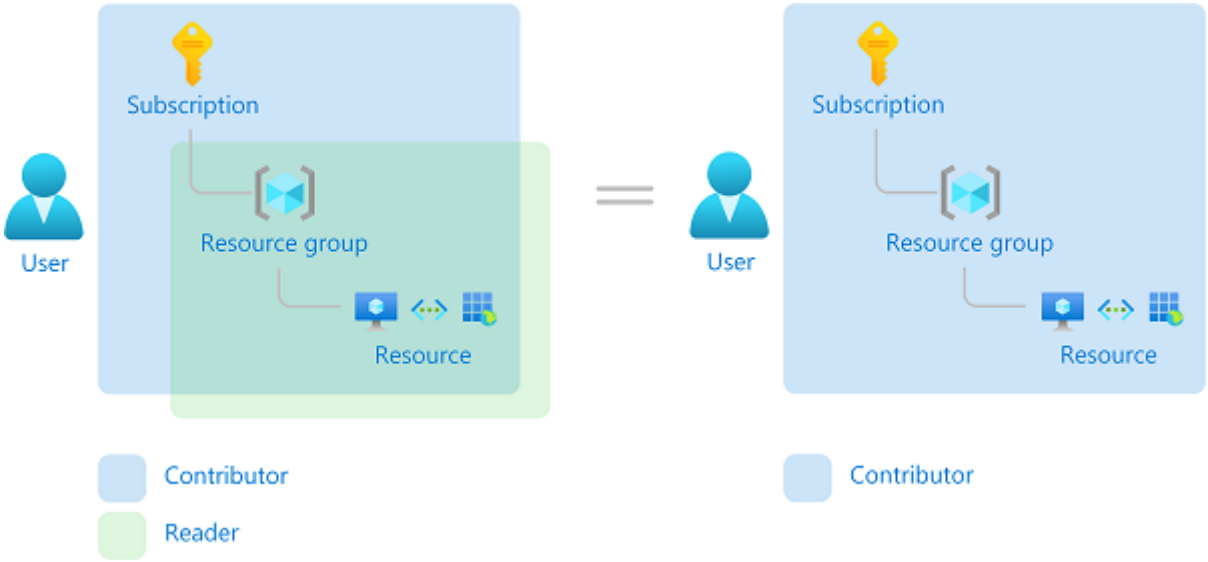
Groups

Role assignments are transitive for groups, which means that if a user is a member of a group and that group is a member of another group that has a role assignment, the user has the permissions in the role assignment.



Multiple role assignments

So what happens if you have multiple overlapping role assignments? Azure RBAC is an additive model, so your effective permissions are the sum of your role assignments. Consider the following example where a user is granted the Contributor role at the subscription scope and the Reader role on a resource group. The sum of the Contributor permissions and the Reader permissions is effectively the Contributor role for the subscription. Therefore, in this case, the Reader role assignment has no impact.



How Azure RBAC determines if a user has access to a resource

The following are the high-level steps that Azure RBAC uses to determine if you have access to a resource. These steps apply to Azure Resource Manager or data plane services integrated with Azure RBAC. This is helpful to understand if you're trying to troubleshoot an access issue.

1. A user (or service principal) acquires a token for Azure Resource Manager.

   The token includes the user's group memberships (including transitive group memberships).

2. The user makes a REST API call to Azure Resource Manager with the token attached.

3. Azure Resource Manager retrieves all the role assignments and deny assignments that apply to the resource upon which the action is being taken.

4. If a deny assignment applies, access is blocked. Otherwise, evaluation continues.

5. Azure Resource Manager narrows the role assignments that apply to this user or their group and determines what roles the user has for this resource.

6. Azure Resource Manager determines if the action in the API call is included in the roles the user has for this resource. If the roles include `Actions` that have a wildcard (`*`), the effective permissions are computed by subtracting the `NotActions` from the allowed `Actions`. Similarly, the same subtraction is done for any data actions.

   ```
   Actions - NotActions = Effective management permissions
   ```

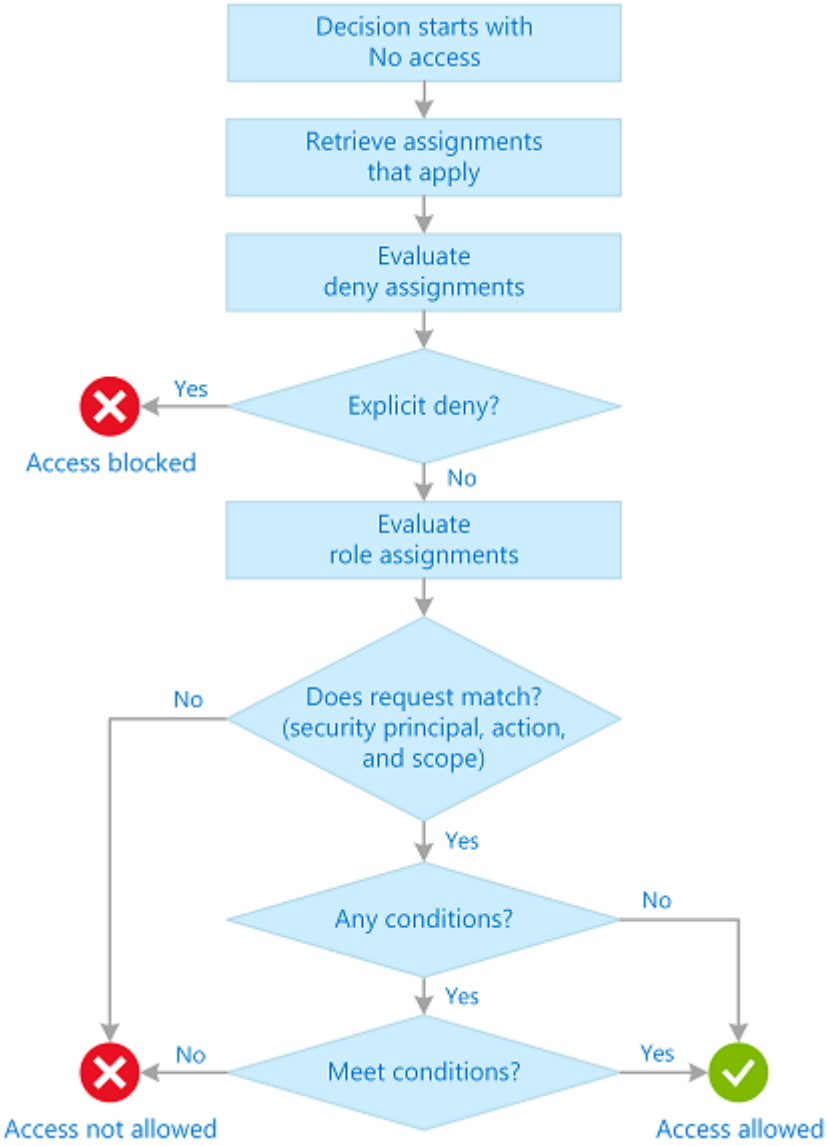
   ```
   DataActions - NotDataActions = Effective data permissions
   ```

7. If the user doesn't have a role with the action at the requested scope, access isn't allowed. Otherwise, any conditions are evaluated.

8. If the role assignment includes conditions, they're evaluated. Otherwise access is allowed.

9. If conditions are met, access is allowed. Otherwise access isn't allowed.

The following diagram is a summary of the evaluation logic.



Where is Azure RBAC data stored?

Role definitions, role assignments, and deny assignments are stored globally to ensure that you have access to your resources regardless of the region you created the resource.

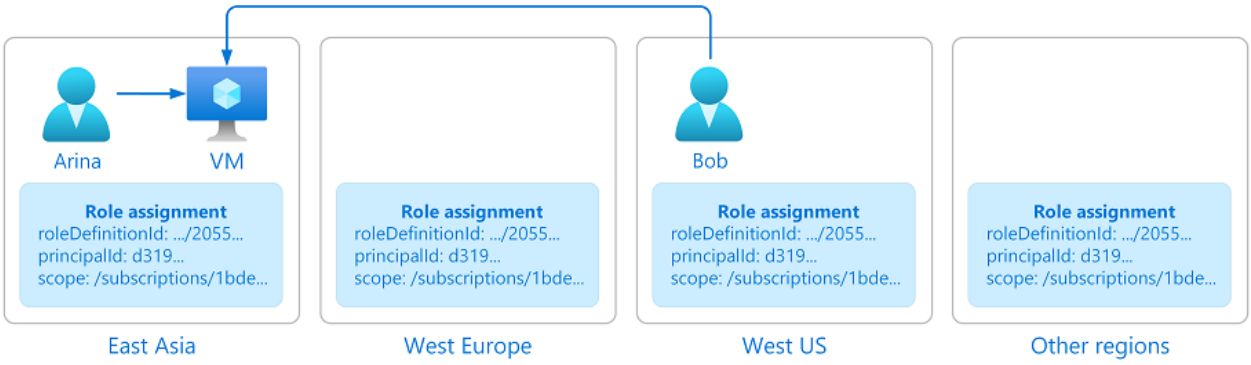
When a role assignment or any other Azure RBAC data is deleted, the data is globally deleted. Principals that had access to a resource via Azure RBAC data will lose their access.

Why is Azure RBAC data global?

Azure RBAC data is global to ensure that customers can timely access resources regardless from where they're accessing. Azure RBAC is enforced by Azure Resource Manager, which has a global endpoint and requests are routed to the nearest region for speed and resilience. Therefore, Azure RBAC must be enforced in all regions and the

data is replicated to all regions. For more information, see Resiliency of Azure Resource Manager.

Consider the following example. Arina creates a virtual machine in East Asia. Bob, who is a member of Arina's team, works in the United States. Bob needs to access the virtual machine that was created in East Asia. To grant Bob timely access to the virtual machine, Azure needs to globally replicate the role assignment that grants Bob access to the virtual machine from anywhere Bob is.



License requirements

Using this feature is free and included in your Azure subscription.

How to set up Key Vault for virtual machines with the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

In the Azure Resource Manager stack, secrets/certificates are modeled as resources that are provided by Key Vault. To learn more about Azure Key Vault, see What is Azure Key Vault? In order for Key Vault to be used with Azure Resource Manager VMs, the *EnabledForDeployment* property on Key Vault must be set to true. This article shows you how to set up Key Vault for use with Azure virtual machines (VMs) using the Azure CLI.

To perform these steps, you need the latest Azure CLI installed and logged in to an Azure account using az login.

Create a Key Vault

Create a key vault and assign the deployment policy with az keyvault create. The following example creates a key vault named `myKeyVault` in the `myResourceGroup` resource group:

Azure CLI

```
az keyvault create -l westus -n myKeyVault -g myResourceGroup --enabled-for-deployment true
```

Update a Key Vault for use with VMs

Set the deployment policy on an existing key vault with az keyvault update. The following updates the key vault named `myKeyVault` in the `myResourceGroup` resource group:

Azure CLI

```
az keyvault update -n myKeyVault -g myResourceGroup --set properties.enabledForDeployment=true
```

Use templates to set up Key Vault

When you use a template, you need to set the `enabledForDeployment` property to `true` for the Key Vault resource as follows:

JSON

```
{
    "type": "Microsoft.KeyVault/vaults",
    "name": "ContosoKeyVault",
    "apiVersion": "2015-06-01",
    "location": "<location-of-key-vault>",
    "properties": {
    "enabledForDeployment": "true",
    ....
    ....
    }
}
```

Next steps

For other options that you can configure when you create a Key Vault by using templates, see Create a key vault.

Set up Key Vault for virtual machines using Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

> ⓘ **Note**
>
> Azure has two different deployment models you can use to create and work with resources: Azure Resource Manager and classic. This article covers the use of the Resource Manager deployment model. We recommend the Resource Manager deployment model for new deployments instead of the classic deployment model.

In Azure Resource Manager stack, secrets/certificates are modeled as resources that are provided by the resource provider of Key Vault. To learn more about Key Vault, see What is Azure Key Vault?

> ⓘ **Note**
>
> 1. In order for Key Vault to be used with Azure Resource Manager virtual machines, the **EnabledForDeployment** property on Key Vault must be set to true. You can do this in various clients.
> 2. The Key Vault needs to be created in the same subscription and location as the Virtual Machine.

Use PowerShell to set up Key Vault

To create a key vault by using PowerShell, see Set and retrieve a secret from Azure Key Vault using PowerShell.

For new key vaults, you can use this PowerShell cmdlet:

Azure PowerShell

```
New-AzKeyVault -VaultName 'ContosoKeyVault' -ResourceGroupName
'ContosoResourceGroup' -Location 'East Asia' -EnabledForDeployment
```

For existing key vaults, you can use this PowerShell cmdlet:

Azure PowerShell

```
Set-AzKeyVaultAccessPolicy -VaultName 'ContosoKeyVault' -
EnabledForDeployment
```

Use CLI to set up Key Vault

To create a key vault by using the command-line interface (CLI), see Manage Key Vault using CLI.

For CLI, you have to create the key vault before you assign the deployment policy. You can do this by using the following command:

Azure CLI

```
az keyvault create --name "ContosoKeyVault" --resource-group
"ContosoResourceGroup" --location "EastAsia"
```

Then to enable Key Vault for use with template deployment, run the following command:

Azure CLI

```
az keyvault update --name "ContosoKeyVault" --resource-group
"ContosoResourceGroup" --enabled-for-deployment "true"
```

Use templates to set up Key Vault

While you use a template, you need to set the `enabledForDeployment` property to `true` for the Key Vault resource.

config

```
{
  "type": "Microsoft.KeyVault/vaults",
  "name": "ContosoKeyVault",
  "apiVersion": "2015-06-01",
  "location": "<location-of-key-vault>",
  "properties": {
    "enabledForDeployment": "true",
    ....
    ....
  }
}
```

For other options that you can configure when you create a key vault by using templates, see Create a key vault.

Guidance for mitigating silicon based micro-architectural and speculative execution side-channel vulnerabilities

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article provides guidance for a new class of silicon based micro-architectural and speculative execution side-channel vulnerabilities that affect many modern processors and operating systems. This includes Intel, AMD, and ARM. Specific details for these silicon-based vulnerabilities can be found in the following security advisories and CVEs:

- ADV180002 - Guidance to mitigate speculative execution side-channel vulnerabilities
- ADV180012 - Microsoft Guidance for Speculative Store Bypass
- ADV180013 - Microsoft Guidance for Rogue System Register Read
- ADV180016 - Microsoft Guidance for Lazy FP State Restore
- ADV180018 - Microsoft Guidance to mitigate L1TF variant
- ADV190013 - Microsoft Guidance to mitigate Microarchitectural Data Sampling vulnerabilities
- ADV220002 - Microsoft Guidance on Intel Processor MMIO Stale Data Vulnerabilities
- CVE-2022-23816 - AMD CPU Branch Type Confusion
- CVE-2022-21123 - AMD CPU Branch Type Confusion

The disclosure of these CPU vulnerabilities has resulted in questions from customers seeking more clarity.

Microsoft has deployed mitigations across all our cloud services. The infrastructure that runs Azure and isolates customer workloads from each other is protected. This means that a potential attacker using the same infrastructure can't attack your application using these vulnerabilities.

Azure is using memory preserving maintenance whenever possible, to minimize customer impact and eliminate the need for reboots. Azure will continue utilizing these methods when making systemwide updates to the host and protect our customers.

More information about how security is integrated into every aspect of Azure is available on the Azure Security Documentation site.

> **Note**
>
> Since this document was first published, multiple variants of this vulnerability class have been disclosed. Microsoft continues to be heavily invested in protecting our customers and providing guidance. This page will be updated as we continue to release further fixes.
>
> **Customers that are running untrusted code within their VM** need to take action to protect against these vulnerabilities by reading below for more guidance on all vulnerabilities.
>
> Other customers should evaluate these vulnerabilities from a Defense in Depth perspective and consider the security and performance implications of their chosen configuration.

Keeping your operating systems up-to-date

While an OS update isn't required to isolate your applications running on Azure from other Azure customers, it is always a best practice to keep your software up-to-date. The latest Security Updates for Windows contain mitigations for these vulnerabilities. Similarly, Linux distributions have released multiple updates to address these vulnerabilities. Here are our recommended actions to update your operating system:

Expand table

Offering	Recommended Action
Azure Cloud Services	Enable auto update or ensure you're running the newest Guest OS.
Azure Linux Virtual Machines	Install updates from your operating system provider. For more information, see Linux later in this document.
Azure Windows Virtual Machines	Install the latest security rollup.
Other Azure PaaS Services	There's no action needed for customers using these services. Azure automatically keeps your OS versions up-to-date.

Additional guidance if you're running untrusted code

Customers who allow untrusted users to execute arbitrary code may wish to implement some extra security features inside their Azure Virtual Machines or Cloud Services. These features protect against the intra-process disclosure vectors that several speculative execution vulnerabilities describe.

Example scenarios where more security features are recommended:

- You allow code that you don't trust to run inside your VM.
  - *For example, you allow one of your customers to upload a binary or script that you then execute within your application*.
- You allow users that you don't trust to log into your VM using low privileged accounts.
  - *For example, you allow a low-privileged user to log into one of your VMs using remote desktop or SSH*.
- You allow untrusted users access to virtual machines implemented via nested virtualization.
  - *For example, you control the Hyper-V host, but allocate the VMs to untrusted users*.

Customers who don't implement a scenario involving untrusted code don't need to enable these extra security features.

Enabling additional security

You can enable more security features inside your VM or Cloud Service if you're running untrusted code. In parallel, ensure your operating system is up-to-date to enable security features inside your VM or Cloud Service

Windows

Your target operating system must be up-to-date to enable these extra security features. While numerous mitigations are enabled by default, the extra features described here must be enabled manually and may cause a performance impact.

Option 1

Step 1: Follow the instructions in KB4072698 to verify protections are enabled using the SpeculationControl PowerShell module.

> **Note**

If you previously downloaded this module, you will need to install the newest version.

To validate enabled protections against these vulnerabilities, see Understanding Get-SpeculationControlSettings PowerShell script output.

If protections aren't enabled, please contact Azure Support to enable additional controls on your Azure VM.

Step 2: To enable Kernel Virtual Address Shadowing (KVAS) and Branch Target Injection (BTI) OS support, follow the instructions in KB4072698 to enable protections using the `Session Manager` registry keys. A reboot is required.

Step 3: For deployments that are using nested virtualization (D3 and E3 only): These instructions apply inside the VM you're using as a Hyper-V host.

1. Follow the instructions in KB4072698 to enable protections using the `MinVmVersionForCpuBasedMitigations` registry keys.
2. Set the hypervisor scheduler type to `Core` by following the instructions here.

Option 2

Disable hyper-threading on the VM - Customers running untrusted code on a hyper-threaded VM might choose to disable hyper-threading or move to a non-hyper-threaded VM size. Reference this doc for a list of hyper-threaded VM sizes (where ratio of vCPU to Core is 2:1). To check if your VM has hyper-threading enabled, refer to the below script using the Windows command line from within the VM.

Type `wmic` to enter the interactive interface. Then type the following command to view the amount of physical and logical processors on the VM.

```
CPU Get NumberOfCores,NumberOfLogicalProcessors /Format:List
```

If the number of logical processors is greater than physical processors (cores), then hyper-threading is enabled. If you're running a hyper-threaded VM, contact Azure Support to get hyper-threading disabled. Once hyper-threading is disabled, support will require a full VM reboot. Refer to Core count to understand why your VM core count decreased.

Option 3

For CVE-2022-23816 and CVE-2022-21123 (AMD CPU Branch Type Confusion), follow both **Option 1** and **Option 2** above.

Linux

Enabling the set of extra security features inside requires that the target operating system be fully up-to-date. Some mitigations will be enabled by default. The following section describes the features which are off by default and/or reliant on hardware support (microcode). Enabling these features may cause a performance impact. Reference your operating system provider's documentation for further instructions

Step 1: Disable hyper-threading on the VM - Customers running untrusted code on a hyper-threaded VM will need to disable hyper-threading or move to a non-hyper-threaded VM. Reference this doc for a list of hyper-threaded VM sizes (where ratio of vCPU to Core is 2:1). To check if you're running a hyper-threaded VM, run the `lscpu` command in the Linux VM.

If `Thread(s) per core = 2`, then hyper-threading has been enabled.

If `Thread(s) per core = 1`, then hyper-threading has been disabled.

Sample output for a VM with hyper-threading enabled:

Console

```
CPU Architecture:      x86_64
CPU op-mode(s):        32-bit, 64-bit
Byte Order:            Little Endian
CPU(s):                8
On-line CPU(s) list:   0-7
Thread(s) per core:    2
Core(s) per socket:    4
Socket(s):             1
NUMA node(s):          1
```

If you're running a hyper-threaded VM, contact Azure Support to get hyper-threading disabled. Once hyper-threading is disabled, **support will require a full VM reboot**. Refer to Core count to understand why your VM core count decreased.

Step 2: To mitigate against any of the below CPU based memory vulnerabilities, refer to your operating system provider's documentation:

- Redhat
- SUSE

- Ubuntu

Core count

When a hyper-threaded VM is created, Azure allocates 2 threads per core - these are called vCPUs. When hyper-threading is disabled, Azure removes a thread and surfaces up single threaded cores (physical cores). The ratio of vCPU to CPU is 2:1, so once hyper-threading is disabled, the CPU count in the VM will appear to have decreased by half. For example, a D8_v3 VM is a hyper-threaded VM running on 8 vCPUs (2 threads per core x 4 cores). When hyper-threading is disabled, CPUs will drop to 4 physical cores with 1 thread per core.

Next steps

For more information about how security is integrated into every aspect of Azure, see Azure Security Documentation.

Join a Red Hat Enterprise Linux virtual machine to a Microsoft Entra Domain Services managed domain

To let users sign in to virtual machines (VMs) in Azure using a single set of credentials, you can join VMs to a Microsoft Entra Domain Services managed domain. When you join a VM to a Domain Services managed domain, user accounts and credentials from the domain can be used to sign in and manage servers. Group memberships from the managed domain are also applied to let you control access to files or services on the VM.

This article shows you how to join a Red Hat Enterprise Linux (RHEL) VM to a managed domain.

Prerequisites

To complete this tutorial, you need the following resources and privileges:

- An active Azure subscription.
  - If you don't have an Azure subscription, create an account.
- A Microsoft Entra tenant associated with your subscription, either synchronized with an on-premises directory or a cloud-only directory.
  - If needed, create a Microsoft Entra tenant or associate an Azure subscription with your account.
- A Microsoft Entra Domain Services managed domain enabled and configured in your Microsoft Entra tenant.
  - If needed, the first tutorial creates and configures a Microsoft Entra Domain Services managed domain.
- A user account that's a part of the managed domain.
- Unique Linux VM names that are a maximum of 15 characters to avoid truncated names that might cause conflicts in Active Directory.

Create and connect to a RHEL Linux VM

If you have an existing RHEL Linux VM in Azure, connect to it using SSH, then continue on to the next step to start configuring the VM.

If you need to create a RHEL Linux VM, or want to create a test VM for use with this article, you can use one of the following methods:

- Microsoft Entra admin center
- Azure CLI

- Azure PowerShell

When you create the VM, pay attention to the virtual network settings to make sure that the VM can communicate with the managed domain:

- Deploy the VM into the same, or a peered, virtual network in which you have enabled Microsoft Entra Domain Services.
- Deploy the VM into a different subnet than your Microsoft Entra Domain Services managed domain.

Once the VM is deployed, follow the steps to connect to the VM using SSH.

Configure the hosts file

To make sure that the VM host name is correctly configured for the managed domain, edit the */etc/hosts* file and set the hostname:

Bash

```
sudo vi /etc/hosts
```

In the *hosts* file, update the *localhost* address. In the following example:

- *aaddscontoso.com* is the DNS domain name of your managed domain.
- *rhel* is the hostname of your RHEL VM that you're joining to the managed domain.

Update these names with your own values:

config

```
127.0.0.1 rhel rhel.aaddscontoso.com
```

When done, save and exit the *hosts* file using the `:wq` command of the editor.

RHEL 6

> **Important**
>
> Keep in consideration Red Hat Enterprise Linux 6.X and Oracle Linux 6.x is already EOL. RHEL 6.10 has available ELS support, which ended on 06/2024.

Install required packages

The VM needs some additional packages to join the VM to the managed domain. To install and configure these packages, update and install the domain-join tools using `yum`.

```
Bash
sudo yum install adcli sssd authconfig krb5-workstation
```

Join VM to the managed domain

Now that the required packages are installed on the VM, join the VM to the managed domain.

1. Use the `adcli info` command to discover the managed domain. The following example discovers the realm *AADDSCONTOSO.COM*. Specify your own managed domain name in ALL UPPERCASE:

   ```
   Bash
   sudo adcli info aaddscontoso.com
   ```

   If the `adcli info` command can't find your managed domain, review the following troubleshooting steps:

   - Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
   - Check that the VM is deployed to the same, or a peered, virtual network in which the managed domain is available.
   - Confirm that the DNS server settings for the virtual network are updated to point to the domain controllers of the managed domain.

2. First, join the domain using the `adcli join` command. This command also creates the keytab to authenticate the machine. Use a user account that's a part of the managed domain.

   ```
   Bash
   sudo adcli join aaddscontoso.com -U contosoadmin
   ```

3. Now configure the `/ect/krb5.conf` and create the `/etc/sssd/sssd.conf` files to use the `aaddscontoso.com` Active Directory domain. Make sure that `AADDSCONTOSO.COM` is replaced by your own domain name:

   Open the `/etc/krb5.conf` file with an editor:

Bash

```
sudo vi /etc/krb5.conf
```

Update the `krb5.conf` file to match the following sample:

config

```
[logging]
 default = FILE:/var/log/krb5libs.log
 kdc = FILE:/var/log/krb5kdc.log
 admin_server = FILE:/var/log/kadmind.log

[libdefaults]
 default_realm = AADDSCONTOSO.COM
 dns_lookup_realm = true
 dns_lookup_kdc = true
 ticket_lifetime = 24h
 renew_lifetime = 7d
 forwardable = true

[realms]
 AADDSCONTOSO.COM = {
 kdc = AADDSCONTOSO.COM
 admin_server = AADDSCONTOSO.COM
 }

[domain_realm]
 .AADDSCONTOSO.COM = AADDSCONTOSO.COM
 AADDSCONTOSO.COM = AADDSCONTOSO.COM
```

Create the `/etc/sssd/sssd.conf` file:

Bash

```
sudo vi /etc/sssd/sssd.conf
```

Update the `sssd.conf` file to match the following sample:

config

```
[sssd]
 services = nss, pam, ssh, autofs
 config_file_version = 2
 domains = AADDSCONTOSO.COM

[domain/AADDSCONTOSO.COM]

 id_provider = ad
```

4. Make sure `/etc/sssd/sssd.conf` permissions are 600 and is owned by root user:

```Bash
sudo chmod 600 /etc/sssd/sssd.conf
sudo chown root:root /etc/sssd/sssd.conf
```

5. Use `authconfig` to instruct the VM about the AD Linux integration:

```Bash
sudo authconfig --enablesssd --enablesssd auth --update
```

6. Start and enable the sssd service:

```Bash
sudo service sssd start
sudo chkconfig sssd on
```

If your VM can't successfully complete the domain-join process, make sure that the VM's network security group allows outbound Kerberos traffic on TCP + UDP port 464 to the virtual network subnet for your managed domain.

Now check if you can query user AD information using `getent`

```Bash
sudo getent passwd contosoadmin
```

Allow password authentication for SSH

By default, users can only sign in to a VM using SSH public key-based authentication. Password-based authentication fails. When you join the VM to a managed domain, those domain accounts need to use password-based authentication. Update the SSH configuration to allow password-based authentication as follows.

1. Open the *sshd_conf* file with an editor:

```Bash
sudo vi /etc/ssh/sshd_config
```

2. Update the line for *PasswordAuthentication* to *yes*:

```
config
PasswordAuthentication yes
```

When done, save and exit the *sshd_conf* file using the `:wq` command of the editor.

3. To apply the changes and let users sign in using a password, restart the SSH service for your RHEL distro version:

```
Bash
sudo service sshd restart
```

Grant the 'AAD DC Administrators' group sudo privileges

To grant members of the *AAD DC Administrators* group administrative privileges on the RHEL VM, you add an entry to the */etc/sudoers*. Once added, members of the *AAD DC Administrators* group can use the `sudo` command on the RHEL VM.

1. Open the *sudoers* file for editing:

```
Bash
sudo visudo
```

2. Add the following entry to the end of */etc/sudoers* file. The *AAD DC Administrators* group contains whitespace in the name, so include the backslash escape character in the group name. Add your own domain name, such as *aaddscontoso.com*:

```
config
# Add 'AAD DC Administrators' group members as admins.
%AAD\ DC\ Administrators@aaddscontoso.com ALL=(ALL) NOPASSWD:ALL
```

When done, save and exit the editor using the `:wq` command of the editor.

Sign in to the VM using a domain account

To verify that the VM successfully joined to the managed domain, start a new SSH connection using a domain user account. Confirm that a home directory is created, and that group

membership from the domain is applied.

1. Create a new SSH connection from your console. Use a domain account that belongs to the managed domain using the `ssh -l` command, such as `contosoadmin@aaddscontoso.com` and then enter the address of your VM, such as *rhel.aaddscontoso.com*. If you use the Azure Cloud Shell, use the public IP address of the VM rather than the internal DNS name.

   ```
   Bash
   ssh -l contosoadmin@AADDSCONTOSO.com rhel.aaddscontoso.com
   ```

2. When you've successfully connected to the VM, verify that the home directory was initialized correctly:

   ```
   Bash
   pwd
   ```

   You should be in the */home* directory with your own directory that matches the user account.

3. Now check that the group memberships are being resolved correctly:

   ```
   Bash
   id
   ```

   You should see your group memberships from the managed domain.

4. If you signed in to the VM as a member of the *AAD DC Administrators* group, check that you can correctly use the `sudo` command:

   ```
   Bash
   sudo yum update
   ```

Next steps

If you have problems connecting the VM to the managed domain or signing in with a domain account, see Troubleshooting domain join issues.

Join an Ubuntu Linux virtual machine to a Microsoft Entra Domain Services managed domain

To let users sign in to virtual machines (VMs) in Azure using a single set of credentials, you can join VMs to a Microsoft Entra Domain Services managed domain. When you join a VM to a Domain Services managed domain, user accounts and credentials from the domain can be used to sign in and manage servers. Group memberships from the managed domain are also applied to let you control access to files or services on the VM.

This article shows you how to join an Ubuntu Linux VM to a managed domain.

Prerequisites

To complete this tutorial, you need the following resources and privileges:

- An active Azure subscription.
  - If you don't have an Azure subscription, create an account.
- A Microsoft Entra tenant associated with your subscription, either synchronized with an on-premises directory or a cloud-only directory.
  - If needed, create a Microsoft Entra tenant or associate an Azure subscription with your account.
- A Microsoft Entra Domain Services managed domain enabled and configured in your Microsoft Entra tenant.
  - If needed, the first tutorial creates and configures a Microsoft Entra Domain Services managed domain.
- A user account that's a part of the managed domain. Make sure the SAMAccountName attribute for the user isn't autogenerated. If multiple user accounts in the Microsoft Entra tenant have the same mailNickname attribute, the SAMAccountName attribute for each user is autogenerated. For more information, see How objects and credentials are synchronized in a Microsoft Entra Domain Services managed domain.
- Unique Linux VM names that are a maximum of 15 characters to avoid truncated names that might cause conflicts in Active Directory.

Create and connect to an Ubuntu Linux VM

If you have an existing Ubuntu Linux VM in Azure, connect to it using SSH, then continue on to the next step to start configuring the VM.

If you need to create an Ubuntu Linux VM, or want to create a test VM for use with this article, you can use one of the following methods:

- Microsoft Entra admin center
- Azure CLI
- Azure PowerShell

When you create the VM, pay attention to the virtual network settings to make sure that the VM can communicate with the managed domain:

- Deploy the VM into the same, or a peered, virtual network in which you have enabled Microsoft Entra Domain Services.
- Deploy the VM into a different subnet than your Microsoft Entra Domain Services managed domain.

Once the VM is deployed, follow the steps to connect to the VM using SSH.

Configure the hosts file

To make sure that the VM host name is correctly configured for the managed domain, edit the */etc/hosts* file and set the hostname:

```Bash
sudo vi /etc/hosts
```

In the *hosts* file, update the *localhost* address. In the following example:

- *aaddscontoso.com* is the DNS domain name of your managed domain.
- *ubuntu* is the hostname of your Ubuntu VM that you're joining to the managed domain.

Update these names with your own values:

```config
127.0.0.1 ubuntu.aaddscontoso.com ubuntu
```

When done, save and exit the *hosts* file using the `:wq` command of the editor.

Install required packages

The VM needs some additional packages to join the VM to the managed domain. To install and configure these packages, update and install the domain-join tools using `apt-get`

During the Kerberos installation, the *krb5-user* package prompts for the realm name in ALL UPPERCASE. For example, if the name of your managed domain is *aaddscontoso.com*, enter *AADDSCONTOSO.COM* as the realm. The installation writes the `[realm]` and `[domain_realm]` sections in */etc/krb5.conf* configuration file. Make sure that you specify the realm an ALL UPPERCASE:

Bash

```
sudo apt-get update
sudo apt-get install krb5-user samba sssd sssd-tools libnss-sss libpam-sss ntp
ntpdate realmd adcli
```

Configure Network Time Protocol (NTP)

For domain communication to work correctly, the date and time of your Ubuntu VM must synchronize with the managed domain. Add your managed domain's NTP hostname to the */etc/ntp.conf* file.

1. Open the *ntp.conf* file with an editor:

   Bash

   ```
   sudo vi /etc/ntp.conf
   ```

2. In the *ntp.conf* file, create a line to add your managed domain's DNS name. In the following example, an entry for *aaddscontoso.com* is added. Use your own DNS name:

   config

   ```
   server aaddscontoso.com
   ```

   When done, save and exit the *ntp.conf* file using the `:wq` command of the editor.

3. To make sure that the VM is synchronized with the managed domain, the following steps are needed:

   - Stop the NTP server
   - Update the date and time from the managed domain
   - Start the NTP service

   To complete these steps, run the following commands. Use your own DNS name with the `ntpdate` command:

Bash

```
sudo systemctl stop ntp
sudo ntpdate aaddscontoso.com
sudo systemctl start ntp
```

Join VM to the managed domain

Now that the required packages are installed on the VM and NTP is configured, join the VM to the managed domain.

1. Use the `realm discover` command to discover the managed domain. The following example discovers the realm *AADDSCONTOSO.COM*. Specify your own managed domain name in ALL UPPERCASE:

   Bash

   ```
   sudo realm discover AADDSCONTOSO.COM
   ```

   If the `realm discover` command can't find your managed domain, review the following troubleshooting steps:

   - Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
   - Check that the VM is deployed to the same, or a peered, virtual network in which the managed domain is available.
   - Confirm that the DNS server settings for the virtual network have been updated to point to the domain controllers of the managed domain.

2. Now initialize Kerberos using the `kinit` command. Specify a user that's a part of the managed domain. If needed, add a user account to a group in Microsoft Entra ID.

   Again, the managed domain name must be entered in ALL UPPERCASE. In the following example, the account named `contosoadmin@aaddscontoso.com` is used to initialize Kerberos. Enter your own user account that's a part of the managed domain:

   Bash

   ```
   sudo kinit -V contosoadmin@AADDSCONTOSO.COM
   ```

3. Finally, join the VM to the managed domain using the `realm join` command. Use the same user account that's a part of the managed domain that you specified in the previous `kinit` command, such as `contosoadmin@AADDSCONTOSO.COM`:

```bash
sudo realm join --verbose AADDSCONTOSO.COM -U 'contosoadmin@AADDSCONTOSO.COM' --install=/
```

It takes a few moments to join the VM to the managed domain. The following example output shows the VM has successfully joined to the managed domain:

```output
Successfully enrolled machine in realm
```

If your VM can't successfully complete the domain-join process, make sure that the VM's network security group allows outbound Kerberos traffic on TCP + UDP port 464 to the virtual network subnet for your managed domain.

If you received the error *Unspecified GSS failure. Minor code can provide more information (Server not found in Kerberos database)*, open the file */etc/krb5.conf* and add the following code in `[libdefaults]` section and try again:

```config
rdns=false
```

Update the SSSD configuration

One of the packages installed in a previous step was for System Security Services Daemon (SSSD). When a user tries to sign in to a VM using domain credentials, SSSD relays the request to an authentication provider. In this scenario, SSSD uses Domain Services to authenticate the request.

1. Open the *sssd.conf* file with an editor:

   ```bash
   sudo vi /etc/sssd/sssd.conf
   ```

2. Comment out the line for *use_fully_qualified_names* as follows:

   ```config
   # use_fully_qualified_names = True
   ```

   When done, save and exit the *sssd.conf* file using the `:wq` command of the editor.

3. To apply the change, restart the SSSD service:

```bash
sudo systemctl restart sssd
```

Configure user account and group settings

With the VM joined to the managed domain and configured for authentication, there are a few user configuration options to complete. These configuration changes include allowing password-based authentication, and automatically creating home directories on the local VM when domain users first sign in.

Allow password authentication for SSH

By default, users can only sign in to a VM using SSH public key-based authentication. Password-based authentication fails. When you join the VM to a managed domain, those domain accounts need to use password-based authentication. Update the SSH configuration to allow password-based authentication as follows.

> **Note**
>
> Ubuntu marketplace images usually have a few configuration options set under /etc/ssh/sshd_config.d, including *PasswordAuthentication* in the 50-cloud-init.conf file, so make sure you also update that file to avoid it overwriting the one set with the steps below.

1. Open the *sshd_conf* file with an editor:

```bash
sudo vi /etc/ssh/sshd_config
```

2. Update the line for *PasswordAuthentication* to *yes*:

```config
PasswordAuthentication yes
```

   When done, save and exit the *sshd_conf* file using the `:wq` command of the editor.

3. To apply the changes and let users sign in using a password, restart the SSH service:

```bash
sudo systemctl restart ssh
```

Configure automatic home directory creation

To enable automatic creation of the home directory when a user first signs in, complete the following steps:

1. Open the `/etc/pam.d/common-session` file in an editor:

   ```bash
   sudo vi /etc/pam.d/common-session
   ```

2. Add the following line in this file below the line `session optional pam_sss.so`:

   ```config
   session required pam_mkhomedir.so skel=/etc/skel/ umask=0077
   ```

   When done, save and exit the *common-session* file using the `:wq` command of the editor.

Grant the 'AAD DC Administrators' group sudo privileges

To grant members of the *AAD DC Administrators* group administrative privileges on the Ubuntu VM, you add an entry to the */etc/sudoers*. Once added, members of the *AAD DC Administrators* group can use the `sudo` command on the Ubuntu VM.

1. Open the *sudoers* file for editing:

   ```bash
   sudo visudo
   ```

2. Add the following entry to the end of */etc/sudoers* file:

   ```config
   # Add 'AAD DC Administrators' group members as admins.
   %AAD\ DC\ Administrators ALL=(ALL) NOPASSWD:ALL
   ```

   When done, save and exit the editor using the `Ctrl-X` command.

Sign in to the VM using a domain account

To verify that the VM successfully joined to the managed domain, start a new SSH connection using a domain user account. Confirm that a home directory is created, and that group membership from the domain is applied.

1. Create a new SSH connection from your console. Use a domain account that belongs to the managed domain using the `ssh -l` command, such as `contosoadmin@aaddscontoso.com` and then enter the address of your VM, such as *ubuntu.aaddscontoso.com*. If you use the Azure Cloud Shell, use the public IP address of the VM rather than the internal DNS name.

   ```Bash
   sudo ssh -l contosoadmin@AADDSCONTOSO.com ubuntu.aaddscontoso.com
   ```

2. When you've successfully connected to the VM, verify that the home directory was initialized correctly:

   ```Bash
   sudo pwd
   ```

   You should be in the */home* directory with your own directory that matches the user account.

3. Now check that the group memberships are being resolved correctly:

   ```Bash
   sudo id
   ```

   You should see your group memberships from the managed domain.

4. If you signed in to the VM as a member of the *AAD DC Administrators* group, check that you can correctly use the `sudo` command:

   ```Bash
   sudo apt-get update
   ```

Next steps

If you have problems connecting the VM to the managed domain or signing in with a domain account, see Troubleshooting domain join issues.

Join an Ubuntu Linux virtual machine to a Microsoft Entra Domain Services managed domain

To let users sign in to virtual machines (VMs) in Azure using a single set of credentials, you can join VMs to a Microsoft Entra Domain Services managed domain. When you join a VM to a Domain Services managed domain, user accounts and credentials from the domain can be used to sign in and manage servers. Group memberships from the managed domain are also applied to let you control access to files or services on the VM.

This article shows you how to join an Ubuntu Linux VM to a managed domain.

Prerequisites

To complete this tutorial, you need the following resources and privileges:

- An active Azure subscription.
  - If you don't have an Azure subscription, create an account.
- A Microsoft Entra tenant associated with your subscription, either synchronized with an on-premises directory or a cloud-only directory.
  - If needed, create a Microsoft Entra tenant or associate an Azure subscription with your account.
- A Microsoft Entra Domain Services managed domain enabled and configured in your Microsoft Entra tenant.
  - If needed, the first tutorial creates and configures a Microsoft Entra Domain Services managed domain.
- A user account that's a part of the managed domain. Make sure the SAMAccountName attribute for the user isn't autogenerated. If multiple user accounts in the Microsoft Entra tenant have the same mailNickname attribute, the SAMAccountName attribute for each user is autogenerated. For more information, see How objects and credentials are synchronized in a Microsoft Entra Domain Services managed domain.
- Unique Linux VM names that are a maximum of 15 characters to avoid truncated names that might cause conflicts in Active Directory.

Create and connect to an Ubuntu Linux VM

If you have an existing Ubuntu Linux VM in Azure, connect to it using SSH, then continue on to the next step to start configuring the VM.

If you need to create an Ubuntu Linux VM, or want to create a test VM for use with this article, you can use one of the following methods:

- Microsoft Entra admin center
- Azure CLI
- Azure PowerShell

When you create the VM, pay attention to the virtual network settings to make sure that the VM can communicate with the managed domain:

- Deploy the VM into the same, or a peered, virtual network in which you have enabled Microsoft Entra Domain Services.
- Deploy the VM into a different subnet than your Microsoft Entra Domain Services managed domain.

Once the VM is deployed, follow the steps to connect to the VM using SSH.

Configure the hosts file

To make sure that the VM host name is correctly configured for the managed domain, edit the */etc/hosts* file and set the hostname:

```Bash
sudo vi /etc/hosts
```

In the *hosts* file, update the *localhost* address. In the following example:

- *aaddscontoso.com* is the DNS domain name of your managed domain.
- *ubuntu* is the hostname of your Ubuntu VM that you're joining to the managed domain.

Update these names with your own values:

```config
127.0.0.1 ubuntu.aaddscontoso.com ubuntu
```

When done, save and exit the *hosts* file using the `:wq` command of the editor.

Install required packages

The VM needs some additional packages to join the VM to the managed domain. To install and configure these packages, update and install the domain-join tools using `apt-get`

During the Kerberos installation, the *krb5-user* package prompts for the realm name in ALL UPPERCASE. For example, if the name of your managed domain is *aaddscontoso.com*, enter *AADDSCONTOSO.COM* as the realm. The installation writes the `[realm]` and `[domain_realm]` sections in */etc/krb5.conf* configuration file. Make sure that you specify the realm an ALL UPPERCASE:

Bash

```
sudo apt-get update
sudo apt-get install krb5-user samba sssd sssd-tools libnss-sss libpam-sss ntp
ntpdate realmd adcli
```

Configure Network Time Protocol (NTP)

For domain communication to work correctly, the date and time of your Ubuntu VM must synchronize with the managed domain. Add your managed domain's NTP hostname to the */etc/ntp.conf* file.

1. Open the *ntp.conf* file with an editor:

   Bash

   ```
   sudo vi /etc/ntp.conf
   ```

2. In the *ntp.conf* file, create a line to add your managed domain's DNS name. In the following example, an entry for *aaddscontoso.com* is added. Use your own DNS name:

   config

   ```
   server aaddscontoso.com
   ```

   When done, save and exit the *ntp.conf* file using the `:wq` command of the editor.

3. To make sure that the VM is synchronized with the managed domain, the following steps are needed:

   - Stop the NTP server
   - Update the date and time from the managed domain
   - Start the NTP service

   To complete these steps, run the following commands. Use your own DNS name with the `ntpdate` command:

Bash

```
sudo systemctl stop ntp
sudo ntpdate aaddscontoso.com
sudo systemctl start ntp
```

Join VM to the managed domain

Now that the required packages are installed on the VM and NTP is configured, join the VM to the managed domain.

1. Use the `realm discover` command to discover the managed domain. The following example discovers the realm *AADDSCONTOSO.COM*. Specify your own managed domain name in ALL UPPERCASE:

   Bash

   ```
   sudo realm discover AADDSCONTOSO.COM
   ```

   If the `realm discover` command can't find your managed domain, review the following troubleshooting steps:

   - Make sure that the domain is reachable from the VM. Try `ping aaddscontoso.com` to see if a positive reply is returned.
   - Check that the VM is deployed to the same, or a peered, virtual network in which the managed domain is available.
   - Confirm that the DNS server settings for the virtual network have been updated to point to the domain controllers of the managed domain.

2. Now initialize Kerberos using the `kinit` command. Specify a user that's a part of the managed domain. If needed, add a user account to a group in Microsoft Entra ID.

   Again, the managed domain name must be entered in ALL UPPERCASE. In the following example, the account named `contosoadmin@aaddscontoso.com` is used to initialize Kerberos. Enter your own user account that's a part of the managed domain:

   Bash

   ```
   sudo kinit -V contosoadmin@AADDSCONTOSO.COM
   ```

3. Finally, join the VM to the managed domain using the `realm join` command. Use the same user account that's a part of the managed domain that you specified in the previous `kinit` command, such as `contosoadmin@AADDSCONTOSO.COM`:

```bash
sudo realm join --verbose AADDSCONTOSO.COM -U 'contosoadmin@AADDSCONTOSO.COM' --install=/
```

It takes a few moments to join the VM to the managed domain. The following example output shows the VM has successfully joined to the managed domain:

```output
Successfully enrolled machine in realm
```

If your VM can't successfully complete the domain-join process, make sure that the VM's network security group allows outbound Kerberos traffic on TCP + UDP port 464 to the virtual network subnet for your managed domain.

If you received the error *Unspecified GSS failure. Minor code can provide more information (Server not found in Kerberos database)*, open the file */etc/krb5.conf* and add the following code in `[libdefaults]` section and try again:

```config
rdns=false
```

Update the SSSD configuration

One of the packages installed in a previous step was for System Security Services Daemon (SSSD). When a user tries to sign in to a VM using domain credentials, SSSD relays the request to an authentication provider. In this scenario, SSSD uses Domain Services to authenticate the request.

1. Open the *sssd.conf* file with an editor:

   ```bash
   sudo vi /etc/sssd/sssd.conf
   ```

2. Comment out the line for *use_fully_qualified_names* as follows:

   ```config
   # use_fully_qualified_names = True
   ```

   When done, save and exit the *sssd.conf* file using the `:wq` command of the editor.

3. To apply the change, restart the SSSD service:

```bash
sudo systemctl restart sssd
```

Configure user account and group settings

With the VM joined to the managed domain and configured for authentication, there are a few user configuration options to complete. These configuration changes include allowing password-based authentication, and automatically creating home directories on the local VM when domain users first sign in.

Allow password authentication for SSH

By default, users can only sign in to a VM using SSH public key-based authentication. Password-based authentication fails. When you join the VM to a managed domain, those domain accounts need to use password-based authentication. Update the SSH configuration to allow password-based authentication as follows.

> **Note**
>
> Ubuntu marketplace images usually have a few configuration options set under /etc/ssh/sshd_config.d, including *PasswordAuthentication* in the 50-cloud-init.conf file, so make sure you also update that file to avoid it overwriting the one set with the steps below.

1. Open the *sshd_conf* file with an editor:

```bash
sudo vi /etc/ssh/sshd_config
```

2. Update the line for *PasswordAuthentication* to *yes*:

```config
PasswordAuthentication yes
```

   When done, save and exit the *sshd_conf* file using the `:wq` command of the editor.

3. To apply the changes and let users sign in using a password, restart the SSH service:

```bash
sudo systemctl restart ssh
```

Configure automatic home directory creation

To enable automatic creation of the home directory when a user first signs in, complete the following steps:

1. Open the `/etc/pam.d/common-session` file in an editor:

   ```bash
   sudo vi /etc/pam.d/common-session
   ```

2. Add the following line in this file below the line `session optional pam_sss.so`:

   ```config
   session required pam_mkhomedir.so skel=/etc/skel/ umask=0077
   ```

   When done, save and exit the *common-session* file using the `:wq` command of the editor.

Grant the 'AAD DC Administrators' group sudo privileges

To grant members of the *AAD DC Administrators* group administrative privileges on the Ubuntu VM, you add an entry to the */etc/sudoers*. Once added, members of the *AAD DC Administrators* group can use the `sudo` command on the Ubuntu VM.

1. Open the *sudoers* file for editing:

   ```bash
   sudo visudo
   ```

2. Add the following entry to the end of */etc/sudoers* file:

   ```config
   # Add 'AAD DC Administrators' group members as admins.
   %AAD\ DC\ Administrators ALL=(ALL) NOPASSWD:ALL
   ```

   When done, save and exit the editor using the `Ctrl-X` command.

Sign in to the VM using a domain account

To verify that the VM successfully joined to the managed domain, start a new SSH connection using a domain user account. Confirm that a home directory is created, and that group membership from the domain is applied.

1. Create a new SSH connection from your console. Use a domain account that belongs to the managed domain using the `ssh -l` command, such as `contosoadmin@aaddscontoso.com` and then enter the address of your VM, such as *ubuntu.aaddscontoso.com*. If you use the Azure Cloud Shell, use the public IP address of the VM rather than the internal DNS name.

   ```Bash
   sudo ssh -l contosoadmin@AADDSCONTOSO.com ubuntu.aaddscontoso.com
   ```

2. When you've successfully connected to the VM, verify that the home directory was initialized correctly:

   ```Bash
   sudo pwd
   ```

   You should be in the */home* directory with your own directory that matches the user account.

3. Now check that the group memberships are being resolved correctly:

   ```Bash
   sudo id
   ```

   You should see your group memberships from the managed domain.

4. If you signed in to the VM as a member of the *AAD DC Administrators* group, check that you can correctly use the `sudo` command:

   ```Bash
   sudo apt-get update
   ```

Next steps

If you have problems connecting the VM to the managed domain or signing in with a domain account, see Troubleshooting domain join issues.

Last updated on 02/13/2025

Configure managed identities on Azure virtual machines (VMs)

Managed identities for Azure resources provide Azure services with an automatically managed identity in Microsoft Entra ID. You can use this identity to authenticate to any service that supports Microsoft Entra authentication, without having credentials in your code.

For information about Azure Policy definition and details, see Use Azure Policy to assign managed identities (preview).

In this article, you learn how to enable and disable system and user-assigned managed identities for an Azure Virtual Machine (VM), using the Azure portal.

Prerequisites

- If you're unfamiliar with managed identities for Azure resources, check out the overview section.
- If you don't already have an Azure account, sign up for a free account before continuing.

System-assigned managed identity

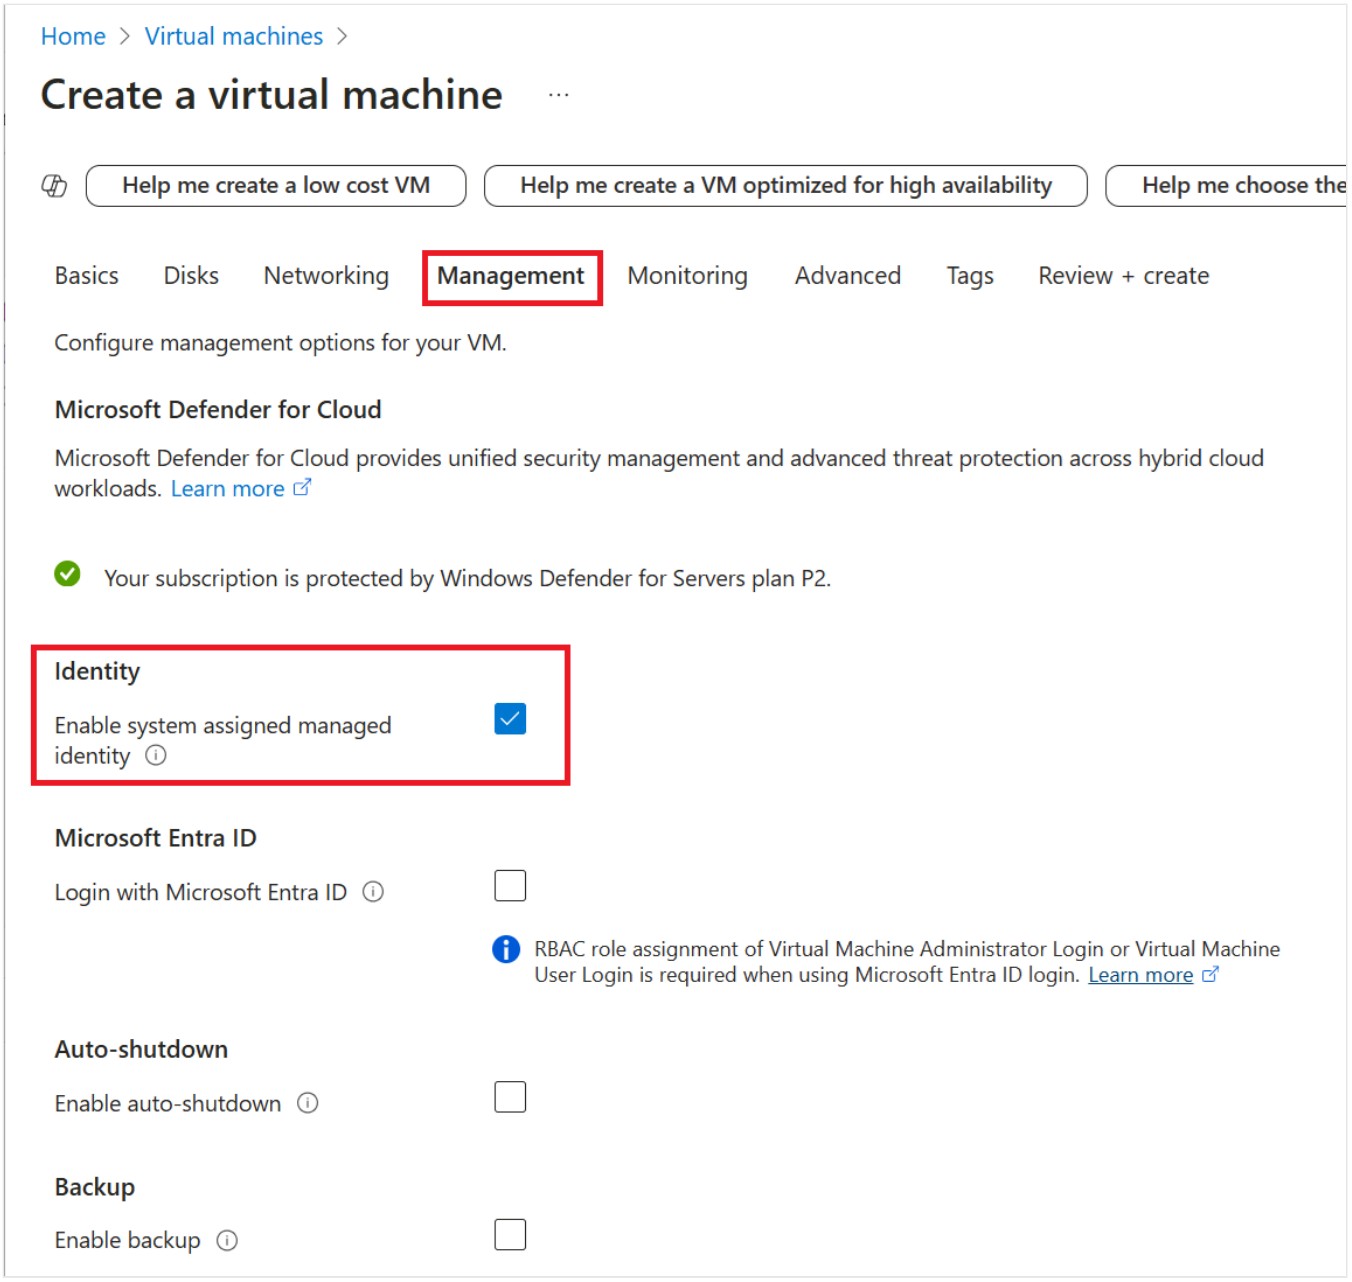
In this section, you learn how to enable and disable the system-assigned managed identity for VM using the Azure portal.

Enable system-assigned managed identity during creation of a VM

To enable system-assigned managed identity on a VM during its creation, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

When creating a Windows virtual machine or Linux virtual machine, select the **Management** tab.

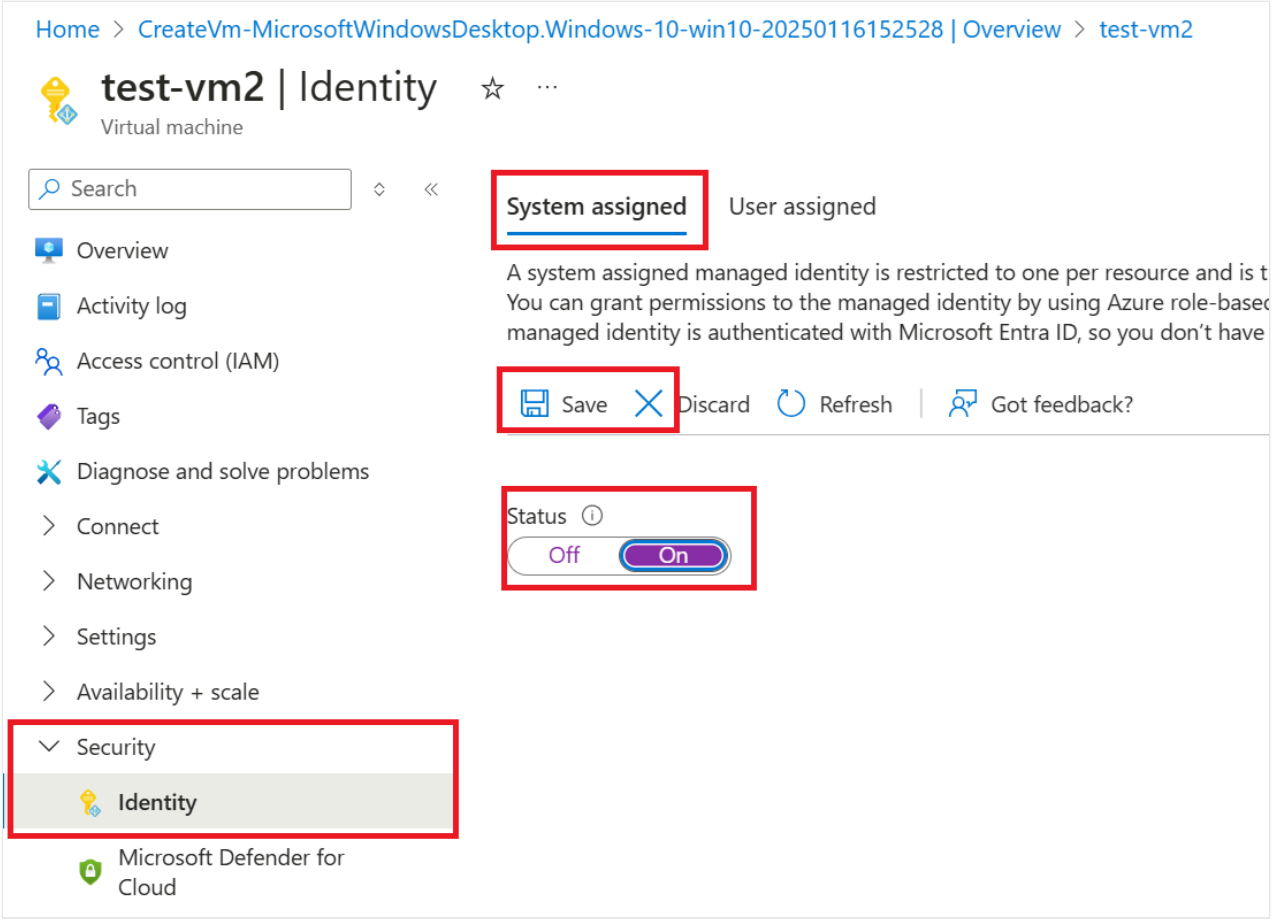
In the **Identity** section, select the **Enable system assigned managed identity** check-box.



Enable system-assigned managed identity on an existing VM

To enable system-assigned managed identity on a VM that was originally provisioned without it, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

1. Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired Virtual Machine and in the **Security** section select **Identity**.
3. Under **System assigned**, **Status**, select **On** and then click **Save**:

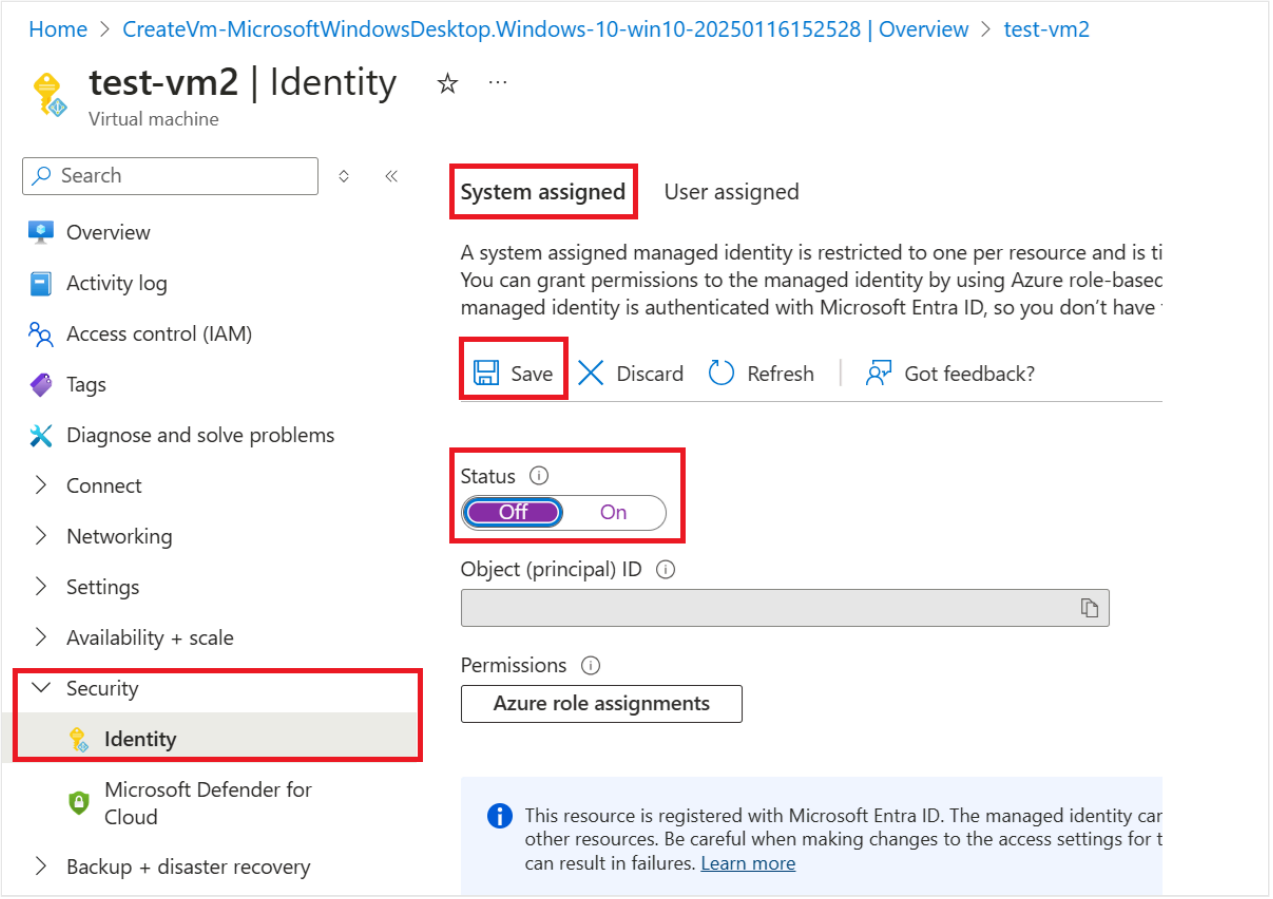


Remove system-assigned managed identity from a VM

To remove system-assigned managed identity from a VM, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

If you have a Virtual Machine that no longer needs system-assigned managed identity:

1. Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired Virtual Machine and in the **Security** section select **Identity**.
3. Under **System assigned**, **Status**, select **Off** and then click **Save**:



User-assigned managed identity

In this section, you learn how to add and remove a user-assigned managed identity from a VM using the Azure portal.

Assign a user-assigned identity during the creation of a VM

To assign a user-assigned identity to a VM, your account needs the Virtual Machine Contributor and Managed Identity Operator role assignments. No other Microsoft Entra directory role assignments are required.

Currently, the Azure portal does not support assigning a user-assigned managed identity during the creation of a VM. First create a Windows virtual machine or Linux virtual machine, then assign a user-assigned managed identity to the VM.

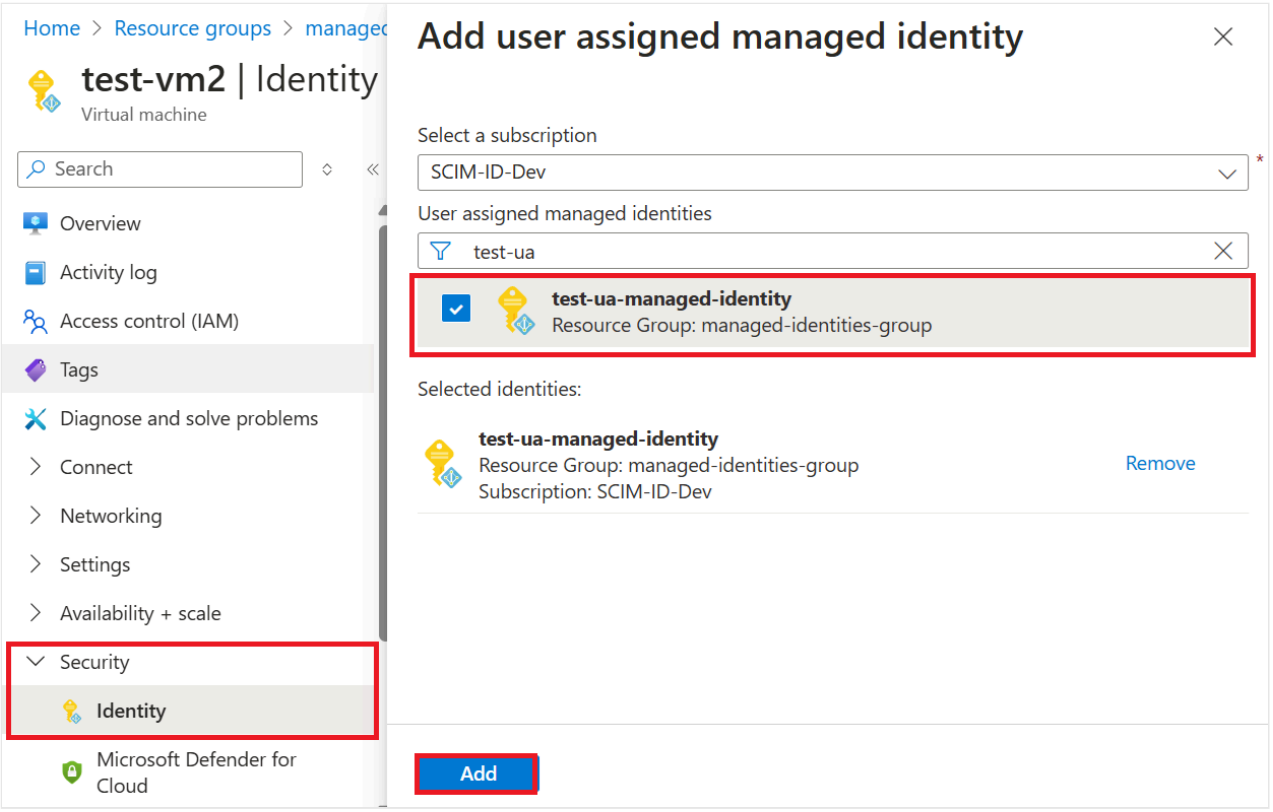
Assign a user-assigned managed identity to an existing VM

To assign a user-assigned identity to a VM, your account needs the Virtual Machine Contributor and Managed Identity Operator role assignments. No other Microsoft Entra directory role assignments are required.

1. Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.

2. Navigate to the desired VM and click **Security** > **Identity**, **User assigned** and then **+Add**. Click the user-assigned identity you want to add to the VM and then click **Add**.

3. Select the previously created user assigned managed identity from the list.

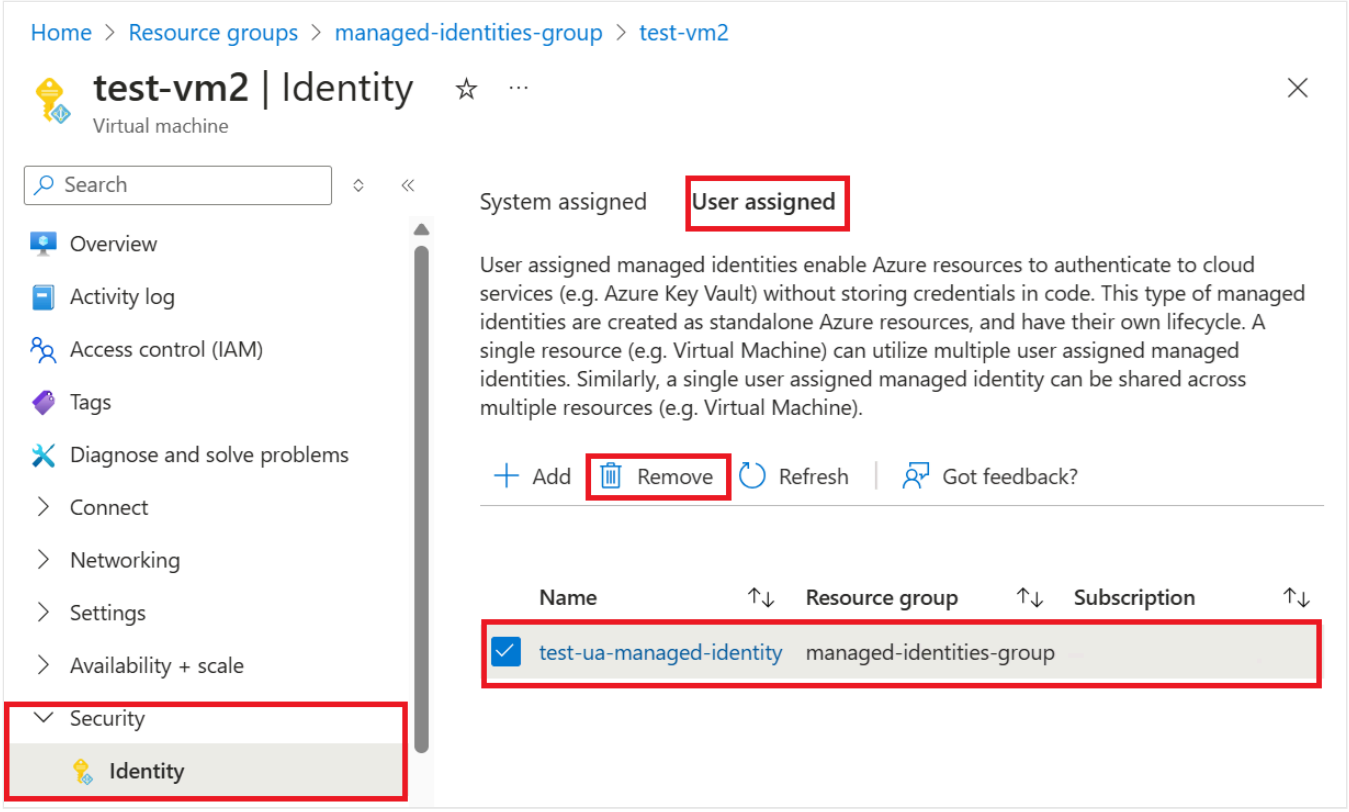


Remove a user-assigned managed identity from a VM

To remove a user-assigned identity from a VM, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.

Navigate to the desired VM and select **Security** > **Identity**, **User assigned**, the name of the user-assigned managed identity you want to delete and then click **Remove** (click **Yes** in the confirmation pane).



Next steps

- Using the Azure portal, give an Azure VM's managed identity access to another Azure resource.

Last updated on 01/16/2025

Configure managed identities on Azure virtual machines (VMs)

Managed identities for Azure resources provide Azure services with an automatically managed identity in Microsoft Entra ID. You can use this identity to authenticate to any service that supports Microsoft Entra authentication, without having credentials in your code.

For information about Azure Policy definition and details, see Use Azure Policy to assign managed identities (preview).

In this article, you learn how to enable and disable system and user-assigned managed identities for an Azure Virtual Machine (VM), using the Azure portal.

Prerequisites

- If you're unfamiliar with managed identities for Azure resources, check out the overview section.
- If you don't already have an Azure account, sign up for a free account before continuing.

System-assigned managed identity

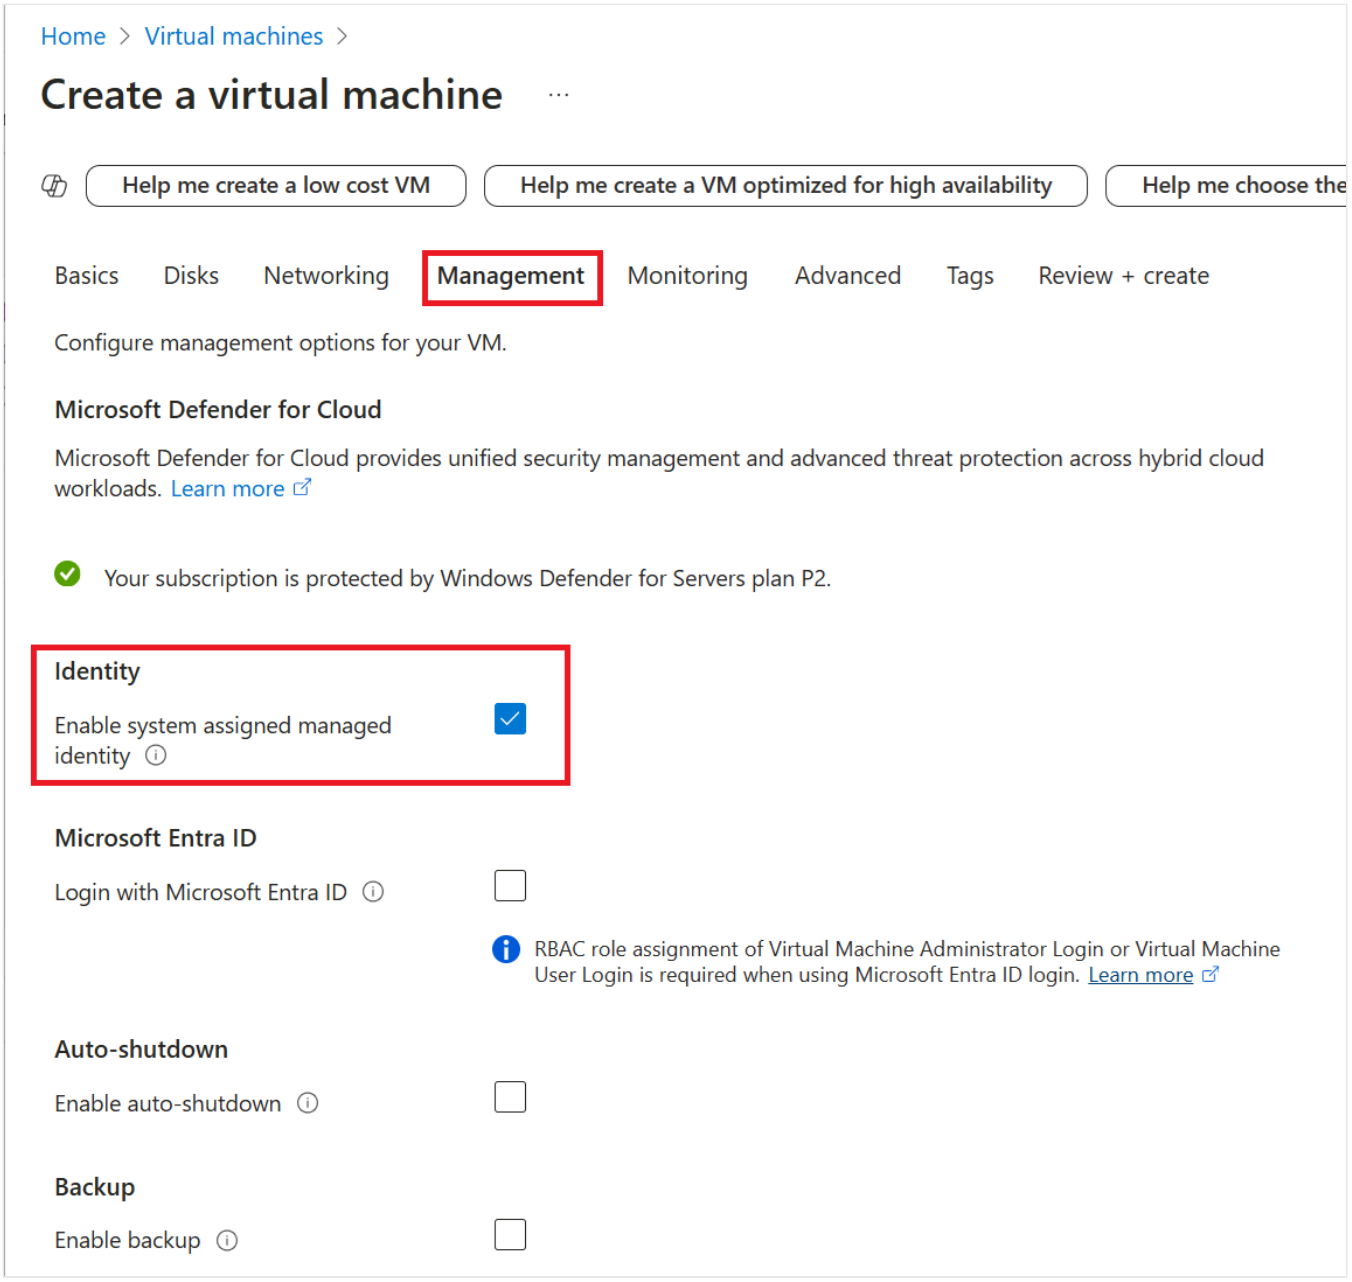
In this section, you learn how to enable and disable the system-assigned managed identity for VM using the Azure portal.

Enable system-assigned managed identity during creation of a VM

To enable system-assigned managed identity on a VM during its creation, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

When creating a Windows virtual machine or Linux virtual machine, select the **Management** tab.

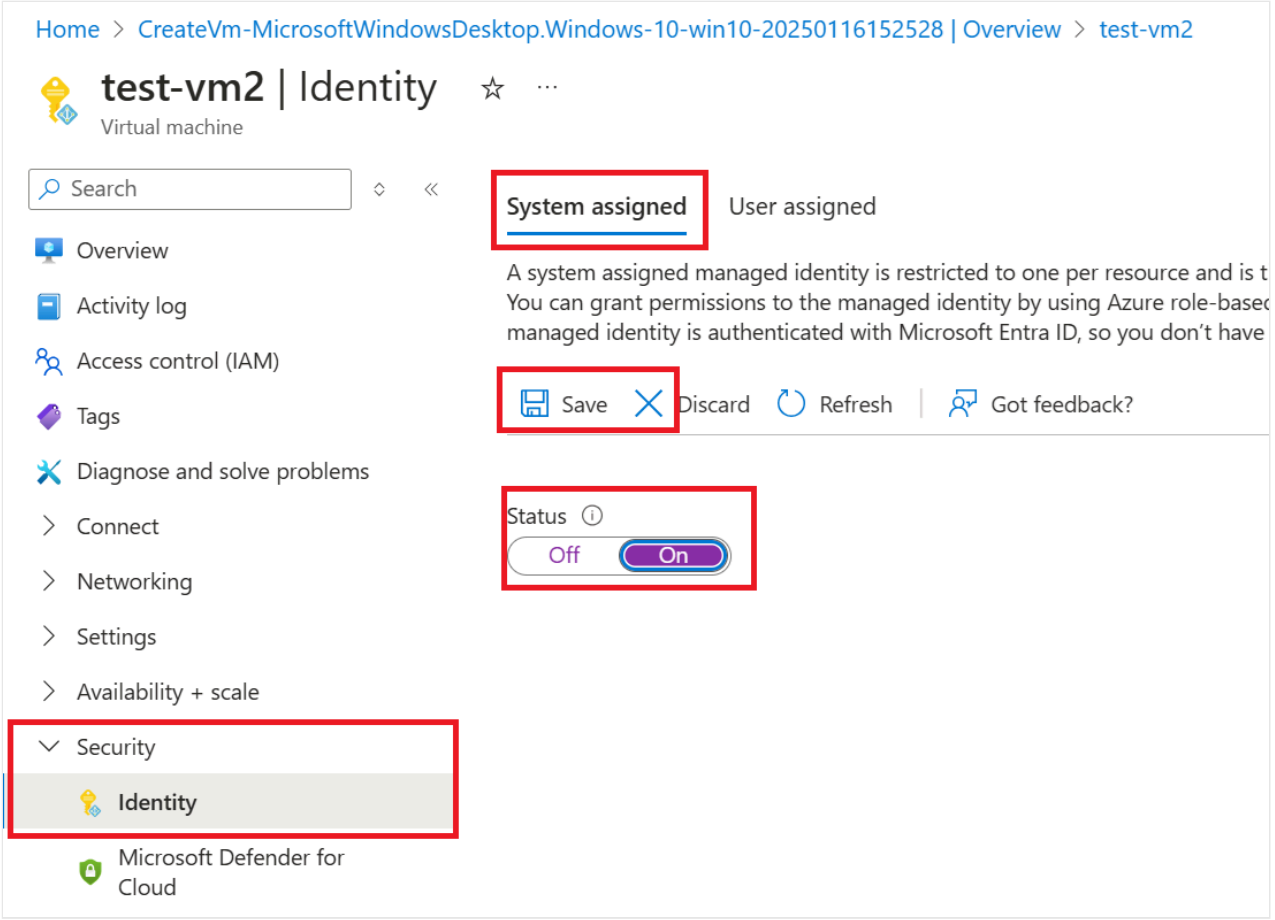
In the **Identity** section, select the **Enable system assigned managed identity** check-box.



Enable system-assigned managed identity on an existing VM

To enable system-assigned managed identity on a VM that was originally provisioned without it, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

1. Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired Virtual Machine and in the **Security** section select **Identity**.
3. Under **System assigned**, **Status**, select **On** and then click **Save**:

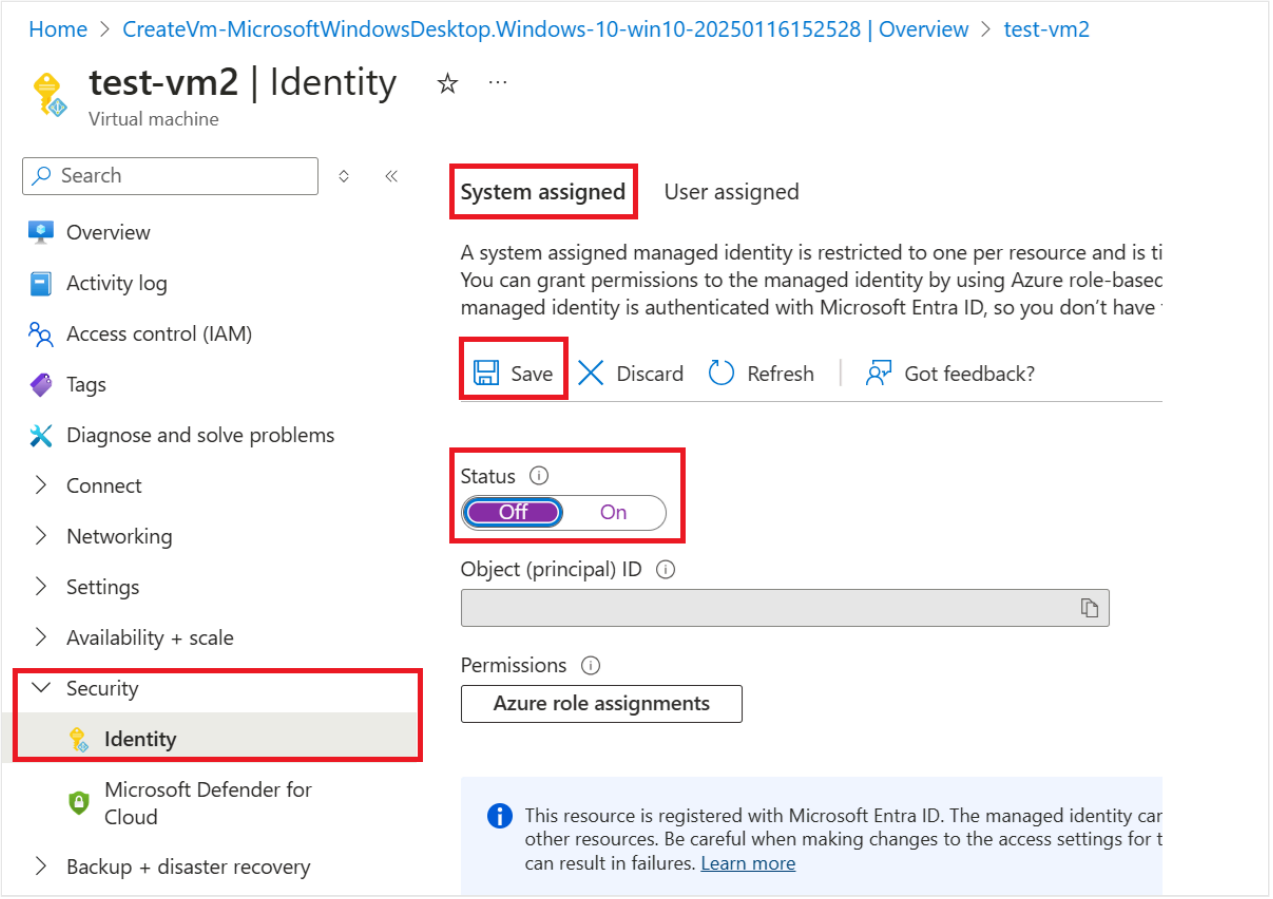


Remove system-assigned managed identity from a VM

To remove system-assigned managed identity from a VM, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

If you have a Virtual Machine that no longer needs system-assigned managed identity:

1. Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.
2. Navigate to the desired Virtual Machine and in the **Security** section select **Identity**.
3. Under **System assigned**, **Status**, select **Off** and then click **Save**:



User-assigned managed identity

In this section, you learn how to add and remove a user-assigned managed identity from a VM using the Azure portal.

Assign a user-assigned identity during the creation of a VM

To assign a user-assigned identity to a VM, your account needs the Virtual Machine Contributor and Managed Identity Operator role assignments. No other Microsoft Entra directory role assignments are required.

Currently, the Azure portal does not support assigning a user-assigned managed identity during the creation of a VM. First create a Windows virtual machine or Linux virtual machine, then assign a user-assigned managed identity to the VM.

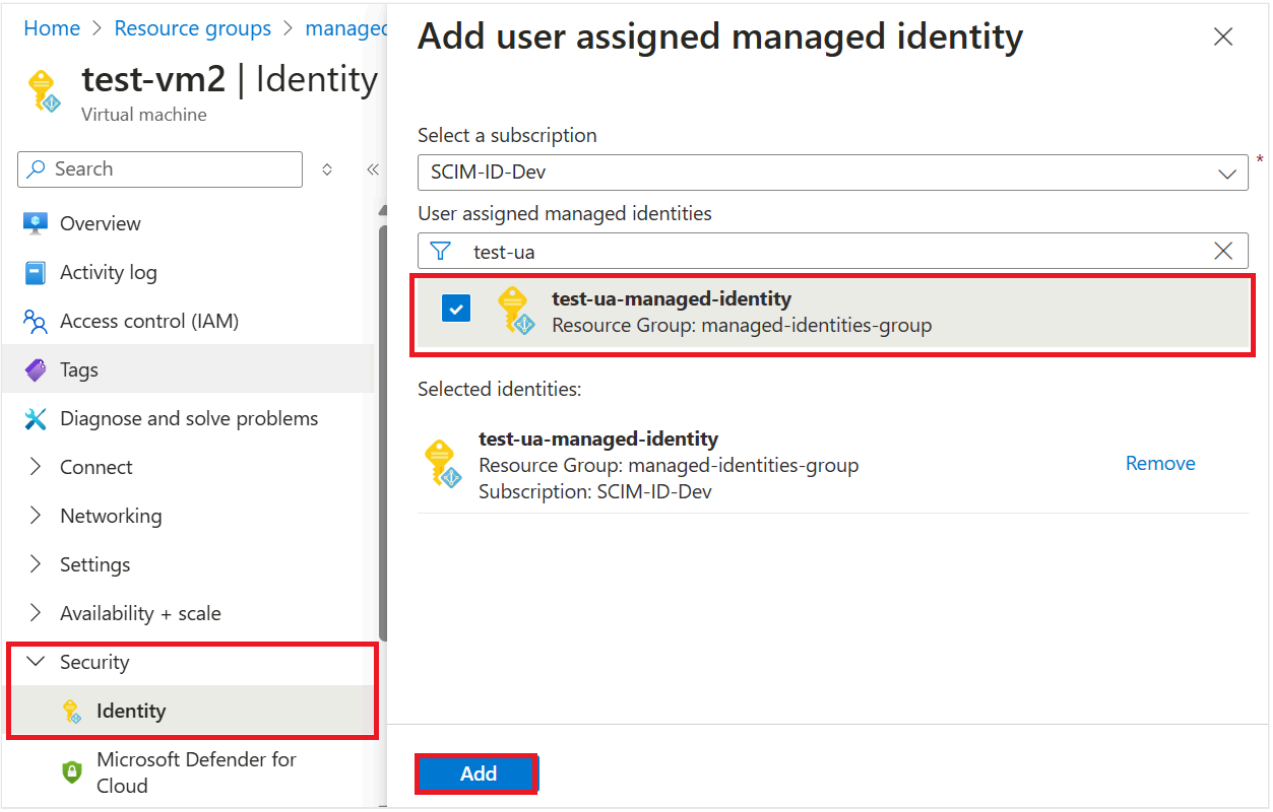
Assign a user-assigned managed identity to an existing VM

To assign a user-assigned identity to a VM, your account needs the Virtual Machine Contributor and Managed Identity Operator role assignments. No other Microsoft Entra directory role assignments are required.

1. Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.

2. Navigate to the desired VM and click **Security** > **Identity**, **User assigned** and then **+Add**. Click the user-assigned identity you want to add to the VM and then click **Add**.

3. Select the previously created user assigned managed identity from the list.

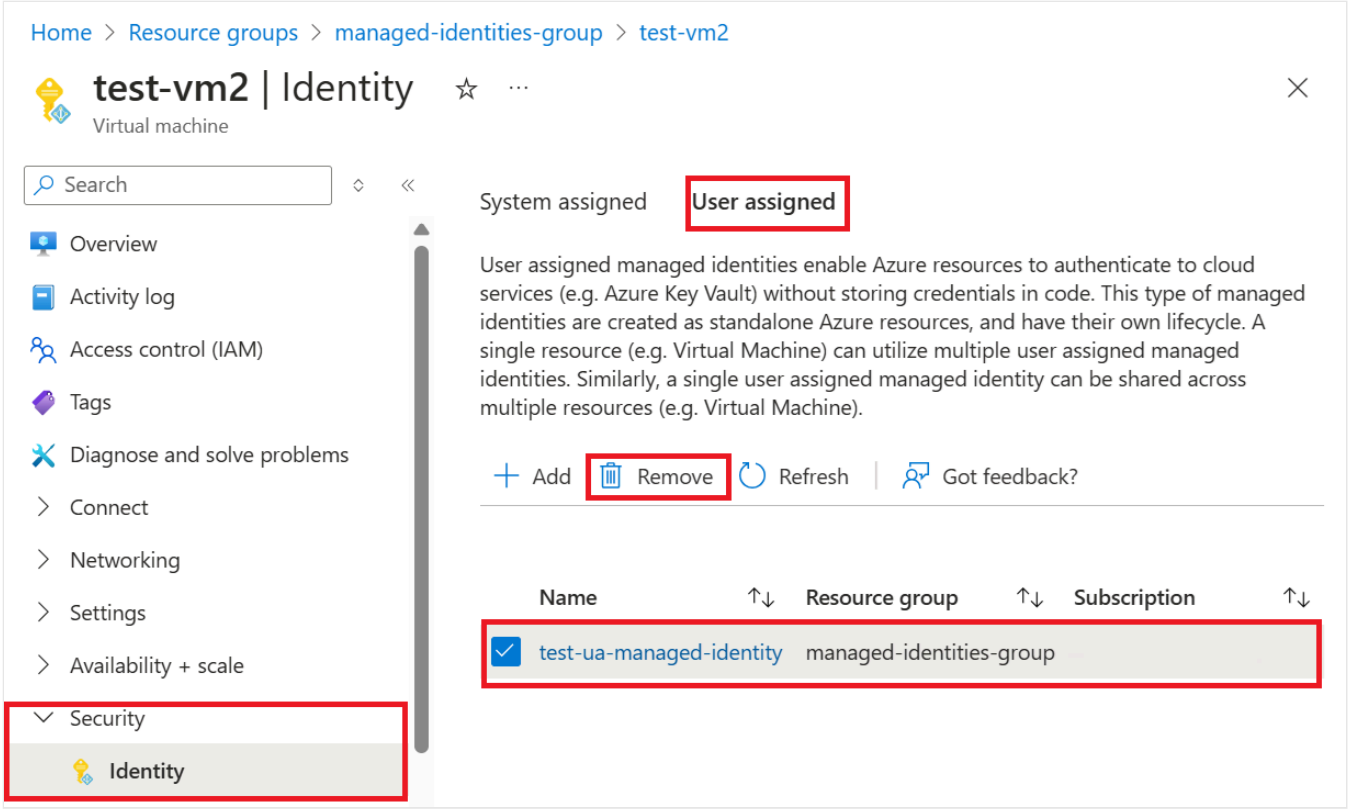


Remove a user-assigned managed identity from a VM

To remove a user-assigned identity from a VM, your account needs the Virtual Machine Contributor role assignment. No other Microsoft Entra directory role assignments are required.

Sign in to the Azure portal using an account associated with the Azure subscription that contains the VM.

Navigate to the desired VM and select **Security** > **Identity**, **User assigned**, the name of the user-assigned managed identity you want to delete and then click **Remove** (click **Yes** in the confirmation pane).



Next steps

- Using the Azure portal, give an Azure VM's managed identity access to another Azure resource.

Sign in to a Linux virtual machine in Azure by using Microsoft Entra ID and OpenSSH

06/27/2025

To improve the security of Azure Linux virtual machines (VMs) or Azure Arc-enabled Linux servers, you can integrate with Microsoft Entra authentication. You can now use Microsoft Entra ID as a core authentication platform and a certificate authority to SSH into a Linux VM by using Microsoft Entra ID and OpenSSH certificate-based authentication. This functionality allows organizations to manage access to VMs with Azure role-based access control (RBAC) and Conditional Access policies.

This article shows you how to create and configure a Linux VM and log in with Microsoft Entra ID by using OpenSSH certificate-based authentication.

There are many security benefits of using Microsoft Entra ID with OpenSSH certificate-based authentication to sign in to Linux VMs in Azure. They include:

- Use your Microsoft Entra credentials to sign in to Azure Linux VMs.
- Get SSH key-based authentication without needing to distribute SSH keys to users or provision SSH public keys on any Azure Linux VMs that you deploy. This experience is much simpler than having to worry about sprawl of stale SSH public keys that could cause unauthorized access.
- Reduce reliance on local administrator accounts, credential theft, and weak credentials.
- Help secure Linux VMs by configuring password complexity and password lifetime policies for Microsoft Entra ID.
- With RBAC, specify who can sign in to a VM as a regular user or with administrator privileges. When users join your team, you can update the Azure RBAC policy for the VM to grant access as appropriate. When employees leave your organization and their user accounts are disabled or removed from Microsoft Entra ID, they no longer have access to your resources.
- With Conditional Access, configure policies to require multifactor authentication or to require that your client device is managed (for example, compliant or Microsoft Entra hybrid joined) before you can use it SSH into Linux VMs.
- Use Azure deploy and audit policies to require Microsoft Entra login for Linux VMs and flag unapproved local accounts.

Sign in to Linux VMs with Microsoft Entra ID works for customers who use Active Directory Federation Services.

Supported Linux distributions and Azure regions

The following Linux distributions are currently supported for deployments in a supported region:

Expand table

Distribution	Version
AlmaLinux	AlmaLinux 8, AlmaLinux 9
Azure Linux (formerly known as Common Base Linux Mariner)	CBL-Mariner 2.0, Azure Linux 3.0
Debian	Debian 9, Debian 10, Debian 11, Debian 12
openSUSE	openSUSE Leap 42.3, openSUSE Leap 15.1 to 15.5, openSUSE Leap 15.6+
Oracle	Oracle Linux 8, Oracle Linux 9
RedHat Enterprise Linux (RHEL)	RHEL 7.4 to RHEL 7.9, RHEL 8.3+, RHEL 9.0+
Rocky	Rocky 8, Rocky 9
SUSE Linux Enterprise Server (SLES)	SLES 12, SLES 15.1 to 15.5, SLES 15.6+
Ubuntu	Ubuntu 16.04 to Ubuntu 24.04

> **Note**
>
> SUSE made a breaking change with version 15.6 that is incompatible with the older versions. Since the Microsoft Entra login VM extension always installs the latest package, this will not work on older SUSE versions. You can install the aadsshlogin packages from packages.microsoft.com for older SUSE versions. After adding the repo, one can manually install them with this command: `sudo zypper install aadsshlogin=1.0.027980001`.

The following Azure regions are currently supported for this feature:

- Azure Global
- Azure Government
- Microsoft Azure operated by 21Vianet

Use of the SSH extension for the Azure CLI on Azure Kubernetes Service (AKS) clusters is not supported. For more information, see Support policies for AKS.

If you choose to install and use the Azure CLI locally, it must be version 2.22.1 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install the Azure CLI.

> **Note**
>
> This functionality is also available for Azure Arc-enabled servers.

Meet requirements for login with Microsoft Entra ID using OpenSSH certificate-based authentication

To enable Microsoft Entra login through SSH certificate-based authentication for Linux VMs in Azure, be sure to meet the following network, virtual machine, and client (SSH client) requirements.

Network

VM network configuration must permit outbound access to the following endpoints over TCP port 443.

Azure Global:

- `https://packages.microsoft.com`: For package installation and upgrades.
- `http://169.254.169.254`: Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.com`: For PAM-based (pluggable authentication modules) authentication flows.
- `https://pas.windows.net`: For Azure RBAC flows.

Azure Government:

- `https://packages.microsoft.com`: For package installation and upgrades.
- `http://169.254.169.254`: Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.us`: For PAM-based authentication flows.
- `https://pasff.usgovcloudapi.net`: For Azure RBAC flows.

Microsoft Azure operated by 21Vianet:

- `https://packages.microsoft.com`: For package installation and upgrades.
- `http://169.254.169.254`: Azure Instance Metadata Service endpoint.
- `https://login.chinacloudapi.cn`: For PAM-based authentication flows.
- `https://pas.chinacloudapi.cn`: For Azure RBAC flows.

Virtual machine

Ensure that your VM is configured with the following functionality:

- System-assigned managed identity. This option is automatically selected when you use the Azure portal to create VMs and select the Microsoft Entra login option. You can also enable system-assigned managed identity on a new or existing VM by using the Azure CLI.
- `aadsshlogin` and `aadsshlogin-selinux` (as appropriate). These packages are installed with the AADSSHLoginForLinux VM extension. The extension is installed when you use the Azure portal or the Azure CLI to create VMs and enable Microsoft Entra login (**Management** tab).

Client

Ensure that your client meets the following requirements:

- SSH client support for OpenSSH-based certificates for authentication. You can use the Azure CLI (2.21.1 or later) with OpenSSH (included in Windows 10 version 1803 or later) or Azure Cloud Shell to meet this requirement.
- SSH extension for the Azure CLI. You can install this extension by using `az extension add --name ssh`. You don't need to install this extension when you're using Azure Cloud Shell, because it comes preinstalled.

  If you're using any SSH client other than the Azure CLI or Azure Cloud Shell that supports OpenSSH certificates, you'll still need to use the Azure CLI with the SSH extension to retrieve ephemeral SSH certificates and optionally a configuration file. You can then use the configuration file with your SSH client.
- TCP connectivity from the client to either the public or private IP address of the VM. (ProxyCommand or SSH forwarding to a machine with connectivity also works.)

> **Important**
>
> SSH clients based on PuTTY now supports OpenSSH certificates and can be used to log in with Microsoft Entra OpenSSH certificate-based authentication.

Enable Microsoft Entra login for a Linux VM in Azure

To use Microsoft Entra login for a Linux VM in Azure, you need to first enable the Microsoft Entra login option for your Linux VM. You then configure Azure role assignments for users who

are authorized to sign in to the VM. Finally, you use the SSH client that supports OpenSSH, such as the Azure CLI or Azure Cloud Shell, to SSH into your Linux VM.

There are two ways to enable Microsoft Entra login for your Linux VM:

- The Azure portal experience when you're creating a Linux VM
- The Azure Cloud Shell experience when you're creating a Linux VM or using an existing one

Azure portal

You can enable Microsoft Entra login for any of the supported Linux distributions by using the Azure portal.

For example, to create an Ubuntu Server 18.04 long-term support (LTS) VM in Azure with Microsoft Entra login:

1. Sign in to the Azure portal by using an account that has access to create VMs, and then select + **Create a resource**.
2. Select **Create** under **Ubuntu Server 18.04 LTS** in the **Popular** view.
3. On the **Management** tab:
   a. Select the **Login with Microsoft Entra ID** checkbox.
   b. Ensure that the **System assigned managed identity** checkbox is selected.
4. Go through the rest of the experience of creating a virtual machine. You'll have to create an administrator account with username and password or SSH public key.

Azure Cloud Shell

Azure Cloud Shell is a free, interactive shell that you can use to run the steps in this article. Common Azure tools are preinstalled and configured in Cloud Shell for you to use with your account. Just select the **Copy** button to copy the code, paste it in Cloud Shell, and then select the Enter key to run it.

There are a few ways to open Cloud Shell:

- Select **Try It** in the upper-right corner of a code block.
- Open Cloud Shell in your browser.
- Select the Cloud Shell button on the menu in the upper-right corner of the Azure portal.

If you choose to install and use the Azure CLI locally, this article requires you to use version 2.22.1 or later. Run `az --version` to find the version. If you need to install or upgrade, see Install the Azure CLI.

1. Create a resource group by running az group create.
2. Create a VM by running az vm create. Use a supported distribution in a supported region.
3. Install the Microsoft Entra login VM extension by using az vm extension set.

The following example deploys a VM and then installs the extension to enable Microsoft Entra login for a Linux VM. VM extensions are small applications that provide post-deployment configuration and automation tasks on Azure Virtual Machines. Customize the example as needed to support your testing requirements.

Azure CLI

```
az group create --name AzureADLinuxVM --location southcentralus
az vm create \
    --resource-group AzureADLinuxVM \
    --name myVM \
    --image Ubuntu2204 \
    --assign-identity \
    --admin-username azureuser \
    --generate-ssh-keys
az vm extension set \
    --publisher Microsoft.Azure.ActiveDirectory \
    --name AADSSHLoginForLinux \
    --resource-group AzureADLinuxVM \
    --vm-name myVM
```

It takes a few minutes to create the VM and supporting resources.

The AADSSHLoginForLinux extension can be installed on an existing (supported distribution) Linux VM with a running VM agent to enable Microsoft Entra authentication. If you're deploying this extension to a previously created VM, the VM must have at least 1 GB of memory allocated or the installation will fail.

The `provisioningState` value of `Succeeded` appears when the extension is successfully installed on the VM. The VM must have a running VM agent to install the extension.

Enable Microsoft Entra login for a Azure Arc-enabled Linux servers

You can find the relevant details on SSH access to Azure Arc-enabled servers

Configure role assignments for the VM

Now that you've created the VM, you need to assign one of the following Azure roles to determine who can sign in to the VM. To assign these roles, you must have the Virtual Machine

Data Access Administrator role, or any role that includes the `Microsoft.Authorization/roleAssignments/write` action such as the Role Based Access Control Administrator role. However, if you use a different role than Virtual Machine Data Access Administrator, we recommend you add a condition to reduce the permission to create role assignments.

- **Virtual Machine Administrator Login:** Users who have this role assigned can sign in to an Azure virtual machine with administrator privileges.
- **Virtual Machine User Login:** Users who have this role assigned can sign in to an Azure virtual machine with regular user privileges.

To allow a user to sign in to a VM over SSH, you must assign the Virtual Machine Administrator Login or Virtual Machine User Login role on the resource group that contains the VM and its associated virtual network, network interface, public IP address, or load balancer resources.

An Azure user who has the Owner or Contributor role assigned for a VM doesn't automatically have privileges to Microsoft Entra sign in to the VM over SSH. There's an intentional (and audited) separation between the set of people who control virtual machines and the set of people who can access virtual machines.

There are two ways to configure role assignments for a VM:

- Azure portal experience
- Azure Cloud Shell experience

> **Note**
>
> The Virtual Machine Administrator Login and Virtual Machine User Login roles use `dataActions` and can be assigned at the management group, subscription, resource group, or resource scope. We recommend that you assign the roles at the management group, subscription, or resource group level and not at the individual VM level. This practice avoids the risk of reaching the Azure role assignments limit per subscription.

Azure portal

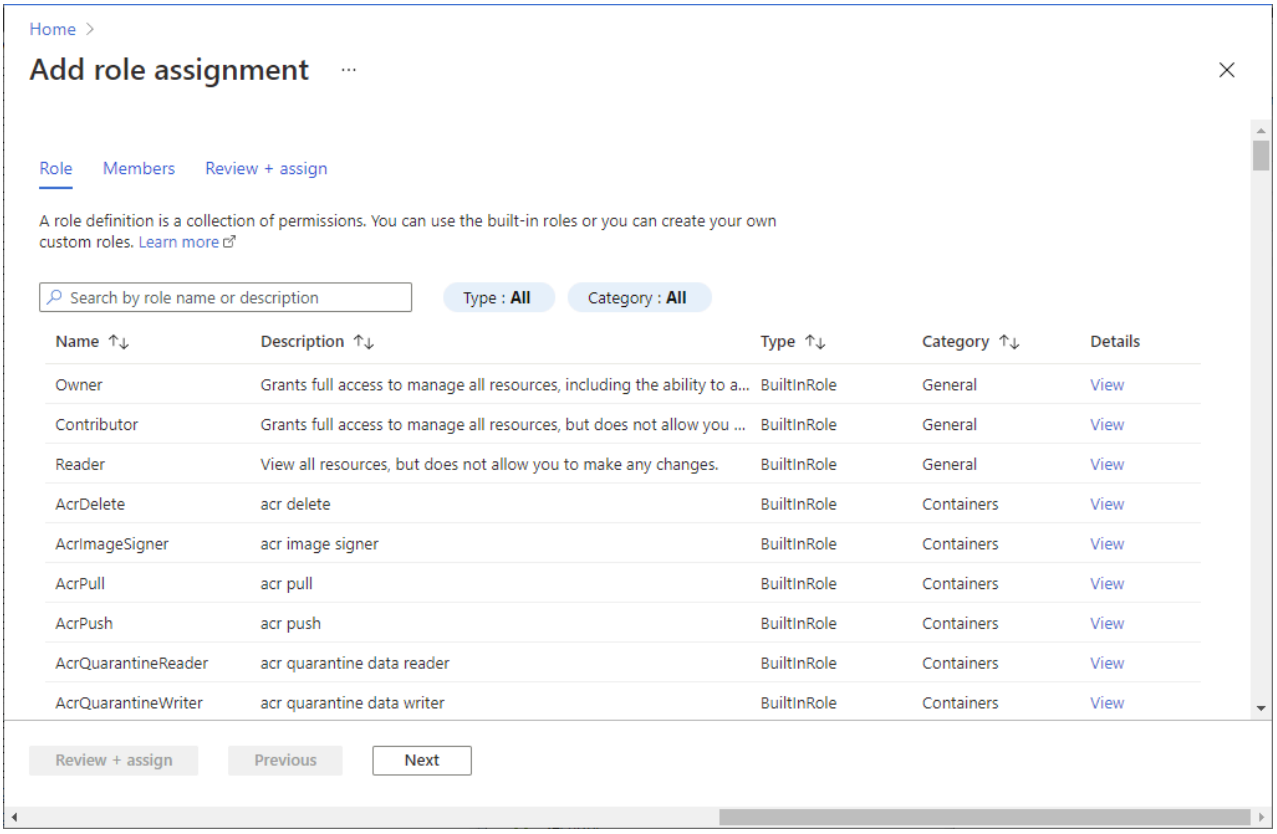
To configure role assignments for your Microsoft Entra ID-enabled Linux VMs:

1. For **Resource Group**, select the resource group that contains the VM and its associated virtual network, network interface, public IP address, or load balancer resource.
2. Select **Access control (IAM)**.
3. Select **Add** > **Add role assignment** to open the **Add role assignment** page.

4. Assign the following role. For detailed steps, see Assign Azure roles by using the Azure portal.

Expand table

Setting	Value
Role	**Virtual Machine Administrator Login** or **Virtual Machine User Login**
Assign access to	User, group, service principal, or managed identity



After a few moments, the security principal is assigned the role at the selected scope.

Azure Cloud Shell

The following example uses az role assignment create to assign the Virtual Machine Administrator Login role to the VM for your current Azure user. You obtain the username of your current Azure account by using az account show, and you set the scope to the VM created in a previous step by using az vm show.

You can also assign the scope at a resource group or subscription level. Normal Azure RBAC inheritance permissions apply.

Azure CLI

```
username=$(az account show --query user.name --output tsv)
rg=$(az group show --resource-group myResourceGroup --query id -o tsv)

az role assignment create \
    --role "Virtual Machine Administrator Login" \
    --assignee $username \
    --scope $rg
```

> **Note**
>
> If your Microsoft Entra domain and login username domain don't match, you must specify the object ID of your user account by using `--assignee-object-id`, not just the username for `--assignee`. You can obtain the object ID for your user account by using **az ad user list**.

For more information on how to use Azure RBAC to manage access to your Azure subscription resources, see Steps to assign an Azure role.

Install the SSH extension for the Azure CLI

If you're using Azure Cloud Shell, no other setup is needed because both the minimum required version of the Azure CLI and the SSH extension for the Azure CLI are already included in the Cloud Shell environment.

Run the following command to add the SSH extension for the Azure CLI:

Azure CLI

```
az extension add --name ssh
```

The minimum version required for the extension is 0.1.4. Check the installed version by using the following command:

Azure CLI

```
az extension show --name ssh
```

Enforce Conditional Access policies

You can enforce Conditional Access policies that are enabled with Microsoft Entra login, such as:

- Requiring multifactor authentication.
- Requiring a compliant or Microsoft Entra hybrid joined device for the device running the SSH client.
- Checking for risks before authorizing access to Linux VMs in Azure.

The application that appears in the Conditional Access policy is called *Azure Linux VM Sign-In*.

> **Note**
>
> Conditional Access policy enforcement that requires device compliance or Microsoft Entra hybrid join on the device that's running the SSH client works only with the Azure CLI that's running on Windows and macOS. It's not supported when you're using the Azure CLI on Linux or Azure Cloud Shell.

Missing application

If the Azure Linux VM Sign-In application is missing from Conditional Access, make sure the application isn't in the tenant:

1. Sign in to the Microsoft Entra admin center as at least a Cloud Application Administrator.
2. Browse to **Entra ID** > **Enterprise apps**.
3. Remove the filters to see all applications, and search for **Virtual Machine**. If you don't see Microsoft Azure Linux Virtual Machine Sign-In as a result, the service principal is missing from the tenant.

Log in by using a Microsoft Entra user account to SSH into the Linux VM

Log in by using the Azure CLI

Enter `az login`. This command opens a browser window, where you can sign in by using your Microsoft Entra account.

Azure CLI

```
az login
```

Then enter `az ssh vm`. The following example automatically resolves the appropriate IP address for the VM.

Azure CLI

```
az ssh vm -n myVM -g AzureADLinuxVM
```

If you're prompted, enter your Microsoft Entra login credentials at the login page, perform multifactor authentication, and/or satisfy device checks. You'll be prompted only if your the Azure CLI session doesn't already meet any required Conditional Access criteria. Close the browser window, return to the SSH prompt, and you'll be automatically connected to the VM.

You're now signed in to the Linux virtual machine with the role permissions as assigned, such as VM User or VM Administrator. If your user account is assigned the Virtual Machine Administrator Login role, you can use sudo to run commands that require root privileges.

Log in by using Azure Cloud Shell

You can use Azure Cloud Shell to connect to VMs without needing to install anything locally to your client machine. Start Cloud Shell by selecting the shell icon in the upper-right corner of the Azure portal.

Cloud Shell automatically connects to a session in the context of the signed-in user. Now run `az login` again and go through the interactive sign-in flow:

Azure CLI

```
az login
```

Then you can use the normal `az ssh vm` commands to connect by using the name and resource group or IP address of the VM:

Azure CLI

```
az ssh vm -n myVM -g AzureADLinuxVM
```

> **Note**
>
> Conditional Access policy enforcement that requires device compliance or Microsoft Entra hybrid join is not supported when you're using Azure Cloud Shell.

Log in by using the Microsoft Entra service principal to SSH into the Linux VM

The Azure CLI supports authenticating with a service principal instead of a user account. Because service principals aren't tied to any particular user, customers can use them to SSH into a VM to support any automation scenarios they might have. The service principal must have VM Administrator or VM User rights assigned. Assign permissions at the subscription or resource group level.

The following example will assign VM Administrator rights to the service principal at the resource group level. Replace the placeholders for service principal object ID, subscription ID, and resource group name.

Azure CLI

```
az role assignment create \
    --role "Virtual Machine Administrator Login" \
    --assignee-object-id <service-principal-objectid> \
    --assignee-principal-type ServicePrincipal \
    --scope "/subscriptions/<subscription-id>/resourceGroups/<resourcegroup-name>"
```

Use the following example to authenticate to the Azure CLI by using the service principal. For more information, see the article Sign in to the Azure CLI with a service principal.

Azure CLI

```
az login --service-principal -u <sp-app-id> -p <password-or-cert> --tenant
<tenant-id>
```

When authentication with a service principal is complete, use the normal the Azure CLI SSH commands to connect to the VM:

Azure CLI

```
az ssh vm -n myVM -g AzureADLinuxVM
```

Export the SSH configuration for use with SSH clients that support OpenSSH

Sign in to Azure Linux VMs with Microsoft Entra ID supports exporting the OpenSSH certificate and configuration. That means you can use any SSH clients that support OpenSSH-based certificates to sign in through Microsoft Entra ID. The following example exports the configuration for all IP addresses assigned to the VM:

Azure CLI

```
az ssh config --file ~/.ssh/config -n myVM -g AzureADLinuxVM
```

Alternatively, you can export the configuration by specifying just the IP address. Replace the IP address in the following example with the public or private IP address for your VM. (You must bring your own connectivity for private IPs.) Enter `az ssh config -h` for help with this command.

Azure CLI

```
az ssh config --file ~/.ssh/config --ip 10.11.123.456
```

You can then connect to the VM through normal OpenSSH usage. Connection can be done through any SSH client that uses OpenSSH.

Run sudo with Microsoft Entra login

After users who are assigned the VM Administrator role successfully SSH into a Linux VM, they'll be able to run sudo with no other interaction or authentication requirement. Users who are assigned the VM User role won't be able to run sudo.

Connect to VMs in virtual machine scale sets

Virtual machine scale sets are supported, but the steps are slightly different for enabling and connecting to VMs in a virtual machine scale set:

1. Create a virtual machine scale set or choose one that already exists. Enable a system-assigned managed identity for your virtual machine scale set:

   Azure CLI

   ```
   az vmss identity assign --name myVMSS --resource-group AzureADLinuxVM
   ```

2. Install the Microsoft Entra extension on your virtual machine scale set:

   Azure CLI

   ```
   az vmss extension set --publisher Microsoft.Azure.ActiveDirectory --name
   AADSSHLoginForLinux --resource-group AzureADLinuxVM --vmss-name myVMSS
   ```

Virtual machine scale sets usually don't have public IP addresses. You must have connectivity to them from another machine that can reach their Azure virtual network. This example shows

how to use the private IP of a VM in a virtual machine scale set to connect from a machine in the same virtual network:

Azure CLI

```
az ssh vm --ip 10.11.123.456
```

> **Note**
>
> You can't automatically determine the virtual machine scale set VM's IP addresses by using the `--resource-group` and `--name` switches.

Migrate from the previous (preview) version

If you're using the previous version of Microsoft Entra login for Linux that was based on device code flow, complete the following steps by using the Azure CLI:

1. Uninstall the AADLoginForLinux extension on the VM:

   Azure CLI

   ```
   az vm extension delete -g MyResourceGroup --vm-name MyVm -n AADLoginForLinux
   ```

   > **Note**
   >
   > Uninstallation of the extension can fail if there are any Microsoft Entra users currently logged in on the VM. Make sure all users are logged out first.

2. Enable system-assigned managed identity on your VM:

   Azure CLI

   ```
   az vm identity assign -g myResourceGroup -n myVm
   ```

3. Install the AADSSHLoginForLinux extension on the VM:

   Azure CLI

   ```
   az vm extension set \
       --publisher Microsoft.Azure.ActiveDirectory \
       --name AADSSHLoginForLinux \
   ```

```
    --resource-group myResourceGroup \
    --vm-name myVM
```

Use Azure Policy to meet standards and assess compliance

Use Azure Policy to:

- Ensure that Microsoft Entra login is enabled for your new and existing Linux virtual machines.
- Assess compliance of your environment at scale on a compliance dashboard.

With this capability, you can use many levels of enforcement. You can flag new and existing Linux VMs within your environment that don't have Microsoft Entra login enabled. You can also use Azure Policy to deploy the Microsoft Entra extension on new Linux VMs that don't have Microsoft Entra login enabled, as well as remediate existing Linux VMs to the same standard.

In addition to these capabilities, you can use Azure Policy to detect and flag Linux VMs that have unapproved local accounts created on their machines. To learn more, review Azure Policy.

Troubleshoot sign-in issues

Use the following sections to correct common errors that can happen when you try to SSH with Microsoft Entra credentials.

Couldn't retrieve token from local cache

If you get a message that says the token couldn't be retrieved from the local cache, you must run `az login` again and go through an interactive sign-in flow. Review the section about logging in by using Azure Cloud Shell.

Access denied: Azure role not assigned

If you see an "Azure role not assigned" error on your SSH prompt, verify that you've configured Azure RBAC policies for the VM that grants the user either the Virtual Machine Administrator Login role or the Virtual Machine User Login role. If you're having problems with Azure role assignments, see the article Troubleshoot Azure RBAC.

Problems deleting the old (AADLoginForLinux) extension

If the uninstallation scripts fail, the extension might get stuck in a transitioning state. When this happens, the extension can leave packages that it's supposed to uninstall during its removal. In such cases, it's better to manually uninstall the old packages and then try to run the `az vm extension delete` command.

To uninstall old packages:

1. Log in as a local user with admin privileges.
2. Make sure there are no logged-in Microsoft Entra users. Call the `who -u` command to see who is logged in. Then use `sudo kill <pid>` for all session processes that the previous command reported.
3. Run `sudo apt remove --purge aadlogin` (Ubuntu/Debian), `sudo yum remove aadlogin` (RHEL), or `sudo zypper remove aadlogin` (openSUSE or SLES).
4. If the command fails, try the low-level tools with scripts disabled:
   a. For Ubuntu/Debian, run `sudo dpkg --purge aadlogin`. If it's still failing because of the script, delete the `/var/lib/dpkg/info/aadlogin.prerm` file and try again.
   b. For everything else, run `rpm -e --noscripts aadogin`.
5. Repeat steps 3-4 for package `aadlogin-selinux`.

Extension installation errors

Installation of the AADSSHLoginForLinux VM extension to existing computers might fail with one of the following known error codes.

Non-zero exit code 22

If you get exit code 22, the status of the AADSSHLoginForLinux VM extension shows as **Transitioning** in the portal.

This failure happens because a system-assigned managed identity is required.

The solution is to:

1. Uninstall the failed extension.
2. Enable a system-assigned managed identity on the Azure VM.
3. Run the extension installation command again.

Non-zero exit code 23

If you get exit code 23, the status of the AADSSHLoginForLinux VM extension shows as **Transitioning** in the portal.

This failure happens when the older AADLoginForLinux VM extension is still installed.

The solution is to uninstall the older AADLoginForLinux VM extension from the VM. The status of the new AADSSHLoginForLinux VM extension will then change to **Provisioning succeeded** in the portal.

Installation failures when using an HTTP proxy

The extension needs an HTTP connection to install packages and check for the existence of a system identity. It runs in the context of `walinuxagent.service` and requires a change to let the agent know about the proxy settings. Open `/lib/systemd/system/walinuxagent.service` file on the target machine and add the following line after `[Service]`:

```
[Service]
Environment="http_proxy=http://proxy.example.com:80/"
Environment="https_proxy=http://proxy.example.com:80/"
Environment="no_proxy=169.254.169.254"
```

Restart the agent (`sudo systemctl restart walinuxagent`). Now try again.

The az ssh vm command fails with KeyError access_token

If the `az ssh vm` command fails, you're using an outdated version of the Azure CLI client.

The solution is to upgrade the Azure CLI client to version 2.21.0 or later.

SSH connection is closed

After a user successfully signs in by using `az login`, connection to the VM through `az ssh vm -ip <address>` or `az ssh vm --name <vm_name> -g <resource_group>` might fail with "Connection closed by <ip_address> port 22."

One cause for this error is that the user isn't assigned to the Virtual Machine Administrator Login or Virtual Machine User Login role within the scope of this VM. In that case, the solution is to add the user to one of those Azure RBAC roles within the scope of this VM.

This error can also happen if the user is in a required Azure RBAC role, but the system-assigned managed identity has been disabled on the VM. In that case, perform these actions:

1. Enable the system-assigned managed identity on the VM.

2. Allow several minutes to pass before the user tries to connect by using `az ssh vm --ip <ip_address>`.

Connection problems with virtual machine scale sets

VM connections with virtual machine scale sets can fail if the scale set instances are running an old model.

Upgrading scale set instances to the latest model might resolve the problem, especially if an upgrade hasn't been done since the Microsoft Entra Login extension was installed. Upgrading an instance applies a standard scale set configuration to the individual instance.

AllowGroups or DenyGroups statements in sshd_config cause the first sign in to fail for Microsoft Entra users

If *sshd_config* contains either `AllowGroups` or `DenyGroups` statements, the first login fails for Microsoft Entra users. If the statement was added after users have already had a successful login, they can log in.

One solution is to remove `AllowGroups` and `DenyGroups` statements from *sshd_config*.

Another solution is to move `AllowGroups` and `DenyGroups` to a `match user` section in *sshd_config*. Make sure the match template excludes Microsoft Entra users.

Getting Permission Denied when trying to connect from Azure Shell to Linux Red Hat/Oracle 7.X VM.

The OpenSSH server version in the target VM 7.4 is too old. Version incompatible with OpenSSH client version 8.8. Refer to RSA SHA256 certificates no longer work for more information.

Workaround:

- Adding option `"PubkeyAcceptedKeyTypes= +ssh-rsa-cert-v01@openssh.com"` in the `az ssh vm` command.

Azure CLI

```
az ssh vm -n myVM -g MyResourceGroup -- -A -o "PubkeyAcceptedKeyTypes= +ssh-rsa-cert-v01@openssh.com"
```

- Adding the option `"PubkeyAcceptedKeyTypes= +ssh-rsa-cert-v01@openssh.com"` in the `/home/<user>/.ssh/config file`.

Add the `"PubkeyAcceptedKeyTypes +ssh-rsa-cert-v01@openssh.com"` into the client config file.

config

```
Host *
PubkeyAcceptedKeyTypes +ssh-rsa-cert-v01@openssh.com
```

Next steps

- What is a device identity?
- Common Conditional Access policies

Sign in to Windows virtual machine in Azure using Microsoft Entra ID and Azure Roles Based Access Control

Organizations can improve the security of Windows Server virtual machines in Azure by integrating with Microsoft Entra authentication. You can now use Microsoft Entra ID as a core authentication platform to Remote Desktop Protocol (RDP) into supported versions of Windows Server. You can then centrally control and enforce Azure role-based access control (RBAC) and Conditional Access policies that allow or deny access to the virtual machines.

This article shows you how to create and configure a Windows Server virtual machine and sign in by using Microsoft Entra ID-based authentication.

There are many security benefits of using Microsoft Entra ID-based authentication to sign in to Windows Server virtual machines in Azure. They include:

- Use Microsoft Entra authentication including passwordless to sign in to Windows Server virtual machines. Reduce reliance on local administrator accounts.
- Use Password complexity and password lifetime policies that you configure for Microsoft Entra ID also help secure Windows Server virtual machines.
- Use Azure role-based access control:
  - Specify who can sign in as a regular user or with administrator privileges.
  - When users join or leave your team, you can update Azure role-based access control policy to grant access as appropriate.
  - When employees leave your organization and their user accounts are disabled or removed from Microsoft Entra ID, they no longer have access to your resources.
- Use Conditional Access policy "phishing resistant MFA" and other signals such as user sign-in risk.
- Use Azure Policy to deploy and audit policies to require Microsoft Entra sign in for Windows Server virtual machines and to flag the use of unapproved local accounts on the virtual machines.
- Use Intune to automate and scale Microsoft Entra join with mobile device management (MDM) autoenrollment of Azure Windows VMs that are part of your virtual desktop infrastructure (VDI) deployments. MDM autoenrollment requires Microsoft Entra ID P1 licenses.

MDM autoenrollment requires Microsoft Entra ID P1 licenses. Windows Server VMs don't support MDM enrollment.

> **Important**
>
> After you enable this capability, your Azure virtual machine will be Microsoft Entra joined. You can't join them to another domain, like on-premises Active Directory or Microsoft Entra Domain Services. If you need to do so, disconnect the device from Microsoft Entra by uninstalling the extension. In addition, if you deploy a supported golden image, you can enable Microsoft Entra ID authentication by installing the extension. Conditional Access isn't supported with Windows Server with Microsoft Entra join extension in Azure Windows virtual machines.

Requirements

Supported Azure regions and Windows distributions

This feature currently supports the following Windows Server distributions:

- Windows 11 24H2 or later installed.
- Windows Server 2025 or later installed with Desktop Experience.

This feature is now available in the following Azure clouds:

- Azure Global
- Azure Government
- Microsoft Azure operated by 21Vianet

> **Note**
>
> CIS hardened images support Microsoft Entra ID authentication for Microsoft Windows Enterprise and Microsoft Windows Server offerings. For more information, see: CIS Hardened Images on Microsoft Windows Enterprise.

Network requirements

To enable Microsoft Entra authentication to virtual machines in Azure, you need to ensure that your network configuration permits outbound access to the following endpoints over TCP port

443.

Azure Global:

- `https://enterpriseregistration.windows.net`: Device registration.
- `http://169.254.169.254`: Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.com`: Authentication flows.
- `https://pas.windows.net`: Azure role-based access control flows.

Azure Government:

- `https://enterpriseregistration.microsoftonline.us`: Device registration.
- `http://169.254.169.254`: Azure Instance Metadata Service endpoint.
- `https://login.microsoftonline.us`: Authentication flows.
- `https://pasff.usgovcloudapi.net`: Azure role-based access control flows.

Microsoft Azure operated by 21Vianet:

- `https://enterpriseregistration.partner.microsoftonline.cn`: Device registration.
- `http://169.254.169.254`: Azure Instance Metadata Service endpoint.
- `https://login.chinacloudapi.cn`: Authentication flows.
- `https://pas.chinacloudapi.cn`: Azure role-based access control flows.

Authentication requirements

- **User account type**: Only standard Microsoft Entra user accounts from the same tenant as the azure windows virtual machine are supported. Guest accounts (B2B users) cannot be used for authentication.
- **Managed identities**: You must enable system-assigned managed identity on your Azure virtual machine before installing the Microsoft Entra sign in virtual machine extension. Managed Identities are stored in a single Microsoft Entra tenant and currently don't support cross directory scenarios.
- **Role assignments**: Users must be assigned either the **Virtual Machine Administrator Login** or **Virtual Machine User Login** role to sign in to the VM. Having the Owner or

Contributor role alone doesn't grant sign-in privileges.

- **Virtual Machine Administrator Login:** Users who have this role assigned can sign in to an Azure virtual machine with administrator privileges.
- **Virtual Machine User Login:** Users who have this role assigned can sign in to an Azure virtual machine with regular user privileges.
- **Authentication methods**:
  - Passwordless authentication is recommended and supported via Microsoft Entra credentials
  - Password-based authentication is supported with proper role assignments
  - Windows Hello for Business is supported using the certificate trust model only (not key trust model)
  - Local administrator accounts created manually by adding users to local groups aren't supported

Enable Microsoft Entra sign in for a Windows virtual machine in Azure

To use Microsoft Entra sign in for a Windows virtual machine, you must:

1. Enable the Microsoft Entra sign in extension for the device.
2. Configure Azure role assignments for users.

Enable Microsoft Entra sign in extension

- Azure virtual machine running Windows

You must enable system-assigned managed identity on your Azure virtual machine before you install the Microsoft Entra sign in virtual machine extension. Managed Identities are stored in a single Microsoft Entra tenant and currently don't support cross directory scenarios.

The following sample demonstrates Azure templates for Azure Virtual Machine extensions.

JSON

```
{
  "$schema": "http://schema.management.azure.com/schemas/2015-01-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {
```

```
    "vmName": {
      "type": "string"
    },
    "location": {
      "type": "string"
    }
  },
  "resources": [
    {
      "name": "[concat(parameters('vmName'),'/AADLogin')]",
      "type": "Microsoft.Compute/virtualMachines/extensions",
      "location": "[parameters('location')]",
      "apiVersion": "2015-06-15",
      "properties": {
        "publisher": "Microsoft.Azure.ActiveDirectory",
        "type": "AADLoginForWindows",
        "typeHandlerVersion": "1.0",
        "autoUpgradeMinorVersion": true
      }
    }
  ]
}
```

Configure role assignments

To assign user roles, you must have the Virtual Machine Data Access Administrator role, or any role that includes the `Microsoft.Authorization/roleAssignments/write` action such as the Role Based Access Control Administrator role. However, if you use a different role than Virtual Machine Data Access Administrator, we recommend you add a condition to reduce the permission to create role assignments.

- **Virtual Machine Administrator Login:** Users who have this role assigned can sign in to an Azure virtual machine with administrator privileges.
- **Virtual Machine User Login:** Users who have this role assigned can sign in to an Azure virtual machine with regular user privileges.

> ⓘ Note
>
> Manually elevating a user to become a local administrator on the device by adding the user to a member of the local administrators' group or by running `net localgroup administrators /add "AzureAD\UserUpn"` command isn't supported. You need to use roles in Azure to authorize sign in.

> ⓘ Note

An Azure user who has the Owner or Contributor role assigned doesn't automatically have privileges to sign in to devices. The reason is to provide audited separation between the set of people who control virtual machines and the set of people who can access virtual machines.

The following documentation provides step-by-step details to add user accounts to role assignments in Azure:

- Assign Azure roles by using the Azure portal
- Assign Azure roles by using the Azure CLI
- Assign Azure roles by using Azure PowerShell

Sign in by using Microsoft Entra credentials to a Windows VM

You can sign in over RDP using one of two methods:

- Passwordless using any of the supported Microsoft Entra credentials (recommended)
- Password/passwordless using Windows Hello for Business deployed using certificate trust model

Sign in using passwordless authentication with Microsoft Entra ID

To use passwordless authentication for your Windows Server VMs in Azure, the session host (VM) must be running:

- Windows 11 with 2022-10 Cumulative Updates for Windows 11 (KB5018418) or later installed.
- Windows 10, version 20H2 or later with 2022-10 Cumulative Updates for Windows 10 (KB5018410) or later installed.
- Windows Server 2022 with 2022-10 Cumulative Update for Microsoft server operating system (KB5018421) or later installed.
- Windows Server 2025 or later installed.

Note

When using the **web account to sign in to the remote computer** option, there's no requirement for the local device to be joined to a domain or Microsoft Entra ID.

To connect to the remote computer:

- Launch **Remote Desktop Connection** from Windows Search, or by running `mstsc.exe`.
- Select **Use a web account to sign in to the remote computer** option in the **Advanced** tab. This option is equivalent to the `enablerdsaadauth` RDP property. For more information, see Supported RDP properties with Remote Desktop Services.
- Specify the name of the remote computer and select **Connect**.

> **Important**
>
> IP address can't be used with **Use a web account to sign in to the remote computer** option. The name must match the hostname of the remote device in Microsoft Entra ID and be network addressable, resolving to the IP address of the remote device.

- When prompted for credentials, specify your user name in `user@domain.com` format.
- You're then prompted to allow the remote desktop connection when connecting to a new PC. Microsoft Entra remembers up to 15 hosts for 30 days before prompting again. If you see this dialogue, select **Yes** to connect.

> **Important**
>
> If your organization is using Microsoft Entra Conditional Access, your device must satisfy the Conditional Access requirements to allow connection to the remote computer. Conditional Access policies might be applied to the application **Microsoft Remote Desktop (a4a365df-50f1-4397-bc59-1a1564b8bb9c)** for controlled access.

> **Note**
>
> The Windows lock screen in the remote session doesn't support Microsoft Entra authentication tokens or passwordless authentication methods like FIDO keys. The lack of support for these authentication methods means that users can't unlock their screens in a remote session. When you try to lock a remote session, either through user action or system policy, the session is instead disconnected and the service sends a message to the user. Disconnecting the session also ensures that when the connection is relaunched after

a period of inactivity, Microsoft Entra ID reevaluates the applicable Conditional Access policies.

Sign in using password/passwordless authentication with Microsoft Entra ID

Both Password-based authentication, and Passwordless authentication are supported to sign in to Windows virtual machines.

> **Important**
>
> Remote connection to VMs that are joined to Microsoft Entra ID is allowed only from Windows 10 or later PCs that are either Microsoft Entra registered(minimum required build is 20H1) or Microsoft Entra joined or Microsoft Entra hybrid joined to the *same* directory as the VM. Additionally, to RDP by using Microsoft Entra credentials, users must belong to one of the two Azure roles, Virtual Machine Administrator Login or Virtual Machine User Login.
>
> If you're using a Microsoft Entra registered windows 10 or later PC, you must enter credentials in the `AzureAD\UPN` format (for example, `AzureAD\john@contoso.com`). At this time, you can use Azure Bastion to sign in with Microsoft Entra authentication via the Azure CLI and the native RDP client mstsc.

To sign in to your Windows Server 2019 virtual machine by using Microsoft Entra ID:

1. Go to the overview page of the virtual machine enabled with Microsoft Entra sign in.
2. Select **Connect** to open the **Connect to virtual machine** pane.
3. Select **Download RDP File**.
4. Select **Open** to open the Remote Desktop Connection client.
5. Select **Connect** to open the Windows sign in dialog.
6. Sign in by using your Microsoft Entra credentials.

You're now signed in to the Windows Server 2019 Azure virtual machine with the role permissions as assigned, such as VM User or VM Administrator.

> **Note**

You can save the `.RDP` file locally on your computer to start future remote desktop connections to your virtual machine, instead of going to the virtual machine overview page in the Azure portal and using the connect option.

Enforce Conditional Access policies

You can enforce Conditional Access policies, such as "phishing resistant MFA" or user sign-in risk check, before users can access Windows Server virtual machines in Azure. To apply a Conditional Access policy, you must select the **Microsoft Azure Windows Virtual Machine Sign-in** app from the cloud apps or actions assignment option.

Conditional Access policies that restrict sign in using device configuration rules aren't supported when connecting from a Windows Server device. For a guide on setting conditional access policies, see: Tutorial: Secure user sign-in events with Microsoft Entra multifactor authentication.

> **Note**
>
> If you require MFA as a control, then you must supply an MFA claim as part of the client that initiates the RDP session to the target Windows Server virtual machine. The Remote Desktop application supports Conditional Access policies, however if you're using web sign in, you must use a Windows Hello for Business PIN or biometric authentication. Support for biometric authentication was added to the RDP client in Windows 10 version 1809. Remote desktop using Windows Hello for Business authentication is available only for deployments that use a certificate trust model and isn't available for a key trust model.

Use Azure Policy to meet standards and assess compliance

Use Azure Policy to:

- Ensure that Microsoft Entra sign in is enabled for your new and existing Windows Server virtual machines.
- Assess compliance of your environment at scale on a compliance dashboard.

With this capability, you can use many levels of enforcement. You can flag new and existing Windows Server virtual machines within your environment that don't have Microsoft Entra sign

in enabled. You can also use Azure Policy to deploy the Microsoft Entra extension to Windows virtual machines in Azure.

In addition to these capabilities, you can use Azure Policy to detect and flag Windows machines that have unapproved local accounts created on their devices. To learn more, review Azure Policy.

Troubleshoot deployment problems

The AADLoginForWindows extension must be installed successfully for the device to complete the Microsoft Entra join process. If the extension fails to be installed correctly, perform the following steps:

1. Connect to the device and examine the *CommandExecution.log* file under *C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.ActiveDirectory.AADLoginForWindows\1.0.0.1*.

   If the extension restarts after the initial failure, the log with the deployment error will be saved as *CommandExecution_YYYYMMDDHHMMSSSSS.log*.

2. Open a PowerShell window on the device. Verify that the following queries against the Azure Instance Metadata Service endpoint running on the host return the expected output:

   For Azure virtual machines:

Expand table

Command to run	Expected output
`curl.exe -H Metadata:true "http://169.254.169.254/metadata/instance?api-version=2017-08-01"`	Correct information about the Azure virtual machine
`curl.exe -H Metadata:true "http://169.254.169.254/metadata/identity/info?api-version=2018-02-01"`	Valid tenant ID associated with the Azure subscription
`curl.exe -H Metadata:true "http://169.254.169.254/metadata/identity/oauth2/token?resource=urn:ms-drs:enterpriseregistration.windows.net&api-version=2018-02-01"`	Valid access token issued by Microsoft Entra ID for the managed identity that is assigned to this virtual machine

3. Ensure that the required endpoints are accessible from the device via PowerShell:

   - `curl.exe https://login.microsoftonline.com/ -D -`
   - `curl.exe https://login.microsoftonline.com/<TenantID>/ -D -`
   - `curl.exe https://enterpriseregistration.windows.net/ -D -`
   - `curl.exe https://device.login.microsoftonline.com/ -D -`
   - `curl.exe https://pas.windows.net/ -D -`

   Replace `<TenantID>` with the Microsoft Entra tenant ID associated with the Azure subscription. `login.microsoftonline.com/<TenantID>`, `enterpriseregistration.windows.net`, and `pas.windows.net` should return 404 Not Found, which is expected behavior.

4. View the device state by running `dsregcmd /status`. The goal is for the device state to show as `AzureAdJoined : YES`.

   Microsoft Entra join activity is captured in Event Viewer under the *User Device Registration\Admin* log at *Event Viewer (local)\Applications* and *Services Logs\Microsoft\Windows\User Device Registration\Admin*.

If the AADLoginForWindows extension fails with an error code, you can perform the following steps.

Device name already exists

If a device object with the same displayName as the hostname of the Azure virtual machine exists, the device fails to join Microsoft Entra with a hostname duplication error. Avoid duplication by modifying the hostname.

Terminal error code 1007 and exit code -2145648574

Terminal error code 1007 and exit code -2145648574 translate to `DSREG_E_MSI_TENANTID_UNAVAILABLE`. The extension can't query the Microsoft Entra tenant information.

Connect to the device as a local administrator and verify that the endpoint returns a valid tenant ID from Azure Instance Metadata Service. Run the following command from an elevated PowerShell window on the device:

```
curl -H Metadata:true http://169.254.169.254/metadata/identity/info?api-version=2018-02-01
```

This problem can also happen when the admin attempts to install the AADLoginForWindows extension, but the device doesn't have a system-assigned managed identity. In that case, go to the **Identity** pane of the device. On the **System assigned** tab, verify that the **Status** toggle is set to **On**.

Exit code -2145648607

Exit code -2145648607 translates to `DSREG_AUTOJOIN_DISC_FAILED`. The extension can't reach the `https://enterpriseregistration.windows.net` endpoint.

1. Verify that the required endpoints are accessible from the device via PowerShell:

   - `curl https://login.microsoftonline.com/ -D -`
   - `curl https://login.microsoftonline.com/<TenantID>/ -D -`
   - `curl https://enterpriseregistration.windows.net/ -D -`
   - `curl https://device.login.microsoftonline.com/ -D -`
   - `curl https://pas.windows.net/ -D -`

   Replace `<TenantID>` with the Microsoft Entra tenant ID of the Azure subscription. If you need to find the tenant ID, you can hover over your account name or select **Entra ID** > **Overview** > **Properties** > **Tenant ID**.

   Attempts to connect to `enterpriseregistration.windows.net` might return 404 Not Found, which is expected behavior. Attempts to connect to `pas.windows.net` might prompt for PIN credentials or might return 404 Not Found. (You don't need to enter the PIN.) Either one is sufficient to verify that the URL is reachable.

2. If any of the commands fails with "Couldn't resolve host `<URL>`," try running this command to determine which DNS server Windows is using:

   `nslookup <URL>`

   Replace `<URL>` with the fully qualified domain names that the endpoints use, such as `login.microsoftonline.com`.

3. See whether specifying a public DNS server allows the command to succeed:

   `nslookup <URL> 208.67.222.222`

4. If necessary, change the DNS server assigned to the network security group that the device belongs to.

Exit code 51

Exit code 51 translates to "This extension isn't supported on this operating system."

The AADLoginForWindows extension is intended to be installed only on Azure virtual machines with Windows Server 2022 or Windows 10 1809 or later. Ensure that your version of Windows Server is supported. If it isn't supported, uninstall the extension.

Troubleshoot sign-in problems

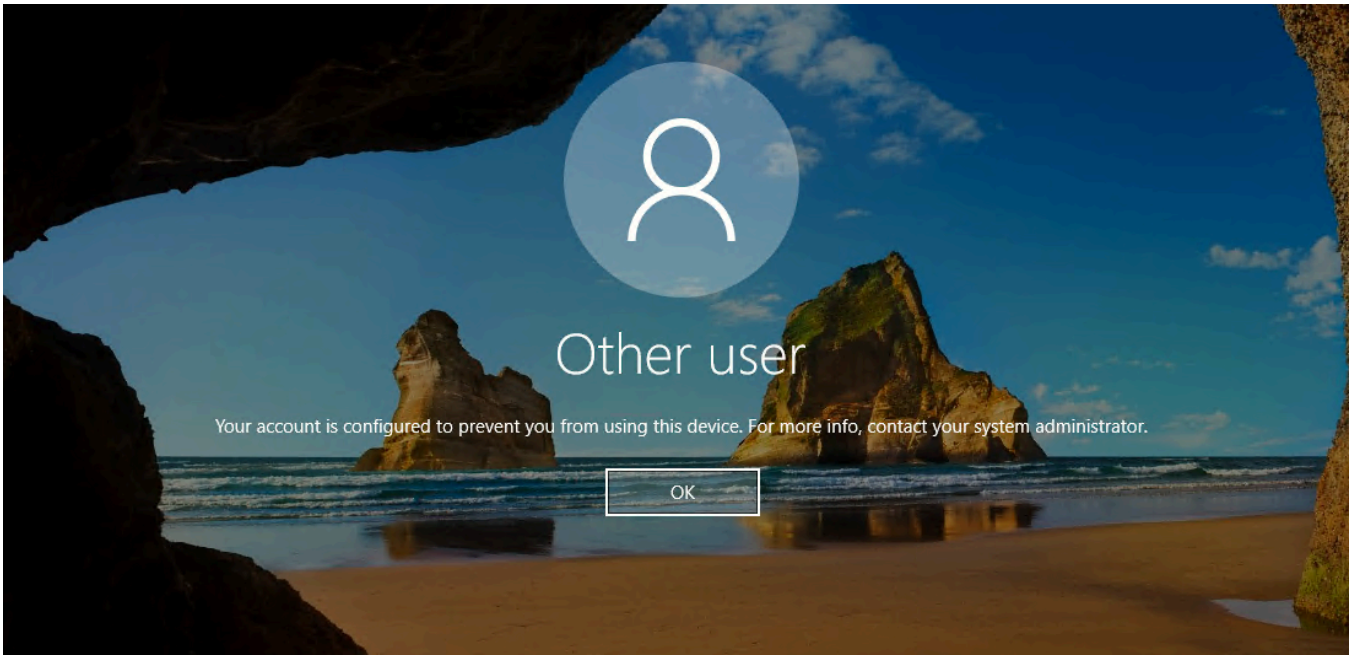
Use the following information to correct sign-in problems.

You can view the device and single sign-on (SSO) state by running `dsregcmd /status`. The goal is for the device state to show as `AzureAdJoined : YES` and for the SSO state to show `AzureAdPrt : YES`.

RDP sign-in via Microsoft Entra accounts is captured in Event Viewer under the *Applications and Services Logs\Microsoft\Windows\AAD\Operational* event logs.

Azure role not assigned

You might get the following error message when you initiate a remote desktop connection to your device: "Your account is configured to prevent you from using this device. For more info, contact your system administrator."

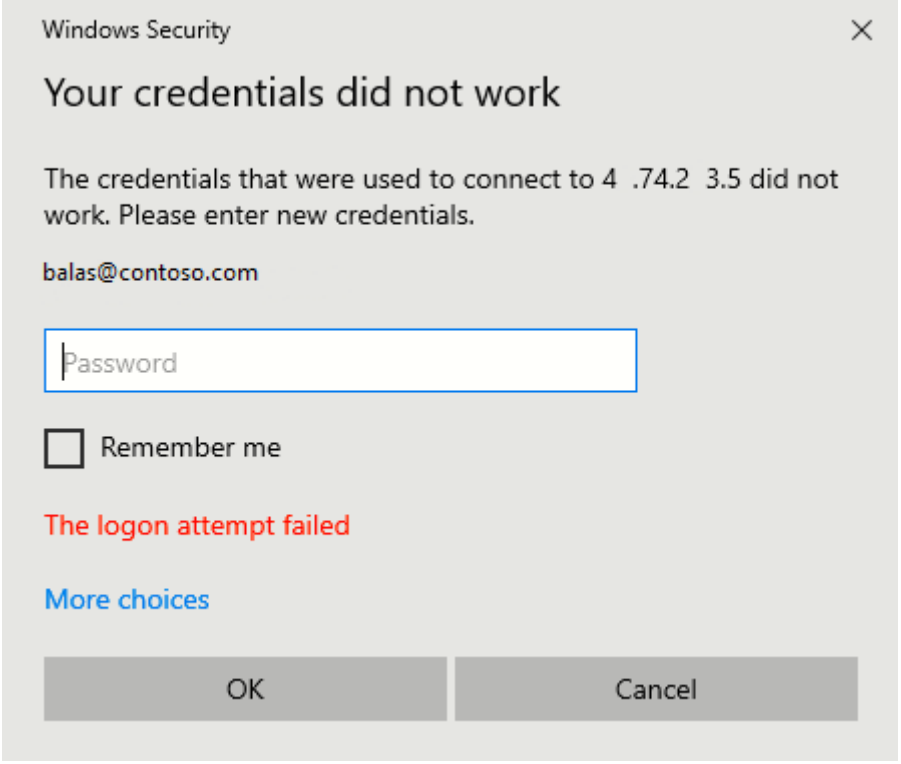


Verify the Azure role-based access control policies that grant the user the Virtual Machine Administrator Login or Virtual Machine User Login role.

If you're having problems with Azure role assignments, see Troubleshoot Azure role-based access control.

Unauthorized client or password change required

You might get the following error message when you initiate a remote desktop connection to your device: "Your credentials didn't work."



Try these solutions:

- The Windows 10 or later PC that you're using to initiate the remote desktop connection must be Microsoft Entra joined, or Microsoft Entra hybrid joined to the same Microsoft Entra directory. For more information about device identity, see the article What is a device identity?.

  Windows 10 Build 20H1 added support for a Microsoft Entra registered PC to initiate an RDP connection to your virtual machine. When you're using a client device that's Microsoft Entra registered (not Microsoft Entra joined or Microsoft Entra hybrid joined) as the RDP client to initiate connections to your virtual machine, you must enter credentials in the format `AzureAD\UPN` (for example, `AzureAD\john@contoso.com`).

  Verify that the AADLoginForWindows extension wasn't uninstalled after the Microsoft Entra join finished.

Also, make sure that the security policy **Network security: Allow PKU2U authentication requests to this computer to use online identities** is enabled on both the server *and* the client.

- Verify that the user doesn't have a temporary password. Temporary passwords can't be used to sign in to a remote desktop connection.

  Sign in with the user account in a web browser. For instance, sign in to the Azure portal in a private browsing window. If you're prompted to change the password, set a new password. Then try connecting again.

AADSTS293004: The target-device identifier in the request xxx wasn't found in the tenant xxx

Cause:

The computer name entered in mstsc doesn't match with any one of the "hostnames" attributes for target AADJ device. For example, AADJ device host name is the short name like device_1, but the computer name entered in mstsc is the FQDN like device_1.contoso.com.

Try these solutions:

There are multiple ways to resolve the issue:

1. Modify the HOSTS entry on client machine, add an A DNS record that points the correct device name (confirm from AAD Device record) to the IP of target machine. Use that device name in mstsc.
2. Check if the target machine is managed and if the hostname is set through Group Policy or MDM via the DNS Client PrimaryDnsSuffix value ADMX_DnsClient Policy CSP | Microsoft Learn. If this is set and is incorrect, it needs to be removed or set correctly.
3. When customer requires to use FQDN to connect but AAD Device name is a short name, login to the target machine via local admin, add a "**Primary DNS Suffix**" for their domain suffix. Detailed instructions:

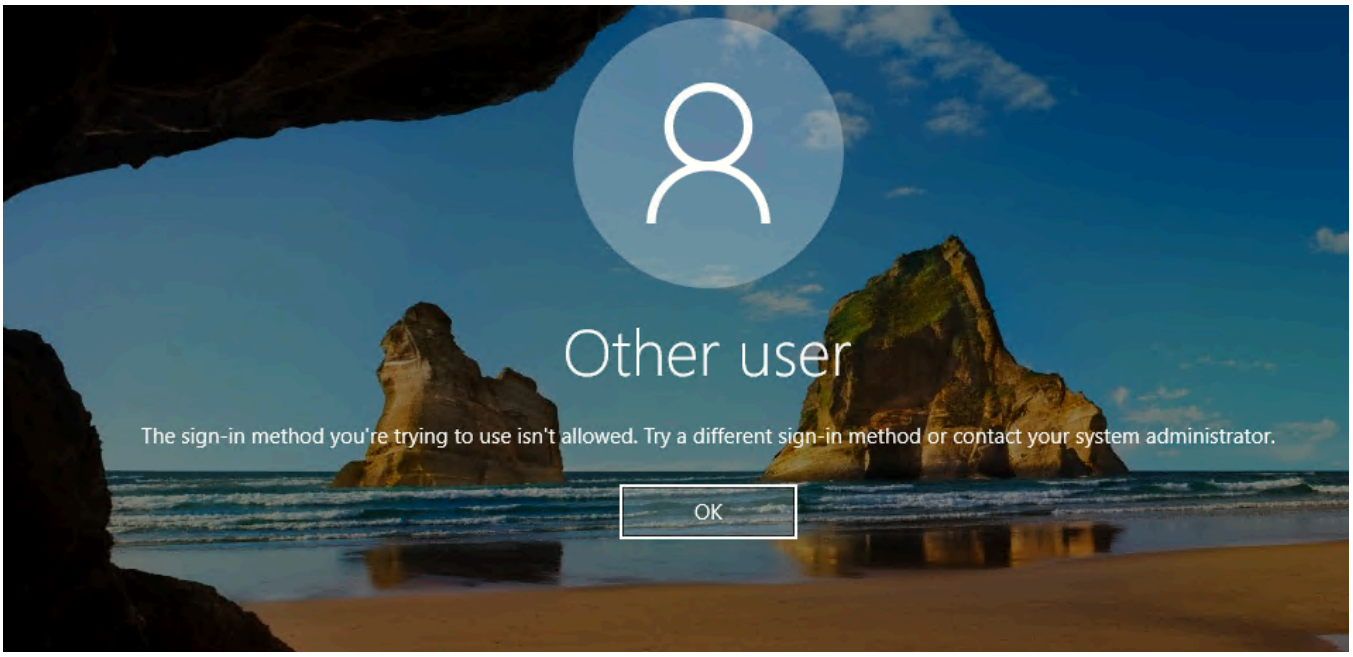
- Navigate to **Advanced System Settings/System Properties** ->** Computer Name** tab -> select the "**Change**" button to rename the computer -> select "**More**..." under the existing computer name -> Type in your domain name and select **OK** -> Save and reboot.
- Once it's done, we can RDP with FQDN directly and no need to modify the HOSTS entry.

> ⓘ **Note**

In such case, when Primary DNS Suffix is added, the Device-Sync scheduled task is triggered when adding the FQDN into AAD device "hostnames" attributes. This is why it resolves the issue.

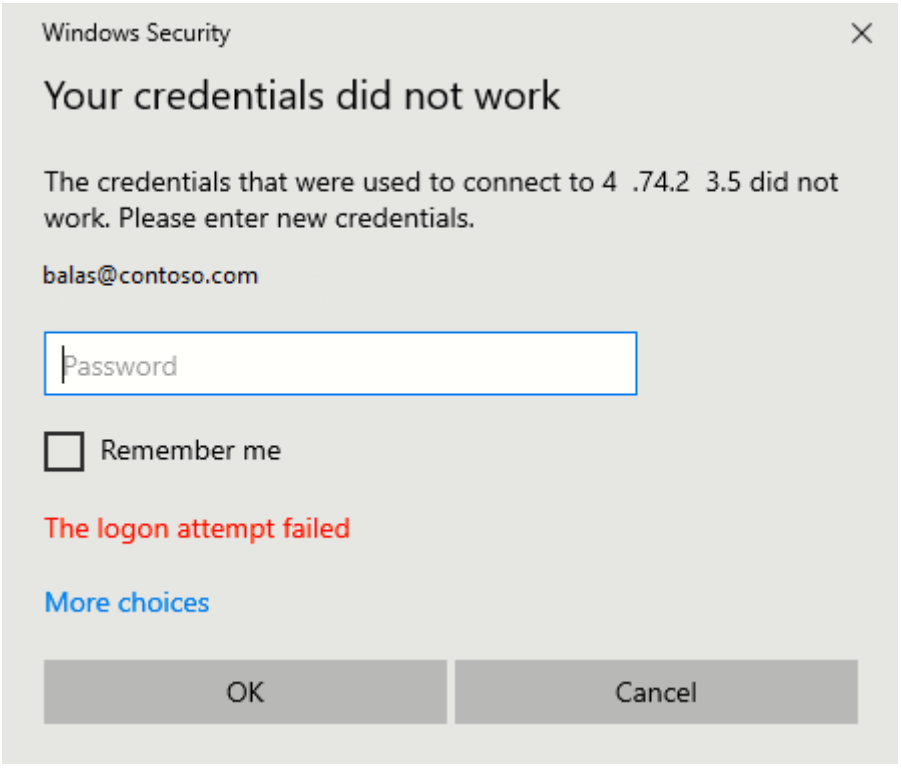
MFA sign-in method required

You might see the following error message when you initiate a remote desktop connection to your device: "The sign-in method you're trying to use isn't allowed. Try a different sign-in method or contact your system administrator."



If you configure a Conditional Access policy that requires MFA, you need to ensure that the device initiating the connection uses strong authentication such as Windows Hello.

Another MFA-related error message is the one described previously: "Your credentials didn't work."



If you configure a legacy per-user **Enabled/Enforced Microsoft Entra multifactor authentication** setting and you see the error, you can resolve the problem by removing the per-user MFA setting. For more information, see the article Enable per-user Microsoft Entra multifactor authentication to secure sign-in events.

If Windows Hello for Business isn't an option, configure a Conditional Access policy that excludes the Microsoft Azure Windows Virtual Machine Sign-in app. To learn more about Windows Hello for Business, see Windows Hello for Business overview.

Support for biometric authentication with RDP was added in Windows 10 version 1809. Using Windows Hello for Business authentication during RDP is available for deployments that use a certificate trust model or key trust model.

Share your feedback about this feature or report problems with using it on the Microsoft Entra feedback forum.

Missing application

If the Microsoft Azure Windows Virtual Machine Sign-in application is missing from Conditional Access, make sure that the application is in the tenant:

1. Sign in to the Microsoft Entra admin center as at least a Cloud Application Administrator.
2. Browse to **Entra ID** > **Enterprise apps**.

3. Remove the filters to see all applications, and search for **VM**. If you don't see **Microsoft Azure Windows Virtual Machine Sign-in** as a result, the service principal is missing from the tenant.

Another way to verify it is via Graph PowerShell:

1. Install the Graph PowerShell SDK.
2. Run `Connect-MgGraph -Scopes "ServicePrincipalEndpoint.ReadWrite.All"`, followed by `"Application.ReadWrite.All"`.
3. Sign in with a Global Administrator account.
4. Consent to the permission prompt.
5. Run `Get-MgServicePrincipal -ConsistencyLevel eventual -Search '"DisplayName:Azure Windows VM Sign-In"'`.

    - If this command results in no output and returns you to the PowerShell prompt, you can create the service principal with the following Graph PowerShell command:

      ```
      New-MgServicePrincipal -AppId 372140e0-b3b7-4226-8ef9-d57986796201
      ```

    - Successful output shows that the Microsoft Azure Windows Virtual Machine Sign-in app and its ID were created.

6. Sign out of Graph PowerShell by using the `Disconnect-MgGraph` command.

Some tenants might see the application named Azure Windows VM Sign-in instead of Microsoft Azure Windows Virtual Machine Sign-in. The application has the same Application ID of 372140e0-b3b7-4226-8ef9-d57986796201.

Unable to use this capability when require compliant device Conditional Access policy is enforced on Azure Windows VM Sign-in resource and you're connecting from a Windows Server device

Windows Server device compliance configuration in Conditional Access policy isn't supported.

Next steps

Guest updates and host maintenance overview

Article • 09/27/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

This article provides an overview of guest update and host maintenance options for Azure virtual machines (VMs).

Azure periodically updates its infrastructure to improve reliability, performance, and security or to launch new features. Most updates are transparent to you. To incorporate these updates, Azure uses a robust infrastructure that includes region pairs and availability zones combined with multiple tools and features.

Azure also offers you the ability to control updates on Azure machines like virtual machine scale sets, host machines, guest VMs, and extensions attached to VMs. This control is possible through maintenance configurations, which you can use to set up recurring schedules for times when you want available platform updates to occur.

With Azure infrastructure updates, you can:

- Upgrade network components.
- Decommission hardware on networks.
- Patch software components in hosting environments.
- Update guest operating system (OS) software on VMs.

To perform these updates, use the tools that are available in Azure.

The maintenance platform aims to provide you with a *unified maintenance experience* for all Azure resources that are affected during maintenance. The maintenance experience is available for host (Azure Dedicated Host and isolated VMs) and guest (VMs and Azure Arc VMs) resources, Azure Kubernetes Service, Salesforce Marketing Cloud (SFMC), and network gateways (Azure VPN Gateway, Azure ExpressRoute, and virtual network gateways in Azure). To deploy, use either the Azure portal, PowerShell, or the Azure CLI.

Maintenance control provides you with an option to skip or defer certain updates and schedule them only during your preferred maintenance window. In exceptional circumstances where a high-severity security issue arises that could potentially compromise customer services, Azure reserves the right to bypass these schedules to implement urgent changes. This measure is taken solely to help ensure the safety and

integrity of customer services. It's employed only when the updates have no effect on customer resources. Such instances are infrequent and are invoked only as a last resort to safeguard resources.

Host maintenance

Host maintenance is performed on the physical hosts where VMs are located and is usually transparent to you. Some updates might have an effect on hosts that you can tolerate. During these updates, the VMs that are allocated on the hosts might freeze (*non-rebootful updates*), reboot (*rebootful updates*), or migrate live to another updated host. Azure chooses the update mechanism that affects your VMs the least.

Dedicated hosts, isolated VMs, and shared hosts

The host maintenance experience is available for dedicated hosts, isolated VMs, and shared hosts. Dedicated hosts are hosts in which one customer owns all VMs. Shared hosts are hosts in which VMs from multiple customers reside together. Isolated VMs are large machines that are isolated to a specific hardware type and dedicated to a single customer.

On dedicated hosts, you have the host maintenance experience available for all updates. You can opt into maintenance control and schedule a maintenance window based on your needs within 35 days from the last maintenance date. Isolated VMs have the maintenance control experience available like dedicated hosts.

You can use maintenance control to:

- Apply all updates together.
- Wait up to 35 days to apply updates for host machines.
- Set up a maintenance schedule or use Azure Functions to automate platform updates.
- Configure maintenance across subscriptions and resource groups.

On shared hosts, the maintenance experience is available for rebootful updates or high-impact updates. Currently, the maintenance control experience isn't available for updates that take less than 30 seconds.

Maintenance notifications

Azure provides notifications before, during, and after maintenance operations. Scheduled events provide notifications before an event starts and while it's in progress so that your application can react automatically. Flash Health events provide information

that you can consume to analyze alerts and trends in VM availability for reporting and root cause analysis.

Scheduled events

Scheduled events provide advance notification of upcoming availability impacts so that you can prepare your application ahead of time. They're delivered directly to the affected VM and to all VMs in the same placement group for automated resilience. For information on scheduled events, see Scheduled events for Windows VMs and Scheduled events for Linux.

Flash Health events

Flash Health events provide near real-time information about past availability impacts so that you can react to events and easily mitigate incidents. Flash information is available in Azure Monitor, Azure Resource Graph, or Azure Event Grid to integrate with your systems and processes.

Guest updates

This section explains guest update options.

OS image upgrade

Automatic OS upgrades are available for virtual machine scale sets. An upgrade works by replacing the OS disk of a VM with a new disk that was created by using the latest image version. Any configured extensions and custom data scripts are run on the OS disk, while data disks are retained. To minimize the application downtime, upgrades take place in batches. No more than 20% of the scale set upgrades at any time.

Maintenance control is also available for OS image upgrades. You can opt in to this experience by using maintenance configurations to schedule when to apply these image upgrades. To use this experience, scale sets need to have automatic OS upgrades enabled. You can schedule recurrence for up to a week (seven days). A minimum of five hours is required for the maintenance window.

Guest VM patching

Automatic VM guest patching is integrated with Azure Update Manager. You can save recurring deployment schedules to install updates for your Windows Server and Linux

machines in Azure, in on-premises environments, and in other cloud environments that are connected by using Azure Arc-enabled servers.

Guest extension upgrades

Automatic Extension Upgrade is available for Azure Virtual Machines and Azure Virtual Machine Scale Sets. When Automatic Extension Upgrade is enabled on a VM or scale set, the extension is automatically upgraded whenever the extension publisher releases a new version for that extension. The extension upgrade process replaces the existing extension version on a VM with the new version of the same extension.

The health of the VM is monitored after the new extension is installed. If the VM isn't in a healthy state within five minutes of the upgrade completion, the extension version rolls back to the previous version. Maintenance control on extensions is currently available only via the CLI and PowerShell. You can schedule recurrence for up to a week (seven days). A minimum of five hours is required for the maintenance window.

Hotpatch

Hotpatching is a new way to install updates on new Windows Server Azure Edition VMs that doesn't require a reboot after installation. Hotpatching for Windows Server Azure Edition VMs has the following benefits:

- Lower workload effect with fewer reboots.
- Faster deployment of updates because the packages are smaller, install faster, and have easier patch orchestration with Update Manager.
- Better protection because the hotpatch update packages are scoped to Windows security updates that install faster without rebooting.

Azure update management

You can use Update Manager in Azure Automation to manage system updates for your Windows and Linux VMs in Azure, in on-premises environments, and in other cloud environments. You can quickly assess the status of available updates on all agent machines and manage the process of installing required updates for servers.

Update Manager

Update Manager is a unified service in Azure that helps you manage and govern updates (Windows and Linux), both on-premises and with other cloud platforms, across hybrid environments from a single dashboard. The new functionality provides a native

and an out-of-the-box experience with granular access controls. You have the flexibility to create schedules or act now and the ability to check updates automatically. The enhanced functionality ensures that administrators have visibility into the health of all systems in the environment. For more information, see Key benefits.

Azure Virtual Machine Scale Set automatic OS image upgrades

Enabling automatic OS image upgrades on your scale set helps ease update management by safely and automatically upgrading the OS disk for all instances in the scale set.

Automatic OS upgrade has the following characteristics:

- Once configured, the latest OS image published by image publishers is automatically applied to the scale set without user intervention.
- Upgrades batches of instances in a rolling manner each time a new image is published by the publisher.
- Integrates with application health probes and Application Health extension.
- Works for all virtual machine sizes, and for both Windows and Linux images including custom images through Azure Compute Gallery.
- You can opt out of automatic upgrades at any time (OS Upgrades can be initiated manually as well).
- The OS Disk of a virtual machine is replaced with the new OS Disk created with latest image version. Configured extensions and custom data scripts are run, while persisted data disks are retained.
- Extension sequencing is supported.
- Can be enabled on a scale set of any size.

> **Note**
>
> Before enabling automatic OS image upgrades, check **requirements section** of this documentation.

How does automatic OS image upgrade work?

An upgrade works by replacing the OS disk of a virtual machine with a new disk created using the image version. Any configured extensions and custom data scripts are run on the OS disk, while data disks are retained. To minimize the application downtime, upgrades take place in batches, with no more than 20% of the scale set upgrading at any time.

You must integrate an Azure Load Balancer application health probe or Application Health extension to track the health of the application after an upgrade. This allows the platform to validate the virtual machine health to ensure updates are applied in a safe manner. We recommend incorporating an application heartbeat to validate upgrade success.

Availability-first Updates

The availability-first model for platform orchestrated updates described below ensures that availability configurations in Azure are respected across multiple availability levels.

Across regions:

- An update moves across Azure globally in a phased manner to prevent Azure-wide deployment failures.
- A 'phase' can have one or more regions, and an update moves across phases only if eligible virtual machines in the previous phase update successfully.
- Geo-paired regions won't be updated concurrently and cannot be in the same regional phase.
- The success of an update is measured by tracking the health of a virtual machine post update.

Within a region:

- Virtual machines in different Availability Zones are not updated concurrently with the same update.

Within a 'set':

- All virtual machines in a common scale set are not updated concurrently.
- Virtual machines in a common Virtual Machine Scale Set are grouped in batches and updated within Update Domain boundaries as described below.

The platform orchestrated updates process is followed for rolling out supported OS platform image upgrades every month. For custom images through Azure Compute Gallery, an image upgrade is only kicked off for a particular Azure region when the new image is published and replicated to the region of that scale set.

Upgrading virtual machines in a scale set

The region of a scale set becomes eligible to get image upgrades either through the availability-first process for platform images or replicating new custom image versions for Share Image

Gallery. The image upgrade is then applied to an individual scale set in a batched manner as follows:

1. Before you begin the upgrade process, the orchestrator ensures that no more than 20% of instances in the entire scale set are unhealthy (for any reason).
2. The upgrade orchestrator identifies the batch of virtual machines to upgrade, with any one batch having a maximum of 20% of the total instance count, subject to a minimum batch size of one virtual machine. There is no minimum scale set size requirement and scale sets with 5 or fewer instances have 1 virtual machine per upgrade batch (minimum batch size).
3. The OS disk of every virtual machine in the selected upgrade batch is replaced with a new OS disk created from the image. All specified extensions and configurations in the scale set model are applied to the upgraded instance.
4. For scale sets with configured application health probes or Application Health extension, the upgrade waits up to 5 minutes for the instance to become healthy, before moving on to upgrade the next batch. If an instance does not recover its health in 5 minutes after an upgrade, then by default the previous OS disk for the instance is restored.
5. The upgrade orchestrator also tracks the percentage of instances that become unhealthy post an upgrade. The upgrade stops if more than 20% of upgraded instances become unhealthy during the upgrade process.
6. The above process continues until all instances in the scale set have been upgraded.

The scale set OS upgrade orchestrator checks for the overall scale set health before upgrading every batch. While you're upgrading a batch, there could be other concurrent planned or unplanned maintenance activities that could impact the health of your scale set instances. In such cases if more than 20% of the scale set's instances become unhealthy, then the scale set upgrade stops at the end of current batch.

To modify the default settings associated with Rolling Upgrades, review Azure's Rolling Upgrade Policy.

VMSS Flex considerations

> **Important**
>
> Auto OS image upgrades for VMSS Flex is currently in PREVIEW. See the **Supplemental Terms of Use for Microsoft Azure Previews** for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

When upgrading virtual machines in a scale set that uses Flexible orchestration mode, the following considerations apply:

- **Image reference consistency**
  Virtual machines must use the same image reference as defined in the virtual machine scale set (VMSS) model.

- **Image version requirement**
  For VMSS Flex, the image version configured on the virtual machine must be set to latest.

- **Provisioning data behavior**
  During an automatic OS image upgrade, provisioning data on the virtual machine is overwritten by the VMSS model. This includes administrator credentials and custom data. This behavior is specific to VMSS Flex and aligns with how reimage operations work in Flexible orchestration mode.

- **Application health monitoring**
  VMSS Flex supports application health monitoring through the Application Health Extension. The extension version on the virtual machine must match the version configured on the VMSS.

- **MaxSurge limitation**
  Automatic OS Image Upgrades can't be enabled at the same time as MaxSurge for VMSS Flex.

> ⓘ **Note**
>
> Using MaxSurge together with Automatic OS Image Upgrades in Flexible orchestration mode isn't currently supported.

OS image upgrade versus reimage

Both **OS Image Upgrade** and Reimage are methods used to update virtual machines within a scale set, but they serve different purposes and have distinct impacts.

OS image upgrade involves updating the underlying operating system image that is used to create new instances in a scale set. When you perform an OS image upgrade, Azure creates new virtual machines with the updated OS image and gradually replace the old virtual machines in the scale set with the new ones. This process is typically performed in stages to ensure high availability. OS image upgrades are a non-disruptive way to apply updates or changes to the

underlying OS of the virtual machines in a scale set. Existing virtual machines are not affected until they are replaced with the new instances.

Reimaging a virtual machine in a scale set is a more immediate and disruptive action. When you choose to reimage a virtual machine , Azure stops the selected virtual machine, perform the reimage operation, and then restart the virtual machine using the same OS image. This effectively reinstalls the OS on that specific virtual machine. Reimaging is typically used when you need to troubleshoot or reset a specific virtual machine due to issues with that instance.

Key differences:

- OS Image Upgrade is a gradual and non-disruptive process that updates the OS image for the entire Virtual Machine Scale Set over time, ensuring minimal impact on running workloads.
- Reimage is a more immediate and disruptive action that affects only the selected virtual machine, stopping it temporarily and reinstalling the OS.

When to use each method:

- Use OS Image Upgrade when you want to update the OS image for the entire scale set while maintaining high availability.
- Use Reimage when you need to troubleshoot or reset a specific virtual machine within the virtual Machine Scale Set.

It's essential to carefully plan and choose the appropriate method based on your specific requirements to minimize any disruption to your applications and services running in a Virtual Machine Scale Set.

Supported OS images

Only certain OS platform images are currently supported. Custom images are supported if the scale set uses custom images through Azure Compute Gallery.

The following platform SKUs are currently supported (and more are added periodically):

Requirements for configuring automatic OS image upgrade

- The *version* property of the image must be set to latest.
- Must use application health probes or Application Health extension for non-Service Fabric scale sets. For Service Fabric requirements, see Service Fabric requirement.
- Use Compute API version 2018-10-01 or higher.
- Ensure that external resources specified in the scale set model are available and updated. Examples include SAS URI for bootstrapping payload in virtual machine extension properties, payload in storage account, reference to secrets in the model, and more.
- For scale sets using Windows virtual machines, starting with Compute API version 2019-03-01, the *virtualMachineProfile.osProfile.windowsConfiguration.enableAutomaticUpdates* property must set to *false* in the scale set model definition. The *enableAutomaticUpdates* property enables in-VM patching where "Windows Update" applies operating system patches without replacing the OS disk. With automatic OS image upgrades enabled on your scale set, which can be done by setting the *automaticOSUpgradePolicy.enableAutomaticOSUpgrade* to *true*, an extra patching process through Windows Update is not required.
- The patch orchestration mode must *not* be set to `AutomaticByPlatform` in the scale set model definition. With automatic OS image upgrades enabled on your scale set, a platform orchestration patching process is not required.

> **Note**
>
> After an OS disk is replaced through reimage or upgrade, the attached data disks may have their drive letters reassigned. To retain the same drive letters for attached disks, it is suggested to use a custom boot script.

Service Fabric requirements

If you are using Service Fabric, ensure the following conditions are met:

- Service Fabric durability level is Silver or Gold. If Service Fabric durability is Bronze, only Stateless-only node types support automatic OS image upgrades).
- The Service Fabric extension on the scale set model definition must have TypeHandlerVersion 1.1 or above.
- Durability level should be the same at the Service Fabric cluster and Service Fabric extension on the scale set model definition.
- More health probes or use of application health extension is not required for Silver or Gold durability. Bronze durability with Stateless-only node types requires an additional health probe.

- The property *virtualMachineProfile.osProfile.windowsConfiguration.enableAutomaticUpdates* property must set to *false* in the scale set model definition. The *enableAutomaticUpdates* property enables in-VM patching using "Windows Update" and is not supported on Service Fabric scale sets. You should use the *automaticOSUpgradePolicy.enableAutomaticOSUpgrade* property instead.

Ensure that durability settings are not mismatched on the Service Fabric cluster and Service Fabric extension, as a mismatch results in upgrade errors. Durability levels can be modified per the guidelines outlined on this page.

Automatic OS image upgrade for custom images

Automatic OS image upgrade is supported for custom images deployed through Azure Compute Gallery. Other custom images are not supported for automatic OS image upgrades.

Additional requirements for custom images

- The setup and configuration process for automatic OS image upgrade is the same for all scale sets as detailed in the configuration section of this page.
- Scale sets instances configured for automatic OS image upgrades are upgraded to the version of the Azure Compute Gallery image when a new version of the image is published and replicated to the region of that scale set. If the new image is not replicated to the region where the scale is deployed, the scale set instances are not upgraded to the version. Regional image replication allows you to control the rollout of the new image for your scale sets.
- The new image version should not be excluded from the version for that gallery image. Image versions excluded from the gallery image's version are not rolled out to the scale set through automatic OS image upgrade.

> **Note**
>
> It can take up to 3 hours for a scale set to trigger the first image upgrade rollout after the scale set is first configured for automatic OS upgrades due to certain factors such as Maintenance Windows or other restrictions. Customers on the latest image may not get an upgrade until a new image is available.

Configure automatic OS image upgrade

To configure automatic OS image upgrade, ensure that the *automaticOSUpgradePolicy.enableAutomaticOSUpgrade* property is set to *true* in the scale set model definition.

> ⓘ Note
>
> **Upgrade Policy mode** and **Automatic OS Upgrade Policy** are separate settings and control different aspects of the scale set. When there are changes in the scale set template, the Upgrade Policy `mode` determines what happens to existing instances in the scale set. However, Automatic OS Upgrade Policy `enableAutomaticOSUpgrade` is specific to the OS image and tracks changes the image publisher has made and determines what happens when there is an update to the image.

> ⓘ Note
>
> If `enableAutomaticOSUpgrade` is set to *true*, `enableAutomaticUpdates` is automatically set to *false* and cannot be set to *true*.

REST API

The following example describes how to set automatic OS upgrades on a scale set model:

```
PUT or PATCH on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Com
pute/virtualMachineScaleSets/myScaleSet?api-version=2021-03-01`
```

JSON

```
{
  "properties": {
    "upgradePolicy": {
      "automaticOSUpgradePolicy": {
        "enableAutomaticOSUpgrade":  true
      }
    }
  }
}
```

Azure PowerShell

Use the New-AzVmss cmdlet to configure automatic OS image upgrades for your scale set during provisioning. The following example configures automatic upgrades for the scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure PowerShell

```
New-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myScaleSet" -
AutomaticOSUpgrade $true
```

Use the Update-AzVmss cmdlet to configure automatic OS image upgrades for your existing scale set. The following example configures automatic upgrades for the scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure PowerShell

```
Update-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myScaleSet" -
AutomaticOSUpgrade $true
```

Azure CLI 2.0

Use az vmss create to configure automatic OS image upgrades for your scale set during provisioning. Use Azure CLI 2.0.47 or above. The following example configures automatic upgrades for the scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure CLI

```
az vmss create --name myScaleSet --resource-group myResourceGroup --enable-auto-os-
upgrade true --upgrade-policy-mode Rolling
```

Use az vmss update to configure automatic OS image upgrades for your existing scale set. Use Azure CLI 2.0.47 or above. The following example configures automatic upgrades for the scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure CLI

```
az vmss update --name myScaleSet --resource-group myResourceGroup --enable-auto-os-
upgrade true --upgrade-policy-mode Rolling
```

> **Note**
>
> After configuring automatic OS image upgrades for your scale set, you must also bring the scale set virtual machines to the latest scale set model if your scale set uses the 'Manual'

upgrade policy.

ARM templates

The following example describes how to set automatic OS upgrades on a scale set model via Azure Resource Manager templates (ARM templates):

JSON

```
"properties": {
   "upgradePolicy": {
     "mode": "Automatic",
     "RollingUpgradePolicy": {
         "BatchInstancePercent": 20,
         "MaxUnhealthyInstancePercent": 25,
         "MaxUnhealthyUpgradedInstancePercent": 25,
         "PauseTimeBetweenBatches": "PT0S"
     },
    "automaticOSUpgradePolicy": {
      "enableAutomaticOSUpgrade": true,
        "useRollingUpgradePolicy": true,
        "disableAutomaticRollback": false
    }
  },
  },
"imagePublisher": {
   "type": "string",
   "defaultValue": "MicrosoftWindowsServer"
 },
 "imageOffer": {
   "type": "string",
   "defaultValue": "WindowsServer"
 },
 "imageSku": {
   "type": "string",
   "defaultValue": "2022-datacenter"
 },
 "imageOSVersion": {
   "type": "string",
   "defaultValue": "latest"
 }
```

Bicep

The following example describes how to set automatic OS upgrades on a scale set model via Bicep:

JSON

```
properties: {
    overprovision: overProvision
    upgradePolicy: {
      mode: 'Automatic'
      automaticOSUpgradePolicy: {
        enableAutomaticOSUpgrade: true
      }
    }
}
```

Using Application Health Extension

During an OS Upgrade, virtual machines in a scale set are upgraded one batch at a time. The upgrade should continue only if the customer application is healthy on the upgraded virtual machines. We recommend that the application provides health signals to the scale set OS Upgrade engine. By default, during OS Upgrades the platform considers virtual machine power state and extension provisioning state to determine if a virtual machine is healthy after an upgrade. During the OS Upgrade of a virtual machine, the OS disk on a virtual machine is replaced with a new disk based on latest image version. After the OS Upgrade has completed, the configured extensions are run on these virtual machines. The application is considered healthy only when all the extensions on the instance are successfully provisioned.

A scale set can optionally be configured with Application Health Probes to provide the platform with accurate information on the ongoing state of the application. Application Health Probes are Custom Load Balancer Probes that are used as a health signal. The application running on a scale set virtual machine can respond to external HTTP or TCP requests indicating whether it's healthy. For more information on how Custom Load Balancer Probes work, see to Understand load balancer probes. Application Health Probes are not supported for Service Fabric scale sets. Non-Service Fabric scale sets require either Load Balancer application health probes or Application Health extension.

If the scale set is configured to use multiple placement groups, probes using a Standard Load Balancer need to be used.

> ⓘ **Note**
>
> Only one source of health monitoring can be used for a Virtual Machine Scale Set, either an Application Health Extension or a Health Probe. If you have both options enabled, you need

to remove one before using orchestration services like Instance Repairs or Automatic OS Upgrades.

Configuring a Custom Load Balancer Probe as Application Health Probe on a scale set

As a best practice, create a load balancer probe explicitly for scale set health. The same endpoint for an existing HTTP probe or TCP probe can be used, but a health probe could require different behavior from a traditional load-balancer probe. For example, a traditional load balancer probe could return unhealthy if the load on the instance is too high, but that would not be appropriate for determining the instance health during an automatic OS upgrade. Configure the probe to have a high probing rate of less than two minutes.

The load-balancer probe can be referenced in the *networkProfile* of the scale set and can be associated with either an internal or public facing load-balancer as follows:

JSON

```
"networkProfile": {
  "healthProbe" : {
    "id": "[concat(variables('lbId'), '/probes/', variables('sshProbeName'))]"
  },
  "networkInterfaceConfigurations":
  ...
}
```

Note

When using Automatic OS Upgrades with Service Fabric, the new OS image is rolled out Update Domain by Update Domain to maintain high availability of the services running in Service Fabric. To utilize Automatic OS Upgrades in Service Fabric your cluster node type must be configured to use the Silver Durability Tier or higher. For Bronze Durability tier, automatic OS image upgrade is only supported for Stateless node types. For more information on the durability characteristics of Service Fabric clusters, see this documentation.

Using Application Health extension

The Application Health extension is deployed inside a Virtual Machine Scale Set instance and reports on virtual machine health from inside the scale set instance. You can configure the

extension to probe on an application endpoint and update the status of the application on that instance. This instance status is checked by Azure to determine whether an instance is eligible for upgrade operations.

As the extension reports health from within a virtual machine, the extension can be used in situations where external probes such as Application Health Probes (that utilize custom Azure Load Balancer probes) can't be used.

There are multiple ways of deploying the Application Health extension to your scale sets as detailed in the examples in this article.

> ⓘ **Note**
>
> Only one source of health monitoring can be used for a Virtual Machine Scale Set, either an Application Health Extension or a Health Probe. If you have both options enabled, you need to remove one before using orchestration services like Instance Repairs or Automatic OS Upgrades.

Configure custom metrics for rolling upgrades on Virtual Machine Scale Sets (Preview)

> ⓘ **Note**
>
> **Custom metrics for rolling upgrades on Virtual Machine Scale Sets is currently in preview.** Previews are made available to you on the condition that you agree to the supplemental terms of use. Some aspects of these features may change prior to general availability (GA).

Custom metrics for rolling upgrades enables you to utilize the application health extension to emit custom metrics to your Virtual Machine Scale Set. These custom metrics can be used to tell the scale set the order in which virtual machines should be updated when a rolling upgrade is triggered. The custom metrics can also inform your scale set when an upgrade should be skipped on a specific instance. This allows you to have more control over the ordering and the update process itself.

Custom metrics can be used in combination with other rolling upgrade functionality such as automatic OS upgrades, automatic extension upgrades and MaxSurge rolling upgrades.

For more information, see custom metrics for rolling upgrades on Virtual Machine Scale Sets

Get the history of automatic OS image upgrades

You can check the history of the most recent OS upgrade performed on your scale set with Azure PowerShell, Azure CLI 2.0, or the REST APIs. You can get history for the last five OS upgrade attempts within the past two months.

Keep credentials up to date

If your scale set uses any credentials to access external resources, such as a virtual machine extension configured to use a SAS token for storage account, then ensure that the credentials are updated. If any credentials including certificates and tokens have expired, the upgrade fails and the first batch of virtual machines are left in a failed state.

The recommended steps to recover virtual machines and re-enable automatic OS upgrade if there's a resource authentication failure are:

- Regenerate the token (or any other credentials) passed into your extensions.
- Ensure that any credential used from inside the virtual machine to talk to external entities is up to date.
- Update extensions in the scale set model with any new tokens.
- Deploy the updated scale set, which updates all virtual machines including the failed ones.

REST API

The following example uses REST API to check the status for the scale set named *myScaleSet* in the resource group named *myResourceGroup*:

```
GET on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Com
pute/virtualMachineScaleSets/myScaleSet/osUpgradeHistory?api-version=2021-03-01`
```

The GET call returns properties similar to the following example output:

JSON

```
{
    "value": [
        {
            "properties": {
        "runningStatus": {
          "code": "RollingForward",
```

```
          "startTime": "2018-07-24T17:46:06.1248429+00:00",
          "completedTime": "2018-04-21T12:29:25.0511245+00:00"
        },
        "progress": {
          "successfulInstanceCount": 16,
          "failedInstanceCount": 0,
          "inProgressInstanceCount": 4,
          "pendingInstanceCount": 0
        },
        "startedBy": "Platform",
        "targetImageReference": {
          "publisher": "MicrosoftWindowsServer",
          "offer": "WindowsServer",
          "sku": "2016-Datacenter",
          "version": "2016.127.20180613"
        },
        "rollbackInfo": {
          "successfullyRolledbackInstanceCount": 0,
          "failedRolledbackInstanceCount": 0
        }
      },
      "type": "Microsoft.Compute/virtualMachineScaleSets/rollingUpgrades",
      "location": "westeurope"
    }
  ]
}
```

Azure PowerShell

Use the Get-AzVmss cmdlet to check OS upgrade history for your scale set. The following example details how you review the OS upgrade status for a scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure PowerShell

```
Get-AzVmss -ResourceGroupName "myResourceGroup" -VMScaleSetName "myScaleSet" -
OSUpgradeHistory
```

Azure CLI 2.0

Use az vmss get-os-upgrade-history to check the OS upgrade history for your scale set. Use Azure CLI 2.0.47 or above. The following example details how you review the OS upgrade status for a scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure CLI

```
az vmss get-os-upgrade-history --resource-group myResourceGroup --name myScaleSet
```

How to get the latest version of a platform OS image?

You can get the available image versions for automatic OS upgrade supported SKUs using the below examples:

REST API

```
GET on
`/subscriptions/subscription_id/providers/Microsoft.Compute/locations/{location}/publi
shers/{publisherName}/artifacttypes/vmimage/offers/{offer}/skus/{skus}/versions?api-
version=2021-03-01`
```

Azure PowerShell

Azure PowerShell

```
Get-AzVmImage -Location "westus" -PublisherName "Canonical" -offer "0001-com-ubuntu-
server-jammy" -sku "22_04-lts"
```

Azure CLI 2.0

Azure CLI

```
az vm image list --location "westus" --publisher "Canonical" --offer "0001-com-
ubuntu-server-jammy" --sku "22_04-lts" --all
```

Manually trigger OS image upgrades

With automatic OS image upgrade enabled on your scale set, you don't need to manually trigger image updates on your scale set. The OS upgrade orchestrator automatically applies the latest available image version to your scale set instances without any manual intervention.

For specific cases where you don't want to wait for the orchestrator to apply the latest image, you can trigger an OS image upgrade manually using the below examples.

> ⓘ **Note**
>
> Manual trigger of OS image upgrades does not provide automatic rollback capabilities. If an instance does not recover its health after an upgrade operation, its previous OS disk can't be

restored.

REST API

Use the Start OS Upgrade API call to start a rolling upgrade to move all Virtual Machine Scale Set instances to the latest available image OS version. Instances that are already running the latest available OS version are not affected. The following example details how you can start a rolling OS upgrade on a scale set named *myScaleSet* in the resource group named *myResourceGroup*:

```
POST on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Com
pute/virtualMachineScaleSets/myScaleSet/osRollingUpgrade?api-version=2021-03-01`
```

Azure PowerShell

Use the Start-AzVmssRollingOSUpgrade cmdlet to check OS upgrade history for your scale set. The following example details how you can start a rolling OS upgrade on a scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure PowerShell

```
Start-AzVmssRollingOSUpgrade -ResourceGroupName "myResourceGroup" -VMScaleSetName
"myScaleSet"
```

Azure CLI 2.0

Use az vmss rolling-upgrade start to check the OS upgrade history for your scale set. Use Azure CLI 2.0.47 or above. The following example details how you can start a rolling OS upgrade on a scale set named *myScaleSet* in the resource group named *myResourceGroup*:

Azure CLI

```
az vmss rolling-upgrade start --resource-group "myResourceGroup" --name "myScaleSet" -
-subscription "subscriptionId"
```

Leverage Activity Logs for Upgrade Notifications and Insights

Activity Log is a subscription log that provides insight into subscription-level events that have occurred in Azure. Customers are able to:

- See events related to operations performed on their resources in Azure portal
- Create action groups to tune notification methods like email, sms, webhooks, or ITSM
- Set up suitable alerts using different criteria using Portal, ARM resource template, PowerShell or CLI to be sent to action groups

Customers receive three types of notifications related to Automatic OS Upgrade operation:

- Submission of upgrade request for a particular resource
- Outcome of submission request along with any error details
- Outcome of upgrade completion along with any error details

Setting up Action Groups for Activity log alerts

An action group is a collection of notification preferences defined by the owner of an Azure subscription. Azure Monitor and Service Health alerts use action groups to notify users that an alert has been triggered.

Action groups can be created and managed using:

- ARM Resource Manager
- Portal
- PowerShell:
  - New-AzActionGroup
  - Get-AzActionGroup
  - Remove-AzActionGroup
- CLI

Customers can set up the following using action groups:

- SMS and/or Email notifications
- Webhooks - Customers can attach webhooks to their automation runbooks and configure their action groups to trigger the runbooks. You can start a runbook from a webhook
- ITSM Connections

Investigate and Resolve Auto Upgrade Errors

The platform can return errors on virtual machines while performing Automatic Image Upgrade with Rolling Upgrade policy. The Get Instance View of a virtual machine contains the detailed

error message to investigate and resolve an error. The Rolling Upgrades - Get Latest can provide more details on rolling upgrade configuration and status. The Get OS Upgrade History provides details on the last image upgrade operation on the scale set. Below are the topmost errors that can result in Rolling Upgrades.

RollingUpgradeInProgressWithFailedUpgradedVMs

- Error is triggered for a virtual machine failure.
- The detailed error message mentions whether the rollout continues/pauses based on the configured threshold.

MaxUnhealthyUpgradedInstancePercentExceededInRollingUpgrade

- Error is triggered when the percent of upgraded virtual machines exceed the max threshold allowed for unhealthy virtual machines.
- The detailed error message aggregates the most common error contributing to the unhealthy virtual machines. See MaxUnhealthyUpgradedInstancePercent.

MaxUnhealthyInstancePercentExceededInRollingUpgrade

- Error is triggered when the percent of unhealthy virtual machines exceed the max threshold allowed for unhealthy virtual machines during an upgrade.
- The detailed error message displays the current unhealthy percent and the configured allowable unhealthy virtual machine percentage. See maxUnhealthyInstancePercent.

MaxUnhealthyInstancePercentExceededBeforeRollingUpgrade

- Error is triggered when the percent of unhealthy virtual machines exceed the max threshold allowed for unhealthy virtual machines before an upgrade takes place.
- The detailed error message displays the current unhealthy percent and the configured allowable unhealthy virtual machine percentage. See maxUnhealthyInstancePercent.

InternalExecutionError

- Error is triggered when an unhandled, unformatted or unexpected occurs during execution.
- The detailed error message displays the cause of the error.

RollingUpgradeTimeoutError

- Error is triggered when the rolling upgrade process has timed out.
- The detailed error message displays the length of time the system timed out after attempting to update.

In-place upgrade for VMs running Windows Server in Azure

An in-place upgrade allows you to go from an older operating system to a newer one while keeping your settings, server roles, and data intact. This article teaches you how to move your Azure VMs to a later version of Windows Server using an in-place upgrade. Currently, upgrading to Windows Server 2012, Windows Server 2016, Windows Server 2019, Windows Server 2022, and Windows Server 2025 are supported.

> **⊗ Caution**
>
> Following the process in this article causes a disconnection between the data plane and the control plane of the virtual machine (VM). Azure capabilities such as Auto guest patching, Auto OS image upgrades, Hotpatching, and Azure Update Manager won't be available. This means that the source image information in the VM properties, including the publisher, offer, and plan, remains unchanged. The image used to deploy the VM remains the same, and only the OS is upgraded. To utilize these features, create a new VM using your preferred operating system instead of performing an in-place upgrade.

> **ⓘ Important**
>
> **Virtual Machine (VM)** running in Azure and experiencing Windows Update issues? Trying to diagnose and resolve Windows Update or Windows OS Upgrade issues for your Azure Virtual Machine? Try one of the following tools:
>
> - Azure VM Windows Update Error Detection Tool to diagnose specific Windows Update errors
> - Azure VM Windows Servicing Stack Reset Tool to reset the Windows Servicing stack.
> - Azure Virtual Machine (VM) Windows OS Upgrade Assessment Tool to validate the OS upgrade path and any known issues
>
> *If you're experiencing Windows Update or Windows OS Upgrade issues with virtual machines, before contacting support, run these tools.*

Prerequisites

Before you begin an in-place upgrade:

- Review the upgrade requirements for the target operating system:
  - Upgrade options for Windows Server 2012 from Windows Server 2008 (64-bit) or Windows Server 2008 R2
  - Upgrade options for Windows Server 2016 from Windows Server 2012 or Windows Server 2012 R2
  - Upgrade options for Windows Server 2019 from Windows Server 2012 R2 or Windows Server 2016
  - Upgrade options for Windows Server 2022 from Windows Server 2016 or Windows Server 2019
  - Upgrade options for Windows Server 2025 from Windows Server 2022, Windows Server 2019, Windows Server 2016, or Windows Server 2012 R2
- Run the Azure Virtual Machine (VM) Windows OS Upgrade Assessment Tool to validate the OS upgrade path and any known issues.
- Verify the operating system disk has enough free space to perform the in-place upgrade. If more space is needed follow these steps to expand the operating system disk attached to the VM.
- Disable antivirus and anti-spyware software and firewalls. These types of software can conflict with the upgrade process. Re-enable antivirus and anti-spyware software and firewalls after the upgrade is completed.

Upgrade VM to volume license (KMS server activation)

The upgrade media provided by Azure requires the VM to be configured for Windows Server volume licensing. This is the default behavior for any Windows Server VM that was installed from a generalized image in Azure. If the VM was imported into Azure, then it might need to be converted to volume licensing to use the upgrade media provided by Azure. To confirm the VM is configured for volume license activation follow these steps to configure the appropriate KMS client setup key. If the activation configuration was changed, then follow these steps to verify connectivity to Azure KMS service.

Upgrade to Managed Disks

The in-place upgrade process requires the use of Managed Disks on the VM to be upgraded. Most VMs in Azure are using Managed Disks, and retirement for unmanaged disks support was announced in November of 2022. If the VM is currently using unmanaged disks, then follow these steps to migrate to Managed Disks.

Create snapshot of the operating system disk

We recommend that you create a snapshot of your operating system disk and any data disks before starting the in-place upgrade process. This enables you to revert to the previous state of the VM if anything fails during the in-place upgrade process. To create a snapshot on each disk, follow these steps to create a snapshot of a disk.

> **Note**
>
> During the upgrade process, the upgrade media disk is only created in the `en-US` language. Currently, no other languages or editions are supported. To avoid errors caused by previously using a different language ISO to install the OS, you can set the system language to `en-US` or change the system locale to `English (United States)` in Control Panel.

Create upgrade media disk

To start an in-place upgrade the upgrade media must be attached to the VM as a Managed Disk. To create the upgrade media, modify the variables in the following PowerShell script for Windows Server 2025. The upgrade media disk can be used to upgrade multiple VMs, but it can only be used to upgrade a single VM at a time. To upgrade multiple VMs simultaneously multiple upgrade disks must be created for each simultaneous upgrade.

Expand table

Parameter	Definition
resourceGroup	Name of the resource group where the upgrade media Managed Disk will be created. The named resource group is created if it doesn't exist.
location	Azure region where the upgrade media Managed Disk is created. This must be the same region as the VM to be upgraded.
zone	Azure zone in the selected region where the upgrade media Managed Disk will be created. This must be the same zone as the VM to be upgraded. For regional VMs (nonzonal) the zone parameter should be "".

Parameter	Definition
diskName	Name of the Managed Disk that will contain the upgrade media
sku	Windows Server upgrade media version. This must be either: `server2025Upgrade` or `server2022Upgrade` or `server2019Upgrade` or `server2016Upgrade` or `server2012Upgrade`. The upgrade media disk is created using the latest version of the specified SKU.

If you have more than one subscription, you should run `Set-AzContext -Subscription '<subscription name or id>` to specify which subscription to use.

PowerShell script

Azure PowerShell

```
#
# Customer specific parameters

# Resource group of the source VM
$resourceGroup = "WindowsServerUpgrades"

# Location of the source VM
$location = "WestUS2"

# Zone of the source VM, if any
$zone = ""

# Disk name for the that will be created
$diskName = "WindowsServer2025UpgradeDisk"

# Target version for the upgrade - must be one of these five strings:
server2025Upgrade, server2022Upgrade, server2019Upgrade, server2016Upgrade or
server2012Upgrade
$sku = "server2025Upgrade"

# Common parameters

$publisher = "MicrosoftWindowsServer"
$offer = "WindowsServerUpgrade"
$managedDiskSKU = "Standard_LRS"

#
# Get the latest version of the special (hidden) VM Image from the Azure Marketplace

$versions = Get-AzVMImage -PublisherName $publisher -Location $location -Offer
$offer -Skus $sku | sort-object -Descending {[version] $_.Version    }
$latestString = $versions[0].Version
```

```
# Get the special (hidden) VM Image from the Azure Marketplace by version - the
image is used to create a disk to upgrade to the new version

$image = Get-AzVMImage -Location $location `
                       -PublisherName $publisher `
                       -Offer $offer `
                       -Skus $sku `
                       -Version $latestString

#
# Create Resource Group if it doesn't exist
#

if (-not (Get-AzResourceGroup -Name $resourceGroup -ErrorAction SilentlyContinue)) {
    New-AzResourceGroup -Name $resourceGroup -Location $location
}

#
# Create Managed Disk from LUN 0
#

if ($zone){
    $diskConfig = New-AzDiskConfig -SkuName $managedDiskSKU `
                                   -CreateOption FromImage `
                                   -Zone $zone `
                                   -Location $location
} else {
    $diskConfig = New-AzDiskConfig -SkuName $managedDiskSKU `
                                   -CreateOption FromImage `
                                   -Location $location
}

Set-AzDiskImageReference -Disk $diskConfig -Id $image.Id -Lun 0

New-AzDisk -ResourceGroupName $resourceGroup `
           -DiskName $diskName `
           -Disk $diskConfig
```

Attach upgrade media to the VM

Attach the upgrade media for the target Windows Server version to the VM which will be upgraded. This can be done while the VM is in the running or stopped state.

Portal instructions

1. Sign in to the Azure portal.

2. Search for and select **Virtual machines**.

3. Select a virtual machine to perform the in-place upgrade from the list.
4. On the **Virtual machine** page, select **Disks**.
5. On the **Disks** page, select **Attach existing disks**.
6. In the drop-down for **Disk name**, select the name of the upgrade disk created in the previous step.
7. Select **Save** to attach the upgrade disk to the VM.

Perform in-place upgrade to Windows Server 2016, 2019, 2022, or 2025

To initiate the in-place upgrade the VM must be in the `Running` state. Once the VM is in a running state use the following steps to perform the upgrade.

1. Connect to the VM using RDP or RDP-Bastion.
2. Determine the drive letter for the upgrade disk (typically E: or F: if there are no other data disks).
3. Start Windows PowerShell.
4. Change directory to the only directory on the upgrade disk.
5. Execute the following command to start the upgrade:

   PowerShell

   ```
   .\setup.exe /auto upgrade /dynamicupdate disable
   ```

   You can use /eula accept switch in the Windows Server upgrade command to automatically accept the Microsoft Software License Terms (End User License Agreement or EULA) during the upgrade process. Using the /eula accept switch can help avoid issues where the upgrade process stalls because the EULA wasn't accepted manually. This switch ensures that the upgrade process can proceed smoothly without requiring user interaction to accept the license terms.

   PowerShell

   ```
   .\setup.exe /auto upgrade /dynamicupdate disable /eula accept
   ```

6. Select the correct "Upgrade to" image based on the current version and configuration of the VM using the Windows Server upgrade matrix.

During the upgrade process, the VM will automatically disconnect from the RDP session. After the VM is disconnected from the RDP session the progress of the upgrade can be monitored through the screenshot functionality available in the Azure portal.

Perform in-place upgrade to Windows Server 2012 only

To initiate the in-place upgrade the VM must be in the `Running` state. Once the VM is in a running state use the following steps to perform the upgrade.

1. Connect to the VM using RDP or RDP-Bastion.
2. Determine the drive letter for the upgrade disk (typically E: or F: if there are no other data disks).
3. Start Windows PowerShell.
4. Change directory to the only directory on the upgrade disk.
5. Execute the following command to start the upgrade:

   PowerShell

   ```
   .\setup.exe
   ```

6. When Windows Setup launches, select **Install now**.
7. For **Get important updates for Windows Setup**, select **No thanks**.
8. Select the correct Windows Server 2012 "Upgrade to" image based on the current version and configuration of the VM using the Windows Server upgrade matrix.
9. On the **License terms** page, select **I accept the license terms** and then select **Next**.
10. For **What type of installation do you want?" select **Upgrade: Install Windows and keep files, settings, and applications**.
11. Setup will product a **Compatibility report**, you can ignore any warnings and select **Next**.
12. When complete, the machine reboots, automatically disconnecting you from the RDP session. After the VM is disconnected from the RDP session the progress of the upgrade can be monitored through the screenshot functionality available in the Azure portal.

Post upgrade steps

Once the upgrade process has completed successfully the following steps should be taken to clean up any artifacts which were created during the upgrade process:

- Delete the snapshots of the OS disk and data disk(s) if they were created.
- Delete the upgrade media Managed Disk.
- Enable any antivirus, anti-spyware, or firewall software that may have been disabled at the start of the upgrade process.

> **Important**
>
> The image plan information will not change after the upgrade process.

Recover from failure

If the in-place upgrade process failed to complete successfully you can return to the previous version of the VM if snapshots of the operating system disk and data disk(s) were created. To revert the VM to the previous state using snapshots complete the following steps:

1. Create a new Managed Disk from the OS disk snapshot and each data disk snapshot following the steps in Create a disk from a snapshot making sure to create the disks in the same Availability Zone as the VM if the VM is in a zone.
2. Stop the VM.
3. Swap the OS disk of the VM.
4. Detach any data disks from the VM.
5. Attach data disks created from the snapshots in step 1.
6. Restart the VM.

Next steps

- For more information, see Perform an in-place upgrade of Windows Server
- For information about using Azure Migrate to upgrade, see Azure Migrate Windows Server upgrade

Azure Virtual Machine (VM) Windows OS Upgrade assessment tool

Applies to: ✔ Windows VMs

Summary

This article provides information about the Azure Virtual Machine (VM) Windows OS Upgrade Assessment tool, a PowerShell script designed to assess the readiness of a Windows machine (desktop or server) for an **in-place OS upgrade**, with special considerations for **Azure VMs**. The tool evaluates OS version, supported upgrade paths, system disk space, and Azure security features like **Trusted Launch**, **Secure Boot**, and **virtual trusted platform modules (vTPMs)**.

Features

- **OS version detection**
  - Identifies whether the system is Windows 10, 11, or a Windows Server edition.
- **Server upgrade path check**
  - Matches current server version to supported upgrade targets.
- **Hardware validation**
  - Disk space (greater than or equal to 64 GB).
  - Physical memory (greater than or equal to 4 GB).
- **Azure VM security feature verification**
  - Trusted Launch.
  - Secure Boot.
  - vTPM.
- **Azure Virtual Desktop detection**
  - Flags unsupported pooled host pool configurations.
- **Upgrade recommendations**
  - Outputs supported upgrade paths or relevant upgrade guidance.

For more information, see Azure VM Windows OS Upgrade Assessment Script.

Output

```
Windows Version: Windows 10 Pro

[Passed] Disk Space (Free: 101.46 GB)
[Passed] Physical Memory (Total: 16 GB)
[Failed] VM Generation: Gen2 required for upgrade
[Failed] Trusted Launch
[Failed] Secure Boot
[Failed] TPM Enabled

FAILED: The VM is running Windows 10 Gen1. Upgrade to Windows 11 is only supported for Gen2 VMs
```

How to run the tool

You can run the tool in any of the following manners.

1. Download from GitHub and run within the VM

Download the scripts from GitHub and then run them manually. To access the scripts, follow the resource links in the previous sections.

2. Use prepackaged run command scripts

For more information, see Run scripts in your Windows VM by using action run commands.

Recommended workflow

1. Run `Windows_OSUpgrade_Assessment_Validation` to verify the OS can be upgraded.
2. Apply the suggested fixes or refer to the official documentation.

In-place upgrade for supported VMs running Windows in Azure (Windows client)

Applies to: ✔ Windows VMs

Original product version: Windows 10, version 1803, all editions, Windows 10, version 1709, all editions, Virtual Machine running Windows, Windows 10, Windows 8.1, Windows 7 Enterprise
Original KB number: 4014997

Summary

This article describes how to do an in-place system upgrade of supported Windows 10-based and Windows-11-based Azure Virtual Machines (VMs). It also describes workarounds for Azure VMs that aren't supported for in-place system upgrades.

> ⓘ Note
>
> **Looking for Windows Server?**
> For Azure VMs running Windows Server, see In-place upgrade for supported Windows Server VMs.

> ⊗ Caution
>
> Following the process in this article causes a disconnection between the data plane and the control plane of the VM. Azure capabilities like Auto guest patching, Auto OS image upgrades, Hotpatching, and Azure Update Manager aren't available. To use these features, create a new VM by using your preferred operating system instead of performing an in-place upgrade.

> ⓘ Important
>
> **Virtual machine (VM)** running in Azure and experiencing Windows Update issues?

> Trying to diagnose and resolve Windows Update or Windows OS upgrade issues for your Azure VM? Try one of the following tools:
>
> - Azure VM Windows Update Error Detection Tool to diagnose specific Windows Update errors.
> - Azure VM Windows Windows Update Reset Tool to reset the Windows servicing stack.
> - Azure VM Windows OS Upgrade Assessment Tool to validate the OS upgrade path and any known issues.
>
> If you're experiencing performance problems with VMs, run these tools first before contacting support.

Symptoms

Consider the following scenario:

- You have a VM that's running Windows in a Microsoft Azure environment.
- You run an in-place upgrade of the VM to a newer version of the operating system.

In this scenario, the upgrade may fail or become blocked and require direct console access.

Cause

In-place system upgrades are supported for specific versions of Azure Windows VMs. We're working to broaden support of in-place system upgrade (as a Feature Update) to other versions soon.

Windows versions supported for in-place system upgrades

- Windows 10 single-session, all editions, all versions

  > **Note**
  > - You can't do an in-place upgrade from a single-session SKU of Windows to a multi-session SKU. For more information, see Can I upgrade a Windows VM to Windows Enterprise multi-session? .
  > - When migrating from Windows 10 to Windows 11, follow best practices by deploying new VMs. This approach avoids potential compatibility issues and

ensures an optimized configuration. The VM must meet the hardware requirements for Windows 11.

Windows versions that don't support in-place system upgrades (consider using a workaround)

- Windows 10 and 11 multi-session (all versions) — commonly used as Azure Virtual Desktop session hosts
- Windows 10 and 11 single-session up to Windows 10 and 11 multisesion (cross-SKU)
- Windows 8.1
- Windows 7 Enterprise

> **Important**
>
> **Azure Virtual Desktop session hosts:** In-place upgrade **isn't supported** for pooled or multisesion Azure Virtual Desktop session hosts. These VMs use Windows 10/11 Enterprise multisesion, which doesn't support in-place feature updates. Attempting an in-place upgrade (IPU) on an Azure Virtual Desktop session host can result in a broken session host, failed user connections, and loss of session host availability. For Azure Virtual Desktop environments, use image-based replacement instead. See Azure Virtual Desktop session host upgrade guidance later in this article.

In-place system upgrade process for a Windows 10 VM

This process takes 45-60 minutes to complete and restarts the VM. To perform the in-place system upgrade, follow these steps:

1. Run the Azure Virtual Machine (VM) Windows OS Upgrade Assessment Tool to validate the OS upgrade path and check for any known issues.
2. Verify that the Windows 10 VM doesn't use Ephemeral OS Disk. This feature isn't currently supported.
3. Verify that the Windows 10 VM has at least 2 GB of RAM, and 12 GB of free disk space on the system disk.

4. To prevent data loss, back up the Windows 10 VM by using Azure Backup. You can also use a third-party backup solution from Azure Marketplace Backup & Recovery.

5. To check whether the backup was successful, turn off the original Windows 10 VM and verify that you can restore a new VM from the backup and that all applications are running successfully.

   > **Note**
   >
   > You can use either the original Windows 10 VM or the restored VM as a source for an in-place system upgrade. The VMs can't run simultaneously unless you change one VM's system name and IP address to avoid conflicts.

6. Connect to the Windows 10 VM, and then go to **Settings** > **Updates & Security** > **Windows Update**.

7. In Windows Update, select **Check for updates**.

8. When the Feature Update item appears, select **Download and install now**.

The update downloads and installs. User settings and data are preserved, and the VM restarts automatically.

If you have general questions about this procedure, post them to Microsoft Q&A. Add the `azure-virtual-machines` tag to your questions.

Workaround

To work around this issue, create an Azure VM that's running a supported version. Download and upgrade the VHD of the VM.

To prevent data loss, back up the Windows 10 VM by using Azure Backup. Or, use a third-party backup solution from Azure Marketplace Backup & Recovery.

Download and upgrade the VHD

Step 1: Do an in-place upgrade in a local Hyper-V VM

1. Download the VHD of the VM.
2. Attach the VHD to a local Hyper-V VM.
3. Start the VM.

4. Run the in-place upgrade.

Step 2: Upload the VHD to Azure

Follow the steps in the following article to upload the VHD to Azure and to deploy the VM.

Upload a generalized VHD and use it to create new VMs in Azure

> **Note**
>
> When you perform an in-place upgrade on Azure Windows VMs, the VM properties on the Azure portal aren't updated. The changes are reflected only within the OS. This means that the source image information in the VM properties (including the publisher, offer, and plan) remains unchanged. The image that's used to deploy the VM remains the same. Only the OS is upgraded.

Azure Virtual Desktop session host upgrade guidance

Azure Virtual Desktop session hosts that use Windows 10 or Windows 11 Enterprise multi-session don't support IPUs. Attempting an IPU on these VMs can cause:

- Broken session host registration with the Azure Virtual Desktop host pool.
- User connection failures.
- Loss of FSLogix profile container connectivity.
- Session host unavailability requiring manual recovery.

Recommended approach: Image-based replacement

Instead of upgrading the OS on an existing session host, replace session hosts with new VMs built from an updated image:

1. **Create a new golden image** — Build a new VM image with the target Windows version, install required applications, and configure FSLogix and other Azure Virtual Desktop components.
2. **Add new session hosts** — Deploy new session hosts from the updated image into the existing host pool.
3. **Drain existing session hosts** — Set existing (old-version) session hosts to drain mode so no new user sessions connect to them.

4. **Remove old session hosts** — After users move to the new session hosts, remove the old VMs from the host pool and deallocate them.

For more information, see:

- Create a golden image in Azure
- Host pool management approaches for Azure Virtual Desktop

Azure Virtual Desktop personal desktop exception

For Azure Virtual Desktop **personal desktop** session hosts that use Windows 10 or Windows 11 **single-session** (not multisesion), in-place upgrade follows the same process as standard Azure VMs. See In-place system upgrade process for a Windows 10 VM earlier in this article.

> **Note**
>
> Personal desktops that use single-session Windows are eligible for in-place upgrade, but personal desktops that use multisesion Windows aren't. Verify the Windows SKU before attempting an upgrade. Run `winver` or check `SystemInfo` on the session host to confirm whether it's single-session or multisesion.

Azure Virtual Machine (VM) Windows OS Upgrade assessment tool

Applies to: ✔ Windows VMs

Summary

This article provides information about the Azure Virtual Machine (VM) Windows OS Upgrade Assessment tool, a PowerShell script designed to assess the readiness of a Windows machine (desktop or server) for an **in-place OS upgrade**, with special considerations for **Azure VMs**. The tool evaluates OS version, supported upgrade paths, system disk space, and Azure security features like **Trusted Launch**, **Secure Boot**, and **virtual trusted platform modules (vTPMs)**.

Features

- **OS version detection**
  - Identifies whether the system is Windows 10, 11, or a Windows Server edition.
- **Server upgrade path check**
  - Matches current server version to supported upgrade targets.
- **Hardware validation**
  - Disk space (greater than or equal to 64 GB).
  - Physical memory (greater than or equal to 4 GB).
- **Azure VM security feature verification**
  - Trusted Launch.
  - Secure Boot.
  - vTPM.
- **Azure Virtual Desktop detection**
  - Flags unsupported pooled host pool configurations.
- **Upgrade recommendations**
  - Outputs supported upgrade paths or relevant upgrade guidance.

For more information, see Azure VM Windows OS Upgrade Assessment Script.

Output

```
Windows Version: Windows 10 Pro

[Passed] Disk Space (Free: 101.46 GB)
[Passed] Physical Memory (Total: 16 GB)
[Failed] VM Generation: Gen2 required for upgrade
[Failed] Trusted Launch
[Failed] Secure Boot
[Failed] TPM Enabled

FAILED: The VM is running Windows 10 Gen1. Upgrade to Windows 11 is only supported for Gen2 VMs
```

How to run the tool

You can run the tool in any of the following manners.

1. Download from GitHub and run within the VM

Download the scripts from GitHub and then run them manually. To access the scripts, follow the resource links in the previous sections.

2. Use prepackaged run command scripts

For more information, see Run scripts in your Windows VM by using action run commands.

Recommended workflow

1. Run `Windows_OSUpgrade_Assessment_Validation` to verify the OS can be upgraded.
2. Apply the suggested fixes or refer to the official documentation.

Automatic Guest Patching for Azure Virtual Machines and Scale Sets

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

Enabling automatic guest patching for your Azure Virtual Machines (VMs) and Scale Sets (VMSS) helps ease update management by safely and automatically patching virtual machines to maintain security compliance, while limiting the blast radius of VMs.

Automatic VM guest patching has the following characteristics:

- Patches classified as *Critical* or *Security* are automatically downloaded and applied on the VM.
- Patches are applied during off-peak hours for IaaS VMs in the VM's time zone.
- Patches are applied during all hours for VMSS Flex.
- Azure manages the patch orchestration and follows availability-first principles.
- Virtual machine health, as determined through platform health signals, is monitored to detect patching failures.
- Application health can be monitored through the Application Health extension.
- Works for all VM sizes.

How does automatic VM guest patching work?

If automatic VM guest patching is enabled on a VM, then the available *Critical* and *Security* patches are downloaded and applied automatically on the VM. This process kicks off automatically every month when new patches are released. Patch assessment and installation are automatic, and the process includes rebooting the VM as configured. The rebootSetting parameter on the VM Model takes precedence over settings in another system, such as Maintenance Configuration.

The VM is assessed periodically every few days and multiple times within any 30-day period to determine the applicable patches for that VM. The patches can be installed any day on the VM during off-peak hours for the VM. This automatic assessment ensures that any missing patches are discovered at the earliest possible opportunity.

Patches are installed within 30 days of the monthly patch releases, following availability-first orchestration. Patches are installed only during off-peak hours for the VM, depending on the time zone of the VM. The VM must be running during the off-peak hours for patches to be automatically installed. If a VM is powered off during a periodic assessment, the platform automatically assess and apply patches (if necessary) during the next periodic assessment (usually within a few days) when the VM is powered on.

Definition updates and other patches not classified as *Critical* or *Security* won't be installed through automatic VM guest patching. To install patches with other patch classifications or schedule patch installation within your own custom maintenance window, you can use Azure Update Manager.

Enabling Automatic Guest Patching on single-instance VMs or Virtual Machine Scale Sets in Flexible orchestration mode allows the Azure platform to update your fleet in phases. Phased deployment follows Azure's Safe Deployment Practices and reduces the impact radius if any issues are identified with the latest update. Health monitoring is recommended for single instance VMs and required for Virtual Machine Scale Sets in Flexible orchestration mode to detect issues any issues with the update.

Availability-first Updates

Azure orchestrates the patch installation process across all public and private clouds for VMs that have enabled Automatic Guest Patching. The orchestration follows availability-first principles across different levels of availability provided by Azure.

For a group of virtual machines undergoing an update, the Azure platform orchestrates updates:

Across regions:

- A monthly update is orchestrated across Azure globally in a phased manner to prevent global deployment failures.
- A phase can have one or more regions, and an update moves to the next phases only if eligible VMs in a phase update successfully.
- Geo-paired regions aren't updated concurrently and can't be in the same regional phase.
- The success of an update is measured by tracking the VM's health post update. VM Health is tracked through platform health indicators for the VM.

Within a region:

- VMs in different Availability Zones aren't updated concurrently with the same update.
- VMs that aren't part of an availability set are batched on a best effort basis to avoid concurrent updates for all VMs in a subscription.

Within an availability set:

- All VMs in a common availability set aren't updated concurrently.
- VMs in a common availability set are updated within Update Domain boundaries and VMs across multiple Update Domains aren't updated concurrently.

- In an Update Domain, no more than 20% of the VMs within an availability set are be updated at a time. For availability sets with fewer than 10 VMs, VMs update one at a time within an Update Domain.

Restricting the number of concurrently patched VMs across regions, within a region, or within an availability set limits the impact of a faulty patch on a given set of VMs. With health monitoring, any potential issues are flagged before they impact the entire workload.

The patch installation date for a given VM may vary month-to-month, as a specific VM may be picked up in a different batch between monthly patching cycles.

Which patches are installed?

The patches installed depend on the rollout stage for the VM. Every month, a new global rollout is started where all security and critical patches assessed for an individual VM are installed for that VM. The rollout is orchestrated across all Azure regions in batches.

The exact set of patches to be installed vary based on the VM configuration, including OS type, and assessment timing. It's possible for two identical VMs in different regions to get different patches installed if there are more or less patches available when the patch orchestration reaches different regions at different times. Similarly, but less frequently, VMs within the same region but assessed at different times (due to different Availability Zone or Availability Set batches) might get different patches.

As the Automatic VM Guest Patching doesn't configure the patch source, two similar VMs configured to different patch sources, such as public repository vs private repository, may also see a difference in the exact set of patches installed.

For OS types that release patches on a fixed cadence, VMs configured to the public repository for the OS can expect to receive the same set of patches across the different rollout phases in a month. For example, Windows VMs configured to the public Windows Update repository.

As a new rollout is triggered every month, a VM receives at least one patch rollout every month if the VM is powered on during off-peak hours. This process ensures that the VM is patched with the latest available security and critical patches on a monthly basis. To ensure consistency in the set of patches installed, you can configure your VMs to assess and download patches from your own private repositories.

Supported OS images

> **Important**

Automatic VM guest patching, on-demand patch assessment and on-demand patch installation are supported only on VMs created from images with the exact combination of publisher, offer and sku from the below supported OS images list. Custom images or any other publisher, offer, sku combinations aren't supported. More images are added periodically. Don't see your SKU in the list? Request support by filing out Image Support Request.

Patch orchestration modes

VMs on Azure now support the following patch orchestration modes:

AutomaticByPlatform (Azure-orchestrated patching):

- This mode is supported for both Linux and Windows VMs.
- This mode enables automatic VM guest patching for the virtual machine and subsequent patch installation is orchestrated by Azure.
- During the installation process, this mode assesses the VM for available patches and save the details in Azure Resource Graph.
- This mode is required for availability-first patching.
- This mode is only supported for VMs that are created using the supported OS platform images above.
- For Windows VMs, setting this mode also disables the native Automatic Updates on the Windows virtual machine to avoid duplication.
- To use this mode on Linux VMs, set the property `osProfile.linuxConfiguration.patchSettings.patchMode=AutomaticByPlatform` in the VM template.
- To use this mode on Windows VMs, set the property `osProfile.windowsConfiguration.patchSettings.patchMode=AutomaticByPlatform` in the VM template.
- Enabling this mode sets the Registry Key SOFTWARE\Policies\Microsoft\Windows\WindowsUpdate\AU\NoAutoUpdate to 1

AutomaticByOS:

- This mode is supported only for Windows VMs.
- This mode enables Automatic Updates on the Windows virtual machine, and patches are installed on the VM through Automatic Updates.
- This mode doesn't support availability-first patching.
- This mode is set by default if no other patch mode is specified for a Windows VM.
- To use this mode on Windows VMs, set the property `osProfile.windowsConfiguration.enableAutomaticUpdates=true`, and set the property `osProfile.windowsConfiguration.patchSettings.patchMode=AutomaticByOS` in the VM template.
- Enabling this mode sets the Registry Key SOFTWARE\Policies\Microsoft\Windows\WindowsUpdate\AU\NoAutoUpdate to 0

Manual:

- This mode is supported only for Windows VMs.
- This mode disables Automatic Updates on the Windows virtual machine. When deploying a VM using CLI or PowerShell, setting `--enable-auto-updates` to `false` also sets `patchMode` to `manual` and disables Automatic Updates.
- This mode doesn't support availability-first patching.
- This mode should be set when using custom patching solutions.

- To use this mode on Windows VMs, set the property `osProfile.windowsConfiguration.enableAutomaticUpdates=false`, and set the property `osProfile.windowsConfiguration.patchSettings.patchMode=Manual` in the VM template.
- Enabling this mode sets the Registry Key SOFTWARE\Policies\Microsoft\Windows\WindowsUpdate\AU\NoAutoUpdate to 1

ImageDefault:

- This mode is supported only for Linux VMs.
- This mode doesn't support availability-first patching.
- This mode honors the default patching configuration in the image used to create the VM.
- This mode is set by default if no other patch mode is specified for a Linux VM.
- To use this mode on Linux VMs, set the property `osProfile.linuxConfiguration.patchSettings.patchMode=ImageDefault` in the VM template.

> **Note**
>
> For Windows VMs, the property `osProfile.windowsConfiguration.enableAutomaticUpdates` can only be set when the VM is first created. This impacts certain patch mode transitions. Switching between AutomaticByPlatform and Manual modes is supported on VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=false`. Similarly switching between AutomaticByPlatform and AutomaticByOS modes is supported on VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=true`. Switching between AutomaticByOS and Manual modes isn't supported. Azure recommends that Assessment Mode be enabled on a VM even if Azure Orchestration isn't enabled for patching. This allows the platform to assess the VM every 24 hours for any pending updates, and save the details in Azure Resource Graph. The platform performs assessment to report consolidated results when the machine's desired patch configuration state is applied or confirmed. This is reported as a 'Platform'-initated assessment.

Requirements for enabling automatic VM guest patching

- The virtual machine must have the Azure VM Agent for Windows or Linux installed.
- For Linux VMs, the Azure Linux agent must be version 2.2.53.1 or higher. Update the Linux agent if the current version is lower than the required version.
- For Windows VMs, the Windows Update service must be running on the virtual machine.

- The virtual machine must be able to access the configured update endpoints. If your virtual machine is configured to use private repositories for Linux or Windows Server Update Services (WSUS) for Windows VMs, the relevant update endpoints must be accessible.
- Use Compute API version 2021-03-01 or higher to access all functionality including on-demand assessment and on-demand patching.
- Custom images aren't currently supported.
- VMSS Flexible Orchestration requires the installation of Application Health extension. This is optional for IaaS VMs.

Enable automatic VM guest patching

Automatic VM guest patching can be enabled on any Windows or Linux VM that is created from a supported platform image.

REST API for Linux VMs

The following example describes how to enable automatic VM guest patching:

```
PUT on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVirtualMachine?api-version=2020-12-01`
```

JSON

```
{
  "location": "<location>",
  "properties": {
    "osProfile": {
      "linuxConfiguration": {
        "provisionVMAgent": true,
        "patchSettings": {
          "patchMode": "AutomaticByPlatform"
        }
      }
    }
  }
}
```

REST API for Windows VMs

The following example describes how to enable automatic VM guest patching:

```
PUT on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVirtualMachine?api-version=2020-12-01`
```

JSON

```
{
  "location": "<location>",
  "properties": {
    "osProfile": {
      "windowsConfiguration": {
        "provisionVMAgent": true,
        "enableAutomaticUpdates": true,
        "patchSettings": {
          "patchMode": "AutomaticByPlatform"
        }
      }
    }
  }
}
```

Azure PowerShell when creating a Windows VM

Use the Set-AzVMOperatingSystem cmdlet to enable automatic VM guest patching when creating a VM.

Azure PowerShell

```
Set-AzVMOperatingSystem -VM $VirtualMachine -Windows -ComputerName $ComputerName -Credential $Credential -ProvisionVMAgent -EnableAutoUpdate -PatchMode "AutomaticByPlatform"
```

Azure PowerShell when updating a Windows VM

Use the Set-AzVMOperatingSystem and Update-AzVM cmdlet to enable automatic VM guest patching on an existing VM.

Azure PowerShell

```
$VirtualMachine = Get-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM"
Set-AzVMOperatingSystem -VM $VirtualMachine -PatchMode "AutomaticByPlatform"
Update-AzVM -ResourceGroupName "myResourceGroup" -VM $VirtualMachine
```

Azure CLI for Windows VMs

Use az vm create to enable automatic VM guest patching when creating a new VM. The following example configures automatic VM guest patching for a VM named *myVM* in the resource group named *myResourceGroup*:

Azure CLI

```
az vm create --resource-group myResourceGroup --name myVM --image Win2019Datacenter
--enable-agent --enable-auto-update --patch-mode AutomaticByPlatform
```

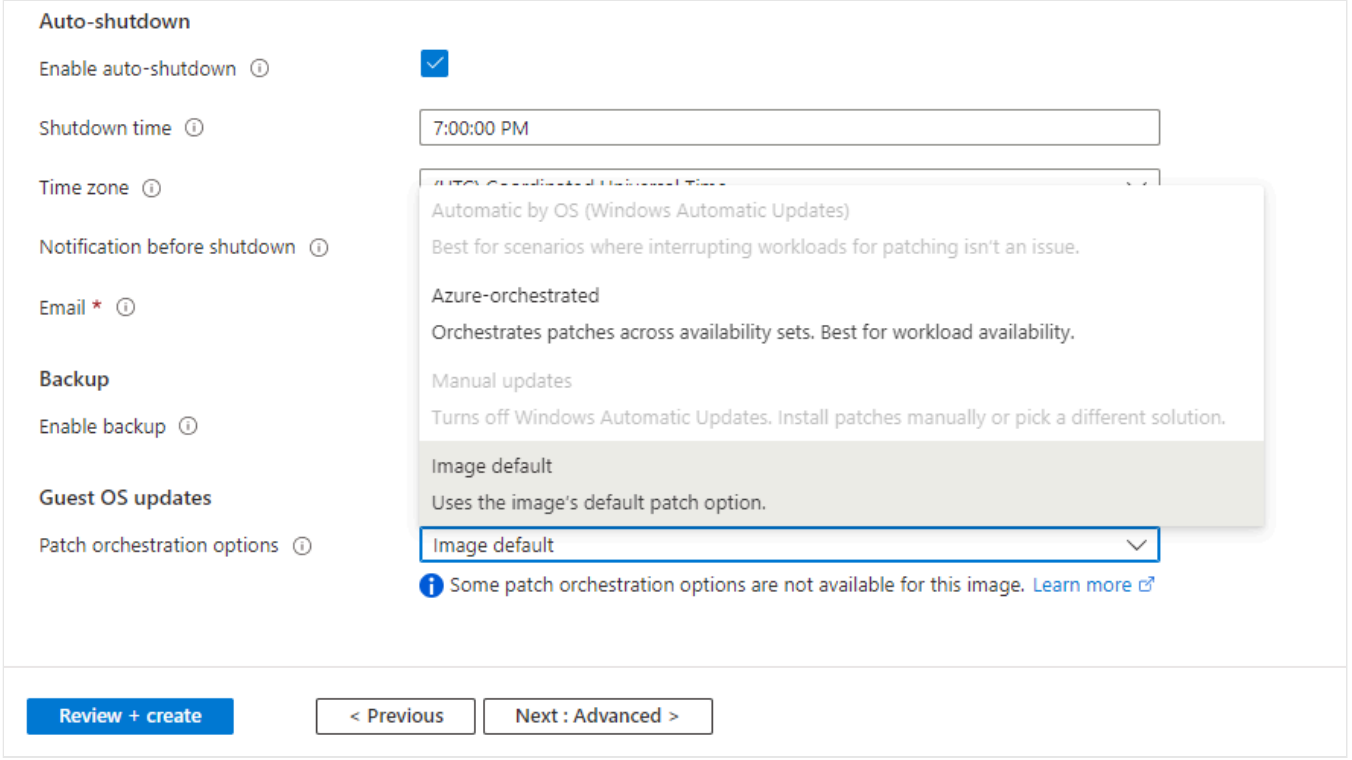
To modify an existing VM, use az vm update

Azure CLI

```
az vm update --resource-group myResourceGroup --name myVM --set
osProfile.windowsConfiguration.enableAutomaticUpdates=true
osProfile.windowsConfiguration.patchSettings.patchMode=AutomaticByPlatform
```

Azure portal

When creating a VM using the Azure portal, patch orchestration modes can be set under the **Management** tab for both Linux and Windows.



Enablement and assessment

> **Note**

It can take more than three hours to enable automatic VM guest updates on a VM, as the enablement is completed during the VM's off-peak hours. As assessment and patch installation occur only during off-peak hours, your VM must be also be running during off-peak hours to apply patches.

When automatic VM guest patching is enabled for a VM, a VM extension of type `Microsoft.CPlat.Core.LinuxPatchExtension` is installed on a Linux VM or a VM extension of type `Microsoft.CPlat.Core.WindowsPatchExtension` is installed on a Windows VM. This extension doesn't need to be manually installed or updated, as this extension is managed by the Azure platform as part of the automatic VM guest patching process.

It can take more than three hours to enable automatic VM guest updates on a VM, as the enablement is completed during the VM's off-peak hours. The extension is also installed and updated during off-peak hours for the VM. If the VM's off-peak hours end before enablement can be completed, the enablement process resumes during the next available off-peak time.

The platform makes periodic patching configuration calls to ensure alignment when model changes are detected on IaaS VMs or scale sets in Flexible orchestration. Certain model changes such as, but not limited to, updating assessment mode, patch mode, and extension update may trigger a patching configuration call.

Automatic updates are disabled in most scenarios, and patch installation is done through the extension going forward. The following conditions apply.

- If a Windows VM previously had Automatic Windows Update turned on through the AutomaticByOS patch mode, then Automatic Windows Update is turned off for the VM when the extension is installed.
- For Ubuntu VMs, the default automatic updates are disabled automatically when Automatic VM Guest Patching completes enablement.
- For RHEL, automatic updates need to be manually disabled. Execute:

Bash

```
sudo systemctl stop packagekit
```

Bash

```
sudo systemctl mask packagekit
```

To verify whether automatic VM guest patching has completed and the patching extension is installed on the VM, you can review the VM's instance view. If the enablement process is complete, the extension is installed and the assessment results for the VM are available under

`patchStatus`. The VM's instance view can be accessed through multiple ways as described below.

REST API

```
GET on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVirtualMachine/instanceView?api-version=2020-12-01`
```

Azure PowerShell

Use the Get-AzVM cmdlet with the `-Status` parameter to access the instance view for your VM.

Azure PowerShell

```
Get-AzVM -ResourceGroupName "myResourceGroup" -Name "myVM" -Status
```

PowerShell currently only provides information on the patch extension. Information about `patchStatus` will also be available soon through PowerShell.

Azure CLI

Use az vm get-instance-view to access the instance view for your VM.

Azure CLI

```
az vm get-instance-view --resource-group myResourceGroup --name myVM
```

Understanding the patch status for your VM

The `patchStatus` section of the instance view response provides details on the latest assessment and the last patch installation for your VM.

The assessment results for your VM can be reviewed under the `availablePatchSummary` section. An assessment is periodically conducted for a VM that has automatic VM guest patching enabled. The count of available patches after an assessment is provided under `criticalAndSecurityPatchCount` and `otherPatchCount` results. Automatic VM guest patching installs all patches assessed under the *Critical* and *Security* patch classifications. Any other assessed patch is skipped.

The patch installation results for your VM can be reviewed under the `lastPatchInstallationSummary` section. This section provides details on the last patch installation attempt on the VM, including the number of patches that were installed, pending, failed, or skipped. Patches are installed only during the off-peak hours maintenance window for the VM. Pending and failed patches are automatically retried during the next off-peak hours maintenance window.

Disable automatic VM guest patching

Automatic VM guest patching can be disabled by changing the patch orchestration mode for the VM.

To disable automatic VM guest patching on a Linux VM, change the patch mode to `ImageDefault`.

To enable automatic VM guest patching on a Windows VM, the property `osProfile.windowsConfiguration.enableAutomaticUpdates` determines which patch modes can be set on the VM and this property can only be set when the VM is first created. This impacts certain patch mode transitions:

- For VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=false`, disable automatic VM guest patching by changing the patch mode to `Manual`.
- For VMs that have `osProfile.windowsConfiguration.enableAutomaticUpdates=true`, disable automatic VM guest patching by changing the patch mode to `AutomaticByOS`.
- Switching between AutomaticByOS and Manual modes isn't supported.

Use the examples from the enablement section above in this article for API, PowerShell and CLI usage examples to set the required patch mode.

On-demand patch assessment

If automatic VM guest patching is already enabled for your VM, a periodic patch assessment is performed on the VM during the VM's off-peak hours. This process is automatic and the results of the latest assessment can be reviewed through the VM's instance view as described earlier in this document. You can also trigger an on-demand patch assessment for your VM at any time. Patch assessment can take a few minutes to complete and the status of the latest assessment is updated on the VM's instance view.

> ⓘ **Note**

On-demand patch assessment doesn't automatically trigger patch installation. If you have enabled automatic VM guest patching, then the assessed and applicable patches for the VM are installed during the VM's off-peak hours, following the availability-first patching process described earlier in this document.

REST API

Use the Assess Patches API to assess available patches for your virtual machine.

```
POST on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVirtualMachine/assessPatches?api-version=2020-12-01`
```

Azure PowerShell

Use the Invoke-AzVmPatchAssessment cmdlet to assess available patches for your virtual machine.

Azure PowerShell

```
Invoke-AzVmPatchAssessment -ResourceGroupName "myResourceGroup" -VMName "myVM"
```

Azure CLI

Use az vm assess-patches to assess available patches for your virtual machine.

Azure CLI

```
az vm assess-patches --resource-group myResourceGroup --name myVM
```

On-demand patch installation

If automatic VM guest patching is already enabled for your VM, a periodic patch installation of Security and Critical patches is performed on the VM during the VM's off-peak hours. This process is automatic and the results of the latest installation can be reviewed through the VM's instance view as described earlier in this document.

You can also trigger an on-demand patch installation for your VM at any time. Patch installation can take a few minutes to complete and the status of the latest installation is

updated on the VM's instance view.

You can use on-demand patch installation to install all patches of one or more patch classifications. You can also choose to include or exclude specific packages for Linux or specific KB IDs for Windows. When triggering an on-demand patch installation, ensure that you specify at least one patch classification or at least one patch (package for Linux, KB ID for Windows) in the inclusion list.

REST API

Use the Install Patches API to install patches on your virtual machine.

```
POST on
`/subscriptions/subscription_id/resourceGroups/myResourceGroup/providers/Microsoft.Compute/virtualMachines/myVirtualMachine/installPatches?api-version=2020-12-01`
```

Example request body for Linux:

JSON

```
{
  "maximumDuration": "PT1H",
  "Setting": "IfRequired",
  "linuxParameters": {
    "classificationsToInclude": [
      "Critical",
      "Security"
    ]
  }
}
```

Example request body for Windows:

JSON

```
{
  "maximumDuration": "PT1H",
  "rebootSetting": "IfRequired",
  "windowsParameters": {
    "classificationsToInclude": [
      "Critical",
      "Security"
    ]
  }
}
```

Azure PowerShell

Use the Invoke-AzVMInstallPatch cmdlet to install patches on your virtual machine.

Example to install certain packages on a Linux VM:

Azure PowerShell

```
Invoke-AzVmInstallPatch -ResourceGroupName "myResourceGroup" -VMName "myVM" -
MaximumDuration "PT90M" -RebootSetting "Always" -Linux -
ClassificationToIncludeForLinux "Security" -PackageNameMaskToInclude ["package123"]
-PackageNameMaskToExclude ["package567"]
```

Example to install all Critical patches on a Windows VM:

Azure PowerShell

```
Invoke-AzVmInstallPatch -ResourceGroupName "myResourceGroup" -VMName "myVM" -
MaximumDuration "PT2H" -RebootSetting "Never" -Windows   -
ClassificationToIncludeForWindows Critical
```

Example to install all Security patches on a Windows VM, while including and excluding patches with specific KB IDs and excluding any patch that requires a reboot:

Azure PowerShell

```
Invoke-AzVmInstallPatch -ResourceGroupName "myResourceGroup" -VMName "myVM" -
MaximumDuration "PT90M" -RebootSetting "Always" -Windows -
ClassificationToIncludeForWindows "Security" -KBNumberToInclude ["KB1234567",
"KB123567"] -KBNumberToExclude ["KB1234702", "KB1234802"] -ExcludeKBsRequiringReboot
```

Azure CLI

Use az vm install-patches to install patches on your virtual machine.

Example to install all Critical patches on a Linux VM:

Azure CLI

```
az vm install-patches --resource-group myResourceGroup --name myVM --maximum-
duration PT2H --reboot-setting IfRequired --classifications-to-include-linux
Critical
```

Example to install all Critical and Security patches on a Windows VM, while excluding any patch that requires a reboot:

Azure CLI

```
az vm install-patches --resource-group myResourceGroup --name myVM --maximum-duration PT2H --reboot-setting IfRequired --classifications-to-include-win Critical Security --exclude-kbs-requiring-reboot true
```

Strict Safe Deployment on Canonical Images

Microsoft and Canonical have partnered to make it easier for our customers to stay current with Linux OS updates and increase the security and resiliency of their Ubuntu workloads on Azure. By using Canonical's snapshot service, Azure now applies the same set of Ubuntu updates consistently to your fleet across regions.

Azure stores the package related updates within the customer repository for up to 90 days, depending on the available space. This allows customers to update their fleet leveraging Strict Safe Deployment for VMs that are up to three months behind on updates.

There's no action required for customers that have enabled Auto Patching. The platform installs a package that is snapped to a point-in-time by default. In the event a snapshot-based update can't be installed, Azure applies the latest package on the VM to ensure the VM remains secure. The point-in-time updates are consistent on all VMs across regions to ensure homogeneity. Customers can view the published date information related to the applied update in Azure Resource Graph and the Instance View of the VM.

Image End-of-Life (EOL)

Publishers may no longer support generating new updates for their images after a certain date. This is commonly referred to as End-of-life (EOL) for the image. Azure doesn't recommend using images after their EOL date, since it exposes the service to security vulnerabilities or performance issues. The Azure Guest Patching Service (AzGPS) communicates necessary steps for customers and impacted partners. AzGPS removes the image from the support list after the EOL date. VMs that use an end of life image on Azure might continue to work beyond their date. However, any issues experienced by these VMs aren't eligible for support.

Last updated on 12/01/2025

Hotpatch for Windows Server

07/17/2025Applies to: ✅ Windows Server 2025, ✅ Windows Server 2022

Hotpatching is a way to install OS security updates on Windows Server without having to restart your machine. Hotpatching patches the in-memory code of running processes without the need to restart the process. Hotpatching also provides the following benefits:

- Fewer binaries mean updates install faster and consume less disk and CPU resources.
- Lower workload impact with less need to restart your machine.
- Better protection, as the Hotpatch update packages are scoped to Windows security updates that install faster without requiring you to restart your machine.
- Reduces the time exposed to security risks and change windows, and easier patch orchestration with Azure Update Manager.

Supported platforms

Azure and Azure Local virtual machines

The following table lists the exact combinations of publisher, OS offer, and SKU that support Hotpatching for Windows Server 2022 and Windows Server 2025 on Azure. Virtual machines (VMs) you create on Azure Local using these combinations also support Hotpatching.

> **Note**
>
> Windows Server container base images, custom images, or any other combination of publisher, offer, and SKU aren't supported.

Expand table

Publisher	OS Offer	SKU
MicrosoftWindowsServer	WindowsServer	2022-Datacenter-Azure-Edition-Core
MicrosoftWindowsServer	WindowsServer	2022-Datacenter-Azure-Edition-Core-smalldisk
MicrosoftWindowsServer	WindowsServer	2022-Datacenter-Azure-Edition-Hotpatch
MicrosoftWindowsServer	WindowsServer	2022-Datacenter-Azure-Edition-Hotpatch-smalldisk
MicrosoftWindowsServer	WindowsServer	2025-Datacenter-Azure-Edition

Publisher	OS Offer	SKU
MicrosoftWindowsServer	WindowsServer	2025-Datacenter-Azure-Edition-smalldisk
MicrosoftWindowsServer	WindowsServer	2025-Datacenter-Azure-Edition-Core
MicrosoftWindowsServer	WindowsServer	2025-Datacenter-Azure-Edition-Core-smalldisk

For more information about the available images, see Windows Server on Azure Marketplace.

Azure Arc-connected machines

> **Important**
>
> Azure Arc-enabled Hotpatch for Windows Server 2025 is now available for a monthly subscription fee. To learn more about pricing, see Tired of all the restarts? Get hotpatching for Windows Server.

Azure Arc-connected Windows Server 2025 machines can receive Hotpatches if you enable the feature on Azure Arc Portal. To start using Azure Arc-enabled Hotpatch, connect Azure Arc to machines using one of the following editions:

- Windows Server 2025 Datacenter Edition
- Windows Server 2025 Standard Edition

How Hotpatch works

Hotpatch first establishes a baseline with the current Cumulative Update for Windows Server. Every three months, the baseline periodically refreshes with the latest Cumulative Update. You then receive Hotpatch releases for the next two months after the Cumulative Update. For example, if January is a Cumulative Update, February and March would have Hotpatch releases. For more information about the Hotpatch release schedule, see the Windows Server Hotpatch Calendar.

There are two types of baselines: **Planned baselines** and **Unplanned baselines**.

- **Planned baselines** are released on a regular cadence, with Hotpatch releases in between. Planned baselines include all the updates in a comparable Latest Cumulative Update for that month and require you to restart your machine.

    - For example, a planned one year release period might include four planned baseline releases in a calendar year and eight Hotpatch releases.

- **Unplanned baselines** are released during an unplanned important update, such as a zero-day fix, when that particular update can't be released as a Hotpatch. When unplanned baselines release, a Hotpatch release is replaced with an unplanned baseline for that month. Unplanned baselines also include all the updates in a comparable Latest Cumulative Update for that month, and therefore require you to restart your machine.
    - Because these events are unplanned, developers can't predict unplanned baselines in advance.

Hotpatch updates don't require you to restart your machine. Because Hotpatches patch the in-memory code of running processes without needing to restart them, your applications aren't affected. This lack of restarting doesn't affect the performance or functionality implications of the patch itself.

Supported updates

Hotpatch covers Windows Security updates and maintains parity with the content of security updates issued to in the regular non-Hotpatch Windows update channel.

There are a few important things you need to consider when enabling Hotpatch on a supported version of Windows Server. You still need to restart your machine to install updates that aren't included in the Hotpatch program. You also need to periodically restart after installing a new baseline. Restarting keeps your VM in sync with nonsecurity patches included in the latest cumulative updates.

The following patches currently aren't included in the Hotpatch program and require you to update your machine during Hotpatch release months:

- Nonsecurity updates for Windows
- .NET updates
- Non-Windows updates, such as drivers, firmware updates, and so on.

Patch orchestration process

Hotpatch is an extension of Windows Update and typical management processes. However, the tools for patch management vary depending on which platform you're using.

Azure

- VMs you create in Azure using a supported Windows Server image have Automatic VM Guest Patching enabled by default.
- Hotpatch automatically downloads and applies patches classified as Critical or Security to your VM.
- Hotpatch applies patches during off-peak hours in the VM time zone.
- Azure manages patches for you, applying patches according to availability-first principles.
- Azure monitors VM health through platform health signals to detect patching failures.

> **Note**
>
> You can't create Azure Virtual Machine Scale Sets with Uniform orchestration on Azure Edition images with Hotpatch. To learn more about which features Uniform orchestration for scale sets supports, see A comparison of Flexible, Uniform, and availability sets.

Azure Local

Azure Local can orchestrate Hotpatch updates for VMs using the following tools:

- Group Policy configures Windows Update client settings.
- SCONFIG configures Windows Update client settings for Server Core.
- Non-Microsoft patch management solutions.

Azure Arc-connected machines

Azure Arc-connected machines can install and manage Hotpatch updates using the following tools:

- Azure Update Manager
- Group Policy configures Windows Update client settings.
- SCONFIG configures Windows Update client settings for Server Core.
- Non-Microsoft patch management solutions.

For more information about which tools Hotpatch uses, check out our Azure Update Manager documentation.

Understand the patch status for your VM in Azure

To view the patch status for your VM, open the Overview page for your VM in the Azure portal. From there, under **Operations**, select **Updates**. You should see the patch status and most recently installed patches under **Recommended updates**.

In the **Recommended updates** page, you can see the Hotpatch status of your VM and if there are any available patches for your VM. As we stated in How Hotpatch works, Automatic VM Guest Patching automatically installs all Critical and Security patches on your VM.

Patches outside of those two categories aren't automatically installed, and are instead displayed in the **Update compliance** tab as a list of available patches. You can also check the **Update history** tab to view patch installation details for update deployments on your VM from the past 30 days.

Automatic VM Guest Patching regularly runs assessments of available patches, which you can view in the **Updates** tab. You can manually start an assessment by selecting the **Assess Now** button. You can also install patches on-demand by selecting the **Install updates now** button. This option lets you choose whether to install all updates under specific patch classifications. You can also select individual updates to include or exclude by providing a list of knowledge base articles. However, keep in mind that patches you install manually don't follow availability-first principles and might require you to restart your VM.

You can also view installed patches by running the Get-HotFix cmdlet in PowerShell or by viewing the **Settings** menu in Desktop Experience.

Rollback support for Hotpatching

Hotpatch updates don't support automatic rollback. If you experience an issue during or after an update, you must uninstall the latest update and install the last functional baseline update. This process requires that you restart the VM.

Next steps

- Enable Hotpatch for Azure Arc-enabled servers
- Automatic VM Guest Patching
- Enable Hotpatch for Azure Edition virtual machines built from ISO
- Azure Update Management

Automatic Extension Upgrade for virtual machines and scale sets in Azure

07/24/2025

Automatic Extension Upgrade is available for Azure Virtual Machines and Azure Virtual Machine Scale Sets. When Automatic Extension Upgrade is enabled on a virtual machine (VM) or scale set, Azure automatically monitors for new extension versions, assess the quality & safety of the new version, approves the version for rollout and then automatically upgrades all VMs using the extension. Azure upgrades all the VMs gradually following Safe Deployment Practices (SDP) to prevent bad version from causing outage and ensure high availabilty for applications. This gradual rollout can take 1-2 months to complete based on time required for assessment, the severity of the upgrade and the scale of VMs needed to be upgraded.

Automatic Extension Upgrade has the following features:

- Azure VMs, virtual machine scale sets and Arc VMs are supported.
- Upgrades are applied in an availability-first deployment model following (Safe Deployment Practices)[/azure/well-architected/operational-excellence/safe-deployments] (SDP).
- For a virtual machine scale set, by default, no more than 20% of the scale set VMs are upgraded in a single batch. This batch size can be changed by defining VMSS Rolling Upgrade Policy.
- For Azure VMs & Arc VMs, no more than 20% of the VMs are upgraded in a single batch. This batch size cannot be changed.
- All failed upgrades are automatically rolled back to try and bring the VM back to healthy state.
- All upgrades are rebootless. Therefore VM does not need a reboot after the upgrade.
- All VM sizes are supported.
- Both Windows and Linux extensions are compatible.
- Automatic upgrades are enabled by default starting API version `2025-04-01`.
- Each supported extension is enrolled individually. You can choose which extensions to upgrade automatically.
- All public, sovereign and airgapped cloud regions are supported.

How does Automatic Extension Upgrade work?

The extension upgrade process removes the existing extension on a VM and reinstalls the extension with the new version.

1. When the extension publisher publishes a new version of the same extension, Azure detects the new version and starts a quality assessment process. This process validates the version for security, quality and safe upgrades without failures. The version is approved for rollout once it passes the assessment.
2. Azure starts with one region or zone (Rollout starts from canary region) and once it is completely upgraded, it moves to the next region or zone.
3. Within a region/zone, Azure groups VMs into smaller batches (based on default or rolling upgrade policies) and upgrades one batch at a time. Azure moves to the next batch once the previous batch is successfully upgraded.
4. Azure monitors for VM and App health (using App health extension) after the upgrade to detect failures. If the VM isn't healthy within five minutes of the upgrade, the upgrade is rollback and previous version of the extension is installed. The upgrade is automatically retried after some time without needing customer intervention.

Availability-first Upgrades

The availability-first model for platform-orchestrated upgrades ensures that availability configurations in Azure are respected across multiple availability levels.

For a group of VMs undergoing an upgrade, the Azure platform orchestrates upgrades across regions, within a region, and within a set.

Across regions

- An upgrade moves across Azure globally in a phased manner to prevent Azure-wide deployment failures.
- A phase can have one or more regions, and an upgrade moves across phases only if eligible VMs in the previous phase upgrade successfully.
- Geo-paired regions aren't upgraded concurrently and can't be in the same regional phase.
- The success of an upgrade is measured by tracking the health of a VM post upgrade. VM health is tracked through platform health indicators for the VM (VM health & App Health reported by App Health Extension)

Within a region

- VMs in different availability zones aren't upgraded concurrently with the same upgrade.
- Single VMs that aren't part of an availability set are batched on a best-effort basis to avoid concurrent upgrades for all VMs in a subscription.

Within a set

- All VMs in a common availability set or scale set aren't upgraded concurrently.
- VMs in a common availability set are upgraded within update domain boundaries. VMs across multiple update domains aren't upgraded concurrently.
- VMs in a common virtual machine scale set are grouped in batches and upgraded within update domain boundaries. Upgrade policies defined on the scale set are honored during the upgrade. Each group is upgraded by using a rolling upgrade strategy.

Upgrade process for virtual machine scale sets

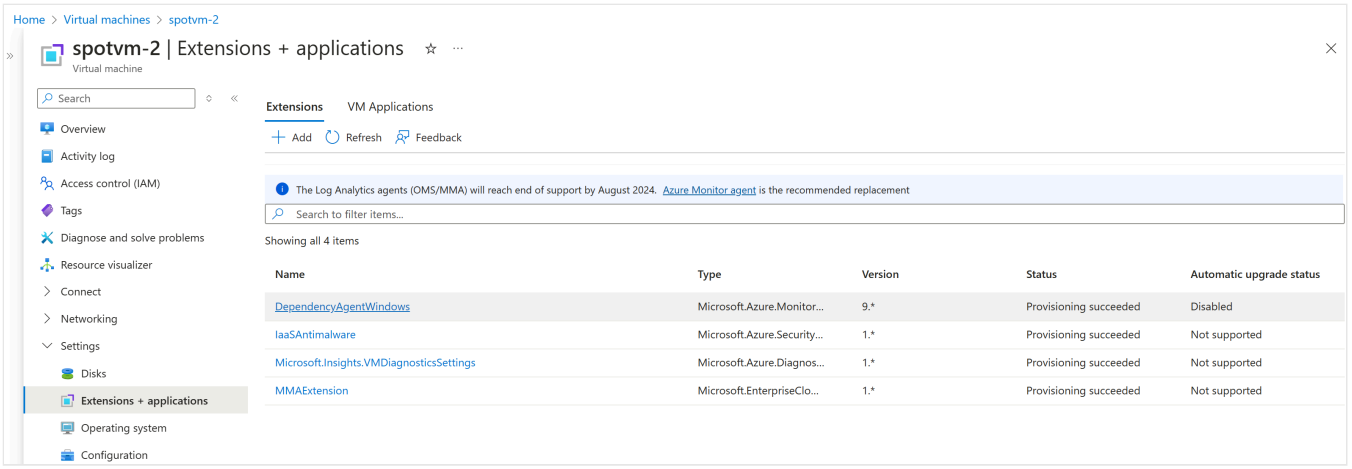
- Before the upgrade process starts, the orchestrator ensures that no more than 20% of VMs in the entire scale set are unhealthy (for any reason).
- The upgrade orchestrator identifies the batch of VM instances to upgrade. An upgrade batch can have a maximum of 20% of the total VM count, subject to a minimum batch size of one VM. The orchestrator considers the definition of the upgrade policy and availability zones while the batch is identified.
- After the upgrade, the VM health is always monitored before moving to the next batch. For scale sets with configured application health probes or the Application Health extension, application health is also monitored. The upgrade waits up to five minutes (or the defined health probe configuration) for the VM to become healthy before upgrading the next batch. If a VM doesn't recover its health after an upgrade, then by default, the previous extension version on the VM is reinstalled.
- The upgrade orchestrator also tracks the percentage of VMs that become unhealthy after an upgrade. The upgrade stops if more than 20% of upgraded instances become unhealthy during the upgrade process.

This process continues until all instances in the scale set are upgraded.

The scale set upgrade orchestrator checks for the overall scale set health before upgrading every batch. During a batch upgrade, other concurrent planned or unplanned maintenance activities could affect the health of your scale set VMs. In such cases, if more than 20% of the scale set's instances become unhealthy, the scale set upgrade stops at the end of the current batch.

Supported extensions

To check if your extensions are supported for automatic upgrade, view Automatic Upgrade status on Azure Portal - Extension blade.



Following are popular extensions supported for automatic upgrades (and more are added periodically):

Expand table

Publisher	Type
Microsoft.Azure.Automation.HybridWorker	HybridWorkerForLinux

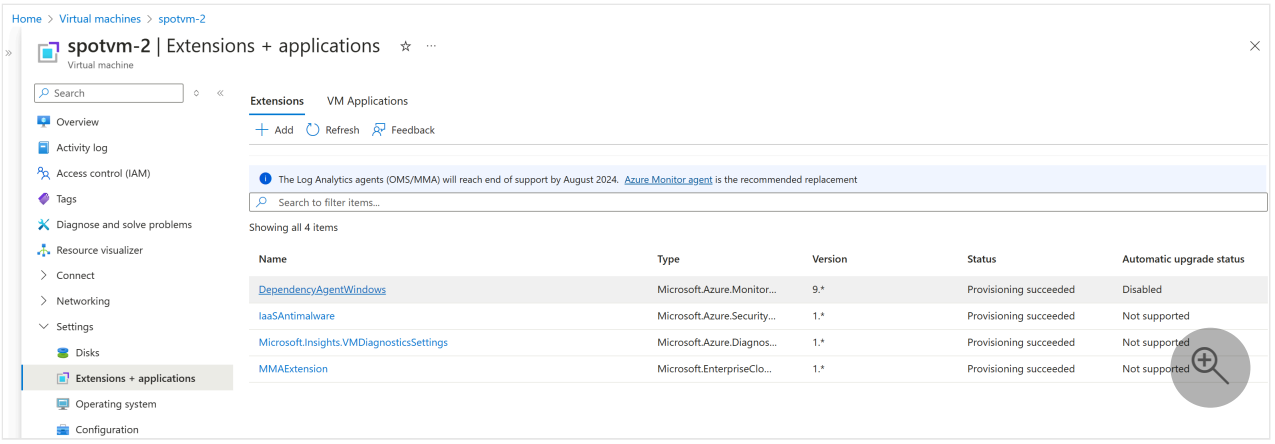
Enable Automatic Extension Upgrade

To enable Automatic Extension Upgrade for an extension, you must ensure that the property `enableAutomaticUpgrade` is set to `true` and added to every extension definition individually.

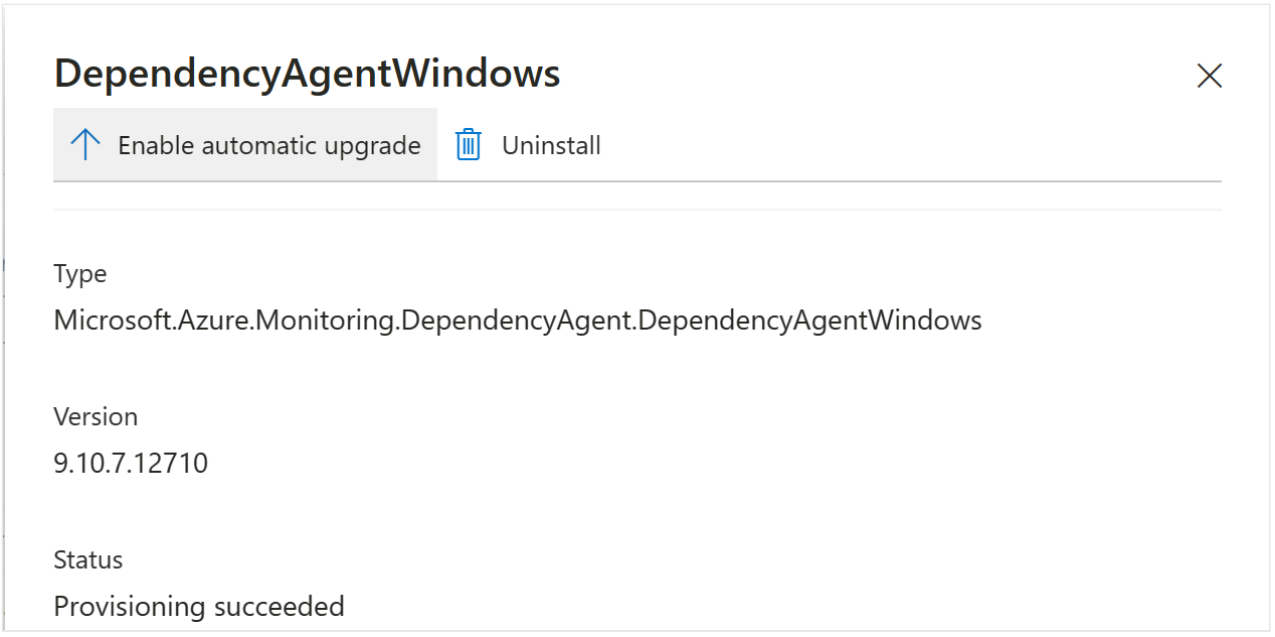
Use the Azure portal

In the Azure portal, use the **Extension** pane to enable automatic upgrade of extensions on existing VMs and virtual machine scale sets.

1. Go to the Virtual Machines or Virtual Machines Scale Sets pane, and select the resource name.
2. Under **Settings**, go to the **Extensions + applications** pane, which shows all extensions installed on the resource. The **Automatic upgrade status** column shows you if the automatic upgrade of the extension is enabled, disabled, or not supported.
3. Select the extension name to open the **Extensions** details pane.



4. Select **Enable automatic upgrade** to enable automatic upgrade of the extension. Use this button to disable an automatic upgrade, if necessary.



For virtual machines

REST API

To enable Automatic Extension Upgrade for an extension (in this example, the Dependency Agent extension) on an Azure VM, use the following call:

```
PUT on
`/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/
Microsoft.Compute/virtualMachines/<vmName>/extensions/<extensionName>?api-
version=2019-12-01`
```

JSON

```
{
    "name": "extensionName",
    "type": "Microsoft.Compute/virtualMachines/extensions",
    "location": "<location>",
    "properties": {
        "autoUpgradeMinorVersion": true,
        "enableAutomaticUpgrade": true,
        "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
        "type": "DependencyAgentWindows",
        "typeHandlerVersion": "9.5"
        }
}
```

For virtual machine scale sets

REST API

```
PUT on
`/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/
Microsoft.Compute/virtualMachineScaleSets/<vmssName>?api-version=2019-12-01`
```

JSON

```
{
   "location": "<location>",
   "properties": {
        "virtualMachineProfile": {
            "extensionProfile": {
                "extensions": [
                {
                "name": "<extensionName>",
                  "properties": {
                        "autoUpgradeMinorVersion": true,
                        "enableAutomaticUpgrade": true,
                    "publisher": "Microsoft.Azure.Monitoring.DependencyAgent",
                    "type": "DependencyAgentWindows",
                    "typeHandlerVersion": "9.5"
                    }
                }
                ]
            }
        }
    }
}
```

> ⓘ Note
>
> These operations set the `enableAutomaticUpgrade` property to `true` on the virtual machine scale set resource but not on the underlying VMs.

If the virtual machine scale set defines automatic or rolling upgrade mode in the upgradeProfile, the virtual machine scale set automatically propagates the change to each underlying VM.

If the virtual machine scale set defines manual mode in the `upgradeProfile`, you also need to manually update each instance and propagate the change to each underlying VM.

Extension upgrades with multiple extensions

A VM or virtual machine scale set can have multiple extensions with Automatic Extension Upgrade enabled. The same VM or scale set can also have other extensions without Automatic Extension Upgrade enabled.

If multiple extension upgrades are available for a VM, the upgrades might be batched together, but each extension upgrade is applied individually on a VM. A failure on one extension doesn't affect the other extensions that might be upgrading. For example, if two extensions are scheduled for an upgrade, and the first extension upgrade fails, the second extension is still upgraded.

You can also apply Automatic Extension Upgrade when a VM or virtual machine scale set has multiple extensions configured with extension sequencing. Extension sequencing is for the first-time deployment of the VM. Any future extension upgrades on an extension are applied independently.

Difference between EnableAutomaticUpgrade and AutoUpgradeMinorVersion

- `AutoUpgradeMinorVersion`:
  - This property is used during VM creation and while you upgrade the VM with a new configuration.
  - When set to `true`, it ensures that the latest minor version of the extension is automatically installed on the VM.
  - It overrides the `TypeHandlerVersion` with the latest stable minor version available.

    - When you upgrade the VM configuration, if a new minor version is available, it's considered a configuration change. The extension is reinstalled with the latest minor version.
    - In this way, newly created VMs keep up to date with the latest stable minor extension version.
    - If you want to manually set the extension to a specific version, set this property to `false`.

- `EnableAutomaticUpgrade`:
    - This property affects existing VMs.
    - It doesn't affect the version installed during VM creation.
    - After VM creation, if the VM isn't running the latest minor version of the extension, enable this property to trigger an automatic upgrade.
    - Upgrades don't cause VM reboot and are rolled out in a safe rolling manner. Failed upgrades are rolled back immediately to provide high service availability and reliability.
    - Existing VMs stay secure and up to date by automatically updating them to the latest minor version.

We recommend that you enable both properties to help keep all VMs secure and up to date.

Upgrades to major extension versions are never performed automatically by either properties because major versions can include breaking changes. You must manually set `TypeHandlerVersion` to a major version and manually upgrade each existing VM to the latest major version.

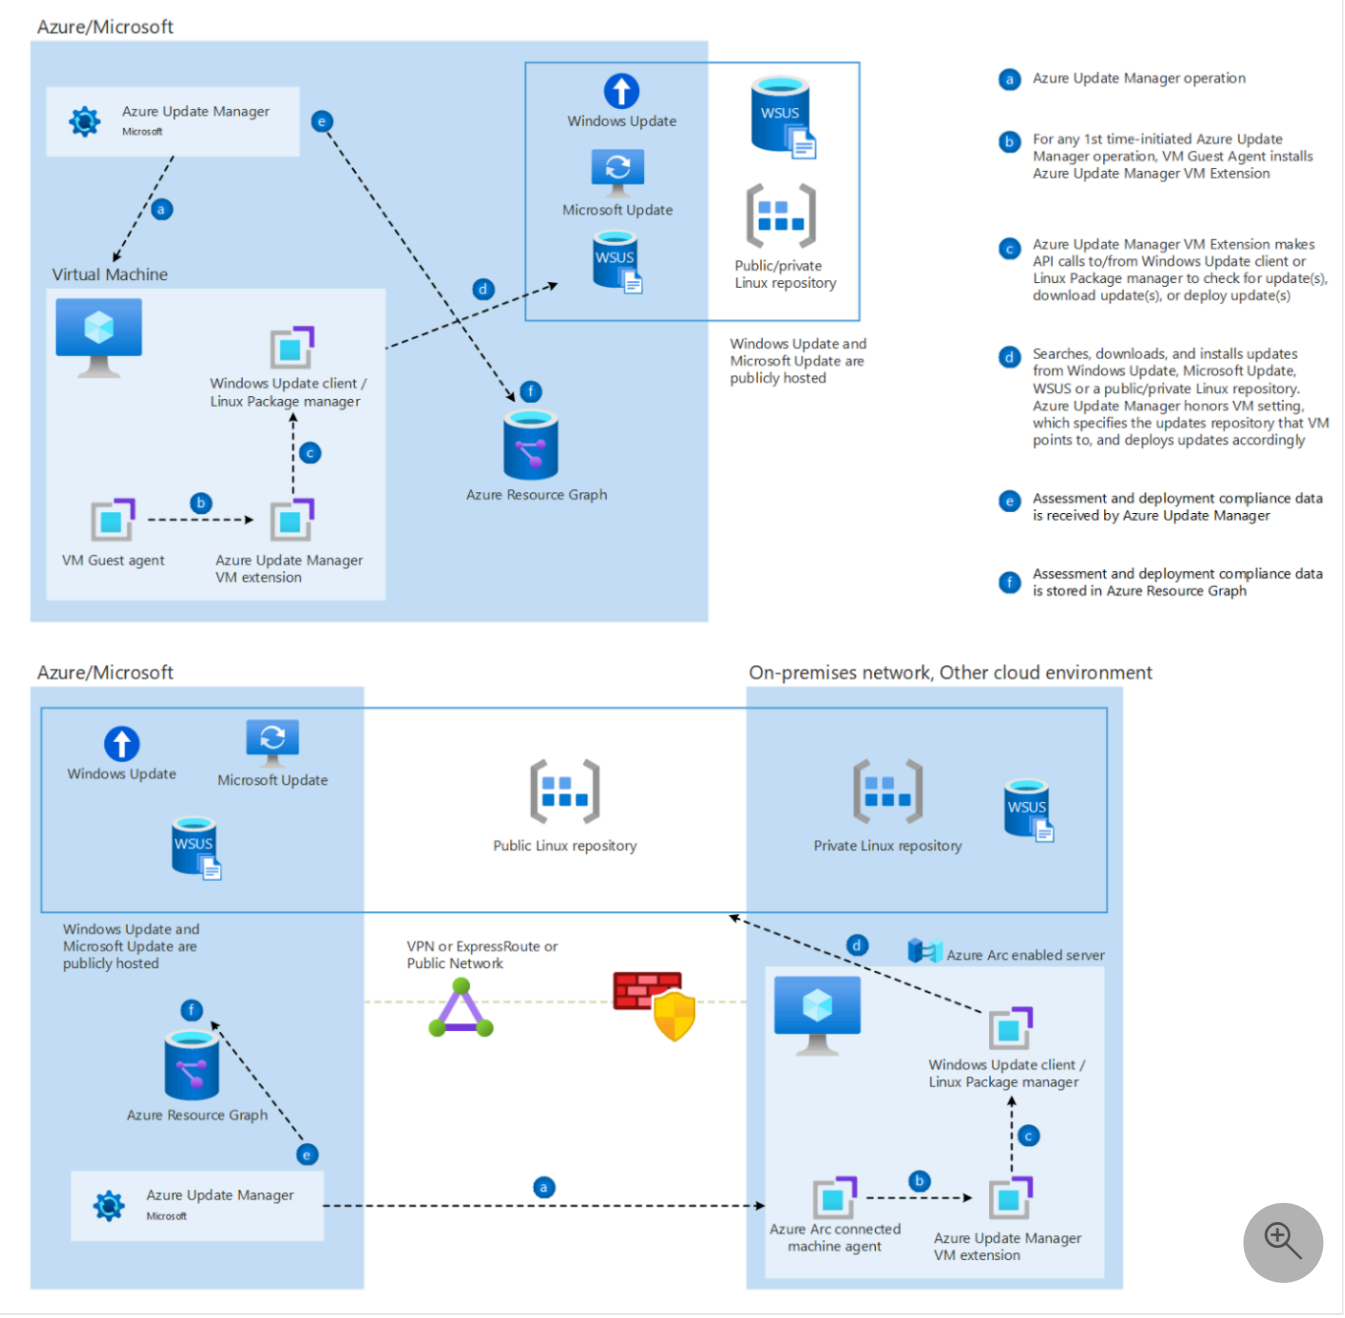
How Update Manager works

Azure Update Manager assesses and applies updates to all Azure virtual machines (VMs) and Azure Arc-enabled servers for both Windows and Linux.



Update Manager VM extensions

When an Update Manager operation is enabled or triggered on your Azure VM or Azure Arc-enabled server, Update Manager installs an Azure extension or Azure Arc-enabled server extensions (respectively) on your machine to manage the updates.

The extensions are automatically installed when you start any Update Manager operation on your machine for the first time. These operations include **Check for updates**, **Install one-time**

update, and **Periodic Assessment**. The extensions are also automatically installed when a scheduled update deployment runs on your machine for the first time.

You don't have to explicitly install the extensions and their lifecycles. Update Manager manages the installation and configuration by using the following agents. These agents are required for Update Manager to work on your machines.

- For Azure VMs: Azure Windows VM Agent or Azure Linux VM Agent
- For Azure Arc-enabled servers: Azure Connected Machine agent

> **Note**
>
> Azure Arc connectivity is a prerequisite for Update Manager and non-Azure machines, including Azure Arc-enabled VMware vSphere and Azure Arc-enabled System Center Virtual Machine Manager.

For Azure machines, Update Manager installs a single extension. For Azure Arc-enabled machines, Update Manager installs two extensions. The following tabs provide details about the extensions:

Azure VM extensions

Expand table

Operating system	Extension
Windows	Microsoft.CPlat.Core.WindowsPatchExtension
Linux	Microsoft.CPlat.Core.LinuxPatchExtension

To view the available extensions for a VM in the Azure portal:

1. Go to the Azure portal and select a VM.
2. On the VM's home page, under **Settings**, select **Extensions + applications**.
3. On the **Extensions** tab, you can view the available extensions.

Update source

Update Manager honors the update source settings on the machine and fetches updates accordingly. Update Manager doesn't publish or provide updates.

Windows

If the Windows Update Agent (WUA) is configured to fetch updates from the Windows Update repository, the Microsoft Update repository, or Windows Server Update Services (WSUS), Update Manager honors these settings. For more information, see Configure Windows Update settings for Azure Update Manager. By default, *WUA is configured to fetch updates from the Windows Update repository*.

Update process

Update Manager performs the following steps:

1. Retrieve the assessment information about the status of system updates specified by the Windows Update client or Linux package manager.
2. Initiate the download and installation of updates by using the Windows Update client or Linux package manager.

The machines report their update status based on the source that they're configured to synchronize with. If the Windows Update service is configured to report to WSUS, the results in Update Manager might differ from what Microsoft Update shows, depending on when WSUS last synchronized with Microsoft Update. This behavior is the same for Linux machines that are configured to report to a local repository instead of a public package repository.

Update Manager finds only updates that the Windows Update service finds when you select the **Check for updates** button on the local Windows system. On Linux systems, Update Manager discovers only updates in the local repository.

Update Manager uses WUA APIs to install updates. The updates installed via WUA APIs don't appear on the Windows Update page within the Settings app on the machine. As a result, the updates installed through Update Manager aren't visible on the Windows Update page in the Settings app. The Windows Update page in the Settings app shows the progress and history of updates that the Windows Update orchestrator workflow manages. Learn more.

Update-related data stored in Azure Resource Graph

The Update Manager extension pushes all the pending update information and update installation results to Azure Resource Graph. Resource Graph retains data for the following time periods:

Expand table

Data	Retention period in Resource Graph
Pending updates (Resource Graph table name: `patchassessmentresources`)	7 days
Update installation results (Resource Graph table name: `patchinstallationresources`)	30 days

For more information, see the log structure of Azure Resource Graph and sample queries.

Installation of patches in Update Manager

Update Manager installs patches in the following manner:

1. Update Manager makes a fresh assessment of the available updates on the VM.
2. For Windows, the selected updates that meet the customer's criteria are installed one by one. For Linux, they're installed in batches.
3. During update installation, Update Manager checks maintenance window utilization at multiple steps.

   For Windows and Linux, 10 and 15 minutes (respectively) of the maintenance window are reserved for reboot at any point. Before Update Manager proceeds with the installation of the remaining updates, it checks whether the expected reboot time plus the average update installation time (for the next update or the next set of updates) doesn't exceed the maintenance window.

   In the case of Windows, the average update installation time is 10 minutes for all types of updates, except for service pack updates. For service pack updates, it's 15 minutes.
4. An ongoing update installation (after it's started based on the preceding calculation) isn't forcibly stopped, even if it exceeds the maintenance window, to avoid landing the machine in a possibly undetermined state. However, Update Manager doesn't install the remaining updates after the maintenance window ends, and it shows a "Maintenance window exceeded" error.
5. Update Manager marks an installation as successful only if all selected updates are installed and all operations involved (including reboot and assessment) succeed. Otherwise, the installation is marked as **Failed** or **Completed with warnings**. For example:

Expand table

Scenario	Update installation status
Installation of one of the selected updates fails.	**Failed**
A reboot doesn't happen for any reason, and the wait time for reboot times out.	**Failed**
The machine fails to start during a reboot.	**Failed**
Initial or final assessment failed.	**Failed**
Updates require a reboot, but the **Never reboot** option is selected.	**Completed with warnings**
ESM packages skipped patching in Ubuntu 18 or earlier if an Ubuntu Pro license wasn't present.	**Completed with warnings**

6. An assessment happens at the end. Sometimes, the reboot and assessment don't happen; for example, if the maintenance window ends or the update installation fails.

Maintenance for virtual machines in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure periodically updates its platform to improve the reliability, performance, and security of the host infrastructure for virtual machines. The purpose of these updates ranges from patching software components in the hosting environment to upgrading networking components or decommissioning hardware.

Updates rarely affect the hosted VMs. When updates do have an effect, Azure chooses the least impactful method for updates:

- If the update doesn't require a reboot, the VM is paused while the host is updated, or the VM is live-migrated to an already updated host.
- If maintenance requires a reboot, you're notified of the planned maintenance. Azure also provides a time window in which you can start the maintenance yourself, at a time that works for you. The self-maintenance window is typically 35 days (for Host machines) unless the maintenance is urgent. Azure is investing in technologies to reduce the number of cases in which planned platform maintenance requires the VMs to be rebooted. For instructions on managing planned maintenance, see Handling planned maintenance notifications using the Azure CLI, PowerShell or portal.

This page describes how Azure performs both types of maintenance. For more information about unplanned events (outages), see Manage the availability of VMs for Windows or the corresponding article for Linux.

Within a VM, you can get notifications about upcoming maintenance by using Scheduled Events for Windows or for Linux.

Maintenance that doesn't require a reboot

Most platform updates don't affect customer VMs. When a no-impact update isn't possible, Azure chooses the update mechanism that's least impactful to customer VMs.

When VM impacting maintenance is required it will almost always be completed through a VM pause for less than 10 seconds. In rare circumstances, no more than once every 18 months for general purpose VM sizes, Azure uses a mechanism that will pause

the VM for about 30 seconds. After any pause operation the VM clock is automatically synchronized upon resume.

Memory-preserving maintenance works for more than 90 percent of Azure VMs. It doesn't work for G, M, N, and H series. Azure increasingly uses live-migration technologies and improves memory-preserving maintenance mechanisms to reduce the pause durations.

These maintenance operations that don't require a reboot are applied one fault domain at a time. They stop if they receive any warning health signals from platform monitoring tools. Maintenance operations that do not require a reboot may occur simultaneously in paired regions or Availability Zones. For a given change, the deployment are mostly sequenced across Availability Zones and across Region pairs, but there can be overlap at the tail.

These types of updates can affect some applications. When the VM is live-migrated to a different host, some sensitive workloads might show a slight performance degradation in the few minutes leading up to the VM pause. To prepare for VM maintenance and reduce impact during Azure maintenance, try using Scheduled Events for Windows or Linux for such applications.

For greater control on all maintenance activities including zero-impact and rebootless updates, you can create a Maintenance Configuration feature. Creating a Maintenance Configuration gives you the option to skip all platform updates and apply the updates at your choice of time. For more information, see Managing platform updates with Maintenance Configurations.

Live migration

Live migration is an operation that doesn't require a reboot and that preserves memory for the VM. It causes a pause or freeze, typically lasting no more than 5 seconds. Except for G, L, N, and H series, all infrastructure as a service (IaaS) VMs, are eligible for live migration. Live Migration is available on majority of M-Series SKUs. Eligible VMs represent more than 90 percent of the IaaS VMs that are deployed to the Azure fleet.

> **Note**
>
> You won't receive a notification in the Azure portal for live migration operations that don't require a reboot. To see a list of live migrations that don't require a reboot, query for scheduled events.

The Azure platform starts live migration in the following scenarios:

- Planned maintenance
- Hardware failure
- Allocation optimizations

Some planned-maintenance scenarios use live migration, and you can use Scheduled Events to know in advance when live migration operations will start.

Live migration can also be used to move VMs when Azure Machine Learning algorithms predict an impending hardware failure or when you want to optimize VM allocations. For more information about predictive modeling that detects instances of degraded hardware, see Improving Azure VM resiliency with predictive machine learning and live migration. Live-migration notifications appear in the Azure portal in the Monitor and Service Health logs as well as in Scheduled Events if you use these services.

Maintenance that requires a reboot

In the rare case where VMs need to be rebooted for planned maintenance, you'll be notified in advance. Planned maintenance has two phases: the self-service phase and a scheduled maintenance phase.

During the *self-service phase*, which typically lasts four weeks, you start the maintenance on your VMs. As part of the self-service, you can query each VM to see its status and the result of your last maintenance request.

> **Note**
>
> For VM-series that do not support **Live Migration**, local (ephemeral) disks data can be lost during the maintenance events. See each individual VM-series for information on if Live Migration is supported.

When you start self-service maintenance, your VM is redeployed to an already updated node. Because the VM is redeployed, the temporary disk is lost and public dynamic IP addresses associated with the virtual network interface are updated.

If an error arises during self-service maintenance, the operation stops, the VM isn't updated, and you get the option to retry the self-service maintenance.

When the self-service phase ends, the *scheduled maintenance phase* begins. During this phase, you can still query for the maintenance phase, but you can't start the maintenance yourself.

For more information on managing maintenance that requires a reboot, see **Handling planned maintenance notifications** using the Azure CLI, PowerShell or portal.

Availability considerations during scheduled maintenance

If you decide to wait until the scheduled maintenance phase, there are a few things you should consider to maintain the highest availability of your VMs.

Paired regions

Each Azure region is paired with another region within the same geographical vicinity. Together, they make a region pair. During the scheduled maintenance phase, Azure updates only the VMs in a single region of a region pair. For example, while updating the VM in North Central US, Azure doesn't update any VM in South Central US at the same time. However, other regions such as North Europe can be under maintenance at the same time as East US. Understanding how region pairs work can help you better distribute your VMs across regions. For more information, see Azure region pairs.

Availability zones

Availability zones are unique physical locations within an Azure region. Each zone is made up of one or more datacenters equipped with independent power, cooling, and networking. To ensure resiliency, there’s a minimum of three separate zones in all enabled regions.

An availability zone is a combination of a fault domain and an update domain. If you create three or more VMs across three zones in an Azure region, your VMs are effectively distributed across three fault domains and three update domains. The Azure platform recognizes this distribution across update domains to make sure that VMs in different zones are not updated at the same time.

Each infrastructure update rolls out zone by zone, within a single region. But, you can have deployment going on in Zone 1, and different deployment going in Zone 2, at the same time. Deployments are not all serialized. But, a single deployment that requires a reboot only rolls out one zone at a time to reduce risk. In general, updates that require a reboot are avoided when possible, and Azure attempts to use Live Migration or provide customers control.

Virtual machine scale sets

Virtual machine scale sets in **Flexible** orchestration mode are an Azure compute resource allow you to combine the scalability of virtual machine scale sets in Uniform orchestration mode with the regional availability guarantees of availability sets.

With Flexible orchestration, you can choose whether your instances are spread across multiple zones, or spread across fault domains within a single region.

Availability sets and Uniform scale sets

When deploying a workload on Azure VMs, you can create the VMs within an *availability set* to provide high availability to your application. Using availability sets, you can ensure that during either an outage or maintenance events that require a reboot, at least one VM is available.

Within an availability set, individual VMs are spread across up to 20 update domains. During scheduled maintenance, only one update domain is updated at any given time. Update domains aren't necessarily updated sequentially.

Virtual machine *scale sets* in **Uniform** orchestration mode are an Azure compute resource that you can use to deploy and manage a set of identical VMs as a single resource. The scale set is automatically deployed across UDs, like VMs in an availability set. As with availability sets, when you use Uniform scale sets, only one UD is updated at any given time during scheduled maintenance.

For more information about setting up your VMs for high availability, see Manage the availability of your VMs for Windows or the corresponding article for Linux.

Next steps

You can use the Azure CLI, Azure PowerShell, or the portal to manage planned maintenance.

Handling planned maintenance notifications

07/09/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure periodically performs updates to improve the reliability, performance, and security of the host infrastructure for virtual machines. Updates are changes like patching the hosting environment or upgrading and decommissioning hardware. A majority of these updates are completed without any impact to the hosted virtual machines. However, there are cases where updates do have an impact:

- If the maintenance doesn't require a reboot, Azure pauses the VM for few seconds while the host is updated. These types of maintenance operations are applied fault domain by fault domain. Progress is stopped if any warning health signals are received.
- If maintenance requires a reboot, you get a notice of when the maintenance is planned. You're given a time window of about 35 days where you can start the maintenance yourself, when it works for you.

Planned maintenance that requires a reboot is scheduled in waves. Each wave has different scope (regions).

- A wave starts with a notification to customers. Virtual Machine related Maintenance notifications are available under Service Health in the Azure portal. For a small subset of Virtual Machine Planned Maintenance specific scenarios, Azure may also communicate the schedule by sending an additional email to the members of Subscription Owners group. Azure Service Health enables users to configure their own custom alerts for the Planned Maintenance category. With Azure Service Health alerts, you can add more recipients and messaging options like email, SMS, and webhooks using Activity Log Alerts.
- Except a subset of event types, the Service Health Planned Maintenance Notification now also has an additional tab "Impacted Resources" which lists the VM names in scope of the event. Read more about Impacted Resources Preview Feature.
- Once a notification goes out, a *self-service window* is made available. During this window, you can query which of your virtual machines are affected and start maintenance based on your own scheduling needs. The self-service window is typically about 35 days.
- After the self-service window, a *scheduled maintenance window* begins. At some point during this window, Azure schedules and applies the required maintenance to your virtual machine.

The goal in having two windows is to give you enough time to start maintenance and reboot your virtual machine while knowing when Azure will automatically start maintenance.

You can use the Azure portal, PowerShell, REST API, and CLI to query for the maintenance windows for your VMs and start self-service maintenance.

Should you start maintenance using during the self-service window?

The following guidelines should help you decide whether to use this capability and start maintenance at your own time.

> **Note**
>
> Self-service maintenance might not be available for all of your VMs. To determine if proactive redeploy is available for your VM, look for the **Start now** in the maintenance status. Self-service maintenance is currently not available for Cloud Services (Web/Worker Role) and Service Fabric.

Self-service maintenance isn't recommended for deployments using **availability sets**. Availability sets are already only updated one update domain at a time.

- Let Azure trigger the maintenance. For maintenance that requires reboot, maintenance will be done update domain by update domain. The update domains don't necessarily receive the maintenance sequentially, and that there's a 30-minute pause between update domains.
- If a temporary loss of some capacity (1 update domain) is a concern, you can add instances during the maintenance period.
- For maintenance that doesn't require reboot, updates are applied at the fault domain level.

Don't use self-service maintenance in the following scenarios:

- If you shut down your VMs frequently, either manually, using DevTest Labs, using auto-shutdown, or following a schedule, it could revert the maintenance status and therefore cause additional downtime.
- On short-lived VMs that you know will be deleted before the end of the maintenance wave.
- For workloads with a large state stored in the local (ephemeral) disk that is desired to be maintained upon update.
- For cases where you resize your VM often, as it could revert the maintenance status.

- If you have adopted scheduled events that enable proactive failover or graceful shutdown of your workload, 15 minutes before start of maintenance shutdown

Use self-service maintenance, if you're planning to run your VM uninterrupted during the scheduled maintenance phase and none of the counter-indications mentioned above are applicable.

It's best to use self-service maintenance in the following cases:

- You need to communicate an exact maintenance window to your management or end-customer.
- You need to complete the maintenance by a given date.
- You need to control the sequence of maintenance, for example, multi-tier application to guarantee safe recovery.
- More than 30 minutes of VM recovery time is needed between two update domains (UDs). To control the time between update domains, you must trigger maintenance on your VMs one update domain (UD) at a time.

FAQ

Q: Why do you need to reboot my virtual machines now?

A: While the majority of updates and upgrades to the Azure platform don't impact virtual machine's availability, there are cases where we can't avoid rebooting virtual machines hosted in Azure. We have accumulated several changes that require us to restart our servers that will result in virtual machines reboot.

Q: If I follow your recommendations for High Availability by using an Availability Set, am I safe?

A: Virtual machines deployed in an availability set or virtual machine scale sets have the notion of Update Domains (UD). When performing maintenance, Azure honors the UD constraint and won't reboot virtual machines from different UD (within the same availability set). Azure also waits for at least 30 minutes before moving to the next group of virtual machines.

For more information about high availability, see Availability for virtual machines in Azure.

Q: How do I get notified about planned maintenance?

A: A planned maintenance wave starts by setting a schedule to one or more Azure regions. Virtual Machine related Maintenance notifications are available under Service Health in the Azure portal. For a small subset of Virtual Machine Planned Maintenance specific scenarios, Azure may also communicate the schedule by sending an additional email to the members of Subscription Owners group.

Except a subset of event types, the Service Health Planned Maintenance Notification now also has an additional tab "Impacted Resources" which lists the VM names in scope of the event. Read more about Impacted Resources Preview Feature.

Azure Service Health enables users to configure their own custom alerts for the Planned Maintenance category. With Azure Service Health alerts you can add more recipients and messaging options like email, SMS, and webhooks using Activity Log Alerts.

In case you deploy a virtual machine to a region where planned maintenance is already scheduled, you won't receive the notification but rather need to check the maintenance state of the VM.

Q: I don't see any indication of planned maintenance in the portal, PowerShell, or CLI. What is wrong?

A: Information related to planned maintenance is available during a planned maintenance wave only for the VMs that are going to be impacted by it. In other words, if you see not data, it could be that the maintenance wave has already completed (or not started) or that your virtual machine is already hosted in an updated server.

Q: Is there a way to know exactly when my virtual machine will be impacted?

A: When setting the schedule, we define a time window of several days. However, the exact sequencing of servers (and VMs) within this window is unknown. Customers who would like to know the exact time for their VMs can use scheduled events and query from within the virtual machine and receive a 15-minute notification before a VM reboot.

Q: How long will it take you to reboot my virtual machine?

A: Depending on the size of your VM, reboot may take up to several minutes during the self-service maintenance window. During the Azure initiated reboots in the scheduled maintenance window, the reboot will typically take about 25 minutes. Note that in case you use Cloud Services (Web/Worker Role), Virtual Machine Scale Sets, or availability sets, you'll be given 30 minutes between each group of VMs (UD) during the scheduled maintenance window.

Q: What is the experience in the case of Virtual Machine Scale Sets?

A: Planned maintenance is now available for Virtual Machine Scale Sets. For instructions on how to initiate self-service maintenance refer planned maintenance for virtual machine scale sets document.

Q: What is the experience in the case of Cloud Services (Web/Worker Role) and Service Fabric?

A: While these platforms are impacted by planned maintenance, customers using these platforms are considered safe given that only VMs in a single Upgrade Domain (UD) will be impacted at any given time. Self-service maintenance is currently not available for Cloud Services (Web/Worker Role) and Service Fabric.

Q: I don't see any maintenance information on my VMs. What went wrong?

A: There are several reasons why you're not seeing any maintenance information on your VMs:

1. You're using a subscription marked as Microsoft internal.
2. Your VMs aren't scheduled for maintenance. It could be that the maintenance wave has ended, canceled, or modified so that your VMs are no longer impacted by it.
3. You have deallocated VM and then started it. This can cause VM to move to a location which doesn't have planned maintenance wave scheduled. So the VM won't show maintenance information any more.
4. You don't have the **Maintenance** column added to your VM list view. While we have added this column to the default view, customers who configured to see non-default columns must manually add the **Maintenance** column to their VM list view.

Q: My VM is scheduled for maintenance for the second time. Why?

A: There are several use cases where you'll see your VM scheduled for maintenance after you have already completed your maintenance-redeploy:

1. We have canceled the maintenance wave and restarted it with a different payload. It could be that we've detected faulted payload and we simply need to deploy an additional payload.
2. Your VM was *service healed* to another node due to a hardware fault.
3. You have selected to stop (deallocate) and restart the VM.
4. You have **auto shutdown** turned on for the VM.

Q: Can I find out exactly when my VM will be rebooted during the planned maintenance window?

A: Azure provides a general maintenance window, but doesn't share the exact time when VM will be rebooted within that window. The reboot can happen at any point during that time. You can utilize self-maintenance window to control the maintenance from your end.

Next steps

You can handle planned maintenance using the Azure CLI, Azure PowerShell or portal.

Handling planned maintenance notifications using the Azure CLI

Article • 08/23/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can use the CLI to see when VMs are scheduled for maintenance. Planned maintenance information is available from az vm get-instance-view.

Maintenance information is returned only if there is maintenance planned.

Azure CLI

```
az vm get-instance-view -n myVM -g myResourceGroup --query
instanceView.maintenanceRedeployStatus
```

Output

```
      "maintenanceRedeployStatus": {
      "additionalProperties": {},
      "isCustomerInitiatedMaintenanceAllowed": true,
      "lastOperationMessage": null,
      "lastOperationResultCode": "None",
      "maintenanceWindowEndTime": "2018-06-04T16:30:00+00:00",
      "maintenanceWindowStartTime": "2018-05-21T16:30:00+00:00",
      "preMaintenanceWindowEndTime": "2018-05-19T12:30:00+00:00",
      "preMaintenanceWindowStartTime": "2018-05-14T12:30:00+00:00"
```

Start maintenance

The following call will start maintenance on a VM if `IsCustomerInitiatedMaintenanceAllowed` is set to true.

Azure CLI

```
az vm perform-maintenance -g myResourceGroup -n myVM
```

Classic deployments

> **Important**
>
> VMs created through the classic deployment model will be retired on September 1, 2023.
>
> If you use IaaS resources from Azure Service Management, please complete your migration by September 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.
>
> For more information, see Migrate your IaaS resources to Azure Resource Manager by September 1, 2023.

If you still have legacy VMs that were deployed using the classic deployment model, you can use the Azure classic CLI to query for VMs and initiate maintenance.

Make sure you are in the correct mode to work with classic VM by typing:

```
azure config mode asm
```

To get the maintenance status of a VM named *myVM*, type:

```
azure vm show myVM
```

To start maintenance on your classic VM named *myVM* in the *myService* service and *myDeployment* deployment, type:

```
azure compute virtual-machine initiate-maintenance --service-name myService
--name myDeployment --virtual-machine-name myVM
```

Next steps

You can also handle planned maintenance using the Azure PowerShell or portal.

Handling planned maintenance notifications using the portal

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Once a planned maintenance wave is scheduled, you can check for a list of virtual machines that are impacted.

You can use the Azure portal and look for VMs scheduled for maintenance.

1. Sign in to the Azure portal.
2. Search for or select **Virtual Machines**.
3. In the Virtual Machines pane, select the **More** menu and then select **Maintenance - > Virtual machine maintenance** to open the list with maintenance columns.

   Maintenance status: Shows the maintenance status for the VM. The following are the potential values:

Expand table

Value	Description
Start now	The VM is in the self-service maintenance window that lets you initiate the maintenance yourself. See below on how to start maintenance on your VM.
Scheduled	The VM is scheduled for maintenance with no option for you to initiate maintenance. You can learn of the maintenance window by selecting the Maintenance - Scheduled window in this view or by clicking on the VM.
Already updated	Your VM is already updated and no further action is required at this time.
Retry later	You have initiated maintenance with no success. You will be able to use the self-service maintenance option at a later time.
Retry now	You can retry a previously unsuccessful self-initiated maintenance.
-	Your VM is not part of a planned maintenance wave.

   Maintenance - Self-service window: Shows the time window when you can self-start maintenance on your VMs.

Maintenance - Scheduled window: Shows the time window when Azure will maintain your VM in order to complete maintenance.

Notification and alerts in the portal

Azure Service Health has a dedicated tab for Planned Maintenance where all Azure services (for example, Virtual Machines) publish their upcoming Maintenance events.

Virtual Machine related Maintenance notifications are available under Service Health in the Azure portal. For some specific Virtual Machine Planned Maintenance scenarios, Azure might communicate the schedule by sending an additional email (besides Service Health) to the Subscription Classic Admin, Co-Admin, and Subscription Owners group.

Azure Service Health enables users to configure their own custom Service Health alerts for the Planned Maintenance category. With Azure Service Health alerts, you can assign different Action-Groups to include additional recipients and channels (such as emails and SMS) based on event or service type, like Virtual Machine maintenance in this context. For more information, see Create activity log alerts on service notifications.

While creating alerts specific to Virtual Machine maintenance, make sure you set the **Event type** as **Planned maintenance** and **Services** as **Virtual Machine Scale Sets** and/or **Virtual Machines**.

Start Maintenance on your VM from the portal

While looking at the VM details, you will be able to see more maintenance-related details.
At the top of the VM details view, a new notification ribbon will be added if your VM is included in a planned maintenance wave. In addition, a new option is added to start maintenance when possible.

Click on the maintenance notification to see the maintenance page with more details on the planned maintenance. From there, you will be able to **start maintenance** on your VM.

Once you start maintenance, your virtual machine will be maintained and the maintenance status will be updated to reflect the result within few minutes.

If you missed the self-service window, you will still be able to see the window when your VM will be maintained by Azure.

> ⓘ **Note**

In most cases, scheduled maintenance cannot be delayed. If you need a scheduled maintenance to be delayed, contact support and Azure will make a best-effort to postpone.

Next steps

You can also handle planned maintenance using the Azure CLI or PowerShell.

Feedback

Provide product feedback | Get help at Microsoft Q&A

Handling planned maintenance using PowerShell

Article • 08/23/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can use Azure PowerShell to see when VMs are scheduled for maintenance. Planned maintenance information is available from the Get-AzVM cmdlet when you use the `-status` parameter.

Maintenance information is returned only if there is maintenance planned. If no maintenance is scheduled that impacts the VM, the cmdlet does not return any maintenance information.

PowerShell

```
Get-AzVM -ResourceGroupName myResourceGroup -Name myVM -Status
```

Output

```
MaintenanceRedeployStatus               :
  IsCustomerInitiatedMaintenanceAllowed : True
  PreMaintenanceWindowStartTime         : 5/14/2018 12:30:00 PM
  PreMaintenanceWindowEndTime           : 5/19/2018 12:30:00 PM
  MaintenanceWindowStartTime            : 5/21/2018 4:30:00 PM
  MaintenanceWindowEndTime              : 6/4/2018 4:30
  LastOperationResultCode               : None
```

The following properties are returned under MaintenanceRedeployStatus:

Expand table

Value	Description
IsCustomerInitiatedMaintenanceAllowed	Indicates whether you can start maintenance on the VM at this time
PreMaintenanceWindowStartTime	The beginning of the maintenance self-service window when you can initiate maintenance on your VM

Value	Description
PreMaintenanceWindowEndTime	The end of the maintenance self-service window when you can initiate maintenance on your VM
MaintenanceWindowStartTime	The beginning of the maintenance scheduled in which Azure initiates maintenance on your VM
MaintenanceWindowEndTime	The end of the maintenance scheduled window in which Azure initiates maintenance on your VM
LastOperationResultCode	The result of the last attempt to initiate maintenance on the VM

You can also get the maintenance status for all VMs in a resource group by using Get-AzVM and not specifying a VM.

PowerShell

```
Get-AzVM -ResourceGroupName myResourceGroup -Status
```

The following PowerShell example takes your subscription ID and returns a list of VMs indicating whether they are scheduled for maintenance.

PowerShell

```
function MaintenanceIterator {
  param (
    $SubscriptionId
  )

  Select-AzSubscription -SubscriptionId $SubscriptionId | Out-Null

  $rgList = Get-AzResourceGroup
  foreach ($rg in $rgList) {
    $vmList = Get-AzVM -ResourceGroupName $rg.ResourceGroupName
    foreach ($vm in $vmList) {
      $vmDetails = Get-AzVM -ResourceGroupName $rg.ResourceGroupName -Name
$vm.Name -Status
      [pscustomobject]@{
        Name                                = $vmDetails.Name
        ResourceGroupName                   = $rg.ResourceGroupName
        IsCustomerInitiatedMaintenanceAllowed =
[bool]$vmDetails.MaintenanceRedeployStatus.IsCustomerInitiatedMaintenanceAll
owed
        LastOperationMessage                =
$vmDetails.MaintenanceRedeployStatus.LastOperationMessage
      }
    }
```

```
  }
}
```

Start maintenance on your VM using PowerShell

Using information from the function in the previous section, the following starts maintenance on a VM if **IsCustomerInitiatedMaintenanceAllowed** is set to true.

PowerShell

```
MaintenanceIterator -SubscriptionId <Subscription ID> |
    Where-Object -FilterScript {$_.IsCustomerMaintenanceAllowed} |
        Restart-AzVM -PerformMaintenance
```

Classic deployments

> **ⓘ Important**
>
> VMs created through the classic deployment model will be retired on September 1, 2023.
>
> If you use IaaS resources from Azure Service Management, please complete your migration by September 1, 2023. We encourage you to make the switch sooner to take advantage of the many feature enhancements in Azure Resource Manager.
>
> For more information, see **Migrate your IaaS resources to Azure Resource Manager by September 1, 2023**.

If you still have legacy VMs that were deployed using the classic deployment model, you can use PowerShell to query for VMs and initiate maintenance.

To get the maintenance status of a VM, type:

```
Get-AzureVM -ServiceName <Service name> -Name <VM name>
```

To start maintenance on your classic VM, type:

```
Restart-AzureVM -InitiateMaintenance -ServiceName <service name> -Name <VM
name>
```

Next steps

You can also handle planned maintenance using the Azure CLI or portal.

Managing VM updates with Maintenance Configurations

Article • 04/02/2025

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Azure frequently updates its infrastructure to improve reliability, performance, and security, or to launch new features. Most updates are transparent to users, but some sensitive workloads can't tolerate even few seconds of a virtual machine (VM) freezing or disconnecting for maintenance. Sensitive workloads might include gaming, media streaming, and financial transactions.

You can use the Maintenance Configurations feature to control and manage updates for many Azure VM resources. Maintenance Configurations is integrated with Azure Resource Graph for a low-latency and high-scale customer experience.

> **ⓘ Important**
>
> To use Maintenance Configurations, you must have a role of at least contributor and ensure that your subscription is registered with a maintenance resource provider.

Scopes

Maintenance Configurations currently supports three scopes: host, OS image, and guest. Although each scope allows scheduling and managing updates, the major difference lies in the resources that they support:

Expand table

Scope	Supported resources
Host	Isolated VMs, isolated virtual machine scale sets, dedicated hosts
OS image	Virtual machine scale sets
Guest	VMs, Azure Arc-enabled servers

Host

With the host scope, you can manage platform updates that don't require a restart on your isolated VMs, isolated virtual machine scale sets, and dedicated hosts.

Features and limitations unique to this scope include:

- You can set schedules anytime within 35 days. After 35 days, updates are automatically applied.
- A minimum of a two-hour maintenance window is required.
- Rack-level maintenance isn't currently supported.

Learn more about Azure dedicated hosts.

OS image

Using the OS image scope with Maintenance Configurations lets you decide when to apply upgrades to OS disks in your virtual machine scale sets through an easier and more predictable experience. An upgrade works by replacing the OS disk of a VM with a new disk created from the latest image version. Any configured extensions and custom data scripts are run on the OS disk, while data disks are retained.

Features and limitations unique to this scope include:

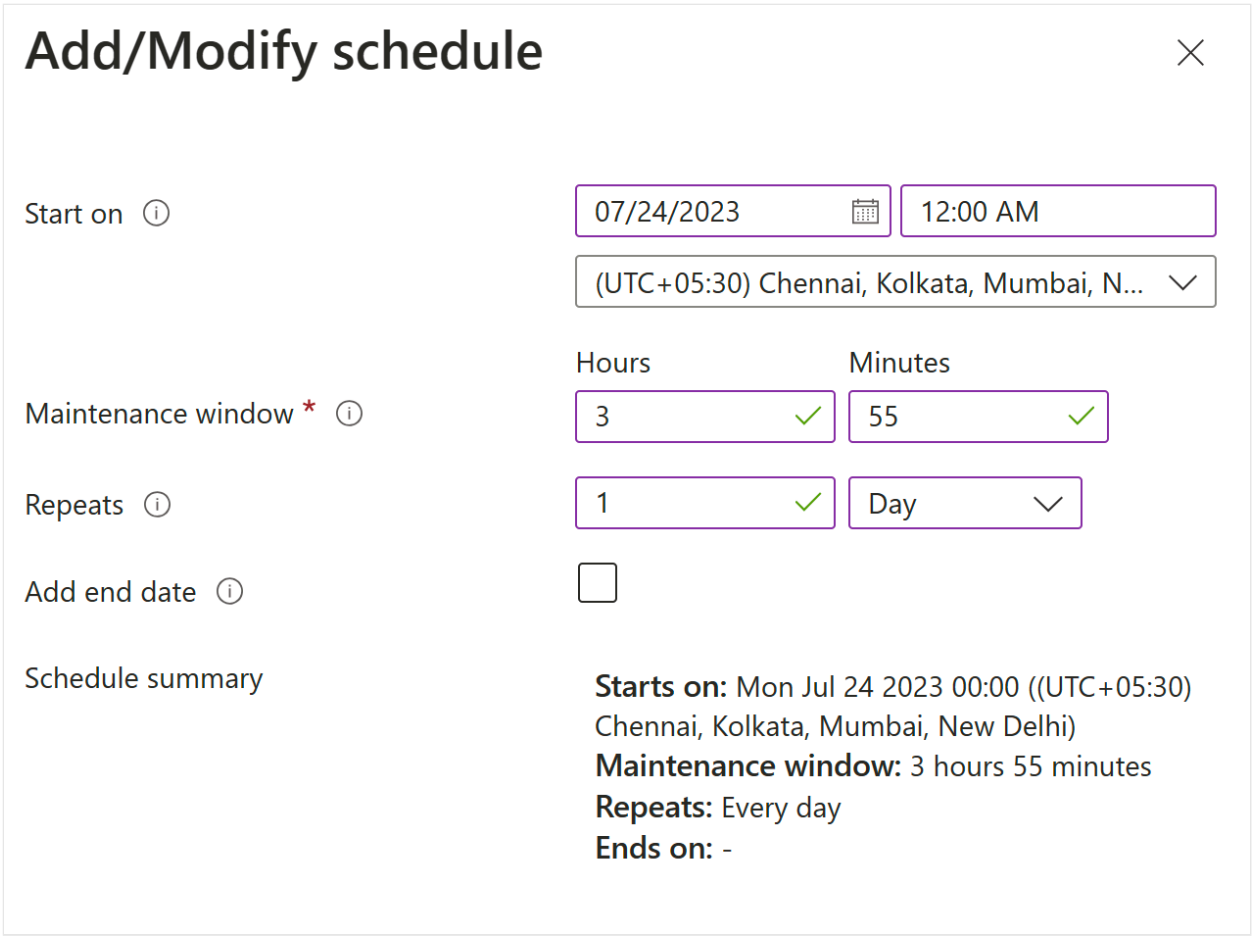
- For scale sets to use Maintenance Configurations, they need to have automatic OS upgrades enabled.
- You can schedule recurrence up to a week (7 days).
- A minimum of 5 hours is required for the maintenance window.

Guest

The guest scope integrates with Azure Update Manager. You can use it to save recurring deployment schedules to install updates for your Windows Server and Linux machines in Azure, in on-premises environments, and in other cloud environments connected through Azure Arc-enabled servers.

Features and limitations unique to this scope include:

- Patch orchestration for virtual machines needs to be set to `AutomaticByPlatform`.
- The upper maintenance window is 3 hours and 55 minutes.
- A minimum of 1 hour and 30 minutes is required for the maintenance window.
- The value of **Repeats** should be at least 6 hours.
- The start time for a schedule should be at least 15 minutes after the schedule's creation time.



Note

- The character count for the resource group name and the maintenance configuration name should be less than 128.
- For newly created schedules, there is a 15-minute delay in evaluating the trigger time, while for existing schedules, there is a 3-minute delay. Therefore, it is advisable to avoid creating schedules between 23:57 to 00:00 for existing schedules and between 23:45 to 00:00 for new schedules. This is because, after the evaluation stage of the trigger time, the system rechecks the start date and time before executing the job. If configured within these time limits, the evaluation and execution times differ, potentially resulting in the schedule not triggering or causing the VM to become unresponsive or shut down.

Maintenance Configurations provides two scheduled patching modes for VMs in the guest scope: Static Mode and Dynamic Scope Mode. By default, the system operates in Static Mode if you don't configure a Dynamic Scope Mode.

To schedule or modify the maintenance configuration in either mode, recommended buffer of 15 minutes before the scheduled patch time is required. For instance, if you

schedule the patching job for 3:00 PM, all modifications (including adding VMs, removing VMs, or altering the dynamic scope) should finish before 2:45 PM.

To learn more about this topic, see Schedule recurring updates for machines by using the Azure portal and Azure Policy.

> **Important**
>
> If you move a resource to a different resource group or subscription, scheduled patching for the resource stops working, because the system currently doesn't support this scenario. As a workaround, follow the steps in the **troubleshooting article**.

Shut-down machines

You can't apply maintenance updates to any shut-down machines. Ensure that your machine is turned on at least 15 minutes before a scheduled update, or the update might not be applied.

If your machine is shut down at the time of your scheduled update, the maintenance configuration might appear to be disassociated in the Azure portal. This is only a display issue. The maintenance configuration isn't disassociated, and you can check it via the Azure CLI.

Management options

You can create and manage maintenance configurations by using any of the following options:

- Azure CLI
- Azure PowerShell
- Azure portal

For an Azure Functions sample, see Scheduling maintenance updates with maintenance configurations and Azure Functions.

Service limits

We recommend the following limits for indicators:

Expand table

Indicator	Public Cloud Limit	Mooncake/Fairfax Limit
Number of schedules per subscription per region	250	250
Total number of resource associations to a schedule	3,000	3,000
Resource associations on each dynamic scope	1,000	1,000
Number of dynamic scopes per resource group or subscription per region	250	250
Number of dynamic scopes per schedule	200	100
Total number of subscriptions attached to all dynamic scopes per schedule	200	100

We recommend the following limits for each dynamic scope in the guest scope only:

Expand table

Resource	Limit
Resource associations	1,000
Number of tag filters	50
Number of resource group filters	50

> **Note**
>
> Maintenance configurations will initiate updates on all resources associated with it simultaneously. Customers have the flexibility to decide on the isolation and maintenance windows for their workloads. They can create single or multiple maintenance configurations based on the isolation that is optimal for their workloads. For example, if a customer wants to isolate updates for their development environment resources from the production environment resources, they can create separate maintenance configurations for each environment. This way, workloads in maintenance configuration with development resources are updated first, while the remaining workloads are updated in another configuration that does not overlap. This approach allows customers to control workload isolation and manage updates independently.

Next steps

- For troubleshooting, see Troubleshoot issues with Maintenance Configurations.
- To learn more, see Maintenance for virtual machines in Azure.

Control updates with Maintenance Configurations and the Azure CLI

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can use the Maintenance Configurations feature to control when to apply platform updates to various Azure resources. This article covers the Azure CLI options for using this feature. For more information about the benefits of using Maintenance Configurations, its limitations, and other management options, see Managing platform updates with Maintenance Configurations.

> **ⓘ Important**
>
> Specific *scopes* support certain machine types and schedules. Be sure to select the right scope for your virtual machine (VM).

Create a maintenance configuration

The first step in creating a maintenance configuration is creating a resource group as a container for your configuration. This example creates a resource group named *myMaintenanceRG* in *eastus*. If you already have a resource group that you want to use, you can skip this part and replace the resource group name with your own in the rest of the examples.

Azure CLI

```
az group create \
   --location eastus \
   --name myMaintenanceRG
```

After you create the resource group, use `az maintenance configuration create` to create a maintenance configuration.

Host

This example creates a maintenance configuration named *myConfig* scoped to host machines, with a scheduled window of 5 hours on the fourth Monday of every month:

Azure CLI

```
az maintenance configuration create \
   --resource-group myMaintenanceRG \
   --resource-name myConfig \
   --maintenance-scope host \
   --location eastus \
   --maintenance-window-duration "05:00" \
   --maintenance-window-recur-every "Month Fourth Monday" \
   --maintenance-window-start-date-time "2020-12-30 08:00" \
   --maintenance-window-time-zone "Pacific Standard Time"
```

Using `--maintenance-scope host` ensures that the maintenance configuration is used for controlling updates to the host infrastructure. If you try to create a configuration with the same name but in a different location, you'll get an error. Configuration names must be unique to your resource group.

To check if you successfully created the maintenance configuration, you can query for available maintenance configurations by using `az maintenance configuration list`:

Azure CLI

```
az maintenance configuration list
   --query "[].{Name:name, ID:id}"
   --output table
```

You can express maintenance recurrence as daily, weekly, or monthly. Here are some examples:

- **Daily**: A `maintenance-window-recur-every` value of `"Day"` or `"3Days"`.
- **Weekly**: A `maintenance-window-recur-every` value of `"3Weeks"` or `"Week Saturday,Sunday"`.
- **Monthly**: A `maintenance-window-recur-every` value of `"Month day23,day24"` or `"Month Last Sunday"` or `Month Fourth Monday`.

Virtual machine scale sets

This example creates a maintenance configuration named *myConfig* with the OS image scope for virtual machine scale sets, with a scheduled window of 5 hours on the fourth Monday of every month:

Azure CLI

```
az maintenance configuration create \
   --resource-group myMaintenanceRG \
```

```
    --resource-name myConfig \
    --maintenance-scope osimage \
    --location eastus \
    --maintenance-window-duration "05:00" \
    --maintenance-window-recur-every "Month Fourth Monday" \
    --maintenance-window-start-date-time "2020-12-30 08:00" \
    --maintenance-window-time-zone "Pacific Standard Time"
```

Guest VMs

This example creates a maintenance configuration named *myConfig* scoped to guest machines (VMs and Azure Arc-enabled servers), with a scheduled window of 2 hours every 20 days. Learn more about maintenance configurations on guest VMs.

Azure CLI

```
az maintenance configuration create \
    --resource-group myMaintenanceRG \
    --resource-name myConfig \
    --maintenance-scope InGuestPatch \
    --location eastus \
    --maintenance-window-duration "02:00" \
    --maintenance-window-recur-every "20days" \
    --maintenance-window-start-date-time "2022-12-30 07:00" \
    --maintenance-window-time-zone "Pacific Standard Time" \
    --install-patches-linux-parameters package-name-masks-to-exclude="ppt"
package-name-masks-to-include="apt" classifications-to-include="Other" \
    --install-patches-windows-parameters kb-numbers-to-exclude="KB123456" kb-
numbers-to-include="KB123456" classifications-to-include="FeaturePack" \
    --reboot-setting "IfRequired" \
    --extension-properties InGuestPatchMode="User"
```

Assign the configuration

Use `az maintenance assignment create` to assign the configuration to your machine.

Isolated VM

Apply the configuration to an isolated host VM by using the ID of the configuration. Specify `--resource-type virtualMachines`. Supply the name of the VM for `--resource-name`, the VM's resource group for `--resource-group`, and the location of the VM for `--location`.

Azure CLI

```
az maintenance assignment create \
   --resource-group myMaintenanceRG \
   --location eastus \
   --resource-name myVM \
   --resource-type virtualMachines \
   --provider-name Microsoft.Compute \
   --configuration-assignment-name myConfig \
   --maintenance-configuration-id "/subscriptions/{subscription
ID}/resourcegroups/myMaintenanceRG/providers/Microsoft.Maintenance/maintenan
ceConfigurations/myConfig"
```

Dedicated host

To apply a configuration to a dedicated host, you need to include `--resource-type hosts`, `--resource-parent-name` with the name of the host group, and `--resource-parent-type hostGroups`.

The parameter `--resource-id` is the ID of the host. You can use az-vm-host-get-instance-view to get the ID of your dedicated host.

Azure CLI

```
az maintenance assignment create \
   --resource-group myDHResourceGroup \
   --resource-name myHost \
   --resource-type hosts \
   --provider-name Microsoft.Compute \
   --configuration-assignment-name myConfig \
   --maintenance-configuration-id "/subscriptions/{subscription
ID}/resourcegroups/myDhResourceGroup/providers/Microsoft.Maintenance/mainten
anceConfigurations/myConfig" \
   --location eastus \
   --resource-parent-name myHostGroup \
   --resource-parent-type hostGroups
```

Virtual machine scale sets

Azure CLI

```
az maintenance assignment create \
   --resource-group myMaintenanceRG \
   --location eastus \
   --resource-name myVMSS \
   --resource-type virtualMachineScaleSets \
   --provider-name Microsoft.Compute \
   --configuration-assignment-name myConfig \
   --maintenance-configuration-id "/subscriptions/{subscription
```

```
ID}/resourcegroups/myMaintenanceRG/providers/Microsoft.Maintenance/maintenan
ceConfigurations/myConfig"
```

Guest VMs

Azure CLI

```
az maintenance assignment create \
   --resource-group myMaintenanceRG \
   --location eastus \
   --resource-name myVM \
   --resource-type virtualMachines \
   --provider-name Microsoft.Compute \
   --configuration-assignment-name myConfig \
   --maintenance-configuration-id "/subscriptions/{subscription
ID}/resourcegroups/myMaintenanceRG/providers/Microsoft.Maintenance/maintenan
ceConfigurations/myConfig"
```

Check the configuration

You can verify that the configuration was applied correctly, or check to see what configuration is currently applied, by using `az maintenance assignment list`.

Isolated VM

Azure CLI

```
az maintenance assignment list \
   --provider-name Microsoft.Compute \
   --resource-group myMaintenanceRG \
   --resource-name myVM \
   --resource-type virtualMachines \
   --query "[].{resource:resourceGroup, configName:name}" \
   --output table
```

Dedicated host

Azure CLI

```
az maintenance assignment list \
   --resource-group myDHResourceGroup \
   --resource-name myHost \
   --resource-type hosts \
   --provider-name Microsoft.Compute \
```

```
    --resource-parent-name myHostGroup \
    --resource-parent-type hostGroups \
    --query "[].{ResourceGroup:resourceGroup,configName:name}" \
    --output table
```

Virtual machine scale sets

Azure CLI

```
az maintenance assignment list \
    --provider-name Microsoft.Compute \
    --resource-group myMaintenanceRG \
    --resource-name myVMSS \
    --resource-type virtualMachines \
    --query "[].{resource:resourceGroup, configName:name}" \
    --output table
```

Guest VMs

Azure CLI

```
az maintenance assignment list \
    --provider-name Microsoft.Compute \
    --resource-group myMaintenanceRG \
    --resource-name myVM \
    --resource-type virtualMachines \
    --query "[].{resource:resourceGroup, configName:name}" \
    --output table
```

Check for pending updates

Use `az maintenance update list` to see if there are pending updates. Update `--subscription` to be the ID for the subscription that contains the VM.

If there are no updates, the command returns an error message that contains the text `Resource not found...StatusCode: 404`.

If there are updates, the command returns only one, even if multiple updates are pending. The data for this update is returned in an object:

text

```
[
  {
```

```
    "impactDurationInSec": 9,
    "impactType": "Freeze",
    "maintenanceScope": "Host",
    "notBefore": "2020-03-03T07:23:04.905538+00:00",
    "resourceId": "/subscriptions/9120c5ff-e78e-4bd0-b29f-
75c19cadd078/resourcegroups/DemoRG/providers/Microsoft.Compute/hostGroups/de
moHostGroup/hosts/myHost",
    "status": "Pending"
  }
]
```

Isolated VM

Check for pending updates for an isolated VM. In this example, the output is formatted as a table for readability:

Azure CLI

```azurecli
az maintenance update list \
   --subscription {subscription ID} \
   --resource-group myMaintenanceRg \
   --resource-name myVM \
   --resource-type virtualMachines \
   --provider-name Microsoft.Compute \
   --output table
```

Dedicated host

Check for pending updates for a dedicated host. In this example, the output is formatted as a table for readability. Replace the values for the resources with your own.

Azure CLI

```azurecli
az maintenance update list \
   --subscription {subscription ID} \
   --resource-group myHostResourceGroup \
   --resource-name myHost \
   --resource-type hosts \
   --provider-name Microsoft.Compute \
   --resource-parentname myHostGroup \
   --resource-parent-type hostGroups \
   --output table
```

Apply updates

Use `az maintenance apply update` to apply pending updates. On success, this command returns JSON that contains the details of the update. Calls to apply updates can take up to 2 hours to complete.

Isolated VM

Create a request to apply updates to an isolated VM:

Azure CLI

```
az maintenance applyupdate create \
   --subscription {subscriptionID} \
   --resource-group myMaintenanceRG \
   --resource-name myVM \
   --resource-type virtualMachines \
   --provider-name Microsoft.Compute
```

Dedicated host

Apply updates to a dedicated host:

Azure CLI

```
az maintenance applyupdate create \
   --subscription {subscriptionID} \
   --resource-group myHostResourceGroup \
   --resource-name myHost \
   --resource-type hosts \
   --provider-name Microsoft.Compute \
   --resource-parent-name myHostGroup \
   --resource-parent-type hostGroups
```

Virtual machine scale sets

Apply updates to a scale set:

Azure CLI

```
az maintenance applyupdate create \
   --subscription {subscriptionID} \
   --resource-group myMaintenanceRG \
   --resource-name myVMSS \
   --resource-type virtualMachineScaleSets \
   --provider-name Microsoft.Compute
```

Check the status of applying updates

You can check on the progress of the updates by using `az maintenance applyupdate get`.

To see results for the last update, use `default` as the update name. Or replace `myUpdateName` with the name of the update that was returned when you ran `az maintenance applyupdate create`.

text

```
Status         : Completed
ResourceId     : /subscriptions/12ae7457-4a34-465c-94c1-
17c058c2bd25/resourcegroups/TestShantS/providers/Microsoft.Comp
ute/virtualMachines/DXT-test-04-iso
LastUpdateTime : 1/1/2020 12:00:00 AM
Id             : /subscriptions/12ae7457-4a34-465c-94c1-
17c058c2bd25/resourcegroups/TestShantS/providers/Microsoft.Comp
ute/virtualMachines/DXT-test-04-
iso/providers/Microsoft.Maintenance/applyUpdates/default
Name           : default
Type           : Microsoft.Maintenance/applyUpdates
```

`LastUpdateTime` is the time when the update finished, whether you initiated the update or the platform initiated it because you didn't use the self-maintenance window. If an update was never applied through Maintenance Configurations, `LastUpdateTime` shows the default value.

Isolated VM

Azure CLI

```
az maintenance applyupdate get \
   --subscription {subscriptionID} \
   --resource-group myMaintenanceRG \
   --resource-name myVM \
   --resource-type virtualMachines \
   --provider-name Microsoft.Compute \
   --apply-update-name myUpdateName \
   --query "{LastUpdate:lastUpdateTime, Name:name,
ResourceGroup:resourceGroup, Status:status}" \
   --output table
```

Dedicated host

Azure CLI

```
az maintenance applyupdate get \
   --subscription {subscriptionID} \
   --resource-group myMaintenanceRG \
   --resource-name myHost \
   --resource-type hosts \
   --provider-name Microsoft.Compute \
   --resource-parent-name myHostGroup \
   --resource-parent-type hostGroups \
   --apply-update-name myUpdateName \
   --query "{LastUpdate:lastUpdateTime, Name:name,
ResourceGroup:resourceGroup, Status:status}" \
   --output table
```

Virtual machine scale sets

Azure CLI

```
az maintenance applyupdate get \
   --subscription {subscriptionID} \
   --resource-group myMaintenanceRG \
   --resource-name myVMSS \
   --resource-type virtualMachineScaleSets \
   --provider-name Microsoft.Compute \
   --apply-update-name myUpdateName \
   --query "{LastUpdate:lastUpdateTime, Name:name,
ResourceGroup:resourceGroup, Status:status}" \
   --output table
```

Delete a maintenance configuration

To delete a maintenance configuration, use `az maintenance configuration delete`. Deleting the configuration removes the maintenance control from the associated resources.

Azure CLI

```
az maintenance configuration delete \
   --subscription 1111abcd-1a11-1a2b-1a12-123456789abc \
   -resource-group myResourceGroup \
   --resource-name myConfig
```

Control updates with Maintenance Configurations and Azure PowerShell

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can use the Maintenance Configurations feature to control when to apply platform updates to various Azure resources. This article covers the Azure PowerShell options for dedicated hosts and isolated virtual machines (VMs). For more information about the benefits of using the Maintenance Configurations feature, its limitations, and other management options, see Managing platform updates with Maintenance Configurations.

If you're looking for information about using Maintenance Configurations for scale sets, see Maintenance control for Azure Virtual Machine Scale Sets.

> **ⓘ Important**
>
> Specific *scopes* support certain machine types and schedules. Be sure to select the right scope for your VM.

Enable the Azure PowerShell module

Make sure that `PowerShellGet` is up to date:

Azure PowerShell

```
Install-Module -Name PowerShellGet -Repository PSGallery -Force
```

Install the `Az.Maintenance` Azure PowerShell module:

Azure PowerShell

```
Install-Module -Name Az.Maintenance
```

Check that you're running the latest version of `Az.Maintenance` (version 1.2.0):

Azure PowerShell

```
Get-Module -ListAvailable -Name Az.Maintenance
```

Ensure that you're running the appropriate version of `Az.Maintenance`:

Azure PowerShell

```
Import-Module -Name Az.Maintenance -RequiredVersion 1.2.0
```

If you're installing locally, be sure to open your Azure PowerShell prompt as an administrator.

You might be asked to confirm that you want to install from an untrusted repository. Enter **Y** or select **Yes to All** to install the module.

Create a maintenance configuration

The first step in creating a maintenance configuration is creating a resource group as a container for your configuration. This example creates a resource group named *myMaintenanceRG* in *eastus*. If you already have a resource group that you want to use, you can skip this part and replace the resource group name with your own in the rest of the examples.

Azure PowerShell

```
New-AzResourceGroup `
   -Location eastus `
   -Name myMaintenanceRG
```

You can declare a scheduled window when Azure will recurrently apply the updates on your resources. After you create a scheduled window, you no longer have to apply the updates manually.

You can express maintenance recurrence as daily, weekly, or monthly. Here are some examples:

- **Daily**: A `RecurEvery` value of `"Day"` or `"3Days"`.
- **Weekly**: A `RecurEvery` value of `"3Weeks"` or `"Week Saturday,Sunday"`.
- **Monthly**: A `RecurEvery` value of `"Month day23,day24"` or `"Month Last Sunday"` or `"Month Fourth Monday"`.

Host

This example creates a maintenance configuration named *myConfig* scoped to `Host`, with a scheduled window of 5 hours on the fourth Monday of every month. The `duration` value of the schedule for this scope should be at least two hours. To begin, define the parameters for `New-AzMaintenanceConfiguration`:

Azure PowerShell

```
$RGName = "myMaintenanceRG"
$configName = "myConfig"
$scope = "Host"
$location = "eastus"
$timeZone = "Pacific Standard Time"
$duration = "05:00"
$startDateTime = "2022-11-01 00:00"
$recurEvery = "Month Fourth Monday"
```

After you define the parameters, you can use the `New-AzMaintenanceConfiguration` cmdlet to create your configuration:

Azure PowerShell

```
New-AzMaintenanceConfiguration
   -ResourceGroup $RGName `
   -Name $configName `
   -MaintenanceScope $scope `
   -Location $location `
   -StartDateTime $startDateTime `
   -TimeZone $timeZone `
   -Duration $duration `
   -RecurEvery $recurEvery
```

Using `$scope = "Host"` ensures that the maintenance configuration is used for controlling updates on host machines. Be sure to create a configuration for the specific scope of the machines that you're targeting. Learn more about scopes.

OS image

This example creates a maintenance configuration named *myConfig* scoped to `osimage`, with a scheduled window of 8 hours every 5 days. The `duration` value of the schedule for this scope should be at least 5 hours. This scope allows a maximum of 7 days for schedule recurrence.

Azure PowerShell

```
$RGName = "myMaintenanceRG"
$configName = "myConfig"
```

```
$scope = "osimage"
$location = "eastus"
$timeZone = "Pacific Standard Time"
$duration = "08:00"
$startDateTime = "2022-11-01 00:00"
$recurEvery = "5days"
```

After you define the parameters, you can use the `New-AzMaintenanceConfiguration` cmdlet to create your configuration:

Azure PowerShell

```
New-AzMaintenanceConfiguration
   -ResourceGroup $RGName `
   -Name $configName `
   -MaintenanceScope $scope `
   -Location $location `
   -StartDateTime $startDateTime `
   -TimeZone $timeZone `
   -Duration $duration `
   -RecurEvery $recurEvery
```

Guest

The most recent addition to the Maintenance Configurations feature is the `InGuestPatch` scope. This example shows how to create a maintenance configuration for a guest scope by using Azure PowerShell. For more information about this scope, see Guest.

Azure PowerShell

```
$RGName = "myMaintenanceRG"
$configName = "myConfig"
$scope = "InGuestPatch"
$location = "eastus"
$timeZone = "Pacific Standard Time"
$duration = "04:00"
$startDateTime = "2022-11-01 00:00"
$recurEvery = "Week Saturday, Sunday"
$WindowsParameterClassificationToInclude = "FeaturePack","ServicePack";
$WindowParameterKbNumberToInclude = "KB123456","KB123466";
$WindowParameterKbNumberToExclude = "KB123456","KB123466";
$RebootOption = "IfRequired";
$LinuxParameterClassificationToInclude = "Other";
$LinuxParameterPackageNameMaskToInclude = "apt","httpd";
$LinuxParameterPackageNameMaskToExclude = "ppt","userpk";
```

After you define the parameters, you can use the `New-AzMaintenanceConfiguration` cmdlet to create your configuration:

Azure PowerShell

```
New-AzMaintenanceConfiguration
   -ResourceGroup $RGName `
   -Name $configName `
   -MaintenanceScope $scope `
   -Location $location `
   -StartDateTime $startDateTime `
   -TimeZone $timeZone `
   -Duration $duration `
   -RecurEvery $recurEvery `
   -WindowParameterClassificationToInclude
$WindowsParameterClassificationToInclude `
   -WindowParameterKbNumberToInclude $WindowParameterKbNumberToInclude `
   -WindowParameterKbNumberToExclude $WindowParameterKbNumberToExclude `
   -InstallPatchRebootSetting $RebootOption `
   -LinuxParameterPackageNameMaskToInclude
$LinuxParameterPackageNameMaskToInclude `
   -LinuxParameterClassificationToInclude
$LinuxParameterClassificationToInclude `
   -LinuxParameterPackageNameMaskToExclude
$LinuxParameterPackageNameMaskToExclude `
   -ExtensionProperty @{"InGuestPatchMode"="User"}
```

If you try to create a configuration with the same name but in a different location, you'll get an error. Configuration names must be unique to your resource group.

You can check if you successfully created the maintenance configurations by using Get-AzMaintenanceConfiguration:

Azure PowerShell

```
Get-AzMaintenanceConfiguration | Format-Table -Property Name,Id
```

Assign the configuration

After you create your configuration, you might want to also assign machines to it by using Azure PowerShell. You can use the New-AzConfigurationAssignment cmdlet.

Isolated VM

Assign the configuration to a VM by using the ID of the configuration. Specify `-ResourceType VirtualMachines`. Supply the name of the VM for `-ResourceName`, and

supply the resource group of the VM for `-ResourceGroupName`.

Azure PowerShell

```
New-AzConfigurationAssignment `
   -ResourceGroupName "myResourceGroup" `
   -Location "eastus" `
   -ResourceName "myVM" `
   -ResourceType "VirtualMachines" `
   -ProviderName "Microsoft.Compute" `
   -ConfigurationAssignmentName "configName" `
   -MaintenanceConfigurationId "configID"
```

Dedicated host

To apply a configuration to a dedicated host, you need to include `-ResourceType hosts`, `-ResourceParentName` with the name of the host group, and `-ResourceParentType hostGroups`:

Azure PowerShell

```
New-AzConfigurationAssignment `
   -ResourceGroupName "myResourceGroup" `
   -Location "eastus" `
   -ResourceName "myHost" `
   -ResourceType "hosts" `
   -ResourceParentName myHostGroup `
   -ResourceParentType hostGroups `
   -ProviderName "Microsoft.Compute" `
   -ConfigurationAssignmentName "configName" `
   -MaintenanceConfigurationId "configID"
```

Virtual machine scale sets

Azure PowerShell

```
New-AzConfigurationAssignment `
   -ResourceGroupName "myResourceGroup" `
   -Location "eastus" `
   -ResourceName "myVMSS" `
   -ResourceType "VirtualMachineScaleSets" `
   -ProviderName "Microsoft.Compute" `
   -ConfigurationAssignmentName "configName" `
   -MaintenanceConfigurationId "configID"
```

Guest

Azure PowerShell

```
New-AzConfigurationAssignment `
   -ResourceGroupName "myResourceGroup" `
   -Location "eastus" `
   -ResourceName "myGuest" `
   -ResourceType "VirtualMachines" `
   -ProviderName "Microsoft.Compute" `
   -ConfigurationAssignmentName "configName" `
   -MaintenanceConfigurationId "configID"
```

Check for pending updates

The check for pending updates, use Get-AzMaintenanceUpdate. Use `-subscription` to specify the Azure subscription of the VM, if it's different from the one that you're logged in to.

If there are no updates to show, this command returns nothing. Otherwise, it returns a `PSApplyUpdate` object:

JSON

```
{
   "maintenanceScope": "Host",
   "impactType": "Freeze",
   "status": "Pending",
   "impactDurationInSec": 9,
   "notBefore": "2020-02-21T16:47:44.8728029Z",
   "properties": {
      "resourceId": "/subscriptions/39c6cced-4d6c-4dd5-af86-
57499cd3f846/resourcegroups/Ignite2019/providers/Microsoft.Compute/virtualMa
chines/MCDemo3"
}
```

Isolated VM

Check for pending updates for an isolated VM. In this example, the output is formatted as a table for readability:

Azure PowerShell

```
Get-AzMaintenanceUpdate `
  -ResourceGroupName "myResourceGroup" `
  -ResourceName "myVM" `
```

```
    -ResourceType "VirtualMachines" `
    -ProviderName "Microsoft.Compute" | Format-Table
```

Dedicated host

Check for pending updates for a dedicated host. In this example, the output is formatted as a table for readability:

Azure PowerShell

```
Get-AzMaintenanceUpdate `
    -ResourceGroupName "myResourceGroup" `
    -ResourceName "myHost" `
    -ResourceType "hosts" `
    -ResourceParentName "myHostGroup" `
    -ResourceParentType "hostGroups" `
    -ProviderName "Microsoft.Compute" | Format-Table
```

Virtual machine scale sets

Azure PowerShell

```
Get-AzMaintenanceUpdate `
    -ResourceGroupName "myResourceGroup" `
    -Location "eastus" `
    -ResourceName "myVMSS" `
    -ResourceType "VirtualMachineScaleSets" `
    -ProviderName "Microsoft.Compute" | Format-Table
```

Apply updates

Use New-AzApplyUpdate to apply pending updates. Applying update calls can take up to 2 hours to complete.

This cmdlet works only for the host and OS image scopes. It doesn't work for the guest scope.

Isolated VM

Create a request to apply updates to an isolated VM:

Azure PowerShell

```
New-AzApplyUpdate `
  -ResourceGroupName "myResourceGroup" `
  -ResourceName "myVM" `
  -ResourceType "VirtualMachines" `
  -ProviderName "Microsoft.Compute"
```

On success, this command returns a `PSApplyUpdate` object. You can use the `Name` attribute in the `Get-AzApplyUpdate` command to check the update status, as described later in this article.

Dedicated host

Apply updates to a dedicated host:

Azure PowerShell

```
New-AzApplyUpdate `
   -ResourceGroupName "myResourceGroup" `
   -ResourceName "myHost" `
   -ResourceType "hosts" `
   -ResourceParentName "myHostGroup" `
   -ResourceParentType "hostGroups" `
   -ProviderName Microsoft.Compute
```

Virtual machine scale sets

Azure PowerShell

```
New-AzApplyUpdate `
   -ResourceGroupName "myResourceGroup" `
   -Location "eastus" `
   -ResourceName "myVMSS" `
   -ResourceType "VirtualMachineScaleSets" `
   -ProviderName "Microsoft.Compute"
```

Check update status

To check the status of an update, use Get-AzApplyUpdate. The following commands show the status of the latest update by using `default` for the `-ApplyUpdateName` parameter. You can substitute the name of the update (returned by the New-AzApplyUpdate command) to get the status of a specific update.

This cmdlet works only for the host and OS image scopes. It doesn't work for the guest scope.

text

```
Status         : Completed
ResourceId     : /subscriptions/12ae7457-4a34-465c-94c1-
17c058c2bd25/resourcegroups/TestShantS/providers/Microsoft.Comp
ute/virtualMachines/DXT-test-04-iso
LastUpdateTime : 1/1/2020 12:00:00 AM
Id             : /subscriptions/12ae7457-4a34-465c-94c1-
17c058c2bd25/resourcegroups/TestShantS/providers/Microsoft.Comp
ute/virtualMachines/DXT-test-04-
iso/providers/Microsoft.Maintenance/applyUpdates/default
Name           : default
Type           : Microsoft.Maintenance/applyUpdates
```

`LastUpdateTime` is the time when the update finished, whether you initiated the update or the platform initiated it because you didn't use the self-maintenance window. If an update was never applied through Maintenance Configurations, `LastUpdateTime` shows the default value.

Isolated VM

Check for updates to a specific virtual machine:

Azure PowerShell

```
Get-AzApplyUpdate `
  -ResourceGroupName "myResourceGroup" `
  -ResourceName "myVM" `
  -ResourceType "VirtualMachines" `
  -ProviderName "Microsoft.Compute" `
  -ApplyUpdateName "applyUpdateName"
```

Dedicated host

Check for updates to a dedicated host:

Azure PowerShell

```
Get-AzApplyUpdate `
   -ResourceGroupName "myResourceGroup" `
   -ResourceName "myHost" `
   -ResourceType "hosts" `
   -ResourceParentName "myHostGroup" `
```

```
    -ResourceParentType "hostGroups" `
    -ProviderName "Microsoft.Compute" `
    -ApplyUpdateName "applyUpdateName"
```

Virtual machine scale sets

Azure PowerShell

```
New-AzApplyUpdate `
    -ResourceGroupName "myResourceGroup" `
    -Location "eastus" `
    -ResourceName "myVMSS" `
    -ResourceType "VirtualMachineScaleSets" `
    -ProviderName "Microsoft.Compute" `
    -ApplyUpdateName "applyUpdateName"
```

Delete a maintenance configuration

To delete a maintenance configuration, use Remove-AzMaintenanceConfiguration:

Azure PowerShell

```
Remove-AzMaintenanceConfiguration `
    -ResourceGroupName "myResourceGroup" `
    -Name "configName"
```

Control updates with Maintenance Configurations and Bicep

Article • 11/11/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

You can use the Maintenance Configurations feature to control when to apply platform updates to various Azure resources. This article covers the Bicep language for using this feature. For more information about the benefits of using the Maintenance Configurations feature, its limitations, and other management options, see Managing platform updates with Maintenance Configurations.

> **Important**
>
> Specific *scopes* support certain machine types and schedules. Be sure to select the right scope for your VM.

Prerequisites

Before proceeding, visit Bicep Modules to learn more about how bicep deployment can be organized into modules

- Scope of resource deployment should be understood before proceeding with the Bicep template. For more information, see Scope Functions for Bicep.
- It's essential to know how and where resources are deployed.
- Bicep modules must be used to perform deployments. Deploying resources at different scopes require the use of modules.

> **Tip**
>
> Always provide the right set of dependencies since module execute on different scopes. For example - the scope for configuration assignment in maintenance configuration when using dynamic scope should be `Subscription` and when using static assignment (no dynamic scopes configured) should be `ResourceId`

Bicep resource definition

Refer to the below guides for the resource format and resource definition of the Bicep template before proceeding ahead with the working example.

- Maintenance Configurations
- Configuration Assignments
- Apply Updates

Example

There are three bicep files that need to be created. We recommend keeping all the three files in the same folder. You can also keep them in different folders but make sure to update the path of the file names in `example.bicep` file mentioned.

Template execution

PowerShell

```
az deployment group create --name samplebicep --template-file .\ds.bicep --
resource-group  testrg --parameters '{}' --debug --subscription abc4def8-
er57-2345-f4t8-dff65f67afr3
```

Example template

example.bicep

Bicep

```
metadata description = 'Demo Main'

module mrpmc1 './maintenanceconfig.bicep' = {

  name: 'mrpmc'

  params: {

   configName: 'test-MaintConfig-Bicep'

  }

}

module ca1 './config_assignment.bicep' = {
```

```
  name: 'mrpmcconfigassign2'

  scope: subscription()

  params : {

  configId:
'${resourceGroup().id}/providers/microsoft.maintenance/maintenanceConfigurat
ions/test-MaintConfig-Bicep'

  }

  dependsOn: [

    mrpmc1

  ]

}
```

maintenanceconfig.bicep

Bicep

```
metadata description = 'Demo1'

param location string = 'Canada Central'

param configName string = ''

targetScope = 'resourceGroup'

resource MaintConfig4 'Microsoft.Maintenance/maintenanceConfigurations@2023-
04-01' = {

  name: configName //'test-MaintConfig-Bicep'

  location: location

Control updates with Maintenance Configurations and the Azure portal

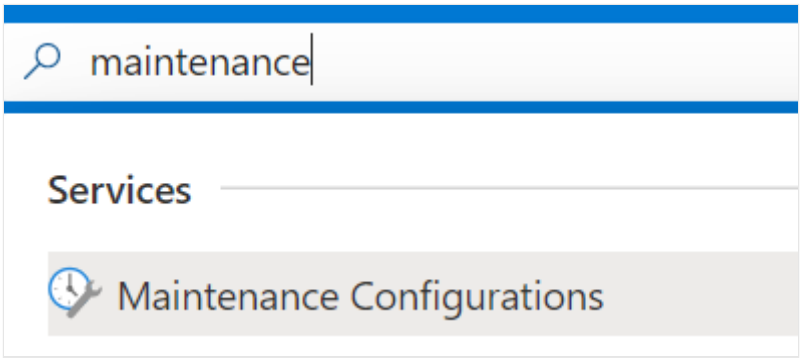
Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

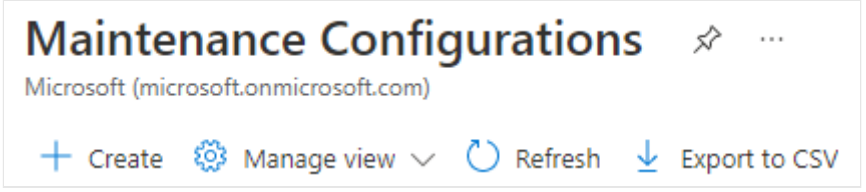
With the Maintenance Configurations feature, you can control when to apply updates to various Azure resources. This article covers the Azure portal options for using this feature. For more information about the benefits of using Maintenance Configurations, its limitations, and other management options, see Managing platform updates with Maintenance Configurations.

Create a maintenance configuration

1. Sign in to the Azure portal.
2. Search for **maintenance configurations**, and then open the **Maintenance Configurations** result.

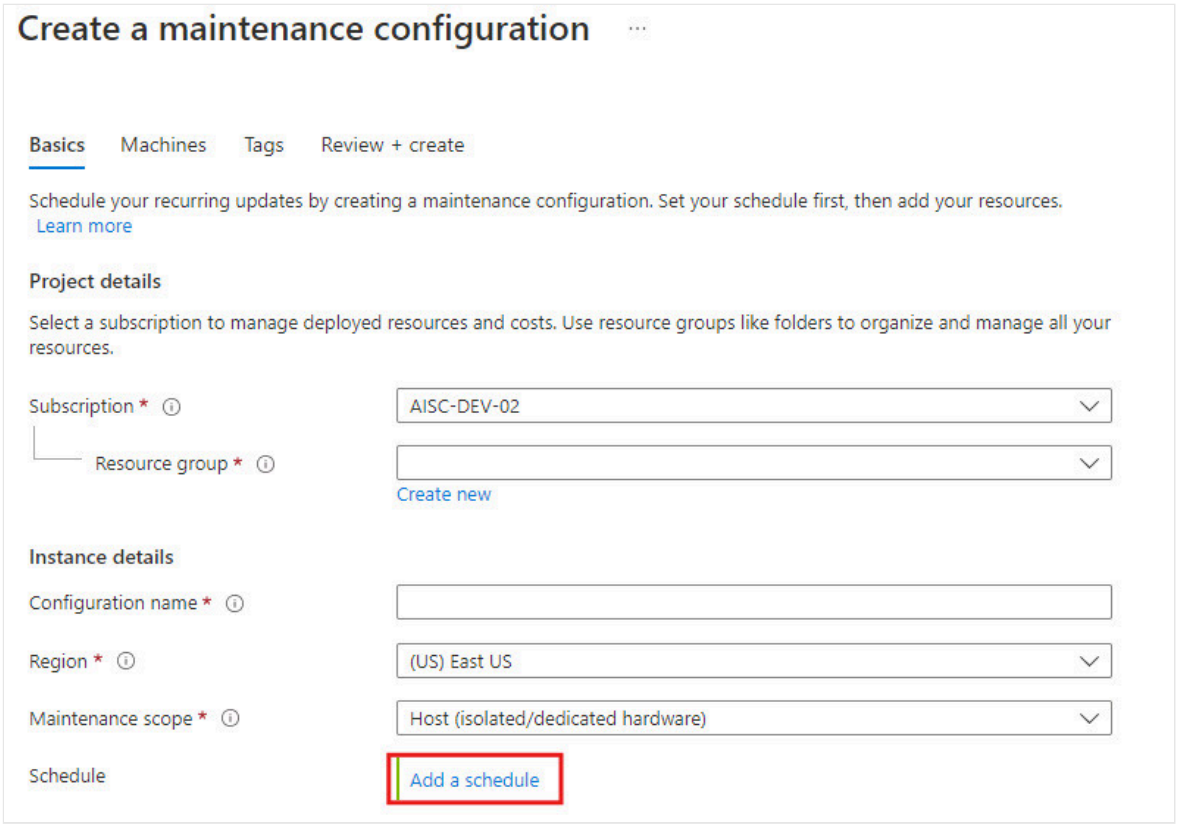


3. Select **Create**.



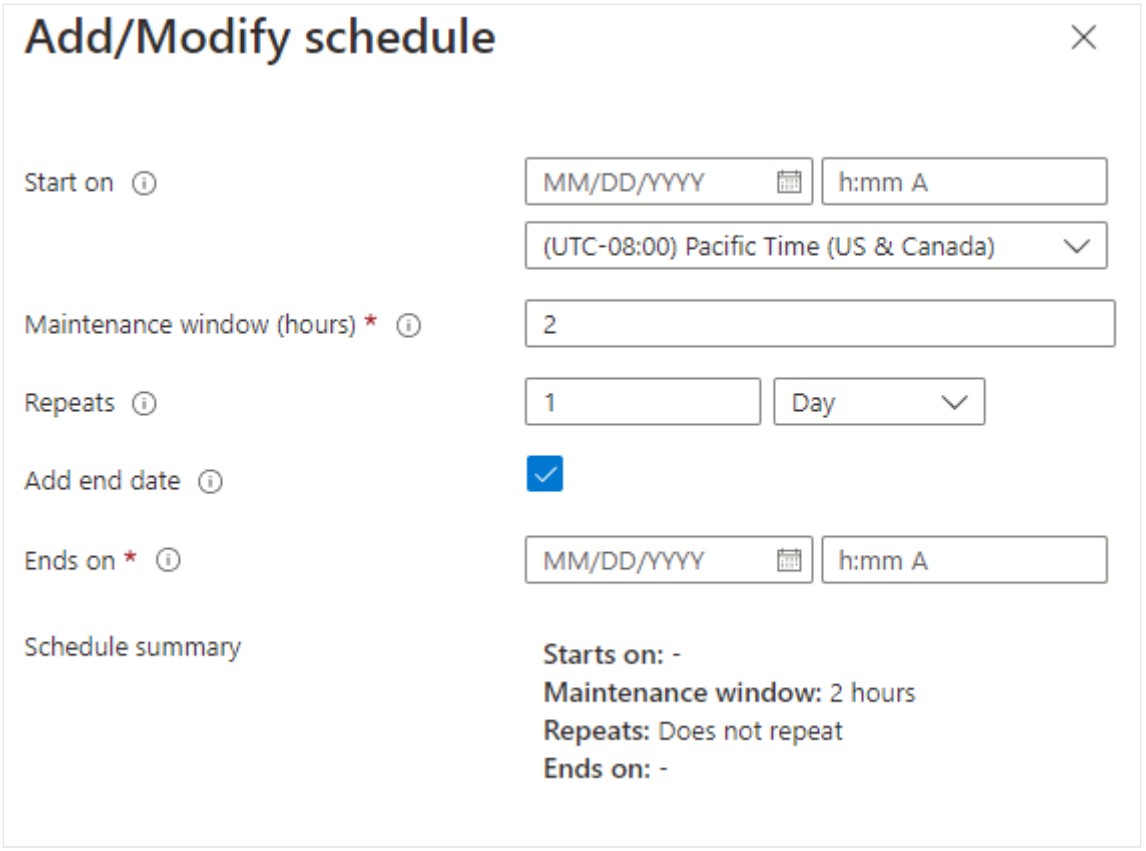
4. On the **Basics** tab, choose a subscription and resource group, provide a name for the configuration, choose a region, and select one of the scopes that you want to apply updates for. Then select **Add a schedule** to add or modify the schedule for your configuration.

> **Important**
>
> Certain virtual machine types and schedules require a specific kind of scope. To find the right scope for your virtual machine, see Scopes.



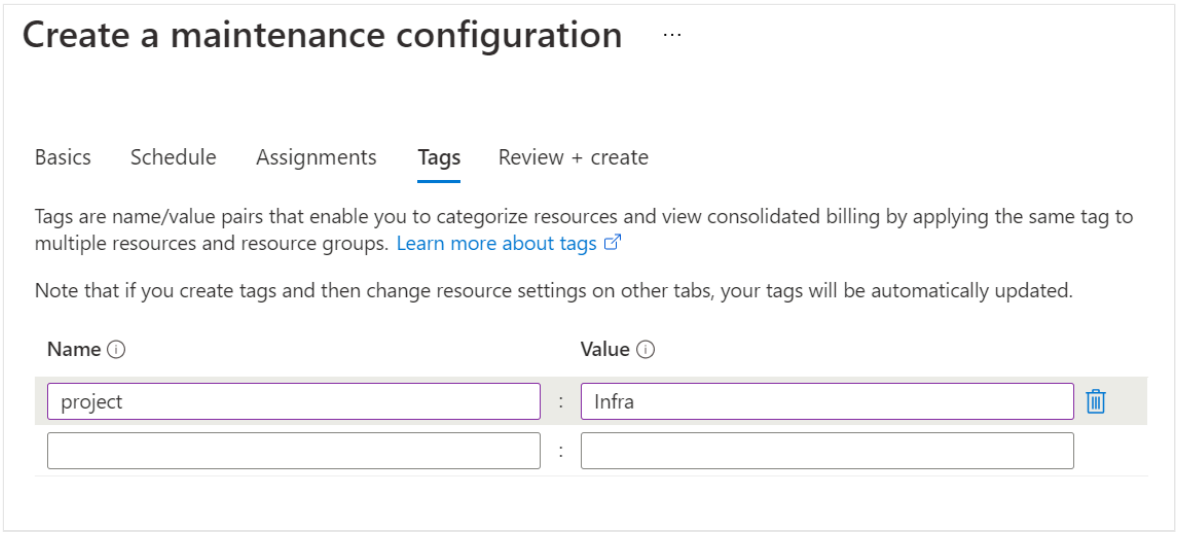
5. On the **Add/Modify schedule** pane, declare a scheduled window when Azure will apply the updates on your resources. Set a start date, maintenance window, and recurrence if your resource requires it. After you create a scheduled window, you no longer have to apply the updates manually. When you finish, select **Next**.

> **Important**
>
> The duration of the maintenance window must be 2 hours or longer.



6. On the **Machines** tab, assign resources now or skip this step and assign resources later (after you deploy the maintenance configuration). Then select **Next**.

7. On the **Tags** tab, add tags and values. Then select **Next**.

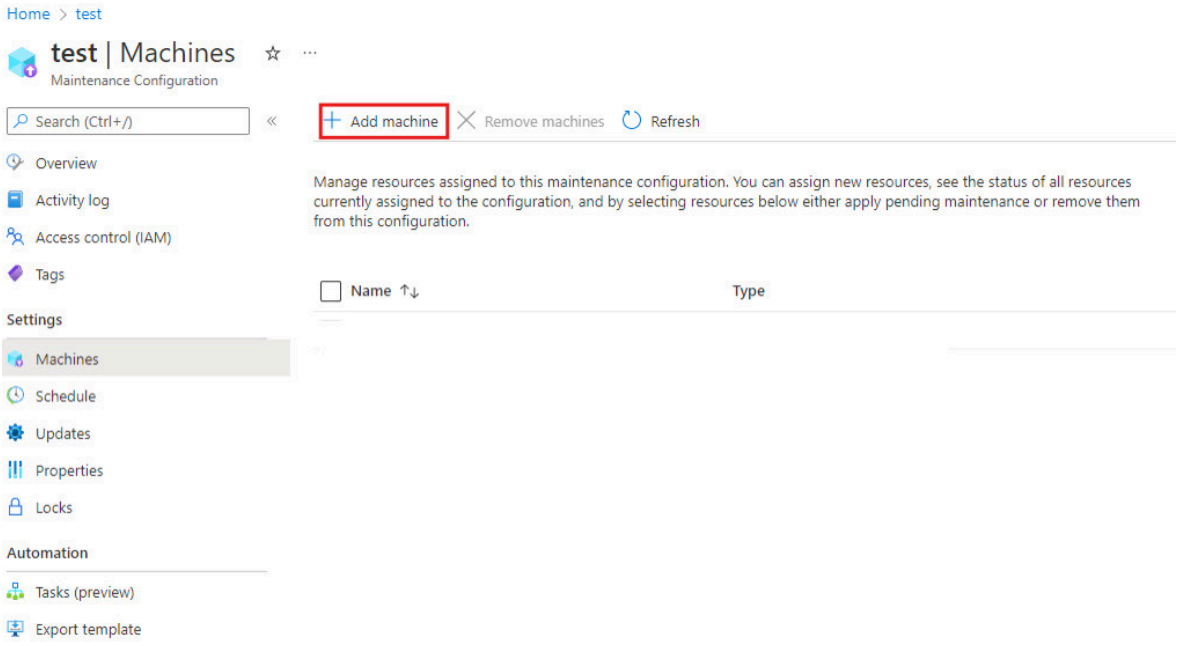


8. On the **Review + create** tab, review the summary. Then select **Create**.

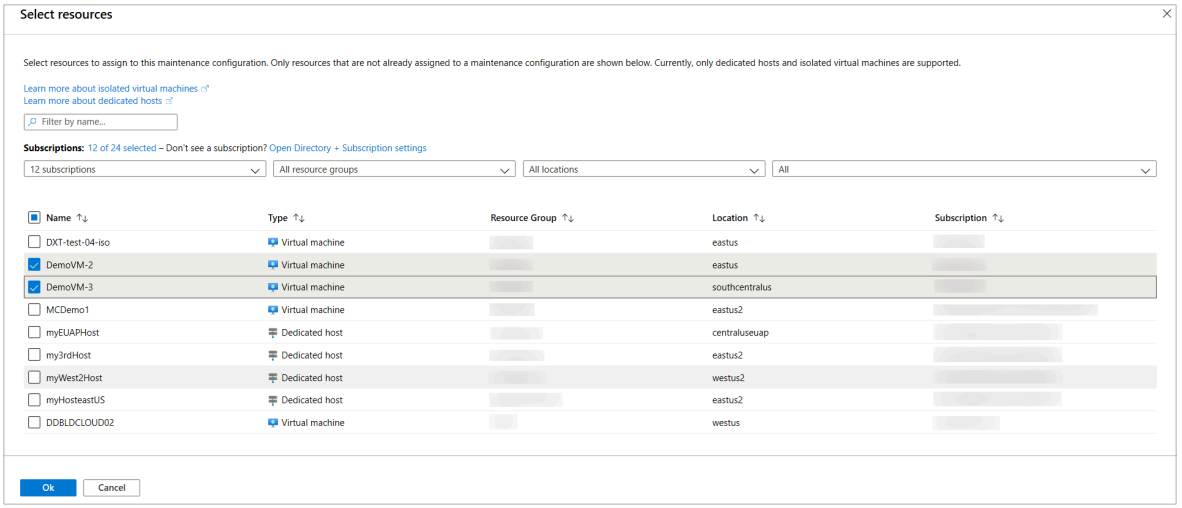
9. After the deployment is complete, select **Go to resource**.

Assign the configuration

1. On the details page of the maintenance configuration, select **Machines**, and then select **Add machine**.

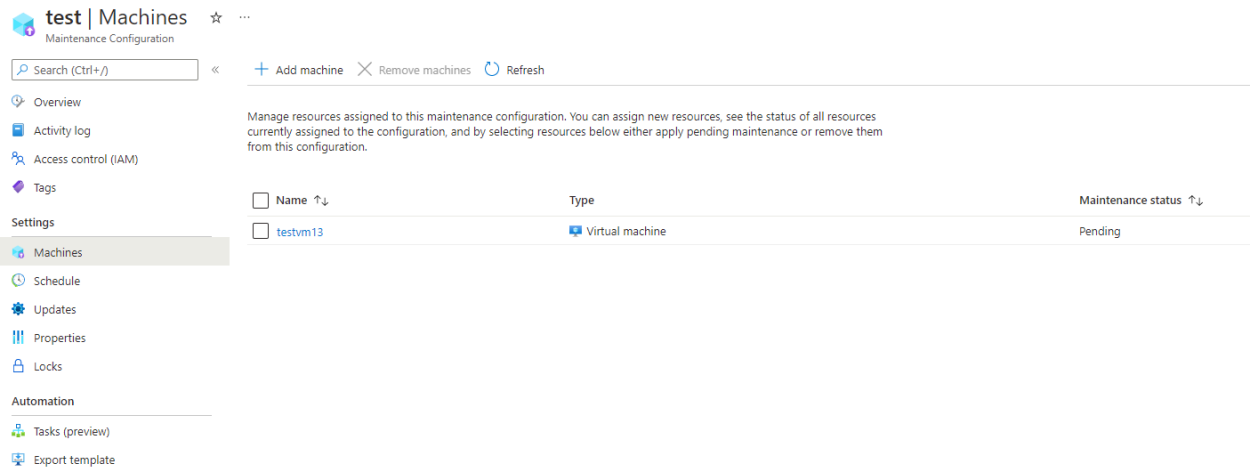


2. On the **Select resources** pane, select the resources that you want the maintenance configuration assigned to. The VMs that you select need to be running. If you try to assign a configuration to a VM that's stopped, an error occurs. When you finish, select **Ok**.

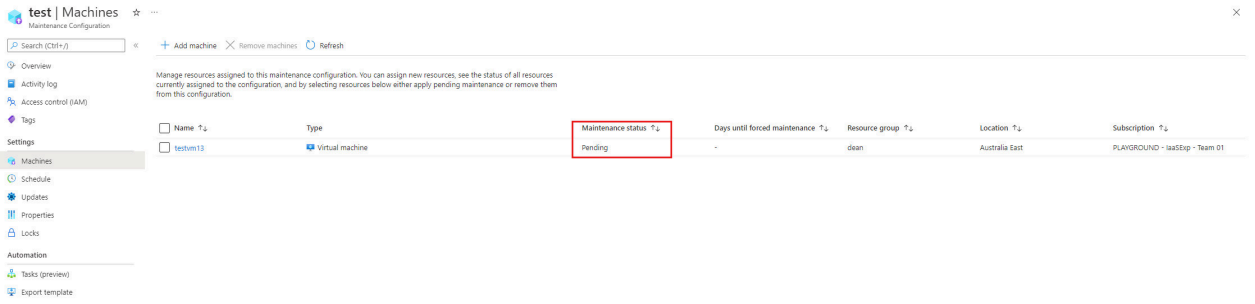


Check the configuration and status

You can verify that the configuration was applied correctly, or check which machines are assigned to a maintenance configuration, by going to **Maintenance Configurations** > **Machines**.



The **Maintenance status** column shows whether any updates are pending for a maintenance configuration.



Delete a maintenance configuration

To delete a maintenance configuration, open the configuration details and select **Delete**.

Troubleshoot problems with Maintenance Configurations

Article • 04/02/2025

This article outlines common problems and errors that might arise during the deployment or use of Maintenance Configurations for scheduled patching on virtual machines (VMs), along with strategies to address them.

A VM shuts down and is unresponsive when you use a static scope in guest maintenance

Problem

A maintenance configuration doesn't install a scheduled patch on the VMs and gives a `ShutdownOrUnresponsive` error.

Resolution

In a static scope, it's essential to avoid relying on outdated VM configurations. Therefore, it's imperative to ensure that the VM is up and running while the patch is being installed. **If the VM instance is recreated with the same name, it's crucial to prioritize reassigning the configuration after the VM instance is recreated.**

The system will automatically perform this action within 12 hours of recreation if not performed by the user. If the maintenance configuration of the attached recreated VM is triggered within 12 hours of recreating the VM with the same name, a `ShutdownOrUnresponsive` error is displayed. Therefore, it's recommended to either perform the previously mentioned action or wait for 12 hours before applying the patch to the machine via maintenance configuration.

Scheduled patching times out or fails

Problem

Scheduled patching fails with a `TimeOut` or `Failed` error after you move a VM by re-creating it with the same name in a different region. The portal might show the same VM twice because the previously created VM is removed from the back end.

Resolution

If the VM instance is recreated with the same name, it's crucial to prioritize reassigning the configuration after the VM instance is recreated in a different region.

The system will automatically perform this action within 12 hours of recreation if not performed by the user. If the maintenance configuration of the attached recreated VM is triggered within 12 hours of recreating the VM with the same name, a `TimeOut` or `Failed` error is displayed. Therefore, it's recommended to either perform the previously mentioned action or wait for 12 hours before applying the patch to the machine via maintenance configuration.

Unable to delete configuration assignment

Problem

Configuration assignment couldn't be removed or deleted from a particular maintenance configuration

Resolution

Use the following steps to mitigate this issue:

1. Delete the existing maintenance configuration in which you are encountering this issue.
2. Create a new maintenance configuration and assign the required set of dynamic scope and VMs as attached in the deleted maintenance configuration.

If you want to create new maintenance configuration with the same name as the deleted maintenance configuration, you will have to wait 20 minutes for the cleanup to take place in the backend. The system doesn't allow the creation of maintenance configuration with the same name if cleanup isn't performed in the backend.

Scheduled patching stops working after the resource is moved

Problem

If you move a resource to a different resource group or subscription, scheduled patching for the resource stops working.

Resolution

The system currently doesn't support moving resources across resource groups or subscriptions. As a workaround, use the following steps for the resource that you want to move. **As a prerequisite, first remove the assignment before following the steps.**

If you're using a `static` scope:

1. Move the resource to a different resource group or subscription.
2. Re-create the resource assignment.

If you're using a `dynamic` scope:

1. Initiate or wait for the next scheduled run. This action prompts the system to completely remove the assignment, so you can proceed with the next steps.
2. Move the resource to a different resource group or subscription.
3. Re-create the resource assignment.

If any of the steps are missed, move the resource to the previous resource group or subscription ID and reattempt the steps.

> ⓘ **Note**
>
> If the resource group is deleted, recreate it with the same name. If the subscription ID is deleted, reach out to the support team for mitigation.

Maintenance Configuration didn't trigger on the configured date time

Problem

After creating a Maintenance Configuration with a repeat value of either week or month, you expect the schedule to start at the specified date and time and then recur based on the chosen interval. However, the schedule didn't trigger at the start date and time.

Resolution

The Maintenance Configuration first run occurs on the first recurrence value following the specified start date, not necessarily on the start date itself. For example, if the maintenance configuration starts on January 17 (Wednesday) and is set to recur every

Monday, the first run of the schedule will be on the first Monday after January 17, which is January 22.

You can view first 4 instances of the scheduled run when creating a new maintenance configuration from Azure Portal.

Creation of a dynamic scope fails

Problem

You can't create a dynamic scope because of role-based access control (RBAC).

Resolution

To create a dynamic scope, you must have the permission at the subscription level or at the resource group level. Specifically, following are the requirements you need to take care of.

1. The subscription under which dynamic scope is getting created should be registered to Maintenance RP.
2. It's recommended to have the 'Scheduled Patching Contributor' role to be assigned to the following scopes:
   a. The subscription/resource group at which the dynamic scope is being created.
   b. The maintenance configuration scope.

For more information, see the list of permissions list for various resources here.

An update is stuck and not progressing

Problem

Applies to: ✔ Dedicated Hosts ✔ VMs

If you redeploy a resource to a different cluster, and you create a pending update request by using the old cluster value, the request becomes stuck indefinitely.

Resolution

If the status of an operation to apply an update is closed or not found, retry after 120 hours. If the problem persists, contact the support team for assistance.

A dedicated host is updated after a maintenance configuration is attached

Problem

A maintenance configuration doesn't block the update of a dedicated host, and the host is updated even after you attach a maintenance configuration.

Resolution

If you re-create a dedicated host with the same name, Maintenance Configurations retains the old dedicated host ID, which prevents it from blocking updates. You can resolve this problem by removing the maintenance configuration and reassigning it. **The system will automatically perform this action within 12 hours of recreation if not performed by the user.** It's recommended to either perform the previously mentioned action or wait for 12 hours before this action is performed automatically.

A schedule isn't triggered

Problem

If a resource has two maintenance configurations with the same trigger time and patch installation configuration, and both are assigned to the same VM or resource, only one maintenance configuration is triggered.

Resolution

Modify the start time of one of the maintenance configurations to mitigate the problem. This is a workaround to a current system limitation in which Maintenance Configurations can't identify which maintenance configuration to trigger.

You can't create a dynamic scope for a resource group

Problem

Dynamic scope validation fails because of a null value in the location.

Resolution

This problem with dynamic scope validation causes regression in the validation process. We recommend that you provide the required set of locations for a dynamic scope at the resource group level.

A dynamic scope isn't executed and no resources are patched

Problem

Dynamic scope flattening fails because of throttling, and the service can't determine which VMs are associated with the VM.

Resolution

Make sure that the number of subscriptions per dynamic scope isn't more than 200. Learn more about the service limits of dynamic scoping.

Configuration assignment of a dedicated host isn't cleaned up after the host's removal

Problem

After you delete the dedicated hosts, configuration assignments that are attached to dedicated hosts still exist.

Resolution

Before you delete a dedicated host, be sure to delete the maintenance configuration that's associated with it. If the dedicated host is deleted but still appears in the portal, contact the support team for assistance. Cleanup processes are currently in place for dedicated hosts, to help prevent any impact on customers.

Can't provide multiple tag values for dynamic scopes

Problem

If you use the Azure portal, you can't provide multiple tag values for dynamic scopes.

Resolution

This feature currently isn't available in the portal. As a workaround, you can use the Azure CLI or Azure PowerShell to create a dynamic scope. The system accepts multiple values for tags when you use the Azure CLI or Azure PowerShell option.

A maintenance configuration is triggered again with an older trigger time

Problem

There's a known issue in Maintenance Configurations related to the caching of old maintenance policies. If an old policy is cached, and a new instance moves the new policy processing, the old machine might trigger the schedule with the outdated start time.

Resolution

We recommend that you update the maintenance configuration at least 1 hour before the scheduled time. If the problem persists, contact the support team for assistance.

A maintenance configuration times out while waiting for an ongoing update to finish on a resource

Problem

In rare cases, if the host update window happens to coincide with the VM guest patching window, and if the guest patching window doesn't have sufficient time to run after the host update, the system shows this error message: "Schedule timeout, waiting for an ongoing update to complete the resource." The reason is that the platform allows only one update at a time.

Resolution

Change the maintenance configuration schedule for the guest update for a time after the ongoing update is finished.

New maintenance configuration retains attributes of deleted configuration

Problem

A newly created maintenance configuration with the same name as a previously deleted configuration is inheriting properties from the deleted configuration.

Resolution

Ensure a minimum wait time of 20 minutes between deleting a maintenance configuration and creating a new one with the same name. If the problem persists, contact the support team for assistance.

Maintenance assignment fails with `InternalServerError` error

Problem

Maintenance assignment fails with `InternalServerError` when using either bicep template or MRP API. The assignment can be done successfully using either portal or CLI or PowerShell.

Resolution

It is recommended to use the location/region in a normalized form for the bicep template and MRP API. The normalized form involves removing whitespace and converting the text to lowercase. For example, `EAST US 2` will result in an internal server error, whereas `eastus2` will be processed successfully.

Workload isolation in maintenance configuration

Problem

Unexpected outage due to assumption of maintenance configuration respecting workload isolation

Resolution

Maintenance configurations will initiate updates on all resources associated with it simultaneously. Customers have the flexibility to decide on the isolation and

maintenance windows for their workloads. They can create single or multiple maintenance configurations based on the isolation that is optimal for their workloads.

For example, if a customer wants to isolate updates for their development environment resources from the production environment resources, they can create separate maintenance configurations for each environment. This way, workloads in maintenance configuration with development resources are updated first, while the remaining workloads are updated in another configuration that does not overlap. This approach allows customers to control workload isolation and manage updates independently.

Maintenance Configurations doesn't support an API

The feature currently doesn't support the following APIs:

- Get Apply Update at Subscription Level
- Get Apply Update at Resource Group Level
- Get Pending Update at Subscription Level
- Get Pending Update at Resource Group Level

Maintenance control for Azure Virtual Machine Scale Sets

Article • 10/22/2024

Applies to: ✔ Uniform scale sets

Manage automatic OS image upgrades for your Virtual Machine Scale Sets using maintenance control.

Maintenance control lets you decide when to apply updates to OS disks in your Virtual Machine Scale Sets through an easier and more predictable experience.

Maintenance configurations work across subscriptions and resource groups.

The entire workflow comes down to these steps:

- Create a maintenance configuration.
- Associate a Virtual Machine Scale Set to a maintenance configuration.
- Enable automatic OS upgrades.

Limitations

- VMs must be in a scale set.
- User must have **Resource Contributor** access.
- Maintenance duration must be 5 hours or longer in the maintenance configuration.
- Maintenance recurrence must be set to 'Day' or 'Week' in the maintenance configuration.

Management options

You can create and manage maintenance configurations using any of the following options:

- Azure PowerShell
- Azure CLI
- Azure portal

Next steps

Virtual Machine Scale Set maintenance control by using PowerShell

Feedback

Maintenance control for OS image upgrades on Azure Virtual Machine Scale Sets using PowerShell

Article • 08/22/2024

Applies to: ✔ Uniform scale sets

Maintenance control lets you decide when to apply automatic guest OS image upgrades to your Virtual Machine Scale Sets. This topic covers the Azure PowerShell options for Maintenance control. For more information on using Maintenance control, see Maintenance control for Azure Virtual Machine Scale Sets.

Enable the PowerShell module

Make sure `PowerShellGet` is up to date.

Azure PowerShell

```
Install-Module -Name PowerShellGet -Repository PSGallery -Force
```

Install the `Az.Maintenance` PowerShell module.

Azure PowerShell

```
Install-Module -Name Az.Maintenance
```

If you're installing locally, make sure you open your PowerShell prompt as an administrator.

You may also be asked to confirm that you want to install from an *untrusted repository*. Type `Y` or select **Yes to All** to install the module.

Connect to an Azure account

Connect to your desired Azure account using Connect-AzAccount and Set-AzAccount.

Azure PowerShell

```
Connect-AzAccount
Set-AzContext 00a000aa-0a00-0a0a-00aa-a00a000aaa00
```

```
$RGName="myMaintenanceRG"
$MaintenanceConfig="myMaintenanceConfig"
$location="eastus2"
$vmss="myMaintenanceVMSS"
```

Create a maintenance configuration

Create a resource group as a container for your configuration. In this example, a resource group named *myMaintenanceRG* is created in *eastus2*. If you already have a resource group that you want to use, you can skip this part. Just replace the resource group name with your own in the rest of the examples.

Azure PowerShell

```
New-AzResourceGroup `
   -Location $location `
   -Name $RGName
```

Use New-AzMaintenanceConfiguration to create a maintenance configuration. This example creates a maintenance configuration named *myConfig* scoped to the OS image.

Azure PowerShell

```
$config = New-AzMaintenanceConfiguration `
   -ResourceGroup $RGName `
   -Name $MaintenanceConfig `
   -MaintenanceScope OSImage `
   -Location $location `
   -StartDateTime "2020-10-01 00:00" `
   -TimeZone "Pacific Standard Time" `
   -Duration "05:00" `
   -RecurEvery "Day"
```

ⓘ Important

Maintenance **duration** must be *5 hours* or longer. Maintenance **recurrence** must be set to *Day*.

Using `-MaintenanceScope OSImage` ensures that the maintenance configuration is used for controlling updates to the guest OS.

If you try to create a configuration with the same name, but in a different location, you'll get an error. Configuration names must be unique to your resource group.

You can query for available maintenance configurations using Get-AzMaintenanceConfiguration.

Azure PowerShell

```
Get-AzMaintenanceConfiguration | Format-Table -Property Name,Id
```

Associate your Virtual Machine Scale Set to the maintenance configuration

A Virtual Machine Scale Set can be associated to any Maintenance configuration regardless of the region and subscription of the Maintenance configuration. By opting in to the Maintenance configuration, new OS image updates for the scale set will be automatically scheduled on the next available maintenance window.

Use New-AzConfigurationAssignment to associate your Virtual Machine Scale Set the maintenance configuration.

Azure PowerShell

```
New-AzConfigurationAssignment `
   -ResourceGroupName $RGName `
   -Location $location `
   -ResourceName $vmss `
   -ResourceType VirtualMachineScaleSets `
   -ProviderName Microsoft.Compute `
   -ConfigurationAssignmentName $config.Name`
   -MaintenanceConfigurationId $config.Id
```

Enable automatic OS upgrade

You can enable automatic OS upgrades for each Virtual Machine Scale Set that is going to use maintenance control. For more information about enabling automatic OS upgrades on your Virtual Machine Scale Set, see Azure Virtual Machine Scale Set automatic OS image upgrades.

Maintenance control for OS image upgrades on Azure Virtual Machine Scale Sets using Azure CLI

Article • 08/22/2024

Maintenance control lets you decide when to apply automatic guest OS image upgrades to your Virtual Machine Scale Sets. This topic covers the Azure CLI options for Maintenance control. For more information on using Maintenance control, see Maintenance control for Azure Virtual Machine Scale Sets.

Create a maintenance configuration

Use `az maintenance configuration create` to create a maintenance configuration. This example creates a maintenance configuration named *myConfig* scoped to the osimage.

Azure CLI

```
az group create \
   --location eastus \
   --name myMaintenanceRG
az maintenance configuration create \
   -g myMaintenanceRG \
   --resource-name myConfig \
   --maintenance-scope osimage\
   --location eastus
```

Copy the configuration ID from the output to use later.

Using `--maintenance-scope osimage` ensures that the maintenance configuration is used for controlling updates to the guest OS.

If you try to create a configuration with the same name, but in a different location, you will get an error. Configuration names must be unique to your resource group.

You can query for available maintenance configurations using `az maintenance configuration list`.

Azure CLI

```
az maintenance configuration list --query "[].{Name:name, ID:id}" -o table
```

Create a maintenance configuration with a scheduled window

You can also declare a scheduled window when Azure will apply the updates on your resources. This example creates a maintenance configuration named *myConfig* with a scheduled window of 5 hours on the fourth Monday of every month. Once you create a scheduled window, you no longer have to apply the updates manually.

> **ⓘ Important**
>
> Maintenance **duration** must be *5 hours* or longer. Maintenance **recurrence** must be set to *Day*.

Azure CLI

```
az maintenance configuration create \
   -g myMaintenanceRG \
   --resource-name myConfig \
   --maintenance-scope osimage \
   --location eastus \
   --maintenance-window-duration "05:00" \
   --maintenance-window-recur-every "Day" \
   --maintenance-window-start-date-time "2020-12-30 08:00" \
   --maintenance-window-time-zone "Pacific Standard Time"
```

Assign the configuration

Use `az maintenance assignment create` to assign the configuration to your Virtual Machine Scale Set.

Enable automatic OS upgrade

You can enable automatic OS upgrades for each Virtual Machine Scale Set that is going to use maintenance control. For more information about enabling automatic OS upgrades on your Virtual Machine Scale Set, see Azure Virtual Machine Scale Set automatic OS image upgrades.

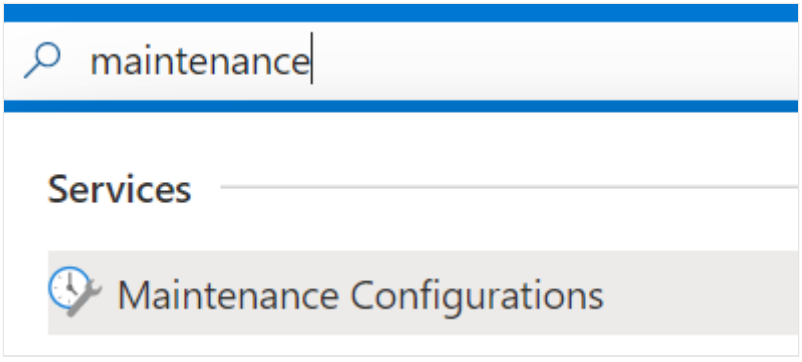
Maintenance control for OS image upgrades on Azure Virtual Machine Scale Sets using Azure portal

Article • 08/22/2024

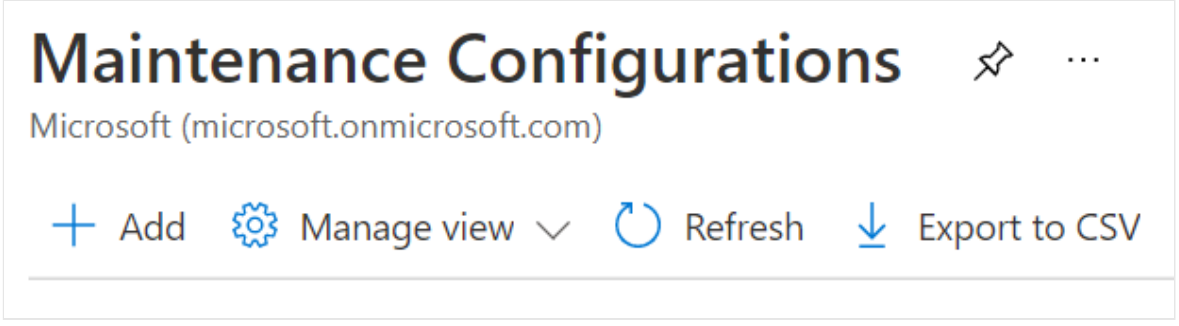
Maintenance control lets you decide when to apply automatic guest OS image upgrades to your Virtual Machine Scale Sets. This topic covers the Azure portal options for Maintenance control. For more information on using Maintenance control, see Maintenance control for Azure Virtual Machine Scale Sets.

Create a maintenance configuration

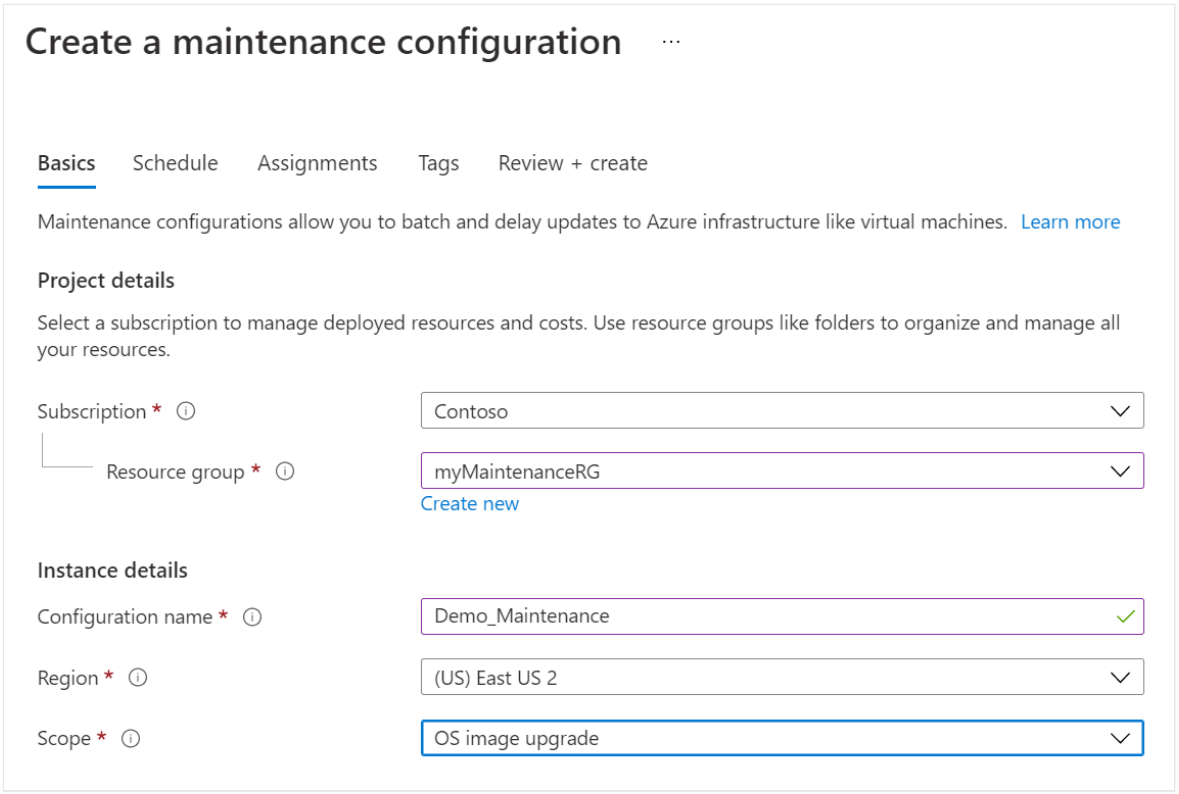
1. Sign in to the Azure portal.
2. Search for **Maintenance Configurations**.



3. Select **Add**.

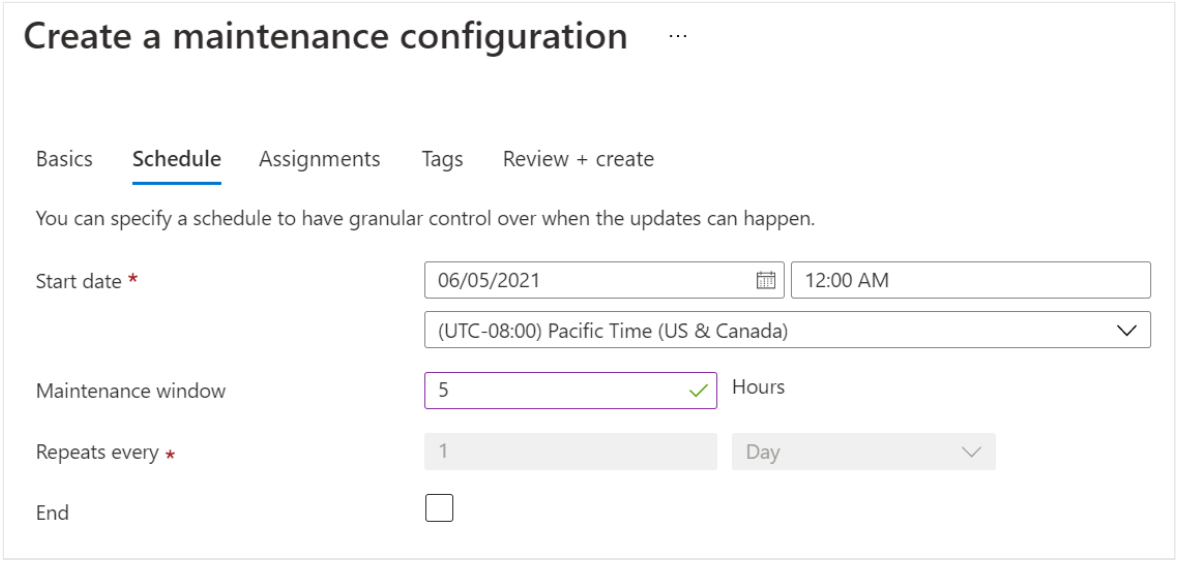


4. In the Basics tab, choose a subscription and resource group, provide a name for the configuration, choose a region, and select *OS image upgrade* for the scope. Select **Next**.



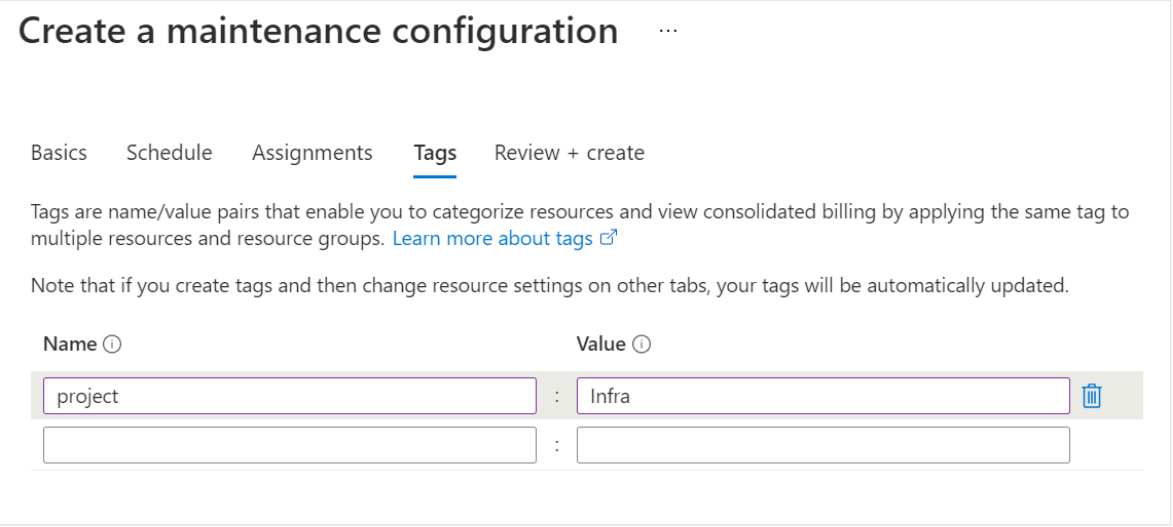
5. In the Schedule tab, declare a scheduled window when Azure will apply the updates on your resources. Set a start date, maintenance window, and recurrence. Once you create a scheduled window, you no longer have to apply the updates manually. Select **Next**.

> **Important**
>
> Maintenance window **duration** must be *5 hours* or longer. Maintenance **recurrence** must be set to repeat at least once a day.



6. In the Assignment tab, assign resources now or skip this step and assign resources after the maintenance configuration deployment. Select **Next**.

7. Add tags and values. Select **Next**.

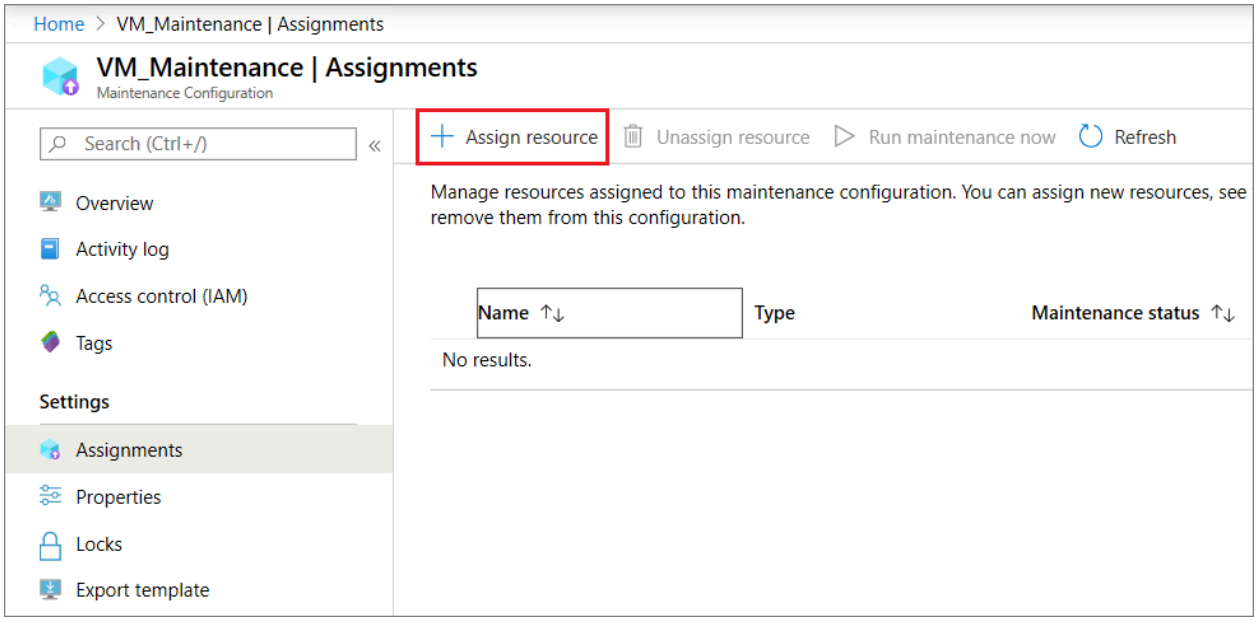


8. Review the summary. Select **Create**.

9. After the deployment is complete, select **Go to resource**.

Assign the configuration

On the details page of the maintenance configuration, select **Assignments** and then select **Assign resource**.



Select the Virtual Machine Scale Set resources that you want the maintenance configuration assigned to and select **Ok**.

Maintenance control for OS image upgrades on Azure Virtual Machine Scale Sets using an ARM template

Article • 08/22/2024

Maintenance control lets you decide when to apply automatic OS image upgrades to your Virtual Machine Scale Sets. For more information on using Maintenance control, see Maintenance control for Azure Virtual Machine Scale Sets.

This article explains how you can use an Azure Resource Manager (ARM) template to create a maintenance configuration. You will learn how to:

- Create the configuration
- Assign the configuration to a virtual machine

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

Create the configuration

While creating the configuration, it is important to note that there are different scopes and each will have unique properties in their creation template. Make sure you are using the right one.

For more information about this Maintenance Configuration template, see maintenanceConfigurations.

Host and OS image

JSON

```
{
  "type": "Microsoft.Maintenance/maintenanceConfigurations",
  "apiVersion": "2021-09-01-preview",
  "name": "string",
  "location": "string",
  "tags": {

Azure Metadata Service: Scheduled Events for Linux VMs

06/06/2025

Applies to: ✔ Linux VMs ✔ Flexible scale sets ✔ Uniform scale sets

Scheduled Events is an Azure Metadata Service that gives your application time to prepare for virtual machine (VM) maintenance. It provides information about upcoming maintenance events (for example, reboot) so that your application can prepare for them and limit disruption. It's available for all Azure Virtual Machines types, including PaaS and IaaS on both Windows and Linux.

For information about Scheduled Events on Linux, see Scheduled Events for Linux VMs.

Scheduled events provide proactive notifications about upcoming events, for reactive information about events that happened in the past see VM availability information in Azure Resource Graph and Create an availability alert rule for Azure virtual machine.

> ⓘ **Note**
>
> Scheduled Events is generally available in all Azure Regions. See Version and Region Availability for latest release information.

Why use Scheduled Events?

Many applications can benefit from time to prepare for VM maintenance. The time can be used to perform application-specific tasks that improve availability, reliability, and serviceability, including:

- Checkpoint and restore.
- Connection draining.
- Primary replica failover.
- Removal from a load balancer pool.
- Event logging.
- Graceful shutdown.

With Scheduled Events, your application can discover when maintenance will occur and trigger tasks to limit its impact.

Scheduled Events provides events in the following use cases:

- Platform initiated maintenance (for example, VM reboot, live migration or memory preserving updates for host).
- Virtual machine is running on degraded host hardware that is predicted to fail soon.
- Virtual machine was running on a host that suffered a hardware failure.
- User-initiated maintenance (for example, a user restarts or redeploys a VM).
- Spot VM and Spot scale set instance evictions.

The Basics

Metadata Service exposes information about running VMs by using a REST endpoint that's accessible from within the VM. The information is available via a nonroutable IP and isn't exposed outside the VM.

Scope

Scheduled events are delivered to and can be acknowledged by:

- Standalone Virtual Machines.
- All the VMs in an Azure cloud service (classic).
- All the VMs in an availability set.
- All the VMs in a scale set placement group.

Scheduled Events for all virtual machines (VMs) in an entire Availability Set or a Placement Group for a Virtual Machine Scale Set are delivered to all other VMs in the same group or set regardless of Availability Zone usage.

As a result, check the `Resources` field in the event to identify which VMs are affected.

> **Note**
>
> GPU accelerated Virtual Machines in a scale set using one fault domain (FD = 1) only receive scheduled events for the impacted resource. Events won't be broadcasted to all VMs in the same placement group.

Endpoint discovery

For VNET enabled VMs, Metadata Service is available from a static nonroutable IP, `169.254.169.254`. The full endpoint for the latest version of Scheduled Events is:

```
http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

If the VM isn't created within a Virtual Network, the default cases for cloud services and classic VMs, other logic is required to discover the IP address to use. To learn how to discover the host endpoint, see this sample.

Version and region availability

The Scheduled Events service is versioned. Versions are mandatory; the current version is `2020-07-01`.

Expand table

Version	Release Type	Regions	Release Notes
2020-07-01	General Availability	All	• Added support for Event Duration
2019-08-01	General Availability	All	• Added support for EventSource
2019-04-01	General Availability	All	• Added support for Event Description
2019-01-01	General Availability	All	• Added support for Virtual Machine Scale Sets EventType 'Terminate'
2017-11-01	General Availability	All	• Added support for Spot VM eviction EventType 'Preempt'
2017-08-01	General Availability	All	• Removed prepended underscore from resource names for IaaS VMs • Metadata header requirement enforced for all requests
2017-03-01	Preview	All	• Initial release

> **Note**
>
> Previous preview releases of Scheduled Events supported {latest} as the api-version. This format is no longer supported and will be deprecated in the future.

Enabling and disabling Scheduled Events

Scheduled Events is enabled for your service the first time you make a request for events. You should expect a delayed response in your first call of up to two minutes and you'll start

receiving events within 5 minutes. Scheduled Events is disabled for your service if it doesn't make a request to the endpoint for 24 hours.

User-initiated maintenance

User-initiated VM maintenance via the Azure portal, API, CLI, or PowerShell results in a scheduled event. You then can test the maintenance preparation logic in your application, and your application can prepare for user-initiated maintenance.

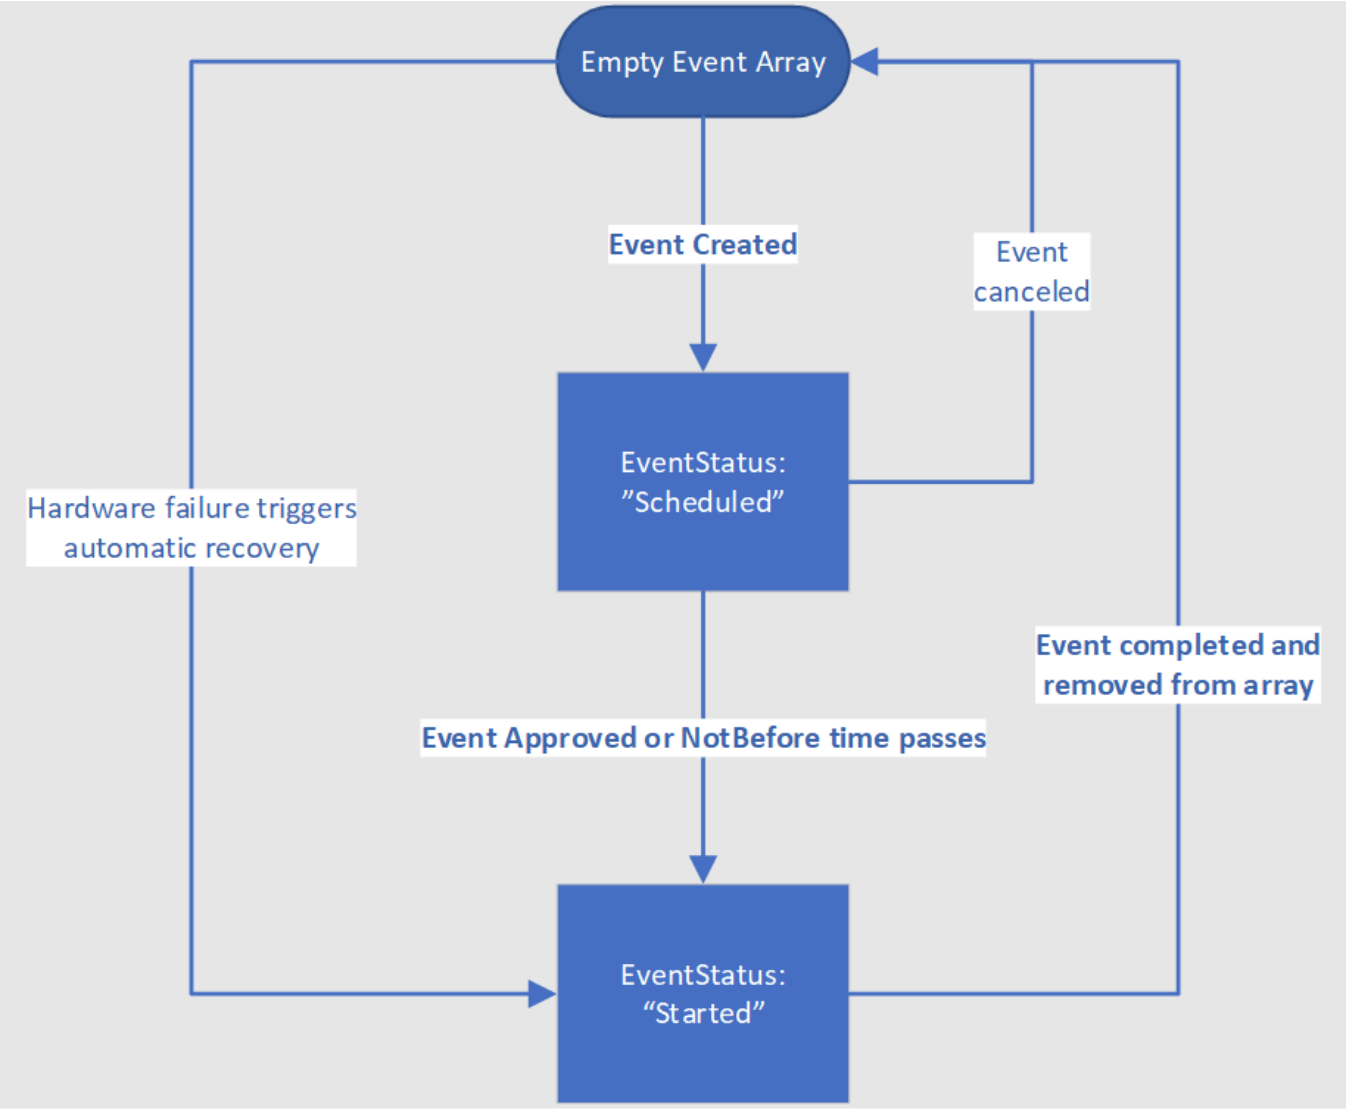
If you restart a VM, an event with the type `Reboot` is scheduled. If you redeploy a VM, an event with the type `Redeploy` is scheduled. Typically events with a user event source can be immediately approved to avoid a delay on user-initiated actions. We advise having a primary and secondary VM communicating and approving user generated scheduled events in case the primary VM becomes unresponsive. Immediately approving events prevents delays in recovering your application back to a good state.

Scheduled events for Virtual Machine Scale Sets Guest OS upgrades or reimages are supported for general purpose VM sizes that support memory preserving updates only. It doesn't work for G, M, N, and H series. Scheduled events for Virtual Machine Scale Sets Guest OS upgrades and reimages are disabled by default. To enable scheduled events for these operations on supported VM sizes, first enable them using OSImageNotificationProfile.

Use the API

High level overview

There are two major components to handling Scheduled Events, preparation and recovery. All current scheduled events impacting a VM are available to read via the IMDS Scheduled Events endpoint. When the event reaches a terminal state, it's removed from the list of events. The following diagram shows the various state transitions that a single scheduled event can experience:



For events in the EventStatus:"Scheduled" state, you need to take steps to prepare your workload. Once the preparation is complete, you should then approve the event using the scheduled event API. Otherwise, the event is automatically approved when the NotBefore time is reached. If the VM is on shared infrastructure, the system will then wait for all other tenants on the same hardware to also approve the job or timeout. Once approvals are gathered from all impacted VMs or the NotBefore time is reached, then Azure generates a new scheduled event payload with EventStatus:"Started" and triggers the start of the maintenance event. When the event reaches a terminal state, it's removed from the list of events. That serves as the signal for the customer to recover their VMs.

The psudeo code demonstrates a process for how to read and manage scheduled events in your application:

```
current_list_of_scheduled_events = get_latest_from_se_endpoint()
#prepare for new events
for each event in current_list_of_scheduled_events:
  if event not in previous_list_of_scheduled_events:
    prepare_for_event(event)
```

```
#recover from completed events
for each event in previous_list_of_scheduled_events:
  if event not in current_list_of_scheduled_events:
    receover_from_event(event)
#prepare for future jobs
previous_list_of_scheduled_events = current_list_of_scheduled_events
```

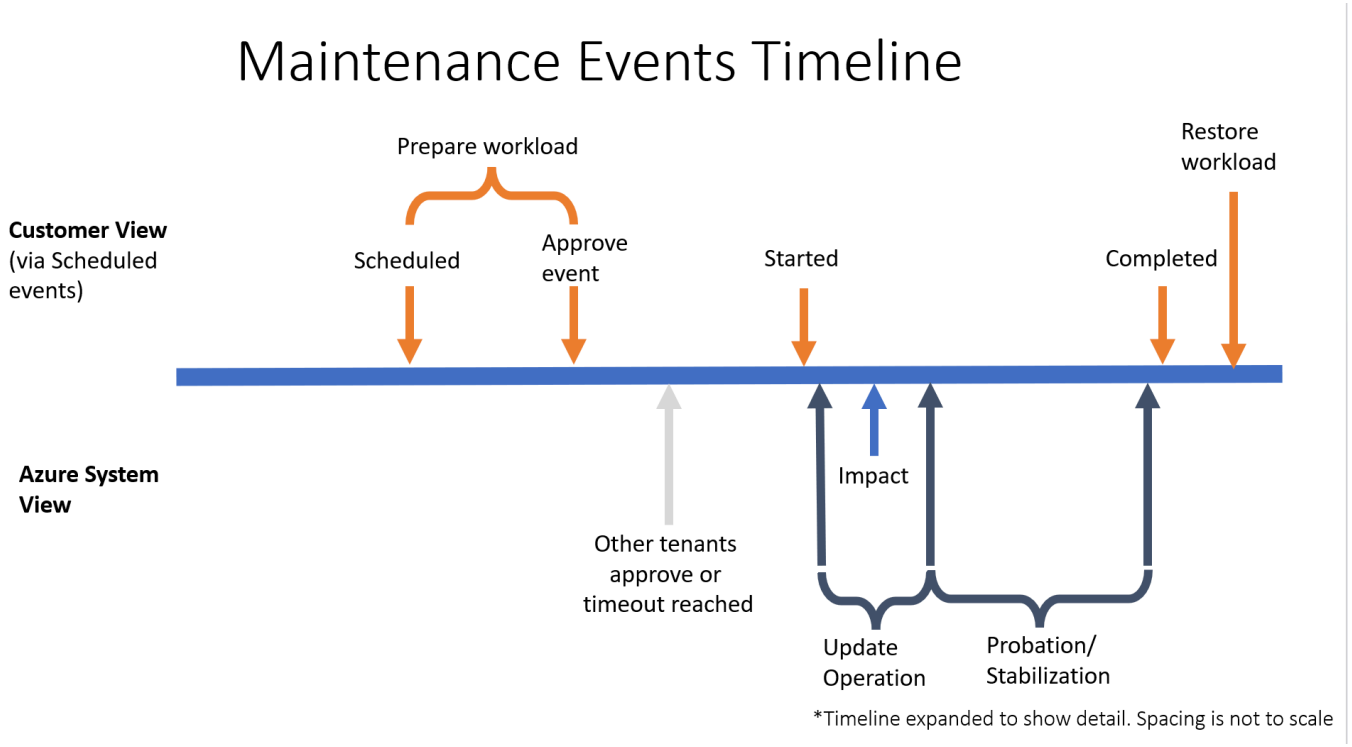
As scheduled events are often used for applications with high availability requirements, there are a few exceptional cases that should be considered:

1. Once a scheduled event is completed and removed from the array, there will be no further impacts without a new event including another EventStatus:"Scheduled" event
2. Azure monitors maintenance operations across the entire fleet and in rare circumstances determines that a maintenance operation too high risk to apply. In that case the scheduled event goes directly from "Scheduled" to being removed from the events array
3. If there is a hardware failure, Azure bypasses the "Scheduled" state and immediately move to the EventStatus:"Started" state.
4. While the event is still in EventStatus:"Started" state, there may be another impact of a shorter duration than what was advertised in the scheduled event.

As part of Azure's availability guarantee, VMs in different fault domains won't be impacted by routine maintenance operations at the same time. However, they may have operations serialized one after another. VMs in one fault domain can receive scheduled events with EventStatus:"Scheduled" shortly after another fault domain's maintenance is completed. Regardless of what architecture you chose, always keep checking for new events pending against your VMs.

While the exact timings of events vary, the following diagram provides a rough guideline for how a typical maintenance operation proceeds:

- EventStatus:"Scheduled" to Approval Timeout: 15 minutes
- Impact Duration: 7 seconds
- EventStatus:"Started" to Completed (event removed from Events array): 10 minutes



All operations impacting VM availability create a scheduled event, however not all scheduled events appear in other Azure surfaces such as Azure Activity Logs or Resource Health. Checking scheduled events regularly will ensure that you have the most up-to-date information about any upcoming impacts to your VMs.

Headers

When you query Metadata Service, you must provide the header `Metadata:true` to ensure the request wasn't unintentionally redirected. The `Metadata:true` header is required for all scheduled events requests. Failure to include the header in the request results in a "Bad Request" response from Metadata Service.

Query for events

You can query for scheduled events by making the following call:

Bash sample

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

PowerShell sample

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -Uri
"http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01" |
ConvertTo-Json -Depth 64
```

Python sample

```
import json
import requests

metadata_url ="http://169.254.169.254/metadata/scheduledevents"
header = {'Metadata' : 'true'}
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data
```

A response contains an array of scheduled events. An empty array means that currently no events are scheduled. In the case where there are scheduled events, the response contains an array of events.

```
{
    "DocumentIncarnation": {IncarnationID},
    "Events": [
        {
            "EventId": {eventID},
            "EventType": "Reboot" | "Redeploy" | "Freeze" | "Preempt" |
"Terminate",
            "ResourceType": "VirtualMachine",
            "Resources": [{resourceName}],
            "EventStatus": "Scheduled" | "Started",
            "NotBefore": {timeInUTC},
            "Description": {eventDescription},
            "EventSource" : "Platform" | "User",
            "DurationInSeconds" : {timeInSeconds},
        }
    ]
}
```

Event properties

Expand table

Property	Description
Document Incarnation	Integer that increases when the events array changes. Documents with the same incarnation contain the same event information, and the incarnation is incremented when an event changes.
EventId	Globally unique identifier for this event. Example: • 602d9444-d2cd-49c7-8624-8643e7171297
EventType	Expected impact this event will cause. Values: • `Freeze`: The Virtual Machine is scheduled to pause for a few seconds. CPU and network connectivity may be suspended, but there's no impact on memory or open files. • `Reboot`: The Virtual Machine is scheduled for reboot (non-persistent memory is lost). In rare cases a VM scheduled for EventType:"Reboot" may experience a freeze event instead of a reboot. Follow the instructions above for how to know if the event is complete and it's safe to restore your workload. • `Redeploy`: The Virtual Machine is scheduled to move to another node (ephemeral disks are lost). • `Preempt`: The Spot Virtual Machine is being deleted (ephemeral disks are lost). This event is made available on a best effort basis • `Terminate`: The virtual machine is scheduled to be deleted.
ResourceType	Type of resource this event affects. Values: • `VirtualMachine`
Resources	List of resources this event affects. Example: • ["FrontEnd_IN_0", "BackEnd_IN_0"]
EventStatus	Status of this event.

Property	Description
	Values: • `Scheduled`: This event is scheduled to start after the time specified in the `NotBefore` property. • `Started`: This event has started. No `Completed` or similar status is ever provided. The event is no longer returned when the event is finished.
NotBefore	Time after which this event can start. The event is guaranteed to not start before this time. Will be blank if the event after the event starts. Example: • Mon, 19 Sep 2016 18:29:47 GMT
Description	Description of this event. Example: • Host server is undergoing maintenance. • Host Server infrastructure is undergoing maintenance. • Virtual machine is being paused because of a memory-preserving Live Migration operation. • Virtual machine is going to be restarted as requested by authorized user. • Host server is undergoing an emergency repair.
EventSource	Initiator of the event. Example: • `Platform`: Platform initiated this event. • `User`: The user initiated this event.
DurationInSeconds	The expected duration of the interruption caused by the event. There may be secondary impacts of a shorter duration during the impact window. Example: • `9`: The interruption caused by the event lasts for 9 seconds. • `0`: The event won't interrupt the VM or impact its availability (for example, update to the network) • `-1`: The default value used if the impact duration is either unknown or not applicable.

Event scheduling

Each event is scheduled a minimum amount of time in the future based on the event type. This time is reflected in an event's `NotBefore` property.

Expand table

EventType	Minimum notice
Freeze	15 minutes
Reboot	15 minutes
Redeploy	10 minutes
Preempt	30 seconds
Terminate	User Configurable: 5 to 15 minutes

This means that you can detect a future schedule of event at least by the minimum notice time before the event occurs. Once an event is scheduled, it will move into the `Started` state after it's been approved or the `NotBefore` time passes. However, in rare cases, the operation is canceled by Azure before it starts. In that case the event is removed from the Events array, and the impact won't occur as previously scheduled.

> **Note**
>
> In some cases, Azure is able to predict host failure due to degraded hardware and attempts to mitigate disruption to your service by scheduling a migration. Affected virtual machines will receive a scheduled event with a `NotBefore` that is typically a few days in the future. The actual time varies depending on the predicted failure risk assessment. Azure tries to give 7 days of advance notice when possible. The actual notice time varies and might be shorter if there's a high chance of the hardware failing imminently. To minimize risk to your service in case the hardware fails before the system-initiated migration, we recommend that you self-redeploy your virtual machine as soon as possible.

> **Note**
>
> In the case the host node experiences a hardware failure, Azure bypasses the minimum notice period and immediately begin the recovery process for affected virtual machines. This reduces recovery time in the case that the affected VMs are unable to respond.

During the recovery process, an event is created for all impacted VMs with `EventType = Reboot` and `EventStatus = Started`.

Polling frequency

You can poll the endpoint for updates as frequently or infrequently as you like. However, the longer the time between requests, the more time you potentially lose to react to an upcoming event. Most events have 5 to 15 minutes of advance notice, although in some cases advance notice might be as little as 30 seconds. To ensure that you have as much time as possible to take mitigating actions, we recommend that you poll the service once per second.

Start an event

After you learn of an upcoming event and finish your logic for graceful shutdown, you can approve the outstanding event by making a `POST` call to Metadata Service with `EventId`. This call indicates to Azure that it can shorten the minimum notification time (when possible). The event may not start immediately upon approval. In some cases Azure requires the approval of all the VMs hosted on the node before proceeding with the event.

The following JSON sample is expected in the `POST` request body. The request should contain a list of `StartRequests`. Each `StartRequest` contains `EventId` for the event you want to expedite:

```
{
    "StartRequests" : [
        {
            "EventId": {EventId}
        }
    ]
}
```

The service always returns a 200 success code if it's passed a valid event ID, even if another VM already approved the event. A 400 error code indicates that the request header or payload was malformed.

> **Note**
>
> Events won't proceed unless they are either approved via a POST message or the NotBefore time elapses. This includes user triggered events such as VM restarts from the Azure portal.

Bash sample

```
curl -H Metadata:true -X POST -d '{"StartRequests": [{"EventId": "f020ba2e-3bc0-
4c40-a10b-86575a9eabd5"}]}' http://169.254.169.254/metadata/scheduledevents?api-
version=2020-07-01
```

PowerShell sample

```
Invoke-RestMethod -Headers @{"Metadata" = "true"} -Method POST -body
'{"StartRequests": [{"EventId": "5DD55B64-45AD-49D3-BBC9-F57D4EA97BD7"}]}' -Uri
http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01 |
ConvertTo-Json -Depth 64
```

Python sample

```
import json
import requests

def confirm_scheduled_event(event_id):
   # This payload confirms a single event with id event_id
   payload = json.dumps({"StartRequests": [{"EventId": event_id }]})
   response = requests.post("http://169.254.169.254/metadata/scheduledevents",
                            headers =  {'Metadata' : 'true'},
                            params = {'api-version':'2020-07-01'},
                            data = payload)
   return response.status_code
```

> **Note**
>
> Acknowledging an event allows the event to proceed for all `Resources` in the event, not just the VM that acknowledges the event. Therefore, you can choose to elect a leader to coordinate the acknowledgment, which might be as simple as the first machine in the `Resources` field.

Example responses

The following events are an example that from two VMs which were live migrated to another node.

The `DocumentIncarnation` is changing every time there's new information in `Events`. An approval of the event would allow the freeze to proceed for both WestNO_0 and WestNO_1.

JSON

```
{
    "DocumentIncarnation":  1,
    "Events":  [
               ]
}

{
    "DocumentIncarnation":  2,
    "Events":  [
                   {
                       "EventId":  "C7061BAC-AFDC-4513-B24B-AA5F13A16123",

    "DocumentIncarnation":  4,
    "Events":  [
                ]
}
```

Python Sample

The sample queries Metadata Service for scheduled events and approves each outstanding event. You can find the code in the vm-scheduled-events-mock-server repository in the Listener.py file.

Python

```python
#!/usr/bin/python
import json
import requests
from time import sleep

# The URL to access the metadata service
metadata_url ="http://169.254.169.254/metadata/scheduledevents"
# This must be sent otherwise the request will be ignored
header = {'Metadata' : 'true'}
# Current version of the API
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data

def confirm_scheduled_event(event_id):
    # This payload confirms a single event with id event_id
    # You can confirm multiple events in a single request if needed
    payload = json.dumps({"StartRequests": [{"EventId": event_id }]})
    response = requests.post(metadata_url,
                             headers= header,
                             params = query_params,
                             data = payload)
    return response.status_code

def log(event):
    # This is an optional placeholder for logging events to your system
    print(event["Description"])
    return

def advanced_sample(last_document_incarnation):
```

```
    # Poll every second to see if there are new scheduled events to process
    # Since some events may have necessarily short warning periods, it is
    # recommended to poll frequently
    found_document_incarnation = last_document_incarnation
    while (last_document_incarnation == found_document_incarnation):
        sleep(1)
        payload = get_scheduled_events()
        found_document_incarnation = payload["DocumentIncarnation"]

    # We recommend processing all events in a document together,
    # even if you won't be actioning on them right away
    for event in payload["Events"]:

        # Events that already started, logged for tracking
        if (event["EventStatus"] == "Started"):
            log(event)

        # Approve all user initiated events. These are typically created by an
        # administrator and approving them immediately can help to avoid delays
        # in admin actions
        elif (event["EventSource"] == "User"):
            confirm_scheduled_event(event["EventId"])

        # For this application, freeze events less that 9 seconds are considered
        # no impact. This will immediately approve them
        elif (event["EventType"] == "Freeze" and
            int(event["DurationInSeconds"]) >= 0  and
            int(event["DurationInSeconds"]) < 9):
            confirm_scheduled_event(event["EventId"])

        # Events that may be impactful (for example reboot or redeploy) may need
custom
        # handling for your application
        else:
            #TODO Custom handling for impactful events
            log(event)
    print("Processed events from document: " + str(found_document_incarnation))
    return found_document_incarnation

def main():
    # This will track the last set of events seen
    last_document_incarnation = "-1"

    input_text = "\
        Press 1 to poll for new events \n\
        Press 2 to exit \n "
    program_exit = False

    while program_exit == False:
        user_input = input(input_text)
        if (user_input == "1"):
            last_document_incarnation = advanced_sample(last_document_incarnation)
        elif (user_input == "2"):
            program_exit = True
```

```
if __name__ == '__main__':
    main()
```

Testing Scheduled Events

Two common ways to test your applications response to scheduled events are manually triggering user imitated events or using a mock server.

You can manually trigger redeploy and reboot events through the Azure Portal or Azure CLI by selecting the 'reboot' or 'redeploy' VM option from the VM blade. This will create an event and send it to your workload.

Operations that impact multiple VMs, such as host updates, cannot be triggered on demand so you can use a mock server instead. The vm-scheduled-events-mock-server provides a framework for testing your application's response to different scenarios by replaying real events flows back for development and testing. By default the server supports 9 different scenarios, all captured from VMs running in Azure and representing the most common cases. The scenarios can be expanded to include more options depending on your applications particular characteristics.

- Learn how to log scheduled events by using Azure Event Hubs in the Azure Samples GitHub repository.
- Use the vm-scheduled-events-mock-server to test your application's response to common scheduled events scenarios.

Azure Metadata Service: Scheduled Events for Windows VMs

06/06/2025

Applies to: ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Scheduled Events is an Azure Metadata Service that gives your application time to prepare for virtual machine (VM) maintenance. It provides information about upcoming maintenance events (for example, reboot) so that your application can prepare for them and limit disruption. It's available for all Azure Virtual Machines types, including PaaS and IaaS on both Windows and Linux.

For information about Scheduled Events on Linux, see Scheduled Events for Linux VMs.

Scheduled events provide proactive notifications about upcoming events, for reactive information about events that happened in the past see VM availability information in Azure Resource Graph and Create an availability alert rule for Azure virtual machine.

> ⓘ **Note**
>
> Scheduled Events is generally available in all Azure Regions. See Version and Region Availability for latest release information.

Why use Scheduled Events?

Many applications can benefit from time to prepare for VM maintenance. The time can be used to perform application-specific tasks that improve availability, reliability, and serviceability, including:

- Checkpoint and restore.
- Connection draining.
- Primary replica failover.
- Removal from a load balancer pool.
- Event logging.
- Graceful shutdown.

With Scheduled Events, your application can discover when maintenance will occur and trigger tasks to limit its impact.

Scheduled Events provides events in the following use cases:

- Platform initiated maintenance (for example, VM reboot, live migration or memory preserving updates for host).
- Virtual machine is running on degraded host hardware that is predicted to fail soon.
- Virtual machine was running on a host that suffered a hardware failure.
- User-initiated maintenance (for example, a user restarts or redeploys a VM).
- Spot VM and Spot scale set instance evictions.

The Basics

Metadata Service exposes information about running VMs by using a REST endpoint that's accessible from within the VM. The information is available via a nonroutable IP and isn't exposed outside the VM.

Scope

Scheduled events are delivered to and can be acknowledged by:

- Standalone Virtual Machines.
- All the VMs in an Azure cloud service (classic).
- All the VMs in an availability set.
- All the VMs in a scale set placement group.

Scheduled Events for all virtual machines (VMs) in an entire Availability Set or a Placement Group for a Virtual Machine Scale Set are delivered to all other VMs in the same group or set regardless of Availability Zone usage.

As a result, check the `Resources` field in the event to identify which VMs are affected.

> **Note**
>
> GPU accelerated Virtual Machines in a scale set using one fault domain (FD = 1) only receive scheduled events for the impacted resource. Events won't be broadcasted to all VMs in the same placement group.

Endpoint discovery

For VNET enabled VMs, Metadata Service is available from a static nonroutable IP, `169.254.169.254`. The full endpoint for the latest version of Scheduled Events is:

```
http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

If the VM isn't created within a Virtual Network, the default cases for cloud services and classic VMs, other logic is required to discover the IP address to use. To learn how to discover the host endpoint, see this sample.

Version and region availability

The Scheduled Events service is versioned. Versions are mandatory; the current version is `2020-07-01`.

Expand table

Version	Release Type	Regions	Release Notes
2020-07-01	General Availability	All	• Added support for Event Duration
2019-08-01	General Availability	All	• Added support for EventSource
2019-04-01	General Availability	All	• Added support for Event Description
2019-01-01	General Availability	All	• Added support for Virtual Machine Scale Sets EventType 'Terminate'
2017-11-01	General Availability	All	• Added support for Spot VM eviction EventType 'Preempt'
2017-08-01	General Availability	All	• Removed prepended underscore from resource names for IaaS VMs • Metadata header requirement enforced for all requests
2017-03-01	Preview	All	• Initial release

> **Note**
>
> Previous preview releases of Scheduled Events supported {latest} as the api-version. This format is no longer supported and will be deprecated in the future.

Enabling and disabling Scheduled Events

Scheduled Events is enabled for your service the first time you make a request for events. You should expect a delayed response in your first call of up to two minutes and you'll start

receiving events within 5 minutes. Scheduled Events is disabled for your service if it doesn't make a request to the endpoint for 24 hours.

User-initiated maintenance

User-initiated VM maintenance via the Azure portal, API, CLI, or PowerShell results in a scheduled event. You then can test the maintenance preparation logic in your application, and your application can prepare for user-initiated maintenance.

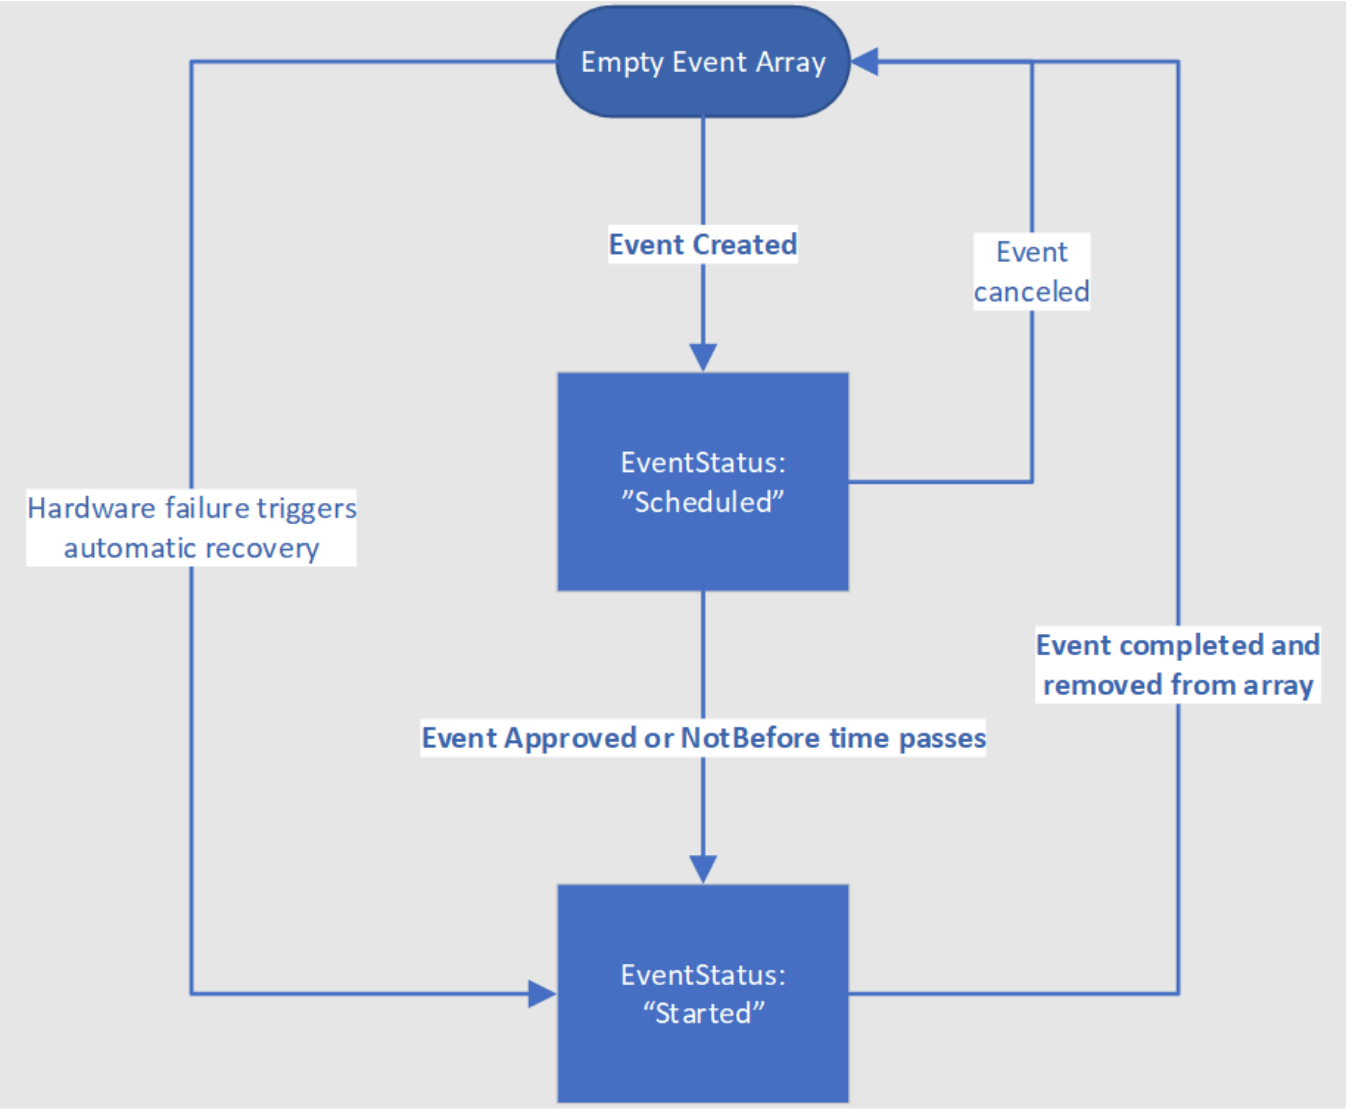
If you restart a VM, an event with the type `Reboot` is scheduled. If you redeploy a VM, an event with the type `Redeploy` is scheduled. Typically events with a user event source can be immediately approved to avoid a delay on user-initiated actions. We advise having a primary and secondary VM communicating and approving user generated scheduled events in case the primary VM becomes unresponsive. Immediately approving events prevents delays in recovering your application back to a good state.

Scheduled events for Virtual Machine Scale Sets Guest OS upgrades or reimages are supported for general purpose VM sizes that support memory preserving updates only. It doesn't work for G, M, N, and H series. Scheduled events for Virtual Machine Scale Sets Guest OS upgrades and reimages are disabled by default. To enable scheduled events for these operations on supported VM sizes, first enable them using OSImageNotificationProfile.

Use the API

High level overview

There are two major components to handling Scheduled Events, preparation and recovery. All current scheduled events impacting a VM are available to read via the IMDS Scheduled Events endpoint. When the event reaches a terminal state, it's removed from the list of events. The following diagram shows the various state transitions that a single scheduled event can experience:



For events in the EventStatus:"Scheduled" state, you need to take steps to prepare your workload. Once the preparation is complete, you should then approve the event using the scheduled event API. Otherwise, the event is automatically approved when the NotBefore time is reached. If the VM is on shared infrastructure, the system will then wait for all other tenants on the same hardware to also approve the job or timeout. Once approvals are gathered from all impacted VMs or the NotBefore time is reached, then Azure generates a new scheduled event payload with EventStatus:"Started" and triggers the start of the maintenance event. When the event reaches a terminal state, it's removed from the list of events. That serves as the signal for the customer to recover their VMs.

The psudeo code demonstrates a process for how to read and manage scheduled events in your application:

```
current_list_of_scheduled_events = get_latest_from_se_endpoint()
#prepare for new events
for each event in current_list_of_scheduled_events:
  if event not in previous_list_of_scheduled_events:
    prepare_for_event(event)
```

```
#recover from completed events
for each event in previous_list_of_scheduled_events:
  if event not in current_list_of_scheduled_events:
    receover_from_event(event)
#prepare for future jobs
previous_list_of_scheduled_events = current_list_of_scheduled_events
```

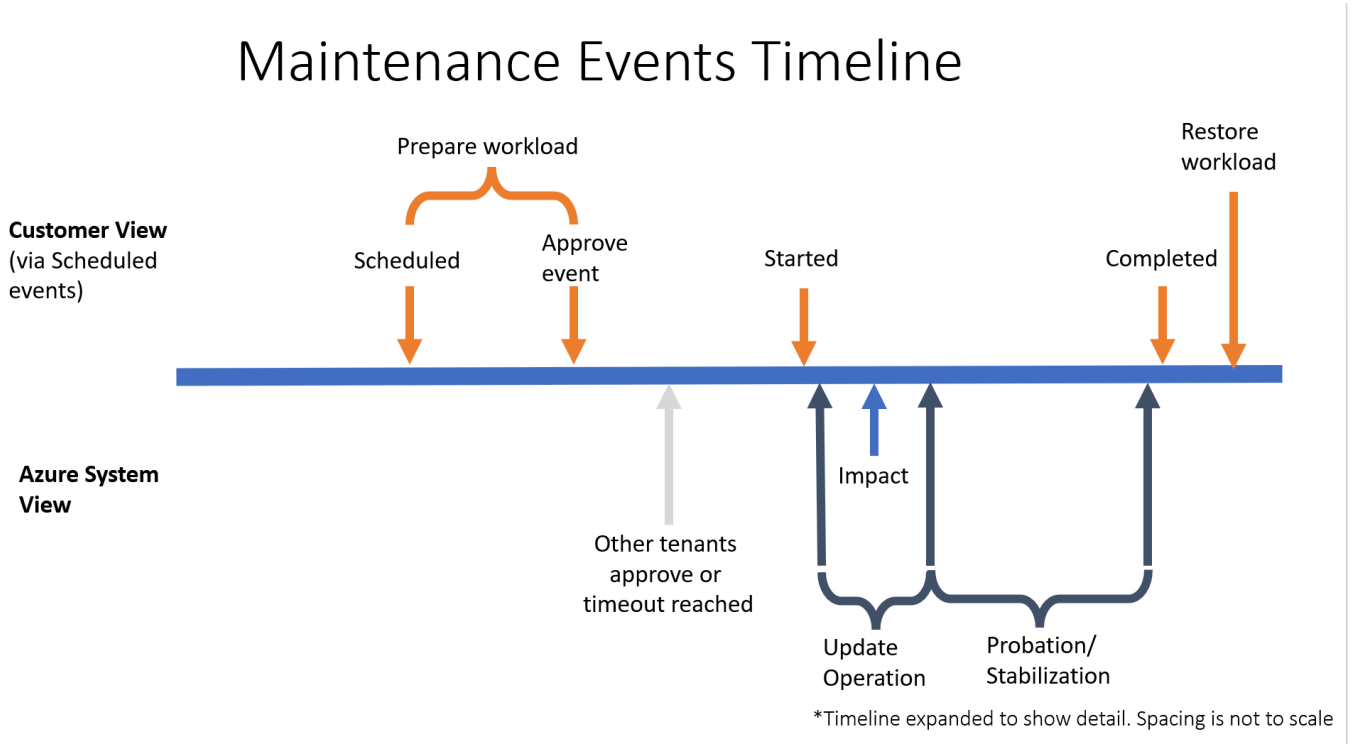
As scheduled events are often used for applications with high availability requirements, there are a few exceptional cases that should be considered:

1. Once a scheduled event is completed and removed from the array, there will be no further impacts without a new event including another EventStatus:"Scheduled" event
2. Azure monitors maintenance operations across the entire fleet and in rare circumstances determines that a maintenance operation too high risk to apply. In that case the scheduled event goes directly from "Scheduled" to being removed from the events array
3. If there is a hardware failure, Azure bypasses the "Scheduled" state and immediately move to the EventStatus:"Started" state.
4. While the event is still in EventStatus:"Started" state, there may be another impact of a shorter duration than what was advertised in the scheduled event.

As part of Azure's availability guarantee, VMs in different fault domains won't be impacted by routine maintenance operations at the same time. However, they may have operations serialized one after another. VMs in one fault domain can receive scheduled events with EventStatus:"Scheduled" shortly after another fault domain's maintenance is completed. Regardless of what architecture you chose, always keep checking for new events pending against your VMs.

While the exact timings of events vary, the following diagram provides a rough guideline for how a typical maintenance operation proceeds:

- EventStatus:"Scheduled" to Approval Timeout: 15 minutes
- Impact Duration: 7 seconds
- EventStatus:"Started" to Completed (event removed from Events array): 10 minutes



All operations impacting VM availability create a scheduled event, however not all scheduled events appear in other Azure surfaces such as Azure Activity Logs or Resource Health. Checking scheduled events regularly will ensure that you have the most up-to-date information about any upcoming impacts to your VMs.

Headers

When you query Metadata Service, you must provide the header `Metadata:true` to ensure the request wasn't unintentionally redirected. The `Metadata:true` header is required for all scheduled events requests. Failure to include the header in the request results in a "Bad Request" response from Metadata Service.

Query for events

You can query for scheduled events by making the following call:

Bash sample

```
curl -H Metadata:true http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01
```

PowerShell sample

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -Uri
"http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01" |
ConvertTo-Json -Depth 64
```

Python sample

```
import json
import requests

metadata_url ="http://169.254.169.254/metadata/scheduledevents"
header = {'Metadata' : 'true'}
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data
```

A response contains an array of scheduled events. An empty array means that currently no events are scheduled. In the case where there are scheduled events, the response contains an array of events.

```
{
    "DocumentIncarnation": {IncarnationID},
    "Events": [
        {
            "EventId": {eventID},
            "EventType": "Reboot" | "Redeploy" | "Freeze" | "Preempt" |
"Terminate",
            "ResourceType": "VirtualMachine",
            "Resources": [{resourceName}],
            "EventStatus": "Scheduled" | "Started",
            "NotBefore": {timeInUTC},
            "Description": {eventDescription},
            "EventSource" : "Platform" | "User",
            "DurationInSeconds" : {timeInSeconds},
        }
    ]
}
```

Event properties

Expand table

Property	Description
Document Incarnation	Integer that increases when the events array changes. Documents with the same incarnation contain the same event information, and the incarnation is incremented when an event changes.
EventId	Globally unique identifier for this event. Example: • 602d9444-d2cd-49c7-8624-8643e7171297
EventType	Expected impact this event will cause. Values: • `Freeze`: The Virtual Machine is scheduled to pause for a few seconds. CPU and network connectivity may be suspended, but there's no impact on memory or open files. • `Reboot`: The Virtual Machine is scheduled for reboot (non-persistent memory is lost). In rare cases a VM scheduled for EventType:"Reboot" may experience a freeze event instead of a reboot. Follow the instructions above for how to know if the event is complete and it's safe to restore your workload. • `Redeploy`: The Virtual Machine is scheduled to move to another node (ephemeral disks are lost). • `Preempt`: The Spot Virtual Machine is being deleted (ephemeral disks are lost). This event is made available on a best effort basis • `Terminate`: The virtual machine is scheduled to be deleted.
ResourceType	Type of resource this event affects. Values: • `VirtualMachine`
Resources	List of resources this event affects. Example: • ["FrontEnd_IN_0", "BackEnd_IN_0"]
EventStatus	Status of this event.

Property	Description
	Values: • `Scheduled`: This event is scheduled to start after the time specified in the `NotBefore` property. • `Started`: This event has started. No `Completed` or similar status is ever provided. The event is no longer returned when the event is finished.
NotBefore	Time after which this event can start. The event is guaranteed to not start before this time. Will be blank if the event after the event starts. Example: • Mon, 19 Sep 2016 18:29:47 GMT
Description	Description of this event. Example: • Host server is undergoing maintenance. • Host Server infrastructure is undergoing maintenance. • Virtual machine is being paused because of a memory-preserving Live Migration operation. • Virtual machine is going to be restarted as requested by authorized user. • Host server is undergoing an emergency repair.
EventSource	Initiator of the event. Example: • `Platform`: Platform initiated this event. • `User`: The user initiated this event.
DurationInSeconds	The expected duration of the interruption caused by the event. There may be secondary impacts of a shorter duration during the impact window. Example: • `9`: The interruption caused by the event lasts for 9 seconds. • `0`: The event won't interrupt the VM or impact its availability (for example, update to the network) • `-1`: The default value used if the impact duration is either unknown or not applicable.

Event scheduling

Each event is scheduled a minimum amount of time in the future based on the event type. This time is reflected in an event's `NotBefore` property.

Expand table

EventType	Minimum notice
Freeze	15 minutes
Reboot	15 minutes
Redeploy	10 minutes
Preempt	30 seconds
Terminate	User Configurable: 5 to 15 minutes

This means that you can detect a future schedule of event at least by the minimum notice time before the event occurs. Once an event is scheduled, it will move into the `Started` state after it's been approved or the `NotBefore` time passes. However, in rare cases, the operation is canceled by Azure before it starts. In that case the event is removed from the Events array, and the impact won't occur as previously scheduled.

> **Note**
>
> In some cases, Azure is able to predict host failure due to degraded hardware and attempts to mitigate disruption to your service by scheduling a migration. Affected virtual machines will receive a scheduled event with a `NotBefore` that is typically a few days in the future. The actual time varies depending on the predicted failure risk assessment. Azure tries to give 7 days of advance notice when possible. The actual notice time varies and might be shorter if there's a high chance of the hardware failing imminently. To minimize risk to your service in case the hardware fails before the system-initiated migration, we recommend that you self-redeploy your virtual machine as soon as possible.

> **Note**
>
> In the case the host node experiences a hardware failure, Azure bypasses the minimum notice period and immediately begin the recovery process for affected virtual machines. This reduces recovery time in the case that the affected VMs are unable to respond.

During the recovery process, an event is created for all impacted VMs with `EventType = Reboot` and `EventStatus = Started`.

Polling frequency

You can poll the endpoint for updates as frequently or infrequently as you like. However, the longer the time between requests, the more time you potentially lose to react to an upcoming event. Most events have 5 to 15 minutes of advance notice, although in some cases advance notice might be as little as 30 seconds. To ensure that you have as much time as possible to take mitigating actions, we recommend that you poll the service once per second.

Start an event

After you learn of an upcoming event and finish your logic for graceful shutdown, you can approve the outstanding event by making a `POST` call to Metadata Service with `EventId`. This call indicates to Azure that it can shorten the minimum notification time (when possible). The event may not start immediately upon approval. In some cases Azure requires the approval of all the VMs hosted on the node before proceeding with the event.

The following JSON sample is expected in the `POST` request body. The request should contain a list of `StartRequests`. Each `StartRequest` contains `EventId` for the event you want to expedite:

```
{
    "StartRequests" : [
        {
            "EventId": {EventId}
        }
    ]
}
```

The service always returns a 200 success code if it's passed a valid event ID, even if another VM already approved the event. A 400 error code indicates that the request header or payload was malformed.

> **Note**
>
> Events won't proceed unless they are either approved via a POST message or the NotBefore time elapses. This includes user triggered events such as VM restarts from the Azure portal.

Bash sample

```
curl -H Metadata:true -X POST -d '{"StartRequests": [{"EventId": "f020ba2e-3bc0-
4c40-a10b-86575a9eabd5"}]}' http://169.254.169.254/metadata/scheduledevents?api-
version=2020-07-01
```

PowerShell sample

```
Invoke-RestMethod -Headers @{"Metadata" = "true"} -Method POST -body
'{"StartRequests": [{"EventId": "5DD55B64-45AD-49D3-BBC9-F57D4EA97BD7"}]}' -Uri
http://169.254.169.254/metadata/scheduledevents?api-version=2020-07-01 |
ConvertTo-Json -Depth 64
```

Python sample

```
import json
import requests

def confirm_scheduled_event(event_id):
   # This payload confirms a single event with id event_id
   payload = json.dumps({"StartRequests": [{"EventId": event_id }]})
   response = requests.post("http://169.254.169.254/metadata/scheduledevents",
                            headers =  {'Metadata' : 'true'},
                            params = {'api-version':'2020-07-01'},
                            data = payload)
   return response.status_code
```

> **Note**
>
> Acknowledging an event allows the event to proceed for all `Resources` in the event, not just the VM that acknowledges the event. Therefore, you can choose to elect a leader to coordinate the acknowledgment, which might be as simple as the first machine in the `Resources` field.

Example responses

The following events are an example that from two VMs which were live migrated to another node.

The `DocumentIncarnation` is changing every time there's new information in `Events`. An approval of the event would allow the freeze to proceed for both WestNO_0 and WestNO_1.

JSON

```
{
    "DocumentIncarnation":  1,
    "Events":  [
               ]
}

{
    "DocumentIncarnation":  2,
    "Events":  [
                   {
                       "EventId":  "C7061BAC-AFDC-4513-B24B-AA5F13A16123",

    "Events":  [
                ]
}
```

Python Sample

The sample queries Metadata Service for scheduled events and approves each outstanding event. You can find the code in the vm-scheduled-events-mock-server repository in the Listener.py file.

Python

```python
#!/usr/bin/python
import json
import requests
from time import sleep

# The URL to access the metadata service
metadata_url ="http://169.254.169.254/metadata/scheduledevents"
# This must be sent otherwise the request will be ignored
header = {'Metadata' : 'true'}
# Current version of the API
query_params = {'api-version':'2020-07-01'}

def get_scheduled_events():
    resp = requests.get(metadata_url, headers = header, params = query_params)
    data = resp.json()
    return data

def confirm_scheduled_event(event_id):
    # This payload confirms a single event with id event_id
    # You can confirm multiple events in a single request if needed
    payload = json.dumps({"StartRequests": [{"EventId": event_id }]})
    response = requests.post(metadata_url,
                             headers= header,
                             params = query_params,
                             data = payload)
    return response.status_code

def log(event):
    # This is an optional placeholder for logging events to your system
    print(event["Description"])
    return

def advanced_sample(last_document_incarnation):
```

```
    # Poll every second to see if there are new scheduled events to process
    # Since some events may have necessarily short warning periods, it is
    # recommended to poll frequently
    found_document_incarnation = last_document_incarnation
    while (last_document_incarnation == found_document_incarnation):
        sleep(1)
        payload = get_scheduled_events()
        found_document_incarnation = payload["DocumentIncarnation"]

    # We recommend processing all events in a document together,
    # even if you won't be actioning on them right away
    for event in payload["Events"]:

        # Events that already started, logged for tracking
        if (event["EventStatus"] == "Started"):
            log(event)

        # Approve all user initiated events. These are typically created by an
        # administrator and approving them immediately can help to avoid delays
        # in admin actions
        elif (event["EventSource"] == "User"):
            confirm_scheduled_event(event["EventId"])

        # For this application, freeze events less that 9 seconds are considered
        # no impact. This will immediately approve them
        elif (event["EventType"] == "Freeze" and
            int(event["DurationInSeconds"]) >= 0  and
            int(event["DurationInSeconds"]) < 9):
            confirm_scheduled_event(event["EventId"])

        # Events that may be impactful (for example reboot or redeploy) may need
custom
        # handling for your application
        else:
            #TODO Custom handling for impactful events
            log(event)
    print("Processed events from document: " + str(found_document_incarnation))
    return found_document_incarnation

def main():
    # This will track the last set of events seen
    last_document_incarnation = "-1"

    input_text = "\
        Press 1 to poll for new events \n\
        Press 2 to exit \n "
    program_exit = False

    while program_exit == False:
        user_input = input(input_text)
        if (user_input == "1"):
            last_document_incarnation = advanced_sample(last_document_incarnation)
        elif (user_input == "2"):
            program_exit = True
```

```
if __name__ == '__main__':
    main()
```

Testing Scheduled Events

Two common ways to test your applications response to scheduled events are manually triggering user imitated events or using a mock server.

You can manually trigger redeploy and reboot events through the Azure Portal or Azure CLI by selecting the 'reboot' or 'redeploy' VM option from the VM blade. This will create an event and send it to your workload.

Operations that impact multiple VMs, such as host updates, cannot be triggered on demand so you can use a mock server instead. The vm-scheduled-events-mock-server provides a framework for testing your application's response to different scenarios by replaying real events flows back for development and testing. By default the server supports 9 different scenarios, all captured from VMs running in Azure and representing the most common cases. The scenarios can be expanded to include more options depending on your applications particular characteristics.

- Review the Scheduled Events code samples in the Azure Instance Metadata Scheduled Events GitHub repository.
- Review the Node.js Scheduled Events code samples in Azure Samples GitHub repository.
- Read more about the APIs that are available in the Instance Metadata Service.
- Learn about planned maintenance for Windows virtual machines in Azure.
- Learn how to monitor scheduled events for your VMs through Log Analytics.
- Learn how to log scheduled events using Azure Event Hubs in the Azure Samples GitHub repository.
- Use the vm-scheduled-events-mock-server to test your application's response to common scheduled events scenarios.

Monitor scheduled events for your Windows VMs

Article • 12/19/2024

Applies to: VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

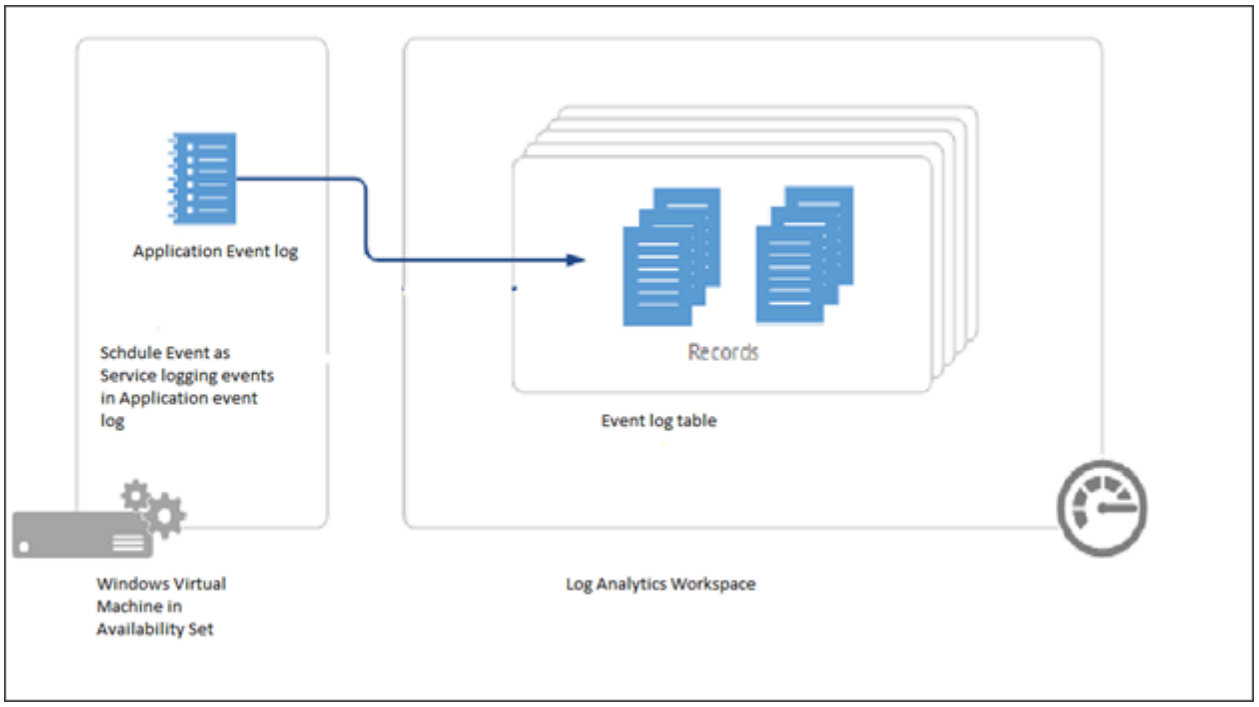
Updates are applied to different parts of Azure every day, to keep the services running on them secure, and up-to-date. In addition to planned updates, unplanned events may also occur. For example, if any hardware degradation or fault is detected, Azure services may need to perform unplanned maintenance. Using live migration, memory preserving updates and keeping a strict limit on the impact of updates, allow these events to be almost transparent to customers. At most, they can cause a few seconds of virtual machine freeze. For some applications however, even a few seconds of virtual machine freeze could cause an impact. Knowing in advance about upcoming Azure maintenance is important to ensure the best experience for those applications. Scheduled Events service provides you with a programmatic interface to be notified about upcoming maintenance, and enables you to gracefully handle the maintenance.

This article shows how you can use scheduled events to be notified about maintenance events that could affect your VMs and build some basic automation that can help with monitoring and analysis.

Routing scheduled events to Log Analytics

Scheduled Events is available as part of the Azure Instance Metadata Service, which is available on every Azure virtual machine. Customers can write automation to query the endpoint of their virtual machines to find scheduled maintenance notifications and perform mitigations, like saving the state and taking the virtual machine out of rotation. We recommend building automation to record the Scheduled Events so you can have an auditing log of Azure maintenance events.

In this article, we walk you through how to capture maintenance Scheduled Events to Log Analytics. Then, we trigger some basic notification actions, like sending an email to your team and getting a historical view of all events that have affected your virtual machines. For the event aggregation and automation we use Log Analytics, but you can use any monitoring solution to collect these logs and trigger automation.



Prerequisites

For this example, you need to create a Windows Virtual Machine in an Availability Set. Scheduled Events provide notifications about changes that can affect any of the virtual machines in your availability set, Cloud Service, Virtual Machine Scale Set or standalone VMs. A service is run that polls for scheduled events on one of the VMs that act as a collector, to get events for all of the other VMs in the availability set.

Don't delete the group resource group at the end of the tutorial.

You also need to create a Log Analytics workspace that we use to aggregate information from the VMs in the availability set.

Set up the environment

You should now have 2 initial VMs in an availability set. Now we need to create a 3rd VM, called `myCollectorVM`, in the same availability set.

Azure PowerShell

```
New-AzVm `
    -ResourceGroupName "myResourceGroupAvailability" `
    -Name "myCollectorVM" `
    -Location "East US" `
    -VirtualNetworkName "myVnet" `
    -SubnetName "mySubnet" `
    -SecurityGroupName "myNetworkSecurityGroup" `
    -OpenPorts 3389 `
```

```
    -PublicIpAddressName "myPublicIpAddress3" `
    -AvailabilitySetName "myAvailabilitySet" `
    -Credential $cred
```

1. Download the installation .zip file of the project from GitHub.

2. Connect to **myCollectorVM** and copy the .zip file to the virtual machine and extract all of the files. On your VM, open a PowerShell prompt. Move your prompt into the folder containing `SchService.ps1`, for example: `PS C:\Users\azureuser\AzureScheduledEventsService-master\AzureScheduledEventsService-master\Powershell>`, and set up the service.

   PowerShell

   ```
   .\SchService.ps1 -Setup
   ```

3. Start the service.

   PowerShell

   ```
   .\SchService.ps1 -Start
   ```

4. Validate the service status and make sure it is running.

   PowerShell

   ```
   .\SchService.ps1 -status
   ```

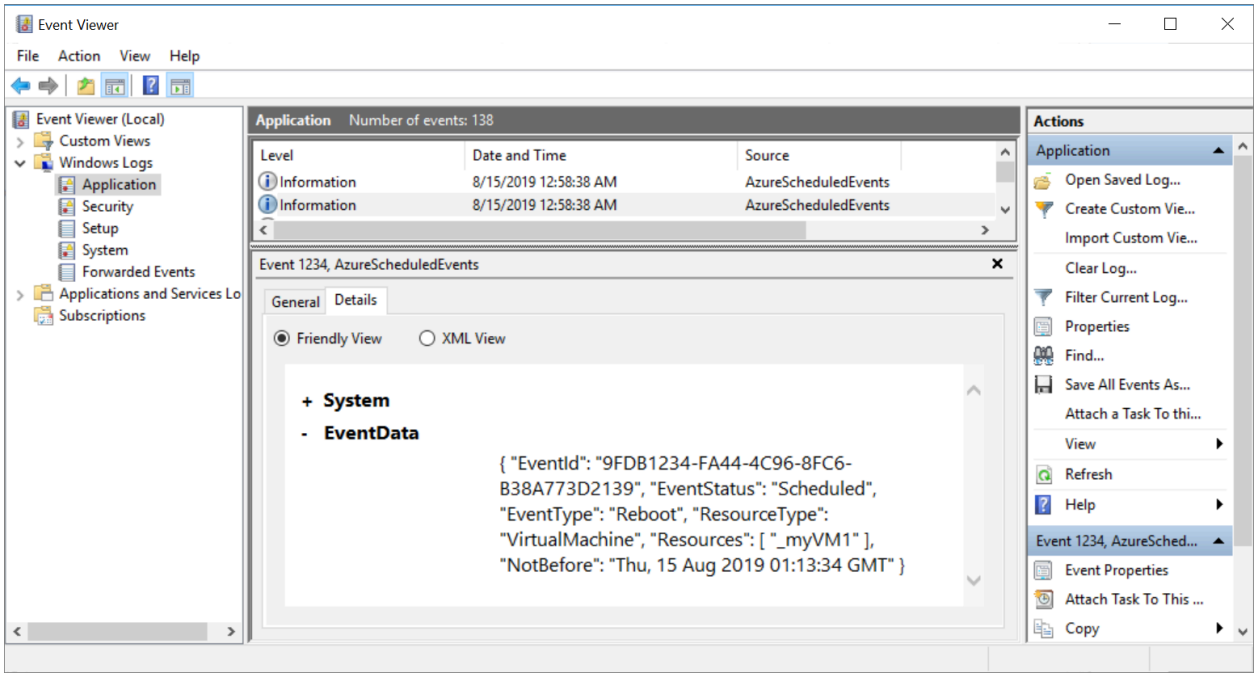
   The validation command should return `Running`.

The service will now start polling every 10 seconds for any scheduled events and approve the events to expedite the maintenance. Freeze, Reboot, Redeploy, and Preempt are the events captured by Schedule events. You can extend the script to trigger some mitigations prior to approving the event.

When any of the above events are captured by Schedule Event service, it will get logged in the Application Event Log Event Status, Event Type, Resources (Virtual machine names) and NotBefore (minimum notice period). You can locate the events with ID 1234 in the Application Event Log.

Once the service is set up and started, it will log events in the Windows Application logs. To verify this works, restart one of the virtual machines in the availability set and you

should see an event being logged in Event viewer in Windows Logs > Application log showing the VM restarted.



When events are captured by the Schedule Event service, it will get logged in the application even log with Event Status, Event Type, Resources (VM name) and NotBefore (minimum notice period). You can locate the events with ID 1234 in the Application Event Log.

> ⓘ **Note**
>
> In this example, the virtual machines were are in an availability set, which enabled us to designate a single virtual machine as the collector to listen and route scheduled events to our log analytics works space. If you have standalone virtual machines, you can run the service on every virtual machine, and then connect them individually to your log analytics workspace.
>
> For our set up, we chose Windows, but you can design a similar solution on Linux.

At any point you can stop/remove the Scheduled Event Service by using the switches `-stop` and `-remove`.

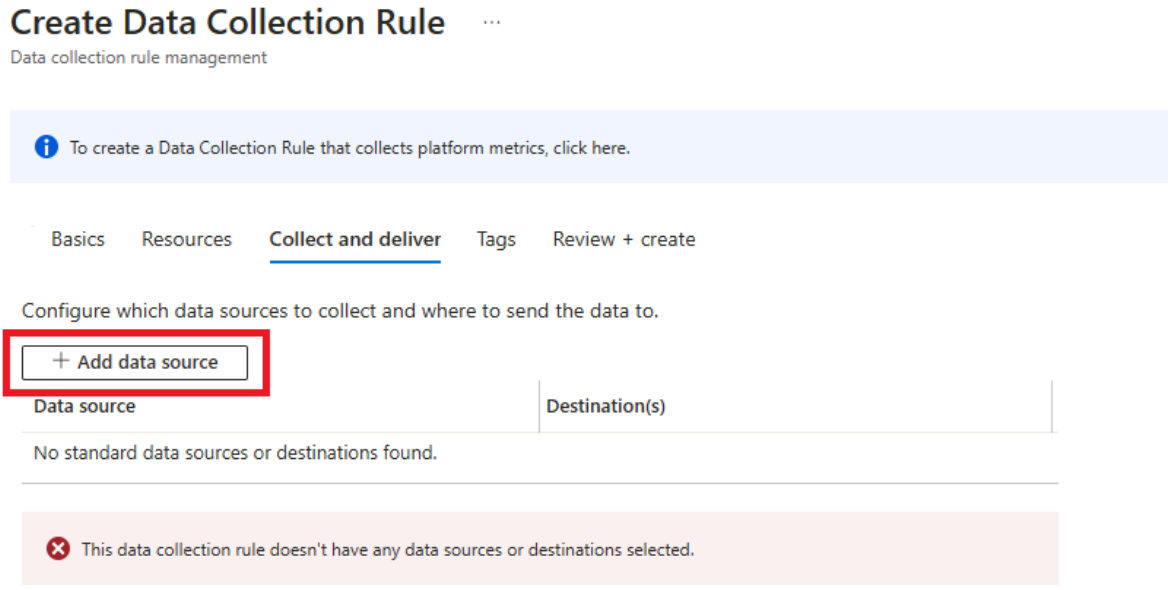
Connect to the Log Analytics Workspace

We now want to connect a Log Analytics Workspace to the collector VM. The Log Analytics workspace acts as a repository and we will configure event log collection to capture the application logs from the collector VM.

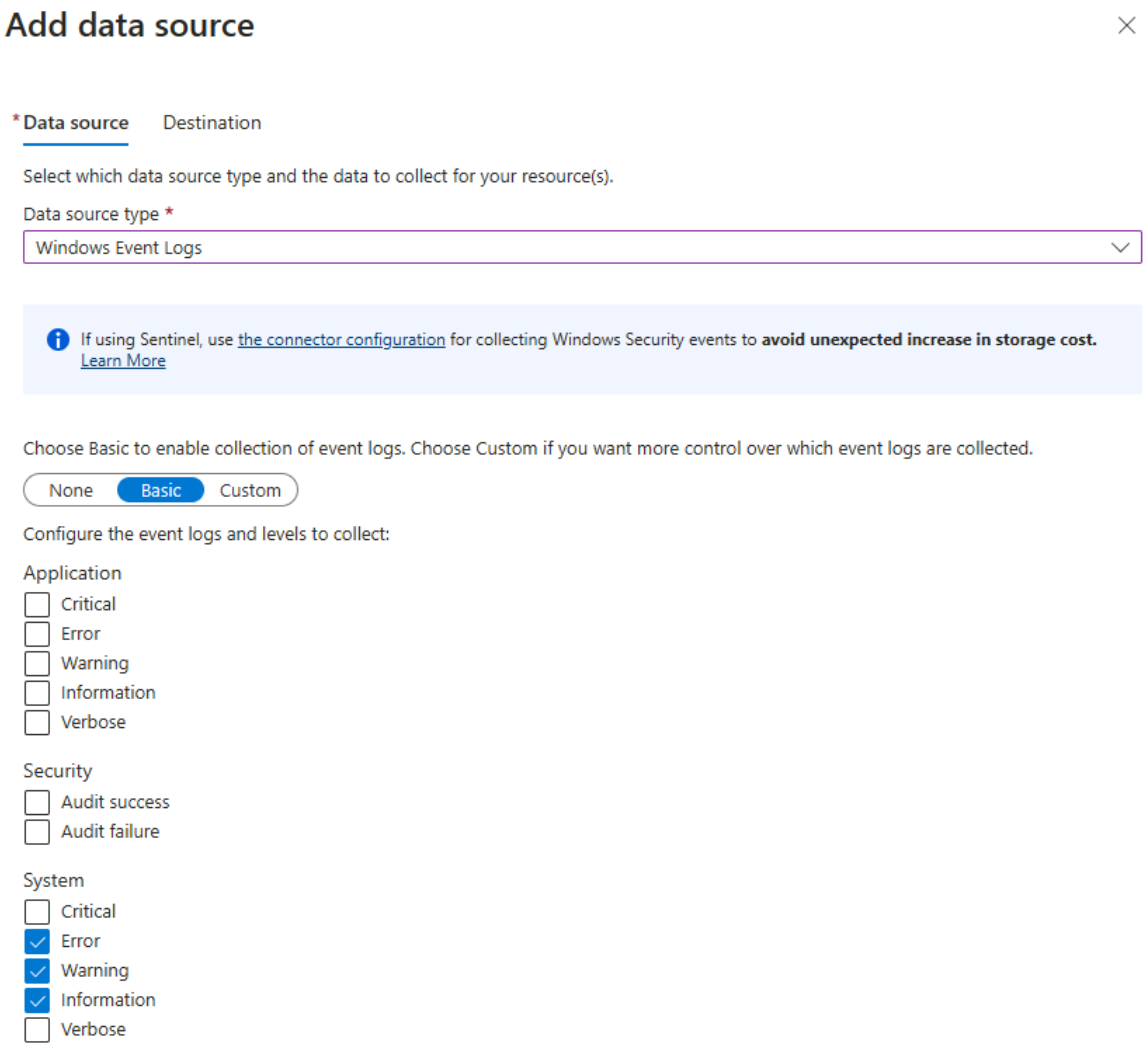
To route the Scheduled Events to the Events Log, which is saved as Application log by our service, you will need to connect your virtual machine to your Log Analytics workspace.

Set up data collection

1. Open the Azure portal.
2. In the search bar at the top, type **Log Analytics Workspaces** and select it from the search results.
3. Choose the workspace you created to open its page.
4. Under Settings, select **Agents** and then click **Virtual Machines**.
5. Under the **Windows servers** tab, click **Data Collection Rules**.
6. Enter the **Collect and Deliver** tab and click **Add data source**



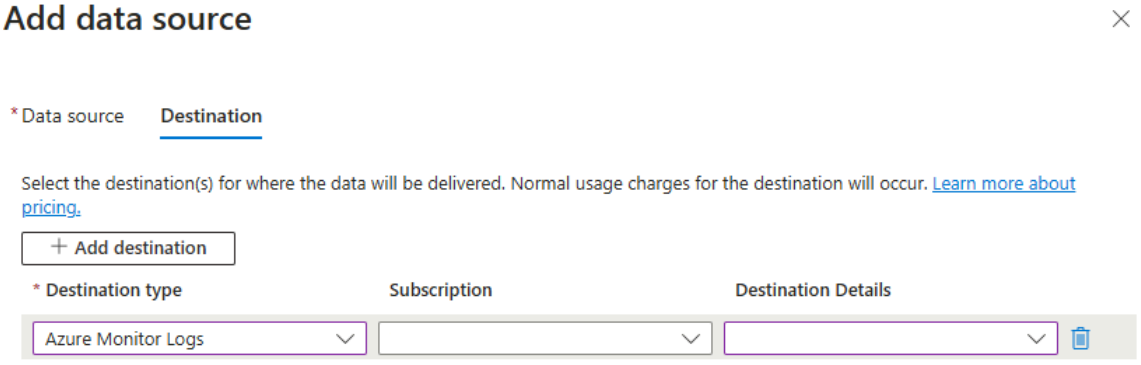
7. Under the **Data source** tab, select **Windows Event Logs** from the dropdown.
8. Select the event logs you'd like to collect. Ensure that **ERROR**, **WARNING**, and **INFORMATION** are selected.



9. Click **Next : Destination >**

10. Under the **Destination** tab, click **Add destination**.

11. Fill out the **Destination Type**, **Subscription**, and **Destination Details** sections with your collector VM and its subscription's details.



12. Once you've selected the correct VM, the Microsoft Monitoring agent will be automatically installed on your virtual machine. It will take a few minutes to

connect your VM to the workspace and install the extension.

> **Note**
>
> There is some delay, and it may take up to 10 minutes before the log is available.

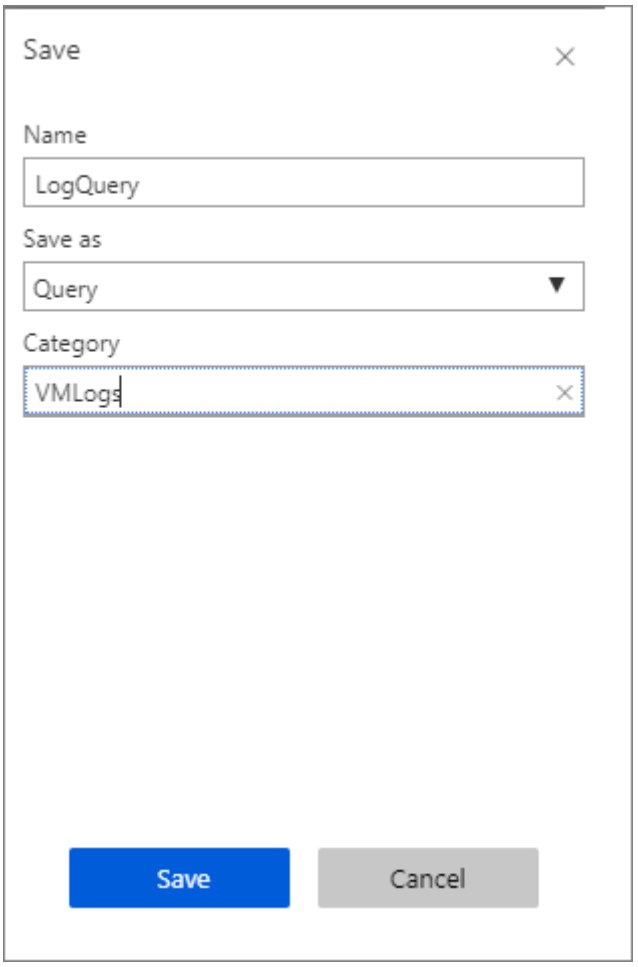
Creating an alert rule with Azure Monitor

Once the events are pushed to Log Analytics, you can run the following query to look for the schedule Events.

1. At the top of the page, select **Logs** and paste the following into the text box:

```
Event
| where EventLog == "Application" and Source contains
"AzureScheduledEvents" and RenderedDescription contains "Scheduled" and
RenderedDescription contains "EventStatus"
| project TimeGenerated, RenderedDescription
| extend ReqJson= parse_json(RenderedDescription)
| extend EventId = ReqJson["EventId"]
,EventStatus = ReqJson["EventStatus"]
,EventType = ReqJson["EventType"]
,NotBefore = ReqJson["NotBefore"]
,ResourceType = ReqJson["ResourceType"]
,Resources = ReqJson["Resources"]
| project-away RenderedDescription,ReqJson
```

2. Select **Save**, and then type `ogQuery` for the name, leave **Query** as the type, type `VMLogs` as the **Category**, and then select **Save**.



3. Select **New alert rule**.
4. In the **Create rule** page, leave `collectorworkspace` as the **Resource**.
5. Under **Condition**, select the entry *Whenever the customer log search is <login undefined>*. The **Configure signal logic** page will open.
6. Under **Threshold value**, enter *0* and then select **Done**.
7. Under **Actions**, select **Create action group**. The **Add action group** page will open.
8. In **Action group name**, type *myActionGroup*.
9. In **Short name**, type *myActionGroup*.
10. In **Resource group**, select **myResourceGroupAvailability**.
11. Under Actions, in **ACTION NAME** type **Email**, and then select **Email/SMS/Push/Voice**. The **Email/SMS/Push/Voice** page will open.
12. Select **Email**, type in your e-mail address, then select **OK**.
13. In the **Add action group** page, select **OK**.

14. In the **Create rule** page, under **ALERT DETAILS**, type *myAlert* for the **Alert rule name**, and then type *Email alert rule* for the **Description**.

15. When you're finished, select **Create alert rule**.

16. Restart one of the VMs in the availability set. Within a few minutes, you should get an e-mail that the alert has been triggered.

To manage your alert rules, go to the resource group, select **Alerts** from the left menu, and then select **Manage alert rules** from the top of the page.

Monitor Azure Virtual Machines

Article • 08/22/2024

This article describes:

- The types of monitoring data you can collect for this service.
- Ways to analyze that data.

> **Note**
>
> If you're already familiar with this service and/or Azure Monitor and just want to know how to analyze monitoring data, see the **Analyze** section near the end of this article.

When you have critical applications and business processes that rely on Azure resources, you need to monitor and get alerts for your system. The Azure Monitor service collects and aggregates metrics and logs from every component of your system. Azure Monitor provides you with a view of availability, performance, and resilience, and notifies you of issues. You can use the Azure portal, PowerShell, Azure CLI, REST API, or client libraries to set up and view monitoring data.

- For more information on Azure Monitor, see the Azure Monitor overview.
- For more information on how to monitor Azure resources in general, see Monitor Azure resources with Azure Monitor.

This article provides an overview of how to monitor the health and performance of Azure virtual machines (VMs).

> **Note**
>
> This article provides basic information to help you get started with monitoring Azure Virtual Machines. For a complete guide to monitoring your entire environment of Azure and hybrid virtual machines, see the **Monitor virtual machines deployment guide**.

Overview: Monitor VM host and guest metrics and logs

You can collect metrics and logs from:

- The **VM host** - This data relates to the Hyper-V session managing the guest operating systems, and includes information about CPU, network, and disk utilization.
- The **VM guest** - This data relates to the operating system and applications running inside the virtual machine.

Host-level data gives you an understanding of the VM's overall performance and load, while the guest-level data gives you visibility into the applications, components, and processes running on the machine and their performance and health. For example, if you're troubleshooting a performance issue, you might start with host metrics to see which VM is under heavy load, and then use guest metrics to drill down into the details of the operating system and application performance.

VM host data

VM host data is available without additional setup.

Expand table

Scenario	Details	Data collection	Available data	Recommendations
VM host metrics and logs	Monitor the stability, health, and efficiency of the physical host on which the VM is running. Scale up or scale down based on the load on your application.	Available by default without any additional setup.	• Host performance metrics • Activity logs • Boot diagnostics	Enable recommended alert rules to be notified when key host metrics deviate from their expected baseline values.

VM guest data

VM guest data lets you analyze and troubleshoot the performance and operational efficiency of workloads running on your VMs. To monitor VM guest data, you need to install Azure Monitor Agent on the VM and set up a data collection rule (DCR). The VM Insights feature automatically installs Azure Monitor Agent on your VM and sets up a default data collection rule for quick and easy onboarding.

Expand table

Scenario	Details	Data collection	Available data	Recommendations
Basic monitoring: key performance indicators	Identify issues related to operating system performance - including CPU and disk utilization - available memory, and network performance by collecting a predefined, basic set of key performance counters.	Enable VM insights	Predefined set of key guest performance counters	• Use as a starting point. • Enable recommended Azure Monitor Baseline Alerts for VMs. • Add guest performance counters of interest and recommended operating system logs, as needed.
Basic monitoring: application component mapping	Map application components on a particular VM and across VMs, and discover the dependencies that exist between application components. This information is important for troubleshooting, optimizing performance, and planning for changes or updates to the application infrastructure.	Enable the Map feature of VM insights	Dependencies between application components running on the VM	

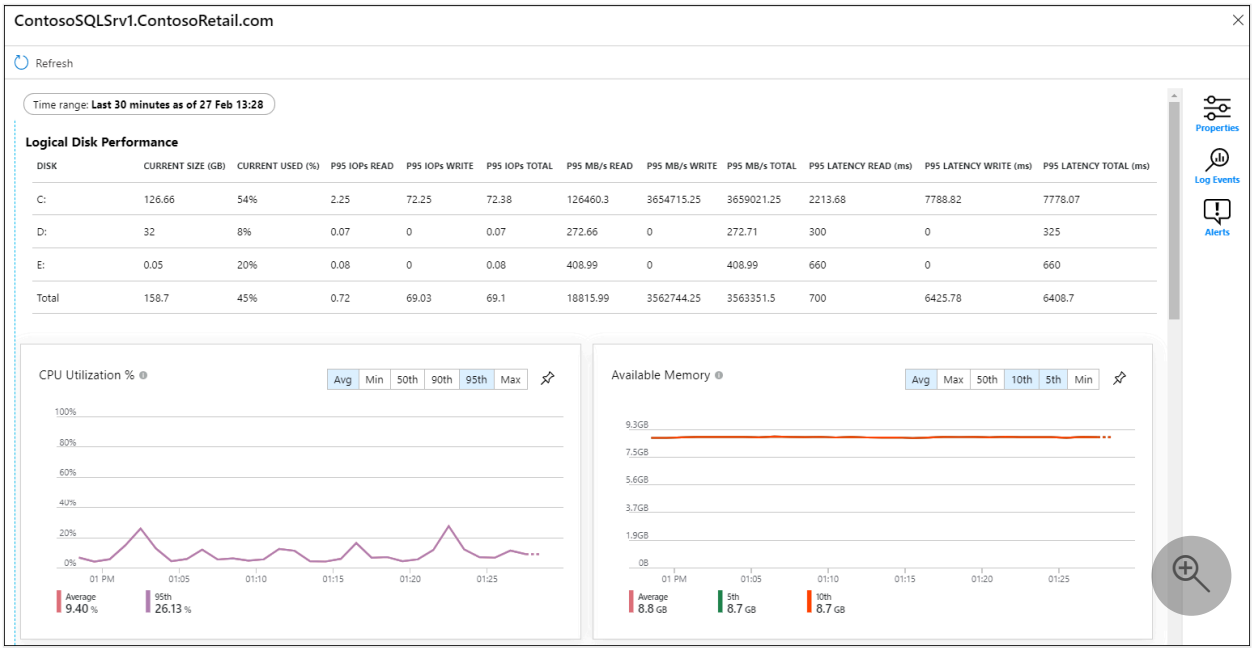
Scenario	Details	Data collection	Available data	Recommendations
VM operating system metrics and logs (recommended)	Monitor application performance and events, resource consumption by specific applications and processes, and operating system-level performance and events. This data is important for troubleshooting application-specific issues, optimizing resource usage within VMs, and ensuring optimal performance for workloads running inside VMs.	Install Azure Monitor Agent on the VM and set up a DCR.	• Guest performance counters • Windows events • Syslog events	• In Windows, collect application logs at the **Critical**, **Error**, and **Warning** levels. • In Linux, collect **LOG_SYSLOG** facility logs at the **LOG_WARNING** level.
Advanced/custom VM guest data	Monitoring of web servers, Linux appliances, and any type of data you want to collect from a VM.	Install Azure Monitor Agent on the VM and set up a DCR.	• IIS logs • SNMP traps • Any data written to a text or JSON file	

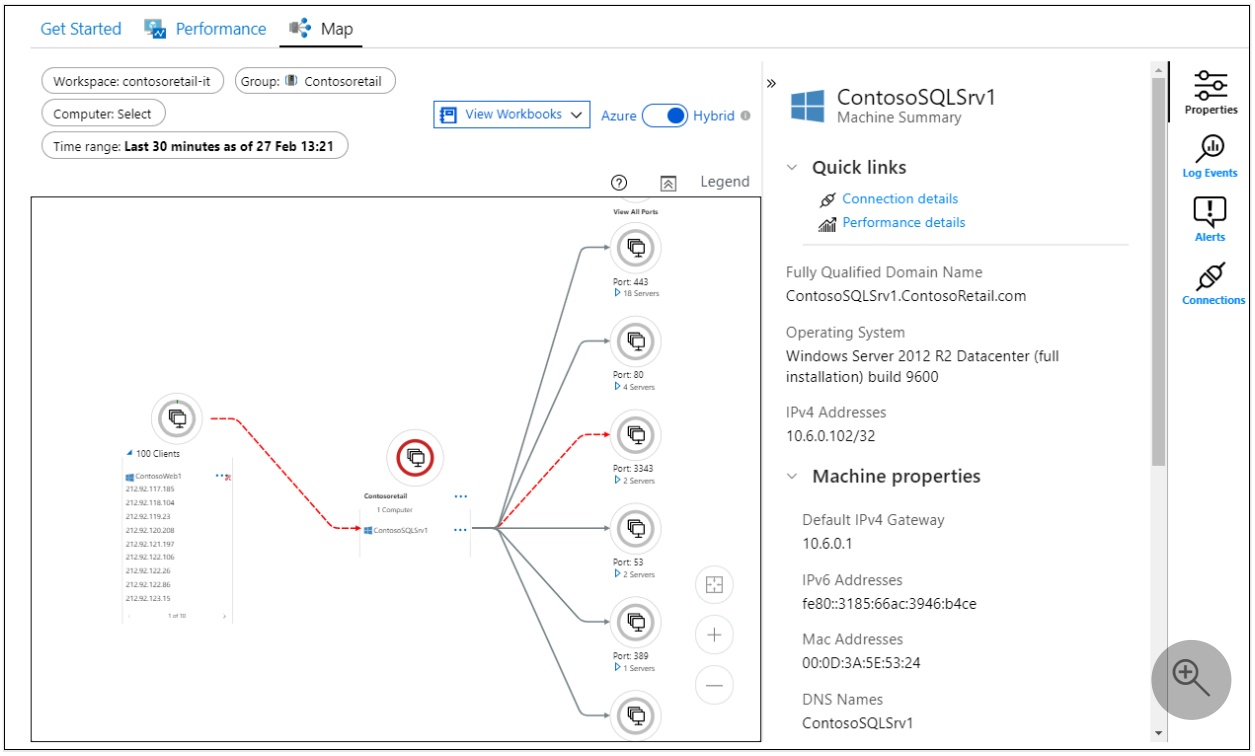
VM insights

VM insights monitors your Azure and hybrid virtual machines in a single interface. VM insights provides the following benefits for monitoring VMs in Azure Monitor:

- Simplified onboarding of the Azure Monitor agent and the Dependency agent, so that you can monitor a virtual machine (VM) guest operating system and workloads.

- Predefined data collection rules that collect the most common set of performance data.
- Predefined trending performance charts and workbooks, so that you can analyze core performance metrics from the virtual machine's guest operating system.
- The Dependency map, which displays processes that run on each virtual machine and the interconnected components with other machines and external sources.





For a tutorial on enabling VM insights for a virtual machine, see Enable monitoring with VM insights for Azure virtual machine. For general information about enabling insights and various methods for onboarding VMs, see Enable VM insights overview.

If you enable VM insights, the Azure Monitor agent is installed and starts sending a predefined set of performance data to Azure Monitor Logs. You can create other data collection rules to collect events and other performance data. To learn how to install the Azure Monitor agent and create a data collection rule (DCR) that defines the data to collect, see Tutorial: Collect guest logs and metrics from an Azure virtual machine.

In VM insights, you can use the Azure Monitor Map feature to view application components that run in Azure or your environment. The Dependency agent VM extension is available for Windows and Linux.

Data storage

For Azure Monitor:

- Metrics data is stored in the Azure Monitor metrics database.
- Log data is stored in the Azure Monitor logs store. Log Analytics is a tool in the Azure portal that can query this store.
- The Azure activity log is a separate store with its own interface in the Azure portal.

You can optionally route metric and activity log data to the Azure Monitor logs store. You can then use Log Analytics to query the data and correlate it with other log data.

Many services can use diagnostic settings to send metric and log data to other storage locations outside Azure Monitor. Examples include Azure Storage, hosted partner systems, and non-Azure partner systems, by using Event Hubs.

For detailed information on how Azure Monitor stores data, see Azure Monitor data platform.

Azure Monitor platform metrics

Azure Monitor provides platform metrics for most services. These metrics are:

- Individually defined for each namespace.
- Stored in the Azure Monitor time-series metrics database.
- Lightweight and capable of supporting near real-time alerting.
- Used to track the performance of a resource over time.

Collection: Azure Monitor collects platform metrics automatically. No configuration is required.

Routing: You can also route some platform metrics to Azure Monitor Logs / Log Analytics so you can query them with other log data. Check the **DS export** setting for

each metric to see if you can use a diagnostic setting to route the metric to Azure Monitor Logs / Log Analytics.

- For more information, see the Metrics diagnostic setting.
- To configure diagnostic settings for a service, see Create diagnostic settings in Azure Monitor.

For a list of all metrics it's possible to gather for all resources in Azure Monitor, see Supported metrics in Azure Monitor.

Platform metrics for Azure VMs include important *host metrics* such as CPU, network, and disk utilization. Host OS metrics relate to the Hyper-V session that's hosting a guest operating system (guest OS) session.

Metrics for the *guest OS* that runs in a VM must be collected through one or more agents, such as the Azure Monitor agent, that run on or as part of the guest OS. Guest OS metrics include performance counters that track guest CPU percentage or memory usage, both of which are frequently used for autoscaling or alerting. For more information, see Guest OS and host OS metrics.

For detailed information about how the Azure Monitor agent collects VM monitoring data, see Monitor virtual machines with Azure Monitor: Collect data.

For a list of available metrics for Virtual Machines, see Virtual Machines monitoring data reference.

Azure activity log

The activity log contains subscription-level events that track operations for each Azure resource as seen from outside that resource; for example, creating a new resource or starting a virtual machine.

Collection: Activity log events are automatically generated and collected in a separate store for viewing in the Azure portal.

Routing: You can send activity log data to Azure Monitor Logs so you can analyze it alongside other log data. Other locations such as Azure Storage, Azure Event Hubs, and certain Microsoft monitoring partners are also available. For more information on how to route the activity log, see Overview of the Azure activity log.

Data collection rules

Data collection rules (DCRs) define data collection from the Azure Monitor Agent and are stored in your Azure subscription. For VMs, DCRs define data such as events and performance counters to collect, and specify locations such as Log Analytics workspaces to send the data. A single VM can be associated with multiple DCRs, and a single DCR can be associated with multiple VMs.

VM insights DCR

VM insights creates a DCR that collects common performance counters for the client operating system and sends them to the InsightsMetrics table in the Log Analytics workspace. For a list of performance counters collected, see How to query logs from VM insights. You can use this DCR with other VMs instead of creating a new DCR for each VM.

You can also optionally enable collection of processes and dependencies, which populates the following tables and enables the VM insights Map feature.

- VMBoundPort: Traffic for open server ports on the machine
- VMComputer: Inventory data for the machine
- VMConnection: Traffic for inbound and outbound connections to and from the machine
- VMProcess: Processes running on the machine

Analyze monitoring data

There are many tools for analyzing monitoring data.

Azure Monitor tools

Azure Monitor supports the following basic tools:

- Metrics explorer, a tool in the Azure portal that allows you to view and analyze metrics for Azure resources. For more information, see Analyze metrics with Azure Monitor metrics explorer.
- Log Analytics, a tool in the Azure portal that allows you to query and analyze log data by using the Kusto query language (KQL). For more information, see Get started with log queries in Azure Monitor.
- The activity log, which has a user interface in the Azure portal for viewing and basic searches. To do more in-depth analysis, you have to route the data to Azure Monitor logs and run more complex queries in Log Analytics.

Tools that allow more complex visualization include:

- Dashboards that let you combine different kinds of data into a single pane in the Azure portal.
- Workbooks, customizable reports that you can create in the Azure portal. Workbooks can include text, metrics, and log queries.
- Grafana, an open platform tool that excels in operational dashboards. You can use Grafana to create dashboards that include data from multiple sources other than Azure Monitor.
- Power BI, a business analytics service that provides interactive visualizations across various data sources. You can configure Power BI to automatically import log data from Azure Monitor to take advantage of these visualizations.

Azure Monitor export tools

You can get data out of Azure Monitor into other tools by using the following methods:

- **Metrics:** Use the REST API for metrics to extract metric data from the Azure Monitor metrics database. The API supports filter expressions to refine the data retrieved. For more information, see Azure Monitor REST API reference.
- **Logs:** Use the REST API or the associated client libraries.
- Another option is the workspace data export.

To get started with the REST API for Azure Monitor, see Azure monitoring REST API walkthrough.

Kusto queries

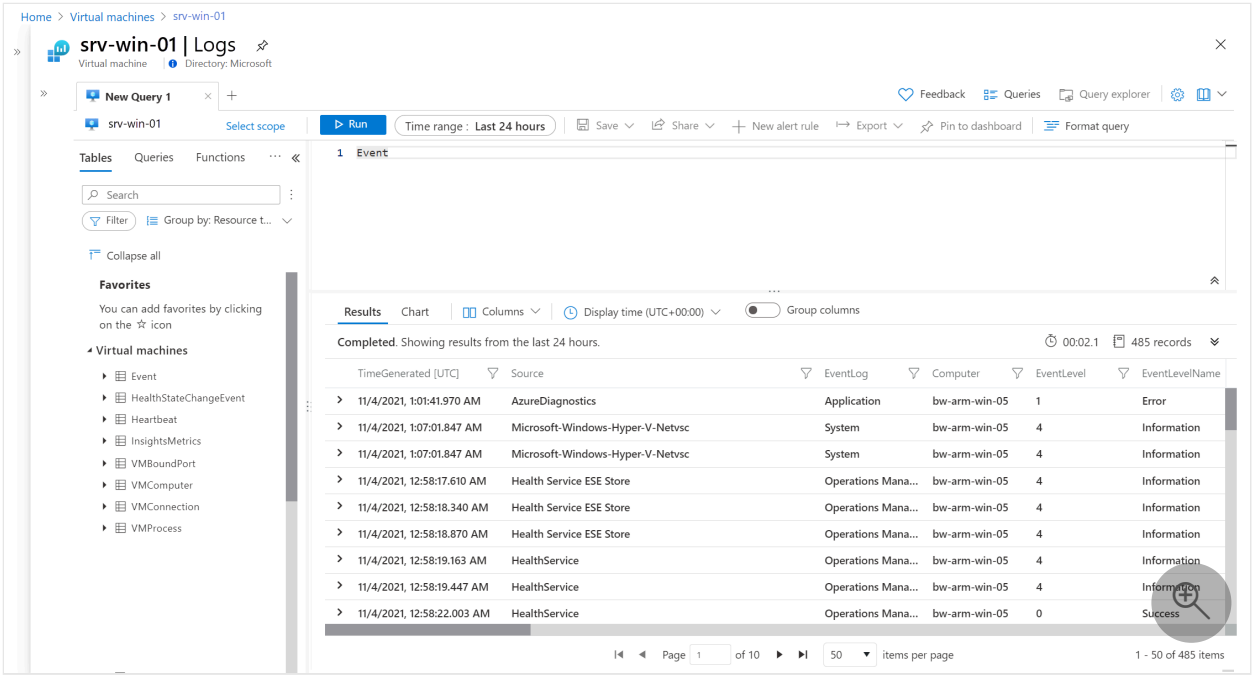
You can analyze monitoring data in the Azure Monitor Logs / Log Analytics store by using the Kusto query language (KQL).

> **Important**
>
> When you select **Logs** from the service's menu in the portal, Log Analytics opens with the query scope set to the current service. This scope means that log queries will only include data from that type of resource. If you want to run a query that includes data from other Azure services, select **Logs** from the **Azure Monitor** menu. See **Log query scope and time range in Azure Monitor Log Analytics** for details.

For a list of common queries for any service, see the Log Analytics queries interface.

To analyze log data that you collect from your VMs, you can use log queries in Log Analytics. Several built-in queries for VMs are available to use, or you can create your own queries. You can interactively work with the results of these queries, include them in a workbook to make them available to other users, or generate alerts based on their results.

To access built-in Kusto queries for your VM, select **Logs** in the **Monitoring** section of the left navigation on your VM's Azure portal page. On the **Logs** page, select the **Queries** tab, and then select the query to run.



Alerts

Azure Monitor alerts proactively notify you when specific conditions are found in your monitoring data. Alerts allow you to identify and address issues in your system before your customers notice them. For more information, see Azure Monitor alerts.

There are many sources of common alerts for Azure resources. For examples of common alerts for Azure resources, see Sample log alert queries. The Azure Monitor Baseline Alerts (AMBA) site provides a semi-automated method of implementing important platform metric alerts, dashboards, and guidelines. The site applies to a continually expanding subset of Azure services, including all services that are part of the Azure Landing Zone (ALZ).

The common alert schema standardizes the consumption of Azure Monitor alert notifications. For more information, see Common alert schema.

Types of alerts

You can alert on any metric or log data source in the Azure Monitor data platform. There are many different types of alerts depending on the services you're monitoring and the monitoring data you're collecting. Different types of alerts have various benefits and drawbacks. For more information, see Choose the right monitoring alert type.

The following list describes the types of Azure Monitor alerts you can create:

- Metric alerts evaluate resource metrics at regular intervals. Metrics can be platform metrics, custom metrics, logs from Azure Monitor converted to metrics, or Application Insights metrics. Metric alerts can also apply multiple conditions and dynamic thresholds.
- Log alerts allow users to use a Log Analytics query to evaluate resource logs at a predefined frequency.
- Activity log alerts trigger when a new activity log event occurs that matches defined conditions. Resource Health alerts and Service Health alerts are activity log alerts that report on your service and resource health.

Some Azure services also support smart detection alerts, Prometheus alerts, or recommended alert rules.

For some services, you can monitor at scale by applying the same metric alert rule to multiple resources of the same type that exist in the same Azure region. Individual notifications are sent for each monitored resource. For supported Azure services and clouds, see Monitor multiple resources with one alert rule.

You can create a single multi-resource alert rule that applies to all VMs in a particular resource group or subscription within the same region. See Create availability alert rule for Azure virtual machine (preview) for a tutorial using the availability metric.

Recommended alert rules

For some Azure services, you can enable recommended out-of-the-box alert rules.

The system compiles a list of recommended alert rules based on:

- The resource provider's knowledge of important signals and thresholds for monitoring the resource.
- Data that tells what customers commonly alert on for this resource.

> **Note**
>
> Recommended alert rules are available for:

- Virtual machines
- Azure Kubernetes Service (AKS) resources
- Log Analytics workspaces

Recommended alert rules for Azure VMs include the VM availability metric, which alerts when a VM stops running.

For more information, see Tutorial: Enable recommended alert rules for Azure virtual machine.

Common alert rules

To see common VM log alert rules in the Azure portal, go to the **Queries** pane in Log Analytics. For **Resource type**, enter **Virtual machines**, and for **Type**, enter **Alerts**.

For a list and discussion of common Virtual Machines alert rules, see Common alert rules.

Advisor recommendations

For some services, if critical conditions or imminent changes occur during resource operations, an alert displays on the service **Overview** page in the portal. You can find more information and recommended fixes for the alert in **Advisor recommendations** under **Monitoring** in the left menu. During normal operations, no advisor recommendations display.

For more information on Azure Advisor, see Azure Advisor overview.

Other VM monitoring options

Azure VMs has the following non-Azure Monitor monitoring options:

Boot diagnostics

Boot diagnostics is a debugging feature for Azure VMs that allows you to diagnose VM boot failures by collecting serial log information and screenshots of a VM as it boots up. When you create a VM in the Azure portal, boot diagnostics is enabled by default. For more information, see Azure boot diagnostics.

Troubleshoot VM performance issues with Performance Diagnostics

The Performance Diagnostics tool helps troubleshoot performance issues on Windows or Linux virtual machines by quickly diagnosing and providing insights on issues it currently finds on your machines. It supports two different modes:

- **Continuous diagnostics (preview)** collects data at five-second intervals and reports actionable insights about high resource usage every five minutes.
- **On-demand diagnostics** helps you troubleshoot an ongoing performance issue with more in-depth data, insights, and recommendations based on data collected at a single point in time.

For more information, go to Troubleshoot performance issues on Azure virtual machines using Performance Diagnostics.

Azure Virtual Machines monitoring data reference

Article • 01/24/2025

This article contains all the monitoring reference information for this service.

See Monitor Azure Virtual Machines for details on the data you can collect for Azure Virtual Machines and how to use it.

Metrics

This section lists all the automatically collected platform metrics for this service. These metrics are also part of the global list of all platform metrics supported in Azure Monitor.

For information on metric retention, see Azure Monitor Metrics overview.

> **Important**
>
> Metrics for the guest operating system (guest OS) that runs in a virtual machine (VM) aren't listed here. Guest OS metrics must be collected through one or more agents that run on or as part of the guest operating system. Guest OS metrics include performance counters that track guest CPU percentage or memory usage, both of which are frequently used for autoscaling or alerting.
>
> Host OS metrics are available and listed in the following tables. Host OS metrics relate to the Hyper-V session that's hosting your guest OS session. For more information, see **Guest OS and host OS metrics**.

Supported metrics for Microsoft.Compute/virtualMachines

The following table lists the metrics available for the Microsoft.Compute/virtualMachines resource type.

- All columns might not be present in every table.
- Some columns might be beyond the viewing area of the page. Select **Expand table** to view all available columns.

Table headings

- **Category** - The metrics group or classification.
- **Metric** - The metric display name as it appears in the Azure portal.

- **Name in REST API** - The metric name as referred to in the REST API.
- **Unit** - Unit of measure.
- **Aggregation** - The default aggregation type. Valid values: Average (Avg), Minimum (Min), Maximum (Max), Total (Sum), Count.
- **Dimensions** - Dimensions available for the metric.
- **Time Grains** - Intervals at which the metric is sampled. For example, `PT1M` indicates that the metric is sampled every minute, `PT30M` every 30 minutes, `PT1H` every hour, and so on.
- **DS Export**- Whether the metric is exportable to Azure Monitor Logs via diagnostic settings. For information on exporting metrics, see Create diagnostic settings in Azure Monitor.

Expand table

Metric	Name in REST API	Unit	Aggregation	Dimensions	Time Grains	DS Export
Available Memory Bytes (Preview) Amount of physical memory, in bytes, immediately available for allocation to a process or for system use in the Virtual Machine	`Available Memory Bytes`	Bytes	Average	<none>	PT1M	Yes
CPU Credits Consumed Total number of credits consumed by the Virtual Machine. Only available on B-series burstable VMs	`CPU Credits Consumed`	Count	Average	<none>	PT1M	Yes
CPU Credits Remaining Total number	`CPU Credits Remaining`	Count	Average	<none>	PT1M	Yes

Metric	Name in REST API	Unit	Aggregation	Dimensions	Time Grains	DS Export
of credits available to burst. Only available on B-series burstable VMs						
Data Disk Bandwidth Consumed Percentage Percentage of data disk bandwidth consumed per minute. Only available on VM series that support premium storage.	`Data Disk Bandwidth Consumed Percentage`	Percent	Average	`LUN`	PT1M	Yes
Data Disk IOPS Consumed Percentage Percentage of data disk I/Os consumed per minute. Only available on VM series that support premium storage.	`Data Disk IOPS Consumed Percentage`	Percent	Average	`LUN`	PT1M	Yes
Data Disk Latency (Preview) Average time to complete each IO during monitoring period for Data Disk. Values are in milliseconds.	`Data Disk Latency`	Milliseconds	Average	`LUN`	PT1M	Yes

Metric	Name in REST API	Unit	Aggregation	Dimensions	Time Grains	DS Export
Data Disk Max Burst Bandwidth Maximum bytes per second throughput Data Disk can achieve with bursting	`Data Disk Max Burst Bandwidth`	Count	Average	`LUN`	PT1M	Yes
Data Disk Max Burst IOPS Maximum IOPS Data Disk can achieve with bursting	`Data Disk Max Burst IOPS`	Count	Average	`LUN`	PT1M	Yes
Data Disk Queue Depth Data Disk Queue Depth(or Queue Length)	`Data Disk Queue Depth`	Count	Average	`LUN`	PT1M	Yes
Data Disk Read Bytes/Sec Bytes/Sec read from a single disk during monitoring period	`Data Disk Read Bytes/sec`	BytesPerSecond	Average	`LUN`	PT1M	Yes
Data Disk Read Operations/Sec Read IOPS from a single disk during monitoring period	`Data Disk Read Operations/Sec`	CountPerSecond	Average	`LUN`	PT1M	Yes
Data Disk Target Bandwidth	`Data Disk Target Bandwidth`	Count	Average	`LUN`	PT1M	Yes

Metric	Name in REST API	Unit	Aggregation	Dimensions	Time Grains	DS Export

VM Availability Metric (Preview) Measure of Availability of Virtual machines over time.	`VmAvailabilityMetric`	Count	Average, Minimum, Maximum	`Context`	PT1M	Yes

For an example that shows how to collect the *Percentage CPU* metric from a VM, see Get virtual machine usage metrics using the REST API.

VM availability metric (preview)

The VM availability metric is currently in public preview. This metric value indicates whether a machine is currently running and available. You can use the metric to trend availability over time and to alert if the machine is stopped. VM availability displays the following values.

The VM availability metric is computed based on an aggregate of different signals from the host.

To learn how to use the VM availability metric to monitor Azure Virtual Machine availability, see Use Azure Monitor to monitor Azure Virtual Machine availability.

Expand table

Value	Description
1	VM is running and available.
0	VM is unavailable. The VM could be stopped or rebooting. If you shut down a VM from within the VM, it emits this value.
Null (dashed line)	State of the VM is unknown. If you stop a VM from the Azure portal, CLI, or PowerShell, it immediately stops emitting the availability metric, and you see null values.

Context dimension informs whether VM availability was influenced due to Azure or user orchestrated activity. It can assume values of *Platform*, *Customer*, or *Unknown*.

Expand table

Display name	Description
Aggregation	*Average* (default aggregation): for prioritized investigations based on extent of downtime incurred. *Min*: immediately pinpoints all the times where the VM was unavailable. *Max*: immediately pinpoints all the instances where the VM was available. For more information on chart range, granularity, and data aggregation, see Azure Monitor metrics aggregation and display explained.
Data retention	Data for the VM availability metric is stored for 93 days to help trend analysis and historical lookback.
Pricing	Refer to the Pricing breakdown, specifically in the *Metrics* and *Alert Rules* sections.

Metric dimensions

For information about what metric dimensions are, see Multi-dimensional metrics.

The dimension Logical Unit Number (`LUN`) is associated with some of the preceding metrics.

Azure Monitor Logs tables

This section lists the Azure Monitor Logs tables relevant to this service, which are available for query by Log Analytics using Kusto queries. The tables contain resource log data and possibly more depending on what is collected and routed to them.

Expand table

Table	Categories	Data collection method	Supports basic log plan	Queries
ADAssessmentRecommendation Recommendations generated by AD assessments that are started through a scheduled task. When you schedule the assessment it runs by default every seven days and uploads the data into Azure Log Analytics.	workloads	Active Directory On-Demand Assessment	No	Yes
AzureActivity Entries from the Azure Activity log that provides insight into any subscription-level or management group level events that have occurred in Azure.	resources, audit, security	Export Activity log	No	Yes
CommonSecurityLog This table is for collecting events in the Common Event Format, that are most often sent from different security appliances such as Check Point, Palo Alto and more.	security	Common Event Format (CEF) via AMA connector for Microsoft Sentinel	No	Yes
ConfigurationChange View changes to in-guest configuration data such as Files Software Registry Keys Windows Services and Linux Daemons	management	Enable Change Tracking and Inventory	No	Yes
ConfigurationData View the last reported state for in-guest configuration data such as Files Software Registry Keys Windows Services and Linux Daemons	management	Enable Change Tracking and Inventory	No	Yes
ContainerLog Log lines collected from stdout and stderr streams for containers.	container, applications	Container Insights	No	Yes
DnsEvents	network	Stream and filter data from Windows DNS servers with Azure Monitor Agent	No	Yes
DnsInventory	network	Stream and filter data from	No	-

Table	Categories	Data collection method	Supports basic log plan	Queries
		Windows DNS servers with Azure Monitor Agent		
Event Events from Windows Event Log on Windows computers using Azure Monitor Agent Analytics agent.	virtualmachines	Collect events with Azure Monitor Agent	No	Yes
HealthStateChangeEvent Workload Monitor Health. This data represents state transitions of a health monitor.	undefined	VM Insights	No	-
Heartbeat Records logged by Azure Monitor Agent once per minute to report on agent health.	virtualmachines, container, management	Azure Monitor Agent	No	Yes
InsightsMetrics Table that stores metrics. 'Perf' table also stores many metrics and over time they all will converge to InsightsMetrics.	virtualmachines, container, resources	VM Insights, Container Insights	No	Yes
Perf Performance counters from Windows and Linux agents that provide insight into the performance of hardware components operating systems and applications.	virtualmachines, container	Collect performance counters from VMs with Azure Monitor Agent	No	Yes
ProtectionStatus Antimalware installation info and security health status of the machine:	security	Enable Azure Monitor Agent in Defender for Cloud	No	Yes
SQLAssessmentRecommendation Recommendations generated by SQL assessments that are started through a scheduled task. When you schedule the assessment it runs by default every seven days and uploads the data into Azure Log Analytics.	workloads	SQL Server On-Demand Assessment	No	Yes
SecurityBaseline	security	Enable Azure Monitor Agent	No	-

Table	Categories	Data collection method	Supports basic log plan	Queries
		in Defender for Cloud		
SecurityBaselineSummary	security	Enable Azure Monitor Agent in Defender for Cloud	No	-
SecurityEvent Security events collected from windows machines by Azure Security Center or Azure Sentinel.	security	Windows Security Events via AMA connector for Microsoft Sentinel	No	Yes
Syslog Syslog events on Linux computers using Azure Monitor Agent.	virtualmachines, security	Collect Syslog events with Azure Monitor Agent	No	Yes
Update Details for update schedule run. Includes information such as which updates where available and which were installed.	management, security	Enable Update Management	No	Yes
UpdateRunProgress Breaks down each run of your update schedule by the patches available at the time with details on the installation status of each patch.	management	Enable Update Management	No	Yes
UpdateSummary Summary for each update schedule run. Includes information such as how many updates weren't installed.	virtualmachines	Enable Update Management	No	Yes
VMBoundPort Traffic for open server ports on the monitored machine.	virtualmachines	VM Insights	No	-
VMComputer Inventory data for servers collected by the Service Map and VM insights solutions using the Dependency agent and Azure Monitor Agent.	virtualmachines	VM Insights	No	-
VMConnection Traffic for inbound and outbound	virtualmachines	VM Insights	No	-

Table	Categories	Data collection method	Supports basic log plan	Queries
connections to and from monitored computers.				
VMProcess Process data for servers collected by the Service Map and VM insights solutions using the Dependency agent and Azure Monitor Agent.	virtualmachines	VM Insights	No	-
W3CIISLog Internet Information Server (IIS) log on Windows computers using Azure Monitor Agent.	management, virtualmachines	Collect IIS logs with Azure Monitor Agent	No	Yes
WindowsFirewall	security	Enable Azure Monitor Agent in Defender for Cloud	No	-

Activity log

The linked table lists the operations that can be recorded in the activity log for this service. These operations are a subset of all the possible resource provider operations in the activity log.

For more information on the schema of activity log entries, see Activity Log schema.

The following table lists a few example operations that relate to creating VMs in the activity log. For a complete list of operations, see Microsoft.Compute resource provider operations.

Expand table

Operation	Description
Microsoft.Compute/virtualMachines/start/action	Starts the virtual machine
Microsoft.Compute/virtualMachines/restart/action	Deletes a managed cluster
Microsoft.Compute/virtualMachines/write	Creates a new virtual machine or updates an existing one
Microsoft.Compute/virtualMachines/deallocate/action	Powers off the virtual machine and releases the compute resources
Microsoft.Compute/virtualMachines/extensions/write	Creates a new virtual machine extension or updates an existing one

Operation	Description
Microsoft.Compute/virtualMachineScaleSets/write	Starts the instances of the virtual machine scale set

Connect self-managed Prometheus to Azure Monitor managed service for Prometheus

Summarize this article for me

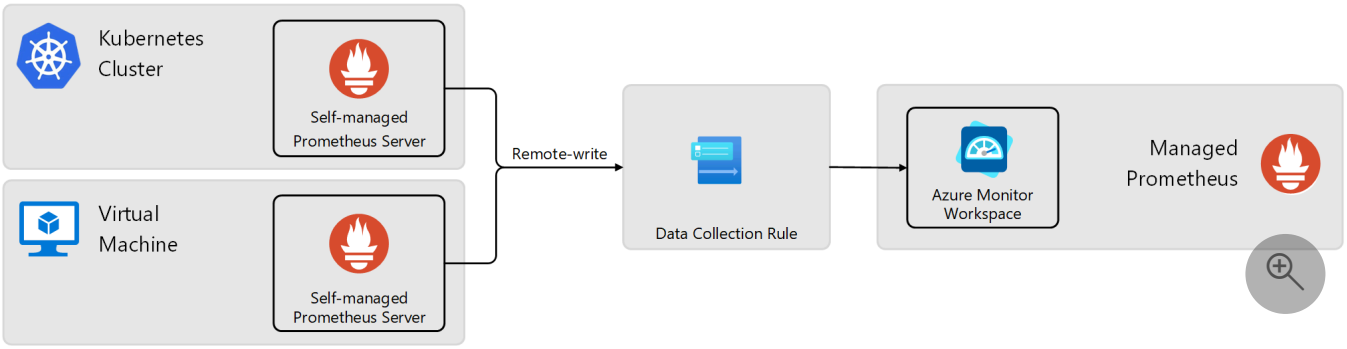
Azure Monitor managed service for Prometheus is intended to be a replacement for self-managed Prometheus so you don't need to manage a Prometheus server in your Kubernetes clusters. There may be scenarios though where you want to continue to use self-managed Prometheus in your Kubernetes clusters while also sending data to Managed Prometheus for long term data retention and to create a centralized view across your clusters. This may be a temporary solution while you migrate to Managed Prometheus or a long term solution if you have specific requirements for self-managed Prometheus.

> **Important**
>
> If you are currently using the Azure Monitor sidecar container to remote-write metrics to Azure Monitor Workspace, we recommend transitioning to a direct Prometheus configuration following the guidance in this article. This transition enables direct ingestion without requiring the sidecar component.

Architecture

Remote_write is a feature in Prometheus that allows you to send metrics from a local Prometheus instance to remote storage or to another Prometheus instance. Use this feature to send metrics from self-managed Prometheus running in your Kubernetes clusters or virtual machines to an Azure Monitor workspace used by Managed Prometheus.

The following diagram illustrates this configuration. A data collection rule (DCR) in Azure Monitor provides an endpoint for the self-managed Prometheus instance to send metrics and defines the Azure Monitor workspace where the data will be sent.



> **Important**
>
> Review key concepts about Azure Monitor managed service for Prometheus when you remote-write from self-hosted Prometheus: Migrate to Azure Monitor managed service for Prometheus.

Authentication types

The configuration requirements for remote-write depend on the authentication type used to connect to the Azure Monitor workspace. The following table describes the supported authentication types. The details for each configuration are described in the following sections.

Expand table

Type	Clusters supported
System-assigned managed identity	Azure Kubernetes service (AKS) Azure VM/VMSS
User-assigned managed identity	Azure Kubernetes service (AKS) Arc-enabled Kubernetes Azure VM/VMSS
Microsoft Entra ID	Azure Kubernetes service (AKS) Arc-enabled Kubernetes cluster Cluster running in another cloud or on-premises Azure VM/VMSS Arc-enabled servers VM running in another cloud or on-premises
Microsoft Entra workload identity	Azure Kubernetes service (AKS) Arc-enabled Kubernetes cluster

Prerequisites

Supported versions

- Prometheus version 2.45 or greater is required for user-assigned managed identity authentication.
- Prometheus version 2.48 or greater is required for Microsoft Entra application authentication.

- Prometheus version 3.50 or greater is required for system-assigned managed identity authentication.
- Prometheus version 3.60 or greater is required for Microsoft Entra workload identity authentication.

Azure Monitor workspace

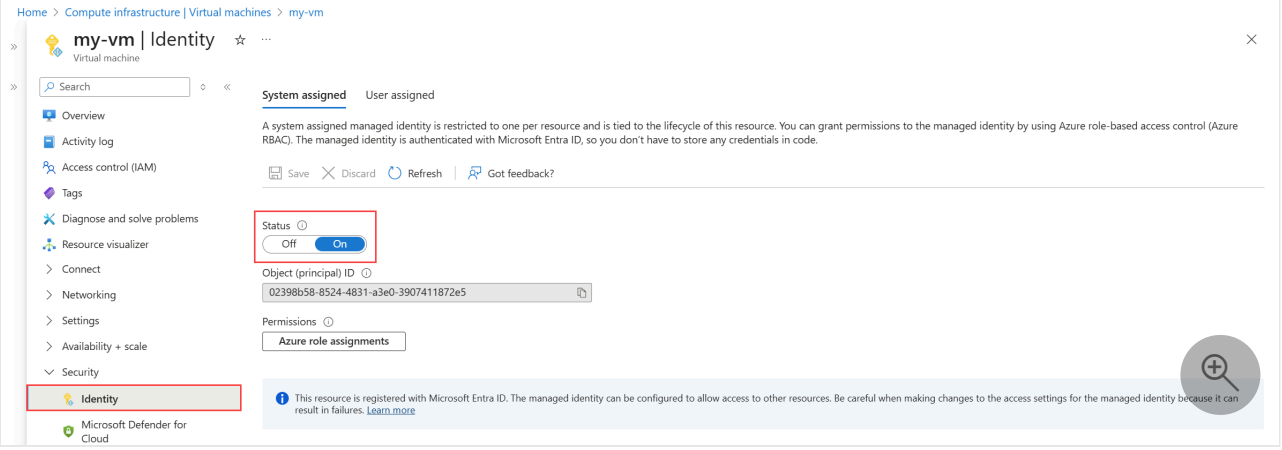
Your Azure Monitor workspace must be created before you can configure remote-write. This automatically enables Managed prometheus. If you don't already have one, see Manage an Azure Monitor workspace.

Create identity for authentication

Before you can configure remote-write, you must create the identity that you'll use to authenticate to the Azure Monitor workspace. The following sections describe how to create each type of identity if you aren't reusing an existing one.

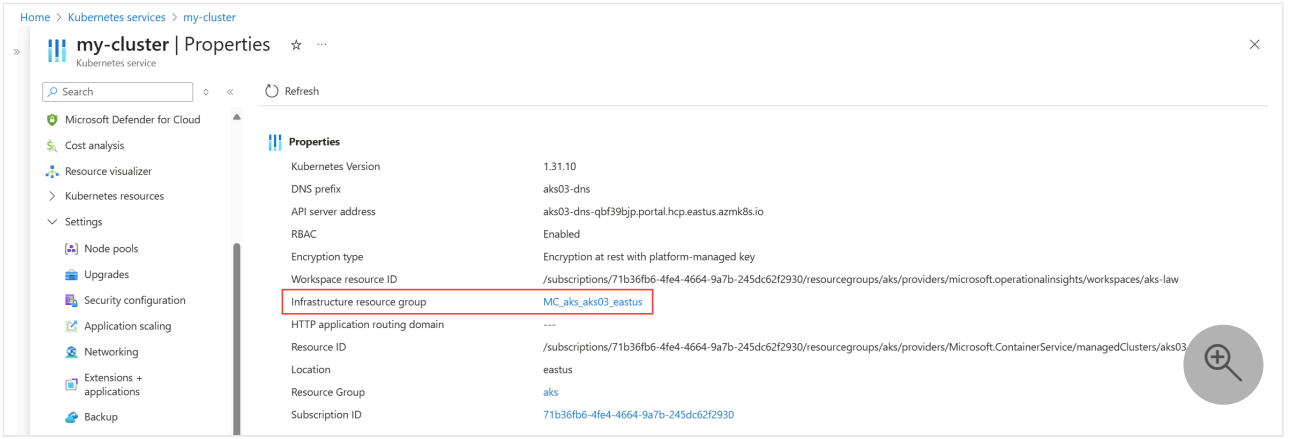
System-assigned Managed identity

You don't directly create a system-assigned managed identity but instead enable it for an Azure virtual machine or virtual machine scale set. For an Azure VM, you can enable the identity when you create the VM or enable it later from its **Identity** page in the Azure portal. For a VMSS, you must enable it after creation. For the different options to enable system-managed identity, see Configure managed identities on Azure virtual machines (VMs) and Configure managed identities for Azure resources on a virtual machine scale set.



For an AKS cluster, the managed identity must be assigned to virtual machine scale sets in the cluster. AKS creates a resource group that contains the virtual machine scale sets. Access this resource group from the **Properties** page in the cluster's menu in the Azure portal. Click on **Infrastructure Resource Group** to view list the resources in this resource

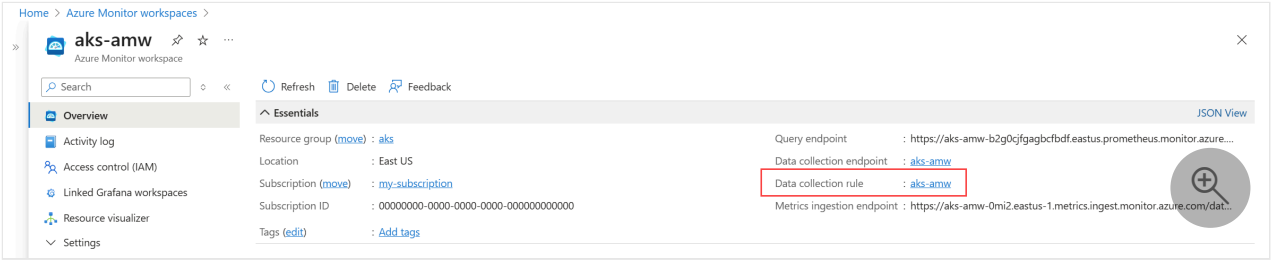
group. You must enable system managed identity for each virtual machine scale set in the resource group.



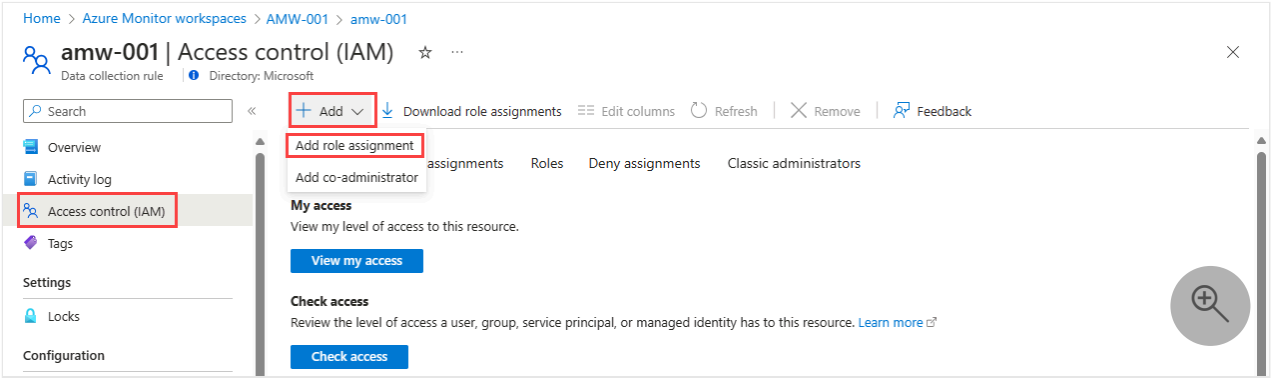
Assign roles

Once the identity that you're going to use is created, it needs to be given access to the data collection rule (DCR) associated with the Azure Monitor workspace that will receive the remote-write data. This DCR is automatically created when you create the workspace. You'll specify this identity in the remote-write configuration for the cluster or VM.

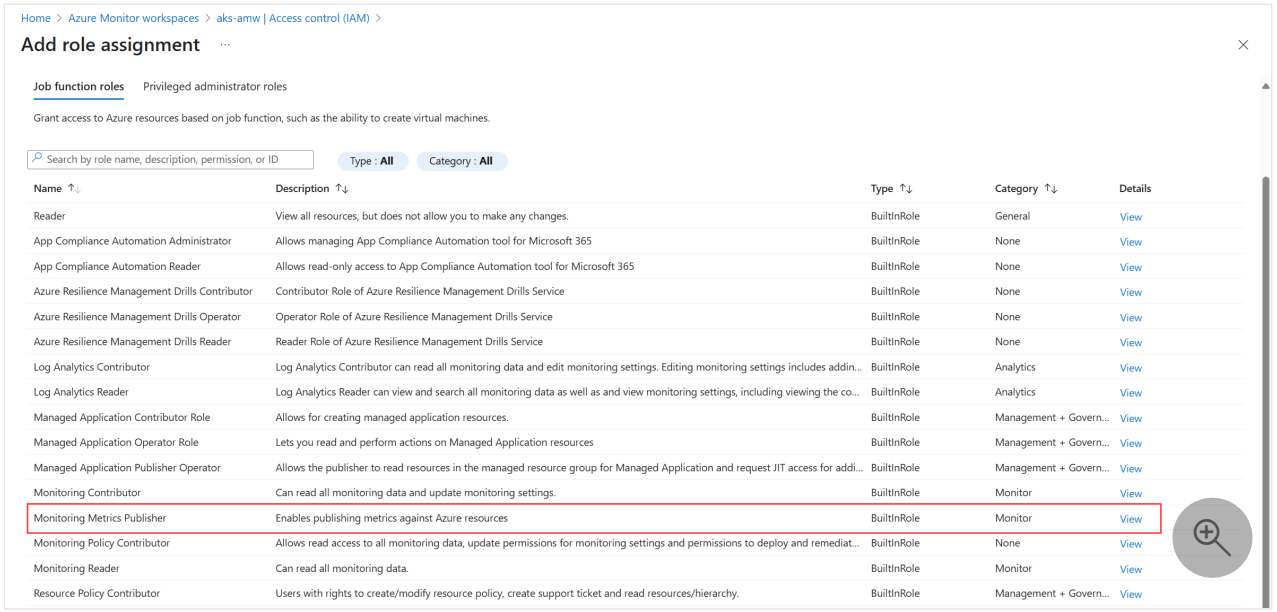
1. On the Azure Monitor workspace's overview pane, select the Data collection rule link. This opens the data collection rule (DCR) that is associated with the workspace.



2. On the page for the data collection rule, select **Access control (IAM)**. Select **Add** and then **Add role assignment**.



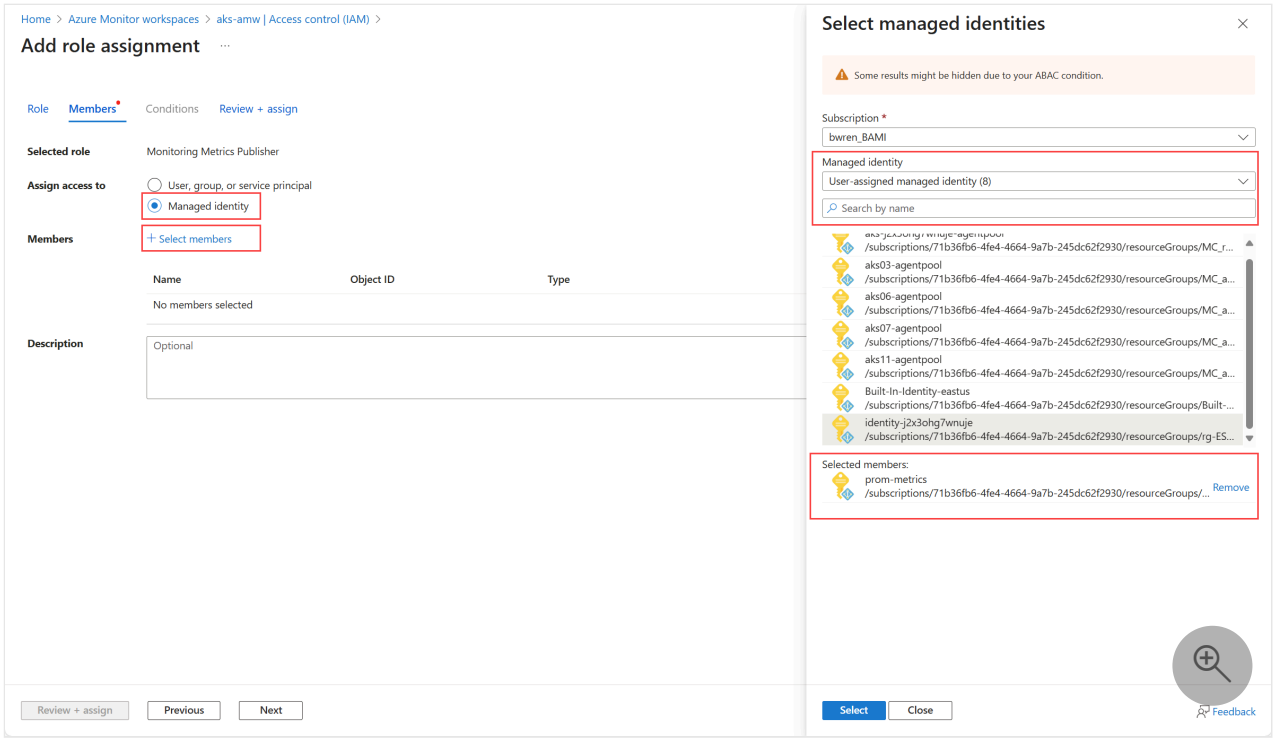
3. Select the **Monitoring Metrics Publisher** role, and then select **Next**.



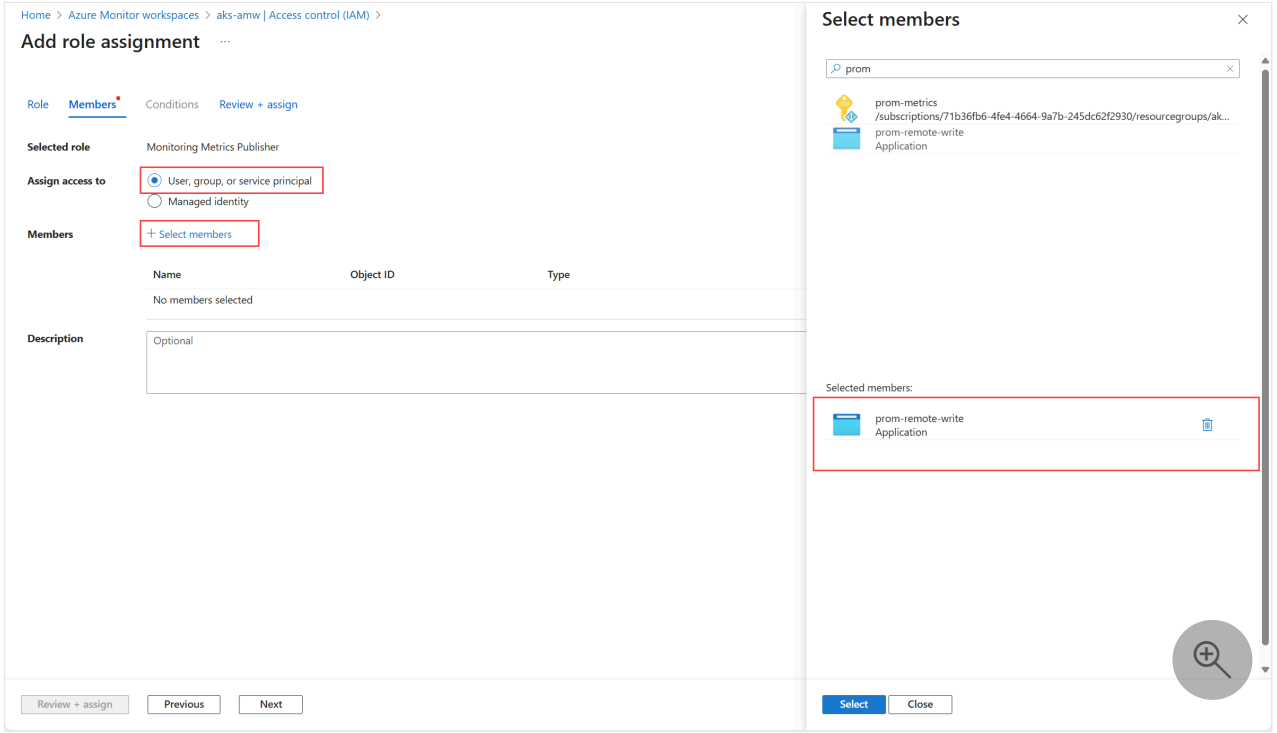
4. Select the identity to be assigned the role.

   a. For system-assigned managed identity, select **Managed identity** and then **Select members**. In the **Managed identity** dropdown, select the VM/VMSS or each of the VMSS in the AKS cluster.

   b. For user-assigned managed identity, select **User-assigned managed identity** section. Select the identity that you created.



c. For Entra ID, select **User, group, or service principal**, and then **Select members**. Select the application that you created, and then choose **Select**.

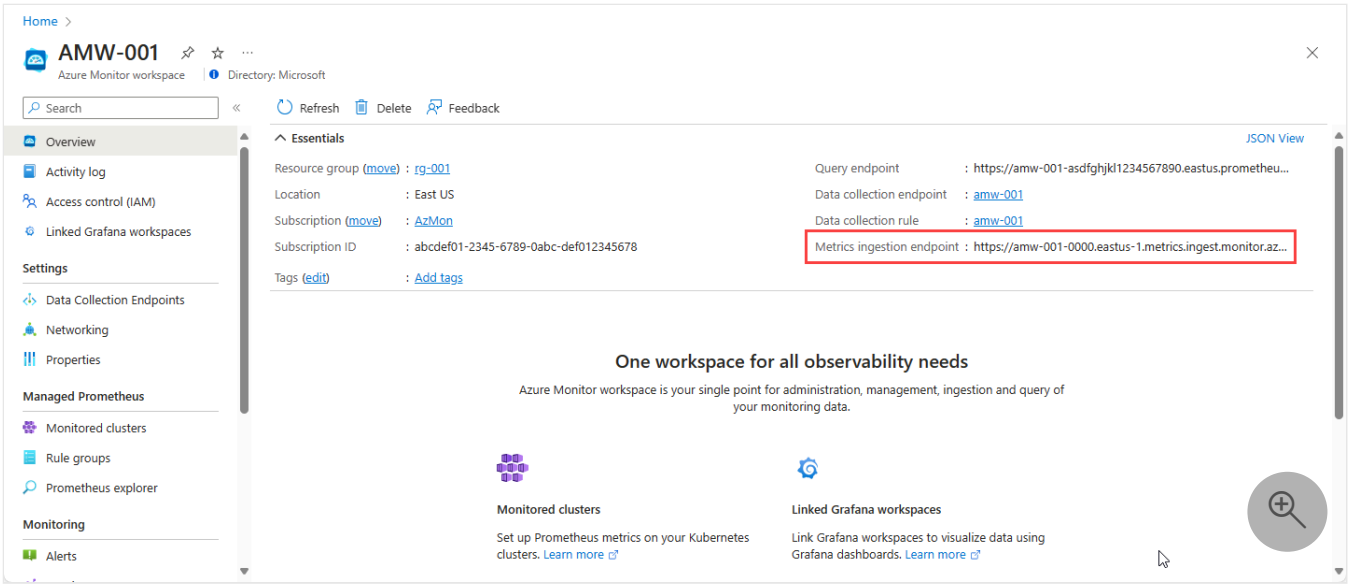


5. Select **Select** to confirm your selection and then **Review + assign** to complete the role assignment.

Configure remote-write in configuration file

Remote write is configured in the Prometheus configuration file `prometheus.yml` or in Prometheus Operator. The final step is to add remote write to the configuration file for your

self-managed Prometheus server. In addition to details for the identity that you created, you'll also need the metrics ingestion endpoint (URL) for the Azure Monitor workspace. Get this value from the **Overview** page for your Azure Monitor workspace in the Azure portal, and make a note of it.



Configure remote write with Prometheus config file

To send data to your Azure Monitor workspace, add the following section to the configuration file (`prometheus.yml`) of your self-managed Prometheus instance.

> **Note**
>
> For system-assigned managed identity, leave the client ID field blank (client_id: "").

Managed identity

Azure CLI

```
prometheus:
  prometheusSpec:
    remote_write:
    - url: "<metrics ingestion endpoint for your Azure Monitor workspace>"
      azuread:
        cloud: 'AzurePublic'  # Options are 'AzurePublic', 'AzureChina', or
'AzureGovernment'.
        managed_identity:
          client_id: "<client-id of the managed identity>"
```

Entra ID

Azure CLI

```
prometheus:
  prometheusSpec:
    remote_write:
    - url: "<metrics ingestion endpoint for your Azure Monitor workspace>"
      azuread:
        cloud: 'AzurePublic'  # Options are 'AzurePublic', 'AzureChina', or
'AzureGovernment'.
        oauth:
          client_id: "<client-id from the Entra app>"
          client_secret: "<client secret from the Entra app>"
          tenant_id: "<Azure subscription tenant Id>"
```

Workload identity

Azure CLI

```
prometheus:
  prometheusSpec:
    podMetadata:
      labels:
        azure.workload.identity/use: "true"
    remote_write:
    - url: "<metrics ingestion endpoint for your Azure Monitor workspace>"
      azuread:
        cloud: 'AzurePublic'  # Options are 'AzurePublic', 'AzureChina', or
'AzureGovernment'.
        workload_identity:
          client_id: "<client-id from the Entra app>"
          tenant_id: "<Azure subscription tenant Id>"
```

Apply the configuration file updates:

Virtual Machine

For a virtual machine, the configuration file will be `prometheus.yml` unless you specify a different one using `prometheus --config.file <path-to-config-file>` when starting the Prometheus server.

Kubernetes cluster

For a Kubernetes cluster, the configuration file is typically stored in a ConfigMap. Following is a sample ConfigMap that includes a remote-write configuration using managed identity for self-managed Prometheus running in a Kubernetes cluster.

yml

```
  GNU nano 6.4
apiVersion: v1
kind: ConfigMap
metadata:
  name: prometheus-server-conf # must match what your pod mounts
  namespace: monitoring  # adjust to your namespace
data:
  prometheus.yml: |-
   global:
     scrape_interval: 15s
     evaluation_interval: 15s
     external_labels:
       cluster: "aks11"

   scrape_configs:
     - job_name: "prometheus"
       static_configs:
         - targets: ["localhost:9090"]

   remote_write:
     - url: "https://aks-amw-0mi2.eastus-
1.metrics.ingest.monitor.azure.com/dataCollectionRules/dcr-
00000000000000000000000000000000/streams/Microsoft-
PrometheusMetrics/api/v1/write?api-version=2023-04-24"
       azuread:
         cloud: 'AzurePublic'
         managed_identity:
           client_id: "00001111-aaaa-2222-bbbb-3333cccc4444"
```

Use the following command to apply the configuration file updates.

Bash

```
kubectl apply -f <configmap-file-name>.yaml
```

Restart Prometheus to pick up the new configuration. If you are using a deployment, you can restart the pods by running the following command.

Bash

```
kubectl -n monitoring rollout restart deploy <prometheus-deployment-name>
```

> ⓘ **Note**
>
> After you edit the configuration file, restart Prometheus to apply the changes.

For information on tuning the remote write configuration, see Remote write tuning.

Troubleshoot

HTTP 403 error in the Prometheus log

It takes about 30 minutes for the assignment of the role to take effect. During this time, you may see an HTTP 403 error in the Prometheus log. Check that you have configured the managed identity or Microsoft Entra ID application correctly with the **Monitoring Metrics Publisher** role on the workspace's DCR. If the configuration is correct, wait 30 minutes for the role assignment to take effect.

No Kubernetes data is being collected

If data isn't being collected in Managed Prometheus, run the following command to find errors in the remote write container.

Azure CLI

```
kubectl --namespace <Namespace> describe pod <Prometheus-Pod-Name>
```

Container restarts repeatedly

A container regularly restarting is likely due to misconfiguration of the container. Run the following command to view the configuration values set for the container. Verify the configuration values especially `AZURE_CLIENT_ID` and `IDENTITY_TYPE`.

azureccli

```
kubectl get pod <Prometheus-Pod-Name> -o json | jq -c  '.spec.containers[] |
select( .name | contains("<Azure-Monitor-Side-Car-Container-Name>"))'
```

The output from this command has the following format:

```
{"env":[{"name":"INGESTION_URL","value":"https://my-azure-monitor-
workspace.eastus2-1.metrics.ingest.monitor.azure.com/dataCollectionRules/dcr-
00000000000000000/streams/Microsoft-PrometheusMetrics/api/v1/write?api-
version=2021-11-01-preview"},{"name":"LISTENING_PORT","value":"8081"},
{"name":"IDENTITY_TYPE","value":"userAssigned"},
{"name":"AZURE_CLIENT_ID","value":"00000000-0000-0000-0000-
00000000000"}],"image":"mcr.microsoft.com/azuremonitor/prometheus/promdev/prom-
remotewrite:prom-remotewrite-20221012.2","imagePullPolicy":"Always","name":"prom-
remotewrite","ports":[{"containerPort":8081,"name":"rw-
port","protocol":"TCP"}],"resources":{},"terminationMessagePath":"/dev/termination-
```

```
log","terminationMessagePolicy":"File","volumeMounts":
[{"mountPath":"/var/run/secrets/kubernetes.io/serviceaccount","name":"kube-api-
access-vbr9d","readOnly":true}]}
```

Data dropped due in high volume environments

The Data Collection Rule (DCR) and Data Collection Endpoint (DCE) for the Azure Monitor workspace are subject ingestion limits listed in Azure Monitor service limits. You're most subject to these limits when configuring remote write for multiple clusters sending data to the same endpoint.

Consider Remote write tuning to adjust configuration settings for better performance. If you still see data drops, consider creating additional DCRs and DCEs to distribute the ingestion load across multiple endpoints. This approach helps optimize performance and ensures efficient data handling. See Instructions on how to create custom Data collection endpoint(DCE) and custom Data collection rule(DCR) for an existing Azure monitor workspace(AMW) to ingest Prometheus metrics.

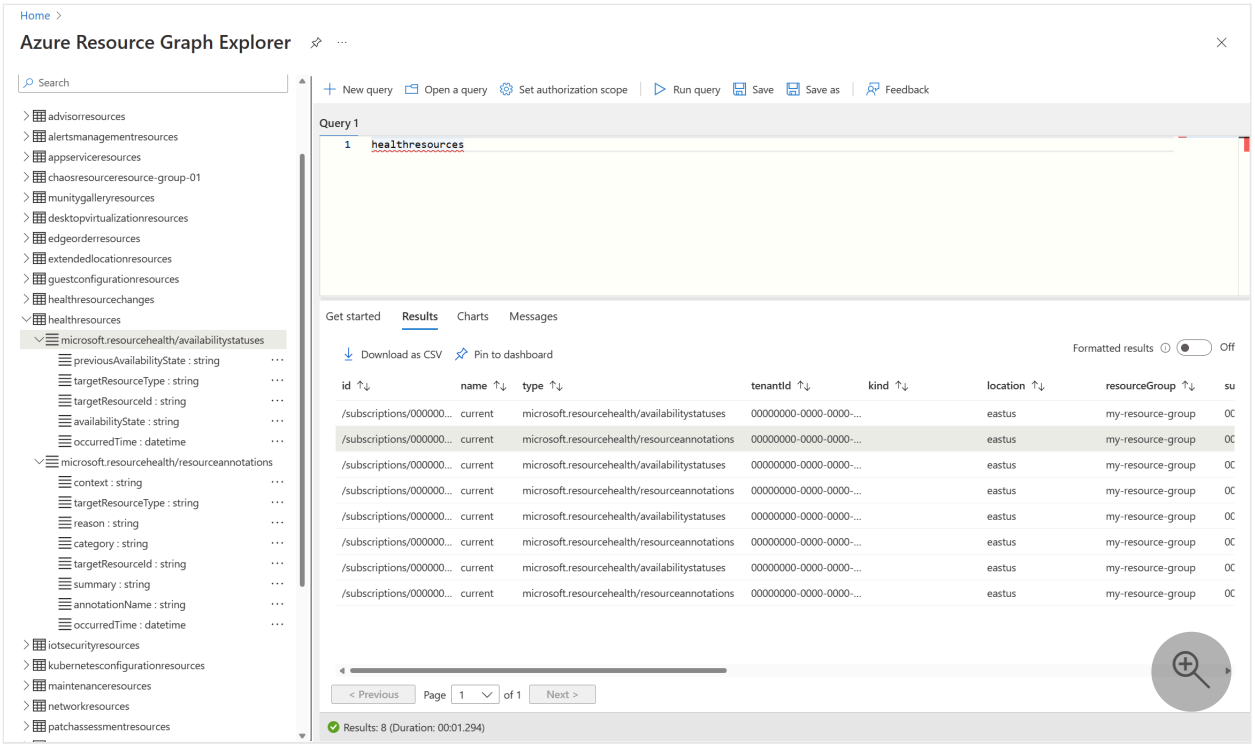
VM availability information in Azure Resource Graph

Article • 08/22/2024

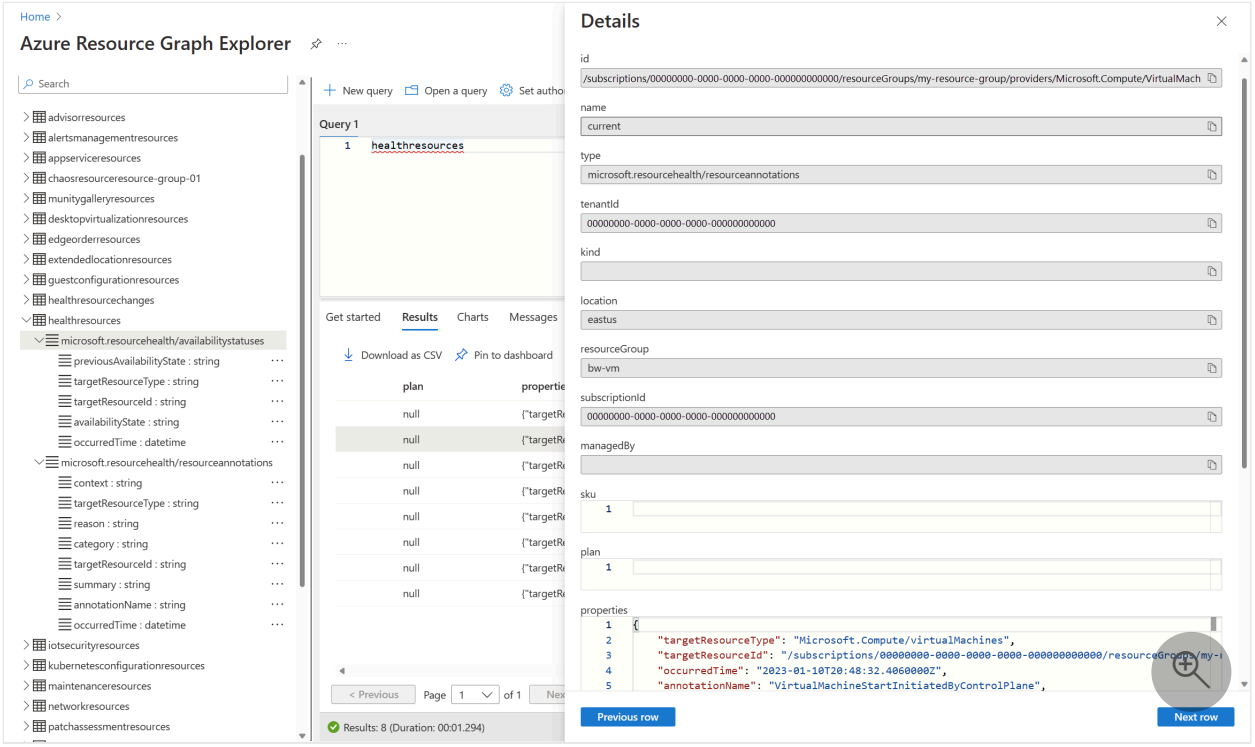
Azure Resource Graph is an Azure service that allows you to use the same KQL query language used in log queries to query your Azure resources at scale with complex filtering, grouping, and sorting by resource properties. You can use VM health annotations to Azure Resource Graph (ARG) for detailed failure attribution and downtime analysis including the following:

- Query the latest snapshot of VM availability together across all your Azure subscriptions.
- Assess the impact to business SLAs and trigger decisive mitigation actions, in response to disruptions and type of failure signature.
- Set up custom dashboards to supervise the comprehensive health of applications by joining VM availability information with additional resource metadata in Resource Graph.
- Track relevant changes in VM availability across a rolling 14 days window, by using the change tracking mechanism for conducting detailed investigations.

To get started with Resource Graph, open **Resource Graph Explorer** in the Azure portal. Select the **Table** tab and have a look at the microsoft.resourcehealth/availabilitystatuses and microsoft.resourcehealth/resourceannotations tables which are described below. Click on **healthresources** to create a simple query and then click **Run** to return the records.



To view the details for a record, scroll to the right and select **See details**.



There will be two types of events populated in the HealthResources table:

microsoft.resourcehealth/availabilitystatuses

This event denotes the latest availability status of a VM, based on the health checks performed by the underlying Azure platform. The availability states currently emitted for VMs are as follows:

- **Available**: The VM is up and running as expected.
- **Unavailable**: A disruption to the normal functioning of the VM has been detected.
- **Unknown**: The platform is unable to accurately detect the health of the VM. Check back in a few minutes.

The availability state is in the `properties` field of the record which includes the following properties:

Expand table

Field	Description
targetResourceType	Type of resource for which health data is flowing
targetResourceId	Resource ID
occurredTime	Timestamp when the latest availability state is emitted by the platform
previousAvailabilityState	Previous availability state of the VM
availabilityState	Current availability state of the VM

A sample `properties` value looks similar to the following:

JSON

```
{
    "targetResourceType": "Microsoft.Compute/virtualMachines",
    "targetResourceId":
"/subscriptions/<subscriptionId>/resourceGroups/<ResourceGroupName>/providers/Microsoft.Compute/virtualMachines/<VMName>",
    "occurredTime": "2022-10-11T11:13:59.9570000Z",
    "previousAvailabilityState": "Available",
    "availabilityState": "Unavailable"
}
```

microsoft.resourcehealth/resourceannotations

This event contextualizes any changes to VM availability, by detailing necessary failure attributes to help you investigate and mitigate the disruption as needed. The full list of VM health annotations are listed at [Resource Health virtual machine Health Annotations] (../service-health/resource-health-vm-annotation.md).

These annotations can be broadly classified into the following:

- **Downtime Annotations**: Emitted when the platform detects VM availability transitioning to Unavailable. Examples include host crashes or reboot operations.
- **Informational Annotations**: Emitted during control plane activities with no impact to VM availability. Examples include VM allocation, stop, delete, start. Usually, no additional customer action is required in response.
- **Degraded Annotations**: Emitted when VM availability is detected to be at risk. Examples include when failure prediction models predict a degraded hardware component that can cause the VM to reboot at any given time. You should redeploy by the deadline specified in the annotation message to avoid any unanticipated loss of data or downtime.

Expand table

Field	Description
targetResourceType	Type of resource for which health data is flowing
targetResourceId	Resource ID
occurredTime	Timestamp when the latest availability state is emitted by the platform
annotationName	Name of the Annotation emitted
reason	Brief overview of the availability impact observed by the customer
category	Denotes whether the platform activity triggering the annotation was either planned maintenance or unplanned repair. This field is not applicable to customer/VM-initiated events. Possible values: Planned | Unplanned | Not Applicable | Null
context	Denotes whether the activity triggering the annotation was due to an authorized user or process (customer initiated), due to the Azure platform (platform initiated), or due to activity in the guest OS that has resulted in availability impact (VM initiated). Possible values: Platform-Initiated | User-initiated | VM-initiated | Not Applicable | Null
summary	Statement detailing the cause for annotation emission, along with remediation steps that can be taken by users

See Azure Resource Graph sample queries by table for sample queries using this data.

VM watch: Enhancing VM health monitoring (preview)

Article • 04/29/2025

VM watch is a standardized, lightweight, and adaptable service offering for virtual machines (VMs) and virtual machine scale sets. It runs health checks within a VM at configurable intervals and sends the results via a uniform data model to Azure. The AI operations (AIOps) engines for production monitoring in Azure consume these health results for regression detection and prevention.

VM watch is delivered via the Application Health VM extension to provide ease of deployment and manageability for customers. In addition, VM watch is offered at no extra cost.

Monitoring specifics for VM watch

- **Ease of adoption**: VM watch is available through the Application Health VM extension.
- **Flexible deployment**: You can enable VM watch by using an Azure Resource Manager template (ARM template), PowerShell, or the Azure CLI.
- **Compatibility**: VM watch operates seamlessly in both Linux and Windows environments. It's suitable for individual VMs and virtual machine scale sets alike.
- **Resource governance**: VM watch provides efficient monitoring without affecting system performance. Resource caps on the CPU and memory utilization of the VM watch process help protect VMs.
- **Out-of-the-box readiness**: VM watch comes equipped with a suite of default tests that you can configure for your scenarios.

VM watch Memory Constraints

To maintain consistent performance across different virtual machine (VM) configurations, **VM watch** enforces memory usage limits according to the VM SKU's total available memory. The memory caps are adjusted dynamically based on the VM's memory tier.

Expand table

VM Memory Range	VM watch Memory Cap
Less than 8 GB	80MB
8 GB to 16 GB	200MB
Greater than 16 GB	400MB

Network

Expand table

Signal name	Type	Description
Outbound connectivity	Check	Verify the network outbound connectivity from the Azure VM.
DNS Resolution	Check	Verify if one or more DNS names can be resolved.
TCPSynRetransmits (Linux Only)	Metric	The number of times the system retransmits a TCP SYN and SYN/ACK packet before giving up on establishing a connection.
SegmentsRetransmitted	Metric	The number of transmitted TCP segments that contain one or more previously transmitted octets.
NormalizedSegmentsRetransmitted	Metric	**SegmentsRetransmitted** / (**SegmentsSent** + **SegmentsRetransmitted**)
ConnectionResets	Metric	The number of times that TCP connections made a direct transition to the `CLOSED` state from either the `ESTABLISHED` state or the `CLOSE_WAIT` state.
NormalizedConnectionResets	Metric	The percentage of connections that were reset during the last measurement interval.
FailedConnectionAttempts	Metric	The number of times that TCP connections made a direct transition to the `CLOSED` state from either the `SYN_SENT` state or the `SYN_RCVD` state.
NormalizedFailedConnectionAttempts	Metric	**FailedConnectionAttempts** / (**ActiveConnectionOpenings** + **PassiveConnectionOpenings**)
ActiveConnectionOpenings	Metric	The number of times that TCP connections made a direct transition to the `SYN_SENT` state from the `CLOSED` state.
PassiveConnectionOpenings	Metric	The number of times that TCP connections made a direct transition to the `SYN_RCVD` state from the `LISTEN` state.
CurrentConnections	Metric	The number of connections established.
SegmentsReceived	Metric	The number of segments received, including segments received in error.
SegmentsSent	Metric	The number of segments sent, including segments on current connections but excluding segments that

Signal name	Type	Description
		contain only retransmitted octets.

Disk

Expand table

Signal name	Type	Description
Azure Disk I/O	Check	Verify file creation, write, and read. Delete operations on each drive mounted to the VM.
FreeSpaceInBytes	Metric	The free disk space of the target mount point.
UsedSpaceInBytes	Metric	The used disk space of the target mount point.
CapacityInBytes	Metric	The disk space capacity of the target mount point.
UsedPercent	Metric	The percentage of used disk space for the target mount point.
WriteOps	Metric	The write operations per second for the target disk/partition.
ReadOps	Metric	The read operations per second for the target disk/partition.

CPU

Expand table

Signal name	Type	Description
ProcessCPUCoreUsage	Metric	An instantaneous measurement of the percentage of a single CPU core that the target process is using (100 = 100%, a whole core).
ProcessCPUMachineUsage	Metric	The percentage of the machine's total CPU that this process is using.
MachineTotalCpuUsage	Metric	The VM's total instantaneous CPU utilization.

Memory

Expand table

Signal name	Type	Description
ProcessRSSPercent	Metric	**Process RSS** / (**Machine Total Memory** * **100%**)

Signal name	Type	Description
ProcessPageFaults	Metric	The number of page faults since the process started.
MachineMemoryTotalInBytes	Metric	The VM's total Memory in Bytes.
MachineMemoryUsedPercent	Metric	**Machine Used Memory** / (**Machine Total Memory** * 100%)
TotalPageFaults	Metric	The total number of page faults for all running processes since they started.

Process

Expand table

Signal name	Type	Description
Process Creation	Check	Start a lightweight process to validate that process creation is possible.
Running Process(es)	Check	Verify if the target process or processes are running.
UpTime	Metric	How long the target process has been up and running since the last process startup.

IMDS

Expand table

Signal name	Type	Description
IMDS	Check	Verify that the user can reach an Azure Instance Metadata Service (IMDS) endpoint from within the VM. VM information is returned from the IMDS endpoint query.

Clock

Expand table

Signal name	Type	Description
Clock Skew	Check	Verify the clock skew between the remote Network Time Protocol (NTP) server and the Azure VM. For a Windows VM, fall back to check if the Windows Time service is synced with `w32tm` if the remote NTP server is inaccessible.

OS

Expand table

Signal name	Type	Description
System Errors	Metric	Collect the number of errors from the system-level event log (Windows only) where the SystemData <=2 (including LOG_ALWAYS, Critical, Error). The measurementTarget is defined as the Source_EventId of the EventLog using default Windows locale. Each collection is limited to more than 10 different measurement targets.

azblob

Expand table

Signal name	Type	Description
Azure Storage blob connectivity	Check	Verify the connectivity to the Azure Storage blob and download the blob by using MSI or a shared access signature (SAS) token.

Hardware

Expand table

Signal name	Type	Description
Hardware Health Monitor	EventLog	Collect hardware health info from the Windows event log. Currently, only disk-related critical events are collected, including events with ID 7, 500, 504, 505, 512, and 549.
Hardware Health Nvidia Smi	EventLog	Collect GPU stats including memory and GPU usage, temp and others by running nvidia-smi command (Linux Ubuntu only)

Install VM watch (preview)

Article • 01/13/2025

You can enable VM watch by using an Azure Resource Manager template (ARM template), PowerShell, or the Azure CLI on Azure virtual machines (VMs) and Azure virtual machine scale sets. You can enable VM watch on both Linux and Windows virtual machines. VM watch is delivered through the Application Health VM extension for ease of adoption.

The code in this article details the steps to install the Application Health VM extension and enable VM watch. Note that the code segments require user input. Any labels within angle brackets (`<>`) in the code need to be replaced with values that are specific to your installation. Here's a list of parameters with instructions on what to replace them with.

Expand table

Parameter	Description
`<your subscription id>`	The Azure subscription ID in which you want to install VM watch.
`<your vm name>`	The name of the virtual machine to which the extension is being installed.
`<your resource group name>`	The name of the resource group in your Azure subscription that your VM will be assigned to.
`<your location>`	The Azure region in which your VM is installed.
`<your extension name`	The name that will be assigned to the Application Health VM extension that you're installing.
`<application health extension type>`	Specifies whether the Windows or Linux Application Health extension will be installed.
`<your vm scale set name>`	The name of the virtual machine scale set in which you want to install VM watch.

Prerequisites

1. Register the feature

Register for adopting VM watch by running the following commands via the Azure CLI:

```
```

```
az feature register --name VMWatchPreview --namespace Microsoft.Compute --
subscription <your subscription id>
az provider register --namespace Microsoft.Compute --subscription <your
subscription id>
```

Validate feature registration

Validate that you successfully registered for the VM watch feature by running the following command:

```
az feature show --namespace Microsoft.Compute --name VMWatchPreview --
subscription <your subscription id>
```

2. Ensure that a VM is installed

For information on how to create a VM and/or virtual machine scale set, see the quickstart guide for Windows and the quickstart guide for Linux.

> **ⓘ Important**
>
> If the Application Health extension is already installed on the VM, ensure that the settings `autoUpgradeMinorVersion` and `enableAutomaticUpgrade` are set to `true`.

Install VM watch on an Azure virtual machine

> **ⓘ Important**
>
> The code segment is identical for both Windows and Linux, except for the value of the parameter `<application health extension type>` passed in to the extension type. Replace `<application health extension type>` with `"ApplicationHealthLinux"` for Linux installations and `"ApplicationHealthWindows"` for Windows installations.

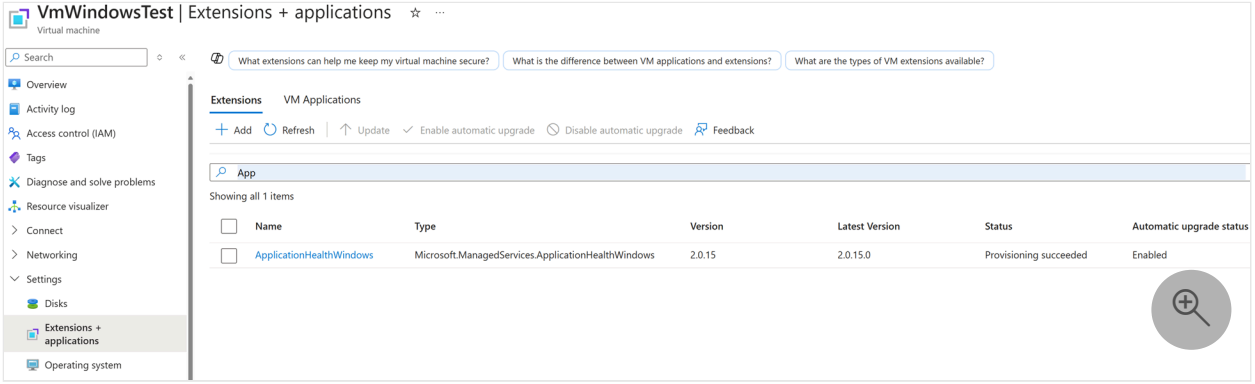
CLI

```
az vm extension set --resource-group <your resource group> --vm-name
<your vm name> --name <application health extension type> --publisher
Microsoft.ManagedServices --version 2.0 --settings '{"vmWatchSettings":
{"enabled": true}}' --enable-auto-upgrade true
```

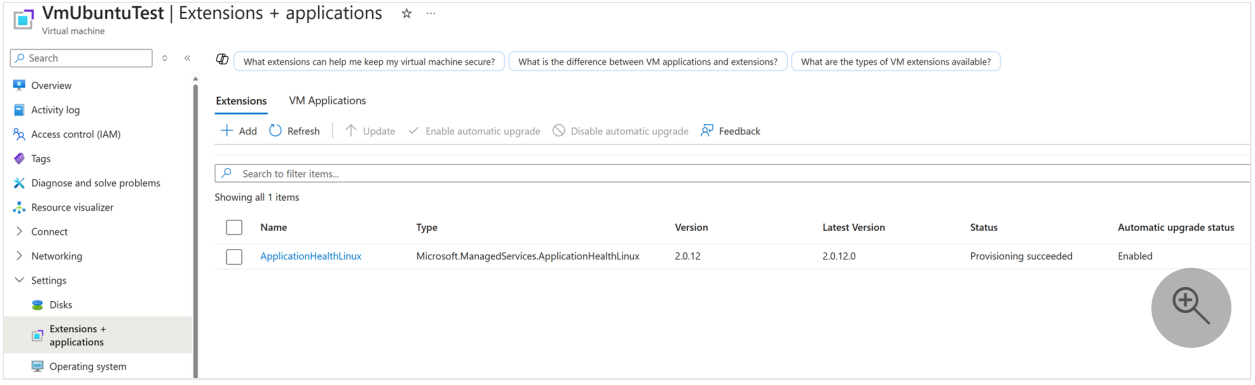
Validate that the Application Health VM extension is installed on the Azure VM

Go to the Azure portal and confirm that the Application Health VM extension was successfully installed.

The following screenshot shows a Windows installation.



The following screenshot shows a Linux installation.



To confirm that VM watch was enabled on this VM, go back to the overview page and select the JSON view for the VM. Ensure that the configuration exists in the JSON.

```
"settings": {
    "vmWatchSettings": {
        "enabled": true
```

```
    }
}
```

Install VM watch on an Azure virtual machine scale set

> **Important**
>
> The code segment is identical for both Windows and Linux, except for the value of the parameter `<application health extension type>` passed in to the extension type. Replace `<application health extension type>` with `"ApplicationHealthLinux"` for Linux installations and `"ApplicationHealthWindows"` for Windows installations.

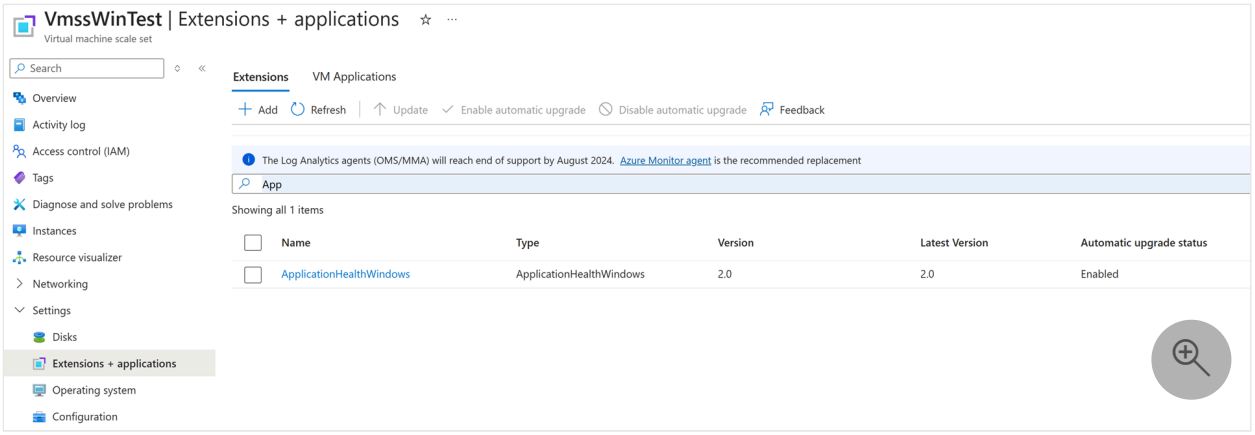
CLI

```
az vmss extension set --resource-group '<your resource group name>' --
vmss-name '<your vm scale set name>' --name <application health
extension type> --publisher Microsoft.ManagedServices --version 2.0 --
settings '{"vmWatchSettings": {"enabled": true}}' --enable-auto-upgrade
true
```

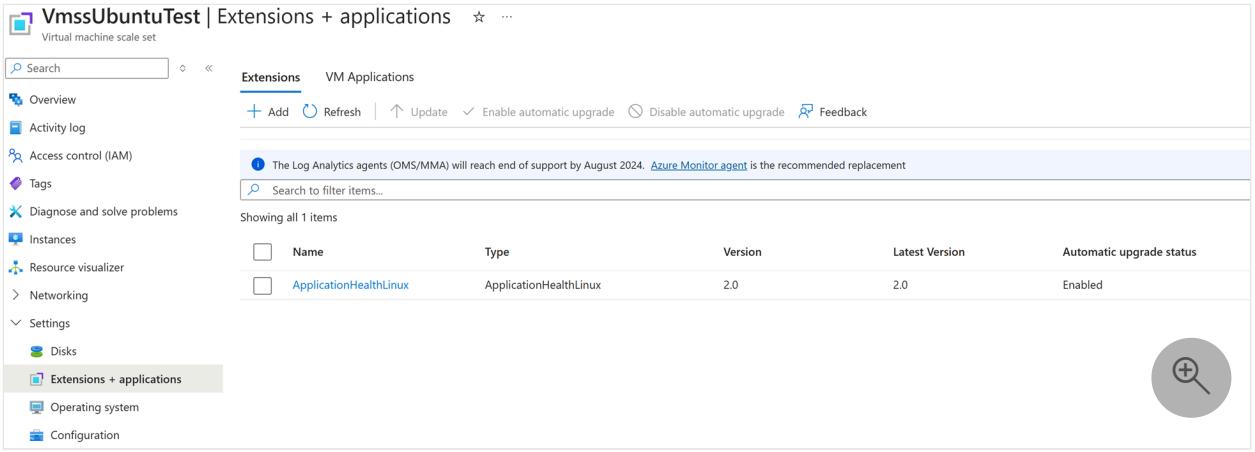
Validate that the Application Health VM extension is installed in the virtual machine scale set

Go to the Azure portal and confirm that the Application Health VM extension was successfully installed.

The following screenshot shows a Windows installation.



The following screenshot shows a Linux installation.



To confirm that VM watch was enabled on this scale set, go back to the overview page and select the JSON view for the scale set. Ensure that the configuration exists in the JSON.

```
"settings": {
    "vmWatchSettings": {
        "enabled": true
    }
}
```

VM watch Collectors Suite

Article • 03/03/2025

VM watch collectors are designed to gather VM health data on various resources like disk and network, by running health checks within the VM. This suite of collectors aid in identifying issues, monitoring performance trends, and optimizing resources to enhance the overall user experience.

This article provides a summary of all available collectors in VM watch, along with the corresponding checks, metrics, logs, and parameter configurations. For detailed descriptions of each check, metric, and log, refer to the VM watch overview page.

Prerequisites

This article assumes that you're familiar with:

- VM watch checks, metrics, and logs
- Install VM watch to virtual machines and scale sets

Note

Expand table

Name	Description
Collector	Logical grouping of similar tests where you can collect checks, metrics, and logs to determine the health of a particular resource
Signals	What is emitted to reflect the health status of VMs. The three types of signals emitted are checks, metrics, and logs
Group	Indicates whether the collectors are part of the core or optional group. Core group collectors are enabled by default, while optional group collectors can be enabled or disabled based on your requirements
Tags	Used to categorize and filter checks, metrics, and logs
Eligibility	Determines whether a collector is eligible to be executed based on the environment attributes you specify
Default Behavior	Standard setting and action that would be followed if no custom configurations are provided.
Overwritable Parameters	Associated parameters that can be customized to override the default configuration

Groups, tags and corresponding checks, metrics, and event logs

Eligibility, default behavior, and overwritable parameters

Expand table

Collector Name	Eligibility	Default Behavior	Overwritable Parameters
outbound_connectivity	Eligible if EnvironmentAttribute "OutboundConnectivityDisabled" isn't set or set to "false"	This collector is executed every 60s. In each execution, it sends an http GET request to `http://www.msftconnecttest.com/connecttest.txt` with a time-out of 5s. If the request fails, it retries at most two more times with and interval of 10s. The verification is marked as "Failed" if all the retries fail.	• OUTBOUND_CONNECTIVITY_INTERVAL interval of the Collector. Default: 60s • OUTBOUND_CONNECTIVITY_URLS: the Collector sends http GET requests to. U string using `,` as separator. Default: `http://www.msftconnecttest.com/connec` • OUTBOUND_CONNECTIVITY_TIMEOUT_ the http GET request time-out in millise • OUTBOUND_CONNECTIVITY_TOTAL_AT number of attempts to send http reque fails. Default: 3 • OUTBOUND_CONNECTIVITY_RETRY_IN the retry interval in seconds if the previ Default: 10
dns	Eligible if EnvironmentAttribute "OutboundConnectivityDisabled" isn't set or set to "false"	This Collector is executed every 180s. In each execution, it tries to resolve the DNS name `www.msftconnecttest.com` . The verification is marked as "Failed" if the DNS name can't be resolved.	• DNS_INTERVAL: the execution interval c Default: 180s • DNS_NAMES: the domain names to be by `,`. Default: `www.msftconnecttest.com`
tcp_stats	Always eligible	This collector is executed every 180s. In each execution, it collects the TCP statistics of the last 180s.	• TCP_STATS_INTERVAL: the execution int Default: 180s

Collector Name	Eligibility	Default Behavior	Overwritable Parameters
clock_skew	Eligible if EnvironmentAttribute "OutboundConnectivityDisabled" isn't set or set to "false"	This collector is executed every 180s. In each execution, it retrieves the clock offset between the remote NTP server `time.windows.com` and the VM. The verification is marked as "Failed" if the clock skew is larger than 5.0 seconds. In Windows VM, if connecting to remote NTP server fails, it fallbacks to check Windows Time Service with w32tm command. The verification is marked as "Failed" if the w32tm command returns "Leap Indicator: 3(not synchronized)".	• CLOCK_SKEW_INTERVAL: the execution Collector. Default: 180s • CLOCK_SKEW_NTP_SERVER: the remote calculate clock skew. Default: time.wind • CLOCK_SKEW_TIME_SKEW_THRESHOLD threshold in seconds of clock offset to r as "Failed". Default: 5.0
disk_io	Always eligible if mount points aren't specified. If mount points are explicitly specified, only eligible when data disks are attached to the VM	This collector is executed every 180s. In each execution, it verifies the disk io availability in each available mount point by creating a folder, creating a file, writing bytes to it, deleting it and delete the folder. Then it collects the disk usage info including used space, free space, total capacity and used percentage from each mount point.	• DISK_IO_INTERVAL: the execution interv Default: 180s • DISK_IO_MOUNT_POINTS: the mount p No default value • DISK_IO_IGNORE_FS_LIST: the file syster ignored separated by `,`. Default: tmpfs,devtmpfs,devfs,iso9660,overlay,au • DISK_IO_FILENAME: the name of the file file read/write. Default: vmwatch-{times
disk_iops	Always eligible	This collector is executed every 180s. In each execution, it collects the disk read and write operations per second metrics from each available disk device.	• DISK_IOPS_INTERVAL: the execution int Default: 180s • DISK_IOPS_DEVICES: the device names default value • DISK_IOPS_IGNORE_DEVICE_REGEX: the name that should be ignored. Default: l
imds	Always eligible	This collector is executed every 180s. In each execution, it queries the IMDS endpoint `http://169.254.169.254/metadata/instance/compute` and verifies the response body contains the information (SubscriptionId, ResourceGroup, VMId, ResourceId) of the VM. The query time-out is 10s. If the query fails, it retries at most another three more times with an interval of 15s, 30s, and 45s.	• IMDS_INTERVAL: the execution interval Default: 180s • IMDS_ENDPOINT: the URL of the IMDS Default: `http://169.254.169.254/metadat` • IMDS_TIMEOUT_IN_SECONDS: the time each query. Default: 10 • IMDS_QUERY_TOTAL_ATTEMPTS: the to attempts to send http request if the pre Default: 4 • IMDS_RETRY_INTERVAL_IN_SEONDS: th seconds if the previous http request fail
process	Always eligible	This collector is executed every 180s. In each execution, it creates and executes command `${SYTEM_DIR}\system32\cmd.exe /c echo hello` in Windows machine and `/bin/sh -c echo hello` in Linux machine. The time-out of process execution is 10s.	• PROCESS_INTERVAL: the execution inte Default: 180s • PROCESS_TIMEOUT: the time-out of pro Default: 10s
process_memory	Always eligible	This collector is executed every 180s. In each execution, it selects the top three processes with the most memory usage and reports the ProcessRSSPercent, ProcessPageFaults, MachineMemoryTotalInBytes, MachineMemoryUsedPercent, and TotalPageFaults.	• PROCESS_MEMORY_INTERVAL: the exec Collector. Default: 180s
process_cpu	Always eligible	This collector is executed every 180s. In each execution, it selects the top three processes with the most CPU usage and reports the ProcessCoreUsage, ProcessMachineUsage, and MachineTotalCpuUsage.	• PROCESS_CPU_INTERVAL: the executior Collector. Default: 180s
process_monitor	Always eligible	Not executed. If explicitly enabled by the user, this collector verifies if the selected process is running and collect its running time in seconds.	• PROCESS_MONITOR_INTERVAL: the exe Collector. Default: 180s • PROCESS_MONITOR_PROCESS_NAMES Expression of process names to be mon `,`. No default value
system_error	Eligible in Windows machine	The Collector is executed every three mins. In each execution, it subscribes to the "System" channel of Windows EventLog and queries events with level defined in SystemData <=2 (including	• SYSTEM_ERROR_MEASUREMENT_TARG total different measurementTargets in e Default: 10

Collector Name	Eligibility	Default Behavior	Overwritable Parameters
		LOG_ALWAYS, Critical, Error). The measurementTarget is defined as Source_EventId of the EventLog using default Windows locale. A cap of no more than 10 different measurementTargets is applied in each collection.	
az_storage_blob	Eligible if EnvironmentAttribute "OutboundConnectivityDisabled" isn't set or set to "false"	Not executed. If explicitly enabled by the user, this collector verifies if the VM can have access to the selected Azure Storage Blob by using either Managed Identity or SAS token.	• AZ_STORAGE_BLOB_INTERVAL: the exec Collector. Default: 180s • AZ_STORAGE_ACCOUNT_NAME: the Az name. No default value • AZ_STORAGE_CONTAINER_NAME: the A Container name. No default value • AZ_STORAGE_BLOB_NAME: the Azure S No default value • AZ_STORAGE_BLOB_DOMAIN_NAME: th domain name. No default value • AZ_STORAGE_SAS_TOKEN_BASE64: the Azure Storage SAS token. No default va • AZ_STORAGE_USE_MANAGED_IDENTIT identity will be used for authentication. • AZ_STORAGE_MANAGED_IDENTITY_CLI identity client ID for authentication. No
hardware_health_monitor	Eligible in Windows machine	Not executed. If explicitly enabled by the user, this collector collects hardware health info from Windows event log, currently only disk related critical events are collected, including events with ID 7, 500, 504, 505, 512 and 549.	• HARDWARE_HEALTH_MONITOR_INTER interval of the Collector. Default: 180s
hardware_health_nvidia_smi	Eligible in Linux Ubuntu machine	Not executed. If explicitly enabled by the user, this collector collects hardware health info from Windows event log, currently only disk related critical events are collected, including events with ID 7, 500, 504, 505, 512 and 549.	• HARDWARE_HEALTH_NVIDIA_SMI_INTE interval of the Collector. Default: 60s • HARDWARE_HEALTH_NVIDIA_SMI_INTE running /usr/bin/nvidia-smi command.

Configure VM watch

Article • 02/28/2025

VM watch signals are logically grouped into Collectors Suite, which can be categorized into two groups: core and optional. By default, only core group collectors are enabled with default configurations. However, these default settings can be easily overwritten from `vmWatchSettings` using either ARM template, Azure CLI, or PowerShell.

This article describes how to configure VM watch to suit your specific requirements.

Prerequisites

This article assumes that you're familiar with:

- VM watch checks, metrics, and logs
- Installing VM watch to virtual machines and scale sets
- VM watch Collectors Suite

Access `vmWatchSettings` on Azure virtual machines

> **ⓘ Important**
>
> The code segment is identical for both Windows and Linux except for the value of the parameter `<application health extension type>` passed into the Extension Type. Replace `<application health extension type>` with `ApplicationHealthLinux` for Linux and `ApplicationHealthWindows` for Windows installations.

ARM Template

1. Navigate to the Overview page on Azure portal and click on the JSON view for the VM to find the code segment below.
2. Copy the code segment to an IDE such as Visual Studio Code and make customizations as needed

```
{
   "settings": {
      "vmWatchSettings": {
         "enabled": true
      }
```

```
    }
}
```

Customize VM watch configurations

VM watch signals can be customized by configuring the `vmWatchSettings` properties to meet specific requirements. The following table lists the properties for `vmWatchSettings`.

vmWatchSettings Properties

Expand table

Name	Type	Description	Is Required
enabled	`bool`	This allows you to enable or disable VM watch	true
signalFilters	`object`	This filters the enabled / disabled signals, either by tag or collector name.	false
parameterOverrides	`object`	This specifies the parameters that can be overwritten for each signal execution. The full list of overwritable parameters can be found in the VM watch Collectors Suite page.	false
environmentAttributes	`object`	This specifies any environment attributes that help decide if a test is eligible to execute or not.	false

> **Important**
>
> For the full list of collectors, associated signals, tags, overwritable parameters, and environment attributes, visit VM watch Collectors Suite page

Switch on/off VM watch

VM watch can be switched on / off by configuring the `enabled` property, as shown in the code segment.

```
{
   "vmWatchSettings": {
      "enabled": true
```

```
    }
}
```

> **Note**

Expand table

Name	Description
true	This setting enables VM watch
false	This setting disables VM watch

Enable/Disable signal execution

By default, only the core group signals are enabled. However, the `signalFilters` property can be used to control and configure the signals to be executed. This property includes the following subfields.

Expand table

Subfields	Description
enabledTags	This enables the signals in the optional group specified with tags provided by the user
disabledTags	This disables the signals in the core and optional groups specified with tags provided by the user
enabledOptionalSignals	This enables signals specified in optional group. Provide collector name(s) as parameter
disabledSignals	This disables the signals specified in the core and optional groups. Provide collector name(s) as parameter

For instance, to enable signals in the optional group containing `Network` tag and disable signals containing `Disk` tag, specify such tags under the `enabledTags` and `disabledTags` as shown:

```
{
   "vmWatchSettings": {
      "enabled": true,
      "signalFilters": {
```

```
         "enabledTags": [
            "Network"
         ],
         "disabledTags": [
            "Disk"
         ]
      }
   }
}
```

Similarly, to enable an optional group signal with name `hardware_health_monitor`, and disable signals with name `process` and `dns`, specify such names under the `enabledOptionalSignals` and `disabledSignals` as shown:

```
{
   "vmWatchSettings": {
      "enabled": true,
      "signalFilters": {
         "enabledOptionalSignals": [
            "hardware_health_monitor"
         ],
         "disabledSignals": [
            "process",
            "dns"
         ]
      }
   }
}
```

Configure signal execution frequency

The signal execution frequency can be customized by adjusting the `parameterOverrides` property. For instance, to set the `outbound_connectivity` test execution frequency to 120 seconds, specify the following configuration:

```
{
   "vmWatchSettings": {
      "enabled": true,
      "parameterOverrides": {
         "OUTBOUND_CONNECTIVITY_INTERVAL": "120s"
      }
   }
}
```

Override default signal execution parameters

Signal execution parameters can be overwritten by setting the `parameterOverrides` property. For instance, to set `disk_io` signal mount point to `/mnt`, the following configuration can be specified:

```
{
   "vmWatchSettings": {
      "enabled": true,
      "parameterOverrides": {
         "DISK_IO_MOUNT_POINTS": "/mnt"
      }
   }
}
```

Environment attribute enrichments

In addition to tags, VM watch also checks the eligibility of the signals before execution. The `environmentAttributes` can be specified to help VM watch determine the eligibility of each signal for execution. For instance, if outbound traffic has been disabled on a VM, this information can be provided to VM watch. This ensures that any outbound network-related signal execution will be marked as ineligible.

```
{
   "vmWatchSettings": {
      "enabled": true,
      "environmentAttributes": {
         "OutboundConnectivityDisabled": true
      }
   }
}
```

Configure Event Hubs for VM watch

Article • 03/03/2025

VM watch can send signal data to a preconfigured Event Hub.

This article provides instructions on configuring Event Hubs to access signals collected by VM watch

Prerequisites

This article assumes that you're familiar with:

- Azure Event Hubs
- VM watch checks, metrics, and logs
- Install VM watch to virtual machines and scale sets

Enable Event Hubs Output

1: Prepare Event Hubs for VM watch

- Deploy an Event Hub
- Authorize access to the Azure Event Hub

> **ⓘ Important**
>
> VM watch supports managed identity, SAS token, and connection string as authentication methods. When multiple authentication methods are provided, managed identity is prioritized as the highest, while the connection string is assigned the lowest priority.

2: Enable Event Hubs output for VM watch

For each Event Hub authentication method, you need to combine both the common and authentication specific parameter settings. Instructions are given for each authentication scenario. For virtual machines and virtual machine scale sets, specify the following settings within `vmWatchSettings` in the JSON configurations. See Configure VM watch for instructions on how to access `vmWatchSettings` using ARM template, Azure CLI, or PowerShell.

Common parameters for Event Hubs output

For all authentication methods, the following parameter set applies:

Expand table

Parameter	Is required	Description
`EVENT_HUB_OUTPUT_NAMESPACE`	Yes	Event hub name space name, without the domain name `".servicebus.windows.net"`
`EVENT_HUB_OUTPUT_NAME`	Yes	Event hub name within the given namespace
`EVENT_HUB_OUTPUT_DOMAIN_NAME`	No	Event hub domain name. Default value `"servicebus.windows.net"`
`EVENT_HUB_OUTPUT_CLOSE_TIMEOUT`	No	Client close time-out. Default is 30s
`EVENT_HUB_OUTPUT_PARTITION_ID`	No	Metric tag or field name to use for the event partition key. Default is null
`EVENT_HUB_OUTPUT_MAX_MESSAGE_SIZE`	No	The maximum batch message size in bytes. Setting this parameter to 0 means using the default size from the Azure Event Hubs Client library (1,000,000 bytes). Default is 0
`SEND_INTERNAL_TELEMETRY_TO_EVENT_HUB`	No	To receive VM watch internal metrics (startup and heartbeat events), set this value to "true." Default is "false"

Authentication specific parameters for Event Hubs output

Managed Identity

Expand table

Parameter	Is required	Description
`EVENT_HUB_OUTPUT_USE_MANAGED_IDENTITY`	No	Set this value to "true." Default is "false"
`EVENT_HUB_OUTPUT_MANAGED_IDENTITY_CLIENT_ID`	No	If you're using a specific managed identity to authenticate, specify this value

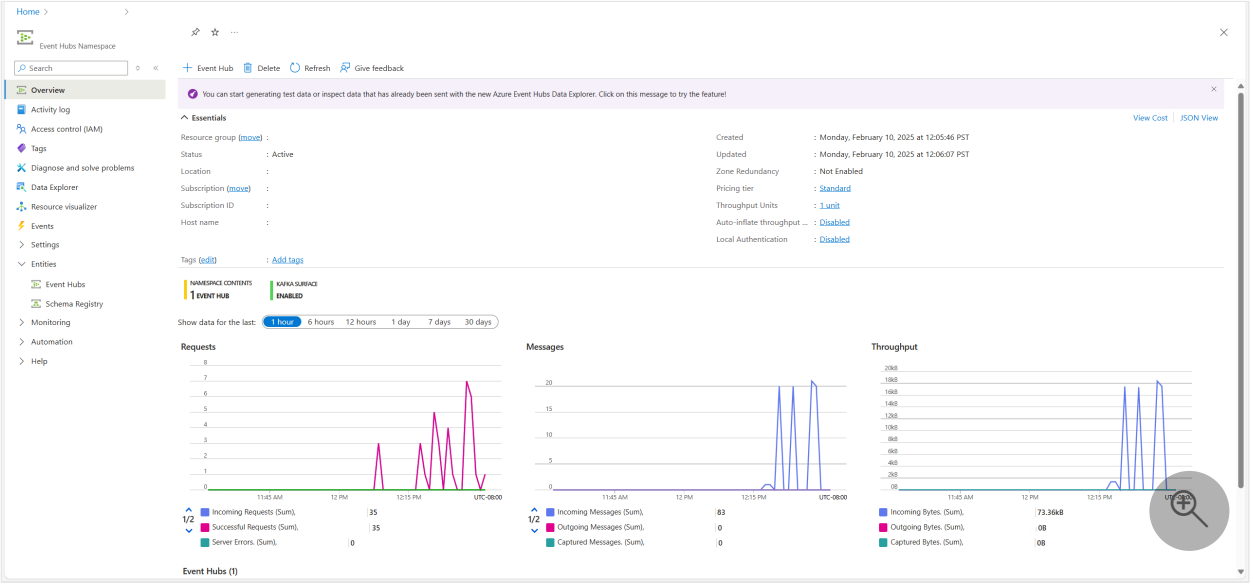
For example, the following VM watch JSON configuration sets the environment variables `EVENT_HUB_OUTPUT_NAMESPACE`, `EVENT_HUB_OUTPUT_NAME`, and `EVENT_HUB_OUTPUT_USE_MANAGED_IDENTITY`. This allows Event Hubs to use managed identity as the authentication method without needing to specify a managed identity client ID.

```
{
  "vmWatchSettings": {
    "enabled": true,
    "parameterOverrides": {
      "EVENT_HUB_OUTPUT_NAMESPACE": "<example event hub namespace>",
      "EVENT_HUB_OUTPUT_NAME": "<example event hub name>",
      "EVENT_HUB_OUTPUT_USE_MANAGED_IDENTITY": "true"
    }
  }
}
```

3: Examine events in Event Hubs

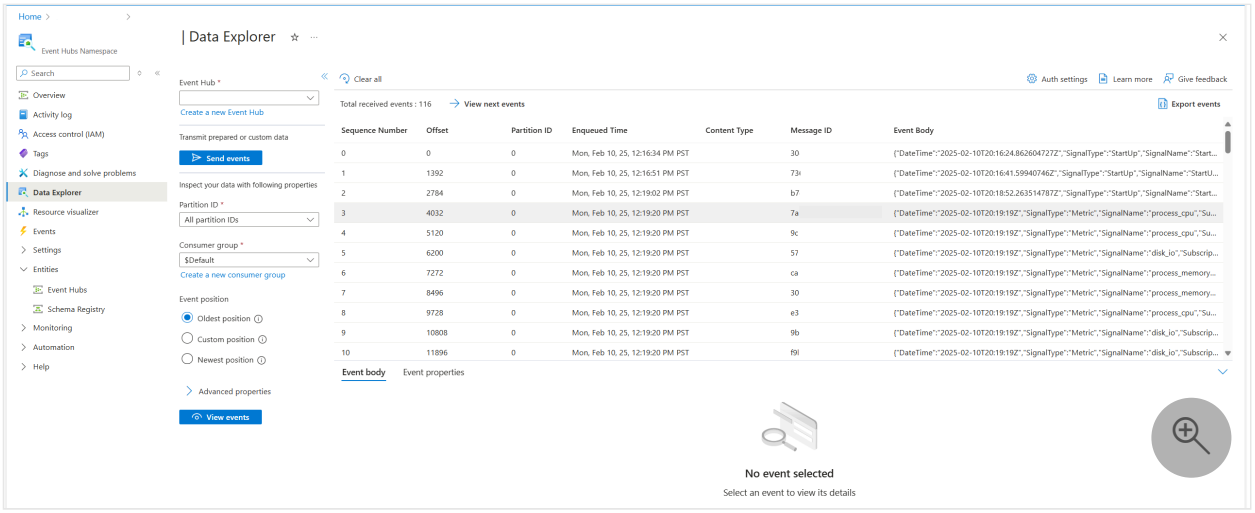
Once VM watch settings are successfully configured to use Event Hubs as the output, VM watch restarts. Events start flowing into Event Hubs within a few minutes. You can use the Azure portal to observe the incoming messages.

The following screenshot shows data flowing into the Event Hub



Also, you can use the Event Hubs Data Explorer feature to view incoming event and content.

The following screenshot shows Event Hubs Data Explorer



Event Hubs Events schema

Each Event Hub event has the following schema:

Expand table

Field Name	Data Type	Description
`DateTime`	time	The time the signal was emitted
`SignalType`	string	The type of the signal, which can be either "StartUp," "Heartbeat," "Check," "Metric," or "EventLog"
`SignalName`	string	The name of the signal
`SubscriptionId`	string	The VM subscription ID
`ResourceGroup`	string	The VM resource group name
`ResourceId`	string	The Azure resource URI of the VM
`VmId`	string	The unique ID of the VM queried from IMDS endpoint within the VM
`Vmss`	string	The virtual machine scale set name, if applicable
`Offer`	string	The Azure VM offer
`VmSize`	string	The VM size
`MeasurementTarget`	string	The target that the signal is measuring at. `Name` field and `MeasurementTarget` are used together for raw signal aggregation
`SignalValue`	json	The value of this signal, where the schema depends on the SignalType

Field Name	Data Type	Description
`Version`	string	The version of the Event Hub output event schema

Debug Event Hubs connection issues

If there are no events in Event Hubs after several minutes, check the VM watch logs in the following directories on the virtual machine or virtual machine scale set to diagnose the issue:

Linux

```
/var/log/azure/Microsoft.ManagedServices.ApplicationHealthLinux/vmwatch.log
```

Project Flash - Advancing Azure Virtual Machine availability monitoring

Article • 08/22/2024

Flash, as the project is internally known, derives its name from our steadfast commitment to building a robust, reliable, and rapid mechanism for customers to monitor virtual machine (VM) health. Our primary objective is to ensure customers can reliably access actionable and precise telemetry, promptly receive alerts on changes, and periodically monitor data at scale. We also place strong emphasis on developing a centralized and coherent experience that customers can conveniently use to meet their unique observability requirements. It's our mission to ensure you can:

- **Consume accurate and actionable data** on VM availability disruptions (for example, VM reboots and restarts, application freezes due to network driver updates, and 30-second host OS updates), along with precise failure details (for example, platform versus user-initiated, reboot versus freeze, planned versus unplanned).
- **Analyze and alert on trends in VM availability** for quick debugging and month-over-month reporting.
- **Periodically monitor data at scale** and build custom dashboards to stay updated on the latest availability states of all resources.
- **Receive automated root cause analyses (RCAs)** detailing impacted VMs, downtime cause and duration, consequent fixes, and similar—all to enable targeted investigations and post-mortem analyses.
- **Receive instantaneous notifications** on critical changes in VM availability to quickly trigger remediation actions and prevent end-user impact.
- **Dynamically tailor and automate platform recovery policies** , based on ever-changing workload sensitivities and failover needs.

Flash solutions

The Flash initiative is dedicated to developing solutions over the years that cater to the diverse monitoring needs of our customers. To help you determine the most suitable Flash monitoring solution(s) for your specific requirements, refer to the following table:

Expand table

Solution	Description
Azure Resource Graph (General Availability)	For investigations at scale, centralized resource repository and history lookup, large customers want to periodically consume resource availability telemetry across all their workloads, at once, using Azure Resource Graph (ARG).
Event Grid system topic (Public Preview)	To trigger time-sensitive and critical mitigations (redeploy, restart VM actions) for prevention of end-user impact, customers (for example, Pearl Abyss, Krafton) want to receive alerts within seconds of critical changes in resource availability via Event Handlers in Event Grid.
Azure Monitor (Public Preview)	To track trends, aggregate platform metrics (CPU, disk etc.), and set up precise threshold-based alerts, customers want to consume an out-of-box VM Availability metric via Azure Monitor.
Resource Health (General Availability)	To perform instantaneous and convenient Portal UI health checks per-resource customers can quickly view the RHC blade on the portal. They can also access a 30-day historical view of health checks for that resource for quick and easy troubleshooting.

Holistic VM availability monitoring

For a holistic approach to monitoring VM availability, including scenarios of routine maintenance, live migration, service healing, and VM degradation, we recommend you utilize both scheduled events (SE) and Flash health events.

Scheduled events are designed to offer an early warning, giving up to 15-minute advance notice prior to maintenance activities. This lead time enables you to make informed decisions regarding upcoming downtime, allowing you to either avoid or prepare for it. You have the flexibility to either acknowledge these events or delay actions during this 15-minute period, depending on your readiness for the upcoming maintenance.

On the other hand, Flash Health events are focused on real-time tracking of ongoing and completed availability disruptions, including VM degradation. This feature empowers you to effectively monitor and manage downtime, supporting automated mitigation, investigations, and post-mortem analysis.

To get started on your observability journey, you can explore the suite of Azure products to which we emit high-quality VM availability data. These products include resource health, activity logs, Azure resource graph, Azure monitor metrics and Azure Event Grid system topic.

Next steps

To learn more about the solutions offered, proceed to corresponding solution article:

- Use Azure Resource Graph to monitor Azure Virtual Machine availability
- Use Event Grid system topics to monitor Azure Virtual Machine availability
- Use Azure Monitor to monitor Azure Virtual Machine availability
- Use Azure Resource Health to monitor Azure Virtual Machine availability

For a general overview of how to monitor Azure Virtual Machines, see Monitor Azure virtual machines and the Monitoring Azure virtual machines reference.

Project Flash - Use Azure Resource Graph to monitor Azure Virtual Machine availability

Article • 08/22/2024

Azure Resource Graph is one solution offered by Flash. Flash is the internal name for a project dedicated to building a robust, reliable, and rapid mechanism for customers to monitor virtual machine (VM) health.

This article covers the use of Azure Resource Graph to monitor Azure Virtual Machine availability. For a general overview of Flash solutions, see the Flash overview.

For documentation specific to the other solutions offered by Flash, choose from the following articles:

- Use Event Grid system topics to monitor Azure Virtual Machine availability
- Use Azure Monitor to monitor Azure Virtual Machine availability
- Use Azure Resource Health to monitor Azure Virtual Machine availability

Azure Resource Graph - HealthResources

This feature is currently generally available. It's useful for conducting large-scale investigations. It offers a highly user-friendly experience for information retrieval with its use of kusto query language (KQL). It can also serve as a central hub for resource information and allows easy retrieval of historical data.

In addition to already flowing VM availability states, we published VM availability annotations to Azure Resource Graph (ARG) for detailed failure attribution and downtime analysis, along with enabling a 14-day change tracking mechanism to trace historical changes in VM availability for quick debugging. With these new additions, we're excited to announce the general availability of VM availability information in the HealthResources dataset in ARG! With this offering users can:

- Efficiently query the latest snapshot of VM availability across all Azure subscriptions at once and at low latencies for periodic and fleetwide monitoring.
- Accurately assess the impact to fleetwide business SLAs and quickly trigger decisive mitigation actions, in response to disruptions and type of failure signature.
- Set up custom dashboards to supervise the comprehensive health of applications by joining VM availability information with resource metadata present in ARG.

- Track relevant changes in VM availability across a rolling 14-day window, by using the change-tracking mechanism for conducting detailed investigations.

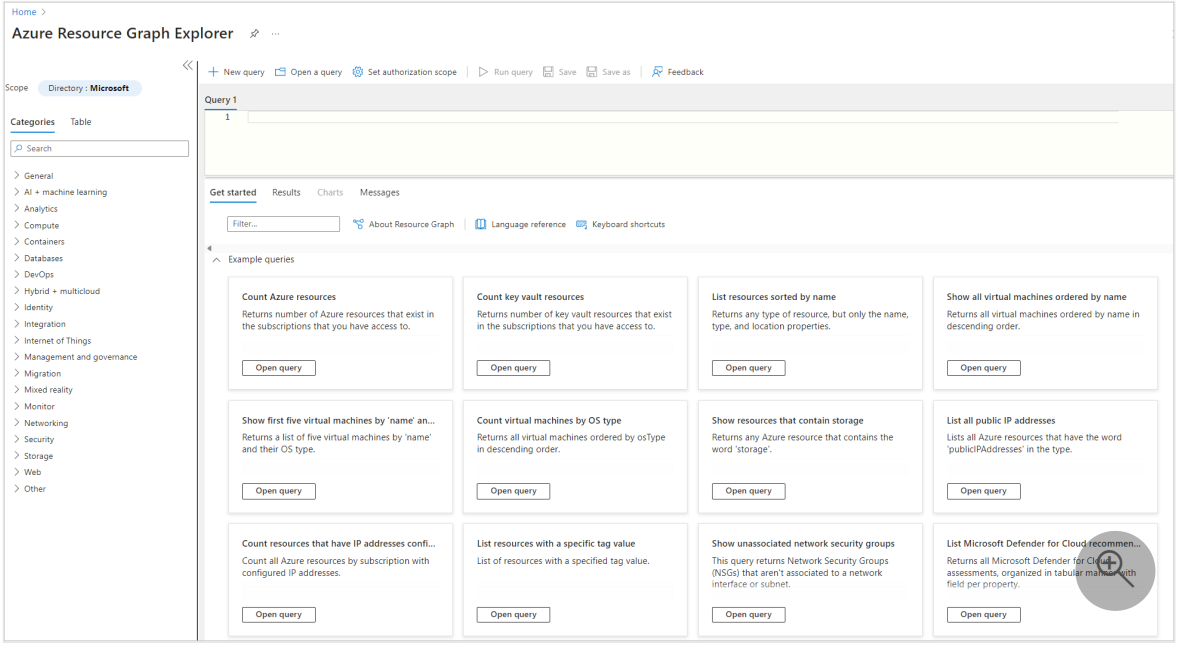
Sample queries

- Azure Resource Graph sample queries for Azure Service Health - Azure Service Health | Microsoft Learn
- VM availability information in Azure Resource Graph - Azure Virtual Machines | Microsoft Learn
- List of sample Azure Resource Graph queries by table - Azure Resource Graph | Microsoft Learn

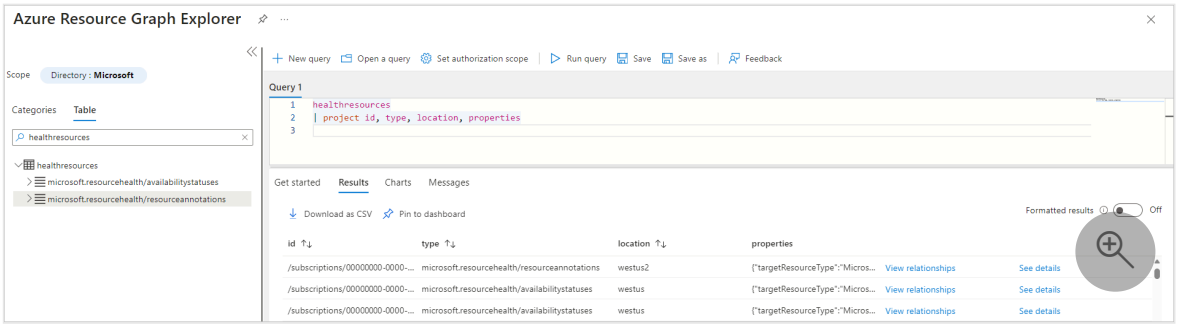
Get started

Users can query ARG via PowerShell, REST API, Azure CLI, or even the Azure portal. The following steps detail how data can be accessed from Azure portal.

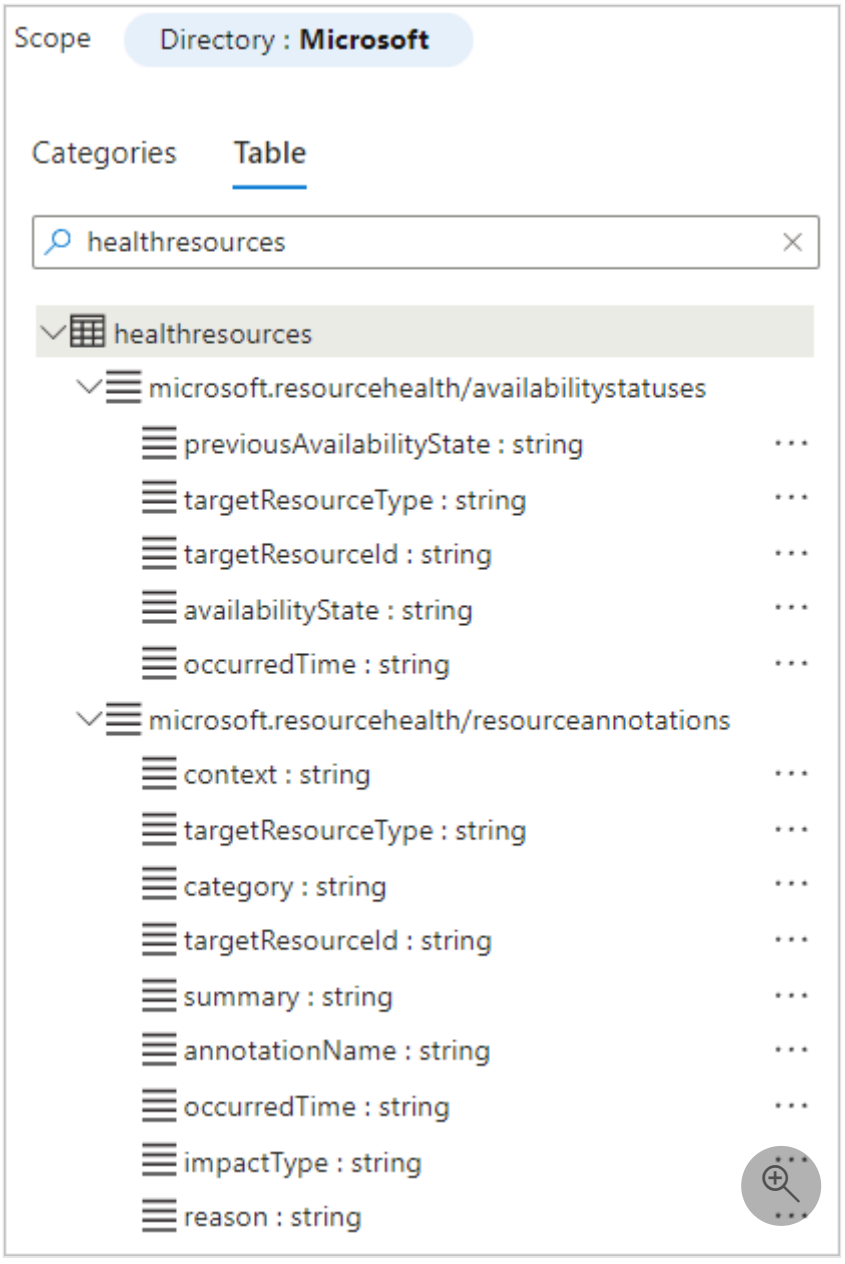
1. Once on the Azure portal, navigate to Resource Graph Explorer.



2. Select the Table tab and (single) click on the HealthResources table to retrieve the latest snapshot of VM availability information (availability state and health annotations).



There are two types of events populated in the HealthResources table:



- resourcehealth/availabilitystatuses

This event denotes the latest availability status of a VM, based on the health checks performed by the underlying Azure platform. The availability states we currently emit for VMs are:

- Available: The VM is up and running as expected.

- Unavailable: We detected disruptions to the normal functioning of the VM, and therefore, applications won't run as expected.
- Unknown: The platform is unable to accurately detect the health of the VM. Users can usually check back in a few minutes for an updated state.

To poll the latest VM availability state, refer to the properties field, which contains the following details:

Sample

```
{
 "targetResourceType": "Microsoft.Compute/virtualMachines",
 "previousAvailabilityState": "Available",
 "targetResourceId":
"/subscriptions//resourceGroups//providers/Microsoft.Compute/virtualMachines
/",
 "occurredTime": "2022-10-11T11:13:59.9570000Z",
 "availabilityState": "Unavailable"
 }
```

Property description

Expand table

Property	Description	Corresponding resource health category (RHC)
targetResourceType	Type of resource for which health data is flowing	resourceType
targetResourceId	Resource ID	resourceId
occurredTime	Timestamp when the platform emits the latest availability state	eventTimestamp
previousAvailabilityState	Previous availability state of the VM	previousHealthStatus
availabilityState	Current availability state of the VM	currentHealthStatus

See the HealthResources section of the samples queries documentation for a list of starter queries to further explore this data.

- resourcehealth/resourceannotations (NEWLY ADDED)

This event contextualizes any changes to VM availability, by detailing necessary failure attributes to help users investigate and mitigate the disruption as needed. See the full list of VM availability annotations emitted by the platform. These annotations can be broadly classified into three buckets:

- Downtime Annotations: These annotations are emitted when the platform detects VM availability transitioning to Unavailable. (For example, during unexpected host crashes, rebootful repair operations).
- Informational Annotations: These annotations are emitted during control plane activities with no impact to VM availability. (Such as VM allocation/Stop/Delete/Start). Usually, no further customer action is required in response.
- Degraded Annotations: These annotations are emitted when VM availability is detected to be at risk. (For example, when failure prediction models predict a degraded hardware component that can cause the VM to reboot at any given time). We strongly urge users to redeploy by the deadline specified in the annotation message, to avoid any unanticipated loss of data or downtime. You may receive an alert in Azure virtual machine scale sets Resource Health or Activity log in one of the following scenarios:
  - VMs in the Azure virtual machine scale sets are in the process of being stopped, deallocated, deleted, or started.
  - You performed scaling in or out operations on the virtual machine scale sets.
  - The alert indicates that the aggregated platform health of the virtual machine scale sets is in a transient state of "Degraded."

To poll the associated VM availability annotations for a resource, if any, refer to the properties field, which contains the following details:

Sample

```
{
 "targetResourceType": "Microsoft.Compute/virtualMachines",
"targetResourceId":
"/subscriptions//resourceGroups//providers/Microsoft.Compute/virtualMachines
/",
 "annotationName": "VirtualMachineHostRebootedForRepair",
 "occurredTime": "2022-09-25T20:21:37.5280000Z",
 "category": "Unplanned",
 "summary": "We're sorry, your virtual machine isn't available because an
unexpected failure on the host server. Azure has begun the auto-recovery
process and is currently rebooting the host server. No further action is
required from you at this time. The virtual machine will be back online
after the reboot completes.",
```

```
  "context": "Platform Initiated",
  "reason": "Unexpected host failure"
  }
```

Property description

Expand table

Property	Description	Corresponding RHC
targetResourceType	Type of resource for which health data is flowing	resourceType
targetResourceId	Resource ID	resourceId
occurredTime	Timestamp when the latest availability state is emitted by the platform	eventTimestamp
annotationName	Name of the Annotation emitted	eventName
reason	Brief overview of the availability impact observed by the customer	title
category	Denotes whether the platform activity that triggered the annotation was either planned maintenance or unplanned repair. This field isn't applicable to customer/VM-initiated events. Possible values: Planned, Unplanned, Not Applicable, Null	category
context	Denotes whether the activity that triggered the annotation was due to an authorized user or process (customer-initiated), the Azure platform (platform-initiated), or activity in the guest OS that resulted in availability impact (VM initiated). Possible values: Platform-initiated, User-initiated, VM-initiated, Not Applicable, Null	context
summary	Statement detailing the cause for annotation emission, along with remediation steps that users can take	summary

See the HealthResources section of the samples queries documentation for a list of starter queries to further explore this data.

We have multiple enhancements planned for the annotation metadata that is surfaced in the HealthResources dataset. These enrichments give users access to richer failure attributes to decisively prepare a response to a disruption. In parallel, we aim to extend the duration of historical lookback to a minimum of 30 days so users can comprehensively track past changes in VM availability.

Next steps

To learn more about the solutions offered, proceed to corresponding solution article:

- Use Event Grid system topics to monitor Azure Virtual Machine availability
- Use Azure Monitor to monitor Azure Virtual Machine availability

Project Flash - Use Azure Event Grid to monitor Azure Virtual Machine availability

Article • 08/22/2024

Azure Event Grid is one solution offered by Flash. Flash is the internal name for a project dedicated to building a robust, reliable, and rapid mechanism for customers to monitor virtual machine (VM) health.

This article covers the use of Azure Event Grid system topics to monitor Azure Virtual Machine availability. For a general overview of Flash solutions, see the Flash overview.

For documentation specific to the other solutions offered by Flash, choose from the following articles:

- Use Azure Monitor to monitor Azure Virtual Machine availability
- Use Azure Resource Health to monitor Azure Virtual Machine availability
- Use Azure Resource Graph to monitor Azure Virtual Machine availability

Azure Event Grid system topic - HealthResources

To ensure seamless operation of business-critical applications, it's crucial to have real time awareness of any event that might adversely impact VM availability. This awareness enables you to swiftly take remedial actions to shield end-users from any disruption. To support you in your daily operations, we're delighted to announce the public preview of the HealthResources Event Grid system topic with newly added VM availability annotations!

This system topic provides in-depth VM health data, giving you immediate insights into changes in VM availability states along with the necessary context. You can receive events on single-instance VMs and Virtual Machine Scale Set VMs for the Azure subscription for which this topic was created. Data is published to this topic by Azure Resource Notifications (ARN), our state-of-the-art publisher-subscriber service, equipped with robust Role-Based Access Control (RBAC) and advanced filtering capabilities. This empowers you to effortlessly subscribe to an Event Grid system topic and seamlessly direct relevant events utilizing the advanced filtering capabilities provided by Event Grid, to downstream tools in real-time. This enables you to respond and mitigate issues instantly.

Get started

- Step 1: Users start by creating a systemtopic within the Azure subscription for which they want to receive notifications.
- Step 2: Users then proceed to create an event subscription within the system topic in Step 1. During this step, they specify the endpoint (such as Event Hubs or Azure Monitor Alerts) to which the events are routed. Users can also configure event filters to narrow down the scope of delivered events.

As you start subscribing to events from the HealthResources system topic, consider the following best practices:

- Choose an appropriate destination or event handler based on the anticipated scale and size of events.
- For fan-in scenarios where notifications from multiple system topics need to be consolidated, event hubs are highly recommended as a destination. This practice is especially useful for real-time processing scenarios to maintain data freshness and for periodic processing for analytics, with configurable retention periods.
- NEW: Customers can now subscribe to Health Resources events and send them to Azure Monitor alerts as new destination. For step-by-step guide, see Subscribe to Health Resources events and send them to Azure monitor alerts.

We have plans to transition the preview into a fully fledged general availability feature. As part of the preview, we emit events scoped to changes in VM availability states with the following sample schema:

Sample

```
{
 "id": "4c70abbc-4aeb-4cac-b0eb-ccf06c7cd102",
 "topic": "/subscriptions/,
 "subject":
"/subscriptions//resourceGroups//providers/Microsoft.Compute/virtualMachines
//providers/Microsoft.ResourceHealth/AvailabilityStatuses/current",
 "data": {
 "resourceInfo": {

"id":"/subscriptions//resourceGroups//providers/Microsoft.Compute/virtualMac
hines//providers/Microsoft.ResourceHealth/AvailabilityStatuses/current",
 "properties": {

"targetResourceId":"/subscriptions//resourceGroups//providers/Microsoft.Comp
ute/virtualMachines/"
 "targetResourceType": "Microsoft.Compute/virtualMachines",
```

```
 "occurredTime": "2022-09-25T20:21:37.5280000Z"
 "previousAvailabilityState": "Available",
 "availabilityState": "Unavailable"
 }
 },
 "apiVersion": "2020-09-01"
 },
 "eventType":
"Microsoft.ResourceNotifications.HealthResources.AvailabilityStatusesChanged
",
 "dataVersion": "1",
 "metadataVersion": "1",
 "eventTime": "2022-09-25T20:21:37.5280000Z"
 }
```

The properties field is fully consistent with the `microsoft.resourcehealth/availabilitystatuses` event in ARG. The Event Grid solution offers near-real-time alerting capabilities on the data present in ARG.

Next steps

To learn more about the solutions offered, proceed to corresponding solution article:

- Use Azure Monitor to monitor Azure Virtual Machine availability
- Use Azure Resource Health to monitor Azure Virtual Machine availability
- Use Azure Resource Graph to monitor Azure Virtual Machine availability

For a general overview of how to monitor Azure Virtual Machines, see Monitor Azure virtual machines and the Monitoring Azure virtual machines reference.

Project Flash - Use Azure Monitor to monitor Azure Virtual Machine availability

Article • 10/18/2024

Azure Monitor is one solution offered by Flash. Flash is the internal name for a project dedicated to building a robust, reliable, and rapid mechanism for customers to monitor virtual machine (VM) health.

This article covers the use of the Azure Monitor VM availability metric to monitor Azure Virtual Machine availability. For a general overview of Flash solutions, see the Flash overview.

For documentation specific to the other solutions offered by Flash, choose from the following articles:

- Use Azure Resource Health to monitor Azure Virtual Machine availability
- Use Azure Resource Graph to monitor Azure Virtual Machine availability
- Use Event Grid system topics to monitor Azure Virtual Machine availability

Azure monitor - VM availability metric

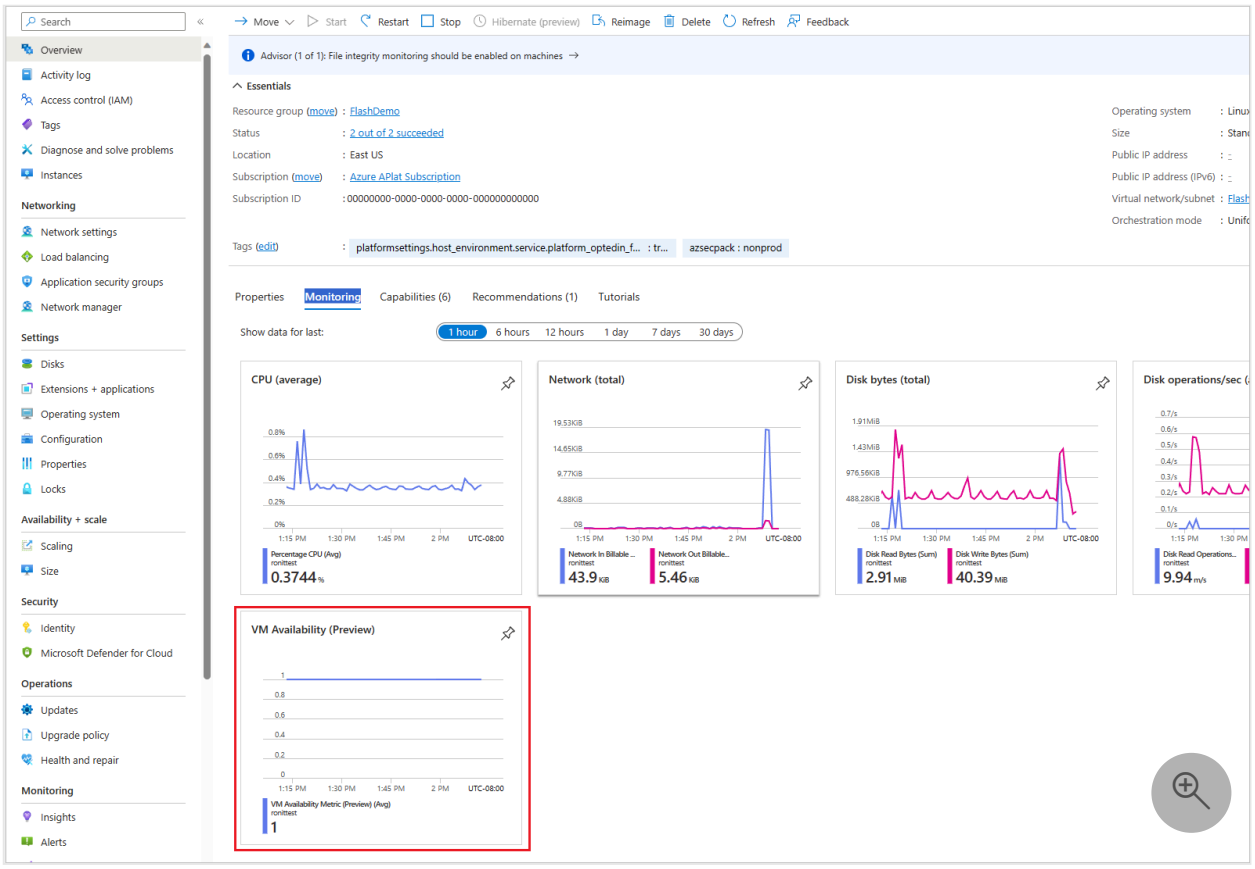
Currently in public preview. The VM availability metric is well-suited for tracking trends, aggregating platform metrics (such as CPU and disk usage), and configuring precise threshold-based alerts. Customers can utilize this out-of-the-box VM availability metric in Azure Monitor. This metric displays the trend of VM availability over time, so users can:

- Set up threshold-based metric alerts on dipping VM availability to quickly trigger appropriate mitigation actions.
- Correlate the VM availability metric with existing platform metrics like memory, network, or disk for deeper insights into concerning changes that impact the overall performance of workloads.
- Easily interact with and chart metric data during any relevant time window on Metrics Explorer, for quick and easy debugging.
- Route metrics to downstream tooling like Grafana dashboards, for constructing custom visualizations and dashboards.

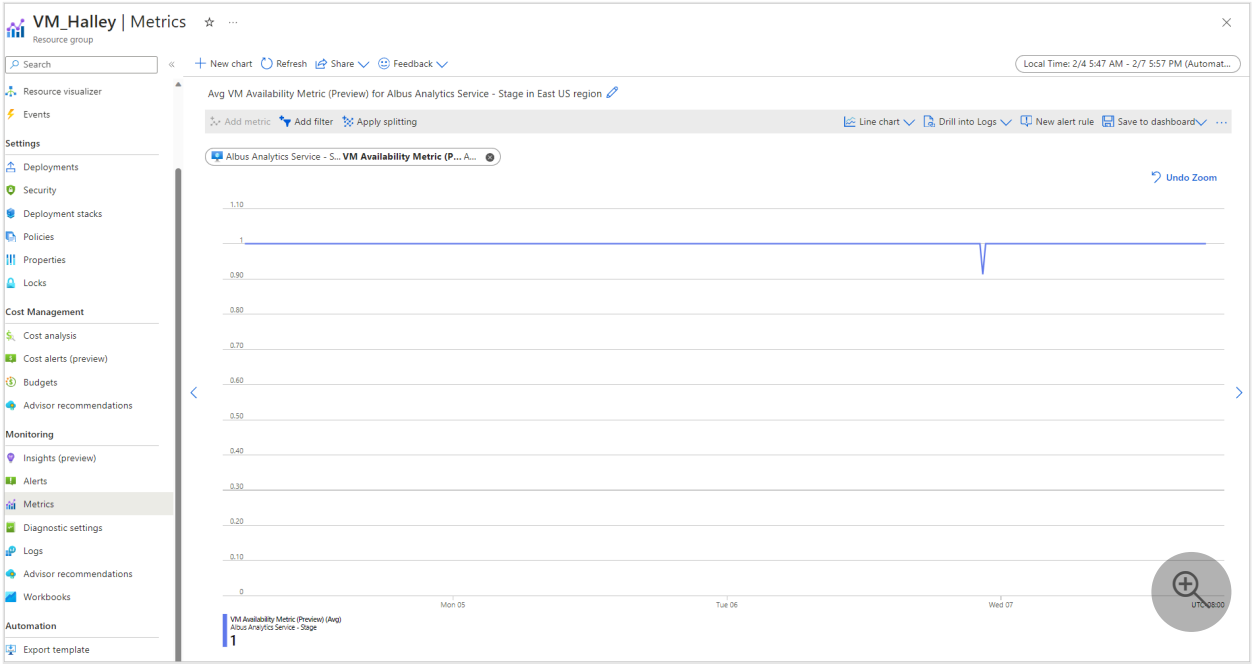
Get started

Users can either consume the metric programmatically via the Azure Monitor REST API or directly from the Azure portal. The following steps highlight metric consumption from the Azure portal.

Once on the Azure portal, navigate to the VM overview blade. The new metric is displayed as VM Availability (Preview), along with other platform metrics under the Monitoring tab.

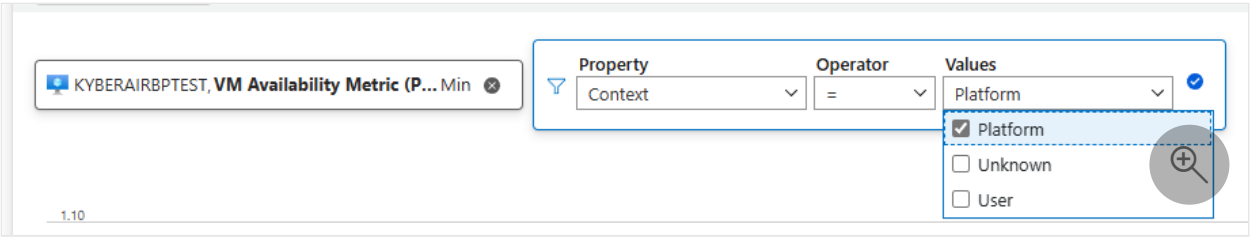


To navigate to the metrics explorer for further analysis, select the VM availability metric chart on the overview page.



For a description of the metric's display values, see VM availability metric.

Users can split the VM availability by the 'Context' property.



> **Note**
>
> The context for Service Healing and Live Migration is currently unknown by default.

Users can create an alert rule based on dimension values. Under the Condition tab, choose VM Availability Metric as the Signal name. In the Split by dimensions section, enter Context as the dimension name and select the corresponding dimension values.

Project Flash - Use Azure Resource Health to monitor Azure Virtual Machine availability

Article • 08/22/2024

Azure Resource Health is one solution offered by Flash. Flash is the internal name for a project dedicated to building a robust, reliable, and rapid mechanism for customers to monitor virtual machine (VM) health.

This article covers the use of Azure Resource Health to monitor Azure Virtual Machine availability. For a general overview of Flash solutions, see the Flash overview.

For documentation specific to the other solutions offered by Flash, choose from the following articles:

- Use Azure Resource Graph to monitor Azure Virtual Machine availability
- Use Event Grid system topics to monitor Azure Virtual Machine availability
- Use Azure Monitor to monitor Azure Virtual Machine availability

Azure Resource Health

It offers immediate and user-friendly health checks for individual resources through the portal. Customers can quickly access the resource health blade on the portal and also review a 30-day historical record of health checks, making it an excellent tool for fast and straightforward troubleshooting. The existing Azure Resource Health feature helps you to diagnose and get support for service problems that affect your Azure resources. It reports on the current and past health of your resources, showing any time ranges that each of your resources have been unavailable.

But we know that our customers and partners are interested in understanding what causes underlying technical issues, and in improving how they can receive communications about any issues—to feed into monitoring processes, to explain hiccups to other stakeholders, and ultimately to inform business decisions.

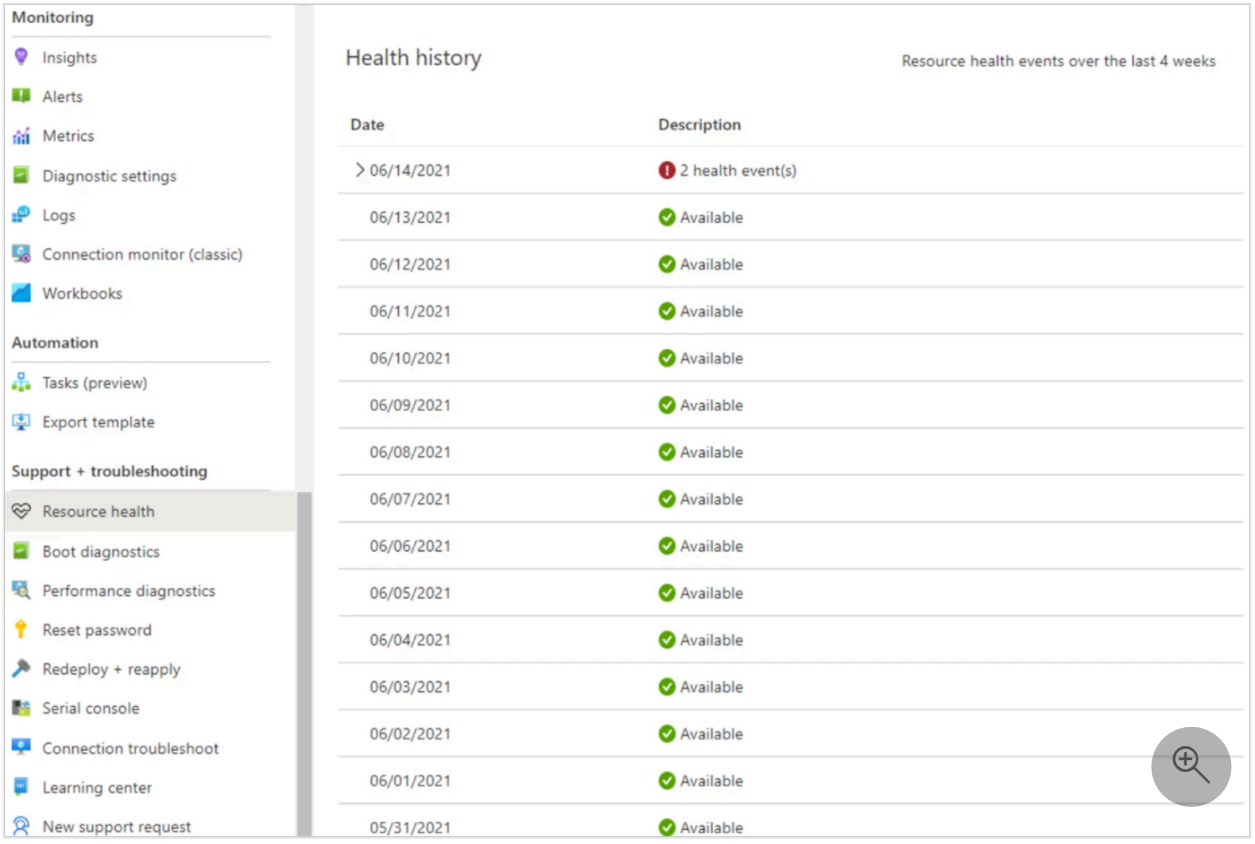
Root causes for VM issues in Azure Resource Health

We recently shipped an improvement to the resource health experience that will enhance the information we share with customers about VM failures and provide further context on the root cause that led to the issue. Now, in addition to getting a fast

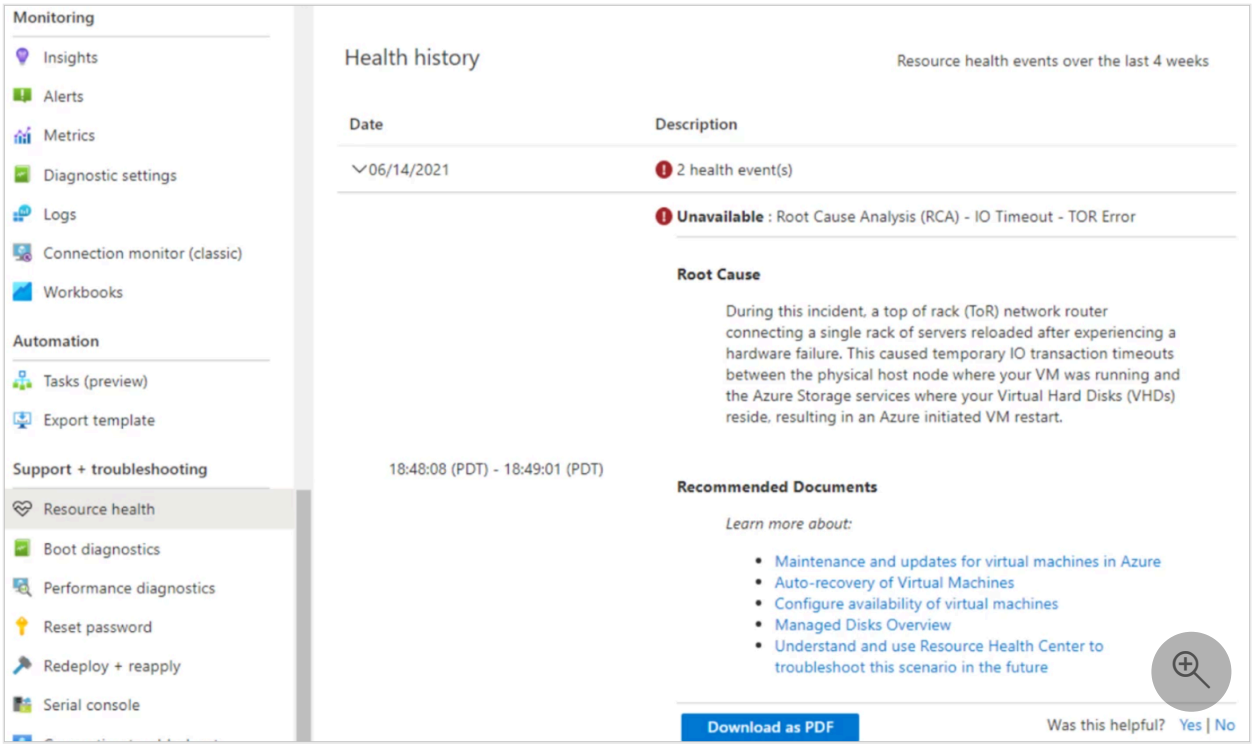
notification when a VM's availability is impacted, customers can expect a root cause to be added at a later point once our automated Root Cause Analysis (RCA) system identifies the failing Azure platform component that led to the VM failure. Let's walk through an example to see how this works process in practice:

At time T1, a server rack goes offline due to a networking issue, causing VMs on the rack to lose connectivity. Recent reliability improvements related to network architecture will be shared in a future Advancing Reliability blog post—watch this space!

At time T2, Azure's internal monitoring recognizes that it's unable to reach VMs on the rack and begins to mitigate by redeploying the impacted VMs to a new rack. During this time, an annotation is sent to resource health notifying customers that their VM is currently impacted and unavailable.



At time T3, platform telemetry from the top of rack switch, the host machine, and internal monitoring systems are correlated together in our RCA engine to derive the root cause of the failure. Once computed, the RCA is then published back into resource health along with relevant architectural resiliency recommendations that customers can implement to minimize the probability of impact in the future.



While the initial downtime notification functionality is several years old, the publishing of a root cause statement is a new addition. Now, let's dive into the details of how we derive these root causes.

Root Cause Analysis engine

Let's take a closer look at the prior example and walk through the details of how the RCA engine works and the technology behind it. At the core of our RCA engine for VMs is Azure Data Explorer (ADX), a big data service optimized for high volume log telemetry analytics. Azure Data Explorer enables the ability to easily parse terabytes of log telemetry from devices and services that comprise the Azure platform, join them together, and interpret the correlated information streams to derive a root cause for different failure scenarios. This ends up being a multistep data engineering process:

Phase 1: Detecting downtime

The first phase in root cause analysis is to define the trigger under which the analysis is executed. For Virtual Machines, we want to determine root causes whenever a VM unexpectedly reboots, so the trigger is a VM transitioning from an up state to a down state. Identifying these transitions from platform telemetry is straightforward in most scenarios, but more complicated around certain kinds of infrastructure failure where platform telemetry might get lost due to device failure or power loss. To handle these classes of failures, other techniques are required—like tracking data loss as a possible indication of a VM availability transition. Azure Data Explorer excels at this time of series analysis, and a more detailed look at techniques around this process can be found in the

Microsoft Tech Community: Calculating downtime using Window functions and Time Series functions in Azure Data Explorer.

Phase 2: Correlation analysis

Once a trigger event is defined (in this case, a VM transitioning to an unhealthy state) the next phase is correlation analysis. In this step, we use the presence of the trigger event to correlate telemetry from points across the Azure platform, like:

- Azure host: the physical blade hosting VMs.
- TOR: the top of rack network switch.
- Azure Storage: the service that hosts Virtual Disks for Azure Virtual Machines.

Each of these systems has their own telemetry feeds that need to get parsed and correlated with the VM downtime trigger event. This process is done through understanding the dependency graph for a VM and the underlying systems that can cause a VM to fail, and then joining all these dependent systems' health telemetry together, filtered on events that occurred close to the time of the VM transition. Azure Data Explorer's intuitive and powerful query language helps by offering documented patterns like time window join for correlating temporal telemetry streams together. At the end of this correlation process, we have a dataset that represents VM downtime transitions with correlated platform telemetry from all the dependent systems that could cause or could have information useful in determining what led to the VM failure.

Phase 3: Root cause attribution

The next step in the process is attribution. Now that we've collected all the relevant data together in a single dataset, attribution rules get applied to interpret the information and translate it into a customer-facing root cause statement. If you go back to our original example of a TOR failure, after our correlation analysis we might have many interesting pieces of information to interpret. For example, systems monitoring the Azure hosts might have logs indicating they lost connectivity to the hosts during this time. We might also have signals related to virtual disk connectivity problems, and explicit signals from the TOR device about the failure. All these pieces of information are now scanned over, and the explicit TOR failure signal is prioritized over the other signals as the root cause. This prioritization process, and the rules behind it, are constructed with domain experts and modified as the Azure platform evolves. Machine learning and anomaly detection mechanisms sit on top of these attributed root causes, to help identify opportunities to improve these classification rules and detect pattern changes in the rate of these failures to feed back into safe deployment pipelines.

Phase 4: RCA publishing

The last step is publishing root causes to Azure Resource Health, where they become visible to customers. Publishing is done by a simple Azure Functions application, which periodically queries the processed root cause data in Azure Data Explorer, and emits the results to the resource health backend. Because information streams can come in with various data delays, RCAs can occasionally be updated in this process to reflect better sources of information having arrived leading to a more specific root cause that what was originally published.

Going forward

Identifying and communicating the root cause of any issues to our customers and partners is just the beginning. Our customers may need to take these RCAs and share them with their customers and coworkers. We want to build on the work here to make it easier to identify and track resource RCAs, and easily share them out. To accomplish that, we're working on backend changes to generate unique per-resource and per-downtime tracking IDs that we can expose to you, so that you can easily match downtimes to their RCAs. We're also working on new features to make it easier to email RCAs out, and eventually subscribe to RCAs for your VMs. This feature will make it possible to sign up for RCAs directly in your inbox after an unavailability event with no further action needed on your part.

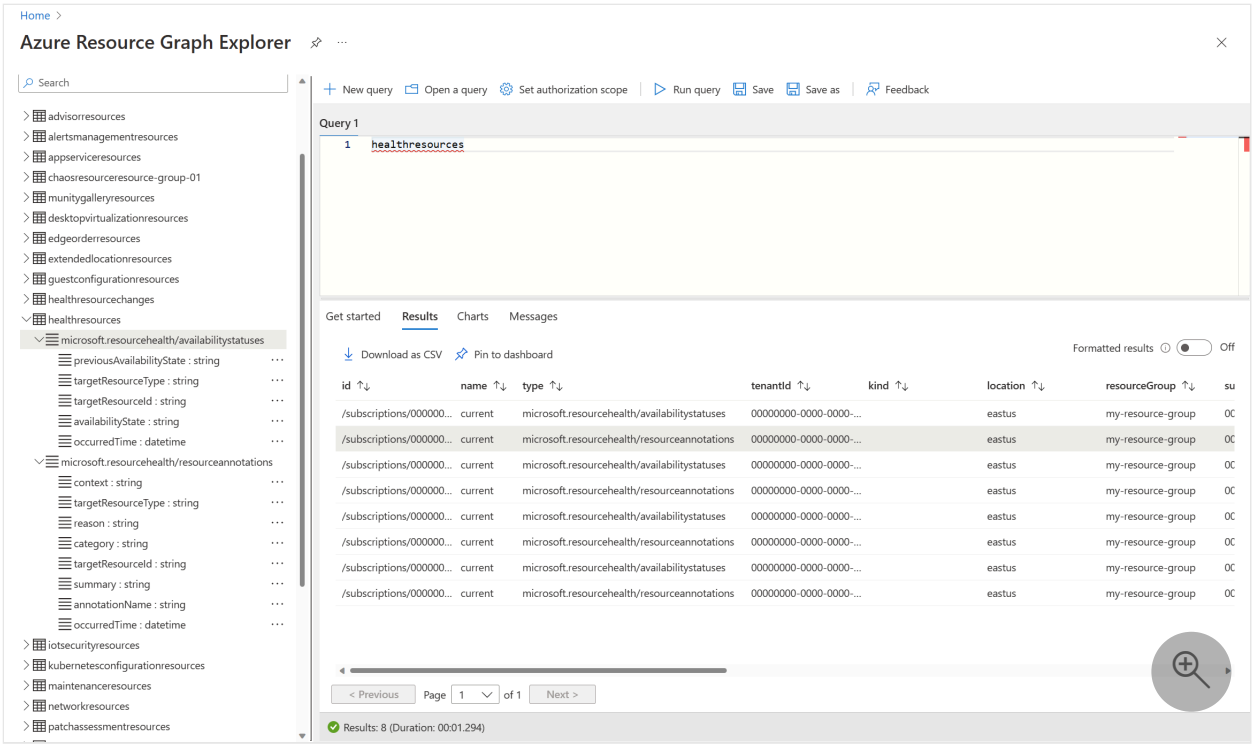
VM availability information in Azure Resource Graph

Article • 08/22/2024

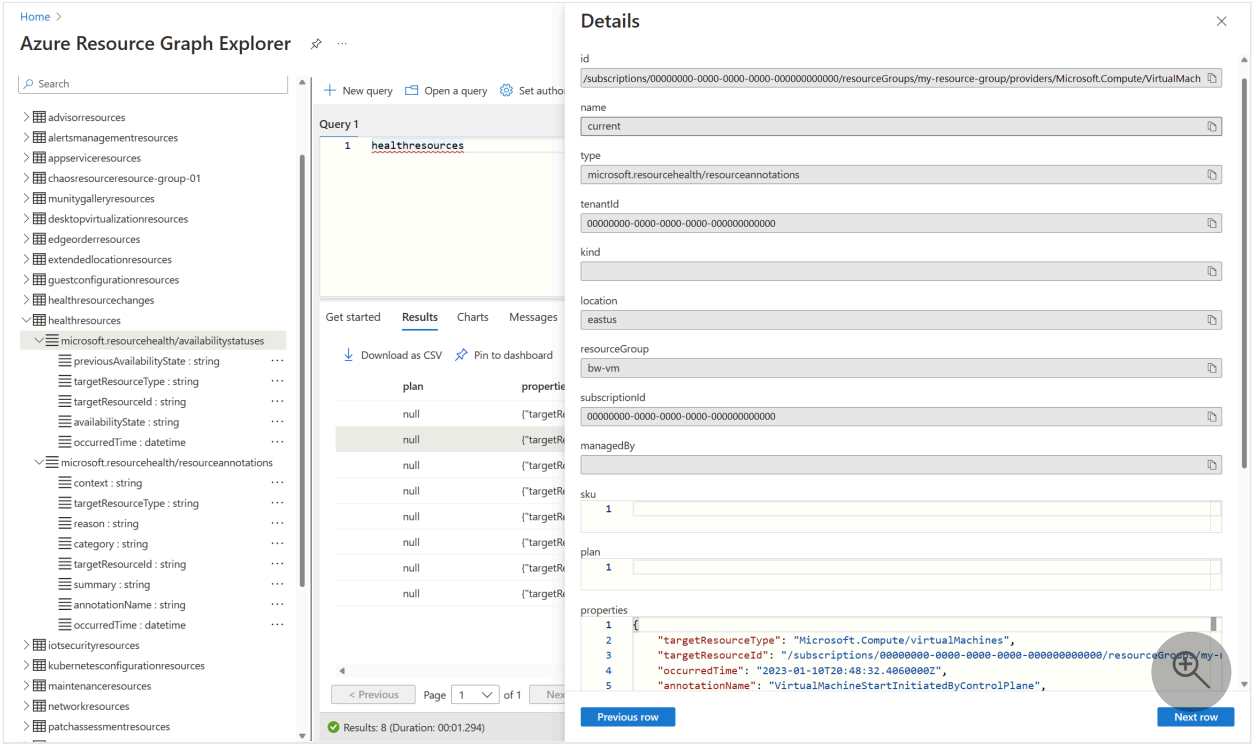
Azure Resource Graph is an Azure service that allows you to use the same KQL query language used in log queries to query your Azure resources at scale with complex filtering, grouping, and sorting by resource properties. You can use VM health annotations to Azure Resource Graph (ARG) for detailed failure attribution and downtime analysis including the following:

- Query the latest snapshot of VM availability together across all your Azure subscriptions.
- Assess the impact to business SLAs and trigger decisive mitigation actions, in response to disruptions and type of failure signature.
- Set up custom dashboards to supervise the comprehensive health of applications by joining VM availability information with additional resource metadata in Resource Graph.
- Track relevant changes in VM availability across a rolling 14 days window, by using the change tracking mechanism for conducting detailed investigations.

To get started with Resource Graph, open **Resource Graph Explorer** in the Azure portal. Select the **Table** tab and have a look at the microsoft.resourcehealth/availabilitystatuses and microsoft.resourcehealth/resourceannotations tables which are described below. Click on **healthresources** to create a simple query and then click **Run** to return the records.



To view the details for a record, scroll to the right and select **See details**.



There will be two types of events populated in the HealthResources table:

microsoft.resourcehealth/availabilitystatuses

This event denotes the latest availability status of a VM, based on the health checks performed by the underlying Azure platform. The availability states currently emitted for VMs are as follows:

- **Available**: The VM is up and running as expected.
- **Unavailable**: A disruption to the normal functioning of the VM has been detected.
- **Unknown**: The platform is unable to accurately detect the health of the VM. Check back in a few minutes.

The availability state is in the `properties` field of the record which includes the following properties:

Expand table

Field	Description
targetResourceType	Type of resource for which health data is flowing
targetResourceId	Resource ID
occurredTime	Timestamp when the latest availability state is emitted by the platform
previousAvailabilityState	Previous availability state of the VM
availabilityState	Current availability state of the VM

A sample `properties` value looks similar to the following:

JSON

```
{
    "targetResourceType": "Microsoft.Compute/virtualMachines",
    "targetResourceId":
"/subscriptions/<subscriptionId>/resourceGroups/<ResourceGroupName>/providers/Microsoft.Compute/virtualMachines/<VMName>",
    "occurredTime": "2022-10-11T11:13:59.9570000Z",
    "previousAvailabilityState": "Available",
    "availabilityState": "Unavailable"
}
```

microsoft.resourcehealth/resourceannotations

This event contextualizes any changes to VM availability, by detailing necessary failure attributes to help you investigate and mitigate the disruption as needed. The full list of VM health annotations are listed at [Resource Health virtual machine Health Annotations] (../service-health/resource-health-vm-annotation.md).

These annotations can be broadly classified into the following:

- **Downtime Annotations**: Emitted when the platform detects VM availability transitioning to Unavailable. Examples include host crashes or reboot operations.
- **Informational Annotations**: Emitted during control plane activities with no impact to VM availability. Examples include VM allocation, stop, delete, start. Usually, no additional customer action is required in response.
- **Degraded Annotations**: Emitted when VM availability is detected to be at risk. Examples include when failure prediction models predict a degraded hardware component that can cause the VM to reboot at any given time. You should redeploy by the deadline specified in the annotation message to avoid any unanticipated loss of data or downtime.

Expand table

Field	Description
targetResourceType	Type of resource for which health data is flowing
targetResourceId	Resource ID
occurredTime	Timestamp when the latest availability state is emitted by the platform
annotationName	Name of the Annotation emitted
reason	Brief overview of the availability impact observed by the customer
category	Denotes whether the platform activity triggering the annotation was either planned maintenance or unplanned repair. This field is not applicable to customer/VM-initiated events. Possible values: Planned | Unplanned | Not Applicable | Null
context	Denotes whether the activity triggering the annotation was due to an authorized user or process (customer initiated), due to the Azure platform (platform initiated), or due to activity in the guest OS that has resulted in availability impact (VM initiated). Possible values: Platform-Initiated | User-initiated | VM-initiated | Not Applicable | Null
summary	Statement detailing the cause for annotation emission, along with remediation steps that can be taken by users

See Azure Resource Graph sample queries by table for sample queries using this data.

Understanding Azure virtual machine usage

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

By analyzing your Azure usage data, powerful consumption insights can be gained – insights that can enable better cost management and allocation throughout your organization. This document provides a deep dive into your Azure Compute consumption details. For more details on general Azure usage, navigate to Understanding your bill.

Download your usage details

To begin, download your usage details. The table provides the definition and example values of usage for Virtual Machines deployed via the Azure Resource Manager. This document doesn't contain detailed information for VMs deployed via our classic model.

Expand table

Field	Meaning	Example Values
Usage Date	The date when the resource was used	`11/23/2017`
Meter ID	Identifies the top-level service for which this usage belongs to	`Virtual Machines`
Meter Sub-Category	The billed meter identifier. For Compute Hour usage, there's a meter for each VM Size + OS (Windows, Non-Windows) + Region. For Premium software usage, there's a meter for each software type. Most premium software images have different meters for each core size. For more information, visit the Compute Pricing Page	`2005544f-659d-49c9-9094-8e0aea1be3a5`
Meter Name	This value is specific for each service in	`Compute Hours`

Field	Meaning	Example Values
	Azure. For compute, it is always "Compute Hours".	
Meter Region	Identifies the location of the datacenter for certain services that are priced based on datacenter location.	`JA East`
Unit	Identifies the unit that the service is charged in. Compute resources are billed per hour.	`Hours`
Consumed	The amount of the resource that has been consumed for that day. For Compute, we bill for each minute the VM ran for a given hour (up to six decimals of accuracy).	`1, 0.5`
Resource Location	Identifies the datacenter where the resource is running.	`JA East`
Consumed Service	The Azure platform service that you used.	`Microsoft.Compute`
Resource Group	The resource group in which the deployed resource is running in. For more information, see Azure Resource Manager overview.	`MyRG`

Instance ID	The identifier for the resource. The identifier contains the name you specify for the resource when it was created. For VMs, the Instance ID contains the SubscriptionId, ResourceGroupName, and VM Name (or scale set name for scale set usage).	`/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/MyRG/providers/Microsoft.Compute/virtualMachines/MyVM1`
		or
		`/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/MyRG/providers/Microsoft.Compute/virtualMachineScaleSets/MyVMSS1`

Field	Meaning	Example Values
Tags	Tag you assign to the resource. Use tags to group billing records. Learn how to tag your Virtual Machines using the CLI or PowerShell This is available for Resource Manager VMs only.	`{"myDepartment":"RD","myUser":"myName"}`

More Info	Service-specific metadata. For VMs, we populate the following data in the additional info field:
	
	Image Type- specific image that you ran. Find the full list of supported strings under Image Types.
	
	Service Type: the size that you deployed.
	
	VM Name: name of your VM. This field is only populated for scale set VMs. If you need your VM Name for scale set VMs, you can find that in the Instance ID string.
	
	UsageType: Specifies the type of usage.
	
	ComputeHR is the Compute Hour usage for the underlying VM, like Standard_D1_v2.
	
	ComputeHR_SW is the premium software charge if the VM is using premium software.
		Virtual Machines
		`{"ImageType":"Canonical","ServiceType":"Standard_DS1_v2","VM Name":"", "UsageType":"ComputeHR"}`
		
		Virtual Machine Scale Sets
		`{"ImageType":"Canonical","ServiceType":"Standard_DS1_v2","VM Name":"myVM1", "UsageType":"ComputeHR"}`
		
		Premium Software
		`{"ImageType":"","ServiceType":"Standard_DS1_v2","VM Name":"", "UsageType":"ComputeHR_SW"}`

Image Type

For some images in the Azure gallery, the image type is populated in the Additional Info field. This enables users to understand and track what they have deployed on their Virtual Machine. The following values that are populated in this field based on the image you have deployed:

- BitRock
- Canonical FreeBSD
- Open Logic
- Oracle
- SLES for SAP
- SQL Server 14 Preview on Windows Server 2012 R2 Preview
- SUSE
- SUSE Premium
- StorSimple Cloud Appliance
- Red Hat
- Red Hat for SAP Business Applications
- Red Hat for SAP HANA
- Windows Client BYOL
- Windows Server BYOL
- Windows Server Preview

Service Type

The service type field in the Additional Info field corresponds to the exact VM size you deployed. Premium storage VMs (SSD-based) and nonpremium storage VMs (HDD-based) are priced the same. If you deploy an SSD-based size, like Standard_DS2_v2, you see the non-SSD size (`Standard\_D2\_v2 VM`) in the Meter Sub-Category column and the SSD-size (`Standard\_DS2\_v2`) in the Additional Info field.

Region Names

The region name populated in the Resource Location field in the usage details varies from the region name used in the Azure Resource Manager. Here's a mapping between the region values:

Expand table

Resource Manager Region Name	Resource Location in Usage Details
australiaeast	AU East
australiasoutheast	AU Southeast
brazilsouth	BR South
CanadaCentral	CA Central
CanadaEast	CA East
CentralIndia	IN Central

Resource Manager Region Name	Resource Location in Usage Details
centralus	Central US

Resource Manager Region Name	Resource Location in Usage Details
westus	West US
westus2	US West 2

Virtual machine usage FAQ

What resources are charged when deploying a VM?

VMs acquire costs for the VM itself, any premium software running on the VM, the storage account\managed disk associated with the VM, and the networking bandwidth transfers from the VM.

How can I tell if a VM is using Azure Hybrid Benefit in the Usage CSV?

If you deploy using the Azure Hybrid Benefit, you're charged the Non-Windows VM rate since you're bringing your own license to the cloud. In your bill, you can distinguish which Resource Manager VMs are running Azure Hybrid Benefit because they have either “Windows_Server BYOL” or “Windows_Client BYOL” in the ImageType column.

How are Basic vs. Standard VM Types differentiated in the Usage CSV?

Both Basic and Standard A-Series VMs are offered. If you deploy a Basic VM, in the Meter Sub Category, it has the string “Basic.” If you deploy a Standard A-Series VM, then the VM size appears as “A1 VM” since Standard is the default. To learn more about the differences between Basic and Standard, see the Pricing Page.

What are ExtraSmall, Small, Medium, Large, and ExtraLarge sizes?

ExtraSmall - ExtraLarge are the legacy names for Standard_A0 – Standard_A4. In classic VM usage records, you might see this convention used if you have deployed these sizes.

What is the difference between Meter Region and Resource Location?

The Meter Region is associated with the meter. For some Azure services who use one price for all regions, the Meter Region field could be blank. However, since VMs have dedicated prices per region for Virtual Machines, this field is populated. Similarly, the Resource Location for Virtual Machines is the location where the VM is deployed. The Azure regions in both fields are the same, although they might have a different string convention for the region name.

Why is the ImageType value blank in the Additional Info field?

The ImageType field is only populated for a subset of images. If you didn't deploy one of the listed images, the ImageType is blank.

Why is the VMName blank in the Additional Info?

The VMName is only populated in the Additional Info field for VMs in a scale set. The InstanceID field contains the VM name for nonscale set VMs.

What does ComputeHR mean in the UsageType field in the Additional Info?

ComputeHR stands for 'Compute Hour', which represents the usage event for the underlying infrastructure cost. If the UsageType is ComputeHR_SW, the usage event represents the premium software charge for the VM.

How do I know if I'm charged for premium software?

When exploring which VM Image best fits your needs, be sure to check out Azure Marketplace. The image has the software plan rate. If you see “Free” for the rate, there's no extra cost for the software.

What is the difference between 'Microsoft.ClassicCompute' and 'Microsoft.Compute' in the Consumed service?

Microsoft.ClassicCompute represents classic resources deployed via the Azure Service Manager. If you deploy via the Resource Manager, then Microsoft.Compute is populated in the consumed service. Learn more about the Azure Deployment models.

Why is the InstanceID field blank for my Virtual Machine usage?

If you deploy via the classic deployment model, the InstanceID string isn't available.

Why are the tags for my VMs not flowing to the usage details?

Tags flow to the Usage CSV for Resource Manager VMs only. Classic resource tags aren't available in the usage details.

How can the consumed quantity be more than 24 hours one day?

In the Classic model, billing for resources is aggregated at the Cloud Service level. If you have more than one VM in a Cloud Service that uses the same billing meter, your usage is aggregated together. VMs deployed via Resource Manager are billed at the VM level, so this aggregation won't apply.

Why is pricing not available for DS/FS/GS/LS sizes on the pricing page?

Premium storage capable VMs are billed at the same rate as nonpremium storage capable VMs. Only your storage costs differ. Visit the storage pricing page for more information.

Use tags to organize your Azure resources and management hierarchy

09/15/2025

Tags are metadata elements that you apply to your Azure resources. They are key-value pairs that help you identify resources based on settings that are relevant to your organization. If you want to track the deployment environment for your resources, add a key named `Environment`. To identify the resources deployed to production, give them a value of `Production`. The full key-value pair is `Environment = Production`.

This article describes the conditions and limitations for using tags.

Tag usage and recommendations

You can apply tags to your Azure resources, resource groups, and subscriptions but not to management groups.

For recommendations on how to implement a tagging strategy, see Resource naming and tagging decision guide.

Resource tags support all cost-accruing services. To ensure that cost-accruing services are provisioned with a tag, use one of the tag policies.

> **⚠ Warning**
>
> Tags are stored as plain text. Do not add sensitive values to tags. Sensitive values could be exposed through many methods, including cost reports, commands that return existing tag definitions, deployment histories, exported templates, and monitoring logs.

> **⚠ Warning**
>
> Be careful when using non-English language in your tags. It can cause decoding progress failure while loading your virtual machine's metadata from IMDS (Instance Metadata Service).

> **ⓘ Important**
>
> Tag names are case-insensitive for operations. An operation updates or retrieves a tag with a tag name, regardless of the casing. However, the resource provider might keep the

casing you provide for the tag name. You see that casing in cost reports.

Tag values are case-sensitive.

> **Note**
>
> This article provides steps about how to delete personal data from the device or service and can be used to support your obligations under the GDPR. For general information about GDPR, see the GDPR section of the Microsoft Trust Center and the GDPR section of the Service Trust portal.

Required access

There are two ways to get the required access to tag resources:

- You can have write access to the `Microsoft.Resources/tags` resource type. This access lets you tag any resource, even if you don't have access to the resource itself. The Tag Contributor role grants this access. For example, this role can't apply tags to resources or resource groups through the Azure portal. However, it can apply tags to subscriptions through the Azure portal. It supports all tag operations through Azure PowerShell and REST API.
- You can have write access to the resource itself. The Contributor role grants the required access to apply tags to any entity. To apply tags to only one resource type, use the Contributor role for that resource. To apply tags to virtual machines, use the Virtual Machine Contributor role.

Inherit tags

Resources don't inherit the tags you apply to a resource group or a subscription. To apply tags from a subscription or resource group to the resources, see Assign policy definitions for tag compliance.

You can group costs for an Azure resource by using the **cm-resource-parent** tag. This tag lets you review tagged costs in Microsoft Cost Management without having to use filters. The key for this tag is `cm-resource-parent` and its value is the resource ID of the Azure resource you want to group costs by. For example, to group costs by an Azure Virtual Desktop host pool, provide the resource ID of the host pool. For more information, see Group related resources in the Resources view.

Tags and billing

Use tags to group your billing data. For example, if you're running multiple virtual machines for different organizations, use the tags to group usage by cost center. You can also use tags to categorize costs by runtime environment, including the billing usage for virtual machines running in the production environment.

To retrieve information about tags, download the usage file from the Azure portal. For more information, see Download or view your Azure billing invoice. For services that support tags with billing, the tags appear in the **Tags** column.

For REST API operations, see the Azure Billing REST API overview.

Unique tags pagination

When you call the Unique tags API, there's a limit to the size of each API response page. A tag that has a large set of unique values requires the API to fetch the next page to retrieve the remaining set of values. When the results are divided over multiple pages, the API response shows the tag key again to indicate that the values are still under this key.

This behavior can cause some tools like the Azure portal to show the tag key twice.

Limitations

The following limitations apply to tags:

- Not all resource types support tags. To determine if you can apply a tag to a resource type, see Tag support for Azure resources.
- Each resource type might have specific requirements when working with tags. For example, you can only update tags on virtual machine extensions when the virtual machine is running. If you receive an error message while trying to update a tag, follow the instructions in the message.
- Each resource, resource group, and subscription can have a maximum of 50 tag name-value pairs. If you need to apply more tags than the maximum allowed number, use a JSON string for the tag value. The JSON string can contain many of the values that you apply to a single tag name. A resource group or subscription can contain many resources that each have 50 tag name-value pairs.
- The tag name has a limit of 512 characters and the tag value has a limit of 256 characters. For storage accounts, the tag name has a limit of 128 characters and the tag value has a

limit of 256 characters.

- Classic resources such as Cloud Services don't support tags.
- Azure IP Groups and Azure Firewall policies don't support PATCH operations. Therefore, PATCH API method operations can't update tags through the Azure portal. Instead, use the update commands for those resources. For example, you can update tags for an IP group with the az network ip-group update command.
- Tag names can't contain these characters: `<`, `>`, `%`, `&`, `\`, `?`, `/`

  > **Note**
  >
  > - Azure DNS zones don't support the use of spaces or parentheses in the tag or a tag that starts with a number. Azure DNS tag names don't support special and Unicode characters. The value can contain all characters.
  > - Traffic Manager doesn't support the use of spaces, `#`, or `:` in the tag name. The tag name can't start with a number.
  > - Azure Front Door doesn't support the use of `#` or `:` in the tag name.
  > - The following Azure resources only support 15 tags:
  >   - Azure Automation
  >   - Azure Content Delivery Network
  >   - Azure Public DNS (Zone and A records)
  >   - Azure Private DNS (Zone and A records)
  >   - Azure Log Analytics saved search

Azure Instance Metadata Service

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

The Azure Instance Metadata Service (IMDS) provides information about currently running virtual machine instances. You can use it to manage and configure your virtual machines. This information includes the SKU, storage, network configurations, and upcoming maintenance events. For a complete list of the data available, see the Endpoint Categories Summary.

IMDS is available for running instances of virtual machines (VMs) and scale set instances. All endpoints support VMs created and managed by using Azure Resource Manager. Only the Attested category and Network portion of the Instance category support VMs created by using the classic deployment model. The Attested endpoint does so only to a limited extent.

IMDS is a REST API that's available at a well-known, non-routable IP address (`169.254.169.254`). You can only access it from within the VM. Communication between the VM and IMDS never leaves the host. Have your HTTP clients bypass web proxies within the VM when querying IMDS.

Usage

Access Azure Instance Metadata Service

To access IMDS, create a VM from Azure Resource Manager or the Azure portal, and use the following samples. For more examples, see Azure Instance Metadata Samples.

Here's sample code to retrieve all metadata for an instance. To access a specific data source, see Endpoint Categories for an overview of all available features.

Request

> **Important**
>
> This example bypasses proxies. You **must** bypass proxies when querying IMDS. See Proxies for additional information.

> **Note**
>
> IMDS requests must be sent using the VM's primary NIC and primary IP, and DHCP must be enabled.

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance?api-version=2025-04-07" | ConvertTo-Json -Depth 64
```

`-NoProxy` requires PowerShell V6 or greater. See our samples repository for examples with older PowerShell versions.

Response

> **Note**
>
> The response is a JSON string. The following example response is formatted for readability.

Windows

JSON

```

        }]
    }
}
```

Security and authentication

The Instance Metadata Service is only accessible from within a running virtual machine instance on a non-routable IP address. VMs can only interact with their own metadata/functionality. The API is HTTP only and never leaves the host.

In order to ensure that requests are directly intended for IMDS and prevent unintended or unwanted redirection of requests, requests:

- **Must** contain the header `Metadata: true`
- Must **not** contain an `X-Forwarded-For` header

Any request that doesn't meet **both** of these requirements are rejected by the service.

> **Important**
>
> IMDS is **not** a channel for sensitive data. The API is unauthenticated and open to all processes on the VM. Information exposed through this service should be considered as shared information to all applications running inside the VM.

If it isn't necessary for every process on the VM to access IMDS endpoint, you can set local firewall rules to limit the access. For example, if only a known system service needs to access instance metadata service, you can set a firewall rule on IMDS endpoint, only allowing the specific process(es) to access, or denying access for the rest of the processes.

Proxies

IMDS is **not** intended to be used behind a proxy and doing so is unsupported. Most HTTP clients provide an option for you to disable proxies on your requests, and this functionality must be utilized when communicating with IMDS. Consult your client's documentation for details.

> **Important**
>
> Even if you don't know of any proxy configuration in your environment, **you still must override any default client proxy settings**. Proxy configurations can be automatically discovered, and failing to bypass such configurations exposes you to outage risks should the machine's configuration be changed in the future.

Rate limiting

In general, requests to IMDS are limited to 5 requests per second (on a per VM basis). Requests exceeding this threshold will be rejected with 429 responses. Requests to the Managed Identity category are limited to 20 requests per second and 5 concurrent requests (on a per VM basis).

HTTP verbs

The following HTTP verbs are currently supported:

Expand table

Verb	Description
`GET`	Retrieve the requested resource

Parameters

Endpoints may support required and/or optional parameters. See Schema and the documentation for the specific endpoint in question for details.

Query parameters

IMDS endpoints support HTTP query string parameters. For example:

URL

```
http://169.254.169.254/metadata/instance/compute?api-version=2025-04-07&format=json
```

Specifies the parameters:

Expand table

Name	Value
`api-version`	`2025-04-07`
`format`	`json`

Requests with duplicate query parameter names will be rejected.

Route parameters

For some endpoints that return larger json blobs, we support appending route parameters to the request endpoint to filter down to a subset of the response:

URL

```
http://169.254.169.254/metadata/<endpoint>/[<filter parameter>/...]?<query
parameters>
```

The parameters correspond to the indexes/keys that would be used to walk down the json object were you interacting with a parsed representation.

For example, `/metadata/instance` returns the json object:

JSON

```
{
    "compute": { ... },
    "network": {
        "interface": [
            {
                "ipv4": {
                   "ipAddress": [{
                       "privateIpAddress": "10.144.133.132",
                       "publicIpAddress": ""
                    }],
                    "subnet": [{
                        "address": "10.144.133.128",
                        "prefix": "26"
                    }]
                },
                "ipv6": {
                    "ipAddress": [{
                        "privateIpAddress":
"b4bc:8fce:f33b:4990:cced:d94e:ab4f:6ea0"
                    }]
                },
                "macAddress": "0011AAFFBB22"
            },
            ...
        ]
    }
}
```

If we want to filter the response down to just the compute property, we would send the request:

URL

```
http://169.254.169.254/metadata/instance/compute?api-version=<version>
```

Similarly, if we want to filter to a nested property or specific array element we keep appending keys:

URL

```
http://169.254.169.254/metadata/instance/network/interface/0?api-version=<version>
```

would filter to the first element from the `Network.interface` property and return:

JSON

```
{
    "ipv4": {
       "ipAddress": [{
            "privateIpAddress": "10.144.133.132",
            "publicIpAddress": ""
        }],
        "subnet": [{
            "address": "10.144.133.128",
            "prefix": "26"
        }]
    },
    "ipv6": {
        "ipAddress": [{
            "privateIpAddress": "b4bc:8fce:f33b:4990:cced:d94e:ab4f:6ea0"
        }]
    },
    "macAddress": "0011AAFFBB22"
}
```

> **Note**
>
> When filtering to a leaf node, `format=json` doesn't work. For these queries `format=text` needs to be explicitly specified since the default format is json.

Schema

Data format

By default, IMDS returns data in JSON format (`Content-Type: application/json`). However, endpoints that support response filtering (see Route Parameters) also support the format `text`.

To access a non-default response format, specify the requested format as a query string parameter in the request. For example:

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance?api-version=2025-04-07&format=text"
```

In json responses, all primitives will be of type `string`, and missing or inapplicable values are always included but will be set to an empty string.

Versioning

IMDS is versioned and specifying the API version in the HTTP request is mandatory. The only exception to this requirement is the versions endpoint, which can be used to dynamically retrieve the available API versions.

As newer versions are added, older versions can still be accessed for compatibility if your scripts have dependencies on specific data formats.

When you don't specify a version, you get an error with a list of the newest supported versions:

JSON

```
{
    "error": "Bad request. api-version is invalid or was not specified in the
request. For more information refer to aka.ms/azureimds",
    "newest-versions": [
        "2025-04-07",
        "2024-07-17",
        "2024-03-15"
    ]
}
```

Swagger

A full Swagger definition for IMDS is available at: https://github.com/Azure/azure-rest-api-specs/blob/main/specification/imds/data-plane/InstanceMetadataService/readme.md

Regional availability

The service is **generally available** in all Azure clouds.

Root endpoint

The root endpoint is `http://169.254.169.254/metadata`.

Endpoint categories

The IMDS API contains multiple endpoint categories representing different data sources, each of which contains one or more endpoints. See each category for details.

Expand table

Category root	Description	Version introduced
`/metadata/attested`	See Attested Data	2018-10-01
`/metadata/identity`	See Managed Identity via IMDS	2018-02-01
`/metadata/instance`	See Instance Metadata	2017-04-02
`/metadata/loadbalancer`	See Retrieve Load Balancer metadata via IMDS	2020-10-01
`/metadata/scheduledevents`	See Scheduled Events via IMDS	2017-08-01
`/metadata/versions`	See Versions	N/A

Versions

List API versions

Returns the set of supported API versions.

```
GET /metadata/versions
```

Parameters

None (this endpoint is unversioned).

Response

JSON

```
{
  "apiVersions": [
    "2017-03-01",
    "2017-04-02",
    ...
  ]
}
```

Instance metadata

Get VM metadata

Exposes the important metadata for the VM instance, including compute, network, and storage.

```
GET /metadata/instance
```

Parameters

Expand table

Name	Required/Optional	Description
`api-version`	Required	The version used to service the request.
`format`	Optional*	The format (`json` or `text`) of the response. *Note: May be required when using request parameters

This endpoint supports response filtering via route parameters.

Response

Windows

}
```

Schema breakdown:

Compute

Expand table

Data	Description	Version introduced
`azEnvironment`	Azure Environment where the VM is running in	2018-10-01
`additionalCapabilities.hibernationEnabled`	Identifies if hibernation is enabled on the VM	2021-11-01
`customData`	This feature is deprecated and disabled in IMDS. It has been superseded by `userData`	2019-02-01
`evictionPolicy`	Sets how a Spot VM will be evicted.	2020-12-01
`extendedLocation.type`	Type of the extended location of the VM.	2021-03-01
`extendedLocation.name`	Name of the extended location of the VM	2021-03-01
`host.id`	Name of the host of the VM. Note that a VM will either have a host or a hostGroup but not both.	2021-11-15
`hostGroup.id`	Name of the hostGroup of the VM. Note that a VM will either have a host or a hostGroup but not both.	2021-11-15
`isHostCompatibilityLayerVm`	Identifies if the VM runs on the Host Compatibility Layer	2020-06-01
`licenseType`	Type of license for Azure Hybrid Benefit. This is only present for AHB-enabled VMs	2020-09-01
`location`	Azure Region the VM is running in	2017-04-02
`name`	Name of the VM	2017-04-02
`offer`	Offer information for the VM image and is only present for images deployed from Azure image gallery	2017-04-02
`osProfile.adminUsername`	Specifies the name of the admin account	2020-07-15
`osProfile.computerName`	Specifies the name of the computer	2020-07-15
`osProfile.disablePasswordAuthentication`	Specifies if password authentication is	2020-10-01

Data	Description	Version introduced
	disabled. This is only present for Linux VMs	
`osType`	Linux or Windows	2017-04-02
`physicalZone`	Physical zone of the VM	2023-11-15
`placementGroupId`	Placement Group of your scale set	2017-08-01
`plan`	Plan containing name, product, and publisher for a VM if it's an Azure Marketplace Image	2018-04-02
`platformUpdateDomain`	Update domain the VM is running in	2017-04-02
`platformFaultDomain`	Fault domain the VM is running in	2017-04-02
`platformSubFaultDomain`	Sub fault domain the VM is running in, if applicable.	2021-10-01
`priority`	Priority of the VM. Refer to Spot VMs for more information	2020-12-01
`provider`	Provider of the VM	2018-10-01
`publicKeys`	Collection of Public Keys assigned to the VM and paths	2018-04-02
`publisher`	Publisher of the VM image	2017-04-02
`resourceGroupName`	Resource group for your Virtual Machine	2017-08-01
`resourceId`	The fully qualified ID of the resource	2019-03-11
`sku`	Specific SKU for the VM image	2017-04-02
`securityProfile.secureBootEnabled`	Identifies if UEFI secure boot is enabled on the VM	2020-06-01
`securityProfile.virtualTpmEnabled`	Identifies if the virtual Trusted Platform Module (TPM) is enabled on the VM	2020-06-01
`securityProfile.encryptionAtHost`	Identifies if Encryption at Host is enabled on the VM	2021-11-01
`securityProfile.securityType`	Identifies if the VM is a Trusted VM or a Confidential VM	2021-12-13
`storageProfile`	See Storage Profile below	2019-06-01
`subscriptionId`	Azure subscription for the Virtual Machine	2017-08-01

Data	Description	Version introduced
`tags`	Tags for your Virtual Machine	2017-08-01
`tagsList`	Tags formatted as a JSON array for easier programmatic parsing	2019-06-04
`userData`	The set of data specified when the VM was created for use during or after provisioning (Base64 encoded)	2021-01-01
`version`	Version of the VM image	2017-04-02
`virtualMachineScaleSet.id`	ID of the Virtual Machine Scale Set created with flexible orchestration the Virtual Machine is part of. This field isn't available for Virtual Machine Scale Sets created with uniform orchestration.	2021-03-01
`vmId`	Unique identifier for the VM. The blog referenced only suits for VMs that have SMBIOS < 2.6. For VMs that have SMBIOS >= 2.6, the UUID from DMI is displayed in little-endian format, thus, there's no requirement to switch bytes.	2017-04-02
`vmScaleSetName`	Virtual Machine Scale Set Name of your scale set	2017-12-01
`vmSize`	VM size	2017-04-02
`zone`	Availability Zone of your virtual machine	2017-12-01

† This version isn't fully available yet and may not be supported in all regions.

Storage profile

The storage profile of a VM is divided into three categories: image reference, OS disk, and data disks, plus an additional object for the local temporary disk.

The image reference object contains the following information about the OS image, please note that an image could come either from the platform, marketplace, community gallery, or direct shared gallery but not both:

Expand table

Data	Description	Version introduced
`id`	Resource ID	2019-06-01
`offer`	Offer of the platform or marketplace image	2019-06-01
`publisher`	Publisher of the platform or marketplace image	2019-06-01
`sku`	Sku of the platform or marketplace image	2019-06-01
`version`	Version of the image	2019-06-01
`communityGalleryImageId`	Resource ID of the community image, empty otherwise	2023-07-01
`sharedGalleryImageId`	Resource ID o direct shared image, empty otherwise	2023-07-01
`exactVersion`	Version of the community or direct shared image	2023-07-01

The OS disk object contains the following information about the OS disk used by the VM:

Expand table

Data	Description
`caching`	Caching requirements
`createOption`	Information about how the VM was created
`diffDiskSettings`	Ephemeral disk settings
`diskSizeGB`	Size of the disk in GB
`image`	Source user image virtual hard disk
`managedDisk`	Managed disk parameters
`name`	Disk name
`vhd`	Virtual hard disk
`writeAcceleratorEnabled`	Whether or not writeAccelerator is enabled on the disk

The data disks array contains a list of data disks attached to the VM. Each data disk object contains the following information:

Expand table

Data	Description	Version introduced
`bytesPerSecondThrottle`*	Disk read/write quota in bytes	2021-05-01
`caching`	Caching requirements	2019-06-01
`createOption`	Information about how the VM was created	2019-06-01
`diffDiskSettings`	Ephemeral disk settings	2019-06-01
`diskCapacityBytes`*	Size of disk in bytes	2021-05-01
`diskSizeGB`	Size of the disk in GB	2019-06-01
`encryptionSettings`	Encryption settings for the disk	2019-06-01
`image`	Source user image virtual hard disk	2019-06-01
`isSharedDisk`*	Identifies if the disk is shared between resources	2021-05-01
`isUltraDisk`	Identifies if the data disk is an Ultra Disk	2021-05-01
`lun`	Logical unit number of the disk	2019-06-01
`managedDisk`	Managed disk parameters	2019-06-01
`name`	Disk name	2019-06-01
`opsPerSecondThrottle`*	Disk read/write quota in IOPS	2021-05-01
`osType`	Type of OS included in the disk	2019-06-01
`vhd`	Virtual hard disk	2019-06-01
`writeAcceleratorEnabled`	Whether or not writeAccelerator is enabled on the disk	2019-06-01

*These fields are only populated for Ultra Disks; they are empty strings from non-Ultra Disks.

The encryption settings blob contains data about how the disk is encrypted (if it's encrypted):

Expand table

Data	Description	Version introduced
`diskEncryptionKey.sourceVault.id`	The location of the disk encryption key	2021-11-01
`diskEncryptionKey.secretUrl`	The location of the secret	2021-11-01
`keyEncryptionKey.sourceVault.id`	The location of the key encryption key	2021-11-01
`keyEncryptionKey.keyUrl`	The location of the key	2021-11-01

The resource disk object contains the size of the Local Temp Disk attached to the VM, if it has one, in kilobytes. If there's no local temp disk for the VM, this value is 0.

Expand table

Data	Description	Version introduced
`resourceDisk.size`	Size of the local temp disk for the VM (in kB)	2021-02-01

Network

Expand table

Data	Description	Version introduced
`ipv4.ipAddress.privateIpAddress`	Local IPv4 address of the VM	2017-04-02
`ipv4.ipAddress.publicIpAddress`	Public IPv4 address of the VM	2017-04-02
`ipv4.subnet.address`	Subnet address of the VM	2017-04-02
`ipv4.subnet.prefix`	Subnet prefix, example 24	2017-04-02
`ipv6.ipAddress.privateIpAddress`	Local IPv6 address of the VM	2017-04-02
`macAddress`	VM mac address	2017-04-02

> **Note**
>
> The nics returned by the network call are not guaranteed to be in order.

Get user data

When creating a new VM, you can specify a set of data to be used during or after the VM provision, and retrieve it through IMDS. Check the end to end user data experience here.

To set up user data, utilize the quickstart template here. The sample below shows how to retrieve this data through IMDS. This feature is released with version `2021-01-01` and above.

> **Note**
>
> Security notice: IMDS is open to all applications on the VM, sensitive data should not be placed in the user data.

Windows

PowerShell

```
$userData = Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy
-Uri "http://169.254.169.254/metadata/instance/compute/userData?api-
version=2025-04-07&format=text"
[System.Text.Encoding]::UTF8.GetString([Convert]::FromBase64String($userData))
```

Sample 1: Tracking VM running on Azure

As a service provider, you may require to track the number of VMs running your software or have agents that need to track uniqueness of the VM. To be able to get a unique ID for a VM, use the `vmId` field from Instance Metadata Service.

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute/vmId?api-version=2025-04-
07&format=text"
```

Response

Output

```
5c08b38e-4d57-4c23-ac45-aca61037f084
```

Sample 2: Placement of different data replicas

For certain scenarios, placement of different data replicas is of prime importance. For example, HDFS replica placement or container placement via an orchestrator might require you to know the `platformFaultDomain` and `platformUpdateDomain` the VM is running on. You can also use Availability Zones for the instances to make these decisions. You can query this data directly via IMDS.

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute/platformFaultDomain?api-
version=2025-04-07&format=text"
```

Response

Output

```
0
```

Sample 3: Get VM tags

VM tags are included the instance API under instance/compute/tags endpoint. Tags may have been applied to your Azure VM to logically organize them into a taxonomy. The tags assigned to a VM can be retrieved by using the request below.

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute/tags?api-version=2025-04-
07&format=text"
```

Response

Output

```
Department:IT;ReferenceNumber:123456;TestStatus:Pending
```

The `tags` field is a string with the tags delimited by semicolons. This output can be a problem if semicolons are used in the tags themselves. If a parser is written to programmatically extract the tags, you should rely on the `tagsList` field. The `tagsList` field is a JSON array with no delimiters, and consequently, easier to parse. The tagsList assigned to a VM can be retrieved by using the request below.

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute/tagsList?api-version=2025-04-
07" | ConvertTo-Json -Depth 64
```

Response

Windows

JSON

```
{
    "value":  [
                  {
                      "name":  "Department",
                      "value":  "IT"
                  },
                  {
                      "name":  "ReferenceNumber",
                      "value":  "123456"
                  },
                  {
                      "name":  "TestStatus",
                      "value":  "Pending"
                  }
              ],
    "Count":  3
}
```

Sample 4: Get more information about the VM during support case

As a service provider, you may get a support call where you would like to know more information about the VM. Asking the customer to share the compute metadata can provide basic information for the support professional to know about the kind of VM on Azure.

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/compute?api-version=2025-04-07" |
ConvertTo-Json -Depth 64
```

Response

> **Note**
>
> The response is a JSON string. The following example response is pretty-printed for readability.

Windows

JSON

```
{

```

Sample 5: Get the Azure Environment where the VM is running

Azure has various sovereign clouds like Azure Government. Sometimes you need the Azure Environment to make some runtime decisions. The following sample shows you how you can achieve this behavior.

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance/compute/azEnvironment?api-version=2025-04-07&format=text"
```

Response

Output

```
AzurePublicCloud
```

The cloud and the values of the Azure environment are listed here.

Expand table

Cloud	Azure environment
All generally available global Azure regions	AzurePublicCloud
Azure Government	AzureUSGovernmentCloud

Cloud	Azure environment
Microsoft Azure operated by 21Vianet	AzureChinaCloud
Azure Germany	AzureGermanCloud

Sample 6: Retrieve network information

Request

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri
"http://169.254.169.254/metadata/instance/network?api-version=2025-04-07" |
ConvertTo-Json  -Depth 64
```

Response

JSON

```
{
  "interface": [
    {
      "ipv4": {
        "ipAddress": [
          {
            "privateIpAddress": "10.1.0.4",
            "publicIpAddress": "X.X.X.X"
          }
        ],
        "subnet": [
          {
            "address": "10.1.0.0",

}
```

Sample 7: Retrieve public IP address

Windows

PowerShell

```
Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -NoProxy -Uri "http://169.254.169.254/metadata/instance/network/interface/0/ipv4/ipAddress/0/publicIpAddress?api-version=2025-04-07&format=text"
```

> **Note**
>
> - If you're looking to retrieve IMDS information for **Standard** SKU Public IP address, review Load Balancer Metadata API for more infomration.

Attested data

Get Attested data

IMDS helps to provide guarantees that the data provided is coming from Azure. Microsoft signs part of this information, so you can confirm that an image in Azure Marketplace is the one you're running on Azure.

```
GET /metadata/attested/document
```

Parameters

Expand table

Name	Required/Optional	Description
`api-version`	Required	The version used to service the request.

Name	Required/Optional	Description
`nonce`	Optional	A 10-digit string that serves as a cryptographic nonce. If no value is provided, IMDS uses the current UTC timestamp.

Response

JSON

```
{
    "encoding":"pkcs7",

}
```

The signature blob is a pkcs7 -signed version of document. It contains the certificate used for signing along with certain VM-specific details.

For VMs created by using Azure Resource Manager, the document includes `vmId`, `sku`, `nonce`, `subscriptionId`, `timeStamp` for creation and expiry of the document, and the plan information about the image. The plan information is only populated for Azure Marketplace images.

For VMs created by using the classic deployment model, only the `vmId` and `subscriptionId` are guaranteed to be populated. You can extract the certificate from the response, and use it to confirm that the response is valid and is coming from Azure.

The decoded document contains the following fields:

Expand table

Data	Description	Version introduced
`licenseType`	Type of license for Azure Hybrid Benefit. This is only present for AHB-enabled VMs.	2020-09-01
`nonce`	A string that can be optionally provided with the request. If no `nonce` was supplied, the current Coordinated Universal Time timestamp is used.	2018-10-01
`plan`	The Azure Marketplace Image plan. Contains the plan ID (name), product image or offer (product), and publisher ID (publisher).	2018-10-01
`timestamp.createdOn`	The UTC timestamp for when the signed document was created	2018-20-01
`timestamp.expiresOn`	The UTC timestamp for when the signed document expires	2018-10-01
`vmId`	Unique identifier for the VM	2018-10-01
`subscriptionId`	Azure subscription for the Virtual Machine	2019-04-30
`sku`	Specific SKU for the VM image (correlates to `compute/sku` property from the Instance Metadata endpoint [`/metadata/instance`])	2019-11-01

> **Note**
>
> For Classic (non-Azure Resource Manager) VMs, only the vmId is guaranteed to be populated.

Example document:

JSON

```
{
   "nonce":"20201130-211924",
   "plan":{
      "name":"planName",
      "product":"planProduct",
      "publisher":"planPublisher"
   },
   "sku":"Windows-Server-2012-R2-Datacenter",
   "subscriptionId":"aaaa0a0a-bb1b-cc2c-dd3d-eeeeee4e4e4e",
   "timeStamp":{
      "createdOn":"11/30/20 21:19:19 -0000",
      "expiresOn":"11/30/20 21:19:24 -0000"
   },
   "vmId":"02aab8a4-74ef-476e-8182-f6d2ba4166a6"
}
```

Signature Validation Guidance

When validating the signature, you should confirm that the signature was created with a certificate from Azure. This is done by validating the certificate Subject Alternative Name (SAN).

Example SAN `DNS Name=eastus.metadata.azure.com, DNS Name=metadata.azure.com`

> **Note**
>
> The domain for the public cloud and each sovereign cloud will be different.

Expand table

Cloud	Domain in SAN
All generally available global Azure regions	*.metadata.azure.com
Azure Government	*.metadata.azure.us
Azure operated by 21Vianet	*.metadata.azure.cn
Azure Germany	*.metadata.microsoftazure.de

> **Note**
>
> The certificates might not have an exact match for the domain. For this reason, the certification validation should accept any subdomain (for example, in public cloud general availability regions accept `*.metadata.azure.com`).

We don't recommend certificate pinning for intermediate certs. For further guidance, see Certificate pinning - Certificate pinning and Azure services. Please note that the Azure Instance Metadata Service will NOT offer notifications for future Certificate Authority changes. Instead, you must follow the centralized Azure Certificate Authority details article for all future updates.

Sample 1: Validate that the VM is running in Azure

Vendors in Azure Marketplace want to ensure that their software is licensed to run only in Azure. If someone copies the VHD to an on-premises environment, the vendor needs to be able to detect that. Through IMDS, these vendors can get signed data that guarantees response only from Azure.

> **Note**

This sample requires the jq utility to be installed.

Validation

Windows

PowerShell

```
# Get the signature
$attestedDoc = Invoke-RestMethod -Headers @{"Metadata"="true"} -Method GET -
NoProxy -Uri http://169.254.169.254/metadata/attested/document?api-version=2025-
04-07
# Decode the signature
$signature = [System.Convert]::FromBase64String($attestedDoc.signature)
```

Verify that the signature is from Microsoft Azure and checks the certificate chain for errors.

PowerShell

```
# Get certificate chain
$cert = [System.Security.Cryptography.X509Certificates.X509Certificate2]
($signature)
$chain = New-Object -TypeName
System.Security.Cryptography.X509Certificates.X509Chain
$chain.Build($cert)
# Print the Subject of each certificate in the chain
foreach($element in $chain.ChainElements)
{
    Write-Host $element.Certificate.Subject
}

# Get the content of the signed document
Add-Type -AssemblyName System.Security
$signedCms = New-Object -TypeName System.Security.Cryptography.Pkcs.SignedCms
$signedCms.Decode($signature);
$content =
[System.Text.Encoding]::UTF8.GetString($signedCms.ContentInfo.Content)
Write-Host "Attested data: " $content
$json = $content | ConvertFrom-Json
# Do additional validation here
```

The `nonce` in the signed document can be compared if you provided a `nonce` parameter in the initial request.

Managed identity

A managed identity, assigned by the system, can be enabled on the VM. You can also assign one or more user-assigned managed identities to the VM. You can then request tokens for managed identities from IMDS. Use these tokens to authenticate with other Azure services, such as Azure Key Vault.

For detailed steps to enable this feature, see Acquire an access token.

Load Balancer Metadata

When you place virtual machine or virtual machine set instances behind an Azure Standard Load Balancer, you can use IMDS to retrieve metadata related to the load balancer and the instances. For more information, see Retrieve load balancer information.

Scheduled events

You can obtain the status of the scheduled events by using IMDS. Then the user can specify a set of actions to run upon these events. For more information, see Scheduled events for Linux or Scheduled events for Windows.

Sample code in different languages

The following table lists samples of calling IMDS by using different languages inside the VM:

Expand table

Language	Example
Bash	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.sh
C#	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.cs
Go	https://github.com/Microsoft/azureimds/blob/master/imdssample.go
Java	https://github.com/Microsoft/azureimds/blob/master/imdssample.java
NodeJS	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.js
Perl	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.pl
PowerShell	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.ps1
Puppet	https://github.com/keirans/azuremetadata
Python	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.py

Language	Example
Ruby	https://github.com/Microsoft/azureimds/blob/master/IMDSSample.rb

Errors and debugging

If there's a data element not found or a malformed request, the Instance Metadata Service returns standard HTTP errors. For example:

Expand table

HTTP status code	Reason
`200 OK`	The request was successful.
`400 Bad Request`	Missing `Metadata: true` header or missing parameter `format=json` when querying a leaf node
`404 Not Found`	The requested element doesn't exist
`405 Method Not Allowed`	The HTTP method (verb) isn't supported on the endpoint.
`410 Gone`	Retry after some time for a max of 70 seconds
`429 Too Many Requests`	API Rate Limits have been exceeded
`500 Service Error`	Retry after some time

Frequently asked questions

- **I'm getting the error `400 Bad Request, Required metadata header not specified`. What does this mean?**
  - IMDS requires the header `Metadata: true` to be passed in the request. Passing this header in the REST call allows access to IMDS.
- **Why am I not getting compute information for my VM?**
  - Currently, IMDS only supports instances created with Azure Resource Manager.
- **I created my VM through Azure Resource Manager some time ago. Why am I not seeing compute metadata information?**
  - If you created your VM after September 2016, add a tag to start seeing compute metadata. If you created your VM before September 2016, add or remove extensions

or data disks to the VM instance to refresh metadata.

- **Is user data the same as custom data?**
  - User data offers the similar functionality to custom data, allowing you to pass your own metadata to the VM instance. The difference is, user data is retrieved through IMDS, and is persistent throughout the lifetime of the VM instance. Existing custom data feature will continue to work as described in this article. However you can only get custom data through local system folder, not through IMDS.

- **Why am I not seeing all data populated for a new version?**
  - If you created your VM after September 2016, add a tag to start seeing compute metadata. If you created your VM before September 2016, add or remove extensions or data disks to the VM instance to refresh metadata.

- **Why am I getting the error `500 Internal Server Error` or `410 Resource Gone`?**
  - Retry your request. For more information, see Transient fault handling. If the problem persists, create a support issue in the Azure portal for the VM.

- **Would this work for scale set instances?**
  - Yes, IMDS is available for scale set instances.

- **I updated my tags in my scale sets, but they don't appear in the instances (unlike single instance VMs). Am I doing something wrong?**
  - Currently tags for scale sets only show to the VM on a reboot, reimage, or disk change to the instance.

- **Why am I'm not seeing the SKU information for my VM in `instance/compute` details?**
  - For custom images created from Azure Marketplace, Azure platform doesn't retain the SKU information for the custom image and the details for any VMs created from the custom image. This is by design and hence not surfaced in the VM `instance/compute` details.

- **Why is my request timed out (or failed to connect) for my call to the service?**

  - Metadata calls must be made from the primary IP address assigned to the primary network card of the VM. Additionally, if you've changed your routes, there must be a route for the 169.254.169.254/32 address in your VM's local routing table.

    Windows

    1. Dump your local routing table and look for the IMDS entry. For example:

       Console

```
route print
```

Output

```
IPv4 Route Table
===========================================================================
=======
Active Routes:
Network Destination        Netmask          Gateway       Interface
Metric
        0.0.0.0          0.0.0.0      172.16.69.1      172.16.69.7
10
        127.0.0.0        255.0.0.0         On-link         127.0.0.1
331
        127.0.0.1  255.255.255.255         On-link         127.0.0.1
331
127.255.255.255  255.255.255.255         On-link         127.0.0.1
331
    168.63.129.16  255.255.255.255      172.16.69.1      172.16.69.7
11
169.254.169.254  255.255.255.255      172.16.69.1      172.16.69.7
11
... (continues) ...
```

2. Verify that a route exists for `169.254.169.254`, and note the corresponding network interface (for example, `172.16.69.7`).

3. Dump the interface configuration and find the interface that corresponds to the one referenced in the routing table, noting the MAC (physical) address.

Console

```
ipconfig /all
```

Output

```
... (continues) ...
Ethernet adapter Ethernet:

Connection-specific DNS Suffix  . :
xic3mnxjiefupcwr1mcs1rjiqa.cx.internal.cloudapp.net
Description . . . . . . . . . . . : Microsoft Hyper-V Network
Adapter
Physical Address. . . . . . . . . : 00-0D-3A-E5-1C-C0
DHCP Enabled. . . . . . . . . . . : Yes
Autoconfiguration Enabled . . . . : Yes
Link-local IPv6 Address . . . . . :
fe80::3166:ce5a:2bd5:a6d1%3(Preferred)
IPv4 Address. . . . . . . . . . . : 172.16.69.7(Preferred)
```

```
Subnet Mask . . . . . . . . . . . : 255.255.255.0
... (continues) ...
```

4. Confirm that the interface corresponds to the VM's primary NIC and primary IP. You can find the primary NIC and IP by looking at the network configuration in the Azure portal, or by looking it up with the Azure CLI. Note the private IPs (and the MAC address if you're using the CLI). Here's a PowerShell CLI example:

   Azure PowerShell

   ```
   $ResourceGroup = '<Resource_Group>'
   $VmName = '<VM_Name>'
   $NicNames = az vm nic list --resource-group $ResourceGroup --vm-name
   $VmName | ConvertFrom-Json | Foreach-Object { $_.id.Split('/')[-1] }
   foreach($NicName in $NicNames)
   {
       $Nic = az vm nic show --resource-group $ResourceGroup --vm-name
   $VmName --nic $NicName | ConvertFrom-Json
       Write-Host $NicName, $Nic.primary, $Nic.macAddress
   }
   ```

   Output

   ```
   wintest767 True 00-0D-3A-E5-1C-C0
   ```

5. If they don't match, update the routing table so that the primary NIC and IP are targeted.

- **Fail over clustering in Windows Server**
  - When you're querying IMDS with failover clustering, it's sometimes necessary to add a route to the routing table. Here's how:

    1. Open a command prompt with administrator privileges.
    2. Run the following command, and note the address of the Interface for Network Destination (`0.0.0.0`) in the IPv4 Route Table.

    bat

    ```
    route print
    ```

> **Note**
>
> The following example output is from a Windows Server VM with failover cluster enabled. For simplicity, the output contains only the IPv4 Route Table.

Output

```
IPv4 Route Table
===========================================================================
Active Routes:
Network Destination        Netmask          Gateway       Interface  Metric
        0.0.0.0          0.0.0.0         10.0.1.1        10.0.1.10    266
        10.0.1.0  255.255.255.192         On-link         10.0.1.10    266
        10.0.1.10  255.255.255.255         On-link         10.0.1.10    266
        10.0.1.15  255.255.255.255         On-link         10.0.1.10    266
        10.0.1.63  255.255.255.255         On-link         10.0.1.10    266
        127.0.0.0        255.0.0.0         On-link         127.0.0.1    331
        127.0.0.1  255.255.255.255         On-link         127.0.0.1    331
127.255.255.255  255.255.255.255         On-link         127.0.0.1    331
    169.254.0.0      255.255.0.0         On-link     169.254.1.156    271
    169.254.1.156  255.255.255.255         On-link     169.254.1.156    271
169.254.255.255  255.255.255.255         On-link     169.254.1.156    271
        224.0.0.0        240.0.0.0         On-link         127.0.0.1    331
        224.0.0.0        240.0.0.0         On-link     169.254.1.156    271
255.255.255.255  255.255.255.255         On-link         127.0.0.1    331
255.255.255.255  255.255.255.255         On-link     169.254.1.156    271
255.255.255.255  255.255.255.255         On-link         10.0.1.10    266
```

Run the following command and use the address of the Interface for Network Destination (`0.0.0.0`), which is (`10.0.1.10`) in this example.

bat

```
route add 169.254.169.254/32 10.0.1.10 metric 1 -p
```

Support

If you aren't able to get a metadata response after multiple attempts, you can create a support issue in the Azure portal.

Product feedback

You can provide product feedback and ideas to our user feedback channel under Virtual Machines > Instance Metadata Service here

Next steps

Metadata Security Protocol (MSP)

10/08/2025

Metadata Security Protocol (MSP) is a feature in the Azure Virtual Machines and Azure Virtual Machine Scale Sets services. It enhances the security of the Azure Instance Metadata Service and WireServer services. These services are available in Azure infrastructure as a service (IaaS) virtual machines (VMs) or virtual machine scale sets at 169.254.169.254 and 168.63.129.16, respectively.

Organizations use Instance Metadata Service and WireServer for providing metadata and bootstrapping VM credentials. As a result, threat actors frequently target these services. Common vectors include confused deputy attacks against in-guest workloads and sandbox escapes. These vectors are of particular concern for hosted-on-behalf-of workloads where untrusted code loads into the VM.

With metadata services, the trust boundary is the VM itself. Any software within the guest is authorized to request secrets from Instance Metadata Service and WireServer. VM owners are responsible for carefully sandboxing any software that they run inside the VM and ensuring that external actors can't exfiltrate data. In practice, the complexity of the problem leads to mistakes at scale, which in turn lead to exploits.

Although numerous defense-in-depth strategies exist, providing secrets over an unauthenticated HTTP API carries inherent risk. Across the industry, this class of vulnerabilities has affected hundreds of companies, affected millions of individuals, and caused financial losses in the hundreds of millions of dollars.

MSP closes the most common vulnerabilities by:

- Addressing the root cause of these attacks.
- Introducing strong authentication and authorization concepts to cloud metadata services.

Compatibility

MSP is supported on Azure IaaS VMs and virtual machine scale sets that run these operating systems:

- Windows 10 or later (x64)
- Windows Server 2019 (x64)
- Windows Server 2022 (x64)
- Windows Server 2025 (x64)
- Mariner 2.0 (x64, ARM64)
- Azure Linux (Mariner 3.0) (x64, ARM64)

- Ubuntu 20.04+ (x64, ARM64)

The following items are currently not supported:

- Red Hat Enterprise Linux 9+
- Rocky Linux 9+
- SUSE Linux Enterprise Server 15 SP4+
- Ephemeral disks
- Compatibility with Azure Backup
- ARM64

Enhanced security

The Guest Proxy Agent (GPA) hardens against these types of attacks by:

- Limiting metadata access to a subset of the VM (applying the principle of least-privileged access).

- Switching from a *default-open* model to a *default-closed* model.

  For instance, with nested virtualization, a misconfigured L2 VM that has access to the L1 VM's vNIC can communicate with a metadata service as the L1. With the GPA, a misconfigured L2 could no longer gain access, because it would be unable to authenticate with the service.

At provisioning time, the metadata service establishes a trusted delegate within the guest (the GPA). A long-lived secret is negotiated to authenticate with the trusted delegate. The delegate must endorse all requests to the metadata service by using a hash-based message authentication code (HMAC). The HMAC establishes a point-to-point trust relationship with strong authorization.

The GPA uses eBPF to intercept HTTP requests to the metadata service. eBPF enables the GPA to verify the identity of the in-guest software that made the request. The GPA uses eBPF to intercept requests without requiring an extra kernel module. GPA uses this information to compare the identity of the client against an allowlist defined as a part of the VM model in Azure Resource Manager (ARM). The GPA then endorses requests by adding a signature header. So, you can enable the MSP feature on existing workloads without breaking changes.

By default, the existing authorization levels are enforced:

- Instance Metadata Service is open to all users.
- WireServer is root/admin only.

This restriction is currently accomplished with firewall rules in the guest. This is still a default-open mechanism. If that rule can be disabled or bypassed for any reason, the metadata service still accepts the request. The authorization mechanism enabled here is default-closed. Bypassing interception maliciously or by error doesn't grant access to the metadata service.

You can set up an advanced authorization configuration (that is, authorize specific in-guest processes and users to access only specific endpoints) by defining a custom allowlist with role-based access control (RBAC) semantics.

> ⚠ **Warning**
>
> Please note that on Windows, the users can enable GuestProxyAgent (GPA) from an ARM template. However, in Linux it's a two-step process. The VM/VMSS is provisioned first and only then can the GPA be configured.

MSP feature configuration

10/08/2025

Metadata Security Protocol (MSP) offers customization to maximally restrict metadata server access in your workload. This article introduces fundamental concepts that you can quickly enable on any supported virtual machine (VM) or virtual machine scale set.

If you're familiar with how your workload uses metadata services, you can harden access further by following the guide for advanced configuration.

You can configure MSP via:

- Azure Resource Manager templates
- REST API
- PowerShell
- Azure portal

Concepts

Expand table

Term	Definition
Metadata services	A general term for the industry practice of offering private, non-internet, anonymous HTTP APIs available at a fixed location. The location is typically `169.254.169.254`. Although the exact features, details, and service count vary by cloud provider, they all share a similar architecture and purpose.
Azure Instance Metadata Service	A user-facing metadata service that comes with support and full API documentation. It's intended for both Azure and non-Microsoft integrations. It offers a mix of metadata and credentials.
WireServer	A platform-facing metadata service that organizations use to implement core infrastructure as a service (IaaS) functionality. It isn't intended for general consumption, and Azure offers no support for doing so. Although the consumers of the service are related to an Azure implementation, the service must still be considered in security assessments. WireServer resources are treated as privileged by default. However, you shouldn't view Instance Metadata Service resources as nonprivileged. Depending on your workload, Instance Metadata Service can also provide sensitive information.
Guest Proxy Agent (GPA)	An in-guest agent that enables MSP protections.

Azure Resource Manager fields

You manage all configuration via new properties in the `securityProfile` section of your resource's configuration.

The minimum API version to configure MSP is `2024-03-01`.

General configuration

`ProxyAgentSettings` is the new property in the VM model for Azure VMs and virtual machine scale sets that you use to configure the MSP feature.

Expand table

Parameter name	Type	Default	Details
`enabled`	`Bool`	`false`	Specifies whether the MSP feature should be enabled on the VM or virtual machine scale set. Default is `false`. This property controls: • Applying other settings. • Platform latched-key generation. • Automatic GPA installation (when `true`) or uninstallation (when `false`) on a Windows VM or virtual machine scale set.
`imds`	`HostEndpointSettings`	Not applicable	Instance Metadata Service-specific configuration. See Configuration for each metadata service later in this article.
`wireServer`	`HostEndpointSettings`	Not applicable	Settings for the WireServer endpoint. See Configuration for each metadata service later in this article.
`keyIncarnationId`	`Integer`	`0`	A counter for key generation. Increasing this value instructs MSP to reset the key used for securing a communication channel between guest and host. The GPA notices the key reset and automatically acquires a new one. This property is only for recovery and troubleshooting purposes.

Configuration for each metadata service

You can configure individual protections for each metadata service. The schema is the same for each service.

Inline and linked configurations are mutually exclusive on a per-service basis.

Inline configuration

You can define an inline configuration by using the `mode` property of `HostEndpointSettings`. Inline configurations don't support customization.

In the following table, `mode` is an enumeration that's expressed as `String`.

Expand table

`mode` value	GPA behavior	Service behavior
`Disabled`	The GPA doesn't set up eBPF interception of requests to this service. Requests go directly to the service.	Unchanged. The service does *not* require the GPA to endorse (sign) requests.
`Audit`	The GPA intercepts requests to this service and determines if the current configuration authorizes them. The request is always forwarded to the service, but the result and caller information are logged.	Unchanged. The service does *not* require the GPA to endorse (sign) requests.
`Enforce`	The GPA intercepts requests to this service and determines if the current configuration authorizes them. If the caller is authorized, the GPA signs the request to endorse it. If the caller isn't authorized, the GPA responds with status code `401` or `403`. All outcomes are recorded in the audit log.	The GPA *must* endorse (sign) requests to the service. Unsigned requests are rejected with a `401` status code.

> **Important**
>
> You can't use this property at the same time as `inVMAccessControlProfileReferenceId`.

In WireServer `Enforce` mode, the GPA implicitly requires that a process runs as `Administrator` or `root` to access WireServer. This requirement is equivalent to the in-guest firewall rule that exists even when MSP is disabled, but with a more secure implementation.

Linked configuration

The `inVMAccessControlProfiles` resource type defines a per-service configuration that can be linked against a VM or virtual machine scale set. These configurations support full

customizations. For full details, see Advanced configuration for MSP.

Expand table

`HostEndpointSettings` property	Type	Details
`inVMAccessControlProfileReferenceId`	`String`	The resource ID of the configuration to apply.

This property must be a full Resource Manager ID, which takes this form: `/subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Microsoft.Compute/galleries/{galleryName}/inVMAccessControlProfiles/{profile}/versions/{version}`.

> **Important**
>
> You can't use this property at the same time as `mode`.

Full example

- VM: `https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Compute/virtualMachines/{virtualMachine-Name}?api-version=2024-03-01`
- Virtual machine scale set: `https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Compute/virtualMachineScaleSets/{vmScaleSet-name}/virtualMachines/{instance-id}?api-version=2024-03-01`

The following example uses `mode`:

JSON

```
{
  "name": "GPAWinVM",
  "location": "centraluseuap",
  "properties": {
    ...
    ...
    "securityProfile": {
      "proxyAgentSettings": {
        "enabled": true,
        "wireServer": {
          "mode": "Enforce"
        },
        "imds": {
```

```
            "mode": "Audit"
          }
        }
      },
    }
}
```

The following example uses `inVMAccessControlProfileReferenceId:`

JSON

```
{
  "name": "GPAWinVM",
  "location": "centraluseuap",
  "properties": {
    ...
    ...
    "securityProfile": {
      "proxyAgentSettings": {
        "enabled": true,
        "wireServer": {
          "inVMAccessControlProfileReferenceId":
"/subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Micr
osoft.Compute/galleries/{galleryName}/inVMAccessControlProfiles/{profile}/versions
/{version}"
        },
        "imds": {
          "inVMAccessControlProfileReferenceId":
"/subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Micr
osoft.Compute/galleries/{galleryName}/inVMAccessControlProfiles/{profile}/versions
/{version}"
        }
      },
    }
}
```

Audit logs

In `Audit` and `Enforce` modes, audit logs are generated on the local disk.

Expand table

OS family	Audit log location
Linux	`/var/lib/azure-proxy-agent/ProxyAgent.Connection.log`
Windows	`C:\WindowsAzure\ProxyAgent\Logs\ProxyAgent.Connection.log`

Recommended progression

Customers often aren't aware of the full extent of WireServer and Instance Metadata Service usage in their workload. Your VM's usage is a combination of any custom integrations that you create and the implementation details of any other software that you run. We recommend starting with a simpler configuration and iterating over time as you gain more information. In general, it's best to go in this order:

1. Enable MSP for WireServer and Instance Metadata Service, in `Audit` mode. This step enables you to confirm compatibility and learn more about your workload. It also generates valuable data for detecting threat actors.
2. Review the audit data. Pay close attention to any flagged requests. These requests might be signs of an ongoing attack or a workload incompatibility.
3. Remediate any problems. Under the default setup, anything that's flagged is a misuse of the metadata services. Contact your security team or the corresponding service owners as needed.
4. Switch from `Audit` mode to `Enforce` mode. Flagged requests are rejected to help protect your workload.
5. Experiment with advanced configuration. The default configuration mirrors pre-MSP security rules, which are often overly permissive. Defining a custom configuration for your workload enables you to further enhance security by applying the principle of least-privileged access.

Don't worry about following a perfect progression. *Any* level of MSP enablement greatly improves your security and helps protect against most real-world attacks.

Deploy a VM or virtual machine scale set with MSP

10/08/2025

This article explains how to enable the Metadata Security Protocol (MSP) feature while provisioning a new virtual machine (VM) or virtual machine scale set.

> ⚠ **Warning**
>
> Please note that on Windows, the users can enable GuestProxyAgent (GPA) from an ARM template. However, in Linux it's a two-step process. The VM/VMSS is provisioned first and only then can the GPA be configured.

Prerequisites

- Ensure that your image of choice is compatible.
- Familiarize yourself with the basic configuration options.

Deploy a VM with MSP

Use an ARM template

To deploy a VM with MSP via an Azure Resource Manager template (ARM template), update `proxyAgentSettings` and ensure that the minimum API version is `2024-03-01`. See the ARM template examples.

Use the REST API

To use the REST API, deploy a VM as you normally would, but with the MSP configuration also applied. Here's an example that references a linked advanced configuration:

HTTP

```
https://management.azure.com/subscriptions/{subscription-
id}/resourceGroups/{resource-group-
name}/providers/Microsoft.Compute/virtualMachines/{virtualMachine-Name}?api-
version=2024-03-01

{
  "name": "GPAWinVM",
```

```
  "location": "centraluseuap",
  "properties": {
    ...
    ...
    "securityProfile": {
      "proxyAgentSettings": {
        "enabled": true,
        "keyIncarnationId": 0,
        "wireServer": {
          "inVMAccessControlProfileReferenceId":
"/subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Micr
osoft.Compute/galleries/{galleryName}/inVMAccessControlProfiles/{wireServerProfile
Name}/versions/{version}"
        },
        "imds": {
          "inVMAccessControlProfileReferenceId":
"/subscriptions/{SubscriptionId}/resourceGroups/{ResourceGroupName}/providers/Micr
osoft.Compute/galleries/{galleryName}/inVMAccessControlProfiles/{imdsProfileName}/
versions/{version}"
        }
      }
    },
  }
}
```

Validate linked rules

After you deploy the VM, validate that the linked rules were applied to your VM. The steps for this validation in a newly provisioned VM are the same as the steps for an existing VM.

Deploy a virtual machine scale set with MSP

Using the same steps for a virtual machine scale set applies MSP to every VM within that scale set.

Enable MSP on an existing VM or virtual machine scale set

09/18/2025

This article explains the ways that you can enable Metadata Security Protocol (MSP) on an existing virtual machine (VM) or virtual machine scale set. You can enable MSP on a VM by using the Azure portal, an Azure Resource Manager template (ARM template), or the REST API.

Prerequisites

- Ensure that your image of choice is compatible.
- Familiarize yourself with the basic configuration options.

Enable MSP on a VM

Use the Azure portal

See Configure MSP via the portal.

Use an ARM template

See examples

With REST API

Enable MSP with both WireServer and Azure Instance Metadata Service protected in `Audit` mode:

HTTP

```
PATCH https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Compute/virtualMachines/{virtualMachine-Name}?api-version=2024-03-01

{
  "properties": {
    "securityProfile": {
      "proxyAgentSettings": {
        "enabled": true,
        "wireServer": {
```

```
          "mode": "Audit"
        },
        "imds": {
          "mode": "Audit"
        }
      }
    },
  }
}
```

For Windows VMs, if `ProxyAgentSettings.Enabled` is `true`, the `Microsoft.CPlat.ProxyAgent.ProxyAgentWindows` extension is installed by default.

For Linux VMs, setting `ProxyAgentSettings.Enabled` to `true` doesn't implicitly install the Proxy Agent extension. To enable the Proxy Agent through the Proxy Agent extension, there must be an explicit `PUT` REST API call on the `Microsoft.CPlat.ProxyAgent.ProxyAgentLinux` extension. The purpose of the Proxy Agent extension is to enable, automatically update, and report the status of the Proxy Agent.

Validate linked rules

To validate that the linked rules were applied to your VM, check the VM instance view to confirm the status of the `Microsoft.CPlat.ProxyAgent.ProxyAgentWindows` extension for Windows and the `Microsoft.CPlat.ProxyAgent.ProxyAgentLinux` extension for Linux.

The `ComponentStatus/ProxyAgentStatus/succeeded` status should have an `imdsRuleId` value and a `wireServerRuleId` value. These values should map to the reference ID of `InVMAccessControlProfile`.

JSON

```
"extensions": [
    {
      "name": "AzureGuestProxyAgentExtension",

          "time": "2024-09-24T16:42:59+00:00"
        }
      ]
    }
```

Enable MSP on a virtual machine scale set

The preceding steps for enabling MSP on a VM also apply to a virtual machine scale set.

Configure MSP via the portal

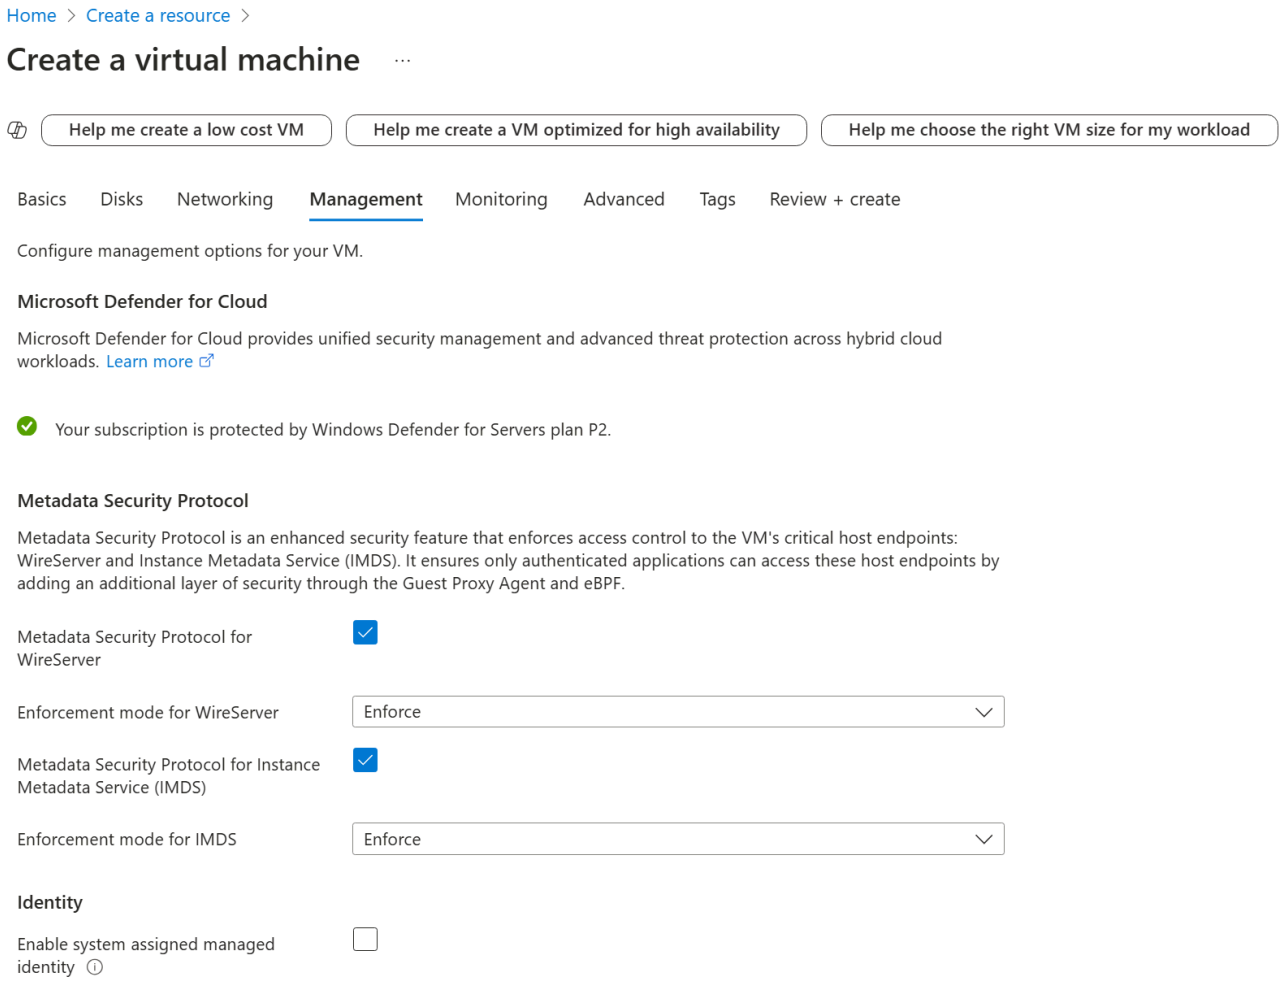
06/19/2025

Azure portal has preview support for configuring some aspects of Metadata Security Protocol (MSP).

> **Note**
>
> Currently, the portal is available only for subscriptions registered with the `Microsoft.Compute/ProxyAgentPreview` Azure Feature Exposure Control (AFEC) flag.

Deploy a VM with MSP

On the **Create a virtual machine** pane, make selections in the **Metadata Security Protocol** area.

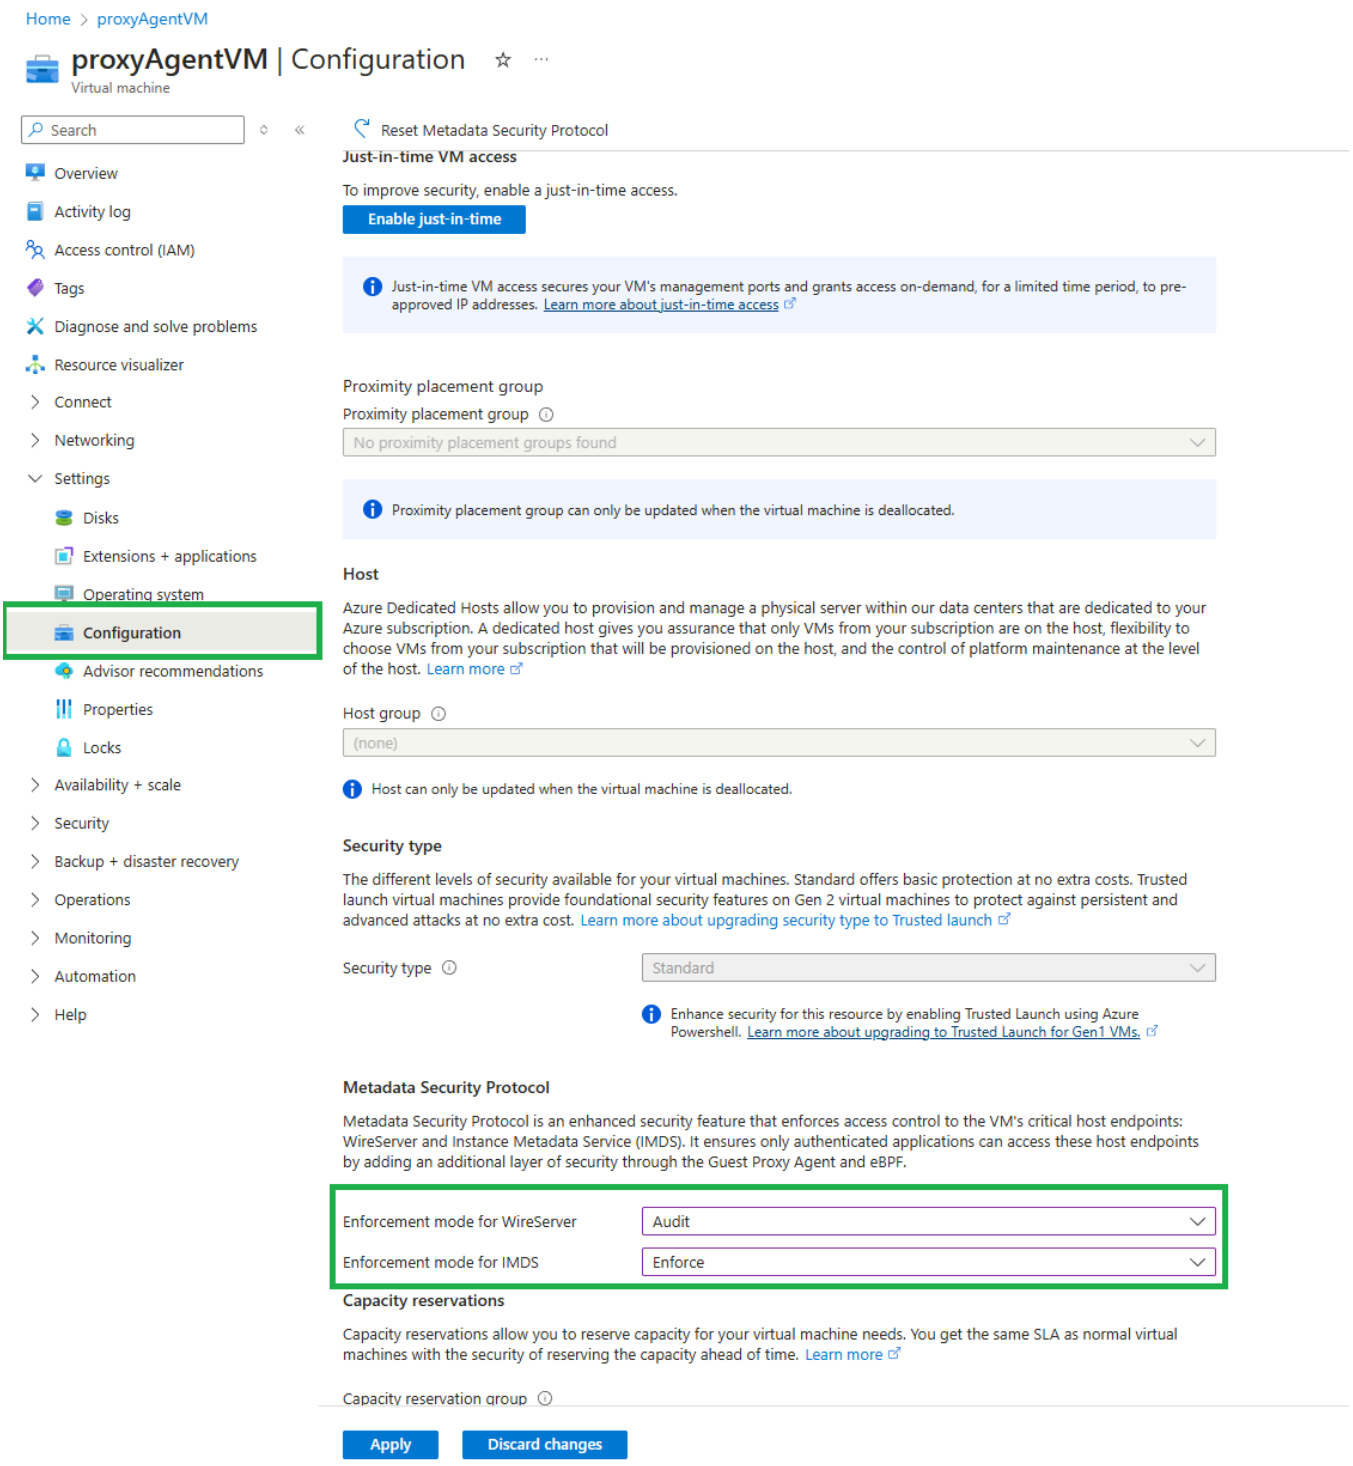


> **Note**

The portal currently supports only inline/basic configuration.

Enable MSP on an existing VM

Go to your virtual machine, and then go to **Settings** > **Configuration**. Make your selections in the **Metadata Security Protocol** area.



Disable MSP

05/29/2025

You can disable Metadata Security Protocol (MSP) by using the REST API and (partially) by using the Azure portal.

REST API

Set `securityProfile.proxyAgentSettings.enabled` to `false`:

HTTP

```
PATCH https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Compute/virtualMachines/{virtualMachine-Name}?api-version=2024-03-01
{
  "properties": {
    "securityProfile": {
      "proxyAgentSettings": {
        "enabled": false,
      }
    },
  }
}
```

Azure portal

The portal doesn't allow disabling MSP completely at this time. But you can disable enforcement of security requirements to allow requests to flow normally.

Go to your virtual machine, and then go to **Settings** > **Configuration**. In the **Metadata Security Protocol** area, in the boxes for enforcement mode, select **Disabled**.

Reset Metadata Security Protocol

Just-in-time VM access secures your VM's management ports and grants access on-demand, for a limited time period, to pre-approved IP addresses. Learn more about just-in-time access

Proximity placement group

Proximity placement group

No proximity placement groups found

Proximity placement group can only be updated when the virtual machine is deallocated.

Host

Azure Dedicated Hosts allow you to provision and manage a physical server within our data centers that are dedicated to your Azure subscription. A dedicated host gives you assurance that only VMs from your subscription are on the host, flexibility to choose VMs from your subscription that will be provisioned on the host, and the control of platform maintenance at the level of the host. Learn more

Host group

(none)

Host can only be updated when the virtual machine is deallocated.

Security type

The different levels of security available for your virtual machines. Standard offers basic protection at no extra costs. Trusted launch virtual machines provide foundational security features on Gen 2 virtual machines to protect against persistent and advanced attacks at no extra cost. Learn more about upgrading security type to Trusted launch

Security type: Standard

Enhance security for this resource by enabling Trusted Launch using Azure Powershell. Learn more about upgrading to Trusted Launch for Gen1 VMs.

Metadata Security Protocol

Metadata Security Protocol is an enhanced security feature that enforces access control to the VM's critical host endpoints: WireServer and Instance Metadata Service (IMDS). It ensures only authenticated applications can access these host endpoints by adding an additional layer of security through the Guest Proxy Agent and eBPF.

Enforcement mode for WireServer: Disabled

Select enforce mode to enforce the access control

Enforcement mode for IMDS: Disabled

Select enforce mode to enforce the access control

Capacity reservations

Capacity reservations allow you to reserve capacity for your virtual machine needs. You get the same SLA as normal virtual

Reset a latched key

05/29/2025

If a virtual machine (VM) loses its copy of the latched key, a disk is migrated to a new VM. If any other key mismatch occurs, the VM can't access WireServer or Azure Instance Metadata Service. Resetting the key brings the VM back to a healthy state if the key is lost or unmatched between host and guest.

> **Note**
>
> The VM owner must request the key reset. Metadata services can't distinguish between an attacker or the Guest Proxy Agent requesting a reset when the key is lost, so resets can't be issued from within the VM.

Reset a VM's key

The platform always ensures that the `keyIncarnationId` value in the VM model matches the actual key in storage. Incrementing this value triggers a key reset. For more information, see MSP feature configuration.

HTTP

```
PATCH
https://management.azure.com/subscriptions/{subscription_id}/resourceGroups/{resou
rce_group_name}/providers/Microsoft.Compute/virtualMachines/{virtualMachine_Name}?
api-version=2024-03-01
{
  "properties": {
    "securityProfile": {
      "proxyAgentSettings": {
        "keyIncarnationId": 10
      }
    }
  }
}
```

Confirm the reset

Check the `AzureProxyAgentExtension` value of the VM instance view to confirm that the new key is generated. Your new `keyIncarnationId` value appears after the change propagates end to end.

JSON

```
"keyLatchStatus":{
    "status":"RUNNING",
    "message":"Found key details from local and ready to use. - 122",
    "states":{

"imdsRuleId":"/SUBSCRIPTIONS/{subscription_id}/RESOURCEGROUPS/{resource_group}/PRO
VIDERS/MICROSOFT.COMPUTE/GALLERIES/GALLERYXX/INVMACCESSCONTROLPROFILES/WINDOWSIMDS
/VERSIONS/{data_version}",
        "secureChannelState":"WireServer Enforce - IMDS Enforce",
        "keyIncarnationId":"10",
        "keyGuid":"e3882f98-da8d-4410-8394-06c23462781c",

"wireServerRuleId":"/SUBSCRIPTIONS/{subscription_id}/RESOURCEGROUPS/{resource_grou
p}/PROVIDERS/MICROSOFT.COMPUTE/GALLERIES/GALLERYXX/INVMACCESSCONTROLPROFILES/WINDO
WSWIRESERVER/VERSIONS/{data_version}"
        }
    }
```

> **Note**
>
> These requests are idempotent. However, if multiple requests are made with multiple `keyIncarnationId` values, there's no guarantee on the number and order of `keyIncarnationId` values that you observe. The final state reflects whichever request used the largest value.

Reset a virtual machine scale set's key

Key data is unique for each instance in a virtual machine scale set. The key must be reset on a per-instance basis.

You can reset a key only for a particular scale set's VM instance. You can't reset a key for all the scale set instances in a single API.

See the earlier instructions for resetting a VM's key, and substitute in your scale set instance's resource ID. For example:

`https://management.azure.com/subscriptions/{subscription_id}/resourceGroups/{resource_group_name}/providers/Microsoft.Compute/virtualMachineScaleSets/{vmScaleSet_name}/virtualMachines/{instance_id}?api-version=2024-03-01`

Convert audit logs to an allowlist

09/18/2025

With Metadata Security Protocol (MSP), you can define a custom role-based access control (RBAC) allowlist to help secure metadata service endpoints. The contents of the allowlist come from audit logs. A new resource type in Azure Compute Gallery, `InVMAccessControlProfile`, enables the allowlist.

To learn more about RBAC and the `InVMAccessControlProfile` resource type, see Advanced configuration for MSP.

Structure of an allowlist

An allowlist consists of:

- **Identities**: Processes on the machine.
- **Privileges**: Endpoints that the identities access.
- **Roles**: A grouping of privileges.
- **Role assignments**: Roles and the list of identities granted access for those roles.

Collect audit logs

If you enable MSP in `audit` or `enforce` mode, you can collect log data from virtual machine client via Azure Monitor.

- Windows: Azure monitoring agent collects Windows Events via Custom XPath `Windows Azure!*[System[Provider[@Name=`GuestProxyAgent`]]]`
- Linux: Collect Syslog events with Azure Monitor Agent by selecting `Log_DAEMON` and `LOG_DEBUG`

Query audit logs

Once the audit logs are collected as explained in the previous section, you can verify the logs:

Windows Kusto Query: Go to Log Analytics and run query

```
Kusto
```

```
/// Windows VMs
Event
| where TimeGenerated >ago(1d)
| where EventLog == "Windows Azure" and Source == "GuestProxyAgent"
| where _ResourceId startswith "/subscriptions/<your subscription
id>/resourcegroups/<your recrouce group>"
| where RenderedDescription  has  "processFullPath" and RenderedDescription  has
"runAsElevated" and RenderedDescription has "processCmdLine"
| extend json = parse_json(RenderedDescription)
| extend method = json.method, url = json.url, processFullPath =
json.processFullPath, username = json.userName, runAsElevated = json.runAsElevated
| extend userGroups = json.userGroups, ip = json.ip, port = json.port,
processCmdLine = json.processCmdLine
| project TimeGenerated, _ResourceId, url, ip, port, processFullPath, method,
username, runAsElevated, processCmdLine
```

Linux Kusto Query: Go to Log Analytics and run query

Kusto

```
/// Linux VMs
Syslog
| where TimeGenerated >ago(1d)
| where  ProcessName == "azure-proxy-agent"
| where _ResourceId startswith "/subscriptions/<your subscription
id>/resourcegroups/<your recrouce group>"
| where SyslogMessage  has  "processFullPath" and SyslogMessage  has
"runAsElevated" and SyslogMessage has "processCmdLine"
| extend message = substring(SyslogMessage, indexof(SyslogMessage, "{"))
| extend json = parse_json(message)
| extend method = json.method, url = json.url, processFullPath =
json.processFullPath, username = json.userName, runAsElevated = json.runAsElevated
| extend userGroups = json.userGroups, ip = json.ip, port = json.port,
processCmdLine = json.processCmdLine
| project TimeGenerated, _ResourceId, url, ip, port, processFullPath, method,
username, runAsElevated, processCmdLine
```

If you own the Azure VM, you can get the file logs inside the Azure VM by following these steps

1. Find the Proxy Agent json config file:
    - Windows VM: `GuestProxyAgent.json` under the folder as `GuestProxyAgent windows service`
    - Linux VM: `etc/azure/proxy-agent.json` file
2. Turn on the file log by updating setting `logFolder` in the json config file. Set it to

- `%SYSTEMDRIVE%\\WindowsAzure\\ProxyAgent\\Logs` for Windows VMs
- `/var/log/azure-proxy-agent` for Linux VMs.

3. Restart Service

- `GuestProxyAgent` for Windows VMs
- `azure-proxy-agent` for Linux VMs4

4. Wait for `ProxyAgent.Connection.log` to populate while customer services is running.
5. Pull the ProxyAgent connection file logs from the Azure VMs

    - Windows: `C:\WindowsAzure\ProxyAgent\Logs\ProxyAgent.Connection.log`
    - Linux: `/var/log/azure-proxy-agent/ProxyAgent.Connection.log`

Convert logs to rules

To create an allowlist, you can use an automated method or a manual method.

Generate an allowlist automatically

You can use an allowlist generator tool to generate the access control rules. The tool helps parse the audit logs and provides a UI to generate the rules.

1. Download and run the allowlist generator tool. On the latest release page, under **Assets**, select `allowListTool.exe`.

    The tool parses the `ProxyAgentConnection` logs and displays the current privileges and identities on the VM.

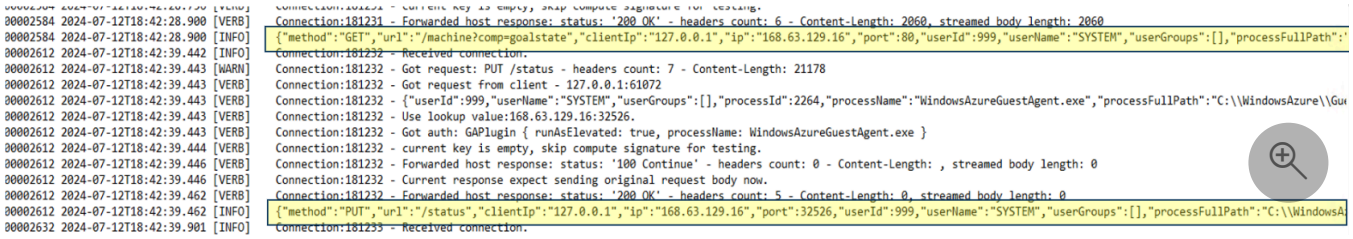
2. Create roles and role assignments:

    - To create a role, select a grouping of privileges and give the role a descriptive name.
    - To create a role assignment, select a role and a grouping of identities. These identities can access the privileges grouped in that role. Give the role assignment a descriptive name.

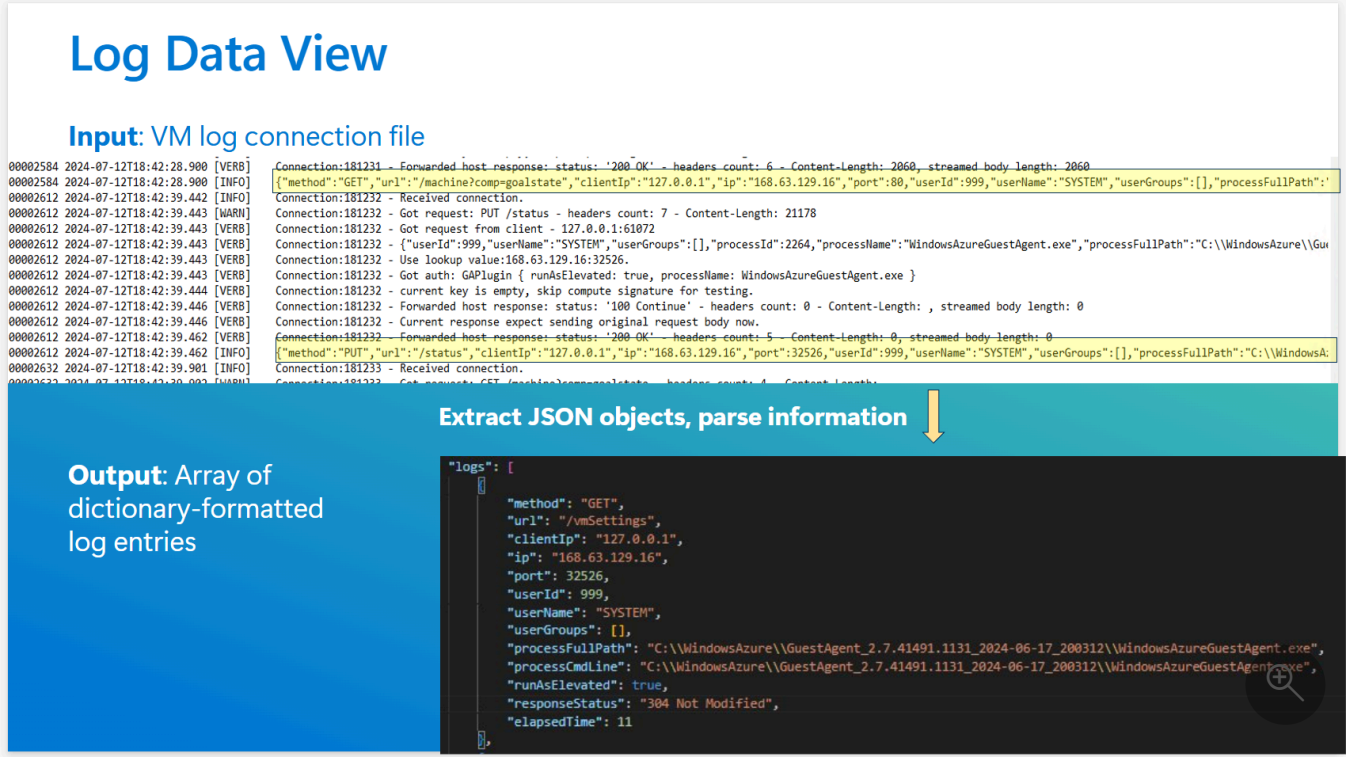
Manually create an allowlist

After you enable a VM with MSP in `Audit` or `Enforce` mode, the proxy agent captures all the requests being made to the host endpoints.

In the connection logs, you can analyze the applications that are making the requests to the Azure Instance Metadata Service or WireServer endpoints.

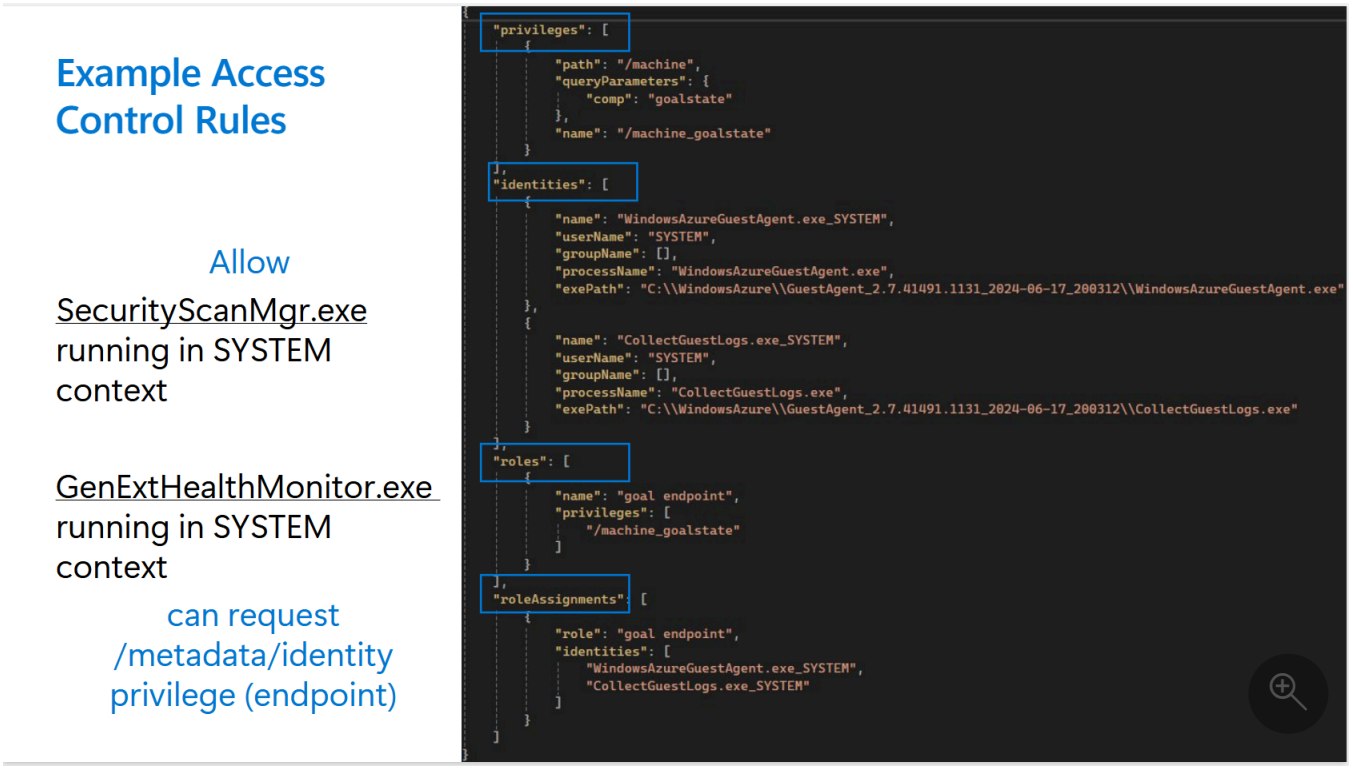


The following example shows the format of the captured JSON.



In the log file, you can identify the endpoints that you want to secure. These endpoints appear in `privileges` in the final `InVMAccessControlProfile` instance. You can also identify the identities (`identities`) that should have access.

A simple rules schema might look like the following example.



Create an InVMAccessControlProfile instance by using an ARM template

1. Create a new private gallery in Azure Compute Gallery.
2. Create an `InVMAccessControlProfile` definition with parameters for:
    - Gallery name to store in (from step 1)
    - Profile name
    - OS type
    - Host endpoint type (WireServer or Instance Metadata Service)
3. Create a specific version.

Sample InVMAccessControlProfile

Here's a sample `InVMAccessControlProfile` instance:

```
"properties": {
    "mode": "Enforce",
    "defaultAccess": "Allow",
    "rules": {
      "privileges": [
        {
```

```
      "name": "GoalState",
      "path": "/machine",
      "queryParameters": {
        "comp": "goalstate"
      }
    }
  ],
  "roles": [
    {
      "name": "Provisioning",
      "privileges": [
        "GoalState"
      ]
    },
    {
      "name": "ManageGuestExtensions",
      "privileges": [
        "GoalState"
      ]
    },
    {
      "name": "MonitoringAndSecret",
      "privileges": [
        "GoalState"
      ]
    }
  ],
  "identities": [
    {
      "name": "WinPA",
      "userName": "SYSTEM",
      "exePath": "C:\\Windows\\System32\\cscript.exe"
    },
    {
      "name": "GuestAgent",
      "userName": "SYSTEM",
      "processName": "WindowsAzureGuestAgent.exe"
    },
    {
      "name": "WaAppAgent",
      "userName": "SYSTEM",
      "processName": "WaAppAgent.exe"
    },
    {
      "name": "CollectGuestLogs",
      "userName": "SYSTEM",
      "processName": "CollectGuestLogs.exe"
    },
    {
      "name": "AzureProfileExtension",
      "userName": "SYSTEM",
      "processName": "AzureProfileExtension.exe"
    },
    {
      "name": "AzurePerfCollectorExtension",
```

```
          "userName": "SYSTEM",
          "processName": "AzurePerfCollectorExtension.exe"
        },
        {
          "name": "WaSecAgentProv",
          "userName": "SYSTEM",
          "processName": "WaSecAgentProv.exe"
        }
      ],
      "roleAssignments": [
        {
          "role": "Provisioning",
          "identities": [
            "WinPA"
          ]
        },
        {
          "role": "ManageGuestExtensions",
          "identities": [
            "GuestAgent",
            "WaAppAgent",
            "CollectGuestLogs"
          ]
        },
        {
          "role": "MonitoringAndSecret",
          "identities": [
            "AzureProfileExtension",
            "AzurePerfCollectorExtension",
            "WaSecAgentProv"
          ]
        }
      ]
    },
```

Using PowerShell

If you're using PowerShell to generate an `InVMAccessControlProfile`, ensure that you have the minimum version of 10.1.0 of PowerShell

Follow the step-by-step guide below to generate an `InVMAccessControlProfile`:

1. Log in to your Azure Account

PowerShell

```
Connect-AzAccount
```

2. Create the Resource Group where the private gallery is created. You can skip this step if you already have a Resource Group created.

PowerShell

```
$resourceGroup = "MyResourceGroup4"
$location = "EastUS2EUAP"
New-AzResourceGroup -Name $resourceGroup -Location $location
```

3. Create a private gallery. This gallery is used as a container for the `InVMAccessControlProfile` artifact

PowerShell

```
$galleryName = "MyGallery4"
New-AzGallery -ResourceGroupName $resourceGroup -GalleryName $galleryName -
Location $location -Description "My custom image gallery"
```

4. Create the `InVMAccessControlProfile` artifact in the private gallery created in the previous step. Click here to learn more about the various parameters for this artifact.

PowerShell

```
$InVMAccessControlProfileName= "testInVMAccessControlProfileP"

New-AzGalleryInVMAccessControlProfile -ResourceGroupName  $resourceGroup  -
GalleryName $galleryName   -GalleryInVMAccessControlProfileName
$InVMAccessControlProfileName -Location $location -OsType "Windows" -
ApplicableHostEndPoint "WireServer" -Description "this test1"
```

5. Get Gallery `InVMAccessControlProfile`

PowerShell

```
$inVMAccessCP=Get-AzGalleryInVMAccessControlProfile -ResourceGroupName
$resourceGroup  -GalleryName $galleryName   -GalleryInVMAccessControlProfileName
$InVMAccessControlProfileName
```

![Screenshot of the output for Get command for InVMAccessControlProfile.](../images/

6. Update Gallery `InVMAccessControlProfile` Once the `InVMAccessControlProfile` is created, the only attribute editable is the description. For any other changes, create a new artifact.

To update the description:

PowerShell

```
Update-AzGalleryInVMAccessControlProfile -ResourceGroupName  $resourceGroup  -
GalleryName $galleryName   -GalleryInVMAccessControlProfileName
```

```
$InVMAccessControlProfileName -Location $location -Description "this test2"
```

```
PS C:\Users\       > $inVMAccessCP=Get-AzGalleryInVMAccessControlProfile -ResourceGroupName  $resourceGroup  -GalleryNam
e $galleryName   -GalleryInVMAccessControlProfileName $InVMAccessControlProfileName
PS C:\Users\       > $inVMAccessCP | ConvertTo-Json -Depth 10
{
  "Id": "/subscriptions/                                    /resourceGroups/MyResourceGroup4/providers/Microsoft.Compute
/galleries/MyGallery4/inVMAccessControlProfiles/testInVMAccessControlProfileP",
  "Name": "testInVMAccessControlProfileP",
  "Type": "Microsoft.Compute/galleries/inVMAccessControlProfiles",
  "Location": "EastUS2EUAP",
  "Tags": {},
  "Properties": {
    "Description": "this test2",
    "OsType": "Windows",
    "ApplicableHostEndpoint": "WireServer",
    "ProvisioningState": "Succeeded"
  }
}
```

7. Create `InVMAccessControlProfileVersion`

To create an InVMAccessControlProfileVersion, a payload is required. Since these payloads can be large, especially due to the rules property, it's not practical to use a single PowerShell command to create the entire resource in one go. The rules property in any version payload consists of four arrays: privileges, roles, identities, and roleAssignments. These arrays can make the payload large and complex. To simplify this process, we introduced the GalleryInVMAccessControlProfileVersionConfig PowerShell object. You can learn more about it here.

This object allows you to incrementally build the configuration using various commands to add or remove rule properties. Once the configuration object is ready, you can use it to create an `InVMAccessControlProfileVersion`, described in the upcoming sections.

Alternatively, if you already have the rules property as a JSON string and prefer not to use the configuration object, you can skip these steps and create the InVMAccessControlProfileVersion using an ARM template deployment, which is also covered later in the section.

Payload for reference:

JSON

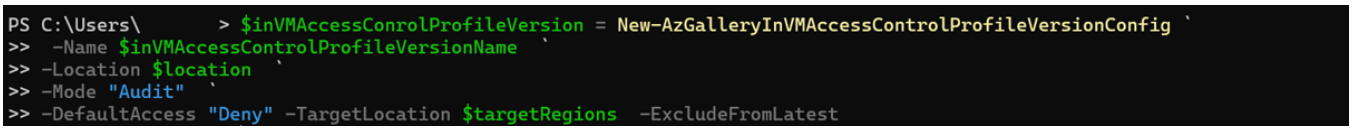
```
{
  "name": "1.0.0",
  "location": "East US 2 EUAP",
  "properties": {
    "mode": "Audit",
    "defaultAccess": "Deny",
    "rules": {
      "privileges": [
        {
          "name": "GoalState",
          "path": "/machine",
          "queryParameters": {
            "comp": "goalstate"
          }
```

```
        }
      ],
      "roles": [
        {
          "name": "Provisioning",
          "privileges": [
            "GoalState"
          ]
        }
      ],
      "identities": [
        {
          "name": "WinPA",
          "userName": "SYSTEM",
          "groupName": "Administrators",
          "exePath": "C:\\Windows\\System32\\cscript.exe",
          "processName": "cscript"
        }
      ],
      "roleAssignments": [
        {
          "role": "Provisioning",
          "identities": [
            "WinPA"
          ]
        }
      ]
    },
    "targetLocations": [
      {
        "name": "East US 2 EUAP"
      }
    ],
    "excludeFromLatest": false
  }
}
```

8. Create `InVMAccessControlProfileVersion` Config

PowerShell

```
$inVMAccessControlProfileVersionName= "1.0.0"
$targetRegions= @("EastUS2EUAP", "CentralUSEUAP")
$inVMAccessConrolProfileVersion = New-
AzGalleryInVMAccessControlProfileVersionConfig `
 -Name $inVMAccessControlProfileVersionName  `
-Location $location  `
-Mode "Audit"  `
-DefaultAccess "Deny" -TargetLocation $targetRegions  -ExcludeFromLatest
```



Run this command to add each privilege:

PowerShell

```
Add-AzGalleryInVMAccessControlProfileVersionRulesPrivilege `
  -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
  -PrivilegeName "GoalState" `
  -Path "/machine" `
  -QueryParameter @{ comp = "goalstate" }
```

To remove a privilege:

PowerShell

```
Remove-AzGalleryInVMAccessControlProfileVersionRulesPrivilege `
 -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
 -PrivilegeName "GoalState2"
```

Run this command to add each role:

PowerShell

```
Add-AzGalleryInVMAccessControlProfileVersionRulesRole `
 -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
 -RoleName "Provisioning" `
 -Privilege @("GoalState")
```

Run this command to remove roles:

PowerShell

```
Remove-AzGalleryInVMAccessControlProfileVersionRulesRole `
 -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
 -RoleName "Provisioning2"
```

Add `RulesIdentity`:

PowerShell

```
Add-AzGalleryInVMAccessControlProfileVersionRulesIdentity `
  -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
  -IdentityName "WinPA" `
  -UserName "SYSTEM" `
```

```
  -GroupName "Administrators" `
  -ExePath "C:\Windows\System32\cscript.exe" `
  -ProcessName "cscript"
```

Remove `RulesIdentity`:

PowerShell

```
Remove-AzGalleryInVMAccessControlProfileVersionRulesIdentity `
  -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
  -IdentityName "WinPA2"
```

Run this command to add each Role Assignment:

PowerShell

```
Add-AzGalleryInVMAccessControlProfileVersionRulesRoleAssignment `
  -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
  -Role "Provisioning" `
  -Identity @("WinPA")
```

Remove Role Assignment:

PowerShell

```
Remove-AzGalleryInVMAccessControlProfileVersionRulesRoleAssignment `
  -GalleryInVmAccessControlProfileVersion $inVMAccessConrolProfileVersion `
  -Role "Provisioning2"
```

9. Create Gallery `InVMAccessControlProfileVersion`

PowerShell

```
New-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName $resourceGroup -
GalleryName $galleryName -GalleryInVMAccessControlProfileName
$InVMAccessControlProfileName   -GalleryInVmAccessControlProfileVersion
$inVMAccessConrolProfileVersion
```

```
PS C:\myWorkingDirectory\MSPGallery_v1> New-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName $resourceGroup -
GalleryName $galleryName -GalleryInVMAccessControlProfileName   $InVMAccessControlProfileName   -GalleryInVmAccessContro
lProfileVersion $inVMAccessConrolProfileVersion

Id                : /subscriptions/                                    /resourceGroups/MyResourceGroup/providers/Micros
                    oft.Compute/galleries/MyGallery/inVMAccessControlProfiles/testInVMAccessControlProfileP/versions/1.
                    0.0
Name              : 1.0.0
Type              : Microsoft.Compute/galleries/inVMAccessControlProfiles
Location          : EastUS2EUAP
Tags              : {}
TargetLocations   : {eastus2euap, centraluseuap}
ExcludeFromLatest : False
PublishedDate     : 19-06-2025 18:20:10
ProvisioningState : Succeeded
ReplicationStatus : Microsoft.Azure.Management.Compute.Models.ReplicationStatus
Mode              : Audit
DefaultAccess     : Deny
Rules             : Microsoft.Azure.Management.Compute.Models.AccessControlRules
```

10. Get `InVMAccessControlProfileVersion`

PowerShell

```
$ver = Get-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName
$resourceGroup -GalleryName $galleryName -GalleryInVMAccessControlProfileName
$InVMAccessControlProfileName `
 -GalleryInVMAccessControlProfileVersionName  $inVMAccessControlProfileVersionName
 $ver | ConvertTo-Json -Depth 10
```

11. Update `InVMAccessControlProfileVersion`

It's recommended to create a new `InVMAccessControlProfileVersion` since most parameters can't be updated. Here's an example:

PowerShell

```
$targetRegions= @("EastUS2EUAP")

$ver = Get-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName
$resourceGroup -GalleryName $galleryName -GalleryInVMAccessControlProfileName
$InVMAccessControlProfileName `
 -GalleryInVMAccessControlProfileVersionName  $inVMAccessControlProfileVersionName

Update-AzGalleryInVMAccessControlProfileVersion `
  -GalleryInVmAccessControlProfileVersion $ver `
-TargetLocation $targetRegions -ExcludeFromLatest $true
```

```
PS C:\Users\       > Update-AzGalleryInVMAccessControlProfileVersion `
>>   -GalleryInVmAccessControlProfileVersion $ver `
>> -TargetLocation $targetRegions -ExcludeFromLatest $true

Id                : /subscriptions/                                    /resourceGroups/MyResourceGroup4/providers/Mic
                    rosoft.Compute/galleries/MyGallery4/inVMAccessControlProfiles/testInVMAccessControlProfileP/versi
                    ons/1.0.0
Name              : 1.0.0
Type              : Microsoft.Compute/galleries/inVMAccessControlProfiles
Location          : EastUS2EUAP
Tags              : {}
TargetLocations   : {eastus2euap}
ExcludeFromLatest : True
PublishedDate     : 11-07-2025 06:00:12
ProvisioningState : Succeeded
ReplicationStatus : Microsoft.Azure.Management.Compute.Models.ReplicationStatus
Mode              : Audit
DefaultAccess     : Deny
Rules             :
    Privileges    : Microsoft.Azure.Management.Compute.Models.AccessControlRulesPrivilege
    Roles         : Microsoft.Azure.Management.Compute.Models.AccessControlRulesRole
    Identities    : Microsoft.Azure.Management.Compute.Models.AccessControlRulesIdentity
    RoleAssignments : Microsoft.Azure.Management.Compute.Models.AccessControlRulesRoleAssignment

PS C:\Users\       > $ver = Get-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName $resourceGroup -GalleryName
```

12. Delete `InVMAccessControlProfileVersion`

PowerShell

```
Remove-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName $resourceGroup
-GalleryName $galleryName -GalleryInVMAccessControlProfileName
$InVMAccessControlProfileName `
 -GalleryInVMAccessControlProfileVersionName  $inVMAccessControlProfileVersionName
```

```
PS C:\Users\       > Remove-AzGalleryInVMAccessControlProfileVersion -ResourceGroupName $resourceGroup -GalleryName $gal
leryName -GalleryInVMAccessControlProfileName   $InVMAccessControlProfileName `
>>  -GalleryInVMAccessControlProfileVersionName  $inVMAccessControlProfileVersionName

Remove-AzGalleryInVMAccessControlProfileVersion operation
This cmdlet will remove the specified resource.  Do you want to continue?
[Y] Yes  [N] No  [S] Suspend  [?] Help (default is "Y"): y

13. List all gallery `InVMAccessControlProfile`

PowerShell

```
Get-AzGalleryInVMAccessControlProfile -ResourceGroupName "myResourceGroup" -
GalleryName "myGallery"
```

```
PS C:\myWorkingDirectory\MSPGallery_v2> Get-AzGalleryInVMAccessControlProfile -ResourceGroupName  $resourceGroup  -Galle
ryName $galleryName

Id         : /subscriptions/                                    /resourceGroups/MyResourceGroup2/providers/Microsoft.Co
             mpute/galleries/MyGallery2/inVMAccessControlProfiles/testInVM2
Name       : testInVM2

Type       : Microsoft.Compute/galleries/inVMAccessControlProfiles
Location   : EastUS2EUAP
Tags       : {}
Properties : Microsoft.Azure.Management.Compute.Models.GalleryInVMAccessControlProfileProperties
```

Using CLI

Follow the step-by-step guide below to generate an `InVMAccessControlProfile`:

1. Log in to your Azure Account

```cli
az login
```

2. Create a resource group in your desired location

```cli
az group create  --resource-group ResourceGroupForINVM  --location eastus
```

3. Create a gallery that will house the `InVMAccessControlProfile` resource

```cli
 az sig create --resource-group ResourceGroupForINVM --gallery-name MyGallery67 --
location eastus
```

3. Create an `InVMAccessControlProfile` under the gallery created in the prior step For additional details of commands: az sig in-vm-access-control-profile | Microsoft Learn

```cli
 az sig in-vm-access-control-profile create --resource-group ResourceGroupForINVM
--gallery-name MyGallery67 --name myInVMAccessControlProfileName --location eastus
--os-type Linux  --applicable-host-endpoint WireServer
```

Run this command to see additional details about the commands and properties

```cli
az sig in-vm-access-control-profile create --help
```

```
C:\Users\       >az sig in-vm-access-control-profile create --resource-group ResourceGroupForINVM --gallery-name MyGalle
ry67 --name myInVMAccessControlProfileName --location eastus --os-type Linux  --applicable-host-endpoint WireServer
{
  "id": "/subscriptions/                                  /resourceGroups/ResourceGroupForINVM/providers/Microsoft.Com
pute/galleries/MyGallery67/inVMAccessControlProfiles/myInVMAccessControlProfileName",
  "location": "eastus",
  "name": "myInVMAccessControlProfileName",
  "properties": {
    "applicableHostEndpoint": "WireServer",
    "osType": "Linux",
    "provisioningState": "Succeeded"
  },
  "resourceGroup": "ResourceGroupForINVM",
  "type": "Microsoft.Compute/galleries/inVMAccessControlProfiles"
}
```

4. Update the `InVMAccessControlProfile` You can only update the description of the `InVMAccessControlProfile`. If additional changes needed, delete the current `InVMAccessControlProfile` and create a new one

cli

```
az sig in-vm-access-control-profile update --resource-group ResourceGroupForINVM -
--gallery-name MyGallery67 --name myInVMAccessControlProfileName  --description
test
```

```
C:\Users\       >az sig in-vm-access-control-profile update --resource-group ResourceGroupForINVM --gallery-name MyGalle
ry67 --name myInVMAccessControlProfileName  --description test
{
  "id": "/subscriptions/                                  /resourceGroups/ResourceGroupForINVM/providers/Microsoft.Com
pute/galleries/MyGallery67/inVMAccessControlProfiles/myInVMAccessControlProfileName",
  "location": "eastus",
  "name": "myInVMAccessControlProfileName",
  "properties": {
    "applicableHostEndpoint": "WireServer",
    "description": "test",
    "osType": "Linux",
    "provisioningState": "Succeeded"
  },
  "resourceGroup": "ResourceGroupForINVM",
  "type": "Microsoft.Compute/galleries/inVMAccessControlProfiles"
}
```

5. Get operation for `InVMAccessControlProfile`

cli

```
az sig in-vm-access-control-profile show --resource-group ResourceGroupForINVM --
gallery-name MyGallery67 --name myInVMAccessControlProfileName
```

```
C:\Users\       >az sig in-vm-access-control-profile show --resource-group ResourceGroupForINVM --gallery-name MyGallery
67 --name myInVMAccessControlProfileName
{
  "id": "/subscriptions/                                  /resourceGroups/ResourceGroupForINVM/providers/Microsoft.Com
pute/galleries/MyGallery67/inVMAccessControlProfiles/myInVMAccessControlProfileName",
  "location": "eastus",
  "name": "myInVMAccessControlProfileName",
  "properties": {
    "applicableHostEndpoint": "WireServer",
    "description": "test",
    "osType": "Linux",
    "provisioningState": "Succeeded"
  },
  "resourceGroup": "ResourceGroupForINVM",
  "type": "Microsoft.Compute/galleries/inVMAccessControlProfiles"
}
```

6. List all `InVMAccessControlProfile` artifacts

This command shows the list of all `InVMAccessControlProfile` under a specific gallery

cli

```
az sig in-vm-access-control-profile show --resource-group ResourceGroupForINVM --
gallery-name MyGallery67
```

```
C:\myWorkingDirectory>az sig in-vm-access-control-profile list --resource-group ResourceGroupForINVM --gallery-name MyGa
llery67
[
  {
    "id": "/subscriptions/                                /resourceGroups/ResourceGroupForINVM/providers/Microsoft.C
ompute/galleries/MyGallery67/inVMAccessControlProfiles/myInVMAccessControlProfileName",
    "location": "eastus",
    "name": "myInVMAccessControlProfileName",
    "properties": {
      "applicableHostEndpoint": "WireServer",
      "description": "test",
      "osType": "Linux",
      "provisioningState": "Succeeded"
    },
    "resourceGroup": "ResourceGroupForINVM",
    "type": "Microsoft.Compute/galleries/inVMAccessControlProfiles"
  }
]
```

7. Create `InVMAccessControlProfileVersion`

You must provide a payload to create an `InVMAccessControlProfileVersion`. This payload can be large, especially because of the rule's property, which may contain extensive configurations. Instead of passing individual parts of the rules property directly, we've introduced a rules parameter that accepts a JSON file as an input. This approach simplifies the process and keeps the command clean and manageable. Here is an example rules.json file:

```
{
  "privileges": [
    {
      "name": "GoalState",
      "path": "/machine",
      "queryParameters": {
        "comp": "goalstate"
      }
    }
  ],
  "roles": [
    {
      "name": "Provisioning",
      "privileges": [
        "GoalState"
      ]
    }
  ],
  "identities": [
    {
      "name": "WinPA",
      "userName": "SYSTEM",
```

```
      "groupName": "Administrators",
      "exePath": "C:\\Windows\\System32\\cscript.exe",
      "processName": "cscript"
    }
  ],
  "roleAssignments": [
    {
      "role": "Provisioning",
      "identities": [
        "WinPA"
      ]
    }
  ]
}
```

See addtional command details here: az sig in-vm-access-control-profile-version | Microsoft Learn

Once you have create your version of rules.json file, use the following command to create the `InVMAccessControlProfileVersion`

cli

```
az sig in-vm-access-control-profile-version create \
  --resource-group ResourceGroupForINVM  \
  --gallery-name MyGallery67  \
  --profile-name myInVMAccessControlProfileName \
  --version-name 1.0.0 \
  --mode Audit \
  --default-access Deny  \
  --target-regions EastUS2EUAP  \
  --exclude-from-latest true \
  --rules @rules.json
```

8. Get `InVMAccessControlProfileVersion`

cli

```
az sig in-vm-access-control-profile-version show --resource-group
ResourceGroupForINVM --gallery-name MyGallery67 --profile-name
myInVMAccessControlProfileName --profile-version 1.0.0
```

9. List all `InVMAccessControlProfileVersion` artifacts

cli

```
az sig in-vm-access-control-profile-version list --resource-group
ResourceGroupForINVM --gallery-name MyGallery67 --profile-name
myInVMAccessControlProfileName
```

10. Delete `InVMAccessControlProfileVersion`

Before you delete any `InVMAccessControlProfileVersion` ensure it is not being used by any `InVMAccessControlProfile` on any Virtual Machine or Vitual Machine Scale Sets.

cli

```
az sig in-vm-access-control-profile-version delete --resource-group
ResourceGroupForINVM --gallery-name MyGallery67 --profile-name
myInVMAccessControlProfileName --profile-version 1.0.0
```

11. Delete `InVMAccessControlProfile`

cli

```
az sig in-vm-access-control-profile delete --resource-group ResourceGroupForINVM -
-gallery-name MyGallery67 --name myInVMAccessControlProfileName
```

Advanced configuration for MSP

05/29/2025

When you're working with Metadata Security Protocol (MSP), you can optionally define custom role-based access control (RBAC) allowlists for metadata service endpoints on a per-user and/or per-process basis. A new resource type in Azure Compute Gallery, `InVMAccessControlProfile`, enables these allowlists.

Motivation

Traditionally, metadata services treat the entire virtual machine (VM) as the trust boundary and allow any software running in the guest to access them. This access is overly permissive, especially if your workload isn't strictly implemented with a modern cloud-native architecture. Microsoft Security Response Center (MSRC) found that most security attacks can be prevented if organizations limit access to only the necessary software.

The `InVMAccessControlProfile` resource type enables you to define more granular control on the applications or users who can access the endpoints. You can use it to write rules like these examples:

- Only the Guest Proxy Agent (GPA) and SQL Server can access the network configuration.
- Only the monitoring extension can access tokens for managed identities.

The new resource type facilitates managing these configurations at scale. The rules that are appropriate for your VM depend on what software it's running. You can use `InVMAccessControlProfile` to define your configuration once and link it against all applicable VMs.

> **Note**
>
> We recommend treating these controls as *defense in depth* in your threat modeling. These controls can significantly enhance the security of a workload, but they're best used as extra protection instead of as core isolation mechanisms.
>
> In cloud-native multitenant workloads, especially if untrusted code is executed, hardware-backed or hypervisor-backed isolation provides greater protection. (For example, Azure Container Instances offers this kind of isolation.) MSP authorization rules complement hardware-backed isolation.

Properties

Expand table

Property	Type	Details
`mode`	Enumeration: `"Audit" | "Enforce" | "Disabled"`	See Inline configuration.
`defaultAccess`	Enumeration: `"Allow" | "Deny"`	Controls if an endpoint is accessible or restricted when no privileges for that resource are specified. See Privileges later in this article.
`rules`	`object`	The RBAC definition to apply. See Writing rules later in this article.

MSP allowlist (RBAC) concepts

The first step of access control is to verify the identity of the client. Normally, identity verification uses some type of a credential. MSP was designed to avoid introducing any breaking changes to clients, to maximize compatibility and make onboarding easier. Additionally, having clients upgraded with credentials introduces another layer of trust bootstrapping problems to solve.

Instead, MSP supports defining virtual identities against existing OS and process metadata. A VM's kernel keeps track of which user account a process belongs to, in addition to other metadata about its invocation. The GPA can identify which process made the HTTP request. As a result, the GPA can access that metadata to determine the identity of a caller and make authorization decisions.

Roles

You use roles to group multiple privileges into a named, reusable unit. Grouping privileges into roles improves organization and readability.

Role assignments

Role assignments pair an identity with a role. Requests that come from a process that matches the identity have all the privileges associated with that role.

Identities

With MSP, you can define a set of conditions to be evaluated against a property bag of process metadata. If all the conditions match, the process is considered to belong to this identity and is granted privileges.

The GPA supports writing *exact match* rules against these metadata items:

Expand table

Process metadata	Description
`username`	The human-readable name of the account that the process is running under.
`groupName`	The human-readable name of the group that contains the account that the process is running under. A user can belong to multiple groups. Conditions here are implemented as a *set contains* operation.
`processName`	The display name of the process. This name is purely defense in depth.
`exePath`	The full path of the running executable file. For some programs, the runtime (not the file) appears. An example of such a program is Python.

The ideal way to configure your workload is to run each application in a dedicated user account with uniquely scoped groups, and then write rules only against those properties. The user ID can't be spoofed, and there's no pattern matching to contend with. But because this method isn't practical in all workloads, we offer the other properties.

If you specify multiple properties, the matching is performed as a logical `AND`. For example, consider this identity definition:

JSON

```
{
    "name": "WebServer",
    "exePath": "/usr/sbin/apache2",
    "processName": "apache2",
    "groupName": "www-data"
}
```

The definition would generate the following validation:

c#

```
bool isWebServerIdentity = properties["exePath"] == "/usr/sbin/apache2"
    && properties["exePath"] == "apache2"
    && properties["groups"].contains("www-data");
```

Privileges

Privileges grant access to specific endpoints. Some endpoints are RESTful and can be expressed purely as a path. Others are influenced by query parameters.

Privileges are defined with a `name` value, a `path` value, and an optional set of `queryParameters` values:

JSON

```
"privileges": [
    {
        "name": "GoalState",
        "path": "/machine",
        "queryParameters": {"comp": "goalstate"}
    },
    {
        "name": "config",
        "path": "/machine",
        "queryParameters": {"comp": "config"}
    }
]
```

Comparison rules

- String matching is *case-insensitive*.
- If *no* query parameters are specified, the privilege grants access to *all* possible values on that path.

Default access rules

You can use default access (`defaultAccess`) modes to slowly lock down a workload. You can also use them to simplify rule authoring when you want to restrict access to only specific endpoints.

Expand table

`defaultAccess` mode	Behavior
`Deny`	If no explicit assignment exists to authorize the guest app to access the requested resource, the request is rejected.
`Allow`	If no rules exist for a specific privilege, access is allowed by default. If any privilege for that resource exists, the behavior reverts to denying by default for that resource.

- If query parameters are provided, the question "*Is a privilege defined?*" for determining if `defaultAccess` applies becomes: "*Does any rule match this path + every specified query parameter in the rule is present + matches in the request?*". Extra query parameters are ignored in this assessment.
- The request is rejected if duplicate query parameter keys in a request are invalid.

Writing rules

Specifying an allowlist via RBAC rules is optional. But if you specify one, you must supply *all* fields. For example, if you didn't have any `roles` values to define, you would still provide the empty array.

The easiest way to generate rules is by first running MSP in `Audit` mode. Then, use the audit logs to generate rules.

The following full Azure Instance Metadata Service schema expansion shows an example of the `rules` subsection:

JSON

```
{
  "defaultAccess": "allow",
  "mode": "enforce",
  "rules": {
    "privileges": [
      {
        "name": "Msi",
        "path": "/metadata/identity/oauth2/token"
      }
    ],
    "roles": [
      {
        "name": "MyWebApp",
        "privileges": [
          "Msi"
        ]
      }
    ],
    "identities": [
      {
        "name":"MyWebApp1",
        "processName":"WebApp1"
      }
    ],
    "roleAssignments": [
      {
        "role": "MyWebApp",
        "identities": [
          "MyWebApp1"
```

```
        ]
      }
    ]
  },
  "id": "D/uTRPye9b9xSUCRIgfRDF41zeY="
}
```

The following full WireServer schema expansion shows an example of the `rules` subsection:

JSON

```
{
  "defaultAccess": "allow",
  "mode": "enforce",
  "rules": {
    "privileges": [
      {
        "name": "GoalState",
        "path": "/machine",
        "queryParameters": {
          "comp": "goalstate"
        }
      }
    ],
    "roles": [
      {
        "name": "Provisioning",
        "privileges": [
          "GoalState"
        ]
      }
    ],
    "identities": [
      {
        "name": "WinPA",
        "exePath": "C:\\Windows\\OEM\\Unattend.wsf.exe",
        "processName": "winpa.exe",
        "userName": "SYSTEM"
      }
    ],
    "roleAssignments": [
      {
        "role": "Provisioning",
        "identities": [
          "WinPA"
        ]
      }
    ]
  },
  "id": "D/uTRPye9b9xSUCRIgfRDF41zeY="
}
```

Implicit and default configurations

The following RBAC definition is applied as default behavior for defense-in-depth access rules that existed before MSP:

JSON

```
{
    "imds": {
        "defaultAccess": "Allow",
        "mode": "Disabled",
    },
    "wireServer": {
        "defaultAccess": "Allow",
        "mode": "Enforce",
    }
}
```

Remember that WireServer allows only access from administrator or root processes. The `defaultAccess` value is still `Allow` here because this rule isn't user configurable. It's part of the GPA. The GPA checks if the client is an admin user before evaluating any RBAC rules for a WireServer request. If the client is not an admin user, the request is immediately rejected.

Troubleshoot MSP

05/29/2025

This article provides some basic troubleshooting guidance for using the Metadata Security Protocol (MSP) feature with virtual machines (VMs) or virtual machine scale sets. If you can't resolve your problem by using this guidance, contact the support team.

Deployment failed for a new VM or virtual machine scale set

Windows

In Windows, the platform automatically installs the necessary components: Guest Proxy Agent (GPA) and eBPF. If the installation fails:

1. Ensure that you're using a supported OS version.
2. Ensure that the failure code is MSP related.
3. Retry the deployment. Transient failures are a part of cloud computing.

Linux

Ensure that you're using a valid image:

- The GPA must be included in your image. That's a requirement for deploying with MSP enabled.
- Your cloud-init version must be a newer, MSP-aware version. If it's not, a race condition occurs between it and the GPA.

The exact failure depends on whether your image is misconfigured or a platform failure occurred:

Expand table

GPA installed	Cloud-init version	Expected failure	Cause
No	Earlier than 24.3	`Linux.OSProvisioningInternalError` `Linux.Cloud-Init` successfully reported ready for provisioning, but the platform failed to record success.	VM might fail provisioning even though cloud-init reports ready.
No	24.3 or later	`Linux.Cloud-Init` failed because `azure-proxy-agent` is not found.	Cloud-init reports failure to the platform after detecting that the GPA is not installed.
Yes	Earlier than 24.3	`Linux.OSProvisioningInternalError`	Cloud-init might report ready before the GPA is configured, because it's GPA-unaware. Failures might happen up to 100% of the time, depending on the scenario.
Yes	24.3 or later	Cloud-init reports that the GPA is unhealthy.	Any of these items could be the cause: eBPF setup failure, failure to enable cgroup v2, generic startup failure, failure to acquire a key.

MSP is enabled but not applied

To avoid service disruptions when you're enabling MSP on an existing VM or virtual machine scale set, protections aren't applied until the VM indicates that it successfully set up and acquired the long-lived key. This delay means the VM model can show that MSP is enabled. However, the GPA might still be unhealthy and indicate that protections aren't activated.

Confirm that the problem still exists

Sometimes the delay is longer than anticipated. To begin, check the status report of the GPA:

1. Get the `status.json` file:

   - For a Windows VM, the ProxyAgent service logs from inside the VMs because they have more details. The log folder is `C:\WindowsAzure\ProxyAgent\Logs`. ProxyAgent captures its overall status in `C:\WindowsAzure\ProxyAgent\Logs\status.json`.
   - For a Linux VM, the ProxyAgent service (`azure-proxy-agent`) logs from inside the VMs because they have more details. The log folder is `/var/log/azure-proxy-agent/`. ProxyAgent captures its overall status in `/var/log/azure-proxy-agent/status.json`.

2. Check `proxyAgentStatus` in the `status.json` file and ensure that the value is `SUCCESS`. If it's not `SUCCESS`, check these other statuses:

Expand table

Status	Expected value
`keyLatchStatus`	`RUNNING`
`ebpfProgramStatus`	`RUNNING`
`proxyListenerStatus`	`RUNNING`

GPA is missing or not running

Windows VM

Control Resource Plane (CRP) implicitly installs these Windows services by using guest extensions:

- GPA: `GuestProxyAgent`
- Kernel drivers for eBPF: `eBPFCore`, `NetEbpfExt`

Linux VM

For Linux VMs, the GPA must be included in the base image. Or you can explicitly add the GPA VM extension `Microsoft.CPlat.ProxyAgent.ProxyAgentLinux` before you enable the MSP feature.

Prerequisites are:

- Linux kernel 5.15 or later, which has all the required eBPF features.
- The cgroup v2 feature mounted by default. The GPA hooks up the cgroup/connect4 eBPF event.

When you enable MSP, CRP installs one service (`azure-proxy-agent`) in the VM.

```
# systemctl status azure-proxy-agent.service
● azure-proxy-agent.service - Microsoft Azure GuestProxyAgent
     Loaded: loaded (/lib/systemd/system/azure-proxy-agent.service; enabled; vendor preset: enabled)
     Active: active (running) since Fri 2024-09-13 18:52:00 UTC; 1 week 5 days ago
   Main PID: 4040671 (azure-proxy-age)
      Tasks: 10 (limit: 19169)
     Memory: 491.2M
        CPU: 1d 8h 13min 2.321s
     CGroup: /system.slice/azure-proxy-agent.service
             └─4040671 /usr/sbin/azure-proxy-agent
```

GPA is running, but you can't set it up

eBPF setup failure

For eBPF setup to be successful, `eBPFCore` and `NetEbpfExt` must be in a `RUNNING` state.

Here's the code that shows the `RUNNING` state for a Windows VM:

```
c:\>sc query eBPFCore

SERVICE_NAME: eBPFCore
        TYPE               : 1  KERNEL_DRIVER
        STATE              : 4  RUNNING
                                (STOPPABLE, NOT_PAUSABLE, IGNORES_SHUTDOWN)
        WIN32_EXIT_CODE    : 0  (0x0)
        SERVICE_EXIT_CODE  : 0  (0x0)
        CHECKPOINT         : 0x0
        WAIT_HINT          : 0x0
```

Here's the code that shows the `RUNNING` state for a Linux VM:

```
c:\>sc query NetEbpfExt

SERVICE_NAME: NetEbpfExt
        TYPE               : 1  KERNEL_DRIVER
        STATE              : 4  RUNNING
                                (STOPPABLE, NOT_PAUSABLE, IGNORES_SHUTDOWN)
        WIN32_EXIT_CODE    : 0  (0x0)
        SERVICE_EXIT_CODE  : 0  (0x0)
        CHECKPOINT         : 0x0
        WAIT_HINT          : 0x0
```

Failure to load eBPF

The GPA uses some eBPF features that require Linux kernel 5.15 or later. If you're trying to enable the MSP feature on an unsupported Linux distribution, you might see a message similar to this example:

```
    "ebpfProgramStatus": {
      "status": "STOPPED",
      "message": "Failed to load program 'connect4' with error: the BPF_PROG_LOAD syscall failed. Verifier output: ; int
connect4(struct bpf_sock_addr *ctx)\n0: (bf) r6 = r1\n; __u64 cookie = bpf_get_socket_cookie(ctx);\n1: (85) call
bpf_get_socket_cookie#46\n2: (b7) r1 = 0\n; destination_entry entry = {0};\n3: (63) *(u32 *)(r10 -44) = r1\nlast_idx 3 first_idx
0\nregs=2 stack=0 before 2: (b7) r1 = 0\n4: (63) *(u32 *)(r10 -48) = r1\n5: (63) *(u32 *)(r10 -52) = r1\n;
entry.destination_ip.ipv4 = ctx->user_ip4;\n6: (61) r1 = *(u32 *)(r6 +4)\n; entry.destination_ip.ipv4 = ctx->user_ip4;\n7: (63) *
(u32 *)(r10 -56) = r1\n; entry.destination_port = ctx->user_port;\n8: (61) r1 = *(u32 *)(r6 +24)\n; entry.destination_port = ctx-
>user_port;\n9: (63) *(u32 *)(r10 -40) = r1\n; entry.protocol = ctx->protocol;\n10: (61) r1 = *(u32 *)(r6 +36)\n; entry.protocol
= ctx->protocol;\n11: (63) *(u32 *)(r10 -36) = r1\n12: (bf) r2 = r10\n; \n13: (07) r2 += -56\n; destination_entry *policy =
bpf_map_lookup_elem(&policy_map, &entry);\n14: (18) r1 = 0xffff8baa17403400\n16: (85) cal..."
    },
```

Try get the kernel version by using `uname -r`. If the version is earlier than 5.15, opt out of the MSP feature, upgrade your OS image to the latest version, and then enable MSP.

Failure to attach cgroup for redirection

`GuestProxyAgent` requires cgroup v2 mounted by default to hook up cgroup/connect4 eBPF events. If you try to enable the MSP feature on an unsupported Linux distribution, you might see a message like the following `status.json` example:

```
    "ebpfProgramStatus": {
      "status": "STOPPED",
      "message": "Failed to attach program 'connect4' with error: `bpf_link_create` failed"
    },
```

To resolve this problem, try these methods:

- Check if the current Linux VM supports cgroup v2 by using this command:

  ```
  grep cgroup /proc/filesystems
  ```

  If `nodev cgroup2` is listed, this OS supports cgroup v2. If `nodev cgroup2` isn't listed, opt out of the MSP feature, update to the latest OS version, and then enable MSP.

- Check if cgroup v2 is mounted by default. Use the following command:

  ```
  mount | grep cgroup2
  ```

  If no record appears, ask the VM owner to set it up by using the following command and then restart the VM:

```
sudo grubby --update-kernel=ALL --args="systemd.unified_cgroup_hierarchy=1"
```

Failure to acquire a key or rejected key

The GPA can't acquire a key if the platform no longer offers it. Actions like migrating a disk to a new VM, or deleting the VM's OS disk and replacing it, can cause this failure.

Follow the instructions for resetting a key in this article. Resetting the key allows the platform to offer a new one. The GPA periodically attempts to recover. After you complete the reset, the GPA automatically acquires a new key and goes back to a healthy state.

You need to reset a key

If your VM's long-lived key is lost, it no longer communicates with Azure Instance Metadata Service or WireServer. Without the key, a new one can't be safely issued to the VM automatically. Additionally, if the key is compromised in some way, it must be reset to maintain security.

To reset a key:

1. Refer to Reset a latched key for complete documentation on the `KeyIncarnationId` field of the `ProxyAgentSettings` section of the VM model.
2. Select a new `KeyIncarnationId` value, and apply it to the VM model by using a `PUT` operation.

> **Note**
>
> If you're sending multiple requests or otherwise using automation, you must ensure that the values you send are strictly monotonically increasing. Otherwise, the change might not be applied.

You got an error code

Frequently asked questions about MSP

05/29/2025

This article answers common questions from customers who work with the Metadata Security Protocol (MSP) feature. If you don't see a question that can help you, contact the support team.

Usage

How do I check if the feature is enabled?

You can check MSP enablement programmatically by using the GET VM API to retrieve the virtual machine (VM) model. The `proxyAgentSettings` properties report MSP configuration.

Additionally, the `GuestProxyAgent` instance view in the VM runtime status reports the state of MSP from its perspective in the VM. If MSP is disabled, the value is `"Disabled"`.

How do I check component health?

The `GuestProxyAgent` instance view reports the status of the Guest Proxy Agent (GPA) and its dependencies. Each component's `status` value shows `RUNNING` when it's healthy.

Expand table

Component	Field
GPA	`keyLatchStatus.status`
eBPF integration	`ebpfProgramStatus.status`

Here's a full example:

JSON

```
{
  "version": "1.0.20",
  "status": "SUCCESS",
  "monitorStatus": {
    "status": "RUNNING",
    "message": "Monitor thread has not started yet."
  },
  "keyLatchStatus": {
    "status": "RUNNING",
    "message": "Found key details from local and ready to use. 122",

  },
  "telemetryLoggerStatus": {
    "status": "RUNNING",
    "message": "Telemetry event logger thread started."
  },
  "proxyConnectionsCount": 590
}
```

Can I provision a new Linux VM with MSP enabled without including the GPA in my image?

No. Linux provisioning doesn't have a step where the platform can install other software before the customer receives the VM. Also, most Linux customers don't want this model. It's more in line with the Windows philosophy.

For security reasons, MSP doesn't allow you to successfully provision a VM if you didn't establish a secure connection. The GPA is responsible for establishing the secure connection, so it needs to already be present.

If you don't want to use an image with the GPA included, you must create the VM first and then enable MSP afterward. During the preview, we monitor usage patterns and evaluate potential ways to support the scenario, by allowing the GPA to be installed as a VM extension rather than directly included.

Features

Is ARM64 supported?

ARM64 support is not available while the MSP feature is in preview.

Design

How is the latched key created, and how does it bind to the VM?

An Azure host generates the latched key and stores it as platform data. The key is unique to each VM. You can use it only on that VM's private connection to WireServer and Azure Instance Metadata Service.

How is the allowlist (policy) provisioned?

The allowlist is defined as part of the VM model. The MSP feature configuration article explains how to create an allowlist.

The Guest Proxy Agent retrieves this policy periodically from WireServer, like any other VM metadata. The allowlist allows users to centrally manage the policy in the same way that they would manage other VM settings. It also prevents users within the VM from tampering with it.

Where is the allowlist enforced (GPA or WireServer)?

Both components play a role in enforcement. MSP uses a shared responsibility model:

- WireServer and Instance Metadata Service are responsible for ensuring that only the trusted delegate (the GPA), and clients that the trusted delegate endorses, can access the VM's metadata and secrets.

  Metadata services can't, and shouldn't, perform VM introspection. They alone can't determine which software within a VM made a request.

- The trusted delegate (the GPA) is responsible for determining the identity of clients and endorsing requests.

  The GPA can rely on the OS kernel to authoritatively identify which process within the VM made a request.

The most important element is that MSP is a *default-closed* model, whereas other security measures (like in guest firewall rules) are *default-open*. If the GPA is down or otherwise bypassed, WireServer rejects any requests because the latched key doesn't endorse them.

Why is this feature opt-in and not required or automatically enabled?

Nearly every infrastructure as a service (IaaS) VM or virtual machine scale set in Azure uses Instance Metadata Service. The diversity of workloads requires flexibility. Although the design of MSP abstracts away most breaking changes, if a workload is ultimately dependent on a less secure configuration, enforcing stronger security breaks the workload.

Why does MSP require a new agent instead of using an Azure Guest Agent update?

The GPA has different responsibilities than the Azure Guest Agent. The GPA also has higher performance requirements.

Get Virtual Machine usage metrics using the REST API

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This example shows how to retrieve the CPU usage for a Linux Virtual Machine using the Azure REST API.

Complete reference documentation and samples for the REST API are available in the Azure Monitor REST reference article.

Build the request

Use the following GET request to collect the Percentage CPU metric from a virtual machine.

HTTP

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmname}/prov
iders/microsoft.insights/metrics?api-version=2018-01-
01&metricnames=Percentage%20CPU&timespan=2018-06-05T03:00:00Z/2018-06-
07T03:00:00Z
```

Request headers

The following headers are required:

Expand table

Request header	Description
Content-Type:	Required. Set to `application/json`.
Authorization:	Required. Set to a valid `Bearer` access token.

URI parameters

Expand table

Name	Description
subscriptionId	The subscription ID that identifies an Azure subscription. If you have multiple subscriptions, see Working with multiple subscriptions.
resourceGroupName	The name of the Azure resource group associated with the resource. You can get this value from the Azure Resource Manager API, CLI, or the portal.
vmname	The name of the Azure Virtual Machine.
metricnames	Comma-separated list of valid Load Balancer metrics.
api-version	The API version to use for the request. This document covers api-version `2018-01-01`, included in the above URL.
timespan	String with the following format `startDateTime_ISO/endDateTime_ISO` that defines the time range of the returned metrics. This optional parameter is set to return a day's worth of data in the example.

Request body

No request body is needed for this operation.

Handle the response

Status code 200 is returned when the list of metric values is returned successfully. A full list of error codes is available in the reference documentation.

Example response

JSON

```
{
    "cost": 0,
    "timespan": "2018-06-08T23:48:10Z/2018-06-09T00:48:10Z",
    "interval": "PT1M",
    "value": [
        {
            "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/virtualMachines/{vmname}/providers/microsoft.insights/metrics?api-version=2018-01-01&metricnames=Percentage%20CPU",
            "type": "Microsoft.Insights/metrics",
            "name": {
```

```
                "value": "Percentage CPU",
                "localizedValue": "Percentage CPU"

Azure boot diagnostics

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Boot diagnostics is a debugging feature for Azure virtual machines (VM) that allows diagnosis of VM boot failures. Boot diagnostics enables a user to observe the state of their VM as it is booting up by collecting serial log information and screenshots.

Boot diagnostics storage account

When you create a VM in Azure portal, boot diagnostics is enabled by default. The recommended boot diagnostics experience is to use a managed storage account, as it yields significant performance improvements in the time to create an Azure VM. Using a managed storage account eliminates the time needed to create a user storage account to store the boot diagnostics data. When using a managed storage account: The managed storage account is not directly accessible, and the boot diagnostics data blobs (which comprise of logs and snapshot images) stored in the managed storage account are not currently billed.

An alternative boot diagnostic experience is to use a custom storage account. A user can either create a new storage account or use an existing one. When the storage firewall is enabled on the custom storage account (**Enabled from all networks** option isn't selected), you must:

- Make sure that access through the storage firewall is allowed for the Azure platform to publish the screenshot and serial log. To do this, go to the custom boot diagnostics storage account in the Azure portal and then select **Networking** from the **Security + networking** section. Check if the **Allow Azure services on the trusted services list to access this storage account** checkbox is selected.
- Allow storage firewall for users to view the boot screenshots or serial logs. To do this, add your network or the client/browser's Internet IPs as firewall exclusions. For more information, see Configure Azure Storage firewalls and virtual networks.

To configure the storage firewall for Azure Serial Console, see Use Serial Console with custom boot diagnostics storage account firewall enabled.

> ⓘ **Note**
>
> The custom storage account associated with boot diagnostics requires the storage account and the associated virtual machines reside in the same region and subscription. To view the boot diagnostics data, users must also have the correct level of view and read permissions.

Boot diagnostics view

Go to the virtual machine blade in the Azure portal, the boot diagnostics option is under the *Help* section in the Azure portal. Selecting boot diagnostics display a screenshot and serial log information. The serial log contains kernel messaging and the screenshot is a snapshot of your VMs current state. Based on if the VM is running Windows or Linux determines what the expected screenshot would look like. For Windows, users see a desktop background and for Linux, users see a login prompt.

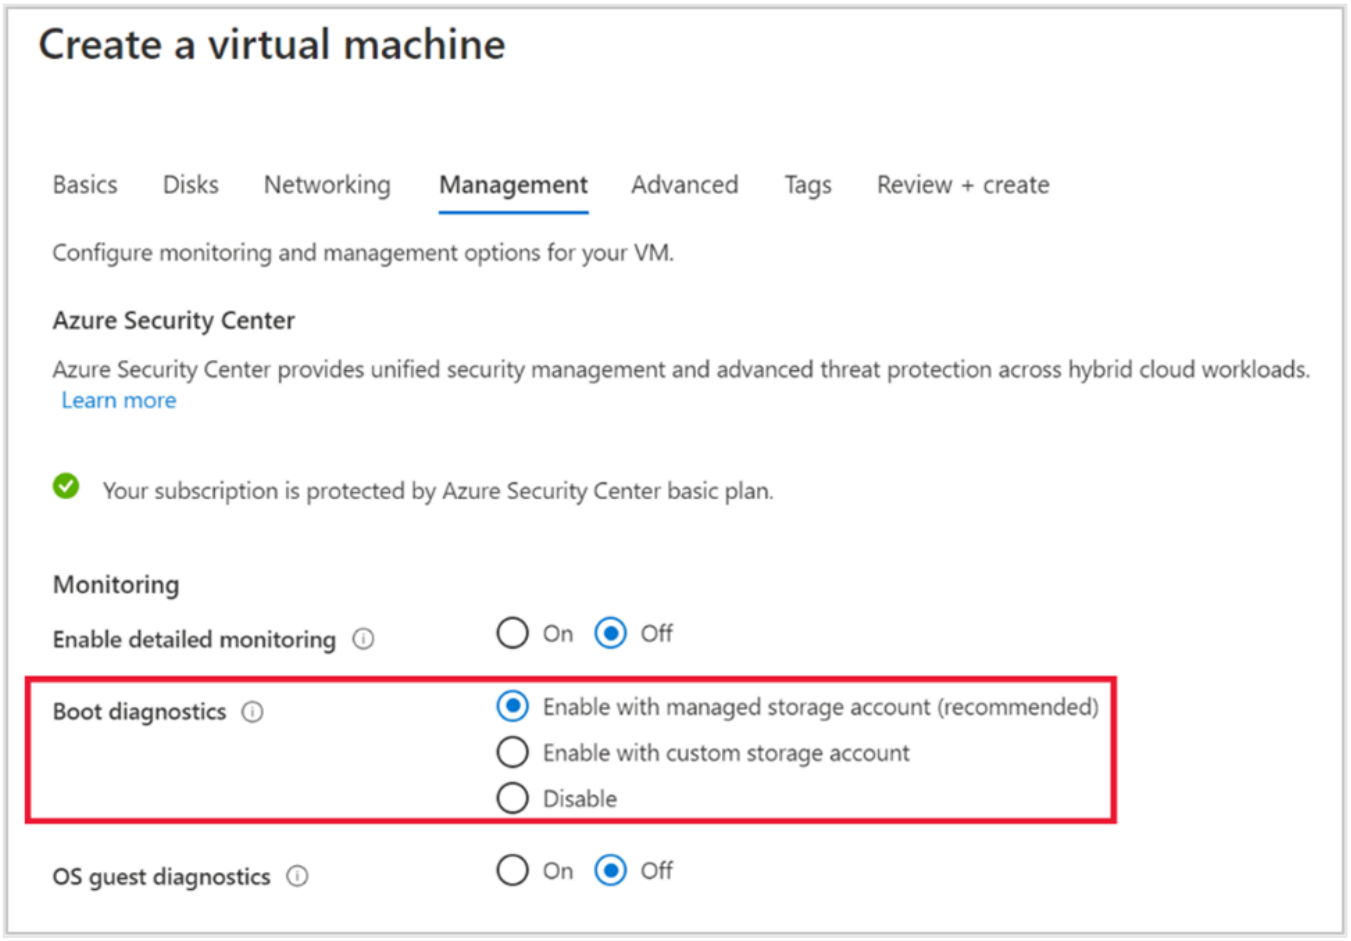
Enable managed boot diagnostics

Managed boot diagnostics can be enabled through the Azure portal, CLI and ARM Templates.

Enable managed boot diagnostics using the Azure portal

When you create a VM in the Azure portal, the default setting is to have boot diagnostics enabled using a managed storage account. Navigate to the *Management* tab during the VM creation to view it.



Enable managed boot diagnostics using CLI

Boot diagnostics with a managed storage account is supported in Azure CLI 2.12.0 and later. If you don't input a name or URI for a storage account, a managed account is used. For more information and code samples, see the CLI documentation for boot diagnostics.

Enable managed boot diagnostics using PowerShell

Boot diagnostics with a managed storage account is supported in Azure PowerShell 6.6.0 and later. If you don't input a name or URI for a storage account, a managed account is used. For more information and code samples, see the PowerShell documentation for boot diagnostics.

Enable managed boot diagnostics using Azure Resource Manager (ARM) templates

Everything after API version 2020-06-01 supports managed boot diagnostics. For more information, see boot diagnostics instance view.

ARM

```
            "name": "[parameters('virtualMachineName')]",
            "type": "Microsoft.Compute/virtualMachines",
            "apiVersion": "2020-06-01",
            "location": "[parameters('location')]",
            "dependsOn": [
                "[concat('Microsoft.Network/networkInterfaces/',
parameters('networkInterfaceName'))]"
            ],
            "properties": {
                "hardwareProfile": {
                    "vmSize": "[parameters('virtualMachineSize')]"
                },
                "storageProfile": {
                    "osDisk": {
                        "createOption": "fromImage",
                        "managedDisk": {
                            "storageAccountType": "[parameters('osDiskType')]"
                        }
                    },
                    "imageReference": {
                        "publisher": "publisherName",
                        "offer": "imageOffer",
                        "sku": "imageSKU",
                        "version": "imageVersion"
                    }
                },
                "networkProfile": {
                    "networkInterfaces": [
                        {
                            "id": "
[resourceId('Microsoft.Network/networkInterfaces',
parameters('networkInterfaceName'))]"
                        }
                    ]
                },
                "osProfile": {
                    "computerName": "[parameters('virtualMachineComputerName')]",
                    "adminUsername": "[parameters('adminUsername')]",
                    "linuxConfiguration": {
                        "disablePasswordAuthentication": true
                    }
                },
                "diagnosticsProfile": {
                    "bootDiagnostics": {
                        "enabled": true
                    }
                }
            }
        }
    ],
```

> ⓘ Note

Replace publisherName, imageOffer, imageSKU and imageVersion accordingly.

Limitations

- Managed boot diagnostics is only available for Azure Resource Manager VMs.
- Managed boot diagnostics doesn't support VMs using unmanaged OS disks.
- Boot diagnostics doesn't support premium storage accounts or zone redundant storage accounts. If either of these are used for boot diagnostics users receive an `StorageAccountTypeNotSupported` error when starting the VM.
- Managed storage accounts are supported in Resource Manager API version "2020-06-01" and later.
- Portal only supports the use of boot diagnostics with a managed storage account for single instance VMs.
- Users can't configure a retention period for Managed Boot Diagnostics. The logs are overwritten when the total size crosses 1 GB.
- If the OS disk is swapped after enabling boot diagnostics, the VM will required a stop/start before boot diagnostics will work again. To avoid this, disable boot diagnostics before swapping the OS disk and enable again after the OS disk swap has been completed.

Next steps

Learn more about the Azure Serial Console and how to use boot diagnostics to troubleshoot virtual machines in Azure.

Last updated on 12/01/2025

Essential machine management (preview)

Essential machine management simplifies the onboarding and configuration of management for Azure virtual machines (VMs) and arc-enabled servers. When you enable a subscription for essential machine management, all VMs and arc-enabled servers in that subscription are automatically enrolled and configured with a curated set of management features. This ensures that your machines are consistently configured for monitoring, security, and management.

Prerequisites

- Log Analytics workspace to collect log data collected from VMs.
- Azure Monitor workspace to collect metrics data collected from VMs.
- User assigned managed identity as described in Managed identity section below.

Required permissions

User

The user performing the enrollment must have the following roles in the subscription being enabled:

- Essential Machine Management Administrator
- Managed Identity Operator roles
- Resource Policy Contributor

If you're using a Log Analytics workspace or Azure Monitor workspace in a different subscription than the one being enabled for essential machine management:

- The user account must also have the **Essential Machine Management Administrator** role in the resource group of the Log analytics workspace or Azure Monitor workspace.
- The **Microsoft.ManagedOps** resource provider needs to be registered in the subscription of the Log analytics workspace or Azure Monitor workspace. Use the Azure PowerShell command: `Register-AzResourceProvider -ProviderNamespace "Microsoft.ManagedOps"`.

Managed identity

The enrollment requires a user assigned managed identity with **Contributor** permission for the subscription.

If you're using a Log Analytics workspace or Azure Monitor workspace in a different subscription than the one being enabled for essential machine management, then the managed identity must also have **Contributor** permissions in the resource group of the Log Analytics workspace or Azure Monitor workspace.

Features enabled

Essential machine management enables a standard set of features and allows you to optionally enable additional security features.

Essentials tier

The following features are part of the essentials tier.

Expand table

Feature	Description
Azure Monitor	Monitors and provides insights into VM performance and health. Configures metric-based recommended alerts.
Azure Update Manager	Automates the deployment of operating system updates to VMs.
Azure Machine Configuration	Audits the Azure security baseline policy
Azure Change Tracking and Inventory	Tracks changes to VM configurations and maintains an inventory of resources.

Essentials tier pricing

> **Note**
>
> During the initial phase of public preview, the Essential Machine Management features are provided at no extra charge. Logs generated from Change Tracking and Inventory incur a separate charge for both Azure Virtual Machines and Arc-enabled servers.

- For Azure Virtual Machines only, capabilities enabled by Essential Machine Management are provided at no extra charge.
- For Azure Arc-enabled servers with Windows Server Software Assurance, Windows Server PayGo, and Windows Server Extended Security Updates, capabilities enabled by Essential Machine Management are provided at no extra charge.

- For all other Arc-enabled servers, Essential Machine Management will be priced at $9 per server per month once billing is enabled at a future date. An announcement and documentation update will be posted when billing begins.

Security tier

The following security features are available as part of essential machine management. You can choose to enable any combination of these features for the enrolled VMs. Features in this section may incur an additional charge.

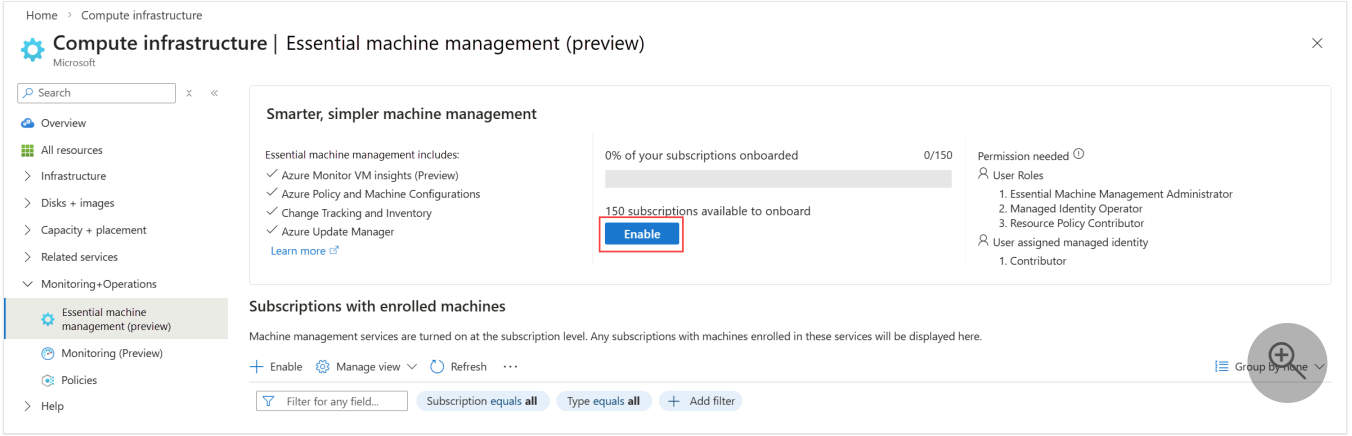
Expand table

Feature	Description	Cost
Foundational CSPM	Provides foundational cloud security posture management (CSPM) capabilities to assess and improve the security of your cloud resources.	No
Defender CSPM	Advanced cloud security posture management (CSPM) capabilities to enhance the security of your cloud resources.	Yes
Defender for cloud	Advanced threat protection and security management for VMs.	Yes

Enable a subscription

To enable machine management for a subscription, select **Essential machine management** from the **Configuration** menu, and click **Enable**.

> **Note**
>
> During public preview, the Azure portal is the only supported method for enabling machine management.



▼ Scope tab

The **Scope** tab includes the subscription that you want to enable and the managed identity.

Expand table

Setting	Description
Select a subscription	Click to select the subscription to enable. A list is provided with all subscriptions you have access to and the number of Azure VMs and Arc-enabled VMs in each.
Required user role assignments	Lists the required roles that your user account must be assigned to.
Current user role assignments	Lists the roles that are currently assigned to your user account.
User assigned managed identity	Select the managed identity to use for onboarding VMs in the subscription.
Required identity role assignment	Lists the required roles the managed identity must be assigned.
Current identity role assignment	Lists the roles currently assigned to the managed identity.

▼ Configure tab

The **Configure** tab includes the Log Analytics workspace and Azure Monitor workspace that will collect data from the managed VMs.

Expand table

Setting	Description
Log Analytics workspace	Select the Log Analytics workspace to use for collecting log data from VMs.
Azure Monitor workspace	Select the Azure Monitor workspace to use for collecting metrics data from VMs.

▼ Security tab

The **Security** tab allows you to select additional security services for the managed VMs.

Expand table

Setting	Description
Foundational CSPM	Continuously assess your cloud environment with agentless, risk-prioritized insights. Recommended for all workloads. This add-on incurs no additional charge.
Defender CSPM	Continuously assess your cloud environment with agentless, risk-prioritized insights. Recommended for all workloads. This add-on incurs an additional charge.
Defender for cloud	Comprehensive server protection with integrated endpoint detection and response (EDR), vulnerability management, file integrity monitoring, and advanced threat detection. Recommended for business-critical workloads. This add-on incurs an additional charge.

Existing VMs

Essential machine management is enabled for each subscription to automatically onboard all Azure VMs and arc-enabled servers in that subscription. Once enabled, any VMs added to the subscription are enrolled and configured with the selected features. The following behavior applies to existing VMs in the subscription when essential machine management is enabled.

- Existing services will retain their configuration. For example, if a VM is already using Update Management with a maintenance schedule, it will still follow that maintenance schedule.
- After the subscription is enabled, remediation tasks are created to enable the selected service for all existing VMs in the subscription.

> ⚠ **Warning**
>
> Use caution with the public preview if you have existing VMs with Change Tracking enabled. In this case, an additional Change Tracking DCR will be created and associated with the VM. Since Change Tracking supports only a single DCR though, either DCR could be assigned. If you would like to use the ManagedOps DCR, please remove the existing DCR.

Excluding VMs

There is currently no ability to exclude VMs in the enabled subscription. All VMs in the subscription are onboarded and configured with the selected features.

Disable a subscription

Disable a subscription by selecting it and then clicking **Offboard**. When you disable a subscription, any VMs added to that subscription are no longer configured with the selected management features. The configuration isn't changed for existing VMs though. They will continue to be managed with the existing features until you manually remove them.

> ⚠ **Warning**
>
> When you disable a subscription, machines in that subscription no longer use consolidated pricing. Pricing for these machines will revert to standard pricing for each individual service, which will most likely increase your costs. Ensure that you disable any unneeded services on existing VMs to avoid additional charges.

Troubleshooting

See Troubleshoot essential machine management (preview) for help resolving common issues with essential machine management. This article also identifies the objects created during enrollment and how to verify their creation.

Detailed configuration

The following table describes the specific configuration applied to each VM when essential machine management is enabled.

Expand table

Feature	Configuration details
Azure Monitor	- Installs Azure Monitor agent - Collects standard set of performance counters. - Configures metric-based recommended alerts
Azure Update Manager	- Installs extension (`Microsoft.CPlat.Core.LinuxPatchExtension` or `Microsoft.CPlat.Core.WindowsPatchExtension`) - Periodic assessment enabled.

Feature	Configuration details
Azure Machine Configuration	- Installs extension (`Microsoft.GuestConfiguration.ConfigurationforLinux` or `Microsoft.GuestConfiguration.ConfigurationforWindows`) - Applies the Linux security baseline and Windows security baseline in **Audit only** mode.
Azure Change Tracking and Inventory	- Installs extension (`Microsoft.Azure.ChangeTrackingAndInventory. ChangeTracking-Windows` or `Microsoft.Azure.ChangeTrackingAndInventory.ChangeTracking-Linux`) - Uses Log Analytics workspace specified in onboarding. - Collects basic files and registry keys.
Defender CSPM	- All settings on by default.

Next steps

- Troubleshoot any issues with essential machine management.

Last updated on 04/06/2026

Troubleshoot essential machine management (preview)

Summarize this article for me

This article provides troubleshooting steps for issues that may occur when enabling essential machine management. If you receive an error during enrollment, then there should be a specific resolution. If you don't get any errors during enrollment, but the machines in the subscription are not being onboarded to the selected services, then use the sections below to validate the different steps of the enrollment process to identify where any issues may have occurred.

Errors during enrollment

Following are common errors that may occur when enabling essential machine management for a subscription.

Could not validate resource existence.
The error message will include the resource ID of the Log Analytics workspace or Azure Monitor workspace that you selected during enrollment.

1. Check whether you have the **Essential Machine Management Administrator** role in the resource group of the Log analytics workspace or Azure Monitor workspace.
2. If the workspaces are in a different subscription than the one being enabled for essential machine management, verify that you have `Microsoft.ManagedOps` resource provider registered in the subscription.

Change Log Analytics workspace or Azure Monitor workspace
If you've already configured essential machine management and then enable it again using a different Log Analytics workspace or Azure Monitor workspace, you'll get an error saying that the workspace can't be changed once it's set.

To change either of the workspaces, you must first disable the subscription and then re-enable it with the new workspaces. All machines in the subscription will be re-enrolled and configured with the new workspaces, but any data already collected in the old workspace will be retained.

Disable Defender for cloud
You'll receive and error if you attempt to disable Defender for cloud for subscription that was already enabled for essential machine management. You must disable the subscription from the Defender for cloud portal.

Verify objects created

If you didn't see any errors during enrollment, start by verifying that the objects in the following table are created in the resource group for the Log Analytics workspace and Azure Monitor workspace. These are the data collection rules (DCRs) and solutions that enable change tracking and data collection for Azure Monitor.

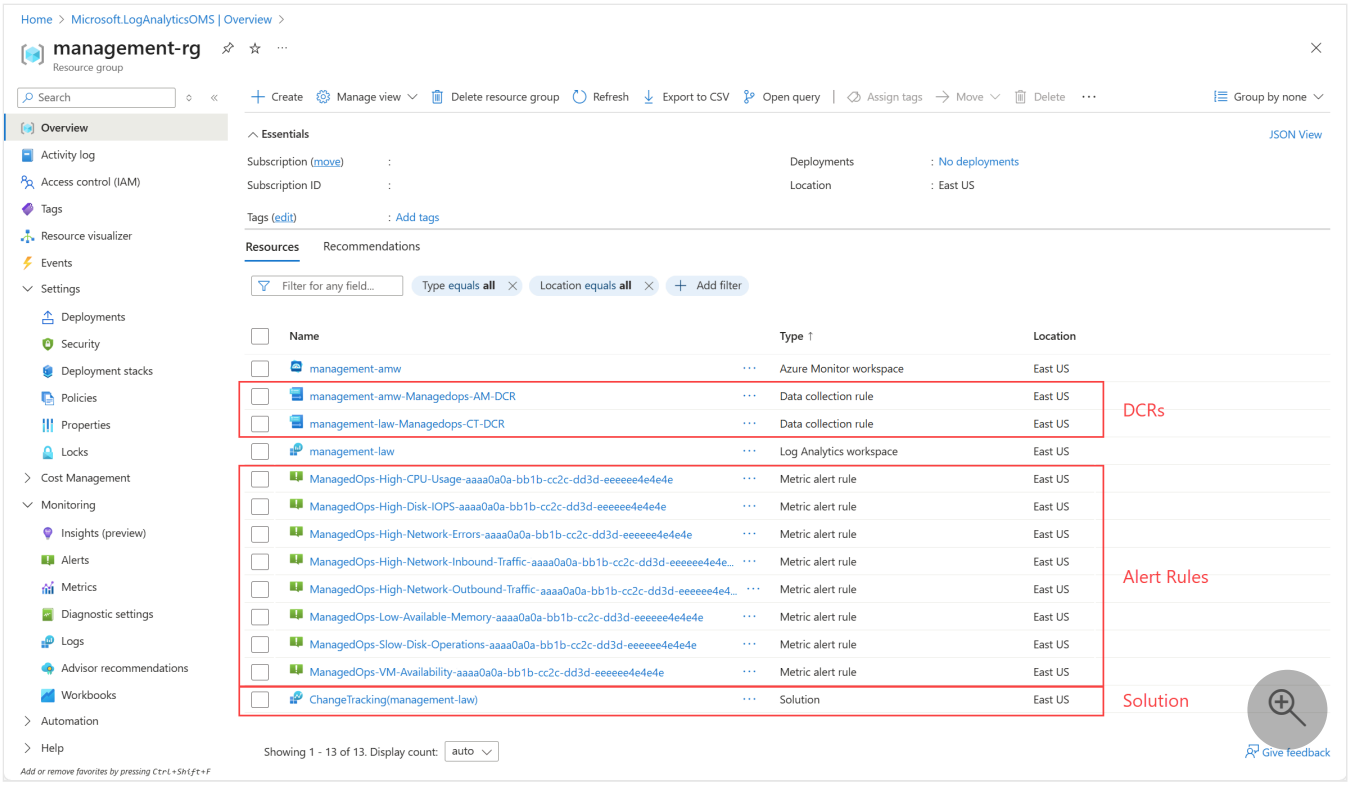
Expand table

Type	Name	Description
DCR	`<workspace id>-Managedops-AM-DCR` [1]	OpenTelemetry metrics from VM guests
DCR	`<workspace id>-Managedops-CT-DCR` [1]	Change tracking and inventory. Collects files, registry keys, softwares, Windows services, Linux daemons
Solution	`ChangeTracking(workspace name)`	Solution added to Log Analytics workspace to support Change tracking and inventory.

[1] The `<workspace id>` in the DCR name may be truncated.

Verify that the alert rules were created by checking for the following rules in the resource group for the Azure Monitor workspace.

- `ManagedOps-High-CPU-Usage-Alert`
- `ManagedOps-High-Disk-IOPS-Alert`
- `ManagedOps-High-Network-Errors-Alert`
- `ManagedOps-High-Network-Inbound-Traffic-Alert`
- `ManagedOps-High-Network-Outbound-Traffic-Alert`
- `ManagedOps-Low-Available-Memory-Alert`
- `ManagedOps-Slow-Disk-Operations-Alert`
- `ManagedOps-VM-Availability-Alert`

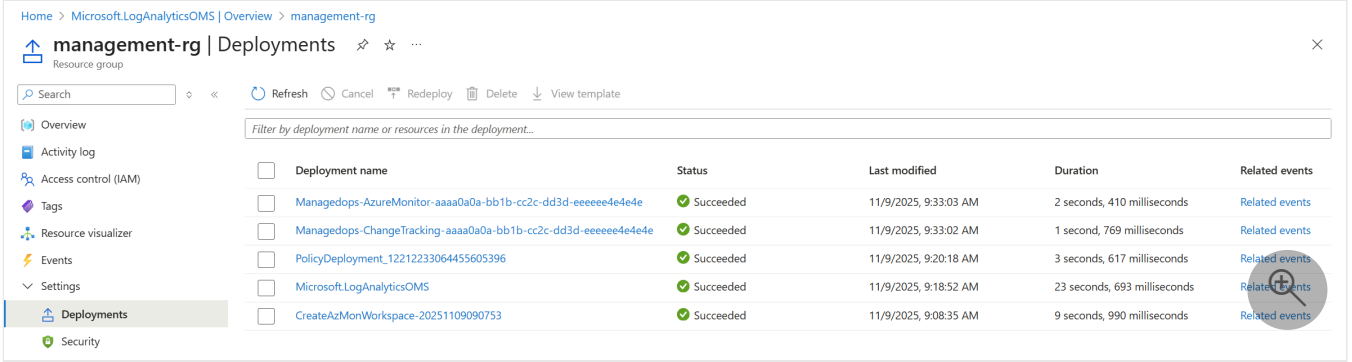


Check deployments for errors

If you don't see any of these objects within a few minutes of enabling the subscription, check for any errors in the deployments that are responsible for creating them. Open **Deployments** in the resource group and search for deployments with `Managedops` in the name. Click **Related events** to view the Activity log entries for the deployment. Alternatively, you can check the Activity log directly for the resource group and search for `Managedops` to identify any activity related to machine enablement.

The deployment names will look similar to the following:

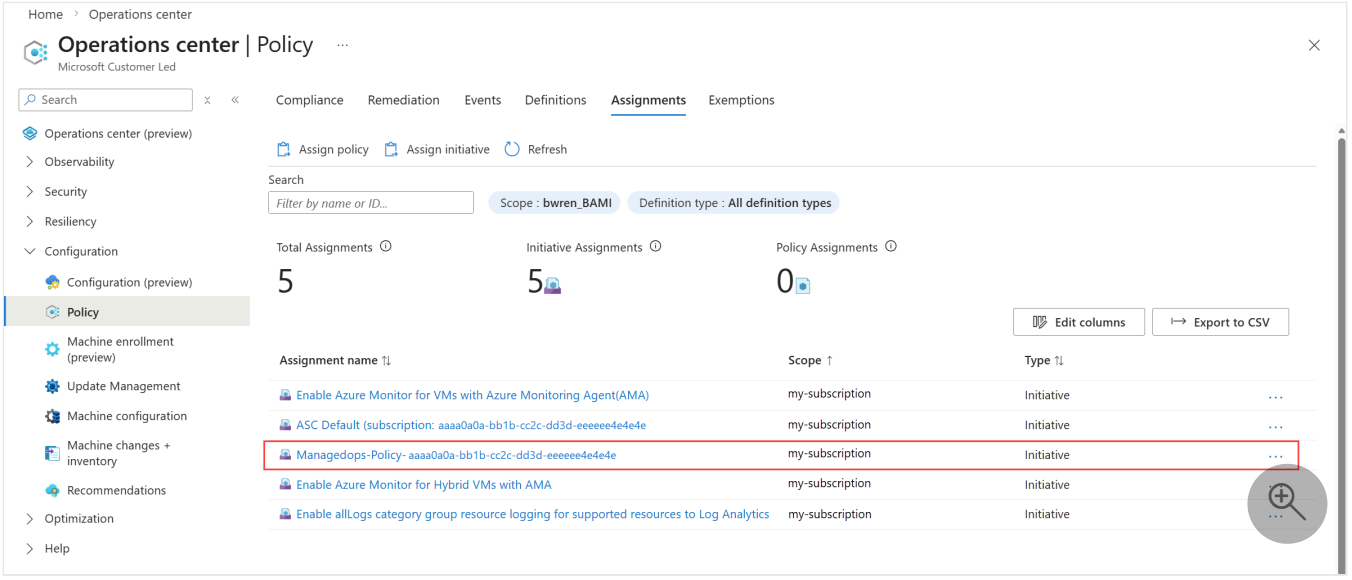
- `Managedops-ChangeTracking-{Subscription Id}`
- `Managedops-AzureMonitor-{Subscription Id}`



Verify policy assignments

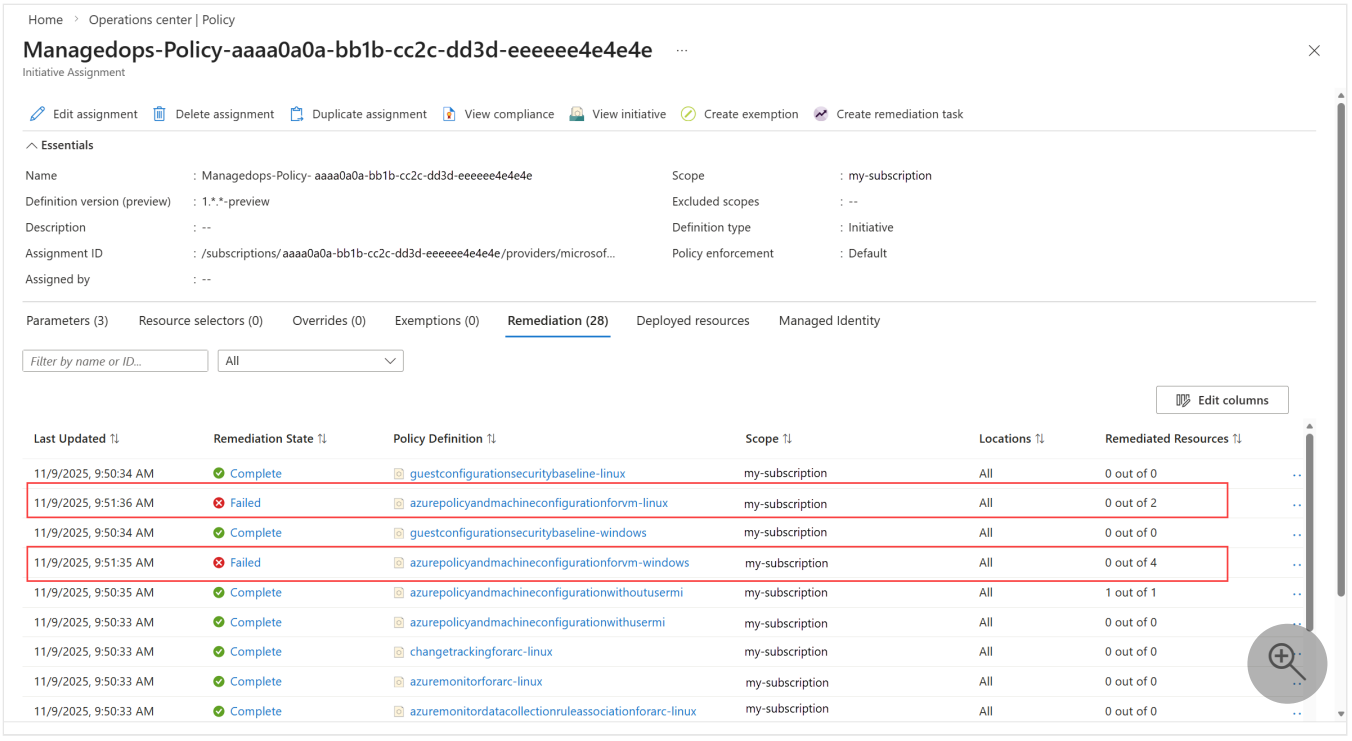
If the required objects have been created, and there are no errors in the deployments, verify that the policy assignment exists in the subscription. The assignment is responsible for applying the required configurations to the VMs in the subscription.

Open the **Policy** page in the Azure portal and select **Assignments**. Search for `ManagedOpsPolicy`. If you don't see the policy assignment, then you may not have enough permission to make a policy assignment in that subscription. Verify permissions at Required permissions.

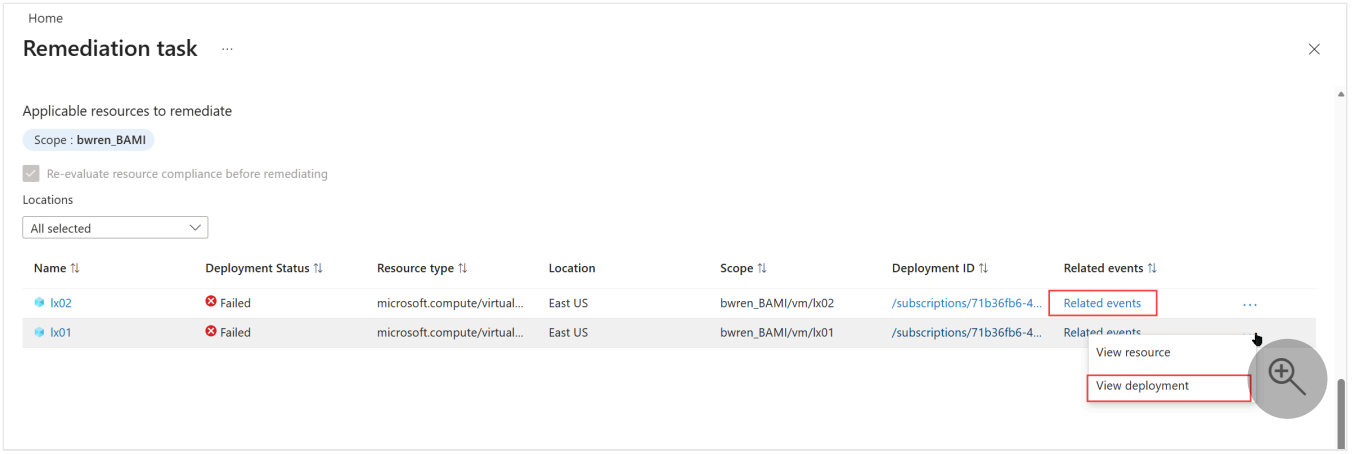


Check remediation tasks

If the assignments look correct, check the remediation tasks which are created to enable the selected features on all existing VMs in the subscription. Click on the assignment and select **Remediation**. If any of the **Remediated Resources** are not showing that all resources are remediated, or if the **Remediation State** is **Failed**, then click on the **Complete** or **Failed** status to open the details for that remediation task.



In the details of the remediation task, click on **Related Events** or **View Deployment** to locate a detailed error message.



Contact Microsoft

If you've completed all of the previous steps and are still having issues with essential machine management, contact Microsoft at machineenrollmentsupport@microsoft.com.

Last updated on 03/11/2026

Backup and restore options for virtual machines in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

You can protect your data by taking backups at regular intervals. There are several backup options available for virtual machines (VMs), depending on your use-case.

Azure Backup

You'll use Azure Backup for most use-cases involving backup operations on Azure VMs running production workloads. Azure Backup supports application-consistent backups for both Windows and Linux VMs. Azure Backup creates recovery points that are stored in geo-redundant recovery vaults. When you restore from a recovery point, you can restore entire VM or specific files.

For a simple, hands-on introduction to Azure Backup for Azure VMs, see the Azure Backup quickstart.

For more information on how Azure Backup works, see Plan your VM backup infrastructure in Azure

Azure Site Recovery

Azure Site Recovery protects your VMs from a major disaster scenario. These scenarios may include widespread service interruptions or regional outages caused by natural disasters. You can configure Azure Site Recovery for your VMs so that your applications are recoverable in matter of minutes with a single click. You can replicate to an Azure region of your choice, since recovery isn't restricted to paired regions.

You can run disaster-recovery drills with on-demand test failovers, without affecting your production workloads or ongoing replication. Create recovery plans to orchestrate failover and failback of the entire application running on multiple VMs. The recovery plan feature is integrated with Azure Automation runbooks.

You can get started by replicating your virtual machines.

Managed snapshots

In development and test environments, snapshots provide a quick and simple option for backing up VMs that use managed disks. A managed snapshot is a full, read-only copy of a managed disk. Snapshots exist independently of their source disks.

Snapshots can be used to create new managed disks when a VM is rebuilt. They're billed based on the used portion of the disk. For example, if you create a snapshot of a managed disk with provisioned capacity of 64 GB and actual used data size of 10 GB, snapshot will be billed only for the used data size of 10 GB.

For more information on creating snapshots, see:

- Create copy of VHD stored as a Managed Disk

Virtual machine restore points

At this time, you can use Azure REST APIs to back up and restore your VMs. This approach is most often used by independent software vendor (ISVs) or organizations with a relatively small number of VMs to manage.

You can use the API to create a VM restore point collection. The restore point collection itself contains individual restore points for specific VMs. Each restore point stores a VM's configuration and a snapshot for each attached managed disk. To save space and costs, you can exclude any disk from your VM restore points.

Once created, VM restore points can then be used to restore individual disks. To restore a VM, restore all relevant disks and attach them to a new VM.

Learn more about working with VM restore points and the restore point collections API.

Next steps

You can try out Azure Backup by following the Azure Backup quickstart.

You can also plan and implement reliability for your virtual machine configuration. For more information see Virtual Machine Reliability.

Reliability in Azure Virtual Machines

Azure Virtual Machines provides on-demand, scalable compute resources. As a foundational infrastructure service, it's designed to deliver enterprise-grade reliability and availability for mission-critical workloads.

When you use Azure, reliability is a shared responsibility. Microsoft provides a range of capabilities to support resiliency and recovery. You're responsible for understanding how those capabilities work within all of the services you use, and selecting the capabilities you need to meet your business objectives and uptime goals.

This article describes how to make Virtual Machines resilient to a variety of potential outages and problems, including transient faults, availability zone outages, region outages, and service maintenance. It also describes how you can use backups to recover from other types of problems, and highlights some key information about the Virtual Machines service level agreement (SLA).

> **Important**
>
> When you consider the reliability of a virtual machine (VM), you also need to consider the reliability of your disks, network infrastructure, and applications that run on your VMs. Improving the resiliency of the VM alone might have limited impact if the other components aren't equally resilient. Depending on your resiliency requirements, you might need to make configuration changes across multiple areas.

Production deployment recommendations

For more information about how to deploy VMs to support your solution's reliability requirements and how reliability affects other aspects of your architecture, see Architecture best practices for Virtual Machines and scale sets in the Azure Well-Architected Framework.

Reliability architecture overview

VMs are the fundamental compute unit in Azure, whether you provision the VMs yourself or use other Azure compute services that transparently provision and manage them for you.

An individual VM is also known as a *single instance VM*. It runs on a specific host, which is a physical server. Most VMs share their host with other VMs.

When you create your VMs, you can influence where they run within the underlying infrastructure. Typically, you make placement decisions based on your requirements for

reliability, latency, and isolation. Azure provides several configuration options that affect how your VMs are placed.

- **Region:** You can select which Azure region that your VM should run in. A region is a geographic area that might contain multiple datacenters, each with a large number of hosts.

- **Availability zone:** Availability zones are physically separate groups of datacenters within each Azure region. In regions that support availability zones, you can select which zone the VM runs in. For more information, see Resilience to availability zone failures.

- **Availability sets:** An availability set is a logical grouping of VMs that allows Azure to understand how your application is built to provide for redundancy and availability.

  When you use availability sets, Azure distributes a group of VMs across different fault domains. This distribution minimizes the risk of localized hardware failures by grouping VMs that share a common power source and network switch.

  Availability sets can also place different VMs in different update domains, which controls how the Azure platform rolls out platform updates. By using update domains, you can ensure that only a subset of your VMs is restarted for updates at one time.

- **Proximity placement groups:** For workloads that need to achieve the lowest possible latency between VMs, you can use a proximity placement group to ensure that Azure places the VMs physically close to each other. However, proximity placement means that an outage of the datacenter can affect all of the VMs in the group. To achieve high reliability, you might need to provision multiple proximity placement groups in different availability zones.

- **Dedicated hosts:** You can use Azure Dedicated Host to provision your own physical server that runs one or more VMs, such as for strict compliance requirements. However, when you provision a dedicated host, an outage in its datacenter can affect all of the VMs on that host. To achieve high reliability, you might need to provision multiple dedicated hosts in different availability zones.

If you create a set of VMs that perform similar functions, consider using Azure Virtual Machine Scale Sets to create and manage the VMs as a group. Scale sets also provide more reliability options, such as spreading the VMs across multiple availability zones.

For more information about availability for VMs, see Availability options for Virtual Machines.

Resilience to transient faults

Transient faults are short, intermittent failures in components. They occur frequently in a distributed environment like the cloud, and they're a normal part of operations. Transient faults correct themselves after a short period of time. It's important that your applications can handle transient faults, usually by retrying affected requests.

All cloud-hosted applications should follow the Azure transient fault handling guidance when they communicate with any cloud-hosted APIs, databases, and other components. For more information, see Recommendations for handling transient faults.

Applications that run on your VMs should implement appropriate fault-handling strategies to ensure that any temporary interruptions in service don't affect your workload.

Resilience to availability zone failures

Availability zones are physically separate groups of datacenters within an Azure region. When one zone fails, services can fail over to one of the remaining zones.

An individual VM can be deployed in a *zonal* configuration, which means that it's pinned to a single availability zone that you select. By itself, a zonal VM isn't resilient to zone outages. However, you can create multiple VMs and place them in different availability zones, then spread your applications and data across the VM instances. Alternatively, you can use virtual machine scale sets to deploy a set of VMs across multiple availability zones.

If you don't configure a VM to be zonal, it's considered *nonzonal* or *regional*. Nonzonal VMs might be placed in any availability zone within the region. If any availability zone in the region experiences an outage, nonzonal VMs might be in the affected zone and can experience downtime.

Region support

Zonal VMs can be deployed into any region that supports availability zones.

However, some VM types and sizes are only available in specific regions, or specific zones within a region. To check which regions and zones support the VM types that you need, use the following resources:

- To check the VM types available in each region, see Products available by region.
- To check the supported VM types and sizes within each zone of a specific region, see Check VM SKU availability.

Cost

There's no cost difference between a zonal and nonzonal VM.

Configure availability zone support

This section explains how to configure availability zone support for your VM instance.

> **Note**
>
> When you select which availability zones to use, you're actually selecting the *logical availability zone*. If you deploy other workload components in a different Azure subscription, they might use a different logical availability zone number to access the same physical availability zone. For more information, see **Physical and logical availability zones**.

- **Create a zonal VM.** You can create a zonal VM by using the following guides:
  - Create VMs in an availability zone by using the Azure portal
  - Create a VM in an availability zone by using the Azure CLI
  - Create a VM in an availability zone by using Azure PowerShell
- **Convert existing VMs to a zonal configuration.** You can move from a nonzonal VM to a zonal VM. This process creates a new VM in the target availability zone and requires that the VM be stopped during the move process. For more information, see Move Azure single instance VMs from regional to zonal target availability zones.
- **Change the availability zone of an existing zonal VM.** Zonal VMs can't be moved to a different availability zone. You need to deploy a new zonal VM in the desired availability zone instead.
- **Convert a zonal VM to a nonzonal configuration.** Zonal VMs can't be converted to a nonzonal configuration. You need to deploy a new nonzonal VM instead.

Behavior when all zones are healthy

This section describes what to expect when VM instances are configured with availability zone support and all availability zones are operational.

- **Traffic routing between zones:** You're responsible for routing traffic between VMs, including VMs that are in different availability zones. Common approaches include Azure Load Balancer and Azure Application Gateway. For more information, see Load balancing options.

- **Data replication between zones:** You're responsible for any data replication that needs to happen between VMs, including across VMs in different availability zones. Databases and other similar stateful applications that run on VMs often provide capabilities to replicate data.

Behavior during a zone failure

This section describes what to expect when VM instances are configured with availability zone support and there's an outage in their availability zones.

- **Detection and response:** You're responsible for detecting and responding to zone failures that affect your VMs.
- **Notification**: Microsoft doesn't automatically notify you when a zone is down. However, you can use Azure Resource Health to monitor for the health of an individual resource, and you can set up Resource Health alerts to notify you of problems. You can also use Azure Service Health to understand the overall health of the service, including any zone failures, and you can set up Service Health alerts to notify you of problems.
- **Active requests:** Any active requests or other work that occurs on the VM during the zone failure are likely to be terminated.
- **Expected data loss:** Zonal VM disks might be unavailable during a zone failure.

  If you use zone-redundant storage (ZRS) disks and an outage affects your VM, you can force detach your ZRS disks from the failed VM. This approach allows you to attach the ZRS disks to another VM.
- **Expected downtime:** VMs remain down until the availability zone recovers.
- **Traffic rerouting:** You're responsible for rerouting traffic to other VMs in healthy zones.

  If you configure a zone-resilient load balancer and it performs health checks, the load balancer typically detects failed VMs and can route traffic to other VM instances in healthy zones.

Zone recovery

When the zone is healthy, VMs in the zone restart. You're responsible for any zone recovery procedures and data synchronization that your workloads require.

Test for zone failures

You can use Azure Chaos Studio to simulate the loss of a VM as part of an experiment. Chaos Studio provides built-in faults for VMs, including the ability to shut down a VM. You can use these capabilities to simulate zone-level failures and test your failover processes.

Custom multi-zone solutions for resiliency

When you deploy multiple VMs into different zones, you're responsible for configuring and managing replication, load balancing, failover, and failback processes.

Some applications provide built-in capabilities that can help when you deploy across multiple VMs. For example, SQL Server on Azure VMs provides a set of capabilities to simplify your configuration and management processes across availability zones.

You can consider using Azure Site Recovery zone-to-zone disaster recovery (DR) when your application runs in a single zone at a time and you don't require near-instant failover between zones. Zone-to-zone DR has some important limitations, so review your requirements thoroughly.

Resilience to region-wide failures

VMs are single-region resources. If the region becomes unavailable, your VM is also unavailable.

Custom multi-region solutions for resiliency

You can deploy multiple VMs into different regions, but you need to implement replication, load balancing, and failover processes.

Site Recovery is a service that enables DR by replicating VMs and their data to a secondary region. You can select almost any Azure region as your secondary region, including nonpaired region combinations. For more information, see Azure to Azure DR architecture.

Some applications create clusters or other constructs to replicate data and distribute work across multiple VMs, including in different regions. These applications can simplify the configuration of a multi-region solution.

For an example architecture that illustrates using VMs across multiple regions, see Multi-region load balancing with Azure Traffic Manager, Azure Firewall, and Application Gateway.

Resilience to service maintenance

Azure performs regular periodic maintenance on VMs to ensure reliability. There are multiple ways that you can ensure your workloads remain operational during maintenance activities:

- When you use availability sets or virtual machine scale sets, you can configure update domains. Update domains help distribute maintenance activities across different VMs at different times, so your VMs don't all restart simultaneously.
- You can customize the timing that maintenance is applied to your VMs by using *maintenance control*. You can use maintenance configurations to schedule it at a time that suits your workload.
- You can receive notifications of upcoming maintenance activities.

For more information, see Guest updates and host maintenance overview.

Backup and restore

Azure Backup provides native backup support for VMs. Azure Backup creates and manages backups, and provides application-consistent protection for the entire VM, including all attached disks. A VM backup solution with Azure Backup is ideal when you need coordinated backup of multiple disks or application-aware backups. However, for database workloads, consider application-specific backup solutions that provide transaction-consistent protection and faster recovery options.

With Azure Backup for VMs, you can customize the backup frequency, retention duration, and storage configuration to suit your needs. For more information, see Azure Backup for VMs.

Backup also supports disks that are attached to VMs. For more information, see Overview of Azure Disk Backup.

For most solutions, you shouldn't rely exclusively on backups. Instead, use the other capabilities described in this guide to support your resiliency requirements. However, backups protect against some risks that other approaches don't. For more information, see What are redundancy, replication, and backup?.

Service-level agreement

The service-level agreement (SLA) for Azure services describes the expected availability of each service and the conditions that your solution must meet to achieve that availability expectation. For more information, see SLAs for online services.

For Virtual Machines, the SLA provides a base level of availability. The uptime percentage defined in the SLA increases when you have two or more VMs and you take the following

actions:

- Configure those VMs to be deployed across two or more availability zones.
- Configure those VMs to be deployed into an availability set.

Virtual machines in Azure

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

Azure virtual machines (VMs) are one of several types of on-demand, scalable computing resources that Azure offers. Typically, you choose a virtual machine when you need more control over the computing environment than the other choices offer. This article gives you information about what you should consider before you create a virtual machine, how you create it, and how you manage it.

An Azure virtual machine gives you the flexibility of virtualization without having to buy and maintain the physical hardware that runs it. However, you still need to maintain the virtual machine by performing tasks, such as configuring, patching, and installing the software that runs on it.

Azure virtual machines can be used in various ways. Some examples are:

- **Development and test** – Azure virtual machines offer a quick and easy way to create a computer with specific configurations required to code and test an application.
- **Applications in the cloud** – Because demand for your application can fluctuate, it might make economic sense to run it on a virtual machine in Azure. You pay for extra virtual machines when you need them and shut them down when you don't.
- **Extended datacenter** – virtual machines in an Azure virtual network can easily be connected to your organization's network.

What do I need to think about before creating a virtual machine?

There's always a multitude of design considerations when you build out an application infrastructure in Azure. These aspects of a virtual machine are important to think about before you start:

- The names of your resources
- The location where the resources are stored
- The size of the virtual machine
- The maximum number of virtual machines that can be created
- The operating system that the virtual machine runs

- The configuration of the virtual machine after it starts
- The related resources that the virtual machine needs

> **Note**
>
> Trusted Launch as default (TLaD) is available in preview for new Generation 2 Virtual machines (VMs). With TLaD, any new Generation 2 VMs created through any client tools defaults to Trusted Launch with secure boot and vTPM enabled. Register for the TLaD preview to validate the default changes in your respective environment and prepare for the upcoming change.

Parts of a VM and how they're billed

When you create a virtual machine, you're also creating resources that support the virtual machine. These resources come with their own costs that should be considered.

The default resources supporting a virtual machine and how they're billed are detailed in the following table:

Expand table

Resource	Description	Cost
Virtual network	For giving your virtual machine the ability to communicate with other resources	Virtual Network pricing
A virtual Network Interface Card (NIC)	For connecting to the virtual network	There's no separate cost for NICs. However, there's a limit to how many NICs you can use based on your VM's size. Size your VM accordingly and reference Virtual Machine pricing.
A private IP address and sometimes a public IP address.	For communication and data exchange on your network and with external networks	IP Addresses pricing
Network security group (NSG)	For managing the network traffic to and from your VM. For example, you might need to open port 22 for SSH access, but you might want to block traffic to port 80. Blocking and allowing port access is done through the NSG.	There are no additional charges for network security groups in Azure.

Resource	Description	Cost
OS Disk and possibly separate disks for data.	It's a best practice to keep your data on a separate disk from your operating system, in case you ever have a VM fail, you can detach the data disk, and attach it to a new VM.	All new virtual machines have an operating system disk and a local disk. Azure doesn't charge for local disk storage. The operating system disk, which is usually 127GiB but is smaller for some images, is charged at the regular rate for disks. You can see the cost for attach Premium (SSD based) and Standard (HDD) based disks to your virtual machines on the managed disks pricing page.
In some cases, a license for the OS	For providing your virtual machine runs to run the OS	The cost varies based on the number of cores on your VM, so size your VM accordingly. The cost can be reduced through the Azure Hybrid Benefit.

You can also choose to have Azure can create and store public and private SSH keys - Azure uses the public key in your VM and you use the private key when you access the VM over SSH. Otherwise, you need a username and password.

By default, these resources are created in the same resource group as the VM.

Locations

There are multiple geographical regions around the world where you can create Azure resources. Usually, the region is called **location** when you create a virtual machine. For a virtual machine, the location specifies where the virtual hard disks are stored.

This table shows some of the ways you can get a list of available locations.

Expand table

Method	Description
Azure portal	Select a location from the list when you create a virtual machine.
Azure PowerShell	Use the Get-AzLocation command.
REST API	Use the List locations operation.

Method	Description
Azure CLI	Use the az account list-locations operation.

Availability

There are multiple options to manage the availability of your virtual machines in Azure.

- **Availability Zones** are physically separated zones within an Azure region. Availability zones guarantee virtual machine connectivity to at least one instance at least 99.99% of the time when you have two or more instances deployed across two or more Availability Zones in the same Azure region.
- **Virtual Machine Scale Sets** let you create and manage a group of load balanced virtual machines. The number of virtual machine instances can automatically increase or decrease in response to demand or a defined schedule. Scale sets provide high availability to your applications, and allow you to centrally manage, configure, and update many virtual machines. Virtual machines in a scale set can also be deployed into multiple availability zones, a single availability zone, or regionally.

Fore more information see Availability options for Azure virtual machines and SLA for Azure virtual machines.

Sizes and pricing

The size of the virtual machine that you use is determined by the workload that you want to run. The size that you choose then determines factors such as processing power, memory, storage capacity, and network bandwidth. Azure offers a wide variety of sizes to support many types of uses.

Azure charges an hourly price based on the virtual machine's size and operating system. For partial hours, Azure charges only for the minutes used. Storage is priced and charged separately.

Scaling to multiple VMs

The number of virtual machines that your application uses can scale up and out to whatever is required to meet your needs. Azure offers several automatic scaling systems and instance types based on the size of your workload. For more information on scaling, compare VM-based compute products.

Virtual machine total core limits

Your subscription has default quota limits in place that could impact the deployment of many virtual machines for your project. The current limit on a per subscription basis is 20 virtual machine total cores per region. Limits can be raised by filing a support ticket requesting an increase Quota and capacity are checked separately during deployment. Even with approved quota, deployment can still fail if there isn't enough capacity in the target region or availability zone.

Managed disks

Managed disks handles Azure Storage account creation and management in the background for you, and ensures that you don't have to worry about the scalability limits of the storage account. You specify the disk size and the performance tier (Standard or Premium), and Azure creates and manages the disk. As you add disks or scale the virtual machine up and down, you don't have to worry about the storage being used. If you're creating new virtual machines, use the Azure CLI or the Azure portal to create virtual machines with Managed OS and data disks. If you have virtual machines with unmanaged disks, you can convert your virtual machines to be backed with managed disks.

You can also manage your custom images in one storage account per Azure region, and use them to create hundreds of virtual machines in the same subscription. For more information about managed disks, see the managed disks Overview.

Distributions

Microsoft Azure supports various Linux and Windows distributions. You can find available distributions in the marketplace, Azure portal or by querying results using CLI, PowerShell, and REST APIs.

This table shows some ways that you can find the information for an image.

Expand table

Method	Description
Azure portal	The values are automatically specified for you when you select an image to use.
Azure PowerShell	Get-AzVMImagePublisher -Location *location* Get-AzVMImageOffer -Location *location* -Publisher *publisherName*

Method	Description
	Get-AzVMImageSku -Location *location* -Publisher *publisherName* -Offer *offerName*
REST APIs	List image publishers List image offers List image skus
Azure CLI	az vm image list-publishers --location *location* az vm image list-offers --location *location* --publisher *publisherName* az vm image list-skus --location *location* --publisher *publisherName* --offer *offerName*

Microsoft works closely with partners to ensure the images available are updated and optimized for an Azure runtime. For more information on Azure partner offers, see the Azure Marketplace

Cloud-init

Azure supports for cloud-init across most Linux distributions that support it. We're actively working with our Linux partners to make cloud-init enabled images available in the Azure Marketplace. These images make your cloud-init deployments and configurations work seamlessly with virtual machines and virtual machine scale sets.

For more information, see Using cloud-init on Azure Linux virtual machines.

Storage

- Introduction to Microsoft Azure Storage
- Add a disk to a Linux virtual machine using the azure-cli
- How to attach a data disk to a Linux virtual machine in the Azure portal

Local temporary storage

Some Azure VM sizes include local temporary ephemeral storage, with some of the newer sizes using Temporary local NVMe disks. Local temporary storage uses additional disks provisioned directly as local storage to an Azure virtual machine host, rather than on remote Azure Storage. This type of storage is best suited for data that does not need to be retained permanently, such as caches, buffers, and temporary files. Since data stored on these disks isn't backed up, it's lost when the VM is deallocated or deleted. The ephemeral storage is recreated on startup. Local ephemeral disks are different from Ephemeral OS disks.

Local temporary disks present just like other remote storage such as Premium SSD v2 disks, but have added performance benefits and don't count against the IOPS and throughput limits of the VM.

The following lists key characteristics of local ephemeral storage:

- **Ultra-low latency**: Read/write operations occur on hardware physically co-located with the VM's compute resources, minimizing network hops and enabling sub-millisecond response times.
- **Superior IOPS and throughput**: Performance scales with the underlying local storage, often delivering 8-10 times higher IOPS than Standard HDDs when using Premium SSD as the base, with limits tied to the VM size (up to the NVMe disk capacity, capped at 2,040 GiB).

Azure VM sizes featuring a 'd' in their naming convention - such as the Da***d***sv6, Ea***d***sv6, and FXm***d***sv2 series - include dedicated local NVMe storage. These sizes enable placing temporary files, swap space, or high-I/O components like SQL Server's `tempdb` database files on the ephemeral disk for enhanced performance.

Service disruptions

At Microsoft, we work hard to make sure that our services are always available to you when you need them. Forces beyond our control sometimes impact us in ways that cause unplanned service disruptions.

Microsoft provides a Service Level Agreement (SLA) for its services as a commitment for uptime and connectivity. The SLA for individual Azure services can be found at Azure Service Level Agreements.

Azure already has many built-in platform features that support highly available applications. For more about these services, read Disaster recovery and high availability for Azure applications.

This article covers a true disaster recovery scenario, when a whole region experiences an outage due to major natural disaster or widespread service interruption. These are rare occurrences, but you must prepare for the possibility that there's an outage of an entire region. If an entire region experiences a service disruption, the locally redundant copies of your data would temporarily be unavailable. If you enabled geo-replication, three additional copies of your Azure Storage blobs and tables are stored in a different region. In the event of a complete regional outage or a disaster in which the primary region isn't recoverable, Azure remaps all of the DNS entries to the geo-replicated region.

In the case of a service disruption of the entire region where your Azure virtual machine application is deployed, we provide the following guidance for Azure virtual machines.

Option 1: Initiate a failover by using Azure Site Recovery

You can configure Azure Site Recovery for your VMs so that you can recover your application with a single click in matter of minutes. You can replicate to Azure region of your choice and not restricted to paired regions. You can get started by replicating your virtual machines. You can create a recovery plan so that you can automate the entire failover process for your application. You can test your failovers beforehand without impacting production application or the ongoing replication. In the event of a primary region disruption, you just initiate a failover and bring your application in target region.

Option 2: Wait for recovery

In this case, no action on your part is required. Know that we're working diligently to restore service availability. You can see the current service status on our Azure Service Health Dashboard.

This option is the best if you don't set up Azure Site Recovery, read-access geo-redundant storage, or geo-redundant storage prior to the disruption. If you set up geo-redundant storage or read-access geo-redundant storage for the storage account where your VM virtual hard drives (VHDs) are stored, you can look to recover the base image VHD and try to provision a new VM from it. This option isn't preferred because there are no guarantees of synchronization of data, which means this option isn't guaranteed to work.

> **Note**
>
> Be aware that you don't have any control over this process, and it will only occur for region-wide service disruptions. Because of this, you must also rely on other application-

specific backup strategies to achieve the highest level of availability. For more information, see the section on Data strategies for disaster recovery.

Resources for service disruptions

- Start protecting your applications running on Azure virtual machines using Azure Site Recovery
- To learn more about how to implement a disaster recovery and high availability strategy, see Disaster recovery and high availability for Azure applications.
- To develop a detailed technical understanding of a cloud platform's capabilities, see Azure resiliency technical guidance.
- If the instructions aren't clear, or if you would like Microsoft to do the operations on your behalf, contact Customer Support.

Data residency

In Azure, the feature to enable storing customer data in a single region is currently only available in the Southeast Asia Region (Singapore) of the Asia Pacific Geo and Brazil South (Sao Paulo State) Region of Brazil Geo. For all other regions, customer data is stored in Geo. For more information, see Trust Center.

An overview of Azure VM backup

This article describes how the Azure Backup service backs up Azure virtual machines (VMs).

Azure Backup provides independent and isolated backups to guard against unintended destruction of the data on your VMs. Backups are stored in a Recovery Services vault with built-in management of recovery points. Configuration and scaling are simple, backups are optimized, and you can easily restore as needed.

As part of the backup process, a snapshot is taken, and the data is transferred to the Recovery Services vault with no impact on production workloads. The snapshot provides different levels of consistency, as described here. You can opt for an agent-based application-consistent/file-consistent backup or an agentless crash-consistent backup in the backup policy.

Azure Backup also has specialized offerings for database workloads like SQL Server and SAP HANA that are workload-aware, offer 15 minute RPO (recovery point objective), and allow backup and restore of individual databases.

You can now also back up your virtual machines with Azure Backup in Azure Extended Zones (preview). Azure Extended Zones (preview) provide enhanced resiliency by distributing resources across multiple physical locations within an Azure region. This approach minimizes the impact of potential failures for critical infrastructure. By using Extended Zones, your organizations can achieve higher availability and fault tolerance for their applications. Learn how to back up an Azure VM in Azure Extended Zones (preview).

Backup process

Here's how Azure Backup completes a backup for Azure VMs:

1. For Azure VMs that are selected for backup, Azure Backup starts a backup job according to the backup schedule you specify.

2. If you have opted for application or file-system consistent backups, the VM needs to have a backup extension installed to coordinate for the snapshot process.

   If you have opted for crash-consistent backups, no agents are required in the VMs.

3. During the first backup, a backup extension is installed on the VM if the VM is running.

   - For Windows VMs, the VMSnapshot extension is installed.
   - For Linux VMs, the VMSnapshotLinux extension is installed.

4. For Windows VMs that are running, Azure Backup coordinates with Windows Volume Shadow Copy Service (VSS) to take an app-consistent snapshot of the VM.

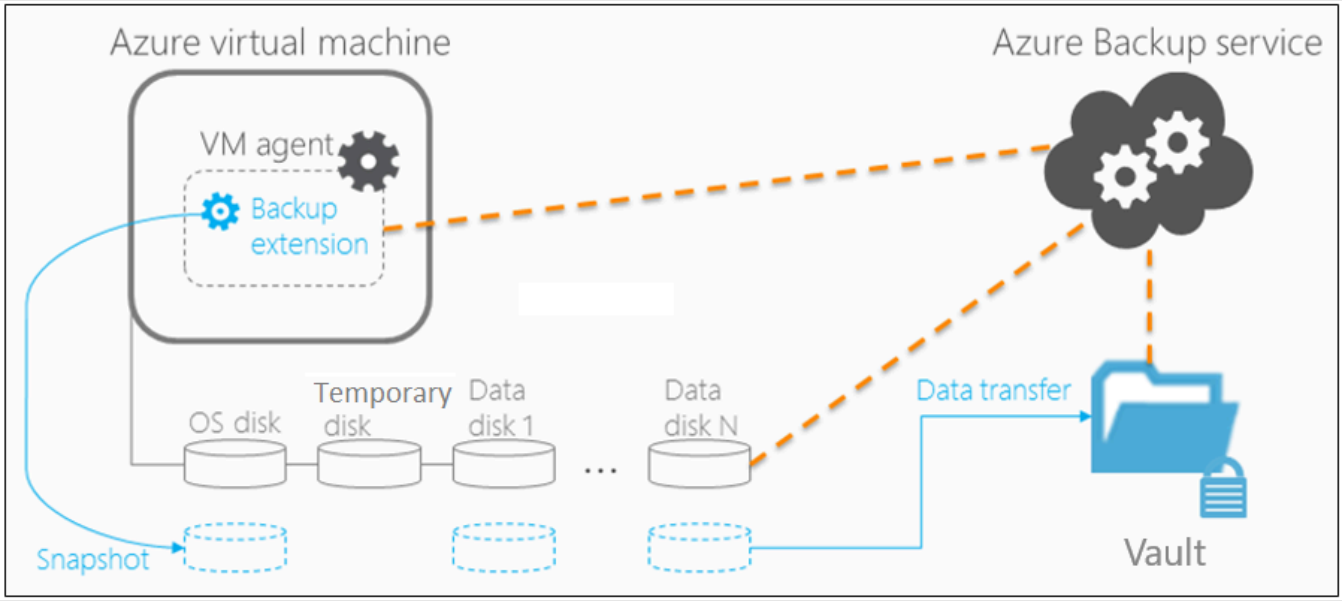
- By default, Backup takes full VSS backups.
- If Backup can't take an app-consistent snapshot, then it takes a file-consistent snapshot of the underlying storage (because no application writes occur while the VM is stopped).

5. For Linux VMs, Backup takes a file-consistent backup. For app-consistent snapshots, you need to manually customize pre/post scripts.

6. For Windows VMs, **Microsoft Visual C++ 2015 Redistributable (x64) version 14.40.33810.0** is installed, the startup of Volume Shadow Copy Service (VSS) is changed to automatic, and a Windows Service **IaaSVmProvider** is added.

7. After Backup takes the snapshot, it transfers the data to the vault.

    - The backup is optimized by backing up each VM disk in parallel.
    - For each disk that's being backed up, Azure Backup reads the blocks on the disk and identifies and transfers only the data blocks that changed (the delta) since the previous backup.
    - Snapshot data might not be immediately copied to the vault. It might take some hours at peak times. Total backup time for a VM will be less than 24 hours for daily backup policies.



Encryption of Azure VM backups

When you back up Azure VMs with Azure Backup, VMs are encrypted at rest with Storage Service Encryption (SSE). Azure Backup can also back up Azure VMs that are encrypted by using Azure Disk Encryption.

Expand table

Encryption	Details	Support
SSE	With SSE, Azure Storage provides encryption at rest by automatically encrypting data before storing it. Azure Storage also decrypts data before retrieving it. Azure Backup supports backups of VMs with two types of Storage Service Encryption: • **SSE with platform-managed keys**: This encryption is by default for all disks in your VMs. See more here. • **SSE with customer-managed keys**. With CMK, you manage the keys used to encrypt the disks. See more here.	Azure Backup uses SSE for at-rest encryption of Azure VMs.
Azure Disk Encryption	Azure Disk Encryption encrypts both OS and data disks for Azure VMs. Azure Disk Encryption integrates with BitLocker encryption keys (BEKs), which are safeguarded in a key vault as secrets. Azure Disk Encryption also integrates with Azure Key Vault key encryption keys (KEKs).	Azure Backup supports backup of managed and unmanaged Azure VMs encrypted with BEKs only, or with BEKs together with KEKs. Both BEKs and KEKs are backed up and encrypted. Because KEKs and BEKs are backed up, users with the necessary permissions can restore keys and secrets back to the key vault if needed. These users can also recover the encrypted VM. Encrypted keys and secrets can't be read by unauthorized users or by Azure.

For managed and unmanaged Azure VMs, Backup supports both VMs encrypted with BEKs only or VMs encrypted with BEKs together with KEKs.

The backed-up BEKs (secrets) and KEKs (keys) are encrypted. They can be read and used only when they're restored back to the key vault by authorized users. Neither unauthorized users, or Azure, can read or use backed-up keys or secrets.

BEKs are also backed up. So, if the BEKs are lost, authorized users can restore the BEKs to the key vault and recover the encrypted VMs. Only users with the necessary level of permissions can back up and restore encrypted VMs or keys and secrets.

Snapshot creation

Azure Backup takes snapshots according to the backup schedule.

If you have opted for application or file-system-consistent backups, the VM needs to have a backup extension installed to coordinate for the snapshot process. For *agentless multi-disk crash-consistent* backups, the VM agent is not required for snapshots.

- **Windows VMs:** For Windows VMs, the Backup service coordinates with VSS to take an app-consistent snapshot of the VM disks. By default, Azure Backup takes a full VSS backup (it truncates the logs of application such as SQL Server at the time of backup to get application level consistent backup). If you're using a SQL Server database on Azure VM backup, then you can modify the setting to take a VSS Copy backup (to preserve logs). For more information, see this article.

- **Linux VMs:** To take app-consistent snapshots of Linux VMs, use the Linux pre-script and post-script framework to write your own custom scripts to ensure consistency.
  - Azure Backup invokes only the pre/post scripts written by you.
  - If the pre-scripts and post-scripts execute successfully, Azure Backup marks the recovery point as application-consistent. However, when you're using custom scripts, you're ultimately responsible for the application consistency.
  - Learn more about how to configure scripts.

- **FSFreeze and safeFreezelockFile**: **Fsfreeze** is a utility used to freeze and thaw the *filesystem* to make their state on consistent during VM backups.

  - **Freeze**: When you freeze a filesystem, the currently running operations are allowed to complete. However, new write system operations and the operations that modify the filesystem are stopped.

  - **Thawing**: This operation reverses the freeze operation. When you thaw a filesystem, the previously stopped operations continue to run effectively, unblocking any modifications.

  During the *Freeze* operation, Azure Backup invokes a file safeFreezelockFile. This prevents the other process to invoke the similar operation so that backup process isn't interrupted. Once the operation is complete, the lock is released.

> ⓘ **Note**
>
> The snapshot process starts with invoking the backup extension (agent-based), using tools such as VSS for Windows or freeze for Linux to ensure data consistency. When consistent, the Restore Point Collection monitors the extension and initiates snapshot creation. Afterward, metadata is updated with restore point paths and commit details to finalize the backup for restoration.

Snapshot consistency

The following table explains the different types of snapshot consistency:

Expand table

Snapshot	Details	Recovery	Consideration
Application-consistent	This is the default setting in the VM backup policy. App-consistent backups capture memory content and pending I/O operations. App-consistent snapshots use a VSS writer (or pre/post scripts for Linux) to ensure the consistency of the app data before a backup occurs.	When you're recovering a VM with an app-consistent snapshot, the VM boots up. There's no data corruption or loss. The apps start in a consistent state.	Windows: All VSS writers succeeded Linux: Pre/post scripts are configured and succeeded
File-system consistent	This is the default setting in the VM backup policy. File-system consistent backups provide consistency by taking a snapshot of all files at the same time.	When you're recovering a VM with a file-system consistent snapshot, the VM boots up. There's no data corruption or loss. Apps need to implement their own "fix-up" mechanism to make sure that restored data is consistent.	Windows: Some VSS writers failed Linux: Default (if pre/post scripts aren't configured or failed)
Crash-consistent	Crash-consistent snapshot is an opt-in setting in the VM backup policy. Azure Backup also takes crash-consistent backups if the VM is not running during backup and when application/file-consistent backups fail. Only the data that already exists on the disk at the time of the backup operation is captured and backed up; data in read/write host cache isn't captured.	Starts with the VM boot process followed by a disk check to fix corruption errors. Any in-memory data or write operations that weren't transferred to disk before the crash are lost. Apps implement their own data verification. For example, a database app can use its transaction log for verification. If the transaction log has entries that aren't in the database, the database software rolls transactions back until the data is consistent.	When you have opted for application/file-system backup and VM is in shutdown (stopped/ deallocated) state and when the snapshot is retried. You have opted for agentless crash consistent backups

> **Note**

If the provisioning state is **succeeded**, Azure Backup takes file-system consistent backups. If the provisioning state is **unavailable** or **failed**, crash-consistent backups are taken. If the provisioning state is **creating** or **deleting**, that means Azure Backup is retrying the operations.

Backup and restore considerations

Expand table

Consideration	Details
Disk	Backup of VM disks is parallel. For example, if a VM has four disks, the Backup service attempts to back up all four disks in parallel. Backup is incremental (only changed data).
Scheduling	To reduce backup traffic, back up different VMs at different times of the day and make sure the times don't overlap. Backing up VMs at the same time causes traffic jams.
Preparing backups	Keep in mind the time needed to prepare the backup. The preparation time might include installing or updating the backup extension and triggering a snapshot according to the backup schedule.
Data transfer	Consider the time needed for Azure Backup to identify the incremental changes from the previous backup. In an incremental backup, Azure Backup determines the changes by calculating the checksum of the block. If a block is changed, it's marked for transfer to the vault. The service analyzes the identified blocks to attempt to further minimize the amount of data to transfer. After the evaluation of all changed blocks is complete, Azure Backup transfers the changes to the vault. There might be a lag between taking the snapshot and copying it to vault. At peak times, it can take up to eight hours for the snapshots to be transferred to the vault. The backup time for a VM will be less than 24 hours for the daily backup.
Initial backup	The total backup time for incremental backups is less than 24 hours, which might not be the case for the first backup. The time needed for the initial backup will depend on the size of the data and when the backup is processed.
Restore queue	Azure Backup processes restore jobs from multiple storage accounts at the same time, and it puts restore requests in a queue.
Restore copy	During the restore process, data is copied from the vault to the storage account. The total restore time depends on the I/O operations per second (IOPS) and the throughput of the storage account.

Consideration	Details
	To reduce the copy time, select a storage account that isn't loaded with other application writes and reads.

> **Note**
>
> Azure Backup now enables you to back up your Azure VMs multiple times a day using the Enhanced policy. With this capability, you can also define the duration in which your backup jobs would trigger and align your backup schedule with the working hours when there are frequent updates to Azure Virtual Machines. Learn more.

Backup performance

These common scenarios can affect the total backup time:

- **Adding a new disk to a protected Azure VM:** If a VM is undergoing incremental backup and a new disk is added, the backup time will increase. The total backup time might last more than 24 hours because of initial replication of the new disk, along with delta replication of existing disks.
- **Fragmented disks:** Backup operations are faster when disk changes are contiguous. If changes are spread out and fragmented across a disk, backup will be slower.
- **Disk churn:** If protected disks that are undergoing incremental backup have a daily churn of more than 200 GB, backup can take a long time (more than eight hours) to complete.
- **Backup versions:** The latest version of Backup (known as the Instant Restore version) uses a more optimized process than checksum comparison for identifying changes. But if you're using Instant Restore and have deleted a backup snapshot, the backup switches to checksum comparison. In this case, the backup operation will exceed 24 hours (or fail).

Restore performance

These common scenarios can affect the total restore time:

- The total restore time depends on the Input/output operations per second (IOPS) and the throughput of the storage account.
- The total restore time can be affected if the target storage account is loaded with other application read and write operations. To improve restore operation, select a storage account that isn't loaded with other application data.

Best practices

When you're configuring VM backups, we suggest following these practices:

- Modify the default schedule times that are set in a policy. For example, if the default time in the policy is 12:00 AM, increment the timing by several minutes so that resources are optimally used.
- If you're restoring VMs from a single vault, we highly recommend that you use different general-purpose v2 storage accounts to ensure that the target storage account doesn't get throttled. For example, each VM must have a different storage account. For example, if 10 VMs are restored, use 10 different storage accounts.
- For backup of VMs that are using premium storage with Instant Restore, we recommend allocating *50%* free space of the total allocated storage space, which is required **only** for the first backup. The 50% free space isn't a requirement for backups after the first backup is complete
- The limit on the number of disks per storage account is relative to how heavily the disks are being accessed by applications that are running on an infrastructure as a service (IaaS) VM. As a general practice, if 5 to 10 disks or more are present on a single storage account, balance the load by moving some disks to separate storage accounts.
- To restore VMs with managed disks using PowerShell, provide the additional parameter ***TargetResourceGroupName*** to specify the resource group to which managed disks will be restored, Learn more here.

Backup costs

Azure VMs backed up with Azure Backup are subject to Azure Backup pricing.

Billing doesn't start until the first successful backup finishes. At this point, the billing for both storage and protected VMs begins. Billing continues as long as any backup data for the VM is stored in a vault. If you stop protection for a VM, but backup data for the VM exists in a vault, billing continues.

Billing for a specified VM stops only if the protection is stopped and all backup data is deleted. When protection stops and there are no active backup jobs, the size of the last successful VM backup becomes the protected instance size used for the monthly bill.

If you have opted for agent-based application consistent or file-system consistent backups, the protected-instance size calculation is based on the *actual* size of the VM. The VM's size is the sum of all the data in the VM, excluding the temporary storage. Pricing is based on the actual data that's stored on the data disks, not on the maximum supported size for each data disk that's attached to the VM.

> **Note**

The agentless multi-disk crash consistent VM backup feature is generally available. This release includes changes to billing; see the pricing details.

Similarly, the backup storage bill is based on the amount of data that's stored in Azure Backup, which is the sum of the actual data in each recovery point.

For example, take an A2-Standard-sized VM that has two additional data disks with a maximum size of 32 TB each. The following table shows the actual data stored on each of these disks:

Expand table

Disk	Max size	Actual data present
OS disk	32 TB	17 GB
Local/temporary disk	135 GB	5 GB (not included for backup)
Data disk 1	32 TB	30 GB
Data disk 2	32 TB	0 GB

The actual size of the VM in this case is 17 GB + 30 GB + 0 GB = 47 GB. This protected-instance size (47 GB) becomes the basis for the monthly bill. As the amount of data in the VM grows, the protected-instance size used for billing changes to match.

Next steps

- Prepare for Azure VM backup.

Last updated on 01/08/2026

Quickstart: Back up a virtual machine in Azure with the Azure CLI

The Azure CLI is used to create and manage Azure resources from the command line or in scripts. You can protect your data by taking backups at regular intervals. Azure Backup creates recovery points that can be stored in geo-redundant recovery vaults. This article details how to back up a virtual machine (VM) in Azure with the Azure CLI. You can also perform these steps with Azure PowerShell or in the Azure portal.

This quickstart enables backup on an existing Azure VM. If you need to create a VM, you can create a VM with the Azure CLI.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Get started with Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Authenticate to Azure using Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use and manage extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.
- This quickstart requires version 2.0.18 or later of the Azure CLI. If using Azure Cloud Shell, the latest version is already installed.

Create a Recovery Services vault for Azure VM backup

A Recovery Services vault is a logical container that stores the backup data for each protected resource, such as Azure VMs. When the backup job for a protected resource runs, it creates a

recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time.

Create a Recovery Services vault with az backup vault create. Specify the same resource group and location as the VM you wish to protect. If you used the VM quickstart, then you created:

- a resource group named *myResourceGroup*,
- a VM named *myVM*,
- resources in the *eastus* location.

Azure CLI

```
az backup vault create --resource-group myResourceGroup \
    --name myRecoveryServicesVault \
    --location eastus
```

By default, the Recovery Services vault is set for Geo-Redundant storage. Geo-Redundant storage ensures your backup data is replicated to a secondary Azure region that's hundreds of miles away from the primary region. If the storage redundancy setting needs to be modified, use az backup vault backup-properties set cmdlet.

Azure CLI

```
az backup vault backup-properties set \
    --name myRecoveryServicesVault  \
    --resource-group myResourceGroup \
    --backup-storage-redundancy "LocallyRedundant/GeoRedundant"
```

Enable backup for an Azure VM

Create a protection policy to define: when a backup job runs, and how long the recovery points are stored. The default protection policy runs a backup job each day and retains recovery points for 30 days. You can use these default policy values to quickly protect your VM. To enable backup protection for a VM, use az backup protection enable-for-vm. Specify the resource group and VM to protect, then the policy to use:

Azure CLI

```
az backup protection enable-for-vm \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --vm myVM \
    --policy-name DefaultPolicy
```

> **Note**
>
> If the VM isn't in the same resource group as that of the vault, then myResourceGroup refers to the resource group where vault was created. Instead of VM name, provide the VM ID as indicated below.

Azure CLI

```
az backup protection enable-for-vm \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --vm $(az vm show -g VMResourceGroup -n MyVm --query id | tr -d '"') \
    --policy-name DefaultPolicy
```

> **Important**
>
> While using CLI to enable backup for multiple VMs at once, ensure that a single policy doesn't have more than 100 VMs associated with it. This is a recommended best practice. Currently, the PowerShell client doesn't explicitly block if there are more than 100 VMs, but the check is planned to be added in the future.

Prerequisites to backup encrypted VMs

To enable protection on encrypted VMs (encrypted using BEK and KEK), you must provide the Azure Backup service permission to read keys and secrets from the key vault. To do so, set a *keyvault* access policy with the required permissions, as demonstrated below:

Azure CLI

```
# Enter the name of the resource group where the key vault is located on this
variable
AZ_KEYVAULT_RGROUP=TestKeyVaultRG

# Enter the name of the key vault on this variable
AZ_KEYVAULT_NAME=TestKeyVault

# Get the object id for the Backup Management Service on your subscription
AZ_ABM_OBJECT_ID=$( ad sp list --display-name "Backup Management Service" --query
'[].id' -o tsv --only-show-errors )

# This command will grant the permissions required by the Backup Management Service
to access the key vault
az keyvault set-policy --key-permissions get list backup --secret-permissions get
list backup \
```

```
  --resource-group $AZ_KEYVAULT_RGROUP --name $AZ_KEYVAULT_NAME --object-id
$AZ_ABM_OBJECT_ID
```

Trigger an Azure VM backup job

To trigger a backup job rather than wait for the default policy to run the job at the scheduled time, use az backup protection backup-now. This first backup job creates a full recovery point. Each backup job after this initial backup creates incremental recovery points. Incremental recovery points are storage and time-efficient, as they only transfer changes made since the last backup.

The following parameters are used to back up the VM:

- `--container-name` is the name of your VM
- `--item-name` is the name of your VM
- `--retain-until` value should be set to the last available date, in UTC time format (**dd-mm-yyyy**), that you wish the recovery point to be available

The following example backs up the VM named *myVM* and sets the expiration of the recovery point to October 18, 2017:

Azure CLI

```
az backup protection backup-now \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --container-name myVM \
    --item-name myVM \
    --backup-management-type AzureIaaSVM
    --retain-until 18-10-2017
```

Monitor the backup job for the Azure VM

To monitor the status of backup jobs, use az backup job list:

Azure CLI

```
az backup job list \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --output table
```

The output is similar to the following example, which shows the backup job is *InProgress*:

Output

```
Name      Operation         Status      Item Name    Start Time UTC       Duration
--------  ---------------   ----------  -----------  -------------------  -----------
---
a0a8e5e6  Backup            InProgress  myvm         2017-09-19T03:09:21
0:00:48.718366
fe5d0414  ConfigureBackup   Completed   myvm         2017-09-19T03:03:57
0:00:31.191807
```

When the *Status* of the backup job reports *Completed*, your VM is protected with Recovery Services and has a full recovery point stored.

Clean up deployment for the Azure VM backup

When no longer needed, you can disable protection on the VM, remove the restore points and Recovery Services vault, then delete the resource group and associated VM resources. If you used an existing VM, you can skip the final az group delete command to leave the resource group and VM in place.

If you want to try a Backup tutorial that explains how to restore data for your VM, go to Next steps.

Azure CLI

```azurecli
az backup protection disable \
    --resource-group myResourceGroup \
    --vault-name myRecoveryServicesVault \
    --container-name myVM \
    --item-name myVM \
    --backup-management-type AzureIaaSVM
    --delete-backup-data true
az backup vault delete \
    --resource-group myResourceGroup \
    --name myRecoveryServicesVault \
az group delete --name myResourceGroup
```

Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point. To learn more about Azure Backup and Recovery Services, continue to the tutorials.

- Back up multiple Azure VMs
- Restore an Azure VM using REST API

Last updated on 12/19/2025

Quickstart: Back up a virtual machine in Azure with PowerShell

The Azure PowerShell AZ module is used to create and manage Azure resources from the command line or in scripts.

Azure Backup backs up on-premises machines and apps, and Azure VMs. This article shows you how to back up an Azure VM with the AZ module. Alternatively, you can back up a VM using the Azure CLI, or in the Azure portal.

This quickstart enables backup on an existing Azure VM. If you need to create a VM, you can create a VM with Azure PowerShell.

This quickstart requires the Azure PowerShell AZ module version 1.0.0 or later. Run `Get-Module -ListAvailable Az` to find the version. If you need to install or upgrade, see Install Azure PowerShell module.

> **Note**
>
> We recommend that you use the Azure Az PowerShell module to interact with Azure. To get started, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Sign in and register

1. Sign in to your Azure subscription with the `Connect-AzAccount` command and follow the on-screen directions.

   PowerShell

   ```
   Connect-AzAccount
   ```

2. The first time you use Azure Backup, you must register the Azure Recovery Service provider in your subscription with Register-AzResourceProvider, as follows:

   PowerShell

   ```
   Register-AzResourceProvider -ProviderNamespace "Microsoft.RecoveryServices"
   ```

Create a Recovery Services vault for Azure VM backup

A Recovery Services vault is a logical container that stores backup data for protected resources, such as Azure VMs. When a backup job runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time.

When you create the vault:

- For the resource group and location, specify the resource group and location of the VM you want to back up.
- If you used this sample script to create the VM, the resource group is **myResourceGroup**, the VM is ***myVM**, and the resources are in the **WestEurope** region.
- Azure Backup automatically handles storage for backed up data. By default the vault uses Geo-Redundant Storage (GRS). Geo-redundancy ensures that backed up data is replicated to a secondary Azure region, hundreds of miles away from the primary region.

Now create a vault:

1. Use the New-AzRecoveryServicesVault to create the vault:

   PowerShell

   ```
   New-AzRecoveryServicesVault `
       -ResourceGroupName "myResourceGroup" `
       -Name "myRecoveryServicesVault" `
   -Location "WestEurope"
   ```

2. Set the vault context with Set-AzRecoveryServicesVaultContext, as follows:

   PowerShell

   ```
   Get-AzRecoveryServicesVault `
       -Name "myRecoveryServicesVault" | Set-AzRecoveryServicesVaultContext
   ```

3. Change the storage redundancy configuration (LRS/GRS) of the vault with Set-AzRecoveryServicesBackupProperty, as follows:

   PowerShell

   ```
   Get-AzRecoveryServicesVault `
       -Name "myRecoveryServicesVault" | Set-AzRecoveryServicesBackupProperty -
   BackupStorageRedundancy LocallyRedundant/GeoRedundant
   ```

> **Note**
>
> Storage Redundancy can be modified only if there are no backup items protected to the vault.

Enable backup for an Azure VM

You enable backup for an Azure VM, and specify a backup policy.

- The policy defines when backups run, and how long recovery points created by the backups should be retained.
- The default protection policy runs a backup once a day for the VM, and retains the created recovery points for 30 days. You can use this default policy to quickly protect your VM.

Enable backup as follows:

1. First, set the default policy with Get-AzRecoveryServicesBackupProtectionPolicy:

   PowerShell

   ```
   $policy = Get-AzRecoveryServicesBackupProtectionPolicy     -Name
   "DefaultPolicy"
   ```

2. Enable VM backup with Enable-AzRecoveryServicesBackupProtection. Specify the policy, the resource group, and the VM name.

   PowerShell

   ```
   Enable-AzRecoveryServicesBackupProtection `
       -ResourceGroupName "myResourceGroup" `
       -Name "myVM" `
       -Policy $policy
   ```

Trigger an Azure VM backup job

Backups run according to the schedule specified in the backup policy. You can also run an on-demand backup:

- The first initial backup job creates a full recovery point.
- After the initial backup, each backup job creates incremental recovery points.

- Incremental recovery points are storage and time-efficient, as they only transfer changes made since the last backup.

To run an on-demand backup, you use the Backup-AzRecoveryServicesBackupItem.

- You specify a container in the vault that holds your backup data with Get-AzRecoveryServicesBackupContainer.
- Each VM to back up is treated as an item. To start a backup job, you obtain information about the VM with Get-AzRecoveryServicesBackupItem.

Run an on-demand backup job as follows:

1. Specify the container, obtain VM information, and run the backup.

   PowerShell

   ```
   $backupcontainer = Get-AzRecoveryServicesBackupContainer `
       -ContainerType "AzureVM" `
       -FriendlyName "myVM"

   $item = Get-AzRecoveryServicesBackupItem `
       -Container $backupcontainer `
       -WorkloadType "AzureVM"

   Backup-AzRecoveryServicesBackupItem -Item $item
   ```

2. You might need to wait up to 20 minutes, since the first backup job creates a full recovery point. Monitor the job as described in the next procedure.

Monitor the backup job for the Azure VM

To monitor the status of backup jobs, use Get-AzRecoveryservicesBackupJob cmdlet.

PowerShell

```
Get-AzRecoveryservicesBackupJob
```

Output is similar to the following example, which shows the job as **InProgress**:

Output

```
WorkloadName   Operation         Status       StartTime              EndTime
JobID
------------   ---------         ------       ---------              -------
-----
myvm           Backup            InProgress   9/18/2017 9:38:02 PM
9f9e8f14
```

```
myvm            ConfigureBackup    Completed    9/18/2017 9:33:18 PM    9/18/2017
9:33:51 PM    fe79c739
```

When the job status is **Completed**, the VM is protected and has a full recovery point stored.

Manage VM backups

If you want to perform more actions such as change policy, edit policy etc.. refer to the manage VM backups section.

Clean up the deployment for Azure VM backup

If you no longer need to back up the VM, you can clean it up.

- If you want to try out restoring the VM, skip the clean-up.
- If you used an existing VM, you can skip the final Remove-AzResourceGroup cmdlet to leave the resource group and VM in place.

Disable protection, remove the restore points and vault. Then delete the resource group and associated VM resources, as follows:

PowerShell

```powershell
Disable-AzRecoveryServicesBackupProtection -Item $item -RemoveRecoveryPoints
$vault = Get-AzRecoveryServicesVault -Name "myRecoveryServicesVault"
Remove-AzRecoveryServicesVault -Vault $vault
Remove-AzResourceGroup -Name "myResourceGroup"
```

Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point.

Last updated on 12/19/2025

Quickstart: Back up a virtual machine in Azure

This quickstart describes how to enable backup on an existing Azure VM by using the Azure portal. If you need to create a VM, you can create a VM with the Azure portal.

Azure backups can be created through the Azure portal. This method provides a browser-based user interface to create and configure Azure backups and all related resources. You can protect your data by taking backups at regular intervals. Azure Backup creates recovery points that can be stored in geo-redundant recovery vaults. This article details how to back up a virtual machine (VM) with the Azure portal.

Sign in to Azure

Sign in to the Azure portal.

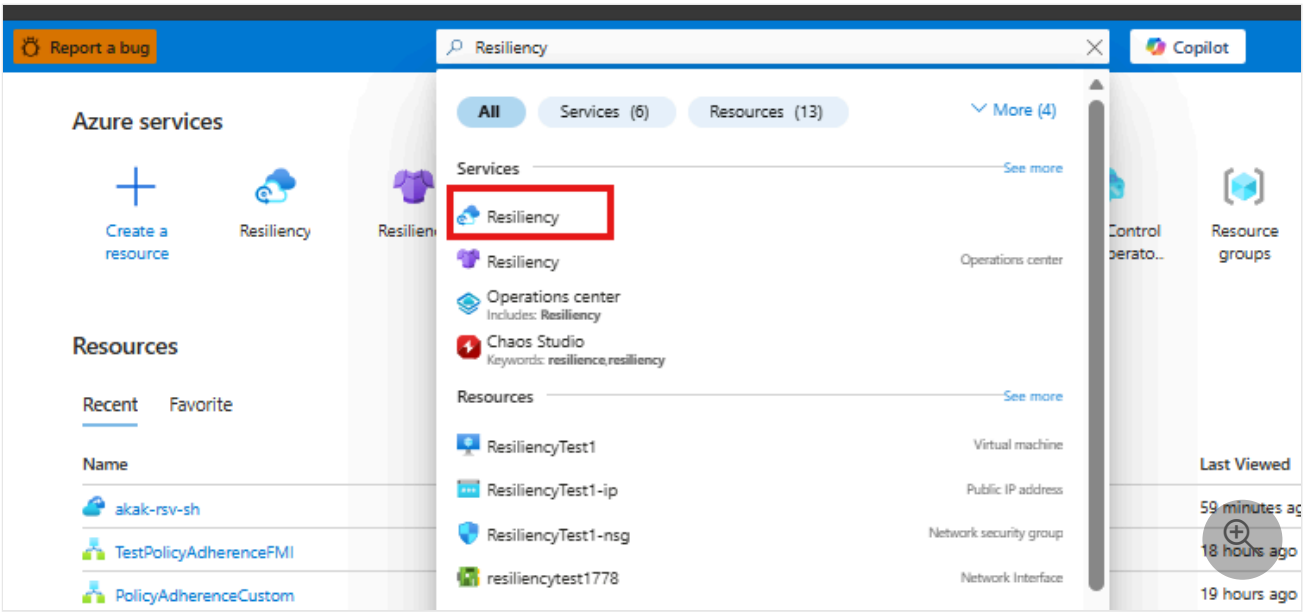
Create a Recovery Services vault

A Recovery Services vault is a management entity that stores recovery points that are created over time. It provides an interface to perform backup-related operations. These operations include taking on-demand backups, performing restores, and creating backup policies.

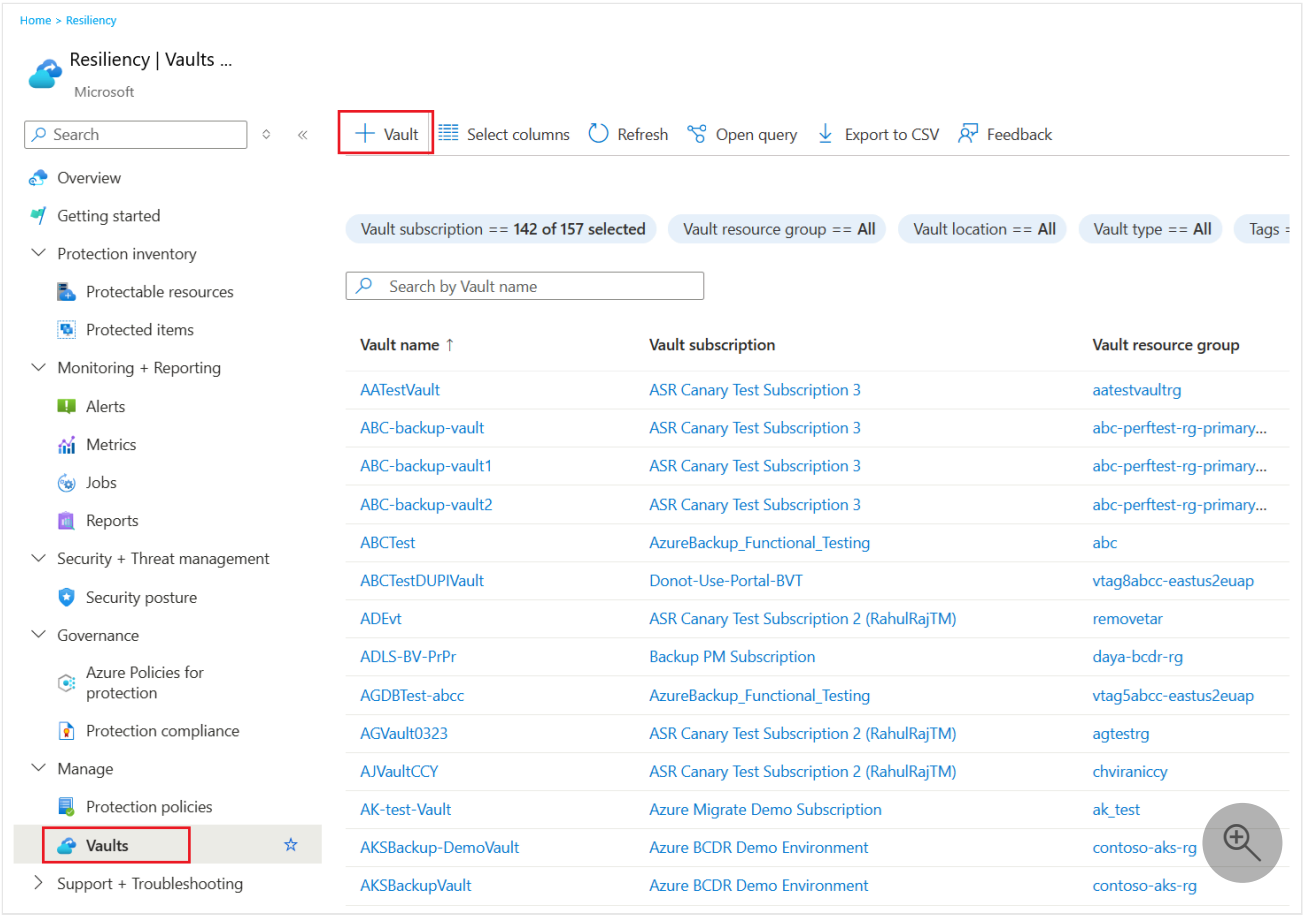
To create a Recovery Services vault:

1. Sign in to the Azure portal.

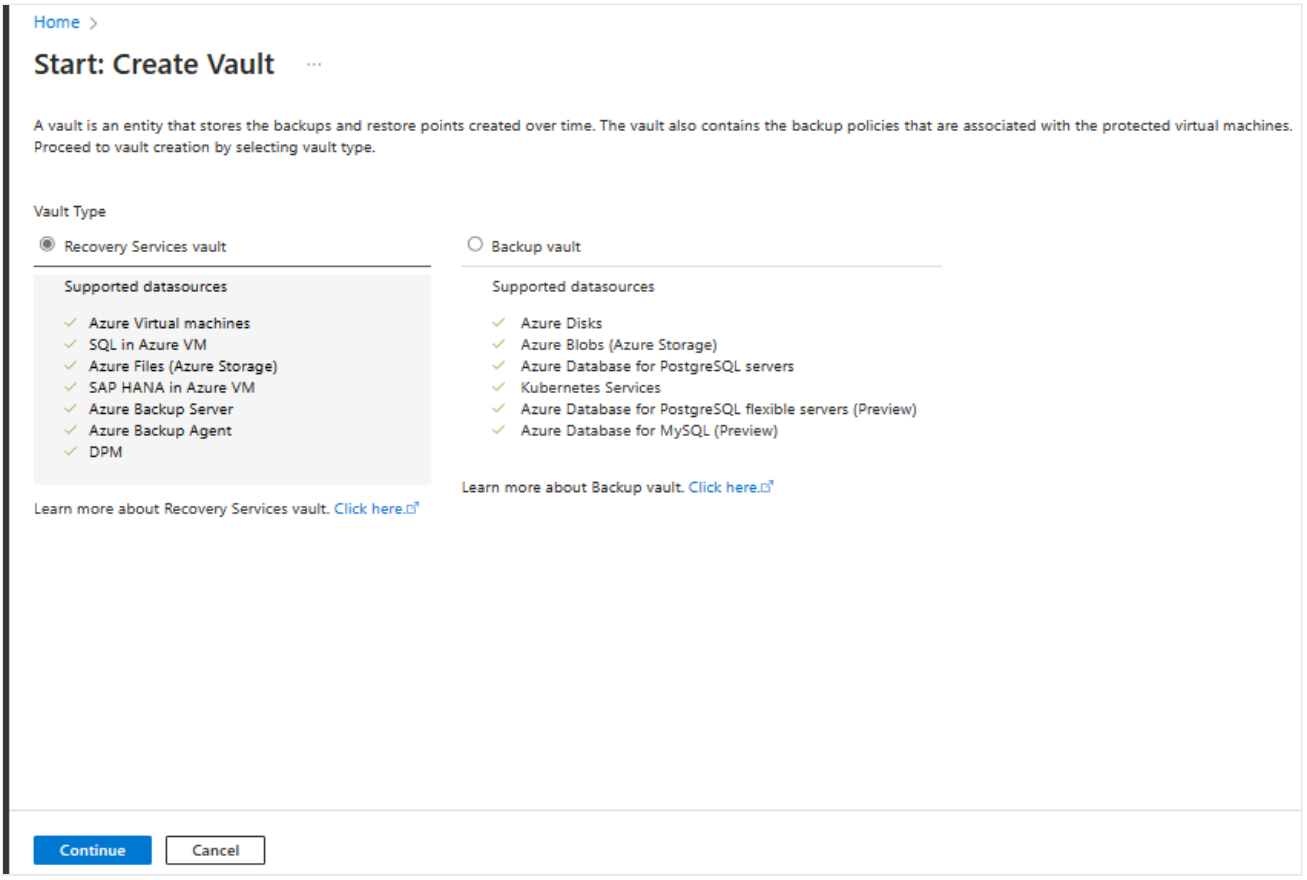
2. Search for **Resiliency**, and then go to the **Resiliency** dashboard.



3. On the **Vault** pane, select **+ Vault**.



4. Select **Recovery Services vault** > **Continue**.



5. On the **Create Recovery Services vault** pane, enter the following values:

   - **Subscription**: Select the subscription to use. If you're a member of only one subscription, you see that name. If you're not sure which subscription to use, use the default subscription. Multiple choices appear only if your work or school account is associated with more than one Azure subscription.

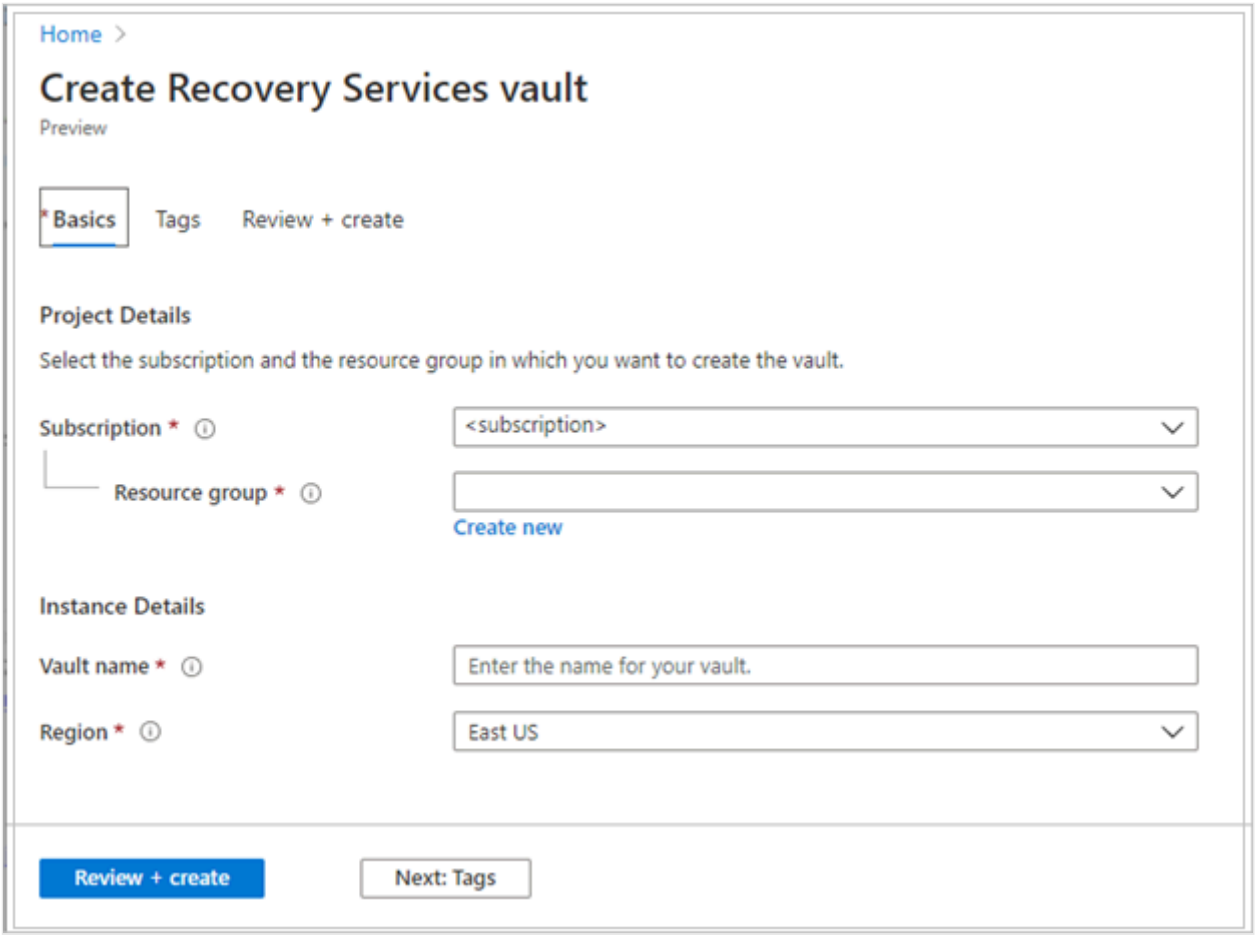
   - **Resource group**: Use an existing resource group or create a new one. To view a list of available resource groups in your subscription, select **Use existing**. Then select a resource in the dropdown list. To create a new resource group, select **Create new**, and then enter the name. For more information about resource groups, see Azure Resource Manager overview.

   - **Vault name**: Enter a friendly name to identify the vault. The name must be unique to the Azure subscription. Specify a name that has at least 2 but not more than 50 characters. The name must start with a letter and consist only of letters, numbers, and hyphens.

   - **Region**: Select the geographic region for the vault. For you to create a vault to help protect any data source, the vault *must* be in the same region as the data source.

     > **Important**

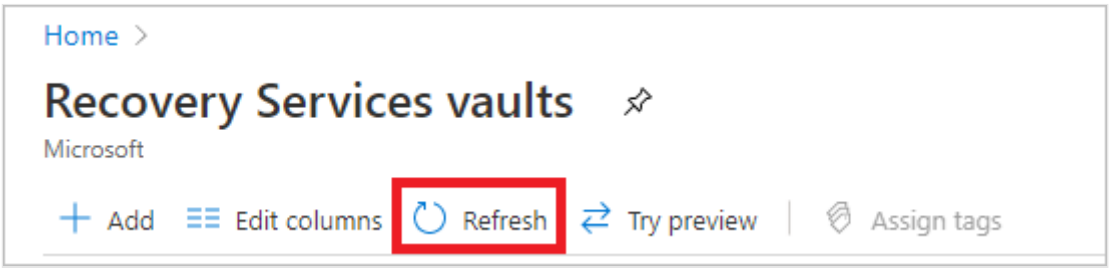
If you're not sure of the location of your data source, close the window. Go to the list of your resources in the portal. If you have data sources in multiple regions, create a Recovery Services vault for each region. Create the vault in the first location before you create a vault in another location. You don't need to specify storage accounts to store the backup data. The Recovery Services vault and Azure Backup handle that step automatically.



6. After you provide the values, select **Review + create**.

7. To finish creating the Recovery Services vault, select **Create**.

   It can take a while to create the Recovery Services vault. Monitor the status notifications in the **Notifications** area at the upper right. After the vault is created, it appears in the list of Recovery Services vaults. If the vault doesn't appear, select **Refresh**.



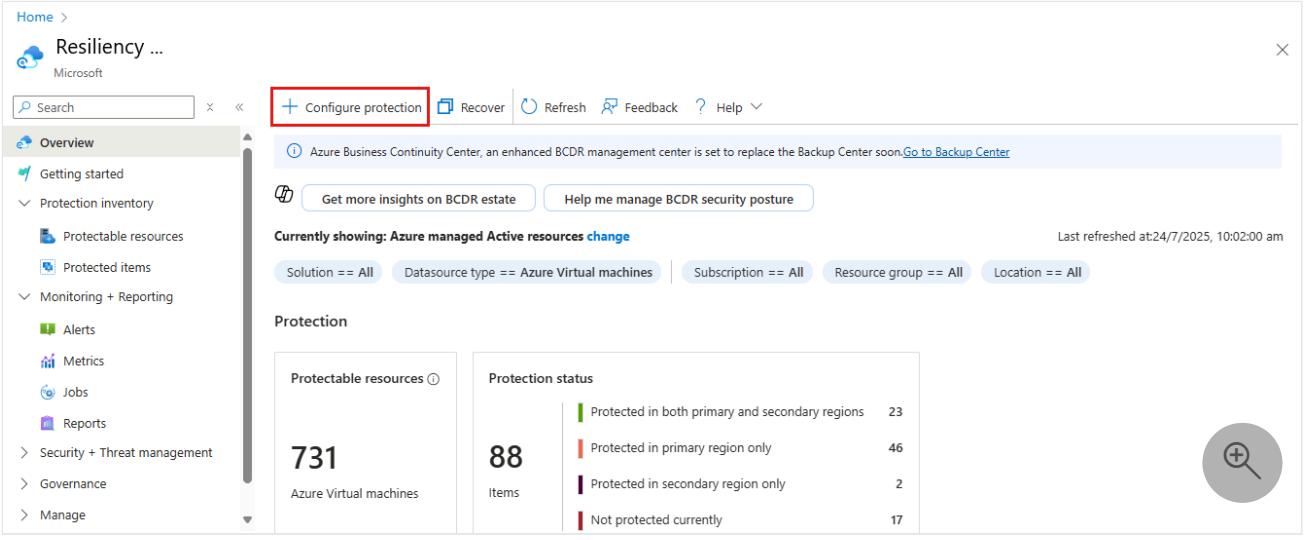
Azure Backup now supports immutable vaults that help you ensure that after recovery points are created, they can't be deleted before their expiry according to the backup policy. You can make the immutability irreversible to help protect your backup data from various threats, including ransomware attacks and malicious actors. Learn more about Azure Backup immutable vaults.

> **Important**
>
> If you have Azure Files for protection, after vault creation, configure backup for Azure Files, and then initiate an on-demand backup. Learn more about the best practices for Azure Files backup.

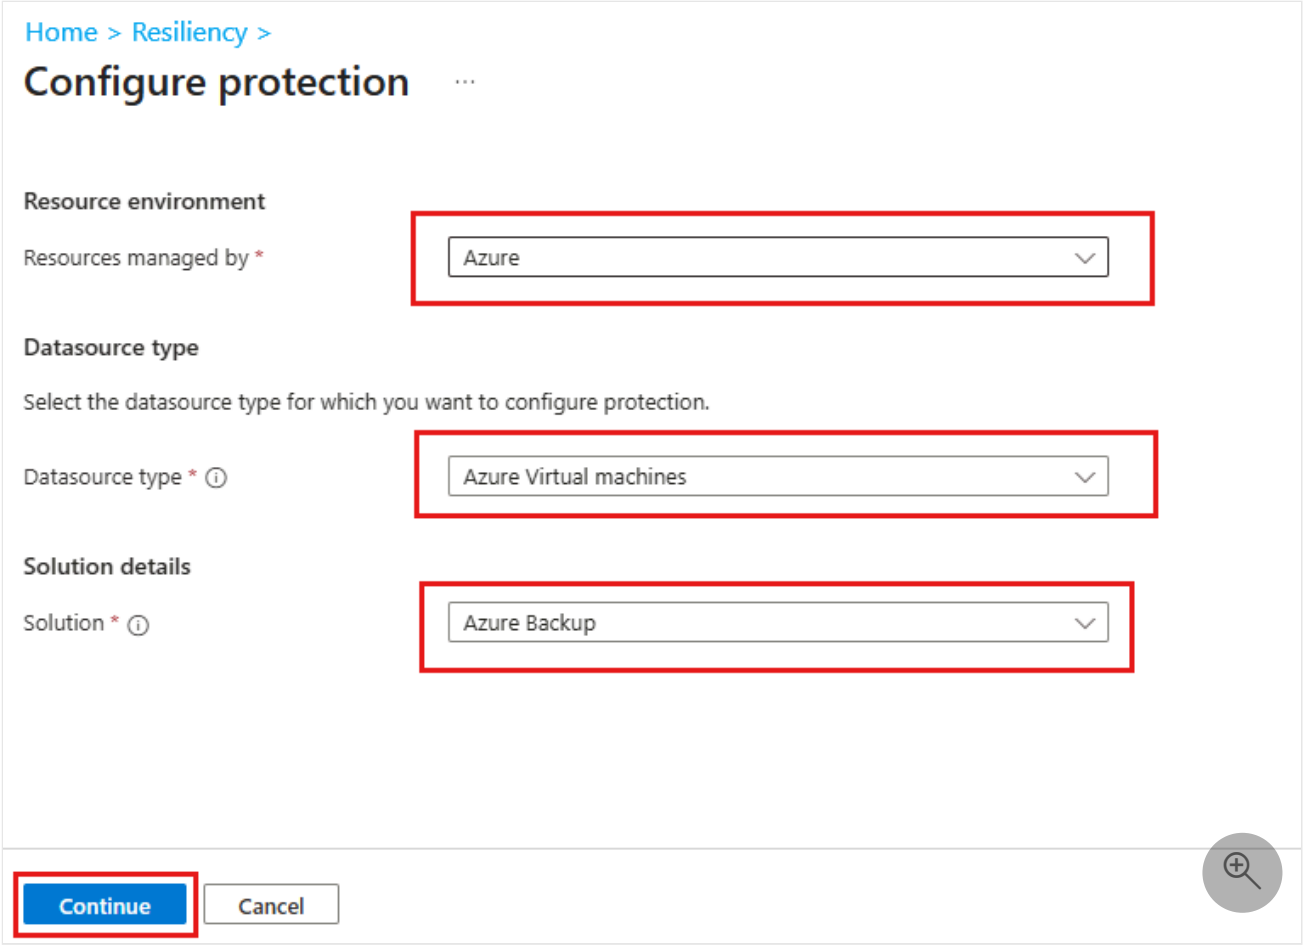
Apply a backup policy

To apply a backup policy to your Azure VMs, follow these steps:

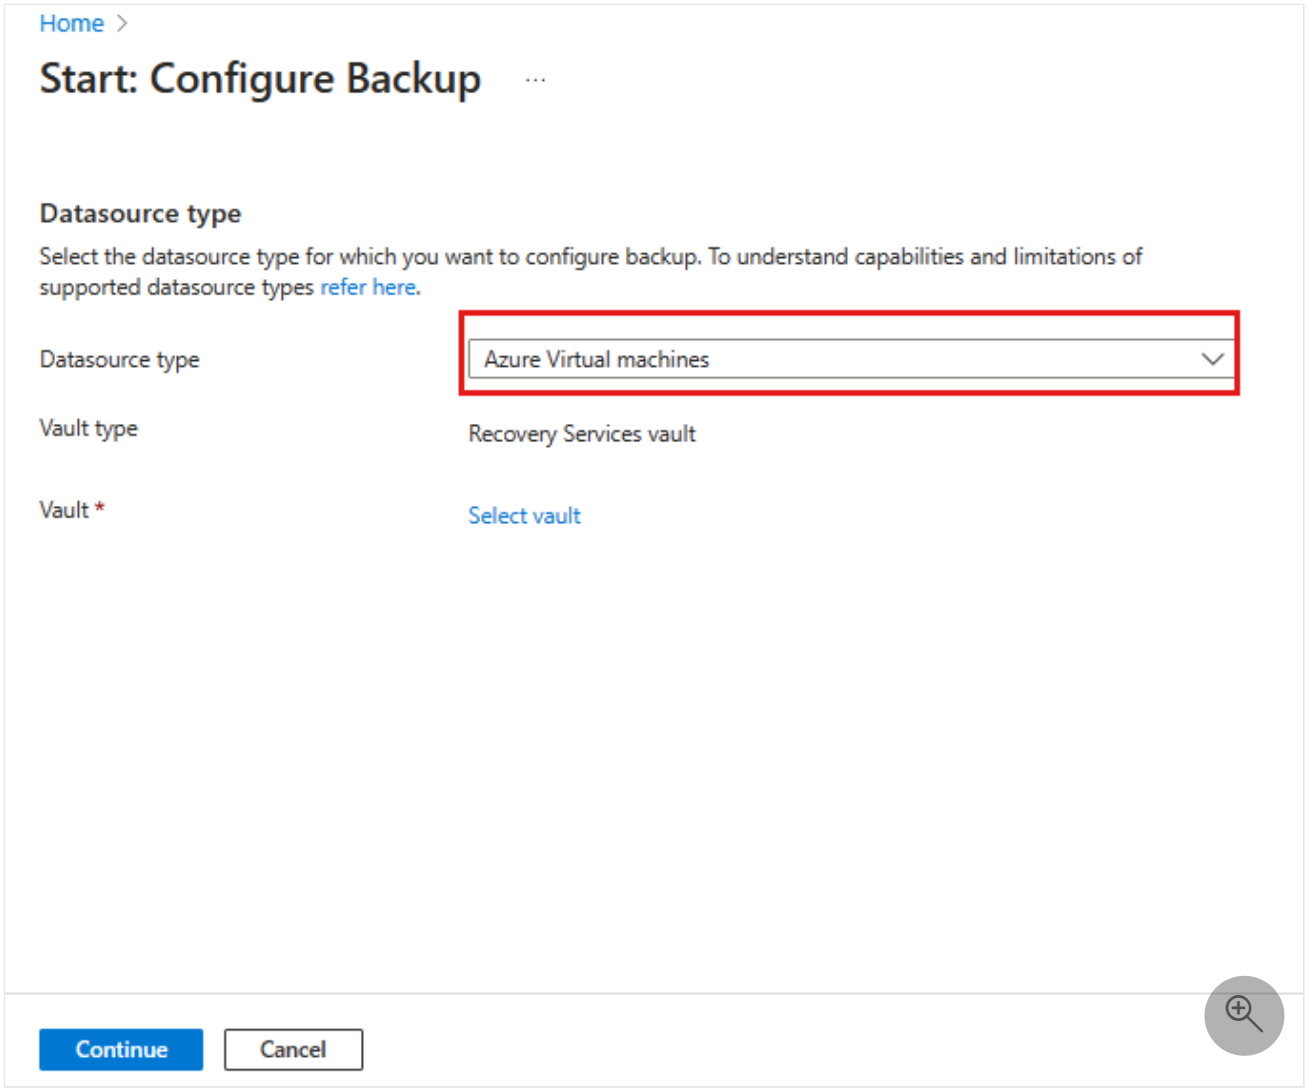
1. Go to **Resiliency** and select **+ Configure protection**.



2. On the **Configure protection** pane, select **Resource managed by** as **Azure**, **Datasource type** as **Azure Virtual machines**, **Solution** as **Azure Backup**, and then select **Continue**.

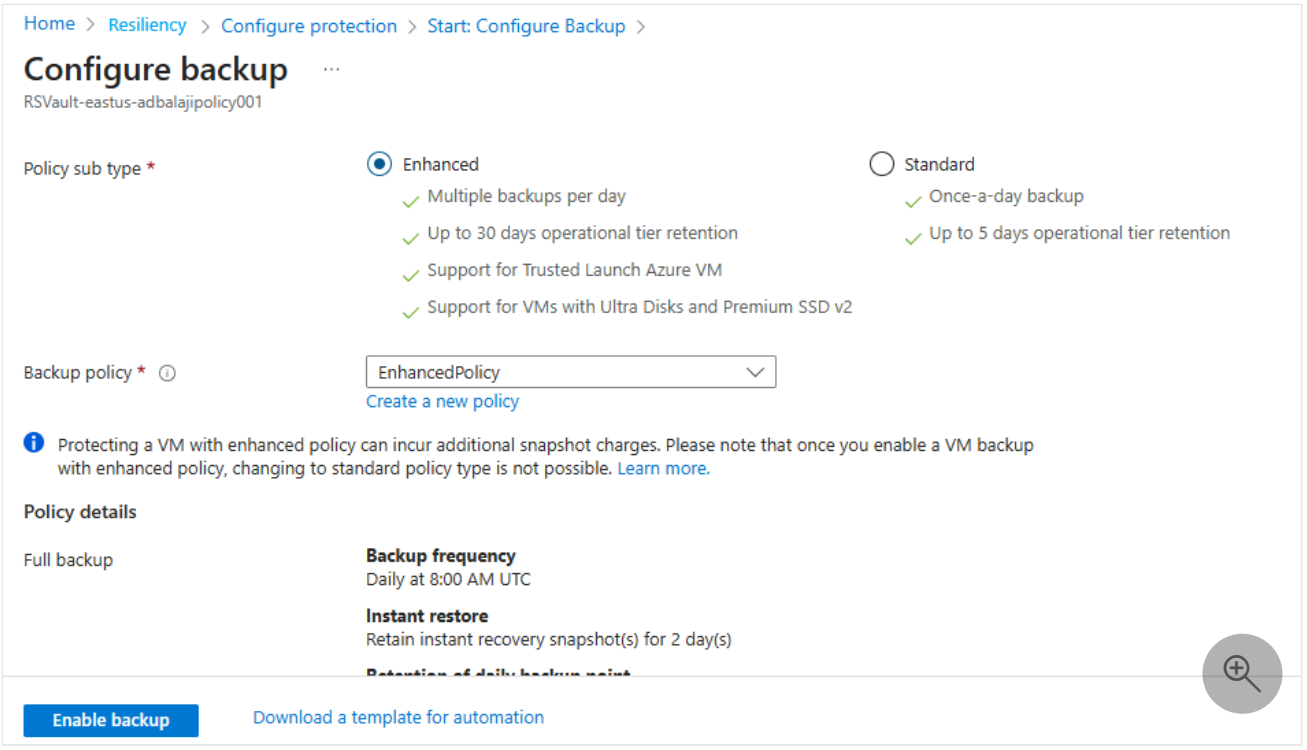


3. On the **Start: Configure Backup** pane, select **Azure Virtual machines** as the **Datasource type** and select the vault you have created. Then select **Continue**.



4. On the **Configure backup** pane, select the **Policy sub type** as **Enhanced**, **Standard**.

- **Enhanced Backup policy**: This policy allows multiple daily backups, enabling hourly backups. To enable Azure Backup on Azure VMs in Azure Extended Zones, you can only use the Enhanced policy.
- **Standard Backup policy**: This policy allows VM backup once a day. The daily backups are retained for 30 days. Instant recovery snapshots are retained for two days.

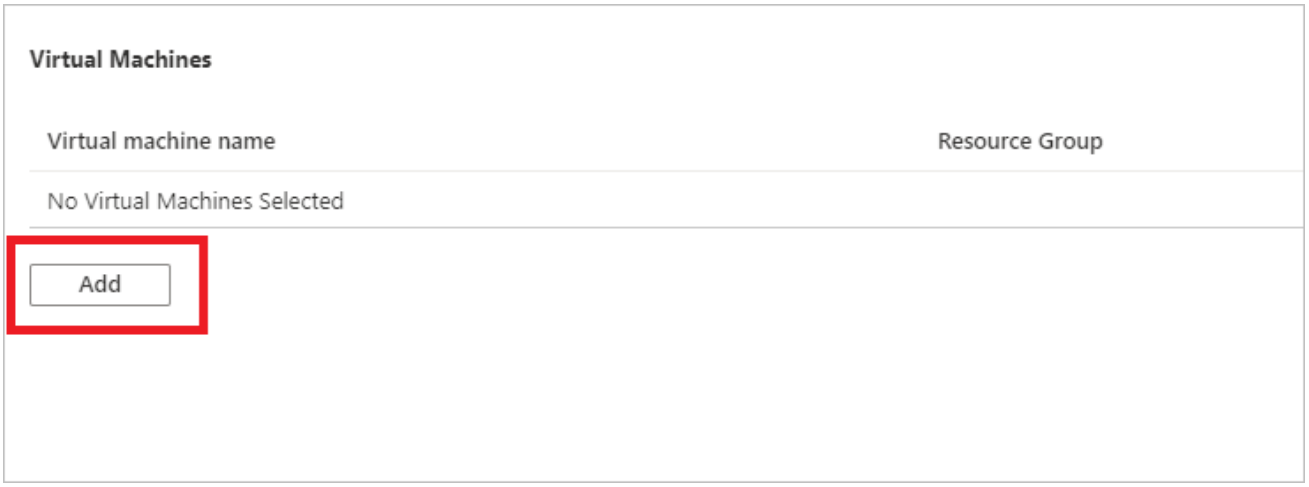


If you don't want to use the default policy, select **Create New**, and create a custom policy as described in the next procedure.

Select a VM to back up

Create a scheduled daily backup to a Recovery Services vault.

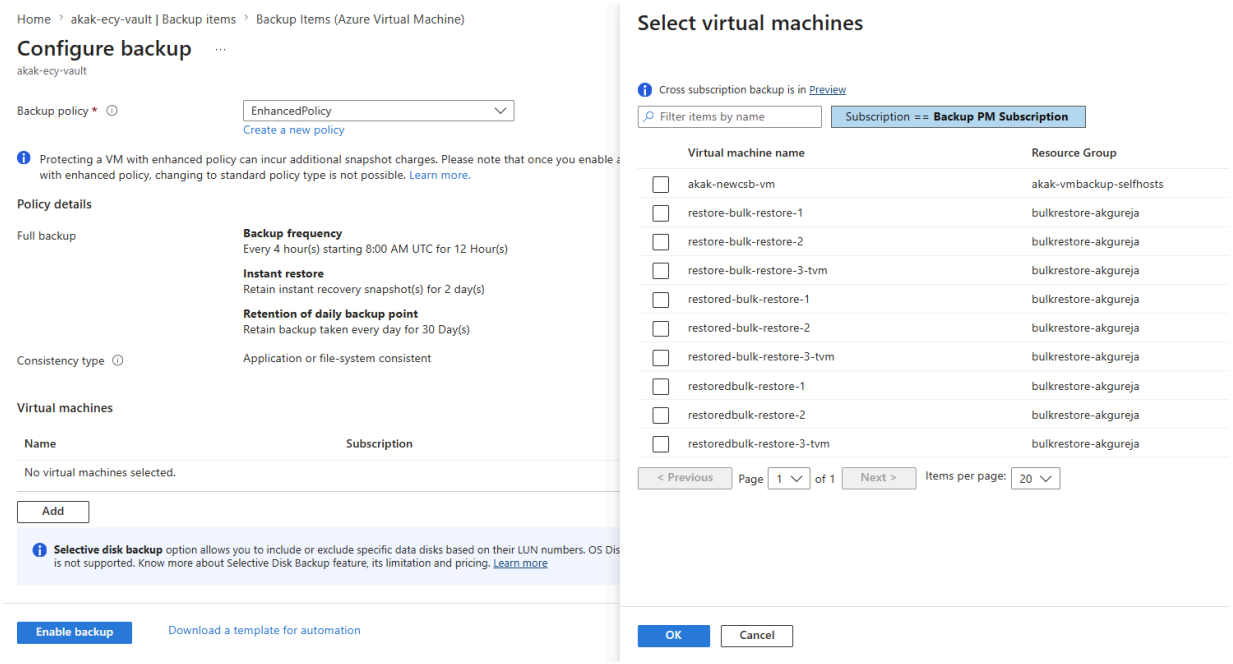
1. Under **Virtual Machines**, select **Add**.



2. The **Select virtual machines** blade will open. Select the VMs you want to back up using the policy. Then select **OK**.

   - The selected VMs are validated.
   - You can only select VMs in the same region as the vault.

- VMs can only be backed up in a single vault.



> **Note**
>
> All the VMs in the same region as the vault are available to configure backup, including eligible VMs in a different subscription when the VM and vault are in the same tenant. When configuring backup, you can browse to the virtual machine name and its resource group, even though you don't have the required permission on those VMs. If your VM is in soft deleted state, then it won't be visible in this list. If you need to re-protect the VM, then you need to wait for the soft delete period to expire or undelete the VM from the soft deleted list. For more information, see the soft delete for VMs article.

Enable backup on a VM

A Recovery Services vault is a logical container that stores the backup data for each protected resource, such as Azure VMs. When the backup job for a protected resource runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time.

To enable VM backup, in **Backup**, select **Enable backup**. This deploys the policy to the vault and to the VMs, and installs the backup extension on the VM agent running on the Azure VM.

After enabling backup:

- The Backup service installs the backup extension whether or not the VM is running.

- An initial backup will run in accordance with your backup schedule.
- When backups run, note that:
  - A VM that's running has the greatest chance for capturing an application-consistent recovery point.
  - However, even if the VM is turned off, it's backed up. Such a VM is known as an offline VM. In this case, the recovery point will be crash-consistent.
- Explicit outbound connectivity isn't required to allow backup of Azure VMs.

Create a custom policy

If you selected to create a new backup policy, fill in the policy settings.

1. In **Policy name**, specify a meaningful name.

2. In **Backup schedule**, specify when backups should be taken. You can take daily or weekly backups for Azure VMs.

3. In **Instant Restore**, specify how long you want to retain snapshots locally for instant restore.

   - When you restore, backed up VM disks are copied from storage, across the network to the recovery storage location. With instant restore, you can leverage locally stored snapshots taken during a backup job, without waiting for backup data to be transferred to the vault.
   - You can retain snapshots for instant restore for between one to five days. The default value is two days.

4. In **Retention range**, specify how long you want to keep your daily or weekly backup points.

5. In **Retention of monthly backup point** and **Retention of yearly backup point**, specify whether you want to keep a monthly or yearly backup of your daily or weekly backups.

6. Select **OK** to save the policy.

   > ⓘ **Note**
   >
   > To store the restore point collection (RPC), the Backup service creates a separate resource group (RG). This RG is different than RG of the VM. Learn more.

Azure Backup service creates a separate resource group to store the instant recovery points of managed virtual machines. The default naming format of resource group created by Azure Backup service is AzureBackupRG_{Geo}_{n}. It is optional to customize the name as per your requirement. Learn More
Azure Backup Resource Group (Optional)
Enter the name
n
Suffix (Optional)
OK

Note

Azure Backup doesn't support automatic clock adjustment for daylight-saving changes for Azure VM backups. As time changes occur, modify backup policies manually as required.

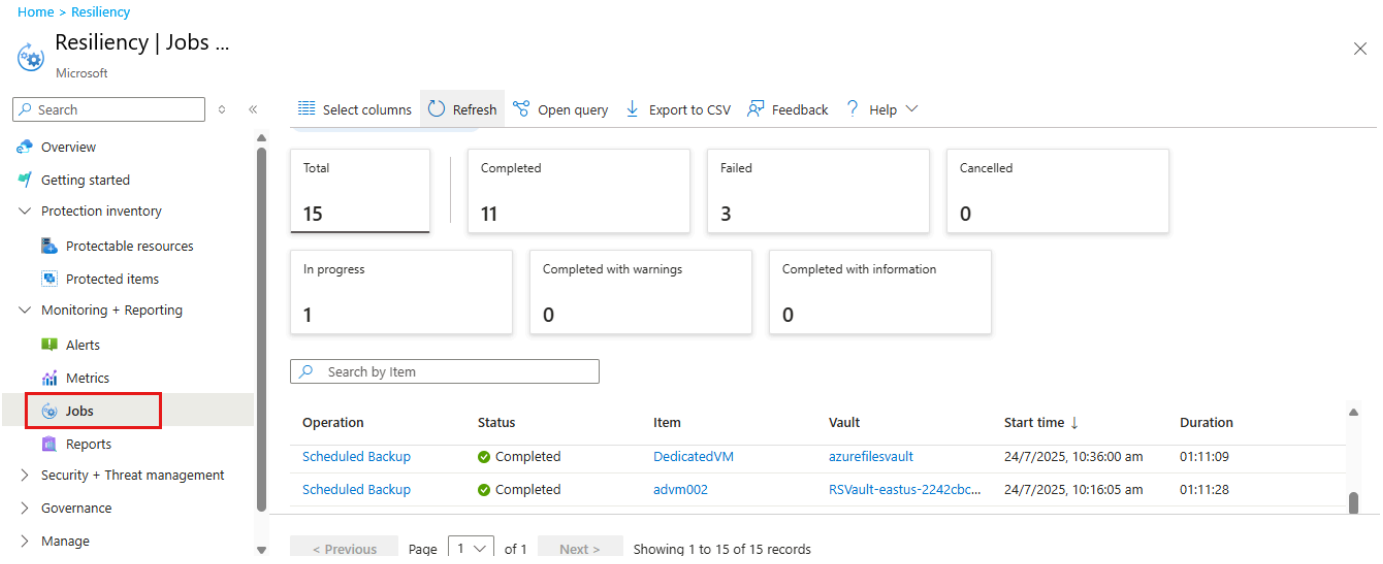
Start a backup job

The initial backup will run in accordance with the schedule, but you can run it immediately as follows:

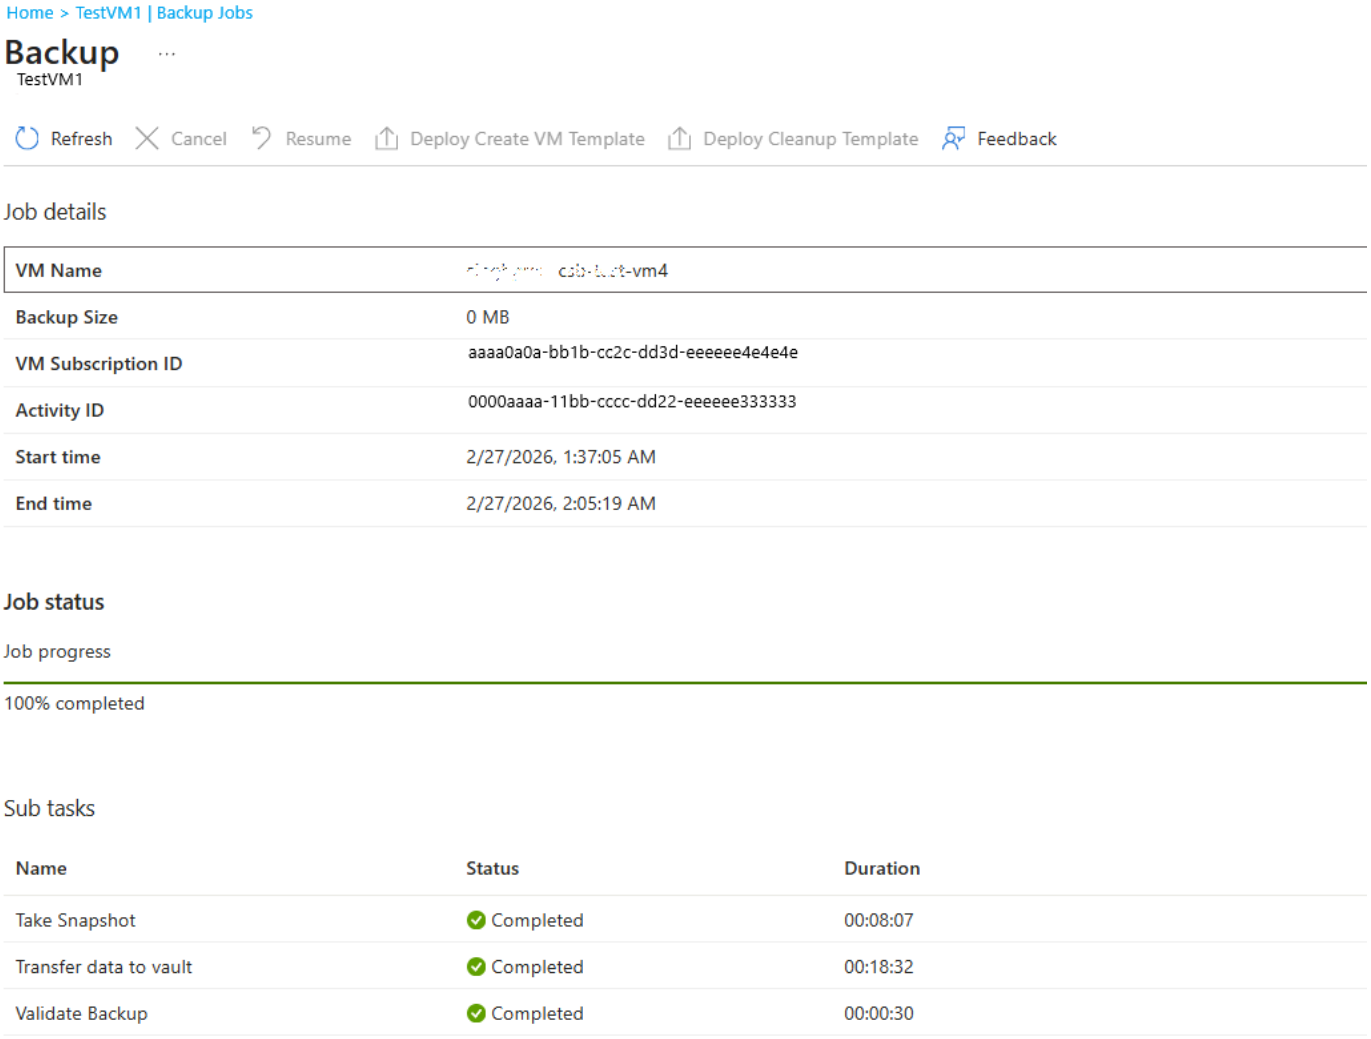
1. Go to **Resiliency** and then select **Protection Inventory** > **Protected items**.
2. On the **Protected items** pane, filter **Datasource type** by Virtual machines, and then select the **more icon** > **Details** corresponding to the VM instance you want to back up.
3. On the selected VM instance pane, right-click the relevant row or select the more icon (...), and then select **Backup Now**.
4. On the **Backup now** pane, use the calendar control to select the last day that the recovery point should be retained. Then select **OK**.

Monitor the backup job

Backup job details show **Snapshot** and **Transfer data to vault** subtasks. **Snapshot** ensures availability of a recovery point for Instant Restore. **Transfer data to vault** creates a recovery point in the vault for long-term retention and starts after **Snapshot** completes.



There are **Sub Tasks** running at the backend, one for front-end backup job that can be checked from the **Backup Job** details blade as given below:



For information on VM backup job phases and how to interpret the progress bar, see Verify the backup job status.

Depending on disk size and churn, **Transfer data to vault** can take time to complete. See the related article for job-status combinations, parallel backup behavior, and recovery-point guidance.

Optional steps

Install the VM agent

Azure Backup backs up Azure VMs by installing an extension to the Azure VM agent running on the machine. If your VM was created from an Azure Marketplace image, the agent is installed and running. If you create a custom VM, or you migrate an on-premises machine, you might need to install the agent manually, as summarized in the table.

Expand table

VM	Details
Windows	1. Download and install the agent MSI file. 2. Install with admin permissions on the machine. 3. Verify the installation. In *C:\WindowsAzure\Packages* on the VM, right-click **WaAppAgent.exe** > **Properties**. On the **Details** tab, **Product Version** should be 2.6.1198.718 or higher. If you're updating the agent, make sure that no backup operations are running, and reinstall the agent.
Linux	Install by using an RPM or a DEB package from your distribution's package repository. This is the preferred method for installing and upgrading the Azure Linux agent. All the endorsed distribution providers integrate the Azure Linux agent package into their images and repositories. The agent is available on GitHub, but we don't recommend installing from there. If you're updating the agent, make sure no backup operations are running, and update the binaries.

Clean up deployment

When no longer needed, you can disable protection on the VM, remove the restore points and Recovery Services vault, then delete the resource group and associated VM resources

Learn how to stop protection and delete VM backups.

Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point. To learn more about Azure Backup and Recovery Services, continue to the tutorials.

- Back up multiple Azure VMs
- Restore an Azure VM using REST API

Back up a virtual machine in Azure with an ARM template

Azure Backup backs up on-premises machines and apps, and Azure VMs. This article shows you how to back up an Azure VM with an Azure Resource Manager template (ARM template) and Azure PowerShell. This quickstart focuses on the process of deploying an ARM template to create a Recovery Services vault. For more information on developing ARM templates, see the Azure Resource Manager documentation and the template reference.

An Azure Resource Manager template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. You describe your intended deployment without writing the sequence of programming commands to create the deployment.

A Recovery Services vault is a logical container that stores backup data for protected resources, such as Azure VMs. When a backup job runs, it creates a recovery point inside the Recovery Services vault. You can then use one of these recovery points to restore data to a given point in time. Alternatively, you can back up a VM using Azure PowerShell, the Azure CLI, or in the Azure portal.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

Review the template

The template used in this quickstart is from Azure quickstart Templates. This template allows you to deploy simple Windows VM and Recovery Services vault configured with the *DefaultPolicy* for *Protection*.

        "[resourceId('Microsoft.Compute/virtualMachines', variables('vmName'))]"
      ]
    }
  ]
}
```

The resources defined in the template are:

- Microsoft.Storage/storageAccounts
- Microsoft.Network/publicIPAddresses
- Microsoft.Network/networkSecurityGroups
- Microsoft.Network/virtualNetworks
- Microsoft.Network/networkInterfaces
- Microsoft.Compute/virtualMachines
- Microsoft.RecoveryServices/vaults
- Microsoft.RecoveryServices/vaults/backupFabrics/protectionContainers/protectedItems

Deploy the template

To deploy the template, select **Try it** to open the Azure Cloud Shell, and then paste the following PowerShell script into the shell window. To paste the code, right-click the shell window and then select **Paste**.

Azure PowerShell

```
$projectName = Read-Host -Prompt "Enter a project name (limited to eight characters) that is used to generate Azure resource names"
$location = Read-Host -Prompt "Enter the location (for example, centralus)"
$adminUsername = Read-Host -Prompt "Enter the administrator username for the virtual machine"
$adminPassword = Read-Host -Prompt "Enter the administrator password for the virtual machine" -AsSecureString
$dnsPrefix = Read-Host -Prompt "Enter the unique DNS Name for the Public IP used to access the virtual machine"

$resourceGroupName = "${projectName}rg"
$templateUri = "https://raw.githubusercontent.com/Azure/azure-quickstart-templates/master/quickstarts/microsoft.recoveryservices/recovery-services-create-vm-and-configure-backup/azuredeploy.json"

New-AzResourceGroup -Name $resourceGroupName -Location $location
New-AzResourceGroupDeployment -ResourceGroupName $resourceGroupName -TemplateUri $templateUri -projectName $projectName -adminUsername $adminUsername -adminPassword $adminPassword -dnsLabelPrefix $dnsPrefix
```

Azure PowerShell is used to deploy the ARM template in this quickstart. The Azure portal, Azure CLI, and REST API can also be used to deploy templates.

Validate the deployment

Start a backup job

The template creates a VM and enables backup on the VM. After you deploy the template, you need to start a backup job. For more information, see Start a backup job.

Monitor the backup job

To monitor the backup job, see Monitor the backup job.

Clean up resources

If you no longer need to back up the VM, you can clean it up.

- If you want to try out restoring the VM, skip the cleanup.
- If you used an existing VM, you can skip the final Remove-AzResourceGroup cmdlet to leave the resource group and VM in place.

Disable protection, remove the restore points and vault. Then delete the resource group and associated VM resources, as follows:

PowerShell

```
Disable-AzRecoveryServicesBackupProtection -Item $item -RemoveRecoveryPoints
$vault = Get-AzRecoveryServicesVault -Name "myRecoveryServicesVault"
Remove-AzRecoveryServicesVault -Vault $vault
Remove-AzResourceGroup -Name "myResourceGroup"
```

Next steps

In this quickstart, you created a Recovery Services vault, enabled protection on a VM, and created the initial recovery point.

- Learn how to back up VMs in the Azure portal.
- Learn how to quickly restore a VM
- Learn how to create ARM templates.
- Learn how to restore an Azure VM using REST API

Tutorial: Back up multiple virtual machines by using the Azure portal

This tutorial describes how to back up multiple virtual machines (VMs) by using the Azure portal.

Azure stores backup data in a Recovery Services vault, which is accessible from the **Settings** menu of most services. This integration simplifies the backup process. However, managing each database or virtual machine separately can be tedious. To streamline backups for multiple virtual machines (for department or location), you can create a backup policy and apply it to the relevant machines.

In this tutorial, you:

- ✓ Create a Recovery Services vault.
- ✓ Set the vault to help protect virtual machines.
- ✓ Create a custom backup and retention policy.
- ✓ Assign the policy to help protect multiple virtual machines.
- ✓ Trigger an on-demand back up for virtual machines.

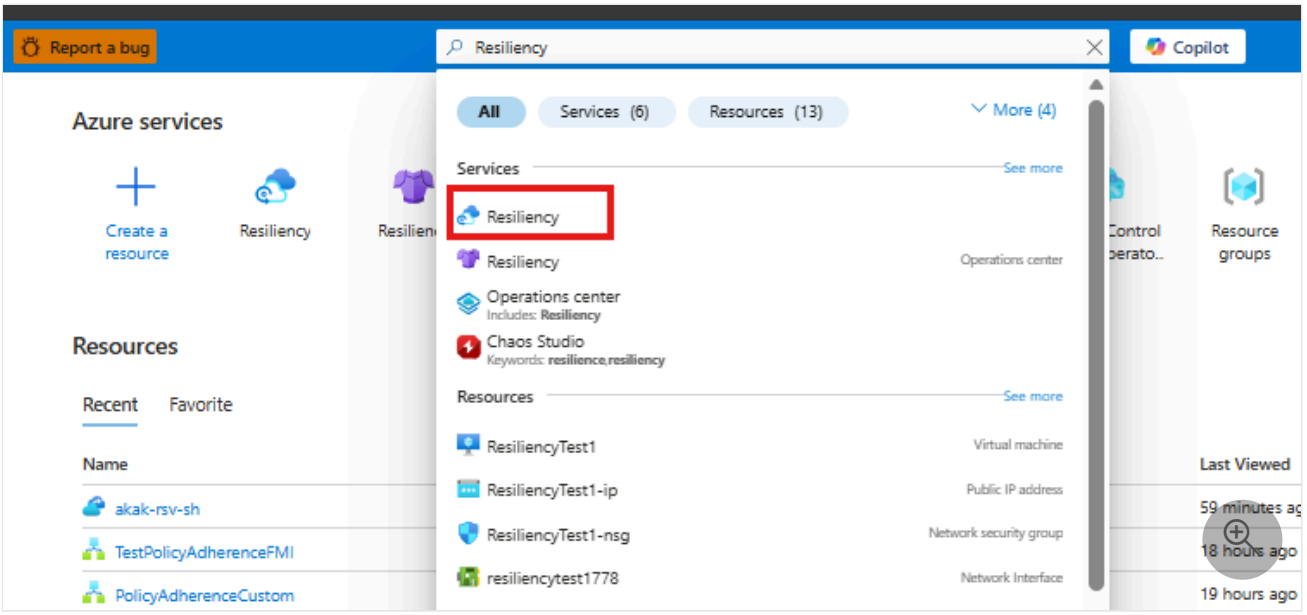
> ⓘ **Note**
>
> The functionality that the following sections describe can also be accessed via Resiliency. Resiliency in Azure is a cloud-native unified experience for resiliency posture management that enables you to manage your protection estate across solutions and environments.

Create a Recovery Services vault

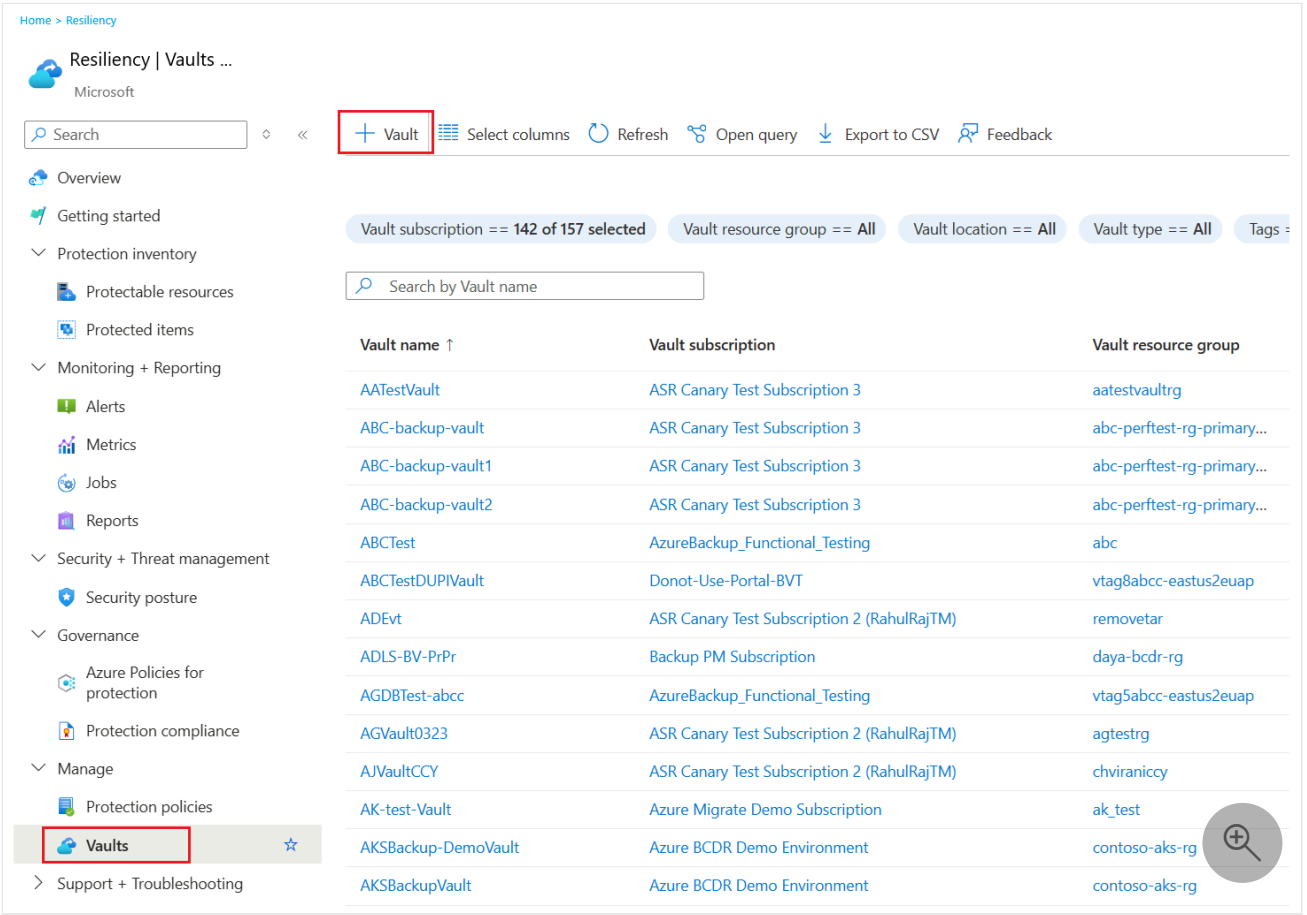
A Recovery Services vault is a management entity that stores recovery points that are created over time. It provides an interface to perform backup-related operations. These operations include taking on-demand backups, performing restores, and creating backup policies.

To create a Recovery Services vault:

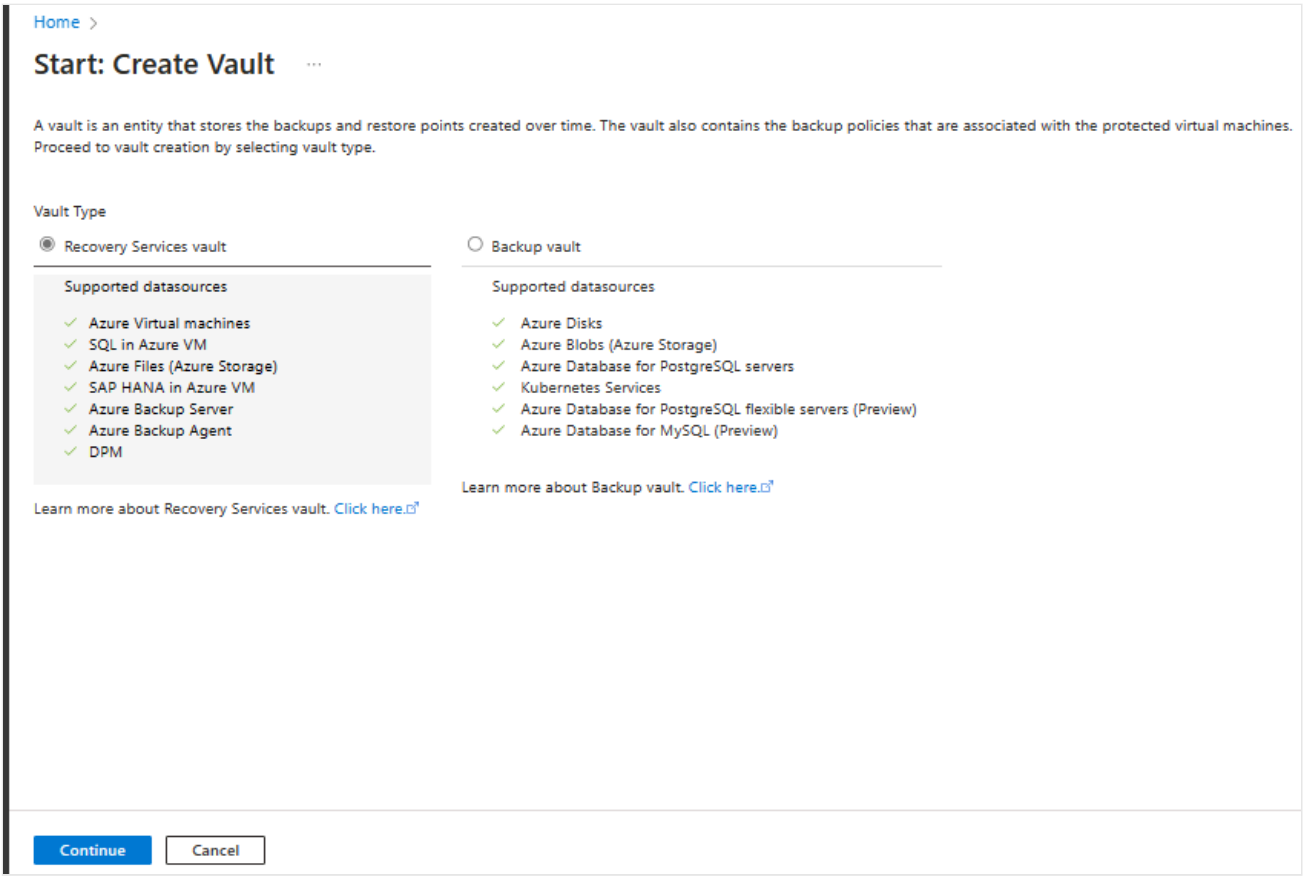
1. Sign in to the Azure portal.
2. Search for **Resiliency**, and then go to the **Resiliency** dashboard.



3. On the **Vault** pane, select **+ Vault**.



4. Select **Recovery Services vault** > **Continue**.



5. On the **Create Recovery Services vault** pane, enter the following values:

   - **Subscription**: Select the subscription to use. If you're a member of only one subscription, you see that name. If you're not sure which subscription to use, use the default subscription. Multiple choices appear only if your work or school account is associated with more than one Azure subscription.

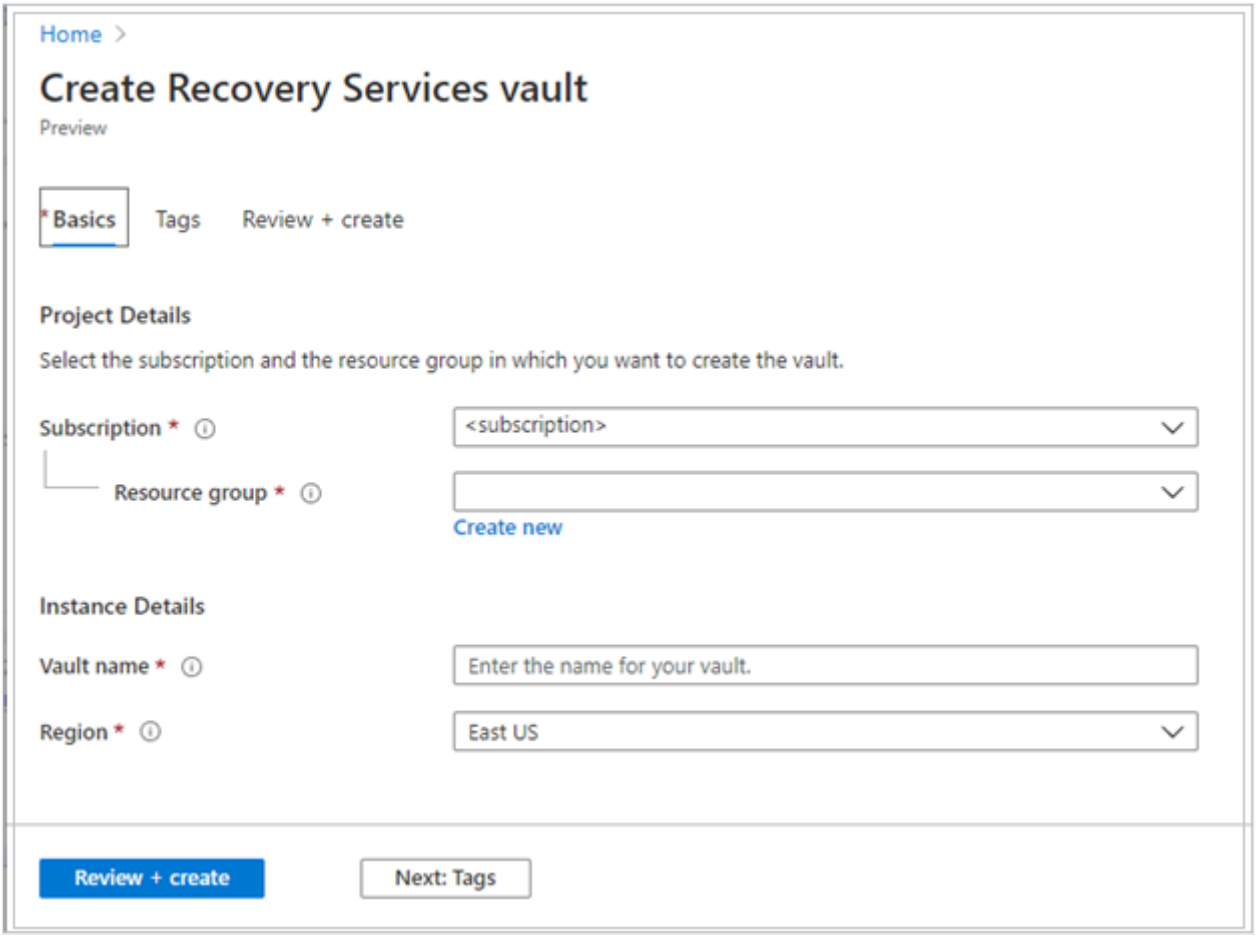
   - **Resource group**: Use an existing resource group or create a new one. To view a list of available resource groups in your subscription, select **Use existing**. Then select a resource in the dropdown list. To create a new resource group, select **Create new**, and then enter the name. For more information about resource groups, see Azure Resource Manager overview.

   - **Vault name**: Enter a friendly name to identify the vault. The name must be unique to the Azure subscription. Specify a name that has at least 2 but not more than 50 characters. The name must start with a letter and consist only of letters, numbers, and hyphens.

   - **Region**: Select the geographic region for the vault. For you to create a vault to help protect any data source, the vault *must* be in the same region as the data source.

     > **Important**

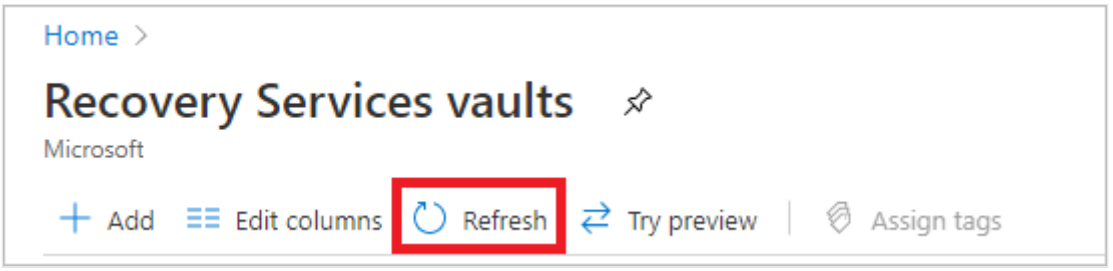
If you're not sure of the location of your data source, close the window. Go to the list of your resources in the portal. If you have data sources in multiple regions, create a Recovery Services vault for each region. Create the vault in the first location before you create a vault in another location. You don't need to specify storage accounts to store the backup data. The Recovery Services vault and Azure Backup handle that step automatically.



6. After you provide the values, select **Review + create**.

7. To finish creating the Recovery Services vault, select **Create**.

   It can take a while to create the Recovery Services vault. Monitor the status notifications in the **Notifications** area at the upper right. After the vault is created, it appears in the list of Recovery Services vaults. If the vault doesn't appear, select **Refresh**.



Azure Backup now supports immutable vaults that help you ensure that after recovery points are created, they can't be deleted before their expiry according to the backup policy. You can make the immutability irreversible to help protect your backup data from various threats, including ransomware attacks and malicious actors. Learn more about Azure Backup immutable vaults.

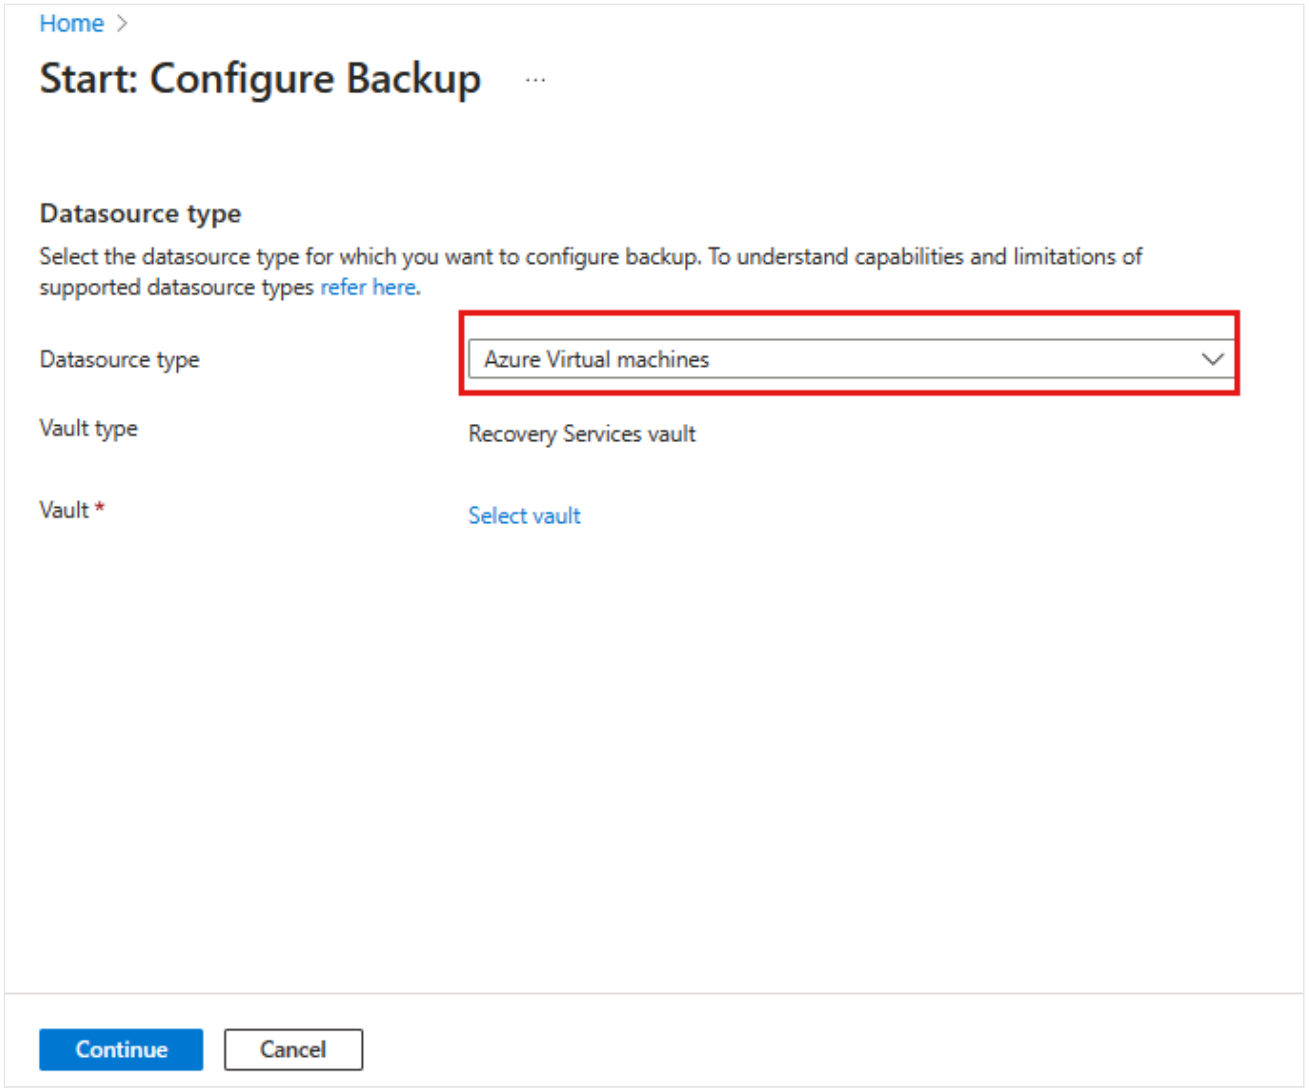
When you create a Recovery Services vault, the vault has geo-redundant storage by default. To provide data resiliency, geo-redundant storage replicates the data multiple times across two Azure regions.

Set a backup policy for VMs

After creation of the Recovery Services vault is complete, configure the vault for the data type backup and set the backup policy. The policy defines the schedule for recovery points and their retention period. In this tutorial, assume that you have a business (a sports complex with a hotel, stadium, and restaurants) that requires VM data protection.

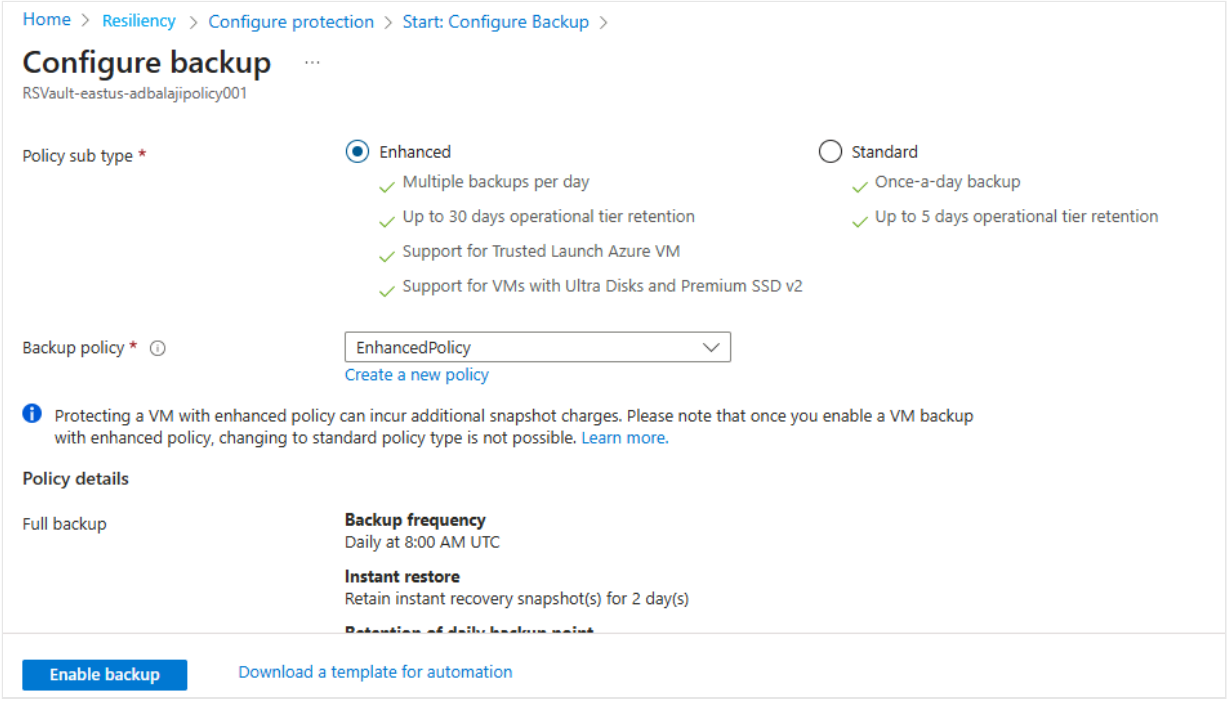
To set a backup policy for your Azure VMs, follow these steps:

1. Go to **Resiliency**. On the **Overview** tab, select **+ Configure protection**.
2. On the **Configure protection** pane, under **Where is your workload running?**, select **Azure**. Under **What do you want to back up?**, select **Virtual machine**. Then select **Continue**.
3. On the **Start: Configure Backup** pane, select **Azure Virtual machines** as the **Datasource type** value, and then select the vault that you created. Then select **Continue**.



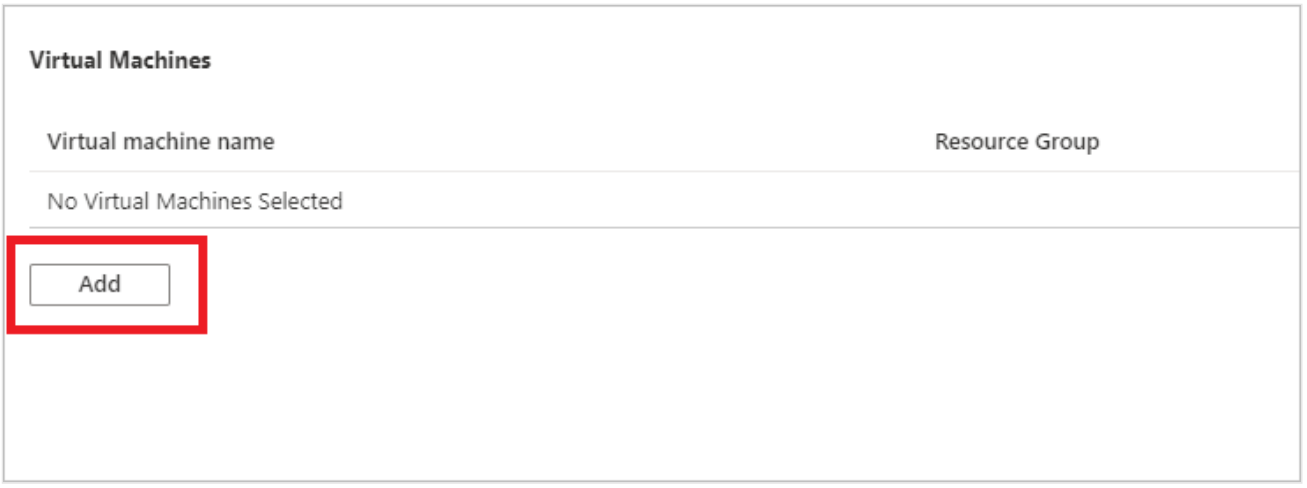
4. Assign a backup policy:

- The default policy backs up the VM once a day. The daily backups are retained for 30 days. Instant recovery snapshots are retained for 2 days.



- If you don't want to use the default policy, select **Create a new policy**, and then create a custom policy.

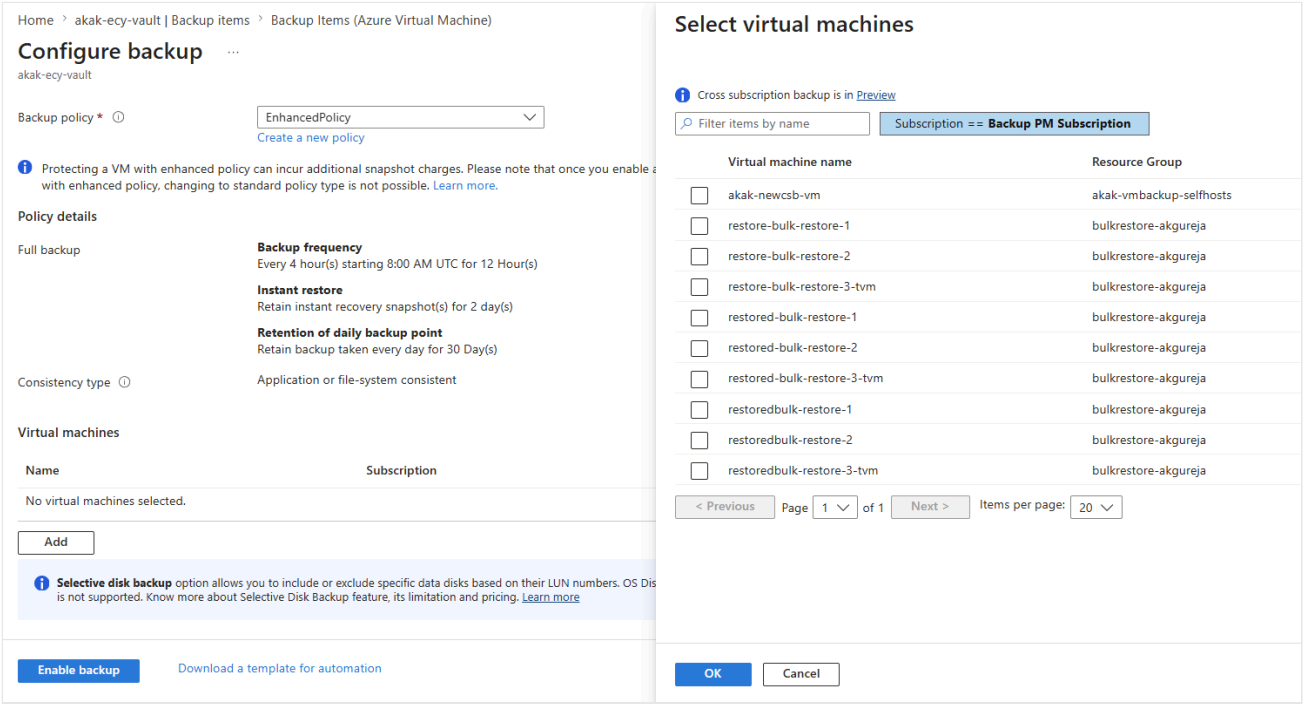
5. Under **Virtual Machines**, select **Add**.



6. The **Select virtual machines** pane opens. Select the VMs that you want to back up by using the policy. Then select **OK**.

   The following considerations apply:

   - The selected VMs are validated.
   - You can select only VMs in the same region as the vault.
   - VMs can be backed up only in a single vault.



> **Note**

All the VMs in the same region as the vault are available for configuring a backup, including eligible VMs in a different subscription when the VM and vault are in the same tenant. When you configure backup, you can browse to each VM's name and its resource group, even though you don't have the required permission on those VMs.

If your VM is in soft-deleted state, it isn't visible in this list. If you need to protect the VM again, wait for the soft-delete period to expire or restore the VM from the soft-deleted list. For more information, see the article about soft delete for VMs.

7. In **Backup**, select **Enable backup**. This selection deploys the policy to the vault and to the VMs. It also installs the backup extension on the VM agent that runs on the Azure VM.

After you enable a backup:

- The Azure Backup service installs the backup extension whether or not the VM is running.
- An initial backup runs in accordance with your backup schedule.

When backups run, note that:

- A VM that's running has the greatest chance for capturing an application-consistent recovery point.
- Even if a VM is offline, it's backed up. In this case, the recovery point is crash-consistent.
- Explicit outbound connectivity isn't required for backing up Azure VMs.

> ⓘ **Note**
>
> You can also set an Enhanced policy to back up Azure VMs multiple times a day.

Run an initial backup

You enabled backups for the Recovery Services vaults, but you haven't created an initial backup. A best practice for disaster recovery is to trigger the initial backup so that your data is protected.

The initial backup runs in accordance with the schedule, but you can run it immediately as follows:

1. Go to **Resiliency** and select **Protected items**.
2. On the **Protected items** pane, for **Datasource type**, select **Azure Virtual machines**. Then search for the VM that you configured for backups.

3. Right-click the relevant row or select the more icon (...), and then select **Backup Now**.

4. In **Backup Now**, use the calendar control to select the last day that the recovery point should be retained. Then select **OK**.

5. Monitor the portal notifications. To monitor the job's progress, go to **Resiliency** > **Jobs** and filter the list for **In progress** jobs.

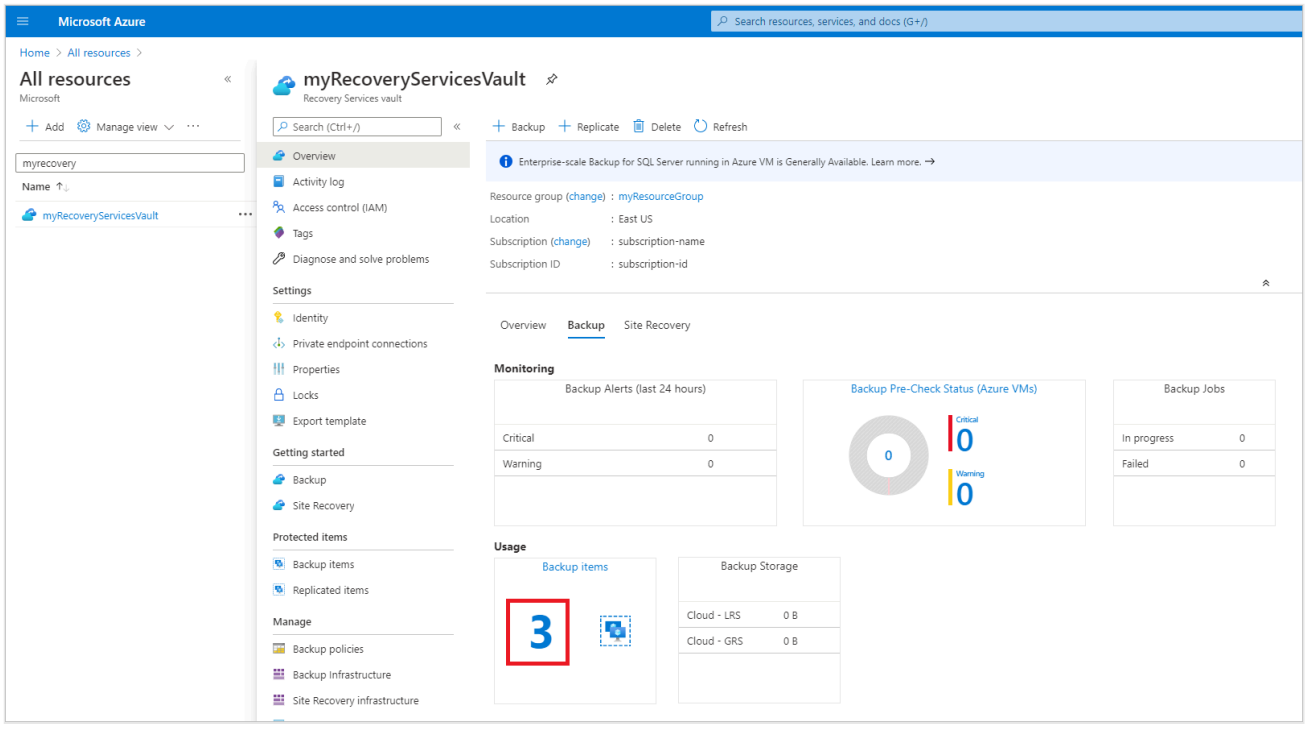
   Depending on the size of your VM, creating the initial backup might take a while.

Clean up resources

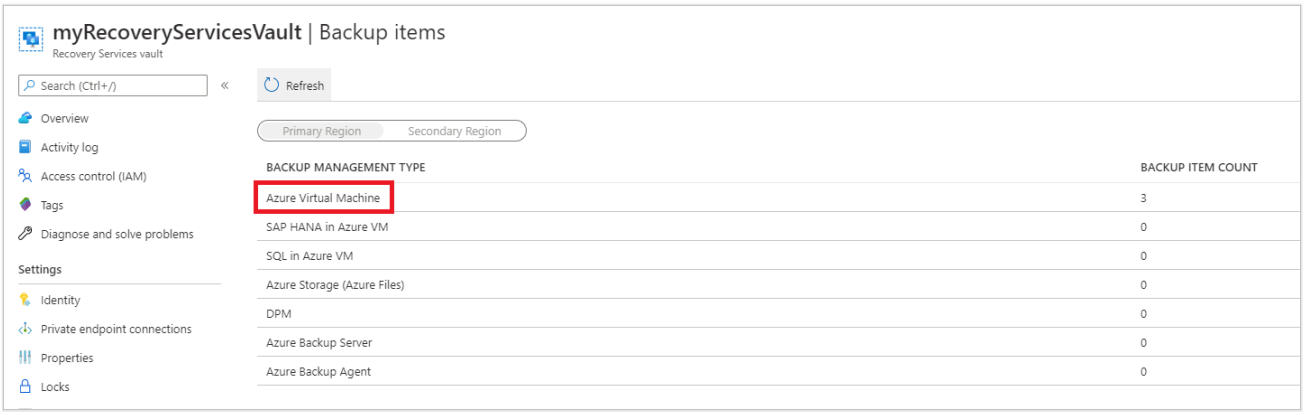
If you plan to work with subsequent tutorials, don't clean up the resources that you created in this tutorial.

If you don't plan to continue, delete all resources that you created in this tutorial. In the Azure portal, follow these steps:

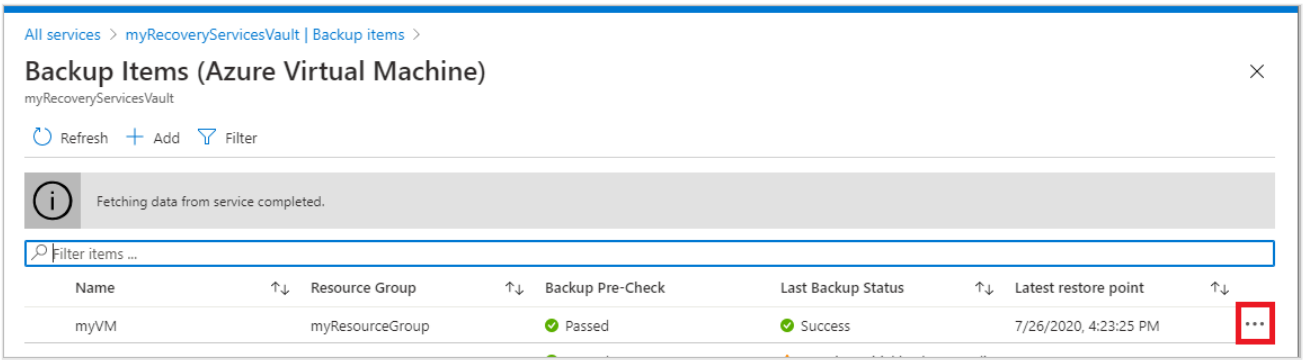
1. On the **myRecoveryServicesVault** dashboard, under **Backup items**. select **3**.



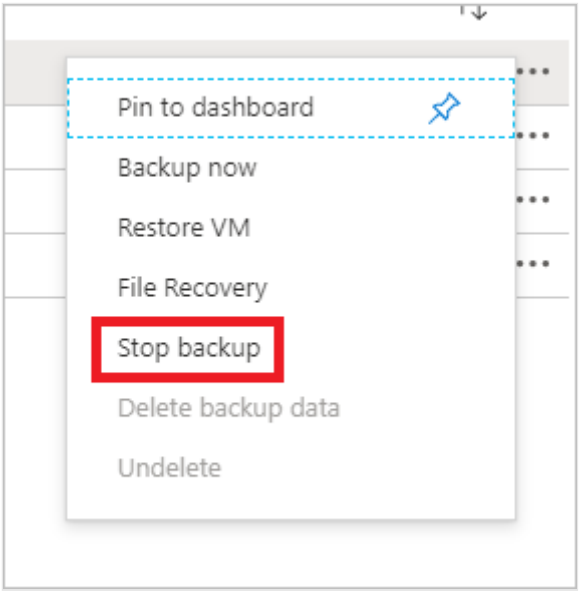
2. On the **Backup items** pane, select **Azure Virtual Machine** to open the list of virtual machines associated with the vault.



3. In the list of backup items, select the ellipsis for the **myVM** item.



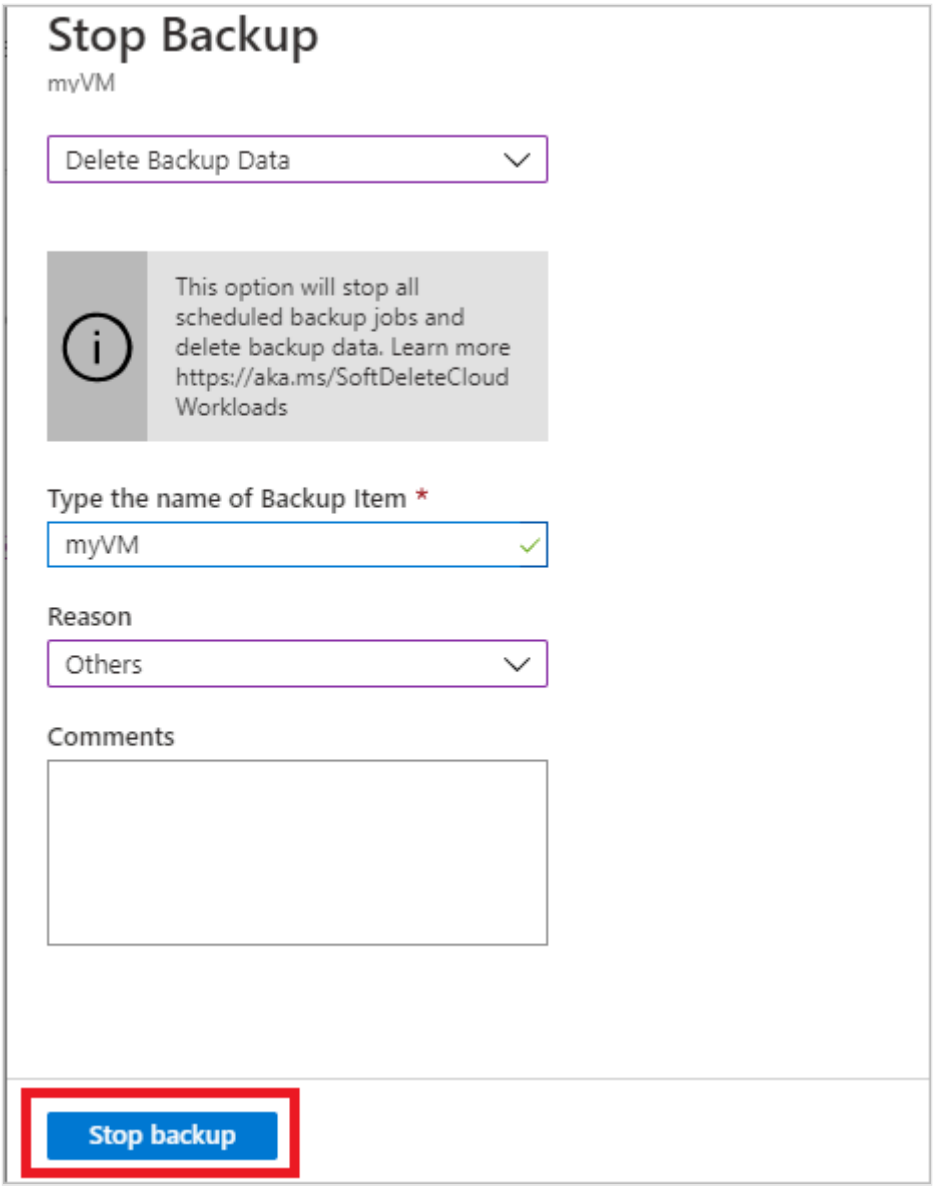
4. On the menu that opens, select **Stop backup**.



5. On the **Stop Backup** pane, in the uppermost box, select **Delete Backup Data**.

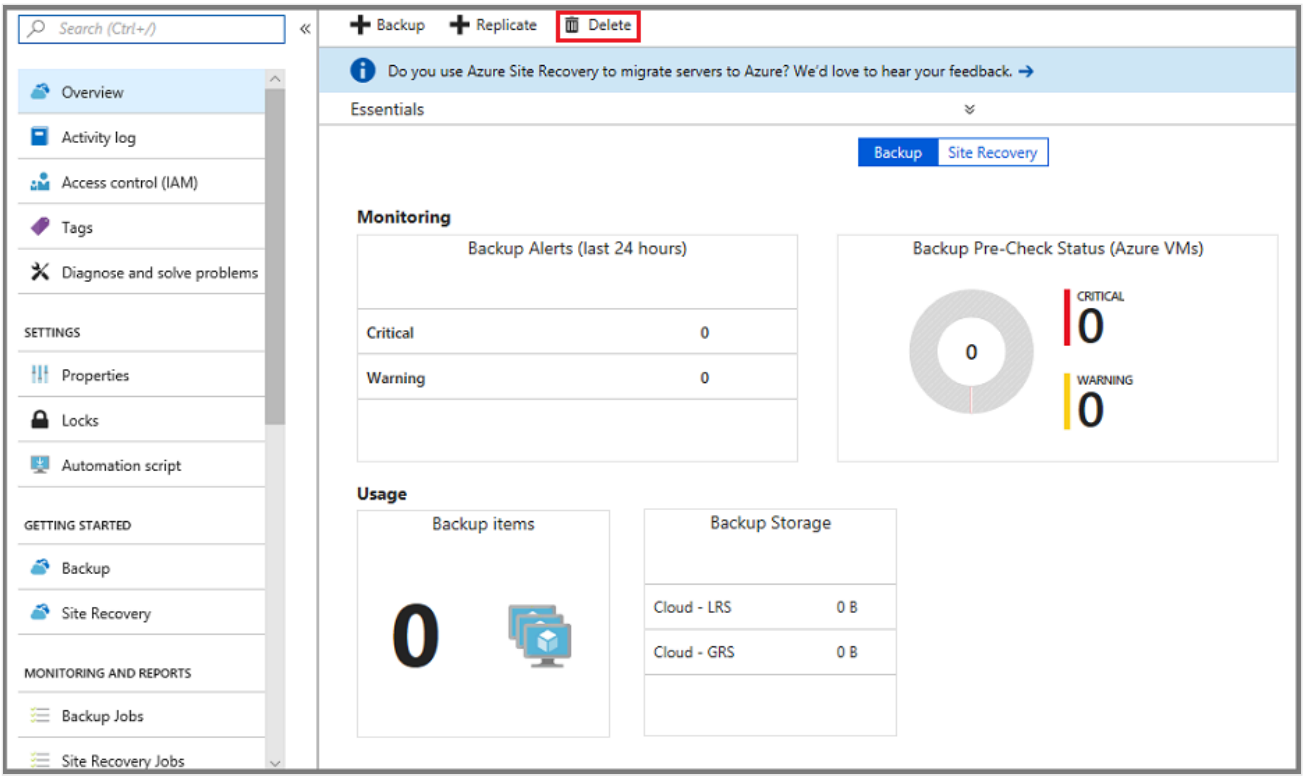
6. In the **Type the name of the Backup Item** box, enter **myVM**.

7. After the backup item is verified, a check mark appears. Select the **Stop backup** button to stop the policy and delete the restore points.



> **Note**
>
> Deleted items stay in a soft-deleted state for 14 days. You can delete the vault after that period. For more information, see Delete an Azure Backup Recovery Services vault.

8. When no more items are in the vault, select **Delete**.



After you delete the vault, you return to the list of Recovery Services vaults.

Next step

Continue to the next tutorial to restore an Azure virtual machine from disk:

Restore a VM by using the Azure CLI

Last updated on 03/26/2026

How to restore Azure VM data in Azure portal

This article describes how to restore Azure VM data from the recovery points stored in Azure Backup Recovery Services vaults.

Restore options

Azure Backup provides several ways to restore a VM.

Expand table

Restore option	Details
Create a new VM	Quickly creates and gets a basic VM up and running from a restore point. You can specify a name for the VM and select the resource group and virtual network (VNet) in which it will be placed. The new VM must be created in the same region as the source VM. If a VM restore fails because an Azure VM SKU wasn't available in the specified region of Azure, or because of any other issues, Azure Backup still restores the disks in the specified resource group.
Restore disk	Restores a VM disk, which can then be used to create a new VM. Azure Backup provides a template to help you customize and create a VM. The restore job generates a template that you can download and use to specify custom VM settings, and create a VM. The disks are copied to the Resource Group you specify. Alternatively, you can attach the disk to an existing VM, or create a new VM using PowerShell. This option is useful if you want to customize the VM, add configuration settings that weren't there at the time of backup, or add settings that must be configured using the template or PowerShell.
Replace existing	You can restore a disk, and use it to replace a disk on the existing VM. The current VM must exist. If it's been deleted, this option can't be used.

Restore option	Details
	Azure Backup takes a snapshot of the existing VM before replacing the disk. The snapshot is copied to the vault and retained in accordance with the retention policy. When you choose a Vault-Standard recovery point, a VHD file with the content of the chosen recovery point is also created in the staging location you specify. Existing disks connected to the VM are replaced with the selected restore point. After the disk replacement operation is complete, the original disk is retained in the resource group. You can choose to manually delete the original disks if they aren't needed. Replace existing is supported for unencrypted managed VMs, including VMs created using custom images. It's unsupported for classic VMs, unmanaged VMs, and generalized VMs. If the restore point has more or less disks than the current VM, then the number of disks in the restore point will only reflect the VM configuration. Replace existing is also supported for VMs with linked resources, like user-assigned managed-identity or Key Vault.
Cross Region (secondary region)	Cross Region restore can be used to restore Azure VMs in the secondary region, which is an Azure paired region. You can restore all the Azure VMs for the selected recovery point if the backup is done in the secondary region. During the backup, snapshots aren't replicated to the secondary region. Only the data stored in the vault is replicated. So secondary region restores are only vault tier restores. The restore time for the secondary region will be almost the same as the vault tier restore time for the primary region. This feature is available for the options below: - Create a VM - Restore Disks If the source machine has more than 16 disks, VHDs won't be created in Cross Region Restore. We don't currently support the Replace existing disks option. Permissions The restore operation on secondary region can be performed by Backup Admins and App admins.
Cross Subscription	Allows you to restore managed Azure virtual machines or disks to a different subscription within the same tenant as the protected VM, subject to Azure RBAC

Restore option	Details
Restore	permissions. The default target subscription is the protected VM subscription. Cross Subscription Restore works with Cross Region Restore and Cross Zonal Restore. Supported behavior depends on the recovery point tier: - Snapshot-tier recovery points can be restored only in the protected VM subscription. - Vault-tier recovery points can be restored in the protected VM subscription or the vault subscription. To restore a vault-tier recovery point to another subscription, the Cross Subscription Restore property must be enabled on the Recovery Services vault. Original location restore and Replace existing disk are supported only in the protected VM subscription. Cross Subscription Restore is supported for Restore with Managed System Identities (MSI). It's unsupported for legacy recovery points from VMs that used unmanaged disks, ADE encrypted VMs, and VMs with CMK encrypted disks.
Cross Zonal Restore	Allows you to restore Azure Virtual Machines or disks pinned to any zone to different available zones (as per the Azure RBAC capabilities) from restore points. Note that when you select a zone to restore, it selects the logical zone (and not the physical zone) as per the Azure subscription you will use to restore to. You can trigger Cross Zonal Restore for managed virtual machines only. Cross Zonal Restore is supported for Restore with Managed System Identities (MSI). Cross Zonal Restore supports restore of an Azure zone pinned/non-zone pinned VM from a vault with Zonal-redundant storage (ZRS) enabled. Learn how to set Storage Redundancy. It's supported to restore an Azure zone pinned VM only from a vault with Cross Region Restore (CRR) (if the secondary region supports zones) or Zone Redundant Storage (ZRS) enabled. Cross Zonal Restore is supported from secondary regions. It's unsupported from snapshots restore point. It's unsupported for Encrypted Azure VMs.

Tip

To receive alerts/notifications when a restore operation fails, use **Azure Monitor alerts for Azure Backup**. This helps you to monitor such failures and take necessary actions to

remediate the issues.

> **Note**
>
> You can also recover specific files and folders on an Azure VM. Learn more.

Storage accounts

Some details about storage accounts:

- **Create VM**: When you create a new VM, VHD files are also copied when restoring VMs with disks < 4 TB or VMs containing < 16 disks from a Vault-Standard recovery point. These files are then moved to Managed storage. To prevent extra charges, delete VHDs from the Staging Storage Account.
- **Restore disk**: The VM restore job generates a template, which you can download and use to specify custom VM settings. VHD files are also copied when restoring managed disks < **4 TB** or VMs containing < **16 disks** from a Vault-Standard recovery point, including legacy recovery points from VMs that used unmanaged disks. These files are then moved to Managed storage. To prevent extra charges, delete VHDs from the Staging Storage Account.
- **Replace disk**: When replacing a managed disk from a Vault-Standard recovery point that's < **4 TB** or a VM containing < **16 disks**, a VHD file is created in the specified storage account. After replacement, source VM disks remain in the designated Resource Group, and VHDs stay in the storage account; you can delete or retain the source disk and the VHDs as needed.
- **Storage account location**: The storage account must be in the same region as the vault. Only these accounts are displayed. If there are no storage accounts in the location, you need to create one.
- **Storage type**: Blob Storage account isn't supported because the Premium Storage account it requires is excluded for cost optimization.
- **Storage redundancy**: Zone redundant storage (ZRS) is supported. The replication and redundancy information for the account is shown in parentheses after the account name.
- **Premium storage**:
  - When you restore non-premium VMs, premium storage accounts aren't supported.
  - When you restore managed VMs, premium storage accounts configured with network rules aren't supported.

Before you start

To restore a VM (create a new VM), make sure you have the correct Azure role-based access control (Azure RBAC) permissions for the Restore VM operation.

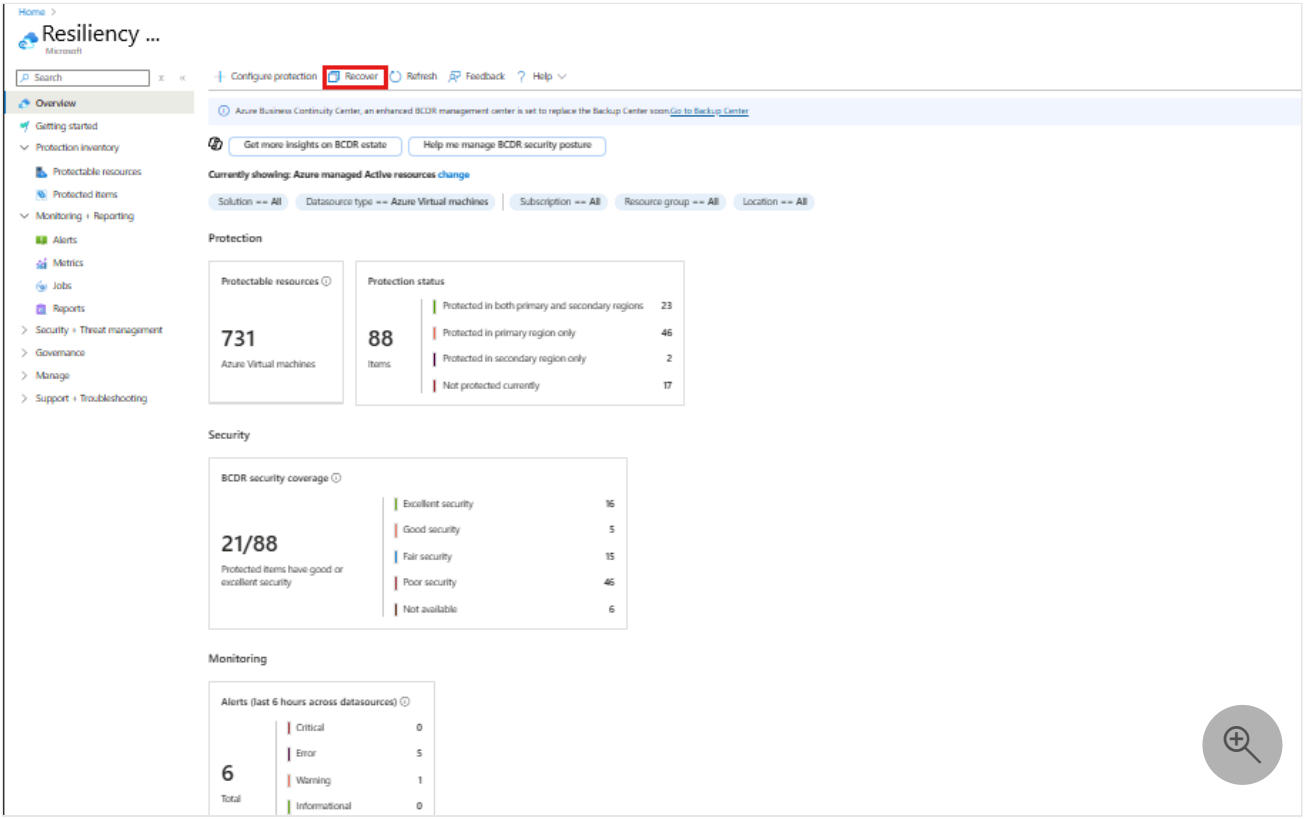
If you don't have permissions, you can restore a disk, and then after the disk is restored, you can use the template that was generated as part of the restore operation to create a new VM.

> **Note**
>
> The functionality that the following sections describe can also be accessed via Resiliency. Resiliency in Azure is a cloud-native unified experience for resiliency posture management that enables you to manage your protection estate across solutions and environments.

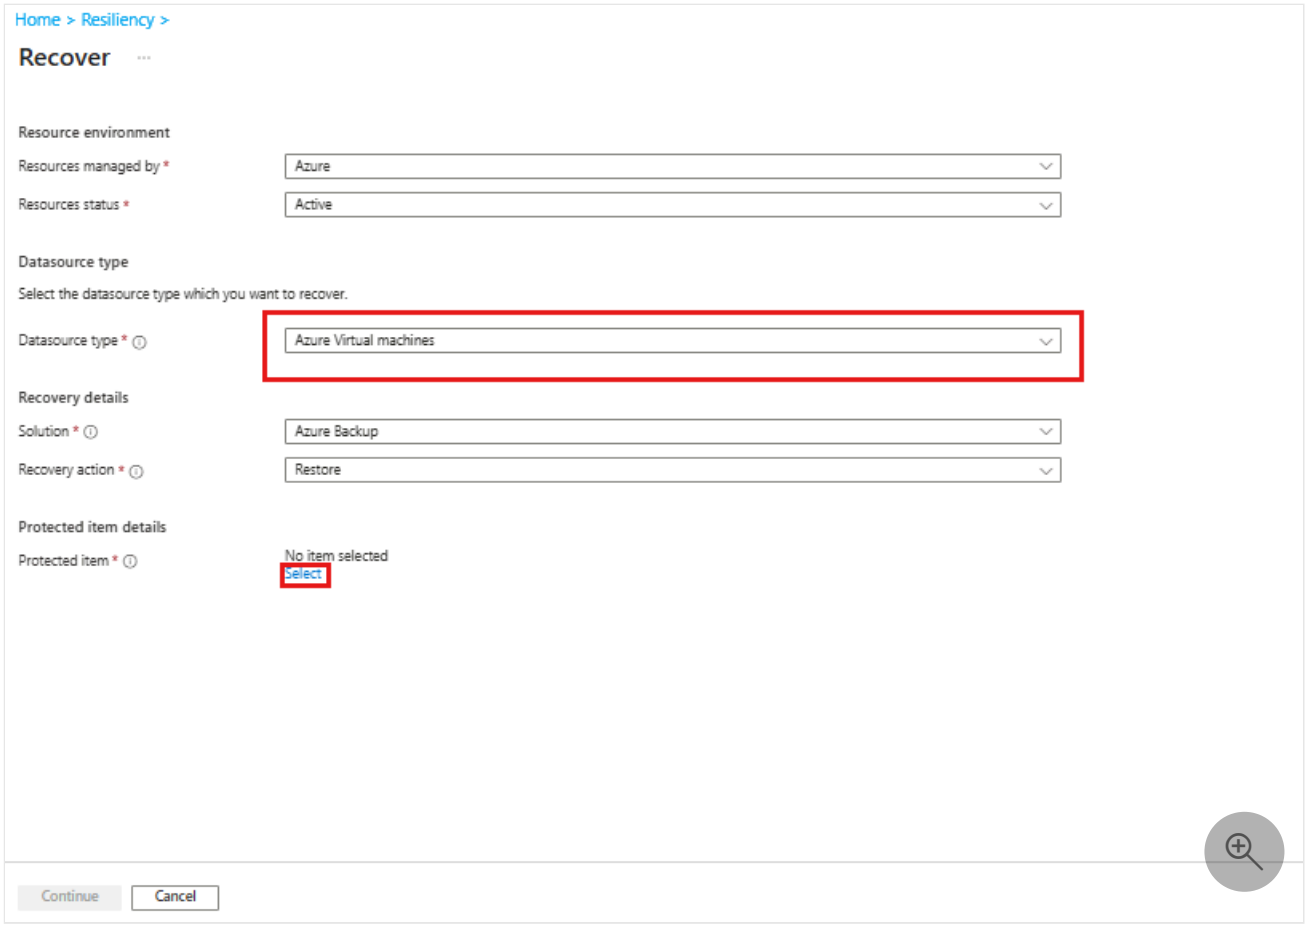
Select a restore point

To select a restore point for a VM restore, follow these steps:

1. Go to **Resiliency** in the Azure portal and select **Recover**.



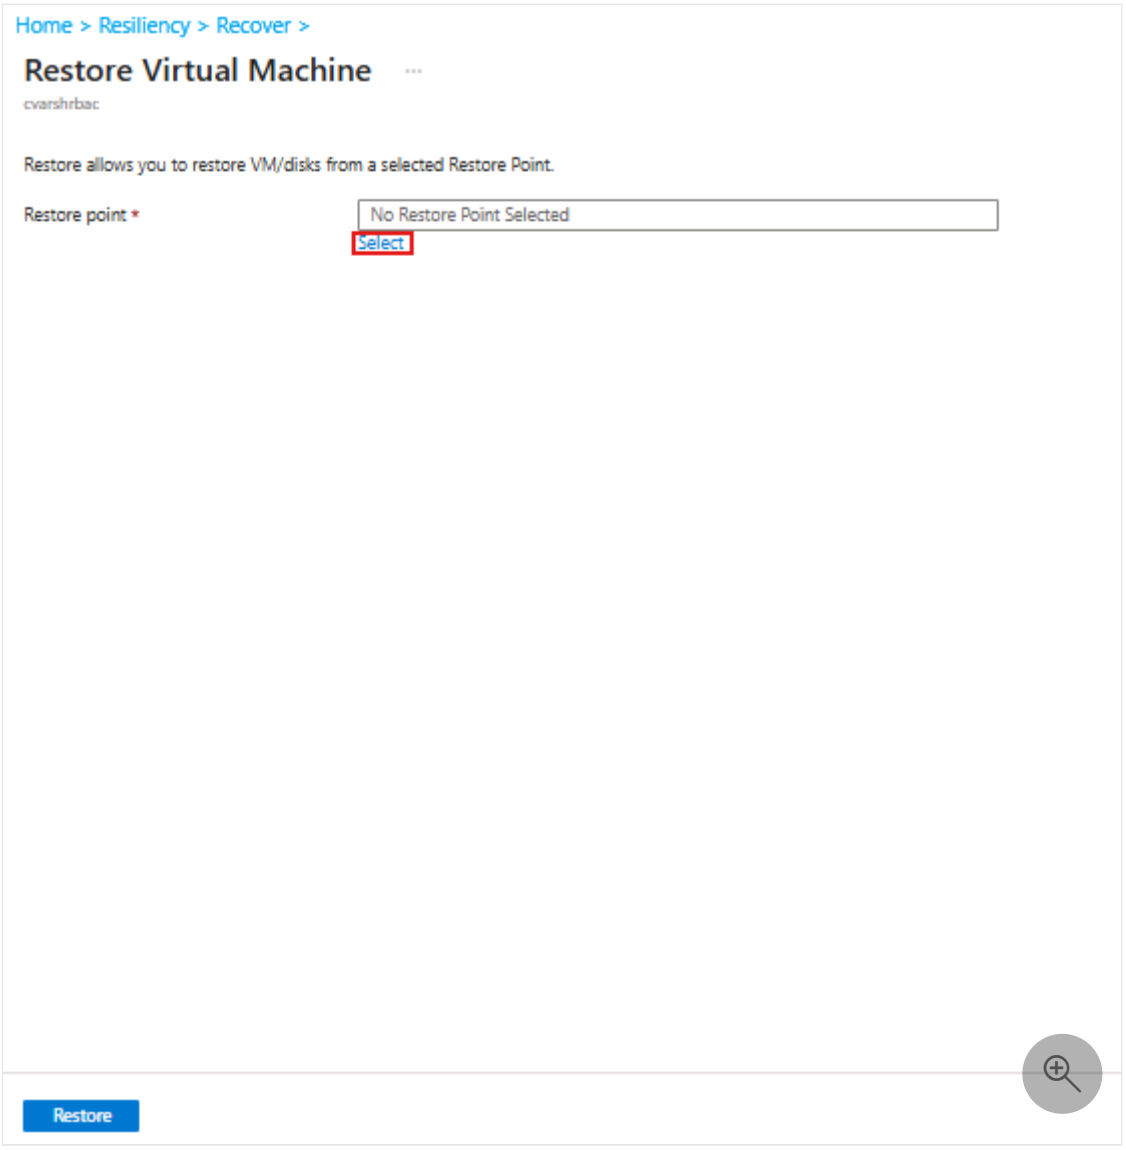
2. On the **Recover** pane, select **Datasource type** as **Azure Virtual machines**, and then under **Protected item**, click **Select**.



3. On the **Select Protected item** pane, select a protected VM from the list, and then click **Select**.

4. On the **Recover** pane, select **Continue**.

5. On the **Restore Virtual Machine** pane, under **Restore point**, click **Select**.

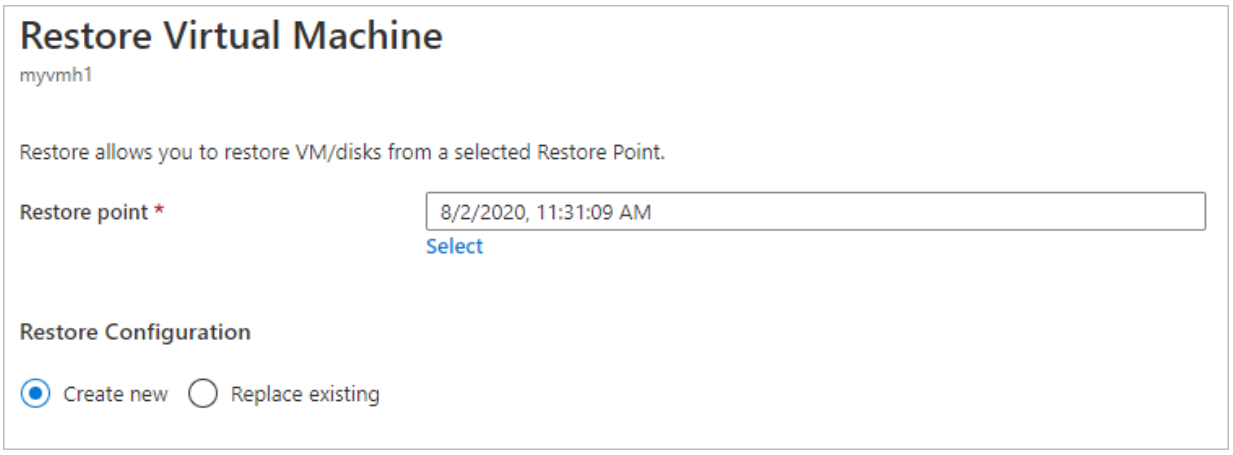


6. On the **Select restore point** pane, select a restore point from the list, and then select **OK** to use for recovery.

Choose a VM restore configuration

1. In **Restore Virtual Machine**, select a restore option:

   - **Create new**: Use this option if you want to create a new VM. You can create a VM with simple settings, or restore a disk and create a customized VM.
   - **Replace existing**: Use this option if you want to replace disks on an existing VM.



2. Specify settings for your selected restore option.

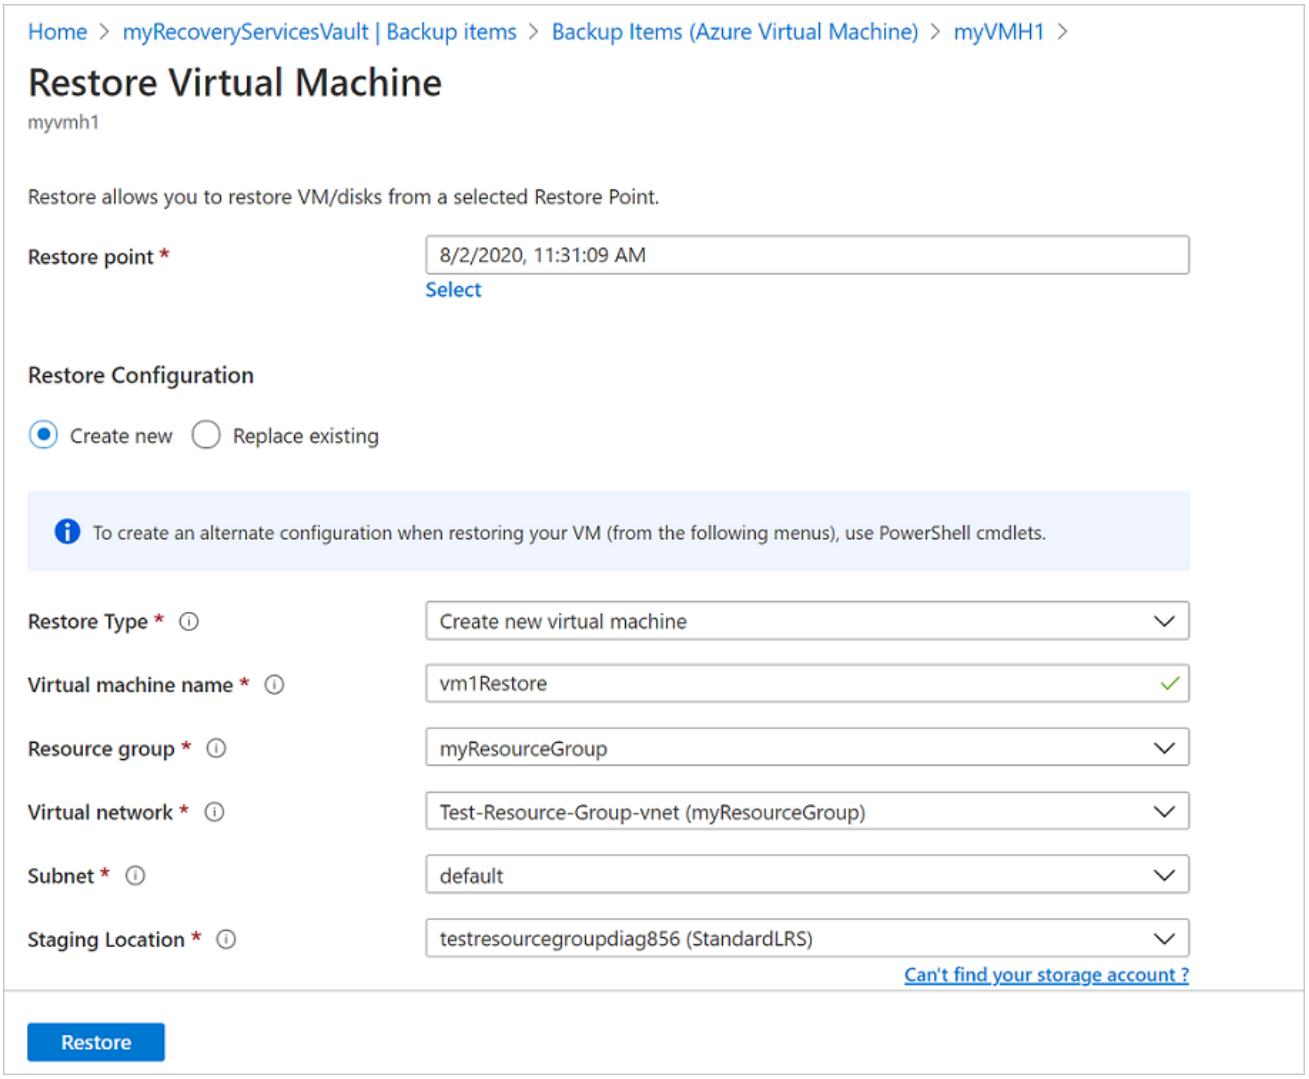
> **Note**
>
> Use the **Replace existing** option only when the **Transfer Data to Vault** subtask in the job details shows successfully completed. Otherwise, use the **Create New** option for the latest recovery point restoration. For more information about backup phases and progress interpretation, see Verify the backup job status.

Create a VM

As one of the restore options, you can create a VM quickly with basic settings from a restore point.

1. In **Restore Virtual Machine** > **Create new** > **Restore Type**, select **Create new virtual machine**.
2. In **Virtual machine name**, specify a VM that doesn't exist in the subscription.
3. In **Resource group**, select an existing resource group for the new VM, or create a new one with a globally unique name. If you assign a name that already exists, Azure assigns the group the same name as the VM.
4. In **Virtual network**, select the VNet in which the VM will be placed. All VNets associated with the subscription in the same location as the vault, which is active and not attached with any affinity group, are displayed. Select the subnet.

   The first subnet is selected by default.
5. In **Staging Location**, specify the storage account for the VM. Learn more.

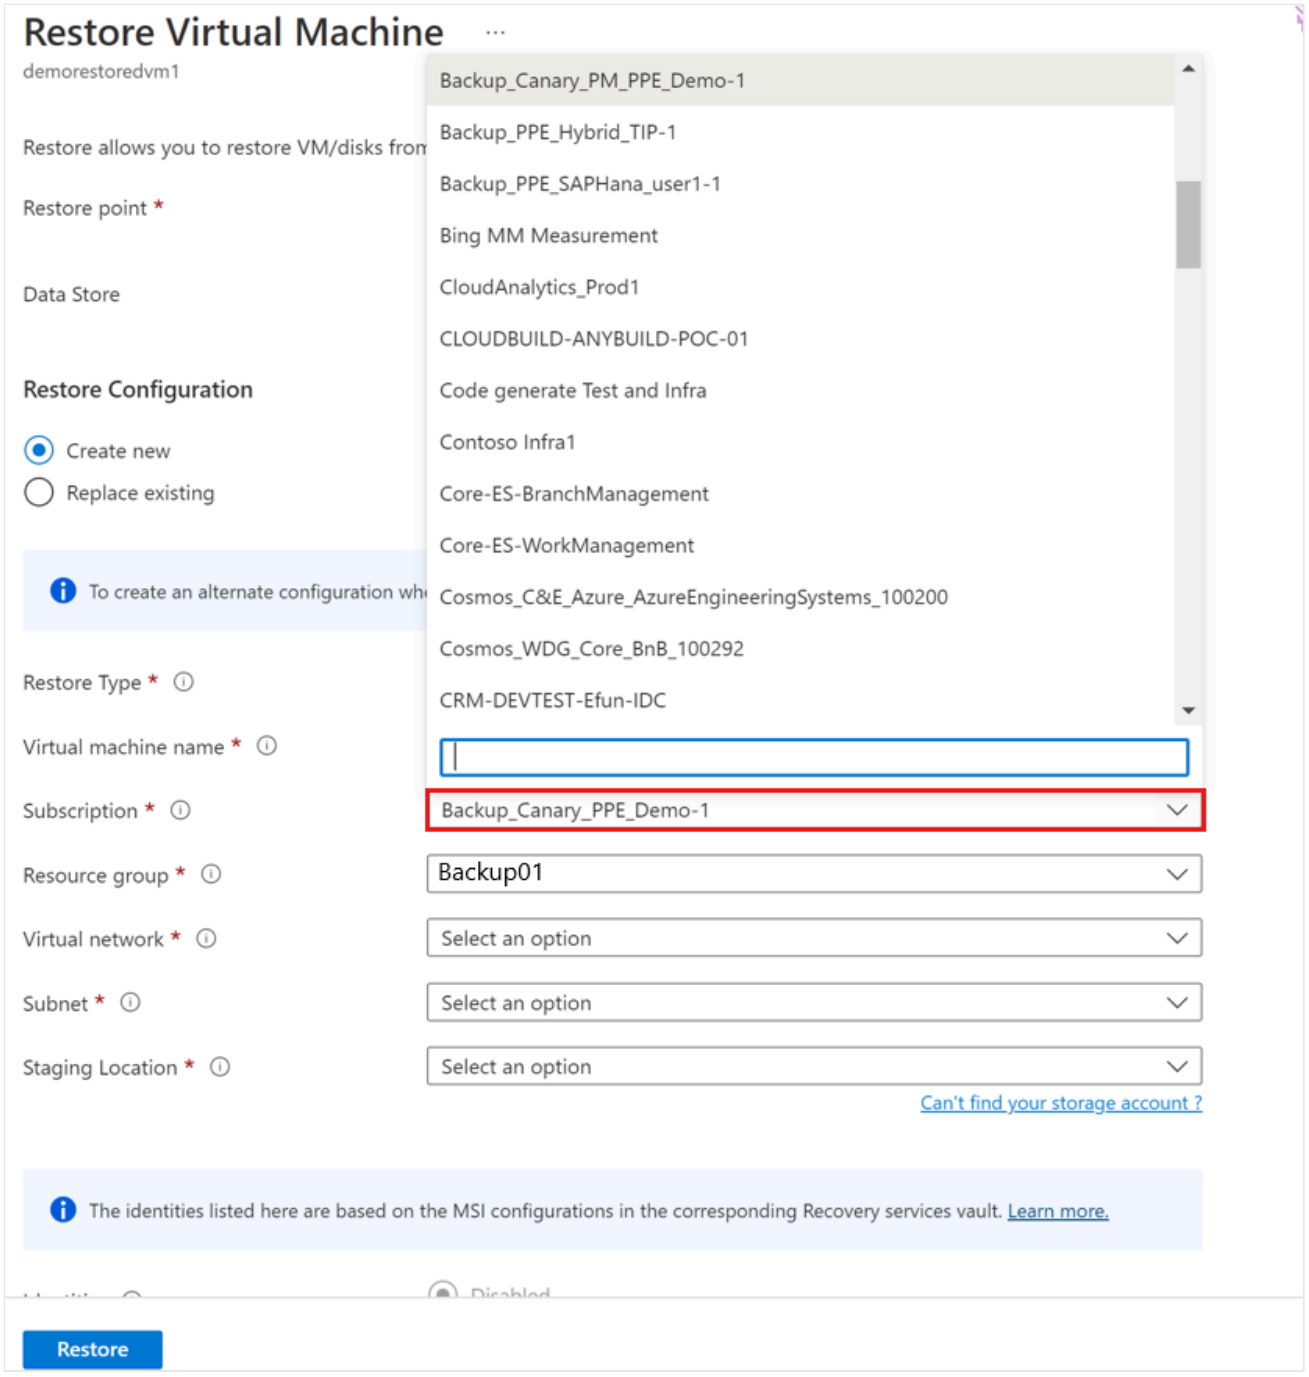


6. Choose the required subscription from the **Subscription** dropdown menu to restore an Azure VM.

   By default, Azure Backup selects the protected VM subscription. You can choose a different subscription in the same tenant if the selected recovery point and vault settings support that target.

   For snapshot-tier recovery points, restore is supported only in the protected VM subscription. For vault-tier recovery points, restore is supported in the protected VM subscription or the vault subscription. To restore to any other subscription, Cross Subscription Restore must be enabled on the vault.

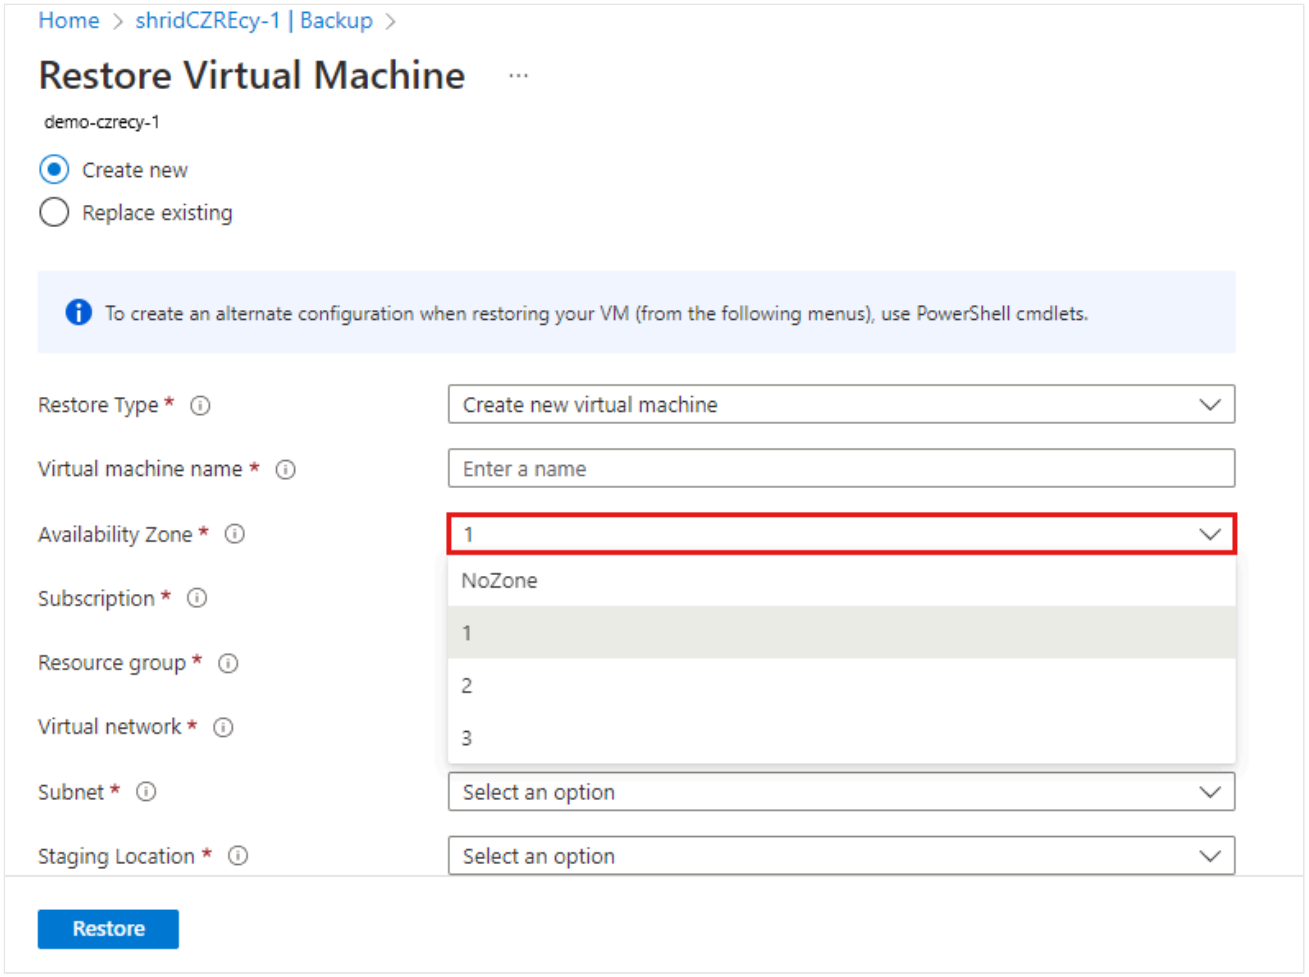
   The following screenshot lists all subscriptions under the tenant where you've permissions, which enable you to restore the Azure VM to another subscription.



7. Choose the required zone from the **Availability Zone** drop-down list to restore an Azure VM pinned to any zone to a different zone.

   Azure Backup now supports Cross Zonal Restore (CZR), you can now restore an Azure VM from the default zone to any available zones. Default zone is the zone in which Azure VM is running.

   The following screenshot lists all zones that enable you to restore Azure VM to another zone.



> **Note**
>
> Azure Backup supports CZR only for vaults with ZRS or CRR redundancy.

8. Select **Restore** to trigger the restore operation.

> **Note**
>
> - Before you modify any NSG settings, ensure the VM restore operation is complete. Learn about tracking the restore operation.
> - During an Alternate Location Restore (Create new VM), the restored VM retains the same SKU as the original VM at the time of the recovery point creation. Any SKU changes made after the backup date don't reflect in the restored VM.

Restore disks

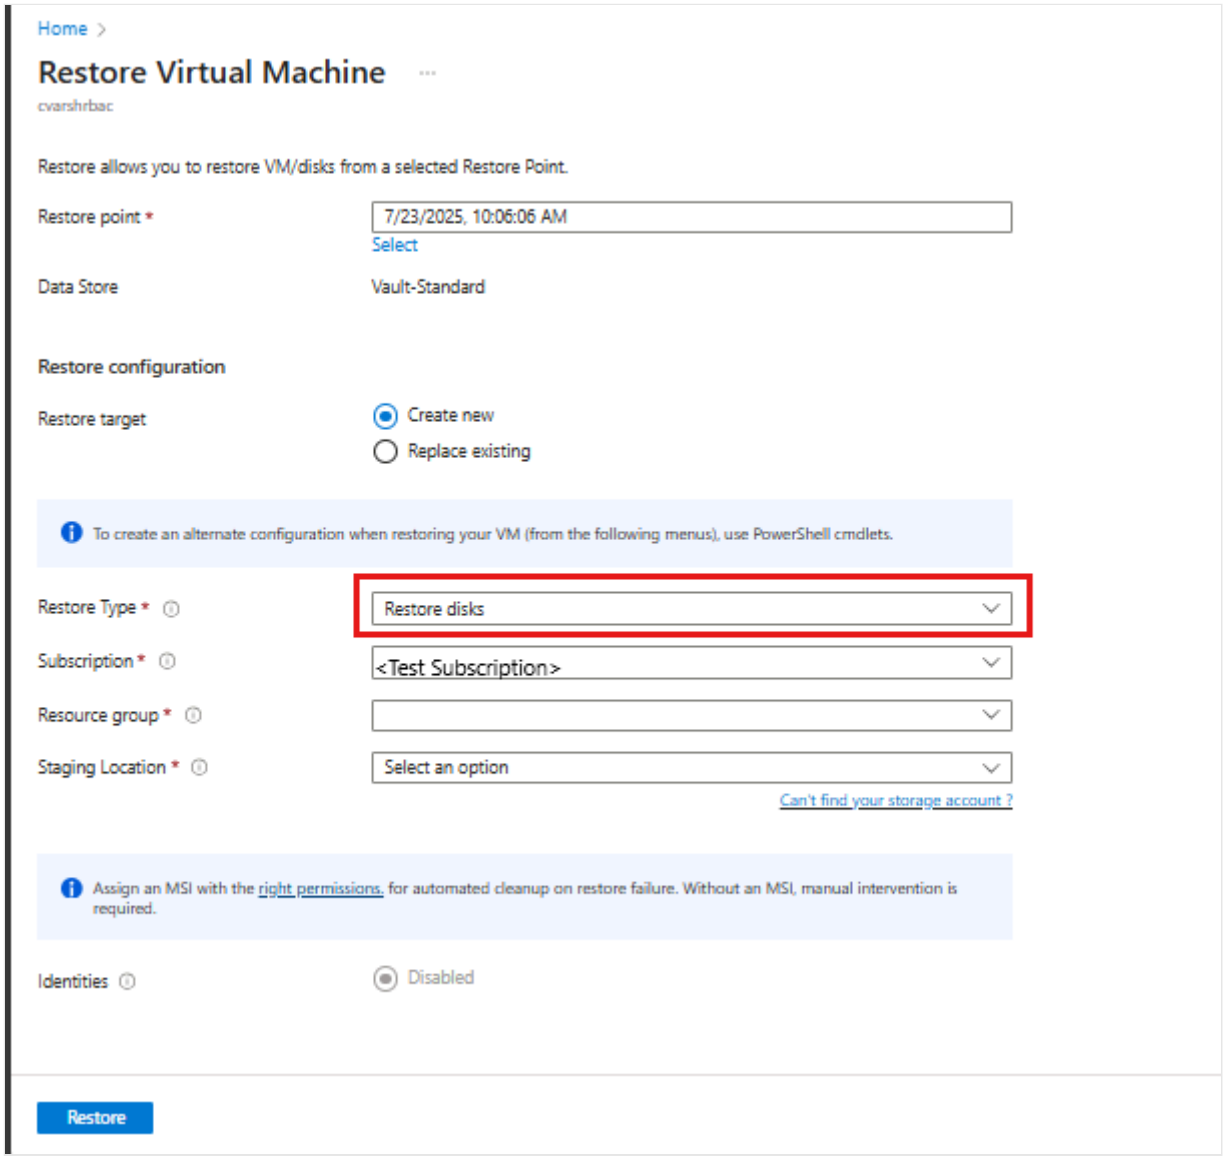
As one of the restore options, you can create a disk from a restore point. Then with the disk, you can do one of the following actions:

- Use the template that's generated during the restore operation to customize settings, and trigger VM deployment. You edit the default template settings, and submit the template for VM deployment.
- Attach restored disks to an existing VM.
- Create a new VM from the restored disks using PowerShell.

1. Under **Restore configuration** > **Create new** > **Restore Type**, select **Restore disks**.

2. Under **Resource group**, select an existing resource group for the restored disks, or create a new one with a globally unique name.

3. On **Staging location**, specify the storage account. The template file is stored here, and VHD files are also created in some scenarios. Learn more.



4. Choose the required subscription from the **Subscription** dropdown menu to restore the VM disks.

By default, Azure Backup selects the protected VM subscription. You can choose a different subscription in the same tenant if the selected recovery point and vault settings support that target.

For snapshot-tier recovery points, restore is supported only in the protected VM subscription. For vault-tier recovery points, restore is supported in the protected VM subscription or the vault subscription. To restore to any other subscription, you must enable Cross Subscription Restore on the vault.

5. Choose the required zone from the **Availability Zone** drop-down list to restore the VM disks to a different zone.

   Azure Backup now supports Cross Zonal Restore (CZR). Like Azure VM, you can now restore Azure VM disks from the default zone to any available zones. Default zone is the zone in which the VM disks reside.

   > ⓘ **Note**
   >
   > Azure Backup supports CZR only for vaults with ZRS or CRR redundancy.

6. Select **Restore** to trigger the restore operation.

When your virtual machine uses managed disks and you select the **Create virtual machine** option, Azure Backup doesn't use the specified storage account. In the case of **Restore disks** and **Instant Restore**, the storage account is used only for storing the template. Managed disks are created in the specified resource group. For legacy recovery points from VMs that used unmanaged disks, Azure Backup restores the disks as managed disks and uses the storage account only for restore metadata and temporary VHD files.

While you restore disks for a Managed VM from a Vault-Standard recovery point, it restores the Managed disk and Azure Resource Manager (ARM) templates, along with the VHD files of the disks in staging location. If you restore disks from an Instant recovery point, it restores the Managed disks and ARM templates only.

> ⓘ **Note**
>
> - For restoring disk from a Vault-Standard recovery point that is/was greater than 4 TB, Azure Backup doesn't restore the VHD files.

- For information on managed/premium disk performance after restored via Azure Backup, see the Latency section.

Use templates to customize a restored VM

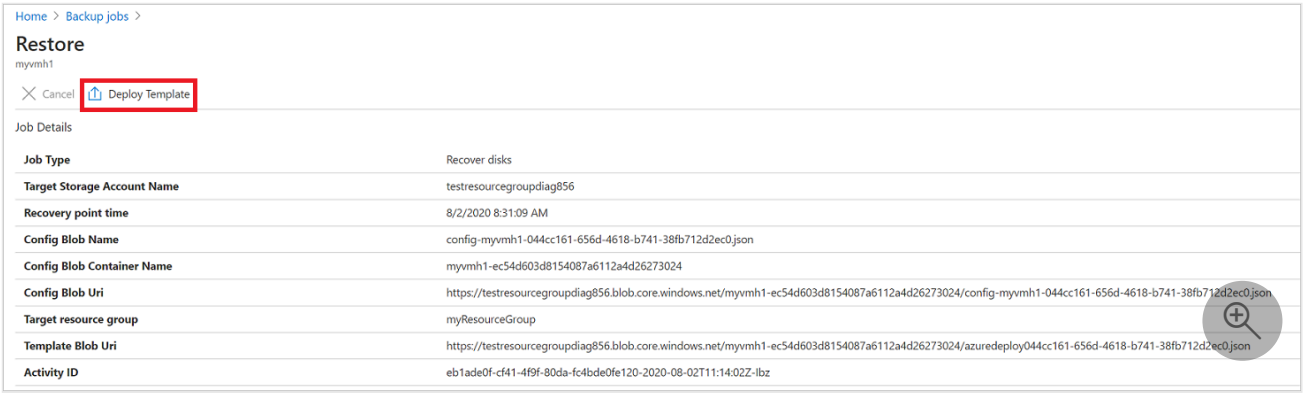
After the disk is restored, use the template that was generated as part of the restore operation to customize and create a new VM:

1. Go to the **Recovery Services vault**, and then select **Monitoring** > **Backup Jobs**.

   Alternatively, you can go to **Resiliency**, and then select **Monitoring + Reporting** > **Jobs**.

2. On the **Backup Jobs** pane, select the relevant restore job.

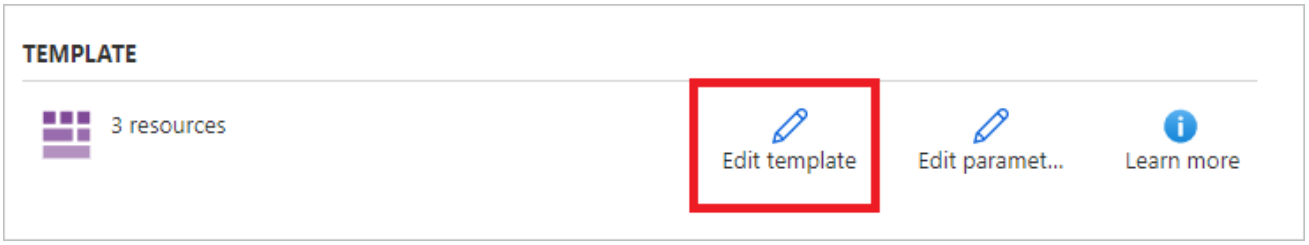
3. In **Restore**, select **Deploy Template** to initiate template deployment.



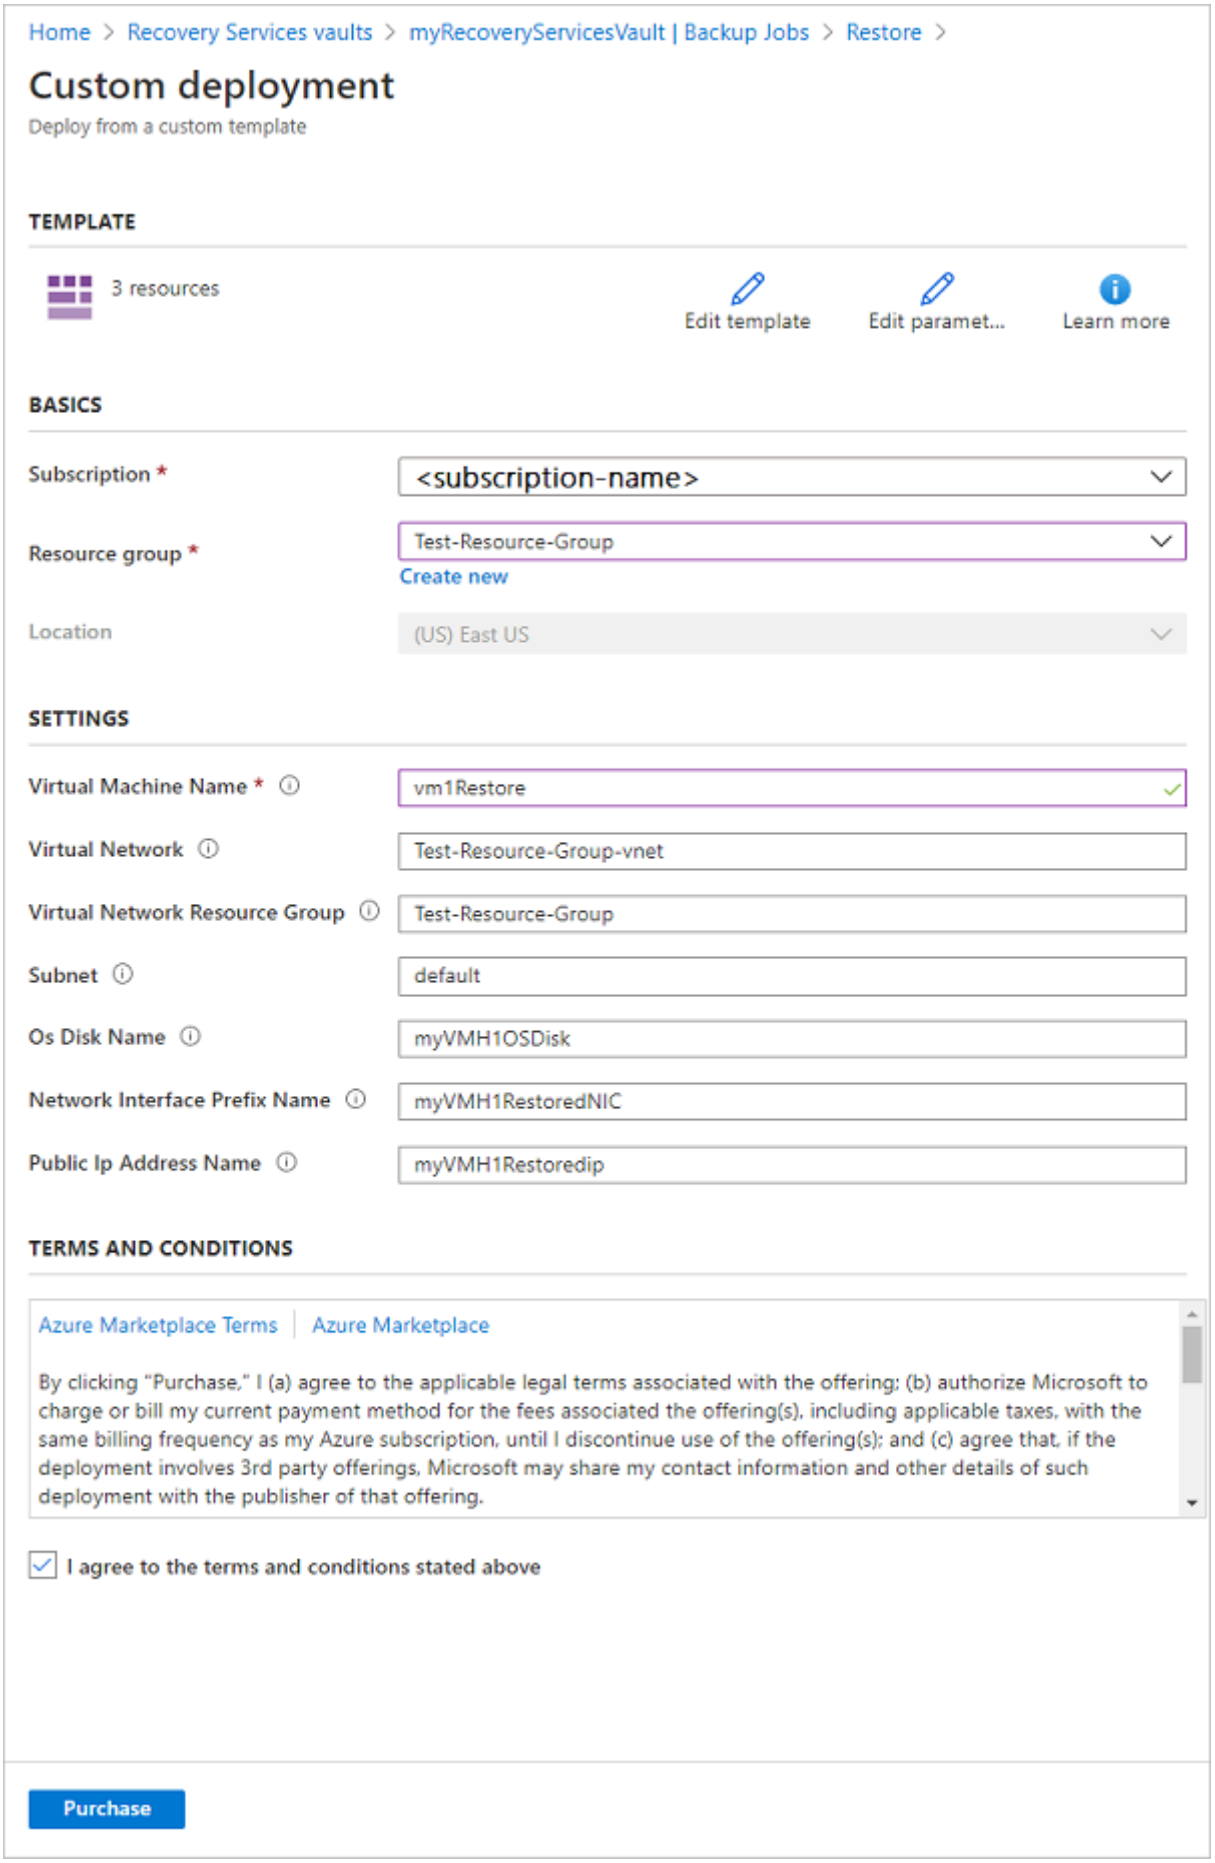
> **Note**
>
> For a shared access signature (SAS) that has **Allow storage account key access** set to disabled, the template won't deploy when you select **Deploy Template**.

4. To customize the VM setting provided in the template, select **Edit template**. If you want to add more customizations, select **Edit parameters**.

   - Learn more about deploying resources from a custom template.
   - Learn more about authoring templates.



5. Enter the custom values for the VM, accept the **Terms and Conditions** and select **Purchase**.

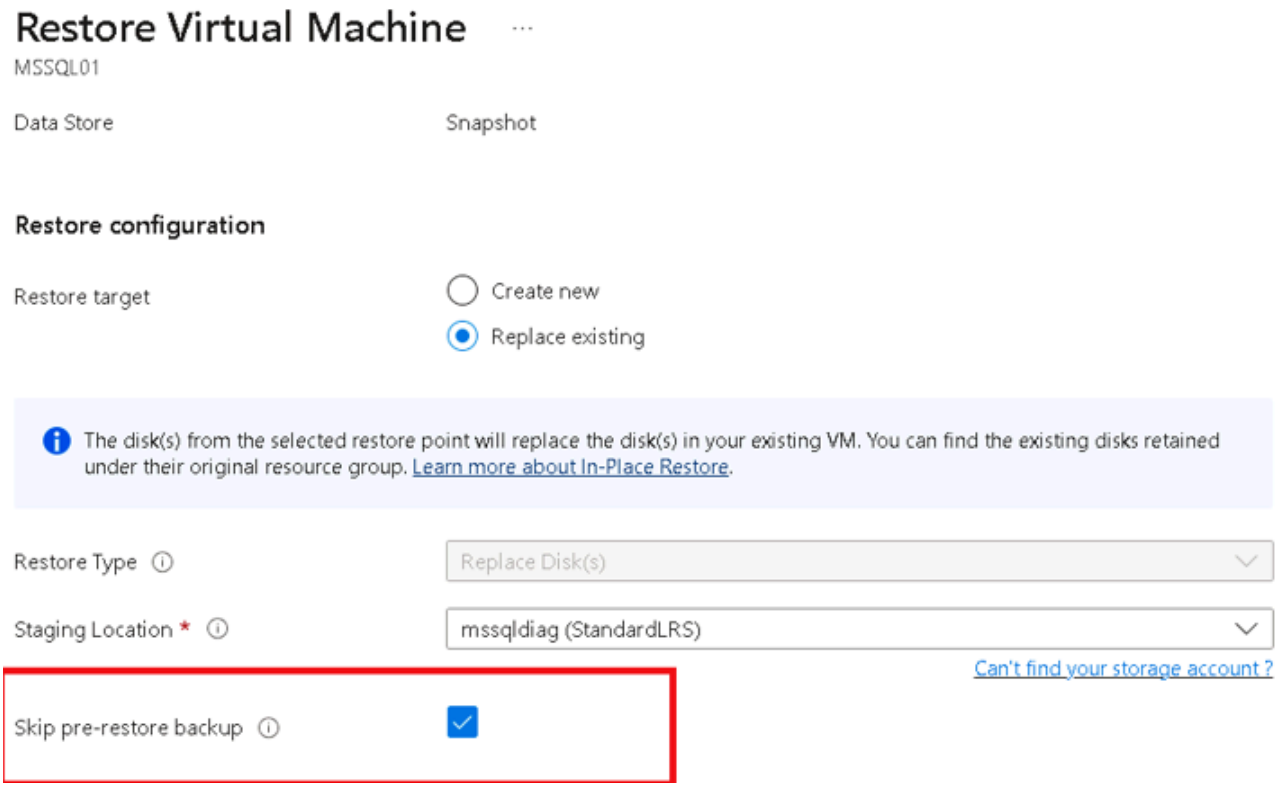


Replace existing disks

As one of the restore options, you can replace an existing VM disk with the selected restore point. Review all restore options.

Replace existing VM disk is supported only in the protected VM subscription.

1. In **Restore configuration**, select **Replace existing**.
2. In **Restore Type**, select **Replace disk/s**. This is the restore point that will be used to replace existing VM disks.
3. In **Staging Location**, specify a storage account. VHD files are created here in some scenarios. Learn more.



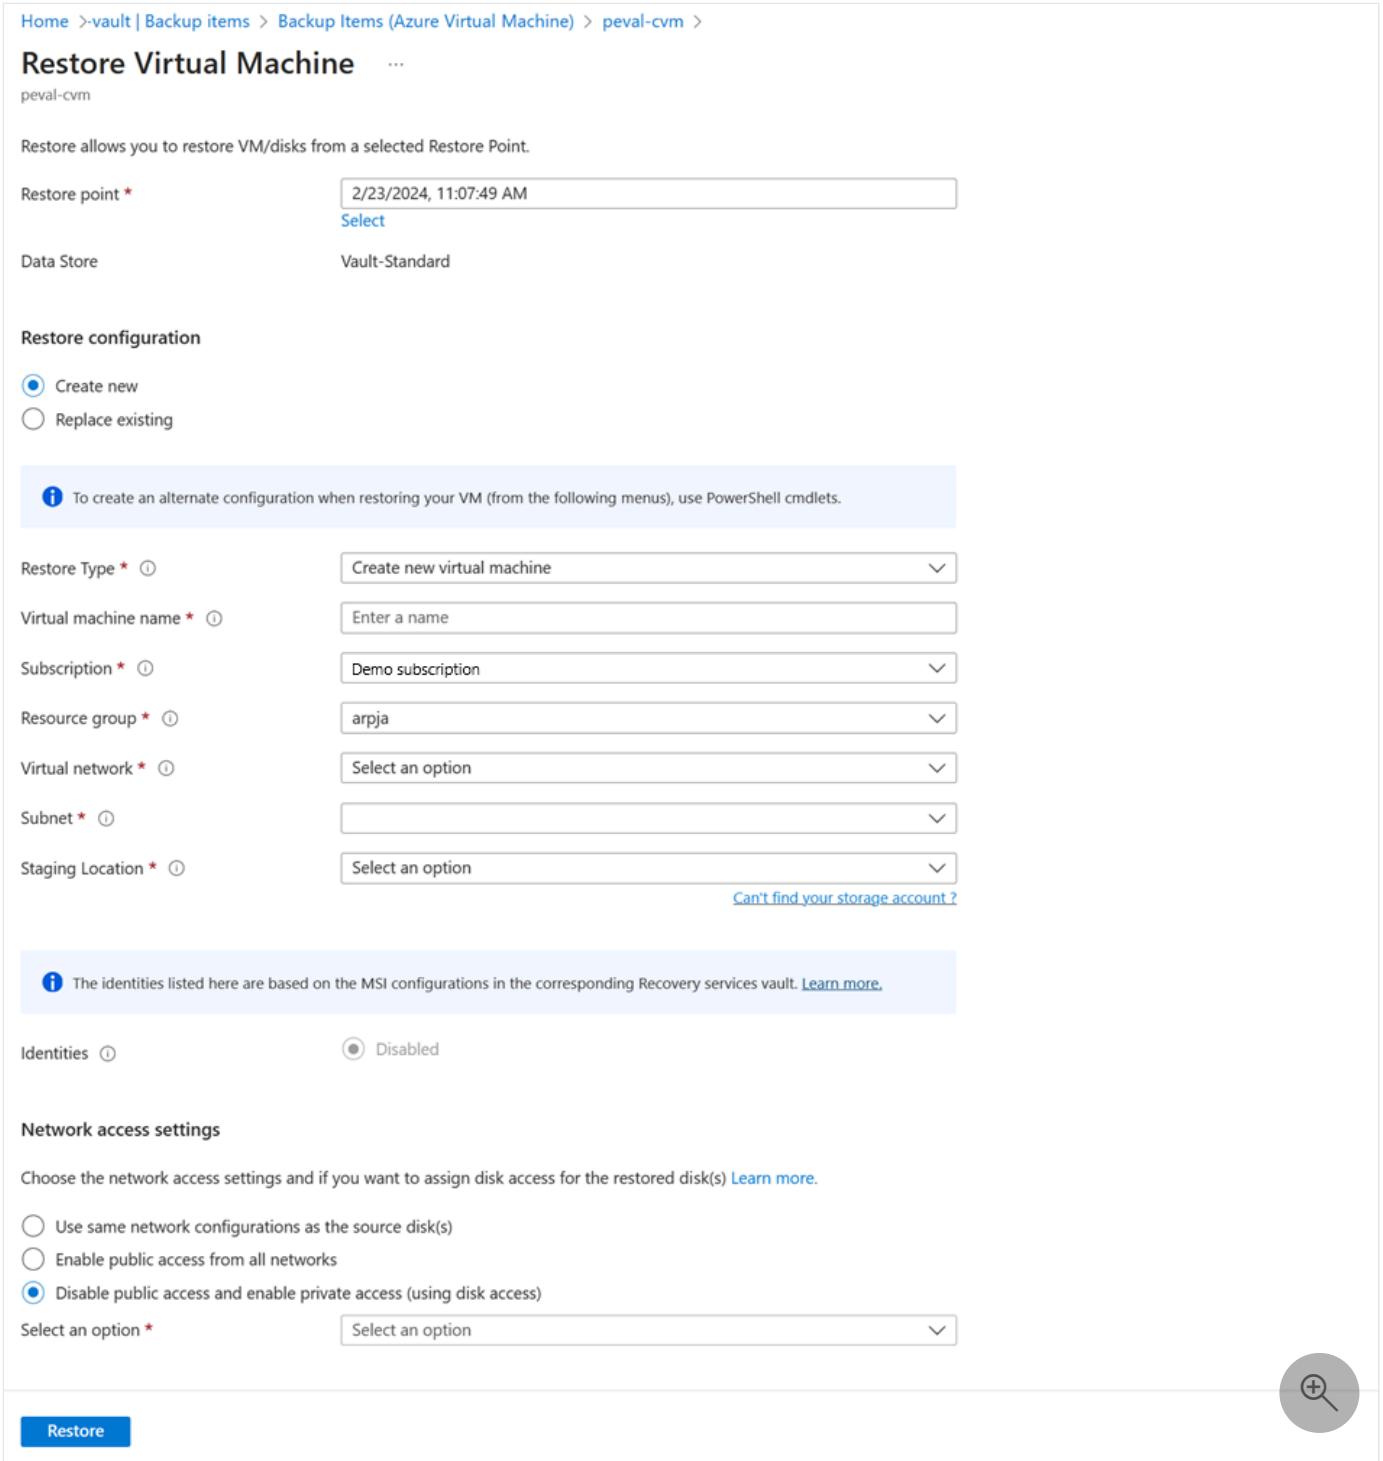
Assign network access settings during restore

Azure Backup also allows you to configure the access options for the restored disks once the restore operation is complete. You can set the disk access preferences at the time of initiating the restore.

> **Note**
>
> This feature is generally available for backed-up VMs that use private endpoint-enabled disks.

To enable disk access on restored disks during VM restore, choose one of the following options:

- **Use the same network configurations as the source disk(s)**: This option allows the restored disks to use the disk access and network configurations same as that of the source disks.
- **Enable public access from all networks**: This option allows the restored disk to be publicly accessible from all networks.
- **Disable public access and enable private access (using disk access)**: This option allows you to disable the public access and assign disk access to the restored disks for private access.



> ⓘ Note

The option to choose the network configuration of the restored disks the same as that of the source disks or specify the access from specific networks only is currently not available from Azure PowerShell/ Azure CLI.

Cross Region Restore

As one of the restore options, Cross Region Restore (CRR) allows you to restore Azure VMs in a secondary region, which is an Azure paired region.

To begin using the feature, read the Before You Begin section.

To see if CRR is enabled, follow the instructions in Configure Cross Region Restore.

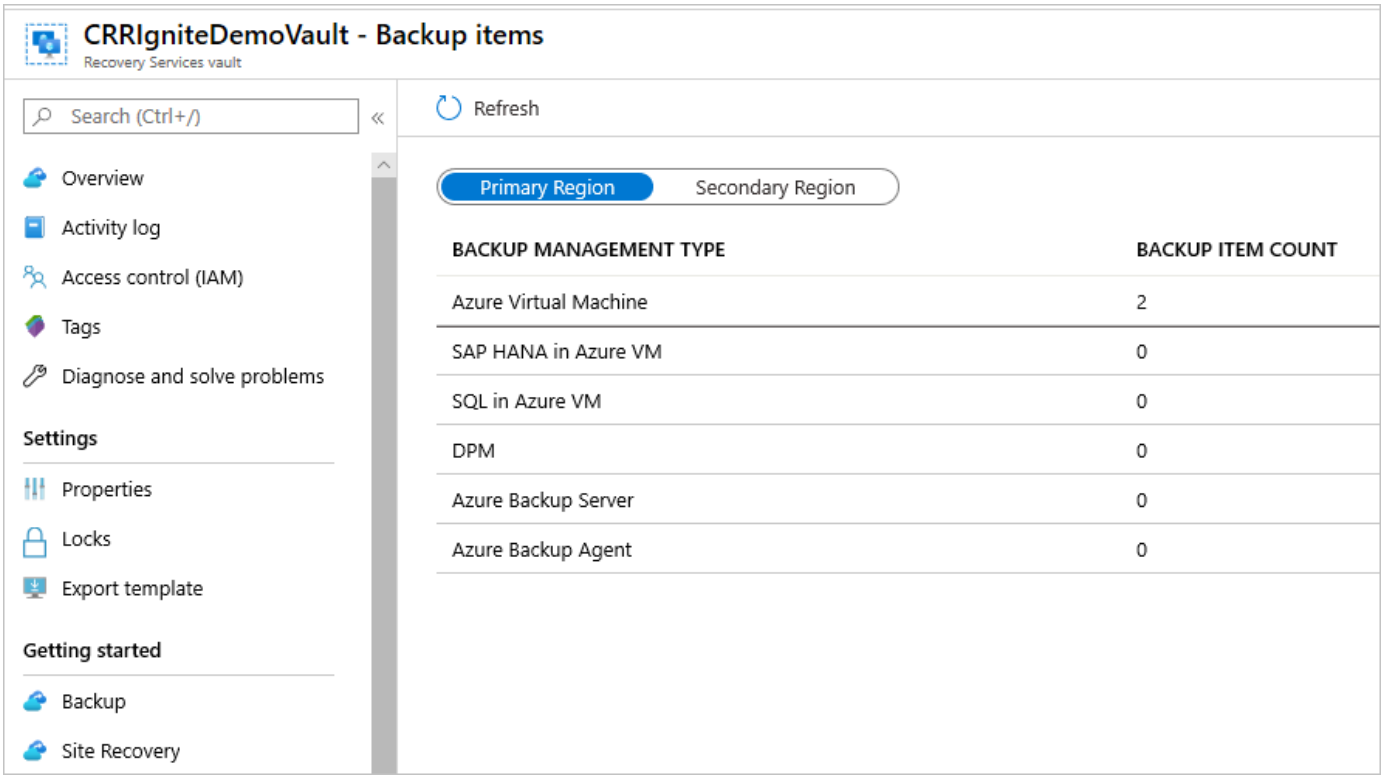
> **Note**
>
> Cross-region restore is currently not supported for machines running on Ultra Disks. Learn more about Ultra Disk backup supportability.

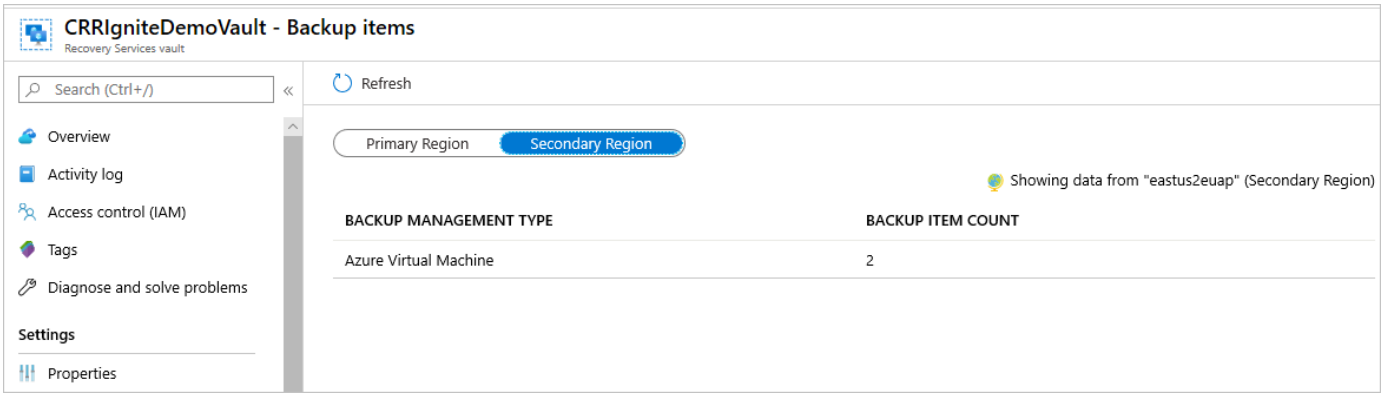
View backup items in secondary region

If CRR is enabled, you can view the backup items in the secondary region.

1. From the portal, go to **Recovery Services vault** > **Backup items**.
2. Select **Secondary Region** to view the items in the secondary region.

> **Note**
>
> Only Backup Management Types supporting the CRR feature will be shown in the list. Currently, only support for restoring secondary region data to a secondary region is allowed.
>
> CRR for Azure VMs is supported for Azure Managed VMs (including encrypted Azure VMs). See the management types that support Cross Region Restore.

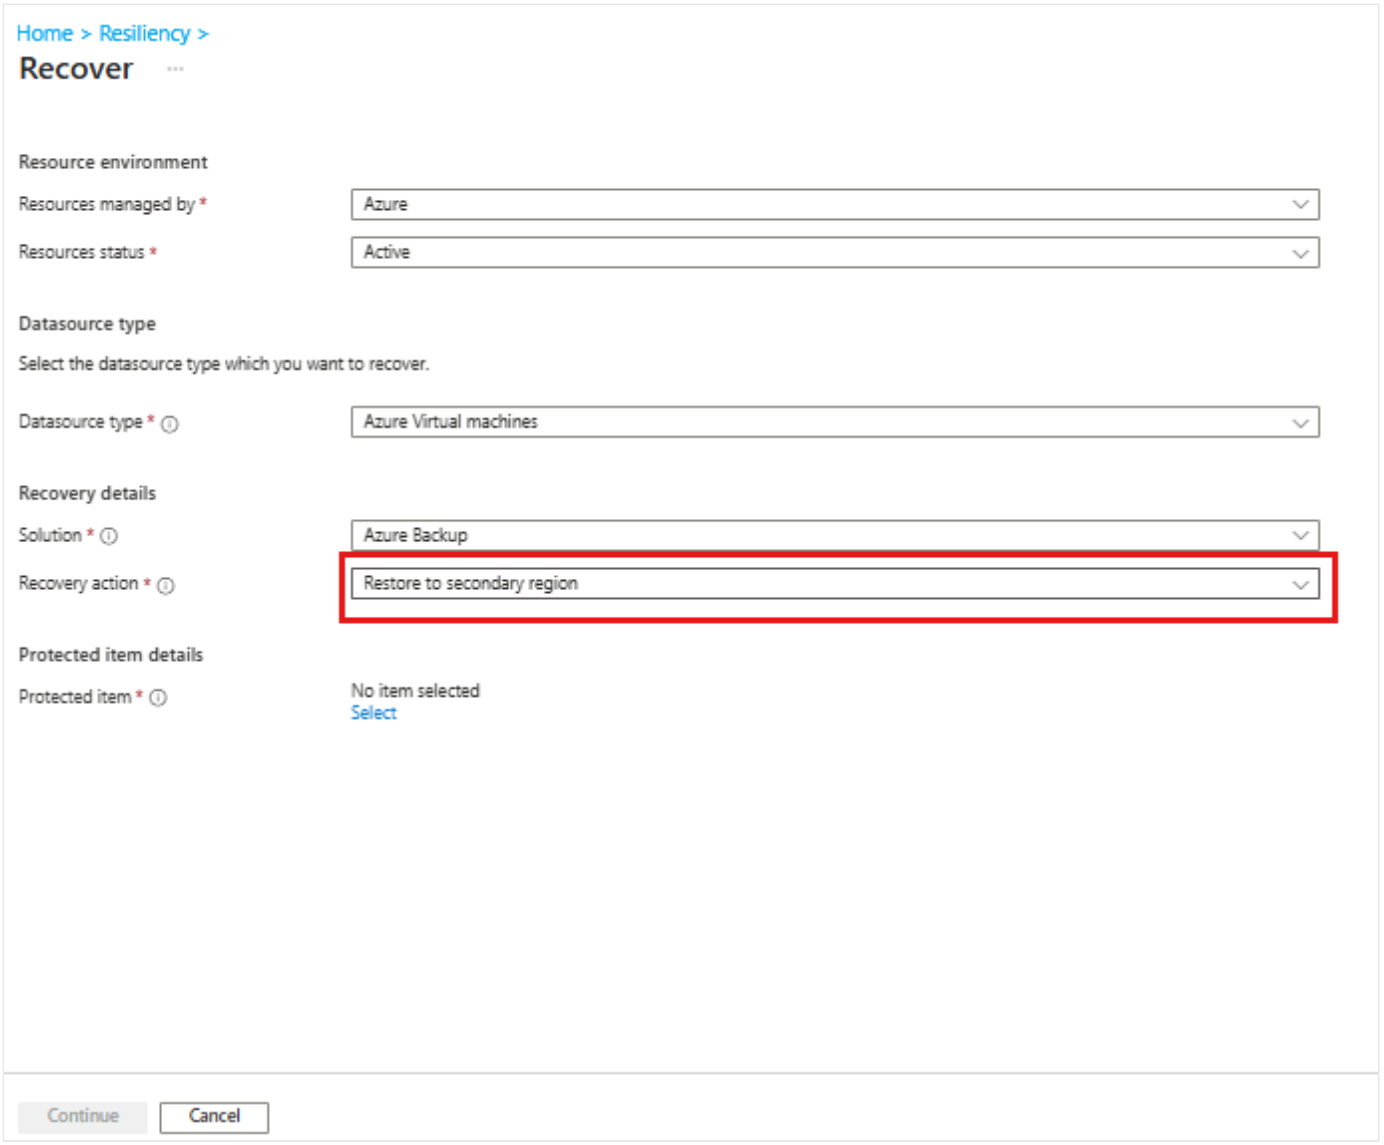




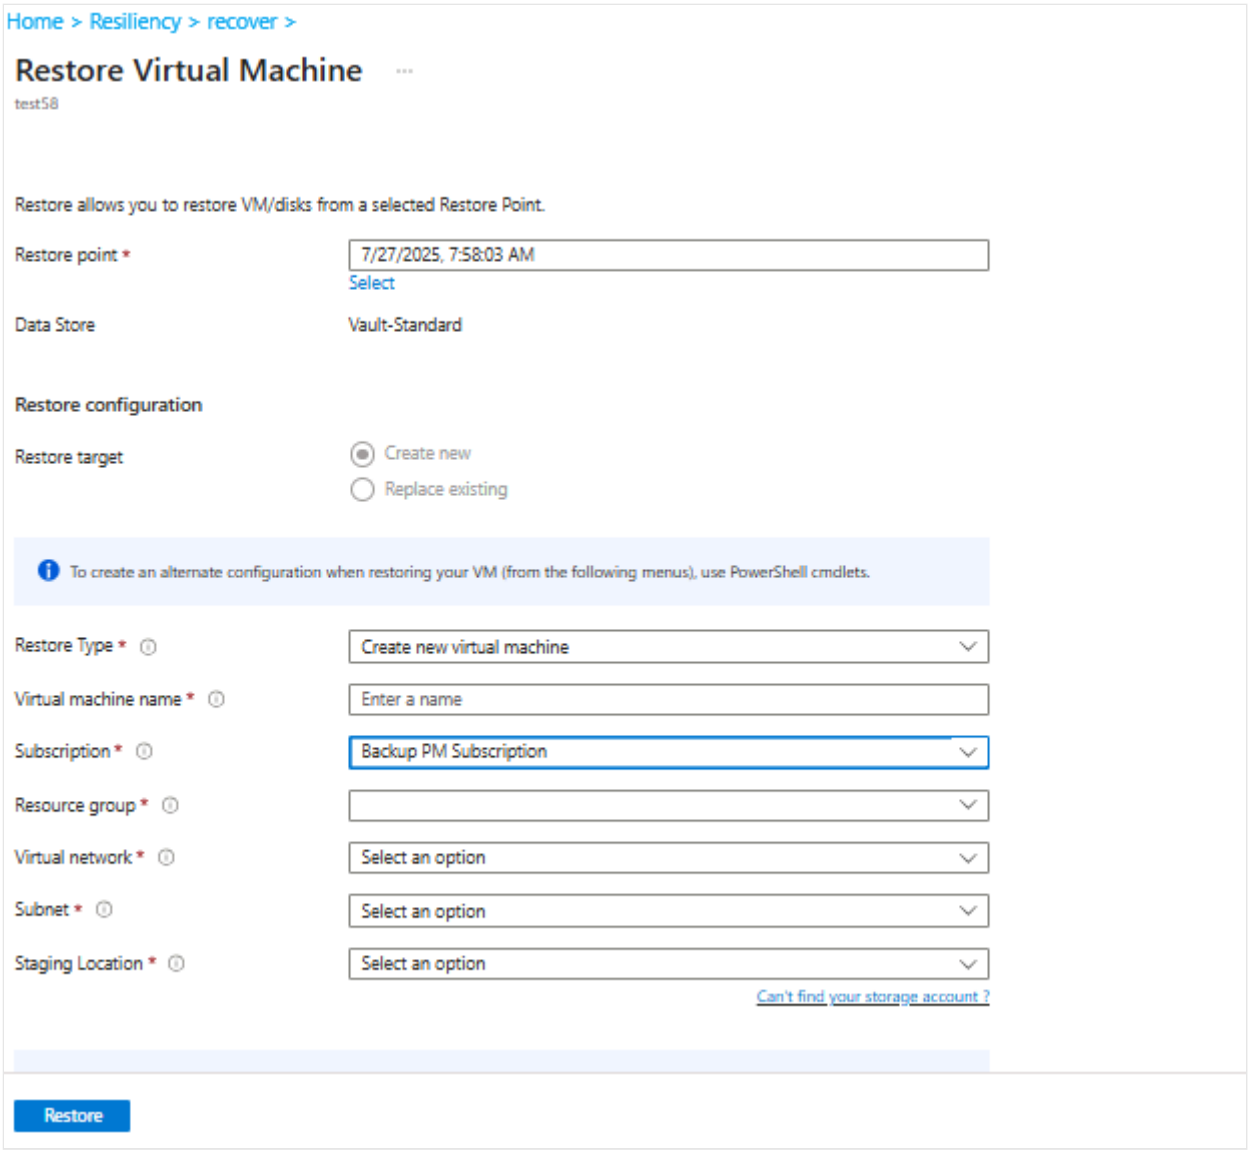
Restore in secondary region

The secondary region restore user experience is similar to the primary region restore user experience. When configuring details in the Restore Configuration pane to configure your restore, you're prompted to provide only secondary region parameters.

For Azure VM backups, the secondary region RPO can be up to *36 hours* in the worst case. With the Standard policy, the primary region RPO is up to *24 hours*, and replication to the secondary region can take up to *12 hours*. With the Enhanced policy, more frequent local recovery point creation can improve the best-case achievable secondary region RPO. However, because vaulting is daily, the worst-case secondary region RPO can still be up to *36 hours*.



Screenshot shows how to start secondary region restore of a VM. ":::



- To restore and create a VM, refer to Create a VM.
- To restore as a disk, refer to Restore disks.

> **Note**
>
> - The Cross Region Restore feature restores CMK (customer-managed keys) enabled Azure VMs, which aren't backed-up in a CMK enabled Recovery Services vault, as non-CMK enabled VMs in the secondary region.
> - The Azure roles needed to restore in the secondary region are the same as those in the primary region.
> - When you restore an Azure VM, Azure Backup configures the virtual network settings in the secondary region automatically. If you are restoring disks while deploying the template, ensure to provide the virtual network settings, corresponding to the secondary region.
> - If VNet/Subnet is not available in the primary region or is not configured in the secondary region, Azure portal doesn't auto-populate any default values during restore

operation.

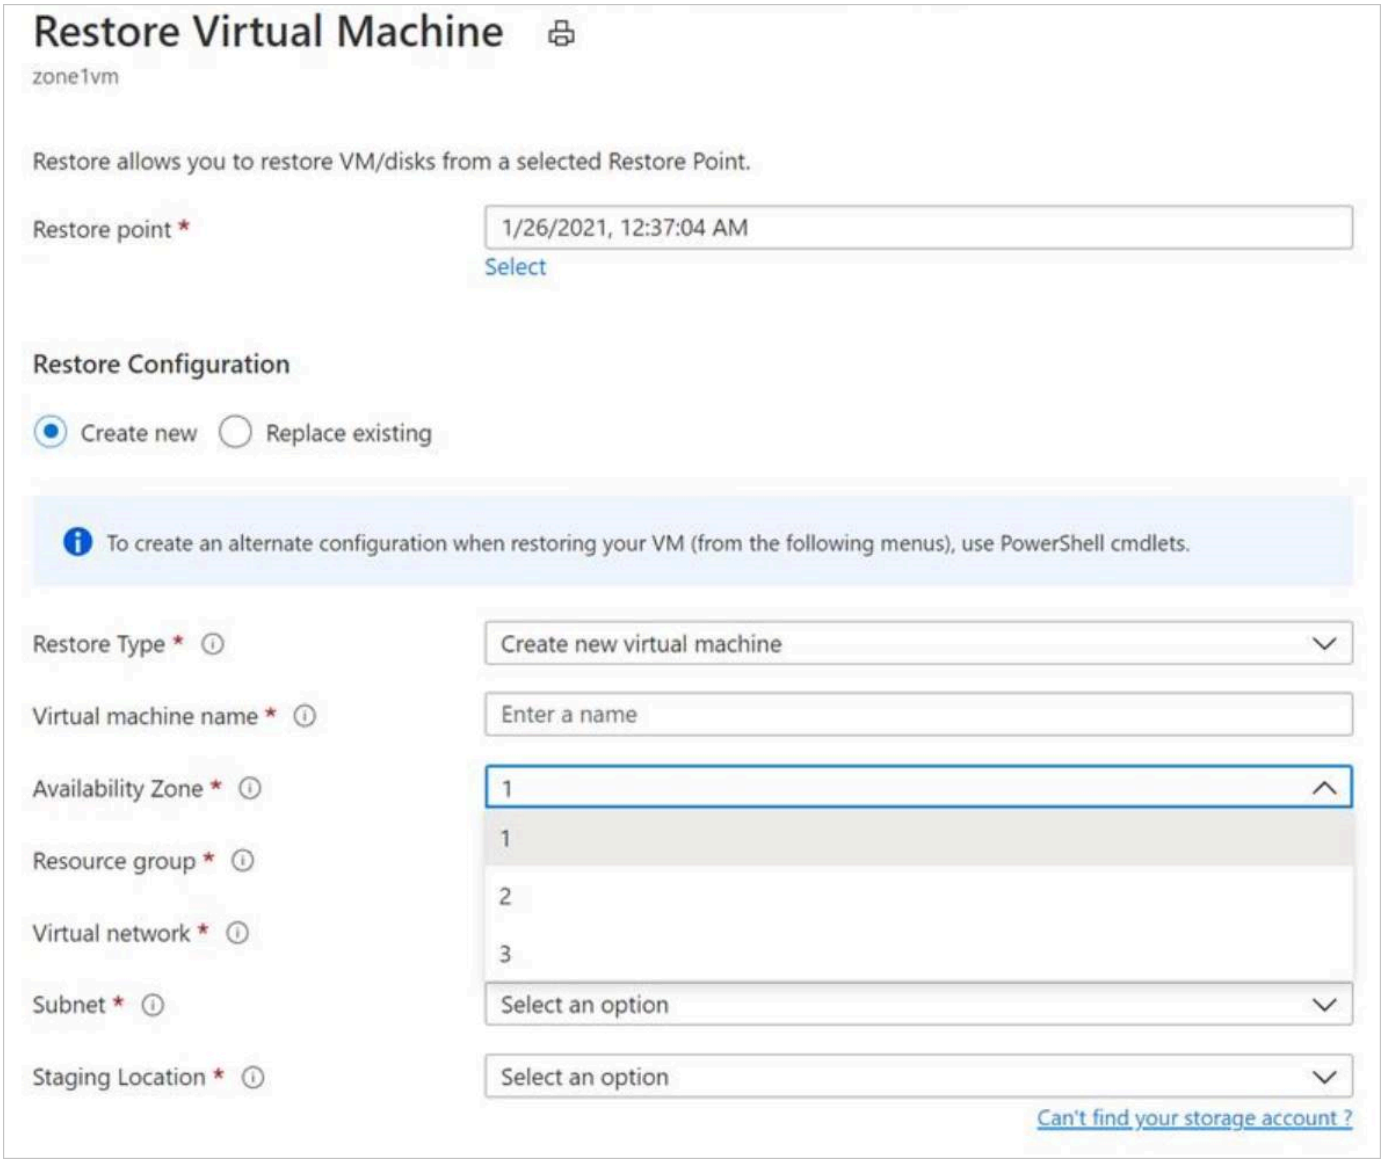
- For Cross Region Restores, the **Staging Location** (that is the storage account location) must be in the region that the Recovery Services vault treats as the *secondary* region. For example, a Recovery Services vault is located in East US 2 region (with Geo-Redundancy and Cross Region Restore enabled). This means that the *secondary* region would be *Central US*. Therefore, you need to create a storage account in *Central US* to perform a Cross Region Restore of the VM.
  Learn more about **Azure cross-region replication pairings for all geographies**.

Azure zone pinned VMs can be restored in any availability zones of the same region.

In the restore process, you'll see the option **Availability Zone.** You'll see your default zone first. To choose a different zone, choose the number of the zone of your choice. If the pinned zone is unavailable, you won't be able to restore the data to another zone because the backed-up data isn't replicated across zones. The restore in availability zones is possible from recovery points in vault tier only.

In summary, the **Availability Zone** will only appear when

- The source VM is zone pinned and is NOT encrypted
- The recovery point is present in vault tier (Snapshots only are not supported)
- The recovery option is to either create a new VM or to restore disks (replace disks option replaces source data and hence the availability zone option is not applicable)
- Creating VM/disks in the same region when vault's storage redundancy is ZRS (Doesn't work when vault's storage redundancy is GRS even though the source VM is zone pinned)
- Creating VM/disks in the paired region when vault's storage redundancy is enabled for Cross-Region-Restore AND if the paired region supports zones

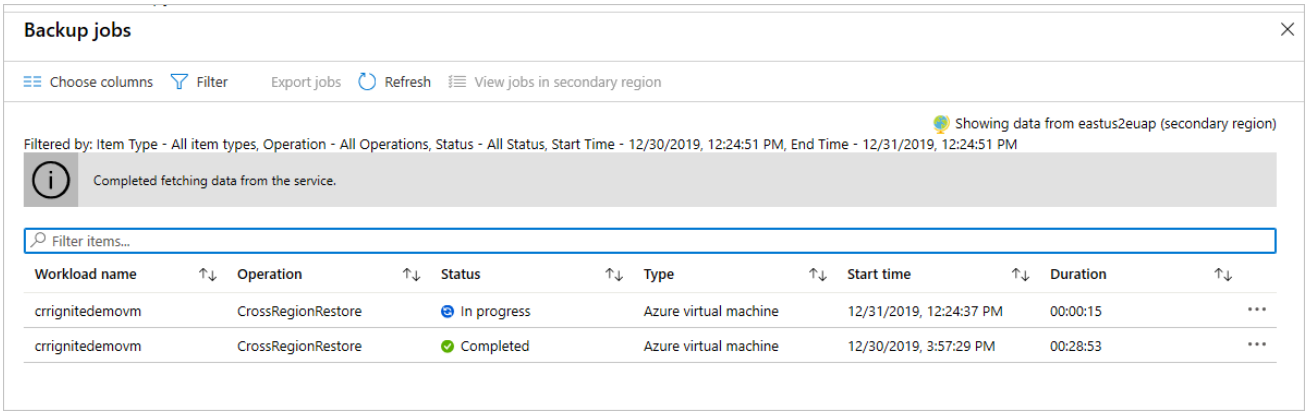


> ⓘ **Note**
>
> Cross region restore jobs once triggered, can't be canceled.

Monitoring secondary region restore jobs

1. From the portal, go to **Recovery Services vault** > **Backup Jobs**

2. Select **Secondary Region** to view the items in the secondary region.

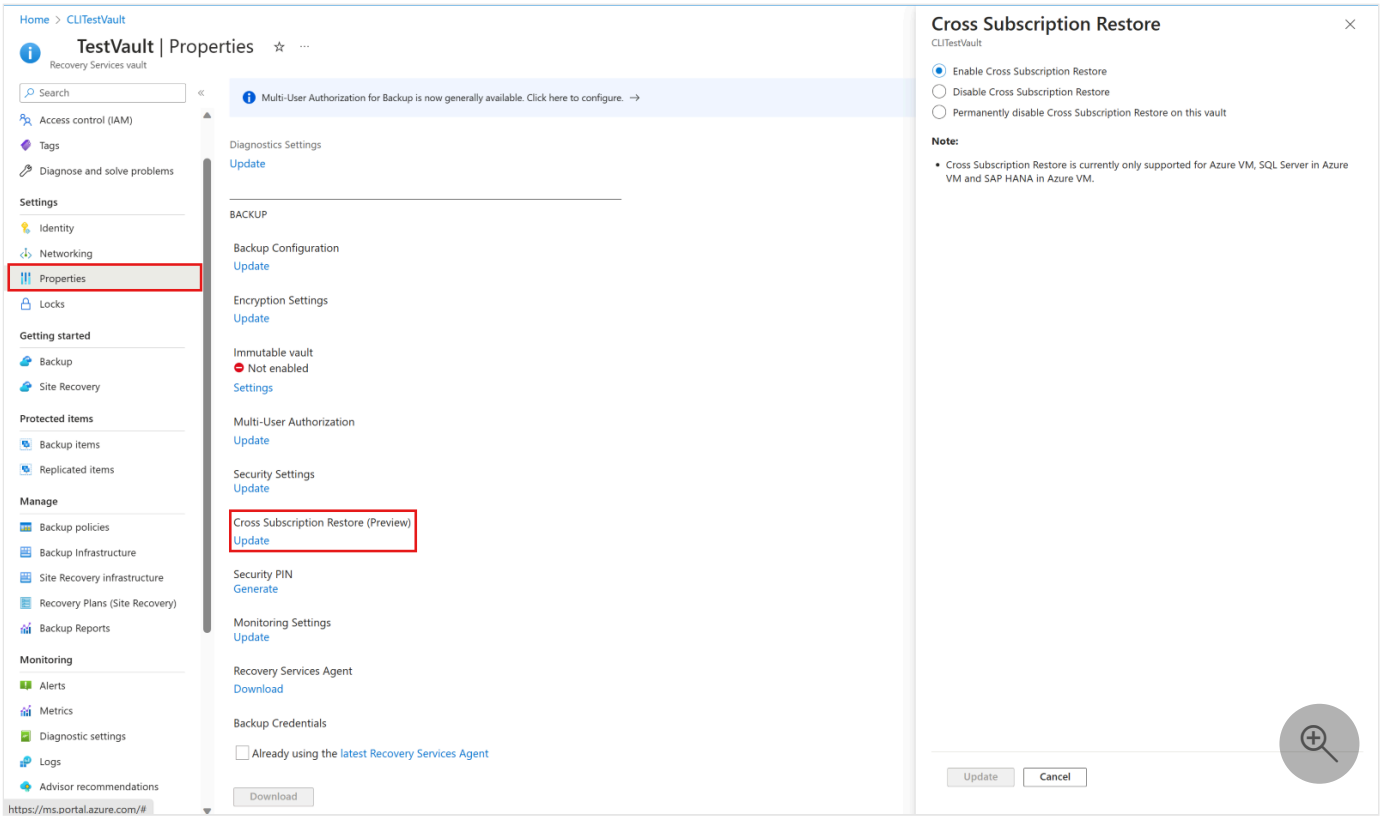


Cross Subscription Restore for Azure VM

Azure Backup now allows you to perform Cross Subscription Restore (CSR), which helps you restore Azure VMs or disks across subscriptions in the same tenant, based on the selected recovery point tier and vault settings.

For Azure VM backups protected across subscriptions, the default restore target is the protected VM subscription. Snapshot-tier recovery points can be restored only in that subscription. Vault-tier recovery points can be restored in the protected VM subscription or the vault subscription. To restore a vault-tier recovery point to any other subscription, you must enable CSR on the vault.

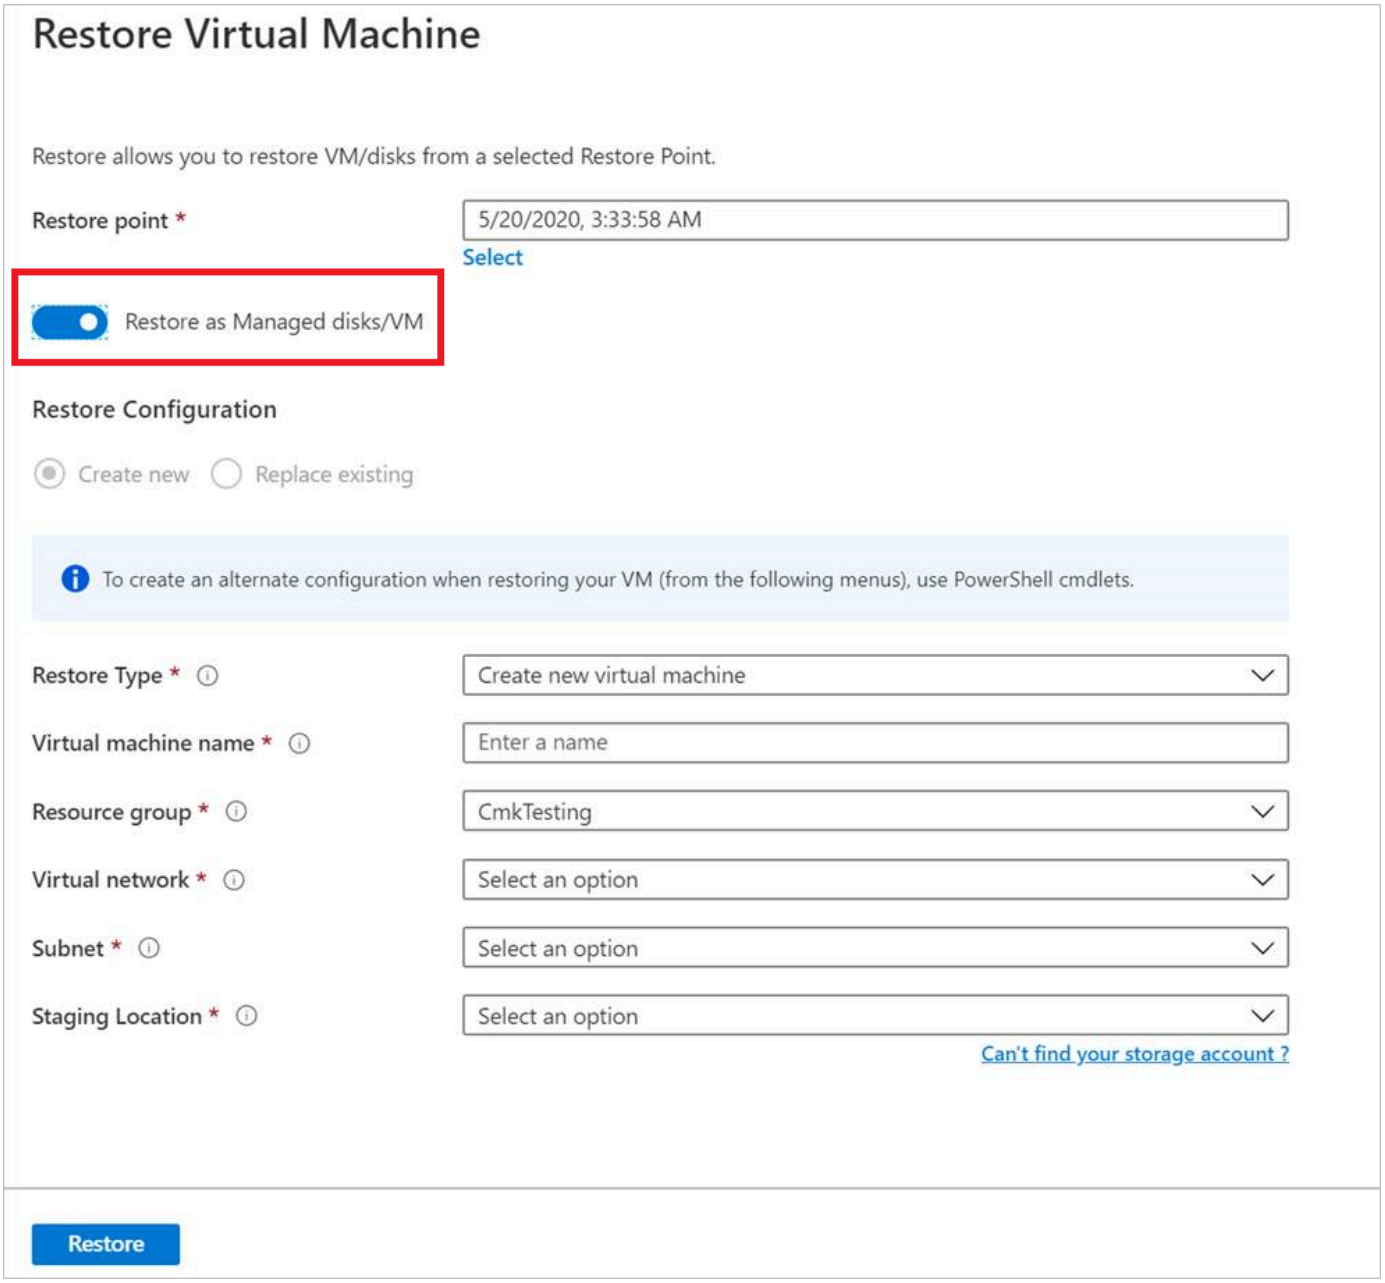
This feature is enabled for Recovery Services vault by default. However, there may be instances when you may need to block Cross Subscription Restore based on your cloud infrastructure. So, you can enable, disable, or permanently disable Cross Subscription Restore for the existing vaults by going to *Vault* > **Properties** > **Cross Subscription Restore**.



> **Note**
>
> - CSR once permanently disabled on a vault can't be re-enabled because it's an irreversible operation.
> - If CSR is disabled but not permanently disabled, then you can reverse the operation by selecting *Vault* > **Properties** > **Cross Subscription Restore** > **Enable**.
> - If a Recovery Services vault is moved to a different subscription when CSR is disabled or permanently disabled, restore to the original subscription fails.

Restore legacy recovery points from VMs that used unmanaged disks

Recovery points from VMs that used unmanaged disks can be restored only as managed disks. Restore to unmanaged disks isn't supported. These restore operations are triggered only from the vault tier. This feature isn't available for unmanaged encrypted VMs.



Restore VMs with special configurations

There are many common scenarios in which you might need to restore VMs.

Expand table

Scenario	Guidance
Restore VMs using Hybrid Use Benefit	If a Windows VM uses Hybrid Use Benefit (HUB) licensing, restore the disks, and create a new VM using the provided template (with **License Type** set to **Windows_Server**), or PowerShell. This setting can also be applied after creating the VM.
Restore VMs during an Azure datacenter disaster	If the vault uses GRS and the primary datacenter for the VM goes down, Azure Backup supports restoring backed-up VMs to the paired datacenter. You select a storage account in the paired datacenter, and restore as normal. Azure Backup uses the compute service in the paired region to create the restored VM. Learn more

Scenario	Guidance
	about datacenter resiliency. If the vault uses GRS, you can choose the new feature, Cross Region Restore. This lets you restore to a second region in either full or partial outage scenarios, or even if there's no outage at all.
Bare-metal restore	The major difference between Azure VMs and on-premises hypervisors is that there's no VM console available in Azure. A console is required for certain scenarios, such as recovering by using a bare-metal recovery (BMR)-type backup. However, VM restore from the vault is a full replacement for BMR.
Restore VMs with special network configurations	Special network configurations include VMs using internal or external load balancing, using multiple NICS, or multiple reserved IP addresses. You restore these VMs by using the restore disk option. This option makes a copy of the VHDs into the specified storage account, and you can then create a VM with an internal or external load balancer, multiple NICS, or multiple reserved IP addresses, in accordance with your configuration. To restore VMs with special network configurations, you should use the **Restore Disk** option. This option creates a copy of the virtual hard disks (VHDs) into the specified storage account. Once the VHDs are copied, you can proceed to create a VM that matches your required network configuration, whether it involves internal or external load balancing, multiple NICs, or multiple reserved IP addresses. Note that VM NICs won't be created if the machine has Public IP and NAT gateway. Consider this limitation when you plan to restore VMs with special network configurations.
Network Security Group (NSG) on NIC/Subnet	Azure VM backup supports backing up and restoring NSG information at vnet, subnet, and NIC level.
Zone Pinned VMs	If you back up an Azure VM that's pinned to a zone (with Azure Backup), then you can restore it in the same zone where it was pinned. Learn more
Restore VM in any availability set	When you restore a VM from the portal, there's no option to choose an availability set. A restored VM doesn't have an availability set. If you use the restore disk option, then you can specify an availability set when you create a VM from the disk using the provided template or PowerShell.
Restore special VMs such as SQL VMs	If you're backing up a SQL VM using Azure VM backup and then use the restore VM option or create a VM after restoring disks, then the newly created VM must be registered with the SQL provider as mentioned here. This will convert the restored VM into a SQL VM.

Restore domain controller VMs

Expand table

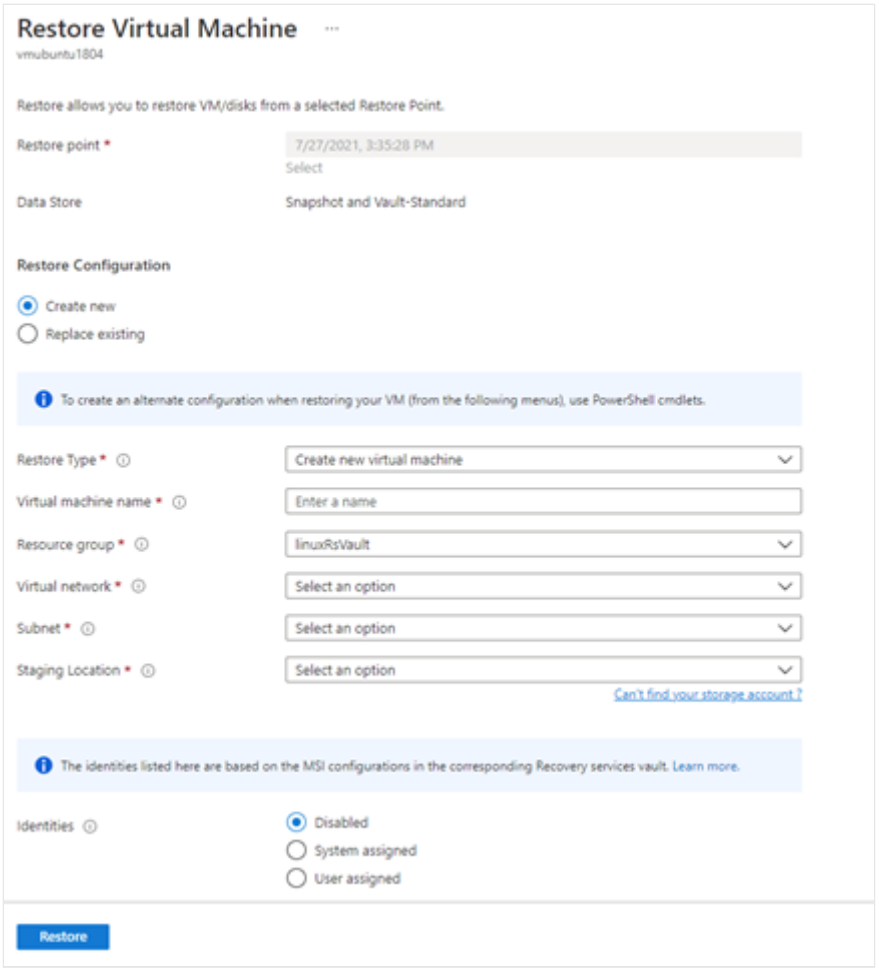
Scenario	Guidance
Restore a single domain controller VM in a single domain	Restore the VM like any other VM. Note that: From an Active Directory perspective, the Azure VM is like any other VM. Directory Services Restore Mode (DSRM) is also available, so all Active Directory recovery scenarios are viable. Learn more about backup and restore considerations for virtualized domain controllers.
Restore multiple domain controller VMs in a single domain	If other domain controllers in the same domain can be reached over the network, the domain controller can be restored like any VM. If it's the last remaining domain controller in the domain, or a recovery in an isolated network is performed, use a forest recovery.
Restore a single domain controller VM in a multiple domain configuration	Restore the disks and create a VM by using PowerShell
Restore multiple domains in one forest	We recommend a forest recovery.

For more information, see Back up and restore Active Directory domain controllers.

Restore VMs with managed identities

Managed identities eliminate the need for the user to maintain the credentials. Managed identities provide an identity for applications to use when connecting to resources that support Microsoft Entra authentication.

Azure Backup offers the flexibility to restore the managed Azure VM with managed identities. You can choose to select system-managed identities or user-managed identities as shown in the figure below. This is introduced as one of the input parameters in the **Restore configuration** pane of Azure VM. Managed identities are used for accessing the storage accounts and automated cleanup of any resources created during restore process. These managed identities have to be associated to the vault.



If you choose to select system-assigned or user-assigned managed identities, check for the below actions for managed identity on the target staging Storage Account and Resource Group.

                ],
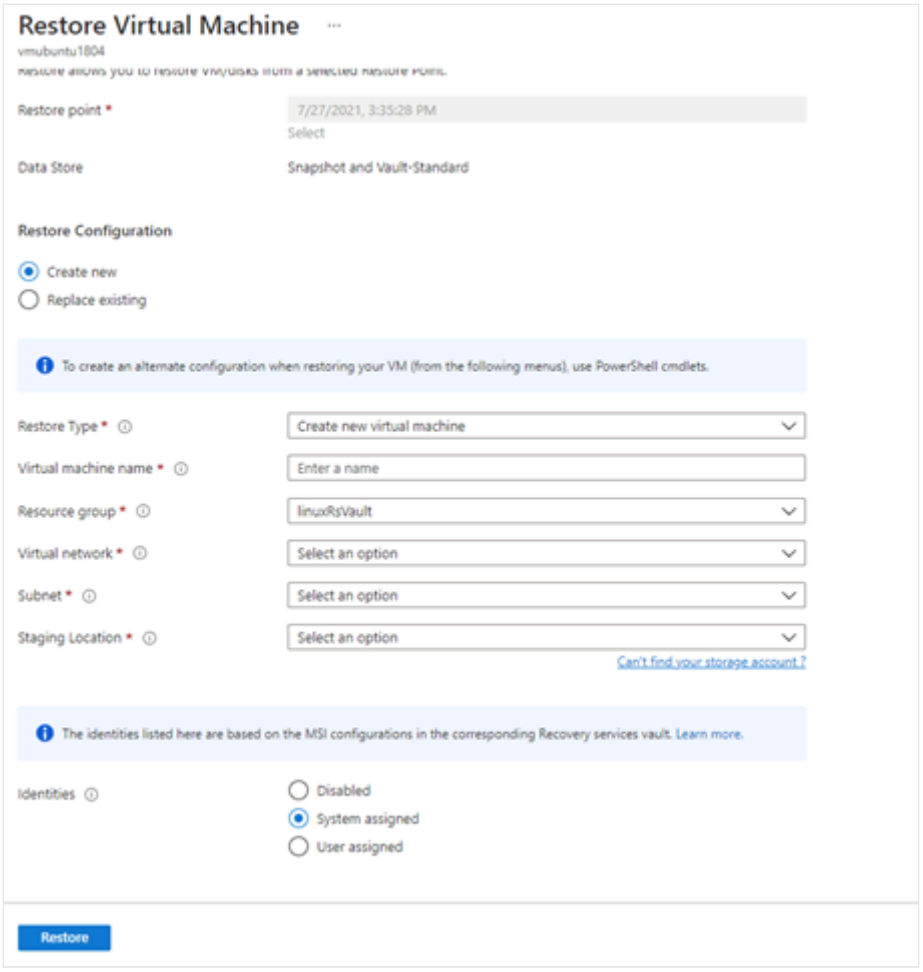
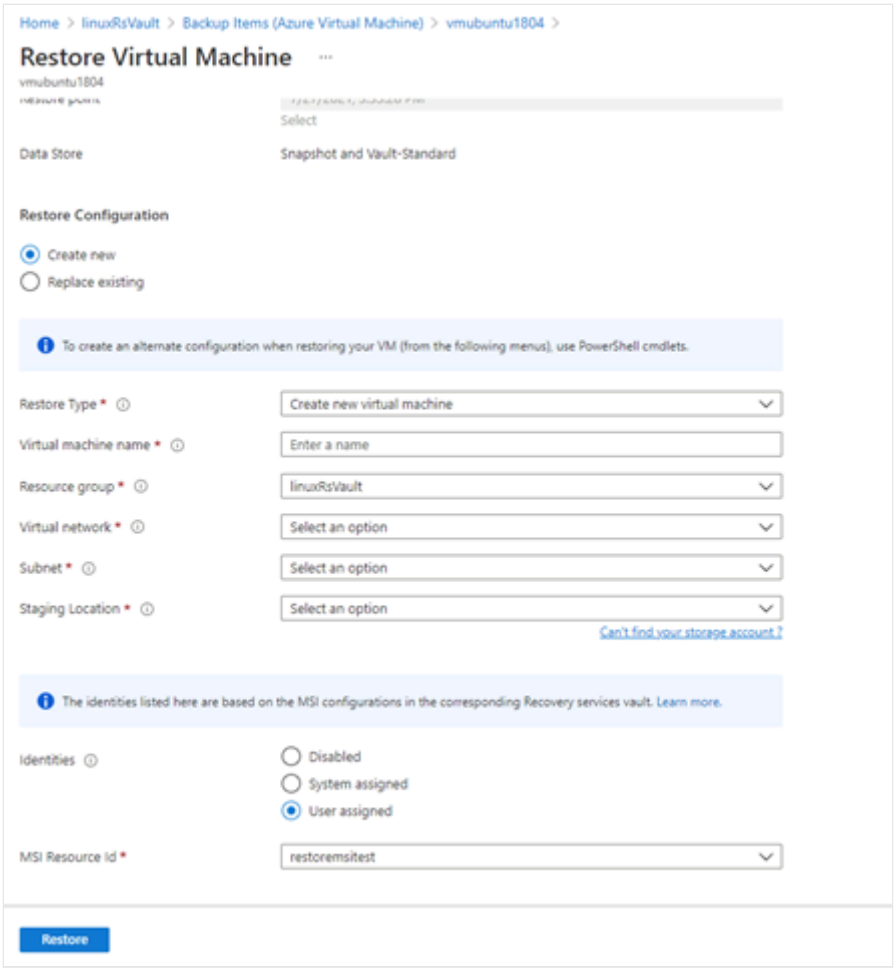
```

Or, add the **VM restore operator** role assignment on the staging location (Storage Account) and target Resource Group for the successful restore operation.



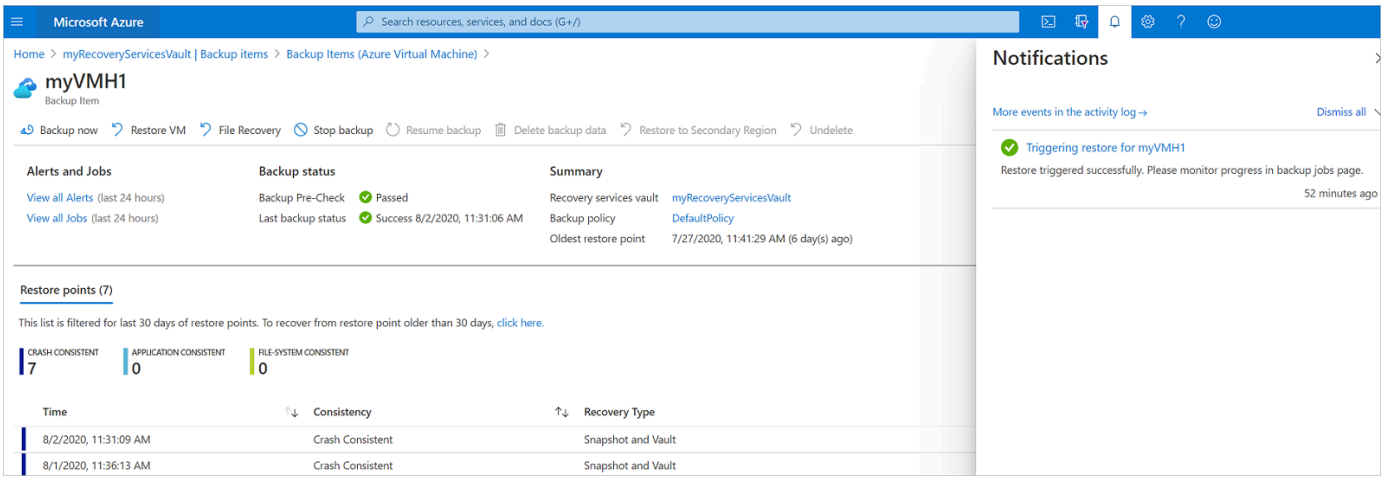
You can also select the user-managed identity by providing the input as their MSI Resource ID as provided in the figure below.



> **Note**
>
> The support is available for only managed VMs, and not supported for classic VMs and unmanaged VMs. For the storage accounts that are restricted with firewalls, system MSI is only supported.
>
> Cross Region Restore isn't supported with managed identities.
>
> Currently, this is available in all Azure public and national cloud regions.

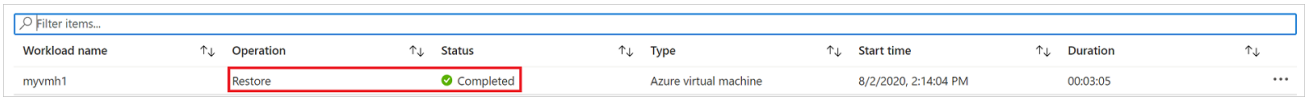
Track the restore operation

After you trigger the restore operation, the backup service creates a job for tracking. Azure Backup displays notifications about the job in the portal. If they aren't visible, select the **Notifications** symbol, and then select **More events in the activity log** to see the Restore Process Status.



Track restore as follows:

1. To view operations for the job, select the notifications hyperlink. Alternatively, in the vault, select **Backup jobs**, and then select the relevant VM.



2. To monitor restore progress, select any restore job with a status of **In-progress**. This displays the progress bar, which displays information about the restore progress:

    - **Estimated time of restore**: Initially provides the time taken to complete the restore operation. As the operation progresses, the time taken reduces and reaches zero when the restore operation finishes.
    - **Percentage of restore**. Shows the percentage of restore operation that's done.
    - **Number of bytes transferred**: If you're restoring by creating a new VM, it shows the bytes that were transferred against the total number of bytes to be transferred.

Post-restore steps

There are a few things to note after restoring a VM:

- Extensions present during the backup configuration are installed, but not enabled. If you see an issue, reinstall the extensions. In the case of disk replacement, reinstallation of extensions is not required.

- When you choose Create a new VM (or restore disks and then create a VM), the restored VM is a new resource. RBAC role assignments that were scoped to the original VM do not carry over; reassign roles on the new VM as needed.

- If the backed-up VM had a static IP address, the restored VM will have a dynamic IP address to avoid conflict. You can add a static IP address to the restored VM.
- A restored VM doesn't have an availability set. If you use the restore disk option, then you can specify an availability set when you create a VM from the disk using the provided template or PowerShell.
- If you use a cloud-init-based Linux distribution, such as Ubuntu, for security reasons the password is blocked after the restore. Use the `VMAccess` extension on the restored VM to reset the password. We recommend using SSH keys on these distributions, so you don't need to reset the password after the restore.
- If you're unable to access a VM once restored because the VM has a broken relationship with the domain controller, then follow the steps below to bring up the VM:
  - Attach OS disk as a data disk to a recovered VM.
  - Manually install VM agent if Azure Agent is found to be unresponsive by following this link.
  - Enable Serial Console access on VM to allow command-line access to VM

    Windows Command Prompt

    ```
    bcdedit /store <drive letter>:\boot\bcd /enum
    bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /set
    {bootmgr} displaybootmenu yes
    bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /set
    {bootmgr} timeout 5
    bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /set
    {bootmgr} bootems yes
    bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /ems {<<BOOT
    LOADER IDENTIFIER>>} ON
    bcdedit /store <VOLUME LETTER WHERE THE BCD FOLDER IS>:\boot\bcd /emssettings
    EMSPORT:1 EMSBAUDRATE:115200
    ```

  - When the VM is rebuilt use Azure portal to reset local administrator account and password
  - Use Serial console access and CMD to disjoin VM from domain

    Windows Command Prompt

    ```
    cmd /c "netdom remove <<MachineName>> /domain:<<DomainName>> /userD:
    <<DomainAdminhere>> /passwordD:<<PasswordHere>> /reboot:10 /Force"
    ```

- Once the VM is disjoined and restarted, you'll be able to successfully RDP to the VM with local admin credentials and rejoin VM back to domain successfully.

Backing up restored VMs

- If you restored a VM to the same resource group with the same name as the originally backed-up VM, backup continues on the VM after restore.
- If you restored the VM to a different resource group or you specified a different name for the restored VM, you need to set up backup for the restored VM.

Next steps

- If you experience difficulties during the restore process, review common issues and errors.
- After the VM is restored, learn about managing virtual machines

---

Support matrix for Azure VM backups

You can use the Azure Backup service to back up on-premises machines and workloads, along with Azure virtual machines (VMs). This article summarizes support settings and limitations when you back up Azure VMs by using Azure Backup.

Other support matrices include:

- General support matrix for Azure Backup
- Support matrix for Azure Backup servers and System Center Data Protection Manager (DPM) backup
- Support matrix for backup with the Microsoft Azure Recovery Services (MARS) agent

Supported scenarios

Here's how you can back up and restore Azure VMs by using the Azure Backup service.

Expand table

Scenario	Backup	Agent	Restore
Direct backup of Azure VMs	Back up the entire VM.	For application or file-system consistent backups, no additional agent is needed on the Azure VM. Azure Backup installs and uses an extension to the Azure VM agent that's running on the VM. You can also use agentless crash-consistent backups. Learn more.	Restore as follows: - **Create a basic VM**. This is useful if the VM has no special configuration, such as multiple IP addresses. - **Restore the VM disk**. Restore the disk. Then attach it to an existing VM, or create a new VM from the disk by using PowerShell. - **Replace the VM disk**. If a VM exists and it uses managed disks (unencrypted), you can restore a disk and use it to replace an existing disk on the VM. - **Restore specific files or**

Scenario	Backup	Agent	Restore
			folders. You can restore files or folders from a VM instead of restoring the entire VM.
Direct backup of Azure VMs (Windows only)	Back up specific files, folders, or volumes.	Install the Azure Recovery Services agent. You can run the MARS agent alongside the backup extension for the Azure VM agent to back up the VM at the file or folder level.	Restore specific files or folders.
Backup of Azure VMs to the backup server	Back up files, folders, or volumes; system state or bare metal files; and app data to System Center DPM or to Microsoft Azure Backup Server (MABS). DPM or MABS then backs up to the backup vault.	Install the DPM or MABS protection agent on the VM. The MARS agent is installed on DPM or MABS.	Restore files, folders, or volumes; system state or bare metal files; and app data.

Learn more about using a backup server and about support requirements.

Supported backup actions

Expand table

Action	Support
Back up a VM that's shut down or offline	Supported. Snapshot is crash-consistent only, not app consistent.
Back up disks after migrating to managed disks	Supported. Backup will continue to work. No action is required.
Back up managed disks after enabling a resource group lock	Not supported. Azure Backup can't delete the older restore points. Backups will start to fail when the limit of restore points is reached.

Action	Support
Modify backup policy for a VM	Supported. The VM will be backed up according to the schedule and retention settings in the new policy. If retention settings are extended, existing recovery points are marked and kept. If they're reduced, existing recovery points will be pruned in the next cleanup job and eventually deleted.
Cancel a backup job	Supported during the snapshot process. Not supported when the snapshot is being transferred to the vault.
Back up the VM to a different region	Not supported. The VM and Recovery Services vault must be in the same region.
Back up the VM to a different subscription	Supported when the VM and Recovery Services vault are in the same tenant and same region. - Cross-subscription backup isn't supported for Confidential VMs (CVMs), including ADE encrypted CVMs. - Movement of backed-up data between vaults isn't supported. - Movement of a Recovery Services vault across subscriptions or between resource groups also isn't supported when the vault contains cross-subscription protected Azure VM backup items. Learn how to Back up Azure VMs in a Recovery Services vault for steps involved.
Back up daily via the Azure VM extension	Four backups per day: one scheduled backup as defined in the backup policy, and three on-demand backups. To allow user retries in case of failed attempts, the hard limit for on-demand backups is set to nine attempts in a 24 hour UTC period.
Back up daily via the MARS agent	Three scheduled backups per day.
Back up daily via DPM or MABS	Two scheduled backups per day.
Back up monthly or yearly	Not supported when you're backing up with the Azure VM extension. Only daily and weekly are supported. You can set up the policy to retain daily or weekly backups for a monthly or yearly retention period.
Automatically adjust the clock	Not supported. Azure Backup doesn't automatically adjust for daylight saving time when you're backing up a VM.

Action	Support
	Modify the policy manually as needed.
Disable security features for hybrid backup	Not supported.
Back up Azure VMs with Azure Extended zones	Supported through Enhanced policy. Snapshot is crash-consistent only, you can also retain snapshots locally for instant restore.
Back up a VM whose machine time is changed	Not supported. If you change the machine time to a future date/time after enabling backup for that VM, even if the time change is reverted, successful backup isn't guaranteed.
Do multiple backups per day	Supported through **Enhanced policy**. For hourly backup, the minimum recovery point objective (RPO) is 4 hours and the maximum is 24 hours. You can set the backup schedule to 4, 6, 8, 12, and 24 hours, respectively. Note that the maximum limit of instant recovery point retention range depends on the number of snapshots you take per day. If the snapshot count is more (for example, every *4 hours* frequency in *24 hours* duration - *6* scheduled snapshots), then the maximum allowed days for retention reduces. However, if you choose lower RPO of *12* hours, the snapshot retention is increased to *30 days*. Learn about how to back up an Azure VM using Enhanced policy.
Back up a VM with a deprecated plan when the publisher has removed it from Azure Marketplace	Not supported. Backup is supported. Restore to existing/original VM is supported. Restore by creating a new VM will fail. If you've already configured backup for a VM with a deprecated virtual machine offer and encounter a restore error, see Troubleshoot backup errors with Azure VMs.
Back up VMs with docker (containers)	Not supported
Soft Delete for backups	Not Supported with Azure role-based access control (Azure RBAC) permissions at the resource group level. Requires Azure RBAC permissions at the subscription level, including the `Microsoft.DataProtection/locations/checkFeatureSupport/action` permission.

Operating system support (Windows)

The following table summarizes the supported operating systems when you're backing up Azure VMs running Windows.

Expand table

Scenario	OS support
Back up with the Azure VM agent extension for application-consistent backup	- Windows 11 client (64 bit only) - Windows 10 client (64 bit only) - Windows Server 2025 (Datacenter, Datacenter Core, and Standard) - Windows Server 2022 (Datacenter, Datacenter Core, and Standard) - Windows Server 2019 (Datacenter, Datacenter Core, and Standard) - Windows Server 2016 (Datacenter, Datacenter Core, and Standard) Note that *32 bit Operating Systems* aren't supported.
Back up Azure VM directly using agentless crash-consistent backup	Agentless crash-consistent backups are operating system agnostic.
Back up with the MARS agent	Supported operating systems
Back up with DPM or MABS	Supported operating systems for backup with MABS and DPM

Support for Linux backup

Here's what's supported if you want to back up Linux machines.

Expand table

Action	Support
Back up Linux Azure VMs with the Linux Azure VM agent	Supported for file-consistent backup. Also supported for app-consistent backup that uses custom scripts. During restore, you can create a new VM, restore a disk and use it to create a VM, or restore a disk and use it to replace a disk on an existing VM. You can also restore individual files and folders. *Note: Azure Backup requires the /var and /var/lib directories on Linux machines not to be mounted with the noexec flag. Certain backup operations rely on executing helper scripts from /var/lib, and enforcing noexec prevents these components from running.*
Back up Azure VM directly by using agentless crash-consistent backup	Agentless crash-consistent backups are operating system agnostic.
Back up Linux Azure VMs with the MARS agent	Not supported. The MARS agent can be installed only on Windows machines.
Back up Linux Azure VMs with DPM or MABS	Not supported.
Back up Linux Azure VMs with Docker mount points	Currently, Azure Backup doesn't support exclusion of Docker mount points because these are mounted at different paths every time.
Backup Linux Azure VMs with ZFS Pool Configuration	Not supported

Operating system support (Linux)

For Linux VM backups using the Linux Azure VM agent, Azure Backup supports the list of Linux distributions endorsed by Azure. Note the following:

- Agent-based VM backup doesn't support CoreOS Linux.
- Agent-based VM backup doesn't support 32-bit operating systems.
- Other bring-your-own Linux distributions might work as long as the Azure VM agent for Linux is available on the VM, and as long as Python is supported.
- Agent-based VM backup doesn't support a proxy-configured Linux VM if it doesn't have Python version 2.7 or later installed.
- Agentless crash-consistent backups are operating system agnostic and can be used to back up VMs whose operating system isn't supported for agent-based backups.

- Azure Backup doesn't support backing up Network File System (NFS) files that are mounted from storage, or from any other NFS server, to Linux or Windows machines. It backs up only disks that are locally attached to the VM.

Support matrix for managed pre and post scripts for Linux databases

Azure Backup provides the following support for customers to author their own pre and post scripts.

Expand table

Supported database	OS version	Database version
Oracle in Azure VMs	Oracle Linux	Oracle 12.x or later

Support for Confidential VM backup (preview)

The following table lists the supported scenarios for Confidential VM backup:

Expand table

Scenario	Supportability
Virtual Machine size	**v6-series** is supported. **v5-series** isn't supported.
Region availability	Supported in UAE North, Korea Central.
Key rotation for backups	When key rotation occurs on a confidential virtual machine, the keys for the VM disks, related restore points, and snapshots update automatically. **Known issue:** The key rotation in this *preview release* might have performance issues or fail in the following scenarios: - More than 40 disks are attached to one DES when (only) restore points are associated with these disks. - If you also directly create disk snapshots outside of Azure backup for these disks connected to the same DES, this lowers the safe threshold of 40 disks to DES mapping. **Recommendation**: Keep the number of disks connected to each DES to a minimum until the issue is resolved.
Backup capabilities	- You can backup Confidential VMs with OS disk encryption only. - Backup and restore fail if the CVM v2 opt-out feature flag is enabled for your

Scenario	Supportability
	subscription. - Multi-disk crash consistent backup is unsupported. - Cross Region Restore is currently unsupported as CVM v6 VM size isn't generally available in Azure paired regions.

Support for agentless multi-disk crash-consistent VM backup

The following table lists the supported scenarios for agentless multi-disk crash-consistent Azure Virtual Machine (VM) backup:

Expand table

Scenario	Supportability
Region availability	Supported in all Azure public regions.
Backup policy type	Agentless crash-consistent backup is supported only with Enhanced Policy.
VM type and size	- Supported for VM sizes that are premium storage capable (VM size that include "*s*" in their name) such as `DSv2`. - Trusted Launch VMs are supported. - VMs with Ultra Disks, Premium SSD v2, Ephemeral OS disks, Shared disks, and Write Accelerated disks aren't supported. - VM sizes using Azure Boost aren't supported - Intel V6 and above (Dsv6-series, Edsv6-series, Esv6-series, and more) and AMD V7 and above (Dasv7-series, Dadsv7-series, Easv7-series, Faldsv7-series, and more)
Pre/post script	Not applicable Pre/Post scripts are used for app-consistent Linux VM backup.

Learn more about Agentless multi-disk crash-consistent VM backup.

Backup frequency and retention

Expand table

Setting	Limits
Maximum recovery points per protected instance (machine or workload)	9999.

Setting	Limits
Maximum expiry time for a recovery point	No limit (99 years).
Maximum backup frequency to a vault (Azure VM extension)	Once a day.
Maximum backup frequency to a vault (MARS agent)	Three backups per day.
Maximum backup frequency to DPM or MABS	Every 15 minutes for SQL Server. Once an hour for other workloads.
Recovery point retention	Daily, weekly, monthly, and yearly.
Maximum retention period	Depends on backup frequency.
Recovery points on DPM or MABS disk	64 for file servers, and 448 for app servers. Tape recovery points are unlimited for on-premises DPM.

Supported restore methods

Expand table

Restore option	Details
Create a new VM	This option quickly creates and gets a basic VM up and running from a restore point. You can specify a name for the VM, select the resource group and virtual network in which it will be placed, and specify a storage account for the restored VM. The new VM must be created in the same region as the source VM.
Restore disk	This option restores a VM disk, which can you can then use to create a new VM. Azure Backup provides a template to help you customize and create a VM. The restore job generates a template that you can download and use to specify custom VM settings and create a VM. The disks are copied to the resource group that you specify. Alternatively, you can attach the disk to an existing VM, or create a new VM by using PowerShell. This option is useful if you want to customize the VM, add configuration settings that weren't there at the time of backup, or add settings that must be configured via the template or PowerShell.

Restore option	Details
Replace existing	You can restore a disk and use it to replace a disk on the existing VM. The current VM must exist. If it has been deleted, you can't use this option. Azure Backup takes a snapshot of the existing VM before replacing the disk, and it stores the snapshot in the staging location that you specify. Existing disks connected to the VM are replaced with the selected restore point. The snapshot is copied to the vault and retained in accordance with the retention policy. After the replace-disk operation, the original disk is retained in the resource group. You can choose to manually delete the original disks if they aren't needed. This option is supported for unencrypted managed VMs and for VMs created from custom images. It's not supported for unmanaged disks and VMs, classic VMs, and generalized VMs. If the restore point has more or fewer disks than the current VM, the number of disks in the restore point will only reflect the VM configuration. This option is also supported for VMs with linked resources, like user-assigned managed identity and Azure Key Vault.
Cross Region (secondary region)	You can use cross-region restore to restore Azure VMs in the secondary region, which is an Azure paired region. You can restore all the Azure VMs for the selected recovery point if the backup is done in the secondary region. This feature is available for the following options: - Create a VM - Restore disks We don't currently support the Replace existing disks option. Backup admins and app admins have permissions to perform the restore operation on a secondary region.
Cross Subscription	Allowed only if the Cross Subscription Restore property is enabled for the required target scenario. You can restore managed Azure virtual machines or disks to a different subscription within the same tenant by using the following options: - Create a VM - Restore disks The default target subscription is the protected VM subscription. Snapshot-tier recovery points can be restored only in the protected VM subscription. Vault-tier recovery points

Restore option	Details
	can be restored in the protected VM subscription or the vault subscription. To restore a vault-tier recovery point to another subscription, Cross Subscription Restore must be enabled on the vault. Original location restore and Replace existing remain supported only in the protected VM subscription. Cross Subscription Restore is unsupported for: - Legacy recovery points from VMs that used unmanaged disks and VMs with disks having Azure Encryptions (ADE). - VMs with CMK encrypted disks.
Cross Zonal Restore	You can use cross-zonal restore to restore Azure zone-pinned VMs in available zones. You can restore Azure VMs or disks to different zones (one of the Azure RBAC capabilities) from restore points. Note that when you select a zone to restore, it selects the logical zone (and not the physical zone) as per the Azure subscription you will use to restore to. This feature is available for the following options: - Create a VM - Restore disks Cross-zonal restore is unsupported for snapshots of restore points. Cross-zonal restore doesn't support restoring encrypted Azure VMs directly. If you perform a restore, the restored VM uses **SSE encryption** by default. You must manually reapply **CMK encryption** to the restored VM after the restore process is complete.

Support for file-level restore

Expand table

Restore	Supported
Restore files across operating systems	You can restore files on any machine that has the same OS as the backed-up VM, or a compatible OS. See the compatible OS table.
Restore files from encrypted VMs	Not supported.
Restore files from network-restricted storage accounts	Not supported.
Restore files on VMs by using Windows Storage Spaces	Not supported.
Restore files on a Linux VM by using LVM or RAID arrays	Not supported on the same VM.

Restore	Supported
	Restore on a compatible VM.
Restore files with special network settings	Not supported on the same VM. Restore on a compatible VM.
Restore files from a shared disk, temporary drive, deduplicated disk, Ultra Disk, Premium SSD v2, or disk with a write accelerator enabled	Not supported. See Azure VM storage support.

Support for VM management

The following table summarizes support for backup during VM management tasks, such as adding or replacing VM disks.

Expand table

Restore	Supported
Restore across a subscription	Cross-subscription restore is now supported in Azure VMs.
Restore across a region	Supported.
Restore across a zone	Cross-zonal restore is now supported in Azure VMs.
Restore to an existing VM	Use the replace-disk option.
Restore a disk with a storage account enabled for Azure Storage service-side encryption (SSE)	Not supported. Restore to an account that doesn't have SSE enabled.
Restore to mixed storage accounts	Not supported. Based on the storage account type, all restored disks will be either premium or standard, and not mixed.
Restore a VM directly to an availability set	For managed disks, you can restore the disk and use the availability set option in the template. For legacy recovery points from VMs that used unmanaged disks, restore the disks as managed disks, and then create a VM in the availability set.
Restore backup of unmanaged VMs after upgrading to a managed VM	Supported. You can restore legacy recovery points as managed disks and then create a managed VM.

Restore	Supported
Restore a VM from a restore point before the VM was migrated to managed disks	Supported. Restore the recovery point as managed disks, and then create a VM with the restored managed disks.
Restore a VM that has been deleted	Supported. You can restore the VM from a recovery point.
Restore a domain controller VM	Supported. For details, see Restore domain controller VMs.
Restore a VM in a different virtual network	Supported. The virtual network must be in the same subscription and region.

VM compute support

Expand table

Compute	Support
Back up VMs of a certain size	You can back up any Azure VM that has at least two CPU cores and 1 GB of RAM. Learn more.
Back up VMs in availability sets	Supported. You can't restore a VM in an availability set by using the option to quickly create a VM. Instead, when you restore the VM, restore the disk and use it to deploy a VM, or restore a disk and use it to replace an existing disk.
Back up VMs that are deployed with Azure Hybrid Benefit	Supported.
Back up VMs that are deployed from Azure Marketplace (published by Microsoft or a third party)	Supported. The VMs must be running a supported operating system. When you're recovering files on the VM, you can restore only to a compatible OS (not an earlier or later OS). We don't restore Azure Marketplace VMs backed as VMs, because these need purchase information. They're restored only as disks.

Compute	Support
Back up VMs that are deployed from a custom image (third-party)	Supported. The VMs must be running a supported operating system. When you're recovering files on VMs, you can restore only to a compatible OS (not an earlier or later OS).
Back up VMs that are migrated to Azure	Supported. To back up a VM, make sure that the VM agent is installed on the migrated machine.
Back up multiple VMs and provide consistency	Azure Backup doesn't provide data and application consistency across multiple VMs.
Back up a VM with diagnostic settings	Not supported. If the restore of the Azure VM with diagnostic settings is triggered via the Create new option, the restore fails.
Restore zone-pinned VMs	Supported (where availability zones are available). Azure Backup now supports restoring Azure VMs to a any availability zones other than the zone that's pinned in VMs. This support enables you to restore VMs when the primary zone is unavailable.
Back up Gen2 VMs	Supported. Azure Backup supports backup and restore of Gen2 VMs. When these VMs are restored from a recovery point, they're restored as Gen2 VMs.
Back up Azure VMs with locks	Supported for managed VMs. Not supported for unmanaged VMs.
Restore spot VMs	Not supported. Azure Backup restores spot VMs as regular Azure VMs.
Restore VMs in an Azure dedicated host	Supported. When you're restoring an Azure VM through the Create new option, the VM can't be restored in the dedicated host, even when the restore is successful. To achieve this, we recommend that you restore as disks. While you're restoring as disks by using the template, create a VM in a dedicated host, and then attach the disks.

Compute	Support
	This is not applicable in a secondary region while you're performing cross-region restore.
Configure standalone Azure VMs in Windows Storage Spaces	Not supported.
Configure standalone Azure VMs in Windows Storage Spaces direct	Not supported.
Restore Virtual Machine Scale Sets	Supported for the flexible orchestration model to back up and restore a single Azure VM.
Restore with managed identities	Supported for managed Azure VMs. Not supported for classic and unmanaged Azure VMs. Cross-region restore isn't supported with managed identities. Currently, this is available in all Azure public and national cloud regions. Learn more.
Back up trusted launch VMs	Supported via Enhanced policy and Standard policy. **Feature details**: - Backup of a VM with Data disks having Security Type 'TrustedLaunch' or 'ConfidentialVM' is not supported. This can happen if you attach the OS disk from a Trusted Launch as a Data disk to another VM. - Item-level restore is supported for the applicable scenarios. **Backup support via Enhanced policy**: - Azure portal, PowerShell, and REST API clients support trusted launch VM backup with Enhanced policy. - The Azure portal allows you to enable backup through a Recovery Services vault, the VM management pane, and the VM creation pane. - Resiliency supports backup, alerts, and monitoring for trusted launch VMs. **Backup support via Standard policy**: - CLI (version 2.73.0 and later), PowerShell (version Az 14.0.0 and later), and REST API (version 2025-01-01 and later) only support trusted launch VM backup with Standard policy. - Trusted Launch virtual machines with standard policy use managed disk snapshots for Instant Restore. In this scenario, you incur Snapshot storage

Compute	Support
	cost same as that of Enhanced policy. Learn more. Note that migration of an existing Gen2 VM (protected by Azure Backup Standard policy) to Trusted Launch VM requires first switching to Enhanced policy.
Back up confidential VMs	Supported (in preview). Learn more about the supported scenarios.

VM storage support

Expand table

Component	Support
Azure VM data disks	Support for backup of Azure VMs is up to 32 disks. Backup of Azure VMs that use unmanaged disks isn't supported. Backup for classic VMs is no longer available. *To ensure continued functionality, migrate disks in Azure Classic Storage to Azure Resource Manager (ARM) Storage, because Classic Storage accounts don't support ARM-based Virtual Machines (VMs).*
Data disk size	Individual disk size can be up to 64 TB and a maximum of 512 TB combined for all disks in a VM.
Storage type	Standard HDD, Standard SSD, Premium SSD, Premium SSD v2 and Ultra Disk. Backup and restore of zone-redundant storage disks is supported.
Managed disks	Supported.
Encrypted disks	Supported. Azure VMs enabled with Azure Disk Encryption can be backed up (with or without the Microsoft Entra app). Encrypted VMs can't be recovered at the file or folder level. You must recover the entire VM. You can enable encryption on VMs that Azure Backup is already protecting. You can back up and restore disks encrypted via platform-managed keys or customer-managed keys. You can also assign a disk-encryption set while restoring in the same region. That is, providing a disk-encryption set while performing cross-region restore is currently not supported. However, you

Component	Support
	can assign the disk-encryption set to the restored disk after the restore is complete.
Disks with a write accelerator enabled	Azure VMs with disk backup for a write accelerator became available in all Azure public regions on May 18, 2022. If disk backup for a write accelerator is not required as part of VM backup, you can choose to remove it by using the selective disk feature. **Important** Virtual machines with write accelerator disks need internet connectivity for a successful backup, even though those disks are excluded from the backup.
Disks enabled for access with a private endpoint	Supported.
Disks with both public and private access disabled	Supported.
Backup and restore of deduplicated VMs or disks	Azure Backup doesn't support deduplication. For more information, see this article. Azure Backup doesn't deduplicate across VMs in the Recovery Services vault. If there are VMs in a deduplication state during restore, the files can't be restored because the vault doesn't understand the format. However, you can successfully perform the full VM restore.
Adding a disk to a protected VM	Supported.
Resizing a disk on a protected VM	Supported.
Shared storage	Backing up VMs by using Cluster Shared Volumes (CSV) or Scale-Out File Server isn't supported. CSV writers are likely to fail during backup. On restore, disks that contain CSV volumes might not come up.
Shared disks	Not supported. - You can exclude shared disk with Enhanced policy and backup the other supported disks in the VM. - You can use S2D to create a shared disk or standalone volumes by combining capacities from disks in different VMs. Azure Backup doesn't support backup of a shared volume (between VMs for database cluster or cluster Configuration) created using S2D.
Ultra Disks	Supported with Enhanced policy.Learn about the disk considerations for Azure VM.

Component	Support
	- Configuration of Ultra Disk protection is supported via Recovery Services vault and via virtual machine blade. - File-level restore is currently not supported for machines using Ultra Disks. - GRS vaults and Cross-Region Restore are currently supported in the following regions for machines using Ultra Disks: South Central US, Brazil South, Canada East, Canada Central, East US2, South East Asia, West US, Central US, Korea South, Korea Central, South Central US, West Europe, North Central US, East Asia, USGov Texas, USGov Arizona, USGov Texas, West US2, North Europe, East US, West Central US, East US.
Premium SSD v2	Supported with Enhanced policy. Learn about the disk considerations for Azure VM. - Configuration of Premium SSD v2 protection is supported via Recovery Services vault and via virtual machine blade. - File-level restore is currently not supported for machines using Premium SSD v2 disks. - GRS vaults and Cross-Region Restore are currently supported in the following regions for machines using Premium SSD v2 disks: Brazil South, Central US, East Asia, East US, East US2, North Central US, North Europe, South Central US, South East Asia, UK South, UK West, West Europe, West US, West US3, Norway West, Norway East, Japan West, Japan East.
Temporary disks	Azure Backup doesn't back up temporary disks.
NVMe/ephemeral disks	Supported.
Resilient File System (ReFS) restore	Supported. Volume Shadow Copy Service (VSS) supports app-consistent backups on ReFS.
Dynamic disk with spanned or striped volumes	Supported, unless you enable the selective disk feature on an Azure VM.
VMs with encryption at host	Supported
Disks with enabled Data Access with Microsoft Entra authentication for disk upload/download	Not Supported
Storage Replicas	Not supported
Performance-plus disks	Recovering from snapshot tier (instant restore) will recover disks as performance-plus disks. Recovering from vault does not respect the

Component	Support
	performance-plus flag and will restore disks as normal disks.

VM network support

Expand table

Component	Support
Number of network interfaces (NICs)	Supported up to the maximum number for a specific Azure VM size. NICs are created when the VM is created during the restore process. The number of NICs on the restored VM mirrors the number of NICs on the VM at the time of the backup. The number of NICs on the restore VM depends on the NICs in the restore point, which in turn depends on the NICs in the source VM at the time of backup.
External or internal load balancer	Supported. Learn more about restoring VMs with special network settings.
Multiple reserved IP addresses	Supported. Learn more about restoring VMs with special network settings.
VMs with multiple network adapters	Supported. Learn more about restoring VMs with special network settings.
VMs with public IP addresses	Supported. Associate an existing public IP address with the NIC, or create an address and associate it with the NIC after the restore is done.
Network security group (NSG) on a NIC or subnet	Supported.
Static IP address	Not supported. A new VM that's created from a restore point is assigned a dynamic IP address. For classic VMs, you can't back up a VM with a reserved IP address and no defined endpoint.
Dynamic IP address	Supported.

Component	Support
	If the NIC on the source VM uses dynamic IP addressing, the NIC on the restored VM will also use it by default.
Azure Traffic Manager	Supported. If the backed-up VM is in Traffic Manager, manually add the restored VM to the same Traffic Manager instance.
Azure DNS	Supported.
Custom DNS	Supported.
Outbound connectivity via HTTP proxy	Supported. An authenticated proxy isn't supported.
Virtual network service endpoints	Supported. Storage account settings for a firewall and a virtual network should allow access from all networks.

Support for VM security and encryption

Azure Backup supports encryption for in-transit and at-rest data.

For network traffic to Azure:

- The Backup traffic from servers to the Recovery Services vault is encrypted via Advanced Encryption Standard 256.
- Backup data is sent over a secure HTTPS link.
- Backup data is stored in the Recovery Services vault in encrypted form.
- Only you have the encryption key to unlock this data. Microsoft can't decrypt the backup data at any point.

  > ⚠ **Warning**
  >
  > After you set up the vault, only you have access to the encryption key. Microsoft never maintains a copy and doesn't have access to the key. If the key is misplaced, Microsoft can't recover the backup data.

For data security:

- When you're backing up Azure VMs, you need to set up encryption *within* the virtual machine.
- Azure Backup supports Azure Disk Encryption, which uses BitLocker on virtual machines running Windows and uses *dm-crypt* on Linux virtual machines.
- On the back end, Azure Backup uses Azure Storage service-side encryption to help protect data at rest.

Expand table

Machine	In transit	At rest
On-premises Windows machines without DPM or MABS	✓	✓
Azure VMs	✓	✓
On-premises or Azure VMs with DPM	✓	✓
On-premises or Azure VMs with MABS	✓	✓

VM compression support

Azure Backup supports the compression of backup traffic. Note the following:

- For Azure VMs, the VM extension reads the data directly from the Azure storage account over the storage network. It isn't necessary to compress this traffic.
- If you're using DPM or MABS, you can save bandwidth by compressing the data before it's backed up.

Expand table

Machine	Compress to DPM/MABS (TCP)	Compress to vault (HTTPS)
On-premises Windows machines without DPM or MABS	Not applicable	✓
Azure VMs	Not applicable	Not applicable
On-premises or Azure VMs with DPM	✓	✓
On-premises or Azure VMs with MABS	✓	✓

Next steps

- Back up Azure VMs.
- Back up Windows machines directly, without a backup server.
- Set up MABS for backup to Azure, and then back up workloads to MABS.
- Set up DPM for backup to Azure, and then back up workloads to DPM.

Last updated on 04/24/2026

Estimate and understand Azure Backup pricing

09/19/2025

This article describes how to estimate and understand the costs associated with using Azure Backup. You learn about the available pricing tools, key parameters that affect backup costs, and how to use the Azure Backup pricing estimator to budget for different workloads and scenarios.

To learn about Azure Backup pricing, visit the Azure Backup pricing page.

Download detailed estimates for Azure Backup pricing

If you're looking to estimate your costs for budgeting or cost comparison purposes, download the detailed Azure Backup pricing estimator.

What does the estimator contain?

The Azure Backup cost estimator sheet has an option for you to estimate all possible workloads you're looking to back up using Azure Backup. These workloads include:

- Azure VMs
- On-premises servers
- SQL in Azure VMs
- SAP HANA in Azure VMs
- Azure files shares

Estimate costs for backing up Azure VMs or on-premises servers

To estimate the costs of backing up Azure VMs or on-premises servers using Azure Backup, you'll need the following parameters:

- Size of the VMs or on-premises servers that you're trying to back up
  - Enter the **used size** of disks or servers required to be backed up
- Number of servers with that size

- What is the expected amount of data churn on these servers?
  Churn refers to the amount of change in data. For example, if you had a VM with 200 GB of data to be backed up and 10 GB of it changes every day, the daily churn is 5%.
  - Higher churn will mean that you back up more data
  - Pick **Low** or **Moderate** for file servers and **High** if you're running databases
  - If you know your **churn%**, you can use the **Enter your own%** option
- Choose the backup policy
  - How long do you expect to retain **Daily** backups? (in days)
  - How long do you expect to retain **Weekly** backups? (in weeks)
  - How long do you expect to retain **Monthly** backups? (in months)
  - How long do you expect to retain **Yearly** backups? (in years)
  - How long do you expect to retain **Instant restore snapshots**? (1-5 days)
    - This option lets you restore from as far back as seven days in a quick manner using snapshots stored on disks.
- **Optional** – Selective Disk backup
  - If you're using the **Selective Disk Backup** option while backing up Azure VMs, choose the **Exclude Disk** option and enter the percentage of disks excluded from backup in terms of size. For example, if you have a VM connected to three disks with 200 GB used in each disk and if you want to exclude two of them from backing up, enter 66.7%.
- **Optional** – Backup Storage Redundancy
  - This indicates the redundancy of the Storage Account your backup data goes into. We recommend using **GRS** for the highest availability. Since it ensures that a copy of your backup data is kept in a different region, it helps you meet multiple compliance standards. Change the redundancy to **LRS** if you're backing up development or test environments that don't need an enterprise-level backup. Select the **RAGRS** option in the sheet if you want to understand costs when Cross-Region Restore is enabled for your backups.
- **Optional** – Modify regional pricing or apply discounted rates
  - If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option and enter the rates with which you want to run the estimates.

Estimate costs for backing up SQL servers in Azure VMs

To estimate the costs of backing up SQL servers running in Azure VMs using Azure Backup, you'll need the following parameters:

- Size of the SQL servers that you're trying to back up
- Number of SQL servers with the above size
- What is the expected compression for your SQL servers' backup data?
    - Most Azure Backup customers see that the backup data has 80% compression compared to the SQL server size when the SQL compression is **enabled**.
    - If you expect to see a different compression, enter the number in this field
- What is the expected size of log backups?
    - The % indicates daily log size as a % of the SQL server size
- What is the expected amount of daily data churn on these servers?
    - Typically, databases have **High** churn
    - If you know your **churn%**, you can use the **Enter your own%** option
- Choose the backup policy
    - Backup Type
        - The most effective policy you can choose is **Daily differentials** with weekly/monthly/yearly full backups. Azure Backup can restore from differentials through single-click as well.
        - You can also choose to have a policy with daily/weekly/monthly/yearly full backups. This option will consume slightly more storage than the first option.
    - How long do you expect to retain **log** backups? (in days) [7-35]
    - How long do you expect to retain **Daily** backups? (in days)
    - How long do you expect to retain **Weekly** backups? (in weeks)
    - How long do you expect to retain **Monthly** backups? (in months)
    - How long do you expect to retain **Yearly** backups? (in years)

- **Optional** – Backup Storage Redundancy
  - This indicates the redundancy of the Storage Account your backup data goes into. We recommend using **GRS** for the highest availability. Since it ensures that a copy of your backup data is kept in a different region, it helps you meet multiple compliance standards. Change the redundancy to **LRS** if you're backing up development or test environments that don't need an enterprise-level backup.

- **Optional** – Modify regional pricing or apply discounted rates
  - If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option and enter the rates with which you want to run the estimates.

Estimate costs for backing up SAP HANA servers in Azure VMs

To estimate the costs of backing up SAP HANA servers running in Azure VMs using Azure Backup, you'll need the following parameters:

- Total size of the SAP HANA databases that you're trying to back up. This should be the sum of full backup size of each of the databases, as reported by SAP HANA.

- Number of SAP HANA servers with the above size

- What is the expected size of log backups?
  - The % indicates average daily log size as a % of the total size of SAP HANA databases that you're backing up on the SAP HANA server

- What is the expected amount of daily data churn on these servers?
  - The % indicates average daily churn size as a % of the total size of SAP HANA databases that you're backing up on the SAP HANA server
  - Typically, databases have **High** churn
  - If you know your **churn%**, you can use the **Enter your own%** option

- Choose the backup policy
  - Backup Type
    - The most effective policy you can choose is **Daily differentials** with **weekly/monthly/yearly** full backups. Azure Backup can restore from differentials through single-click as well.
    - You can also choose to have a policy with **daily/weekly/monthly/yearly** full backups. This option will consume slightly more storage than the first option.
  - How long do you expect to retain **log** backups? (in days) [7-35]
  - How long do you expect to retain **Daily** backups? (in days)

    - How long do you expect to retain **Weekly** backups? (in weeks)
    - How long do you expect to retain **Monthly** backups? (in months)
    - How long do you expect to retain **Yearly** backups? (in years)

- **Optional** – Backup Storage Redundancy
    - This indicates the redundancy of the Storage Account your backup data goes into. We recommend using **GRS** for the highest availability. Since it ensures that a copy of your backup data is kept in a different region, it helps you meet multiple compliance standards. Change the redundancy to **LRS** if you're backing up development or test environments that don't need an enterprise-level backup.

- **Optional** – Modify regional pricing or apply discounted rates
    - If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option and enter the rates with which you want to run the estimates.

Estimate costs for backing up Azure file shares

To estimate the costs of backing up Azure file shares using the snapshot-based backup solution offered by Azure Backup, you'll need the following parameters:

- Size (**in GB**) of the file shares that you want to back up.

- If you want to back up file shares spread across multiple storage accounts, specify the number of storage accounts hosting the file shares with the above size.

- Expected amount of data churn on the file shares that you want to back up.
  Churn refers to the amount of change in data and it directly impacts the snapshot storage size. For example, if you have a file share with 200 GB of data to be backed up, and 10 GB of it changes every day, the daily churn is 5%.
    - Higher churn means the amount of data change in the file share contents every day is high, and so incremental snapshot (capturing only the data changes) size would also be more.
    - Select Low (1%), Moderate (3%), or High (5%) based on your file share characteristics and usage.
    - If you know the exact **churn%** for your file share, you can select the **Enter your own%** option from the drop-down. Specify the values (in %) for daily, weekly, monthly, and yearly churn.

- Type of storage account (standard or premium) and the storage redundancy setting of the storage account hosting the backed-up file share.
  In the current backup solution for Azure file shares, snapshots are stored in the same

storage account as the backed-up file share. So the storage cost associated with snapshots is billed as part of your Azure files bill, based on the snapshot pricing for the account type and redundancy setting of the storage account hosting the backed-up file share and snapshots.

- Retention for different backups
  - How long do you expect to retain “Daily” backups? (in days)
  - How long do you expect to retain “Weekly” backups? (in weeks)
  - How long do you expect to retain “Monthly” backups? (in months)
  - How long do you expect to retain “Yearly” backups? (in years)

  Refer to the Azure File share support matrix for the maximum supported retention values in each category.

- **Optional** – Modify regional pricing or apply discounted rates.
  - The default values set for snapshot storage cost per GB and protected instance cost in the estimator are for the East US region. If you want to check your estimates for a different region or discounted rates, select **Yes** for the **Try estimates for a different region?** option, and enter the rates with which you want to run the estimates.

Frequently asked questions-Back up Azure VMs

This article answers common questions about backing up Azure VMs with the Azure Backup service.

Backup

Which VM images can be enabled for backup when I create them?

When you create a VM, you can enable backup for VMs running supported operating systems.

Why is the Initial backup taking longer time to complete?

Initial backup is always a full backup and its duration depends on the size of the data and when the backup is processed.

To improve backup performance, see, backup best practices; Backup considerations and Backup Performance

Although the total backup time for incremental backups is less than 24 hours that might not be the case for the first backup.

Is the backup cost included in the VM cost?

No. Backup costs are separate from a VM's costs. Learn more about Azure Backup pricing.

Which permissions are required to enable backup for a VM?

If you're a VM contributor, you can enable backup on the VM. If you're using a custom role, you need the following permissions to enable backup on the VM:

- Microsoft.RecoveryServices/Vaults/write

- Microsoft.RecoveryServices/Vaults/read
- Microsoft.RecoveryServices/locations/*
- Microsoft.RecoveryServices/Vaults/backupFabrics/protectionContainers/protectedItems/*/read
- Microsoft.RecoveryServices/Vaults/backupFabrics/protectionContainers/protectedItems/read
- Microsoft.RecoveryServices/Vaults/backupFabrics/protectionContainers/protectedItems/write
- Microsoft.RecoveryServices/Vaults/backupFabrics/backupProtectionIntent/write
- Microsoft.RecoveryServices/Vaults/backupPolicies/read
- Microsoft.RecoveryServices/Vaults/backupPolicies/write

If your Recovery Services vault and VM have different resource groups, make sure you have write permissions in the resource group for the Recovery Services vault.

Does an on-demand backup job use the same retention schedule as scheduled backups?

No. Specify the retention range for an on-demand backup job. By default, it's retained for 30 days when triggered from the portal.

I recently enabled Azure Disk Encryption on some VMs. Will my backups continue to work?

Provide permissions for Azure Backup to access the Key Vault. Specify the permissions in PowerShell as described in the **Enable backup** section in the Azure Backup PowerShell documentation.

I migrated VM disks to managed disks. Will my backups continue to work?

Yes, backups work seamlessly. There's no need to reconfigure anything.

Why can't I see my VM in the Configure Backup wizard?

The wizard only lists VMs in the same region as the vault, and that aren't already being backed up.

My VM is shut down. Will an on-demand or a scheduled backup work?

Yes. Backups run when a machine is shut down. The recovery point is marked as crash consistent.

Can I cancel an in-progress backup job?

Yes. You can cancel the backup job in a **Taking snapshot** state. You can't cancel a job if data transfer from the snapshot is in progress.

I enabled a lock on the resource group created by Azure Backup Service (for example, `AzureBackupRG_<geo>_<number>`). Will my backups continue to work?

If you lock the resource group created by the Azure Backup Service, backups start to fail. Remove the lock, and clear the restore point collection from that resource group to make the future backups successful. Follow these steps to remove the restore point collection.

I have a lock at the resource group level that contains all the resources related to my virtual machine. Will my backup work?

Azure Backup creates a separate resource group in the format `AzureBackupRG_<geo>_<number>` to store ResourcePointCollections objects. Since this resource group is service owned, locking it will cause backups to fail. Locks can be only applied to customer-created resource groups.

Does Azure Backup support Standard SSD-managed disks?

Yes, Azure Backup supports Standard SSD managed disks.

Can we back up a VM with a Write Accelerator (WA)-enabled disk?

Snapshots can be taken on only data disks that are WA enabled and not OS disks. So, only data disks that are WA enabled can be protected.

I have a VM with Write Accelerator (WA) disks and SAP HANA installed. How do I back up?

Azure Backup can back up the WA-enabled data disk. However, the backup won't provide database consistency.

Azure Backup provides a streaming backup solution for SAP HANA databases with an RPO of 15 minutes. It's Backint certified by SAP to provide a native backup support leveraging SAP HANA's native APIs. Learn more about backing up SAP HANA databases in Azure VMs.

What is the maximum delay I can expect in backup start time from the scheduled backup time I have set in my VM backup policy?

The scheduled backup is triggered within 2 hours of the scheduled backup time. For example, If 100 VMs have their backup start time scheduled at 2:00 AM, then by 4:00 AM at the latest all the 100 VMs have their backup job in progress. If scheduled backups have been paused because of an outage and resumed or retried, then the backup can start outside of this scheduled two-hour window.

What is the minimum allowed retention range for a daily backup point?

Azure Virtual Machine backup policy supports a minimum retention range from seven days up to 9999 days. By default, backup of VMs are kept for *7 days* in snapshot and *180 days* in vault. Any modification to an existing VM backup policy with less than seven days will require an update to meet the minimum retention range of seven days.

What happens if I change the case of the name of my VM or my VM resource group?

If you change the case (to upper or lower) of your VM or VM resource group, the case of the backup item name won't change; this is expected Azure Backup behavior. The case change won't appear in the backup item, but is updated at the backend.

Can I back up or restore selective disks attached to a VM?

Azure Backup now supports selective disk backup and restore using the Azure Virtual Machine backup solution. For more information, see Selective disk backup and restore for Azure VMs.

Are managed identities preserved if a tenant change occurs during backup?

If tenant changes occur, you're required to disable and re-enable managed identities to make backups work again.

Does Azure Backup support backing up NFS files mounted from storage?

Azure Backup doesn't support backing up NFS files that are mounted from storage, or from any other NFS server, to Linux or Windows machines. It only backs up disks that are locally attached to the VM.

What are the VM configurations stored in the virtual machine backup?

All the VM configurations required to perform the restore operations are stored in the VM backup. That includes the encryption copies of the VM encrypted keys, which are accessible to you on restore. The encryption copies can only be decrypted using the key vault. Temporary disks and memory state aren't captured in the snapshot.

Can we back up tags from Azure VM? If so, how many tags?

Azure Backup can back up and restore tags, except NICs and IPs. Azure Backup honors the subscription limitations of Azure Resource Group and restores up to 50 tags.

For detailed information, see Subscription limits.

Can I take on-demand (ad-hoc) backup without scheduling backup for an Azure VM?

No, you can't trigger on-demand backups by disabling scheduled backup.

How does Azure Backup process work for cluster nodes?

Every Azure VM in a cluster is considered as an individual Azure VM. So, all backup operations are applicable as per individual Azure VMs.

Does Azure Backup interfere with application performance?

Creating a VM Snapshot takes few minutes, and there will be a minimal interference on application performance at this stage. But, data transfer to a vault takes a couple of hours; so we recommend scheduling backups during off business hours. Learn more about best practices for backup and restore.

Will a new disk added to VM be backed up automatically?

Yes, a new disk added to a VM will be backed up automatically during the next backup, unless selective disk backup is configured on the VM. A newly added disk to the VM has a Full snapshot (Initial Replica) taken on the first backup, the existing disks continue the Incremental logic chain.

Can I restore the files and folders from an encrypted VM backup?

Restoring files and folders from encrypted VM backup is currently not supported, you must recover the entire VM to restore files and folders. See, steps to restore an encrypted Azure Virtual machine. However you can recover files from backups before they were encrypted.

Can I stop a VM and scale it up during the Transfer data to vault phase?

Yes, you can do this when *Transfer data to vault* phase is in progress.

Does Azure Backup take backup of keys for ADE encrypted VMs and restore it along with the restored disk?

Azure Backup backs up encryption keys and secrets of the backup data. Generally, the keys aren't restored in the Key vault, but Azure Backup allows restoring the keys during the loss of keys.

Can I remove all restore points and retain the latest one?

No, you can't retain one single restore point. When you delete the previous restore points, the chain gets deleted. Therefore, you can't selectively retain or delete a recovery point.

In Azure VM Backup, what is the Snapshot Tier and Storage Redundancy for snapshot taken as part of backup?

In Azure VM Backup, snapshots are taken using the Standard HDD tier type, regardless of the source VM disk tier. By default, the storage redundancy for these snapshots is Locally Redundant Storage (LRS). However, if the VM backups are managed by an Enhanced Policy and the underlying source disk storage locates in the region that supports Zone Redundancy, snapshots are of Zone Redundant Storage.

How long can I retain backup points of Azure VMs using the backup policy?

The maximum retentions of the backup points are:

- **Retention of daily backup points**: 9999 days
- **Retention of weekly backup points**: 5163 weeks
- **Retention of monthly backup points**: 1188 months

- **Retention of yearly backup points**: 99 years

Can I back up a VM disks that are created in the Azure Classic Storage?

No, the support for disks created in Azure Classic Storage is no longer available. To ensure continued functionality, you must migrate these disks to Azure Resource Manager Storage. Also, Classic Storage accounts can't support ARM-based Virtual Machines (VMs), and no workarounds exist to enable compatibility.

> **Important**
>
> Support for backup of all Classic VMs is planned for deprecation on September 30, 2025. We recommend that you migrate the Classic VMs and associated disks to Azure Resource Manager Storage before this timeline to avoid disruptions.

How Soft-Delete behavior occurs when the retention of the backup policy is changed or modified?

When the retention period of a backup policy is changed, the soft-delete behavior for restore points (RPs) is determined based on the current policy at the time of evaluation—not the policy in place when the RP was created.

I have an Azure VM stored in a zone with a Premium SSD ZRS disk. What happens if I restore this VM to a Paired region using CRR where ZRS isn't supported?

When restoring a VM to a peered region that doesn't support Zone-Redundant Storage (ZRS), Azure Backup will automatically create the disk in the same performance tier (e.g., Standard or Premium) as the original disk, but with Locally Redundant Storage (LRS) instead of ZRS. This ensures that the restore operation completes successfully, even though the redundancy model changes.

Is 64 TB disk support for Azure Backup available in all regions?

Azure Backup supports individual disk sizes up to 64 TB and a combined total of 512 TB per VM. This support is available in all Azure regions where Azure Backup services are offered.

How does the MDCC backup works via Enhanced Policy with and without selecting the option "only Crash Consistency Snapshot"?

The behavior of MDCC backup under Enhanced Policy depends on whether the **"Only Crash Consistency Snapshot"** checkbox is selected:

When the checkbox is NOT selected:

Enhanced Policy will attempt to take application-consistent or filesystem-consistent backups. However, if these attempts fail, the policy will fallback to crash-consistent backups at specific intervals:

- A crash-consistent snapshot will be taken on the 4th, 6th, and 8th attempt.
- This fallback ensures backup continuity even when consistency cannot be guaranteed. Reasons for fallback to MDCC include offline VMs, VMs with unsupported OS, Guest Agent issues, VMSnapshotLinux extension provisioning issues etc.

When the checkbox is selected:

The policy won't attempt application or filesystem consistency. Instead, it will directly initiate a crash-consistent MDCC backup without any retries for higher consistency levels.

This option is useful when speed and simplicity are prioritized over consistency guarantees.

When we migrate a protected item from the Standard to Enhanced policy, which retention period applies on the restore points?

Retention Period applies as per the new enhanced policy for all the restore points.

Why don’t I see the updated expiry time for my Recovery Points immediately after changing the backup policy?

When you modify a backup policy (for example, changing the retention duration), the updated expiry time for Recovery Points (RPs) isn't reflected instantly on the Azure portal. This is expected behavior.

The expiry time is updated only after the system runs its daily cleanup process (also known as the expired Recovery Points pruning job). This job typically runs once every 24 hours. Therefore, it may take up to 24 hours for the new expiry time to appear on the portal for existing or newly created Recovery Points.

If you don’t see the updated expiry time immediately, please wait for up to 24 hours before raising a support request.

Restore

How do I decide whether to restore disks only or a full VM?

Think of a VM restore as a quick create option for an Azure VM. This option changes disk names, containers used by the disks, public IP addresses, and network interface names. The change maintains unique resources when a VM is created. The VM isn't added to an availability set.

You can use the restore disk option if you want to:

- Customize the VM that gets created. For example, change the size.
- Add configuration settings that weren't there at the time of backup.
- Control the naming convention for resources that are created.
- Add the VM to an availability set.
- Add any other setting that must be configured using PowerShell or a template.

Can I restore backups of unmanaged VM disks after I upgrade to managed disks?

Yes, you can use backups taken before disks were migrated from unmanaged to managed. Azure Backup restores those legacy recovery points as managed disks.

How do I restore a VM to a restore point before the VM was migrated to managed disks?

The restore process remains the same. If the recovery point is from a point in time when the VM had unmanaged disks, follow Restore legacy recovery points from VMs that used unmanaged disks. If the VM had managed disks, restore the disks as managed disks by following managed disk restore. Then you can create a VM from those disks.

Learn more about doing this in PowerShell.

If the restore fails to create the VM, what happens to the disks included in the restore?

In the event of a managed VM restore, even if the VM creation fails, the disks will still be restored.

Can I restore a VM that's been deleted?

Yes. Even if you delete the VM, you can go to the corresponding backup item in the vault and restore from a recovery point.

How do I restore a VM to the same availability sets?

For managed disk Azure VMs, restoring to the availability sets is enabled by providing an option in the template while restoring as managed disks. This template has the input parameter called **Availability sets**.

How do we get faster restore performance?

Instant Restore capability helps with faster backups and instant restores from the snapshots.

What happens when we change the key vault settings for the encrypted VM?

After you change the key vault settings for the encrypted VM, backups will continue to work with the new set of details. However, after the restore from a recovery point before the change, you'll have to restore the secrets in a key vault before you can create the VM from it. For more information, see this article.

Operations like secret/key roll-over don't require this step and the same key vault can be used after restore.

Can I access the VM once restored due to a VM having a broken relationship with the domain controller?

Yes, you can access the VM once restored due to a VM having a broken relationship with the domain controller. For more information, see this article.

Can I cancel an in-progress restore job?

Yes, you can cancel the restore job till the data transfer phase. Once it enters VM creation phase, you can't cancel the restore job.

Why is my restore operation taking long time to complete?

The total restore time depends on the input/output operations per second (IOPS) speed and the throughput of the storage account. The total restore time can be affected if the target storage account is loaded with other application read and write operations. To improve the speed of restore operation, select a storage account that isn't loaded with other application data. Learn about the best practices for Azure VM backup and restore.

How do we handle "Create New Virtual Machine"-restore type conflicts with governance policies?

Azure Backup uses "attach" disks from recovery points and doesn't look at your image references or galleries. So in the policy you can check "storageProfile.osDisk.createOption as Attach", and the script condition will be:

```
if (storageProfile.osDisk.createOption == "Attach") then { exclude <Policy> }
```

How do I restore a VM into powered down state?

To restore a VM in powered down state, you can create a VM or restore disks, but you can't replace an existing VM. Learn more about the available restore options.

Can I restore Azure VM that is in the powered-off state?

Azure VM must be in the powered-off state while you restore. Otherwise, the restore operation would fail in the pre-check stage, with the error code *UserErrorVmNotShutDown*.

Also, before you swap VM disks, you must power off the VM.

Is there a limit to trigger restore in a day?

The restore limit applies per data source within a 24-hour window. You can restore the same VM up to 20 times in that period. Restoring multiple VMs simultaneously is allowed, but may trigger throttling from other Azure services, such as Azure Resource Manager due to request limits.

How does restored disk SKU depend on target SA provided?

This guidance applied to older restore flows that restored disks as unmanaged VHDs. Recovery points from VMs that used unmanaged disks are now restored only as managed disks, so the target storage account doesn't determine the final disk type. The storage account is used only to hold restore metadata and temporary VHD files.

> **Note**
>
> - Azure Backup currently doesn't support taking different SAs as inputs for different disks.

Can I delete JSON template and VHD files after the restore process is complete?

Yes, you can delete these files once the restoration process is complete. By default, Azure Backup retains these files for future use.

How do I run restore operation for Cross Region Restore (CRR) of ADE encrypted VMs?

The encrypted keys aren't expected to be present in the target region as part of Cross Regions Restore (CRR). Therefore, you need to restore the encrypted keys and secrets using the

restored file. When the restore is complete, you can create Azure encrypted VM using restored disks.

Are there any recommended naming conventions of an Azure VM in Azure Backup?

Microsoft Windows allows a VM name that has maximum of 15 characters. Also, you can't specify a DNS host name that differs from the *NETBIOS* host name. However, you can create host headers for a website hosted on an Azure VM with the name as per recommendation.

Learn more about the VM naming convention limitations for Azure VMs.

Can I restore an Azure Virtual Machine in a different subscription?

Yes, Cross Subscription Restore now allows you to restore Azure VMs from a recovery point in one subscription to another under tenant as per Azure role-based access control (Azure RBAC) rules. Cross Subscription Restore is unsupported from snapshots.

Does Cross Subscription Restore support all Azure VM?

No, it's unsupported for Encrypted Azure VMs.

Can I use Azure VM snapshots to restore in another subscription?

No, Cross Subscription Restore is unsupported from snapshot restore.

Can I perform Cross Subscription Restore for Azure VMs running in secondary regions?

Yes.

Can I use Enhanced policy for Cross Subscription Restore?

Yes, it's supported for Cross subscription Restore.

Can I restore an Azure zone pinned Virtual Machine in a different zone?

Yes, Cross Zonal Restore now allows you to restore Azure zone pinned VMs to a different available zone using a recovery point in a vault with Zone-redundant storage (ZRS) enabled as per Azure role-based access control (Azure RBAC) rules. It's also supported from vaults with Cross Region Restore (CRR).

Can I restore an Azure nonzone pinned Virtual Machine in a different zone?

Yes, Cross Zonal Restore now allows you to restore Azure non-zone pinned VMs to any available zones using a recovery point in a vault with Zone-redundant storage (ZRS) enabled as per Azure role-based access control (Azure RBAC) rules.

Does Cross Zonal Restore support all Azure VM?

No, it's unsupported for Encrypted Azure VMs.

Can I use Azure VM snapshots to restore in another zone?

No, Cross Zonal Restore is unsupported from snapshot restore.

Can I restore Azure zone pinned VMs to secondary regions?

Yes, Azure Backup support restore of Azure zone pinned VMs to secondary regions.

Can I use Enhanced policy for Cross Zonal Restore?

Yes, it's supported for Cross Zonal Restore.

How do I clear iSCSI session and its processes after running the Python script for Linux ILR?

After you unmount disks from the Azure portal, run the Python script with `clean` parameter (`python scriptName.py clean`) to clear the session and remove the mount paths of the recovery point from the machine.

Why do restored VMs lose the Offer/SKU/Publisher properties of the source VM?

During a virtual machine (VM) restore using Azure Backup, you might notice that the restored VM doesn't retain the Offer, SKU, and Publisher properties that were present on the source VM. This is an expected behavior, and happens due to the following reasons:

- **MarketPlace Image VMs**: Only VMs created from a MarketPlace image has the Offer, SKU, and Publisher details. These properties are derived from the VM image itself. When a VM is created from a MarketPlace image, the createOption is set to **from image**. This ensures that the Offer, SKU, and Publisher properties are included during the VM creation process.
- **VMs Created from Disks**: When a VM is created from disks (such as restored VMs, uploaded VMs, or VMs created from snapshots), the createOption is set to **Attach** instead of "from image". In this case, the Offer, SKU, and Publisher properties are not included because these properties are read-only and can only be added during the initial VM creation process when the createOption is **from image**.

What is the expected throughput when we perform the restore from the Vault storage.

For Tier-2 restores (restores from vault data), the time required depends on the amount of allocated data that needs to be transferred. In one observed case, disks with approximately 2 TB of allocated data each contributed significantly to the overall transfer time. While a transfer rate of 30 MBps is considered optimal, we achieved around 50 MBps in this instance.

For example, if a customer has a 16-TB disk with 2 TB of allocated data per segment, the total restore time could extend up to 20 hours at the optimal transfer rate.

Manage VM backups

What happens if I modify a backup policy?

The VM is backed up using the schedule and retention settings in the modified policy.

- If retention is extended, existing recovery points are marked and kept in accordance with the new policy.
- If retention is reduced, recovery points are marked for pruning in the next cleanup job, and subsequently deleted.

However, recovery points are specific to retention range frequency. For example, adding or modifying a yearly retention policy doesn't affect the retention of preexisting monthly recovery points.

How do I move a VM backed up by Azure Backup to a different resource group?

1. Temporarily stop the backup and retain backup data.

2. To move virtual machines configured with Azure Backup, do the following steps:
   a. Find the location of your virtual machine.
   b. Find a resource group with the following naming pattern: `AzureBackupRG_<location of your VM>_1`. For example, *AzureBackupRG_westus2_1*
   c. In the Azure portal, check **Show hidden types**.
   d. Find the resource with type **Microsoft.Compute/restorePointCollections** that has the naming pattern `AzureBackup_<name of your VM that you're trying to move>_###########`.
   e. Delete this resource. This operation deletes only the instant recovery points, not the backed-up data in the vault.
   f. After the delete operation is complete, you can move your virtual machine.

3. Move the VM to the target resource group.

4. Resume the backup.

You can restore the VM from available restore points that were created before the move operation.

What happens after I move a VM to a different resource group?

Once a VM is moved to a different resource group, it's a new VM as far as Azure Backup is concerned.

After moving the VM to a new resource group, you can reprotect the VM either in the same vault or a different vault. Since this is a new VM for Azure Backup, you are billed for it separately.

The old VM's restore points will be available for restore if needed. If you don't need this backup data, you can stop protecting your old VM with delete data.

Is there a limit on number of VMs that can be associated with the same backup policy?

Yes, there's a limit of 100 VMs that can be associated to the same backup policy. We recommend that for more than 100 VMs, create multiple backup policies with same schedule or different schedule.

There's a daily limit of 1000 for overall configure/modify protections in a vault.

How can I view the retention settings for my backups?

Currently, you can view retention settings at a backup item (VM) level based on the backup policy that's assigned to the VM.

One way to view the retention settings for your backups, is to navigate to the backup item dashboard for your VM, in the Azure portal. Selecting the link to its backup policy helps you view the retention duration of all the daily, weekly, monthly, and yearly retention points associated with the VM.

You can also use Backup Explorer to view the retention settings for all your VMs within a single pane of glass. Go to the Backup Explorer from any Recovery Services vault, go to the **Backup Items** tab and select the Advanced View to see detailed retention information for each VM.

When the snapshot is moved from a storage account to a vault, how is encryption in the transit managed?

Azure VM Backup uses HTTPS communication for encryption in transit. The data transfer uses Azure fabric (and not public endpoints), which do not need Internet access for VM backup.

How can I disable the File Recovery option?

This API provision a script for invoking an **iSCSI connection** for file recovery from Azure Backup.

- You can disable this option using **custom role-definitions** by excluding API action.
- You can also use the private endpoints to restrict access to the iSCSI server from within the private network.
- You can also disable this option across an organization using the deny assignment feature.

I have changed the retention policy, what is the time needed for the policy to be effective?

The policy takes effect immediately after the modifications of the parameters, such as retention, schedule, and so on. This is applicable for all new backups taken from the modified policy. However, the pruning of the recovery points (if applicable) according to the new policy takes 24 hours.

How do I extend or reduce the retention of a specific recovery point?

This feature is currently not supported. You can post any feature ask in the Azure Backup community portal.

How to modify retention period for Stopped backups?

Retention of stopped backups cannot be modified since they do not have any policy attached to it. However, you can resume protection and assign a policy.

How long are the stopped backups retained?

Stopped backups are retained until manually deleted.

I'm unable to select a virtual network, subnet, or storage account in the secondary region when performing a Cross Region Restore.

You need to check the subscription permissions in the secondary region. Write to us at AskAzureBackupTeam@microsoft.com for subscription enrollment.

How can I check the traffic between Azure Backup service and Azure VM?

Because Azure resources handle this traffic, it can't be determined by an external user.

What is the minimum RPO and RTO for VM backups in Azure Backup?

RPO: The minimum RPO is 1 day or 24 hours when you're using Standard policy. If you use Enhanced policy, the minimum RPO is 4 hours.

Why does the error VMMarketplaceInvalidInputmessage appear?

This error appears when you try to start a VM after creating an Azure VM from a non-Marketplace image or swap the OS disk of a VM with a non-Marketplace image, and then the VM deployment fails. To resolve this issue, remove the plan information from the VM.

How do I manage key rotations? How to ensure which key is used during backup and if it’s present to be used with the restored VM?

Azure Backup backs up the secrets and KEK data of the key version during backup, and restores the same. However, booting ADE VMs with older version keys are also possible.

How often are Microsoft managed keys rotated for Azure Backup?

Microsoft-managed keys are rotated as per compliance requirements. If you have specific key rotation requirements, we recommend that you move to customer-managed keys so that you can manage and audit the rotation manually. Learn more [about Azure Storage encryption] (..\storage\common\storage-service-encryption.md).

When Vault is configured with CRR, what happens to the secondary data if the primary region fails?

Backup data fully replicated to the secondary region before the failure of the primary region remains intact. This remains true even after the primary region recovers from the failure. In other words, the virtual machine can be recovered in the secondary region with the data it had before the failure, based on the replication schedule. For Azure VM backups, the secondary region RPO can be up to 36 hours in the worst case. With the Standard policy, this is based on up to 24 hours in the primary region plus up to 12 hours for replication to the secondary region. With the Enhanced policy, more frequent local recovery point creation can improve the best-case achievable secondary region RPO, but the worst-case can still be up to 36 hours.

When I update the backup policy, why is the expiry time not getting updated immediately?

Expiry Time of recovery points are updated when Garbage Collector (GC) runs, which is *every 24 hours*. Once you update the backup policy, it can take up to *24 hours* to show the updates in the **Expiry Time**, if there are no delays in GC jobs.

Why the expiry time for latest recovery points doesn't appear in the Azure portal for VMs?

The expiry time for the latest recovery point doesn't appear because it has infinite retention until a newer one gets created. The expiry time of other recovery points will be available in the Azure portal after 24 hours of creation, depending on when the garbage collection runs (that will be within 24 hours).

Will an Azure VM restore operation to original or alternate location affect a scheduled backup?

No, the restore operation (to the original or an alternate location) doesn't affect scheduled backups.

- **Restore to Original Location**: Azure Backup replaces the existing VM's disks with the ones from the restore point. This process includes taking a snapshot of the current VM before the restore ensuring that the backup schedule remains.

- **Restore to Alternate Location**: Azure Backup creates a new VM using the restore point. This new VM won't have the same backup schedule as the original VM; you need to configure the Backup policy manually. Learn about Azure VM restore.

In these restore scenarios, the original backup policy and schedule for the original VM remain unaffected. However, if you want the restored VM (in the alternate location) to have a backup schedule, you need to set up the Backup policy.

What happens to the backup configuration if I do Original/Alternate Location Restore of Azure VMs?

In case of an Original Location Restore (OLR) or an Alternate Location Restore (ALR) for Azure VMs, Azure Backup performs the backup configuration as:

Expand table

Restore type	Backup configuration	Backup data
Original Location Restore (OLR)	The backup configuration remains the same. The restored VM uses the same backup policy and schedule as the original VM.	The existing backup data is preserved, and new backups are triggered as per the original backup schedule.
Alternate Location Restore (ALR)	The new VM created in the alternate location doesn't inherit the backup configuration of the original VM. You need to configure a new backup policy for this VM manually.	The backup data for the original VM remains unaffected. However, the new VM starts with a fresh backup history once you configure its backup.

> ⓘ Note
>
> - **OLR**: Provides a seamless continuation of backups with the same policy.
> - **ALR**: Requires manual setup of backup policies for the new VM.

Why VMs with the Storage Spaces direct and Storage Spaces aren't supported with the Azure VM Backup?

Storage Spaces Direct isn't supported since it has data spread across two different virtual machines.

Storage spaces in a single VM not supported for application consistent VM backup. For application consistent VM backup, VSS freezes the I/O and ensures that disk snapshots are consistent. Storage Spaces can still perform writes in the background, breaking the application consistent guarantee. This can result in a small probability that the backup taken isn't application consistent. Today, backup, and recovery of VM with storage spaces isn't blocked in the product.

If I remove one of the disks from VM and increase the size of existing disk, what happens to the backups and if next backup creates Full Backup for all disk?

If you remove a disk, the snapshot or data transfer operation won't run for the removed disk. Number of disks included in the restore point differs depending on the VM state at the time of the backup.

Resizing a disk continues with incremental backups unless the underlying storage account of the disk changes, which results in a full backup.

What is directory "/var/log/azure/Microsoft.Azure.RecoveryServices.VMSnapshotLinux"?

This is the directory used by Backup Extension VMSnapshotLinux and it gets created when backups are enabled on VM using Recovery Services Vault. Logs are written in this location during backups, restores, or extension operations such as schedule updates, generally they should use up only a few GB and the size of the logs is not proportional with the size of the backup.

If backup fails with a timeout error for large disk VMs after running sometime, when can I retrigger the backup job again and will the backup continue from where it failed?

For Initial Replica, a full backup will be reinitiated in case of failure. However, for Incremental the snapshot from the last successful backup will be compared to the latest snapshot to copy the changed data into the vault.

Why Premium SSD v2 with GRS Vaults/Cross Region Restore is not supported?

Premium SSD v2/Ultra Disks are currently not available in all regions, so Geo-Redundant Storage (GRS) can't be enabled.

> ⓘ **Note**
>
> GRS functions only when both paired regions support Premium SSD v2/Ultra Disks.

Why don’t I see the updated expiry time for my Recovery Points immediately after changing the backup policy?

When you modify a backup policy (for example, changing the retention duration), the updated expiry time for Recovery Points (RPs) is not reflected instantly on the Azure portal. This is expected behavior.

The expiry time is updated only after the system runs its daily cleanup process (also known as the expired Recovery Points pruning job). This job typically runs once every 24 hours. Therefore, it may take up to 24 hours for the new expiry time to appear on the portal for existing or newly created Recovery Points.

If you don’t see the updated expiry time immediately, please wait for up to 24 hours before raising a support request.

About Site Recovery

Article • 04/01/2025

Welcome to the Azure Site Recovery service! This article provides a quick service overview.

As an organization, you need to adopt a business continuity and disaster recovery (BCDR) strategy that keeps your data safe, and your apps and workloads online, when planned and unplanned outages occur.

Azure Recovery Services contributes to your BCDR strategy:

- **Site Recovery service**: Site Recovery helps ensure business continuity by keeping business apps and workloads running during outages. Site Recovery replicates workloads running on physical and virtual machines (VMs) from a primary site to a secondary location. When an outage occurs at your primary site, you fail over to a secondary location, and access apps from there. After the primary location is running again, you can fail back to it.
- **Backup service**: The Azure Backup service keeps your data safe and recoverable.

Azure Site Recovery has an option of *High Churn*, enabling you to configure disaster recovery for Azure VMs having data churn up to 100 MB/s. This helps you to enable disaster recovery for more IO intensive workloads. Learn more.

Site Recovery can manage replication for:

- Azure VMs replicating between Azure regions
- Replication from Azure Extended Zones to the region
- On-premises VMs, Azure Stack VMs, and physical servers

> **Note**
>
> The Azure Site Recovery functionality for Extended Zones is in preview state.

What does Site Recovery provide?

Expand table

Feature	Details
Simple BCDR solution	Using Site Recovery, you can set up and manage replication, failover, and failback from a single location in the Azure portal.
VMware VM replication	You can replicate VMware VMs to Azure using the improved Azure Site Recovery replication appliance that offers better security and resilience than the configuration

Feature	Details
	server. For more information, see Disaster recovery of VMware VMs.
On-premises VM replication	You can replicate on-premises VMs and physical servers to Azure. Replication to Azure eliminates the cost and complexity of maintaining a secondary datacenter.
Workload replication	Replicate any workload running on supported Azure VMs, on-premises Hyper-V and VMware VMs, and Windows/Linux physical servers.
Data resilience	Site Recovery orchestrates replication without intercepting application data. When you replicate to Azure, data is stored in Azure storage, with the resilience that provides. When failover occurs, Azure VMs are created based on the replicated data. This also applies to Extended Zones to Azure region Azure Site Recovery scenario.
RTO and RPO targets	Keep recovery time objectives (RTO) and recovery point objectives (RPO) within organizational limits. Site Recovery provides continuous replication for Azure VMs and VMware VMs, and replication frequency as low as 30 seconds for Hyper-V. You can reduce RTO further by integrating with Azure Traffic Manager.
Keep apps consistent over failover	You can replicate using recovery points with application-consistent snapshots. These snapshots capture disk data, all data in memory, and all transactions in process.
Testing without disruption	You can easily run disaster recovery drills, without affecting ongoing replication.
Flexible failovers	You can run planned failovers for expected outages with zero-data loss. Or, unplanned failovers with minimal data loss, depending on replication frequency, for unexpected disasters. You can easily fail back to your primary site when it's available again.
Customized recovery plans	Using recovery plans, you can customize and sequence the failover and recovery of multi-tier applications running on multiple VMs. You group machines together in a recovery plan, and optionally add scripts and manual actions. Recovery plans can be integrated with Azure Automation runbooks. **Note**: This functionality is currently supported for Region-to-Region replication and will be available on Azure Extended Zones soon.
BCDR integration	Site Recovery integrates with other BCDR technologies. For example, you can use Site Recovery to protect the SQL Server backend of corporate workloads, with native support for SQL Server Always On, to manage the failover of availability groups.
Azure automation integration	A rich Azure Automation library provides production-ready, application-specific scripts that can be downloaded and integrated with Site Recovery.
Network integration	Site Recovery integrates with Azure for application network management. For example, to reserve IP addresses, configure load-balancers, and use Azure Traffic Manager for efficient network switchovers.

Feature	Details
Shared disk	You can protect, monitor, failover, and re-protect your workloads running on Windows Server Failover Clusters (WSFC) on Azure VMs using shared disk. You can use shared disks for your critical applications such as SQL FCI, SAP ASCS, Scale-out File Servers, etc., while ensuring business continuity and disaster recovery with Azure Site Recovery.

What can I replicate?

Expand table

Supported	Details
Replication scenarios	Replicate Azure VMs from 1. One Azure region to another. 2. One Azure Extended zone to the Azure region it's connected to. Replicate on-premises VMware VMs, Hyper-V VMs, physical servers (Windows and Linux), Azure Stack VMs to Azure. Replicate AWS Windows instances to Azure. Replicate on-premises VMware VMs, Hyper-V VMs managed by System Center VMM, and physical servers to a secondary site.
Regions	Review supported regions for Site Recovery.
Replicated machines	Review the replication requirements for Azure VM replication, on-premises VMware VMs and physical servers, and on-premises Hyper-V VMs.
Workloads	You can replicate any workload running on a machine that's supported for replication. Learn more about the app-specific workload summary.

Next steps

- Read more about workload support.
- Get started with Azure VM replication between regions.
- Get started with VMware VM replication.
- Get started with Disaster recovery for VMs on Azure Extended Zones.

Tutorial: Set up disaster recovery for Linux virtual machines

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Flexible scale sets

This tutorial shows you how to set up disaster recovery for Azure VMs running Linux. In this article, learn how to:

- ✔ Enable disaster recovery for a Linux VM
- ✔ Run a disaster recovery drill to check it works as expected
- ✔ Stop replicating the VM after the drill

When you enable replication for a VM, the Site Recovery Mobility service extension installs on the VM, and registers it with Azure Site Recovery. During replication, VM disk writes are sent to a cache storage account in the source VM region. Data is sent from there to the target region, and recovery points are generated from the data. When you fail a VM over to another region during disaster recovery, a recovery point is used to create a VM in the target region.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

1. Check that your Azure subscription allows you to create a VM in the target region. If you just created your free Azure account, you're the administrator of the subscription, and you have the permissions you need.
2. If you're not the subscription administrator, work with the administrator to assign you:
   - Either the Virtual Machine Contributor built-in role, or specific permissions to:
     - Create a VM in the selected virtual network.
     - Write to an Azure storage account.
     - Write to an Azure managed disk.
   - The Site Recovery Contributor built-in role, to manage Site Recovery operations in the vault.
3. Check that the Linux VM is running a supported operating system.
4. If VM outbound connections use a URL-based proxy, make sure it can access these URLs. Using an authenticated proxy isn't supported.

Expand table

Name	Public cloud	Government cloud	Details
Storage	`*.blob.core.windows.net`	`*.blob.core.usgovcloudapi.net`	Write data from the VM to the cache storage account in the source region.

Name	Public cloud	Government cloud	Details
Microsoft Entra ID	`login.microsoftonline.com`	`login.microsoftonline.us`	Authorize and authenticate to Site Recovery service URLs.
Replication	`*.hypervrecoverymanager.windowsazure.com`	`*.hypervrecoverymanager.windowsazure.com`	VM communication with the Site Recovery service.
Service Bus	`*.servicebus.windows.net`	`*.servicebus.usgovcloudapi.net`	VM writes to Site Recovery for monitoring and diagnostic data.

5. If you're using network security groups (NSGs) to limit network traffic for VMs, create NSG rules that allow outbound connectivity (HTTPS 443) for the VM using these service tags (groups of IP addresses). Try out the rules on a test NSG first.

Expand table

Tag	Allow
Storage tag	Allows data to be written from the VM to the cache storage account.
Microsoft Entra ID tag	Allows access to all IP addresses that correspond to Microsoft Entra ID.
Events Hub tag	Allows access to Site Recovery monitoring.
Azure Site Recovery tag	Allows access to the Site Recovery service in any region.
GuestAndHybridManagement	Use if you want to automatically upgrade the Site Recovery Mobility agent that's running on VMs enabled for replication.

6. Make sure VMs have the latest root certificates. On Linux VMs, follow the guidance provided by your Linux distributor, to get the latest trusted root certificates and certificate revocation list on the VM.

Create a VM and enable disaster recovery

You can optionally enable disaster recovery when you create a VM.

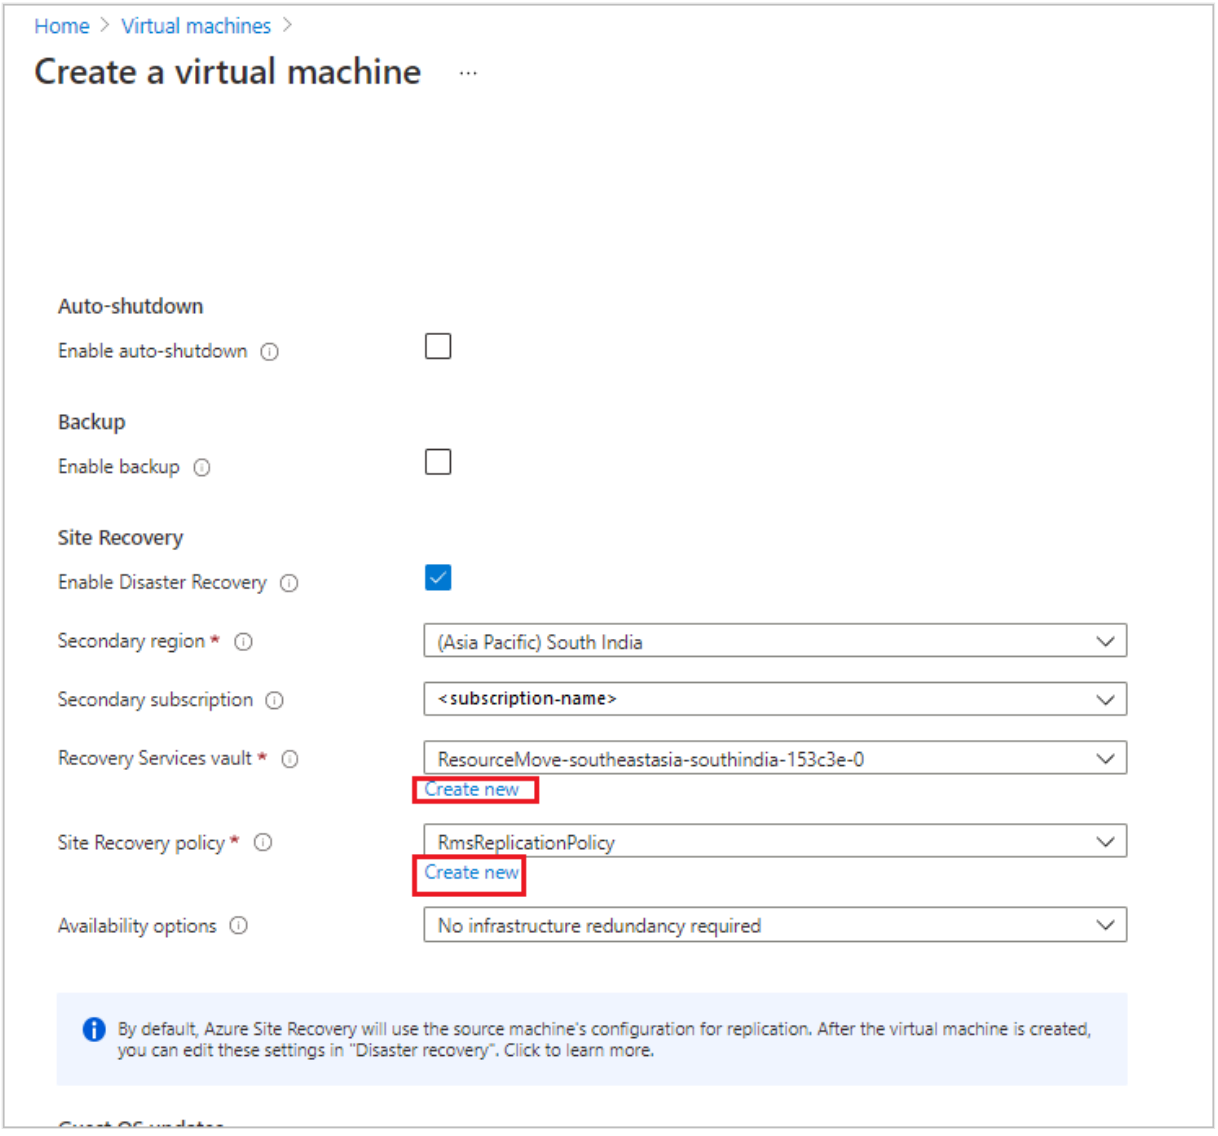
1. Create a Linux VM.
2. On the **Management** tab, under **Site Recovery** select **Enable disaster recovery**.
3. In **Secondary region**, select the target region to which you want to replicate the VM for disaster recovery.
4. In **Secondary subscription**, select the target subscription in which the target VM will be created. The target VM is created when you fail over the source VM from the source region to the target region.

5. In **Recovery Services vault**, select the vault you want to use for the replication. If you don't have a vault, select **Create new**. Select a resource group in which to place the vault, and a vault name.

6. In **Site Recovery policy**, leave the default policy, or select **Create new** to set custom values.

    - Recovery points are created from snapshots of VM disks taken at a specific point in time. When you fail over a VM, you use a recovery point to restore the VM in the target region.
    - A crash-consistent recovery point is created every five minutes. This setting can't be modified. A crash-consistent snapshot captures data that was on the disk when the snapshot was taken. It doesn't include anything in memory.
    - By default Site Recovery keeps crash-consistent recovery points for 24 hours. You can set a custom value between 0 and 72 hours.
    - An app-consistent snapshot is taken every 4 hours.
    - By default Site Recovery stores recovery points for 24 hours.

7. In **Availability options**, specify whether the VM will deploy as standalone, in an availability zone, or in an availability set.

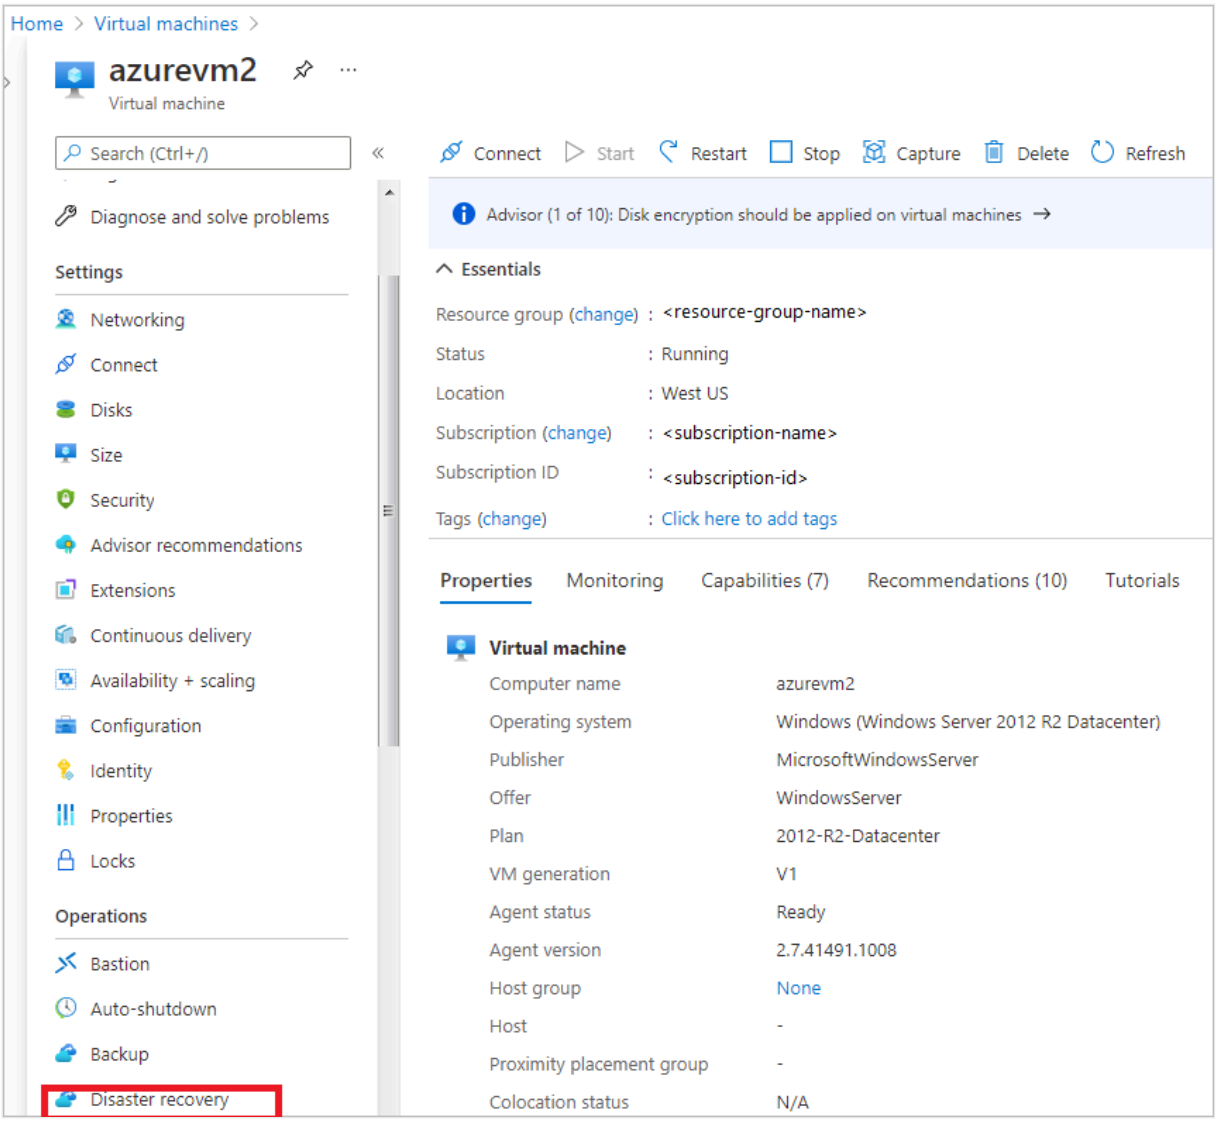


8. Finish creating the VM.

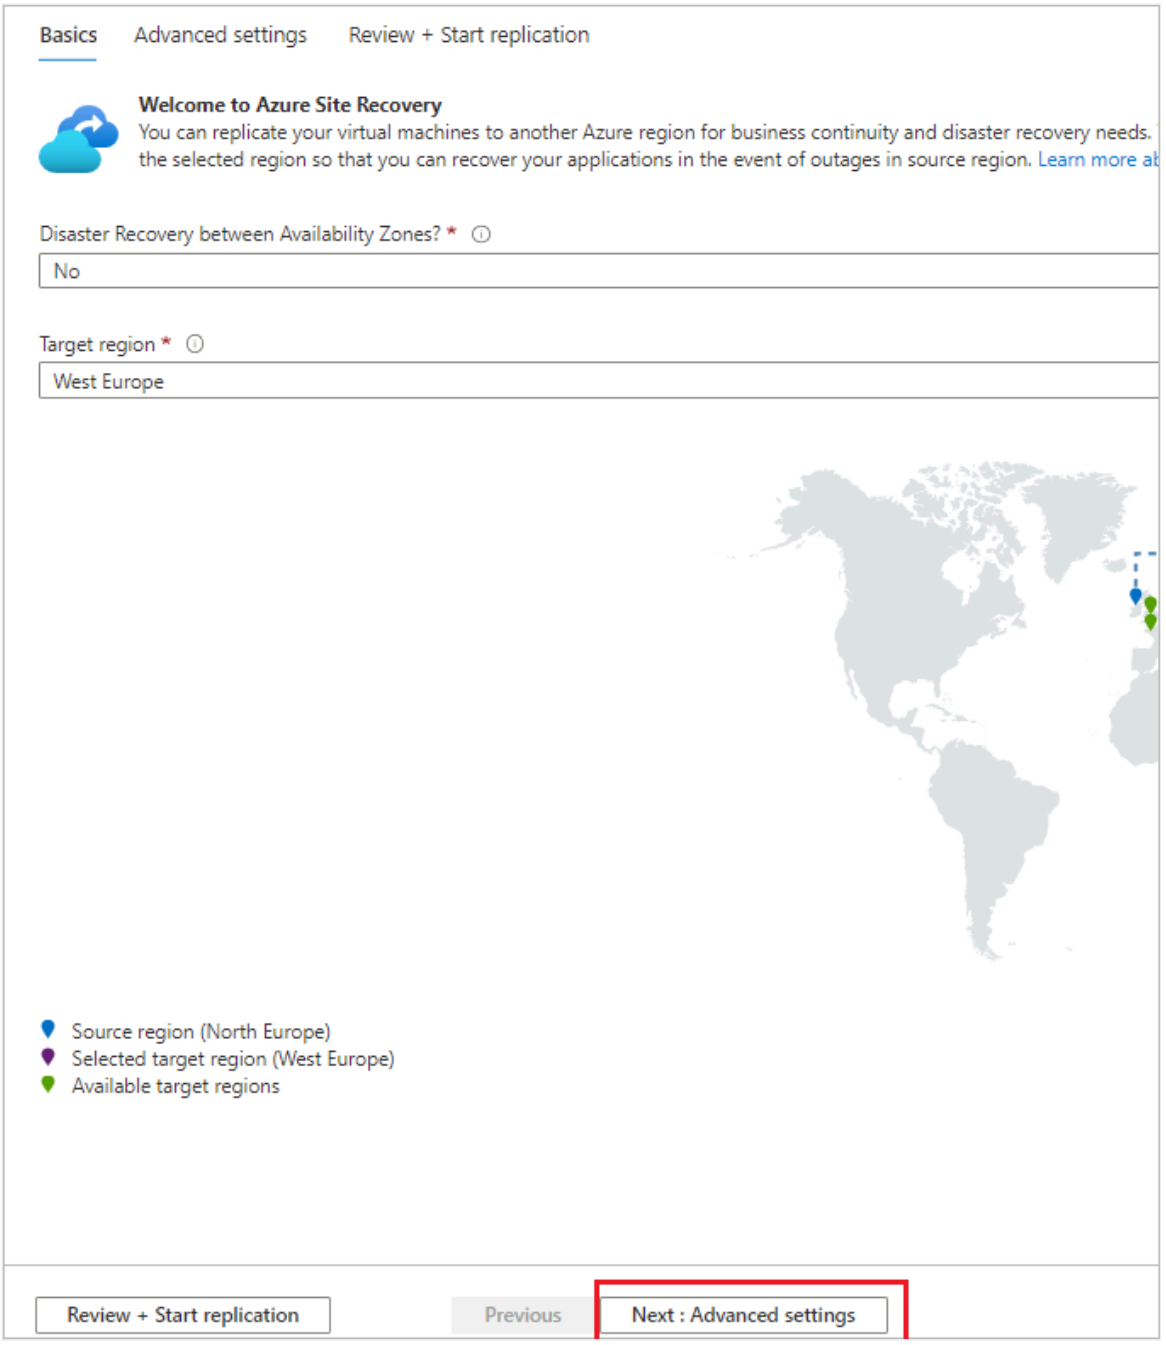
Enable disaster recovery for an existing VM

If you want to enable disaster recovery on an existing VM, use this procedure.

1. In the Azure portal, open the VM properties page.
2. In **Operations**, select **Disaster recovery**.



3. In **Basics**, if the VM is deployed in an availability zone, you can select disaster recovery between availability zones.
4. In **Target region**, select the region to which you want to replicate the VM. The source and target regions must be in the same Microsoft Entra tenant.

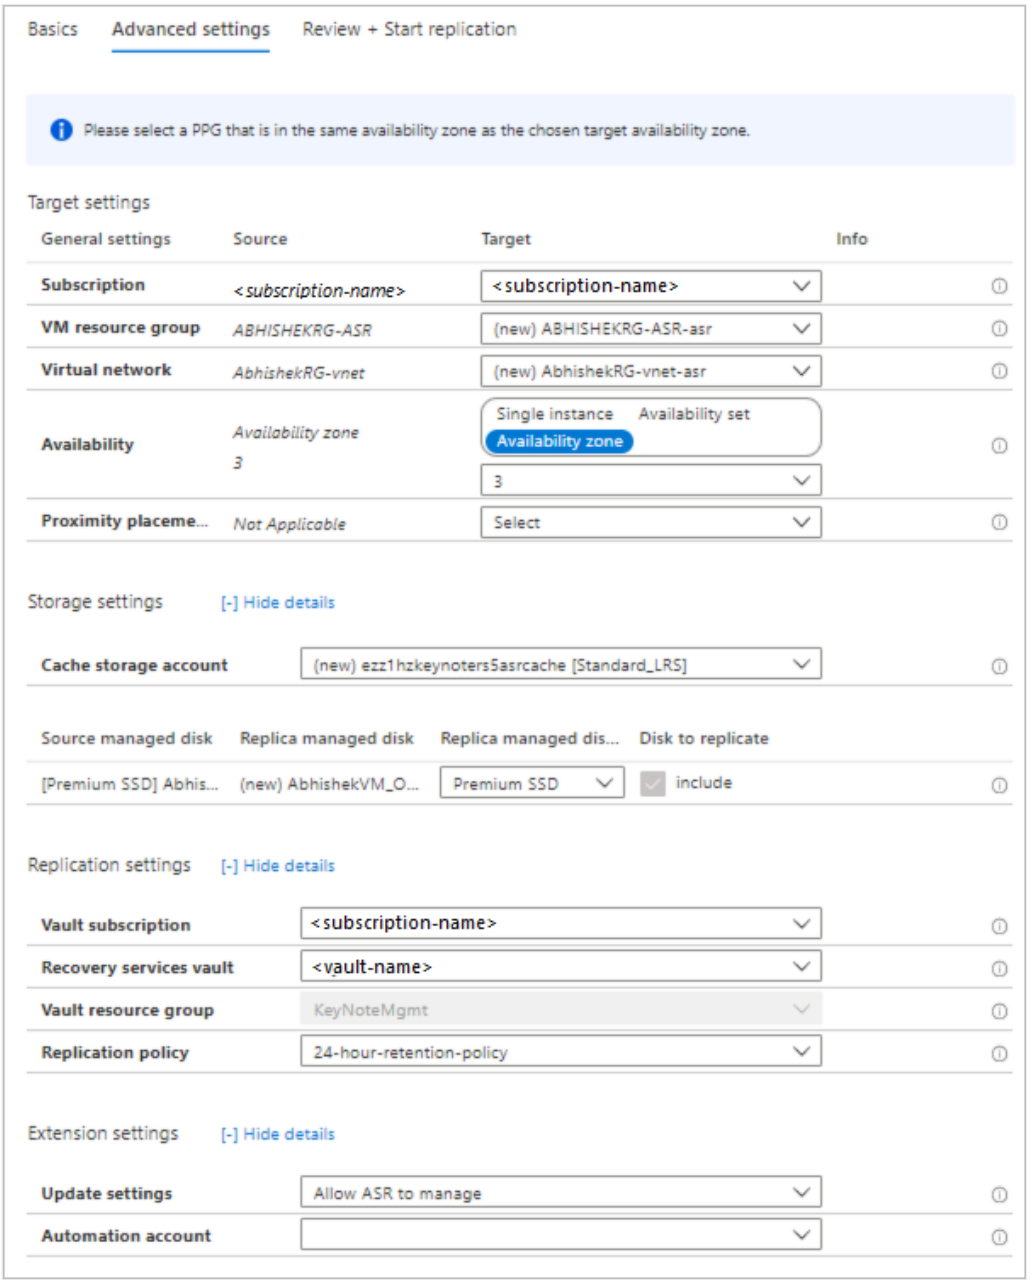


5. Select **Next: Advanced settings**.

6. In **Advanced settings**, you can review settings, and modify values to custom settings. By default, Site Recovery mirrors the source settings to create target resources.

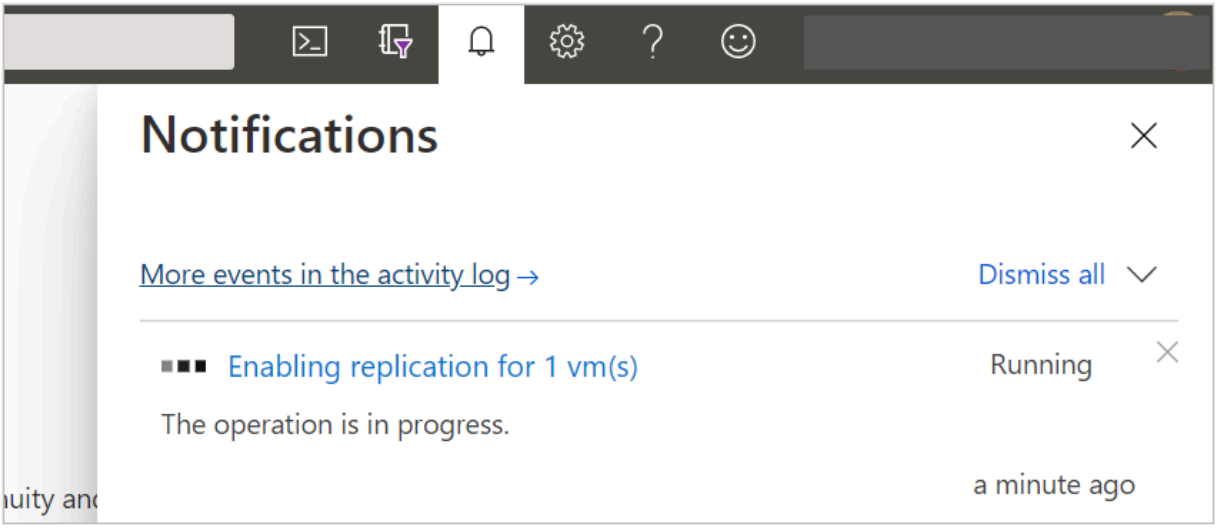
   - **Target subscription**. The subscription in which the target VM is created after failover.
   - **Target VM resource group**. The resource group in which the target VM is created after failover.
   - **Target virtual network**. The Azure virtual network in which the target VM is located when it's created after failover.
   - **Target availability**. When the target VM is created as a single instance, in an availability set, or availability zone.
   - **Proximity placement**. If applicable, select the proximity placement group in which the target VM is located after failover.
   - **Storage settings-Cache storage account**. Recovery uses a storage account in the source region as a temporary data store. Source VM changes are cached in this account, before being replicated to the target location.
     - By default one cache storage account is created per vault and reused.

    - You can select a different storage account if you want to customize the cache account for the VM.
- **Storage settings-Replica managed disk**. By default, Site Recovery creates replica managed disks in the target region.
    - By default the target managed disk mirror the source VM managed disks, using the same storage type (standard HDD/SSD, or premium SSD).
    - You can customize the storage type as needed.
- **Replication settings**. Shows the vault in which the VM is located, and the replication policy used for the VM. By default, recovery points created by Site Recovery for the VM are kept for 24 hours.
- **Extension settings**. Indicates that Site Recovery manages updates to the Site Recovery Mobility Service extension that's installed on VMs you replicate.
    - The indicated Azure Automation account manages the update process.
    - You can customize the automation account.



7. Select **Review + Start replication**.

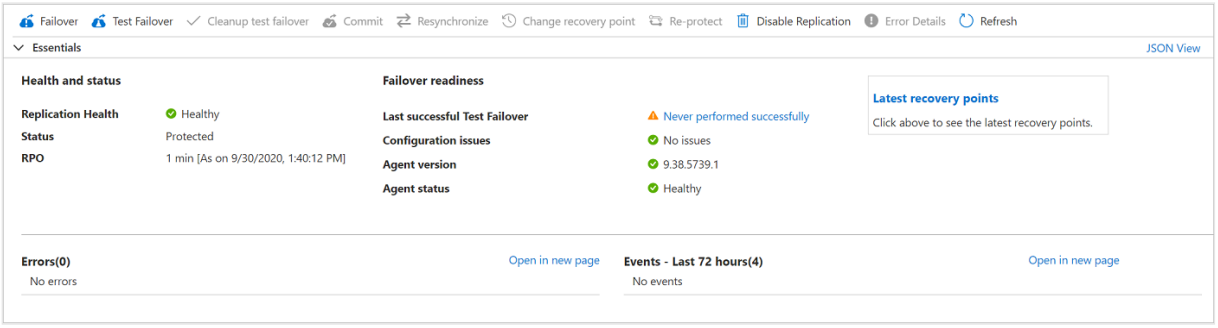
8. Select **Start replication**. Deployment starts, and Site Recovery starts creating target resources. You can monitor replication progress in the notifications.



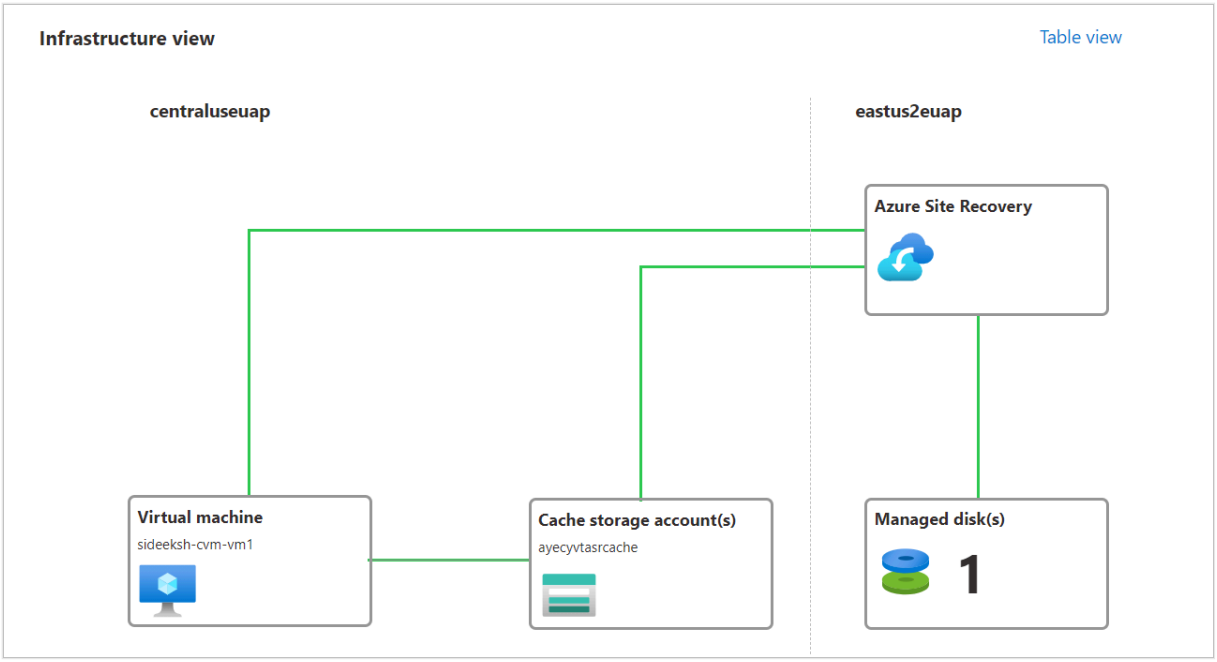
Check VM status

After the replication job finishes, you can check the VM replication status.

1. Open the VM properties page.
2. In **Operations**, select **Disaster recovery**.
3. Expand the **Essentials** section to review defaults about the vault, replication policy, and target settings.
4. In **Health and status**, get information about replication state for the VM, the agent version, failover readiness, and the latest recovery points.



5. In **Infrastructure view**, get a visual overview of source and target VMs, managed disks, and the cache storage account.

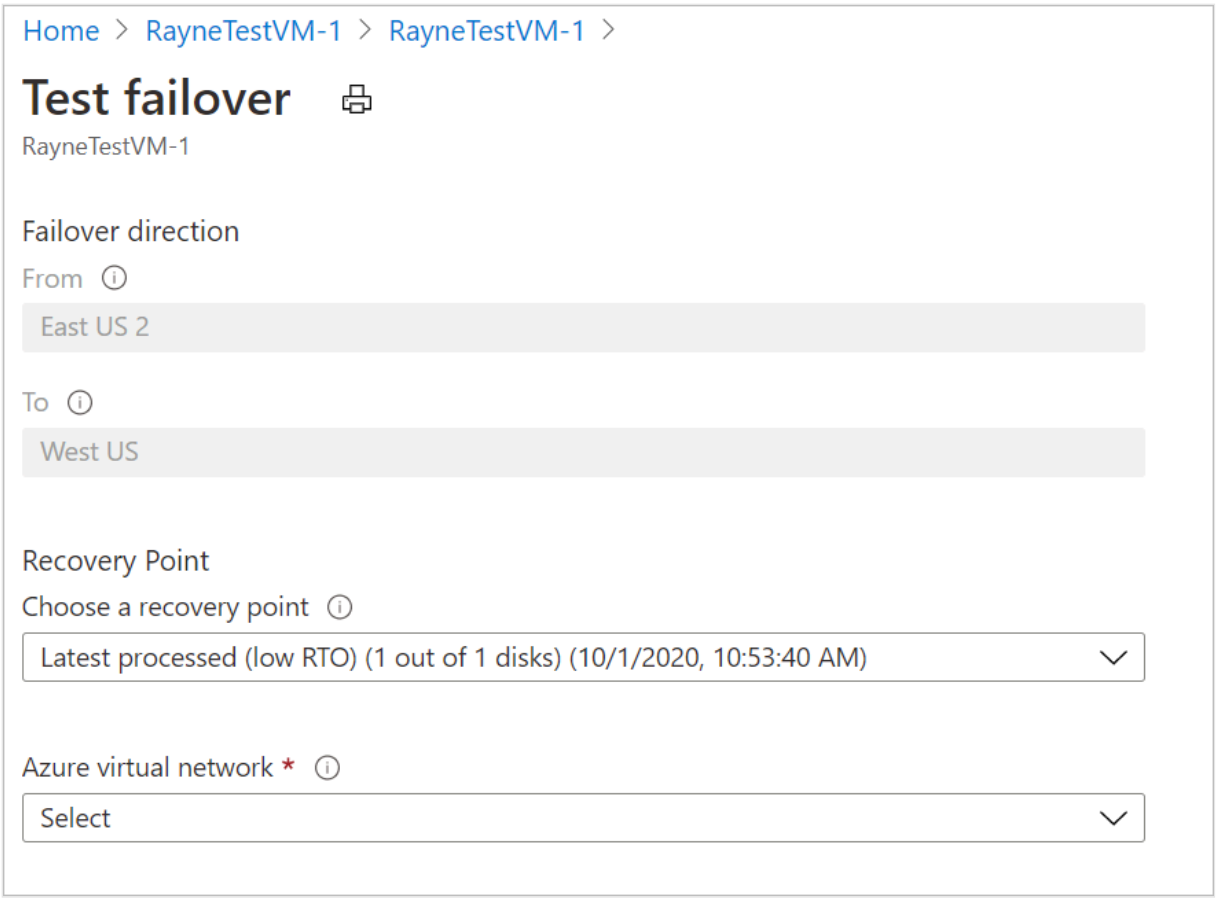


Run a drill

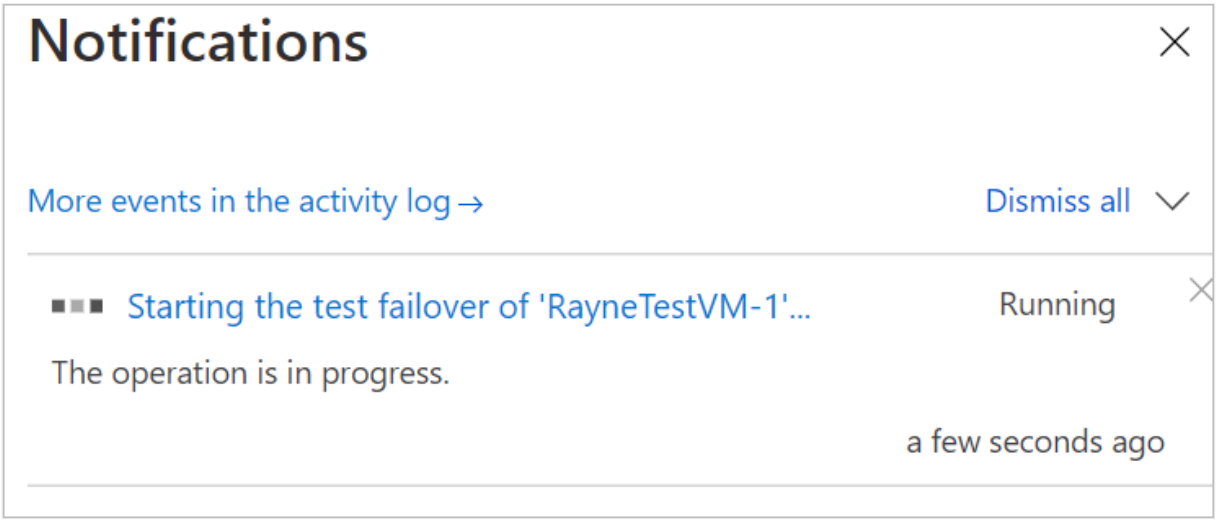
Run a drill to make sure disaster recovery works as expected. When you run a test failover, it creates a copy of the VM, with no impact on ongoing replication, or on your production environment.

1. In the VM disaster recovery page, select **Test failover**.
2. In **Test failover**, leave the default **Latest processed (low RPO)** setting for the recovery point.

   This option provides the lowest recovery point objective (RPO), and generally spins up the VM most quickly in the target region. It first processes all the data that has been sent to Site Recovery service, to create a recovery point for each VM, before failing over to it. This recovery point has all the data replicated to Site Recovery when the failover was triggered.
3. Select the virtual network in which the VM will be located after failover.



4. The test failover process begins. You can monitor the progress in notifications.

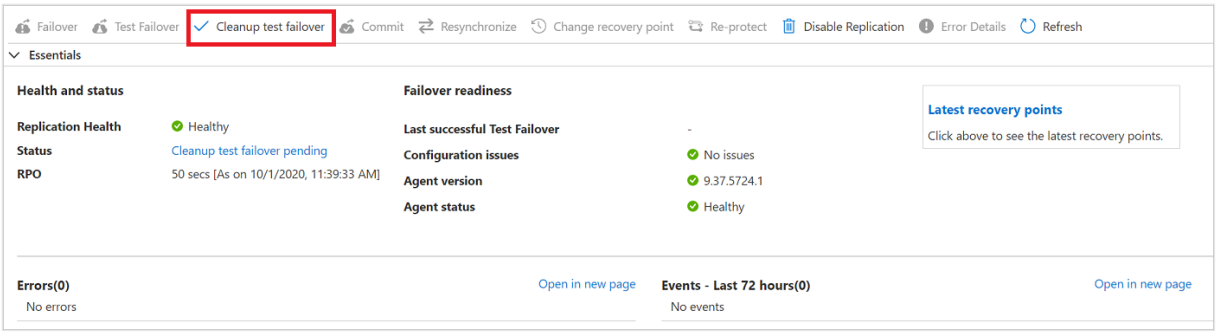


After the test failover completes, the VM is in the *Cleanup test failover pending* state on the **Essentials** page.

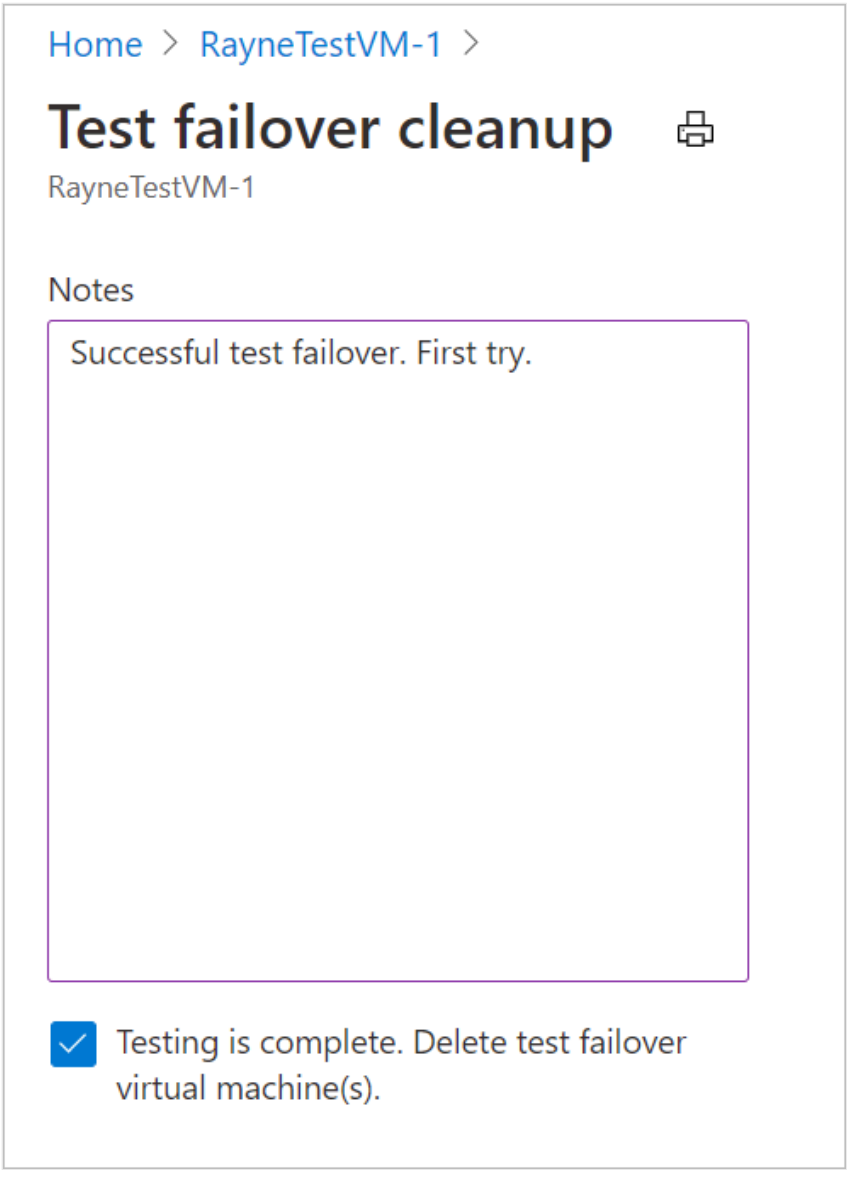
Clean up resources

The VM is automatically cleaned up by Site Recovery after the drill.

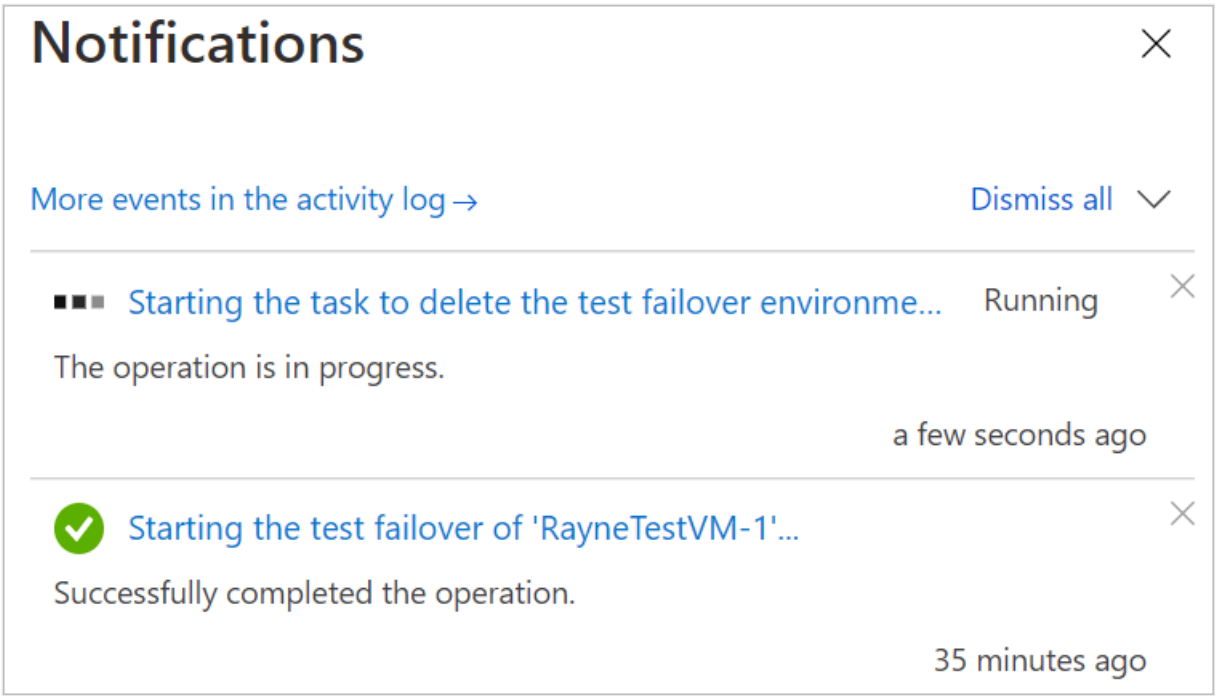
1. To begin automatic cleanup, select **Cleanup test failover**.



2. In **Test failover cleanup**, type in any notes you want to record for the failover, and then select **Testing is complete. Delete test failover virtual machine**. Then select **OK**.



3. The delete process begins. You can monitor progress in notifications.



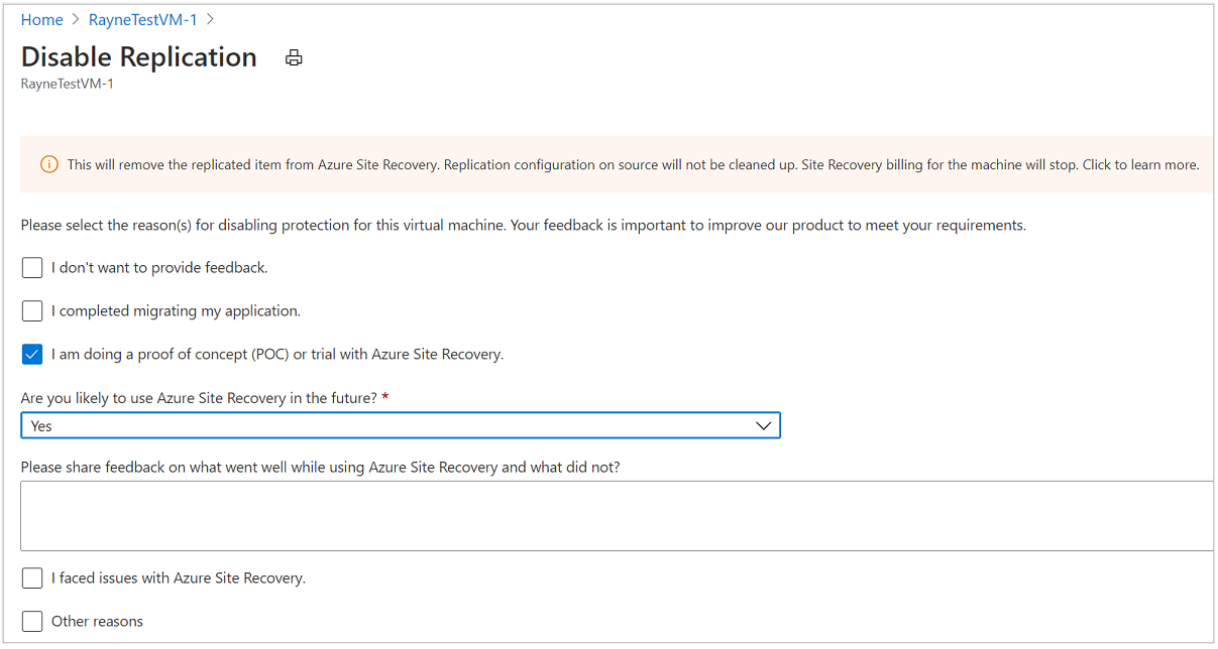
Stop replicating the VM

After completing a disaster recovery drill, we suggest you continue to try out a full failover. If you don't want to do a full failover, you can disable replication. Disabling replication will:

- Remove the VM from the Site Recovery list of replicated machines.
- Stop Site Recovery billing for the VM.
- Automatically clean up source replication settings.

Stop replication as follows:

1. In the VM disaster recovery page, select **Disable Replication**.
2. In **Disable Replication**, select the reasons that you want to disable replication. Then select **OK**.



The Site Recovery extension installed on the VM during replication isn't removed automatically. If you disable replication for the VM, and you don't want to replicate it again at a later time, you can remove the

Site Recovery extension manually, as follows:

1. Go to the VM > **Settings** > **Extensions**.
2. In the **Extensions** page, select each *Microsoft.Azure.RecoveryServices* entry for Linux.
3. In the properties page for the extension, select **Uninstall**.

Next steps

In this tutorial, you configured disaster recovery for an Azure VM, and ran a disaster recovery drill. Now, you can perform a full failover for the VM.

Fail over a VM to another region

Tutorial: Enable disaster recovery for Windows VMs

Article • 08/22/2024

Applies to: ✔ Windows VMs ✔ Flexible scale sets

This tutorial shows you how to set up disaster recovery for Azure VMs running Windows. In this article, learn how to:

- ✔ Enable disaster recovery for a Windows VM
- ✔ Run a disaster recovery drill to check it works as expected
- ✔ Stop replicating the VM after the drill

When you enable replication for a VM, the Site Recovery Mobility service extension installs on the VM, and registers it with Azure Site Recovery. During replication, VM disk writes are sent to a cache storage account in the source region. Data is sent from there to the target region, and recovery points are generated from the data. When you fail over a VM during disaster recovery, a recovery point is used to create a VM in the target region.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

1. Check that your Azure subscription allows you to create a VM in the target region. If you just created your free Azure account, you're the administrator of the subscription, and you have the permissions you need.
2. If you're not the subscription administrator, work with the administrator to assign you:
   - Either the Virtual Machine Contributor built-in role, or specific permissions to:
     - Create a VM in the selected virtual network.
     - Write to an Azure storage account.
     - Write to an Azure-managed disk.
   - The Site Recovery Contributor built-in role, to manage Site Recovery operations in the vault.
3. We recommend you use a Windows VM running Windows Server 2012 or later. The VM disk shouldn't be encrypted for the purpose of this tutorial.
4. If VM outbound connections use a URL-based proxy, make sure it can access these URLs. Using an authenticated proxy isn't supported.

Expand table

Name	Public cloud	Government cloud	Details
Storage	`*.blob.core.windows.net`	`*.blob.core.usgovcloudapi.net`	Write data from the VM to the cache storage

Name	Public cloud	Government cloud	Details
			account in the source region.
Microsoft Entra ID	`login.microsoftonline.com`	`login.microsoftonline.us`	Authorize and authenticate to Site Recovery service URLs.
Replication	`*.hypervrecoverymanager.windowsazure.com`	`*.hypervrecoverymanager.windowsazure.com`	VM communication with the Site Recovery service.
Service Bus	`*.servicebus.windows.net`	`*.servicebus.usgovcloudapi.net`	VM writes to Site Recovery monitoring and diagnostic data.

5. If you're using network security groups (NSGs) to limit network traffic for VMs, create NSG rules that allow outbound connectivity (HTTPS 443) for the VM using these service tags (groups of IP addresses). Try out the rules on a test NSG first.

Expand table

Tag	Allow
Storage tag	Allows data to be written from the VM to the cache storage account.
Microsoft Entra ID tag	Allows access to all IP addresses that correspond to Microsoft Entra ID.
EventsHub tag	Allows access to Site Recovery monitoring.
AzureSiteRecovery tag	Allows access to the Site Recovery service in any region.
GuestAndHybridManagement	Use if you want to automatically upgrade the Site Recovery Mobility agent that's running on VMs enabled for replication.

6. On Windows VMs, install the latest Windows updates, to make sure that VMs have the latest root certificates.

Create a VM and enable disaster recovery

You can optionally enable disaster recovery when you create a VM.

1. Create a VM.
2. On the **Management** tab, select **Enable disaster recovery**.
3. In **Secondary region**, select the target region to which you want to replicate a VM for disaster recovery.

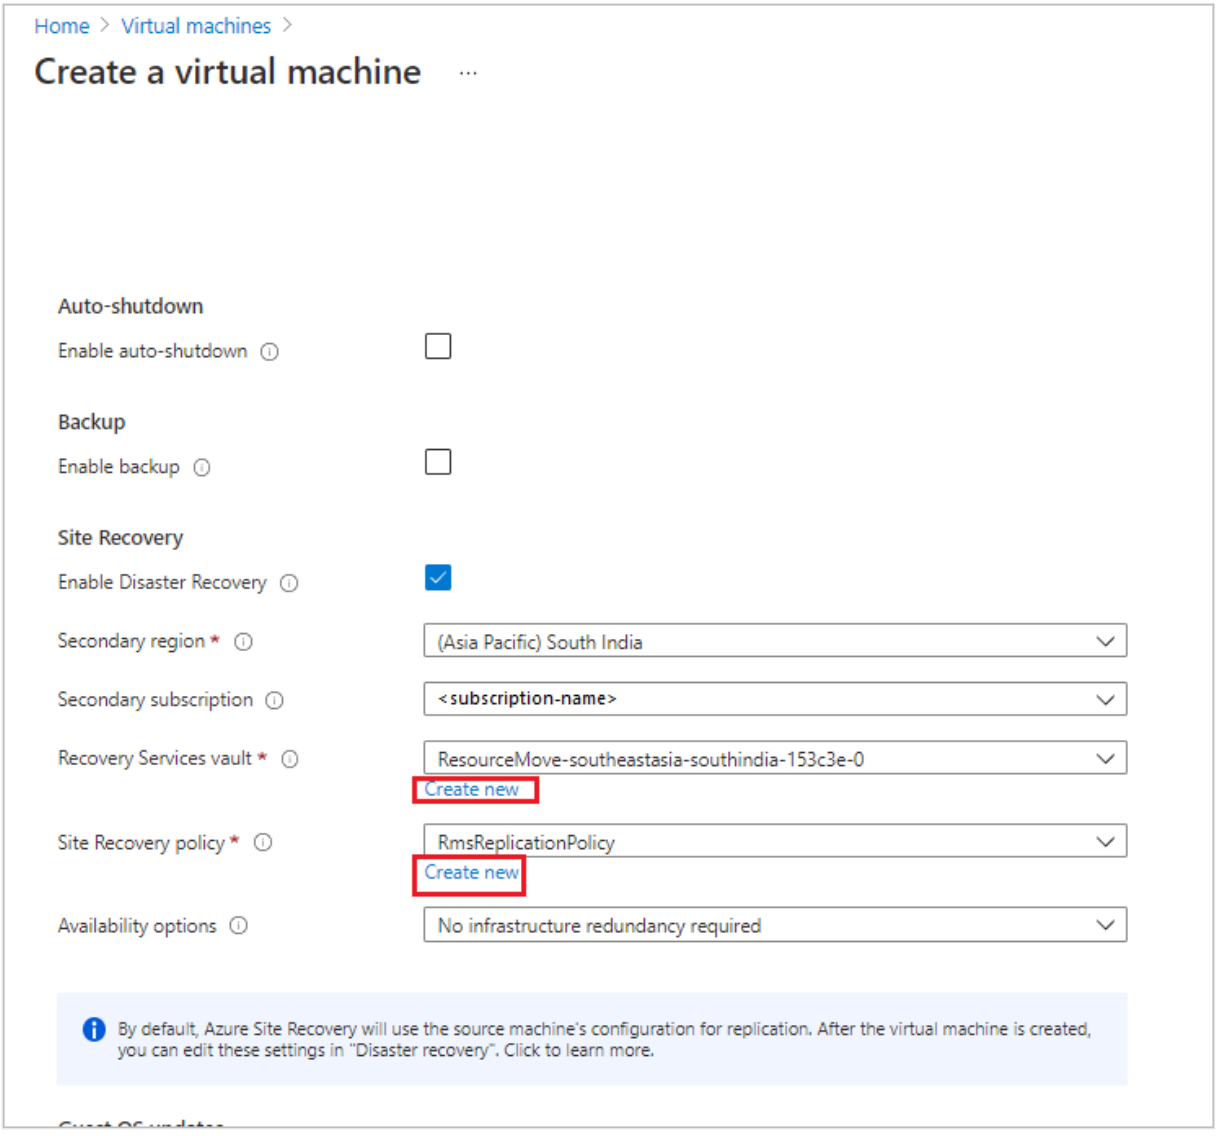
4. In **Secondary subscription**, select the target subscription in which the target VM will be created. The target VM is created when you fail over the source VM from the source region to the target region.

5. In **Recovery Services vault**, select the vault you want to use for the replication. If you don't have a vault, select **Create new**. Select a resource group in which to place the vault, and a vault name.

6. In **Site Recovery policy**, leave the default policy, or select **Create new** to set custom values.

    - Recovery points are created from snapshots of VM disks taken at a specific point in time. When you fail over a VM, you use a recovery point to restore the VM in the target region.
    - A crash-consistent recovery point is created every five minutes. This setting can't be modified. A crash-consistent snapshot captures data that was on the disk when the snapshot was taken. It doesn't include anything in memory.
    - By default Site Recovery keeps crash-consistent recovery points for 24 hours. You can set a custom value between 0 and 72 hours.
    - An app-consistent snapshot is taken every 4 hours. An app-consistent snapshot
    - By default Site Recovery stores recovery points for 24 hours.

7. In **Availability options**, specify whether the VM is deploy as standalone, in an availability zone, or in an availability set.



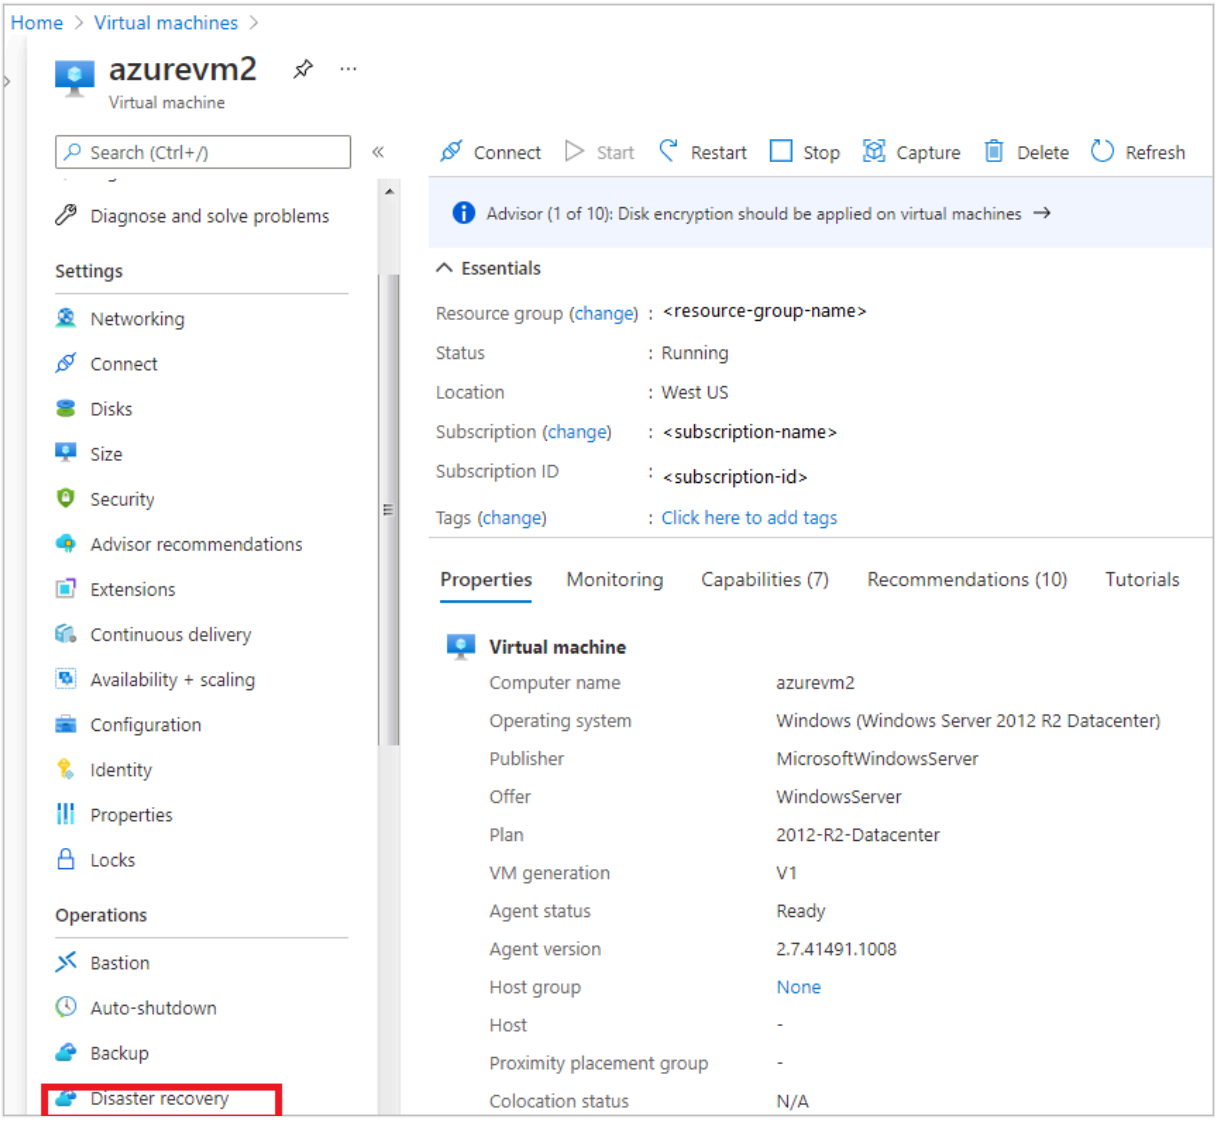
8. Finish creating the VM.

> **Note**
>
> When you enable replication while creating a Windows VM, only the OS disk gets replicated. Data disks need to be initialized by you, after which Azure Site Recovery automatically replicates them.

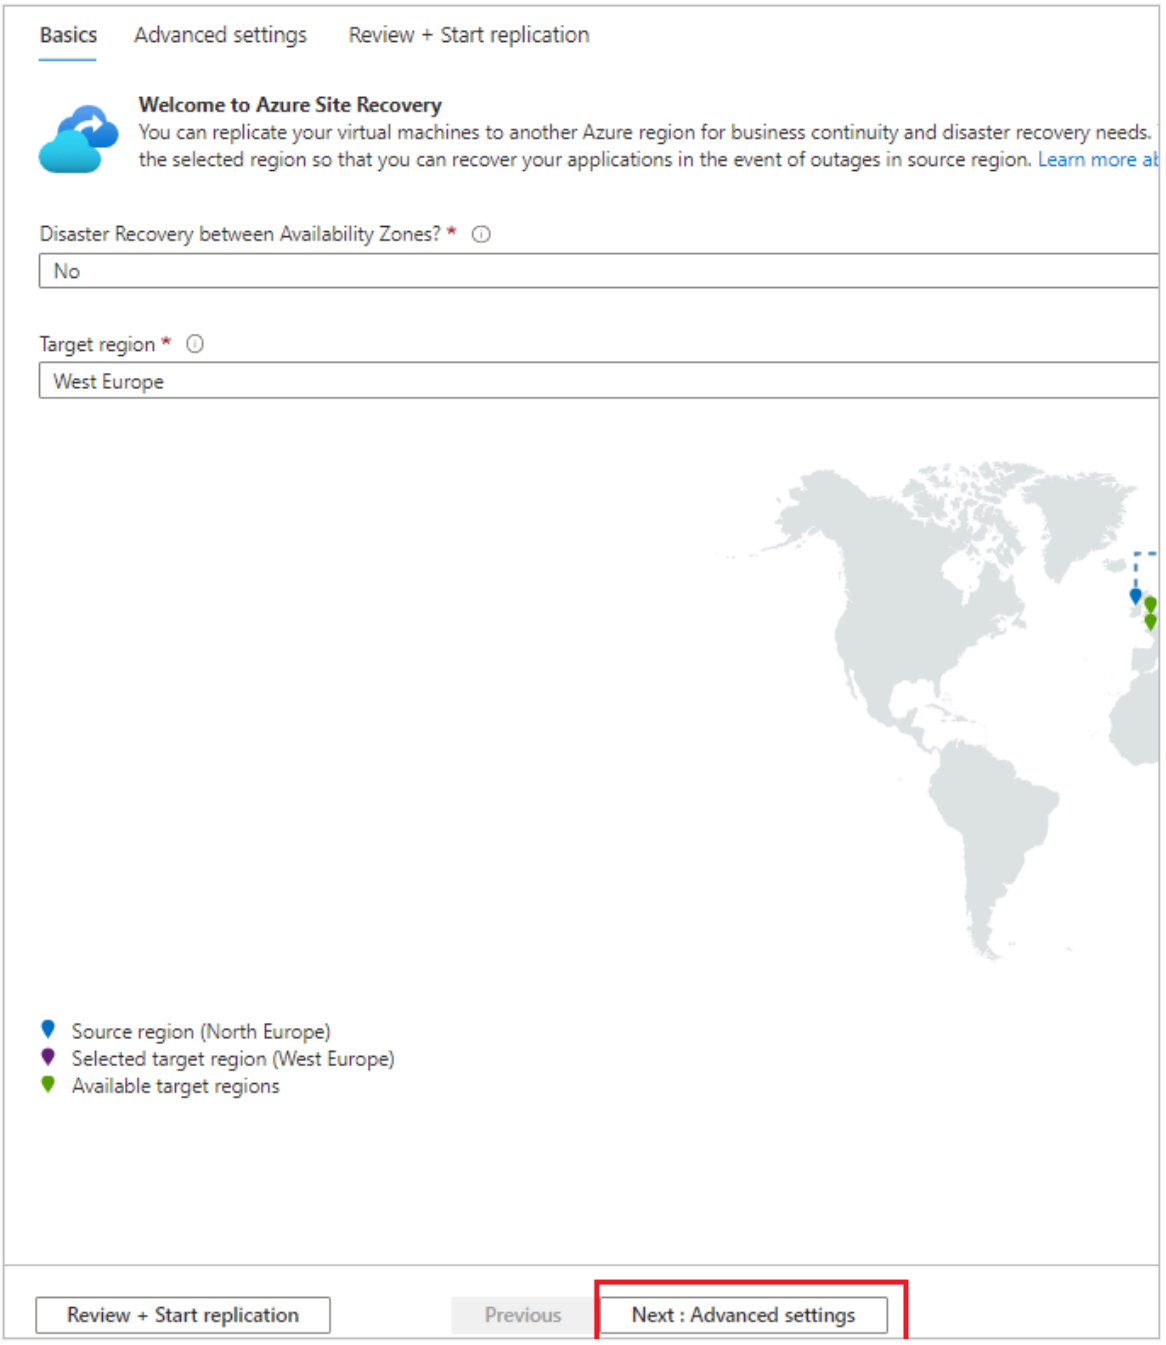
Enable disaster recovery for an existing VM

If you want to enable disaster recovery on an existing VM instead of for a new VM, use this procedure.

1. In the Azure portal, open the VM properties page.
2. In **Operations**, select **Disaster recovery**.



3. In **Basics**, if the VM is deployed in an availability zone, you can select disaster recovery between availability zones.
4. In **Target region**, select the region to which you want to replicate the VM. The source and target regions must be in the same Microsoft Entra tenant.

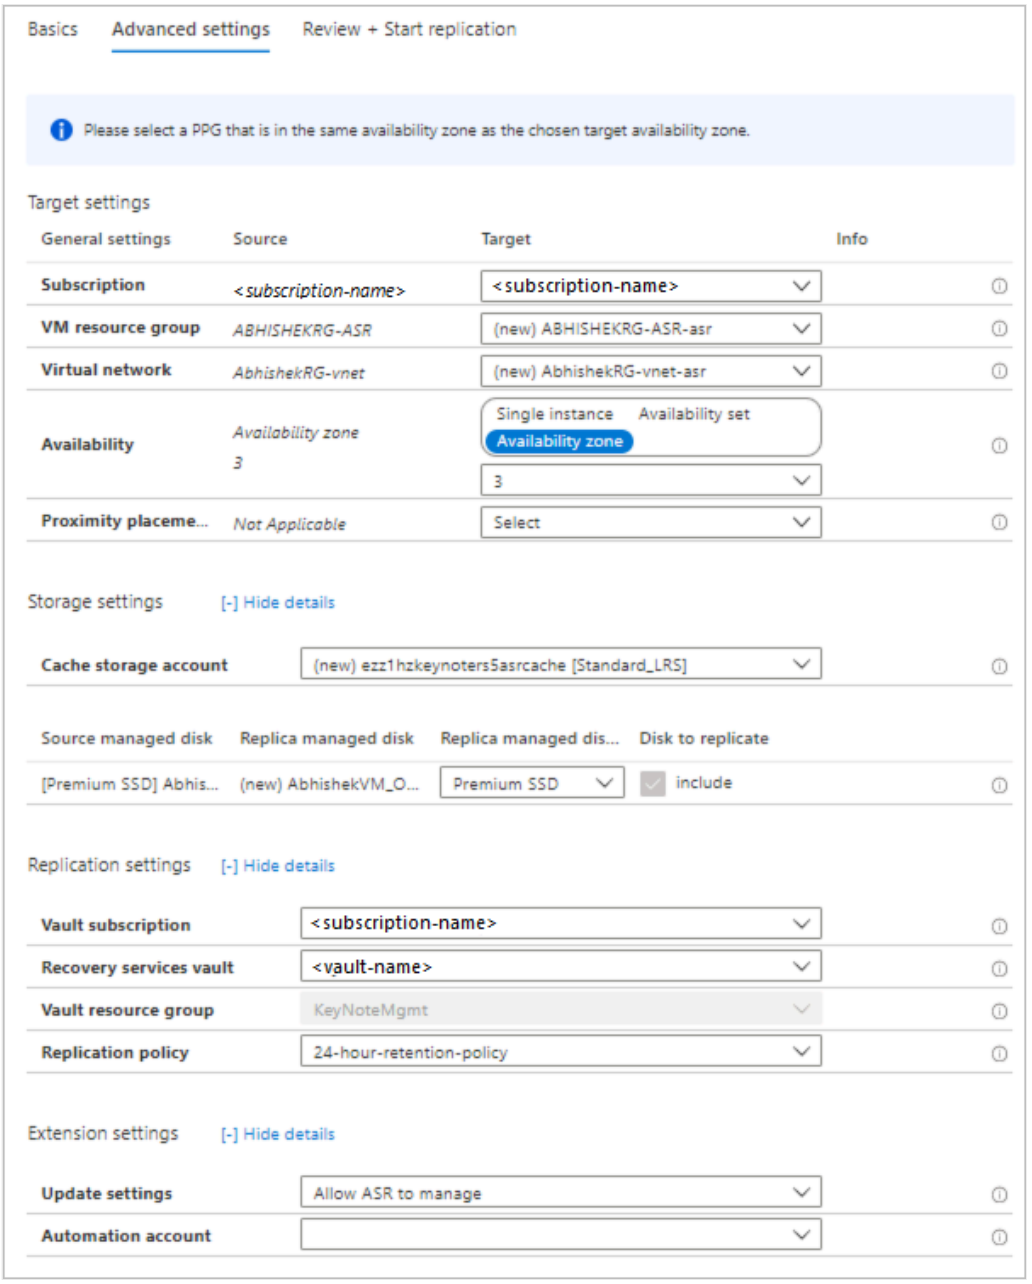


5. Select **Next: Advanced settings**.

6. In **Advanced settings**, you can review settings, and modify values to custom settings. By default, Site Recovery mirrors the source settings to create target resources.

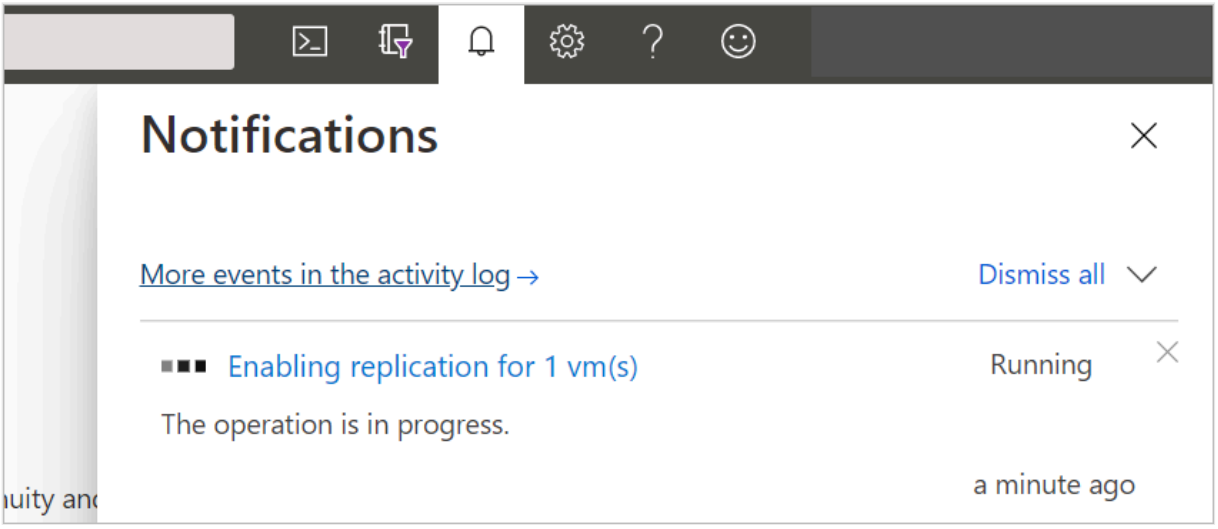
   - **Target subscription**. The subscription in which the target VM is created after failover.
   - **Target VM resource group**. The resource group in which the target VM is created after failover.
   - **Target virtual network**. The Azure virtual network in which the target VM is located when it's created after failover.
   - **Target availability**. When the target VM is created as a single instance, in an availability set, or availability zone.
   - **Proximity placement**. If applicable, select the proximity placement group in which the target VM is located after failover.
   - **Storage settings-Cache storage account**. Recovery uses a storage account in the source region as a temporary data store. Source VM changes are cached in this account, before being replicated to the target location.
     - By default one cache storage account is created per vault and reused.

    - You can select a different storage account if you want to customize the cache account for the VM.
- **Storage settings-Replica managed disk**. By default, Site Recovery creates replica managed disks in the target region.
    - By default the target managed disk mirror the source VM managed disks, using the same storage type (standard HDD/SSD, or premium SSD).
    - You can customize the storage type as needed.
- **Replication settings**. Shows the vault in which the VM is located, and the replication policy used for the VM. By default, recovery points created by Site Recovery for the VM are kept for 24 hours.
- **Extension settings**. Indicates that Site Recovery manages updates to the Site Recovery Mobility Service extension that's installed on VMs you replicate.
    - The indicated Azure automation account manages the update process.
    - You can customize the automation account.



7. Select **Review + Start replication**.

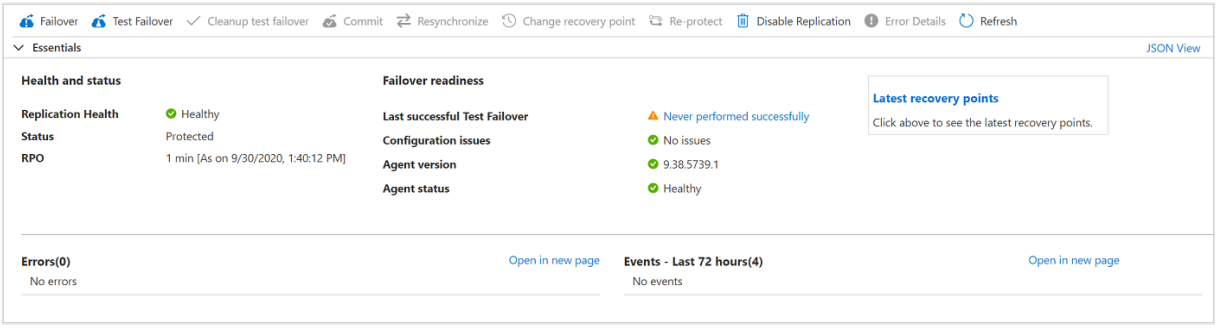
8. Select **Start replication**. Deployment starts, and Site Recovery starts creating target resources. You can monitor replication progress in the notifications.



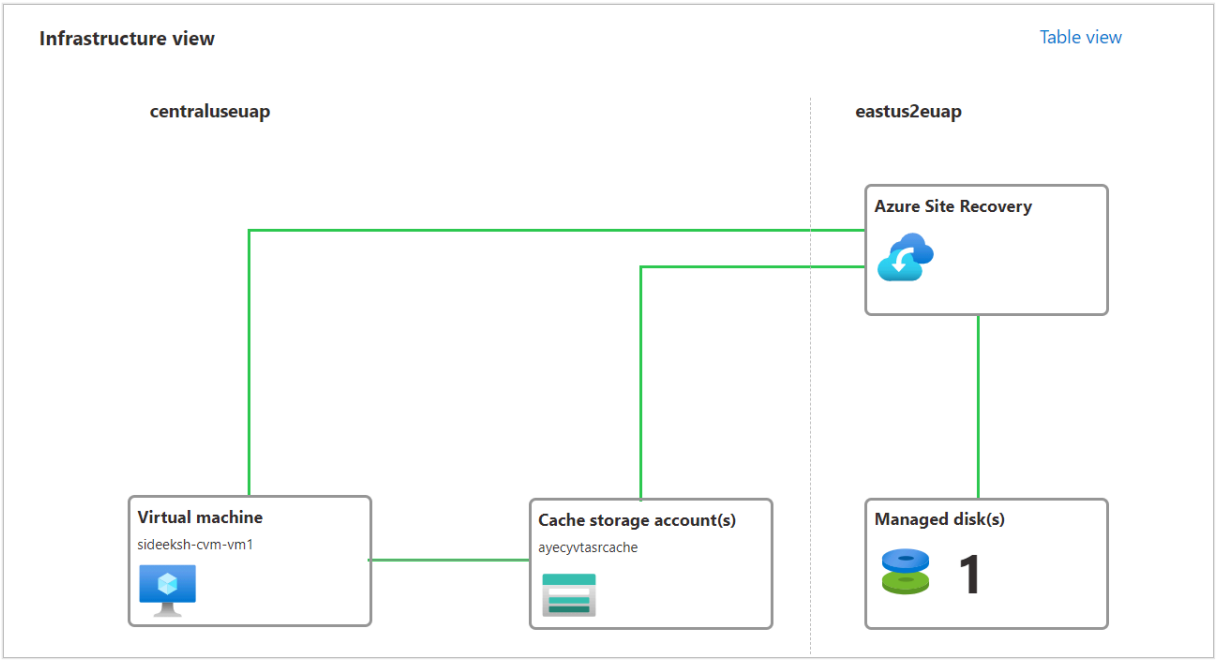
Check VM status

After the replication job finishes, you can check the VM replication status.

1. Open the VM properties page.
2. In **Operations**, select **Disaster recovery**.
3. Expand the **Essentials** section to review defaults about the vault, replication policy, and target settings.
4. In **Health and status**, get information about replication state for the VM, the agent version, failover readiness, and the latest recovery points.



5. In **Infrastructure view**, get a visual overview of source and target VMs, managed disks, and the cache storage account.

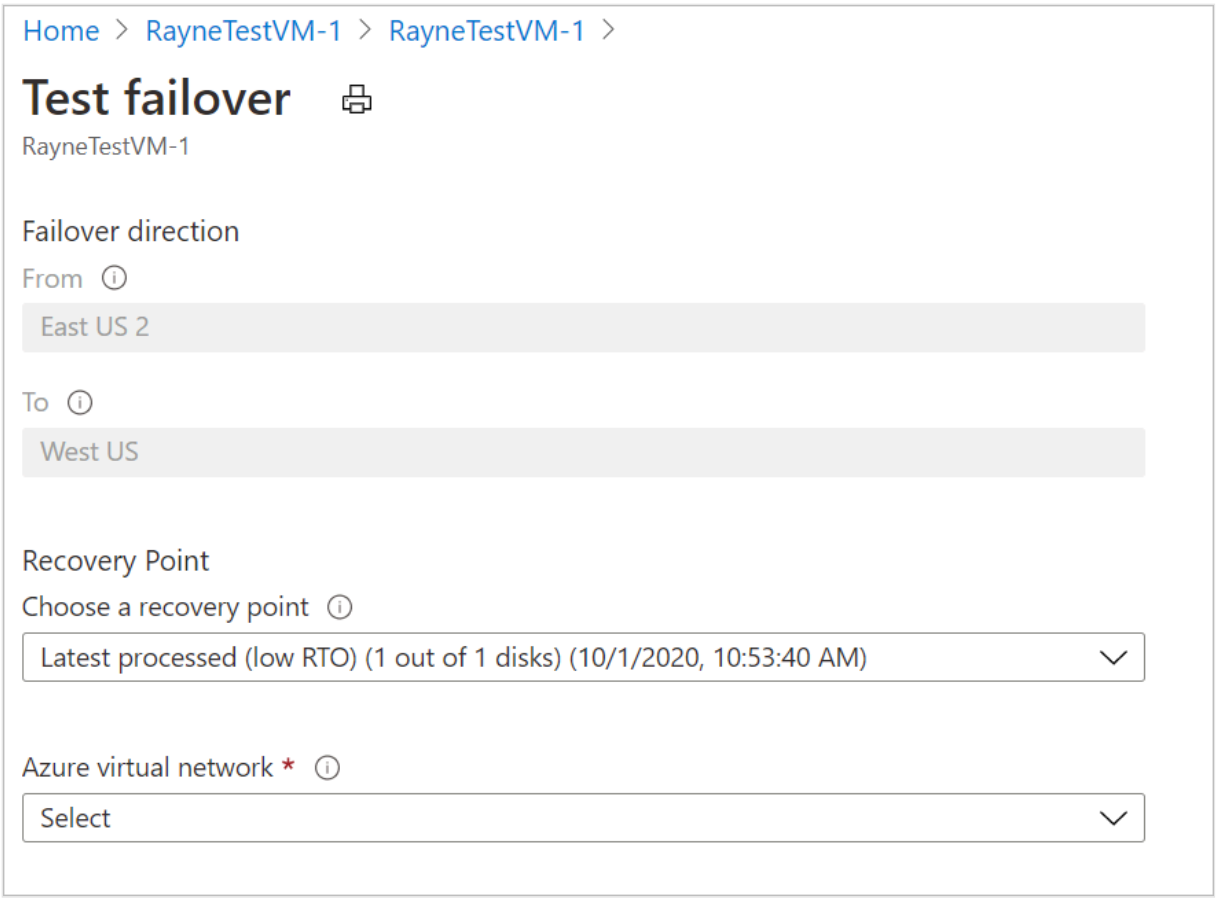


Run a drill

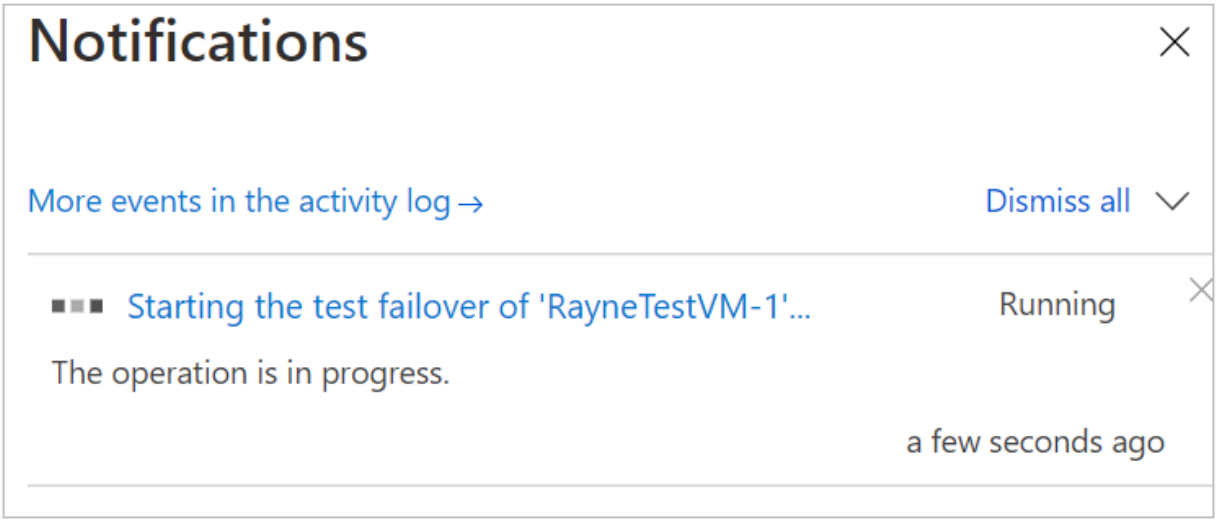
Run a drill to make sure disaster recovery works as expected. When you run a test failover, it creates a copy of the VM, with no impact on ongoing replication, or on your production environment.

1. In the VM disaster recovery page, select **Test failover**.
2. In **Test failover**, leave the default **Latest processed (low RPO)** setting for the recovery point.

   This option provides the lowest recovery point objective (RPO), and generally the quickest spin up of the target VM. It first processes all the data that has been sent to Site Recovery service, to create a recovery point for each VM, before failing over to it. This recovery point has all the data replicated to Site Recovery when the failover was triggered.
3. Select the virtual network in which the VM will be located after failover.



4. The test failover process begins. You can monitor the progress in notifications.

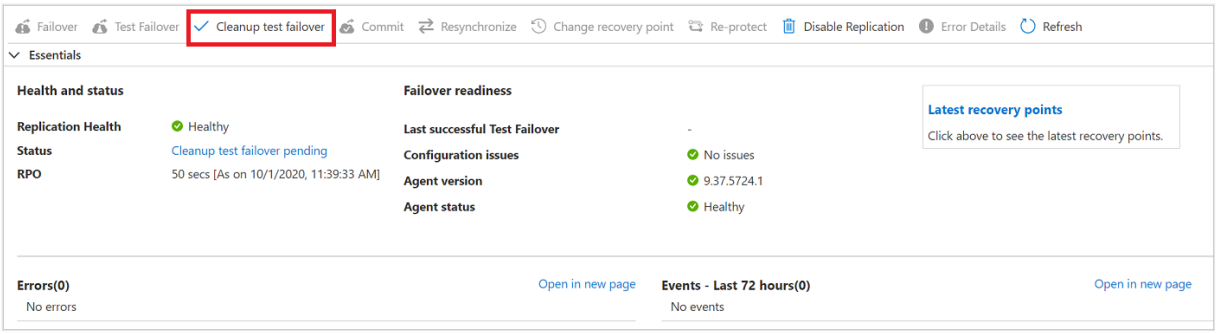


After the test failover completes, the VM is in the *Cleanup test failover pending* state on the **Essentials** page.

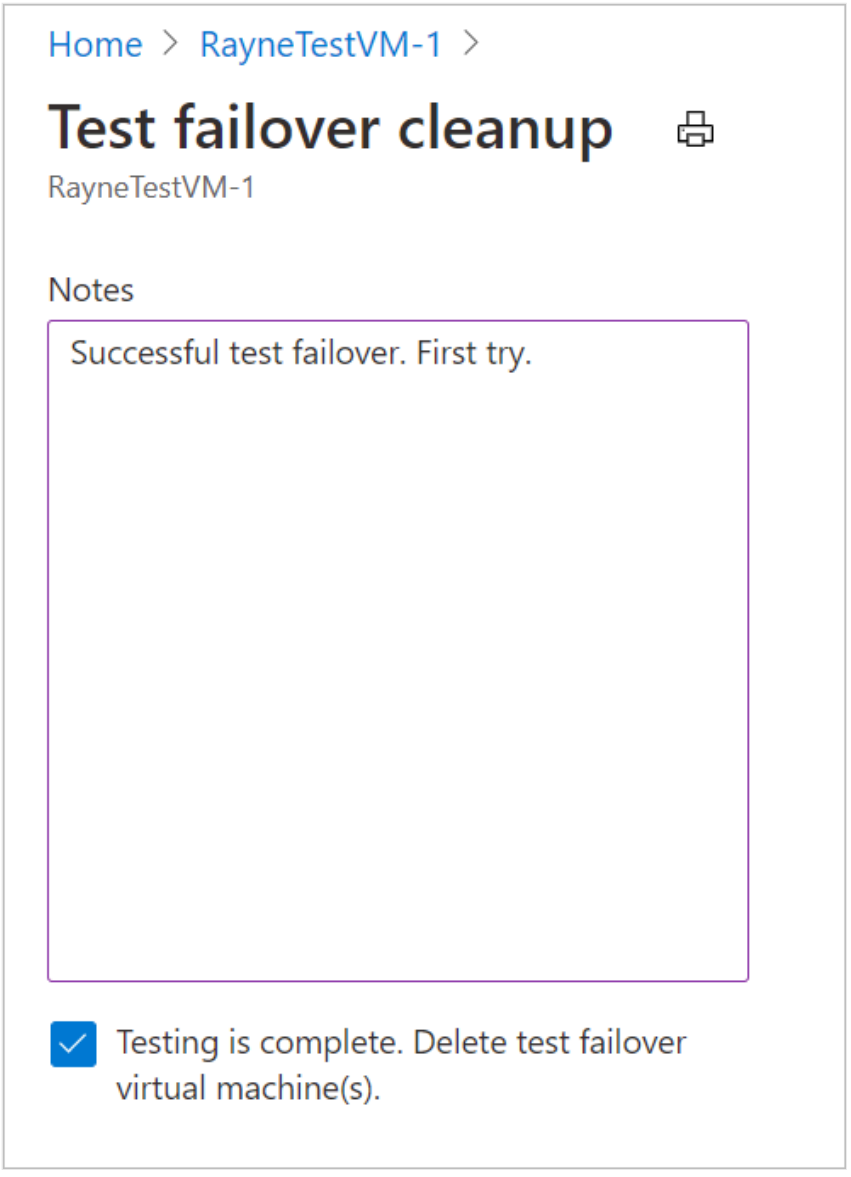
Clean up resources

The VM is automatically cleaned up by Site Recovery after the drill.

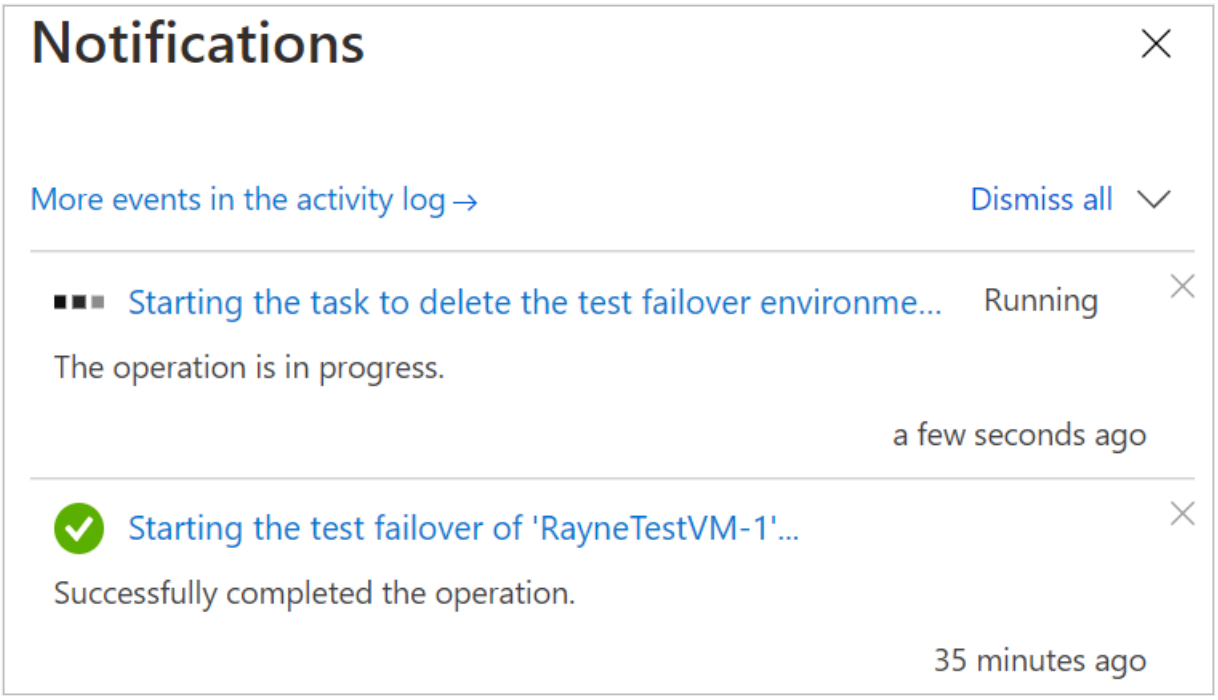
1. To begin automatic cleanup, select **Cleanup test failover**.



2. In **Test failover cleanup**, type in any notes you want to record for the failover, and then select **Testing is complete. Delete test failover virtual machine**. Then select **OK**.



3. The delete process begins. You can monitor progress in notifications.



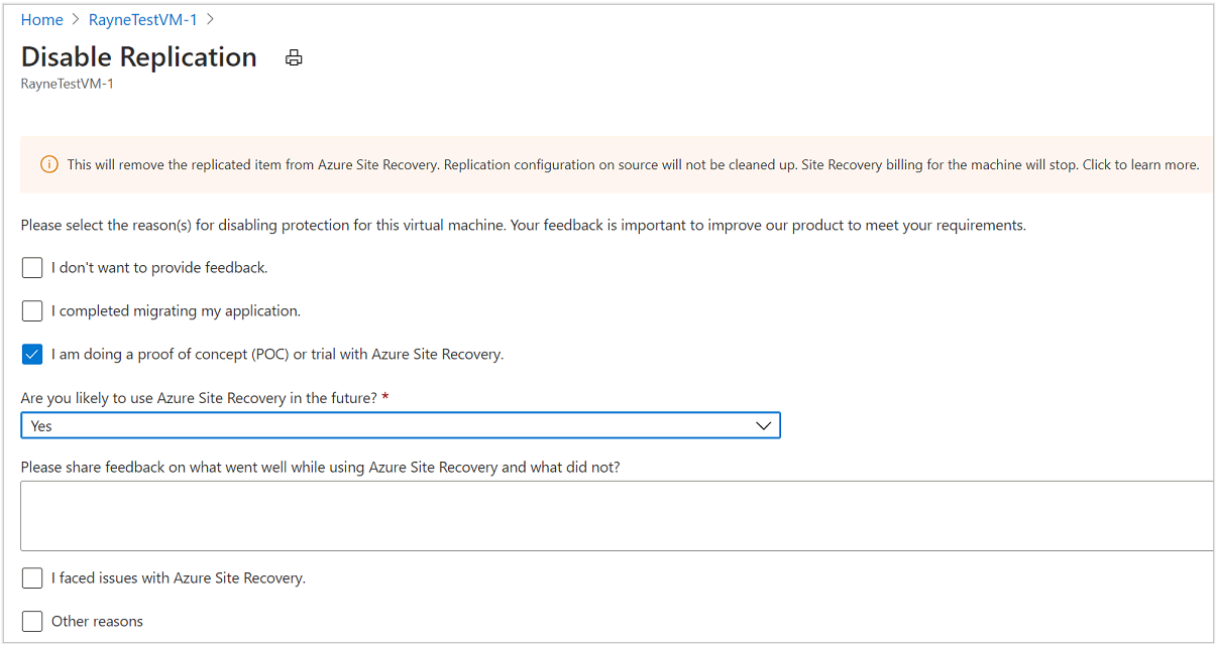
Stop replicating the VM

After completing a disaster recovery drill, we suggest you continue to try out a full failover. If you don't want to do a full failover, you can disable replication. This does the following:

- Removes the VM from the Site Recovery list of replicated machines.
- Stops Site Recovery billing for the VM.
- Automatically cleans up source replication settings.

Stop replication as follows:

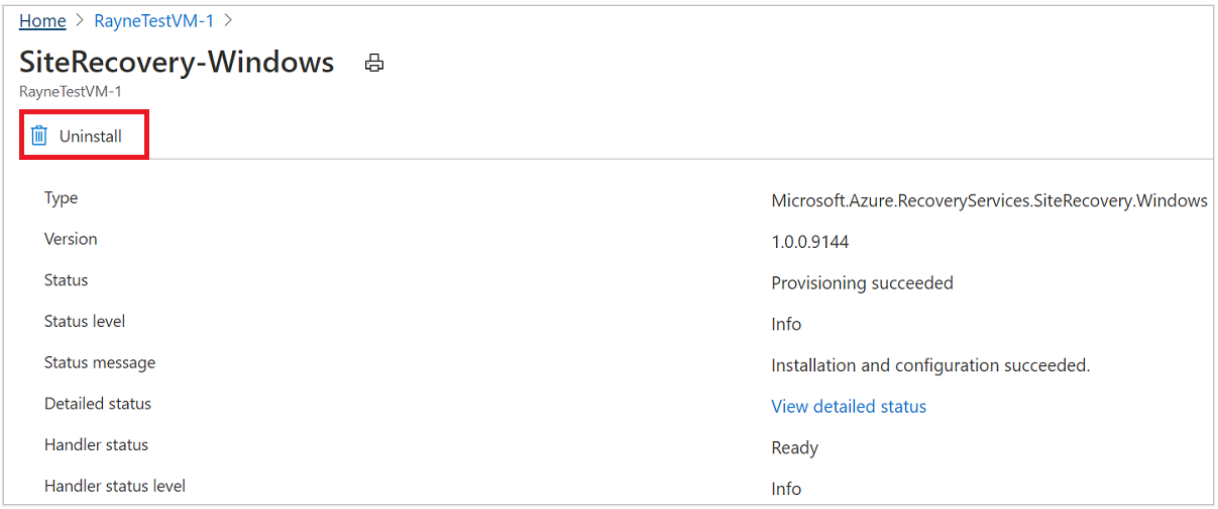
1. In the VM disaster recovery page, select **Disable Replication**.
2. In **Disable Replication**, select the reasons that you want to disable replication. Then select **OK**.



The Site Recovery extension installed on the VM during replication isn't removed automatically. If you disable replication for the VM, and you don't want to replicate it again at a later time, you can remove the

Site Recovery extension manually, as follows:

1. Go to the VM > **Settings** > **Extensions**.
2. In the **Extensions** page, select each *Microsoft.Azure.RecoveryServices* entry for Linux.
3. In the properties page for the extension, select **Uninstall**.



Next steps

In this tutorial, you configured disaster recovery for an Azure VM, and ran a disaster recovery drill. Now, you can perform a full failover for the VM.

Fail over a VM to another region

Tutorial: Fail over Azure VMs to a secondary region

09/08/2025

Learn how to fail over Azure VMs that are enabled for disaster recovery with Azure Site Recovery, to a secondary Azure region. After failover, you reprotect VMs in the target region so that they replicate back to the primary region. In this article, you learn how to:

- ✓ Check prerequisites
- ✓ Verify VM settings
- ✓ Run a failover to the secondary region
- ✓ Start replicating the VM back to the primary region.

> **Note**
>
> This tutorial shows you how to fail over VMs with minimal steps. If you want to run a failover with full settings, learn about Azure VM networking, automation, and troubleshooting.

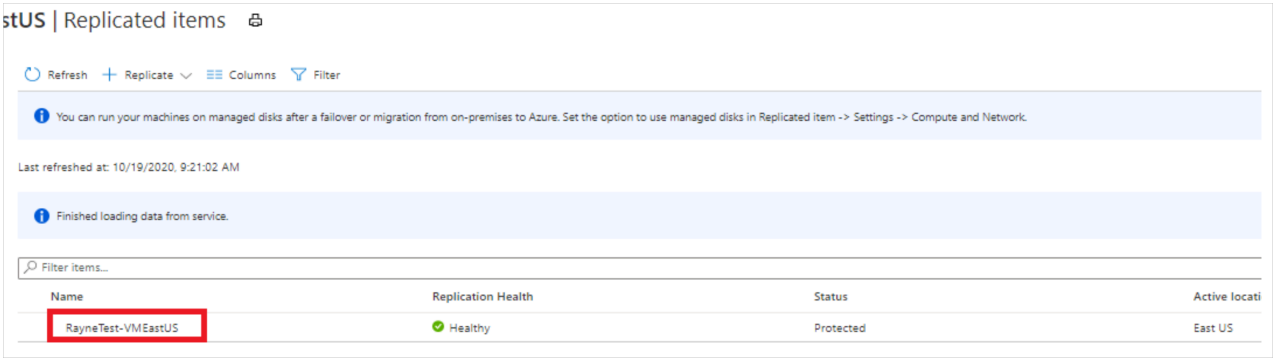
Prerequisites

Before you start this tutorial, you should have:

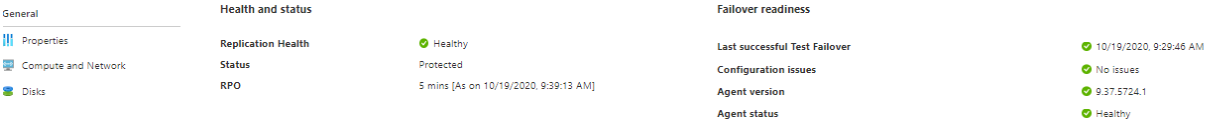
1. Set up replication for one or more Azure VMs. If you haven't, complete the first tutorial in this series to do that.
2. We recommend you run a disaster recovery drill for replicated VMs. Running a drill before you run a full failover helps ensure everything works as expected, without impacting your production environment.

Verify the VM settings

1. In the vault > **Replicated items**, select the VM.



2. On the VM **Overview** page, check that the VM is protected and healthy, before you run a failover.

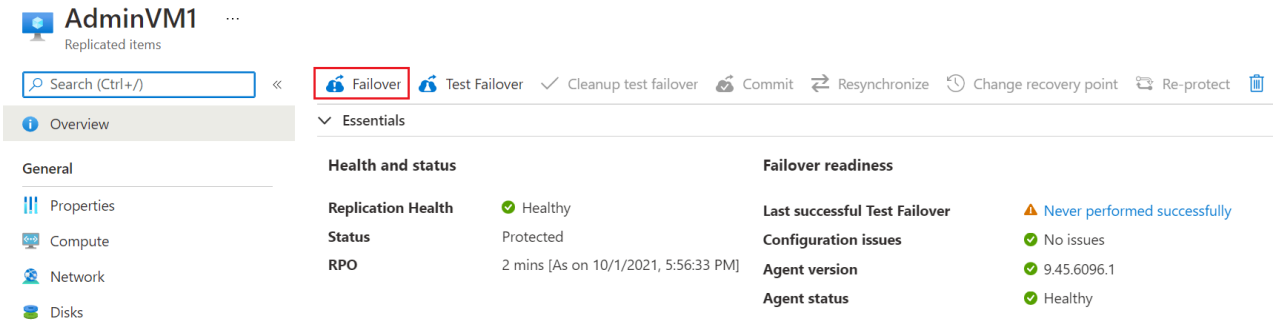


3. Before you fail over, check that:

   - The VM is running a supported Windows or Linux operating system.
   - The VM complies with compute, storage, and networking requirements.

Run a failover

1. On the VM **Overview** page, select **Failover**.



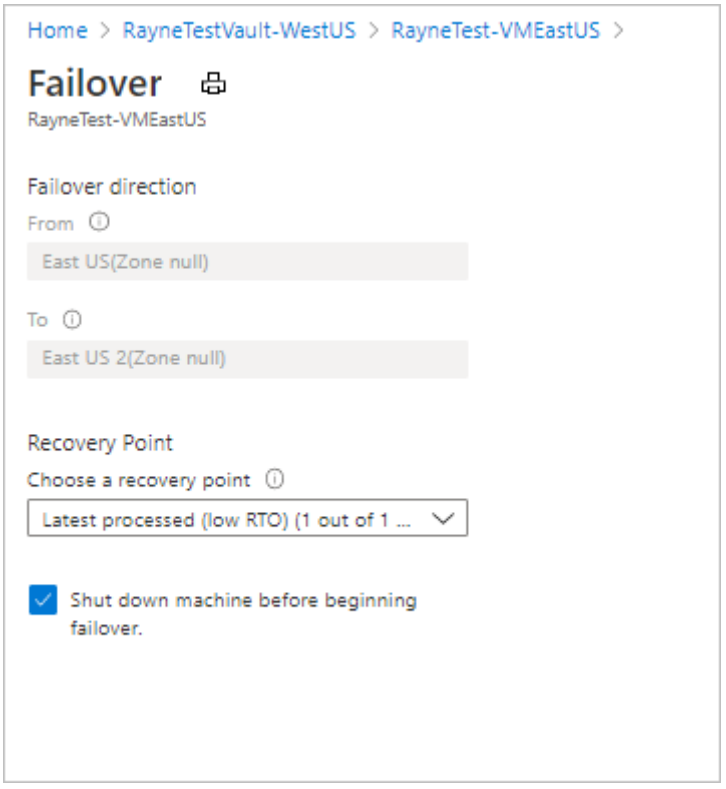
2. In **Failover**, choose a recovery point. The Azure VM in the target region is created using data from this recovery point.

   - **Latest processed**: Uses the latest recovery point processed by Site Recovery. The time stamp is shown. No time is spent processing data, so it provides a low recovery time objective (RTO).
   - **Latest**: Processes all the data sent to Site Recovery, to create a recovery point for each VM before failing over to it. Provides the lowest recovery point objective (RPO), because all data is replicated to Site Recovery when the failover is triggered.
   - **Latest app-consistent**: This option fails over VMs to the latest app-consistent recovery point. The time stamp is shown.

- **Custom**: Fail over to particular recovery point. Custom is only available when you fail over a single VM, and don't use a recovery plan.

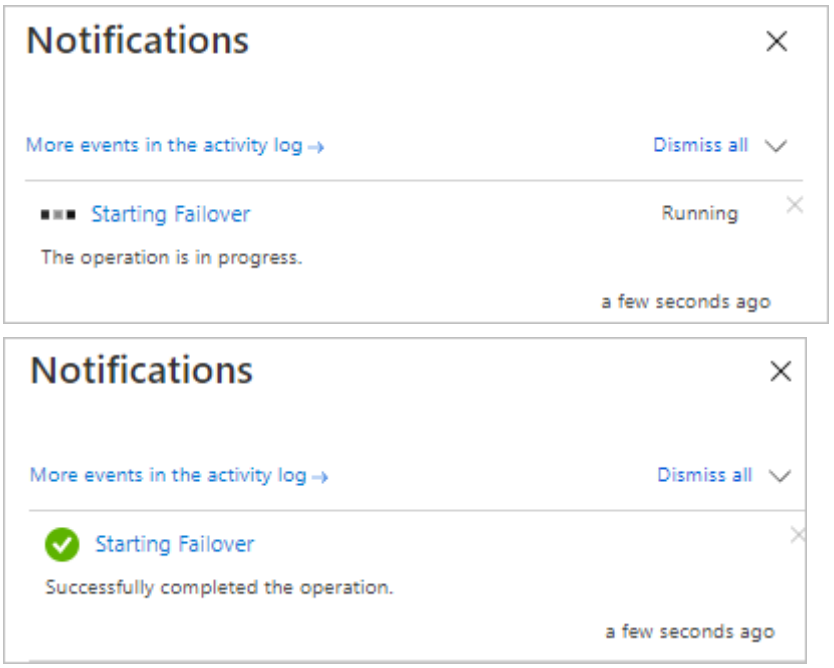
> ⓘ Note
>
> If you added a disk to a VM after you enabled replication, replication points shows disks available for recovery. For example, a replication point created before you added a second disk will show as "1 of 2 disks".

3. Select **Shut down machine before beginning failover** if you want Site Recovery to try to shut down the source VMs before starting failover. Shutdown helps to ensure no data loss. Failover continues even if shutdown fails.



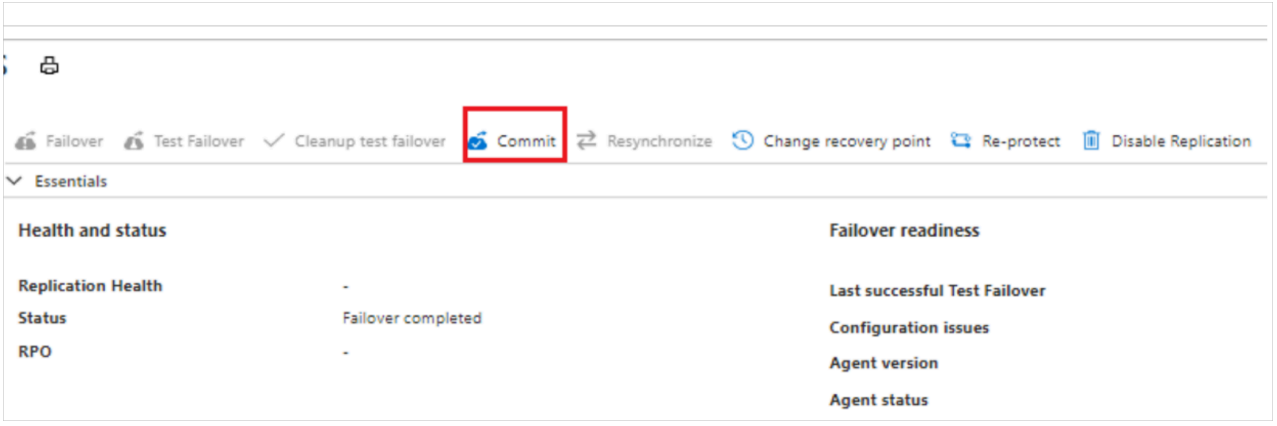
4. To start the failover, select **OK**.

5. Monitor the failover in notifications.



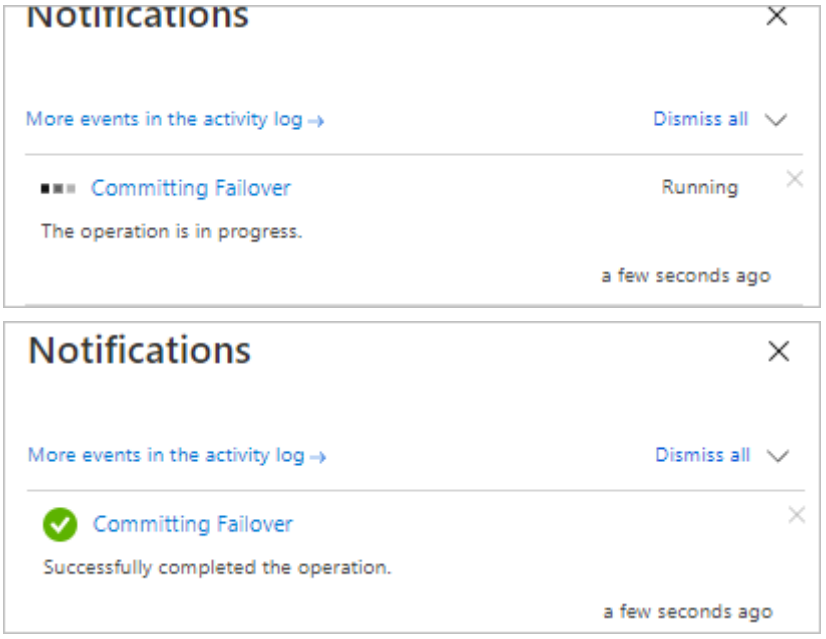
6. After the failover, the Azure VM created in the target region appears in **Virtual Machines**. Make sure that the VM is running, and sized appropriately. If you want to use a different recovery point for the VM, select **Change recovery point**, on the **Essentials** page.

7. When you're satisfied with the failed over VM, select **Commit** on the overview page, to finish the failover.



8. In **Commit**, select **OK** to confirm. Commit deletes all the available recovery points for the VM in Site Recovery, and you won't be able to change the recovery point.

9. Monitor the commit progress in notifications.

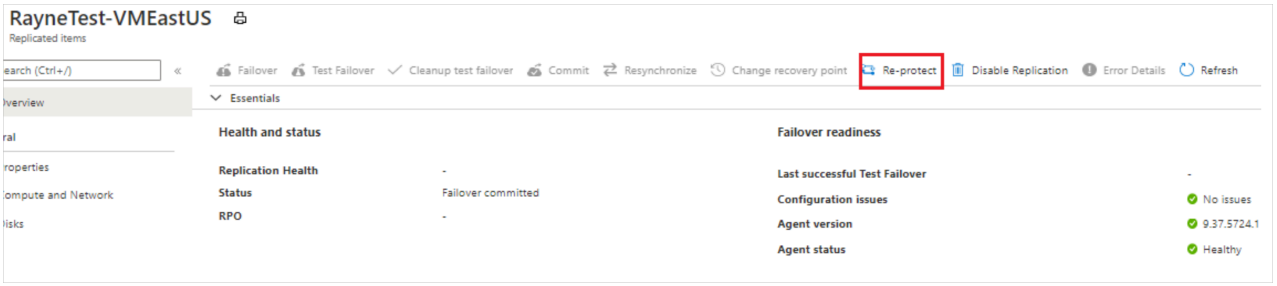


> **Note**
>
> You may also get alternative virtual machine SKU recommendation during test failover. Learn more.

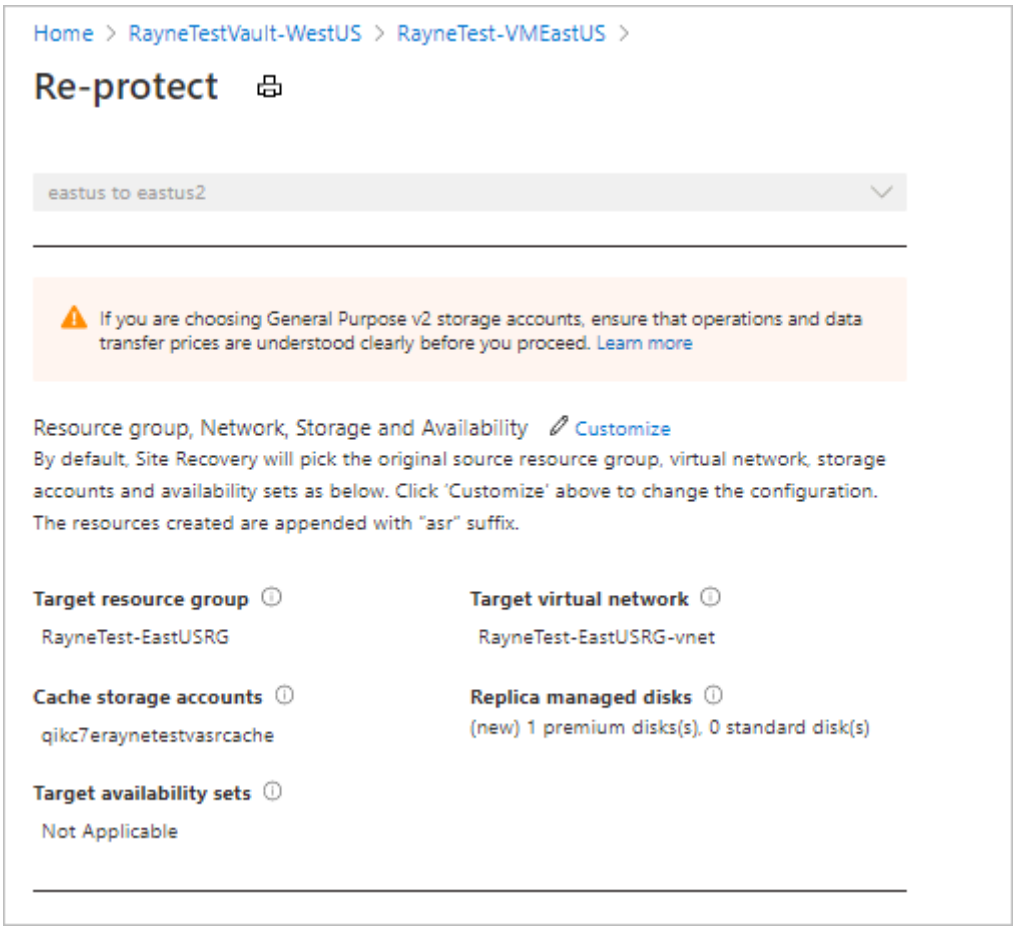
Reprotect the VM

After failover, you reprotect the VM in the secondary region, so that it replicates back to the primary region.

1. Make sure that VM **Status** is *Failover committed* before you start.
2. Check that you can access the primary region is available, and that you have permissions to create VMs in it.
3. On the VM **Overview** page, select **Re-Protect**.

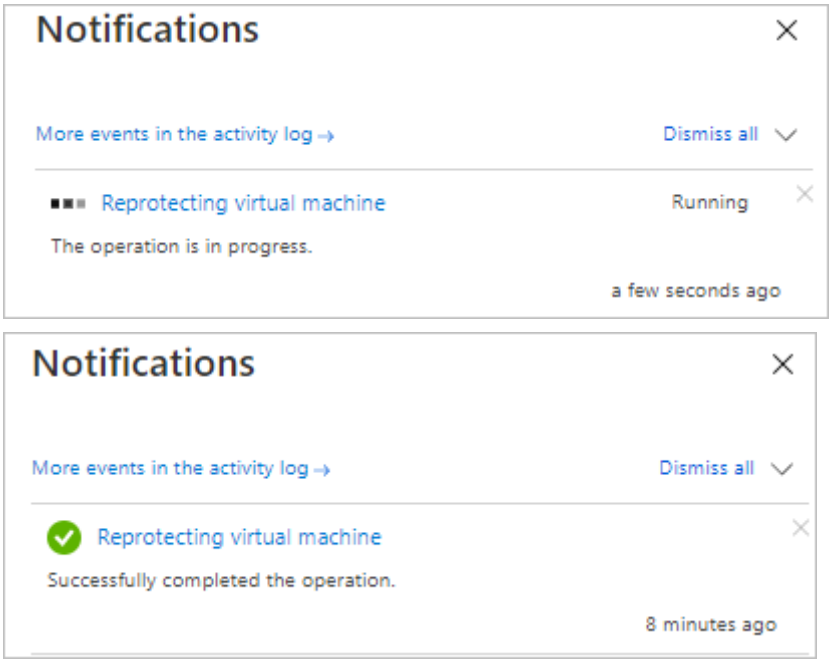


4. In **Re-protect**, verify the replication direction (secondary to primary region), and review the target settings for the primary region. Resources marked as new are created by Site Recovery as part of the reprotect operation.



5. Select **OK** to start the reprotect process. The process sends initial data to the target location, and then replicates delta information for the VMs to the target.

6. Monitor reprotect progress in the notifications.



Next steps

In this tutorial, you failed over from the primary region to the secondary, and started replicating VMs back to the primary region. Now you can fail back from the secondary region to the primary.

Tutorial: Fail back Azure VM to the primary region

Article • 02/11/2025

After failing over an Azure VM to a secondary Azure region, follow this tutorial to fail the VM to the primary Azure region, using Azure Site Recovery. In this article, you learn how to:

- ✓ Review the prerequisites.
- ✓ Fail back the VM in the secondary region.
- ✓ Reprotect primary VMs back to the secondary region.

> **Note**
>
> This tutorial shows you how to fail back with minimal steps. If you want to run a failover with full settings, learn about Azure VM networking, automation, and troubleshooting.

Prerequisites

Before you start this tutorial, you should have:

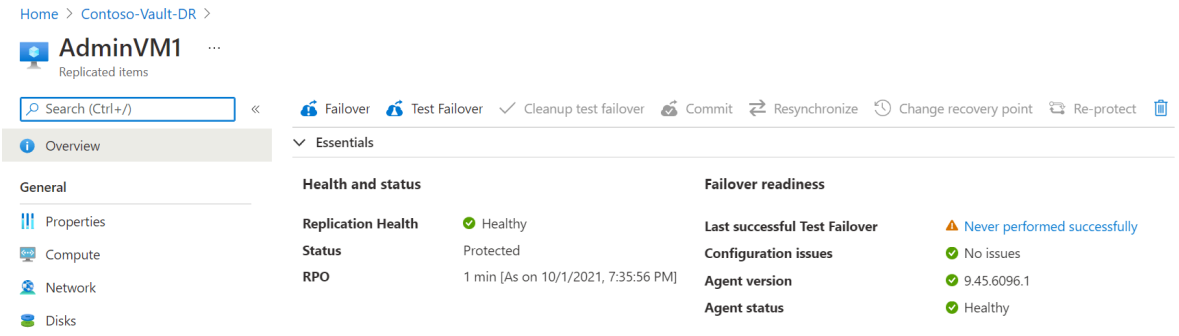
1. Set up replication for at least one Azure VM, and tried out a disaster recovery drill for it.
2. Failed over the VM from the primary region to a secondary region, and reprotected it so that it replicates from the secondary region to the primary.
3. Check that the primary region is available, and that you're able to create and access new resources in it.
4. Source region VM must be shut down before attempting a failback since, changes are synced from failover VM disks to the source region disks during failback. If the source VM is powered on then it fails and thus fails the failback operation.

Fail back to the primary region

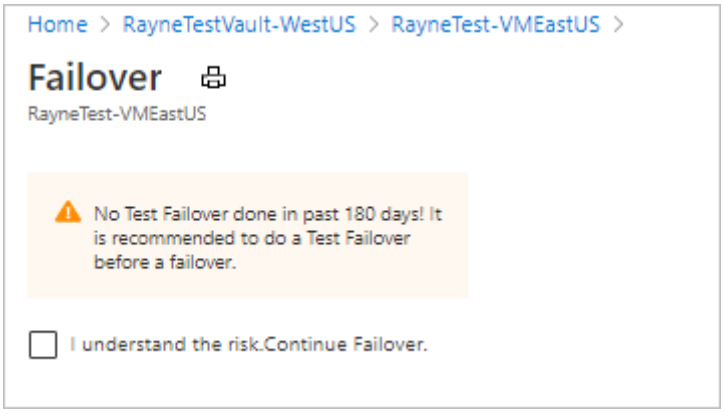
After VMs are reprotected, you can fail back to the primary region as needed.

1. In the vault > **Replicated items**, select the VM.

2. On the VM overview page, check that the VM is healthy, and that synchronization is complete, before you run a failover. The VM should be in a *Protected* state.



3. On the overview page, select **Failover**. Since we're not doing a test failover this time, we're prompted to verify.



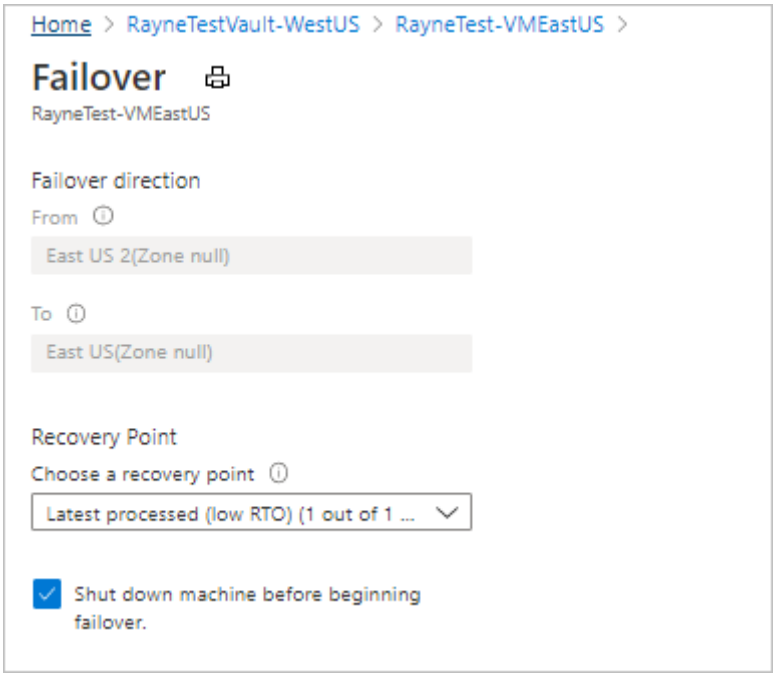
4. In **Failover**, note the direction from secondary to primary, and select a recovery point. The Azure VM in the target (primary region) is created using data from this point.

    - **Latest processed**: Uses the latest recovery point processed by Site Recovery. The time stamp is shown. No time is spent processing data, so it provides a low recovery time objective (RTO).
    - **Latest**: Processes all the data sent to Site Recovery, to create a recovery point for each VM before failing over to it. Provides the lowest recovery point objective (RPO), because all data is replicated to Site Recovery when the failover is triggered.
    - **Latest app-consistent**: This option fails over VMs to the latest app-consistent recovery point. The time stamp is shown.
    - **Custom**: Fail over to particular recovery point. Custom is only available when you fail over a single VM, and don't use a recovery plan.

> ⓘ Note

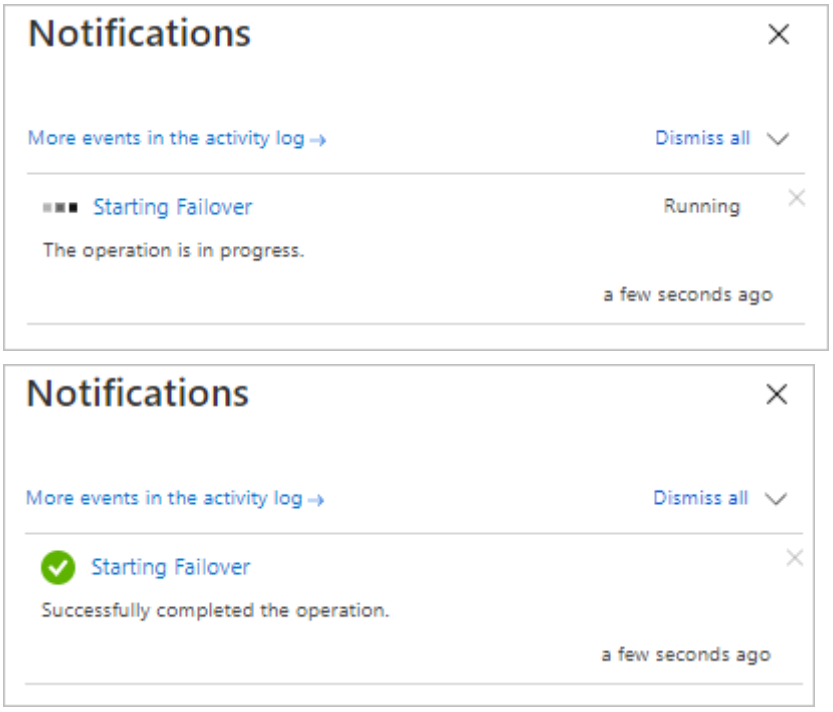
> If you fail over a VM to which you added a disk after you enabled replication for the VM, replication points will show the disks available for recovery. For example, a replication point that was created before you added a second disk will show as "1 of 2 disks".

5. Select **Shut down machine before beginning failover** if you want Site Recovery to attempt to shut down the source VMs before starting failover. Shutdown helps to ensure no data loss. Failover continues even if shutdown fails.



6. To start the failover, select **OK**.

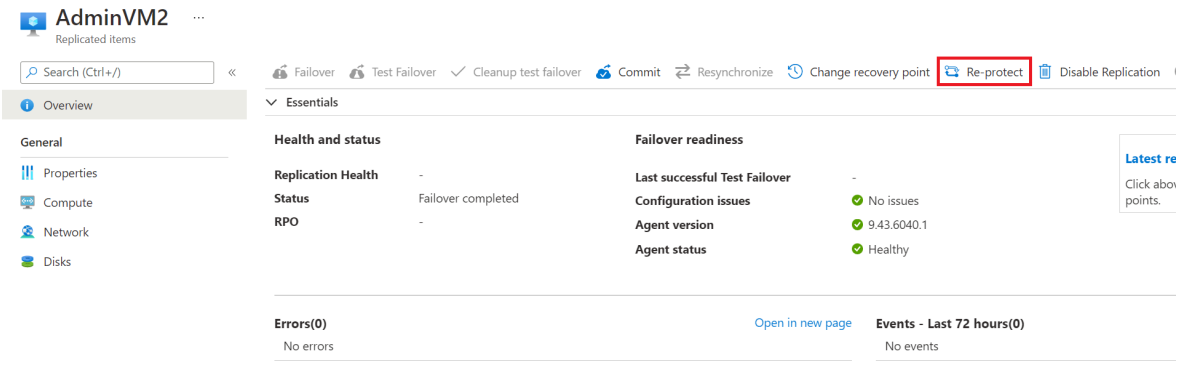
7. Monitor the failover in notifications.



Reprotect VMs

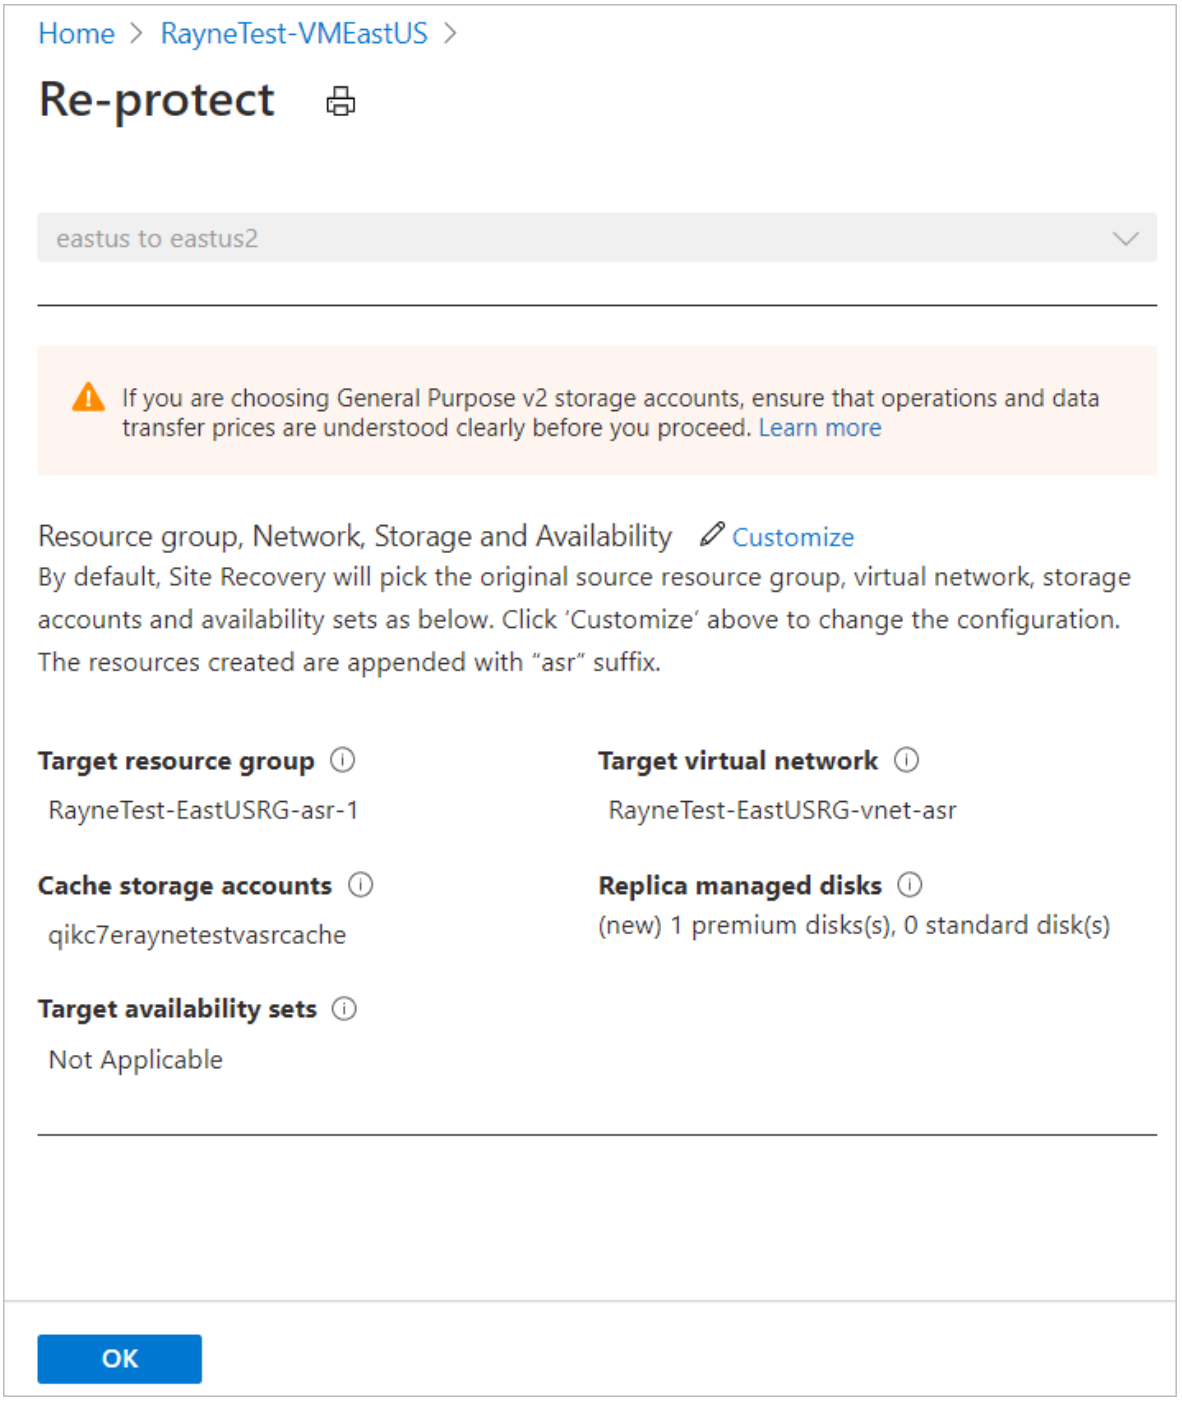
After failing back VMs to the primary region, you need to reprotect them, so that they start replicating to the secondary region again.

1. In the **Overview** page for the VM, select **Re-protect**.

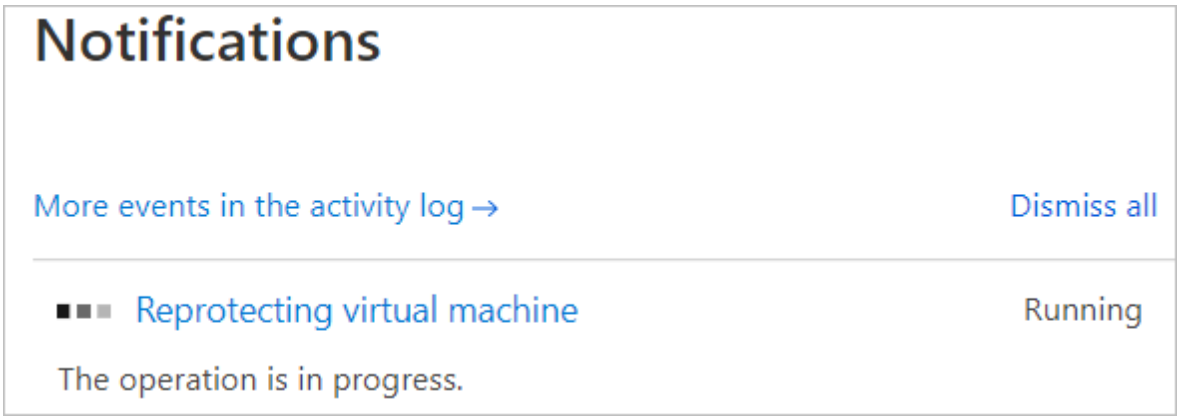


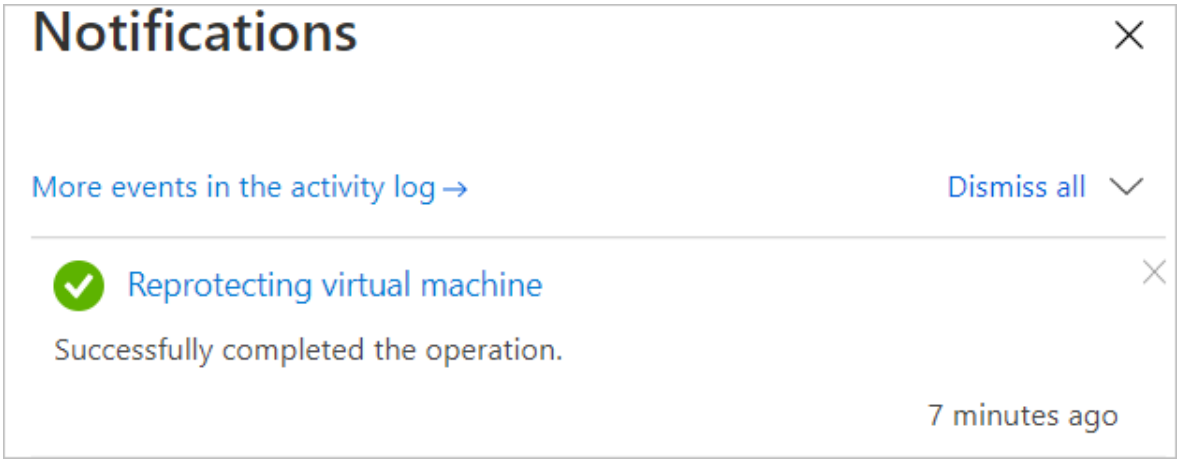
2. Review the target settings for the primary region. Resources marked as new are created by Site Recovery as part of the reprotect operation.

3. Select **OK** to start the reprotect process. The process sends initial data to the target location, and then replicates delta information for the VMs to the target.



4. Monitor reprotect progress in notifications.





Clean up resources

For VMs with managed disks, after failback is complete and VMs are reprotected for replication from primary to secondary, Site Recovery automatically cleans up machines in the secondary disaster recovery region. You don't need to manually delete VMs and NICs in the secondary region. VMs with unmanaged disks aren't cleaned up.

If you completely disable replication after failing back, Site Recovery cleans up machines protected by it. In this case, it also cleans up disks for VMs that don't use managed disks.

Next steps

In this tutorial, you failed VMs back from the secondary region to the primary. This is the last step in the process that includes enabling replication for a VM, trying out a disaster recovery drill, failing over from the primary region to the secondary, and finally failing back.

Now, try out disaster recovery to Azure for an on-premises VM.

Overview of VM restore points

Summarize this article for me

Business continuity and disaster recovery solutions are primarily designed to address sitewide data loss. Solutions that operate at this scale often manage and run across automated failovers and failbacks in multiple regions. You can use Azure virtual machine (VM) restore points to implement granular backup and retention policies.

You can protect your data and guard against extended downtime by creating VM restore points at regular intervals. There are several backup options available for VMs, depending on your use case. For more information, see Backup and restore options for VMs in Azure.

About VM restore points

An individual VM restore point is a resource that stores VM configuration and point-in-time application-consistent snapshots of all the managed disks attached to the VM. You can use VM restore points to easily capture multidisk-consistent backups. VM restore points contain a disk restore point for each of the attached disks. A disk restore point consists of a snapshot of an individual managed disk.

VM restore points support both application consistency and crash consistency.

Application consistency is supported for VMs running Windows operating systems and support file system consistency for VMs running Linux operating systems. Application-consistent restore points use Volume Shadow Copy Service (VSS) writers (or pre- and postscripts for Linux) to ensure the consistency of the application data before a restore point is created. To get an application-consistent restore point, the application running in the VM needs to provide a VSS writer (for Windows) or pre- and postscripts (for Linux) to achieve application consistency.

A multidisk crash-consistent VM restore point stores the VM configuration and point-in-time write-order-consistent snapshots for all managed disks attached to a VM. This information is the same as the status of data in the VM after a power outage or a crash. The `consistencyMode` optional parameter has to be set to `crashConsistent` in the creation request.

> **Note**
>
> Multidisk crash consistency can't be guaranteed in below scenarios:
>
> - For disks configured with read/write host caching, multidisk crash consistency can't be guaranteed because writes that occur while the snapshot is taken might not be

acknowledged by Azure Storage. If maintaining consistency is crucial, we recommend that you use the application-consistency mode.

- Crash-consistent restore points created for Intel V6+ (Dsv6-series, Edsv6-series, Esv6-series etc.) and AMD V7+ (Dasv7-series, Dadsv7-series, Easv7-series, Faldsv7-series etc.) Virtual Machines (VMs) with more than one data disk may not be consistent across disks. These SKUs use Azure Boost, which offloads storage operations to hardware for performance. For VM SKUs using the latest gen of Azure boost, current Crash consistent restore point orchestration does not guarantee simultaneous snapshots across multiple disks, leading to timing gaps (sub-second skew) between disks.

VM restore points are organized into restore point collections. A restore point collection is an Azure Resource Manager resource that contains the restore points for a specific VM. If you want to utilize Azure Resource Manager templates (ARM templates) for creating restore points and restore point collections, see the public Virtual-Machine-Restore-Points repository in GitHub.

The following image illustrates the relationship between restore point collections, VM restore points, and disk restore points.

VM restore points are incremental. The first restore point stores a full copy of all disks attached to the VM. For each successive restore point for a VM, only the incremental changes to your disks are backed up. To reduce your costs, you can optionally exclude any disk when you create a restore point for your VM.

Restore points for VMs inside virtual machine scale set and availability set (AvSet)

Currently, you can create restore points in only one VM at a time. You can't create a single restore point across multiple VMs. Because of this limitation, we currently support creating restore points for individual VMs with a virtual machine scale set in Flexible Orchestration mode or an availability set. If you want to back up instances within a virtual machine scale set instance or your availability set instance, you must individually create restore points for all the VMs that are part of the instance.

> **Note**
>
> A virtual machine scale set with Uniform orchestration isn't supported by restore points. You can't create restore points of VMs inside a virtual machine scale set with Uniform orchestration.

Throttling limits for Restore points

Expand table

Scope	Operation	Limit per hour
VM	RestorePoints.RestorePointOperation.PUT (Create new **Application Consistent**)	3
VM	RestorePoints.RestorePointOperation.PUT (Create new **Crash Consistent**)	3
Target restore point collection	RestorePoints.RestorePointOperation.PUT (Copy any VM Restore Point)	3

The throttling would fail with error code 429. Please retry the operation after the specified duration.

Limitations

- Restore points are supported only for managed disks.
- Ultra Disks, Premium SSD v2 disks, Write-accelerated disks, Ephemeral OS disks, and shared disks aren't supported for crash consistency mode.
- Ephemeral OS disks, and shared disks aren't supported for application consistency mode.
- The API version for an application-consistent restore point is 2021-03-01, or later.
- The API version for a crash-consistent restore point is 2021-07-01, or later.
- Crash consistent restore point is supported on all Azure public regions.

- Crash consistent restore point is supported for VM sizes that support Premium storage like DSv2.
- A maximum of 500 VM restore points can be retained at any time for a VM, irrespective of the number of restore point collections or consistency type.
- Concurrent creation of restore points for a VM isn't supported.
- Restore points for virtual machine scale sets in Uniform orchestration mode aren't supported.
- Movement of VMs between resource groups or subscriptions isn't supported when the VM has restore points. Moving the VM between resource groups or subscriptions doesn't update the source VM reference in the restore point and causes a mismatch of Resource Manager IDs between the actual VM and the restore points.

> **Note**
>
> Public preview of cross-region copying of VM restore points is available, with the following limitations:
>
> - Private links aren't supported when you copy restore points across regions or create restore points in a region other than the source VM.
> - Customer-managed key encrypted restore points, when copied to a target region, are created as platform-managed key encrypted restore points.

Troubleshoot VM restore points

Most common restore point failures are attributed to the communication with the VM agent and extension. To resolve failures, follow the steps in Troubleshoot restore point failures.

Next steps

- Create a VM restore point.
- Learn more about backup and restore options for VMs in Azure.
- Learn more about the extensions used with application consistency mode.
- Learn more about how to copy VM restore points across regions.

Last updated on 02/13/2026

Quickstart: Create VM restore points using APIs

Article • 08/22/2024

You can protect your data by taking backups at regular intervals. Azure VM restore point APIs are a lightweight option you can use to implement granular backup and retention policies. VM restore points support application consistency for VMs running Windows operating systems and support file system consistency for VMs running Linux operating system.

You can use the APIs to create restore points for your source VM in either the same region, or in other regions. You can also copy existing VM restore points between regions.

Prerequisites

- Learn more about the requirements for a VM restore point.
- Consider the limitations before creating a restore point.

Create VM restore points

The following sections outline the steps you need to take to create VM restore points with the Azure Compute REST APIs.

You can find more information in the Restore Points, PowerShell, and Restore Point Collections API documentation.

Step 1: Create a VM restore point collection

Before you create VM restore points, you must create a restore point collection. A restore point collection holds all the restore points for a specific VM. Depending on your needs, you can create VM restore points in the same region as the VM, or in a different region. To create a restore point collection, call the restore point collection's Create or Update API.

- If you're creating restore point collection in the same region as the VM, then specify the VM's region in the location property of the request body.
- If you're creating the restore point collection in a different region than the VM, specify the target region for the collection in the location property, but also specify

the source restore point collection ARM resource ID in the request body.

To create a restore point collection, call the restore point collection's Create or Update API.

Step 2: Create a VM restore point

After you create the restore point collection, the next step is to create a VM restore point within the restore point collection. For more information about restore point creation, see the Restore Points - Create API documentation. For creating crash consistent restore points (in preview) "consistencyMode" property has to be set to "CrashConsistent" in the creation request.

> **Tip**
>
> To save space and costs, you can exclude any disk from either local region or cross-region VM restore points. To exclude a disk, add its identifier to the `excludeDisks` property in the request body.

Step 3: Track the status of the VM restore point creation

Restore point creation in your local region will be completed within a few seconds. Scenarios, which involve the creation of cross-region restore points will take considerably longer. To track the status of the creation operation, follow the guidance in Get restore point copy or replication status. This is only applicable for scenarios where the restore points are created in a different region than the source VM.

Get restore point copy or replication status

Copying the first VM restore point to another region is a long running operation. The VM restore point can be used to restore a VM only after the operation is completed for all disk restore points. To track the operation's status, call the Restore Point - Get API on the target VM restore point and include the `instanceView` parameter. The return will include the percentage of data that has been copied at the time of the request.

During restore point creation, the `ProvisioningState` will appear as `Creating` in the response. If creation fails, `ProvisioningState` is set to `Failed`.

VMSnapshot extension

Article • 08/22/2024

Application-consistent restore points use the Volume Shadow Copy Service (VSS) service (or pre-/postscripts for Linux) to verify application data consistency prior to creating a restore point. Achieving an application-consistent restore point involves the VM's running application providing a VSS service (for Windows) or pre- and postscripts (for Linux).

For Windows images, the **VMSnapshot Windows** extension, and for Linux images, the **VMSnapshot Linux** extension, are used for taking application consistent restore points. When there's a create application consistent restore point request issued from a VM, Azure installs the VM snapshot extension if it's not already present. The extension is updated automatically.

> **Important**
>
> Azure begins creating a restore point only after all extensions (including but not limited to VMSnapshot) provisioning state are complete.

Extension logs

You can view logs for the VMSnapshot extension on the VM under `C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot` for Windows and under `/var/log/azure/Microsoft.Azure.RecoveryServices.VMSnapshotLinux/extension.log` for Linux.

Troubleshooting

Most common restore point failures are attributed to the communication with the VM agent and extension. To resolve failures, follow the steps in Troubleshoot restore point failures.

During certain VSS writer failure, Azure takes file system-consistent restore points for the next three times (irrespective of the frequency at which the restore point creation is scheduled) upon failing the initial creation request. From the fourth time onward, an application-consistent restore point is attempted.

Follow these steps to troubleshoot VSS writer issues.

> **Note**
>
> Avoid manually deleting the extension because it leads to failure of the subsequent creation of an application-consistent restore point.

Next steps

Create a VM restore point

Overview of cross-region copy of VM restore points (in preview)

Article • 08/22/2024

Azure virtual machine (VM) restore point APIs are a lightweight option you can use to implement granular backup and retention policies. VM restore points support application consistency and crash consistency (in preview). You can copy a VM restore point from one region to another region. This capability can help you build business continuity and disaster recovery solutions for Azure VMs.

Scenarios where this API can be helpful:

- Extend multiple copies of restore points to different regions.
- Extend local restore point solutions to support disaster recovery from region failures.

> ⓘ **Note**
>
> To copy a restore point across a region, you need to precreate a `RestorePointCollection` resource in the target region.

Limitations

- Private links aren't supported when you copy restore points across regions or create restore points in a region other than the source VM.
- Azure confidential VMs aren't supported.
- The API version for a cross-region copy of the VM restore point feature is 2021-03-01, or later.
- Copy of a copy isn't supported. You can't copy a restore point that was already copied from another region. For example, if you copied RP1 from East US to West US as RRP1, you can't copy RRP1 from West US to another region (or back to East US).
- Multiple copies of the same restore point in a single target region aren't supported. A single restore point in the source region can be copied only once to a target region.
- Copying a restore point that's CMK encrypted in the source is encrypted by using CMK in the target region. This feature is currently in preview.
- The target restore point only shows the creation time when the source restore point was created.

- Currently, the replication progress is updated every 10 minutes. For disks that have low churn, there can be scenarios where only the initial (0) and the final replication progress (100) appear.
- The maximum copy time supported is two weeks. For a huge amount of data to be copied to a target region, depending on the bandwidth available between the regions, the copy time could be a couple of days. If the copy time exceeds two weeks, the copy operation is terminated automatically.
- No error details are provided when a disk restore point copy fails.
- When a disk restore point copy fails, the intermediate completion percentage where the copy failed isn't shown.
- Restoring a disk from the restore point doesn't automatically check if the disk restore point replication is completed. You need to manually check the percent completion if the replication status is 100% and then start restoring the disk.
- Restore points that are copied to the target region don't have a reference to the source VM. They have a reference to the source restore points. So, if the source restore point is deleted, there's no way to identify the source VM by using the target restore points.
- Copying restore points in a nonsequential order isn't supported. For example, you might have the three restore points RP1, RP2, and RP3. If you already successfully copied RP1 and RP3, you aren't allowed to copy RP2.
- The full snapshot on the source side should always exist and can't be deleted to save cost. For example, if RP1 (full snapshot), RP2 (incremental), and RP3 (incremental) exist in the source and are successfully copied to the target, you can delete RP2 and RP3 on the source side to save cost. Deleting RP1 on the source side results in creating a full snapshot, say RRP1, the next time, and copying also results in a full snapshot. The storage layer maintains the relationship with each pair of source and target snapshot that needs to be preserved.

Troubleshoot VM restore points

Most common restore point failures are attributed to the communication with the VM agent and extension. To resolve failures, follow the steps in Troubleshoot restore point failures.

Next steps

- Copy a VM restore point.
- Learn more about backup and restore options for VMs in Azure.

Manage VM restore points

Article • 08/22/2024

This article explains how to copy and restore a VM from a VM restore point and track the progress of the copy operation. This article also explains how to create a disk from a disk restore point and to create a shared access signature for a disk.

Copy a VM restore point between regions

The VM restore point APIs can be used to restore a VM in a different region than the source VM. Use the following steps:

Step 1: Create a destination VM restore point collection

To copy an existing VM restore point from one region to another, your first step is to create a restore point collection in the target or destination region. To do this, reference the restore point collection from the source region as detailed in Create a VM restore point collection.

Azure PowerShell

```
New-AzRestorePointCollection `
    -ResourceGroupName 'myResourceGroup' `
    -Name 'myRPCollection' `
    -Location 'WestUS' `
    -RestorePointCollectionId '/subscriptions/<SUBSCRIPTION
ID>/resourceGroups/<RG>/providers/Microsoft.Compute/restorePointCollections/
<SOURCE RESTORE POINT COLLECTION>'
```

Step 2: Create the destination VM restore point

After the restore point collection is created, trigger the creation of a restore point in the target restore point collection. Ensure that you've referenced the restore point in the source region that you want to copy and specified the source restore point's identifier in the request body. The source VM's location is inferred from the target restore point collection in which the restore point is being created. See the Restore Points - Create API documentation to create a `RestorePoint`.

Azure PowerShell

```
New-AzRestorePoint `
    -ResourceGroupName 'myResourceGroup' `
```

```
    -RestorePointCollectionName 'myRPCollection'
    -Name 'myRestorePoint'
```

Step 3: Track copy status

To track the status of the copy operation, follow the guidance in the Get restore point copy or replication status section below. This is only applicable for scenarios where the restore points are copied to a different region than the source VM.

Azure PowerShell

```
Get-AzRestorePoint `
    -ResourceGroupName 'myResourceGroup' `
    -RestorePointCollectionName 'myRPCollection'
    -Name 'myRestorePoint'
```

Get restore point copy or replication status

Copying the first VM restore point to another region is a long running operation. The VM restore point can be used to restore a VM only after the operation is completed for all disk restore points. To track the operation's status, call the Restore Point - Get API on the target VM restore point and include the `instanceView` parameter. The return will include the percentage of data that has been copied at the time of the request.

During restore point creation, the `ProvisioningState` will appear as `Creating` in the response. If creation fails, `ProvisioningState` is set to `Failed`.

Create a disk using disk restore points

You can use the VM restore points APIs to restore a VM disk, which can then be used to create a new VM. Use the following steps:

Step 1: Retrieve disk restore point identifiers

Call the Restore Point Collections - Get API on the restore point collection to get access to associated restore points and their IDs. Each VM restore point will in turn contain individual disk restore point identifiers.

Step 2: Create a disk

After you have the list of disk restore point IDs, you can use the Disks - Create Or Update API to create a disk from the disk restore points. You can choose a zone while creating the disk. The zone can be different from zone in which the disk restore point exists.

Restore a VM with a restore point

To restore a full VM from a VM restore point, you must restore individual disks from each disk restore point. This process is described in the Create a disk section. After you restore all the disks, create a new VM and attach the restored disks to the new VM. You can also use the ARM template to restore a full VM along with all the disks.

Get a shared access signature for a disk

To create a Shared Access Signature (SAS) for a disk within a VM restore point, pass the ID of the disk restore points via the `BeginGetAccess` API. If no active SAS exists on the restore point snapshot, a new SAS is created. The new SAS URL is returned in the response. If an active SAS already exists, the SAS duration is extended, and the pre-existing SAS URL is returned in the response.

For more information about granting access to snapshots, see the Grant Access API documentation.

Create virtual machine restore points using Azure CLI

Article • 08/22/2024

You can protect your data and guard against extended downtime by creating VM restore points at regular intervals. You can create VM restore points, and exclude disks while creating the restore point, using Azure CLI. Azure CLI is used to create and manage Azure resources using command line or scripts. Alternatively, you can create VM restore points using the Azure portal or using PowerShell.

The az restore-point module is used to create and manage restore points from the command line or in scripts.

In this tutorial, you learn how to:

- ✓ Create a VM restore point collection
- ✓ Create a VM restore point
- ✓ Track the progress of Copy operation
- ✓ Restore a VM

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

- Learn more about the support requirements and limitations before creating a restore point.

Step 1: Create a VM restore point collection

Use the az restore-point collection create command to create a VM restore point collection, as shown below:

```
az restore-point collection create --location "norwayeast" --source-id
"/subscriptions/{subscription-
id}/resourceGroups/ExampleRg/providers/Microsoft.Compute/virtualMachines/Exa
mpleVM" --tags myTag1="tagValue1" --resource-group "ExampleRg" --collection-
name "ExampleRpc"
```

Step 2: Create a VM restore point

Create a VM restore point with the az restore-point create command as follows:

```
az restore-point create --resource-group "ExampleRg" --collection-name
"ExampleRpc" --name "ExampleRp"
```

To create a crash consistent restore point set the optional parameter "consistency-mode" to "CrashConsistent". This feature is currently in preview.

Exclude disks when creating a restore point

Exclude the disks that you do not want to be a part of the restore point with the `--exclude-disks` parameter, as follows:

```
az restore-point create --exclude-disks "/subscriptions/{subscription-
id}/resourceGroups/ExampleRg/providers/Microsoft.Compute/disks/ExampleDisk1"
--resource-group "ExampleRg" --collection-name "ExampleRpc" --name
"ExampleRp"
```

Step 3: Track the status of the VM restore point creation

Use the az restore-point show command to track the progress of the VM restore point creation.

```
az restore-point show --resource-group "ExampleRg" --collection-name
"ExampleRpc" --name "ExampleRp"
```

Restore a VM from VM restore point

To restore a VM from a VM restore point, first restore individual disks from each disk restore point. You can also use the ARM template to restore a full VM along with all the disks.

```
# Create Disks from disk restore points
$osDiskRestorePoint = az restore-point show --resource-group "ExampleRg" --
collection-name "ExampleRpc" --name "ExampleRp" --query
"sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id"
$dataDisk1RestorePoint = az restore-point show --resource-group "ExampleRg"
--collection-name "ExampleRpcTarget" --name "ExampleRpTarget" –query
"sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id"
$dataDisk2RestorePoint = az restore-point show --resource-group "ExampleRg"
--collection-name "ExampleRpcTarget" --name "ExampleRpTarget" –query
"sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id"

az disk create --resource-group “ExampleRg” --name “ExampleOSDisk” --sku
Premium_LRS --size-gb 128 --source $osDiskRestorePoint

az disk create --resource-group “ExampleRg” --name “ExampleDataDisk1” --sku
Premium_LRS --size-gb 128 --source $dataDisk1RestorePoint

az disk create --resource-group “ExampleRg” --name “ExampleDataDisk1” --sku
Premium_LRS --size-gb 128 --source $dataDisk2RestorePoint
```

Once you have created the disks, create a new VM and attach these restored disks to the newly created VM.

Create virtual machine restore points using PowerShell

Article • 08/22/2024

> **Note**
>
> We recommend that you use the Azure Az PowerShell module to interact with Azure. To get started, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

You can create Virtual Machine restore points using PowerShell scripts. The Azure PowerShell Az module is used to create and manage Azure resources from the command line or in scripts.

You can protect your data and guard against extended downtime by creating VM restore points at regular intervals. This article shows you how to create VM restore points, and exclude disks from the restore point, using the Az.Compute module. Alternatively, you can create VM restore points using the Azure CLI or in the Azure portal.

In this tutorial, you learn how to:

- ✓ Create a VM restore point collection
- ✓ Create a VM restore point
- ✓ Track the progress of Copy operation
- ✓ Restore a VM

Prerequisites

- Learn more about the support requirements and limitations before creating a restore point.

Step 1: Create a VM restore point collection

Use the New-AzRestorePointCollection cmdlet to create a VM restore point collection.

```
New-AzRestorePointCollection -ResourceGroupName ExampleRG -Name ExampleRPC -
VmId “/subscriptions/{SubscriptionId}/resourcegroups/
```

```
ExampleRG/providers/microsoft.compute/virtualmachines/Example-vm-1” -
Location “WestEurope”
```

Step 2: Create a VM restore point

Create a VM restore point with the New-AzRestorePoint cmdlet as shown below:

```
New-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName
ExampleRPC -Name ExampleRP
```

To create a crash consistent restore point set the optional parameter "ConsistencyMode" to "CrashConsistent". This feature is currently in preview.

Exclude disks from the restore point

Exclude certain disks that you do not want to be a part of the restore point with the `-DisksToExclude` parameter, as follows:

```
New-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName
ExampleRPC -Name ExampleRP -DisksToExclude
“/subscriptions/{SubscriptionId}/resourcegroups/
ExampleRG/providers/Microsoft.Compute/disks/example-vm-1-data_disk_1”
```

Step 3: Track the status of the VM restore point creation

You can track the progress of the VM restore point creation using the Get-AzRestorePoint cmdlet, as follows:

```
Get-AzRestorePoint -ResourceGroupName ExampleRG -RestorePointCollectionName
ExampleRPC -Name ExampleRP
```

Restore a VM from VM restore point

To restore a VM from a VM restore point, first restore individual disks from each disk restore point. You can also use the ARM template to restore a full VM along with all the disks.

```
# Create Disks from disk restore points
$restorePoint = Get-AzRestorePoint -ResourceGroupName ExampleRG -
RestorePointCollectionName ExampleRPC -Name ExampleRP

$osDiskRestorePoint =
$restorePoint.SourceMetadata.StorageProfile.OsDisk.DiskRestorePoint.Id
$dataDisk1RestorePoint =
$restorePoint.sourceMetadata.storageProfile.dataDisks[0].diskRestorePoint.id
$dataDisk2RestorePoint =
$restorePoint.sourceMetadata.storageProfile.dataDisks[1].diskRestorePoint.id

New-AzDisk -DiskName “ExampleOSDisk” (New-AzDiskConfig  -Location eastus -
CreateOption Restore -SourceResourceId $osDiskRestorePoint) -
ResourceGroupName ExampleRg

New-AzDisk -DiskName “ExampleDataDisk1” (New-AzDiskConfig  -Location eastus
-CreateOption Restore -SourceResourceId $dataDisk1RestorePoint) -
ResourceGroupName ExampleRg

New-AzDisk -DiskName “ExampleDataDisk2” (New-AzDiskConfig  -Location eastus
-CreateOption Restore -SourceResourceId $dataDisk2RestorePoint) -
ResourceGroupName ExampleRg
```

After you create the disks, create a new VM and attach these restored disks to the newly created VM.

Create virtual machine restore points using Azure portal

Article • 08/22/2024

You can create virtual machine restore points through the Azure portal. You can protect your data and guard against extended downtime by creating VM restore points at regular intervals. This article shows you how to create VM restore points using the Azure portal. Alternatively, you can create VM restore points using the Azure CLI or using PowerShell.

In this tutorial, you learn how to:

- ✓ Create a VM restore point collection
- ✓ Create a VM restore point
- ✓ Track the progress of Copy operation
- ✓ Restore a VM

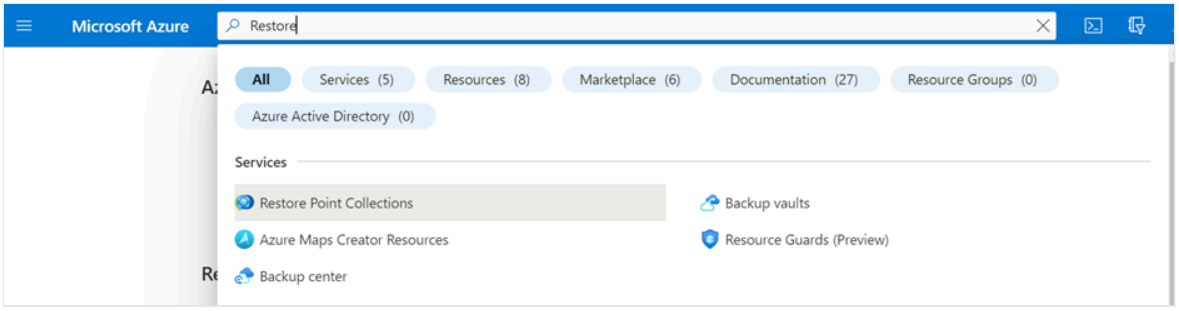
Prerequisites

- Learn more about the support requirements and limitations before creating a restore point.

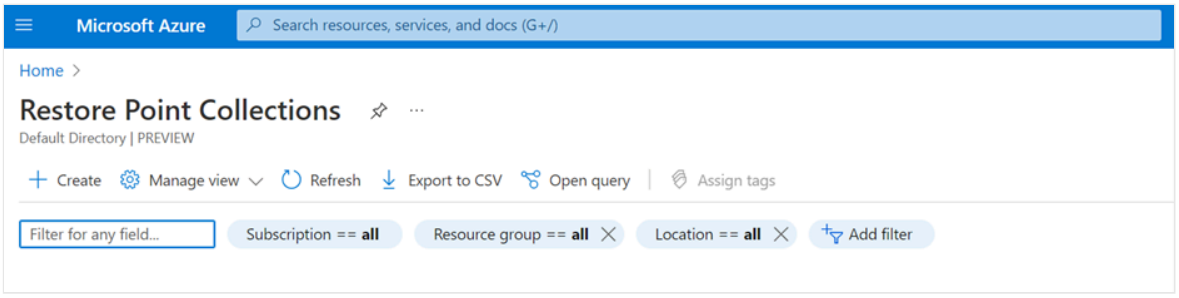
Step 1: Create a VM restore point collection

Use the following steps to create a VM restore points collection:

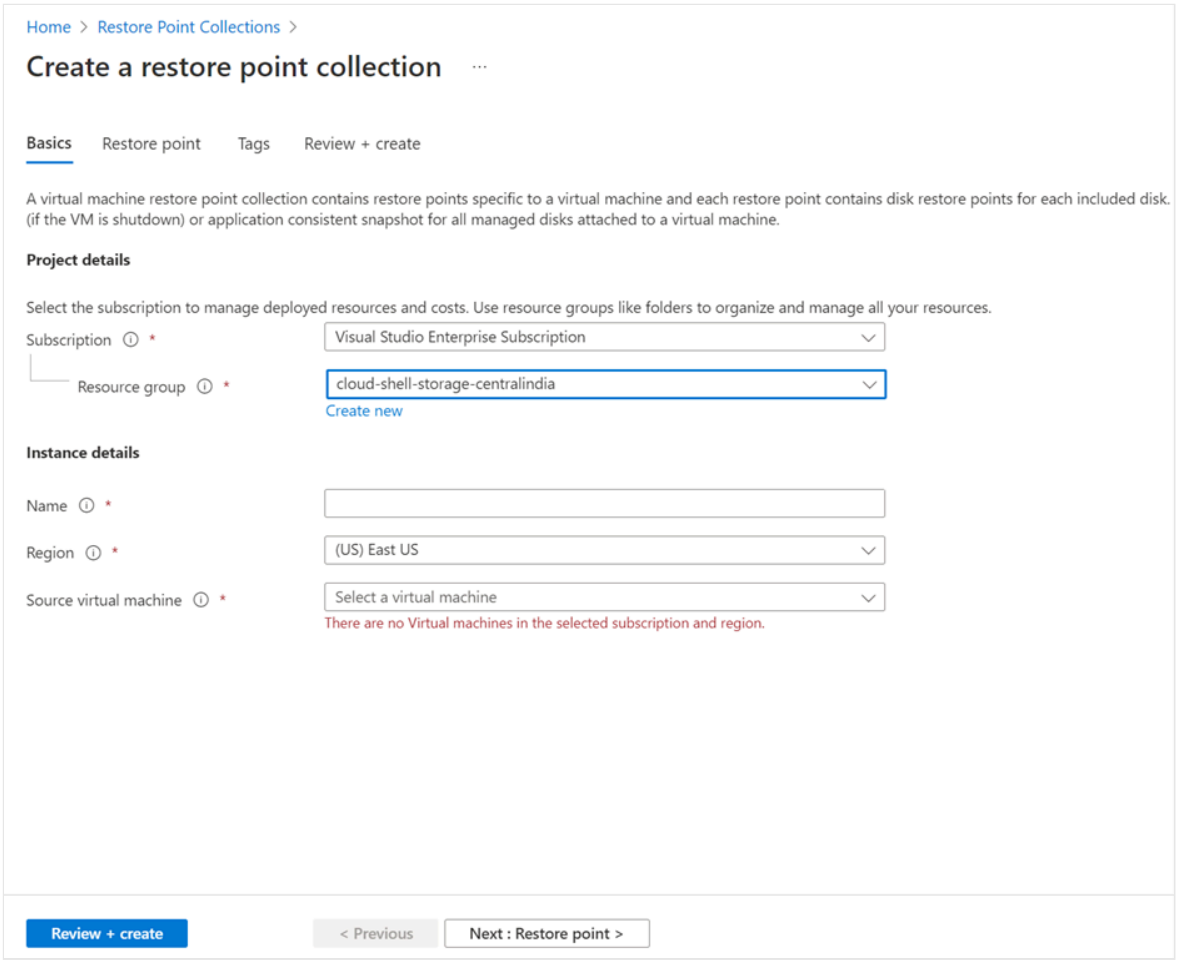
1. Sign in to the Azure portal.
2. In the Search box, enter **Restore Point Collections**.



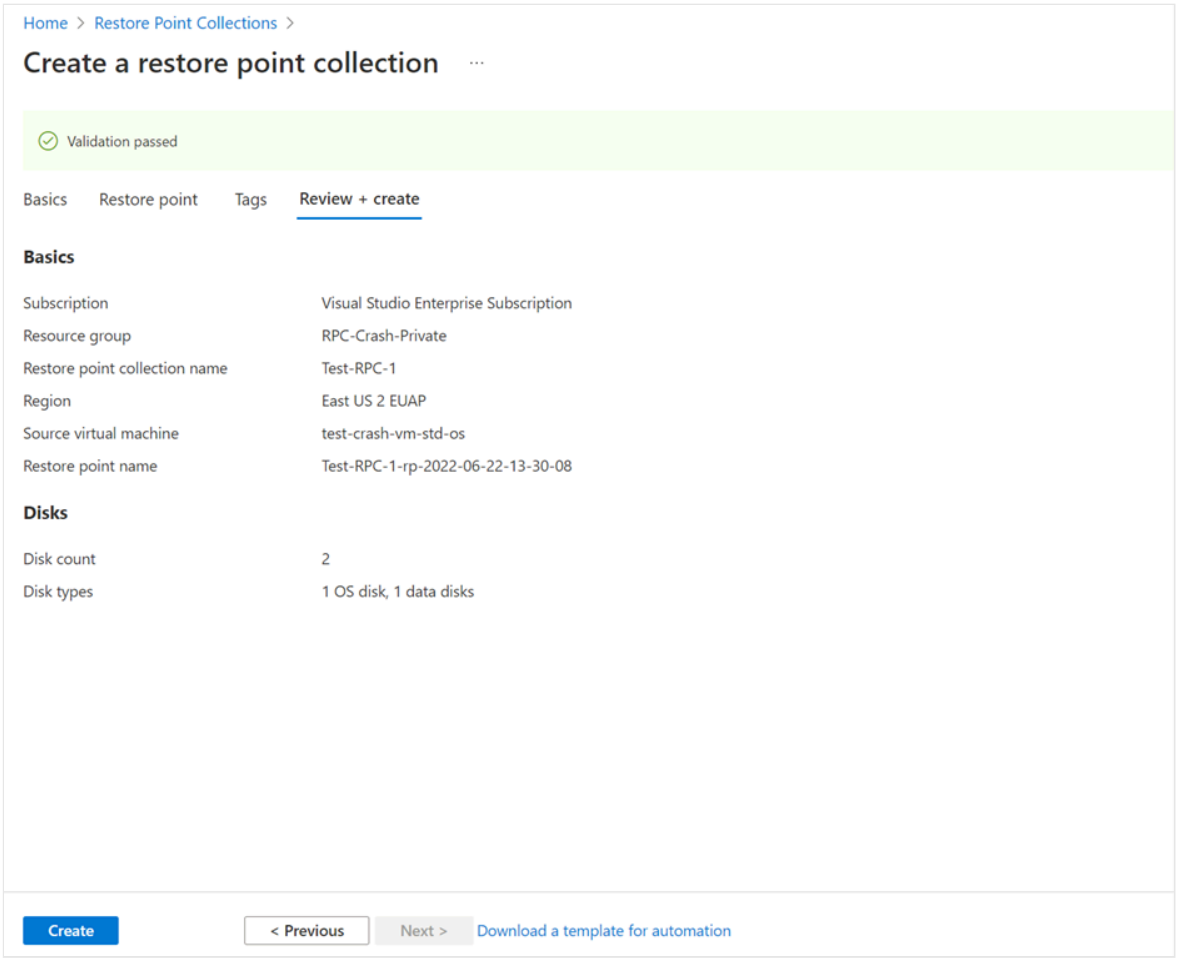
3. Select + **Create** to create a new Restore Point Collection.



4. Enter the details and select the VM for which you want to create a restore point collection.



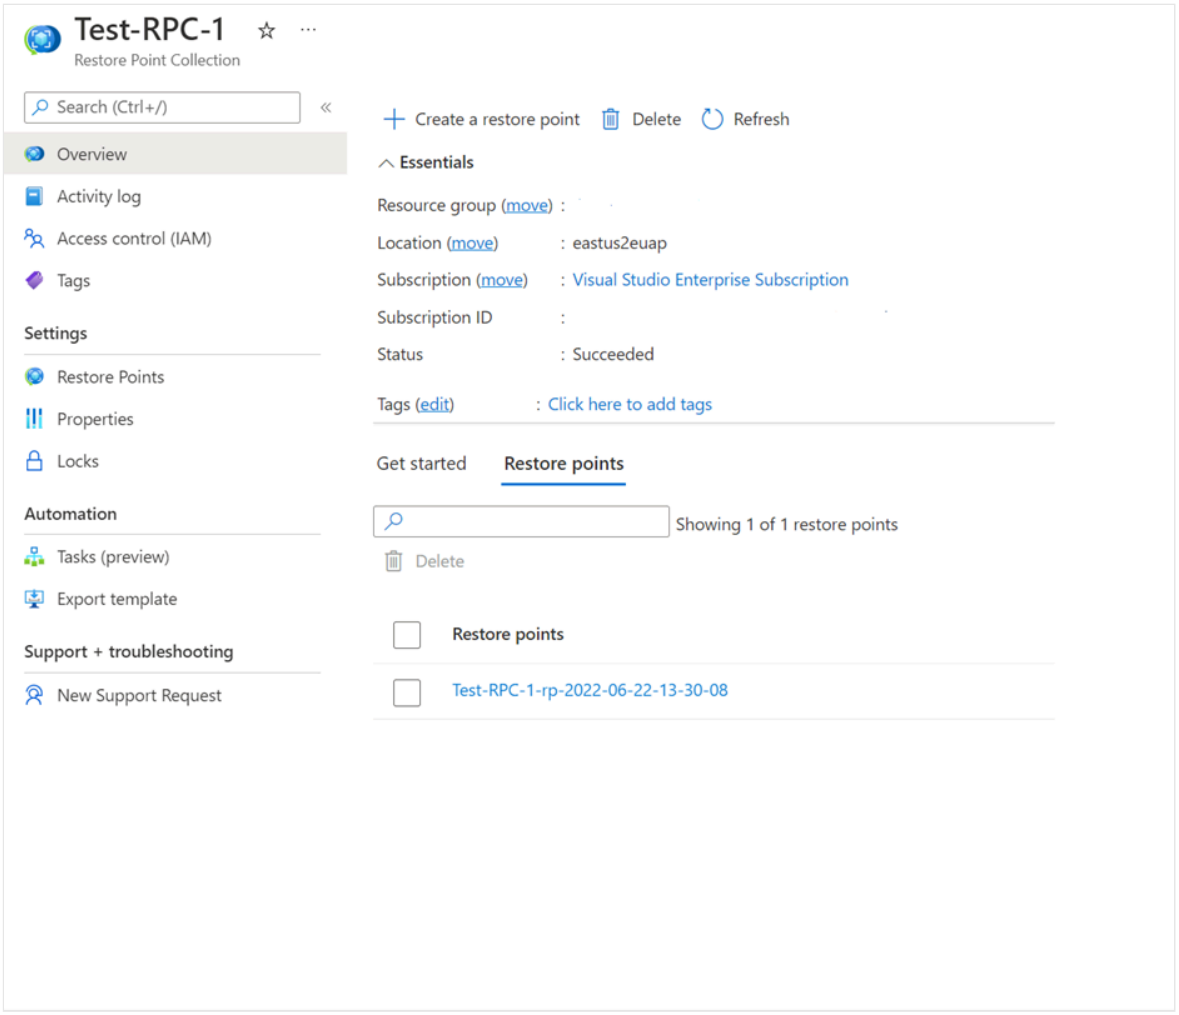
5. Select **Next: Restore Point** to create your first restore point or select **Review + Create** to create an empty restore point collection.



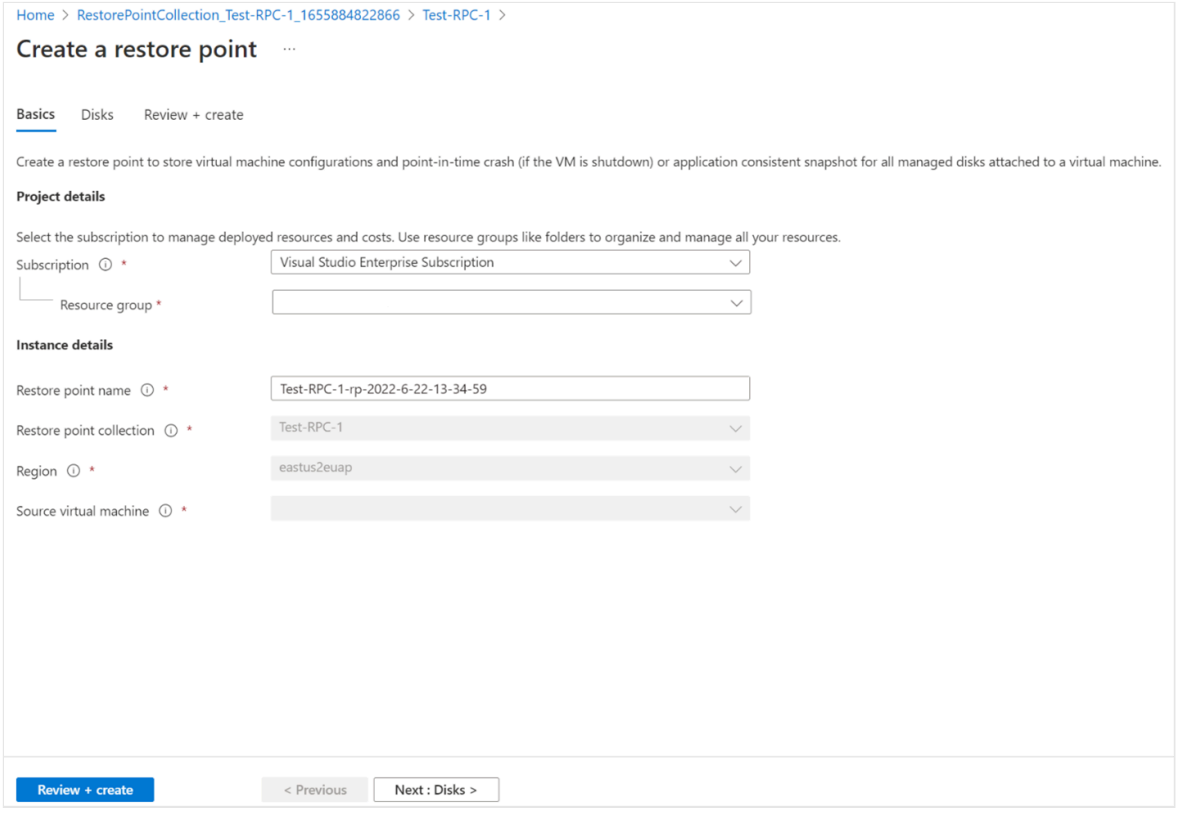
Step 2: Create a VM restore point

Use the following steps to create a VM restore point:

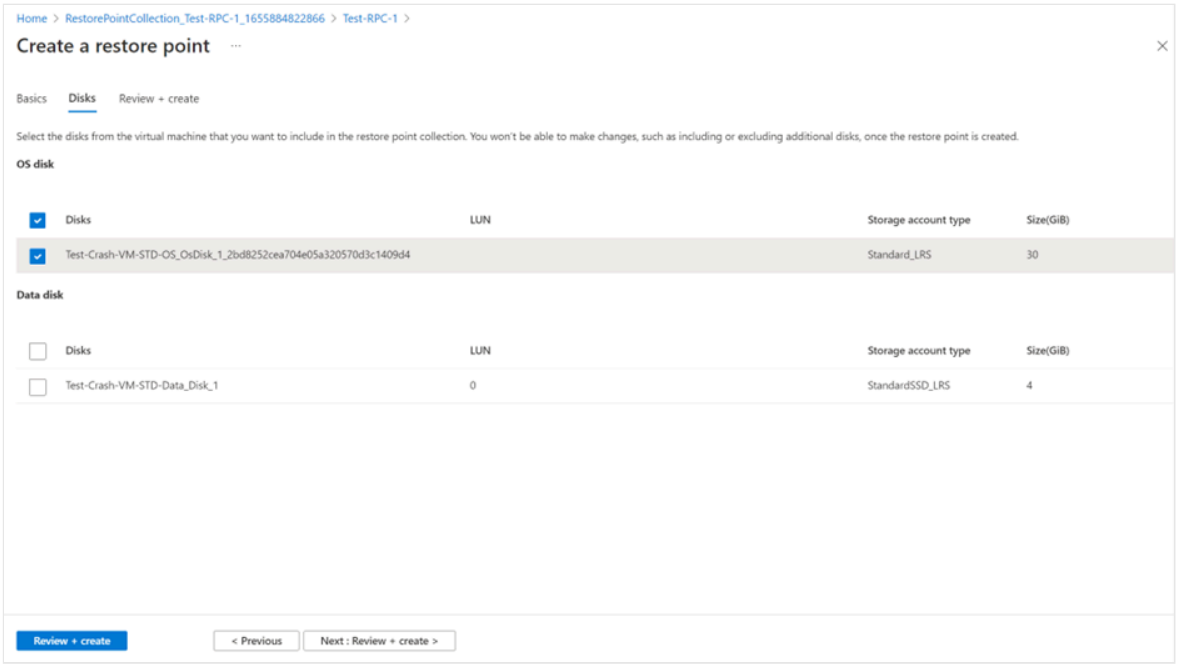
1. Navigate to the restore point collection where you want to create restore points and select + **Create a restore point** to create new restore point for the VM.



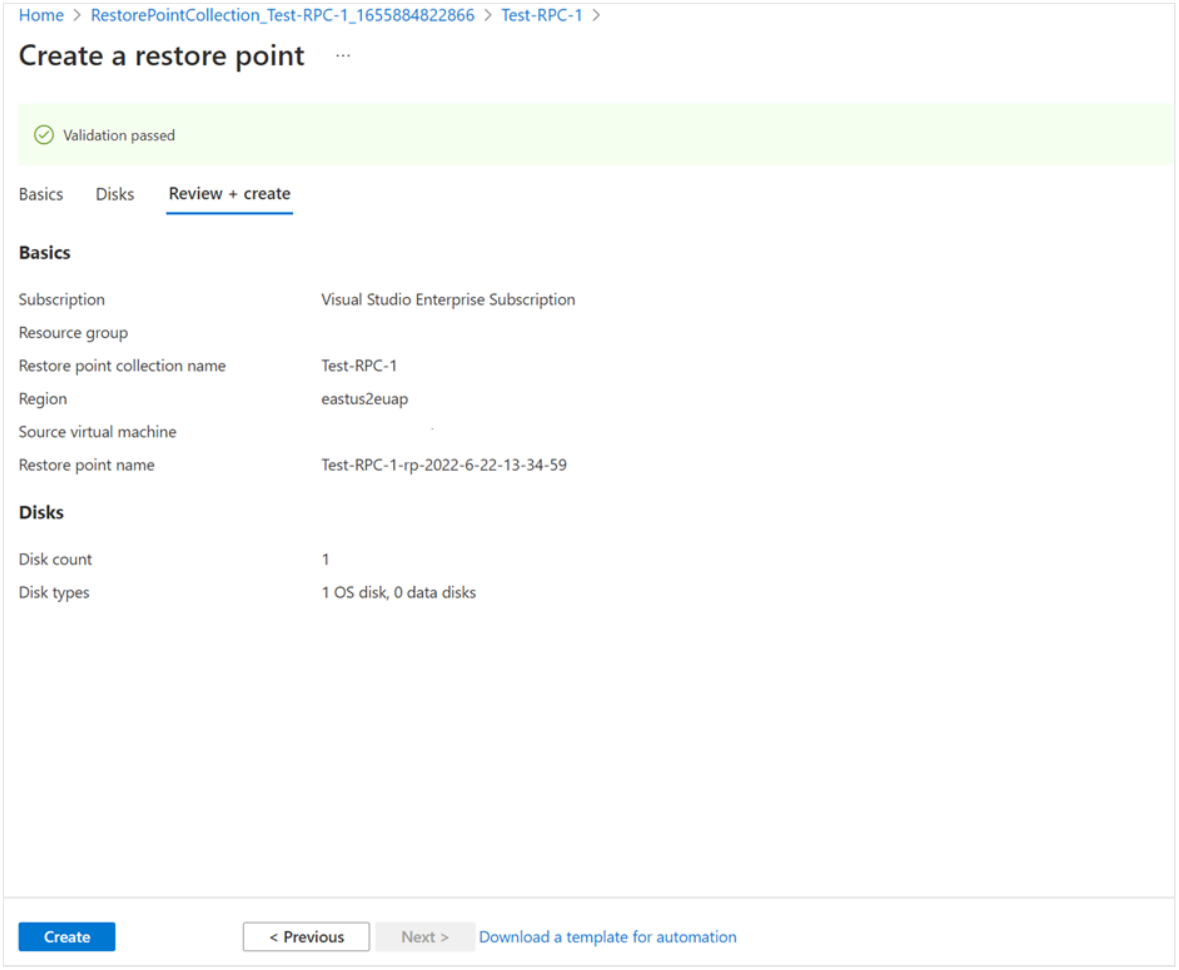
2. Enter a name for the restore point and other required details and select **Next: Disks >**.



3. Select the disks to be included in the restore point.

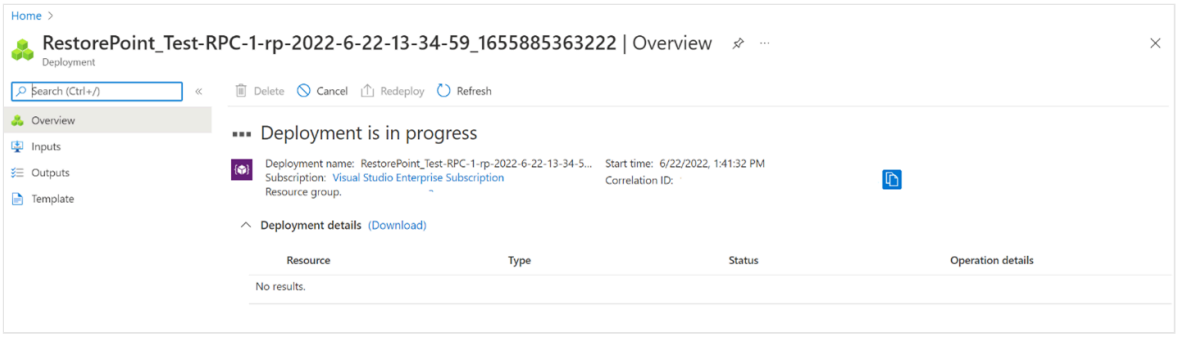


4. Select **Review + create** to validate the settings. Once validation is completed, select **Create** to create the restore point.



Step 3: Track the status of the VM restore point creation

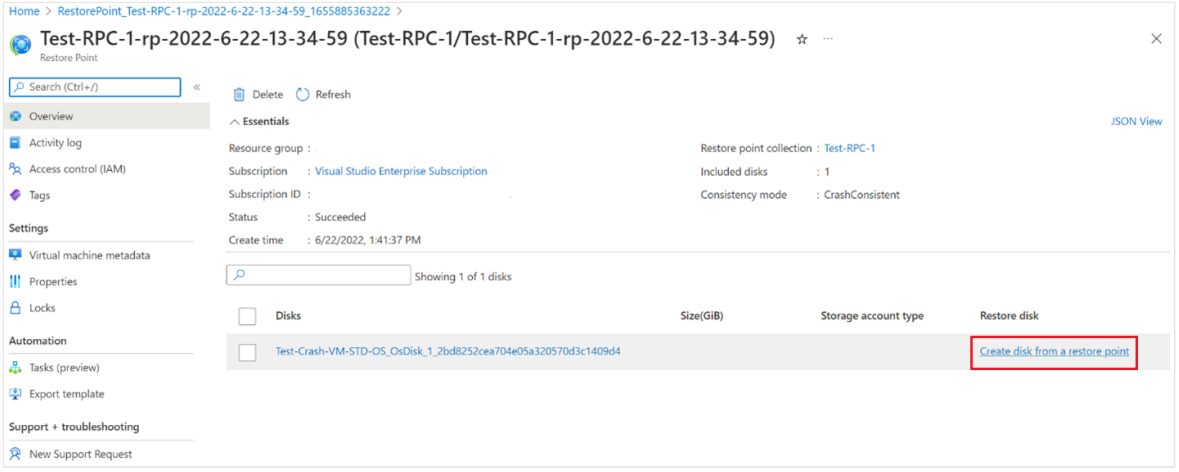
1. Select the notification to track the progress of the restore point creation.



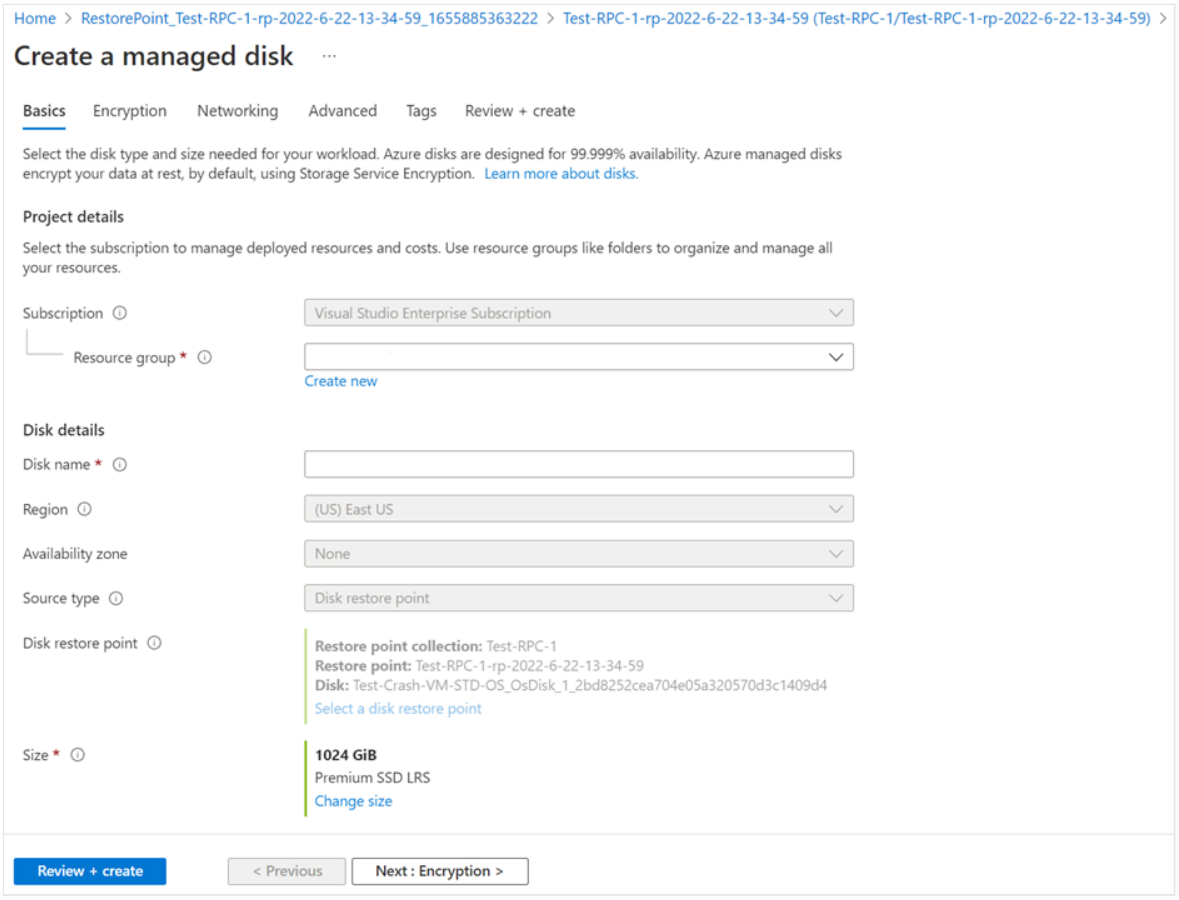
Restore a VM from a restore point

To restore a VM from a VM restore point, first restore individual disks from each disk restore point. You can also use the ARM template to restore a VM along with all the disks.

1. Select **Create a disk from a restore point** to restore a disk from a disk restore point. Do this for all the disks that you want to restore.



2. Enter the details in the **Create a managed disk** dialog to create disks from the restore points. Once the disks are created, create a new VM and attach these restored disks to the newly created VM.



Next steps

Learn more about Backup and restore options for virtual machines in Azure.

Cross-region copy of VM restore points

Article • 08/22/2024

In this article, you learn how to copy virtual machine (VM) restore points to another region.

Prerequisites

To copy a restore point across a region, you need to precreate a `restorePointCollection` resource in the target region.

Learn more about cross-region copy and its limitation before you copy restore points.

Create a restore point collection in a target region

The first step in copying an existing VM restore point from one region to another is to create a `restorePointCollection` resource in the target region by referencing `restorePointCollection` from the source region.

URI request

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/restorePointCollections/{rest
orePointCollectionName}&api-version={api-version}
```

Request body

```
{
    "name": "name of target restorePointCollection resource",
    "location": "location of target restorePointCollection resource",
    "tags": {
        "department": "finance"
    },
    "properties": {
         "source": {
               "id":
"/subscriptions/{subid}/resourceGroups/{resourceGroupName}/providers/microso
```

```
ft.compute/restorePointCollections/{restorePointCollectionName}"
          }
    }
}
```

Response

The request response includes a status code and a set of response headers.

Status code

The operation returns 201 during creation and 200 during the update.

Response body

```
{
    "name": "name of the copied restorePointCollection resource",
    "id": "CSM Id of copied restorePointCollection resource",
    "type": "Microsoft.Compute/restorePointCollections",
    "location": "location of the copied restorePointCollection resource",
    "tags": {
        "department": "finance"
    },
    "properties": {
        "source": {
            "id":
"/subscriptions/{subid}/resourceGroups/{resourceGroupName}/providers/microso
ft.compute/restorePointCollections/{restorePointCollectionName}",
            "location": "location of source RPC"
        }
    }
}
```

Create a VM restore point in a target region

The next step is to trigger the copy of a restore point in the target `RestorePointCollection` resource by referencing the restore point in the source region that needs to be copied.

URI request

```
PUT
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/restorePointCollections/{rest
orePointCollectionName}/restorePoints/{restorePointName}&api-version={api-
version}
```

Request body

```
{
    "name": "name of the restore point resource",
    "properties": {
        "sourceRestorePoint": {
            "id":
"/subscriptions/{subid}/resourceGroups/{resourceGroupName}/providers/microso
ft.compute/restorePointCollections/{restorePointCollectionName}/restorePoint
s/{restorePointName}"
        }
    }
}
```

> ⓘ **Note**
>
> The location of `sourceRestorePoint` is inferred from that of the source `RestorePointCollection`.

Response

The request response includes a status code and a set of response headers.

Status code

This operation is long running, so the operation returns 201 during creation. The client is expected to poll for the status by using the operation. Both the `location` and `Azure-AsyncOperation` headers are provided for this purpose.

During restore point creation, `ProvisioningState` appears as `Creating` in the GET restore point API response. If creation fails, `ProvisioningState` appears as `Failed`. `ProvisioningState` is set to `Succeeded` when the data copy across regions is initiated.

> **Note**
>
> You can track the copy status by calling GET instance view (`?$expand=instanceView`) on the target VM restore point. For steps on how to do this, see the section "Get the VM restore points Copy/Replication status." The VM restore point is considered usable (can be used to restore a VM) only when a copy of all the disk restore points are successful.

Response body

```
{
    "id": "CSM Id of the restore point",
    "name": "name of the restore point",
    "properties": {
        "optionalProperties": "opaque bag of properties to be passed to
extension",
        "sourceRestorePoint": {
            "id":
"/subscriptions/{subid}/resourceGroups/{resourceGroupName}/providers/microso
ft.compute/restorePointCollections/{restorePointCollectionName}/restorePoint
s/{restorePointName}"
        },
        "consistencyMode": "CrashConsistent | FileSystemConsistent |
ApplicationConsistent",
        "sourceMetadata": {
            "vmId": "Unique Guid of the VM from which the restore point was
created",
            "location": "source VM location",
            "hardwareProfile": {
                "vmSize": "Standard_A1"
            },
            "osProfile": {
                "computername": "",
                "adminUsername": "",
                "secrets": [
                    {
                        "sourceVault": {
                            "id":
"/subscriptions/<subId>/resourceGroups/<rgName>/providers/Microsoft.KeyVault
/vaults/<keyvault-name>"
                        },
                        "vaultCertificates": [
                            {
                                "certificateUrl": "https://<keyvault-
name>.vault.azure.net/secrets/<secret-name>/<secret-version>",
                                "certificateStore": "certificateStoreName on
Windows"
```

```
                        }
                    ]
                }
            ],
            "customData": "",
            "windowsConfiguration": {
                "provisionVMAgent": "true|false",
                "winRM": {
                    "listeners": [

Get the VM restore points Copy/Replication status

After the copy of VM restore points is initiated, you can track the copy status by calling the GET instance view (`?$expand=instanceView`) on the target VM restore point.

URI request

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Compute/restorePointCollections/{rest
orePointCollectionName}/restorePoints/{restorePointName}?
$expand=instanceView&api-version={api-version}
```

Response

```
{

Support matrix for VM restore points

Summarize this article for me

This article summarizes the support matrix and limitations of using VM restore points.

VM restore points support matrix

The following table summarizes the support matrix for VM restore points.

Expand table

Scenarios	Supported by VM restore points
VMs using Managed disks	Yes
VMs using unmanaged disks	No
VM sizes	**Crash consistency** is supported for VM SKUs that support Premium storage. Crash-consistent restore points created for Intel V6+ (Dsv6-series, Edsv6-series, Esv6-series, etc.) and AMD V7+ (Dasv7-series, Dadsv7-series, Easv7-series, Faldsv7-series, etc.) Virtual Machines (VMs) with **more than one data disk might not be consistent across disks**. **Application consistency** is supported for all VM SKUs.
VMs using Ultra Disks	Yes. Supported for application consistency. Not supported for crash consistency. Exclude these disks and create a VM restore point when using crash consistency.
VMs using Premium SSD v2 disks	Yes. Supported for application consistency. Not supported for crash consistency. Exclude these disks and create a VM restore point when using crash consistency.
VMs using Ephemeral OS Disks	No. Exclude these disks and create a VM restore point.
VMs using shared disks	No. Exclude these disks and create a VM restore point.
VMs with extensions	Yes
VMs with trusted launch OS disk	Yes
Data disks restored from Trusted launch enabled OS Disk	No
Confidential VMs	Supported for application consistency only with size v6-series in UAE North and Korea Central (**preview**) v5-series isn't supported. Not supported for crash consistency.

Scenarios	Supported by VM restore points
Generation 2 VMs (UEFI boot)	Yes
VMs with NVMe disks (Storage optimized - Lsv2-series)	Yes for **Application consistent**. **Crash-consistent** restore points created for Intel V6+ (Dsv6-series, Edsv6-series, Esv6-series, etc.) and AMD V7+ (Dasv7-series, Dadsv7-series, Easv7-series, Faldsv7-series, etc.) Virtual Machines (VMs) with more than one data disk might not be consistent across disks.
VMs in Proximity placement groups	Yes
VMs in an availability set	Yes. You can create VM restore points for individual VMs within an availability set. You need to create restore points for all the VMs within an availability set to protect an entire availability set instance.
VMs inside VMSS with uniform orchestration	No
VMs inside VMSS with flexible orchestration	Yes. You can create VM restore points for individual VMs within the virtual machine scale set flex. However, you need to create restore points for all the VMs within the virtual machine scale set flex to protect an entire virtual machine scale set flex instance.
Spot VMs (Low priority VMs)	Yes
VMs with dedicated hosts	Yes
VMs with Host caching enabled	Yes
VMs created from marketplace images	Yes
VMs created from custom images	Yes
VM with HUB (Hybrid Use Benefit) license	Yes
VMs migrated from on-prem using Azure Migrate	Yes
VMs with RBAC policies	Yes
Temporary disk in VMs	Yes. You can create VM restore point for VMs with temporary disks. However, the restore points created don't contain the data from the temporary disks.
VMs with Standard HDDs	Yes
VMs with Standard SSDs	Yes

Scenarios	Supported by VM restore points
VMs with Premium SSDs	Yes
VMs with ZRS disks	Yes
VMs with server-side encryption using service-managed keys	Yes. The encryption of source disk won't be enabled on the restore point.
VMs with server-side encryption using customer-managed keys	Yes. The encryption of source disk won't be enabled on the restore point.
VMs with double encryption at rest	Yes. The encryption of source disk won't be enabled on the restore point.
VMs with Host based encryption enabled with PMK/CMK/Double encryption	Yes. The encryption of source disk won't be enabled on the restore point.
VMs with ADE (Azure Disk Encryption)	Yes. The encryption of source disk won't be enabled on the restore point.
VMs using Accelerated Networking	Yes
Azure Boost compatible Virtual machine sizes	Yes for **Application consistent**. **Crash-consistent** restore points created for Intel V6+ (Dsv6-series, Edsv6-series, Esv6-series, etc.) and AMD V7+ (Dasv7-series, Dadsv7-series, Easv7-series, Faldsv7-series, etc.) Virtual Machines (VMs) with more than one data disk may not be consistent across disks.
Minimum Frequency at which App consistent restore point can be taken	3 hours
Minimum Frequency at which crash consistent restore points can be taken	1 hour
API version for Application consistent restore point	2021-03-01 or later
API version for Crash consistent restore point	2021-07-01 or later

> ⓘ **Note**

Restore Points (App consistent or crash consistent) can be created by customer at the minimum supported frequency as mentioned above. Taking restore points at a frequency lower than supported would result in failure.

Operating system support for application consistency

Windows

The following Windows operating systems are supported when creating restore points for Azure VMs running on Windows.

- Windows 10 Client (64 bit only)
- Windows Server 2022 (Datacenter/Datacenter Core/Standard)
- Windows Server 2019 (Datacenter/Datacenter Core/Standard)
- Windows Server 2016 (Datacenter/Datacenter Core/Standard)
- Windows Server 2012 R2 (Datacenter/Standard)
- Windows Server 2012 (Datacenter/Standard)
- OS that have reached extended security update won't be supported. Check your product's lifecycle here

Restore points don't support 32-bit operating systems.

Linux

For Azure VM Linux VMs, restore points support the list of Linux distributions endorsed by Azure. Note the following:

- Restore points don't support Core OS Linux.
- Restore points don't support 32-bit operating systems.
- Other bring-your-own Linux distributions might work as long as the Azure VM agent for Linux is available on the VM, and as long as Python is supported.
- Restore points don't support a proxy-configured Linux VM if it doesn't have Python version 2.7 or higher installed.
- Restore points don't back up NFS files that are mounted from storage, or from any other NFS server, to Linux or Windows machines. It only backs up disks that are locally attached to the VM.

Operating system support for crash consistency

- All Operating systems are supported.

Other limitations

- Restore points are supported only for managed disks.
- Ephemeral OS disks, and Shared disks aren't supported via both consistency modes.
- Restore points APIs require an API of version 2021-03-01 or later for application consistency.
- Restore points APIs require an API of version 2021-03-01 or later for crash consistency.
- A maximum of 10,000 restore point collections can be retained at per subscription per region level.
- A maximum of 500 VM restore points can be retained at any time for a VM, irrespective of the number of restore point collections.
- Concurrent creation of restore points for a VM isn't supported.
- Movement of virtual machines between resource groups or subscriptions is supported when VM has restore points. New restore point creation will fail on the previous VM as the VM no longer exists after the movement. You need to clean up the restore point collection and restore points of the old VM if no longer needed.

Confidential Virtual Machines (Preview)

Expand table

Scenarios	Supported by VM restore points
Consistency type	Application consistent restore points
Regions supported	UAE North and Korea Central
VM Sizes	v6-series is supported. v5-series isn't supported.
Key rotation	Supported. When key rotation occurs on a confidential virtual machine, the keys for the VM disks, related restore points, and snapshots update automatically. **Known issue:** The key rotation in this preview release might have performance issues or fail in the following scenarios: - More than 40 disks are attached to one DES when (only) restore points are associated with these disks. If you also directly create disk snapshots outside of Azure backup for these disks connected to the same DES, this lowers the safe threshold of 40 disks to DES mapping. **Recommendation:** Keep the number of disks connected to each DES to a minimum until the issue is resolved.

Scenarios	Supported by VM restore points
Prerequisites	Before you configure backup for CVM, ensure that the following prerequisites are met: Register for the preview feature in your Azure subscription - Name: `RestorePointSupportForConfidentialVMV2` Provider: `Microsoft.Compute`. The registration is autoapproved. You can follow the steps here to do this on the portal. You can also run the following PowerShell cmdlet. `azurepowershell-interactive Register-AzProviderFeature -FeatureName "RestorePointSupportForConfidentialVMV2" -ProviderNamespace "Microsoft.Compute"` Identify or create a Confidential VM (CVM) in a supported region. See the supported regions.

> **Note**
>
> Public preview of cross-region copy of VM restore points is available, with the following limitations:
>
> - Private links aren't supported when copying restore points across regions or creating restore points in a region other than the source VM.
> - Customer-managed key encrypted restore points, when copied to a target region or created directly in the target region are created as platform-managed key encrypted restore points.
> - No portal support for cross region copy and cross region creation of restore points

Next steps

- Learn how to create VM restore points using CLI, Azure portal, and PowerShell.

Troubleshoot restore point failures: Issues with the agent or extension

Article • 08/22/2024

This article provides troubleshooting steps that can help you resolve restore point errors related to communication with the VM agent and extension.

If your Azure issue is not addressed in this article, visit the Azure forums on Microsoft Q & A and Stack Overflow. You can post your issue in these forums, or post to @AzureSupport on Twitter. You also can submit an Azure support request. To submit a support request, on the Azure support page, select **Get support**.

Step-by-step guide to troubleshoot restore point failures

Most common restore point failures can be resolved by following the troubleshooting steps listed below:

Step 1: Check the health of Azure VM

- **Ensure Azure VM provisioning state is 'Running'**: If the VM provisioning state is in the **Stopped/Deallocated/Updating** state, it interferes with the restore point operation. In the Azure portal, go to **Virtual Machines** > **Overview** and ensure the VM status is **Running** and retry the restore point operation.
- **Review pending OS updates or reboots**: Ensure there are no pending OS updates or pending reboots on the VM.

Step 2: Check the health of Azure VM Guest Agent service

Ensure Azure VM Guest Agent service is started and up-to-date:

On a Windows VM

- Navigate to **services.msc** and ensure **Windows Azure VM Guest Agent service** is up and running. Also, ensure the latest version is installed. Learn more.
- The Azure VM Agent is installed by default on any Windows VM deployed from an Azure Marketplace image from the portal, PowerShell, Command Line

Interface, or an Azure Resource Manager template. A manual installation of the Agent may be necessary when you create a custom VM image that's deployed to Azure.

- Review the support matrix to check if VM runs on the supported Windows operating system.

Step 3: Check the health of Azure VM Extension

- **Ensure all Azure VM Extensions are in 'provisioning succeeded' state**: If any extension is in a failed state, then it can interfere with the restore point operation.
  - In the Azure portal, go to **Virtual machines** > **Settings** > **Extensions** > **Extensions status** and check if all the extensions are in **provisioning succeeded** state.
  - Ensure all extension issues are resolved and retry the restore point operation.
- **Ensure COM+ System Application** is up and running. Also, the **Distributed Transaction Coordinator service** should be running as **Network Service account**.

Follow the troubleshooting steps in troubleshoot COM+ and MSDTC issues in case of issues.

Step 4: Check the health of Azure VM Snapshot Extension

Restore points use the VM Snapshot Extension to take an application consistent snapshot of the Azure virtual machine. Restore points install the extension as part of the first restore point creation operation.

- **Ensure VMSnapshot extension isn't in a failed state**: Follow the steps in Troubleshooting to verify and ensure the Azure VM snapshot extension is healthy.

- **Check if antivirus is blocking the extension**: Certain antivirus software can prevent extensions from executing.

  At the time of the restore point failure, verify if there are log entries in **Event Viewer Application logs** with *faulting application name: IaaSBcdrExtension.exe*. If you see entries, the antivirus configured in the VM could be restricting the execution of the VMSnapshot extension. Test by excluding the following directories in the antivirus configuration and retry the restore point operation.
  - `C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot`
  - `C:\WindowsAzure\Logs\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot`

- **Check if network access is required**: Extension packages are downloaded from the Azure Storage extension repository and extension status uploads are posted to Azure Storage. Learn more.
  - If you're on a non-supported version of the agent, you need to allow outbound access to Azure storage in that region from the VM.
  - If you've blocked access to `168.63.129.16` using the guest firewall or with a proxy, extensions will fail regardless of the above. Ports 80, 443, and 32526 are required. Learn more.

- **Ensure DHCP is enabled inside the guest VM**: This is required to get the host or fabric address from DHCP for the restore point to work. If you need a static private IP, you should configure it through the **Azure portal**, or **PowerShell** and make sure the DHCP option inside the VM is enabled. Learn more.

- **Ensure the VSS writer service is up and running**: Follow these steps to troubleshoot VSS writer issues.

Common issues

DiskRestorePointUsedByCustomer - There is an active shared access signature outstanding for disk restore point

Error code: DiskRestorePointUsedByCustomer

Error message: There is an active shared access signature outstanding for disk restore point. Call EndGetAccess before deleting the restore point.

You can't delete a restore point if there are active Shared Access Signatures (SAS) on any of the underlying disk restore points. End the shared access on the disk restore points and retry the operation.

OperationNotAllowed - Changes were made to the Virtual Machine while the operation 'Create Restore Point' was in progress.

Error code: OperationNotAllowed

Error message: Changes were made to the Virtual Machine while the operation 'Create Restore Point' was in progress. Operation Create Restore Point cannot be completed at this time. Please try again later.

Restore point creation fails if there are changes being made in parallel to the VM model, for example, a new disk being attached or an existing disk being detached. This is to ensure data integrity of the restore point that is created. Retry creating the restore point once the VM model has been updated.

OperationNotAllowed - Operation 'Create Restore Point' is not allowed as disk(s) have not been allocated successfully.

Error code: OperationNotAllowed

Error message: Operation 'Create Restore Point' is not allowed as disk(s) have not been allocated successfully. Please exclude these disk(s) using excludeDisks property and retry.

If any one of the disks attached to the VM isn't allocated properly, the restore point fails. You must exclude these disks before triggering creation of restore points for the VM. If you're using ARM processor API to create a restore point, to exclude a disk, add its identifier to the excludeDisks property in the request body. If you're using CLI, PowerShell, or Portal, set the respective parameters.

OperationNotAllowed - Creation of Restore Point of a Virtual Machine with Shared disks is not supported.

Error code: VMRestorePointClientError

Error message: Creation of Restore Point of a Virtual Machine with Shared disks is not supported. You may exclude this disk from the restore point via excludeDisks property.

Restore points are currently not supported for shared disks. You need to exclude these disks before triggering creation of restore point for the VM. If you are using ARM processor API to create restore point, to exclude a disk, add its identifier to the excludeDisks property in the request body. If you are using CLI, PowerShell, or Portal, follow the respective steps.

VMAgentStatusCommunicationError - VM agent unable to communicate with compute service

Error code: VMAgentStatusCommunicationError

Error message: VM has not reported status for VM agent or extensions.

The Azure VM agent might be stopped, outdated, in an inconsistent state, or not installed. These states prevent the creation of restore points.

- In the Azure portal, go to **Virtual Machines** > **Settings** > **Properties** and ensure that the VM **Status** is **Running** and **Agent status** is **Ready**. If the VM agent is stopped or is in an inconsistent state, restart the agent.
  - Restart the Guest Agent for Windows VMs.
  - Restart the Guest Agent for Linux VMs.
- In the Azure portal, go to **Virtual Machines** > **Settings** > **Extensions** and ensure all extensions are in **provisioning succeeded** state. If not, follow these steps to resolve the issue.

VMRestorePointInternalError - Restore Point creation failed due to an internal execution error while creating VM snapshot. Please retry the operation after some time.Internal

Error code: VMRestorePointInternalError

Error message: Restore Point creation failed due to an internal execution error while creating VM snapshot. Please retry the operation after some time.

After you trigger a restore point operation, the compute service starts the job by communicating with the VM backup extension to take a point-in-time snapshot. Any of the following conditions might prevent the snapshot from being triggered. If the snapshot isn't triggered, restore point creation will fail. Complete the following troubleshooting steps in the order listed, and then retry your operation:

Cause 1: **The agent is installed in the VM, but it's unresponsive (for Windows VMs)**

Cause 2: **The agent installed in the VM is out of date (for Linux VMs)**

Cause 3: **The snapshot status can't be retrieved, or a snapshot can't be taken**

Cause 4: **VM-Agent configuration options aren't set (for Linux VMs)**

Cause 5: **Application control solution is blocking IaaSBcdrExtension.exe**

This error could also occur when one of the extension failures puts the VM into provisioning failed state. If the above steps didn't resolve your issue, then do the following:

In the Azure portal, go to **Virtual Machines** > **Settings** > **Extensions** and ensure all extensions are in **provisioning succeeded** state. Learn more about Provisioning states.

- If any extension is in a failed state, it can interfere with the restore point operation. Ensure the extension issues are resolved and retry the restore point operation.
- If the VM provisioning state is in an updating state, it can interfere with the restore point operation. Ensure that it's healthy and retry the restore point operation.

VMRestorePointClientError - Restore Point creation failed due to COM+ error.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed due to COM+ error. Please restart windows service "COM+ System Application" (COMSysApp). If the issue persists, restart the VM.

Restore point operations fail if the COM+ service is not running or if there are any errors with this service. Restart the COM+ System Application, and restart the VM and retry the restore point operation.

VMRestorePointClientError - Restore Point creation failed due to insufficient memory available in COM+ memory quota.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed due to insufficient memory available in COM+ memory quota. Please restart windows service "COM+ System Application" (COMSysApp). If the issue persists, restart the VM.

Restore point operations fail if there's insufficient memory in the COM+ service. Restarting the COM+ System Application service and the VM usually frees up the memory. Once restarted, retry the restore point operation.

VMRestorePointClientError - Restore Point creation failed due to VSS Writers in bad state.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed due to VSS Writers in bad state. Restart VSS Writer services and reboot VM.

Restore point creation invokes VSS writers to flush in-memory IOs to the disk before taking snapshots to achieve application consistency. If the VSS writers are in bad state, it

affects the restore point creation operation. Restart the VSS writer service and restart the VM before retrying the operation.

VMRestorePointClientError - Restore Point creation failed due to failure in installation of Visual C++ Redistributable for Visual Studio 2012.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed due to failure in installation of Visual C++ Redistributable for Visual Studio 2012. Please install Visual C++ Redistributable for Visual Studio 2012. If you are observing issues with installation or if it is already installed and you are observing this error, please restart the VM to clean installation issues.

Restore point operations require Visual C++ Redistributable for Visual Studio 2021. Download Visual C++ Redistributable for Visual Studio 2012 and restart the VM before retrying the restore point operation.

VMRestorePointClientError - Restore Point creation failed as the maximum allowed snapshot limit of one or more disk blobs has been reached. Please delete some existing restore points of this VM and then retry.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed as the maximum allowed snapshot limit of one or more disk blobs has been reached. Please delete some existing restore points of this VM and then retry.

The number of restore points across the restore point collections and resource groups for a VM can't exceed 500. To create a new restore point, delete the existing restore points.

VMRestorePointClientError - Restore Point creation failed with the error "COM+ was unable to talk to the Microsoft Distributed Transaction Coordinator".

Error code: VMRestorePointClientError

Error message: Restore Point creation failed with the error "COM+ was unable to talk to the Microsoft Distributed Transaction Coordinator".

Follow these steps to resolve this error:

- Open services.msc from an elevated command prompt
- Make sure that **Log On As** value for **Distributed Transaction Coordinator** service is set to **Network Service** and the service is running.
- If this service fails to start, reinstall this service.

VMRestorePointClientError - Restore Point creation failed due to inadequate VM resources.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed due to inadequate VM resources. Increase VM resources by changing the VM size and retry the operation. To resize the virtual machine, refer https://azure.microsoft.com/blog/resize-virtual-machines/ .

Creating a restore point requires enough compute resource to be available. If you get the above error when creating a restore point, you need resize the VM and choose a higher VM size. Follow the steps in how to resize your VM . Once the VM is resized, retry the restore point operation.

VMRestorePointClientError - Restore point creation failed due to no network connectivity on the virtual machine.

Error code: VMRestorePointClientError

Error message: Restore Point creation failed due to no network connectivity on the virtual machine. Ensure that VM has network access. Either allowlist the Azure datacenter IP ranges or set up a proxy server for network access. For more information, see https://go.microsoft.com/fwlink/?LinkId=800034 . If you are already using proxy server, make sure that proxy server settings are configured correctly.

After you trigger creation of restore point, the compute service starts communicating with the VM snapshot extension to take a point-in-time snapshot. Any of the following conditions might prevent the snapshot from being triggered. If the snapshot isn't triggered, a restore point failure might occur. Complete the following troubleshooting step, and then retry your operation:

[The snapshot status can't be retrieved, or a snapshot can't be taken].(#the-snapshot-status-cant-be-retrieved-or-a-snapshot-cant-be-taken)

VMRestorePointClientError - RestorePoint creation failed since a concurrent 'Create RestorePoint' operation was triggered on the VM.

Error code: VMRestorePointClientError

Error message: RestorePoint creation failed since a concurrent 'Create RestorePoint' operation was triggered on the VM.

Your recent restore point creation failed because there's already an existing restore point being created. You can't create a new restore point until the current restore point is fully created. Ensure the restore point creation operation currently in progress is completed before triggering another restore point creation operation.

To check the restore points in progress, do the following steps:

1. Sign in to the Azure portal, select **All services**. Enter **Recovery Services** and select **Restore point collection**. The list of Restore point collections appears.
2. From the list of Restore point collections, select a Restore point collection in which the restore point is being created.
3. Select **Settings** > **Restore points** to view all the restore points. If a restore point is in progress, wait for it to complete.
4. Retry creating a new restore point.

DiskRestorePointClientError - Keyvault associated with DiskEncryptionSet is not found.

Error code: DiskRestorePointClientError

Error message: Keyvault associated with DiskEncryptionSet not found. The resource may have been deleted due to which Restore Point creation failed. Please retry the operation after re-creating the missing resource with the same name.

If you are creating restore points for a VM that has encrypted disks, you must ensure the keyvault where the keys are stored, is available. We use the same keys to create encrypted restore points.

BadRequest - This request can be made with api-version '2021-03-01' or newer

Error code: BadRequest

Error message: This request can be made with api-version '2022-03-01' or newer.

Restore points are supported only with API version 2022-03-01 or later. If you are using REST APIs to create and manage restore points, use the specified API version when calling the restore point API.

InternalError / InternalExecutionError / InternalOperationError / InternalDiskRestorePointError - An internal execution error occurred. Please retry later.

Error code: InternalError / InternalExecutionError / InternalOperationError / InternalDiskRestorePointError

Error message: An internal execution error occurred. Please retry later.

After you trigger creation of restore point, the compute service starts communicating with the VM snapshot extension to take a point-in-time snapshot. Any of the following conditions might prevent the snapshot from being triggered. If the snapshot isn't triggered, a restore point failure might occur. Complete the following troubleshooting steps in the order listed, and then retry your operation:

- **Cause 1:** **The agent is installed in the VM, but it's unresponsive (for Windows VMs)**.
- **Cause 2:** **The agent installed in the VM is out of date (for Linux VMs)**.
- **Cause 3:** **The snapshot status can't be retrieved, or a snapshot can't be taken**.
- **Cause 4:** **Compute service does not have permission to delete the old restore points because of a resource group lock**.
- **Cause 5**: There's an extension version/bits mismatch with the Windows version you're running, or the following module is corrupt:

  C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot\<extension version>\iaasvmprovider.dll

  To resolve this issue, check if the module is compatible with x86 (32-bit)/x64 (64-bit) version of *regsvr32.exe*, and then follow these steps:

  1. In the affected VM, go to **Control panel** > **Program and features**.
  2. Uninstall **Visual C++ Redistributable x64** for **Visual Studio 2013**.
  3. Reinstall **Visual C++ Redistributable** for **Visual Studio 2013** in the VM. To install, follow these steps:

a. Go to the folder: **C:\Packages\Plugins\Microsoft.Azure.RecoveryServices.VMSnapshot\<LatestVersion>**.

b. Search and run the **vcredist2013_x64** file to install.

4. Retry the restore point operation.

OSProvisioningClientError - Restore points operation failed due to an error. For details, see restore point provisioning error Message details

Error code: OSProvisioningClientError

Error message: OS Provisioning did not finish in the allotted time. This error occurred too many times consecutively from image. Make sure the image has been properly prepared (generalized).

This error is reported from the IaaS VM. Take necessary actions as described in the error message and retry the operation.

AllocationFailed - Restore points operation failed due to an error. For details, see restore point provisioning error Message details

Error code: AllocationFailed

Error message: Allocation failed. If you are trying to add a new VM to an Availability Set or update/resize an existing VM in an Availability Set, please note that such Availability Set allocation is scoped to a single cluster, and it is possible that the cluster is out of capacity. Learn more about improving likelihood of allocation success.

This error is reported from the IaaS VM. Take necessary actions as described in the error message and retry the operation.

Causes and solutions

The agent is installed in the VM, but it's unresponsive (for Windows VMs)

Solution

The VM agent might have been corrupted, or the service might have been stopped. Reinstalling the VM agent helps get the latest version. It also helps restart communication with the service.

1. Determine whether the Microsoft Azure Guest Agent service is running in the VM services (services.msc). Try to restart the Microsoft Azure Guest Agent service and initiate the restore point operation.
2. If the Microsoft Azure Guest Agent service isn't visible in services, in Control Panel, go to **Programs and Features** to determine whether the Microsoft Azure Guest Agent service is installed.
3. If the Microsoft Azure Guest Agent appears in **Programs and Features**, uninstall the Microsoft Azure Guest Agent.
4. Download and install the latest version of the agent MSI. You must have Administrator rights to complete the installation.
5. Verify that the Microsoft Azure Guest Agent services appear in services.
6. Retry the restore point operation.

Also, verify that Microsoft .NET 4.5 is installed in the VM. .NET 4.5 is required for the VM agent to communicate with the service.

The agent installed in the VM is out of date (for Linux VMs)

Solution

Most agent-related or extension-related failures for Linux VMs are caused by issues that affect an outdated VM agent. To troubleshoot this issue, follow these general guidelines:

1. Follow the instructions for updating the Linux VM agent.

   > **Note**
   >
   > We *strongly recommend* that you update the agent only through a distribution repository. We don't recommend downloading the agent code directly from GitHub and updating it. If the latest agent for your distribution is not available, contact distribution support for instructions on how to install it. To check for the most recent agent, go to the Windows Azure Linux agent page in the GitHub repository.

2. Ensure that the Azure agent is running on the VM by running the following command: `ps -e`

If the process isn't running, restart it by using the following commands:

- For Ubuntu/Debian:

```
Bash

sudo systemctl start walinuxagent
```

- For other Linux distributions:

```
Bash

sudo systemctl start waagent
```

3. Configure the auto restart agent.
4. Retry the restore point operation. If the failure persists, collect the following logs from the VM:
   - /var/lib/waagent/*.xml
   - /var/log/waagent.log
   - /var/log/azure/*

If you require verbose logging for waagent, follow these steps:

1. In the `/etc/waagent.conf` file, locate the following line: **Enable verbose logging (y|n)**.
2. Change the **Logs.Verbose** value from *n* to *y*.
3. Save the change, and then restart waagent by completing the steps described earlier in this section.

VM-Agent configuration options are not set (for Linux VMs)

A configuration file (`/etc/waagent.conf`) controls the actions of waagent. Configuration File Options **Extensions.Enable** should be set to **y** and **Provisioning.Agent** should be set to **auto** for restore points to work. For the full list of VM-Agent Configuration File Options, see https://github.com/Azure/WALinuxAgent#configuration-file-options.

Application control solution is blocking IaaSBcdrExtension.exe

If you're running AppLocker (or another application control solution), and the rules are publisher or path based, they may block the **IaaSBcdrExtension.exe** executable from running.

Solution

Exclude the `/var/lib` path or the **IaaSBcdrExtension.exe** executable from AppLocker (or other application control software.)

The snapshot status can't be retrieved, or a snapshot can't be taken

Restore points rely on issuing a snapshot command to the underlying storage account. Restore point can fail either because it has no access to the storage account, or because the execution of the snapshot task is delayed.

Solution

The following conditions might cause the snapshot task to fail:

Expand table

Cause	Solution
The VM status is reported incorrectly because the VM is shut down in Remote Desktop Protocol (RDP).	If you shut down the VM in RDP, check the portal to determine whether the VM status is correct. If it's not correct, shut down the VM in the portal by using the **Shutdown** option on the VM dashboard.
The VM can't get the host or fabric address from DHCP.	DHCP must be enabled inside the guest for restore point to work. If the VM can't get the host or fabric address from DHCP response 245, it can't download or run any extensions. If you need a static private IP, you should configure it through the **Azure portal**, or **PowerShell** and make sure the DHCP option inside the VM is enabled. Learn more about setting up a static IP address with PowerShell.

Remove lock from the recovery point resource group

1. Sign in to the Azure portal.
2. Go to **All Resources**, select the restore point collection resource group.

3. In the **Settings** section, select **Locks** to display the locks.

4. To remove the lock, select **Delete**.

Move Azure resources to a new resource group or subscription

07/29/2025

This article explains how to move Azure resources between resource groups within the same subscription or across different subscriptions. If the move involves different subscriptions, both subscriptions must be part of the same Microsoft Entra ID tenant. You can use tools like the Azure portal, Azure PowerShell, Azure CLI, the REST API, or Python to move the resources.

During the move operation, both the source and target resource groups are locked. You can't create, delete, or update resources within these resource groups while the move is in progress. However, existing resources remain fully operational. For example, if you move a virtual machine from one resource group to another, you can't delete it or modify its properties (such as its size) during the move. Despite this restriction, the virtual machine continues to operate normally, and services relying on it don't experience any downtime. The lock can last up to four hours. Most moves are completed faster, and the lock is removed accordingly.

Only top-level (parent) resources should be specified in the move request. Child resources move automatically with their parent but can't be moved independently. For example, you can move a parent resource like `Microsoft.Compute/virtualMachines`, and its child resource such as `Microsoft.Compute/virtualMachines/extensions` moves with it. However, you can't move the child resource on its own.

While moving a resource preserves its dependencies with child resources, dependencies with other resources can break and might need to be configured again. Moving a resource only changes its associated resource group and doesn't alter the physical region of the resource.

> **Note**
>
> Azure resources can't be moved if a read-only lock exists on the source, destination resource group, or subscription.

Changed resource ID

When you move a resource, you change its resource ID. The standard format for a resource ID is `/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/{resourceProviderNamespace}/{resourceType}/{resourceName}`. When you move a resource to a new resource group or subscription, you change one or more values in that path.

If you use the resource ID anywhere, change that value. For example, if you have a custom dashboard in the portal that references a resource ID, update that value. Look for any scripts or templates that need to be updated for the new resource ID.

Checklist before moving resources

Some important steps precede moving a resource. You can avoid errors if you verify these conditions.

1. The source and destination subscriptions must be active. If you have trouble enabling an account that's disabled, create an Azure support request. Select **Subscription Management** for the issue type.

2. The source and destination subscriptions must exist within the same Microsoft Entra tenant. Use the Azure CLI or PowerShell to check that both subscriptions have the same tenant ID.

   Azure CLI

   Azure CLI

   ```
   az account show --subscription <your-source-subscription> --query
   tenantId
   az account show --subscription <your-destination-subscription> --query
   tenantId
   ```

   If the tenant IDs for the source and destination subscriptions don't match, use the following methods to reconcile them:

   - Transfer billing ownership of an Azure subscription.
   - Associate or add an Azure subscription to your Microsoft Entra tenant.

3. To move resources to or from a Cloud Solution Provider (CSP) partner, see Transfer Azure subscriptions between subscribers and CSPs.

4. The resources you want to move must support the move operation. For a list of which resources support move operations, see Azure resource types for move operations.

5. Some services have specific limitations or requirements when moving resources. Check the following move guidance before moving resources within these services:

   - If you're using Azure Stack Hub, you can't move resources between groups.
     - Azure App Services

- Azure DevOps Services
- Classic deployment model for classic compute, storage, virtual networks, and cloud services
- Cloud Services (extended support)
- Networking
- Azure Recovery Services
- Virtual machines
- To move an Azure subscription to a new management group, see Move subscriptions.

6. The destination subscription must be registered for the resource provider of the resource you're moving. If it's not, you receive an error stating that the **subscription isn't registered for a resource type**. You might see this error when moving a resource to a new subscription, but you didn't previously use the resource type in the subscription.

   Azure CLI

   To get the registration status:

   Azure CLI

   ```
   az account set -s <destination-subscription-name-or-id>
   az provider list --query "[].{Provider:namespace,
   Status:registrationState}" --out table
   ```

   To register a resource provider:

   Azure CLI

   ```
   az provider register --namespace Microsoft.Batch
   ```

7. Before starting a move operation, check the subscription quota for the subscription to which you're moving resources. Verify if you can request an increase in a quota that would cause a destination subscription to exceed its limit. For detailed guidance about limits and how to request an increase, see Azure subscription and service limits, quotas, and constraints.

8. The account moving the resources must have at least the following permissions:

   - At the source resource group: **Microsoft.Resources/subscriptions/resourceGroups/moveResources/action**

- At the destination resource group:
  Microsoft.Resources/subscriptions/resourceGroups/write

9. If you move a resource with an active Azure role assignment (or its child resource with this same assignment), the role assignment doesn't move and becomes orphaned. You must create the role assignment again after the move. Although the system automatically removes the orphaned role assignment, we recommend that you remove it before the move.

   To learn more about how to manage role assignments, see List Azure role assignments and Assign Azure roles.

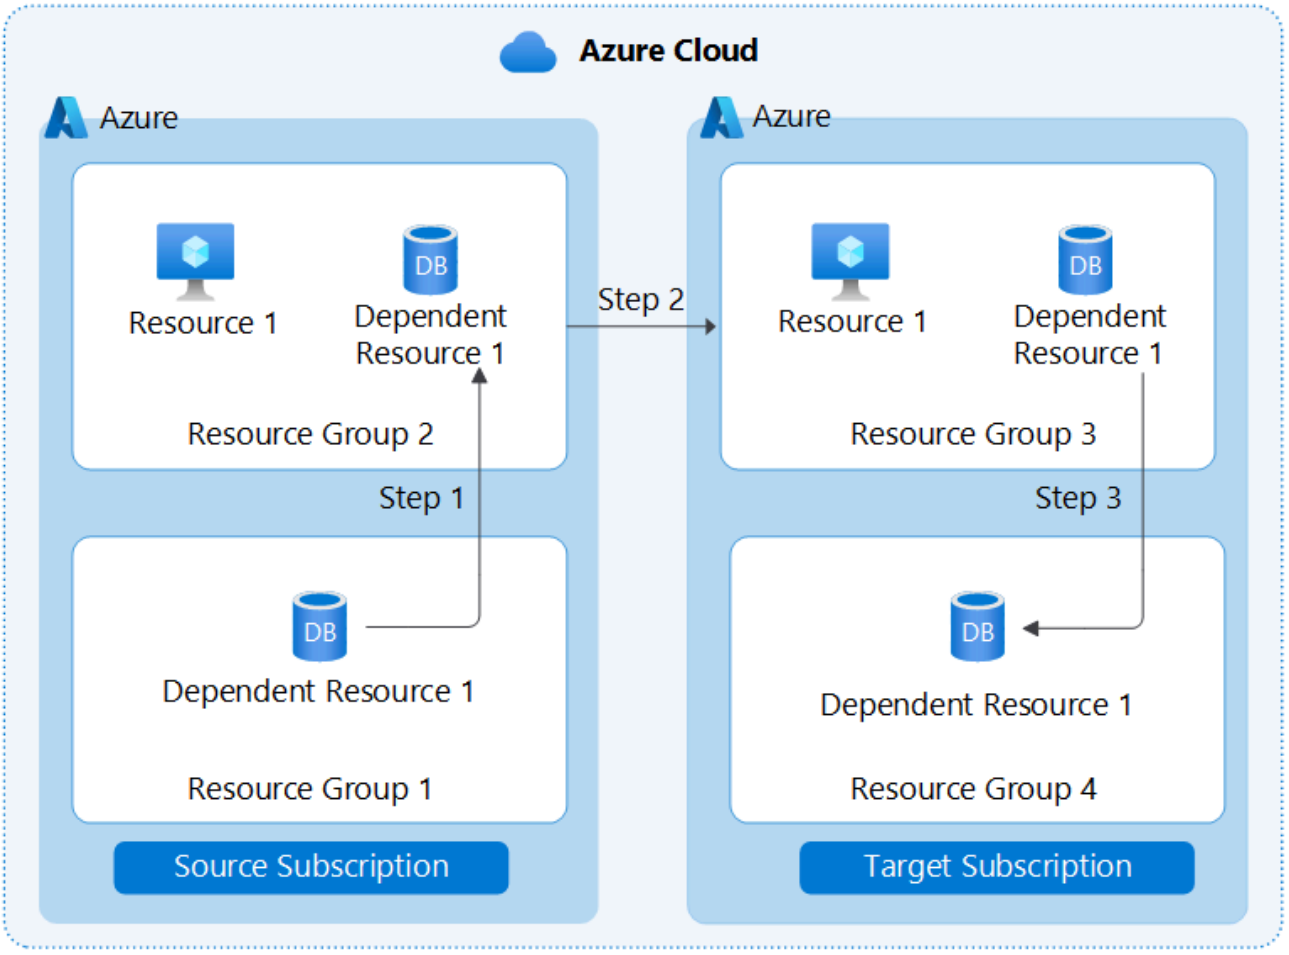
10. **For a move across subscriptions, the resource and its dependent resources must be located in the same resource group and they must be moved together.** For example, a virtual machine with managed disks requires you to move the virtual machine, managed disks, and other dependent resources together.

    If you're moving a resource to a new subscription, check if the resource has any dependent resources and if they're located in the same resource group. If the resources aren't in the same resource group, check if you can combine them into the same resource group. If you can, use one move operation across resource groups to consolidate all the resources into the same resource group.

    For more information, see Scenario for move across subscriptions.

Scenario for moving across subscriptions

Moving resources from one subscription to another is a three-step process. To illustrate these steps, the following diagram depicts only one dependent resource:

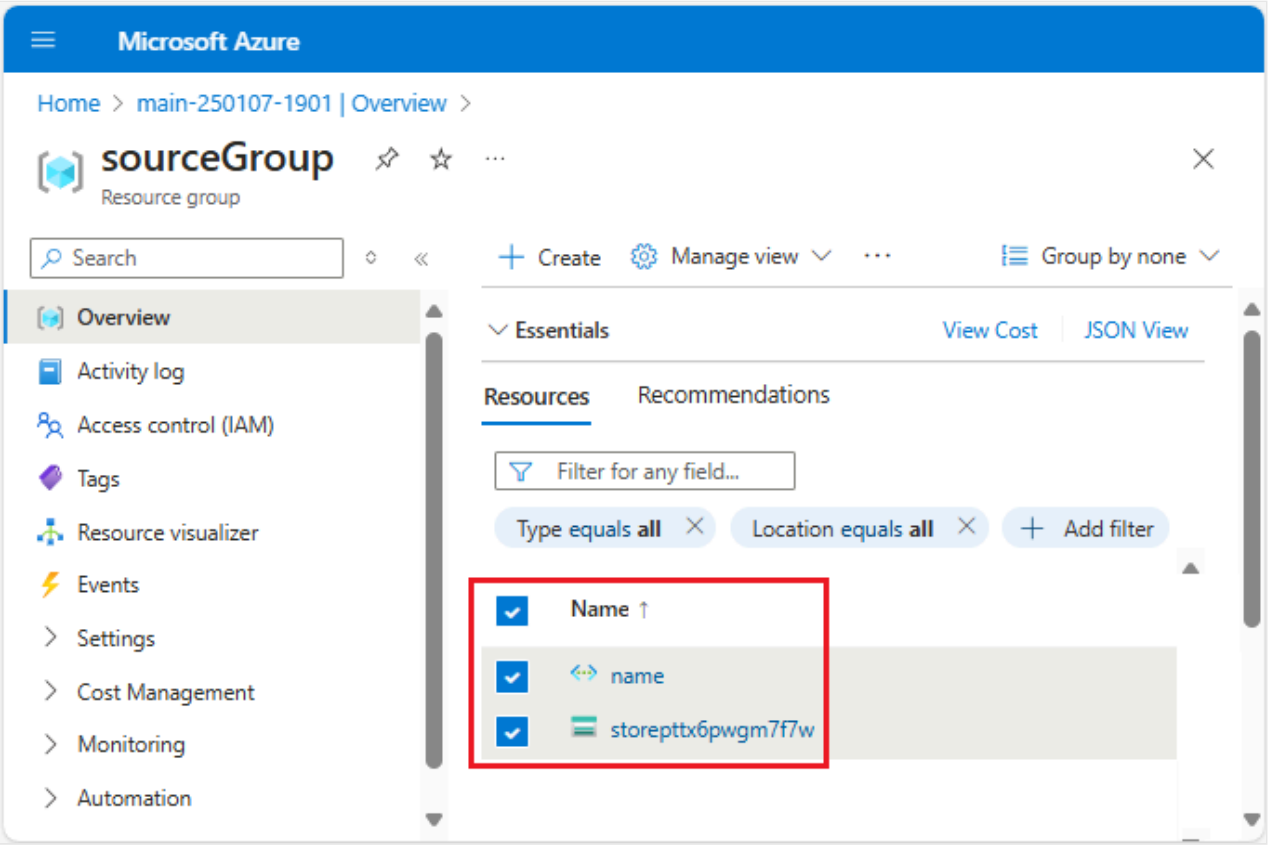


- Step 1: If dependent resources are distributed across different resource groups, first move them into one resource group.
- Step 2: Move the resource and dependent resources together from the source subscription to the target subscription.
- Step 3: Optionally, redistribute the dependent resources to different resource groups within the target subscription.

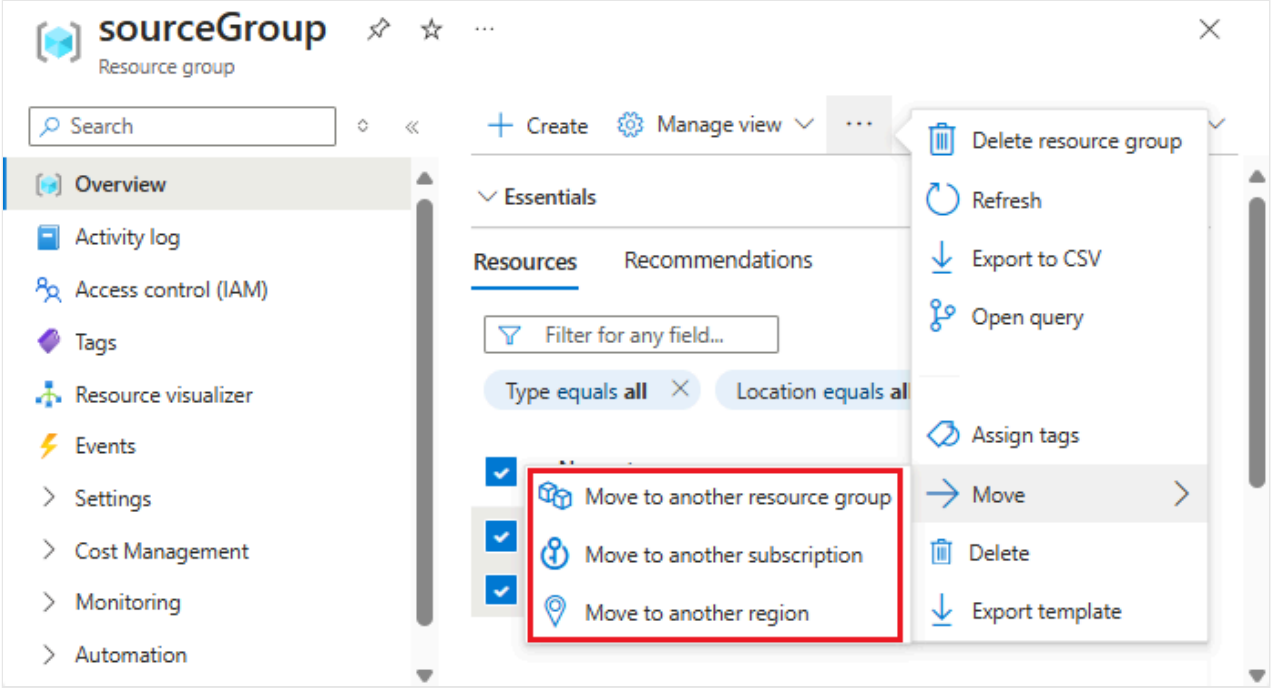
Move resources

Use the Azure portal

1. To move resources, select the resource group that contains those resources.
2. Select the resources that you want to move. To move all of the resources, select the checkbox at the top of list. Or, select resources individually.



3. Select the **Move** button.

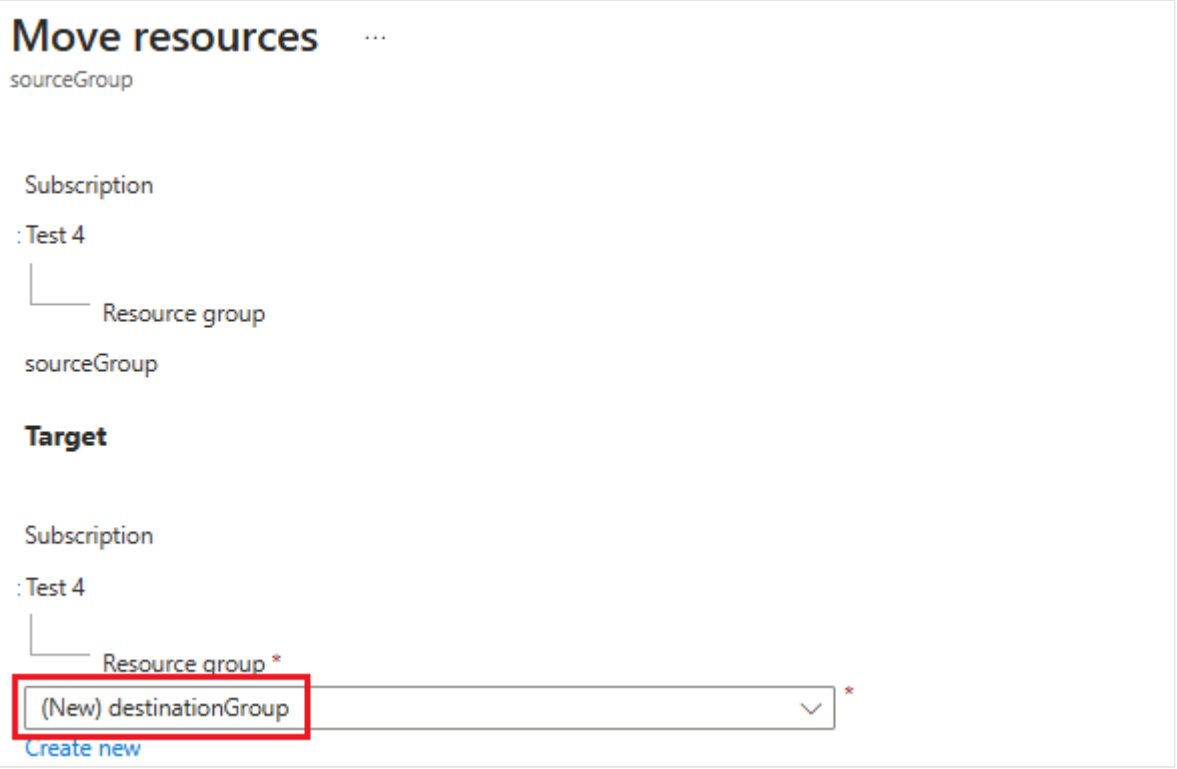


This button gives you three options:

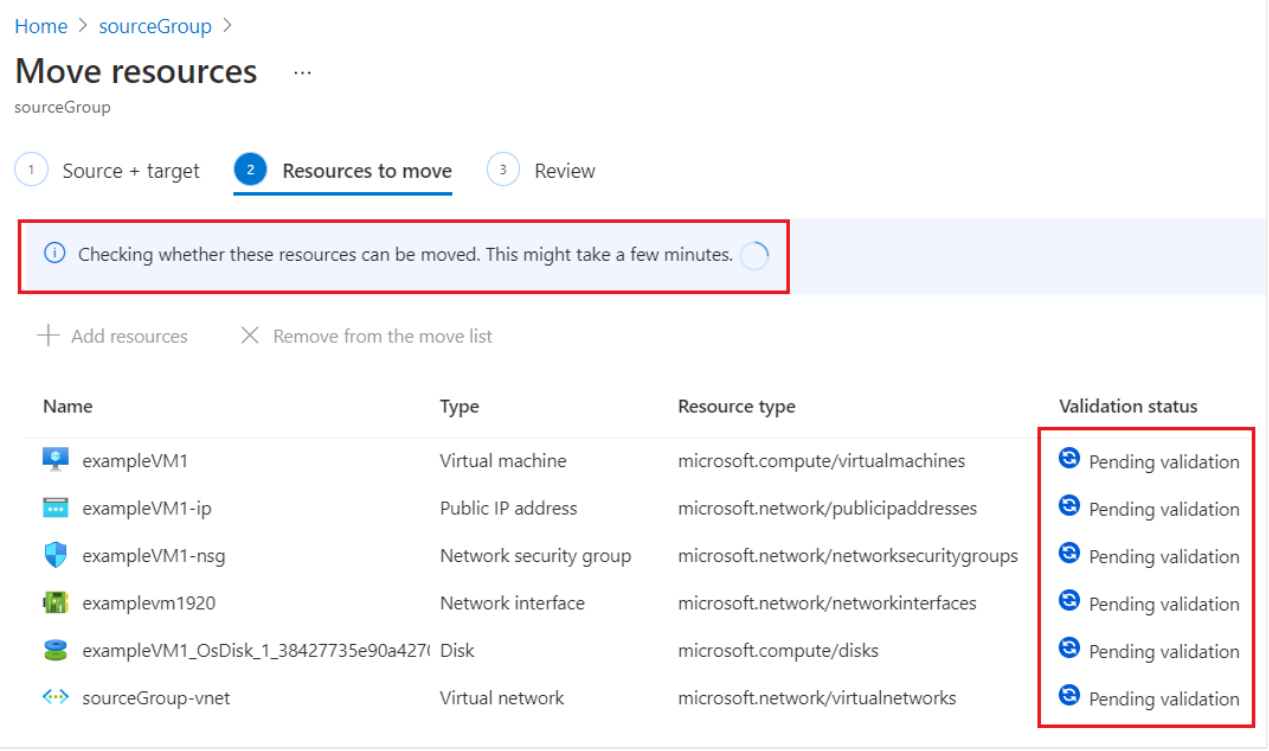
- Move to a new resource group.
- Move to a new subscription.
- Move to a new region. To change regions, see Move resources across regions (from resource group) with Azure Resource Mover.

4. Select if you're moving the resources to a new resource group or subscription.

5. The source resource group sets automatically. Specify the destination resource group. If you're moving to a new subscription, specify this option. Select **Next**.

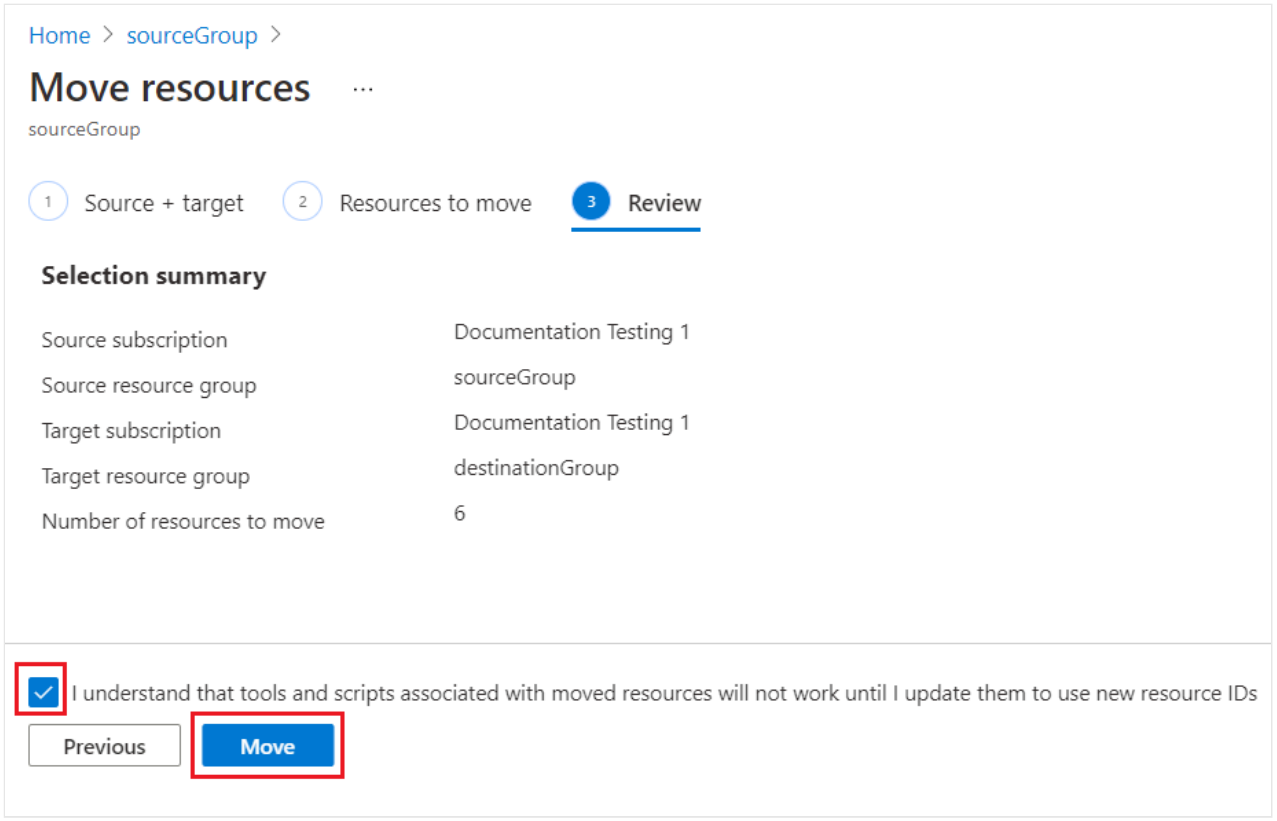


6. The portal validates that the resources can be moved. Wait for validation to complete.

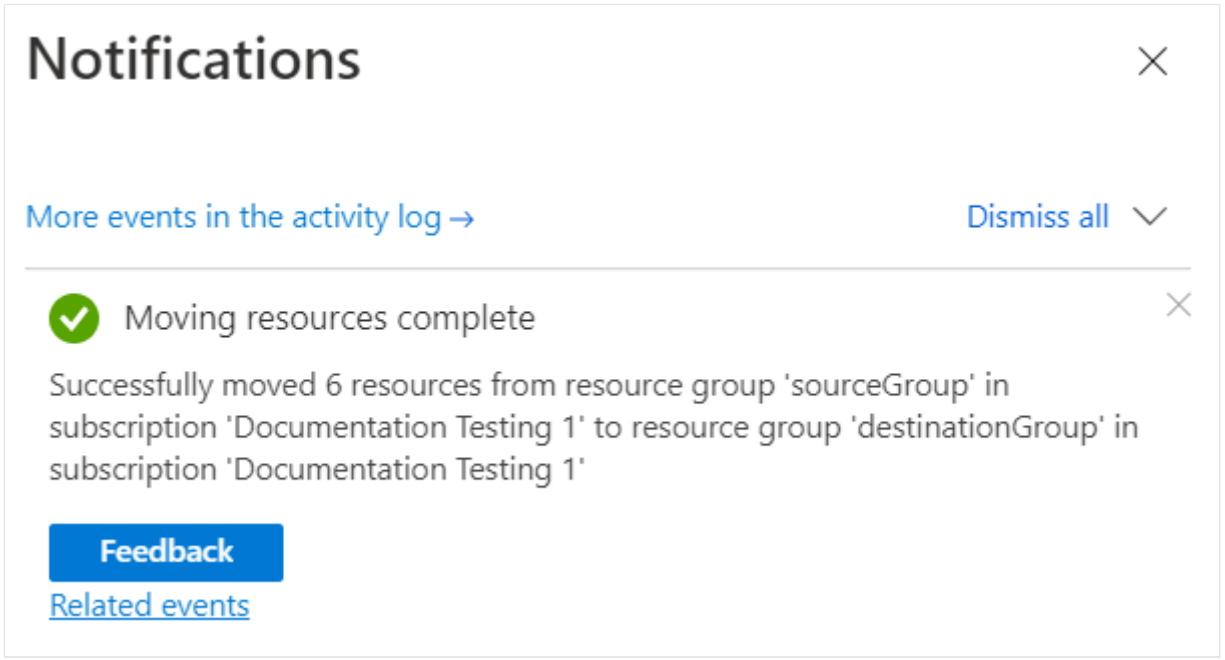


7. When validation completes successfully, select **Next**.

8. Acknowledge that you need to update tools and scripts for these resources. To start moving the resources, select **Move**.



9. The Azure portal notifies you when the move completes.



Use the Azure CLI

Validate

To test your move scenario without actually moving resources in real time, use the az resource invoke-action command. Use this command only when you need to model the results without following through. To run this operation, you need the resource ID of the source resource group, target resource group, and each resource that you're moving.

Use `\"` to escape double quotes in the body of the request.

Azure CLI

```
az resource invoke-action --action validateMoveResources \
  --ids "/subscriptions/{subscription-id}/resourceGroups/{source-rg}" \
  --request-body "{  \"resources\": [\"/subscriptions/{subscription-
id}/resourceGroups/{source-rg}/providers/{resource-provider}/{resource-
type}/{resource-name}\", \"/subscriptions/{subscription-
id}/resourceGroups/{source-rg}/providers/{resource-provider}/{resource-
type}/{resource-name}\", \"/subscriptions/{subscription-
id}/resourceGroups/{source-rg}/providers/{resource-provider}/{resource-
type}/{resource-name}\"],\"targetResourceGroup\":\"/subscriptions/{subscription-
id}/resourceGroups/{destination-rg}\" }"
```

If validation passes, you see:

Azure CLI

```
{} Finished ..
```

If validation fails, you see an error message that explains why you can't move the resources.

Move

To move existing resources to another resource group or subscription, use the az resource move command. In the `--ids` parameter, provide a space-separated list of the resource IDs to move.

The following commands show how to move several resources to a new resource group. They work with the Azure CLI in a Bash terminal or in an Azure PowerShell console. To move resources to a new subscription, provide the `--destination-subscription-id` parameter.

Azure CLI

Azure CLI

```
webapp=$(az resource show -g OldRG -n ExampleSite --resource-type
"Microsoft.Web/sites" --query id --output tsv)
plan=$(az resource show -g OldRG -n ExamplePlan --resource-type
"Microsoft.Web/serverfarms" --query id --output tsv)
az resource move --destination-group newgroup --ids $webapp $plan
```

Use Azure PowerShell

Validate

To test your move scenario without actually moving resources in real time, use the Invoke-AzResourceAction command in Azure PowerShell. Use this command only when you need to model the results without following through.

Azure PowerShell

```
$sourceName = "sourceRG"
$destinationName = "destinationRG"
$resourcesToMove = @("app1", "app2")

$sourceResourceGroup = Get-AzResourceGroup -Name $sourceName
$destinationResourceGroup = Get-AzResourceGroup -Name $destinationName

$resources = Get-AzResource -ResourceGroupName $sourceName | Where-Object {
$_.Name -in $resourcesToMove }

Invoke-AzResourceAction -Action validateMoveResources `
  -ResourceId $sourceResourceGroup.ResourceId `
  -Parameters @{
  resources = $resources.ResourceId;  # Wrap in an @() array if providing a single
resource ID string.
  targetResourceGroup = $destinationResourceGroup.ResourceId
  }
```

An output doesn't display if the validation succeeds. However, if the validation fails, an error message explains why you can't move the resources.

Move

To move existing resources to another resource group or subscription, use the Move-AzResource command. The following example shows how to move several resources to a new resource group.

Azure PowerShell

```
$sourceName = "sourceRG"
$destinationName = "destinationRG"
$resourcesToMove = @("app1", "app2")

$resources = Get-AzResource -ResourceGroupName $sourceName | Where-Object {
$_.Name -in $resourcesToMove }
```

```
Move-AzResource -DestinationResourceGroupName $destinationName -ResourceId
$resources.ResourceId
```

To move to a new subscription, include a value for the `DestinationSubscriptionId` parameter.

Use Python

Validate

To test your move scenario without actually moving resources in real time, use the ResourceManagementClient.resources.begin_validate_move_resources method. Use this method only when you need to model the results without following through.

Python

```python
import os
from azure.identity import AzureCliCredential
from azure.mgmt.resource import ResourceManagementClient

credential = AzureCliCredential()
subscription_id = os.environ["AZURE_SUBSCRIPTION_ID"]

resource_client = ResourceManagementClient(credential, subscription_id)

source_name = "sourceRG"
destination_name = "destinationRG"
resources_to_move = ["app1", "app2"]

destination_resource_group = resource_client.resource_groups.get(destination_name)

resources = [
  resource for resource in
resource_client.resources.list_by_resource_group(source_name)
  if resource.name in resources_to_move
]

resource_ids = [resource.id for resource in resources]

validate_move_resources_result =
resource_client.resources.begin_validate_move_resources(
  source_name,
  {
  "resources": resource_ids,
  "target_resource_group": destination_resource_group.id
  }
).result()

print("Validate move resources result: {}".format(validate_move_resources_result))
```

An output doesn't display if the validation succeeds. However, if the validation fails, an error message explains why you can't move the resources.

Move

To move existing resources to another resource group or subscription, use the ResourceManagementClient.resources.begin_move_resources method in Python. The following example shows how to move several resources to a new resource group.

Python

```
import os
from azure.identity import AzureCliCredential
from azure.mgmt.resource import ResourceManagementClient

credential = AzureCliCredential()
subscription_id = os.environ["AZURE_SUBSCRIPTION_ID"]

resource_client = ResourceManagementClient(credential, subscription_id)

source_name = "sourceRG"
destination_name = "destinationRG"
resources_to_move = ["app1", "app2"]

destination_resource_group = resource_client.resource_groups.get(destination_name)

resources = [
  resource for resource in
resource_client.resources.list_by_resource_group(source_name)
  if resource.name in resources_to_move
]

resource_ids = [resource.id for resource in resources]

resource_client.resources.begin_move_resources(
  source_name,
  {
  "resources": resource_ids,
  "target_resource_group": destination_resource_group.id
  }
)
```

Use REST API

Validate

The validate move operation operation tests your move scenario without actually moving resources. Use this operation to check if the move can succeed. Validation is automatically

called when you send a move request. Use this operation only when you need to model the results without following through. To run this operation, you need the:

- Name of the source resource group
- Resource ID of the target resource group
- Resource ID of each resource to move
- The access token for your account

Send the following request:

HTTP

```
POST https://management.azure.com/subscriptions/<subscription-id>/resourceGroups/<source-group>/validateMoveResources?api-version=2019-05-10
Authorization: Bearer <access-token>
Content-type: application/json
```

With a request body:

JSON

```
{
 "resources": ["<resource-id-1>", "<resource-id-2>"],
 "targetResourceGroup": "/subscriptions/<subscription-id>/resourceGroups/<target-group>"
}
```

If the request is formatted correctly, the operation returns:

HTTP

```
Response Code: 202
cache-control: no-cache
pragma: no-cache
expires: -1
location: https://management.azure.com/subscriptions/<subscription-id>/operationresults/<operation-id>?api-version=2018-02-01
retry-after: 15
...
```

A **202** status code indicates that the validation request was accepted, but it hasn't yet determined if the move operation will succeed. The `location` value contains a URL that you use to check the status of the long-running operation.

To check the status, send the following request:

HTTP

```
GET <location-url>
Authorization: Bearer <access-token>
```

You continue to receive a **202** status code while the operation runs. Wait the number of seconds indicated in the `retry-after` value before trying again. You receive a **204** status code if the move validation succeeds. If the move validation fails, you receive an error message that resembles:

JSON

```
{"error":{"code":"ResourceMoveProviderValidationFailed","message":"<message>"...}}
```

Move

To move existing resources to another resource group or subscription, use the Move resources operation.

HTTP

```
POST https://management.azure.com/subscriptions/{source-subscription-id}/resourcegroups/{source-resource-group-name}/moveResources?api-version={api-version}
```

Specify the target resource group and resources to move in the body of the request.

JSON

```
{
 "resources": ["<resource-id-1>", "<resource-id-2>"],
 "targetResourceGroup": "/subscriptions/<subscription-id>/resourceGroups/<target-group>"
}
```

Frequently asked questions

My resource move operation that usually takes a few minutes is running for almost an hour. Is something wrong?

Moving a resource is a complex operation with different phases. It can involve more than just the resource provider of the resource you're trying to move. Azure Resource Manager allows a move operation four hours to finish because of the dependencies between resource providers.

This duration gives them time to recover from transient issues. If your move request is within the four-hour period, the operation keeps trying to complete and might succeed. The operation locks the source and destination resource groups during this time to avoid consistency issues.

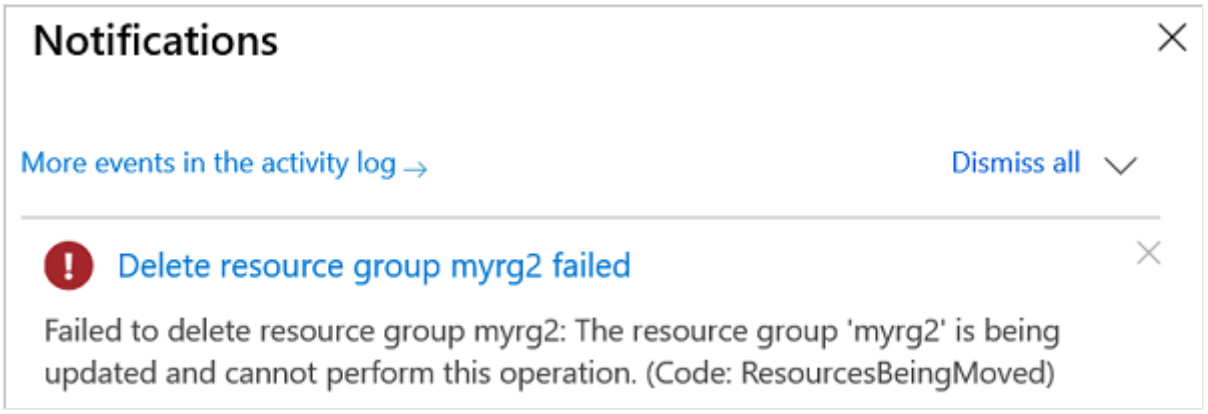
Why is my resource group locked for four hours during resource move?

- Move operations are allowed four hours to complete. The operation locks the source and destination resource groups during this time to prevent them from being modified.
- There are two phases in a move request. Resources move during the first phase, and resource providers that depend on the resources being moved are notified during the second phase. A resource group can be locked for all four hours when a resource provider fails either phase. Resource Manager initiates any failed steps during the span of the move operation.
- Resource Manager unlocks both resource groups if a resource doesn't move within four hours. Resources that move successfully are in the destination resource group. Resources that fail to move remain in the source resource group.

What are the implications of the source and destination resource groups being locked during the resource move?

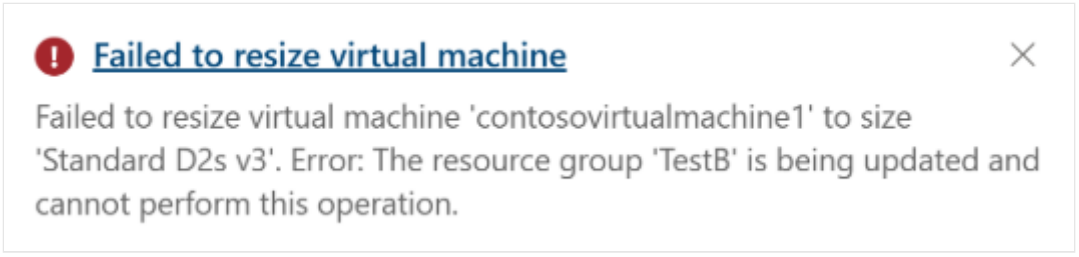
The lock prevents you from deleting either resource group. The lock also prevents you from creating a new resource, deleting a resource, or updating a resource's properties within each resource group (for example, changing a virtual machine's size).

The following image shows an error message from the Azure portal when you try to delete a resource group that's part of an ongoing move:



In the preceding image, the virtual machine resource belongs to a resource group ("TestB") that's currently undergoing a move operation. When you attempt to update a virtual machine's

property (such as its size), the Azure portal returns an error message. This error occurs because the resource group is locked during the move, which protects its resources from being modified.



Additionally, the source and the destination resource groups can't participate in other move operations simultaneously during a resource move. For example, if you're moving resources from resource group A to resource group B, both resource group A and resource group B can't be involved in another move operation at the same time. You can't simultaneously move resources to or from resource group C. This restriction prevents multiple conflicting operations from locking resource groups during the move process.

What does the error code "MissingMoveDependentResources" mean?

When you move a resource, its dependent resources must exist in the destination resource group or subscription, or be included in the move request. You get the ### MissingMoveDependentResources** error code when a dependent resource doesn't meet this requirement. The error message provides details about the dependent resource that you need to include in the move request.

For example, moving a virtual machine could require moving seven resource types with three different resource providers. Those resource providers and types are:

- Microsoft.Compute
  - virtualMachines
  - disks
- Microsoft.Network
  - networkInterfaces
  - publicIPAddresses
  - networkSecurityGroups
  - virtualNetworks
- Microsoft.Storage
  - storageAccounts

Another common example involves moving a virtual network where you might have to move several other resources associated with that virtual network. The move request could require moving public IP addresses, route tables, virtual network gateways, network security groups, and other resources. A virtual network gateway should be in the same resource group as its virtual network since they can't move separately.

What does the error code "RequestDisallowedByPolicy" mean?

Resource Manager validates your move request before attempting a move. This validation includes checking policies defined for the resources involved in the move. For example, the validation fails when you're attempting to move a key vault but your organization has a policy to deny creating a key vault in the target resource group. The returned error code is ### RequestDisallowedByPolicy**.

For more information about policies, see What is Azure Policy?.

Why can't I move some resources in Azure?

Not all Azure resources allow move operations.

How many resources can I move in one operation?

Separate large moves into different move operations when possible. Resource Manager immediately returns an error when there are more than 800 resources in a single operation. However, moving fewer than 800 resources can also fail by timing out.

What is the meaning of the error that a resource isn't in a "succeeded" state?

When you get an error message indicating that you can't move a resource because it isn't in a **Succeeded** state, it might be because a dependent resource is blocking the move. Typically, the error code is **MoveCannotProceedWithResourcesNotInSucceededState**.

If the source or target resource group contains a virtual network, the states of all resources that depend on that virtual network are checked during the move. This check includes resources that directly and indirectly depend on the network. The move is blocked if any resources aren't in a succeeded state. For example, if a virtual machine using a virtual network that doesn't report a succeeded state, the move is blocked. The move is blocked even when the virtual machine isn't one of the resources being moved. The move is also blocked even when the virtual machine isn't in the source or destination resource group.

To resolve this issue, move your resources to a resource group that doesn't have a virtual network or contact support.

Can I move a resource group to a different subscription?

No, you can't move a resource group to a new subscription. But, you can move all resources in a resource group to a resource group in another subscription. Settings such as tags, role assignments, and policies don't transfer automatically from the original resource group to the destination resource group. You need to apply these settings manually to the new resource group.

Next steps

To verify which Azure resources support move operations, see Move operation support for resources.

Move a Marketplace Azure Virtual Machine to another subscription

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

To move a Marketplace virtual machine to a different subscription, you must move the OS disk to that subscription and then recreate the virtual machine.

You don't need this procedure to move a data disk to a new subscription. Instead, create a new virtual machine in the new subscription from the Marketplace, then move and attach the data disk.

This script demonstrates three operations:

- Create a snapshot of an OS disk.
- Move the snapshot to a different subscription.
- Create a virtual machine based on that snapshot.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Quickstart for Bash in Azure Cloud Shell.

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample script

To move a Marketplace virtual machine to a different subscription, you must create a new virtual machine for the same Marketplace offer from the moved OS disk.

> **Note**
>
> If the virtual machine plan is no longer available in the Marketplace, you can't use this procedure.

Azure CLI

```
#!/bin/bash
# Set variable values before proceeding.

# Variables
sourceResourceGroup= Resource group for the current virtual machine
sourceSubscription= Subscription for the current virtual machine
vmName= Name of the current virtual machine

destinationResourceGroup= Resource group for the new virtual machine, create
if necessary
destinationSubscription= Subscription for the new virtual machine

# Set your current subscription for the source virtual machine
az account set --subscription $sourceSubscription

# Load variables about your virtual machine
# osType = windows or linux
osType=$(az vm get-instance-view --resource-group $sourceResourceGroup \
    --name $vmName --subscription $sourceSubscription \
    --query 'storageProfile.osDisk.osType' --output tsv)

# offer = Your offer in Marketplace
offer=$(az vm get-instance-view --resource-group $sourceResourceGroup \
    --name $vmName --query 'storageProfile.imageReference.offer' --output
tsv)

# plan = Your plan in Marketplace
plan=$(az vm get-instance-view --resource-group $sourceResourceGroup \
    --name $vmName --query 'plan' --output tsv)

# publisher = Your publisher in Marketplace
publisher=$(az vm get-instance-view --resource-group $sourceResourceGroup \
    --name $vmName --query 'storageProfile.imageReference.publisher' --
output tsv)

# Get information to create new virtual machine
planName=$(az vm get-instance-view --resource-group $sourceResourceGroup \
    --subscription $sourceSubscription --query 'plan.name' --name $vmName)
planProduct=$(az vm get-instance-view --resource-group $sourceResourceGroup
\
    --subscription $sourceSubscription --query 'plan.product' --name
```

```
$vmName)
planPublisher=$(az vm get-instance-view --resource-group
$sourceResourceGroup \
    --subscription $sourceSubscription --query 'plan.publisher' --name
$vmName)

# Get the name of the OS disk
osDiskName=$(az vm show --resource-group $sourceResourceGroup --name $vmName
\
    --query 'storageProfile.osDisk.name' --output tsv)

# Verify the terms for your market virtual machine
az vm image terms show --offer $offer --plan '$plan' --publisher $publisher
\
    --subscription $sourceSubscription

# Deallocate the virtual machine
az vm deallocate --resource-group $sourceResourceGroup --name $vmName

# Create a snapshot of the OS disk
az snapshot create --resource-group $sourceResourceGroup --name
MigrationSnapshot \
    --source
"/subscriptions/$sourceSubscription/resourceGroups/$sourceResourceGroup/prov
iders/Microsoft.Compute/disks/$osDiskName"

# Move the snapshot to your destination resource group
az resource move --destination-group $destinationResourceGroup \
    --destination-subscription-id $destinationSubscription \
    --ids
"/subscriptions/$sourceSubscription/resourceGroups/$sourceResourceGroup/prov
iders/Microsoft.Compute/snapshots/MigrationSnapshot"

# Set your subscription to the destination value
az account set --subscription $destinationSubscription

# Accept the terms from the Marketplace
az vm image terms accept --offer $offer --plan '$plan' --publisher
$publisher \
    --subscription $destinationSubscription

# Create disk from the snapshot
az disk create --resource-group $destinationResourceGroup --name
DestinationDisk \
    --source
"/subscriptions/$destinationSubscription/resourceGroups/$destinationResource
Group/providers/Microsoft.Compute/snapshots/MigrationSnapshot" \
    --os-type $osType

# Create virtual machine from disk
az vm create --resource-group $destinationResourceGroup --name $vmName \
    --plan-name $planName --plan-product $planProduct  --plan-publisher
$planPublisher \
    --attach-os-disk
"/subscriptions/$destinationSubscription/resourceGroups/$destinationResource
```

```
Group/providers/Microsoft.Compute/disks/DestinationDisk" \
    --os-type $osType
```

Clean up resources

After the sample has been run, use the following commands to remove the resource groups and all associated resources:

Azure CLI

```
az group delete --name $sourceResourceGroup --subscription
$sourceSubscription
az group delete --name $destinationResourceGroup --subscription
$destinationSubscription
```

Azure CLI references used in this article

- az account set
- az disk create
- az group delete
- az resource move
- az snapshot create
- az vm create
- az vm deallocate
- az vm delete
- az vm get-instance-view
- az vm image terms accept
- az vm image terms show
- az vm show

Next steps

- Move VMs to another Azure region
- Move a VM to another subscription or resource group

Move VMs to another Azure region

There are scenarios in which you'd want to move your existing Azure IaaS virtual machines (VMs) from one region to another. For example, you want to improve the reliability and availability of your existing VMs, improve manageability, or move for governance reasons. For more information, see the Azure VM move overview.

You can use Azure Site Recovery service to move Azure VMs to a secondary region.

In this tutorial, you learn how to:

- ✓ Verify prerequisites for the move
- ✓ Prepare the source VMs and the target region
- ✓ Copy the data and enable replication
- ✓ Test the configuration and perform the move
- ✓ Delete the resources in the source region

> **ⓘ Important**
>
> To move Azure VMs to another region, we recommend using Azure Resource Mover. Resource Mover provides:
>
> - A single hub for moving resources across regions.
> - Reduced move time and complexity. Everything you need is in a single location.
> - A simple and consistent experience for moving different types of Azure resources.
> - An easy way to identify dependencies across resources you want to move. This helps you to move related resources together, so that everything works as expected in the target region, after the move.
> - Automatic cleanup of resources in the source region, if you want to delete them after the move.
> - Testing. You can try out a move, and then discard it if you don't want to do a full move.

> **ⓘ Note**
>
> This tutorial shows you how to move Azure VMs from one region to another as is. If you need to improve availability by moving VMs in an availability set to zone pinned VMs in a different region, see the Move Azure VMs into Availability Zones tutorial.

Prerequisites

- Make sure that the Azure VMs are in the Azure region from which you want to move.
- Verify that your choice of source region - target region combination is supported, and make an informed decision about the target region.
- Make sure that you understand the scenario architecture and components.
- Review the support limitations and requirements.
- Verify account permissions. If you created your free Azure account, you're the administrator of your subscription. If you're not the subscription administrator, work with the administrator to assign the permissions that you need. To enable replication for a VM and essentially copy data by using Azure Site Recovery, you must have:
    - Permission to create a VM in Azure resources. The Virtual Machine Contributor built-in role has these permissions, which include:
    - Permission to create a VM in the selected resource group
    - Permission to create a VM in the selected virtual network
    - Permission to write to the selected storage account
    - Permission to manage Azure Site Recovery operations. The Site Recovery Contributor role has all the permissions that are required to manage Site Recovery operations in a Recovery Services vault.
- Make sure that all the latest root certificates are on the Azure VMs that you want to move. If the latest root certificates aren't on the VM, security constraints will prevent the data copy to the target region.
- For Windows VMs, install all the latest Windows updates on the VM, so that all the trusted root certificates are on the machine. In a disconnected environment, follow the standard Windows Update and certificate update processes for your organization.
- For Linux VMs, follow the guidance provided by your Linux distributor to get the latest trusted root certificates and certificate revocation list on the VM.
- Make sure that you're not using an authentication proxy to control network connectivity for VMs that you want to move.
- If the VM that you're trying to move doesn't have access to the internet, or it's using a firewall proxy to control outbound access, check the requirements.

- Identify the source networking layout and all the resources that you're currently using. This includes but isn't limited to load balancers, network security groups (NSGs), and public IPs.
- Verify that your Azure subscription allows you to create VMs in the target region that's used for disaster recovery. Contact support to enable the required quota.
- Make sure that your subscription has enough resources to support VMs with sizes that match your source VMs. If you're using Site Recovery to copy data to the target, Site Recovery chooses the same size or the closest possible size for the target VM.
- Make sure that you create a target resource for every component that's identified in the source networking layout. This step is important to ensure that your VMs have all the functionality and features in the target region that you had in the source region.

  > **Note**
  >
  > Azure Site Recovery automatically discovers and creates a virtual network when you enable replication for the source VM. You can also pre-create a network and assign it to the VM in the user flow to enable replication. As mentioned later, you need to manually create any other resources in the target region.

  To create the most commonly used network resources that are relevant for you based on the source VM configuration, see the following documentation:
  - Network security groups
  - Load balancers
  - Public IP
  - For any other networking components, see the networking documentation.

Prepare

The following steps show how to prepare the virtual machine for the move using Azure Site Recovery as a solution.

Create the vault in any region, except the source region

1. Sign in to the Azure portal.
2. In search, type Recovery Services > click Recovery Services vaults
3. In the Recovery Services vaults menu, click + **Add**.
4. In **Name**, specify the friendly name **ContosoVMVault**. If you have more than one subscription, select the appropriate one.

5. Create the resource group **ContosoRG**.
6. Specify an Azure region. To check supported regions, see geographic availability in Azure Site Recovery pricing details.
7. In **Recovery Services vaults**, select **ContosoVMVault** > **Replicated items** > **+Replicate**.
8. In the dropdown, select **Azure Virtual Machines**.
9. In **Source location**, select the source Azure region where your VMs are currently running.
10. Select the Resource Manager deployment model. Then select the **Source subscription** and **Source resource group**.
11. Select **OK** to save the settings.

Enable replication for Azure VMs and start copying the data

Site Recovery retrieves a list of the VMs that are associated with the subscription and resource group.

1. In the next step, select the VM that you want to move, then select **OK**.
2. In **Settings**, select **Disaster recovery**.
3. In **Configure disaster recovery** > **Target region**, select the target region to which you'll replicate.
4. For this tutorial, accept the other default settings.
5. Select **Enable replication**. This step starts a job to enable replication for the VM.

Move

The following steps show how to perform the move to the target region.

1. Go to the vault. In **Settings** > **Replicated items**, select the VM and then select **Failover**.
2. In **Failover**, select **Latest**.
3. Select **Shut down machine before beginning failover**. Site Recovery attempts to shut down the source VM before triggering the failover. Failover continues even if shutdown fails. You can follow the failover progress on the **Jobs** page.
4. After the job is finished, check that the VM appears in the target Azure region as expected.

Discard

In case you checked the moved VM and need to make changes to the point of failover or want to go back to a previous point, in the **Replicated items**, right-select the VM > **Change recovery point**. This step provides you the option to specify a different recovery point and failover to that one.

Commit

Once you have checked the moved VM and are ready to commit the change, in the **Replicated items**, right-select the VM > **Commit**. This step finishes the move process to the target region. Wait until the commit job finishes.

Clean up

The following steps will guide you through how to clean up the source region as well as related resources that were used for the move.

For all resources that were used for the move:

- Go to the VM. Select **Disable Replication**. This step stops the process from copying the data for the VM.

  > **Important**
  >
  > It's important to perform this step to avoid being charged for Azure Site Recovery replication.

If you have no plans to reuse any of the source resources, complete these additional steps:

1. Delete all the relevant network resources in the source region that you identified in the prerequisites.
2. Delete the corresponding storage account in the source region.

Next steps

In this tutorial, you moved an Azure VM to a different Azure region. Now you can configure disaster recovery for the VM that you moved.

- Learn more about how to Set up disaster recovery after migration.

Move Azure virtual machines into Availability Zones

Summarize this article for me

This article describes how to move Azure virtual machines to an availability zone in a different region. If you want to move to a different zone in the same region, review this article.

Availability Zones in Azure help protect your applications and data from datacenter failures. Each Availability Zone is made up of one or more datacenters equipped with independent power, cooling, and networking. To ensure resiliency, there's a minimum of three separate zones in all enabled regions. The physical separation of Availability Zones within a region helps protect applications and data from datacenter failures. With Availability Zones, Azure offers a service-level agreement (SLA) of 99.99% for uptime of virtual machines (VMs). Availability Zones are supported in select regions, as mentioned in Regions with availability zones.

In a scenario where you deploy your virtual machines as *single instance* into a specific region, and you want to improve your availability by moving these virtual machines into an Availability Zone, you can use Azure Site Recovery. This action can further be categorized into:

- Move single-instance virtual machines into Availability Zones in a target region
- Move virtual machines in an availability set into Availability Zones in a target region

Important

To move Azure virtual machines to an availability zone in a different region, use Azure Resource Mover. Resource Mover is in public preview and provides:

- A single hub for moving resources across regions.
- Reduced move time and complexity. Everything you need is in a single location.
- A simple and consistent experience for moving different types of Azure resources.
- An easy way to identify dependencies across resources you want to move. This feature helps you move related resources together, so that everything works as expected in the target region after the move.
- Automatic cleanup of resources in the source region, if you want to delete them after the move.
- Testing. You can try out a move, and then discard it if you don't want to do a full move.

Check prerequisites

- Check whether the target region has support for availability zones. Check that your choice of source region/target region combination is supported. Make an informed decision on the target region.
- Make sure that you understand the scenario architecture and components.
- Review the support limitations and requirements.
- Check account permissions. If you just created your free Azure account, you're the admin of your subscription. If you're not the subscription admin, work with the admin to assign the permissions you need. To enable replication for a virtual machine and eventually copy data to the target by using Azure Site Recovery, you must have:

    1. Permission to create a virtual machine in Azure resources. The *Virtual Machine Contributor* built-in role has these permissions, which include:
        - Permission to create a virtual machine in the selected resource group
        - Permission to create a virtual machine in the selected virtual network
        - Permission to write to the selected storage account
    2. Permission to manage Azure Site Recovery tasks. The *Site Recovery Contributor* role has all permissions required to manage Site Recovery actions in a Recovery Services vault.

Prepare the source virtual machines

1. Your virtual machines should use managed disks if you want to move them to an Availability Zone by using Site Recovery. You can convert existing Windows virtual machines that use unmanaged disks to use managed disks. Follow the steps at Convert a Windows virtual machine from unmanaged disks to managed disks. Ensure that the availability set is configured as *managed*.
2. Check that all the latest root certificates are present on the Azure virtual machines you want to move. If the latest root certificates aren't present, security constraints prevent enabling data copy to the target region.
3. For Windows virtual machines, install all the latest Windows updates on the virtual machine, so that all the trusted root certificates are on the machine. In a disconnected environment, follow the standard Windows update and certificate update processes for your organization.

4. For Linux virtual machines, follow the guidance provided by your Linux distributor to get the latest trusted root certificates and certificate revocation list on the virtual machine.

5. Make sure you don't use an authentication proxy to control network connectivity for virtual machines that you want to move.

6. Verify outbound connectivity requirements for virtual machines.

7. Identify the source networking layout and the resources you currently use for verification, including load balancers, NSGs, and public IP.

Prepare the target region

1. Check that your Azure subscription lets you create virtual machines in the target region used for disaster recovery. If necessary, contact support to enable the required quota.

2. Make sure your subscription has enough resources to support virtual machines with sizes that match your source virtual machines. If you use Site Recovery to copy data to the target, it picks the same size or the closest possible size for the target virtual machine.

3. Create a target resource for every component identified in the source networking layout. This action ensures that after you cut over to the target region, your virtual machines have all the functionality and features that you had in the source.

   > **Note**
   >
   > When you enable replication for the source virtual machine, Azure Site Recovery automatically discovers and creates a virtual network and storage account. You can also pre-create these resources and assign them to the virtual machine as part of the enable replication step. For any other resources, you need to manually create them in the target region.

   The following documents explain how to create the most commonly used network resources that are relevant to you, based on the source virtual machine configuration.

   - Network security groups
   - Load balancers
   - Public IP

   For any other networking components, refer to the networking documentation.

   > **Important**

Ensure that you use a zone-redundant load balancer in the target. You can read more at Standard Load Balancer and Availability Zones.

4. Create a non-production network in the target region if you want to test the configuration before you cut over to the target region. This approach causes minimal interference with the production environment.

Enable replication

The following steps guide you through using Azure Site Recovery to enable replication of data to the target region before you move the data into Availability Zones.

> **Note**
>
> These steps are for a single virtual machine. You can extend the same steps to multiple virtual machines. Go to the Recovery Services vault, select + **Replicate**, and select the relevant virtual machines together.

1. In the Azure portal, select **Virtual machines**, and select the virtual machine you want to move into Availability Zones.
2. In **Backup + disaster recovery**, select **Disaster recovery**.
3. In **Configure disaster recovery** > **Target region**, select the target region to which you'll replicate. Ensure this region supports availability zones.
4. Select **Next: Advanced settings**.
5. Choose the appropriate values for the target subscription, target virtual machine resource group, and virtual network.
6. In the **Availability** section, choose the Availability Zone into which you want to move the virtual machine.

   > **Note**
   >
   > If you don't see the option for availability set or Availability Zone, ensure that the prerequisites are met and the preparation of source virtual machines is complete.

7. Select **Enable Replication**. This action starts a job to enable replication for the virtual machine.

Check settings

After the replication job finishes, you can check the replication status, modify replication settings, and test the deployment.

1. In the virtual machine menu, select **Disaster recovery**.
2. You can check replication health, the recovery points that are created, and the source and target regions on the map.

Test the configuration

1. In the virtual machine menu, select **Disaster recovery**.
2. Select the **Test Failover** icon.
3. In **Test Failover**, select a recovery point to use for the failover:
   - **Latest processed**: Fails the virtual machine over to the latest recovery point that the Site Recovery service processes. The time stamp is shown. By using this option, the service spends no time processing data, so it provides a low recovery time objective (RTO).
   - **Latest app-consistent**: This option fails over all virtual machines to the latest app-consistent recovery point. The time stamp is shown.
   - **Custom**: Select any recovery point.
4. Select the test target Azure virtual network to which you want to move the Azure virtual machines to test the configuration.

   > **ⓘ Important**
   >
   > Use a separate Azure virtual machine network for the test failure, and not the production network in the target region into which you want to move your virtual machines.

5. Select **OK** to start testing the move. To track progress, select the virtual machine to open its properties. Or, you can select the **Test Failover** job in the vault name > **Settings** > **Jobs** > **Site Recovery jobs**.
6. After the failover finishes, the replica Azure virtual machine appears in the Azure portal > **Virtual Machines**. Make sure that the virtual machine is running, sized appropriately, and connected to the appropriate network.

7. If you want to delete the virtual machine created as part of testing the move, select **Cleanup test failover** on the replicated item. In **Notes**, record and save any observations associated with the test.

Move to the target region and confirm

1. In the virtual machine menu, select **Disaster recovery**.
2. Select the **Failover** icon.
3. In **Failover**, select **Latest**.
4. Select **Shut down machine before beginning failover**. Site Recovery attempts to shut down the source virtual machine before triggering the failover. Failover continues even if shutdown fails. You can follow the failover progress on the **Jobs** page.
5. After the job finishes, check that the virtual machine appears in the target Azure region as expected.
6. In **Replicated items**, right-click the virtual machine > **Commit**. This action finishes the move process to the target region. Wait until the commit job finishes.

Discard the resource in the source region

Go to the virtual machine. Select **Disable Replication**. This action stops the process of copying the data for the virtual machine.

> **Important**
>
> To avoid charges for Site Recovery replication after the move, perform the preceding step. The source replication settings are cleaned up automatically. The Site Recovery extension that you install as part of the replication isn't removed and needs to be removed manually.

Next steps

In this tutorial, you increased the availability of an Azure virtual machine by moving into an availability set or Availability Zone. Now you can set disaster recovery set up disaster recovery after migration for the moved virtual machine.

Move a Maintenance Control configuration to another region

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Follow this article to move a Maintenance Control configuration to a different Azure region. You might want to move a configuration for a number of reasons. For example, to take advantage of a new region, to deploy features or services available in a specific region, to meet internal policy and governance requirements, or in response to capacity planning.

Maintenance control, with customized maintenance configurations, allows you to control how platform updates are applied to VMs, and to Azure Dedicated Hosts. There are a couple of scenarios for moving maintenance control across regions:

- To move your maintenance control configuration, but not the resources associated with the configuration, follow the instructions in this article.
- To move the resources associated with a maintenance configuration, but not the configuration itself, follow these instructions.
- To move both the maintenance configuration and the resources associated with it, first follow the instructions in this article. Then, follow these instructions.

Prerequisites

Before you begin moving a maintenance control configuration:

- Maintenance configurations are associated with Azure VMs or Azure Dedicated Hosts. Make sure that VM/host resources exist in the new region before you begin.
- Identify:
  - Existing maintenance control configurations.
  - The resource groups in which existing configurations currently reside.
  - The resource groups to which the configurations will be added after moving to the new region.
  - The resources associated with the maintenance configuration you want to move.
  - Check that the resources in the new region are the same as those associated with the current maintenance configurations. The configurations can have the same names in the new region as they did in the old, but this isn't required.

Prepare and move

1. Retrieve all of the maintenance configurations in each subscription. Run the CLI az maintenance configuration list command to do this, replacing $subId with your subscription ID.

```
az maintenance configuration list --subscription $subId --query "[*].
{Name:name, Location:location, ResGroup:resourceGroup}" --output table
```

2. Review the returned table list of configuration records within the subscription. Here's an example. Your list will contain values for your specific environment.

Expand table

Name	Location	Resource group
Skip Maintenance	eastus2	configuration-resource-group
IgniteDemoConfig	eastus2	configuration-resource-group
defaultMaintenanceConfiguration-eastus	eastus	test-configuration

3. Save your list for reference. As you move the configurations, it helps you to verify that everything's been moved.

4. As a reference, map each configuration/resource group to the new resource group in the new region.

5. Create new maintenance configurations in the new region using PowerShell, or CLI.

6. Associate the configurations with the resources in the new region, using PowerShell, or CLI.

Verify the move

After moving the configurations, compare configurations and resources in the new region with the table list you prepared.

Clean up source resources

After the move, consider deleting the moved maintenance configurations in the source region, PowerShell, or CLI.

Next steps

Follow these instructions if you need to move resources associated with maintenance configurations.

Move resources in a Maintenance Control configuration to another region

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

Follow this article to move resources associated with a Maintenance Control configuration to a different Azure region. You might want to move a configuration for a number of reasons. For example, to take advantage of a new region, to deploy features or services available in a specific region, to meet internal policy and governance requirements, or in response to capacity planning.

Maintenance control, with customized maintenance configurations, allows you to control how platform updates are applied to VMs, and to Azure Dedicated Hosts. There are a couple of scenarios for moving maintenance control across regions:

- To move the resources associated with a maintenance configuration, but not the configuration itself, follow this article.
- To move your maintenance control configuration, but not the resources associated with the configuration, follow these instructions.
- To move both the maintenance configuration and the resources associated with it, first follow these instructions. Then, follow the instructions in this article.

Prerequisites

Before you begin moving the resources associated with a Maintenance Control configuration:

- Make sure that the resources you're moving exist in the new region before you begin.
- Verify the Maintenance Control configurations associated with the Azure VMs and Azure Dedicated Hosts that you want to move. Check each resource individually. There's currently no way to retrieve configurations for multiple resources.
- When retrieving configurations for a resource:
  - Make sure you use the subscription ID for the account, not an Azure Dedicated Host ID.
  - CLI: The --output table parameter is used for readability only, and can be deleted or changed.

- PowerShell: The Format-Table Name parameter is used for readability only, and can be deleted or changed.
- If you use PowerShell, you get an error if you try to list configurations for a resource that doesn't have any associated configurations. The error will be similar to: "Operation failed with status: 'Not Found'. Details: 404 Client Error: Not Found for url".

Prepare to move

1. Before you start, define these variables. We've provided an example for each.

Expand table

Variable	Details	Example
$subId	ID for subscription containing the maintenance configurations	"our-subscription-ID"
$rsrcGroupName	Resource group name (Azure VM)	"VMResourceGroup"
$vmName	VM resource name	"myVM"
$adhRsrcGroupName	Resource group (Dedicated hosts)	"HostResourceGroup"
$adh	Dedicated host name	"myHost"
$adhParentName	Parent resource name	"HostGroup"

2. To retrieve the maintenance configurations using the PowerShell Get-AZConfigurationAssignment command:

   - For Azure Dedicated Hosts, run:

```
Get-AzConfigurationAssignment -ResourceGroupName $adhRsrcGroupName
-ResourceName $adh -ResourceType hosts -ProviderName
Microsoft.Compute -ResourceParentName $adhParentName -
ResourceParentType hostGroups | Format-Table Name
```

   - For Azure VMs, run:

```
Get-AzConfigurationAssignment -ResourceGroupName $rgName -
ResourceName $vmName -ProviderName Microsoft.Compute -ResourceType
```

```
virtualMachines | Format-Table Name
```

3. To retrieve the maintenance configurations using the CLI az maintenance assignment command:

   - For Azure Dedicated Hosts:

     ```
     az maintenance assignment list --subscription $subId --resource-group $adhRsrcGroupName --resource-name $adh --resource-type hosts --provider-name Microsoft.Compute --resource-parent-name $adhParentName --resource-parent-type hostGroups --query "[].{HostResourceGroup:resourceGroup,ConfigName:name}" --output table
     ```

   - For Azure VMs:

     ```
     az maintenance assignment list --subscription $subId --provider-name Microsoft.Compute --resource-group $rsrcGroupName --resource-name $vmName --resource-type virtualMachines --query "[].{HostResourceGroup:resourceGroup, ConfigName:name}" --output table
     ```

Move

1. Follow these instructions to move the Azure VMs to the new region.
2. After the resources are moved, reapply maintenance configurations to the resources in the new region as appropriate, depending on whether you moved the maintenance configurations. You can apply a maintenance configuration to a resource using PowerShell or CLI.

Verify the move

Verify resources in the new region, and verify associated configurations for the resources in the new region.

Clean up source resources

After the move, consider deleting the moved resources in the source region.

Next steps

Follow these instructions if you need to move maintenance configurations.

Migrate from Amazon EC2 to Azure Virtual Machines

Summarize this article for me

If you use Amazon Elastic Compute Cloud (Amazon EC2) and plan to migrate your workload to Azure, this guide can help you understand the migration process, feature mappings, and best practices. It's for Amazon Web Services (AWS) professionals who are familiar with Amazon EC2 and plan to move workloads to Azure Virtual Machines. The guide highlights key similarities and differences between the platforms and outlines important architectural considerations. It also provides best practices for performance, cost, and availability to help you plan and complete a successful migration to an Azure infrastructure as a service (IaaS) environment.

What you will accomplish

This guide describes how to do the following tasks:

- Map Amazon EC2 instance families and sizes to the right Azure virtual machine (VM) series and SKUs.
- Translate Amazon machine image (AMI)-based workloads to Microsoft Marketplace or custom images.
- Design Azure storage architectures that meet or exceed existing Amazon Elastic Block Store (Amazon EBS) performance characteristics.
- Recreate Amazon Virtual Private Cloud (Amazon VPC) networking, security, and load-balancing patterns by using Azure-native services.
- Learn about availability, scaling, and placement strategies in Azure that align with AWS designs.
- Build the prerequisite knowledge and skills for a successful migration.
- Validate performance, resiliency, and functionality after migration.

Example scenario: Migrate a production Amazon EC2-based application stack

An organization runs a production web application on Amazon EC2 that uses the following components:

- General-purpose Amazon EC2 instances in multiple availability zones
- Amazon Elastic Load Balancing (Amazon ELB)
- Auto Scaling groups (ASGs) for elasticity
- Amazon EBS volumes for persistent storage

- Custom AMIs as a golden image baseline

The goal is to migrate this workload to Virtual Machines while you maintain availability, performance, and scaling characteristics.

Use Azure Migrate to migrate your Amazon EC2 instances to Azure

Azure Migrate provides a unified platform to assess and migrate on-premises servers, infrastructure, applications, and data. You can use Azure Migrate to discover, assess, and migrate Amazon EC2 instances to Azure.

> **Tip**
>
> Use Azure Migrate when your migration effort grows beyond a few manual builds and requires a repeatable, scalable approach.
>
> Use these guidelines to determine when Azure Migrate suits your VM migration:
>
> - For VMs that use the same operating system, have similar sizes, and have simple dependencies, use Azure Migrate when you migrate five or more VMs.
> - For VMs that use different operating systems or sizes, have multiple disks, or have complex dependencies, use Azure Migrate when you migrate three or more VMs.

For more information, see Migrate Amazon EC2 instances by using Azure Migrate.

Architectural overview

In AWS, the workload uses Amazon EC2 instances distributed across availability zones inside an Amazon VPC, fronted by an Amazon ELB and scaled by using ASGs. Amazon EBS provides storage, and custom AMIs provide images.

In Azure, the following components form the equivalent architecture:

- Virtual Machines or Azure Virtual Machine Scale Sets
- Azure Virtual Network with subnets
- Azure Load Balancer or Azure Application Gateway
- Azure Managed Disks
- Marketplace images or custom images stored in Azure Compute Gallery

Production environment considerations

When you transition from Amazon EC2 to Virtual Machines, plan for the following considerations:

- Differences in VM sizing, disk performance coupling, and networking limits
- Image format and agent compatibility because you can't import AMIs directly
- Availability constructs, like availability zones versus availability sets
- Network security rule evaluation and service integration
- Differences in monitoring, logging, and automation

Step 1: Plan

Inventory the existing Amazon EC2 workload and capture how it behaves in production.

The key assessment activities include the following items:

- Identify Amazon EC2 instance families, sizes, and CPU architecture, like `x86` or `ARM64`.
- Capture baseline and peak CPU, memory, disk input/output operations per second (IOPS), throughput, latency, and network usage.
- Document Amazon EBS volume types and performance settings.
- Review ASG policies and placement strategies.
- Enumerate security group and network access control list (NACL) rules.
- Identify AMI sources, like public, vendor, or custom images.

Formalize your findings by categorizing each capability into one of the following groups:

- Direct matches in Azure
- Matches that have configuration differences
- Capabilities that require alternative designs

Direct capability mapping

Expand table

Amazon EC2 capability	Azure Virtual Machines equivalent	Migration approach
Amazon EC2 instance families like `t`, `m`, `c`, `r`, `i`, and `p`	Azure VM series like B, D, F, E, L, and NC, ND, or NP	Select Azure VM SKUs that have equivalent CPU-to-memory ratios and architecture.

Amazon EC2 capability	Azure Virtual Machines equivalent	Migration approach
ASGs	Virtual Machine Scale Sets	Set up autoscaling in Virtual Machine Scale Sets and distribute instances across zones.
Amazon ELB: Amazon Application Load Balancer (ALB) and Amazon Network Load Balancer (NLB)	Load Balancer and Application Gateway	Map layer-4 or layer-7 behavior and health probes.
Amazon EBS volumes	Azure Managed Disks	Map Amazon EBS volume types to the right disk SKUs and validate limits.
Availability zones	Azure availability zones	Deploy VMs or Virtual Machine Scale Sets instances across zones where supported.

Capability mismatches and alternative strategies

Some Amazon EC2 capabilities don't map directly to Azure:

- **AMI portability:** Azure doesn't support a lift-and-shift approach for AMIs. You must map images to Marketplace images or rebuild them as custom images.
- **Bursting behavior:** AWS supports CPU bursts beyond the `t` family. Azure limits CPU bursts to the B-series.
- **Disk performance scale:** AWS decouples disk performance from instance size. In Azure, both disk SKU and VM size constrain disk performance.
- **Hypervisor access:** Amazon EC2 bare-metal instances expose more control than Azure VMs. For hardware isolation requirements in Azure, use Azure Dedicated Host.

Step 2: Prepare

Prepare the Azure environment before you migrate workloads:

- Design Azure virtual networks and subnets that align with existing Amazon VPC segmentation.
- Establish identity and access control by using Azure role-based access control (Azure RBAC).
- Choose availability zones or availability sets based on your workload requirements and regional support.
- Select base Marketplace images that match the operating system version, architecture, and boot mode.

- Remove AWS-specific agents and ensure Azure VM Agent support.
- Use Azure Migrate for discovery, dependency map creation, and rightsizing recommendations when you migrate multiple VMs.

Step 3: Execute

Each stage of the migration process requires careful planning and execution to ensure a successful transition from Amazon EC2 to Virtual Machines. This section describes how to migrate compute, images, storage, networking, and availability features.

Compute

When you migrate from Amazon EC2 to Virtual Machines, you must know how instance families map to Azure VM series to plan your workloads effectively. Both platforms organize their compute offerings by performance characteristics, but their naming conventions and configuration options differ.

Amazon EC2 instance families

AWS organizes compute resources into instance families based on workload type:

- **General purpose:** Balanced CPU, memory, and networking, like `t3` and `m5`.
- **Compute optimized:** High CPU-to-memory ratio for compute-intensive tasks, like `c5` and `c6g`.
- **Memory optimized:** Large memory footprint for in-memory databases or analytics, like `r5` and `x1e`.
- **Storage optimized:** High disk throughput for large datasets, like `i3` and `d2`.
- **Accelerated computing:** GPU-based workloads for machine learning or graphics, like `p3` and `g4dn`.

AWS instances scale vertically by selecting larger sizes within a family, like moving from `m5.large` to `m5.4xlarge`, and horizontally by using ASGs.

Azure VM series

Azure uses VM series to categorize compute resources:

- **D-series:** General-purpose workloads, similar to the AWS `m` family
- **F-series:** Compute optimized, comparable to the AWS `c` family
- **E-series:** Memory optimized, similar to the AWS `r` family

- **M-series:** Ultra-high memory for SAP HANA and large databases
- **L-series:** Storage optimized with local Non-Volatile Memory Express (NVMe) disks, and comparable to the AWS `i` family
- **NC, ND, and NP-series:** GPU enabled for AI and machine learning workloads, similar to the AWS `p` and `g` families

Azure defines VM sizes by a SKU, like `Standard_D4s_v5`. The SKU specifies the following properties:

- Virtual CPU (vCPU) count
- Memory, expressed in gibibytes (GiB)
- Temporary storage
- Generation

For more information, see VM size naming conventions.

Key differences

- **Naming:** AWS uses family and size, like `c5.xlarge`. Azure uses VM series and VM SKU, like `Standard_F4s_v2`.
- **Performance tiers:** Azure sets disk performance according to VM size and disk SKU. AWS uses Amazon EBS-optimized instances.
- **Regional availability:** Features vary by region on both platforms. On Azure, features like availability zones and spot capacity are available only in specific regions.
- **Burstable options:** The AWS `t` family supports burstable workloads, and AWS provides burst capability on other eligible instance sizes. Azure limits bursting to the B-series.
- **Hypervisor access:** Some AWS sizes allow for more direct control over the hypervisor, like `i3.metal`. Azure provides less control at this layer.

Mapping strategy

Use the Azure VM size documentation and AWS instance type guide to complete the following tasks:

1. Identify your Amazon EC2 instance family and size.
2. Match to an Azure VM series with equivalent CPU-to-memory ratio and the required CPU architecture, like `x86` or `ARM`.
3. Validate storage and network requirements to prevent overprovisioning or underprovisioning:

    - **Establish a baseline in AWS.** Capture typical and peak Amazon EBS IOPS, throughput, and latency, and capture network bandwidth and packets-per-second

(PPS) usage.
    - **Map to Azure limits.** Confirm disk SKU and VM size caps and the VM's network limits, including whether it supports Azure accelerated networking.
    - **Test in Azure.** Run quick storage and network benchmarks before you finalize the VM size.
4. If you use accelerators, like GPU or Field-Programmable Gate Array (FPGA), ensure that the Azure VM series supports them.
5. Consider Azure-specific features like spot VMs for cost savings or virtual machine scale sets for elasticity.

Images

When you migrate workloads that start from an AMI, plan for an *image translation* step.

> **Important**
>
> Azure doesn't support lift and shift of AMIs. You can't import an AMI and run it unchanged on Azure.
>
> Map an AMI to a Marketplace image (catalog to catalog) or map a custom AMI to a custom Azure image (custom to custom) instead. Then validate drivers, agents, and generation compatibility.

Find a matching (catalog) image

Start by identifying what the AMI represents:

- Operating system distribution and version, like Ubuntu 22.04, RHEL 8.9, and Windows Server 2022
- CPU architecture, like `x86_64` versus `ARM64`
- Boot mode and VM generation assumptions, like UEFI with Gen2 VMs or BIOS with Gen1 VMs
- Installed components, like monitoring agents, security tools, and web and app runtimes
- Licensing model, like bring-your-own versus marketplace-provided

Then find an equivalent Azure image:

- Marketplace images best match to public AMIs.
- Images that your organization publishes through Compute Gallery are most similar to private or shared AMIs.

If your AWS workload depends on a vendor AMI, like a firewall, appliance, or hardened image, identify the vendor's equivalent offering in Marketplace and confirm that it meets the following requirements:

- Supported VM sizes and required networking features
- Required disk layout and performance
- Licensing and support terms

Roll your own (custom-to-custom)

If the AMI is a custom image, like a golden image, a hardened baseline, or an image with a preinstalled app, the Azure equivalent is a custom image that you store and version in Compute Gallery.

Use the following steps as a recommended starting point:

1. **Pick a clean base image** from Marketplace that matches the operating system, version, and architecture that you need.
2. **Automate customization** by applying packages, configuration, agents, and hardening through a repeatable pipeline.
3. **Validate the image** when you deploy test VMs and run smoke tests.
4. **Publish and version the image** in Compute Gallery and replicate it to target regions.

Consider the following common tooling patterns:

- **Azure VM Image Builder** is a managed image build service for image creation and distribution.
- **HashiCorp Packer**, including the Azure builders, is for building images in continuous integration and continuous delivery (CI/CD) pipelines.
- **Configuration management tools** like Ansible, Chef, or Puppet help keep customization reproducible.

Consider these operational requirements to plan your *where do you start* checklist:

- **Generalization:**
  - On Windows, run Sysprep before you capture the image.
  - On Linux, install the Azure Linux VM Agent (`waagent`) before you capture the image.
- **Drivers and agents:** Ensure that the image supports the Azure VM Agent and remove any AWS-specific agents or tools that no longer apply.
- **VM generation:** Choose Gen1 or Gen2 early because your base image choice typically determines the generation.
- **Identity and secrets:** Use managed identity and Azure Key Vault instead of embedding secrets in images.

- **Updates:** Patch the image during build and define an image refresh cadence.

Storage

Storage architecture is a critical factor when you migrate from Amazon EC2 to Virtual Machines. Both platforms provide persistent and ephemeral storage options, but implementation and performance models differ.

Amazon EC2 storage options

- **Amazon EBS:** Persistent block storage for Amazon EC2 instances. Supports solid-state drive (SSD) and hard disk drive (HDD) volumes:
  - General-purpose SSD that uses `gp3` and `gp2`
  - Provisioned IOPS SSD that uses `io1` and `io2`
  - Throughput-optimized HDD that uses `st1`
  - Cold HDD that uses `sc1`
- **Network-attached storage (NAS):** Shared file storage for Linux and Windows workloads:
  - **Amazon Elastic File System (Amazon EFS)**
  - **Amazon FSx**, like Windows File Server, NetApp ONTAP, and Lustre
- **Instance store:** Ephemeral storage that's physically attached to the host. Data is deleted when the instance stops or terminates.
- **Amazon Simple Storage Service (Amazon S3):** Object storage for unstructured data, backups, and archival storage.

Key features of Amazon EC2 storage options include the following items:

- Snapshots for Amazon EBS volumes are stored in Amazon S3.
- Performance depends on volume type and size.
- Encryption via AWS Key Management Service (AWS KMS).

Azure VM storage options

- **Managed disks:** Azure manages persistent block storage:
  - **Azure Standard HDD:** Cost effective for infrequent access, nonproduction workloads, and long-term backups.
  - **Azure Standard SSD:** Balanced performance for general workloads.
  - **Azure Premium SSD:** Low latency for production and performance-sensitive apps.
  - **Azure Ultra Disk Storage:** High throughput for data-intensive workloads.
- **Ephemeral OS disks:** Temporary storage for stateless workloads.
- **Externalized storage (NAS and object storage):** Network-attached and object-based storage for shared file access, backups, archival, and large-scale data:

- Azure Blob Storage
- Azure Files
- Azure NetApp Files

Key features of Azure VM storage options include the following items:

- Disk performance tiers depend on VM size and disk SKU.
- Azure VM storage includes built-in snapshot capabilities and integrates with Azure Backup.
- Encryption at rest uses default keys and supports customer-managed keys.

Architectural differences

Expand table

Feature	Amazon EC2 (Amazon EBS)	Azure Virtual Machines (managed disks)
Performance scaling	Based on volume type and size	Based on VM size and disk SKU
Snapshot integration	Stored in Amazon S3	Built-in, integrates with Azure Backup
Encryption	AWS KMS	Azure disk encryption and Key Vault
Resiliency	Availability zone-level replication optional	Zone-redundant storage (ZRS) available

For NAS, Amazon EFS and Amazon FSx map most directly to Azure Files and Azure NetApp Files.

Storage migration considerations

- Map Amazon EBS volumes to Azure Managed Disk tiers:
  - The `gp2` and `gp3` volume types map to Standard SSD for light or moderate use.
  - The `gp2` volume type maps to Premium SSD.
  - The `gp3` volume type maps to Premium SSD v2.
  - The `io2` volume type maps to Ultra Disk Storage.
- Validate IOPS and throughput requirements. Premium SSD and Ultra Disk Storage support high-performance workloads.
- Plan for encryption compliance. Use Azure disk encryption and Key Vault for sensitive data.
- For externalized storage migration, you can use the following approaches:

    - Migrate Amazon S3 to Blob Storage by using AzCopy or Azure Storage migration tools.
    - Migrate Amazon EFS and Amazon FSx to Azure Files for general-purpose file shares, or to Azure NetApp Files for high-performance NAS.

Validate IOPS and throughput requirements carefully because both disk SKU and VM size constrain Azure disk performance.

Networking

Networking architecture is a critical component when you migrate from Amazon EC2 to Virtual Machines. Both platforms provide secure, isolated networks, but terminology, configuration, and feature sets differ.

Amazon EC2 networking

- **Amazon VPC:** Logical isolation of resources within AWS.
- **Subnets:** Network segments within an Amazon VPC for isolation and segmentation.
- **Security groups:** Stateful firewall rules applied at the instance level.
- **Network ACLs:** Stateless rules applied at the subnet level.
- **Elastic IP addresses:** Static public IP addresses for instances.
- **Load balancing:** Amazon ELB supports layer-4 and layer-7 traffic.
- **Hybrid connectivity:** Virtual private network (VPN) and AWS Direct Connect for private links to on-premises.

Azure VM networking components

- **Virtual network:** An isolated and segmented network environment equivalent to an Amazon VPC.
- **Subnets:** Network segments within a virtual network that provide isolation and support network security groups (NSGs) for traffic filtering.
- **NSGs:** Stateful inbound and outbound traffic rules applied at the subnet or network interface card (NIC) level.
- **Azure Firewall:** A managed, cloud-based firewall used for centralized policy enforcement.
- **Azure Private Link:** Private IP address-based access to Azure services.
- **Public IP addresses:** Static or dynamic public IP addresses that you assign to resources.
- **Load balancing:** Load Balancer at layer 4 and Application Gateway at layer 7 with Secure Sockets Layer (SSL) termination and Azure Web Application Firewall.
- **Azure Bastion:** Secure Remote Desktop Protocol (RDP) and Secure Shell (SSH) access without exposing public IP addresses.
- **Azure ExpressRoute:** Private dedicated connectivity to Azure for hybrid scenarios.

Key differences

Expand table

Feature	Amazon EC2 (Amazon VPC)	Azure Virtual Machines (virtual network)
Firewall integration	Security groups and NACLs	NSGs and Azure Firewall
Private service access	Amazon VPC endpoints	Private Link
Hybrid connectivity	VPN and AWS Direct Connect	Azure VPN Gateway and ExpressRoute
Secure remote access	Jump hosts	Azure Bastion

Migration considerations

1. **Plan virtual network architecture:** Align with existing Amazon VPC design for subnet segmentation.
2. **Security rules:** Convert AWS security group rules to NSGs. Review inbound and outbound traffic.
3. **Hybrid connectivity:** Replace AWS Direct Connect with ExpressRoute for private connectivity.
4. **Load balancing:** Map Amazon ELB configurations to Load Balancer or Application Gateway.
5. **Access control:** Use Azure Bastion for secure remote access instead of exposing public IP addresses.

Clustering, availability, and zones

High-availability and resiliency strategies vary between Amazon EC2 and Virtual Machines. These concepts are essential for a fault-tolerant architecture.

Amazon EC2 availability features

- **Availability zones:** Isolated locations within a region for redundancy.
- **ASGs:** Automatic scaling of instance counts based on demand.
- **Amazon ELB:** Traffic distribution across multiple instances.
- **Placement groups:** Instance placement for low-latency or high-throughput workloads.

Azure VM availability features

- **Availability zones:** Physically separate datacenters within a region for zone-level resiliency.
- **Availability sets:** Logical grouping to protect against rack-level failures.
- **Virtual Machine Scale Sets:** Built-in orchestration for horizontal workload scale.
- **Load Balancer and Application Gateway:** Layer-4 and layer-7 traffic distribution.

Mapping translation

Expand table

Feature	Amazon EC2	Azure Virtual Machines	Migration considerations
Zone redundancy	Availability zone-based deployment	Availability zones and ZRS	Map AWS availability zone deployment to Azure availability zones. When you use Virtual Machine Scale Sets, distribute instances across zones for maximum resiliency.
Rack-level protection	Not explicit	Availability sets	Use availability sets for rack-level resiliency.
Automatic scaling	ASGs	Virtual Machine Scale Sets	Map AWS ASGs to Virtual Machine Scale Sets. Consider zone-distributed Virtual Machine Scale Sets where supported.
Load balancing	Amazon ELB that provides layer-4 and layer-7 capabilities	Load Balancer and Application Gateway	Set up load balancing. Replace Amazon ELB with Load Balancer or Application Gateway.

Best practices

- Deploy across multiple zones for disaster recovery.
- Use Virtual Machine Scale Sets with autoscaling policies for elasticity.
- Use ZRS for critical data.
- Integrate Azure Monitor for health checks and alerting.

Scaling and placement

AWS and Azure use different constructs for scaling and placement. These differences affect elasticity and fault isolation during migration.

AWS approach

- **ASGs:** Automatically adjust Amazon EC2 instance count based on demand by using launch templates, which define instance configuration and life cycle, including NICs and disks.
- **Partition placement groups:** Spread Amazon EC2 instances across multiple partitions for resiliency and low-latency workloads.

Azure approach

- **Virtual Machine Scale Sets:** Provides native orchestration for horizontal scaling, integrated with Load Balancer or Application Gateway.
- **VM profiles:** Defines VM configuration and support deep deletion for resource cleanup.
- **Fault domains and availability sets:** Provides rack-level isolation similar to AWS partitioning. For dedicated hardware, use Dedicated Host.

Key differences

Expand table

Feature	Amazon EC2	Azure Virtual Machines
Scaling construct	ASGs	Virtual Machine Scale Sets and autoscaling
Instance configuration	Launch template	VM configuration profile and deep deletion
Placement strategy	Partition placement groups	Fault domains, availability sets, and Dedicated Host

Step 4: Evaluate

After the migration completes, do the following validation steps:

- Validate operating system boot and agent health.
- Confirm that disk throughput, latency, and network performance meet expectations.
- Test scaling behavior and load balancing.
- Validate application functionality and dependencies.
- Set up Azure Monitor alerts and logging.

Successful validation indicates that the workload is ready for production cutover.

Discover, assess, and migrate Amazon Web Services (AWS) EC2 instances to Azure

This tutorial shows you how to discover, assess, and migrate Amazon Web Services (AWS) EC2 instances to Azure VMs by using Azure Migrate: Server Assessment and the Migration and modernization tool.

> **Note**
>
> You migrate AWS VMs to Azure by treating them as physical servers.

In this tutorial, you learn how to:

- ✓ Verify prerequisites for migration.
- ✓ Prepare Azure resources with the Migration and modernization tool. Set up permissions for your Azure account and resources to work with Azure Migrate and Modernize.
- ✓ Prepare AWS Elastic Compute Cloud (EC2) instances for migration.
- ✓ Add the Migration and modernization tool in the Azure Migrate and Modernize hub.
- ✓ Set up the replication appliance and deploy the configuration server.
- ✓ Install the Mobility service on the AWS VMs you want to migrate.
- ✓ Enable replication for VMs.
- ✓ Track and monitor the replication status.
- ✓ Run a test migration to make sure everything's working as expected.
- ✓ Run a full migration to Azure.

If you don't have an Azure subscription, create a free account before you begin.

Discover and assess

Before you migrate to Azure, we recommend that you perform a VM discovery and migration assessment. This assessment helps right-size your AWS VMs for migration to Azure and estimate potential Azure run costs.

To set up an assessment:

1. Follow the tutorial to set up Azure and prepare your AWS VMs for an assessment. Note that:

- Azure Migrate and Modernize uses password authentication to discover AWS instances. AWS instances don't support password authentication by default. Before you can discover an instance, you need to enable password authentication.
  - For Windows machines, allow WinRM port 5985 (HTTP). This port allows remote WMI calls.
  - For Linux machines:
    a. Sign in to each Linux machine.
    b. Open the *sshd_config* file: `vi /etc/ssh/sshd_config`.
    c. In the file, locate the `PasswordAuthentication` line and change the value to `yes`.
    d. Save the file and close it. Restart the ssh service.
- If you're using a root user to discover your Linux VMs, ensure that root login is allowed on the VMs.
  a. Sign in to each Linux machine.
  b. Open the *sshd_config* file: `vi /etc/ssh/sshd_config`.
  c. In the file, locate the `PermitRootLogin` line and change the value to `yes`.
  d. Save the file and close it. Restart the ssh service.

2. Then, follow this tutorial to set up an Azure Migrate project and appliance to discover and assess your AWS VMs.

Although we recommend that you try out an assessment, performing an assessment isn't a mandatory step to be able to migrate VMs.

Prerequisites

- Ensure that the AWS VMs you want to migrate are running a supported operating system (OS) version. AWS VMs are treated like physical machines for the migration. Review the supported operating systems and kernel versions for the physical server migration workflow. You can use standard commands like `hostnamectl` or `uname -a` to check the OS and kernel versions for your Linux VMs. We recommend that you perform a test migration (test failover) to validate if the VM works as expected before you proceed with the migration.
- Make sure your AWS VMs comply with the supported configurations for migration to Azure.
- Verify that the AWS VMs that you replicate to Azure comply with Azure VM requirements.
- Some changes are needed on the VMs before you migrate them to Azure:
  - For some operating systems, Azure Migrate and Modernize makes these changes automatically.

- It's important to make these changes before you begin migration. If you migrate the VM before you make the change, the VM might not boot up in Azure. Review the Windows and Linux changes you need to make.

Prepare Azure resources for migration

Prepare Azure for migration with the Migration and modernization tool.

Expand table

Task	Details
Create an Azure Migrate project	Your Azure account needs Contributor or Owner permissions to create a new project.
Verify permissions for your Azure account	Your Azure account needs permissions to create a VM and write to an Azure managed disk.

Assign permissions to create a project

1. In the Azure portal, open the subscription and select **Access control (IAM)**.
2. In **Check access**, find the relevant account and select it to view permissions.
3. You should have **Contributor** or **Owner** permissions.

    - If you just created a free Azure account, you're the owner of your subscription.
    - If you're not the subscription owner, work with the owner to assign the role.

Assign Azure account permissions

Assign the VM Contributor role to the Azure account. This role provides permissions to:

- Create a VM in the selected resource group.
- Create a VM in the selected virtual network.
- Write to an Azure managed disk.

Create an Azure network

Set up an Azure virtual network. When you replicate to Azure, the Azure VMs that are created are joined to the Azure virtual network that you specified when you set up migration.

Prepare AWS instances for migration

To prepare for AWS to Azure migration, you need to prepare and deploy a replication appliance for migration.

Prepare a machine for the replication appliance

The Migration and modernization tool uses a replication appliance to replicate machines to Azure. The replication appliance runs the following components:

- **Configuration server**: The configuration server coordinates communications between the AWS environment and Azure and manages data replication.
- **Process server**: The process server acts as a replication gateway. It receives replication data and optimizes that data with caching, compression, and encryption. Then it sends the data to a cache storage account in Azure.

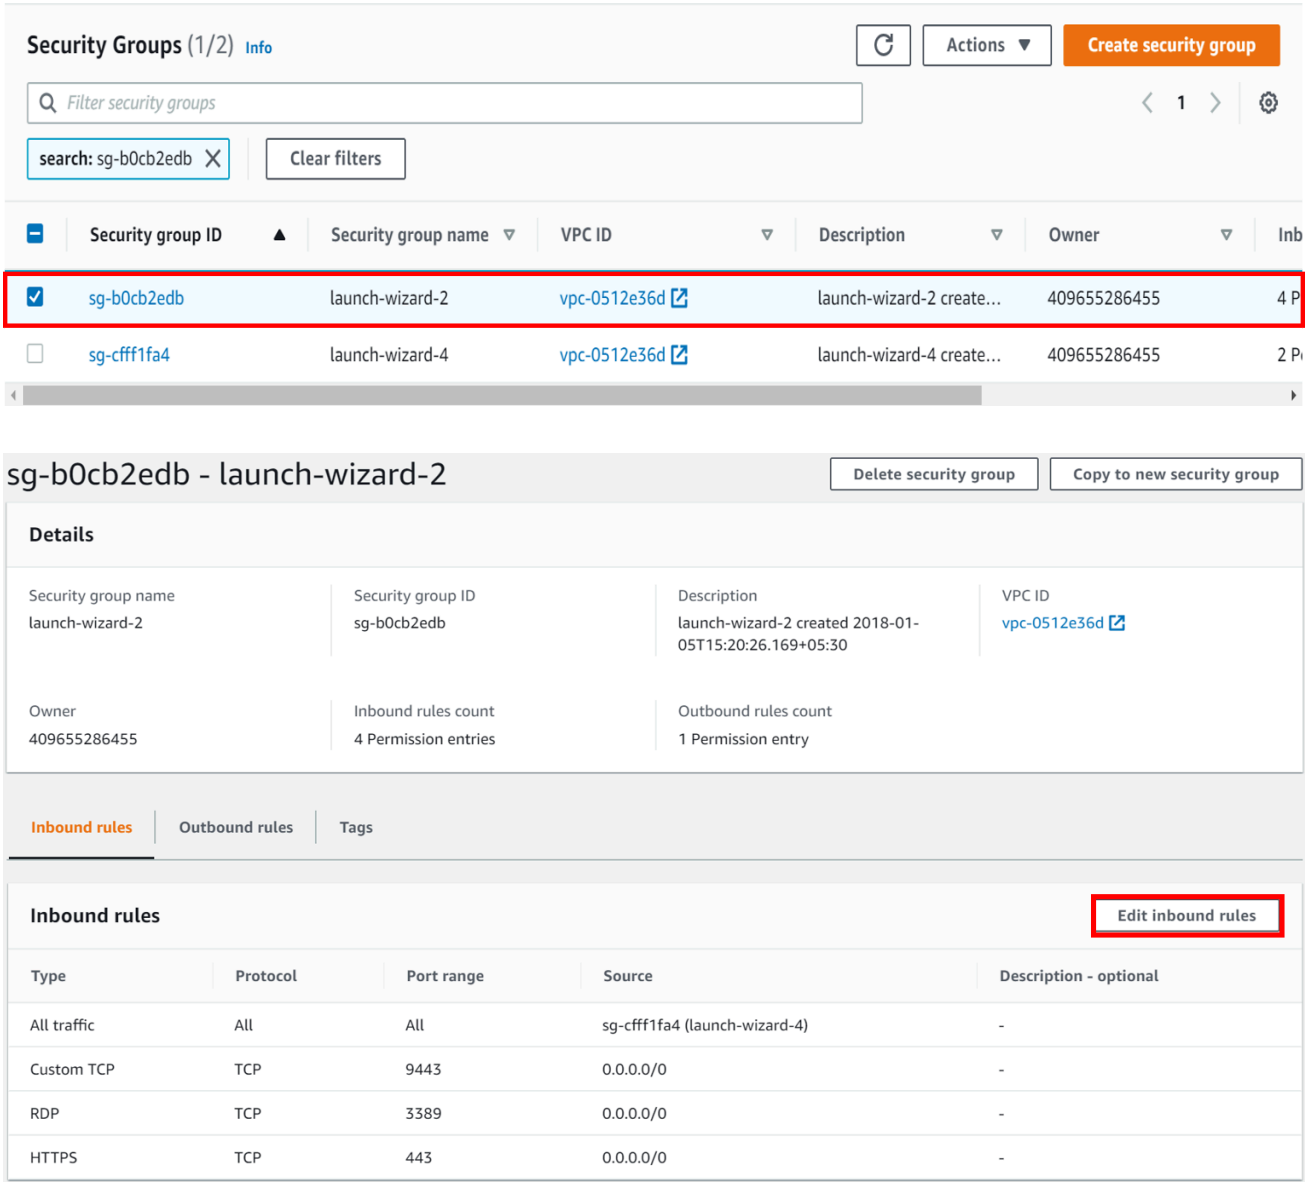
To prepare for appliance deployment:

- Set up a separate EC2 VM to host the replication appliance. This instance must be running Windows Server 2022. Review the hardware, software, and networking requirements for the appliance.

- The appliance shouldn't be installed on a source VM that you want to replicate or on the Azure Migrate: Discovery and assessment appliance you might have installed before. It should be deployed on a different VM.

- The source AWS VMs to be migrated should have a network line of sight to the replication appliance. Configure necessary security group rules to enable this capability. We recommend that you deploy the replication appliance in the same virtual private cloud (VPC) as the source VMs to be migrated. If the replication appliance needs to be in a different VPC, the VPCs must be connected through VPC peering.

- The source AWS VMs communicate with the replication appliance on ports HTTPS 443 (control channel orchestration) and TCP 9443 (data transport) inbound for replication management and replication data transfer. The replication appliance in turn orchestrates and sends replication data to Azure over port HTTPS 443 outbound. To configure these rules, edit the security group inbound/outbound rules with the appropriate ports and source IP information.



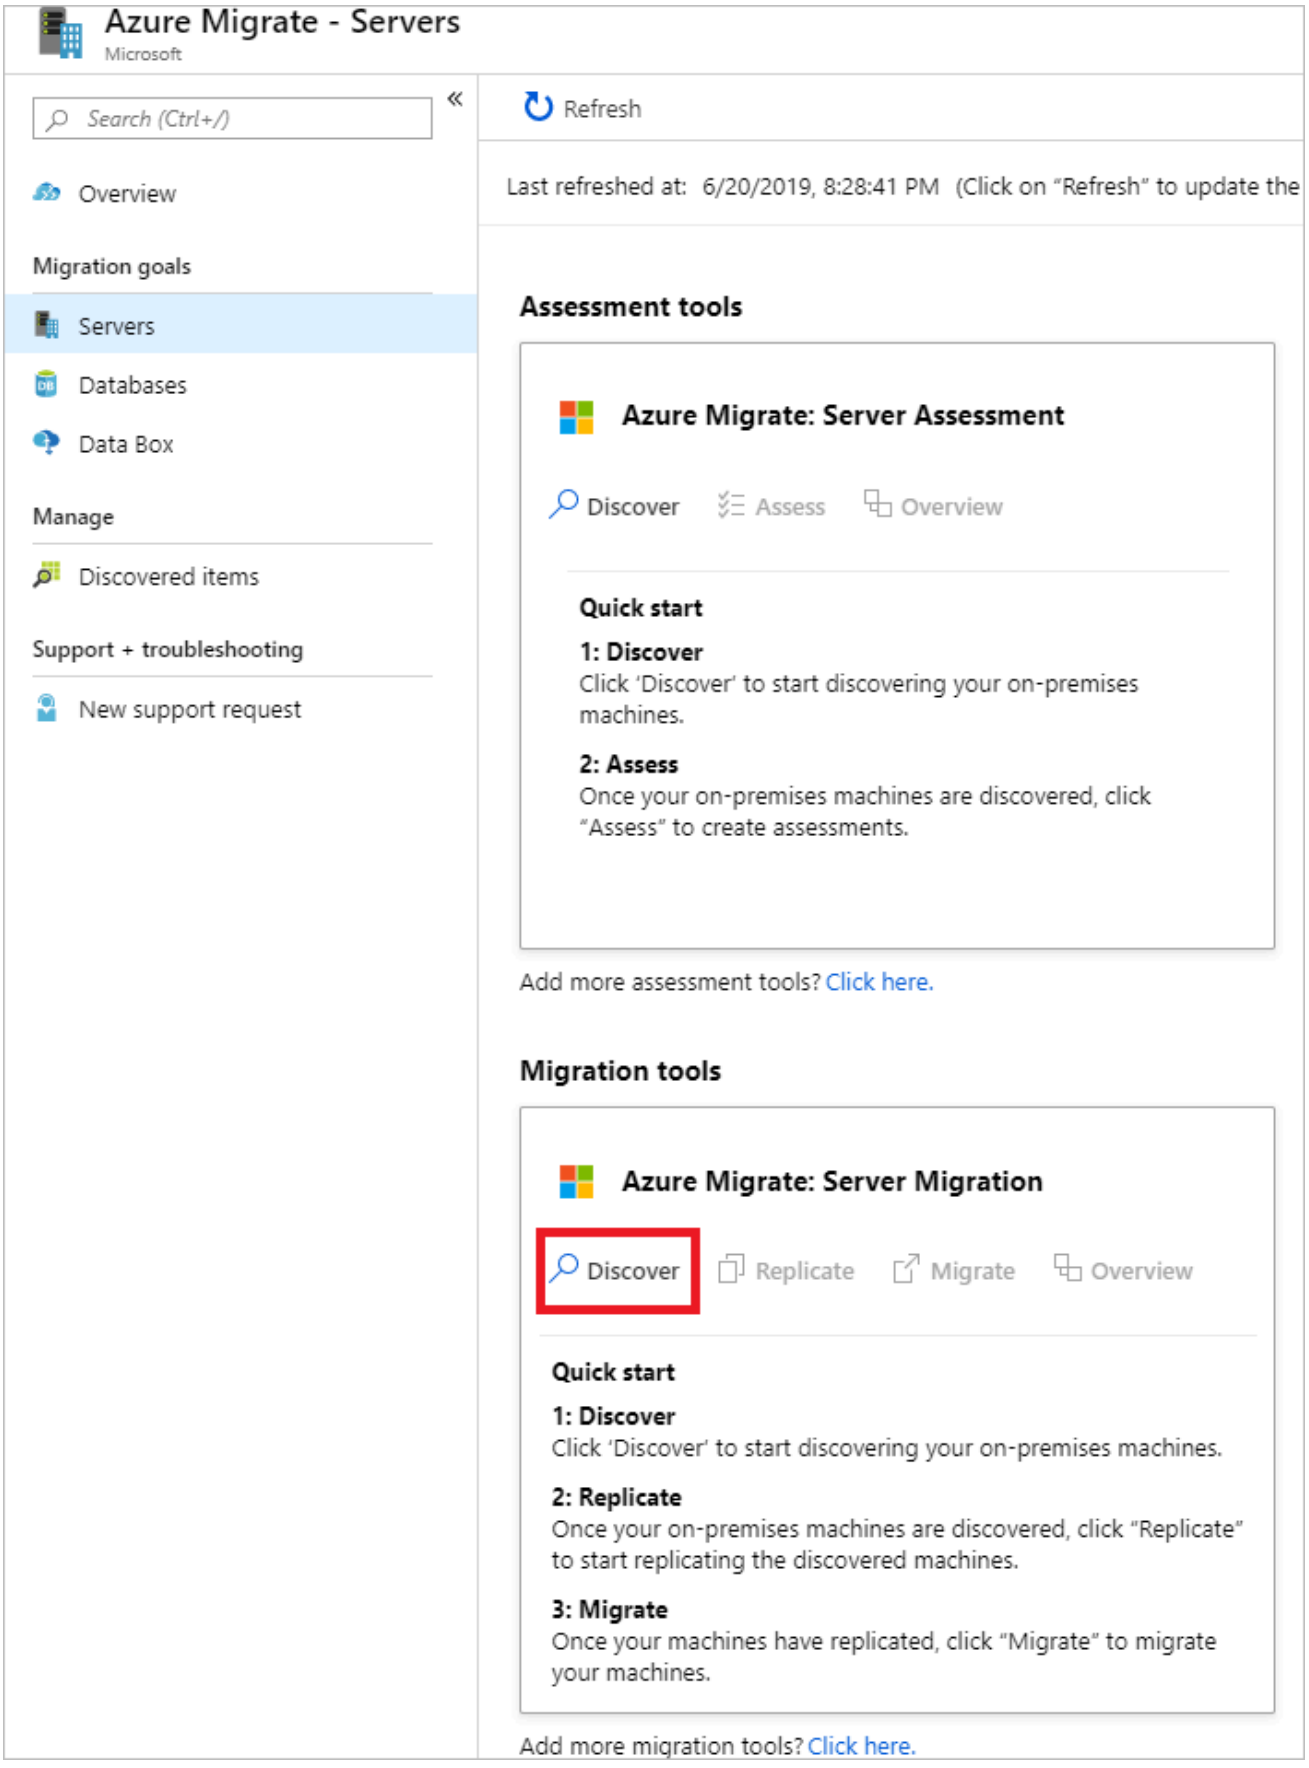
- The replication appliance uses MySQL. Review the options for installing MySQL on the appliance.
- Review the Azure URLs required for the replication appliance to access public and government clouds.

Set up the replication appliance

The first step of migration is to set up the replication appliance. To set up the appliance for AWS VMs migration, you must download the installer file for the appliance and then run it on the VM you prepared.

Download the replication appliance installer

1. In the Azure Migrate project, select **Servers, databases, and web apps** > **Migration and modernization** > **Discover**.



2. In **Discover machines** > **Are your machines virtualized?**, select **Not virtualized/Other**.

3. In **Target region**, select the Azure region to which you want to migrate the machines.

4. Select **Confirm that the target region for migration is <region-name>**.

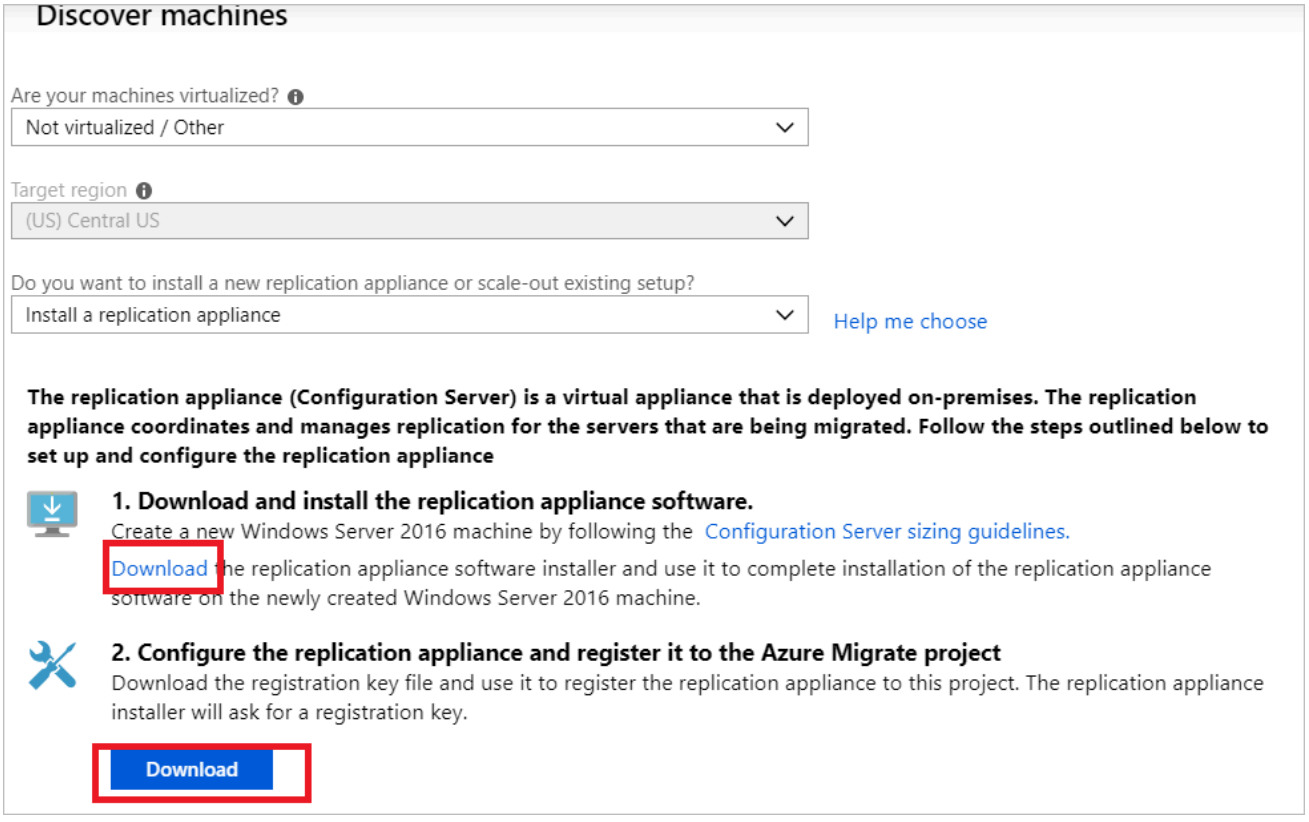
5. Select **Create resources**. This step creates an Azure Site Recovery vault in the background.

    - If you already set up migration with the Migration and modernization tool, the target option can't be configured because resources were set up previously.
    - You can't change the target region for this project after you select this button.
    - To migrate your VMs to a different region, you need to create a new or different Azure Migrate project.

    > ⓘ Note
    >
    > If you selected private endpoint as the connectivity method for the Azure Migrate project when it was created, the Recovery Services vault is also configured for private endpoint connectivity. Ensure that the private endpoints are reachable from the replication appliance. Learn more.

6. In **Do you want to install a new replication appliance?**, select **Install a replication appliance**.

7. In **Download and install the replication appliance software**, download the appliance installer and the registration key. You need the key to register the appliance. The key is valid for five days after download.

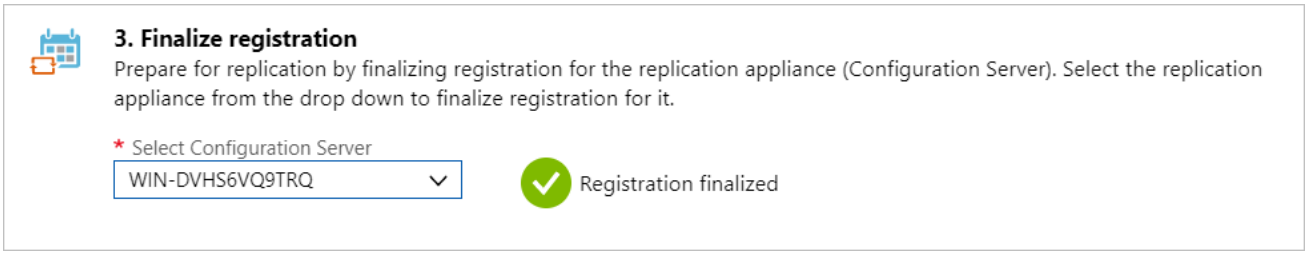


8. Copy the appliance setup file and key file to the Windows Server 2022 AWS VM you created for the replication appliance.

9. Run the replication appliance setup file, as described in the next procedure.
    a. Under **Before You Begin**, select **Install the configuration server and process server**. Then select **Next**.
    b. In **Third-Party Software License**, select **I accept the third-party license agreement**. Then select **Next**.
    c. In **Registration**, select **Browse**, and then go to where you put the vault registration key file. Select **Next**.
    d. In **Internet Settings**, select **Connect to Azure Site Recovery without a proxy server**. Then select **Next**.
    e. The **Prerequisites Check** page runs checks for several items. When it's finished, select **Next**.
    f. In **MySQL Configuration**, provide a password for the MySQL database. Then select **Next**.
    g. In **Environment Details**, select **No**. You don't need to protect your VMs. Then select **Next**.
    h. In **Install Location**, select **Next** to accept the default.
    i. In **Network Selection**, select **Next** to accept the default.
    j. In **Summary**, select **Install**.
    k. **Installation Progress** shows you information about the installation process. When it's finished, select **Finish**. A window displays a message about a reboot. Select **OK**.
    l. Next, a window displays a message about the configuration server connection passphrase. Copy the passphrase to your clipboard and save the passphrase in a temporary text file on the source VMs. You need this passphrase later during the Mobility service installation process.

10. After the installation finishes, the Appliance configuration wizard launches automatically. (You can also launch the wizard manually by using the `cspsconfigtool` shortcut that was created on the appliance desktop.) In this tutorial, we manually install the Mobility service on source VMs to be replicated. You need to create a dummy account in this step to proceed. For your dummy account, use "guest" as the friendly name, "username" as the username, and "password" as the password for the account. You use this dummy account in the Enable Replication stage.

11. After the appliance restarts after setup, in **Discover machines**, select the new appliance in **Select Configuration Server** and select **Finalize registration**. The **Finalize registration** step performs a couple of final tasks to prepare the replication appliance.



Install the Mobility service agent

A Mobility service agent must be preinstalled on the source AWS VMs to be migrated before you can initiate replication. The approach you choose to install the Mobility service agent might depend on your organization's preferences and existing tools. The "push" installation method built into Site Recovery isn't currently supported. Approaches you might want to consider:

- AWS System Manager
- System Center Configuration Manager
- Azure Arc for servers and custom script extensions
- Install Mobility agent for Windows
- Install Mobility agent for Linux

1. Extract the contents of the installer tarball to a local folder (for example, /tmp/MobSvcInstaller) on the AWS VM, as follows:

```
mkdir /tmp/MobSvcInstaller
tar -C /tmp/MobSvcInstaller -xvf <Installer tarball>
cd /tmp/MobSvcInstaller
```

2. Run the installer script:

```
sudo ./install -r MS -v VmWare -q -c CSLegacy
```

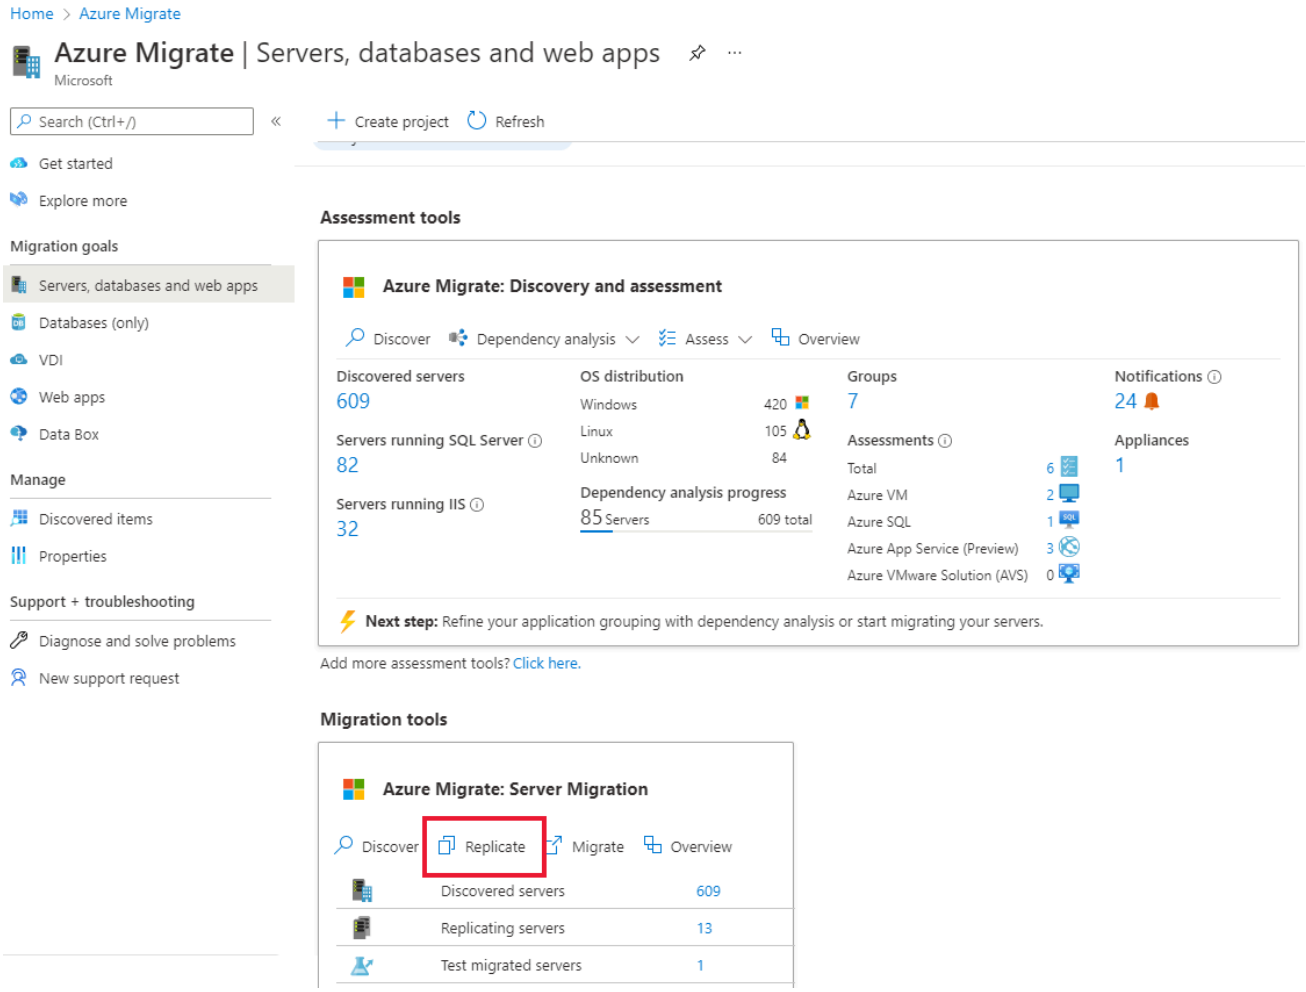
3. Register the agent with the replication appliance:

```
/usr/local/ASR/Vx/bin/UnifiedAgentConfigurator.sh -i <replication appliance IP address> -P <Passphrase File Path>
```

Enable replication for AWS VMs

> **Note**
>
> Through the portal, you can add up to 10 VMs for replication at once. To replicate more VMs simultaneously, you can add them in batches of 10.

1. In the Azure Migrate project, select **Servers, databases, and web apps** > **Migration and modernization** > **Replicate**.

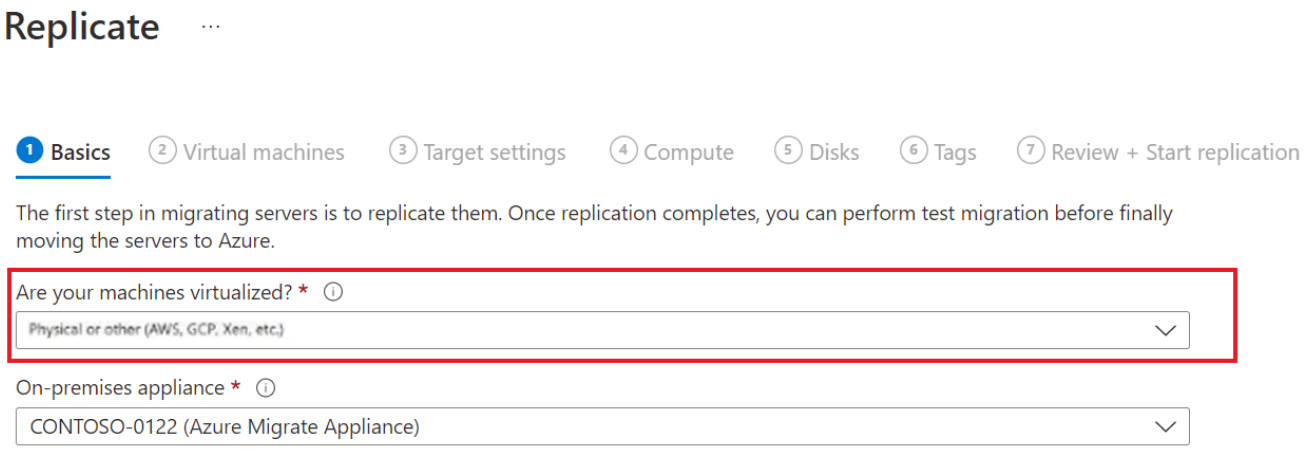


2. In **Replicate**, > **Source settings** > **Are your machines virtualized?**, select **Not virtualized/Other**.

3. In **On-premises appliance**, select the name of the Azure Migrate appliance that you set up.

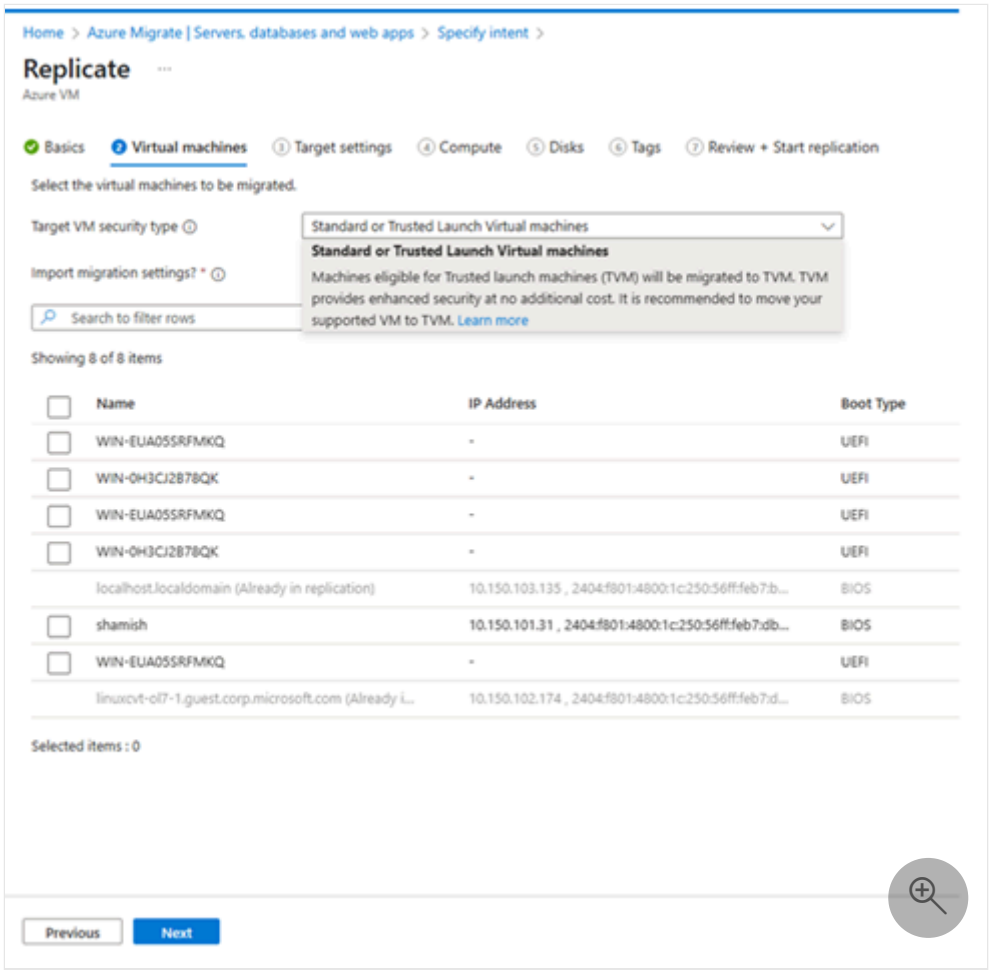
4. In **Process Server**, select the name of the replication appliance.

5. In **Guest credentials**, select the dummy account you created previously during the replication installer setup to install the Mobility service manually. (Push installation isn't supported.) Then select **Next: Virtual machines**.



6. In **Virtual Machines**, in **Import migration settings from an assessment?**, leave the default setting **No, I'll specify the migration settings manually**.

7. Check each VM you want to migrate. Then select **Next: Target settings**.



8. In **Target settings**, select the subscription and target region to which you'll migrate. Specify the resource group in which the Azure VMs will reside after migration.

9. In **Virtual Network**, select the Azure virtual network/subnet to which the Azure VMs will be joined after migration.

10. In **Cache storage account**, keep the default option to use the cache storage account that was automatically created for the project. Use the dropdown list if you want to specify a different storage account to use as the cache storage account for replication.

    > ⓘ **Note**
    >
    > - If you selected private endpoint as the connectivity method for the Azure Migrate project, grant the Recovery Services vault access to the cache storage account. Learn more.
    > - To replicate by using Azure ExpressRoute with private peering, create a private endpoint for the cache storage account. Learn more.

11. In **Availability options**, select:

    - **Availability Zone**: Pins the migrated machine to a specific availability zone in the region. Use this option to distribute servers that form a multinode application tier across availability zones. If you select this option, you need to specify the availability zone to use for each of the selected machines on the **Compute** tab. This option is only available if the target region selected for the migration supports availability zones.
    - **Availability Set**: Places the migrated machine in an availability set. The target resource group that was selected must have one or more availability sets in order to use this option.
    - **No infrastructure redundancy required**: Select this option if you don't need either of these availability configurations for the migrated machines.

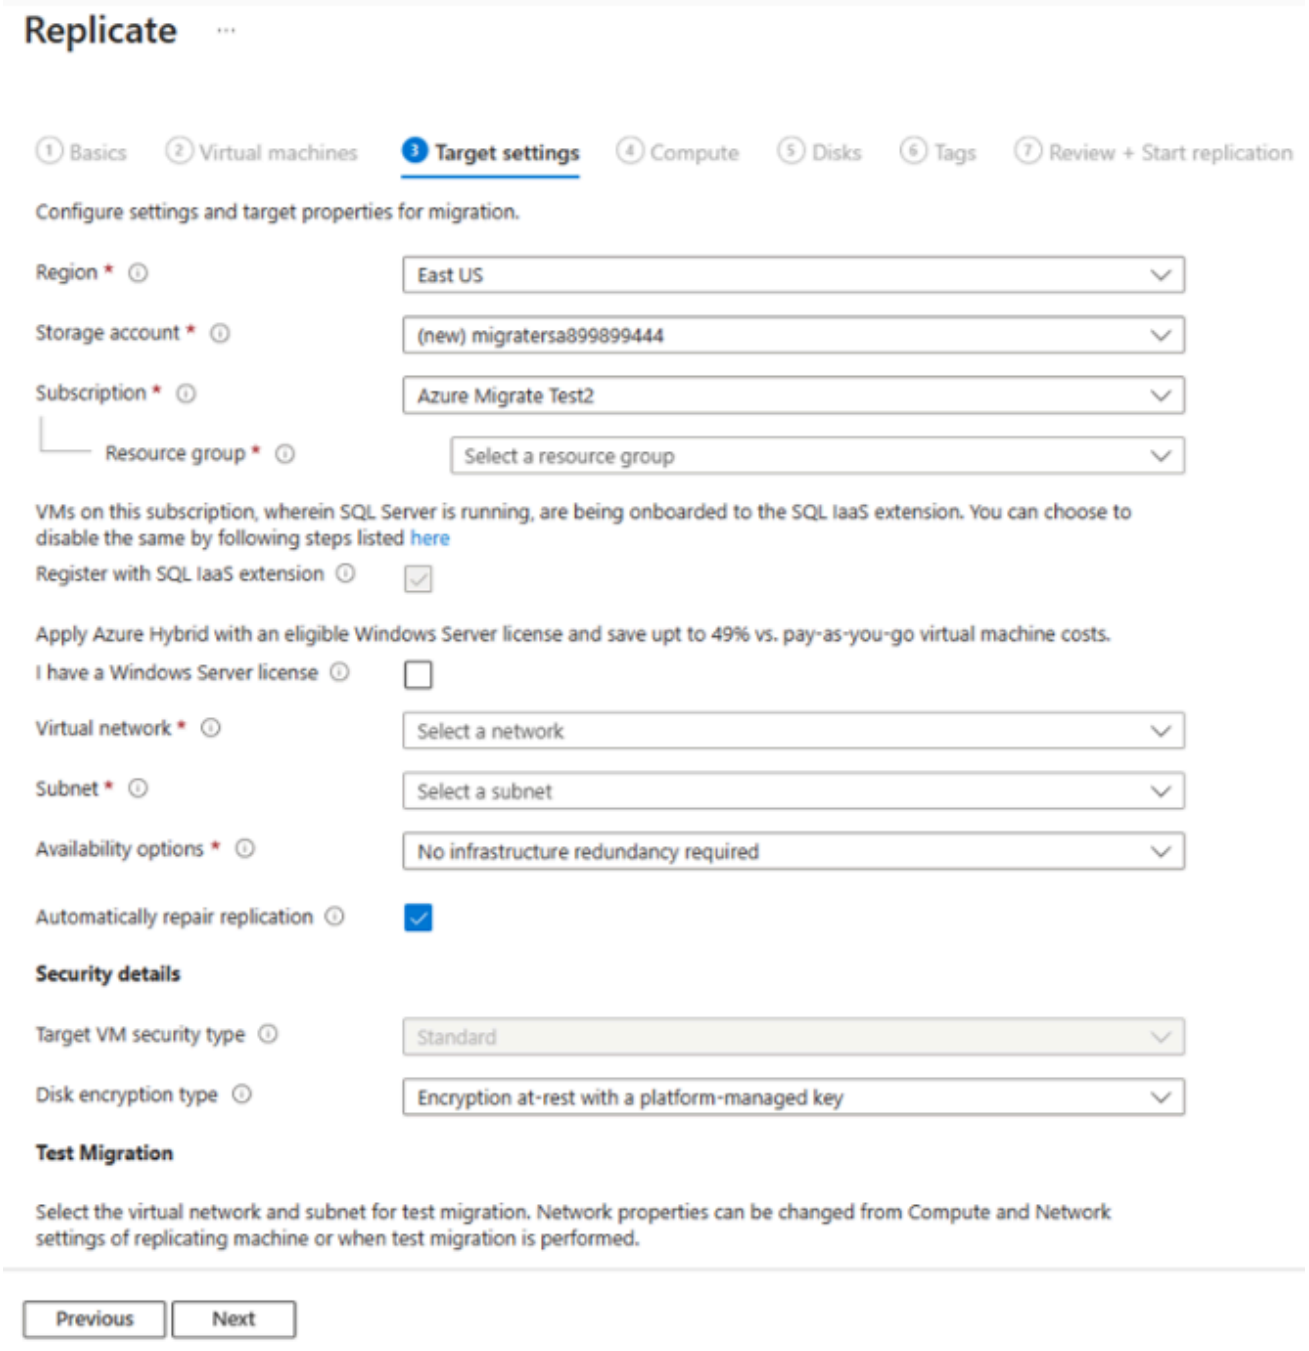
12. In **Disk encryption type**, select:

    - Encryption-at-rest with a platform-managed key.
    - Encryption-at-rest with a customer-managed key.
    - Double encryption with platform-managed and customer-managed keys.

    > ⓘ **Note**
    >
    > To replicate VMs with customer-managed keys, you need to create a disk encryption set under the target resource group. A disk encryption set object maps managed disks to an Azure Key Vault instance that contains the customer-managed key to use for server-side encryption.

13. In **Azure Hybrid Benefit**:

    - Select **No** if you don't want to apply Azure Hybrid Benefit. Then select **Next**.
    - Select **Yes** if you have Windows Server machines that are covered with active Software Assurance or Windows Server subscriptions, and you want to apply the benefit to the machines you're migrating. Then select **Next**.



14. In **Compute**, review the VM name, size, OS disk type, and availability configuration (if selected in the previous step). VMs must conform with Azure requirements.

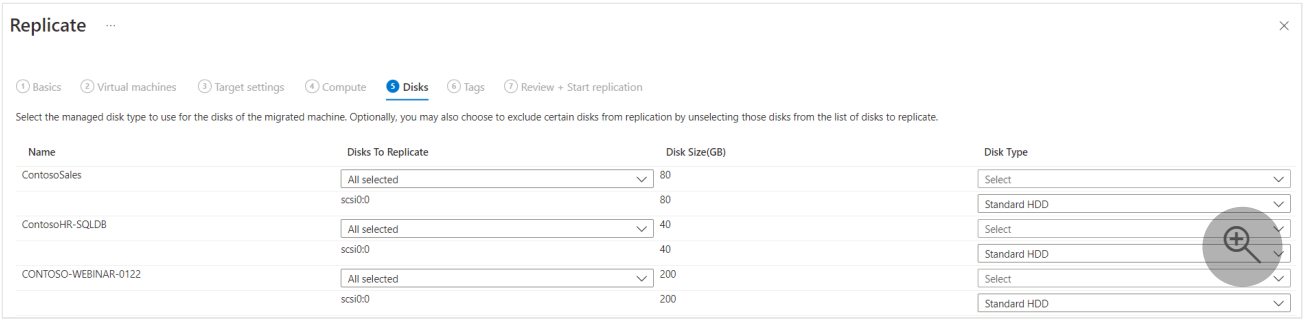
    - **VM size**: If you're using assessment recommendations, the VM size dropdown list shows the recommended size. Otherwise, Azure Migrate and Modernize picks a size

based on the closest match in the Azure subscription. Alternatively, pick a manual size in **Azure VM size**.

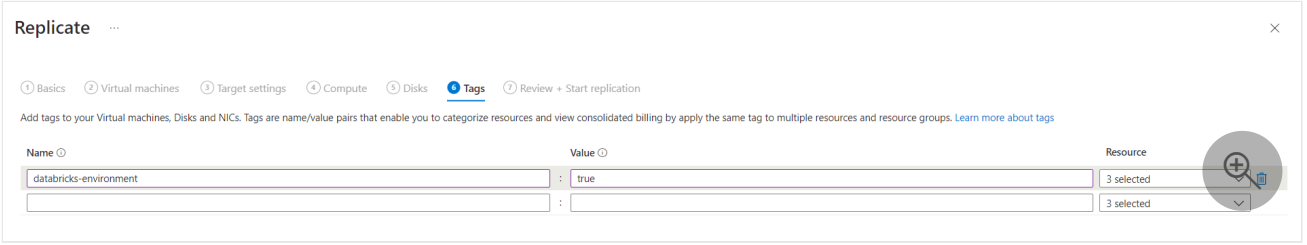
- **OS disk**: Specify the OS (boot) disk for the VM. The OS disk is the disk that has the operating system bootloader and installer.
- **Availability Zone**: Specify the availability zone to use.
- **Availability Set**: Specify the availability set to use.

15. In **Disks**, specify whether the VM disks should be replicated to Azure and select the disk type (Standard SSD/HDD or premium managed disks) in Azure. Then select **Next**.

    - You can exclude disks from replication.
    - If you exclude disks, they won't be present on the Azure VM after migration.



16. In **Tags**, choose to add tags to your virtual machines, disks, and NICs.



17. In **Review and start replication**, review the settings and select **Replicate** to start the initial replication for the servers.

> ⓘ Note
>
> To update replication settings any time before replication starts, select **Manage** > **Replicating machines**. Settings can't be changed after replication starts.

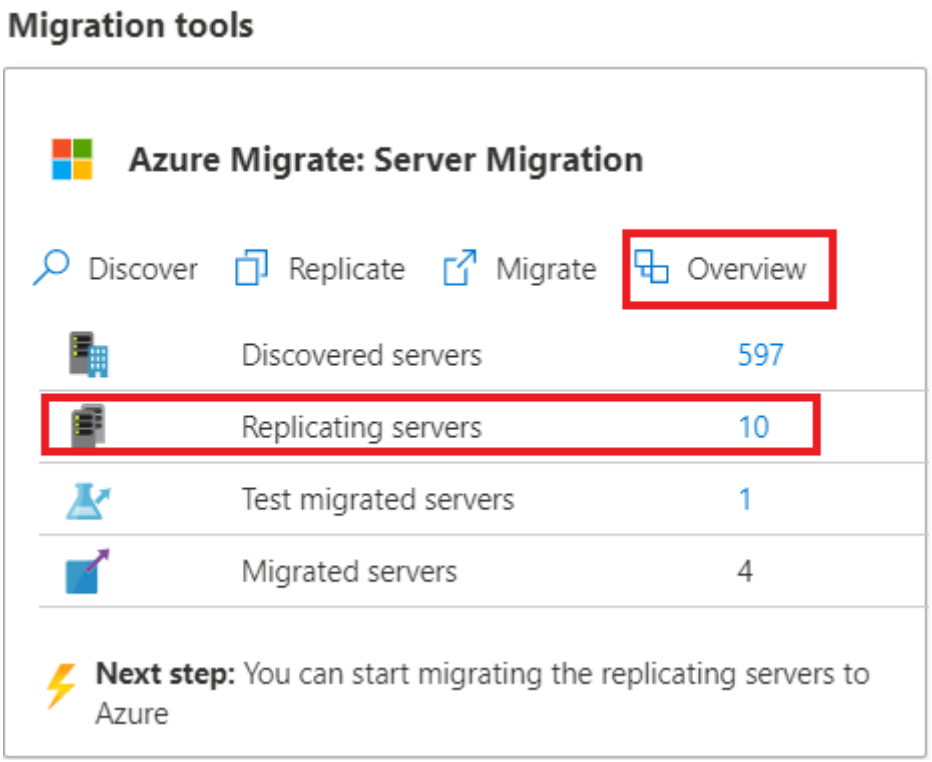
Track and monitor replication status

- When you select **Replicate**, a Start Replication job begins.

- When the Start Replication job finishes successfully, the VMs begin their initial replication to Azure.
- After that initial replication finishes, delta replication begins. Incremental changes to AWS VM disks are periodically replicated to the replica disks in Azure.

You can track job status in the portal notifications.

You can monitor replication status by selecting **Replicating servers** in **Azure Migrate: Server Migration**.



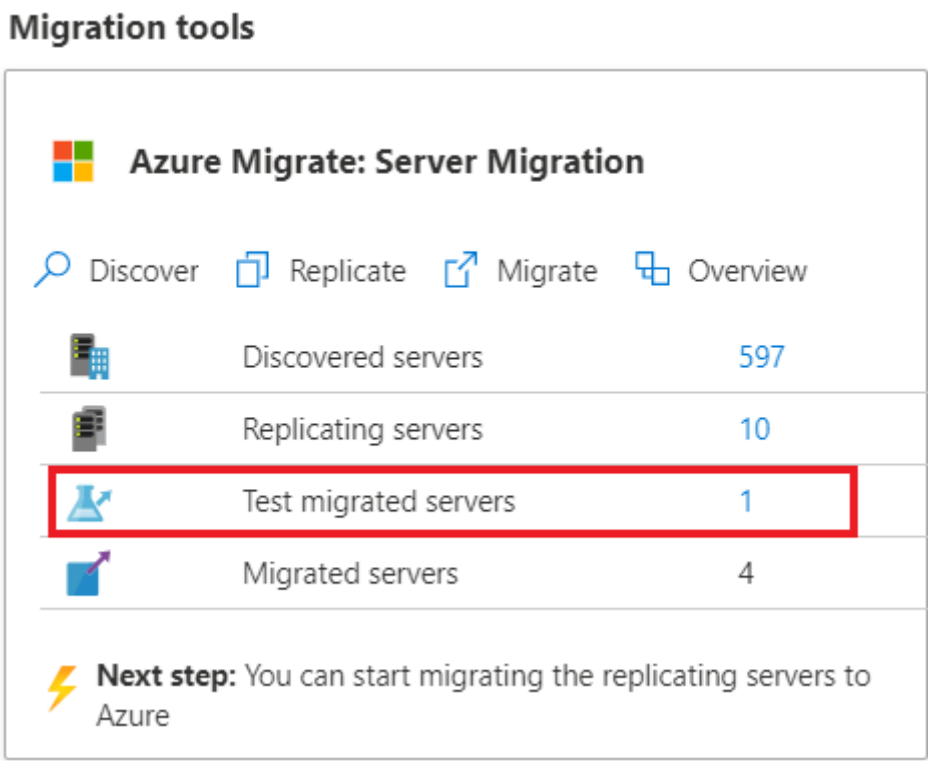
Run a test migration

When delta replication begins, you can run a test migration for the VMs before you run a full migration to Azure. We highly recommend the test migration. It provides an opportunity to discover any potential issues and fix them before you proceed with the actual migration. We recommend that you do this step at least once for each VM before you migrate it.

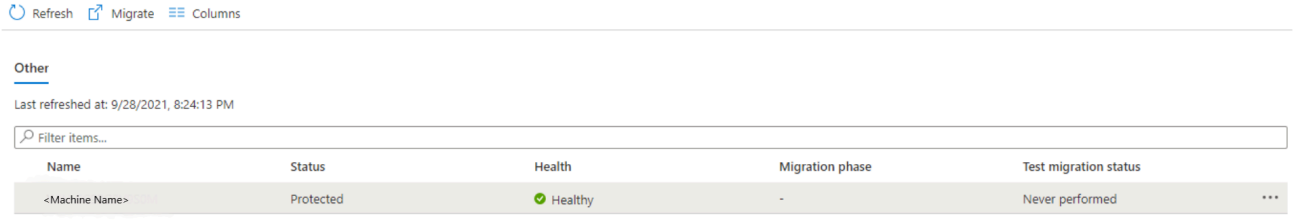
- Running a test migration checks that migration works as expected without affecting the AWS VMs, which remain operational and continue replicating.
- Test migration simulates the migration by creating an Azure VM by using replicated data. (The test usually migrates to a nonproduction virtual network in your Azure subscription.)
- You can use the replicated test Azure VM to validate the migration, perform app testing, and address any issues before full migration.

To do a test migration:

1. In **Migration goals**, select **Servers, databases, and web apps** > **Migration and modernization** > **Test migrated servers**.



2. Right-click the VM you want to test and select **Test migrate**.

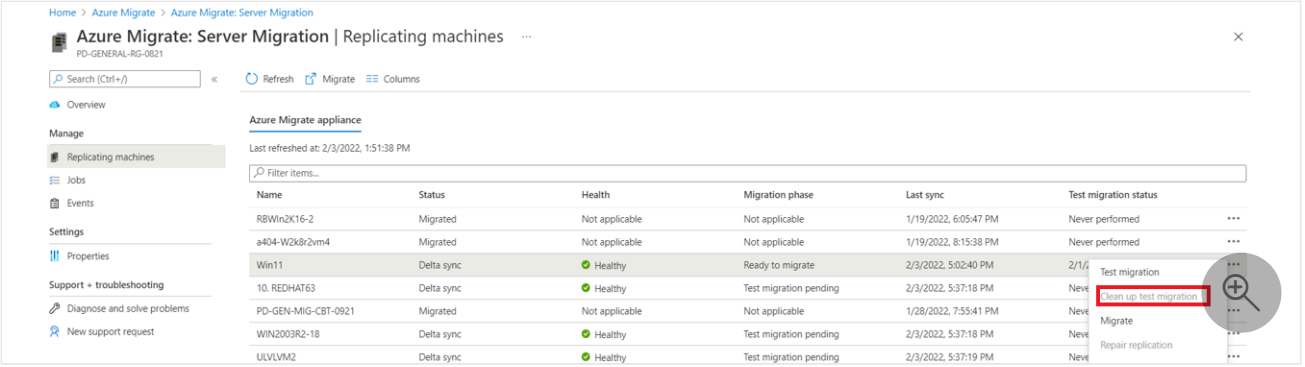


3. In **Test Migration**, select the Azure virtual network in which the Azure VM will be located after the migration. We recommend that you use a nonproduction virtual network.

4. The Test Migration job starts. Monitor the job in the portal notifications.

5. After the migration finishes, view the migrated Azure VM in **Virtual Machines** in the Azure portal. The machine name has the suffix **-Test**.

6. After the test is finished, right-click the Azure VM in **Replicating machines** and select **Clean up test migration**.

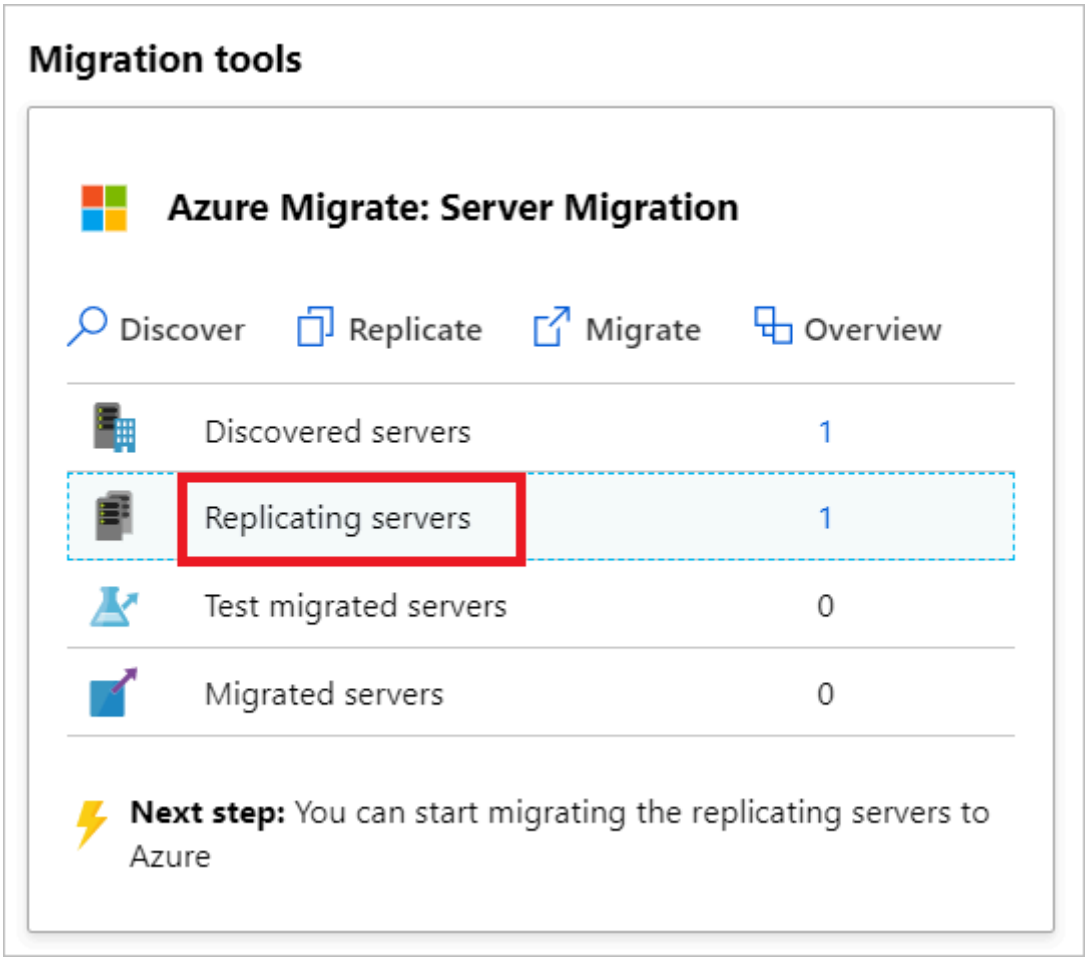


> **Note**
>
> You can now register your servers running SQL Server with SQL VM RP to take advantage of automated patching, automated backup, and simplified license management by using the SQL IaaS Agent Extension.
>
> - Select **Manage** > **Replicating servers** > **Machine containing SQL server** > **Compute and Network** and select **yes** to register with SQL VM RP.
> - Select **Azure Hybrid Benefit for SQL Server** if you have SQL Server instances that are covered with active Software Assurance or SQL Server subscriptions and you want to apply the benefit to the machines you're migrating to.

Migrate AWS VMs

After you verify that the test migration works as expected, you can migrate the AWS VMs.

1. In the Azure Migrate project, select **Servers, databases, and web apps** > **Migration and modernization** > **Replicating servers**.



2. In **Replicating machines**, right-click the VM and select **Migrate**.
3. In **Migrate** > **Shut down virtual machines and perform a planned migration with no data loss**, select **Yes** > **OK**.

> ⓘ Note
>
> Automatic shutdown isn't supported while migrating AWS VMs.

4. A migration job starts for the VM. You can view the job status by selecting the notification bell icon on the top right of the portal page. You can also go to the **Jobs** page of the Migration and modernization tool. (Select **Overview** on the tool tile and select **Jobs** from the left menu.)
5. After the job finishes, you can view and manage the VM from the **Virtual Machines** page.

Complete the migration

1. After the migration is finished, right-click the VM and select **Stop migration**. This action:
   - Stops replication for the AWS VM.

    - Removes the AWS VM from the **Replicating servers** count in the Migration and modernization tool.
    - Cleans up replication state information for the VM.
2. Verify and troubleshoot any Windows activation issues on the Azure VM.
3. Perform any post-migration app tweaks, such as updating host names, database connection strings, and web server configurations.
4. Perform final application and migration acceptance testing on the migrated application now running in Azure.
5. Cut over traffic to the migrated Azure VM instance.
6. Update any internal documentation to show the new location and IP address of the Azure VMs.

Post-migration best practices

- For increased resilience:
    - Keep data secure by backing up Azure VMs by using Azure Backup. Learn more.
    - Keep workloads running and continuously available by replicating Azure VMs to a secondary region with Site Recovery. Learn more.
- For increased security:
    - Lock down and limit inbound traffic access with Microsoft Defender for Cloud - Just-in-time administration.
    - Manage and govern updates on Windows and Linux machines with Azure Update Manager.
    - Restrict network traffic to management endpoints with network security groups.
    - Deploy Azure Disk Encryption to help secure disks and keep data safe from theft and unauthorized access.
    - Read more about securing IaaS resources and Microsoft Defender for Cloud.
- For monitoring and management:
    - Consider deploying Microsoft Cost Management to monitor resource usage and spending.

Troubleshooting and tips

Question: I can't see my AWS VM in the discovered list of servers for migration.
Answer: Check if your replication appliance meets the requirements. Make sure Mobility Agent is installed on the source VM to be migrated and is registered to the Configuration Server. Check the network setting and firewall rules to enable a network path between the replication appliance and source AWS VMs.

Question: How do I know if my VM was successfully migrated?
Answer: Post migration, you can view and manage the VM from the **Virtual Machines** page. Connect to the migrated VM to validate.

Question: I'm unable to import VMs for migration from my previously created Server Assessment results.
Answer: Currently, we don't support the import of assessment for this workflow. As a workaround, you can export the assessment and then manually select the VM recommendation during the Enable Replication step.

Question: I'm getting the error "Failed to fetch BIOS GUID" while trying to discover my AWS VMs.
Answer: Always use root login for authentication and not any pseudo user. Also, review supported operating systems for AWS VMs.

Question: My replication status isn't progressing.
Answer: Check if your replication appliance meets the requirements. Make sure that you enabled the required ports on your replication appliance TCP port 9443 and HTTPS 443 for data transport. Ensure that no stale duplicate versions of the replication appliance are connected to the same project.

Question: I'm unable to discover AWS instances by using Azure Migrate and Modernize because of the HTTP status code of 504 from the remote Windows management service.
Answer: Make sure to review the Azure Migrate appliance requirements and URL access needs. Make sure no proxy settings are blocking the appliance registration.

Question: Do I have to make any changes before I migrate my AWS VMs to Azure?
Answer: You might have to make the following changes before you migrate your EC2 VMs to Azure:

- If you're using cloud-init for your VM provisioning, you might want to disable cloud-init on the VM before you replicate it to Azure. The provisioning steps performed by cloud-init on the VM might be specific to AWS and won't be valid after the migration to Azure.
- If the VM is a paravirtualized (PV) VM and not a hardware VM, you might not be able to run it as is on Azure. PV VMs use a custom boot sequence in AWS. You might be able to overcome this challenge by uninstalling PV drivers before you perform a migration to Azure.
- We always recommend that you run a test migration before the final migration.

Question: Can I migrate AWS VMs running the Amazon Linux operating system?
Answer: VMs running Amazon Linux can't be migrated as is because the Amazon Linux OS is only supported on AWS. To migrate workloads running on Amazon Linux, you can spin up a RHEL VM

in Azure. Then you can migrate the workload running on the AWS Linux machine by using a relevant workload migration approach. For example, depending on the workload, there might be workload-specific tools to aid the migration. These tools might be for databases or deployment tools for web servers.

Next steps

Last updated on 04/23/2025

Retired VM Sizes Migration Guide

This migration guide is designed for users of Azure virtual machines (VMs) scheduled for retirement. This guide helps you transition to the latest VM series, helping you minimize disruptions while optimizing cost and performance. The guide covers General Purpose, Storage Optimized, and other VM series. It also surfaces critical information for HPC HBv2-series VMs undergoing retirement; specialized workload validation is recommended when migrating HPC workloads.

This guide covers:

- Recommended replacement VM series
- Detailed migration steps
- Common questions and guidance on handling RIs.

By migrating to newer VM series, you gain access to improved price-performance ratios, broader regional availability, and the latest hardware capabilities.

Recommended Replacement VM Series

Expand table

Current VM Series	Target VM Series	Differences in Specification in Target VM*
D Ds Dv2 Dsv2	Dsv5/Ddsv5/Dasv5/Dadsv5 Dasv6/Dadsv6/Dsv6/Ddsv6 Dasv7/Dadsv7 Esv6/Edsv6/Easv6/Eadsv6 Easv7/Eadsv7	D/Ev5 disk controller type: SCSI D/Ev6, D/Ev7 disk controller type: NVMe Local Storage Throughput: 9000 IOPS / 125 MBps Remote Storage Throughput: 3750 IOPS / 82 MBps
Ls	Lsv3/Lasv3 Lsv4/Lasv4	Local Storage: Supported - NVMe Remote Storage Throughput: 12800 IOPS / 200 MBps Disk Controller Type: SCSI and NVMe
Av2 Amv2	Bsv2/Basv2 Dsv5/Ddv5/Dasv5 Esv5/Edv5/Easv5 Dsv6/Ddsv6/Dasv6 Esv6/Edsv6/Easv6	B/Bp/Bav2, D/Ev5 disk controller type: SCSI D/Ev6 disk controller type: NVMe Remote Storage Throughput: 3750 IOPS / 85 MBps

Current VM Series	Target VM Series	Differences in Specification in Target VM*
Bv1	Bsv2/Basv2 Dlsv5/Dldsv5/Dalsv5/Daldsv5 Dlsv6/Dldsv6/Dalsv6/Daldsv6	B/Bp/Bav2, D/Ev5 disk controller type: SCSI D/Ev6 disk controller type: NVMe Remote Storage Throughput: 3750 IOPS / 85 MBps Disk Controller Type: SCSI

> The following SKUs aren't available in the Sovereign clouds: Bsv2, Bpsv2, Basv2

Recommended Replacement Isolated VM Sizes

Expand table

Current VM Size	Target VM Sizes	Differences in Specification in Target VM*
Standard_E64i_v3 Standard_E64is_v3	Standard_E192is_v6 Standard_E192ids_v6 Standard_E104i_v5 Standard_E104id_v5	Local Storage: Supported - NVMe Local Storage Throughput: 37,500 IOPS / 180 MBps Remote Storage Throughput: 3,750 IOPS / 106 MBps Disk Controller Type: NVMe

Current VM Size	Target VM Sizes	Differences in Specification in Target VM*
	Standard_E104is_v5 Standard_E104ids_v5 Standard_E80is_v4 Standard_E80ids_v4	

*Refers to the smallest VM size in the given target VM series. Full VM specifications are available on each target VM series' product sizes page.

For optimal performance and experience, we recommend using the newer v5 and v6 VM series. This ensures you have access to the latest features such as Premium Storage, Accelerated Networking, and Nested Virtualization. While the v6 VM series is preferred, there are certain scenarios where you might want to consider the v5 or even the v4 VM series. Here are some reasons why:

- v6 VMs require enabling NVMe which means that you must have a supported OS.
- v6 VMs support Generation 2 VMs only.
- v6 VMs require MANA (Microsoft Azure Network Adapter) and a MANA supported operating system.
- v6 VMs may not have available capacity in the regions and zones you need.

Note that Lsv4 and Lasv4 series are the latest generation L-series VMs.

Use the Azure VM size documentation to help identify suitable VM sizes.

Migration Steps

Optional: For Reserved Instance (RI) customers only

- Review your current reservations using the Azure Reservation Management page.
- If applicable, exchange existing reservations for newer VM series or trade in your reservations for an **Azure Savings Plan for compute**.
- **HBv2 customers**: 1-year and 3-year HBv2 Reserved Instance purchases ended on April 2, 2026. If you have active HBv2 RIs, consider exchanging them for supported HPC series RIs (such as HBv3, HBv4, HBv5, or HX) or trading them in for an Azure Savings Plan for compute before the retirement date of May 31, 2027.

Identify the Target VM Size

- Evaluate your current VM's workload and performance requirements.

- Select a comparable size from the above table that meets your CPU, memory, and storage needs.

Check and Request Quota Increases

- Before resizing, verify that your subscription has sufficient quota for the target v6 VM series.
- Request more quota through the Azure portal if needed.

Resize the Virtual Machine

You can resize your VM through the Azure portal, Azure CLI, or PowerShell. Follow these steps:

1. **Stop (deallocate) the VM**.
2. **Resize** the VM to your selected v6 series.
3. **Start the VM** after resizing.

Refer to the full Azure VM resizing guide for more detailed instructions.

FAQ

Q: Which sizes are being retired?

To review retired sizes, see retired Azure VM sizes. View retired isolated sizes at Isolation for VMs in Azure.

> **Note**
>
> HPC HBv2-series VMs are also retiring. See the HBv2 row in the table below for the applicable dates.

Expand table

VM Series	3 YR RI expiration date	1 YR RI expiration date	Retirement Date
D	05/01/2025	05/01/2027	05/01/2028

Bv1	11/15/2025	11/15/2027	11/15/2028
HBv2	04/02/2026	04/02/2026	05/31/2027

Q: Why should I migrate my VM?

Migration is mandatory to avoid unexpected shutdown. Additionally, migration yields the following benefits:

- **Performance**: Newer VM series offer better price-to-performance ratios.
- **Regional Availability**: The v5 and v6 series has broader regional support across Azure data centers.
- **Future-proofing**: Migrate ahead of the retirement schedule to avoid disruption.

Q: What will happen to my VM if I do not resize my VM to a target size within the retirement timeline?

After retirement, VMs using this size will be deallocated and stop incurring charges. The size is no longer supported or covered by an SLA; in-memory and temporary disk data is lost, but managed disk data is preserved. To resume service, you may resize to a supported size and restart the VM.

Specifically for HBv2-series: after May 31, 2027, HBv2-series VMs (Standard_HB120rs_v2 and derived sizes) will be automatically set to a deallocated state. After that date, HBv2 VMs will

stop working, lose SLA and support, and stop incurring billing charges.

Q: Can I recover my VM after it has been deallocated?

Yes, you can resize and restart your deallocated VM following the Azure VM resizing guide.

Q: Will VM migration disrupt pay-as-you-go or Savings Plan Pricing billing?

No. If you're using pay-as-you-go or a savings plan, migrating to a newer VM type won't disrupt your current billing. The migration process remains seamless with no changes required in your subscription or payment plan.

Q: How can I migrate my VM if I am on Reserved Instances (RIs) with a retired VM?

If you have active Reserved Instances for D, Dv2, Dsv2, or L-series VMs, follow these steps:

Step 1: Review Current Reservations

- Check your active RIs in the Azure portal.

Identify which RIs are expiring or will be affected by the VM retirement.

Step 2: Migrate and Manage Your RIs

Depending on your business needs, consider these options:

1. **Exchange Existing Reservations**:
    - Swap current RIs for a new VM series without any penalties.
    - Refer to the RI Exchange Guide
2. **Trade-In for Savings Plan**:
    - Convert your existing RIs into an **Azure Savings Plan for compute**.
    - This offers flexibility across VM families and regions.
    - Follow the Azure RI Trade-In Tutorial.
3. **Purchase New RIs**:
    - Buy new reservations that align with your new v6 VM series.

- Consider shorter terms (1-year) for flexibility.

Retired VM Sizes Migration Guide

This migration guide is designed for users of Azure virtual machines (VMs) scheduled for retirement. This guide helps you transition to the latest VM series, helping you minimize disruptions while optimizing cost and performance. The guide covers General Purpose, Storage Optimized, and other VM series. It also surfaces critical information for HPC HBv2-series VMs undergoing retirement; specialized workload validation is recommended when migrating HPC workloads.

This guide covers:

- Recommended replacement VM series
- Detailed migration steps
- Common questions and guidance on handling RIs.

By migrating to newer VM series, you gain access to improved price-performance ratios, broader regional availability, and the latest hardware capabilities.

Recommended Replacement VM Series

	Standard_E104is_v5 Standard_E104ids_v5 Standard_E80is_v4 Standard_E80ids_v4	

*Refers to the smallest VM size in the given target VM series. Full VM specifications are available on each target VM series' product sizes page.

For optimal performance and experience, we recommend using the newer v5 and v6 VM series. This ensures you have access to the latest features such as Premium Storage, Accelerated Networking, and Nested Virtualization. While the v6 VM series is preferred, there are certain scenarios where you might want to consider the v5 or even the v4 VM series. Here are some reasons why:

- v6 VMs require enabling NVMe which means that you must have a supported OS.
- v6 VMs support Generation 2 VMs only.
- v6 VMs require MANA (Microsoft Azure Network Adapter) and a MANA supported operating system.
- v6 VMs may not have available capacity in the regions and zones you need.

Note that Lsv4 and Lasv4 series are the latest generation L-series VMs.

Use the Azure VM size documentation to help identify suitable VM sizes.

Migration Steps

Optional: For Reserved Instance (RI) customers only

- Review your current reservations using the Azure Reservation Management page.
- If applicable, exchange existing reservations for newer VM series or trade in your reservations for an **Azure Savings Plan for compute**.
- **HBv2 customers**: 1-year and 3-year HBv2 Reserved Instance purchases ended on April 2, 2026. If you have active HBv2 RIs, consider exchanging them for supported HPC series RIs (such as HBv3, HBv4, HBv5, or HX) or trading them in for an Azure Savings Plan for compute before the retirement date of May 31, 2027.

Identify the Target VM Size

- Evaluate your current VM's workload and performance requirements.

- Select a comparable size from the above table that meets your CPU, memory, and storage needs.

Check and Request Quota Increases

- Before resizing, verify that your subscription has sufficient quota for the target v6 VM series.
- Request more quota through the Azure portal if needed.

Resize the Virtual Machine

You can resize your VM through the Azure portal, Azure CLI, or PowerShell. Follow these steps:

1. **Stop (deallocate) the VM**.
2. **Resize** the VM to your selected v6 series.
3. **Start the VM** after resizing.

Refer to the full Azure VM resizing guide for more detailed instructions.

FAQ

Q: Which sizes are being retired?

To review retired sizes, see retired Azure VM sizes. View retired isolated sizes at Isolation for VMs in Azure.

> **Note**
>
> HPC HBv2-series VMs are also retiring. See the HBv2 row in the table below for the applicable dates.

HBv2	04/02/2026	04/02/2026	05/31/2027

Q: Why should I migrate my VM?

Migration is mandatory to avoid unexpected shutdown. Additionally, migration yields the following benefits:

- **Performance**: Newer VM series offer better price-to-performance ratios.
- **Regional Availability**: The v5 and v6 series has broader regional support across Azure data centers.
- **Future-proofing**: Migrate ahead of the retirement schedule to avoid disruption.

Q: What will happen to my VM if I do not resize my VM to a target size within the retirement timeline?

After retirement, VMs using this size will be deallocated and stop incurring charges. The size is no longer supported or covered by an SLA; in-memory and temporary disk data is lost, but managed disk data is preserved. To resume service, you may resize to a supported size and restart the VM.

Specifically for HBv2-series: after May 31, 2027, HBv2-series VMs (Standard_HB120rs_v2 and derived sizes) will be automatically set to a deallocated state. After that date, HBv2 VMs will

stop working, lose SLA and support, and stop incurring billing charges.

Q: Can I recover my VM after it has been deallocated?

Yes, you can resize and restart your deallocated VM following the Azure VM resizing guide.

Q: Will VM migration disrupt pay-as-you-go or Savings Plan Pricing billing?

No. If you're using pay-as-you-go or a savings plan, migrating to a newer VM type won't disrupt your current billing. The migration process remains seamless with no changes required in your subscription or payment plan.

Q: How can I migrate my VM if I am on Reserved Instances (RIs) with a retired VM?

If you have active Reserved Instances for D, Dv2, Dsv2, or L-series VMs, follow these steps:

Step 1: Review Current Reservations

- Check your active RIs in the Azure portal.

Identify which RIs are expiring or will be affected by the VM retirement.

Step 2: Migrate and Manage Your RIs

Depending on your business needs, consider these options:

1. **Exchange Existing Reservations**:
    - Swap current RIs for a new VM series without any penalties.
    - Refer to the RI Exchange Guide
2. **Trade-In for Savings Plan**:
    - Convert your existing RIs into an **Azure Savings Plan for compute**.
    - This offers flexibility across VM families and regions.
    - Follow the Azure RI Trade-In Tutorial.
3. **Purchase New RIs**:
    - Buy new reservations that align with your new v6 VM series.

- Consider shorter terms (1-year) for flexibility.

Migration Guide for GPU Compute Workloads in Azure

As more powerful GPUs become available in the marketplace and in Microsoft Azure datacenters, we recommend re-assessing the performance of your workloads and considering migrating to newer GPUs.

For the same reason, as well as to maintain a high-quality and reliable service offering, Azure periodically retires the hardware that powers older VM sizes. The first group of GPU products to be retired in Azure are the original NC, NC v2 and ND-series VMs, powered by NVIDIA Tesla K80, P100, and P40 datacenter GPU accelerators respectively. These products will be retired on August 31st 2023, and the oldest VMs in this series launched in 2016.

Since then, GPUs have made incredible strides alongside the entire deep learning and HPC industry, typically exceeding a doubling in performance between generations. Since the launch of NVIDIA K80, P40, and P100 GPUs, Azure has shipped multiple newer generations and categories of VM products geared at GPU-accelerated compute and AI, based around NVIDIA's T4, V100, and A100 GPUs, and differentiated by optional features such as InfiniBand-based interconnect fabrics. These are all options we encourage customers to explore as migration paths.

In most cases, the dramatic increase in performance offered by newer generations of GPUs lowers overall TCO by decreasing the duration of job, for burstable jobs- or reducing the quantity of overall GPU-enabled VMs required to cover a fixed-size demand for compute resources, even though costs per GPU-hour may vary. In addition to these benefits, customers may improve Time-to-Solution via higher-performing VMs, and improve the health and supportability of their solution by adopting newer software, CUDA runtime, and driver versions.

Migration vs. Optimization

Azure recognizes that customers have a multitude of requirements that may dictate the selection of a specific GPU VM product, including GPU architectural considerations, interconnects, TCO, Time to Solution, and regional availability based on compliance locality or latency requirements- and some of these even change over time.

At the same time, GPU acceleration is a new and rapidly evolving area.

Thus, there is no true one-size fits-all guidance for this product area, and a migration is a perfect time to re-evaluate potentially dramatic changes to a workload- like moving from a clustered deployment model to a single large 8-GPU VM or vice versa, leveraging reduced precision datatypes, adopting features like Multi-Instance GPU, and much more.

These sorts of considerations- when made the context of already dramatic per-generation GPU performance increases, where a feature such as the addition of TensorCores can increase performance by an order of magnitude, are extremely workload-specific.

Combining migration with application re-architecture can yield immense value and improvement in cost and time-to-solution.

However, these sorts of improvements are beyond the scope of this document, which aims to focus on direct equivalency classes for generalized workloads that may be run by customers today, to identify the most similar VM options in both price *and* performance per GPU to existing VM families undergoing retirement.

Thus, this document assumes that the user may not have any insight or control over workload-specific properties like the number of required VM instances, GPUs, interconnects, and more.

Recommended Upgrade Paths

NC-Series VMs featuring NVIDIA K80 GPUs

The NC (v1)-Series VMs are Azure's oldest GPU-accelerated compute VM type, powered by 1 to 4 NVIDIA Tesla K80 datacenter GPU accelerators paired with Intel Xeon E5-2690 v3 (Haswell) processors. Once a flagship VM type for demanding AI, ML, and HPC applications, they remained a popular choice late into the product lifecycle (particularly via NC-series promotional pricing) for users who valued having a very low absolute cost per GPU-hour over GPUs with higher throughput-per-dollar.

Today, given the relatively low compute performance of the aging NVIDIA K80 GPU platform, in comparison to VM series featuring newer GPUs, a popular use case for the NC-series is real-time inference and analytics workloads, where an accelerated VM must be available in a steady state to serve request from applications as they arrive. In these cases the volume or batch size of requests may be insufficient to benefit from more performant GPUs. NC VMs are also popular for developers and students learning about, developing for, or experimenting with GPU acceleration, who need an inexpensive cloud-based CUDA deployment target upon which to iterate that doesn't need to perform to production levels.

In general, NC-Series customers should consider moving directly across from NC sizes to NC T4 v3 sizes, Azure's new GPU-accelerated platform for light workloads powered by NVIDIA Tesla T4 GPUs.

NC v2-Series VMs featuring NVIDIA Tesla P100 GPUs

The NC v2-series virtual machines are a flagship platform originally designed for AI and Deep Learning workloads. They offered excellent performance for Deep Learning training, with per-GPU performance roughly 2x that of the original NC-Series and are powered by NVIDIA Tesla P100 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. Like the NC and ND -Series, the NC v2-Series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

In general, NCv2-Series customers should consider moving directly across to NC A100 v4 sizes, Azure's new GPU-accelerated platform powered by NVIDIA Ampere A100 PCIe GPUs.

ND-Series VMs featuring NVIDIA Tesla P40 GPUs

The ND-series virtual machines are a midrange platform originally designed for AI and Deep Learning workloads. They offered excellent performance for batch inferencing via improved single-precision floating point operations over their predecessors and are powered by NVIDIA Tesla P40 GPUs and Intel Xeon E5-2690 v4 (Broadwell) CPUs. Like the NC and NC v2-Series, the ND-Series offers a configuration with a secondary low-latency, high-throughput network through RDMA, and InfiniBand connectivity so you can run large-scale training jobs spanning many GPUs.

NP-Series VMs

> **Important**
>
> NP-series sizes (Standard_NP10s, Standard_NP20s, Standard_NP40s) are scheduled for **retirement on May 31, 2027**. After this date, remaining NP-series VMs are automatically deallocated, stop working, stop incurring charges, and no longer have SLA or support. Managed disk data is preserved.
>
> **Reserved Instance purchase cutoff**: Purchases of 1-year and 3-year Azure Reserved VM Instances for NP-series ended on **April 2, 2026**. Customers with capacity planning tied to Reserved Instances should migrate or adjust reservations accordingly.

The NP-series VMs are powered by AMD Xilinx Alveo U250 FPGAs and are used for custom FPGA-accelerated workloads such as ML inference, video transcoding, and database search & analytics. Unlike GPU-based VM series, NP-series use FPGA acceleration via Xilinx XRT/Vitis toolchains. Migrating to GPU-based alternatives requires porting workloads from FPGA-based frameworks to GPU-based frameworks such as CUDA.

Recommended migration targets based on workload characteristics:

- NCasT4_v3 (NVIDIA T4) – Best for inference, interactive graphics, and cost-sensitive workloads.
- NDv2 (NVIDIA V100 with NVLink) – Best for GPU-accelerated AI training and HPC workloads requiring high GPU memory and interconnect.
- NCads_H100_v5 (NVIDIA H100) – Best for modern AI training and batch inference on the latest GPU generation.

Expand table

Current VM Size	Target VM Size	GPU	GPU Count	GPU Generation	vCPUs	Memory (GiB)
Standard_NP10s	Standard_NC4as_T4_v3	NVIDIA T4	1	Turing	4	28
Standard_NP20s	Standard_NC16as_T4_v3 or Standard_ND40rs_v2 (training)	NVIDIA T4 or V100	1 or 8	Turing or Volta	16 or 40	110 or 672
Standard_NP40s	Standard_NC64as_T4_v3 or	NVIDIA T4 or	4 or 1	Turing or Hopper	64 or 24	440 or 220

Current VM Size	Target VM Size	GPU	GPU Count	GPU Generation	vCPUs	Memory (GiB)
	Standard_NC24ads_A100_v4 (high-end)	H100				

Migration Steps

General Changes

1. Choose a series and size for migration. Leverage the pricing calculator for further insights.
2. Get quota for the target VM series
3. Resize the current N* series VM size to the target size. This may also be a good time to update the operating system used by your Virtual Machine image, or adopt one of the HPC images with drivers pre-installed as your starting point.

   > **Important**
   >
   > Your VM image may have been produced with an older version of the CUDA runtime, NVIDIA driver, and (if applicable, for RDMA-enabled sizes only) Mellanox OFED drivers than your new GPU VM series requires, which can be updated by following the instructions in the Azure Documentation.

Breaking Changes

Select target size for migration

After assessing your current usage, decide what type of GPU VM you need. Depending on the workload requirements you have few different choices.

> **Note**
>
> A best practice is to select a VM size based on both cost and performance. The recommendations in this guide are based on a general-purpose, one-to-one comparison of performance metrics and the nearest match in another VM series. Before deciding on the right size, get a cost comparison using the Azure Pricing Calculator.
>
> **NP-series customers**: When selecting alternatives to NP-series VMs, consider both cost and performance. Newer GPU generations (T4, V100, H100) can significantly reduce time-to-

solution for AI and analytics workloads. For detailed NP-series migration guidance, see the NP-Series VMs section above.

> **Important**
>
> All legacy NC, NC v2 and ND-Series sizes are available in multi-GPU sizes, including 4-GPU sizes with and without InfiniBand interconnect for scale-out, tightly-coupled workloads that demand more compute power than a single 4-GPU VM, or a single K80, P40, or P100 GPU can supply respectively. Although the recommendations above offer a straightforward path forward, users of these sizes should consider achieving their performance goals with more powerful NVIDIA V100 GPU-based VM series like the NC v3-Series and ND v2-series, which typically enable the same level of workload performance at lower costs and with improved manageability by providing considerably greater performance per GPU and per VM before multi-GPU and multi-node configurations are required, respectively.

Get quota for the target VM family

Follow the guide to request an increase in vCPU quota by VM family. Select the target VM size you have selected for migration.

Resize the current virtual machine

You can resize the virtual machine.

Next steps

For a full list of GPU enabled virtual machine sizes, see GPU - accelerated compute overview

NV series migration guide

> **Important**
>
> The NV-series is retired as of September 6th, 2023, and is no longer available. Please refer to the NV-series retirement page for more information.

As more powerful GPU VM sizes become available in Azure datacenters, assess your workloads and migrate virtual machines (VMs) in the NV and NV_Promo series. These legacy VMs can be migrated into new VM series, such as NVsv3 and NVasv4, for better performance with reduced cost. The NVsv3 VM series is powered by Nvidia M60 GPUs. The NVasv4 series is powered by AMD Radeon Instinct MI25 GPUs.

The main differences between the NV and NV_Promo series and the newer NVsv3 and NVasv4 series are:

- Improved performance.
- Support for Premium storage.
- The option to choose from a fractional GPU size to multi-GPU configurations.

Both the NVsv3 and NVasv4 series have more modern cores and greater capacity.

The following section summarizes the differences between the legacy NV series and the NVsv3 and NVv4 series.

NVsv3 series

The NVv3-series VMs are powered by NVIDIA Tesla M60 GPUs and NVIDIA GRID technology with Intel E5-2690 v4 (Broadwell) CPUs and Intel Hyper-Threading Technology. These VMs are targeted for GPU accelerated graphics applications and virtual desktops where customers want to:

- Visualize their data.
- Simulate results to view.
- Work on CAD.
- Render and stream content.

These VMs can also run single precision workloads, such as encoding and rendering.

NVv3 VMs support Premium storage and come with twice the system memory (RAM) when compared with the NV series. For the most up-to-date specifications, see GPU accelerated compute VM sizes: NVsv3 series.

Expand table

Current VM size	Target VM size	Difference in specification
Standard_NV6 Standard_NV6_Promo	Standard_NV12s_v3	vCPU: 12 (+6) Memory: GiB 112 (+56) Temp storage (SSD) GiB: 320 (-20) Max data disks: 12 (-12) Accelerated networking: Yes Premium storage: Yes
Standard_NV12 Standard_NV12_Promo	Standard_NV24s_v3	vCPU: 24 (+12) Memory: GiB 224 (+112) Temp storage (SSD) GiB: 640 (-40) Max data disks: 24 (-24) Accelerated networking: Yes Premium storage: Yes
Standard_NV24 Standard_NV24_Promo	Standard_NV48s_v3	vCPU: 48 (+24) Memory: GiB 448 (+224) Temp storage (SSD) GiB: 1280 (-160) Max data disks: 32 (-32) Accelerated networking: Yes Premium storage: Yes

NVv4 series

NVv4-series VMs are powered by AMD Radeon Instinct MI25 GPUs and AMD EPYC 7V12 (Rome) CPUs. With the NVv4 series, Azure introduces VMs with partial GPUs. Choose the right size VM for GPU accelerated graphics applications and virtual desktops that start at one-eighth of a GPU with a 2-GiB frame buffer to a full GPU with a 16-GiB frame buffer.

NVv4 VMs currently support only the Windows guest operating system. For the most up-to-date specifications, see GPU accelerated compute VM sizes: NVv4 series.

Expand table

Current VM size	Target VM size	Difference in specification
Standard_NV6 Standard_NV6_Promo	Standard_NV16as_v4	vCPU: 16 (+10) Memory: GiB 56

Current VM size	Target VM size	Difference in specification
		Temp storage (SSD) GiB: 352 (+12) Max data disks: 16 (-8) Accelerated networking: Yes Premium storage: Yes
Standard_NV12 Standard_NV12_Promo	Standard_NV32as_v4	vCPU: 32 (+20) Memory: GiB 112 Temp storage (SSD) GiB: 704 (+24) Max data disks: 32 (+16) Accelerated networking: Yes Premium storage: Yes
Standard_NV24 Standard_NV24_Promo	N/A	N/A

Migration steps for general changes

To deal with general changes:

1. Choose a series and size for migration.
2. Get a quota for the target VM series.
3. Resize the current NV-series VM size to the target size.

If the target size is NVv4, make sure to remove the Nvidia GPU driver and install the AMD GPU driver.

Migration steps for breaking changes

To deal with breaking changes, follow the steps in the next sections.

Select a target size for migration

After you assess your current usage, decide what type of GPU VM you need. Depending on the workload requirements, you have a few different choices. Here's how to choose:

- If the workload is graphics or visualizations and has a hard dependency on using the Nvidia GPU, migrate to the NVsv3 series.
- If the workload is graphics or visualizations and has no hard dependency on a specific type of GPU, migrate to the NVsv3 or NVVasv4 series.

> **Note**
>
> A best practice is to select a VM size based on both cost and performance. The recommendations in this article are based on a one-to-one comparison of performance metrics for the NV and NV_Promo sizes and the nearest match in another VM series. Before you decide on the right size, get a cost comparison by using the Azure Pricing Calculator.

Get a quota for the target VM family

Follow the guide to request an increase in vCPU quota by VM family. Select the NVSv3 series or NVv4 series as the VM family name depending on the target VM size you selected for migration.

Resize the current VM

You can resize the VM.

FAQ

Q: Which GPU driver should I use for the target VM size?

A: For the NVsv3 series, use the Nvidia GRID driver. For NVv4, use the AMD GPU drivers.

Q: I use the Nvidia GPU driver extension today. Will it work for the target VM size?

A: The current Nvidia driver extension will work for NVsv3. Use the AMD GPU driver extensions if the target VM size is NVv4.

Q: Which target VM series should I use if I have dependency on CUDA?

A: NVv3 supports CUDA. The NVv4 VM series with the AMD GPUs doesn't support CUDA.

Last updated on 07/11/2025

Azure Dedicated Host SKU Retirement Migration Guide

As hardware ages, it must be retired and workloads must be migrated to newer, faster, and more efficient Azure Dedicated Host SKUs. The legacy Dedicated Host SKUs should be migrated to newer Dedicated Host SKUs. The main differences between the retiring Dedicated Host SKUs and the newly recommended Dedicated Host SKUs are:

- Newer, more efficient processors
- Increased RAM
- Increased available vCPUs
- Greater regional capacity compared to the retiring Dedicated Host SKUs

Review the FAQs before you get started on migration. The next section will go over which Dedicated Host SKUs to migrate to help aid in migration planning and execution.

Host SKUs being retired

Some Azure Dedicated Host SKUs will be retired soon. Refer to the Azure Dedicated Host SKU Retirement documentation to learn more.

Dsv3-Type1 and Dsv3-Type2

The Dsv3-Type1 and Dsv3-Type2 run Dsv3-series VMs, which offer a combination of vCPU, memory, and temporary storage best suited for most general-purpose workloads. We recommend migrating your existing VMs to one of the following Dedicated Host SKUs:

- Dsv3-Type3
- Dsv3-Type4

Note that both the Dsv3-Type3 and Dsv3-Type4 won't be impacted by the 31 March 2023 retirement date. We recommend moving to either the Dsv3-Type3 or Dsv3-Type4 based on regional availability, pricing, and your organization’s needs.

Esv3-Type1 and Esv3-Type2

The Esv3-Type1 and Esv3-Type2 run Esv3-series VMs, which offer a combination of vCPU, memory, and temporary storage best suited for most memory-intensive workloads. We recommend migrating your existing VMs to one of the following Dedicated Host SKUs:

- Esv3-Type3

- Esv3-Type4

Note that both the Esv3-Type3 and Esv3-Type4 won't be impacted by the 31 March 2023 retirement date. We recommend moving to either the Esv3-Type3 or Esv3-Type4 based on regional availability, pricing, and your organization's needs.

Migrating to supported hosts

To migrate your workloads and avoid Dedicated Host SKU retirement, follow the directions for your migration method of choice.

Automatic migration (Resize)

Moving a host and all associated VMs to newer generation hardware can be done through the host resize feature. Resize simplifies the migration process and avoids having to manually create new hosts and move all VMs individually.

Resize limitations:

- Host can only be resized to an ADH within the same VM family. A Dsv3-Type3 host can be resized to Dsv3-Type4 but **not** to an **E**sv3-Type4.
- You can only resize to newer generation of hardware. A Dsv3-Type3 host can be resized to Dsv3-Type4 but **not** Dsv3-Type2.
- Resizing changes the 'Host Asset ID'. The 'Host ID' remains the same.
- The host and all associated VMs become unavailable during the resize operation.

> ⚠ **Warning**
>
> The resize operation causes the loss of any non-persistent data such as temp disk data. Save all your work to persistent data storage before triggering resize.

> ⓘ **Note**
>
> If the source host is already running on the latest hardware, 'Size' page would display an empty list. If you're looking for enhanced performance, consider switching to a different VM family.

Portal

1. Search for and select the host.

2. In the left menu under **Settings**, select **Size**.
3. Once on the size page from the list of SKUs, select the desired SKU to resize to.
4. Selecting a target size from the list would enable **Resize** button on the bottom on the page.
5. Click **Resize**, host's 'Provisioning State' changes from 'Provisioning Succeeded' to 'Updating'
6. Once the resizing is complete, the host's 'Provisioning State' reverts to 'Provisioning Succeeded'

Manual migration

This includes steps for manually placed VMs, automatically placed VMs, and virtual machine scale sets on your Dedicated Hosts:

Manually Placed VMs

1. Choose a target Dedicated Host SKU to migrate to.
2. Ensure you have quota for the VM family associated with the target Dedicated Host SKU in your given region.
3. Provision a new Dedicated Host of the target Dedicated Host SKU in the same Host Group.
4. Stop and deallocate the VM(s) on your old Dedicated Host.
5. Reassign the VM(s) to the target Dedicated Host.
6. Start the VM(s).
7. Delete the old host.

More detailed instructions can be found in the following sections.

> ⓘ **Note**
>
> **Certain sections are different for automatically placed VMs or virtual machine scale set**. These differences will explicitly be called out in the respective steps.

Ensure quota for the target VM family

Be sure that you have enough vCPU quota for the VM family of the Dedicated Host SKU that you'll be using. If you need quota, follow this guide to request an increase in vCPU quota for

your target VM family in your target region. Select the Dsv3-series or Esv3-series as the VM family, depending on the target Dedicated Host SKU.

Create a new Dedicated Host

Within the same Host Group as the existing Dedicated Host, create a Dedicated Host of the target Dedicated Host SKU.

Stop the VM(s) or virtual machine scale set

PowerShell

Refer to the PowerShell documentation to stop a VM through PowerShell or stop a virtual machine scale set through PowerShell.

Reassign the VM(s) to the target Dedicated Host

> ⓘ Note
>
> **Skip this step for automatically placed VMs and virtual machine scale set.**

Once the target Dedicated Host has been created and the VM has been stopped, reassign the VM to the target Dedicated Host.

Start the VM(s) or virtual machine scale set

> ⓘ Note
>
> **Automatically placed VM(s) and virtual machine scale set require that you delete the old host *before* starting the autoplaced VM(s) or virtual machine scale set.**

PowerShell

Refer to the PowerShell documentation to start a VM through PowerShell or start a virtual machine scale set through PowerShell.

Delete the old Dedicated Host

Once all VMs have been migrated from your old Dedicated Host to the target Dedicated Host, delete the old Dedicated Host.

Use infrastructure automation tools with virtual machines in Azure

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets ✔ Uniform scale sets

To create and manage Azure virtual machines (VMs) in a consistent manner at scale, some form of automation is typically desired. There are many tools and solutions that allow you to automate the complete Azure infrastructure deployment and management lifecycle. This article introduces some of the infrastructure automation tools that you can use in Azure. These tools commonly fit in to one of the following approaches:

- Automate the configuration of VMs
  - Tools include Ansible, Chef, Puppet, Bicep, and Azure Resource Manager template.
  - Tools specific to VM customization include cloud-init for Linux VMs, PowerShell Desired State Configuration (DSC), and the Azure Custom Script Extension for all Azure VMs.
- Automate infrastructure management
  - Tools include Packer to automate custom VM image builds, and Terraform to automate the infrastructure build process.
  - Azure Automation can perform actions across your Azure and on-premises infrastructure.
- Automate application deployment and delivery
  - Examples include Azure DevOps Services and Jenkins.

Terraform

Terraform is an automation tool that allows you to define and create an entire Azure infrastructure with a single template format language - the HashiCorp Configuration Language (HCL). With Terraform, you define templates that automate the process to create network, storage, and VM resources for a given application solution. You can use your existing Terraform templates for other platforms with Azure to ensure consistency and simplify the infrastructure deployment without needing to convert to an Azure Resource Manager template.

Learn how to:

- Install and configure Terraform with Azure.
- Create an Azure infrastructure with Terraform.

Azure Automation

Azure Automation uses runbooks to process a set of tasks on the VMs you target. Azure Automation is used to manage existing VMs rather than to create an infrastructure. Azure Automation can run across both Linux and Windows VMs, and on-premises virtual or physical machines with a hybrid runbook worker. Runbooks can be stored in a source control repository, such as GitHub. These runbooks can then run manually or on a defined schedule.

Azure Automation also provides a Desired State Configuration (DSC) service that allows you to create definitions for how a given set of VMs should be configured. DSC then ensures that the required configuration is applied and the VM stays consistent. Azure Automation DSC runs on both Windows and Linux machines.

Learn how to:

- Create a PowerShell runbook.
- Use Hybrid Runbook Worker to manage on-premises resources.
- Use Azure Automation DSC.

Azure DevOps Services

Azure DevOps Services is a suite of tools that help you share and track code, use automated builds, and create a complete continuous integration and development (CI/CD) pipeline. Azure DevOps Services integrates with Visual Studio and other editors to simplify usage. Azure DevOps Services can also create and configure Azure VMs and then deploy code to them.

Learn more about:

- Azure DevOps Services.

Azure Resource Manager template

Azure Resource Manager is the deployment and management service for Azure. It provides a management layer that enables you to create, update, and delete resources in your Azure subscription. You use management features, like access control, locks, and tags, to secure and organize your resources after deployment.

Learn how to:

- Deploy Spot VMs using a Resource Manager template.
- Create a Windows virtual machine from a Resource Manager template.
- Download the template for a VM.
- Create an Azure Image Builder template.

Bicep

Bicep is a domain-specific language (DSL) that uses declarative syntax to deploy Azure resources. In a Bicep file, you define the infrastructure you want to deploy to Azure, and then use that file throughout the development lifecycle to repeatedly deploy your infrastructure. Your resources are deployed in a consistent manner.

Get started with the Quickstart.

Cloud-init

Cloud-init is a widely used approach to customize a Linux VM as it boots for the first time. You can use cloud-init to install packages and write files, or to configure users and security. Because cloud-init is called during the initial boot process, there are no extra steps or required agents to apply your configuration. For more information on how to properly format your `#cloud-config` files, see the cloud-init documentation site. `#cloud-config` files are text files encoded in base64.

Cloud-init also works across distributions. For example, you don't use **apt-get install** or **yum install** to install a package. Instead you can define a list of packages to install. Cloud-init automatically uses the native package management tool for the distro you select.

We're actively working with our endorsed Linux distro partners in order to have cloud-init enabled images available in the Azure Marketplace. These images make your cloud-init deployments and configurations work seamlessly with VMs and Virtual Machine Scale Sets. Learn more details about cloud-init on Azure:

- Cloud-init support for Linux virtual machines in Azure
- Try a tutorial on automated VM configuration using cloud-init.

PowerShell DSC

PowerShell Desired State Configuration (DSC) is a management platform to define the configuration of target machines. DSC can also be used on Linux through the Open Management Infrastructure (OMI) server.

DSC configurations define what to install on a machine and how to configure the host. A Local Configuration Manager (LCM) engine runs on each target node that processes requested actions based on pushed configurations. A pull server is a web service that runs on a central host to store the DSC configurations and associated resources. The pull server communicates with the LCM engine on each target host to provide the required configurations and report on compliance.

Learn how to:

- Create a basic DSC configuration.
- Configure a DSC pull server.
- Use DSC for Linux.

Azure Custom Script Extension

The Azure Custom Script Extension for Linux or Windows downloads and executes scripts on Azure VMs. You can use the extension when you create a VM, or anytime after the VM is in use.

Scripts can be downloaded from Azure storage or any public location such as a GitHub repository. With the Custom Script Extension, you can write scripts in any language that runs on the source VM. These scripts can be used to install applications or configure the VM as desired. To secure credentials, sensitive information such as passwords can be stored in a protected configuration. These credentials are only decrypted inside the VM.

Learn how to:

- Create a Linux VM with the Azure CLI and use the Custom Script Extension.
- Create a Windows VM with Azure PowerShell and use the Custom Script Extension.

Ansible

Ansible is an automation engine for configuration management, VM creation, or application deployment. Ansible uses an agent-less model, typically with SSH keys, to authenticate and manage target machines. Configuration tasks are defined in playbooks, with several Ansible modules available to carry out specific tasks. For more information, see How Ansible works.

Learn how to:

- Install and configure Ansible on Linux for use with Azure.
- Create a Linux virtual machine.
- Manage a Linux virtual machine.

Chef

Chef is an automation platform that helps define how your infrastructure is configured, deployed, and managed. Some components include Chef Habitat for application lifecycle automation rather than the infrastructure, and Chef InSpec that helps automate compliance with security and policy requirements. Chef Clients are installed on target machines, with one or more central Chef Servers that store and manage the configurations. For more information, see An Overview of Chef.

Learn how to:

- Deploy Chef Automate from the Azure Marketplace.
- Install Chef on Windows and create Azure VMs.

Puppet

Puppet is an enterprise-ready automation platform that handles the application delivery and deployment process. Agents are installed on target machines to allow Puppet Master to run manifests that define the desired configuration of the Azure infrastructure and VMs. Puppet can integrate with other solutions such as Jenkins and GitHub for an improved devops workflow. For more information, see How Puppet works.

Learn how to:

- Deploy Puppet.

Packer

Packer automates the build process when you create a custom VM image in Azure. You use Packer to define the OS and run post-configuration scripts that customize the VM for your specific needs. Once configured, the VM is then captured as a Managed Disk image. Packer automates the process to create the source VM, network and storage resources, run configuration scripts, and then create the VM image.

Learn how to:

- Use Packer to create a Linux VM image in Azure.
- Use Packer to create a Windows VM image in Azure.

Jenkins

Jenkins is a continuous integration server that helps deploy and test applications, and create automated pipelines for code delivery. There are hundreds of plugins to extend the core Jenkins platform, and you can also integrate with many other products and solutions through webhooks. You can manually install Jenkins on an Azure VM, run Jenkins from within a Docker container, or use a pre-built Azure Marketplace image.

Learn how to:

- Create a development infrastructure on a Linux VM in Azure with Jenkins, GitHub, and Docker.

Next steps

There are many different options to use infrastructure automation tools in Azure. You have the freedom to use the solution that best fits your needs and environment. To get started and try some of the tools built-in to Azure, see how to automate the customization of a Linux or Windows VM.

User Data for Azure Virtual Machine

Article • 08/22/2024

User data allows you to pass your own scripts or metadata to your virtual machine.

What is "user data"

User data is a set of scripts or other metadata that's inserted to an Azure virtual machine at provision time. Any application on the virtual machine can access the user data from the Azure Instance Metadata Service (IMDS) after provision.

User data is a new version of custom data and it offers added benefits:

- User data can be retrieved from Azure Instance Metadata Service(IMDS) after provision.
- User data is persistent. It will be available during the lifetime of the VM.
- User data can be updated from outside the VM, without stopping or rebooting the VM.
- User data can be queried via GET VM/VMSS API with $expand option.

In addition, if user data isn't added at provision time, you can still add it after provision.

Security warning

> ⚠ **Warning**
>
> User data will not be encrypted, and any process on the VM can query this data. You should not store confidential information in user data.

Make sure you get the latest Azure Resource Manager API to use the new user data features. The contents should be base64 encoded before passed to the API. The size can't exceed 64 KB.

Create user data for Azure VM/VMSS

Adding user data when creating new VM

Use this Azure Resource Manager template to create a new VM with user data. If you're using rest API, for single VMs, add 'UserData' to the "properties" section with the

PUT request to create the VM.

JSON

```
{
  "name": "testVM",
  "location": "West US",
  "properties": {
    "hardwareProfile": {
      "vmSize": "Standard_A1"
    },
    "storageProfile": {
      "osDisk": {
        "osType": "Windows",
        "name": "osDisk",
        "createOption": "Attach",
        "vhd": {
          "uri":
"http://myaccount.blob.core.windows.net/container/directory/blob.vhd"
        }
      }
    },
    "userData": "c2FtcGxlIHVzZXJEYXRh",
    "networkProfile": { "networkInterfaces" : [ { "name" : "nic1" } ] },
  }
}
```

Adding user data when you create new Virtual Machine Scale Set

Using rest API, add 'UserData' to the "virtualMachineProfile" section with the PUT request when creating the Virtual Machine Scale Set.

JSON

```
{
  "location": "West US",
  "sku": {
    "name": "Standard_A1",
    "capacity": 1
  },
  "properties": {
    "upgradePolicy": {
      "mode": "Automatic"
    },
    "virtualMachineProfile": {
      "userData": "VXNlckRhdGE=",
      "osProfile": {
        "computerNamePrefix": "TestVM",
        "adminUsername": "TestUserName",
        "windowsConfiguration": {
          "provisionVMAgent": true,
          "timeZone": "Dateline Standard Time"
```

```
        }
      },
      "storageProfile": {
        "osDisk": {
          "createOption": "FromImage",
          "caching": "ReadOnly"
        },
        "imageReference": {
          "publisher": "publisher",
          "offer": "offer",
          "sku": "sku",
          "version": "1.2.3"
        }
      },
      "networkProfile": {"networkInterfaceConfigurations":
[{"name":"nicconfig1","properties":{"ipConfigurations":
[{"name":"ip1","properties":{"subnet":{"id":"vmssSubnet0"}}}]}}]},
      "diagnosticsProfile": {
        "bootDiagnostics": {
          "enabled": true,
          "storageUri": "https://crputest.blob.core.windows.net"
        }
      }
    },
    "provisioningState": 0,
    "overprovision": false,
    "uniqueId": "00000000-0000-0000-0000-000000000000"
  }
}
```

Retrieving user data

Applications running inside the VM can retrieve user data from IMDS endpoint. For details, see IMDS sample code here.

Customers can retrieve existing value of user data via rest API using $expand=userData endpoint (request body can be left empty).

Single VMs:

`GET "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachines/{VMName}?$expand=userData"`

Virtual Machine Scale Set:

`GET "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualM`

`achineScaleSets/{VMSSName}?$expand=userData"`

Virtual Machine Scale Set VM:

`GET "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachineScaleSets/{VMSSName}/virtualmachines/{vmss instance id}?$expand=userData"`

Updating user data

With REST API, you can use a normal PUT or PATCH request to update the user data. The user data is updated without the need to stop or reboot the VM.

`PUT "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachines/{VMName}`

`PATCH "/subscriptions/{guid}/resourceGroups/{RGName}/providers/Microsoft.Compute/virtualMachines/{VMName}`

The VM.Properties in these requests should contain your desired UserData field, like this:

JSON

```
"properties": {
        "hardwareProfile": {
          "vmSize": "Standard_D1_v2"
        },
        "storageProfile": {
          "imageReference": {
            "sku": "2016-Datacenter",
            "publisher": "MicrosoftWindowsServer",
            "version": "latest",
            "offer": "WindowsServer"
          },
          "osDisk": {
            "caching": "ReadWrite",
            "managedDisk": {

          }
        },
        "userData": "U29tZSBDdXN0b20gRGF0YQ=="
      }
```

> ⓘ **Note**
>
> If you pass in an empty string for "userData" in this case, the user data is deleted.

User data and custom data

Custom data continues to work the same way as today. Note you can't retrieve custom data from IMDS.

Adding user data to an existing VM

If you have an existing VM/VMSS without user data, you can still add user data to this VM by using the updating commands, as described in the "Updating the User data" section. Make sure you upgrade to the latest version of Azure Resource Manger API.

Next steps

Try out Azure Instance Metadata Service, learn how to get the VM instance metadata and user data from its endpoint.

Custom data and cloud-init on Azure Virtual Machines

Article • 09/09/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

You might need to inject a script or other metadata into a Microsoft Azure virtual machine (VM) at provisioning time. In other clouds, this concept is often called *user data*. Microsoft Azure has a similar feature called *custom data*.

Custom data is made available to the VM during first startup or setup, which is called *provisioning*. Provisioning is the process where VM creation parameters (for example, host name, username, password, certificates, custom data, and keys) are made available to the VM. A provisioning agent, such as the Linux Agent or cloud-init, processes those parameters.

Pass custom data to the VM

To use custom data, you must Base64-encode the contents before passing the data to the API--unless you're using a CLI tool that does the conversion for you, such as the Azure CLI. The size can't exceed 64 KB.

In the CLI, you can pass your custom data as a file, as the following example shows. The file is converted to Base64.

Azure CLI

```
az vm create \
  --resource-group myResourceGroup \
  --name myVM \
  --image Ubuntu2204 \
  --custom-data cloud-init.txt \
  --generate-ssh-keys
```

In Azure Resource Manager, there's a base64 function:

JSON

```
"name": "[parameters('virtualMachineName')]",
"type": "Microsoft.Compute/virtualMachines",
"apiVersion": "2019-07-01",
"location": "[parameters('location')]",
"dependsOn": [
```

```
..],
"variables": {
        "customDataBase64": "[base64(parameters('stringData'))]"
    },
"properties": {
..
    "osProfile": {
        "computerName": "[parameters('virtualMachineName')]",
        "adminUsername": "[parameters('adminUsername')]",
        "adminPassword": "[parameters('adminPassword')]",
        "customData": "[variables('customDataBase64')]"
        },
```

Process custom data

The provisioning agents installed on the VMs handle communication with the platform and placing data on the file system.

Windows

Custom data is placed in *%SYSTEMDRIVE%\AzureData\CustomData.bin* as a binary file, but it isn't processed. If you want to process this file, you need to build a custom image and write code to process *CustomData.bin*.

Linux

On Linux operating systems, custom data is passed to the VM via the *ovf-env.xml* file. That file is copied to the */var/lib/waagent* directory during provisioning. Newer versions of the Linux Agent copy the Base64-encoded data to */var/lib/waagent/CustomData* for convenience.

Azure currently supports two provisioning agents:

- **Linux Agent**. By default, the agent doesn't process custom data. You need to build a custom image with the data enabled. The relevant settings are:
  - `Provisioning.DecodeCustomData`
  - `Provisioning.ExecuteCustomData`

  When you enable custom data and run a script, the virtual machine will not report a successful VM provision until the script has finished executing. If the script exceeds the total VM provisioning time limit of 40 minutes, VM creation fails.

  If the script fails to run, or errors happen during execution, that's not a fatal provisioning failure. You need to create a notification path to alert you for the

completion state of the script.

To troubleshoot custom data execution, review */var/log/waagent.log*.

- **cloud-init**. By default, this agent processes custom data. It accepts multiple formats of custom data, such as cloud-init configuration and scripts.

  Similar to the Linux Agent, if errors happen during execution of the configuration processing or scripts when cloud-init is processing the custom data, that's not a fatal provisioning failure. You need to create a notification path to alert you for the completion state of the script.

  However, unlike the Linux Agent, cloud-init doesn't wait for custom data configurations from the user to finish before reporting to the platform that the VM is ready. For more information on cloud-init on Azure, including troubleshooting, see cloud-init support for virtual machines in Azure.

FAQ

Can I update custom data after the VM has been created?

For single VMs, you can't update custom data in the VM model. But for Virtual Machine Scale Sets, you can update custom data. For more information, see Modify a Scale Set. When you update custom data in the model for a Virtual Machine Scale Set:

- Existing instances in the scale set don't get the updated custom data until they're updated to the latest model and reimaged.
- New instances receive the new custom data.

Can I place sensitive values in custom data?

We advise *not* to store sensitive data in custom data. For more information, see Azure data security and encryption best practices.

Is custom data made available in IMDS?

Custom data isn't available in Azure Instance Metadata Service (IMDS). We suggest using user data in IMDS instead. For more information, see User data through Azure Instance Metadata Service.

Plan to manage costs for virtual machines

Article • 08/22/2024

This article describes how you plan for and manage costs for virtual machines. Before you deploy the service, you can use the Azure pricing calculator to estimate costs for virtual machines. Later, as you deploy Azure resources, review the estimated costs.

If you'd like to learn how to monitor costs for virtual machines, see Monitor costs for virtual machines. If you'd like to review the best practices for virtual machine cost optimization, see Best practices for virtual machine cost optimization.

In this article, you'll:

- Learn how to estimate costs before using virtual machines
- Gain an understanding of the billing model for virtual machines
- Learn how to review costs of virtual machine deployments in the Azure portal

Prerequisites

Cost analysis in Cost Management supports most Azure account types but not all of them. To view the full list of supported account types, see Understand Cost Management data. To view cost data, you need at least read access for an Azure account. For information about assigning access to Microsoft Cost Management data, see Assign access to data.

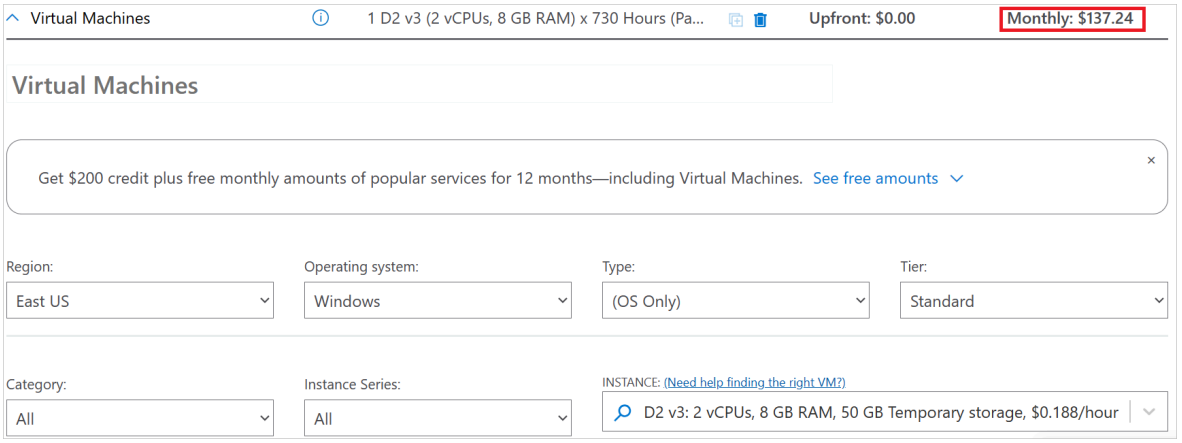
Estimate costs before using virtual machines

Use the Azure pricing calculator to estimate costs before you add virtual machines.

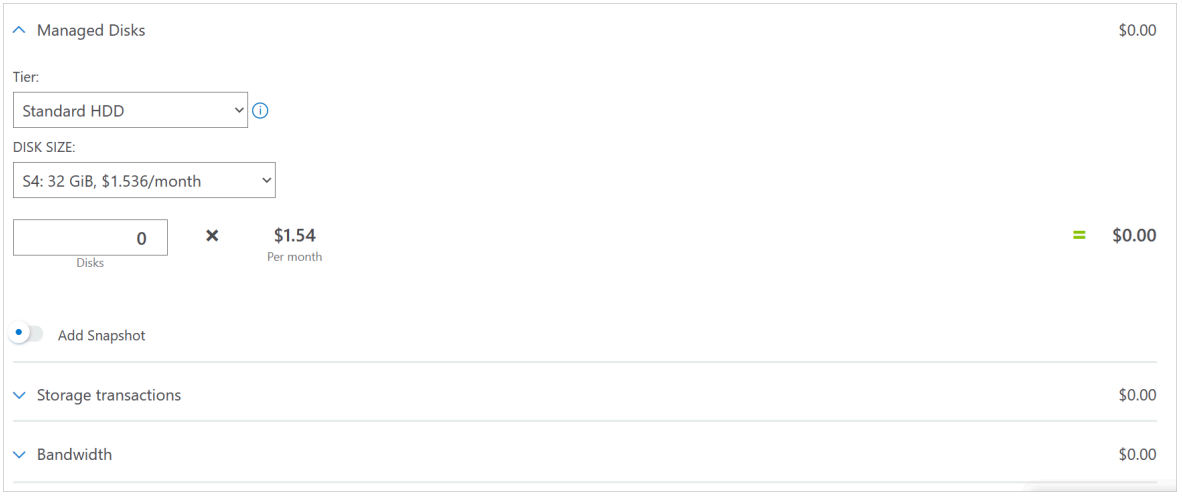
1. On the **Virtual Machines** tile under the **Products** tab, select **Add to estimate** and scroll down to the **Your Estimate** section.

2. Select options from the drop-downs. There are various options available to choose from. The options that have the largest impact on your estimate total are your virtual machine's operating system, the operating system license if applicable, the VM size you select under **INSTANCE**, the number of instances you choose, and the amount of time your month your instances to run.

Notice that the total estimate changes as you select different options. The estimate appears in the upper corner and the bottom of the **Your Estimate** section.



3. Below the **Savings Options** section, there are choices for optional, additional resources you can deploy with your virtual machine, including **Managed Disks**, **Storage transactions**, and **Bandwidth**. For optimal performance, we recommend pairing your virtual machines with managed disks, but make sure to review the additional cost incurred by these resources.



As you add new resources to your workspace, return to this calculator and add the same resource here to update your cost estimates.

For more information, see Azure Virtual Machines pricing for Windows or Linux.

Understand the full billing model for virtual machines

Virtual machines run on Azure infrastructure that accrues costs when you deploy new resources. It's important to understand that there could be other infrastructure costs that might accrue.

How you're charged for virtual machines

When you create or use virtual machines resources, you might get charged for the following meters:

- **Virtual machines** - You're charged for it based on the number of hours per VM.
  - The price also changes based on your VM size.
  - The price also changes based on the region where your virtual machine is located.
  - As virtual machine instances go through different states, they're billed differently.
- **Storage** - Pricing changes based on multiple factors, including disk types, transactions, and configurations.
  - For more information about Disk Storage billing, see Understand Azure Disk Storage billing.
- **Virtual network** - You're charged for it based on the number of GBs of data transferred.
- **Bandwidth** - You're charged for it based on the number of GBs of data transferred.
- **Azure Monitor** - You're charged for it based on the number of GBs of data ingested.
- **Azure Bastion** - You're charged for it based on the number of GBs of data transferred.
- **Azure DNS** - You're charged for it based on the number of DNS zones hosted in Azure and the number of DNS queries received.
- **Load balancer, if used** - You're charged for it based on the number of rulesets, hours used, and GB of data processed.

Any premium software from the Azure Marketplace comes with its own billing meters.

At the end of your billing cycle, the charges for each meter are summed. Your bill or invoice shows a section for all virtual machines costs. There's a separate line item for each meter.

Other costs that might accrue with virtual machines

When you create resources for virtual machines, resources for other Azure services are also created. They include:

- Virtual Network
- Virtual Network Interface Card (NIC)
  - NICs don't incur any costs by themselves. However, your VM size limits how many NICs you can deploy, so play accordingly.

- A private IP and sometimes a public IP
- Network Security Group (NSG)
  - NSGs don't incur any costs.
- OS disk and, optionally, additional disks
- In some cases, a load balancer

For more information, see the Parts of a VM and how they're billed section of the virtual machines documentation overview.

Costs might accrue after resource deletion

After you delete virtual machines resources, the following resources might continue to exist. They continue to accrue costs until you delete them.

- Any disks deployed other than the OS and local disks
  - By default, the OS disk is deleted with the VM, but it can be set not to during the VM's creation
- Virtual network
  - Your virtual NIC and public IP, if applicable, can be set to delete along with your virtual machine
- Bandwidth
- Load balancer

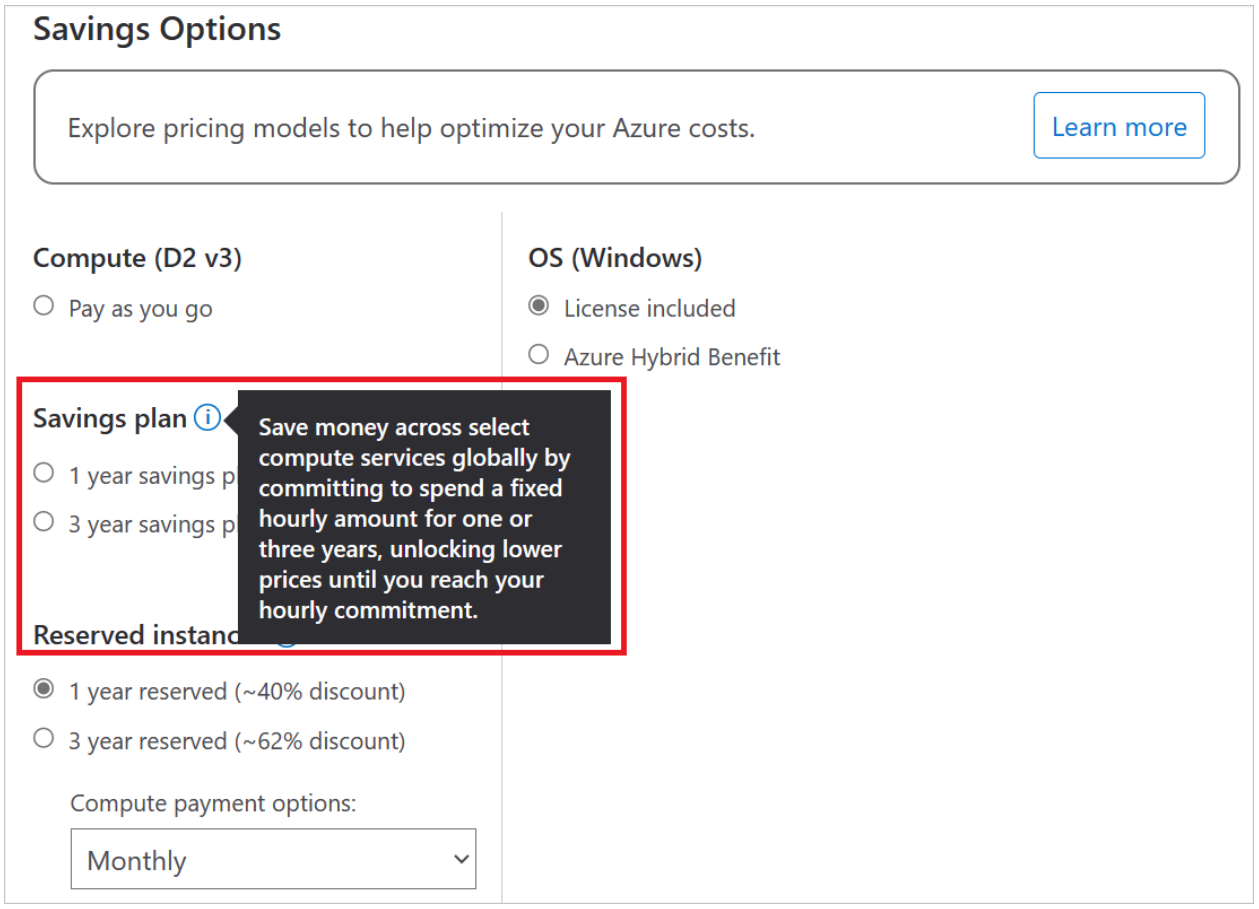
If your OS disk isn't deleted with your VM, it likely incurs P10 disk costs even in a stopped state. The OS disk size is smaller by default for some images and incurs lower costs accordingly.

For virtual networks, one virtual network is billed per subscription and per region. Virtual networks can't span regions or subscriptions. Setting up private endpoints in vNet setups may also incur charges.

Bandwidth is charged by usage; the more data transferred, the more you're charged.

Using a savings plan with virtual machines

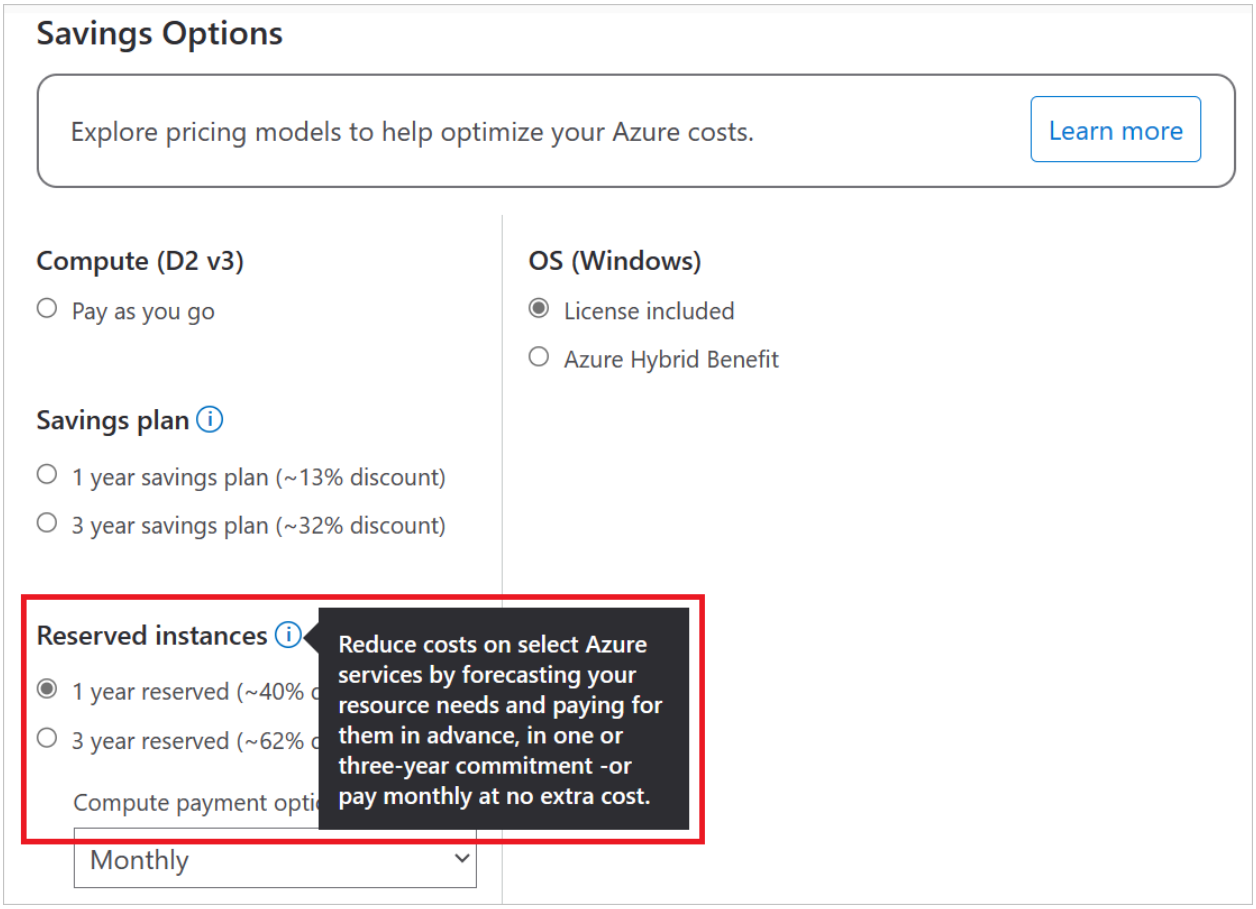
You can choose to spend a fixed hourly amount for your virtual machines, unlocking lower prices until you reach your hourly commitment. These savings plans are available in one- and three-year options.



Using Azure Prepayment with virtual machines

You can pay for virtual machines charges with your Azure Prepayment credit. However, you can't use Azure Prepayment credit to pay for charges for third party products and services including those from the Azure Marketplace.

When you prepay for virtual machines, you're purchasing reserved instances. Committing to a reserved VM instance can save you money. The reservation discount is applied automatically to the number of running virtual machines that match the reservation scope and attributes. Reserved instances are available in one- and three-year plans.



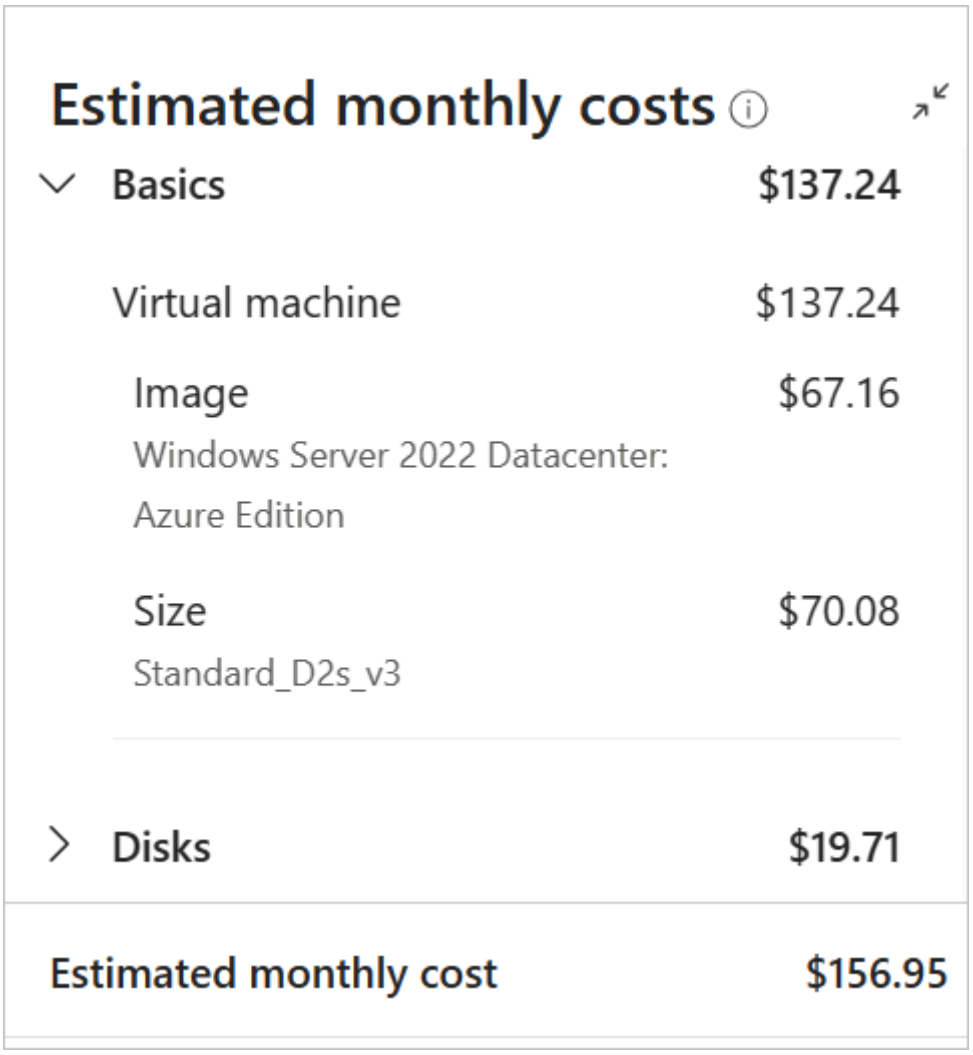
For more information, see Save costs with Azure Reserved VM Instances.

Review estimated costs in the Azure portal

As you create resources for virtual machines, you see estimated costs.

To create a virtual machine and view the estimated price:

1. Sign in to the Azure portal.
2. Enter *virtual machines* in the search.
3. Under **Services**, select **Virtual machines**.
4. In the **Virtual machines** page, select **Create** and then **Azure virtual machine**. The **Create a virtual machine** page opens.
5. On the right side, you see a summary of the estimated costs. Adjust the options in the creation settings to see how the price changes and review the estimated costs.



6. Finish creating the resource.

If your Azure subscription has a spending limit, Azure prevents you from spending over your credit amount. As you create and use Azure resources, your credits are used. If you reach your credit limit, the resources that you deployed are disabled for the rest of that billing period. You can't change your credit limit, but you can remove it. For more information about spending limits, see Azure spending limit.

Next steps

In this article, you learned about estimating costs of virtual machines, the virtual machine billing model, and reviewing virtual machine costs in the Azure portal.

Monitor costs for virtual machines

Article • 08/22/2024

This article describes how you monitor costs for virtual machines.

If you'd like to see how the billing model works for virtual machines and how to plan for costs ahead of resource deployment, see Plan to manage costs. If you'd like to review the best practices for virtual machine cost optimization, see Best practices for virtual machine cost optimization.

After you start using virtual machine resources, use Cost Management features to set budgets and monitor costs. You can also review forecasted costs and identify spending trends to identify areas where you might want to act. Costs for virtual machines are only a portion of the monthly costs in your Azure bill. Although this article explains how to plan for and manage costs for virtual machines, your bill includes the costs of all Azure services and resources used in your Azure subscription, including the third-party services. You can learn more about the billing model in Plan to manage costs.

In this article, you'll learn how to:

- Monitor virtual machine costs
- Create budgets for virtual machines
- Export virtual machine cost data

Prerequisites

Cost analysis in Cost Management supports most Azure account types but not all of them. To view the full list of supported account types, see Understand Cost Management data. To view cost data, you need at least read access for an Azure account. For information about assigning access to Microsoft Cost Management data, see Assign access to data.

Monitor costs

As you use Azure resources with virtual machines, you incur costs. Azure resource usage unit costs vary by time intervals (seconds, minutes, hours, and days) or by unit usage (bytes, megabytes, and so on.) As soon as virtual machine use starts, costs are incurred, and you can see the costs in cost analysis.

When you use cost analysis, you view virtual machine costs in graphs and tables for different time intervals. Some examples are by day, current and prior month, and year.

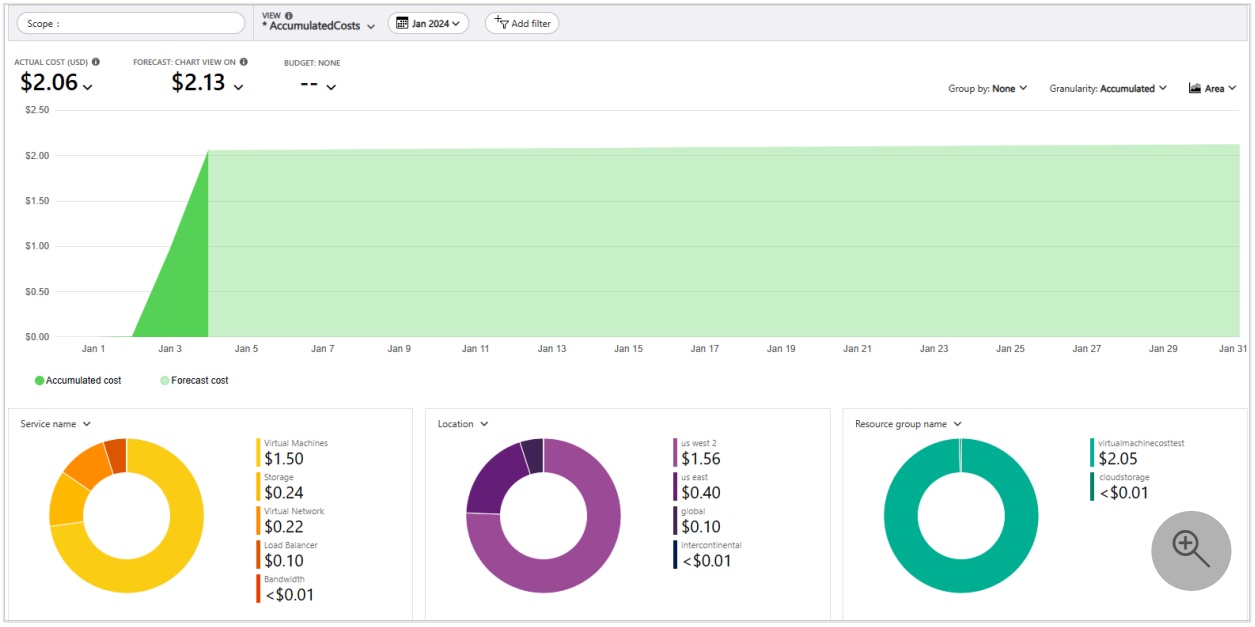
You also view costs against budgets and forecasted costs. Switching to longer views over time can help you identify spending trends, and you can see where you might be overspending. If you create budgets, you can also easily see where they're exceeded.

To view virtual machine costs in cost analysis:

1. Sign in to the Azure portal.
2. Open the scope in the Azure portal and select **Cost analysis** in the menu. For example, go to **Subscriptions**, select a subscription from the list, and then select **Cost analysis** in the menu. Select **Scope** to switch to a different scope in cost analysis.
3. By default, cost for services are shown in the first donut chart. Select the area in the chart labeled virtual machines.

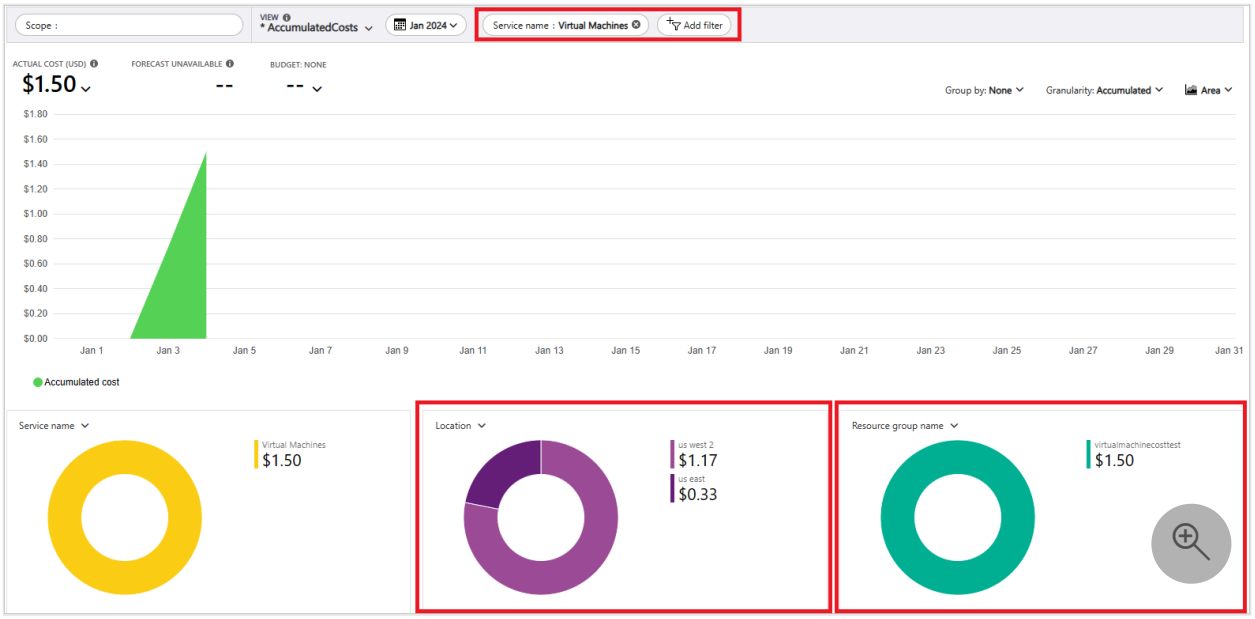
> **Note**
>
> If you just created your virtual machine, cost and usage data is typically only available within 8-24 hours.

Actual monthly costs are shown when you initially open cost analysis. Here's an example showing all monthly usage costs.



To narrow costs for a single service, like virtual machines, select **Add filter** and then select **Service name**. Then, select **Virtual Machines**.

Here's an example showing costs for just virtual machines.



In the preceding example, you see the current cost for the service. Costs by Azure regions (locations) and virtual machines costs by resource group are also shown. From here, you can explore costs on your own.

Create budgets

You can create budgets to manage costs and create alerts that automatically notify stakeholders of spending anomalies and overspending risks. Alerts are based on spending compared to budget and cost thresholds. Budgets and alerts are created for Azure subscriptions and resource groups, so they're useful as part of an overall cost monitoring strategy.

Budgets can be created with filters for specific resources or services in Azure if you want more granularity present in your monitoring. Filters help ensure that you don't accidentally create new resources that cost you more money. For more information about the filter options available when you create a budget, see Group and filter options.

Export cost data

You can also export your cost data to a storage account. This is helpful when you need or others to do additional data analysis for costs. For example, a finance team can analyze the data using Excel or Power BI. You can export your costs on a daily, weekly, or monthly schedule and set a custom date range. Exporting cost data is the recommended way to retrieve cost datasets.

Next steps

In this article, you learned how to monitor virtual machine costs, create budgets, and export cost data.

Best practices for virtual machine cost optimization

Article • 08/22/2024

This article describes the best practices for managing costs for virtual machines.

If you'd like to see how the billing model works for virtual machines and how to plan for costs ahead of resource deployment, see Plan to manage costs. If you'd like to learn how to monitor costs for virtual machines, see Monitor costs for virtual machines.

In this article, you'll learn:

- Best practices for managing and reducing costs for virtual machines
- How to use Azure policies to manage and reduce costs

Best practices to manage and reduce costs for virtual machines

The following are some best practices you can use to reduce the cost of your virtual machines:

- Use the virtual machines selector to identify the best VMs for your needs
  - For development and test environments:
    - Use B-Series virtual machines
      - Use at least B2 for Windows machines
    - Use HDDs instead of SSDs when you can
    - Use locally redundant storage (LRS) accounts instead of geo- or zone-redundant storage accounts
    - Use Logic Apps or Azure Automation to implement an automatic start and stop schedule for your VMs
  - For production environments:
    - Use the dedicated Standard pricing tier or higher
    - Use a Premium SSD v2 disk and programmatically adjust its performance to account for either higher or lower demand based on your workload patterns
    - For other disk types, size your disks to achieve your desired performance without the need for over-provisioning. Account for fluctuating workload patterns, and minimizing unused provisioned capacity
- Use role-based-access-control (RBAC) to control who can create resources
- Use Azure Spot virtual machines where you can

- For Windows virtual machines, consider Azure Hybrid Benefit for Windows Server to save cost on licensing
- Use cost alerts to monitor usage and spending
- Automate shutdown of underutilized VMs, for example CPU utilization below 10% for 1 hour, by using alerts, action groups, and Automation runbooks
- Minimize idle instances by configuring autoscaling
- Configure Azure Bastion for operational access

Use policies to help manage and reduce costs for virtual machines

You can use Azure Policy to help govern and optimize the costs of your resources.

There are built-in policies for virtual machines and networking services that can help with cost savings:

- **Allowed virtual machine SKUs** - This policy enables you to specify a set of virtual machine size SKUs that your organization can deploy. You could use this policy to restrict any virtual machine sizes that exceed your desired budget. This policy would require updates to maintain as new virtual machine SKUs are added.
  - https://github.com/Azure/azure-policy/blob/master/built-in-policies/policyDefinitions/Compute/VMSkusAllowed_Deny.json
  - You can review the available VM sizes and cross-reference their associated costs on the pricing pages for Windows and Linux.
- **Network interfaces should not have public IPs** - This policy restricts the creation of public IP addresses, except in cases where they are explicitly allowed. Restricting unnecessary exposure to the internet can help reduce bandwidth and virtual network data costs.

You can also make custom policies using Azure Policy. Some examples include:

- Implement policies to restrict what resources can be created:
  - https://github.com/Azure/azure-policy/blob/master/built-in-policies/policyDefinitions/General/AllowedResourceTypes_Deny.json
- Implement policies to not allow certain resources to be created:
  - https://github.com/Azure/azure-policy/blob/master/built-in-policies/policyDefinitions/General/InvalidResourceTypes_Deny.json
- Using the resource policy to limit the allowed locations where virtual machines can be deployed.
- Auditing resources that are incurring costs even after virtual machine deletion.
- Auditing resources to enforce the use of the Azure Hybrid Benefit.

Next steps

In this article, you learned the best practices for managing and reducing costs for virtual machines and how to use Azure policies to manage and reduce costs.

For more information on virtual machine cost optimization, see the following articles:

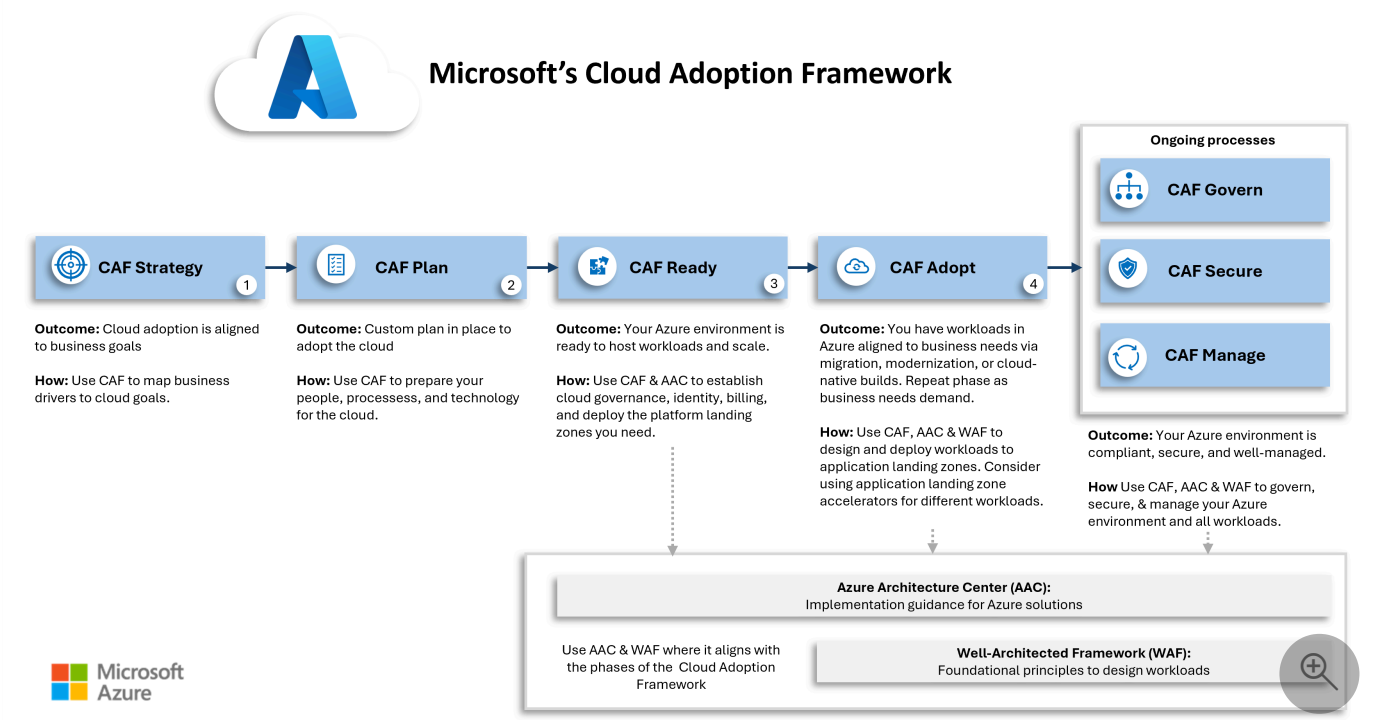
What is the Microsoft Cloud Adoption Framework?

The Microsoft Cloud Adoption Framework (CAF) is a structured roadmap that helps organizations successfully adopt Azure and integrate it into their existing IT environments. It provides best practices and guidance to help organizations make the right decisions for their business throughout the cloud journey.



How does the Cloud Adoption Framework work?

The Cloud Adoption Framework organizes Azure guidance into seven core methodologies that together guide an organization's cloud journey. The foundational methodologies (Strategy, Plan, Ready, and Adopt) are sequential. They help you define business outcomes, prepare your organization and environment, and deploy workloads to Azure. These phases are where most organizations start and are revisited as cloud adoption matures. Once workloads are running in Azure, the operational methodologies (Govern, Secure, and Manage) define different aspects of your cloud operations that help ensure your Azure environment remains compliant, protected, and optimized over time.

Expand table

CAF methodology (phases)	Outcome	How
1. Strategy	Cloud adoption aligned to business goals	Map business drivers to cloud outcomes.
2. Plan	A plan for cloud adoption	Operating model, cloud skills, migration plan, and cloud cost estimation.
3. Ready	An Azure environment ready for workloads	Azure purchasing, tenant setup, platform landing zone, application landing zones.
4. Adopt	Workloads in Azure meeting business needs	Migrate, modernize, or build-cloud native workloads.
5. Govern	Control workloads	Assess cloud risks and mitigate with Azure and Microsoft tools.
6. Secure	Protect workloads	Apply security control with with Azure and Microsoft tools.
7. Manage	Optimize workloads	Administer workloads with Azure and Microsoft tools.

Why use the Cloud Adoption Framework?

The Cloud Adoption Framework is about adopting cloud technologies and integrating them into your business. It provides proven practices to govern, secure, and manage all workloads. It provides structured processes for migrating, modernizing, and building cloud-native solutions. Throughout each stage of adoption, the framework guides you to the right tools, architectures, and other resources to help you achieve your organizational goals. The framework integrates with the Well-Architected Framework and Azure Architecture Center.

Who is the Cloud Adoption Framework for?

The Microsoft Cloud Adoption Framework serves organizations across all industries and scales pursuing strategic Azure cloud adoption. This framework adapts to your specific cloud maturity level, from initial Azure evaluation through advanced multicloud optimization strategies. It's designed for anyone in the organization responsible for technology adoption, whether that responsibility spans business strategy, technology governance, cloud integration, or day-to-day operations.

Expand table

Organization Type	How the framework accelerates success
Startups	Build cloud-native applications using best practices. Access Microsoft for Startups for Azure credits and technical resources.
Enterprise	Establish a governance foundation to control workloads at enterprise scale.

Cloud Adoption Framework scenarios

The Cloud Adoption Framework has specific guidance aligned to common scenarios across our customer base.

Expand table

CAF Scenario	Purpose
Data	How to unify your data platform for AI and analytics
AI adoption	How to adopt AI (generative and nongenerative)
AI agents	How and when to adopt AI agents
Azure Virtual Desktop	How to adopt Azure Virtual Desktop
Azure VMware Solution	How to adopt Azure VMware Solution
Oracle on Azure	Run Oracle workloads on Azure.
SAP on Azure	How to run SAP workloads on Azure

Architect workloads on Azure

Explore best practices and patterns for building workloads on Microsoft Azure.

Design for the cloud

- Learn fundamental architecture styles
- Use best practices in cloud applications
- Avoid performance anti-patterns
- Use responsible engineering practices
- Use cloud design patterns

Choose the right technology

- Choose a compute service
- Choose a container service
- Choose a data store
- Choose AI services
- Choose a messaging service

Implement an Azure landing zone

- Deploy a platform landing zone
- Automate through subscription vending
- Application landing zone solutions

Specialized scenarios

- Architecture for startups
- Architecture for SaaS and multitenant applications
- Build mission-critical workloads
- Azure for AWS professionals
- Azure for Google Cloud professionals

Technology areas

Explore architectures and guides for different technologies.

Hybrid + multicloud

- Hybrid architecture design
- Azure hybrid options
- Connect a cross-premises network to Azure
- Azure Local baseline architecture
- Hybrid Kubernetes clusters
- Hybrid file services

Identity

- Identity architecture design
- Identity in multitenant architectures
- Integrate on-premises AD with Microsoft Entra ID
- Extend AD DS to Azure
- Create an AD DS forest in Azure

Networking

- Choose a hybrid network architecture
- Hub-spoke topology
- ExpressRoute with VPN failover
- Implement a secure hybrid network
- Highly available network virtual appliances

Security

- Security architecture design
- Azure security in AWS
- Zero-trust network with Azure Firewall and Application Gateway
- Securely managed web applications

Web apps

- Enterprise web app patterns
- Basic web application
- Baseline zone-redundant web application
- Protect APIs with Application Gateway and API Management
- Serverless web application

Cloud adoption and workload design

Build a strong cloud adoption strategy and a consistent approach to workload design.

Cloud Adoption Framework for Azure

Azure Well-Architected Framework pillars

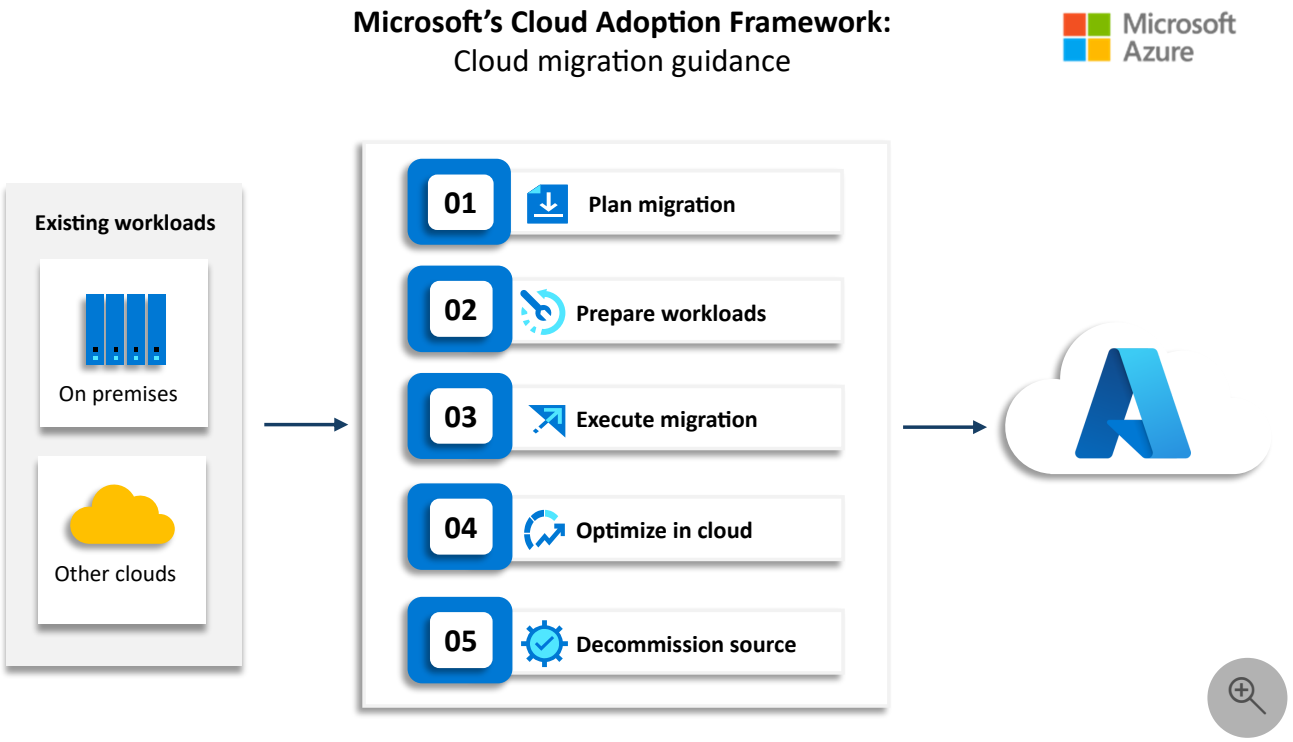
Well-architected workloads

Well-architected service guides

Plan your migration

A migration plan defines the specific order, timing, and approach for migrating workloads to Azure. This plan translates high-level migration strategies into actionable deployment sequences. It builds on the cloud adoption plan by addressing tactical decisions such as workload prioritization, migration sequencing, and data transfer methods.

Prerequisites: Migration adoption plan, Azure landing zone



Assess migration readiness and skills

A readiness assessment ensures that your team has the skills and support needed to execute the migration plan. This step identifies capability gaps and accelerates progress through targeted training or external support.

1. **Evaluate your team's Azure skills.** Review your team's experience with Azure services, migration tools, and cutover. This evaluation helps you identify specific knowledge gaps and determine what training your team needs to succeed.

2. **Engage external expertise when needed.** If your team lacks experience with cloud migration, bring in Microsoft or a Microsoft partner. External experts can validate your migration strategy, recommend appropriate tools, and help establish realistic timelines. This support reduces risk and speeds up your migration, especially for complex or large-scale projects.

Choose your data migration path

A data migration path is how you move data from your current location to Azure. The right path ensures your data transfers securely, quickly, and cost-effectively. First, check what network connections you have available, ExpressRoute, VPN, or public internet, to understand your options.

1. **Use ExpressRoute when you have it.** ExpressRoute gives you a private, dedicated connection to Azure that's faster and more secure than internet connections. If you already have ExpressRoute or plan to get it, use this method for all your workloads. Keep in mind that ExpressRoute requires setup time and has data transfer costs.

2. **Use VPN if ExpressRoute isn't available.** Choose a VPN when you need secure data transfer but don't have ExpressRoute. A VPN creates an encrypted tunnel over the internet to Azure, though it's typically slower than ExpressRoute. Make sure you have a VPN Gateway configured in Azure before starting.

3. **Use Azure Data Box for large amounts of data.** Data Box is best for offline migrations with lots of data. Microsoft ships you a physical device to copy your data onto, then you ship it back. This option avoids using your network but takes the longest due to shipping time.

4. **Use public internet for less sensitive data.** This option works when your data doesn't need encryption and you can't use ExpressRoute or Data Box. While this method is available everywhere, it's the least secure and can slow down your other internet activities.

Expand table

Data Migration Path	When to use	Pros	Cons
ExpressRoute	Any workload when available	Secure and fast	Setup required, costs money
VPN	Secure transfers when no ExpressRoute	More secure than public internet	Requires setup, slower than ExpressRoute
Azure Data Box	Offline migration with large amounts of data	Moves data without using your network	Slowest method due to shipping
Public internet	Nonsensitive data and can't use Data Box	Works everywhere	Least secure, uses your bandwidth

Determine the migration sequence

Migration sequencing reduces risk and builds team confidence by establishing a logical order for workload migration. The sequence determines which workloads move first and how dependent components migrate together to prevent service disruptions. Organize large portfolios into migration waves. For detailed guidance on wave planning, see Migration wave planning.

Find dependencies

1. **Discover all dependencies first.** Dependencies between workloads cause service disruptions if not migrated together. Map internal and external dependencies to discover these connections before creating migration groups.

2. **Analyze dependency types and criticality.** Different dependency types require different migration approaches. Distinguish between these categories:

Expand table

Dependency type	Description	Migration approach
Direct dependencies	Require immediate communication and low latency between components.	Move all directly connected components together to maintain performance and avoid disruptions.
Indirect dependencies	Involve occasional or non-critical interactions between systems.	Migrate together or in separate waves if the connection tolerates latency or supports hybrid use.
Business dependencies	Depend on organizational or management relationships.	Group and migrate related workloads and reporting systems together to align with business priorities.

3. **Group workloads by dependency relationships.** Create groups based on shared databases, APIs, authentication services, or network connections. These groups form the foundation of your migration waves and ensure all components required for functionality move together. When uncertainty exists about dependency criticality, group the components together. This conservative approach provides flexibility for future separation.

4. **Document each dependency group systematically.** Tag assets based on their dependency groups using consistent naming conventions. Document each group with:

    - **Group name and ID** - Unique identifier and descriptive name

- **Component inventory** - All infrastructure elements, applications, and services
- **Critical dependencies** - Essential connections requiring special handling
- **Migration constraints** - Business, technical, or timing requirements

5. **Validate group completeness.** Confirm each group includes all necessary components for applications to operate, including supporting infrastructure such as load balancers, DNS records, or caching layers.

Address split-environment operations

1. **Plan for unmovable dependencies.** Identify components that must stay in your source environment due to technical or regulatory reasons. Document why they can't move, how they connect to other systems, and what data they share. This documentation helps you create strategies for these components to work smoothly with your cloud systems.

2. **Minimize split-environment operation time.** When components can move to the cloud later but not immediately, document their connections and data flows with cloud systems. Create a clear plan with timelines and risk management approaches to reduce the time your workload operates across both environments. Consider delaying the migration until more components can move together.

3. **Connect environments effectively.** Use integration methods like API gateways, message queues, and data synchronization to create reliable connections between your cloud workloads and source environment components. These approaches reduce delays, improve security, and prepare the way for eventually moving remaining components to the cloud.

Prioritize workloads to migrate

1. **Review workload details.** Work with stakeholders to review business and technical details for each workload. Ensure that downtime or failure impacts are well understood and align with current business priorities. Use the migration adoption plan to verify details like business unit, workload owner, technical dependencies, and criticality classification. These details help prioritize and sequence workloads effectively.

Expand table

Priority	Business value	Effort	Description
High	High	Low	Quick wins - migrate first for immediate impact

Priority	Business value	Effort	Description
Medium-High	High	High	Strategic investments - plan carefully with adequate resources
Medium-Low	Low	Low	Easy candidates - fill gaps between major migrations
Low	Low	High	Avoid or defer - focus resources on higher-value opportunities

2. **Start with simpler workloads to reduce risk.** Begin migrating workloads that are less complex and have lower risk. This approach helps your team gain confidence and refine migration processes before tackling more challenging workloads. Target internal tools, development environments, or low-usage applications with standalone architectures and minimal integration points.

3. **Move non-production environments before production.** Nonproduction environments provide a safe space to test the full migration process. Migrate development, staging, and QA environments before production to validate readiness. This order allows teams to test configurations, performance, and recovery procedures without affecting users. Use nonproduction migrations to train operations teams.

4. **Schedule critical systems after you demonstrate initial success.** Critical applications require proven migration capabilities before you move them to Azure. Plan these migrations for later waves when your team demonstrates competency with Azure services. Business deadlines such as hardware refresh cycles might require you to prioritize critical applications earlier with more safeguards and extended testing periods.

5. **Include representative complex workloads to test scenarios.** Add one or two complex workloads to each early wave to expose challenges you face with mission-critical applications. Choose workloads that represent common patterns such as multi-tier applications or database-dependent systems.

Create a detailed migration schedule

1. **Set start and end dates for each migration.** Include buffer time for testing and issue resolution to ensure smooth execution. This detailed scheduling reduces the risk of delays and supports effective resource planning.

2. **Align timelines with business events.** Avoid scheduling migrations during critical business periods such as financial close, product launches, or holiday seasons. This alignment reduces the risk of business disruption and ensures stakeholder confidence.

3. **Use project management tools to track progress.** Use tools like Azure DevOps to manage dependencies, track milestones, and communicate changes effectively. These tools provide visibility into migration progress and support proactive issue resolution.

Choose the migration method for each workload

Migration methods fall into two categories: migration with downtime and migration with near-zero downtime. Choose the best migration method for each workload based on its downtime tolerance and business criticality.

1. **Choose downtime migration for workloads that tolerate planned outages.** Downtime migration is simpler and faster because it doesn't require real-time synchronization between source and target environments. This method works well for noncritical workloads such as development environments, test systems, or applications with scheduled maintenance windows. Document the acceptable downtime duration for each workload and schedule migrations during low-usage periods to minimize business effects.

2. **Choose near-zero downtime migration for critical workloads.** Near-zero downtime migration ensures that critical workloads remain operational during the transition through continuous data replication and cutover techniques. This method is essential for customer-facing applications, real-time transaction systems, or workloads with strict service level agreements. Validate that the workload architecture supports continuous replication and that network bandwidth can handle real-time data transfer. Test connectivity and replication processes in a nonproduction environment to confirm readiness for this migration method.

Expand table

Migration Method	When to use	Pros	Cons
Downtime migration	Noncritical workloads, development environments	Simpler process, faster execution	Service interruption required
Near-zero downtime migration	Critical workloads, strict SLAs	Minimal service disruption	Complex setup and requires testing

Define rollback plan

A rollback plan enables teams to quickly reverse changes when a deployment fails or introduces risk. A well-defined plan minimizes downtime, limits business impact, and maintains

system reliability. Always establish rollback criteria and procedures before initiating any migration or deployment.

1. **Define failed deployment.** Collaborate with business stakeholders, workload owners, and operations teams to decide what counts as a failed deployment. Examples include failed health checks, poor performance, security issues, or unmet success metrics. This definition ensures rollback decisions align with your organization's risk tolerance. Include specific conditions that trigger a rollback in your deployment plan, such as CPU usage limits, response time thresholds, or error rates. This evaluation makes rollback decisions clear and consistent during incidents.

2. **Automate rollback steps in CI/CD pipelines.** Use tools like Azure Pipelines or GitHub Actions to automate rollback tasks. For example, set up pipelines to redeploy a prior version if health checks fail.

3. **Create workload-specific rollback instructions.** Write rollback steps that match your workload type, environment, and deployment method. For example, IaC deployments require reapplying past templates. App rollbacks involve redeploying a prior container image. Attach rollback scripts, configuration snapshots, and IaC templates to your rollback plan. These assets speed up the process and reduce the need for manual steps.

4. **Test rollback procedures.** Simulate deployment failures in a staging environment to confirm your rollback works. Find and fix gaps in automation, permissions, or dependencies. Verify that the rollback procedure restores the system to a stable, known-good state.

5. **Improve rollback strategies.** After each deployment or rollback, review what worked and what didn't. Update rollback rules, steps, and scripts based on lessons learned. Factor in design changes or new tools. Keep your guides updated so rollback plans stay current and useful.

Engage stakeholders on migration plan

Stakeholder approval validates that your migration plan meets business requirements and risk tolerance. You should secure formal approval before executing migrations.

1. **Document the migration plan with business justification.** Create a structured plan showing workload name, owner, criticality, migration method, downtime window, and business effects. Include rationale for each approach and explain how it minimizes risk.

2. **Present tested rollback procedures.** Show specific rollback plans with steps, timeframes, and success criteria. Include automated and manual capabilities. Document preproduction test results to prove quick service restoration.

3. **Validate schedules against business constraints.** Review timelines with stakeholders to avoid critical business periods, maintenance freezes, and seasonal peaks. Provide alternative options with trade-offs if conflicts exist.

4. **Obtain formal approval and rollback authority.** Secure written approval from stakeholders for the migration plan and rollback procedures. Define decision-making authority and establish emergency communication channels.

5. **Define success criteria and review checkpoints.** Set measurable metrics including performance benchmarks, functionality validation, and user acceptance criteria. Schedule formal review points for go/no-go decisions.

Common Azure CLI commands for managing Azure resources

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

The Azure CLI allows you to create and manage your Azure resources on macOS, Linux, and Windows. This article details some of the most common commands to create and manage virtual machines (VMs).

This article requires the Azure CLI version 2.0.4 or later. Run `az --version` to find the version. If you need to upgrade, see Install Azure CLI. You can also use Cloud Shell from your browser.

Basic Azure Resource Manager commands in Azure CLI

For more detailed help with specific command line switches and options, you can use the online command help and options by typing `az <command> <subcommand> --help`.

Create VMs

Expand table

Task	Azure CLI commands
Create a resource group	`az group create --name myResourceGroup --location eastus`
Create a Linux VM	`az vm create --resource-group myResourceGroup --name myVM --image LinuxImageName`
Create a Windows VM	`az vm create --resource-group myResourceGroup --name myVM --image win2016datacenter`

Manage VM state

Expand table

Task	Azure CLI commands
Start a VM	`az vm start --resource-group myResourceGroup --name myVM`
Stop a VM	`az vm stop --resource-group myResourceGroup --name myVM`
Deallocate a VM	`az vm deallocate --resource-group myResourceGroup --name myVM`
Restart a VM	`az vm restart --resource-group myResourceGroup --name myVM`
Redeploy a VM	`az vm redeploy --resource-group myResourceGroup --name myVM`
Delete a VM	`az vm delete --resource-group myResourceGroup --name myVM`

Get VM info

Expand table

Task	Azure CLI commands
List VMs	`az vm list`
Get information about a VM	`az vm show --resource-group myResourceGroup --name myVM`
Get usage of VM resources	`az vm list-usage --location eastus`
Get all available VM sizes	`az vm list-sizes --location eastus`

Disks and images

Expand table

Task	Azure CLI commands
Add a data disk to a VM	`az vm disk attach --resource-group myResourceGroup --vm-name myVM --disk myDataDisk --size-gb 128 --new`
List attached disks to a VM	`az vm show --resource-group groupName --name vmName --query "storageProfile"`
Remove a data disk from a VM	`az vm disk detach --resource-group myResourceGroup --vm-name myVM --disk myDataDisk`
Resize a disk	`az disk update --resource-group myResourceGroup --name myDataDisk --size-gb 256`

Task	Azure CLI commands
Snapshot a disk	`az snapshot create --resource-group myResourceGroup --name mySnapshot --source myDataDisk`
Create image of a VM	`az image create --resource-group myResourceGroup --source myVM --name myImage`
Create VM from image	`az vm create --resource-group myResourceGroup --name myNewVM --image myImage`

Next steps

For additional examples of the CLI commands, see the Create and Manage Linux VMs with the Azure CLI tutorial.

Common PowerShell commands for creating and managing Azure Virtual Machines

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs ✔ Flexible scale sets

This article covers some of the basic Azure PowerShell commands that you can use to create and manage virtual machines in your Azure subscription. For more detailed help with specific command-line switches and options, you can use the **Get-Help** *command*.

These variables might be useful if running more than one of the commands in this article:

- $location - The location of the virtual machine. You can use Get-AzLocation to find a geographical region that works for you.
- $myResourceGroup - The name of the resource group that contains the virtual machine.
- $myVM - The name of the virtual machine.

Create a VM - simplified

Expand table

Task	Command
Create a simple VM	New-AzVM -Name $myVM New-AzVM has a set of *simplified* parameters, where all that is required is a single name. The value for -Name will be used as the name for all of the resources required for creating a new VM. You can specify more, but this is all that is required.
Create a VM from a custom image	New-AzVm -ResourceGroupName $myResourceGroup -Name $myVM ImageName "myImage" -Location $location You need to have already created your own managed image. You can use an image to make multiple, identical VMs.

Create a VM - advanced

Expand table

Task	Command
Create a VM configuration	$vm = New-AzVMConfig -VMName $myVM -VMSize "Standard_D1_v1" The VM configuration is used to define or update settings for the VM. The configuration is initialized with the name of the VM and its size.
Add configuration settings	$vm = Set-AzVMOperatingSystem -VM $vm -Windows -ComputerName $myVM -Credential $cred -ProvisionVMAgent -EnableAutoUpdate Operating system settings including credentials are added to the configuration object that you previously created using New-AzVMConfig.
Add a network interface	$vm = Add-AzVMNetworkInterface -VM $vm -Id $nic.Id A VM must have a network interface to communicate in a virtual network. You can also use Get-AzNetworkInterface to retrieve an existing network interface object.
Specify a platform image	$vm = Set-AzVMSourceImage -VM $vm -PublisherName "publisher_name" -Offer "publisher_offer" -Skus "product_sku" -Version "latest" Image information is added to the configuration object that you previously created using New-AzVMConfig. The object returned from this command is only used when you set the OS disk to use a platform image.
Create a VM	New-AzVM -ResourceGroupName $myResourceGroup -Location $location -VM $vm All resources are created in a resource group. Before you run this command, run New-AzVMConfig, Set-AzVMOperatingSystem, Set-AzVMSourceImage, Add-AzVMNetworkInterface, and Set-AzVMOSDisk.
Update a VM	Update-AzVM -ResourceGroupName $myResourceGroup -VM $vm

Task	Command
	Get the current VM configuration using Get-AzVM, change configuration settings on the VM object, and then run this command.

Get information about your VMs

Expand table

Task	Command
List VMs in a subscription	Get-AzVM
List VMs in a resource group	Get-AzVM -ResourceGroupName $myResourceGroup To get a list of resource groups in your subscription, use Get-AzResourceGroup.
Get information about a VM	Get-AzVM -ResourceGroupName $myResourceGroup -Name $myVM

Manage your VMs

Expand table

Task	Command
Start a VM	Start-AzVM -ResourceGroupName $myResourceGroup -Name $myVM
Stop a VM	Stop-AzVM -ResourceGroupName $myResourceGroup -Name $myVM
Restart a running VM	Restart-AzVM -ResourceGroupName $myResourceGroup -Name $myVM
Delete a VM	Remove-AzVM -ResourceGroupName $myResourceGroup -Name $myVM

Next steps

- See the basic steps for creating a virtual machine in Create a Windows VM using Resource Manager and PowerShell.

Common PowerShell commands for Azure Virtual Networks

Article • 08/22/2024

Applies to: ✔ Linux VMs ✔ Windows VMs

If you want to create a virtual machine, you need to create a virtual network or know about an existing virtual network in which the VM can be added. Typically, when you create a VM, you also need to consider creating the resources described in this article.

See How to install and configure Azure PowerShell for information about installing the latest version of Azure PowerShell, selecting your subscription, and signing in to your account.

Some variables might be useful for you if running more than one of the commands in this article:

- $location - The location of the network resources. You can use Get-AzLocation to find a geographical region that works for you.
- $myResourceGroup - The name of the resource group where the network resources are located.

Create network resources

Expand table

Task	Command
Create subnet configurations	$subnet1 = New-AzVirtualNetworkSubnetConfig -Name "mySubnet1" -AddressPrefix XX.X.X.X/XX $subnet2 = New-AzVirtualNetworkSubnetConfig -Name "mySubnet2" -AddressPrefix XX.X.X.X/XX A typical network might have a subnet for an internet facing load balancer and a separate subnet for an internal load balancer.
Create a virtual network	$vnet = New-AzVirtualNetwork -Name "myVNet" -ResourceGroupName $myResourceGroup -Location $location -AddressPrefix XX.X.X.X/XX -Subnet $subnet1, $subnet2
Test for a unique domain name	Test-AzDnsAvailability -DomainNameLabel "myDNS" -Location $location You can specify a DNS domain name for a public IP resource, which creates a

Task	Command
	mapping for domainname.location.cloudapp.azure.com to the public IP address in the Azure-managed DNS servers. The name can contain only letters, numbers, and hyphens. The first and last character must be a letter or number and the domain name must be unique within its Azure location. If **True** is returned, your proposed name is globally unique.
Create a public IP address	$pip = New-AzPublicIpAddress -Name "myPublicIp" -ResourceGroupName $myResourceGroup -DomainNameLabel "myDNS" -Location $location -AllocationMethod Dynamic The public IP address uses the domain name that you previously tested and is used by the frontend configuration of the load balancer.
Create a frontend IP configuration	$frontendIP = New-AzLoadBalancerFrontendIpConfig -Name "myFrontendIP" -PublicIpAddress $pip The frontend configuration includes the public IP address that you previously created for incoming network traffic.
Create a backend address pool	$beAddressPool = New-AzLoadBalancerBackendAddressPoolConfig -Name "myBackendAddressPool" Provides internal addresses for the backend of the load balancer that are accessed through a network interface.
Create a probe	$healthProbe = New-AzLoadBalancerProbeConfig -Name "myProbe" -RequestPath 'HealthProbe.aspx' -Protocol http -Port 80 -IntervalInSeconds 15 -ProbeCount 2 Contains health probes used to check availability of virtual machines instances in the backend address pool.
Create a load balancing rule	$lbRule = New-AzLoadBalancerRuleConfig -Name HTTP -FrontendIpConfiguration $frontendIP -BackendAddressPool $beAddressPool -Probe $healthProbe -Protocol Tcp -FrontendPort 80 -BackendPort 80 Contains rules that assign a public port on the load balancer to a port in the backend address pool.
Create an inbound NAT rule	$inboundNATRule = New-AzLoadBalancerInboundNatRuleConfig -Name "myInboundRule1" -FrontendIpConfiguration $frontendIP -Protocol TCP -FrontendPort 3441 -BackendPort 3389 Contains rules mapping a public port on the load balancer to a port for a specific virtual machine in the backend address pool.
Create a load balancer	$loadBalancer = New-AzLoadBalancer -ResourceGroupName $myResourceGroup -Name "myLoadBalancer" -Location $location -FrontendIpConfiguration $frontendIP -InboundNatRule $inboundNATRule -

Task	Command
	LoadBalancingRule $lbRule -BackendAddressPool $beAddressPool -Probe $healthProbe
Create a network interface	$nic1= New-AzNetworkInterface -ResourceGroupName $myResourceGroup -Name "myNIC" -Location $location -PrivateIpAddress XX.X.X.X -Subnet $subnet2 -LoadBalancerBackendAddressPool $loadBalancer.BackendAddressPools[0] -LoadBalancerInboundNatRule $loadBalancer.InboundNatRules[0] Create a network interface using the public IP address and virtual network subnet that you previously created.

Get information about network resources

Expand table

Task	Command
List virtual networks	Get-AzVirtualNetwork -ResourceGroupName $myResourceGroup Lists all the virtual networks in the resource group.
Get information about a virtual network	Get-AzVirtualNetwork -Name "myVNet" -ResourceGroupName $myResourceGroup
List subnets in a virtual network	Get-AzVirtualNetwork -Name "myVNet" -ResourceGroupName $myResourceGroup | Select Subnets
Get information about a subnet	Get-AzVirtualNetworkSubnetConfig -Name "mySubnet1" -VirtualNetwork $vnet Gets information about the subnet in the specified virtual network. The $vnet value represents the object returned by Get-AzVirtualNetwork.
List IP addresses	Get-AzPublicIpAddress -ResourceGroupName $myResourceGroup Lists the public IP addresses in the resource group.
List load balancers	Get-AzLoadBalancer -ResourceGroupName $myResourceGroup Lists all the load balancers in the resource group.
List network interfaces	Get-AzNetworkInterface -ResourceGroupName $myResourceGroup Lists all the network interfaces in the resource group.

Task	Command
Get information about a network interface	Get-AzNetworkInterface -Name "myNIC" -ResourceGroupName $myResourceGroup Gets information about a specific network interface.
Get the IP configuration of a network interface	Get-AzNetworkInterfaceIPConfig -Name "myNICIP" -NetworkInterface $nic Gets information about the IP configuration of the specified network interface. The $nic value represents the object returned by Get-AzNetworkInterface.

Manage network resources

Expand table

Task	Command
Add a subnet to a virtual network	Add-AzVirtualNetworkSubnetConfig -AddressPrefix XX.X.X.X/XX -Name "mySubnet1" -VirtualNetwork $vnet Adds a subnet to an existing virtual network. The $vnet value represents the object returned by Get-AzVirtualNetwork.
Delete a virtual network	Remove-AzVirtualNetwork -Name "myVNet" -ResourceGroupName $myResourceGroup Removes the specified virtual network from the resource group.
Delete a network interface	Remove-AzNetworkInterface -Name "myNIC" -ResourceGroupName $myResourceGroup Removes the specified network interface from the resource group.
Delete a load balancer	Remove-AzLoadBalancer -Name "myLoadBalancer" -ResourceGroupName $myResourceGroup Removes the specified load balancer from the resource group.
Delete a public IP address	Remove-AzPublicIpAddress-Name "myIPAddress" -ResourceGroupName $myResourceGroup Removes the specified public IP address from the resource group.

Next Steps

Use the network interface that you just created when you create a VM.

Virtual machines in an Azure Resource Manager template

Article • 08/22/2024

Applies to: ✔ Windows VMs

This article describes aspects of an Azure Resource Manager template that apply to virtual machines. This article doesn't describe a complete template for creating a virtual machine; for that you need resource definitions for storage accounts, network interfaces, public IP addresses, and virtual networks. For more information about how these resources can be defined together, see the Resource Manager template walkthrough.

There are many templates in the gallery that include the VM resource. Not all elements that can be included in a template are described here.

This example shows a typical resource section of a template for creating a specified number of VMs:

JSON

```
"resources": [
  {
    "apiVersion": "2016-04-30-preview",
    "type": "Microsoft.Compute/virtualMachines",
    "name": "[concat('myVM', copyindex())]",
    "location": "[resourceGroup().location]",
    "copy": {
      "name": "virtualMachineLoop",
      "count": "[parameters('numberOfInstances')]"
    },
    "dependsOn": [

            ],
            "commandToExecute": "powershell.exe -ExecutionPolicy
Unrestricted -File start.ps1"
          }
        }
      }
    ]
  }
]
```

> **Note**
>
> This example relies on a storage account that was previously created. You could create the storage account by deploying it from the template. The example also relies on a network interface and its dependent resources that would be defined in the template. These resources are not shown in the example.

API Version

When you deploy resources using a template, you have to specify a version of the API to use. The example shows the virtual machine resource using this apiVersion element:

JSON

```
"apiVersion": "2016-04-30-preview",
```

The version of the API you specify in your template affects which properties you can define in the template. In general, you should select the most recent API version when creating templates. For existing templates, you can decide whether you want to continue using an earlier API version, or update your template for the latest version to take advantage of new features.

Use these opportunities for getting the latest API versions:

- REST API - List all resource providers
- PowerShell - Get-AzResourceProvider
- Azure CLI - az provider show

Parameters and variables

Parameters make it easy for you to specify values for the template when you run it. This parameters section is used in the example:

JSON

```
"parameters": {
  "adminUsername": { "type": "string" },
  "adminPassword": { "type": "securestring" },
  "numberOfInstances": { "type": "int" }
},
```

When you deploy the example template, you enter values for the name and password of the administrator account on each VM and the number of VMs to create. You have the option of specifying parameter values in a separate file that's managed with the template, or providing values when prompted.

Variables make it easy for you to set up values in the template that are used repeatedly throughout it or that can change over time. This variables section is used in the example:

JSON

```
"variables": {
  "storageName": "mystore1",
  "accountid": "[concat('/subscriptions/', subscription().subscriptionId,
    '/resourceGroups/', resourceGroup().name,
  '/providers/','Microsoft.Storage/storageAccounts/',
variables('storageName'))]",
  "wadlogs": "<WadCfg>
    <DiagnosticMonitorConfiguration overallQuotaInMB=\"4096\"
xmlns=\"http://schemas.microsoft.com/ServiceHosting/2010/10/DiagnosticsConfi
guration\">
      <DiagnosticInfrastructureLogs
```

```
scheduledTransferLogLevelFilter=\"Error\"/>
      <WindowsEventLog scheduledTransferPeriod=\"PT1M\" >
        <DataSource name=\"Application!*[System[(Level = 1 or Level = 2)]]\"
/>
        <DataSource name=\"Security!*[System[(Level = 1 or Level = 2)]]\" />
        <DataSource name=\"System!*[System[(Level = 1 or Level = 2)]]\" />
      </WindowsEventLog>",
  "wadperfcounters": "<PerformanceCounters scheduledTransferPeriod=\"PT1M\">
      <PerformanceCounterConfiguration
counterSpecifier=\"\\Process(_Total)\\Thread Count\" sampleRate=\"PT15S\"
unit=\"Count\">
        <annotation displayName=\"Threads\" locale=\"en-us\"/>
      </PerformanceCounterConfiguration>
    </PerformanceCounters>",
  "wadcfgxstart": "[concat(variables('wadlogs'),
variables('wadperfcounters'),
    '<Metrics resourceId=\"')]",
  "wadmetricsresourceid": "[concat('/subscriptions/',
subscription().subscriptionId,
    '/resourceGroups/', resourceGroup().name ,
    '/providers/', 'Microsoft.Compute/virtualMachines/')]",
  "wadcfgxend": "\"><MetricAggregation scheduledTransferPeriod=\"PT1H\"/>
    <MetricAggregation scheduledTransferPeriod=\"PT1M\"/>
    </Metrics></DiagnosticMonitorConfiguration>
    </WadCfg>"
},
```

When you deploy the example template, variable values are used for the name and identifier of the previously created storage account. Variables are also used to provide the settings for the diagnostic extension. Use the best practices for creating Azure Resource Manager templates to help you decide how you want to structure the parameters and variables in your template.

Resource loops

When you need more than one virtual machine for your application, you can use a copy element in a template. This optional element loops through creating the number of VMs that you specified as a parameter:

JSON

```
"copy": {
  "name": "virtualMachineLoop",
  "count": "[parameters('numberOfInstances')]"
},
```

Also, notice in the example that the loop index is used when specifying some of the values for the resource. For example, if you entered an instance count of three, the

names of the operating system disks are myOSDisk1, myOSDisk2, and myOSDisk3:

JSON

```
"osDisk": {
  "name": "[concat('myOSDisk', copyindex())]",
  "caching": "ReadWrite",
  "createOption": "FromImage"
}
```

> **Note**
>
> This example uses managed disks for the virtual machines.

Keep in mind that creating a loop for one resource in the template may require you to use the loop when creating or accessing other resources. For example, multiple VMs can't use the same network interface, so if your template loops through creating three VMs it must also loop through creating three network interfaces. When assigning a network interface to a VM, the loop index is used to identify it:

JSON

```
"networkInterfaces": [ {
  "id": "[resourceId('Microsoft.Network/networkInterfaces',
    concat('myNIC', copyindex()))]"
} ]
```

Dependencies

Most resources depend on other resources to work correctly. Virtual machines must be associated with a virtual network and to do that it needs a network interface. The dependsOn element is used to make sure that the network interface is ready to be used before the VMs are created:

JSON

```
"dependsOn": [
  "[concat('Microsoft.Network/networkInterfaces/', 'myNIC', copyindex())]"
],
```

Resource Manager deploys in parallel any resources that aren't dependent on another resource being deployed. Be careful when setting dependencies because you can inadvertently slow your deployment by specifying unnecessary dependencies.

Dependencies can chain through multiple resources. For example, the network interface depends on the public IP address and virtual network resources.

How do you know if a dependency is required? Look at the values you set in the template. If an element in the virtual machine resource definition points to another resource that is deployed in the same template, you need a dependency. For example, your example virtual machine defines a network profile:

JSON

```
"networkProfile": {
  "networkInterfaces": [ {
    "id": "[resourceId('Microsoft.Network/networkInterfaces',
      concat('myNIC', copyindex())]"
  } ]
},
```

To set this property, the network interface must exist. Therefore, you need a dependency. You also need to set a dependency when one resource (a child) is defined within another resource (a parent). For example, the diagnostic settings and custom script extensions are both defined as child resources of the virtual machine. They can't be created until the virtual machine exists. Therefore, both resources are marked as dependent on the virtual machine.

Profiles

Several profile elements are used when defining a virtual machine resource. Some are required and some are optional. For example, the hardwareProfile, osProfile, storageProfile, and networkProfile elements are required, but the diagnosticsProfile is optional. These profiles define settings such as:

- size
- name and credentials
- disk and operating system settings
- network interface
- boot diagnostics

Disks and images

In Azure, vhd files can represent disks or images. When the operating system in a vhd file is specialized to be a specific VM, it's referred to as a disk. When the operating

system in a vhd file is generalized to be used to create many VMs, it's referred to as an image.

Create new virtual machines and new disks from a platform image

When you create a VM, you must decide what operating system to use. The imageReference element is used to define the operating system of a new VM. The example shows a definition for a Windows Server operating system:

JSON

```
"imageReference": {
  "publisher": "MicrosoftWindowsServer",
  "offer": "WindowsServer",
  "sku": "2012-R2-Datacenter",
  "version": "latest"
},
```

If you want to create a Linux operating system, you might use this definition:

JSON

```
"imageReference": {
  "publisher": "Canonical",
  "offer": "UbuntuServer",
  "sku": "20.04.2-LTS",
  "version": "latest"
},
```

> ⓘ **Note**
>
> Modify `publisher`, `offer`, `sku` and `version` values accordingly.

Configuration settings for the operating system disk are assigned with the osDisk element. The example defines a new managed disk with the caching mode set to **ReadWrite** and that the disk is being created from a platform image:

JSON

```
"osDisk": {
  "name": "[concat('myOSDisk', copyindex())]",
  "caching": "ReadWrite",
```

```
  "createOption": "FromImage"
},
```

Create new virtual machines from existing managed disks

If you want to create virtual machines from existing disks, remove the imageReference and the osProfile elements and define these disk settings:

JSON

```
"osDisk": {
  "osType": "Windows",
  "managedDisk": {
    "id": "[resourceId('Microsoft.Compute/disks', [concat('myOSDisk',
copyindex())])]"
  },
  "caching": "ReadWrite",
  "createOption": "Attach"
},
```

Create new virtual machines from a managed image

If you want to create a virtual machine from a managed image, change the imageReference element and define these disk settings:

JSON

```
"storageProfile": {
  "imageReference": {
    "id": "[resourceId('Microsoft.Compute/images', 'myImage')]"
  },
  "osDisk": {
    "name": "[concat('myOSDisk', copyindex())]",
    "osType": "Windows",
    "caching": "ReadWrite",
    "createOption": "FromImage"
  }
},
```

Attach data disks

You can optionally add data disks to the VMs. The number of disks depends on the size of operating system disk that you use. With the size of the VMs set to Standard_DS1_v2, the maximum number of data disks that could be added to the them is two. In the example, one managed data disk is being added to each VM:

JSON

```
"dataDisks": [
  {
    "name": "[concat('myDataDisk', copyindex())]",
    "diskSizeGB": "100",
    "lun": 0,
    "caching": "ReadWrite",
    "createOption": "Empty"
  }
],
```

Extensions

Although extensions are a separate resource, they're closely tied to VMs. Extensions can be added as a child resource of the VM or as a separate resource. The example shows the Diagnostics Extension being added to the VMs:

JSON

```
{
  "name": "Microsoft.Insights.VMDiagnosticsSettings",
  "type": "extensions",
  "location": "[resourceGroup().location]",
  "apiVersion": "2016-03-30",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/myVM', copyindex())]"
  ],
  "properties": {
    "publisher": "Microsoft.Azure.Diagnostics",
    "type": "IaaSDiagnostics",
    "typeHandlerVersion": "1.5",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "xmlCfg": "[base64(concat(variables('wadcfgxstart'),
      variables('wadmetricsresourceid'),
      concat('myVM', copyindex()),
      variables('wadcfgxend')))]",
      "storageAccount": "[variables('storageName')]"
    },
    "protectedSettings": {
      "storageAccountName": "[variables('storageName')]",
      "storageAccountKey": "[listkeys(variables('accountid'),
        '2015-06-15').key1]",
      "storageAccountEndPoint": "https://core.windows.net"
    }
  }
},
```

This extension resource uses the storageName variable and the diagnostic variables to provide values. If you want to change the data that is collected by this extension, you can add more performance counters to the wadperfcounters variable. You could also choose to put the diagnostics data into a different storage account than where the VM disks are stored.

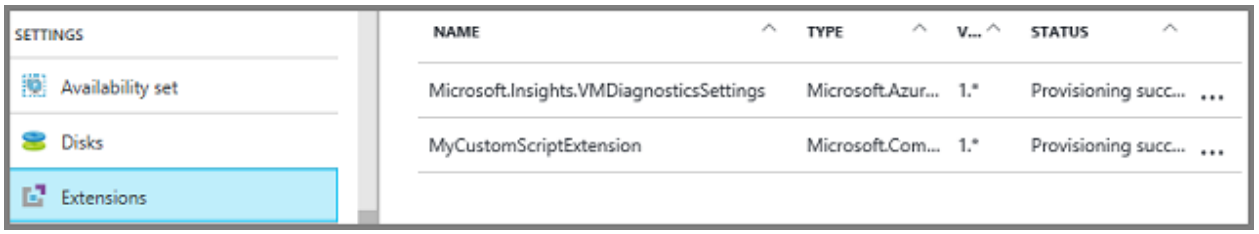
There are many extensions that you can install on a VM, but the most useful is probably the Custom Script Extension. In the example, a PowerShell script named start.ps1 runs on each VM when it first starts:

JSON

```
{
  "name": "MyCustomScriptExtension",
  "type": "extensions",
  "apiVersion": "2016-03-30",
  "location": "[resourceGroup().location]",
  "dependsOn": [
    "[concat('Microsoft.Compute/virtualMachines/myVM', copyindex())]"
  ],
  "properties": {
    "publisher": "Microsoft.Compute",
    "type": "CustomScriptExtension",
    "typeHandlerVersion": "1.7",
    "autoUpgradeMinorVersion": true,
    "settings": {
      "fileUris": [
        "[concat('https://', variables('storageName'),
          '.blob.core.windows.net/customscripts/start.ps1')]"
      ],
      "commandToExecute": "powershell.exe -ExecutionPolicy Unrestricted -
File start.ps1"
    }
  }
}
```

The start.ps1 script can accomplish many configuration tasks. For example, the data disks that are added to the VMs in the example aren't initialized; you can use a custom script to initialize them. If you have multiple startup tasks to do, you can use the start.ps1 file to call other PowerShell scripts in Azure storage. The example uses PowerShell, but you can use any scripting method that is available on the operating system that you're using.

You can see the status of the installed extensions from the Extensions settings in the portal:

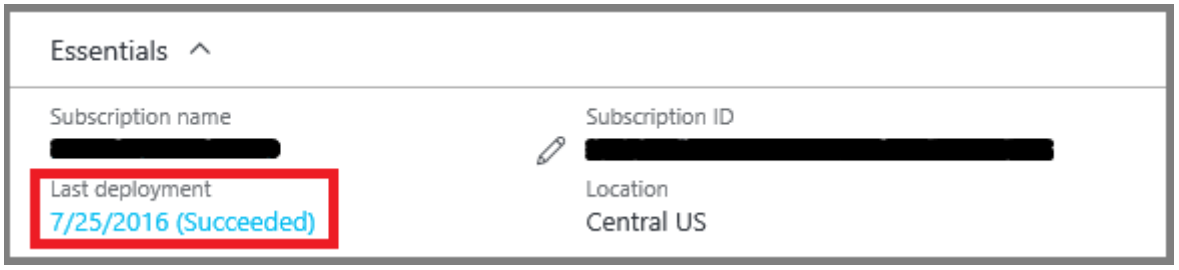


You can also get extension information by using the **Get-AzVMExtension** PowerShell command, the **vm extension get** Azure CLI command, or the **Get extension information** REST API.

Deployments

When you deploy a template, Azure tracks the resources that you deployed as a group and automatically assigns a name to this deployed group. The name of the deployment is the same as the name of the template.

If you're curious about the status of resources in the deployment, view the resource group in the Azure portal:



It's not a problem to use the same template to create resources or to update existing resources. When you use commands to deploy templates, you have the opportunity to say which mode you want to use. The mode can be set to either **Complete** or **Incremental**. The default is to do incremental updates. Be careful when using the **Complete** mode because you may accidentally delete resources. When you set the mode to **Complete**, Resource Manager deletes any resources in the resource group that aren't in the template.

Next Steps

- Create your own template using Authoring Azure Resource Manager templates.
- Deploy the template that you created using Create a Windows virtual machine with a Resource Manager template.
- Learn how to manage the VMs that you created by reviewing Create and manage Windows VMs with the Azure PowerShell module.

- For the JSON syntax and properties of resource types in templates, see Azure Resource Manager template reference.

Frequently asked question about Linux Virtual Machines

This article addresses some common questions about Linux virtual machines created in Azure using the Resource Manager deployment model. For the Windows version of this topic, see Frequently asked question about Windows Virtual Machines

What can I run on an Azure VM?

All subscribers can run server software on an Azure virtual machine. For more information, see Linux on Azure-Endorsed Distributions

How much storage can I use with a virtual machine?

Each data disk can be up to 32,767 GiB. The number of data disks you can use depends on the size of the virtual machine. For details, see Sizes for Virtual Machines.

Azure managed disks are the recommended disk storage offerings for use with Azure Virtual Machines for persistent storage of data. You can use multiple managed disks with each Virtual Machine. Managed disks offer two types of durable storage options: Premium and Standard managed disks. For pricing information, see managed disks Pricing.

Azure storage accounts can also provide storage for the operating system disk and any data disks. Each disk is a .vhd file stored as a page blob. For pricing details, see Storage Pricing Details.

How can I access my virtual machine?

Establish a remote connection to sign on to the virtual machine, using Secure Shell (SSH). See the instructions on how to connect from Windows or from Linux and Mac. By default, SSH allows a maximum of 10 concurrent connections. You can increase this number by editing the configuration file.

If you're having problems, check out Troubleshoot Secure Shell (SSH) connections.

Can I use the temporary disk, mounted under (/mnt) to store data?

Don't use the temporary disk, mounted under (/mnt) to store data. It's only there for temporary storage and if you want swap files. Data stored in there can't be recovered and it will be removed during certain virtual machine operations (stop/start, redeploy, and others).

Can I copy or clone an existing Azure VM?

Yes. For instructions, see How to create a copy of a Linux virtual machine in the Resource Manager deployment model.

Why am I not seeing Canada Central and Canada East regions through Azure Resource Manager?

The two new regions of Canada Central and Canada East aren't automatically registered for virtual machine creation for existing Azure subscriptions. This registration is done automatically when a virtual machine is deployed through the Azure portal to any other region using Azure Resource Manager. After a virtual machine is deployed to any other Azure region, the new regions should be available for subsequent virtual machines.

Can I add a NIC to my VM after it's created?

Yes, this is now possible. The VM first needs to be stopped deallocated. Then you can add or remove a NIC (unless it's the last NIC on the VM).

Are there any computer name requirements?

Yes. The computer name can be a maximum of 64 characters in length. See Naming conventions rules and restrictions for more information around naming your resources.

Are there any resource group name requirements?

Yes. The resource group name can be a maximum of 90 characters in length. See Naming conventions rules and restrictions for more information about resource groups.

What are the username requirements when creating a VM?

Usernames should be 1 - 32 characters in length.

The following usernames aren't allowed:

- `1`
- `123`
- `a`
- `actuser`
- `adm`
- `admin`
- `admin1`
- `admin2`
- `administrator`
- `aspnet`
- `backup`
- `console`
- `david`
- `guest`
- `john`
- `owner`
- `root`
- `server`
- `sql`
- `support_388945a0`
- `support`
- `sys`
- `test`
- `test1`
- `test2`
- `test3`
- `user`

- `user1`
- `user2`
- `user3`
- `user4`
- `user5`
- `video`

What are the password requirements when creating a VM?

There are varying password length requirements, depending on the tool you're using:

- Azure portal - between 12 - 72 characters
- Azure PowerShell - between 8 - 123 characters
- Azure CLI - between 12 - 123 characters
- Azure Resource Manager (ARM) templates - 12 - 72 characters and control characters aren't allowed

Passwords must also meet three out of the following four complexity requirements:

- Have lower characters
- Have upper characters
- Have a digit
- Have a special character (Regex match [\W_])

The following passwords aren't allowed:

- abc@123
- P@$$w0rd
- P@ssw0rd
- P@ssword123
- Pa$$word
- pass@word1
- Password!
- Password1
- Password22
- iloveyou!

Frequently asked question about Windows Virtual Machines

This article addresses some common questions about Windows virtual machines created in Azure using the Resource Manager deployment model. For the Linux version of this topic, see Frequently asked question about Linux Virtual Machines.

What can I run on an Azure VM?

All subscribers can run server software on an Azure virtual machine. For information about the support policy for running Microsoft server software in Azure, see Microsoft server software support for Azure Virtual Machines.

Certain versions of Windows 7, Windows 8.1, and Windows 10 are available to MSDN Azure benefit subscribers and MSDN Dev and Test Pay-As-You-Go subscribers, for development and test tasks. For details, including instructions and limitations, see Windows Client images for MSDN subscribers.

How much storage can I use with a virtual machine?

Each data disk can be up to 32,767 GiB. The number of data disks you can use depends on the size of the virtual machine. For details, see Sizes for Virtual Machines.

Azure managed disks are the recommended disk storage offerings for use with Azure Virtual Machines for persistent storage of data. You can use multiple managed disks with each Virtual Machine. Managed disks offer two types of durable storage options: Premium and Standard managed disks. For pricing information, see managed disks Pricing.

Azure storage accounts can also provide storage for the operating system disk and any data disks. Each disk is a .vhd file stored as a page blob. For pricing details, see Storage Pricing Details.

How can I access my virtual machine?

Establish a remote connection using Remote Desktop Connection (RDP) for a Windows VM. For instructions, see How to connect and sign on to an Azure virtual machine running Windows. A maximum of two concurrent connections are supported, unless the server is configured as a Remote Desktop Services session host.

If you're having problems with Remote Desktop, see Troubleshoot Remote Desktop connections to a Windows-based Azure Virtual Machine.

If you're familiar with Hyper-V, you might be looking for a tool similar to VMConnect. Azure doesn't offer a similar tool because console access to a virtual machine isn't supported.

Can I use the temporary disk (the D: drive by default) to store data?

Don't use the temporary disk to store data. It is only temporary storage, so you would risk losing data that can't be recovered. Data loss can occur when the virtual machine moves to a different host. Resizing a virtual machine, updating the host, or a hardware failure on the host are some of the reasons a virtual machine might move.

If you have an application that needs to use the D: drive letter, you can reassign drive letters so that the temporary disk uses something other than D:. For instructions, see Change the drive letter of the Windows temporary disk.

How can I change the drive letter of the temporary disk?

You can change the drive letter by moving the page file and reassigning drive letters, but you need to make sure you do the steps in a specific order. For instructions, see Change the drive letter of the Windows temporary disk.

Can I add an existing VM to an availability set?

No. If you want your VM to be part of an availability set, you need to create the VM within the set. There currently isn't a way to add a VM to an availability set after it has been created.

Can I upload a virtual machine to Azure?

Yes. For instructions, see Migrating on-premises VMs to Azure.

Can I resize the OS disk?

Yes. For instructions, see How to expand the OS drive of a Virtual Machine in an Azure Resource Group.

Can I copy or clone an existing Azure VM?

Yes. Using managed images, you can create an image of a virtual machine and then use the image to build multiple new VMs. For instructions, see Create a custom image of a VM.

Why am I not seeing Canada Central and Canada East regions through Azure Resource Manager?

The two new regions of Canada Central and Canada East are not automatically registered for virtual machine creation for existing Azure subscriptions. This registration is done automatically when a virtual machine is deployed through the Azure portal to any other region using Azure Resource Manager. After a virtual machine is deployed to any other Azure region, the new regions should be available for subsequent virtual machines.

Does Azure support Linux VMs?

Yes. To quickly create a Linux VM to try out, see Create a Linux VM on Azure using the Portal.

Can I add a NIC to my VM after it's created?

Yes, this is now possible. The VM first needs to be stopped deallocated. Then you can add or remove a NIC (unless it's the last NIC on the VM).

Are there any computer name requirements?

Yes. The computer name can be a maximum of 15 characters in length. See Naming conventions rules and restrictions for more information around naming your resources.

Are there any resource group name requirements?

Yes. The resource group name can be a maximum of 90 characters in length. See Naming conventions rules and restrictions for more information about resource groups.

What are the username requirements when creating a VM?

Usernames can be a maximum of 20 characters in length and cannot end in a period (".").

The following usernames are not allowed:

- `1`
- `123`
- `a`
- `actuser`
- `adm`
- `admin`
- `admin1`
- `admin2`
- `administrator`
- `aspnet`
- `backup`
- `console`
- `david`
- `guest`
- `john`
- `owner`
- `root`
- `server`
- `sql`
- `support_388945a0`
- `support`
- `sys`
- `test`
- `test1`

- `test2`
- `test3`
- `user`
- `user1`
- `user2`

What are the password requirements when creating a VM?

There are varying password length requirements, depending on the tool you are using:

- Azure portal - between 12 - 123 characters
- Azure PowerShell - between 8 - 123 characters
- Azure CLI - between 12 - 123

- Have lower characters
- Have upper characters
- Have a digit
- Have a special character (Regex match [\W_])

The following passwords are not allowed:

Expand table

abc@123	iloveyou!	P@$$w0rd	P@ssw0rd	P@ssword123
Pa$$word	pass@word1	Password!	Password1	Password22

For additional information and restrictions for password creation reference this password guidance documentation.

Support and troubleshooting for Azure VMs

Article • 08/22/2024

Here are suggestions for where you can get help when developing your Azure Virtual Machines solutions.

Self help troubleshooting

Various articles explain how to determine, diagnose, and fix issues that you might encounter when using Azure Virtual Machines. Use these articles to troubleshoot deployment failures, unexpected restarts, connection issues and more.

For a full list of self help troubleshooting content, see Azure Windows Virtual Machines troubleshooting documentation and Azure Linux Virtual Machines troubleshooting documentation.

Post a question on Microsoft Q&A

For quick and reliable answers on your technical product questions from Microsoft Engineers, Azure Most Valuable Professionals (MVPs), or our expert community, engage with us on Microsoft Q&A, Azure's preferred destination for community support.

If you can't find an answer to your problem using search, submit a new question to Microsoft Q&A. Use one of the following tags when asking your question:

Expand table

Area	Tag
Azure Virtual Machines	azure-virtual-machines
Azure SQL Virtual Machines	azure-sql-virtual-machines
Azure Virtual Machine Scale Sets	azure-virtual-machine-scale-set

Create an Azure support request

Explore the range of Azure support options and choose the plan that best fits, whether you're a developer just starting your cloud journey or a large organization deploying business-critical, strategic applications. Azure customers can create and manage support requests in the Azure portal.

- If you already have an Azure Support Plan, open a support request here.
- To sign up for a new Azure Support Plan, compare support plans and select the plan that works for you.

Create a GitHub issue

If you need help with the language and tools used to develop and manage Azure Virtual Machines, open an issue in its repository on GitHub.
